The classical version of the three-wave interaction models the creation and destruction of waves; the quantized version models the creation and destruction of particles. The quantum three-wave interaction is described and the Bethe ansatz for the eigenfunctions is given in closed form. The Bethe equations are derived in a rigorous fashion and are shown to have a thermodynamic limit. The Dirac sea of negative energy states is obtained as the infinite density limit. Finite particle/hole excitations are determined and the asymptotic relation of energy and momentum is obtained. The Yang–Yang functional for the relative free energy of finite density excitations is constructed and is shown to be convex and bounded below. The equations of thermal equilibrium are obtained. © *1998 American Institute of Physics.* [S0022-2488(98)01801-5]

I. INTRODUCTION

The creation and destruction of particles is a fundamental process in high-energy physics. Among other things, the presence of such processes implies that the entries of the scattering matrix between states with different numbers of elementary excitations (or physical particles) can be nonzero.

Integrable systems provide solvable paradigms for various physical phenomena: e.g., for lattice statistical models, the algebraic decay of correlation functions at a critical point may be observed. The creation and destruction of particle pairs is modeled by the quantum three-wave interaction (3WI), which is obtained by quantizing a particular reduction of the $N=3$ case of the AKNS hierarchy as in Wadati and Ohkuma,[1] or by taking the continuum limit of the GL(3) lattice magnet as in Kulish and Reshetikhin.[2] The result is an interacting many-body system which does not conserve the number of particles: the interaction permits two distinct types of particles to combine to form a third, and also the reverse process.

The quantum 3WI has been considered in three forms. In one, all particles are bosons, in the ''Fermion I'' model two fermions interact to form a boson, and in the ''Fermion II'' model a boson and a fermion interact to form a fermion. In this paper we consider the Fermion I model. We find the associated first quantization problem, obtain the eigenfunctions of the Hamiltonian in closed form, and derive the Bethe equations rigorously from the requirement that the wave functions be periodic.

Because the model is first order in the derivatives, the energy is not bounded below. Nevertheless, as in Dirac's model of the electron, a stable ground state may be constructed by filling all negative energy states. One can then consider all states with reference to the filled Dirac sea of negative energy states. This approach is used in Korepin[3] and in Bergknoff and Thacker[4] to calculate the excitation spectrum of the massive Thirring model from the Bethe ansatz states.

We prove the existence of a thermodynamic limit as the length of the interval tends to infinity

with constant density. The Dirac sea is obtained in the infinite density limit. Finite particle/hole excitations from the Dirac sea correspond to the solutions of certain integral equations. Such excitations have positive relative energy, and we determine the asymptotic relation between energy and momentum. Following the treatment of a one-dimensional boson gas with delta-function interactions by Yang and Yang[5] we derive a functional for the relative free energy of finite (local) density perturbations from the Dirac sea. We prove that the functional is convex and bounded below and obtain the equation for thermal equilibrium.

Kulish and Reshetikhin[2] used the quantum inverse scattering method (also called the algebraic Bethe ansatz) to investigate GL(N) invariant transfer matrices on a one-dimensional lattice. They obtained quantized N wave models as a formal continuum limit and found explicitly the Bethe equations for the bosonic 3WI. Wadati and Ohkuma[1] also considered the bosonic case. Ohkuma and Wadati[6] treated the Fermion I and Fermion II cases and gave an algorithm for constructing the Bethe wave functions.

Ohkuma[7] investigated the Fermion I quantization of the three-wave interaction, wrote down the Bethe equations, and calculated the free energy and excitations from a ground state. However, a momentum cutoff is introduced in Ohkuma.[7] The results depend on the cutoff and do not have a finite limit when the cutoff is taken to infinity. By constructing all physical states with reference to a Dirac sea we obtain limits that are finite and are independent of any cutoff. The methods provide a basis for calculating the free energy of other integrable models whose spectrum is unbounded below.

The quantized field of the 3WI may be rewritten as a first quantization for a many-body problem. Such a reduction was carried out by Lieb and Liniger[8] for the quantization of a Bose gas–essentially the quantization of the nonlinear Schrödinger equation. They obtained a Helmholtz equation in the interior of the fundamental domain, together with boundary conditions at the interfaces associated with the interactions; see also Ref. 9. A novel feature of the 3WI is that the system of equations links functions with different numbers of variables, corresponding to the fact that individual particle numbers are not conserved.

As in Lieb and Liniger[8] we solve the differential equations in certain fundamental cones $\mathscr{C}^{m,n,p}$ and then extend the densities to all space, first by antisymmetrizing across the boundaries of $\mathscr{C}^{m,n,p}$ and then by periodicity. The differential equations for the densities force discontinuities where fermions of different types interact. However, like fermions do not interact, so to avoid discontinuities on the boundaries of the fundamental cones we impose a regularity requirement, (2.5). This requirement forces one to antisymmetrize the basic solutions of the differential equations over momenta. This in turn is fundamental to obtaining the Bethe equations, as we show by example in Sec. V.

In Secs. III and IV we sketch, in greater detail than in Refs. 1 and 6, a derivation of an algorithm for the eigenfunctions of the 3WI, and go on to obtain the explicit form of the eigenfunctions (cf. Theorem 5.1). This form generalizes the Bethe ansatz (Refs. 8 and 10–12) to systems in which the eigenvectors are superpositions of states, having different numbers of particles. In Sec. V we derive the Bethe equations from the requirement of periodicity.

In Sec. VI we reformulate the finite Bethe equations as a system of integral equations and prove existence of a certain thermodynamic limit at finite density. The Dirac sea is then obtained as an infinite density limit. In Sec. VII integral equations for the particle/hole excited states are obtained, and energy/momentum asymptotics are found. Finite density perturbations of the Dirac sea are constructed in Sec. VIII. In Sec. IX we investigate the (relative) free energy functional. The formal Euler–Lagrange equations for its minimum are the same as those proposed by Ohkuma[7] if one imposes a cutoff. Without a cutoff they have no strict solutions, but there is a natural interpretation which does yield meaningful equations for the thermal equilibrium state.

II. THE THREE-WAVE INTERACTION

The Hamiltonian of the classical three-wave interaction is

$$H=\int \sum_{j=0}^{2} ic_j \frac{\partial \Psi_j^\dagger}{\partial x} \Psi_j+\gamma(\Psi_0^\dagger \Psi_1 \Psi_2+\Psi_2^\dagger \Psi_1^\dagger \Psi_0)dx=T+\gamma(V^\dagger+V), \tag{2.1}$$

where Ψ_j are complex-valued functions and † denotes complex conjugation. The constants c_j are wave speeds, and γ is a coupling constant. Zakharov and Manakov[13] found a Lax pair for the classical system and Beals and Sattinger[14] gave a set of action-angle variables. However, integrability of the classical system will play no role in our analysis of the quantized model.

The system is formally quantized by taking the $\Psi_j^\dagger$ and Ψ_j to be creation and annihilation operators on a Fock space, † denoting Hermitian adjoints. We take $\Psi_0(x,t)$ to be a boson field operator, and Ψ_1 and Ψ_2 to be fermion fields. Thus the operators are required to satisfy the equal time commutation $([,]_-)$ or anticommutation $([,]_+)$ relations:

$$\begin{gathered}[\Psi_j(x,t),\Psi_{j'}(x',t)]_+=0, \quad [\Psi_j(x,t),\Psi_{j'}^\dagger(x',t)]_+=\delta_{jj'}\delta(x-x'),\\ [\Psi_0(x,t),\Psi_0(x',t)]_-=0, \quad [\Psi_0(x,t),\Psi_0^\dagger(x',t)]_-=\delta(x-x'),\\ [\Psi_0(x,t),\Psi_j(x',t)]_-=0, \quad [\Psi_0^\dagger(x,t),\Psi_j(x',t)]_-=0, \quad j,j'=1,2.\end{gathered} \tag{2.2}$$

The Hermitian operator T represents the kinetic energy, with distinct wave speeds c_j for each field. The interaction term $V^\dagger$ formally annihilates the two particles with wave speeds c_1 and c_2 (particles of type 1 and 2) and creates one with wave speed c_0, while V destroys a type 0 particle and creates types 1 and 2.

We assume throughout that the speeds of the fermions bracket the boson speed: $(c_1-c_0)\times(c_2-c_0)<0$. In addition, we make the simplifying assumption that

$$c_1-c_0=\alpha=c_0-c_2, \tag{2.3}$$

where α is an arbitrary constant. Without loss of generality we assume throughout this paper that $\alpha>0$.

The Hamiltonian is defined on a Hilbert space $\mathscr{H}$ consisting of the tensor product of a boson and two fermion Fock spaces. There exists a nonzero vector $|0\rangle$ in the Fock space, called the pseudovacuum, such that

$$\Psi_j(x,t)|0\rangle=0, \quad j=0,1,2.$$

Define particle number operators

$$N_j=\int dx\ \Psi_j^\dagger \Psi_j, \quad j=0,1,2.$$

The coordinates of particles of types 0, 1, and 2 are denoted by x_j, y_j, and z_j, respectively. Let

$$\Psi_0^\dagger(x)=\Psi_0^\dagger(x_1,\ldots,x_m)=\Psi_0^\dagger(x_1)\cdots\Psi_0^\dagger(x_m)$$

and define $\Psi_1^\dagger(y)$ and $\Psi_2^\dagger(z)$ similarly. Then set

$$\Psi^\dagger(x,y,z)=\Psi_0^\dagger(x)\Psi_1^\dagger(y)\Psi_2^\dagger(z), \quad x\in R^m, \quad y\in R^n, \quad z\in R^p.$$

Fundamental states in $\mathscr{H}$ are given formally by

$$\Psi^\dagger(x,y,z)|0\rangle,$$

which are eigenstates of N_0, N_1, and N_2 with eigenvalues, m, n, and p, respectively. A general state vector in this subspace may be written in the form

$$|\psi_{m,n,p}\rangle = \frac{1}{m!n!p!}\int_{R^{m,n,p}} f_{mnp}(x,y,z)\Psi^\dagger(x,y,z)|0\rangle\ dx\ dy\ dz, \tag{2.4}$$

where f_{mnp} belongs to $\mathscr{L}_2(R^{m,n,p})$ and $dx = dx_1 dx_2 \cdots dx_m$, etc. Since $\Psi^\dagger(x,y,z)$ is symmetric in the x_j and antisymmetric in the y_k and z_l, the density function f_{mnp} may be assumed to possess these same symmetries.

If a density f_{mnp} is associated with an eigenstate, then, as shown in Sec. IV, it must be discontinuous across the hyperplanes $y_k = z_l$, which we call the *interaction manifolds*. It is natural to assume that these are the only discontinuities. We therefore assume continuity across the hyperplanes $y_k = y_{k+1}$, provided $y_k \neq z_l$ for all z_l, and similarly with respect to the z coordinates. Continuity plus antisymmetry across these hyperplanes implies the following.

$$\begin{aligned} &\textit{Regularity condition}\text{: } f_{mnp} \text{ vanishes as } y_k \to y_{k\pm1} \text{ if } y_{k\pm1} \neq z_l \text{ for all } l \\ &\qquad\qquad \text{and similarly as } z_l \to z_{l\pm1} \neq y_k, \text{ all } k. \end{aligned} \tag{2.5}$$

By symmetry, we may replace the integration in (2.4) by integration over the cone $C^{m,n,p}$ given by

$$x_1 < x_2 < \cdots < x_m, \quad y_1 < y_2 < \cdots < y_n, \quad z_1 < z_2 < \cdots < z_p,$$

and write

$$|\psi_{m,n,p}\rangle = \int_{C^{m,n,p}} f_{mnp}(x,y,z)\Psi^\dagger(x,y,z)|0\rangle\ dx\ dy\ dz. \tag{2.6}$$

From now on, we write the state vectors in the form (2.6) and assume that the densities f_{mnp} are supported on the cone $C^{m,n,p}$ and satisfy the regularity condition (2.5), which implies that the antisymmetric extensions of the f_{mnp} are continuous across the collision manifolds $y_j = y_k$ and $z_j = z_k$ of like fermions.

The classical version of the Hamiltonian (2.1) is integrable and possesses an infinite number of conservation laws: see Ref. 13. Three important conserved quantities for each version are

$$N = \int 2\Psi_0^\dagger\Psi_0 + \Psi_1^\dagger\Psi_1 + \Psi_2^\dagger\Psi_2\ dx,$$

$$D = \int \Psi_1^\dagger\Psi_1 - \Psi_2^\dagger\Psi_2\ dx,$$

$$P = \int \sum_{j=0}^{2} i\Psi_j^\dagger \frac{\partial\Psi_j}{\partial x}\ dx.$$

In the quantized version operators N and D give conserved particle numbers, and P is the momentum operator. Indeed it is not difficult to show from (2.2) that N, D, and P commute with H.

III. REDUCTION TO FIRST QUANTIZATION

The quantum field problem can be rewritten as a first quantization problem for a many-body problem.

Denote the subspace of states $|\psi_{m,n,p}\rangle$ by $\mathscr{F}_{mnp}$. These are eigenstates of N and D with eigenvalues $N=2m+n+p$ and $D=n-p$, respectively, but are not eigenstates of the Hamiltonian H, since $V^\dagger$ and V create and destroy particles. However, since N and D commute with H, the quantum numbers N and D label a subspace that is invariant under H, N, and D. We denote this space by $\mathscr{F}_{N,D}$.

We now fix N and D. Within $\mathscr{F}_{N,D}$, densities can be labeled by m alone and we denote the corresponding subspace by $\mathscr{F}_m$. Note that both of $N\pm D$ must be non-negative even integers. When there are no bosons present ($m=0$), there are $(N\pm D)/2$ fermions of types 1 and 2, respectively. The maximum number of bosons occurs when the maximal number of fermions have combined, yielding $M=\min(N\pm D)/2=\frac{1}{2}(N-|D|)$.

The operators T, $V^\dagger$, and V act on the subspaces $\mathscr{F}_m$ as follows:

$$T:\mathscr{F}_m\to\mathscr{F}_m, \quad V^\dagger:\mathscr{F}_m\to\mathscr{F}_{m+1}, \quad V:\mathscr{F}_m\to\mathscr{F}_{m-1}.$$

An eigenstate of the Hamiltonian in $\mathscr{F}_{N,D}$ is a sum of vectors $|\psi_m\rangle\in\mathscr{F}_m$, and the eigenvalue equation becomes the coupled system

$$\begin{aligned}
(E-T)|\psi_0\rangle &= \gamma V|\psi_1\rangle \\
&\vdots \\
(E-T)|\psi_m\rangle &= \gamma V^\dagger|\psi_{m-1}\rangle+\gamma V|\psi_{m+1}\rangle \\
&\vdots \\
(E-T)|\psi_M\rangle &= \gamma V^\dagger|\psi_{M-1}\rangle
\end{aligned} \tag{3.1}$$

since $V|\psi_0\rangle=V^\dagger|\psi_M\rangle=0$.

Let f_m be the density corresponding to the vector $|\psi_m\rangle$. Equations (3.1) may be converted to a system of partial differential equations by calculating the action of T, $V^\dagger$, and V on the densities f_m. The calculation of the action of T is straightforward, while the calculation of V and $V^\dagger$ is somewhat more involved; details are given in Ref. 15. The action of T is

$$T|\psi_m\rangle = T\int_{\mathscr{C}^{m,n,p}} f_m(x,y,z)\Psi^\dagger(x,y,z)|0\rangle dx\ dy\ dz \tag{3.2}$$

$$= \int_{\mathscr{C}^{m,n,p}} (X_m f_m(x,y,z))\Psi^\dagger(x,y,z)|0\rangle dx\ dy\ dz, \tag{3.3}$$

where

$$X_m f = ic_0\sum_{j=0}^{m}\frac{\partial f}{\partial x_j}+ic_1\sum_{k=0}^{n}\frac{\partial f}{\partial y_k}+ic_2\sum_{l=0}^{p}\frac{\partial f}{\partial z_l}. \tag{3.4}$$

We use $V^\dagger$ to denote the action on densities as well as the action on vectors. Then

$$V^\dagger f_m = \sum_{j,k,l=1}^{m+1,n,p}(-1)^{n(m)+k+l} f_m(\hat{x}_j;\langle y,x_j,k\rangle;\langle z,x_j,l\rangle), \tag{3.5}$$

where $(x,y,z)\in\mathscr{C}^{m+1,n-1,p-1}, n(m)=(N+D)/2-m,$ and

$$\hat{x}_j=(x_1,\ldots,x_{j-1},x_{j+1},\ldots,x_m)\in\mathscr{C}^m$$

$$\langle y,x_j,k\rangle=(y_1,\ldots,y_{k-1},x_j,y_k,\ldots,y_{n-1})\in\mathscr{C}^n,\quad \text{etc.}$$

Remarks: (1) Since f_m is supported on $\mathscr{C}^{m,n,p}$, $f_m(\hat{x}_j;\langle y,x_j,k\rangle;\langle z,x_j,l\rangle)=0$ unless $x_j\in(y_{k-1},y_k)\cap(z_{l-1},z_l)$. Hence

$$(V^\dagger f_m)(x;y;z)=\sum_{j=1}^{m+1}(-1)^{n(m)+k_j+l_j}f_m(\hat{x}_j;\langle y,x_j,k_j\rangle;\langle z,x_j,l_j\rangle),\tag{3.6}$$

where k_j and l_j are uniquely determined by the constraint

$$x_j\in(y_{k_j-1},y_{k_j})\cap(z_{l_j-1},z_{l_j}).\tag{3.7}$$

(2) In (3.6) we interpret the value of f_m on the interaction manifold $x_j=y_{k_j}=z_{l_j}$ as the average of its values as $y_{k_j}\to z_{l_j}\pm$.

(3) The action of $V^\dagger$ can be thought of as gluing a type 1 fermion at y_k and a type 2 fermion at z_l to form a boson at x_j. The coordinates are relabeled to take into account the shift in numbers of variables, summed over all possible pairs. Similarly, the action of V can be thought of as the decomposition of a boson into a pair of fermions, summed over the bosons. In fact the operation of V on densities is given by

$$(Vf_m)(x,y,z)=\sum_{k,l=1}^{n+1,p+1}(-1)^{n(m)+k+l}f_m(\langle x,y_k,j_k\rangle;\hat{y}_k;\hat{z}_l)\,\delta(y_k-z_l),\tag{3.8}$$

where j_k is uniquely determined by the constraint $y_k\in(x_{j_k-1},x_{j_k})$.

We illustrate in some low-order cases. For $2m+n+p=N=2$, $f_0=f_0(y,z)$, $f_1=f_1(x)$:

$$(V^\dagger f_0)(x)=-f_0(x,x),\quad Vf_0=0,$$

$$V^\dagger f_1=0,\quad (Vf_1)(y,z)=f_1(y)\,\delta(y-z).$$

For $2m+n+p=N=4$, $f_0=f_0(y_1,y_2,z_1,z_2)$, $f_1=f_1(x,y,z)$, $f_2=f_2(x_1,x_2)$:

$$(V^\dagger f_0)(x,y,z)=f_0(x,y,x,z)-f_0(x,y,z,x)-f_0(y,x,x,z)+f_0(y,x,z,x),$$

$$(V^\dagger f_1)(x_1,x_2)=-f_1(x_1,x_2,x_2)-f_1(x_2,x_1,x_1),$$

$$V^\dagger f_2=0,\quad Vf_0=0,$$

$$(Vf_1)(y_1,y_2,z_1,z_2)=f_1(y_1,y_2,z_1)\,\delta(y_1-z_2)-f_1(y_1,y_2,z_2)\,\delta(y_1-z_1)$$

$$-f_1(y_2,y_1,z_1)\,\delta(y_2-z_2)+f_1(y_2,y_1,z_2)\,\delta(y_2-z_1),$$

$$(Vf_2)(x,y,z)=[f_2(y,x)+f_2(x,y)]\,\delta(y-z).$$

IV. THE BETHE ANSATZ

The differential equations for the densities, supplemented with the regularity condition (2.5) at the boundaries of the cones $\mathscr{C}^{m,n,p}$, describe the spectral problem in first quantization.

From the results of Sec. III the differential equations for the densities are

$$\begin{aligned} &X_0 f_0 + \gamma V f_1 = E f_0, \\ &\vdots \\ &X_m f_m + \gamma V f_{m+1} + \gamma V^\dagger f_{m-1} = E f_m \\ &\vdots \\ &X_M f_M + \gamma V^\dagger f_{M-1} = E f_M . \end{aligned} \tag{4.1}$$

Wadati and Ohkuma[1] gave an algorithm for constructing the general eigenstates. In the next two sections we find these eigenstates in closed form, in two steps. In this section we construct ''local solutions'' of Eqs. (4.1); on each of the cones $\mathscr{C}^{mnp}$ they are multiples of an exponential solution of the associated differential equation.

Because the operator V introduces delta function singularities on the interaction manifolds, solutions must have discontinuities across these manifolds. However, the local solutions violate (2.5) and thus they have additional discontinuities if extended by antisymmetry. We denote the densities of the local solutions by h_m to distinguish them from the regular densities, which will satisfy (2.5). We obtain these regular densities in Sec. V by taking linear combinations of the h_m: antisymmetrizing over the momenta.

A. Low-order cases

Two low-order cases illustrate the main features of these equations. For $N=2$, $D=0$, Eqs. (4.1) are

$$ic_1 \frac{\partial h_0}{\partial y} + ic_2 \frac{\partial h_0}{\partial z} + \gamma h_1(y)\,\delta(y-z) = E h_0(y,z), \tag{4.2a}$$

$$ic_0 \frac{\partial h_1}{\partial x} - \gamma h_0(x,x) = E h_1(x), \tag{4.2b}$$

where $h_0 = h_0(y,z)$ and $h_1 = h_1(x)$. In the first equation the interaction term vanishes off the interaction manifold $y=z$ so we take the solutions to be multiples of an exponential in each of the open sectors $y<z$ and $y>z$ of $\mathscr{C}^{0,1,1}$:

$$h_0(y,z) = \begin{cases} \phi_1^0 \exp i(\eta y - \zeta z), & y<z, \\ \phi_2^0 \exp i(\eta y - \zeta z), & y>z, \end{cases}$$

where $E = -(c_1\eta - c_2\zeta)$, and ϕ_1^0 and ϕ_2^0 are constants to be determined.

In (4.2b) we take $h_0(x,x)$ on the interaction manifold to be the average of the values of $h_0(y,z)$ from the left and right. Hence the second equation is

$$\left(ic_0 \frac{\partial}{\partial x} - E \right) h_1(x) = \gamma \frac{\phi_1^0 + \phi_2^0}{2} e^{i(\eta-\zeta)x}.$$

We seek a solution of the form $h_1(x) = Ae^{i(\eta-\zeta)x}$, so that

$$h_1(x)=g(\eta,\zeta)\,\frac{\phi_1^0+\phi_2^0}{2}\exp\, i(\eta-\zeta)x,\quad g(\eta,\zeta)=\frac{\gamma}{(c_1-c_0)\eta-(c_2-c_0)\zeta}.$$

By (2.3),

$$g(\eta,\zeta)=\frac{\gamma}{\alpha(\eta+\zeta)}:=g(\eta+\zeta).$$

We use this form of g from now on.

Finally, we determine the ratio ϕ_1^0/ϕ_2^0 by integrating (4.2a) across the interaction manifold $y=z$. We change variables, letting $d=y-z$ and $s=y+z$, and obtain

$$i(c_1-c_2)\,\frac{\partial h_0}{\partial d}+i(c_1+c_2)\,\frac{\partial h_0}{\partial s}+\gamma h_1\delta(d)=Eh_0,$$

$$h_0=h_0\left(\frac{s+d}{2},\,\frac{s-d}{2}\right),\quad h_1=h_1\left(\frac{s+d}{2}\right).$$

Integrating across the jump at $d=0$ $(y=z=x)$ we obtain

$$i(c_1-c_2)(\phi_2^0-\phi_1^0)\exp\, ix(\eta-\zeta)+\gamma g(\eta+\zeta)\,\frac{\phi_1^0+\phi_2^0}{2}\exp\, ix(\eta-\zeta)=0;$$

hence

$$\frac{\phi_2^0}{\phi_1^0}=\frac{2i(c_1-c_2)-\gamma g}{2i(c_1-c_2)+\gamma g}.$$

Using our assumption (2.3) we may write this in the simplified form

$$\phi_2^0=\theta(\eta+\zeta)\phi_1^0,\quad \theta(\lambda)=\frac{\lambda+i\omega}{\lambda-i\omega},$$

where

$$\omega=\frac{\gamma^2}{4\alpha^2}.$$

Setting $\phi_1^0=1$, we have

$$h_0(y,z)=\begin{cases}\exp\, i(\eta y-\zeta z), & y<z,\\ \theta(\eta-\zeta)\exp\, i(\eta y-\zeta z), & y>z,\end{cases}$$

and

$$h_1(x)=\tfrac{1}{2}g(\eta+\zeta)(1+\theta(\eta+\zeta))\exp\, ix(\eta-\zeta).$$

For $N=3$ and $D=1$ Eqs. (4.1) are

$$ic_1\,\frac{\partial h_0}{\partial y_1}+ic_1\,\frac{\partial h_0}{\partial y_2}+ic_2\,\frac{\partial h_0}{\partial z}-Eh_0(y_1,y_2;z)=\gamma(h_1(y_1;y_2)\,\delta(y_1-z)-h_1(y_2;y_1)\,\delta(y_2-z)),\tag{4.3a}$$

$$ic_0\frac{\partial h_1}{\partial x}+ic_1\frac{\partial h_1}{\partial y}-Eh_1(x;y)=\gamma(h_0(y,x;x)-h_0(x,y;x)), \tag{4.3b}$$

with $h_0=h_0(y_1,y_2;z)$ and $h_1=h_1(x:y)$. Arguing as above, we obtain

$$h_0(y;z)=\begin{cases}\exp\, i(\eta_1y_1+\eta_2y_2-\zeta z), & y_1<y_2<z,\\ \theta(\eta_2+\zeta)\exp\, i(\eta_1y_1+\eta_2y_2-\zeta z), & y_1<z<y_2,\\ \theta(\eta_1+\zeta)\theta(\eta_2+\zeta)\exp\, i(\eta_1y_1+\eta_2y_2-\zeta z), & z<y_1<y_2,\end{cases}$$

and

$$h_1(x;y)=\frac{1}{2}\begin{cases}(1+\theta(\eta_2+\zeta))g(\eta_2+\zeta)\exp\, i((\eta_2-\zeta)x+\eta_1y), & y<x,\\ -\theta(\eta_2+\zeta)(1+\theta(\eta_1+\zeta))g(\eta_1+\zeta)\exp\, i((\eta_1-\zeta)x+\eta_2y), & x<y.\end{cases}$$

B. The general case

The two preceding cases show that when y_k and z_l are transposed (with y_k moving to the right of z_l), h_0 is multiplied by $\theta(\eta_k+\zeta_l)$, where η_k and $-\zeta_l$ are the momenta of the corresponding fermions. Since the differential equations are local and involve only pairwise interactions, this situation extends to the general case.

We begin by introducing some notation and conventions. For fixed N and D, $\mathscr{C}^{m,n,p}$ is uniquely determined by m, so from now on we denote it by $\mathscr{C}^m$. The domain $\mathscr{C}^m$ is a union of

$$\frac{(m+n+p)!}{m!n!p!}$$

open sectors determined by the interspacing of the particles of type 0, 1, and 2. We label them by $m+n+p$-tuples $\sigma=(\epsilon_1,\epsilon_2,\ldots,\epsilon_{m+n+p})$, where $\epsilon_j=0,-1$, or $+1$ if the particle in the jth position along the real line is of type 0, 1, or 2, respectively. For example,

$$\sigma=(1,0,-1,1)\leftrightarrow\{z_1<x_1<y_1<z_2\}.$$

The boundary of $\mathscr{C}^m$ consists of the interaction manifolds $y_j=z_k$ together with the sets $y_j=y_{j+1}$ and $z_k=z_{k+1}$ at which like fermions coalesce.

A *transposition* consists of interchanging a -1 with a $+1$ to its immediate right, e.g., $(1,0,-1,1)\mapsto(1,0,1,-1)$. Each transposition corresponds to interchanging an adjacent pair of coordinates y_k and z_l; thus to every interaction manifold there is a corresponding transposition. The sectors of $\mathscr{C}^m$ are partially ordered by the number of transpositions; thus, for example, $(1,0,-1,1)<(1,0,1,-1)$. By definition, no transpositions occur between -1's and 1's separated by one or more zeroes.

Since Vh_1 is supported on the interaction manifold, $h_0=h_0(y;z)$ satisfies

$$X_0h_0=ic_1\sum_{j=1}^{n}\frac{\partial h_0}{\partial y_j}+ic_2\sum_{k=1}^{p}\frac{\partial h_0}{\partial z_k}=Eh_0 \tag{4.4}$$

in each open sector $\sigma\subset\mathscr{C}^0$.

Let

$$\sigma_0=\{y_1<\cdots<y_n<z_1<\cdots<z_p\}\sim(-1,\ldots,-1,1,\ldots,1).$$

We take

$$h_0 = \exp\, i\left(\sum_{j=1}^{n} \eta_j y_j - \sum_{k=1}^{p} \zeta_k z_k \right), \quad (y;z) \in \sigma_0,$$

with

$$E = -c_1 \sum_{j=1}^{n} \eta_j + c_2 \sum_{k=1}^{p} \zeta_k. \tag{4.5}$$

The solution in a general sector $\sigma \in \mathscr{C}^0$ is

$$h_0 = \phi_\sigma^0 \exp\, i\left(\sum_{j=1}^{n} \eta_j y_j - \sum_{k=1}^{p} \zeta_k z_k \right), \quad (y;z) \in \sigma, \tag{4.6}$$

where the constant ϕ_σ^0 is uniquely determined by σ, and is given in (4.8) below.

Lemma 4.1. Let $\sigma < \sigma'$ differ by a single transposition of fermions of types 1 and 2 at y_j, z_k with momenta η_j and $-\zeta_k$, respectively. Then

$$\phi_{\sigma'}^0 = \theta(\eta_j + \zeta_k)\, \phi_\sigma^0. \tag{4.7}$$

Remark: For $\sigma' < \sigma$ the phase factor is

$$[\theta(\eta_j + \zeta_k)]^{-1} = \theta(-\eta_j - \zeta_k).$$

Thus within a *fixed* particle number sector these conditions on the wave function are of the usual Bethe ansatz type; the ratio of phases that differ by a permutation of neighboring particles is a function of the momenta.

Proof: All the interactions are pairwise and local, so the same computations for the case $N = 2$ and $D = 0$ extend to the general case. The ratio of the constants ϕ_σ^0 and $\phi_{\sigma'}^0$, is determined entirely from the first and second equations in the hierarchy (4.1). □

Each $\sigma \in \mathscr{C}^0$ is obtained from $\sigma_0 = (-1,\ldots,-1,1,\ldots,1)$ by a unique set of transpositions (y_j, z_k), which we denote by T_σ. Thus

$$\phi_\sigma^0 = \prod_{(j,k) \in T_\sigma} \theta(\eta_j + \zeta_k). \tag{4.8}$$

Now consider the higher-order components of the density: h_m, $m \geqslant 1$. The sectors of $\mathscr{C}^m$ are characterized by $(m+n+p)$-tuples σ with m zeroes. We assign momenta to σ as follows. Regard each 0 in σ as a pair $(-1,1)$. Starting from the left, assign the -1's momenta η_1, $\eta_2,\ldots$; the $+1$'s momenta $-\zeta_1$, $-\zeta_2,\ldots$; and assign the 0's the sums of momenta $\eta_j - \zeta_k$, with the η's and ζ's taken in their normal order. For example,

$$(-1,0,1,0) \leftrightarrow (\eta_1, \eta_2 - \zeta_1, -\zeta_2, \eta_3 - \zeta_3),$$

$$(-1,1,1,0,1,0,-1) \leftrightarrow (\eta_1, -\zeta_1, -\zeta_2, \eta_2 - \zeta_3, -\zeta_4, \eta_3 - \zeta_5, \eta_4).$$

For fixed locations of the zeroes in σ the basic exponential solution is defined by

$$e_\sigma^m = \exp\, i\left(\sum_{r=1}^{m} x_r(\eta_{i_r} - \zeta_{j_r}) + \sum_{s=1}^{n} y_s \eta_{a_s} - \sum_{t=1}^{p} z_t \zeta_{b_t} \right), \tag{4.9}$$

where

$$i_r(j_r) = \#x\text{'s and } y\text{'s}(z\text{'s}) \text{ to the left of } x_r, \text{ inclusive of } x_r;$$
$$a_s(b_t) = \#x\text{'s and } y\text{'s}(z\text{'s}) \text{ to the left of } y_s, \ (z_t), \text{ inclusive of } y_s, \ (z_t). \tag{4.10}$$

Remark: From (3.7), $i_r = r + k_r - 1$, and $j_r = r + l_r - 1$.
For example,

$$e^m_\sigma(x;y;z) = \exp\, ix_1(x_1(\eta_2 - \zeta_1) + x_2(\eta_3 - \zeta_3) + y_1\eta_1 - z_1\zeta_2), \quad \sigma = (-1,0,1,0);$$
$$e^m_\sigma(x;y;z) = \exp\, i(x_1(\eta_2 - \zeta_3) + x_2(\eta_3 - \zeta_5) + y_1\eta_1 + y_2\eta_4 - z_1\zeta_1 - z_2\zeta_2 - z_3\zeta_4), \tag{4.11}$$
$$\sigma = (-1,1,1,0,1,0,-1)$$

We now describe the general case. For any $\sigma \in \mathscr{C}^m$ define g_σ by

$$g_\sigma = \prod_{r=1}^m g_{i_r j_r}, \quad g_{i_r j_r} = g(\eta_{i_r} + \zeta_{j_r}), \tag{4.12}$$

where i_r and j_r are given in (4.10). For example, for $(-1,0,1,0)$, $i_1 = 2$, $j_1 = 1$, $i_2 = 3$, $j_2 = 2$, and

$$g_\sigma = g_{21} g_{32}.$$

The components of $\mathscr{C}^m$ are determined by the location of the zeroes and the numbers and orders of $+1$'s and -1's between successive zeroes. The factor g_σ is constant on each connected component of $\mathscr{C}^m$. For $\sigma \in \mathscr{C}^m$, we define

$$\phi^m_\sigma = \phi^0_\Sigma \prod_{r=1}^m (-1)^{n(m)+k_r+l_r} \frac{1 + \theta(\eta_{i_r} + \zeta_{j_r})}{2}, \tag{4.13}$$

where $\Sigma \in \mathscr{C}^0$ is obtained from σ by replacing each 0 in σ by $(-1,1)$, and ϕ^0_Σ is given by (4.8).

Theorem 4.2: *The basic solutions of Eqs. (4.1) are given by*

$$h_m(x,y,z) = \psi^m_\sigma e^m_\sigma(x,y,z), \tag{4.14}$$

where

$$\psi^m_\sigma = \phi^m_\sigma g_\sigma = \phi^0_\Sigma \left(\frac{\gamma}{\alpha}\right)^m \prod_{r=1}^m \frac{(-1)^{n(m)+k_r+l_r}}{\eta_{i_r} + \zeta_{j_r} - i\omega}$$

and the ϕ^m_σ are given by (4.8) and (4.13); the g_σ by (4.12); and the e^m_σ by (4.9).

The proof is given in Ref. 15. In addition to Lemma 4.1, it relies on the identity

$$(-1)^{n(m)+K_r+l_r} \frac{\phi^m_{\sigma_r} + \phi^m_{\sigma'_r}}{2} = \phi^{m+1}_\sigma, \quad 1 \leqslant r \leqslant m+1,$$

where σ_r and σ'_r are obtained from σ by replacing the rth; zero by $(-1,1)$ and by $(1,-1)$, respectively. This condition insures compatibility between the phases in *different* particle number sectors; it has no analogue in the usual Bethe ansatz.

V. THE BETHE EQUATIONS

In Sec. IV we constructed basic solutions h_m of Eqs. (4.1). As noted in Sec. II we want to impose the regularity condition (2.5) that eigendensities have no unnecessary discontinuities, i.e., that their antisymmetric extensions be continuous across the collision manifold of like fermions. To obtain this property, we antisymmetrize the basic solutions over the momenta.

Permuting the momenta of the basic solution of (4.4) and (4.5) gives another solution. The general solution of (4.4) and (4.5) is a linear combination

$$e_0(J,K)=\exp\, i\left(\sum_{j=1}^{n} y_j\eta_{J_j}-\sum_{k=1}^{p} z_k\zeta_{K_k}\right),$$

where $J$and K are permutations of 1,...,n and 1,...,p, respectively. In particular,

$$f_0(y;z)=\sum_{J,K}\ \text{sgn}\ (J)\ \text{sgn}\ (K)e_0(J,K)$$

satisfies $X_0f_0=Ef_0$ in

$$\sigma_0=\{y_1<\cdots<y_n<z_1<\cdots<z_p\},$$

and satisfies the regularity condition (2.5).

The density in the other sectors is given by

$$f_0(y;z)=\sum_{J,K}\ \text{sgn}(J)\text{sgn}(K)\phi^0_\sigma(J,K)e_0(J,K), \tag{5.1}$$

where $(y;z)\in\sigma$ and

$$\phi^0_\sigma(J,K)=\prod_{(j,k)\in T_\sigma}\theta(\eta_{J_j}+\zeta_{K_k}).$$

The corresponding densities for higher m are consequently

$$f_m(x;y;z)=\sum_{J,K}\ \text{sgn}\ (J)\ \text{sgn}\ (K)\phi^m_\sigma(J,K)g_\sigma(J,K)e^m_\sigma(J,K),\quad (x;y;z)\in\sigma, \tag{5.2}$$

where $e^m_\sigma(J,K)$, $g_\sigma(J,K)$, and $\phi^m_\sigma(J,K)$ are obtained from (4.9), (4.12), and (4.13) by making the substitutions $j,\ k\mapsto J_j\ K_k$. For example, to obtain densities which vanish when $y_1=y_2\neq z$ in the case $N=3$, and $D=1$, we antisymmetric the base function over the momenta: setting

$$e_0(j,k)=\exp\, i(\eta_jy_1+\eta_ky_2-\zeta z),$$

we take

$$f_0(y_1,y_2,z)=\begin{cases} e_0(1,2)-e_0(2,1), & y_1<y_2<z,\\ \theta(\eta_2+\zeta)e_0(1,2)-\theta(\eta_1+\zeta)e_0(2,1), & y_1<z<y_2,\\ \theta(\eta_1+\zeta)\theta(\eta_2+\zeta)[e_0(1,2)-e_0(2,1)], & z<y_1<y_2.\end{cases}$$

Now $f_0(y_1,y_2,z)$ vanishes when $y_1=y_2\neq z$; but we cannot assert anything for the case $y_1<z<y_2$, since y_1 and y_2 cannot coalesce without equaling z. The corresponding density f_1 is also obtained as a superposition: setting

$$w(j,k)=g(\eta_k+\zeta)(1+\theta(\eta_k+\zeta))\exp\, i((\eta_k-\zeta)x+\eta_j y)$$

we find

$$f_1(x,y)=\begin{cases} w(1,2)-w(2,1), & y<x,\\ -\theta(\eta_2+\zeta)w(2,1)+\theta(\eta_1+\zeta)w(1,2), & x<y.\end{cases}$$

Theorem 5.1: *The antisymmetrized wave functions (5.1) and (5.2) satisfy the regularity condition (2.5) and thus determine a basis of eigenstates for the Hamiltonian (2.1).*

Proof: Consider a pair (y_k,y_{k+1}) (the proof is the same for contiguous z's) and assume there are no intervening x's or z's. Group the terms in the sum (5.1) into pairs corresponding to $J=(\ldots,j,j+1,...)$ and $J'=(\ldots,j+1,j,\ldots)$. At $y_j=y_{j+1}$ we have $e_0(J,K)=e_0(J',K)$, and the coefficient of this common value is

$$\phi^0_\sigma(J,K)-\phi^0_\sigma(J',K).$$

For any given pair (j,k) either $y_j<y_{j+1}<z_k$ or $z_k<y_j<y_{j+1}$. In the first case, neither (j,k) nor $(j+1,k)$ belong to T_σ, so neither of the factors $\theta(\eta_{J_i}-\zeta_{K_k})$ and $\theta(\eta_{J_{j+1}}-\zeta_{K_k})$ belong to the products $\phi^0_\sigma(J,K)$ and $\phi^0_\sigma(J',K)$. In the second case, both (j,k) and $(j+1,k)$ belong to T_σ, so both factors belong to both the products, and $\phi^0_\sigma(J,K)=\phi^0_\sigma(J',K)$. Therefore the coefficient of $e_0(J,K)=\epsilon_0(J',K)$ vanishes in either case, and the sum is zero. This establishes the result for f_0.

We proceed in the same way to verify that the higher-order densities f_m, $m\geqslant 1$, vanish when y_j and y_{j+1} coincide. In view of (4.16), we must show that

$$\phi^m_\sigma(J,K)g_\sigma(J,K)=\phi^m_\sigma(J',K)g_\sigma(J',K).$$

From (4.12) the constants $g_\sigma(J,K)$ depend only on the momenta associated with the bosons (the zeroes of σ), and so are unchanged under any permutation of the fermion momenta. The same applies to the product in (4.13): it depends only on the boson, not the fermion momenta. Therefore the issue for the higher-order densities reduces to the proposition $\phi^0_\Sigma(J,K)=\phi^0_\Sigma(J',K)$, which was established in the first step of this proof. □

Given the f_m defined on the cells

$$\{0\leqslant x_1<\cdots<x_m\leqslant L,\ 0\leqslant y_1<\cdots<y_n\leqslant L,\ 0\leqslant z_1<\cdots<z_p\leqslant L\},$$

we extend them to the hypercube $0\leqslant x_i,\ y_j,\ z_k\leqslant L$ by

$$h_m(x;y;z)=\text{sgn}\ (J)\ \text{sgn}\ (K)f_m(Mx,Jy,Kz), \tag{5.3}$$

where Mx, Jy, and Kz are the unique permutations of the variables x, y, and z for which

$$x_{M_1}<\cdots<x_{M_m},\quad y_{J_1}<\cdots<y_{J_n},\quad z_{K_1}<\cdots<z_{K_p}.$$

We now impose periodic boundary conditions on the wave functions h_m. These periodicity conditions lead to constraints on the momenta, known as the Bethe equations.

For example, in the simplest case $N=2$ and $D=0$ (cf. Sec. IV) we obtained

$$f_0(y,z)=\begin{cases}\exp\, i(\eta y-\zeta z), & y<z,\\ \theta(\eta+\zeta)\exp\, i(\eta y-\zeta z), & y>z.\end{cases}$$

The periodicity conditions

$$f_0(0,z)=f_0(L,z),\quad f_0(y,0)=f_0(y,L)$$

lead immediately to the Bethe equations

$$1=\theta(\eta+\zeta)e^{i\eta L},\quad e^{i\zeta L}=\theta(\eta+\zeta).$$

For the case $n=2$ and $p=1$, the conditions (5.3) lead to

$$f_0(y_1,y_2,0)=f_0(y_1,y_2,L),\quad f_0(0,y_2,z)=-f_0(y_2,L,z).$$

From the definition of f_0 in this case we obtain, respectively,

$$\theta(\eta_1+\zeta)\,\theta(\eta_2+\zeta)(\exp\, i(\eta_1y_1+\eta_2y_2)-\exp\, i(\eta_1y_2+\eta_2y_1))$$

$$=\exp\, i(\eta_1y_1+\eta_2y_2-L\zeta)-\exp\, i(\eta_1y_2+\eta_2y_1-L\zeta)$$

and (say for $y_2<z$)

$$\exp\, i(\eta_2y_2-\zeta z)-\exp\, i(\eta_1y_2-\zeta z)=-\theta(\eta_2+\zeta)\exp\, i(\eta_1y_2+\eta_2L-\zeta z)+\theta(\eta_1+\zeta)$$
$$\times\exp\, i(\eta_2y_2+\eta_1L-\zeta z).$$

From these two equations we get the Bethe equations

$$\exp\, iL\zeta=\theta(\eta_1+\zeta)\,\theta(\eta_2+\zeta),$$

$$1=\theta(\eta_1+\zeta)\exp\, i\eta_1L,\quad 1=\theta(\eta_2+\zeta)\exp\, i\eta_2L.$$

All other periodicity conditions follow from these.

Remark: The second example shows that one must antisymmetrize in momenta to achieve periodicity. For example, suppose $N=3$, $D=1$, and $0<y_2<z$. The condition $h_0(0,y_2,z)=-h_0(y_2,L,z)$ for the basic wave function obtained in Sec. IV becomes

$$h_0(0,y_2,z)=\exp\, i(\eta_2y_2-\zeta z)=-h_0(y_2,L,z)=\theta(\eta_2+\zeta)\exp\, i(\eta_1y_2+\eta_2L-\zeta z),$$

leading to the contradiction

$$\exp\, i\eta_2y_2=-\theta(\eta_2+\zeta)\exp\, i(\eta_1y_2+\eta_2L).$$

Theorem 5.2: *Let*

$$e^{i\eta_kL}=\prod_{l=1}^{p}\theta(\zeta_l+\eta_k),\quad k=1,...,n,\tag{5.4}$$

$$e^{i\zeta_lL}=\prod_{k=1}^{n}\theta(\eta_k+\zeta_l),\quad l=1,...,p.\tag{5.5}$$

Then the densities h_m defined by (5.1), (5.2), and (5.3) are L-periodic in each variable.

The equations (5.4) and (5.5) are known as the Bethe equations. The proof is given in Ref. 15.

VI. CONSTRUCTION OF A DIRAC GROUND STATE

A solution of the Bethe equations gives an eigenvector of the Hamiltonian with energy

$$E=-c_1\sum_{k=1}^{n}\eta_k+c_2\sum_{l=1}^{p}\zeta_l,\tag{6.1}$$

where n and p denote the maximum number of particles of types 1 and 2 for states in the space $\mathscr{F}_{N,D}$, i.e., $n=\frac{1}{2}(N+D)$ and $p=\frac{1}{2}(N-D)$; cf. (4.5). The energy is not bounded below. We construct a stable ground state by filling all negative energy states.

Taking logarithms in the Bethe equations 5.4 and 5.5, we get

$$\begin{aligned}\eta_k-\frac{2\pi}{L}I_k&=\sum_{l=1}^{p}\frac{1}{iL}\log\,\theta(\eta_k+\zeta_l),\quad k=1,\ldots,n,\\ \zeta_l-\frac{2\pi}{L}J_l&=\sum_{k=1}^{n}\frac{1}{iL}\log\,\theta(\eta_k+\zeta_l),\quad l=1,\ldots,p,\end{aligned}\tag{6.2}$$

where

$$\theta(\lambda)=\frac{\lambda+i\omega}{\lambda-i\omega},\quad \omega=\frac{\gamma^2}{4\alpha^2},\tag{6.3}$$

and I_k are distinct integers, as are J_l.

Taking

$$\frac{1}{i}\log\,\theta(\lambda)=\pi-2\tan^{-1}\frac{\lambda}{\omega},\tag{6.4}$$

we write the Bethe equations in the equivalent form

$$\begin{aligned}\eta_k&=\frac{2\pi}{L}I_k+\frac{2}{L}\sum_{l=1}^{p}\tan^{-1}\frac{\eta_l+\zeta_l}{\omega},\\ \zeta_l&=\frac{2\pi}{L}J_l+\frac{2}{L}\sum_{k=1}^{n}\tan^{-1}\frac{\eta_k+\zeta_l}{\omega},\end{aligned}\tag{6.5}$$

where the I_k are distinct half-integers if p is odd, distinct integers if p is even, and similarly for the J_l in relation to n. We assume for convenience that both are even and, without loss of generality, that

$$I_1<I_2<\cdots<I_n;\quad J_1<J_2<\cdots<J_p.\tag{6.6}$$

These conditions imply that there is a solution to 6.5 for which the η_k and the ζ_l are themselves strictly increasing. Indeed Eqs. (6.7) are the variational equations for the functional

$$\Sigma=\frac{1}{2}\left(\sum_{k=1}^{n}\eta_k^2+\sum_{l=1}^{p}\zeta_l^2\right)+\frac{\pi}{L}\left(\sum_{k=1}^{n}I_k\eta_k+\sum_{l=1}^{p}J_l\zeta_l\right)-\sum_{k,l=1}^{n,p}M(\eta_k+\zeta_l),$$

where

$$M(\lambda)=\int_0^{\lambda}\frac{2}{L}\tan^{-1}\frac{s}{\omega}\,ds.$$

For convenience in this section we take $\omega=1$. (This amounts to fixing a length scale, since ω has the dimension 1/length.)

Theorem 6.1: *The Bethe equations have at least one solution for each set of distinct integers I_k and distinct integers J_l.*

Proof: The term $M(\lambda)$ grows only linearly in its argument, so the quadratic terms dominate Σ as $\eta, \zeta \to \infty$. It follows that S is bounded below and tends to infinity for large values of its argument. It therefore always has a minimum. □

Uniqueness of the solutions is a subtler question. For large values of the densities, Σ is not convex, so in principle it could have multiple critical points. In the limiting cases of interest, however, we will obtain uniqueness results. In fact we use the finite case to motivate the limiting cases. Therefore we save space and smooth the exposition by stating most of the finite case results without proof and leaving mathematical details for the limiting cases.

We now turn to the construction of a stable ground state, or vacuum state. For the ground state we assume that $D=0$ (hence $n=p=N/2$) and we consider the case when the velocities of the fermions have opposite signs:

$$c_2<0<c_1. \tag{6.7}$$

Thus $\eta>0$ and $\zeta>0$ mean negative energy for the corresponding particles. *Our procedure will be to fill the available negative energy states from the top down* by choosing consecutive integers I_k, and J_l such that the solution $\{\eta_k, \zeta_l\}$ is positive *but minimally so*; we then take the infinite length and infinite density limits. The equations (6.5) are symmetric, so we take the data $I_k=J_k$ and look for a solution with $\eta_k=\zeta_k$. Thus we want

$$I_k=J_k=k-\kappa_n, \tag{6.8}$$

where κ_n is an integer to be chosen.

Theorem 6.2: *There is a largest integer $\kappa_n=O(n)$ such that (6.5) with data (6.8) has a positive solution. This solution is unique and satisfies $\eta_k=\zeta_k$, and $\eta_1<\cdots<\eta_n$. Moreover, $\eta_1\to 0$ as $n\to\infty$, $L\to\infty$ with n/L bounded above.*

We refer to the solution in Theorem 6.2 as the *cutoff ground state* (CGS). Our interest is the infinite length, finite density limit, and then the infinite density limit. For this purpose we recast (6.5) as a pair of integral equations. Assuming still that $n=p$, we let $\Delta=2\pi n/L$ and define functions on the interval $[0,\Delta)$ by

$$\begin{aligned} I(\xi)&=\frac{2\pi}{L}I_k, \quad J(\xi)=\frac{2\pi}{L}J_k, \quad \frac{2\pi(k-1)}{L}\leqslant\xi<\frac{2\pi k}{L}, \\ \eta(\xi)&=\eta_k, \quad \zeta_L(\xi)=\zeta_k, \quad \frac{2\pi(k-1)}{L}\leqslant\xi<\frac{2\pi k}{L}. \end{aligned} \tag{6.9}$$

(We hope that context will prevent confusion between the use of η and ζ to denote *functions* and the use of η as ζ as pure variables.)

Equations (6.2) with $n=p$ are equivalent to integral equations

$$\begin{aligned} \eta(\xi)&=I(\xi)+\frac{1}{\pi}\int_0^{2\pi n/L}\tan^{-1}\left(\eta(\xi)+\zeta(\xi')\right)d\xi, \\ \zeta(\xi)&=J(\xi)+\frac{1}{\pi}\int_0^{2\pi n/L}\tan^{-1}\left(\eta(\xi')+\zeta(\xi)\right)d\xi'. \end{aligned} \tag{6.10}$$

It can be shown that for every set of data I, J corresponding to sets of integers indexed as in (6.6), there is a solution (η,ζ) with positive jumps at each of the points of discontinuity $2\pi k/L$. We define approximate inverse functions accordingly:

$$\xi(\eta)=\inf\{\xi:\eta(\xi)\geqslant\eta\}; \quad \xi(\zeta)=\inf\{\xi:\zeta(\xi)\geqslant\zeta\}. \tag{6.11}$$

Remark: These functions have jumps of size $2\pi/L$, so their difference quotients with respect to η and to ζ respectively count the number of particles associated to a given momentum interval.

With the Bethe equations in the form (6.10), it is clear how to pass to the infinite length, finite density limit. To pass also to the infinite density limit we observe that (6.10) is equivalent to

$$\eta(\xi)-\eta(0)=I(\xi)-I(0)+\frac{1}{\pi}\int_0^{2\pi n/L}[\tan^{-1}(\eta(\xi)+\zeta(\xi'))-\tan^{-1}(\eta(0)+\zeta(\xi'))]\,d\xi';$$
$$\zeta(\xi)-\zeta(0)=J(\xi)-J(0)+\frac{1}{\pi}\int_0^{2\pi n/L}[\tan^{-1}(\eta(\xi')+\zeta(\xi))-\tan^{-1}\,(\eta(\xi')+\zeta(0))]\,d\xi'. \tag{6.12}$$

The data (6.8) give rise to the functions $I(\xi)=J(\xi)=\xi-c_\Delta$ in the $L\to\infty$ limit, Δ finite, and in this limit $\eta(0)=z(0)=0$. Thus in the form (6.12) we pass to the $\Delta=\infty$ limit and find the equations for the *ground state* $(\eta_0;\zeta_0=\eta_0)$:

$$\eta_0(\xi)=\xi+\frac{1}{\pi}\int_0^{\infty}[\tan^{-1}(\eta_0(\xi)+\eta_0(\xi'))-\tan^{-1}\,(\eta_0(\xi'))]\,d\xi'. \tag{6.13}$$

We obtain existence and uniqueness of the solution to (6.13) by converting it to a linear integral equation for the derivative of the inverse function:

$$\rho_0(\eta(\xi))=\frac{1}{(d\eta_0/d\xi)(\xi)}. \tag{6.14}$$

Differentiate (6.9), multiply by ρ_0, and change the variable of integration to obtain

$$\rho_0(\eta)=1-\frac{1}{\pi}\int_0^{\infty}\frac{\rho_0(\eta')d\eta'}{1+(\eta+\eta')^2}=1-K(\rho_0). \tag{6.15}$$

Remarks: (1) In view of the remark after (6.9), ρ_0 may be thought of as the *particle density function* for the ground state.

(2) Note that the kernel of the integral operator K satisfies

$$\sup_{\eta\geqslant 0}\frac{1}{\pi}\int_0^{\infty}\frac{d\eta'}{1+(\eta+\eta')^2}=\frac{1}{2}. \tag{6.16}$$

Therefore T has norm $\frac{1}{2}$ as an operator in $L^\infty(\mathbb{R}_+)$ and (6.16) has a unique solution, obtainable by successive approximations. The solution is positive and bounded.

In the next section we need both the analytic continuation $\rho_{0,t}$ of ρ to the negative axis and a dual function $\rho^*_{0,t}$ that is the analytic continuation of the solution to the same equation but with a change of sign:

$$\rho_0^*(\eta)=1+\frac{1}{\pi}\int_0^{\infty}\frac{\rho_0^*(\eta')d\eta'}{1+(\eta+\eta')^2}=1+K\rho^*_{0,t}(\eta),\quad \eta\geqslant 0. \tag{6.17}$$

In terms of these functions we define functions ξ_0 and ξ_0^*:

$$\xi_0(\eta)=\int_0^{\eta}\rho_{0,t}(s)ds,\quad \xi_0^*(\eta)=\int_0^{\eta}\rho^*_{0,t}(s)ds,\quad \eta\in\mathbb{R}. \tag{6.18}$$

Theorem 6.3: *The extension $\rho_{0,t}$ of the particle density function ρ_0 and the dual function $\rho^*_{0,t}$ satisfy the estimates*

$$0<\rho_{0,t}(\eta)<1<\rho^*_{0,t}<2, \quad \eta\in\mathbb{R};$$

$$\rho_{0,t}(\eta)=1+O(1/\eta), \quad \rho^*_{0,t}(\eta)=2+O(1/\eta) \quad \text{as} \quad \eta\to\infty; \tag{6.19}$$

$$\pi\eta\rho_{0,t}(\eta)=-1+O(\log|\eta|/|\eta|), \quad \rho^*_{0,t}=1+O(1/\eta) \quad \text{as} \quad \eta\to-\infty.$$

The functions ξ_0 and ξ_0^* have asymptotics

$$\xi_0(\eta)=\eta+O(1), \quad \xi_0^*(\eta)=2\eta+O(1) \quad \textit{as} \quad \eta\to+\infty;$$
$$\pi\xi_0(\eta)=-\log\eta+O(1), \quad \xi_0^*(\eta)=\eta+O(1) \quad \textit{as} \quad \eta\to-\infty. \tag{6.20}$$

In particular the function ξ_0 is a diffeomorphism of the line. Its inverse function η_0 satisfies the integral equation (6.13) on $\mathbb{R}_+$.

Proof: It follows from (6.16) that the solution extends analytically. The kernel is positive, so $0<\rho_0<1$. The asymptotics of ρ_0 and of ξ_0 are easily verified from (6.15). The argument for $\rho^*_{0,t}$ and ξ_0^* are similar. Finally (6.13) results from substituting (6.16) in the definition of ξ_0 and using $\rho_0 d\eta'=d\xi'$ to change the variable of integration. □

We conclude this section with the integral expressions of various quantities associated with a state described by a pair of functions η,ζ. For a finite number of particles the momentum P and energy E are

$$P=\sum_{k=1}^n \eta_k-\sum_{l=1}^n \zeta_l=\frac{L}{2\pi}\int_0^{2\pi n/L}\eta(\xi)d\xi-\frac{L}{2\pi}\int_0^{2\pi n/L}\zeta(\xi)\,d\xi,$$
$$E=-c_1\sum_{k=1}^n \eta+c_2\sum_{l=1}^n \zeta_l=-\frac{c_1L}{2\pi}\int_0^{2\pi n/L}\eta(\xi)\,d\xi+\frac{c_2L}{2\pi}\int_0^{2\pi n/L}\zeta(\xi)\,d\xi. \tag{6.21}$$

The particle number $n=p$ itself can be expressed in terms of the inverse functions:

$$n=\frac{L}{2\pi}\sup\,\xi(\eta)=\frac{L}{2\pi}\sup\,\xi(\zeta). \tag{6.22}$$

Therefore in the infinite length limit the particle densities per unit length are

$$\frac{1}{2\pi}\sup\,\xi(\eta)=\frac{1}{2\pi}\int\rho(\eta)\,d\eta, \quad \frac{1}{2\pi}\sup\,\xi(\zeta)=\frac{1}{2\pi}\int\sigma(\zeta)\,d\zeta. \tag{6.23}$$

VII. FINITE PARTICLE EXCITED STATES

In this section we construct particle-hole excitations of the ground state. These have finite positive energy with respect to the ground state in the infinite density limit, confirming the stability of the ground state.

We begin with a single particle/hole excited state for an η particle, with momentum $\eta_p<0$ for the particle and $\eta_h>0$ for the hole. Consider first a cutoff ground state with a high particle density, so that there are large momentum particles. Denote the functions for this CGS by $\eta,\zeta=\eta$. We change the CGS data by choosing k such that η_k is close to η_h and changing I_k to I_k-s, where the integer s is chosen so that I_k-s is close to $L\xi_0(\eta_p)/2\pi$. In the integral equation picture (6.10) the new data is given by functions I, $J=I$. Here $I=I$ except on an interval of length

$2\pi/L$ located near $\xi_h=\xi_0(\eta_h)$, on which it differs from I by approximately $\xi_p-\xi_h$, $\xi_p=\xi_0(\eta_p)$. This change in data changes the η solution by a bounded amount on that interval and otherwise changes both $\eta(\xi)$ and $\zeta(\xi)$ by $O(1/L)$. Therefore we write the solution $(\overline{\eta},\overline{\zeta})$ of the perturbed equation as

$$\overline{\eta}(\xi)=\eta(\xi)+e_1(\xi)/L+f(\xi),\quad \overline{\zeta}(\xi)=\zeta(\xi)+e_2(\xi)/L, \tag{7.1}$$

where e_1 vanishes on the critical interval and f is supported on the critical interval. With a similar notation for energy and momentum, the excitation momentum and energy are

$$\begin{aligned}\delta P&=\overline{P}-P=\frac{1}{2\pi}\int_0^\Delta [e_1(\xi)-e_2(\xi)]\,d\xi+f,\\ \delta E&=\overline{E}-E=\frac{1}{2\pi}\int_0^\Delta [c_1e_1(\xi)-c_2e_2(\xi)]\,d\xi+c_1f.\end{aligned} \tag{7.2}$$

Here we abuse notation and write f also for the *value* of $\overline{\eta}-\eta$ on the critical interval.

With large L the integral equations (6.10) give

$$e_1(\xi)\approx\frac{1}{\pi}\int_0^\Delta\frac{[e_1(\xi)+e_2(\xi')]\,d\xi'}{1+(\eta(\xi)+\eta(\xi'))^2}; \tag{7.3a}$$

$$f\approx\xi_p-\xi_h+\frac{1}{\pi}\int_0^\Delta[\tan^{-1}(\eta_h+f+\eta(\xi'))-\tan^{-1}(\eta_h+\eta(\xi'))]\,d\xi'; \tag{7.3b}$$

$$e_2(\xi)\approx 2[\tan^{-1}(\eta_h+f+\eta(\xi))-\tan^{-1}(\eta_h+\eta(\xi))]+\frac{1}{\pi}\int_0^\Delta\frac{[e_1(\xi')+e_2(\xi)]\,d\xi'}{1+(\eta(\xi)+\eta(\xi'))^2}. \tag{7.3c}$$

Here (7.3a) is valid outside the critical interval.

In the infinite length, infinite density limit (6.13) and (7.3b) show that $f=\eta_h-\eta_p$, so $\overline{\eta}\approx\eta_h$ on the critical interval, as desired. In this limit the remaining equations (7.3) become

$$\begin{aligned}e_1(\eta)&=\frac{1}{\pi}\int_0^\infty\frac{[e_1(\eta)+e_2(\eta')]\rho_0(\eta')\,d\eta'}{1+(\eta+\eta')^2},\\ e_2(\eta)&=\frac{1}{\pi}\int_0^\infty\frac{[e_1(\eta')+e_2(\eta)]\rho_0(\eta')d\eta'}{1+(\eta+\eta')^2}+2\tan^{-1}(\eta_p+\eta)-2\tan^{-1}(\eta_h+\eta).\end{aligned} \tag{7.4}$$

We write $\tilde{e}_j(\eta)$ for $e_j(\xi_0(\eta))\rho_0(\eta)$: The integral equation (6.15) for ρ_0 allows (7.4) to be rewritten:

$$\begin{aligned}\tilde{e}_1(\eta)&=K(\tilde{e}_2)(\eta),\\ \tilde{e}_2(\eta)&=2\tan^{-1}(\eta_p+\eta)-2\tan^{-1}(\eta_h+\eta)+K(\tilde{e}_1)(\eta).\end{aligned} \tag{7.5}$$

In the limit the excitation momentum and energy are

$$\delta P=\frac{1}{2\pi}\int_0^\infty[\tilde{e}_1(\eta)-\tilde{e}_2(\eta)]\,d\eta+(\eta_p-\eta_h), \tag{7.6}$$

$$\delta E = \frac{1}{2\pi}\int_0^\infty [-c_1\tilde{e}_1(\eta)+c_2\tilde{e}_2(\eta)]\,d\eta - c_1(\eta_p-\eta_h)$$
$$= -\alpha\left(\frac{1}{2\pi}\int_0^\infty [\tilde{e}_1(\eta)+\tilde{e}_2(\eta)]\,d\eta+\eta_p-\eta_h\right)$$
$$+c_0\left(\frac{1}{2\pi}\int_0^\infty [\tilde{\epsilon}_1(\eta)-\tilde{e}_2(\eta)]\,d\eta-\eta_p+\eta_h\right).$$

[The last part of (7.6) follows from the second part, since $2\alpha=c_1-c_2$ and $2c_0=c_1+c_2$.]

The system (7.5) and the equations (7.6) thus characterize this single-particle/hole excitation of the ground state. Again the fact that K has norm $\frac{1}{2}$ implies that (7.6) has, for each choice of η_h and η_p, a unique solution. Positivity of the kernel implies that the solution (e_1,e_2) is negative when $\eta_p-\eta_h$ is negative, so the excitation energy is positive. We can be more precise.

Theorem 7.1: *The excited state momentum and the excitation energy can be expressed in terms of the (extended) functions ξ_0, ξ_0^* of Theorem 6.3. They have the form*

$$\delta P = P_p - P_h = P(\eta_p)-P(\eta_h)=\xi_0(\eta_p)-\xi_0(\eta_h);$$
$$\delta E = E_p - E_h = E(\eta_p)-E(\eta_h)=[-\alpha\xi_0^*(\eta_p)-c_0\xi_0(\eta_p)]-[-\alpha\xi_0^*(\eta_h)-c_0\xi_0(\eta_h)]. \tag{7.7}$$

These functions have the asymptotics

$$E_p\sim 2\alpha e^{\pi|P_p|} \quad as\ \ P_p\to-\infty,$$
$$E_h\sim -c_1P_h \quad as\ \ P_h\to+\infty. \tag{7.8}$$

Proof: The inhomogeneous term for the pair (η_p,η_h) is the sum of the inhomogeneous term for the pair $(\eta_p,0)$ and the inhomogeneous term for the pair $(0,\eta_h)$ and is an odd function of its two arguments. Therefore it suffices to consider the case $\eta_p=\tilde{\eta}$ and $\eta_h=0$. We make the $\tilde{\eta}$ dependence explicit by writing $\tilde{e}_1(\eta,\tilde{\eta})$ and $\tilde{e}_2(\eta,\tilde{\eta})$. Set

$$f_1=\frac{1}{2\pi}\frac{\partial}{\partial\tilde{\eta}}[\tilde{e}_1+\tilde{e}_2],\quad f_2=\frac{1}{2\pi}\frac{\partial}{\partial\tilde{\eta}}[\tilde{e}_2-\tilde{e}_1]. \tag{7.9}$$

(Note that the $\tilde{e}_j$ vanish at $\tilde{\eta}=0$, so the sum and difference can be recovered by integrating the f_j from $\tilde{\eta}=0$.) Adding and subtracting first derivatives with respect to $\tilde{\eta}$ in (7.5), we find that as functions of η the f_j satisfy

$$f_1=Kf_1+k,\quad f_2=-Kf_2+k,\quad k(\eta,\tilde{\eta})=\frac{1}{\pi}\frac{1}{1+(\eta+\tilde{\eta})^2}. \tag{7.10}$$

Note that k is the kernel of the operator K. Let F_j denote the integral operator that has kernel f_j and denote the identity operator Id. Then (7.10) is equivalent to the operator equations

$$(Id-K)(Id+F_1)=Id,\quad (Id+K)(Id-F_2)=Id. \tag{7.11}$$

The integral $\int_0^\infty f_j(\eta,\tilde{\eta})\,d\eta$ is the same as the function $F_j(1)(\tilde{\eta})$, where 1 denotes the function that is identically 1. It follows from (7.9) and (7.10) that

$$\frac{1}{2\pi}\int_0^\infty \tilde{e}_1(\eta,\tilde{\eta})d\eta+\tilde{\eta}=\frac{1}{2}\int_0^{\tilde{\eta}}\left[\int_0^\infty (f_1-f_2)+2\right]d\eta$$
$$=\frac{1}{2}\int_0^{\tilde{\eta}}[(F_1(1)+1)+(1-F_2(1))], \tag{7.12}$$

$$\frac{1}{2\pi}\int_0^\infty \tilde{e}_2(\eta,\tilde{\eta})d\eta = \frac{1}{2}\int_0^{\tilde{\eta}}\left[\int_0^\infty (f_1+f_2)\right]d\eta$$
$$= \frac{1}{2}\int_0^{\tilde{\eta}}[F_1(1)+F_2(1)]d\eta$$
$$= \frac{1}{2}\int_0^{\tilde{\eta}}[(F_1(1)+1)-(1-F_2(1))]\,d\eta.$$

In view of (7.11), $F_1(1)+1$ is the solution of $u=Ku+1$, while $1-F_2(1)$ is the solution of $v=-Kv+1$. By (6.17) and (6.16) these functions are $\rho^*_{0,t}$ and ρ_0, respectively. It follows that

$$\frac{1}{2\pi}\int_0^\infty \tilde{e}_1(\eta,\tilde{\eta})\,d\eta+\tilde{\eta} = \frac{1}{2}[\xi_0^*(\tilde{\eta})+\xi_0(\tilde{\eta})], \tag{7.13}$$

$$\frac{1}{2\pi}\int_0^\infty \tilde{e}_2(\eta,\tilde{\eta})\,d\eta = \frac{1}{2}[\xi_0^*(\tilde{\eta})-\xi_0(\tilde{\eta})]. \tag{7.14}$$

The momentum term $P(\tilde{\eta})$ in (7.6) is the difference of the two expressions (7.13) and (7.14). Similarly, the excitation energy term $E(\tilde{\eta})$ in (7.6) is the linear combination of (7.13) and (7.14) with coefficients $-c_1$ and c_2, respectively. This proves (7.7). The asymptotics (7.8) follow from (7.7) and the asymptotics (6.20) of ξ_0 and ξ_0^*. □

Exactly similar considerations apply to a single particle/hole ζ excitation, with the roles of e_1 and e_2 interchanged. In particular, the indices 1 and 2 in (7.9) should be interchanged throughout.

Compound excitations may be treated in exactly the same way. Consider the case of particle/hole excitations in η described by $\eta_{h,i}\geqslant 0$, $\eta_{p,i}\leqslant 0$, $i=1,...,r$, and in ζ described by $\zeta_{h,j}\geqslant 0$, $\zeta_{p,j}\leqslant 0$, $j=1,...,s$. Then in the infinite density limit the Bethe equations become

$$\begin{aligned}\tilde{e}_1(\eta) &= K(\tilde{e}_2)(\eta)+2\sum_{j=1}^{s}[\tan^{-1}(\eta+\zeta_{p,j})-\tan^{-1}(\eta+\zeta_{h,j})],\\ \tilde{e}_2(\eta) &= K(\tilde{e}_1)(\eta)+2\sum_{i=1}^{r}[\tan^{-1}(\eta+\eta_{p,i})-\tan^{-1}(\eta+\eta_{h,i})].\end{aligned} \tag{7.15}$$

This state is a superposition of corresponding single-particle/hole excited states. Therefore the associated momentum and excitation energy are given by

$$\begin{aligned}\delta P &= \sum_{i=1}^{r}[\xi_0(\eta_{p,i})-\xi_0(\eta_{h,i})]+\sum_{j=1}^{s}[\xi_0(\zeta_{h,j})-\xi_0(\zeta_{p,j})],\\ \delta E &= -\alpha\left(\sum_{i=1}^{r}[\xi_0^*(\eta_{p,i})-\xi_0^*(\eta_{h,i})]+\sum_{j=1}^{s}[\xi_0^*(\zeta_{p,j})-\xi_0^*(\zeta_{h,j})]\right)\\ &\quad +c_0\left(\sum_{i=1}^{r}[\xi_0(\eta_{p,i})-\xi_0(\eta_{h,i})]-\sum_{j=1}^{s}[\xi_0(\zeta_{p,j})-\xi_0(\zeta_{h,j})]\right).\end{aligned} \tag{7.16}$$

VIII. FINITE DENSITY PERTURBATIONS OF THE GROUND STATE

In this section we study large deviations from the ground state. Again we motivate the procedure by looking briefly at the finite length, finite particle case in the form of the integral

equations (6.10). Denote by $I_0 = J_0$ the data that corresponds to the CGS data (6.8). The CGS data uses all the integers from an interval with endpoints $\pm O(n/2)$ and we are temporarily applying a low-energy cutoff that corresponds to the upper end of this interval, so the data that corresponds to an admissible perturbation of the CGS satisfies $I,\ J \leqslant I_0$. The solution can be found by iteration from the integral equations (6.10). The monotonicity properties of the mapping imply that the solution is dominated by the CGS (η_0, ζ_0):

$$\eta(\xi) \leqslant \eta_0(\xi), \quad \zeta(\xi) \leqslant \zeta_0(\xi). \tag{8.1}$$

Moreover if the perturbation is to have finite relative energy density in the limit, we expect that $I,\ J \approx I_0$ for large ξ. Note also that the jumps in the data must be at least as great as the jumps $2\pi/L$ in I_0. We pass to the infinite length, infinite (total) density limit and look for a solution of an analogue of (6.12):

$$\begin{aligned} &\eta(\xi) - I(\xi) + \frac{1}{\pi}\int_0^\infty [\tan^{-1}(\eta(\xi)+\zeta(\xi')) - \tan^{-1}(\eta_0(0)+\zeta_0(\xi'))]\ d\xi'; \\ &\zeta(\xi) - J(\xi) + \frac{1}{\pi}\int_0^\infty [\tan^{-1}(\eta(\xi')+\zeta(\xi)) - \tan^{-1}(\xi_0(\xi')+\zeta_0(\xi))]\ d\xi'. \end{aligned} \tag{8.2}$$

According to the preceding discussion the natural assumptions on the data are

$$\frac{dI}{d\xi} \geqslant 1, \quad \frac{dJ}{d\xi} \geqslant 1; \quad I(\xi) \approx J(\xi) \approx \xi, \quad \xi \gg 0. \tag{8.3}$$

It can be shown that finite particle solutions whose data is such that the formal limits are (8.2) converge to solutions of (8.2). However, it is more convenient for what follows to write the equations for the particle density functions $\rho = d\xi/d\eta$ and $\sigma = d\xi/d\zeta$:

$$\begin{aligned} \rho(\eta)\cdot I'(\eta) &= 1 - \frac{1}{\pi}\int_{-\infty}^{\infty} \frac{\sigma(\zeta)d\zeta}{1+(\eta+\zeta)^2} = 1 - (K\sigma)(\eta), \\ \sigma(\zeta)\cdot J'(\zeta) &= 1 - \frac{1}{\pi}\int_{-\infty}^{\infty} \frac{\rho(\eta)d\eta}{1+(\eta+\zeta)^2} = 1 - (K\rho)(\zeta), \end{aligned} \tag{8.4}$$

where

$$I'(\eta) = \frac{dI}{d\xi}(\xi(\eta)), \quad J'(\zeta) = \frac{dJ}{d\xi}(\xi(\zeta)).$$

We have removed the upper bound on particle energies, so the integrations in (8.4) need to be taken over the whole line. Now K has norm 1 as an operator in $L^\infty(\mathbb{R})$ so solvability of (8.4) becomes an issue. We rewrite (8.4) in the form

$$\rho = \Theta(1 - K\sigma), \quad \sigma = \Psi(1 - K\rho) \tag{8.4$'$}$$

and adopt the point of view that the functions Θ and Ψ are the data. For the ground state the data are $\Psi_0 = \Theta_0$, the Heaviside function: $\Theta_0(s) = 0$, $s < 0$; $\Theta_0 = 1$, $s \geqslant 0$. More generally we can express the conditions (8.3) and the assumption that our states are perturbations of the ground state by requiring

$$0 \leqslant \Theta, \quad \Psi \leqslant 1; \qquad \lim_{|\eta| \to \infty} (\Theta - \Theta_0) = \lim_{|\zeta| \to \infty} (\Psi - \Psi_0) = 0, \tag{8.5}$$

while (8.1) gives an implicit constraint on the data (Θ, Ψ) in terms of the solution. In fact (8.1) implies the reverse relation between the inverse functions, leading to

$$\int_{-\infty}^{\eta} (\rho - \rho_0) \geqslant 0, \quad \int_{-\infty}^{\zeta} (\sigma - \sigma_0) \geqslant 0, \quad \text{all} \quad \eta, \sigma. \tag{8.6}$$

Moreover the cutoff solution (η,ζ) and the corresponding CGS (η_0, ζ_0) at any given step were defined over the same ξ interval, so the relative particle density should be zero:

$$\int_{-\infty}^{\infty} (\rho - \rho_0) = 0 = \int_{-\infty}^{\infty} (\sigma - \sigma_0). \tag{8.7}$$

We show below that (8.7) is necessary for the relative energy density to be finite.

Theorem 8.1: *Under assumption* (8.5) *the equations (8.4) have a unique solution. For the solution we have*

$$\begin{gathered} 0 \leqslant \rho \leqslant 1, \quad 0 \leqslant \sigma \leqslant 1, \\ \lim_{\eta \to \infty} \rho(\eta) = \lim_{\zeta \to \infty} \sigma(\zeta) = 1, \qquad \lim_{\eta \to -\infty} \rho(\eta) = \lim_{\zeta \to -\infty} \sigma(\zeta) = 0. \end{gathered} \tag{8.8}$$

Proof: We use Θ and Ψ also to denote the operations of multiplication by the corresponding functions. Then the equations are

$$\rho + \Theta K \sigma = \Theta, \quad \sigma + \Psi K \rho = \Psi.$$

We apply the operator $\mathrm{Id} - \Psi K$ to the first equation and $\mathrm{Id} - \Theta K$ to the second and reorganize to obtain

$$(\mathrm{Id} - \Theta K \Psi K)\rho = \Theta - \Theta K \Psi, \quad (\mathrm{Id} - \Psi K \Theta K)\sigma = \Psi - \Psi K \Theta. \tag{8.9}$$

It is enough to show that $\Theta K \Psi$ and $\Psi K \Theta$ have norm <1. The assumptions on Θ and Ψ imply easily that the integral of the kernel of either operator against either variable is bounded away from 1, so the operators have norm <1 in any L^p, $1 \leqslant p \leqslant \infty$. The asymptotics follow easily from the assumptions about Θ and Ψ, together with the trivial estimaes

$$0 \leqslant \rho \leqslant \Theta, \quad 0 \leqslant \sigma \leqslant \Psi. \qquad \square$$

One must make stronger assumptions to ensure finiteness of the integrals (8.6) and (8.7) and the relative energy density

$$E = -\frac{c_1}{2\pi} \int_{-\infty}^{\infty} (\rho - \rho_0)\, \eta \, d\eta + \frac{c_2}{2\pi} \int_{-\infty}^{\infty} (\sigma - \sigma_0)\, \zeta \, d\zeta. \tag{8.10}$$

Theorem 8.2: *The integrals (8.6) and (8.7) are finite if* $(\Theta - \Theta_0)$ *and* $(\Psi - \Psi_0)$ *are integrable.*

If $\eta(\Theta_0 - \Theta)$ *and* $\zeta(\Psi_0 - \Psi)$ *are integrable, then* E *is finite if and only if (8.7) holds. If so, then* $E \geqslant 0$.

Proof: Note that

$$\rho - \rho_0 = (\Theta - \Theta_0)(1 - K\sigma_0) - \Theta K(\sigma - \sigma_0), \tag{8.11}$$

with a similar equation for $\sigma-\sigma_0$. Analyzing this system as above, we see that integrability of $\rho-\rho_0$ and $\sigma-\sigma_0$ follows from integrability of the data in the analogue of (8.9), which follows in turn from integrability of $\Theta-\Theta_0$ and $\Psi-\Psi_0$.

Note that integrability of $\eta(\rho_0-\rho)$ at $-\infty$ follows immediately from (8.11) and integrability of $\eta(\Theta_0-\Theta)$. At $+\infty$ we observe from (8.11) that the necessary and sufficient condition is the integrability of $\eta K(\sigma-\sigma_0)$. Assume that $\zeta^2(\Psi-\Psi_0)$ is integrable at $-\infty$. Then $\zeta^2(\sigma-\sigma_0)$ is also integrable at $-\infty$ and Lebesgue's Dominated Convergence Theorem implies that

$$\lim_{\eta\to+\infty} K(\sigma-\sigma_0)=\int_{-\infty}^{\infty}(\sigma-\sigma_0)\,d\zeta. \tag{8.12}$$

This proves the necessity of the conditions (8.7).

Conversely one can deduce the integrability of $\eta K(\sigma-\sigma_0)$ and $\zeta K(\rho-\rho_0)$ from conditions (8.7) together with integrability of $\eta(\rho_0-\rho)$ and $\zeta(\sigma_0-\sigma)$. To see this, note that the mean-value zero condition allows us to replace the kernel of K with the kernel

$$\widetilde{k}(\eta,\zeta)=\frac{1}{\pi}\left[\frac{1}{1+(\eta+\zeta)^2}-\frac{1}{1+\eta^2}\right]. \tag{8.13}$$

The corresponding operator takes $L^1(\mathbb{R},(1+|z|)d\zeta)$ to $L^1(\mathbb{R},(1+|\eta|)d\eta)$, since we can multiply $\widetilde{k}$ by $(1+|\eta|)/(1+|z|)$, take the absolute value, and estimate the integral with respect to η.

Finally, to show positivity of the relative energy density we let g_1 and g_2 denote the integrals in (8.6), so that

$$\frac{dg_1}{d\eta}=\rho,\quad \frac{dg_2}{d\zeta}=\sigma,\quad g_j\geqslant 0,\quad g_j(\pm\infty)=0. \tag{8.14}$$

Integrating by parts in (8.10) we find that

$$E=\frac{c_1}{2\pi}\int_{-\infty}^{\infty}g_1(\eta)\,d\eta-\frac{c_2}{2\pi}\int_{-\infty}^{\infty}g_2(\zeta)\,d\zeta\geqslant 0.$$

□

IX. THERMODYNAMICS

We consider now the thermodynamics of the finite density perturbations of the ground state that were constructed in the preceding section. We follow, with appropriate modifications, Yang and Yang[5] and Ohkuma.[7] Consider first the case of finite L, a state with a very large number of particles, and data I, J as in (8.1). Define

$$\begin{aligned} h(s)&=s-\frac{1}{\pi}\int_0^{\Delta}[\tan^{-1}(s+\zeta(\xi'))-\tan^{-1}(\eta(0)+\zeta(\xi'))]\,d\xi',\quad s\geqslant\eta(0),\\ k(t)&=t-\frac{1}{\pi}\int_0^{\Delta}[\tan^{-1}(\eta(\xi')+t)-\tan^{-1}(\eta(\xi')+\zeta(0))]\,d\xi',\quad t\geqslant\zeta(0). \end{aligned} \tag{9.1}$$

These are strictly increasing functions with the properties that at the (discrete) values taken by the data the values are

$$h(\eta(\xi))=I(\xi),\quad k(\zeta(\xi))=J(\xi).$$

The number m of η particles from our state with momenta in a small interval $(\eta, \eta+d\eta)$ is proportional to the length of the corresponding ξ interval, i.e., if $\eta=\eta(\xi)$ and $\eta+d\eta=\eta(\xi+d\xi)$, then

$$m\approx\frac{L}{2\pi}\,d\xi.$$

The function I has jumps that are positive integer multiples of $L/2\pi$, so

$$m\leqslant n=\frac{L}{2\pi}\,(I(\xi+d\xi)-I(\xi)).$$

If data I at the m jump sites in the interval $(\xi,\xi+d\xi)$ is changed in such a way that I remains strictly increasing and the values of $LI/2\pi$ are integers, the effect on the total energy of the corresponding state will be negligible: $O((d\eta)^2)$. The possible sites are indexed by the n integers between $LI(\xi)/2\pi$ and $L(I\xi)/2\pi$. Thus the contribution to entropy from the interval is $\log\binom{n}{m}$.

In the infinite length and infinite density limits the density functions for the numbers n and m above have densities with respect to the momentum η given by $\rho=d\xi/d\eta$ and $\rho_t=dh/d\eta$, respectively. As before ρ is the particle density. We take $\rho_h=\rho_t-\rho$ to be the *hole density* and ρ_t to be the (formal) total density. Similar considerations apply to ζ particles and give particle density σ and hole density $\sigma_h=\sigma_t-\sigma$. In the notation of Sec. VIII the relations among these functions are

$$\begin{gathered}\rho=\Theta\rho_t,\quad \rho_h=(1-\Theta)\rho_t,\quad \sigma=\Psi\sigma_t,\quad \sigma_h=(1-\Psi)\sigma_t,\\ \rho_t=1-K\sigma=1-K\Psi\sigma_t,\quad \sigma_t=1-K\rho=1-K\Theta\rho_t.\end{gathered}\tag{9.2}$$

Returning to the interval $(\xi,\xi+d\xi)$, let $(\eta,\eta+d\eta)$ denote its image under h^{-1}. According to the preceding argument and Stirling's formula, the entropy density over $(\eta+d\eta)$ is approximately

$$\begin{aligned}\frac{L}{2\pi}\,[\rho_t\log\rho_t-\rho\log\rho-\rho_h\log\rho_h]&=\frac{L}{2\pi}\,[\rho\log(\rho_t/\rho)+\rho_h\log(\rho_t/\rho_h)]\\ &=-\frac{L}{2\pi}\,\rho_t[\Theta\log\Theta+(1-\Theta)\log(1-\Theta)].\end{aligned}\tag{9.3}$$

A similar formula holds for particles of the second type. Thus in the infinite length, infinite density limit the entropy per unit length is

$$\begin{aligned}S=&\frac{1}{2\pi}\int_{-\infty}^{\infty}[\rho_t\log\rho_t-\rho\log\rho-\rho_h\log\rho_h]\,d\eta\\ &+\frac{1}{2\pi}\int_{-\infty}^{\infty}[\sigma_t\log\sigma_t-\sigma\log\sigma-\sigma_h\log\sigma_h]\,d\zeta.\end{aligned}\tag{9.4}$$

The entropy density for the ground state is zero.

At a given finite temperature T the free energy density of a perturbation (ρ,σ) of the ground state relative to that of the ground state is

$$F_T(\rho,\sigma)=E-TS,\tag{9.5}$$

where the relative energy density E is given by (8.9). In order for E to be finite, we showed that the relative particle densities must vanish:

$$\int_{-\infty}^{\infty}(\rho-\rho_0)\ d\eta=0=\int_{-\infty}^{\infty}(\sigma-\sigma_0)\ d\zeta. \tag{9.6}$$

Thus the equilibrium solution should minimize F subject to the constraints (9.6).

We consider briefly the formal argument for an equilibrium. Equations (9.2) relate variations in ρ_t, ρ_h, σ_t, and σ_h to variations in the particle densities ρ and Θ:

$$\begin{aligned}\dot\rho t&=-K\dot\sigma, \quad \dot\rho_h=-\dot\rho-K\dot\sigma,\\ \dot\sigma_t&=-K\dot\rho, \quad \dot\sigma_h=-\dot\sigma-K\dot\rho.\end{aligned} \tag{9.7}$$

The constraints (9.6) require

$$\int_{-\infty}^{\infty}\dot\rho\ d\eta=0=\int_{-\infty}^{\infty}\dot\sigma\ d\zeta. \tag{9.8}$$

Taking into account (9.7) and the symmetry of the operator K, we can express the variation in the free energy as

$$\begin{aligned}\dot F=&\int_{-\infty}^{\infty}\dot\rho[-c_1\eta+T\ \log(\rho/\rho_h)+TK\ \log(\sigma_t/\sigma_h)]\ d\eta\\ &+\int_{-\infty}^{\infty}\dot\sigma[c_2\zeta+T\ \log(\sigma/\sigma_h)+TK\ \log(\rho_t/\rho_h)]\ d\zeta.\end{aligned} \tag{9.9}$$

Following Yang and Yang,[5] one can introduce functions ϵ_j:

$$e^{-\epsilon_1/T}=\rho/\rho_h, \quad e^{-\epsilon_2/T}=\sigma/\sigma_h, \tag{9.10}$$

and derive Euler–Lagrange equations in the form

$$\begin{aligned}\epsilon_1&=A_1T-c_1\eta+TK\ \log(1+e^{-e_2/T}),\\ \epsilon_2&=A_2T+c_2\zeta+TK\ \log(1+e^{-e_1/T}),\end{aligned} \tag{9.11}$$

where the A_j are the Lagrange multipliers that correspond to (9.8).

As noted in the Introduction, there are two difficulties with this argument. First, Eqs. (9.11) have no solution: taking derivatives one sees that the ϵ_j should be decreasing functions, so the functions $\log(1+e^{-e_j/T})$ are increasing and bounded above, but they are taken by K to decreasing functions and thus one needs $\epsilon_1\leqslant -c_1\eta+O(1)$ at $+\infty$. Therefore $\log(1+e^{-e_1/T})$ is non-negative and grows like η at $+\infty$, so $K\log(1+e^{-e_1/T})$ cannot be defined. Second, it is not clear that the free energy is bounded below.

The first difficulty is easily dealt with. We may assume that $\dot r$ and $\dot s$ are test functions, and (9.9) simply means that they are derivatives of test functions. Therefore the condition $\dot F=0$ simply means that the derivatives of the two bracketed terms vanish. Now K anticommutes with derivation, so the correct form of (9.11) is

$$\frac{d\epsilon_1}{d\eta}=-c_1+K\left(\Psi\ \frac{d\epsilon_2}{d\zeta}\right), \quad \frac{d\epsilon_2}{d\zeta}=c_2+K\left(\Theta\ \frac{d\epsilon_1}{d\eta}\right). \tag{9.12}$$

Combining this with

$$\Theta = \frac{\epsilon^{-\epsilon_1/T}}{1+e^{-e_1/T}}, \quad \Psi = \frac{e^{-\epsilon_2/T}}{1+e^{-e_2/T}} \tag{9.13}$$

yields a well-behaved system of equations for the thermal equilibrium particle distribution $(\rho,\sigma)=(\rho^{(T)},\sigma^{(T)})$.

To deal with the second difficulty we prove the following.

Theorem 9.1: *The free energy functional F_T is convex and bounded below by $-CT^2$, where C is a constant that depends only on the velocities c_j.*

Proof: From (9.9), the second derivative of the free energy for the variation $(\dot\rho,\dot\sigma)$ is

$$\begin{aligned} &T\int_{-\infty}^{\infty}\dot\rho\left[\frac{\dot\rho}{\rho}-\frac{\dot\rho_h}{\rho_h}+K\left(\frac{\dot\sigma_t}{\sigma_t}-\frac{\dot\sigma_h}{\sigma_h}\right)\right]d\eta+T\int_{-\infty}^{\infty}\dot\sigma\left[\frac{\dot\sigma}{\sigma}-\frac{\dot\sigma_h}{\sigma_h}+K\left(\frac{\dot\rho_t}{\rho_t}-\frac{\dot\rho_h}{\rho_h}\right)\right]d\zeta \\ &\quad=T\int_{-\infty}^{\infty}\left[\dot\rho\left(\frac{\dot\rho}{\rho}-\frac{\dot\rho_h}{\rho_h}\right)+(K\dot\sigma)\left(\frac{\dot\rho_t}{\rho_t}-\frac{\dot\rho_h}{\rho_h}\right)\right]d\eta+T\int_{-\infty}^{\infty}\left[\dot\sigma\left(\frac{\dot\sigma}{\sigma}-\frac{\dot\sigma_h}{\sigma_h}\right)+(K\dot\rho)\left(\frac{\dot\sigma_t}{\sigma_t}-\frac{\dot\sigma_h}{\sigma_h}\right)\right]dz. \end{aligned} \tag{9.14}$$

We use (9.7) and reorganize to find that the second derivative is

$$T\int_{-\infty}^{\infty}\left(\frac{\sqrt{\rho_t}}{\sqrt{\rho\rho_h}}\,\dot\rho+\frac{\sqrt{\rho}}{\sqrt{\rho_t\rho_h}}\,K\dot\sigma\right)^2 d\eta+T\int_{-\infty}^{\infty}\left(\frac{\sqrt{\sigma_t}}{\sqrt{\sigma\sigma_h}}\,\dot\sigma+\frac{\sqrt{\sigma}}{\sqrt{\sigma_t\sigma_h}}\,K\dot\rho\right)^2 d\zeta. \tag{9.15}$$

To prove boundedness we introduce the function

$$G(s)=G(1-s)=-s\,\log\,s-(1-s)\log(1-s), \quad 0\leqslant s\leqslant 1.$$

Then $G(\Theta)=G(|\Theta_0-\Theta|)$ and the entropy density can be written

$$2\pi S(\rho,\sigma)=\int_{-\infty}^{\infty}\rho_t G(\Theta)\,d\eta+\int_{-\infty}^{\infty}\sigma_t G(\Psi)\,d\zeta. \tag{9.16}$$

For the first integral we partition the line into three sets:

$$\begin{aligned} I_1&=\{\eta: G(\Theta)\leqslant|\eta(\Theta_0-\Theta)|/\delta\}, \\ I_2&=\{\eta:|\Theta_0-\Theta|\geqslant 1/2, G(\Theta)>|\eta(\Theta_0-\Theta)|/\delta\}, \\ I_3&=\{\eta:|\Theta_0-\Theta|<1/2, G(\Theta)>|\eta(\Theta_0-\Theta)|/\delta\}, \end{aligned} \tag{9.17}$$

where the constant δ is to be chosen. Note that $0\leqslant G(t)\leqslant\log 2$, so $\eta\in I_2$ implies $|\eta|<2\delta\log 2$. Also

$$-\log\,t\geqslant -2t\,\log\,t\geqslant G(t), \quad 0\leqslant t\leqslant\tfrac{1}{2},$$

so $\eta\in I_3$ implies $|\Theta_0-t|<\exp(-|\eta|/\delta)$. Now $-t\,\log\,t$ is increasing on the interval $[0,1/e]$, so we conclude that $\eta\in I_3$ implies that either $|\eta|/\delta<1$ or

$$G(\Theta)=G(|\Theta_0-\Theta|)\leqslant -2|\Theta_0-\Theta|\log|\Theta_0-\Theta|\leqslant 2\,\frac{|\eta|}{\delta}\,e^{-|\eta|/\delta}.$$

Since $1<2\log 2$ we can combine these estimates and obtain

$$\int_{-\infty}^{\infty}\rho_t G(\Theta)\ d\eta \leqslant \frac{1}{\delta}\int_{-\infty}^{\infty}\rho_t(\Theta_0-\Theta)\,\eta\ d\eta+4\delta\log 2+2\int_{-\infty}^{\infty}\frac{|\eta|}{\delta}\,e^{-|\eta|/\delta}\,d\eta$$

$$=\int_{-\infty}^{\infty}\rho_t(\Theta_0-\Theta)\,\eta\ d\eta+4\delta\log 2+4\delta. \tag{9.18}$$

We claim that

$$\int_{-\infty}^{\infty}\rho_t(\Theta_0-\Theta)\,\eta\ d\eta\leqslant\int_{-\infty}^{\infty}(\rho_0-\rho)\,\eta\ d\eta+\int_{-\infty}^{\infty}(\sigma_0-\sigma)\zeta\ d\zeta. \tag{9.19}$$

In fact (8.11) can be rewritten

$$\rho_t(\Theta_0-\Theta)=\rho-\rho_0+\Theta_0 K(\rho-\rho_0). \tag{9.20}$$

Using $\langle,\rangle$ to denote the standard inner product, we want to prove that

$$\int_{-\infty}^{\infty}\Theta_0 K(\sigma-\sigma_0)\,\eta\ d\eta=\langle K(\sigma-\sigma_0),\Theta_0\eta\rangle\leqslant\langle\sigma_0-\sigma,\zeta\rangle=-\langle Dg_2,z\rangle=\langle g_2,1\rangle, \tag{9.21}$$

where D denotes differentiation and g_2 is the function in (8.14). We use the fact that derivation anticommutes with K and integrate by parts to obtain

$$\langle K(\sigma-\sigma_0),\Theta_0\eta\rangle=\langle KDg_2,\Theta_0\eta\rangle=-\langle DKg_2,\Theta_0\eta\rangle=\langle Kg_2,D(\Theta_0\eta)\rangle=\langle g_2,K\Theta_0\rangle.$$

Now $0\leqslant K\theta_0\leqslant 1$ and $g_2\geqslant 0$, so this proves (9.19). Using (9.18), (9.19), and the analogous results for σ, we obtain

$$F_T(\rho,\sigma)\leqslant\left(c_1-\frac{2T}{\delta}\right)\int_{-\infty}^{\infty}(\rho_0-\rho)\,\eta\ d\eta+4\delta(1+\log 2)+\left(-c_2-\frac{2T}{\delta}\right)$$

$$\times\int_{-\infty}^{\infty}(\sigma_0-\sigma)\zeta\ d\zeta+4\delta(1+\log 2). \tag{9.22}$$

We take $\delta=2T/(c_1-c_2)$ and obtain $C=8(1+\log 2)/(c_1-c_2)$. □

Proof of Serban's conjecture

M. C. Bergère[a)]
CEA-Saclay, Service de Physique Théorique, F-91191 Gif sur Yvette Cedex, France

(Received 30 April 1997; accepted for publication 8 September 1997)

We prove Serban's conjecture which greatly simplifies the expression of the advanced single-particle Green function in the Calogero–Sutherland model. The importance of proving this conjecture is that it reorganizes the form factor in terms of two dimensional Coulomb gas correlators and confirms the possible existence of a bosonization procedure for this system. © *1998 American Institute of Physics.* [S0022-2488(97)02912-5]

I. INTRODUCTION

The Calogero–Sutherland model[1] attracted much attention during the last few years, due to its connection to random matrix theory, fractional statistics in one dimension, conformal field theory, etc. This model is exactly solvable and its solution is known to a large extent. The corresponding Hamiltonian

$$H=-\frac{1}{2}\sum_{i=1}^{N}\frac{d^2}{dx_i^2}+\beta(\beta-1)\frac{\pi^2}{L^2}\sum_{i<j}\frac{1}{\sin^2\left(\frac{\pi}{L}(x_i-x_j)\right)} \tag{1.1}$$

describes the motion of N particles along a circle of length L. The eigenstates of this Hamiltonian can be expressed[2] in terms of the so-called Jack polynomials in the variables $z_i=\exp(2i\pi x_i/L)$. For $\beta=0$ or 1, the particles behave like free spinless bosons or fermions, and for rational β the model describes particles with a fractional statistic (excitations from the Fermi sea with kq quasiparticles and kp quasiholes if k is a positive integer and $\beta=p/q$).

The two points correlation functions were calculated using two different methods. The first one generalizes Dyson's work on the correlations of the eigenvalues of random matrices[3] which led to explicit expressions for the static density–density correlations for $\beta=1/2,1,2$. For these values of β, Simons, Lee, and Al'tshuler in Ref. 3, using supersymmetric techniques initiated by Efetov,[3] calculated the dynamical density–density correlations; then Haldane and Zirnbauer obtained in Ref. 4, the retarded (for $\beta=2$) and the advanced (for $\beta=1/2,1,2$) single-particle Green functions.

The other method works for any rational β and uses the properties of Jack polynomials. The dynamical density–density correlations and the retarded single-particle Green functions were obtained for integer β by Lesage, Pasquier, and Serban in Ref. 5 and for rational β by Ha in Ref. 6. The correlations functions can be expressed in terms of ''form factors'' for some operator A

$$|F|^2=|\langle v_1,\ldots,v_p;w_1,\ldots,w_q|A|0\rangle|^2, \tag{1.2}$$

where the v's and the w's are the rapidities of the quasiholes and of the quasiparticles, respectively. F can be decomposed as a product

$$F=F^{(0)}\times F_\beta^{(1)}.$$

The expression $F^{(0)}$ is a purely statistical contribution given by

[a)]Membre du C.N.R.S.

0022-2488/98/39(1)/30/17/$15.00
© 1998 American Institute of Physics

$$|F^{(0)}|^2=\frac{\Pi_{i<j}|v_i-v_j|^{2/\beta}\Pi_{k<l}|w_k-w_l|^{2\beta}}{\Pi_i(v_F^2-v_i^2)^{1-1/\beta}\Pi_k(w_k^2-v_F^2)^{1-\beta}\Pi_{i,k}(v_i-w_k)^2}, \tag{1.3}$$

where v_F is half the size (in rapidity) of the Fermi sea. In the case of the advanced Green function ($A=\Psi^+$) it was found in Ref. 4 that there are two contributions: one with one quasiparticle (zero quasihole) and one with $q+1$ quasiparticles and p quasiholes (if $\beta=p/q$). For this second contribution, $F_\beta^{(1)}$ was found in Ref. 4, for $\beta=2,1,1/2$, to be

$$F_2^{(1)}=C_2\,\frac{d}{dz}\left(\frac{(z-v_1)(z-v_2)}{(z-w_1)^2}\right)_{z=w_0}, \quad F_1^{(1)}=0, \tag{1.4}$$

$$F_{1/2}^{(1)}=C_{1/2}\int_{w_0}^{\infty}\frac{dz}{\sqrt{z-w_0}}\left(\frac{z-v_1}{\sqrt{(z-w_1)(z-w_2)}}-1\right).$$

Moreover, the authors proposed the following conjecture: for any positive integer $\beta=p$,

$$F_p^{(1)}=C_p\left(\frac{d}{dz}\right)^{p-1}\left\{\frac{\Pi_{i=1}^p(z-v_i)}{(z-w_1)^p}\right\}_{z=w_0}. \tag{1.5}$$

Recently, the single particle advanced Green function have been calculated for all rational β by Serban, Lesage, and Pasquier.[7] Their method was to sum the corresponding combination of Jack polynomials over all Young tableau with r (w_0 in the thermodynamic limit) columns of length $N-1$, p legs and q arms, and to take the thermodynamic limit, that is N going to infinity. They obtained (1.3) for $F^{(0)}$, and $F_\beta^{(1)}$ as

$$\begin{aligned}F_\beta^{(1)}=&\frac{\Pi_{i=0}^q\Pi_{j=1}^p(w_i-v_j)^\beta}{\Pi_{i<j}(v_i-v_j)\Pi_{0\leqslant i<j\leqslant q}(w_i-w_j)^{2\beta-1}}\\&\times\int_{w_q}^{w_{q-1}}d\xi_{q-1}\cdots\int_{w_2}^{w_1}d\xi_1\prod_{i<j}(\xi_i-\xi_j)\prod_{i=1}^{q-1}\prod_{j=0}^{q}(\xi_i-w_j)^{\beta-1}\\&\times\partial_{v_1}\cdots\partial_{v_p}\left[\prod_{i<j}(v_i-v_j)\prod_{j=1}^{p}\left(\prod_{i=0}^{q}(w_i-v_j)^{1-\beta}\prod_{i=1}^{q-1}(\xi_i-v_j)^{-1}\right)\right].\end{aligned} \tag{1.6}$$

Then, Serban conjectured that this expression reduces to

$$F_\beta^{(1)}=(\beta-1)\,\frac{[\Gamma(\beta)]^q}{2i\pi}\oint_{C_w}dz\,\frac{\Pi_{i=1}^p(v_i-z)}{\Pi_{j=0}^q(w_j-z)^\beta}, \tag{1.7}$$

where the contour C_w surrounds the points $w_1,\ldots,w_q$.

The conjecture was proven for β integer (that is Haldane and Zirnbauer conjecture (1.5)), and the result (1.4) for $\beta=1/2$ has been obtained from (1.7), as well as the numerical equality between (1.6) and (1.7) for $\beta=1/2$ and 3/2.

In this publication, we prove Serban's conjecture, not only for $\beta=p/q$, but for a set of different β_i attached to each rapidity w_i. The importance of proving this conjecture is due to the interpretation of the result in terms of basic conformal operators. It was already pointed out by Khveshchenko[8] that the density–density correlation function and that the one particle retarded Green function could be simply re-expressed in terms of 2D Coulomb gas correlators

$$\langle V_{a_1}(z_1)\cdots V_{a_n}(z_n)\rangle=\prod_{i<j}(z_i-z_j)^{a_ia_j}\quad\text{if}\quad\sum_{i=1}^{n}a_i=0 \tag{1.8}$$

and zero otherwise. Equation (1.7) proves, in the more complicate situation of the advanced Green function, that the same property is true

$$F=F^{(0)}\times F_{\beta}^{(1)}=\frac{(\beta-1)[\Gamma(\beta)]^q}{\Pi_i(v_F^2-v_i^2)^{(\beta-1)/2\beta}\Pi_k(w_k^2-v_F^2)^{(1-\beta)/2}}$$
$$\times\frac{1}{2i\pi}\oint_{C_w}dz\left\langle V_{-\sqrt{\beta}}(z)\prod_{i=1}^{p}V_{-1/\sqrt{\beta}}(v_i)\prod_{k=0}^{q}V_{\sqrt{\beta}}(w_k)\right\rangle, \tag{1.9}$$

where a charge $\sqrt{\beta}$ is given to the quasiparticle operator, $-1/\sqrt{\beta}$ to the quasihole operator, and $-\sqrt{\beta}$ to the screening operator introduced in order to have conservation of the charge. At the present time, we do not know what has to be done with the terms coming from the Fermi sea (v_F dependent) but this might be overcome naturally if we later develop a bozonisation procedure of the Calogero–Sutherland model. Several arguments plead in favour of such a construction and specially in Ref. 9, it is shown that the Jack polynomials are the singular vectors of the Virasoro and of the W_N algebra. It is, however, surprising to see in (1.9) that the correlators V_a are not taken in complexified space-time points but in the rapidities. Let us finally mention that the relation between (1.6) and (1.7) can certainly be q-deformed if we work with the relativistic Ruijsenaars–Schneider model,[10] where the Jack polynomials are q-deformed into the Macdonald polynomials.[11]

II. PROOF OF THE CONJECTURE

Given a set of $(q+1)$ variables β_i (large enough to make all integrals convergent), and two sets of variables, $(q+1)$ variables w_i and p variables v_i, we define C as

$$C=\int_{w_q}^{w_{q-1}}d\xi_{q-1}\cdots\int_{w_2}^{w_1}d\xi_1\prod_{i<j}(\xi_i-\xi_j)\prod_{i=1}^{q-1}\prod_{j=0}^{q}|\xi_i-w_j|^{\beta_j-1}$$
$$\times\frac{\partial_{v_1}\cdots\partial_{v_p}[\Pi_{j=0}^{q}\Pi_{k=1}^{p}(w_j-v_k)^{1-\beta_j}\Pi_{i=1}^{q-1}\Pi_{k=1}^{p}(\xi_i-v_k)^{-1}\Pi_{k<l}(v_k-v_l)]}{\Pi_{j=0}^{q}\Pi_{k=1}^{p}(w_j-v_k)^{1-\beta_j}\Pi_{k<l}(v_k-v_l)}. \tag{2.1}$$

Our result is

$$C=\frac{\Pi_{j=0}^{q}\Gamma(\beta_j)}{\Gamma(\Sigma_{j=0}^{q}\beta_j-p-1)}\frac{\Pi_{0\leqslant i<j\leqslant q}(w_i-w_j)^{\beta_i+\beta_j-1}}{\Pi_{j=0}^{q}\Pi_{k=1}^{p}(w_j-v_k)}$$
$$\times\frac{(-1)}{2i\pi}\oint_{C_0}dz\,\frac{\Pi_{k=1}^{p}(z-v_k)}{(w_0-z)^{\beta_0}\Pi_{j=1}^{q}(z-w_j)^{\beta_j}}, \tag{2.2}$$

where $w_0>w_1$ and C_0 surrounds the cut $[w_0,+\infty]$; we suppose that $\Sigma_{j=0}^{q}\beta_j>p+1$ to ensure the convergence of the integral in (2.2), otherwise subtractions has to be considered.

Here, we indicate how to find the subtraction terms in the integrand (2.2) in the special case where $\Sigma_{j=1}^{q}\beta_j=r$ is an integer and when $\beta_0+r\leqslant p+1$; we proceed by analytic continuation in β_0 so that the expression (2.2) remains equal to (2.1). Indeed, if $\Sigma_{j=1}^{q}\beta_j$ is an integer, we may organize the branch cuts of $\Pi_{j=1}^{q}(z-w_j)^{\beta_j}$ so that they lie between w_1 and w_q. Then, for β_0 large enough to ensure the convergence of (2.2), the integral dz is nothing (up to a sign) but the same integral on a contour C_w which surrounds the points $w_1,\ldots,w_q$ [see Eq. (1.7)]. When β_0 decreases in such a way that $\beta_0+r\leqslant p+1$, the integral on C_w still exists and is equal to (2.1) by analytic continuation. If we wish, in that case, to come back to the contour C_0, we must make subtractions which ensure the convergence when $z\to\infty$ and which do not destroy the equality between (2.2) and (2.1). Clearly, if we subtract to

$$f_{\{\beta\}}(v_k,w_j,z)=\frac{\Pi_{k=1}^{p}(z-v_k)}{\Pi_{j=1}^{q}(z-w_j)^{\beta_j}}$$

a finite number of terms defined as the Taylor expansion of $f_{\{\beta\}}$ around the point $v_k=w_j=w_0$ (the first subtracted term being $(z-w_0)^{p-r}$), the subtracted terms contribute nothing to the integral (2.2) on the contour C_w, and consequently, let C unchanged and equal to (2.1); however, these subtractions make the integral dz convergent at infinity and they allow the contour C_w to be transformed back into the contour C_0.

We note that if all the variables β_j are equal to p/q, we have

$$\frac{\Pi_{j=0}^{q}\Gamma(\beta_j)}{\Gamma(\Sigma_{j=0}^{q}\beta_j-p-1)}=(\beta-1)[\Gamma(\beta)]^q, \tag{2.3}$$

which appears in (1.7). Also, in that case, and if $p/q\leqslant 1$, one subtraction only is needed to make the integral (2.2) convergent; the integrand in (2.2) becomes

$$\frac{1}{(w_0-z)^{\beta}}\left\{\frac{\Pi_{k=1}^{p}(z-v_k)}{\Pi_{j=1}^{q}(z-w_j)^{\beta}}-1\right\}$$

which is for instance the case for $\beta=1/2$ in (1.4).

The proof of the result (2.1–2) requires several steps of different nature; in order to have an easier reading, the main part of the proof is written in this section while four appendices are devoted to technical details.

The expression C in (2.1) is made of two parts: on the first line, the integrals $d\xi$, on the second line the derivatives ∂_v, the factorization being prevented by the $(\xi-v)^{-1}$ terms. Appendix A generalizes Cauchy's identity in order to eliminate the $(\xi-v)^{-1}$ terms. C becomes a sum of terms, each of them being factorized into $d\xi$ integrals and ∂_v derivatives without $(\xi-v)^{-1}$ terms. Appendix B generalizes a result by Dixon[12] who performs a change of variables which makes obvious the calculation of the integrals $d\xi$; the generalization consists in adding the variable w_0 to Dixon's result which generates a contour integral $\oint dz$. These two Appendices are sufficient to prove the conjecture in the case $(q-1)\geqslant p$. However, the case $(q-1)\leqslant p$ is more difficult because we have extra ∂_v derivatives to perform over terms which do not contain $(\xi-v)^{-1}$ anymore. Appendix C is devoted to the calculation and to the properties of these ∂_v derivatives. Finally, Appendix D, which also, is only needed in the case $q-1\leqslant p$, develops the properties of the integrals

$$I_P=\frac{1}{2i\pi}\oint_{C_0}dz\,\frac{P(z)}{(w_0-z)^{\beta_0}\Pi_{j=1}^{q}(z-w_j)^{\beta_j}}, \tag{2.4}$$

where $P(z)$ is a polynomial in z and where C_0 surrounds the cut $[w_0,+\infty]$.

Let us mention that the proof is written for a set of generic values of the variables v_i without care to the case where several v's are equal; however, our result remain valid in that case since (2.1) has no pole singularity at $v_i=v_j$ (Appendix C (C2)).

First case: $q-1\geqslant p$:

In expression (2.1), we use the generalized Cauchy's identity (A3) to write

$$\frac{\Pi_{i<j}(\xi_i-\xi_j)\Pi_{k<l}(v_k-v_l)}{\Pi_{i=1}^{q-1}\Pi_{j=1}^{p}(\xi_i-v_j)}=\sum_{I_p}(-)^{\delta_{I_p}}\det\left|\frac{1}{\xi_{j_k}-v_j}\right|\prod_{\substack{i<j\\ i,j\notin I_p}}(\xi_i-\xi_j), \tag{2.5}$$

where $I_p=(j_1<j_2<\cdots<j_p)\subset(1,...,q-1)$ and $\delta_{I_p}=(q-1)p-\Sigma_{i=1}^{p}j_i$. Because of the absence of terms of the type (v_i-v_j) on the right hand side of (2.5), and because each term of the determinant is a product of $(\xi-v_j)^{-1}$ for different j's, the action of the derivatives ∂_{v_j} in (2.1) factorizes. We get a product of the type

$$\prod_{j=1}^{p}\frac{\partial_{v_j}[\Pi_{i=0}^{q}(w_i-v_j)^{1-\beta_i}(\xi_{a_j}-v_j)^{-1}]}{\Pi_{i=0}^{q}(w_i-v_j)^{1-\beta_i}}=\prod_{j=1}^{p}\left\{\left[\sum_{i=0}^{q}\frac{\beta_i-1}{w_i-v_j}-\frac{\partial}{\partial\xi_{a_j}}\right](\xi_{a_j}-v_j)^{-1}\right\}, \quad (2.6)$$

where the a_j's are a permutation of the j_k's in I_p. The right hand side of (2.6) can now be taken inside the integrals $d\xi$ to be integrated by parts (we assume that the corresponding Re β_i's>1 to avoid the contribution of the end-points); the expression (2.6) becomes

$$\prod_{j=1}^{p}\left[\sum_{i=0}^{q}\frac{\beta_i-1}{(w_i-v_j)(\xi_{a_j}-w_i)}\right]. \quad (2.7)$$

For any product of terms in the determinant (2.5), we have obtained a product of terms (2.7); consequently, the determinant in (2.5) can be replaced by the determinant

$$\det\left|\sum_{i=0}^{q}\frac{\beta_i-1}{(\xi_{j_k}-w_i)(w_i-v_j)}\right|=\sum_{J_p}\prod_{i\in J_p}(\beta_i-1)\det\left|\frac{1}{\xi_{j_k}-w_{l_j}}\right|\det\left|\frac{1}{w_{l_k}-v_j}\right|, \quad (2.8)$$

where $J_p=(l_1<l_2<\cdots<l_p)\subset(0,...,q)$.

The situation now, is that the determinant $|(\xi_{j_k}-v_i)^{-1}|$ in (2.5) is replaced by the determinant $|(\xi_{j_k}-w_{l_j})^{-1}|$ with the l_j's in J_p. We may now use the generalized Cauchy's identity (A3) backwards to sum over the different I_p's and we obtain, inside the sum over J_p,

$$\frac{\Pi_{i<j}(\xi_i-\xi_j)\Pi_{j<k}(w_{l_j}-w_{l_k})}{\Pi_{i=1}^{q-1}\Pi_{k=1}^{p}(\xi_i-w_{l_k})}=(-)^{\delta_{J_p}-\eta}\frac{\Pi_{i<j}(\xi_i-\xi_j)\Pi_{j<k}(w_{l_j}-w_{l_k})}{\Pi_{i=1}^{q}\Pi_{k=1}^{p}|\xi_i-w_{l_k}|}, \quad (2.9)$$

where the l_j's belong to J_p, and $\delta_{J_p}=pq-\Sigma_{k=1}^{p}l_k$ (here, $\eta=1$ if $l_1=0$ and 0 otherwise).

We proved, up to now, that

$$C=\frac{1}{\Pi_{k<l}(v_k-v_l)}\sum_{J_p}(-)^{\delta_{J_p}}\prod_{i\in J_p}(\beta_i-1)\prod_{j<k}(w_{l_j}-w_{l_k})\det\left|\frac{1}{w_{l_k}-v_j}\right|$$
$$\times\int_{w_q}^{w_{q-1}}d\xi_{q-1}\cdots\int_{w_2}^{w_1}d\xi_1\prod_{i<j}(\xi_i-\xi_j)\prod_{i=1}^{q-1}\prod_{j=0}^{q}|\xi_i-w_j|^{\beta'_j-1}, \quad (2.10)$$

where $\beta'_j=\beta_j$ if $j\notin J_p$ and $\beta'_j=\beta_j-1$ if $j\in J_p$.

We are now in a position to use Dixon's result with an extra variable w_0 (B4), (B13) and to write the second line of (2.10) as

$$\frac{\Pi_{j=0}^{q}\Gamma(\beta'_j)}{\Gamma(\Sigma_{j=0}^{q}\beta_j-p-1)}\prod_{0\le i<j\le q}(w_i-w_j)^{\beta'_i+\beta'_j-1}\frac{(-1)}{2i\pi}\oint_{C_0}dz\,\frac{1}{(w_0-z)^{\beta'_0}\Pi_{j=1}^{q}(z-w_j)^{\beta'_j}}. \quad (2.11)$$

The expression C becomes

$$C=\frac{\Pi_{j=0}^{q}\Gamma(\beta_j)}{\Gamma(\Sigma_{j=0}^{q}\beta_j-p-1)}\,\frac{\Pi_{0\leqslant i<j\leqslant q}(w_i-w_j)^{\beta_i+\beta_j-2}}{\Pi_{k<l}(v_k-v_l)}\,\frac{(-1)}{2i\pi}\oint_{C_0}dz\,\frac{1}{(w_0-z)^{\beta_0}\Pi_{j=1}^{q}(z-w_j)^{\beta_j}}$$

$$\times\sum_{J_p}(-)^{\delta_{J_p}}\prod_{k=1}^{p}(z-w_{l_k})\det\left|\frac{1}{w_{l_k}-v_j}\right|\prod_{\substack{i<j\\ i,j\notin J_p}}(w_i-w_j). \tag{2.12}$$

Again, as a consequence of the generalized Cauchy's identity, we may now sum over all J_p's; from (A8) with $q+1>p$; the third line of (2.12) is nothing but

$$\prod_{k=1}^{p}(z-v_k)\,\frac{\Pi_{0\leqslant i<j\leqslant q}(w_i-w_j)\Pi_{k<l}(v_k-v_l)}{\Pi_{i=0}^{q}\Pi_{j=1}^{p}(w_i-v_j)}. \tag{2.13}$$

The fact that the indices of the w's run from 0 to q (instead of 1 to $q+1$) makes in (A8), a shift by p of δ_{J_p}; this explains why we do not have a $(-)^p$ in (2.13).

This result ends the proof for the case $(q-1)\geqslant p$.

Second case: $q-1\leqslant p$:

Again, we use the generalized Cauchy's identity in order to calculate the left hand side of (2.5), but here we have more variables v_j than variables ξ_i; using the relation (A2), we write

$$\frac{\Pi_{i<j}(\xi_i-\xi_j)\Pi_{k<l}(v_k-v_l)}{\Pi_{i=1}^{q-1}\Pi_{j=1}^{p}(\xi_i-v_j)}=\sum_{I_{q-1}}(-)^{\delta_{I_{q-1}}}\det\left|\frac{1}{\xi_i-v_{j_k}}\right|\prod_{\substack{k<l\\ k,l\notin I_{q-1}}}(v_k-v_l), \tag{2.14}$$

where $I_{q-1}=(j_1<j_2<\cdots<j_{q-1})\subset(1,...,p)$ and $\delta_{I_{q-1}}=\Sigma_{k=1}^{q-1}j_k-q+1$. Consequently, the derivatives ∂_{v_j} split into two parts depending on whether j is in I_{q-1} or not. The second line of (2.1) becomes

$$\frac{1}{\Pi_{k<l}(v_k-v_l)}\sum_{I_{q-1}}(-)^{\delta_{I_{q-1}}}\frac{\Pi_{j\notin I_{q-1}}(\partial_{v_j})[\Pi_{i=0}^{q}\Pi_{j\notin I_{q-1}}(w_i-v_j)^{1-\beta_i}\Pi_{\substack{k<l\\ k,l\notin I_{q-1}}}(v_k-v_l)]}{\Pi_{i=0}^{q}\Pi_{j\notin I_{q-1}}(w_i-v_j)^{1-\beta_i}}$$

$$\times\frac{\Pi_{j\in I_{q-1}}(\partial_{v_j})\left[\Pi_{i=0}^{q}\Pi_{j\in I_{q-1}}(w_i-v_j)^{1-\beta_i}\det\left|\frac{1}{\xi_i-v_{j_k}}\right|\right]}{\Pi_{i=0}^{q}\Pi_{j\in I_{q-1}}(w_i-v_j)^{1-\beta_i}}. \tag{2.15}$$

In the third line of (2.15), the derivatives ∂_v factorize so that this term can be calculated in exactly the same way as for the case $(q-1)\geqslant p$. The determinant $(\xi_i-v_{j_k})^{-1}$ can be replaced in the same manner by

$$\det\left|\sum_{r=0}^{q}\frac{\beta_r-1}{(\xi_i-w_r)(w_r-v_{j_k})}\right|=\sum_{J_{q-1}}\prod_{r\in J_{q-1}}(\beta_r-1)\det\left|\frac{1}{\xi_i-w_r}\right|\det\left|\frac{1}{w_r-v_{j_k}}\right|, \tag{2.16}$$

where $J_{q-1}=(l_1<l_2<\cdots<l_{q-1})\subset(0,...,q)$. We now use Cauchy's identity (A1), to write

$$\det\left|\frac{1}{\xi_i-w_r}\right|=(-)^{q(q-1)/2+\delta_{J_{q-1}}-\eta}\,\frac{\Pi_{i<j}(\xi_i-\xi_j)\Pi_{j<k}(w_{l_j}-w_{l_k})}{\Pi_{i=1}^{q-1}\Pi_{j=1}^{q-1}|\xi_i-w_{l_j}|}, \tag{2.17}$$

where $\delta_{J_{q-1}}=\Sigma_{j=1}^{q-1}l_j-q+1$ and $\eta=1$ if $l_1=0$ (and 0 otherwise).

Again, after inserting (2.17) into the integrals $d\xi$, we may integrate using Dixon's change of variables (B4), (B13) to get

$$(-)^{q(q-1)/2}\cdot\frac{\Pi_{j=0}^{q}\Gamma(\beta_j)}{\Gamma(\Sigma_{j=0}^{q}\beta_j-q)}\prod_{0\leqslant i<j\leqslant q}(w_i-w_j)^{\beta_i+\beta_j-2}$$
$$\times\frac{(-1)}{2i\pi}\oint_{C_0}dz\,\frac{1}{(w_0-z)^{\beta_0}\Pi_{j=1}^{q}(z-w_j)^{\beta_j}}$$
$$\times\sum_{J_{q-1}}(-)^{\delta_{J_{q-1}}}\prod_{j=1}^{q-1}(z-w_{l_j})\det\left|\frac{1}{w_{l_j}-v_{j_k}}\right|\prod_{\substack{i<j\\ i,j\notin J_{q-1}}}(w_i-w_j). \tag{2.18}$$

Using a consequence of the generalized Cauchy's identity for a given set of $q-1$ variables v_{j_k}'s in I_{q-1}, the third line of (2.18) can be summed over J_{q-1}; here again, because the w's are labeled from 0 to $q+1$, $\delta_{J_{q-1}}$ has to be shifted by $q-1$ in order to apply (A8) with $q+1>q-1$. We get for the third line of (2.15)

$$(-)^{(q-1)(q-2)/2}\frac{\Pi_{j=0}^{q}\Gamma(\beta_j)}{\Gamma(\Sigma_{j=0}^{q}\beta_j-q)}\frac{\Pi_{0\leqslant i<j\leqslant q}(w_i-w_j)^{\beta_i+\beta_j-1}\Pi_{\substack{k<l\\ k,l\in I_{q-1}}}(v_k-v_l)}{\Pi_{i=0}^{q}\Pi_{j\in I_{q-1}}(w_i-v_j)}$$
$$\times\frac{(-1)}{2i\pi}\oint_{C_0}dz\,\frac{\Pi_{j\in I_{q-1}}(z-v_j)}{(w_0-z)^{\beta_0}\Pi_{j=1}^{q}(z-w_j)^{\beta_j}}. \tag{2.19}$$

At this point, we proved that, in the case $(q-1)\leqslant p$, the expression C may be written as

$$C=(-)^{(q-1)(q-2)/2}\frac{\Pi_{j=0}^{q}\Gamma(\beta_j)}{\Gamma(\Sigma_{j=0}^{q}\beta_j-q)}\frac{\Pi_{0\leqslant i<j\leqslant q}(w_i-w_j)^{\beta_i+\beta_j-1}}{\Pi_{i=0}^{q}\Pi_{j=1}^{p}(w_i-v_j)\Pi_{k<l}(v_k-v_l)}$$
$$\times\sum_{I_{q-1}}(-)^{\delta_{I_{q-1}}}\frac{\Pi_{j\notin I_{q-1}}(\partial_{v_j})[\Pi_{i=0}^{q}\Pi_{j\notin I_{q-1}}(w_i-v_j)^{1-\beta_i}\Pi_{\substack{k<l\\ k,l\notin I_{q-1}}}(v_k-v_l)]}{\Pi_{i=0}^{q}\Pi_{j\notin I_{q-1}}(w_i-v_j)^{-\beta_i}}$$
$$\times\prod_{\substack{k<l\\ k,l\in I_{q-1}}}(v_k-v_l)\,\frac{(-1)}{2i\pi}\oint_{C_0}dz\,\frac{\Pi_{j\in I_{q-1}}(z-v_j)}{(w_0-z)^{\beta_0}\Pi_{j=1}^{q}(z-w_j)^{\beta_j}}. \tag{2.20}$$

The purpose of Appendices C and D is to calculate the sum over I_{q-1} in (2.20). In (D20) we show that the second and third lines of (2.20) are equal to

$$(-)^{(q-1)(q-2)/2}\frac{\Gamma(\Sigma_{j=0}^{q}\beta_j-q)}{\Gamma(\Sigma_{j=0}^{q}\beta_j-p-1)}\prod_{k<l}(v_k-v_l)$$
$$\times\frac{(-1)}{2i\pi}\oint_{C_0}dz\,\frac{\Pi_{k=1}^{p}(z-v_k)}{(w_0-z)^{\beta_0}\Pi_{j=1}^{q}(z-w_j)^{\beta_j}} \tag{2.21}$$

and this ends the proof of the conjecture in the case $(q-1)\leqslant p$.

ACKNOWLEDGMENTS

I thank D. Serban for her constant encouragement, for many discussions about the work in Ref. 7, and for her careful reading of the manuscript.

APPENDIX A

Given two sets of variables $(x_1,\ldots,x_n)$ and $(y_1,\ldots,y_m)$, if $n=m$, Cauchy's identity is

$$\frac{\Pi_{i<j}(x_i-x_j)\Pi_{k<l}(y_k-y_l)}{\Pi_{i=1}^{n}\Pi_{k=1}^{n}(x_i-y_k)}=(-)^{n(n-1)/2}\det\left|\frac{1}{x_i-y_k}\right| \tag{A1}$$

(apart from the sign, this result is relatively evident from the properties of the determinant, the homogeneity and the pole structure). Now, if $n\leqslant m$, we may generalize this relation by systematically organizing the residues of the poles; we get

$$\frac{\Pi_{i<j}(x_i-x_j)\Pi_{k<l}(y_k-y_l)}{\Pi_{i=1}^{n}\Pi_{k=1}^{m}(x_i-y_k)}=\sum_{I_n}(-)^{\delta_{I_n}}\det\left|\frac{1}{x_i-y_{j_k}}\right|\prod_{\substack{k<l\\ k,l\notin I_n}}(y_k-y_l), \tag{A2}$$

where $I_n=(j_1<j_2<\ldots<j_n)\subset(1,\ldots,m)$ and $\delta_{I_n}=\Sigma_{i=1}^{n}j_i-n$. Of course, if $n\geqslant m$, the situation is symmetric and we have

$$\frac{\Pi_{i<j}(x_i-x_j)\Pi_{k<l}(y_k-y_l)}{\Pi_{i=1}^{n}\Pi_{k=1}^{m}(x_i-y_k)}=\sum_{I_m}(-)^{\delta_{I_m}}\det\left|\frac{1}{x_{l_i}-y_k}\right|\prod_{\substack{i<j\\ i,j\notin I_m}}(x_i-x_j), \tag{A3}$$

where $I_m=(l_1<l_2<\cdots<l_m)\subset(1,\ldots,n)$ and $\delta_{I_m}=mn-\Sigma_{k=1}^{m}l_k$. We call (A2)–(A3) generalized Cauchy's identities. In (A2)–(A3), we adopt the convention that $\Pi_{\substack{i<j\\ i,j\notin I}}(z_i-z_j)=1$ if there is 0 or 1 variable $z\notin I$.

Let us note the following property: for $n<m$, if we let a given variable $x_p\to\infty$, the left-hand side of (A2) behaves as $x_p^{-(m-n+1)}\leqslant x_p^{-2}$ while the right-hand side behaves as x_p^{-1}. Consequently, the coefficient of x_p^{-1} in the right-side of (A2) is zero. This coefficient can be calculated: we define the matrix $\Delta_{I_n,p}$ such that

$$\begin{aligned}(\Delta_{I_n,p})_{ik}&=\frac{1}{x_i-y_{j_k}}\quad\text{for } i\neq p,\\ &=1\quad\text{for } i=p\end{aligned} \tag{A4}$$

then,

$$\sum_{I_n}(-)^{\delta_{I_n}}\det(\Delta_{I_n,p})\prod_{\substack{k<l\\ k,l\notin I_n}}(y_k-y_l)=0 \tag{A5}$$

We are now using (A5) to calculate

$$\Phi(z)=\sum_{I_n}(-)^{\delta_{I_n}}\prod_{k=1}^{n}(z-y_{j_k})\det\left|\frac{1}{x_i-y_{j_k}}\right|\prod_{\substack{k<l\\ k,l\notin I_n}}(y_k-y_l). \tag{A6}$$

The determinant in (A6) is a sum of terms of the type $(x_1-y_{\alpha_1})^{-1}(x_2-y_{\alpha_2})^{-1}\cdots(x_n-y_{\alpha_n})^{-1}$, where $(\alpha_1,\ldots,\alpha_n)$ is a permutation of $(j_1,\ldots,j_n)$. For such a term, we write

$$\prod_{k=1}^{n}(z-y_{j_k})=\prod_{k=1}^{n}(z-y_{\alpha_k})=\sum_{J}\prod_{k\notin J}(z-x_k)\prod_{j\in J}(x_j-y_{\alpha_j}),$$

where J is a set of $|J|$ indices $\subset(1,...n)$. Consequently, when summing over all terms of the determinant, we get

$$\prod_{k=1}^{n}(z-y_{j_k})\det\left|\frac{1}{x_i-y_{j_k}}\right|=\sum_J\prod_{k\notin J}(z-x_k)\det\left|\left(\frac{1}{x_i-y_{j_k}}\right)_J\right|,$$

where the matrices $((x_i-y_{j_k})^{-1})_J$ have $|J|$ lines of 1 corresponding to the indices $i\in J$. Their determinants are trivially zero for $|J|\geqslant 2$. Now, for $|J|=1$, the sum over I_n in (A6) gives zero because of (A5); the only non-vanishing contribution comes from $|J|=0$. We just proved that

$$\Phi(z)=\prod_{k=1}^{n}(z-x_k)\,\frac{\Pi_{i<j}(x_i-x_j)\Pi_{k<l}(y_k-y_l)}{\Pi_{i=1}^{n}\Pi_{j=1}^{m}(x_i-y_j)}. \tag{A7}$$

By symmetry, for $n>m$, we have

$$\sum_{I_m}(-)^{\delta_{I_m}}\prod_{i=1}^{m}(z-x_{I_i})\det\left|\frac{1}{x_{I_i}-y_k}\right|\prod_{\substack{i<j\\ i,j\notin I_m}}(x_i-x_j)$$

$$=\prod_{i=1}^{m}(z-y_i)\,\frac{\Pi_{i<j}(x_i-x_j)\Pi_{k<l}(y_k-y_l)}{\Pi_{i=1}^{n}\Pi_{j=1}^{m}(x_i-y_j)}, \tag{A8}$$

where, this time, we used determinants of matrices with columns of (-1)'s. Let us mention that if the indices of the x's run from 0 to $n-1$ instead of 1 to n (as it is the case in Eqs. (2.12, 2.18)), then, δ_{I_m} has to be replaced in (A8) by $\delta_{I_m}+m$.

APPENDIX B

In this Appendix, we calculate the integrals $d\xi$ which appear in the first line of (2.1). We first calculate the integrals without the variable w_0; the end of the Appendix is devoted to the introduction of w_0 generating a contour integral in the complex plane. Let us define

$$J_{q-1}=\int_{w_q}^{w_{q-1}}d\xi_{q-1}\cdots\int_{w_2}^{w_1}d\xi_1\prod_{i<j}(\xi_i-\xi_j)\prod_{i=1}^{q-1}\prod_{j=1}^{q}|\xi_i-w_j|^{\beta_j-1}. \tag{B1}$$

Clearly,

$$J_1=\frac{\Gamma(\beta_1)\Gamma(\beta_2)}{\Gamma(\beta_1+\beta_2)}(w_1-w_2)^{\beta_1+\beta_2-1}.$$

A naive calculation of J_2 gives three products of hypergeometric functions, namely,

$$J_2=\prod_{i<j}(w_i-w_j)^{\beta_i+\beta_j-1}\,\frac{\Gamma(\beta_1)(\Gamma(\beta_2))^2\Gamma(\beta_3)}{\Gamma(\beta_1+\beta_2)\Gamma(\beta_2+\beta_3)}$$

$$\times\begin{bmatrix}F(\beta_3,-\beta_1;\beta_2+\beta_3;\alpha)F(1-\beta_3,\beta_1;\beta_1+\beta_2;1-\alpha)\\ +F(\beta_3,1-\beta_1;\beta_2+\beta_3;\alpha)F(-\beta_3,\beta_1;\beta_1+\beta_2;1-\alpha)\\ -F(\beta_3,1-\beta_1;\beta_2+\beta_3;\alpha)F(1-\beta_3,\beta_1;\beta_1+\beta_2;1-\alpha)\end{bmatrix}, \tag{B2}$$

where $\alpha=(w_2-w_3)/(w_1-w_3)$. The remarkable fact is that the square bracket $[\cdots]$ in (B2) is α independent and equal to

$$\frac{\Gamma(\beta_1+\beta_2)\Gamma(\beta_2+\beta_3)}{\Gamma(\beta_1+\beta_2+\beta_3)\Gamma(\beta_2)}.$$

This result is due to Elliot,[13] who generalizes Legendre's relation from the theory of elliptic integrals. A generalization of Elliot's result has been given by Dixon,[12] who proved that

$$J_{q-1}=\frac{\Pi_{j=1}^{q}\Gamma(\beta_j)}{\Gamma(\Sigma_{j=1}^{q}\beta_j)}\prod_{i<j}(w_i-w_j)^{\beta_i+\beta_j-1} \tag{B3}$$

by performing a clever change of variables: given the function

$$f(\theta)=\prod_{j=1}^{q}(\theta-w_j)$$

we define new variables

$$x_j=(-)^{q-1}\frac{\Pi_{i=1}^{q-1}(\xi_j-w_i)}{f'(w_j)} \quad \text{for } j=1,...,q.$$

It is easy to verify that all variables x_j are $\geqslant 0$; moreover, we have

$$\sum_{j=1}^{q}x_j=1$$

so that x_q can be considered as dependant of the other x's. The jacobian of the transformation is

$$\frac{d(\xi_1,..,\xi_{q-1})}{d(x_1,...,x_{q-1})}=\frac{\Pi_{i<j}(w_i-w_j)}{\Pi_{i<j}(\xi_i-\xi_j)}.$$

Consequently,

$$J_{q-1}=\prod_{i<j}(w_i-w_j)^{\beta_i+\beta_j-1}\int_0^1\cdot\cdot\int_0^1\prod_{j=1}^{q}[dx_j\,x_j^{\beta_j-1}]\delta\left(\sum_{j=1}^{q}x_j-1\right)$$

which proves (B3).

Next, we wish to calculate (or to transform into a single contour integral in the complex plane) the integrals

$$K_{q-1}=\int_{w_q}^{w_{q-1}}d\xi_{q-1}\cdots\int_{w_2}^{w_1}d\xi_1\prod_{i<j}(\xi_i-\xi_j)\prod_{i=1}^{q-1}\prod_{j=0}^{q}|\xi_i-w_j|^{\beta_j-1}. \tag{B4}$$

In order to transform K_{q-1}, we write

$$\prod_{i=1}^{q-1}|\xi_i-w_0|=\sum_{j=1}^{q}A_j\prod_{i=1}^{q-1}|\xi_i-w_j| \tag{B5}$$

with

$$A_j=\frac{\Pi_{k\neq j}(w_0-w_k)}{\Pi_{k\neq j}|w_j-w_k|}. \tag{B6}$$

In order to calculate $|\xi_i - w_0|^{\beta_0 - 1}$, we use the following integral representation:

$$(a+b)^{\gamma} = \frac{1}{\Gamma(-\gamma)} \frac{1}{2i\pi} \int_{\sigma - i\infty}^{\sigma + i\infty} dz\ \Gamma(-z)\Gamma(z-\gamma) a^z b^{\gamma - z}, \tag{B7}$$

where Re $\gamma \leqslant \sigma \leqslant 0$. Strictly speaking, this integral representation is a priori valid for Re $\gamma < 0$. However, we may, by deformation of the contour, generalize to Re $\gamma > 0$ provided that $|\text{Im } \gamma| > 0$ in order to avoid a possible pinch of the contour and the extraction of residues. Consequently, we assume that β_0 has a small imaginary part for the demonstration and we analytically continue the result to real β_0. Now, we generalize (B7) and write

$$\prod_{i=1}^{q-1} |\xi_i - w_0|^{\beta_0 - 1} = \frac{1}{\Gamma(1-\beta_0)} \frac{1}{(2i\pi)^{q-1}} \times \int \cdots \int \prod_{j=1}^{q-1} dz_j \prod_{j=1}^{q} \left\{ \Gamma(-z_j) A_j^{z_j} \prod_{i=1}^{q-1} |\xi_i - w_j|^{z_j} \right\} \delta_{Z, \beta_0 - 1}, \tag{B8}$$

where $\delta_{Z, \beta_0 - 1}$ is a symbol which simplifies the writing and which means that

$$z_q = \beta_0 - 1 - \sum_{j=1}^{q-1} z_j .$$

We may now apply (B1, B3) in order to integrate the $d\xi$ integrals with β_j replaced by $\beta_j + z_j$ and get

$$\frac{1}{\Gamma(\Sigma_{j=0}^{q} \beta_j - 1)} \frac{1}{\Gamma(1-\beta_0)} \prod_{1 \leqslant i < j \leqslant q} (w_i - w_j)^{\beta_i + \beta_j - 1} \times \frac{1}{(2i\pi)^{q-1}} \int \cdots \int \prod_{j=1}^{q-1} dz_j \prod_{j=1}^{q} \{ \Gamma(-z_j)\Gamma(\beta_j + z_j)(w_0 - w_j)^{\beta_0 - 1 - z_j} \} \delta_{Z, \beta_0 - 1} . \tag{B9}$$

We now consider the integral

$$\frac{1}{2i\pi} \oint_{C_0} dz\ \frac{1}{(w_0 - z)^{\beta_0} \Pi_{j=1}^{q} (z - w_j)^{\beta_j}}, \tag{B10}$$

where C_0 surrounds the cut $[w_0, \infty]$. The integral (B10) can be calculated from the integral of the discontinuity along the cut $[w_0, +\infty]$

$$-\frac{\sin \pi\beta_0}{\pi} \int_0^{\infty} dx\ x^{-\beta_0} \prod_{j=1}^{q} (x + w_0 - w_j)^{-\beta_j}. \tag{B11}$$

Next, we use again the integral representation (B7), for $j = 1$ to $q-1$, in order to write (B11) as

$$-\frac{\sin \pi\beta_0}{\pi} \frac{1}{\Pi_{j=1}^{q-1} \Gamma(\beta_j)} \frac{1}{(2i\pi)^{q-1}} \int \cdots \int \prod_{j=1}^{q-1} [dz_j \Gamma(-z_j)\Gamma(\beta_j + z_j)(w_0 - w_j)^{-z_j - \beta_j}] \times \int_0^{\infty} dx\ x^{-\beta_0 + \Sigma_{j=1}^{q-1} z_j} (x + w_0 - w_q)^{-\beta_q}.$$

After integration of the dx integral, (B10) is equal to

$$-\frac{\sin \pi\beta_0}{\pi}\frac{1}{\Pi_{j=1}^{q}\Gamma(\beta_j)}\frac{1}{(2i\pi)^{q-1}}$$
$$\times\int\cdot\cdot\int\prod_{j=1}^{q-1}dz_j\prod_{j=1}^{q}[\Gamma(-z_j)\Gamma(\beta_j+z_j)(w_0-w_j)^{-z_j-\beta_j}]\delta_{Z,\beta_0-1}. \tag{B12}$$

If we compare (B12) and (B9), we just proved that

$$K_{q-1}=\frac{\Pi_{j=0}^{q}\Gamma(\beta_j)}{\Gamma(\Sigma_{j=0}^{q}\beta_j-1)}\prod_{0\leqslant i<j\leqslant q}(w_i-w_j)^{\beta_i+\beta_j-1}\frac{(-1)}{2i\pi}\oint_{C_0}dz\,\frac{1}{(w_0-z)^{\beta_0}\Pi_{j=1}^{q}(z-w_j)^{\beta_j}}. \tag{B13}$$

This ends the calculation of K_{q-1} which represents the central part in the proof of the conjecture.

APPENDIX C

In this Appendix we calculate and we give some properties of the expression

$$A=\frac{\partial_{v_1}\cdot\cdot\partial_{v_p}[\Pi_{i=0}^{q}\Pi_{j=1}^{p}(w_i-v_j)^{1-\beta_i}\Pi_{k<l}(v_k-v_l)]}{\Pi_{i=0}^{q}\Pi_{j=1}^{p}(w_i-v_j)^{1-\beta_i}\Pi_{k<l}(v_k-v_l)}. \tag{C1}$$

In order to calculate this expression, we simply calculate the residues of the poles in the variables v_j; the first property which is clear is that there is no singularity when two v's coincide. The only way to get a pole at $v_i=v_j$ is when the derivatives ∂_{v_i} or/and ∂_{v_j} act upon the term (v_i-v_j) at the numerator of (C1). Clearly, for $f(w,v)$ symmetric in v_i and v_j,

$$\frac{\partial_{v_i}\partial_{v_j}[f(w,v)(v_i-v_j)]}{f(w,v)(v_i-v_j)}=\frac{f''_{ij}(w,v)}{f(w,v)}-\frac{f'_i(w,v)-f'_j(w,v)}{f(w,v)(v_i-v_j)} \tag{C2}$$

and the residue of the pole at $v_i=v_j$ is zero (and this property remains evidently true when performing the other derivatives). Consequently, we are going to extract the poles when $v_i=w_k$ neglecting systematically all poles at $v_i=v_j$ since their residues vanish. We write

$$A=\prod_{i=0}^{q}\frac{R_i}{w_i-v_1} \tag{C3}$$

and we find

$$R_i=(\beta_i-1)\frac{\partial_{v_2}\cdot\cdot\partial_{v_p}[f_2\cdot\cdot f_p\Pi_{j>1}(w_i-v_j)\Delta_1]}{f_2\cdot\cdot f_p\Pi_{j>1}(w_i-v_j)\Delta_1}, \tag{C4}$$

where $f_k=\Pi_{i=0}^{q}(w_i-v_k)^{1-\beta_i}$ and $\Delta_1=\Pi_{1<i<j}(v_i-v_j)$.

We now extract the poles in v_2 and write

$$A=\sum_{\{i_1,i_2\}=0}^{q}\frac{R_{i_1,i_2}}{(w_{i_1}-v_1)(w_{i_2}-v_2)}. \tag{C5}$$

We find

$$R_{i_1,i_2}=(\beta_{i_1}-1)(\beta_{i_2}-1-\delta_{i_1,i_2})\ \frac{\partial_{v_3}..\partial_{v_p}[f_3..f_p\Pi_{j>2}(w_{i_1}-v_j)(w_{i_2}-v_j)\Delta_2]}{f_3..f_p\Pi_{j>2}(w_{i_1}-v_j)(w_{i_2}-v_j)\Delta_2}, \tag{C6}$$

where $\Delta_2=\Pi_{2<i<j}(v_i-v_j)$. We can proceed and extract successively all the poles in v_i; the result can be written in the following way: given $(q+1)$ complementary (and possibly empty) sets $I_0,I_1,\ldots,I_q$ such that

$$I_r\cap I_s=\Phi,\quad \cup_{r=0}^{q}I_r=(1,..,p), \tag{C7}$$

then

$$A=\sum_{\{I_0,\ldots,I_q\}}\prod_{r=0}^{q}\left\{\frac{\Gamma(\beta_r)}{\Gamma(\beta_r-|I_r|)}\sum_{j\in I_r}\ \frac{1}{w_r-v_j}\right\}, \tag{C8}$$

where $|I_r|$ is the number of elements in I_r.

Let us write, as an example, the case where $\beta=p$ integer and where we have only two variables w_0 and w_1. Then,

$$A=(p-1)(p-1)!\sum_{I\subset(1,..,p)}C_{p-2}^{|I|-1}\prod_{i\in I}\ \frac{1}{w_0-v_i}\prod_{i\notin I}\ \frac{1}{w_1-v_i}. \tag{C9}$$

In the rest of the appendix, we show that A is the ratio of two determinants, and we develop a recurrent construction satisfied by expressions of the same type of A.

We define successively the following symbols: given the symbol $[u]=[u]_0$ attached to a given variable u, and the symbols

$$[u]_n=nu^{n-1}+u^n[u] \tag{C10}$$

then, we define the completely symmetric symbols

$$[v_1,..,v_p]=\frac{1}{\Delta}\det\begin{vmatrix}[v_1]_0 & [v_2]_0 & \cdot\cdot & [v_p]_0\\ [v_1]_1 & [v_2]_1 & \cdot\cdot & [v_p]_1\\ \cdot & \cdot & & \cdot\\ \cdot & \cdot & & \cdot\\ [v_1]_{p-1} & [v_2]_{p-1} & \cdot\cdot & [v_p]_{p-1}\end{vmatrix}, \tag{C11}$$

where $\Delta=(-)^{n(n-1)/2}\Pi_{i<j}(v_i-v_j)$ is the Vandermonde determinant. Clearly, these symbols can also be defined recursively by

$$\begin{aligned}[v,w]&=\frac{(1+v[v])[w]}{v-w}+\frac{(1+w[w])[v]}{w-v},\\ [u,v,w]&=\frac{(2u+u^2[u])[v,w]}{(u-v)(u-w)}+\text{circ.perm.},\\ &\cdots\\ [v_1,..,v_p]&=\frac{((p-1)v_1^{p-2}+v_1^{p-1}[v_1])[v_2,..,v_p]}{\Pi_{i=2}^{p}(v_1-v_i)}+\text{circ.perm.}\end{aligned} \tag{C12}$$

To illustrate this construction, we give two examples. First, let us define

$$[u]=\frac{\beta}{u}. \tag{C13}$$

Then, it is easy to construct the different symbols; using the properties of determinants, we obtain

$$[v_1,..,v_p]=\frac{\Gamma(\beta+p)}{\Gamma(\beta)}\frac{1}{v_1\ldots v_p}. \tag{C14}$$

Moreover, since

$$[v]_n=\frac{\partial_v(v^{\beta+n})}{v^{\beta}}$$

we have

$$[v_1,..,v_p]=\frac{\partial_{v_1}\cdots\partial_{v_p}[v_1^{\beta}..v_p^{\beta}\Pi_{i<j}(v_i-v_j)]}{v_1^{\beta}..v_p^{\beta}\Pi_{i<j}(v_i-v_j)}. \tag{C15}$$

As a second example, we define

$$[u]=\sum_{i=0}^{q}\frac{\beta_i-1}{w_i-u}. \tag{C16}$$

Then, from

$$[v]_n=\frac{\partial_v[v^n\Pi_{i=0}^{q}(w_i-v)^{1-\beta_i}]}{\Pi_{i=0}^{q}(w_i-v)^{1-\beta_i}} \tag{C17}$$

and the properties of determinants, we find that

$$[v_1,..,v_p]=A \tag{C18}$$

as given in (C1) and (C8).

APPENDIX D

We are interested in the structure of the integrals

$$I_{P(z)}=\frac{1}{2i\pi}\oint_{C_0}dz\,\frac{P(z)}{(w_0-z)^{\beta_0}\Pi_{j=1}^{q}(z-w_j)^{\beta_j}}, \tag{D1}$$

where $P(z)$ is a polynomial and where the sum over the variables β is large enough to make the integral convergent along the cut $C_0=[w_0,+\infty]$. To simplify the writing of this Appendix, we keep abusively a z dependence on the left hand side of (D1). From

$$\frac{1}{2i\pi}\oint_{C_0}dz\,\frac{\partial}{\partial z}\left\{\frac{z^n}{(w_0-z)^{\beta_0-1}\Pi_{j=1}^{q}(z-w_j)^{\beta_j-1}}\right\}=0, \tag{D2}$$

we obtain the relation

$$-nI_{z^{n-1}\Pi_{j=0}^{q}(z-w_j)}+\sum_{j=0}^{q}(\beta_j-1)I_{z^n\Pi_{i\neq j}(z-w_i)}=0 \tag{D3}$$

In the special case where $n=0$, we have

$$\sum_{j=0}^{q}(\beta_j-1)I_{\Pi_{i\neq j}(z-w_i)}=0 \tag{D4}$$

Equation (D4) shows that the function I_{z^q} is linearly dependent of the functions I_{z^p} for $0\leqslant p<q$. Also, for $n>0$, equation (D3) shows that the functions I_{z^p} for $p>q$ can be decomposed on the basis of the q functions I_{z^p} $(0\leqslant p<q)$. We have constructed a q dimensional vectorial space E_q.

The decomposition of the functions $I_{P(z)}$ on the basis of functions I_{z^p} $(0\leqslant p<q)$ is particularly simple if the polynomial $P(z)$ is of degree $<q$; it becomes particularly difficult otherwise because of the relations (D3)–(D4). We are going to introduce other basis for the vectorial space E_q which are specially adapted when the polynomial $P(z)$ is known from its roots $P(z)=\Pi_i(z-v_i)$. Let us give ourselves q different values of the variable v say $v_1,..,v_q$; then, we define a basis of E_q as a set of q independent functions

$$I_{(j)}=I_{\Pi_{i\neq j}(z-v_i)} \quad \text{for } j=1,..,q. \tag{D5}$$

The transformation from the basis I_{z^p} to the basis (D5) can be written as

$$I_{z^p}=\sum_{j=1}^{q}\frac{v_j^p}{\Pi_{i\neq j}(v_j-v_i)}I_{(j)} \tag{D6}$$

and consequently, if $P_{q-1}(z)$ is a polynomial in z of degree at most $q-1$, then

$$I_{P_{q-1}(z)}=\sum_{j=1}^{q}\frac{P_{q-1}(v_j)}{\Pi_{i\neq j}(v_j-v_i)}I_{(j)}. \tag{D7}$$

As we already mentioned, the decomposition of $I_{z^q},I_{z^{q+1}}\cdots$ is more elaborate; let us give the example of I_{z^q}. From (D4), we have

$$D_{q+1}I_{z^q}+\sum_{j=0}^{q}(\beta_j-1)I_{\Pi_{i\neq j}(z-w_i)-z^q}=0, \tag{D8}$$

where $D_p=\Sigma_{j=0}^{q}\beta_j-p$. Since the polynomial $\Pi_{i\neq j}(z-w_i)-z^q$ is of degree $q-1$ in z, we may apply (D7); we obtain

$$I_{z^q}=\sum_{r=1}^{q}\frac{\left[v_r^q-\frac{1}{D_{q+1}}\Sigma_{j=0}^{q}(\beta_j-1)\Pi_{i\neq j}(v_r-w_i)\right]}{\Pi_{s\neq r}(v_r-v_s)}I_{(r)}. \tag{D9}$$

Given a polynomial $P_q(z)$ of degree q in z (with the coefficient of $z^q=1$), we may write

$$I_{P_q(z)}=\sum_{r=1}^{q}\frac{\left[P_q(v_r)-\frac{1}{D_{q+1}}\Sigma_{j=0}^{q}(\beta_j-1)\Pi_{i\neq j}(v_r-w_i)\right]}{\Pi_{s\neq r}(v_r-v_s)}I_{(r)}. \tag{D10}$$

If moreover, the choice of the variables $v_1,..,v_q$ which defines the basis $I_{(r)}$ coincide with the roots of the polynomial $P_q(z)$, that is $P_q(v_r)=0$ for $r=1,..,q$, then

$$I_{\Pi_{i=1}^{q}(z-v_i)}=\frac{(-)^{q+1}}{D_{q+1}}\sum_{r=1}^{q}\frac{\Pi_{i=0}^{q}(w_i-v_r)}{\Pi_{s\neq r}(v_r-v_s)}[v_r]I_{(r)}, \tag{D11}$$

where the symbol $[v]$ is defined in Appendix C (C6).

We now extend the above construction to polynomials of degree larger than q. Given a set of $p>q$ values $v_1,..,v_p$ of a variable v, we define a set of p functions as

$$\overline{I_{(r)}}=I_{\Pi_{i\neq r}(z-v_i)}. \tag{D12}$$

Clearly these p functions are necessarily dependent in the vectorial space E_q. Nevertheless, the relation (D6) remains valid

$$I_{z^j}=\sum_{r=1}^{p}\frac{v_r^j}{\Pi_{i\neq r}(v_r-v_i)}\overline{I_{(r)}}\quad\text{for } j=0,1,..,p-1. \tag{D13}$$

Now, using (D3) with $n=p-q$, and performing the same transformation (D8) to (D11), we obtain

$$I_{\Pi_{i=1}^{p}(z-v_i)}=\frac{(-)^{q+1}}{D_{p+1}}\sum_{r=1}^{p}\frac{\Pi_{j=0}^{q}(w_j-v_r)}{\Pi_{i\neq r}(v_r-v_i)}[v_r]_{p-q}\ \overline{I_{(r)}}, \tag{D14}$$

where $[v_r]_n$ is defined in Appendix C (C10).

Let us illustrate this result on the example where $p=q+1$. In that case the $q+1$ functions $\overline{I_{(r)}}$ can themselves be decomposed according to (D11) generating a set of $q(q+1)/2$ functions

$$\overline{I_{(r,s)}}=\prod_{\substack{i=1\\ i\neq r,s}}^{q+1}(z-v_i). \tag{D15}$$

When transforming (D14) in terms of $\overline{I_{(r,s)}}$, we obtain two contributions depending whether we express $\overline{I_{(r)}}$ or $\overline{I_{(s)}}$ in terms of $\overline{I_{(r,s)}}$; these two contributions construct the combination

$$\frac{[v_r]_1[v_s]_0}{v_r-v_s}+\frac{[v_s]_1[v_r]_0}{v_s-v_r}=[v_r,v_s], \tag{D16}$$

where $[v_r,v_s]$ is defined in Appendix C (C12). The expression (D14) becomes

$$I_{\Pi_{i=1}^{q+1}(z-v_i)}=\frac{(-)^{2q+2}}{D_{q+2}D_{q+1}}\sum_{r<s}\frac{\Pi_{j=0}^{q}[(w_j-v_r)(w_j-v_s)]}{\Pi_{i\neq r,s}[(v_r-v_i)(v_s-v_i)]}[v_r,v_s]\overline{I_{(r,s)}}. \tag{D17}$$

We insist again on the fact that this decomposition is not a decomposition over a basis of E_q but it is exactly the kind of decomposition we need to prove the conjecture in the case $q-1\leqslant p$.

We may generalize (D17) and we may prove by recurrence for any $p>q$, that

$$I_{\Pi_{i=1}^{p}(z-v_i)}=(-)^{(p-q+1)(q+1)}\frac{\Gamma(\Sigma_{j=0}^{q}\beta_j-p-1)}{\Gamma(\Sigma_{j=0}^{q}\beta_j-q)}\sum_{J_{q-1}}\frac{\Pi_{j=0}^{q}\Pi_{k\notin J_{q-1}}(w_j-v_k)}{\Pi_{s\notin J_{q-1}}\Pi_{i\in J_{q-1}}(v_s-v_i)}$$
$$\times\sum_{r\notin J_{q-1}}\frac{[v_r]_{p-q}[\cup_{\substack{k\notin J_{q-1}\\ k\neq r}}(v_k)]}{\Pi_{\substack{i\notin J_{q-1}\\ i\neq r}}(v_r-v_i)}\overline{I_{J_{q-1}}},\tag{D18}$$

where $J_{q-1}=(j_1,..,j_{q-1})\subset(1,..,p)$ and where the notation $\overline{I_{J_{q-1}}}$ means $\overline{I_{(\cup k\notin J_{q-1})}}$. By Appendix C (C12), the sum over r in the third line of (D18) reconstructs $[\cup_{k\notin J_{q-1}}(v_k)]$.

We now rewrite (D18) in a way which is directly applicable to Sec. II Eqs. (2.20–21). We have

$$\frac{1}{\Pi_{s\notin J_{q-1}}\Pi_{i\in J_{q-1}}(v_s-v_i)}=(-)^{(2p-q)(q-1)/2+\delta_{J_{q-1}}}\frac{\Pi_{\substack{k<l\\ k,l\notin J_{q-1}}}(v_k-v_l)\Pi_{\substack{k<l\\ k,l\in J_{q-1}}}(v_k-v_l)}{\Pi_{k<l}(v_k-v_l)},\tag{D19}$$

where $\delta_{J_{q-1}}=\Sigma_{k=1}^{q-1}j_k-q+1$. From the definition of the symbol $[\cup_{k\notin J_{q-1}}(v_k)]$ as given in Appendix C (C18, C1), we may write

$$\sum_{J_{q-1}}(-)^{\delta_{J_{q-1}}}\frac{\Pi_{j\notin J_{q-1}}(\partial_{v_j})[\Pi_{i=0}^{q}\Pi_{j\notin J_{q-1}}(w_i-v_j)^{1-\beta_i}\Pi_{\substack{k<l\\ k,l\notin J_{q-1}}}(v_k-v_l)]}{\Pi_{i=0}^{q}\Pi_{j\notin J_{q-1}}(w_i-v_j)^{-\beta_i}}$$
$$\times\frac{\Pi_{\substack{k<l\\ k,l\in J_{q-1}}}(v_k-v_l)}{2i\pi}\oint_{C_0}dz\,\frac{\Pi_{j\in J_{q-1}}(z-v_j)}{(w_0-z)^{\beta_0}\Pi_{j=1}^{q}(z-w_j)^{\beta_j}}$$
$$=(-)^{(q-1)(q-2)/2}\frac{\Gamma(\Sigma_{j=0}^{q}\beta_j-q)}{\Gamma(\Sigma_{j=0}^{q}\beta_j-p-1)}\frac{\Pi_{k<l}(v_k-v_l)}{2i\pi}\oint_{C_0}dz\,\frac{\Pi_{j=1}^{p}(z-v_j)}{(w_0-z)^{\beta_0}\Pi_{j=1}^{q}(z-w_j)^{\beta_j}}\tag{D20}$$

which is the relation used at the end of Sec. II.

A quantum particle interacting with a thin solenoid and a magnetic flux is described by a five-parameter family of Hamilton operators, obtained via the method of self-adjoint extensions. One of the parameters, the value of the flux, corresponds to the Aharonov–Bohm effect; the other four parameters correspond to the strength of a singular potential barrier. The spectrum and eigenstates are computed and the scattering problem is solved. © *1998 American Institute of Physics.* [S0022-2488(98)01101-3]

I. INTRODUCTION

The purpose of this paper is to obtain and study the most general family of operators that describe the essential features of a quantum mechanical particle under the joint effect of the electromagnetic potential due to a flux ϕ together with the potential barrier supported on the infinite thin shielded solenoid.

Our initial task is to provide a class of well-defined operators corresponding to the formal differential (plus distributional) expression

$$-\sum_{\ell=1}^{3}\left(\frac{\partial}{\partial x_\ell}-A(\partial_\ell)\right)^2+\lambda\,\delta(r),$$

where x_1,x_2,x_3 are the standard coordinates in $\mathbb{R}^3$, $A=\iota(\phi/2\pi r^2)(-x_2dx_1+x_1dx_2)$ is a pure gauge potential, and $r=((x_1)^2+(x_2)^2)^{1/2}$. For that aim, we first reduce the problem to two dimensions by making use of translational symmetry with respect to the coordinate x_3. Let r, θ be, respectively, the radial and angular coordinate in $\mathbb{R}^2$, $0\leqslant r$ and $0\leqslant\theta\leqslant 2\pi$. Set $\alpha=-\phi/2\pi$. We concentrate on the case when $\alpha\notin\mathbb{Z}$ and owing to the gauge symmetry $A'=A+e^{-\iota n\theta}de^{i\nu\theta}$, $n\in\mathbb{Z}$, we can restrict ourselves to the case

$$\alpha\in\,]0,1[\,. \tag{1}$$

The method we adopt in this paper is based on self-adjoint extensions of symmetric operators. From this perspective, we try to combine two well-known cases which were already extensively discussed in the literature. The first one, with $\alpha=0$, corresponds to the so-called point interaction (cf. Ref. 1) and was studied in detail in Ref. 2. An operator in a one-parameter family is defined on a domain which is characterized by a linear relation between certain coefficients which are built up from the asymptotic behavior, as $r\to 0$, of (singular) wave functions. The starting point was a symmetric operator with a domain formed by wave functions with supports separated from the origin. The deficiency indices turned out to be (1,1).

The second case, with $\lambda=0$, corresponds to the pure Aharonov–Bohm (A–B) potential[3] and was investigated many times on different levels (see Refs. 4–8). The generalized eigenfunctions are required to belong to $H^{2,2}_{\mathrm{loc}}(\mathbb{R}^2\backslash\{0\})$ and at the origin the regular condition

$$\lim_{r\to 0_+} f(r,\theta)=0 \tag{2}$$

is imposed. As the Hamiltonian enjoys rotational symmetry, the generalized eigenfunctions are known and the scattering problem is solved explicitly.

However, it has been known already for some time that, when decomposing the Hilbert space into a direct sum as follows,

$$L^2(\mathbb{R}^2,d^2x)\simeq L^2(\mathbb{R}_+,rdr)\otimes L^2([0,2\pi],d\theta)=\oplus_{m=-\infty}^{\infty}L^2(\mathbb{R}_+,rdr)\otimes\chi_m, \tag{3}$$

where

$$\chi_m(\theta)=(2\pi)^{-1/2}e^{im\theta}, \tag{4}$$

the A–B operator decomposes correspondingly and in the channels $m=-1$ and $m=0$ the boundary condition (2) is not the most general one. But since the other boundary conditions admit wave functions that are singular at the origin, they were usually ruled out.

In our opinion, it makes good sense to consider the most general case and hence to allow even a sort of interaction between the two channels. Thus we apply to the pure A–B Hamiltonian exactly the same procedure that was used in the case of point interactions. The deficiency indices one obtains this way are (2,2) and this indicates clearly that the result is not simply a superposition of the two special cases.

II. FIVE-PARAMETER FAMILY OF HAMILTON OPERATORS AND THEIR RESOLVENTS

In order to get operators that can be consistently interpreted as describing the physical situation we are interested in, we start with the case of pure A–B effect and introduce the point interaction at $0\in\mathbb{R}^2$ in the usual way. Namely, first we consider the restriction of the self-adjoint pure A–B operator H to the space of functions with supports outside of $\{0\}$, obtaining thus a closable symmetric operator. Then we shall find all possible self-adjoint extensions of its closure $\widetilde{H}$.

The adjoint $\widetilde{H}^*$ is defined as the differential operator $-(\boldsymbol{\nabla}-A(\boldsymbol{\nabla}))^2$ on the domain

$$\psi\in\mathscr{D}(\widetilde{H}^*)\Leftrightarrow\psi\in L^2(\mathbb{R}^2)\cap H^{2,2}_{\mathrm{loc}}(\mathbb{R}^2\backslash\{0\})\quad\text{and}\quad(\boldsymbol{\nabla}-A(\boldsymbol{\nabla}))^2\psi\in L^2(\mathbb{R}^2). \tag{5}$$

On general grounds, $\widetilde{H}$ has equal deficiency indices. To find the corresponding deficiency spaces we employ the decomposition (3). Since the orthogonal projection onto $L^2(\mathbb{R}_+)\otimes\chi_m$ commutes with $\widetilde{H}$ on $\mathscr{D}(\widetilde{H})$, we can solve the eigenvalue problem

$$\widetilde{H}^*f=k^2f, \tag{6}$$

with $k=e^{\imath\pi/4}$ and $k=e^{\imath 3\pi/4}$, in each sector m of the angular momentum. Setting $f(r,\theta)=g(r)\chi_m(\theta)$, (6) becomes

$$-\left(\frac{\partial^2}{\partial r^2}+\frac{1}{r}\frac{\partial}{\partial r}-\frac{(m+\alpha)^2}{r^2}\right)g=k^2g, \tag{7}$$

which, by the standard substitution $r\to kr$, leads to the Bessel equation.

Next, selecting in the two-dimensional space of solutions the one which vanishes at the infinity, we arrive at the Henkel functions

$$g(r)=H^{(1)}_{|m+\alpha|}(kr). \tag{8}$$

To ensure the integrability we still have to control the asymptotics as $r\to 0_+$. The case $\alpha=0$ is known; the L^2 solutions exist only in the sector $m=0$ and thus the the deficiency indices are (1,1). Assuming now that $0<\phi<2\pi$ and recalling the asymptotics

$$H_\nu^{(1)}(z)=\frac{2^\nu \imath}{\sin(\pi\nu)\ \Gamma(1-\nu)}\, z^{-\nu}+\frac{2^{-\nu}\imath e^{-i\pi\nu}}{\sin(\pi\nu)\ \Gamma(1+\nu)}\, z^{\nu}+O(z^{-\nu+2}), \tag{9}$$

as $z\to 0$, the integrability at 0 means that $2|m+\alpha|-1<1$, which selects precisely two angular momentum sectors: $m=-1$ and $m=0$. Thus the deficiency indices of $\widetilde{H}$ are (2,2) and the deficiency space $\mathscr{N}_\imath$ is spanned by $f_\imath^1$ and $f_\imath^2$ given by

$$f_\imath^1(r,\theta)=N_1 H^{(1)}_{1-\alpha}(kr)e^{-\imath\theta},\quad f_\imath^2(r,\theta)=N_2 H^{(1)}_{\alpha}(kr), \tag{10}$$

where $k=e^{\imath\pi/4}$ ($k=\sqrt{\imath}$ with $\mathrm{Im}\,k>0$) and the normalization constants N_1, N_2 will be determined later on.

This means that all self-adjoint extensions are in one-to-one correspondence with the elements of the unitary group $U(2)$ and are determined by boundary conditions at the origin. We treat them in detail in the next section. Thus we get, apart from α characterizing the magnetic flux, four additional parameters.

It is now straightforward to determine the domain $\mathscr{D}(\widetilde{H})$. As $\widetilde{H}=\widetilde{H}^{**}$ it holds true that

$$\psi\in\mathscr{D}(\widetilde{H})\Leftrightarrow\psi\in\mathscr{D}(\widetilde{H}^*)\quad\text{and}\quad\langle\psi,\widetilde{H}^*\varphi\rangle=\langle\widetilde{H}^*\psi,\varphi\rangle,\quad\forall\varphi\in\mathscr{N}_\imath+\mathscr{N}_{-\imath}.$$

Consequently we find that $g(r)\otimes\chi_m(\theta)\in\mathscr{D}(\widetilde{H})$, with $m=-1$, 0, if and only if $g\in L^2(\mathbb{R}_+,rdr)\cap H^{2,2}_{\mathrm{loc}}(]0,+\infty[)$, $(\partial_r^2+r^{-1}\partial_r-r^{-2}(m+\alpha)^2)g\in L^2(\mathbb{R}_+,rdr)$, and

$$\lim_{r\to 0_+} rW(g,h_\pm)=0, \tag{11}$$

where $h_\pm=H^{(1)}_{|m+\alpha|}(\sqrt{\pm\imath}r)$ (with $\mathrm{Im}\,\sqrt{\pm\imath}>0$) and the symbol $W(g,h)$ stands for the Wronskian,

$$W(g,h):=\overline{g}\partial_r h-\overline{h}\partial_r g.$$

At this point, let us make a short digression and recall a useful formula comparing resolvents of two self-adjoint extensions. It is stated in the framework of Krein's approach to the theory of self-adjoint extensions and was presented originally in Ref. 9. Let us consider a general situation when a closed symmetric operator X is given and A_0 is a self-adjoint extension of X, $X\subset A_0=A_0^*\subset X^*$. Assume that the deficiency indices of X are (d,d), $d<\infty$. Set

$$\mathscr{N}_z:=\mathrm{Ker}(X^*-z),\quad R_z^0:=(A_0-z)^{-1},\quad z\in\mathbb{C}\backslash\mathbb{R}. \tag{12}$$

The following facts are well known and easy to check. First,

$$\psi\in\mathscr{N}_w\Rightarrow\psi+(z-w)R_z^0\psi=(A_0-w)R_z^0\psi\in\mathscr{N}_z. \tag{13}$$

Second, if $U_z^0:\mathscr{N}_z\to\mathscr{N}_{\overline{z}}$, $z\in\mathbb{C}\backslash\mathbb{R}$, is the unitary mapping defining the self-adjoint extension A_0, then

$$\forall\psi\in\mathscr{N}_z,\quad U_z^0\psi=-(A_0-z)(A_0-\overline{z})^{-1}\psi. \tag{14}$$

Fix $w\in\mathbb{C}\backslash\mathbb{R}$ and a basis $\{f_w^\ell\}_\ell$ in $\mathscr{N}_w$. Set

$$f_z^\ell=f_w^\ell+(z-w)R_z^0 f_w^\ell=(A_0-w)R_z^0 f_w^\ell,\quad z\in\mathbb{C}\backslash\mathbb{R}. \tag{15}$$

Since $(A_0-w)R_z^0$ is injective and $\dim\mathscr{N}_w=\dim\mathscr{N}_z=d$, $\{f_z^1,\ldots,f_z^d\}$ is a basis in $\mathscr{N}_z$. Suppressing the superscript ℓ one can verify readily that

$$\forall z,z' \in \mathbb{C}\backslash\mathbb{R}, \quad f_z = f_{z'} + (z-z')R^0_z f_{z'}, \tag{16}$$

$$\forall z \in \mathbb{C}\backslash\mathbb{R}, \quad U^0_z f_z = -f_{\overline{z}}. \tag{17}$$

Thus, in order to reproduce the vector-valued function f_z, one can take any $z' \in \mathbb{C}\backslash\mathbb{R}$ instead of w. Furthermore, the matrix of U^0_z in the bases $\{f^{\vee}_z\}_{\vee}$, $\{f^{\vee}_{\overline{z}}\}_{\vee}$ equals -1.

To proceed further let us introduce a matrix $P(z,w)=(P^{jk}(z,w))$ of scalar products relating two spaces $\mathscr{N}^{\cdot}_z$ and $\mathscr{N}^{\cdot}_w$,

$$P^{jk}(z,w) := \langle f^j_z, f^k_w \rangle. \tag{18}$$

One finds that

$$P(z,z) = P(\overline{z,z}), \tag{19}$$

and if U is any matrix expressed in the bases $\{f^{\vee}_z\}$, $\{f^{\vee}_{\overline{z}}\}$, and representing a unitary mapping $\mathscr{N}^{\cdot}_z \to \mathscr{N}^{\cdot}_{\overline{z}}$, then

$$P(z,z) = U^* P(\overline{z,z}) U. \tag{20}$$

Furthermore, if $\mathscr{P}_z$ is the orthogonal projector onto $\mathscr{N}^{\cdot}_z$, then

$$\mathscr{P}_z = \sum_{jk} (P(z,z)^{-1})^{jk} f^j_z \langle f^k_z, \cdot \rangle. \tag{21}$$

Our primary interest is to compare A_0 with another self-adjoint extension A of X corresponding to a family of unitary mappings $U_z : \mathscr{N}^{\cdot}_z \to \mathscr{N}^{\cdot}_{\overline{z}}$. Krein's formula tells us that

$$R_z - R^0_z = (\overline{z} - z)^{-1} \mathscr{P}^*_z (U_z - U^0_z) \mathscr{P}_{\overline{z}}, \tag{22}$$

with the symbol $\mathscr{P}^*_z$ standing for the embedding of $\mathscr{N}^{\cdot}_z$ into the global Hilbert space. This means that there exists a family of $d \times d$ matrices, $M_z = (M^{jk}_z)$, such that

$$R_z - R^0_z = \sum_{jk} M^{jk}_z f^j_z \langle f^k_{\overline{z}}, \cdot \rangle. \tag{23}$$

We claim that

$$M_z - M_w = (z-w) M_z P(\overline{z},w) M_w, \tag{24}$$

$$(\overline{w} - w) M_w = (U^{-1} + 1) P(w,w)^{-1}, \tag{25}$$

where U is the matrix of $U_w : \mathscr{N}^{\cdot}_w \to \mathscr{N}^{\cdot}_{\overline{w}}$ in the bases $\{f^j_w\}$ and $\{f^j_{\overline{w}}\}$. The proof is quite straightforward and relies on Krein's formula, the first resolvent identity, and the explicit expression for $\mathscr{P}_z$. Provided M_w and M_z are invertible one can also write

$$M^{-1}_w - M^{-1}_z = (z-w) P(\overline{z},w). \tag{26}$$

What we shall need in the sequel is the particular choice of $w = -\iota$. In this case,

$$M^{-1}_z = 2\iota P(\iota,\iota)(U+1)^{-1} - (z+\iota) P(\overline{z},-\iota), \tag{27}$$

where this time U is the matrix of $U_\iota : \mathscr{N}^{\cdot}_\iota \to \mathscr{N}^{\cdot}_{-\iota}$ in the above specified bases.

Next we apply this general procedure to our problem, with $A_0 \equiv H$-the pure A–B operator. Thus, for $z \in \mathbb{C}\backslash\mathbb{R}_+$, we choose in $\mathscr{N}_z$ a particular basis which depends holomorphically on z by

$$f_z^\ell = (1+(z-\iota)R_z)f_\iota^\ell, \quad \ell = 1,2, \tag{28}$$

where R_z is the resolvent of the pure A–B operator defined by its integral kernel (Green's function)

$$G_z(r,\theta;r',\theta') = \frac{1}{2\pi}\sum_{m\in\mathbb{Z}} e^{\iota m(\theta-\theta')}\int_0^\infty (k^2-z)^{-1} J_{|m+\alpha|}(kr)J_{|m+\alpha|}(kr')k\ dk. \tag{29}$$

Recalling that

$$H_\nu^{(1)}(z) = \frac{2}{\pi\iota}\, e^{-\iota\pi\nu/2}K_\nu(-\iota z), \tag{30}$$

where

$$K_\nu(z) = \int_0^\infty e^{-z\cosh t}\cosh \nu t\ dt, \tag{31}$$

and using the formulas 8.13(3) and 8.5(12) of Ref. 10,

$$\int_0^\infty K_\mu(ay)J_\mu(xy)y\ dy = \left(\frac{x}{a}\right)^\mu (x^2+a^2)^{-1}, \tag{32}$$

$$\int_0^\infty \frac{x^\mu}{x^2+a^2}\, J_\mu(yx)x\ dx = a^\mu K_\mu(ay), \quad \mu\in\,]-1,3/2[, \quad \mathrm{Re}\ a>0, \tag{33}$$

we have

$$f_z^1(r,\theta) = N_1 e^{-\iota\pi(1-\alpha)/4}(\sqrt{z})^{1-\alpha}H_{1-\alpha}^{(1)}(\sqrt{z}r)e^{-\iota\theta},$$

$$f_z^2(r,\theta) = N_2 e^{-\iota\pi\alpha/4}(\sqrt{z})^{\alpha}H_{\alpha}^{(1)}(\sqrt{z}r), \tag{34}$$

where $z\in\mathbb{C}\backslash\mathbb{R}_+$, $\mathrm{Im}\ \sqrt{z}>0$. Particularly,

$$f_{-\iota}^1(r,\theta) = N_1 e^{\iota\pi(1-\alpha)/2}H_{1-\alpha}^{(1)}(kr)e^{-\iota\theta}, \quad f_{-\iota}^2(r,\theta) = N_2 e^{\iota\pi\alpha/2}H_\alpha^{(1)}(kr), \tag{35}$$

where $k = \sqrt{-\iota} = e^{\iota 3\pi/4}$.

A word of warning should be said here. We use the branch $(e^{\iota\varphi})^\nu = e^{\iota\varphi\nu}$, for $0\leqslant\varphi<2\pi$, which differs from the usual choice made in surveys such as Refs. 10 and 11.

Next we compute the matrix $P(z,z')$:

$$P^{\ell,m}(z,z') := \langle f_z^\ell, f_{z'}^m\rangle = P^{\ell,\ell}(z,z')\delta_{\ell,m}, \quad \ell,m = 1,2. \tag{36}$$

Since $\overline{K_\nu(z)} = K_\nu(\overline{z})$ and using the formula 6.521 of Ref. 11,

$$\int_0^\infty K_\nu(ar)K_\nu(br)r\ dr = \frac{\pi(ab)^{-\nu}(a^{2\nu}-b^{2\nu})}{2\sin(\pi\nu)(a^2-b^2)}, \tag{37}$$

we find that

$$P^{\ell,\ell'}(z,z')=N_\ell^2\,\frac{4e^{-\iota\pi\nu}}{\sin(\pi\nu)}\,\frac{(\overline{z})^\nu-(z')^\nu}{z-z'}, \tag{38}$$

where

$$\nu=\begin{cases}1-\alpha, & \text{if } \ell=1,\\ \alpha, & \text{if } \ell=2.\end{cases}$$

Making use of the identity

$$\int_0^\infty |H_\nu^{(1)}(kr)|^2 r\,dr=(\pi\,\cos(\pi\nu/2))^{-1},\quad k=\sqrt{\pm\iota},\quad \text{Im } k>0, \tag{39}$$

we choose now

$$N_1=2^{-1/2}\,\sin^{1/2}(\pi\alpha/2),\quad N_2=2^{-1/2}\,\cos^{1/2}(\pi\alpha/2). \tag{40}$$

In this case the basis $\{f_\iota^\ell\}$ (10), as well as the basis $\{f_{-\iota}^\ell\}$, is orthonormal, i.e., in the matrix notation,

$$P(\iota,\iota)=P(-\iota,-\iota)=I, \tag{41}$$

where I is the 2×2 unit matrix. Moreover, introducing the matrix

$$D=\mathrm{diag}(1-\alpha,\alpha), \tag{42}$$

we also have

$$P(\overline{z},-\iota)=(z+\iota)^{-1}\,\sin^{-1}(\pi D/2)e^{-\iota\pi D}(e^{3\iota\pi D/2}-z^D). \tag{43}$$

Here and everywhere in what follows we use the obvious notation: if a function F is well defined on the set $\{1-\alpha,\alpha\}$, then

$$F(D):=\mathrm{diag}(F(1-\alpha),F(\alpha)).$$

We conclude that all self-adjoint extensions H^U of $\widetilde{H}$ are bijectively labelled by 2×2 unitary matrices U by means of

$$\mathscr{D}(H^U):=\left\{\psi;\psi=\widetilde{\psi}+\sum_\ell\, c_\ell\psi^\ell\right\}, \tag{44}$$

where $\widetilde{\psi}\in D(\widetilde{H})$ and

$$\psi^\ell=f_\iota^\ell+\sum_m\, f_{-\iota}^m U^{m,\ell},\quad \ell=1,2,$$

and

$$H^U\psi=\widetilde{H}\widetilde{\psi}+\sum_\ell\, c_\ell\left(\iota f_\iota^\ell-\iota\sum_m\, f_{-\iota}^m U^{m,\ell}\right). \tag{45}$$

According to the above discussion, $U=-1$ corresponds to the pure A–B operator H. Moreover, diagonal matrices U describe those extensions that preserve the angular momentum (otherwise nonconserved).

III. BOUNDARY CONDITIONS

The family of operators H^U, defined so far abstractly, can be equivalently characterized as differential operators with some well-specified boundary conditions. For this purpose, we introduce four linear functionals Φ_a^n, $n=1,2$, $a=1,2$, corresponding to the two critical angular sectors and to the first two leading terms giving the asymptotic behavior of the radial part of ψ as $r\to 0$. We define

$$\begin{aligned}
\Phi_1^1(\psi) &:= \lim_{r\to 0} r^{1-\alpha}\int_0^{2\pi}\psi(r,\theta)e^{\iota\theta}\,d\theta/2\pi,\\
\Phi_2^1(\psi) &:= \lim_{r\to 0} r^{-1+\alpha}\left[\int_0^{2\pi}\psi(r,\theta)e^{\iota\theta}\,d\theta/2\pi - r^{-1+\alpha}\Phi_1^1(\psi)\right],\\
\Phi_1^2(\psi) &:= \lim_{r\to 0} r^{\alpha}\int_0^{2\pi}\psi(r,\theta)d\theta/2\pi,\\
\Phi_2^2(\psi) &:= \lim_{r\to 0} r^{-\alpha}\left[\int_0^{2\pi}\psi(r,\theta)d\theta/2\pi - r^{-\alpha}\Phi_1^2(\psi)\right].
\end{aligned} \tag{46}$$

This definition is, of course, dictated by the asymptotic behavior of Hankels functions [cf. (9)]. So for $\psi\in\mathscr{D}(H^U)$, the part of ψ which is singular or becomes singular after differentiation by ∂_τ is given by

$$(\Phi_1^1(\psi)r^{-1+\alpha}+\Phi_2^1(\psi)r^{1-\alpha})e^{-\iota\theta}+\Phi_1^2(\psi)r^{-\alpha}+\Phi_2^2(\psi)r^{\alpha}.$$

Let us first check the symmetry condition $\langle\varphi_1,H^U\varphi_2\rangle=\langle H^U\varphi_1,\varphi_2\rangle$, for $\varphi_1,\ \varphi_2\in\mathscr{D}(H^U)$. The integration by parts gives (W=Wronskian)

$$\lim_{r\to 0+}\int_0^{2\pi} rW(\varphi_1,\varphi_2)\,d\theta=0.$$

Only the singular parts of φ_1,φ_2 can contribute and thus one arrives at

$$\Phi_1(\varphi_1)^{*}D\Phi_2(\varphi_2)=\Phi_1(\varphi_2)^{*}D\Phi_2(\varphi_1),\quad \forall\varphi_1,\varphi_2\in\mathscr{D}(H^U), \tag{47}$$

where we have introduced

$$\Phi_a(\psi):=\begin{pmatrix}\Phi_a^1(\psi)\\ \Phi_a^2(\psi)\end{pmatrix},\quad a=1,2, \tag{48}$$

and D was defined in (42).

Next we apply the functionals Φ_a^n to the functions $f^{\nearrow}_{\pm\iota}$. Namely, introduce four matrices Φ_{ab}, where the label $a=1,2$ refers to the first (respectively, the second) leading coefficient, and $b=\pm$ refers to the sign in $\mathscr{N}^{\cdot}_{\pm\iota}$. They are defined by

$$(\Phi_{ab})^{n\nearrow}:=\Phi_a^n(f^{\nearrow}_{b\iota}); \tag{49}$$

so the rows of these matrices are numbered by the angular momentum n (for the sake of convenience we shifted the index by 2, $n=m+2\in\{1,2\}$) and the columns by l, corresponding to the basis in $\mathscr{N}^{\cdot}_{\pm i}$. In view of the asymptotic expansion of the functions f^l_{bi} [cf. (10) and (35)], they read explicitly

$$\Phi_{1,+}=\Phi_{1,-}=\frac{-\iota 2^{-1/2}}{\sin(\pi\alpha)}\cos^{1/2}(\pi D/2)2^{D}\Gamma(1-D)^{-1}\exp(-\iota\pi D/4),$$

$$\Phi_{2,+}=\frac{\iota 2^{-1/2}}{\sin(\pi\alpha)}\cos^{1/2}(\pi D/2)2^{-D}\Gamma(1+D)^{-1}\exp(-\iota 3\pi D/4), \tag{50}$$

$$\Phi_{2,-}=\frac{\iota 2^{-1/2}}{\sin(\pi\alpha)}\cos^{1/2}(\pi D/2)2^{-D}\Gamma(1+D)^{-1}\exp(\iota\pi D/4).$$

From the definition (44) of $\mathscr{D}(H^U)$ follows that $\psi\in L^2(\mathbb{R}^2)$ belongs to the domain of H^U if and only if

$$\begin{pmatrix}\Phi_1(\psi)\\ \Phi_2(\psi)\end{pmatrix}\in\mathrm{Ran}\begin{pmatrix}\Phi_{1,+}+\Phi_{1,-}U\\ \Phi_{2,+}+\Phi_{2,-}U\end{pmatrix}. \tag{51}$$

Inversely, assume that we are given a couple of 2×2 matrices X_1, X_2 such that $\mathrm{rank}(X_1^t,X_2^t)=2$, and consider the boundary condition

$$\begin{pmatrix}\Phi_1(\psi)\\ \Phi_2(\psi)\end{pmatrix}\in\mathrm{Ran}\begin{pmatrix}X_1\\ X_2\end{pmatrix}. \tag{52}$$

The symmetry property (47) leads to the requirement

$$X_1^* DX_2=X_2^* DX_1. \tag{53}$$

In fact, relying on the explicit form of the matrices Φ_{ab}, one can show quite straightforwardly that for any couple X_1, X_2 with the above properties there exist exactly one 2×2 unitary matrix U and $Y\in\mathrm{GL}(2,\mathbb{C})$ such that

$$X_1Y=\Phi_{1,+}+\Phi_{1,-}U,\quad X_2Y=\Phi_{2,+}+\Phi_{2,-}U. \tag{54}$$

On the contrary, if U is unitary, then $X_a=\Phi_{a,+}+\Phi_{a,-}U$, $a=1,2$, verify (53) and $\mathrm{rank}(X_1^t,X_2^t)=2$. This way we have rederived a well-known result that all self-adjoint extensions of $\widetilde{H}$ are in one-to-one correspondence with points of a real four-dimensional submanifold of the Grassmann manifold $G_2(\mathbb{C}^4)$ determined by the equation (53).

One can rewrite the boundary condition (52) in a more convenient form when making use of the biholomorphic diffeomorphism $G_2(\mathbb{C}^4)\to G_2(\mathbb{C}^4)^\sharp$. Here $G_2(\mathbb{C}^4)^\sharp$ stands for the Grassmann manifold in the space dual to $\mathbb{C}^4$. The points of $G_2(\mathbb{C}^4)^\sharp$ are represented by couples of matrices A_1, $A_2\in\mathrm{Mat}(2,\mathbb{C})$, with $\mathrm{rank}(A_1,A_2)=2$, modulo the left action of $\mathrm{GL}(2,\mathbb{C})$. The diffeomorphism is given by

$$\mathrm{Ran}\begin{pmatrix}X_1\\ X_2\end{pmatrix}\in G_2(\mathbb{C}^4)\mapsto\mathrm{Ran}\begin{pmatrix}A_1^t\\ A_2^t\end{pmatrix}\in G_2(\mathbb{C}^4),\quad\text{where } A_1X_1+A_2X_2=0. \tag{55}$$

The real submanifold of $G_2(\mathbb{C}^4)$ determined by (53) is mapped bijectively onto the real four-dimensional submanifold of $G_2(\mathbb{C}^4)^\sharp$ determined by

$$A_1D^{-1}A_2^*=A_2D^{-1}A_1^*. \tag{56}$$

We conclude that each self-adjoint extension of $\widetilde{H}$ is determined by a boundary condition of the type

$$A_1\Phi_1(\psi)+A_2\Phi_2(\psi)=0, \tag{57}$$

where A_1, $A_2 \in \mathrm{Mat}(2,\mathbb{C})$ verify (56) and $\mathrm{rank}(A_1,A_2)=2$. Two couples (A_1,A_2) and (A_1',A_2') define the same self-adjoint operator if and only if there exists $Y \in \mathrm{GL}(2,\mathbb{C})$ such that $A_1' = YA_1$, $A_2' = YA_2$.

Let us now restrict ourselves to an open dense subset of the manifold of boundary conditions (57) which we obtain by fixing $A_1 = I$ and setting $A_2 = -\Lambda$. The condition (57) means, of course, that

$$\begin{pmatrix} \Phi_1^1(\psi) \\ \Phi_1^2(\psi) \end{pmatrix} = \Lambda \begin{pmatrix} \Phi_2^1(\psi) \\ \Phi_2^2(\psi) \end{pmatrix}, \quad \forall \psi \in \mathscr{D}(H^U). \tag{58}$$

The restriction (56) then reads

$$D\Lambda = \Lambda^* D. \tag{59}$$

All matrices Λ obeying (59) can be parametrized by the aid of four real (or two real and one complex) parameters, namely

$$\Lambda = \begin{pmatrix} u & \alpha\overline{w} \\ (1-\alpha)w & v \end{pmatrix}, \quad \text{with } u,v \in \mathbb{R} \quad \text{and } w \in \mathbb{C}. \tag{60}$$

From (55) follows that one can choose $X_1 = \Lambda$, $X_2 = I$. In virtue of (54), this leads to a relation between Λ and U,

$$\Lambda = (\Phi_{1,+} + \Phi_{1,-}U)(\Phi_{2,+} + \Phi_{2,-}U)^{-1}, \tag{61}$$

provided the relevant matrix is invertible. We use the following parametrization of U,

$$U = e^{\iota\omega} \begin{pmatrix} qe^{\iota a} & -(1-q^2)^{1/2}e^{-\iota b} \\ (1-q^2)^{1/2}e^{\iota b} & qe^{-\iota a} \end{pmatrix}, \tag{62}$$

where a, b, q, $\omega \in \mathbb{R}$, $0 \leqslant q \leqslant 1$. The matrix $(\Phi_{2,+} + \Phi_{2,-}U)$ is invertible exactly when $d \neq 0$ where

$$d := \sin\omega + q\,\sin(a - \pi\alpha). \tag{63}$$

In this case, the parameters of the matrix Λ can be expressed explicitly in terms of a, b, q, ω:

$$\begin{aligned} u &= d^{-1}2^{2-2\alpha}\frac{\Gamma(2-\alpha)}{\Gamma(\alpha)}\left(\cos\left(\omega + \frac{\pi}{2}\,\alpha\right) + q\,\cos\left(a - \frac{\pi}{2}\,\alpha\right)\right), \\ \overline{w} &= d^{-1}(2(1-q^2)\sin(\pi\alpha))^{1/2}e^{-\iota(b-\pi\alpha/2-\pi/4)}, \\ w &= d^{-1}(2(1-q^2)\sin(\pi\alpha))^{1/2}e^{\iota(b-\pi\alpha/2-\pi/4)}, \\ v &= -d^{-1}2^{2\alpha}\frac{\Gamma(1+\alpha)}{\Gamma(1-\alpha)}\left(\sin\left(\omega - \frac{\pi}{2}\,\alpha\right) + q\,\sin\left(a - \frac{\pi}{2}\,\alpha\right)\right). \end{aligned} \tag{64}$$

Obviously, the parameters $u = v = 0$ and $w = 0$ correspond to the pure A–B case. Moreover, the resulting Hamiltonian preserves the angular momentum if and only if Λ is diagonal (w is responsible for the nonconservation of the angular momentum).

IV. SPECTRUM AND EIGENSPACES

In order to find the spectrum one can use Krein's formula for the resolvent $R_z^U=(H^U-z)^{-1}$,

$$R_z^U=R_z+\sum_{k,\ell} f_z^k M_z^{k\ell}\langle f_{\bar{z}}^{\ell},\cdot\rangle. \tag{65}$$

Using (41), (43), and (27) we get

$$M_z^{-1}=\sin^{-1}(\pi D/2)\ (z^D e^{-\imath\pi D}(U+1)-e^{\imath\pi D/2}U-e^{-\imath\pi D/2})(U+1)^{-1}. \tag{66}$$

Since R_z^U is a rank two perturbation of R_z, H^U and H have the same absolutely continuous spectrum, namely, $[0,\infty[$.

The discrete spectrum is determined by the equation $\det M_z^{-1}=0$, i.e.,

$$\det(p^{2D}(U+1)-e^{\imath\pi D/2}U-e^{-\imath\pi D/2})=0, \tag{67}$$

where we have introduced $p>0$ by $p^2=-z$. According to the discussion below there are no non-negative eigenvalues. If $d\neq 0$ [cf. (63)], then $(e^{\imath\pi D/2}U-e^{-\imath\pi D/2})$ is invertible and, owing to (61),

$$\begin{aligned}(U+1)(e^{\imath\pi D/2}U-e^{-\imath\pi D/2})^{-1}=&-\cos^{-1/2}(\pi D/2)2^{-D}\Gamma(1-D)e^{-\imath\pi D/4}\\ &\times\Lambda\cos^{1/2}(\pi D/2)2^{-D}\Gamma(1+D)e^{-\imath\pi D/4}.\end{aligned} \tag{68}$$

In this case, (67) is equivalent to

$$\det\left(\frac{\Gamma(1-D)}{\Gamma(1+D)}\left(\frac{p}{2}\right)^{2D}\Lambda+1\right)=0. \tag{69}$$

Rewriting (69) in terms of the parameters u, v, w [cf. (60)] we get

$$\left(\left(\frac{p}{2}\right)^{2\alpha-2}+\frac{\Gamma(\alpha)}{\Gamma(2-\alpha)}u\right)\left(\left(\frac{p}{2}\right)^{-2\alpha}+\frac{\Gamma(1-\alpha)}{\Gamma(1+\alpha)}v\right)=|w|^2. \tag{70}$$

Consider the lhs of (70) as a function $F(p)$ defined on $]0,+\infty[$. Since the rhs of (70) is always non-negative some elementary analysis gives immediately the number of solutions. The number of roots of $F(p)$ equals 0 or 1 or 2. There is no root iff $u\geqslant 0$, $v\geqslant 0$, and there are two roots iff $u<0$, $v<0$ (it may happen that the two roots coincide giving a multiple root). Denote by p_1 the smallest root of $F(p)$, if any. In the case of two roots, let p_2 be the greater one. Then clearly $F(p)$ is decreasing on $]0,p_1]$ from $+\infty$ to zero and is increasing on $[p_2,+\infty]$ from zero to the asymptotic value $uv/\alpha(1-\alpha)$.

We conclude that there are

$$\begin{aligned}&\text{two eigenvalues} && \text{if } u<0,\ v<0, \quad \text{and } \det\Lambda=uv-\alpha(1-\alpha)|w|^2>0,\\ &\text{no eigenvalue} && \text{if } u\geqslant 0,\ v\geqslant 0, \quad \text{and } \det\Lambda=uv-\alpha(1-\alpha)|w|^2\geqslant 0,\\ &&& \text{one eigenvalue} \quad \text{otherwise.}\end{aligned} \tag{71}$$

We stress once more that all eigenvalues, if any, are negative. Again, it may happen (when $w=0$) that two eigenvalues coincide, producing consequently a multiple eigenvalue.

For generic α not much can be said about what are the solutions, except the case $w=0$ when $p=2(-u\Gamma(\alpha)/\Gamma(2-\alpha))^{2-2\alpha}$ if $u<0$ and/or $p=2(-v\Gamma(1-\alpha)/\Gamma(1+\alpha))^{2\alpha}$ if $v<0$, and the case $u=v=0$ when $p=2/|w|$. An interesting particular case is $\alpha=1/2$ when we can give a complete answer about the values of the two solutions [the first case in (71)],

$$p_{\pm}=2\,\frac{u+v\pm(|w|^2+(u-v)^2)^{1/2}}{|w|^2-4uv}, \tag{72}$$

and of the solution [the third case in (71)],

$$p=2\,\frac{u+v+(|w|^2+(u-v)^2)^{1/2}}{|w|^2-4uv}. \tag{73}$$

Similar but more complicated analysis can be also performed for $\alpha=1/3$, 1/4 and partially for other fractional values of α.

As far as the eigenvectors are concerned, they have to be obtained, of course, as solutions of the differential equation (6) including the corresponding boundary conditions (58). First of all, it is clear that in the sectors of the angular momentum $m\neq -1,0$, there is a complete system of generalized (and normalized) eigenfunctions coinciding with those of the pure A–B effect,

$$(2\pi)^{-1/2}J_{|m+\alpha|}(kr)e^{\imath m\theta},\quad m=\ldots,-3,-2,1,2,\ldots,k>0. \tag{74}$$

Next we pass to the sectors $m=-1$ and $m=0$.

As far as the (true) eigenfunctions are concerned, the L^2-integrability condition at infinity restricts the eigenvalue k^2 to $k^2<0$, and picks up a unique solution, up to a multiplicative constant, in each sector $m=-1$ and $m=0$ (this means that both exponential growth and oscillatory behavior at infinity are excluded). Hence setting as before $k=ip$, with $p>0$, the eigenfunction must have the form

$$\xi H^{(1)}_{1-\alpha}(\imath pr)e^{-\imath\theta}+\eta H^{(1)}_{\alpha}(\imath pr), \tag{75}$$

where $\xi,\ \eta\in\mathbb{C}$. The boundary conditions (58) lead to the following relation between ξ and η,

$$\left(I+\left(\frac{\imath p}{2}\right)^{D}\Gamma(1-D)\Lambda\Gamma(1+D)^{-1}e^{-\imath\pi D}\left(\frac{\imath p}{2}\right)^{D}\right)\begin{pmatrix}\xi\\ \eta\end{pmatrix}=0. \tag{76}$$

Setting the determinant of this system of linear equations to zero we recover the equation on eigenvalues (70). Any nontrivial solution (ξ,η) of (76) determines an eigenfunction in accordance with (75).

As far as the generalized eigenfunctions are concerned, the eigenvalue equation admits a four-parameter solution

$$(\xi J_{-1+\alpha}(kr)+\eta J_{1-\alpha}(kr))e^{-\imath\theta}+\xi' J_{-\alpha}(kr)+\eta' J_{\alpha}(kr), \tag{77}$$

where $k>0$ and $\xi,\eta,\xi',\eta'\in\mathbb{C}$. In view of the asymptotics of $J_\nu(z)\simeq\Gamma(1+\nu)^{-1}(z/2)^{\nu}(1+O(z^2))$ and again by taking into account the boundary conditions (58) we find the relation

$$\begin{pmatrix}\xi\\ \xi'\end{pmatrix}=(k/2)^{D}\Gamma(1-D)\Lambda\Gamma(1+D)^{-1}(k/2)^{D}\begin{pmatrix}\eta\\ \eta'\end{pmatrix}. \tag{78}$$

A possible choice is

$$\begin{pmatrix} \eta \\ \eta' \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} \eta \\ \eta' \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \end{pmatrix},$$

and in this way we obtain two independent solutions

$$\begin{aligned} b_1(k) &= (\xi_1 J_{-1+\alpha}(kr) + J_{1-\alpha}(kr)) e^{-\iota\theta} + \eta_1 J_{-\alpha}(kr), \\ b_2(k) &= \xi_2 J_{-1+\alpha}(kr) e^{-\iota\theta} + \eta_2 J_{-\alpha}(kr) + J_{\alpha}(kr), \end{aligned} \tag{79}$$

where

$$\begin{aligned} \begin{pmatrix} \xi_1 & \xi_2 \\ \eta_1 & \eta_2 \end{pmatrix} &= (k/2)^D \Gamma(1-D) \Lambda \Gamma(1+D)^{-1} (k/2)^D \\ &= \begin{pmatrix} u \dfrac{\Gamma(\alpha)}{\Gamma(2-\alpha)} \left(\dfrac{k}{2}\right)^{2-2\alpha} & \overline{w} \dfrac{k}{2} \\ w \dfrac{k}{2} & v \dfrac{\Gamma(1-\alpha)}{\Gamma(1+\alpha)} \left(\dfrac{k}{2}\right)^{2\alpha} \end{pmatrix}. \end{aligned} \tag{80}$$

Set

$$N(k) := \begin{pmatrix} \xi_1 & \xi_2 \\ \eta_1 & \eta_2 \end{pmatrix} + \exp(\iota\pi D). \tag{81}$$

Now we seek a pair of eigenfunctions that are complete and orthonormal in the generalized sense. In order to compute the scalar products of $b_1(k)$ and $b_2(k)$, we need to know the integrals involving the products $J_\mu(ay)J_\mu(xy)$ and $J_{-\mu}(ay)J_\mu(xy)$. Recalling the relation between the functions $H_\mu^{(1)}$ and K_μ (30) and using the limit value of (32) we have

$$\int_0^\infty H_\mu^{(1)}(ay) J_\mu(xy) y \, dy = \frac{1}{\iota\pi a} \left(\frac{x}{a}\right)^\mu \left(\frac{1}{x-a-\iota 0} - \frac{1}{x+a} \right). \tag{82}$$

Next, with the help of the distributional identity $(x-\iota 0)^{-1} = \mathscr{P}(1/x) + \iota\pi\delta(x)$, where $\mathscr{P}$ denotes the principal part, we get two identities by taking the real and imaginary parts of (82),

$$\int_0^\infty J_\mu(ay) J_\mu(xy) y \, dy = \frac{1}{a} \, \delta(x-a), \tag{83}$$

$$\int_0^\infty J_{-\mu}(ay) J_\mu(xy) y \, dy = \frac{\cos(\pi\mu)}{a} \, \delta(x-a) + \frac{\sin(\pi\mu)}{\pi a} \left(\frac{x}{a}\right)^\mu \left(\mathscr{P}\left(\frac{1}{x-a}\right) - \frac{1}{x+a} \right). \tag{84}$$

Applying (83) and (84) to the solutions (79) arranged in a row $B(k) = (b_1(k), b_2(k))$, we obtain the following 2×2 matrix of scalar products,

$$\langle B(k'), B(k) \rangle = N(k')^* N(k) \, \frac{1}{k} \, \delta(k-k'). \tag{85}$$

We observe that

$$\det N(k) = \left(\frac{uv}{\alpha(1-\alpha)} - w\overline{w} \right) \frac{k^2}{4} + \frac{u\Gamma(\alpha) e^{\iota\pi\alpha} k^{2-2\alpha}}{2^{2-2\alpha}\Gamma(2-\alpha)} - \frac{v\Gamma(1-a) e^{-\iota\pi\alpha} k^{2\alpha}}{2^{2\alpha}\Gamma(1+\alpha)} - 1 \tag{86}$$

equals minus the lhs of (69), with p being replaced by $-\imath k$, and thus, in view of our analysis of Eq. (70), $\det N(k)$ is nonvanishing for all $k\geqslant 0$. Therefore $(g_1(k),g_2(k)):=B(k)N(k)^{-1}$, being given by

$$\begin{aligned} g_1(k;r,\theta)&=\det{}^{-1}\,N(k)((\xi_1\eta_2-\xi_2\eta_1+\xi_1 e^{\imath\pi\alpha})J_{\alpha-1}(kr)e^{-\imath\theta}\\ &\quad+(\eta_2+e^{\imath\pi\alpha})J_{1-\alpha}(kr)e^{-\imath\theta}-\eta_1 J_\alpha(kr)+\eta_1 e^{\imath\pi\alpha}J_{-\alpha}(kr)),\\ g_2(k;r,\theta)&=\det{}^{-1}\,N(k)(-\xi_2 e^{-\imath\pi\alpha}J_{\alpha-1}(kr)e^{-\imath\theta}-\xi_2 J_{1-\alpha}(kr)e^{-\imath\theta}\\ &\quad+(\xi_1-e^{-\imath\pi\alpha})J_\alpha(kr)+(\xi_1\eta_2-\xi_2\eta_1-\eta_2 e^{-\imath\pi\alpha})J_{-\alpha}(kr)), \end{aligned} \tag{87}$$

where ξ_1, ξ_2, η_1, and η_2 are defined by (80), form a complete orthonormal basis of generalized eigenvectors in the subspace corresponding to the absolutely continuous spectrum in the two considered sectors,

$$\langle g_j(k'),g_\ell(k)\rangle=\frac{1}{k}\,\delta(k-k')\,\delta_{j,\ell}. \tag{88}$$

V. SCATTERING

The existence of a complete and orthonormal basis of generalized eigenvectors is sufficient to show that the wave (Møller) operators $W_\pm=\lim_{t\to\pm\infty}e^{\imath tH}e^{-\imath tH^0}$ exist and are complete. In fact, they can be exhibited explicitly as well as the scattering operator $S=(W_+)^*W_-$.

From what we have said so far it is evident that $W_\pm$ and S preserve the sectors $m\neq -1,0$, and there they are exactly the same as in the pure A–B case; in particular $S_m=e^{2\imath\delta_m}$, where $\delta_m=(|m|-|m+\alpha|)\,\pi/2$. Thus we restrict ourselves to the subspace $L^2(\mathbb{R}_+,rdr)\otimes(\mathbb{C}\chi_{-1}\oplus\mathbb{C}\chi_0)$, of remaining sectors $m=-1,0$, which is, of course, also preserved by all the relevant operators (if there is no danger of confusion we denote the restriction of an operator by the same symbol).

Using the basis $\{g_1(k),g_2(k)\}$ we define a unitary operator $\mathscr{F}$ from $L^2(\mathbb{R}_+,kdk)\otimes\mathbb{C}^2$ to $L^2(\mathbb{R}_+,rdr)\otimes(\mathbb{C}\chi_{-1}\oplus\mathbb{C}\chi_0)$ by

$$\mathscr{F}[\widetilde{\psi}]=\psi:=\sum_{j=1}^{2}\int_0^\infty g_j(k)\widetilde{\psi}_j(k)k\;dk, \tag{89}$$

with the inverse $\mathscr{F}^{-1}[\psi]=\widetilde{\psi}$ given by

$$\widetilde{\psi}_j(k):=\langle g_j(k),\psi\rangle. \tag{90}$$

The operator $\mathscr{F}$ satisfies

$$e^{-\imath tH}\mathscr{F}[\widetilde{\psi}]=\mathscr{F}[e^{-\imath tk^2}\widetilde{\psi}]. \tag{91}$$

We append the superscript '^{0}' to the relevant objects like $g_j^0(k)$ or $\mathscr{F}^0$ corresponding to the free case ($\alpha=0$, $\Lambda=0$); particularly

$$g_1^0(k;r,\theta)=J_1(kr)e^{-\imath\theta},\quad g_2^0(k;r,\theta)=J_0(kr). \tag{92}$$

Now we seek a pair of 2×2 matrices $\Omega_\pm=\Omega_\pm(k)$, generally depending on k and acting in an obvious way as a multiplication operator on $L^2(\mathbb{R}_+,kdk)\otimes\mathbb{C}^2$, so that

$$W_\pm\mathscr{F}^0=\mathscr{F}\;\Omega_\pm. \tag{93}$$

Then it follows that $S\mathscr{F}^0=\mathscr{F}^0\Omega_+^*\Omega_-$, and this means that $\Sigma:=\Omega_+^*\Omega_-$ is nothing but the scattering matrix in the momentum representation (restricted to the sectors $m=-1,0$).

We have to verify that

$$\lim_{t\to\pm\infty}\|e^{-\iota tH^0}\mathscr{F}^0[\psi]-e^{-\iota tH}\mathscr{F}[\Omega_\pm\psi]\|=0. \tag{94}$$

Due to (91), the condition (94) means that

$$\lim_{t\to\pm\infty}\left\|\sum_j\int_0^\infty e^{-\iota tk^2}\left(g_j^0(k)-\sum_\ell g_\ell(k)\Omega_\pm(k)_{\ell j}\right)\psi_j(k)k\,dk\right\|=0. \tag{95}$$

It is sufficient to prove (95) only for $\psi_j(k)$ from the dense subspace $C_0^\infty(\mathbb{R}_+)\subset L^2(\mathbb{R}_+,kdk)$. By the stationary phase method, the convergence of such an integral, as $t\to\pm\infty$, will be established provided the coefficient standing in front of the term $e^{\pm\iota kr}$ vanishes. In view of the known large x expansion

$$J_\mu(x)=(2\pi x)^{-1/2}(e^{\iota(x-\pi\mu/2-\pi/4)}+e^{-\iota(x-\pi\mu/2-\pi/4)})+\mathscr{O}(x^{-3/2}), \tag{96}$$

we obtain, by looking separately at the coefficients in front of $e^{-\iota\theta}$ and 1, that

$$\begin{aligned}\Omega_+(k)^{-1}&=\mathrm{diag}(-e^{-\iota\pi\alpha/2},e^{\iota\pi\alpha/2})\widetilde{N}(k)N(k)^{-1}=\det{}^{-1}\,N(k)\,\mathrm{diag}(-e^{-\iota\pi\alpha/2},e^{\iota\pi\alpha/2})\\&\times\begin{pmatrix}\xi_1\eta_2-\xi_2\eta_1-e^{\iota\pi\alpha}(\eta_2-\xi_1)-e^{2\iota\pi\alpha} & (e^{\iota\pi\alpha}-e^{-\iota\pi\alpha})\xi_2\\ (e^{\iota\pi\alpha}-e^{\iota\pi\alpha})\eta_1 & \xi_1\eta_2-\xi_2\eta_1-e^{-\iota\pi\alpha}(\eta_2-\xi_1)-e^{-2\iota\pi\alpha}\end{pmatrix},\end{aligned} \tag{97}$$

where

$$\widetilde{N}(k):=\begin{pmatrix}\xi_1 & \xi_2\\ \eta_1 & \eta_2\end{pmatrix}+\exp(-\iota\pi D), \tag{98}$$

and also

$$\Omega_-(k)=\mathrm{diag}(-e^{-\iota\pi\alpha/2},e^{\iota\pi\alpha/2}). \tag{99}$$

Note that

$$\widetilde{N}(k)^*\widetilde{N}(k)=N(k)^*N(k) \tag{100}$$

and so $\Omega_+(k)$ is unitary. Consequently, we can express (the entries of) Σ in terms of the parameters u,v,w [see (80)] as

$$\begin{aligned}\Sigma_{11}&=\det{}^{-1}\,N(k)\left(e^{-\iota\pi\alpha}\left(\frac{uv}{\alpha(1-\alpha)}-|w|^2\right)\frac{k^2}{4}+\frac{u\Gamma(\alpha)k^{2-2\alpha}}{2^{2-2\alpha}\Gamma(2-\alpha)}-\frac{u\Gamma(1-\alpha)k^{2\alpha}}{2^{2\alpha}\Gamma(1+\alpha)}-e^{\iota\pi\alpha}\right),\\ \Sigma_{12}&=-\det{}^{-1}\,N(k)\,\iota\,\sin(\pi\alpha)\overline{wk},\\ \Sigma_{21}&=-\det{}^{-1}\,N(k)\,\iota\,\sin(\pi\alpha)wk,\\ \Sigma_{22}&=\det{}^{-1}\,N(k)\left(e^{\iota\pi\alpha}\left(\frac{uv}{\alpha(1-\alpha)}-|w|^2\right)\frac{k^2}{4}+\frac{u\Gamma(\alpha)k^{2-2\alpha}}{2^{2-2\alpha}\Gamma(2-\alpha)}-\frac{v\Gamma(1-\alpha)k^{2\alpha}}{2^{2\alpha}\Gamma(1+\alpha)}-e^{-\iota\pi\alpha}\right),\end{aligned} \tag{101}$$

where $\det N(k)$ is given by (86). Obviously, Σ is unitary.

Let us specialize these formulas to three particular cases.

(i) If $w=0$ (conserved angular momentum), then

$$\Sigma=\mathrm{diag}\left(\frac{u\Gamma(\alpha)(k/2)^{2-2\alpha}-e^{\imath\pi\alpha}\Gamma(2-\alpha)}{e^{\imath\pi\alpha}u\Gamma(\alpha)(k/2)^{2-2\alpha}-\Gamma(2-\alpha)},\ \frac{v\Gamma(1-\alpha)(k/2)^{2\alpha}+e^{-\imath\pi\alpha}\Gamma(1+\alpha)}{e^{-\imath\pi\alpha}v\Gamma(1-\alpha)(k/2)^{2\alpha}+\Gamma(1+\alpha)}\right). \quad (102)$$

(ii) If $u=v=0$ (maximal nonconservation of angular momentum), then

$$\Sigma=Q^{-1}\times\begin{pmatrix} e^{-\imath\pi\alpha}|w|^2(k^2/4)+e^{\imath\pi\alpha} & \imath\,\sin(\pi\alpha)\overline{wk} \\ \imath\,\sin(\pi\alpha)wk & e^{\imath\pi\alpha}|w|^2(k^2/4)+e^{-\imath\pi\alpha}\end{pmatrix}, \quad (103)$$

where

$$Q=|w|^2\,\frac{k^2}{4}+1.$$

(iii) If $\alpha=1/2$, then

$$\Sigma=Q^{-1}\times\begin{pmatrix} -\imath-\imath(uv-|w|^2/4)k^2+(u-v)k & -\imath\overline{wk} \\ -\imath wk & \imath+\imath(uv-|w|^2/4)k^2+(u-v)k\end{pmatrix}, \quad (104)$$

where

$$Q=-1+(uv-|w|^2/4)k^2+\imath(u+v)k.$$

We conclude this section by giving (the kernel of) the full scattering operator in the angular representation,

$$S(k;\theta,\theta_0)=\frac{1}{2\pi}\sum_{m,n=-\infty}^{\infty}S(k;m,n)e^{\imath(m\theta-n\theta_0)}, \quad (105)$$

where

$$S(k;m,n)=\begin{cases} e^{\imath\pi(|m|-|m+\alpha|)}\delta_{mn} & \text{if } m \text{ or } n\neq -1,0, \\ \Sigma_{m+2,n+2} & \text{if } m,n=-1,0\end{cases}$$

(the shift by 2 is due to our labelling of rows and columns of Σ). The double infinite sum can be performed in the sectors $m,n\neq -1,0$ (a known result borrowed from the pure A–B effect) and yields

$$S(k;\theta,\theta_0)=\cos(\pi\alpha)\,\delta(\theta-\theta_0)+\frac{1}{2\pi}\sin(\pi\alpha)\,\frac{e^{-\imath(\theta-\theta_0)/2}}{\sin(\theta/2-\theta_0/2)}$$
$$+\frac{1}{2\pi}\sum_{m,n=-1}^{0}(\Sigma_{m+2,n+2}-e^{-(2m+1)\imath\pi\alpha}\delta_{mn})e^{\imath(m\theta-n\theta_0)}. \quad (106)$$

We recall that the differential cross section in the plane is given by $d\sigma(\theta)/d\theta=(2\pi/k)|S(k;\theta,\theta_0)|^2$.

VI. CONCLUSIONS

We have introduced and studied a five-parameter family of operators that describes a quantum mechanical particle interacting with a magnetic flux α caused by an infinite thin material solenoid.

We conjecture that such a situation is described by a (singular) δ-type potential barrier and by a electromagnetic potential concentrated along the z axis (the magnetic field vanishes in the remaining region) at least in some well-defined limit when the thickness of the solenoid$\to 0$ and its length$\to\infty$. Moreover, the limit should be largely independent of the details of approximating potentials (see, e.g., Ref. 2 for the case of point interaction and Ref. 12 for pure A–B potential), the discussion of which goes, however, beyond the scope of this paper.

One of the five parameters is just the value of the flux α and the other four correspond to the strength of a singular potential barrier (sort of a combination of Dirac δ and δ') and can be interpreted as penetrability coefficients of the shielded solenoid.

A general operator of this family corresponds to an intricate mixture between the Aharonov–Bohm effect and the point interactions which is manifested more concretely via the mixing between the angular and the radial boundary conditions. It is interesting that the result we have obtained is richer than a simple superposition of the point interaction and the pure A–B effect. For instance, for a range of parameters there are two bound states possible while for the usual interactions with a support concentrated along the z axis and symmetric under the z translations (or, equivalently, for a point interaction in two dimensions) there is always (except for the free case) exactly one bound state, and for the pure A–B effect there are no bound states at all.

In the present paper we have derived an explicit formula for the scattering matrix $S(k;\theta,\theta_0)$ depending on the five parameters. Naturally, it would be of interest to examine the differential cross-section numerically, particularly its dependance on the parameters, and to deduce some physical consequences. This is what we plan to do separately.

It is a matter of experimental measurements (interference, scattering, or in condensed matter) to establish which of the extensions in our family correspond to realizable models. On general grounds, one can distinguish some class of extensions by, e.g., symmetry requirements (conservation of the angular momentum), or postulating that there are no bound states (solenoid as a repulsive barrier).

After completing most of our work we became aware of Ref. 13 which has an overlap with some of our results, see also Ref. 14.

(Received 21 January 1997; accepted for publication 5 June 1997)

We study Schrödinger operators H_0 with a gap in the essential spectrum, perturbed by either a decreasing electric potential or a decreasing magnetic field; in both cases the strength of the perturbation is measured by a coupling constant $\lambda \geqslant 0$. Here we are mainly interested in the asymptotic behavior (as $\lambda \to \infty$) of certain counting functions for the eigenvalues that are produced by the perturbation inside the spectral gap. The case where we perturb by a potential can be handled using current technology, even if H_0 contains a fixed magnetic background. For perturbations by magnetic fields, however, we require rather strong assumptions—like exponential decay of the perturbations—to obtain a lower bound on the counting function. To gain some additional intuition, we use separation of variables in the closely related model of a Schrödinger operator with constant magnetic field in $\mathbf{R}^2$, perturbed by a rotationally symmetric magnetic field that decays at infinity.

I. INTRODUCTION

(1) We consider Schrödinger operators with a spectral gap, perturbed by either a decreasing electric potential or a decreasing magnetic field. The strength of these perturbations depends on a coupling parameter λ. With λ growing, eigenvalues may move into the gap or out of the gap. Most of our results concern (lower) bounds for the number of eigenvalues that cross a fixed energy level E in the gap, as the coupling parameter increases from 0 to λ. Using the currently available technology, the first case (electric perturbations) can be handled in reasonable generality—even if the unperturbed reference operator H contains magnetic terms. In contrast, the second case (magnetic perturbations) resists virtually all attempts to adapt the methods that are so effective in the first case. It is one of the aims of the present paper to point out the differences between these two apparently similar situations.

To be more precise, we take for the unperturbed operator H a Schrödinger operator,

$$H = H(\vec{a}, V) = (-i\nabla - \vec{a}(x))^2 + V(x),$$

in $\mathbf{R}^n$, with a real electric potential $V \in L_\infty(\mathbf{R}^n)$ and a magnetic potential $\vec{a} \in C^1(\mathbf{R}^n, \mathbf{R}^n)$. Our basic assumption is that H has a gap in the essential spectrum; for instance, this is the case for many periodic potentials V, for some periodic magnetic fields, and also for combinations of electric and magnetic potentials. We also fix some energy level E inside the gap.

(2) In the first part of the paper (Sections II and III) we suppose that H_λ is defined as a relatively compact perturbation of H by an electric potential λW,

$$H_\lambda = H(\vec{a}, V) - \lambda W, \quad \lambda \in \mathbf{R},$$

where $\lambda \in \mathbf{R}$ is a coupling constant and $W \in L_\infty(\mathbf{R}^n)$ goes to zero at infinity.

As λ grows, some eigenvalue branches of the family H_λ may cross E, and it is a natural question to determine for which perturbations such crossings will occur. This question arises, for instance, in the quantum mechanical theory of impurities in insulators and semiconductors—see, e.g., the bibliography in Refs. 1, 2, 3.

In a second step, one would like to find the asymptotics of the corresponding *counting function*,

$$\widetilde{N}(E,H_\lambda) := \sum_{0<\mu<\lambda} \dim \ker(H_\mu - E), \quad \text{as} \quad \lambda \to +\infty.$$

Here the case of perturbations by non-negative or non-positive electric potentials is sufficiently well-understood[1,2,4,5–10] (see also the bibliography in Refs. 11, 12), since in this case the Birman–Schwinger principle provides a reduction to compact symmetric operators, and one can use standard variational techniques. Some of these methods can be successfully applied to divergence type operators.[13,14]

The case of W changing sign is more difficult since the corresponding Birman–Schwinger kernel is non-symmetric and does not easily yield useful spectral information. Still, an approach developed in Refs. 1, 4, 15 made it possible to investigate the existence of eigenvalue branches crossing E and to obtain *lower bounds* for the counting function for several types of decay; in Ref. 9, the ideas of Refs. 4, 15 were modified and all cases of polynomial decay were investigated. Note that *upper bounds* for the counting function are much more difficult due to possible oscillations of a single eigenvalue branch around a fixed level E (cf., however, the special results[16] for W of compact support).

So far, perturbations by a potential W with changing sign have been considered in the case of $\vec{a}=0$ only, and the first aim of our paper is to obtain similar results for perturbations of magnetic Schrödinger operators. We find that only minor changes in the scheme of Refs. 4, 15, 9 are needed, and we state and prove the corresponding results in Sections II and III. Since the magnetic case is quite similar to the non-magnetic one, we confine ourselves to the most typical cases.

(3) The second—and main—aim of the paper is to find out what the same ideas will accomplish in the case of perturbations by a magnetic potential $\vec{a}$ that decays at infinity (Section IV). Here we study magnetic Schrödinger operators of the form

$$H_\lambda = H(\lambda\vec{a},V) = (-i\nabla - \lambda\vec{a}(x))^2 + V.$$

Since a magnetic perturbation is never positive definite in the sense of quadratic forms, it is clear that the situation is difficult from the very beginning. A rather restricted class of perturbations (where the magnetic potential has compact support) was considered in Ref. 17. Here the perturbation was given by a constant field in a ball of radius R, with the support of the vector potential being contained in a ball of radius $R+1$, say. It was shown that, for R sufficiently large, cR^n eigenvalue branches cross E, as the coupling goes to ∞; here c is some positive constant. The intuition behind this result is based on the ''repulsive'' effect of a strong magnetic field, expressed in terms of a well-known quadratic form bound.[18] This bound suggests that a sufficiently strong (and not too localized) magnetic field should push eigenvalues up, so that at least some of them have to cross a given E. A further discussion of this intuition can be found in Ref. 19. In the present paper, we show that the technique of Refs. 4, 15, 9 leads to an asymptotic lower bound for the counting function $\widetilde{N}(E,H_\lambda)$, similar to the case of perturbations by an electric potential, under the—rather strong—assumption that the field and the vector potential decay rapidly, whereas one might conjecture that only some decay of the magnetic field is needed. We state the corresponding result in Theorem IV.1 and indicate which parts of the proof fail if we try to relax our assumption of rapid decay.

We still feel that the basic intuition may be correct and it is only the inadequacy of the methods used so far which prevents proving a more general result. Some support for this view comes from a closely related model problem which admits the separation of variables in polar coordinates. We present this example at the end of Section IV and show that in this case, under natural and rather general conditions, eigenvalue branches behave according to our intuition.

II. PERTURBATIONS OF MAGNETIC SCHRÖDINGER OPERATORS BY DECAYING ELECTRIC POTENTIALS: MAIN THEOREMS

We restrict our discussion to the most important and typical cases; more general results could be easily obtained by following the line of argument given for non-magnetic operators in Ref. 15 and for perturbations of magnetic operators by an electric potential (which does not change sign) in Ref. 7.

We assume that $\vec{a} \in C^1(\mathbf{R}^n, \mathbf{R}^n)$ has bounded derivatives, that $V \in L_\infty(\mathbf{R}^n)$, and that there exists a gap in the essential spectrum of H. For instance, the last condition is satisfied if either the magnetic tensor,

$$B = [b_{jk}]_{j,k=1}^n, \quad b_{jk} = \partial_j \vec{a}_k - \partial_k \vec{a}_j,$$

is constant and non-degenerate (this requires n to be even) and V is small, or $H(0,V)$ has a gap in the spectrum and the vector potential a is small (in the case of the constant B, it suffices to require that B be small).[20] There are also situations where a periodic magnetic field creates a structure of ''wells and barriers'' that lead to gaps in the essential spectrum;[19] this works for any dimension $\geqslant 2$.

If W decays slowly at infinity, we will have to assume in addition that $\rho(\cdot, H)$, the integrated density of states for H, exists:

$$\rho(\lambda, H) = \lim_{\text{vol } Q_R \to +\infty} \frac{1}{\text{vol } Q_R} N(\lambda, H(Q_R)), \tag{1}$$

where Q_R are expanding cubes, and $H(Q_R)$ is the operator of the Dirichlet problem for H in Q_R.

We suppose that $W \in L_\infty$ decays at infinity as $|x|^{-m}$ with some $m > 0$:

$$|W(x)| \leqslant C(1+|x|)^{-m}; \tag{2}$$

if $m \in (0,2]$, we assume that it stabilizes to a positively homogeneous continuous function $\widetilde{W}: \mathbf{R}^n \backslash 0 \to \mathbf{R}$ of order $-m$:

$$(W(tx) - \widetilde{W}(tx)) t^m \to 0, \text{ as } t \to +\infty, \tag{3}$$

uniformly in $x \in S_{n-1}$.

Set $N(\lambda, H-E, W) = \widetilde{N}(E, H - \lambda W)$ and $W_\pm(x) = \max\{\pm W(x), 0\}$.

Our first result deals with W decaying faster than quadratically; this is the easiest case.

II.1. Theorem: *Let (2) hold with $m > 2$. Then*

$$\liminf_{\lambda \to +\infty} N(\lambda, H-E, W) \lambda^{-n/2} \geqslant c(W_+), \tag{4}$$

where

$$c(W_+) = (2\pi)^{-n} |v_n| \int_{\mathbf{R}^n} W_+(x)^{n/2} dx, \tag{5}$$

and $|v_n|$ *is the volume of the unit ball of* $\mathbf{R}^n$.

We next discuss the borderline case where $m=2$ in (2), (3).

II.2. Theorem: *Let (2) and (3) hold with* $m=2$. *Then*

$$\liminf_{\lambda\to+\infty} N(\lambda,H-E,W)\lambda^{-n/2}(\ln\lambda)^{-1}\geqslant c_{\mathrm{int}}(\widetilde{W}_+), \tag{6}$$

where

$$c_{\mathrm{int}}(\widetilde{W}_+)=(2\pi)^{-n}\frac{1}{2}|v_n|\int_{S_{n-1}}\widetilde{W}_+(x)^{n/2}dS(x). \tag{7}$$

We finally have the case of slow decay where $m\in(0,2)$.

II.3. Theorem: *Let (2) and (3) hold with* $m\in(0,2)$, *and let a limit (1) exist for all* λ. *Then*

$$\liminf_{\lambda\to+\infty} N(\lambda,H-E,W)\lambda^{-n/m}\geqslant|c_{\mathrm{st}}^{+}(\widetilde{W}_+)-c_{\mathrm{st}}^{-}(\widetilde{W}_-)|, \tag{8}$$

where

$$c_{\mathrm{st}}^{+}(\widetilde{W}_+)=\int_{\mathbf{R}^n}dx\int_{E<t<E+\widetilde{W}_+(x)}d\rho(t,H), \tag{9}$$

$$c_{\mathrm{st}}^{-}(\widetilde{W}_-)=\int_{\mathbf{R}^n}dx\int_{E-\widetilde{W}_-(x)<t<E}d\rho(t,H). \tag{10}$$

Note that the integral in (9) converges if and only if $m\in(0,2)$.

In Ref. 10, formulas for the principal term of the asymptotics for W not changing sign are obtained. The results of Ref. 10 and formulas (4), (6), and (8), taken together, show that asymptotically,

$$N(\lambda,H-E,W)\geqslant|N(\lambda,H-E,W_+)-N(\lambda,H-E,-W_-)|.$$

III. PROOFS OF THEOREMS II.1–II.3

A. Some preliminary definitions and results

Let $\mathscr{A}$ be a quadratic form in $\mathscr{H}$, the Hilbert space, with the domain $D(\mathscr{A})$, and let $V\subset D(\mathscr{A})$ be a subspace. We assume that $\mathscr{A}$ is closable, and we set

$$\mathscr{N}(\lambda,\mathscr{A},V)=\sup\{\dim L\,|\,L\subset V,\mathscr{A}[u]<\lambda\|u\|^2_{\mathscr{H}},\forall u\in L\}.$$

For A an operator in $\mathscr{H}$ and $\mathscr{A}[u]=\langle Au,u\rangle_{\mathscr{H}}$, $D(\mathscr{A})=D(A)$, write $\mathscr{N}(\lambda,A,V)$ instead of $\mathscr{N}(\lambda,\mathscr{A},V)$.

We also set $N((a,b);A)=\dim P_{(a,b)}(A)$, where $P_{(a,b)}(A)$ is a spectral projection of A, and we set $N(\lambda;A)=N((-\infty,\lambda),A)$.

Let $\vec{a}\in C^1(\mathbf{R}^n,\mathbf{R}^n)$ with bounded derivatives, and let $U\subset\mathbf{R}^n$ be an open domain. Set

$$H^1_{\vec{a}}(\mathbf{R}^n)=\left\{u\in L_2(\mathbf{R}^n)\,|\,\|u\|_{\vec{a},1}=\left(\sum_{|\alpha|\leqslant 1}\|(D+\vec{a}(x))^{\alpha}u\|^2_{L_2}\right)^{1/2}<\infty\right\}. \tag{11}$$

This is a Hilbert space, and $C_0^{\infty}(\mathbf{R}^n)$ is a dense subspace.

Denote by $\mathring{H}^1_{\vec{a}}(U)$ the closure of $C_0^\infty(U)$ in $H^1_{\vec{a}}(\mathbf{R}^n)$. As usual, we will not distinguish in the notation between a function in $\mathring{H}^1_{\vec{a}}(U)$ and its trivial extension by 0 to all of $\mathbf{R}^n$.

It is a standard fact that $H(\vec{a},V):C_0^\infty(\mathbf{R}^n)\to L_2(\mathbf{R}^n)$ is essentially self-adjoint under the above assumptions; the closure is denoted by $H(\vec{a},V)$, too.

The proof of the following lemma is a variant of standard arguments in the theory of elliptic operators—only the part of the operator ∇ is now being played by its magnetic analogue $\nabla+i\vec{a}(x)$, and usual Sobolev spaces are being replaced by magnetic ones.

Let U be a bounded domain with the sufficiently smooth boundary, and let $H(U)$ be the operator of the Dirichlet problem for H in U.

III.1. Lemma: Let Π *be a bounded operator in* $L_2(U)$ *such that* $H(U)+\Pi$ *is invertible. Then there exists a constant* C [*depending only on the norms of the operators* Π *and* $(H(U)+\Pi)^{-1}$], *such that*

$$\|u\|_{\vec{a},1}\leqslant C\|(H(U)+\Pi)u\|_{L_2},\quad \forall u\in D(H(U)). \tag{12}$$

B. Some bounds for counting functions

Denote by B_l an open ball of radius l, centered at the origin, and let $\Omega(R,R_1)$ stand for any of the sets $Q_R, B_R, \overline{Q_R}, \overline{B_R}, \overline{B_R}\setminus B_{R_1}, Q_R\setminus\overline{Q_{R_1}}$, and $\Omega_0(R,R_1)$ for any of the sets $B_R, Q_R, B_R\setminus\overline{B_{R_1}}, Q_R\setminus\overline{Q_{R_1}}$.

The following lemma (even in a more general form) is well-known—see, e.g., Ref. 21.

III.2. Lemma: Let $s>0$ *be an integer.*

Then there exists $C=C_{s,n}$ *such that for any* $\lambda>0$ *and any* $R/2>R_1>1$,

$$\mathcal{N}(\lambda;(-\Delta)^s;C_0^\infty(\Omega_0(R,R_1)))\leqslant C\lambda^{n/2s}\ \text{meas}\ \Omega_0(R,R_1), \tag{13}$$

$$\mathcal{N}(\lambda;\|\cdot\|^2_{H^s};C_0^\infty(\Omega(R,R_1)))\leqslant C(1+\lambda^{n/2s})\text{meas}\ \Omega(R,R_1). \tag{14}$$

III.3. Lemma: Let a *and* V *be as above, so that, in particular,* V *and* ∇a *are bounded. Then there exists* C *such that for any* $\lambda>0$, *any* $R/2>R_1>1$, *and any* $x_0\in\mathbf{R}^n$,

$$\mathcal{N}(\lambda;H(\vec{a},V);C_0^\infty(x_0+\Omega_0(R,R_1)))\leqslant C(1+\lambda^{n/2})\text{meas}\ \Omega_0(R,R_1), \tag{15}$$

$$\mathcal{N}(\lambda;\|H(\vec{a},V)\cdot\|^2;C_0^\infty(\Omega(R,R_1)))\leqslant C(1+\lambda^{n/4})\text{meas}\ \Omega(R,R_1). \tag{16}$$

Proof: It is easy to see that there exist $C_j=C_j(N,V,R)$, $j=1,2$, such that

$$\langle(-\Delta)u,u\rangle_{L_2}\leqslant C_1\langle H(\vec{a},V)u,u\rangle_{L_2}+C_2\|u\|^2_{L_2},\quad \forall u\in\mathbf{C}_0^\infty(\Omega_0(R,R_1)),$$

and

$$\|u\|^2_{0,2}\leqslant C_1\|H(\vec{a},V)^2u\|_{L_2}+C_2\|u\|^2_{L_2},\quad \forall u\in\mathbf{C}_0^\infty(\Omega(R,R_1)).$$

By applying the usual variational techniques,[9,22] we see that (15) and (16) follow from (13) and (14), respectively, with the constant depending on x_0,R,R_1, though.

To reduce the proof in the general case to that of a fixed R and $x_0=0$, construct a partition of unity,

$$\sum_{k\in\mathbf{Z}^n}\chi^2_{r,k}=1,\ \text{supp}\ \chi_{r,k}\subset r\cdot k+(-r^{1/2}/4,r+r^{1/2}/4)^n, \tag{17}$$

$$|D^{\alpha}\chi_{r,k}| \leqslant C_{\alpha} r^{-|\alpha|/2}, \quad \forall \alpha, \tag{18}$$

with C_{α} independent of $r \geqslant 1/4$. It follows from (18) that

$$|\langle [H(\vec{a},V),\chi_{r,k}]\chi_{r,k}u,u\rangle| \leqslant C_1 r^{-1/2}(\langle H(\vec{a},V)u,u\rangle + C_2\|u\|^2_{L_2}), \tag{19}$$

with C_1, C_2 independent of r. Due to (17) and the locality of $H(A,V)$, (19) holds for $|\langle \Sigma_k [H(A,V),\chi_{r,k}]\chi_{r,k}u,u\rangle|$ as well, and we conclude that there exist C_1, C_2 such that uniformly in $r \geqslant 1$,

$$\langle H(\vec{a},V)u,u\rangle \geqslant (1 - C_1 r^{-1/2}) \sum_k \langle H(\vec{a},V)\chi_{r,k}u, \chi_{r,k}u\rangle - C_2 r^{-1/2}\|u\|^2_{L_2}. \tag{20}$$

Now, (20) and usual variational arguments give for $r = 2C_2^2$ the estimate

$$\mathcal{N}(\lambda; H(\vec{a},V); \mathbf{C}_0^{\infty}(x_0 + \Omega_0(R,R_1))) \leqslant \sum_{k \in I(R,R_1,r)} \mathcal{N}(C_3(1+\lambda); H(\vec{a},V); \mathbf{C}_0^{\infty}(U^+_{r,k})) \tag{21}$$

where $U^+_{r,k} = r\cdot k + (-r^{1/2}/4, r + r^{1/2}/4)^n$, and

$$I(R,R_1,r) = \{k \mid U^+_{r,k} \cap (x_0 + \Omega_0(R,R_1)) \neq \emptyset\};$$

C_3 is independent of k, of course.

$H(\vec{a},V)$ is unitarily equivalent to $H(\vec{a} - \vec{a}(rk), V_k)$, where $V_k(\cdot) = V(rk + \cdot)$, therefore

$$\mathcal{N}(C_3(1+\lambda); H(\vec{a},V); \mathbf{C}_0^{\infty}(U^+_{r,k})) = \mathcal{N}(C_3(1+\lambda); H(\vec{a} - \vec{a}(rk), V_k); \mathbf{C}_0^{\infty}(U^+_{r,0})),$$

and since V_k and $(\vec{a} - \vec{a}(rk))|_{U^+_{r,k}}$ are uniformly bounded with respect to k, we deduce from (13) an estimate,

$$\mathcal{N}(C_3(1+\lambda); H(\vec{a},V); \mathbf{C}_0^{\infty}(U^+_{r,k})) \leqslant C_4(1+\lambda^{n/2}) \text{meas } U^+_{r,k}, \tag{22}$$

with C_4 independent of k. By substituting (22) into (21), we obtain (13).

(14) is proved similarly, (12) being used. This concludes the proof of the Lemma. ■

C. A variational principle for a lower bound for $N_+(\lambda; H-E; W)$

Let E be in a gap of H and fix $a < a' < E < b' < b$ such that the interval $[a,b]$ lies in the gap. Basic for the approach developed in Ref. 1 are exponential decay estimates for the resolvent operator $(H-E)^{-1}$ of the type

$$\|\chi_R (H-E)^{-1}(1-\chi_n)\| \leqslant C e^{-\alpha(n-R)}, \quad a < E < b, \tag{23}$$

where $H = -\Delta + V$ and χ_R is the characteristic function of the ball of radius R, centered at the origin, for $n \geqslant 2R \geqslant 1$, with suitable constants C and $\alpha > 0$. We now have to work with the magnetic Sobolev spaces H^1_a and $\mathring{H}^1_a$ instead of H^1 and $\mathring{H}^1$, respectively, but it is easy to see that the ''boosting argument'' used in Ref. 1 in the proof of (23) for Schrödinger operators $-\Delta + V$ can be adapted to the magnetic case. In particular, if $U \subset \mathbf{R}^n$ is open, and $H(U)$ denotes the operator $H = H(\vec{a},V)$ acting in $L_2(U)$ with (homogeneous) Dirichlet boundary conditions, the above estimate and Lemma 2.1 show that eigenfunctions of $H(B_n)$ that are associated with

eigenvalues $\mu \in [a',b']$ are localized in a boundary region $\{n/2<|x|<n\}$, up to exponentially small errors. We may thus obtain the ''magnetic analogues'' of two basic results from Refs. 4, 15 which are formulated below.

Fix functions $\psi_l \geqslant 0$ with the properties

$$\operatorname{supp} \psi_l \subset \mathbf{R}^n \setminus B_{l/4}, \quad \psi_l|_{\mathbf{R}^n \setminus B_{l/2}} = 1,$$

$$|D^\alpha \psi_l| \leqslant C_\alpha l^{-|\alpha|}, \quad \forall \alpha,$$

uniformly in $l \geqslant 1$, and put

$$\Pi_l = P_{(a,b)}(H(B_l)), \quad c = b-a, \quad \widetilde{H}_l = H(B_l) + c\psi_l \Pi_l \psi_l .$$

III.4. Lemma: There exists $l_0>0$ such that $[a',b'] \cap \sigma(\widetilde{H}_l) = \emptyset$, for all $l>l_0$.

III.5. Theorem: *For $0<\lambda<\lambda'$, we have*

$$N(\lambda', H-E, W) \geqslant \limsup_{l \to +\infty} |N(E, \widetilde{H}_l) - N(E, \widetilde{H}_l - \lambda W)|.$$

D. Proof of Theorem II.1

Fix $s \in (1/m, 1/2)$, set $R = \lambda^s$, and construct functions $\chi_R^{\pm}$ with the following properties:

$$0 \leqslant \chi_R^{\pm} \leqslant 1, \quad (\chi_R^+)^2 + (\chi_R^-)^2 = 1, \tag{24}$$

$$\operatorname{supp} \chi_R^+ \subset \mathbf{R}^n \setminus B_{R-R^{1/2}}, \quad \operatorname{supp} \chi_R^- \subset B_R, \tag{25}$$

$$|D^\alpha \chi_R^{\pm}| \leqslant C_\alpha R^{-|\alpha|/2}, \quad \forall \alpha. \tag{26}$$

We may apply Theorem III.5 with $l \geqslant R$, and we shall obtain bounds for $N(E;\widetilde{H}_l)$ and for $N(E,\widetilde{H}_l - \lambda W)$ by using the cut-off functions $\chi_R^{\pm}$.

Due to (24) and (26) we have

$$\langle \widetilde{H}_l u, u \rangle = \sum_{j=\pm} \langle \widetilde{H}_l \chi_R^j u, \chi_R^j u \rangle + T_R(u),$$

with $T_R(u)$ admitting an estimate $|T_R(u)| \leqslant CR^{-1/2} \langle \widetilde{H}_l u, u \rangle$. Here and below we may and shall assume that $H \geqslant 1$ (hence $\widetilde{H}_l \geqslant 1$). If this is not the case we replace V and E by $V + C_0$ and $E + C_0$, respectively, where C_0 is large enough. Therefore, for some $C_1, C_2 > 0$,

$$\langle (\widetilde{H}_l - E)u, u \rangle \geqslant (1 - C_1 R^{-1/2}) \sum_{j=\pm} \langle (\widetilde{H}_l - E - C_2 R^{-1/2}) \chi_R^j u, \chi_R^j u \rangle,$$

and due to (24) and (25),

$$N(E, \widetilde{H}_l) \leqslant (1 - C_1 R^{-1/2})^{-1} N(E + C_2 R^{-1/2}, \widetilde{H}_{l,R}) + N(E + C_2 R^{-1/2}; H(B_R)), \tag{27}$$

where $\widetilde{H}_{l,R} = H(B_l \setminus \overline{B_{R_1}}) + c\psi_l \Pi_l \psi_l$ is an operator in $L_2(B_l \setminus \overline{B_{R_1}})$, and $R_1 = R - R^{1/2}$.

Similarly,

$$N(E, \widetilde{H}_l - \lambda W) \leqslant N(E, (1 - C_2 R^{-1/2}) \widetilde{H}_{l,R} - \lambda W) + N(E, (1 - C_2 R^{-1/2}) H(B_R) - \lambda W). \tag{28}$$

Estimates from below are evident:

$$N(E,\widetilde{H}_l)\geqslant N(E,\widetilde{H}_{l,R})+N(E,H(B_{R_1})), \tag{29}$$

$$N(E,\widetilde{H}_l-\lambda W)\geqslant N(E,\widetilde{H}_{l,R}-\lambda W)+N(E,H(B_{R_1})-\lambda W). \tag{30}$$

Due to our choice of R and (2) we have $|\lambda W|=o(1)$ outside B_{R_1} therefore there exists (a function) $\epsilon=\epsilon(R)\to 0$ as $R\to+\infty$ such that

$$N(E,(1-C_2R^{-1/2})\widetilde{H}_{l,R}-\lambda W)\leqslant N(E+\epsilon,\widetilde{H}_{l,R}),$$

$$N(E,\widetilde{H}_{l,R}-\lambda W)\geqslant N(E-\epsilon,\widetilde{H}_{l,R}),$$

and one easily deduces from (27)–(30) an estimate,

$$|N(E,\widetilde{H}_l)-N(E,\widetilde{H}_l-\lambda W)|\geqslant\max\{\mathscr{D}_+(\lambda,R),\mathscr{D}_-(\lambda,R)\}-\mathscr{D}_0(l,R), \tag{31}$$

where

$$\mathscr{D}_0(l,R)=N(E+\epsilon,\widetilde{H}_{l,R})-N(E-\epsilon,\widetilde{H}_{l,R}),$$

$$\mathscr{D}_\pm(\lambda,R)=\mp N(E\pm\epsilon_1,H(B_{R\pm R^{1/2}}))\pm N(E,(1\pm\epsilon_1)H(B_{R\mp R^{1/2}})-\lambda W),$$

and $\epsilon,\epsilon_1\to 0$ as $R\to+\infty$.

Construct $\phi_C^\pm$ such that $0\leqslant\phi_C^\pm\leqslant 1$,

$$(\phi_C^+)^2+(\phi_C^-)^2=1,\quad |D^\alpha\phi_C^\pm|\leqslant C_\alpha C^{-|\alpha|},\quad \forall\alpha,$$

$$\text{supp }\phi_C^-\subset B_{R-R^{1/2}+2C},\quad \phi_C^-=1\ \text{ on }\ B_{R-R^{1/2}+C},$$

with C_α independent of $C\geqslant 1$. For $u\in D(\widetilde{H}_{l,R})$, we may identify ϕ_C^+u with a function from $D(\widetilde{H}_l)$. Using this observation and the density of $\mathbf{C}_0^\infty(\overline{B_l\backslash B_{R_1}})\cap D(\widetilde{H}_{l,R})$ in $D(\widetilde{H}_{l,R})$, we obtain similarly to (27),

$$\mathscr{D}_0(l,R)\leqslant N(2\epsilon^2,(\widetilde{H}_{l,R}-E)^2)\leqslant\mathscr{N}(2\epsilon^2+\nu,\|(\widetilde{H}_l-E)\cdot\|^2,D(\widetilde{H}_l))+\mathscr{N}(2\epsilon^2+\nu,\|(H-E)\cdot\|^2,\mathbf{C}_0^\infty(B_{R_1+2C}\backslash B_{R_1})), \tag{32}$$

where $\nu\to 0$ as $C\to+\infty$. If $2\epsilon^2+\nu$ is small enough, the first term in the RHS of (32) is zero because E is in a gap of $\widetilde{H}_l$, due to Lemma III.4. Thus, it suffices to estimate the second term, and one can easily deduce from Lemma III.3 an upper bound via $C_2(C)R^{n-1}=o(R^n)$.

Thus, we may rewrite (31) as

$$|N(E,\widetilde{H}_l)-N(E,\widetilde{H}_l-\lambda W)|\geqslant\max\{\mathscr{D}_+(\lambda,R),\mathscr{D}_-(\lambda,R)\}+o(R^n). \tag{33}$$

One can compute the asymptotics of $N(E\pm\epsilon_1,H(B_{R\pm R^{1/2}}))$ and that of $N(E,(1\mp\epsilon_1)H(B_{R\pm R^{1/2}})-\lambda W)$ using the IMS-localization formula.[23] On the region where $|\lambda W|$ is not too large, we use the crude estimates provided by Lemma III.3 (and the corresponding terms can be included in the o-term of the asymptotics); the region where $|\lambda W|$ is large can be partitioned into subregions such that on each subregion, $|a-a(x^j)|$ is small with respect to $|\lambda W|^{1/2}$ (here x^j is a point from the subregion). By making an appropriate gauge transformation, we may deal with a (relatively) small magnetic potential. This means that the proof of Lemma III.3 and the

classical Weyl formula for the Laplacian now give the principal term of the asymptotics (the same as in the Weyl formula) where $\lambda W \gg 1$; where $-\lambda W \gg 1$, we see that the corresponding ''local counting function'' is zero. In the result, we obtain

$$N(E \pm \epsilon_1, H(B_{R \pm R^{1/2}})) = O(R^n), \tag{34}$$

$$N(E, (1 \mp \epsilon_1) H(B_{R \pm R^{1/2}}) - \lambda W) = c(W_+) \lambda^{n/2} + o(\lambda^{n/2}), \tag{35}$$

where $c(W_+)$ is given by (5).

Clearly, (33)–(35) yield (4). ■

E. Proof of Theorem II.2

Set $R = C_0 \lambda^{1/2}$ and argue as in the previous subsection. We obtain (31) with $\epsilon \to 0$ as $C_0 \to +\infty$. Hence, if we fix $C_0 > 0$ sufficiently large, the first term in the RHS in (32) will be zero and we will obtain (33). Once again we have (34) but due to the condition $m = 2$ (35) takes the form

$$N(E, (1 \mp \epsilon_1) H(B_{R \pm R^{1/2}}) - \lambda W) = c_{\text{int}}(\widetilde{W}_+) \lambda^{n/2} \ln \lambda + o(\lambda^{n/2} \ln \lambda), \tag{36}$$

with $c_{\text{int}}(\widetilde{W}_+)$ given by (7).

(33), (34), and (36) give (6).

For the sake of completeness, we recall why (35) and (36) are different. In both cases it can be shown that the principal term of the asymptotics is given by

$$(2\pi)^{-n} \operatorname{meas}\{(x,\xi) \mid |x| \leqslant R, |\xi|^2 - \lambda W_+(x) < 0\} = \lambda^{n/2} (2\pi)^{-n} |v_n| \int_{|x| \leqslant R} W_+^{n/2}(x) dx,$$

hence, if $m > 2$ and therefore $\int_{\mathbf{R}^n} W_+(x)^{n/2} dx$ converges, then the principal term of the asymptotics is equal to $c_+(W) \lambda^{n/2}$. If $m = 2$ then

$$\begin{aligned} \int_{|x| \leqslant R} W_+(x)^{n/2} dx &= \int_{\ln \ln \lambda \leqslant |x| \leqslant R} \widetilde{W}_+(x)^{n/2} dx (1 + o(1)) + o(\ln \lambda) \\ &= \int_{\ln \ln \lambda \leqslant |x| \leqslant C_0 \lambda^{1/2}} dr r^{-1} \int_{S_{n-1}} \widetilde{W}_+(x)^{n/2} dS(x) (1 + o(1)) + o(\ln \lambda) \\ &= \frac{1}{2} \ln \lambda \int_{S_{n-1}} \widetilde{W}_+(x)^{n/2} dS(x) (1 + o(1)), \end{aligned}$$

so that the principal term is equal to $c_{\text{int}}(\widetilde{W}_+) \lambda^{n/2} \ln \lambda$. ■

F. Proof of Theorem II.3

One modifies the proof of Theorem 1.3 in Ref. 9 in the same manner as the proofs of Theorems II.1 and II.2, above are modifications of the similar theorems for the non-magnetic case in Ref. 9. ■

IV. PERTURBATIONS BY DECAYING MAGNETIC POTENTIALS

A. Rapidly decreasing magnetic potentials

In this section, we start again from the assumption that $V \in L_\infty(\mathbf{R}^n)$ and that $H = H(0,V)$ has a gap in its (essential) spectrum. We fix E in a gap, and consider $H_\lambda := H(\lambda \vec{a}, V)$ with a magnetic

potential $a \in C^1(\mathbf{R}^n, \mathbf{R}^n)$ rapidly decaying at infinity. As before, our basic strategy is to consider an approximating problem on large balls, B_l, and to compare the number of eigenvalues below E for the perturbed problem with the corresponding number for the unperturbed problem. We expect that there should be three regions which have to be treated in a different fashion.

(1) There is a region B_R where the field produced by $\lambda \vec{a}$ eliminates all (or at least almost all) eigenvalues below E, by the Avron–Herbst–Simon bound for the quadratic forms.

(2) There is a ''transition region'' $B_{R' \setminus R}$ where the field drops in strength and is too weak to move the lowest point of the spectrum above E. Under the assumption of exponential decay, however, this transition region will be small, and we can employ a trace estimate for the magnetic Schrödinger semi-groups.

(3) Finally, in the region between the radii R' and l, the perturbation $\lambda \vec{a}$ will be so small that it can be neglected.

As it turns out, all this works if we link an exponential upper bound for a with a suitable lower bound for the strength of the field B. The rates of decay of the vector potential and the field are governed by a monotonic function $q:[0,\infty) \to \mathbf{R}_+$ such that

$$q(r) \to +\infty, \quad \text{as} \quad r \to +\infty, \tag{37}$$

and ϕ, the inverse of q, enjoys the property

$$\lim_{\varepsilon \to +0} \lim_{\lambda \to +\infty} \phi(\lambda^{1 \pm \varepsilon})/\phi(\lambda) = 1. \tag{38}$$

We assume that for any $\varepsilon > 0$ there exist positive constants $c_\varepsilon, C_\varepsilon$ such that

$$c_\varepsilon q(|x|)^{-1-\varepsilon} \leqslant b_{ij}(x), \quad \forall |x| \geqslant C_\varepsilon, \tag{39}$$

for at least one fixed pair of indices $i,j \in \{1,\ldots,n\}$, and

$$\|\vec{a}(x)\| \leqslant C_\varepsilon q(|x|)^{-1+\varepsilon}. \tag{40}$$

It is essential for our result to make sense that we require the lower bound of Eq. (39) for $|x| > C_\epsilon$ only (instead of for all $x \in \mathbf{R}^n$). In a two-dimensional situation, any (non-trivial) exponentially decreasing vector potential gives rise to a field with total magnetic flux zero and we see that the field has to change sign somewhere.

IV.1 Theorem: *Let (36)–(39) hold, and suppose that* $\rho(E, H(0,V))$, *the integrated density of states for* $H(0,V)$, *exists. Then, as* $\lambda \to +\infty$,

$$\liminf_{\lambda \to +\infty} \phi(\lambda)^{-n} \widetilde{N}(E, H(\lambda \vec{a}, V)) \geqslant |v_n| \rho(E, H(0,V)). \tag{41}$$

Example: Let $n=2$ and $\vec{a}(x,y) = (yq(r)^{-1}, -xq(r)^{-1})$, where (for large r) $q(r) = \exp(r^s)$, $s > 0$, and $r = \sqrt{x^2+y^2}$.

Then (37)–(40) hold with the indicated q and $\phi(\lambda) = (\ln \lambda)^{1/s}$.

In the case of magnetic perturbations, upper bounds for $\widetilde{N}(E, H_\lambda)$ are not just much harder to obtain, but in many cases actually impossible. In fact, there are situations with $B = d\vec{a}$ of compact support in $\mathbf{R}^2$ and non-zero flux $F = \int B$ which produce oscillating eigenvalue branches in the gap by a mechanism related to the Bohm–Aharonov effect.[24–26]

The setup for the proof of Theorem IV.1 is similar to the one for Theorem II.1. For $l \geqslant 1$, we define a function ψ_l and an operator Π_l as in Section III, and we introduce operators $\widetilde{H}_{\lambda,l} = H_\lambda(B_l) + c\psi_l \Pi_l \psi_l$, where the constant $c > 0$ is the same as in Section III.

Our proof of Theorem IV.1 is based on the following variant of Theorem III.5 which can be proved by the same arguments as in Refs. 4, 15 since the magnetic potential decays at infinity.

IV.2. Theorem: *For* $0<\lambda<\lambda'$, *we have*

$$\widetilde{N}(E,H_{\lambda'})\geqslant \limsup_{l\to+\infty}|N(E,\widetilde{H}_{l,0})-N(E,\widetilde{H}_{l,\lambda})|. \tag{42}$$

Proof of Theorem IV.1:

To estimate the functions in the RHS of (42), we fix $\varepsilon>0$ and set $R=R(\lambda,\varepsilon)=\phi(\lambda^{1+\varepsilon})$. Outside a ball $B_{\lambda^{1+\varepsilon}}$, λa is small due to (40); therefore the same arguments as in Section III allow us to deduce an estimate:

$$|N(E,\widetilde{H}_{l,\lambda})-N(E,\widetilde{H}_{l,0})|\geqslant -C\phi(\lambda^{1+\varepsilon})^{n-1/2}+N(E-\nu,H(B_R))-N(E+\nu,H_\lambda(B_R)), \tag{43}$$

where $\nu\to 0+$ as $\lambda\to+\infty$. The asymptotics of $N(E-\nu,H(B_R))$ is evident:

$$N(E-\nu,H(B_R))\sim|v_n|\rho(E,H(0,V))R^n, \quad \text{as } \lambda\to+\infty. \tag{44}$$

Suppose we have proved that

$$\lim_{\varepsilon\to+0}\ \lim_{\lambda\to+\infty}\ \phi(\lambda^{1+\varepsilon})^{-n}N(E+\nu,H_\lambda(B_R))=0. \tag{45}$$

Then we gather (42)–(45), take (38) into account, and obtain (41).

To prove (45), we use a partition of unity and the IMS-localization formula as we did in Section III, with the supports $\overline{U_j}$ of the functions involved being of diameter less than $M_1>>1$. Without loss of generality we may also assume that ∂U_j has measure 0, for all j. Fix $M>1$ and set [using the pair of indices i,j from condition (39)]

$$I_+=\{j|\lambda b_{ij}(x)\geqslant M,\ \forall x\in\overline{U_j}\},\quad I_-=\{j\notin I_+|\overline{U_j}\cap B_R\neq\emptyset\}.$$

It follows from (39) that

$$\sum_{j\in I_-}\ \text{meas } U_j\leqslant C(\text{vol } B_R-\text{vol } B_{\phi(\lambda^{1-\varepsilon})}), \tag{46}$$

where the constant is independent of M_1 and $\varepsilon>0$.

Set $U_j=\text{int }\overline{U_j}$. We have

$$N(E,H_\lambda(B_R))\leqslant\sum_{j\in I_+}N(E+\nu,H_\lambda(U_j))+\sum_{j\in I_-}N(E+\nu,H_\lambda(U_j)), \tag{47}$$

where $\nu\to 0$ as $M_1\to+\infty$. If $j\in I_+$ and M is large enough, the first eigenvalue of $H_\lambda(U_j)$ is greater than $E+\nu$—see Ref. 18. Hence the first group of summands is equal to zero and may be dropped.

By Lemma IV.3, given below, there exists a constant C such that all the terms in the second sum admit a uniform bound,

$$N(2E,H_\lambda(U_j))\leqslant C\ \text{vol } U_j. \tag{48}$$

Then, by gathering (46)–(48) and using (38), we obtain (45); this concludes the proof of Theorem IV.1. ■

The following lemma uses a trace class estimate of Simon[27] to establish the estimate claimed in Eq. (48). Note that the assumptions on $\vec{a}$ and V are far more general than our standard conditions.

IV.3. Lemma: Let $\Omega \subset \mathbf{R}^n$ be a bounded, open set such that $\partial\Omega$ has measure zero. Let $\vec{a} \in C^1(\mathbf{R}^n, \mathbf{R}^n)$, $0 \leqslant V \in L_{1,\mathrm{loc}}(\mathbf{R}^n)$ and let $H^\Omega(\vec{a},V) = (-i\nabla - \vec{a}(x))^2 + V(x)$ and $H^\Omega = H^\Omega(0,0)$ denote Schrödinger operators in $L_2(\Omega)$ with Dirichlet boundary condition on $\partial\Omega$.

Then for any $\eta \in \mathbf{R}$ there exists a constant C which is independent of Ω such that

$$N(\eta, H^\Omega(a,V)) \leqslant C \text{ meas } \Omega.$$

Proof: For all $t>0$ the semigroups obey the trace estimate,[27]

$$\mathrm{Tr}\, \exp(-tH^\Omega(a,V)) \leqslant \mathrm{Tr}\, \exp(-tH^\Omega(0,0)).$$

We take $t=1$, and denote the eigenvalues of $H^\Omega(a,V)$ by $\mu_1(a,V) \leqslant \mu_2(a,V) \leqslant \dots$.

We then have

$$\begin{aligned} N(\eta, H^\Omega(a,V)) &= \sum_{\mu_s(a,V)<\eta} 1 \leqslant \sum_{s \geqslant 1} \exp(\eta - \mu_s(a,V)) \\ &= \exp(\eta)\, \mathrm{Tr}\, \exp(-H^\Omega(a,V)) \\ &\leqslant \exp(\eta)\, \mathrm{Tr}\, \exp(-H^\Omega(0,0)). \end{aligned}$$

It is easy to modify the estimate of Ref. 27, eq. (9.4), to yield

$$\mathrm{Tr}\, e^{-H^\Omega(0,0)} \leqslant C_n \text{ meas } \Omega,$$

and the desired result follows. ■

Remark: A careful inspection of the proof of Theorem IV.1 shows that it is enough to produce an estimate,

$$N(2E; H(U_j)) \leqslant C,$$

with a constant C depending only on a bound for the *diameter* of the sets U_j. The corresponding variant of Lemma IV.3 is then slightly simpler to prove since $\mathrm{Tr}\, e^{\Delta_Q}$ can be easily estimated for a cube Q.

Remark: Finally, we wish to comment on why our method seems to require the strong assumptions made in Theorem IV.1.

The main problem stems from the incompatibility of gauge transformations with the very construction of our approximating problems involving the operators $\widetilde{H}_{R,l}$ acting in the region where the field is small. If we wish to go beyond the assumptions made in Theorem IV.1, we can no longer assume that the vector potential $\lambda\vec{a}$ is small in the entire region $B_l \setminus B_{R'}$. It would seem natural to split this region into ''cones'' by suitable cut-off functions. Due to the non-local part $\psi_l \Pi_l \psi_l$ in the operator $\widetilde{H}_{R,l}$ even this splitting is problematic. Moreover, as λ increases, any attempt at changing to a different gauge on such a cone will lead to uncontrollable fluctuations in the $\psi_l \Pi_l \psi_l$-terms.

B. A separable example

For Schrödinger operators of the type $H_\lambda = -\Delta + V - \lambda W$, $\lambda > 0$, where V is a (non-constant) periodic potential, and W a potential which decays at infinity, separation of variables seems to be impossible. There is, however, a related separable model involving purely magnetic Schrödinger operators: this model consists of a Schrödinger operator H_0 in $\mathbf{R}^2$ with a constant magnetic field, perturbed by a decreasing, radially symmetric magnetic field. As is well known, the spectrum of

H_0 is given by a discrete set of points (the *Landau levels*), each Landau level being an eigenvalue of infinite multiplicity. We may consider this as a case of a band-gap structure, where the bands are degenerated into points.

Let us now fix the notation. To define the operators H_0 and H_λ, we use the radial gauge and let for $(x,y)\in\mathbf{R}^2$,

$$\vec{a}_0(x,y):=(y,-x),\quad \vec{a}_1(x,y):=(yf(r),-xf(r)),$$

and

$$\vec{A}_\lambda(x,y):=\vec{a}_0(x,y)+\lambda\vec{a}_1(x,y),$$

where $r=\sqrt{x^2+y^2}$, and $f\in C^1([0,\infty))$ satisfies

$$rf(r)\to 0,\quad r\to\infty. \tag{49}$$

We define the Schrödinger operators,

$$H_0:=(-i\nabla-\vec{a}_0(x,y))^2,\quad H_\lambda:=(-i\nabla-\vec{A}_\lambda(x,y))^2,$$

for $\lambda\in\mathbf{R}$; the operators H_λ are essentially self-adjoint on $\mathbf{C}_0^\infty(\mathbf{R}^2)$. Following to some extent the calculations of Miller and Simon,[23,28] we wish to find out whether eigenvalues of H_λ move through the gaps of H_0, as λ increases from 0 to ∞.

We begin with a few remarks.

(1) The magnetic field associated with the perturbation $\vec{a}_1$ is easily computed to be

$$B_1(r)=2f(r)+rf'(r),$$

and the total magnetic flux through the circle $B(0,R)$, associated with $\vec{a}_1$, is $2\pi R^2 f(R)$. In particular, the flux through the plane $\mathbf{R}^2$ will be zero if $r^2f(r)\to 0$, as $r\to\infty$.

(2) Obviously, (49) implies $\vec{a}_1(x,y)\to 0$, as $r\to\infty$; it is well-known that under this condition the resolvent difference $(H_\lambda+i)^{-1}-(H_0+i)^{-1}$ is compact and thus

$$\sigma_{\mathrm{ess}}(H_\lambda)=\sigma_{\mathrm{ess}}(H_0),\quad \lambda\in\mathbf{R}. \tag{50}$$

Since $\sigma_{\mathrm{ess}}(H_0)$ consists of isolated points, it is also clear that the continuous spectrum of H_λ is empty. [As proved in Ref. 29, (50) also holds if the magnetic field decays at infinity.]

We will now try to determine whether eigenvalues of H_λ move through the gaps of H_0, as $\lambda\to\infty$. As in Ref. 23, we start from the observation that the angular momentum operator L_z commutes with H_λ, for all $\lambda\in\mathbf{R}$. The spectrum of L_z is given by $\mathbf{Z}$, and the m-th eigenspace is spanned by the funtions $u(r)e^{im\vartheta}$, with $u\in L_2(0,\infty;rdr)$. Let $\mathscr{L}_m$ denote this eigenspace. We observe that the functions $e^{im\vartheta}$ coincide with the eigenfunctions of the Laplace–Beltrami-operator $-d^2/d\vartheta^2$ on the unit circle: in fact, the eigenvalues of the Laplace–Beltrami operator are given by the numbers m^2, with $m=0,1,2,\ldots$, and the m-th eigenspace is spanned by the functions $e^{\pm im\vartheta}$.

Passing to polar coordinates, we find that $H_{\lambda,m}$, defined as the part of H_λ in $\mathscr{L}_m$, acts as

$$H_{\lambda,m}(u(r)e^{im\vartheta})=\left(-u''(r)-\frac{1}{r}u'(r)+V_{\lambda,m}(r)u(r)\right)e^{im\vartheta},$$

where $V_{\lambda,m}(r):=m^2/r^2+r^2(1+\lambda f(r))^2+2m(1+\lambda f(r))$, for $u(r)e^{im\vartheta}$ in the domain of H_λ. Hence the eigenvalues of $H_{\lambda,m}$ are the same as the eigenvalues of the operator,

$$h_{\lambda,m}u := -u'' - \frac{1}{r}u' + V_{\lambda,m}(r)u,$$

in $L_2(0,\infty;rdr)$, for all $m \in \mathbf{Z}$. By the unitary equivalence $H_\lambda \cong \oplus_{m\in\mathbf{Z}} H_{\lambda,m}$, the spectrum of H_λ coincides with the closure of $\cup_{m\in\mathbf{Z}}\sigma(h_{\lambda,m})$.

As usual, it is advantageous to pass from the weighted space $L_2(0,\infty;rdr)$ to the standard L_2-space.[30] This leads to the operators

$$\widetilde{h}_{\lambda,m}u := -u'' + \widetilde{V}_{\lambda,m}u,$$

with

$$\widetilde{V}_{\lambda,m} = \left(m^2 - \frac{1}{4}\right)\frac{1}{r^2} + r^2 + 2r^2\lambda f(r) + \lambda^2 r^2 f^2(r) + 2m + 2m\lambda f(r).$$

The operators $h_{\lambda,m}$ and $\widetilde{h}_{\lambda,m}$ are unitarily equivalent. We recall that $\widetilde{h}_{\lambda,m}$ is essentially self-adjoint on $\mathbf{C}_0^\infty(0,\infty)$ for all $0 \neq m \in \mathbf{Z}$; in the special case $m=0$, we take the Friedrichs extension starting from the form domain $\mathbf{C}_0^\infty(0,\infty)$. It is evident that $\widetilde{h}_{\lambda,m}$ has compact resolvent for all $0 \neq m \in \mathbf{Z}$ and all $\lambda \in \mathbf{R}$. In the case $m=0$ one can convince oneself that $\widetilde{h}_{0,0}$ has compact resolvent by various arguments. E.g., if $\widetilde{h}_{0,0}$ had some essential spectrum, then the operator $-\Delta + |x|^2$ in $L_2(\mathbf{R}^2)$, the harmonic oscillator in 2 dimensions, would have to possess some essential spectrum too, as may be seen by arguing backwards in our above decomposition of a spherically symmetric operator.

IV.4. Lemma: For any $m \in \mathbf{Z}$ fixed, we have

$$\inf \sigma(\widetilde{h}_{\lambda,m}) \to \infty, \quad \lambda \to \infty, \tag{51}$$

provided $f(r) > 0$, for all $r \in (0,\infty)$.

Proof: We have to show that

$$\inf\{(\widetilde{h}_{\lambda,m}\phi,\phi); \phi \in \mathbf{C}_0^\infty(0,\infty), \|\phi\| = 1\} \to \infty, \quad \lambda \to \infty. \tag{52}$$

We may henceforth restrict our attention to real-valued functions.

We first consider the case $m \neq 0$. Since

$$\|u'\|^2 - \int_0^\infty \frac{1}{4r^2}u^2 \geqslant 0,$$

it is enough to look at the potential coming from the remaining terms. Here we first note that

$$\frac{m^2}{r^2} + 2m\lambda f(r) + \lambda^2 r^2 f^2(r) = \left(\frac{m}{r} + \lambda r f(r)\right)^2 \geqslant 0,$$

and we are left with

$$\widetilde{W}_{\lambda,m}(r) := r^2 + 2r^2\lambda f(r) + 2m.$$

Clearly, for any $\varepsilon > 0$, we have

$$\widetilde{W}_{\lambda,m}(r) \to \infty, \quad \text{uniformly on } [\varepsilon,\infty), \quad \text{as } \rangle\lambda \to \infty,$$

and (52) follows.

The case $m=0$ is more delicate. If we make the assumption that (52) is not true for $m=0$, then there exists a finite number c such that $\tilde{h}_{\lambda_k,0}$ has an eigenvalue $E_k \leqslant c$, for a sequence of $\lambda_k \to \infty$. As before, we find that $\tilde{W}_{\lambda_k,0}$ tends to infinity, uniformly on any fixed interval $[\varepsilon,\infty)$. Hence the eigenfunctions ψ_k of $\tilde{h}_{\lambda_k,0}$ which are associated with the eigenvalues E_k have the property that their part in (ε,∞) tends to 0, as $k\to\infty$. Hence the sequence (ψ_k) tends weakly to 0. At the same time,

$$(\tilde{h}_{0,0}\psi_k,\psi_k) \leqslant (\tilde{h}_{\lambda_k,0}\psi_k,\psi_k) \leqslant c,$$

implying that $\sigma_{\mathrm{ess}}(\tilde{h}_{0,0}) \neq \emptyset$; this, however, is incompatible with the fact that $\tilde{h}_{0,0}$ has compact resolvent. ■

In conclusion, we have proved the following properties of our example.

IV.5. Theorem: *Suppose* $f \in C^1([0,\infty))$ *satisfies* $f(r)>0$ *on* $(0,\infty)$, *and* $rf(r)\to 0$, *as* $r\to\infty$. *Let* H_λ *be defined as above. Then*

(i) $\sigma_{\mathrm{ess}}(H_\lambda)=\sigma_{\mathrm{ess}}(H_0)$ (=*the set of Landau levels for* H_0),

(ii) *Each (non-trivial) spectral gap of* H_0 *is crossed by an infinite number of eigenvalues of* H_λ, *as* λ *increases from 0 to* ∞.

Proof: In view of eq. (50) we only have to say something about the second statement.

Each Landau level Λ_j being an eigenvalue of infinite multiplicity, it follows that there exists an infinite number of $m \in \mathbf{Z}$ such that Λ_j is an eigenvalue of $\tilde{h}_{0,m}$. By eq. (51) however, all eigenvalues of $\tilde{h}_{\lambda,m}$ will eventually move out to infinity, as we let λ increase from 0 to ∞. ■

Remark: We do not expect that the discrete eigenvalues of H_λ are monotonically increasing with λ; eventually, however, all of them move up towards $+\infty$.

(Received 17 March 1997; accepted for publication 10 July 1997)

Infinite-dimensional algebras of hidden symmetries of the self-dual Yang–Mills equations are considered. A current-type algebra of symmetries and an affine extension of conformal symmetries introduced recently are discussed using the twistor picture. It is shown that the extended conformal symmetries of the self-dual Yang–Mills equations have a simple description in terms of Ward's twistor construction. © *1998 American Institute of Physics.* [S0022-2488(97)01112-2]

I. INTRODUCTION

The self-dual Yang–Mills (SDYM) equations in the space R^4 are manifestly invariant under the group of gauge transformations and the group of conformal transformations of the space R^4. Besides these symmetries, the SDYM equations have infinite-dimensional algebras of ''hidden symmetries''[1–6] related to gauge transformations. In Refs. 1–5 the Yang gauge[7] in which two components of gauge potential are equal to zero was used. Crane generalized the results of Refs. 1–5 on the case when a gauge is not fixed and gave the twistor interpretation of the action of symmetries on solutions of the SDYM equations.[8]

In the frames of approach of Refs. 1–4 it has been shown[9] that on the space $\mathscr{M}$ of local solutions of the SDYM equations one can also define an (infinitesimal) action of the affine Lie algebra related to conformal transformations of R^4. Later, the action of the subalgebra of this algebra was also defined on the space of solutions of the vacuum self-dual gravity equations.[10] In this paper we shall show that the new symmetry algebra described in Ref. 9 has a simple interpretation in terms of vector fields acting on transition matrices of Ward's holomorphic vector bundles over twistor space.

II. DEFINITIONS AND NOTATION

We consider the Euclidean space $R^{4,0}$ with the metric $\delta_{\mu\nu}$ and potentials A_μ of the Yang–Mills (YM) fields $F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu+[A_\mu,A_\nu]$, where $\mu,\nu,\ldots=1,...,4$. For simplicity we consider the fields A_μ and $F_{\mu\nu}$ with values in the Lie algebra $su(n)$.

The SDYM equations have the form

$$\frac{1}{2}\,\epsilon_{\mu\nu\rho\sigma}F_{\rho\sigma}=F_{\mu\nu}, \tag{1}$$

where $\epsilon_{\mu\nu\rho\sigma}$ is the completely antisymmetric tensor on $R^{4,0}$ and $\epsilon_{1234}=1$.

It is easily seen that eqs. (1) are invariant under the algebra of infinitesimal local gauge transformations:

$$\delta_\varphi A_\mu=\partial_\mu\varphi+[A_\mu,\varphi], \tag{2}$$

a)Electronic mail: ita@thsun1.jinr.dubna.su

where $\varphi(x)\in su(n)$, $x\in R^{4,0}$. It is also well-known that the SDYM equations (1) are invariant with respect to the algebra $so(5,1)$ of infinitesimal conformal transformations:

$$\delta_N A_\mu = N^\nu \partial_\nu A_\mu + A_\nu \partial_\mu N^\nu, \quad \partial_\mu := \frac{\partial}{\partial x^\mu}, \tag{3}$$

where $N=N^\nu\partial_\nu$ is any generator of the 15-parameter conformal group:

$$X_a=\delta_{ab}\eta^b_{\mu\nu}x_\mu\partial_\nu,\ \ Y_a=\delta_{ab}\overline{\eta}^b_{\mu\nu}x_\mu\partial_\nu,\ \ P_\mu=\partial_\mu,$$

$$K_\mu=\frac{1}{2}\,x_\sigma x_\sigma\partial_\mu - x_\mu D, \quad D=x_\sigma\partial_\sigma, \quad a,b,\ldots=1,2,3, \tag{4}$$

where $\{X_a\}$ and $\{Y_a\}$ generate two commuting SO(3) subgroups in SO(4), P_μ are the translation generators, K_μ are the generators of special conformal transformations and D is the dilatation generator. Here $\eta^a_{\mu\nu}=\{\epsilon^a_{bc},\mu=b,\nu=c;-\delta^a_\mu,\nu=4;-\delta^a_\nu,\mu=4\}$ is the self-dual 't Hooft tensor and $\overline{\eta}^a_{\mu\nu}=\{\epsilon^a_{bc},\mu=b,\nu=c;-\delta^a_\mu,\nu=4;\delta^a_\nu,\mu=4\}$ is the anti-self-dual 't Hooft tensor.

Let $J=(J^\nu_\mu)$ be the most general complex structure on $R^{4,0}$:[11]

$$J^\nu_\mu = s_a\overline{\eta}^a_{\mu\sigma}\delta^{\sigma\nu} \Rightarrow J^\sigma_\mu J^\nu_\sigma = -\delta^\nu_\mu, \tag{5}$$

where real numbers s_a parametrize a two-sphere S^2, $s_a s_a=1$. Using J, one can introduce (0,1) vector fields

$$\overline{V_1}=\frac{1}{2}\,(\partial_1+i\partial_2)-\frac{\lambda}{2}\,(\partial_3+i\partial_4)=\partial_{\bar y}-\lambda\partial_z,\ \ \overline{V_2}=\frac{1}{2}\,(\partial_3-i\partial_4)+\frac{\lambda}{2}\,(\partial_1-i\partial_2)=\partial_{\bar z}+\lambda\partial_y, \tag{6}$$

where $y=x_1+ix_2$, $z=x_3-ix_4$, $\overline{y}=x_1-ix_2$, $\overline{z}=x_3+ix_4$ are complex coordinates on $R^4\simeq C^2$, and $\lambda=(s_1+is_2)/(1+s_3)$ is a local complex coordinate on $S^2\simeq CP^1$.

Let S^1 denote a contour $|\lambda|=1$ in the λ-plane enclosing the origin in the counter-clockwise direction, C_+ denote all complex numbers $\lambda\in CP^1$ with $|\lambda|\leqslant 1+\alpha$, where α is any positive real number, and C_- denote all complex numbers $\lambda\in CP^1$ with $|\lambda|\geqslant 1-\alpha$ (including $\lambda=\infty$). Then C_+ and C_- form a two-set open cover of the Riemann sphere CP^1 with the intersection $C_\alpha = C_+\cap C_- = \{\lambda: 1-\alpha\leqslant|\lambda|\leqslant 1+\alpha\}$. Vector field $\partial_{\bar\lambda}:=\partial/\partial\bar\lambda$ is antiholomorphic (0,1) vector field with respect to the standard complex structure $\epsilon = id\lambda\otimes\partial_\lambda - id\lambda\otimes\partial_{\bar\lambda}$ on S^2.

Twistor space $\mathcal{Z}$ for $R^{4,0}$ is the space $\mathcal{Z}=R^{4,0}\times CP^1\simeq CP^3-CP^1\subset CP^3$ which is the space of all the constant complex structures on $R^{4,0}$.[12] This space can be covered by two coordinate patches $\mathcal{Z}=U_+\cup U_-$:

$$U_+=\{x\in R^{4,0},\lambda\in C_+\},\quad U_-=\{x\in R^{4,0},\lambda\in C_-\}, \tag{7}$$

with the intersection $U=U_+\cap U_-=\{x\in R^{4,0},\lambda\in C_\alpha=C_+\cap C_-\}$.

Twistor space $\mathcal{Z}$ is a trivial bundle π: $\mathcal{Z}\to R^{4,0}$ over $R^{4,0}$ (π:$\{x_\mu,\lambda,\bar\lambda\}\to\{x_\mu\}$) with fibre CP^1 and is a complex manifold with complex structure $\mathcal{J}=(J,\epsilon)$ on $\mathcal{Z}$. Vector fields V_1^{-},V_2^{-} from (6) and $V_3^{-}=\partial_{\bar\lambda}$ are vector fields of type (0,1) with respect to complex structure $\mathcal{J}$. Holomorphic coordinates on U_+ and U_- are $\{v^1_+=y-\lambda\bar z, v^2_+=z+\lambda\bar y, v^3_+=\lambda\}$ and $\{v^1_-=1/\lambda\ y-\bar z, v^2_-=1/\lambda\ z+\bar y, v^3_-=1/\lambda\}$. Twistor space is also a nontrivial holomorphic bundle p: $\mathcal{Z}\to CP^1$ over CP^1 with holomorphic sections (projective lines CP^1_x) parametrized by points $x\in C^4$:

$$CP^1_x=\{v^1_+=y+\lambda\tilde z,\ \ v^2_+=z+\lambda\tilde y,\ \ (y,z,\tilde y,\tilde z)\in C^4\}. \tag{8}$$

On $\mathcal{Z}$ one can introduce a real structure as a map $\tau: R^{4,0}\times S^2 \to R^{4,0}\times S^2$ defined by the formula: $\tau(x_\mu,\lambda)=(x_\mu,-1/\bar{\lambda})$, $x_\mu \in R^{4,0}$. Then, for real holomorphic sections of the bundle $\mathcal{Z}\to CP^1$ satisfying the equations $\tau(v^1_+)=\bar{v}^2_-$, $\tau(v^2_+)=-\bar{v}^1_-$ we have $\tilde{z}=-\bar{z}$, $\tilde{y}=\bar{y}$.[12,11]

III. WARD'S TWISTOR CORRESPONDENCE AND GAUGE-TYPE HIDDEN SYMMETRIES

The potentials A_μ define a connection $D:=dx^\mu(\partial_\mu+A_\mu)$ in the principal $SU(n)$-bundle $P=P(R^{4,0},SU(n))$ over $R^{4,0}$. In the standard manner we introduce the complex vector bundle $E=P\times_{SU(n)}C^n$ associated to P. Sections of this bundle are C^n-valued vector-functions depending on $x\in R^{4,0}$. Using the projection $\pi: \mathcal{Z}\to R^{4,0}$, we can pull back the bundle E with self-dual connection D to the bundle $\tilde{E}:=\pi^*E$ over $\mathcal{Z}$, and the pulled back connection $\tilde{D}:=\pi^*D$ will be flat along the fibres CP^1_x of the bundle $\mathcal{Z}\to R^{4,0}$. We can take it in the form $\tilde{D}=D+d\lambda\partial_\lambda+d\bar{\lambda}\partial_{\bar{\lambda}}$.

Let us consider local holomorphic sections ξ of the bundle $\tilde{E}$ or, in other words, local solutions of the equations $\tilde{D}^{(0,1)}_{\bar{a}}\xi=0$:

$$[(D_1+iD_2)-\lambda(D_3+iD_4)]\xi(x,\lambda,\bar{\lambda})=0, \tag{9a}$$

$$[(D_3-iD_4)+\lambda(D_1-iD_2)]\xi(x,\lambda,\bar{\lambda})=0, \tag{9b}$$

$$\partial_{\bar{\lambda}}\xi(x,\lambda,\bar{\lambda})=0, \tag{10}$$

where $\tilde{D}^{(0,1)}_{\bar{a}}$ are components of $\tilde{D}$ along (0,1) vector fields $\overline{V_a}$. We can solve eq. (10), and then eqs. (9) on $\xi(x,\lambda)$ are usually called the linear system for the SDYM equations.[13,14] It is easily seen that the compatibility conditions of the linear system (9) coincide with the SDYM equations (1).

Equations (9) have a local solution $\xi_+(x,\lambda)$ over $U_+\subset\mathcal{Z}$, a local solution $\xi_-(x,\lambda)$ over $U_-\subset\mathcal{Z}$ and $\xi_+=\xi_-$ on $U_+\cap U_-$. We can always represent $\xi_\pm$ in the form $\xi_\pm=\psi_\pm\chi_\pm$, where $SL(n,C)$-valued functions $\psi_\pm$ are holomorphic in λ on $U_\pm$, and vector-functions $\chi_\pm\in C^n$ defined on $U_\pm$ are related by

$$\chi_-=\mathcal{T}\chi_+ \tag{11}$$

on $U=U_+\cap U_-\subset\mathcal{Z}$. Here $\chi_+=\chi_+(v^a_+)$ and $\chi_-=\chi_-(v^a_-)$ are Čech fibre coordinates of the bundle $\tilde{E}$ over U_+ and U_-, and $\mathcal{T}$ is the transition matrix in the bundle $\tilde{E}$. Matrix $\mathcal{T}$ is a holomorphic $SL(n,C)$-valued function on U with non-vanishing determinant. By Ward's construction, the bundle $\tilde{E}$ is holomorphically trivial on each fibre CP^1_x, i.e., $\tilde{E}|_{CP^1_x}=CP^1_x\times C^n$.[14] This means that on CP^1_x matrix $\mathcal{T}$ can be factorized in the form

$$\mathcal{T}=\psi_-^{-1}(x,\lambda)\psi_+(x,\lambda) \tag{12}$$

for each point x from an open subset of $R^{4,0}$.

Remark: If we are given a matrix-valued function $\mathcal{T}\in G$ on $C_\alpha=C_+\cap C_-\subset CP^1$, then the Riemann–Hilbert problem is to find matrix-valued functions $\psi_+\in G$ and $\psi_-\in G$ such that ψ_+ is regular (i.e., holomorphic with non-vanishing determinant) on C_+, ψ_- is regular on C_- and $\mathcal{T}=\psi_-^{-1}\psi_+$ is regular on $C_\alpha=C_+\cap C_-$. Solution of the Riemann–Hilbert problem exists (Birkhoff's theorem) and is unique up to the left multiplication by matrix g not depending on λ: $\psi_\pm\to g\psi_\pm$ (for discussion see, e.g., Ref. 15). Thus, the splitting (12) gives a solution of a parametric Riemann–Hilbert problem (x_μ are external parameters). Besides, the matrix $\mathcal{T}$ in (12) will not change if we replace $\psi_\pm(x,\lambda)$ by $g(x)\psi_\pm(x,\lambda)$ (standard gauge transformation).

Matrix-valued functions $\psi_{\pm}$ define a trivialization of the bundle $\widetilde{E}$ over $U_{\pm}$. It follows from (9)–(12) that

$$(\partial_{\bar{y}}\psi_{+}-\lambda\partial_{z}\psi_{+})\psi_{+}^{-1}=(\partial_{\bar{y}}\psi_{-}-\lambda\partial_{z}\psi_{-})\psi_{-}^{-1}=-(A_{\bar{y}}(x)-\lambda A_{z}(x)), \tag{13a}$$

$$(\partial_{\bar{z}}\psi_{+}+\lambda\partial_{y}\psi_{+})\psi_{+}^{-1}=(\partial_{\bar{z}}\psi_{-}+\lambda\partial_{y}\psi_{-})\psi_{-}^{-1}=-(A_{\bar{z}}(x)+\lambda A_{y}(x)), \tag{13b}$$

and the potentials $\{A_{\mu}\}$ defined by (13) satisfy the SDYM equations.

For a Hermitian vector bundle when the structure group is SU(n) the real structure τ on the twistor space $\mathcal{Z}$ induces a Hermitian structure in the bundle $\widetilde{E}$.[12] Then, fields $\{A_{\mu}\}$, matrices $\psi_{\pm}$ and $\mathcal{F}$ have to satisfy the following unitarity conditions (see e.g. Ref. 8):

$$A_{y}^{\dagger}=-A_{\bar{y}},\quad A_{z}^{\dagger}=-A_{\bar{z}},\quad A_{\bar{y}}^{\dagger}=-A_{y},\quad A_{\bar{z}}^{\dagger}=-A_{z}, \tag{14a}$$

$$\psi_{+}^{\dagger}(\lambda)=\psi_{-}^{-1}\left(-\frac{1}{\bar{\lambda}}\right),\quad \psi_{-}^{\dagger}(\lambda)=\psi_{+}^{-1}\left(-\frac{1}{\bar{\lambda}}\right), \tag{14b}$$

$$\mathcal{F}^{\dagger}(\lambda)=\mathcal{F}\left(-\frac{1}{\bar{\lambda}}\right), \tag{14c}$$

where † denotes Hermitian conjugation.

From (13) one can see that gauge potentials A_{μ} do not change after transformations

$$\psi_{+}\to\psi_{+}^{equ}=\psi_{+}h_{+},\quad \psi_{-}\to\psi_{-}^{equ}=\psi_{-}h_{-}, \tag{15}$$

where h_{+} is any regular holomorphic matrix-valued function on U_{+}, and h_{-} is any regular holomorphic matrix-valued function on U_{-}. This means that the bundles with transition matrices $h_{-}^{-1}\mathcal{F}h_{+}$ and $\mathcal{F}$ are holomorphically equivalent. Notice that for the Hermitian vector bundles $\widetilde{E}$ with transition matrices $\mathcal{F}$ satisfying the ''hermiticity'' condition (14c) the equality $h_{+}^{\dagger}(\lambda)=h_{-}^{-1}(-1/\bar{\lambda})$ has to be fulfilled.

Thus, we have described a one-to-one correspondence between gauge equivalence classes of solutions to the SDYM equations on the Euclidean 4-space and equivalence classes of holomorphic vector bundles $\widetilde{E}$ over twistor space $\mathcal{Z}$, that are holomorphically trivial over each real projective line CP_{x}^{1} in $\mathcal{Z}$ (the Euclidean version of Ward's theorem[16,12,11]).

Now we will briefly remind the description of gauge-type ''hidden symmetries.'' First, we should define an infinite-dimensional complex Lie (pseudo)group H (current-type group) of holomorphic maps from $U=U_{+}\cap U_{-}\subset\mathcal{Z}$ to the group SL(n,C) with standard pointwise multiplication and the corresponding complex Lie algebra $\mathcal{H}$ of holomorphic maps from U to the Lie algebra $sl(n,C)$. We shall also consider subgroups $H_{\pm}\subset H$ of elements from H which can be extended continuously to holomorphic maps from $U_{\pm}$ to SL(n,C) and the corresponding algebras $\mathcal{H}_{\pm}\subset\mathcal{H}$.

The action of group H on transition matrix $\mathcal{F}$ preserving the hermiticity condition (14c) is given by:[8]

$$\mathcal{F}\to\widetilde{\mathcal{F}}=u(h).\mathcal{F}:=h(\lambda).\mathcal{F}(\lambda)h^{\dagger}\left(-\frac{1}{\bar{\lambda}}\right), \tag{16}$$

where $h(\lambda)\equiv h(y-\lambda\bar{z},z+\lambda\bar{y},\lambda)$, $\mathcal{F}\equiv\mathcal{F}(y-\lambda\bar{z},z+\lambda\bar{y},\lambda)$, $h^{\dagger}(-1/\bar{\lambda})\equiv h^{\dagger}(y+\bar{z}/\bar{\lambda},z-\bar{y}/\bar{\lambda},-1/\bar{\lambda})$, and in (16) we simply omitted a part of arguments. To this action the following action of the Lie algebra $\mathcal{H}$ on $\mathcal{F}$ corresponds:

$$\mathscr{F}\to\delta_\varphi\mathscr{F}=\varphi(\lambda)\mathscr{F}(\lambda)+\mathscr{F}(\lambda)\varphi^\dagger\left(-\frac{1}{\bar\lambda}\right), \tag{17}$$

where $\varphi(\lambda)\equiv\varphi(y-\lambda\bar z,z+\lambda\bar y,\lambda)\in sl(n,C)$ is any element of $\mathscr{H}$ (of course, $\varphi^\dagger(-1/\bar\lambda)$ is also an element of $\mathscr{H}$).

Consider now the following $sl(n,C)$-valued function ϕ on U

$$\phi\equiv\varphi_- -\varphi_+ :=\psi_-(\delta_\varphi\mathscr{F})\psi_+^{-1}=\psi_-\varphi(\lambda)\psi_-^{-1}+\psi_+\varphi^\dagger\left(-\frac{1}{\bar\lambda}\right)\psi_+^{-1}, \tag{18}$$

where for holomorphic ϕ expanded in Laurent series $\phi=\Sigma_{n=-\infty}^{\infty}\lambda^n\phi_n(x)$ we put

$$\varphi_+ :=\tilde\phi_0(x)-\sum_{n=1}^{\infty}\lambda^n\phi_n(x),\quad \varphi_- :=\hat\phi_0(x)+\sum_{n=-\infty}^{-1}\lambda^n\phi_n(x),\quad \hat\phi_0(x)-\tilde\phi_0(x)=\phi_0(x). \tag{19}$$

Thus, the function $\varphi_+(\lambda)\in sl(n,C)$ is holomorphic in $\lambda\in C_+\subset CP^1$, and the function $\varphi_-(\lambda)\in sl(n,C)$ is holomorphic in $\lambda\in C_-\subset CP^1$.

It follows from (13) and (18) that

$$(D_{\bar y}-\lambda D_z)\phi\equiv(\partial_{\bar y}-\lambda\partial_z)\phi+[A_{\bar y}-\lambda A_z,\phi]=0\Rightarrow(D_{\bar y}-\lambda D_z)\varphi_+=(D_{\bar y}-\lambda D_z)\varphi_-, \tag{20a}$$

$$(D_{\bar z}+\lambda D_y)\phi\equiv(\partial_{\bar z}+\lambda\partial_y)\phi+[A_{\bar z}+\lambda A_y,\phi]=0\Rightarrow(D_{\bar z}+\lambda D_y)\varphi_+=(D_{\bar z}+\lambda D_y)\varphi_-. \tag{20b}$$

The action of algebra $\mathscr{H}$ on matrix-valued functions $\psi_\pm\in\mathrm{SL}(n,C)$ and on gauge potentials $\{A_\mu\}$ is given by formulas

$$\delta_\varphi\psi_+ :=-\varphi_+\psi_+,\quad \delta_\varphi\psi_- :=-\varphi_-\psi_-, \tag{21}$$

$$\delta_\varphi A_{\bar y}-\lambda\delta_\varphi A_z :=D_{\bar y}\varphi_+-\lambda D_z\varphi_+=D_{\bar y}\varphi_--\lambda D_z\varphi_-, \tag{22a}$$

$$\delta_\varphi A_{\bar z}+\lambda\delta_\varphi A_y :=D_{\bar z}\varphi_++\lambda D_y\varphi_+=D_{\bar z}\varphi_-+\lambda D_y\varphi_-. \tag{22b}$$

It follows from (22) that

$$\delta_\varphi A_y=\oint_{S^1}\frac{d\lambda}{2\pi i\lambda^2}(D_{\bar z}\varphi_++\lambda D_y\varphi_+),\quad \delta_\varphi A_z=\oint_{S^1}\frac{d\lambda}{2\pi i\lambda^2}(D_{\bar y}\varphi_+-\lambda D_z\varphi_+),$$

$$\delta_\varphi A_{\bar y}=\oint_{S^1}\frac{d\lambda}{2\pi i\lambda}(D_{\bar y}\varphi_+-\lambda D_z\varphi_+),\quad \delta_\varphi A_{\bar z}=\oint_{S^1}\frac{d\lambda}{2\pi i\lambda}(D_{\bar z}\varphi_++\lambda D_y\varphi_+), \tag{23}$$

where $S^1=\{\lambda\in CP^1:|\lambda|=1\}$. Thus, in (17), (21) and (22) we have described the action of the current algebra $\mathscr{H}$ on the space of local solutions of the SDYM equations.

IV. HIDDEN SYMMETRIES FROM THE AFFINIZATION OF CONFORMAL ALGEBRA

In Ref. 9 to each generator N of the group SO(5,1) of conformal transformations of the Euclidean space $R^{4,0}$ Popov and Preitschopf associated an infinite number of infinitesimal symmetry transformations δ_N^n $(n=0,1,2,...)$ acting on solutions of the SDYM equations. They considered potentials A_μ with values in complex Lie algebras and did not discuss the problems of reality

for gauge fields. Considering potentials A_μ with values in su(n), we examine not only the infinitesimal symmetries from Ref. 9, which do not preserve, generally speaking, the unitarity conditions (14), but also the symmetries preserving the unitarity.

In formulas (4) we have specified a homomorphism of the Lie algebra so(5,1) of the conformal group into the Lie algebra of vector fields M, N... on $R^{4,0}$. Now we have to define the action of SO(5,1) on $\mathscr{Z}$, which preserves the holomorphicity of the bundle $\widetilde{E}\to\mathscr{Z}$. Such lift $N\to\widetilde{N}$ of vector fields on $\mathscr{Z}$ was described in Ref. 17, and the lifted generators

$$\widetilde{X}_a=X_a,\quad \widetilde{Y}_a=Y_a+2Z_a,\quad \widetilde{P}_\mu=P_\mu,\quad \widetilde{K}_\mu=K_\mu+\overline{\eta}^{\sigma}_{\sigma\mu}x_\sigma Z_a,\quad \widetilde{D}=D, \tag{24}$$

$$Z_1=\frac{1}{2}\,i(\lambda^2-1)\partial_\lambda-\frac{1}{2}\,i(\overline{\lambda^2}-1)\partial_{\overline{\lambda}},\quad Z_2=\frac{1}{2}\,(\lambda^2+1)\partial_\lambda+\frac{1}{2}\,(\overline{\lambda^2}+1)\partial_{\overline{\lambda}},\quad Z_3=i\lambda\partial_\lambda-i\overline{\lambda}\partial_{\overline{\lambda}} \tag{25}$$

are infinitesimal automorphisms of the complex structure $\mathscr{J}$ on $\mathscr{Z}$. This means, in particular, that for any generator $\widetilde{N}$ from (24) the following relations

$$[\overline{V_a},\widetilde{N}]=\overline{\alpha^b_a}(\widetilde{N})\overline{V_b} \tag{26}$$

take place for some functions $\overline{\alpha^b_a}(\widetilde{N})$ and vector fields $\overline{V_1},\overline{V_2}$ from (6) and $\overline{V_3}=\partial_{\overline{\lambda}}$.

Having generators $\widetilde{N}$ of infinitesimal holomorphic diffeomorphisms (24) of the space $\mathscr{Z}$, we consider the holomorphic vector fields $N_n=\lambda^{-n}\widetilde{N}$, $n=0,\pm1,\pm2,...$, and define the following infinitesimal transformations of transition matrix $\mathscr{F}$ of the bundle $\widetilde{E}$

$$\delta^n_N\mathscr{F}:=N_n(\mathscr{F})=\lambda^{-n}\widetilde{N}(\mathscr{F}),\quad n=0,\pm1,\pm2,\dots. \tag{27}$$

In virtue of (26) transformations (27) are holomorphic and, therefore, define the infinitesimal symmetries of the SDYM equations.

Let us introduce the $sl(n,C)$-valued function (compare with (18) from Sec. III)

$$\phi_{N_n}=\phi^-_{N_n}-\phi^+_{N_n}:=\psi_-(\delta^n_N\mathscr{F})\psi_+^{-1}=\lambda^{-n}(\widetilde{N}\psi_+)\psi_+^{-1}-\lambda^{-n}(\widetilde{N}\psi_-)\psi_-^{-1}, \tag{28}$$

$$\phi^+_{N_n}:=\widetilde{\phi}^0_{N_n}(x)-\sum_{k=1}^{\infty}\lambda^k\phi^k_{N_n}(x),\quad \phi^-_{N_n}:=\hat{\phi}^0_{N_n}(x)+\sum_{k=-\infty}^{-1}\lambda^k\phi^k_{N_n}(x),\quad \hat{\phi}^0_{N_n}-\widetilde{\phi}^0_{N_n}=\phi^0_{N_n}. \tag{29}$$

Be reminded that the splitting of the sl(n,C)-valued function $\phi_{N_n}(x,\lambda)$ into the difference of the function $\phi^-_{N_n}\in\mathrm{sl}(n,C)$ holomorphic in $\lambda\in C_-$ and of the function $\phi^+_{N_n}\in\mathrm{sl}(n,C)$ holomorphic in $\lambda\in C_+$ is a solution of the infinitesimal variant of the Riemann–Hilbert problem.

Remark: Notice that $\phi^\pm_{N_0}=-(\widetilde{N}\psi_\pm)\psi_\pm^{-1}$, but $\phi^+_{N_n}\neq-\lambda^{-n}(\widetilde{N}\psi_+)\psi_+^{-1}$, and $\phi^-_{N_n}\neq-\lambda^{-n}(\widetilde{N}\psi_-)\psi_-^{-1}$, when $n\neq0$. If we fix the gauge $\psi_+(\lambda=0)=1$, then the functions $\phi^+_{N_0}$ coincide with the functions $-\psi_{\widetilde{N}}$, $\widetilde{N}\in so(5,1)$, which are generating functions for symmetries introduced in Ref. 9.

It follows from (13), (26), and (28) that (cf. Sec. III):

$$(D_{\overline{y}}-\lambda D_z)\phi_{N_n}=0\Rightarrow(D_{\overline{y}}-\lambda D_z)\phi^+_{N_n}=(D_{\overline{y}}-\lambda D_z)\phi^-_{N_n}, \tag{30a}$$

$$(D_{\overline{z}}+\lambda D_y)\phi_{N_n}=0\Rightarrow(D_{\overline{z}}+\lambda D_y)\phi^+_{N_n}=(D_{\overline{z}}+\lambda D_y)\phi^-_{N_n}, \tag{30b}$$

$$\delta_N^n \psi_+ = -\phi_{N_n}^+ \psi_+ , \quad \delta_N^n \psi_- = -\phi_{N_n}^- \psi_- , \tag{31}$$

$$\delta_N^n A_{\bar{y}} - \lambda \delta_N^n A_z := D_{\bar{y}} \phi_{N_n}^+ - \lambda D_z \phi_{N_n}^+ = D_{\bar{y}} \phi_{N_n}^- - \lambda D_z \phi_{N_n}^- ,$$

$$\delta_N^n A_{\bar{z}} + \lambda \delta_N^n A_y := D_{\bar{z}} \phi_{N_n}^+ + \lambda D_y \phi_{N_n}^+ = D_{\bar{z}} \phi_{N_n}^- + \lambda D_y \phi_{N_n}^- , \tag{32}$$

We have

$$\delta_N^n A_y = \oint_{S^1} \frac{d\lambda}{2\pi i \lambda^2} (D_{\bar{z}} \phi_{N_n}^+ + \lambda D_y \phi_{N_n}^+), \quad \delta_N^n A_z = -\oint_{S^1} \frac{d\lambda}{2\pi i \lambda^2} (D_{\bar{y}} \phi_{N_n}^+ - \lambda D_z \phi_{N_n}^+),$$

$$\delta_N^n A_{\bar{y}} = \oint_{S^1} \frac{d\lambda}{2\pi i \lambda} (D_{\bar{y}} \phi_{N_n}^+ - \lambda D_z \phi_{N_n}^+), \quad \delta_N^n A_{\bar{z}} = \oint_{S^1} \frac{d\lambda}{2\pi i \lambda} (D_{\bar{z}} \phi_{N_n}^+ + \lambda D_y \phi_{N_n}^+). \tag{33}$$

Thus, to each generator N of the group of conformal transformations of the space $R^{4,0}$ we have corresponded an infinite number of generators δ_N^n of symmetry transformations of the SDYM equations and defined their action on the transition matrix $\mathscr{T}$, on the group-valued functions $\psi_\pm$ and on gauge potentials A_μ.

By direct calculations, it is not hard to show that

$$\delta_N^0 A_\mu = \mathscr{L}_N A_\mu \equiv N^\nu \partial_\nu A_\mu + A_\nu \partial_\mu N^\nu, \tag{34}$$

i.e. $\delta_N^0 A_\mu$ coincide with infinitesimal conformal transformation (3). Symmetries (33) with $n \geqslant 0$ are in one-to-one correspondence with the symmetries introduced in Ref. 9. To show this correspondence in more detail, let us discuss the algebraic properties of the symmetry transformations δ_N^n.

The commutator of two transformations can be easily calculated using formula (27). We have

$$[\delta_M^m, \delta_N^n] \mathscr{T} = \lambda^{-m-n} [\widetilde{M}, \widetilde{N}](\mathscr{T}) + m\lambda^{-m-n-1} \widetilde{N}^\lambda \widetilde{M}(\mathscr{T}) - n\lambda^{-m-n-1} \widetilde{M}^\lambda \widetilde{N}(\mathscr{T}), \tag{35}$$

where $\widetilde{N}^\lambda$ and $\widetilde{M}^\lambda$ are components of vector fields $\widetilde{N}$ and $\widetilde{M}$ along ∂_λ. Substituting (24) into (35), we obtain

$$[\delta_M^m, \delta_N^n] = \delta_{[M,N]}^{m+n}, \quad m,n, = 0, \pm 1, \pm 2, ... \tag{36}$$

for $M, N \in \mathscr{A} = \{P_\mu, X_a, D\}$, i.e., δ_M^m with generators M from the 8-dimensional Lie algebra $\mathscr{A}$ (see Ref. 9) form the affine Lie algebra $\mathscr{A} \otimes C[\lambda, \lambda^{-1}]$. For generators $\delta_{Y_a}^m$ we have

$$[\delta_{Y_1}^m, \delta_{Y_1}^n] = i(m-n)(\delta_{Y_1}^{m+n-1} - \delta_{Y_1}^{m+n+1}), \tag{37a}$$

$$[\delta_{Y_2}^m, \delta_{Y_2}^n] = (m-n)(\delta_{Y_2}^{m+n-1} + \delta_{Y_2}^{m+n+1}), \tag{37b}$$

$$[\delta_{Y_3}^m, \delta^n{}_{Y_3}] = 2i(m-n)\delta_{Y_3}^{m+n}, \tag{37c}$$

$$[\delta_{Y_1}^m, \delta_{Y_2}^n] = \delta_{[Y_1,Y_2]}^{m+n} + m(\delta_{Y_1}^{m+n-1} + \delta_{Y_1}^{m+n+1}) - in(\delta_{Y_2}^{m+n-1} - \delta_{Y_2}^{m+n+1}), \tag{38a}$$

$$[\delta_{Y_1}^m, \delta_{Y_3}^n] = \delta_{[Y_1,Y_3]}^{m+n} + 2im\delta_{Y_1}^{m+n} - in(\delta_{Y_3}^{m+n-1} - \delta_{Y_3}^{m+n+1}), \tag{38b}$$

$$[\delta_{Y_2}^m, \delta_{Y_3}^n] = \delta_{[Y_2,Y_3]}^{m+n} + 2im\delta_{Y_2}^{m+n} - n(\delta_{Y_3}^{m+n-1} + \delta_{Y_3}^{m+n+1}), \tag{38c}$$

$$[\delta^m_{Y_1},\delta^n_N]=\delta^{m+n}_{[Y_1,N]}-in(\delta^{m+n-1}_N-\delta^{m+n+1}_N), \tag{39a}$$

$$[\delta^m_{Y_2},\delta^n_N]=\delta^{m+n}_{[Y_2,N]}-n(\delta^{m+n-1}_N+\delta^{m+n+1}_N), \tag{39b}$$

$$[\delta^m_{Y_3},\delta^n_N]=\delta^{m+n}_{[Y_3,N]}-2in\,\delta^{m+n}_N, \tag{39c}$$

where $N\in\mathscr{A}=\{P_\mu,X_a,D\}$. Notice that the imaginary unit i can be removed from structure constants in (37)–(39) by the following change of generators $\delta^m_{Y_1}\to i\delta^m_{Y_1}$, $\delta^m_{Y_3}\to i\delta^m_{Y_3}$ (see Ref. 9). Then ''half'' of the algebra (36)–(39) with $m,n\geqslant 0$ will coincide with the one considered in Ref. 9. Let us emphasize that in (36)–(39) the numbers $m,n,=0,\pm 1,...$ are any integer numbers. It is important to understand that the change $\delta^m_{Y_1}\to i\delta^m_{Y_1}$, $\delta^m_{Y_3}\to i\delta^m_{Y_3}$ is possible only by considering complex gauge fields or by transition from the signature (4,0) to the signature (2,2).

Finally, for generators K_μ of special conformal transformations, the commutators of transformations $\delta^m_{K_\mu}$ with other transformations will be again the symmetry transformations, but with coefficients depending on the coordinates on $\mathscr{Z}$. For example,

$$[\delta^m_{P_1},\delta^n_{K_1}]=\delta^{m+n}_{[P_1,K_1]}+\frac{m}{2}\,v^2_+\delta^{m+n+1}_{P_1}-\frac{m}{2}\,v^1_+\delta^{m+n}_{P_1}, \tag{40}$$

where $v^1_+=y-\lambda\overline{z}$, $v^2_+=z+\lambda\overline{y}$ are holomorphic coordinates on $U_+\subset\mathscr{Z}$. This means that the structure constants in all the commutators with $\delta^m_{K_\mu}$ are replaced by the ''structure functions,'' that has been noticed by Popov and Preitschopf.[9] We do not write out these commutators looking similar to (40). In twistor terms, commutators like (40) appear because of the fact that the expansion in Laurent series in λ and formulas like (27), (29) etc. may be used only by the existence of the holomorphic projection $p:\mathscr{Z}\to CP^1$ leading to the distinguishing of coordinate λ. Special conformal transformations K_μ and transformations $\delta^m_{K_\mu}$ related to K_μ do not preserve the bundle $\mathscr{Z}\to CP^1$ and make invalid the formulas based on the expansion in λ. On formal level, this is connected with the fact that special conformal transformations transform λ into a function on x_μ and λ, and this leads to appearance of ''structure functions'' in formulas like (40). For correct discussion of symmetries related to K_μ, it is necessary to pass from the flat hyperKähler space $R^{4,0}$ to the four-sphere S^4 which is conformally flat (but not hyperKähler) manifold.

Be reminded that for real gauge fields with values in the Lie algebra $su(n)$ the transition functions $\mathscr{F}$ in the bundle $\widetilde{E}$ have to satisfy the condition (14c). Generally speaking, infinitesimal transformations do not (infinitesimally) preserve this condition, since

$$(\delta^n_N\mathscr{F}|_{\lambda\to -1/\overline{\lambda}})^\dagger=(-1)^n\lambda^n\widetilde{N}.\mathscr{F}(\lambda)=(-1)^n\delta^{-n}_N.\mathscr{F}(\lambda). \tag{41}$$

However, we can introduce infinitesimal symmetry transformations $\delta^n_{N_R}$ preserving reality conditions by setting

$$\delta^n_{N_R}.\mathscr{F}:=\delta^n_N.\mathscr{F}+(-1)^n\delta^{-n}_N.\mathscr{F}=(\lambda^{-n}+(-\lambda)^n)\widetilde{N}.\mathscr{F}\equiv N^R_n.\mathscr{F}. \tag{42}$$

For transformations (42), the formulas for $\phi_{N^R_n}$, $\delta^n_{N_R}\psi_\pm$ and $\delta^n_{N_R}A_\mu$ will have the same form as formulas (28)–(33) with the replacement N_n by N^R_n, and that is why we shall not write them out. As to the algebraic properties of transformations (42), then, by direct calculation, it can be shown that generators $\delta^n_{P^R_\mu}$, $\delta^n_{X^R_a}$ and $\delta^n_{D^R}$ form a closed algebra. Commutation relations analogous to (36)–(39), which we do not write out, easily follow from the definition (42).

V. CONCLUSION

Symmetries of the SDYM and the self-dual gravity equations are important in quantization of Yang–Mills model, $N=2$ strings and related models, that have been discussed, for example, in recent papers.[18,19] We think that the twistor point of view on symmetries of the SDYM equations used in this paper clarifies the geometric and algebraic sense of the so called ''hidden symmetries'' and makes them not so mystical. It would be interesting to consider the affine Lorentz symmetries[10] of the self-dual gravity equations from the twistor point of view. Notice that all the results of our paper may be generalized on the SDYM equations in the $4k$-dimensional spaces considered e.g. in Ref. 20.

(Received 28 March 1996; accepted for publication 16 September 1997)

We define a large class of quantum sources and prove a quantum analog of the asymptotic equipartition property. Our proof relies on using local measurements on the quantum source to obtain an associated classical source. The classical source provides an upper bound for the dimension of the relevant subspace of the quantum source, via the Shannon–McMillan noiseless coding theorem. Along the way we derive a bound for the von Neumann entropy of the quantum source in terms of the Shannon entropy of the classical source, and we provide a definition of ergodicity of the quantum source. Several explicit models of quantum sources are also presented. © *1998 American Institute of Physics.* [S0022-2488(98)00401-0]

I. INTRODUCTION

A. Context

The possibility of building a quantum computer has stimulated new interest in the quantum analog of classical information theory (see Ref. 1 for an introduction and review of current ideas). Shannon, McMillan, Khinchin, and others provided a firm foundation for the classical theory, and used the mathematics of stochastic processes to prove important theorems. In particular they obtained limits on the amount of information that can be transmitted through a channel. Although a quantum computer does not yet exist, it is reasonable to suppose that similar issues of channel capacity are relevant to its operation. So it is interesting to investigate this question, using our current understanding of quantum mechanics.

There has been much work done on this and related questions. In particular, Schumacher stated and proved a capacity result for a quantum channel in Refs. 2 and 3. Our particular interest is in the *extended* quantum signal source described by Schumacher. This is a quantum system whose state space is a (tensor) product of many copies of one fundamental state space M. The source produces a signal that is encoded by a state in M; the ensemble of possible signals is represented by a density operator ρ on M. The extended source corresponds to a sequence of such states, and has a natural interpretation as a message. The probabilistic character of the message is contained in the density operator on the tensor product of copies of M. One choice of density operator is $\rho\otimes\cdots\otimes\rho$. This corresponds to independent signals at all times, and there are no correlations between signals in the message. For this reason we call this a quantum Bernoulli source (a precise definition is provided in Sec. II). Schumacher proves his quantum noiseless coding theorem for such a source. He introduces the notion of fidelity of a quantum channel, and states his results in terms of this. On the most basic level his results show that the state space for the extended source has a relevant subspace whose dimension is determined by the von Neumann entropy of ρ. As far as the information content of the source is concerned, the rest of the state space can be ignored.

B. Results

Our main interest in this paper is to extend Schumacher's result to a large class of quantum sources. We define precisely what we mean by this in Sec. II. Roughly speaking, we consider sources that allow correlations on all time scales between signals in a message. In classical information theory the corresponding result is the Shannon–McMillan theorem, which shows that under very general assumptions the ensemble of all possible messages can be split into a relevant and an irrelevant part. The criterion for splitting is provided by the entropy of the source. The corresponding result for the quantum theory should be a splitting of the state space into a relevant subspace and an irrelevant subspace, with the von Neumann entropy as the criterion. This is precisely what Schumacher proved for the quantum Bernoulli source. We obtain such a splitting in the general case, and derive an estimate for the dimension of the relevant subspace, by computing the entropy of a classical source that is obtained by making measurements on the quantum system.

To summarize, we show that a general quantum source can be encoded by a quantum system whose dimension is smaller than the original. We give estimates for the dimension of the reduced space, based on the results of local measurements of the source. For the case of a quantum source emitting orthogonal states our estimate is tight, and for a Bernoulli source reproduces Schumacher's result. We also derive an inequality relating this experimental entropy to the true von Neumann entropy.

C. Layout

The paper is organized as follows. In sec. II we define quantum sources and recall some standard results about the construction of infinite quantum systems. We also provide some explicit examples that serve to illustrate our ideas. In Sec. III we recall the classical notion of an ergodic source, and propose a definition of ergodicity for a quantum source. As a check we prove that a quantum Bernoulli source is ergodic. In Sec. IV we recall the notion of quantum entropy. In Sec. V we pursue the quantum analog of the Shannon–McMillan theorem. To do this we use the notion of a positive operator-valued measure, and construct an associated classical source. The entropy of this associated source satisfies a lower bound involving the von Neumann entropy of the quantum source. It also determines the dimension of a relevant subspace of the quantum system, which in turn yields our quantum noiseless coding theorem.

II. QUANTUM SOURCES

A. Setup

According to the mathematical theory of information, see, e.g., Refs. 4–6, a (classical) *source* is a stochastic process. In this paper, we are concerned with discrete sources that can be described as follows. We are given a finite set $\mathscr{X}$, called the alphabet, and consider the space $\mathscr{X}^{\cdot\infty}$ of all infinite sequences $\underline{x}=\{x_n\}_{n\in Z}$, called messages. The time evolution is given by the shift T: $\mathscr{X}^{\cdot\infty}\to\mathscr{X}^{\cdot\infty}$ defined by $(T\underline{x})_n:=x_{n+1}$. The stochastic character of the process is governed by a probability measure μ on $\mathscr{X}^{\cdot\infty}$. The triple $(\mathscr{X}^{\cdot\infty},T,\mu)$ is called a source. We say that the source is *stationary*, if T preserves the measure μ.

We begin by describing informally the properties of a quantum source. In the next section we will provide a rigorous mathematical description. By analogy with the classical case, a quantum source will be a triple, consisting of *quantum messages*, the *time shift*, and a *probability distribution* for the messages. For technical reasons, it is useful to describe the space of quantum messages (which is a linear space) by the algebra of observables on it.

A *quantum source* sends a series of signals, each of which is a vector in a finite-dimensional Hilbert space $\mathscr{H}$. We assume that the source is discrete, i.e., each signal is an element of a finite set $\mathscr{S}=\{|\psi_1\rangle,\ldots,|\psi_s\rangle\}$ of normalized vectors in $\mathscr{H}$. To avoid unnecessary redundancy, we assume that the space $\mathscr{H}$ is spanned by $\mathscr{S}$, i.e. $\mathscr{H}\simeq\mathbb{C}^d$, where $d\leqslant s$. We do not assume that the elements of $\mathscr{S}$ are orthogonal to each other or even linearly independent. Indeed, this is an

important difference from the classical situation, which does not allow for forming linear superpositions of states. Denote by p_j the *a priori* probability of the state $|\psi_j\rangle$ being sent. The density matrix corresponding to the ensemble of signals $\mathscr{S}$ is then given by

$$\rho = \sum_{1 \leqslant j \leqslant s} p_j |\psi_j\rangle\langle\psi_j|. \tag{II.1}$$

As a consequence of our assumptions, $\mathrm{tr}(\rho) = 1$. Clearly, an ensemble of signals $\mathscr{S}$ and the associated *a priori* probabilities determines uniquely the density matrix ρ. On the other hand, any given density matrix corresponds to infinitely many different sets of signals. For a discussion of this point, see Ref. 7.

The observables associated with quantum signals are $d \times d$ Hermitian matrices; more formally (we will need this viewpoint shortly) they are elements of the $\mathbb{C}^*$-algebra $\mathscr{A} = \mathscr{L}(\mathscr{H})$ of linear operators on $\mathscr{H}$. Abusing slightly the language, we will refer to $\mathscr{A}$ as the algebra of observables. Using the language adopted in the operator algebra approach to quantum physics, see, e.g., Refs. 8 and 9, we define the *state* on the algebra of observables $\mathscr{A}$ associated with the density matrix ρ to be

$$\tau_1(A) := \mathrm{tr}(A\rho) = \sum_{1 \leqslant j \leqslant s} p_j \langle\psi_j|A|\psi_j\rangle. \tag{II.2}$$

B. Definition

We now propose a formal definition of a quantum source. To this end, we construct the state on the algebra of observables associated with entire (infinite) quantum messages rather than individual signals. This is technically somewhat delicate, as it involves infinite tensor products of Hilbert spaces. Let $I \subset \mathbb{Z}$ be a finite set of the form $\{M, M+1, \ldots, N-1, N\}$, where $M < N$, i.e., I is a finite collection of consecutive integers. By $\mathscr{T}$ we denote the partially ordered set of all such I's. We set $H_I := \otimes_{j \in I} \mathscr{H}_j$, where $\mathscr{H}_j = \mathscr{H}$ for all $j \in I$, and define the corresponding observable algebra $\mathsf{A}_I := \mathscr{L}(H_I) \simeq \otimes^{|I|} \mathscr{L}(\mathscr{H})$, where $|I|$ denotes the number of elements in I. For $I \subset J$, there is a natural embedding $\mathscr{L}(H_I) \hookrightarrow \mathscr{L}(H_J)$, and so we can form the union $\mathsf{A}_{\mathrm{loc}} := \cup_{I \in \mathscr{T}} \mathsf{A}_I$. The latter is a normed algebra, and we refer to its elements as *local observables*. Roughly, $\mathsf{A}_{\mathrm{loc}}$ is a collection of operators acting on the infinite tensor product $\otimes_{j \in \mathbb{Z}} \mathscr{H}_j$; every element of $\mathsf{A}_{\mathrm{loc}}$ acts as the identity on all but a finite number of factors in this product. For a local observable $A \in \mathsf{A}_{\mathrm{loc}}$, we let $\mathrm{supp}(A)$ denote its support, i.e., the smallest $I \in \mathscr{T}$ such that $A \in \mathsf{A}_I$. The norm closure A of $\mathsf{A}_{\mathrm{loc}}$ is a $\mathbb{C}^*$-algebra called the algebra of *quasilocal observables*. These concepts are borrowed from algebraic field theory and statistical mechanics, and we refer the reader to Refs. 8 and 9 for a thorough presentation.

We will use the net $\{\mathsf{A}_I\}_{I \in \mathscr{T}}$ of matrix algebras to construct the Hilbert space of states of a quantum source. Assume that we have a family $\{\Pi_I\}_{I \in \mathscr{T}}$, $\Pi_I \in \mathsf{A}_I$, satisfying the following assumptions:

1°. Each Π_I is a positive operator.

2°. If $|I| = 1$, then $\Pi_I = \rho$.

3°. Let $I \subset J$ be such that $J \setminus I \in \mathscr{T}$. Then

$$\mathrm{tr}_{H_I} \Pi_J = \Pi_I, \tag{II.3}$$

where tr_{H_I} denotes the partial trace over the factor H_I in the tensor product $H_J = H_I \otimes H_{J \setminus I}$ or $H_J = H_{J \setminus I} \otimes H_I$.

Note that the last condition implies, in particular, that $\mathrm{tr}\, \Pi_I = 1$. In other words, $\{\Pi_I\}_{I \in \mathscr{T}}$ is a *consistent* family of density matrices, and it can be thought of as a quantum mechanical counterpart of a consistent family of cylinder measures.

For each $I \in \mathscr{I}$ we define a state τ_I on A_I by

$$\tau_I(A) := \mathrm{tr}(A\Pi_I), \tag{II.4}$$

and observe that $|\tau_I(A)| \leqslant \|A\|$, uniformly in I. The consistency condition (II.3) implies that τ_I is well defined, and that the generalized limit $\tau(A) := \lim_{I \nearrow \mathbb{Z}} \tau_I(A)$ exists for all $A \in \mathsf{A}_{\mathrm{loc}}$, and satisfies $|\tau(A)| \leqslant \|A\|$. As a consequence, τ can be uniquely extended to a state on the $\mathbb{C}^*$-algebra A of quasilocal observables. We use the same symbol τ to denote this extension.

Let H, π be the GNS representation, see, e.g., Ref. 9, associated with the state τ. The Hilbert space H is the state space of the quantum source. If no confusion arises, we will write A instead of $\pi(A)$.

The additive group $\mathbb{Z}$ underlying the above construction plays the role of (discrete) time translations. Its action on the algebra of local observables is defined as follows:

$$A_I \ni A \simeq A \otimes I \to \alpha(A) := I \otimes A \simeq A \in A_{I+1}. \tag{II.5}$$

In other words, α pushes the observable to the right by one unit of time. Clearly, $\|\alpha(A)\| = \|A\|$, and so α has a unique extension to all of A, which we will denote by the same symbol. The family of automorphisms $\{\alpha^n\}_{n \in \mathbb{Z}}$ defines then a representation of $\mathbb{Z}$. The triple $(\mathsf{A}, \alpha, \tau)$ is called a *quantum source*.

We say that the quantum source is *stationary*, if the state τ is invariant under α, i.e.

$$\tau(\alpha(A)) = \tau(A), \tag{II.6}$$

for all $A \in \mathsf{A}$. From now on we will be assuming that our source is stationary. A standard result in operator algebras implies that the automorphism α is unitarily implementable on the GNS Hilbert space associated with the invariant state τ, i.e., $\alpha(A) = FAF^{-1}$ on H. We will call the unitary operator F a *quantum shift*.

Because of stationarity, we can always assume that $I \in \mathscr{I}$ is of the form $\{1,...,n\}$. To simplify the notation, we will write then Π_n instead of Π_I, and τ_n instead of τ_I.

C. Examples

The simplest example of a quantum source is a *Bernoulli source*, which we now describe. As in the classical case, a Bernoulli source produces messages that are sequences of independent signals. Accordingly, the family of density matrices $\{\Pi_I\}$ is given as follows:

$$\Pi_I = \otimes_{i \in I} \rho_i, \tag{II.7}$$

where each ρ_i equals ρ. It immediately follows that the consistency condition (II.3) is satisfied, and that the source is stationary. This is the class of sources considered by Schumacher.[2] One special feature of a Bernoulli source is that whenever $\mathrm{supp}(A) \cap \mathrm{supp}(B) = \varnothing$, we have $\tau(AB) = \tau(A)\,\tau(B)$.

There are many examples of non-Bernoulli sources. We present here a special class of stationary sources. These are all described by a signal density matrix ρ and another matrix $R \in \mathscr{L}(\mathscr{H} \otimes \mathscr{H})$ satisfying several consistency and positivity conditions. The most basic conditions are

$$R = R^*, \quad \mathrm{tr}_1((\rho \otimes I)R) = \rho, \quad \mathrm{tr}_2(R) = I. \tag{II.8}$$

Here I is the identity matrix on $\mathscr{H}$, and we introduce the notation tr_i for the partial trace over the ith factor in the n-fold tensor product $\otimes^n \mathscr{H}$. The density matrices $\{\Pi_n\}$ are then constructed recursively as follows:

$$\Pi_1 = \rho,$$

$$\Pi_{n+1} = \tfrac{1}{2}(\Pi_n \otimes I_1)(I_{n-1} \otimes R) + \tfrac{1}{2}(I_{n-1} \otimes R)(\Pi_n \otimes I_1).$$

We have denoted by I_n the identity matrix on the product $\otimes^n \mathscr{H}$. The consistency of this definition [(II.3)] is immediate. The positivity of the density matrices Π_n is a further constraint on R. We have several explicit examples for which the positivity can be proven.

In the simplest situation the matrix R satisfies the following additional conditions:

$$R \geqslant 0,$$

$$[\rho \otimes I_1, R] = 0,$$

$$[I_1 \otimes R, R \otimes I_1] = 0. \tag{II.9}$$

It follows readily that all the matrices Π_n are positive, for all $n \geqslant 1$. For example, suppose $\rho = \Sigma_{j=1}^{d} \lambda_j P_j$, where $\{\lambda_j\}$ are the eigenvalues of ρ, and $\{P_j\}$ are the corresponding orthogonal projections. Then we can take $R = \Sigma_{j=1}^{d} P_j \otimes P_j$, and all the above properties are easily seen to hold.

For our second example $\mathscr{H} = \mathbb{C}^2$, and we assume that ρ is strictly positive. Let $\{\sigma_j\}$ be the Pauli matrices:

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

By choosing a suitable basis we can write

$$\rho = \frac{1}{2} I + \frac{a}{2} \sigma_3, \tag{II.10}$$

where $|a| < 1$. Then we take the matrix R to be

$$R = I \otimes \rho + \left(\frac{a}{2} I - \frac{1}{2} \sigma_3 \right) \otimes (b\sigma_1 + c\sigma_2). \tag{II.11}$$

The consistency conditions are easily verified. Positivity of all matrices $\{\Pi_n\}$ holds for $|b|$, $|c|$ sufficiently small; the proof is given in the Appendix.

D. Reduction to classical source

The density matrix Π_n can also be written in terms of the states $\{\psi_j\}$ that span $\mathscr{S}$ [compare (II.1)] as follows:

$$\Pi_n = \sum_{1 \leqslant j_1, \ldots, j_n \leqslant s} p_{j_1, \ldots, j_n} |\psi_{j_1}\rangle\langle\psi_{j_1}| \otimes \cdots \otimes |\psi_{j_n}\rangle\langle\psi_{j_n}|.$$

The numbers $p_{j_1, \ldots, j_n}$ satisfy obvious consistency conditions. If the states $\{\psi_j\}$ are linearly independent, then they are also non-negative. Further, if the states are orthogonal, the density matrices $\{\Pi_n\}$ commute. In this case, the quantum source is equivalent to a classical source.

III. ERGODIC QUANTUM SOURCES

A. Definition

According to the individual ergodic theorem,[10] for any function $f \in L^1(\mathscr{X}^{\cdot\infty})$, the sequence of time averages

$$\langle f\rangle_N(\underline{x}) := \frac{1}{N}\sum_{0\leqslant n\leqslant N-1} f(T^n\underline{x}), \tag{III.1}$$

converges almost everywhere to a limit $\overline{f}$. The function $\overline{f}$ is invariant under T. The source $(\mathscr{X}^{\cdot\infty},T,\mu)$ is called *ergodic*, if the only functions invariant under T are constants. Consequently, for an ergodic source $\overline{f}=\int_{\mathscr{X}^{\cdot\infty}} f(\underline{x})\,d\mu(\underline{x})$. This condition is one of the several equivalent statements that could be used to define ergodicity; see, e.g., Ref. 10. There is no natural concept of convergence almost everywhere in quantum mechanics. Consequently, we adopt a notion of convergence that is natural for the algebra A. Our definition of ergodicity of a quantum source is specifically designed to suit the purposes of this paper, although it may have broader applications.

We say that a quantum source is *ergodic* if the following condition is satisfied. For any $A \in \mathsf{A}$, the time averages,

$$\langle A\rangle_N := \frac{1}{N}\sum_{0\leqslant n\leqslant N-1} F^nAF^{-n}, \tag{III.2}$$

converge in a suitable sense to the limit $\tau(A)I$, as $N\to\infty$. Specifically, we require weak convergence, i.e., for all $\phi,\ \psi\in H$,

$$\lim_{N\to\infty}(\phi,(\langle A\rangle_N-\tau(A)I)\psi)=0. \tag{III.3}$$

For $A\in\mathsf{A}$, we let $[A]$ denote the corresponding element of H. Substituting $\phi=[I]$ and $\psi=[B]$, $B\in\mathsf{A}_{\mathrm{loc}}$ in (III.3), we find that for an ergodic source,

$$\lim_{N\to\infty}\tau(\langle A\rangle_N B)=\tau(A)\tau(B), \tag{III.4}$$

for all $A,B\in\mathsf{A}_{\mathrm{loc}}$.

B. Bernoulli source

The simplest example of an ergodic source is a Bernoulli source.

Proposition III.1: A quantum Bernoulli source is ergodic.

Proof: Let $A,B,C\in\mathsf{A}_{\mathrm{loc}}$. We assert that

$$\tau(B^\dagger\langle A\rangle_N C)\to\tau(B^\dagger C)\tau(A), \tag{III.5}$$

which is equivalent to (III.3) with $\phi=[B]$, $\psi=[C]$. To prove this, we observe that there is n_0, such that

$$\tau(B^\dagger F^nAF^{-n}C)=\tau(F^nAF^{-n})\tau(B^\dagger C)=\tau(A)\tau(B^\dagger C),$$

for $n>n_0$ (this follows from the fact that the supports of A, B, and C are all finite). Consequently,

$$\tau(B^\dagger\langle A\rangle_N C)=\frac{1}{N}\sum_{0\leqslant n\leqslant n_0}\tau(B^\dagger F^nAF^{-n}C)+\frac{N-n_0-1}{N}\,\tau(A)\tau(B^\dagger C).$$

But

$$\frac{1}{N}\left|\sum_{0\leqslant n\leqslant n_0}\tau(B^\dagger F^n A F^{-n} C)\right| \leqslant \frac{n_0+1}{N}\,\|A\|\|B\|\|C\| \to 0,$$

and so $\lim_{N\to\infty}\tau(B^\dagger\langle A\rangle_N C)=\tau(A)\,\tau(B^\dagger C)$.

The remainder of the proof is a series of straightforward approximation arguments.

1°. We claim that (III.5) holds for all $A,B,C\in\mathsf{A}$. To prove this, observe that for all N,

$$\|\langle A\rangle_N\|\leqslant\|A\|. \tag{III.6}$$

For $A\in\mathsf{A}$, let $A_j\in\mathsf{A}_{\rm loc}$ be such that $\|A-A_j\|\to 0$, as $j\to\infty$. For any $B,C\in\mathsf{A}_{\rm loc}$, write

$$\begin{aligned}\tau(B^\dagger\langle A\rangle_N C-\tau(A)B^\dagger C)&=\tau(B^\dagger\langle A_j\rangle_N C-\tau(A_j)B^\dagger C)\\&\quad+\tau(B^\dagger\langle A-A_j\rangle_N C)+\tau(A_j-A)\,\tau(B^\dagger C),\end{aligned}$$

and choose j such that $\|A-A_j\|\leqslant\epsilon/(3\|B\|\|C\|)$. Now choose $N_0=N_0(j)$ such that $|\tau(B^\dagger\langle A_j\rangle_N C-\tau(A_j)B^\dagger C)|<\epsilon/3$, for all $N>N_0$. Then, using (III.6),

$$\begin{aligned}|\tau(B^\dagger\langle A\rangle_N C-\tau(A)B^\dagger C)|&<\epsilon/3+\|\langle A-A_j\rangle_N\|\|B\|\|C\|+\|A_j-A\|\|B\|\|C\|\\&<2\|A-A_j\|\|B\|+\epsilon/3\leqslant\epsilon,\end{aligned}$$

for all $N>N_0$. We have thus shown that (III.5) holds for all $A\in\mathsf{A}$ and $B,C\in\mathsf{A}_{\rm loc}$. Repeating twice almost *verbatim* the above 3ϵ argument we establish (III.5) for all $A,B,C\in\mathsf{A}$.

2°. Having established (III.3) for $\phi=[B]$, $\psi=[C]$, and $A\in\mathsf{A}$, we now show that it holds for arbitrary ϕ, $\psi\in\mathsf{H}$. Let $\phi\in\mathsf{H}$, and let B_j be such that $\|\phi-[B_j]\|<\epsilon/(2\|[C]\|\|A\|)$. Write

$$(\phi,(\langle A\rangle_N-\tau(A)I)[C])=([B_j],(\langle A\rangle_N-\tau(A)I)[C])+(\phi-[B_j],(\langle A\rangle_N-\tau(A)I)[C]),$$

and choose $N_0=N_0(j)$ so that $|([B_j],(\langle A\rangle_N-\tau(A)I)[C])|<\epsilon/2$, for all $N>N_0$. Then

$$|(\phi,(\langle A\rangle_N-\tau(A)I)[C])|<\epsilon/2+\|\phi-[B_j]\|\|[C]\|\|A\|<\epsilon.$$

Repeating this argument we establish (III.3) for all $\psi\in\mathsf{H}$. The proof of the proposition is complete.

IV. ENTROPY OF A QUANTUM SOURCE

A. Definition

In this section we construct the entropy of a quantum source. Our construction is largely standard; see, e.g., Refs. 11 and 12, but we include most of the details to make the presentation self-contained. The key mathematical input is the following lemma, known as Klein's inequality,[13] whose proof can be found in Ref. 12, as well as on p. 1122 of Ref. 11.

Lemma IV.1: Let A and B be positive trace class operators on a Hilbert space. Then

$$\mathrm{tr}(A\,\log A-A\,\log B)\geqslant\mathrm{tr}(A-B). \tag{IV.1}$$

We define the entropy associated with a sequence of n signals to be

$$H_n(\Pi):=-\mathrm{tr}_{\mathscr{H}^{\otimes n}}(\Pi_n\,\log\,\Pi_n). \tag{IV.2}$$

Substituting $A=\Pi_{m+n}$ and $B=\Pi_m\otimes\Pi_n$ in (IV.1), we obtain the following subadditivity property of $H_n(\Pi)$ (this is a special case of the well-known subadditivity of quantum mechanical entropy; see Ref. 11):

$$H_{m+n}(\Pi)\leqslant H_m(\Pi)+H_n(\Pi). \tag{IV.3}$$

A standard argument, see, e.g., Ref. 6, pp. 48–49, shows that the limit

$$h(\Pi)=\lim_{n\to\infty}\frac{1}{n}H_n(\Pi) \tag{IV.4}$$

exists. We call $h(\Pi)$ the entropy of the quantum source. Notice also that subadditivity implies the inequality

$$h(\Pi)\leqslant -\mathrm{tr}_{\mathscr{H}}(\rho\ \log\ \rho)\leqslant \log\ d. \tag{IV.5}$$

where ρ is the density matrix for the signals, and d is the dimension of the signal Hilbert space $\mathscr{H}$.

B. Examples

We can easily compute the entropy of two basic types of quantum sources introduced in Sec. II.

For a Bernoulli source, $\Pi_n=\rho\otimes\cdots\otimes\rho$, and so

$$\begin{aligned}\frac{1}{n}H_n(\Pi)&=-\frac{1}{n}\,\mathrm{tr}_{\mathscr{H}^{\otimes n}}((\otimes^n\rho)(\log\otimes^n\rho))\\&=-\frac{1}{n}\sum_{1\leqslant j\leqslant n}\mathrm{tr}_{\mathscr{H}^{\otimes n}}((\otimes^n\rho)(I\otimes\cdots\otimes\log\ \rho\otimes\cdots\otimes I))\\&=-\mathrm{tr}_{\mathscr{H}}(\rho\ \log\ \rho).\end{aligned}$$

As a result, $h(\Pi)=-\mathrm{tr}(\rho\ \log\rho)$, i.e., the entropy of a Bernoulli source is equal to the von Neumann entropy of the signal density matrix.

For the non-Bernoulli source defined in (II.9) a similar calculation yields $h(\Pi)=-\mathrm{tr}((\rho\otimes I)R\ \log R)$. We have not found a closed form expression for the entropy of the other non-Bernoulli source described in Sec. II.

V. ASYMPTOTIC EQUIPARTITION PROPERTY

A. Classical result

The classical asymptotic equipartition property, also known as the Shannon–McMillan theorem—see, e.g., Refs. 4 and 6—states that if $(\mathscr{X}^{\cdot\infty},T,\mu)$ is an ergodic source with entropy $h(\mu)$, then the sequence,

$$f_n(\underline{x}):=-\frac{1}{n}\log\ \mu(\{\underline{y}\in\mathscr{X}^{\cdot\infty}:y_1=x_1,\ldots,y_n=x_n\}), \tag{V.1}$$

converges in measure to $h(\mu)$. In other words, given $\delta,\epsilon>0$, there is n_0 such that for all $n\geqslant n_0$,

$$\mu(\{\underline{x}\in\mathscr{X}:|f_n(\underline{x})-h(\mu)|>\delta\})<\epsilon. \tag{V.2}$$

This is interpreted as saying that for any length n, there are two categories of messages sent by a source: (i) a small fraction of ''likely'' messages, each of which carries equal probability,

$$\mu(\{\underline{y}\in\mathscr{X}^{\infty}: y_1=x_1,\ldots,y_n=x_n\})\sim e^{-nh(\mu)}, \tag{V.3}$$

and (ii) the bulk of ''unlikely'' messages, whose total probability goes to zero as n goes to infinity. There are approximately $e^{nh(\mu)}$ likely messages, which is much less than the total number of messages $e^{n\log r}$ [unless $h(\mu)$ happens to equal $\log r$].

The goal of this section is to establish an analogous result for quantum sources. Our theorem generalizes Schumacher's result[2,3] to general, not necessary Bernoulli, sources.

B. POM

Let $\mathbf{A}=\{A_1,\ldots,A_r\}$, $r<\infty$ be a family of observables on $\mathscr{H}$ such that $A_j\geqslant 0$, for all j, and

$$A_1+\cdots+A_r=I. \tag{V.4}$$

Such a family is called a *positive operator-valued measure* (POM); see Ref. 7 and references therein. A POM is called *pure* if each A_J is a rank one operator. For example, any family of $d=\dim\mathscr{H}$ pairwise orthogonal projections on $\mathscr{H}$ satisfies the above conditions, and so is a pure POM. We will call the set $\mathscr{X}_{\mathbf{A}}=\{1,...,r\}$ the classical alphabet associated with the POM $\mathbf{A}$, and denote by $\mathscr{X}_{\mathbf{A}}^{\infty}$ the space of all infinite messages over the alphabet $\mathscr{X}_{\mathbf{A}}$. We can define a probability measure on $\mathscr{X}_{\mathbf{A}}^{\infty}$ associated with the quantum source $(\mathbf{A},\tau,\alpha)$. For $\{k_1,\ldots,k_n\}\in\mathscr{X}^n$, we define

$$\mu_n^{\mathbf{A}}(\{\underline{x}: x_1=k_1,\ldots,x_n=k_n\}):=\tau_n(A_{k_1}\otimes\cdots\otimes A_{k_n}). \tag{V.5}$$

This defines a consistent family of cylinder measures, as

$$\sum_{k\in\mathscr{X}_{\mathbf{A}}}\mu_{n+1}^{\mathbf{A}}(\{\underline{x}: x_1=k_1,\ldots,x_n=k_n,x_{n+1}=k\})=\tau_{n+1}\left(A_{k_1}\otimes\cdots\otimes A_{k_n}\otimes\sum_{k\in\mathscr{X}_{\mathbf{A}}}A_k\right)=\tau_{n+1}(A_{k_1}\otimes\cdots$$
$$\otimes A_{k_n}\otimes I)=\tau_n(A_{k_1}\otimes\cdots\otimes A_{k_n})=\mu_n^{\mathbf{A}}(\{\underline{x}: x_1=k_1,\ldots,x_n=k_n\}).$$

Let $\mu^{\mathbf{A}}$ denote the probability measure obtained from $\{\mu_n^{\mathbf{A}}\}$ by means of Kolmogorov's extension theorem. By T we denote the shift operator on $\mathscr{X}_{\mathbf{A}}^{\infty}$. Then the triple $(\mathscr{X}_{\mathbf{A}}^{\infty},T,\mu^{\mathbf{A}})$ forms a classical information source. We emphasize that it depends on the choice of $\mathbf{A}$. Obviously, this source is stationary.

C. Classical ergodicity from quantum

In fact, this source is ergodic if the underlying quantum source is ergodic. We state it as the following lemma.

Lemma V.1: If (A,α,τ) *is ergodic, then for any choice of* $\mathbf{A}$, *the classical source constructed above is ergodic.*

Proof: We show that $(\mathscr{X}_{\mathbf{A}}^{\infty},T,\mu^{\mathbf{A}})$ has the following property: for every $f\in L^1(\mathscr{X}^{\infty},d\mu^{\mathbf{A}})$, the sequence $\langle f\rangle_N$ converges in L^1 to $\int f\,d\mu^{\mathbf{A}}$. Using Fatou's lemma, and recalling the individual ergodic theorem, this implies that the only functions invariant under T are constants, and so the classical source is ergodic. We first observe that it is sufficient to show that if $\mathscr{C}$ is a cylinder set, and $\chi_{\mathscr{C}}$ denotes the corresponding characteristic function, then

$$\int_{\mathscr{X}_{\mathbf{A}}^{\infty}}|\langle\chi_{\mathscr{C}}\rangle_N(\underline{x})-\mu^{\mathbf{A}}(\mathscr{C})|\,d\mu^{\mathbf{A}}(\underline{x})\to 0, \tag{V.6}$$

as $N\to\infty$. A standard ''$\epsilon/3$'' argument then implies that for all $f\in L^1(\mathscr{X}^{\infty},d\mu^{\mathbf{A}})$, $\langle f\rangle_N$ converges to $\int f\,d\mu^{\mathbf{A}}$ in the L^1 norm. Furthermore, since $d\mu^{\mathbf{A}}$ is a probability measure, (V.6) will follow

from convergence of $\langle \chi_{\mathscr{C}} \rangle_N$ to $\mu^{\mathbf{A}}(\mathscr{C})$ in the L^2 norm. This in turn is implied by the following stronger result. Suppose $\mathscr{C}$ and $\mathscr{D}$ are cylinder sets, and $\chi_{\mathscr{C}}$ and $\chi_{\mathscr{D}}$ are the corresponding characteristic functions; then

$$\int_{\mathscr{X}_{\mathbf{A}}^{\infty}} \langle \chi_{\mathscr{C}} \rangle_N(\underline{x}) \chi_{\mathscr{D}}(\underline{x}) d\mu^{\mathbf{A}}(\underline{x}) \to \mu^{\mathbf{A}}(\mathscr{C}) \mu^{\mathbf{A}}(\mathscr{D}), \tag{V.7}$$

as $N \to \infty$.

In order to prove (V.7), let $\mathscr{C} = \{\underline{x} : x_1 = k_1, \ldots, x_n = k_n\}$, $\mathscr{D} = \{\underline{x} : x_{j+1} = l_1, \ldots, x_{j+m} = l_m\}$. The corresponding observables are given by

$$G(\mathscr{C}) = A_{k_1} \otimes \cdots \otimes A_{k_n}, \quad G(\mathscr{D}) = A_{l_1} \otimes \cdots \otimes A_{l_m}.$$

There is N_0 such that for all $n > N_0$, $T^n(\mathscr{C}) \cap \mathscr{D} = \varnothing$. Therefore,

$$\frac{1}{N} \int_{\mathscr{X}_{\mathbf{A}}^{\infty}} \sum_{i=N_0+1}^{N-1} \mathscr{X}_{\mathscr{C}}(T^i \underline{x}) \mathscr{X}_{\mathscr{D}}(\underline{x}) d\mu^{\mathbf{A}}(\underline{x}) = \frac{1}{N} \tau\left(\sum_{i=N_0+1}^{N-1} \alpha^i(G(\mathscr{C})) G(\mathscr{D}) \right)$$

$$= \tau(\langle G(\mathscr{C}) \rangle_N) G(\mathscr{D})) - \frac{1}{N} \tau\left(\sum_{i=0}^{N_0} \alpha^i(G(\mathscr{C})) G(\mathscr{D}) \right).$$

By our assumption of quantum ergodicity, the first term above converges to $\mu^{\mathbf{A}}(\mathscr{C}) \mu^{\mathbf{A}}(\mathscr{D})$, as $N \to \infty$. The second term is bounded as follows:

$$\left| \frac{1}{N} \tau\left(\sum_{i=0}^{N_0} \alpha^i(G(\mathscr{C})) G(\mathscr{D}) \right) \right| \leqslant \frac{N_0 + 1}{N} \prod_{p=1}^{n} \|A_{k_p}\| \prod_{q=1}^{l} \|A_{l_q}\|,$$

which converges to 0 as $N \to \infty$. Finally,

$$\frac{1}{N} \int_{\mathscr{X}_A^{\infty}} \sum_{i=0}^{N_0} \chi_{\mathscr{C}}(T^i \underline{x}) \chi_{\mathscr{D}}(\underline{x}) d\mu^A(\underline{x}) \geqslant \frac{N_0 + 1}{N} \to 0,$$

and the proof is complete.

D. Bounds for the entropy

Let $h_{\mathbf{A}}$ denote the Shannon entropy of the classical source $(\mathscr{X}_{\mathbf{A}}^{\infty}, T, \mu^{\mathbf{A}})$ (Refs. 5 and 6). In other words,

$$h_{\mathbf{A}} = -\lim_{n \to \infty} \frac{1}{n} \sum_{k_1, \ldots, k_n \in \mathscr{X}_{\mathbf{A}}} \mu_{\mathbf{A}}(\{\underline{x} : x_1 = k_1, \ldots, x_n = k_n\}) \times \log \mu_{\mathbf{A}}(\{\underline{x} : x_1 = k_1, \ldots, x_n = k_n\})$$

$$= -\lim_{n \to \infty} \frac{1}{n} \sum_{k_1, \ldots, k_n \in \mathscr{X}_{\mathbf{A}}} \tau(A_{k_1} \otimes \cdots \otimes A_{k_n}) \log \tau(A_{k_1} \otimes \cdots \otimes A_{k_n}).$$

A remarkable fact about $h_{\mathbf{A}}$ is that it can be bounded from below in terms of $h(\Pi)$, the quantum entropy of the source, and a quantity depending exclusively on the statistical properties of the signal ensemble.

Theorem V.2: *For any POM* **A** *the following inequality holds*:

$$h_{\mathbf{A}} \geqslant h(\Pi) - \sum_{1 \leqslant k \leqslant r} \operatorname{tr}(A_k \rho) \log \operatorname{tr}(A_k). \tag{V.8}$$

Remark: In particular, if **A** is a pure POM consisting of d mutually orthogonal projections, then $h_{\mathbf{A}} \geqslant h(\Pi)$.

Proof: The proof of this theorem is based on the following lemma.

Lemma V.3: Let $\mathscr{F}$ be a Hilbert space of finite dimension N, and let B be a density matrix on $\mathscr{F}$. If $A_1,\ldots,A_r$ are positive operators such that $A_1+\cdots+A_r=I$, then

$$\sum_{1 \leqslant j \leqslant r} \operatorname{tr}(A_j B) \log \operatorname{tr}(A_j B) \leqslant \operatorname{tr}(B \log B) + \sum_{1 \leqslant j \leqslant r} \operatorname{tr}(A_j B) \log \operatorname{tr}(A_j). \tag{V.9}$$

Proof: Let A_j^{kl} denote the matrix entries of A_j in an orthonormal basis consisting of eigenvectors of B. Then $\operatorname{tr}(A_j B) = \Sigma_k \, \lambda_k A_j^{kk}$, where $\lambda_1,\ldots,\lambda_N$ are the eigenvalues of B. The function $[0,1] \ni x \to f(x) := x \log x$ is convex, and so by Jensen's inequality,

$$\begin{aligned}
\sum_j f\left(\sum_k \lambda_k A_j^{kk} \right) &= \sum_j \operatorname{tr}(A_j) f\left(\sum_k \frac{A_j^{kk}}{\operatorname{tr}(A_j)} \lambda_k \right) + \sum_j \sum_k \frac{A_j^{kk}}{\operatorname{tr}(A_j)} \lambda_k f(\operatorname{tr}(A_j)) \\
&\leqslant \sum_j \sum_k A_j^{kk} f(\lambda_k) + \sum_j \operatorname{tr}(A_j B) \log \operatorname{tr}(A_j) \\
&= \sum_k f(\lambda_k) + \sum_j \operatorname{tr}(A_j B) \log \operatorname{tr}(A_j),
\end{aligned}$$

which implies (V.9).

As a consequence of this lemma, and condition 3° in the definition of a consistent family of density matrices,

$$\begin{aligned}
&\sum_{k_1,\ldots,k_n \in \mathscr{X}_{\mathbf{A}}} \operatorname{tr}((A_{k_1} \otimes \cdots \otimes A_{k_n}) \Pi_n) \log \operatorname{tr}((A_{k_1} \otimes \cdots \otimes A_{k_n} \Pi_n)) \\
&\quad \leqslant \operatorname{tr}(\Pi_n \log \Pi_n) + \sum_{k_1,\ldots,k_n \in \mathscr{X}_{\mathbf{A}}} \operatorname{tr}((A_{k_1} \otimes \cdots \otimes A_{k_n}) \Pi_n) \log \operatorname{tr}(A_{k_1} \otimes \cdots \otimes A_{k_n}) \\
&\quad = \operatorname{tr}(\Pi_n \log \Pi_n) + \sum_{1 \leqslant j \leqslant n} \sum_{k_1,\ldots,k_n \in \mathscr{X}_{\mathbf{A}}} \operatorname{tr}((A_{k_1} \otimes \cdots \otimes A_{k_n}) \Pi_n) \log \operatorname{tr}(A_{k_j}) \\
&\quad = \operatorname{tr}(\Pi_n \log \Pi_n) + n \sum_{1 \leqslant k \leqslant r} \operatorname{tr}(A_k \rho) \log \operatorname{tr}(A_k),
\end{aligned}$$

and the claim follows.

E. Main theorem

The theorem below is the main result of this section. It can be regarded as a quantum version of the Shannon–McMillan theorem.

Theorem V.4: *Let (A,τ,α) be an ergodic source, and let* **A** *be a POM, for which the operators $\{A_j\}$, $1 \leqslant j \leqslant r$, are orthogonal projections. Let $h_{\mathbf{A}}$ be the Shannon entropy of the associated classical source, and define*

$$M = \max_{1 \leqslant j \leqslant r} \operatorname{rank}(A_j), \quad m = \min_{1 \leqslant j \leqslant r} \operatorname{rank}(A_j).$$

Then, given $\delta,\epsilon>0$, *there is* n_0, *such that for all* $n\geqslant n_0$,

$$\mathscr{H}^{\otimes n}=\mathscr{S}_n\oplus\mathscr{S}_n^{\perp},$$

where $\mathscr{S}_n$ *is a subspace whose dimension satisfies*

$$\frac{\log m-\delta}{\log d}\leqslant\frac{\log\dim\mathscr{S}_n}{\log\dim\mathscr{H}^{\otimes n}}-\frac{h_{\mathbf{A}}}{\log d}\leqslant\frac{\log M+\delta}{\log d}. \tag{V.10}$$

Further, let $P_{\mathscr{S}_n}$ *be the orthogonal projection onto* $\mathscr{S}_n$. *Then for any observable* $C\in\mathscr{L}(\mathscr{H}^{\otimes n})$,

$$|\tau(CP_{\mathscr{S}_n})-\tau(C)|<\epsilon\|C\|. \tag{V.11}$$

Remark 1: We can regard $\mathscr{S}_n$ as a significant subspace of $\mathscr{H}^{\otimes n}$ in the sense that the expectation of any observable is almost completely determined by its restriction to $\mathscr{S}_n$. If the states $\{|\psi_j\rangle\}$ are orthogonal, we can take the d orthogonal projections $\{|\psi_j\rangle\langle\psi_j|\}$ for the POM. In this case the entropy $h_{\mathbf{A}}$ is equal to the von Neumann entropy, since the density operators all commute. Then there is a direct correspondence with the classical Shannon–McMillan theorem, and the quantum theory is just a restatement of the classical result.

Remark 2: In the Bernoulli case we can take the POM $\mathbf{A}$ to be d orthogonal projections onto the eigenvectors of ρ, in which case the inequality of Theorem V.2 is saturated. If ρ has a simple spectrum, this means that the Shannon entropy equals the von Neumann entropy of the quantum source. Our result then agrees with Schumacher's conclusion that the information contained in the quantum source resides in a subspace whose dimension is asymptotically $e^{nh_{\mathbf{A}}}$. In the general case we obtain only an upper bound for the dimension of the relevant subspace, and this upper bound depends on the choice of POM. For example, if each operator A_j in the POM $\mathbf{A}$ is equal to $(1/d)I$, where I is the identity, then the Shannon entropy is $h_{\mathbf{A}}=\log d$. Since this is the maximum possible entropy for a POM with d operators, we can conclude that all information about the quantum source has been lost in this measurement process. As these results show, it is advantageous to use a POM composed of orthogonal projections.

Proof: we use the POM to construct the classical source $\mathscr{X}_{\mathbf{A}}^{\infty}$ with entropy $h_{\mathbf{A}}$. Let $f_n(\underline{x})$ be the empirical entropy of a message $\underline{x}$ of length n defined in (V.1). Given $\epsilon,\delta>0$, let us define the sets

$$U_{n,\delta}=\{\underline{x}\in\mathscr{X}:|f_n(\underline{x})-h_{\mathbf{A}}|>\delta\},$$

$$L_{n,\delta}=\{\underline{x}\in\mathscr{X}:|f_n(\underline{x})-h_{\mathbf{A}}|\leqslant\delta\}.$$

By the Shannon–McMillan theorem, given $\epsilon,\delta>0$, there is n_0, such that for all $n\geqslant n_0$,

$$\sum_{\mathbf{x}\in U_{n,\delta}}\mu_{\mathbf{A}}(\{\underline{x}\})<\epsilon.$$

Since the operators $\{A_j\}$ are orthogonal projections, each tensor product $A_{k_1}\otimes\cdots\otimes A_{k_n}$ is an orthogonal projection, and hence so is the sum of these operators over the set $L_{n,\delta}$. Let $\mathscr{S}_n$ denote the range of this projection, and let $P_{\mathscr{S}_n}$ denote the orthogonal projection onto this subspace. Then for any observable C, we have

$$|\tau(CP_{\mathscr{S}_n})-\tau(C)|\leqslant\epsilon\|C\|.$$

It remains to estimate the dimension of $\mathscr{S}_n$. Since the projections $\{A_j\}$ are orthogonal, its dimension is given by

$$\dim(\mathscr{S}_n)=\sum_{\mathbf{x}\in L_{n,\delta}}\prod_{j=1}^{n}\operatorname{rank}(A_{x_j}).$$

Therefore,

$$m^n|L_{n,\delta}|\leqslant\dim(\mathscr{S}_n)\leqslant M^n|L_{n,\delta}|,$$

where $|L_{n,\delta}|$ is the size of the set $L_{n,\delta}$. The Shannon–McMillan theorem implies that

$$(1-\epsilon)e^{n(h_{\mathbf{A}}+\delta)}\geqslant|L_{n,\delta}|\geqslant e^{n(h_{\mathbf{A}}-\delta)}.$$

This leads to

$$\frac{\log m}{\log d}-\frac{\delta}{\log d}\leqslant\frac{\dim(\mathscr{S}_n)}{n\log d}-\frac{h_{\mathbf{A}}}{\log d}\leqslant\frac{\log M}{\log d}+\frac{\delta}{\log d}+\frac{\log(1-\epsilon)}{n},$$

and the result follows.

APPENDIX: PROOF OF POSITIVITY

We present here the proof that the R matrix (II.11) defines a family of positive density matrices, when $|b|$ and $|c|$ are sufficiently small. It is convenient to introduce the matrices

$$\omega=\frac{a}{2}\,I-\frac{1}{2}\,\sigma_3,$$

$$Q=\rho^{-1}(b\sigma_1+c\sigma_2).$$

Note that we assume $|a|<1$, so ρ^{-1} exists. Then for all $n\geqslant 2$ we define

$$S_n=I_{n-2}\otimes\omega\otimes Q.$$

It follows by direct calculation that for all $n\geqslant 1$,

$$\Pi_{n+1}=\Pi_n\otimes\rho+\tfrac{1}{2}(\Pi_n\otimes\rho)S_{n+1}+\tfrac{1}{2}S_{n+1}^{\dagger}(\Pi_n\otimes\rho).$$

In order to proceed we make the inductive assumption that $\Pi_n>0$; this implies, in particular that $(\Pi_n+u)^{-1}$ is bounded for every $u\geqslant 0$. We will prove that $(\Pi_{n+1}+u)^{-1}$ is bounded for every $u\geqslant 0$; together with the positivity of $\Pi_1=\rho$, this will establish the desired result.

Note first that $\|S_n\|\leqslant\|\omega\|\|Q\|$, and this bound is uniform in n. For convenience we define

$$w=\|\omega\|,\quad q=\|Q\|.$$

Furthermore, for any $u\geqslant 0$,

$$(\Pi_{n+1}+u)^{-1}=(\Pi_n\otimes\rho+u)^{-1}(I+\tfrac{1}{2}(\Pi_n\otimes\rho)S_{n+1}(\Pi_n\otimes\rho+u)^{-1}$$
$$+\tfrac{1}{2}S_{n+1}^{\dagger}(\Pi_n\otimes\rho)(\Pi_n\otimes\rho+u)^{-1})^{-1}.$$

Our inductive assumption implies that $(\Pi_n\otimes\rho+u)^{-1}$ is bounded for $u\geqslant 0$. Choosing $|b|$, $|c|$ sufficiently small guarantees that $\|S_n^{\dagger}\|<\epsilon$ for any $\epsilon>0$. Furthermore,

$$(\Pi_n\otimes\rho)S_{n+1}(\Pi_n\otimes\rho+u)^{-1}=([\Pi_n(I_{n-1}\otimes\omega)\Pi_n^{-1}]\otimes Q^{\dagger})(\Pi_n\otimes\rho)(\Pi_n\otimes\rho+u)^{-1}.$$

Since $\|Q^{\dagger}\|=q$ can be made arbitrarily small by choosing $|b|$, $|c|$ sufficiently small, the boundedness of $(\Pi_{n+1}+u)^{-1}$ will follow from a bound for the operator $\Pi_n(I_{n-1}\otimes\omega)\Pi_n^{-1}$, which is uniform in n. Accordingly let us define for $n\geqslant 1$,

$$A_n=\Pi_n(I_{n-1}\otimes\omega)\Pi_n^{-1}.$$

By imitating the derivation above, we obtain the recursion relation

$$A_n=(I+\tfrac{1}{2}A_{n-1}\otimes Q^{\dagger}+\tfrac{1}{2}S_n^{\dagger})(I_{n-1}\otimes\omega)(I+\tfrac{1}{2}A_{n-1}\otimes Q^{\dagger}+\tfrac{1}{2}S_n^{\dagger})^{-1}. \tag{A.1}$$

It is immediate that $\|A_1\|=\|\omega\|\leqslant 1$. We make the inductive assumption that $\|A_{n-1}\|\leqslant 1$; then (A1) implies the estimate

$$\|A_n\|\leqslant\left(1+\frac{q}{2}+\frac{wq}{2}\right)w\left(1-\frac{q}{2}-\frac{wq}{2}\right)^{-1}. \tag{A.2}$$

If we choose

$$q<2\frac{1-w}{(1+w)^2}, \tag{A.3}$$

then (A2) implies that $\|A_n\|\leqslant 1$. Hence by choosing (A3) we obtain that A_n is uniformly bounded for all n, and hence that $(\Pi_{n+1}+u)^{-1}$ is bounded for all $u\geqslant 0$. Therefore the positivity of the density matrices is proved.

We show that the one-dimensional projection of Chern–Simons gauged nonlinear Schrödinger model is equivalent to an Abelian gauge field theory of a continuum Heisenberg spin chain. In such a theory, the matter field has geometrical meaning of coordinates in tangent plane to the spin phase space, while the $U(1)$ gauge symmetry relates to rotation in the plane. This allows us to construct the infinite hierarchy of integrable gauge theories and related magnetic models. To each of them a $U(1)$ invariant gauge fixing constraint of non-Abelian BF theory is derived. The corresponding moving frames hierarchy is obtained and the spectral parameter is interpreted as a constant-valued statistical gauge potential constrained by the 1-cocycle condition. © *1998 American Institute of Physics.*

I. INTRODUCTION

The nonlinear Schrödinger equation (NLS) in two space dimensions interacting with Abelian Chern–Simons gauge field (the Jackiw–Pi model) has attracted much attention recently due to the beautiful structure of the static limit, admitting N-soliton solution.[1] After quantization these solitons become quasiparticles with arbitrary statistics, called anyons, while the Chern–Simons gauge field is interpreted as the ''statistical'' one. The anyons have an interesting application to the planar physical phenomena as the Quantum Hall Effect.[2,3] Very recently, attempts to study the generalized statistics of many particle systems in $1+1$ dimensions and the relation with $2+1$-dimensional anyons were done.[4–6] For configurations depending of the one space direction (the *lineal* theory), the reduced theory describes $1+1$-dimensional NLS, interacting with an Abelian BF gauge field. Due to the pure gauge form it is possible to exclude this field from the gauge-invariant description. However, since in one dimension NLS is an integrable system, an interesting problem of the relation between a long-range structure of the statistical gauge field in two and integrability in one dimensions arises.

In the present paper we show that the ''trivial'' gauge field plays the crucial role for integrability of the NLS model. Namely, the homogeneous statistical gauge field is identical to the spectral parameter for the NLS linear problem. Our construction is based on a mapping of the reduced Jackiw–Pi model to non-Abelian BF gauge theory. This mapping has to appear as the gauge fixing condition corresponding to the classical Heisenberg spin model. Then, the matter field has the geometrical meaning of coordinates in tangent to the spin phase space plane, while $U(1)$ gauge symmetry relates to the rotation in the plane.

In Sec. I we consider dimensional reduction of the Jackiw–Pi model. We find a representation of the model as a $U(1)$-invariant gauge fixing condition of non-Abelian BF theory. This allows us to construct an infinite hierarchy of associated integrable models and the related gauge fixing constraints. In Sec. II we show that the model has natural interpretation as the gauge theory of a continuum Heisenberg model defined on the sphere S^2 or hyperboloid $S^{1,1}$, according to the sign

of nonlinearity. Then, we derive the associated Heisenberg and moving frame hierarchies. Section III is devoted to a $U(1)$ gauge-invariant description of integrable time hierarchy in the BF theory context. We show that the B field plays the role of squared eigenfunctions for the Zakharov–Shabat linear problem. In terms of the recursion operator eigenvalue problem, the hierarchy of constraints is related to the evolution hierarchy and higher Poisson structures. In the Conclusion we discuss the chiral solitons for odd members of the hierarchy and some open problems.

II. THE JACKIW–PI MODEL IN 1+1 DIMENSIONS

The Lagrangian of a $2+1$-dimensional nonlinear Schrödinger model interacting with a Chern–Simons gauge field is[1]

$$\mathscr{L}=\frac{i}{2}\,(\overline{\psi}\,D_0\psi-\overline{D_0\psi}\,\psi)-\overline{D_1\psi}\,D_1\psi-\overline{D_2\psi}\,D_2\psi+g|\psi|^4+\frac{k}{4}\,\epsilon^{\mu\nu\lambda}A_\mu\,\partial_\nu\,A_\lambda\,, \tag{2.1}$$

where $\psi=\psi(x_1,x_2,t)$ is complex matter and $A_\mu=A_\mu(x_1,x_2,t)$, $(\mu=0,1,2)$, is a $U(1)$ Abelian (statistical) gauge field. Here, $D_\mu=\partial_\mu-(i/2)A_\mu$, denotes the covariant derivative, g and k are the self-interaction and the Chern–Simons coupling constants, respectively. The related Euler–Lagrange equations of motion are

$$i\,D_0\psi+(D_1^2+D_2^2)\psi+2g|\psi|^2\psi=0, \tag{2.2a}$$

$$\epsilon^{ij}\,\partial_i A_j=-\frac{1}{k}\,|\psi|^2, \tag{2.2b}$$

$$\partial_0 A_i-\partial_i A_0=-\frac{i}{k}\,\epsilon^{ij}(\overline{D_j\psi}\,\psi-\overline{\psi}\,D_j\psi),(i,j=1,2). \tag{2.2c}$$

In the special case when the coupling constants connected by the relation $g=1/k$, the static configurations of this model are subject to the self-dual Chern–Simons equations.[1] The last one admits the linear representation[7] and has been related to the Liouville model with N-vortex/soliton solutions.[1] However, there is no evidence that dynamics of these solitons according to Eqs. (2.2) is also integrable. Recently,[8] the integrable dynamics of the Chern–Simons solitons has been described by the Davey–Stewartson equation, being considered as the $2+1$-dimensional extension of the NLS. Furthermore, it is shown below that model (2.1) reduced to $1+1$ dimension is also integrable. The corresponding soliton dynamics subject to the NLS.

Let us consider the boundary as a rectangle on the plane. Then, the boundary dynamics of (2.1) is described by the $1+1$ reduced model. For the x_2-independent part we obtain the Lagrangian,

$$\mathscr{L}=\frac{i}{2}\,(\overline{\psi}\,D_0\psi-\overline{D_0\psi}\,\psi)-\overline{D_1\psi}\,D_1\psi-\frac{1}{4}\,B^2\overline{\psi}\psi+g|\psi|^4+\frac{k}{4}\,B\epsilon^{\mu\nu}F_{\mu\nu}, \tag{2.3}$$

where $B\equiv A_2$ is the gauge field component in the compactified direction, and $F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu$ $(\mu=0,1)$. For the vanishing matter field $\psi=0$, this Lagrangian reduces to a pure Abelian BF theory and this is why the model (2.3) can be considered as the $1+1$-dimensional BF gauged NLS. Due to the nonpropagating character, the gauge field can be eliminated from (2.3). Nevertheless, as we can see below, (2.3) is equivalent to the classical spin model and the statistical gauge potential carries an important information about the spectrum of the model. Moreover, when $\psi\neq 0$, the model (2.3) still is the BF theory, however, for a non-Abelian gauge group in a special gauge.

To proceed first we redefine gauge potentials (and the related covariant derivatives) as

$$W_0 \equiv A_0 - \frac{1}{2} B^2, \quad W_1 \equiv A_1 . \tag{2.4}$$

Then, the Lagrangian (2.3) becomes

$$\mathscr{L} = \frac{i}{2} (\overline{\psi} D_0 \psi - \overline{D_0 \psi}\, \psi) - \overline{D_1 \psi} D_1 \psi + g |\psi|^4 + \frac{k}{4} B \epsilon^{\mu\nu} F_{\mu\nu} + \Delta \mathscr{L}, \tag{2.5}$$

where

$$\Delta \mathscr{L} = - \frac{k}{6} \partial_1 B^3, \tag{2.6}$$

is the total derivative (which becomes nontrivial at the boundaries) and does not influence equations of motion. The Euler–Lagrange equations for (2.5) are given by the system

$$i\ D_0 \psi + D_1^2 \psi + 2g |\psi|^2 \psi = 0, \tag{2.7a}$$

$$\partial_0 W_1 - \partial_1 W_0 = 0, \tag{2.7b}$$

and

$$\partial_1 B = - \frac{1}{k} |\psi|^2, \tag{2.8a}$$

$$\partial_0 B = \frac{i}{k} (\overline{D_1 \psi}\, \psi - \overline{\psi} D_1 \psi), \tag{2.8b}$$

where $D_\mu = \partial_\mu - i/2 W_\mu$. Equations (2.7) are exactly the gauged NLS model (or the Heisenberg model in the tangent space form), while (2.8) are the defining relations for B (the trace of higher dimension) in terms of the charge conservation law. However, Eq. (2.8a)—the reduced Chern–Simons Gauss law—is more fundamental than (2.8b). Indeed, Eqs. (2.7) imply the charge conservation law

$$\partial_0 |\psi|^2 + i \partial_1 (\overline{D_1 \psi}\, \psi - \overline{\psi} D_1 \psi) = 0. \tag{2.9}$$

Then, Eq. (2.8b) arises from the Gauss law (2.8a) and (2.9) in a similar way to the Chern–Simons theory.[1] In other words, Eqs. (2.8) guarantee the existence of the first conservation law for (2.7). In fact, the dual current $C_\mu = \epsilon_{\mu\nu}\, \partial_\nu B$, due to (2.8), is conserved.

The above systems (2.7) and (2.8) are invariant under $U(1)$ gauge transformations,

$$\psi \to \psi e^{i\alpha}, \quad A_0 \to A_0 + 2\, \partial_0 \alpha, \quad A_1 \to A_1 + 2\, \partial_1 \alpha, \tag{2.10}$$

preserving the B field: $B \to B$. From the Lagrangian (2.5) we recognize that the B field plays the role of the Lagrange multiplier for the zero strength constraint (2.7b). Moreover, according to the one-dimensional Chern–Simons (or better to say the BF) Gauss law (2.8a), creation of a particle at a point on the line, where $|\psi|^2 \neq 0$, is accompanied with creation of the local B field gradient. This gradient represents a one-dimensional analog of the statistical magnetic field. For vanishing ψ, the B field is homogeneous, and defined up to the additive constant. Integrating (2.8a) along the x_1 line, then we obtain

$$B(+\infty)-B(-\infty)=-\frac{1}{k}\int_{-\infty}^{+\infty}|\psi|^2\,dx_1. \tag{2.11}$$

For nontrivial charged configurations (solitons) the right-hand side (rhs) does not vanish and the related B field takes the shift on the boundaries.

Actually, Eqs. (2.7) are the $1+1$-dimensional analog of the Ginzburg–Landau equations for a superconductor in the vanishing electric field, $E=\partial_0 A_1-\partial_1 A_0=0$. An important consequence of the gauge invariance (2.10) is that (2.7a) is independent of the local gauge transformations parameter $\alpha=\alpha(x,t)$. This property can be considered as a generalization of the well-known isospectrality condition for integrable systems. Indeed, the second equation (2.7) allows one to exclude the potentials A_0 and A_1 by $U(1)$ gauge transformation. Due to (2.7b) a real function $\phi(x,t)$ exists such that $A_\mu=2\,\partial_\mu\phi$. Then, we define new $\Psi=\psi e^{i\phi}$, subject to the Nonlinear Schrödinger equation,

$$i\,\partial_0\Psi+\partial_1^2\Psi+2g|\Psi|^2\Psi=0. \tag{2.12}$$

This equation admits an infinite number of conservation laws. The conservation law (2.9) in terms of Ψ is the first member of this hierarchy, having a physical meaning of the charge (number of particles) conservation.

In a traditional approach the NLS integrability follows from the Lax pair or the Zero Curvature representation with a constant spectral parameter, of which the NLS is independent (isospectrality).[9] This fact can be explained now as the consequence of a $U(1)$ gauge invariance of the gauged NLS (2.7).

The integrability of (2.7) becomes transparent if we represent the self-interaction term in a pure geometrical way. Thus, for redefined fields,

$$V_0=W_0+4g|\psi|^2,\quad V_1=W_1, \tag{2.13}$$

Eqs. (2.7) have the form

$$i\,D_0\psi+D_1^2\psi=0, \tag{2.14a}$$

$$\partial_0 V_1-\partial_1 V_0=-4g\partial_1|\psi|^2, \tag{2.14b}$$

of the linear Schrödinger equation (the quantum mechanics) in the electric field proportional to the gradient of the local particles density. The system (2.14) is equivalent to the following one:

$$D_0\psi=D_1\psi_0, \tag{2.15a}$$

$$[D_0,D_1]=2g(\overline{\psi}\psi_0-\overline{\psi_0}\psi), \tag{2.15b}$$

with the constraint,

$$\psi_0=i\,D_1\psi. \tag{2.16}$$

The above equations (2.15) define the constant curvature surface with the scalar curvature equal to coupling constant g. In fact, we can show that if ψ and ψ_0 are the zweibein fields, then the first equation (2.15a) is the torsionless condition for definition of the spin connection, identified with the Abelian gauge field V_μ. Then, the the second equation is just the constant curvature condition,

$$R=g, \tag{2.17}$$

where R is the scalar curvature, written in terms of zweibeins and the spin connection. The model (2.17) is known as the Jackiw–Teitelboim lineal gravity,[10] while (2.15) as the BF gauge theoretical formulation of it in terms of the Einstein–Cartan variables.[11] The system (2.15) appears as the Euler–Lagrange equations for the BF action (4.1), discussed in Sec. IV. Depending on the sign of g the corresponding BF theory has non-Abelian SU(2), $(g=1)$, or SU(1,1), $(g=-1)$, gauge group. Thus, the reduced Jackiw–Pi model (2.14) is defined by gauge condition (2.16) of Euclidean BF gravity characterizing a surface of the Jackiw–Teitelboim model.

The mapping (2.15), (2.16) allows us to construct an infinite hierarchy of gauge constraints, compatible with (2.16), and describing the hierarchy of corresponding equations of motion. Equation (2.15b) can be written in the form

$$\partial_0 V_1-\partial_1\left(V_0+4ig\int^x(\overline{\psi}\psi_0-\overline{\psi_0}\psi)(x')dx'\right)=0. \tag{2.18a}$$

Then, as in the above procedure from (2.7) to (2.14), but going in the opposite direction, we introduce the flat Abelian gauge field,

$$W_0=V_0+4ig\int^x(\overline{\psi}\psi_0-\overline{\psi_0}\psi)(x')dx',\quad W_1=V_1. \tag{2.18b}$$

Then, in terms of redefined covariant derivatives, (2.15) becomes

$$D_0\psi=D_1\psi_0+2g\psi\int^x(\overline{\psi}\psi_0-\overline{\psi_0}\psi)(x')dx', \tag{2.19a}$$

$$\partial_0 W_1-\partial_1 W_0=0. \tag{2.19b}$$

Of course, for nonsingular gauge configurations we can always exclude field W_μ. But, we find it is important to keep this gauge field, playing the role similar to the spectral parameter in the usual Inverse Scattering approach. Then, model (2.12) written in terms of Ψ, is explicitly invariant under the local gauge transformations (2.10) and the gauge invariance plays the role of generalized isospectrality. Below we show how far this analogy can be continued. It is convenient to write Eq. (2.19a) and its complex conjugate in the matrix form

$$\begin{pmatrix} D_0\psi \\ \overline{D_0\psi}\end{pmatrix}=\begin{pmatrix} D_1+2g\psi\int^x\overline{\psi} & -2g\psi\int^x\psi \\ -2g\overline{\psi}\int^x\overline{\psi} & \overline{D_1}+2g\overline{\psi}\int^x\psi\end{pmatrix}\begin{pmatrix}\psi_0\\ \overline{\psi_0}\end{pmatrix}, \tag{2.20}$$

Then, the constraint (2.16) can be written as

$$\begin{pmatrix}\psi_0^{(1)}\\ \overline{\psi_0^{(1)}}\end{pmatrix}=i\sigma_3\begin{pmatrix} D_1\psi \\ \overline{D_1\psi}\end{pmatrix}=\Lambda\begin{pmatrix}\psi\\ \overline{\psi}\end{pmatrix}, \tag{2.21}$$

where we introduce the integrodifferential operator,

$$\Lambda=i\sigma_3\begin{pmatrix} D_1+2g\psi\int^x\overline{\psi} & -2g\psi\int^x\psi \\ -2g\overline{\psi}\int^x\overline{\psi} & \overline{D_1}+2g\overline{\psi}\int^x\psi\end{pmatrix}. \tag{2.22a}$$

For a skew-symmetric linear operator (see Sec. IV) we have to consider the integral part defined by the symmetric boundaries,

$$\int^x f(y)dy=\frac{1}{2}\left(\int_{-\infty}^x f(y)dy+\int_\infty^x f(y)dy\right). \tag{2.22b}$$

The above operator Λ represents the $U(1)$ gauge covariant extension of the AKNS operator $\mathscr{L}$.[12] In fact,

$$\Lambda=\mathscr{L}+\tfrac{1}{2}W_1 I, \tag{2.23a}$$

where

$$\mathscr{L}=i\sigma_3\begin{pmatrix}\partial_1+2g\psi\int^x\overline{\psi} & -2g\psi\int^x\psi\\ -2g\overline{\psi}\overline{\int^x\psi} & \partial_1+2g\overline{\psi}\overline{\int^x\psi}\end{pmatrix}. \tag{2.23b}$$

Here I is the identity matrix and Λ is covariant under $U(1)$ gauge transformations (2.10). Then, gauged NLS (2.7) has the form

$$i\sigma_3\begin{pmatrix}D_0\psi\\ \overline{D_0\psi}\end{pmatrix}=\Lambda^2\begin{pmatrix}\psi\\ \overline{\psi}\end{pmatrix}. \tag{2.24}$$

This representation suggests how to create the whole hierarchy of equations associated with gauged NLS (2.24). We define the set of constraints,

$$\begin{pmatrix}\psi_0^{(n)}\\ \overline{\psi_0^{(n)}}\end{pmatrix}=\Lambda^n\begin{pmatrix}\psi\\ \overline{\psi}\end{pmatrix}, \tag{2.25}$$

labeled with an integer n. As mentioned above, (2.15) describes a classical motion for the BF theory, with ψ_0 playing the role of Lagrange multipliers. The arbitrariness of ψ_0 guarantees the general time reparametrization invariance of the theory, while a specific choice for ψ_0 defines the corresponding evolution. The hierarchy (2.25) can be considered as the hierarchy of gauge fixing constraints of BF theory. Then, every constraint is related to the nonlinear spin model (Heisenberg hierarchy), being just the tangent space representation for the model.

The first few constraints from (2.25) are given by

$$\begin{pmatrix}\psi_0^{(0)}\\ \overline{\psi_0^{(0)}}\end{pmatrix}=\begin{pmatrix}\psi\\ \overline{\psi}\end{pmatrix}, \tag{2.26}$$

$$\begin{pmatrix}\psi_0^{(1)}\\ \overline{\psi_0^{(1)}}\end{pmatrix}=i\sigma_3\begin{pmatrix}D_1\psi\\ \overline{D_1\psi}\end{pmatrix}, \tag{2.27}$$

$$\begin{pmatrix}\psi_0^{(2)}\\ \overline{\psi_0^{(2)}}\end{pmatrix}=-\begin{pmatrix}D_1^2\psi+2g|\psi|^2\psi\\ \overline{D_1^2\psi+2g|\psi|^2\psi}\end{pmatrix}, \tag{2.28}$$

$$\begin{pmatrix}\psi_0^{(3)}\\ \overline{\psi_0^{(3)}}\end{pmatrix}=-i\sigma_3\begin{pmatrix}D_1^3\psi+6g|\psi|^2D_1\psi\\ \overline{D_1^3\psi+6g|\psi|^2D_1\psi}\end{pmatrix}. \tag{2.29}$$

Thus, for every n, the corresponding $\psi_0^{(n)}$ defines the evolution equation,

$$i\sigma_3\begin{pmatrix} D_{0_n}\psi \\ \overline{D_{0_n}\psi}\end{pmatrix}=\Lambda^n\begin{pmatrix}\psi\\ \overline{\psi}\end{pmatrix}=\begin{pmatrix}\psi_0^{(n)}\\ \overline{\psi_0^{(n)}}\end{pmatrix}, \tag{2.30a}$$

$$[D_{0_n},D_1]=0. \tag{2.30b}$$

The first members of the hierarchy, $(n=1,2,3)$ are

$$D_{0_1}\psi-D_1\psi=0, \tag{2.31}$$

$$i\ D_{0_2}\psi+D_1^2\psi+2g|\psi|^2\psi=0, \tag{2.32}$$

$$D_{0_3}\psi+D_1^3\psi+6g|\psi|^2\ D_1\psi=0. \tag{2.33}$$

This $U(1)$ gauged hierarchy has the flat Abelian connection (2.30b). It means that every equation (2.30) in terms of the gauge-invariant variables, like (2.12), reduces to the form of the usual NLS hierarchy. Indeed, due to (2.30b) for any n there exists a real function $\alpha_n=\alpha_n(x,t_n)$, such that

$$W_1=\partial_1\alpha_n, \quad W_{0_n}=\partial_{0_n}\alpha_n. \tag{2.34}$$

Therefore, for the gauge-invariant fields $\Psi=\psi e^{i\alpha_n}$, the hierarchy (2.30) reduces to the NLS one,

$$i\sigma_3\begin{pmatrix}\partial_{0_n}\Psi\\ \overline{\partial_{0_n}\Psi}\end{pmatrix}=\mathscr{L}^n\begin{pmatrix}\Psi\\ \overline{\Psi}\end{pmatrix}=\begin{pmatrix}\Psi_0^{(n)}\\ \overline{\Psi_0^{(n)}}\end{pmatrix}. \tag{2.35}$$

However, the gauged hierarchy (2.30) contains much more information in the addition. As we show in the next section, restricted on the subclass of constant gauge potentials, Equations (2.30) provide the linear problem for any of Eqs. (2.35). Moreover, every equation of the hierarchy (2.30) can be reduced dimensionally from the related $2+1$-dimensional Chern–Simons gauged theory.

III. ABELIAN GAUGE THEORY FOR MOVING FRAMES HIERARCHY

The hierarchy of Abelian gauge theories described in the previous section by (2.30), is equivalent to the system (2.15) with the hierarchy of $U(1)$ gauge-invariant constraints (2.25). But system (2.15) is the constant curvature surface equation written in the Einstein–Cartan zweibein formalism. As we see below, every constraint (2.25) supplied to (2.15), defines an evolution equation for three-dimensional unit vector **s**, and can be considered as a nonlinear σ model on the sphere S^2 or pseudosphere $S^{1,1}$.

Let us consider the Lie group G with element g, generated by τ_i $(i=1,2,3)$, satisfying the relations

$$\tau_i\tau_j=h_{ij}+ic_{ijk}\tau_k, \tag{3.1}$$

where h_{ij} and c_{ijk} are the Killing metric and the structure constants of the algebra, respectively. We define an orthonormal trihedral set of unit vectors $\mathbf{n}_i$ in the adjoint representation,

$$(\mathbf{n}_i,\tau)=\mathbf{n}_i^k\tau_k=h_{kl}\mathbf{n}_i^k\tau^l=g\tau_ig^{-1}. \tag{3.2}$$

The Killing metric h_{ij} and structure constants $c_{ijk}=-c_{jik}$ define correspondingly the inner and the cross product between three vectors, transforming in the adjoint representation:

$$(\mathbf{n}_i,\mathbf{n}_j)=h_{ij}, \tag{3.3a}$$

$$\mathbf{n}_i\wedge\mathbf{n}_j=c_{ijk}\mathbf{n}_k. \tag{3.3b}$$

Given smooth vector fields $\mathbf{n}_i=\mathbf{n}_i(x,t)$ define at each space x and time t three vectors $(\mathbf{n}_1(x,t),\mathbf{n}_2(x,t),\mathbf{n}_3(x,t))$ forming an orthonormal basis, called the moving frame. The chiral current,

$$J_\mu=g^{-1}\,\partial_\mu g, \tag{3.4}$$

in the adjoint representation defines rotation of the moving frame by equations,

$$\partial_\mu\mathbf{n}_i=(J_\mu^{\mathrm{ad}})_{ik}\mathbf{n}_k, \tag{3.5}$$

where

$$(J_\mu^{\mathrm{ad}})_{ik}=-ic_{ijk}(J_\mu)_j=i(J_\mu)_jc_{jik}, \tag{3.6}$$

and $J_\mu=\Sigma(J_\mu)_j(1/2)\tau_j$. Matrices J_μ^{ad} have the symmetry, $(J_\mu^{\mathrm{ad}})_{ij}h_{jj}=-(J_\mu^{\mathrm{ad}})_{ji}h_{ii}$, and are antisymmetric for the SU(2) case $h_{ij}=\delta_{ij}$, $c_{ijk}=\epsilon_{ijk}$.

The current (3.4) satisfies the zero curvature equations,

$$\partial_\mu J_\nu-\partial_\nu J_\mu+[J_\mu,J_\nu]=0, \tag{3.7}$$

as compatibility conditions for the system (3.5). We decompose matrix J_μ to the diagonal and off diagonal parts, $J_\mu=J_\mu^{(0)}+J_\mu^{(1)}$, parametrized in the form[13]

$$J_\mu^{(0)}=i/4\sigma_3V_\mu,\quad J_\mu^{(1)}=\begin{pmatrix}0 & -g\overline{\psi_\mu}\\ \psi_\mu & 0\end{pmatrix}, \tag{3.8}$$

where $g=+1$ for $su(2)$, and $g=-1$, for $su(1,1)$ cases. Then, in the adjoint representation (3.6) we have the form,

$$(J_\mu)^{\mathrm{ad}}=\frac{1}{2}\begin{pmatrix}0 & V_\mu & 4g\Re(\psi_\mu)\\ -V_\mu & 0 & 4g\Im(\psi_\mu)\\ -4\Re(\psi_\mu) & -4\Im(\psi_\mu) & 0\end{pmatrix}. \tag{3.9}$$

The moving frame rotates according to equations

$$\partial_\mu\mathbf{n}_i=-1/2V_\mu\epsilon_{ij}\mathbf{n}_j-gU_{i\mu}\mathbf{s}, \tag{3.10a}$$

$$\partial_\mu\mathbf{s}=U_{i\mu}\mathbf{n}_i, \tag{3.10b}$$

where $U_\mu\equiv2(\Re(\psi_\mu),\Im(\psi_\mu))$. For vector $\mathbf{s}\equiv\mathbf{n}_3$ the constraint, $(\mathbf{s}(x,t),\mathbf{s}(x,t))=h_{33}$, is valid, where $h_{33}=1$, which means that it belongs to the two-dimensional sphere S^2 or pseudosphere $S^{1,1}$, correspondingly. Two vector fields $(\mathbf{n}_1(x),\mathbf{n}_2(x))$ at each (x,t) form a basis in the tangent plane to the corresponding manifold for $\mathbf{s}(x)$. However, by Eq. (3.10) vectors $\mathbf{n}_1$ and $\mathbf{n}_2$ are not determined uniquely. If we choose the other pair $\mathbf{n}_1'$, $\mathbf{n}_2'$, as the rotated basis,

$$\mathbf{n}_1'=\cos\,\alpha\mathbf{n}_1-\sin\,\alpha\mathbf{n}_2,\quad \mathbf{n}_2'=\cos\,\alpha\mathbf{n}_2+\sin\,\alpha\mathbf{n}_1, \tag{3.11}$$

the related V_μ' and ψ_μ' are the $U(1)$ gauge transformed fields,

$$V'_\mu = V_\mu + 2\,\partial_\mu \alpha, \quad \psi'_\mu = e^{i\alpha}\psi_\mu . \tag{3.12a}$$

The expression (3.11) suggests that we introduce a complex basis $\mathbf{n}_+ = \mathbf{n}_1 + i\mathbf{n}_2$, $\mathbf{n}_- = \mathbf{n}_1 - i\mathbf{n}_2$, satisfying the following relations:

$$(\mathbf{n}_\pm, \mathbf{n}_\pm) = 0, \quad (\mathbf{n}_+, \mathbf{n}_-) = 2g, \tag{3.12b}$$

$$\mathbf{n}_+ \times \mathbf{s} = i\mathbf{n}_+, \mathbf{n}_- \times \mathbf{s} = -i\mathbf{n}_-, \quad \mathbf{n}_- \times \mathbf{n}_+ = 2ig\mathbf{s}. \tag{3.12c}$$

Then, we get

$$\psi_\mu = 1/2g(\partial_\mu \mathbf{s}, \mathbf{n}_+), \quad \overline{\psi_\mu} = 1/2g(\partial_\mu \mathbf{s}, \mathbf{n}_-). \tag{3.13a}$$

In terms of (3.12) the moving frame system (3.10) becomes

$$D_\mu \mathbf{n}_+ = -2g\psi_\mu \mathbf{s}, \tag{3.13b}$$

$$\partial_\mu \mathbf{s} = \psi_\mu \mathbf{n}_- + \overline{\psi_\mu}\mathbf{n}_+ , \tag{3.13c}$$

where $D_\mu \equiv \partial_\mu - i/2V_\mu$, is a $U(1)$ covariant derivative. This form is explicitly invariant under the local $U(1)$ gauge transformations,

$$\mathbf{n}_+ \to e^{i\alpha}\mathbf{n}_+ , \quad \mathbf{n}_- \to e^{-i\alpha}\mathbf{n}_- , \quad V_\mu \to V_\mu + 2\,\partial_\mu \alpha, \quad \mathbf{s} \to \mathbf{s}, \tag{3.14}$$

that are just the local rotations in tangent to the vector $\mathbf{s}$ plane. From (3.13) it follows that V_μ and ψ_μ fields subject to the system (the integrability condition),

$$D_0\psi = D_1\psi_0, \tag{3.15a}$$

$$[D_0, D_1] = 2g(\overline{\psi}\psi_0 - \overline{\psi_0}\psi), \tag{3.15b}$$

where we skip the index for the ψ_1 field. This system coincides with (2.15). Moreover, the reduced Jackiw–Pi model (2.7) corresponds to the constraint (2.16). Under this constraint, the moving frame evolution (3.13) describes

$$D_0 \mathbf{n}_+ = -2gi\, D_1\psi \mathbf{s}, \tag{3.16a}$$

$$D_1 \mathbf{n}_+ = -2g\psi \mathbf{s}, \tag{3.16b}$$

$$\partial_0 \mathbf{s} = i\, D_1\psi\, \mathbf{n}_- - i\, \overline{D_1}\,\overline{\psi}\, \mathbf{n}_+ , \tag{3.16c}$$

$$\partial_1 \mathbf{s} = \psi \mathbf{n}_- + \overline{\psi}\mathbf{n}_+ . \tag{3.16d}$$

Differentiating (3.16d),

$$\partial_1^2 \mathbf{s} = D_1\psi\, \mathbf{n}_- + \overline{D_1}\,\overline{\psi}\, \mathbf{n}_+ - 4g|q_1|^2 \mathbf{s}, \tag{3.17}$$

we immediately see that vector $\mathbf{s}$ satisfies the Landau–Lifshitz equation for the continuum isotropical Heisenberg spin chain model,

$$\partial_0 \mathbf{s} = \mathbf{s} \times \partial_1^2 \mathbf{s}, \tag{3.18}$$

where **s** belongs to the two-dimensional sphere S^2 $(g=1)$,[14] or pseudosphere $S^{1,1}$ $(g=-1)$.[15] The above results illuminate the role of the Chern–Simons statistical gauge field in the Heisenberg model. Two components, A_0, A_1, are just the gauge degrees of freedom of rotation in the tangent plane, while the $B=A_2$ component is defined by relations

$$\partial_1 B=-\frac{1}{4gk}\,(\partial_1\mathbf{s})^2, \tag{3.19a}$$

$$\partial_0 B=\frac{1}{k}\,\partial_1\mathbf{s}(\partial_1^2\mathbf{s}\wedge\mathbf{s}). \tag{3.19b}$$

The right-hand side of Eq. (3.19a) is the energy density of the model (3.18). As in Sec. II, [see Eq. (2.8a)], the local magnetic energy is always accompanied with the gradient of the B field. From Eqs. (3.19) it is evident that the total magnetic energy is a conserved quantity, defining the asymptotic jump,

$$B(+\infty)-B(-\infty)=-\frac{1}{4gk}\int_{-\infty}^{+\infty}(\partial_1\mathbf{s})^2\,dx. \tag{3.20}$$

As shown in Sec. II, the gauge constraint (2.16) is the second member of the infinite hierarchy of the gauge constraints (2.25). To show that every constraint from this hierarchy corresponds to the moving frame system and the spin model, we can proceed analogously to the case (2.18)–(2.19). After redefinition (2.18) the system (3.13) becomes

$$\begin{pmatrix} D_0\mathbf{n}_+ \\ D_0\mathbf{n}_- \end{pmatrix}=-2gs\begin{pmatrix} \psi_0 \\ \overline{\psi_0} \end{pmatrix}+2g\begin{pmatrix} \mathbf{n}_+ \\ -\mathbf{n}_- \end{pmatrix}\int^x(\overline{\psi}\psi_0-\overline{\psi_0}\psi), \tag{3.21}$$

$$\begin{pmatrix} D_1\mathbf{n}_+ \\ D_1\mathbf{n}_- \end{pmatrix}=-2gs\begin{pmatrix} \psi \\ \overline{\psi} \end{pmatrix}, \tag{3.22}$$

$$\partial_0\mathbf{s}=\psi_0\mathbf{n}_-+\overline{\psi_0}\mathbf{n}_+\,,\quad \partial_1\mathbf{s}=\psi\mathbf{n}_-+\overline{\psi}\mathbf{n}_+\,. \tag{3.23}$$

The tangent space vectors evolution (3.21) is convenient to be rewritten as

$$\begin{pmatrix} D_0\mathbf{n}_+ \\ D_0\mathbf{n}_- \end{pmatrix}=-2g\begin{pmatrix} \mathbf{s}-\mathbf{n}_+\int^x\overline{\psi} & \mathbf{n}_+\int^x\psi \\ \mathbf{n}_-\int^x\overline{\psi} & \mathbf{s}-\mathbf{n}_-\int^x\psi \end{pmatrix}\begin{pmatrix} \psi_0 \\ \overline{\psi_0} \end{pmatrix}. \tag{3.24}$$

Then, we note that compatibility condition for the system (3.22)–(3.24) is given by (2.20). Moreover, the hierarchy of the gauge fixing constraints (2.25) produces the hierarchy of the moving frame evolutions (3.24) and the related higher-order analogs of the NLS (2.30). This moving frame hierarchy generates also the higher-order analogs of the Heisenberg model (3.18). To follow this direction we need to extract information only in terms of the spin vector **s**. First we note, that the integrand of (3.21),

$$2ig(\overline{\psi}\psi_0-\overline{\psi_0}\psi)=\mathbf{s}(\partial_0\mathbf{s}\wedge\partial_1\mathbf{s}), \tag{3.25}$$

is the topological charge density for the spin configuration on the space–time world sheet, or the volume element on the spin phase space. Then, we obtain the recursion relations for the evolution equations,

$$\partial_{0_n}\mathbf{s}=\left[\mathbf{s}\wedge\partial_1-\partial_1\mathbf{s}\int^x\mathbf{s}(\partial_1\mathbf{s}\wedge\cdot)\right]\partial_{0_{n-1}}\mathbf{s}, \tag{3.26}$$

where the integer n describes the nth member of the hierarchy. The first few evolutions are given by

$$\partial_0\mathbf{s}=\partial_1\mathbf{s}, \tag{3.27}$$

$$\partial_0\mathbf{s}=\mathbf{s}\wedge\partial_1^2\mathbf{s}, \tag{3.28}$$

$$\partial_0\mathbf{s}=\mathbf{s}\wedge\mathbf{s}\wedge\partial_1^3\mathbf{s}-\tfrac{3}{2}(\partial_1\mathbf{s}\ \partial_1\mathbf{s})\partial_1\mathbf{s}. \tag{3.29}$$

The moving frame approach allows us to introduce also the traditional zero curvature description. To proceed, we need to find an appropriate reduction for (3.7)–(3.8). We note that the NLS (2.12) can be considered as a quantum mechanic, with the potential function proportional to the probability density, $U(x)=\Psi(x)\Psi(x)$. But, as is well known,[16] the Galilean boosts representation in the quantum mechanics makes use of 1-cocycle ω_1:

$$U(v)\Psi(x)=e^{-2\pi i\omega_1(x;v)}\Psi(x-vt), \tag{3.30}$$

with the following condition to satisfy:

$$\omega_1(x-ut;v)-\omega_1(x;u+v)+\omega_1(x;u)=0,(\mathrm{mod}\ Z), \tag{3.31}$$

where $U(v)$ is the unitary operator shifting the coordinates as

$$U(v)xU^{-1}(v)=x-vt. \tag{3.32}$$

Then, condition (3.31) ensures the group multiplication for $U(v)$ operators:

$$U(v)U(u)=U(u+v). \tag{3.33}$$

The quantity $\omega_1(x;v)$ is given by

$$2\pi\omega_1(x;v)=-\frac{v^2}{4}t+\frac{v}{2}x, \tag{3.34}$$

and provides the local phase transformation for the wave function. Thus, the NLS model (2.12) is invariant under the Galileo transformations,

$$x\to x'=x-vt,\quad t\to t'=t, \tag{3.35a}$$

$$\Psi\to\Psi'\ \exp\ i\left(\frac{v^2}{4}t'+\frac{v}{2}x'\right). \tag{3.35b}$$

This invariance can be interpreted in two ways. First, that the space–time transformation to a constant velocity moving frame should be accompanied with the phase transformation for the ''wave function'' Ψ. This is the 1-cocycle representation, as given above. In the second interpretation we can say that any one-parameter group ($v=\mathrm{const}$) of the phase transformations (3.35b) becomes the symmetry of the model (2.12) if we transform coordinates to the moving frame with velocity v according to (3.35a). The second interpretation has the flavor of the $U(1)$ Abelian local gauge theory with the gauge potentials transforming on the constant value. In fact, the linear in space and time phase transformations (3.35b) satisfying (3.31) generate a subgroup of the Abelian

gauge transformations, shifting the W_1 potential (2.4) on the constant velocity. This is why it is of interest to consider the restricted class of the constant gauge potentials. As shown below they are associated with the spectral parameter in the linear problem for the NLS. Therefore, in our approach the whole structure of the linear problem with the spectral parameter has the origin from the $U(1)$ gauge potential W_1, while the related phase is the linear function of space and time.

Our idea has been suggested by some known facts from the theory of superconductivity[17] and the field theory with curved momentum space.[18] For the superconductor in the ground state under the external electromagnetic action the generalized canonical momentum $\mathbf{p}=m\mathbf{v}+e/c\mathbf{A}$ vanishes. This fact provides the relation between superconducting electrons velocity and the vector potential,

$$\mathbf{v}=-e/c\mathbf{A}, \tag{3.36}$$

restricting Abelian gauge transformations to the London gauge,[17]

$$\text{div } \mathbf{A}=0. \tag{3.37}$$

In one space dimension this gauge leads to the constant gauge potential A. Furthermore, for constant potentials A_μ, transition to the new momentum,

$$p_\mu \rightarrow p_\mu - c_\mu, \tag{3.38}$$

generates the group of parallel transitions in the momentum space. For the nonrelativistic theory it is just the Galileo transformation. Finally, as was shown recently,[13] the spectral parameter arises as the constant-valued statistical gauge field of compactified $2+1$-dimensional theory. All results mentioned above suggest that the spectral parameter is deeply connected with the Abelian gauge field.

Let us consider the moving frame equations (3.16),

$$D_0\mathbf{n}_+=-2gi\ D_1\psi\ \mathbf{s}+2ig|\psi|^2\mathbf{n}_+, \tag{3.39a}$$

$$D_1\mathbf{n}_+=-2g\psi\mathbf{s}, \tag{3.39b}$$

$$\partial_0\mathbf{s}=i\ D_1\psi\ \mathbf{n}_- - i\ \overline{D_1}\overline{\psi}\mathbf{n}_+, \tag{3.39c}$$

$$\partial_1\mathbf{s}=\psi\mathbf{n}_- + \overline{\psi}\mathbf{n}_+, \tag{3.39d}$$

written in terms of the zero strength gauge potential W_μ (2.13),

$$\partial_0 W_1 - \partial_1 W_0 = 0. \tag{3.39e}$$

The general solution of the last equation is of the pure gauge form given in terms of the real function,

$$W_\mu=\partial_\mu\alpha. \tag{3.40}$$

For a restricted class of functions, linear in x and t, we put

$$W_1=2\lambda=\text{const}. \tag{3.41}$$

In this case the NLS (2.7a) becomes

$$i\ \partial_0\psi-2i\lambda\ \partial_1\psi+\partial_1^2\psi+2g|\psi|^2\psi=0, \tag{3.42}$$

where we have to choose $W_0=1/2W_1^2=2\lambda^2$. In the constant velocity frame, $v=-2\lambda$, this equation acquires the normal form (2.12)

$$i\ \partial_{0'}\psi+\partial_{1'}^2\psi+2g|\psi|^2\psi=0, \tag{3.43}$$

and any λ dependence disappears. However, it remains in the corresponding moving frame system (3.39) having the form

$$\partial_{1'}\begin{pmatrix}\mathbf{n}_+\\ \mathbf{n}_-\\ \mathbf{s}\end{pmatrix}=\begin{pmatrix} i\lambda & 0 & -2g\psi\\ 0 & -i\lambda & -2g\overline{\psi}\\ \overline{\psi} & \psi & 0\end{pmatrix}.\begin{pmatrix}\mathbf{n}_+\\ \mathbf{n}_-\\ \mathbf{s}\end{pmatrix}, \tag{3.44a}$$

$$\partial_{0'}\begin{pmatrix}\mathbf{n}_+\\ \mathbf{n}_-\\ \mathbf{s}\end{pmatrix}=\begin{pmatrix} -i\lambda^2+2ig|\psi|^2 & 0 & -2ig\ \partial_{1'}\psi+2g\lambda\psi\\ 0 & i\lambda^2-2ig|\psi|^2 & 2ig\ \partial_{1'}\overline{\psi}+2g\lambda\overline{\psi}\\ -(i\partial_{1'}\overline{\psi}+\lambda\overline{\psi}) & i\ \partial_{1'}\psi-\lambda\psi & 0\end{pmatrix}\begin{pmatrix}\mathbf{n}_+\\ \mathbf{n}_-\\ \mathbf{s}\end{pmatrix}. \tag{3.44b}$$

In the normal basis $\mathbf{n}_1,\mathbf{n}_2,\mathbf{s}$, we have equations

$$\partial_{1'}\begin{pmatrix}\mathbf{n}_1\\ \mathbf{n}_2\\ \mathbf{s}\end{pmatrix}=\begin{pmatrix} 0 & -\lambda & -gU_1\\ \lambda & 0 & -gU_2\\ U_1 & U_2 & 0\end{pmatrix}\begin{pmatrix}\mathbf{n}_1\\ \mathbf{n}_2\\ \mathbf{s}\end{pmatrix} \tag{3.45a}$$

$$\partial_{0'}\begin{pmatrix}\mathbf{n}_1\\ \mathbf{n}_2\\ \mathbf{s}\end{pmatrix}=\begin{pmatrix} 0 & \lambda^2-2g|\psi|^2 & g\ \partial_{1'}U_2+g\lambda U_1\\ -\lambda^2+2g|\psi|^2 & 0 & -g\ \partial_{1'}U_1+g\lambda U_2\\ -\partial_{1'}U_2-\lambda U_1 & \partial_{1'}U_1-\lambda U_2 & 0\end{pmatrix}\begin{pmatrix}\mathbf{n}_1\\ \mathbf{n}_2\\ \mathbf{s}\end{pmatrix}, \tag{3.45b}$$

where we defined [see Eqs. (3.10)] $U_1=2\Re(\psi)$, $U_2=2\Im(\psi)$. The first system (3.45a) in terms of the gauge-invariant fields as in (2.12) ($\lambda=0$), has the form of the Frenet equations for the curve. This suggests the idea to interpret the gauge-invariant form of (3.45) as a moving curve equation.[19] But due to the essential role of the space–time curvature that is proportional to the nonlinearity and can be negative, this analogy does not seem so useful. In opposite, we find that a more general setting—the moving frame method is going deeply in to the problem and naturally illuminates the gauge theoretical structure of it.

Note that the potentials choice,

$$W_1=2\lambda,\quad W_0=2\lambda^2, \tag{3.46}$$

which allowed us to remove the λ dependence from equations of motion (3.42), is exactly the 1-cocycle (3.35b). To reproduce the usual Lax-type representation we use the spinor representation of system (3.45), and according to (3.6) we have 2×2 Zakharov–Shabat spectral problem,

$$J_1=+\frac{i}{2}\lambda\sigma_3+\begin{pmatrix}0 & -g\overline{\psi}\\ \psi & 0\end{pmatrix}, \tag{3.47a}$$

$$J_0=i\sigma_3\left[-\frac{\lambda^2}{2}+g|\psi|^2\right]+\begin{pmatrix}0 & g(i\partial_1+\lambda)\overline{\psi}\\ (i\partial_1-\lambda)\psi & 0\end{pmatrix}, \tag{3.47b}$$

for the NLS (3.43).

To derive the hierarchy of moving frames, providing the linear problem for any of equations (2.35), we need to modify the above Galileo transformation approach (3.42)–(3.43). Let us first rewrite the hierarchy (2.30) for the constant potentials W_μ, denoting $W_1=2\lambda$:

$$
\begin{aligned}
i\partial_{0_n}\begin{pmatrix}\psi\\ -\bar{\psi}\end{pmatrix}+\frac{1}{2}\,W_{0_n}\begin{pmatrix}\psi\\ \bar{\psi}\end{pmatrix}&=(\mathscr{L}+\lambda I)^n\begin{pmatrix}\psi\\ \bar{\psi}\end{pmatrix}\\
&=\sum_{k=0}^{n}\binom{k}{n}\lambda^{n-k}\mathscr{L}^k\begin{pmatrix}\psi\\ \bar{\psi}\end{pmatrix}\\
&=\sum_{k=0}^{n}\binom{k}{n}\lambda^{n-k}\begin{pmatrix}\psi_0^{(k)}\\ \bar{\psi}_0^{(k)}\end{pmatrix}\\
&=\lambda^n\begin{pmatrix}\psi\\ \bar{\psi}\end{pmatrix}+\sum_{k=1}^{n-1}\binom{k}{n}\lambda^{n-k}\begin{pmatrix}\psi_0^{(k)}\\ \bar{\psi}_0^{(k)}\end{pmatrix}+\begin{pmatrix}\psi_0^{(n)}\\ \bar{\psi}_0^{(n)}\end{pmatrix}\\
&=\lambda^n\begin{pmatrix}\psi\\ \bar{\psi}\end{pmatrix}+\sum_{k=1}^{n-1}\binom{k}{n}\lambda^{n-k}i\sigma_3\partial_{0_k}\begin{pmatrix}\psi\\ \bar{\psi}\end{pmatrix}+\mathscr{L}^n\begin{pmatrix}\psi\\ \bar{\psi}\end{pmatrix},
\end{aligned}
\tag{3.48}
$$

where $[\mathscr{L},\lambda I]=0$ is used. Choosing the gauge potentials $W_{0_n}=2\lambda^n$, and collecting all terms with the time hierarchy derivatives on the left-hand side, we get

$$
i\left\{\partial_{0_n}-\sum_{k=1}^{n-1}\binom{k}{n}\lambda^{n-k}\partial_{0_k}\right\}\begin{pmatrix}\psi\\ -\bar{\psi}\end{pmatrix}=\mathscr{L}^n\begin{pmatrix}\psi\\ \bar{\psi}\end{pmatrix}. \tag{3.49}
$$

Defining the new time hierarchy $\{t_{0_1'},t_{0_2'},\ldots,t_{0_n'},\ldots\}$, such that

$$
\partial_{0_n'}=\partial_{0_n}-\sum_{k=1}^{n-1}\binom{k}{n}\lambda^{n-k}\partial_{0_k}, \tag{3.50}
$$

we obtain for (3.49) the usual NLS hierarchy form (2.35):

$$
i\sigma_3\partial_{0_n'}\begin{pmatrix}\psi\\ \bar{\psi}\end{pmatrix}=\mathscr{L}^n\begin{pmatrix}\psi\\ \bar{\psi}\end{pmatrix}. \tag{3.51}
$$

The matrix structure of the above time hierarchy transformation can be realized by the upper triangular matrix,

$$
\begin{pmatrix}t_1'\\ t_2'\\ t_3'\\ \vdots\\ t_n'\end{pmatrix}=\begin{pmatrix}1 & a_{12} & a_{13} & \cdots & a_{1n}\\ 0 & 1 & a_{23} & \cdots & a_{2n}\\ 0 & 0 & 1 & \cdots & a_{3n}\\ 0 & \vdots & 0 & \cdots & \vdots\\ 0 & 0 & 0 & \cdots & 1\end{pmatrix}\begin{pmatrix}t_1\\ t_2\\ t_3\\ \vdots\\ t_n\end{pmatrix}, \tag{3.52}
$$

while the time derivatives transform by the lower triangular matrix,

$$\begin{pmatrix} \partial_{0_1} \\ \partial_{0_2} \\ \partial_{0_3} \\ \vdots \\ \partial_{0_n} \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & \cdots & 0 \\ a_{12} & 1 & 0 & \cdots & 0 \\ a_{13} & a_{23} & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \cdots & 0 \\ a_{1n} & a_{2n} & a_{3n} & \cdots & 1 \end{pmatrix} \begin{pmatrix} \partial_{0'_1} \\ \partial_{0'_2} \\ \partial_{0'_3} \\ \vdots \\ \partial_{0'_n} \end{pmatrix}, \tag{3.53}$$

with coefficients chosen as an appropriate polynomial of the parameter λ.

By using the moving frame formulas (3.21)–(3.24) we can construct the hierarchy of moving frames, which provides also the linear problem for any member of the hierarchy (3.51). For the space part we have

$$\begin{pmatrix} D_1\mathbf{n}_+ \\ D_1\mathbf{n}_- \\ \partial_1\mathbf{s} \end{pmatrix} = \begin{pmatrix} 0 & 0 & -2g\psi \\ 0 & 0 & -2g\overline{\psi} \\ \overline{\psi} & \psi & 0 \end{pmatrix} \begin{pmatrix} \mathbf{n}_+ \\ \mathbf{n}_- \\ \mathbf{s} \end{pmatrix}, \tag{3.54}$$

in which $W_1 = 2\lambda$ gives us the space part of the moving frame system and is universal for the whole hierarchy,

$$\partial_1 \begin{pmatrix} \mathbf{n}_+ \\ \mathbf{n}_- \\ \mathbf{s} \end{pmatrix} = \begin{pmatrix} i\lambda & 0 & -2g\psi \\ 0 & -i\lambda & -2g\overline{\psi} \\ \overline{\psi} & \psi & 0 \end{pmatrix} \begin{pmatrix} \mathbf{n}_+ \\ \mathbf{n}_- \\ \mathbf{s} \end{pmatrix}. \tag{3.55}$$

For the time evolution we start from the system for the t_n time:

$$\begin{pmatrix} D_{0_n}\mathbf{n}_+ \\ D_{0_n}\mathbf{n}_- \\ \partial_{0_n}\mathbf{s} \end{pmatrix} = -2g \begin{pmatrix} \mathbf{s}-\mathbf{n}_+\int^x \overline{\psi} & \mathbf{n}_+\int^x \psi \\ s-\mathbf{n}_-\int^x \psi & \mathbf{s}-\mathbf{n}_-\int^x \psi \\ -\dfrac{1}{2g}\,\mathbf{n}_- & -\dfrac{1}{2g}\,\mathbf{n}_+ \end{pmatrix} \begin{pmatrix} \psi_0^{(n-1)} \\ \overline{\psi_0^{(n-1)}} \end{pmatrix}. \tag{3.56}$$

After substituting the value $W_{0_n} = 2\lambda^n$ and (2.25), we have the expression

$$\partial_{0_n} \begin{pmatrix} \mathbf{n}_+ \\ \mathbf{n}_- \\ \mathbf{s} \end{pmatrix} = i\lambda^n \begin{pmatrix} \mathbf{n}_+ \\ -\mathbf{n}_- \\ 0 \end{pmatrix} - 2g \begin{pmatrix} \mathbf{s}-\mathbf{n}_+\int^x \overline{\psi} & \mathbf{n}_+\int^x \psi \\ \mathbf{n}_-\int^x \overline{\psi} & \mathbf{s}-\mathbf{n}_-\int^x \psi \\ -\dfrac{1}{2g}\,\mathbf{n}_- & -\dfrac{1}{2g}\,\mathbf{n}_+ \end{pmatrix} \Lambda^{n-1} \begin{pmatrix} \psi \\ \overline{\psi} \end{pmatrix}. \tag{3.57}$$

Then, for the transformed time hierarchy using (3.50) and (3.57), we get

$$\partial_{0'_n}\begin{pmatrix}\mathbf{n}_+\\ \mathbf{n}_-\\ \mathbf{s}\end{pmatrix}=i\lambda^n(3-2^n)\begin{pmatrix}1&0&0\\0&-1&0\\0&0&0\end{pmatrix}\begin{pmatrix}\mathbf{n}_+\\ \mathbf{n}_-\\ \mathbf{s}\end{pmatrix}-2g\begin{pmatrix}\mathbf{s}-\mathbf{n}_+\int^x\overline{\psi} & \mathbf{n}_+\int^x\psi\\ \mathbf{n}_-\int^x\psi & \mathbf{s}-\mathbf{n}_-\int^x\psi\\ -\frac{1}{2g}\mathbf{n}_- & -\frac{1}{2g}\mathbf{n}_+\end{pmatrix}$$
$$\times\left\{\Lambda^{n-1}-\sum_{k=1}^{n-1}\binom{k}{n}\lambda^{n-k}\Lambda^{k-1}\right\}\begin{pmatrix}\psi\\ \overline{\psi}\end{pmatrix}. \tag{3.58}$$

The system (3.55), (3.58) is the moving frame system for the hierarchy (3.51). The space part is linear in the spectral parameter λ, while the time part contains the nth degree polynomial for the nth member of the hierarchy. To reproduce this dependence in the explicit form, according to (2.23a), we decompose the gauge covariant operator $\Lambda=\mathscr{L}+2I$. As a result we have the moving frame evolution in terms of the usual AKNS operator $\mathscr{L}$,

$$\partial_{0'_n}\begin{pmatrix}\mathbf{n}_+\\ \mathbf{n}_-\\ \mathbf{s}\end{pmatrix}=i\lambda^n(3-2^n)\begin{pmatrix}1&0&0\\0&-1&0\\0&0&0\end{pmatrix}\begin{pmatrix}\mathbf{n}_+\\ \mathbf{n}_-\\ \mathbf{s}\end{pmatrix}-2g\begin{pmatrix}\mathbf{s}-\mathbf{n}_+\int^x\overline{\psi} & \mathbf{n}_+\int^x\psi\\ \mathbf{n}_-\int^x\overline{\psi} & \mathbf{s}-\mathbf{n}_-\int^x\psi\\ -\frac{1}{2g}\mathbf{n}_- & -\frac{1}{2g}\mathbf{n}_+\end{pmatrix}$$
$$\times\left\{\sum_{l=0}^{n-1}\binom{l}{n-1}-\sum_{k=1}^{n-1}\sum_{l=0}^{k-1}\binom{k}{n}\binom{l}{k-1}\right\}\lambda^{n-1-l}\mathscr{L}^l\begin{pmatrix}\psi\\ \overline{\psi}\end{pmatrix}. \tag{3.59}$$

For $n=2$ these moving frame system coincides with the one (3.44) obtained by the Galileo transformations. This suggests that we should construct the hierarchy of the Galileo transformations with the properly defined time hierarchy for any of Eqs. (3.51) and the 1-cocycle conditions.

IV. BF GAUGE THEORY AND THE TIME HIERARCHY

In the present section we map the integrable hierarchy from Sec. III to the non-Abelian BF gauge theory. The BF theory is described by the action

$$S=\frac{kL}{4\pi}\int_{\Sigma_2}\mathrm{Tr}(BF), \tag{4.1}$$

where $F=\epsilon^{\mu\nu}F_{\mu\nu}$ is the gauge curvature tensor in the adjoint representation of the appropriately chosen group, while B is the world scalar Lagrange multipliers, transforming according to the coadjoint representation.[11] This model, formulated in terms of 2-form F, and the zero-form B for any 2-dimensional manifold Σ_2 defines the topological field theory.[20] For the noncompact groups SO(2,1) and ISO(1,1) it provides a gauge theoretical formulation of the Jackiw–Teitelboim lineal gravity theories.[11,21,22] This model, being the constant curvature theory, includes the world scalar Lagrangian multiplier field together with the Riemann scalar R and is a type of scalar–tensor theories or the ''dilaton'' gravity. In the gauge formulation of the gravity theory one introduces instead of the metric tensor $g_{\mu\nu}$, the Einstein–Cartan zweibeins and the spin connection viewed as independent variables. Then, the diffeomorphism invariance of the gravity theory becomes a part of the local gauge invariance. The matter ψ and the gauge field V from the Sec. II are just the zweibeins and the spin-connection fields,[23] defining the moving frame equations. The SU(2) and

SU(1,1) with the compact Abelian $U(1)$ subgroup in our case, correspond to the Euclidean gravity, with the local $O(2)$ rotations in the tangent plane, instead of the $O(1,1)$ Lorentz rotations.

To describe the time evolution, we suppose that $\Sigma_2 = R \times T$. Then the action (4.1) is

$$S = \frac{kL}{2\pi} \int \mathrm{Tr}\, B(\partial_0 J_1 - \partial_1 J_0 + [J_0, J_1]) d^2x = \frac{kL}{2\pi} \int \mathrm{Tr}(B\ \partial_0 J_1 + J_0(\partial_1 B + [J_1, B])) d^2x, \tag{4.2}$$

where we integrated the second term by parts. In terms of (3.8) parametrization and with the B field given by $B = i\phi_0\sigma_3 + g\phi\sigma_- - \overline{\phi}\sigma_+$, the action becomes

$$S = \gamma \int \left(\overline{\phi}\ \partial_0 \psi + \phi\ \partial_0 \overline{\psi} + \frac{1}{2}\ \phi_0 \partial_0 V_1 - \mathscr{H} \right) d^2x, \tag{4.3}$$

where the Hamiltonian density is given by

$$\mathscr{H} = -\{\overline{\psi_0}(D_1\phi + 2ig\phi_0\psi) + \psi_0(\overline{D_1\phi} - 2ig\phi_0\overline{\psi}) + V_0\ \tfrac{1}{2}\ (\partial_1\phi_0 + i\phi\overline{\psi} - i\overline{\phi}\psi)\}, \tag{4.4}$$

and γ is the renormalized coupling constant. Since the action is already in the first-order form we can immediately write the canonical brackets.[24]

$$\{\psi(x), \overline{\phi}(y)\} = \frac{1}{\gamma}\ \delta(x-y), \quad \{\overline{\psi}(x), \phi(y)\} = \frac{1}{\gamma}\ \delta(x-y),$$
$$\{V_1(x), \phi_0(y)\} = \frac{2}{\gamma}\ \delta(x-y). \tag{4.5}$$

The nondynamical Lagrange multipliers ψ_0, $\overline{\psi_0}$, and V_0 lead to the BF ''Gauss law'' constraints,

$$D_1\phi + 2ig\psi\phi_0 = 0, \quad \overline{D_1\phi} - 2ig\overline{\psi}\phi_0 = 0, \tag{4.6}$$

$$\partial_1\phi_0 + i\phi\overline{\psi} - i\overline{\phi}\psi = 0. \tag{4.7}$$

Due to the canonical brackets (4.5) the Gauss law constraints generate the SU(2) ($g=1$), or SU(1,1) ($g=-1$), algebra of the gauge transformations in the dynamical fields ψ, $\overline{\psi}$, and V_1. Since the Hamiltonian (4.4) is proportional to the constraints (4.6), (4.7), it is weakly vanishing, $H \approx 0$. The above properties characterize any reparametrization-invariant theory.

We can partially solve constraints (4.6), (4.7) by integration of the last one,

$$\phi_0 = -i \int^x (\overline{\psi}\phi - \psi\overline{\phi}). \tag{4.8}$$

Then, substituting to the first two (4.6), we get

$$\mathscr{M}_\psi(\phi) \equiv D_1\phi + 2g\psi \int^x (\overline{\psi}\phi - \psi\overline{\phi})(y)\, dy = 0, \tag{4.9a}$$

$$\overline{\mathscr{M}_\psi(\phi)} \equiv \overline{D_1\phi} - 2g\overline{\psi} \int^x (\overline{\psi}\phi - \psi\overline{\phi})(y)\, dy = 0, \tag{4.9b}$$

where we defined the integrodifferential operators $\mathscr{M}$. These two relations combined can be written in terms of the $U(1)$ gauge covariant Λ operator (2.22):

$$i\sigma_3\begin{pmatrix}\mathscr{M}_\psi(\phi)\\ \mathscr{M}_\psi(\phi)\end{pmatrix}=\Lambda\begin{pmatrix}\phi\\ \phi\end{pmatrix}=0. \tag{4.10}$$

This means that the constraint surface of the BF theory is defined by zero modes of the covariant Λ operator. In terms of the usual $\mathscr{L}$ operator (2.23) we have the relation

$$\mathscr{L}\begin{pmatrix}\phi\\ \phi\end{pmatrix}=-\frac{1}{2}V_1\begin{pmatrix}\phi\\ \phi\end{pmatrix}, \tag{4.11}$$

which for the constant-valued gauge potential, like in (3.41), $V_1=-2\lambda$, becomes the eigenvalue problem for the operator $\mathscr{L}$:

$$\mathscr{L}\begin{pmatrix}\phi\\ \phi\end{pmatrix}=\lambda\begin{pmatrix}\phi\\ \phi\end{pmatrix}. \tag{4.12}$$

Comparison with the theory of solitons[12] shows that our world scalars ϕ and $\overline{\phi}$ are very similar to the squared eigenfunctions for the Zhakharov–Shabat problem. Moreover, the constraints surface system (4.6), (4.7) is related to the Maxwell–Bloch equations,[25] describing the propagation of pulses through an inhomogeneously broadened and resonant medium, where ψ is the electric field envelope, ϕ is the polarization, and ϕ_0 is the excitation number density. It would be interesting to illuminate the relation between the last problem and the BF theory.

We can express the action (4.3) in terms of the bilinear form. For any two complex functions ϕ and χ vanishing at infinity, we define

$$\langle\phi,\chi\rangle=\int_{-\infty}^{\infty}(\overline{\phi}\chi+\phi\overline{\chi})dx=2\Re\int_{-\infty}^{\infty}\overline{\phi}\chi\ dx. \tag{4.13}$$

Then, the operator $\mathscr{M}_\psi(\phi)$ from (4.9) is skew symmetric with respect to this bilinear form,

$$\langle\phi,\mathscr{M}\chi\rangle=-\langle\mathscr{M}\phi,\chi\rangle, \tag{4.14}$$

if for the integral part of $\mathscr{M}$ we use the proper definition (2.22b). Another skew symmetric operator is the imaginary unit $i=\sqrt{-1}$,

$$\langle\phi,i\chi\rangle=-\langle i\phi,\chi\rangle. \tag{4.15}$$

In spite of the skew symmetry of these two operators, the product

$$\mathscr{R}=i\mathscr{M}, \tag{4.16}$$

being the recursion operator, is not Hermitian. This is due to the noncommutativity of the operators,

$$[i,\mathscr{M}](\phi)=-4ig\psi\int^{x}\overline{\phi}\psi. \tag{4.17}$$

To derive the Hamiltonian dynamics for action (4.3) we introduce the $U(1)$ gauge-invariant variables. Representing potential V_1 in a pure gauge form,

$$V_1=2\,\partial_1\alpha(x), \tag{4.18}$$

for the gauge-invariant $B(x)$ (the magnetic field analog),

$$\phi_0 = \int^x B(y)dy, \tag{4.19}$$

the Poisson bracket (4.5) results from the following canonical bracket:

$$\{\alpha(x), B(y)\} = -\frac{1}{\gamma}\,\delta(x-y). \tag{4.20}$$

Defining the $U(1)$ gauge-invariant fields,

$$\psi = \Psi e^{i\alpha}, \quad \phi = \Phi e^{i\alpha}, \tag{4.21}$$

for action (4.3) we get

$$S = \gamma \int \left[\overline{\Phi}\,\partial_0\Psi + \Phi\,\partial_0\overline{\Psi} + \left\{ \overline{\psi_0} e^{i\alpha}\left(\partial_1\Phi + 2ig\Psi \int^x B \right) + \text{c.c.} \right\} \right.$$
$$\left. + \frac{1}{2}\,(V_0 - 2\,\partial_0\alpha)\{B + i\overline{\Psi}\Phi - i\overline{\Phi}\Psi\} \right]. \tag{4.22}$$

After redefinition of the Lagrange multipliers,

$$\mathscr{V}_0 \equiv V_0 - 2\,\partial_0\alpha, \quad \overline{\Psi}_0 \equiv \overline{\psi_0} e^{i\alpha}, \quad \Psi_0 \equiv \psi_0 e^{-i\alpha}, \tag{4.23}$$

the action is written only in terms of the gauge-invariant dynamical variables Ψ, $\overline{\Psi}$, Φ, $\overline{\Phi}$:

$$S = \gamma \int \left[\overline{\Phi}\,\partial_0\Psi + \Phi\,\partial_0\overline{\Psi} + \left\{ \overline{\Psi}_0\left(\partial_1\Phi + 2ig\Psi \int^x B \right) + \text{c.c.} \right\} + \frac{1}{2}\,\mathscr{V}_0\{B + i\overline{\Psi}\Phi - i\overline{\Phi}\Psi\} \right]. \tag{4.24}$$

We can solve the Gauss law constraint explicitly,

$$B = -i(\overline{\Psi}\Phi - \Psi\overline{\Phi}). \tag{4.25}$$

Then the action is

$$S = \gamma \int (\overline{\Phi}\,\partial_0\Psi + \Phi\,\partial_0\overline{\Psi}) - H, \tag{4.26a}$$

where the Hamiltonian in terms of the bilinear form (4.13) becomes

$$H = -\gamma\langle \Psi_0, M_\Psi \Phi\rangle = \gamma\langle M_\Psi \Psi_0, \Phi\rangle. \tag{4.26b}$$

Here, the skew symmetric operator M is the noncovariant form of the $\mathscr{M}$ operator (4.9):

$$M_\Psi(\Phi) \equiv \partial_1\Phi + 2g\Psi \int^x (\overline{\Psi}\Phi - \Psi\overline{\Phi})(y)dy = 0, \tag{4.27}$$

and coincides with the one introduced by Magri.[26] The Poisson brackets for $U(1)$ gauge-invariant dynamical variables,

$$\{\Psi(x), \overline{\Phi}(y)\} = \frac{1}{\gamma}\,\delta(x-y), \quad \{\overline{\Psi}(x), \Phi(y)\} = \frac{1}{\gamma}\,\delta(x-y), \tag{4.28}$$

generate the Hamiltonian equations, given by

$$\partial_0\Psi=\{\Psi,H\}=\frac{1}{\gamma}\frac{\delta H}{\delta\overline{\Phi}}=M_\Psi(\Psi_0), \tag{4.29a}$$

$$\partial_0\overline{\Psi}=\{\overline{\Psi},H\}=-\frac{1}{\gamma}\frac{\delta H}{\delta\Phi}=\overline{M_\Psi(\Psi_0)}, \tag{4.29b}$$

or in terms of the recursion operator, $R=iM$,

$$i\ \partial_0\Psi=R_\Psi(\Psi_0),\quad -i\ \partial_0\overline{\Psi}=\overline{R_\Psi(\Psi_0)}. \tag{4.30}$$

Thus, we can see the effect of introducing the Φ field, as the canonical momentum conjugate to the dynamical field Ψ, is to eliminate the nondynamical Lagrange multipliers Ψ_0.[21] Due to the arbitrariness of these multipliers, by the recursion operator R, we can construct the whole hierarchy of the multipliers,

$$\Psi_0^{(n)}=R_\Psi(\Psi_0^{(n-1)})=\cdots=R_\Psi^n(\Psi_0^{(0)}). \tag{4.31}$$

Then, the related actions,

$$S_{n+1}=\gamma\int(\overline{\Phi}\ \partial_{0_{n+1}}\Psi+\Phi\ \partial_{0_{n+1}}\overline{\Psi})-H_{n+1}, \tag{4.32a}$$

with the Hamiltonian

$$H_{n+1}=-\gamma\langle\Psi_0^{(n)},M_\Psi\Phi\rangle=\gamma\langle M_\Psi\Psi_0^{(n)},\Phi\rangle, \tag{4.32b}$$

define the evolution hierarchy,

$$i\ \partial_{0_{n+1}}\Psi=R_\Psi^{n+1}(\Psi_0^{(0)}),\quad -i\ \partial_{0_{n+1}}\overline{\Psi}=\overline{R_\Psi^{n+1}(\Psi_0^{(0)})}. \tag{4.33}$$

By skew symmetry property of the M operator we have the relations

$$\begin{aligned}H_{n+1}&=-\gamma\langle R^{(n)}(\Psi_0^{(0)}),M(\Phi)\rangle=-\gamma\langle R^{(n-1)}(\Psi_0^{(0)}),MR(\Phi)\rangle\\&=-\gamma\langle R^{(n-2)}(\Psi_0^{(0)}),MR^2(\Phi)\rangle\\&=\cdots=-\gamma\langle\Psi_0^{(0)},MR^n(\Phi)\rangle,\end{aligned} \tag{4.34}$$

or

$$H_{n+1}=\gamma\langle iR^{(n+1)}(\Psi_0^{(0)}),\Phi\rangle=\gamma\langle i\Psi_0^{(n+1)},\Phi^{(0)}\rangle=\gamma\langle\Psi_0^{(0)},iR^{n+1}(\Phi)\rangle=\gamma\langle\Psi_0^{(0)},i\Phi^{(n+1)}\rangle, \tag{4.35}$$

where

$$\Phi^{(n+1)}=R^{n+1}(\Phi^{(0)}),\quad \Phi^{(0)}\equiv\Phi. \tag{4.36}$$

If the constraint surface is defined by the relation

$$R(\Phi^{(0)})=0, \tag{4.37}$$

then it satisfies the constraints

$$R^2(\Phi^{(0)})=R^3(\Phi^{(0)})=\cdots=0, \tag{4.38}$$

for any degree n. Moreover, the surface (4.37) defines evolution,

$$i\ \partial_{0_1}\Psi=R(\Psi^{(0)}), \tag{4.39}$$

while the higher degree surface (4.38) generates the higher evolution,

$$i\ \partial_{0_n}\Psi=R^n(\Psi^{(0)}). \tag{4.40}$$

This just confirms the evident fact that the first member of the hierarchy (4.39) completely defines the higher evolutions.

Hence, in the Hamiltonian interpretation, the canonical bracket (4.28) for the first member of hierarchy (4.39):

$$\{\Psi(x),\overline{\Phi}^{(0)}(y)\}=\frac{1}{\gamma}\,\delta(x-y),\quad \{\overline{\Psi}(x),\Phi^{(0)}(y)\}=\frac{1}{\gamma}\,\delta(x-y), \tag{4.41}$$

defines the higher Poisson brackets,

$$\{\Psi(x),\overline{\Phi}^{(n)}(y)\}=\{\Psi(x),\overline{R^n\Phi^{(0)}}(y)\}\ =\frac{1}{\gamma}\,\delta(x-y),$$

$$\{\overline{\Psi}(x),\Phi^{(n)}(y)\}=\{\overline{\Psi}(x),R^n\Phi^{(0)}(y)\}\ =\frac{1}{\gamma}\,\delta(x-y). \tag{4.42}$$

In addition, every Hamiltonian (4.35) corresponds to the higher integrals of motion for the model. Thus, the BF formulation provides a natural description of the whole integrable hierarchy.

The above procedure can be extended to the case of spectral parameter dependence, by reduction of the $U(1)$ connection to the constant value, as in Secs. II and III. The details of the calculation will be published soon.

V. CONCLUSION

The main ingredient of our consideration is the moving frame method. Historically,[27] the moving frame idea has origin from mechanics where studying the rigid body motion, one gets one-parameter frames family depending on time and completely characterizing the rigid motion. Darboux[28] and Cotton[29] has generalized the one-parameter frame to several parameters. The richness of the theory was demonstrated by Cartan[30] (*la méthode du répère mobile*), who successfully applied it to research in differential geometry. We find that this deep method is conceptually simple to study integrable models and the underlying gauge theoretical structure.

In the recent study of the dimensionally reduced Jackiw–Pi model,[4–6] to produce dynamics for the B field, an extension of the Lagrangian was given and the chiral solitons, propagating only in one direction was constructed. From our consideration it is clear that the chiral solitons can be created by the odd members of the hierarchy with the odd dispersion. This fact is valid, even for the linear approximation. Thus, for the NLS (2.32) the linear wave with the wave number k is propagating with velocity $v=k$, while the wave for $-k$ is propagating in the opposite direction with the same velocity. On the contrary, for the next member of the hierarchy, Eq. (2.33), both waves with $+k$ and $-k$ are propagating in the same direction with velocity $v=k^2$. The similar structure is valid also for solitons. This shows that the chiral solitons in our approach belong to the odd members of the NLS hierarchy.

In conclusion, as shown in the present paper, the $1+1$-dimensional projection of Chern–Simons gauge interacting theory contains the hidden hierarchy of integrable systems. The statistical gauge field, after projection, still plays the crucial role defining spectral characteristics of the system. The key point for the construction is the mapping to non-Abelian BF theory, which covers all the rich structure of an integrable system.[31–33] The commutativity of spectral flows naturally provides the hierarchy of the gauge fixing constraints and the corresponding time hierarchy. We hope that our procedure could clarify some difficult questions of the diffeomorphism invariance breaking in the theories like gravity, and the time hierarchy creation with the physical degrees of freedom from the reparametrization invariance.

Two-body Dirac equations for general covariant interactions and their coupled Schrödinger-like forms

Peter Long and Horace W. Crater
The University of Tennessee Space Institute, Tullahoma, Tennessee 37388

(Received 9 July 1997; accepted for publication 28 August 1997)

We present new and useful ''external potential'' forms of the two-body Dirac equations of constraint dynamics for combined scalar, vector, pseudoscalar, pseudovector, and tensor interactions. These equations have potential applications in two-body problems for bound states in meson spectroscopy and phase shift analysis in nucleon–nucleon scattering. Toward this end, we derive their coupled Schrödinger-like forms using matrix techniques and obtain the corresponding radial equations to these forms from scalar and vector spherical harmonic decompositions. © *1998 American Institute of Physics.* [S0022-2488(98)00801-9]

I. INTRODUCTION

Dirac proposed in 1928 a single-particle wave equation for the behavior of a relativistic spin-1/2 particle.[1] The Dirac equation applies to the model of a single spin-1/2 particle in an external field. Its successful application to hydrogenic systems is dependent on the approximation that the proton is static and its magnetic moment can be ignored compared to the electron magnetic moment (i.e., there is no dipole–dipole electromagnetic interaction between the electron and proton). In general in systems such as mesons, muonium, positronium, and the deuteron, the constituent particles can have equal or near equal mass and magnetic moment: the external potential model breaks down. Theories that put both particles on an equal footing in describing two interacting spin-1/2 particles have all built on the single particle Dirac equation. Breit introduced an extension of Dirac's equation to the two-body problem in 1929.[2–4] Breit's form does not retain the manifest covariance of the original Dirac equation and relativistic corrections beyond the Coulomb potential must be handled perturbatively to avoid singularities.[5–8] Nevertheless, the Breit equation has produced accurate positronium and muonium spectra.[2–5]

The general subject matter of this work, two-body bound state wave equations, is an old problem but, judging by the very large variety of approaches,[9] one with no consensus, without yet an agreed upon formalism. Gradually over the past 15 years several authors have followed an approach[10–17] to this problem that appears to have been quite successful and shows additional promise by overcoming defects in many of the approaches listed in Ref. 9. This approach is that of Dirac's Hamiltonian constraint mechanics[18] and provides a manifestly covariant detour around many of the problems that plague the implementations and applications of the Bethe–Salpeter equation. What is remarkable about the constraint approach is that it provides a covariant three-dimensional rearrangement of the Bethe–Salpeter equation with none of the accompanying problems, including those of relative time excitations.[19] It also has all of the formal familiarity of the local nonrelativistic Schrödinger equation. The methods described in this paper derive directly from Dirac's relativistic Hamiltonian formalism (developed during the 1960s[18]) and Todorov's covariant two-body model, based on his two-body generalization of the one-body Einstein mass-shell relation ($m^2+\mathbf{p}^2=E^2$) (developed during the 1970s[9,20]). Dirac's Hamiltonian formalism is well suited for the covariant canonical quantization of relativistic two-body dynamics models such as Todorov's. Crater and Van Alstine adapted a theoretical hybrid of these two methods to a covariant description of interacting spin-1/2 particles—the coupled two-body Dirac equations.

A simplified first impression of the Crater–Van Alstine adaptation, which would not be too far off, would be to say that Dirac's constraint mechanics supplies a Hamiltonian formalism into

0022-2488/98/39(1)/124/37/$15.00
© 1998 American Institute of Physics

which Todorov's canonically conjugate variables are introduced for the purposes of calculation. Furthermore, in his quasipotential approach to the two body problem, Todorov introduced an effective ''external potential'' framework in which the potentials appear in the two-body problem, giving it an important intuitive appeal, both for ease of interpretation and practical implementation.[20] For spinless particles the Dirac constraint approach incorporates two coupled Klein–Gordon equations while for systems of two interacting spin-1/2 particles (positronium, mesons) it includes two coupled Dirac equations.

In a series of papers[10,11,13–16] Crater and Van Alstine have embedded Todorov's effective particle approach in the framework of Dirac's Hamiltonian constraint mechanics for a description of two-body systems which incorporates spin with applications to QED and quark model calculations based on QCD. Their approach yields manifestly covariant coupled equations in which interactions are introduced via minimal substitution: $p^\mu \to \pi^\mu = p^\mu - A^\mu$ for the Lorentz vector interaction and $m \to M = m + S$ for the Lorentz scalar interaction. Unlike with the Breit equation, the relativistic spin corrections need not be treated only perturbatively.[21] Since the operators are quantum mechanically well defined, one can use nonperturbative techniques (analytic as well as numerical) for the solution of bound state problems.

In recent work[14] Crater and Van Alstine have extended this approach to interactions beyond scalar and four-vector, including pseudoscalar, pseudovector, and tensor interactions in the two-body Dirac equations in the ''external potential'' framework introduced by Todorov. Their results were separate sets of coupled equations for each of these interactions acting singly, and several equations for some of the simpler interactions acting simultaneously in combination. Those authors presented a method for deriving the general case two-body Dirac equations for all interactions acting together simultaneously: however, they did not derive this important general result nor did they carry out the equally important Pauli reductions to Schrödinger-like forms.

In this paper we present the logical conclusion of results discussed in Ref. 14, deriving the general coupled equations for all interactions acting at once. We then reduce these equations to a Schrödinger-like form (its so-called Pauli-reduction) that is very useful for numerical calculations of the energy eigenstates for more realistic quark model interactions and for the difficult phase shift analysis problem of nucleon–nucleon scattering.

II. CONSTRAINT TWO-BODY DIRAC EQUATIONS

This section presents a review of previous material on constraint dynamics. One first introduces the relevant dynamical variables for the two-body Dirac equations of constraint dynamics (which we collectively call Todorov variables):

(i) relative position, $x_1 - x_2$;
(ii) total momentum, $P = p_1 + p_2$;
(iii) total c.m. ($\mathbf{P}=0$) energy, $w = \sqrt{-P^2}$;
(iv) constituent on-shell c.m. energies, $\epsilon_1 = (w^2 + m_1^2 - m_2^2)/2w$, $\epsilon_2 = (w^2 + m_2^2 - m_1^2)/2w$;
(v) relativistic reduced mass for fictitious particle of relative motion, $m_w = m_1 m_2 / w$;
(vi) c.m. energy of fictitious particle of relative motion, $\epsilon_w = (w^2 - m_1^2 - m_2^2)/2w$, and
(vii) relative momentum, $p = (\epsilon_2 p_1 - \epsilon_1 p_2)/w$. On mass shell,

$$p^2 = \epsilon_w^2 - m_w^2 = \frac{w^4 - 2(m_1^2 + m_2^2) + (m_1^2 - m_2^2)^2}{4w^2} \equiv b^2(w) = \epsilon_1^2 - m_1^2 = \epsilon_2^2 - m_2^2. \tag{2.1}$$

In terms of these variables,

$$p_1 = \epsilon_1 \hat{P} + p, \quad p_2 = \epsilon_2 \hat{P} - p, \tag{2.2}$$

where $\hat{P} = P/w$. Then one writes the Dirac equations for two free particles

$$\mathscr{S}_{10}\psi=(\theta_1\cdot p_1+m_1\theta_{51})\psi=0, \tag{2.3a}$$

$$\mathscr{S}_{20}\psi=(\theta_2\cdot p_2+m_2\theta_{52})\psi=0, \tag{2.3b}$$

where ψ is just the product of the two single-particle Dirac wave functions. These equations are compatible (they trivially commute $[\mathscr{S}_{10},\mathscr{S}_{20}]_-=0$) and become

$$\mathscr{S}_{10}\psi=(\theta_1\cdot p+\epsilon_1\theta_1\cdot\hat{P}+m_1\theta_{51})\psi=0, \tag{2.4a}$$

$$\mathscr{S}_{20}\psi=(-\theta_2\cdot p+\epsilon_2\theta_2\cdot\hat{P}+m_2\theta_{52})\psi=0, \tag{2.4b}$$

when expressed in terms of the Todorov variables. The ''theta'' matrices

$$\theta_i^\mu\equiv i\sqrt{\tfrac{1}{2}}\,\gamma_{5i}\gamma_i^\mu, \quad \mu=0,1,2,3, \quad i=1,2, \tag{2.5}$$

$$\theta_{5i}\equiv i\sqrt{\tfrac{1}{2}}\,\gamma_{5i}, \tag{2.6}$$

satisfy the fundamental anticommutation relations

$$[\theta_i^\mu,\theta_i^\nu]_+=-g^{\mu\nu}, \tag{2.7a}$$

$$[\theta_{5i},\theta_i^\mu]_+=0, \tag{2.7b}$$

$$[\theta_{5i},\theta_{5i}]_+=-1. \tag{2.7c}$$

(Projected ''theta'' matrices then satisfy

$$[\theta_i\cdot\hat{P},\theta_i\cdot\hat{P}]_+=1, \tag{2.8}$$

$$[\theta_i\cdot\hat{P},\theta_{i\perp}^\mu]_+=0, \tag{2.9}$$

where $\theta_{i\perp}^\mu=\theta_{i\nu}(\eta^{\mu\nu}+\hat{P}^\mu\hat{P}^\nu)$.) They are modified Dirac matrices[22] which ensure that the Dirac operators $\mathscr{S}_{10}$ and $\mathscr{S}_{20}$ are the square root operators of the corresponding mass-shell operators $-\frac{1}{2}(p_1^2+m_1^2)$ and $-\frac{1}{2}(p_2^2+m_2^2)$.

Using the Todorov variables and the above brackets, the difference

$$(\mathscr{S}_{10}^2-\mathscr{S}_{20}^2)\psi=0=-\tfrac{1}{2}(p_1^2+m_1^2-p_2^2-m_2^2)\psi \tag{2.10}$$

leads to an equation

$$P\cdot p\,\psi=\tfrac{1}{2}[w(\epsilon_1-\epsilon_2)-(m_1^2-m_2^2)]\psi=0, \tag{2.11}$$

which puts a constraint on the relative momentum (eliminating the relative energy in the c.m. frame).

We define covariant (c.m. projected) versions of the Dirac α and β matrices by

$$\beta_i=-\gamma_i\cdot\hat{P}=2\,\theta_{5i}\theta_i\cdot\hat{P}, \tag{2.12}$$

$$\alpha_i^\mu=2\,\theta_{i\perp}^\mu\,\theta_i\cdot\hat{P}, \tag{2.13}$$

and

$$\Sigma_i^\mu=\gamma_{5i}\alpha_i^\mu=2\sqrt{2}\,i\,\theta_{5i}\theta_i\cdot\hat{P}\,\theta_{\perp i}, \quad i=1,2, \tag{2.14}$$

which take on the simple form $\alpha_i^\mu=(0,\boldsymbol{\alpha}_i)$ and $\Sigma_i^\mu=(0,\boldsymbol{\Sigma}_i)$ in the center-of-mass system for which $\hat{P}=(1,\mathbf{0})$.

If we attempt to introduce scalar interactions between particles by naively making the minimal substitutions

$$m_i\rightarrow M_i=m_i+S_i\,,\quad i=1,2 \tag{2.15}$$

(as done in the one-body equation), the resulting Dirac equations

$$\mathscr{S}_1\psi=(\theta_1\cdot p+\boldsymbol{\epsilon}_1\theta_1\cdot\hat{P}+M_1\theta_{51})\psi=0, \tag{2.16a}$$

$$\mathscr{S}_2\psi=(-\theta_2\cdot p+\boldsymbol{\epsilon}_2\theta_2\cdot\hat{P}+M_2\theta_{52})\psi=0, \tag{2.16b}$$

will not be compatible because

$$[.\mathscr{S}_1,.\mathscr{S}_2]_-\psi=[\theta_1\cdot p,M_2\theta_{52}]+[M_1\theta_{51},-\theta_2\cdot p]-=-i(\partial M_1\cdot\theta_1\theta_{52}+\partial M_2\cdot\theta_2\theta_{51})\psi\neq 0 \tag{2.17}$$

(∂ is the four-gradient).

In the earlier work,[10,13] compatibility was achieved for scalar and timelike vector interactions with the help of supersymmetry arguments. For world scalar interactions, this results in the introduction of interactions by way of constituent mass potentials M_i related to one another through a relativistic ''third law''

$$\partial(M_1^2-M_2^2)=0, \tag{2.18}$$

depending on the separation variable only through the spacelike projection perpendicular to the total momentum

$$M_i=M_i(x_\perp), \tag{2.19}$$

where[18]

$$x_\perp^\mu=(\eta^{\mu\nu}+\hat{P}^\mu\hat{P}^\nu)(x_1-x_2)_\nu\,. \tag{2.20}$$

Integration of the ''third law'' condition yields

$$M_1^2-M_2^2=m_1^2-m_2^2 \tag{2.21}$$

with the hyperbolic solution

$$M_1=m_1\ \mathrm{ch}(L)+m_2\ \mathrm{sh}(L),\quad M_2=m_2\ \mathrm{ch}(L)+m_1\ \mathrm{sh}(L), \tag{2.22}$$

given in terms of a single invariant function $L=L(x_\perp)$.

Without the $x_\perp$ dependence of the potential and the relativistic ''third law'' conditions the constraints would not be compatible. While the physical importance of the $x_\perp$ dependence lies in its exclusion of the relative time from the dynamics in the c.m. frame, the ''third law'' condition relates the effective potentials each particle feels in the presence of the other in just such a way that the constraints become compatible.

The compatible spin-dependent constraints $\mathscr{S}_1$ and $\mathscr{S}_2$ below are then commuting quantum operators (the constraints are strongly compatible)

$$[.\mathscr{S}_1,.\mathscr{S}_2]=0, \tag{2.23}$$

with the resulting two-body Dirac equations for scalar interactions being

$$\mathscr{S}_1\psi=(\theta_1\cdot p+\epsilon_1\theta_1\cdot\hat{P}+M_1\theta_{51}-i\partial L\cdot\theta_2\theta_{52}\theta_{51})\psi=0, \tag{2.24a}$$

$$\mathscr{S}_2\psi=(-\theta_2\cdot p+\epsilon_2\theta_2\cdot\hat{P}+M_2\theta_{52}+i\partial L\cdot\theta_1\theta_{52}\theta_{51})\psi=0, \tag{2.24b}$$

where

$$\partial L=\frac{\partial M_1}{M_2}=\frac{\partial M_2}{M_1}. \tag{2.25}$$

The strong compatibility of the two constraints has been achieved by a supersymmetry which produces the extra spin-dependent recoil terms involving ∂L. These extra terms vanish, however, when one of the particles becomes infinitely massive (as seen by the parametrization $M_i=m_i+S_i$ of the scalar potential) so that one recovers the expected one-body Dirac equation in an external scalar potential. Notice the ''effective potential'' framework each particle has in the presence of the other in Eqs. (2.24). One of the primary purposes of this paper is to show we can maintain such a framework when all interactions are introduced simultaneously.

The Dirac constraint operators satisfy[10,13]

$$(\mathscr{S}_1^2-\mathscr{S}_2^2)\psi=-\tfrac{1}{2}(p_1^2+m_1^2-p_2^2-m_2^2)\psi=-P\cdot p\,\psi=0, \tag{2.26}$$

so that the relative momentum remains orthogonal to the total momentum even in the presence of scalar interactions.

One solves the compatibility problem without having to invent new supersymmetries if the scalar potential is replaced by vector, pseudoscalar, pseudovector, or tensor potentials, by first rewriting the supersymmetric or ''external potential'' form Eqs. (2.24) of the two-body Dirac equations for scalar interaction in the hyperbolic form[14] below:

$$\mathscr{S}_1\psi=(\mathrm{ch}(\Delta)\mathbf{S}_1+\mathrm{sh}(\Delta)\mathbf{S}_2)\psi=0, \tag{2.27a}$$

$$\mathscr{S}_2\psi=(\mathrm{ch}(\Delta)\mathbf{S}_2+\mathrm{sh}(\Delta)\mathbf{S}_1)\psi=0, \tag{2.27b}$$

where Δ generates the scalar potential terms in (2.24) provided that

$$\Delta=-\theta_{51}\theta_{52}L(x_\perp). \tag{2.28}$$

The operators $\mathbf{S}_1$ and $\mathbf{S}_2$ are auxiliary constraints of the form

$$\mathbf{S}_1\psi\equiv(\mathscr{S}_{10}\,\mathrm{ch}(\Delta)+\mathscr{S}_{20}\,\mathrm{sh}(\Delta))\psi=0, \tag{2.29a}$$

$$\mathbf{S}_2\psi\equiv(\mathscr{S}_{20}\,\mathrm{ch}(\Delta)+\mathscr{S}_{10}\,\mathrm{sh}(\Delta))\psi=0. \tag{2.29b}$$

Second, if one postulates that Eqs. (2.29a) and (2.29b) are valid for arbitrary Δ, then a direct consequence is that[12,14,21]

$$[P\cdot p,\Delta]\psi=0, \tag{2.30}$$

or $\Delta(x)=\Delta(x_\perp)$ and

$$P\cdot p\,\psi=0. \tag{2.31}$$

This, in turn leads to the weak compatibility of both sets of constraints:[21,14,12]

$$[\mathscr{S}_1,\mathscr{S}_2]\psi=0 \tag{2.32}$$

and

$$[\mathbf{S}_1,\mathbf{S}_2]\psi=0. \tag{2.33}$$

In our work here we shall consider Eqs. (2.27) and (2.29) for a sum of the four ''polar'' and four ''axial'' interactions. The four polar interactions[23] are

$$\Delta_L=-L\theta_{51}\theta_{52}\equiv-1\frac{L}{2}\mathscr{O}_1,\mathscr{O}_1=-\gamma_{51}\gamma_{52},\quad \text{scalar,} \tag{2.34a}$$

$$\Delta_J=J\hat{P}\cdot\theta_1\hat{P}\cdot\theta_2\equiv\mathscr{O}_2\frac{J}{2}=\beta_1\beta_2\frac{J}{2}\mathscr{O}_1,\quad \text{timelike vector,} \tag{2.34b}$$

$$\Delta_{\mathscr{G}}=\mathscr{G}\theta_{1\perp}\cdot\theta_{2\perp}\equiv\mathscr{O}_3\frac{\mathscr{G}}{2}=\gamma_{1\perp}\cdot\gamma_{2\perp}\frac{\mathscr{G}}{2}\mathscr{O}_1,\quad \text{spacelike vector,} \tag{2.34c}$$

$$\Delta_{\mathscr{F}}=4\mathscr{F}\theta_{1\perp}\cdot\theta_{2\perp}\theta_{51}\theta_{52}\hat{P}\cdot\theta_1\hat{P}\cdot\theta_2\equiv\mathscr{O}_4\frac{\mathscr{F}}{2}=\alpha_1\cdot\alpha_2\frac{\mathscr{F}}{2}\mathscr{O}_1,\quad \text{tensor (polar),} \tag{2.34d}$$

and would correspond to interactions with two polar vertices in an effective exchange model. The polar matrices are ''doubly odd,'' i.e., are odd in the number of theta matrices of both particle one and particle two. Because of this they each will anticommute with the singly odd theta matrices in $\mathscr{S}_{i0}$ of different types and the natural brackets are anticommutators. Their sum,

$$\Delta_p=\Delta_L+\Delta_J+\Delta_{\mathscr{G}}+\Delta_{\mathscr{F}}, \tag{2.35}$$

would be used in Eqs. (2.27) and (2.29) with no alteration.

The four ''axial'' interactions are[23]

$$\Delta_C=C/2\equiv\mathscr{E}_1\frac{C}{2}=-\gamma_{51}\gamma_{52}\frac{C}{2}\mathscr{O}_1,\quad \text{pseudoscalar,} \tag{2.36a}$$

$$\Delta_H=-2H\hat{P}\cdot\theta_1\hat{P}\cdot\theta_2\theta_{51}\theta_{52}\equiv-\mathscr{E}_2\frac{H}{2}=\beta_1\gamma_{51}\beta_2\gamma_{52}\frac{H}{2}\mathscr{O}_1,\quad \text{timelike pseudovector,} \tag{2.36b}$$

$$\Delta_I=-2I\theta_{1\perp}\cdot\theta_{2\perp}\theta_{51}\theta_{52}\equiv-\mathscr{E}_3\frac{I}{2}=-\gamma_{51}\gamma_{1\perp}\cdot\gamma_{52}\gamma_{2\perp}\frac{I}{2}\mathscr{O}_1,\quad \text{spacelike pseudovector,} \tag{2.36c}$$

$$\Delta_Y=-2Y\theta_{1\perp}\cdot\theta_{2\perp}\hat{P}\cdot\theta_1\hat{P}\cdot\theta_2\equiv-\mathscr{E}_4\frac{Y}{2}=-\Sigma_1\cdot\Sigma_2\frac{Y}{2}\mathscr{O}_1,\quad \text{tensor (axial).} \tag{2.36d}$$

These Δ_a's correspond to interactions with two axial vertices in an effective exchange model. The axial matrices are ''doubly even,'' i.e., are even in the number of theta matrices of both particle one and particle two. Because of this they each will commute with the singly odd theta matrices in $\mathscr{S}_{i0}$ of different types and the natural brackets to use are commutators. Their sum

$$\Delta_a=\Delta_C+\Delta_H+\Delta_I+\Delta_Y \tag{2.37}$$

would be used in Eqs. (2.27) and (2.29) but with the $\mathrm{sh}(\Delta_a)$ terms in Eq. (2.27) appearing with a negative sign instead of the plus sign as occurs for polar interactions.[14] In contrast, Eq. (2.29) has no sign changes for Δ_a.

For systems with both polar and axial interactions,[14] one uses $\Delta_p-\Delta_a$ in (2.27) and $\Delta_p+\Delta_a$ in (2.29) in place of Δ. The terms $L,\ J,\ \mathscr{G},\ \mathscr{F},\ C,\ H,\ I,\ Y$ are arbitrary invariant functions of $x_\perp$. Equation (2.29) alone is more convenient to use for the construction of Breit-like equations from the constraint formalism for general interactions. Equation (2.27) in conjunction with Eq. (2.29) is more convenient if one's aim (as is ours here) is to obtain a set of Dirac equations in an ''external potential'' form similar to that exhibited in the one-body Dirac equation, with the transformation properties one would expect for such potentials.

In subsequent sections we derive the ''external potential'' forms of the two-body Dirac equations for the sum of all eight covariant interactions. We then derive from them the necessary Schrödinger-like equations for the combined eight interactions.

III. ''EXTERNAL POTENTIAL'' FORM OF THE CONSTRAINT TWO-BODY DIRAC EQUATIONS

The compatibility of the general forms of the hyperbolic constraints (2.27a) and (2.27b) for arbitrary $\Delta(x_\perp)$ leads to a systematic method for the introduction of interactions. We find the $\mathscr{S}_1$ and $\mathscr{S}_2$ constraints (2.24) for the scalar interaction by inserting the appropriate invariant matrix Δ_L in Eqs. (2.27a) and (2.27b) and then expanding (2.29a) and (2.29b) in terms of $\Delta(x_\perp)$.

The derivation of generalizations of the form (2.24) to arbitrary combinations of the eight different invariant forms discussed above is the subject of this section.

A. Deriving the general constraints $\mathscr{S}_1$ and $\mathscr{S}_2$

For each of the individual eight interaction matrices, $\Delta_L,\Delta_J,\Delta_{\mathscr{G}},\Delta_{\mathscr{F}},\Delta_C,\Delta_H,\Delta_I,\Delta_Y$, we can derive[14] the corresponding ''external potential'' forms of the two-body Dirac equations $\mathscr{S}_1\psi=0$ and $\mathscr{S}_2\psi=0$. The basic method is same for both the axial interactions Δ_a's and polar interactions Δ_p's; the only difference arises in the choice of commutation and anticommutation brackets used in the derivation.[24]

Polar constraints from the general hyperbolic form: For each of the individual invariant polar matrices Δ_p's, Δ_L, Δ_J, $\Delta_{\mathscr{G}}$, and $\Delta_{\mathscr{F}}$ (or their sum), a generalization of Eq. (2.27) for ''external potential'' forms of the constraints $\mathscr{S}_1$ and $\mathscr{S}_2$ have the following relation to the auxiliary constraints $\mathbf{S}_1$ and $\mathbf{S}_2$:

$$\mathscr{S}_1\psi=[\mathrm{ch}(\Delta_p)\mathbf{S}_1+\mathrm{sh}(\Delta_p)\mathbf{S}_2]\psi=0, \tag{3.1a}$$

$$\mathscr{S}_2\psi=[\mathrm{ch}(\Delta_p)\mathbf{S}_2+\mathrm{sh}(\Delta_p)\mathbf{S}_1]\psi=0. \tag{3.1b}$$

Explicitly, using the generalization of these auxiliary constraints of Eq. (2.29), we find[14] that $\mathscr{S}_1$ becomes

$$\begin{aligned}\mathscr{S}_1\psi=\mathscr{S}_{10}&+\mathrm{ch}\ \Delta_p[\mathscr{S}_{10},\mathrm{ch}\ \Delta_p]_-+\mathrm{ch}\ \Delta_p[\mathscr{S}_{20},\mathrm{sh}\ \Delta_p]_+\\&+\mathrm{sh}\ \Delta_p[\mathscr{S}_{20},\mathrm{ch}\ \Delta_p]_-+\mathrm{sh}\ \Delta_p[\mathscr{S}_{10},\mathrm{sh}\ \Delta_p]_+ .\end{aligned} \tag{3.2}$$

Working out the commutation and anticommutation relations[24] in (3.2) yields[14] the generalized expression for $\mathscr{S}_1$ in the case of a polar Δ, i.e., $\Delta=\Delta_p$,

$$\begin{aligned}\mathscr{S}_1=\mathscr{S}_{10}+i\theta_2\cdot\partial\Delta_p-i\{&[\mathrm{ch}\ \Delta_p,\theta_1^\mu]_-\ \mathrm{sh}\ \Delta_p-[\mathrm{ch}\ \Delta_p,\theta_2^\mu]_-\mathrm{ch}\ \Delta_p-[\mathrm{sh}\ \Delta_p,\theta_2^\mu]_+\ \mathrm{sh}\ \Delta_p\\&+[\mathrm{sh}\ \Delta_p,\theta_1^\mu]_+\ \mathrm{ch}\ \Delta_p\}\partial_\mu\Delta_p+\{\mathrm{ch}\ \Delta_p[\theta_1^\mu,\mathrm{ch}\ \Delta_p]_--\mathrm{ch}\ \Delta_p[\theta_2^\mu,\mathrm{sh}\ \Delta_p]_+\\&-\mathrm{sh}\ \Delta_p[\theta_2^\mu,\mathrm{ch}\ \Delta_p]_-+\mathrm{sh}\ \Delta_p[\theta_1^\mu,\mathrm{sh}\ \Delta_p]_+\}p_\mu+\mathrm{ch}\ \Delta_p[\epsilon_1\theta_1\cdot\hat{P},\mathrm{ch}\ \Delta_p]_-+\mathrm{ch}\ \Delta_p[\epsilon_2\theta_2\\&\cdot\hat{P},\mathrm{sh}\ \Delta_p]_++\mathrm{sh}\ \Delta_p[\epsilon_2\theta_2\cdot\hat{P},\mathrm{ch}\ \Delta_p]_-+\mathrm{sh}\ \Delta_p[\epsilon_1\theta_1\cdot\hat{P},\mathrm{sh}\ \Delta_p]_++\mathrm{ch}\ \Delta_p[m_1\theta_{51},\mathrm{ch}\ \Delta_p]_-\\&+\mathrm{ch}\ \Delta_p[m_2\theta_{52},\mathrm{sh}\ \Delta_p]_++\mathrm{sh}\ \Delta_p[m_2\theta_{52},\mathrm{ch}\ \Delta_p]_-+\mathrm{sh}\ \Delta_p[m_1\theta_{51},\mathrm{sh}\ \Delta_p]_+\ .\end{aligned}\tag{3.3}$$

The expression for $\mathscr{S}_2$ is obtained by a similar method.

Axial constraints from the general hyperbolic form: For each of the individual invariant axial matrices Δ_a's, Δ_C, Δ_H, Δ_I, and Δ_Y (or their sum), the appropriate generalizations of Eq. (2.27) for the ''external potential'' forms $\mathscr{S}_1$ and $\mathscr{S}_2$ of the constraints have the following relations to the auxilary constraints $\mathbf{S}_1$ and $\mathbf{S}_2$ (Ref. 14):

$$\mathscr{S}_1\psi=[\mathrm{ch}\ \Delta_a\mathbf{S}_1-\mathrm{sh}\ \Delta_a\mathbf{S}_2]\psi=0,\tag{3.4a}$$

$$\mathscr{S}_2\psi=[\mathrm{ch}\ \Delta_a\mathbf{S}_2-\mathrm{sh}\ \Delta_a\mathbf{S}_1]\psi=0.\tag{3.4b}$$

The minus sign replaces the plus sign in Eqs. (3.1a) and (3.1b) so that one may take advantage of the different commutation relation of the Δ_a's and Δ_p's referred to below Eqs. (2.34) and (2.36) in conjunction with various hyperbolic identities.

The explicit calculation of $\mathscr{S}_1$ in the axial case is similar to the polar case, only the commutation relations are different due to their different symmetries. In terms of the axial invariant matrix Δ_a, $\mathscr{S}_1$ is[14]

$$\begin{aligned}\mathscr{S}_1\psi=\mathscr{S}_{10}&+\mathrm{ch}\ \Delta_a[\mathscr{S}_{10},\mathrm{ch}\ \Delta_a]_-+\mathrm{ch}\ \Delta_a[\mathscr{S}_{20},\mathrm{sh}\ \Delta_a]_-\\&-\mathrm{sh}\ \Delta_a[\mathscr{S}_{20},\mathrm{ch}\ \Delta_a]_--\mathrm{sh}\ \Delta_a[\mathscr{S}_{10},\mathrm{sh}\ \Delta_a]_-\ .\end{aligned}\tag{3.5}$$

Working out the commutation and anticommutation relations[24] in (3.5) yields[14] the generalized expression for $\mathscr{S}_1$ in the case of an axial Δ, i.e., $\Delta=\Delta_a$,

$$\begin{aligned}\mathscr{S}_1=\mathscr{S}_{10}+i\theta_2\cdot\partial\Delta_a-i\{&[\mathrm{ch}\ \Delta_a,\theta_1^\mu]_-\mathrm{sh}\ \Delta_a-[\mathrm{ch}\ \Delta_a,\theta_2^\mu]_-\mathrm{ch}\ \Delta_a+[\mathrm{sh}\ \Delta_a,\theta_2^\mu]_-\mathrm{sh}\ \Delta_a\\&-[\mathrm{sh}\ \Delta_a,\theta_1^\mu]_-\mathrm{ch}\ \Delta_a\}\partial_\mu\Delta_a+\{\mathrm{ch}\ \Delta_a[\theta_1^\mu,\mathrm{ch}\ \Delta_a]_--\mathrm{ch}\ \Delta_a[\theta_2^\mu,\mathrm{sh}\ \Delta_a]_-\\&+\mathrm{sh}\ \Delta_a[\theta_2^\mu,\mathrm{ch}\ \Delta_a]_--\mathrm{sh}\ \Delta_a[\theta_1^\mu,\mathrm{sh}\ \Delta_a]_-\}p_\mu+\mathrm{ch}\ \Delta_a[\epsilon_1\theta_1\cdot\hat{P},\mathrm{ch}\ \Delta_a]_-+\mathrm{ch}\ \Delta_a[\epsilon_2\theta_2\\&\cdot\hat{P},\mathrm{sh}\ \Delta_a]_--\mathrm{sh}\ \Delta_a[\epsilon_2\theta_2\cdot\hat{P},\mathrm{ch}\ \Delta_a]_--\mathrm{sh}\ \Delta_a[\epsilon_1\theta_1\cdot\hat{P},\mathrm{sh}\ \Delta_a]_-+\mathrm{ch}\ \Delta_a[m_1\theta_{51},\mathrm{ch}\ \Delta_a]_-\\&+\mathrm{ch}\ \Delta_a[m_2\theta_{52},\mathrm{sh}\ \Delta_a]_--\mathrm{sh}\ \Delta_a[m_2\theta_{52},\mathrm{ch}\ \Delta_a]_--\mathrm{sh}\ \Delta_a[m_1\theta_{51},\mathrm{sh}\ \Delta_a]_-\ .\end{aligned}\tag{3.6}$$

The expression for $\mathscr{S}_2$ is obtained by a similar method.

In spite of the length of Eqs. (3.3) and (3.6), for the simple case of individual interactions (i.e., $\Delta=\Delta_L$ or $\Delta=\Delta_J$, *not* $\Delta=\Delta_L+\Delta_J+\cdots$) many of the commutators vanish, and in practice the calculations are fairly short. Equations (3.7a)–(3.14a) display the result of the calculation for the four polar interactions (Δ_p's:$\Delta_L,\Delta_J,\Delta_{\mathscr{G}},\Delta_{\mathscr{F}}$), and the four axial interactions (Δ_a's:$\Delta_C,\Delta_H,\Delta_I,\Delta_Y$) *acting independently*. As presented in Ref. 14 we obtain the following two-body Dirac equations:

1. Polar interactions—Δ_p's

a. Scalar interaction: $\Delta=\Delta_L$:

$$\mathscr{S}_1\psi=\left(\theta_1\cdot p+\epsilon_1\theta_1\cdot\hat{P}+m_1\ \mathrm{ch}(L\mathscr{O}_1)\theta_{51}-m_2\ \mathrm{sh}(L\mathscr{O}_1)\theta_{52}-i\theta_2\cdot\frac{\partial L}{2}\mathscr{O}_1\right)\psi=0, \quad (3.7a)$$

$$\mathscr{S}_2\psi=\left(-\theta_2\cdot p+\epsilon_2\theta_2\cdot\hat{P}+m_2\ \mathrm{ch}(L\mathscr{O}_1)\theta_{52}-m_1\ \mathrm{sh}(L\mathscr{O}_1)\theta_{51}+i\theta_1\cdot\frac{\partial L}{2}\mathscr{O}_1\right)\psi=0. \quad (3.7b)$$

b. Timelike vector interaction: $\Delta=\Delta_J$:

$$\mathscr{S}_1\psi=\left(\theta_1\cdot p+\epsilon_1\ \mathrm{ch}(J\mathscr{O}_2)\theta_1\cdot\hat{P}+\epsilon_2\ \mathrm{sh}(J\mathscr{O}_2)\theta_2\cdot\hat{P}+m_1\theta_{51}+i\theta_2\cdot\frac{\partial J}{2}\mathscr{O}_2\right)\psi=0, \quad (3.8a)$$

$$\mathscr{S}_2\psi=\left(-\theta_2\cdot p+\epsilon_2\ \mathrm{ch}(J\mathscr{O}_2)\theta_2\cdot\hat{P}+\epsilon_1\ \mathrm{sh}(J\mathscr{O}_2)\theta_1\cdot\hat{P}+m_2\theta_{52}-i\theta_1\cdot\frac{\partial J}{2}\mathscr{O}_2\right)\psi=0. \quad (3.8b)$$

c. Spacelike vector interaction: $\Delta=\Delta_{\mathscr{G}}$:

$$\mathscr{S}_1\psi=\left(\exp(\mathscr{G})\theta_1\cdot p+\epsilon_1\theta_1\cdot\hat{P}+m_1\theta_{51}+i\ \exp(\mathscr{G})\theta_2\cdot\frac{\partial\mathscr{G}}{2}\mathscr{O}_3\right)\psi=0, \quad (3.9a)$$

$$\mathscr{S}_2\psi=\left(-\exp(\mathscr{G})\theta_2\cdot p+\epsilon_2\theta_2\cdot\hat{P}+m_2\theta_{52}-i\ \exp(\mathscr{G})\theta_1\cdot\frac{\partial\mathscr{G}}{2}\mathscr{O}_3\right)\psi=0. \quad (3.9b)$$

d. Polar tensor interaction: $\Delta=\Delta_{\mathscr{T}}$:

$$\mathscr{S}_1\psi=\Big(\exp(\mathscr{T}\mathscr{E}_2)\theta_1\cdot p+\epsilon_1\ \mathrm{ch}(\mathscr{T}\mathscr{O}_4)\theta_1\cdot\hat{P}+\epsilon_2\ \mathrm{sh}(\mathscr{T}\mathscr{O}_4)\theta_2\cdot\hat{P}+m_1\ \mathrm{ch}(\mathscr{T}\mathscr{O}_4)\theta_{51}$$
$$+m_2\ \mathrm{sh}(\mathscr{T}\mathscr{O}_4)\theta_{52}+i\ \exp(\mathscr{T}\mathscr{E}_2)\theta_2\cdot\frac{\partial\mathscr{T}}{2}\mathscr{O}_4\Big)\psi=0, \quad (3.10a)$$

$$\mathscr{S}_2\psi=\Big(-\exp(\mathscr{T}\mathscr{E}_2)\theta_2\cdot p+\epsilon_2\ \mathrm{ch}(\mathscr{T}\mathscr{O}_4)\theta_2\cdot\hat{P}+\epsilon_1\ \mathrm{sh}(\mathscr{T}\mathscr{O}_4)\theta_1\cdot\hat{P}+m_2\ \mathrm{ch}(\mathscr{T}\mathscr{O}_4)\theta_{52}$$
$$+m_1\ \mathrm{sh}(\mathscr{T}\mathscr{O}_4)\theta_{51}-i\ \exp(\mathscr{T}\mathscr{E}_2)\theta_1\cdot\frac{\partial\mathscr{T}}{2}\mathscr{O}_4\Big)\psi=0. \quad (3.10b)$$

2. Axial interactions—Δ_a's

a. Pseudoscalar interaction: $\Delta=\Delta_C$:

$$\mathscr{S}_1\psi=\left(\theta_1\cdot p+\epsilon_1\theta_1\cdot\hat{P}+m_1\theta_{51}+i\theta_2\cdot\frac{\partial C}{2}\mathscr{E}_1\right)\psi=0, \quad (3.11a)$$

$$\mathscr{S}_2\psi=\left(-\theta_2\cdot p+\epsilon_2\theta_2\cdot\hat{P}+m_2\theta_{52}-i\theta_1\cdot\frac{\partial C}{2}\mathscr{E}_1\right)\psi=0. \quad (3.11b)$$

b. Timelike pseudovector interaction: $\Delta=\Delta_H$:

$$\mathscr{S}_1\psi=\Big(\theta_1\cdot p+\epsilon_1\ \mathrm{ch}(H\mathscr{E}_2)\,\theta_1\cdot\hat{P}+\epsilon_2\ \mathrm{sh}(H\mathscr{E}_2)\,\theta_2\cdot\hat{P}$$
$$+m_1\ \mathrm{ch}(H\mathscr{E}_1)\,\theta_{51}+m_2\ \mathrm{sh}(H\mathscr{E}_1)\,\theta_{52}-i\,\theta_2\cdot\frac{\partial H}{2}\,\mathscr{E}_2\Big)\psi=0, \tag{3.12a}$$

$$\mathscr{S}_2\psi=\Big(-\theta_2\cdot p+\epsilon_2\ \mathrm{ch}(H\mathscr{E}_2)\,\theta_2\cdot\hat{P}+\epsilon_1\ \mathrm{sh}(H\mathscr{E}_2)\,\theta_1\cdot\hat{P}$$
$$+m_2\ \mathrm{ch}(H\mathscr{E}_1)\,\theta_{52}+m_1\ \mathrm{sh}(H\mathscr{E}_1)\,\theta_{51}+i\,\theta_1\cdot\frac{\partial H}{2}\,\mathscr{E}_2\Big)\psi=0. \tag{3.12b}$$

c. Spacelike pseudovector interaction: $\Delta=\Delta_I$:

$$\mathscr{S}_1\psi=\Big(\exp(I\mathscr{O}_1)\,\theta_1\cdot p+\epsilon_1\theta_1\cdot\hat{P}+m_1\ \mathrm{ch}(I\mathscr{E}_3)\,\theta_{51}$$
$$+m_2\ \mathrm{sh}(I\mathscr{E}_3)\,\theta_{52}-i\ \exp(I\mathscr{O}_1)\,\theta_2\cdot\frac{\partial I}{2}\,\mathscr{E}_3\Big)\psi=0, \tag{3.13a}$$

$$\mathscr{S}_2\psi=\Big(-\exp(I\mathscr{O}_1)\,\theta_2\cdot p+\epsilon_2\theta_2\cdot\hat{P}+m_2\ \mathrm{ch}(I\mathscr{E}_3)\,\theta_{52}$$
$$+m_1\ \mathrm{sh}(I\mathscr{E}_3)\,\theta_{51}+i\exp(I\mathscr{O}_1)\,\theta_1\cdot\frac{\partial I}{2}\,\mathscr{E}_3\Big)\psi=0. \tag{3.13b}$$

d. Pseudotensor interaction: $\Delta=\Delta_Y$:

$$\mathscr{S}_1\psi=\Big(\exp(Y\mathscr{O}_2)\,\theta_1\cdot p+\epsilon_1\ \mathrm{ch}(Y\mathscr{E}_4)\,\theta_1\cdot\hat{P}+\epsilon_2\ \mathrm{sh}(Y\mathscr{E}_4)\,\theta_2\cdot\hat{P}$$
$$+m_1\theta_{51}-i\ \exp(Y\mathscr{O}_2)\,\theta_2\cdot\frac{\partial Y}{2}\,\mathscr{E}_4\Big)\psi=0, \tag{3.14a}$$

$$\mathscr{S}_2=-\exp\Big(Y\mathscr{O}_2\Big)\,\theta_2\cdot p+\epsilon_2\ \mathrm{ch}(Y\mathscr{E}_4)\,\theta_2\cdot\hat{P}+\epsilon_1\ \mathrm{sh}(Y\mathscr{E}_4)\,\theta_1\cdot\hat{P}$$
$$+m_2\theta_{52}+i\ \exp(Y\mathscr{O}_2)\,\theta_1\cdot\frac{\partial Y}{2}\,\mathscr{E}_4\psi=0. \tag{3.14b}$$

Combining polar and axial interactions: We emphasize that the preceding expressions for $\mathscr{S}_i$, (3.3) and (3.6), are also suitable for the calculation of combinations of interactions: one finds the constraints for the combined polar interaction $\Delta_p=\Delta_L+\Delta_J+\Delta_{\mathscr{G}}+\Delta_{\mathscr{F}}$ using (3.3), and the constraints for the combined axial interaction $\Delta_a=\Delta_C+\Delta_H+\Delta_I+\Delta_Y$ using (3.6). The combination of all eight interactions (four polar plus four axial) is our desired result: the equivalent of Eqs. (3.7a)–(3.10b), for the polar interactions, and Eqs. (3.11a)–(3.14b), for the axial interactions, in two compact general Dirac equations. To combine all eight interaction we need to find a general relation, like (3.3) and (3.6), that is valid for the mixed symmetries of the general invariant matrix $\Delta=\Delta_a+\Delta_p$. For this purpose it is useful to define the matrices

$$\Delta_+\equiv\Delta_p+\Delta_a, \tag{3.15}$$

and

$$\Delta_- \equiv \Delta_p - \Delta_a . \tag{3.16}$$

To find the two-body Dirac equations $\mathscr{S}_1\psi=0$ and $\mathscr{S}_2\psi=0$ for the general *compound* interaction $\Delta=\Delta_+=\Delta_p+\Delta_a$, we use as in the previous derivations for the *separate* polar and axial interactions Δ_p and Δ_a the auxilary constraints, but with $\Delta=\Delta_+=\Delta_p+\Delta_a$:

$$\mathbf{S}_1\psi=[\mathscr{S}_{10}\ \mathrm{ch}\ \Delta_+ + \mathscr{S}_{20}\ \mathrm{sh}\ \Delta_+]\psi=0, \tag{3.17a}$$

$$\mathbf{S}_2\psi=[\mathscr{S}_{20}\ \mathrm{ch}\ \Delta_+ + \mathscr{S}_{10}\ \mathrm{sh}\ \Delta_+]\psi=0. \tag{3.17b}$$

We then insert these into the constrains (with $\Delta=\Delta_-=\Delta_p-\Delta_a$)

$$\mathscr{S}_1\psi=[\mathrm{ch}\ \Delta_-\mathbf{S}_1+\mathrm{sh}\ \Delta_-\mathbf{S}_2]\psi=0, \tag{3.18a}$$

$$\mathscr{S}_2\psi=[\mathrm{ch}\ \Delta_-\mathbf{S}_2+\mathrm{sh}\ \Delta_-\mathbf{S}_1]\psi=0, \tag{3.18b}$$

and expand using the identities

$$\mathrm{ch}\ \Delta_\pm=\mathrm{ch}\ \Delta_p\ \mathrm{ch}\ \Delta_a \pm \mathrm{sh}\ \Delta_p\ \mathrm{sh}\ \Delta_a , \tag{3.19a}$$

$$\mathrm{sh}\ \Delta_\pm=\mathrm{sh}\ \Delta_p\ \mathrm{ch}\ \Delta_a \pm \mathrm{ch}\ \Delta_p\ \mathrm{sh}\ \Delta_a . \tag{3.19b}$$

The result[24,14] is

$$\begin{aligned}
\mathscr{S}_1=\mathscr{S}_{10}&+i\theta_2\cdot\partial\Delta_+ - i\{[\mathrm{ch}\ \Delta_p\ \mathrm{ch}\ \Delta_a,\theta_1^\mu]_-\mathrm{sh}\ \Delta_+ - [\mathrm{ch}\ \Delta_p\ \mathrm{ch}\ \Delta_a,\theta_2^\mu]_-\ \mathrm{ch}\ \Delta_+\\
&-[\mathrm{sh}\ \Delta_p\ \mathrm{sh}\ \Delta_a,\theta_1^\mu]_+\ \mathrm{sh}\ \Delta_+ + [\mathrm{sh}\ \Delta_p\ \mathrm{sh}\ \Delta_a,\theta_2^\mu]_+\ \mathrm{ch}\ \Delta_+\}\partial_\mu\Delta_+\\
&-i\{[\mathrm{ch}\ \Delta_p\ \mathrm{sh}\ \Delta_a,\theta_2^\mu]_-\ \mathrm{sh}\ \Delta_+ - [\mathrm{ch}\ \Delta_p\ \mathrm{sh}\ \Delta_a,\theta_1^\mu]_-\ \mathrm{ch}\ \Delta_+ - [\mathrm{sh}\ \Delta_p\ \mathrm{ch}\ \Delta_a,\theta_2^\mu]_+\ \mathrm{sh}\ \Delta_+\\
&+[\mathrm{sh}\ \Delta_p\ \mathrm{ch}\ \Delta_a,\theta_1^\mu]_+\ \mathrm{ch}\ \Delta_+\}\partial_\mu\Delta_+ + \{\mathrm{ch}\ \Delta_-[\theta_{1\perp}^\mu,\mathrm{ch}\ \Delta_p\ \mathrm{ch}\ \Delta_a]_-\\
&-\mathrm{ch}\ \Delta_-[\theta_{2\perp}^\mu,\mathrm{sh}\ \Delta_p\ \mathrm{ch}\ \Delta_a]_+ - \mathrm{sh}\ \Delta_-[\theta_{2\perp}^\mu,\mathrm{ch}\ \Delta_p\ \mathrm{ch}\ \Delta_a]_-\\
&+\mathrm{sh}\ \Delta_-[\theta_{1\perp}^\mu,\mathrm{sh}\ \Delta_p\ \mathrm{ch}\ \Delta_a]_+\}p_\mu + \{\mathrm{ch}\ \Delta_-[\theta_{1\perp}^\mu,\mathrm{sh}\ \Delta_p\ \mathrm{sh}\ \Delta_a]_+\\
&-\mathrm{ch}\ \Delta_-[\theta_{2\perp}^\mu,\mathrm{ch}\ \Delta_p\ \mathrm{sh}\ \Delta_a]_- - \mathrm{sh}\ \Delta_-[\theta_{2\perp}^\mu,\mathrm{sh}\ \Delta_p\ \mathrm{sh}\ \Delta_a]_+\\
&+\mathrm{sh}\ \Delta_-[\theta_{1\perp}^\mu,\mathrm{ch}\ \Delta_p\ \mathrm{sh}\ \Delta_a]_-\}p_\mu + \mathrm{ch}\ \Delta_-[\epsilon_1\theta_1\cdot\hat{P},\mathrm{ch}\ \Delta_p\ \mathrm{ch}\ \Delta_a]_- + \mathrm{ch}\ \Delta_-[\epsilon_2\theta_2\\
&\cdot\hat{P},\mathrm{sh}\ \Delta_p\ \mathrm{ch}\ \Delta_a]_+ + \mathrm{sh}\ \Delta_-[\epsilon_2\theta_2\cdot\hat{P},\mathrm{ch}\ \Delta_p\ \mathrm{ch}\ \Delta_a]_- + \mathrm{sh}\ \Delta_-[\epsilon_1\theta_1\cdot\hat{P},\mathrm{sh}\ \Delta_p\ \mathrm{ch}\ \Delta_a]_+\\
&+\mathrm{ch}\ \Delta_-[\epsilon_1\theta_1\cdot\hat{P},\mathrm{sh}\ \Delta_p\ \mathrm{sh}\ \Delta_a]_+ + \mathrm{ch}\ \Delta_-[\epsilon_2\theta_2\cdot\hat{P}\ \mathrm{ch}\ \Delta_p\ \mathrm{sh}\ \Delta_a]_- + \mathrm{sh}\ \Delta_-[\epsilon_2\theta_2\\
&\cdot\hat{P},\mathrm{sh}\ \Delta_p\ \mathrm{sh}\ \Delta_a]_+ + \mathrm{sh}\ \Delta_-[\epsilon_1\theta_1\cdot\hat{P},\mathrm{ch}\ \Delta_p\ \mathrm{ch}\ \Delta_a]_- + \mathrm{ch}\ \Delta_-[m_1\theta_{51},\mathrm{ch}\ \Delta_p\ \mathrm{ch}\ \Delta_a]_-\\
&+\mathrm{ch}\ \Delta_-[m_2\theta_{52},\mathrm{sh}\ \Delta_p\ \mathrm{ch}\ \Delta_a]_+ + \mathrm{sh}\ \Delta_-[m_2\theta_{52},\mathrm{ch}\ \Delta_p\ \mathrm{ch}\ \Delta_a]_-\\
&+\mathrm{sh}\ \Delta_-[m_1\theta_{51},\mathrm{sh}\ \Delta_p\ \mathrm{ch}\ \Delta_a]_+ + \mathrm{ch}\ \Delta_-[m_1\theta_{51},\mathrm{sh}\ \Delta_p\ \mathrm{sh}\ \Delta_a]_+\\
&+\mathrm{ch}\ \Delta_-[m_2\theta_{52},\mathrm{ch}\ \Delta_p\ \mathrm{sh}\ \Delta_a]_- + \mathrm{sh}\ \Delta_-[m_2\theta_{52},\mathrm{sh}\ \Delta_p\ \mathrm{sh}\ \Delta_a]_+\\
&+\mathrm{sh}\ \Delta_-[m_1\theta_{51},\mathrm{ch}_p\ \mathrm{ch}\ \Delta_a]_- .
\end{aligned} \tag{3.20}$$

The calculation for $\mathscr{S}_2$ is entirely similar in method and result.[14]

We can now use the above expression (3.20) (and its analog for $\mathscr{S}_2$) to calculate the general hyperbolic constraint, $\mathscr{S}_1$ (and $\mathscr{S}_2$), for all eight interactions acting in concert, i.e., for the general invariant matrix,

$$\Delta = \Delta_+ = \underbrace{\Delta_L + \Delta_J + \Delta_{\mathscr{G}} + \Delta_{\mathscr{F}}}_{\Delta_p} + \underbrace{\Delta_C + \Delta_H + \Delta_I + \Delta_Y}_{\Delta_a}, \tag{3.21}$$

where

$$\Delta_p = \Delta_L + \Delta_J + \Delta_{\mathscr{G}} + \Delta_{\mathscr{F}}, \tag{3.22}$$

$$\Delta_a = \Delta_C + \Delta_H + \Delta_I + \Delta_Y . \tag{3.23}$$

The resulting complete hyperbolic two-body Dirac equations for all eight interaction acting together are[25]

$$\begin{aligned}\mathscr{S}_1\psi = \Big\{ &\exp(\mathscr{G} + \mathscr{F}\mathscr{E}_2 + I\mathscr{O}_1 + Y\mathscr{O}_2)\Big[\theta_1\cdot p - \frac{i}{2}\,\theta_2\cdot\partial(L\mathscr{O}_1 - J\mathscr{O}_2 - \mathscr{G}\mathscr{O}_3 - \mathscr{F}\mathscr{O}_4 - C\mathscr{E}_1 + H\mathscr{E}_2 \\ &+ I\mathscr{E}_3 + Y\mathscr{E}_4)\Big] + \epsilon_1\ \mathrm{ch}(J\mathscr{O}_2 + \mathscr{F}\mathscr{O}_4 + H\mathscr{E}_2 + Y\mathscr{E}_4)\,\theta_1\cdot\hat{P} \\ &+ \epsilon_2\ \mathrm{sh}(J\mathscr{O}_2 + \mathscr{F}\mathscr{O}_4 + H\mathscr{E}_2 + Y\mathscr{E}_4)\,\theta_2\cdot\hat{P} + m_1\ \mathrm{ch}(-L\mathscr{O}_1 + \mathscr{F}\mathscr{O}_4 + H\mathscr{E}_2 + I\mathscr{E}_3)\,\theta_{51} \\ &+ m_2\ \mathrm{sh}(-L\mathscr{O}_1 + \mathscr{F}\mathscr{O}_4 + H\mathscr{E}_2 + I\mathscr{E}_3)\,\theta_{52}\Big\}\psi = 0,\end{aligned} \tag{3.24a}$$

$$\begin{aligned}\mathscr{S}_2\psi = \Big\{ &-\exp(\mathscr{G} + \mathscr{F}\mathscr{E}_2 + I\mathscr{O}_1 + Y\mathscr{O}_2)\Big[\theta_2\cdot p - \frac{i}{2}\,\theta_1\cdot\partial(L\mathscr{O}_1 - J\mathscr{O}_2 - \mathscr{G}\mathscr{O}_3 \\ &- \mathscr{F}\mathscr{O}_4 - C\mathscr{E}_1 + H\mathscr{E}_2 + I\mathscr{E}_3 + Y\mathscr{E}_4)\Big] + \epsilon_1\ \mathrm{sh}(J\mathscr{O}_2 + \mathscr{F}\mathscr{O}_4 + H\mathscr{E}_2 + Y\mathscr{E}_4)\,\theta_1\cdot\hat{P} \\ &+ \epsilon_2\ \mathrm{ch}(J\mathscr{O}_2 + \mathscr{F}\mathscr{O}_4 + H\mathscr{E}_2 + Y\mathscr{E}_4)\,\theta_2\cdot\hat{P} + m_1\ \mathrm{sh}(-L\mathscr{O}_1 + \mathscr{F}\mathscr{O}_4 + H\mathscr{E}_2 + I\mathscr{E}_3)\,\theta_{51} \\ &+ m_2\ \mathrm{ch}(-L\mathscr{O}_1 + \mathscr{F}\mathscr{O}_4 + H\mathscr{E}_2 + I\mathscr{E}_3)\,\theta_{52}\Big\}\psi = 0.\end{aligned} \tag{3.24b}$$

Note the common structures in these ''external potential'' two-body Dirac equations: coordinate-dependent kinetic term, recoil terms (not present in the one body Dirac equation), timelike or energy potential terms (including the c.m. constituent energies), and scalar potential terms (including the constituent masses).

With these results the content of the two-body Dirac equations (3.7a)–(3.14a) has been condensed into Eqs. (3.24a) and (3.24b). One can easily generate all the relations (3.7a)–(3.14b) from (3.24a) and (3.24b) by imposing the appropriate limits: for example, letting all interactions vanish in (3.24a) and (3.24b) except C reproduces the pseudoscalar constraint equations (3.11a) and (3.11b). A similar limiting procedure (i.e., letting all interaction terms vanish except the one of interest) reproduces the other constraints of Eqs. (3.7a)–(3.14a), as it must for (3.24a) and (3.24b) to be valid. In the extremely long calculation (here omitted) that leads to the above two equations the interference terms between all of the interactions are of the form given here, involving exponentials and hyperbolic functions with arguments presented as sums of the arguments for the individual interactions.

In the simplified case of combined scalar, time- and spacelike vector, and pseudoscalar interactions, we use the hyperbolic parametrization introduced earlier plus two others,

$$M_1 = m_1\ \mathrm{ch}(L) + m_2\ \mathrm{sh}(L), \tag{3.25a}$$

$$M_2 = m_2\ \mathrm{ch}(L) + m_1\ \mathrm{sh}(L), \tag{3.25b}$$

$$E_1 = \epsilon_1\ \mathrm{ch}(J) + \epsilon_2\ \mathrm{sh}(J), \tag{3.26a}$$

$$E_2 = \epsilon_2\ \mathrm{ch}(J) + \epsilon_1\ \mathrm{sh}(J), \tag{3.26b}$$

$$G = e^{\mathscr{G}}, \tag{3.27}$$

where L, J, and $\mathscr{G}$ generate scalar, timelike vector and spacelike vector interactions, respectively, while C generates pseudoscalar interactions. The resultant ''external potential'' forms of the two-body Dirac equations with

$$\Delta = \Delta_J + \Delta_L + \Delta_{\mathscr{G}} + \Delta_C \tag{3.28}$$

are

$$\mathscr{S}_1\psi = \left(G\,\theta_1\cdot p + E_1\,\theta_1\cdot\hat{P} + M_1\,\theta_{51} + i\,\frac{G}{2}\,(\theta_2\cdot\partial\mathscr{G}\mathscr{O}_3 + \theta_2\cdot\partial J\mathscr{O}_2 - \theta_2\cdot\partial L\mathscr{O}_1 + \theta_2\cdot\partial C\mathscr{E}_1)\right)\psi = 0, \tag{3.29a}$$

$$\mathscr{S}_2\psi = \left(-G\,\theta_2\cdot p + E_2\,\theta_2\cdot\hat{P} + M_2\,\theta_{52} - i\,\frac{G}{2}\,(\theta_1\cdot\partial\mathscr{G}\mathscr{O}_3 + \theta_1\cdot\partial J\mathscr{O}_2 - \theta_1\cdot\partial L\mathscr{O}_1 + \theta_1\cdot\partial C\mathscr{E}_1)\right)\psi = 0. \tag{3.29b}$$

The scalar generator produces the mass or scalar potential M_i terms, the timelike vector generator produces the energy or timelike potential E_i terms, and the spacelike vector generator produces the transverse or spacelike momentum G terms, while the pseudoscalar generator produces only spin-dependent terms. Note that the vector and scalar interactions also have additional spin-dependent recoil terms essential for compatibility. The above features are just what one would expect for interactions transforming in this way and are direct consequences of the hyperbolic parametrization of the constraints.

We point out that the above equations (without the pseudoscalar interactions) have been used successfully in quark model calculations of the meson spectra.[11,16] Any realistic model, however, must ultimately include all eight types of interactions (it being recognized, of course, that the interactions are effective or semiphenomenological).

It is of interest and importance here to characterize the contributions of each of the eight different interactions. The advantage of writing the constraints in the ''external potential'' forms given in Eqs. (3.24a) and (3.24b) is that it forces the remaining potentials from the group into forms that one can interpret as spin-dependent combinations of the simpler scalar and vector potentials. We can see this most simply by examining the groupings of the different potentials in Eqs. (3.24a) and (3.24b). Consider first the timelike pseudovector interaction defined by the function $H(x_\perp)$ and the nature of its contributions, compared with the scalar and timelike vector contributions given in Eq. (3.29). Suppose all interactions are zero except for J, L, and H. Comparison of Eqs. (3.24a) and (3.24b) with Eqs. (3.12a), (3.12b), and (3.29) show us that the timelike pseudovector interaction H contributes both to the mass potential M_i terms as well as the energy or timelike vector potential E_i terms. Furthermore, since the matrix $\mathscr{E}_2$ is spin independent, so are those contributions.

The polar–tensor interaction defined by the function $\mathscr{F}(x_\perp)$ likewise contributes both to the mass potential M_i terms as well as the energy or timelike potential E_i terms. However, unlike with $H(x_\perp)$, since the matrix $\mathscr{O}_4$ is spin independent, so are the contributions to those terms. Note also that just like the spacelike vector generator $\mathscr{G}$, $\mathscr{F}$ produces spacelike vector-dependent potential terms that are momentum dependent. These same features are shared by $I(x_\perp)$, the spacelike pseudovector interaction, and $Y(x_\perp)$, the axial–tensor interaction, with the former contributing spin-dependent terms to the mass potential and the latter contributing spin-dependent terms to the timelike vector potential. Both interactions produces transverse momentum-dependent potential terms.

Later we shall compare the above expectations with the actual contributions to the various parts of the Schrödinger-like Pauli reduction.

IV. PAULI REDUCTION

We now use the two-body Dirac equations for ψ, (3.24a) and (3.24b), to derive the Schrödinger-like eigenvalue equation from the combined interactions: $L(x_\perp)$, $J(x_\perp)$, $H(x_\perp)$, $C(x_\perp)$, $\mathscr{G}(x_\perp)$, $\mathscr{F}(x_\perp)$, $I(x_\perp)$, $Y(x_\perp)$ for future application to the quark model. The basic method we will use has some similarities to the reduction of the single particle Dirac equation to a Schrödinger-like form (Pauli reduction). First we perform the matrix multiplications in (3.24a) and (3.24b) using the matrices $\mathscr{O}_1$, $\mathscr{O}_2$, $\mathscr{O}_3$, $\mathscr{O}_4$, $\mathscr{E}_1$, $\mathscr{E}_2$, $\mathscr{E}_3$, $\mathscr{E}_4$ to write out explicitly the resulting set of simultaneous equations. This is done in analogy to the Pauli reduction of the single-particle Dirac equation. We then solve the simultaneous equation set by a process of substitution and elimination, and in the process transform from a set of coupled first-order differential equations [for ψ_1, ψ_2, ψ_3, ψ_4 of Eq. (4.1)] to a single second-order Schrödinger-like eigenvalue equation for a newly defined wave function ϕ. This places the equations in a form that one can use most efficiently in quark-model calculations.

Crater and Van Alstine have carried and applied this procedure out for combined scalar, timelike vector, and spacelike vector interactions $(L,J,\mathscr{G})$.[15,16] The result in the general case was four coupled Schrödinger-like equations coupling two spin components of the upper-upper (ψ_1) and lower-lower (ψ_4) portions of the wave function. Mourad and Sazdjian[17] have carried out a similar procedure for these three interactions but starting with Eqs. (2.29a) and (2.29b) instead of the ''external potential'' forms of Eqs. (3.24a) and (3.24b). They further developed a technique to reduce the number of coupled equations in the general case from four to two, by using different combinations of the above wave functions. Our calculations below are for all eight interactions from the ''external potential'' forms of the equations and include a procedure analogous to that introduced in Ref. 17 but applied to Eqs. (3.24a) and (3.24b).

The wave function ψ appearing in the two-body Dirac equations (3.24a) and (3.24b) is a Dirac spinor written

$$\psi=\begin{bmatrix}\psi_1\\ \psi_2\\ \psi_3\\ \psi_4\end{bmatrix}, \tag{4.1}$$

where each ψ_i is itself a four-component spinor. The wave function ψ has a total of 16 components (a result of the direct product multiplication of the Dirac spinors of particle one and particle two, each of which has four components) and the matrices $\mathscr{O}_i$'s, $\mathscr{E}_i$'s are all 16×16. In terms of the gamma matrices we use the Dirac representations with block forms

$$\beta_1=\begin{pmatrix}1_8 & 0\\ 0 & -1_8\end{pmatrix},\quad \gamma_{51}=\begin{pmatrix}0 & 1_8\\ 1_8 & 0\end{pmatrix},\quad \beta_1\gamma_{51}\equiv\rho_1=\begin{pmatrix}0 & 1_8\\ -1_8 & 0\end{pmatrix}, \tag{4.2a}$$

$$\beta_2=\begin{pmatrix}\beta & 0\\ 0 & \beta\end{pmatrix},\quad \beta=\begin{pmatrix}1_4 & 0\\ 0 & -1_4\end{pmatrix}, \tag{4.2b}$$

$$\gamma_{52}=\begin{pmatrix}\gamma_5 & 0\\ 0 & \gamma_5\end{pmatrix},\quad \gamma_5=\begin{pmatrix}0 & 1_4\\ 1_4 & 0\end{pmatrix}, \tag{4.2c}$$

$$\beta_2\gamma_{52}\equiv\rho_2=\begin{pmatrix}\rho & 0\\ 0 & \rho\end{pmatrix},\quad \rho=\begin{pmatrix}0 & 1_4\\ -1_4 & 0\end{pmatrix}, \tag{4.2d}$$

$$\beta_1\gamma_{51}\gamma_{52}=\begin{pmatrix}0 & \gamma_5\\ -\gamma_5 & 0\end{pmatrix},\quad \gamma_{51}\gamma_{52}=\begin{pmatrix}0 & \gamma_5\\ \gamma_5 & 0\end{pmatrix},\quad \beta_2\gamma_{52}\gamma_{51}=\begin{pmatrix}0 & \rho\\ \rho & 0\end{pmatrix}. \tag{4.2e}$$

$$\Sigma_i=\gamma_{5i}\beta_i\gamma_{\perp i},\quad i=1,2. \tag{4.2f}$$

The last matrices are four-vector generalizations of the Pauli matrices of particles one and two. In the c.m. frame the time component is zero and the spatial components are the usual Pauli matrices for each particle. In terms of these matrices we rewrite (3.24a) and (3.24b) by multiplying the first by $\sqrt{2}i\beta_1$ and the second by $\sqrt{2}i\beta_2$ yielding

$$\begin{aligned}&[T_1(\beta_1\beta_2)+U_1(\beta_1\beta_2)\gamma_{51}\gamma_{52}]\psi\\ &\quad=\mathrm{ch}(H-\beta_1\beta_2\Sigma_1\cdot\Sigma_2\mathscr{F})(E_1(\beta_1\beta_2\Sigma_1\cdot\Sigma_2)+M_1(\beta_1\beta_2\Sigma_1\cdot\Sigma_2)\beta_1)\gamma_{51}\psi\\ &\qquad+\mathrm{sh}(H-\beta_1\beta_2\Sigma_1\cdot\Sigma_2\mathscr{F})(E_2(\beta_1\beta_2\Sigma_1\cdot\Sigma_2)+M_2(\beta_1\beta_2\Sigma_1\cdot\Sigma_2)\beta_2)\gamma_{52}\psi,\end{aligned} \tag{4.3a}$$

$$\begin{aligned}&-[T_2(\beta_1\beta_2)+U_2(\beta_1\beta_2)\gamma_{51}\gamma_{52}]\psi\\ &\quad=\mathrm{ch}(H-\beta_1\beta_2\Sigma_1\cdot\Sigma_2\mathscr{F})(E_2(\beta_1\beta_2\Sigma_1\cdot\Sigma_2)+M_2(\beta_1\beta_2\Sigma_1\cdot\Sigma_2)\beta_2)\gamma_{52}\psi\\ &\qquad+\mathrm{sh}(H-\beta_1\beta_2\Sigma_1\cdot\Sigma_2\mathscr{F})(E_1(\beta_1\beta_2\Sigma_1\cdot\Sigma_2)+M_1(\beta_1\beta_2\Sigma_1\cdot\Sigma_2)\beta_1)\gamma_{51}\psi\end{aligned} \tag{4.3b}$$

in which the kinetic and recoil terms are

$$\begin{aligned}T_1(\beta_1\beta_2)=\exp(\mathscr{G}+\mathscr{F}\beta_1\beta_2)\Big[&\mathrm{ch}(I+Y\beta_1\beta_2)\Sigma_1\cdot p-\frac{i}{2}\beta_1\beta_2(\mathrm{ch}(I+Y\beta_1\beta_2)\Sigma_2\cdot\partial(H\beta_1\beta_2-C\\ &+(\mathscr{G}\beta_1\beta_2+\mathscr{F})\Sigma_1\cdot\Sigma_2)+\mathrm{sh}(I+Y\beta_1\beta_2)\Sigma_2\cdot\partial(J\beta_1\beta_2-L+(I\beta_1\beta_2+Y)\Sigma_1\cdot\Sigma_2))\Big],\end{aligned} \tag{4.4a}$$

$$\begin{aligned}T_2(\beta_1\beta_2)=\exp(\mathscr{G}+\mathscr{F}\beta_1\beta_2)\Big[&\mathrm{ch}(I+Y\beta_1\beta_2)\Sigma_2\cdot p-\frac{i}{2}\beta_1\beta_2(\mathrm{ch}(I+Y\beta_1\beta_2)\Sigma_1\cdot\partial(H\beta_1\beta_2-C\\ &+(\mathscr{G}\beta_1\beta_2+\mathscr{F})\Sigma_1\cdot\Sigma_2)+\mathrm{sh}(I+Y\beta_1\beta_2)\Sigma_1\cdot\partial(J\beta_1\beta_2-L+(I\beta_1\beta_2+Y)\Sigma_1\cdot\Sigma_2))\Big],\end{aligned} \tag{4.4b}$$

$$U_1(\beta_1\beta_2)=\exp(\mathscr{G}+\mathscr{F}\beta_1\beta_2)\Big[\mathrm{sh}(I+Y\beta_1\beta_2)\Sigma_1\cdot p-\frac{i}{2}\,\beta_1\beta_2(\mathrm{ch}(I+Y\beta_1\beta_2)\Sigma_2\cdot\partial(J\beta_1\beta_2-L$$
$$+(I\beta_1\beta_2+Y)\Sigma_1\cdot\Sigma_2)+\mathrm{sh}(I+Y\beta_1\beta_2)\Sigma_2\cdot\partial(H\beta_1\beta_2-C+(\mathscr{G}\beta_1\beta_2+\mathscr{F})\Sigma_1\cdot\Sigma_2))\Big], \tag{4.4c}$$

$$U_2(\beta_1\beta_2)=\exp(\mathscr{G}+\mathscr{F}\beta_1\beta_2)\Big[\mathrm{sh}(I+Y\beta_1\beta_2)\Sigma_2\cdot p-\frac{i}{2}\,\beta_1\beta_2(\mathrm{ch}(I+Y\beta_1\beta_2)\Sigma_1\cdot\partial(J\beta_1\beta_2-L$$
$$+(I\beta_1\beta_2+Y)\Sigma_1\cdot\Sigma_2)+\mathrm{sh}(I+Y\beta_1\beta_2)\Sigma_1\cdot\partial(H\beta_1\beta_2-C+(\mathscr{G}\beta_1\beta_2+\mathscr{F})\Sigma_1\cdot\Sigma_2))\Big], \tag{4.4d}$$

while the generalized (spin-dependent) timelike and scalar potentials are

$$E_1(\beta_1\beta_2\Sigma_1\cdot\Sigma_2)=\epsilon_1\ \mathrm{ch}(J-\beta_1\beta_2\Sigma_1\cdot\Sigma_2Y)+\epsilon_2\ \mathrm{sh}(J-\beta_1\beta_2\Sigma_1\cdot\Sigma_2Y), \tag{4.5a}$$

$$E_2(\beta_1\beta_2\Sigma_1\cdot\Sigma_2)=\epsilon_2\ \mathrm{ch}(J-\beta_1\beta_2\Sigma_1\cdot\Sigma_2Y)+\epsilon_1\ \mathrm{sh}(J-\beta_1\beta_2\Sigma_1\cdot\Sigma_2Y), \tag{4.5b}$$

$$M_1(\beta_1\beta_2\Sigma_1\cdot\Sigma_2)=m_1\ \mathrm{ch}(L+\beta_1\beta_2\Sigma_1\cdot\Sigma_2I)+m_2\ \mathrm{sh}(L+\beta_1\beta_2\Sigma_1\cdot\Sigma_2I), \tag{4.5c}$$

$$M_2(\beta_1\beta_2\Sigma_1\cdot\Sigma_2)=m_2\ \mathrm{ch}(L+\beta_1\beta_2\Sigma_1\cdot\Sigma_2I)+m_1\ \mathrm{sh}(L+\beta_1\beta_2\Sigma_1\cdot\Sigma_2I). \tag{4.5d}$$

The end result of the matrix multiplications in (4.3a) and (4.3b) is a set of eight simultaneous equations for the Dirac spinors $\psi_1,\psi_2,\psi_3,\psi_4$: a set of four from the first of the constraint two-body Dirac equations $\mathscr{S}_1\psi=0$, and another set of four simultaneous equations from the second of the constraint two-body Dirac equations $\mathscr{S}_2\psi=0$. Explicitly, in an arbitrary frame, the result of the matrix calculation produces the eight simultaneous equations ($\Sigma_i^\mu\psi\to\sigma_i^\mu\psi_{1,2,3,4}$):

$$T_1(+1)\psi_1+U_1(+1)\psi_4=\mathrm{ch}(H-\sigma_1\cdot\sigma_2\mathscr{F})(E_1(\sigma_1\cdot\sigma_2)+M_1(\sigma_1\cdot\sigma_2))\psi_3$$
$$+\mathrm{sh}(H-\sigma_1\cdot\sigma_2\mathscr{F})(E_2(\sigma_1\cdot\sigma_2)+M_2(\sigma_1\cdot\sigma_2))\psi_2, \tag{4.6a}$$

$$T_1(-1)\psi_2+U_1(-1)\psi_3=\mathrm{ch}(H+\sigma_1\cdot\sigma_2\mathscr{F})(E_1(-\sigma_1\cdot\sigma_2)+M_1(-\sigma_1\cdot\sigma_2))\psi_4$$
$$+\mathrm{sh}(H+\sigma_1\cdot\sigma_2\mathscr{F})(E_2(-\sigma_1\cdot\sigma_2)-M_2(-\sigma_1\cdot\sigma_2))\psi_1, \tag{4.6b}$$

$$T_1(-1)\psi_3+U_1(-1)\psi_2=\mathrm{ch}(H+\sigma_1\cdot\sigma_2\mathscr{F})(E_1(-\sigma_1\cdot\sigma_2)-M_1(-\sigma_1\cdot\sigma_2))\psi$$
$$+\mathrm{sh}(H+\sigma_1\cdot\sigma_2\mathscr{F})(E_2(-\sigma_1\cdot\sigma_2)+M_2(-\sigma_1\cdot\sigma_2))\psi_4, \tag{4.6c}$$

$$T_1(+1)\psi_4+U_1(+1)\psi_1=\mathrm{ch}(H-\sigma_1\cdot\sigma_2\mathscr{F})(E_1(\sigma_1\cdot\sigma_2)-M_1(\sigma_1\cdot\sigma_2))\psi_2$$
$$+\mathrm{sh}(H-\sigma_1\cdot\sigma_2\mathscr{F})(E_2(\sigma_1\cdot\sigma_2)-M_2(\sigma_1\cdot\sigma_2))\psi_3, \tag{4.6d}$$

$$-T_2(+1)\psi_1-U_2(+1)\psi_4=\mathrm{ch}(H-\sigma_1\cdot\sigma_2\mathscr{F})(E_2(\sigma_1\cdot\sigma_2)+M_2(\sigma_1\cdot\sigma_2))\psi_2$$
$$+\mathrm{sh}(H-\sigma_1\cdot\sigma_2\mathscr{F})(E_1(\sigma_1\cdot\sigma_2)+M_1(\sigma_1\cdot\sigma_2))\psi_3, \tag{4.6e}$$

$$-T_2(-1)\psi_2-U_2(-1)\psi_3=\mathrm{ch}(H+\sigma_1\cdot\sigma_2\mathscr{F})(E_2(-\sigma_1\cdot\sigma_2)-M_2(-\sigma\cdot\sigma_2))\psi_1$$
$$+\mathrm{sh}(H+\sigma_1\cdot\sigma_2\mathscr{F})(E_1(-\sigma_1\cdot\sigma_2)+M_1(-\sigma_1\cdot\sigma_2))\psi_4, \tag{4.6f}$$

$$-T_2(-1)\psi_3-U_2(-1)\psi_2=\mathrm{ch}(H+\sigma_1\cdot\sigma_2\mathscr{F})(E_2(-\sigma_1\cdot\sigma_2)+M_2(-\sigma_1\cdot\sigma_2))\psi_4 + \mathrm{sh}(H+\sigma_1\cdot\sigma_2\mathscr{F})(E_1(-\sigma_1\cdot\sigma_2)-M_1(-\sigma_1\cdot\sigma_2))\psi_1, \tag{4.6g}$$

$$-T_2(+1)\psi_4-U_2(+1)\psi_1=\mathrm{ch}(H-\sigma_1\cdot\sigma_2\mathscr{F})(E_2(\sigma_1\cdot\sigma_2)-M_2(\sigma_1\cdot\sigma_2))\psi_3 + \mathrm{sh}(H-\sigma_1\cdot\sigma_2\mathscr{F})(E_1(\sigma_1\cdot\sigma_2)-M_1(\sigma_1\cdot\sigma_2))\psi_2. \tag{4.6h}$$

We now reduce the above set of eight equations to a second-order Schrödinger-like equation by a process of substitution and elimination using the combination of the four Dirac-spinors given below:

$$\phi_\pm\equiv\psi_1\pm\psi_4, \tag{4.7a}$$

$$\chi_\pm\equiv\psi_2\pm\psi_3. \tag{4.7b}$$

Equation (4.6a) plus Eq. (4.6d) yields

$$D_1^{++}\phi_+=E_1^{++}(\sigma_1\cdot\sigma_2)\chi_+-M_1^{+-}(\sigma_1\cdot\sigma_2)\chi_-. \tag{4.8}$$

Equation (4.6e) plus Eq. (4.6h) yields

$$-D_2^{++}\phi_+=E_2^{++}(\sigma_1\cdot\sigma_2)\chi_++M_2^{+-}(\sigma_1\cdot\sigma_2)\chi_-. \tag{4.9}$$

Equation (4.6b) plus Eq. (4.6c) yields

$$D_1^{-+}\chi_+=E_1^{-+}(\sigma_1\cdot\sigma_2)\phi_+-M_1^{-+}(\sigma_1\cdot\sigma_2)\phi_-. \tag{4.10}$$

Equation (4.6b) minus Eq. (4.6c) yields

$$D_1^{--}\chi_-=-E_1^{--}(\sigma_1\cdot\sigma_2)\phi_-+M_1^{--}(\sigma_1\cdot\sigma_2)\phi_+. \tag{4.11}$$

with the following definitions for the kinetic-recoil terms:

$$D_1^{++}\equiv T_1(+1)+U_1(+1)=e^{(\mathscr{G}+\mathscr{F}+I+Y)}\Big[\sigma_1\cdot p-\frac{i}{2}\,\sigma_2\cdot\partial[H-C+J-L + (\mathscr{G}+\mathscr{F}+I+Y)\sigma_1\cdot\sigma_2]\Big], \tag{4.12a}$$

$$D_2^{++}\equiv T_2(+1)+U_2(+1)=e^{(\mathscr{G}+\mathscr{F}+I+Y)}\Big[\sigma_2\cdot p-\frac{i}{2}\,\sigma_1\cdot\partial[H-C+J-L + (\mathscr{G}+\mathscr{F}+I+Y)\sigma_1\cdot\sigma_2]\Big], \tag{4.12b}$$

$$D_1^{-+}\equiv T_1(-1)+U_1(-1)=e^{(\mathscr{G}-\mathscr{F}+I-Y)}\Big[\sigma_1\cdot p+\frac{i}{2}\,\sigma_2\cdot\partial[-H-C-J-L + (-\mathscr{G}+\mathscr{F}-I+Y)\sigma_1\cdot\sigma_2]\Big], \tag{4.12c}$$

$$D_1^{--} \equiv T_1(-1) - U_1(-1) = e^{(\mathscr{G}-\mathscr{F}-I+Y)}\Big[\sigma_1\cdot p + \frac{i}{2}\,\sigma_2\cdot\partial[-H-C+J+L + (-\mathscr{G}+\mathscr{F}+I-Y)\sigma_1\cdot\sigma_2]\Big]. \tag{4.12d}$$

Notice how the spacelike interactions $(\mathscr{G},\mathscr{F},I,Y)$ group together to produce extra spin-dependent recoil terms and coordinate-dependent multiplicative factors to the spacelike momentum p. (We anticipated this in the last section.) Likewise, the scalar, timelike vector, pseudoscalar, and timelike pseudovector interactions (L,J,C,H) group together. The (spin-dependent) potential terms appearing are

$$E_1^{++}(\sigma_1\cdot\sigma_2) = \mathrm{ch}(H-\mathscr{F}\sigma_1\cdot\sigma_2)E_1(\sigma_1\cdot\sigma_2) + \mathrm{sh}(H-\mathscr{F}\sigma_1\cdot\sigma_2)E_2(\sigma_1\cdot\sigma_2), \tag{4.13a}$$

$$M_1^{+-}(\sigma_1\cdot\sigma_2) = \mathrm{ch}(H-\mathscr{F}\sigma_1\cdot\sigma_2)M_1(\sigma_1\cdot\sigma_2) - \mathrm{sh}(H-\mathscr{F}\sigma_1\cdot\sigma_2)M_2(\sigma_1\cdot\sigma_2), \tag{4.13b}$$

$$E_2^{++}(\sigma_1\cdot\sigma_2) = \mathrm{ch}(H-\mathscr{F}\sigma_1\cdot\sigma_2)E_2(\sigma_1\cdot\sigma_2) + \mathrm{sh}(H-\mathscr{F}\sigma_1\cdot\sigma_2)E_1(\sigma_1\cdot\sigma_2), \tag{4.13c}$$

$$M_2^{+-}(\sigma_1\cdot\sigma_2) = \mathrm{ch}(H-\mathscr{F}\sigma_1\cdot\sigma_2)M_2(\sigma_1\cdot\sigma_2) - \mathrm{sh}(H-\mathscr{F}\sigma_1\cdot\sigma_2)M_1(\sigma_1\cdot\sigma_2), \tag{4.13d}$$

$$E_1^{-+}(\sigma_1\cdot\sigma_2) = \mathrm{ch}(H+\mathscr{F}\sigma_1\cdot\sigma_2)E_1(-\sigma_1\cdot\sigma_2) + \mathrm{sh}(H+\mathscr{F}\sigma_1\cdot\sigma_2)E_2(-\sigma_1\cdot\sigma_2), \tag{4.13e}$$

$$M_1^{-+}(\sigma_1\cdot\sigma_2) = \mathrm{ch}(H+\mathscr{F}\sigma_1\cdot\sigma_2)M_1(-\sigma_1\cdot\sigma_2) + \mathrm{sh}(H+\mathscr{F}\sigma_1\cdot\sigma_2)M_2(-\sigma_1\cdot\sigma_2), \tag{4.13f}$$

$$E_1^{--}(\sigma_1\cdot\sigma_2) = \mathrm{ch}(H+\mathscr{F}\sigma_1\cdot\sigma_2)E_1(-\sigma_1\cdot\sigma_2) - \mathrm{sh}(H+\mathscr{F}\sigma_1\cdot\sigma_2)E_2(-\sigma_1\cdot\sigma_2), \tag{4.13g}$$

$$M_1^{--}(\sigma_1\cdot\sigma_2) = \mathrm{ch}(H+\mathscr{F}\sigma_1\cdot\sigma_2)M_1(-\sigma_1\cdot\sigma_2) - \mathrm{sh}(H+\mathscr{F}\sigma_1\cdot\sigma_2)M_2(-\sigma_1\cdot\sigma_2). \tag{4.13h}$$

These, together with Eqs. (4.5), display explicitly the additional contributions discussed earlier of the four interactions $H,\mathscr{F},I,Y$ to the scalar and timelike potentials generated by L and J, respectively. At this level H and $\mathscr{F}$ contribute to both while Y contributes just to the timelike and I just to the scalar potentials.

Solve Eqs. (4.8) and (4.9) for χ_+ and χ_-:

$$\chi_+ = \frac{1}{\mathscr{D}(\sigma_1\cdot\sigma_2)}\,(M_2^{+-}(\sigma_1\cdot\sigma_2)D_1^{++} - M_1^{+-}(\sigma_1\cdot\sigma_2)D_2^{++})\phi_+, \tag{4.14a}$$

$$\chi_- = -\frac{1}{\mathscr{D}(\sigma_1\cdot\sigma_2)}\,(E_2^{++}(\sigma_1\cdot\sigma_2)D_1^{++} + E_1^{++}(\sigma_1\cdot\sigma_2)D_2^{++})\phi_+, \tag{4.14b}$$

in which

$$\mathscr{D}(\sigma_1\cdot\sigma_2) \equiv E_1^{++}(\sigma_1\cdot\sigma_2)M_2^{+-}(\sigma_1\cdot\sigma_2) + E_2^{++}(\sigma_1\cdot\sigma_2)M_1^{+-}(\sigma_1\cdot\sigma_2). \tag{4.15}$$

Solve Eqs. (4.10) and (4.11) for ϕ_+:

$$E_1^{--}(\sigma_1\cdot\sigma_2)D_1^{-+}\chi_+ - M_1^{-+}(\sigma_1\cdot\sigma_2)D_1^{--}\chi_- = \mathscr{B}^2(\sigma_1\cdot\sigma_2)\phi_+, \tag{4.16}$$

in which

$$\mathscr{B}^2(\sigma_1\cdot\sigma_2)\equiv E_1^{-+}(\sigma_1\cdot\sigma_2)E_1^{--}(\sigma_1\cdot\sigma_2)-M_1^{-+}(\sigma_1\cdot\sigma_2)M_1^{--}(\sigma_1\cdot\sigma_2). \tag{4.17}$$

Next combine Eq. (4.15) with Eqs. (4.14a) and (4.14b) to yield finally our four-component equation

$$\left[E_1^{--}(\sigma_1\cdot\sigma_2)D_1^{-+}\,\frac{1}{\mathscr{D}(\sigma_1\cdot\sigma_2)}\,(M_2^{+-}(\sigma_1\cdot\sigma_2)D_1^{++}-M_1^{+-}(\sigma_1\cdot\sigma_2)D_2^{++})+M_1^{-+}(\sigma_1\cdot\sigma_2)\right.$$
$$\left.\times D_1^{--}\,\frac{1}{\mathscr{D}(\sigma_1\cdot\sigma_2)}\,(E_2^{++}(\sigma_1\cdot\sigma_2)D_1^{++}+E_1^{++}(\sigma_1\cdot\sigma_2)D_2^{++})\right]\phi_+=\mathscr{B}^2(\sigma_1\cdot\sigma_2)\phi_+ . \tag{4.18}$$

Note that, in spite of appearances, as a consequence of the relativistic ''third law'' this expression is symmetrical in particles one and two. For example, using

$$\epsilon_1^2-\epsilon_2^2=m_1^2-m_2^2 \tag{4.19a}$$

$$\text{or}\quad \epsilon_1^2-m_1^2=\epsilon_2^2-m_2^2=b^2(w), \tag{4.19b}$$

we find that since

$$\begin{aligned}\mathscr{B}^2(\sigma_1\cdot\sigma_2)&=E_1^{-+}(\sigma_1\cdot\sigma_2)E_1^{--}(\sigma_1\cdot\sigma_2)-M_1^{-+}(\sigma_1\cdot\sigma_2)M_1^{--}(\sigma_1\cdot\sigma_2)\\&=\mathrm{ch}^2(H+\sigma_1\cdot\sigma_2\mathscr{F})(E_1(-\sigma_1\cdot\sigma_2)^2-M_1(-\sigma_1\cdot\sigma_2)^2)\\&\quad-\mathrm{sh}^2(H+\sigma_1\cdot\sigma_2\mathscr{F})(E_2(-\sigma_1\cdot\sigma_2)^2-M_2(-\sigma_1\cdot\sigma_2)^2),\end{aligned} \tag{4.20}$$

we obtain the simplification

$$\begin{aligned}\mathscr{B}^2(\sigma_1\cdot\sigma_2)&=E_1(-\sigma_1\cdot\sigma_2)^2-M_1(-\sigma_1\cdot\sigma_2)^2\\&=E_2(-\sigma_1\cdot\sigma_2)^2-M_2(-\sigma_1\cdot\sigma_2)^2\\&=b^2(w)+(\epsilon_1^2+\epsilon_2^2)\mathrm{sh}^2(J+\sigma_1\cdot\sigma_2Y)+2\epsilon_1\epsilon_2\ \mathrm{sh}(J+\sigma_1\cdot\sigma_2Y)\mathrm{ch}(J+\sigma_1\cdot\sigma_2Y)\\&\quad-(m_1^2+m_2^2)\mathrm{sh}^2(L-\sigma_1\cdot\sigma_2I)-2m_1m_2\ \mathrm{sh}(L-\sigma_1\cdot\sigma_2I)\mathrm{ch}(L-\sigma_1\cdot\sigma_2I).\end{aligned} \tag{4.21}$$

Note that this nonderivative part of our effective potential for our four-component second-order equation (4.18) is independent of both the complicated $\mathscr{F}$ and H interactions and contains the covariant eigenvalue $b^2(w)$. Its spin dependence is in accord with our earlier expectations for spacelike pseudovector and axial tensor interactions. Also, the denominator term $\mathscr{D}(\sigma_1\cdot\sigma_2)$ in Eq. (4.15) is, like the right-hand side of Eq. (4.18) above, independent of $\mathscr{F}$ and H:

$$\begin{aligned}\mathscr{D}(\sigma_1\cdot\sigma_2)&=E_1(\sigma_1\cdot\sigma_2)M_2(\sigma_1\cdot\sigma_2)+E_2(\sigma_1\cdot\sigma_2)M_1(\sigma_1\cdot\sigma_2)\\&=(\epsilon_1m_2+\epsilon_2m_1)\mathrm{ch}(J+L+(I-Y)(\sigma_1\cdot\sigma_2))\\&\quad+(\epsilon_1m_1+\epsilon_2m_2)\mathrm{sh}(J+L+(I-Y)(\sigma_1\cdot\sigma_2)).\end{aligned} \tag{4.22}$$

In light of the definitions of $D_i^{\pm\pm}$, Eq. (4.18) is a second-order Schrödinger-like eigenvalue equation for the newly defined wave function ϕ_+:

$$(p_\perp^2+\Phi(r,\sigma_1\sigma_2,w))\phi_+=b^2(w)\phi_+\,. \tag{4.23}$$

(Note that in the c.m. system $p_\perp^2=\mathbf{p}^2$.)

In the simplified case of combined scalar, time- and spacelike vector, and pseudoscalar interactions, the spin dependence on the scalar and timelike potentials disappears. Equation (4.18) becomes

$$\left[E_1D_1^{-+}\,\frac{1}{E_1M_2+E_2M_1}\,(M_2D_1^{++}-M_1D_2^{++})+M_1D_1^{--}\,\frac{1}{E_1M_2+E_2M_1}\,(E_2D_1^{++}+E_1D_2^{++})\right]\phi_+$$
$$=(E_1^2-M_1^2)\phi_+ \tag{4.24}$$

with the kinetic-recoil terms in it reducing to terms

$$D_1^{++}=e^{\mathscr{G}}\left[\sigma_1\cdot p-\frac{i}{2}\,\sigma_2\cdot\partial[-C+J-L+\mathscr{G}\sigma_1\cdot\sigma_2]\right], \tag{4.25a}$$

$$D_2^{++}=e^{\mathscr{G}}\left[\sigma_2\cdot p-\frac{i}{2}\,\sigma_1\cdot\partial[-C+J-L+\mathscr{G}\sigma_1\cdot\sigma_2]\right], \tag{4.25b}$$

$$D_1^{-+}=e^{\mathscr{G}}\left[\sigma_1\cdot p+\frac{i}{2}\,\sigma_2\cdot\partial[-C-J-L-\mathscr{G}\sigma_1\cdot\sigma_2]\right], \tag{4.25c}$$

$$D_1^{--}=e^{\mathscr{G}}\left[\sigma_1\cdot p+\frac{i}{2}\,\sigma_2\cdot\partial[-C+J+L-\mathscr{G}\sigma_1\cdot\sigma_2]\right], \tag{4.25d}$$

while the timelike and scalar potentials reduce to

$$E_1=\epsilon_1\ \mathrm{ch}(J)+\epsilon_2\ \mathrm{sh}(J), \tag{4.26a}$$

$$E_2=\epsilon_2\ \mathrm{ch}(J)+\epsilon_1\ \mathrm{sh}(J), \tag{4.26b}$$

$$M_1=m_1\ \mathrm{ch}(L)+m_2\ \mathrm{sh}(L), \tag{4.26c}$$

$$M_2=m_2\ \mathrm{ch}(L)+m_1\ \mathrm{sh}(L). \tag{4.26d}$$

Note that the scalar potentials are the same as in Eq. (2.22).

We now proceed to find the form for Eqs. (4.18) displaying all the general spin-dependent structures in $\Phi(r,\sigma_1,\sigma_2,w)$ explicitly. We proceed to the general case of all eight interactions acting simultaneously and then present the results for the simpler set of potentials. We express Eq. (4.18) explicitly in terms of its matrix (σ_1,σ_2), and operator p structure in the c.m. system $[\hat{P}=(1,\mathbf{0})]$.

We use the following abbreviations for the kinetic portions by defining the scalar function h,c,n, and vector functions **k,e,q,z,d,o**:

$$h\equiv \mathrm{e}^{(\mathscr{G}+\mathscr{F}+I+Y)},\quad \mathbf{k}\equiv\tfrac{1}{2}\nabla\ \ln(h),\quad \mathbf{z}\equiv\tfrac{1}{2}\nabla(H-C+J-L), \tag{4.27a}$$

$$c\equiv \mathrm{e}^{(\mathscr{G}-\mathscr{F}+I-Y)},\quad \mathbf{e}\equiv\tfrac{1}{2}\nabla\ \ln(c),\quad \mathbf{d}\equiv\tfrac{1}{2}\nabla(H+C+J+L), \tag{4.27b}$$

$$n\equiv \mathrm{e}^{(\mathscr{G}-\mathscr{F}-I+Y)},\quad \mathbf{q}\equiv\tfrac{1}{2}\nabla\ \ln(n),\quad o\equiv\tfrac{1}{2}\nabla(H+C-J-L). \tag{4.27c}$$

We are working in the c.m. frame [i.e., $x_\perp=(\mathbf{r},0)$], so all the interaction functions $[L(x_\perp),J(x_\perp),H(x_\perp),C(x_\perp),\mathscr{G}(x_\perp),\mathscr{F}(x_\perp),I(x_\perp),Y(x_\perp)]$ are functions of $r,F=F(r)$. Using

$$\nabla F(r)=\frac{dF(r)}{dr}\,\hat{\mathbf{r}}\equiv F'(r)\hat{\mathbf{r}},\quad \text{where } \hat{\mathbf{r}} \text{ denotes the unit vector,} \tag{4.28}$$

we can express the vector terms (**k**,**e**,**q**,**z**,**d**,**o**) explicitly in terms of the unit vector $\hat{\mathbf{r}}$. With these newly defined terms the first-order differential operators of Eqs. (4.12a)–(4.12d) become

$$D_1^{++}\equiv h[\boldsymbol{\sigma_1}\cdot\mathbf{p}-i\boldsymbol{\sigma_2}\cdot(\mathbf{z}+\mathbf{k}\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})], \tag{4.29a}$$

$$D_2^{++}\equiv h[\boldsymbol{\sigma_2}\cdot\mathbf{p}-i\boldsymbol{\sigma_1}\cdot(\mathbf{z}+\mathbf{k}\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})], \tag{4.29b}$$

$$D_1^{-+}\equiv c[\boldsymbol{\sigma_1}\cdot\mathbf{p}-i\boldsymbol{\sigma_2}\cdot(\mathbf{d}+\mathbf{e}\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})], \tag{4.29c}$$

$$D_1^{--}\equiv n[\boldsymbol{\sigma_1}\cdot\mathbf{p}-i\boldsymbol{\sigma_2}\cdot(\mathbf{o}+\mathbf{q}\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})]. \tag{4.29d}$$

We also define the following combinations involving the inverse matrix factors in Eq. (4.18):

$$F_1(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})\equiv\frac{M_2^{+-}(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})}{\mathscr{D}(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})}, \tag{4.30a}$$

$$F_2(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})\equiv\frac{M_1^{+-}(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})}{\mathscr{D}(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})}, \tag{4.30b}$$

$$F_3(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})\equiv\frac{E_2^{++}(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})}{\mathscr{D}(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})}, \tag{4.30c}$$

$$F_4(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})\equiv\frac{E_1^{++}(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})}{\mathscr{D}(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})}. \tag{4.30d}$$

Using these definitions, Eq. (4.18) becomes

$$\begin{aligned}
&c[E_1^{--}(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})[\boldsymbol{\sigma_1}\cdot\mathbf{p}-i\boldsymbol{\sigma_2}\cdot(\mathbf{d}+\mathbf{e}\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})]hF_1(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})[\boldsymbol{\sigma_1}\cdot\mathbf{p}-i\boldsymbol{\sigma_2}\cdot(\mathbf{z}+\mathbf{k}\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})]\phi_+\\
&\quad+n[M_1^{-+}(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})[\boldsymbol{\sigma_1}\cdot\mathbf{p}-i\boldsymbol{\sigma_2}\cdot(\mathbf{o}+\mathbf{q}\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})]hF_3(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})[\boldsymbol{\sigma_1}\cdot\mathbf{p}-i\boldsymbol{\sigma_2}\cdot(\mathbf{z}+\mathbf{k}\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})]\phi_+\\
&\quad-c[E_1^{--}(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})[\boldsymbol{\sigma_1}\cdot\mathbf{p}-i\boldsymbol{\sigma_2}\cdot(\mathbf{d}+\mathbf{e}\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})]hF_2(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})\\
&\quad\times[\boldsymbol{\sigma_2}\cdot\mathbf{p}-i\boldsymbol{\sigma_1}\cdot(\mathbf{z}+\mathbf{k}\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})]\phi_++n[M_1^{-+}(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})[\boldsymbol{\sigma_1}\cdot\mathbf{p}-i\boldsymbol{\sigma_2}\cdot(\mathbf{o}+\mathbf{q}\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})]\\
&\quad\times hF_4(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})[\boldsymbol{\sigma_2}\cdot\mathbf{p}-i\boldsymbol{\sigma_1}\cdot(\mathbf{z}+\mathbf{k}\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})]\phi_+=\mathscr{B}^2(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})\phi_+\,.
\end{aligned} \tag{4.31}$$

For future reference we will refer to the four sets of additive terms on the left-hand side as (4.31a)–(4.31d).

Matrix wave functions: Because of the complicated spin dependence in the general case one must find as simple approach as possible for its explicit display. Simply working through the various identities involving products of powers of $\boldsymbol{\sigma_1}$ and $\boldsymbol{\sigma_2}$, although straightforward, would involve 144 terms. A simpler approach is to simply write ϕ_+ as a linear combination of total spin wave functions and replace $\sigma_1\cdot\sigma_2$ by -3 for singlet and $+1$ for triplet states, thus facilitating considerably the reduction of the matrix form of Eq. (4.31) to the desired Schrödinger-like eigenvalue form Eq. (4.23). The multiplication properties of a matrix form for the wave functions with the Pauli matrices $\boldsymbol{\sigma_1}$ and $\boldsymbol{\sigma_2}$, Eq. (4.33), instead of a spinor form, make them a particularly suitable choice. For this reason we transform the four-component spinor ϕ_+ into a 2×2 matrix wave function composed of a scalar spherical harmonic part (corresponding to spin zero) and a vector spherical harmonic part (corresponding to spin one) by the redefinition (in the c.m. system)

$$\phi_+ \rightarrow \phi_+ \sigma_y \equiv \Phi \equiv \phi + \boldsymbol{\phi}\cdot\boldsymbol{\sigma}. \tag{4.32}$$

The above definition includes a transpose and left multiplication by σ_y. This leads to the properties

$$\boldsymbol{\sigma}_1 \phi_+ \rightarrow \boldsymbol{\sigma}\Phi, \quad \boldsymbol{\sigma}_2 \phi_+ \rightarrow -\Phi\boldsymbol{\sigma}. \tag{4.33}$$

This in turn leads to

$$\boldsymbol{\sigma}_1\cdot\boldsymbol{\sigma}_2 \phi_+ \rightarrow -\boldsymbol{\sigma}\cdot\Phi\boldsymbol{\sigma} = -3\phi + \boldsymbol{\phi}\cdot\boldsymbol{\sigma}, \tag{4.34}$$

which shows the singlet and triplet nature of the two parts of the matrix wave function. In general, since an arbitrary function $F(\boldsymbol{\sigma}_1\cdot\boldsymbol{\sigma}_2)$ can be expanded into a form

$$F(\boldsymbol{\sigma}_1\cdot\boldsymbol{\sigma}_2) = A + B\boldsymbol{\sigma}_1\cdot\boldsymbol{\sigma}_2, \tag{4.35}$$

we have

$$\begin{aligned} F(\boldsymbol{\sigma}_1\cdot\boldsymbol{\sigma}_2)\phi_+ &= (A + B\boldsymbol{\sigma}_1\cdot\boldsymbol{\sigma}_2)\phi_+ \rightarrow [A\Phi - B\boldsymbol{\sigma}\cdot\Phi\boldsymbol{\sigma}] \\ &= (A-3B)\phi + (A+B)\boldsymbol{\phi}\cdot\boldsymbol{\sigma} \\ &= F(-3)\phi + F(+1)\boldsymbol{\phi}\cdot\boldsymbol{\sigma}. \end{aligned} \tag{4.36}$$

Using this identity the right-hand side of Eq. (4.31) becomes simply

$$\mathscr{B}^2(\boldsymbol{\sigma}_1\cdot\boldsymbol{\sigma}_2)\phi_+ \rightarrow .\mathscr{B}^2(-3)\phi + \mathscr{B}^2(+1)\boldsymbol{\phi}\cdot\boldsymbol{\sigma}. \tag{4.37}$$

In computing the four sets of terms on left-hand side of Eq. (4.31), we use the identities

$$\boldsymbol{\sigma}_1\cdot\mathbf{A}\phi_+ \rightarrow \boldsymbol{\sigma}\cdot\mathbf{A}\Phi = \mathbf{A}\cdot\boldsymbol{\phi} + \boldsymbol{\sigma}\cdot[\mathbf{A}\phi + i\mathbf{A}\times\boldsymbol{\phi}], \tag{4.38a}$$

$$\boldsymbol{\sigma}_2\cdot\mathbf{A}\phi_+ \rightarrow -\mathbf{A}\cdot\Phi\boldsymbol{\sigma} = -\mathbf{A}\cdot\boldsymbol{\phi} - \boldsymbol{\sigma}\cdot[\mathbf{A}\phi - i\mathbf{A}\times\boldsymbol{\phi}]. \tag{4.38b}$$

The calculation of Eq. (4.31) then proceeds by reducing the left-hand side to a form like the right-hand side of (4.37), $(\mathrm{R} + \mathbf{R}\cdot\boldsymbol{\sigma})$, i.e., to a form $\mathrm{L} + \mathbf{L}\cdot\boldsymbol{\sigma}$ in which we call L the ''scalar,'' and **L** the ''vector'' term, respectively. We define the left-hand side of (4.31) in these terms as

$$\begin{aligned} \Pi\Phi = \mathscr{L} &= \mathrm{L} + \mathbf{L}\cdot\boldsymbol{\sigma} \equiv \text{left-hand side}(4.31), \\ &= (4.31\mathrm{a}) + (4.31\mathrm{b}) + (4.31\mathrm{c}) + (4.31\mathrm{d}). \end{aligned} \tag{4.39}$$

The reduction of (4.31) follows by equating the like terms on the right-hand (R and **R**, which we have calculated already) and left-hand sides (L and **L**, which remain to be calculated):

$$\mathrm{L}\phi + \mathbf{L}\cdot\boldsymbol{\sigma} = \mathrm{R}\phi + \mathbf{R}\cdot\boldsymbol{\sigma} \Rightarrow \left\{ \begin{array}{l} \mathrm{L} = \mathrm{R} \\ \mathbf{L} = \mathbf{R} \end{array} \right\}. \tag{4.40}$$

Having defined the left-hand side in the terms $\mathrm{L} + \mathbf{L}\cdot\boldsymbol{\sigma}$ we now proceed to calculate L and **L** explicitly (see Appendix A).

Using the expression derived in Appendix A for L, equating the ''scalar'' terms (L=R), bringing through the operator **p** in the various portions, performing the various scalar products and vector cross products, and converting back to the variables $J, L, C, H, \mathscr{G}, \mathscr{F}, I, Y, \mathscr{D}, \mathscr{B}$, we obtain the following expression for the Schrödinger-like ''scalar'' form L=R:

$$e^{(2\mathscr{G}+4\mathscr{F}-2H)}\frac{\mathscr{D}(3)}{\mathscr{D}(1)}\left[\{\mathbf{p}^2-i[2\mathscr{G}+4\mathscr{F}-2H-\ln(\mathscr{D}(1))-J+L+3I+3Y]'\hat{\mathbf{r}}\cdot\mathbf{p}+\tfrac{1}{2}\nabla^2(H-C+J-L-3\mathscr{G}-3\mathscr{F}-3I-3Y)-\tfrac{1}{4}(3H+C+J-L-\mathscr{G}-5\mathscr{F}-3I-3Y+2\ln[\mathscr{D}(1)])'(H-C+J-L-3\mathscr{G}-3\mathscr{F}-3I-3Y)'\}\phi+e^{(2H-2\mathscr{F}-I-Y+J-L)}\frac{w(m_1-m_2)}{\mathscr{D}(1)}(J+L+I-Y)'\frac{\mathbf{L}}{r}\cdot\phi\right]$$
$$=\mathscr{B}^2(3)\phi. \tag{4.41}$$

This equation has the form

$$A\left[\left\{\mathbf{p}^2-iB'\hat{\mathbf{r}}\cdot\mathbf{p}+\frac{1}{2}\nabla^2F-\frac{1}{4}K'F'\right\}\phi+N\frac{w(m_1-m_2)}{\mathscr{D}(1)}U'\frac{\mathbf{L}}{r}\cdot\phi\right]=\mathscr{B}^2(3)\phi, \tag{4.42}$$

in which

$$A=e^{(2\mathscr{G}+4\mathscr{F}-2H)}\frac{\mathscr{D}(3)}{\mathscr{D}(1)}, \tag{4.43a}$$

$$B=2\mathscr{G}+4\mathscr{F}-2H-\ln(\mathscr{D}(1))-J+L+3I+3Y, \tag{4.43b}$$

$$F=H-C+J-L-3\mathscr{G}-3\mathscr{F}-3I-3Y, \tag{4.43c}$$

$$K=3H+C+J-L-\mathscr{G}-5\mathscr{F}-3I-3Y+2\ln(\mathscr{D}(1)), \tag{4.43d}$$

$$N=e^{(2H-2\mathscr{F}-I-Y+J-L)}, \tag{4.43e}$$

$$U=J+L+I-Y. \tag{4.43f}$$

Performing a similar operation for the ''vector'' terms ($\mathbf{L}=\mathbf{R}$) we obtain

$$E\left[\left\{\mathbf{p}^2-\mathbf{pp}\cdot+i(Q-S)'[\hat{\boldsymbol{r}}\mathbf{p}\cdot-\hat{\boldsymbol{r}}\cdot\mathbf{p}]+\left[-Q'S'-\frac{3Q'}{r}+\nabla^2Q\right]\hat{\boldsymbol{r}}\hat{\boldsymbol{r}}\cdot-\nabla^2Q+\frac{Q'}{r}+S'Q'-i\frac{S'}{r}\mathbf{L}\right\}\boldsymbol{\phi}+\frac{T}{r}\frac{(\boldsymbol{\epsilon}_1-\boldsymbol{\epsilon}_2)(m_1+m_2)}{\mathscr{D}(1)}U'\mathbf{L}\boldsymbol{\phi}\right]$$
$$+O\left[\mathbf{pp}\cdot+iQ'\mathbf{p}\hat{\boldsymbol{r}}\cdot+iR'\hat{\boldsymbol{r}}\boldsymbol{p}\cdot+\left(\nabla^2Q-\frac{2Q'}{r}-Q'R'\right)\hat{\boldsymbol{r}}\hat{\boldsymbol{r}}\cdot\right]\boldsymbol{\phi}=\mathscr{B}^2(1)\boldsymbol{\phi} \tag{4.44}$$

in which

$$O=e^{(2\mathscr{G}-2H-4\mathscr{F})}\frac{\mathscr{D}(-1)}{\mathscr{D}(-3)}, \tag{4.45a}$$

$$E=e^{(2\mathscr{G}+2H)}\frac{\mathscr{D}(-1)}{\mathscr{D}(1)}, \tag{4.45b}$$

$$Q=\tfrac{1}{2}(H-C+J-L+\mathscr{G}+I+Y), \tag{4.45c}$$

$$R=\tfrac{1}{2}(3H+C+J-L-5\mathscr{G}+7\mathscr{F}+I+Y)+\ln(\mathscr{D}(-3)), \tag{4.45d}$$

$$S=-\tfrac{1}{2}(3H+C+J-L+3\mathscr{G}-\mathscr{F}+I+Y)+\ln\,(\mathscr{D}(1)), \tag{4.45e}$$

$$T=\mathrm{e}^{(-2H+2\mathscr{F}+L-J+I+Y)}\,\frac{\mathscr{D}(-1)}{\mathscr{D}(1)}. \tag{4.45f}$$

V. REDUCTION TO RADIAL FORM

A. Spin eigenfunctions

To reduce the forms of Eqs. (4.42) and (4.44) further, making them explicit differential equations in the variable r, we define the scalar ϕ and vector $\boldsymbol{\phi}$ wave functions explicitly in terms of their spatial (r,θ,φ) and spin dependence. For spectroscopic analysis we use eigenfunctions of $\mathbf{L}^2,\mathbf{S}^2,\mathbf{J}^2$, J_z where **L**, **S**, and **J** are the orbital, spin, and total angular momentum, respectively. For mesons, the spin eigenvalue can have the value zero or one only: for $s=0$ $j=l$, while for $s=1$ either $j=l$ or $j=l\pm1$. Although the spin states are classified as singlet ($s=0$) and triplet ($s=1$), the wave functions defined below will produce two sets of coupled equations: one set couples the singlet ($s=0$, $l=j$) to the triplet ($s=1$, $l=j$) spin states, the other set couples the two triplet ($s=1$, $l=j\pm1$) spin states.

$s=0,1$, $l=j$ *spin states:* The two $j=l$ ($s=0,1$) spin states have eigenfunctions of the form

$$\Phi=\langle\mathbf{r}|nlsj\rangle=\phi+\boldsymbol{\phi}\cdot\boldsymbol{\sigma}=\frac{u_n(r)_{l0j}}{r}\,\mathscr{Y}_{jm}(\varphi,\theta)+\frac{u_n(r)_{l1j}}{r}\,\mathbf{X}_{jm}(\varphi,\theta)\cdot\boldsymbol{\sigma},$$

$$\phi=\frac{u_n(r)_{l0j}}{r}\,\mathscr{Y}_{jm}(\varphi,\theta), \tag{5.1}$$

$$\boldsymbol{\phi}\cdot\boldsymbol{\sigma}=\frac{u_n(r)_{l1j}}{r}\,\mathbf{X}_{jm}(\varphi,\theta)\cdot\boldsymbol{\sigma},$$

in which n is the radial quantum number ($n=1$ for the ground state). Here the $\mathscr{Y}_{jm}$ are the familiar scalar spherical harmonic functions and the $\mathbf{X}_{jm}$ are vector spherical harmonic functions[26,27]

$$\mathbf{X}_{jm}=\frac{\mathbf{L}}{\sqrt{j(j+1)}}\,\mathscr{Y}_{jm},$$

$$\mathbf{L}=-i\mathbf{r}\times\nabla, \tag{5.2}$$

$$j=0,1,2,...;\quad m=-j,-j+1,...0...,j-1,j.$$

For the $s=0$, $l=j$ case the wave function is

$$\phi=\frac{u(r)_{j0j}}{r}\,\mathscr{Y}_{jm}(\phi,\theta), \tag{5.3}$$

while for the $s=1$, $l=j$ case the wave function is

$$\boldsymbol{\phi}=\frac{u(r)_{j1j}}{r}\,\mathbf{X}_{jm}. \tag{5.4}$$

$s=1$, $l=j\pm1$ *spin states:* The two $l=j\pm1$ ($s=1$) spin states have eigenfunctions of the form

$$\boldsymbol{\phi}=\boldsymbol{\phi}_+ + \boldsymbol{\phi}_- = \frac{u_{j+11j}(r)}{r}\,\mathbf{Y}_{jm+} + \frac{u_{j-11j}(r)}{r}\,\mathbf{Y}_{jm-}, \tag{5.5}$$

where

$$\mathbf{Y}_{jm+} = -\sqrt{\frac{j+1}{2j+1}}\left(\hat{\mathbf{r}} - i\frac{r\mathbf{p}}{j+1}\right)\mathscr{Y}_{jm}, \tag{5.6a}$$

$$\mathbf{Y}_{jm-} = \sqrt{\frac{j}{2j+1}}\left(\hat{\mathbf{r}} + i\,\frac{r\mathbf{p}}{j}\right)\mathscr{Y}_{jm} \tag{5.6b}$$

are respectively eigenfunctions of $\mathbf{L}^2$ with eigenvalues $(j+1)(j+2)$ and $j(j-1)$.

Having defined our wave functions explicitly in terms of their angular dependence we can now carry out the indicated differential operations to produce the coupled radial eigenequations. Some of the various operators and their effect on the wave functions ϕ, $\boldsymbol{\phi}$ are listed here for use in reducing the ''scalar'' wave equation to a coupled differential form:

$$\mathbf{p}^2\phi = \frac{1}{r}\left[-\frac{d^2}{dr^2} + \frac{j(j+1)}{r^2}\right]u(r)_{j0j}\mathscr{Y}_{jm}(\phi,\theta),$$

$$\hat{\mathbf{r}}\cdot\mathbf{p}\phi = -i\frac{d}{dr}\left(\frac{u(r)_{j0j}}{r}\right)\mathscr{Y}_{jm}(\phi,\theta),$$

$$\mathbf{L}\cdot\boldsymbol{\phi} = \frac{u(r)_{l1j}}{r}\sqrt{j(j+1)}\,\mathscr{Y}_{jm}. \tag{5.7}$$

We present a complete list of the operators and their effects on the wave functions ϕ, $\boldsymbol{\phi}$, $\boldsymbol{\phi}_+$, $\boldsymbol{\phi}_-$ in Appendix B.

B. The coupled radial eigenvalue equations

The results of carrying out the differential operations on the ''scalar'' and ''vector'' equations (4.42) and (4.44), and using the relations in Appendix B produces the desired relativistic radial eigenvalue equations for all eight combined interactions:

$s=0$, $j=l$:

$$A\left[\left\{-\frac{d^2}{dr^2} + \frac{j(j+1)}{r^2} - B'\left(\frac{d}{dr} - \frac{1}{r}\right) + \frac{1}{2}\nabla^2 F - \frac{1}{4}K'F'\right\}u_{j0j} + N\,\frac{w(m_1-m_2)}{\mathscr{D}(1)}\,U'\,\frac{\sqrt{j(j+1)}}{r}\,u_{j1j}\right] = \mathscr{B}^2(-3)u_{j0j}. \tag{5.8a}$$

$s=1$, $j=l$:

$$E\left[\left\{-\frac{d^2}{dr^2} + \frac{j(j+1)}{r^2} + (S-Q)'\,\frac{d}{dr} + 2\,\frac{Q'}{r} - \nabla^2 Q + S'Q'\right\}u_{j1j} + T\,\frac{(\epsilon_1-\epsilon_2)(m_1+m_2)}{\mathscr{D}(1)}\,U'\,\frac{\sqrt{j(j+1)}}{r}\,u_{j0j}\right] = \mathscr{B}^2(1)u_{j\mathbf{1}j}. \tag{5.8b}$$

Notice that these two equations decouple either for equal masses or for the ${}^1S_0$ states.

The other two coupled equations have opposite parity from these and do not decouple except for the $^3P_0$ states. (Below we use the abbreviations $u_\pm = u_{j\pm 11j}$).

$s=1$, $j=l+1$:

$$\left\{\left[E+\frac{j}{2j+1}(O-E)\right]\left(-\frac{d^2}{dr^2}+\frac{j(j-1)}{r^2}\right)+\left[E(S-Q)'+\frac{j}{2j+1}(E(Q-S)'+O(Q+R)')\right]\frac{d}{dr}\right.$$
$$+\frac{1}{2j+1}[Q'[E(-j^2+j+2)+O(j^2-2j)]-ES'j(j+1)-OR'j^2]\frac{1}{r}$$
$$\left.+\frac{1}{2j+1}[\nabla^2 Q(-(j+1)E+Oj)+Q'(ES'(j+1)-OR'j)]\right\}u_- + \frac{\sqrt{j(j+1)}}{2j+1}$$
$$\times\left\{(E-O)\left(-\frac{d^2}{dr^2}-(2j+1)\frac{d}{dr}-\frac{j^2-1}{r^2}\right)+[E(S-Q)'-O(R+Q)']\frac{d}{dr}\right.$$
$$+(E[(2-j)Q+S(1+j)]'+O[(2-j)Q-(j+1)R]')\frac{1}{r}$$
$$\left.-(E+O)\nabla^2 Q+Q'(OR'+ES')\right\}u_+ = \mathscr{B}^2(1)u_- . \tag{5.8c}$$

$s=1$, $j=l-1$:

$$\left\{\left[E+\frac{j+1}{2j+1}(O-E)\right]\left(-\frac{d^2}{dr^2}+\frac{(j+1)(j+2)}{r^2}\right)\right.$$
$$+\left[E(S-Q)'+\frac{j+1}{2j+1}(E(Q-S)'+O(Q+R)')\right]\frac{d}{dr}$$
$$+\frac{1}{2j+1}[Q'[E(j^2+3j)-O(j^2+4j+3)]+ES'j(j+1)+OR'(j+1)^2]\frac{1}{r}$$
$$\left.+\frac{1}{2j+1}[\nabla^2 Q(-jE+O(j+1))+Q'(ES'j-OR'(j+1))]\right\}u_+$$
$$+\frac{\sqrt{j(j+1)}}{2j+1}\left\{(E-O)\left(-\frac{d^2}{dr^2}+(2j+1)\frac{d}{dr}-\frac{j(j+2)}{r^2}\right)\right.$$
$$+[E(S-Q)'-O(R+Q)']\frac{d}{dr}+(E[(3+j)Q-Sj]'+O[(3+j)Q+jR]')\frac{1}{r}$$
$$\left.-(E+O)\nabla^2 Q+Q'(OR'+ES')\right\}u_- = \mathscr{B}^2(1)u_+ . \tag{5.8d}$$

In the special case of combined scalar, time-, and spacelike vector and pseudoscalar interactions [see Eq. (4.24)] we have

$$\mathscr{B}^2(-3)=\mathscr{B}^2(1)\equiv\mathscr{B}^2=E_1^2-M_1^2=E_2^2-M_2^2$$
$$=b^2(w)+(\epsilon_1^2+\epsilon_2^2)\mathrm{sh}^2(J)+2\epsilon_1\epsilon_2\mathrm{sh}(J)\mathrm{ch}(J)$$
$$-(m_1^2+m_2^2)\mathrm{sh}^2(L)+2m_1m_2\ \mathrm{sh}(L)\mathrm{ch}(L), \tag{5.9a}$$

$$\mathscr{D}(-3)=\mathscr{D}(-1)=\mathscr{D}(1)\equiv\mathscr{D}=E_1M_2+E_2M_1$$
$$=(\epsilon_1m_2+\epsilon_2m_1)\mathrm{ch}(J+L)+(\epsilon_1m_1+\epsilon_2m_1)\mathrm{sh}(J+L), \tag{5.9b}$$

$$A=O=E=e^{2\mathscr{G}}, \tag{5.9c}$$

$$B=2\mathscr{G}-\ln(\mathscr{D})-J+L, \tag{5.9d}$$

$$F=-C+J-L-3\mathscr{G}, \tag{5.9e}$$

$$K=C+J-L-\mathscr{G}+2\ln(\mathscr{D}), \tag{5.9f}$$

$$N=\frac{1}{T}=\mathrm{e}^{(J-L)}, \tag{5.9g}$$

$$U=J+L, \tag{5.9h}$$

$$Q=\tfrac{1}{2}(-C+J-L+\mathscr{G}), \tag{5.9i}$$

$$R=\tfrac{1}{2}(C+J-L-5\mathscr{G})+\ln(\mathscr{D}), \tag{5.9j}$$

$$S=-\tfrac{1}{2}(C+J-L+3\mathscr{G})+\ln(\mathscr{D}), \tag{5.9k}$$

so that the above equations become simply

$s=0,\ j=l$:

$$\left\{-\frac{d^2}{dr^2}+\frac{j(j+1)}{r^2}-(2\mathscr{G}-\ln(\mathscr{D})-J+L)'\left(\frac{d}{dr}-\frac{1}{r}\right)+\frac{1}{2}\nabla^2(-C+J-L-3\mathscr{G})\right.$$
$$\left.-\frac{1}{4}(C+J-L-\mathscr{G}+2\ln(\mathscr{D}))'(-C+J-L-3\mathscr{G})'\right\}u_{j0j}$$
$$+\mathrm{e}^{(J-L)}\frac{w(m_1-m_2)}{\mathscr{D}}(J+L)'\frac{\sqrt{j(j+1)}}{r}u_{j1j}=\mathscr{B}^2\mathrm{e}^{-2\mathscr{G}}u_{j0j}, \tag{5.10a}$$

coupled to $s=1,\ j=l$:

$$\left\{-\frac{d^2}{dr^2}+\frac{j(j+1)}{r^2}-(2\mathscr{G}+J-L-\ln(\mathscr{D}))'\,\frac{d}{dr}+\frac{(-C+J-L+\mathscr{G})'}{r}-\frac{1}{2}\,\nabla^2(-C+J-L+\mathscr{G})\right.$$
$$\left.+\frac{1}{4}\,(2\ln(\mathscr{D})-(C+J-L+3\mathscr{G}))'(-C+J-L+\mathscr{G})'\right\}u_{j1j}$$
$$+\mathrm{e}^{(L-J)}\,\frac{(\epsilon_1-\epsilon_2)(m_1+m_2)}{\mathscr{D}}\,(J+L)'\,\frac{\sqrt{j(j+1)}}{r}\,u_{j0j}=\mathscr{B}^2e^{-2\mathscr{G}}u_{j1j}\,, \tag{5.10b}$$

and $s=1$, $j=l+1$:

$$\left\{\left(-\frac{d^2}{dr^2}+\frac{j(j-1)}{r^2}\right)+\left[\ln(\mathscr{D})-2\mathscr{G}-\frac{1}{2j+1}\,(J-L)\right]'\,\frac{d}{dr}+\left[-j\,\ln(\mathscr{D})+\frac{1}{2j+1}\,((4j^2+j\right.\right.$$
$$\left.+1)\mathscr{G}+J-L+(j-1)C)\right]'\,\frac{1}{r}+\frac{1}{4}\,(C'^2-(J-L)'^2)+\frac{1}{2j+1}\left(-\frac{1}{2}\,\nabla^2(J-L+\mathscr{G}-C)\right.$$
$$\left.\left.+\mathscr{G}'\left(\frac{2j-3}{4}\,\mathscr{G}-J+L+C\right)'+\frac{1}{2}\,\ln'(\mathscr{D})(J-L-C)'\right)\right\}u_-+\frac{\sqrt{j(j+1)}}{2j+1}\left\{-[J-L]'\,\frac{d}{dr}\right.$$
$$+[(J-L)(1-2j)+3\mathscr{G}-3C]'\,\frac{1}{r}-2\nabla^2(J-L+\mathscr{G}-C)+(J-L+\mathscr{G}-C)'$$
$$\left.\times(\ln(\mathscr{D})-2\mathscr{G})'\right\}u_+=\mathscr{B}^2e^{-2\mathscr{G}}u_-\,, \tag{5.10c}$$

coupled to $s=1$, $j=l-1$:

$$\left\{\left(-\frac{d^2}{dr^2}+\frac{(j+1)(j+2)}{r^2}\right)+\left[\ln(\mathscr{D})-2\mathscr{G}+\frac{1}{2j+1}\,(J-L)\right]'\,\frac{d}{dr}+\left[(j+1)\ln(\mathscr{D})+\frac{1}{2j+1}\right.\right.$$
$$\left.-((4j^2+7j+4)\mathscr{G}+J-L-(j+2)C)\right]'\,\frac{1}{r}+\frac{1}{4}\,(C'^2-(J-L)'^2)+\frac{1}{2j+1}\left(\frac{1}{2}\,\nabla^2(J-L+\mathscr{G}-C)\right.$$
$$\left.\left.+\mathscr{G}'\left(\frac{2j+5}{4}\,\mathscr{G}+J-L-C\right)'-\frac{1}{2}\,\ln'(\mathscr{D})(J-L-C)'\right)\right\}u_++\frac{\sqrt{j(j+1)}}{2j+1}$$
$$\times\left\{-[J-L]'\,\frac{d}{dr}+[(J-L)(2j+3)+3\mathscr{G}-3C]'\,\frac{1}{r}-2\nabla^2(J-L+\mathscr{G}-C)\right.$$
$$\left.+(J-L+\mathscr{G}-C)'\,(\ln(\mathscr{D})-2\mathscr{G})'\right\}u_-=\mathscr{B}^2e^{-2\mathscr{G}}u_+\,. \tag{5.10d}$$

Equations (5.8a)–(5.8d) and their special cases above represent the end point of our calculations.

In summary, the two-body Dirac equations of constraint dynamics (3.18) below form a covariant compatible pair of equations.

$$\mathscr{S}_1\psi=[\mathrm{ch}\;\Delta_-\mathbf{S}_1+\mathrm{sh}\;\Delta_-\mathbf{S}_2]\psi=0, \tag{5.11a}$$

$$\mathscr{S}_2\psi=[\mathrm{ch}\;\Delta_-\mathbf{S}_2+\mathrm{sh}\;\Delta_-\mathbf{S}_1]\psi=0. \tag{5.11b}$$

(The conditions for compatibility eliminate the troublesome variables of relative time and energy in the c.m. frame.) Using the forms given in Eq. (3.17) below,

$$\mathbf{S}_1\psi=[\mathscr{S}_{10}\ \mathrm{ch}\ \Delta_+ +\mathscr{S}_{20}\ \mathrm{sh}\ \Delta_+]\psi=0, \tag{5.12a}$$

$$\mathbf{S}_2\psi=[\mathscr{S}_{20}\ \mathrm{ch}\ \Delta_+ +\mathscr{S}_{10}\ \mathrm{sh}\ \Delta_+]\psi=0, \tag{5.12b}$$

for the auxiliary constraints we obtained the results given in Eqs. (3.24a) and (3.24b) for the ''external potential'' form of the two-body Dirac equations for all eight combined covariant interactions. This generalizes earlier results for the eight interactions acting separately and opens the way toward further applications in the quark model of mesons and the two-body nucleon problem. Toward that end we derived the second-order forms of the equations Eqs. (4.18) and (4.31). We achieved significant simplification in the reduction of these forms by using matrix forms of the wave function and equations, leading ultimately to the four-component Schrödinger-like forms given by the coupled equations Eqs. (4.42) and (4.44). Finally, using vector and scalar spherical harmonics we obtained the radial forms above.

APPENDIX A: CALCULATION OF L AND L

First we write

$$\mathrm{L}_\phi+\mathbf{L}\cdot\boldsymbol{\phi}\equiv\Pi\Phi, \tag{A1}$$

where

$$\Pi\Phi=\Pi_1\Phi+\Pi_2\Phi+\Pi_3\Phi+\Pi_4\Phi, \tag{A2}$$

and $\Pi_1\Phi=$(4.31a), $\Pi_2\Phi=$(4.31b), $\Pi_3\Phi=$(4.31c), and $\Pi_4\Phi=$(4.31d). Notice that *each* Π_i is a product of four matrix factors

$$\Pi_i=[\pi_{i1}][\pi_{i2}][\pi_{i3}][\pi_{i4}]. \tag{A3}$$

Explicitly Π_1 is defined

$$\Pi_1=\underbrace{cE_1^{--}(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})}_{[\pi_{11}]}\underbrace{[\boldsymbol{\sigma_1}\cdot\mathbf{p}-i\boldsymbol{\sigma_2}\cdot(\mathbf{d}+\mathbf{e}\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})]}_{[\pi_{12}]}\underbrace{F_1(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})}_{[\pi_{13}]}\underbrace{[\boldsymbol{\sigma_1}\cdot\mathbf{p}-i\boldsymbol{\sigma_2}\cdot(\mathbf{z}+\mathbf{k}\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})]}_{[\pi_{14}]},$$

$$=[\pi_{11}][\pi_{12}][\pi_{13}][\pi_{14}]. \tag{A4}$$

Due to the properties (4.33), each of the $[\pi_{ij}]$ terms acts on the matrix wave function Φ to produce yet another matrix form

$$[\pi_{ij}]\Phi=\mathscr{Z}_i=\mathrm{Z}_i+\mathbf{Z_i}\cdot\boldsymbol{\sigma}. \tag{A5}$$

The multiplication of each of the four $\Pi_i\Phi$ terms in Eq. (A2) can now proceed as shown in Eq. (A6): by Eq. (A5), each factor $[\pi_{ij}]$ will act on the matrix on its right to produce yet another matrix form

$$[\pi_{i1}][\pi_{i2}][\pi_{i3}][\pi_{i4}]\Phi=[\pi_{i1}][\pi_{i2}][\pi_{i3}]\mathscr{N}_i=[\pi_{i1}][\pi_{i2}]\mathscr{P}_i=[\pi_{i1}]\mathscr{Q}_i=\mathscr{L}_i=\mathrm{L}_i+\mathbf{L}_i\cdot\boldsymbol{\sigma}. \tag{A6}$$

We use the ''script'' notation $\mathscr{N}_i, \mathscr{P}_i, \mathscr{Q}_i, \mathscr{L}_i$ to denote the matrix form, i.e.,; $\mathscr{N}_i \equiv \mathrm{N}_i + \mathbf{N}_i \cdot \boldsymbol{\sigma}$, $\mathscr{P}_i \equiv \mathrm{P}_i + \mathbf{P}_i \cdot \boldsymbol{\sigma}$ an so on. For each of the four matrix multiplications ($\Pi_i \Phi$, $i = 1,2,3,4$) of Eq. (A2) we obtain a term of the form $\mathrm{L}_i + \mathbf{L}_i \cdot \boldsymbol{\sigma}$, $i = 1,2,3,4$. For the complete calculation of Eq. (A2)

$$\begin{aligned} \mathrm{R} &\equiv \mathrm{L}_1 + \mathrm{L}_2 + \mathrm{L}_3 + \mathrm{L}_4, \\ \mathbf{R} &\equiv \mathbf{L}_1 + \mathbf{L}_2 + \mathbf{L}_3 + \mathbf{L}_4, \end{aligned} \tag{A7}$$

Inspection of Eq. (4.31) reveals that the matrix structures of the terms (4.31a) and (4.31b) are the same. In fact (4.31a) becomes (4.31b) (and vice versa) if we make the variable exchanges

$$\begin{aligned} & c \leftrightarrow n, \quad E_1^{--} \leftrightarrow M_1^{-+}, \\ & \mathbf{d} \leftrightarrow \mathbf{o}, \quad \mathbf{e} \leftrightarrow \mathbf{q}, \\ & F_1 \leftrightarrow F_3. \end{aligned} \tag{A8}$$

This simplifies the calculation of Eq. (A2): we can calculate the first term $\Pi_1 \Phi$, which is (4.31a), and then find the second term $\Pi_2 \Phi$, which is (4.31b), by the variable exchanges of Eq. (A8)

Inspection also reveals that the matrix structure of (4.31c) is the same as (4.31d): in fact (4.31c) becomes (4.31d) (and vice versa) if we make the variable exchanges

$$\begin{aligned} & -c \leftrightarrow n, \quad E_1^{--} \leftrightarrow M_1^{-+}, \\ & \mathbf{d} \leftrightarrow \mathbf{o}, \quad \mathbf{e} \leftrightarrow \mathbf{q}, \\ & F_2 \leftrightarrow F_4. \end{aligned} \tag{A9}$$

By calculating the third term $\Pi_3 \Phi$, which is (4.31c), we find the forth term $\Pi_4 \Phi$, which is (4.31d), by making the variable exchanges of Eq. (A9)

In light of the simplification produced by the variable exchanges of relations (A8) and Eq. (A9), we proceed to calculate Eq. (A2): first we calculate $\Pi_1 \Phi = \mathscr{L}_1 = \mathrm{L}_1 + \mathbf{L}_1 \cdot \boldsymbol{\sigma}$, then use it to find $\Pi_2 \Phi = \mathscr{L}_2 = \mathrm{L}_2 + \mathbf{L}_2 \cdot \boldsymbol{\sigma}$ by the variable exchanges (A8),then we calculate $\Pi_3 \Phi = \mathscr{L}_3 = \mathrm{L}_3 + \mathbf{L}_3 \cdot \boldsymbol{\sigma}$ and use it to find $\Pi_4 \Phi = \mathscr{L}_4 = \mathrm{L}_4 + \mathbf{L}_4 \cdot \boldsymbol{\sigma}$ by the variable exchanges (A9).

Calculate $\mathscr{L}_1 = \mathrm{L}_1 + \mathbf{L}_1 \cdot \boldsymbol{\sigma}$:

$$[\pi_{11}][\pi_{12}][\pi_{13}][\pi_{14}]\Phi = [\pi_{11}][\pi_{12}][\pi_{13}]\mathscr{N}_1 = [\pi_{11}][\pi_{12}]\mathscr{P}_1 = [\pi_{11}]\mathscr{Q}_1 = \mathscr{L}_1 = \mathrm{L}_1 + \mathbf{L}_1 \cdot \boldsymbol{\sigma}. \tag{A10}$$

Starting with the right-most term $\mathscr{N}_1$ [it is understood that $\boldsymbol{\sigma}_1$ and $\boldsymbol{\sigma}_2$ act in accordance with Eq. (4.33)],

$$[\pi_{14}]\Phi = [\boldsymbol{\sigma_1} \cdot \mathbf{p} - i\boldsymbol{\sigma_2} \cdot (\mathbf{z} + \mathbf{k}\boldsymbol{\sigma}_1 \cdot \boldsymbol{\sigma}_2)]\Phi = \mathscr{N}_1 = \mathrm{N}_1 + \mathbf{N}_1 \cdot \boldsymbol{\sigma}, \tag{A11}$$

where N_1 and $\mathbf{N}_1$ are

$$\begin{aligned} N_1 &= [\mathbf{p} + i(\mathbf{z} + \mathbf{k})] \cdot \phi, \\ \mathbf{N}_1 &= [\mathbf{p} + i(\mathbf{z} - 3\mathbf{k})]\phi + i[\mathbf{p} - i(\mathbf{z} + \mathbf{k})] \times \phi, \end{aligned} \tag{A12}$$

$$[\pi_{13}]\mathscr{N}_1 = hF_1(\boldsymbol{\sigma_1} \cdot \boldsymbol{\sigma_2})\mathscr{N}_1 = \mathscr{P}_1 = P_1 + \mathbf{P}_1 \cdot \boldsymbol{\sigma}; \tag{A13}$$

P_1 and $\mathbf{P}_1$ are

$$\mathrm{P}_1 = hF_1(-3)N_1, \quad \mathbf{P}_1 = hF_1(+1)\mathbf{N}_1, \tag{A14}$$

$$[\pi_{12}]\mathscr{P}_1 = [\boldsymbol{\sigma_1}\cdot\mathbf{p} - i\boldsymbol{\sigma_2}\cdot(\mathbf{d}+\mathbf{e}\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})]\mathscr{P}_1 = \mathscr{Q}_1 = \mathrm{Q}_1 + \mathbf{Q}_1\cdot\boldsymbol{\sigma}; \tag{A15}$$

and Q_1 and $\mathbf{Q}_1$ are

$$\mathrm{Q}_1 = [\mathbf{p} + i(\mathbf{d}+\mathbf{e})]\cdot\mathbf{P}_1,$$

$$\mathbf{Q}_1 = [\mathbf{p} + i(\mathbf{d}-3\mathbf{e})]P_1 + i[\mathbf{p} - i(\mathbf{d}+\mathbf{e})]\times\mathbf{P}_1, \tag{A16}$$

$$[\pi_{11}]\mathscr{Q}_1 = cE_1^{--}(\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})\mathscr{Q}_1 = \mathscr{L}_1 = \mathrm{L}_1 + \mathbf{L}_1\cdot\boldsymbol{\sigma}, \tag{A17}$$

where finally L_1 and $\mathbf{L}_1$ are

$$\mathrm{L}_1 = cE_1^{--}(-3)Q_1, \quad \mathbf{L}_1 = cE_1^{--}(+1)\mathbf{Q}_1, \tag{A18}$$

Combining the multiplicative factors, the ''scalar'' part of $\mathscr{L}_1$ is therefore

$$\mathrm{L}_1 = cE_1^{--}(-3)[\mathbf{p} + i(\mathbf{d}+\mathbf{e})]\cdot hF_1(+1)\{[\mathbf{p} + i(\mathbf{z}-3\mathbf{k})]\phi + i[\mathbf{p} - i(\mathbf{z}+\mathbf{k})]\times\boldsymbol{\phi}\}, \tag{A19}$$

while the ''vector'' part of $\mathscr{L}_1$ is

$$\begin{aligned}\mathbf{L}_1 = cE_1^{--}(+1)\{&[\mathbf{p} + i(\mathbf{d}-3\mathbf{e})]hF_1(-3)[\mathbf{p} + i(\mathbf{z}+\mathbf{k})]\cdot\boldsymbol{\phi} + i[\mathbf{p} - i(\mathbf{d}+\mathbf{e})]\\ &\times hF_1(+1)\{[\mathbf{p} + i(\mathbf{z}-3\mathbf{k})]\phi + i[\mathbf{p} - i(\mathbf{z}+\mathbf{k})]\times\boldsymbol{\phi}\}\}.\end{aligned} \tag{A20}$$

The ''scalar'' and ''vector'' parts of $\mathscr{L}_2$ are now easily written down by inspection when the variable exchanges of Eq. (A8) are made on L_2 and $\mathbf{L}_2$ of Eqs. (A19) and (A20). We obtain

$$\mathrm{L}_2 = nM_1^{-+}(-3)[\mathbf{p} + i(\mathbf{o}+\mathbf{q})]\cdot hF_3(+1)\{[\mathbf{p} + i(\mathbf{z}-3\mathbf{k})]\phi + i[\mathbf{p} - i(\mathbf{z}+\mathbf{k})]\times\boldsymbol{\phi}\}, \tag{A21}$$

while the ''vector'' part of $\mathscr{L}_2$ is

$$\begin{aligned}\mathbf{L}_2 = nM_1^{-+}(+1)\{&[\mathbf{p} + i(\mathbf{o}-3\mathbf{q})]hF_3(-3)[\mathbf{p} + i(\mathbf{z}+\mathbf{k})]\cdot\boldsymbol{\phi} + i[\mathbf{p} - i(\mathbf{o}+\mathbf{q})]\\ &\times hF_3(+1)\{[\mathbf{p} + i(\mathbf{z}-3\mathbf{k})]\phi + i[\mathbf{p} - i(\mathbf{z}+\mathbf{k})]\times\boldsymbol{\phi}\}\}.\end{aligned} \tag{A22}$$

For the scalar and vector parts of $\mathscr{L}_3$ things go very much like for $\mathscr{L}_1$ except for the first step we use Eq. (4.38b) instead of Eq. (4.38a),

$$[\pi_{34}]\Phi = [\boldsymbol{\sigma_2}\cdot\mathbf{p} - i\boldsymbol{\sigma_1}\cdot(\mathbf{z}+\mathbf{k}\boldsymbol{\sigma_1}\cdot\boldsymbol{\sigma_2})]\Phi = \mathscr{N}_3 = \mathrm{N}_3 + \mathbf{N}_3\cdot\boldsymbol{\sigma}, \tag{A23}$$

where N_3 and $\mathbf{N}_3$ are

$$\begin{aligned}\mathrm{N}_3 &= -[\mathbf{p} + i(\mathbf{z}+\mathbf{k})]\cdot\boldsymbol{\phi},\\ \mathbf{N_3} &= -[\mathbf{p} + i(\mathbf{z}-3\mathbf{k})]\phi + i[\mathbf{p} - i(\mathbf{z}+\mathbf{k})]\times\boldsymbol{\phi}.\end{aligned} \tag{A24}$$

Folding this into our previous results we obtain

$$\mathrm{L}_3 = cE_1^{--}(-3)[\mathbf{p} + i(\mathbf{d}+\mathbf{e})]\cdot hF_2(+1)\{[\mathbf{p} + i(\mathbf{z}-3\mathbf{k})]\phi - i[\mathbf{p} - i(\mathbf{z}+\mathbf{k})]\times\boldsymbol{\phi}\}, \tag{A25}$$

while the ''vector'' part of $\mathscr{L}_3$ is

$$\mathbf{L}_3 = cE_1^{--}(+1)\{[\mathbf{p}+i(\mathbf{d}-3\mathbf{e})]hF_2(-3)[\mathbf{p}+i(\mathbf{z}+\mathbf{k})]\cdot\boldsymbol{\phi}+i[\mathbf{p}-i(\mathbf{d}+\mathbf{e})] \times hF_2(+1)\{[\mathbf{p}+i(\mathbf{z}-3\mathbf{k})]\phi-i[\mathbf{p}-i(\mathbf{z}+\mathbf{k})]\times\boldsymbol{\phi}\}\}. \tag{A26}$$

From this we determine the scalar and vector parts of $\mathscr{S}_4$ by making the variable exchanges of Eq. (A9):

$$L_4 = -nM_1^{-+}(-3)[\mathbf{p}+i(\mathbf{o}+\mathbf{q})]\cdot hF_4(+1)\{[\mathbf{p}+i(\mathbf{z}-3\mathbf{k})]\phi-i[\mathbf{p}-i(\mathbf{z}+\mathbf{k})]\times\boldsymbol{\phi}\}, \tag{A27}$$

while the ''vector'' part of $\mathscr{S}_4$ is

$$\mathbf{L}_4 = -nM_1^{-+}(+1)\{[\mathbf{p}+i(\mathbf{o}-3\mathbf{q})]hF_4(-3)[\mathbf{p}+i(\mathbf{z}+\mathbf{k})]\cdot\boldsymbol{\phi}+i[\mathbf{p}-i(\mathbf{o}+\mathbf{q})]\times hF_4(+1) \times\{[\mathbf{p}+i(\mathbf{z}-3\mathbf{k})]\phi-i[\mathbf{p}-i(\mathbf{z}+\mathbf{k})]\times\boldsymbol{\phi}\}\}. \tag{A28}$$

Combining we obtain

$$\begin{aligned} L_1+L_2+L_3+L_4 = {} & h[cE_1^{--}(-3)(F_1(+1)+F_2(+1))+nM_1^{-+}(-3)(F_3(+1)-F_4(+1))]\mathbf{p}\cdot(\mathbf{p} \\ & +i(\mathbf{z}-3\mathbf{k}))\phi+i\{cE_1^{--}(-3)[h(F_1(+1)+F_2(+1))(\mathbf{d}+\mathbf{e})-\nabla(h(F_1(+1) \\ & +F_2(+1)))]+nM_1^{-+}(-3)[h(\mathbf{F}_3(+1)-F_4(+1))(\mathbf{o}+\mathbf{q})-\nabla(h(F_3(+1) \\ & -F_4(+1)))]\}\cdot(\mathbf{p}+i(\mathbf{z}-3\mathbf{k}))\phi ih[cE_1^{--}(-3)(F_1(+1)-F_2(+1))+nM_1^{-+} \\ & \times(-3)(\mathbf{F}_3(+1)+F_4(+1))]\mathbf{p}\cdot(\mathbf{p}-i((\mathbf{z}+\mathbf{k}))\times\boldsymbol{\phi}-\{cE_1^{--}(-3)[h(\mathbf{F}_1(+1) \\ & -F_2(+1))(\mathbf{d}+\mathbf{e})-\nabla(h(F_1(+1)-F_2(+1))]+nM_1^{-+}(-3)[h(F_3(+1) \\ & +F_4(+1))(\mathbf{o}+\mathbf{q})-\nabla(h(F_3(+1)+F_4(+1)))]\}\cdot(\mathbf{p}-i(\mathbf{z}+\mathbf{k}))\times\boldsymbol{\phi} \end{aligned} \tag{A29}$$

for the scalar portion.

We simplify this, leading to the result Eq. (4.42) given in the text, by using identities such as the following involving the scalar and timelike potentials:

$$E_1^{--}(-3) = \mathrm{ch}(H-3\mathscr{F})E_1(+3)-\mathrm{sh}(H-3\mathscr{F})E_2(+3), \tag{A30a}$$

$$M_1^{-+}(-3) = \mathrm{ch}(H-3\mathscr{F})M_1(+3)+\mathrm{sh}(H-3\mathscr{F})M_2(+3), \tag{A30b}$$

$$\begin{aligned} hc(F_1(+1)+F_2(+1)) &= \frac{1}{\mathscr{D}(1)}\,\mathrm{e}^{(2\mathscr{G}+2I)}\mathrm{e}^{(-H+\mathscr{F})}(M_1(1)+M_2(1)) \\ &= \mathrm{e}^{(2\mathscr{G}-H+\mathscr{F})}(M_1(3)+M_2(3)), \end{aligned} \tag{A30c}$$

$$hn(F_3(+1)-F_4(+1)) = \frac{1}{\mathscr{D}(1)}\,\mathrm{e}^{(2\mathscr{G}+2Y)}\mathrm{e}^{(-H+\mathscr{F})}(E_2(1)-E_1(1)) = \mathrm{e}^{(2\mathscr{G}-H+\mathscr{F})}(E_2(3)-E_1(3)) \tag{A30d}$$

$$\begin{aligned} \mathbf{d}+\mathbf{e}-\frac{\nabla h}{h}-\frac{\nabla(F_1(1)+F_2(1))}{F_1(1)+F_2(1)} &= \mathbf{o}+\mathbf{q}-\frac{\nabla h}{h}-\frac{\nabla(F_3(1)-F_4(1))}{F_3(1)-F_4(1)} \\ &= \frac{\hat{\mathbf{r}}}{2}(3H+C+J-L-\mathscr{G}-5\mathscr{F}-3I-3Y)'+\nabla\,\ln(\mathscr{D}(1)). \end{aligned} \tag{A30e}$$

We can simplify the vector portion below:

$$\begin{aligned}\mathbf{L_1}+\mathbf{L_2}+\mathbf{L_3}+\mathbf{L_4}=&h[cE_1^{--}(+1)(F_1(-3)+F_2(-3))+nM_1^{-+}(+1)(F_3(-3)-F_4(-3))]\mathbf{p}(\mathbf{p}\\&+i(\mathbf{z}+\mathbf{k}))\cdot\boldsymbol{\phi}+i\{cE_1^{--}(+1)[h(F_1(+1)+F_2(+1))(\mathbf{d}-\mathbf{3e})-\nabla(h(F_1(-3)\\&+F_2(-3)))]+nM_1^{-+}(+1)[h(F_3(+1)-F_4(+1))(\mathbf{o}-\mathbf{3q})-\nabla(h(F_3(-3)\\&-F_4(-3)))]\}(\mathbf{p}+i(\mathbf{z}+\mathbf{k}))\cdot\boldsymbol{\phi}ih[cE_1^{--}(+1)(F_1(+1)-F_2(+1))\\&+nM_1^{-+}(+1)(F_3(+1)+F_4(+1))]\mathbf{p}\times(\mathbf{p}+i(\mathbf{z}-\mathbf{3k}))\phi\}+\{[cE_1^{--}(+1)\\&\times[h(F_1(+1)+F_2(+1))(\mathbf{d}+\mathbf{e})+\nabla(h(F_1(+1)+F_2(+1)))]+nM_1^{-+}(+1)\\&\times[h(F_3(+1)-F_4(+1))(\mathbf{o}+\mathbf{q})+\nabla(h(F_3(+1)-F_4(+1)))]\}\\&\times(\mathbf{p}+i(\mathbf{z}-\mathbf{3k}))\phi-h[cE_1^{--}(+1)(F_1(+1)-F_2(+1))\\&+nM_1^{-+}(+1)(F_3(+1)+F_4(+1))]\mathbf{p}\times[((\mathbf{p}-i(\mathbf{z}+\mathbf{k}))\times\boldsymbol{\phi}]+i\{cE_1^{--}(+1)\\&\times[h(F_1(+1)-F_2(+1))(\mathbf{d}+\mathbf{e})+\nabla(h(F_1(+1)-F_2(+1)))]+nM_1^{-+}(+1)\\&\times[h(F_3(+1)+F_4(+1))(\mathbf{o}+\mathbf{q})+\nabla(h(F_3(+1)+F_4(+1)))]\}\\&\times(\mathbf{p}-i(\mathbf{z}+\mathbf{k}))\times\boldsymbol{\phi},\end{aligned}\tag{A31}$$

using similar identities

$$E_1^{--}(+1)=\mathrm{ch}(H+\mathscr{F})E_1(-1)-\mathrm{sh}(H+\mathscr{F})E_2(-1),\tag{A32a}$$

$$M_1^{-+}(+1)=\mathrm{ch}(H+\mathscr{F})M_1(-1)+\mathrm{sh}(H+\mathscr{F})M_2(-1),\tag{A32b}$$

$$\begin{aligned}hc(F_1(-3)+F_2(-3))&=\frac{\mathrm{e}^{(2\mathscr{G}+2I)}}{\mathscr{D}(-3)}\,\mathrm{e}^{(-H-3\mathscr{F})}(M_1(-3)+M_2(-3))\\&=\frac{e^{(2\mathscr{G}-H-3\mathscr{F})}}{\mathscr{D}(-3)}\,(M_1(-1)+M_2(1-)),\end{aligned}\tag{A32c}$$

$$\begin{aligned}hn(F_3(-3)-F_4(-3))&=\frac{\mathrm{e}^{(2\mathscr{G}+2Y)}}{\mathscr{D}(-3)}\,\mathrm{e}^{(-H-3\mathscr{F})}(E_2(-3)-E_1(-3))\\&=\frac{\mathrm{e}^{(2\mathscr{G}-H-3\mathscr{F})}}{\mathscr{D}(-3)}\,(E_2(-1)-E_1(-1)),\end{aligned}\tag{A32d}$$

$$\begin{aligned}\mathbf{d}-\mathbf{3e}-\frac{\nabla h}{h}-\frac{\nabla(F_1(-3)+F_2(-3))}{F_1(-3)+F_2(-3)}&=\mathbf{o}-\mathbf{3q}-\frac{\nabla h}{h}-\frac{\nabla(F_3(-3)-F_4(-3))}{F_3(-3)-F_4(1)}\\&=\frac{\hat{\boldsymbol{r}}}{2}\,(3H+C+J-L-5\mathscr{G}+7\mathscr{F}+I+Y)'\\&\quad+\nabla\,\ln(\mathscr{D}(-3)),\end{aligned}\tag{A32e}$$

$$hc(F_1(+1)-F_2(+1))=\frac{e^{(2\mathscr{G}+2I)}}{\mathscr{D}(+1)}\,e^{(-H+\mathscr{F})}(M_2(+1)-M_1(+1))$$
$$=\frac{e^{(2\mathscr{G}-H+\mathscr{F})}}{\mathscr{D}(+1)}\,(M_2(-1)-M_2(1-)), \tag{A32f}$$

$$hn(F_3(+1)+F_4(+1))=\frac{e^{(2\mathscr{G}+2Y)}}{\mathscr{D}(+1)}\,e^{(-H+\mathscr{F})}(E_2(+1)+E_1(+1))$$
$$=\frac{e^{(2\mathscr{G}-H+\mathscr{F})}}{\mathscr{D}(1)}\,(E_2(-1)+E_1(-1)), \tag{A32g}$$

$$\mathbf{d}+\mathbf{e}+\frac{\nabla h}{h}+\frac{\nabla(F_1(+1)-F_2(+1))}{F_1(+1)+F_2(+1)}=\mathbf{o}+\mathbf{q}+\frac{\nabla h}{h}+\frac{\nabla(F_3(+1)+F_4(+1))}{F_3(+1)+F_4(+1)}$$
$$=\frac{\hat{\boldsymbol{r}}}{2}\,(3H+C+J-L+3\mathscr{G}-\mathscr{F}+I+Y)'-\nabla\,\ln(\mathscr{D}(+1)), \tag{A32h}$$

leading to

$$e^{2\mathscr{G}-2H-4\mathscr{F}}\,\frac{\mathscr{D}(-1)}{\mathscr{D}(-3)}\Bigg[\mathbf{pp}\cdot\boldsymbol{\phi}+\frac{i}{2}\,\mathbf{p}(H-C+J-L+\mathscr{G}+\mathscr{F}+I+Y)'\hat{\boldsymbol{r}}\cdot\boldsymbol{\phi}$$
$$+\frac{i}{2}\,[3H+C+J-L-5\mathscr{G}+7\mathscr{F}+I+Y$$
$$+2\ln(\mathscr{D}(-3))]'\hat{\boldsymbol{r}}(p+(H-C+J-L+\mathscr{G}+\mathscr{F}+I+Y)'\hat{\boldsymbol{r}})\cdot\phi\Bigg]$$
$$-e^{2\mathscr{G}+2H}\,\frac{\mathscr{D}(-1)}{\mathscr{D}(1)}\left\{\mathbf{p}\times\left(\left(\mathbf{p}-\frac{i}{2}\,(H-C+J-L+\mathscr{G}+\mathscr{F}+I+Y)'\hat{r}\right)\times\phi\right)\right.$$
$$+\frac{i}{2}\,[3H+C+J-L+3\mathscr{G}-\mathscr{F}+I+Y+2\ln(\mathscr{D}(1))]'\hat{\boldsymbol{r}}$$
$$\times\left(\left(\mathbf{p}-\frac{i}{2}\,(H-C+J-L+\mathscr{G}+\mathscr{F}+I+Y)'\hat{\boldsymbol{r}}\right)\times\boldsymbol{\phi}\right)$$
$$\left.+\frac{\mathbf{L}}{r}\,e^{(2\mathscr{F}-2H+L-J+I+Y)}\,\frac{(\epsilon_1-\epsilon_2)(m_1+m_2)}{\mathscr{D}(1)}\,\phi\right\}. \tag{A33}$$

Using the following vector identities ($\mathbf{A}=A\hat{\mathbf{r}}$),

$$\mathbf{p}\times(\mathbf{p}\times\boldsymbol{\phi})=\mathbf{p}(\mathbf{p}\cdot\boldsymbol{\phi})-\mathbf{p}^2\boldsymbol{\phi}, \tag{A34a}$$

$$i\mathbf{p}\times(\mathbf{A}\times\boldsymbol{\phi})=\left[A'-\frac{A}{r}\right]\hat{\mathbf{r}}(\hat{\mathbf{r}}\cdot\boldsymbol{\phi})+\left(i\mathbf{A}\cdot\mathbf{p}-\nabla\cdot+\frac{A}{r}\right)\boldsymbol{\phi}, \tag{A34b}$$

$$\hat{\mathbf{r}}\times(\hat{\mathbf{r}}\times\boldsymbol{\phi})=\hat{\mathbf{r}}(\hat{\mathbf{r}}\cdot\boldsymbol{\phi})-\boldsymbol{\phi}, \tag{A34c}$$

$$i\mathbf{A}\times(\mathbf{p}\times\boldsymbol{\phi})=i\mathrm{A}_i\mathbf{p}\phi_i-i\mathbf{A}\cdot\mathbf{p}\boldsymbol{\phi}, \tag{A34d}$$

$$r_i \mathbf{p}\phi_i = \mathbf{r}(\mathbf{p}\cdot\boldsymbol{\phi}) + \mathbf{L}\times\boldsymbol{\phi}, \tag{A34e}$$

leads to the result given in the text [Eq. (4.44)].

APPENDIX B: VECTOR SPHERICAL HARMONICS

We list here the identities used to arrive at Eqs. (5.8a)–(5.8d). For $j=l$ we use

$$\mathbf{p}^2\boldsymbol{\phi} = -\nabla^2\boldsymbol{\phi} = \frac{1}{r}\left[-\frac{d^2}{dr^2} + \frac{j(j+1)}{r^2}\right] u(r)_{j0j}\mathscr{Y}_{jm}(\phi,\theta), \tag{B1}$$

$$i\hat{\mathbf{r}}\cdot\mathbf{p}\boldsymbol{\phi} = \hat{\mathbf{r}}\cdot\nabla\boldsymbol{\phi} = \frac{d}{dr}\left(\frac{u(r)_{j0j}}{r}\right)\mathscr{Y}_{jm}(\phi,\theta), \tag{B2}$$

$$\mathbf{L}\cdot\boldsymbol{\phi} = \frac{u(r)_{l1j}}{r}\sqrt{j(j+1)}\,\mathscr{Y}_{jm}, \tag{B3}$$

$$\mathbf{L}\boldsymbol{\phi} = \sqrt{j(j+1)}\,\frac{u(r)_{j0j}}{r}\,\mathbf{X}_{jm}, \tag{B4}$$

$$-\frac{i}{r}\,\mathbf{L}\times\boldsymbol{\phi} = \frac{u(r)_{j1j}}{r}\,\mathbf{X}_{jm}. \tag{B5}$$

For the cases $l=j\pm1$

$$\boldsymbol{\phi} = \boldsymbol{\phi}_+ + \boldsymbol{\phi}_- = \frac{u_{j+11j}(r)}{r}\,\mathbf{Y}_{jm+} + \frac{u_{j-11j}(r)}{r}\,\mathbf{Y}_{jm-}, \tag{B6}$$

where

$$\mathbf{Y}_{jm+} = -\sqrt{\frac{j+1}{2j+1}}\left(\hat{\mathbf{r}} - i\,\frac{r\mathbf{p}}{j+1}\right)\mathscr{Y}_{jm}, \tag{B7}$$

$$\mathbf{Y}_{jm-} = \sqrt{\frac{j}{2j+1}}\left(\hat{\mathbf{r}} + i\,\frac{r\mathbf{p}}{j}\right)\mathscr{Y}_{jm}. \tag{B8}$$

In the remainder we use the abbreviations $u_\pm = u_{j\pm11j}$ and $\mathbf{Y}_\pm = \mathbf{Y}_{jm\pm}$

$$-\frac{i}{r}\,\mathbf{L}\times\boldsymbol{\phi} = +\left(\frac{j+2}{r}\right)\frac{u_+}{r}\,\mathbf{Y}_+ - \left(\frac{j-1}{r}\right)\frac{u_{-1}}{r}\,\mathbf{Y}_-, \tag{B9}$$

$$\hat{\mathbf{r}}\mathscr{Y}_{jm} = \sqrt{\frac{j}{2j+1}}\,\mathbf{Y}_- - \sqrt{\frac{j+1}{2j+1}}\,\mathbf{Y}_+, \tag{B10}$$

$$\mathbf{p}\mathscr{Y}_{jm} = -\frac{i}{r}\left[(j+1)\sqrt{\frac{j}{2j+1}}\,\mathbf{Y}_- + j\sqrt{\frac{j+1}{2j+1}}\,\mathbf{Y}_+\right], \tag{B11}$$

$$\hat{\mathbf{r}}\cdot\mathbf{p}\boldsymbol{\phi}_\pm = -i\left(\frac{u'_\pm}{r} - \frac{u_\pm}{r^2}\right)\mathbf{Y}_\pm, \tag{B12}$$

$$\hat{\mathbf{r}}\cdot\boldsymbol{\phi}=-\sqrt{\frac{j+1}{2j+1}}\frac{u_+}{r}\mathscr{Y}_{jm}+\sqrt{\frac{j}{2j+1}}\frac{u_-}{r}\mathscr{Y}_{jm}, \tag{B13}$$

$$\hat{\mathbf{r}}(\hat{\mathbf{r}}\cdot\boldsymbol{\phi})=\frac{1}{2j+1}\left[\left[j\,\frac{u_-}{r}-\sqrt{j(j+1)}\,\frac{u_+}{r}\right]\mathbf{Y}_-+\left[(j+1)\,\frac{u_+}{r}-\sqrt{j(j+1)}\,\frac{u_-}{r}\right]\mathbf{Y}_+\right], \tag{B14}$$

$$\begin{aligned}\mathbf{p}(\hat{\mathbf{r}}\cdot\boldsymbol{\phi})=\frac{i}{2j+1}&\left[-j\,\frac{u_-'}{r}-j^2\,\frac{u_-}{r^2}+\left[\sqrt{j(j+1)}\left[\frac{u_+'}{r}+j\,\frac{u_+}{r^2}\right]\right]\mathbf{Y}_-+\left[-(j+1)\,\frac{u_+'}{r}+(j+1)^2\,\frac{u_+}{r^2}\right.\right.\\&\left.\left.+\sqrt{j(j+1)}\left[\frac{u_-'}{r}-(j+1)\,\frac{u_-}{r^2}\right]\right]\mathbf{Y}_+\right],\end{aligned} \tag{B15}$$

$$\mathbf{p}\cdot\boldsymbol{\phi}=\frac{i}{\sqrt{2j+1}}\left[\sqrt{j}\left[j\,\frac{u_-}{r^2}-\frac{u_-'}{r}\right]+\sqrt{j+1}\left[(j+1)\,\frac{u_+}{r^2}+\frac{u_+'}{r}\right]\right]\mathscr{Y}_{jm}, \tag{B16}$$

$$\begin{aligned}\hat{\mathbf{r}}(\mathbf{p}\cdot\boldsymbol{\phi})=\frac{i}{2j+1}&\left[j^2\,\frac{u_-}{r^2}-j\,\frac{u_-'}{r}+\left[\sqrt{j(j+1)}\left[(j+1)\,\frac{u_+}{r^2}+\frac{u_+'}{r}\right]\right]\mathbf{Y}_-\right.\\&\left.-\left[-\frac{u_-'}{r}\right]+(j+1)^2\,\frac{u_+}{r^2}+(j+1)\,\frac{u_+'}{r}+\sqrt{j(j+1)}\left[j\,\frac{u_-}{r^2}\right]\mathbf{Y}_+\right],\end{aligned} \tag{B17}$$

$$\begin{aligned}\mathbf{p}(\mathbf{p}\cdot\boldsymbol{\phi})=\frac{1}{2j+1}&\left[j\left[j(j-1)\,\frac{u_-}{r^3}-\frac{u_-''}{r}\right]+\sqrt{j(j+1)}\left[(j+1)(j-1)\,\frac{u_+}{r^3}+(2j+1)\,\frac{u_+'}{r^2}+\frac{u_+''}{r}\right]\right]\mathbf{Y}_-\\&+\frac{1}{2j+1}\left[(j+1)\left[(j+1)(j+2)\,\frac{u_+}{r^3}-\frac{u_+''}{r}\right]\right.\\&\left.+\sqrt{j(j+1)}\left[j(j+2)\,\frac{u_-}{r^3}-(2j+1)\,\frac{u_-'}{r^2}+\frac{u_-''}{r}\right]\right]\mathbf{Y}_+.\end{aligned} \tag{B18}$$

[22] These theta matrices have algebraic properties that permit more efficient calculation of the commutation relations appropriate to two spinning bodies permitting simplification of otherwise complicated consequences of compatibility $([\mathscr{S}_1,\mathscr{S}_2]_-\psi=0)$ when interactions are present.

[23] We omit here four additional derivative interactions of the form $\alpha_1\cdot\hat{r}\alpha_2\cdot\hat{r}[R+\beta_1\beta_2 S+\rho_1\rho_2 T+\gamma_{51}\gamma_{52}N]$ in which the invariant functions $N(x_\perp),T(x_\perp),S(x_\perp),R(x_\perp)$ describe the derivative interactions (the retardative Breit term is one such example).

[24] As pointed out in Ref. 14, the fundamental anticommutation relations (2.7) of the theta matrices lead directly through a ''pseudoclassical'' correspondence limit (Ref. 10) to a graded symplectic structure in which the θ's become two commuting sets of Grassmann variables. This space possesses a graded Poisson bracket that takes the differential form described in Ref. 10 and references contained therein. When quantized, this bracket becomes a generalized quantum bracket that is sometimes a commutator and sometimes an anticommutator, depending on the nature of its operator arguments. In terms of this bracket, all necessary commutation relations involving the quantum θ's can be carried out through operations that are isomorphic to those involving the classical brackets. The quantum bracket follows closely the classical graded structure by sorting quantum operators into even and odd classes. This accounts for the seemingly random choices of commutators and anticommutators in Eqs. (3.3), (3.6), and (3.20). For details see Ref. 14.

[25] We omit here an extremely long and detailed calculation, involving 32 brackets, each of which involves multiple combinations of the above interaction matrices. Even though the result seems plausible in hindsight (in light of the earlier individual results), we found no simple proof because of the compounding of the various interactions.

Unitary transformation approach to the exact solution for a class of time-dependent nonlinear Hamiltonian systems

M. Maamache
Institut de Physique, Université de Sétif, Sétif, (19000), Algeria

(Received 4 November 1996; accepted for publication 10 June 1997)

By performing unitary transformations on the time-dependent Schrödinger equation, the exact solution for a class of nonlinear Hamiltonian systems is obtained and it is shown that these time-dependent problems are related to the associated time-independent problems. In addition, the evolution operator is derived. Nonadiabatic Berry's phase is calculated on the basis of the exact solution. The theory is applied to some illustrative examples. © *1998 American Institute of Physics.*

I. INTRODUCTION

In quantum mechanics, solving the time-dependent Schrödinger equation is in general very difficult and it is very rare to be able to find an exact solution. Various methods have been used to obtain approximate solutions for such time-dependent problems. The usual methods are the adiabatic approximation, the sudden approximation, and time-dependent perturbation techniques. The existence of invariants[1,2] (constants of the motion or first integral) is one of central importance in the study of such a system, be it classical or quantum. The importance of these invariants is classical mechanics and the associated nonlinear superposition law[3,4] has been adequately discussed. In the quantum case, Lewis and Riesenfeld[5] first exploited the invariant operators to solve quantum-mechanical problems. In particular, they have derived a simple relation between eigenstates of I and solutions of the time-dependent Schrödinger equation and have applied it to the case of a quantal oscillator with time-dependent frequency. Hartley and Ray[6] have applied this technique to derive a quantum-mechanical superposition law for certain nonlinear time-dependent oscillators; an explicit form of the propagator was obtained by Dhara and Lawande.[7]

In light of the above discussion, one important question motivates our work here: how could one treat time-dependent quantum problems without making recourse to the invariant operator theory.

In this paper we answer this question from a new perspective by studying the one degree of freedom quantum time-dependent nonlinear Hamiltonian systems,

$$H=\tfrac{1}{2}\left[Z(t)p^2+Y(t)(pq+qp)+X(t)q^2+V(q,t)\right], \tag{1.1}$$

introducing a suitable transformation to make the transformed Hamiltonian time independent multiplied by a time-dependent factor. Here q,p are the quantum-mechanical operators, $V(q,t)$ is an arbitrary time-dependent potential, and $X(t)$, $Y(t)$, and $Z(t)$ are arbitrary functions of time.

Note that the class of Hamiltonians represented by (1.1) includes, for example, the so-called ''generalized harmonic oscillator'' when $V(q,t)=0$, the Caldirola–Kanai Hamiltonian when $Y(t)=V(q,t)=0$, and the case $Y(t)=0$, $Z(t)=1$ treated by Hartley and Ray[6] and Ray and Reid.[4]

For an integrable system, the Hamiltonian can be transformed into a sum of time-independent commuting operators through a series of time-dependent unitary transformations.[8] As a consequence, the solution of the time-dependent Schrödinger equation for an integrable system can be written as eigenstates of these commuting operators. In this paper, the approach that we use is based on the unitary transformation. In addition, the other advantage of our approach is that the

time evolution from an arbitrary initial state can be calculated in terms of the time-evolution operators. In Sec. II, the formalism is developed based on the unitary transformation to obtain not only the exact solution of the Schrödinger equation, but also the time-evolution operator, and we elucidate the intimate connection between the Hill–Floquet–Bloch function and the solution of the Schrödinger equation for a T-periodic Hamiltonian. The nonadiabatic Berry's phases[8–15] are determined totally by such a unitary transformation. In Sec. III, we obtain with the help of the appropriate transformations the exact solution of the system (1.1), as well as the time-evolution operator, and we find the conditions that govern the class of allowable potentials. Although the class of allowable potentials does not consist of all functions of the independent variables q and t, it is described by an arbitrary function of a single argument and includes time-dependent potentials that can be arbitrarily nonlinear in q. We obtain not only the exact solution of the Schrödinger equation but also the time-evolution operator. On the basis of the exact solution for the system represented by the Hamiltonian (1.1), a nonadiabatic Berry's phase is calculated. In Sec. IV, we give some illustrative examples. We end with a conclusion in Sec. V.

II. FORMALISM

Consider the time-dependent Schrödinger equation,

$$\imath \frac{\partial}{\partial t} |\psi(t)\rangle = H(t)|\psi(t)\rangle, \tag{2.1}$$

with $\hbar = 1$. Suppose that is a time-dependent transformation $U^{-1}(t)$,

$$|\widetilde{\psi}(t)\rangle = U^{-1}(t)|\psi(t)\rangle, \tag{2.2}$$

transforms the wave function to $|\widetilde{\psi}(t)\rangle$, which obeys the Schrödinger equation with the accordingly transformed Hamiltonian $\widetilde{H}$,

$$\imath \frac{\partial}{\partial t} |\widetilde{\psi}(t)\rangle = \widetilde{H}|\widetilde{\psi}(t)\rangle. \tag{2.3}$$

In the above equation, the new Hamiltonian operator,

$$\widetilde{H} = \left[U^{-1}H(t)U - \imath U^{-1} \frac{\partial U}{\partial t} \right], \tag{2.4}$$

is Hermitian. This requires that $U(t)$ must be unitary operator. Since the Hamiltonian of a system is time dependent, $U(t)$ results in a unitary transformation (2.2) for the wave function and a unitary transformation (2.4) for the Hamiltonian so that the form of the Schrödinger equation remains form invariant.

With the help of the appropriate unitary transformation U, we require that the solution of Schrödinger equation looks like a generalized Hill–Floquet–Bloch function, i.e., the product of a wave function satisfying a stationary equation with a time-dependent function. For this, we may make the transformed Hamiltonian $\widetilde{H}$ possessing the following form:

$$\widetilde{H}(t) = g(t)H_0, \tag{2.5}$$

where H_0 is time independent and $g(t)$ is a function of time. To get the form of the solution, let ϕ_n be the eigenstate of H_0 with eigenvalue λ_n, i.e.

$$H_0\phi_n = \lambda_n\phi_n, \quad \lambda_n = cte, \tag{2.6}$$

and suppose that the system is in the nth eigenstate of H_0 initially, at time t it evolves to the state

$$\psi_n(q,t)=\exp\left(\imath\lambda_n\int_0^t dt'\ g(t')\right)U\phi_n(q). \tag{2.7}$$

We now derive the time-evolution operator. Note that the solution (2.7) may be rewritten as

$$\psi_n(q,t)=U\ \exp\left(-\imath\int_0^t dt'\ g(t')H_0\right)\phi_n(q), \tag{2.8}$$

when $t=0$ the quantum wave function is

$$\psi_n(q,0)=U(0)\phi_n(q), \tag{2.9}$$

since

$$\psi_n(q,t)=U\ \exp\left(-\imath\int_0^t dt'\ g(t')H_0\right)U^{-1}(0)\psi_n(q,0), \tag{2.10}$$

the time-evolution operator becomes

$$\mathscr{U}(t,0)=U(t)\exp\left(-\imath\int_0^t dt'\ g(t')H_0\right)U^{-1}(0), \tag{2.11}$$

and has all properties of a unitary evolution operator,

$$\mathscr{U}^{-1}(t,0)=\mathscr{U}(0,t),\quad \mathscr{U}(t_2,t_1)=\mathscr{U}(t_2,0)\mathscr{U}^{-1}(t_1,0). \tag{2.12}$$

The time evolution of arbitrary initial states can be evaluated with the time evolution operator (2.11).

In order to give a derivation of the nonadiabatic Berry's phase, let us look at periodical Hamiltonians $H(t+T)=H(t)$ that are susceptible to describe a cyclic motion of the wave function in analogy with Bloch states in the case of spatially periodic Hamiltonian. Such spatial periodicity induces a direct sum decomposition of the spaces of states corresponding to eigenspaces of the Floquet eigenvalues of H. These eigenvalues $\{\mathscr{E}_n\}$, called ''energy bands'' (or ''quasienergies'') in solid state physics, are periodic functions in the parameters space that is the Brillouin zone.[16] Thus, an initial state $\psi_n(q,0)$ will evolve as

$$\psi_n(q,T)=U(T)\psi_n(q,0)=e^{-\imath\alpha_n(T)}\psi_n(q,0), \tag{2.13}$$

i.e., each state returns to itself after a time T, up to a phase $\alpha_n(T)=\lambda_n\int_0^T dt\,g(t)$, which is called the Hill's phase. As this is the usual condition for the so-called Floquet state (or Bloch state) we can relate the Hill's phase α_n to the quasienergies associated with Bloch wave function:

$$\alpha_n(T)=\mathscr{E}_nT. \tag{2.14}$$

The generalization of the dynamical phase is the time integral of the instantaneous expectation value of the Hamiltonian,

$$\delta_n=\int_0^T\langle\psi_n(q,t)|H(t)|\psi_n(q,t)\rangle dt=\int_0^T dt\left(\lambda_ng(t)+\langle\phi_n(q)|\imath U^{-1}\frac{\partial U}{\partial t}|\phi_n(q)\rangle\right). \tag{2.15}$$

Aharonov and Anandan[10] show that

$$\beta_n=\lambda_n\int_0^T dt\ g(t)-\delta_n=-\langle\phi_n(q)|\imath U^{-1}\frac{\partial U}{\partial t}|\phi_n(q)\rangle dt \tag{2.16}$$

is a purely geometrical property of the evolution, in the sense that it only depends on the path followed by the system in projective Hilbert space. We see that the Hill's phase can be decomposed in two terms, one of them being the nonadiabatic Berry's phase that is determined totally by the unitary transformation.

III. EXACT SOLUTION AND NONADIABATIC BERRY'S PHASE FOR NONLINEAR HAMILTONIAN SYSTEMS

Now we embark on the construction of the exact solution and the nonadiabatic Berry phase for the system described by the Hamiltonian (1.1). The key point of our analysis is to perform the three consecutive transformations:

$$|\psi_n\rangle=U_1|\psi_{1n}\rangle=\exp\left[-\frac{\imath}{2}\int_0^t Y(t')dt'(pq+qp)\right]|\psi_1\rangle, \tag{3.1}$$

$$|\psi_{1n}\rangle=U_2|\psi_{2n}\rangle=\exp[\imath C_1(t)q^2]|\psi_{2n}\rangle, \tag{3.2}$$

and

$$|\psi_{2n}\rangle=U_3|\psi_{3n}\rangle=\exp[\imath C_2(t)(pq+qp)]|\psi_{3n}\rangle, \tag{3.3}$$

where $C_1(t)$ and $C_2(t)$ are real functions of time. These coefficients are chosen in such a way that the Hamiltonian, after these transformations becomes a product of two factors, namely a time-dependent factor multiplied by a simple time-independent Hamiltonian, which represents a harmonic oscillator with a constant frequency Ω_0 with an additional time-independent potential.

The unitary operator $U_1(t)$ has the properties

$$U_1^{-1}f(p)U_1=f\left(p\ \exp\left[-\int_0^t Y(t')dt'\right]\right) \tag{3.4}$$

and

$$U_1^{-1}f(q)U_1=f\left(q\ \exp\left[\int_0^t Y(t')dt'\right]\right). \tag{3.5}$$

In a particular representation, the wave function is given by

$$\langle q|U_1|\psi_n\rangle=\exp\left[-\frac{1}{2}\int_0^t Y(t')dt'\right]\psi_n\left(q\ \exp\left[-\int_0^t Y(t')dt'\right]\right). \tag{3.6}$$

It can easily be shown that under the U_2 transformation, the coordinate and momentum operators change according to

$$U_2^{-1}pU_2=p+2C_1q, \tag{3.7}$$

$$U_2^{-1}f(q)U_2=f(q). \tag{3.8}$$

In order to solve (2.1) with the Hamiltonian specified by (1.1), we first try to remove the mixed terms in q and p in the Hamiltonian (1.1). This can be achieved by the transformation $U_1(t)$. Inserting (3.1) and (3.4)–(3.5) into (2.3), we have

$$\imath\frac{\partial}{\partial t}|\psi_{1n}(t)\rangle=\frac{1}{2}\left[\frac{1}{m(t)}p^2+k(t)q^2+V\left(q\ \exp\left[\int_0^t Y(t')dt'\right],t\right)\right]|\psi_{1n}(t)\rangle, \tag{3.9}$$

where

$$m(t)=\frac{1}{Z(t)}\exp\left[2\int_0^t Y(t')dt'\right], \tag{3.10}$$

$$k(t)=X(t)\exp\left[2\int_0^t Y(t')dt'\right]. \tag{3.11}$$

Now let us perform the transformation $U_2(t)$. Substituting (3.2) into (3.9) and using (3.7) and (3.8), we find the equation of motion for $|\psi_{2n}(t)\rangle$,

$$\begin{aligned}\imath\frac{\partial}{\partial t}|\psi_{2n}(t)\rangle=\frac{1}{2}\left[\frac{1}{m}p^2+2\frac{C_1}{m}(pq+qp)+2\left(\dot{C}_1+2\frac{C_1^2}{m}+\frac{k}{2}\right)q^2\right.\\ \left.+V\left(q\ \exp\left[\int_0^t Y(t')dt'\right],t\right)\right]|\psi_{2n}(t)\rangle.\end{aligned} \tag{3.12}$$

In order to obtain the usual time-dependent harmonic oscillator with a perturbative potential, we remove the cross term in (3.12) via the transformation $U_3(t)$. Since this transformation is formally the same as $U_1(t)$, this suggests that one takes

$$C_2(t)=-\int_0^t\frac{C_1(t')}{m(t')}dt'. \tag{3.13}$$

With this choice, (3.12) is changed under these transformation into

$$\begin{aligned}\imath\frac{\partial}{\partial t}|\psi_{3n}(t)\rangle=\frac{1}{2}\left\{\frac{1}{m}\exp\left[-4\int_0^t\frac{C_1}{m}dt'\right]p^2+2\left(\dot{C}_1+2\frac{C_1^2}{m}+\frac{k}{2}\right)\exp\left[4\int_0^t\frac{C_1}{m}dt'\right]q^2\right.\\ \left.+V\left(q\ \exp\left[\int_0^t\left(Y+2\frac{C_1}{m}\right)dt'\right],t\right)\right\}|\psi_{3n}(t)\rangle.\end{aligned} \tag{3.14}$$

We note that in Eq. (3.14), the argument of the potential V, i.e., $\exp[\int_0^t(Y+2C_1/m)dt']$, is a real function of time that we can call $\rho(t)$. Thus, we can deduce that

$$C_1(t)=\frac{m}{2}\left(\frac{\dot{\rho}}{\rho}-Y\right), \tag{3.15}$$

one can show that (3.14) becomes

$$\imath\frac{\partial}{\partial t}|\psi_{3n}(t)\rangle=\frac{1}{2}\frac{Z}{\rho^2}\left[p^2+\Omega^2q^2+\frac{\rho^2}{Z}V(\rho q,t)\right]|\psi_{3n}(t)\rangle, \tag{3.16}$$

where

$$\Omega^2=\frac{\rho^3}{Z^2}\left(\ddot{\rho}-\frac{\dot{Z}}{Z}\dot{\rho}+\left[(XZ-Y^2)+\frac{\dot{Z}}{Z}Y-\dot{Y}\right]\rho\right). \tag{3.17}$$

The central idea in this procedure is to require that the Hamiltonian governing the evolution of $|\psi_{3n}\rangle$ is the product of two parts. A time-dependent factor and a simple time-independent nonlinear Hamiltonian that represents a harmonic oscillator with a constant frequency Ω_0 with an additional time-independent potential. This condition imposes a constraint on the global time-dependent frequency and in the time-dependent potential. Let us set the global time-dependent frequency appearing in (3.17) equals to a real constant,

$$\Omega^2=\Omega_0^2, \tag{3.18}$$

which amounts to imposing a constraint on ρ. Equation (3.17) then becomes

$$\ddot{\rho}-\frac{\dot{Z}}{Z}\dot{\rho}+\left[(XZ-Y^2)+\frac{\dot{Z}}{Z}Y-\dot{Y}\right]\rho=\frac{\Omega_0^2Z^2}{\rho^3}, \tag{3.19}$$

which is the well-known auxiliary equation.[14] We now conclude our examination of (3.16) to determine the class of admissible potentials. The particular choice,

$$V(q,t)=\frac{Z}{\rho^2}W\left(\frac{q}{\rho}\right), \tag{3.20}$$

implies that the potential appearing in (3.16) is time independent, as required, where W is an arbitrary function of its argument.

It is easy to verify with the help of Eqs. (2.6)–(2.7) that one can write the solution of (3.16) as

$$\psi_{3n}(q,t)=\exp\left[-\imath\lambda_n\int_0^t\frac{Z}{\rho^2}\,dt'\right]\phi_n(q), \tag{3.21}$$

where $\phi_n(q)$ satisfies the eigenequation

$$\tfrac{1}{2}\,(p^2+\Omega_0^2q^2+W(q))\phi_n(q)=\lambda_n\phi_n(q),\quad \lambda_n=\text{const.} \tag{3.22}$$

The implication of the results is clear. The original time-dependent quantum-mechanical problem [posed through the Hamiltonian (1.1)] is completely solved if the wave function for the related (time-independent) Hamiltonian defined in Eq. (3.22) is obtained. The exact solution of the original equation (2.1) can now be found by combining the above results. We finally obtain

$$\begin{aligned}\psi_n(q,t)&=\exp\left[-\imath\lambda_n\int_0^t\frac{Z}{\rho^2}\,dt'\right]U_1U_2U_3\phi_n(q)\\&=\exp\left[-\imath\lambda_n\int_0^t\frac{Z}{\rho^2}\,dt'\right]\frac{1}{\rho^{1/2}}\exp\left[-\imath\left(\frac{Y\rho-\dot{\rho}}{Z\rho}\right)\frac{q^2}{2}\right]\phi_n\left(\frac{q}{\rho}\right).\end{aligned} \tag{3.23}$$

We now derive the time-evolution operator for the nonlinear system (1.1). The time-evolution arbitrary initial state can be evaluated with the time-evolution operator, Eq. (2.11),

$$\begin{aligned}\mathscr{U}(t,0)&=\exp\left\{\frac{\imath}{2Z}\left(\frac{\dot{\rho}}{\rho}-Y\right)q^2\right\}\exp\left\{-\frac{\imath}{2}\,\mathrm{Ln}\left(\frac{\rho}{\rho_0}\right)(pq+qp)\right\}\\&\quad\times\exp\left\{-\frac{\imath}{2}\int_0^t\frac{Z}{\rho^2}\,dt'(p^2+\Omega_0^2q^2+W(q))\right\}\exp\left\{\frac{\imath}{2Z_0}\left(\frac{\dot{\rho}_0}{\rho_0}-Y_0\right)q^2\right\},\end{aligned} \tag{3.24}$$

where ρ_0, $\dot{\rho}_0$, Z_0, and Y_0 are related to the initial values $\rho(0)$, $\dot{\rho}(0)$, $Z(0)$, and $Y(0)$.

If the parameters $X(t)$, $Y(t)$, and $Z(t)$ are periodic functions of time with period T, i.e. $(X,Y,Z)(t+T)=(X,Y,Z)(t)$, Eq. (3.19) may have periodic solutions. When the auxiliary function is periodic, i.e. $\rho(t+T)=\rho(t)$, then after one period of evolution the system returns to the initial state, except for acquiring the Hill's phase,

$$\alpha_n(T)=\lambda_n\int_0^T\frac{Z}{\rho^2}\,dt, \tag{3.25}$$

and a nonadiabatic Berry's phase is derived by use of Eq. (2.16) as

$$\begin{aligned}\beta_n(\mathscr{C})&=-\imath\int_0^T\langle\phi_n(q)|U_3^{-1}U_2^{-1}U_1^{-1}\frac{\partial}{\partial t}U_1U_2U_3|\phi_n(q)\rangle dt\\&=\langle\phi_n(q)|q^2|\phi_n(q)\rangle\oint_{\mathscr{C}}d\rho\left(\frac{\rho Y-\dot\rho}{Z}\right).\end{aligned} \tag{3.26}$$

Thus, $\beta_n(\mathscr{C})$ have a rather interesting structure being the product of two quite distinct parts, the expectation value of q^2 for the corresponding autonomous system and a circuit integral in parameter space. We note that it is always the expectation value of q^2, no matter the potential.

IV. APPLICATIONS

We now discuss applications of our formulas (3.23) and (3.26) to obtain an explicitly exact wave function and a nonadiabatic Berry's phase for some time-dependent problems. Consider first the time-dependent harmonic oscillator for which $W=0$, $Y=0$, $Z(t)=1/M(t)$, and $X(t)=M(t)\omega^2(t)$, where $M(t)$ and $\omega(t)$ are, respectively, the mass and frequency associated with the oscillator. Here Eq. (3.22) simply corresponds to a harmonic oscillator with constant frequency Ω_0;

$$\tfrac{1}{2}\,(p^2+\Omega_0^2q^2)\,\phi_n(q)=\lambda_n\phi_n(q), \tag{4.1}$$

whose solution is well known,

$$\phi_n(q)=\frac{\Omega_0^{1/4}}{(\pi^{1/2}2^n n!)^{1/2}}\,e^{-q^2/2}H_n(q\Omega_0^{1/2}) \tag{4.2}$$

and

$$\lambda_n=(n+\tfrac{1}{2})\Omega_0, \tag{4.3}$$

where H_n is the usual Hermite polynomial of order n. The solution of the Schrödinger equation for the harmonic oscillator with time-dependent mass and frequency may be written as

$$\begin{aligned}\psi_n(q,t)&=\frac{\Omega_0^{1/4}}{(\pi^{1/2}2^n n!)^{1/2}}\,e^{\imath\alpha_n(t)}U_2U_3e^{-q^2/2}H_n(q\Omega_0^{1/2})\\&=\frac{1}{(\pi^{1/2}2^n n!)^{1/2}}\left(\frac{\Omega_0}{\rho^2}\right)^{1/4}e^{\imath\alpha_n(t)}\exp\left\{\imath\,\frac{M}{2}\left(\frac{\dot\rho}{\rho}+\frac{\imath}{M\rho^2}\right)q^2\right\}H_n\left(\Omega_0^{1/2}\frac{q}{\rho}\right),\end{aligned} \tag{4.4}$$

and

$$\alpha_n(t)=-\left(n+\frac{1}{2}\right)\int_0^t\frac{\Omega_0}{M(t')\rho^2(t')}\,dt'. \tag{4.5}$$

Here the auxiliary equation (3.19) is converted in the equation

$$\ddot{\rho}+\frac{\dot{M}}{M}\,\dot{\rho}+\omega^2(t)\rho=\frac{\Omega_0^2}{M(t)\rho^3}. \tag{4.6}$$

There remains the problem of finding the nonadiabatic Berry's phase β_n that satisfies Eq. (3.26). Since the expectation value $\langle\phi_n(q)|q^2|\phi_n(q)\rangle$ refers to the harmonic oscillator, it may be replaced by $(n+1/2)$. If the parameters $M(t),\omega^2(t)$ are periodic functions of time with period T, then after one period the system acquires a nonadiabatic Berry's phase,

$$\beta_n(T)=-(n+1/2)\int_0^T\frac{M(t)\dot{\rho}^2(t)}{\Omega_0}\,dt. \tag{4.7}$$

The wave function (4.4) and the nonadiabatic Berry's phase (4.7) are in agreement with the results obtained, by using the Heisenberg picture approach, in Ref. 15.

A somewhat nontrivial example is that of a time-dependent generalized harmonic oscillator with an additional inverse quadratic potential $W=(g\rho/q)^2$,[14] where g is a constant. In this case Eq. (3.22) resembles the radial time-independent Schrödinger equation of a three-dimensional oscillator corresponding to an angular momentum $l(l+1)=g^2$,

$$\frac{1}{2}\left(p^2+\Omega_0^2q^2+\frac{g^2}{q^2}\right)\phi_n(q)=\lambda_n\phi_n(x), \tag{4.8}$$

whose solution is well known,

$$\phi_n(x)=\left[\frac{2\Omega_0^{1/2}\Gamma(n+1)}{\Gamma(n+l+3/2)}\right]^{1/2}\exp\left[-\frac{1}{2}\,x^2\right](x)^{(l+1)/4}L_n^{l+1/2}(x^2) \tag{4.9}$$

and

$$\lambda_n=2\left(n+\frac{l}{2}+\frac{3}{4}\right)\Omega_0, \tag{4.10}$$

where we have introduced the dimensionless variable $x=\Omega_0^{1/2}q$, and $L_n^{l+1/2}$ denotes the generalized Laguerre polynomials. We finally obtain the exact solution of the time-dependent singular oscillator,

$$\begin{aligned}\psi_n(x,t)&=\exp\left[-2\imath\left(n+\frac{l}{2}+\frac{3}{4}\right)\Omega_0\int_0^t\frac{Z}{\rho^2}\,dt'\right]U_1U_2U_3\phi_n(x)\\&=\exp\left[-2\imath\left(n+\frac{l}{2}+\frac{3}{4}\right)\Omega_0\int_0^t\frac{Z}{\rho^2}\,dt'\right]\psi_n(x,t),\end{aligned} \tag{4.11}$$

where

$$\psi_n(x,t)=\left[\frac{2\Omega_0^{1/2}}{\rho}\,\frac{\Gamma(n+1)}{\Gamma(n+l+3/2)}\right]^{1/2}\exp\left[-\frac{1}{2}\left(\frac{x}{\rho}\right)^2\left\{1+\imath\,\frac{Y\rho^2-\dot{\rho}\rho}{Z}\right\}\right]\left(\frac{x}{\rho}\right)^{(l+1)/4}L_n^{l+1/2}\left(\left(\frac{x}{\rho}\right)^2\right). \tag{4.12}$$

In this case the function ρ satisfies the auxiliary equation (3.19). Now let us calculate the Berry's phase for the singular oscillator from Eq. (3.26). Since the expectation value $\langle\phi_n(q)|q^2|\phi_n(q)\rangle$

refers to the radial part of a three-dimensional harmonic oscillator, it may be replaced by $2(n+l/2+3/4)$. Then after one period, the nonadiabatic Berry's phase in a cyclic evolution is given by

$$\beta_n(\mathscr{C}) = -2\left(n+\frac{c}{2}+\frac{3}{4}\right)\oint_{\mathscr{C}} \Omega_0^{-1}\left[\frac{Y\rho-\dot{\rho}}{Z}\right]d\rho, \tag{4.13}$$

where $\mathscr{C}$ is a closed circuit in the parameter space.

Note that potential $Z/\rho^2 W$ in these two examples does not depend on the auxiliary function $\rho(t)$. In general, however, the perturbative potential depends on ρ and is tailored according to the auxiliary equation for $\rho(t)$.

V. CONCLUSION

In this paper we have presented an alternative treatment for certain nonlinear time-dependent oscillators. The present treatment is based on the use of time-dependent unitary transformations. We have shown that the time-dependent Hamiltonian (1.1) is related to an associated time-independent Hamiltonian multiplied by an overall time-dependent factor. The solution of a Schrödinger equation appears as a generalized Hill–Floquet–Bloch function, i.e., the product of a wave function satisfying a stationary equation with a time-dependent function. The calculation does not presuppose the existence of an invariant operator. Moreover, we have derived an explicit time-evolution operator. We have also found the exact expression of the nonadiabatic Berry's phase in such problems. The theory is applied to the harmonic oscillator with time-dependent mass and frequency, and the time-dependent singular oscillator.

Abelian Chern–Simons theory. I. A topological quantum field theory

Mihaela Manoliu
Department of Mathematics, University of Texas, Austin, Texas 78712

(Received 24 March 1997; accepted for publication 29 August 1997)

We give a construction of the Abelian Chern–Simons gauge theory from the point of view of a $2+1$-dimensional topological quantum field theory. The definition of the quantum theory relies on geometric quantization ideas that have been previously explored in connection to the non-Abelian Chern–Simons theory [J. Diff. Geom. **33**, 787–902 (1991); Topology **32**, 509–529 (1993)]. We formulate the topological quantum field theory in terms of the category of extended 2- and 3-manifolds introduced in a preprint by Walker in 1991 and prove that it satisfies the axioms of unitary topological quantum field theories formulated by Atiyah [Publ. Math. Inst. Hautes Etudes Sci. Pans **68**, 175–186 (1989)]. © *1998 American Institute of Physics.* [S0022-2488(97)01812-4]

I. INTRODUCTION

A $2+1$-dimensional topological quantum field theory (TQFT) with Lagrangian the non-Abelian Chern–Simons invariant of connections was introduced by Witten several years ago.[1] It was shown that this theory generates invariants of framed oriented links in arbitrary 3-manifolds. It also leads to topological invariants of closed oriented 3-manifolds endowed with a 2-framing.[2] Witten's approach[1] to defining these invariants is based on a functional integral formulation, results from two-dimensional conformal field theory and the axioms of TQFT formulated in Ref. 3. A mathematically rigorous derivation of Witten's 3-manifold invariants is given in Refs. 4 and 5. Moreover, Walker[4] gives a complete construction of the SU(2) Chern–Simons theory, proving that it satisfies the axioms of a TQFT. A simpler model of a $2+1$-dimensional TQFT is the Chern–Simons theory with a finite gauge group treated in full detail in Ref. 6.

In line with the above mentioned developments relating to the Chern–Simons gauge theory, in this paper we present a construction of the Abelian Chern–Simons theory as a $2+1$-dimensional TQFT. Given the group $\mathbb{T}$ of complex numbers of unit modulus and an (even) integer k, called the level, we aim to associate to every closed oriented two-dimensional manifold Σ a finite-dimensional vector space $\mathscr{H}(\Sigma)$ and to every compact oriented 3-manifold X a vector Z_X in the vector space $\mathscr{H}(\partial X)$ associated to the boundary ∂X of X.

The first assignment, $\Sigma \to \mathscr{H}(\Sigma)$, results from the geometric quantization of the moduli space $\mathscr{M}_\Sigma$ of flat $\mathbb{T}$ connections on Σ, having in view that $\mathscr{M}_\Sigma$ is identified to the symplectic torus $H^1(\Sigma;\mathbb{R})/H^1(\Sigma;\mathbb{Z})$ with standard symplectic form ω_Σ. There are various models for the quantization of $\mathscr{M}_\Sigma$ according to the type of polarization one chooses on this space. The holomorphic (Kähler) quantization of $\mathscr{M}_\Sigma$ is discussed in Refs. 7–9, where it is shown that the vector spaces constructed for various choices of complex structures on $\mathscr{M}_\Sigma$ are projectively identified. In this paper we choose to quantize $\mathscr{M}_\Sigma$ by using *real* polarizations. To each rational Lagrangian subspace L in $H^1(\Sigma;\mathbb{R})$ there corresponds an invariant real polarization $\mathscr{P}_L$ of the torus $\mathscr{M}_\Sigma \cong H^1(\Sigma;\mathbb{R})/H^1(\Sigma;\mathbb{Z})$. The quantization of $\mathscr{M}_\Sigma$, at level k, in this real polarization constructs a k^g-dimensional inner product space $\mathscr{H}(\Sigma,L)$, where g denotes the genus of Σ. The quantization of symplectic tori in a real polarization is discussed in detail in Ref. 10 and the results obtained there are directly applicable to the case of the moduli space $\mathscr{M}_\Sigma$. According to Ref. 10, for any two rational Lagrangian subspaces L_1, $L_2 \subset H^1(\Sigma;\mathbb{R})$ there is a canonically defined unitary operator $F_{L_2L_1}: \mathscr{H}(\Sigma,L_1) \to \mathscr{H}(\Sigma,L_2)$. The vector spaces associated to Σ and different choices of

0022-2488/98/39(1)/170/37/$15.00
© 1998 American Institute of Physics

rational Lagrangian subspaces in $H^1(\Sigma;\mathbb{R})$ are all projectively identified, similarly to the holomorphic quantization case. The projective factor, an eighth root of unity, is expressible in terms of the Maslov–Kashiwara index of a triple of Lagrangian subspaces of $H^1(\Sigma;\mathbb{R})$. The idea of using real polarizations in quantizing the moduli space $\mathscr{M}_\Sigma$ and the method of construction of the vector space $\mathscr{H}(\Sigma,L)$ was inspired by Ref. 11, where, in the context of the non-Abelian Chern–Simons theory, the authors address the problem of quantizing the moduli space of flat SU(2) connections on a closed oriented 2-manifold in a particular real polarization of that space.

For the second assignment, $X\to Z_X$, we start from the known fact that, for X, a compact oriented 3-manifold with boundary, the image of the restriction map $H^1(X;\mathbb{R})\to H^1(\partial X;\mathbb{R})$ defines a Lagrangian subspace L_X in the symplectic vector space $(H^1(\partial X;\mathbb{R}),\omega_{\partial X})$. Then we provide a canonical construction that defines Z_X as an element of the vector space $\mathscr{H}(\partial X,L_X)$ associated to the closed 2-manifold ∂X and the rational Lagrangian subspace L_X. The construction of Z_X relies on geometric quantization ideas. Following the Chern–Simons line construction exposed in Ref. 12, we introduce a prequantum line bundle $\mathscr{L}_{\partial X}$ over the moduli space of flat connections $\mathscr{M}_{\partial X}$. The line bundle $\mathscr{L}_{\partial X}$ carries a natural connection with curvature of the symplectic form $k\omega_{\partial X}$. The rational Lagrangian subspace $L_X\subset H^1(\partial X;\mathbb{R})$ defines an invariant real polarization on $\mathscr{M}_{\partial X}$. One of the leaves of this polarization is the image Λ_X in $\mathscr{M}_{\partial X}$ of the moduli space $\mathscr{M}_X$ of flat $\mathbb{T}$ connections on X under the map $r_X:\mathscr{M}_X\to\mathscr{M}_{\partial X}$ determined by restricting connections on X to the boundary ∂X. We show that the leaf Λ_X is a Bohr–Sommerfeld leaf, that is, the restriction of the line bundle $\mathscr{L}_{\partial X}$ to Λ_X admits nonzero covariantly constant global sections. The vector Z_X is defined as a section of the line bundle $\mathscr{L}_{\partial X}|_{\Lambda_X}$ times a section of the bundle of half-densities on Λ_X. The former section is defined in terms of the Chern–Simons functional of flat connections on X and the latter in terms of the Reidemeister torsion invariant of the 3-manifold X. For X a closed manifold the construction gives for Z_X a complex number. The definition of Z_X, that is, finding the appropriate ingredients that should enter into this definition, was inspired in part by the results for the non-Abelian Chern–Simons theory from Ref. 11, as well as by the functional integral formulation of the closed 3-manifold SU(2) invariant given in Refs. 1 and 13.

We find that a natural way to incorporate the assignments $\Sigma\to\mathscr{H}(\Sigma)$ and $X\to Z_X$, defined as outlined above, into a TQFT is to make use of the category of *extended* 2- and 3-manifolds introduced by Walker in his treatment[4] of the non-Abelian Chern–Simons theory. In this paper an extended 2-manifold is a pair (Σ,L), with Σ a closed oriented 2-manifold and L a rational Lagrangian subspace in $H^1(\Sigma;\mathbb{R})$. An extended 3-manifold is a triple (X,L,n), with X a compact oriented 3-manifold, L a rational Lagrangian subspace in $H^1(\partial X;\mathbb{R})$, and $n\in\mathbb{Z}/8\mathbb{Z}$. Then the theory assigns to (Σ,L) the finite-dimensional inner product space $\mathscr{H}(\Sigma,L)$ and to (X,L,n) the vector $Z_{(X,L,n)}=e^{(\pi i/4)n}F_{LL_X}(Z_X)$ belonging to the vector space $\mathscr{H}(\partial X,L)$. We prove that these assignments satisfy the axioms[3] of a unitary TQFT, that is, the functoriality, orientation, disjoint union, and gluing properties.

The outline of this paper is the following. In Sec. II we begin by reviewing some fairly standard material on the moduli space of flat $\mathbb{T}$ connections. We describe properties of this moduli space for the case when connections are on two- and three-dimensional manifolds. Section III is devoted to an exposition of the properties of the classical Chern–Simons theory for the Abelian group $\mathbb{T}$ that are relevant for the sections to follow. We recall first the definitions of induced principal bundles and induced connections. Then we introduce the Chern–Simons functional of $\mathbb{T}$ connections on a 3-manifold with and without a boundary and prove a series of properties of this functional. In Sec. IV we give the construction of the prequantum line bundle $\mathscr{L}_\Sigma$ over the moduli space $\mathscr{M}_\Sigma$ of flat $\mathbb{T}$ connections on a closed 2-manifold Σ. Then we show that, if X is a 3-manifold with a boundary, the pullback of the prequantum line bundle $\mathscr{L}_{\partial X}$ over $\mathscr{M}_{\partial X}$ to $\mathscr{M}_X$ has a covariantly constant section defined in terms of the Chern–Simons functional. In Sec. V we define the quantum theory. We construct the finite-dimensional Hilbert space $H(\Sigma,L)$ associated to a closed oriented 2-manifold Σ and a rational Lagrangian subspace $L\subset H^1(\Sigma;\mathbb{R})$. Then, for a compact oriented 3-manifold X, we construct the vector Z_X belonging the Hilbert space

$\mathscr{H}(\partial X, L_X)$. Section VI contains the definition of the Abelian Chern–Simons TQFT. We introduce the notions of extended 2- and 3-manifolds, extended morphisms and gluing of extended 3-manifolds. Using the results of Sec. V, we define then a $2+1$-dimensional TQFT based on this category of extended manifolds and prove that it satisfies the required axioms. We also show that the mapping class group of an extended 2-manifold is unitarily represented on the corresponding quantum Hilbert space.

Throughout this paper, manifolds, bundles, and maps are assumed smooth.

II. THE MODULI SPACE OF FLAT $\mathbb{T}$ CONNECTIONS

A. The space of $\mathbb{T}$ connections

Let M be a smooth manifold and let $\mathscr{A}_M$ denote the space of $\mathbb{T}$ connections on M. An element Θ in $\mathscr{A}_M$ is a connection on a principal $\mathbb{T}$ bundle $P \to M$. Thus $\mathscr{A}_M$ is equal to the union

$$\mathscr{A}_M = \bigsqcup_P \mathscr{A}_P ,$$

over all principal $\mathbb{T}$ bundles P on M. For each bundle P the space $\mathscr{A}_P$ of connections on P is an affine space with vector space $2\pi i \Omega^1(M;\mathbb{R})$, where $\Omega^1(M;\mathbb{R})$ is the space of 1-forms on M (the Lie algebra of $\mathbb{T}$ is identified with $2\pi i\mathbb{R}$).

A bundle isomorphism between two principal $\mathbb{T}$ bundles P and P' over M is a $\mathbb{T}$-equivariant map $\phi: P' \to P$, which covers the identity on M. Two elements Θ and Θ' in $\mathscr{A}_M$ are *gauge equivalent* if there exists an isomorphism $\phi: P' \to P$, such that $\Theta' = \phi^* \Theta$. This defines an equivalence relation $\Theta' \sim \Theta$ on $\mathscr{A}_M$. We let $\mathscr{A}_M/\sim$ denote the space of gauge equivalence classes of $\mathbb{T}$ connections on M.

The space $\mathscr{G}_M = \mathrm{Map}(M, \mathbb{T})$ forms a group under pointwise multiplication. $\mathscr{G}_M$ is the *group of gauge transformations* on M. The space of components $\pi_0(\mathscr{G}_M)$ is isomorphic to $H^1(M;\mathbb{Z})$.[14] For any principal $\mathbb{T}$ bundle $\pi: P \to M$, the group $\mathscr{G}_M$ can be identified with the group $\mathscr{G}_P = \mathrm{Aut}(P)$ of bundle automorphisms of P. We call $\mathscr{G}_P$ the group of gauge transformations of P. For each $\mathbb{T}$ bundle P there is a right action of $\mathscr{G}_M$ on the space of connections $\mathscr{A}_P$. If $u: M \to \mathbb{T}$ is an element of $\mathscr{G}_M$ with associated bundle automorphism $\phi_u: P \to P$, the action of u on $\Theta \in \mathscr{A}_P$ is described by

$$\Theta \cdot u = \phi_u^* \Theta = \Theta + (u \cdot \pi)^* \vartheta, \tag{II.1}$$

where ϑ is the Maurer–Cartan form of $\mathbb{T}$, that is, $\vartheta/2\pi i$ generates $H^1(\mathbb{T};\mathbb{Z}) \subset H^1(\mathbb{T};\mathbb{R})$.

A principal $\mathbb{T}$ bundle $P \to M$ has flat connections if and only if $c_1(P) \in \mathrm{Tors}\, H^2(M;\mathbb{Z})$, that is, its first Chern class is a torsion class. The subspace $\mathscr{A}^f_M \subset \mathscr{A}_M$ of flat $\mathbb{T}$ connections on M is given by the union

$$\mathscr{A}^f_M = \bigsqcup_{\substack{P \\ c_1(P) \in \mathrm{Tors}\, H^2(M;\mathbb{Z})}} \mathscr{A}^f_P ,$$

where $\mathscr{A}^f_P$ is the space of connections Θ on P with curvature $F_\Theta = d\Theta = 0$. For each $\mathbb{T}$ bundle P with first Chern class torsion, the *moduli space of flat connections* on P is the quotient space $\mathscr{M}_P = \mathscr{A}^f_P/\mathscr{G}_P$. If P and P' are $\mathbb{T}$ bundles over M with $c_1(P) = c_1(P') \in \mathrm{Tors}\, H^2(M;\mathbb{Z})$, then there is a canonical isomorphism $\mathscr{M}_P \cong \mathscr{M}_{P'}$.

For each torsion class $p \in \mathrm{Tors}\, H^2(M;\mathbb{Z})$ let

$$\mathscr{A}^f_{M,p} = \bigsqcup_{\substack{P \\ c_1(P) = p}} \mathscr{A}^f_P .$$

The space $\mathcal{M}_{M,p}=\mathcal{A}^{f}_{M,p}/\sim$ is the moduli space of flat connections on principal $\mathbb{T}$ bundles over M with the first Chern class equal to p. For any principal $\mathbb{T}$ bundle $P\to M$ with $c_1(P)=p$, there is a natural isomorphism $\mathcal{M}_{M,p}\cong\mathcal{M}_P$. The moduli space $\mathcal{M}_M=\mathcal{A}^{f}_{M}/\sim$ of gauge equivalence classes of flat $\mathbb{T}$ connections on M is equal to the disjoint union

$$\mathcal{M}_M=\bigsqcup_{p\in \mathrm{Tors}\, H^2(M;\mathbb{Z})}\mathcal{M}_{M,p}.$$

Proposition II.2: Let M be a smooth manifold.
(i) There is a natural identification,

$$\mathcal{M}_M=H^1(M;\mathbb{T}).$$

(ii) $\pi_0(\mathcal{M}_M)\cong\mathrm{Tors}\, H^2(M;\mathbb{Z})$ and each connected component of $\mathcal{M}_M$ is diffeomorphic to the torus $H^1(M;\mathbb{R})/H^1(M;\mathbb{Z})$.

Proof: (i) is a consequence of a standard result in the theory of connections (Ref. 15, Chap. II) that provides the identification $\mathcal{M}_M=\Pi_\alpha\,\mathrm{Hom}(\pi_1(M_\alpha,*),\mathbb{T})$, where α indexes the connected components of M. For (ii), we consider the exact sequence of groups $0\to\mathbb{Z}\to\mathbb{R}\to\mathbb{T}\to 1$ and the induced exact cohomology sequence,

$$0\to H^1(M;\mathbb{Z})\to H^1(M;\mathbb{R})\to H^1(M;\mathbb{T})\xrightarrow{\delta}H^2(M;\mathbb{Z})\xrightarrow{i}H^2(M;\mathbb{R})\to\cdots. \tag{II.3}$$

Since $\mathrm{Im}\,\delta=\mathrm{Ker}\, i=\{p\,|\,p\in\mathrm{Tors}\, H^2(M;\mathbb{Z})\}$, for each torsion class p in $H^2(M;\mathbb{Z})$, we have $\mathcal{M}_{M,p}=\delta^{-1}(p)\cong\delta^{-1}(0)\cong H^1(M;\mathbb{R})/H^1(M;\mathbb{Z})$. □

B. The moduli space of flat $\mathbb{T}$ connections on a 2-manifold

Let Σ be a closed oriented two-dimensional manifold. We note that a principal $\mathbb{T}$ bundle $Q\to\Sigma$ has flat connections if and only if $c_1(Q)=0$, that is, the bundle Q is trivializable. For Σ the exact sequence (II.3) splits to

$$0\to H^1(\Sigma;\mathbb{Z})\to H^1(\Sigma;\mathbb{R})\to H^1(\Sigma;\mathbb{T})\to 0.$$

Thus, the moduli space of flat $\mathbb{T}$ connections on Σ is the torus

$$\mathcal{M}_\Sigma=H^1(\Sigma;\mathbb{T})\cong H^1(\Sigma,\mathbb{R})/H^1(\Sigma,\mathbb{Z}).$$

The space $H^1(\Sigma;\mathbb{R})$ is a symplectic vector space with symplectic form ω_Σ defined in de Rham cohomology by

$$\omega_\Sigma([\alpha],[\beta])=\int_\Sigma\alpha\wedge\beta,\quad [\alpha],[\beta]\in H^1(\Sigma;\mathbb{R}).$$

The integer lattice $H^1(\Sigma;\mathbb{Z})\subset H^1(\Sigma;\mathbb{R})$ is self-dual with respect to ω_Σ. The symplectic form ω_Σ on $H^1(\Sigma;\mathbb{R})$ descends to a symplectic form ω_Σ on the quotient torus $\mathcal{M}_\Sigma\cong H^1(\Sigma;\mathbb{R})/H^1(\Sigma;\mathbb{Z})$. We note that since the tangent space $T\mathcal{M}_\Sigma$ is identified with $2\pi i H^1(\Sigma;\mathbb{R})$, we have

$$\omega_\Sigma([\dot\eta],[\dot\eta'])=-\frac{1}{4\pi^2}\int_\Sigma\dot\eta\wedge\dot\eta', \tag{II.4}$$

for any $[\dot\eta],[\dot\eta']\in T\mathcal{M}_\Sigma$. Moreover, ω_Σ is normalized so that it gives $\mathcal{M}_\Sigma$ total volume equal to 1, that is,

$$\int_{\mathscr{M}_\Sigma} \frac{(\omega_\Sigma)^g}{g!} = 1,$$

where $g = 1/2\dim H^1(\Sigma;\mathbb{R})$. If $-\Sigma$ denotes the manifold Σ with the opposite orientation then by $H^1(-\Sigma;\mathbb{R})$ we understand the symplectic vector space $H^1(\Sigma;\mathbb{R})$ with symplectic form $-\omega_\Sigma$.

C. The moduli space of flat $\mathbb{T}$ connections on a 3-manifold

Let X be a compact oriented 3-manifold with boundary $\partial X \neq \varnothing$. The restriction of a connection over X to the boundary ∂X induces a map $r_x : \mathscr{M}_X \to \mathscr{M}_{\partial X}$. In view of the identifications $\mathscr{M}_X = H^1(X;\mathbb{T})$ and $\mathscr{M}_{\partial X} = H^1(\partial X;\mathbb{T})$, the moduli spaces $\mathscr{M}_X$ and $\mathscr{M}_{\partial X}$ are compact Abelian Lie groups and the restriction map r_X is a group homomorphism. We have the following.

Proposition II.5: (i) The image $\Lambda_X = \mathrm{Im}\{r_X : \mathscr{M}_X \to \mathscr{M}_{\partial X}\}$ *is a Lagrangian submanifold of the symplectic torus* $(\mathscr{M}_{\partial X}, \omega_{\partial X})$.

(ii) $r_X : \mathscr{M}_X \to \Lambda_X$ *is a principal fibre bundle with structure group a compact Abelian Lie group* H *that fits into the exact sequence*

$$1 \to \mathbb{T}^g \to H \to \mathrm{Tors}\, H^2(X;\mathbb{Z}) \to 0,$$

with $q = \dim H^1(X,\partial X;\mathbb{R}) - \dim H^0(\partial X;\mathbb{R}) + \dim H^0(X;\mathbb{R}) - \dim H^0(X,\partial X;\mathbb{R})$.

Proof: There is a long exact cohomology sequence (Ref. 16, Chap. V) associated to the pair of spaces $\partial X \subset X$, which for coefficients in $\mathbb{T}$ gives the exact sequence of homomorphisms of compact Abelian Lie groups:

$$1 \to H^0(X,\partial X;\mathbb{T}) \to H^0(X;\mathbb{T}) \to H^0(\partial X;\mathbb{T}) \to H^1(X,\partial X;\mathbb{T}) \to H^1(X;\mathbb{T}) \xrightarrow{r_X} \underset{\cap}{\Lambda_X}_{H^1(\partial X;\mathbb{T})} \to 1; \quad \text{(II.6)}$$

Λ_X is a compact subgroup and, therefore, a submanifold of $\mathscr{M}_{\partial X} = H^1(\partial X;\mathbb{T})$. At the same time the exact sequence of Abelian groups $0 \to \mathbb{Z} \to \mathbb{R} \to \mathbb{T} \to 1$ induces a long exact cohomology sequence for the relative cohomology $H^\bullet(X,\partial X)$ (Ref. 16, Chap. V). The relevant part of this sequence,

$$\cdots \to H^1(X,\partial X;\mathbb{T}) \to H^2(X,\partial X;\mathbb{Z}) \to H^2(X,\partial X;\mathbb{R}) \to \cdots,$$

implies $\pi_0(H^1(X,\partial X;\mathbb{T})) \cong \mathrm{Tors}\, H^2(X,\partial X;\mathbb{Z})$. The universal coefficient theorem (U.C.T.) (Ref. 16, Chap. V) together with Poincaré duality (P.D.) give the isomorphisms

$$\mathrm{Tors}\, H^2(X,\partial X;\mathbb{Z}) \underset{\text{(U.C.T.)}}{\cong} \mathrm{Tors}\, H_1(X,\partial X;\mathbb{Z}) \underset{\text{(P.D.)}}{\cong} \mathrm{Tors}\, H^2(X;\mathbb{Z}). \quad \text{(II.7)}$$

Thus, (ii) follows from (II.6) and (II.7). To prove (i), first recall that we identify $T\mathscr{M}_X = 2\pi i H^1(X;\mathbb{R})$ and $T\mathscr{M}_{\partial X} = 2\pi i H^1(\partial X;\mathbb{R})$. The differential $\dot{r}_X$ of r_X maps $T\mathscr{M}_X$ onto $T\Lambda_X \subset T\mathscr{M}_{\partial X}$, and we have

$$\omega_{\partial X}(\dot{r}_X[\dot{\Theta}], \dot{r}_X[\dot{\Theta}']) = -\frac{1}{4\pi^2}\int_{\partial X} \dot{r}_X(\dot{\Theta}) \wedge \hat{r}_X(\dot{\Theta}') = -\frac{1}{4\pi^2}\int_X d(\dot{\Theta}\wedge\dot{\Theta}')$$

$$= 0, \quad \text{for any } [\dot{\Theta}], [\dot{\Theta}'] \in T\mathscr{M}_X.$$

Since $\omega_{\partial X}|_{T\Lambda_X} \equiv 0$, Λ_X is an isotropic submanifold of $\mathscr{M}_{\partial X}$. The exact cohomology (homology) sequence with $\mathbb{R}$ coefficients for the pair $\partial X \subset X$ and the Poincaré duality isomorphism $H^{3-i}(X;\mathbb{R}) \cong H_i(X,\partial X;\mathbb{R})$ give the commutative diagram (Ref. 16, Chap. VI):

$$\begin{array}{ccccc} H^1(X;\mathbb{R}) & \xrightarrow{\dot{r}_X} & H^1(\partial X;\mathbb{R}) & \longrightarrow & H^2(X,\partial X;\mathbb{R}) \\ \downarrow\cong & & \downarrow\cong & & \downarrow\cong \\ H_2(X,\partial X;\mathbb{R}) & \longrightarrow & H_1(\partial X;\mathbb{R}) & \xrightarrow{j} & H_1(X;\mathbb{R}) \end{array}$$

where j and $\dot{r}_X$ are adjoint maps. Therefore dim Im $\dot{r}_X$=dim $H^1(\partial X;\mathbb{R})-$dim Ker j. Combining this with the exact sequence condition Im $\dot{r}_X$=Ker j, we find that dim Im $\dot{r}_X$ $=1/2$dim $H^1(\partial X;\mathbb{R})$. Therefore

$$L_X=\mathrm{Im}\{\dot{r}_X:H^1(X;\mathbb{R})\to H^1(\partial X;\mathbb{R})\}$$

is a Lagrangian subspace of $H^1(\partial X;\mathbb{R})$ and Λ_X a Lagrangian submanifold of $(\mathscr{M}_{\partial X},\omega_{\partial X})$. □

III. THE CHERN–SIMONS FUNCTIONAL

A. Induced principal bundles and induced connections

Consider the inclusion homomorphism $\rho:\mathbb{T}\hookrightarrow \mathrm{SU}(2)$,

$$e^{2\pi i\varphi}\mapsto\begin{pmatrix} e^{2\pi i\varphi} & 0 \\ 0 & e^{-2\pi i\varphi}\end{pmatrix},$$

from the circle group $\mathbb{T}$ into the group SU(2). The corresponding inclusion of the Lie algebra Lie $\mathbb{T}=2\pi i\mathbb{R}$ into the Lie algebra $\mathcal{S}\mathfrak{u}(2)$ is ρ_*: Lie $\mathbb{T}\hookrightarrow\mathcal{S}\mathfrak{u}(2)$,

$$\alpha\mapsto\begin{pmatrix}\alpha & 0\\ 0 & -\alpha\end{pmatrix}.$$

On the Lie algebra $\mathcal{S}\mathfrak{u}(2)$ we choose the symmetric invariant bilinear form

$$\langle\cdot,\cdot\rangle^\flat:\mathcal{S}\mathfrak{u}(2)\times\mathcal{S}\mathfrak{u}(2)\to\mathbb{R}$$

$$\times(a,b)\mapsto\langle a,b\rangle^\flat=\frac{1}{8\pi^2}\,\mathrm{Tr}(ab).$$

The bilinear form $\langle\cdot,\cdot\rangle^\flat$ is normalized so that the closed 3-form $\frac{1}{6}\langle\hat{\vartheta}\wedge[\hat{\vartheta},\hat{\vartheta}]\rangle^\flat$, with $\hat{\vartheta}$ the Maurer–Cartan form of SU(2) represents an integral cohomology class in $H^3(\mathrm{SU}(2);\mathbb{R})$. The commutator $[\cdot,\cdot]$ of two $\mathcal{S}\mathfrak{u}(2)$-valued forms is defined by taking the wedge product of forms and the natural Lie bracket in the $\mathcal{S}\mathfrak{u}(2)$ Lie algebra. The bilinear form $\langle\cdot,\cdot\rangle^\flat$ on $\mathcal{S}\mathfrak{u}(2)$ restricts to a symmetric bilinear form $\langle\cdot,\cdot\rangle$ on Lie $\mathbb{T}$:

$$\langle\cdot,\cdot\rangle:\mathrm{Lie}\ \mathbb{T}\times\mathrm{Lie}\ \mathbb{T}\to\mathbb{R}$$

$$\times(\alpha,\beta)\mapsto\langle\alpha,\beta\rangle=\langle\rho_*\alpha,\rho_*\beta\rangle^\flat=\frac{1}{4\pi^2}\,\alpha\beta.$$

As in the previous section we let ϑ denote the Maurer–Cartan form on $\mathbb{T}$ and note that $\rho^*(\hat{\vartheta})=\rho_*\vartheta$.

If M is a smooth manifold and π: $\rho\to M$ a principal $\mathbb{T}$ bundle, we can use the inclusion homomorphism ρ: $\mathbb{T}\hookrightarrow\mathrm{SU}(2)$ to extend the $\mathbb{T}$ bundle P on M to a principal SU(2) bundle $\hat{P}$ on M. The induced SU(2) bundle $\hat{P}$ is defined as the quotient $P\times_{\mathbb{T}}\mathrm{SU}(2)=(P\times\mathrm{SU}(2))/\mathbb{T}$ under the right $\mathbb{T}$ action given by $(p,a)\cdot\lambda=(p\cdot\lambda,\rho(\lambda)^{-1}a)$, for any $\lambda\epsilon\mathbb{T}$ and $(p,a)\epsilon P\times\mathrm{SU}(2)$. Let $[p,a]=(p,a)\cdot\mathbb{T}$ denote the $\mathbb{T}$ orbit through the point (p,a). We have a natural morphism of principal bundles,

$$\rho_P : P \to \hat{P},$$

$$p \mapsto [p, e],$$

covering the identity map on M. Moreover, for any connection Θ on the $\mathbb{T}$ bundle P there is an induced connection $\hat{\Theta}$ on the SU(2) bundle $\hat{P}$. The pullback of $\hat{\Theta}$ under the bundle map $\rho_P : P \to \hat{P}$ is $\rho_P^* \hat{\Theta} = \rho_* \Theta$. Similarly, the curvature forms $F_\Theta = d\Theta$ and $F_{\hat{\Theta}} = d\hat{\Theta} + \frac{1}{2}[\hat{\Theta}, \hat{\Theta}]$ are related by $\rho_P^* F_{\hat{\Theta}} = \rho_* F_\Theta$.

B. The Chern–Simons functional for a closed 3-manifold

Let X be a closed oriented 3-manifold. For any principal $\mathbb{T}$ bundle $P \to X$ there is an induced SU(2) bundle, $\hat{P} = P \times_{\mathbb{T}} \mathrm{SU}(2) \to X$, and for any $\mathbb{T}$ connection Θ on P an induced SU(2) connection $\hat{\Theta}$ on $\hat{P}$. Now, any principal SU(2) bundle over a manifold of dimension $\leqslant 3$ is trivializable. Thus $\hat{P}$ admits a global section, and we have the following.

Definition III.1: The Chern–Simons functional of a $\mathbb{T}$ connection Θ on $P \to X$ is defined by

$$S_{X,P}(\Theta) = \int_X \hat{s}^* \alpha(\hat{\Theta}) \quad (\mathrm{mod}\ 1),$$

where $\alpha(\hat{\Theta}) \in \Omega^3(\hat{P}; \mathbb{R})$ is the Chern–Simons form of the induced SU(2) connection $\hat{\Theta}$ on $\hat{P} = P \times_{\mathbb{T}} \mathrm{SU}(2)$,

$$\alpha(\hat{\Theta}) = \langle \hat{\Theta} \wedge F_{\hat{\Theta}} \rangle^\flat - \tfrac{1}{6} \langle \hat{\Theta} \wedge [\hat{\Theta}, \hat{\Theta}] \rangle^\flat,$$

and $\hat{s} : X \to \hat{P}$ is a global section of the SU(2) bundle $\hat{P}$.

The definition of $S_{X,P}(\Theta)$ does not depend on the choice of section $\hat{s} : X \to \hat{P}$. This is a consequence of the following property of the SU(2) Chern–Simons form $\alpha(\hat{\Theta})$.

Proposition III.2: If $\hat{s}, \hat{s}_1 : X \to \hat{P}$ are two sections of the SU(2) bundle $\hat{P}$ over X, then

$$\int_X \hat{s}_1^* \alpha(\hat{\Theta}) = \int_X \hat{s}^* \alpha(\hat{\Theta}) + \int_X d \langle Ad_{a^{-1}} \hat{s}^* \hat{\Theta} \wedge a^* \hat{\vartheta} \rangle^\flat - \int_X \frac{1}{6} a^* \langle \hat{\vartheta} \wedge [\hat{\vartheta}, \hat{\vartheta}] \rangle^\flat,$$

where $a : X \to \mathrm{SU}(2)$ is the map defined by $\hat{s}_1(x) = \hat{s}(x) \cdot a(x)$, for any $x \in X$.

Proof: The expression follows after simple computations from the standard relation $\hat{s}_1^* \hat{\Theta} = \mathrm{Ad}_{a^{-1}}(\hat{s} \hat{\Theta}) + a^* \hat{\vartheta}$. □

On the right-hand side of the equation in (III.2), the second integral vanishes by Stokes theorem and the assumption $\partial X = \varnothing$, while the last integral is an integer due to the normalization of the bilinear form $\langle \cdot, \cdot \rangle^\flat$ on $\mathcal{Su}(2)$. This proves that $S_{X,P}(\Theta)$ is well defined.

Remark III.3: If $P \to X$ is a trivializable bundle and $s : X \to P$ a section, then taking $\hat{s} : X \to \hat{P}$ to be $\hat{s} = \rho_P \circ s$, we have $\hat{s}^* \alpha(\hat{\Theta}) = s^* \langle \Theta \wedge F_\Theta \rangle$ and the Chern–Simons functional has as expected the expression

$$S_{X,P}(\Theta) = \int_X s^* \langle \Theta \wedge F_\Theta \rangle \quad (\mathrm{mod}\ 1).$$

Theorem III.4: *The Chern–Simons functional $S_{X,P} : \mathcal{A}_P \to \mathbb{R}/\mathbb{Z}$ defined for a closed oriented 3-manifold X and a principal $\mathbb{T}$ bundle $P \to X$ has the following properties:*

(*a*) *Functorality.*

If $\phi : P' \to P$ is a morphism of principal $\mathbb{T}$ bundles covering an orientation preserving diffeomorphism $\phi : X' \to X$ and if Θ is a connection on P, then

$$S_{X',P'}(\phi^*\Theta)=S_{X,P}(\Theta).$$

(b) Orientation

If $-X$ denotes the manifold X with the opposite orientation, then

$$S_{-X,P}(\Theta)=-S_{X,P}(\Theta).$$

(c) Disjoint union

Let X be the disjoint union $X=X_1\sqcup X_2$ and $P=P_1\sqcup P_2$ a principal $\mathbb{T}$ bundle over X. If Θ_i are connections on $P_i\to X_i$, then

$$S_{X_1\sqcup X_2,P_1\sqcup P_2}(\Theta_1\sqcup\Theta_2)=S_{X_1,P_1}(\Theta_1)+S_{X_2,P_2}(\Theta_2).$$

Proof: (a) To the principal $\mathbb{T}$ bundles P and P' there correspond the induced SU(2) bundles $\hat{P}$ and $\hat{P}'$, respectively. The morphism of $\mathbb{T}$ bundles $\phi:P'\to P$ induces a morphism of SU(2) bundles $\hat{\phi}:\hat{P}'\to\hat{P}$ covering $\phi:X'\to X$. It is defined by $\hat{\phi}([p',a])=[\phi(p'),a]$. For any section $\hat{s}':X'\to\hat{P}'$ we have a section $\hat{s}=\hat{\phi}\circ\hat{s}'\circ\overline{\phi^{-1}}:X\to\hat{P}$. Then, since $\hat{\phi}^*\hat{\Theta}$ is the SU(2) connection on $\hat{P}'$ induced from the $\mathbb{T}$ connection $\phi^*\Theta$ on P', we get

$$\begin{aligned}S_{X,P}(\Theta)&=\int_X\hat{s}^*\alpha(\hat{\Theta})\quad(\mathrm{mod}\ 1)\\&=\int_X(\overline{\phi^{-1}})^*\hat{s}'^*\hat{\phi}^*\alpha(\hat{\Theta})\quad(\mathrm{mod}\ 1)\\&=\int_{X'}\hat{s}'^*\alpha(\hat{\phi}^*\hat{\Theta})\quad(\mathrm{mod}\ 1)\\&=S_{X',P'}(\phi^*\Theta).\end{aligned}$$

(b) and (c) are straightforward. □

As a particular case of (a) of Theorem III. 4, we have the following.

Proposition III.5: The functional $S_{X,P}:\mathscr{A}_P\to\mathbb{R}/\mathbb{Z}$ for a closed 3-manifold X is invariant under the group of gauge transformations, that is,

$$S_{X,P}(\Theta\cdot u)=S_{X,P}(\Theta),$$

for any $u\in\mathscr{G}_X$. Hence $S_{X,P}$ descends to a functional on the quotient space $\mathscr{A}_P/\mathscr{G}_P$ of gauge equivalence classes of connections on P.

We also have the following property whose proof is straightforward.

Proposition III.6: The stationary points of the functional $S_{X,P}:\mathscr{A}_P\to\mathbb{R}/\mathbb{Z}$ are the flat connections, that is, $dS_{X,P}(\Theta)=0$ if and only if $F_\Theta=d\Theta=0$.

C. The Chern–Simons functional for a 3-manifold with boundary

Let X be a compact oriented 3-manifold with $\partial X\neq\varnothing$. Let $P\to X$ be a $\mathbb{T}$ bundle with first Chern class torsion. Then the $\mathbb{T}$ bundle $\partial P\to\partial X$ obtained by restricting P to the boundary ∂X is trivializable. As before, we consider the induced SU(2) bundle $\hat{P}=P\times_{\mathbb{T}}SU(2)$ on X and the bundle morphism $\rho_P:P\to\hat{P}$. For any section $s:\partial X\to\partial P$ we have a section $\rho_P\circ s:\partial X\to\partial\hat{P}$. Since the group SU(2) has $\pi_0(\mathrm{SU}(2))=\pi_1(\mathrm{SU}(2))=\pi_2(\mathrm{SU}(2))=0$, we can extend the section $\rho_P\circ s$ over ∂X to a global section $\hat{s}:X\to\hat{P}$. We make the following definition.

Definition III.7: The Chern–Simons functional of a $\mathbb{T}$ connection Θ on $P\to X$ and a section $s:\partial X\to\partial P$ is defined by

$$S_{X,P}(s,\Theta)=\int_X \hat{s}^*\alpha(\hat{\Theta}) \quad (\mathrm{mod}\ 1),$$

where $\alpha(\hat{\Theta})$ is the Chern–Simons form of the induced SU(2) connection $\hat{\Theta}$ on the bundle $\hat{P}$.

We have to check that the definition of $S_{X,P}(s,\Theta)$ does not depend on the choice of extension $\hat{s}$ of the section $\rho_P\circ s:\partial X\to\partial\hat{P}$. So let $\hat{s}_1:X\to\hat{P}$ to another extension. Then there is a map $a:X\to SU(2)$ such that $\hat{s}_1(x)=\hat{s}(x)\cdot a(x)$ and $a(x)=e$, for all $x\in\partial X$, where e denotes the identity element in SU(2). From (III.2) we get

$$\int_X \hat{s}_1^*\alpha(\hat{\Theta})-\int_X \hat{s}^*\alpha(\hat{\Theta})=\int_{\partial X}\langle \mathrm{Ad}_{a^{-1}}\hat{s}^*\hat{\Theta}\wedge a^*\hat{\vartheta}\rangle^b-\int_X \frac{1}{6}\,a^*\langle\hat{\vartheta}\wedge[\hat{\vartheta},\hat{\vartheta}]\rangle^b. \tag{III.8}$$

That $S_{X,P}(s,\Theta)$ is well defined by (III.7) follows now from the fact that, since $a|_{\partial X}=e$, the first integral on the rhs of (III.8) vanishes and the second term is an integer. To justify the last assertion we note the following.

Remark III.9: For each $a:X\to SU(2)$, let $W_{\partial X}(a)$ denote the functional,

$$W_{\partial X}(a)=-\int_X \frac{1}{6}\,a^*\langle\hat{\vartheta}\wedge[\hat{\vartheta},\hat{\vartheta}]\rangle^b.$$

Then, following the argument in Ref. 12, Sec. II, we let X' be a compact oriented 3-manifold with $\partial X'=\partial X$ and $a':X'\to\mathrm{SU}(2)$ a map such that $a'|_{\partial X'}=a|_{\partial X}$. Let $\widetilde{X}=X\cup(-X')$ be the closed 3-manifold obtained by gluing X and X' along their common boundary. The maps a and a' patch together into a map $\tilde{a}:\widetilde{X}\to\mathrm{SU}(2)$, and we have

$$W_{\partial X}(a)-W_{\partial X'}(a')=-\int_{\widetilde{X}}\frac{1}{6}\,\tilde{a}^*\langle\hat{\vartheta}\wedge[\hat{\vartheta},\hat{\vartheta}]\rangle^b\in\mathbb{Z}. \tag{III.10}$$

Since $\widetilde{X}$ is closed, the rhs is an integer due to the normalization of $\langle\cdot,\cdot\rangle^b$. Thus, $W_{\partial X}(a)$ depends modulo integers only on the restriction of $a:X\to\mathrm{SU}(2)$ to ∂X.

If $a|_{\partial X}=e$, we can choose $a':X'\to\mathrm{SU}(2)$ with $a'|_{\partial X'}=a|_{\partial X}$ to be the constant map $a'(x')=e$, for all $x'\in X'$. Then $W_{\partial X'}(a')=0$ and therefore $W_{\partial X}(a)\in\mathbb{Z}$.

Remark III.11: As in (III.3), if $P\to X$ is a trivializable $\mathbb{T}$ bundle and $s:X\to P$ a global section, then for any connection Θ on P the Chern–Simons functional $S_{X,P}(s,\Theta)$ is given by the expression

$$S_{X,P}(s,\Theta)=\int_X s^*\langle\Theta\wedge F_\Theta\rangle \quad (\mathrm{mod}\ 1).$$

The following proposition describes the dependence of the Chern–Simons functional $S_{X,P}(s,\Theta)$ on the section $s:\partial X\to\partial P$.

Proposition III.12: Let $s,s_1:\partial X\to\partial P$ be two sections of the restriction of the $\mathbb{T}$ bundle $P\to X$ to ∂X and let Θ be a connection on P. Then

$$S_{X,P}(s_1,\Theta)=S_{X,P}(s,\Theta)+\int_{\partial X}\langle s^*\Theta\wedge\lambda^*\vartheta\rangle \quad (\mathrm{mod}\ 1),$$

where $\lambda:\partial X\to\mathbb{T}$ is the map defined by $s_1(x)=s(x)\cdot\lambda(x)$, for all $x\in\partial X$.

Proof: The sections $\rho_P\circ s,\rho_P\circ s_1:\partial X\to\partial\hat{P}$ extend to sections $\hat{s},\hat{s}_1:X\to\hat{P}$. The map $a:X\to\mathrm{SU}(2)$ defined by $\hat{s}_1(x)=\hat{s}(x)\cdot a(x)$, for any $x\in X$, restricts to $a|_{\partial X}=\rho\circ\lambda$ over the boundary of X. The difference $S_{X,P}(s_1,\Theta)-S_{X,P}(s,\Theta)$ is given by an expression identical to the rhs of

the equation (III.8). The second term $W_{\partial X}(a)$ is also in this case an integer. To see that, choose in (III.10) a 3-manifold X' with $\partial X' = \partial X$, for which the map $\lambda: \partial X \to \mathbb{T}$ extends to a map $\lambda': X' \to \mathbb{T}$. Let $a' = \rho \cdot \circ \lambda': X' \to \mathrm{SU}(2)$. Then, since $\rho^* \hat{\vartheta} = \rho_* \vartheta$, we get that

$$W_{\partial X'}(a') = -\int_{X'} \frac{1}{6}\, a'^* \langle \hat{\vartheta} \wedge [\hat{\vartheta}, \hat{\vartheta}] \rangle^b = -\int_{X'} \frac{1}{6}\, \lambda'^* \langle \vartheta \wedge [\vartheta, \vartheta] \rangle = 0.$$

Thus (III.10) implies that $W_{\partial X}(a) \in \mathbb{Z}$. The first term on the rhs of (III.8) gives

$$\int_{\partial X} \langle \mathrm{Ad}_{a^{-1}} \hat{s}^* \hat{\Theta} \wedge a^* \hat{\vartheta} \rangle^b = \int_{\partial X} \langle s^* \Theta \wedge \lambda^* \vartheta \rangle,$$

which proves the proposition. □

Theorem III.13: *The Chern–Simons functional $S_{X,P}(\cdot,\cdot)$, defined for a compact oriented 3-manifold X with nonempty boundary and a principal $\mathbb{T}$-bundle $P \to X$ with first Chern class torsion, has the following properties.*

(a) Functoriality

Let $\phi: P' \to \underline{P}$ be a morphism of principal $\mathbb{T}$-bundles covering an orientation preserving diffeomorphism $\underline{\phi}: X' \to X$. If Θ is a connection on P and $s': \partial X' \to \partial P'$ a section of P' over the boundary of X', then

$$S_{X',P'}(s', \phi^* \Theta) = S_{X,P}(\partial \phi \circ s' \circ \partial \overline{\phi}^{-1}, \Theta),$$

where $\partial \phi: \partial P' \to \partial P$ and $\partial \overline{\phi}: \partial X' \to \partial X$ are restrictions to the boundary.

(b) Orientation

If $-X$ denotes the manifold X with the opposite orientation and $s: \partial X \to \partial P$, then

$$S_{-X,P}(s, \Theta) = -S_{X,P}(s, \Theta).$$

(c) Disjoint union

Let X be the disjoint union $X = X_1 \sqcup X_2$ and $P = P_1 \sqcup P_2$ a principal $\mathbb{T}$ bundle over *X with first Chern class torsion. If Θ_i are connections on $P_i \to X_i$ and $s_i: \partial X_i \to \partial P_i$ sections over the boundary, then*

$$S_{X_1 \sqcup X_2, P_1 \sqcup P_2}(s_1 \sqcup S_2, \Theta_1 \sqcup \Theta_2) = S_{X_1,P_1}(s_1, \Theta_1) + S_{X_2,P_2}(s_2, \Theta_2).$$

Proof: (a) Let $\hat{P} = P \times_{\mathbb{T}} \mathrm{SU}(2)$ and $\hat{P}' = P \times_{\mathbb{T}} \mathrm{SU}(2)$ be the induced SU(2) bundles, $\hat{\phi}: \hat{P}' \to \hat{P}$ the induced bundle map, and $\hat{\Theta}$ the induced connection on $\hat{P}$. The sections $s': \partial X' \to \partial P'$ and $s = \partial \phi \circ s' \circ \partial \phi^{-1}: \partial X \to \partial P$ determine sections $\rho_{P'} \circ \underline{s'}: \partial X' \to \partial \hat{P}'$ and $\rho_P \circ s: \partial X \to \partial \hat{P}$. Let $\hat{s}': X' \to \hat{P}'$ be an extension of $\rho_{P'} \circ s'$. Then $\hat{s} = \hat{\phi} \circ \hat{s}' \circ \phi^{-1}: X \to \hat{P}$ is an extension of $\rho_P \circ s$. Moreover, the SU(2) connection on $\hat{P}'$ induced from the $\mathbb{T}$ connection $\phi^* \Theta$ on P' is $\hat{\phi}^* \hat{\Theta}$. Applying the definition (III.7), we get

$$\begin{aligned} S_{X,P}(s, \Theta) &= \int_X \hat{s}^* \alpha(\hat{\Theta}) \quad (\mathrm{mod}\ 1) \\ &= \int_X (\overline{\phi}^{-1})^* \hat{s}'^* \hat{\phi}^* \alpha(\hat{\Theta}) \quad (\mathrm{mod}\ 1) \\ &= \int_{X'} \hat{s}'^* \alpha(\hat{\phi}^* \hat{\Theta}) \quad (\mathrm{mod}\ 1) \\ &= S_{X',P'}(s', \phi^* \Theta). \end{aligned}$$

(b) and (c) are straightforward. □

As a consequence of (III.12) and (a) of Theorem (III.13) we have the following.

Proposition III.14: The functional $S_{X,P}(\cdot,\cdot)$ changes under the group of gauge transformations as

$$S_{X,P}(s,\Theta\cdot u)=S_{X,P}(s,\Theta)+\int_{\partial X}\langle s^*\Theta\wedge u^*\vartheta\rangle \pmod 1,$$

for any $u\in\mathscr{G}_X=\mathrm{Map}(X,\mathbb{T})$.

We also note the following lemma

Lemma III.15: Let X be a compact oriented 3-manifold and $P\to X$ a $\mathbb{T}$ bundle with first Chern class torsion. If Θ and Θ' are connections on P and $s:\partial X\to\partial P$, then

$$S_{X,P}(s,\Theta')-S_{X,P}(s,\Theta)=-\int_{\partial X}s^*\langle\Theta\wedge\omega\rangle+2\int_X\langle F_\Theta\wedge\omega\rangle+\int_X\langle\omega\wedge d\omega\rangle \pmod 1,$$

where $\omega=\Theta'-\Theta$.

Proof: Let $\hat\Theta$ and $\hat\Theta'$ be the SU(2) connections on $\hat P=P\times_{\mathbb{T}}\mathrm{SU}(2)$ induced from the $\mathbb{T}$ connections Θ and Θ' on P. Let $\hat\omega=\hat\Theta'-\hat\Theta$. Then $\rho_P^*\hat\omega=\rho_*\omega$ and $[\hat\omega,\hat\omega]=0$. Routine computations give us, for the difference of the Chern–Simons forms of $\hat\Theta'$ and $\hat\Theta$, the expression

$$\alpha(\hat\Theta')-\alpha(\hat\Theta)=-d\langle\hat\Theta\wedge\hat\omega\rangle^b+2\langle F_{\hat\Theta}\wedge\hat\omega\rangle^b+\langle\hat\omega\wedge d\hat\omega\rangle^b.$$

The 3-forms $\langle\hat{F_\Theta}\wedge\hat\omega\rangle^b$ on $\hat P$ and $\langle F_\Theta\wedge\omega\rangle$ on P are both lifts to $\hat P$ and P, respectively, of the same 3-form on X. The same statement applies to the 3-forms $\langle\hat\omega\wedge d\hat\omega\rangle^b$ on $\hat P$ and $\langle\omega\wedge d\omega\rangle$ on P. Letting $\hat s:X\to\hat P$ be an extension to X of the section $\rho_P\circ s:\partial X\to\partial\hat P$, we can write

$$\int_X\hat s^*d\langle\hat\Theta\wedge\hat\omega\rangle^b=\int_{\partial X}s^*\rho_P^*\langle\hat\Theta\wedge\hat\omega\rangle^b=\int_{\partial X}s^*\langle\rho_*\Theta\wedge\rho_*\omega\rangle^b=\int_{\partial X}s^*\langle\Theta\wedge\omega\rangle.$$

Putting the above results together, we find that the difference,

$$S_{X,P}(s,\Theta')-S_{X,P}(s,\Theta)=\int_X\hat s^*\alpha(\hat\Theta')-\int_X\hat s^*\alpha(\hat\Theta),$$

is given by the expression in Lemma III.15. □

Lemma III.16: Let Θ be a connection on the $\mathbb{T}$ bundle $P\to X$ with $c_1(P)$ torsion and $s:\partial X\to\partial P$ a section over the boundary of X. If $u:X\to\mathbb{T}$ is an element of $\mathscr{G}_X$, then

$$\int_X\langle F_\Theta\wedge u^*\vartheta\rangle=\int_{\partial X}\langle s^*\Theta\wedge u^*\vartheta\rangle \pmod 1.$$

Proof: Let X' be a compact oriented 3-manifold with $\partial X'=\partial X$ and such that the map $u:\partial X\to\mathbb{T}$ extends to a map $u':X'\to\mathbb{T}$. Then glue the manifolds X and X' along their common boundary into the closed 3-manifold $\widetilde X=X\sqcup(-X')$ and extend the connection $\partial\Theta$ on ∂X to a connection Θ' over X'. Let $\widetilde\Theta=\Theta\sqcup\Theta'$ and let $\widetilde u:\widetilde X\to\mathbb{T}$ denote the map with restrictions $\widetilde u|_X=u$ and $\widetilde u|_{X'}=u'$. The integral

$$\int_{\widetilde X}\langle F_{\widetilde\Theta}\wedge\widetilde u^*\vartheta\rangle=\int_X\langle F_\Theta\wedge u^*\vartheta\rangle-\int_{X'}\langle F_{\Theta'}\wedge u'^*\vartheta\rangle\in\mathbb{Z}, \tag{III.17}$$

since $F_{\tilde{\Theta}}/2\pi i$ and $\tilde{u}^*\vartheta/2\pi i$ represent integral cohomology classes. Thus $\int_X \langle F_\Theta \wedge u^*\vartheta\rangle$ depends modulo $\mathbb{Z}$ only on the restrictions $\partial\Theta$ and $u|_{\partial X}$ to the boundary ∂X. To prove the lemma take Θ' extending $\partial\Theta$ over X' to be a connection on the trivial bundle $\pi': P' = X' \times \mathbb{T} \to X'$. Then, if $s': X' \to P'$ is a section, we have, from (III.17),

$$\begin{aligned}\int_X \langle F_\Theta \wedge u^*\vartheta\rangle &= \int_{X'} \langle F_{\Theta'} \wedge u'^*\vartheta\rangle \quad (\mathrm{mod}\ 1)\\ &= \int_{X'} s'^*\langle d\Theta' \wedge \pi'^* u'^*\vartheta\rangle \quad (\mathrm{mod}\ 1),\\ &= \int_{\partial X'} \langle s'^*\Theta' \wedge u'^*\vartheta\rangle \quad (\mathrm{mod}\ 1)\\ &= \int_{\partial X} \langle s^*\Theta \wedge u^*\vartheta\rangle \quad (\mathrm{mod}\ 1),\end{aligned}$$

where $s: \partial X \to \partial P$ is any section over the boundary. □

Proposition III.18: Let $P \to X$ be a $\mathbb{T}$ bundle with first Chern class torsion. For any section $s: \partial X \to \partial P$, the functional $S_{X,P}(s,\cdot): \mathscr{A}_P^f \to \mathbb{R}/\mathbb{Z}$ defined on the space of flat connections is invariant under the group $\mathscr{G}_X$ of gauge transformations, that is,

$$S_{X,P}(s, \Theta \cdot u) = S_{X,P}(s,\Theta),$$

for any $u \in \mathscr{G}_X$. Hence $S_{X,P}(s,\cdot)$ descends to a functional on the moduli space $\mathscr{M}_P$ of flat connections on P.

Proof: If Θ is flat, then Lemma III.16 gives $\int_{\partial X}\langle s^*\Theta \wedge u^*\vartheta\rangle = 0 \ (\mathrm{mod}\ 1)$, for any $u \in \mathscr{G}_X$. The proposition follows from (III.14) and the above result. □

IV. THE PREQUANTUM LINE BUNDLE

A. The line bundle over the moduli space of flat connections

As shown in Sec. II, to each closed oriented two-dimensional manifold Σ there corresponds the symplectic torus $(\mathscr{M}_\Sigma, \omega_\Sigma)$ of gauge equivalence classes of flat $\mathbb{T}$ connections on Σ. The moduli space $\mathscr{M}_\Sigma$ can be regarded[14] as the symplectic quotient of the infinite-dimensional affine space of connections on a trivializable $\mathbb{T}$ bundle over Σ by the action of the group of gauge transformations $\mathscr{G}_\Sigma$. As emphasized in Ref. 17 this point of view of $\mathscr{M}_\Sigma$ arises naturally in connection to the three-dimensional Chern–Simons theory.

Given a positive even integer k, we construct in this section a Hermitian line bundle $\mathscr{L}_\Sigma$ over $\mathscr{M}_\Sigma$ with a unitary connection with curvature $-2\pi i k \omega_\Sigma$. In the language of geometric quantization, such a line bundle is called a *prequantum line bundle* for the symplectic manifold $(\mathscr{M}_\Sigma, k\omega_\Sigma)$. The set of prequantum line bundles for $(\mathscr{M}_\Sigma, k\omega_\Sigma)$ is a principal homogeneous space for the cohomology group $H^1(\mathscr{M}_\Sigma; \mathbb{T})$. Since $H^1(\mathscr{M}_\Sigma; \mathbb{T})$ is nontrivial, by general geometric quantization arguments the choice of the prequantum line bundle is not unique. However, the ''Chern–Simons line construction'' from Ref. 12, Sec. II, which we are going to apply here, singles out a prequantum line bundle $\mathscr{L}_\Sigma$.

Let $Q \to \Sigma$ be a trivializable $\mathbb{T}$ bundle over the closed oriented surface Σ. To each connection η on Q we are going to associate a Hermitian line L_η by the following construction. Let $\Gamma(\Sigma; Q)$ stand for the space of sections of the line bundle $Q \to \Sigma$. Any two sections $s, s_1 \in \Gamma(\Sigma; Q)$ are

related by an element $\lambda:\Sigma\to\mathbb{T}$ of the group of gauge transformations $\mathscr{G}_\Sigma$, defined by $s_1(x)=s(x)\cdot\lambda(x)$. Thus we let L_η be the space of functions $f:\Gamma(\Sigma;Q)\to\mathbb{C}$ satisfying the relation

$$f(s_1)=f(s)c_\Sigma(s^*\eta,\lambda), \tag{IV.1}$$

where $c_\Sigma(s^*\eta,\lambda)$ is the $\mathbb{T}$-valued cocycle,

$$c_\Sigma:2\pi i\Omega^1(\Sigma;\mathbb{R})\times\mathscr{G}_\Sigma\to\mathbb{T},$$

$$c_\Sigma(\alpha,\lambda)=\exp\left(\pi ik\int_\Sigma\langle\alpha\wedge\lambda^*\vartheta\rangle\right)=\exp\left(-\pi ik\int_\Sigma\frac{\alpha}{2\pi i}\wedge\lambda^*(\vartheta/2\pi i)\right). \tag{IV.2}$$

c_Σ satisfies the cocycle identity,

$$c_\Sigma(\alpha,\lambda_1\lambda_2)=c_\Sigma(\alpha,\lambda_1)c_\Sigma(\alpha+\lambda_1^*\vartheta,\lambda_2), \tag{IV.3}$$

if and only if

$$\frac{k}{2}\int_\Sigma\lambda_1^*\left(\frac{\vartheta}{2\pi i}\right)\wedge\lambda_2^*\left(\frac{\vartheta}{2\pi i}\right)\in\mathbb{Z},$$

for any $\lambda_1,\lambda_2\in\mathscr{G}_\Sigma$. This imposes the restriction $k\in2\mathbb{Z}$. Hence, for the remainder of this paper, we are going to assume that k is a positive even integer. We note that $\dim_{\mathbb{C}}L_\eta=1$ and that a section $s:\Sigma\to Q$ determines a trivialization $L_\eta\cong\mathbb{C}$ by mapping $f\mapsto f(s)$. The complex line L_η has a Hermitian inner product determined by the standard inner product of $\mathbb{C}$: $(f_1,f_2)=\overline{f_1(s)}f_2(s)$.

As in Ref. 12, we have the property that, as η varies over the space $\mathscr{A}_Q$ of connections on Q, the lines L_η fit together smoothly into a Hermitian line bundle $\hat{\mathscr{L}}_Q\to\mathscr{A}_Q$.

Theorem IV.4: *Let Σ be a closed oriented 2-manifold. The assignment,*

$$\eta\mapsto L_{\Sigma,\eta}=L_\eta,$$

for η connections on trivializable $\mathbb{T}$ bundles over Σ, is smooth and satisfies the following.

(a) Functoriality

Let $\psi:Q'\to Q$ *be a morphism between trivializable $\mathbb{T}$ bundles covering an orientation preserving diffeomorphism $\psi:\Sigma'\to\Sigma$ and let η be a connection on Q. Then there is an induced isometry,*

$$\psi^*:L_\eta\to L_{\psi^*\eta},$$

$$f\mapsto\psi^*f,$$

where $\psi^*f\in L_{\psi^*\eta}$ is defined by $(\psi^*f)(s')=f(\psi\circ s'\circ\overline{\psi^{-1}})$, for any $s'\in\Gamma(\Sigma';Q')$.

(b) Orientation

If $-\Sigma$ denotes the manifold Σ with the opposite orientation, then there is a natural isometry,

$$L_{-\Sigma,\eta}\cong\overline{L_{\Sigma,\eta}}.$$

(c) Disjoint union

If $\Sigma=\Sigma_1\sqcup\Sigma_2$ is a disjoint union and η_i are connections on trivializable $\mathbb{T}$ bundles over Σ_i, then there is a natural isometry,

$$L_{\eta_1\sqcup\eta_2}\cong L_{\eta_1}\otimes L_{\eta_2}.$$

Proof: (a) To check that $\psi^* f$ does indeed belong to the line $L_{\psi^*\eta}$, let $\lambda':\Sigma'\to\mathbb{T}$ and let $s',s_1'\in\Gamma(\Sigma';Q')$ be sections related by $s_1'(x')=s'(x')\cdot\lambda'(x')$, for all $x'\in\Sigma'$. Then $(\psi\circ s_1'\circ\psi^{-1})(x)=(\psi\circ s'\circ\psi^{-1})(x)\cdot\lambda(x)$ at any $x\in\Sigma$, where $\lambda=\lambda'\circ\psi^{-1}:\Sigma\to\mathbb{T}$. Therefore we obtain

$$(\psi^* f)(s_1')=f(\psi\circ s_1'\circ\overline{\psi^{-1}})=f(\psi\circ s'\circ\overline{\psi^{-1}})c_\Sigma((\overline{\psi^{-1}})^* s'^*\psi^*\eta,\lambda)$$
$$=(\psi^* f)(s')c_{\Sigma'}(s'^*(\psi^*\eta),\lambda').$$

(b) follows from the fact that the $\mathbb{T}$-valued cocycle c_Σ changes to the complex conjugate expression when the orientation of Σ is reversed.

(c) η_i are connections on trivializable $\mathbb{T}$ bundles $Q_i\to\Sigma_i$. Let $s_i:\Sigma_i\to Q_i$ be some sections and $\lambda_i:\Sigma_i\to\mathbb{T}$ gauge transformations and set $s=s_1\sqcup s_2$, $\eta=\eta_1\sqcup\eta_2$, and $\lambda=\lambda_1\sqcup\lambda_2$. Then $c_\Sigma(s^*\eta,\lambda)=c_{\Sigma_1}(s_1^*\eta_1,\lambda_1)c_{\Sigma_2}(s_2^*\eta_2,\lambda_2)$, and this induces the isometry

$$L_{\eta_1}\otimes L_{\eta_2}\to L_{\eta_1\sqcup\eta_2},$$

$$f_1\otimes f_2\mapsto f,$$

where $f(s)=f_1(s_1)f_2(s_2)$, for any section $s=s_1\sqcup s_2$. □

Each section $s:\Sigma\to Q$ induces a trivialization of the line bundle $\hat{\mathscr{L}}_Q$, given by the unitary section,

$$\gamma_s:\mathscr{A}_Q\to\hat{\mathscr{L}}_Q,$$

with $\gamma_s(\eta)\in L_\eta$ defined, for each η, by $(\gamma_s(\eta))(s)=1$. We define the connection $\hat{\nabla}$ on $\hat{\mathscr{L}}_Q$ by

$$\hat{\nabla}\gamma_s=-2\pi ik\hat{\theta}_s\gamma_s, \tag{IV.5}$$

where $\hat{\theta}_s$ is the 1-form on $\mathscr{A}_Q$, given by

$$(\dot{\eta}\lrcorner\hat{\theta}_s)_\eta=-\frac{1}{2}\int_\Sigma s^*\langle\eta\wedge\dot{\eta}\rangle, \tag{IV.6}$$

for any $\eta\in\mathscr{A}_Q$ and $\dot{\eta}\in T_\eta\mathscr{A}_Q$. If $\psi\in\mathscr{G}_Q=\mathrm{Aut}(Q)$, the new section $\psi\circ s:\Sigma\to Q$ induces a new section $\gamma_{\psi\circ s}:\mathscr{A}_Q\to\mathscr{L}_Q$ related to γ_s by

$$\gamma_{\psi\circ s}(\eta)=c_\Sigma(s^*\eta,\lambda_\psi)^{-1}\gamma_s(\eta), \tag{IV.7}$$

where $\lambda_\psi:\Sigma\to\mathbb{T}$ is the map associated to ψ. It follows that the connection form $\hat{\theta}_{\psi\circ s}$ is related to $\hat{\theta}_s$ by

$$(\hat{\theta}_{\psi\circ s})_\eta=(\hat{\theta}_s)_\eta+\frac{1}{2\pi ik}\frac{dc_\Sigma(s^*\eta,\lambda_\psi)}{c_\Sigma(s^*\eta,\lambda_\psi)},$$

which implies that the definition (IV.5) of $\hat{\nabla}$ does not depend on the choice of trivialization of $\hat{\mathscr{L}}_Q\to\mathscr{A}_Q$. Since γ_s is a unitary section and $\hat{\theta}_s$ is real, the connection $\hat{\nabla}$ is compatible with the Hermitian structure on $\hat{\mathscr{L}}_Q$. The curvature of $\hat{\nabla}$ is $-2\pi ik\omega_\Sigma$, where

$$\omega_\Sigma(\dot{\eta},\dot{\eta}')=(d\hat{\theta}_s)(\dot{\eta},\dot{\eta}')=-\int_\Sigma\langle\dot{\eta}\wedge\dot{\eta}'\rangle, \tag{IV.8}$$

is the standard symplectic form on $T\mathscr{A}_Q\cong 2\pi i\Omega^1(\Sigma;\mathbb{R})$.

It follows from (a) of Theorem IV.4 that the action of the group of gauge transformations $\mathcal{G}_Q$ on $\mathcal{A}_Q$ lifts to the line bundle $\hat{\mathcal{L}}_Q$ preserving the Hermitian metric. The lift of $\mathcal{G}_Q$ to $\hat{\mathcal{L}}_Q$ preserves also the connection $\hat{\mathbf{\nabla}}$, and, as $-2\pi i k\omega_\Sigma$ is the curvature of $\hat{\mathbf{\nabla}}$, the $\mathcal{G}_Q$-action on $\mathcal{A}_Q$ preserves the symplectic form ω_Σ.

Since the action of $\mathcal{G}_Q$ on $\mathcal{A}_Q$ is symplectic and lifts to the line bundle $\pi:\hat{\mathcal{L}}_Q\to\mathcal{A}_Q$ preserving the Hermitian metric and the connection $\hat{\mathbf{\nabla}}$, there exists a moment map for this action. Applying the general construction in (Ref. 18, Sec. IV), we find that the explicit form of the moment map $\mu:\mathcal{A}_Q\to(\text{Lie }\mathcal{G}_Q)^*$, $\eta\mapsto\mu(\eta)$ is

$$(\mu(\eta))(\xi)=2k(d\xi\lrcorner\hat{\theta}_s)_\eta=-k\int_\Sigma\langle s^*\eta\wedge d\xi\rangle=-k\int_\Sigma\langle s^*\ d\eta\wedge\xi\rangle,$$

for any $\xi\in\text{Lie }\mathcal{G}_Q\cong 2\pi i\Omega^0(\Sigma;\mathbb{R})$. The preimage $\mu^{-1}(0)$, which is $\mathcal{G}_Q$ invariant, is the space $\mathcal{A}_Q^f$ of flat connections. Hence the space $\mathcal{M}_Q$ of equivalence classes of flat connections is the symplectic quotient, $\mathcal{M}_Q=\mathcal{A}_Q//\mathcal{G}_Q=\mu^{-1}(0)/\mathcal{G}_Q$. The symplectic form ω_Σ on $\mathcal{A}_Q$ pushes down to a symplectic form on $\mathcal{M}_Q$, which we continue to denote by ω_Σ.

The group $\mathcal{G}_Q$ does not act freely on $\mathcal{A}_Q$. However, the stabilizer at a point $\eta\in\mathcal{A}_Q$ is the subgroup $Z\subset\mathcal{G}_Q$ of constant gauge transformations $Z\cong\{\lambda:\Sigma\to\mathbb{T}|\lambda=\text{constant}\}\cong\mathbb{T}$ and Z acts trivially on L_η. Therefore the line bundle $\hat{\mathcal{L}}_Q\to\mathcal{A}_Q^f=\mu^{-1}(0)$ pushes down to a line bundle $\mathcal{L}_Q\to\mathcal{M}_Q$. We have the identification $\Gamma(\mathcal{M}_Q;\mathcal{L}_Q)=\Gamma(\mathcal{A}_Q^f;\hat{\mathcal{L}}_Q)^{\mathcal{G}_Q}$ of the space of sections of $\mathcal{L}_Q\to\mathcal{M}_Q$ with the space of $\mathcal{G}_Q$-invariant sections of $\hat{\mathcal{L}}_Q\to\mathcal{A}_Q^f$. The Hermitian metric and connection on $\hat{\mathcal{L}}_Q$ also push down to $\mathcal{L}_Q$.

Remark IV.9: Let us assume for the moment that in constructing the Hermitian line bundle $\hat{\mathcal{L}}_Q\to\mathcal{A}_Q$ we take the cocycle c_Σ to have, instead of (IV.2), the more general form

$$c_\Sigma(\alpha,\lambda)=\epsilon_\Sigma([\lambda])\exp\left(\pi ik\int_\Sigma\langle\alpha\wedge\lambda^*\vartheta\rangle\right),$$

where $[\lambda]$ denotes the homotopy class of the map $\lambda:\Sigma\to\mathbb{T}$. In order to satisfy the cocycle condition (IV.3), the $\mathbb{T}$-valued multiplier ϵ_Σ must have the property

$$\epsilon_\Sigma([\lambda_1][\lambda_2])=\epsilon_\Sigma([\lambda_1])\epsilon_\Sigma([\lambda_2])\exp\left(\pi ik\int_\Sigma\langle\lambda_1^*\vartheta\wedge\lambda_2^*\vartheta\rangle\right),$$

and k can be any integer. All that has been said up to this point, except (a) of Theorem IV.4, remains true. We get a Hermitian line bundle over $\mathcal{A}_Q$ with a unitary connection with curvature $-2\pi ik\omega_\Sigma$ and the action of $\mathcal{G}_Q$ lifts, preserving the metric and the connection. The restriction of this line to $\mathcal{A}_Q^f$ pushes down to a prequantum line bundle over $\mathcal{M}_Q$. The initial choice (IV.2) for c_Σ, in which ϵ_Σ is taken to be the trivial multiplier (which forces k to be even), is dictated by the requirement to satisfy also the functoriality property [see (a) of Theorem IV.4]. This can be seen immediately if we follow the proof given for (a) of Theorem IV.4. Only for this choice do we get a prequantum line bundle over the moduli space $\mathcal{M}_\Sigma$ for which there is a lift of the group of orientation preserving diffeomorphisms of Σ. The prequantum line bundle over $\mathcal{M}_\Sigma$ picked out by the above stated reasons is also closely connected to the Chern–Simons theory in three dimensions. This connection will become clear later in this section.

Given any two trivializable $\mathbb{T}$ bundles Q and Q' over Σ, let $\psi:Q'\to Q$ be a bundle isomorphism. It follows from (a) of Theorem IV.4 that the induced isomorphism between the spaces of

connections lifts to an isomorphism of line bundles,

$$\begin{array}{ccc} \hat{\mathcal{L}}_Q & \xrightarrow{\psi^*} & \hat{\mathcal{L}}_{Q'} \\ \downarrow & & \downarrow \\ \mathcal{A}_Q & \xrightarrow{\psi^*} & \mathcal{A}_{Q'} \end{array} \tag{IV.10}$$

To each gauge transformation $\phi \in \mathcal{G}_Q$ there corresponds a gauge transformation $\psi^{-1} \circ \phi \circ \psi \in \mathcal{G}_{Q'}$, so that for any connection $\eta \in \mathcal{A}_Q$ we have the commutative diagram

$$\begin{array}{ccc} L_\eta & \xrightarrow{\psi^*} & L_{\psi^*\eta} \\ {\scriptstyle \phi^*}\downarrow & & \downarrow{\scriptstyle (\psi^{-1}\circ\phi\circ\psi)^*} \\ L_{\phi^*\eta} & \xrightarrow{\psi^*} & L_{\psi^*\phi^*\eta} \end{array} \tag{IV.11}$$

of line isomorphisms defined by (a) of Theorem IV (a). The line bundle isomorphism (IV.10) pushes down to an isomorphism between the quotient line bundles by the groups of gauge transformations,

$$\begin{array}{ccc} \mathcal{L}_Q = \hat{\mathcal{L}}_Q/\mathcal{G}_Q & \longrightarrow & \mathcal{L}_{Q'} = \hat{\mathcal{L}}_{Q'}/\mathcal{G}_{Q'} \\ \downarrow & & \downarrow \\ \mathcal{A}_Q/\mathcal{G}_Q & \longrightarrow & \mathcal{A}_{Q'}/\mathcal{G}_{Q'} \end{array} \tag{IV.12}$$

It follows from (IV.11) that the above isomorphism is canonical, that is, independent of the choice of $\mathbb{T}$-bundle isomorphism $\psi: Q' \to Q$. Restricting the above considerations to the subspaces of flat connections, we obtain that, for any two trivializable $\mathbb{T}$ bundles Q and Q' over Σ, there is a canonical isomorphism of Hermitian line bundles with connections

$$\begin{array}{ccc} \mathcal{L}_Q & \longrightarrow & \mathcal{L}_{Q'} \\ \downarrow & & \downarrow \\ \mathcal{M}_Q & \longrightarrow & \mathcal{M}_{Q'} \end{array} \tag{IV.13}$$

Since $\mathcal{M}_\Sigma \cong \mathcal{M}_Q$ for any trivializable $\mathbb{T}$ bundle $Q \to \Sigma$, the above shows that we get a Hermitian line bundle,

$$\mathcal{L}_\Sigma \to \mathcal{M}_\Sigma,$$

with a unitary connection ∇ with curvature $-2\pi i k \omega_\Sigma$, where ω_Σ is the standard symplectic form on $\mathcal{M}_\Sigma$.

B. The Chern–Simons section

We now turn our attention to the three dimensional Chern–Simons theory. Let X be a compact oriented 3-manifold with nonempty boundary and $P \to X$ a principal $\mathbb{T}$ bundle with $c_1(P)$ a torsion class. If Θ is a connection on P, then Proposition III.12 shows that the function

$$e^{\pi ikS_{X,P}(\Theta)}:\Gamma(\partial X;Q)\to\mathbb{C},$$

$$s\mapsto e^{\pi ikS_{X,P}(\Theta)}(s)=e^{\pi ikS_{X,P}(s,\Theta)},$$

is an element of norm 1 in the line $L_{\partial\Theta}$ attached to the restriction of Θ to ∂X,

$$e^{\pi ikS_{X,P}(\Theta)}\in L_{\partial\Theta}. \tag{IV.14}$$

If $\partial X=\varnothing$, then $e^{\pi ikS_{X,P}(\Theta)}\in\mathbb{C}$, so we set $L_{\varnothing}=\mathbb{C}$ to account for this case too.

Theorem IV.15: *Let X be a compact oriented 3-manifold. The assignment,*

$$\Theta\to e^{\pi ikS_{X,P}(\Theta)}\in L_{\partial\Theta},$$

for Θ connections on $\mathbb{T}$-bundles $P\to X$ with $c_1(P)$ torsion, is smooth and satisfies the following.

(a) Functoriality

Let $\phi:P'\to P$ be a morphism of principal $\mathbb{T}$-bundles covering an orientation preserving diffeomorphism $\phi:X'\to X$. If Θ is a connection on P, then

$$(\partial\phi)^*e^{\pi ikS_{X,P}(\Theta)}=e^{\pi ikS_{X',P'}(\phi^*\Theta)},$$

under the induced isometry $(\partial\phi)^*:L_{\partial\Theta}\to L_{\partial\phi^*\Theta}$. In particular, if $\partial X=\varnothing$, then

$$e^{\pi ikS_{X,P}(\Theta)}=e^{\pi ikS_{X',P'}(\phi^*\Theta)}.$$

(b) Orientation

If $-X$ is the manifold X with the opposite orientation, then

$$e^{\pi ikS_{-X,P}(\Theta)}=\overline{e^{\pi ikS_{X,P}(\Theta)}}\in\overline{L_{\partial\Theta}}.$$

(c) Disjoint union

Let X be the disjoint union $X=X_1\sqcup X_2$. If Θ_i are connections on $\mathbb{T}$ bundles $P_i\to X_i$, then we have the identification

$$e^{\pi ikS_{X_1\sqcup X_2,P_1\sqcup P_2}(\Theta_1\sqcup\Theta_2)}=e^{\pi ikS_{X_1,P_1}(\Theta_1)}\otimes e^{\pi ikS_{X_2,P_2}(\Theta_2)},$$

under the isomorphism $L_{\partial\Theta_1\sqcup\partial\Theta_2}\cong L_{\partial\Theta_1}\otimes L_{\partial\Theta_2}$.

(d) Gluing

Let X be a compact oriented 3-manifold and let X^{cut} be the 3-manifold obtained by cutting X along a closed oriented two-dimensional submanifold Σ. Then $\partial X^{\mathrm{cut}}=\partial X\sqcup(-\Sigma)\sqcup\Sigma$.

Let Θ be a connection on a $\mathbb{T}$ bundle $P\to X$, with η the restriction of Θ to Σ, and let Θ^{cut} denote the induced connection on the pullback bundle $P^{\mathrm{cut}}=g^*P$ under the gluing map $g:X^{\mathrm{cut}}\to X$. If

$$\mathrm{Tr}_\eta:L_{\partial\Theta^{\mathrm{cut}}}\cong L_{\partial\Theta}\otimes\overline{L_\eta}\otimes L_\eta\to L_{\partial\Theta}$$

is the contraction map using the Hermitian inner product in $L\eta$, then

$$\mathrm{Tr}_\eta(e^{\pi ikS_{X^{\mathrm{cut}},P^{\mathrm{cut}}}(\Theta^{\mathrm{cut}})})=e^{\pi ikS_{X,P}(\Theta)}. \tag{IV.16}$$

Proof: (a) follows from (a) of Theorem IV.4 and (a) of Theorem III.13.
(b) follows from (b) of Theorem IV.4 and (b) of Theorem III.13.
(c) follows from (c) of Theorem IV.4 and (c) of Theorem III.13.

(d) Let $g:P^{\rm cut}\to P$ be the bundle map from the pullback bundle $P^{\rm cut}=g^*P$ to P, covering the gluing map $g:X^{\rm cut}\to X$. Then $\Theta^{\rm cut}=g^*\Theta$ and $\partial\Theta^{\rm cut}=\partial\Theta\sqcup\eta\sqcup\eta$. Under the isometry $L_{\partial\Theta^{\rm cut}}\to L_{\partial\Theta}\otimes\overline{L_\eta}\otimes L_\eta$, the element $e^{\pi ikS_{X^{\rm cut},P^{\rm cut}}(\Theta^{\rm cut})}\in L_{\partial\Theta^{\rm cut}}$ is mapped to

$$\frac{e^{\pi ikS_{X^{\rm cut},P^{\rm cut}}(s^{\rm cut}\Theta^{\rm cut})}}{e^{\pi ikS_{X,P}(s\Theta)}\overline{f(\sigma)}f(\sigma)}\,(e^{\pi ikS_{X,P}(\Theta)}\otimes\overline{f}\otimes f\,)\in L_{\partial\Theta}\otimes\overline{L_\eta}\otimes L_\eta,\tag{IV.17}$$

where s, σ, and $s^{\rm cut}$ are sections $s:\partial X\to\Pi$, $\sigma:\Sigma\to P|_\Sigma$ and $s^{\rm cut}=s\sqcup\sigma\sqcup\sigma:\partial X^{\rm cut}\to\partial P^{\rm cut}$. Let $\rho_P:P\to\hat P=P\times_{\mathbb{T}}{\rm SU}(2)$ and $\rho_{P^{\rm cut}}:P^{\rm cut}\to\hat P^{\rm cut}=P^{\rm cut}\times_{\mathbb{T}}{\rm SU}(2)=g^*\hat P$ be the bundle maps to the induced SU(2) bundles. There is a SU(2)-bundle morphism $\hat g:\hat P^{\rm cut}\to\hat P$ so that $\rho_P\circ g=\hat g\circ\rho_{P^{\rm cut}}$. Let $\hat s:X\to\hat P$ be the extension of $\rho_P\circ s:\partial X\to\partial\hat P$ and $\hat s^{\rm cut}:X\to\hat P^{\rm cut}$ the pullback of the section $\hat s$. Then $\hat g\circ\hat s^{\rm cut}=\hat s\circ g$ and $\hat s^{\rm cut}|_{\partial X^{\rm cut}}=\rho_{P^{\rm cut}}\circ s^{\rm cut}$. If $\hat\Theta^{\rm cut}=\hat g^*\hat\Theta$ then $\rho^*_{P^{\rm cut}}\hat\Theta^{\rm cut}=\rho_*\Theta^{\rm cut}$. Therefore

$$\begin{aligned}S_{X^{\rm cut},P^{\rm cut}}(S^{\rm cut},\Theta^{\rm cut})&=\int_{X^{\rm cut}}\hat s^{\rm cut*}\alpha(\hat\Theta^{\rm cut})\quad(\text{mod }1)\\&=\int_{X^{\rm cut}}\hat s^{\rm cut*}\alpha(\hat g^*\hat\Theta)\quad(\text{mod }1)\\&=\int_{X^{\rm cut}}g^*\hat s^*\alpha(\hat\Theta)\quad(\text{mod }1)\\&=\int_X\hat s^*\alpha(\hat\Theta)\quad(\text{mod }1)=S_{X,P}(s,\Theta).\end{aligned}$$

Taking in (IV.17) the Hermitian inner product in L_η and using the above result, we get (IV.16).□

Consider now the restriction map $r:\mathscr{A}_P\to\mathscr{A}_{\partial P}$, which sends a connection on the $\mathbb{T}$ bundle $P\to X$ to its restriction over ∂X. As previously shown, to the trivializable $\mathbb{T}$ bundle $\partial P\to\partial X$ there corresponds a Hermitian line bundle $\pi:\hat{\mathscr{L}}_{\partial P}\to\mathscr{A}_{\partial P}$ with connection $\hat\nabla$ and these pull back under r to a Hermitian line bundle $r^*\hat{\mathscr{L}}_{\partial P}\to\mathscr{A}_P$ with connection $r^*\hat\nabla$. The restriction of $r^*\hat{\mathscr{L}}_{\partial P}$ to the subspace $\mathscr{A}_P^f$ of flat connections is a *flat* line bundle, since

$$(r^*\omega_\Sigma)(\dot\Theta,\dot\Theta')=\omega_\Sigma(r_*\dot\Theta,r_*\dot\Theta')=-\int_{\partial X}\langle\partial\dot\Theta\wedge\partial\dot\Theta'\rangle=-\int_X d\langle\dot\Theta\wedge\dot\Theta'\rangle=0,$$

for any $\dot\Theta,\dot\Theta'\in T\mathscr{A}_P^f$.

As $\mathscr{G}_P\subset\mathscr{G}_{\partial P}$, the action of the group of gauge transformations $\mathscr{G}_P$ on $\mathscr{A}_P$ lifts to $r^*\hat{\mathscr{L}}_{\partial P}$. Since $r^*\hat{\mathscr{L}}_{\partial P}=\{(\Theta,f\,)\in\mathscr{A}_P\times\hat{\mathscr{L}}_{\partial P}|r(\Theta)=\pi(f\,)\}$, we see from Theorem IV.14 and Theorem IV.15 (a) that

$$\hat\sigma_P:\mathscr{A}_P\to r^*\hat{\mathscr{L}}_{\partial P},$$

$$\Theta\mapsto(\Theta,e^{\pi ikS_{X,P}(\Theta)}),\tag{IV.18}$$

is a nowhere-zero $\mathscr{G}_P$-invariant section. Moreover, we have the following.

Proposition IV.19: The section $\hat\sigma_P:\mathscr{A}_P^f\to r^*\hat{\mathscr{L}}_{\partial P}$ is covariantly constant.

Proof: Let $s:\partial X\to\partial P$ be a section. The induced section $\gamma_s:\mathscr{A}_{\partial P}\to\hat{\mathscr{L}}_{\partial P}$ pulls back to $(r^*\gamma_s)(\Theta)=(\Theta,\gamma_s(\partial\Theta)):\mathscr{A}_P\to r^*\hat{\mathscr{L}}_{\partial P}$. Since $\mathrm{e}^{\pi ikS_{X,P}(\Theta)}=\mathrm{e}^{\pi ikS_{X,P}(s,\Theta)}\gamma_s(\partial\Theta)$, we can write $\hat\sigma_P=\varphi(r^*\gamma_s)$ with $\varphi(\Theta)=\mathrm{e}^{\pi ikS_{X,P}(s,\Theta)}$. Differentiating φ with respect to $\dot\eta\in T_\Theta\mathscr{A}_P^f$, we find

$$(\dot{\eta}\varphi)(\Theta)=\frac{d}{dt}\Big|_{t=0} e^{\pi i k S_{X,P}(s,\Theta+t\dot{\eta})}=\left[-\pi i k\int_{\partial X} s^*\langle\Theta\wedge\dot{\eta}\rangle\right]\phi(\Theta).$$

On the other hand,

$$(r^*\hat{\nabla})_{\dot{\eta}}(r^*\gamma_s)=-2\pi i k(\dot{\eta}\lrcorner r^*\hat{\theta}_s)(r^*\gamma_s).$$

Combining these two results, we obtain

$$(r^*\hat{\nabla})_{\dot{\eta}}\hat{\sigma}_P=(r^*\hat{\nabla})_{\dot{\eta}}(\varphi(r^*\gamma_s))=0.$$

□

The flat line bundle $r^*\hat{\mathscr{L}}_{\partial P}\to\mathscr{A}_P^f$ together with its metric and connection push down to the quotient by $\mathscr{G}_P$ to a flat Hermitian line bundle which is identified with the pullback $r^*\mathscr{L}_{\partial P}\to\mathscr{M}_P$ of the line bundle $\mathscr{L}_{\partial P}\to\mathscr{M}_{\partial P}$ under the restriction map $r:\mathscr{M}_P\to\mathscr{M}_{\partial P}$. The $\mathscr{G}_P$-invariant and covariantly constant section $\hat{\sigma}_P:\mathscr{A}_P^f\to r^*\hat{\mathscr{L}}_{\partial P}$ corresponds to a covariantly constant section,

$$\sigma_P:\mathscr{M}_P\to r^*\mathscr{L}_{\partial P}. \tag{IV.20}$$

For any two principal $\mathbb{T}$-bundles P and P' over X with $c_1(P)=c_1(P')=p\in\mathrm{Tors}\,H^2(X;\mathbb{Z})$, let $\phi:P'\to P$ be a bundle isomorphism. This induces an isomorphism of Hermitian line bundles with connections $\phi^*:r^*\hat{\mathscr{L}}_{\partial P}\to r^*\hat{\mathscr{L}}_{\partial P'}$, such that for the corresponding Chern–Simons sections (IV.18) we have $\phi^*\hat{\sigma}_P(\Theta)=\hat{\sigma}_{P'}(\phi^*\Theta)$, for any $\Theta\in\mathscr{A}_P$. Restricting these line bundles to the subspaces of flat connections and taking the quotient by the group of gauge transformations, we obtain a canonical isomorphism of flat Hermitian lines,

$$\begin{array}{ccc} r^*\mathcal{L}_{\partial P} & \longrightarrow & r^*\mathcal{L}_{\partial P'} \\ \downarrow & & \downarrow \\ \mathcal{M}_P & \longrightarrow & \mathcal{M}_{P'} \end{array} \tag{IV.21}$$

Thus, for each $p\in\mathrm{Tors}\,H^2(X;\mathbb{Z})$, we obtain a Hermitian line bundle with a flat connection,

$$\mathscr{L}_p\to\mathscr{M}_{X,p},$$

over the connected component $\mathscr{M}_{X,p}$ of the moduli space $\mathscr{M}_X$. The line bundle $\mathscr{L}_p\to\mathscr{M}_{X,p}$ is canonically identified with the restriction to $\mathscr{M}_{X,p}\subset\mathscr{M}_X$ of the pullback of $\mathscr{L}_{\partial X}\to\mathscr{M}_{\partial X}$ under the map $r_X:\mathscr{M}_X\to\mathscr{M}_{\partial X}$. In view of the canonical isomorphism (IV.21), the section (IV.20) defines a nowhere-zero covariantly constant section,

$$\sigma_{X,p}:\mathscr{M}_{X,p}\to\mathscr{L}_p=r_X^*\mathscr{L}_{\partial X}|_{\mathscr{M}_{X,p}}, \tag{IV.22}$$

which we refer to as *the Chern–Simons section*.

The constructions and results of this and previous sections show that the classical Abelian Chern–Simons theory fits into the general picture described in Ref. 17, Sec. 3; that is, it has the properties axiomatized in Ref. 17, Sec. 3.3 of a classical Lagrangian field theory that formally lead, via quantization, to the axioms of a topological quantum field theory. We have in view: (i) the assignment to every two-dimensional closed oriented manifold Σ of a Hermitian line bundle $\mathscr{L}_\Sigma$ with a unitary connection ∇ over the moduli space of flat $\mathbb{T}$ connections on Σ (Sec. IV A and properties expressed in Theorem IV.4); (ii) the assignment to every three-dimensional compact oriented manifold X of the moduli space of flat $\mathbb{T}$ connections $\mathscr{M}_X$ and the map $r_X:\mathscr{M}_X\to\mathscr{M}_{\partial X}$

under which the line bundle $\mathscr{L}_{\partial X}$ pulls back to a line bundle $r_X^*(\mathscr{L}_{\partial X})$ with a unitary section defined by the generalized Chern–Simons section $e^{\pi i k S_{X,P}}$ (Sec. IV.B and properties expressed in Theorem IV.15).

V. THE QUANTUM THEORY

A. The Hilbert space

We consider again a closed oriented two-dimensional manifold Σ and let $g = \frac{1}{2}\dim H^1(\Sigma;\mathbb{R})$. The space of gauge equivalence classes of flat $\mathbb{T}$ connections on Σ is a symplectic $2g$-dimensional manifold $(\mathscr{M}_\Sigma, \omega_\Sigma)$. The construction in Sec. IV provides $(\mathscr{M}_\Sigma, k\omega_\Sigma)$, $k \in 2\mathbb{Z}_+$, with a Hermitian line bundle $\mathscr{L}_\Sigma$ with a unitary connection ∇ with curvature $-2\pi i k \omega_\Sigma$. According to the general geometric quantization scheme, the other data needed for the quantization of the symplectic manifold $(\mathscr{M}_\Sigma, k\omega_\Sigma)$ is a polarization.

Since $(\mathscr{M}_\Sigma, \omega_\Sigma)$ is a symplectic torus, we are going to use the results in Ref. 10 on the quantization with half-densities of symplectic tori in a real polarization. Thus, let $L \subset H^1(\Sigma;\mathbb{R})$ be a *rational* Lagrangian subspace of the symplectic vector space $(H^1(\Sigma;\mathbb{R}), \omega_\Sigma)$. The attribute rational refers to the fact that the intersection $L \cap H^1(\Sigma;\mathbb{Z})$ with the integer lattice $H^1(\Sigma;\mathbb{Z}) \subset H^1(\Sigma;\mathbb{R})$ generates L as a vector space. Under the identification of the tangent space at any point of $\mathscr{M}_\Sigma$ with $2\pi i H^1(\Sigma;\mathbb{R})$, the Lagrangian subspace L determines an invariant real polarization $\mathscr{P}_L$ of $(\mathscr{M}_\Sigma, \omega_\Sigma)$. The polarization $\mathscr{P}_L$ is the tangent bundle along the leaves of an invariant Lagrangian foliation of $\mathscr{M}_\Sigma$.

The bundle of half-densities on $\mathscr{P}_L$ is the line bundle $|\mathrm{Det}\,\mathscr{P}_L^*|^{1/2}$ over $\mathscr{M}_\Sigma$. Its restriction to any leaf Λ of $\mathscr{P}_L$ has a canonical flat connection $\nabla^{\mathscr{P}_L}$ defined as follows.[19] First, let us recall that, since the quotient map $\pi: \mathscr{M}_\Sigma \to \mathscr{M}_\Sigma/\mathscr{P}_L$ is a smooth fibration, for each point in $\mathscr{M}_\Sigma/\mathscr{P}_L$ there is a local neighborhood U such that $\mathscr{P}_L|_{\pi^{-1}(U)}$ is spanned by Hamiltonian vector fields, $[\dot{x}_1],\ldots,[\dot{x}_g]$. Then, on $\pi^{-1}(U)$, the covariant derivative $\nabla^{\mathscr{P}_L}_{[\dot{\omega}]}\mu$ of a section μ of $|\mathrm{Det}\,\mathscr{P}_L^*|^{1/2}$, along a vector field $[\dot{\omega}] \in \mathscr{P}_L|_{\pi^{-1}(U)}$, is defined by

$$(\nabla^{\mathscr{P}_L}_{[\dot{w}]}\mu)([\dot{x}_1],\ldots,[\dot{x}_g]) = [\dot{w}](\mu([\dot{x}_1],\ldots,[\dot{x}_g])).$$

Since the leaves of $\mathscr{P}_L$ are diffeomorphic to g-dimensional tori, the distribution $\mathscr{P}_L$ has a canonical density κ invariant under the Hamiltonian vector fields in $\mathscr{P}_L$ and that assigns to each integral manifold of $\mathscr{P}_L$ the volume 1. The square root of κ trivializes the line bundle $|\mathrm{Det}\,\mathscr{P}_L^*|^{1/2}$ and is a covariantly constant section of $(|\mathrm{Det}\,\mathscr{P}_L^*|^{1/2})|_\Lambda$ for each leaf Λ of $\mathscr{P}_L$.

The Hilbert space of quantization for $(\mathscr{M}_\Sigma, k\omega_\Sigma)$ will be defined in terms of sections of the line bundle $\mathscr{L}_\Sigma \otimes |\mathrm{Det}\,\mathscr{P}_L^*|^{1/2}$. The restriction of this line bundle to a leaf Λ of $\mathscr{P}_L$ has a flat connection defined by

$$\nabla_{[\dot{w}]}(\sigma \otimes \mu) = \nabla_{[\dot{w}]}\sigma \otimes \mu + \sigma \otimes \nabla^{\mathscr{P}_L}_{[\dot{w}]}\mu,$$

for any $[\dot{\omega}] \in \mathscr{P}_L|_\Lambda$ and $\sigma \otimes \mu \in \Gamma(\Lambda; \mathscr{L}_\Sigma \otimes |\mathrm{Det}\,\mathscr{P}_L^*|^{1/2})$. The union of those leaves of $\mathscr{P}_L$ for which the holonomy group of this connection is trivial defines the Bohr–Sommerfeld set $\mathscr{BS}_{\mathscr{P}_L}$ of the polarization $\mathscr{P}_L$. For each leaf Λ belonging to $\mathscr{BS}_{\mathscr{P}_L}$ we let S_Λ denote the one-dimensional vector space of covariantly constant sections of $(\mathscr{L}_\Sigma \otimes |\mathrm{Det}\,\mathscr{P}_L^*|^{1/2})|_\Lambda$. Then the Hilbert space associated to the symplectic manifold $(\mathscr{M}_\Sigma, k\omega_\Sigma)$ with real polarization $\mathscr{P}_L$ is defined to be the complex vector space,

$$\mathscr{H}(\Sigma, L) = \bigoplus_{\Lambda \subset \mathscr{BS}_{\mathscr{P}_L}} S_\Lambda,$$

with the inner product

$$\langle \sigma\otimes\mu,\sigma'\otimes\mu'\rangle=\begin{cases}0, & \text{if } \sigma\otimes\mu\in\mathscr{S}_\Lambda,\quad \sigma'\otimes\mu'\in\mathscr{S}_{\Lambda'},\quad \Lambda\neq\Lambda',\\ \displaystyle\int_\Lambda(\sigma,\sigma')\mu*\mu', & \text{if } \sigma\otimes\mu,\quad \sigma'\otimes\mu'\in\mathscr{S}_\Lambda;\end{cases}$$

(σ,σ') is the function on Λ obtained by taking the Hermitian inner product in the fiber of $\mathscr{L}_\Sigma$ and $\mu*\mu'$ the density on Λ, defined by

$$(\mu*\mu')([\dot{x}_1],\ldots,[\dot{x}_g])=\mu([\dot{x}_1],\ldots,[\dot{x}_g])\mu'([\dot{x}_1],\ldots,[\dot{x}_g]),$$

for some vector fields $[\dot{x}_1],\ldots,[\dot{x}_g]$ spanning $T\Lambda$.

Now recall that we identify $\mathscr{M}_\Sigma=2\pi iH^1(\Sigma;\mathbb{R})/2\pi iH^1(\Sigma;\mathbb{Z})$. Let $[\dot{w}_1],\ldots,[\dot{w}_g]$ be a basis for $2\pi i(L\cap H^1(\Sigma;\mathbb{Z}))$. Then, as shown in Ref. 10, Sec. 3, the Bohr–Sommerfeld leaves of $\mathscr{P}_L$ on $\mathscr{M}_\Sigma$ are determined by the requirement that their preimages in the linear symplectic space $2\pi iH^1(\Sigma;\mathbb{R})$ covering $\mathscr{M}_\Sigma$ satisfy the condition

$$e^{2\pi ik\omega_\Sigma([\dot{w}_i],[x])}=1,\quad i=1,\ldots,g. \tag{V.1}$$

For each $\mathbf{q}=(q_1,\ldots q_g)\in(\mathbb{Z}/k\mathbb{Z})^g$ the linear equations,

$$k\omega_\Sigma([\dot{w}_i],[x])=q_i\pmod k,\quad i=1,\ldots,g, \tag{V.2}$$

for $[x]\in 2\pi iH^1(\Sigma;\mathbb{R})$, define a family of parallel Lagrangian planes projecting onto a Bohr–Sommerfeld leaf Λ_q under the quotient map $2\pi iH^1(\Sigma;\mathbb{R})\to\mathscr{M}_\Sigma$. Thus, the dimension of the Hilbert space $\mathscr{H}(\Sigma,L)$ is k^g.

In conclusion, to each closed oriented surface Σ together with a rational Lagrangian subspace $L\subset H^1(\Sigma;\mathbb{R})$ we associate by the previous construction a finite-dimensional Hilbert space $\mathscr{H}(\Sigma,L)$. We recall the following results from Ref. 10.

If L_1, $L_2\subset H^1(\Sigma;\mathbb{R})$ are two rational Lagrangian subspaces, then there is a canonical unitary operator,

$$F_{L_2L_1}:\mathscr{H}(\Sigma,L_1)\to\mathscr{H}(\Sigma,L_2), \tag{V.3}$$

induced by the Blattner–Kostant–Sternberg (BKS) pairing,

$$\langle\langle .,.\rangle\rangle:\mathscr{H}(\Sigma,L_2)\times\mathscr{H}(\Sigma,L_1)\to\mathbb{C}.$$

The BKS pairing between the Hilbert spaces $\mathscr{H}(\Sigma,L_1)=\oplus_{\Lambda_1\subset\mathscr{BS}_{\mathscr{P}_{L_1}}}S_{\Lambda_1}$ and $\mathscr{H}(\Sigma,L_2)=\oplus_{\Lambda_2\subset\mathscr{BS}_{\mathscr{P}_{L_2}}}S_{\Lambda_2}$ is defined by setting

$$\langle\langle s_2\otimes\mu_2,s_1\otimes\mu_1\rangle\rangle=\int_{\Lambda_1\cap\Lambda_2}(s_2,s_1)\mu_2*\mu_1, \tag{V.4}$$

for any Bohr–Sommerfeld leaves $\Lambda_1\subset\mathscr{BS}_{\mathscr{P}_{L_1}}$, $\Lambda_2\subset\mathscr{BS}_{\mathscr{P}_{L_2}}$ and for any sections $s_1\otimes\mu_1\in S_{\Lambda_1}$, $s_2\otimes\mu_2\in S_{\Lambda_2}$. The density $\mu_2*\mu_1$ on $\Lambda_1\cap\Lambda_2$ is defined as follows.[20,10] For any point $[x]\in\Lambda_1\cap\Lambda_2$, choose a symplectic basis $([\dot{\boldsymbol{v}}_2],[\dot{\boldsymbol{w}}];[\dot{\boldsymbol{v}}_1],[\dot{\boldsymbol{t}}])$ for $(\mathscr{M}_\Sigma,k\omega_\Sigma)$, that is a basis satisfying $k\omega_\Sigma([\dot{w}_i],[\dot{t}_j])=\delta_{ij}$, $k\omega_\Sigma([\dot{v}_{2i}],[\dot{v}_{1j}])=\delta_{ij}$ and $k\omega_\Sigma([\dot{v}_{1i}],[\dot{t}_j])=k\omega_\Sigma([\dot{v}_{2i}],[\dot{t}_j])=0$, and with $[\dot{\boldsymbol{w}}]$ a basis for $T_{[x]}(\Lambda_1\cap\Lambda_2)$, $([\dot{\boldsymbol{v}}_1],[\dot{\boldsymbol{w}}])$ a basis for $T_{[x]}\Lambda_1$ and $([\dot{\boldsymbol{v}}_2],[\dot{\boldsymbol{w}}])$ a basis for $T_{[x]}\Lambda_2$. Then $\mu_2*\mu_1$ is the density on $\Lambda_1\cap\Lambda_2$ defined by

$$(\mu_2*\mu_1)([\dot{\boldsymbol{w}}])=\mu_2([\dot{\boldsymbol{v}}_2],[\dot{\boldsymbol{w}}])\mu_1([\dot{\boldsymbol{v}}_1],[\dot{\boldsymbol{w}}]).$$

The operator $F_{L_2L_1}$ is determined by the relation

$$\langle s_2\otimes\mu_2, F_{L_2L_1}(s_1\otimes\mu_1)\rangle = \langle\langle s_2\otimes\mu_2, s_1\otimes\mu_1\rangle\rangle. \tag{V.5}$$

For the unitarity proof of $F_{L_2L_1}$ we refer to Ref. 10, Sec. IV.

For any three rational Lagrangian subspaces L_1, L_2, $L_3\subset H^1(\Sigma;\mathbb{R})$, the unitary operators relating the Hilbert spaces associated to Σ and each of these Lagrangian subspaces compose transitively up to a projective factor expressible in terms of the Maslov–Kashiwara index $\tau(L_1,L_2,L_3)$:

$$F_{L_1L_3}\circ F_{L_3L_2}\circ F_{L_2L_1} = e^{(-\pi i/4)\tau(L_1,L_2,L_3)}Id. \tag{V.6}$$

For the proof of the above relation we refer to Ref. 10, Sec. VI. The definition of the index τ may be found in Refs. 21, 22, and 10.

B. The vector

We consider a compact oriented 3-manifold X with nonempty boundary ∂X. Through the construction of Sec. IV we have a prequantum line bundle $\mathscr{L}_{\partial X}$ on the symplectic space $(\mathscr{M}_{\partial X}, k\omega_{\partial X})$. The Lagrangian map $r_X:\mathscr{M}_X\to\mathscr{M}_{\partial X}$ determined by the restriction of connections on X to ∂X suggests a natural choice for the polarization needed in quantizing $(\mathscr{M}_{\partial X}, k\omega_{\partial X})$. That is, we take the invariant real polarization $\mathscr{P}_X$ on $\mathscr{M}_{\partial X}$ determined by the rational Lagrangian subspace $L_X\subset H^1(\partial X;\mathbb{R})$, where $L_X=\mathrm{Im}\{\dot{r}_X:H^1(X;\mathbb{R})\to H^1(\partial X;\mathbb{R})\}$. To the pair $(\partial X, L_X)$ corresponds the Hilbert space,

$$\mathscr{H}(\partial X, L_X) = \bigoplus_{\Lambda\subset\mathscr{BS}_{\mathscr{P}_X}} \mathscr{S}_\Lambda,$$

defined as the direct sum of the one-dimensional vector spaces S_Λ of parallel sections of the line bundle $\mathscr{L}_{\partial X}\otimes|\mathrm{Det}\,\mathscr{P}_X^*|^{1/2}$, supported on the leaves Λ contained in the Bohr–Sommerfeld set $\mathscr{BS}_{\mathscr{P}_X}$ of the polarization $\mathscr{P}_X$.

Our goal is to give a canonical construction of a vector Z_X in $\mathscr{H}(\partial X, L_X)$ to be associated to the 3-manifold X. First we note the following.

Proposition V.7: The Lagrangian submanifold $\Lambda_X=\mathrm{Im}\{r_X:\mathscr{M}_X\to\mathscr{M}_{\partial X}\}$ of $\mathscr{M}_{\partial X}$ is contained in the Bohr-Sommerfeld set $\mathscr{BS}_{\mathscr{P}_X}$ and is connected.

Proof: For any flat connection Θ on a $\mathbb{T}$ bundle $P\to X$ and any closed 1-form $\dot{\alpha}$ on X for which the cohomology class $[\alpha]/2\pi i$ in $H^1(X;\mathbb{R})$ is an integral, we have

$$\int_{\partial X}\langle s^*\Theta\wedge\dot{\alpha}\rangle = 0 \pmod 1,$$

for any section $s:\partial X\to\partial P$. This follows from (III.16), since $F_\Theta=0$ and since any integral class $[\dot{\alpha}]$ in $2\pi iH^1(X;\mathbb{Z})$ is the cohomology class $[u^*\vartheta]$ of the pullback of the Maurer–Cartan form ϑ of the group $\mathbb{T}$ through some map $u:X\to\mathbb{T}$. According to the definition (II.4) of the symplectic form $\omega_{\partial X}$ on $\mathscr{M}_{\partial X}=2\pi iH^1(\partial X;\mathbb{R})/2\pi iH^1(\partial X;\mathbb{Z})$, we can rewrite the above equation as

$$\omega_{\partial X}(\dot{r}_X[\dot{\alpha}],[s^*\Theta]) = 0 \pmod 1, \tag{V.8}$$

with $[s^*\Theta]\in 2\pi iH^1(\partial X;\mathbb{R})$ the cohomology class of the 1-form $s^*\Theta$ on ∂X and $\dot{r}_X[\dot{\alpha}]$ the image of $[\dot{\alpha}]$ under the restriction map $\dot{r}_X:H^1(X;\mathbb{R})\to H^1(\partial X;\mathbb{R})$.

Let $g=1/2\dim H^1(\partial X;\mathbb{R})$ and choose a basis $[\dot{w}_1],\ldots,[\dot{w}_g]$ for the subspace $2\pi i(L_X\cap H^1(\partial X;\mathbb{Z}))$ of $2\pi iH^1(\partial X;\mathbb{R})$, with $[\dot{w}_i]=\dot{r}_X[\dot{\alpha}_i]$ for some integral classes $[\dot{\alpha}_i]$

$\in 2\pi i H^1(X;\mathbb{Z})$. Given any $[\eta]\in\Lambda_X$, there exists $[\Theta]\in\mathscr{M}_X$ with Θ a flat connection on a $\mathbb{T}$ bundle $P\to X$ such that its restriction to ∂X is $\partial\Theta=\eta$. For any section $s:\partial X\to\partial P$, the element $[s^*\eta]\in 2\pi i H^1(\partial X;\mathbb{R})$ projects to $[\eta]$ under the quotient map $2\pi i H^1(\partial X;\mathbb{R})\to\mathscr{M}_{\partial X}=2\pi i H^1(\partial X;\mathbb{R})/2\pi i H^1(\partial X;\mathbb{Z})$. Then it follows from (V.8) that

$$\omega_{\partial X}([\dot{w}_i],[s^*\eta])=\omega_{\partial X}(\dot{r}_X[\dot{\alpha}_i],[s^*\Theta])=0 \pmod 1, \quad i=1,\ldots,g.$$

Now, since Λ_X is a Lagrangian submanifold of $(\mathscr{M}_{\partial X},\omega_{\partial X})$ and since $T\Lambda_X=\mathscr{P}_X|_{\Lambda_X}$, each connected component of Λ_X is a leaf of $\mathscr{P}_X$. A comparison of the above equation to the Bohr-Sommerfeld condition (V.2) shows that the leaves of the polarization $\mathscr{P}_X$ contained in Λ_X are all Bohr–Sommerfeld leaves. Moreover, it shows that Λ_X contains only one Bohr–Sommerfeld leaf, that is, Λ_X is connected. □

The above proposition suggests that we might try to define the vector Z_X in $\mathscr{H}(\partial X,L_X)$ as a parallel section of the line bundle $\mathscr{L}_{\partial X}\otimes|\mathrm{Det}\mathscr{P}_X^*|^{1/2}$ restricted to the Bohr–Sommerfeld leaf Λ_X. First we note that, since Λ_X is a connected Lagrangian submanifold of $\mathscr{M}_{\partial X}$, each connected component $\mathscr{M}_{X,p}$ of the moduli space $\mathscr{M}_X=\sqcup_{p\in \mathrm{Tors}H^2(X;\mathbb{Z})}\mathscr{M}_{X,p}$ maps *onto* Λ_X under the continuous map $r_X:\mathscr{M}_X\to\mathscr{M}_{\partial X}$. Now recall from Sec. IV that, for each component $\mathscr{M}_{X,p}$, the restriction $\mathscr{L}_p=r_X^*\mathscr{L}_{\partial X}|_{\mathscr{M}_{X,p}}$ of the pullback under r_X of the prequantum line bundle $\mathscr{L}_{\partial X}\to\mathscr{M}_{\partial X}$ has a nowhere-zero parallel section, the Chern–Simons section $\sigma_{X,p}$. Then, since Λ_X is a Bohr–Sommerfeld leaf and since the map $r_X:\mathscr{M}_{X,p}\to\Lambda_X$ is surjective, it follows that the section $\sigma_{X,p}$ is the pullback of a nowhere-zero covariantly constant section of $\mathscr{L}_{\partial X}|_{\Lambda_X}$, which we continue to denote by $\sigma_{X,p}$. We are thus led to define a section σ_X of $\mathscr{L}_{\partial X}|_{\Lambda_X}$ by

$$\sigma_X=\sum_{p\in \mathrm{Tors}H^2(X;\mathbb{Z})}\sigma_{X,p}. \tag{V.9}$$

σ_X is covariantly constant with respect to the connection $\boldsymbol{\nabla}$ in $\mathscr{L}_{\partial X}$.

What we need now is a covariantly constant global section μ_X of the bundle of half-densities $|\mathrm{Det}\mathscr{P}_X^*|^{1/2}$ over Λ_X. We construct such a section using the Reidemeister torsion (R-torsion) invariant T_X of the 3-manifold X. The R-torsion T_X of a compact manifold X is defined as a norm on the determinant line $|\mathrm{Det}H^\cdot(X;\mathbb{R})|$ of the cohomology of X. The definition and properties of the R-torsion may be found in Refs. 23–26.

For a compact oriented 3-manifold X with nonempty boundary the R-torsion T_X belongs to $|\mathrm{Det}H^0(X;\mathbb{R})|\otimes|\mathrm{Det}H^1(X;\mathbb{R})^*|\otimes|\mathrm{Det}H^2(X;\mathbb{R})|\otimes|\mathrm{Det}H^3(X;\mathbb{R})^*|$. By Poincaré duality $H^2(X;\mathbb{R})\cong H^1(X,\partial X,\mathbb{R})^*$. Choosing canonical trivializations $|\mathrm{Det}H^0(X;\mathbb{R})|\cong\mathbb{R}_+$ and $|\mathrm{Det}H^3(X;\mathbb{R})|\cong\mathbb{R}_+$ with respect to orthonormal bases[24,25] for $H^0(X;\mathbb{R})$ and $H^3(X;\mathbb{R})$, we can then regard T_X as a density,

$$T_X\in|\mathrm{Det}H^1(X;\mathbb{R})^*|\otimes|\mathrm{Det}H^1(X,\partial X;\mathbb{R})^*|. \tag{V.10}$$

We recall from Sec. II that $\mathscr{M}_X=H^1(X;\mathbb{T})$ and that we have an exact sequence (II.6) of compact Abelian Lie groups. The corresponding sequence between the tangent spaces at the identity of the groups in (II.6),

$$0\to H^0(X,\partial X;\mathbb{R})\to H^0(X;\mathbb{R})\to H^0(\partial X;\mathbb{R})\to H^1(X,\partial X;\mathbb{R})\to H^1(X;\mathbb{R})\to T_e\Lambda_X\to 0,$$

induces the following isomorphism between the half-densities spaces:

$$|\mathrm{Det}T_e^*\Lambda_X|^{1/2}\cong|\mathrm{Det}H^1(X;\mathbb{R})^*|^{1/2}\otimes|\mathrm{Det}H^1(X,\partial X;\mathbb{R})|^{1/2}, \tag{V.11}$$

where we used again canonical trivializations for the spaces $H^0(*;\mathbb{R})$. Let us pick an arbitrary element $w\in|\mathrm{Det}H^1(X,\partial X;\mathbb{R})^*|$. Since $H^1(X,\partial X;\mathbb{R})$ is identified with the tangent space at the

identity of the group $H^1(X,\partial X;\mathbb{T})$, w extends to an invariant density $\mathbf{w}$ on $H^1(X,\partial X;\mathbb{T})$. If $w^{-1}\in|\mathrm{Det}H^1(X,\partial X;\mathbb{R})|$ stands for the dual of w, we note that $(T_X)^{1/2}\otimes w^{-1}\in|\mathrm{Det}H^1(X;\mathbb{R})^*|^{1/2}\otimes|\mathrm{Det}H^1(X,\partial X;\mathbb{R})|^{1/2}$. Thus we can define an invariant half-density μ_X on the Abelian group Λ_X, whose value at the identity is

$$(\mu_X)_e=\left[\int_{H^1(X,\partial X;\mathbb{T})}\mathbf{w}\right](T_X)^{1/2}\otimes w^{-1}. \tag{V.12}$$

The identification between the lhs and rhs of the above equation is made via the isomorphism (V.11). As $T\Lambda_X=\mathscr{P}_X|_{\Lambda_X}$, the half-density μ_X, being Λ_X-invariant defines a covariantly constant section of the half-densities bundle $(|\mathrm{Det}\mathscr{P}H_X^*|^{1/2})|_{\Lambda_X}$. We introduce the notation

$$\mu_X=\int_{H^1(X,\partial X;\mathbb{T})}(T_X)^{1/2}, \tag{V.13}$$

with the understanding of μ_X as the invariant extension of (V.12).

Using (V.9) and (V.13), we associate then to the compact oriented 3-manifold X with boundary ∂X the vector Z_X in the Hilbert space $\mathscr{H}(\partial X,L_X)$, defined by the expression

$$Z_X=\frac{k^{m_X}}{[\#\mathrm{Tors}H^2(X;\mathbb{Z})]}\,\sigma_X\otimes\mu_X=\frac{k^{m_X}}{[\#\mathrm{Tors}H^2(X;\mathbb{Z})]}\sum_{p\in\mathrm{Tors}H^2(X;\mathbb{Z})}\sigma_{X,p}\otimes\int_{H^1(X,\partial X;\mathbb{T})}(T_X)^{1/2}, \tag{V.14}$$

where

$$m_X=\tfrac{1}{4}\,(\dim H^1(X;\mathbb{R})+\dim H^1(X,\partial X;\mathbb{R})-\dim H^0(X;\mathbb{R})-\dim H^0(X,\partial X;\mathbb{R})). \tag{V.15}$$

If X is a closed oriented 3-manifold then, according to (V.10), the square root of the R-torsion T_X is a density $(T_X)^{1/2}\in|\mathrm{Det}H^1(X;\mathbb{R})^*|$. Since $T\mathscr{M}_X\cong H^1(X;\mathbb{R})$, this defines an invariant density $(T_X)^{1/2}$ on the moduli space $\mathscr{M}_X$. From (a) of Theorem IV.15 it follows that we have a well-defined function σ_X on $\mathscr{M}_X$ whose restriction to each connected component $\mathscr{M}_{X,p}$ of $\mathscr{M}_X$ is given by $\sigma_{X,p}([\Theta])=\mathrm{e}^{\pi ikS_{X,P}(\Theta)}$, for any $\mathbb{T}$ bundle P with $c_1(P)=p$. As a result of (III.6), σ_X is constant on components. Thus, to the closed oriented 3-manifold X we associate the complex number

$$\begin{aligned}Z_X&=\frac{k^{m_X}}{[\#\mathrm{Tors}\;H^2(X;\mathbb{Z})]}\sum_{p\in\mathrm{Tors}\;H^2(X;\mathbb{Z})}\sigma_{X,p}\int_{\mathscr{M}_X}(T_X)^{1/2}\\&=k^{m_X}\sum_{p\in\mathrm{Tors}\;H^2(X;\mathbb{Z})}\int_{\mathscr{M}_{X,p}}\sigma_{X,p}(T_X)^{1/2}=k^{m_X}\int_{\mathscr{M}_X}\sigma_X(T_X)^{1/2},\end{aligned} \tag{V.16}$$

where

$$m_X=\tfrac{1}{2}\,(\dim\,H^1(X;\mathbb{R})-\dim\,H^0(X;\mathbb{R})). \tag{V.17}$$

VI. THE TOPOLOGICAL QUANTUM FIELD THEORY

The results of the previous section show that we are very close to defining a $2+1$-dimensional topological quantum field theory (TQFT) for the Lie group $\mathbb{T}$ and an even integer k. At this stage we are able to canonically associate to a closed oriented 2-manifold Σ together with a rational Lagrangian subspace $L\subset H^1(\Sigma;\mathbb{R})$ a finite-dimensional Hilbert space $\mathscr{H}(\Sigma,L)$ and to a compact oriented 3-manifold X a vector Z_X in the Hilbert space $\mathscr{H}(\partial X,L_X)$ associated to ∂X and the Lagrangian subspace $L_X\subset H^1(\partial X;\mathbb{R})$ determined by X.

A TQFT is supposed to satisfy the axioms listed in Ref. 3 that refer to functoriality, the orientation and disjoint union properties, and the gluing of manifolds along their common boundaries. In order to construct the Chern–Simons TQFT for the group $\mathbb{T}$ we are going to use the notions introduced in Ref. 4 of extended 2- and 3-manifolds, extended morphisms, and gluing of extended 3-manifolds. We give below the relevant definitions. As in Ref. 4 we use the shortened notation with the prefix ''e'' standing for ''extended.''

Definition VI.1: An e-2-manifold is a pair (Σ,L), with a Σ closed oriented two-dimensional manifold and L a rational Lagrangian subspace of $H^1(\Sigma;\mathbb{R})$.

Definition VI.2: (i) *An e-3-manifold* is a triple $(X,\ L,\ n)$, with X a compact oriented 3-manifold, L a rational Langragian subspace of $H^1(\partial X;\mathbb{R})$, and $n\in\mathbb{Z}/8\mathbb{Z}$.

(ii) The boundary of an e-3-manifold is $\partial(X,L,n)=(\partial X,L)$. A closed e-3-manifold is just a pair $(X,\ n)$ with X a closed oriented 3-manifold and $n\in\mathbb{Z}/8\mathbb{Z}$.

Definition VI.3: An extended morphism from e-2-manifold (Σ',L') to an e-2-manifold (Σ,L) is a pair (h,m) with $h:\Sigma'\to\Sigma$, an orientation preserving diffeomorphism, and $m\in\mathbb{Z}/8\mathbb{Z}$. We refer to extended morphisms between e-2-manifolds as *e-2-morphisms*.

Definition VI.4: Composition of e-2-morphism.

If $(h,m):(\Sigma',L')\to(\Sigma,L)$ and $(h',m'):(\Sigma'',L'')\to(\Sigma',L')$ are e-2-morphisms, their composition is defined to be

$$(h,m)(h',m')=(hh',m+m'+\tau(L'',h'^{*}L',(hh')^{*}L)\pmod 8),$$

where τ is the Maslov–Kashiwara index[21,22] of a triple of Lagrangian subspaces of a symplectic vector space. The e-2-morphism (id,0) acts as the identity and the inverse of an e-2-morphism (h,m) is $(h,m)^{-1}=(h^{-1},-m)$.

Definition VI.5: An extended morphism from an e-3-manifold $(X,\ L,\ n)$ to an e-3-manifold (X',L',n') is a pair (Φ,m) with $\Phi:X'\to X$ an orientation preserving diffeomorphism and $m\in\mathbb{Z}/8\mathbb{Z}$, such that

$$n'=n+m+\tau(L_{X'},L',(\partial\Phi)^{*}L)\pmod 8,$$

where $\partial\Phi:\partial X'\to\partial X$ is the induced diffeomorphism between the boundaries. We refer to extended morphisms between e-3-manifolds as *e-3-morphisms*.

To the e-3-morphism $(\Phi,m):(X',L',n')\to(X,L,n)$ there corresponds an induced e-2-morphism between the boundaries $(\partial\Phi,m):(\partial X',L')\to(\partial X,L)$.

Two closed e-3-manifolds (X,n) and (X',n') are isomorphic if there exist an orientation preserving diffeomorphism $\Phi:X'\to X$ and $n'=n$.

Definition VI.6: *Composition of e-3-morphisms.*

If $(\Phi,m):(X',L',n')\to(X,L,n)$ and $(\Phi',m'):(X'',L'',n'')\to(X',L',n')$ are e-3-morphisms, then their composition is the e-3-morphism,

$$(\Phi,m)(\Phi',m')=(\Phi\Phi',m+m'+\tau(L'',(\partial\Phi')^{*}L',(\partial\Phi\partial\Phi')^{*}L)\pmod 8).$$

The equality

$$n''=n+m+m'+\tau(L'',(\partial\Phi')^{*}L',(\partial\Phi\partial\Phi')^{*}L)+\tau(L_{X''},L'',(\partial\Phi\partial\Phi')^{*}L)\pmod 8,$$

follows from the cocycle and the symplectic invariance properties[21,22] of the index τ.

Definition VI.7: (i) If $(\Sigma_1,\ L_1)$ and $(\Sigma_2,\ L_2)$ are e-2-manifolds, their disjoint union is the e-2-manifold,

$$(\Sigma_1,L_1)\sqcup(\Sigma_2,L_2)=(\Sigma_1\sqcup\Sigma_2,L_1\oplus L_2),$$

where we have in view the identification $H^1(\Sigma_1\sqcup\Sigma_2;\mathbb{R})=H^1(\Sigma_1;\mathbb{R})\oplus H^1(\Sigma_2;\mathbb{R})$.

(ii) If (h_1,m_1) and (h_2,m_2) are e-2-morphisms, then

$$(h_1,m_1)\sqcup(h_2,m_2)=(h_1\sqcup h_2,m_1+m_2).$$

(iii) If (X_1,L_1,n_1) and (X_2,L_2,n_2) are e-3-manifolds, their disjoint union is the e-3-manifold,

$$(X_1,L_1,n_1)\sqcup(X_2,L_2,n_2)=(X_1\sqcup X_2,L_1\oplus L_2,n_1+n_2).$$

Definition VI.8: Gluing e-3-manifolds.

Let $(\widetilde{X},\widetilde{L},\widetilde{n})$ be an e-3-manifold such that $\partial(\widetilde{X},\widetilde{L},\widetilde{n})=(\partial\widetilde{X},\widetilde{L})=(Y,L)\sqcup(-\Sigma_1,L_1)\sqcup(\Sigma_2 L_2)$ and assume there exists an e-2-morphism $(h,m):(\Sigma_1,L_1)\to(\Sigma_2,L_2)$. Under these assumptions, the gluing of $(\widetilde{X},\widetilde{L},\widetilde{n})$ by (h,m) is defined to be the e-3-manifold,

$$(\widetilde{X},\widetilde{L},\widetilde{n})_{(h,m)}=(X,L,\widetilde{n}+m+\tau(\widetilde{L},L_{\widetilde{X}},L_X\oplus L_h)\quad(\mathrm{mod}\ 8)),$$

where X is the 3-manifold obtained by gluing $\widetilde{X}$ by the diffeomorphism $h:\Sigma_1\to\Sigma_2$ and where $\widetilde{L}$, $L_{\widetilde{X}}$, and $L_X\oplus L_h$ are the following Lagrangian subspaces of $H^1(\partial\widetilde{X};\mathbb{R})=H^1(Y;\mathbb{R})\oplus H^1(-\Sigma_1;\mathbb{R})\oplus H^1(\Sigma_2;\mathbb{R})$.

- $\widetilde{L}=L\oplus L_1\oplus L_2$ according to the initial assumption on $(\widetilde{X},\widetilde{L},\widetilde{n})$;
- $L_{\widetilde{X}}=\mathrm{Im}\{H^1(\widetilde{X};\mathbb{R})\to H^1(\partial\widetilde{X};\mathbb{R})\}$;
- $L_X\oplus L_h$ is the direct sum of $L_X=\mathrm{Im}\{H^1(X;\mathbb{R})\to H^1(Y;\mathbb{R})\}\subset H^1(Y;\mathbb{R})$ and of the Lagrangian subspace $L_h\subset H^1(-\Sigma_1;\mathbb{R})\oplus H^1(\Sigma_2;\mathbb{R})$ defined as the graph of the symplectic isomorphism $h^*:H^1(\Sigma_2;\mathbb{R})\to H^1(\Sigma_1;\mathbb{R})$, that is, $L_h=\{(h^*[\dot\eta],[\dot\eta])|[\dot\eta]\in H^1(\Sigma_2;\mathbb{R})\}$.

Having introduced the necessary definitions, we are ready now to construct the TQFT. For each e-2-manifold (Σ,L) we have a finite-dimensional Hilbert space $\mathscr{H}(\Sigma,L)$ by the construction of Sec. V. Now let (X,L,n) be an e-3-manifold. Then to the e-2-manifold $(\partial X,L)$ obtained as the boundary of (X,L,n) there corresponds the Hilbert space $\mathscr{H}(\partial X,L)$. On the other hand, the 3-manifold X determines a Lagrangian subspace $L_X\subset H^1(\partial X;\mathbb{R})$ and therefore an e-2-manifold $(\partial X,L_X)$ with corresponding Hilbert space $\mathscr{H}(\partial X,L_X)$. Let

$$F_{LL_X}:\mathscr{H}(\partial X,L_X)\to\mathscr{H}(\partial X,L)\tag{VI.9}$$

be the unitary isomorphism induced by the BKS pairing (V.4). Then we define the vector $Z_{(X,L,n)}$ in $\mathscr{H}(\partial X,L)$ associated to the e-3-manifold (X,L,n) by

$$Z_{(X,L,n)}=\mathrm{e}^{(\pi i/4)n}F_{LL_X}(Z_X),\tag{VI.10}$$

where Z_X is the canonical vector in $\mathscr{H}(\partial X,L_X)$ defined by the expression (V.14).

The following theorem shows that we have a unitary TQFT.

Theorem VI.11: *The assignments,*

$$e\text{-}2\text{-}manifold\ \ (\Sigma,L)\mapsto Hilbert\ \ space\ \ \mathscr{H}(\Sigma,L),$$

$$e\text{-}3\text{-}manifold\ \ (X,L,n)\mapsto vector\ \ Z_{(X,L,n)}\in\mathscr{H}(\partial X,L),$$

satisfy the following.

(a) Functoriality

To each e-2-morphism (h,m): $(\Sigma',L')\to(\Sigma,L)$ *there corresponds a unitary isomorphism,*

$$U(h,m):\mathscr{H}(\Sigma,L)\to\mathscr{H}(\Sigma',L'),$$

and these compose properly.
Let $(\Phi,m):(X',L',n')\to(X,L,n)$ *be an e-3-morphism between isomorphic e-3-manifolds and* $(\partial\Phi,m):(\partial X',L')\to(\partial X,L)$ *the induced e-2-morphism between the boundaries. Then*

$$U(\partial\Phi,m)Z_{(X,L,n)}=Z_{(X',L',n')}.$$

(b) Orientation
There is a natural isomorphism of Hilbert spaces,

$$\mathscr{H}(-\Sigma,L)\cong\overline{\mathscr{H}(\Sigma,L)}$$

and

$$Z_{(-X,L,n)}=\overline{Z_{(X,L,n)}}.$$

(c) Disjoint union
If $(\Sigma,L)=(\Sigma_1,L_1)\sqcup(\Sigma_2,L_2)$ *is a disjoint union of e-2-manifolds, then there is a natural unitary isomorphism,*

$$\mathscr{H}(\Sigma_1\sqcup\Sigma_2,L_1\oplus L_2)\cong\mathscr{H}(\Sigma_1,L_1)\otimes\mathscr{H}(\Sigma_2,L_2).$$

If $(X,L,n)=(X_1,L_1,n_1)\sqcup(X_2L_2,n_2)$ *is a disjoint union of e-3-manifolds, then*

$$Z_{(X_1\sqcup X_2,L_1\oplus L_2,n_1+n_2)}=Z_{(X_1,L_1,n_1)}\otimes Z_{(X_2,L_2,n_2)}.$$

(d) Cylinder axiom
If Σ *is a closed oriented 2-manifold,* $I=[0,1]$ *the unit interval and* $L_\Sigma\subset H^1(\Sigma;\mathbb{R})$ *a rational Lagrangian subspace, then to the e-3-manifold* $(\Sigma\times I,L_\Sigma\oplus L_\Sigma,0)$ *there corresponds*

$$Z_{(\Sigma\times I,L_\Sigma\oplus L_\Sigma,0)}=\mathrm{Id}:\mathscr{H}(\Sigma,L_\Sigma)\to\mathscr{H}(\Sigma,L_\Sigma).$$

(e) Gluing
Let X *be a compact connected oriented 3-manifold with boundary* ∂X *and let* X^{cut} *denote the manifold obtained by cutting* X *along a codimension one closed oriented submanifold* Σ*. Then* $\partial X^{\mathrm{cut}}=\partial X\sqcup(-\Sigma)\sqcup\Sigma$*. Let* $Z_{(X,L,n)}$ *be the vector associated to the e-3-manifold* (X,L,n) *and* $Z_{(X^{\mathrm{cut}},L\oplus L_\Sigma\oplus L_\Sigma,n^{\mathrm{cut}})}$ *the vector for the cut e-3-manifold* $(X^{\mathrm{cut}},L\oplus L_\Sigma\oplus L_\Sigma,n^{\mathrm{cut}})$*, with* $L_\Sigma\subset H^1(\Sigma;\mathbb{R})$ *an arbitrary rational Lagrangian subspace, and*

$$n^{\mathrm{cut}}=n-\tau(L\oplus L_\Sigma\oplus L_\Sigma,L_{X^{\mathrm{cut}}},L_X\oplus L_\Delta)\pmod 8.$$

The Lagrangian subspace $L_\Delta\subset H^1(-\Sigma;\mathbb{R})\oplus H^1(\Sigma;\mathbb{R})$ *is the diagonal. Then to the gluing of e-3-manifolds,*

$$(X^{\mathrm{cut}},L\oplus L_\Sigma\oplus L_\Sigma,n^{\mathrm{cut}})_{(\mathrm{id}_\Sigma,0)}=(X,L,n),$$

there corresponds the quantum gluing property,

$$Z_{(X,L,n)}=\mathrm{Tr}_\Sigma[Z_{(X^{\mathrm{cut}},L\oplus L_\Sigma\oplus L_\Sigma,n^{\mathrm{cut}})}],$$

where the operator Tr_Σ *is the contraction,*

$$\mathrm{Tr}_\Sigma:\mathscr{H}(\partial X^{\mathrm{cut}},L\oplus L_\Sigma\oplus L_\Sigma)\cong\mathscr{H}(\partial X,L)\otimes\overline{\mathscr{H}(\Sigma,L_\Sigma)}\otimes\mathscr{H}(\Sigma,L_\Sigma)\to\mathscr{H}(\partial X,L),$$

using the Hermitian inner product in $\mathscr{H}(\Sigma,L_\Sigma)$.

Proof: (a) *Functoriality.* The orientation preserving the diffeomorphism $h:\Sigma'\to\Sigma$ induces a map in cohomology $h^*:H^1(\Sigma;*)\to H^1(\Sigma';*)$ and therefore a symplectic diffeomorphism $h^*:\mathscr{M}_\Sigma\to\mathscr{M}_{\Sigma'}$ between the moduli spaces of flat $\mathbb{T}$ connections. Since there exist lifts of h to bundle morphisms between trivializable $\mathbb{T}$ bundles over Σ' and trivializable $\mathbb{T}$ bundles over Σ, it follows from (a) of Theorem (IV.4) and from (IV.13) that there is an induced isomorphism $h^*:\mathscr{L}_\Sigma\to\mathscr{L}_{\Sigma'}$ of prequantum line bundles covering $h^*:\mathscr{M}_\Sigma\to\mathscr{M}_{\Sigma'}$. The Lagrangian subspace $L\subset H^1(\Sigma;\mathbb{R})$ is mapped onto the Lagrangian subspace $h^*L\subset H^1(\Sigma';\mathbb{R})$. The map of line bundles $h^*:\mathscr{L}_\Sigma\otimes|\mathrm{Det}\,\mathscr{P}_L^*|^{1/2}\to\mathscr{L}_{\Sigma'}\otimes|\mathrm{Det}\,\mathscr{P}_{h^*L}^*|^{1/2}$ induces a map of sections, which, having in view the constructions of Sec. V, gives rise to a unitary map of Hilbert spaces $h^*:\mathscr{H}(\Sigma,L)\to\mathscr{H}(\Sigma',h^*L)$. The composition of this map with the isomorphism $F_{L',h^*L}:\mathscr{H}(\Sigma',h^*L)\to\mathscr{H}(\Sigma',L')$ arising from the BKS pairing between $\mathscr{H}(\Sigma',L')$ and $\mathscr{H}(\Sigma',h^*L)$ gives the unitary operator $F_{L',h^*L}\circ h^*:\mathscr{H}(\Sigma,L)\to\mathscr{H}(\Sigma',L')$. Thus we associate to the e-2-morphism (h,m) the unitary operator

$$U(h,m)=\mathrm{e}^{(\pi i/4)m}F_{L',h^*L}\circ h^*:\mathscr{H}(\Sigma,L)\to\mathscr{H}(\Sigma',L').$$

We note that if L and K are rational Lagrangian subspaces in $H^1(\Sigma;\mathbb{R})$, then it follows from the definition of the intertwining isomorphisms (V.3) that the following diagram commutes:

$$\begin{array}{ccc}\mathcal{H}(\Sigma,L) & \xrightarrow{F_{K,L}} & \mathcal{H}(\Sigma,K)\\ {\scriptstyle h^*}\downarrow & & \downarrow{\scriptstyle h^*}\\ \mathcal{H}(\Sigma',h^*L) & \xrightarrow{F_{h^*K,h^*L}} & \mathcal{H}(\Sigma',h^*K)\end{array}\qquad\text{(VI.12)}$$

Now let $(h',m'):(\Sigma'',L'')\to(\Sigma',L')$ be another e-2-morphism. Then, using the properties (V.6), (VI.12), and the multiplication law of e-2-morphisms, we obtain

$$U(h',m')U(h,m)=U((h,m)(h',m')).$$

This proves the first statement in (a) of Theorem VI.11.

We prove now the second statement in (a) of Theorem VI.11. The orientation preserving diffeomorphism of compact oriented 3-manifolds $\Phi:X'\to X$ induces an isomorphism $\Phi^*:\mathscr{M}_X\to\mathscr{M}_{X'}$. Its restriction $(\partial\Phi)^*:\mathscr{M}_{\partial X}\to\mathscr{M}_{\partial X'}$ lifts to an isomorphism of prequantum line bundles $(\partial\Phi)^*:\mathscr{L}_{\partial X}\to\mathscr{L}_{\partial X'}$. Moreover, we have $r_{X'}\circ\Phi^*=(\partial\Phi)^*\circ r_X$, where $r_X:\mathscr{M}_X\to\mathscr{M}_{\partial X}$ and $r_{X'}:\mathscr{M}_{X'}\to\mathscr{M}_{\partial X'}$ are the restriction maps to the boundaries. Therefore $(\partial\Phi)^*L_X=L_{X'}$, so there is an induced bundle isomorphism $(\partial\Phi)^*:\mathscr{L}_{\partial X}\otimes|\,\mathrm{Det}\,\mathscr{P}_X^*|^{1/2}\to\mathscr{L}_{\partial X'}\otimes|\,\mathrm{Det}\,\mathscr{P}_{X'}^*|^{1/2}$. From the construction in Sec. V of the canonical vectors Z_X and $Z_{X'}$ as sections of these line bundles, it follows that

$$(\partial\Phi)^*(Z_X)=Z_{X'},$$

under the unitary map of Hilbert spaces $(\partial\Phi)^*:\mathscr{H}(\partial X,L_X)\to\mathscr{H}(\partial X',L_{X'})$. On the other hand, to the e-2-morphism $(\partial\Phi,m):(\partial X',L')\to(\partial X,L)$ there corresponds to the unitary operator,

$$U(\partial\Phi,m)=\mathrm{e}^{(\pi i/4)m}F_{L',(\partial\Phi)^*L}\circ(\partial\Phi)^*:\mathscr{H}(\partial X,L)\to\mathscr{H}(\partial X',L').$$

Then, using the definitions (V.14), (VI.5) and the properties of (VI.12), (V.6), we find

$$\begin{aligned}U(\partial\Phi,m)Z_{(X,L,n)}&=\mathrm{e}^{(\pi i/4)m}F_{L',(\partial\Phi)^*L}\circ(\partial\Phi)^*(\mathrm{e}^{(\pi i/4)n}F_{LL_X}(Z_X))\\&=\mathrm{e}^{(\pi i/4)n'}F_{L'L_{X'}}(Z_{X'})=Z_{(X',L',n')}.\end{aligned}$$

(b) *Orientation*. Follows from (b) of Theorem (IV.4) and (b) of Theorem (IV.15).

(c) *Disjoint union*. To the disjoint union $\Sigma=\Sigma_1\sqcup\Sigma_2$ there corresponds the product of symplectic spaces,

$$(\mathscr{M}_\Sigma,\omega_\Sigma)=(\mathscr{M}_{\Sigma_1},\omega_{\Sigma_1})\times(\mathrm{M}_{\Sigma_2},\omega_{\Sigma_2})=(\mathscr{M}_{\Sigma_1}\times\mathscr{M}_{\Sigma_2},pr_{\Sigma_1}^*\omega_{\Sigma_1}+pr_{\Sigma_2}^*\omega_{\Sigma_2}),$$

where $pr_{\Sigma_i}:\Sigma_1\times\Sigma_2\to\Sigma_i$ are the natural projections. If $L_i\subset H^1(\Sigma_i;\mathbb{R})$ are rational Lagrangian subspaces, then $L_1\oplus L_2\subset H^1(\Sigma_1\sqcup\Sigma_2;\mathbb{R})=H^1(\Sigma_1;\mathbb{R})\oplus H^1(\Sigma_2;\mathbb{R})$ is again a rational Lagrangian subspace. The Bohr–Sommerfeld orbits Λ of the polarization $P_{L_1\oplus L_2}$ on $\mathscr{M}_{\Sigma_1}\times\mathscr{M}_{\Sigma_2}$ are Cartesian products $\Lambda_1\times\Lambda_2$ of Bohr–Sommerfeld orbits Λ_i for the polarizations $\mathscr{P}_{L_i}$ on $\mathscr{M}_{\Sigma_i}$, $i=1,2$. The proof of (c) follows then from (c) of Theorem (IV.4) and (c) of Theorem (IV.15) and the definitions of the Hilbert spaces associated to e-2-manifolds and of the vectors associated to e-3-manifolds.

(d) *Cylinder axiom*. Since $H^i(\Sigma\times I)\cong H^i(\Sigma)$, $i=0,1,2$, we obtain, in particular, that $\mathscr{M}_{\Sigma\times I}\cong\mathscr{M}_\Sigma$. As $\partial(\Sigma\times I)=(-\Sigma)\sqcup\Sigma$ we have $\mathscr{M}_{\partial(\Sigma\times I)}=\mathscr{M}_\Sigma\times\mathscr{M}_\Sigma$, and the restriction map

$$r_{\Sigma\times I}:\mathscr{M}_{\Sigma\times I}\cong\mathscr{M}_\Sigma\to\mathscr{M}_{\partial(\Sigma\times I)}=\mathscr{M}_\Sigma\times\mathscr{M}_\Sigma$$

is the diagonal map $[\eta],\mapsto([\eta],[\eta])$. Hence the Lagrangian subspace $L_{\Sigma\times I}=L_\Delta$, with L_Δ denoting the diagonal in $H^1(-\Sigma;\mathbb{R})\oplus H^1(\Sigma;\mathbb{R})$ and the Lagrangian submanifold $\Lambda_{\Sigma\times I}=\Delta$, with Δ the diagonal in $\mathscr{M}_\Sigma\times\mathscr{M}_\Sigma$. According to the definitions and constructions of Sec. V we find that the Chern–Simons section over Δ of the prequantum line bundle is $\sigma_{\Sigma\times I}=1$ and that the section $\mu_{\Sigma\times I}$ over Δ of the half-density bundle $|\operatorname{Det}\mathscr{P}_\Delta^*|^{1/2}$ is identified under the isomorphism $\Delta\cong\mathscr{M}_\Sigma$ with the square root $(T_\Sigma)^{1/2}$ of the R-torsion of Σ. In Ref. 27 it is proved that the density T_Σ on $\mathscr{M}_\Sigma$ coincides with the density $|(\omega_\Sigma)^g/g!|$ determined by the symplectic form ω_Σ, where $g=\frac{1}{2}\dim H^1(\Sigma;\mathbb{R})$. In view of the definition (V.14), we find therefore that the canonical vector in $\mathscr{H}(-\Sigma\sqcup\Sigma,L_\Delta)$ associated to the 3-manifold $\Sigma\times I$ is

$$Z_{\Sigma\times I}=k^{(1/4)\dim H^1(\Sigma;\mathbb{R})}\sigma_{\Sigma\times I}\otimes\mu_{\Sigma\times I}=k^{(1/4)dim\ H^1(\Sigma;\mathbb{R})}1\otimes(T_\Sigma)^{1/2}. \tag{VI.13}$$

Let us consider now the e-3-manifold $(\Sigma\times I,L_{2\Sigma,n})$, where $L_{2\Sigma}=L_\Sigma\oplus L_\Sigma$ with $L_\Sigma\subset H^1(\Sigma;\mathbb{R})$ an arbitrary rational Lagrangian subspace. To this e-3-manifold there corresponds the vector in $\mathscr{H}(-\Sigma\sqcup\Sigma,L_{2\Sigma})\cong\overline{\mathscr{H}(\Sigma,L_\Sigma)}\otimes\mathscr{H}(\Sigma,L_\Sigma)$ defined by

$$Z_{(\Sigma\times I,L_{2\Sigma},n)}=\mathrm{e}^{(\pi i/4)n}F_{L_{2\Sigma},L_\delta}(Z_{\Sigma\times I}).$$

Let us introduce a unitary basis $\{v(\Sigma,L_\Sigma)_q\}$ for the Hilbert space $\mathscr{H}(\Sigma,L_\Sigma)$. Using the definition of the unitary operator $F_{L_{2\Sigma},L_\Delta}:\mathscr{H}(-\Sigma\sqcup\Sigma,L_\Delta)\to\mathscr{H}(-\Sigma\sqcup\Sigma,L_{2\Sigma})$ in terms of the BKS pairing (V.4), we find that

$$Z_{(\Sigma\times I,L_{2\Sigma},n)}=\mathrm{e}^{(\pi i/4)n}\sum_q\overline{v(\Sigma,L_\Sigma)_{\mathbf{q}}}\otimes v(\Sigma,L_\Sigma)_{\mathbf{q}}. \tag{VI.14}$$

Thus $Z_{(\Sigma\times I,L_{2\Sigma},0)}=\mathrm{Id}\in\mathrm{Hom}[\mathscr{H}(\Sigma,L_\Sigma),\mathscr{H}(\Sigma,L_\Sigma)]$.

(e) *Gluing*. The moduli space of flat $\mathbb{T}$ connections on $\partial X^{\mathrm{cut}}=\partial X\sqcup(-\Sigma)\sqcup\Sigma$ is the symplectic manifold $(\mathscr{M}_{\partial X^{\mathrm{cut}}},\omega_{\partial X^{\mathrm{cut}}})$, with

$$\mathscr{M}_{\partial X^{\mathrm{cut}}}=\mathscr{M}_{\partial X}\times\mathscr{M}_\Sigma\times\mathscr{M}_\Sigma,$$

$$\omega_{\partial X^{\mathrm{cut}}}=pr_{\partial X}^*(\omega_{\partial X})+pr_{-\Sigma}^*(-\omega_\Sigma)+pr_\Sigma^*(\omega_\Sigma),$$

where $pr_{\partial X}$, $pr_{-\Sigma}$, and pr_{Σ} denote the projection maps from $\mathscr{M}_{\partial X}\times\mathscr{M}_{\Sigma}\times\mathscr{M}_{\Sigma}$ onto the first, second, and third factor, respectively. Let $\Delta\subset\mathscr{M}_{\Sigma}\times\mathscr{M}_{\Sigma}$ denote the diagonal. The manifold

$$C=\mathscr{M}_{\partial X}\times\Delta\subset\mathscr{M}_{\partial X^{\mathrm{cut}}},$$

is a coisotropic submanifold of $(\mathscr{M}_{\partial X^{\mathrm{cut}}},\omega_{\partial X^{\mathrm{cut}}})$. Let $TC^{\perp}$ denote the orthogonal complement with respect to $\omega_{\partial X^{\mathrm{cut}}}$ of the tangent bundle TC. The bundle $TC^{\perp}$ is the tangent bundle to an isotropic foliation $C^{\perp}$ of C. The reduced symplectic manifold $C/C^{\perp}$ is identified with $(\mathscr{M}_{\partial X},\omega_{\partial X})$ and the quotient map $C\to C/C^{\perp}$ with the natural projection $pr_{\partial X}:\mathscr{M}_{\partial X}\times\Delta\to\mathscr{M}_{\partial X}$.

With the usual notations let $\Lambda_{X^{\mathrm{cut}}}$ be the image of $\mathscr{M}_{X^{\mathrm{cut}}}$ under the restriction map $r_{X^{\mathrm{cut}}}:\mathscr{M}_{X^{\mathrm{cut}}}\to\mathscr{M}_{\partial X^{\mathrm{cut}}}$. According to (II.5), $\Lambda_{X^{\mathrm{cut}}}$ is a Lagrangian submanifold of $(\mathscr{M}_{\partial X^{\mathrm{cut}}},\omega_{\partial X^{\mathrm{cut}}})$, and we consider its reduction[28] relative to the coisotropic submanifold C. The intersection $\Lambda_{X^{\mathrm{cut}}}\cap C$ is a manifold and the tangent bundles satisfy $T(\Lambda_{X^{\mathrm{cut}}}\cap C)=T\Lambda_{X^{\mathrm{cut}}}\cap TC$. The reduction of $\Lambda_{X^{\mathrm{cut}}}$ relative to C is the image of $\Lambda_{X^{\mathrm{cut}}}\cap C$ under the quotient map $C\to C/C^{\perp}$. It is a Lagrangian submanifold of $C/C^{\perp}$ that coincides with $\Lambda_X\subset\mathscr{M}_{\partial X}$ under the identification of $C/C^{\perp}$ with $\mathscr{M}_{\partial X}$. That is,

$$\Lambda_X=pr_{\partial X}(\Lambda_{X^{\mathrm{cut}}}\cap C).$$

The kernel of the differential of $p_{\partial X}:\Lambda_{X^{\mathrm{cut}}}\cap C\to\Lambda_X$ is the vector bundle $T\Lambda_{X^{\mathrm{cut}}}\cap TC^{\perp}$.

Now let $g:X^{\mathrm{cut}}\to X$ denote the gluing map and $g^*:\mathscr{M}_X\to\mathscr{M}_{X^{\mathrm{cut}}}$ the induced map between the moduli spaces of flat $\mathbb{T}$ connections. If $r_X:\mathscr{M}_X\to\mathscr{M}_{\partial X}$ and $r_{\Sigma}:\mathscr{M}_X\to\mathscr{M}_{\Sigma}$ are the restriction maps from connections on X to connections on ∂X and Σ, respectively, then we get the commutative diagram

$$\begin{array}{ccc}\mathcal{M}_X & \xrightarrow{r_X\times r_{\Sigma}} & \mathcal{M}_{\partial X}\times\mathcal{M}_{\Sigma}\\ {\scriptstyle g^*}\downarrow & & \downarrow{\scriptstyle id\times i_{\Delta}}\\ \mathcal{M}_{X^{cut}} & \xrightarrow{r_{X^{cut}}} & \mathcal{M}_{\partial X^{cut}}=\mathcal{M}_{\partial X}\times\mathcal{M}_{\Sigma}\times\mathcal{M}_{\Sigma}\end{array}\qquad\text{(VI.15)}$$

where $i_{\Delta}:\mathscr{M}_{\Sigma}\to\mathscr{M}_{\Sigma}\times\mathscr{M}_{\Sigma}$ is the diagonal map $i_{\Delta}([\eta])=([\eta],[\eta])\in\Delta$. We note that

$$\Lambda_{X^{\mathrm{cut}}}\cap C=(r_{X^{\mathrm{cut}}}\circ g^*)(\mathscr{M}_X).\qquad\text{(VI.16)}$$

Recall that $\mathscr{M}_{X^{\mathrm{cut}}}=\bigsqcup_{p^{\mathrm{cut}}\in\mathrm{Tors}\,H^2(X^{\mathrm{cut}};\mathbb{Z})}\mathscr{M}_{X^{\mathrm{cut}},p^{\mathrm{cut}}}$ and $\mathscr{M}_X=\bigsqcup_{p\in\mathrm{Tors}\,H^2(X,\mathbb{Z})}\mathscr{M}_{X,p}$. Thus, for each p^{cut} and each connected component $[\Lambda_{X^{\mathrm{cut}}}\cap C]_c$ of $\Lambda_{X^{\mathrm{cut}}}\cap C$, there is a unique p such that

$$r_{X^{\mathrm{cut}}}^{-1}([\Lambda_{X^{\mathrm{cut}}}\cap C]_c)\cap\mathscr{M}_{X^{\mathrm{cut}},p^{\mathrm{cut}}}=g^*(\mathscr{M}_{X,p}).\qquad\text{(VI.17)}$$

Then (VI.17) and (ii) in Proposition (II.2) imply the relation

$$[\#\pi_0(\Lambda_{X^{\mathrm{cut}}}\cap C)]\cdot[\#\mathrm{Tors}\,H^2(X^{\mathrm{cut}};\mathbb{Z})]=[\#\mathrm{Tors}\,H^2(X;\mathbb{Z})].\qquad\text{(VI.18)}$$

Let us introduce the following Lagrangian subspaces of the symplectic vector space $H^1(X^{\mathrm{cut}};\mathbb{R})=H^1(X;\mathbb{R})\oplus H^1(-\Sigma;\mathbb{R})\oplus H^1(\Sigma;\mathbb{R})$:

$$\begin{aligned}L'&=L_X\oplus L_{\Sigma}\oplus L_{\Sigma},\\ L''&=L\oplus L_{\Sigma}\oplus L_{\Sigma}.\end{aligned}\qquad\text{(VI.19)}$$

To the e-3-manifold $(X^{\mathrm{cut}},L'',n^{\mathrm{cut}})$ corresponds the vector

$$Z_{(X^{\rm cut},L'',n^{\rm cut})}=\mathrm{e}^{(\pi i/4)n^{\rm cut}}F_{L''L_{X^{\rm cut}}}(Z_{X^{\rm cut}})\in\mathscr{H}(\partial X^{\rm cut},L''),\tag{VI.20}$$

obtained as the image of the canonical vector,

$$Z_{X^{\rm cut}}=\frac{k^{m_{X^{\rm cut}}}}{[\#\mathrm{Tors}\ H^2(X^{\rm cut};\mathbb{Z})]}\,\sigma_{X^{\rm cut}}\otimes\mu_{X^{\rm cut}}\in\mathscr{H}(\partial X^{\rm cut},L_{X^{\rm cut}}),\tag{VI.21}$$

defined in Sec. V. Using the composition law (V.6), we can rewrite (VI.20) as

$$Z_{(X^{\rm cut},L'',n^{\rm cut})}=\mathrm{e}^{(\pi i/4)[n^{cut}+\tau(L_{X^{cut}},L',L'')]}F_{L''L'}\circ F_{L'L_{X^{\rm cut}}}(Z_{X^{cut}}).\tag{VI.22}$$

Let us choose unitary bases $\{v(\partial X,L_X)_{\mathbf{q}}\}$ for $\mathscr{H}(\partial X,L_X)$, $\{v(\partial X,L)_{q'}\}$ for $\mathscr{H}(\partial X,L)$, and $\{v(\Sigma,L_\Sigma)_{\ell}\}$ for $\mathscr{H}(\Sigma,L_\Sigma)$. Then we have

$$\begin{aligned}F_{L''L'}\circ F_{L'L_{X^{\rm cut}}}(Z_{X^{\rm cut}})&=F_{L''L'}\left[\sum_{\mathbf{q},\ell,\ell'}M_{\mathbf{q}\ell\ell'}v(\partial X,L_X)_{\mathbf{q}}\otimes\overline{v(\Sigma,L_\Sigma)_{\ell}}\otimes v(\Sigma,L_\Sigma)_{\ell'}\right]\\&=\sum_{\mathbf{q},\ell,\ell'}M_{\mathbf{q}\ell\ell'}[F_{LL_X}v(\partial X,L_X)_{\mathbf{q}}]\otimes\overline{v(\Sigma,L_\Sigma)_{\ell}}\otimes v(\Sigma,L_\Sigma)_{\ell'},\end{aligned}\tag{VI.23}$$

where $F_{LL_X}:\mathscr{H}(\partial X,L_X)\to\mathscr{H}(\partial X,L)$ and

$$M_{\mathbf{q}\mathbf{l}\mathbf{l}'}=\langle v(\partial X,L_X)_{\mathbf{q}}\otimes\overline{v(\Sigma,L_\Sigma)_{\mathbf{l}}}\otimes v(\Sigma,L_\Sigma)_{\mathbf{l}'},F_{L'L_{X^{\rm cut}}}(Z_{X^{\rm cut}})\rangle_{\mathscr{H}(\partial X^{\rm cut},L')}.$$

The last equality in (VI.23) follows from the definition (V.5) of the intertwining isomorphism $F_{L''L'}$ through the BKS pairing (V.4), which, in view of the special form (VI.19) of the Lagrangian subspaces L' and L'', leads to the identification $F_{L''L'}=F_{LL_X}\oplus\mathrm{Id}\oplus\mathrm{Id}$. Applying the contraction operator Tr_Σ to $Z_{(X^{\rm cut},L'',n^{\rm cut})}$ and making use of (VI.23), we get

$$\mathrm{Tr}_\Sigma[Z_{(X^{\rm cut},L'',n^{\rm cut})}]=\mathrm{e}^{(\pi i/4)[n^{\rm cut}+\tau(L_{X^{\rm cut}},L',L'')]}\sum_{\mathbf{q},\ell}M_{\mathbf{q}\ell\ell}F_{LL_X}[v(\partial X,L_X)_{\mathbf{q}}].$$

Now let $L_\Delta\subset H^1(-\Sigma;\mathbb{R})\oplus H^1(\Sigma;\mathbb{R})$ be the diagonal. It is a rational Lagrangian subspace for the symplectic form $pr_{-\Sigma}^*(-\omega_\Sigma)+pr_\Sigma^*(\omega_\Sigma)$ on $H^1(-\Sigma;\mathbb{R})\oplus H^1(\Sigma;\mathbb{R})$. We introduce the notation $L_{2\Sigma}=L_\Sigma\oplus L_\Sigma$ and define $L'_\Delta=L_X\oplus L_\Delta$. Recall that to the cylinder $\Sigma\times I$ there corresponds the canonical vector $Z_{\Sigma\times I}$ in $\mathscr{H}((-\Sigma)\sqcup\Sigma,L_\Delta)$ given by (VI.13). Associated to the e-3-manifold $(\Sigma\times I,L_{2\Sigma},0)$ we have, according to (VI.14), the vector

$$Z_{(\Sigma\times I,L_{2\Sigma},0)}=F_{L_{2\Sigma},L_\Delta}(Z_{\Sigma\times I})=\sum_{\ell}\overline{v(\Sigma,L_\Sigma)_{\ell}}\otimes v(\Sigma,L_\Sigma)_{\ell},$$

in $\mathscr{H}((-\Sigma)\sqcup\Sigma,L_{2\Sigma})$. Using this, we can write the following:

$$\begin{aligned}\sum_{\ell}M_{\mathbf{q}\ell\ell}&=\sum_{\ell}\langle v(\partial X,L_X)_{\mathbf{q}}\otimes\overline{v(\Sigma,L_\Sigma)_{\ell}}\otimes v(\Sigma,L_\Sigma)_{\ell},F_{L'L_{X^{\rm cut}}}(Z_{X^{\rm cut}})\rangle_{\mathscr{H}(\partial X^{\rm cut},L')}\\&=\langle v(\partial X,L_X)_{\mathbf{q}}\otimes Z_{(\Sigma\times I,L_{2\Sigma},0)},F_{L'L_{X^{\rm cut}}}(Z_{X^{\rm cut}})\rangle_{\mathscr{H}(\partial X^{\rm cut},L')}\\&=\langle v(\partial X,L_X)_{\mathbf{q}}\otimes F_{L_{2\Sigma},L_\Delta}(Z_{\Sigma\times I}),F_{L',L_{X^{\rm cut}}}(Z_{X^{\rm cut}})\rangle_{\mathscr{H}(\partial X^{\rm cut},L')}.\end{aligned}$$

Now, since $F_{L'L_{X^{\rm cut}}}=e^{(\pi i/4)\tau(L_{X^{\rm cut}},L'_\Delta,L')}F_{L'L'_\Delta}\circ F_{L'_\Delta,L_{X^{\rm cut}}}$, and $F_{L'L'_\Delta}=Id\otimes F_{L_{2\Sigma},L_\Delta}$ we obtain

$$\begin{aligned}\sum_{\mathbf{q}'} M_{\mathbf{q}\mathbf{q}'}&=\mathrm{e}^{(\pi i/4)\tau(L_{X^{\rm cut}},L'_\Delta,L')}\times\langle F_{L'L'_\Delta}[v(\partial X,L_X)_{\mathbf{q}}\otimes Z_{\Sigma\times I}],F_{L'L'_\Delta}\circ F_{L'_\Delta,L_{X^{\rm cut}}}(Z_{X^{\rm cut}})\rangle_{\mathscr{H}(\partial X^{\rm cut},L')}\\&=\mathrm{e}^{(\pi i/4)\tau(L_{X^{\rm cut}},L'_\Delta,L')}\langle v(\partial X,L_X)_{\mathbf{q}}\otimes Z_{\Sigma\times I},F_{L'_\Delta,L_{X^{\rm cut}}}(Z_{X^{\rm cut}})\rangle_{\mathscr{H}(\partial X^{\rm cut}L'_\Delta)}\\&=\frac{k^{m_{X^{\rm cut}}+(1/4)\dim H^1(\Sigma;\mathbb{R})}}{[\#\mathrm{Tors}\ H^2(X^{\rm cut};\mathbb{Z})]}\,\mathrm{e}^{(\pi i/4)\tau(L_{X^{\rm cut}},L'_\Delta,L')}\\&\quad\times\int_{\Lambda_{X^{\rm cut}}\cap((\Lambda_X)_{\mathbf{q}}\times\Delta)}(s(\partial X)_{\mathbf{q}}\otimes\sigma_{\Sigma\times I},\sigma_{X^{\rm cut}})(\delta_X\otimes\mu_{\Sigma\times I})*\mu_{X^{\rm cut}}.\end{aligned}$$

The last equality follows from the BKS pairing formula defining the operator $F_{L'_\Delta,L_{X^{\rm cut}}}$ and the expressions (VI.21) for $Z_{X^{\rm cut}}$ and (VI.13) for $Z_{\Sigma\times I}$. We also wrote $v(\partial X,L_X)_{\mathbf{q}}=s(\partial X)_{\mathbf{q}}\otimes\delta_X$, where δ_X is the invariant half-density on $\mathscr{P}_X$ such that $\int_{(\Lambda_X)_q}\delta_X^2=1$, for any leaf $(\Lambda_X)_{\mathbf{q}}$ of the polarization $\mathscr{P}_X$ on $\mathscr{M}_{\partial X}$. As previously shown, we have the reduction map $\Lambda_{X^{\rm cut}}\cap C\to\Lambda_X$ and, since $\Lambda_X\cap(\Lambda_X)_q\neq\varnothing$ if and only if $(\Lambda_X)_{\mathbf{q}}=\Lambda_X$, we conclude that $\Lambda_{X^{\rm cut}}\cap((\Lambda_X)_{\mathbf{q}}\times\Delta)=\varnothing$, for all leaves $(\Lambda_X)_{\mathbf{q}}\neq\Lambda_X$. Let us write

$$\mu_{X^{\rm cut}}=a_{X^{\rm cut}}\delta_{X^{\rm cut}},$$

with $\delta_{X^{\rm cut}}$ the invariant half-density on $\mathscr{P}_{X^{\rm cut}}$ satisfying $\int_{\Lambda_{X^{\rm cut}}}\delta_{X^{\rm cut}}^2=1$. We recall from (VI.13) that $\mu_{\Sigma\times I}=(T_\Sigma)^{1/2}=|(\omega_\Sigma)^g/g!|^{1/2}$ and that we have $\int_\Delta(\omega_\Sigma)^g/g!=1$, where $g=(1/2)\dim H^1(\Sigma;\mathbb{R})$. Then, making use of the results in Ref. 10, Sec. IV, we find that for each connected component $[\Lambda_{X^{\rm cut}}\cap C]_c$ of the manifold $\Lambda_{X^{\rm cut}}\cap C=\Lambda_{X^{\rm cut}}\cap(\Lambda_X\times\Delta)$ we have

$$\int_{[\Lambda_{X^{\rm cut}}\cap C]_c}(\delta_X\otimes T_\Sigma^{1/2})*\delta_{X^{\rm cut}}=k^{(1/2)[\dim(\Lambda_{X^{\rm cut}}\cap C)-(1/2)\dim H^1(\partial X^{\rm cut};\mathbb{R})]}[\#\pi_0(\Lambda_{X^{\rm cut}}\cap C)]^{-1/2}.$$

Let us introduce the notation $v(\partial X,L_X)=v(\partial X,L_X)_{\mathbf{q}}$ if $(\Lambda_X)_q=\Lambda_X$. We also note that the function $(s(\partial X)\otimes\sigma_{\Sigma\times I},\sigma_{\partial X^{\rm cut}})$ on $\Lambda_{\partial X^{\rm cut}}\cap C$ is constant on each connected component. Summarizing the previous results and using the fact that $\sigma_{X^{\rm cut}}=\Sigma_{p^{\rm cut}\in\mathrm{Tors}\,H^2(X^{\rm cut};\mathbb{Z})}\sigma_{X^{\rm cut},p^{\rm cut}}$, we can write

$$\begin{aligned}\mathrm{Tr}[Z_{(X^{\rm cut},L'',n^{\rm cut})}]&=\mathrm{e}^{(\pi i/4)[n^{\rm cut}+\tau(L_{X^{\rm cut}},L',L'')+\tau(L_{X^{\rm cut}},L'_\Delta,L')]}\\&\quad\times\frac{a_{X^{\rm cut}}}{[\#\mathrm{Tors}\ H^2(X^{\rm cut};\mathbb{Z})]}\,[\#\pi_0(\Lambda_{X^{\rm cut}}\cap C)]^{-1/2}\\&\quad\times k^{m_{X^{\rm cut}}+(1/4)\dim H^1(\Sigma;\mathbb{R})+(1/2)\dim(\Lambda_{X^{\rm cut}}\cap C)-(1/4)\dim H^1(\partial X^{\rm cut};\mathbb{R})}\\&\quad\times\left[\sum_c\sum_{p^{\rm cut}\in\mathrm{Tors}\,H^2(X^{\rm cut};\mathbb{Z})}(s(\partial X)\otimes\sigma_{\Sigma\times I},\sigma_{X^{\rm cut},p^{\rm cut}})_c\right]F_{LL_X}(v(\partial X,L_X)),\end{aligned}\tag{VI.24}$$

where $(s(\partial X)\otimes\sigma_{\Sigma\times I},\sigma_{X^{\rm cut},p^{\rm cut}})_c$ denotes the value of the function on the component $[\Lambda_{X^{\rm cut}}\cap C]_c$. Then let $[\Theta]\in\mathscr{M}_{X,p}$ with $[\eta]=[\Theta|_\Sigma]$ and $[\partial\Theta]=[\Theta|_{\partial X}]$ and let $[\Theta^{\rm cut}]=[g^*\Theta]$. Using the classical gluing formula (IV.16) and the definitions of $\sigma_{\Sigma\times I}$, $\sigma_{X,p}$, and $\sigma_{X^{\rm cut},p^{\rm cut}}$, we find that

$$(\sigma_{X,p}([\partial\Theta])\otimes\sigma_{\Sigma\times I}([\eta]\sqcup[\eta]),\sigma_{X^{\rm cut},p^{\rm cut}}([\partial\Theta]\sqcup[\eta]\sqcup[\eta]))$$

$$=(e^{\pi ikS_{X,P}(\Theta)},\mathrm{Tr}_{\eta}[e^{\pi ikS_{X^{cut},P^{cut}}(\Theta^{cut})}])=1.$$

Since both $\sigma_{X,p}$ and $s(\partial X)$ are unitary covariantly constant sections of $\mathscr{L}_{\partial X}\otimes|\mathrm{Det}\,\mathscr{P}_X^*|^{1/2}$ over Λ_X, they differ by a constant phase factor. In view of this observation of the previous relation and of the relations (VI.17)–(VI.18), the expression (VI.24) becomes

$$\begin{aligned}\mathrm{Tr}_{\Sigma}[Z_{(X^{\mathrm{cut}},L'',n^{\mathrm{cut}})}]=e^{(\pi i/4)[n^{\mathrm{cut}}+\tau(L_{X^{\mathrm{cut}}},L',L'')+\tau(L_{X^{\mathrm{cut}}},L'_{\Delta},L')]}&\\ \times\frac{a_{X^{\mathrm{cut}}}}{[\#\mathrm{Tors}\ H^2(X^{\mathrm{cut}};\mathbb{Z})]^{1/2}[\#\mathrm{Tors}\ H^2(X;\mathbb{Z})]^{1/2}}&\\ \times k^{m_{X^{\mathrm{cut}}}+(1/4)\dim H^1(\Sigma;\mathbb{R})+(1/2)\dim(\Lambda_{X^{\mathrm{cut}}}\cap C)-(1/4)\dim H^1(\partial X^{\mathrm{cut}};\mathbb{R})}&\\ \times\sum_{p\in\mathrm{Tors}\ H^2(X;\mathbb{Z})}F_{LL_X}(\sigma_{X,p}\otimes\delta_X).&\end{aligned}\tag{VI.25}$$

Let a_X denote the real constant such that $\mu_X=a_X\delta_X$. We claim that the following relations hold:

$$a^2_{X^{\mathrm{cut}}}=a^2_X\,\frac{[\#\mathrm{Tors}\ H^2(X^{\mathrm{cut}};\mathbb{Z})]}{[\#\mathrm{Tors}\ H^2(X;\mathbb{Z})]}\tag{VI.26}$$

and

$$m_{X^{\mathrm{cut}}}+\tfrac{1}{4}\dim H^1(\Sigma;\mathbb{R})+\tfrac{1}{2}\dim(\Lambda_{X^{\mathrm{cut}}}\cap C)-\tfrac{1}{4}\dim H^1(\partial X^{\mathrm{cut}};\mathbb{R})=m_X.\tag{VI.27}$$

We postpone for a moment their proof and note first that by using the definition of n^{cut}, the cocycle relation[22] for the Maslov–Kashiwara index τ and the symplectic additivity property of τ, we have

$$\begin{aligned}&n^{\mathrm{cut}}+\tau(L_{X^{\mathrm{cut}}},L',L'')+\tau(L_{X^{\mathrm{cut}}},L'_{\Delta},L')\pmod 8\\ &=n+\tau(L',L'',L'_{\Delta})\pmod 8\\ &=n+\tau(L_X,L,L_X)+\tau(L_{\Sigma}\oplus L_{\Sigma},L_{\Sigma}\oplus L_{\Sigma},L_{\Delta})\pmod 8\\ &=n\pmod 8.\end{aligned}\tag{VI.28}$$

Putting the results (VI.25)–(VI.28) together, we obtain

$$\mathrm{Tr}_{\Sigma}[Z_{(X^{\mathrm{cut}},L'',n^{\mathrm{cut}})}]=e^{(\pi i/4)n}\,\frac{k^{m_X}}{[\#\mathrm{Tors}\ H^2(X;\mathbb{Z})]}\,F_{LL_X}(\sigma_X\otimes\mu_X)=e^{(\pi i/4)n}F_{LL_X}(Z_X)=Z_{(X,L,n)},$$

which proves the gluing property (e) of theorem (VI.11).

Let us return now to the proof of the equality (VI.27). We have the following relations.

(1) The Mayer–Vietoris cohomology sequence for the spaces $X,X^{\mathrm{cut}},\Sigma$,

$$\cdots\to H^i(X;\mathbb{R})\to H^i(X^{\mathrm{cut}};\mathbb{R})\to H^i(\Sigma;\mathbb{R})\to H^{i+1}(X;\mathbb{R})\to\cdots,\tag{VI.29}$$

together with Poincaré duality, imply the relation

$$\begin{aligned}&\dim H^1(X^{\mathrm{cut}};\mathbb{R})-\dim H^1(X^{\mathrm{cut}},\partial X^{\mathrm{cut}};\mathbb{R})-\dim H^0(X^{\mathrm{cut}};\mathbb{R})+\dim H^0(X^{\mathrm{cut}},\partial X^{\mathrm{cut}};\mathbb{R})\\ &=\dim H^1(X;\mathbb{R})-\dim H^1(X,\partial X;\mathbb{R})-\dim H^0(X;\mathbb{R})+\dim H^0(X,\partial X;\mathbb{R})+\dim H^1(\Sigma;\mathbb{R})\\ &\quad-2\dim H^0(\Sigma;\mathbb{R}).\end{aligned}\tag{VI.30}$$

(ii) The exact cohomology sequence for the pair of spaces $(\partial X \sqcup \Sigma) \subset X$ and (VI.15)–(VI.16) give

$$0 \to H^0(X;\mathbb{R}) \to H^0(\partial X \sqcup \Sigma;\mathbb{R}) \to H^1(X,\partial X \sqcup \Sigma;\mathbb{R}) \to H^1(X;\mathbb{R}) \xrightarrow{i_X^* \times (i_\Sigma^*, i_\Sigma^*)} T(\Lambda_{X^{\mathrm{cut}}} \cap C) \to 0.$$

Together with the isomorphism $H^1(X,\partial X \sqcup \Sigma;\mathbb{R}) \cong H^1(X^{\mathrm{cut}},\partial X^{\mathrm{cut}};\mathbb{R})$, it implies that

$$\begin{aligned}\dim(\Lambda_{X^{\mathrm{cut}}} \cap C) = {} & \dim H^1(X;\mathbb{R}) - \dim H^1(X^{\mathrm{cut}},\partial X^{\mathrm{cut}};\mathbb{R}) + \dim H^0(\partial X;\mathbb{R}) + \dim H^0(\Sigma;\mathbb{R}) \\ & - \dim H^0(X;\mathbb{R}). \end{aligned} \tag{VI.31}$$

(iii) From the exact sequence (II.6) and the fact that $\dim \Lambda_X = \frac{1}{2}\dim H^1(\partial X;\mathbb{R})$, we obtain

$$\begin{aligned}\tfrac{1}{2} \dim H^1(\partial X;\mathbb{R}) = {} & \dim H^1(X;\mathbb{R}) - \dim H^1(X,\partial X;\mathbb{R}) + \dim H^0(\partial X;\mathbb{R}) \\ & - \dim H^0(X;\mathbb{R}) + \dim H^0(X,\partial X;\mathbb{R}). \end{aligned} \tag{VI.32}$$

The claimed formula (VI.27) follows then from the relations (VI.30), (VI.31), (VI.32), and the definition (V.15).

Finally, let us prove the relation (VI.26). Referring back to the definition (V.12), we have

$$\begin{aligned}\mu_X &= \left[\int_{H^1(X,\partial X;\mathbb{T})} \mathbf{w} \right] (T_X)^{1/2} \otimes w^{-1}, \\ \mu_{X^{\mathrm{cut}}} &= \left[\int_{H^1(X^{\mathrm{cut}},\partial X^{\mathrm{cut}};\mathbb{T})} \mathbf{w}_{\mathrm{cut}} \right] (T_{X^{\mathrm{cut}}})^{1/2} \otimes w_{\mathrm{cut}}^{-1}, \end{aligned} \tag{VI.33}$$

with $w \in |\mathrm{Det}\, H^1(X,\partial X;\mathbb{R})^*|$ and $w_{\mathrm{cut}} \in |\mathrm{Det}\, H^1(X^{\mathrm{cut}},\partial X^{\mathrm{cut}};\mathbb{R})^*|$. On the other hand, we introduced a_X and $a_{X^{\mathrm{cut}}}$, such that

$$\begin{aligned}\mu_X &= a_X \delta_X, \\ \mu_{X^{\mathrm{cut}}} &= \alpha_{X^{\mathrm{cut}}} \delta_{X^{\mathrm{cut}}}. \end{aligned} \tag{VI.34}$$

The R-torsion T_X of X is related to the R-torsions $T_{X^{\mathrm{cut}}}$ of X^{cut} and T_Σ by Σ by the gluing formula[26]

$$T_X = T_{X^{\mathrm{cut}}} \otimes (T_\Sigma)^{-1}, \tag{VI.35}$$

where the identification between the lhs and the rhs is made through the isomorphism of determinant lines,

$$|\mathrm{Det}\, H^\bullet(X;\mathbb{R})^*| \cong |\mathrm{Det}\, H^\bullet(X^{\mathrm{cut}};\mathbb{R})^*| \otimes |\mathrm{Det}\, H^\bullet(\Sigma;\mathbb{R})|,$$

arising from the Mayer–Vietoris sequence (VI.29). Using the exact sequence (II.6) and, due to the normalization of the density δ_X^2 on Λ_X, we see that

$$\frac{w \otimes \delta_X^2}{[\int_{H^1(X,\partial X;\mathbb{T})} \mathbf{w}]} \in |\mathrm{Det}\, H^1(X;\mathbb{R})^*|,$$

defines an invariant density on the group $H^1(X;\mathbb{T})$ that gives $H^1(X;\mathbb{T})$ volume 1. Similarly on $H^1(X^{\mathrm{cut}};\mathbb{T})$, we have the density defined by

$$\frac{w_{\mathrm{cut}}\otimes \delta^2_{X^{\mathrm{cut}}}}{[\int_{H^1(X^{\mathrm{cut}},\partial X^{\mathrm{cut}};\mathbb{T})}\mathbf{w}_{cut}]}\in |\mathrm{Det}\ H^1(X^{\mathrm{cut}};\mathbb{R})^*|.$$

The Mayer–Vietoris sequence (VI.29) and Poincaré duality induce the isomorphism of determinant lines,

$$|\mathrm{Det}\ H^1(X;\mathbb{R})^*|\cong |\mathrm{Det}\ H^1(X^{\mathrm{cut}};\mathbb{R})^*|\otimes |\mathrm{Det}\ H^1(X^{\mathrm{cut}},\partial X^{\mathrm{cut}};\mathbb{R})^*|\otimes |\mathrm{Det}\ H^1(\Sigma;\mathbb{R})|$$
$$\otimes |\mathrm{Det}\ H^1(X,\partial X;\mathbb{R})|.$$

Thus, we can define an invariant density ρ_X on the group $H^1(X;\mathbb{T})$ by setting

$$\rho_X=\frac{w_{\mathrm{cut}}\otimes \delta^2_{X^{\mathrm{cut}}}}{[\int_{H^1(X^{\mathrm{cut}},\partial X^{\mathrm{cut}};\mathbb{T})}\mathbf{w}_{\mathrm{cut}}]}\otimes\frac{w_{\mathrm{cut}}}{[\int_{H^1(X^{\mathrm{cut}},\partial X^{\mathrm{cut}};\mathbb{T})}\mathbf{w}_{\mathrm{cut}}]}\otimes T_\Sigma^{-1}\otimes\frac{w^{-1}}{[\int_{H^1(X,\partial X;\mathbb{T})}\mathbf{w}]^{-1}}.$$

From the normalization of the densities on the rhs and from the Mayer–Vietoris cohomology sequence with $\mathbb{T}$ coefficients for $X,X^{\mathrm{cut}},\Sigma$,

$$\cdots\to H^1(X;\mathbb{T})\to H^1(X^{\mathrm{cut}};\mathbb{T})\to H^1(\Sigma;\mathbb{T})\to H^2(X;\mathbb{T})\to H^2(X^{\mathrm{cut}};\mathbb{T})\to H^2(\Sigma;\mathbb{T})\to 0,$$

we see that, since $\pi_0[H^2(X;\mathbb{T})]\cong\pi_0[H^2(X^{\mathrm{cut}};\mathbb{T})]=0$, and since, as shown in the proof of Proposition (II.5), $\pi_0[H^1(X,\partial X;\mathbb{T})]\cong\mathrm{Tors}\ H^2(X;\mathbb{Z})$ and $\pi_0[H^1(X^{\mathrm{cut}},\partial X^{\mathrm{cut}};\mathbb{T})]\cong\mathrm{Tors}\ H^2(X^{\mathrm{cut}};\mathbb{Z})$, the density ρ_X gives to $H^1(X;\mathbb{T})$ volume equal to $[\#\mathrm{Tors}\ H^2(X;\mathbb{Z})]/[\#\mathrm{Tors}\ H^2(X^{\mathrm{cut}};\mathbb{Z})]$. Making use of the gluing formula (VI.35) and the relations (VI.33), (VI.34), we can write

$$\frac{w\otimes\delta^2_X}{[\int_{H^1(X,\partial X;\mathbb{T})}\mathbf{w}]}=\frac{1}{a_X^2}\,T_X\otimes\frac{w^{-1}}{[\int_{H^1(X,\partial X;\mathbb{T})}\mathbf{w}]^{-1}}=\frac{1}{a_X^2}\,T_{X^{\mathrm{cut}}}\otimes(T_\Sigma)^{-1}\otimes\frac{w^{-1}}{[\int_{H^1(X,\partial X;\mathbb{T})}\mathbf{w}]^{-1}}=\frac{a^2_{X^{\mathrm{cut}}}}{a_X^2}\,\rho_X.$$

In view of the previous observation regarding the volume of $H^1(X;\mathbb{T})$ computed with ρ_X and the fact that the density of the above equation gives $H^1(X;\mathbb{T})$ volume 1, the claimed relation (VI.26) follows. □

The mapping class group Γ_Σ of a closed oriented 2-manifold Σ is the group $\mathrm{Diff}_+(\Sigma)/\mathrm{Diff}_0(\Sigma)$ of isotopy classes of orientation preserving diffeomorphisms of Σ. The *mapping class group* $\Gamma_{(\Sigma,L)}$ of an e-2-manifold (Σ,L) is a central extension by $\mathbb{Z}/8\mathbb{Z}$ of Γ_Σ:

$$1\to\mathbb{Z}/8\mathbb{Z}\to\Gamma_{(\Sigma,L)}\to\Gamma_\Sigma\to 1.$$

As a set $\Gamma_{(\Sigma,L)}=\Gamma_\Sigma\times\mathbb{Z}/8\mathbb{Z}$ and the composition law in $\Gamma_{(\Sigma,L)}$ is, according to (VI.4), given by

$$([h],m)([h'],m')=([hh'],m+m'+\tau(L'',h'^*L',(hh')^*L)\pmod 8).$$

In the course of proving (a) of Theorem VI.11, we showed that, given a rational Lagrangian subspace $L\subset H^1(\Sigma;\mathbb{R})$, each element $[h]$ of the mapping class group Γ_Σ determines a unitary map of Hilbert spaces $h^*:\mathscr{H}(\Sigma,L)\to\mathscr{H}(\Sigma,h^*L)$. The composition of this map with the isomorphism $F_{L,h^*L}:\mathscr{H}(\Sigma,h^*L)\to\mathscr{H}(\Sigma,L)$ induced by the BKS pairing is a unitary operator $U_L([h])=F_{L,h^*L}\circ h^*$ on the Hilbert space $\mathscr{H}(\Sigma,L)$. The assignment,

$$[h]\mapsto U_L([h]),$$

defines a unitary projective representation of Γ_Σ on $\mathscr{H}(\Sigma,L)$. For the group $\Gamma_{(\Sigma,L)}$ the assignment,

$$([h],m)\mapsto U_L([h],m)=\mathrm{e}^{(\pi i/4)m}U_L([h]),$$

determines a unitary representation of this group on the Hilbert space $\mathscr{H}(\Sigma,L)$.

Since the mapping class group Γ_Σ acts on $H^1(\Sigma;\mathbb{Z})$, there is a natural homomorphism from Γ_Σ to the group $Sp(\mathscr{Z})$ of symplectic transformations of $(H^1(\Sigma;\mathbb{R}),\omega_\Sigma)$ that preserve the integer lattice $\mathscr{Z}=H^1(\Sigma;\mathbb{Z})$. According to the results in (Ref. 10, Sec. 9.1), for each rational Lagrangian subspace $L\subset H^1(\Sigma;\mathbb{R})$, there is a projective unitary representation of $Sp(\mathscr{Z})$ on the Hilbert space $\mathscr{H}(\Sigma,L)$. Let us choose an integer symplectic basis $([\dot{\mathbf{w}}];[\dot{\mathbf{w}}'])$ for $H^1(\Sigma;\mathbb{R})$, with $[\dot{w}_1],\ldots,[\dot{w}_g]$ spanning L, where $g=\frac{1}{2}\dim H^1(\Sigma;\mathbb{R})$. As shown in (Ref. 10, Sec. III), the choice of such a basis uniquely determines a unitary basis $\{v(\Sigma,L)_{\mathbf{q}}\}_{\mathbf{q}\in(\mathbb{Z}/k\mathbb{Z})^g}$ for $\mathscr{H}(\Sigma,L)$. The generators of $Sp(\mathscr{Z})$ are the elements with matrix form

$$\alpha=\begin{pmatrix} A & 0 \\ 0 & {}^tA^{-1}\end{pmatrix},\quad \beta=\begin{pmatrix} I & B \\ 0 & I\end{pmatrix},\quad \gamma=\begin{pmatrix} 0 & I \\ -I & 0\end{pmatrix},$$

with respect to the basis $([\dot{\mathbf{w}}];[\dot{\mathbf{w}}'])$, where $A\in GL(g,\mathbb{Z})$ and $B\in M(g,\mathbb{Z})$, ${}^tB=B$. The projective unitary representation of $Sp(\mathscr{Z})$ on $\mathscr{H}(\Sigma,L)$ is described by the following operators representing the generators:

$$U_L(\alpha)v(\Sigma,L)_{\mathbf{q}}=v(\Sigma,L)_{{}^tA^{-1}\mathbf{q}},$$

$$U_L(\beta)v(\Sigma,L)_{\mathbf{q}}=e^{(\pi i/k)^t\mathbf{q}B\mathbf{q}}v(\Sigma,L)_{\mathbf{q}},\tag{VI.36}$$

$$U_L(\gamma)v(\Sigma,L)_{\mathbf{q}}=k^{-q/2}\sum_{\mathbf{q}_1\in(\mathbb{Z}/k\mathbb{Z})^g} e^{(2\pi i/k)^t\mathbf{q}\mathbf{q}_1}v(\Sigma,L)_{\mathbf{q}_1}.$$

For $g=1$ we have the torus mapping class group $SL(2,\mathbb{Z})$ with standard generators the matrices,

$$S=\begin{pmatrix} 0 & 1 \\ -1 & 0\end{pmatrix}\quad\text{and}\quad T=\begin{pmatrix} 1 & 1 \\ 0 & 1\end{pmatrix},$$

subject to the relations $(ST)^3=I$, $S^4=I$. The projective unitary representation of $\mathrm{SL}(2,\mathbb{Z})$ on the Hilbert space $\mathscr{H}(T^2,L)$ associated to the torus T^2 and $L\subset H^1(T^2;\mathbb{R})$ is described by the operators:

$$U_L(T)_{qq'}=e^{(\pi i/k)q^2}\delta_{qq'},$$

$$U_L(S)_{qq'}=k^{-1/2}e^{(2\pi i/k)qq'}.$$

It coincides with the representation of the modular group $\mathbb{P}SL(2,\mathbb{Z})$ in two-dimensional rational conformal field theory.[29] The projective representation (VI.36) of $Sp(\mathscr{Z})$ on $\mathscr{H}(\Sigma,L)$ is the same projective representation as the one constructed in Refs. 9 and 30 on the vector space of theta functions at level k obtained through the quantization of the moduli space of flat $\mathbb{T}$ connections on Σ in a holomorphic polarization.

ACKNOWLEDGMENT

I would like to thank Professor Dan Freed for introducing me to the Chern–Simons theory, as well as for the helpful suggestions and advice during the development of this project.

Abelian Chern–Simons theory. II. A functional integral approach

Mihaela Manoliu[a)]
Department of Mathematics, University of Texas, Austin, Texas, 78712

(Received 24 March 1997; accepted for publication 29 August 1997)

Following Witten, [Commun. Math. Phys. **21**, 351–399 (1989)] we approach the Abelian quantum Chern–Simons (CS) gauge theory from a Feynman functional integral point of view. We show that for 3-manifolds with and without a boundary the formal functional integral definitions lead to mathematically proper expressions that agree with the results from the rigorous construction [J. Math. Phys. **39**, 170–206 (1998)] of the Abelian CS topological quantum field theory via geometric quantization. © *1998 American Institute of Physics.* [S0022-2488(98)01401-7]

I. INTRODUCTION

A rigorous construction of the CS theory for the Abelian group $\mathbb{T}$ as a topological quantum field theory satisfying Atiyah's axioms[1] is presented in Ref. 2 ($\mathbb{T}$ denotes the group of complex numbers of unit modulus). It is shown that to a closed oriented two-dimensional manifold Σ together with a rational Lagrangian subspace $L\subset H^1(\Sigma;\mathbb{R})$ one can canonically associate a quantum Hilbert space $\mathscr{H}(\Sigma,L)$ via the geometric quantization of the moduli space $\mathscr{M}_\Sigma$ of flat $\mathbb{T}$ connections on Σ. A compact oriented three-dimensional manifold X determines naturally a Lagrangian subspace $L_X\subset H^1(\partial X;\mathbb{R})$. The constructions in Ref. 2 assign canonically to X a vector Z_X in the Hilbert space $\mathscr{H}(\partial X,L_X)$ associated to the boundary ∂X and the Lagrangian subspace L_X. If the 3-manifold X is closed, then Z_X is a complex number representing a topological invariant of X.

In this paper we follow Witten's[3] approach and introduce the quantity Z_X to be associated to a 3-manifold as a Feynman functional integral (path integral). As in Ref. 3, we formally define Z_X for closed 3-manifolds as an integral over gauge equivalence classes of $\mathbb{T}$ connections on X with action the Chern–Simons functional. For the definition of the functional integral and its subsequent evaluation we rely almost entirely on the results in Refs. 4, 5. The derivation is similar to the one presented in Ref. 6 in the context of the non-Abelian version of the CS theory, which evaluates Z_X in the so-called semiclassical or stationary phase approximation limit. In the Abelian CS theory the functional integral is of a Gaussian type and the stationary phase evaluation of Z_X is the exact result. It is expressed in terms of the CS invariant of flat connections on principal $\mathbb{T}$ bundles over X with first Chern class torsion and the Ray–Singer analytic torsion invariant of X. We extend the definition of Z_X as a functional integral to the case of a 3-manifold X with nonempty boundary ∂X. In this instance the path integral is defined over a space of connections that are fixed over the boundary. Hence it is a function of the boundary connections and, in view of the results in Ref. 2, Sec. V, it can be interpreted as an element of the quantum Hilbert space $\mathscr{H}(\partial X,L_X)$.

In Sec. II we briefly review some results on integration of invariant functions and the stationary phase approximation formula for oscillatory integrals. In Sec. III and Sec. IV we discuss the definition of Z_X for compact 3-manifolds X without boundary and with boundary, respectively. We use the same notations as in Ref. 2 and we refer the reader to this reference for some definitions that we do not restate in order to avoid redundancy.

II. A FINITE-DIMENSIONAL MODEL

We begin with a brief description of a finite-dimensional model that will serve as a prototype for the problem in infinite dimensions of defining Z_X as a functional integral. The main references used are Refs. 4 and 5.

Let G be a compact Lie group acting as a group of isometries of the Riemannian manifold (E,g_E). We assume that the Lie algebra Lie G of G is endowed with an invariant inner product that defines an invariant Riemannian metric on G. Then Vol G denotes the volume of G with respect to this metric. The action of G on E generates a homomorphism of Lie G into the Lie algebra of vector fields on E, which defines for each point $x\in E$ a linear map τ_x:Lie $G\to T_xE$. Let H_x denote the isotropy subgroup of G at the point $x\in E$ and Vol H_x the volume of H_x with respect to the metric induced by the invariant metric in G. We assume that the isotropy subgroups at all points $x\in E$ are conjugate to a fixed subgroup $H\subset G$. Then Vol $H_x=$Vol H, for all $x\in E$. The G-invariant Riemannian metric g_E on E induces a Riemannian metric $g_{E/G}$ on the space E/G of orbits of G in E. It is defined by setting for any $v,w\in T_{[x]}(E/G)$: $g_{E/G}(v,w)=g_E(\hat{v},\hat{w})$, where $\hat{v},\hat{w}\in T_xE$ project onto v,w and belong to the orthogonal complement of τ_x(Lie G) in T_xE. We let μ_E and $\mu_{E/G}$ be the measures on E and E/G determined by these metrics. For any G-invariant function h on E, we have[4]

$$\int_E h(x)\mu_E=\frac{\text{Vol } G}{\text{Vol } H}\int_{E/G} h(x)[\det'(\tau_x^*\tau_x)]^{1/2}\mu_{E/G}. \tag{II.1}$$

The notation det′ refers to the regularized determinant of the operator, that is, the product of all the nonzero eigenvalues. The G-invariant term (Vol G/Vol H)$[\det'(\tau_x^*\tau_x)]^{1/2}$ is the volume of the orbit through the point x.

Let us consider now a G-invariant real-valued function f on E such that the stationary points of f form a G-invariant submanifold F of E and $f(x)=\bar{f}$ for all $x\in F$. The Hessian (Hess f)$_x$ of f at the point $x\in E$ is a linear self-adjoint operator (Hess f)$_x$:$T_xE\to T_xE$ and, since f is G invariant, τ_x(Lie G)$\subset$Ker(Hess f)$_x$. We assume that $T_xF=$Ker(Hess f)$_x$ at every point $x\in F$. We also assume that the space $M=F/G$ of orbits of G in F is a manifold and we let μ_M denote the measure on M determined by the natural metric on M induced from the Riemannian metric of F. The method of the stationary phase Refs. 4 and 7 together with (II.1) give, for the asymptotic evaluation of the oscillatory integral,

$$\frac{1}{\text{Vol } G}\int_E e^{\pi i a f(x)}\mu_E \quad (a\in\mathbb{R}_+), \tag{II.2}$$

in the limit of large a, the following expression:[4,5]

$$\frac{1}{a^{(\dim E-\dim F)/2}}\frac{e^{\pi i a\bar{f}}}{\text{Vol } H}\int_M e^{(\pi i/4)\text{sgn}(\text{Hess } f)_x}\frac{|\det'(\tau_x^*\tau_x)|^{1/2}}{|\det'(\text{Hess } f)_x|^{1/2}}\mu_M. \tag{II.3}$$

sgn(Hess f)$_x$ denotes the signature of the quadratic form associated to (Hess f)$_x$. In the terminology of Refs. 4, 5 the integral (II.2) is the *partition function* of the function(al) f.

III. THE PARTITION FUNCTION FOR CLOSED MANIFOLDS

We turn now to the problem of defining Z_X as a functional integral when X is a *closed* connected oriented 3-manifold. For each torsion class $p\in\text{Tors } H^2(X;\mathbb{Z})$, we choose a principal $\mathbb{T}$ bundle π:$P\to X$ with the first Chern class $c_1(P)=p$. The space $\mathscr{A}_P$ of connections on P is an affine space with vector space $2\pi i\Omega^1(X;\mathbb{R})$. The group of gauge transformations $\mathscr{G}_P\cong\text{Map}(X,\mathbb{T})$ acts on $\mathscr{A}_P$ by

$$\Theta \cdot u = \Theta + (u \cdot \pi)^* \vartheta, \tag{III.1}$$

where ϑ is the Maurer–Cartan form of $\mathbb{T}$. The Chern–Simons functional (see Ref. 2, Def. III.1),

$$S_{X,P} : \mathscr{A}_P \to \mathbb{R}/\mathbb{Z}$$

is invariant under this action. We define Z_X by the expression

$$Z_X = \sum_{p \in \text{Tors } H^2(X;\mathbb{Z})} Z_{X,p}, \tag{III.2}$$

where $Z_{X,p}$ is the partition function of the Chern–Simons functional, that is,

$$Z_{X,p} = \int_{\mathscr{A}_P/\mathscr{G}_P} [\mathscr{D}\Theta] e^{\pi i k S_{X,P}(\Theta)}. \tag{III.3}$$

The rhs of the above equation is just a formal expression meant to suggest that, pending the existence of a ''measure'' $[\mathscr{D}\Theta]$, we integrate over the space of gauge equivalence classes of connections on P. We are going to show in the following that this functional integral can be given a precise meaning.

Let us choose a Riemannian metric on X. For each $q = 0,1,...,\dim X$, the metric determines an inner product on the space $\Omega^q(X;\mathbb{R})$ of q forms on X:

$$(\alpha, \beta) = \int_X \alpha \wedge * \beta. \tag{III.4}$$

In particular, it defines an inner product on the tangent space $T\mathscr{A}_P \cong 2\pi i \Omega^1(X;\mathbb{R})$. This makes $\mathscr{A}_P$ a Riemannian manifold and the group $\mathscr{G}_P$ acts on $\mathscr{A}_P$ by isometries. We let $\hat{\mu}$ denote the measure on $\mathscr{A}_P$ determined by this metric and μ the induced measure on the quotient space $\mathscr{A}_P/\mathscr{G}_P$. For each $\Theta \in \mathscr{A}_P$, let τ_Θ denote the differential of the map from $\mathscr{G}_P$ to $\mathscr{A}_P$, which defines by (III.1) the $\mathscr{G}_P$ action. Since Lie $\mathscr{G}_P \cong 2\pi i \Omega^0(X;\mathbb{R})$, the linear map τ_Θ is identified with the exterior differential $\tau_\Theta = d : \Omega^0(X;\mathbb{R}) \to \Omega^1(X;\mathbb{R})$. Moreover, the inner product in Lie $\mathscr{G}_P$ defined by (III.4) induces an invariant metric on the group $\mathscr{G}_P$. The isotropy subgroup of $\mathscr{G}_P$ at a point $\Theta \in \mathscr{A}_P$ is the group of constant maps from X into $\mathbb{T}$; hence, it is isomorphic to $\mathbb{T}$. We let Vol $\mathbb{T}$ denote the volume of the isotropy subgroup, computed with respect to the metric induced from that of $\mathscr{G}_P$. Its evaluation gives

$$\text{Vol } \mathbb{T} = [\text{Vol } X]^{1/2} = \left[\int_X *1 \right]^{1/2}. \tag{III.5}$$

Thus, besides the fact that we are dealing with infinite-dimensional spaces, the setting is the same as the one in Sec. II. We have the identifications $E = \mathscr{A}_P$, $G = \mathscr{G}_P$, and $f = kS_{X,P}$. The stationary points of the Chern–Simons functional $S_{X,P}$ are the flat connections; hence the critical manifold F is the subspace $\mathscr{A}_P^f = \{\Theta \in \mathscr{A}_P | F_\Theta = d\Theta = 0\}$ and the constant value of the functional $S_{X,P}$ on $\mathscr{A}_P^f$ is the Chern–Simons invariant of flat connections on P. If Θ_P is a flat connection in $\mathscr{A}_P$, any $\Theta \in \mathscr{A}_P$ can be written as $\Theta = \Theta_P + 2\pi i A$, for some $A \in \Omega^1(X;\mathbb{R})$. Using (Ref. 2, Lemma III.5), we can express

$$S_{X,P}(\Theta) = S_{X,P}(\Theta_P) - \int_X A \wedge dA \pmod 1 = S_{X,P}(\Theta_P) - (A, *dA) \pmod 1.$$

The Hessian of the functional $f=kS_{X,P}$ is the linear operator Hess $f=-k*d:\Omega^1(X;\mathbb{R})\to\Omega^1(X;\mathbb{R})$. The quotient manifold $\mathscr{M}_P=\mathscr{A}_P^f/\mathscr{G}_P$, the moduli space of flat $\mathbb{T}$ connections on P, is isomorphic to the torus $H^1(X;\mathbb{R})/H^1(X;\mathbb{Z})$. The inner product (III.4) on 1-forms determines a natural inner product on $H^1(X;\mathbb{R})$ through the Hodge–deRham isomorphism $H^1(X;\mathbb{R})\cong\mathscr{H}^1(X)$ with the space of harmonic 1-forms. Since the tangent space $T_{[\Theta]}\mathscr{M}_P\cong H^1(X;\mathbb{R})$, at any $[\Theta]\in\mathscr{M}_P$, this inner product defines a measure ν on $\mathscr{M}_P$.

In view of these observations and of the results (II.1)–(II.3) from the model of Sec. II, we *formally* write

$$Z_{X,p}=\frac{1}{\mathrm{Vol}\ \mathscr{G}_P}\int_{\mathscr{A}_P}e^{\pi ikS_{X,P}(\Theta)}\hat{\mu} \tag{III.6}$$

$$=\frac{1}{\mathrm{Vol}\ \mathbb{T}}\int_{\mathscr{A}_P/\mathscr{G}_P}e^{\pi ikS_{X,P}(\Theta)}[\det'(\tau_\Theta^*\tau_\Theta)]^{1/2}\mu \tag{III.6$'$}$$

$$=\frac{e^{\pi ikS_{X,P}(\Theta_P)}}{\mathrm{Vol}\ \mathbb{T}}\int_{\mathscr{M}_P}e^{(\pi i/4)\mathrm{sgn}(-*d)}\frac{[\det'(\tau_\Theta^*\tau_\Theta)]^{1/2}}{[\det'(-k*d)]^{1/2}}\,\nu. \tag{III.6$''$}$$

The expression (III.6$'$) will be taken as the formal definition for $Z_{X,p}$ in (III.3). The equality (III.6$''$) is the result of the fact that, since $S_{X,P}$ is a quadratic functional, the stationary phase method that gives for an oscillatory integral of the type (II.2) the asymptotic evaluation (II.3), produces in this case the exact result. We are going to show that the expression in (III.6$''$) has rigorous mathematical meaning if the determinants and signatures of the operators therein are regularized according to the definitions (A1) and (A4).

If $\Delta_q=d^*d+dd^*$ is the Laplacian on $\Omega^q(X;\mathbb{R})$ and if we let $\zeta_q=\zeta_{\Delta_q}$, then for any real number $\lambda>0$,

$$\det'(\lambda\Delta_q)=\lambda^{\zeta_q(0)}\det'(\Delta_q), \tag{III.7}$$

and[8]

$$\zeta_q(0)=-\dim\mathrm{Ker}\ \Delta_q=-\dim\ H^q(X;\mathbb{R}). \tag{III.8}$$

Now, let us make use of the result (A3) to evaluate the regularized determinant $\det'(-k*d)$. We let $S=-k*d$ acting on $\Omega^1(X;\mathbb{R})$ and $T=kd:\Omega^0(X;\mathbb{R})\to\Omega^1(X;\mathbb{R})$. Then $S^2+TT^*=k^2(d^*d+dd^*)=k^2\Delta_1$ and $T^*T=k^2d^*d=k^2\Delta_0$. Using (A3) and (III.7)–(III.8) we get

$$\det'(-k*d)=\frac{[\det'(k^2\Delta_1)]^{1/2}}{[\det'(k^2\Delta_0)]^{1/2}}=\frac{k^{-\dim H^1(X;\mathbb{R})}}{k^{-\dim H^0(X;\mathbb{R})}}\frac{[\det'\ \Delta_1]^{1/2}}{[\det'\ \Delta_0]^{1/2}}. \tag{III.9}$$

We also note that $\tau_\Theta^*\tau_\Theta=d^*d=\Delta_0$. The signature of the operator $-*d$ on $\Omega^1(X;\mathbb{R})$ is regularized via the eta invariant, that is, $\mathrm{sgn}(-*d)=\eta(-*d)$. Inserting the above results into the expression (III.6$''$), we obtain

$$Z_{X,p}=k^{m_X}e^{\pi ikS_{X,P}(\Theta_P)}e^{(\pi i/4)\,\eta(-*d)}\int_{\mathscr{M}_P}\frac{1}{[\mathrm{Vol}\ X]^{1/2}}\frac{[\det'\ \Delta_0]^{3/4}}{[\det'\ \Delta_1]^{1/4}}\,\nu, \tag{III.10}$$

where $m_X=\frac{1}{2}(\dim H^1(X;\mathbb{R})-\dim H^0(X;\mathbb{R}))$. The expression under the integral sign in the above formula is related to the Ray–Singer analytic torsion of X.

The analytic torsion of a closed Riemannian manifold was introduced in Refs. 9 and 10 as a norm on the determinant line $|\mathrm{Det}\, H^{\bullet}(X;\mathbb{R})|$ of the deRham cohomology of the manifold. For a closed 3-manifold X endowed with a Riemannian metric, the Ray–Singer analytic torsion is the density:[10]

$$T_X^a \in |\mathrm{Det}\, H^0(X;\mathbb{R})| \otimes |\mathrm{Det}\, H^1(X;\mathbb{R})^*| \otimes |\mathrm{Det}\, H^2(X;\mathbb{R})| \otimes |\mathrm{Det}\, H^3(X;\mathbb{R})^*|,$$

$$T_X^a = \delta_{|\mathrm{Det}\, H^{\bullet}(X;\mathbb{R})|} \cdot \exp\left[\frac{1}{2}\sum_{q=0}^{\dim X}(-1)^q q\,\zeta_q'(0)\right]. \tag{III.11}$$

The inner product on the space $\mathscr{H}^q(X)$ of harmonic q-forms defined by (III.4) determines an inner product on $H^q(X;\mathbb{R}) \cong \mathscr{H}^q(X)$ and, thus, a density $\delta_{|\mathrm{Det}\, H^{\bullet}(X;\mathbb{R})|}$ on $|\mathrm{Det}\, H^{\bullet}(X;\mathbb{R})|$. If $b_q = \dim \mathscr{H}^q(X)$ and $\nu_1^{(q)},\ldots,\nu_{b_q}^{(q)}$ is any orthonormal basis for $\mathscr{H}^q(X)$, then

$$\delta_{|\mathrm{Det}\, H^{\bullet}(X;\mathbb{R})|} = \bigotimes_{q=0}^{\dim X} |\nu^{(q)}|^{(-1)^q}, \tag{III.12}$$

where $\nu^{(q)} = \nu_1^{(q)} \wedge \cdots \wedge \nu_{b_q}^{(q)}$. According to the definition of regularized determinants we have $\det' \Delta_q = e^{-\zeta_q'(0)}$. Thus, T_X^a can be represented as

$$T_X^a = [(\det' \Delta_0)^0 (\det' \Delta_1)^1 (\det' \Delta_2)^{-2} (\det' \Delta_3)^3]^{1/2} \times |\nu^{(0)}| \otimes |\nu^{(1)}|^{-1} \otimes |\nu^{(2)}| \otimes |\nu^{(3)}|^{-1}. \tag{III.13}$$

The Hodge $*$-operator determines isomorphisms $\Delta_q \cong \Delta_{3-q}$ and Poincaré duality gives $H^q(X;\mathbb{R}) \cong H^{3-q}(X;\mathbb{R})^*$. Moreover, any orthonormal basis $\nu^{(0)}$ of $\mathscr{H}^0(X) \cong \mathbb{R}$ is a constant such that $|\nu^{(0)}| = [\mathrm{Vol}\, X]^{-1/2}$. Hence, the square root of the analytic torsion T_X^a can be regarded as a density $(T_X^a)^{1/2} \in |\mathrm{Det}\, H^1(X;\mathbb{R})^*|$, which is given by the expression

$$(T_X^a)^{1/2} = \frac{1}{[\mathrm{Vol}\, X]^{1/2}} \frac{[\det' \Delta_0]^{3/4}}{[\det' \Delta_1]^{1/4}}\, \nu, \tag{III.14}$$

where $\nu =: |\nu^{(1)}|^{-1} = |\nu_1^{(1)} \wedge \cdots \wedge \nu_{b_1}^{(1)}|^{-1}$ for any orthonormal basis $\nu_1^{(1)},\ldots,\nu_{b_1}^{(1)}$ of $\mathscr{H}^1(X)$. In view of the isomorphism $\mathscr{M}_P \cong H^1(X;\mathbb{R})/H^1(X;\mathbb{Z})$, the square root $(T_X^a)^{1/2}$ of the analytic torsion defines an invariant density on the moduli space of flat connections $\mathscr{M}_P$. Using (III.14), the expression (III.10) reads as

$$Z_{X,p} = k^{m_X} e^{\pi i k S_{X,P}(\Theta_P)} e^{(\pi i/4)\eta(-*d)} \int_{\mathscr{M}_P} (T_X^a)^{1/2}. \tag{III.15}$$

It is proved in Ref. 10 that the analytic torsion of a closed manifold is independent of the metric. Thus T_X^a is a manifold invariant. The only metric dependence in (III.15) comes from the phase factor $e^{(\pi i/4)\eta(-*d)}$. We recall that in the non-Abelian CS theory,[3] Witten compensates the metric dependence of the path integral by adding to the original action a counterterm, the gravitational CS action. Here, in order to make the resulting expression metric independent, *we choose* to modify our original definition (III.6) of $Z_{X,p}$ by multiplying that expression with $e^{-(\pi i/4)\eta(-*d)}$.

Starting with a heuristic functional integral formula, we have thus succeeded to associate to the closed connected 3-manifold X the topological invariant,

$$Z_X = k^{m_X} \sum_{p \in \mathrm{Tors}\, H^2(X;\mathbb{Z})} e^{\pi i k S_{X,P}(\Theta_P)} \int_{\mathscr{M}_P} (T_X^a)^{1/2}. \tag{III.16}$$

We note that the factor k^{m_X} agrees with the one appearing in Ref. 11, in the analogous expression of the closed 3-manifold invariant for the non-Abelian version of the Chern–Simons theory. A close derivation to the one given here for the factor k^{m_X}, as arising from the scaling of regularized determinants of Laplacians, is presented in Ref. 12.

IV. THE PARTITION FUNCTION FOR MANIFOLDS WITH BOUNDARY

We address now the problem of defining Z_X in the case of a compact connected oriented 3-manifold X *with boundary* ∂X. We fix a trivializable $\mathbb{T}$ bundle Q over ∂X and a section $s:\partial X\to Q$. Then, for each $p\in \mathrm{Tors}\, H^2(X;\mathbb{Z})$, we choose a $\mathbb{T}$ bundle $P\to X$ with $c_1(P)=p$ and fix a bundle isomorphism $\phi_P:\partial P\to Q$. The section $s:\partial X\to Q$ determines a section $s_P=\phi_P^{-1}\circ s:\partial X\to \partial P$. If η is a connection on Q, then we define the space

$$\mathscr{A}_P(\eta)=\{\Theta\in\mathscr{A}_P\,|\,\partial\Theta=\phi_P^*\eta\},$$

of connections on P whose restriction $\partial\Theta=\Theta|_{\partial X}$ to the boundary of X is identified with η under the given bundle isomorphism over ∂X. The space $\mathscr{A}_P(\eta)$ is an affine space with vector space $2\pi i\Omega^1_{1,\tan}(X;\mathbb{R})$, where $\Omega^1_{1,\tan}(X;\mathbb{R})$ denotes the space of 1-forms A on X whose geometrical restriction to ∂X is zero.

Let $\mathscr{G}_P(e)$ denote the subgroup in $\mathscr{G}_P$ of gauge transformations that restrict to the identity map over ∂X. The group $\mathscr{G}_P(e)$ acts on $\mathscr{A}_P(\eta)$ through (III.1) and the action is free. Given the section $s_P:\partial X\to\partial P$, the CS functional $S_{X,P}(s_P,\cdot):\mathscr{A}_P(\eta)\to\mathbb{R}/\mathbb{Z}$ (see Ref. 2, Def. III.7) is invariant under the $\mathscr{G}_P(e)$ action on $\mathscr{A}_P(\eta)$. As for the closed manifold case previously discussed, we introduce the partition function of the CS functional,

$$Z_{X,p}(\eta)=\int_{\mathscr{A}_P(\eta)/\mathscr{G}_P(e)}[\mathscr{D}\Theta]\mathrm{e}^{\pi ikS_{X,P}(s_P,\Theta)},\tag{IV.1}$$

and using similar methods aim to show in what follows that one can make sense of such a functional integral.

For this purpose let us choose a Riemannian metric on X. The inner product defined on the tangent space by the metric determines, at each point of ∂X, a normal vector to the boundary. Therefore, a differential form α on X can be decomposed into a tangential and a normal component $\alpha=\alpha_{\tan}+\alpha_{\mathrm{norm}}$ and one has $(*\alpha)_{\mathrm{norm}}=*(\alpha_{\tan})$, $(d\alpha)_{\tan}=d(\alpha_{\tan})$, $(d^*\alpha)_{\mathrm{norm}}=d^*(\alpha_{\mathrm{norm}})$. We introduce the subspaces in $\Omega^q(X;\mathbb{R})$ of q forms on X satisfying *relative* (Dirichelet) boundary conditions:[9]

$$\Omega^q_{\tan}(X;\mathbb{R})=\{\alpha\in\Omega^q(X;\mathbb{R})\,|\,\alpha_{\tan}=(d^*\alpha)_{\tan}=0\ \text{ on }\ \partial X\},$$

and *absolute* (Neumann) boundary conditions:

$$\Omega^q_{\mathrm{norm}}(X;\mathbb{R})=\{\beta\in\Omega^q(X;\mathbb{R})\,|\,\beta_{\mathrm{norm}}=(d\beta)_{\mathrm{norm}}=0\ \text{ on }\ \partial X\}.$$

Then we let $\Delta_q^{\tan}$ and Δ_q^{norm} denote the Laplace operator d^*d+dd^* acting on $\Omega^q_{\tan}(X;\mathbb{R})$ and $\Omega^q_{\mathrm{norm}}(X;\mathbb{R})$, respectively. The Hodge–deRham theory for manifolds with boundary gives the isomorphisms[8,9]

$$H^q(X,\partial X;\mathbb{R})\cong\mathscr{H}^q_{\tan}(X),$$

$$H^q(X;\mathbb{R})\cong\mathscr{H}^q_{\mathrm{norm}}(X),$$

where

$$\mathscr{H}^q_{\tan}(X)=\{\alpha\in\Omega^q(X;\mathbb{R})\,|\,\alpha_{\tan}=0 \ \text{ on } \ \partial X, d\alpha=d^*\alpha=0 \ \text{ on } \ X\},$$

$$\mathscr{H}^q_{\text{norm}}(X)=\{\beta\in\Omega^q(X;\mathbb{R})\,|\,\beta_{\text{norm}}=0 \ \text{ on } \ \partial X, d\beta=d^*\beta=0 \ \text{ on } \ X\},$$

are the spaces of harmonic forms on X with relative and absolute boundary conditions.

Let $\hat{\mu}$ be the measure on $\mathscr{A}_P(\eta)$ determined by the inner product (III.4) defined on each tangent space $T_\Theta\mathscr{A}_P(\eta)\cong\Omega^1_{1,\tan}(X;\mathbb{R})$ by the metric on X and let μ be the induced measure on the quotient space $\mathscr{A}_P(\eta)/\mathscr{G}_P(e)$. For each $\Theta\in\mathscr{A}_P(\eta)$, the $\mathscr{G}_P(e)$ action on $\mathscr{A}_P(\eta)$ determines a linear map $\tau_\Theta=d:\text{Lie}\ \mathscr{G}_P(e)\cong\Omega^0_{\tan}(X;\mathbb{R})\to T_\Theta\mathscr{A}_P(\eta)\cong\Omega^1_{1,\tan}(X;\mathbb{R})$.

The stationary points of the Chern–Simons functional $S_{X,P}(s_P,\cdot):\mathscr{A}_P(\eta)\to\mathbb{R}/\mathbb{Z}$ form the subspace of flat connections $\mathscr{A}^f_P(\eta)=\{\Theta\in\mathscr{A}_P(\eta)|F_\Theta=d\Theta=0\}$. We assume that the connection η over ∂X is flat and extends to flat connections over X. Otherwise, the spaces $\mathscr{A}^f_P(\eta)$ are empty. Let us fix an arbitrary flat connection $\Theta_P\in\mathscr{A}^f_P(\eta)$. Then any connection $\Theta\in\mathscr{A}_P(\eta)$ can be expressed as $\Theta=\Theta_P+2\pi iA$, for some $A\in\Omega^1_{1,\tan}(X;\mathbb{R})$, and we have

$$S_{X,P}(s_P,\Theta)=S_{X,P}(s_P,\Theta_P)-(A,*dA)\quad(\text{mod }1).$$

The deRham theory for manifolds with boundary gives the identification $H^1(X,\partial X;\mathbb{R})=(\text{Ker } d|_{\Omega^1_{1,\tan}(X;\mathbb{R})})/(\text{Im } d|_{\Omega^0_{\tan}(X;\mathbb{R})})$. Thus, the quotient space $\mathscr{M}_P(\eta)=\mathscr{A}^f_P(\eta)/\mathscr{G}_P(e)$ is isomorphic to the torus $H^1(X,\partial X;\mathbb{R})/H^1(X,\partial X;\mathbb{Z})$. The inner product determined on the space $H^1(X,\partial X;\mathbb{R})$ through the isomorphism with $\mathscr{H}^1_{\tan}(X)$ defines a measure ν_t on $\mathscr{M}_P(\eta)$.

As in the closed manifold case, we mimic the finite-dimensional model of Sec. II and *formally* define the partition function of the quadratic functional $S_{X,P}(s_P,\cdot)$ as

$$Z_{X,p}(\eta)=\frac{1}{\text{Vol }\mathscr{G}_P(e)}\int_{\mathscr{A}_P(\eta)}e^{\pi ikS_{X,P}(s_P,\Theta)}\hat{\mu},\tag{IV.2}$$

$$=\int_{\mathscr{A}_P(\eta)/\mathscr{G}_P(e)}e^{\pi ikS_{X,P}(s_P,\Theta)}[\det'(\tau^*_\Theta\tau_\Theta)]^{1/2}\mu,\tag{IV.2$'$}$$

$$=e^{\pi ikS_{X,P}(s_P,\Theta_P)}\int_{\mathscr{M}_P(\eta)}e^{(\pi i/4)\text{sgn}(-*d)}\frac{[\det'(\tau^*_\Theta\tau_\Theta)]^{1/2}}{[\det'(-k*d)]^{1/2}}\,\nu_t.\tag{IV.2$''$}$$

The expression (IV.2$'$) will be taken as the formal definition for $Z_{X,p}(\eta)$ in (IV.1). Taking the regularized determinants and signatures of the operators therein, the expression (IV.2$''$) has rigorous mathematical meaning.

To evaluate $\det'(-k*d)$ we use the result (A3). Let $S=k*d$ acting on the space $\Omega^1_{\tan}(X;\mathbb{R})$ and

$$\widetilde{S}=\begin{pmatrix}0 & S\\ S^* & 0\end{pmatrix}=\begin{pmatrix}0 & -k*d\\ -k*d & 0\end{pmatrix}$$

acting on $\Omega^1_{\tan}(X;\mathbb{R})\oplus\Omega^1_{\text{norm}}(X;\mathbb{R})$. We also let $\widetilde{T}$ be the operator

$$\widetilde{T}=\begin{pmatrix}kd & 0\\ 0 & kd\end{pmatrix}$$

on the space $\Omega^0_{\tan}(X;\mathbb{R})\oplus\Omega^0_{\text{norm}}(X;\mathbb{R})$. Then we find that $\widetilde{S}^2+\widetilde{T}\widetilde{T}^*=k^2(\Delta_1^{\tan}\oplus\Delta_1^{\text{norm}})$ and $\widetilde{T}^*\widetilde{T}=k^2(\Delta_0^{\tan}\oplus\Delta_0^{\text{norm}})$. According to the definition (A2), we have $\det' S=|\det'(S^*S)|^{1/2}=|\det\widetilde{S}|^{1/2}$. Using this and the relation (A3), we can write

$$\det'(-k*d)=|\det'\ \widetilde{S}|^{1/2}=\frac{|\det'(\widetilde{S}^2+\widetilde{T}\widetilde{T}^*)|^{1/4}}{|\det'(\widetilde{T}^*\widetilde{T})|^{1/4}}=\frac{|\det'(k^2\Delta_1^{\tan})\det'(k^2\Delta_1^{\mathrm{norm}})|^{1/4}}{|\det(k^2\Delta_0^{\tan})\det'(k^2\Delta_0^{\mathrm{norm}})|^{1/4}}$$

$$=\frac{k^{-(1/2)[\dim H^1(X;\mathbb{R})+\dim H^1(X,\partial X;\mathbb{R})]}}{k^{-(1/2)[\dim H^0(X;\mathbb{R})+\dim H^0(X,\partial X;\mathbb{R})]}}\frac{|\det'\ \Delta_1^{\tan}\ \det'\ \Delta_1^{\mathrm{norm}}|^{1/4}}{|\det'\ \Delta_0^{\tan}\ \det'\ \Delta_0^{\mathrm{norm}}|^{1/4}}.$$

Inserting the above result together with $\det'(\tau_\Theta^*\tau_\Theta)=\det'\ \Delta_0^{\tan}$ into (IV.2″), we obtain

$$Z_{X,p}(\eta)=k^{m_X}e^{\pi ikS_{X,p}(s_P,\Theta_P)}e^{(\pi i/4)\eta(-*d)}\int_{\mathscr{M}_P(\eta)}\frac{|\det'\ \Delta_0^{\tan}|^{5/8}|\det'\ \Delta_0^{\mathrm{norm}}|^{1/8}}{|\det'\ \Delta_1^{\tan}|^{1/8}|\det'\ \Delta_1^{\mathrm{norm}}|^{1/8}}\ \nu_t,\quad \text{(IV.3)}$$

where $m_X=(1/4)(\dim H^1(X;\mathbb{R})+\dim H^1(X,\partial X;\mathbb{R})-\dim H^0(X;\mathbb{R})-\dim H^0(X,\partial X;\mathbb{R}))$. We are going to relate the term inside the integral sign in (IV.3) to the Ray–Singer analytic torsion of X.

The same definition (III.11) of the analytic torsion as a density T_X^a on $|\mathrm{Det}\ H^\cdot(X;\mathbb{R})|$ applies when X is a Riemannian manifold with boundary.[8,13] In this case the zeta function ζ_q in (III.11) is that of the Laplace operator Δ_q^{norm} on $\Omega^q_{\mathrm{norm}}(X;\mathbb{R})$ and the density $\delta_{|\mathrm{Det}\ H^\cdot(X;\mathbb{R})|}$ on $|\mathrm{Det}\ H^\cdot(X;\mathbb{R})|$ corresponds to the natural inner product on $H^\cdot(X;\mathbb{R})\cong\mathscr{H}^\cdot_{\mathrm{norm}}(X)$. Thus, the analytic torsion of the compact connected 3-manifold X with nonempty boundary ∂X is the density,

$$T_X^a\in|\mathrm{Det}\ H^0(X;\mathbb{R})|\otimes|\mathrm{Det}\ H^1(X;\mathbb{R})^*|\otimes|\mathrm{Det}\ H^2(X;\mathbb{R})|$$

$$T_X^a=[(\det'\ \Delta_0^{\mathrm{norm}})^0(\det'\ \Delta_1^{\mathrm{norm}})^1(\det'\ \Delta_2^{\mathrm{norm}})^{-2}(\det'\ \Delta_3^{\mathrm{norm}})^3]^{1/2}|\nu^{(0)}_{\mathrm{norm}}|\otimes|\nu^{(1)}_{\mathrm{norm}}|^{-1}\otimes|\nu^{(2)}_{\mathrm{norm}}|,$$

where $\nu^{(q)}_{\mathrm{norm}}=\nu_1^{(q)}\wedge\cdots\wedge\nu_{b_q}^{(q)}$, with $b_q=\dim\mathscr{H}^q_{\mathrm{norm}}(X)$ and $\nu_1^{(q)},\ldots,\nu_{b_q}^{(q)}$ an orthonormal basis for $\mathscr{H}^q_{\mathrm{norm}}(X)$. An orthonormal basis $\nu^{(0)}_{\mathrm{norm}}$ of $\mathscr{H}^0(X)\cong\mathbb{R}$ is such that $|\nu^{(0)}_{\mathrm{norm}}|=[\mathrm{Vol}\ X]^{-1/2}$. Poincaré duality gives $H^q(X;\mathbb{R})\cong H^{3-q}(X,\partial X;\mathbb{R})^*$. The spaces $\Omega^q_{\mathrm{norm}}(X;\mathbb{R})$ and $\Omega^{3-q}_{\tan}(X;\mathbb{R})$ are isomorphic under the Hodge $*$ operator and $\det'\ \Delta_q^{\mathrm{norm}}=\det'\ \Delta_{3-q}^{\tan}$. In consequence, the square root of the analytic torsion can be regarded as a half-density $(T_X^a)^{1/2}\in|\mathrm{Det}\ H^1(X;\mathbb{R})^*|^{1/2}\otimes|\mathrm{Det}\ H^1(X,\partial X;\mathbb{R})^*|^{1/2}$, which is given by the expression

$$(T_X^a)^{1/2}=\frac{1}{[\mathrm{Vol}\ X]^{1/4}}\frac{[\det'\ \Delta_0^{\tan}]^{3/4}[\det'\ \Delta_1^{\mathrm{norm}}]^{1/4}}{[\det'\ \Delta_1^{\tan}]^{1/2}}(\nu_n)^{1/2}\otimes(\nu_t)^{1/2}.\quad \text{(IV.4)}$$

Here $\nu_n=:|\nu^{(1)}_{\mathrm{norm}}|^{-1}=|\nu_1^{(1)}\wedge\cdots\wedge\nu_{b_1}^{(1)}|^{-1}$, for any orthonormal basis $\nu_1^{(1)},\ldots,\nu_{b_1}^{(1)}$ of harmonic forms of $\mathscr{H}^1_{\mathrm{norm}}(X)$. Similarly, $\nu_t=:|\nu^{(1)}_{\tan}|^{-1}=|\widetilde{\nu}_1^{(1)}\wedge\cdots\wedge\widetilde{\nu}_{l_1}^{(1)}|^{-1}$, for any orthonormal basis $\widetilde{\nu}_1^{(1)},\ldots,\widetilde{\nu}_{l_1}^{(1)}$ of $\mathscr{H}^1_{\tan}(X)$, where $l_1=\dim\mathscr{H}^1_{\tan}(X)$. Having in view the isomorphism $\mathscr{M}_P(\eta)\cong H^1(X,\partial X;\mathbb{R})/H^1(X,\partial X;\mathbb{Z})$, we note that

$$\int_{\mathscr{M}_P(\eta)}(T_X^a)^{1/2}=:\left[\int_{\mathscr{M}_P(\eta)}\nu_t\right](T_X^a)^{1/2}\otimes(\nu_t)^{-1}\quad \text{(IV.5)}$$

is a half-density in $|\mathrm{Det}\ H^1(X;\mathbb{R})^*|^{1/2}\otimes|\mathrm{Det}\ H^1(X,\partial X;\mathbb{R})|^{1/2}$.

As in the case of a closed manifold, it was proven in Ref. 13 that the analytic torsion T_X^a of a manifold X with a boundary is independent of the metric chosen on X (the metric is assumed to be a direct product metric near ∂X). On the other hand, the partition function $Z_{X,p}(\eta)$ in (IV.3) is a metric-dependent complex number. In light of the previous observations on the analytic torsion, we can get rid of this metric dependence by multiplying $Z_{X,p}(\eta)$ by the half-density,

$$\Upsilon\in|\mathrm{Det}\ H^1(X;\mathbb{R})^*|^{1/2}\otimes|\mathrm{Det}\ H^1(X,\partial X;\mathbb{R})|^{1/2},\quad \text{(IV.6)}$$

$$\Upsilon = 2^{-\chi(\partial X)/2} e^{-(\pi i/4)\eta(-*d)} \frac{1}{[\mathrm{Vol}\ X]^{1/4}} \frac{[\det'\ \Delta_0^{\tan}]^{1/8}[\det'\ \Delta_0^{\mathrm{norm}}]^{-1/8}}{[\det'\ \Delta_1^{\tan}]^{3/8}[\det'\ \Delta_1^{\mathrm{norm}}]^{-3/8}} (\nu_n)^{1/2} \otimes (\nu_t)^{-1/2},$$

where $\chi(\partial X)$ is the Euler characteristic of ∂X. Thus, with the definition (IV.5) in view, we obtain

$$Z_{X,p}(\eta)\Upsilon = k^{m_X} e^{\pi i k S_{X,P}(s_P,\Theta_P)} \int_{\mathscr{M}_P(\eta)} 2^{-x(\partial X)/2} (T_X^a)^{1/2},$$

which is independent of the metric on X. It would be interesting to find a geometrical interpretation of the half-density factor Υ, if any exists.

Hence, to a compact connected 3-manifold X with boundary ∂X, we can associate through the path integral approach outlined above a half-density $Z_X(\eta)$ for every flat connection η over ∂X extending to flat connections over X:

$$Z_X(\eta) \in |\mathrm{Det}\ H^1(X;\mathbb{R})^*|^{1/2} \otimes |\mathrm{Det}\ H^1(X,\partial X;\mathbb{R})|^{1/2}, \tag{IV.7}$$

$$Z_X(\eta) = \sum_{p \in \mathrm{Tors}\ H^2(X;\mathbb{Z})} Z_{X,p}(\eta)\Upsilon = k^{m_X} \sum_{p \in \mathrm{Tors}\ H^2(X;\mathbb{Z})} e^{\pi i k S_{X,P}(s_P,\Theta_P)} \int_{\mathscr{M}_P(\eta)} 2^{-x(\partial X)/2} (T_X^a)^{1/2}.$$

The group $H^1(X,\partial X;\mathbb{T})$ has $\pi_0(H^1(X,\partial X;\mathbb{T})) \cong \mathrm{Tors}\ H^2(X,\partial X;\mathbb{Z}) \cong \mathrm{Tors}\ H^2(X;\mathbb{Z})$ and each connected component is isomorphic to the torus $H^1(X,\partial X;\mathbb{R})/H^1(X,\partial X;\mathbb{Z})$. Thus

$$\int_{\mathscr{M}_P(\eta)} (T_X^a)^{1/2} = \int_{H^1(X,\partial X;\mathbb{R})/H^1(X,\partial X;\mathbb{Z})} (T_X^a)^{1/2} = \frac{1}{[\#\pi_0(H^1(X,\partial X;\mathbb{T}))]} \int_{H^1(X,\partial X;\mathbb{T})} (T_X^a)^{1/2},$$

for all P, and we can write (IV.7) as

$$Z_X(\eta) = \frac{k^{m_X}}{[\#\mathrm{Tors}\ H^2(X;\mathbb{Z})]} \sum_{p \in \mathrm{Tors}\ H^2(X;\mathbb{Z})} e^{\pi i k S_{X,P}(s_P,\Theta_P)} \int_{H^1(X,\partial X;\mathbb{T})} 2^{-x(\partial X)/2} (T_X^a)^{1/2}. \tag{IV.8}$$

Ray and Singer conjectured[9] that for a closed manifold X, the analytic torsion norm T_X^a and the purely topological Reidemeister torsion norm T_X on $|\mathrm{Det}\ H^\bullet(X;\mathbb{R})|$ coincide,

$$T_X^a = T_X. \tag{IV.9}$$

A proof of the Ray–Singer conjecture and a generalization to the case of manifolds with boundary can be found in Ref. 13. It is proven that, for a compact manifold X with boundary ∂X, the two norms on $|\mathrm{Det}\ H^\bullet(X;\mathbb{R})|$, the analytic torsion norm T_X^a and the Reidemeister torsion norm T_X are related by

$$T_X^a = 2^{x(\partial X)/2} T_X. \tag{IV.10}$$

Referring to the results in (Ref. 2, Sec. V), we note that the term $\Sigma_p e^{\pi i k S_{X,P}(s_P,\Theta_P)}$ in (IV.8) gives rise to a section of the prequantum line bundle $\mathscr{L}_{\partial X}$ over the Lagrangian image $\Lambda_X \subset \mathscr{M}_{\partial X}$ of the moduli space of flat $\mathbb{T}$ connections $\mathscr{M}_X$ and that, in view of (IV.5), the half-density $\int_{H^1(X,\partial X;\mathbb{T})} (T_X^a)^{1/2}$ can be interpreted as a section of the bundle of half-densities on Λ_X. Hence, according to the definition of the quantum theory in (Ref. 2, Sec. V), the expression (IV.8) determines an element in the Hilbert space $\mathscr{H}(\partial X, L_X)$. In view of the identification (IV.10), this corresponds to the vector Z_X in $\mathscr{H}(\partial X, L_X)$ defined in (Ref. 2, Eq. V.14). It is interesting that the pure path integral (IV.3) and the half-density factor (IV.6) introduced to compensate for the metric dependence of (IV.3) combine together to produce a result that agrees with the one obtained in the

geometric quantization approach. For a closed connected oriented 3-manifold X also, the expression (III.16) for the topological invariant Z_X associated to X through the path integral approach coincides, in view of (IV.9), with the expression [Ref. 2, Eq. V.16] from the geometric quantization approach to the Abelian CS theory.

APPENDIX: REGULARIZATION OF DETERMINANTS AND SIGNATURES

• *Zeta regularization of determinants*. We follow Ref. 5. A non-negative self-adjoint operator B on a Hilbert space $\mathscr{H}$ is called regular if $\mathrm{Tr}[e^{-tB}-\Pi(B)]=\Sigma_k \alpha_k(B)t^k$ as $t\to+0$, where k runs over a finite set of non-negative numbers. $\Pi(B)$ denotes the projection operator onto the kernel of B. The zeta function $\zeta_B(s)$ of a regular operator B is defined for large Re(s) by the expression

$$\zeta_B(s)=\sum_{\lambda_j\neq 0}\lambda_j^{-s}=\frac{1}{\Gamma(s)}\int_0^\infty \mathrm{Tr}[\mathrm{e}^{-tB}-\Pi(B)]t^{s-1}\,dt,$$

where λ_j are the eigenvalues of B. The function $\zeta_B(s)$ admits a meromorphic continuation to $\mathbb{C}$ and is analytic at $s=0$. The regularized determinant $\det' B$ is defined by the expression

$$\det' B=\mathrm{e}^{-\zeta_B'(0)}. \tag{A1}$$

For an operator $B:\mathscr{H}_0\to\mathscr{H}_1$ between the Hilbert spaces $\mathscr{H}_0$ and $\mathscr{H}_1$, with adjoint operator B^* and such that B^*B is regular, the regularized determinant $\det' B$ is defined by

$$\det' B=\mathrm{e}^{-(1/2)\zeta'_{B^*B}(0)}=[\det'(B^*B)]^{1/2}. \tag{A2}$$

Let S be a self-adjoint operator an a Hilbert space $\mathscr{H}_1$. Let $T:\mathscr{H}_0\to\mathscr{H}_1$ be an operator between the Hilbert spaces $\mathscr{H}_0$ and $\mathscr{H}_1$ with adjoint $T^*:\mathscr{H}_1\to\mathscr{H}_0$ and such that $T(\mathscr{H}_0)\subset\mathrm{Ker}\,S$. The operators S^2 and T^*T are assumed regular. By definition $\det' S=(\det' S^2)^{1/2}$ and $\det' T=(\det' T^*T)^{1/2}$. Then we have[5]

$$\det' S=\frac{[\det'(S^2+TT^*)]^{1/2}}{[\det'(TT^*)]^{1/2}}=\frac{[\det'(S^2+TT^*)]^{1/2}}{[\det'(T^*T)]^{1/2}}. \tag{A3}$$

• *Regularization of signatures*. Let B be a self-adjoint operator on a Hilbert space and define the function

$$\eta_B(s)=\sum_{\lambda_j\neq 0}(\mathrm{sign}\,\lambda_j)|\lambda_j|^{-s},$$

with λ_j the eigenvalues of B. The function $\eta_B(s)$ can be meromorphically continued to $\mathbb{C}$ and has a removable singularity at $s=0$. The *eta invariant* of the operator B is defined as[4]

$$\eta(B)=\eta_B(0). \tag{A4}$$

Infinite and finite Gleason's theorems and the logic of indeterminacy

Itamar Pitowsky[a)]
Department of Philosophy, The Hebrew University, Mount Scopus, Jerusalem 91905, Israel

(Received 20 June 1997; accepted for publication 3 September 1997)

In the first half of the paper I prove Gleason's lemma: *Every non-negative frame function on the set of rays in* $\Re^3$ *is continuous*. This is the central and most difficult part of Gleason's theorem. The proof is a reconstruction of Gleason's idea in terms of orthogonality graphs. The result is a demonstration that this theorem is actually combinatorial in nature. It depends only on a finite graph structure. In the second half of the paper I use the graph construction to obtain results about probability distributions (non-negative frame functions with weight one) on *finite* sets of rays. For example, given any two distinct nonorthogonal rays **a** and **b**, I construct a finite set of rays Γ that contains them, and has the following property: *No probability distribution on* Γ *assigns both* **a** *and* **b** *a truth value (probability zero or one) unless they are both false*. Thus the principle of indeterminacy turns into a theorem of propositional quantum logic (or partial Boolean algebras). © *1998 American Institute of Physics.* [S0022-2488(97)01612-5]

I. GLEASON'S THEOREM

Consider the n-dimensional real space $\Re^n$ equipped with the usual (Euclidean) inner product.

Definition 1: A real function f defined over the unit vectors in $\Re^n$ is called a frame function if the following two conditions hold:

(1) *For all unit vectors* $\mathbf{x}$ $f(\mathbf{x})=f(-\mathbf{x})$.
(2) *There is a constant* $C(f)$ *such that for every orthonormal basis* $\mathbf{x_1},\mathbf{x_2},\ldots,\mathbf{x}_n$ *in* $\Re^n$ *we have* $\Sigma_{k=1}^{n} f(\mathbf{x_k})=C(f)$. *The number* $C(f)$ *is called the weight of the frame function.*

The definition of a frame function can be extended to the n-dimensional complex space by modifying condition 1 to read: $f(e^{i\theta}\mathbf{x})=f(\mathbf{x})$ *for* $0<\theta<2\pi$, *and all unit vectors* $\mathbf{x}$. It can also be extended to include infinite-dimensional (real or complex) separable Hilbert spaces, if we allow the upper limit in the sum to be ∞. Gleason's theorem[1] provides a complete characterization of non-negative frame functions:

Theorem: *Let f be a non-negative frame function on a (real or complex) separable Hilbert space of dimension $n\geqslant 3$. Then there is a self-adjoint, non-negative definite operator W on that space such that $f(\mathbf{x})=\mathbf{x}^{\tau}W\mathbf{x}$ for all unit vectors* $\mathbf{x}$.

Gleason's theorem is a central result for the foundations of quantum mechanics. On the negative side it imposes very severe constraints on the structure of possible hidden variable theories.[2] On the positive side, it shows that the notion of ''state'' in quantum mechanics is determined by the algebraic structure of the closed subspaces of a Hilbert space. In other words, quantum ''logic'' *dictates* the probabilistic structure of quantum mechanics.

Gleason's original proof consists of three mathematically independent parts:

(1) Reduction: A proof that the general theorem follows from the special case of the three-dimensional real space $\Re^3$. This is a straightforward argument based on Hilbert space geometry.

a)Electronic mail: itamarp@vms.huji.ac.il

0022-2488/98/39(1)/218/11/$15.00
© 1998 American Institute of Physics

(2) A proof that every *continuous* non-negative frame function on $\mathfrak{R}^3$ satisfies the theorem. Here Gleason is using the continuity of the function to approximate it uniformly by linear combinations of spherical harmonics. Then, from the definition of a frame functions it follows that only functions of the desired kind could appear in the sum. This is the only truly ''analytic'' part of the original proof.
(3) Every non-negative (in fact, semibounded) frame function on $\mathfrak{R}^3$ is continuous. This part of the proof is at once the most difficult and the most elementary. Its proof requires only basic three-dimensional geometry and the definition of continuity.

The difficulty involved in the third stage of Gleason's proof and the application of ''higher mathematics'' in the second part, motivated the search for simpler demonstrations. Thus, for example, Piron[3] provided a proof of a considerably weaker version. He assumed that there exists a unit vector $\mathbf{p}$ such that $f(\mathbf{p})=C(f)=$the weight of the frame function f. Under this assumption Piron managed to avoid the ''higher mathematics'' of stage 2 and the difficulties of stage 3. Cooke *et al.*[4] succeeded in giving a full proof that avoids the difficulties in stage 2, while complicating (unnecessarily) stage 3. For example, to establish continuity, they use Tychonov's lemma, a highly nonconstructive principle.[5]

In the first part of this paper I shall prove Gleason's continuity theorem, namely: Every semibounded frame function in $\mathfrak{R}^3$ is continuous. The proof is a reconstruction of Gleason's original derivation, in terms of orthogonality graphs (which were introduced by Kochen and Specker). Thus, I shall first show (Sec. II) that certain orthogonality relations are realizable in $\mathfrak{R}^3$ (that is, certain graphs are embeddable). Moreover, we shall see that frame functions defined on the vectors *in those graphs* satisfy certain constraints. This part is purely geometrical. In Sec. III, I shall establish the continuity of the frame function by ''walking'' on the graphs, very much in the fashion of the Kochen and Specher approach. This will demonstrate that Gleason's continuity argument is not merely constructive; it is actually finitistic.[6] At its heart there are some simple combinatorial facts about finite (even if large) graphs. Using the results we can construct finite graphs on which certain finite versions of Gleason's theorem hold (Sec. IV). In particular, Theorem 6—the central result—shows the logical origin of the indeterminacy principle. This is explained in the last section.

II. TWO GEOMETRIC LEMMAS

The following is a straightforward extension of the notion of frame functions to *finite* sets of direction in space. We shall deal mainly with $\mathfrak{R}^3$, but the definition can be easily modified to accommodate real or complex spaces of any dimension.

Definition 2: Let Γ *be a finite set of unit vectors in the three-dimensional real space. A non-negative frame function on* Γ *is a function* $f:\Gamma\rightarrow\mathfrak{R}_t$ *that satisfies*

(1) $f(-\mathbf{x})=f(\mathbf{x})$ *whenever both* $\mathbf{x}$ *and* $-\mathbf{x}$ *are elements of* Γ.
(2) *There is a number* $C(f)$ *such that* $f(\mathbf{x})+f(\mathbf{y})\leqslant C(f)$ *for every orthogonal pair* $\mathbf{x},\mathbf{y}\in\Gamma$, *and* $f(\mathbf{x})+f(\mathbf{y})+f(\mathbf{z})=C(f)$ *for every orthogonal triple* $\mathbf{x},\mathbf{y},\mathbf{z}\in\Gamma$.

The proof of Gleason's theorem follows two lemmas on the embedding of graphs in the set of unit vectors in $\mathfrak{R}^3$. The graphs G_1, and G_2 below should read as follows: Each node in the graph stands for a unit vector. Two nodes in the graph are joined by an edge if, and only if, the corresponding vectors are orthogonal. I shall somewhat loosely identify each ray (that is, a one-dimensional subspace) in $\mathfrak{R}^3$ with a unit vector that spans it. The set of all unit vectors in $\mathfrak{R}^3$ is denoted by S^2. In the following all references to ''open sets'' and ''continuous functions'' correspond to the usual Euclidean topology on S^2.

The two lemmas below are geometric in nature. They follow from the metric structure of $\mathfrak{R}^3$ without any further assumption.

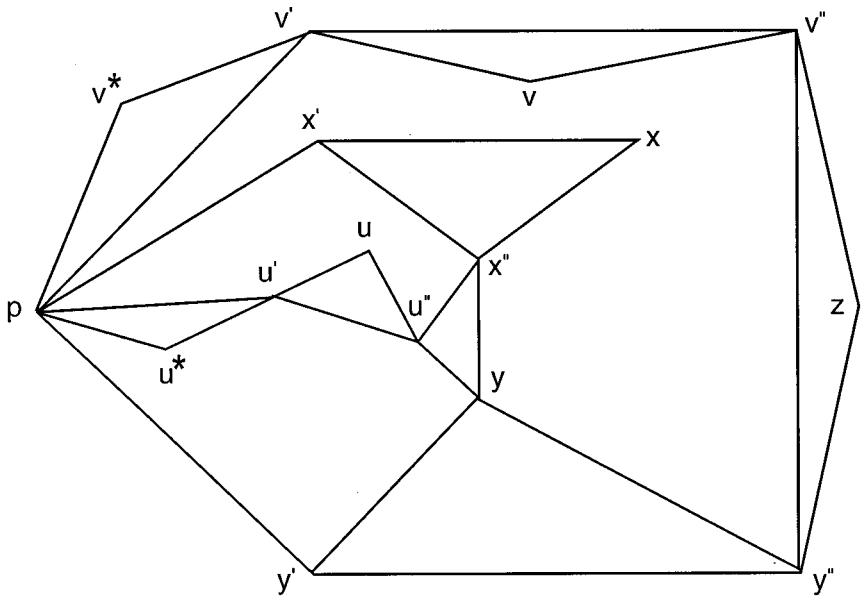

FIG. 1. The graph G_1.

Lemma 1: (a) Let $\mathbf{p}$ *and* $\mathbf{z}$ *be two unit vectors that satisfy* $\mathbf{p}\cdot\mathbf{z}\neq 0,1$. *Then there is a nonempty open set* $U\subset S^{(2)}$ *such that for each* $\mathbf{x}\in U$ *there are* $\mathbf{x}',\mathbf{x}'',\mathbf{y},\mathbf{y}',\mathbf{y}'',\mathbf{u},\mathbf{u}',\mathbf{u}'',\mathbf{v},\mathbf{v}',\mathbf{v}'',\mathbf{u}^*,\mathbf{v}^*\in S^2$, *which, together with* $\mathbf{p},\mathbf{z},\mathbf{x}$, *exhibit the orthogonality relations in the graph* G_1.

(b) Let g *be a non-negative frame function defined on the vectors in* G_1 *and satisfying*

$$g(\mathbf{x}')=g(\mathbf{u}^*),\quad g(\mathbf{y}')=g(\mathbf{v}^*). \tag{1}$$

Then

$$g(\mathbf{x})\leqslant g(\mathbf{z})+2g(\mathbf{p}). \tag{2}$$

Proof: (a) Let α be the angle between $\mathbf{p}$ and $\mathbf{z}$ and assume that $\cos\alpha>0$ (otherwise exchange $\mathbf{z}$ by $-\mathbf{z}$). Also, assume without loss of generality that $\mathbf{p}=(0,0,1)$ and $\mathbf{z}=(\cos\alpha,0,\sin\alpha)$. Consider the symmetric 3×3 matrix:

$$B=\begin{pmatrix} \sin\alpha & 0 & -\frac{1}{2}\cos\alpha \\ 0 & \sin\alpha & 0 \\ -\frac{1}{2}\cos\alpha & 0 & 0 \end{pmatrix}.$$

It has one negative eigenvalue, $\frac{1}{2}\sin\alpha-\frac{1}{2}$, corresponding to the eigenvector $\mathbf{x}_0=(\sqrt{\frac{1}{2}\sin\alpha-1/2},0,\sqrt{\frac{1}{2}\sin\alpha+\frac{1}{2}})=(\cos((\pi+2\alpha)/4),0,\sin((\pi+2\alpha)/4))$. Therefore, the quadric form $\mathbf{w}^{\mathrm{T}}B\mathbf{w}=(w_1^2+w_2^2)\sin\alpha-w_1w_3\cos\alpha$ is negative at $\mathbf{w}=\mathbf{x}_0$, and thus the set $U=\{\mathbf{w}\in S^{(2)};\mathbf{w}^{\mathrm{T}}B\mathbf{w}<\mathbf{0}\}$ is nonempty. Since the form $\mathbf{w}^{\mathrm{T}}B\mathbf{w}$ is continuous, U is opened.

Now let $\mathbf{x}\in U$, $\mathbf{x}=(x_1,x_2,x_3)$. In the following I shall not bother normalizing the vectors to have unit length. This makes no difference because we are interested in orthogonality relations only. Now put $\mathbf{x}'=(-x_2,x_1,0)$ and then $\mathbf{x}'\cdot\mathbf{p}=\mathbf{0}$. The vector $\mathbf{x}''=(x_1x_3,x_2x_3,-(x_1^2+x_2^2))$ is orthogonal to both $\mathbf{x}$ and $\mathbf{x}'$. By assumption we have $\mathbf{x}^{\mathrm{T}}B\mathbf{x}<\mathbf{0}$. Also, it is easy to see that $\mathbf{x}'^{\mathrm{T}}B\mathbf{x}'>\mathbf{0}$. Therefore, by the continuity of the quadric form $\mathbf{w}^{\mathrm{T}}B\mathbf{w}$, there is a vector $\mathbf{y}$

$=(y_1,y_2,y_3)\neq\mathbf{0}$ in the plane orthogonal to $\mathbf{x}''$, such that $\mathbf{y}^{\mathsf{T}}B\mathbf{y}=\mathbf{0}$. Put $\mathbf{y}'=(-y_2,y_1,0)$ and then $\mathbf{y}'\cdot\mathbf{p}=\mathbf{0}$. Thus, the vector $\mathbf{y}''$ which is orthogonal to both $\mathbf{y}$ and $\mathbf{y}'$ is given by $\mathbf{y}''=(y_1y_3,y_2y_3,-(y_1^2+y_2^2))$.

Now, $\mathbf{y}''\cdot\mathbf{z}=y_1y_3\cos\alpha-(y_1^2+y_2^2)\sin\alpha=-\mathbf{y}^{\mathsf{T}}B\mathbf{y}=\mathbf{0}$. To complete the proof we choose $\mathbf{v}''$ to be orthogonal to both $\mathbf{y}''$ and $\mathbf{z}$, the vector $\mathbf{v}'$ orthogonal to both $\mathbf{v}''$ and $\mathbf{p}$, and $\mathbf{v}$ orthogonal to $\mathbf{v}'$ and $\mathbf{v}''$. Similarly, we take $\mathbf{u}''$ to be orthogonal to $\mathbf{x}''$ and $\mathbf{y}$, the vector $\mathbf{u}'$ to be orthogonal to $\mathbf{u}''$ and $\mathbf{p}$ and $\mathbf{u}$ orthogonal to $\mathbf{u}'$ and $\mathbf{u}''$, the vector $\mathbf{u}^*$ orthogonal to $\mathbf{p}$ and $\mathbf{u}'$, and $\mathbf{v}^*$ orthogonal to $\mathbf{p}$ and $\mathbf{v}'$.

(b) Let g be a frame function on the vectors in G_1 that satisfy (1). We have

$$g(\mathbf{y})+g(\mathbf{y}')+g(\mathbf{y}'')=g(\mathbf{y}'')+g(\mathbf{z})+g(\mathbf{v}''),\tag{3}$$

$$g(\mathbf{x})+g(\mathbf{x}')+g(\mathbf{x}'')=g(\mathbf{x}'')+g(\mathbf{y})+g(\mathbf{u}'').\tag{4}$$

And since, in addition, g is non-negative, we have

$$g(\mathbf{v}')+g(\mathbf{v}'')\leqslant g(\mathbf{v})+g(\mathbf{v}')+g(\mathbf{v}'')=g(\mathbf{p})+g(\mathbf{v}')+g(\mathbf{v}^*),\tag{5}$$

$$g(\mathbf{u}')+g(\mathbf{u}'')\leqslant g(\mathbf{u})+g(\mathbf{u}')+g(\mathbf{u}'')=g(\mathbf{p})+g(\mathbf{u}')+g(\mathbf{u}^*).\tag{6}$$

Thus, we get $g(\mathbf{v}'')\leqslant g(\mathbf{p})+g(\mathbf{v}^*)$ and $g(\mathbf{u}'')\leqslant g(\mathbf{p})+g(\mathbf{u}^*)$. Substituting into (3) and (4) we obtain from (1)

$$g(\mathbf{x})=g(\mathbf{y})+g(\mathbf{u}'')-g(\mathbf{x}')\leqslant g(\mathbf{y})+g(\mathbf{p})+g(\mathbf{u}^*)-g(\mathbf{x}')=g(\mathbf{y})+g(\mathbf{p}),\tag{7}$$

$$g(\mathbf{y})=g(\mathbf{z})+g(\mathbf{v}'')-g(\mathbf{y}')\leqslant g(\mathbf{z})+g(\mathbf{p})+g(\mathbf{v}^*)-g(\mathbf{y}')=g(\mathbf{z})+g(\mathbf{p}).\tag{8}$$

Combining (7) and (8) we obtain $g(\mathbf{x})\leqslant g(\mathbf{z})+2g(\mathbf{p})$, as required. ■

Lemma 2: (a) Let $U\subseteq S^2$ be an open set. Then there is $\delta>0$ such that for all $\mathbf{z}_1,\mathbf{z}_2\in S^2$ that satisfy $\|\mathbf{z}_1-\mathbf{z}_2\|<\delta$ there are $\mathbf{x}_1$, $\mathbf{x}_2$, $\mathbf{x}_3$,$\mathbf{x}_4$, $\mathbf{x}_5$, $\mathbf{x}_6$, $\mathbf{x}_7$, $\mathbf{x}_8\in U$ and $\mathbf{y}_1$, $\mathbf{y}_2$, $\mathbf{y}_3$, $\mathbf{y}_4$, $\mathbf{u}_1$, $\mathbf{u}_2$, $\mathbf{u}_3$, $\mathbf{u}_4$, $\mathbf{v}_1$, $\mathbf{v}_2$, $\mathbf{w}_1$, $\mathbf{w}_2$, which together with $\mathbf{z}_1,\mathbf{z}_2$ exhibit the orthogonality relations in the graph G_2.

(b) Let f be any frame function on the vectors in G_2. Then

$$|f(\mathbf{z}_1)-f(\mathbf{z}_2)|\leqslant|f(\mathbf{x}_1)-f(\mathbf{x}_2)|+|f(\mathbf{x}_3)-f(\mathbf{x}_4)|+|f(\mathbf{x}_5)-f(\mathbf{x}_6)|+|f(\mathbf{x}_7)-f(\mathbf{x}_8)|.\tag{9}$$

Proof: (a) Let $\mathbf{x}_0\in U$ and let $\mathbf{z}_0,\mathbf{z}_0\neq\mathbf{x}_0$, be an arbitrary unit vector. Denote by $\mathbf{y}_0$ a unit vector orthogonal to both $\mathbf{x}_0$ and $\mathbf{z}_0$. Assume, without loss of generality, that $\mathbf{x}_0=(1,0,0)$ and that $\mathbf{y}_0=(0,1,0)$. Since $\mathbf{x}_0\in U$, there is $\theta>0$ such that the set of all vectors forming an angle smaller than θ with $\mathbf{x}_0$ is a subset of U. Let $\mathbf{w}_2=(-\sin(\frac{1}{2}\theta),\cos(\frac{1}{2}\theta),0)$. Then there is a neighborhood W of $\mathbf{y}_0$ with the following property: For $\mathbf{y}\in W$ let $\mathbf{x},\overline{\mathbf{x}}$ be unit vectors orthogonal to $\mathbf{y},\mathbf{w}_2$ respectively, *in the plan spanned by* $\mathbf{y}$ *and* $\mathbf{w}_2$. Then $\mathbf{x},\overline{\mathbf{x}}\in U$. (More precisely, the rays spanned by $\mathbf{x},\overline{\mathbf{x}}$ cut U, see Fig. 3.)

Similarly, there is $\phi>0$ such that the set of all unit vectors forming an angle ϕ with $\mathbf{y}_0$ is a subset of W. Let $\mathbf{w}_1$ be a vector in the plane spanned by $\mathbf{y}_0$ and $\mathbf{z}_0$ which forms an angle $\frac{1}{2}\phi$ with $\mathbf{z}_0$ and an angle $\frac{1}{2}(\pi+\phi)$ with $\mathbf{y}_0$. Then there is a neighborhood V of $\mathbf{z}_0$ with the analogous property: Let $\mathbf{z}\in V$ and $\mathbf{y},\overline{\mathbf{y}}$ be the vectors orthogonal to $\mathbf{z},\mathbf{w}_1$, respectively, in the $\mathbf{z}^{-}\mathbf{w}_1$ plane. Then the rays through $\mathbf{y},\overline{\mathbf{y}}$ cut V.

Now take any $\mathbf{z}_1,\mathbf{z}_2\in V$, and let $\mathbf{y}_1,\mathbf{y}_2,\mathbf{y}_3,\mathbf{y}_4\in W$ be vectors such that $\mathbf{y}_1,\mathbf{y}_2$ are orthogonal to $\mathbf{z}_1,\mathbf{w}_1$, respectively, in the $\mathbf{z}_1^{-}\mathbf{w}_1$ plane, and $\mathbf{y}_3,\mathbf{y}_4$ are orthogonal to $\mathbf{w}_1,\mathbf{z}_2$, respectively, in the $\mathbf{w}_1^{-}\mathbf{z}_2$ plane while $\mathbf{v}_1,\mathbf{v}_2$ are the vectors orthogonal to the $\mathbf{z}_1^{-}\mathbf{w}_1$ and $\mathbf{w}_1^{-}\mathbf{z}_2$ planes, respectively.

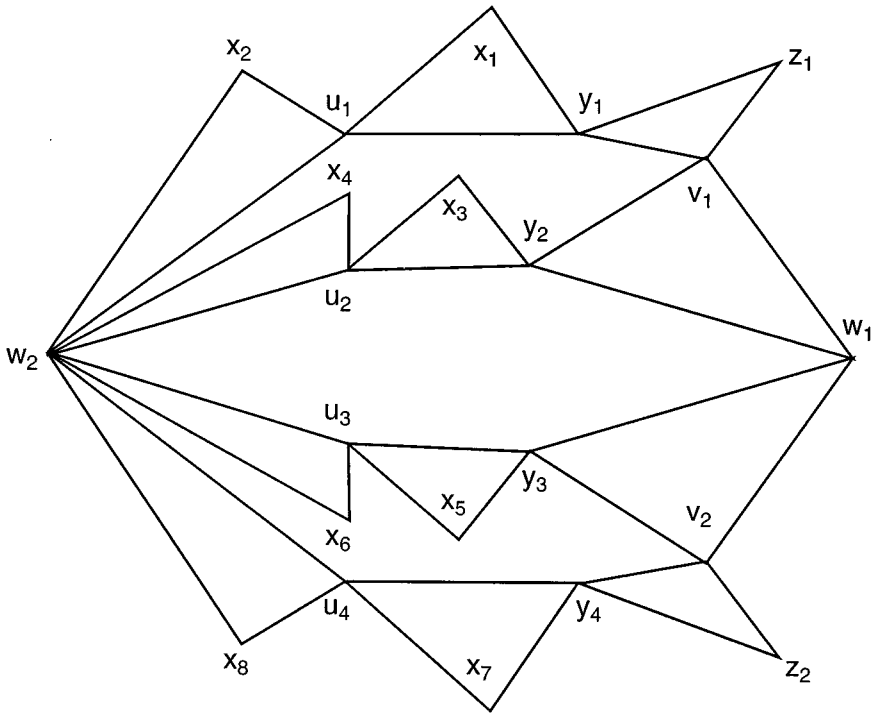

FIG. 2. The graph G_2.

In the same manner let $\mathbf{x}_1,\mathbf{x}_2,\ldots,\mathbf{x}_8 \in U$ be such that $\mathbf{x_{2i-1}},\mathbf{x_{2i}}$ are, respectively, orthogonal to $\mathbf{y}_i,\mathbf{w}_2$ in the $\mathbf{y_i}\bar{}\,\mathbf{w}_2$ plane, and $\mathbf{u_i}$ is a vector orthogonal to this plane ($i=1,2,3,4$). Since $\mathbf{z}_0$ is an arbitrary vector the proof of the first part is complete.

(b) Let f be a non-negative frame function on the vectors in G_2. Then

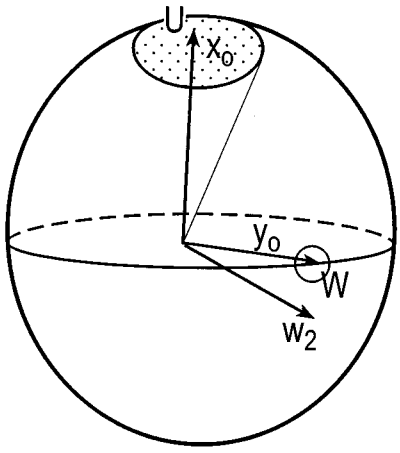

FIG. 3. The set W.

$$f(\mathbf{y}_1)+f(\mathbf{z}_1)+f(\mathbf{v}_1)=f(\mathbf{y}_2)+f(\mathbf{w}_1)+f(\mathbf{v}_1),$$
$$f(\mathbf{y}_4)+f(\mathbf{z}_2)+f(\mathbf{v}_2)=f(\mathbf{y}_3)+f(\mathbf{w}_1)+f(\mathbf{v}_2) \tag{10}$$

Subtracting the second equation (10) from the first, we get in a straightforward way

$$|f(\mathbf{z}_1)-f(\mathbf{z}_2)|\leqslant|f(\mathbf{y}_1)-f(\mathbf{y}_2)|+|f(\mathbf{y}_3)-f(\mathbf{y}_4)|. \tag{11}$$

In a similar manner we have

$$f(\mathbf{y_i})+f(\mathbf{x_{2i-1}})+f(\mathbf{u_i})=f(\mathbf{x_{2i}})+f(\mathbf{w}_2)+f(\mathbf{u_i}),\quad i=1,2,3,4, \tag{12}$$

from which it follows in the same way

$$|f(\mathbf{y}_1)-f(\mathbf{y}_2)|\leqslant|f(\mathbf{x}_1)-f(\mathbf{x}_2)|+|f(\mathbf{x}_3)-f(\mathbf{x}_4)|,$$
$$|f(\mathbf{y}_3)-f(\mathbf{y}_4)|\leqslant|f(\mathbf{x}_5)-f(\mathbf{x}_6)|+|f(\mathbf{x}_7)-f(\mathbf{x}_8)|. \tag{13}$$

Combining (11) and (13) we get inequality (9). ■

III. THE THEOREM ON CONTINUITY AND ITS COMBINATORIAL NATURE

We can now try to prove the following.

Theorem 3: *Let f be a semibounded frame-function in $\mathfrak{R}^3$. Then f is continuous.*

Proof: We can assume that f is bounded from below (otherwise, consider $-f$). By adding a constant to f it remains a frame function and we can make sure that $\inf f(x)=0$, where the infimum is taken over all unit vectors. Let $\varepsilon>0$, and choose a unit vector $\mathbf{p}$ such that $f(\mathbf{p})<\varepsilon$. Let σ be a 90° rotation around the $\mathbf{p}$ axis and define $g(\mathbf{x})=f(\mathbf{x})+f(\sigma\mathbf{x})$ for all rays $\mathbf{x}$. Then g is a frame function, $C(g)=2C(f)$. Let $m=\inf g(\mathbf{x})$, where the infimum is taken over all unit vectors $\mathbf{x}$ for which $\mathbf{x}\cdot\mathbf{p}\neq 0,1$. Choose such a vector $\mathbf{z}$ for which $g(\mathbf{z})<m+\varepsilon$. By Lemma 1, given any $\mathbf{p}$ and $\mathbf{z}$, $\mathbf{p}\cdot\mathbf{z}\neq 0,1$, there is an open set U such that for all $\mathbf{x}\in U$ the graph G_1 is realizable. Note that if $\mathbf{a}$ and $\mathbf{b}$ are any two vectors orthogonal to $\mathbf{p}$, then $g(\mathbf{a})=g(\mathbf{b})$, in particular (1) is satisfied. Therefore, by Lemma 1, also (2) is satisfied for all $\mathbf{x}\in U$. By the choice of $\mathbf{z}$ we have $g(\mathbf{x})\geqslant g(\mathbf{z})-\varepsilon$ for all $\mathbf{x}$ such that $\mathbf{x}\cdot\mathbf{z}\neq 0,1$. Therefore, combining this inequality with (2) we obtain for all $\mathbf{x},\overline{\mathbf{x}}\in U$: $g(\mathbf{x})-g(\overline{\mathbf{x}})\leqslant g(\mathbf{z})+2g(\mathbf{p})-g(\mathbf{z})+\varepsilon\leqslant 5\varepsilon$. Reversing the role of $\mathbf{x},\overline{\mathbf{x}}$ we get

$$|g(\mathbf{x})-g(\overline{\mathbf{x}})|<5\varepsilon,\quad \mathbf{x},\overline{\mathbf{x}}\in U. \tag{14}$$

Consider Lemma 2 applied to the set U and the frame function g. For any sufficiently small positive δ and all $\mathbf{z_1},\mathbf{z_2}$ such that $\|\mathbf{z}_1-\mathbf{z}_2\|<\delta$ there are $\mathbf{x_1},\mathbf{x_2},\ldots,\mathbf{x_g}\in U$ which exhibit the orthogonality relations in the graph G_2. Apply (9) to $\mathbf{x_1},\mathbf{x_2},\ldots,\mathbf{x_8}\in U$. We obtain from (14)

$$|g(\mathbf{z}_1)-g(\mathbf{z}_2)|<20\varepsilon,\quad \|\mathbf{z}_1-\mathbf{z}_2\|<\delta, \tag{15}$$

for all sufficiently close $\mathbf{z_2},\mathbf{z_2}$. In particular let $\mathbf{z_1}=\mathbf{p}$ and denote $U'=\{\mathbf{x};\|\mathbf{x}-\mathbf{p}\|<\delta\}$. Then all $\mathbf{x}\in U'$ satisfy $|g(\mathbf{p})-g(\mathbf{x})|<20\varepsilon$. From the definition of g we get for $\mathbf{x}\in U'$: $f(\mathbf{x})\leqslant g(\mathbf{x})\leqslant|g(\mathbf{p})-g(\mathbf{x})|+g(\mathbf{p})<20\varepsilon+2f(\mathbf{p})<22\varepsilon$. Therefore, for all $\mathbf{x_1},\mathbf{x_2}\in U'$

$$|f(\mathbf{x}_1)-f(\mathbf{x}_2)|<|f(\mathbf{x}_1)|+|f(\mathbf{x}_2)|<44\varepsilon. \tag{16}$$

Now, we take the open set U' and the frame function f and apply Lemma 2 again. We know that there is $\delta'>0$ such that for all $\mathbf{z_1},\mathbf{z_2},\|\mathbf{z_1}-\mathbf{z_2}\|<\delta'$, there are $\mathbf{x_1},\mathbf{x_2},\ldots,\mathbf{x_8}\in U'$ which realize the graph G_2. Combining (13) and (16) we get

$$|f(\mathbf{z}_1)-f(\mathbf{z}_2)|<176\varepsilon,\quad \|\mathbf{z}_1-\mathbf{z}_2\|<\delta'. \tag{17}$$

And since $\varepsilon>0$ is arbitrary we conclude that f is continuous. ■

Despite the frequent references to ''open sets'' the above proof is, in fact, finite. Suppose that $f\geqslant 0$ is a frame function on $\Re^3$ and let $\varepsilon>0$ be a given real number. The first step is to choose vectors $\mathbf{p}$ and $\mathbf{z}$ as in the proof. This, of course, cannot be done explicitly, since f is not given explicitly. However, once $\mathbf{p}$ and $\mathbf{z}$ are fixed, the following is true:

(1) We can explicitly calculate the value of $\delta'>0$ such that if $\|\mathbf{z_1}-\mathbf{z_2}\|<\delta'$, then $|f(\mathbf{z_1})-f(\mathbf{z_2})|<176\varepsilon$.
(2) Given $\mathbf{z_1},\mathbf{z_2}$ such that $\|\mathbf{z_1}-\mathbf{z_2}\|<\delta'$ we can explicitly construct a finite (albeit large) graph and prove that $|f(\mathbf{z_1})-f(\mathbf{z_2})|<176\varepsilon$ just by ''walking'' on this graph.

As for the first point, recall that in Lemma 1 we obtained the open set $U=\{\mathbf{w}\in S^2;\mathbf{w}^{\mathrm{T}}B\mathbf{w}<0\}$ and the vector $\mathbf{x_0}=(\sqrt{\tfrac{1}{2}\sin\alpha-\tfrac{1}{2}},0,\sqrt{\tfrac{1}{2}\sin\alpha+\tfrac{1}{2}})\in U$, where $0<\alpha<1/2\pi$ is the angle between $\mathbf{p}$ and $\mathbf{z}$. From the definition of the quadric form $\mathbf{w}^{\mathrm{T}}B\mathbf{w}$ it follows that U contains the set of all unit vectors whose angle with $\mathbf{x_0}$ is less than θ, where θ is given by $\sin^2\theta=\tan^2(\pi/4-\alpha/2)$.

Now, consider Lemma 2 and the construction of the open sets W (Fig. 3) and V. A simple calculation shows that it is sufficient to take W as the set of all vectors whose angle with $\mathbf{y_0}$ is less than ϕ where $\tan^2\phi=\sin^2(\theta/2)\tan^2(\theta/2)$. This calculation repeats itself when we establish the relation between W and V. Thus V is the set of all unit vectors whose angle with $\mathbf{z_0}$ is less than ϕ' where again $\tan^2\phi'=\sin^2(\phi/2)\tan^2(\phi/2)$. In the proof of the theorem we use twice the construction of Lemma 2, first to show that if we choose $\mathbf{z_0}=\mathbf{p}$ (and therefore V to be a neighborhood of $\mathbf{p}$), then for all $\mathbf{z_1},\mathbf{z_2}\in V$ we have $|g(\mathbf{z_1})-g(\mathbf{z_2})|<20\varepsilon$. Thus we can take $\delta=2\sin\phi'$ in (15) and second we repeat the argument, this time with respect to f. Now V plays the role previously played by U. Hence, we can calculate the value of δ' in (17) in an analogous manner.

To establish the graph structure of the entire proof let us introduce some notations. Once $\mathbf{p}$, $\mathbf{z}$, and $\mathbf{x}\in U$ are chosen, the graph G_1 (Fig. 1) is determined (up to the sign of the vectors). Let us denote the graph G_1 determined by $\mathbf{p}$, $\mathbf{z}$, $\mathbf{x}$ by $G_1[\mathbf{p},\mathbf{z},\mathbf{x}]$. Similarly let $G_2[\mathbf{z_1},\mathbf{z_2},\mathbf{x_1},\mathbf{x_2},\mathbf{x_3},\mathbf{x_4},\mathbf{x_5},\mathbf{x_6},\mathbf{x_7},\mathbf{x_8}]$ denote the graph G_2 (Fig. 2) which contain these vectors. Now consider the graph G_3^*:

$$\begin{aligned}G_3^*[\mathbf{p},\mathbf{z},\mathbf{z}_1,\mathbf{z}_2]=&G_2[\mathbf{z}_1,\mathbf{z}_2,\mathbf{p}_1,\mathbf{p}_2,\ldots,\mathbf{p}_8]\cup G_2[\mathbf{p}_1,\mathbf{p},\mathbf{x}_1,\mathbf{x}_2,\ldots,\mathbf{x}_8]\cup G_2[\mathbf{p}_2,\mathbf{p},\mathbf{x}_9,\mathbf{x}_{10},\ldots,\mathbf{x}_{16}]\\&\cup\cdots\cup G_2[\mathbf{p}_7,\mathbf{p},\mathbf{x}_{49},\mathbf{x}_{50},\ldots,\mathbf{x}_{56}]\cup G_2[\mathbf{p}_8,\mathbf{p},\mathbf{x}_{57},\mathbf{x}_{58},\ldots,\mathbf{x}_{64}]\cup G_1[\mathbf{x}_1,\mathbf{p},\mathbf{z}]\\&\cup G_1[\mathbf{x}_2,\mathbf{p},\mathbf{z}]\cup\cdots\cup G_1[\mathbf{x}_{64},\mathbf{p},\mathbf{z}].\end{aligned}\tag{18}$$

Now remember that σ is a 90° rotation around $\mathbf{p}$ and define G_3 by

$$G_3[\mathbf{p},\mathbf{z},\mathbf{z}_1,\mathbf{z}_2]=G_3^*[\mathbf{p},\mathbf{z},\mathbf{z}_1,\mathbf{z}_2]\cup\sigma G_3^*[\mathbf{p},\mathbf{z},\mathbf{z}_1,\mathbf{z}_2]\cup\sigma^2G_3^*[\mathbf{p},\mathbf{z},\mathbf{z}_1,\mathbf{z}_2]\cup\sigma^3G_3^*[\mathbf{p},\mathbf{z},\mathbf{z}_1,\mathbf{z}_2].\tag{19}$$

Take the graph $G_2[\mathbf{z_1},\mathbf{z_2},\mathbf{p_1},\mathbf{p_2},\mathbf{p_3},\mathbf{p_4},\mathbf{p_5},\mathbf{p_6},\mathbf{p_7},\mathbf{p_8}]$. Using (13) (with the $\mathbf{p_i}$'s instead of $\mathbf{x_i}$'s) we get

$$|f(\mathbf{z}_1)-f(\mathbf{z}_2)|\leqslant|f(\mathbf{p}_1)-f(\mathbf{p}_2)|+|f(\mathbf{p}_3)-f(\mathbf{p}_4)|+|f(\mathbf{p}_5)-f(\mathbf{p}_6)|+|f(\mathbf{p}_7)-f(\mathbf{p}_8)|.\tag{20}$$

Note that we also have

$$|f(\mathbf{p}_{2i-1})-f(\mathbf{p}_{2i})|\leqslant f(\mathbf{p}_{2i-1})+f(\mathbf{p}_{2i}),\quad i=1,2,3,4.\tag{21}$$

By construction, if $\mathbf{a}$ is a node of G_3, so is $\sigma\mathbf{a}$. Therefore, the function $g(\mathbf{w})=f(\mathbf{w})+f(\sigma\mathbf{w})$ is well defined on G_3. Take the graphs $G_2[\mathbf{p_i},\mathbf{p},\mathbf{x_{8i-7}},\mathbf{x_{8i-6}},\mathbf{x_{8i-5}},\mathbf{x_{8i-4}},\mathbf{x_{8i-3}},\mathbf{x_{8i-2}},\mathbf{x_{8i-1}},\mathbf{x_{8i}}]$, $i=1,2,\ldots,8$.

Using (13), applied to the frame function g and these graphs, we get

$$|g(\mathbf{p_i})-g(\mathbf{p})|\leqslant|g(\mathbf{x_{8i-7}})-g(\mathbf{x_{8i-6}})|+|g(\mathbf{x_{8i-5}})-g(\mathbf{x_{8i-4}})| \\ +|g(\mathbf{x_{8i-3}})-g(\mathbf{x_{8i-2}})|+|g(\mathbf{x_{8i-1}})-g(\mathbf{x_{8i}})| \tag{22}$$

for $i=1,2,...,8$. Now consider the graphs $G_1[\mathbf{p},\mathbf{z},\mathbf{x_j}]$ for $j=1,2,...,64$ and the function g. Using Eqs. (2) we conclude that $g(\mathbf{x_j})\leqslant g(\mathbf{z})+2g(\mathbf{p})$. Since, by assumption $g(\mathbf{x_j})\geqslant g(\mathbf{z})-\varepsilon$, we have

$$|g(\mathbf{x_j})-g(\mathbf{x_k})|\leqslant\varepsilon+2g(\mathbf{p}),\quad j,k=1,2,...,64. \tag{23}$$

Remembering that

$$f(\mathbf{p_i})\leqslant g(\mathbf{p_i})\leqslant|g(\mathbf{p_i})-g(\mathbf{p})|+2\,f(\mathbf{p}),\quad i=1,2,...,8, \tag{24}$$

we can combine all this to get $|f(\mathbf{z_1})-f(\mathbf{z_2})|<144f(\mathbf{p})+32\varepsilon<176\varepsilon$. Thus, the entire proof of this inequality depends only on vectors in the big graph G_3.

IV. FINITE GLEASON'S THEOREMS

It is natural to ask at this stage whether we can obtain results analogous to Gleason's theorem on smaller or even finite subsets of directions in $\mathfrak{R}^3$. The first type of finite Gleason's theorem is obtained from the infinite theorem via the compactness theorem of classical logic:

Theorem 4: *Let $A\subseteq\mathfrak{R}_t$ be a nonempty finite set of non-negative real numbers. Then there is a finite subset $\Gamma\subset S^2$ such that every frame function on Γ with range in A is constant.*

The proof is a straightforward application of the compactness theorem.[7] The compactness theorem itself is not constructive, so it does not provide a clue about the structure of the set Γ, or even about its size. Naturally, the most important case is $A=\{0,1\}$. In this case Kochen and Specker's theorem provides an actual construction of Γ.[8] The general constructive case is, to the best of my knowledge, open.

However, we can think of other finite versions of Gleason's theorem. To see that, consider first the following corollary of Gleason's theorem: *Let f be a non-negative frame function on $\mathfrak{R}^3$. If there are three linearly independent unit vectors* **p**, **q**, *and* **r**, *such that $f(\mathbf{p})=f(\mathbf{q})=f(\mathbf{r})=0$, then $f\equiv0$.* The proof follows easily from Gleason's theorem: If $\mathbf{p}^{\mathrm{T}}W\mathbf{p}=\mathbf{q}^{\mathrm{T}}W\mathbf{q}=\mathbf{r}^{\mathrm{T}}W\mathbf{r}=0$ for a basis **p**, **q**, **r**, of $\mathfrak{R}^3$, and a non-negative definite matrix W, then clearly $W\equiv0$. The following lemma is a finite version of this assertion.

Lemma 5: Let **p** *and* **z** *be two linearly independent vectors in $\mathfrak{R}^3$ and let σ be a 90° rotation around* **p**. *Then there is a finite set of unit vectors $\Gamma_1(\mathbf{p},\mathbf{z})\subset S^2$ such that $\mathbf{p},\mathbf{z},\sigma\mathbf{z}\in\Gamma_1(\mathbf{p},\mathbf{z})$, and every non-negative frame function f on $\Gamma_1(\mathbf{p},\mathbf{z})$ which satisfies $f(\mathbf{p})=f(\mathbf{z})=f(\sigma\mathbf{z})=0$ is identically zero.*

Proof: If **p** is orthogonal to **z**, then $\sigma\mathbf{z}$ is orthogonal to both, and then the theorem follows trivially for $\Gamma_1(\mathbf{p},\mathbf{z})=\{\mathbf{p},\mathbf{z},\sigma\mathbf{z}\}$. Therefore, assume that $\mathbf{p}\cdot\mathbf{z}\neq\mathbf{0}$. Consider the graph $G_3(\mathbf{p},\mathbf{z},\mathbf{z_1},\mathbf{z_2})$ in (18) and (19). In the last section we proved that there is a number $\delta>0$ such that if $\mathbf{z_1},\mathbf{z_2}\in S^2$ satisfy $\|\mathbf{z_1}-\mathbf{z_2}\|<\delta$, then we can construct a set of vectors that satisfy the orthogonality relation in G_4. Moreover, the value of δ can be explicitly calculated once **p** and **z** are given. Let f be a frame function defined on the set of vectors in the graph $G_3(\mathbf{p},\mathbf{z},\mathbf{z_1},\mathbf{z_2})$ and satisfies $f(\mathbf{p})$ $f(\mathbf{p})=f(\mathbf{z})=f(\sigma\mathbf{z})=\mathbf{0}$. Then, using inequalities (20)–(24) with $\varepsilon=0$ we conclude that $f(\mathbf{z_1})=f(\mathbf{z_2})$. Now, let **q** be a vector orthogonal to **p** in the plane spanned by **p** and **z**, and let **r** be a vector orthogonal to **p** in the plane spanned by **p** and $\sigma\mathbf{z}$. Hence, **q** and $\mathbf{r}=\sigma\mathbf{q}$ are also orthogonal to each other. Let $\mathbf{z_0}=\mathbf{p},\mathbf{z_1},\mathbf{z_2},\ldots,\mathbf{z_m}=\mathbf{q}$ be unit vectors such that $\|\mathbf{z_i}-\mathbf{z_{i-1}}\|<\delta$, $i=1,2,...,m$. Define the graph

$$G_4(\mathbf{p},\mathbf{z})=G_3(\mathbf{p},\mathbf{z},\mathbf{z_0},\mathbf{z_1})\cup G_3(\mathbf{p},\mathbf{z},\mathbf{z_1},\mathbf{z_2})\cup\cdots\cup G_3(\mathbf{p},\mathbf{z},\mathbf{z_{m-1}},\mathbf{z_m}). \tag{25}$$

and let $\Gamma_1(\mathbf{p},\mathbf{z})$ be the set of all vectors (nodes) in the graph $G_4(\mathbf{p},\mathbf{z})$. If f is a non-negative frame function on $\Gamma_1(\mathbf{p},\mathbf{z})$ which satisfies $f(\mathbf{p})=f(\mathbf{z})=f(\sigma\mathbf{z})=\mathbf{0}$, then $\mathbf{0}=f(\mathbf{p})=f(\mathbf{z_1})=f(\mathbf{z_2})=\cdots=f(\mathbf{z_{m-1}})=f(\mathbf{q})$ and $\mathbf{0}=f(\mathbf{p})=f(\sigma\mathbf{z_1})=f(\sigma\mathbf{z_2})=\cdots=f(\sigma\mathbf{z_{m-1}})=f(\mathbf{r})$. Since $\mathbf{p}$, $\mathbf{q}$, $\mathbf{r}$ is an orthogonal triple the claim follows. ■

Note that the number of vectors in $G_4(\mathbf{p},\mathbf{z})$ depends on $\mathbf{p}$ and $\mathbf{z}$, since the number of copies of G_3 in (22) depends on the size of δ. It may be a large number, but the important thing is that it is finite and that G_4 is given by an explicit construction. It is possible that we can find a smaller graph that still does the job.

Let Γ be a nontrivial finite set of unit vectors in $\Re^3$. Call a non-negative frame function f on Γ *a state* if its weight is $C(f)=1$. Every non-negative frame function that is not identically zero can be normalized to be a state. Using Lemma 5 we can prove the following.

Theorem 6 (The Logical Indeterminacy Principle): *Let* $\mathbf{a}$ *and* $\mathbf{b}$ *be two linearly independent nonorthogonal unit vectors in* $\Re^3$. *Then there is a finite set of unit vectors* $\Gamma(\mathbf{a},\mathbf{b})$ *such that* $\mathbf{a},\mathbf{b}\in\Gamma(\mathbf{a},\mathbf{b})$ *and for which the following statements hold: (a) There is no state* f *on* $\Gamma(\mathbf{a},\mathbf{b})$ *which satisfies* $f(\mathbf{a})=f(\mathbf{b})=1$. *(b) There is no state* f *on* $\Gamma(\mathbf{a},\mathbf{b})$ *which satisfies* $f(\mathbf{a})=1$ and $f(\mathbf{b})=0$ *(c) There is no state* f *on* $\Gamma(\mathbf{a},\mathbf{b})$ *which satisfies* $f(\mathbf{a})=0$ and $f(\mathbf{b})=1$.

Proof: We can assume that the angle between $\mathbf{a}$ and $\mathbf{b}$ is strictly between 0 and $\frac{1}{2}\pi$. (If the angle is greater than $\frac{1}{2}\pi$, substitute $-\mathbf{b}$ for $\mathbf{b}$). Let $\mathbf{p}$ be a unit vector orthogonal to $\mathbf{a}$ in the plane spanned by $\mathbf{a}$ and $\mathbf{b}$, and let $\mathbf{z}$ be a vector orthogonal to $\mathbf{b}$ in the same plane. Let σ be a 90° rotation around $\mathbf{p}$. Then $\sigma\mathbf{a}$ is orthogonal to both $\mathbf{a}$ and $\mathbf{p}$. Also, let ρ be a 90° rotation around $\mathbf{z}$. Then $\rho\mathbf{b}=\sigma\mathbf{a}$ is orthogonal to both $\mathbf{b}$ and $\mathbf{z}$. Now define

$$G_5(\mathbf{a},\mathbf{b})=G_4(\mathbf{p},\mathbf{z})\cup G_4(\mathbf{p},\mathbf{b})\cup G_4(\mathbf{z},\mathbf{a})\cup\text{the triangle}\{\mathbf{a},\mathbf{p},\sigma\mathbf{a}\}\cup\text{the triangle}\{\mathbf{b},\mathbf{z},\sigma\mathbf{a}\}$$
$$\cup\text{the triangle}\{\mathbf{a},\sigma\mathbf{b},\sigma\mathbf{z}\}\cup\text{the triangle}\{\mathbf{z},\mathbf{b},\rho\mathbf{b}\}\cup\text{the edge}\{\mathbf{b},\rho\mathbf{a}\}. \tag{26}$$

Let $\Gamma(\mathbf{a},\mathbf{b})$ be the set of all unit vectors in the graph $G_5(\mathbf{a},\mathbf{b})$. Suppose first that f is a state on $\Gamma(\mathbf{a},\mathbf{b})$ such that $f(\mathbf{a})=f(\mathbf{b})=1$. Since $\mathbf{p}$ is orthogonal to $\mathbf{a}$ we have $f(\mathbf{p})=0$. Since $\mathbf{z}$ is orthogonal to $\mathbf{b}$ we have $f(\mathbf{z})=0$. Also $\sigma\mathbf{z}$ is orthogonal to $\mathbf{a}$ (for $\sigma\mathbf{z}$ lies in the plane spanned by $\mathbf{p}$ and $\sigma\mathbf{a}$) and therefore $f(\sigma\mathbf{z})=0$. By Lemma 5 we get that f is identically zero on $\Gamma_1(\mathbf{p},\mathbf{z})$, a contradiction. Next, assume that $f(\mathbf{a})=1$ and $f(\mathbf{b})=0$. Since $\mathbf{p}$ is orthogonal to $\mathbf{a}$ we have $f(\mathbf{p})=0$. We assumed $f(\mathbf{b})=0$ and since $\sigma\mathbf{b}$ is also orthogonal to $\mathbf{a}$ we have $f(\sigma\mathbf{b})=0$. Again, by Lemma 5, f is identically zero on $\Gamma_1(\mathbf{p},\mathbf{b})$, a contradiction. Finally assume that $f(\mathbf{a})=0$ and that $f(\mathbf{b})=1$. Since $\mathbf{z}$ is orthogonal to $\mathbf{b}$ we have $f(z)=0$, we assumed $f(\mathbf{a})=0$, and since $\rho\mathbf{a}$ is also orthogonal to $\mathbf{b}$ (it lies in the plane spanned by $\mathbf{z}$ and $\rho\mathbf{b}$) we have $f(\rho\mathbf{a})=0$. Hence, by Lemma 5, f is zero on $\Gamma_1(z,\mathbf{a})$, a contradiction. ■

One can probably find realizable graphs that are simpler than G_5 and still do the job.[9] Note that (with the obvious extension of the concept of state) *the last theorem generalizes immediately to any (real or complex) Hilbert space H of finite dimension three or higher*. To see that, we simply embed $\Gamma(\mathbf{a},\mathbf{b})$ into a three-dimensional subspace $H_3\subseteq H$. Next, we take every orthogonal triple in $\Gamma(\mathbf{a},\mathbf{b})$ and add to it unit vectors from H to make it an orthonormal basis of H (we can add the same extra vectors to all orthogonal triples). Clearly all these extra vectors are orthogonal to H_3. Let $\Gamma^*(\mathbf{a},\mathbf{b})=\Gamma(\mathbf{a},\mathbf{b})\cup\{\text{the new vectors}\}$. Then $\Gamma^*(\mathbf{a},\mathbf{b})$ is finite whenever H has a finite dimension. If f is a state on $\Gamma^*(\mathbf{a},\mathbf{b})$ such that $f(\mathbf{a})=1$ or $f(\mathbf{b})=1$, then f is zero on the set of vectors orthogonal to H_3. Therefore, the restriction of such a state f to $\Gamma(\mathbf{a},\mathbf{b})$ is a state on $\Gamma(\mathbf{a},\mathbf{b})$ *as a subset of a three-dimensional space*. Thus, we can use the proof of Theorem 6.

V. THE LOGICAL ORIGINS OF THE INDETERMINACY PRINCIPLE

In the quantum logical approach[10] every unit vector in a Hilbert space (or more precisely, every one-dimensional subspace) corresponds to an atomic proposition that describes some physically possible situation. Two orthogonal vectors correspond to the description of two mutually

exclusive situations. But what about two linearly independent vectors which are not orthogonal? These correspond to ''complementary'' descriptions (to borrow Bohr's terminology).

Furthermore, in this approach quantum states correspond to probability distributions over the set of atomic propositions. A given quantum state may assign an atomic proposition probability one (''true''). Then the state is pure. A quantum state may also assign an atomic proposition probability zero (''false''). In any of these extreme cases of probability zero and one the proposition is *determined by the state*. For a physical system in a known quantum state we can find out in advance (without a measurement) which propositions are determined by the state, and what is their truth value. But there is a limit to the wealth of *a priori* knowledge that is coded into the quantum state. Consider the following:

The Indeterminacy Principle: Let **a** *and* **b** *be two distinct nonorthogonal unit vectors. Then any quantum state* f *must satisfy*

$$f(\mathbf{a}), f(\mathbf{b}) \in \{\mathbf{0}, 1\} \quad \text{only if} \quad f(\mathbf{a}) = f(\mathbf{b}) = \mathbf{0}. \tag{27}$$

In other words, *no quantum state can determine two ''complementary'' propositions unless they are both false*. In case the dimension of the space is three or higher this principle follows easily from Gleason's theorem. Furthermore, Theorem 6 shows that this is, in fact, a *logical* principle in the sense that *it is a theorem of propositional quantum logic*. To see that, let us break the proof of Theorem 6 into two parts:

(1) *Logical or combinatorial part:* We can take the graphs G_5 in (26) as a representation of abstract logical relations in classical propositional logic. In other words, the vertices represent formal atomic propositions, two propositions are joined by an edge if they are mutually exclusive, and three propositions form a triangle if they are inclusive. We can ask for the properties of probability distributions defined on a set of atomic propositions that exhibit these logical relations. Since all the inequalities and identities (1)–(13) and (20)–(24) depend only on the abstract graph structure (that is, only on orthogonality relations and not on other facts) we conclude the following.
Let f *be a real probability distribution defined on the propositions (vertices) of* G_5. *Then* $f(\mathbf{a}), f(\mathbf{b}) \in \{0,1\}$ *only if* $f(\mathbf{a}) = f(\mathbf{b}) = 0$. In this formulation **a** and **b** stand for abstract formal propositions and not their interpretation as vectors.
(2) *Geometric part:* The graph G_5 is realizable as an orthogonality graph for a set of unit vectors $\Gamma(\mathbf{a},\mathbf{b})$ in $\Re^3$.

Notice, however, that the content of the indeterminacy principle is already present in the purely combinatorial part 1. The conclusion (24) holds regardless of the content we assign to the atomic propositions.

Quantum mechanics provides an example (model) of such a set of atomic propositions. More precisely, if we take seriously the quantum-logical interpretation of subspaces and orthogonality, then we can actually construct a set of physically meaningful propositions which exhibit the logical relations in G_5.

Seen in this light Theorem 6 belongs to the logical algebraic approach to quantum theory. This approach attempts to construct as large a part of quantum theory as possible on the basis of logical principles.[11] I believe that the advantages in the present case are quite apparent. There is nothing mysterious about indeterminacy (or ''complementarity'' in the above sense). We can actually construct a finite (and classical) model of a set of atomic propositions, together with the logical relations among them, which ''force'' every probability distribution on them to satisfy (24). The only nonclassical aspect left is the identification of rays (or unit vectors) as propositions and of the orthogonality relation as mutual exclusion. The geometric fact that G_5 is embeddable does the rest.

More broadly, Theorem 6 is part of the attempt to understand the mathematical foundations of quantum mechanics. In particular, it helps to make the distinction between its physical content and mathematical artifact clear.[12]

ACKNOWLEDGMENT

[4] R. Cooke, M. Keane, and W. Moran, Math. Proc. Camb. Philos. Soc. **98**, 117–128 (1985).

[5] Thychonov's lemma asserts that an (infinite) product of compact topological spaces is compact in the product topology. The authors are taking a product of *a continuum* of spaces. Tychonov's lemma for Hausdorf spaces is only slightly weaker than the axiom of choice. See, for example, T. J. Jech, *The Axiom of Choice* (North Holland, Amsterdam, 1973).

[6] G. Hellman, [J. Philos. Logic **22**, 193–203 (1993)] demonstrated that Gleason's theorem as a whole is nonconstructive (cannot be proved by intuitionistic means alone). In order to execute the second stage in the proof we have to assume that every continuous function on $S^{(2)}$ attains its minimum. This fact cannot be proved constructively. Two points should be mentioned, however. First, there are a multitude of constructive reformulations of the minimum principle. Second, it might be possible to use the combinatorial method below to establish bound on the *modulus of continuity* of every frame function, say, prove that every frame function is Lipschitz. This will provide a fully constructive proof of Gleason's theorem as well as Theorem 4 in text.

[7] For the case where A has two elements see J. L. Bell, in *Perspectives on Quantum Reality*, edited by R. Clifton, The University of Western Ontario Series in Philosophy of Science (Kluwer, Dordrecht, 1996), pp. 227–243, in particular the corollary after Theorem 1. The same technique generalizes easily to any finite set A.

[8] In the original proof of Kochen and Specker (Ref. 2) the number of elements of Γ is 117. The present record, due to Kochen and Conway (unpublished), is 31 vectors. See A. Peres, J. Phys. A **24**, L175–L178 (1991); R. Clifton, Am. J. Phys. **61**, 443–447 (1993); J. Zimba and R. Penrose, Stud. Hist. Philos. Sci. **24**, 697–720 (1993); J. Bub, Found. Phys. **26**, 787–812 (1996); J. Bub, *Interpreting the Quantum World* (Cambridge, U.P., Cambridge, 1997).

[9] For *some* choices of **a** and **b** we can find small graphs that satisfy *some* of the relations in theorem 6. For example, Kochen and Specker's 10-element graph [figure 21 in work by Redhead (Ref. 2)] satisfies $f(1)=1\rightarrow f(2)>0$ *for every frame function*. Similarly the subgraph obtained from it by deleting vertices {2,3} satisfies $f(1)=1\rightarrow f(4)<1$. However, these graphs can be realized only for particular choices of **a** and **b**. Since we deal with frame functions (and not just zero–one truth values), it is not possible to simply ''chain'' these graphs and obtain the general result.

[10] The remarks below apply equally well to the two major versions of quantum logic: the older version of G. Birkhoff and J. von Neumann, Ann. Math. **37**, 823–843 (1936), which allows for logical operations among arbitrary propositions, and the more recent (partial Boolean algebra) version of Kochen and Specker (Ref. 2), which does not.

[11] This approach is most explicit in Varadarajan (Ref. 2). For the Parial Boolean Algebras perspective, see S. Kochen, in *Perspectives on Quantum Reality*, The University of Western Ontario Series in Philosophy of Science edited by R. Clifton (Kluwer, Dordrecht, 1996), pp. 237–243. This paper also contains a report on a remarkable result by Conway and Kochen.

[12] An analysis that clarifies this distinction in the context of Bell's inequalities is in I. Pitowsky, *Quantum Probability Quantum Logic*, Lecture Notes in Physics, Vol. 321 (Springer-Verlag, Berlin, 1989); Math. Program. **50**, 359–414 (1991); Br. J. Philos. Sci. **45**, 95–125 (1994).

On the energy spectrum of the hydrogen atom in a photon field. I

Reese T. Prosser[a)]
Dartmouth College, Hanover, New Hampshire 03755

(Received 14 May 1996; accepted for publication 24 September 1997)

In 1930 Weisskopf and Wigner gave an account, based on the Maxwell–Schrödinger equations, of the natural spectral line broadening of radiation emitted by a hydrogen atom. Their calculations were based on an approximation involving certain single-photon transitions in the perturbation series for the solutions of these equations. In Part I of this series of papers the exact expressions for both the line shift and the line broadening are obtained from the Maxwell–Dirac equations in such a way that the Weisskopf–Wigner results appear as a second order approximation. The Maxwell–Dirac Hamiltonian for the coupled fields is first shown to admit a complex analytic dilation in the energy variables. The Fredholm–Born series for the resolvent is shown to converge uniformly when certain high-energy cutoff factors are included in the interaction and the photons are given a small mass. The series is then rearranged to show that the spectrum of the modified dilated Hamiltonian, which consists of a complete set of complex eigenvalues, thresholds, and branch cuts, is only a slight perturbation of the known spectrum of the dilated Hamiltonian for the uncoupled fields. The real part of the shift of each complex eigenvalue then accounts for the spectral line shift, and the complex part accounts for the associated line broadening. Finally, the implications for the scattering matrix and the various phenomena of resonance scattering are discussed. In Part II of this series these results are shown to remain valid when the cutoff factors and the photon mass are removed. © *1998 American Institute of Physics.*

I. INTRODUCTION

The energy spectrum of the relativistic hydrogen atom, according to one of the best known calculations in all of quantum mechanics, consists of the bound state energy levels:[1]

$$\mu+\epsilon_n=\mu\left[1+\frac{e^2}{(\gamma+n_r)^2}\right]^{-1/2}<\mu, \tag{1.1}$$

together with the continuum levels:

$$\mu+\epsilon=(\mu^2+p^2)^{1/2}\geqslant\mu. \tag{1.2}$$

Here, μ and e are the electron mass and charge in atomic units in which $\hbar=c=1$, $\gamma^2=\kappa^2-e^2$, $n=n_r+|\kappa|$ is the principal quantum number, and (j,m,κ) are the angular quantum momentum numbers, of the electron.

These levels appear in each angular momentum sector as the discrete or continuum eigenvalues of the Hamiltonian operator $H_{\rm el}$ associated with the Dirac equation in the absence of radiation, and as singularities in ζ in the matrix elements $\langle g|R_{\rm el}(\zeta)|f\rangle$ of the associated resolvent operator

[a)]The author is deceased, and Part II of the planned series was never completed. The author also had no chance of reading the proofs.

FIG. 1. Spectrum of the Hamiltonian $H_{\rm el}$ when $\theta=0$.

$R_{\rm el}(\zeta)=(H_{\rm el}-\zeta)^{-1}$. These singularities of the resolvent consist of poles at the discrete energy levels $\epsilon_n<\mu$ and a branch cut $[\mu,\infty)$ along the half-line of continuum energy levels ϵ (see Fig. 1).

If one restricts attention to a dense subset of energy states $|f\rangle$, $|g\rangle$ which admit a suitable analytic continuation $|f(\theta)\rangle$, $|g(\theta)\rangle$ into the open sector $S(\theta)=\{E:0\leqslant \arg E\leqslant\theta<\pi/2\}$ of the complex energy plane,[2–4] then the matrix elements $\langle g|H_{\rm el}|f\rangle$ made up from these states (the *analytic* matrix elements) will admit an analytic continuation into the same sector $S(\theta)$. It follows that on the Hilbert space $\mathfrak{h}_{\rm el}(\theta)$ of these analytic states the Hamiltonian $H_{\rm el}$ admits an *analytic dilation*, into the same sector $S(\theta)$. The spectrum of this analytic dilation $H_{\rm el}(\theta)$, acting on the Hilbert space $\mathfrak{h}_{\rm el}$ of analytic states $|f(\theta)\rangle$, is as shown in Fig. 2.

The presence of the radiation field changes this picture only slightly. If we adjoin a field of free photons with Hamiltonian $H_{\rm ph}$, then the spectrum of the (undilated) Hamiltonian $H_0=H_{\rm el}+H_{\rm ph}$ consists of the half-line $[\epsilon_1,\infty)$ with the eigenvalues $\epsilon_n>\epsilon_1$ embedded therein (see Fig. 3).

Moreover, the analytic matrix elements $\langle g|H_0|f\rangle$ of the Hamiltonian H_0 admit a similar analytic continuation into the same sector $S(\theta)$ of the complex energy plane. It follows that the Hamiltonian H_0 admits a similar analytic dilation $H_0(\theta)$ into the same sector $S(\theta)$, whose spectrum on the state space $\mathfrak{h}_0(\theta)$ is as shown in Fig. 4.

If we now introduce the interaction eH_1 between the electron and the radiation field, then it is generally believed that these energy levels are displaced slightly, down and to the left. Since the analytic matrix elements $\langle g|H_1|f\rangle$ of the interaction also admit an analytic continuation into the sector $S(E)$, it follows that the full Hamiltonian H also admits an analytic dilation $H(\theta)$ into this sector. The spectrum of the dilated Hamiltonian $H(\theta)$, acting on the state space $\mathfrak{h}_0(\theta)$, is thought to have the form shown in Fig. 5, in which the eigenvalues and continua are all displaced slightly to the left of, and (except for ϵ_1) slightly below their positions in Fig. 4. This displacement is a consequence of the interaction with the radiation field, and is known to be correct at least to second order in the interaction.[5,6]

It follows that the energy spectrum of the full Hamiltonian $H(\theta)$ of this system has precisely one real energy eigenvalue $\epsilon_1'<\epsilon_1$ in each angular momentum sector, associated with the ground state in that sector, and a half-line continuum $[\epsilon_1',\epsilon_1'+e^{-i\theta}\infty)$ with no embedded eigenvalues. The other discrete energy eigenvalues are now complex eigenvalues of the Hamiltonian, and they are associated with resonance scattering.

In this series of papers we propose to establish these results as rigorously as possible within the context of the quantized Maxwell radiation field interacting with the Dirac hydrogen atom in

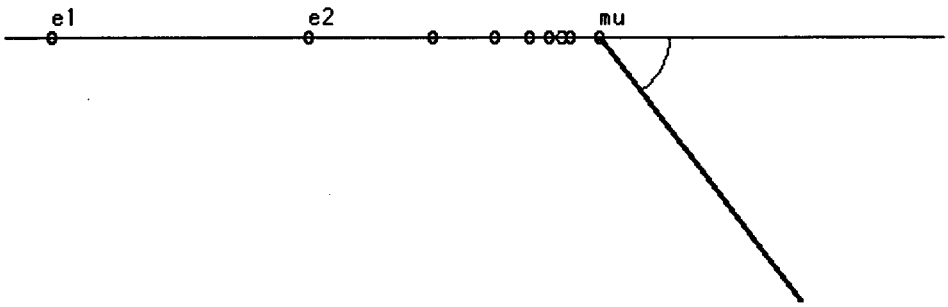

FIG. 2. Spectrum of the Hamiltonian $H_{\rm el}$ when $\theta=\pi/3$.

FIG. 3. Spectrum of the Hamiltonian H_0 when $\theta=0$.

the form described by Dirac.[6] We consider only positive-energy electron states, but we include the complete photon field, and contributions from all orders of the Born series. In order to achieve a convergent theory, however, we shall find in Part I that we must introduce cutoff factors into the interaction term at high (but not low) energies, and at large distances. Moreover, we find that we must give the photons an arbitrarily small mass $\nu>0$. The presence of a photon mass causes an essential change in the spectra of the Hamiltonian operators H_0 and H described here, in that each half-line in Figs. 4 and 5 splits into a simple eigenvalue and a bundle of half-lines, as shown in Fig. 6.

We shall see in Part II that all of the cutoff factors can be removed, and the photon mass can be removed, so that the final theory is a limiting case of a family of convergent theories for which all of these results are valid.

II. THE HAMILTONIAN

We take for the Dirac Hamiltonian $H_{\rm el}$ the form

$$H_{\rm el}=i\alpha\cdot\mathbf{grad}-\beta\mu-\frac{e^2}{r}, \tag{2.1}$$

with μ, e the electron mass and charge, and for the Maxwell Hamiltonian $H_{\rm ph}$ the form

$$H_{\rm ph}=\frac{1}{8\pi}\int[(\dot{\mathbf{A}})^2+(\mathbf{curl}\ \mathbf{A})^2+\nu^2(\mathbf{A})^2]d\mathbf{r}, \tag{2.2}$$

where ν is an arbitrarily small photon mass. As explained in Sec. VII below, we shall find it necessary to take $0<\nu\ll 1$ in order to ensure the convergence of the Fredholm–Born series. We denote by H_0 the Hamiltonian without interaction:

$$H_0=H_{\rm el}+H_{\rm ph}, \tag{2.3}$$

by eH_1 the interaction, with

$$H_1=\alpha\cdot\mathbf{A}, \tag{2.4}$$

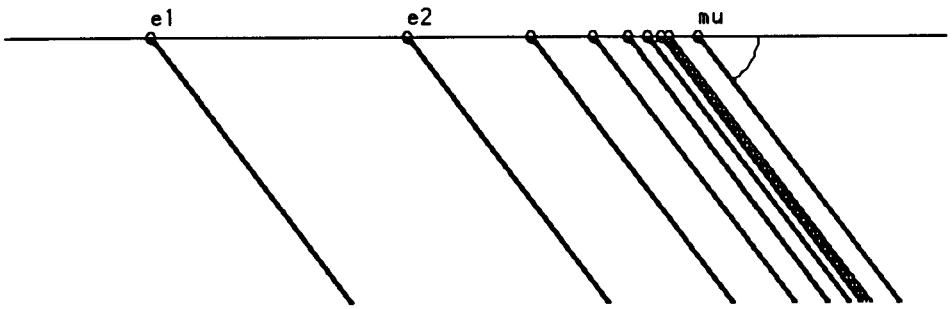

FIG. 4. Spectrum of the Hamiltonian H_0 when $\theta=\pi/3$.

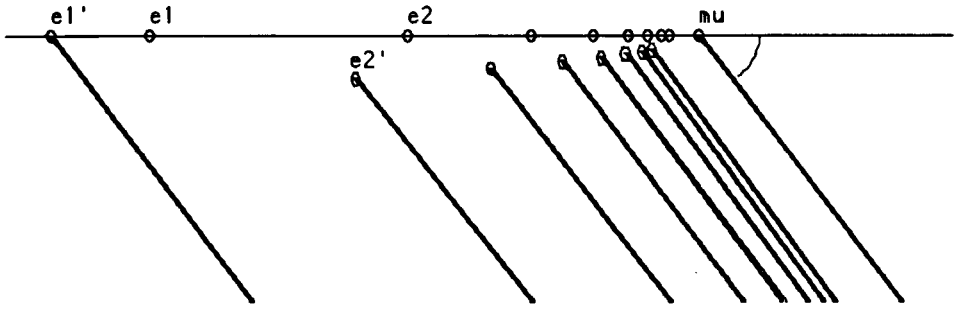

FIG. 5. Spectrum of the Hamiltonian H when $\theta=\pi/3$.

and by H the Hamiltonian with interaction:

$$H=H_0+eH_1, \tag{2.5}$$

with the coupling constant e eventually to be set equal to the electron charge e.

III. THE ELECTRON EIGENSTATES

The discrete eigenstates of the electron Hamiltonian $H_{\rm el}$ all have the form $|n,j,m,\kappa\rangle$, with n the principal quantum number and (j,m,κ) the angular quantum numbers. We shall find it convenient to suppress the dependence on (j,m,κ) and to parametrize the eigenstates by their energy ϵ_n as given by Eq. (1.1). Thus we write

$$|\epsilon_n\rangle=|n,j,m,\kappa\rangle \tag{3.1}$$

and

$$H_{\rm el}|\epsilon_n\rangle=(\mu+\epsilon_n)|\epsilon_n\rangle. \tag{3.2}$$

Similarly, the continuum eigenstates of $H_{\rm el}$ have the form $|p,j,m,\kappa\rangle$ with $p=|\mathbf{p}|$, $\mathbf{p}$ the electron momentum vector. We parametrize these states by their energy $\epsilon_p=(p^2+\mu^2)^{1/2}-\mu$ as given by Eq. (1.2), and write

$$|\epsilon\rangle=|\epsilon(p)\rangle=|p,j,m,\kappa\rangle \tag{3.3}$$

and

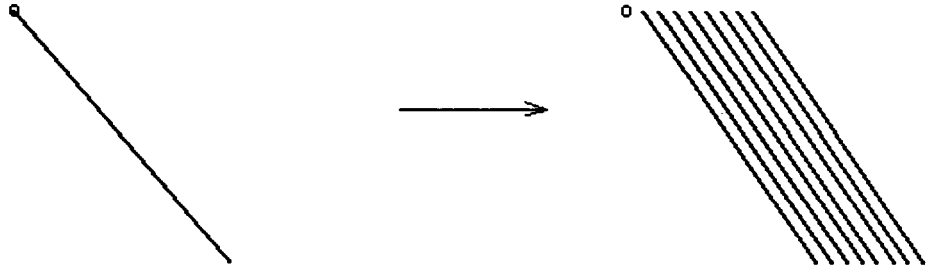

FIG. 6. Effect of replacing $\nu=0$ by $\nu>0$.

$$H_{\rm el}|\epsilon\rangle=(\mu+\epsilon)|\epsilon\rangle. \tag{3.4}$$

(For explicit descriptions of these states, see Ref. 1).

IV. THE PHOTON EIGENSTATES

The free photon states in the radiation field have the form $|k,j,m,\lambda\rangle$, with $k=|\mathbf{k}|$, $\mathbf{k}$ the photon momentum vector and (j,m,λ) the photon angular momentum quantum numbers. We parametrize these states by their energy $\omega_k=(k^2+\nu^2)^{1/2}-\nu$, and for these states we write

$$|\omega\rangle=|\omega(k)\rangle=|k,j,m,\lambda\rangle \tag{4.1}$$

and

$$H_{\rm ph}|\omega\rangle=(\nu+\omega)|\omega\rangle. \tag{4.2}$$

A typical eigenstate of the Hamiltonian $H_0=H_{\rm el}+H_{\rm ph}$, then, consists of the electron together with q photons ($q=0,1,2,...$), and has the form $|\epsilon,\omega_1,\omega_2,\ldots,\omega_q\rangle$, where ϵ takes on the discrete values ϵ_n when $\epsilon<0$ and the continuous values $\epsilon(p)$ when $\epsilon\geqslant 0$, and the ω_i take on the continuous values $\omega_i(k)$. For such states we have

$$H_0|\epsilon,\omega_1,\omega_2,\ldots,\omega_q\rangle=(\mu+q\nu+\epsilon+\omega_1+\cdots+\omega_q)|\epsilon,\omega_1,\omega_2,\ldots,\omega_q\rangle. \tag{4.3}$$

V. THE RESOLVENT $R_0(\zeta)$

Now let $R_0(\zeta)$ be the resolvent of H_0:

$$R_0(\zeta)=(H_0-\zeta)^{-1}. \tag{5.1}$$

Then for states of the form:

$$|f\rangle=\int\cdots\int f(\epsilon_n,\omega_1,\omega_2,\ldots,\omega_q)|\epsilon_n,\omega_1,\omega_2,\ldots,\omega_q\rangle d\omega_1\cdots d\omega_q, \tag{5.2}$$

we have for the matrix element $\langle g|R_0(\zeta)|f\rangle$ the expression

$$\langle g|R_0(\zeta)|f\rangle=\int\cdots\int\frac{\overline{g(\epsilon_n,\omega_1,\ldots,\omega_q)}f(\epsilon_n,\omega_1,\ldots,\omega_q)}{\mu+q\nu+\epsilon_n+\omega_1+\cdots+\omega_q-\zeta}\,d\omega_1\cdots d\omega_q. \tag{5.3}$$

It is clear that, as a function of ζ, this matrix element is analytic in the complex energy plane cut along the half-line $[\mu+\epsilon_n+q\nu,+\infty)$.

Now we choose the functions f and g in such a way that they admit analytic continuations separately in each ω_i to the half-plane $R1(\omega_i)>0$. We may take for these states the form

$$f(\epsilon_n,\omega_1,\ldots,\omega_q)=e^{-(\omega_1+\cdots+\omega_q)}p(\omega_1,\ldots,\omega_q), \tag{5.4}$$

where p is a polynomial in the ω_i. States of this form are known to be dense among all states of the form given in Eq. (5.2); we shall refer to them as *analytic states* (See Ref. 4 for details). If $|f\rangle$ and $|g\rangle$ are analytic states, then we can deform the paths of integration in Eq. (5.3) from $[0,+\infty)$ to $[0,+e^{-i\theta}\infty)$ for any θ in the interval $0<\theta<\pi/2$. Then we see that the matrix element $\langle f|R_0(\zeta)|g\rangle$ above is analytic in the complex ζ-plane cut along the half-lines $[\mu+\epsilon_n+q\nu,\mu+\epsilon_n+q\nu+e^{-i\theta}\infty)$ (see Fig. 4).

A similar argument holds for matrix elements $\langle g|R_0(\zeta)|f\rangle$ when f and g have the form

$$|f\rangle = \int \cdots \int f(\epsilon,\omega_1,\ldots,\omega_q)|\epsilon,\omega_1,\ldots,\omega_q\rangle d\epsilon\, d\omega_1\cdots d\omega_n, \tag{5.5}$$

with $\epsilon>0$, or when either one of the states f,g has the form of Eq. (5.2) and the other has the form of Eq. (5.5). Now if we choose f and g so that they admit analytic continuations separately in each ω_i to the half-plane $\mathrm{Re}(\omega_i)>0$ and in ϵ to the half-plane $\mathrm{Re}(\epsilon)>0$, then we can deform the integral paths in $\langle g|R_0(\zeta)|f\rangle$ as before, and see that the matrix element is analytic in the complex plane cut along the half-line $[\mu+q\nu,\mu+q\nu+e^{-i\theta}\infty)$, $0<\theta<\pi/2$ (see Fig. 4).

Linear combinations of such matrix elements, then, will be analytic in ζ in the complex plane cut by the half-lines $[\mu+q\nu+\epsilon_n,\mu+q\nu+\epsilon_n+e^{-i\theta}\infty)$ and $[\mu+q\nu,\mu+q\nu+e^{-i\theta}\infty)$. The points $\mu+\epsilon_n$ are poles of these matrix elements, while the points $\mu+\epsilon+q\nu$ for $q>0$ are logarithmic branch points.

VI. THE INTERACTION TERM

We write the interaction term H_1 in the angular momentum representation, using the analysis of Moses[7]

$$H_1=\alpha\cdot\mathbf{A}=\alpha\cdot(\mathbf{A}^+ + \mathbf{A}^-)=H_1^+ + H_1^-, \tag{6.1}$$

where $\mathbf{A}^+$ involves the creation of a new photon, and $\mathbf{A}^-$ the destruction of an old one. The matrix elements of $\mathbf{A}^+$ can be described as follows. If $|f\rangle$ and $|g\rangle$ are states of the form described in Eq. (5.5), with $\epsilon>0$, then

$$\langle g|\mathbf{A}^+|f\rangle=(q+1)^{1/2}\int \overline{g(\epsilon',\omega,\omega_1,\ldots,\omega_q)}F(\epsilon',\epsilon,\omega)f(\epsilon,\omega_1,\ldots,\omega_q)d\epsilon'\, d\epsilon\, d\omega\, d\omega_1\cdots d\omega_q. \tag{6.2}$$

Here, $F(\epsilon',\epsilon,\omega)$ is a function depending in a complicated way on the angular quantum numbers of the states $|\epsilon'\rangle$, $|\epsilon\rangle$ and $|\omega\rangle$, whose precise description is not important here (see Moses[7] for details). It is important, however, that the dependence of $F(\epsilon',\epsilon,\omega)$ on the energy variables can be expressed as a finite linear combination of integrals of the form

$$J(\epsilon',\epsilon,\omega)=\int_0^\infty f_1^\natural(ip'r)g_2^\natural(ipr)h^\natural(ikr)w(r)dr/r, \tag{6.3}$$

where $f^\natural$, $g^\natural$, and $h^\natural$ are the radial wave functions for the incoming and outgoing electron and the outgoing photon, which are given in terms of *confluent hypergeometric functions* $\Phi(a,c;z)$, and where w is a weight function inserted to improve the convergence of the integral. When $\epsilon>0$, the electron wave functions have the form

$$\begin{aligned} f^\natural(ipr)&=rf(r)=\frac{\Gamma(\gamma+1)}{\Gamma(2\gamma+1)}\left(\frac{\mu+\epsilon}{\epsilon}\right)^{1/2}(2ipr)^\gamma e^{ipr}\ \mathrm{Re}\ C_1\Phi(\gamma-i\nu,2\gamma+1,-2ipr),\\ g^\natural(ipr)&=rg(r)=\frac{\Gamma(\gamma+1)}{\Gamma(2\gamma+1)}\left(\frac{\mu-\epsilon}{\epsilon}\right)^{1/2}(2ipr)^\gamma e^{ipr}\ \mathrm{Im}\ C_1\Phi(\gamma-i\nu,2\gamma+1,-2ipr). \end{aligned} \tag{6.4}$$

When $\epsilon<0$, we can continue this form analytically in p from p to $\lambda=-ip$ and find

$$\begin{aligned} f^\natural(\lambda r)=rf(r)=+\frac{\Gamma(\gamma+1)}{\Gamma(2\gamma+1)}\left(\frac{\mu+\epsilon}{\epsilon}\right)^{1/2}(2\lambda)^{1/2}(2\lambda r)^\gamma e^{-\lambda r}[C_2\Phi(-n_r,2\gamma+1,2\lambda r)\\ +C_3\Phi(1-n_r,2\gamma+1,2\lambda r)], \end{aligned}$$

$$g^{\natural}(\lambda r)=rg(r)=-\frac{\Gamma(\gamma+1)}{\Gamma(2\gamma+1)}\left(\frac{\mu-\epsilon}{\epsilon}\right)^{1/2}(2\lambda)^{1/2}(2\lambda r)^{\gamma}e^{-\lambda r}[C_2\Phi(-n_r,2\gamma+1,2\lambda r) - C_3\Phi(1-n_r,2\gamma+1,2\lambda r)]. \tag{6.5}$$

The photon wave functions have the form

$$\begin{aligned} h^{\natural}(ikr)&=\frac{\Gamma(j+1)}{\Gamma(2j+2)}(2ikr)^{j+1}e^{ikr}C_4\Phi(j+1,2j+2,-2ikr), \quad \text{if } j+l_1+l_2=\text{odd},\\ &=\frac{\Gamma(j+1)}{\Gamma(2j+2)}(2ikr)^{j}e^{ikr}[C_5\Phi(j+1,2j+2,-2ikr)+C_6\Phi(j,2j+2,-2ikr)],\\ &\quad \text{if } j+l_1+l_2=\text{even}. \end{aligned} \tag{6.6}$$

Here and throughout, $j+l_1+l_2$ denote the usual angular quantum numbers, and the C_i denote normalization constants which normalize these wave functions to the energy scale.

The C_i are independent of the energy variables and bounded in the angular momentum variables. (See Ref. 1 for details.)

For the weight function $w(r)$ we assume the form

$$w(r)=e^{-\sigma\tau-\tau E}, \tag{6.7}$$

where

$$E=\mathrm{Re}(\epsilon'+\epsilon+\omega), \tag{6.8}$$

and $\sigma,\tau\ll 1$. Ultimately (in Part II), we shall want to take $\sigma,\tau\to 0$.

When the integration in J is carried out, the result can be expressed in terms of *Lauricella's hypergeometric function* $F_A^{(3)}$ (see Exton,[8] Chap. 2). When $j+l_1+l_2$ is odd, this expression takes the form

$$F^{+}(\epsilon_{n_2},\epsilon_{n_1},\omega)=\frac{(4\lambda_1\lambda_2)^{1/2}}{\Gamma(a)}\frac{\Gamma(j+1)}{\Gamma(2j+2)}x^{\gamma_1}y^{\gamma_2}z^{j+1}e^{-\tau E}C_7F_A^{(3)}(a;-n_{1r},-n_{2r},j+1;2\gamma_1+1,2\gamma_2+1,2j+2;x,y,z), \tag{6.9}$$

plus similar terms with the n_{ir} replaced with $n_{ir}-1$. Here, $a=\gamma_1+\gamma_2+j+1$, and the variables x,y,z are given by

$$x=\frac{2\lambda_1}{\sigma+\lambda_1+\lambda_2+ik}, \quad y=\frac{2\lambda_2}{\sigma+\lambda_1+\lambda_2+ik}, \quad z=\frac{2ik}{\sigma+\lambda_1+\lambda_2+ik}. \tag{6.10}$$

Note that $|x|<2$, $|y|<2$, $|z|<2$, $|x+y+z|<2$.

When $j+l_1+l_2$ is *even* this expression takes instead the form

$$F^+(\epsilon_{n_2},\epsilon_{n_1},\omega)=\frac{(4\lambda_1\lambda_2)^{1/2}}{\Gamma(a)}\frac{\Gamma(j+1)}{\Gamma(2j+2)}x^{\gamma_1}y^{\gamma_2}z^{j+1}e^{-\tau E}[C_8F_A^{(3)}(a;-n_{1r},-n_{2r},j+1;$$
$$2\gamma_1+1,2\gamma_2+1,2j+2;x,y,z)]+C_9F_A^{(3)}(a;-n_{1r},-n_{2r},j;2\gamma_1+1,2\gamma_2+1,$$
$$2j+2;x,y,z)], \tag{6.11}$$

plus similar terms with the n_{ir} replaced by $n_{ir}-1$. Here, $a=\gamma_1+\gamma_2+j$. From now on we consider in detail only the first of these cases; the second is entirely similar.

The Lauricella function $F_A^{(3)}$ is defined for $|x|+|y|+|z|<1$ by its power series:

$$F_A^{(3)}(a;b,b',b'';c,c',c'';x,y,z)=\sum_{m,n,p=0}^{\infty}\frac{(a)_{m+n+p}(b)_m(b')_n(b'')_p}{(c)_m(c')_n(c'')_p(1)_m(1)_n(1)_p}x^my^nz^p, \tag{6.12}$$

where

$$(a)_m=\frac{\Gamma(a+m)}{\Gamma(a)}. \tag{6.13}$$

In our case this can be rewritten as (see Exton,[7] Chap. 2)

$$F_A^3(a;-n_{1r},-n_{2r},j+1;2\gamma_1+1,2\gamma_2+1,2j+2;x,y,z)$$
$$=\sum_{m,n,p=0}^{\infty}\frac{(a)_{m+n+p}(-n_{1r})_m(-n_{2r})_n(j+1)_p}{(2\gamma_1+1)_m(2\gamma_2+1)_n(1)_m(1)_n(1)_p}x^my^nz^p, \tag{6.14}$$

with $a=\gamma_1+\gamma_2+j+1$. Here, the sums over m and n are finite, and the sum over p gives

$$F_A^{(3)}(a;-n_{1r},-n_{2r},j+1;2\gamma_1+1,2\gamma_2+1,2j+2;x,y,z)$$
$$=\sum_{m=0}^{n_{1r}}\sum_{n=0}^{n_{2r}}\frac{(a)_{m+n}(-n_{1r})_m(-n_{2r})_n}{(2\gamma_1+1)_m(2\gamma_2+1)_n(1)_m(1)_n}x^my^nF_A^{(1)}(a+m+n,j+1,2j$$
$$+2,z), \tag{6.15}$$

where $F_A^{(1)}(a,b,c,z)$ is *Gauss's hypergeometric function*. From *Euler's integral representation* for $F_A^{(1)}$,

$$F_A^{(1)}(a,b,c,z)=\frac{\Gamma(c)}{\Gamma(b)\Gamma(c-b)}\int_0^1\frac{(t)^{b-1}(1-t)^{c-b-1}}{(1-tz)^a}\,dt, \tag{6.16}$$

valid whenever $0<\mathrm{Re}(b)<\mathrm{Re}(c)$, we see that in our case the Gauss function $F_A^{(1)}$, and hence the Lauricella function $F_A^{(3)}$, as a function of z, admits an analytic continuation into the upper half z-plane. It can be shown (see Moses and Prosser[9] for details) that $F_A^{(1)}$ is bounded there by a constant times $|1-z|^{-1}$.

In our case we have

$$\tan(\pi/4-\phi/2)\leqslant|1-z|\leqslant 1 \tag{6.17}$$

when z is given by Eq. (6.10) with k replaced by $e^{-i\phi}k$. When $k^2=\omega^2+2\nu\omega$ and ω is replaced by $e^{-i\theta}\omega$, then $0\leqslant\phi<\theta<\pi/2$. It follows that the function $F(\epsilon_m,\epsilon_n,\omega)$, as a function of $\omega=(k^2+\nu^2)^{1/2}-\nu$, admits an analytic continuation into the sector

$$S(\omega)=\{e^{-i\theta}\omega:0\leqslant\theta\leqslant\theta_{\max}<\pi/2\}, \tag{6.18}$$

and is uniformly bounded there. In fact, since $|x|<2$, $|y|<2$, $|z|<2$, we have

$$|F^+(\epsilon_{n_2},\epsilon_{n_1},\omega)|\leqslant C_{10}\,\frac{(4\lambda_1\lambda_2)^{1/2}}{\tan(\pi/4-\theta/2)}\,\frac{(2)^a}{\Gamma(a)}\,\frac{\Gamma(j+1)}{\Gamma(2j+2)}\,(\lambda_1)^{\gamma_1}(\lambda_2)^{\gamma_2}(k)^{j+1}e^{-\tau k\cos\theta}. \tag{6.19}$$

A similar result holds, of course, for the case $j+l_1+l_2$ odd.

Analogous considerations hold if $\langle g|$ has the form described in Eq. (5.5). Then

$$\langle g|\mathbf{A}^+|f\rangle=(q+1)^{1/2}\int \overline{g(\epsilon',\omega_1,\ldots,\omega_q,\omega)}F^+(\epsilon',\epsilon_{n_1},\omega)f(\epsilon_{n_1},\omega_1,\ldots,\omega_q)d\epsilon'\;d\omega\;d\omega_1\ldots d\omega_q. \tag{6.20}$$

In this case the sum over m in Eq. (6.14) is finite, and the sums over n and p give (see Exton,[8] Chap. 2)

$$\begin{aligned}&F_A^{(3)}(a;-n_{1r},\gamma_2+1,j+1;2\gamma_1+1,2\gamma_2+1,2j+2;x,y,z)\\&\quad=\sum_{m=0}^{n_{1r}}\frac{(a)_m(-n_{1r})_m}{(2\gamma_1+1)_m(1)_m}\,x^mF_A^{(2)}(a+m;\gamma_2+1,j+1;2\gamma_2+1,2j+2;y,z)\end{aligned} \tag{6.21}$$

plus similar terms, where now $F_A^{(2)}(a;b,b';c,c';y,z)$ is *Appell's hypergeometric function* of two variables. From Euler's integral representation for $F_A^{(2)}$,

$$\begin{aligned}F_A^{(2)}(a;b,b';c,c';y,z)&=\frac{\Gamma(c)\Gamma(c')}{\Gamma(b)\Gamma(c-b)\Gamma(b')\Gamma(c'-b')}\\&\quad\times\int_0^1\int_0^1\frac{(s)^{b-1}(1-s)^{c-b-1}(t)^{b'-1}(1-t)^{c'-b'-1}}{(1-sy-tz)^a}\,ds\;dt,\end{aligned} \tag{6.22}$$

valid whenever $0<\mathrm{Re}(b)<\mathrm{Re}(c)$, $0<\mathrm{Re}(b')<\mathrm{Re}(c')$, we see that in our case the Appell function $F_A^{(2)}$, and hence the Lauricella function, $F_A^{(3)}$ admits an analytic continuation separately into the upper half y- and z-planes. Moreover, it can be shown (see Moses and Prosser[10]) that $F_A^{(2)}$ is bounded there by a constant times $\max\{|1-y|^{-1},|1-z|^{-1}\}$. In our case, we know that

$$\begin{aligned}|1-y|&=\frac{|\sigma+\lambda_1-i(p_2-k)e^{-i\theta}|}{|\sigma+\lambda_1+i(p_2+k)e^{-i\theta}|}>\frac{|\sigma+\lambda_1|}{|\sigma+\lambda_1+i(p_2+k)e^{-i\theta}|},\\|1-z|&=\frac{|\sigma+\lambda_1+i(p_2-k)e^{-i\theta}|}{|\sigma+\lambda_1+i(p_2+k)e^{-i\theta}|}=|1-y|.\end{aligned} \tag{6.23}$$

It follows that

$$|F^+(\epsilon',\epsilon_{n_1},\omega)|\leqslant C_{11}(2\lambda_1)^{1/2}\,\frac{1}{\Gamma(a)}\,\frac{\Gamma(\gamma_2+1)}{\Gamma(2\gamma_2+1)}\,\frac{\Gamma(j+1)}{\Gamma(2j+2)}\,|x'|^{\gamma_1}|y'|^{\gamma_2}|z'|^{j+1}e^{-\tau(\epsilon'+\omega)\cos\theta}, \tag{6.24}$$

where

$$x'=\frac{2\lambda_1}{\sigma+\lambda_1-ie^{-i\theta}q},\quad y'=\frac{2p_2}{\sigma+\lambda_1-ie^{-i\theta}q},\quad z'=\frac{2k}{\sigma+\lambda_1-ie^{-i\theta}q}, \tag{6.25}$$

with

$$q=|p_2-k|. \tag{6.26}$$

Since $|x'|<2$, $|y'|<2p_2/\sigma$, $|z'|<2k/\sigma$, it follows that the function $F(\epsilon_{p2},\epsilon_n,\omega)$ as a function of p_2 and k admits an analytic continuation into the sectors $S(p_2)$ and $S(k)$, where

$$\begin{aligned} S(p)&=\{e^{-i\theta}p:0\leqslant\theta\leqslant\theta_{\max}<\pi/2\},\\ S(k)&=\{e^{-i\theta}k:0\leqslant\theta\leqslant\theta_{\max}<\pi/2\}, \end{aligned} \tag{6.27}$$

and is uniformly bounded there. In fact, since $|x'|<2$, $|y'|<2p_2/\sigma$, $|z'|<2k/\sigma$, we have

$$\begin{aligned} |F^+(\epsilon',\epsilon_{n_1},\omega)|\leqslant C_{11}(2\lambda_1)^{1/2}\frac{(2/\sigma)^{\gamma_2+j+1}}{\Gamma(a)}\frac{\Gamma(\gamma_2+1)}{\Gamma(2\gamma_2+1)}\frac{\Gamma(j+1)}{\Gamma(2j+2)}\\ \times(\lambda_1)^{\gamma_1}(p')^{\gamma_2}(k)^{j+1}e^{-\tau(p'+k)\cos\theta}. \end{aligned} \tag{6.28}$$

A similar results holds, of course, for the case $j+l_1+l_2$ odd.

If both $\langle g|$ and $|f\rangle$ have the form in Eq. (5.5), then

$$\langle g|\mathbf{A}^+|f\rangle=\sqrt{q+1}\int\overline{g(\epsilon',\omega_1,\ldots,\omega_q,\omega)}F^+(\epsilon',\epsilon,\omega)f(\epsilon,\omega_1,\ldots,\omega_q)d\epsilon'\ d\epsilon\ d\omega\ d\omega_1\cdots d\omega_q. \tag{6.29}$$

In this case we proceed directly to Euler's integral representation for $F_A^{(3)}$:

$$\begin{aligned} &F_A^{(3)}(a;b,b',b'';c,c',c'';x,y,z)\\ &\quad=\frac{\Gamma(c)\Gamma(c')\Gamma(c'')}{\Gamma(b)\Gamma(c-b)\Gamma(b')\Gamma(c'-b')\Gamma(b'')\Gamma(c''-b'')}\\ &\qquad\times\int_0^1\int_0^1\int_0^1\frac{(r)^{b-1}(1-r)^{c-b-1}(s)^{b'-1}(1-s)^{c'-b'-1}(t)^{b''-1}(1-t)^{c''-b''-1}}{(1-rx-sy-tz)^a}\,dr\ ds\ dt, \end{aligned} \tag{6.30}$$

valid whenever $0<\mathrm{Re}(b)<\mathrm{Re}(c)$, $0<\mathrm{Re}(b')<\mathrm{Re}(c')$, $0<\mathrm{Re}(b'')<\mathrm{Re}(c'')$. From this representation we see that the Lauricella function $F_A^{(3)}$ admits an analytic continuation separately into the upper half x, y, and z planes. It can be shown that $F_A^{(3)}$ is bounded there by a constant times $\max\{|1-x|^{-1},|1-y|^{-1},|1-z|^{-1}\}$. In our case,

$$\begin{aligned} |1-x|&=\frac{|\sigma-i(p_1-p_2-k)e^{-i\theta}|}{|\sigma+i(p_1+p_2+k)e^{-i\theta}|}<1,\\ |1-y|&=\frac{|\sigma+i(p_1-p_2+k)e^{-i\theta}|}{|\sigma+i(p_1+p_2+k)e^{-i\theta}|}<1,\\ |1-z|&=\frac{|\sigma+i(p_1+p_2-k)e^{-i\theta}|}{|\sigma+i(p_1+p_2+k)e^{-i\theta}|}<1. \end{aligned} \tag{6.31}$$

This, with our weight function, leads to the estimate

$$|F^+(\epsilon',\epsilon_{p_1},\omega)|\leqslant C_{12}\frac{1}{\Gamma(a)}\frac{\Gamma(\gamma_1+1)}{\Gamma(2\gamma_2+1)}\frac{\Gamma(\gamma_2+1)}{\Gamma(2\gamma_2+1)}\frac{\Gamma(j+1)}{\Gamma(2j+2)}$$
$$\times|x'|^{\gamma_1}|y'|^{\gamma_2}|z'|^{j+1}e^{-2\tau(\epsilon'+\epsilon+\omega)\cos\theta}, \tag{6.32}$$

where

$$x'=\frac{2p_1}{\sigma-ie^{-i\theta}q},\quad y'=\frac{2p_2}{\sigma-ie^{-i\theta}q},\quad z'=\frac{2k}{\sigma-ie^{-i\theta}q}, \tag{6.33}$$

and

$$q=\min\{|-p_1+p_2+k|,|p_1-p_2+k|,|p_1+p_2-k|\}. \tag{6.34}$$

It follows that the function $F(\epsilon_{p2},\epsilon_{p1},\omega)$ as a function of p_1, p_2 and k admits an analytic continuation into the sectors $S(p_1)$, $S(p_2)$ and $S(k)$ [see Eq. (6.27)] and is uniformly bounded there. In fact, since $|x|<2p_1/\sigma$, $|y|<2p_2/\sigma$, $|z|<2k/\sigma$, we have

$$|F^+(\epsilon',\epsilon,\omega)|\leqslant C_{12}\frac{(2/\sigma)^a}{\Gamma(a)}\frac{\Gamma(\gamma_1+1)}{\Gamma(2\gamma_1+1)}\frac{\Gamma(\gamma_2+1)}{\Gamma(2\gamma_2+1)}\frac{\Gamma(j+1)}{\Gamma(2j+2)}$$
$$\times(p)^{\gamma_1}(p')^{\gamma_2}(k)^{j+1}e^{-\tau(\epsilon'+\epsilon+k)\cos\theta}. \tag{6.35}$$

We can now see that under our assumptions the matrix elements $F^+(\epsilon',\epsilon,\omega)$ are *square-summable* over the energy variables with respect to the measure

$$du=d\rho(\epsilon')d\rho(\epsilon)d\omega, \tag{6.36}$$

where we have set

$$d\rho(\epsilon)=\begin{cases}\sum_n \delta(\epsilon-\epsilon_n)d\epsilon & \text{if } \epsilon<0,\\ d\epsilon & \text{if } \epsilon\geqslant 0.\end{cases} \tag{6.37}$$

This becomes apparent if we recall that the electron quantum number κ is restricted to $|\kappa|\geqslant 1$, so that $\gamma=\sqrt{\kappa^2-e^2}$ is restricted to $\gamma\geqslant 1-e^2/2$, where $e^2=1/137\ll 1$. Hence for the bound states we can write

$$|F^+(\epsilon_{n_2},\epsilon_{n_1},\omega)|^2\leqslant C_{10}^2(\lambda_1\lambda_2)^{3-e^2}\left(\frac{2^a}{\Gamma(a)}\right)^2\left(\frac{j!k^{j+1}e^{-\tau k}}{(2j+1)!}\right)^2. \tag{6.38}$$

For the bound state $|\epsilon_n\rangle$ we have

$$\lambda_n^2=\mu^2-(\mu+\epsilon_n)^2=\mu e^2/2n^2-O(1/n^3), \tag{6.39}$$

so that

$$|F^+(\epsilon_{n_2},\epsilon_{n_1},\omega)|^2\leqslant C_{10}^2\left(\frac{\mu e^2}{n_1n_2}\right)^{3-e^2}\left(\frac{2^a}{\Gamma(a)}\right)^2\left(\frac{j!k^{j+1}e^{-\tau k}}{(2j+1)!}\right)^2. \tag{6.40}$$

It follows that this matrix element is square-integrable with respect to the energy measure du defined above. In this connection, note that

$$\sum_{n_1,n_2}\left(\frac{1}{n_1 n_2}\right)^2=\frac{\pi^4}{36}, \tag{6.41}$$

$$\int_0^\infty k^{2j+3}e^{-2\tau k\cos\theta}dk/k=\frac{(2j+2)!}{(\tau\cos\theta)^{2j+2}}, \tag{6.42}$$

and

$$\frac{(j!)^2}{2j+1!}\leqslant(2)^{-2j}. \tag{6.43}$$

Similarly, for the unbound electron states $|\epsilon\rangle$, we have

$$|F^+(\epsilon',\epsilon,\omega)|^2\leqslant C_{14}^2\left(\frac{\Gamma(\gamma_1+1)(p)^{\gamma_1}e^{-\tau p\cos\theta}}{\Gamma(2\gamma_1+1)}\right)^2\left(\frac{\Gamma(\gamma_2+1)(p')^{\gamma_2}e^{-\tau p'\cos\theta}}{\Gamma(2\gamma_2+1)}\right)^2$$
$$\times\left(\frac{\Gamma(j+1)(k)^{j+1}e^{-\tau k\cos\theta}}{\Gamma(2j+2)}\right)^2, \tag{6.44}$$

and so this matrix element is also square-integrable with respect to the measure du, thanks to the weight function $\omega(\tau)=e^{-\tau E}$.

Similar considerations hold, of course, for the matrix elements $F^+(\epsilon_{n_2},\epsilon_{p_1},\omega)$ and $F^+(\epsilon_{p_2},\epsilon_{n_1},\omega)$.

We shall use the notation

$$\|F^+\|^2=\int|F^+(\epsilon',\epsilon,\omega)|^2\,du \tag{6.45}$$

for the L^2 norm of F^+. We note that in all cases

$$\|F^+\|^2\leqslant C_{13}^2\frac{(\sigma\tau\cos\theta)^{-2a}}{\Gamma(a)^2}, \tag{6.46}$$

where $a=\gamma_1+\gamma_2+j+1$, and C_{13} is essentially independent of the angular quantum numbers.

Finally, we note that the matrix elements F^- of $\mathbf{A}^-$ are just the complex conjugates of the matrix elements F^+ of $\mathbf{A}^+$, and so yield to the same analysis with the same conclusions. In particular,

$$\|F^-\|^2=\|F^+\|^2. \tag{6.47}$$

We put

$$\|F\|^2=\sum_j(\|F_j^+\|^2+\|F_j^-\|^2), \tag{6.48}$$

where the sum is taken over the several components of the interaction.

VII. THE FREDHOLM–BORN SERIES

The *resolvent* $R(\zeta,e)=(H-\zeta)^{-1}$ of the Hamiltonian $H=H_0+eH_1$ can be expressed in terms of the resolvent $R_0(\zeta)=(H_0-\zeta)^{-1}$ of H_0 through the *resolvent equation*:

$$R(\zeta,e)=R_0(\zeta)-eR_0(\zeta)H_1R(\zeta,e). \tag{7.1}$$

If we solve this resolvent equation formally by iteration, we get the Fredholm–Born series:

$$R(\zeta,e)=\sum_{k\geqslant 0}(-e)^k(R_0(\zeta)H_1)^kR_0(\zeta)=R_0(\zeta)-eR_0(\zeta)H_1R_0(\zeta)+e^2R_0(\zeta)H_1R_0(\zeta)H_1R_0(\zeta)$$
$$-\cdots . \tag{7.2}$$

We can also write this equation in the form

$$R(\zeta,e)=R_0(\zeta)-R_0(\zeta)T_0(\zeta,e)R_0(\zeta), \tag{7.3}$$

where

$$T_0(\zeta,e)=\sum_{k\geqslant 0}(-e)^{k+1}(H_1R_0(\zeta))^kH_1=eH_1-e^2H_1R_0(\zeta)H_1+\cdots . \tag{7.4}$$

If ζ lies in the *resolvent set* $\rho(H_0)$ of H_0 (see Fig. 4), and if the operator $R_0(\zeta)H_1$ is bounded in the operator norm with bound b:

$$\|R_0(\zeta)H_1\|\leqslant b, \tag{7.5}$$

then when $eb<1$ the Fredholm–Born series converges in the operator norm to a unique solution $R(\zeta,e_0)$ of the resolvent equation.

Now the resolvent operator $R_0(\zeta)$, for ζ in $\rho(H_0)$ with $R1(\zeta)<\mu+\epsilon+\zeta_1$, is bounded on states $|f_q\rangle$ with q photons by

$$\|R_0(\zeta)\|f_q\rangle\|\leqslant\frac{1}{\delta(\zeta)}\,\||f_q\rangle\|, \tag{7.6}$$

where

$$\delta(\zeta)=\min\{|\zeta-\lambda|:\lambda\,\epsilon\sigma(H_0)\}=\operatorname{dist}\{\zeta,\sigma(H_0)\} \tag{7.7}$$

is the distance of ζ from the spectrum of H_0. It follows that

$$|\langle g_{q+1}|R_0(\zeta)H_1^+|f_q\rangle|^2\leqslant\frac{q+1}{\delta(\zeta-q\nu)^2}\,\|\langle g_{q+1}|\|^2\|F^+\|^2\||f_q\rangle\|^2. \tag{7.8}$$

We note here that, providing $\nu<\epsilon_1$,

$$\frac{q+1}{\delta(\zeta-q\nu)}=\frac{(q+1)\nu}{\nu\delta(\zeta-q\nu)}\leqslant\frac{q\nu+\epsilon_1}{\nu\delta(\zeta-q\nu)}\leqslant\begin{cases}\dfrac{\operatorname{Re}(\zeta)}{\nu\delta(\zeta)} & \text{when } q\nu<\operatorname{Re}(\zeta),\\[2ex] \dfrac{\epsilon_1}{\nu\delta(\zeta)} & \text{when } q\nu>\operatorname{Re}(\zeta).\end{cases} \tag{7.9}$$

It follows that, for all q

$$|\langle g_{q+1}|R_0(\zeta)H_1^+|f_q\rangle|^2\leqslant\frac{C_{14}}{\nu\delta(\zeta)\,\delta(\zeta-q\nu)}\,\|\langle g_{q+1}|\|^2\|F^+\|^2\||f_q\rangle\|^2, \tag{7.10}$$

where here $C_{14}=\max\{\operatorname{Re}(\zeta),\epsilon_1\}$. (Note the role of the photon mass ν in establishing this result.)

Hence

$$\|R_0(\zeta)H_1^+\|^2 \leqslant \frac{C_{14}}{\nu\delta(\zeta)^2}\,\|F^+\|^2. \tag{7.11}$$

Similarly,

$$\|R_0(\zeta)H_1^-\|^2 \leqslant \frac{C_{14}}{\nu\delta(\zeta)^2}\,\|F^-\|^2. \tag{7.12}$$

If we write

$$b(\zeta)^2 = \frac{C_{14}}{\nu\delta(\zeta)^2}\,\|F\|^2, \tag{7.13}$$

then we know that

$$\|R_0(\zeta)H_1\| \leqslant b(\zeta). \tag{7.14}$$

For fixed ζ in $\rho(H_0)$ and small values of e, or for fixed $e>0$ and $\mathrm{Re}(\zeta) \ll 0$, we have $eb(\zeta) < 1$; and for those values of e the Fredholm–Born series for the resolvent $R(\zeta)$ converges in operator norm. When $\zeta < 0$, of course, then

$$b(\zeta)^2 < \frac{C_{14}\|F\|^2}{\nu(\epsilon_1 - \zeta)^2}. \tag{7.15}$$

VIII. ANALYSIS OF THE FREDHOLM–BORN SERIES

First we observe that the angular momentum operators, including the parity and helicity operators, commute with both H_0 and H_1. This means that the state space breaks up into sectors with fixed values of the total angular momentum quantum numbers (J,M,Λ) (where $\Lambda =$ total helicity) and that these sectors are invariant under both H_0 and H_1. Moreover, since these sectors are orthogonal, the square of the norm of a typical state must be the sum of the squares of the norms of the projections of that state into each of the angular momentum sectors. A typical sector will include states of the form $|\epsilon_n, \omega_1, \ldots, \omega_q\rangle$, $q \geqslant 0$, together with all states which can be obtained from these by repeated application of the emission and absorption terms $H_1^{\pm}$ of the interaction operator. In particular, it will contain the bare electron states $|\epsilon_n\rangle$ obtained by absorption of the q photons. The angular quantum numbers of these bare electron states are already determined by the sector quantum numbers (J,M,Λ), so that these states are parametrized by their energy, as our notation suggests. We study in detail only the simplest of these sectors, for which $(J,M,\lambda) = (\frac{1}{2},0,\frac{1}{2})$, but the others can be treated in exactly the same way.

We begin our analysis be rewriting Eq. (7.2) in the form

$$R(\zeta,e) = (I - eK(\zeta) + e^2K(\zeta)^2 - \cdots)R_0(\zeta) = (I + eK(\zeta))^{-1}R_0(\zeta), \tag{8.1}$$

where now we have set

$$K(\zeta) = R_0(\zeta)H_1. \tag{8.2}$$

By the results of the previous section, we know that for $0 \leqslant \theta < \pi/2$, for $\zeta \ll 0$, and for $e \ll 1$ we have (See Eq. (7.14))

$$\|eK(\zeta,\theta)\| \leqslant eb < 1, \tag{8.3}$$

where

$$b^2=\frac{C_{14}\|F\|^2}{\nu(\epsilon_1-\zeta)^2}. \tag{8.4}$$

The Fredholm–Born series for $(I+eK(\zeta,\theta))^{-1}$ then converges in the operator norm, and we have

$$\|(I+eK)^{-1}\|\leqslant\sum_{k\geqslant 0}\|e_0K)\|^k\leqslant\frac{1}{1-eb}. \tag{8.5}$$

Moreover,

$$\begin{aligned}\|R\|&=\|(I+eK)^{-1}R_0\|\leqslant\frac{1}{1-eb}\,\frac{1}{\epsilon_1-\zeta},\\ \|R-R_0\|&=\|eR_0KR\|\leqslant\frac{eb}{1-eb}\,\frac{1}{\epsilon_1-\zeta}.\end{aligned} \tag{8.6}$$

Accordingly, we shall assume throughout this section that θ and ζ and e_0 are fixed, with $0<\theta<\pi/2$, $\zeta\leqslant 0$, and $e_0\leqslant 1$, and shall indicate explicitly the dependence of K on these variables only where relevant. Since the Fredholm–Born series converges in the operator norm, we are free to rearrange this series in any manner we please.

We now classify the states of our sector by the number q of photons present. In particular, we write $\mathfrak{h}_q$ for the space of those states with q photons present, i.e., the qth eigenspace of the photon number operator $N_{\rm ph}$. Thus

$$\mathfrak{h}_q=\{|f_q\rangle: f_q=f(\epsilon,\omega_1,\ldots,\omega_q)\}=\mathfrak{h}_{\rm el}\otimes\mathfrak{h}_{\rm ph}\otimes\cdots\otimes\mathfrak{h}_{\rm ph}\quad(q\ \text{ photons}), \tag{8.7}$$

where $\mathfrak{h}_{\rm el}$ and $\mathfrak{h}_{\rm ph}$ are the one-electron and one-photon state spaces. Then

$$\mathfrak{h}=\sum_q\ \mathfrak{h}_q=\mathfrak{h}_0+\mathfrak{h}_1+\mathfrak{h}_2+\cdots\ . \tag{8.8}$$

(We remark here that the space $\mathfrak{h}_q$ consists of states $|f_q(\epsilon,\omega_1,\ldots,\omega_q)\rangle$ which are *symmetric* in the photon energies ω_1. In rearranging the Fredholm–Born series we shall first ignore this symmetry in computing the matrix elements, and then symmetrize the results. We do this as usual by averaging over the initial states and summing over the final states for each matrix element.)

With this classification we write each operator B on $\mathfrak{h}$ as a matrix with operator entries of the form

$$B_{qp}=E_qBE_p, \tag{8.9}$$

where E_q denotes the orthogonal projection of $\mathfrak{h}$ onto $\mathfrak{h}_q$. In particular, we write

$$\begin{aligned}K_{qp}&=E_qKE_p,\\ (I+eK)^{-1}_{qp}&=E_q(I+eK)^{-1}E_p,\\ R(\zeta,e)_{qp}&=E_qR(\zeta,e)E_p=E_q(I+eK)^{-1}R_0(\zeta)E_p,\ \text{ etc.}\end{aligned} \tag{8.10}$$

We seek to determine these matrix elements $(I+eK)^{-1}_{qp}$ of the operator $(I+eK)^{-1}$.

In order to do so, we introduce the operators Q_q acting on the space $\mathfrak{h}_q$ by setting

$$Q_q=\sum_{k=2p>0}^{\infty}(-e)^{2p}\sum_{q_1,q_2,\ldots,q_{k-1}\geqslant q}K_{q,q_1}K_{q_1,q_2}\cdots K_{q_{k-1},q}, \tag{8.11}$$

where the sum here is restricted to those intermediate states with at least q photons. (Note that only the terms of even order can contribute to the sum over k.) We also introduce the raising and lowering operators $P_q^{\pm}$ by setting

$$\begin{aligned}P_q^+&=-(I+Q_q)eK_{q,q-1}^+,\\ P_q^-&=-eK_{q-1,q}^-(I+Q_q).\end{aligned} \tag{8.12}$$

We introduce the diagonal operators M_{qq} by setting inductively

$$\begin{aligned}I+M_{00}&=I+Q_0,\\ I+M_{(q+1)(q+1)}&=(I+Q_{q+1})+P_{q+1}^+(I+M_{qq})P_{q+1}^-,\end{aligned} \tag{8.13}$$

and the nondiagonal operators M_{rq} by setting

$$M_{rq}=\begin{cases}(I+M_{rr})P_{r+1}^-P_{r+2}^-\cdots P_q^- & \text{if } r<q,\\ P_r^+P_{r-1}^+\cdots P_{q+1}^+(I+M_{qq}) & \text{if } r>q.\end{cases} \tag{8.14}$$

Note that the diagonal operators $I+Q_q$ and $I+M_{qq}$, as well as the resolvent R_0, commute with the photon number operator N_{ph} and so leave the eigenspaces $\mathfrak{h}_q$ invariant.

Now, with these definitions, we can write the matrix for $(I+ek)^{-1}$ in the form

$$I+M=(I+eK)^{-1}, \tag{8.15}$$

or

$$\begin{pmatrix}I+M_{00}&M_{01}&M_{02}&\cdots\\ M_{10}&I+M_{11}&M_{12}&\cdots\\ M_{20}&M_{21}&I+M_{22}&\cdots\\ \vdots&\vdots&\vdots&\ddots\end{pmatrix}=\begin{pmatrix}I&K_{01}^-&0&\cdots\\ K_{10}^+&I&K_{12}^-&\cdots\\ 0&K_{21}^+&I&\cdots\\ \vdots&\vdots&\vdots&\ddots\end{pmatrix}^{-1}. \tag{8.16}$$

It follows that the matrix elements of the operator $(I+eK)^{-1}$, and hence of the resolvent $R=(I+eK)^{-1}R_0$, can each be expressed as a finite sum of products involving only the $K^{\pm}$ and the Q_q. In fact, if $r>q$, then

$$\begin{aligned}(I+eK)_{rq}^{-1}=(-e)^{r-q}&(I+Q_r)K^+(I+Q_{r-1})K^+\cdots K^+(I+Q_{q+1})K^+\sum_{0\leqslant k\leqslant q}(-e)^{2k}\\ &\times(I+Q_q)K^+\cdots K^+(I+Q_{q-k})K^-\cdots K^-(I+Q_q),\end{aligned} \tag{8.17}$$

while if $r\leqslant q$, then

$$\begin{aligned}(I+eK)_{rq}^{-1}=\sum_{0\leqslant k\leqslant q}&(-e)^{2k}(I+Q_r)K^+\cdots K^+(I+Q_{r-k})K^-\cdots K^-(I+Q_r)(-e)^{q-r}\\ &\times K^+(I+Q_{r+1})K^+\cdots K^+(I+Q_{q-1})K^+(I+Q_q).\end{aligned} \tag{8.18}$$

IX. ANALYSIS OF THE DIAGONAL OPERATORS Q_q

We now turn to an analysis of the diagonal operators Q_q [see Eq. (8.11)] acting on the spaces $\mathfrak{h}_q$. For this purpose we introduce

$$V_q=\sum_{k=2p>0}^{\infty}(-e)^{2p}\sum_{q_1,q_2,\ldots,q_{k-1}>q}K_{q,q_1}K_{q_1,q_2}\cdots K_{q_{k-1},q}, \tag{9.1}$$

where now the sum over the q_j is restricted to those intermediate states with at least $q+1$ photons present $(q_j>q)$. Then when $eb<1$, with $b^2=C_{14}\|F\|^2/\nu(\epsilon_1-\zeta)^2$, this series converges, and we have

$$\|V_q\|\leqslant\frac{(eb)^2}{1-(eb)^2}. \tag{9.2}$$

Moreover, we see that

$$Q_q=V_q+V_qQ_q. \tag{9.3}$$

By iteration,

$$Q_q=V_q+V_q^2+V_q^3+\cdots. \tag{9.4}$$

From the estimates above, we know that this series converges when $\|eK\|\leqslant eb<1/\sqrt{2}$, and then

$$\|I+Q_q\|\leqslant\frac{1-(eb)^2}{1-2(eb)^2},\quad I+Q_q=(I-V_q)^{-1}. \tag{9.5}$$

We also see that

$$V_q=e^2K^-(I+Q_{q+1})K^+. \tag{9.6}$$

If we combine Eq. (9.1) and Eq. (9.5), we find that

$$V_q=e^2K^-(I-V_{q+1})^{-1}K^+. \tag{9.7}$$

If we write this in the suggestive form

$$V_q=e^2\,\frac{K^-K^+}{(I-V_{q+1})}, \tag{9.8}$$

then after k iterations we get a sort of continued fraction expansion for V_q:

$$V_q=\cfrac{e^2K^-K^+}{1-\cfrac{e^2K^-K^+}{1-\cfrac{e^2K^-K^+}{\ddots\\ 1-\cfrac{e^2K^-K^+}{1-V_{q+k}}}}}. \tag{9.9}$$

X. ANALYSIS OF THE TRUNCATED RESOLVENT $F_qR(\zeta,e)F_q$

We now consider that part of the resolvent $R(\zeta,e)$ which acts on the subspace $\mathfrak{K}_q=\mathfrak{h}_0+\mathfrak{h}_1+\cdots+\mathfrak{h}_q$ of at most q photons. We let $F_q=E_0=E_1+\cdots+E_q$ be the projection on this subspace $\mathfrak{K}_q$, and consider the truncated resolvent

$$F_qR(\zeta,e)F_q=F_q(I+eK)^{-1}R_0F_q=F_q(I+eK)^{-}F_qR_0, \tag{10.1}$$

where

$$F_q(I+eK)^{-1}F_q=F_q(I+M)F_q=\begin{pmatrix} I+M_{00} & M_{01} & \cdots & M_{0q} \\ M_{10} & I+M_{11} & \cdots & M_{1q} \\ \vdots & \vdots & \ddots & \vdots \\ M_{q0} & M_{q1} & \cdots & I+M_{qq} \end{pmatrix}. \tag{10.2}$$

This operator is related to the operator $(I+M)_q=(I+eF_qKF_q)^{-1}$ acting on the subspace $\mathfrak{K}_q$. In matrix form,

$$\begin{pmatrix} (I+M_q)_{00} & (M_q)_{01}\cdots & (M_q)_{0q} \\ (M_q)_{10} & (I+M_q)_{11}\cdots & (M_q)_{1q} \\ \vdots & \ddots & \vdots \\ (M_q)_{q1} & (M_q)_{q2}\cdots & (I+M_q)_{qq} \end{pmatrix}=\begin{pmatrix} I & K^- & 0\ldots & 0 \\ K^+ & I & K^-\ldots & 0 \\ 0 & K^+ & I\ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0\ldots & I \end{pmatrix}^{-1}. \tag{10.3}$$

If we analyze the matrix form of the operator $I+M_q=((I+eF_qKF_q)^{-1})$ in the same way as we analyzed the matrix form of the operator $I+M=(I+eK)^{-1}$, we find the same structure:

$$\begin{aligned} (I+M_q)_{00}&=(I+Q_q)_0, \\ (I+M_q)_{ss}&=(I+Q_q)_s+(P_q)s_s^+(I+M_q)_{(s-1)(s-1)})(P_q)_s^-, \\ (M_q)_{sr}&=\begin{cases} (I+M_q)_{rr}(P_q)_{r+1}^-(P_q)_{r+2}^-\cdots(P_q)_s^- & \text{if } r>s, \\ (P_q)_r^+(P_q)_{r-1}^+\cdots(P_q)_{s+1}^+(I+M_q)_{ss} & \text{if } r<s, \end{cases} \\ (I+Q_q)_s)&=(I-V_q)_s^{-1}. \end{aligned} \tag{10.4}$$

Examination of the structure for $I+M_q$ reveals that it differs from the structure for $I+M$ only in the terms $(V_q)_s$; i.e., if we replace $(V_q)_s$ by V_s throughout, then $I+M_q$ becomes $I+M$. But [see Eq. (9.9)]

$$(V_q)_s=1-\cfrac{e^2K^-K^+}{1-\cfrac{e^2K^-K^+}{1-\cfrac{e^2K^-K^+}{\ddots}}} \qquad 1-\cfrac{e^2K^-K^+}{1-(V_q)_q} \tag{10.5}$$

while

$$V_s = 1 - \cfrac{e^2 K^- K^+}{1 - \cfrac{e^2 K^- K^+}{1 - \cfrac{e^2 K^- K^+}{\ddots \\ 1 - \cfrac{e^2 K^- K^+}{1 - V_q}}}}. \tag{10.6}$$

This shows that if we replace $(V_q)_q = 0$ by V_q in the continued fraction expansion of $(V_q)_s$, we get V_s. It follows that

$$I + M_q = \begin{pmatrix} I & eK^- & 0\ldots & 0 & 0 \\ eK^+ & I & eK^- \ldots & 0 & 0 \\ 0 & eK^+ & I \ldots & 0 & \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0\ldots & I & eK^- \\ 0 & 0 & 0\ldots & eK^+ & I \end{pmatrix}^{-1}, \tag{10.7}$$

while

$$F_q(I+M)F_q = \begin{pmatrix} I & eK^- & 0\ldots & 0 & 0 \\ eK^+ & I & eK^- \ldots & 0 & 0 \\ 0 & eK^+ & I \ldots & 0 & \\ \vdots & \vdots & \ddots & \vdots & \\ 0 & 0 & 0\ldots & I & eK^- \\ 0 & 0 & 0\ldots & eK^+ & I - V_q \end{pmatrix}^{-1}. \tag{10.8}$$

Since $R = (I+M)R_0$, and since

$$(I - V_q)^{-1} R_0 = ((H_0 - \zeta)(I - V_q))^{-1} = (H_0 - \zeta - U_q)^{-1}, \tag{10.9}$$

where

$$U_q = (H_0 - \zeta)V_q, \tag{10.10}$$

it follows that

$$F_q R(\zeta, e) F_q = (F_q (H_0 - \zeta - U_q) F_q)^{-1}, \tag{10.11}$$

or

$$F_q R(\zeta, e) F_q = \begin{pmatrix} H_0 - \zeta & eH_1^- & 0\ldots & 0 & 0 \\ eH_1^+ & H_0 - \zeta & eH_1^- \ldots & 0 & 0 \\ 0 & eH_1^+ & h_0 - \zeta \ldots & 0 & \\ \vdots & \vdots & \ddots & \vdots & \\ 0 & 0 & 0\ldots & H_0 - \zeta & eH_1^- \\ 0 & 0 & 0\ldots & eH_1^+ & H_0 - \zeta - U_q \end{pmatrix}^{-1}. \tag{10.12}$$

XI. THE CONNECTED COMPONENTS OF THE OPERATOR *M*

With each contribution of the form $((eK^{\pm})^m)_{qp}$ to the matrix element M_{qp} of $I+M$ we shall associate in the usual way a Feynman diagram, with one initial electron and p initial photon lines,

and one final electron and q final photon lines. (Note that two such contributions will have the same Feynman diagram if and only if they have the same symmetrization.) We say that an external photon line is *free* if it is not involved in the interaction, i.e., if it is not connected to the rest of the diagram, and is *interacting* otherwise. We classify each contribution by how many of these external photon lines in the associated Feynman diagram are interacting, i.e., are connected to the rest of the diagram. In general, there must be at least $|p-q|$ such photon lines, and can be at most $p+q$ such lines, so we can write

$$M_{qp}=M_{qp}^{(|p-q|)}+M_{qp}^{(|p-q|+2)}+\cdots+M_{qp}^{(p+q-2)}+M_{qp}^{(p+q)}, \tag{11.1}$$

there being $p\wedge q+1$ terms in all, where $p\wedge q=p+q-|p-q|=\min\{p,q\}$. Of these terms, $M_{qp}^{(p+q-2k)}$ is the sum of all contributions having a diagram with k free photon lines.

In particular, the components of $M_{qp}^{(p+1)}$ all have diagrams with no free photon lines, and so are connected. We refer to these components as *connected components*, and to all the others as *disconnected components*.

The connected components of M_{qp} of order m in e all have kernels of the form $M_{qp}(\epsilon',(\omega')_q;\epsilon,(\omega)_p)$ which involve all the $p+q$ photon lines, and so are nonsingular. In fact, according to Eqs. (7.11)–(7.12), these kernels are all square summable, with Hilbert–Schmidt norm given by

$$\|((eK)^m)_{qp}\|^2\leqslant\|eK\|_2^{2m}\leqslant(eb)^{2m}<1. \tag{11.2}$$

It follows that they determine a Hilbert–Schmidt operator from $\mathfrak{h}_p$ to $\mathfrak{h}_q$. The same is true of the sum $C_{qp}=M_{qp}^{(p+q)}$ of all the connected components of M_{qp}, once we show that this sum converges.

For $\{q,p\}=\{0,0\}$ we have

$$C_{00}=\left(\sum_{k>0}(eK)^{2k}\right)_{00}, \tag{11.3}$$

and it follows that C_{00} has Hilbert–Schmidt norm given by

$$\|C_{00}\|\leqslant\sum_{k>0}\|eK\|_2^{2k}=\frac{(eb)^2}{1-(eb)^2},\quad\text{where}\quad b^2=\|K\|_2^2\leqslant\frac{C\|F\|_2^2}{\nu(\epsilon_1-\zeta)^2}. \tag{11.4}$$

Similarly, for $\{q,p\}\neq\{0,0\}$,

$$C_{qp}=\left(\sum_{k\geqslant 0}(eK)^{p+q+2k}\right)_{qp}, \tag{11.5}$$

and so that C_{qp} has Hilbert–Schmidt norm given by

$$\|C_{qp}\|\leqslant\sum_{k\geqslant 0}\|eK\|_2^{p+q+2k}=\frac{(eb)^{p+q}}{1-(eb)^2}, \tag{11.6}$$

It now follows that the operator C defined by these matrix elements C_{qp} acts on the Hilbert space $\mathfrak{h}$ is a well-defined Hilbert–Schmidt operator, with Hilbert–Schmidt norm given by

$$\|C\|^2=\sum_{p,q\geqslant 0}\|C_{qp}\|_2^2\leqslant\sum_{p,q\geqslant 0}\frac{(eb)^{2p+2q}}{(1-(eb)^2)^2}=\frac{1}{(1-(eb)^2)^4}. \tag{11.7}$$

Now we turn to the sum $M_{qp}^{(|p-q|+2k)}$ of disconnected components with k free photon lines. For $p=q$ we have

$$M_{qq}^{(0)}=\left(\sum_{m>0}(eK)^{2m}\right)_{qq}, \tag{11.8}$$

so that

$$\|M_{qq}^{(0)}\|\leqslant\sum_{m>0}(eb)^{2m}=\frac{(eb)^2}{1-(eb)^2}, \tag{11.9}$$

and

$$M_{qq}^{(2k)}=\left(\sum_{m\geqslant 0}(eK)^{2k+2m}\right)_{qq}, \tag{11.10}$$

so that

$$\|M_{qq}^{(2k)}\|\leqslant\sum_{m\geqslant 0}(eb)^{2k+2m}=\frac{(eb)^{2k}}{1-(eb)^2}. \tag{11.11}$$

For $p\neq q$ we have

$$M_{qp}^{(|p-q|+2k)}=\left(\sum_{m\geqslant 0}(eK)^{|p-q|+2k+2m}\right)_{qp}, \tag{11.12}$$

so that

$$\|M_{qp}^{(|p-q|+2k)}\|\leqslant\sum_{m\geqslant 0}(eb)^{|p-q|+2k+2m}=\frac{(eb)^{|p-q|+2k}}{1-(eb)^2}. \tag{11.13}$$

Since

$$M_{qp}=M_{qp}^{(|p-q|)}+M_{qp}^{(|p-q|+2)}+\ldots+M_{qp}^{(p+q)}, \tag{11.14}$$

it follows that, for $p=q$,

$$\|M_{qq}\|\leqslant\frac{(eb)^2}{1-(eb)^2}+\sum_{k>0}\frac{(eb)^{2k}}{1-(eb)^2}\leqslant\frac{2(eb)^2}{(1-(eb)2)^2}, \tag{11.15}$$

while for $p\neq q$,

$$\|M_{qp}\|\leqslant\sum_{k\geqslant 0}\frac{(eb)^{|p-q|+2k}}{1-(eb)^2}=\frac{(eb)^{|p-q|}}{(1-(eb)^2)^2}. \tag{11.16}$$

If we sum these norms over p, we get

$$\sum_p\|M_{qp}\|\leqslant\frac{2(eb)^2}{(1-(eb)^2)^2}+2\sum_{p>q}\frac{(eb)^{p-q}}{(1-(eb)^2)^2}=\frac{2(eb)^2+2(eb)}{(1-(eb)^2)^2(1-eb)}\leqslant\frac{4(eb)}{(1-eb)^3}. \tag{11.17}$$

Since this holds for all q, we see that

$$\sup_q \sum_p \|M_{qp}\| \leqslant \frac{4eb}{(1-eb)^3}. \tag{11.18}$$

In the same way, we can see that

$$\sup_p \sum_q \|M_{qp}\| \leqslant \frac{2}{(1-eb)^3}. \tag{11.19}$$

It follows that the operator M defined on the Hilbert space $\mathfrak{h}$ by the matrix elements M_{qp} is well-defined, with operator norm bounded by

$$\|M\| \leqslant \frac{4eb}{(1-eb)^3}. \tag{11.20}$$

Because the components of the matrix elements $M_{qp}^{(|p-q|+2k)}$ are disconnected when $k>0$, however, their integral kernels are singular, and so M_{qp} is not a Hilbert–Schmidt operator on $\mathfrak{h}_p$, and hence M is not a Hilbert–Schmidt operator on $\mathfrak{h}$.

XII. THE TRANSFER MAPPING *T*

At this point we recall that every connected component of the matrix element M_{qp} for $M = eK(1-eK)^{-1}$ is a product of the form $((eK^{pm})^m)_{qp}$ whose diagram is connected, and whose norm is bounded by $(eb)^m$. If we now add k free photon lines to the associated diagram, we get a disconnected diagram which describes a component of the form $((eK^{\pm})^m)_{(q+k)(p+k)}$ of the matrix element $M_{(q+k)(p+k)}$, whose norm is bounded by eb_k^m, where b_k is obtained from b by replacing ϵ by $\epsilon_1 + k\nu$ throughout:

$$b_k^2 = \frac{C_{14}\|F\|}{\nu(\epsilon_1 + k\nu - \zeta)^2} \leqslant b^2. \tag{12.1}$$

Moreover, it is clear that every disconnected component of M_{qp}^{p+q-2k} can be obtained from a unique connected component of $M_{(q-k)(p-k)}^{p+q-2k}$ simply by adding k free photon lines to the associated diagram in this way.

This observation suggests that we introduce a *transfer mapping* T, which sends each component of the matrix element M_{qp} into the corresponding component of the matrix element $M_{(q+1)(p+1)}$ obtained by adding one additional free photon line to the associated diagram. This mapping has the effect of replacing $\{p,q\}$ by $\{p+1,q+1\}$, and ϵ_1 by $\epsilon_1+\nu$ throughout in the calculation of the components of $T(M_{qp})$. In this way we assign to the matrix M a new matrix $T(M)$ with elements $T(M)_{(q+1)(p+1)} = T(M_{qp})$. If we agree that $M_{qp}=0$ if $p<0$ or $q<0$, then elements in the top row and the first column of the matrix $T(M)$ are all zero, while each of the other element $T(M)_{qp}$ is obtained from the element $M_{(q-1)(p-1)}$ immediately above and to the left in the matrix:

$$T(M) = \begin{pmatrix} 0 & 0 & 0 & 0 & \cdots \\ 0 & T(M_{00}) & T(M_{01}) & T(M_{02}) & \cdots \\ 0 & T(M_{10}) & T(M_{11}) & T(M_{12}) & \cdots \\ 0 & T(M_{20}) & T(M_{21}) & T(M_{22}) & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}. \tag{12.2}$$

The discussion above shows that if the matrix M has bound $\|M\| \leqslant 4eb/(1-eb)^3$, then the matrix $T(M)$ has bound

$$\|T(M)\| \leqslant 4eb_1/(1-eb_1)^3, \quad \text{where } b_1 = \frac{\epsilon_1 - \zeta}{\epsilon_1 + \nu - \zeta}\, b < b. \tag{12.3}$$

We introduce iterates T^k of the transfer mapping T in the obvious way: $T^k(M) = T(T^{k-1}(M))$. Then $T^k M$ is obtained by adding k free photon lines to the Feynman diagram associated with each component of all the matrix elements M_{qp}, and we have

$$\|T^k(M)\| \leqslant \frac{4eb_k}{(1-eb_k)^3}, \quad \text{where } b_k = \left(\frac{\epsilon_1 + (k-1)\nu - \zeta}{\epsilon_1 + k\nu - \zeta}\right) b_{k-1} < b_{k-1}. \tag{12.4}$$

Using the transfer mapping and its iterates, we can write the matrix element M_{qp} solely in terms of the connected matrix elements C_{sr} as follows: if $p \geqslant q$, then

$$M_{qp} = M_{qp}^{(p+q)} + M_{qp}^{(p+q-2)} + \cdots + M_{qp}^{(p-q)} = C_{qp}^{(p+q)} + T(C_{(q-1)(p-1)}^{(p+q-2)}) + \cdots + T^q(C_{(q-q)(p-q)}^{(p-q)}), \tag{12.5}$$

and similarly if $p \leqslant q$. Formally, this equation tells us how to write the operators M in terms of the operators C:

$$\begin{aligned} M &= C + T(C) + T^2(C) + \cdots, \\ MR_0 &= CR_0 + T(CR_0) + T^2(CR_0) + \cdots. \end{aligned} \tag{12.6}$$

The first expression here is only formal, but the second converges in the operator norm. To see this, we estimate the norm of the right-hand side to get

$$\begin{aligned} \|MR_0\| &\leqslant \sum_{k \geqslant 0} \|T^k C R_0\| \leqslant \sum_{k \geqslant 0} \frac{4eb_k}{(1-eb_k)^3} \frac{1}{\epsilon_1 + k\nu - \zeta} \leqslant \frac{4eb}{(1-eb)^3} \sum_{k \geqslant 0} \frac{(\epsilon_1 - \zeta)^{1/2}}{(\epsilon_1 + k\nu - \zeta)^{3/2}} \\ &\leqslant \frac{4eb}{(1-eb)^3} \int_{-1}^{\infty} \frac{(\epsilon_1 - \zeta)^{1/2}) dx}{(\epsilon_1 + \nu x - \zeta)^{3/2}} \leqslant \frac{4eb}{(1-eb)^3} \frac{2(\epsilon_1 - \zeta)^{1/2}}{\nu(\epsilon_1 - \nu - \zeta)^{1/2}}, \end{aligned} \tag{12.7}$$

so that the series for MR_0 does converge to MR_0 in the operator norm.

We can rephrase this result as an operator equation:

$$MR_0 = CR_0 + T(MR_0) = CR_0 + T(M)R_0. \tag{12.8}$$

Multiplying on the right by $H_0 - \zeta$, we get

$$M = C + T(M), \tag{12.9}$$

which gives us an operator equation which must be satisfied by the operator M.

If we note that $F_0 R_0 = R_0 F_0$ and

$$R_0 = F_0 R_0 + T(R_0), \tag{12.10}$$

then we can write

$$R_0 + MR_0 = F_0 R_0 + CR_0 + T(R_0 + MR_0), \tag{12.11}$$

or

$$R = F_0 R_0 + CR_0 + T(R). \tag{12.12}$$

Similarly, if we note that

$$F_{q+1}=F_0+T(F_q),$$
$$M_{(q+1)(q+1)}=C_{(q+1)(q+1)}+T(M_{qq}), \tag{12.13}$$

then we can write

$$F_{q+1}(I+M)F_{q+1}=F_0+F_{q+1}CF_{q+1}+T(F_q(I+M)F_q), \tag{12.14}$$

which leads to a form for the truncated resolvent $R^{(q)}(\zeta)$:

$$R^{(q+1)}(\zeta)=F_{q+1}R(\zeta)F_{q+1}=F_0R_0(\zeta)+F_{q+1}C(\zeta)R_0(\zeta)F_{q+1}+T(F_qR(\zeta)F_q). \tag{12.15}$$

In the same way, we note that

$$K=F_1KF_1+T(K), \tag{12.16}$$

so that

$$I+K=F_0+F_1KF_1+T(I+K). \tag{12.17}$$

Moreover, if we write $V_q^{(2q)}$ for the connected part of V_q, then

$$V_{q+1}=V_{q+1}^{(2q+2)}+T(V_q). \tag{12.18}$$

It follows that

$$F_{q+1}(I+K-V_{q+1})F_{q+1}=F_0+F_1KF_1+V_{q+1}^{(2q+2)}+T(F_q(I+K-V_q)F_q). \tag{12.19}$$

This leads us to a form for the truncated Hamiltonian $H^{(q)}-\zeta$:

$$\begin{aligned}H^{(q+1)}-\zeta&=F_{q+1}(H_0-\zeta+eH_1-U_{q+1})F_{q+1}\\&=F_0(H_0-\zeta)F_0+F_1(eH_1)F_1-F_{q+1}U_{q+1}^{(2q+2)}F_{q+1}+T(F_q(H_0-\zeta+eH_1-U_q)F_q)\\&=F_0(H_0-\zeta)F_0+F_1(eH_1)F_1-F_{q+1}U_{q+1}^{(2q+2)}F_{q+1}T(H^{(q)}-\zeta)\\&=((I-T)(H_0-\zeta)+T(H^{(q)}-\zeta))+(F_1(eH_1)F_1-F_{q+1}U_{q+1}^{(2q+2)}F_{q+1}).\end{aligned} \tag{12.20}$$

We can write this as

$$H^{(q+1)}-\zeta=(H_1^{(q+1)}-\zeta)+(F_1(eH_1)F_1-F_{q+1}U_{q+1}^{(2q+2)}F_{q+1}), \tag{12.21}$$

where

$$H_1^{(q+1)}-\zeta=(I-T)(H_0-\zeta)+T(H^{(q)}-\zeta). \tag{12.22}$$

If we iterate this relation k times, we get

$$H^{(q+1)}-\zeta=(H_k^{(q+1)}-\zeta)+(F_k(eH_1)F_k-F_{q+1}(U_{q+1}^{(2q-2k)}+\cdots+U_{q+1}^{(2q+2)})F_{q+1}), \tag{12.23}$$

where

$$H_k^{(q+1)}-\zeta=(I-T^k)(H_0-\zeta)+T^k(H^{(q-k)}-\zeta). \tag{12.24}$$

XIII. ANALYSIS OF THE DIAGONAL OPERATORS V_q

We can write the diagonal operators V_q in the form

$$V_q = CV_q + DV_q, \tag{13.1}$$

where CV_q is the sum of the contributions from all the connected Feynman diagrams, and DV_q is the sum of the contributions from all the disconnected diagrams. We can write all contributions to the disconnected part DV_q of V_q entirely in terms of the contributions to the connected parts CV_p of V_p for $p \leqslant q$:

$$DV_q = T(CV_{q-1}) + T^2(CV_{q-2}) + \cdots + T^q(CV_0), \tag{13.2}$$

where the contributions in $T^j(CV_0)$ all have disconnected diagrams with exactly j disconnected photon lines.

Recall that CV_q denotes the sum of the terms with connected diagrams and so is Hilbert–Schmidt on $\mathfrak{h}_q$, with

$$\|CV_q\|_2 \leqslant (eb)^{2q} + (eb)^{2q+2} + \cdots = \frac{(eb)^{2q}}{1-(eb)^2}. \tag{13.3}$$

Moreover, V_q, and hence Q_q, can be expressed in terms of these operators CV_p, for $p \leqslant q$. In particular,

$$V_q = CV_q + T(CV_{q-1}) + \cdots + T^q(CV_0). \tag{13.4}$$

Now we turn to a closer analysis of the operator V_0. Since there are no contributions to $V_0 = CV_0 + DV_0$ from disconnected diagrams, we see that $DV_0 = 0$, so $V_0 = CV_0$. This means that V_0 is already a Hilbert–Schmidt operator on the space $\mathfrak{h}_0$, with

$$\|V_0\|_2 \leqslant \frac{(eb)^2}{1-(eb)^2}. \tag{13.5}$$

It follows that $Q_0 = V_0(I - V_0)^{-1}$ is also Hilbert–Schmidt, with

$$\|Q_0(\zeta, e^2\|_2 \leqslant \frac{(eb)^2}{1-2(eb)^2}. \tag{13.6}$$

We say that a Feynman diagram contains an *insertion* if it contains a proper subdiagram connected to the whole only by electron lines. We say a diagram is a *skeleton diagram* if it contains no insertion, and a nonskeleton diagram otherwise. (See Fig. 7 and Fig. 8.)

Each nonskeleton diagram can evidently be regarded as formed from a skeleton diagram by adding one or more insertions. It follows that each matrix element of the matrix $(I + eK)^{-1}$ can be regarded as formed by summing over all contributions from the different skeleton diagrams, each contribution formed by summing over all possible insertions into each of the electron lines in the skeleton. (See Fig. 9.)

Each insertion has the form

$$T^q(I + Q_0) = T^q((I - V_0)^{-1}), \tag{13.7}$$

where q here is the number of photon lines present in the skeleton at the point of insertion. If we write

$$I + Q_0' = (I + Q_0) + T(I + Q_0) + T^2(I + Q_0) + \cdots = (I - T)^{-1}(I + Q_0), \tag{13.8}$$

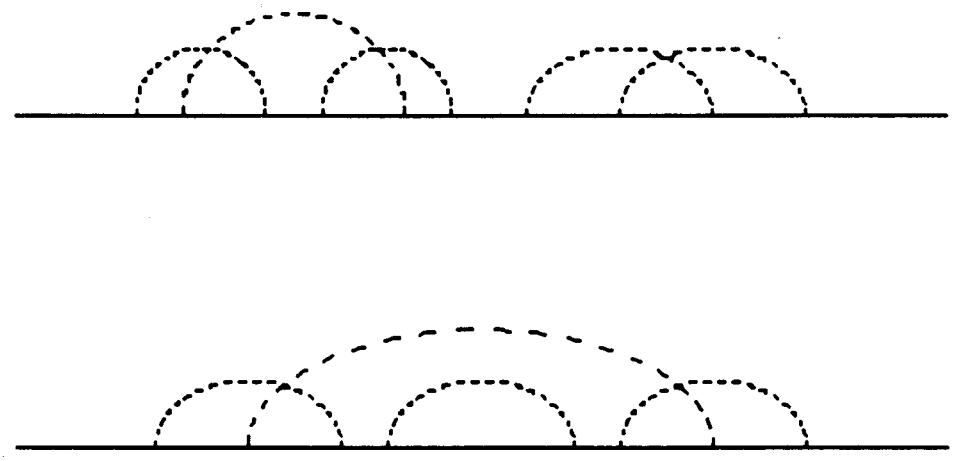

FIG. 7. Reducible vs irreducible graphs.

i.e.,

$$I+Q_0'=\begin{pmatrix} (I+Q_0) & 0 & 0 & 0 & \cdots \\ 0 & T(I+Q_0) & 0 & 0 & \cdots \\ 0 & 0 & T^2(I+Q_0) & 0 & \cdots \\ 0 & 0 & 0 & T^3(I+Q_0) & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}, \tag{13.9}$$

and similarly,

$$I-V_0'=(I-V_0)+T(I-V_0)+T^2(I-V_0)+\cdots=(I-T)^{-1}(I-V_0), \tag{13.10}$$

then we can write $(I+eK)^{-1}$ in the form

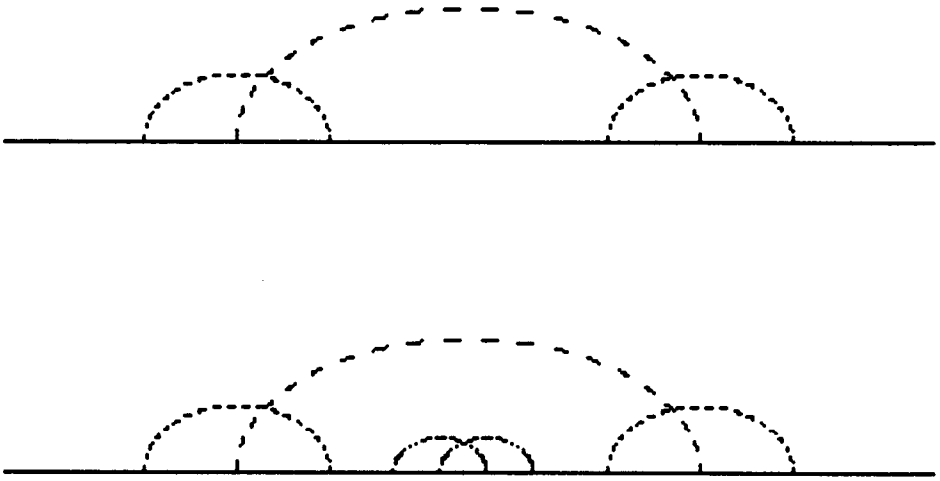

FIG. 8. Skeleton vs nonskeleton graphs.

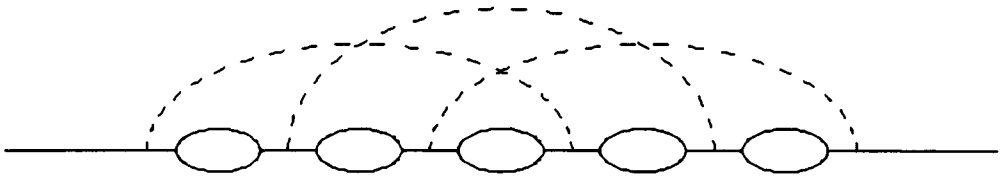

FIG. 9. Skeleton graph with insertions.

$$(I+eK)^{-1}=(I+Q_0')+\sum_{k>0}(-e)^k(((I+Q_0')K)^k(I+Q_0'))_{\mathrm{sk}}=(I-V_0')^{-1}$$

$$+\sum_{k>0}(-e)^k(((I-V_0')^{-1}K)^k(I-V_0')^{-1})_{\mathrm{sk}}, \tag{13.11}$$

where now the sums are restricted to those products associated with skeleton graphs. In this way we can express the resolvent $(I+eK)^{-1}$ in terms of the operator $(I-V_0')^{-1}$ and contributions from skeleton graphs.

In particular, this is also true of V_0 itself: V_0 can be expressed entirely in terms of $(I-V_0')^{-1}$ and contributions from skeleton graphs, in the form (see van Hove[11])

$$V_0'=\Phi(V_0'), \tag{13.12}$$

where

$$\Phi(V)=\sum_{k=2p>0}^{\infty}(-e)^k\Phi_k(V),$$

$$\Phi_k(V)=\sum_{q_1,q_2,\ldots,q_{k-1}>0}(K_{0,q_1}(I-V)^{-1}K_{q_1,q_2}(I-V)^{-1}\cdots(I-V)^{-1}K_{q_{k-1},0})_{\mathrm{sk}}. \tag{13.13}$$

To see this, we consider, for fixed $\zeta\ll 0$ in $\rho(H_0)$ and fixed $e\ll 1$, the class $\mathfrak{C}$ of bounded operators $V=V(\zeta,e^2)$ defined on $\mathfrak{h}_0$, with norm $\|V\|\leqslant 1/2$. If V is in this class, then $I-V$ is invertible, with $\|(I-V)^{-1}\|\leqslant 2$. Hence we can define the mapping Φ on the class $\mathfrak{C}$ by means of Eq. (13.13) above. If $\|eK\|\leqslant eb<1/3$, then

$$\|\Phi(V)\|\leqslant 2/5<1/2. \tag{13.14}$$

Hence if $\|eK\|\leqslant eb<1/3$, then Φ maps the class $\mathfrak{C}$ into itself. Moreover, if V and V' are any two members of this class, then we can establish the identity

$$\Phi(V)-\Phi(V')=\Phi(V)(I-V)^{-1}(V'-V)(I-V')^{-1}\Phi(V'), \tag{13.15}$$

and the bound

$$\|\Phi(V)-\Phi(V')\|\leqslant(16/25)\|V-V'\|. \tag{13.16}$$

It follows that $\Phi(V)$ is a *contraction mapping* on the class $\mathfrak{C}$. By the contraction mapping theorem, there is, for each ζ in $\rho(H_0)$ and for each e with $eb\leqslant 1/3$, a unique operator $V_0'=V_0'(\zeta,e^2)$ in $\mathfrak{C}$ for which

$$V_0'=\Phi(V_0'). \tag{13.17}$$

Moreover, we can construct V_0' recursively from the algorithm

$$V_0^{(0)}=0, \quad V_0^{(n)}=\Phi(V_0^{(n-1)}), \quad V_0^{(n)}\to V_0'. \tag{13.18}$$

Since each contribution to $V_0{}^{(n)}$ is a contribution to V_0, and since each contribution to V_0' is a contribution to some $V_0^{(n)}$, we see that $V_0^{(n)}$ must indeed converge to V_0', and that Eq. (13.12) must hold.

Now we can write the operator $R(\zeta,e)=(I+eK(\zeta))^{-1}R_0(\zeta)$ in the form

$$\begin{aligned} R(\zeta,e)&=\sum_{k\geqslant 0}(-e)^k(R_0(\zeta)H_1)^kR_0(\zeta)\\ &=\sum_{m>0}(-e)^m[((I-V_0'(\zeta e^2))^{-1}R_0(\zeta)H_1)^m(I-V_0'(\zeta,e^2))^{-1}R_0(\zeta)]_{\mathrm{sk}}. \end{aligned} \tag{13.19}$$

But

$$(I-V_0'(\zeta,^2))^{-1}R_0(\zeta)=((H_0-\zeta)(I-V_0'(\zeta,e^2)))^{-1}=(H_0-\zeta-U_0'(\zeta,e^2))^{-1}=R_0(\zeta,e^2), \tag{13.20}$$

where we have put

$$U_0'(\zeta,e^2)=(H_0-\zeta)V_0'(\zeta,e^2) \tag{13.21}$$

and

$$R_0'(\zeta,e^2)=(H_0-\zeta-U_0'(\zeta,e^2))^{-1}. \tag{13.22}$$

Hence

$$R(\zeta,e)=\sum_{m\geqslant 0}(-e)^m((R_0'(\zeta,e^2)H_1)^mR_0'(\zeta,e^2))_{\mathrm{sk}}. \tag{13.23}$$

We can also write this in the form

$$R(\zeta,e)=R_0'(\zeta,e^2)-R_0'(\zeta,e^2)T_0'(\zeta,e)R_0'(\zeta,e^2), \tag{13.24}$$

with

$$T_0'(\zeta,e)=\sum_{m\geqslant 0}(-e)^{m+1}((H_1R_0'(\zeta,e^2))^mH_1)_{\mathrm{sk}}. \tag{13.25}$$

We note that if we rewrite the Hamiltonian H in the form

$$H=(H_0-U_0'(\zeta,e^2))+(eH_1+U_0'(\zeta,e^2)), \tag{13.26}$$

then we can regard H as a *perturbation* of $(H_0-U_0'(\zeta,e^2))$ by $(eH_1+U_0'(\zeta,e^2))$. The effect of the correction $-U_0'(\zeta,e^2)$ to H_0 is to replace $R_0(\zeta)=(H_0-\zeta)^{-1}$ by $R_0'(\zeta,e^2)=(H_0-\zeta-U_0'(\zeta,e^2))^{-1}$ in the Fredholm–Born series for $R(\zeta,e)$; and the effect of the correction $+U_0'(\zeta,e^2)$ to eH_1 is to remove all terms with nonskeleton graphs from this series for $R(\zeta,e)$.

Finally, we note that $V_0(\zeta,e^2)$, and hence $U_0(\zeta,e^2)=(H_0-\zeta)V_0(\zeta,e^2)$, depends *analytically* upon ζ for ζ in $\rho(H_0)$ and analytically upon e^2 for $e^2\ll 1$. In particular,

$$V_0(\zeta,e^2)=\sum_{k>0}\frac{e^{2k}}{k!}V_0^{(k)}(\zeta), \tag{13.27}$$

where

$$V_0^{(k)}(\zeta)=(d/de^2)^k V_0(\zeta,e^2)|_{e^2=0} \tag{13.28}$$

is the sum of all products of order k in e^2 in the definition of V_0. Similarly,

$$U_0(\zeta,e^2)=\sum_{k>0}\frac{e^{2k}}{k!}U_0^{(k)}(\zeta), \tag{13.29}$$

where

$$U_0^{(k)}(\zeta)=(H_0-\zeta)V_0^{(k)}(\zeta). \tag{13.30}$$

This means that we can regard the operator $H_0-\zeta-U_0(\zeta,e^2)$ as an *analytic perturbation* of the operator $H_0-\zeta$ for fixed ζ in $\rho(H_0)$.

XIV. THE SPECTRUM OF THE FULL HAMILTONIAN $H=H(\theta)$

Now we can determine the spectrum of the dilated Hamiltonian $H(\theta)-\zeta$ for fixed dilation angle θ and complex energy ζ, with $0<\theta<\pi/2$ and $\zeta\epsilon\rho(H_0)$.

We begin with the free Hamiltonian operator $H_0-\zeta$ in matrix form:

$$H_0-\zeta=\begin{pmatrix}(H_0-\zeta)_{00} & 0 & 0 & \cdots\\ 0 & (H_0-\zeta)_{11} & 0 & \cdots\\ 0 & 0 & (H_0-\zeta)_{22} & \cdots\\ \vdots & \vdots & \vdots & \ddots\end{pmatrix}, \tag{14.1}$$

where $(H_0-\zeta)_{qq}$ acts on the space $\mathfrak{h}_q$ as multiplication by the free energy operator:

$$\begin{aligned}(H_0-\zeta)_{qq}|\epsilon,\omega_1,\ldots,\omega_q\rangle&=(H_{\rm el}+H_{\rm ph}-\zeta)_{qq}|\epsilon,\omega_1,\ldots,\omega_q\rangle\\&=(\mu+\epsilon+q\nu+\omega_1+\cdots+\omega_q-\zeta)|\epsilon,\omega_1,\ldots,\omega_q\rangle.\end{aligned} \tag{14.2}$$

It follows that the spectrum of $(H_0-\zeta)_{00}=(H_{\rm el}-\zeta)_{00}$, acting on $\mathfrak{h}_0$, consists of the discrete simple eigenvalues $\{\mu+\epsilon_m-\zeta\}$, together with the continuous half-line $L_{\mu-\zeta}$ (see Fig. 2), where

$$L_{\mu-\zeta}=\{(\mu-\zeta+e^{-1\theta}\epsilon(p)):0\leqslant p<\infty\}. \tag{14.3}$$

Similarly, the spectrum of $(H_0-\zeta)_{qq}=(H_{\rm el}+H_{\rm ph}-\zeta)_{qq}$, acting on $\mathfrak{h}_q$ for $q>0$, has no discrete eigenvalues but consists only of the continuous half-lines $L_{\mu+\epsilon_m+q\nu-\zeta}$ and $L_{\mu+q\nu-\zeta}$, where

$$L_{\mu+\epsilon_m+q\nu-\zeta}=\{(\mu+\epsilon_m+q\nu-\zeta+e^{-i\theta}(\omega_1+\cdots+\omega_q)):0\leqslant\omega_i<\infty\}, \tag{14.4}$$

and similarly for $L_{\mu+q\nu-\zeta}$. The spectrum of $H_0-\zeta$, of course, is the union of the spectra of all the $(H-\zeta)_{qq}$ (see Fig. 4 for the case $\nu=0$, and Fig. 6 for the case $\nu>0$).

If we now consider the operator $T(H_0-\zeta)$, obtained by applying the transfer mapping T to $H_0-\zeta$, we see that, since T adds one more free photon line to each Feynman diagram, $T(H_0-\zeta)$, acting on $\mathfrak{h}_{q+1}=\mathfrak{h}_q\otimes\mathfrak{h}_{\rm ph}$, has the form

$$T(H_0-\zeta)_{(q+1)(q+1)}=(H_0-\zeta)_{qq}\otimes I+I\otimes(H_{\rm ph}=(H_0-\zeta)_{(q+1)(q+1)}), \tag{14.5}$$

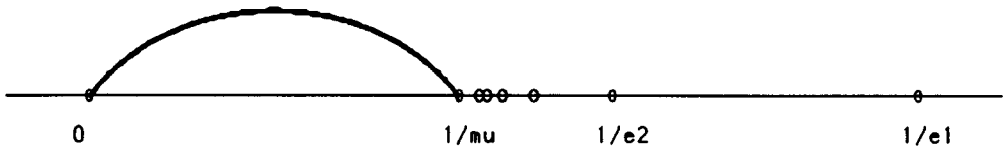

FIG. 10. Spectrum of the resolvent $R_{el}(0)=(H_{el})^{-1}$ when $\theta=\pi/3$.

so

$$T(H_0-\zeta)=\begin{pmatrix} 0 & 0 & 0 & \cdots \\ 0 & (H_0-\zeta)_{11} & 0 & \cdots \\ 0 & 0 & (H_0-\zeta)_{22} & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix}. \tag{14.6}$$

Hence the spectrum of $T(H_0-\zeta)_{(q+1)(q+1)}$, acting on $\mathfrak{h}_{q+1}$, has no discrete eigenvalues and consists only of the continuous half-lines $L_{\mu+\epsilon_m+(q+1)\nu-\zeta}$ and $L_{\mu+(q+1)\nu-\zeta}$. The spectrum of $T(H_0-\zeta)$ then consists of the union of all these half-lines.

The resolvent $R_0(\zeta)=(H_0-\zeta)^{-1}$ has the form

$$R_0(\zeta)=\begin{pmatrix} R_0(\zeta)_{00} & 0 & 0 & \cdots \\ 0 & R_0(\zeta)_{11} & 0 & \cdots \\ 0 & 0 & R_0(\zeta)_{22} & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix}, \tag{14.7}$$

where $R_0(\zeta)_{00}=(H_0-\zeta)_{00}^{-1}$. It follows by the spectral mapping theorem (see Reed and Simon,[12] Vol. IV, p. 109) that the spectrum of the resolvent $R_0(\zeta)_{00}=(H_0-\zeta)_{00}^{-1}$ for $\zeta\epsilon\rho(H_0)$ consists of the discrete eigenvalues $\{(\mu+\epsilon_m-\zeta)^{-1}\}$ together with the continuous circular arc $C_{\mu-\zeta}$, where

$$C_{\mu-\zeta}=(L_{\mu-\zeta})^{-1}=\{(\mu-\zeta+e^{-i\theta}\epsilon(p))^{-1}:0\leqslant p<\infty\}. \tag{14.8}$$

(See Fig. 10.)

Similarly, the spectrum of $(R_0(\zeta))_{qq}=(H_0-\zeta)_{qq}^{-1}$, acting on $\mathfrak{h}_q$ for $q>0$, has no discrete eigenvalues but consists of the continuous circular arcs $C_{\mu+\epsilon_m+q\nu-\zeta}$ and $C_{\mu+q\nu-\zeta}$, where

$$C_{\mu+\epsilon_m+q\nu-\zeta}=(L_{\mu+\epsilon_m+q\nu-\zeta}))^{-1}=\{(\mu+\epsilon_m+q\nu-\zeta+e^{-i\theta}(\omega_1+\cdots\omega_q))^{-1}:0\leqslant\omega_i<\infty\}, \tag{14.9}$$

and similarly for $C_{\mu+q\nu-\zeta}$. The spectrum of $R_0(\zeta)$ is then the union of the spectra of the $(R_0)_{qq}$ (see Fig. 11 for the case $\nu=0$, and Fig. 12 for the case $\nu>0$).

We note that this spectrum lies on or inside the quarter circle $S=\{z:|z|=(\epsilon_1-\zeta)^{-1}$, $\mathrm{Re}(z)\geqslant 0$, $\mathrm{Im}(z)\geqslant 0$, and so is bounded by this quarter circle.

Similarly, the operator $T(R_0(\zeta))=T((H_0-\zeta)^{-1})=(T(H_0-\zeta))^{-1}$ has the form

$$T(R_0(\zeta))=\begin{pmatrix} 0 & 0 & 0 & \cdots \\ 0 & R_0(\zeta)_{11} & 0 & \cdots \\ 0 & 0 & R_0(\zeta)_{22} & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix}. \tag{14.10}$$

It follows that the spectrum of $T(R_0(\zeta))$ has no eigenvalues, but consists only of the continuous circular arcs $C_{\mu+\epsilon_m+q\nu-\zeta}$ and $C_{\mu+q\nu-\zeta}$.

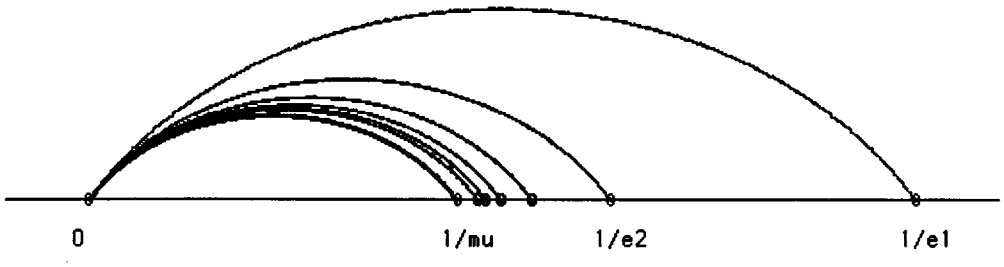

FIG. 11. Spectrum of the resolvent $R_0(0)=(H_0)^{-1}$ when $\theta=\pi/3$.

Now we consider the spectrum of the truncated resolvent operator $R(\zeta)_{00}=F_0R(\zeta)F_0$ acting on the space $\mathfrak{K}_0=\mathfrak{h}_0$:

$$R(\zeta)_{00}=F_0R(\zeta)F_0=F_0(R_0(\zeta)+M(\zeta)R_0(\zeta))F_0=R_0(\zeta)_{00}+M(\zeta)_{00}R_0(\zeta)_{00}$$
$$=R_0(\zeta)_{00}+C(\zeta)_{00}R_0(\zeta)_{00}. \tag{14.11}$$

This calculation shows that $R(\zeta)_{00}$ is a perturbation of $R_0(\zeta)_{00}$ by the compact operator $C(\zeta)_{00}R_0(\zeta)_{00}$. Standard perturbation theory for bounded operators (see Appendix A) now tells us that, for sufficiently small e, the continuous spectrum of $R_0(\zeta)_{00}$ remains unchanged, while the point spectrum may move, expand, or contract. In our case, for sufficiently small e, the continuous circular arc $C_{\mu-\zeta}$ of the spectrum of $R_0(\zeta)_{00}$ remains unchanged, while the discrete simple eigenvalues $(\mu+\epsilon_m-\zeta)^{-1}$ all migrate to nearby positions, which we choose to write as $(\mu+\epsilon_m^{(0)}-\zeta)^{-1}$ (see Fig. 13). We know (see Appendix A) that the eigenvalues $\mu+\epsilon_m^{(0)}=\mu+\epsilon_m^{(0)}\times(e^2)$ all depend analytically on e^2, with $\mu+\epsilon_m^{(0)}(0)=\mu+\epsilon_m$. Thus the spectrum of $R(\zeta)_{00}$ consists of the simple eigenvalues $(\mu+\epsilon_m^{(0)}-\zeta)^{-1}$ together with the circular arc $C_{\mu-\zeta}$. No other eigenvalues appear in the point spectrum of $R(\zeta)_{00}$, at least for sufficiently small values of e (see Appendix B). As e^2 increases, of course, these eigenvalues may disappear and other eigenvalues may appear; we are interested here only in small values of e^2.

We saw in the last section that on $\mathfrak{K}_0=\mathfrak{h}_0$ the operator $R^{(0)}(\zeta)=R(\zeta)_{00}=F_0R(\zeta)F_0$ has the form

$$R^{(0)}(\zeta)=(H^{(0)}-\zeta)^{-1}=((H_0-\zeta-U_0)_{00})^{-1}, \tag{14.12}$$

with $U_0=U_0(\zeta)=(H_0-\zeta)V_0(\zeta)$ and $H^{(0)}-\zeta=H_0-\zeta-U_0$. The spectral mapping theorem (see Ref. 12, Vol. IV, p. 109) now tells us that the spectrum of the operator $H^{(0)}-\zeta=(H_0-\zeta-U_0)_{00}$, acting on $\mathfrak{K}_0=\mathfrak{h}_0$, consists of the simple eigenvalues $\mu+\epsilon_m^{(0)}-\zeta$, together with the continuous half-line $L_{\mu-\zeta}$ (see Fig. 14).

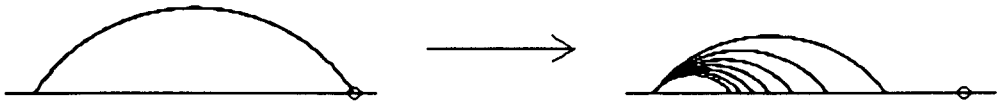

FIG. 12. Effect of replacing $\nu=0$ by $\nu>0$.

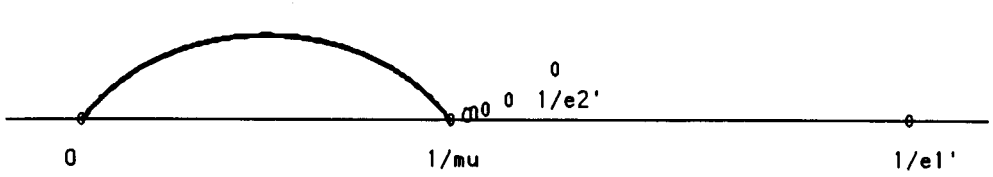

FIG. 13. Spectrum of the resolvent $R^{(0)}(0)=(H^{(0)})^{-1}$ when $\theta=\pi/3$.

From this result we see that the spectrum of the operator $(T(H_0^{(0)}-\zeta))_{11}=((H_0^{(0)}-\zeta)\otimes I+I\otimes(H_{\rm ph})_{11}$, acting on $\mathfrak{h}_1=\mathfrak{h}_0\otimes\mathfrak{h}_{\rm ph}$, consists of the sum of the spectra of $H_0^{(0)}-\zeta$ acting on $\mathfrak{h}_0$ and $H_{\rm ph}$ acting on the one-photon space $\mathfrak{h}_{\rm ph}$:

$$\sigma(T(H_0^{(0)}-\zeta))=\sigma(H_0^{(0)}-\zeta)+\sigma(H_{\rm ph}). \tag{14.13}$$

Thus the spectrum of $T(H_0^{(0)}-\zeta)_{11}$ consists of the half-lines $L_{\mu+\epsilon_m^{(0)}+\nu-\zeta}$ together with the half-line $L_{\mu+\nu-\zeta}$.

It follows that the spectrum of the operator

$$H_0^{(1)}-\zeta=(I-T)(H_0-\zeta)+T(H_0^{(0)}-\zeta)=\begin{pmatrix}(H_0-\zeta)_{00} & 0\\ 0 & T(H_0^{(0)}-\zeta)_{11}\end{pmatrix}, \tag{14.14}$$

acting on the subspace $\mathfrak{K}_1$, consists of the union of the eigenvalues $\mu+\epsilon_m-\zeta$ of $(H_0-\zeta)_{00}$ acting on $\mathfrak{h}_0$ and the half-lines $L_{\mu+\epsilon_m^{(0)}+\nu-\zeta}$ and $L_{\mu+\nu-\zeta}$ of $T(H_0^{(0)}-\zeta)_{11}$ acting on $\mathfrak{h}_1$.

By the spectral mapping theorem again, the spectrum of its inverse

$$(H_0^{(1)}-\zeta)^{-1}=\begin{pmatrix}(H_0-\zeta)_{00}^{-1} & 0\\ 0 & T(H_0^{(0)}-\zeta)_{11}^{-1}\end{pmatrix}, \tag{14.15}$$

or

$$R_0^{(1)}(\zeta)=\begin{pmatrix}R_0(\zeta)_{00} & 0\\ 0 & T(R_0^{(0)}(\zeta))_{11}\end{pmatrix}, \tag{14.16}$$

consists of the eigenvalues $(\mu+\epsilon_m-\zeta)^{-1}$, and the circular arcs $C_{\mu+\epsilon_m^{(0)}+\nu-\zeta}$ and $C_{\mu+\nu-\zeta}$.

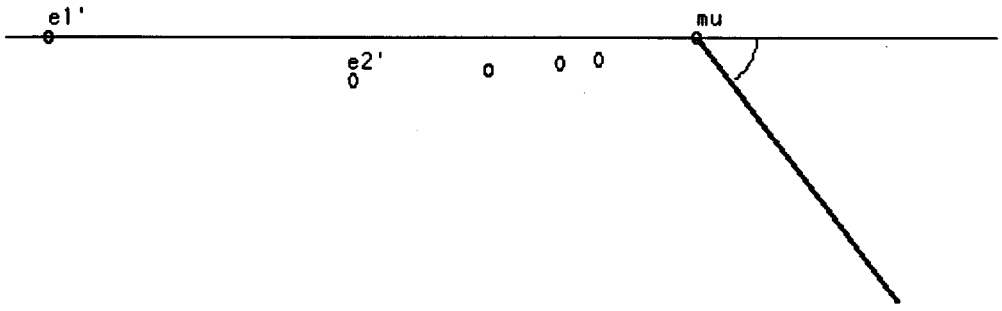

FIG. 14. Spectrum of the operator $H^{(0)}$ when $\theta=\pi/3$.

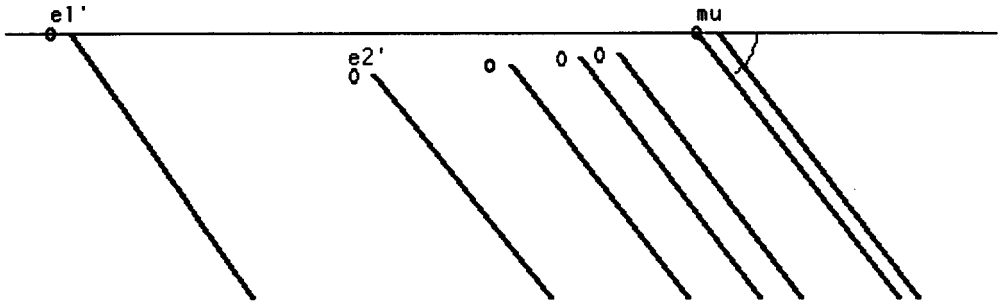

FIG. 15. Spectrum of the operator $H^{(1)}$ when $\theta=\pi/3$.

Now the truncated resolvent operator $F_1R(\zeta)F_1$, acting on $\mathfrak{K}_1$, is a compact perturbation of $(H^{(1)}-\zeta)^{-1}$:

$$\begin{aligned} F_1R(\zeta)F_1 &= F_1(R_0^{(1)}(\zeta)+C(\zeta)R_0(\zeta))F_1 \\ &= \begin{pmatrix} R_0(\zeta) & 0 \\ 0 & T(R_0^{(0)}(\zeta)) \end{pmatrix} + \begin{pmatrix} C_{00}(\zeta)R_0\zeta & C_{01}(\zeta)R_0(\zeta) \\ C_{10}(\zeta)R_0(\zeta) & C_{11}(\zeta)R_0(\zeta) \end{pmatrix}. \end{aligned} \tag{14.17}$$

It follows that the spectrum of $F_1R(\zeta)F_1$ acting on $\mathfrak{K}_1$ consists of the perturbed simple eigenvalues, which we write as $(\mu+\epsilon_m^{(1)}-\zeta)^{-1}$, together with the unperturbed circular arcs $C_{\mu+\epsilon_m^{(0)}+\nu-\zeta}$ and $C_{\mu+\nu-\zeta}$.

By the spectral mapping theorem again, the spectrum of its inverse $H^{(1)}-\zeta=(F_1R(\zeta)F_1)^{-1}$, acting on $\mathfrak{K}_1$:

$$H^{(1)}-\zeta=\begin{pmatrix} H_0-\zeta & 0 \\ 0 & T(H_0^{(0)}-\zeta) \end{pmatrix}+\begin{pmatrix} 0 & eH_1^- \\ eH_1^+ & U_1^{(2)} \end{pmatrix}, \tag{14.18}$$

consists of the eigenvalues $\mu+\epsilon_m^{(1)}-\zeta$ together with the half-lines $L_{\mu+\epsilon_m^{(0)}+\nu-\zeta}$ and $L_{\mu+\nu-\zeta}$ (see Fig. 15). Here, we write U_1 for

$$U_1=(H_0-\zeta)V_1=(H_0-\zeta)(V_1^{(2)}+V_1^{(0)})=U_1^{(2)}+U_1^{(0)}=U_1^{(2)}+T(U_0), \tag{14.19}$$

where $U_1^{(2)}=(H_0-\zeta)V_1^{(2)}$ is the connected part, and $U_1^{(0)}=T(U_0)$ is the disconnected part, of U_1.

Each of the functions $\epsilon_m^{(1)}=\epsilon_m^{(1)}(e^2)$ here is again an analytic function of e^2, with $\epsilon_m^{(1)}(0)=\epsilon_m$. They are possibly different from the functions $\epsilon_m^{(0)}(e^2)$ described above. In any case, $\mu+\epsilon_m^{(1)}$ is a singularity of the truncated resolvent operator $F_1R(\zeta)F_1$ at $\zeta=\mu+\epsilon_m^{(1)}$, just as $\mu+\epsilon_m^{(0)}$ is a singularity of the truncated resolvent operator $F_0R(\zeta)F_0$ at $\zeta=\mu+\epsilon_m^{(0)}$. But since

$$F_0R(\zeta)F_0=F_0(F_1R(\zeta)F_1)F_0, \tag{14.20}$$

we see that these singularities must agree, i.e., that $\epsilon_m^{(1)}(e^2)=\epsilon_m^{(0)}(e^2)$. Hereafter, we shall write this common value as $\epsilon_m'=\epsilon_m'(e^2)$.

Now we can proceed by induction on the photon number q. In the induction step we calculate the spectra of the relevant operators in the following order:

$$\sigma(H^{(q)}-\zeta)\to\sigma(T(H^{(q)}-\zeta))\to\sigma(H_0^{(q+1)}-\zeta)\to\sigma(R_0^{(q+1)}(\zeta))\to\sigma(R^{(q+1)}(\zeta))\to\sigma(H^{(q+1)}-\zeta). \tag{14.21}$$

Suppose we have shown that the spectrum of the operator $H^{(q)}-\zeta$, acting on the subspace $\mathfrak{K}_q$, consists of the eigenvalues $\mu+\epsilon_m^{(q)}-\zeta$ together with the half-lines $L_{\mu+\epsilon_m^{(q-j)}+j\nu-\zeta}$ and $L_{\mu+j\nu-\zeta}$ for $1\leqslant j\leqslant q$. Then the spectrum of the operator $T(H^{(q)}-\zeta)$, acting on the subspace $\mathfrak{K}_{(q+1)}$, consists of the eigenvalue 0, together with the half-lines $L_{\mu+\epsilon_m^{(q-j)}+(j+1)\nu-\zeta}$ and $L_{\mu+(j+1)\nu-\zeta}$ for $0\leqslant j\leqslant q$, and so the spectrum of the operator $H_0^{(q+1)}-\zeta=(I-T)(H_0-\zeta)+T(H^{(q)}-\zeta)$, acting on $\mathfrak{K}_{(q+1)}$, consists of the eigenvalues $\mu+\epsilon_m-\zeta$ together with the half-lines $L_{\mu+\epsilon_m^{(q+1-j)}+j\nu-\zeta}$ and $L_{\mu+j\nu-\zeta}$ for $1\leqslant j\leqslant q+1$.

By the spectral mapping theorem we know that the spectrum of its inverse $R_0^{(q+1)}(\zeta)=(H_0^{(q+1)}-\zeta)^{-1}$ consists of the eigenvalues $(\mu+\epsilon_m-\zeta)^{-1}$ together with the circular arcs $C_{\mu+\epsilon_m^{(q+1-j)}+j\nu-\zeta}$ and $C_{\mu+j\nu-\zeta}$ for $1\leqslant j\leqslant q+1$. Since the bounded operator $R^{(q+1)}(\zeta)=(H^{(q+1)}-\zeta)^{-1}$, which has the form

$$R^{(q+1)}(\zeta)=F_{q+1}R(\zeta)F_{q+1}=F_{q+1}(R_0(\zeta)+M(\zeta)R_0(\zeta))F_{q+1}$$
$$=R_0^{(q+1)}(\zeta)+F_{q+1}C(\zeta)R_0(\zeta)F_{q+1}, \tag{14.22}$$

is a compact perturbation of the bounded operator $R_0^{(q+1)}(\zeta)=(H_0^{(q+1)}-\zeta)^{-1}$, it follows that the spectrum of $R^{(q+1)}(\zeta)=(H^{(q+1)}-\zeta)^{-1}$ consists of the eigenvalues $(\mu+\epsilon_m^{(q+1)}-\zeta)^{-1}$ together with the circular arcs $C_{\mu+\epsilon_m^{(q+1-j)}+j\nu-\zeta}$ and $C_{\mu+j\nu-\zeta}$ for $1\leqslant j\leqslant q+1$. Finally, by the spectral mapping theorem again, the spectrum of the operator $H^{(q+1)}-\zeta$ acting on $\mathfrak{K}_{q+1}$ consists at least of the eigenvalues $\mu+\epsilon_m^{(q+1)}-\zeta$ together with the half-lines $L_{\mu+\epsilon_m^{(q+1-j)}+j\nu-\zeta}$ and $L_{\mu+j\nu-\zeta}$ for $1\leqslant j\leqslant q+1$.

This establishes the desired result, that the spectrum of $H^{(q+1)}$ acting on $\mathfrak{K}_{q+1}$ consists of the eigenvalues $\{\mu+\epsilon_m^{(q+1)}-\zeta\}$ together with the half-lines $L_{\mu+\epsilon_m^{(q+1-j)}+j\nu-\zeta}$ and $L_{\mu+j\nu-\zeta}$ for $1\leqslant j\leqslant q+1$, and thereby completes the induction argument.

Finally, we note that, as in the case $q=0$, $\mu+\epsilon_m^{(q+1)}$ is a singularity of $F_{q+1}R(\zeta)F_{q+1}$ at $\zeta=\mu+\epsilon_m^{(q+1)}$, while $\epsilon_m^{(q)}$ is a singularity of $F_qR(\zeta)F_q$ at $\zeta=\mu+\epsilon_m^{(q)}$. Since

$$F_qR(\zeta)F_q=F_q(F_{q+1}R(\zeta)F_{q+1})F_q, \tag{14.23}$$

it follows that $\epsilon_m^{(q+1)}=\epsilon_m^{(q)}$, and so, by the induction argument, $\epsilon_m^{(q+1)}=\epsilon_m'$.

Now we turn to the spectrum of the full resolvent operator $R(\zeta,e^2)$. We begin by estimating the norm of the difference between $R(\zeta,e^2)$ and the truncated resolvent $R^{(q)}(\zeta,e^2)$. Since

$$R(\zeta,e^2)-R^{(q)}(\zeta,e^2)=\sum_{r\vee s>q}R(\zeta,e^2)_{sr}, \tag{14.24}$$

where $r\vee s=\max\{r,s\}$, we have

$$\|R(\zeta,e^2)-R^{(q)}(\zeta,e^2)\|\leqslant 2\sum_{s>q}\sum_{0\leqslant r\leqslant s}\|R(\zeta,e^2)_{sr}\|\leqslant 2\sum_{s>q}\sum_{0\leqslant r\leqslant s}\|(MR_0(\zeta))_{sr}\|$$
$$\leqslant 2\sum_{s>q}\|(MR_0(\zeta))_{ss}\|+2\sum_{s>q}\sum_{0\leqslant r<s}\|(MR_0(\zeta))_{sr}\|$$
$$\leqslant\frac{4eb}{(1-eb)^3}\sum_{s>q}\frac{(\epsilon_1-\zeta)^{1/2}}{(\epsilon_1+s\nu-\zeta)^{3/2}}\leqslant\frac{4eb}{(1-eb)^3}\frac{2(\epsilon_1-\zeta)^{1/2}}{\nu(\epsilon_1+q\nu-\zeta)^{1/2}}. \tag{14.25}$$

Now we see that as $q\to\infty$, $R^{(q)}(\zeta,e^2)\to R(\zeta,e^2)$ in the operator norm.

From this result we can conclude (See appendix A) that the spectrum of the full resolvent $R(\zeta)$ consists of the union of the spectra of the truncated resolvents $R^{(q)}(\zeta)$ (see Fig. 16). It

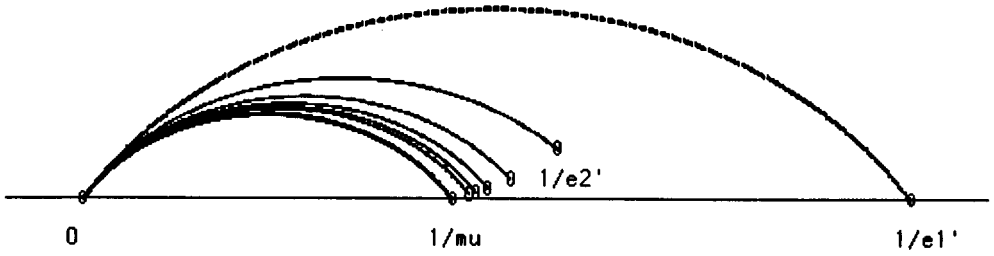

FIG. 16. Spectrum of the resolvent $R(0)=(H)^{-1}$ when $\theta=\pi/3$.

follows from the spectral mapping theorem once more that the spectrum $\sigma(H-\zeta)$ of the full Hamiltonian $H-\zeta$ consists of the union of the spectra of the partial Hamiltonians $H^{(q)}-\zeta$; i.e., it consists of the eigenvalues $\mu+\epsilon'_m-\zeta$, together with the half-lines $L_{\mu+\epsilon'_m+k\nu-\zeta}$, for $0\leqslant k<\infty$, and the half-lines $L_{\mu+k\nu-\zeta}$, for $0\leqslant k<\infty$ (see Fig. 17).

At this point we recall that the spectrum $\sigma(H)$ of the Hamiltonian H is the singular set $\mathrm{sing}(R(\zeta,e))$ of the resolvent $R(\zeta,e)$ regarded as a function of ζ. If we introduce the operators

$$H'_0=H'_0(\zeta,e^2)=(I-T)^{-1}(H_0-U_0(\zeta,e^2))$$
$$=\begin{pmatrix} H_0-U_0(\zeta,e^2) & 0 & 0 & \cdots \\ 0 & T(H_0-U_0) & 0 & \cdots \\ 0 & 0 & T^2(H_0-U_0) & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix}, \tag{14.26}$$

and

$$R'_0(\zeta,e^2)=(H'_0(\zeta,e^2)-\zeta))^{-1}=(I-T)^{-1}(H_0-\zeta-U_0(\zeta,e^2))$$
$$=\begin{pmatrix} (H_0-U_0-\zeta)^{-1} & 0 & 0 & \cdots \\ 0 & (T(H_0-U_0-\zeta))^{-1} & 0 & \cdots \\ 0 & 0 & (T^2(H_0-U_0-\zeta))^{1} & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix}, \tag{14.27}$$

then we can conclude that the singular sets of $R'_0(\zeta,e^2)$ and $R(\zeta,e)$ as functions of ζ are the same:

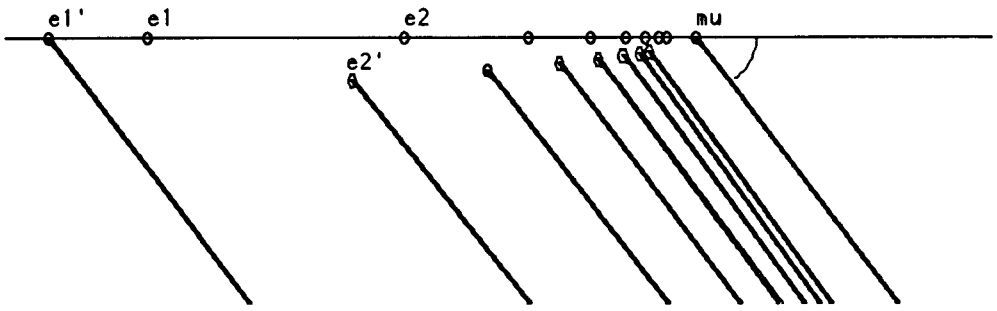

FIG. 17. Spectrum of the full Hamiltonian H when $\theta=\pi/3$.

$$\mathrm{sing}(R_0'(\zeta,e^2))=\mathrm{sing}(R(\zeta,e))=\sigma(H). \tag{14.28}$$

We shall use this fact in Sec. XV.

XV. ANALYSIS OF THE EIGENVALUES ϵ_m'

We have seen that the simple eigenvalues $\mu+\epsilon_m'=\mu+\epsilon_m'(e^2)$, together with the mass values μ and ν, completely determine, at least for small values of e^2, the spectrum of the full Hamiltonian H. In this section we examine the dependence of these simple eigenvalues on e^2. We show that, at least for small e^2, each of them is an analytic function of e^2, and we calculate the first few coefficients in the associated Taylor series expansion. In particular, we show that the leading second-order coefficient agrees with that given by Weisskopf and Wigner[5] and by Dirac,[6] as expected.

We begin by taking $e\ll 1$, and forming the projection operator

$$P(e)=\frac{-1}{2\pi i}\int_{|\mu+\epsilon_m-\eta|=r} R(\eta,e)\,d\eta, \tag{15.1}$$

where $\mu+\epsilon_m$ is the mth simple eigenvalue of H_0, and r is chosen as half the distance of $\mu+\epsilon_m$ from the rest of the spectrum of H_0. If $|\epsilon_m\rangle$ is the eigenfunction of H_0 associated with $\mu+\epsilon_m$, then

$$|\epsilon_m'\rangle=P(e)|\epsilon_m\rangle \tag{15.2}$$

is the corresponding eigenfunction of H associated with the eigenvalue $\mu+\epsilon_m'$, and

$$\mu+\epsilon_m'=\frac{\langle\epsilon_m|HP|\epsilon_m\rangle}{\langle\epsilon_m|P|\epsilon_m\rangle}=\frac{\langle\epsilon_m|(H_0+eH_1)P|\epsilon_m\rangle}{\langle\epsilon_m|P|\epsilon_m\rangle}=\mu+\epsilon_m+\frac{\langle\epsilon_m|(eH_1)P(e)|\epsilon_m\rangle}{\langle\epsilon_m|P(e)|\epsilon_m\rangle}. \tag{15.3}$$

Now

$$\begin{aligned}\langle\epsilon_m|P(e)|\epsilon_m\rangle&=\frac{-1}{2\pi i}\int_{|\epsilon_m-\eta|=r}\langle\epsilon_m|R(\eta,e)_{00}|\epsilon_m\rangle\,d\eta\\&=\frac{-1}{2\pi i}\int_{|\epsilon_m-\eta|=r}\langle\epsilon_m|(H_0-\eta-U_0(\eta,e^2))^{-1}|\epsilon_m\rangle\,d\eta,\end{aligned} \tag{15.4}$$

while

$$\begin{aligned}\langle\epsilon_m|(eH_1)P(e)|\epsilon_m\rangle&=\frac{-1}{2\pi i}\int_{|\epsilon_m-\eta|=r}\langle\epsilon_m|(eH_1R(\eta,e))_{00}|\epsilon_m\rangle\,d\eta\\&=\frac{-1}{2\pi i}\int_{|\epsilon_m-\eta|=r}\langle\epsilon_m|U_0(\eta,e^2)(H_0-\eta-U_0(\eta,e^2))^{-1}|\epsilon_m\rangle\,d\eta.\end{aligned} \tag{15.5}$$

We note here that $\langle\epsilon_m|R_0(\eta)|\epsilon_m\rangle$ is singular at $\eta=\mu+\epsilon_m$, but $\langle\epsilon_m|U_0(\eta,e^2)|\epsilon_m\rangle$ is regular there. Hence

$$\langle\epsilon_m|P(e)|\epsilon_m\rangle=\sum_{k\geqslant 0} b_k e^{2k}, \tag{15.6}$$

with

$$b_k=\frac{-1}{2\pi i}\int_{|\epsilon_m-\eta|=r}\langle\epsilon_m|R_0(\eta)B_k(\eta)|\epsilon_m\rangle d\eta, \tag{15.7}$$

where

$$B_k(\eta)=\frac{(d/de^2)^k}{k!}\,(I-U_0(\eta,e^2)R_0(\eta))^{-1}\Big|_{e^2=0}$$

$$=\sum_{1\leqslant j\leqslant k}(\partial/\partial e_1^2+\cdots+\partial/\partial e_j^2)^k(U_0(\eta,e_1^2)R_0(\eta)\cdots U_0(\eta,e_j^2)R_0(\eta))\Big|_{e_i^2=0}. \tag{15.8}$$

In particular,

$$b_0=1,\quad b_1=0,$$

$$b_2=-\sum_{n\neq m}\frac{\langle\epsilon_m|U_0^{(1)}(\epsilon_m)|\epsilon_n\rangle\langle\epsilon_n|U_0^{(1)}(\epsilon_m)|\epsilon_m\rangle}{(\epsilon_n-\epsilon_m)^2}, \tag{15.9}$$

$$b_3=\text{etc.}$$

Similarly,

$$\langle\epsilon_m|(eH_1)P(e)|\epsilon_m\rangle=\sum_{k>0}a_ke^{2k}, \tag{15.10}$$

where

$$a_k=\frac{-1}{2\pi i}\int_{|\epsilon_m-\eta|=r}\langle\epsilon_m|B_{k+1}(\eta)|\epsilon_m\rangle d\eta, \tag{15.11}$$

with the same operator function $B_k(\eta)$. In particular,

$$a_1=-\langle\epsilon_m|U_0^{(1)}(\epsilon_m)|\epsilon_m\rangle,$$

$$a_2=-\langle\epsilon_m|U_0^{(2)}(\epsilon_m)|\epsilon_m\rangle-\sum_{n\neq m}\frac{\langle\epsilon_m|U_0^{(1)}(\epsilon_m)|\epsilon_n\rangle\langle\epsilon_n|U_0^{(1)}(\epsilon_m)|\epsilon_m\rangle}{(\epsilon_n-\epsilon_m)}, \tag{15.12}$$

$$a_3=-\langle\epsilon_m|U_0^{(3)}(\epsilon_m)|\epsilon_m\rangle-\sum_{i+j=3}\sum_{n\neq m}\frac{\langle\epsilon_m|U_0^{(i)}(\epsilon_m)|\epsilon_n\rangle\langle\epsilon_n|U_0^{(j)}(\epsilon_m)|\epsilon_m\rangle}{(\epsilon_n-\epsilon_m)}$$

$$-\sum_{n\neq m\neq p}\frac{\langle\epsilon_m|U_0^{(1)}\epsilon_n\rangle\langle\epsilon_n|U_0^{(1)}\epsilon_p\rangle\langle\epsilon_p|U_0^{(1)}\epsilon_n\rangle}{(\epsilon_n-\epsilon_m)(\epsilon_p-\epsilon_m)}-2\sum_{n\neq m}\frac{\langle\epsilon_m|U_0^{(1)}\epsilon_n\rangle\langle\epsilon_n|U_0^{(1)}\epsilon_m\rangle\langle\epsilon_n|U_0^{(1)}\epsilon_n\rangle}{(\epsilon_n-\epsilon_m)^2},$$

$$a_4=\text{etc.}$$

Combining these results, we find that

$$\epsilon_m'(e^2)=\epsilon_m+\sum_{k>0}\frac{c_ke^{2k}}{k!}, \tag{15.13}$$

with

$$c_1 = a_1 = \langle \epsilon_m | U_0^{(1)}(\epsilon_m) | \epsilon_m \rangle,$$

$$c_2 = a_2 = -\langle \epsilon_m | U_0^{(2)}(\epsilon_m) | \epsilon_m \rangle - \sum_{n \neq m} \frac{\langle \epsilon_m | U_0^{(1)}(\epsilon_m) | \epsilon_n \rangle \langle \epsilon_n | U_0^{(1)}(\epsilon_m) | \epsilon_m \rangle}{(\epsilon_n - \epsilon_m)},$$

$$\begin{aligned} c_3 = a_3 - a_1 b_2 = &-\langle \epsilon_m | U_0^{(3)}(\epsilon_m) | \epsilon_m \rangle - \sum_{i+j=3} \sum_{n \neq m} \frac{\langle \epsilon_m | U_0^{(i)}(\epsilon_m) | \epsilon_n \rangle \langle \epsilon_n | U_0^{(j)}(\epsilon_m) | \epsilon_m \rangle}{(\epsilon_n - \epsilon_m)} \\ &- \sum_{n \neq m \neq p} \frac{\langle \epsilon_m | U_0^{(1)} \epsilon_n \rangle \langle \epsilon_n | U_0^{(1)} \epsilon_p \rangle \langle \epsilon_p | U_0^{(1)} \epsilon_m \rangle}{(\epsilon_n - \epsilon_m)(\epsilon_p - \epsilon_m)} \\ &- \sum_{n \neq m} \frac{\langle \epsilon_m | U_0^{(1)} \epsilon_n \rangle \langle \epsilon_n | U_0^{(1)} \epsilon_m \rangle \langle \epsilon_m | U_0^{(1)} \epsilon_m \rangle}{(\epsilon_n - \epsilon_m)^2}, \end{aligned} \tag{15.14}$$

$$c_4 = a_4 - a_1 b_3 - a_2 b_2 = \text{etc.}$$

The leading term in this expansion for small e^2 is:

$$\epsilon'_m = \langle \epsilon_m | U_0^{(1)}(\zeta_0) | \epsilon_m \rangle = -\int \int \frac{\langle \epsilon_m | H_1 | \epsilon, \omega \rangle \langle \epsilon, \omega | H_1 | \epsilon_m \rangle}{(\mu + \epsilon + \nu + \omega) - \zeta_0} \, d\rho(\epsilon) d\omega. \tag{15.15}$$

This result agrees with that of Weisskopf and Wigner[5] and that of Dirac.[6] It is not hard to see that when $\nu < \epsilon_2 - \epsilon_1$ these leading terms, except for ϵ_1, all have negative real and imaginary parts, so that, for small e^2, the values of $\mu + \epsilon_m(e^2)$ are all displaced to the left and down (i.e., southwest in the complex energy plane) from the values of $\zeta_0 = \mu + \epsilon_m$. The exception ϵ_1 has no imaginary part, and so the ground state $\mu + \epsilon_1$ is displaced to the left but not down (i.e., west but not south).

The implicit function theorem ensures that the power series for the function $\epsilon_m(e^2)$ converges for all sufficiently small e^2, and that for such e^2 the results described above are valid. It will be possible, however, to continue the function $\zeta(e^2) = \mu + \epsilon_m(e^2)$ analytically in e^2 so long as the condition

$$eb'(\zeta) < 1 \tag{15.16}$$

is met. This condition will be violated whenever the point $\zeta(e^2)$ gets too close to the rest of the spectrum of H_0, so that $\delta'(\zeta)$ gets too small.

It can be shown, at least for small e^2, that the associated eigenvectors $|\epsilon'_m\rangle$ of the operator $H - \zeta - U_0(\zeta, e^2)$ are almost orthogonal, and that together they span the same space as do the eigenvectors $|\epsilon_m\rangle$ of the operator H_0. For these eigenvectors, of course, we have, when $\zeta = \mu + \epsilon'_m$,

$$(H_0 - U_0(\mu + \epsilon'_m, e^q)) | \epsilon'_m \rangle = (\mu + \epsilon'_m) | \epsilon'_m \rangle. \tag{15.17}$$

We note here that the expression for ϵ'_m always contains the factor $(\lambda_m)^{1+2\gamma_m}$ [see Eq. (6.5)], where

$$\lambda_m^2 = \mu^2 - \epsilon_m^2, \tag{15.18}$$

and

$$\gamma^2 = \kappa_m^2 - e^2. \tag{15.19}$$

But $\kappa_m^2 \geqslant 1$, while $e^2 = (137)^{-1} \ll 1$, so certainly $\gamma_m \geqslant 1 - e^2/2$. It follows that

$$\epsilon'_m(e^2) = O(\lambda_m^{1+2\gamma_m}) = O(1/m^{3-e^2}). \tag{15.20}$$

Since

$$\mu + \epsilon'_m(0) = \mu + \epsilon_m = \mu\left[1 - \frac{e^2}{2m^2} + O\left(\frac{e_0^4}{m^4}\right)\right], \tag{15.21}$$

we see that for small e^2 we must have

$$\mu + \epsilon'_m(\epsilon^2) = \mu\left[1 - \frac{e^2}{2m^2} + O\left(\frac{e^2}{m^{3-e^2}}\right)\right], \tag{15.22}$$

so that the relative positions and spacings of the eigenvalues ϵ_m and $\epsilon'_m(e^2)$ remain nearly the same for small e^2.

Finally, we note that each eigenvalue $\epsilon'_m(e^2)$ is independent of the dilation angle θ (see Reed and Simon,[12] Vol. IV, pp. 184 ff), so long as θ is large enough that this eigenvalue is exposed, i.e., so long as

$$-\theta < \arg(\epsilon_2(e^2) - \epsilon_1(e^2)). \tag{15.23}$$

As the dilation angle θ decreases from θ_0 to 0, however, these eigenvalues are covered in succession, beginning with $\epsilon'_2(e^2)$, by the half-line $[\mu + \epsilon'_1, \mu + \epsilon'_1 + e^{-i\theta}\infty)$, and they pass to another sheet of the complex energy plane. The corresponding eigenvectors $|\epsilon'_m(e^2)\rangle$ pass out of the state space $\mathfrak{h}_0$. As θ returns to 0, the only eigenvalue remaining on the principal sheet of the energy plane is the ground state energy eigenvalue $\epsilon'_1(e^2)$.

XVI. ANALYSIS OF THE SCATTERING MATRIX

In this section we consider the scattering of a single photon by the hydrogen atom. The measurable physical quantities for such processes are all contained in the *scattering matrix* $S(E,e)$. The scattering matrix elements are usually given by a formula of the form (see Friedrichs[13])

$$\langle E'|S(E,e)|E\rangle = \lim_{\epsilon\to 0}\ \lim_{\substack{s\to+\infty \\ t\to-\infty}} \langle E'|e^{-iH_0 s}e^{i(H+i0)(s-t)}e^{iH_0 t}|E\rangle = \delta(E'-E)\langle E'|1 - T_0(E+i0,e)|E\rangle, \tag{16.1}$$

where $T_0(\zeta,e)$ is the T-matrix introduced in Sec. VII:

$$T_0(\zeta,e) = eH_1 - e^2 H_1 R(\zeta,e) H_1 = \sum_{k\geqslant 0} e^{k+1}((-H_1 R_0(\zeta))^k H_1), \tag{16.2}$$

and where we choose $|E\rangle = |\epsilon_1, \omega_1, \ldots, \omega_p\rangle$, $|E'\rangle = |\epsilon_1, \omega'_1, \ldots, \omega'_q\rangle$ as eigenvectors of H_0. If we make this choice, then the evaluation of the limit

$$\langle E'|T_0(E+i0)|E\rangle = \lim_{\epsilon\to 0}\langle E'|T_0(E+i\epsilon)|E\rangle \tag{16.3}$$

in the above definition is plagued with multiple singularities in the expansion of the T_0-matrix elements. This behavior can be traced to the fact that, as we know, the operators H_0 and H have different spectra on $\mathfrak{h}$, so that the resolvents $R_0(\zeta)$ and $R(\zeta,e)$ have different singular sets as functions of ζ.

If we replace the Hamiltonian $H_0-\zeta$ with the modified Hamiltonian $H_0'(\zeta,e^2)$ and the resolvent $R_0(\zeta)$ by the modified resolvent $R_0'(\zeta,e^2)$ [see Eq. (13.22)] in the definition of the scattering matrix:

$$\langle E'|S'(E,e)|E\rangle=\lim_{\epsilon\to 0}\lim_{\substack{s\to+\infty\\ t\to-\infty}}\langle E'|e^{-i(H_0-U_0')s}e^{i(H+U_0'+i\epsilon)(s-t)}e^{-i(H_0-U_0')t}|E\rangle$$
$$=\delta(E'-E)\langle E'|1-T'(E+i0,e)|E\rangle, \tag{16.4}$$

where now

$$U_0'=U_0'(E,e^2),$$

$$T'(E+i0,e)=(eH_1+U_0')-(eH_1+U_0')R(E+i0,e)(eH_1+U_0')$$
$$=\sum_{k\geqslant 0}e^{k+1}((-H_1R_0'(E,e^2))^kH_1)_{\rm sk}, \tag{16.5}$$

and if we choose $|E\rangle=|\epsilon_1'(e^2),\omega_1,\ldots,\omega_p\rangle$, $|E'\rangle=|\epsilon_1'(e^2),\omega_1',\ldots,\omega_q'\rangle$ as eigenvectors of H_0-U_0, then the evaluation of the limit

$$\langle E'|T'(E+i0,e)|E\rangle=\lim_{\epsilon\to 0}\langle E'|T'(E+i\epsilon,e)|E\rangle \tag{16.6}$$

can be obtained explicitly. In fact, if we write

$$T(E+i0,e)=\sum_{k>0}e^{k+1}((-H_1R_0(E+i0,e^2))^kH_1)_{\rm sk} \tag{16.7}$$

where the sum here is over skeleton graphs only, then we shall see directly that there are no singularities at the energies $E=\mu+\epsilon_1'(e^2)+\omega$, and the terms of the sum can all be evaluated there. This follows from the fact that the operators $R(\zeta,e)$ and $R_0'(\zeta,e^2)$ have the same singular set as functions of ζ.

The evaluation of the denominators $R_0(E+i0,e^2)$ can be facilitated here by dilating all the internal energy variables ϵ'',ω'', but not the external variables ω_i,ω_j' through the dilation angle $\theta=\pi/3$, as in the previous sections. (It can be shown, by the same methods as those used in Sec. II, that the interaction terms H_1 involving both internal and external variables remain bounded by the same bounds if only the internal energy variables are dilated. See Prosser.[11])

In particular, for the scattering of a single photon of energy ω by an atom in the ground state, we have

$$|E\rangle=|\epsilon_1'(e^2),\omega\rangle,\quad |E'\rangle=|\epsilon_1'(e^2),\omega'\rangle, \tag{16.8}$$

and

$$\langle E'|S'(E,e)|E\rangle=\delta(\omega'-\omega)(1-\langle\epsilon_1'(e^2),\omega'|T'(\mu+\epsilon_1'(e^2)+\nu+\omega+i0,e)|\epsilon_1'(e^2),\omega\rangle). \tag{16.9}$$

As a function of the photon energy ω, the T'-matrix element

$$\langle\epsilon_1',\omega|T'(E,e)|\epsilon_1',\omega\rangle=\langle\epsilon_1',\omega|H_1R(E,e)H_1|\epsilon_1',\omega\rangle \tag{16.10}$$

is analytic throughout the same complex energy domain as is $R_0'(E,e)$ (see Fig. 16). In particular, it will have a singularity whenever

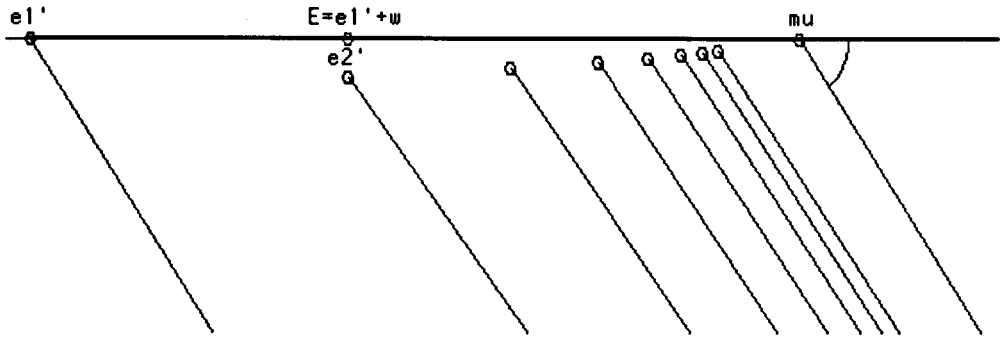

FIG. 18. Resonance values of the energy $E=\epsilon_1'+\omega$.

$$E'=\mu+\epsilon_1'+\nu+\omega=\epsilon_m', \tag{16.11}$$

i.e., whenever

$$\nu+\omega=\epsilon_m'-\epsilon_1'. \tag{16.12}$$

Near these energies E' the T-matrix element above will be large. In particular, it will be large when the photon energy ω has any of the real values (see Fig. 18)

$$\nu+\omega=\mathrm{Re}(\epsilon_m'-\epsilon_1'). \tag{16.13}$$

These values comprise the scattering resonances for this process.

We can now associate the real part $\mathrm{Re}(\epsilon_m'-\epsilon_1')$ of the energy difference $\epsilon_m'-\epsilon_1'$ with the *position* of the resonance, and the imaginary part $\mathrm{Im}(\epsilon_m'-\epsilon_1')$ with the *breadth* of the resonance, in the usual way.

We note that the presence of the branch points $\mu+\epsilon_m'+q\nu$ for $q>0$ in the spectrum of H do not cause the same sort of resonance behavior in the scattering matrix elements, because, while the resolvent $R_0'(\zeta,e^2)$ blows up as $\zeta\to\mu+\epsilon_m'$, it remains bounded as $\zeta\to\mu+\epsilon_m'+q\nu$ for all $q>0$ (see Appendix B).

A similar analysis, of course, can be made for resonance scattering processes involving more photons.

APPENDIX A: PERTURBATION THEORY

In this section we summarize those elements of perturbation theory which are used in Secs. XIV and XV.

Essential spectra

These results rely on a theorem of Weyl:[14] If R and S are two bounded operators on a Hilbert space, with $R-S$ compact, such that the resolvent set $\rho(R)$ of R is dense and connected in the complex plane, and $\rho(S)\cap\rho(R)$ is nonempty, then the essential spectra of R and S must be the same: $\sigma_{\mathrm{ess}}(A)=\sigma_{\mathrm{ess}}(B)$ (See Reed and Simon,[13] Vol. IV, p. 111).

Now suppose A and $A(e)=A+C(e)$ are closed operators with resolvents $R(\zeta)$ and $R(\zeta,e)$. Suppose that the resolvent set $\rho(A)$ of A is dense and connected in the complex plane and includes

the half-plane $\mathrm{Re}(\zeta)\leqslant 0$. Suppose that the difference $A(e)-A=C(e)$ is relatively compact; i.e., that $R(\zeta)C(e)$ is compact for $\mathrm{Re}(\zeta)<0$. Then $R(\zeta)$ and $R(\zeta,e)$ are bounded operators with $R(\zeta,e)-R(\zeta)=R(\zeta)C(e)R(\zeta,e)$ compact, and $\zeta\epsilon p(A)\cap\rho(A(e))$ if $\zeta\ll 0$. By the spectral mapping theorem, the spectrum of $R(\zeta)$ is

$$\sigma(R(\zeta))=\{(\lambda-\zeta)^{-1}:\lambda\epsilon\sigma(A)\}, \tag{A1}$$

and similarly for the spectrum of $R(\zeta,e)$. Hence the resolvents sets of these operators are dense and connected, with nonempty intersection. By Weyl's theorem, the essential spectra of $R(\zeta)$ and $R(\zeta,e)$ must be the same. By the spectral mapping theorem again, the spectra of A and $A(e)$ must also be the same.

Point spectra

As for the point spectra of these operators, we know that under any relatively bounded analytic perturbation $A(e)=A+C(e)$ of A, with $R(\zeta)C(e)$ bounded for $\zeta\leqslant 0$ and with $C(0)=0$, each isolated simple eigenvalue ϵ will, for small values of e, move analytically to a new location $\epsilon(e)$. We shall see that for larger values of e some of these eigenvalues may disappear, and new eigenvalues may appear.

We know that, under the analytic perturbation $A(e)=A+C(e)$ with $C(0)=0$, a simple eigenvalue ϵ of A with normalized eigenfunction $|\epsilon\rangle$ will, for small e, move analytically to an eigenvalue $\epsilon(e)$ of $A(e)$ with normalized eigenfunction $|\epsilon(e)\rangle$ according to the formulas:

$$\epsilon(e)=\frac{\langle\epsilon|A(e)P(e)|\epsilon\rangle}{\langle\epsilon|P(e)|\epsilon\rangle}, \tag{A2}$$

$$|\epsilon(e)\rangle=\frac{|P(e)\epsilon\rangle}{\|P(e)|\epsilon\rangle\|}. \tag{A3}$$

Here $P(e)$ is the projection onto the eigenfunction $|\epsilon(e)\rangle$:

$$P(e)=\frac{-1}{2\pi i}\int_{|\zeta-\epsilon|=r}R(\zeta,e)d\zeta \tag{A4}$$

which is constructed from the resolvent $R(\zeta,e)$ of $A(e)$. The radius r of the integration path is chosen so that the circle $|\zeta-\epsilon|=r$ encloses only the eigenvalue ϵ, and no other point, in the spectrum of A. We also know that $R(\zeta,e)$ satisfies the resolvent equation:

$$R(\zeta,e)=R(\zeta)+R(\zeta,e)C(e)R(\zeta)=(I-R(\zeta)C(e))^{-1}R(\zeta). \tag{A5}$$

If e is so small that $\|R(\zeta)C(e)\|=b<1$ when $|\zeta-\epsilon|=r$, then

$$\|R(\zeta,e)-R(\zeta)\|\leqslant\frac{b/r}{1-b}. \tag{A6}$$

It follows from Eq. (A4) that

$$\|(P(e)-P)|\epsilon\rangle\|\leqslant\frac{b}{1-b}. \tag{A7}$$

Since

$$\langle\epsilon|P(e)|\epsilon\rangle=\langle\epsilon|P|\epsilon\rangle-\langle\epsilon|(P(e)-P)|\epsilon\rangle=1-\langle\epsilon|(P(e)-P)|\epsilon\rangle, \tag{A8}$$

we have

$$1-\frac{b}{1-b}\leqslant|\langle\epsilon|P(e)|\epsilon\rangle|\leqslant 1+\frac{b}{1-b}. \tag{A9}$$

It follows that, for any ζ with $|\zeta-\epsilon|=r$,

$$|\epsilon(e)-\epsilon|=\frac{|\langle\epsilon|(A(e)-A)P(e)|\epsilon\rangle|}{|\langle\epsilon|P(e)|\epsilon\rangle|}=\frac{|\langle\epsilon|C(e)P(e)|\epsilon\rangle|}{|\langle\epsilon|P(e)|\epsilon\rangle|}=\frac{|\langle\epsilon|(A-\zeta)(R(\zeta)C(e))P(e)|\epsilon\rangle|}{|\langle\epsilon|P(e)|\epsilon\rangle|}$$

$$\leqslant\frac{rb}{1-2b}\leqslant r \quad \text{if } b<1/3. \tag{A10}$$

The formula for the eigenfunction $\epsilon(e)$ shows that it can be expanded as a quotient if two analytic functions:

$$\epsilon(e)=\epsilon+\frac{\Sigma_{n=0}^{\infty}a_n(e)}{\Sigma_{n=0}^{\infty}b_n(e)}, \tag{A11}$$

with

$$a_n(e)=\frac{(-1)^{n+1}}{2\pi i}\int_{|\zeta-\epsilon|=r}\langle\epsilon|(A-\zeta)(R(\zeta)C(e))^{n+1}|\epsilon\rangle d\zeta, \tag{A12}$$

$$b_n(e)=\frac{(-1)^{n+1}}{2\pi i}\int_{|\zeta-\epsilon|=r}\langle\epsilon|(C(e)R(\zeta))^{n}|\epsilon\rangle d\zeta. \tag{A13}$$

These formulas lead to those in the text [see Eq. (15.3)ff.].

Comparison theorems

Now suppose that $A(e)=A+C(e)$ and $A'(e)=A+C'(e)$ are two relatively bounded analytic perturbations of A, with eigenvalues $\epsilon(e)$ and $\epsilon'(e)$ and eigenfunctions $|\epsilon(e)\rangle$ and $|\epsilon'(e)\rangle$. If we write $K(e)=R(\zeta)C(e)$ and $K'(e)=R(\zeta)C(e)$, and suppose as above that $\|K(e)\|\leqslant b$, $\|K'(e)\|\leqslant b$ with $b<1$, then

$$\epsilon(e)-\epsilon'(e)=\frac{\langle\epsilon|C(e)P(e)|\epsilon\rangle}{\langle\epsilon|P(e)|\epsilon\rangle}-\frac{\langle\epsilon|C'(e)P'(e)|\epsilon\rangle}{\langle\epsilon|P'(e)|\epsilon\rangle}$$

$$=\frac{a}{c}-\frac{a'}{c'}=\frac{ac'-a'c}{cc'}=\frac{a(c'-c)}{cc'}+\frac{(a-a')c}{cc'}. \tag{A14}$$

Now

$$c=|\langle\epsilon|P(e)|\epsilon\rangle|\geqslant 1-\frac{b}{1-b}=\frac{1-2b}{1-b}, \tag{A15}$$

and similarly for c', while

$$|c-c'|=|\langle\epsilon|(P(e)-P'(e))|\epsilon\rangle|\leqslant\|(I-K(e))^{-1}(K(e)-K'(e))(I-K'(e))^{-1}\|$$

$$\leqslant\frac{1}{(1-b)^2}\|K(e)-K'(e)\|. \tag{A16}$$

Moreover,

$$a=|\langle\epsilon|C(e)P(e)|\epsilon\rangle|\leqslant\frac{rb}{1-b},\tag{A17}$$

and similarly for a', while

$$\begin{aligned}|a-a'|&=|\langle\epsilon|(C(e)P(e)-C'(e)P'(e))|\epsilon\rangle|\\&\leqslant|\langle\epsilon|(H_0-\zeta)(K(e)P(e)-K'(e)P'(e))|\epsilon\rangle|\\&\leqslant r\|(I-K(e))^{-1}(K(e)-K'(e))(I-K'(e))^{-1}\|\leqslant\frac{r}{(1-b)^2}\|K(e)-K'(e)\|.\end{aligned}\tag{A18}$$

Hence

$$\begin{aligned}|\epsilon(e)-\epsilon'(e)|&\leqslant\frac{r(b+1)\|K(e)-K'(e)\|}{(1-b)^3}\,\frac{(1-b)^2}{(1-2b))^2}\\&\leqslant\frac{r(1+b)}{(1-2b)^3}\|K(e)-K'(e)\|\\&\leqslant 18r\|K(e)-K'(e)\|,\quad\text{if}\quad b<1/3.\end{aligned}\tag{A19}$$

Limits

Now suppose $A_n(e)=A+C_n(e)$ is a sequence of relatively bounded analytic perturbations of A, with $R(\zeta)C_n(e)\to R(\zeta)C(e)$ in operator norm as $n\to\infty$. Then $A(e)=A+C(e)$ is again a relatively bounded analytic perturbation of A. Moreover, if $\|R(\zeta)C(e)\|\leqslant b<1/3$ for all ζ with $|\zeta-\epsilon|=r$, then (by adjusting b if necessary) the same will be true for $\|R(\zeta)C(e)\|$ for all sufficiently large n. Hence, by the argument above,

$$|\epsilon(e)-\epsilon_n(e)|\leqslant 18r\|R(\zeta)C(e)-R(\zeta)C_n(e)\|.\tag{A20}$$

Moreover, this holds uniformly in e for all e such that $\|R(\zeta)C(e)\|\leqslant b<1/3\|$. We can conclude that, under these conditions, $\epsilon_n(e)\to\epsilon(e)$ as $n\to\infty$.

Disappearance of old eigenvalues

So long as e remains small, the (analytic) trajectory of the eigenvalue $\epsilon_m(e)$ starts at ϵ_m and remains disjoint the rest of the spectrum $\sigma(H)$ of H. So long as the trajectory of $\epsilon_m(e)$ remains disjoint from the rest of $\sigma(H)$, it can be continued analytically as e increases. For larger values of e, however, the trajectory of $\epsilon_m(e)$ may encounter another part of the spectrum of H, and then disappear behind that part of the spectrum onto another sheet of the complex energy plane. Or the trajectory may move off to ∞ and disappear there. The actual situation depends on the dilation angle θ as well as on the size of e.

Appearance of new eigenvalues

There is also the possibility that new eigenvalues (we call these *spurious eigenvalues*) may appear. Any spurious eigenvalue appearing under a relatively compact perturbation $\mu(e)$ must also be of finite multiplicity, and must also depend analytically on e for $e>0$. Moreover, it must either disappear or tend to a limit $\mu(0)$ as $e\to 0$. If it does not disappear before e gets to zero, then the limiting value $\mu(0)$, since it cannot lie in the resolvent set $\rho(H_0)$ of H_0, must lie somewhere

in the spectrum $\sigma(H_0)$ of H_0. It cannot lie on the interior of any branch cut, since the branch cuts are dependent on θ, while the eigenvalues are not (see Reed and Simon,[13] Vol. IV, Sec. XIII). Hence $\mu(e)$ must lie at one of the branch points $\epsilon_m + q\nu$, or it else it must lie at the branch point at ∞. We shall show in Appendix B that these spurious eigenvalues can be ruled out, at least for small values of e.

APPENDIX B: SPURIOUS EIGENVALUES

In this Appendix we show that the appearance of spurious eigenvalues in the spectrum of the operator $H^{(q)}$ can be ruled out, at least for sufficiently small values of e.

Our proof proceeds by induction. Recall that $H^{(q)} = H_0^{(q)} + F_1(eH_1)F_1 - U_q^{(c)}$ is a relatively compact perturbation of $H_0^{(q)}$. We have seen already that there are no spurious eigenvalues in the spectrum of $H^{(0)}$. Moreover, if there are no spurious eigenvalues in the spectrum of $H^{(q-1)}$, then there are no spurious eigenvalues in the spectrum of $H_0^{(q)} = (I-T)H_0 + T(H^{(q-1)})$. Any spurious eigenvalue μ of $H^{(q)}$, then, must tend, as $e \to 0$, to one of the q half-lines $L_{\epsilon_m^{(k)} + (q-k)\nu}$, $0 \leqslant k \leqslant q-1$, which make up the spectrum of $H_0^{(q)}$. Since the eigenvalues are independent of θ while the branch cuts are not, this means that μ must tend either to the branch point at $\epsilon_m^{(k)} + (q-k)\nu$ or to the branch point at ∞. These are the possibilities which we want to rule out.

We begin by recalling that

$$H^{(q)} = H_0^{(q)} + F_1(eH_1)F_1 - U_q^{(2q)} = (I-T)H_0 + T(H^{(q-1)}) + F_1(eH)F_1 - U_q^{(2q)}. \tag{B1}$$

If we iterate this relation, we find

$$\begin{aligned} H^{(q)} &= ((I-T^k)H_0 + T^k(H^{(q-k)}) + F_k(eH_1)F_k - (U_q^{2(q-k+1)} + \cdots + U_q^{(2q)}) \\ &= H_k^{(q)} + F_k(eH_1)F_k - (U_q^{2(q-k+1)} + \cdots + U_q^{(2q)}). \end{aligned} \tag{B2}$$

Thus $H^{(q)}$ is a bounded perturbation of $H_k^{(q)} = ((I-T^k)H_0 + T^k(H^{(q-k)})$, for any k, $1 \leqslant k \leqslant q$.

Now we fix k, $1 \leqslant k \leqslant q$, and we surround the branch cut $L_{\epsilon_m^{(q-k)} + k\nu}$ with a simple curve Γ_k consisting of the two half-lines $L_{\epsilon_m^{(q-k)} + k\nu - r}$ and $L_{\epsilon_m^{(q-k)} + k\nu + r}$ joined at the top by the semicircle with center at $\epsilon_m^{(q-k)} + k\nu$ and radius r. We choose r to be half the horizontal distance from the half-line $L_{\epsilon_m^{(q-k)} + k\nu}$ to the rest of the spectrum of $H_k^{(q)}$. Note that then the distance from Γ_k to $L_{\epsilon_m^{(q-k)} + k\nu}$ is just

$$\operatorname{dist}(\Gamma_k, L_{\epsilon_m^{(q-k)} + k\nu}) = r \sin\theta. \tag{B3}$$

Using the curve Γ_k, we define the projections $P_k^{(q)}$ and $P^{(q)}$ acting on the space $\mathfrak{K}_q$ as follows: For states $|f\rangle$ in the domain of $\exp(H_0)$ (and hence in the domain of $\exp(H^{(q)})$; i.e., for states of the form

$$|f\rangle = |e^{-E} g(E)\rangle = |e^{-(\epsilon + q\nu + \omega_1 + \cdots + \omega_i)\cos\theta} g(\epsilon, \omega_1, \ldots, \omega_1)\rangle, \tag{B4}$$

where $0 \leqslant i \leqslant qg$ is analytic and square integrable in the energy variables), we set

$$P_k^{(q)}|f\rangle = \frac{-1}{2\pi i} \int_{\Gamma_k} R_k^{(q)}(\eta)|f\rangle \, d\eta, \tag{B5}$$

[where $R_k^{(q)}(\eta)$ is the resolvent of $H_k^{(q)}$], and

$$P^{(q)}|f\rangle = \frac{-1}{2\pi i}\int_{\Gamma_k} R^{(q)}(\eta)|f\rangle d\eta, \tag{B6}$$

where $R^{(q)}(\eta)$ is the resolvent of $H^{(q)}$. Now

$$\|P_k^{(q)}|f\rangle\| \leqslant \left(\frac{1}{2\pi}\int_\gamma \|e^{-E}(E-\eta)^{-1}\| d\eta\right) \||g\rangle\|. \tag{B7}$$

If we write $\eta = \epsilon_m^{(q-k)} + k\nu \pm r + e^{-i\theta}\omega$, then we have

$$\|e^{-E}(E-\eta)^{-1}\| \leqslant \frac{e^{-\omega\cos\theta}}{r\sin\theta}. \tag{B8}$$

It follows that the integrals defining $P_k^{(q)}$ and $P^{(q)}$ converge strongly on all such states, and that

$$\|P_k^{(q)}|f\rangle\| \leqslant \frac{1}{\pi r\sin 2\theta}\||g\rangle\|, \tag{B9}$$

$$\|P^{(q)}|f\rangle\| \leqslant \frac{1}{\pi r\sin\theta}\frac{1}{1-eb}\||g\rangle\|, \tag{B10}$$

$$\|P^{(q)}|f\rangle - P_k^{(q)}|f\rangle\| \leqslant \frac{1}{\pi r\sin 2\theta}\frac{eb}{1-eb}\||g\rangle\|. \tag{B11}$$

The projections $P_k^{(q)}$ and $P^{(q)}$ commute with the operators $H_k^{(q)}$ and $H^{(q)}$, respectively, and project onto the subspaces $P_k^{(q)}\mathfrak{K}_q$ and $P^{(q)}\mathfrak{K}_q$ of $\mathfrak{K}_q$.

On the subspace $P_k^{(q)}\mathfrak{K}_q$, the spectrum of $H_k^{(q)}$ consists precisely of the branch cut $L_{\epsilon_m^{(q-k)}+k\nu}$. In fact, in this subspace the states are all completely disconnected, so that $P_k^{(q)} = F_k$ and $\sigma(H_k^{(q)}) = \sigma(eH_0^{(q-k)}e) + \sigma(H_{\rm ph}+\cdots+H_{\rm ph}) = L_{\epsilon_m^{(q-k)}+k\mu}$. On the subspace $P^{(q)}\mathfrak{K}_q$, the spectrum of $H^{(q)}$ consists of the same branch cut $L_{\epsilon_m^{(q-k)}+k\nu}$, together with any spurious eigenvalues μ which lie inside the curve Γ_k.

Now if $\mu = \mu(e)$ were a simple spurious eigenvalue lying inside Γ_k, and $|\mu\rangle$ were the normalized eigenfunction associated with μ, then $|\mu\rangle$ would lie in the domain of $\exp(H^{(q)})$ and hence of $\exp(H_k^{(q)})$. Hence $P^{(q)}|\mu\rangle = |\mu\rangle$ and $P_k^{(q)}|\mu\rangle = |\mu_k\rangle$ are defined by the integral formulas above, and from the estimate obtained there we have

$$\||\mu\rangle - |\mu_k\rangle\| \leqslant \frac{1}{\pi r\sin 2\theta}\frac{eb}{1-eb} = \frac{C_{15}eb}{1-eb}. \tag{B12}$$

It follows that

$$1 - \frac{C_{15}eb}{(1-eb)} \leqslant |\langle\mu_k|\mu\rangle| \leqslant 1 + \frac{C_{15}eb}{(1-eb)}. \tag{B13}$$

Now we form the operator

$$R_k^{(q)}(\mu)(H^{(q)} - H_k^{(q)}) = R_k^{(q)}(\mu)(F_k(eH_1)F_k - (U_q^{2(q-k+1)} + \cdots + U_q^{(2q)})), \tag{B14}$$

where $F_k = E_1 + \cdots + E_k$ is the projection on the space $\mathfrak{K}_k$, and we consider the inner product

$$\langle\mu_k|\mu\rangle=\langle\mu_k|R_k^{(q)}(\mu)(H_k^{(q)}-H^{(q)})|\mu\rangle=\langle\mu_k|R_k^{(q)}(\mu)(U_q^{(2q-2k)}+\cdots+U_q^{(2q)}-F_k(eH_1)F_k)|\mu\rangle. \tag{B15}$$

The left hand side here is bounded below:

$$|\langle\mu_k|\mu\rangle|\geqslant 1-\frac{C_{15}eb}{1-eb}, \tag{B16}$$

but the right-hand side is bounded above:

$$|\mathrm{RHS}|\leqslant\frac{C_{16}eb}{1-eb}. \tag{B17}$$

It follows that for e sufficiently small Eq. (B15) cannot hold; and so for e sufficiently small the spurious eigenvalue $\mu(e)$ cannot lie inside the curve Γ_k.

To get this upper bound for RHS, we first note that

$$|\langle\mu_k|R_k^{(q)}(\mu)U_q^{(2q-2i)}|\mu\rangle|\leqslant\|\langle\mu_k|\|\,\|P_k^{(q)}R_k^{(q)}(\mu)U_q^{(2q-2i)}\|\,\||\mu\rangle\|. \tag{B18}$$

But

$$\||\mu\rangle\|=1,\quad\text{and}\quad\|\langle\mu_k|\|\leqslant 1+\frac{C_{15}eb}{1-eb}. \tag{B19}$$

Moreover, we know that the components of the operator $H_k^{(q)}$ connect only the last $q-k$ of the q final photon lines (say those with energies $\omega_{k+1},\ldots,\omega_q$) in each diagram, while the components of the operator $U_q^{(2q-2i)}$ must connect the last $q-i$ of the q final photon lines. If $i<k$, then at least $k-i$ of these final photon lines (say those with energies $\omega_{i+1},\ldots,\omega_k$) must be unconnected by $H_k^{(q)}$ but connected by $U_q^{(2q-2i)}$.

If we extract from each component of $U_q^{(2q-2i)}$ the term (eH_1) which connects one of these photon lines, say the one with energy ω_k, and combine it with $R_k^{(q)}(\mu)$, we get

$$\|P_k^{(q)}R_k^{(q)}(\mu)U_q^{(2q-2i)}\|\leqslant\|P_kR_k^{(q)}(\mu)(eH_1^+)\|\left(\sum_{k=1}^{\infty}\|eK\|^{2k+1}\right)\leqslant\|P_k^{(q)}R_k^{(q)}(\mu)(eH_1^+)\|\,\frac{eb}{1-(eb)^2}$$

$$\leqslant\frac{e\|F^+\|}{|\Sigma\omega-\kappa|}\,\frac{eb}{1-(eb)^2}, \tag{B20}$$

where we write $\Sigma\omega=\omega_1+\cdots+\omega_k$ and $\mu=\epsilon_m^{(q-k)}+k\nu+e^{-i\theta}\kappa$, with $\kappa=\kappa_r+i\kappa_i$. Now $\|F^+\|$ has the form (see Sec. VI)

$$\|F^+\|\leqslant C_{16}\,\frac{j!}{(2j+1)!}\,k^{j+1}e^{-\tau\omega\cos\theta}, \tag{B21}$$

where C_{16} is another constant independent of ω and j. Since $k^2=(\omega+\nu)^2-\nu^2=\omega(\omega+2\nu)<(\omega+2\nu)^2$, we can write

$$\|F^+\|\leqslant C_{16}\,\frac{j!}{(2j+1)!}\,\omega(\omega+2\nu)^je^{-\tau\omega\cos\theta}, \tag{B22}$$

and so

$$\|P_k^{(q)}R_k^{(q)}(\mu)U_q^{(2q-2i)}\| \leqslant \frac{C_{16}j!}{(2j+1)!}\,\frac{\omega_k}{\Sigma\omega-\kappa}\,(\omega_k+2\nu)^j e^{-\tau\omega_k\cos\theta}\,\frac{(e)^2b}{1-(eb)^2}. \tag{B23}$$

Elementary calculus shows that

$$\frac{j!}{(2j+1)!}\,(\omega_k+2\nu)^j e^{-\tau\omega_k\cos\theta} \leqslant \frac{e^{2\tau\nu\cos\theta}}{(\tau\cos\theta)^j}, \tag{B24}$$

and

$$\frac{\omega_k}{|\Sigma\omega-\kappa|} \leqslant \begin{cases} \dfrac{|\kappa|}{\kappa_i} = 1/\sin\beta, & \text{if} \quad 0<|\beta|<\pi/2, \\ 1 & \text{if} \quad \pi/2\leqslant|\beta|\leqslant\pi, \end{cases} \tag{B25}$$

where

$$\beta = \arg\kappa. \tag{B26}$$

Hence

$$\|P_k^{(q)}R_k^{(q)}(\mu)U_q^{(2q-2i)}\| \leqslant \frac{C_{16}}{\sin\beta}\,\frac{e^{2\tau\nu\cos\theta}}{(\tau\cos\theta)^j}\,\frac{(e)^2b}{(1-(eb)^2)} \leqslant \frac{C_{17}(e)^2b}{1-(eb)^2}. \tag{B27}$$

We can bound

$$\|P_k^{(q)}R_k^{(q)}(\mu)F_k(eH_1)F_k\| = \|R_k^{(q)}(\mu)P_k^{(q)}F_k(eH_1)F_k\| \tag{B28}$$

in the same way. Since

$$R_k^{(q)}F_k(eH_1)F_k = E_k(eH_1)F_k = E_k(eH_1^+)E_{k-1}, \tag{B29}$$

we have, as before,

$$\|P_k^{(q)}R_k^{(q)}(\mu)F_k(eH_1)F_k\| = \|P_k^{(q)}R_k^{(q)}(\mu)(eH_1^+)\| \leqslant \frac{C_{16}e}{\sin\beta}\,\frac{e^{2\tau\nu\cos\theta}}{(\tau\cos\theta)^j} \leqslant C_{17}e. \tag{B30}$$

We note here that we can ensure that the angle $\beta=\arg\kappa=\arg(\mu-\epsilon_m^{(q-k)}-k\nu)-\theta$ is bounded away from 0, by varying θ slightly, if necessary.

We also note that in the sector with total angular momentum zero, the selection rules restrict the possible values of j for the q photons to $1\leqslant j\leqslant q$.

In the same way, we can rule out the possibility of a simple spurious eigenvalue μ which tends to the other end of the branch cut $L_{\epsilon_m^{(q-k)}+k\nu}$. We have only to rewrite Eq. (B22) in the form

$$\begin{aligned}\|P_k^{(q)}R_k^{(q)}(\mu)U_q^{(2q-2i)}\| &\leqslant \frac{j!}{(2j+1)!}\,\frac{e^{-\tau\omega_k\cos\theta}}{|\Sigma\omega-\kappa|}\,(\omega_k+2\nu)^{j+1}\,\frac{eb}{1-eb} \\ &\leqslant \frac{e^{-\tau\omega_k\cos\theta}}{|\Sigma\omega-\kappa_r-\kappa_i|}\,\frac{e^{2\tau\nu\cos\theta}}{(\tau\cos\theta)^j}\,\frac{eb}{1-eb},\end{aligned} \tag{B31}$$

and use the bound

$$\frac{e^{-\tau\omega_k\cos\theta}}{|\Sigma\omega-\kappa_r-\kappa_i|} \leqslant \frac{e^{-\tau\kappa_r\cos\theta}}{|\kappa_i|}. \tag{B32}$$

This gives the bound

$$\|P_k^{(q)}R_k^{(q)}(\mu)U_q^{(2q-2i)}\| \leqslant \frac{e^{-\tau\kappa_r\cos\theta}}{|\kappa_i|}\,\frac{e^{2\tau\nu\cos\theta}}{(\tau\cos\theta)^j}\,\frac{(e)^2 b}{1-(eb)^2}. \tag{B33}$$

Similarly,

$$\|P_k^{(q)}R_k^{(q)}(\mu)F_k(eH_1)F_k\| \leqslant \frac{e e^{-\tau\kappa_r\cos\theta}}{|\kappa_i|}\,\frac{e^{2\tau\nu\cos\theta}}{(\tau\cos\theta)^j}. \tag{B34}$$

If $\mu=\epsilon_m^{(q-r)}+k\nu+e^{-i\theta}\kappa\to\infty$ inside Γ as $e\to 0$, then $\kappa_r\to\infty$, and, as before, we can ensure that $|\kappa_i|$ is bounded away from 0 by varying θ slightly if necessary. We conclude that for e sufficiently small, (hence for κ_r sufficiently large),

$$\|P_k R_k^{(q)}(\mu)U_q^{(2q-2i)}\| \leqslant \frac{e^{-\tau\kappa_r\cos\theta}}{|\kappa_i|}\,\frac{C_{17}eb}{1-eb}, \tag{B35}$$

and hence that the spurious eigenvalue $\mu\to\infty$ cannot lie inside the curve Γ_k.

If the spurious eigenvalue μ were not simple, then in any case it would have finite multiplicity, and we could choose for $|\mu\rangle$ any normalized eigenvector of $H^{(q)}$, set $|\mu_k\rangle=P_k^{(q)}|\mu\rangle$, and proceed as before to the same conclusion.

Periodic orbit theory analysis of a continuous family of quasi-circular billiards

R. W. Robinett
Department of Physics, The Pennsylvania State University, University Park, Pennsylvania 16802

(Received 31 July 1997; accepted for publication 22 September 1997)

We compute the Fourier transform ($\rho(L)$) of the quantum mechanical energy level density for the problem of a particle in a two-dimensional circular infinite well (or circular billiard) as well as for several special generalizations of that geometry, namely the half-well, quarter-well, and the circular well with a thin, infinite wall along the positive x-axis (hereafter called a circular well plus baffle). The resulting peaks in plots of $|\rho(L)|^2$ versus L are compared to the lengths of the classical closed trajectories in these geometries as a simple example of the application of periodic orbit (PO) theory to a billiard or infinite well system. We then solve the Schrödinger equation for the general case of a circular well with infinite walls both along the positive x-axis and at an arbitrary angle Θ (a circular ''slice'') for which the half-well ($\Theta=\pi$), quarter-well ($\Theta=\pi/2$), and circular well plus baffle ($\Theta=2\pi$) are then all special cases. We perform a PO theory analysis of this general system and calculate $|\rho(L)|^2$ for many intermediate values of Θ to examine how the peaks in $\rho(L)$ attributed to periodic orbits change as the quasi-circular wells are continuously transformed into each other. We explicitly examine the transitions from the half-circular well to the circle plus baffle case (half-well to quarter-circle case) as Θ changes continuously from π to 2π (from π to $\pi/2$) in detail. We then discuss the general $\Theta\rightarrow 0$ limit, paying special attention to the cases where $\Theta=\pi/2^n$, as well as deriving the formulae for the lengths of closed orbits for the general case. We find that such a periodic orbit theory analysis is of great benefit in understanding and visualizing the increasingly complex pattern of closed orbits as $\Theta\rightarrow 0$. © *1998 American Institute of Physics.*

I. INTRODUCTION

There exist a wide variety of semi-classical calculational tools in quantum mechanics which help to make clear the substantial overlap between the classical and quantum mechanical descriptions of a system. Periodic orbit (PO) theory[1–5] is rapidly becoming one of the most useful semi-classical tools which can be used to make very direct connections (via a Fourier transform) between the spectrum of quantized energy levels of a quantum system (often considered as the ''smoking gun'' of wave mechanics) and the periodic orbits or closed trajectories of the corresponding classical system.

Variations of PO theory which are well-suited for spectroscopy[6] have been used to examine the structure of atoms in strong magnetic[7] and electric[8] fields and related techniques have proved useful in discussions of quantum transport.[9] Other familiar and non-trivial potentials which have proved amenable to this treatment include various harmonic-oscillator potentials[10] and especially 2- and 3-dimensional (2D and 3D) ''billiard'' systems.[1,3,5] Examples of this latter case include the exact analytic determination of the energy eigenvalues for the 1D and 3D infinite square wells,[1] the extraction of information on periodic orbits in an otherwise chaotic two-dimensional billiard system[11] as well as the general structure of the spherical and circular infinite well cases[3] and their applications as model systems to the electronic shell structure of clusters[12] and the shell structure

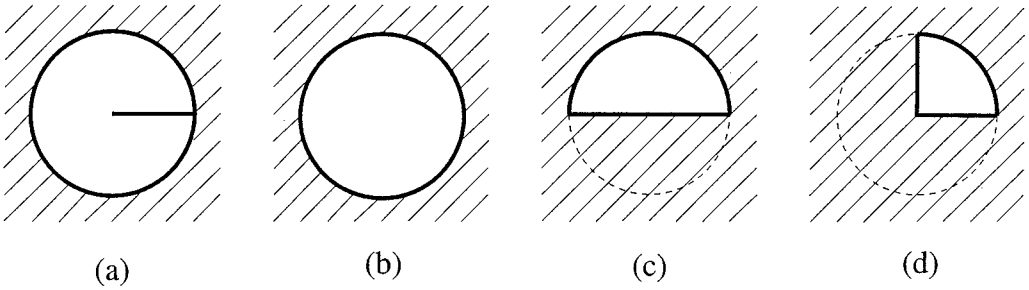

FIG. 1. Geometries for the (a) circular well plus baffle, (b) ordinary circular well, (c) half-circular well, and (d) quarter-circular well.

of heavy nuclei[13] (including the possibility of quantum tunneling[14]). A variety of two-dimensional ''billiard''-type geometries (squares, circles, circular disks) have also been studied[5,15] using these methods to investigate the semi-classical theory of orbital magnetism in the ballistic regime. Modifications of the standard formalism to include diffraction effects have also been considered.[5,16–18]

An interesting variation on the standard simple geometries is to consider billiard systems in which the billiard area or shape is allowed to vary smoothly with some parameter, call it f. One can perform a periodic orbit analysis for each value of f and then ''track'' how the quantum energy levels retain information on the shapes and lengths of the classical orbits as the potential well or billiard system is continuously deformed from one shape to another. An especially simple case, for example, is to perform a periodic orbit analysis for the rectangular box[5] as one side is made longer, starting with a square 2D infinite well potential: we will analyze just such a system (numerically) in what follows as an example.

A far more interesting and less trivial example has been recently considered by Reimann *et al.*[19] who have considered the problem of an annular infinite well (circular well of radius R with an inner circular barrier of radius fR where $0<f<1$) defined by the potential function

$$V(r)=\begin{cases}0, & \text{for } R_{min}=fR<r<R=R_{max},\\ \infty, & \text{otherwise.}\end{cases} \tag{1}$$

With the exception of two features which indicate diffraction (i.e., purely quantum or wave effects) of the particle *around* the inner annulus,[5] the remaining global features of the Fourier transform of the energy level densities are straightforwardly and accurately described by periodic orbit theory as f varies from 0 to 1.[20]

A slightly more challenging version of this problem involves the continuous deformation of ''sliced'' circular wells of varying angular sizes, Θ, as one continuously varies the opening angle Θ. In this case the potential energy function might be described via

$$V(r,\theta)=\begin{cases}0, & \text{for } 0<r<R \text{ and } 0<\theta<\Theta,\\ \infty, & \text{otherwise.}\end{cases} \tag{2}$$

Special cases are shown in Fig. 1 where the half-circular well (c) and quarter-circle well (d) can be studied using very simple symmetry arguments (as in Sec. III below) as being related to the ''ordinary'' circular well (b), which is itself not actually in the class described by Eq. (2). The other special case of a circular well plus a thin, infinite wall along the positive x-axis [case (a),

which we will call the circular well plus baffle] has not been considered before and, together with the half- and quarter-circle wells constitute special cases of a general circular ''slice'' of opening angle Θ where these special cases correspond to $\Theta = 2\pi, \pi, \pi/2$ for cases (a), (c), and (d), respectively. (We note that the circular ''slice'' systems considered here are different, in many ways much simpler, than the so-called ''wedge billiard'' system which has been extensively studied elsewhere.[21])

The purpose of this paper is then several-fold. In Sec. II, we very briefly review the main ideas of periodic orbit theory, especially as applied to 2D and 3D billiard (or infinite well) problems in very simplified form and perform simple numerical tests on a 2D rectangular billiard. Next, in Sec. III, we quickly review the periodic orbit analysis for the four related billiard systems in Fig. 1. Finally, in Sec. IV, we perform a periodic orbit theory analysis for the general circular ''slice'' case with opening angle Θ to compare how the features in the Fourier transform of the energy level spectrum ''track'' the classical closed orbits in these more general versions of the circular well. We derive a general formula for the path lengths of closed orbits in the general $\Theta \to 0$ case, paying special attention to the special cases of $\Theta = \pi/2^n$ which form ''boundaries'' at which new features begin to appear in the $\rho(L)$ spectra.

II. PERIODIC ORBIT THEORY APPLIED TO BILLIARD SYSTEMS

The main quantity of interest in periodic orbit theory is the quantum density of energy levels which is defined via

$$\rho(E) = \sum_n \delta(E - E_n), \tag{3}$$

where the summation is over all of the quantized bound state energy levels. One of the main results of periodic orbit theory[1–3,5] is that this density can be approximated semi-classically as

$$\rho(E) = \rho_0(E) + \sum_{p=1}^{\infty} \sum_{\gamma} \rho_{\gamma,p} \cos\left[p\left(\frac{S_\gamma(E)}{\hbar} - \phi_\gamma \right) \right]. \tag{4}$$

The first term, $\rho_0(E)$, is a smoothly and slowly varying function of the energy variable and will provide no information on the detailed classical orbits. The second, oscillatory term is more interesting since $S_\gamma(E)$ is the classical action corresponding to ''primitive'' (''once-around'' only) periodic orbits characterized by a label γ and $p = 1, \ldots, \infty$ runs over all possible repetitions of such trajectories. This last term arises from a path integral approach and it is thus not surprising that periodic orbits dominate since their phase contributions add coherently, period after period, while the non-periodic orbits contribute phase terms which increasingly tend to cancel over time. It is this important term which contains information on the classical closed trajectories.

Since we wish to concentrate on 2D ''billiard systems,'' we will specialize to that case immediately. For such a ''billiard,'' i.e., for a particle which is free inside an infinite well of arbitrary shape of area A and circumference L and where $\psi = 0$ on the boundary, the smooth part can be written as

$$\rho_0(E) = \frac{A}{4\pi}\left(\frac{2m}{\hbar^2} \right) - \frac{L}{8\pi}\sqrt{\frac{2m}{\hbar^2 E}} \to \frac{A}{4\pi} - \frac{L}{8\pi}\frac{1}{\sqrt{E}}, \tag{5}$$

if we set $\hbar^2/2m=1$ as is often done for simplicity. This piece may well be more familiar in three-dimensions as very similar arguments are used in the counting of the number of states in a 3D cavity typically found in explanations of black-body radiation. The systematic study of the smoothed distribution of eigenvalues for the wave equation in a bounded domain[22] and its expansion in powers of $1/k=1/\sqrt{E}$ was first carried out by Weyl and so the terms in Eq. (5) are often called the Weyl terms.

We are, of course, more interested in the oscillatory piece and for the free-particle in a 2D well the quantized energies, E_n, and ''primitive'' actions, S_γ, are given by

$$E_n=\frac{\hbar^2 k_n^2}{2m}\rightarrow k_n^2 \quad \text{and} \quad S_\gamma(E=k^2)=\hbar k L_\gamma \tag{6}$$

where the k_n are the appropriate wavenumbers and L_γ is the length of the 'primitive' periodic orbit.

Using these and Eq. (3), we then have for the equivalent density of states, but now in k-space (where we once again set $\hbar^2/2m=1$ and also ignore an unimportant overall factor of 1/2),

$$\rho(k)=\sum_n \delta(k-k_n). \tag{7}$$

The corresponding expressions for Eq. (4) in k-space are given, in turn, by

$$\rho(k)=\rho_0(k)+\sum_{p=1}^{\infty}\sum_\gamma \rho_{\gamma,p}\cos[p(kL_\gamma-\phi_\gamma)], \tag{8}$$

and the dimensions are consistent since we take, as usual, $\hbar^2/2m=1$.

We then proceed by multiplying both expressions by e^{ikL} and integrating over k to evaluate the Fourier transform of each side. For the discrete energy level term, we have

$$\rho(L)=\sum_{n=1}^{\infty}\int_{-\infty}^{+\infty}\delta(k-k_n)e^{ikL}dk=\sum_{n=1}^{\infty}e^{ik_nL}, \tag{9}$$

which can be evaluated purely by using a knowledge of the bound state energy spectrum (actually the corresponding wavenumbers, k_n, in this simplest case).

For the semi-classical oscillatory piece we have, after taking the Fourier transform,

$$\rho(L)=\sum_{p=1}^{\infty}\sum_\gamma \rho_{\gamma,p}\delta(L-pL_\gamma), \tag{10}$$

which exhibits a series of δ-function like ''spikes'' at multiples of the lengths of the ''primitive'' closed paths, i.e., at $L=pL_\gamma$. The contribution of the smooth piece, $\rho_0(k)$, yields a δ-function piece at $L=0$ which will appear in the numerical evaluation of Eq. (9), but which gives no interesting information on the periodic orbits.

Thus, if we evaluate the Fourier transform, $\rho(L)$, of the wavenumber spectrum via Eq. (9), using either theoretically calculated or experimentally determined values of the k_n for a given geometry, we should find a series of sharp peaks corresponding to the lengths of classical closed orbits. More complete analyses[5] also retain information on the prefactors ($\rho_{\gamma,p}$), but since we focus here only on the positions of the periodic orbit ''spikes'' in $\rho(L)$ and not on the ''strengths'' of the δ-function peaks, we choose to use the simple version in Eq. (9).

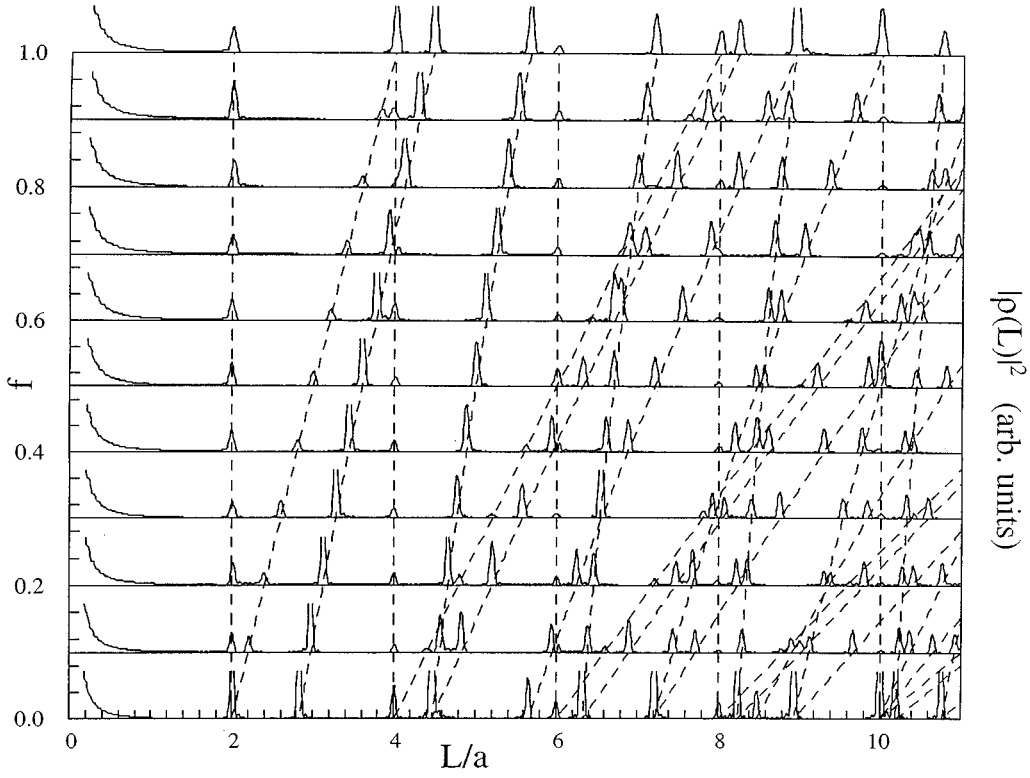

FIG. 2. Fourier transform (squared) of the wavenumber distribution, i.e., $|\rho(L)|^2$ versus L/a, for the 2D rectangular well. For each value of f shown on the left-hand axis, a ''spectrum'' corresponding to $|\rho(L)|^2$ is shown on the horizontal axis. The path length formulae of Eq. (13) are shown as dashed lines.

Because we will evaluate Eq. (9) numerically, we will necessarily use a finite number of wavevectors, namely

$$\rho_N(L)=\sum_{n=1}^{N} e^{ik_nL}, \tag{11}$$

so that the ''experimentally'' determined spikes in $\rho_N(L)$ will have a finite width. The resolution effects (due to using only a finite summation) have been discussed by Balian and Bloch.[3]

As a test of the simplified version of PO theory implied by Eq. (11), we analyze a 2D rectangular billiard with sides $L_x=a$ and $L_y=(1+f)a$ where we allow f to vary in the range $0 \leqslant f \leqslant 1$. (This system is discussed in detail in Ref. 5 where a more complete analytic approach is developed: we study it here in this more approximate formulation as a check on its numerical accuracy.) The quantized wavenumbers are trivially given by

$$k_{(i,j)}=\pi\sqrt{\frac{i^2}{L_x^2}+\frac{j^2}{L_y^2}}=\frac{\pi}{a}\sqrt{i^2+j^2/(1+f)^2}, \tag{12}$$

while the lengths of periodic orbits are equally simply given by the formula

$$L(i,j;f)=2a\sqrt{i^2+(1+f)^2j^2}. \tag{13}$$

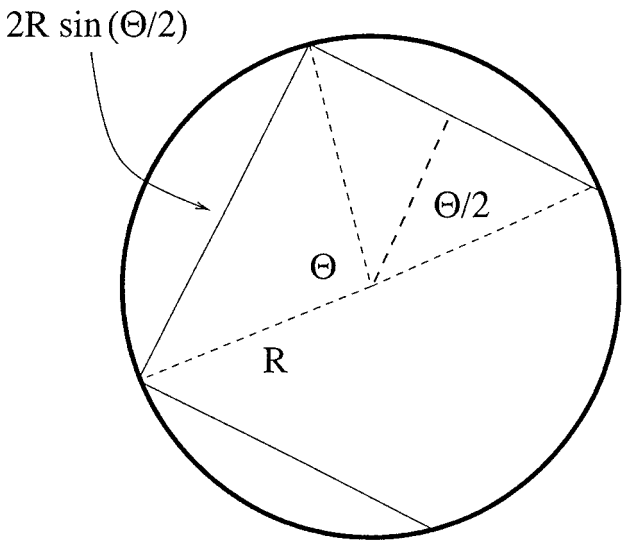

FIG. 3. Geometry leading to closed paths in a circular well. The length of each ''bounce'' is given by $2R\ \sin(\Theta/2)$ and the condition for closed orbits is $\Theta = 2\pi q/p$.

In Fig. 2 we plot the ''trajectories'' of these periodic orbit lengths (as dashed lines) as one varies f in the range (0,1) as the square is enlarged into the 1×2 rectangle. For many values of f, we then perform the numerical Fourier transform in Eq. (11) (using the lowest $N=1000$ eigenvalues) and plot the resulting $|\rho(L)|^2$ versus L/a. The locations of the peaks in $\rho(L)$ are indeed very well described globally by the intersections of the predictions of Eq. (13) with the horizontal lines of constant f. It is just this approach which we will follow when we perform a periodic orbit analysis of the general ''circular slice'' case in Sec. IV, but we first examine several special cases.

III. SPECIAL CASES

The geometry determining the structure of trajectories (closed or not) in the ordinary 2D circular well is well known[3,5,23] and is shown in Fig. 3. The distance traveled between each ''bounce'' with the circular wall is given by $L(\Theta)=2R\ \sin(\Theta/2)$. In order for the trajectory to close on itself giving rise to periodic orbits, one requires the condition that

$$p\Theta = q2\pi, \tag{14}$$

where the integer p is associated with the total number of ''bounces'' or ''hits'' on the wall and q gives the total number of ''revolutions'' made by the particle before coming back to the same point in phase space. Clearly these integers must satisfy $p \geqslant 2q$ and the lengths of periodic orbits is then given by

$$\frac{L(p,q)}{R} = 2p\ \sin\left(\frac{q\pi}{p}\right). \tag{15}$$

Repetitions of these periodic orbits are possible so that integer multiples of these values are also allowed. In fact, if p and q are relatively prime, then this labeling is unambiguous, while if $p = m\tilde{p}$ and $q = m\tilde{q}$ share a common factor, orbits labeled by $(p,q)=m(\tilde{p},\tilde{q})$ can be associated

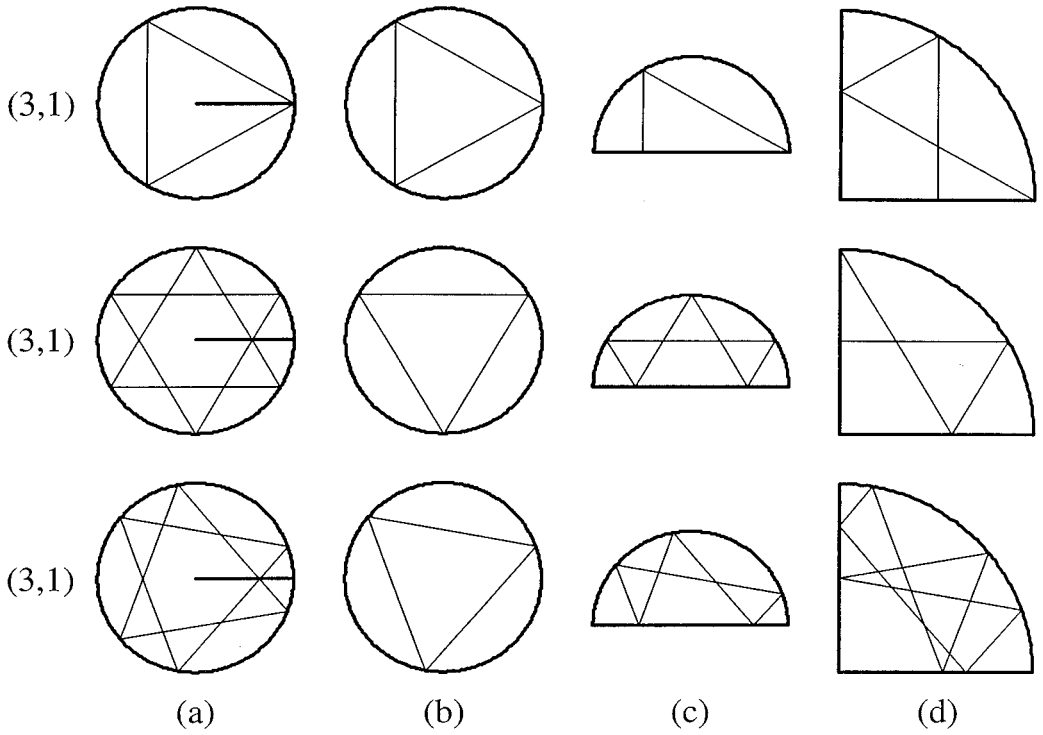

FIG. 4. Examples of possible closed orbits in each of the different wells in Fig. 1 for various values of the initial orientation of the orbit. Typical trajectories for the (a) circular well plus baffle, (b) ordinary circular well, (c) half-circular well, and (d) quarter-circular well are shown. Cases illustrating $(p,q)=(3,1)$ are shown.

with an m-fold repetition of the basic $(\tilde{p},\tilde{q})$ path; we might thus write $(6,2)=2(3,1)$ as the first repetition of the (3,1) trajectory to describe that path ''the second time around.'' For a fixed value of q, as $p\rightarrow\infty$, the path lengths approach the values

$$L(p\rightarrow\infty,q)=2\pi q, \tag{16}$$

and such paths are approaching the limit of uniform circular motion around the inner edge of the circular well. Because of this, there is a ''pile-up'' of periodic orbits as one approaches values of $L=2n\pi$ (from below) which are increasingly closely spaced as p increases. This implies that one can often not totally resolve individual (p,q) orbits near these limiting values in the $\rho(L)$ spectra.

Typical periodic orbits for the circular well for the cases $(p,q)=(3,1)$, (4,1), (5,2), (7,2), (8,3), and (2,1) are shown in Figs. 4–9, respectively, in the second column labeled (b). In each case, we show three different periodic orbits, each labeled by the same (p,q) pair, but differing only in the initial orientation of the trajectory. In each case there is obviously a continuously infinite set of trajectories for each (p,q) label.

The periodic orbits or closed trajectories in the half-circular well in column (c) of Fig. 1 are easily obtained from those of the ordinary circular well. The wall along the x-axis will give rise to specular reflections of any particle incident on it so that an allowed path (again, closed or not) in the ordinary circular well can be simply reflected in the horizontal axis and back into the upper half-plane and will result in an allowed trajectory in the half-well. Any closed path in the full well, therefore, will also be a periodic orbit in the half-well and the spectrum in $\rho(L)$ should exhibit features at the same values of L. In Figs. 4–9, we show the orbits obtained from the full well [i.e., those in column (b)] by reflection as allowed orbits in the half-well, now shown in column (c).

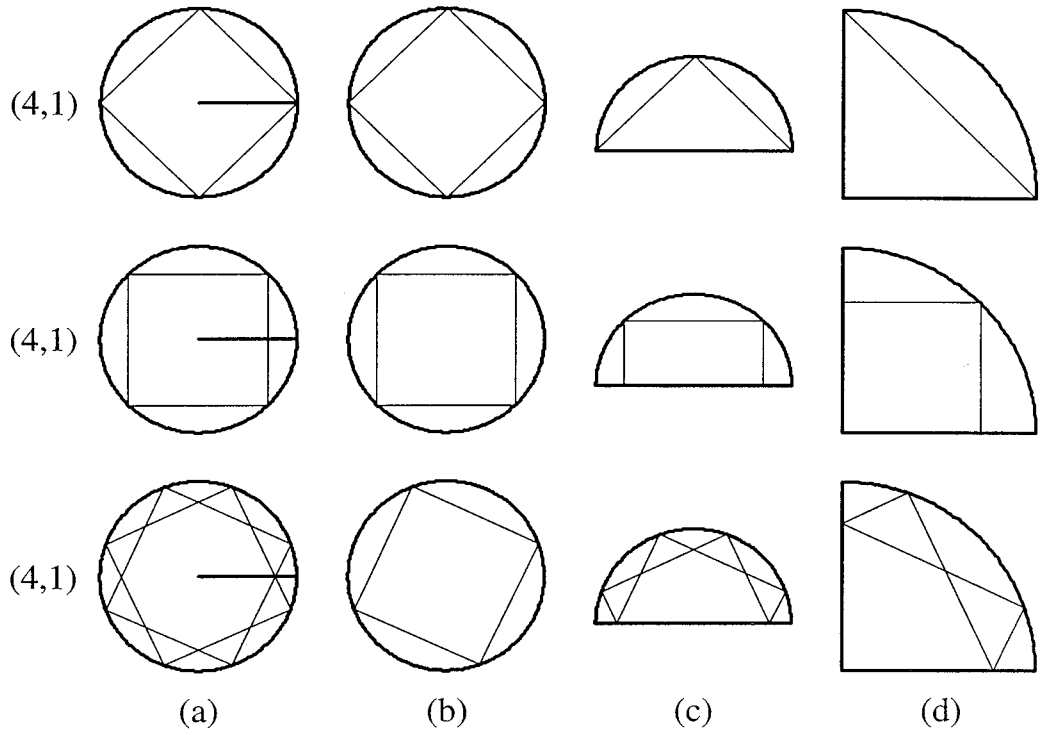

FIG. 5. The same as Fig. 4, but for $(p,q)=(4,1)$.

The one exception is the special (isolated) orbit corresponding to the $(p,q)=(2,1)$ case in Fig. 9 where the orbit through the origin closes on itself with a total path length of $L=2R$ which will lead to features in the $\rho(L)$ spectrum at integral multiples of $2R$ in addition to those in the full well at multiples of $4R$.

The periodic orbits in the quarter-well are obtained similarly by reflecting allowed orbits in the full circular well in *both* the horizontal *and* the vertical axes. Examples of such orbits are shown in Figs. 4–9 in column (d) for the same (p,q) values as used before. In this case we see that the path lengths for *even* values of p are halved as the particles return to their starting point (in phase space) in half the distance, while for *odd* values of p, the same path lengths as for the circular and half-circular wells are found.

Finally, as one can see from the examples in column (a) of Figs. 4–9, the effect of adding the baffle (the thin infinite wall along the positive x-axis) to the ordinary circular well is to double the length of all standard closed orbits as the mirroring effect of the extra wall causes all trajectories to fully retrace their paths in order to return to the same starting point in phase space. Two exceptions are illustrated in Figs. 7 and 8 for the case of *even* q values for the special orientations shown in the top row of column (a) in those two cases (compare the solid and dashed lines.) For these cases, the path lengths are unchanged from their full-well values. [We also note that the specialized geometries corresponding to the $(p,q)=(2,1)$ cases are not entirely well-defined, so that the circular well plus baffle trajectories shown in column (a) in Fig. 9 are certainly somewhat ambiguous.]

In order to compare these predictions for the path lengths of closed trajectories using the Fourier transform in Eq. (11), we require the allowed wavenumber values in these four infinite

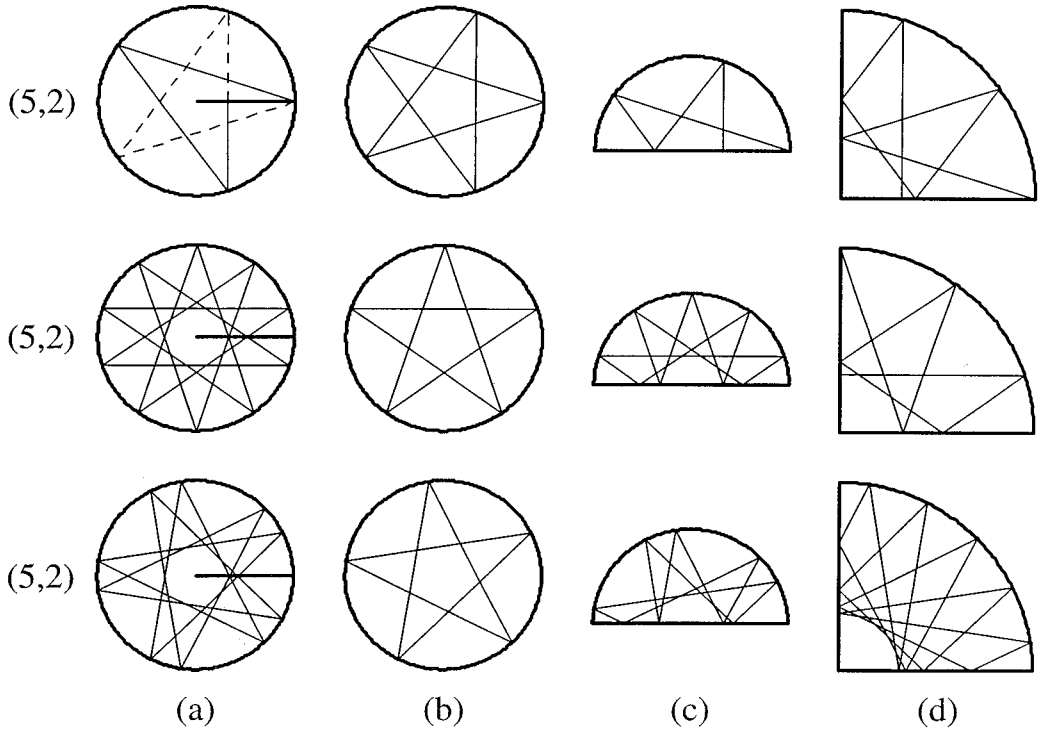

FIG. 6. The same as Fig. 4, but for $(p,q)=(5,2)$.

wells. In each case the effective (infinite well) potential function can be separated into radial and angular parts and the solutions of the Schrödinger equation (or wave equation) can be easily obtained in a product form, namely $\psi(r,\theta)=R(r)\Phi(\theta)$. For example, in the ordinary circular well case, the angular solutions are given by

$$\Phi(\theta)=\begin{cases}\sin(m\theta), & m=1,2,3,\ldots,\\ \cos(m\theta), & m=0,1,2,3,\ldots,\end{cases} \tag{17}$$

where m is an integer while the radial wavefunctions are given by (the well-behaved at the origin or regular) cylindrical Bessel functions, $R(r)=J_m(kr)$. The wavenumber spectrum is then given by $k_{n,m}=a_{n,m}/R$ where the $a_{n,m}$ denote the n-th zero of the m-th Bessel function. The spectrum is thus doubly degenerate for $m\geqslant 1$ [one zero each for the $\sin(m\theta)$ and $\cos(m\theta)$ solutions] and single-valued for the $m=0$ values.

For the half-circle case, the boundary conditions along the x-axis imply that only the $\sin(m\theta)$ solutions in Eq. (17) will be allowed, so that the spectrum in this case corresponds to one ''copy'' of the $m\geqslant 1$ spectrum of the corresponding full-well case. Similarly, the quarter-well problem, with walls along both the x- and y-axes at which the solutions must vanish, can be satisfied by those solutions in Eq. (17) of the form $\sin(m\theta)$ (which vanish along the x-axis) provided that m is an *even* integer and this limited subset of solutions then also satisfies the boundary conditions along the y-axis.

For the full-circle plus baffle case, we can still use solutions of the form $\Phi(\theta)=\sin(m\theta)$ which automatically satisfy the boundary condition along the x-axis (as $\theta\rightarrow 0$ from above) regardless of

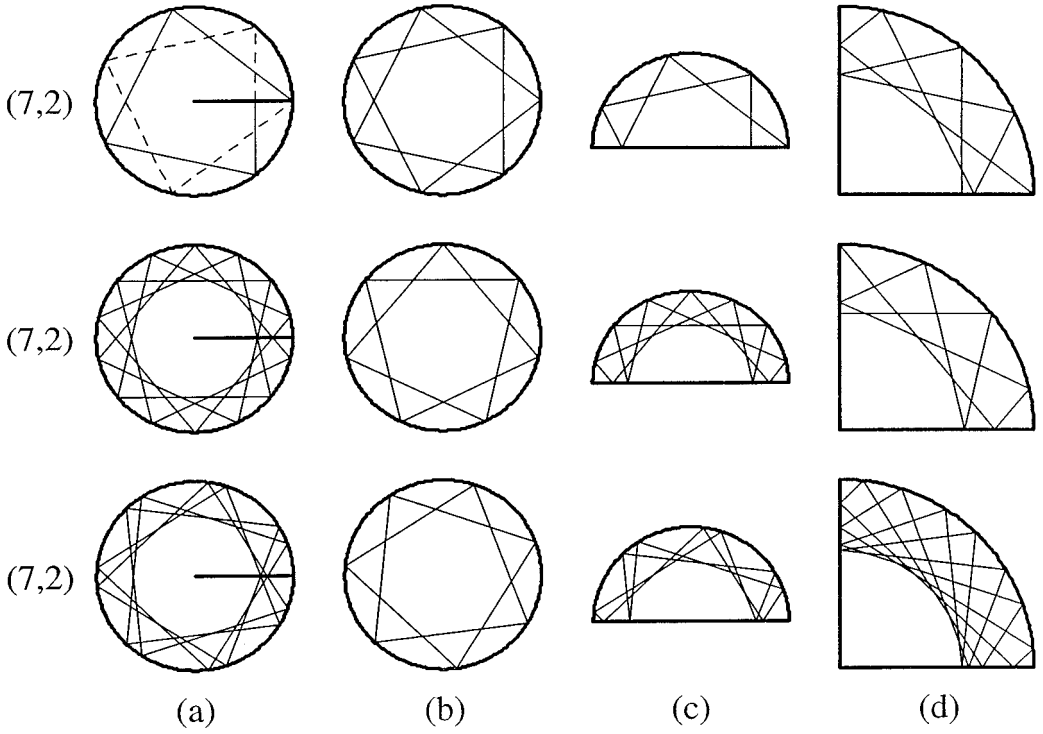

FIG. 7. The same as Fig. 4, but for $(p,q)=(7,2)$.

the value of m. In order that the solutions also vanish on the ''baffle'' as we approach the thin, infinite wall via $\theta \to 2\pi$, we also require that $\sin(m2\pi)=0$ which implies that $m=n/2$ where $n \geqslant 1$ is an integer. Thus, not only are the regular cylindrical Bessel functions still solutions (corresponding to the case where n is *even*), but now Bessel functions of half-integral order (when n is *odd*) are also required for the full solution space. These solutions (up to powers of $\sqrt{r}$) are simply the regular spherical Bessel functions which appear in the solutions of the 3D or spherical infinite well problem. The resulting wavenumber spectrum will then be determined by zeroes of both the regular *cylindrical* and *spherical* Bessel functions.

Armed with these solutions, we can numerically find a large number of the required Bessel function zeroes (we use *Mathematica*® and the FindRoot[ ] command) which we then use in the truncated Fourier transform,

$$\rho(L)=\sum_{n=1}^{N} e^{ik_nL}. \tag{18}$$

For the ordinary circular well case we use the lowest $N=3000$ wavenumbers (including each $m \geqslant 1$ value twice), while for the other three cases we use the lowest $N=2000$ values. The resulting ''spectra'' of $|\rho(L)|^2$ versus L/R are plotted in Fig. 10 for the four special cases we have considered so far, namely (a) full circle plus baffle, (b) ordinary circular well, (c) half-circle, and (d) quarter-circle cases and we label some (but not all) of the observable peaks with the appropriate (p,q) values. The overall pattern of peaks is completely consistent with the observations above and the broad shoulder seen in cases (b)–(d) near $L/R=2\pi$ is indicative of the lack of resolution mentioned earlier. The small peak at $L/R=2$ labeled $(2,1)'$ seen in the half-well case is also evident. We now turn to the more general case corresponding to arbitrary Θ to see how the

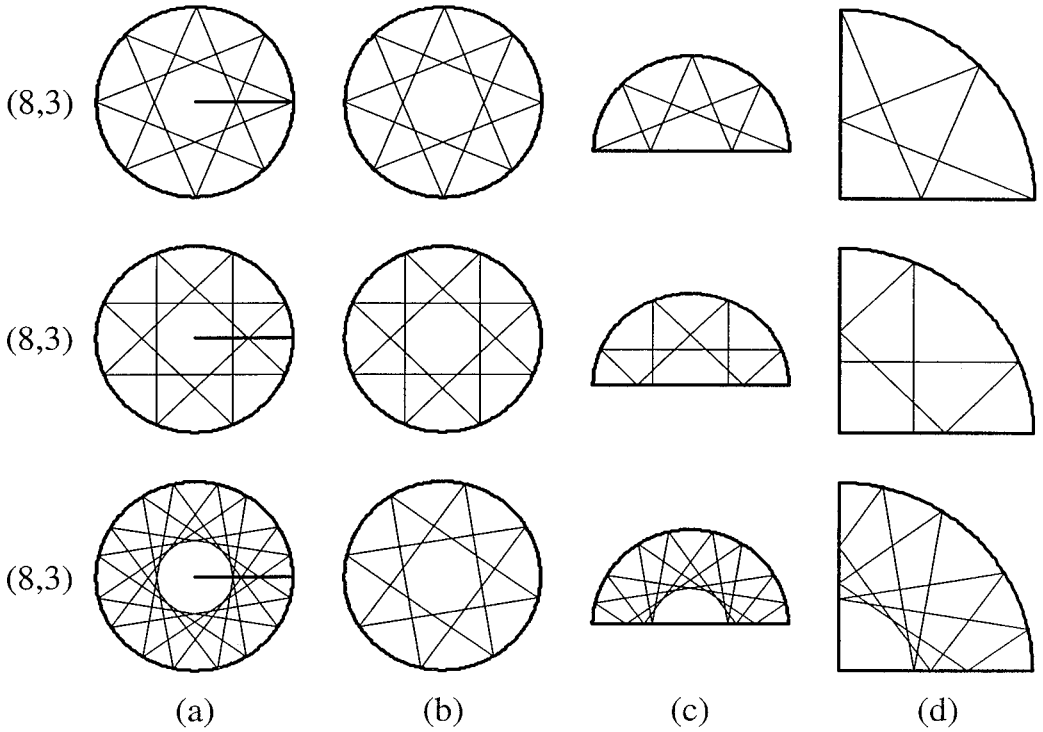

FIG. 8. The same as Fig. 4, but for $(p,q)=(8,3)$.

spectrum of the half-circle [case (c)] is changed to that of the quarter-circle of case (d) [or the circle plus baffle in case (a)] as the angle Θ is decreased (or increased) from π to $\pi/2$ (from π to 2π).

IV. MORE GENERAL CASES

The half-well, quarter-well, and circle plus baffle cases considered so far can all be considered as special cases of a general infinite well with opening angle Θ (i.e., infinite walls at $\theta=0$ and $\theta=\Theta$) as defined by the potential in Eq. (2). A convenient parameterization of the continuous change from the half-well to the circle well plus baffle case is shown in Fig. 11 (top row) where we let $\Theta=\pi(1+f)$ where $0\leqslant f\leqslant 1$. A similar description relevant for the quarter-well limit is to let $\Theta=\pi/(1+f)$ (also with $0\leqslant f\leqslant 1$) as shown in the bottom row of Fig. 11. In that case, one can continue ''shrinking'' the region beyond the quarter-well case by letting $f>1$, and we also discuss the general case below.

We begin the comparison between the classical closed orbits and the wavenumber spectrum for these more general cases by focusing first on the case where Θ increases from π. Two exemplary trajectories corresponding to $(p,q)=(4,1)$ and $(3,1)$ are shown in Fig. 12 to indicate the pattern of allowed closed trajectories. As the angle Θ is increased by a factor of $(1+f)$, the pattern of ''bounces'' discussed above remains basically unchanged except that the opening angles subtended by an individual path length are all similarly increased by the same factor. We thus expect closed orbits with lengths now given by

$$\frac{L(p,q;f)}{R}=2p\,\sin\left(\frac{q\pi(1+f)}{p}\right), \tag{19}$$

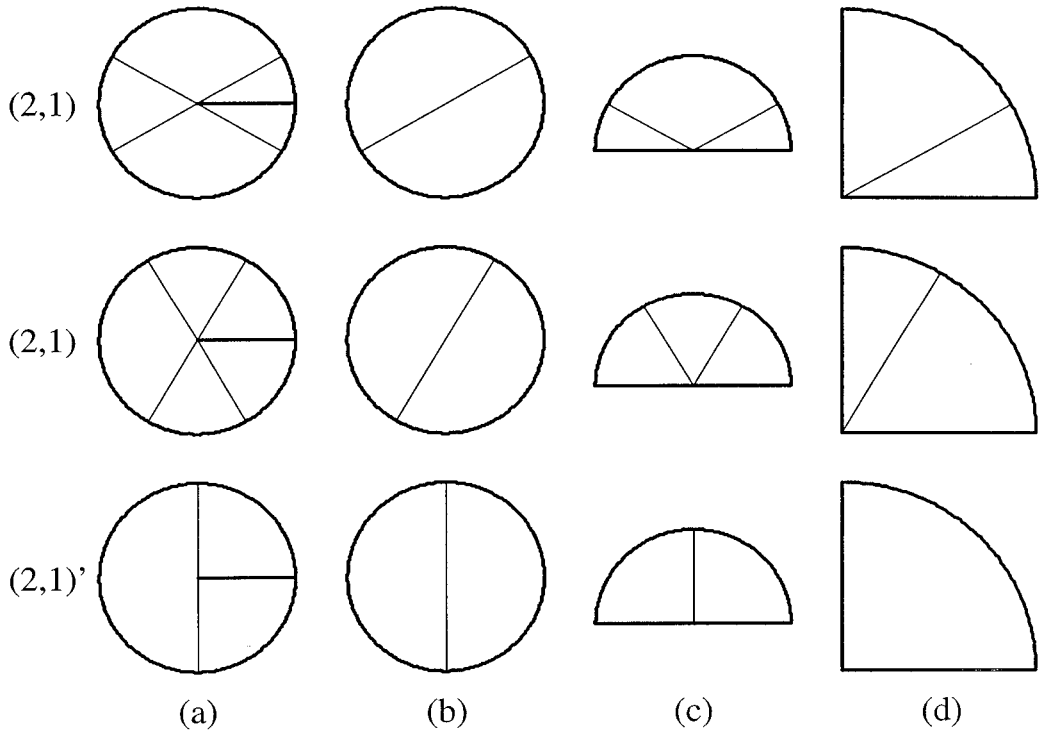

FIG. 9. The same as Fig. 4, but for $(p,q)=(2,1)$. The special case corresponding to $(2,1)'$ where the orbit length is $L=2R$ is shown in the bottom row.

as well as repetitions. This formula clearly describes the ''fate'' of the (4,1) trajectory in Fig. 12(a) as f is increased from 0 to 1. Figure 12(b), however, exhibits what can happen to other trajectories as the opening angle is increased. Beyond a certain critical value of Θ (or equivalently f), the pattern of bounces can no longer be sustained and that path should ''disappear'' from the spectrum. Operationally this occurs when $\sin(q\pi(1+f)/p)=1$ which gives a maximum value of f for certain orbits of

$$f_{max}=\frac{p}{2q}-1, \tag{20}$$

which is only relevant when $f_{max}<1$ or when $4q>p$. At that critical value, the particle makes a total of $2p$ ''bounces'' between the walls and the inner ''cusp'' and at larger angles that trajectory is no longer allowed. This phenomenon will be clearly apparent in the $\rho(L)$ spectra we discuss next.

For the quantum mechanical or wave case, we require the solutions of the Schrödinger equation in this restricted geometry. Just as discussed above, angular solutions of the form $\Phi(\theta)=\sin(m\theta)$ will satisfy the boundary conditions along the positive x-axis, while the vanishing of the wavefunction at the $\theta=\Theta$ boundary requires that $m\Theta=n\pi$ or $m=n/(1+f)$ where $n=1,2,3,\ldots$, for a given value of f. We can still evaluate the zeroes of the corresponding Bessel functions of non-integral order to obtain a long list of allowed wavenumbers. For this case, we have found the lowest-lying $N=3000$ such wavenumbers and have used them in Eq. (18) to calculate $\rho(L)$ for values of f in the range $0\leqslant f\leqslant 1$. Various such spectra are plotted in Fig. 13 (horizontal plots of $|\rho(L)|^2$ versus L/R) for different values of f. The dashed lines correspond to the predictions for classical path lengths given by Eq. (19) and the agreement between the observed peaks in the

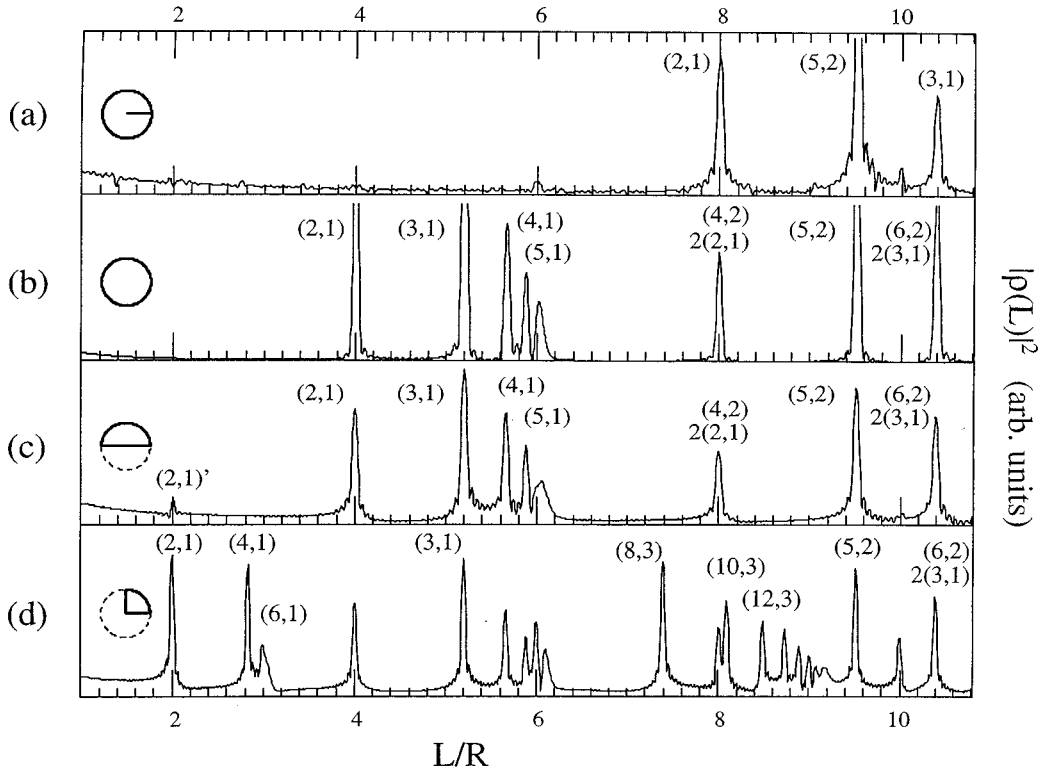

FIG. 10. Fourier transform (squared) of the wavenumber distribution, i.e., $|\rho(L)|^2$ versus L/R, for the cases of the (a) circular well plus baffle, (b) ordinary circular well, (c) half-circular well, and (d) quarter-circular well. Labels indicating the appropriate (p,q) values are shown for some (but not all) of the peaks.

spectra and the predicted locations (intersections of the dashed lines with horizontal lines of constant f) is clearly very good. As often happens, the infinite number of peaks near the limiting cases of circular motion (here just below $L/R=2\pi\rightarrow 4\pi$ as f increases) are not well resolved, especially for larger values of f. The f values at which various of the spectral features ''disappear'' from the spectrum because of the geometrical effects discussed above also is well-reproduced by the predictions of Eq. (20). Specifically, we find the values

(p,q)	f_{max}
(3,1)	1/2=0.500
(5,3)	1/4=0.250
(6,2)	1/2=0.500
(7,2)	3/4=0.750
(7,3)	1/6=0.167

which agree nicely with the spectral pattern in Fig. 13. We note that such ''bifurcations'' of orbits (the appearance or disappearance of classically allowed paths at some critical value of a parameter) also occur in the annular billiard system considered in Refs. 19 and 20: specifically, as the radius of the inner annulus is increased, certain allowed classical orbits are no longer consistent with the restricted geometry and no longer appear in the $\rho(L)$ spectrum.

We now turn our attention to the case where $\Theta=\pi/(1+f)$ is decreased which describes the transition between the half-well to quarter-well cases as f increases from 0 to 1. Just as above we expect closed path lengths (due to the decrease in Θ) now of the form

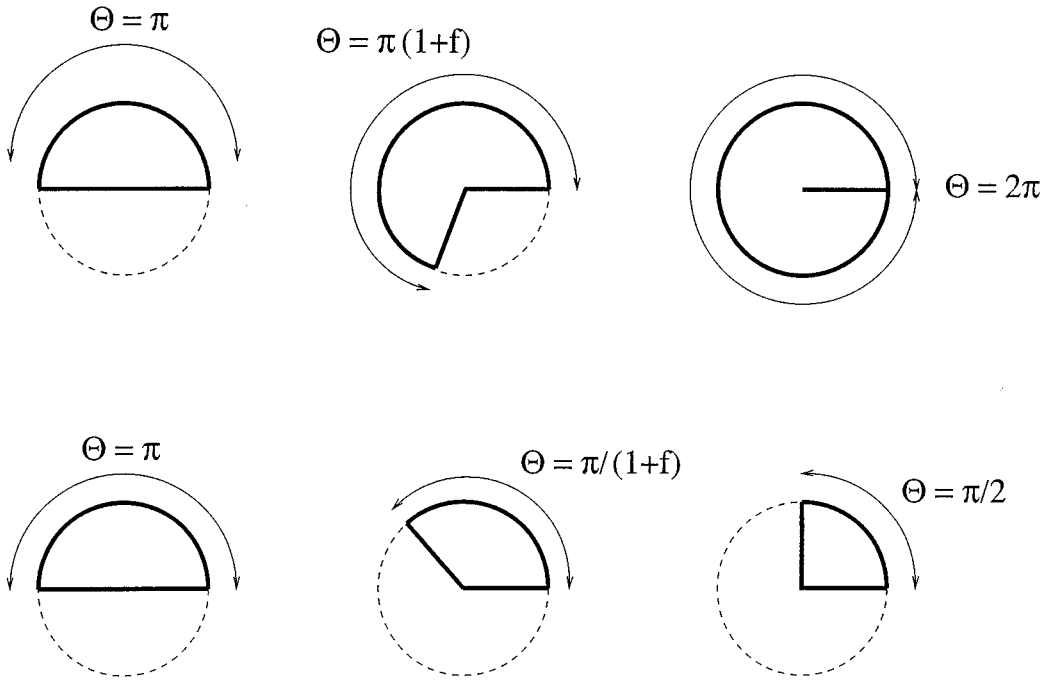

FIG. 11. Definitions of angle Θ for continuous deformation of the half-circle to the circle plus baffle [the top row where $\Theta=\pi(1+f)$] and to the quarter-circle [the bottom row where $\Theta=\pi/(1+f)$]. In each case, one has $0\leqslant f\leqslant 1$.

$$\frac{L(p,q;f)}{R}=2p\ \sin\left(\frac{q\pi}{p(1+f)}\right). \tag{21}$$

Also just as above, for a given value of f, we can now find a large number of low-lying zeroes of Bessel functions of non-integral order, $J_m(kr)$, this time labeled by $m=n(1+f)$ so that when f=1 (corresponding to the quarter-well) this reduces to even integral values as mentioned above. The resulting ''spectra'' of $|\rho(L)|^2$ versus L/R are shown in Figs. 14 and 15 for several values of f over the ranges $L/R=(2.0,8.0)$ and $L/R=(8.0,14.0)$ separately to allow for easier inspection of the more complex pattern of peaks. The predictions for the path lengths in Eq. (21) are once again shown as dashed lines. Once again, there is a large degree of overlap between the locations of the peaks and the predictions of Eq. (21). For example, the dashed ''path length trajectory'' labeled (2,1) is well described by the formula and is consistent with the illustrative example of Fig. 16 where the evolution of such a path is shown.

There are, however, a number of prominent features for the quarter-well case (i.e., along the $f=1$ horizontal line) which are not the limiting cases of the simple generalization of Eq. (15) as given by the dashed lines of Eq. (21) and these cases have been labeled by capital letters from A–K. These paths, which have been traced by solid curves, are instead described by the formulae

$$\frac{L(p,q;f)}{R}=\begin{cases}\left[2p\ \sin\left(\dfrac{2\pi q}{p(1+f)}\right)\right], & \text{for } p \text{ odd},\\ \dfrac{1}{2}\left[2p\ \sin\left(\dfrac{2\pi q}{p(1+f)}\right)\right], & \text{for } p \text{ even}.\end{cases} \tag{22}$$

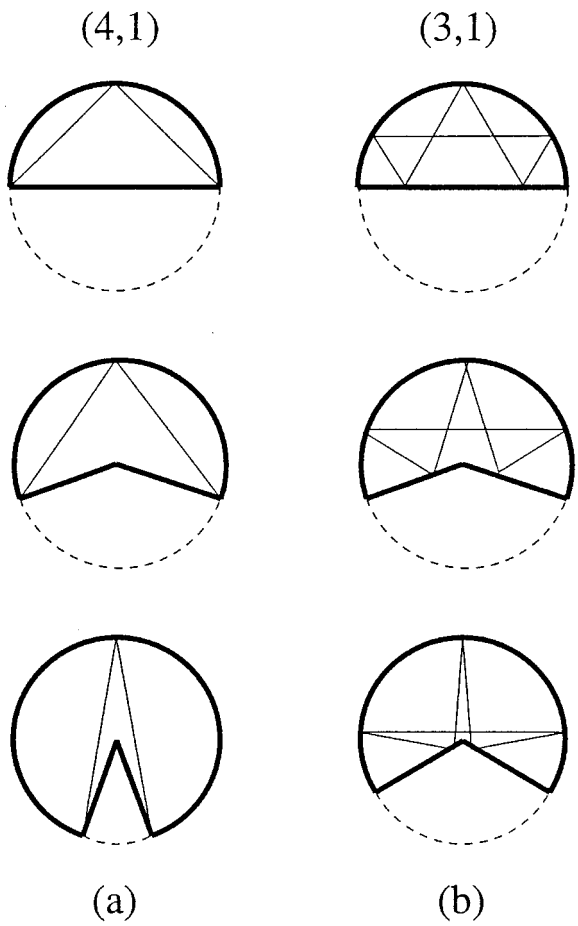

FIG. 12. Diagrams demonstrating the increasing path lengths corresponding to the (a) $(p,q)=(4,1)$ case and (b) (3,1) cases as $\Theta=\pi(1+f)$ is increased; special symmetric paths are chosen for illustrative purposes. For the (4,1) case, the formula $L(p,q;f)/R=2p\sin(\Theta(1+f)q/p)$ in Eq. (19) works for all f values in the range $0\leqslant f\leqslant 1$, while for the (3,1) case, the diagram shows the origin of the maximum value of f given by $f_{max}=p/2q-1=0.5$ corresponding to $\Theta=3\pi/2$.

The origin of these path length formulas is exemplified for a special case [namely $(p,q)=(3,1)$ and hence p odd] in Fig. 17. The evolution of a particularly symmetric (3,1) trajectory is shown in the top row, and in this case it is best to consider the angular size of the well as it is increased from $\pi/2$ to π (i.e., going from right to left). Because of the mirroring effect of the infinite wall along the x-axis, the path lengths for the upper row [where $\Theta=\pi/(1+f)$] are identical to those indicated in the bottom row as exist in the larger ''slice'' of *twice* the opening angle, namely $\Theta=2\pi/(1+f)$. Thus, familiar paths which are allowed for the quarter-well case can be transformed in direct analogy to the half-well to full circle plus baffle case; this identification explains the appearance of the additional factor of 2 in the $2\pi q/p(1+f)$ term in Eq. (22), as opposed to Eq. (19), due to mirroring.

In these cases, there is now a *minimum* value of f which is indicated before the closed orbit can be maintained in the increasingly narrow region. The effect is also illustrated in Fig. 17 for the (3,1) path and is very similar to spirit to the arguments shown in Fig. 11(b). The minimum value of f implied by requiring that $\sin(2\pi q/p(1+f))=1$ (just as above) is

$$f_{min}=\frac{4q}{p}-1, \tag{23}$$

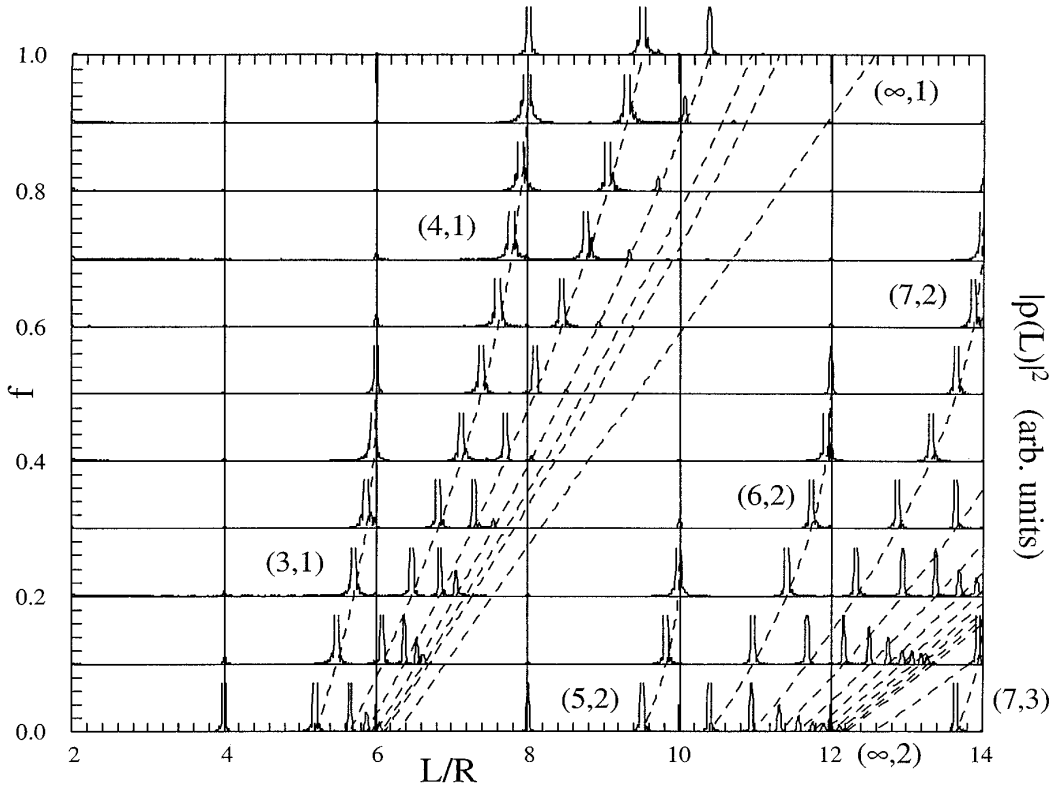

FIG. 13. Fourier transform (squared) of the wavenumber distribution, $|\rho(L)|^2$ versus L/R, for increasing values of $\Theta = \pi(1+f)$. For each value of f shown on the left-hand axis, a ''spectrum'' corresponding to $|\rho(L)|^2$ versus L/R is shown on the horizontal axis. The value $f=0\,(1)$ corresponds to the case of the half-circular (full circle plus baffle) well. The positions of the observable peaks in $\rho(L)$ are well described by the formula in Eq. (19) which are given by the dashed lines, while the values of f at which various of the dashed ''path length trajectories'' disappear are consistent with Eq. (20).

and the locations of these f values for the special ''path length trajectories'' labeled on Figs. 14 and 15 are given by

label	(p,q)	f_{min}
A	(3,1)	1/3=0.333
B	$\frac{1}{2}$(8,3)	1/2=0.500
C	$\frac{1}{2}$(10,3)	1/5=0.200
D	(5,2)	3.5=0.600
E	(6,2)=2(3,1)	1/3=0.333
F	(7,2)	1/7=0.143
G	$\frac{1}{2}$(12,5)	2/3=0.667
H	$\frac{1}{2}$(14,5)	3/7=0.429
I	$\frac{1}{2}$(16,5)	1/4=0.250
J	(7,3)	5/7=0.714
K	$\frac{1}{2}$(18,5)	1/9=0.111

and once again the f values at which the solid ''path length trajectories'' appear from the vertical lines of constant L/R given by $L/R=p$ (for even values of p) and $L/R=2p$ (for odd values of p) are very well reproduced.

With the cases considered so far, it is straightforward to generalize this analysis to the $\Theta \leqslant \pi/2$

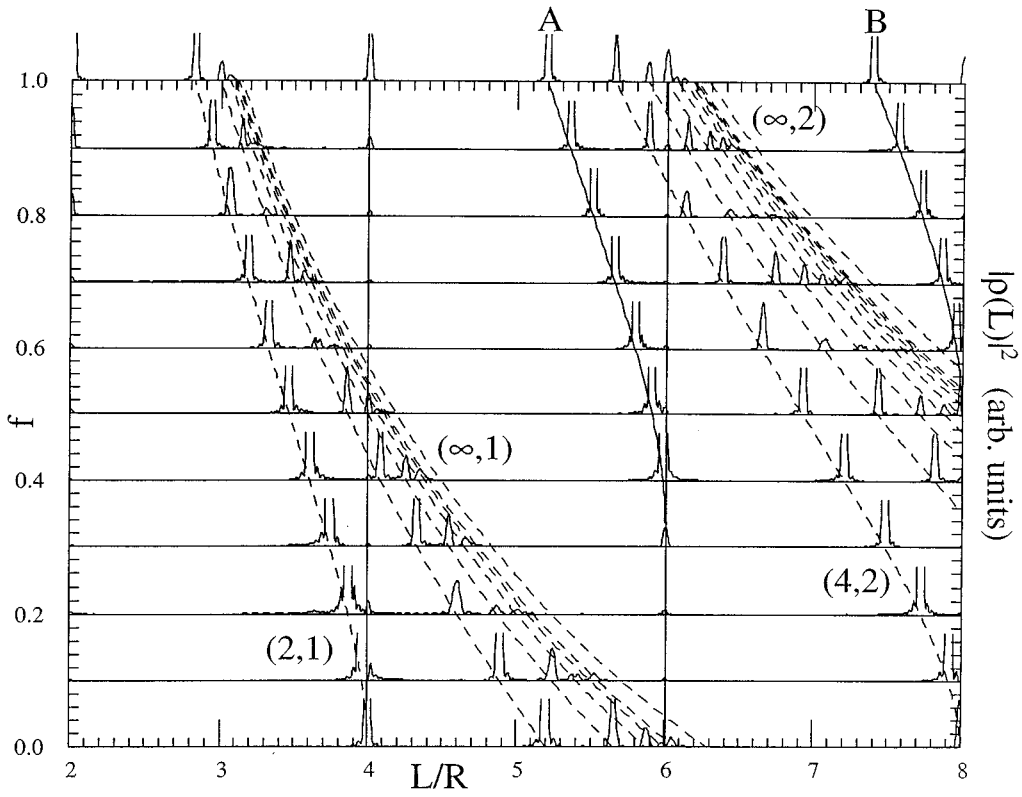

FIG. 14. The Fourier transform (squared) of the wavenumber distribution, $|\rho(L)|^2$ versus L/R, for decreasing values of $\Theta=\pi/(1+f)$. The value $f=0$ (1) corresponds to the case of the half-circular (quarter-circular) well. The range $L/R=(2.0,8.0)$ is shown. The positions of many of the observable peaks in $\rho(L)$ are well described by the formula in Eq. (21) which are given here by the dashed lines. The solid lines are described by the formulae in Eqs. (22) and the values of f at which they ''break out'' from the vertical lines corresponding to even values of L/R are all consistent with the formula $f_{min}=4q/p-1$ in Eq. (23).

region, where $f>1$. For example, in the region $\pi/4\leqslant\Theta\leqslant\pi/2$, where $3\geqslant f\geqslant 1$, the ''new'' closed orbits, i.e., those which appear to ''sprout'' from the vertical lines at even values of L/R, are given by

$$\frac{L(p,q;f)}{R}=\begin{cases}\left[4p\,\sin\left(\dfrac{4\pi q}{p(1+f)}\right)\right], & \text{for } p \text{ odd},\\ \dfrac{1}{2}\left[4p\,\sin\left(\dfrac{4\pi q}{p(1+f)}\right)\right], & \text{for } p=2m,\ m=1,2,3\ldots,\\ \dfrac{1}{4}\left[4p\,\sin\left(\dfrac{4\pi q}{p(1+f)}\right)\right], & \text{for } p=4m,\ m=1,2,3,\ldots,\end{cases} \tag{24}$$

since the values with $p=4m$ can be ''mirrored twice'' and have their path lengths cut in half a second time. In this region, the closed paths will be described by these expressions, as well as those already discussed in Eqs. (21) and (22). As an example of the increasing complexity of both the ''experimental spectra'' given by the peaks in $\rho(L)$ and the theoretical predictions of these three classes of path length formulae, in Fig. 18 we show a portion ($8\leqslant L/R\leqslant 10$) of the spectra covering the range $1\leqslant f\leqslant 3$ (corresponding to $\pi/2\geqslant\Theta\geqslant\pi/4$.) The dashed and solid curves are the

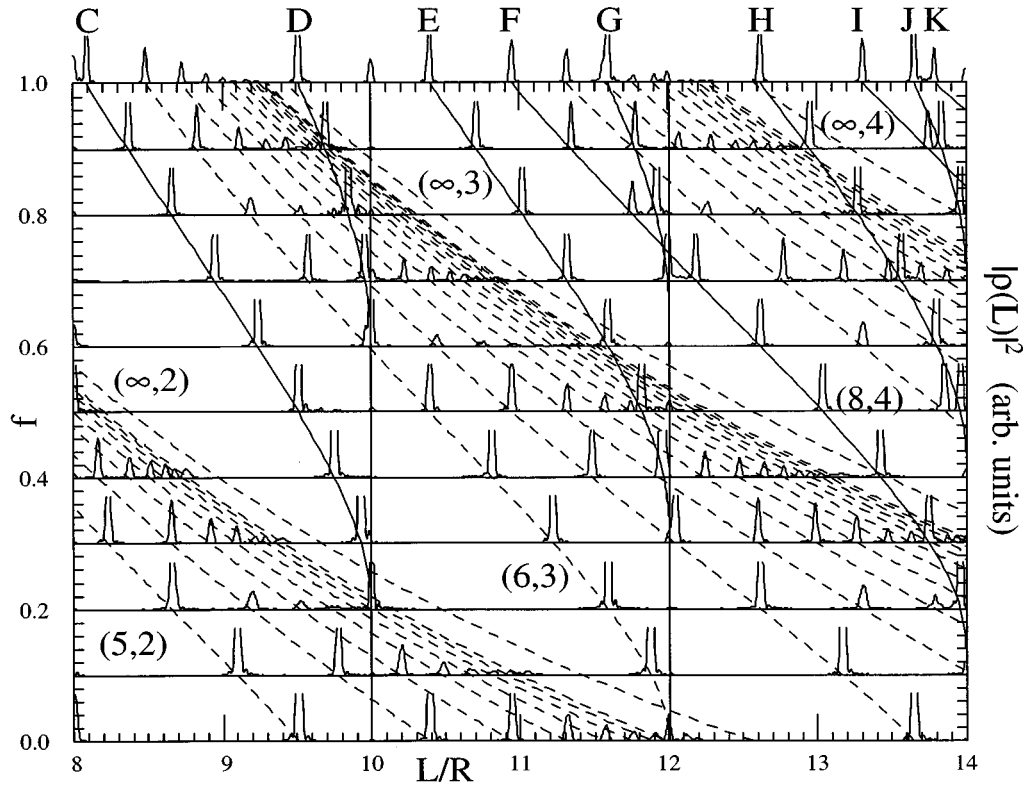

FIG. 15. The same as Fig. 14, except for the range $L/R=(8.0,14.0)$.

expressions in Eqs. (21) and (22) which were already apparent in the $\pi/2 \leqslant \Theta \leqslant \pi$ region, while the bold dashed curves correspond to the new cases described in Eq. (24) for those trajectories which first ''appear'' in the $\Theta \in (\pi/4, \pi/2)$ region. Once again, the agreement between the theoretical predictions (locations of crossings with the horizontal lines of constant f) and the locations of features in the Fourier ''spectra'' is quite good.

This pattern can then be generalized straightforwardly to the general case, namely we find that in the Θ range given by $(\pi/2^{n+1}, \pi/2^n)$ there are $n+2$ new formulae of the form in Eq. (24), namely

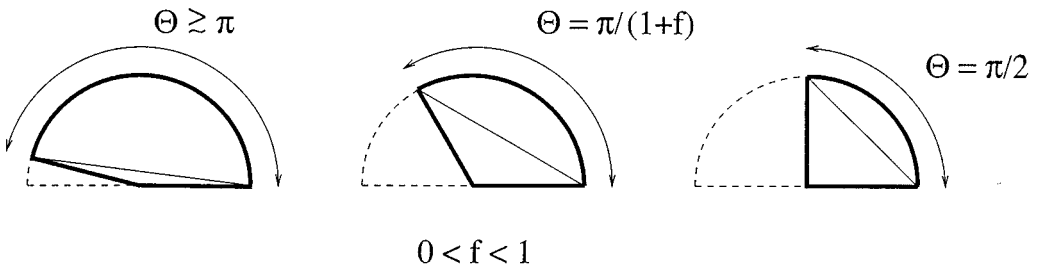

FIG. 16. The diagram illustrating the decreasing path length corresponding to the $(p,q)=(4,1)$ case as $\Theta=\pi/(1+f)$ is decreased.

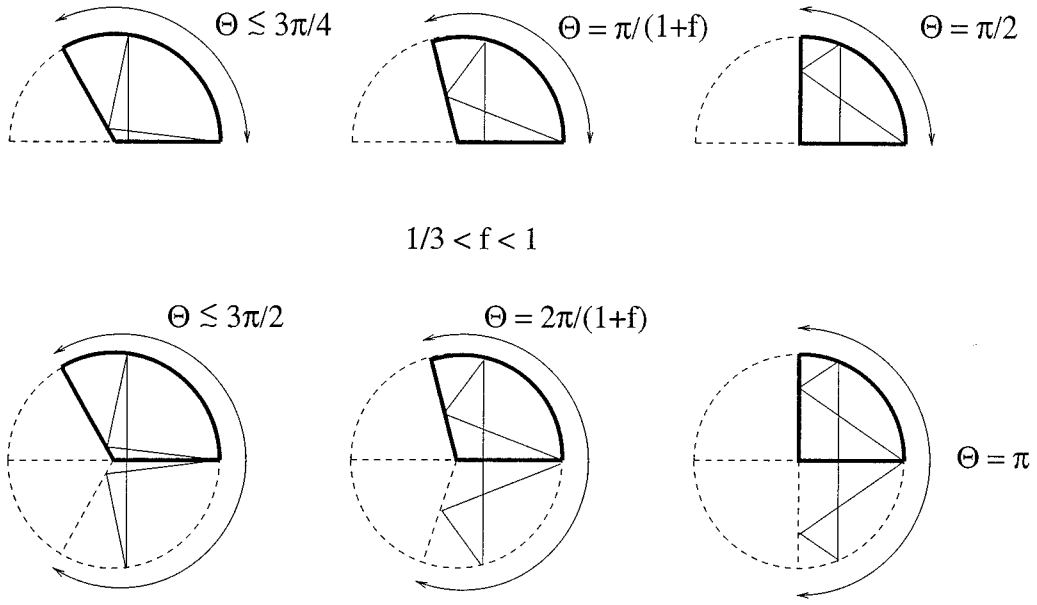

FIG. 17. The same as Fig. 16, but for the case $(p,q)=(3,1)$ illustrating the origin of the path-length formulae in Eq. (22). This figure also illustrates the origin of the minimum f value given by $f_{min}=4q/p-1=1/3$ corresponding to $\Theta=\pi/(1+f_{min})=3\pi/4$.

$$\frac{L(p,q;f)}{R}=\begin{cases}\left[2p\ \sin\left(\dfrac{2^{n+1}\pi q}{p(1+f)}\right)\right], & \text{for } p \text{ odd},\\ \dfrac{1}{2}\left[2p\ \sin\left(\dfrac{2^{n+1}\pi q}{p(1+f)}\right)\right], & \text{for } p=2m,\ m=1,2,3\ldots,\\ \dfrac{1}{4}\left[2p\ \sin\left(\dfrac{2^{n+1}\pi q}{p(1+f)}\right)\right], & \text{for } p=4m,\ m=1,2,3,\ldots,\\ \quad\vdots & \quad\vdots \qquad\qquad \vdots\\ \dfrac{1}{2^n}\left[2p\ \sin\left(\dfrac{2^{n+1}\pi q}{p(1+f)}\right)\right], & \text{for } p=2^n m,\ m=1,2,3,\ldots,\end{cases} \tag{25}$$

in addition to the path length formulae which would have already been considered for larger values of Θ. The values $\Theta=\pi/2^n$ form boundaries at which the new terms in Eq. (25) are added, with new spectral features ''appearing'' from even values of L/R as Θ is decreased from $\pi/2^n$ to $\pi/2^{n+1}$. At each value of $\Theta=\pi/2^n$, there are additional ''mirrorings'' possible for appropriate values of p.

An extension of this geometry which is also more calculationally extensive is to consider a periodic orbit theory analysis of a 3D spherical infinite well and extensions thereof. One of the original references on this subject[3] used the spherical billiard as a numerical example and it is easy to imagine extending this analysis to half-, quarter-, and eighth-spheres, as well as to 3D ''slices'' with arbitrary opening solid angle given by Ω. Many of the same symmetry arguments can be used to extract the special cases, while the general case requires zeroes of spherical Bessel functions of non-integral orders.

In conclusion, we have performed a periodic orbit theory analysis of the problem of a free particle in a two-dimensional infinite well with circular ''slice'' geometry. We have found the general pattern of periodic orbits for an arbitrary opening angle Θ and investigated

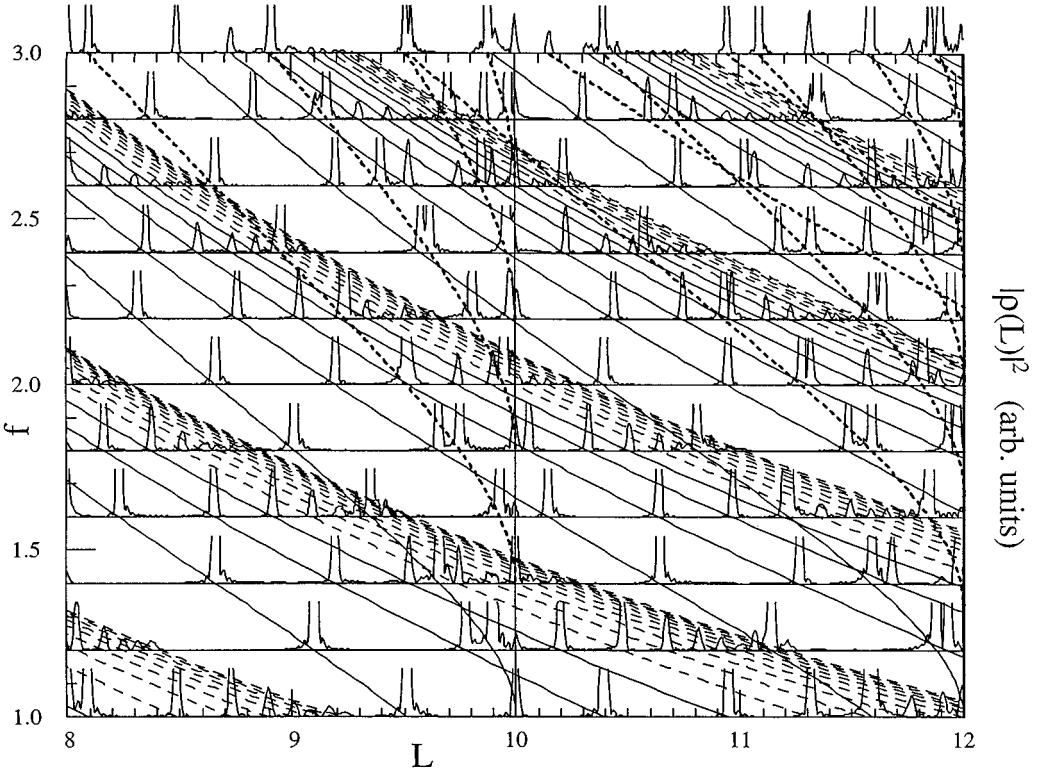

FIG. 18. The Fourier transform (squared) of the wavenumber distribution, $|\rho(L)|^2$ versus L/R, for decreasing values of $\Theta=\pi/(1+f)$ over the region $1\leqslant f\leqslant 3$ over the range $L/R=(8.0,10.0)$. The dashed (solid, bold-dashed) curves correspond to the cases described by [Eq. (21) (Eq. (22), Eq. (24)], respectively.

the appearance and disappearance of allowed orbits at the special cases $\Theta=\pi/2^n$. A simplified PO analysis, focusing on the locations of the peaks in $\rho(L)$, has found excellent global agreement with the increasingly complex pattern of allowed closed paths as Θ is decreased. No obvious signs of diffraction effects (such as seen in the annular ring billiard[19,20]) are apparent. However, a more careful analysis [one which would necessarily include the prefactor terms in Eq. (4)] of this system and the annular billiard, both of which exhibit bifurcations of orbits, should be performed to probe more carefully the structure of the features in the $\rho(L)$ spectrum near the bifurcation points to decide if a complete description requires the inclusion of diffraction effects as discussed in Refs. 5 and 16–18. For example, the diffraction effects seen most clearly in the annular billiard case (corresponding to diffraction around the inner annulus) decrease in magnitude exponentially with increasing inner radius $R_{min}=fR$. One could easily imagine small diffraction features which persist in the $\rho(L)$ spectrum beyond the values of f at which the purely classical trajectories would no longer be allowed due to such diffraction effects. Such extensions of this work are currently under study.

New conformal gauging and the electromagnetic theory of Weyl

James T. Wheeler[a)]
Department of Physics, Utah State University, Logan, Utah 84322

(Received 7 July 1997; accepted for publication 3 September 1997)

A new eight-dimensional conformal gauging solves the auxiliary field problem and eliminates unphysical size change from Weyl's electromagnetic theory. We derive the Maurer–Cartan structure equations and find the zero curvature solutions for the conformal connection. By showing that every one-particle Hamiltonian generates the structure equations we establish a correspondence between phase space and the eight-dimensional base space, and between the action and the integral of the Weyl vector. Applying the correspondence to generic flat solutions yields the Lorentz force law, the form and gauge dependence of the electromagnetic vector potential and minimal coupling. The dynamics found for these flat solutions applies locally in generic spaces. We then provide necessary and sufficient curvature constraints for general curved eight-dimensional geometries to be in 1–1 correspondence with four-dimensional Einstein–Maxwell space–times, based on a vector space isomorphism between the extra four dimensions and the Riemannian tangent space. Despite part of the Weyl vector serving as the electromagnetic vector potential, the entire class of geometries has vanishing dilation, thereby providing a consistent unified geometric theory of gravitation and electromagnetism. In concluding, we give a concise discussion of observability of the extra dimensions. © *1998 American Institute of Physics.* [S0022-2488(98)02601-2]

I. INTRODUCTION

In 1918, following immediately on the heels of Einstein's introduction of general relativity, Weyl proposed a generalization of Riemanian space–time structure[1] to allow for local changes in the standard of length. When the gauge field required to insure this symmetry has nonvanishing curl, the lengths of vectors change as they undergo parallel transport. This nicely completes the picture of Riemann in which vectors are rotated but not changed in length. In Weyl geometry, all properties of transported vectors—magnitude *and* direction—are subject to the transport law.

Weyl identified the gauge field of local dilations with the electromagnetic potential, thereby explaining the gauge freedom of that potential and giving a geometric interpretation of electromagnetic forces. Unfortunately, the theory is inconsistent with experience because it predicts changes in the sizes of objects depending on their paths. Applied, for example, to the case of atoms moving in a background electromagnetic field, the predicted size changes would produce substantial unobserved broadening of atomic spectral lines.

The simplicity and naturalness of Weyl geometry together with the promise of a geometric understanding of electromagnetism makes the failure of Weyl's physical theory puzzling. Indeed, Weyl[1–3] and many other physicists[4–22] included proposed alternative versions of the physical interpretation in attempts to make the theory consistent. Ultimately, the work led to the current U(1) gauge theory of electromagnetism, which maintains much of the beauty of the original proposal without inconsistent predictions such as changes in atomic spectra.

In the present work, we show that a new conformal gauging avoids the standard objection[5] to this 80-year-old theory of Weyl. Since the conformal group contains the Weyl group, the spaces

[a)]Electronic-mail: jwheeler@cc.usu.edu

resulting from its gauging share certain properties with Weyl's original gauge theory of electromagnetism. However, the eight-dimensional character of the new gauging and its interpretation as a generalization of phase space eliminate the problem of unphysical size change. Before discussing these new conformal spaces, which we call *biconformal geometries*, we review some results from previous studies of the conformal group.

The conformal group is the most general set of transformations preserving ratios of infinitesimal lengths. On four-dimensional space–time the conformal group is 15 dimensional, including Lorentz transformations, translations, inverse translations, and dilations. The Lorentz transformations and translations are well known, while the dilations are simple rescalings. The inverse translations have alternatively been called special conformal transformations, conformal boosts, accelerations, or elations. We choose the term inverse translations because these transformations are pure translations at infinity. This is easily seen by translating the inverse coordinate $y^\mu = -x^\mu/x^2 \rightarrow y^\mu + a^\mu$ and then inverting again.

We will also make use of several subgroups of the conformal group. The Lorentz transformations and translations together form the Poincaré group, while the Lorentz transformations and the dilations form the homogeneous Weyl group. Adding the translations to the Weyl group gives the inhomogeneous Weyl group. The Lorentz transformations, dilations, and inverse translations also form an inhomogeneous Weyl group with the only difference being that the translations and inverse translations have opposite behavior under dilations.

Considerable attention[23–27] has been given to four-dimensional space–times which result from gauging the conformal group. In addition to the usual metric and local Lorentz structures of space–time, these models are expected, a *a priori*, to possess five gauge vectors—one for dilations and four for the inverse translations. However, it was long thought that the inverse translations could not be gauged, because the corresponding current is position dependent. From a slightly different perspective, Mansouri *et al.*[23,24] argue that making the inverse translations local is redundant with general coordinate transformations so that the corresponding gauge fields have no new effect. Nonetheless, Crispim Romão, Ferber, and Freund,[25,26] and independently Kaku, Townsend, and Van Nieuwenhuizen[27] show how to gauge the inverse translations, but find them algebraically removable from the problem. This problem is in fact generic: in any four-dimensional scale-invariant torsion-free field theory with action built quadratically from the curvatures of the conformal group these four inverse translational gauge fields may be algebraically removed from the problem.[28] The local inhomogeneous Weyl symmetry of such theories always has an effective field theory equivalent to one based on the homogeneous Weyl group, and therefore sheds no light on Weyl's theory.

By contrast, consideration of the fixed points of the various conformal transformations suggests the use of an eight-dimensional base space instead of a four-dimensional base space, corresponding to the existence of eight distinct translational generators in the Lie algebra. Requiring an eight-dimensional base space makes the gauge fields of the inverse translations act as part of the solder form on the base space, so these fields *necessarily* remain independent. Even in the case of a fully flat biconformal space this solder form contains nontrivial physical information.

Our present investigation of this new conformal gauging focuses principally on the study of flat biconformal spaces, because this is where the connection with well-known systems should be most evident and because the dynamics of flat spaces will also apply locally in generic spaces. Unlike Riemannian geometry, there is an entire nontrivial class of flat solutions. We first derive this class of solutions. Next, we show that the flat spaces possess a symplectic structure which allows their interpretation as one-particle phase spaces and provides a concise description of the corresponding Hamiltonian dynamics. Applying this Hamiltonian correspondence to the most general flat solution gives a geometric derivation of the Lorentz force law, in strong contrast to the original Weyl theory. After indicating briefly how the biconformal electromagnetic theory connects satisfactorily to U(1) gauge theory, we show how to introduce Einstein gravitation, arbitrary additional fields, and electromagnetic sources into the biconformal structure.

The layout of the paper is as follows. In Sec. II we develop biconformal structure as a conformal fiber bundle. We give particular attention to the general procedure for building connections on manifolds based on an underlying symmetry group[29–32] because it is this procedure which motivates our use of an eight-dimensional base manifold. The construction consists of two steps. First, an elementary geometry is found by taking the quotient of a given symmetry group by a subgroup containing no normal subgroup of the full group. Then, the connection of the resulting principal fiber bundle is generalized by including curvature. As an example we review the construction of general space–times by gauging the Poincaré group.[33–36] We then implement these techniques to gauge the conformal group in a new way. First, we construct an elementary geometry as the quotient, $\mathscr{C}/\mathscr{C}_0$, of the conformal group, $\mathscr{C}$, by its isotropy subgroup, $\mathscr{C}_0$. This gives a conformal Cartan connection on an eight-dimensional manifold. Next, we generalize the connection to that of a curved eight-dimensional manifold with the seven-dimensional homogeneous Weyl group as fiber by the addition of horizontal curvature two-forms to the group structure equations. The resulting eight-dimensional base manifold is called a *biconformal space* and the full fiber bundle is called the biconformal bundle.

Our first principal result is presented in Sec. III where we derive the flat solution for a frame field satisfying the zero-curvature Maurer–Cartan structure equations of biconformal space.

In Secs. IV and V we establish our next claim: the classical Hamiltonian dynamics of a single-point particle is equivalent to the specification of a seven-dimensional surface in flat biconformal space. As a consequence of the form of the structure equations, there necessarily exists a set of preferred curves satisfying the Hamiltonian equations of motion. This claim is established in two steps. First, in Sec. IV, we show that the classical Hamiltonian description of a point particle defines a class of eight-dimensional differential geometries with structure equations of manifestly biconformal type. Then in Sec. V we show that there is an embedding, unique up to local symplectic changes of basis, of the Hamiltonian system into a *flat* biconformal geometry. We also demonstrate the necessary existence of a preferred set of curves in the biconformal space satisfying the Hamiltonian equations of motion. The unique local equivalence between hypersurfaces in flat biconformal geometry and Hamiltonian systems provides a clear physical interpretation of the geometric variables of biconformal space.

The central importance of this second result is in definitively establishing the physical interpretation of the new conformal gauging. Our main goal is not to provide an alternate formulation of classical mechanics, but rather to use this embedding as a guide to subsequent physical interpretation of the elementary biconformal variables. Given the result of Sec. IV, that a classical single-particle Hamiltonian system generates a class of biconformal space–times, and its converse in Sec. V, we can conclude that for an isolated test particle in a general biconformal space the four new coordinates may be interpreted locally as the corresponding generalized particle momentum. Our identification therefore provides a physical correspondence principle for biconformal spaces. While in general spaces the extra dimensions will not necessarily represent momentum globally, we can always take the limit of a tightly confined field in a local Lorentz frame, for which the extra dimensions will permit the momentum interpretation. Indeed, when nonflat biconformal spaces are investigated in Sec. VII, we will see that the ''momentumlike'' co-solder form contains the stress-energy tensor of any gravitational sources. This generalization from momentum to the stress-energy tensor is exactly what one would anticipate in moving from a particle interpretation to a field interpretation.

For our third result, in Sec. VI, we apply the Hamiltonian correspondence of the previous sections to the general solution for flat biconformal space, to show how that flat solution predicts the following properties of the electromagnetic vector potential:

(1) The four-vector form of the potential. This is nontrivial, since it involves the reduction of the eight-dimensional one-form $\omega_0^0=\omega_{0\mu}^0(x,y)\mathbf{d}x^\mu+\omega_0^{0\mu}(x,y)\mathbf{d}y_\mu$ to a four-dimensional one-form, $\alpha_\mu(x)\mathbf{d}x^\mu$ on space–time.
(2) Its usual gauge dependence $\alpha'(x)=\alpha(x)+\mathbf{d}\phi$.

(3) Minimal coupling $p_a \to p_a - \lambda \alpha_a$.
(4) The correct equation of motion for a charged particle moving under its influence.

This section therefore provides a consistent realization of Weyl's goal[1] *of expressing electrodynamics in terms of the dilational gauge field*. Upon moving to more general biconformal spaces, the remarks of the preceding paragraph imply that in a local Lorentz frame an isolated, charged test particle will move according to the Lorentz force law.

These predictions of electromagnetic effects in biconformal space follow directly from the relationship of biconformal space to phase space and Hamiltonian dynamics, developed in Secs. IV and V. No further assumption is necessary to derive the Lorentz force law. At the same time, the biconformal theory predicts constancy of size. There is an entire class of *flat* biconformal spaces which includes sufficient freedom in the gauge fields to account for the classical electrodynamics of a charged point particle in an arbitrarily specified background electromagnetic field. The flatness condition includes vanishing dilational curvature, so none of these geometries leads to size change of any kind. In sharp contrast to Weyl geometry in which vanishing dilation implies vanishing gauge vector, the dilational gauge vector in flat biconformal space is *required to be nonzero*.

Section VI ends with a brief comparison of the biconformal model with Weyl's original gauge theory and with the standard U(1) model of electromagnetism.

In Sec. VII, we show how to introduce arbitrary gravitational and electromagnetic sources so that the results of Sec. VI remain valid in the resulting class of curved biconformal spaces. The entire class has vanishing dilation, and the electromagnetic and gravitational fields satisfy the Maxwell and Einstein equations, respectively. *This section therefore provides a consistent realization of Weyl's goal of a unified geometric theory of gravitation and electromagnetism*. While other fundamental interactions have been discovered since Weyl's time, the inclusion of both of the large scale forces in a geometric theory must be considered a step in the right direction; moreover, biconformal spaces contain additional fields which are not studied here. These additional fields might have an interpretation as the additional interactions. In any case, there is always the possibility of adding internal symmetries beyond the conformal symmetry.

The final section consists of a detailed discussion of possible consequences of regarding energy and momentum variables as four of the coordinates in an eight-dimensional space. We consider the necessary isomorphism of mathematical structure, transformation properties, and dynamical laws that must hold between momentum space variables and the biconformal co-space variables. Collisions and interactions are discussed with attention given to continuity and the proper proximity of colliding particles. Finally, we point to some experimental results which suggest a coordinatelike behavior of momentum variables.

II. THE CONSTRUCTION OF SPACE–TIMES WITH LOCAL SYMMETRIES

Before defining and interpreting biconformal spaces at the end of this section, we require some background motivating their construction. While it is customary to begin the discussion of a differential geometry with the specification of a manifold and metric pair, $(\mathcal{M},g)$, our present interest lies in developing a space–time model beginning with locally determined symmetry considerations. This allows us to construct geometries which *a priori* possess specified local symmetries. It is in part the elements of this construction which motivate our choice of an eight-dimensional base manifold for conformal gauging instead of the usual four-dimensional picture. This in turn requires us to interpret the extra four dimensions. The interpretation of the extra coordinates in the zero curvature limit is accomplished in Secs. IV–VI.

We consider symmetry groups which include the local Lorentz symmetry of space–time, seeking a procedure for developing a connection on a space–time $(\mathcal{M},g)$ from a knowledge of an experimentally determined (i.e., ''global'') symmetry group. We use the well-known techniques of Cartan and Klein,[29–32,37–39] proceeding as follows. We begin with a Lie group, $\mathcal{G}$, and a

subgroup $\mathscr{G}_0$ called the isotropy subgroup. The isotropy subgroup should contain no normal subgroup of $\mathscr{G}$ if the full group is to act effectively and transitively on the base space. Defining a projection onto the base space as the quotient $\mathscr{G}/\mathscr{G}_0$, the group manifold becomes a fiber bundle, called by Klein an *elementary geometry*. The full group will act effectively and transitively on the base space of the elementary geometry. The base space will be a manifold if and only if the fibration is regular, i.e., there exists a neighborhood of each point of any fiber which that fiber intersects only once. This regularity condition holds for the groups we consider. This base space of the elementary geometry therefore provides a manifold upon which we now generalize the connection to a Cartan connection by introducing curvature.

The generalization to a Cartan connection occurs by only requiring the action of the full group to be detectable on curves instead of globally. Specifically, we may introduce into the structure equations any curvature two-forms consistent with the resulting Bianchi identities and the following requirement. Let $\mathscr{P}(\lambda)$ be any curve in the bundle, let ω^i_j be a connection on the bundle, and let $f:\mathscr{G}\to V^{N^2}$ be a linear representation of $\mathscr{G}$ by $N\times N$ matrices. Then integrating

$$\mathbf{d}f^i_j=\omega^k_j f^i_k$$

along $\mathscr{P}(\lambda)$ yields a group transformation $f^i_j(\lambda_0)$ at each point $\mathscr{P}(\lambda_0)$. The connection ω^i_j will be a Cartan connection if the transformation $f^i_j(\lambda)$ depends only on the projection of the curve $\mathscr{P}(\lambda)$ into the base space. This condition holds if and only if the curvatures are *horizontal*, i.e., bilinear in those connection forms which vanish on the fibers. The generalization to a curved connection occurs because different curves in the base space between the same pair of points can give different group elements.

If the connection is linear, we can express this condition in terms of mappings of orthonormal frames. Consider again a curve $\mathscr{P}(\lambda)$, an initial point $\mathscr{P}(0)$ on the curve, and a frame $\mathscr{E}_a(0)$ at the point. We then can demand that there shall exist a transformation from the full group $\mathscr{G}$ mapping the initial pair $(\mathscr{P}(0),\mathscr{E}_a(0))$ to a corresponding pair $(\mathscr{P}(\lambda),\mathscr{E}_a(\lambda))$ for any point $\mathscr{P}(\lambda)$ on the curve.

A. Gauging the Poincaré group

We illustrate the method using the Poincaré group. The group may be described locally by its structure equations (equivalent to its Lie algebra), which take the form

$$\mathbf{d}\omega^a_b=\omega^c_b\wedge\omega^a_c,\quad \mathbf{d}\omega^a=\omega^b\wedge\omega^a_b, \tag{2.1}$$

where the one-forms ω^a_b,ω^a $(a,b=1,2,3,4)$ span the ten-dimensional group manifold. The only subgroup $\mathscr{G}_0$ containing no normal subgroup of $\mathscr{G}$ but which does include the Lorentz group is the Lorentz group itself, since the translations form a normal subgroup. The quotient $\mathscr{G}/\mathscr{G}_0$ leads to a four-dimensional base space with Lorentz fibers. It is easy to see that the base space is Minkowski space, and therefore the elementary geometry is the bundle of orthonormal frames over Minkowski space–time.

Continuing with the Lorentz bundle, we alter the connection to that of a curved base space by adding curvature two-forms, Ω^a_b and Ω^a, to the structure equations. Clearly there is one curvature two-form for each generator of the original Lie group. Furthermore, each curvature component is horizontal, depending only on the forms ω^a which vanish on the fibers. Functionally, the curvature components depend only on the quotient space, $\mathscr{G}/\mathscr{G}_0$. Thus,

$$\mathbf{d}\omega^a_b=\omega^c_b\wedge\omega^a_c+\Omega^a_b,\quad \mathbf{d}\omega^a=\omega^b\wedge\omega^a_b+\Omega^a, \tag{2.2}$$

or, in more familiar notation,

$$\mathbf{R}^a{}_b = \mathbf{d}\omega^a{}_b + \omega^a{}_c \wedge \omega^c{}_b \quad T^a = \mathbf{d}\mathbf{e}^a + \omega^a{}_b \wedge \mathbf{e}^b, \tag{2.2$'$}$$

where $\omega^a{}_b$ is the spin connection, $\mathbf{e}^a = \omega^a$ is the vierbein, $\mathbf{R}^a{}_b$ is the curvature two-form, and $\mathbf{T}^a$ is the torsion. Notice that we will always write the metric explicitly, so we need not offset upper and lower indices. The horizontality condition, that $\mathbf{R}^a{}_b = \mathbf{R}^a{}_{bcd}\mathbf{e}^c \wedge \mathbf{e}^d$ with no terms such as $\mathbf{R}^a{}_{bcd}{}^e \mathbf{e}^c \wedge \omega^d_e$ or $\mathbf{R}^a{}_{bcd}{}^{ef}\omega^c_e \wedge \omega^d_f$, guarantees that the generator of a Poincaré transformation found by integrating the connection one-forms along any curve $\mathscr{P}(\lambda)$ will depend only on the projection of the curve into the base manifold, $\pi(\mathscr{P}(\lambda))$. Specifically, define

$$\mathbf{d}_1 \mathscr{P} = \omega^a \mathscr{E}_a, \quad \mathbf{d}_1 \mathscr{E}_a = \omega^b_a \mathscr{E}_b, \tag{2.3}$$

as the change in the point $\mathscr{P}$ and the vector frame $\mathscr{E}_b$ along any curve in the bundle, where $\mathbf{d}_1$ is the one-dimensional exterior derivative on the curve. It is convenient to introduce a full ten-dimensional frame $(\mathscr{E}_a, \mathscr{F}_a{}^b)$ at the initial point, with the frame $\mathscr{E}_a$ being the horizontal part. We choose $(\mathscr{E}_a, \mathscr{F}_a{}^b)$ to be dual to (ω^a, ω^a_b):

$$\begin{aligned} \omega^a(\mathscr{E}_b) &= \delta^a_b, \quad \omega^a(\mathscr{F}_c{}^b) = 0, \\ \omega^a_b(\mathscr{E}_c) &= 0, \quad \omega^a_b(\mathscr{F}_d{}^c) = \delta^a_d \delta^c_b. \end{aligned} \tag{2.4}$$

When Eqs. (2.3) are integrated along a curve $\mathscr{P}(\lambda)$ we find a new point-frame pair at each value of λ. Now let $\mathscr{P}(\lambda)$ be the closed perimeter of an arbitrary infinitesimal plaquette with area element S. Then explicit evaluation of the integral of $\mathbf{d}_1\mathscr{P}$ around the plaquette gives

$$\oint_{\mathscr{P}} \mathbf{d}_1 \mathscr{P} \approx \Omega^a(S)\mathscr{E}_a(0). \tag{2.5}$$

A general infinitesimal surface element S may be expanded in terms of the full frame at the initial point as

$$S = S^{ab}\mathscr{E}_a \wedge \mathscr{E}_b + S^{ab}_c \mathscr{F}^c_a \wedge \mathscr{E}_b + S^{ab}_{cd} \mathscr{F}^c_a \wedge \mathscr{F}^d_b. \tag{2.6}$$

Now taking Ω^a horizontal, $\Omega^a = \Omega^a_{bc}\omega^b \wedge \omega^c$, we use Eqs. (2.4) to evaluate

$$\begin{aligned} \Omega^a(S) &= \Omega^a_{bc}[S^{de}\omega^b(\mathscr{E}_d)\omega^c(\mathscr{E}_e) + S^{de}_f \omega^b(\mathscr{F}^f_d)\omega^c(\mathscr{E}_e) + S^{de}_{fg}\omega^b(\mathscr{F}^f_d)\omega^c(\mathscr{F}^g_e)] \\ &= \Omega^a_{bc} S^{de}\delta^b_d \delta^c_e = \Omega^a(\pi(S)), \end{aligned} \tag{2.7}$$

so that the path dependence of the point $\mathscr{P}(\lambda)$ depends only on the projection of the loop into the base manifold. A completely analogous argument holds for the integral of $\mathscr{E}_a$ and the horizontality of Ω^a_b.

Equations (2.2) or (2.2$'$) now describe a curved four-dimensional space–time with local Lorentz symmetry. The second curvature, $\Omega^a = \mathbf{T}^a$, allows the inclusion of torsion. Because the remaining Lorentz symmetry of the fibers does not mix the components of the torsion with the components of the Riemann curvature, the usual specification of general relativity, $\Omega^a = 0$, is consistent. General relativity also requires identification of the cotangent space T^* with the space spanned by the solder form $\mathbf{e}^a$. This identification is automatic here because $\mathbf{e}^a$ is required *a priori* to span the base space $\mathscr{G}/\mathscr{G}_0$. As we have carried out the construction here, the topology of the manifold is that of the quotient, R^4, but nontrivial base spaces are easily achieved by specifying

an arbitrary manifold $\mathscr{M}$ having the same (Minkowski) cotangent space and structure equations, (2.2). This substitution of $\mathscr{M}$ for $\mathscr{G}/\mathscr{G}_0$ is allowed because it alters only topological properties, while all of the structures of interest described above are local.

B. Biconformal gauging

Understanding a symmetry-based approach has significant advantages as we now turn to our examination of the conformal group. The essential point is that, in contrast to the Poincaré example, the presence of inverse translations means that there are no normal subgroups, making the choice of isotropy subgroup $\mathscr{C}_0$ nontrivial. While biconformal space is based on the choice of the homogeneous Weyl group as $\mathscr{C}_0$, it is instructive to first consider what happens if we use the inhomogeneous Weyl group instead.

As described in the Introduction, considerable attention[23–27] has been given to models which result from the choice of the 11-dimensional inhomogeneous Weyl group as $\mathscr{C}_0$. This choice is natural enough since it gives the same base manifold as in the Poincaré case. It would appear that this model simply extends the Lorentz fiber symmetry of the local Poincaré model to include dilations and inverse translations. However, in generic field theories based on this bundle the four components of the connection corresponding to the inverse translations are generically auxiliary and may be algebraically removed from the problem.[28] The resulting field theory, equivalent to one based on the homogeneous Weyl group, has had at best mixed success as a field theory. In any case, no new symmetries or additional physical fields have been gained in passing from the Weyl group to the full conformal group. By contrast, choosing $\mathscr{C}_0$ to be the *homogeneous* Weyl group from the start, we retain the full 15 degrees of freedom of the original group and acquire many new fields, with the simplest example of a biconformal space having a natural physical interpretation in terms of Hamiltonian dynamics.

We arrive at the biconformal model if we ask what property of the Lorentz transformations made them a suitable fiber symmetry for the Poincaré group. The requirement that the isotropy subgroup should have no subgroup normal in the Poincaré group ruled out the translations, which form a normal subgroup of the Poincaré group. The Lorentz symmetry is therefore the only possible fiber symmetry. However, there is another way to see that we should use the Lorentz group as the isotropy subgroup, based on fixed points. On Minkowski space, the class of translations has no fixed points, while the class of Lorentz transformations leaves the origin fixed (hence the name, ''isotropy subgroup''). Thus, we can distinguish the isotropy subgroup of the fibering from the ''translational'' symmetry of the base manifold by counting fixed points.

Returning to the conformal group, we find that when we distinguish the conformal transformations based on their fixed points, there are simply eight translations acting on *compactified* Minkowski space.[40] A special point, its null cone, and an ideal two-sphere are added at infinity to accomplish the compactification. As a result, the translations are no longer characterized by an absence of fixed points. Instead, the class of translations and the class of inverse translations each has a single fixed point (the origin and the point at infinity, respectively) while the Lorentz subgroup and the dilational subgroup leave both of these points fixed. The dilations also leave the ideal two-sphere fixed.

With these observations, we take the isotropy subgroup $\mathscr{C}_0$ to be the seven-dimensional homogeneous Weyl group, consisting of the six Lorentz transformations together with dilations. Defining a projection as the quotient $\mathscr{C}/\mathscr{C}_0$ we are led to a fiber bundle with an eight-dimensional manifold as the base space and the homogeneous Weyl group as a typical fiber. This will break *both* the translational and inverse translational symmetries when the base manifold becomes curved, but we nonetheless retain the full 15 guage field degrees of freedom.

We choose the O(4,2) representation of the conformal group for our notation,[40] with $(A,B,\ldots)=(0,1,...,5)$. Letting boldface or Greek symbols denote forms and $(a,b,\ldots)=(1,...,4)$, the O(4,2) metric η_{AB} is given by $\eta_{ab}=\mathrm{diag}\,(1,1,1,-1)$ and $\eta_{05}=\eta_{50}=1$ with all other compo-

nents vanishing. Introducing the connection one-form ω_B^A, we may express the covariant constancy of η_{AB} as

$$\mathbf{D}\eta_{AB} \equiv \mathbf{d}\eta_{AB} - \eta_{CB}\omega_A^C - \eta_{AC}\omega_B^C = 0. \tag{2.8}$$

We may break the connection form into four independent Weyl-invariant parts: the *spin connection*, ω_b^a, the *solder form*, ω_0^a, the *co-solder form*, ω_a^0, and the *Weyl vector*, ω_0^0, where the spin connection satisfies

$$\omega_b^a = -\eta_{bc}\eta^{ad}\omega_d^c \tag{2.9a}$$

and the remaining components of ω_B^A are given in terms of these by

$$\omega_0^5 = \omega_5^0 = 0, \tag{2.9b}$$

$$\omega_5^5 = -\omega_0^0, \tag{2.9c}$$

$$\omega_5^a = -\eta^{ab}\omega_b^0, \tag{2.9d}$$

$$\omega_a^5 = -\eta_{ab}\omega_0^b. \tag{2.9e}$$

These constraints reduce the number of independent fields ω_B^A to the required 15 and allow us to restrict $(A,B,\ldots) = (0,1,...,4)$ in all subsequent equations. Now it becomes clear why we write the metric explicitly instead of raising and lowering indices. The convention avoids confusion between the solder and co-solder forms. Staying with the O(4,2) index positions also indicates immediately the scaling properties of any field, since each upper index adds $+1$ to the conformal weight while each lower index adds -1.

The structure constants of the conformal Lie algebra now lead immediately to the Maurer–Cartan structure equations of the conformal group. These are simply

$$\mathbf{d}\omega_B^A = \omega_B^C \wedge \omega_C^A. \tag{2.10}$$

When broken into parts based on homogeneous Weyl transformation properties, Eq. (2.10) gives

$$\begin{aligned} \mathbf{d}\omega_b^a &= \omega_b^c \wedge \omega_c^a + \omega_b^0 \wedge \omega_0^a - \eta_{bc}\eta^{ad}\omega_d^0 \wedge \omega_0^c, \\ \mathbf{d}\omega_0^a &= \omega_0^0 \wedge \omega_0^a + \omega_0^b \wedge \omega_b^a, \\ \mathbf{d}\omega_a^0 &= \omega_a^0 \wedge \omega_0^0 + \omega_a^b \wedge \omega_b^0, \quad \mathbf{d}\omega_0^0 = \omega_0^a \wedge \omega_a^0. \end{aligned} \tag{2.11}$$

Since no finite translation can reach the point at infinity and no inverse translation can reach the origin, the space $\mathscr{C}/\mathscr{C}_0$ gives a copy of (noncompact) Minkowski space for each of the two sets of translations. The generalization to a curved base space is immediate. We have

$$\mathbf{d}\omega_b^a = \omega_b^c \wedge \omega_c^a + \omega_b^0 \wedge \omega_0^a - \eta_{bc}\eta^{ad}\omega_d^0 \wedge \omega_0^c + \Omega_b^a, \tag{2.12a}$$

$$\mathbf{d}\omega_0^a = \omega_0^0 \wedge \omega_0^a + \omega_0^b \wedge \omega_b^a + \Omega_0^a, \tag{2.12b}$$

$$\mathbf{d}\omega_a^0 = \omega_a^0 \wedge \omega_0^0 + \omega_a^b \wedge \omega_b^0 + \Omega_a^0, \tag{2.12c}$$

$$\mathbf{d}\omega_0^0 = \omega_0^a \wedge \omega_a^0 + \Omega_0^0. \tag{2.12d}$$

We will call the four types of curvature Ω^a_b, Ω^a_0, Ω^0_a, and Ω^0_0 the Riemann curvature, torsion, co-torsion, and dilational curvature, respectively. Notice that if we set ω^0_a, ω^0_0, and the corresponding curvatures to zero, we recover Eqs. (2.2) for a four-dimensional space–time with Riemannian curvature Ω^a_b and torsion Ω^a_0. If we set only $\omega^0_a=\Omega^0_a=0$, the structure equations are those of four-dimensional Weyl geometry.

We are now in a position to define a biconformal space. We state the definition for an arbitrary number of dimensions, $2d$, although our results in all subsequent sections are given using $d=4$ for concreteness.

Definition: A *biconformal space* is a principal fiber bundle (P,M,G) with conformal connection form $\omega=\{\omega^a_b,\omega^a_0,\omega^0_a,\omega^0_0\}$ $(a,b=1,...,d)$, where M is the $2d$-dimensional base manifold, G is the Weyl group of d-dimensional Minkowski space, and $\pi:\omega\rightarrow(\omega^a_0,\omega^0_a)$, where π is the canonical projection induced by $\mathscr{P}/\mathscr{G}$.

Thus, just as we can think of a space–time as a manifold and metric pair $(\mathscr{M},g)$, we can think of a biconformal space as a manifold and connection pair $(\mathscr{M},\omega)$. Note that in general relativity, the implicit demand for metric compatibility allows us to generate a unique connection, while at present there is no such theorem for biconformal spaces. We can go the other way, however, since the existence of a biconformal metric follows by combining the horizontal connection forms, (ω^a_0,ω^0_a), with the Killing metric of the conformal group.

For many purposes, the starting point of computation in a biconformal space is given by the structure equations, Eqs. (2.12). Once we specify the connection, these structure equations allow us to compute the curvatures. Conversely, given horizontal curvatures satisfying the Bianchi identities [which follow from Eqs. (2.12) by differentiation], we can integrate to find the connection. Certain combinations are also possible. For example, it is easy to see from Eqs. (2.12) that in torsion-free biconformal spaces, the entire connection and the remaining curvatures are determined by ω^a_0, ω^0_a, and ω^0_0 alone.

Horizontality requires each of the curvatures to take the form

$$\Omega^A_B=\tfrac{1}{2}\Omega^A_{Bcd}\omega^c_0\wedge\omega^d_0+\Omega^{Ac}_{Bd}\omega^d_0\wedge\omega^0_c+\tfrac{1}{2}\Omega^{Acd}_B\omega^0_c\wedge\omega^0_d. \tag{2.13}$$

Based on the interpretation of biconformal space as a generalization of phase space (Secs. IV and V below, see also Ref. 41) we will call Ω^A_{Bcd} the space–time term, Ω^{Ac}_{Bd} the cross term, and Ω^{Acd}_B the momentum term of each type of curvature. In sharp contrast to the four-dimensional gauging, in which the fiber symmetry mixes the curvatures Ω^a_b, Ω^a_0, Ω^0_a, and Ω^0_0 (see Ref. 42), our choice of the homogeneous Weyl group as the structure group not only leaves these independent, but also does not mix the space–time, cross, or momentum terms. The usefulness of this type of isolation of curvature parts is evident in general relativity, where it is consistent with the bundle structure to set the torsion to zero.

Since the base space M is a manifold, we can always introduce coordinates (x^μ,y_ν) so that the connection forms may be written as

$$\omega^A_B=\omega^A_{B\mu}(x,y)\mathbf{d}x^\mu+\omega^{A\mu}_B(x,y)\mathbf{d}y_\mu.$$

Here the capital Latin indices range over $(0,...,4)=(0,a)$ while both Greek and lower case Latin indices range from $(1,...,4)$. The Greek indices apply to general coordinates, while the lower case Latin indices are used for the Weyl invariant parts of the orthonormal O(4,2) frame introduced above. Index positions indicate conformal weight, so all metrics are written explicitly. An exception to these conventions is made in Secs. III and VI where, for the flat solution, the components of the vierbein are δ^a_μ. In these sections we simply write, for example, (x^a,y_b) in place of $(\delta^a_\mu x^\mu,\delta^\nu_b y_\nu)$.

III. FLAT BICONFORMAL SPACE

Before deriving the form of the connection of a flat biconformal space, we discuss a few of its properties.

Definition: The connection of a flat biconformal space is said to be in the *standard flat form* when it is written in the following way:

$$\omega_0^0 = \alpha_a(x)\mathbf{d}x^a - y_a\mathbf{d}x^a \equiv W_a\mathbf{d}x^a, \tag{3.1a}$$

$$\omega_0^a = \mathbf{d}x^a, \tag{3.1b}$$

$$\omega_a^0 = \mathbf{d}y_a - (\alpha_{a,b} + W_aW_b - \tfrac{1}{2}W^2\eta_{ab})\mathbf{d}x^b, \tag{3.1c}$$

$$\omega_b^a = (\eta^{ac}\eta_{bd} - \delta_d^a\delta_b^c)W_c\mathbf{d}x^d. \tag{3.1d}$$

Notice that the Weyl vector, $W_a = \alpha_a(x) - y_a$, depends on an arbitrary four-vector α_a and *also* on the additional four coordinates y_a. The presence of α_a gives the generality required for the electromagnetic vector potential, while the y_a keeps the dilational curvature zero. As a result, unlike Weyl's theory, the flat biconformal model predicts no size change. Also notice that the standard flat form is preserved by *four-dimensional* gauge transformations, $\phi(x)$, and that the gauge transformation must be associated with the undetermined vector field, $\alpha_a(x)$. Thus, the desirable properties of Weyl's original theory survive in this more general gauge theory.

The prediction of the exact form of the Weyl vector necessary for consistently modeling electromagnetism is nontrivial. In general, the dilational gauge vector of biconformal space is of the form

$$\omega_0^0 = \omega_{0\mu}^0(x,y)\mathbf{d}x^\mu + \omega_0^{0\mu}(x,y)\mathbf{d}y_\mu,$$

i.e., an eight-dimensional vector field depending on eight independent variables. Constraining the biconformal geometry to have vanishing curvatures forces $\omega_0^0 = (\alpha_\mu(x) - y_\mu)\mathbf{d}x^\mu$. This is precisely the form required to give the Lorentz force law using the independently established formulation of Hamiltonian dynamics in biconformal space. Different field strengths $\alpha_{[\mu,\nu]}$ are in 1–1 correspondence with the possible flat biconformal spaces, so that with the interpretation of α_μ as the vector potential, electromagnetic phenomena never lead to dilations.

We now turn to our first result.

Theorem: When the curvature of biconformal space vanishes, $\Omega_B^A = 0$, there exist coordinates (x^a, y_a) such that the connection takes the standard flat form. When the topology is that of R^8 the coordinates are global.

Proof: Imposing vanishing curvature, $\Omega_B^A = 0$, the equations to be solved take the form

$$\mathbf{d}\omega_b^a = \omega_b^c \wedge \omega_c^a + \omega_b^0 \wedge \omega_0^a - \eta_{bc}\eta^{ad}\omega_d^0 \wedge \omega_0^c, \tag{3.2a}$$

$$\mathbf{d}\omega_0^a = \omega_0^0 \wedge \omega_0^a + \omega_0^b \wedge \omega_b^a, \tag{3.2b}$$

$$\mathbf{d}\omega_a^0 = \omega_a^0 \wedge \omega_0^0 + \omega_a^b \wedge \omega_b^0, \tag{3.2c}$$

$$\mathbf{d}\omega_0^0 = \omega_0^a \wedge \omega_a^0. \tag{3.2d}$$

The system may be solved by making use of the involution of Eq. (3.2b).[38] This allows us to consistently set $\omega_0^a = 0$ and first solve on the subspace spanned by the remaining 11 one-forms. The initial conditions for these integral submanifolds provide a coordinate x^a such that $\omega^a = \mathbf{d}x^a$ with $x^a = \text{const}$ on each leaf. Each leaf is then a fiber bundle described by the simpler set of structure equations

$$\mathbf{d}\omega_b^a = \omega_b^c \wedge \omega_c^a , \tag{3.3a}$$

$$\mathbf{d}\omega_a^0 = \omega_a^0 \wedge \omega_0^0 + \omega_a^b \wedge \omega_b^0, \tag{3.3b}$$

$$\mathbf{d}\omega_0^0 = 0, \tag{3.3c}$$

which may be recognized as those of a flat Weyl geometry. Equation (3.3c) implies a pure-gauge form for the Weyl vector. Choosing the gauge so that the Weyl vector vanishes (on the $\omega_0^a = 0$ subspace), we are left with the structure equations for a flat Riemannian geometry. Clearly, we have the solution

$$\omega_b^a = 0, \quad \omega_a^0 = \mathbf{d}y_a , \quad \omega_0^0 = 0. \tag{3.4}$$

Next, we reintroduce the remaining four independent one-forms,

$$\omega_0^a = \mathbf{d}x^a, \tag{3.5}$$

so that (x^a, y_a) provide a set of eight independent coordinates. From the linearity of the connection one-forms in the coordinate differentials, ω_b^a, ω_a^0, and ω_0^0 will change only by terms proportional to $\mathbf{d}x^a$. We therefore may write

$$\omega_b^a = C^a{}_{bc}\mathbf{d}x^c, \tag{3.6a}$$

$$\omega_0^a = \mathbf{d}x^a, \tag{3.6b}$$

$$\omega_a^0 = \mathbf{d}y_a + B_{ab}\mathbf{d}x^b, \tag{3.6c}$$

$$\omega_0^0 = W_a \mathbf{d}x^a, \tag{3.6d}$$

where the coefficients W_a, B_{ab}, and $C^a{}_{bc}$ are functions of x^a and y_a to be found by substitution into the full structure equations, Eqs. (3.2). First we determine the form of the Weyl vector, W_a, from Eq. (3.2d). Substitution of Eqs. (3.6b)–(3.6d) yields

$$\mathbf{d}\omega_0^0 = W_{d'}{}^b \mathbf{d}y_b \wedge \mathbf{d}x^a + W_{a,b}\mathbf{d}x^b \wedge \mathbf{d}x^a = \mathbf{d}x^a \wedge (\mathbf{d}y_a + B_{ab}\mathbf{d}x^b). \tag{3.7}$$

Here a lowered comma denotes a partial derivative with respect to x^b while a raised comma denotes a partial with respect to y_b. Equating like components gives

$$W_a{}^{,b} = -\delta_a^b, \tag{3.8a}$$

$$B_{[ab]} = W_{[b,a]}. \tag{3.8b}$$

The first of these is immediately integrated to give

$$W_a = -y_a + \alpha_a(x). \tag{3.9}$$

Next we substitute Eqs. (3.6a) (3.6b), and (3.6d) into Eq. (3.2b) to find $C^a{}_{bc}$ in terms of W_a:

$$\mathbf{d}\omega_0^a = 0 = W_b \mathbf{d}x^b \wedge \mathbf{d}x^a + \mathbf{d}x^b \wedge C^a{}_{bc}\mathbf{d}x^c \tag{3.10}$$

or

$$C^a{}_{[bc]} + W_{[b}\delta_{c]}^a = 0. \tag{3.11}$$

Lowering the upper index in Eq. (3.11) and noting that $C_{abc} \equiv \eta_{ad} C^{d}{}_{bc} = -C_{bac}$, we add two even permutations and subtract the third to find

$$C^{a}{}_{bc} = -(\delta^{a}_{c}\delta^{d}_{b} - \eta^{ad}\eta_{bc}) W_{d}. \tag{3.12}$$

Finally, B_{ab} is found from Eq. (3.2a). The substitution leads to two independent equations, one from $\mathbf{d}x^{a} \wedge \mathbf{d}y_{b}$ cross-terms and the other from terms quadratic in $\mathbf{d}x^{a}$. The first is

$$(\delta^{a}_{c}\delta^{d}_{b} - \eta^{ad}\eta_{bc}) W_{d}{}^{,e} = (\eta^{ae}\eta_{bc} - \delta^{a}_{c}\delta^{e}_{b}),$$

which is identically satisfied by the form of Eq. (3.9) for W_{a}. Writing $W^{a} \equiv \eta^{ab} W_{b}$ and $W^{2} \equiv W^{a} W_{a}$, the second equation becomes

$$\begin{aligned}\delta^{a}_{d} B_{bc} - \delta^{a}_{c} B_{bd} - B^{a}_{d}\eta_{bc} + B^{a}_{c}\eta_{bd} &= (W^{a}{}_{,c} + W^{a} W_{c})\eta_{bd} - (W^{a}{}_{,d} + W^{a} W_{d})\eta_{bc} - (W_{b,c} + W_{b} W_{c})\delta^{a}_{d} \\ &\quad + (W_{b,d} + W_{b} W_{d})\delta^{a}_{c} - W^{2}(\delta^{a}_{c}\eta_{bd} - \delta^{a}_{d}\eta_{bc}).\end{aligned} \tag{3.13}$$

Contraction on the a and c indices gives an expression containing B_{ab} and its trace $B = \eta^{ab} B_{ab}$. A second trace yields $B = W^{2} - W^{a}_{,a}$. B_{ab} is then found to be

$$B_{ab} = -(W_{a,b} + W_{a} W_{b} - \tfrac{1}{2} W^{2}\eta_{ab}).$$

The antisymmetric part of this expression agrees with Eq. (3.8b). The form for B_{ab} above is now found to solve both Eq. (3.13) and the remaining structure equation, Eq. (3.2c), identically.

We conclude that in flat biconformal space there locally exist coordinates x^{a} and y_{a} such that

$$\omega^{0}_{0} = \alpha_{a}(x)\mathbf{d}x^{a} - y_{a}\mathbf{d}x^{a}, \tag{3.1a}$$

$$\omega^{a}_{0} = \mathbf{d}x^{a}, \tag{3.1b}$$

$$\omega^{0}_{a} = \mathbf{d}y_{a} - (\alpha_{a,b} + W_{a} W_{b} - \tfrac{1}{2} W^{2}\eta_{ab})\mathbf{d}x^{b}, \tag{3.1c}$$

$$\omega^{a}_{b} = -(\delta^{a}_{d}\delta^{c}_{b} - \eta^{ac}\eta_{bd}) W_{c}\mathbf{d}x^{d}. \tag{3.1d}$$

That the coordinates (x^{a}, y_{a}) are global follows immediately from the R^{8} topology of the base manifold, completing the proof.

We are now in a position to see in more detail how the biconformal structure corrects Weyl's theory. If we hold the y-coordinate constant in Eqs. (3.1), we find that Eqs. (3.1a), (3.1b), and (3.1d) are the connection forms for a four-dimensional Weyl space–time with conformally flat metric η_{ab}. The remaining expression, Eq. (3.1c), is then simply a one-form constructed from the Weyl–Ricci tensor. However, the dilational curvature of a four-dimensional Weyl geometry is given by the curl of the Weyl vector, equivalent here to the arbitrary curl of α_{a}. Thus, when viewed from Weyl's four-dimensional perspective the solution gives unphysical size change. It is only with the inclusion of the additional momentum variables proportional to y_{a} that the dilational curvature can be seen to vanish.

With the interpretation of the additional four dimensions of biconformal space as momentum variables it is clear that the actual motion of a particle is eight-dimensional. Now consider an experiment designed to detect a change in the relative size of two physical objects, for example, a pair of identical atoms. In order to see a change, a comparison must be made before and after moving the two atoms around some closed space–time loop. However, such motion necessarily involves changes in momentum as well so there is necessarily a change in y_{a} as well as x^{a}, inducing a corresponding loop in flat biconformal space. However, no loop in flat biconformal space ever encloses nonzero dilational flux, or ever results in a measurable size change. The size

change computed in the four-dimensional Weyl geometry is seen to be in error because it involves forcing a closed path while holding the momentum variables constant. Equivalently, the error occurs because the expression for the dilational curvature is incomplete.

We show in the next two sections that there is a direct correspondence between the geometric variables of biconformal geometry and the physical phase space variables of Hamiltonian dynamics. Then, in Sec. VI we apply the Hamiltonian correspondence to the general flat biconformal solution. This leads without further assumption to the Lorentz law of force and the identification of α_a with the electromagnetic vector potential.

IV. HAMILTONIAN DYNAMICS IN FLAT BICONFORMAL SPACE

Leaving biconformal geometry for the moment, we turn to a geometric approach to classical Hamiltonian dynamics. We first show that the action of a classical one-particle system may be used to generate biconformal spaces. Then, in Sec. V, we give a unique prescription for generating a *flat* biconformal space. Begin with eight-dimensional extended phase space with canonical coordinates $(x^i,t;p_i,p_4)$ where $(i,j=1,2,3)$. We assume we are given a super-Hamiltonian, $\mathscr{H}=\mathscr{H}(x^a,p_a)$.[43] Imposing the constraint $\mathscr{H}=0$ then gives p_4 as a function of the remaining seven variables, $p_4=-H(p_i,x^i,t)$, with H the usual Hamiltonian. This constraint insures that time appears as a parameter rather than an independent dynamical variable. Now consider the Hilbert form

$$\omega = H\mathbf{d}t - p_i\mathbf{d}x^i. \tag{4.1}$$

The integral of ω is the action functional. The exterior derivative of ω may always be factored:

$$\mathbf{d}\omega = \frac{\partial H}{\partial x^i}\,\mathbf{d}x^i\wedge\mathbf{d}t + \frac{\partial H}{\partial p_i}\,\mathbf{d}p_i\wedge\mathbf{d}t + \mathbf{d}x^i\wedge\mathbf{d}p_i = \left(\mathbf{d}x^i - \frac{\partial H}{\partial p_i}\,\mathbf{d}t\right)\wedge\left(\mathbf{d}p_i + \frac{\partial H}{\partial x^i}\,\mathbf{d}t\right). \tag{4.2}$$

Therefore, if we define

$$\begin{gathered}\omega^i \equiv \left(\mathbf{d}x^i - \frac{\partial H}{\partial p_i}\,\mathbf{d}t\right), \quad \omega_i \equiv \left(\mathbf{d}p_i + \frac{\partial H}{\partial x^i}\,\mathbf{d}t\right), \\ \omega^4 \equiv \mathbf{d}t, \quad \omega_4 \equiv \mathbf{d}\mathscr{H} = 0,\end{gathered} \tag{4.3}$$

then we can write

$$\mathbf{d}\omega = \omega^a\wedge\omega_a = \omega^i\wedge\omega_i\,. \tag{4.4}$$

This factoring is clearly preserved by local symplectic transformations of the six-basis (ω^i,ω_i), as well as reparametrizations of the time. Obviously these transformations include the usual canonical transformations of coordinates as a special case. One class of such allowed transformations of basis is achieved by the addition of $c_{ab}\omega^b$ to ω_a, where $c_{ab}=c_{ba}$. For the moment we take $c_{ab}=0$, but below we show the existence of a unique choice of c_{ab} that leads to a flat biconformal space.

We may also define a connection one-form, ω^a_b. This choice is uniquely determined by requiring the resulting biconformal space to be flat, but first we show that every possible choice leads to some biconformal space. Without imposing flatness any choice is possible. For this most general case, let ω^a_b be any linear combination of ω^a_0 and ω^0_a, and define the (necessarily horizontal) curvatures to be

$$\Omega^a_b \equiv \mathbf{d}\omega^a_b - \omega^c_b\wedge\omega^a_c - \omega^0_b\wedge\omega^a_0 - \eta_{bc}\,\eta^{ad}\omega^c_0\wedge\omega^0_d, \tag{4.5a}$$

$$\Omega_0^a \equiv \mathbf{d}\omega_0^a - \omega \wedge \omega_0^a - \omega_0^b \wedge \omega_b^a, \tag{4.5b}$$

$$\Omega_a^0 \equiv \mathbf{d}\omega_a^0 - \omega_a^0 \wedge \omega - \omega_a^b \wedge \omega_b^0, \tag{4.5c}$$

$$\Omega_0^0 \equiv \mathbf{d}\omega - \omega_0^a \wedge \omega_a^0 \equiv 0. \tag{4.5d}$$

The necessary presence and form of Eq. (4.4) for $\mathbf{d}\omega$, and the dependence of the curvatures on *both* ω^a and ω_a clearly show this to be a dilationally flat (i.e., $\Omega_0^0 = 0$) biconformal space. Therefore, extended phase space together with a Hamiltonian symplectic structure may be viewed as a certain kind of biconformal space. Turning this around, *we can interpret biconformal space, and therefore conformal gauge theory, as a generalization of one-particle phase space.*

It is worth pointing out that biconformal spaces, while including Hamiltonian extended phase spaces as special cases, also contain all four-dimensional pseudo-Riemannian geometries as other special cases. We therefore have a differential geometry rich enough to describe both general relativity and Hamiltonian particle dynamics. Furthermore, as we show in Sec. VII, biconformal spaces include the even larger class of all four-dimensional Weyl geometries, and this class allows the consistent geometric unification of gravity and electromagnetism.

The presence of both Hamiltonian and Riemannian structures is reassuring, since it is one aim of the study of biconformal spaces to place relativity theory and quantum theory in a common mathematical framework. While the developments here suggest only the possibility of describing, perhaps, a quantum particle in a curved background, the full picture is actually somewhat better because the symplectic two-form of the Hamiltonian structure gives a complex structure to the tangent/cotangent space and an almost complex structure to the biconformal space itself. The biconformal structure therefore gives a natural complexification of space–time in such a way that the usual real structure is immediately evident. One might hope, for example, to see some special significance for the Ashtekar connection when biconformal space is expressed in terms of the SU(2,2) conformal covering group instead of O(4,2). Whether these hopes are realized or not is the subject of current study.

We also note here that the idea of a quantum interpretation of conformal geometry agrees in some ways with earlier proposals[44–47] relating phase space, Weyl geometry, and quantum physics. These proposals, however, lack the full geometric structure of conformal gauge theory, do not demonstrate the intrinsically biconformal structure of Hamiltonian systems, and use a different inner product than that proposed in Sec. VI (see also Ref. 41).

We next show the relationship of the geometry described by Eqs. (4.5) to classical mechanics.

Since the curvatures are two-forms and because $\mathbf{d}\mathscr{H} = 0$, each of the curvatures, Ω^a and Ω_a, is necessarily at least linear in one of the six basis forms (ω^i, ω_i). Thus, six of the structure equations, Eqs. (4.5b) and (4.5c), are in involution. This involution allows us to set $\omega^i = \omega_i = 0$, thereby singling out a fibration of the bundle by one-dimensional submanifolds, i.e., the classical paths of motion. Examination of Eq. (4.3) shows that these conditions simply give Hamilton's equations of motion:

$$\mathbf{d}x^i = \frac{\partial H}{\partial p_i}\,\mathbf{d}t, \quad \mathbf{d}p_i = -\frac{\partial H}{\partial x^i}\,\mathbf{d}t. \tag{4.6}$$

The Fröbenius theorem guarantees the existence of solutions to these equations for the paths. The remaining two structure equations then reduce to

$$\mathbf{d}\omega_j^i = \mathbf{d}\omega = 0, \tag{4.7}$$

which are identically satisfied on curves.

It is of interest to further note that on the full bundle the condition that ω be exact is the Hamiltonian–Jacobi equation, since we may then write $\omega = \mathbf{d}S$. Substituting for ω and expanding $\mathbf{d}S$ gives

$$-H\mathbf{d}t + p_i \mathbf{d}x^i = \frac{\partial S}{\partial x^i}\,\mathbf{d}x^i + \frac{\partial S}{\partial p_a}\,\mathbf{d}p_a + \frac{\partial S}{\partial t}\,\mathbf{d}t, \tag{4.8}$$

so that

$$\frac{\partial S}{\partial p_i} = 0, \quad \frac{\partial S}{\partial p_4} = 0 \tag{4.9}$$

$$\frac{\partial S}{\partial x^i} = p_i, \tag{4.10}$$

and

$$H\left(\frac{\partial S}{\partial x^i}, x^i, t\right) = -\frac{\partial S}{\partial t}. \tag{4.11}$$

Therefore, since ω is the Weyl vector of the generated biconformal space, the Hamilton–Jacobi equation holds if and only if the Weyl vector is pure gauge, $\omega = \mathbf{d}S$. A gauge transformation reduces the Weyl vector to zero. Since the dilational curvature is always zero for the geometry built from a Hamiltonian system, when $\mathbf{d}\omega = 0$ we also have

$$\omega^i \wedge \omega_i = 0, \tag{4.12}$$

implying three linear dependences between these six solder forms. Together with the vanishing of $\mathbf{d}\mathscr{H}$, the Hamilton–Jacobi equation therefore specifies a four-dimensional subspace of the full biconformal space.

V. FLAT BICONFORMAL SPACE AND THE HAMILTONIAN GEOMETRY

In this section, we show how to specify a unique *flat* biconformal space for a given Hamiltonian system. This is achieved by making a judicious choice of the solder and co-solder forms.

This time we initially regard the super-Hamiltonian as an unconstrained function of all eight coordinates. The Hamiltonian, H, is again defined as the solution for $-p_4$ when $\mathscr{H}$ is zero. Thus, when $\mathscr{H}$ is unconstrained, p_4 is also variable and the Hilbert form generalizes to

$$\omega_0^0 = -p_a \mathbf{d}x^a = -p_4(\mathscr{H}, H)\mathbf{d}t - p_i \mathbf{d}x^i. \tag{5.1}$$

Then

$$\mathbf{d}\omega_0^0 = \mathbf{d}x^a \wedge \mathbf{d}p_a, \tag{5.2}$$

where we reserve the symbols ω, ω_i, and ω^i for the special case when $\mathscr{H} = 0$ and $p_4 = -H(x^i, t, p_i)$.

The solder and co-solder forms ω_0^a and ω_a^0 are now identified by comparing the expression for $\mathbf{d}\omega_0^0$ to the flat biconformal solution, Eqs. (3.1). To make Eq. (3.1a) agree with Eq. (5.1) we must have $\alpha_a(x) = 0$ and $y_a = p_a$. We can set $\alpha_a = 0$ with a gauge change as long as $\alpha_{[a,b]} = 0$. Then, with $y_a = p_a$, the remainder of the connection is fully determined to be

$$\omega_0^0 = -p_a \mathbf{d}x^a, \quad \omega_0^a = \mathbf{d}x^a,$$

$$\omega_a^0 = \mathbf{d}p_a - (p_a p_b - \tfrac{1}{2}p^2 \eta_{ab})\mathbf{d}x^b, \tag{5.3}$$

$$\omega_b^a = -(\delta_d^a \delta_b^c - \eta^{ac}\eta_{bd})p_c \mathbf{d}x^d.$$

Note that canonical changes of variables do not change ω_0^0 by more than a scale change, $\mathbf{d}\phi$, so this form of the connection is correct for any canonical variables $(x^i, p_i) \to (q^i, \pi_i)$.

We now restrict to the hypersurface $\mathscr{H} = 0$ so that $p_4 = -H(p_i, x^i, t)$. The symmetric coefficient

$$c_{ab} = p_a p_b - \tfrac{1}{2}p^2 \eta_{ab} \tag{5.4}$$

provides a symplectic change of basis with respect to the manifestly closed and nondegenerate two-form, $\mathbf{d}\omega_0^0 = \omega_0^a \wedge \omega_a^0 = \mathbf{d}x^a \wedge \mathbf{d}p_a$. The differential of ω_0^0 is still seen to factor as in Eq. (4.2) either directly by differentiation or by substitution of $p_4 = -H(p_i, x^i, t)$ into $\omega_0^a \wedge \omega_a^0$, with ω_0^a and ω_a^0 given by Eqs. (5.3). The involution of Eqs. (4.5b) and (4.5c) for ω_i and ω^i still holds, with the classical curves given by $\omega_i = \omega^i = 0$. We therefore recover the Hamiltonian system, and have shown it to lie in a unique flat biconformal space.

The resulting curves in the biconformal space are easily found by first writing the frame field in terms of ω^i and ω_i:

$$\begin{aligned}
\omega_0^0 &= \left(H - p_i \frac{\partial H}{\partial p_i}\right)\mathbf{d}t - p_i \omega^i = L(\dot{x}^i, x^i, t)\mathbf{d}t - p_i \omega^i, \\
\omega_0^i &= \omega^i + \frac{\partial H}{\partial p_i}\,\mathbf{d}t, \\
\omega_0^4 &= \mathbf{d}t, \\
\omega_i^0 &= \omega_i - (p_i p_j + \tfrac{1}{2}(H^2 - p^2)\delta_{ij})\omega^j + \left(p_i H - \frac{\partial H}{\partial x^i} - \frac{1}{2}(H^2 - p^2)\delta_{ij}\frac{\partial H}{\partial p_j}\right)\mathbf{d}t, \\
\omega_4^0 &= \left(Hp_i - \frac{\partial H}{\partial x^i}\right)\omega^i + \left(H\frac{\partial H}{\partial p_i}p_i - \frac{1}{2}(H^2 - p^2) - \frac{\partial H}{\partial x^i}\frac{\partial H}{\partial p_i}\right)\mathbf{d}t, \\
\omega_j^i &= -(\delta_l^i \delta_j^k - \delta^{ik}\eta_{jl})p_k\left(\omega^l + \frac{\partial H}{\partial p_l}\,\mathbf{d}t\right), \\
\omega_4^i &= H\omega^i - \left(\delta^{ij}p_j - H\frac{\partial H}{\partial p_i}\right)\mathbf{d}t, \\
\omega_i^4 &= -\delta_{ij}\omega_4^j.
\end{aligned} \tag{5.5}$$

The simple example of a free particle is instructive. Setting $\omega^i = \omega_i = 0$ and $H^2 = p^2 + m^2 \neq 0$, Eqs. (5.5) reduce to

$$\omega_0^0 = \frac{m^2}{H}\,\mathbf{d}t = m\,\mathbf{d}\tau, \quad \omega_0^a = \frac{\eta^{ab}p_b}{m^2}\,\omega_0^0 = u^a \mathbf{d}\tau = \mathbf{d}x^a,$$

$$\omega_a^0 = \tfrac{1}{2}p_a \omega_0^0 = \tfrac{1}{2}m p_a \mathbf{d}\tau, \quad \omega_b^a = 0,$$

where use of ω_0^0 or proper time $\mathbf{d}\tau$ in place of $\mathbf{d}t$ simplifies the expressions. The solder and co-solder forms are proportional to the displacement and momentum, respectively.

Also, we see again that the involution required to specify the classical paths necessarily exists. Since the biconformal base space is spanned by the eight forms $\mathbf{d}x^a$ and $\mathbf{d}p_a$, the only way the involution could fail is if there was an independent $\mathbf{d}t\wedge\mathbf{d}p_4$ term in the torsion or co-torsion of the $p_4=-H$ hypersurface. However, since $\mathbf{d}H$ is given *a priori* in terms of the other seven forms, this cannot happen. We conclude that the Hamiltonian dynamics of a point particle is equivalent to the specification of a hypersurface, $y_4=y_4(y_i,x^a)$, in a flat biconformal space, and the consequent necessary existence of a preferred congruence of curves in the hypersurface.

The principal significance of this result is *the unambiguous identification of the geometric quantities which arise in the gauging of the 15-dimensional conformal group with corresponding physical quantities in phase space. In particular, the extra four coordinates are identified with momenta and the integral of the Weyl vector is identified with the action*. This insight should not be construed as a replacement for the phase space description of particle mechanics. Rather, the interpretation presented here is to be regarded as the one-particle limit of a full biconformal field theory, and is intended to provide guidance for and a check on that field theory. We shall see in Sec. VII that for curved biconformal spaces, the ''momentumlike'' basis forms ω_a^0 contain the stress-energy source for the Einstein equation, further strengthening the present interpretation.

Notice that for multiparticle systems this interpretation of the variables of flat biconformal space in terms of phase space variables differs from the usual n-particle phase space of more complicated systems. In the case of multiple particles in a small region of (nearly) flat biconformal space, the particles share *both* the momentum and configuration space. Thus, while a single point of a multiparticle phase space characterizes the entire multiparticle system, the many particle biconformal model will be described by many points in the same eight-dimensional space. Nonetheless, the physical interpretation of the extra four coordinates as momenta remains valid, and each particle treated separately will (locally) obey its own set of Hamilton's equations.

The same conclusion holds for the fields in biconformal spaces—the extra dimensions will give the local field momentum. This may be seen in either of two ways. First, fields are the continuum limits of multiparticle systems and their local momentum will therefore be the limit of the particle momenta. Second, whenever a single field quantum is confined to an isolated region which is small relative to the curvature, it will have an interpretation as a single particle. The biconformal co-space must then give the momentum of that particle.

While accomplishing an interpretation of the biconformal variables, we have also circumvented problems with previous treatments of conformal gauge theory. Unlike four-dimensional conformal gaugings which always reduce to a four-dimensional Weyl geometry in which the inverse translations are auxiliary, the current approach retains the full conformal degrees of freedom. The extra four degrees of freedom are now seen to correspond to the inclusion of momentum variables in the physical description.

VI. WEYL'S THEORY IN BICONFORMAL SPACE

Now consider how the dynamics of the Hamiltonian correspondence of Secs. IV and V is modified by the presence of the vector field, α. The Weyl vector is now given by

$$\omega_0^0=-p_a\mathbf{d}x^a+\alpha_a\mathbf{d}x^a\equiv-\pi_a\mathbf{d}x^a \tag{6.1}$$

so that

$$\mathbf{d}\omega_0^0=\mathbf{d}x^a\wedge\mathbf{d}\pi_a\,. \tag{6.2}$$

Specifying $\pi_4=\pi_4(\pi_i,x^a)$ and setting $\omega^i=\omega_i=0$ again leads to Hamilton's equations, in the form

$$\mathbf{d}x^i = -\frac{\partial \pi_4}{\partial \pi_i}\,\mathbf{d}t, \tag{6.3a}$$

$$\mathbf{d}p_i = \frac{\partial \pi_4}{\partial x^i}\,\mathbf{d}t. \tag{6.3b}$$

Maintaining our previous identification $p_4 = -H = -(m^2+p^2)^{1/2}$ we find

$$\pi_4 = -(m^2+p^2)^{1/2} - \alpha_4 = -(m^2+(\pi^i+\alpha^i)(\pi_i+\alpha_i))^{1/2} - \alpha_4. \tag{6.4}$$

Hamilton's equations become

$$\mathbf{d}x^i = \frac{\pi^i+\alpha^i}{(m^2+(\pi+\alpha)^2)^{1/2}}\,\mathbf{d}t = \frac{p^i}{(m^2+p^2)^{1/2}}\,\mathbf{d}t$$

or

$$\dot{x}^i = \frac{p^i}{(m^2+p^2)^{1/2}} \tag{6.5}$$

for the position variables and

$$\mathbf{d}\pi_i = -\frac{\partial \alpha_4}{\partial x^i}\,\mathbf{d}t - \frac{\pi^j+\alpha^j}{(m^2+(\pi+\alpha)^2)^{1/2}}\,\alpha_{j,i}\mathbf{d}t = -\frac{\partial \alpha_4}{\partial x^i}\,\mathbf{d}t - \dot{x}^j\alpha_{j,i}\mathbf{d}t \tag{6.6}$$

for the momentum. The left-hand side of Eq. (6.6) expands to

$$\mathbf{d}\pi_i = \mathbf{d}p_i - \frac{\partial \alpha_i}{\partial t}\,\mathbf{d}t - \alpha_{i,j}\mathbf{d}x^j,$$

which finally leads to

$$\frac{dp_i}{dt} = \left(-\frac{\partial \alpha_4}{\partial x^i} + \frac{\partial \alpha_i}{\partial t}\right) + \dot{x}^j(\alpha_{i,j} - \alpha_{j,t}). \tag{6.7a}$$

For the time component we have

$$\begin{aligned}\frac{dp_4}{dt} &= \frac{d}{dt}(\pi_4+\alpha_4) = \frac{d}{dt}\left(-(m^2+p^2)^{1/2}\right)\\ &= -\frac{1}{(m^2+p^2)^{1/2}}\,p^i\,\frac{dp_i}{dt} = -\dot{x}^i\,\frac{dp_i}{dt} = \dot{x}^i\left(\frac{\partial \alpha_4}{\partial x^i} - \frac{\partial \alpha_i}{\partial t}\right).\end{aligned} \tag{6.7b}$$

Equations (6.7) give the Lorentz force law if we identify

$$\alpha_a = q(\phi, -A_i) = -qA_a.$$

Thus, the existence and form of the electromagnetic force on a charged particle is correctly predicted by the general solution for flat biconformal space. The presence of the vector field α_a, its gauge dependence, and its proper coupling to matter are direct consequences of the local gauge theory of scalings and of our identification of Hamiltonian dynamics as the specification of a

hypersurface in flat biconformal space. Nor does this formulation suffer the objection made to the original Weyl theory. Since we are studying precisely the flat biconformal spaces, there is no dilational curvature and no measurable size change.

In concluding this section, we comment briefly on the relationship of these considerations to the standard U(1) model of electromagnetic field theory. Biconformal space has a natural metric structure based on the Killing metric of the underlying conformal group. The Killing metric has eigenvalues ± 1 and zero signature, hence the local form

$$K_{\mathscr{A}\mathscr{B}} = \mathrm{diag}(\eta_{ab}, -\eta^{ab}), \tag{6.8}$$

where $(\mathscr{A},\mathscr{B}) = (1,...,8)$. Consequently, the proportionality constant in the identification between y_a and p_a is purely imaginary.[48] Since the vector field $\alpha_a(x)$ is real, we have

$$y_a = \lambda(ip_a + \alpha_a) \tag{6.9a}$$

$$= i\lambda(p_a - i\alpha_a) \tag{6.9b}$$

as the relationship between geometric and physical variables. Since the proportionality constant drops out of Hamilton's equations it is not measurable classically, but it must be included whenever particle paths are allowed to deviate from the classical trajectories. Thus, the real-valued four-dimensional scale invariance that preserves the form of the standard flat biconformal connection becomes a U(1) invariance when applied to the physical variables of Eq. (6.9b).

VII. COUPLING TO GRAVITY AND OTHER FIELDS

So far, we have motivated a new eight-dimensional gauging of the conformal group, found the class of flat solutions of the resulting biconformal spaces, and shown how to interpret the flat solutions as a phase space for a single particle coupled to a background electromagnetic field. In this section, we generalize these results to gravitating biconformal spaces in which the solder form satisfies the Einstein equation with arbitrary matter as source, and the vector potential identified in the previous sections satisfies the Maxwell field equations with arbitrary electromagnetic currents. The results of this section therefore comprise a unified geometric theory of gravitation and electromagnetism.

Our starting point is the full set of structure equations, Eqs. (2.12), which define the 15 curvature two-forms Ω^A_B. Each of these curvatures has the three biconformally invariant terms displayed in Eq. (2.13). In addition, we note that the two-form $\mathbf{d}\omega^0_0$ is separately biconformally invariant, and the solder and co-solder forms ω^a_0 and ω^0_a transform tensorially. As long as the corresponding Bianchi identities are satisfied, a specification of any combination of these fields may be used to invariantly determine subclasses of biconformal geometries.

To begin, we seek some general constraints to limit the number of independent fields. For classical geometries it is reasonable to assume that no classical path in phase space encloses a plaquette on which the dilation, Ω^0_0, is nonvanishing. The simplest (but by no means the only) way to guarantee this is to just set $\Omega^0_0 = 0$. We also expect that the space–time torsion will vanish in typical classical models, and again make the simplest hypothesis, that the full torsion (but *not* the co-torsion) is zero. Thus we have the general constraints

$$\Omega^0_0 = 0, \tag{7.1}$$

$$\Omega^a_0 = 0. \tag{7.2}$$

Next, we note that the vanishing of the torsion puts the solder form in involution. Assuming the resulting foliation to be regular, there exists a four-dimensional submanifold of the base space spanned by $\omega_0^a = \mathbf{e}^a$. As a final general constraint, we require the existence of a completion $\mathbf{f}_a$ to the $\mathbf{e}^a$ basis in which the space–time curvature is traceless:

$$\Omega^a_{bac} = 0 \quad [\text{in the } (\mathbf{e}^a, \mathbf{f}_a) \text{ basis}]. \tag{7.3}$$

We shall show that these three constraints are sufficient for the resulting class of geometries to take a recognizable form. There is *no* restriction of the dependence of any of the fields on the eight coordinates, (x^μ, y_ν). Notice that we now return to the use of Greek indices for general coordinates.

In addition to the general constraints above, we posit two field equations. The first provides a source for the Weyl vector, which we take here to be in the typical form for an electromagnetic current

$$*\mathbf{d}*\mathbf{d}\omega_0^0 = \mathbf{J} = J_a(x)\mathbf{e}^a. \tag{7.4a}$$

Finally, part of the co-solder form is determined by an arbitrary stress-energy tensor T_{ab} via

$$\omega_a^0 = \mathscr{T}_a + \cdots, \tag{7.4b}$$

where $\mathscr{T}_a \equiv -\frac{1}{2}(T_{ab} - \frac{1}{3}\eta_{ab}T)\mathbf{e}^b$. The consistency of these expressions and the form of the remaining part of the co-solder form are established using the general equations, Eqs. (7.1)–(7.3), together with the structure equations, Eqs. (2.12).

The central result of this section is that a biconformal space is in 1–1 correspondence with a four-dimensional Einstein–Maxwell space–time if and only if Eqs. (7.1)–(7.4) hold. The 1–1 correspondence is based on an isomorphism between the biconformal co-space at x_0^μ and the tangent space to a four-dimensional space–time at a corresponding point x_0^μ. To see roughly how this isomorphism occurs, note that the biconformal base space is spanned by the differentials $(\mathbf{d}x^\mu, \mathbf{d}y_\nu)$. Setting $x^\mu = x_0^\mu$ gives $\mathbf{d}x_0^\mu = 0$, thereby restricting to the subspace spanned by $\mathbf{d}y_\nu$. We will show that the conditions above make the biconformal space flat in the y variables, giving a four-dimensional Minkowski space with basis $\mathbf{d}y_\nu$. Then, because the basis $\mathbf{d}y_\nu$ transforms oppositely under Lorentz transformations from $\mathbf{d}x^\mu$, and because the $\mathbf{d}x^\mu$ spans the cotangent space of an orthogonal four-dimensional submanifold, there exists an isomorphism between the $\mathbf{d}y_\nu$ space and the *tangent* space of the submanifold. A more complete presentation of the techniques used and some related results are given in Ref. 49.

The equations to be solved are

$$\mathbf{d}\omega_b^a = \omega_b^c \wedge \omega_c^a + \omega_b^a \wedge \omega_0^a - \eta_{bc}\eta^{ad}\omega_d^0 \wedge \omega_0^c + \Omega_b^a, \tag{2.12a$'$}$$

$$\mathbf{d}\omega_0^a = \omega_0^0 \wedge \omega_0^a + \omega_0^b \wedge \omega_b^a, \tag{2.12b$'$}$$

$$\mathbf{d}\omega_a^0 = \omega_a^0 \wedge \omega_0^0 + \omega_a^b \wedge \omega_b^0 + \Omega_a^0, \tag{2.12c$'$}$$

$$\mathbf{d}\omega_0^0 = \omega_0^a \wedge \omega_a^0. \tag{2.12d$'$}$$

The first part of our proof follows Theorem I of Ref. 49. We begin with the Bianchi identity for Eq. (2.12b′), which follows by taking the exterior derivative and using $\mathbf{d}^2 = 0$. The result is

$$\omega_0^b \wedge \Omega_b^a = 0, \tag{7.5}$$

which in particular shows that the momentum term of the curvature vanishes

$$\Omega_b^{acd}=0. \tag{7.6}$$

Similarly, the Bianchi identity for Eq. (2.12d′) requires

$$\Omega_b^{0cd}=0 \tag{7.7}$$

for the co-torsion. Together with the vanishing of the dilation and the torsion, Eqs. (7.6) and (7.7) imply that the bundle is momentum flat, i.e., the momentum term of each curvature vanishes.

Next, we use the involution of the solder form, as noted above. The involution means that the biconformal bundle is foliated by 11-dimensional subbundles on which $\omega_0^a=0$. On this subbundle, using the momentum-flatness, the structure equations reduce to

$$\mathbf{d}\omega_b^a=\omega_b^c\wedge\omega_c^a, \tag{7.8a}$$

$$\mathbf{d}\omega_a^0=\omega_a^0\wedge\omega_0^0+\omega_a^b\wedge\omega_b^0, \tag{7.8b}$$

$$\mathbf{d}\omega_0^0=0. \tag{7.8c}$$

Equations (7.8) are just the structure equations for a flat four-dimensional Weyl geometry. Equation (7.8a) shows that we can perform a Lorentz gauge transformation on the entire bundle such that $\omega_b^a|_{\omega_0^a=0}=0$, while Eq. (7.8c) shows the existence of a scaling such that $\omega_0^0|_{\omega_0^a=0}=0$. Following these gauge changes Eq. (7.8b) takes the simple form

$$\mathbf{d}\omega_a^0=0$$

with the immediate solution

$$\omega_a^0|_{\omega_0^a=0}=f_a{}^\mu(x)\mathbf{d}y_\mu \tag{7.9}$$

where we have introduced four coordinates y_μ to span the four-dimensional base space of the submanifold. Notice that the coefficient matrix $f_a{}^\mu(x)$ must be nondegenerate.

Now, assuming the foliation to be regular, the space of leaves of the foliation is also a four-dimensional manifold spanned by ω_0^a. There exist coordinates x^μ such that

$$\omega_0^a=e_\mu{}^a(x,y)\mathbf{d}x^\mu=\mathbf{e}^a \tag{7.10}$$

so that each leaf of the foliation is given by some constant value $x^\mu=x_0^\mu$.

From the subbundle, with connection $\omega_b^a|_{x_0}=0$, $\omega_0^0|_{x_0}=0$, and $\omega_a^0|_{x_0}=\mathbf{f}_a$, we extend back to the full bundle by allowing x to vary. This can change each connection form at most by a term proportional to $\mathbf{d}x^\mu$ or equivalently $\mathbf{e}^a$, so the full connection may always be given the local form

$$\omega_b^a=C_{bc}^a\mathbf{e}^c, \tag{7.11a}$$

$$\omega_0^a=\mathbf{e}^a(x,y), \tag{7.11b}$$

$$\omega_a^0=f_a{}^\mu(x)\mathbf{d}y_\mu+B_{ab}e^b\equiv\mathbf{f}_a+\mathbf{B}_a, \tag{7.11c}$$

$$\omega_0^0=W_a\mathbf{e}^a, \tag{7.11d}$$

where W_a, B_{ab}, and C_{bc}^a are functions of all eight coordinates (x^μ,y_ν). The functional dependence of $e_\mu{}^a$, while *a priori* unspecified, is actually restricted by Eq. (2.12b′). Since ω_b^a and ω_0^0

depend only on $\mathbf{e}^a$ and not $\mathbf{f}_a$, writing out $\mathbf{de}^a$ in coordinates immediately shows that $\partial^\nu e_\mu{}^a = 0$, where we write $\partial^\nu \equiv \partial/\partial y_\nu$ and $\partial_\nu \equiv \partial/\partial x^\nu$. Therefore, we may drop the y dependence in Eq. (7.11b).

If we had made a different initial choice of the coordinates y_μ, the connection would still be of the form given by Eqs. (7.11), although W_a, B_{ab}, and C^a_{bc} would be different functions. We can therefore assume without loss of generality that the basis $(\mathbf{e}^a, \mathbf{f}_b)$ has been chosen as the one in which the space–time curvature is tracefree.

Next, after dividing B_{ab} into symmetric and antisymmetric parts,

$$B_{ab} \equiv S_{ab}(x) + F_{ab}(x) \tag{7.12}$$

with $S_{ab} = S_{(ab)}$ and $F_{ab} = F_{[ab]}$, we substitute Eq. (7.11c) into the dilation equation, Eq. (2.12d′), to find

$$\mathbf{d}\omega_0^0 = \mathbf{e}^a \wedge \mathbf{f}_a + \mathbf{F} = \mathbf{d}x^\mu \wedge f_\mu{}^\nu(x)\mathbf{d}y_\nu + \mathbf{F}, \tag{7.13}$$

where $\mathbf{F} \equiv F_{ab}\mathbf{e}^a \wedge \mathbf{e}^b = F_{\mu\nu}\mathbf{d}x^\mu \wedge \mathbf{d}x^\nu$ and $f_\mu{}^\nu \equiv e_\mu{}^a f_a{}^\nu$. The mixed terms of Eq. (7.13) yield

$$W_{\mu'}{}^\nu = -f_\mu{}^\nu(x), \tag{7.14}$$

which is immediately integrated to give

$$\omega_0^0 \equiv W_\mu \mathbf{d}x^\mu = (-f_\mu{}^\nu(x)y_\nu + A_\mu(x))\mathbf{d}x^\mu \tag{7.15}$$

up to a gauge transformation. Here $A_\mu(x)$ is an arbitrary integration constant for the y integration.

We could continue to carry the field $f_\mu{}^\nu(x)$ through the remainder of the general constraints, but it is simpler to employ the field equation to remove it now. In a more general class of models, $f_\mu{}^\nu(x)$ provides an additional unspecified set of fields. While it is easy to conjecture that these extra fields may lead to a geometric electroweak theory, $f_\mu{}^\nu(x)$ appears on the surface to be a translational rather than a rotational Yang–Mills field, so that the required quadratic terms are missing from the field strength. The proper role of these fields is under study. For our present purpose, we simply note that the field equation

$$*\mathbf{d}*\mathbf{d}\omega_0^0 = \mathbf{J} = J_a(x)e^a \tag{7.3}$$

has no source for the part of ω_0^0 linear in y, and therefore gives

$$[*\mathbf{d}*\mathbf{d}f_\mu{}^\nu(x)]y_\nu = 0 \tag{7.16}$$

for the y-dependent part of the space–time term. This is a four-dimensional electromagnetic-type equation for the ''potential'' $f_\mu \equiv f_\mu{}^\nu(x)y_\nu$, which has the unique solution $f_\mu{}^\nu(x) = 0$ for vanishing boundary conditions at infinity. To this solution we add the particular solution $f_\nu{}^\nu = \text{const}$, since $f_\mu{}^\nu(x)$ must be invertible as noted above. Finally, a constant change of the y coordinates gives $f_\mu{}^\nu = \delta_\mu^\nu$, simplifying the co-solder form to

$$\omega_a^0 = e_a{}^\mu(x)\mathbf{d}y_\mu + B_{a\mu}(x,y)\mathbf{d}x^\mu, \tag{7.17}$$

where $e_a{}^\mu$ is the inverse to $e_\mu{}^a$.

With the solder form given by Eq. (7.17), Eq. (7.15) becomes

$$\omega_0^0 \equiv W_\mu \mathbf{d}x^\mu = (-y_\mu + A_\mu(x))\mathbf{d}x^\mu. \tag{7.18}$$

Thus, this entire class of geometries has the same ''minimal coupling'' form of the Weyl vector as we found for the flat case. Notice also that the form of Eq. (7.18) is not affected by a purely x-dependent gauge transformation, which is consistent with the interpretation of $\mathbf{A}$ as the electromagnetic vector potential.

Next, we move to Eq. (2.12b′), which becomes

$$\mathbf{d}\mathbf{e}^a = \omega_0^0 \wedge \mathbf{e}^a + \mathbf{e}^b \wedge \omega_b^a . \tag{7.19}$$

This may be uniquely solved for the connection ω_b^a. Let

$$\omega_b^a = \alpha_b^a + \beta_b^a , \tag{7.20}$$

where α_b^a is the usual metric compatible spin connection satisfying

$$\mathbf{d}\mathbf{e}^a = \mathbf{e}^b \wedge \alpha_b^a \tag{7.21}$$

and require

$$\mathbf{e}^b \wedge \beta_b^a + \omega_0^0 \wedge \mathbf{e}^a = 0. \tag{7.22}$$

Equation (7.22) is solved uniquely by

$$\beta_b^a = -W_b \mathbf{e}^a + \eta_{bc}\eta^{ad} W_d \mathbf{e}^c , \tag{7.23}$$

so we have now satisfied two of the four structure equations.

Next, we impose the tracelessness condition for the space–time term of the curvature in the $(\mathbf{e}^a, \mathbf{f}_b)$ basis:

$$\Omega^a{}_{bac} = 0. \tag{7.24}$$

Rearranging Eq. (2.12a) to solve for Ω_b^a we find

$$\Omega_b^a = \mathbf{d}\omega_b^a - \omega_b^c \wedge \omega_c^a - \omega_b^0 \wedge \omega_0^a + \eta_{bc}\eta^{ad}\omega_d^0 \wedge \omega_0^c \tag{2.12a}$$

$$= (\mathbf{d}\alpha_b^a - \alpha_b^c \wedge \alpha_c^a) + (\mathbf{d}\beta_b^a - \beta_b^c \wedge \alpha_c^a - \alpha_b^c \wedge \beta_c^a) - \beta_b^c \wedge \beta_c^a - \omega_b^0 \wedge \mathbf{e}^a + \eta_{bc}\eta^{ad}\omega_d^0 \wedge \mathbf{e}^c$$

$$\equiv \mathbf{R}_b^a(\alpha) + \mathbf{D}\beta_b^a - \beta_b^c \wedge \beta_c^a - \omega_b^0 \wedge \mathbf{e}^a + \eta_{bc}\eta^{ad}\omega_d^0 \wedge \mathbf{e}^c , \tag{7.25}$$

where we have written $\mathbf{D}$ for the covariant exterior derivative using the $\mathbf{e}^a$-compatible connection α_b^a, and $\mathbf{R}_b^a \equiv \mathbf{d}\alpha_b^a - \alpha_b^c \wedge \alpha_c^a$ is the usual Riemann curvature two-form. Substituting Eq. (7.17) for ω_a^0 and (7.23) for β_b^a, some algebra leads to

$$\Omega_b^a = \mathbf{R}_b^a + \eta_{bc}[\mathbf{D}W^c \mathbf{e}^a - \mathbf{D}W^a \mathbf{e}^c + W^2 \mathbf{e}^c \mathbf{e}^a] + \mathbf{f}_b \mathbf{e}^a - \eta_{bc}\eta^{ad}\mathbf{f}_d \mathbf{e}^c + \mathbf{B}_b \mathbf{e}^a - \eta_{bc}\eta^{ad}\mathbf{B}_d \mathbf{e}^c . \tag{7.26}$$

Finally, expand

$$\mathbf{D}W^a = -\eta^{ab}\mathbf{D}y_b + \mathbf{D}A^a . \tag{7.27}$$

While $\mathbf{D}A^a$ is independent of y_μ, we must further expand

$$\mathbf{D}y_b \equiv \mathbf{d}(e_b{}^\mu y_\mu) - \alpha_b^a e_a{}^\mu y_\mu = e_b{}^\mu \mathbf{d}y_\mu + (\mathbf{d}e_b{}^\mu - \alpha_b^a e_a{}^\mu) y_\mu . \tag{7.28}$$

The first term in Eq. (7.28) is simply $\mathbf{f}_a$. For the final term we use the Christoffel connection $\Gamma^\mu{}_{\alpha\beta}$ and the covariant constancy of $e_b{}^\mu$,

$$\mathbf{d}x^\beta D_\beta e_b{}^\mu = \mathbf{d}e_b{}^\mu - \alpha_b^a e_a{}^\mu + e_b{}^\alpha \Gamma^\mu{}_{\alpha\beta}\mathbf{d}x^\beta = 0 \tag{7.29}$$

to write

$$\mathbf{D}y_b = \mathbf{f}_b - e_b{}^\alpha \Gamma^\mu{}_{\alpha\beta}\mathbf{d}x^\beta y_\mu \equiv \mathbf{f}_b - \Gamma_{bc}\mathbf{e}^c \equiv \mathbf{f}_b - \Gamma_b\,. \tag{7.30}$$

Now substitution into Eq. (7.26) shows that the cross and momentum terms of the curvature vanish while the components of the space–time term become

$$\begin{aligned}\Omega^a_{bcd} = \mathbf{R}^a_{bcd} &- (D_c A_b + \beta_{bc} + B_{bc})\,\delta^a_d + (D_d A_b + \Gamma_{bd} + B_{bd})\,\delta^a_c \\ &+ \eta_{bf}\eta^{ag}(D_c A_g + \Gamma_{gc} + B_{gc})\,\delta^f_d - \eta_{bf}\eta^{ag}(D_d A_g + \Gamma_{gd} + B_{gd})\,\delta^f_c \\ &- W_c(W_b\delta^a_d - \eta_{bf}\eta^{ag}W_g\delta^f_d) + W_d(W_b\delta^a_c - \eta_{bf}\eta^{ag}W_g\delta^f_c) + W^2(\eta_{bc}\delta^a_d - \eta_{bd}\delta^a_c).\end{aligned} \tag{7.31}$$

Next, by setting the trace of Ω^a_{bcd} to zero, we can insure that the Einstein equation holds with arbitrary stress-energy tensor. Contracting, we find that the antisymmetric part $\Omega^c_{acb} - \Omega^c_{bca}$ is identically zero while

$$\Omega^c_{acb} = R_{ab} + 2(A_{(a;b)} + \Gamma_{ab} + S_{ab} + W_a W_b) + \eta_{ab}(A_c{}^{;c} + \Gamma_c{}^c + S_c{}^c - 2W^2) = 0 \tag{7.32}$$

relates $B_{(ab)} = S_{ab}$ to the Ricci tensor and the vector potential. If we require

$$S_{ab} \equiv \mathscr{T}_{ab} - (A_{(a;b))} + \Gamma_{ab} + W_a W_b - \tfrac{1}{2}\eta_{ab}W^2), \tag{7.33}$$

where $\mathscr{T}_{ab} \equiv -\tfrac{1}{2}(T_{ab} - \tfrac{1}{3}\eta_{ab}T)$ and T_{ab} is the electromagnetic stress-energy tensor constructed from A_b plus the stress-energy tensor from whatever other phenomenological fields one wishes to add, then Eq. (7.32) reduces to the Einstein equation with source T_{ab}. We shall see below that the choice given by Eq. (7.33) for S_{ab} greatly simplifies the expressions for both the curvature and the co-torsion.

Nothing further is required in order to satisfy the final structure equation, Eq. (2.12c). Instead, we *define* the co-torsion by Eq. (2.12c), giving

$$\Omega^0_a = \mathbf{d}\omega^0_a - \omega^b_a \wedge \omega^0_b - \omega^0_a \wedge \omega^0_0. \tag{2.12c}$$

This is easiest to evaluate if we write ω^0_a in terms of W_a wherever possible, resulting in

$$\omega^0_a = \mathscr{T}_a - \mathbf{D}W_a - W_a\mathbf{W} + \tfrac{1}{2}W^2\eta_{ab}\mathbf{e}^b. \tag{7.34}$$

Using the tracefree condition (i.e., the Einstein equation) to replace $\mathscr{T}_a$ by $\mathscr{R}_a \equiv -\tfrac{1}{2}(R_{ab} - \tfrac{1}{6}\eta_{ab}R)\mathbf{e}^b$ we find that Eq. (2.12c) takes the form

$$\Omega^0_a = \mathbf{D}\omega^0_a - \beta^b_a \wedge \omega^0_b - \omega^0_a \wedge \mathbf{W} = \mathbf{D}\omega^0_a + W_a\mathbf{d}\mathbf{W} - W^b\eta_{ac}\mathbf{e}^c\omega^0_b - \omega^0_a \wedge \mathbf{W}. \tag{7.35}$$

Substituting Eq. (7.34) for ω^0_a and using the Ricci identity $\mathbf{D}^2\omega_a = -\mathbf{R}^b_a\omega_b$ (for an arbitrary one-form ω_a) gives, after several cancellations, the surprisingly simple result

$$\Omega^0_a = \mathbf{D}\mathscr{R}_a + [\mathbf{R}^b_a - (\delta^c_a\delta^b_d - \eta^{bc}\eta_{ad})\mathscr{R}_c\mathbf{e}^d]W_b = \mathbf{D}\mathscr{R}_a + \mathbf{C}^b_a W_b\,, \tag{7.36}$$

where $\mathbf{C}^b_a$ is the Weyl curvature two-form. Notice that all derivatives of the Weyl vector have cancelled, so the resulting co-torsion also has vanishing momentum and cross terms. If we use the contracted second Bianchi identity to write $\mathbf{D}\mathscr{R}_a$ as a divergence of the Weyl curvature, we find

$$\Omega^0_a = -D_b \mathbf{C}^b_a + \mathbf{C}^b_a W_b\,, \tag{7.37}$$

so the co-torsion is simply the Weyl-covariant (not α^a_b-covariant) divergence of the Weyl curvature tensor, hence a direct measure of the deviation of the underlying space–time from conformally flat.[42]

Finally, remarkable cancellations also occur if we use Eq. (7.33) to replace $\mathbf{B}_a$ in the full curvature tensor given by Eq. (7.26). The result is simply

$$\Omega^a_b = \mathbf{C}^b_a\,. \tag{7.38}$$

The biconformal geometry is now fully specified except for the vector potential A_μ. This is fixed by the field equation

$$*\mathbf{d}*\mathbf{d}\omega^0_0 = *\mathbf{d}*\mathbf{dA} = \mathbf{J}, \tag{7.4a}$$

where $\mathbf{J}$ is the electromagnetic current.

To complete the proof of the sufficiency of Eqs. (7.1)–(7.4) for the biconformal space to correspond to an Einstein–Maxwell space–time we only need to show that the biconformal geometry is effectively four-dimensional. This happens because the extra dimensions of the biconformal base space can be identified with the tangent space of the Riemannian space–time. Such an identification works for two reasons. First, the co-vector basis $\mathbf{d}y_\mu$ has the same scale and Lorentz transformation properties as the basis vectors $\partial/\partial x^\mu$ for the tangent space, so we can identify the bases. Second, since both the co-space and the tangent space may be taken as Minkowski vector spaces (i.e., both are flat), the two complete vector spaces may be identified. Thus, while the coordinates y_μ act as momentumlike components of *cotangent* vectors $y_\mu \mathbf{d}x^\mu$, their differentials $\mathbf{d}y_\mu$ from a *tangent* basis. As discussed further in the final section, this isomorphism guarantees that the extra four dimensions do not lead to undesired new macroscopic effects.

Notice that, while the content of the biconformal space does not exceed that of an Einstein–Maxwell space–time, we cannot claim that a biconformal space satisfying Eqs. (7.1)–(7.4) is homeomophic to a four-dimensional Weyl geometry because the Weyl vector of the biconformal space retains linear y_μ dependence. It is this difference that leads to the vanishing dilation of the biconformal space.

The converse, that a four-dimensional Einstein–Maxwell space–time extends to a unique biconformal space satisfying Eqs. (7.1)–(7.4), is immediate, since, given the stress-energy tensor and electromagnetic current determining the space–time, we can find the solder form and the electromagnetic vector potential and from these directly write down the connection of the associated biconformal space as

$$\omega^0_0 = (-y_\mu + A_\mu)\mathbf{d}x^\mu, \tag{7.39a}$$

$$\omega^a_0 = \mathbf{e}^a(x), \tag{7.39b}$$

$$\omega^0_a = \mathscr{T}_a - \mathbf{D}W_a - W_a\mathbf{W} + \tfrac{1}{2}W^2\eta_{ab}\mathbf{e}^b, \tag{7.39c}$$

$$\omega^a_b = \alpha^a_b - W_b\mathbf{e}^a + \eta_{bc}\eta^{ad}W_d\mathbf{e}^c, \tag{7.39d}$$

where we invert the vector space isomorphism above to map the tangent space into the extra four dimensions of the biconformal space. The form above for the connection leads directly to the biconformal curvatures

$$\Omega^0_0 = 0, \tag{7.40a}$$

$$\Omega_0^a = 0, \tag{7.40b}$$

$$\Omega_a^0 = -D_b \mathbf{C}_a^b + \mathbf{C}_a^b W_b, \tag{7.40c}$$

$$\Omega_b^a = \mathbf{C}_b^a, \tag{7.40d}$$

and the field equations are unchanged. In terms of the natural conformal expressions $\mathscr{R}_a$, $\mathscr{T}_a$, and ω_0^0, the field equations are

$$\mathscr{R}_a = \mathscr{T}_a, \tag{7.41a}$$

$$*\mathbf{d}*\mathbf{d}\omega_0^0 = \mathbf{J}. \tag{7.41b}$$

The expressions for the curvature above make use of the tracelessness condition $\Omega_{bac}^a = 0$ to write the co-solder form in terms of the Ricci tensor instead of the stress-energy tensor. Considering the form of the curvature if we do not impose the tracelessness condition, we can interpret the Einstein equation as being that condition that reduces Ω_b^a and Ω_a^0 to the Weyl curvature and its divergence, respectively.

It should be pointed out that Eqs. (7.40) are quite remarkable for biconformal curvatures in that none of the curvatures has a cross term or momentum term. Despite the eight-dimensional formulation of the theory, all terms containing $\mathbf{d}y_\mu$ have dropped out. The space spanned by the y coordinates is therefore flat, and plays no role in the gravitational effects of this class of models.

At this point, we can only conjecture whether or not these biconformal spaces satisfy some action principle. There are certainly some action densities which are natural candidates. Specifically the curvature-quadratic eight-form $\Omega_B^A \wedge *\Omega_B^A$ is closely related to the action of the four-dimensional theories discussed in the Introduction, and clearly has the flat biconformal spaces of Sec. III as particular solutions. However, even expressing the resulting field equations is complicated, first because there are 12 Weyl-invariant parts to the curvature and second because the Bianchi identities used to reduce the field equations are correspondingly lengthy. We therefore postpone further investigation of field actions to subsequent research.

In the final section, we discuss the observability of the extra dimensions of biconformal spaces.

VIII. DISCUSSION

By placing conformal gauging on an eight-dimensional base space instead of the usual four-dimensional base space, we have overcome the long-standing problem of size change in physical models based on scale invariance. In this section, we demonstrate that our interpretation of biconformal gauge theory is consistent with experience. In particular, we examine the observable consequences of the added dimensions with regard to structure and function.

Three techniques have been used for adding extra dimensions in fundamental models of the world: (a) topological compactification of the extra dimensions, (b) construction of laws of motion or field equations that dynamically reduce the extra dimensions to a sufficiently small scale that they play no macroscopic role,[50] or (c) identification of the extra dimensions with everyday properties already associated with macroscopic matter. Technique (a) is routinely employed in Kaluza–Klein field theories, while technique (b) has been used recently[51,52] in an attempt to associate a fifth dimension with mass. The third technique, (c), was used in the development of special relativity where time came to be seen as a coordinate in a higher- (i.e., four) dimensional space rather than as a parameter of an intrinsically different type on a three-dimensional space. The local interpretation of biconformal space is of type (c). One should therefore *not* think in terms of compactification or other standard Kaluza–Klein ideas. Instead, we regard the extra four dimensions of the biconformal co-space as familiar, routinely observable macroscopic dimensions,

and ask whether a coordinate interpretation of four-momentum is consistent with experience. We demonstrate this consistency by focusing on the two necessary axes of correspondence:

Intrinsic structure: The biconformal co-space must have the same mathematical structure and transformation properties as momentum space.

Dynamical function: The biconformal dynamical laws and description of collisions or interactions must accord with experience.

We address each of these in turn, then conclude by citing positive evidence for a coordinate interpretation of momentum.

A. Intrinsic structure

For either flat or curved space–times, momentum space is the tangent space at each point of space–time. To identify the biconformal co-space with the tangent space we must check that both the Minkowski vector space structure of the tangent space and transformation properties of the tangent basis are reflected in the co-space.

The biconformal co-space is a Minkowski vector space if and only if it is flat. This flatness is obvious for the flat solutions studied in Secs. III–VI, while it is a consequence of the vanishing torsion and dilation in the curved models of Sec. VII. In either of these classes it is therefore possible to set up a vector space isomorphism between the tangent space and the co-space. We note that the same isomorphism also holds between the tangent space of a Riemannian space–time and the co-space coordinates of a *normal biconformal space*.[49] Normal spaces are defined to be torsion-free spaces in which the dilational curvature is closed, the Weyl one-form is exact, and the space–time term of the curvature tensor is trace-free. We therefore have two large, disjoint classes of biconformal geometries in which the biconformal co-space is isomorphic to the Riemannian tangent space.

There are two transformation properties of momentum variables which we must also check. First, under Lorentz transformations, p_μ transforms with the inverse to the *same* transformation as x^μ in flat spaces or $\mathbf{d}x^\mu$ in curved spaces. That is, there must not be two independent Lorentz transformations which can be applied to the space and co-space separately. This is a notable property of the eight-dimensional gauging of the four-dimensional conformal group. Because we began with the space–time conformal group, there is only a single set of local Lorentz transformations. Moreover, y_μ has the proper covariant form. The second transformation property required of momentum is that its scaling weight be -1, since (using Planck's constant) momentum has geometric units of inverse length. This corresponds correctly to the inverse length units of y_μ.

B. Dynamical function

We now consider whether Hamiltonian dynamical laws and our experience of collisions or interactions are consistent with a coordinate interpretation of momentum. There are three essential points concerning a coordinate interpretation which must correspond to our usual experience.

(1) Hamiltonian dynamical equations should describe the classical motion of particles and fields.
(2) While there is no continuity requirement on momenta, coordinates should not change discontinuously.
(3) From our experience we know that collisions only occur between particles which are nearby in their space–time coordinates, and do *not* necessarily occur when their momentum separation becomes small. We must show how this observation is consistent with the single proper biconformal separation, which depends on both position separation and on momentum separation.

For agreement on point 1, we require a match of dynamical properties between the Hamiltonian dynamics of momentum space and the dynamics of biconformal spaces. In Secs. III–VI, we

showed that the usual Hamiltonian dynamical picture is a natural property of flat biconformal spaces. Not only do the co-space coordinates act as momenta, but the structure equation

$$\mathbf{d}\omega_0^0 = \omega_0^a \omega_a^0$$

shows that $\mathbf{d}\omega_0^0$ is a manifestly closed, nondegenerate two-form, hence symplectic, and we have the usual Hamiltonian dynamical structure associated with one-particle phase space. Indeed, we demonstrate that any Hamiltonian system generates a super-Hamiltonian hypersurface in a unique flat biconformal space, and conversely that a hypersurface in a flat biconformal space gives a unique Hamiltonian system.

In the dilation-free curved geometries of Sec. VII and in normal biconformal spaces we can expect the Hamiltonian dynamical laws of flat biconformal space to hold *locally*. As long as we look at a sufficiently small neighborhood to permit a single-particle picture, the considerations of Secs. III–VI hold without modification. That fields on space–time also pose no problem may be seen from three different perspectives:

(a) The observable properties of fields are characterized by tensors built on the tangent space, so the isomorphism between the tangent space and the co-space insures that the same properties can be measured in both models.
(b) Fields and their properties are derivable as the continuum limit of many individual particles, so as long as interactions between particles are correctly predicted, the field limit may be expected to hold.
(c) Fields must admit classical, single particle limits. Thus, the highly localized field of an isolated electron moves according to a classical single particle Hamiltonian.

The net effect of these considerations is that there is no particle or field property that one might observe in a flat, dilation-free, or normal biconformal space that could not also be described in the tangent bundle of a four-dimensional Riemannian geometry. Moreover, biconformal spaces automatically predict the presence and form of electromagnetic fields and the Lorentz force law, properties which in a Riemannian space–time must be added by hand.

Now consider point 2. The nearly instantaneous change of momentum which occurs when, say, a ball bounces off a wall, seems to violate the notion of continuous motion in the momentum dimensions. However, the continuity of the actual dynamics underlying the bounce can be seen in either of two ways. Most simply, we can choose the super-Hamiltonian with a phenomenological potential representing the wall. A realistic potential will not have an actual discontinuity, so the resulting motion predicted by Hamilton's equations [or by the biconformal involution of Eqs. (4.5b) and (4.5c)] will be continuous.

A more fundamental way of seeing the continuity of momentum during the collision is to use the electrodynamic law predicted by local biconformal theory to examine the actual motion of each constituent particle of the ball in the appropriate background field. In this view, the apparent discontinuity arises because the region of biconformal space chosen for study is too large for the flat approximation to be valid. Shrinking the region to one where a single-particle interpretation is expected to hold solves the problem.

Moving to point 3, we know that in order to collide or interact strongly, the proper separation of two particles must be small. For this fact to be consistent with our experience that collisions occur whenever the space–time separation becomes small regardless of the momentum separation, is nontrivial. Indeed, recent models[51,52] in which a fifth dimension proportional to mass is added to space–time fail this test—in those models, two particles of vastly different mass will not generally collide.

In the biconformal models presented here, we find that the proper distance between colliding objects behaves according to our experience. The proper interval is given by the conformal Killing

metric of Eq. (6.8). While Eq. (6.8) applies to the orthonormal (ω_0^a, ω_a^0) basis, we easily change to the $(\mathbf{e}^a, \mathbf{f}_a)$ basis, where we find that the metric takes the form

$$g_{ab} = \begin{pmatrix} -2\mathscr{W}_{(ab)} & \delta_m{}^n \\ \delta_n{}^m & 0 \end{pmatrix},$$

where $\mathscr{W}_{ab} = \mathscr{T}_{ab} + \alpha_{a,b} + W_a W_b - \frac{1}{2} W^2 \eta_{ab}$. Therefore the squared interval ds^2 between the ball and the wall in terms of their phase space separations $(\Delta x^m, \Delta p_n)$ is

$$ds^2 = -2\mathscr{W}_{mn} \Delta x^m \Delta x^n + 2\Delta x^m \Delta p_m$$

which vanishes when the spacetime separation Δx^m vanishes and does not necessarily vanish when the momentum separation $\Delta p_m = 0$. This is exactly what is required.

In parts A and B we have shown that there is no mystery to the extra four dimensions of the biconformal co-space. Indeed, the coordinates for these extra directions are always immediately available as the energy and momentum of the system under study. Thus, if we want to probe the full biconformal geometry by ''walking off'' in the extra directions, we already know exactly how to do it. We must vary our energy or the direction of our motion. Any change of the tangent to our world line is a change in location in the momentum sector of biconformal space. Of course, because we are constrained to obey the classical laws of physics, we only experience four degrees of freedom, not eight (except as initial dynamical conditions, when we need all eight). In particular, conservation of energy and momentum constrain motions to $\mathbf{d}y_\mu = 0$ subspaces.

The new picture would be particularly convincing if there were some direct positive evidence that (perhaps under extreme conditions) the full eight-dimensional character of the world is manifest. For such evidence we must study biconformal spaces in which the fields take on a more general y dependence. Therefore, the following observations are necessarily conjectural, the investigation of the microscopic meaning of biconformal space lying clearly beyond the scope of the present paper. Nonetheless, as long as the deviation from the normal or dilation-free classes are small, we may expect the new evidence to show up as a dependence of some physical fields or parameters on momentum as well as position. We briefly discuss two physical variables which have this property: quantum mechanical wave functions, and running coupling constants.

The most evident dependence of fundamental physics on momentum is the phase space duality found in quantum mechanics. It is well understood that the wave function of a particle may be equally well represented using either momentum or position coordinates. In a very direct sense, the momentum of the particle is used as a coordinate. Representations such as the number basis for the harmonic oscillator, which lies midway between momentum and position variables, are also frequently used.

The fact that we do not independently probe both position and momentum simultaneously suggests that even at the quantum level (at least semi-classically) matter is substantially restricted to the neighborhood of some phase-space hypersurface. This might be understood in terms of biconformal space as near-normal biconformal behavior, with microscopic deviations from an involute or nearly involute subspace. The picture is consistent with the view of the path integral approach, which says that a quantum system essentially probes all phase space paths. In the biconformal picture, a path integral would simply be taken over all eight coordinates.

A second piece of evidence that momentum components act as independent coordinates is the existence of running coupling constants in quantum field theory. It is found experimentally that, at high energies, the strength of the electromagnetic and weak couplings vary with energy. Such energy-momentum dependence is easily understood if energy and momentum are coordinates, but is otherwise a somewhat nontransparent result of detailed field theoretic calculation.

Considerable progress has been made in establishing the connection between quantum systems and scale-invariant systems.[53,54] It remains to be seen to what degree specific biconformal models can be developed which will make these final observations precise.

(Received 19 August 1997; accepted for publication 30 September 1997)

In this paper we consider the second law of thermodynamics for a dissipative system and its symmetry property in terms of contact geometry. We first show that the inaccessibility condition of Caratheodory and the assumption of semipositive definite property of the dissipative energy are equivalent to Clausius' inequality. The inaccessibility condition then gives rise to a generalized Gibbs relation (GGR). By means of the GGR a 1-form ω can be defined such that the zero of ω reproduces the GGR. Such 1-form ω has the property $\omega\wedge(d\omega)^n\neq 0$ and $\omega\wedge(d\omega)^{n+1}=0$. The integral surface of the GGR is an n-dimensional 1-graph space G (Legendre submanifold) of a 1-jet space $J^1(E_n,R)$, where E_n is the base space of $J^1(E_n,R)$ with thermodynamic variables as its coordinates. The $(2n+1)$-dimensional $J^1(E_n,R)$ equipped with the 1-form ω is also called a contact bundle K, where the intensive thermodynamic variables are considered as the contact elements to K at every x. Next we construct an isovector field X_f such that the inaccessibility condition is invariant under the contact transformations generated by X_f. Finally, suppose under some specific assumptions the dynamical equations of the thermodynamic variables x can be approximated by the flow equations of a vector field X_G on G. We can lift X_G to X_f such that the 1-graph space G as well as the inaccessibility condition are preserved under the contact transformations generated by X_f.

I. INTRODUCTION

In equilibrium thermodynamics it is well recognized that Caratheodory's inaccessibility condition[1] is equivalent to the Gibbs relation where the integral surface of the Gibbs relation gives rise to the fundamental equation of equilibrium thermodynamics. In 1973 Hermann[2] suggested that classical thermodynamics could be formulated in a geometric setting in terms of a $(2n+1)$-dimensional contact manifold K with thermodynamic space E_n as the base space of K. Recently, Mrugala, Nulton, Schön, and Salamon[3] further studied the application of contact geometry to equilibrium thermodynamics pioneered by Hermann. In this paper we generalize the work of Mrugala *et al.* to irreversible thermodynamics. First we show that Caratheodory's inaccessibility condition and the assumption of semipositive definite property of dissipative energy are equivalent to Clausius' inequality.[4] The inaccessibility condition then yields the generalized Gibbs relation as well as a generalized Helmholtz potential function. We then define a 1-form ω in terms of the generalized Gibbs relation (GGR) such that the zero of ω reproduces the GGR again. The integral surface of the Pfaffian equation $\omega=0$ is an n-dimensional 1-graph space G (Legendre submanifold) of the 1-jet space $J^1(E_n,R)$ with coordinate cover (x,x^0,y), where x, x^0, y are the coordinates appearing in the GGR. In fact, x denotes the thermodynamic variables, y the intensive thermodynamic variables, and $x^0=g(x)$ is the integral of the GGR. The $(2n+1)$-dimensional 1-jet space $J^1(E_n,R)$ equipped with the 1-form ω is also called a contact bundle K whose base E_n is the thermodynamic space with coordinates x. The contact structure of the contact bundle is

specified by the 1-form ω where $\omega\wedge(d\omega)^n\neq 0$ and $\omega\wedge(d\omega)^{n+1}=0$. Let f be a C^1 function defined on K. To every f we can construct a unique vector field $X_f\in TK$ which transforms the contact ideal generated by ω into itself. The orbital equations of X_f (flows of X_f) form a 1-parameter group of transformations (contact transformations) that carry a Legendre submanifold into another Legendre submanifold. Second, we examine the conditions on f such that X_f preserves the Legendre submanifold **L**. We show that the flows of X_f lie on **L** if and only if f vanishes on **L**. As a consequence of this result, the inaccessibility condition is invariant under the contact transformations generated by such vector field X_f. Finally, suppose under some specific assumptions the dynamical equations of x can be formulated as the flows of a vector field X_G on the 1-graph space G, we can embed the flows of X_G in the flows of X_f such that G is invariant under the contact transformations generated by X_f.

Consider a system of molecules in r components contained in a region $\Omega\subset\Re^3$ with volume V where no chemical reactions take place. Let ϵ be the internal energy density, $\nu=\rho^{-1}$ the specific volume, c_i the molar fraction of species i, p the hydrostatic pressure, and $\phi_i^{(\alpha)}$ the generalized fluxes. For example, $\phi_i^{(1)}=\mathbf{J}_i$ is the mass flux vector, $\phi_i^{(2)}=\boldsymbol{\pi}_i$ is the traceless symmetric part of the pressure tensor $\overleftrightarrow{P}_i$, $\phi_i^{(3)}=\mathbf{Q}_i$ is the heat flux vector, etc. Here the subscript i refers to the ith molecular species and α represents the various kinds of fluxes. Except for the case of $\alpha=1$ and $\alpha=3$, in general $\phi_i^{(\alpha)}$ is a tensor function of order α which is related to the velocity moments given by Grad or by Eu.[5] Let $\hat{\phi}_i^{(\alpha)}=\rho^{-1}\phi_i^{(\alpha)}$. From physical point of view we may include sufficiently many fluxes for an appropriate description of irreversible processes. As in extended irreversible thermodynamics[6] we consider $\hat{\phi}_i^{(\alpha)}$ as well as the conserved thermodynamic variables ϵ, υ, c_i as a set of thermodynamic variables. For convenience we denote $x=(x^1,x^2,\ldots,x^n)=(\epsilon,\upsilon,c_1,\ldots,\hat{\phi}_r^{(k)})$. Let $\theta\in[a,b]$ be an empirical temperature in an arbitrary scale which can be employed to measure the hotness or the coldness of a nonequilibrium system at a local point $(\mathbf{r},t)$. At the moment it is difficult to discuss the relationship between θ and x. However, in Sec. II we show that θ is a monotonically increasing function of the local thermodynamic temperature T which can be considered as a C^1 function of x via the constitutive relation. Consider the fiber bundle $\Re^3\times\Re^1\times E_n$ with $(\mathbf{r},t)\in\Re^3\times\Re^1$ as the base space and E_n as the fiber, where E_n is an n-dimensional space with the fields x as local coordinates. The local state of a nonequilibrium system is then specified by x, where $x^i:\Re^3\times\Re^1\rightarrow\Re$ is assumed to be a function of x of class C^1 in Ω and satisfies the following set of dynamical equations:

$$d_t\rho=-\rho\nabla\cdot\mathbf{u}, \tag{1}$$

$$\rho d_t c_i=-\nabla\cdot\mathbf{J}_i,\quad 1\leqslant i\leqslant r, \tag{2}$$

$$\rho d_t\mathbf{u}=-\nabla\cdot\overleftrightarrow{P};\quad \overleftrightarrow{P}=\sum_a\overleftrightarrow{\pi}_a+p_b\hat{I}+p\hat{I}, \tag{3}$$

$$\rho d_t\epsilon=-\nabla\cdot\mathbf{Q}-\overleftrightarrow{P}:\nabla\mathbf{u}, \tag{4}$$

$$\rho d_t\hat{\phi}_i^{(\alpha)}=Z_i^{(\alpha)}+\Lambda_i^{(\alpha)},\quad 1\leqslant i\leqslant r,\quad 1\leqslant\alpha\leqslant k, \tag{5}$$

where $d_t=\partial_t+\mathbf{u}\cdot\nabla$ is the substantial differential operator, $\mathbf{u}$ the hydrodynamic velocity, p_b the bulk viscous pressure (the excess normal stress), $\hat{I}$ a unit second rank tensor. Furthermore, $Z_i^{(\alpha)}$ is a kinematic term depending on $\hat{\phi}_i^{(\alpha)}$ as well as the gradients of ϵ, υ, c_i, etc. In addition it contains the term $-\nabla\cdot\Psi_i^{(\alpha)}$, where $\Psi_i^{(\alpha)}$ is the flux of $\hat{\phi}_i^{(\alpha)}$.[7] On the other hand, $\Lambda_i^{(\alpha)}$ is a dissipative term which does not involve the gradients of x. In general $\Lambda_i^{(\alpha)}$ is a nonlinear function of x such that the decomposition of $Z_i^{(\alpha)}$ and $\Lambda_i^{(\alpha)}$ in (5) is unique. The detailed expressions of $Z_i^{(\alpha)}$ and $\Lambda_i^{(\alpha)}$ depend on the specific model under consideration. For example, Jou *et al.*[8] considered the following set of equations for (5):

$$\rho d_t p_b = -\tau_0^{-1}\rho\zeta\nabla\cdot\mathbf{u} + \tau_0^{-1}\rho\beta'\zeta g\nabla\cdot\mathbf{Q} - \tau_0^{-1}\rho p_b = Z^b + \Lambda^b, \tag{6a}$$

$$\rho d_t \mathbf{Q} = -\tau_1^{-1}\rho\lambda\nabla g + \tau_1^{-1}\rho\beta\lambda g^2\nabla\cdot\overleftrightarrow{\pi} + \tau_1^{-1}\rho\beta'\lambda g\nabla p_b - \tau_1^{-1}\rho\mathbf{Q} = Z^h + \Lambda^h, \tag{6b}$$

$$\rho d_t \overleftrightarrow{\pi} = -\tau_2^{-1}2\rho\eta[\nabla\mathbf{u}]^{(2)} + \tau_2^{-1}2\rho\beta\eta g[\nabla\mathbf{Q}]^{(2)} - \tau_2^{-1}\rho\overleftrightarrow{\pi} = Z^t + \Lambda^t, \tag{6c}$$

where $\Lambda^b = -\tau_0^{-1}\rho p_b$, $\Lambda^h = -\tau_1^{-1}\rho\mathbf{Q}$, $\Lambda^t = -\tau_2^{-1}\rho\overleftrightarrow{\pi}$, ζ, λ, and η are the bulk viscosity, thermal conductivity, and shear viscosity, respectively, τ_0, τ_1, τ_2 are the relaxation times for the fluxes p_b, $\mathbf{Q}$, and $\overleftrightarrow{\pi}$, respectively, β' and β are constants, and g is a positive, monotonically increasing function of θ of class C^1 on $[a,b]$. Later it will be identified with the local thermodynamic temperature T in absolute temperature scale. Furthermore, $[\nabla\mathbf{u}]^{(2)}$ represents the traceless symmetric part of $[\nabla\mathbf{u}]$.

In equilibrium thermodynamics the static pressure p is considered as a force for the volume change, and the chemical potentials μ_i as the generalized forces for the change of matter. Thus in the absence of external forces, the infinitesimal work dw is given by $dw = -p\,d\nu + \Sigma_i\mu_i dc_i$. A closer examination of (4) shows that the contribution of work due to $\Sigma_i\mu_i dc_i$ is not included in (4). Furthermore, since dissipative fluxes $\hat{\phi}_i^{(\alpha)}$ are considered as the (additional) independent variables in addition to ϵ, ν, and c_i, the classical internal energy balance Eq. (4) must be generalized in an appropriate manner so that contributions due to the dissipative fluxes are properly taken into consideration. To this end, we multiple (1) by p, (2) by $-\mu_i$ and sum over i, (5) by $X_i^{(\alpha)}$ and sum over i and α. Adding these results to (4) yields the following equation equivalent to (4):

$$\rho\left\{ d_t\epsilon + p d_t\nu - \sum_i \mu_i d_t c_i + \sum_{i,\alpha} X_i^{(\alpha)} : d_t\hat{\phi}_i^{(\alpha)} \right\}$$

$$= -\nabla\cdot\mathbf{Q} - (\overleftrightarrow{\pi} + p_b\hat{I}) : \nabla\mathbf{u} + \sum_i \mu_i\nabla\cdot\mathbf{J}_i + \sum_{i,\alpha} X_i^{(\alpha)} : [Z_i^{(\alpha)} + \Lambda_i^{(\alpha)}] = -\nabla\cdot\mathbf{Q}_c + \Sigma_d, \tag{7}$$

where

$$\mathbf{Q}_c = \mathbf{Q} - \sum_i \mu_i\mathbf{J}_i + \sum_{i,\alpha} X_i^{(\alpha)} : \Psi_i^{(\alpha)}, \tag{8}$$

$$\Sigma_d = -(\overleftrightarrow{\pi} + p_b\hat{I}) : \nabla\mathbf{u} + \sum_i \mathbf{J}_i\cdot\nabla\mu_i - \sum_{i,\alpha} \Psi_i^{(\alpha)} : (\nabla\cdot X_i^{(\alpha)}) + \sum_{i,\alpha} X_i^{(\alpha)} : [Z_i^{(\alpha)} + \nabla\cdot\Psi_i^{(\alpha)} + \Lambda_i^{(\alpha)}]. \tag{9}$$

Here '':'' denotes contraction of tensors, and $X_i^{(\alpha)}$ is the generalized potential conjugate to $\hat{\phi}_i^{(\alpha)}$. Notice that $Z_i^{(\alpha)}$ contains a term $-\nabla\cdot\Psi_i^{(\alpha)}$ which cancels the term $\nabla\cdot\Psi_i^{(\alpha)}$ in the last term of (9). In general, $X_i^{(\alpha)}$ is a nonlinear function of x. However, if $X_i^{(\alpha)}$ is linearized in powers of $\hat{\phi}_i^{(\alpha)}$, then $X_i^{(\alpha)}$ can be written as

$$X_b = -\tau_0(\rho\zeta)^{-1}p_b, \quad X_h = -\tau_1(\rho\lambda g)^{-1}\mathbf{Q}, \quad X_t = -\tau_2(\rho 2\eta)^{-1}\overleftrightarrow{\pi} \tag{10}$$

and so on, where X_b, X_h, and X_i are the conjugates of p_b, $\mathbf{Q}$, and $\overleftrightarrow{\pi}$, respectively.

Since the mass fluxes $\mathbf{J}_i$ as well as the tensorial fluxes $\Psi_i^{(\alpha)}$ can also contribute to the heat flux, $\mathbf{Q}_c$ is the net heat flux across the surface enclosing the local system centered at $\mathbf{r}$ with volume element $d\mathbf{r}$. The outward normal to the surface is assigned as the positive direction of $\mathbf{Q}_c$. On the other hand, it is well known that $\nabla\mathbf{u}$ and $\nabla\mu_i$ can be considered as the thermodynamic forces attributable to the viscous flow and diffusion, respectively. Similarly $\nabla\cdot X_i^{(\alpha)}$ can also be consid-

ered as the generalized forces attributable to the tensorial flows $\Psi_i^{(\alpha)}$. Thus the first three terms of Σ_d represent dissipative internal work. We therefore call Σ_d the rate of dissipative energy, which cannot be converted into other form of useful work. Hereafter we assume that Σ_d is semipositive definite.

In view of (7) we define the generalized infinitesimal work dw for a nonequilibrium local system by

$$dw=-p\,d\nu+\sum_i \mu_i dc_i-\sum_{i,\alpha} X_i^{(\alpha)}:d\hat{\phi}_i^{(\alpha)} \tag{11}$$

and define the local rate of change of heat per unit mass (dq/dt) by

$$\rho\,\frac{dq}{dt}=-\nabla\cdot\mathbf{Q}_c\,. \tag{12}$$

According to the traditional convention work is considered positive if it is done on the system, and negative if it is done by the system. On the other hand, heat is considered positive if it is absorbed by the system, and negative if it is liberated by the system.

In terms of (11) and (12), the balance equation for the internal energy density per unit mass by (7) can be rewritten as

$$d\epsilon=dq+dw+dq_d \tag{13}$$

with $dq_d=\rho^{-1}\Sigma_d dt$, and $dx^i=(\nabla x^i)\cdot d\mathbf{r}+(\partial_t x^i)dt$ is the substantial differential for $x^i=\epsilon,\ \nu,\ c_i$, and $\hat{\phi}_i^{(\alpha)}$.

Equation (13) is the first law of thermodynamics in local form for a dissipative system. It should be remarked that dq, dw, and dq_d in (13) cannot be interpreted as 1-forms in the vector space $\wedge^1(E_n)$ of differential forms, since they represent only the infinitesimal changes of the corresponding quantities. In other words, we consider the fiber bundle $E_n\times\wedge^1(E_n)$ with E_n as the base space and $\wedge^1(E_n)$ as the fiber. Denote $\hat{x}=(x^2,\ldots,x^n)$. Suppose p, μ_i, and $X_i^{(\alpha)}$ are C^1 functions of $\hat{x}$ and θ. For convenience we denote $\{-p,\{\mu_i\},-\{X_i^{(\alpha)}\},1\leqslant i\leqslant r,1\leqslant\alpha\leqslant k\}$ by $(w_2,w_3,\ldots,w_n)$. Define the work 1-form by

$$w=-p\,d\nu+\sum_i \mu_i dc_i-\sum_{i,\alpha} X_i^{(\alpha)}:d\hat{\phi}_i^{(\alpha)}=\sum_{j\geqslant 2} w_j(\hat{x},\theta)dx^j. \tag{14}$$

Let $\xi=d\epsilon+p\,d\nu-\Sigma_i\mu_i dc_i+\Sigma_{i,\alpha}X_i^{(\alpha)}:d\hat{\phi}_i^{(\alpha)}=dx^1-w$. We now formulate the local form of the second law as

$$\xi\wedge d\xi=0, \tag{15a}$$

$$\Sigma_d\geqslant 0;\ \ \Sigma_d=0\quad \text{at thermodynamic equilibrium.} \tag{15b}$$

In the next section we consider the global formulations of the first law and the second law.

II. GLOBAL FORMULATION OF THE FIRST LAW AND THE SECOND LAW

In order to formulate the first law and the second law in global form, we first define $(E,V,m_iN_i,\Phi_i^{(\alpha)})$ by

$$(E,V,m_iN_i,\Phi_i^{(\alpha)})=\int d\mathbf{r}\rho(\epsilon,\nu,c_i,\hat{\phi}_i^{(\alpha)}).$$

Suppose f is a function of $(\overline{r,t})$. Let $F(t)=\int d\mathbf{r}\rho f(\mathbf{r},t)$. It can be shown that

$$\frac{dF}{dt}=\int\left[\frac{\partial}{\partial t}(\rho f)+\nabla\cdot(\mathbf{u}\rho f)\right]d\mathbf{r}=\int d\mathbf{r}\rho d_t f.$$

Here $\mathbf{u}$ is the hydrodynamic velocity, $d_t=\partial_t+\mathbf{u}\cdot\nabla$, and f may be a scalar function, a vector function, or a tensor function of any order. Next, let $(p^*,\mu_i^*,(X_i^{(\alpha)})^*)$ be the global variables conjugate to $(V,N_i,\Phi_i^{(\alpha)})$. We define p^*, (μ_i^*) and $(X_i^{(\alpha)})^*$, respectively, by

$$\int d\mathbf{r}p(\rho d_t\nu)=p^*\frac{dV}{dt},$$

$$\int d\mathbf{r}\mu_i(\rho d_t c_i)=\mu_i^*\frac{dN_i}{dt},$$

$$\int d\mathbf{r}X_i^{(\alpha)}:(\rho d_t\phi_i^{(\alpha)})=(X_i^{(\alpha)})^*:\frac{d\Phi_i^{(\alpha)}}{dt},$$

where the molecular mass m_i of species i has been absorbed in μ_i^*. Denote $\hat{z}=(V,\{N_i\},\{\Phi_i^{(\alpha)}\})=(z^2,\ldots,z^n)$ and $\hat{z}^*=(p^*,\{\mu_i^*\},\{(X_i^{(\alpha)})^*\})=(z_2^*,\ldots,z_n^*)$. Then z^i's are the global thermodynamic variables, while z_i^*'s are their conjugate variables. It should be remarked that z_i^* is a function of z constructed according to phenomenological considerations.

The global formulation of the first law and the second law depend on the boundary condition of the material system. For example, if the boundary is only permeable to the mass flows, then the infinitesimal work dW can be written as

$$dW=-p^*dV+\sum_i\mu_i^*dN_i.$$

By the volume integral of (7) we obtain the first law in global form as

$$dE=dW+dQ+dQ_d, \tag{16}$$

with $dQ_d=[\int d\mathbf{r}\Sigma_d]dt$, and

$$dQ=dt\left[\int d\mathbf{r}(-\nabla\cdot\mathbf{Q}_c)\right]=dt\left[\int d\mathbf{r}\rho\frac{dq}{dt}\right],$$

$$dW=dt\left[\int d\mathbf{r}\rho\left\{-pd_t\nu+\sum_i\mu_i d_t c_i-\sum_{i,\alpha}X_i^{(\alpha)}:d_t\hat{\phi}_i^{(\alpha)}\right\}\right],$$

$$dE=dt\left[\int d\mathbf{r}\rho d_t\epsilon\right].$$

Let

$$\Omega=-p^*dV+\sum_i\mu_i^*dN_i-\sum_{i,\alpha}(X_i^{(\alpha)})^*:d\Phi_i^{(\alpha)}$$

be the work 1-form,[9] and set

$$\hat{\Omega}(t)=dE-\Omega.$$

The global form of the second law can be written as

$$\hat{\Omega}\wedge d\hat{\Omega}=0, \tag{17a}$$

$$Q_d\geqslant 0;\ \ Q_d=0 \quad \text{at thermal equilibrium.} \tag{17b}$$

Notice that $\hat{\Omega}$ is the heat 1-form if $dQ_d=0$. Thus (17a) is the inaccessibility condition of Caratheodory. In a previous paper we have shown that (17a) and (17b) in conjunction with (16) are equivalent to Kelvin's principle as well as Clausius' principle.[10]

Next we consider Clausius' inequality for cyclic processes where the material system is in contact with heat baths during the cycles. Suppose γ is a closed path in the thermodynamic space B with coordinates $(E,V,N_i,\Phi_i^{(\alpha)})$. Let T^* be the temperature of the heat reservoir and dQ the amount of heat exchanged between the system and the reservoir during an infinitesimal portion of γ. Then Clausius' inequality can be expressed as

$$\oint_\gamma ((T^*)^{-1}dQ)(\gamma)\leqslant 0. \tag{18}$$

It is well known that the path integral in (18) vanishes at thermodynamic equilibrium. Hence the maximum value of the path integral is zero. To this end we introduce a semipositive quantity $D(t)$ such that

$$\oint_\gamma ((T^*)^{-1}dQ+dD)(\gamma)=0 \tag{19}$$

subject to the constraint of the first law given by (16). Thus we rewrite (19) in terms of a Lagrange multiplier λ as the following:

$$\begin{aligned}&\oint_\gamma ((T^*)^{-1}dQ+dD+\lambda[dE-\Omega-dQ-dQ_d])(\gamma)\\ &\quad=\oint_\gamma (\lambda(dE-\Omega)+((T^*)^{-1}-\lambda)dQ+(dD-\lambda dQ_d))(\gamma)=0\end{aligned} \tag{20}$$

for all λ and γ in B.

From a physical point of view dQ, dQ_d, and dD depend on the irreversible path γ. Furthermore, $(dE-\Omega)$, dQ, and $(dD-\lambda dQ_d)$ have different physical significance. The term $(dE-\Omega)$ represents the change of internal energy and work along γ, dQ represents the change of heat between the system and its surroundings, while dQ_d represents the dissipative energy. Since (20) must be satisfied for all λ and all γ in B, we first set $\lambda=(T^*)^{-1}$. But the first term $(dE-\Omega)$ and the last term $(dD-\lambda dQ_d)$ are functionally independent. Thus (20) can be satisfied if and only if

$$\oint_\gamma (T^*)^{-1}(dE-\Omega)=0 \quad \text{and} \quad \oint_\gamma [dD-(T^*)^{-1}dQ_d]=0$$

for all γ. Consequently $dD=(T^*)^{-1}dQ_d$, or $dQ_d=T^*dD\geqslant 0$. In addition, there exists a scalar-valued function S defined on B such that

$$\hat{\Omega}=dE-\Omega=T^*dS. \tag{21}$$

Hence, by Clausius' inequality (18) we can obtain (21). Conversely, by (16), (17a), and (17b) we can obtain Clausius' inequality (18). In (21), $(T^*)^{-1}$ is an integrating factor of $\hat{\Omega}=dE-\Omega$. Equation (21) can be rewritten as the following generalized Gibbs relation:

$$T^*dS=dE+p^*dV-\sum_i \mu_i^* dN_i+\sum_{i,\alpha} (X_i^{(\alpha)})^*:d\Phi_i^{(\alpha)}. \tag{22}$$

Here S is called the generalized entropy function or calotropy function.

Proposition 1: The second law of thermodynamic formulated in (17a) and (17b) is equivalent to Clausius' inequality (18). Furthermore, there exists a generalized entropy function S such that $\hat{\Omega}=dE-\Omega=T^*dS$.

Now we consider the emergence of $(T^*)^{-1}$ as an integrating factor of $\hat{\Omega}$ via an alternative approach in terms of (17a). From geometric point of view this alternative approach is closely related to the notion of contact geometry. It is well known that (17a) is equivalent to the condition $d\hat{\Omega}=0$ for $\hat{\Omega}=0$.[11] This condition in turn is equivalent to the following condition:

$$\partial_k w_l=\partial_l w_k \quad \text{for all} \quad \theta\in[a,b],k,l\geqslant 2, \tag{23}$$

$\partial_k=(\partial/\partial z^k)$, $w=(-p^*,\{\mu_i^*\},\{-(X_i^{(\alpha)})^*\})=(w_2,\ldots,w_n)$. Hereafter we assume that the w_k's are C^1 functions of $(\hat{z},\theta)$. So far θ has been considered as a continuous parameter which does not participate in the exterior calculus in $\hat{\Omega}$ and $d\hat{\Omega}$. We now consider θ as well as $\hat{z}$ as independent variables. By (23) there exists a C^1 function $F(\hat{x},\theta)$ such that $w_j=-\partial_j F$. Let $u=-\partial_\theta F$. Then $\hat{\Omega}$ can be rewritten as

$$\hat{\Omega}=d(E-F)-ud\theta$$

and

$$d\hat{\Omega}=-du\wedge d\theta.$$

Since $\hat{\Omega}\wedge d\hat{\Omega}=-d(E-F)\wedge du\wedge d\theta=0$, there exists a C^1 function $H(u(\hat{z},\theta),\theta)$ such that $E-F=H(u(\hat{z},\theta),\theta)$. Let $H_1=\partial_u H\neq 0$, and $H_2=\partial_\theta H$. Then $\hat{\Omega}$ can be expressed as

$$\hat{\Omega}=H_1du+(H_2-u)d\theta. \tag{24}$$

Notice that (17a) is also equivalent to $d\hat{\Omega}=\eta\wedge\hat{\Omega}$ for some 1-form η. Thus

$$d\hat{\Omega}=-du\wedge d\theta=\eta\wedge\hat{\Omega}=H_1\eta\wedge du+(H_2-u)\eta\wedge d\theta, \tag{25}$$

where η, H_1 and H_2 are determined later.

Set

$$\eta=f_1(u,\theta)du+f_2(u,\theta)d\theta.$$

Then

$$d\hat{\Omega}=-du\wedge d\theta=[(H_2-u)f_1-H_1f_2]du\wedge d\theta,$$

which implies the following constraints for H_1, H_2, f_1 and f_2,

$$H_1f_2-(H_2-u)f_1=1. \tag{26}$$

Since $(\eta+\lambda\hat{\Omega})=\eta\wedge\hat{\Omega}$, we look for some function $\lambda=\lambda(u,\theta)$ such that $(\eta+\lambda\hat{\Omega})=d\mu$ is an exact 1-form. By (26) we have

$$\begin{aligned}\eta+\lambda\hat{\Omega}=d\mu&=(f_1+\lambda H_1)du+[f_2+\lambda(H_2-u)]d\theta\\&=H_1^{-1}d\theta+(f_1+\lambda H_1)[du+H_1^{-1}(H_2-u)d\theta].\end{aligned}\tag{27}$$

It is evident that $(\eta+\lambda\hat{\Omega})$ becomes an exact 1-form if $f_1+\lambda H_1=0$ with $H_1=g(\theta)$. Thus

$$d\mu=g^{-1}d\theta,$$

$$\hat{\Omega}=g(\theta)du+(H_2-u)d\theta,$$

and

$$d\hat{\Omega}=-g'(\theta)du\wedge d\theta+\left(\frac{\partial H_2}{\partial u}-1\right)du\wedge d\theta=-du\wedge d\theta.$$

Consequently $(\partial H_2/\partial u)=g'$, and $\hat{\Omega}$ becomes

$$\hat{\Omega}=gdu+(g'-1)ud\theta+c(\theta)d\theta=gud\left\{\ln(|gu|)-\int g^{-1}d\theta\right\}+db,\tag{28}$$

where $db=c(\theta)d\theta$.

Again by (17a) we can choose $c(\theta)=0$ so that $\hat{\Omega}$ can be rewritten as $\hat{\Omega}=sd\varphi$. By (27) and (28) we obtain

$$du=\eta+\lambda\hat{\Omega}=\eta+\lambda gud\ \ln(|gu|)-\lambda gu(g^{-1}d\theta)=g^{-1}d\theta.\tag{29}$$

We can now determine η and λ. Let $\lambda gu=-1$. Then $\lambda=-(gu)^{-1}$ and $\eta=u^{-1}du+g'g^{-1}d\theta$. Therefore $f_1=u^{-1}$, $f_2=g'g^{-1}$, $H_1=g$, $H_2=g'u$ and

$$\hat{\Omega}=gud\left\{\ln(|gu|)-\int g^{-1}d\theta\right\},\tag{30}$$

$$d\hat{\Omega}=(\eta+\lambda\hat{\Omega})\wedge\hat{\Omega}=g^{-1}(\theta)d\theta\wedge\hat{\Omega}.\tag{31}$$

So far the results in (30) and (31) are unique in terms of g. We can choose $g>0$ for all $\theta\in[a,b]$. Equation (31) can be solved to yield

$$\hat{\Omega}=T^*dS,\tag{32}$$

where S is a scalar-valued function defined on B, and

$$T^*=T_0^*\ \exp\left(\int g^{-1}d\theta\right),\quad T_0^*>0.$$

Notice that (32) is identical to (21). Since we have chosen $g>0$ for all $\theta\in[a,b]$, T^* can be identified as the thermodynamic temperature in the absolute temperature scale. Finally we consider the relationship between u and S. To this end we denote $F(\hat{z},\theta)=F^*(\hat{z},T^*)$, and $u^*=-\partial_{T^*}F^*(\hat{z},T^*)$. Then $u=-\partial_\theta F(\hat{z},\theta)=g^{-1}T^*u^*$, or $gu=T^*u^*$. Equation (30) then becomes

$$\hat{\Omega}=T^*dS=gud\left\{\ln(|gu|)-\int g^{-1}d\theta\right\}=T^*du^*.$$

Without loss of generality we set $u^*=S$. On the other hand, $\hat{\Omega}=d(E-F)-ud\theta$ can be rewritten as

$$\hat{\Omega}=T^*dS=dE-dF^*-SdT^*$$

which gives rise to the following result:

$$dF^*=-SdT^*+dE-T^*dS=-SdT^*-p^*dV+\sum_i \mu_i^* dN_i-\sum_{i,} (X_i^{(\alpha)}):d\Phi_i^{(\alpha)}. \tag{33}$$

In view of (33) F^* is called the generalized Helmholtz potential function. We summarize our results as the following.

Proposition 2: Suppose $\partial_k w_l=\partial_l w_k$ for all $\theta\in[a,b]$ and $k,l\geqslant 2$. Then there exists a thermodynamic temperature T^* and a scalar-valued function S defined on B such that $\hat{\Omega}=T^*dS$. Furthermore, there exists a function F^* such that dF^* is given by (33).

We make two remarks before closing the discussions of this section. First, suppose the local formulation of the second law is expressed as $\xi\wedge d\xi=0$ and $\Sigma_d\geqslant 0$. By following the same arguments as given above, we can prove the existence of a local thermodynamic temperature T and a scalar-valued function $\psi=\psi(\epsilon,v,c_i,\phi_i^{(\alpha)})$ such that $\xi=Td\psi$. Second, denote $x=(S,V,\{N_i\},\{\Phi_i^{(\alpha)}\})=(x^1,x^2,\ldots,x^n)=(x^1,\hat{x})$ and $y=(T^*,-p^*,\{\mu_i^*\},\{-(X_i^{(\alpha)})^*\})=(y_1,\ldots,y_n)=(y_1,\hat{y})$. Then the generalized Gibbs relation (22) can be rewritten as

$$dx^0=\sum_i y_i dx^i=y_i dx^i, \tag{34}$$

where $x^0=E=g(x)$ with $y_i=\partial_i g$. Let $F^*=E-T^*S=x^0-y_1x^1$. Then the 1-form for F^* given by (33) becomes

$$du^0=-x^1dy_1+\hat{y}_i d\hat{x}^i, \tag{35}$$

where $u^0=F^*=x^0-y_1x^1$. Thus the relation $u^0=x^0-y_1x^1$ defines a transformation φ which carries $(x^1,\ldots,x^n)$ to $(y_1,x^2,\ldots,x^n)$. Let $\omega=dx^0-y_idx^i$ and $\hat{\omega}=du^0+x^1dy_1-\hat{y}_id\hat{x}^i$. Then $\varphi^*\hat{\omega}=\omega$, where φ^* is the pull back of φ. The transformation φ is called the Legendre transformation. The Legendre transformation is closely related to the notion of contact geometry, which plays an important role in thermodynamics. This topic will be discussed in detail in the next section.

III. CONTACT GEOMETRY AND THERMODYNAMICS

In this section we consider the notion of contact geometry[12] in thermodynamics. Let E_n be the thermodynamic base space with coordinate cover $x=(S,V,\{N_i\},\{\Phi_i^{(\alpha)}\})=(x^1,x^2,\ldots,x^n)$ and let $G=E_n\times\mathfrak{R}$ with coordinate cover $(x,x^0)=(x,E)$. By the generalized Gibbs relation $dx^0=y_idx^i$, $y=(T^*,-p^*,\{\mu_i^*\},\{-(X_i^{(\alpha)})^*\})=(y_1,\ldots,y_n)$, x^0 is a C^1 function of x. Denote $x^0=g(x)$. Consider the $(2n+1)$-dimensional kinematic space $K=E_n\times\mathfrak{R}\times E_n'$ with coordinate cover (x,x^0,y) where x, x^0, y are independent coordinates. Define the 1-form ω in terms of the generalized Gibbs relation as

$$\omega=dx^0-y_idx^i\in\Lambda^1(K). \tag{36}$$

For every $x\in E_n$ the vector subspace of codimension 1 of T_xK defined by $\Delta_x=\{\nu\in T_xK|\langle\omega(x),\nu(x)\rangle=\omega_i\nu^i=0;\omega=\omega_idx^i,\nu=\nu^i\partial_i\}$ is called the contact hyperplane to K at x. Since $\omega\wedge(d\omega)^n\neq 0$ and $\omega\wedge(d\omega)^{n+1}=0$, the 1-form ω defines a nondegenerate hyperplane distribution $x\to\Delta_x$, where Δ_x is the kernel of ω. This distribution of hyperplanes (field of hyper-

planes) is called the contact structure of K. If λ is a nowhere vanishing function on K, then $\lambda\omega$ defines the same distribution of contact hyperplanes as ω. The differentiable manifold K equipped with the 1-form ω is called a contact manifold. By Darboux's theorem every differential 1-form defining a nondegenerate field of hyperplanes on a manifold of dimension $(2n+1)$ can be written in some local coordinate system in normal form $\omega = dx^0 - y_i dx^i$, where (x, x^0, y) are the local coordinates of K.

Consider the regular map $\psi: E_n \to G$ defined by $\psi(x) = (x, x^0)$ with $x^0 = g(x)$ and $\psi^* \mu \neq 0$, where $\mu = dx^1 \wedge dx^2 \wedge \ldots \wedge dx^n$, and ψ^* is the pull back of ψ. We extend ψ to the map $\psi: E_n \to K$ by the requirement $\psi^* \omega = 0$. Then $\psi^* \omega = \psi^*(dx^0 - y_i dx^i) = dx^0 - \psi^*(y_i) dx^i = 0$, or $\psi^*(y_i) = \partial_i g$. Thus ψ defines a global section of K. This global section can be identified as the Legendre submanifold $\mathbf{L}$ of K,

$$L = \{(x, x^0, y) \in K | x^0 = g(x), y_i = \partial_i g\}.$$

This Legendre submanifold is sometimes called the 1-graph space G.[13] Although the y_i's are independent of x and x^0 in K, however $\psi^*(y_i) = \partial_i g$, i.e., the pull back of y_i on G is $\partial_i g$.

In the contact manifold K with normal coordinates (x, x^0, y), there is a special vector field $X_E = \partial_0 = (\partial / \partial x^0)$ such that

$$i(X_E)\omega = X_E \rfloor \omega = 1, \quad i(X_E) d\omega = X_E \rfloor d\omega = 0, \tag{37}$$

where "$\rfloor$" is an inner multiplication defined by $i(X)\omega = X \rfloor \omega = \nu^i \omega_i$ for $X = \nu^i \partial_i$ and $\omega = \omega_i dx^i$. Since the tangent bundle TK can be uniquely decomposed into $TK = \ker d\omega \oplus \ker \omega$, where $\ker d\omega$ is a vector bundle generated by X_E and $\ker \omega$ is a horizontal bundle, every vector field X on TK can be uniquely decomposed as

$$X = aX_E + (X - aX_E).$$

By (37) we obtain $a = i(X)\omega$. Thus

$$X = (i(X)\omega)\partial_0 + [X - (i(X)\omega)\partial_0] = X_V + X_H.$$

We can easily verify that $i(X_V)\omega = i(X)\omega = 1$, $i(X_H)\omega = 0$, $i(X_V) d\omega = 0$, and $i(X) d\omega = i(X_H) d\omega$. Thus $X_V \in \ker d\omega$, and $X_H \in \ker \omega$. In other words, X_H lies in the contact hyperplane Δ_x, while X_V is tangent to the fiber if K is considered as a fiber bundle.

To every vector field $X \in TK$, there is a unique differentiable function f defined on K given by $f = i(X)\omega$. Since

$$i(X_H) d\omega = i(X) d\omega = -\{df - [i(X_E) df]\omega\} = -Df,$$

we have $i(X_E) Df = 0$, where

$$Df = df - [i(X_E) df]\omega$$

is called the covariant derivative of f. Let ω^b be the map; $X_H \to Df$. Consider the inverse map $\omega^\# = (\omega^b)^{-1}$. Alternatively, given Df we construct X_H such that $i(X_H) d\omega = -Df = -df + [i(X_E) df]\omega$, and $i(X_H)\omega = 0$. Thus let

$$X_H = u^0 \partial_0 + u^i \partial_i + u_i \partial^i,$$

where $\partial_0 = (\partial / \partial x^0)$, $\partial_i = (\partial / \partial x^i)$, and $\partial^i = (\partial / \partial y_i)$. Then

$$i(X_H) d\omega = u^i dy_i - u_i dx^i = -(y_i \partial_0 + \partial_i) f dx^i - (\partial^i f) dy_i.$$

Hence $u_i=(y_i\partial_0+\partial_i)f$, $u^i=-\partial^i f$ and

$$X_H=u^0\partial_0+(\partial^i f)\partial_i+[(y_i\partial_0+\partial_i)f]\partial^i.$$

On the other hand, $i(X_H)\omega=0$ yields $u^0=-y_i\partial^i f$. Therefore

$$X_H=-[y_i\partial^i f]\partial_0+y_i(\partial_0 f)\partial^i+[(\partial_i f)\partial^i-(\partial^i f)\partial_i]=-\omega^{\#}f.$$

Now that $X_V=(i(X_E)\omega)X_E=f\partial_0$, to every differentiable function f defined on K, there is a unique vector field X_f given by

$$X_f=X_V+X_H=f\partial_0-\omega^{\#}f=f\partial_0+\{-(y_i\partial^i f)\partial_0+y_i(\partial_0 f)\partial^i+[(\partial_i f)\partial^i-(\partial^i f)\partial_i]\}.$$

For convenience we rewrite X_f as

$$X_f=(f-y_i\partial^i f)\partial_0-(\partial_i f)\partial^i+[y_i(\partial_0 f)+(\partial_i f)]\partial^I=f^0\partial_0+f^i\partial_i+f_i\partial^i, \tag{38}$$

where f^0, f^i, and f_i are C^1 functions of (x,x^0,y) given by

$$f^0=f+y_i(-\partial^i f)=f+y_i f^i,$$

$$f^i=-\partial^i f,$$

$$f_i=(\partial_0 f)y_i+\partial_i f=(\partial_i+y_i\partial_0)f.$$

Thus (38) establishes a one-to-one correspondence between a C^1 function defined on K and a vector field (contact vector field) X_f. This one-to-one correspondence gives rise to an isomorphism h from the Lie algebra of vector fields onto the vector space of real-valued functions on K, whose Lie algebra structure is defined by the Jacobi bracket $[f,g]=i([X_f,X_g])\omega$ with $X_f=h^{-1}(f)$ and $X_g=h^{-1}(g)$.

In view of (38) the flows (orbital equations) of X_f can be written as

$$\frac{dx^0}{d\tau}=f^0(x,x^0,y)=f+y_i f^i,$$

$$\frac{dx^i}{d\tau}=f^i(x,x^0,y)=-\partial^i f, \tag{39}$$

$$\frac{dy_i}{d\tau}=f_i(x,x^0,y)=(y_i\partial_0+\partial_i)f.$$

These flow equations generate a 1-parameter family of maps $T_x(\tau)$: $K\to K$ with $T_x(\tau)=\exp(\tau X_f)$. Since X_f can be considered as a derivation on C^1 functions defined on K, the natural extension of X_f as a derivation on differential forms $\wedge(K)$ is the Lie derivative $L(X_f)$, where $L(X_f)\omega=i(X_f)d\omega+d(i(X_f)\omega)$. Let C be the (contact) ideal generated by ω. If $\eta\in C$, then $\eta=\lambda\omega$, $\lambda\in C^0(K)$. By (38) we have $L(X_f)\omega=(\partial_0 f)\omega=\lambda\omega$. Thus $L(X_f)C\subset C$. A vector field which carries a contact ideal onto itself is called an isovector field. Consider the composition of the regular map ψ and the 1-parameter group of maps $T_x(\tau)$, $\psi_x(\tau)=T_x(\tau)\circ\psi$. Notice that

$$\overline{\psi_x^*}(\tau)\mu=\overline{\psi^*}[(e^{\tau L(X_f)})^*\mu]=\overline{\psi^*}[\mu+\tau(L(X_f))^*\mu+\cdots]\neq 0$$

and

$$\overline{\psi_x}(\tau)\omega=\overline{\psi^*}[(e^{\tau L(X_f)})^*\omega]=\overline{\psi^*}[\omega+\tau\lambda\omega+\cdots]=0,$$

$\overline{\psi_x}$ is an embedding of $\overline{\psi}$ in a 1-parameter group of maps generated by X_f. We call $\overline{\psi_x}$ a 1-parameter group of regular maps or contact transformations generated by X_f. As $\psi_x(\tau)\omega=0$, ψ_x carries Legendre submanifold of K into another Legendre submanifold of K.

Let **L** be a Legendre submanifold of K given by the 1-graph space

$$G=\{(x,x^0,y)|x^0=g(x),y_i=\partial_i g,i=1,2,...,n\}.$$

Notice that $\{X_i=y_i\partial_0+\partial_i,\ i=1,2,...,n\}$ is a linearly independent set of vector fields such that $i(X_i)\omega=0$. Thus $X_i\in\ker\omega$. In general $X_f=f^0\partial_0+f^i\partial_i+f_i\partial^i\in\ker\omega$ if and only if $f^0-y_if^i=0$. On the other hand, X_f is tangent to G if and only if $f|_G=0$, i.e., $f^0(x,g(x),\nabla g)=(\partial_i g)f^i(x,g(x),\nabla g)$ where $\nabla g=(\partial_i g,\ldots,\partial_n g)$. By (38) and (39) we notice that

$$\begin{aligned}\left.\frac{dy_i}{d\tau}\right|_G&=(y_i\partial_0+\partial_i)f|_G=(\partial_i g)\partial_0 f^0+\partial_i f^0-(\partial_i g\partial_j g)\partial_0 f^j-(\partial_j g)\partial_i f^j\\&=(\partial_i g)(\partial_j g)\partial_0 f^i+(\partial_i\partial_j g)f^j+(\partial_j g)(\partial_i f^j)\\&\quad-(\partial_i g\partial_j g)\partial_0 f^j-(\partial_j g)\partial_i f^j\\&=(\partial_i\partial_j g)f^j=\frac{d}{d\tau}(\partial_i g).\end{aligned}$$

Hence the flows of X_f lie on G if and only if $f|_G=0$.

Proposition 3: Let f be a scalar-valued function defined on K and let **L** be a Legendre submanifold of K given by the 1-graph space G. Then **L** is invariant under the contact transformations generated by X_f if and only if $f|_G=0$.

Suppose $X_G=f^0(x,x^0)\partial_0+f^i(x,x^0)\partial_i$ is a vector field tangent to G. We can lift X_G to X_f by

$$X_f=X_G+[(y_i\partial_0+\partial_i)f]\partial^i=f^0\partial_0+f^i\partial_i+f_i\partial^i,\tag{40}$$

where $f=f^0-y_jf^i$. Comparing with (38), X_f indeed is the lift of X_G from G to TK. Furthermore, since $X_f|_G=X_G$, X_G is the projection of X_f on G. Hence,

Corollary 1: Let $X_G=f^0(x,x^0)\partial_0+f^i(x,x^0)\partial_i$ be a vector field tangent to G, such that $f^0=(\partial_i g)f^i$. Then X_f given by (40) is the lift of X_G, and X_G is the projection of X_f on G, where $f=f^0-y_if^i$. Furthermore, the 1-graph space G is invariant under the contact transformations generated by X_f.

We now apply the results obtained above to thermodynamics. Let $\hat{\Omega}=dE-\Omega$. The inaccessibility condition (17a) is equivalent to (21), which gives rise to the generalized Gibbs relation (22). Equation (22) can be recast in canonical form as $dx^0=y_idx^i$ with (y,x) as canonical coordinates. Then we define the contact 1-form $\omega=dx^0-y_idx^i$, where $\omega\wedge(d\omega)^n\neq0$ and $\omega\wedge(d\omega)^{n+1}=0$. Let K be a $(2n+1)$-dimensional manifold with coordinate cover (x,x^0,y), whose contact structure is specified by the 1-form ω. The 1-graph space $G=\{(x,x^0,y)|x^0=g(x),y_i=\partial_i g\}$ is a Legendre submanifold of K, where x^0 is the internal energy of the thermodynamic system, $x=(S,V,\{N_i\},\{\Phi_i^{(\alpha)}\})$ is the set of thermodynamic variables, and $y=(T^*,-p^*,\{\mu_i^*\},\{-(X_i^{(\alpha)})^*\})$ is a set of intensive variables conjugate to x. Alternatively we can adopt the entropy representation with $x^0=S$, $x=(E,V,\{N_i\},\{\Phi_i^{(\alpha)}\})$, and $y=((T^*)^{-1},p^*(T^*)^{-1},\{-\mu_i^*(T^*)^{-1}\},\{(X_i^{(\alpha)})^*(T^*)^{-1}\})$.

Corollary 2: The inaccessibility condition (17a) is invariant under the contact transformations generated by X_f given by (38) if $f|_G=0$. Particularly, if $X_G=f^0(x,x^0)\partial_0+f^i(x,x^0)\partial_i$ is a vector field on G, then X_G can be lifted to $X_f=X_G+[(y_i\partial_0+\partial_i)f]\partial^i$, $f=f^0-y_if^i$, such that G is invariant under the contact transformations generated by X_f.

We make some remarks in the following discussions. First, there is a one-to-one correspondence between f and X_f. In general a Legendre submanifold is carried into another Legendre submanifold under the contact transformations generated by X_f. Most of the Legendre transfor-

mations encountered in equilibrium thermodynamics are discrete transformations. It is impossible to find X_f which can generate such discrete transformations. Second, given f we can find the zero set of $f(x,x^0,y)$ and solve the equation $f(x,g(x),\nabla g(x))=0$ for $g(x)$. The solutions of g gives rise to the 1-graph space G, where G is invariant under the contact transformations generated by X_f. It should be noted that in general, the zero set of X_f is a $2n$-dimensional submanifold of X_f, whereas G is an n-dimensional Legendre submanifold of K. Furthermore the solutions of g may not be unique. Other conditions based on thermodynamic considerations must be imposed in order to obtain a unique solution of g. Third, suppose g is given. We can find a vector field $X_G=f^0(x,x^0)\partial_0+f^i(x,x^0)\partial_i$ such that $f^0=(\partial_i g)f^i$, $x^0=g(x)$. However, the choice of f^i is arbitrary. For equilibrium thermodynamics, the flows of X_G can be considered as a thermodynamic process under consideration. Once f^i has been chosen, f can be constructed by $f(x,x^0,y)=f^0(x,x^0)-y_i f^i(x,x^0)$. Finally suppose under some specific assumptions or approximations the dynamical equations of the global thermodynamic variables x^i can be expressed as $(dx^i/dt)=f^i(x,t)$. Furthermore, suppose g is also known. We can construct X_G and lift it to X_f by the method described in Corollary 1. In other words we embed the dynamical equations for x^i in the flow equations of X_f. The thermodynamic laws are then invariant under the contact transformations generated by X_f.

In the next section we consider some examples to further elucidate these remarks. The first three examples are based on equilibrium thermodynamics where $\Phi_i^{(\alpha)}=0$. The last example is associated with nonequilibrium thermodynamics.

IV. EXAMPLES

Example 1: Let $x^0=E$, $x^1=S$, $x^2=V$, $x^3=N$, $y_1=T$, $y_2=-p$, and $y_3=\mu$. The fundamental equation of thermodynamics at equilibrium can be written as $x^0=y_i x^i$, where the Gibbs relation is $dx^0=y_i dx^i$ and the Gibbs–Duhem relation is $x^i dy_i=0$. Let $f=x^0-y_i x^i=f^0-y_i f^i$. Then $f^0=x^0$ and $f^i=x^i$. By (38) and (39) the orbital equations of X_f have the solutions $x^i=x^i(0)e^{-\tau}$, $x^0=x^0(0)e^{-\tau}$, $y_i=y_i(0)$. The zero set of f is simply $x^0=y_i x^i$. If the constitutive relations are assumed for $y_i=y_i(x)$ then $x^0=g(x)=(\partial_i g)x^i=y_i(x)x^i$ is the Legendre submanifold of K with coordinate cover (x,x^0,y). Hence $G=\{(x,x^0,y)|x^0=g(x),y_i=\partial_i g\}$ is invariant under the contact transformation generated by X_f.

Example 2: Let $x^0=S$, $x^1=E$, $x^2=V$, $y_1=T^{-1}$, $y_2=pT^{-1}$. The entropy for an ideal gas can be written as

$$x^0=g(x^1,x^2)=\frac{3R}{2}\ln(x^1)+R\ln(x^2)-\left\{\frac{3R}{2}\ln(c_\nu)+R\ln(R)\right\}.$$

Thus $y_1=\partial_1 g=(3R/2)(x^1)^{-1}$ and $y_2=\partial_2 g=R(x^2)^{-1}$. In other words, we have the constitutive relations $T=(2E/3R)$, $p=V^{-1}(RT)$. Set $f^1=-x^1$ and $f^2=-x^2$. By (39) we have $x^1=x^1(0)e^{-\tau}$, $x^2=x^2(0)e^{-\tau}$, $f^0=(\partial_i g)f^i=-(5R/2)$ and $f=f^0-y_i f^i=-(5R/2)+y_i x^i$. Thus $x^0=-\frac{5}{2}R\tau+C$, $y_1=y_1(0)e^{\tau}$, and $y_2=y_2(0)e^{\tau}$, where $C=\frac{3}{2}R\ln(x^1(0)/c_\nu)+R\ln(x^2(0)/R)$. Notice that $f|_G=-\frac{5}{2}R+(\partial_1 g)x^1+(\partial_2 g)x^2=0$. Since $(y_1/y_2)=(y_1(0)/y_2(0))=p=\text{const}$, the flows of X_f describe an isobaric process on the Legendre submanifold given by the 1-graph space G.

Example 3: Let $x^0=E$, $x^1=S$, $x^2=V$, $x^3=N$, $y_1=T$, $y_2=-p$, and $y_3=\mu$.

(a) Consider $f=E-\frac{3}{2}NRT$ or $f(x,x^0,y)=x^0-(3R/2)x^3y_1=f^0-y_i x^i$. Then $f^0=x^0$, $f^1=\frac{3}{2}Rx^3$, $f^2=f^3=0$ and the vector field X_f associated with f can be constructed according to (38) as $X_f=x^0\partial_0+\frac{3}{2}Rx^3\partial_1+y_1\partial^1-\frac{3}{2}Ry_1\partial^3$. The orbital equations of X_f have the following solutions:

$$x^0=x^0(0)e^{\tau},\quad x^1=x^1(0)+\tfrac{3}{2}Rx^3(0)\tau,\quad x^2=x^2(0),\quad x^3=x^3(0),$$

$$y_1=y_1(0)e^{\tau},\quad y_2=y_2(0),\quad y_3=y_3(0)e^{\tau}-\tfrac{3}{2}Ry_1(0)\tau e^{\tau}.$$

It is important to note that the zero set of f, $x^0=\frac{3}{2}Rx^3y_1$ is a two-dimensional surface in the contact space K with coordinate cover (x,x^0,y). On the other hand it is impossible to determine a unique G by the zero set of f.

(b) Consider a system of monatomic ideal gas at equilibrium. To this end, let $f=\mu N+TS-\frac{5}{2}NRT$ or $f(x,x^0,y)=x^3y_3+x^1y_1-\frac{5}{2}Rx^3y_1=f^0-y_ix^i$. Then $f^0=0$, $f^1=-x^1+\frac{5}{2}Rx^3$, $f^2=0$, $f^3=-x^3$. By (38) we have $f_1=y_1$, $f_2=0$, $f_3=-\frac{5}{2}Ry_1+y_3$. Thus the orbital equations of X_f have the following solutions:

$$x^0=x^0(0),\quad x^1=x^1(0)e^{-\tau}+\tfrac{5}{2}Rx^3(0)\tau e^{-\tau},\quad x^2=x^2(0),\quad x^3=x^3(0)e^{-\tau},$$

$$y_1=y_1(0)e^{\tau},\quad y_2=y_2(0),\quad y_3=y_3(0)e^{\tau}-\tfrac{5}{2}Ry_1(0)\tau e^{\tau}.$$

Next we find the 1-graph space G such that $f|_G=0$. It is impossible to solve the equation $x^3\partial_3 g+x^1\partial_1 g=\frac{5}{2}Rx^3\partial_1 g$ for a unique g. Since the system under consideration is an ideal gas, by the equation of states $E=\frac{3}{2}NRT$ and $PV=NRT$, we have

$$T=\partial_1 g=\frac{2}{3x^3}\,g \quad \text{and} \quad -p=\partial_2 g=-\frac{2}{3x^2 g}.$$

Thus $g=Cx^3(x^2)^{-2/3}\exp(2x^1/3Rx^3)$. But

$$\mu=\partial_3 g=-\frac{1}{N}\,TS+\frac{5}{2}RT=\frac{5}{3}g-\frac{2}{3x^2}\,g.$$

Hence

$$E=x^0=g(x)=\alpha(x^3)^{5/3}(x^2)^{-(2/3)}\exp(2x^1/3Rx^3).$$

Set

$$E_0=x^0(0)=\alpha(x^3(0))^{5/3}(x^2(0))^{-(2/3)}\exp(2x^1(0)/3Rx^3(0)).$$

Then

$$E=\left(\frac{N}{N_0}\right)^{5/3}\left(\frac{V}{V_0}\right)^{-(2/3)}\exp\left(\frac{2}{3R}\left(\frac{S}{N}-\frac{S_0}{N_0}\right)\right)$$

or

$$S=\frac{N}{N_0}\,S_0+NR\,\ln\left\{\left(\frac{E}{E_0}\right)^{3/2}\left(\frac{V}{V_0}\right)\left(\frac{N}{N_0}\right)^{-(5/2)}\right\}$$

with $S_0=N_0R\,\ln\{E_0^{(3/2)}V_0N_0^{-(5/2)}\}$.

This example was originally proposed by Mrugala, Nulton, Schön, and Salamon.[3] Their solution is incomplete.

Example 4: In this example we consider a fluid undergoing a plane Couette flow between two parallel plates, where the lower plate is fixed and the upper plate is moving at a constant velocity u_0 in the positive x-axis.[13] The velocity vector has a gradient in the direction of the y-axis, while it has a translational symmetry in z. Thus this is a 1-dimensional problem. We assume that the fluid is incompressible and diathermic (i.e., nonheat conducting). Further we assume that both the temperature and the pressure of the system are constant. Under these assumptions, the conservative equations can be written as

$$\partial_t \rho = -\nabla \cdot (\rho \mathbf{u}) = 0,$$

$$\rho d_t \mathbf{u} = -\nabla p - \nabla \cdot \overleftrightarrow{\pi} = -\nabla \cdot \overleftrightarrow{\pi},$$

$$\rho d_t E = -\nabla \cdot \mathbf{Q} - \overleftrightarrow{P} : \nabla \mathbf{u} = 0,$$

where $\overleftrightarrow{P}$ is the stress tensor and $\overleftrightarrow{\pi}$ is the traceless symmetric part of $\overleftrightarrow{P}$. Since there is no heat flux nor viscous heating effect ($\overleftrightarrow{P}:\nabla \mathbf{u}=0$), E is constant. Consider the case where the system is near equilibrium. We can assume that $\boldsymbol{\pi}$ obeys the Maxwell equation

$$\rho d_t \hat{\pi} = -2p\gamma - (p/\eta_0)\overleftrightarrow{\pi},$$

with $\hat{\pi} = \rho^{-1}\overleftrightarrow{\pi}$, $\gamma = \frac{1}{2}\nabla \mathbf{u}$, and η_0 is the Newtonian viscosity of the fluid. By the geometry of the flow, the velocity vector $\mathbf{u}$ is simply $u_x(y)$ which is independent of x, and $\overleftrightarrow{\pi} = \pi_{xy}$. Denote $u = u_x$, $\pi = \pi_{xy}$. We have the following model equations for the plane Couette flow:

$$\partial_t u = -\rho^{-1}\partial_y \pi, \tag{41}$$

$$\partial_t \pi = -2p\gamma - p\eta_0^{-1}\pi, \tag{42}$$

with

$$\gamma = \frac{1}{2}\frac{\partial u_x}{\partial y}.$$

By eliminating π in (41) and (42) we obtain a wave equation of hyperbolic type,

$$\partial_{tt} u + 2k\partial_t u = c^2 \partial_{yy} u,$$

where $k = \frac{1}{2}(p/\eta_0)$ and $c^2 = pp^{-1}$. Next we set up the initial and boundary conditions as follows:

$$\begin{aligned} u(0,t) &= 0, \quad u(D,t) = u_0(t), \\ u(y,0) &= 0, \quad \pi(y,0) = 0. \end{aligned} \tag{43}$$

Here D is the distance between the two parallel plates. Since the fluid is viscous there is a transient period of time that $u_0(t)$ is smaller than u_0. Thus we assume $u_0(t) = u_0(1 - e^{-2kt})$. Equations (41)–(42) together with (43) now yield the following solutions for u and π,

$$u(y,t) = D^{-1}u_0 y A(t),$$

$$\pi(y,t) = \pi_0[(1+2kt)A(t) - 2kt],$$

where $A(t) = 1 - e^{-2kt}$, and $\pi_0 = -\eta_0 u_0 D^{-1}$. Notice that $u_0 D^{-1}$ is the shear rate, π_0 is the static shear stress and k^{-1} is the stress relaxation time.

For the problem of plane Couette flow there is only one thermodynamic variable π. Let X be the conjugate variable of π. As the system is near equilibrium we can approximate X by $X = -(2p)^{-1}\pi$.[14] In terms of normal coordinates (x, x^0, y) we set $\pi = x$, $X = y$, and $x^0 = g(x) = -(4p)^{-1}x^2$, with $S = T^{-1}x^0$ as the generalized entropy (calotropy) and $dS = T^{-1}dx$ as the generalized Gibbs relation.

Now (42) can be rewritten as

$$\frac{dx}{dt} = -2k\pi_0 A(t) - 2kx = f^1(x).$$

Thus we set

$$f^0(x)=\frac{dg}{dx}\ f^1(x)=kp^{-1}\pi_0 A(t)x+kp^{-1}x^2=kp^{-1}\pi_0 A(t)x-4kx^0,$$

$$f(x)=f^0(x)-yf^1(x)=-4kx^0+k\pi_0 A(t)(p^{-1}x+2y)+2kxy.$$

By (38) we have $f_1(x)=kp^{-1}\pi_0 A(t)-2ky$ and the vector field

$$X_f=f^0\partial_0+f^i\partial_i+f_i\partial^i,$$

where $\partial_0=(\partial/\partial x^0)$, $\partial_1=(\partial/\partial x)$, $\partial^1=(\partial/\partial y)$. The orbital equations of X_f are simply $(dx^0/dt)=f^0(x)$, $(dx/dt)=f^1(x)$, and $(dy/dt)=f_1(x)$. Hence we have embedded the dynamical equations of x in the flow equations of X_f. The flows of X_f form a 1-parameter group of contact transformations that preserve the Legendre submanifold $L=\{(x,x^0,y)|x^0=g(x),y=g'(x)\}$.

Finally we remark that Grmela and Jou have also applied the notion of contact geometry in their study of extended kinetic theory from a molecular point of view.[15] However their approach is different from the one presented in this paper.

(Received 15 July 1997; accepted for publication 28 August 1997)

A radiative equation of the Cattaneo–Vernotte type is derived from information theory and the radiative transfer equation. The equation thus derived is a radiative analog of the equation that is used for the description of hyperbolic heat conduction. It is shown, without recourse to any phenomenological assumption, that radiative transfer may be included in a natural way in the framework of extended irreversible thermodynamics (EIT). © *1998 American Institute of Physics.* [S0022-2488(98)03001-1]

I. INTRODUCTION

Radiative transfer has recently become an active area of research within extended irreversible thermodynamics (EIT). However, most approaches to the subject have considered the description of purely radiation systems (photon gas),[1–3] whereas a joint thermodynamical description of radiation and matter is certainly necessary. This conclusion can be reached as follows. Because photons do not interact among themselves, it is the interaction between radiation and matter that drives an isolated radiative system towards equilibrium.[4] More generally, since in the absence of matter photons cross a small volume centered about any given point without any interaction, it is clear that the distribution function cannot be determined by the macroscopic properties at the point considered: instead, it will be determined by the properties of the emitting source. Similar arguments to the previous ones have led to the idea[5,6] that it does not seem possible to reach valid thermodynamical conclusions with regards to radiative transfer on the basis of any picture that does not take into account the absorption and emission of radiation by matter. Some phenomenological models that include matter as well as radiation have been proposed (see, e.g., Refs. 7 and 8). However, a microscopic approach should be sought in order to see to what extent the hypotheses that lie at the ground of such phenomenological models can be justified. In this paper, we make use of information theory in order to present such a microscopic approach. It will be very useful, before doing so, to briefly recall two information-theoretical results in conductive, purely matter systems. For an ideal monatomic gas, maximization of the entropy density under the constraints of fixed molecule number density n, vanishing barycentric velocity, fixed internal energy density ρu_m (ρ stands for the matter density), and fixed conductive heat flux $\mathbf{q}$ leads, keeping terms up to second-order in $\mathbf{q}$, to the following results[3] (see also Ref. 6) for the generalized Gibbs equation and for the temperature θ of extended irreversible thermodynamics

$$ds_m=\frac{1}{\theta}\,du_m-\frac{2m}{5nk_B^2T_m^3\rho}\,\mathbf{q}\,d\mathbf{q}, \tag{1}$$

[a)]Dedicated to Professor José Casas-Vázquez with occasion of his 60th anniversary and of the 25th anniversary of the first paper on Extended Irreversible Thermodynamics by his UAB group.
[b)]Electronic mail: jfort@songoku.udg.es

$$\frac{1}{\theta}=\frac{1}{T_m}\left(1+\frac{2\rho}{5n^3k_B{}^3T_m{}^3}\,\mathbf{q}\cdot\mathbf{q}\right), \tag{2}$$

where s_m is the specific entropy, m is the molecular mass (so that $\rho=mn$), k_B stands for the Boltzmann constant, T_m is the kinetic local-equilibrium temperature, which satisfies that[9,6]

$$u_m=3k_BT_m/2m, \tag{3}$$

and the definition of θ for the matter system under consideration is

$$\theta^{-1}\equiv\frac{\partial s_m}{\partial u_m}. \tag{4}$$

Equations (1) and (2) have also been derived without making use of information theory but beginning with the postulates of extended irreversible thermodynamics and making use of the results of Grad's 13-moment kinetic theory method.[9] This has provided a conceptually reasonable, sound framework for a thermodynamical description of heat conduction in further-away-from-equilibrium states than those corresponding to local-equilibrium thermodynamics. Our purpose is here to propose the information-theoretical basis of such a framework for radiative, instead of conductive, heat transfer. Therefore, in the following sections we do not consider a matter system under a conductive heat flux $\mathbf{q}$ but a radiation-matter system under a radiative heat flux, which we shall call $\mathbf{F}$.

II. INFORMATION THEORY

Assuming that the matter content of the system is a classical ideal monatomic gas, the entropy density of the system is[4]

$$\rho s=\rho s_m+\rho s_r=-k_B\int_{R^3}\frac{d^3p_m}{(2\pi\hbar)^3}\,f_m\,\ln\,f_m+2k_B\int_{R^3}\frac{d^3p_r}{(2\pi\hbar)^3}\,[(1+f_r)\ln(1+f_r)-f_r\,\ln\,f_r], \tag{5}$$

where the subindexes m and r stand for matter and radiation (photons), and s, f, and p are the corresponding entropies per unit mass, distribution functions, and momenta, respectively. Here $\hbar$ is the Planck constant h divided by 2π. We have used the same notation as in Ref. 4: for example, f_m stands for the number of molecules in d^3p_m and d^3x, divided by $d^3p_md^3x/(2\pi\hbar)^3$, with d^3x a differential of volume (in this way, $\ln f_m$ is dimensionless).

We will make use of the well-known information-theoretical approach[10,11] by maximizing (5) under the macroscopic constraints of fixed total energy density ρu, molecular number density n, and radiative energy flux $\mathbf{F}$ of the system,

$$\rho u=\rho u_m+\rho u_r=\int_{R^3}\frac{d^3p_m}{(2\pi\hbar)^3}\,\frac{p_m^2}{2m}\,f_m+2\int_{R^3}\frac{d^3p_r}{(2\pi\hbar)^3}\,p_rcf_3, \tag{6}$$

$$n=\int_{R^3}\frac{d^3p_m}{(2\pi\hbar)^3}\,f_m, \tag{7}$$

$$\mathbf{F}=2\int_{R^3}\frac{d^3p_r}{(2\pi\hbar)^3}\,p_rc\mathbf{c}f_r, \tag{8}$$

where u_m is the matter specific internal energy and u_r is the radiation energy, also per unit mass of matter. In Eq. (6) we have assumed that the barycentric velocity of the matter gas vanishes (this

allows us to concentrate on the topic that is of interest: we are neglecting heat convection in addition to heat conduction). In Eq. (8), $\mathbf{c}=c\hat{\Omega}$ is the velocity of a photon moving in a direction with unit vector $\hat{\Omega}$ and c is the speed of light *in vacuo*. Maximization of (5) under the constraints (6)–(8) finally yields for the distribution functions

$$f_m=\exp\left[-1-\lambda-\beta\,\frac{p_m^2}{2m}\right], \tag{9}$$

$$f_r=\frac{1}{\exp[\beta p_r c-\boldsymbol{\gamma}\cdot p_r c\,\mathbf{c}]-1}, \tag{10}$$

where λ, β, and $\boldsymbol{\gamma}$ are Lagrange multipliers.

III. EXTENDED IRREVERSIBLE THERMODYNAMICS OF RADIATIVE SYSTEMS

We now follow the usual information-theoretical procedure[9,12] in order to derive an extended Gibbs equation, which will be used to show that radiative transfer can be included in the framework of EIT. Since we have assumed the matter gas to be at rest, the equation of continuity implies that matter density does not change in time, i.e., the density differential vanishes, so that $dn=0$. From this fact and Eq. (5) it is not difficult to find out expressions for ds_m and ds_r, in which we make use of (9) and (10), respectively. In this way and after use of (6)–(8) we arrive at $ds_m=k_B\beta\,du_m$ and $ds_r=k_B\beta\,du_r-(k_B/\rho)\boldsymbol{\gamma}\cdot d\mathbf{F}$. Therefore

$$ds=ds_m+ds_r=k_B\beta\,du-\frac{k_B}{\rho}\,\boldsymbol{\gamma}\cdot d\mathbf{F}, \tag{11}$$

where we note that the entropy per unit mass of the radiation-matter system under consideration is a function of the *total* (radiation and matter) specific energy u and of the radiative heat flux $\mathbf{F}$. Because of this information-theoretical result, we propose the following generalization of the definition (4),

$$\theta^{-1}\equiv\frac{\partial s}{\partial u}. \tag{12}$$

From Eqs. (12) and (11) we have

$$\theta=\frac{1}{k_B\beta}. \tag{13}$$

On the other hand, it will be useful to follow Mihalas and Mihalas[13] by introducing a radiative *parameter* T_r through the following equation;

$$\rho u_r=aT_r^4, \tag{14}$$

with $a=\pi^2k_B^4/15c^3\hbar^3$ the blackbody constant.

After substitution of the matter distribution function (9) into (7) and into ρu_m, given by (6), and integration over all possible values of $\mathbf{p}_m$, it is easy to reach the result $\rho u_m=3n/2\beta$, which together with (3) implies that $T_m=1/k_B\beta$. Thus we have, taking into account Eq. (13),

$$\theta=T_m, \tag{15}$$

and this result is consistent with Eq. (2), because we are not dealing with conductive but with radiative heat transfer (i.e., we have $\mathbf{q}=0$ although $\mathbf{F}\neq 0$ in general).

We now look for a relationship between θ and T_r. We make use of the radiation distribution function (10) into (8) and into ρu_r, given by (6). Since both integrations over $\mathbf{p}_r$ are rather complicated, we assume that $\boldsymbol{\gamma}=(0,0,\gamma)$, integrate with the use of formula 3.411-1 of Ref. 14 and obtain

$$\rho u_r=\frac{a}{{k_B}^4\beta^4}\,\frac{1+\epsilon^2/3}{(1-\epsilon^2)^3}, \tag{16}$$

$$\mathbf{F}=\frac{4ca}{3{k_B}^4\beta^4}\,\frac{\boldsymbol{\epsilon}}{(1-\epsilon^2)^3}\equiv(0,0,F), \tag{17}$$

with

$$\boldsymbol{\epsilon}\equiv\frac{c}{\beta}\,\boldsymbol{\gamma}\equiv(0,0,\epsilon). \tag{18}$$

From Eqs. (14), (16), and (13) we obtain

$$\theta=T_r\left(\frac{(1-\epsilon^2)^3}{1+\epsilon^2/3}\right)^{1/4}. \tag{19}$$

This equation relates θ to T_r, but ϵ should be written in terms of macroscopic observables if we want the radiative theory to be put at the same level as the conductive one: according to the conductive relationship (2), for a given value of m (i.e., for a given matter gas) θ is a known function of T_m if the values of the macroscopic observables ρ and $\mathbf{q}$ are known. We can cope with this problem by noting that (16), (17), and (14) can be combined to yield

$$F=4caT_r{}^4\,\frac{\epsilon}{3+\epsilon^2}, \tag{20}$$

from which it follows that

$$\epsilon=\frac{2-\sqrt{4-3F^2/c^2a^2T_r{}^8}}{F/caT_r^4}. \tag{21}$$

We make use of (20) in the denominator in (19) and then apply Eq. (21). Since we will here be interested in near-equilibrium results, we assume that the value of F is low enough so that θ can be approximated by its MacLaurin expansion up to second order in F. This yields

$$\frac{1}{\theta}=\frac{1}{T_r}\left(1+\frac{15}{32c^2a^2T_r{}^8}\,F^2\right), \tag{22}$$

and this equation, which applies to radiative transfer, is analogous to the conductive equation (2). The second-order result (22) is in agreement with the expression for θ that has been obtained [Eqs. (27) and (17) in Ref. 3] by partial derivation of the radiative entropy density (which was derived on phenomenological grounds in Refs. 1 and 15) with respect to the radiative energy density. Equation (22) has also been previously derived by Casas-Vázquez and Jou for a purely radiation system [see Eq. (30) in Ref. 16], by making use of a fluctuation theory result and of the EIT phenomenology. However, there is a very important difference between these approaches and the information-theoretical one presented here: since in our definition (12) for θ we have made use of the total radiation *and matter* entropy and energy densities, the conceptual objections presented in

the first lines in this letter do not apply to our analysis. A generalized Gibbs equation can be finally derived from (11), (18), (13), and (21). Keeping in mind that we are interested in the second-order approximation for θ and s, we obtain

$$ds=\frac{1}{\theta}\,du-\frac{3}{4c^2a\rho T_r^5}\,\mathbf{F}\cdot d\mathbf{F}, \tag{23}$$

which is analogous to the conductive result (1). On the other hand, we note from (3), (15), and (22) that u_m is a function of T_r [or u_r, see Eq. (14)] and $\mathbf{F}$. Therefore, although in Eq. (23) we have taken the total specific energy $u=u_m+u_r$ and $\mathbf{F}$ as independent variables, it is clear that in this model u_r and $\mathbf{F}$ may also be chosen as independent variables. It is easy to relate du_m to du_r and $d\mathbf{F}$. Making use of the relationship thus obtained and of (23), applying (22), and neglecting higher-order terms, one finally obtains the extended Gibbs equation in the new variables,

$$ds=\left(\frac{1}{\theta}\left\{1+\frac{3k_B\rho^{1/4}}{8\,ma^{1/4}u_r^{3/4}}\right\}+\frac{315k_BF^2}{256\,m\rho^2c^2u_r^3}\right)du_r-\left(\frac{45k_B}{32mc^2\rho^2u_r^2}+\frac{3a^{1/4}}{4c^2\rho^{9/4}u_r^{3/4}}\right)\mathbf{F}\cdot d\mathbf{F}. \tag{24}$$

From this equation, (22), and (14), it is straightforward to check that ds is an exact differential, i.e.,

$$\frac{\partial^2 s}{\partial\mathbf{F}\partial u_r}=\frac{\partial^2 s}{\partial u_r\partial\mathbf{F}}, \tag{25}$$

so that the total (i.e., radiation and matter) specific entropy of the system is a state function, as it should.

IV. APPLICATION

Kremer and Müller[1] were able to deduce a radiative equation which is essentially of the Cattaneo-Vernotte relaxational type [their second Eq. (7.1)], but the corresponding relaxation time and radiative conductivity were not found out. We will now provide a microscopic derivation of that relaxational equation and find out the relaxation time and radiative conductivity explicitly.

Let us mention, for the sake of completeness, that making use of Eq. (7) it is not difficult to show that the matter distribution function (9) is locally Maxwellian, with temperature $T_m=\theta$ [see Eq. (15)]. On the other hand, making use of Eqs. (18), (21), (13), and (22), the information-theoretical radiative distribution function (10) reads, up to second order in $\mathbf{F}$,

$$f_r=f_r^{(0)}(1+\phi^{(1)}+\phi^{(2)}+\cdots), \tag{26}$$

with

$$f_r^{(0)}=\frac{1}{e^x-1}, \tag{27}$$

$$\phi^{(1)}=\frac{3x}{4}\,\frac{e^x}{e^x-1}\,\hat{\Omega}\cdot\mathbf{f}, \tag{28}$$

$$\phi^{(2)}=\tilde{\phi}^{(2)}+\tilde{\tilde{\phi}}^{(2)}, \tag{29}$$

$$\tilde{\phi}^{(2)}=-\frac{15x}{32}\,\frac{e^x}{e^x-1}\,\mathbf{f}\cdot\mathbf{f}, \tag{30}$$

$$\tilde{\tilde{\phi}}^{(2)}=\frac{9x^2}{32}\,\frac{e^x(e^x+1)}{(e^x-1)^2}\,(\hat{\Omega}\cdot\mathbf{f})^2, \tag{31}$$

where we have defined the following dimensionless quantities:

$$\mathbf{x}\equiv\frac{c}{k_B T_r}\,\mathbf{p}_r\,,\quad x\equiv|\mathbf{x}|,\quad \hat{\Omega}\equiv\frac{\mathbf{c}}{c}=\frac{\mathbf{p}_r}{p_r}=\frac{\mathbf{x}}{x},\quad \mathbf{f}\equiv\frac{\mathbf{F}}{caT_r^4}=\frac{\mathbf{F}}{cu_r\rho}, \tag{32}$$

f being the reduced flux. We have written (27)–(31) in terms of T_r, rather than in terms of $\theta=T_m$, for later convenience. The distribution function (26)–(31) is a radiative analog of the Dominguez–Jou distribution function [Eqs. (30), (33), and (34) in Ref. 3], which was also derived making use of information theory but applies to a nonrelativistic classical monatomic ideal gas under a conductive heat flux. Both in radiative and conductive systems (present paper and Ref. 3, respectively), information theory provides a simple derivation for the second-order non-equilibrium correction $\phi^{(2)}$. This correction is very difficult to find out in the framework of the kinetic theory of gases[17,18] of conductive, purely matter systems. It is worthwhile to mention that information theory is very simple mathematically but has the disadvantage that the question of what constraints should be imposed in maximizing the entropy density is an open one at present. On the other hand, it has been stressed[5] that a well-established phenomenological thermodynamics of radiative transfer does not seem to be available. This is in contrast with the situation in purely matter systems, where phenomenological thermodynamics may be a useful guide in the choice of the information-theoretical constraints (see Refs. 6, 12, 19, and, in connection with this, pages 46–47 in Ref. 9).

Our purpose here is to show that a relaxational equation follows from the radiative distribution function. In order to do so, we shall first show that although both (22) and (23) on one hand, and (26)–(31) on the other, have been obtained working up to second order in **F**, only the first nonequilibrium correction $\phi^{(1)}$ contributes to the second-order entropy corresponding to (22) and (23). Making use of Eq. (26) and of the MacLaurin expansion

$$\ln(a_0+a_1F+a_2F^2+\cdots)=\ln a_0+\frac{a_1}{a_0}F+\left(\frac{2a_2}{a_0}-\frac{a_1^2}{a_0^2}\right)\frac{F^2}{2}+O(F^3)$$

into the expression for ρs_r, given by Eq. (1), we obtain, up to second order,

$$\begin{aligned}\rho s_r=\rho s_r^{(0)}&+2k_B\int_{R^3}\frac{d^3p_r}{(2\pi\hbar)^3}\,f_r^{(0)}\,\ln\left(\frac{1}{f_r^{(0)}}+1\right)\phi^{(1)}\\&-2k_B\int_{R^3}\frac{d^3p_r}{(2\pi\hbar)^3}\,f_r^{(0)}\,\ln\left(\frac{1}{f_r^{(0)}}+1\right)\phi^{(2)}\\&-k_B\int_{R^3}\frac{d^3p_r}{(2\pi\hbar)^3}\,\frac{f_r^{(0)}}{1+f_r^{(0)}}\,\phi^{(1)^2},\end{aligned} \tag{33}$$

with

$$\rho s_r^{(0)}=2k_B\int_{R^3}\frac{d^3p_r}{(2\pi\hbar)^3}\,[(1+f_r^{(0)})\ln(1+f_r^{(0)})-f_r^{(0)}\,\ln\,f_r^{(0)}].$$

The second term on the right-hand side of (33) vanishes because (27) and (28) imply that the corresponding integrand changes sign under the transformation $\mathbf{p}_r\to-\mathbf{p}_r$. The third term, which contains $\phi^{(2)}$, is also seen to vanish after substitution of (27) and (29)–(31), application of the integral theorem (which is easy to prove)

$$\int_{R^3} d^3x\ F(x)(\mathbf{x}\cdot\mathbf{g})^2 = \frac{|\mathbf{g}|^2}{3} \int_{R^3} d^3x\ x^2 F(x)$$

[with $\mathbf{g}$ any vector and $F(x)$ an arbitrary function], and use of the integrals

$$\int_0^\infty dx\ \frac{x^4 e^x}{(e^x-1)^2} = \frac{4\pi^4}{15}, \quad \int_0^\infty dx\ \frac{x^5 e^{2x}}{(e^x-1)^3} = \frac{2\pi^4}{3} + 60\zeta(5)$$

and

$$\int_0^\infty dx\ \frac{x^5 e^x}{(e^x-1)^3} = \frac{2\pi^4}{3} - 60\zeta(5),$$

$\zeta(z)$ being the Riemann zeta function. The vanishing of the second and third terms on the right-hand side of the radiative entropy density (33) can be regarded as the radiative analogue of the (e.g., kinetic-theoretical) result[17,9] for purely matter systems

$$\int_{R^3} \frac{d^3p_m}{(2\pi\hbar)^3}\ f_m^{(0)} \phi_m^{(k)} = 0,$$

with $f_m^{(0)}$ the Maxwell–Boltzmann distribution function and $\phi_m^{(k)}$ the kth-order correction due to heat conduction and/or convection: this leads to[9]

$$\rho s_m = \rho s_m^{(0)} - \frac{k_B}{2} \int_{R^3} \frac{d^3p_m}{(2\pi\hbar)^3}\ f_m^{(0)} \phi_m^{(1)^2},$$

so that $\phi_m^{(2)}$ does not contribute to the second-order approximation to the matter entropy density in conductive and/or convective situations, just as (33) becomes

$$\rho s_r = \rho s_r^{(0)} - k_B \int_{R^3} \frac{d^3p_r}{(2\pi\hbar)^3} \frac{f_r^{(0)}}{1+f_r^{(0)}}\ \phi^{(1)^2},$$

so that $\phi^{(2)}$ does not contribute to the second-order radiation entropy density in radiative situations. We mention that this conclusion can also be reached, after rather tedious calculations, by checking that integration of the first and fourth terms on the right-hand side of (33) yields the same result for ρs_r as that obtained by substitution of (10) into ρs_r, given by (5), integration, and expansion of the result up to second order in $\mathbf{F}$. By following either of the procedures it is obtained that

$$\rho s_r = \rho s_r^{(0)} - \frac{3}{8ac^2T_r^5} F^2 + O(F^3), \tag{34}$$

with $\rho s_r^{(0)} = 4aT_r^3/3$.

In the special case of thermodynamic equilibrium ($\mathbf{F}=0$), Eq. (21) becomes $\epsilon = 0$, (15) and (19) yield $\theta = T_m = T_r$, and (26)–(31) reduce to the Planck distribution function, $f_r = f_r^{(0)}$, as they should. In the same case, (34) becomes the usual expression for the radiation entropy density in equilibrium, i.e.,[4] $\rho s_r = \rho s_r^{(0)} = 4aT_r^3/3$, and we have, instead of (23), that $ds = (1/T_r)du$. This is a Gibbs equation. Therefore, analogously to what is done in phenomenological thermodynamics of matter systems,[9] T_r may be called the local-equilibrium temperature and $s_r^{(0)} \equiv s_{rle}$ may be called the local-equilibrium radiative entropy.

We now turn our attention to the second-order theory. In order to verify its consistency, it is rather important to note that Eq. (34) can also be obtained very easily (although without finding $\rho s_r^{(0)}$ explicitly) from (23), (22), and the radiative part of the local Gibbs equation, i.e., $ds_{rle} = (1/T_r)du_r$, in the following way. From $ds_m = (1/\theta)du_m$ [see the text above Eq. (11) and Eq. (13)] and (23) we have $ds_r = (1/\theta)du_r - (3/4c^2 a\rho T_r^5)\mathbf{F}\cdot d\mathbf{F}$. By integration with the use of (22) and (14) we find the second-order result $s_r = s_{rle} - (3/8ac^2\rho T_r^5)F^2$, in agreement with Eq. (34).

The fact, derived above Eq. (34), that $\phi^{(1)}$ contributes to the second-order radiation specific entropy, whereas $\phi^{(2)}$ does not, implies that the second-order thermodynamical results (22) and (23) correspond to the first-order distribution function, i.e., $f_r \approx f_r^{(0)}(1+\phi^{(1)})$ (we stress that the same happens in EIT of purely matter systems, see pp. 83–87 in Ref. 9). From this result, we will finally be able to find an evolution equation.

It is well known that information theory on its own cannot yield evolution equations, simply because all it yields is an expression for the distribution function and an (extended) Gibbs equation. However, the information-theoretical distribution function can be[20] and has in fact been combined with dynamical methods, such as the Boltzmann equation,[21] the Liouville equation,[22] the statistical operator method,[23] or the radiative transfer equation.[24] As it is well known,[25,8], multiplication of the radiative transfer equation by $\hat{\Omega}$ and integration yields, under the grey approximation,

$$\frac{1}{c}\frac{\partial \mathbf{F}}{\partial t} + c\boldsymbol{\nabla}\cdot\mathbf{P}_r = -\sigma_a \mathbf{F}, \tag{35}$$

with σ_a the absorption coefficient, $[\boldsymbol{\nabla}\cdot\mathbf{P}_r]_i \equiv \Sigma_{k=1}^3 \partial P_{r\ ki}/\partial x_k$ and $P_{r\ ki}$ the components of the pressure tensor of radiation, namely,

$$P_{r\ ki} = \frac{2}{c}\int_{R^3} \frac{d^3 p_r}{(2\pi\hbar)^3}\, p_r c_k c_i f_r . \tag{36}$$

Substitution of $f_r \approx f_r^{(0)}(1+\phi^{(1)})$ in this expression and use of Eqs. (27), (28), and (32) shows that $\phi^{(1)}$ does not contribute to the pressure tensor. Use of formula (3.411.1) in Ref. 14 allows us to perform the remaining integration. This yields

$$P_{r\ ki} = \frac{a}{3} T_r^4 \delta_{ki}, \tag{37}$$

with $\delta_{ki} = 1$ for $k = i$ and $\delta_{ki} = 0$ for $k \neq i$. Use of (37) in Eq. (35) yields

$$\tau\frac{\partial \mathbf{F}}{\partial t} + \mathbf{F} = -\lambda \boldsymbol{\nabla} T_r, \tag{38}$$

with

$$\tau = \frac{1}{c\sigma_a}, \quad \lambda = \frac{4ca}{3\sigma_a} T_r^3. \tag{39}$$

Equation (38) is in agreement with a result previously derived in Ref. 1, but here it has been possible to introduce $\boldsymbol{\nabla} T_r$ instead of the gradient of the radiative energy density, and also to find out the explicit expressions (39) for the radiative relaxation time τ and the radiative conductivity λ. It is encouraging that in steady states Eqs. (38) and (39) become $\mathbf{F} = -(4ca/3\sigma_a)T_r^3 \boldsymbol{\nabla} T_r$, and this Fourier-type equation has been used since many years ago[26] in the theory of stellar interiors. We have seen that information theory provides a statistical-mechanical derivation of the more general results (38) and (39). Similar, less rigorous expressions have been recently advanced on

phenomenological grounds.[8] Here, information theory has also allowed us to distinguish and relate T_m to T_r [defined by Eqs. (3) and (14), respectively] through (22) and (15), i.e.,

$$\frac{1}{T_m}=\frac{1}{T_r}\left(1+\frac{15}{32c^2a^2T_r^8}F^2\right).$$

We stress that this result is valid under the same conditions as those under which (38) and (39) hold.

From the generalized Gibbs equation (23), the energy balance law, namely[27] $\rho\partial u/\partial t=\nabla\cdot\mathbf{F}$, and Eqs. (38) and (39) it is not difficult to follow the usual procedure[9] and identify the entropy production rate, for low enough values of the flux $\mathbf{F}$, as

$$\sigma^s=\frac{3\sigma_a}{4caT_r^5}\mathbf{F}\cdot\mathbf{F}, \tag{40}$$

which is semi-positive definite, in agreement with the second law. According to (39) and (40), we may write $\sigma^s=(1/\lambda T_r^2)\mathbf{F}\cdot\mathbf{F}$, which is analogous to the conductive result[9] $\sigma^s=(1/\lambda' T_m^2)\mathbf{q}\cdot\mathbf{q}$, with λ' the thermal conductivity. Equation (40) shows that in the absence of matter ($\sigma_a=0$) there is no entropy production. This corresponds to the fact that photons do not interact among themselves. Because radiative transfer in the vacuum in absolutely nonlocal, it has been previously argued[6,5] that the entropy production must arise from the interaction of radiation with matter, although the explicit formula (40) does not seem to have been derived or proposed before.

We may also note that Eq. (38) is of the Cattaneo–Vemotte type: because of conceptual motivations (see, e.g., Ref. 9), and also because Fourier's law of heat conduction, i.e., $\mathbf{q}=-\lambda'\nabla T_m$, is known to fail in very fast processes,[28] a more general law, similar to (38), for heat conduction (instead of heat radiation), namely

$$\tau'\frac{\partial\mathbf{q}}{\partial t}+\mathbf{q}=-\lambda'\nabla T_m, \tag{41}$$

with τ' the conductive relaxation time, has been considered since long ago.[29,30] Equation (41) was a fundamental starting point[31] for the development of the theory presently called extended irreversible thermodynamics (see, e.g., Refs. 9 and 20). The similarity between Eqs. (41) and (38), in itself, indicates the reasonability of including radiative transfer in the framework of EIT.

Still from another point of view, we may compare our results with previous proposals (see, e.g., Ref. 7) by saying that it seems now possible to approach the irreversible thermodynamics of radiative transfer without need, in principle, to make use of a temperature field that depends on frequency and direction. This is analogous to the fact that in nonequilibrium thermodynamics of heat conduction and convection[17,9] there is no need to introduce a temperature field that depends on the molecular speed (or energy) and direction of motion.

Just to summarize, information theory provides a nonequilibrium extension of Planck's distribution function [Eqs. (26)–(31)], a microscopic derivation of a radiative equation of the Cattaneo–Vemotte type [Eqs. (38) and (39)], and it also leads to the conclusion that the range of nonequilibrium phenomena for which EIT provides an adequate framework is enlarged with the inclusion of radiative transfer.

ACKNOWLEDGMENTS

The authors would like to thank Professor D. Jou for stimulating discussions and Professor A. S. Cukrowski for providing us with the integral theorem used under Eq. (33) and with Ref. 18. Conditions of Cayley's type for ellipsoidal billiard

Vladimir Dragović[a] and Milena Radnović
Mathematical institute SANU Kneza Mihaila 35, 11000 Beograd, Yugoslavia

(Received 5 March 1997; accepted for publication 15 August 1997)

The billiard system within an ellipsoid in three-dimensional space is considered. We describe periodical trajectories of that mechanical system deriving analytical condition of Cayley's type for generalized Poncelet's theorem, using methods of algebrogeometric integration. © *1998 American Institute of Physics.*
[S0022-2488(98)02001-5]

I. INTRODUCTION

The 19th century classics already understood a deep connection between the projective geometry and the theory of algebraic curves and algebraic functions. The full Poncelet's theorem is one of the clearest examples. It claims that, as well known, *if two conics are given in a plane, then some polygonal line inscribed in one and circumscribed about the other conic is closed after n steps if and only if any such a line is closed after the same number of steps*. Connection of that purely geometrical claim with the theory of elliptic functions was discovered by Jacobi, and especially Cayley. Introducing the notion of Cayley's cubic and applying interesting algebraic geometry, Cayley deduced analytical condition on two conics for the existence of a polygon with n sides inscribed in one and circumscribed about the other conic. Detailed proof of the Cayley's condition can be found in Lebesgue's book *Les Coniques*.[1]

This subject matter also gets the attention of outstanding mathematicians nowadays. Griffiths and Harris have relatively soon given, in a series of papers,[2,3] algebrogeometric proofs in a classical manner of both Poncelet's theorem and Cayley's condition, reducing the problem to the question if some point on an elliptical curve is of finite order. The curve they consider consists of pairs $(x,\xi)\in C\times D^*$, $x\in\xi$. C,D are the conics, and D^* is the dual conic—it consists of tangent lines to D. This curve differs from Cayley's cubic. Griffiths and Harris proposed an interesting generalization of Poncelet's theorem.[2]

Except geometrical, the full Poncelet's theorem has certain significance in mechanics too, especially in the theory of integrable systems. It is well known that the billiard inside an ellipse represents an integrable mechanical system.[4] The integrability is shown exactly in existence, for a given trajectory, of a conic confocal with the boundary, such that the trajectory is tangent to the conic between every two bounces.

It is quite natural to generalize the billiard system in an ellipsoid in R^n. Trajectory is then tangent to $n-1$ quadrics confocal with the boundary.[5,6] (Trajectories of the systems perturbed by potentials from Ref. 7 have the same property, too.) The corresponding generalization of Poncelet's theorem is proved in Refs. 5, 6: *if there is a closed trajectory of the billiard inside one and tangent to $n-1$ given confocal quadrics in R^n, then there are infinitely many such trajectories.*

Strong penetration of algebraic geometry in the theory of integrable systems dates from the mid-1970s, from works by Novikov, Dubrovin, Krichever, Mumford, Van Moerbeck,... . Ideas of finite zone integration are applied to the billiard system, as a system with discrete time, in papers of Veselov and Moser.[8–10]

In this paper, a generalization of Cayley's condition connected with the generalized Poncelet's theorem from Refs. 5, 6 is established. Direct application of Cayley's or Griffiths' and Harris' proof is not fruitful from our point of view. Some results and problems in this way are described

[a]Electronic mail: vladad@mi.sanu.ac.yu

in Ref. 11. So, we used some of Grifitths' and Harris' ideas, modified for hyperelliptic curves, and applied them to so-called *isospectral curves* of Veselov and Moser.[8–10] Derived conditions look like classical Cayley's formulas by their form. We should remark that, even in the planar case, the conditions obtained in this paper are not identical to those of Cayley's, although they are equivalent.

II. XYZ MODEL AND ISOSPECTRAL CURVES

In this section, following the Veselov and Moser paper,[8] the billiard will be considered as a system with discrete time, and its integration will be shown.

Let an ellipsoid in R^N be given by the equation

$$(Ax,x)=1.$$

(We can assume that A is a diagonal matrix, with all elements on the diagonal different.) The billiard inside that ellipsoid is determined by the equations

$$x_{k+1}-x_k=\mu_k y_{k+1}, \quad y_{k+1}-y_k=\nu_k A x_k,$$

with

$$\mu_k=-\frac{2(Ay_{k+1},x_k)}{(Ay_{k+1},y_{k+1})}, \quad \nu_k=-\frac{2(Ax_k,y_k)}{(Ax_k,Ax_k)}.$$

The sequence x_k represents the points of consecutive bounces of the billiard, and $y_k=(x_k-x_{k-1})/|x_k-x_{k-1}|$ are the momenta.

The Heisenberg XYZ model can be joined to the billiard system with discrete time, in the way given by Veselov and Moser in Ref. 8, which is going to be shown here.

Consider the mapping ϕ: $(x,y)\to(x',y')$,

$$x'_k=Jy_{k+1}=J(y_k+\nu_k A x_k), \quad y'_k=-J^{-1}x_k, \quad J=A^{-1/2}.$$

Notice that the dynamics of mapping ϕ contains the billiard dynamics:

$$x''_k=Jy'_{k+1}=-x_{k+1}, \quad y''_k=-J^{-1}x'_k=-y_{k+1}.$$

Define the sequence $(\overline{x_k},\overline{y_k})$ by

$$(\overline{x_0},\overline{y_0})=(x_0,y_0), \quad (\overline{x_{k+1}},\overline{y_{k+1}})=\phi(\overline{x_k},\overline{y_k}).$$

This sequence satisfies the following relations:

$$\overline{x_{k+1}}=J\overline{y_k}+\nu_k J^{-1}\overline{x_k}, \quad \overline{y_{k+1}}=-J^{-1}\overline{x_k},$$

where the multiplier v_k is such that $|\overline{y_k}|=1$, $(A\overline{x_k},\overline{x_k})=1$. These relations can be written in the following way:

$$\overline{x_{k=1}}+\overline{x_{k-1}}=\nu_k J^{-1}\overline{x_k}.$$

Let $q_k=J^{-1}\overline{x_k}$. We have

$$q_{k+1}+q_{k-1}=\nu_k J^{-1}q_k, \quad |q_k|=1.$$

These equations represent the equations of a discrete Heisenberg XYZ system.

Claim.[8] *Let* $(\overline{x_k},\overline{y_k})$ *be the sequence connected with the elliptical billiard in the way described now. Then* $q_k=J^{-1}\overline{x_k}$ *is the solution of the discrete Heisenberg system.*

Conversely, if qk *is the solution of Heisenberg system, then the sequence* $x_k=(-1)^k J_{q2k}$ *represents a trajectory of a discrete ellipsoidal billiard system.*

According to the usual scheme of algebrogeometric integration, the algebraic curve, on whose Jacobian variety the flow becomes linear, is found in Ref. 8.

The equations of the discrete XYZ model are equivalent to the isospectral deformation (see Ref. 8):

$$L_{k+1}(\lambda)=A_k(\lambda)L_k(\lambda)A_k^{-1}(\lambda),$$

where

$$L_k(\lambda)=J^2+\lambda q_{k-1}\wedge Jq_k-\lambda^2 q_{k-1}\otimes q_{k-1},$$

$$A_k(\lambda)=J-\lambda q_k\otimes q_{k-1}.$$

As all the matrices $L_k(\lambda)$ are similar to each other, they all have the same *spectral curve* Γ:

$$\det(L(\lambda)-\mu I)=0.$$

The equation of that curve is

$$\nu^2=\prod_{i=1}^{N-1}(\mu-\mu_i)\prod_{j=1}^{N}(\mu-J_j^2),$$

with $v=\lambda\Pi_{i=1}^{N-1}(\mu-\mu_i)$, $J=\mathrm{diag}(J_1,...,J_N)$, and $\mu_1,\ldots,\mu_{N-1}$ are the roots of the function

$$\phi_\mu(x,Jy)=\sum_{i=1}^{N}\frac{F_i(x,y)}{\mu-J_i^2},$$

$$F_i=x_i^2+\sum_{j\neq i}\frac{(x\wedge Jy)_{ij}^2}{J_i^2-J_j^2},\quad x=q_{k-1},\quad y=q_k.$$

Knowing the eigenvectors ψ_k of the matrices $L_k(\lambda)$, it is possible to determine uniquely the members of the sequence q_k. If D_k is the pole divisor of the function ψ_k on the curve Γ, we have[8]

$$D_{k+1}=D_k+P_\infty-P_0,$$

where the point P_∞ corresponds to the value $\mu=\infty$, and P_0 to $\mu=0$, $\lambda=(q_k,J^{-1}q_{k+1})^{-1}$.

III. CHARACTERIZATION OF PERIODICAL BILLIARD TRAJECTORIES

In this section, we are going to establish a connection between periodic billiard trajectories and points of finite order on the Jacobian variety of a corresponding hyperelliptic curve.

The next claim gives the connection between periodic sequences q_k and periodic divisors D_k.

Lemma 1: The sequence of divisors D_k *is* n *periodic if and only if the sequence* q_k *is also periodic with the period* n *or* $q_{k+n}=-q_k$ *for all* k.

Proof: If it is, for all k, $q_{k+n}=q_k$, or for all k it is $q_{k+n}=-q_k$, obviously we have $L_{k+n}=L_k$. Thus the sequence of the eigenvectors ψ_k is periodical with the period n. It follows that the sequence of the divisors is also periodic.

Suppose now $D_{k+n}=D_k$ for all k. Thus $\psi_{k+n}=C_k\psi_k$. We have (see Ref. 8)

$$\psi_{k+1}=A_k(\lambda)\psi_k.$$

Let μ_1 and μ_2 be the values of parameter μ that correspond to $\lambda=1$ on the curve Γ, and

$$\Psi_k=(\psi_k(1,\mu_1),\psi_k(1,\mu_2)).$$

From $\psi_{k+1}=A_k(\lambda)\psi_k$, we obtain $A_k(1)=\Psi_{k+1}\Psi_k^{-1}$. It follows that

$$A_k(1)=\frac{C_{k+1}}{C_k}A_{k+n}(1).$$

From the condition on A_k for all k (see Ref. 8), we get $C_k=C_{k+1}$. Thus, the sequence

$$A_k(1)=J-q_k\otimes q_{k-1}$$

is n periodic. Therefore

$$q_{k+n}=\alpha_k q_k,\quad q_{k+n-1}=\frac{1}{\alpha_k}q_{k-1}.$$

From $|q_k|=1$, we have $\alpha_k=1$ or $\alpha_k=-1$, with all α_k mutually equal, which concludes the proof. □

Since $q_{k+2n}=(-1)^n q_k$ for an n-periodic billiard, we have the following lemma.

Lemma 2: If the billiard is periodic with the period n, then the divisor sequence D_k joined to the corresponding Heisenberg XYZ system is also periodic, with period $2n$.

Proof: Let $x_{k+n}=x_k$. Join to the billiard trajectory (x_k,y_k) the corresponding flow $(\overline{x_k},\overline{y_k})$. Since

$$(\overline{x_{2k}},\overline{y_{2k}})=(-1)^k(x_k,y_k),\quad (\overline{x_{2k+1}},\overline{y_{2k+1}})=\phi(\overline{x_{2k}},\overline{y_{2k}}),$$

where ϕ is linear, we have

$$\overline{x_{k+2n}}=(-1)^n\overline{x_k}.$$

It follows that $q_{k+2n}=(-1)^n q_k$. According to Lemma 1, the divisor sequence D_k is $2n$ periodic. □

IV. THE CONDITION OF CAYLEY'S TYPE

By Lemmas 1 and 2, the problem of periodic billiard is reduced to the problem of finite-order points on the Jacobian variety of the corresponding isospectral curve. In the three-dimensional case, this curve is hyperelliptic of genus 2. The procedure similar to that given by Griffiths and Harris in Ref. 3 can be applied to hyperelliptic curves.

Let C be a hyperelliptic curve of genus 2, $J(C)$ its Jacobian variety, and

$$u:\mathrm{Div}\ C\to J(C),$$

the Abel–Jacobi map. We are interested in the points $P\in C$ with

$$nu(P)=0,$$

or, more general, in the points $P_1,\ldots,P_n\in C$ with

$$u(P_1)+\cdots+u(P_n)=0,$$

on $J(C)$. After the Abel's theorem,[12] there exists a meromorphic function f on the curve C with zeros $P_1,\dots,P_n$ and poles $Q_1,\dots,Q_n$ if and only if

$$u(P_1)+\cdots+u(P_n)-u(Q_1)-\cdots-u(Q_n)=0.$$

Thus $u(P_1)+\cdots+u(P_n)=0$ if and only if there exists a meromorphic function f with zeros $P_1,\dots,P_n$ and a pole of order n in the point P_∞. The point $u(P_\infty)$ is chosen to be neutral in $J(C)$.

Let $L(nP_\infty)$ be the vector space of meromorphic functions on C with a pole of order of at most n at the point P_∞. After the Riemann–Roch theorem,[12] we have

$$\dim L(nP_\infty)=n-1,$$

since all divisors D with $\deg D\geqslant 3$ on a hyperelliptic curve of genus 2 are nonspecial.

Let $f_1,\dots,f_{n-1}$ be a basis for the vector space $L(nP_\infty)$. The mapping

$$F:C\to P^{n-2},\quad X\mapsto[f_1(X),\dots,f_{n-1}(X)]$$

is a projective embedding whose image is a smooth algebraic curve of degree n. Hyperplane sections of this curve are zeros of functions from $L(nP_\infty)$. Thus, the following claim holds.

Lemma 3: The condition $u(P_1)+\cdots+u(P_n)=0$ *is equivalent to*

$$\operatorname{rank}\begin{bmatrix} f_1(P_1) & \cdots & f_{n-1}(P_1)\\ \cdots & \cdots & \cdots\\ f_1(P_n) & \cdots & f_{n-1}(P_n)\end{bmatrix}<n-1,$$

or, for $P_1=\cdots=P_n=P$,

$$\operatorname{rank}\begin{bmatrix} f_1(P) & \cdots & f_{n-1}(P)\\ f_1'(P) & \cdots & f_{n-1}'(P)\\ \cdots & \cdots & \cdots\\ f_1^{(n-1)}(P) & \cdots & f_{n-1}^{(n-1)}(P)\end{bmatrix}<n-1.$$

In our case C is the isospectral curve

$$\Gamma:y^2=(x-\mu_1)(x-\mu_2)(x-J_1^2)(x-J_2^2)(x-J_3^2).$$

Take point P_∞, which corresponds to $x=\infty$ to be neutral on the Jacobian variety $J(C)$. Let P_0 be one of the points that correspond to the value $x=0$. By Lemma 2, we are interested in the condition $u(2n(P_\infty-P_0))=0$, e.g., $u(2nP_0)=0$.

We can choose, similarly as in Ref. 3, the following basis for $L(2nP_\infty)$:

$$1,x,\dots,x^n,y,xy,\dots,x^{n-3}y.$$

The condition

$$\operatorname{rank}\begin{bmatrix} f_1(P_0) & \cdots & f_{2n-1}(P_0)\\ f_1'(P_0) & \cdots & f_{2n-1}'(P_0)\\ \cdots & \cdots & \cdots\\ f_1^{(2n-1)}(P_0) & \cdots & f_{2n-1}^{(2n-1)}(P_0)\end{bmatrix}<2n-1,$$

is equivalent to

$$\operatorname{rank}\begin{bmatrix} \dfrac{d^{n+1}y}{dx^{n+1}} & \cdots & \dfrac{d^{n+1}(x^{n-3}y)}{dx^{n+1}} \\ \cdots\cdots\cdots\cdots\cdots\cdots\cdots & & \\ \dfrac{d^{2n-1}y}{dx^{2n-1}} & \cdots & \dfrac{d^{2n-1}(x^{n-3}y)}{dx^{2n-1}} \end{bmatrix} < n-2,$$

where d^k/dx^k stands for $d^k/dx^k|_{x=0}$.

Finally, we obtained the following.

Theorem: *A condition on the three-dimensional billiard system trajectory to be n periodic is*

$$\operatorname{rank}\begin{bmatrix} A_{n+1} & A_n & \cdots & A_4 \\ A_{n+2} & A_{n+1} & \cdots & A_5 \\ \cdots\cdots\cdots\cdots\cdots\cdots\cdots & & & \\ A_{2n-1} & A_{2n-2} & \cdots & A_{n+2} \end{bmatrix} < n-2,$$

where

$$\sqrt{(x-\mu_1)(x-\mu_2)(x-J_1^2)(x-J_2^2)(x-J_3^2)} = A_0 + A_1 x + A_2 x^2 + \cdots .$$

By direct generalizing, it is possible to derive a corresponding condition on the billiard inside an ellipsoid in R^N.

V. DISCUSSIONS

At the end, we are going to emphasize that the condition obtained in this way is very similar to the classical Cayley's condition. But, even in the two-dimensional case, the corresponding procedure does not lead to formulas identical to Cayley's.

Let $(Cx,x)=0$ and $(Dx,x)=0$ be equations of two conics in a projective plane. Cayley's condition for the existence of a polygon with n vertices inscribed in C and circumscribed about D is (see Refs. 1, 3)

$$\begin{vmatrix} C_2 & C_3 & \cdots & C_{p+1} \\ C_3 & C_4 & \cdots & C_{p+2} \\ \cdots\cdots\cdots\cdots\cdots\cdots & & & \\ C_{p+1} & C_{p+2} & \cdots & C_{2p} \end{vmatrix} = 0, \quad n = 2p+1,$$

$$\begin{vmatrix} C_3 & C_4 & \cdots & C_{p+1} \\ C_4 & C_5 & \cdots & C_{p+2} \\ \cdots\cdots\cdots\cdots\cdots\cdots & & & \\ C_{p+1} & C_{p+2} & \cdots & C_{2p-1} \end{vmatrix} = 0, \quad n = 2p,$$

where $\sqrt{\det(tC+D)} = C_0 + C_1 t + C_2 t^2 + \cdots$.

Let $\Gamma: \nu^2 = (\mu-\mu_1)(\mu-J_1^2)(\mu-J_2^2)$ be the isospectral curve that corresponds to the XYZ model related to the billiard inside C with caustic D. Cayley's cubic $y^2 = \det(tC+D)$ and Γ are both elliptic curves, but they are obtained in a totally different way with no obvious connection.

Consider an n-periodic billiard with n even. The elliptical integral,

$$M(A,B)=\int_{\theta_A}^{\theta_b}\frac{d\theta}{\sqrt{1-k^2\cos^2\theta}}$$

is a metric on the conic C. (k is the eccentricity of the caustic ellipse D.) According to this metric, the length of the ellipse are between two bounces is always the same.[4] Since M is centrally symmetric, we have that $x_{k+p}=-x_k$, where $n=2p$.

It follows that the corresponding sequence of divisors is also n periodic for even n, and $2n$ periodic for odd n. By direct application of Ref. 3, we get the condition

$$\begin{vmatrix} B_3 & B_4 & \cdots & B_{2p+2} \\ B_4 & B_5 & \cdots & B_{2p+3} \\ \cdots & \cdots & \cdots & \cdots \\ B_{2p+2} & B_{2p+3} & \cdots & B_{4p+1} \end{vmatrix}=0, \quad n=2p+1,$$

$$\begin{vmatrix} B_3 & B_4 & \cdots & B_{p+1} \\ B_4 & B_5 & \cdots & B_{p+2} \\ \cdots & \cdots & \cdots & \cdots \\ B_{p+1} & B_{p+2} & \cdots & B_{2p-1} \end{vmatrix}=0, \quad n=2p,$$

where $\sqrt{(\mu-\mu_1)(\mu-J_1^2)(\mu-J_2^2)}=B_0+B_{1\mu}+B_2\mu^2+\cdots$.

Notice that the two matrices obtained for n odd are not of the same order. We are going to compare them in case $n=3$.

The condition on the billiard trajectory inside the conic C with caustic D to be periodic with period 3, according to Cayley's theorem,[1] is

$$C_2=0,$$

where C_2 is the coefficient with t^2 in the Maclaurin expansion for $\sqrt{\det(Ct+D)}$. According to our formula, this condition becomes

$$\begin{vmatrix} B_3 & B_4 \\ B_4 & B_5 \end{vmatrix}=0.$$

(Received 22 November 1996; accepted for publication 7 July 1997)

In this paper, it is shown that the initial value problems of Heisenberg Spin Chain Systems with external magnetic field from compact Riemannian manifolds into S^2 admit global weak solutions. © *1998 American Institute of Physics.* [S0022-2488(97)01712-X]

I. INTRODUCTION

Let Ω be a bounded domain in Euclidean space R^3. Then the three-dimensional classical dynamics on Ω for the isotropic Heisenberg chain with spin density $u=(u^1,u^2,u^3)$ is described by the so-called Hamilton density

$$H=\frac{\alpha}{2}\,|\nabla u|^2-H_0 u,$$

where α is the exchange constant, u is the spin vector, and H_0 is an external magnetic field. It is a Hamiltonian dynamics appearing in the study of condensed matter physics. It is well known that the spin equation of ferromagnetic motion has the form

$$\partial_t u=\alpha u\times\Delta u+u\times H_0,$$

where $\times$ denotes the vector cross product in R^3. It is worthwhile to point out that $|u|=1$, i.e., the so-called magnetically saturated condition (see Refs. 1–3). When the external magnetic field disappears, the above system becomes

$$\partial_t u=\alpha u\times\Delta u.$$

In this paper we will pay attention to the mathematical study of the existence of weak solutions for the initial value problems of Heisenberg chain equations. Let (M,g) be a closed Riemannian manifold with metric $g=(g_{ij})$. Let Δ_M denote the Laplace–Beltrami operator of (M,g) with respect to metric g. In local coordinates $(x^1,\ldots,x^m)$ on M, the Laplace–Beltrami operator can be expressed as

$$\Delta_M=\frac{1}{\sqrt{g}}\,\frac{\partial}{\partial x^i}\left(g^{ij}\sqrt{g}\,\frac{\partial}{\partial x^j}\right),$$

where (g^{ij}) is the inverse of (g_{ij}). Let S^2 be a unit sphere of three-dimensional Euclidean space. Then we also call the following system a Heisenberg chain system (or ferromagnetic chain system):

$$\partial_t u=\alpha u\times\Delta_M u+F(x,t,u),$$

[a)]Permanent address: Institute of Mathematics, Academia Sinica, Beijing 100080, Peoples' Republic of China. Electronic mail: wyd@math03.math.ac.cn

where $u(x,t)$; $M\times R^+\to S^2$ is an unknown mapping and $F(x,t,u):M\times R^+\times S^2\to R^3$ is a smooth vector function which satisfies for any $z\in S^2$

$$F(x,t,z)\cdot z=0.$$

We will consider the following initial value problem:

$$\partial_t u=u\times\Delta_M u+F(x,t,u) \quad \text{in } M\times R^+,$$

$$u(\cdot,0)=u_0 \quad \text{on } M.$$

Definition: If for any smooth function $v\in C^\infty(M\times[0,T],R^3)$ and any T the following integral relation is always true,

$$\int_M (u(T)v(T)-u_0v(0))\,dM-\int_M u\partial_t v\,dM=-\int_M (u\times\nabla u)\nabla v\,dM+\int_M F(x,t,u)v\,dM,$$

we say that u is a global weak solution for the above initial value problem of the Heisenberg chain system.

Now let us recall some known results. In the case $M=R^1$ and $F(x,t,z)=0$, in Ref. 4 Zhou, *et al*. showed that the initial value problem of the Heisenberg chain system admits a unique global smooth solution, if the initial value mapping is smooth.

In the case M is a bounded domain with smooth boundary in R^m $(m\geqslant 2)$, in Refs. 5 and 6 Zhou and Guo established the existence of global solutions for the initial value problems of Heisenberg chain systems, but the image manifolds of solutions are three-dimensional Euclidean spaces. It seems that the target manifolds of spin vector field should be S^2 in physical problems.

Recently, in Ref. 7 the author showed that the initial value problem of the Heisenberg chain system without external magnetic field from a closed Riemannian manifold into S^2 admits a global weak solution. However, some techniques and methods employed there are not valid for the present situation. In this paper our strategy is to adopt an auxillary approximate system of the Heisenberg chain system as follows,

$$\partial_t u=\varepsilon\Delta_M u+\frac{u}{\max\{1,|u|\}}\times\Delta_M u+F\left(x,t,\frac{u}{\max\{1,|u|\}}\right),$$

and then to let $\varepsilon\to 0$ to obtain the solution of Heisenberg chain system. We can also use the methods employed here to approach the existence of weak solutions for the Heisenberg chain system with damping term, i.e., the so-called Landau–Lifchitz system. We will show it in another paper. Our main results in this paper are the following.

Theorem: Let (M,g) be a closed Riemannian manifold. Assume that for any $z\in S^2$, we always have $F(x,t,z)\cdot z=0$ and $u_0(x)\in H^1(M,S^2)$. Then the initial value problem of the Heisenberg chain system admits a global weak solution $u\in L^\infty_{\rm loc}(0,\infty;H^1(M,S^2))\cap C^{1/2}_{\rm loc}(0,\infty;L^2(M,S^2))$.

II. PROOF OF THEOREM

First, we extend smoothly $F(x,t,z)$ as a mapping from $M\times R^+\times B_1(0)$ into R^3, where $B_1(0)$ denotes a closed unit ball centered at the origin of R^3. Let $a(r):[0,1]\to[0,1]$ be a smooth function satisfying $a(r)=0$ on $[0,\delta]$ and $a(r)=1$ on $[1-\delta,1]$, where $\delta<\frac{1}{3}$ is a positive real number. Then, we define $F_e(x,t,z)=a(|z|)F(x,t,z/|z|)$ when $|z|>\delta$, and $F_e(x,t,z)=0$ when $z\in B_\delta(0)$. Obviously, we have $F_e(x,t,z)|_{S^2}=F(x,t,z)$ and $F_e(x,t,z)\cdot z=0$ for any $z\in B_1(0)$. For the sake of convenience, we still denote $F_e(x,t,z)$ by $F(x,t,z)$. Obviously, we always have

$$F(x,t,z)\cdot z=0$$

for any $(x,t,z)\in M\times R^+\times B_1(0)$. In order to establish the existence of global weak solutions for the initial value problem of the Heisenberg chain system from M into S^2, instead of the Heisenberg chain system we discuss the initial value problem of an auxillary approximate system as follows:

$$(\mathrm{IP})\begin{cases} \partial_t u=\varepsilon\Delta_M u+\dfrac{u}{\max\{1,|u|\}}\times\Delta_M u+F\left(x,t,\dfrac{u}{\max\{1,|u|\}}\right), & M\times R^+,\\ u(\cdot,0)=u_0, \quad \text{on } M. \end{cases}$$

Now we construct approximation solutions of the problem (IP) by the standard Galerkin method. Let $\omega_j(x)$ $(j=1,2,...)$ be the normalized eigenfunctions of the equation

$$\Delta_M u+\lambda u=0 \quad \text{in } M,$$

corresponding to the eigenvalues λ_j $(j=1,2,...)$. It is well known that

$$\left\{\frac{1}{\sqrt{\mathrm{vol}(M)}}=\omega_0, \quad \omega_j \;\; j=1,2,...\right\}$$

forms a normalized orthogonal basis in $H^1(M)$.

We write the approximation solutions $u^N(x,t)$ of the problem (IP) in the following form:

$$u^N(x,t)=\sum_{j=0}^{N}\alpha_{jN}(t)\omega_j(x),$$

where $\alpha_{jN}(t)$ $(j=0,1,2,...,N;\ N=1,2,...)$ are the undetermined coefficient vector functions of variable $t\in R^+$. According to the Galerkin method, the coefficient vector functions $\alpha_{jN}(t)$ $(j=0,1,2,...,N;\ N=1,2,...)$ are assumed to satisfy the following system of ordinary differential equations of first order:

$$\begin{aligned}\int_M \partial_t u^N\cdot\omega_s\,dM=\varepsilon\int_M \omega_s\cdot\Delta_M u^N\,dM+\int_M\omega_s\cdot\left(\frac{u^N}{\max\{1,|u^N|\}}\times\Delta_M u^N\right)dM\\ +\int_M\omega_s\cdot F\left(x,t,\frac{u^N}{\max\{1,|u^N|\}}\right)dM,\end{aligned}\tag{2.1}$$

$s=1,2,...,N;$ with the initial value conditions

$$\alpha_{sN}(0)=\int_M\omega_s u_0(x)dM, \quad s=0,1,2,...,N.\tag{2.2}$$

Obviously, the initial problem of the above first-order ordinary differential equations (2.1) and (2.2) can be written as

$$\frac{d}{dt}\alpha_{jN}(t)=-\varepsilon\lambda_j\alpha_{jN}(t)+f_j(x,t,\alpha_{0N},\ldots,\alpha_{NN}),$$

$$\alpha_{jN}(0)=\int_M\omega_s u_0(x)dM,$$

where $\lambda_0=0$ and

$$f_s(x,t,\alpha_{0N},\ldots,\alpha_{NN})=\int_M \omega_s\cdot\left(\frac{u^N}{\max\{1,|u^N|\}}\times\Delta_M u^N\right)dM+\int_M \omega_s\cdot F\left(x,t,\ \frac{u^N}{\max\{1,|u^N|\}}\right)dM.$$

It is easy to verify that $f_s(x,t,\alpha_{0N},\ldots,\alpha_{NN})$ $(s=0,1,...,N)$ are uniformly Lipchitz continuous. By the classical ordinary differential system theory we know that the initial problems (2.1) and (2.2) admit a unique and smooth local solution. Moreover, multiplying the two sides of (2.1) by u^N we can easily derive from (2.1) and (2.2) the following integral relation:

$$\int_M |u^N(T)|^2\ dM+\varepsilon\int_0^T\int_M |\nabla u^N|^2\ dM\ dt\leqslant \mathrm{Vol}(M). \tag{2.3}$$

And also it is easy to see from (2.1) and (2.2) that

$$\int_0^T\int_M \partial_t u^N\cdot\Delta_M u^N\ dM\ dt=\varepsilon\int_0^T\int_M |\Delta_M u^N|^2\ dM\ dt + \int_0^T\int_M F\left(x,t,\ \frac{u^N}{\max\{1,|u^N|\}}\right)\cdot\Delta_M u^N\ dM\ dt.$$

This implies

$$\varepsilon\int_M |\Delta_M u^N|^2\ dM\ dt+\frac{d}{dt}\int_M |\nabla u^N|^2\ dM\leqslant C(T)\int_M |\nabla u^N|^2\ dM+C(T), \tag{2.4}$$

since we have for $(x,t)\in M\times[0,T]$

$$\left|\nabla\left(\frac{u^N}{\max\{1,|u^N|\}}\right)\cdot\ \frac{\partial F\left(x,t,\ \frac{u^N}{\max\{1,|u^N|\}}\right)}{\partial z}\cdot\nabla\mathbf{u}^N\right|\leqslant C(T)|\nabla u^N|^2$$

and

$$\left|\nabla F\left(\cdot,t,\ \frac{u^N}{\max\{1,|u^N|\}}\right)\cdot\nabla u^N\right|\leqslant C(T)|\nabla u^N|.$$

Hence, using the Gronwall inequality we can infer from (2.4)

$$E(u^N(T))\leqslant C(T)+C(T)E(u_0),$$

where

$$E(u)=\int_M |\nabla u|^2\ dM.$$

Therefore, we conclude from the above *a priori* estimates that the ordinary differential system (2.1) and (2.2) has a unique global solution. From (2.1) and (2.2) we can also infer

$$\int_0^T\int_M |\partial_t u^N|^2\ dM\ dt = \int_0^T\int_M \partial_t u^N\cdot\left[\frac{u^N}{\max\{|u^N|,1\}}\times\Delta_M u^N\right] + \int_0^T\int_M \partial_t u^N\cdot F\left(x,t,\frac{u^N}{\max\{1,|u^N|\}}\right)dM\ dt + \varepsilon E(u^N(0))-\varepsilon E(u^N(T)). \tag{2.5}$$

Using the Holder inequality on the right of (2.5) we obtain

$$\varepsilon E(u^N(T))+\frac{1}{2}\int_0^T\int_M |\partial_t u^N|^2\ dM\ dt \leqslant \varepsilon E(u^N(0))+\int_0^T\int_M |\Delta_M u|^2\ dM\ dt + C(T).$$

Noting (2.4), we obtain from the last inequality

$$\varepsilon E(u^N(T))+\frac{1}{2}\int_0^T\int_M |\partial_t u^N|^2\ dM\ dt \leqslant \left(\varepsilon+\frac{1}{\varepsilon}\right)E(u_0)+C(T,\varepsilon,E(u_0)). \tag{2.6}$$

Therefore, when ε is fixed and $N\to\infty$, from the above *a priori* estimates we conclude that there is a function $u^\varepsilon\in W_2^{1,2}(M\times[0,T],R^3)$ for any $T\leqslant\infty$ such that

(i) $\partial_t u^N\to\partial_t u^\varepsilon$ weakly in $L^2(M\times[0,T],R^n)$,
(ii) $\Delta_M u^N\to\Delta_M u^\varepsilon$ weakly in $L^2(M\times[0,T],R^n)$,
(iii) $\nabla u^N\to\nabla u^\varepsilon$ weakly * in $L^\infty(M\times[0,T],R^n)$,
(iv) $u^N\to u^\varepsilon$ for all $t\in R^+$ and a.e. $x\in M$.

Moreover, from (2.1) and (2.2) we also conclude that for any smooth function $v\in C_\infty(M\times[0,T];R^n)$, we have

$$\int_0^T\int_M \partial_t u^\varepsilon v\ dM\ dt = \int_0^T\int_M v\cdot\left[\frac{u^\varepsilon}{\max\{|u^\varepsilon|,1\}}\times\Delta_M u^\varepsilon\right]dM\ dt + \varepsilon\int_0^T\int_M \Delta_M u^\varepsilon v\ dM\ dt+\int_0^T\int_M vF\left(x,t,\frac{u^\varepsilon}{\max\{1,|u^\varepsilon|\}}\right)dM\ dt.$$

This implies u^ε is a global weak solution of the problem (IP).

Lemma 2.1: If u^ε is a global weak solution of the problem (IP), then there holds

$$|u^\varepsilon|\leqslant 1$$

for all $t\in R^+$ and a.e. $x\in M$.

Proof: We choose $\psi=u^\varepsilon-(u^\varepsilon/|u^\varepsilon|)\min\{1,|u^\varepsilon|\}$ as a test function of the first equation of (IP). Then, multiplying the first equation of (IP) by ψ and noting $F(x,t,z)\cdot z=0$, we obtain

$$\frac{1}{2}\frac{d}{dt}\int_{|u^\varepsilon|\geqslant 1}|u^\varepsilon|^2\left(1-\frac{1}{|u^\varepsilon|}\right)dM = \frac{1}{2}\int_{|u^\varepsilon|\geqslant 1}\frac{u^\varepsilon\cdot\partial_t u^\varepsilon}{|u^\varepsilon|}\,dM - \varepsilon\int_{|u^\varepsilon|\geqslant 1}\frac{|u^\varepsilon\cdot\nabla u^\varepsilon|^2}{|u^\varepsilon|^3}\,dM-\varepsilon\int_{|u^\varepsilon|\geqslant 1}|\nabla u^\varepsilon|^2\left(1-\frac{1}{|u^\varepsilon|}\right)dM. \tag{2.7}$$

Letting $u^\varepsilon/|u^\varepsilon|$ be a test function of (IP) on set $\{|u^\varepsilon|\geqslant 1\}$, we have

$$\frac{1}{2}\int_{|u^\varepsilon|\geqslant 1}\frac{u^\varepsilon\cdot\partial_t u^\varepsilon}{|u^\varepsilon|}\,dM=\frac{\varepsilon}{2}\int_{|u^\varepsilon|\geqslant 1}\frac{|u^\varepsilon\cdot\nabla u^\varepsilon|^2}{|u^\varepsilon|^3}\,dM-\frac{\varepsilon}{2}\int_{|u^\varepsilon|\geqslant 1}|\nabla u^\varepsilon|^2\frac{1}{|u^\varepsilon|}\,dM$$
$$+\int_{|u^\varepsilon|=1}\frac{\partial u^\varepsilon}{\partial n}\cdot u^\varepsilon\,dS. \tag{2.8}$$

Here n is outward normal direction of the boundary of set $\{|u^\varepsilon|\geqslant 1\}$. Since $\partial u^\varepsilon/\partial n\cdot u^\varepsilon=\frac{1}{2}\partial|u^\varepsilon|^2/\partial n\leqslant 0$ on the boundary set $\{|u^\varepsilon|=1\}$, it is easy to see that (2.7) and (2.8) imply the following integral inequality:

$$\frac{1}{2}\frac{d}{dt}\int_{|u^\varepsilon|\geqslant 1}|u^\varepsilon|^2\left(1-\frac{1}{|u^\varepsilon|}\right)dM+\varepsilon\int_{|u^\varepsilon|\geqslant 1}|\nabla u^\varepsilon|^2\left(1-\frac{1}{|u^\varepsilon|}\right)dM\leqslant 0. \tag{2.9}$$

However, obviously this inequality implies

$$|u^\varepsilon|\leqslant 1$$

for any $t\in R^+$ and a.e. $x\in M$, since $|u^\varepsilon(x,0)|=|u_0(x)|=1$. Thus we complete the proof of the lemma.

Lemma 2.2: If u^ε is a global weak solution of (IP), then, as $\varepsilon\to 0$, there exists a function $u\in L^\infty(0,T;H^1(M,S^2))$ such that

$$u^\varepsilon\to u$$

weakly * in $L^\infty(0,T;H^1(M,S^2))$ and

$$|u(x,t)|=1$$

for all $t\in R^+$ and a.e. $x\in M$.

Proof: Obviously, we have $E(u^\varepsilon(t))\leqslant C(T)$ for $t\in[0,T]$. It implies there exists a function $u\in L^\infty(0,T;H^1(M,R^3))$ such that, neglecting a subsequence, $u^\varepsilon\to u$ weakly * in $L^\infty(0,T;H^1(M,R^3))$. Since u^ε is a global weak solution of (IP) and $F(x,t,z)\cdot z=0$, it is easy to see

$$\int_M|u^\varepsilon(T)|^2\,dM-\int_M|u^\varepsilon(0)|^2\,dM+\varepsilon\int_0^T\int_M|\nabla u^\varepsilon|^2\,dM\,dt=0.$$

Noting $|u^\varepsilon(0)|=1$, we have

$$\int_M(|u^\varepsilon(T)|^2-1)dM=-\varepsilon\int_0^T\int_M|\nabla u^\varepsilon|^2\,dM\,dt.$$

As $\varepsilon\to 0$, noting that $u^\varepsilon(\cdot,T)\to u(\cdot,T)$ strongly in $L^2(M)$ for any fixed T, we obtain

$$\int_M(|u(T)|^2-1)dM=0.$$

Yet, from Lemma 2.1 we know there holds $|u^\varepsilon(T)|\leqslant 1$ for any ε. Since $u^\varepsilon\to u$ for all $t\in[0,T]$ and a.e. $x\in M$, we also have

$$|u(T)|\leqslant 1.$$

Therefore, we conclude that there holds

$$|u(x,t)|^2=1$$

for all $t\in R^+$ and for a.e. $x\in M$, so $u(x,t)\in L^\infty(0,T;H^1(M,S^2))$.

Now we claim that $u(x,t)$ is a global weak solution of the initial value problem of Heisenberg chain system from M into S^2. In fact, since u^ε is a global weak solution of (IP) and $|u^\varepsilon(x,t)|\leqslant 1$, then for any smooth vector function $v\in C^\infty(M\times[0,T],R^n)$, we have

$$\int_0^T\int_M u^\varepsilon\partial_t v\ dM\ dt=\int_M u^\varepsilon(T)v(T)dM-\int_M u^\varepsilon(0)v(0)dM+\varepsilon\int_0^T\int_M\nabla u^\varepsilon\nabla v\ dM\ dt$$
$$+\int_0^T\int_M(u^\varepsilon\times\nabla u^\varepsilon)\nabla v\ dM\ dt-\int_0^T\int_M F(x,t,u^\varepsilon)v\ dM\ dt. \quad (2.10)$$

This implies

$$\int_0^T\int_M u^\varepsilon\partial_t v\ dM\ dt=\int_M u^\varepsilon(T)v(T)dM-\int_M u_0v(0)dM+\varepsilon\int_0^T\int_M\nabla u^\varepsilon\nabla v\ dM\ dt$$
$$+\int_0^T\int_M(u^\varepsilon\times\boldsymbol{\nabla}u^\varepsilon)\boldsymbol{\nabla}v\ dM\ dt-\int_0^T\int_M F(x,t,u^\varepsilon)v\ dM\ dt.$$

Note that $u^\varepsilon\to u$ for a.e. $x\in M$ and all $t\in[0,T]$ and for any ε

$$|F(x,t,u^\varepsilon)|\leqslant C(T).$$

So, by the well-known controlled convergence theorem we have that $F(x,t,u^\varepsilon)\to F(x,t,u)$ strongly in $L^p(M\times[0,T])$ for any $p\in[2,\infty)$. Hence,

$$\int_0^T\int_M F(x,t,u^\varepsilon)v\ dM\ dt\to\int_0^T\int_M F(x,t,u)v\ dM\ dt.$$

Then letting $\varepsilon\to 0$ in the above integral relation, we obtain

$$\int_0^T\int_M u\partial_t v\ dM\ dt=\int_M u(T)v(T)dM-\int_M u_0v(0)dM+\int_0^T\int_M(u\times\nabla u)\nabla v\ dM\ dt$$
$$-\int_0^T\int_M F(x,t,u)v\ dM\ dt.$$

Furthermore, from (2.10) we easily see there holds for any v

$$\int_0^T\int_M\partial_t u^\varepsilon v\ dM\ dt\leqslant C(\varepsilon,T)\left(\int_0^T\int_M(v^2+|\nabla v|^2)dM\ dt\right)^{1/2},$$

where $C(\varepsilon,T)\leqslant C(T)$ when ε is small enough. Hence, $\partial_t u^\varepsilon\in L^2_{\rm loc}(0,\infty;H^{-1}(M))$. Applying the interpolation formula of the Hilbert space with negative order we obtain

$$\|u^\varepsilon(\cdot,t_2)-u^\varepsilon(\cdot,t_1)\|_{L^2(M)}\leqslant C\|u^\varepsilon(\cdot,t_2)-u^\varepsilon(\cdot,t_1)\|^{1/2}_{H^1(M)}\cdot\|u^\varepsilon(\cdot,t_2)-u^\varepsilon(\cdot,t_1)\|^{1/2}_{H^{-1}(M)}$$
$$\leqslant C\ \sup_{0\leqslant t\leqslant T}\|\partial_t u^\varepsilon\|^{1/2}_{H^{-1}(M)}\cdot\sup_{0\leqslant t\leqslant T}\|u^\varepsilon\|^{1/2}_{H^1(M)}|t_2-t_1|^{1/2},$$
$$\leqslant C(T)|t_2-t_1|^{1/2}.$$

When $\varepsilon\leqslant 1$, $C(T)$ does not depend on ε. So, as $\varepsilon\to 0$, we have

$$\|u(\cdot,t_2)-u(\cdot,t_1)\|_{L^2(M)}\leqslant C(T)|t_2-t_1|^{1/2}.$$

Thus we have completed the proof of the Theorem.

If (M,g) is a compact Riemannian manifold with smooth boundary, we consider the following:

$$(\mathrm{IBP})\begin{cases}\partial_t u=u\times\Delta_M u+F(x,t,u) & \text{in } M\times R^+,\\ \dfrac{\partial u}{\partial n}=0 & \text{on } \partial M,\\ u(\cdot,0)=u_0 & \text{in } M,\end{cases}$$

where $u_0(x)\in H^1(M,S^2)$ satisfies $\partial u_0/\partial n=0$ in the sense of distribution. In the same spirit as we proved the above Theorem we can give the proof of the following

Theorem 2.1: Let (M,g) be a compact Riemannian manifold with smooth boundary ∂M. Assume that $F(x,t,z)\cdot z=0$ for any $z\in S^2$ and $u_0\in H^1(M,S^2)$ with $\partial u_0/\partial n=0$ in the sense of distribution. Then the problem (IBP) admits a global weak solution $u\in L^\infty_{\mathrm{loc}}(0,\infty;H^1(M,S^2))\cap C^{1/2}_{\mathrm{loc}}(0,\infty;L^2(M,S^2))$.

Theorem 2.2: If M is a compact manifold with $\dim(M)=1$, $F(x,t,u)$ and u_0 satisfy the same conditions as in the Theorem. Then the initial value problem of Heisenberg chain system admits a global weak solution $u\in L^\infty_{\mathrm{loc}}(0,\infty;H^1(M,S^2))\cap C^{1/2,1/4}_{\mathrm{loc}}(M\times[0,\infty))$, i.e., $u(x,0)=u_0$ in the classical sense.

Proof: In fact, since the Theorem asserts

$$\|u(x,t_1)-u(x,t_2)\|_{L^2}\leqslant C(T)|t_1-t_2|^{1/2},$$

using the Gagliardo–Nirenberg inequality we obtain

$$\|u(x,t_1)-u(x,t_2)-m\|_{L^\infty}\leqslant\|u(x,t_1)-u(x,t_2)-m\|_{L^2}^{1/2}\|u_x(x,t_1)-u_x(x,t_2)\|_{L^2}^{1/2},$$

where

$$m=\frac{1}{\mathrm{vol}(M)}\int_M(u(x,t_1)-u(x,t_2))\,dM\leqslant\left(\frac{1}{\mathrm{vol}(M)}\int_M(u(x,t_1)-u(x,t_2))^2dM\right)^{1/2}$$
$$\leqslant C(T,M)|t_1-t_2|^{1/2}.$$

Hence it is easy to see

$$\sup_{x\in M}|u(x,t_1)-u(x,t_2)|\leqslant C(T)|t_1-t_2|^{1/4},$$

for any $t_1,t_2\in[0,T]$. Noting the Sobolev embedding theorem we have

$$|u(x_1,t_1)-u(x_2,t_2)|\leqslant C(T)(|t_1-t_2|^{1/4}+|x_1-x_2|^{1/2}),$$

for any (x_1,t_1), $(x_2,t_2)\in M\times[0,T]$. Thus we complete the proof of Theorem 2.2.

(Received 20 February 1997; accepted for publication 4 September 1997)

The theory of distributions in non-Riemannian spaces is used to obtain exact static thin domain wall solutions of Einstein-Cartan equations of gravity. Curvature δ-singularities are found while Cartan torsion is given by Heaviside functions. Weitzenböck planar walls are characterized by torsion δ-singularities and zero curvature. It is shown that Weitzenböck static thin domain walls do not exist exactly as in general relativity. The global structure of Weitzenböck nonstatic torsion walls is investigated. © *1998 American Institute of Physics.*

I. INTRODUCTION

The geometry of δ-torsion singularities[1] have been extensively studied in connection with spacetime defects.[2–4] An interesting class of Weitzenböck spacetime defects representing torsion loops and line defects representing cosmic strings was recently investigated by Letelier.[5] Also, pure Riemannian defects (disclinations) with zero Cartan's torsion over lines (strings) and walls (domain walls) have been investigated by Letelier[5,6] and Wang. In their study they have considered that metric is continuous across the junction and the first derivative is represented by a Heaviside function. Thus in their approach, the δ-singularity just appears on the Riemann curvature. We shall adopt here the same procedure when dealing with Riemann-Cartan domain walls.

A Riemann-Cartan domain wall solution of the Einstein-Cartan field equation is found where the torsion 2-form is a Heaviside function and the curvature is of δ-singularity-type like in Letelier and Wang[5,6] Riemannian domain walls. The solution is obtained by assuming the symmetric energy-momentum tensor in Einstein-Cartan gravity is the same as the general relativistic thin domain wall tensor proposed by Vilenkin.[7] In the case of static Weitzenböck wall it is shown that the Vilenkin thin domain wall energy-momentum tensor does not satisfy the Einstein-Cartan field equations. Therefore, by gluing together pieces of Minkowski spaces it is possible to find solutions of Einstein-Cartan field equations as is done in Einstein field equations of general relativity.[8] Thick domain walls in Einstein-Cartan theory of gravitation can be investigated in the near future. In a certain sense this paper extends the investigation carried out by A. Wang[9,10] on plane-symmetric walls in general relativity. The important features of this paper is the fact that both torsion and curvature are necessary to guarantee that static thin domain walls exist in Einstein-Cartan theory of gravity.

II. GEOMETRY OF WEITZENBÖCK WALLS

Spacetime defects[2,5,6] appear in distinct forms. For example, they appear as torsion line defects (cosmic strings) or as torsion loops. Domain walls appear in the context of general relativity as another type of defect in spacetime. In particular, plane cosmic walls[11] have been studied in the case of plane gravitational collapse. I shall be concerned with the investigation of a type of defect which is very common in the differential geometry of fractures where torsion δ-functions are

generated from Heaviside functions. Here a static plane symmetric spacetime with zero Riemann-Cartan curvature and nonvanishing torsion, the so-called Weitzenböck spacetime, is found where one of the metric functions is a Heaviside function.

The metric is therefore a piecewise constant and torsion is a δ-singularity which changes when one passes from one plane to the other. The Weitzenböck geometry of fractures is then developed. Let us now consider the plane symmetric metric

$$ds^2=(\omega^0)^2-(\omega^1)^2-(\omega^2)^2-(\omega^3)^2, \tag{1}$$

where

$$\omega^0=e^{F/2}dt, \quad \omega^1=e^{H/2}dx, \quad \omega^2=e^{H/2}dy, \quad \omega^3=e^{G/2}dz. \tag{2}$$

The torsion 2-forms are chosen according to

$$\begin{aligned} &T^0=J^0\omega^0\wedge\omega^3, \quad T^1=J^1\omega^3\wedge\omega^1+J^2\omega^0\wedge\omega^1, \\ &T^2=J^1\omega^3\wedge\omega^2+J^2\omega^0\wedge\omega^2, \quad T^3=J^3\omega^0\wedge\omega^3. \end{aligned} \tag{3}$$

Making use of Cartan's calculus where the torsion 2-forms are given by

$$T^a=d\omega^a+\omega^a{}_b\wedge\omega^b \text{ (a,b=0,1,2,3)}, \tag{4}$$

one obtains the following 1-form connections:

$$\begin{aligned} &\omega^0{}_3=\left[J^0+e^{-G/2}\frac{F'}{2}\right]\omega^0, \quad \omega^1{}_0=\left[J^2+e^{-F/2}\frac{\dot{H}}{2}\right]\omega^0, \\ &\omega^1{}_3=\left[J^1+e^{-G/2}\frac{H'}{2}\right]\omega^1, \quad \omega^2{}_3=-\left[J^1+e^{-G/2}\frac{H'}{2}\right]\omega^2, \end{aligned} \tag{5}$$

and $J^3=(\dot{G}/2)\,e^{-F/2}$.

Making the choices

$$J^0=-e^{-G/2}\frac{F'}{2}, \quad J^1=e^{-G/2}\frac{H'}{2}, \quad J^2=e^{-F/2}\frac{\dot{H}}{2}, \tag{6}$$

one notices that for this choice of torsion functions $\omega^a_b\equiv 0$ and from the second Cartan's structure equation

$$R^a{}_b=d\omega^a{}_b+\omega^a{}_c\wedge\omega^c{}_b, \tag{7}$$

$R^a{}_b=0$ where $R^a{}_b\equiv 1/2R^a{}_{bcd}\omega^c\wedge\omega^d$ are the curvature 2-forms, thus the curvature $R^a{}_{bcd}$ vanishes.

Let us now consider the static case where $\dot{H}=\dot{G}=\dot{F}=0$.

To simplify matters one considers $J^{(0)}\equiv 0$, which implies $F'=0$ and $F=const.$ Making the choice $G=G(z)=const.$, the only surviving equation is

$$H'(z)=c_1J^1, \tag{8}$$

where c_1 is a constant. Choosing $J^1\equiv\delta(z)$, where $\delta(z)$ is Dirac δ-function, equation (8) has the following solution:

$$H(z)\equiv\theta_0(z)=\begin{cases}1, z>0\\ 0, z<0,\end{cases} \tag{9}$$

where $\theta_0(z)$ is the Heaviside function. Thus the metric is basically given by a Heaviside function and torsion is a δ -singularity.[6]

Notice that outside the defect $(z\neq 0)H(z)=0$, $F=0$, $G=const.$ and the spacetime is Minkowskian. $ds^2=dt^2-dx^2-dy^2-dz'^2$, where $dz'^2=c^2dz^2$ and since c is a constant $z'=cz$ which means a translation along the z-axis. To resume we show that a new class of fractures in Weitzenböck spacetime exists besides torsion loops and torsion lines.

From this computation it is easy to show that static thin Weitzenböck domain walls are forbidden in Einstein-Cartan theory of gravity. Thin domain walls have the following energy-momentum tensor

$$T_a{}^b=\sigma\ \mathrm{diag}(1,1,1,0)\,\delta(z). \tag{10}$$

From the Einstein-Cartan field equations

$$R_{ab}(\Gamma)-\tfrac{1}{2}g_{ab}R(\Gamma)=T_{ab} \tag{11}$$

and the Weitzenböck condition of vanishing total curvature $R_{abcd}(\Gamma)=0$, it is obvious that $\sigma=0$ and thus there is no static thin domain wall formation in Weitzenböck universe. Therefore, we are compelled to consider Riemann-Cartan domain walls. In fact, in the next section I shall present a simple solution of Einstein-Cartan field equations of gravity representing a static thin domain walls.

III. RIEMANN-CARTAN THIN DOMAIN WALLS

In this section I shall be concerned with finding a solution to Einstein-Cartan theory of gravity which describes a thin domain wall[12] given by the energy-momentum tensor equation (10).

I shall compute this solution by solving the system composed by the first and second Cartan's equations of structure given in the last section and the Einstein-Cartan field equation (11). From the 1-form connections (7) and the second Cartan structure equation, after some algebra, one obtains the components of the Riemann-Cartan nonvanishing components of curvature

$$\begin{aligned}
R^2{}_{112} &= -\frac{(H')^2}{4}e^{-F},\\
R^2{}_{332} &= -\frac{e^{-F}}{2}\left[H''+\frac{H'F'}{2}-\frac{(H')^2}{2}\right]=R^3{}_{223},\\
R^1{}_{331} &= -\frac{e^{-F}}{2}\left[H''+\frac{H'F'}{2}\right],\\
R^0{}_{330} &= -\frac{e^{-F}}{2}\left[2J^{0\prime}-\frac{F'J^0}{2}+\frac{F'^2}{2}\right],\\
R^0{}_{110} &= R^2{}_{002}=-\frac{e^{-F}}{2}\left[2J^{0\prime}+\frac{F'H'}{2}\right]
\end{aligned} \tag{12}$$

where to simplify matters we chose J^0 as the only nonvanishing component of Cartan's torsion 2-forms. This choice is compatible with Cartan's first equation of structure (4). The metric is also chosen to be static and Vilenkin hypothesis $F=G$ is also used. The Einstein tensor is defined as

$$G_{ab}=R_{ab}(\Gamma)-\tfrac{1}{2}g_{ab}R(\Gamma), \tag{13}$$

where Γ is the Riemann-Cartan connection.

The Ricci-Cartan tensor and Ricci scalar are given by

$$\begin{aligned} R_{00}&=\frac{e^{-F}}{2}\left[\frac{F'}{2}J^0-\frac{F'^2}{2}\right],\\ R_{11}&=\frac{e^{-F}}{2}\left[2J^{0\prime}+\frac{H'^2}{2}+H''+F'H'\right],\\ R_{22}&=\frac{e^{-F}}{2}[-2J^{0\prime}+H''],\\ R_{33}&=\frac{e^{-F}}{2}\left[2J^{0\prime}-\frac{F'J^0}{2}+\frac{F'^2-H'^2}{2}-H'F'\right], \end{aligned} \tag{14}$$

and

$$R\equiv R^0{}_0+R^1{}_1+R^2{}_2+R^3{}_3=\frac{e^{-F}}{2}[H''+F'H'-2J^{0\prime}+F'J^0-F'^2]. \tag{15}$$

Collecting all those terms, substitution into the Einstein-Cartan equations yields

$$\begin{aligned} G_{00} &= \frac{e^{-F}}{2}\left[2J^{0\prime}-H''-\frac{F'H'}{2}\right]=\sigma\delta(z),\\ G_{11} &= \frac{e^{-F}}{2}\left[H''-\frac{H'^2}{2}+\frac{F'H'^2}{2}\right]=-\sigma\delta(z),\\ G_{22} &= \frac{e^{-F}}{2}\left[-4J^{0\prime}+H''+\frac{H'F'}{2}+\frac{F'J^0}{2}-F'^2\right]=-\sigma\delta(z),\\ G_{33} &= \frac{e^{-F}}{2}\left[-\frac{H'^2}{2}+H''-\frac{F'H'}{2}\right]=0. \end{aligned} \tag{16}$$

This system of nonlinear ODE can be easily solved if one considers $F'=0$. With this choice Cartan torsion reduces to a Heaviside function since

$$J^{0\prime}=\frac{c\sigma}{4}\delta(z)\rightarrow J^0=\frac{c\sigma}{2}\theta_0(z), \tag{17}$$

and the metric function H″ reads

$$H''=-\frac{c\sigma}{2}\delta(z)\rightarrow H'=-\frac{c\sigma}{2}\theta_0(z). \tag{18}$$

Expression (17) means that torsion undergoes a jump across the hyperplane $z=0$ while from (18) most of the curvature components behave like a δ-singularity. For example, $R^0{}_{330}=R^0{}_{220}=R^0{}_{110}=R^1{}_{331}=R^2{}_{332}=c\sigma\delta(z)$ while $R^2{}_{112}=-(c^2/4)\sigma^2\theta_0{}^2(z)$ which is the square of the Heaviside function.

From (18) expression (12) reduces to

$$R^0{}_{330}=\tau[2\sigma\delta(z)],$$

$$R^0{}_{110}=R^2{}_{002}=\delta(z)k,$$

$$R^1{}_{331}=c[\sigma\delta(z)], \tag{19}$$

$$R^2{}_{112}=cH'^2=-\frac{c^2}{4}\sigma^2\theta_0(z),$$

$$R^2{}_{332}=c[2\sigma\delta(z)],$$

where $k\equiv 2c$. All curvature components vanish except $R^2{}_{112}$ and $R^2{}_{332}$. Since the spacetime outside z=0 plane has to be locally flat, vanishing of these components leads to $H'=0$ which yields $H=const.$ and the spacetime metric is Minkowskian. Thus our domain wall geometry is composed of two Minkowski half-spaces glued together across a torsion and curvature junction. As in the Letelier[5] paper, no attempt is made to find a field theory interpretation for the solution discussed here. It is easy to show that the Bianchi identities are identically satisfied.

This solution is similar to a solution found by Holvorcen and Letelier[12] for plane symmetric cosmic walls and gravitational collapse. To resume we have investigated two classes of solutions that represent static thin planar walls in spacetime with torsion. In one of the solutions torsion is a δ-singularity. In the other, torsion is a Heaviside function while the Riemannian curvature possess a δ-singular behavior. Notice that no physical interpretation is tried for the Weitzenböck class of solutions. Nevertheless, they may represent a class of gravitational ghosts like ghost neutrinos where the stress-energy tensor vanishes although the current is distinct from zero. Indeed, our solution is not able to represent ghost neutrinos since our axial torsion vanishes and thus no axial current of ghost neutrinos[13] is possible. Nevertheless, Letelier has found recently[2] a class of Weitzenböck spacetime defects where an axial torsion exists, being a candidate for a ghost neutrino space. Torsion and curvature δ-singularities have also been found in Jackiw[14] three dimensional planar gravity. Since domain walls in the large scale structure of the universe are either unstable or thick, the domain wall solution discussed here can only be considered as a thin domain wall approximation of a static thick domain wall in Riemann-Cartan spacetime. Work in this direction shall be addressed in the near future. A detailed investigation of the global properties of Riemann-Cartan domain walls can appear elsewhere.

IV. GLOBAL STRUCTURE OF TORSION WALLS

The investigation of maximal extension of metrics in Riemann-Cartan spacetime, like the one studied in the last section, can be extremely difficult. Therefore, to simplify matters in this section I shall address some important questions concerning nonstatic Weitzenböck torsion walls which answer many questions which appear in the more general case of domain walls in Riemann-Cartan spaces. Therefore, let us consider the metric used in Ref. 9 to investigate gravitationally repulsive domain wall solutions of Einstein's equations of general relativity. The metric is given by

$$ds^2=e^{2\nu(t,|z|)}(-dt^2+dz^2)+B(t,|z|)(dx^2+dy^2). \tag{20}$$

In the notation of Cartan's calculus, metric (20) reads

$$ds^2=-(\omega^0)^2+(\omega^1)^2+(\omega^2)^2+(\omega^3)^2, \tag{21}$$

where the basis 1-forms $\omega^a(a=0,1,2,3)$ are

$$\omega^0=e^{\nu}dt, \quad \omega^1=e^{\nu}dz, \omega^2=\sqrt{B}dx, \quad \omega^3=\sqrt{B}dy. \tag{22}$$

Choosing Cartan torsion 2-forms *a priori* by

$$T^A = J^A \omega^0 \wedge \omega^1, \tag{23}$$

where (A=0,1) and $T^i = 0$ for (i=2,3) and using Cartan's first structure equation (4), one is able to compute the following connection 1-forms:

$$\omega^0{}_1 = (J^0 + e^{-\nu}\nu_z)\omega^0, \quad \omega^2{}_0 = \frac{1}{2}\frac{B_t}{B}e^{-\nu}\omega^2,$$
$$\omega^3{}_0 = \frac{1}{2}\frac{B_t}{B}e^{-\nu}\omega^3, \quad \omega^2{}_1 = \frac{1}{2}\frac{B_z}{B}e^{-\nu}\omega^2, \quad \omega^3{}_1 = \frac{1}{2}\frac{B_z}{B}e^{-\nu}\omega^3, \tag{24}$$

and

$$J^1 = e^{-\nu}\nu_t, \tag{25}$$

the others zero. From the second Cartan's structure equation (7), one notices that the Weitzenböck condition of zero curvature can be obtained by making $\omega^a{}_b \equiv 0$. Substitution of this expression into (24) yields

$$J^0 = -e^{-\nu}\nu_z, \quad B_t = B_z = 0. \tag{26}$$

Since by definition a Weitzenböck torsion wall is one where the torsion must be equal to a δ-singularity, one should impose this condition in expression (26). This procedure can be obtained by considering the following ansatz:

$$\nu = -(t - \theta_0(z)). \tag{27}$$

Substitution of (26) into (27) yields immediately

$$J^0 = -e^{(t-\theta_0(z))}\delta(z), \quad J^1 = -e^{(t-\theta_0(z))} \tag{28}$$

for δ-singularity distributions of torsion forms. From the second equation in (26) one obtains $B = B_0 = const.$ Thus the nonstatic spacetime metric is

$$ds^2 = e^{-2(t-\theta_0(z))}(-dt^2 + dz^2) + (B_0)^2(dx^2 + dy^2). \tag{29}$$

Metric (29) can be rewritten in a conformal form

$$ds^2 = e^{-2(t-\theta_0(z))}[-dt^2 + dz^2 + (B_0)^2 e^{2(t-\theta_0(z))}(dx^2 + dy^2)]. \tag{30}$$

From the properties of the θ_0 function above, one has outside the torsion wall

$$ds^2 = \alpha e^{-2t}[-dt^2 + dz^2 + (B_0)^2 e^{2t}(dx^2 + dy^2)](z < 0), \tag{31}$$

where α is a constant.

This metric is nothing more than a metric conformal to de Sitter spacetime.

At $z > 0$ the spacetime is

$$ds^2 = e^{-2(t-1)}(-dt^2 + dz^2) + (B_0)^2(dx^2 + dy^2) \tag{32}$$

or

$$ds^2 = \alpha' e^{-2t}[-dt^2 + dz^2 + \gamma' e^{2t}(dx^2 + dy^2)](z > 0). \tag{33}$$

At t=0 the spacetimes outside the wall are flat as characterized by a spacetime defect. As $t\to\infty$ from (26) the torsion J^0 also ''explodes'' and the torsion wall suffers gravitational collapse. The solution at z=0 is obtained by gluing together the two halves of the de Sitter spaces given by the line elements (31) and (33).

Let us now consider the motion equations. In general, when one deals with spacetime with torsion test particles follow distinct paths. The first are autoparallels and the second are geodesics. Since we are just concerned with Weitzenböck spaces where the Riemann-Cartan connection vanishes autoparallel are straight lines. Thus geodesic equations read

$$\ddot{t}+\dot{t}^2+\dot{z}^2=0, \quad \ddot{z}+\dot{t}\dot{z}=0, \quad \ddot{x}=\ddot{y}=0, \tag{34}$$

where dots in (34) are the mean derivation with respect to proper time S. The geodesic of the z-coordinate is easily solved by $\dot{z}=e^{-t}$ and $\ddot{z}=-e^{-t}$. Thus considering $\dot{t}>0$ $(s>0)$, $\dot{z}>0$ and $\ddot{z}<0$ and since the speed of the test particle vanishes at $t\to\infty$ and the acceleration is opposite to the velocity, the test particle falls back to the torsion defect. The test particle is clearly bound. Notice that another solution to the geodesic motion would be $\dot{z}=-e^{-t}$ and $\ddot{z}=e^{-t}\dot{t}$, and in this case test particles are moving towards the torsion defect at $z=0$ plane. Since once more acceleration is opposite to the velocity it may be possible, in principle, that a repulsive gravitational force exists at the torsion wall and can be used to hold or at least decrease the speed of the gravitational collapse due to torsion effects.

More realistic models of nonstatic domain walls in Riemann-Cartan spacetime may be found elsewhere. Discussion of stability of cosmic strings in general relativity may be found in the paper by Gleiser and Pullin.[15] The issue of stability of domain walls in the context of Einstein-Cartan gravity may be found elsewhere as well as the study of transparency of domain walls to neutrino waves.

This is closely related to Trautman's[16] idea to use spin and torsion in the context of Einstein-Cartan theory of gravity to hold or avert gravitational collapse of stellar objects. To be pure,[5] a spacetime defect needs to be empty of matter and fields outside the defect. Therefore, to obey the rule we must force the torsion 2-form component J^1 to vanish. In this case, from expressions (25) ν_t and the metric shall not depend on a time coordinate. Thus a static torsion defect is obtained where Cartan torsion is given only by a Dirac δ-function.

From metric (29) it is easily seen that the spacetime off the wall is flat. Therefore, the metric off the wall is time independent. However, from expression (28) it is seen that the thin wall is not static. This situation occurs also in the study of thin domain walls in general relativity.

ACKNOWLEDGMENTS

I am very much in debt to Professor P. S. Letelier and Professor A. Wang for helpful discussions on the subject of this paper. Financial support from CNPq. and UERJ (FAPERJ) is gratefully acknowledged.

Rotating dust solutions of Einstein's equations with 3-dimensional symmetry groups. I. Two Killing fields spanned on u^α and w^α

Andrzej Krasiński
N. Copernicus Astronomical Center and College of Science, Polish Academy of Sciences, Bartycka 18, 00 716 Warszawa, Poland

(Received 14 May 1997; accepted for publication 7 July 1997)

For a rotating dust with a 3-dimensional symmetry group all possible metric forms can be classified and, within each class, explicitly written out. This is made possible by the formalism of Plebański based on the Darboux theorem. In the resulting coordinates, the Killing vector fields (if any exist) assume a special form. Each Killing vector field may be either spanned on the fields of velocity and rotation or linearly independent of them. By considering all such cases one arrives at the classification. With respect to the structures of the groups, this is just the Bianchi classification, but with all possible orientations of the orbits taken into account. In this paper, which is part 1 of a 3-part series, all solutions are considered for which two Killing fields are spanned on velocity and rotation. The solutions of Lanczos and Gödel are identified as special cases, and their new invariant definitions are provided. In addition, a new invariant definition is given of the Ozsvath class III solution. © *1998 American Institute of Physics.* [S0022-2488(97)03112-5]

I. INTRODUCTION AND SUMMARY

The theorem of Darboux presented in Sec. II allows one to introduce invariantly defined coordinates in which the velocity field of a fluid (not assumed to be perfect) acquires a ''canonical'' form. In this paper it is further assumed that the fluid moves with zero acceleration and nonzero rotation. These assumptions result in a simplification of the metric tensor and in limitations imposed on the Killing vectors, if any exist. Within this special class of coordinates, any single Killing field may also be reduced to a ''canonical'' form, a different one in the case when it is spanned on the vector fields of velocity u^α and rotation w^α, and a different one when it is linearly independent of u^α and w^α. This gives rise to a classification of possible symmetries in rotating matter.

When there exist three linearly independent Killing fields, the classification described above gives rise to a complete classification of all possible metric forms. With respect to the algebras of the symmetry groups, this is just the Bianchi classification, but with all orientations of the orbits in the spacetime taken into account.

In every case that emerges, the commutation relations of the algebra have been solved, resulting in explicit formulae for the Killing fields, and then the Killing equations have been solved, resulting in the formulae for the metric tensors compatible with the symmetry groups considered. The degree of success in solving the Einstein equations varied very strongly from case to case. In most cases, no headway was made. In some cases the Einstein equations have been integrated either to an autonomous set of first-order equations or to a single nonlinear differential equation of second or third order. In a few cases solutions known earlier were identified in the present scheme and new invariant definitions for some of them were provided (those by Lanczos[1] and Gödel[2] will be mentioned in this paper). In three cases new solutions were found.

Since the number of cases is rather large, the results will be presented in three papers. The present paper deals with the simplest situation when two of the Killing fields are spanned on

0022-2488/98/39(1)/380/21/$15.00

velocity and rotation (the case of all three Killing fields being spanned on u and w is trivial—see Sec. VI).

The Darboux theorem was first applied as a tool for investigating the equations of motion and the Einstein equations by Plebański.[3] He showed that if a perfect fluid is rotating and isentropic while the particle number is conserved, then a similar consideration to the one presented here applies. The approach of Plebański was used by this author[4–8] to find a large collection of stationary, cylindrically symmetric solutions of Einstein's equations.

For a perfect fluid the assumptions of geodesic motion and nonzero rotation imply that the pressure is constant (see Ref. 9). Hence, from the point of view of thermodynamics, geodesic and rotating perfect fluids are isentropic and fall within the class considered by Plebański.[3] However, the approach based on the Darboux theorem applies to any timelike congruence that is of class C^1 and has zero acceleration and nonzero rotation. In particular, the velocity field of a rotating charged dust with zero Lorentz force, that was considered in several papers, has this property. The papers in which such solutions were discussed will be mentioned at the end of Sec. VIII; they are all within the same class of the classification introduced here.

In Sec. II the Darboux theorem is introduced. In Sec. III, the classification of first-order differential forms based on the Darboux theorem is applied to geodesic vector fields with rotation. When the vector field is the velocity field of a fluid, a class of preferred coordinates results, which shall be termed ''Plebański coordinates.'' In Sec. IV, by way of an example, the consideration of Sec. III is applied to the rotating dust solution of Stephani.[10] In Sec. V it is shown that each Killing vector field that might possibly exist in a rotating dust spacetime is determined by two functions of two variables. If the Killing field is not spanned on velocity and rotation, then the Plebański coordinates may be adapted to it so that it acquires the unique form $k^\alpha = \delta^\alpha_1$. The Gödel solution is used to illustrate the various forms of the Killing fields that may arise.

In Sec. VI, the consideration of Secs. III and V is applied to the situation when there exist three Killing vector fields. When all three of them are spanned on u^α and w^α, the result is trivial: the group becomes two-dimensional, and this case is not considered here. When two of them are spanned on u^α and w^α while the third one is not, two cases arise that correspond to different Bianchi types (II and I) of the groups. These are investigated in Secs. VII and VIII. The solutions of Lanczos[1] and of Gödel[2] emerge as special cases in both types. The Bianchi type II metrics are defined by a single third-order differential equation, the Bianchi type I metrics are determined by a set of autonomous first-order differential equations.

Finally, in Sec. IX, other invariant definitions are given: for the class III solution by Ozsvath[11] and for the solution of Gödel.[2] The former results from the following assumptions.

(1) The source in the Einstein equations is a geodesic, rotating perfect fluid.
(2) The rotation vector field is covariantly constant.

The Gödel solution, which is a subcase of this, emerges when it is assumed in addition that the shear of the fluid flow is zero.

So far, Bianchi-type solutions of Einstein's equations with a rotating source have been searched for and found by trial and error (often with nonperfect fluid sources, e.g., with heat-flow). The results of the present series of papers show that, in the case of a dust source at least, the number of allowed possibilities is limited. It is hoped that the results will direct further research toward better-defined targets.

II. THE CLASSIFICATION OF DIFFERENTIAL FORMS OF FIRST ORDER AND THE DARBOUX THEOREM

The Darboux theorem presented below exploits the simple fact that if a differential form q of first order is defined on an n-dimensional manifold M_n, then its domain is not necessarily n-dimensional. Two cases are well-known.

(1) If q is a perfect differential so that $q=df$, where f is a scalar function on M_n, then f can be chosen as one of the coordinates, and the form becomes one-dimensional.
(2) If q has an integrating factor so that $q=gdf$, where f and g are independent scalar functions on M_n, then f and g can be chosen as two of the coordinates, and then the domain of q is the two-dimensional (f,g)-surface.

The Darboux theorem summarizes all the cases that can occur. It is based on the following classification (see also Ref. 3)

Definition: Let q be a differential form of first order.
If $Q_{2l}:=dq\wedge\cdots\wedge dq$ (multiplied l times) $\neq 0$, but $q\wedge Q_{2l}=0$, then q is said to be of class $2l$.
If $Q_{2l+1}:=q\wedge Q_{2l}\neq 0$, but $dQ_{2l+1}\equiv dq\wedge Q_{2l}=0$, then q is said to be of class $(2l+1)$. □
Then the following holds.

The theorem of Darboux: The form q is of class $2l$ if and only if there exists a set of $2l$ independent functions $(\xi_1,\ldots,\xi_l,\eta_1,\ldots,\eta_l)$ such that

$$q=\eta_1 d\xi_1+\eta_2 d\xi_2+\cdots+\eta_l d\xi_l. \tag{2.1}$$

The form q is of class $(2l+1)$ if and only if there exists a set of $(2l+1)$ independent functions $(\tau,\xi_1,\ldots,\xi_l,\eta_1,\ldots,\eta_l)$ such that

$$q=d\tau+\eta_1 d\xi_1+\eta_2 d\xi_2+\cdots+\eta_l d\xi_l. \tag{2.2}$$

A proof of this theorem can be found in Ref. 12.

Evidently, the class of q cannot be larger than the dimension of the manifold on which q is defined. Hence, the Darboux theorem implies that in a four-dimensional spacetime V_4 any differential form of first order can be represented as

$$q=\sigma d\tau+\eta d\xi, \tag{2.3}$$

where σ, τ, η and ξ are scalar functions on V_4.

Any vector field u^α on V_4 defines the following differential form:

$$q_u:=u_\alpha dx^\alpha. \tag{2.4}$$

According to (2.3), in the most general case there exist scalar functions σ, τ, η and ξ such that

$$u_\alpha=\sigma\tau_{,\alpha}+\eta\xi_{,\alpha}. \tag{2.5}$$

Note that the functions in (2.5) are not uniquely defined. Since we shall not use (2.5) in the most general case, we shall determine the nonuniqueness only in the subcase that is of direct interest to us (see Sec. III).

For the most general case of (2.5), the four functions are independent in the sense that the Jacobian,

$$\frac{\partial(\sigma,\tau,\eta,\xi)}{\partial(x^0,x^1,x^2,x^3)}\neq 0. \tag{2.6}$$

Hence, they can be chosen as coordinates in the spacetime. In Refs. 4 and 7 it was shown that if u^α is the velocity field of an isentropic perfect fluid in which the particle number is conserved, then $\sigma=1/H$, where H is the enthalpy per one particle of the fluid, and further limitations on u_α follow from the particle number conservation. No other applications of (2.5) in the general case are known to this author.

III. GEODESICALLY MOVING FLUIDS

To any timelike vector field u_α normalized to unity (so that $u_\alpha u^\alpha = 1$) the formula from Refs. 13 and 14 may be applied:

$$u_{\alpha;\beta} = \dot{u}_\alpha u_\beta + \sigma_{\alpha\beta} + \omega_{\alpha\beta} + \tfrac{1}{3}\,\theta h_{\alpha\beta}, \tag{3.1}$$

which gives rise to the well-known definitions of acceleration $\dot{u}^\alpha$, expansion θ, shear $\sigma_{\alpha\beta}$ and rotation $\omega_{\alpha\beta}$. In the signature $(+---)$ used here, the projection tensor $h_{\alpha\beta}$ is

$$h_{\alpha\beta} = g_{\alpha\beta} - u_\alpha u_\beta. \tag{3.2}$$

The following properties of $\dot{u}^\alpha$, $\sigma_{\alpha\beta}$ and $\omega_{\alpha\beta}$ will be useful in further considerations:

$$\dot{u}_\alpha u^\alpha = 0, \quad \sigma_{\alpha\beta} u^\beta = \omega_{\alpha\beta} u^\beta = 0. \tag{3.3}$$

We shall assume from now on that u_α is the velocity field of a fluid and that $\dot{u}_\alpha = 0$, i.e., that the particles of the fluid move on geodesics. Then, from (2.5) we have

$$\omega_{\alpha\beta} = \tfrac{1}{2}\,(u_{\alpha,\beta} - u_{\beta,\alpha}) = \tfrac{1}{2}\,(\sigma_{,\beta}\tau_{,\alpha} - \sigma_{,\alpha}\tau_{,\beta} + \eta_{,\beta}\xi_{,\alpha} - \eta_{,\alpha}\xi_{,\beta}), \tag{3.4}$$

and from (3.3) we have

$$(u^\beta \sigma_{,\beta})\tau_{,\alpha} - (u^\beta \tau_{,\beta})\sigma_{,\alpha} + (u^\beta \eta_{,\beta})\xi_{,\alpha} - (u^\beta \xi_{,\beta})\eta_{,\alpha} = 0. \tag{3.5}$$

There are two possibilities now.

I. At least one of the four scalar products in (3.5) is nonzero. In this case (3.5) implies that at most three of the functions (σ,τ,η,ξ) are independent, and so the form (2.4) will not be of class 4.

II. All the four scalar products are zero. However, this means that the gradients of (σ,τ,ξ,η) are at every point confined to the 3-space element orthogonal to u_α, i.e., that there is a functional relation among these four functions. Again, the form (2.4) cannot be of class 4.

Hence, for a geodesically moving fluid the form (2.4) is of class at most 3, i.e., at most 3 independent functions τ, η, ξ exist such that

$$u_\alpha = \tau_{,\alpha} + \eta\xi_{,\alpha}. \tag{3.6}$$

From here on, the reasoning used in Refs. 3 and 4 applies almost unchanged. With (3.6) we have in (3.4),

$$\omega_{\alpha\beta} = \tfrac{1}{2}\,(\eta_{,\beta}\xi_{,\alpha} - \eta_{,\alpha}\xi_{,\beta}), \tag{3.7}$$

and in (3.5),

$$(u^\beta \eta_{,\beta})\xi_{,\alpha} - (u^\beta \xi_{,\beta})\eta_{,\alpha} = 0. \tag{3.8}$$

There are again two possibilities.

I. Either $(u^\beta \eta_{,\beta})$ and $(u^\beta \xi_{,\beta})$ do not vanish simultaneously, and then (3.8) implies that η and ξ are functionally related, in which case (3.6) implies that u_α is a gradient of a function, and so $\omega_{\alpha\beta} \equiv 0$.

II. Or ξ and η are not functionally related, in which case

$$u^\beta \xi_{,\beta} = u^\beta \eta_{,\beta} = 0, \tag{3.9}$$

and $\omega_{\alpha\beta} \neq 0$. We shall be interested only in the second case. The functions $\{\tau,\xi,\eta\}$ in (3.6) are determined up to the following transformations:

$$\xi=F(\xi',\eta'),\quad \eta=G(\xi',\eta'),\quad \tau=\tau'-S(\xi',\eta'), \tag{3.10}$$

where the functions F and G must obey the equation

$$F_{,\xi'}G_{,\eta'}-F_{,\eta'}G_{,\xi'}=1, \tag{3.11}$$

and then S is determined by

$$S_{,\xi'}=GF_{,\xi'}-\eta',\quad S_{,\eta'}=GF_{,\eta'}. \tag{3.12}$$

Equation (3.11) is the integrability condition of Eqs. (3.12) and it ensures that the Jacobian of the transformation (3.10) equals 1. It follows that one of the functions $\{F,G\}$ can be chosen arbitrarily, the other one is then determined by (3.11) and S is fixed up to an additive constant by (3.12). The inverse transformation to (3.10) is of exactly the same form, with the corresponding F, G and S obeying (3.11) and (3.12).

Let us now make the additional assumption that the number of particles of the fluid is conserved, i.e.,

$$(\sqrt{-g}nu^{\alpha})_{,\alpha}=0, \tag{3.13}$$

where g is the determinant of the metric tensor and n is the particle number density. This equation is a necessary and sufficient condition for the existence of a function ζ such that

$$\sqrt{-g}nu^{\alpha}=\epsilon^{\alpha\beta\gamma\delta}\xi_{,\beta}\eta_{,\gamma}\zeta_{,\delta}. \tag{3.14}$$

Note that (3.6) and (3.9) imply that

$$u^{\alpha}\tau_{,\alpha}=1, \tag{3.15}$$

and then Eq. (3.14) implies that

$$\epsilon^{\alpha\beta\gamma\delta}\tau_{,\alpha}\xi_{,\beta}\eta_{,\gamma}\zeta_{,\delta}\equiv\frac{\partial(\tau,\eta,\xi,\zeta)}{\partial(x^0,x^1,x^2,x^3)}=\sqrt{-g}n\neq 0. \tag{3.16}$$

Equation (3.14) implies also that

$$u^{\alpha}\zeta_{,\alpha}=0. \tag{3.17}$$

The function ζ is determined by (3.14) up to the transformations

$$\zeta=\zeta'+T(\xi',\eta'), \tag{3.18}$$

where T is an arbitrary function. Equation (3.16) certifies that $\{\tau,\xi,\eta,\zeta\}$ can be used as coordinates in the spacetime. If they are chosen as the $\{x^0,x^1,x^2,x^3\}=\{t,x,y,z\}$ coordinates, respectively, then Eq. (3.6) implies

$$u_0=1,\quad u_1=y,\quad u_2=u_3=0. \tag{3.19}$$

We will use these coordinates throughout the remaining part of the paper and call them ''Plebański coordinates.'' Equation (3.16) implies now that

$$g=-n^{-2}, \tag{3.20}$$

and Eq. (3.14) implies

$$u^{\alpha}=\delta^{\alpha}_0, \tag{3.21}$$

i.e., the Plebański coordinates are comoving. The rotation vector defined by

$$w^\alpha = -(1/\sqrt{-g})\,\epsilon^{\alpha\beta\gamma\delta}u_\beta u_{\gamma,\delta}, \tag{3.22}$$

assumes the form

$$w^\alpha = n\,\delta^\alpha_3. \tag{3.23}$$

Equations (3.19) and (3.21) imply that

$$g_{00}=1, \quad g_{01}=y, \quad g_{02}=g_{03}=0, \tag{3.24}$$

and also that the only nonvanishing components of the rotation tensor are

$$\omega_{12}=-\omega_{21}=1/2. \tag{3.25}$$

Note that, in contrast to Refs. 3 and 4 where barotropic perfect fluids were considered, we have not assumed anything about the form of the energy–momentum tensor so far.

If we now assume that the fluid is perfect, then we conclude from the equations of motion $T^{\alpha\beta}{}_{;\beta}=0$ that either $\omega=0$ or $p=\text{const}$ (see also Ref. 9). This means that a geodesic perfect fluid can be rotating only if it is in fact dust; the constant p can be reinterpreted as the cosmological constant. In this case, the energy–density obeys the conservation equation $(\sqrt{-g}\epsilon u^\alpha)_{,\alpha}=0$ and Eq. (3.13) need not be assumed separately. [For dust, results closely analogous to (3.19)–(3.25) were obtained by Ellis,[15] by adapting an orthonormal vector basis and a coordinate system to u^α and w^α. Of the exact solutions with nonzero rotation found by Ellis most, but not all, do belong to the collection considered in this series of papers. They will be described in paper 2.]

IV. EXAMPLE: THE STEPHANI SOLUTION[10]

The Stephani metric with $p=\text{const}\neq 0$ [Eq. (4.22) in Ref. 10] is not in fact a perfect fluid solution, as was found out while trying to construct the Plebański coordinates for it. (The error is deeply hidden and so far could not be corrected. I am grateful to H. Stephani for cooperation on this point.) Therefore, we shall consider only the dust solution, Eq. (4.8) in Ref. 10. In the original notation except for the signature, the solution is

$$ds^2=\eta_{ab}dx^a dx^b - N^2(dx^1)^2, \tag{4.1}$$

where $a,b=0,2,3$, $\eta_{ab}=\text{diag}(1,-1,-1)$ and

$$N:=\tfrac{1}{2}M\,\ln T + g_a x^a + h,$$

$$T^2:=\eta_{ab}(x^a-f^a)(x^b-f^b), \tag{4.2}$$

the functions $M(x^1)$, $f^a(x^1)$, $g_a(x^1)$, and $h(x^1)$ all being arbitrary. The velocity field and the energy–density of the dust are, respectively,

$$u_a=T_{,a}, \quad u_1=0, \tag{4.3}$$

$$\kappa\epsilon = M/(NT^2). \tag{4.4}$$

The formula for the velocity field can be written as

$$u_\alpha = T_{,\alpha} - T_{,1}x^1{}_{,\alpha}, \tag{4.5}$$

which immediately suggests the choice of the Plebański coordinates of Sec. III:

$$\tau=T, \quad \xi=x^1, \quad \eta=-T_{,1}. \tag{4.6}$$

Equation (3.14) defining ζ is here

$$MT^{-2}\eta^{ab}T_{,b}=-\epsilon^{a1cd}T_{,1c}\zeta_{,d}. \tag{4.7}$$

The following identity is useful in calculations:

$$T_{,0}{}^2-T_{,2}{}^2-T_{,3}{}^2=1. \tag{4.8}$$

Using this, one can verify that only two of the three equations (4.7) are independent. The solution of (4.7) is

$$\zeta=M[U+\lambda(T_{,1})], \tag{4.9}$$

where $\lambda(T,_1)$ is an arbitrary function, and U is defined by

$$U=\int [f^3{}_{,1}(1-X^2)-f^0{}_{,1}Y(X)+f^2{}_{,1}XY(X)]^{-1}dX, \tag{4.10}$$

the function $Y(X)$ being determined by

$$T_{,1}(1-X^2-Y^2)^{1/2}=-f^0{}_{,1}+f^2{}_{,1}X+f^3{}_{,1}Y. \tag{4.11}$$

In the integral (4.10), the coordinate x^1 and the quantity $T,_1$ are to be treated as parameters independent of X. After the integral is calculated, one should substitute for $T,_1$ from (4.11), while X and Y are to be replaced by

$$X=(x^2-f^2)/(x^0-f^0), \quad Y=(x^3-f^3)/(x^0-f^0). \tag{4.12}$$

The integral in (4.10) is expressible in terms of elementary functions, but the result is rather complicated.

As can be seen, the solution (4.1)–(4.4) becomes very complicated in the Plebański coordinates and it is unlikely that it could be found in such a form from the Einstein equations. Thus, although the coordinates are invariantly defined, they are not necessarily convenient for explicit calculations.

A collection of other solutions represented in the Plebański coordinates can be found in the extended version of Ref. 6.

V. THE KILLING VECTOR FIELDS COMPATIBLE WITH ROTATION

We shall assume that the symmetries of the spacetime (if any exist) are inherited by the source, i.e., that if the Lie derivative of the metric tensor $g_{\alpha\beta}$ along the vector field k^α is zero, $\mathcal{L}_k g_{\alpha\beta}=0$, then the velocity field and the particle number density are also invariant: $\mathcal{L}_k u^\alpha=0=\mathcal{L}_k n$. (For a pure perfect fluid source the inheritance is guaranteed.) It follows that the rotation tensor must also be invariant, $\mathcal{L}_k\omega_{\alpha\beta}=0$.

In consequence of (3.21) the equation $\mathcal{L}_k u^\alpha\equiv k^\mu u^\alpha{}_{,\mu}-u^\mu k^\alpha{}_{,\mu}=0$ implies that

$$k^\alpha{}_{,t}=0. \tag{5.1}$$

In consequence of (3.23) and of the assumption $\mathcal{L}_k n\equiv k^\alpha n_{,\alpha}=0$, the equation $\mathcal{L}_k w^\alpha=0$ implies

$$k^\alpha{}_{,z}=0. \tag{5.2}$$

The equation $\mathcal{L}_k\omega_{\alpha\beta}=0$, in consequence of (3.25) implies

$$k^1{}_{,x}+k^2{}_{,y}=0, \tag{5.3}$$

and the equation $\mathcal{L}_k u_\alpha = 0$, in consequence of (3.19) implies

$$k^0{}_{,x} = -k^2 - y k^1{}_{,x}, \quad k^0{}_{,y} = -y k^1{}_{,y}. \tag{5.4}$$

(The equations $\mathcal{L}_k u_\alpha = 0$ and $\mathcal{L}_k u^\alpha = 0$ provide independent pieces of information because the equations $\mathcal{L}_k g_{\alpha\beta} = 0$ have not been used so far.) Equation (5.3) is the integrability condition of Eqs. (5.4). The general solution of Eqs. (5.1)–(5.4) is

$$k^0 = C + \phi - y\phi_{,y}, \quad k^1 = \phi_{,y}, \quad k^2 = -\phi_{,x}, \quad k^3 = \lambda, \tag{5.5}$$

where $\phi(x,y)$ and $\lambda(x,y)$ are arbitrary functions and C is an arbitrary constant. Symmetries need not be present, in fact the Stephani[10] solution considered in Sec. IV is an example of a rotating dust solution with no symmetries. In this case $\phi = \lambda = C = 0$. However, if any symmetries are present, then the Killing vector fields must have the form (5.5).

Suppose that ϕ is not a constant, i.e., that a Killing vector field k^α exists that has a nonzero component in the x- or y-direction (in invariant terms this means that the vector field k^α is not spanned on the vector fields of velocity, u^α, and rotation, w^α). We can then, within the Plebański class defined in Sec. III, adapt the coordinates to k^α in such a way that $k^{\alpha'} = \delta_1^{\alpha'}$, i.e., so that the metric becomes independent of x'. From (3.10)–(3.12) and (3.18) the transformation functions are

$$t' = t - S(x,y), \quad x' = F(x,y), \quad y' = G(x,y), \quad z' = z + T(x,y), \tag{5.6}$$

where T is arbitrary, while F, G, and S obey

$$F_{,x}G_{,y} - F_{,y}G_{,x} = 1, \quad S_{,x} = GF_{,x} - y, \quad S_{,y} = GF_{,y}. \tag{5.7}$$

In order to lead to $k^{\alpha'} = \delta_1^{\alpha'}$ the functions F, G, and T must obey in addition

$$-(\phi + C) + GF_{,x}\phi_{,y} - GF_{,y}\phi_{,x} = 0,$$

$$F_{,x}\phi_{,y} - F_{,y}\phi_{,x} = 1, \quad G_{,x}\phi_{,y} - G_{,y}\phi_{,x} = 0, \tag{5.8}$$

$$T_{,x}\phi_{,y} - T_{,y}\phi_{,x} = -\lambda. \tag{5.9}$$

The unique solution of Eqs. (5.8) is $G = \phi + C$, which obeys (5.7) as well [in virtue of the second of (5.8)]. Equation (5.9) simply defines the accompanying T which is seen to exist always. Since ϕ was assumed nonconstant, the transformation is nonsingular (in fact its Jacobian equals just 1), and results in $\phi = y$ in the new coordinates. As already noticed, the metric becomes independent of x after the transformation. This property is preserved by the transformations (5.6), but with F, G, S, and T restricted now by

$$G = y, \quad F = x + H(y), \quad T = T(y), \quad S = \int y H_{,y} dy + A, \tag{5.10}$$

where A is an arbitrary constant and H, T are arbitrary functions. The functions given by (5.10) fulfill (5.7) identically. Note that the transformation to $k^{\alpha'} = \delta_1^{\alpha'}$ exists irrespectively of any possible functional relation among λ, ϕ, and C in (5.5); the only case when it fails is $\phi = \text{const}$.

A solution of the Einstein equations may have more than one Killing vector field of the form (5.5). In that case, the transformation (5.8)–(5.9) changes only one of them to the preferred form, the others will preserve their more complicated appearance. An example of this situation is the Gödel solution[2] transformed to the Plebański coordinates; see Refs. 4 and 5:

$$ds^2 = (dt + y dx)^2 - \tfrac{1}{2} y^2 dx^2 - (\kappa\epsilon y^2)^{-1} dy^2 - 2\kappa\epsilon^{-1} dz^2, \tag{5.11}$$

where $\kappa = 8\pi G/c^4$ and ϵ is the energy–density related to the cosmological constant by

$$\Lambda = \tfrac{1}{2}\kappa\epsilon. \tag{5.12}$$

(Note that if the cosmological constant is reinterpreted as pressure, then the resulting perfect fluid has the equation of state $\epsilon = p$. Hence, the Gödel solution may have been the first example considered in the literature of a ''stiff perfect fluid,'' now familiar from the studies of solution-generating techniques; see, e.g., Verdaguer.[16]) The symmetry group of this solution is 5-dimensional, the independent 1-parametric subgroups were given in Ref. 4. Those connected with nonconstant ϕ in (5.5) are the following three:

$$x = x' + s_1, \tag{5.13}$$

$$x = e^{-s_2}x', \quad y = e^{s_2}y', \tag{5.14}$$

$$\begin{aligned} t &= t' + (2\sqrt{2}/K)\arctan[\sqrt{2}s_3(Ky')^{-1}(1-s_3x')^{-1}], \\ x &= [K^2x'y'^2(1-s_3x') - 2s_3]/[2s_3^2 + K^2y'^2(1-s_3x')^2], \\ y &= (1-s_3x')^2y' + 2s_3^2/(K^2y'), \end{aligned} \tag{5.15}$$

where s_1, s_2, and s_3 are the group parameters and $K := (\kappa\epsilon)^{1/2}$. The Killing vectors are, respectively, $k^\alpha_{(1)} = \delta^\alpha_1$ [corresponding to $C = \lambda = 0$, $\phi = y$, the one constructed in (5.8)–(5.9)], $k^\alpha_{(2)} = -x\delta^\alpha_1 + y\delta^\alpha_2$ (corresponding to $\phi = -xy$) and $k^\alpha_{(3)} = 4(K^2y)^{-1}\delta^\alpha_0 + [x^2 - 2/(Ky)^2]\delta^\alpha_1 - 2xy\delta^\alpha_2$ [corresponding to $\phi = x^2y + 2/(K^2y)$].

VI. THE ALGEBRA OF THREE KILLING FIELDS

Suppose that three Killing vector fields exist and all three are spanned on u^α and w^α, so that $\phi = \text{const}$ in (5.5) for each of them, i.e.,

$$k^\alpha_{(i)} = C_i\delta^\alpha_0 + \lambda_i(x,y)\,\delta^\alpha_3, \quad i = 1,2,3. \tag{6.1}$$

From the Killing equations one can then easily conclude that constants α_1, α_2, and α_3 exist such that $\alpha_1 k_{(1)} + \alpha_2 k_{(2)} + \alpha_3 k_{(3)} = 0$, i.e., the symmetry group is in fact two-dimensional. Hence, no three-dimensional symmetry group with the generators (6.1) exists; for a three-dimensional group at least one of the generators must be linearly independent of u^α and w^α at every point of the spacetime region under consideration. [The algebra (6.1) corresponds to a three-dimensional group that has two-dimensional orbits, and it turns out that in the case considered the group has to be two-dimensional as well. As will follow from the whole of the present work, three-dimensional symmetry groups with two-dimensional orbits just do not exist for rotating dust.]

In Secs. VII and VIII we shall consider the situation when exactly one generator, $k^\alpha_{(1)}$, is everywhere linearly independent of u^α and w^α, while the other two, $k^\alpha_{(2)}$ and $k^\alpha_{(3)}$, are of the form (6.1). In agreement with the result of Sec. V, the Plebański coordinates can be adapted to $k^\alpha_{(1)}$ so that

$$k^\alpha_{(1)} = \delta^\alpha_1, \tag{6.2}$$

while

$$k^\alpha_{(2)} = C_2\delta^\alpha_0 + \lambda_2(x,y)\,\delta^\alpha_3, \quad k^\alpha_{(3)} = C_3\delta^\alpha_0 + \lambda_3(x,y)\,\delta^\alpha_3, \tag{6.3}$$

and the coordinate transformations preserving (6.2) and (6.3) are (5.10). Note that C_2 and C_3 cannot vanish simultaneously because otherwise the Killing equations immediately imply that either $k^\alpha_{(3)} = \text{const}\, k^\alpha_{(2)}$ (in which case the symmetry group is two-dimensional) or the metric is singular. However, with no loss of generality we can assume that

$$C_2 \neq 0 = C_3, \tag{6.4}$$

because the Killing vector fields are determined up to linear combinations among them. Hence, if initially $C_2 \neq 0 \neq C_3$, then we take $k'^\alpha_{(3)} = k^\alpha_{(3)} - (C_3/C_2)k^\alpha_{(2)}$ instead of $k^\alpha_{(3)}$ as the basis generator. If initially $C_2 = 0 \neq C_3$, then we exchange the labels ''2'' and ''3.''

We shall keep the choice (6.4) throughout Secs. VII and VIII.

VII. THE GENERATORS, THE KILLING EQUATIONS AND THE EINSTEIN EQUATIONS FOR A BIANCHI TYPE II ALGEBRA

All the cases that arise follow as limits at different stages of calculation from the generic case $\lambda_2 \neq 0$, and we shall consider it first. The commutators of the Killing vectors are

$$[k_{(1)}, k_{(2)}]^\alpha = (\lambda_{2,x}/\lambda_3)k^\alpha_{(3)}, \quad [k_{(2)}, k_{(3)}]^\alpha = 0,$$
$$[k_{(1)}, k_{(3)}]^\alpha = (\lambda_{3,x}/\lambda_3)k^\alpha_{(3)}. \tag{7.1}$$

The Killing vector fields will thus form a Lie algebra when

$$\lambda_{2,x} = b\lambda_3, \quad \lambda_{3,x} = c\lambda_3, \tag{7.2}$$

where b and c are arbitrary constants. The case $c \neq 0$ has to be considered separately. Then

$$\lambda_3 = \beta(y)e^{cx}, \quad \lambda_2 = (b/c)\beta(y)e^{cx} + \alpha(y), \tag{7.3}$$

where $\alpha(y)$ and $\beta(y)$ are arbitrary functions. However, in this case we can take $k'^\alpha_{(2)} = k^\alpha_{(2)} - (b/c)k^\alpha_{(3)}$ as the new basis generator instead of $k^\alpha_{(2)}$, and the result is equivalent to assuming $b = 0$. Hence, with $c \neq 0$, we can take $b = 0$ with no loss of generality.

The further procedure consists of the following steps.

(1) Adapt the coordinates to the Killing fields to make them as simple as possible.
(2) Solve the Killing equations for the components of the metric tensor.
(3) Simplify the metric as far as possible by coordinate transformations.
(4) Solve the Einstein equations.

The coordinate transformations in steps 1 and 3 in general lead out of the Plebański class defined in Sec. III.

This procedure will be presented in some detail below. In the present case the result from the Einstein equations is that either $c = 0$ or there is no rotation. Since we are interested in rotating solutions only, the case $c \neq 0 = b$ need not be followed further. We thus assume

$$c = 0. \tag{7.4}$$

Then

$$\lambda_3 = \beta(y), \quad \lambda_2 = b\beta(y)x + \alpha(y). \tag{7.5}$$

The algebra of the Killing vector fields is of Bianchi type II when $b \neq 0$ and of Bianchi type I when $b = 0$.

In order to simplify the Killing vectors we now transform the coordinates as follows:

$$(t',x',y')=(t,x,y), \quad z'=-(\alpha/C_2)t+z/\beta. \tag{7.6}$$

The transformation is not of the form (5.10), so the new coordinates do not belong to the Plebański class, and the forms of velocity, rotation, and the metric will no longer agree with (3.19)–(3.25). The Killing vector fields in the new coordinates become

$$k^\alpha_{(1)}=\delta^\alpha_1, \quad k^\alpha_{(2)}=\delta^\alpha_0+bx\delta^\alpha_3, \quad k^\alpha_{(3)}=\delta^\alpha_3, \tag{7.7}$$

while the velocity and rotation fields become

$$u^\alpha=\delta^\alpha_0-(\alpha/C_2)\delta^\alpha_3, \quad w^\alpha=(n/\beta)\delta^\alpha_3. \tag{7.8}$$

The transformed metric is independent of x and z, while the Killing equations for $k^\alpha_{(2)}$ imply

$$\begin{gathered}
g_{00}=1+(\alpha/C_2)^2h_{33}(y), \quad g_{01}=y+(\alpha/C_2)g_{13}, \\
g_{02}=0, \quad g_{03}=(\alpha/C_2)h_{33}(y), \\
g_{11}=h_{33}(y)(bt)^2-2h_{13}(y)bt+h_{11}(y), \\
g_{12}=-h_{23}(y)bt+h_{12}(y), \quad g_{13}=-h_{33}(y)bt+h_{13}(y), \\
g_{22}=h_{22}(y), \quad g_{23}=h_{23}(y), \quad g_{33}=h_{33}(y),
\end{gathered} \tag{7.9}$$

where $h_{ij}(y)$, $i,j=1,2,3$, are arbitrary functions of y, to be found from the Einstein equations.

The orbits of the symmetry group are now the hypersurfaces $y=\text{const}$. In order to follow the standard technique of the Bianchi-type spaces we should now carry out a coordinate transformation that preserves (7.7) and makes the y-coordinate curves orthogonal to the group orbits, so that $g'_{02}=g'_{12}=g'_{23}=0$ after the transformation. This step is not in fact necessary for solving the Einstein equations (in general it only reshuffles the unknown functions without eliminating any of them), but in the case under consideration it leads to a simplification. The transformation is

$$\begin{gathered}
t=t'+f_0(y'), \quad x=x'+f_1(y'), \quad y=f_2(y'), \\
z=z'+bf_1(y')t'+f_3(y'),
\end{gathered} \tag{7.10}$$

where $f_\alpha(y')$ must obey

$$\begin{gathered}
f_{0,y'}=-f_2f_{1,y'}+(\alpha/C_2)h_{23}f_{2,y'}, \\
(-f_2^2+h_{11}-h_{13}^2/h_{33})f_{1,y'}+(h_{12}-h_{13}h_{23}/h_{33}+\alpha f_2h_{23}/C_2)f_{2,y'}=0, \\
f_{3,y'}=-(\alpha/C_2)f_{0,y'}+(bf_0-h_{13}/h_{33})f_{1,y'}-(h_{23}/h_{33})f_{2,y'}.
\end{gathered} \tag{7.11}$$

The equations are well-defined because of the following.

I. $h_{33}\neq 0$; otherwise the rotation vector would be null, which is a physical impossibility.

II. $-f_2^2+h_{11}-h_{13}^2/h_{33}\neq 0$; otherwise the determinant of the metric tensor becomes positive; i.e., the metric acquires an unphysical signature.

Equations (7.11) are to be understood as follows. The function $f_2(y')$ can be chosen arbitrarily, therefore we choose it so that $g'_{22}=-1$ after the transformation. With $f_2(y')$ thus chosen, $f_1(y')$ is found from the second of (7.11), then $f_0(y')$ is found from the first of (7.11), and finally $f_3(y')$ is found from the third of (7.11).

After the transformation the metric becomes (primes dropped)

$$
\begin{gathered}
g_{00}=1+(\alpha/C_2+bf_1)^2h_{33},\\
g_{01}=Y(y)+(\alpha/C_2+bf_1)(-h_{33}bt+h_{13}-bf_0h_{33}),\\
g_{02}=g_{12}=g_{23}=0,\\
g_{03}=(\alpha/C_2+bf_1)h_{33},\\
g_{11}=h_{33}b^2(t+f_0)^2-2h_{13}b(t+f_0)+h_{11},\\
g_{13}=-h_{33}b(t+f_0)+h_{13},\\
g_{22}=-1,\quad g_{33}=h_{33}(y),
\end{gathered}
\tag{7.12}
$$

where $h_{ij}(y)$, $i,j=1,2,3$, $f_0(y), f_1(y)$, $Y(y)=f_2(y)$ and $\alpha(y)$ are functions to be found from the Einstein equations, and b and C_2 are arbitrary constants, $C_2\neq 0$.

For convenience in calculations we introduce the new functions $G(y)$, $A(y)$, $k_{13}(y)$, and $F(y)$ by

$$
\begin{gathered}
g_{33}=-G^2(y),\quad \alpha/C_2+bf_1=A(y),\quad h_{13}=-G^2(k_{13}+bf_0),\\
h_{11}=Y^2-F^2-k_{13}^2G^2+b^2G^2f_0^2-2bf_0k_{13}G^2.
\end{gathered}
\tag{7.13}
$$

The velocity field in the coordinates of (7.12)–(7.13) is

$$
u^\alpha=\delta^\alpha_0-A\delta^\alpha_3. \tag{7.14}
$$

Now the metric form is:

$$
ds^2=(dt+Ydx)^2-(Fdx)^2-dy^2-G^2[Adt-(bt-k_{13})dx+dz]^2. \tag{7.15}
$$

The components of the Einstein tensor will be referred to the orthonormal tetrad of forms $e^i=e^i_\alpha dx^\alpha$, $i=0,1,2,3$, uniquely implied by (7.15). Note that $e^0=u_\alpha dx^\alpha$. Hence, the Einstein equations are

$$
\begin{gathered}
G_{00}=\kappa\epsilon,\\
G_{11}=G_{22}=G_{33}=\Lambda,\quad G_{ij}=0,\quad \text{when } i\neq j,
\end{gathered}
\tag{7.16}
$$

where ϵ is the energy–density and Λ is the cosmological constant.

The equation $G_{12}=0$ implies that $bA_{,y}=0$. The case $b=0$ will be considered separately below, so we take here

$$
A=\text{const.} \tag{7.17}
$$

Then $G_{02}=0$ implies

$$
k_{13}=\text{const.} \tag{7.18}
$$

We can then carry out the coordinate transformation:

$$
z=z'-At-k_{13}x,\quad (t,x,y)=(t',x',y'), \tag{7.19}
$$

which has the same result as if

$$A = k_{13} = 0, \tag{7.20}$$

and we shall assume this from now on. The metric is still independent of x and of z, while $A = k_{13} = 0$ implies $g_{13} = 0$, i.e., the Killing vectors $k^{\alpha}_{(1)} = \delta^{\alpha}_{1}$ and $k^{\alpha}_{(3)} = \delta^{\alpha}_{3}$ are orthogonal to each other. The equation $G_{01} = 0$ then has the integral

$$Y_{,y} G/F = B = \text{const}, \tag{7.21}$$

and we can assume $B \neq 0$ because rotation would be zero with $B = 0 = Y_{,y}$.

At this point, only the diagonal components of the Einstein tensor are still nonzero, of which G_{00} just defines the energy–density, and the other three are functionally dependent (i.e., if $G_{11} = \Lambda = G_{22}$ are fulfilled, then so is $G_{33} = \Lambda$). They determine $F(y)$ and $G(y)$.

It is convenient to introduce $Y(y)$ as the new variable. The equation $G_{11} + G_{22} = 2\Lambda$ can then be written, with the help of (7.21), as

$$(F^2 G_{,Y}/G)_{,Y} = 2\Lambda G^2/B^2 - \tfrac{1}{2}, \tag{7.22}$$

and so

$$F^2 = \left(C - \frac{1}{2} Y + 2 \frac{\Lambda}{B^2} \int G^2 dY \right) G/G_{,Y}, \tag{7.23}$$

where C is a new arbitrary constant (we can assume $G_{,Y} \neq 0$ because $G_{,Y} = 0$ implies $b = 0$ from $G_{11} - G_{22} = 0$, and $b = 0$ will be considered separately). Using (7.23) in $G_{22} = \Lambda$ we obtain the following integro-differential equation that determines G:

$$-\frac{1}{4} b^2 G G_{,Y} + \frac{1}{2} (B/G)^2 \left(C - \frac{1}{2} Y + 2 \frac{\Lambda}{B^2} \int G^2 dY \right)^2 (G_{,Y}/G - G_{,YY}/G_{,Y}) = 0. \tag{7.24}$$

In the special case $\Lambda = 0$ this becomes an ordinary second-order differential equation. It is easy to get rid of the integral by transforming (7.24) appropriately and differentiating the result by Y [in this way a third-order differential equation for $G(Y)$ is obtained] or by introducing the new variable $u(Y)$ by $dY/du = 1/G^2$ [this results in a second-order equation for $G(u)$]. However, no progress toward solving (7.24) results in either case.

With the help of the equations $G_{11} = \Lambda = G_{22}$ the formula for energy–density may be simplified to

$$\kappa \epsilon = (B/G)^2 - (bG)^2 - 2\Lambda. \tag{7.25}$$

Note that the solutions considered here have a meaningful limit $b = 0$.

When $G = \text{const}$, Eqs. (7.23) and (7.24) no longer apply and one has to go back to the Einstein equations. They imply

$$G^2 = B^2/(4\Lambda) \tag{7.26}$$

(i.e., necessarily $\Lambda > 0$) and

$$F^2 = \tfrac{1}{2} Y^2 + DY + E, \tag{7.27}$$

where D and E are constants. If Y is chosen as the new coordinate in place of y, then from (7.21) and (7.26) the metric component g_{YY} is

$$g_{YY} = -(G/BF)^2 = -1/(4\Lambda F^2), \tag{7.28}$$

and the resulting metric is the Gödel solution (see Ref. 4). Note that $G=\text{const}$ is equivalent to $\epsilon=\text{const}$; see Eq. (7.25).

When $G_{,Y}\neq 0=b$, Eq. (7.24) implies $G=e^{DY+E}$, and this leads to the Lanczos solution (see Ref. 4).

These derivations of the Lanczos and Gödel solutions lead to their invariant definitions that are based on weaker assumptions than the definitions known so far. The definitions are:

(1) The source in the Einstein equations is a rotating dust.
(2) The spacetime has a 3-dimensional symmetry group.
(3) Two of the symmetry generators are spanned on the vector fields of velocity u^α and rotation w^α, while the third one is linearly independent of u^α and w^α at every point.
(4) The generators form a Bianchi type II algebra.
(5) In the solutions of the Einstein equations, the Bianchi type I limit is taken of the Bianchi type II symmetry.
(6) The Gödel solution results when the matter–density is constant; the Lanczos solution results when the density is not constant.

The generalization with respect to the earlier definition is contained in point 3: in previous derivations the two generators were assumed to be collinear with u^α and w^α, respectively, from the beginning.

VIII. THE GENERATORS, THE KILLING EQUATIONS AND THE EINSTEIN EQUATIONS FOR A BIANCHI TYPE I ALGEBRA

We shall consider the case $b=c=0$ in (7.1)–(7.2). The reasoning up to Eq. (7.16) applies also here, but (7.17) no longer follows. Instead, the equation $G_{13}=0$ can be integrated with the result

$$k_{13,y}=BF/G^3-YA_{,y}, \tag{8.1}$$

where B is an arbitrary constant; the equation $G_{01}=0$ can be integrated to

$$Y_{,y}=(C-BA)F/G, \tag{8.2}$$

where C is an arbitrary constant; and the equation $G_{03}=0$ can be integrated to

$$A_{,y}=(BY-D)/(FG^3), \tag{8.3}$$

where D is one more arbitrary constant.

At this point, only the diagonal components of the Einstein tensor survive, and $G_{00}=\kappa\epsilon-\Lambda$ just defines the energy–density. The equations $G_{11}=\Lambda=G_{22}=G_{33}$ can be written as

$$-\frac{B}{4FG}k_{13,y}+\frac{C-BA}{4FG}Y_{,y}+G_{,yy}/G-\frac{2BY-D}{4FG}A_{,y}=\Lambda, \tag{8.4}$$

$$-\frac{B}{4FG}k_{13,y}+\frac{C-BA}{4FG}Y_{,y}+\frac{F_{,y}G_{,y}}{FG}-\frac{D}{4FG}A_{,y}=\Lambda, \tag{8.5}$$

$$\frac{3B}{4FG}k_{13,y}-\frac{C-BA}{4FG}Y_{,y}+F_{,yy}/F+\frac{3D}{4FG}A_{,y}=\Lambda. \tag{8.6}$$

[In order to arrive at this form, one has to calculate B from (8.1) and replace one factor B in B^2 by the resulting expression; then replace one $Y_{,y}$ in $Y_{,y}^2$ from (8.2) and replace one $A_{,y}$ in $A_{,y}^2$ from

(8.3).] The set (8.4)–(8.6) can be integrated to a first-order set. Subtracting (8.6) from (8.4) and multiplying the result by FG we obtain an equation that is easily integrated to

$$FG_{,y}-GF_{,y}-Bk_{13}-\tfrac{1}{2}BAY+\tfrac{1}{2}CY-\tfrac{1}{2}DA=E=\text{const}. \tag{8.7}$$

Now adding (8.3) and (8.4), and multiplying the result by FG we obtain another integrable equation whose integral can be written in the form

$$FG_{,y}=\frac{1}{2}Bk_{13}+\frac{1}{2}BAY-\frac{1}{2}CY+2\Lambda\int FGdy+H_0, \tag{8.8}$$

where H_0 is an arbitrary constant. The integral can be calculated if the new variable $u(y)$ is introduced by

$$dy/du=1/(FG). \tag{8.9}$$

From (8.7) and (8.8) it follows that

$$GF_{,y}=-\frac{1}{2}Bk_{13}-\frac{1}{2}DA-E+2\Lambda\int FGdy+H_0. \tag{8.10}$$

In the set (8.4)–(8.6) there remains one equation that has still not been used. However, at this point it merely introduces a relation between the arbitrary constants, i.e., implicitly defines H_0 in terms of the other constants. This is seen as follows: substitute for $k_{13,y}$, $Y_{,y}$, $F_{,y}$, $G_{,y}$, and $A_{,y}$ from (8.1)–(8.3), (8.8), and (8.10) in (8.5), thereby obtaining an algebraic equation (i.e., one without derivatives). Differentiate it by y and eliminate the derivatives in the same way again. What results is an identity $0=0$. Hence, the left-hand side of (8.5) is identically constant in virtue of the other equations.

In terms of the variable u from (8.9), Eqs. (8.1)–(8.3), (8.8), and (8.10) form an autonomous set of first-order equations that can be investigated further by qualitative methods (see, e.g., Ref. 17). This is left as a subject for a separate study.

In analogy with the Bianchi type I spatially homogeneous (nonrotating) dust solutions (see Ref. 18) one might expect further progress by adapting the coordinates suitably (in the case considered in Ref. 18, the metric can be diagonalized). However, this author was not able to achieve any such progress.

The functions $A(y)$ and $k_{13}(y)$ have invariant meaning: they are proportional to the scalar products of the Killing vectors [see Eqs. (7.7) and (7.15) with $b=0$]:

$$A=-g_{\alpha\beta}k^{\alpha}_{(2)}k^{\beta}_{(3)}/G^2, \quad k_{13}=-g_{\alpha\beta}k^{\alpha}_{(1)}k^{\beta}_{(3)}/G^2 \tag{8.11}$$

(note that $G^2=-g_{\alpha\beta}k^{\alpha}_{(3)}k^{\beta}_{(3)}$, i.e., it is a scalar, too). Hence, $A=0$ and $k_{13}=0$ are invariant properties. Note that $A=0$ implies, through (8.3), that either $Y=\text{const}$ (in which case there is no rotation) or $B=D=0$. In the latter case, $k_{13}=\text{const}$ and the coordinate transformation $z=z'-k_{13}x$ leads to $k_{13}=0$ in the new coordinates. With $A=k_{13}=0$, the Lanczos and Gödel models result from the Einstein equations as the only solutions. Hence, one more invariant definition of these models follows, similar to the six-point definition at the end of Sec. VII. Points 1, 2, 3, and 6 remain unchanged, while points 4 and 5 are replaced by the following.

(4) The generators form a Bianchi type I algebra.

(5) From the two generators spanned on u^{α} and w^{α}, two linear combinations can be constructed that are orthogonal to each other.

Point $5'$ is equivalent to the existence of coordinates in which $A=0$.

Note that the Bianchi type I models considered in this section are more general than the Bianchi type I limit of the models from Sec. VII; those from Sec. VII had $A=k_{13}=0$ in virtue of Einstein's equations.

The assumption $k_{13}=0$ (i.e., $g_{\alpha\beta}k^{\alpha}_{(1)}k^{\beta}_{(3)}=0$) alone does not lead to any immediate progress in solving the Einstein equations.

The Lanczos solution was originally derived in Ref. 1 (an English translation, Ref. 19, is now available), and rediscovered in Ref. 20. Its limit of zero cosmological constant was rediscovered in Ref. 21 as the cylindrically symmetric subcase of a family of stationary axially symmetric solutions. Geometrical and physical properties of the Lanczos solution were discussed in Ref. 1, and, in a more modern language, also in Ref. 22 (the latter only for the case $\Lambda=0$).

Coordinate transforms of the Gödel solution were published as new solutions in Refs. 23 and 24 (concerning Ref. 23 see also Ref. 25).

A metric form that is a modest generalization of the Gödel solution (it has two unknown functions of one variable in place of Gödel's e^{x^1} and e^{2x^1}) came to be known as ''Gödel-type metric'' and became the subject of a rather large number of papers; the activity seems to have started with Ref. 26, one of the most recent appearances of it is Ref. 27. However, it was proven already in Ref. 28 that the only perfect fluid solution with this metric is the Gödel solution itself; indeed, all other ''Gödel-type solutions'' have various nonperfect fluid sources, and therefore they do not show up in the scheme considered here.

As mentioned in Sec. I, several authors considered rotating charged dust solutions under the additional assumption that the electromagnetic field $F_{\mu\nu}$ exerts no force on the charged dust particles, i.e., that $F_{\mu\nu}u^{\nu}=0$. These solutions were all derived with another, rather natural assumption: that all charges are attached to dust particles so that no currents are present apart from the one created by the dust flow. Those solutions are found in Refs. 29–36. The one in Ref. 29 has only two-dimensional symmetry, so it could not come up in this investigation. The remaining ones are stationary and cylindrically symmetric and would have shown up here, had we allowed charges and electromagnetic fields in the source. They have the following properties.

The one from Ref. 30 becomes a vacuum solution in the limit $F_{\mu\nu}=0$.

The one from Ref. 31 does not allow this limit at all.

The limit $F_{\mu\nu}=0$ of the solution from Ref. 32 is the Minkowski metric.

The Som–Raychaudhuri solution[33] reproduces the $\Lambda=0$ subcase of the Lanczos solution when $F_{\mu\nu}=0$.

The first of the six solutions by Banerjee and Banerji[34] reduces to the Gödel solution when $F_{\mu\nu}=0$. The other five behave as follows: 2 and 6 become vacuum solutions when $F_{\mu\nu}=0$, no. 5 becomes the Minkowski spacetime, no. 3 does not allow this limit at all, and no. 4 has has a two-dimensional symmetry group.

Both solutions by Mitskiévič and Tsalakou[35] are generalizations of the Gödel solution; the first one of them is in addition a generalization of the full ($\Lambda\neq 0$) Lanczos solution (In fact, the second solution has a nonzero pressure gradient that remains nonzero even after the limit $F_{\mu\nu}=0$ is taken. Another limiting transition, given in the paper, reduces the solution to Gödel's.) In the limit $\Lambda=0$, the first solution reduces to the one by Som and Raychaudhuri.[33]

The two solutions from Ref. 36 are coordinate transforms of those from Ref. 35.

Three other generalizations of the Gödel solution exist in the literature that have zero acceleration. Two were provided by Raval and Vaidya;[37] the first of them is stationary, the second expanding, both have anisotropic pressure. The third is the solution by Rebouças[38] in which the source is a free electromagnetic field (see also Ref. 39). The metric of the Rebouças solution is the same as that in the first Banerjee–Banerji solution. This coincidence was explained by Raychaudhuri and Guha Thakurta:[40] The two electromagnetic fields (one generated by a current, the other source-free) are related by a point-dependent duality rotation.

IX. ANOTHER INVARIANT DEFINITION OF THE GÖDEL AND OZSVATH CLASS III SOLUTIONS

Assumptions about invariant properties of the velocity field of matter usually lead to progress in solving the Einstein equations; the most impressive example were the shear-free normal models of Barnes,[41] where a large class of solutions resulted from the assumptions of zero shear and zero rotation in a perfect fluid source. Inspired by this, one can try to make assumptions about other vector fields characterizing fluid sources, e.g., the rotation. Indeed, it turns out that the assumption

$$w_{\alpha;\beta}=0, \tag{9.1}$$

i.e., the rotation field being covariantly constant, together with the assumption of geodesic motion of a perfect fluid source, leads uniquely to two solutions of Einstein's equations. However, both of them were obtained before by other methods. One is the Ozsvath class III metric,[11] originally identified as one of the solutions that are homogeneous in four dimensions; the other is the Gödel solution[2] which is the shear-free limit of the Ozsvath solution.

From (9.1) and from the Ricci identity $2w_{\alpha;[\beta\gamma]}=R^{\rho}{}_{\alpha\beta\gamma}w_{\rho}$ one obtains for the Ricci tensor,

$$R^{\rho}{}_{\gamma}w_{\rho}=0, \tag{9.2}$$

and then from the Einstein equations for a perfect fluid,

$$G_{\alpha\beta}+\Lambda g_{\alpha\beta}=\kappa[(\epsilon+p)u_{\alpha}u_{\beta}-pg_{\alpha\beta}], \quad \kappa=8\pi G/c^4, \tag{9.3}$$

and from $u^{\alpha}w_{\alpha}=0$ one obtains

$$\Lambda=\tfrac{1}{2}\kappa(\epsilon-p). \tag{9.4}$$

In the case $\Lambda=0$, this is the well-known ''stiff perfect fluid.'' Equation (9.4) is a necessary condition for (9.1) when the source is a perfect fluid.

As stated at the end of Sec. III, if the perfect fluid moves geodesically with rotation, then necessarily $p=\text{const}$. Equation (9.4) implies then that $\epsilon=\text{const}$, i.e., a geodesically moving and rotating perfect fluid whose rotation vector is covariantly constant must have constant matter density. Since $\Lambda=0$ may be assumed with no loss of generality (this leads only to redefining p), we shall assume this from now on. Then $\epsilon=p$ and $\epsilon+p=2p$ is a conserved quantity. Hence, we may assume

$$n=\epsilon+p=2p=\text{const} \tag{9.5}$$

in all formulae. In particular, (3.20) implies then that

$$g=\det(g_{\alpha\beta})=-(2p)^{-2}. \tag{9.6}$$

Using (9.6) and (3.23) in (9.1) we obtain, in the Plebański coordinates,

$$\tfrac{1}{2}n(g_{\alpha 3,\beta}-g_{\beta 3,\alpha}+g_{\alpha\beta,3})=0. \tag{9.7}$$

After a simple algebraic manipulation this set of equations yields the following result:

$$g_{33}=-A^2=\text{const}, \quad g_{\alpha\beta,z}=0, \quad g_{13,t}=g_{23,t}=0,$$

$$g_{23,x}-g_{13,y}=0. \tag{9.8}$$

The second equation in (9.8) means that w^α is a Killing vector, as should be expected from (9.1), (9.6), and (3.23). Equations (9.8) imply that g_{13} and g_{23} depend only on x and y, and that there exists a function $\mathscr{F}(x,y)$ such that

$$g_{23}=\mathscr{F}_{,y}, \quad g_{13}=\mathscr{F}_{,x}. \tag{9.9}$$

Since we assumed that rotation is nonzero, we know that $g_{33}=-g_{\alpha\beta}w^\alpha w^\beta/n^2\neq 0$, and so we are allowed to carry out the coordinate transformation:

$$z=z'-\mathscr{F}/g_{33}, \tag{9.10}$$

that, in virtue of (9.9), will lead to

$$g_{13}=g_{23}=0 \tag{9.11}$$

in the new coordinates. We have thus arrived at the metric form:

$$ds^2=(dt+ydx)^2-h(t,x,y)[dx+k(t,x,y)dy]^2-l(t,x,y)dy^2-A^2dz^2, \tag{9.12}$$

where h, k, and l are functions to be found from the Einstein equations and A is an arbitrary constant.

From now on, the allowed coordinate transformations are (5.6)–(5.7), but with $T=$const.

The components of the Einstein tensor will now be referred to the orthonormal tetrad implied by (9.12). The equation $G_{12}=0$ is integrated with the result

$$k_{,t}=K(x,y)l^{1/2}/h^{3/2}-1/h. \tag{9.13}$$

The equation $G_{22}=\kappa p$, with l eliminated by (9.6), is integrated with the result

$$h=[H^2(x,y)+K^2/(4\kappa p)]^{1/2}+H\,\sin[2(\kappa p)^{1/2}t+\tau(x,y)], \tag{9.14}$$

where $H(x,y)$, $k(x,y)$, and $\tau(x,y)$ are arbitrary functions. Now $G_{11}+G_{22}=2\kappa p$ imposes an additional condition on (9.13) and (9.14) that leads to $H=0$ or

$$H=(A^2-\kappa/p)^{1/2}K/(2\kappa). \tag{9.15}$$

The case $H=0$ leads to the Gödel solution (see below), so we shall consider the more general case (9.15). Then, from (9.14),

$$h=[K/(2\kappa)]\{A+(A^2-\kappa/p)^{1/2}\,\sin[2(\kappa p)^{1/2}t+\tau]\}. \tag{9.16}$$

With such h, Eq. (9.13) can be integrated with the result

$$k=[2A(\kappa p)^{1/2}h]^{-1}(A^2-\kappa/p)^{1/2}\,\cos[2(\kappa p)^{1/2}t+\tau]+L(x,y), \tag{9.17}$$

where L is a new arbitrary function. The function l is then calculated from (9.6), and an explicit solution of Einstein's equations is determined by (9.16) and (9.17).

The transformations (5.6)–(5.7) with $T=$const can now be used to simplify the metric tensor so that $L=0$. The transformation that yields this is given in Appendix A. The still allowed coordinate transformations that preserve the property $L=0$ are given by (5.6)–(5.7) with $T=$const and with the additional condition

$$KF_{,x}F_{,y}+[\kappa/(A^2pK)]G_{,x}G_{,y}=0. \tag{9.18}$$

With $L=0$, from the equations $G_{01}=G_{02}=0$ one obtains further

$$\tau_{,x}=2y(\kappa p)^{1/2}-A(p/\kappa)^{1/2}K_{,y},$$
$$\tau_{,y}=-(\kappa/p)^{1/2}K_{,x}/(AK^2). \tag{9.19}$$

The integrability condition of (9.19) is

$$(p/\kappa)^{1/2}(AK)_{,yy}+(\kappa p)^{1/2}[1/(AK)]_{,xx}-2(\kappa p)^{1/2}=0. \tag{9.20}$$

By the same method as was used in Ref. 4 it can now be shown that Eq. (9.20) is at the same time the integrability condition for such a coordinate transformation (5.6)–(5.7)–(9.18) after which (see Appendix A again)

$$K=(\kappa/A)y^2, \tag{9.21}$$

and then (9.19) implies

$$\tau=c=\text{const.} \tag{9.22}$$

The value of c can be set arbitrarily by transformations of t of the form $t=t'+\text{const}$. To match Ref. 11 one should choose

$$c=-\pi/2. \tag{9.23}$$

Finally, the functions h, k, and l in (9.12) are thus

$$h=\tfrac{1}{2}y^2\{1+[1-\kappa/(pA^2)]^{1/2}\cos[2(\kappa p)^{1/2}t]\},$$
$$k=\tfrac{1}{2}[(\kappa p)^{1/2}h]^{-1}[1-\kappa/(pA^2)]^{1/2}\sin[2(\kappa p)^{1/2}t], \tag{9.24}$$
$$l=(4p^2A^2h)^{-1}.$$

This is equivalent under a simple coordinate transformation to the Ozsvath class III solution from Ref. 11.

The velocity field $u^\alpha=\delta^\alpha_0$ for this solution has nonzero shear. The shear will vanish if and only if:

$$A^2=\kappa/p, \tag{9.25}$$

and then the Gödel solution in the form (5.11) results.

The invariant definitions of the Ozsvath class III and of the Gödel solutions given at the end of Sec. I follow from the derivation in this section.

X. CONCLUDING REMARKS

These are the main results of the paper.

1. With nonzero rotation, any Killing field, existing for a metric whose matter source inherits the symmetry, must have the form (5.5) when represented in the Plebański coordinates. When $\phi_{;\alpha}\neq 0$, the Plebański coordinates can be adapted to the Killing field so that $k^\alpha=\delta^\alpha{}_1$.

2. When two of the generators of the group are spanned on the velocity and rotation vector fields, while the third one is not, the collection of solutions with a dust source is exhausted by the following two sets.

(a) The set of Sec. VII, defined by a single differential equation (7.24), where the metric is (7.15) with $A=k_{13}=0$, F defined by (7.23) and $y(Y)$ defined by (7.21).

(b) The set of Sec. VIII, where the metric is (7.15) with $b=0$, and the metric functions are defined by an autonomous set of first-order equations (8.1)–(8.3), (8.8), and (8.10) [the integral in (8.8) and (8.10) can be calculated if the variable is changed as in (8.9)].

3. The solutions of Lanczos[1,19] and Gödel[2] are limiting cases of both sets; their invariant definitions are given at the end of Sec. VII and of Sec. VIII.

4. With no symmetries pre-assumed, if the source is a rotating geodesic perfect fluid whose rotation vector field is covariantly constant, then the solution of the Einstein equations is the homogeneous (in four dimensions) Ozsvath class III solution.[11] If shear is zero in addition, then the Gödel solution (Ref. 2; see also Ref. 4) results.

Note the modification that the results 2(a) and 2(b) introduce in theorem 3.1 of King and Ellis.[42] Those authors considered spatially homogeneous models in which the velocity field of matter was tilted (i.e., was not orthogonal) with respect to the hypersurfaces of homogeneity. Theorem 3.1 says, among other things, that there are no tilted models of type I and that tilted models of type II have zero vorticity. Evidently, this does not apply to the case where the hypersurfaces of homogeneity are timelike. The solutions of Sec. VII are of Bianchi type II, they are ''tilted'' (because the velocity field is tangent to the hypersurfaces of homogeneity), yet rotation is not zero. The solutions of Sec. VIII are tilted in the same sense, yet they are of Bianchi type I.

Other solutions that have been published earlier will be mentioned where appropriate in papers 2 and 3. A general overview of literature on related subjects will be included in paper 3.

ACKNOWLEDGMENT

The algebraic calculations for this paper were done with the help of the program Ortocartan.[43,44]

APPENDIX A: THE TRANSFORMATION TO $L=0$ IN (9.17)

A transformation of the class (5.6)–(5.7) with $T=\text{const}$ changes the functions h and k to such ones that can be cast in the form (9.16) and (9.17), respectively, with the new functions K', τ', and L' expressed through the old ones as follows:

$$K'=K(F_{,x'}+LG_{,x'})^2+\kappa G_{,x'}^2/(A^2pK), \tag{A1}$$

$$\tau'=\tau-2(\kappa p)^{1/2}S+U, \tag{A2}$$

$$L'=K'^{-1}[KF_{,x'}F_{,y'}+2KLF_{,y'}G_{,x'}+KL+KL^2G_{,x'}G_{,y'}+\kappa G_{,x'}G_{,y'}/(A^2pK)], \tag{A3}$$

where S in (A2) is the function from (5.6)–(5.7) and U is determined by

$$\cot U=2A(\kappa p)^{1/2}[2G_{,x'}(F_{,x'}+LG_{,x'})]^{-1}[-K(F_{,x'}+LG_{,x'})^2/(2\kappa)+G_{,x'}^2/(2A^2pK)]. \tag{A4}$$

Note that we are applying here (5.6)–(5.7) in reverse, i.e., with the roles of x^α and x'^α interchanged. The functions of the inverse transformation, denoted again by S, F, G, and T, still obey (5.7). For consistency of all the formulae it is convenient to choose U from the segment $(\pi, 2\pi)$. Then, the limiting cases $G_{,x'}=0$ and $F_{,x'}+LG_{,x'}=0$ are included in (A4) as the limits $U=2\pi$ and $U=\pi$, respectively (these limiting cases occur when $L_{,xx}=0$ in the original coordinates).

From (A3), the equation $L'=0$ turns out to be consistent with (5.6)–(5.7). In order to see this, one can solve (A3) and (5.7) for $F_{,x'}$ and $F_{,y'}$ and then impose the integrability condition $F_{,x'y'}-F_{,y'x'}=0$. What comes out is a well-defined (though highly nonlinear) partial differential equation of second order for G whose coefficients depend only on K and L.

The transformation preserving the property $L=0$ are (5.6)–(5.7) with (9.18), the latter easily follows from (A3). Equation (A1) with $L=0$ then shows how K is changed by such a transformation; this is useful in showing that coordinates exist in which $K_{,x}=0$ [see the remark after (9.20)]. The proof is identical as in Appendix C to Ref. 4. Note that the conclusion in Ref. 4 is weaker than it could be: the $K(x)$ [$v(t)$ in Ref. 4] is determined up to an additive constant C. Hence, by a transformation of the form $y=y'+\text{const}$ and by an appropriate choice of C one can remove the linear and the constant terms in K (resp., v) so that $K\propto y^2$ (resp., $v\propto t^2$ in Ref. 4).

Rotating dust solutions of Einstein's equations with 3-dimensional symmetry groups. II. One Killing field spanned on u^α and w^α

Andrzej Krasiński
N. Copernicus Astronomical Center and College of Science, Polish Academy of Sciences, Bartycka 18, 00 716 Warszawa, Poland

(Received 10 June 1997; accepted for publication 8 July 1997)

This is the second part of a series of 3 papers. Using the same method and the same coordinates as in part 1, rotating dust solutions of Einstein's equations are investigated that possess 3-dimensional symmetry groups, under the assumption that only one of the Killing fields is spanned on the fields of velocity u^α and rotation w^α, while the other two define vectors that are linearly independent of u^α and w^α at every point of the spacetime region under consideration. The Killing fields are found and the Killing equations solved for the components of the metric tensor in every case that arises. The Einstein equations are simplified in a few cases, three (most probably) new solutions are found, and several classes of solutions known earlier are identified in the present scheme. They include those by Ozsváth, Maitra, Ellis, King, and Vishveshwara and Winicour. © *1998 American Institute of Physics.* [S0022-2488(97)03212-X]

I. SUMMARY OF THE METHOD

This is a concise summary of results that will be used in this paper. For proofs, motivations, and references see Paper 1.[1]

Every timelike vector field u^α of unit length that has zero acceleration and nonzero rotation defines the functions $\tau(x)$, $\eta(x)$, and $\xi(x)$ such that

$$u_\alpha=\tau_{,\alpha}+\eta\xi_{,\alpha}. \tag{1.1}$$

These functions are defined up to the transformations

$$\tau=\tau'-S(\xi',\eta'), \quad \xi=F(\xi',\eta'), \quad \eta=G(\xi',\eta'), \tag{1.2}$$

where the functions F and G obey

$$F_{,\xi'}G_{,\eta'}-F_{,\eta'}G_{,\xi'}=1 \tag{1.3}$$

(this guarantees that the Jacobian of the transformation is 1), and S is determined by

$$S_{,\xi'}=GF_{,\xi'}-\eta', \quad S_{,\eta'}=GF_{,\eta'}. \tag{1.4}$$

If u^α is the velocity field of a fluid whose number of particles is conserved:

$$(\sqrt{-g}nu^\alpha)_{,\alpha}=0 \tag{1.5}$$

(where g is the determinant of the metric tensor and n is the particle number density), then one more function $\zeta(x)$ exists such that

$$\sqrt{-g}nu^\alpha=\epsilon^{\alpha\beta\gamma\delta}\xi_{,\beta}\eta_{,\gamma}\zeta_{,\delta}, \tag{1.6}$$

and it is determined up to the transformations

$$\zeta=\zeta'+T(\zeta',\eta'). \tag{1.7}$$

Note that n is not defined uniquely by (1.5). For example, if $u^\alpha=\delta^\alpha_0$ and n obeys (1.5), then $n'=nf(x,y,z)$ (where f is an arbitrary function) will also obey (1.5). This nonuniqueness allows for a greater freedom in the choice of ζ than (1.7), and the freedom will be used in some cases.

The following relations hold:

$$u^\alpha\tau_{,\alpha}=1, \quad u^\beta\xi_{,\beta}=u^\beta\eta_{,\beta}=u^\beta\zeta_{,\beta}=0,$$

$$\frac{\partial(\tau,\eta,\xi,\zeta)}{\partial(x^0,x^1,x^2,x^3)}=\sqrt{-g}n\neq 0. \tag{1.8}$$

The last of (1.8) guarantees that $\{\tau,\xi,\eta,\zeta\}$ can be chosen as coordinates; they will be called Plebański coordinates. Then, with $\{\tau,\xi,\eta,\zeta\}=\{x^0,x^1,x^2,x^3\}=\{t,x,y,z\}$,

$$u_\alpha=\delta^\alpha{}_0, \quad u_\alpha=\delta^0{}_\alpha+y\,\delta^1{}_\alpha,$$

$$g_{00}=1, \quad g_{01}=y, \quad g_{02}=g_{03}=0, \quad g=\det(g_\alpha\beta)=-n^{-2}, \tag{1.9}$$

$$w^\alpha=n\,\delta^\alpha_3, \quad \omega_{\alpha\beta}=-\omega_{\beta\alpha}=(1/2)\,\delta^1{}_\alpha\delta^2{}_\beta,$$

where w^α is the rotation vector field, and $\omega_{\alpha\beta}$ is the rotation tensor corresponding to the velocity field u_α:

$$\omega_{\alpha\beta}=\tfrac{1}{2}\,(u_{\alpha,\beta}-u_{\beta,\alpha}-\dot{u}_\alpha u_\beta+\dot{u}_\beta u_\alpha), \quad w^\alpha=-(1/\sqrt{-g})\,\epsilon^{\alpha\beta\gamma\delta}u_\beta\omega_{\gamma\delta}. \tag{1.10}$$

If $\omega_{\alpha\beta}\neq 0$ and $\dot{u}^\alpha=0$ (what is assumed throughout), then necessarily the pressure $p=\text{const}$ and κp may be interpreted as the cosmological constant ($\kappa:=8\pi G/c^4$).

If any Killing vector field exists on a manifold (on which all the assumptions specified so far are fulfilled), then, in the coordinates of (1.9), it must be of the form

$$k^\alpha=(C+\phi-y\phi_{,y})\,\delta^\alpha{}_0+\phi_{,y}\delta^\alpha{}_1-\phi_{,x}\delta^\alpha{}_2+\lambda\,\delta^\alpha{}_3, \tag{1.11}$$

where C is an arbitrary constant and $\phi(x,y)$ and $\lambda(x,y)$ are arbitrary functions of two coordinates. Whenever $\phi_{,\alpha}\neq 0$, a transformation of the class (1.2)–(1.4) can be found that leads to

$$k^\alpha=\delta^\alpha{}_1. \tag{1.12}$$

The metric then becomes independent of x, and the coordinates preserving (1.12) are determined up to the transformations

$$t'=t-\int yH_{,y}dy+A, \quad x'=x+H(y), \quad y'=y, \quad z'=z+T(y), \tag{1.13}$$

where A is an arbitrary constant and H,T are arbitrary functions.

The condition $\phi_{,\alpha}\neq 0$ that allows one to fulfill (1.12) means that the Killing vector k^α is linearly independent of the vectors u^α and w^α at every point of the spacetime region under consideration. In Paper 1, solutions of the Killing equations and of the Einstein equations were considered under the assumption that there exist three Killing vector fields on the manifold, two of which have $\phi=\text{const}$ in (1.11), while the third one has $\phi_{,\alpha}\neq 0$ and can be transformed to the form (1.12). In the present paper it is assumed that only one Killing field has $\phi=\text{const}$ (it will be $k_{(3)}$; see below), and two have $\phi_{,\alpha}\neq 0$. Only one of the two can then be transformed to the form (1.12) (it will be $k_{(1)}$); the other one ($k_{(2)}$) will preserve its general form (1.11).

In the whole paper, whenever reference is made to the Einstein tensor, the components quoted are projections of the coordinate components $G_{\alpha\beta}$ onto the orthonormal tetrad $e_i{}^\alpha$, i.e., $G_{ij} = e_i{}^\alpha e_j{}^\beta G_{\alpha\beta}$. In every case it will be self-evident how the tetrad is defined.

II. THE LIE ALGEBRA OF THE SYMMETRY GROUP

According to the assumptions made in the preceding section, there exist the following three Killing vector fields:

$$\begin{aligned} k^\alpha_{(1)} &= \delta^\alpha_1, \\ k^\alpha_{(2)} &= (C_2 + \phi - y\phi_{,y})\delta^\alpha_0 + \phi_{,y}\delta^\alpha_1 - \phi_{,x}\delta^\alpha_2 + \lambda_2(x,y)\delta^\alpha_3, \\ k^\alpha_{(3)} &= C_3\delta^\alpha_0 + \lambda_3(x,y)\delta^\alpha_3, \end{aligned} \tag{2.1}$$

where C_2 and C_3 are arbitrary constants, and ϕ, λ_2, and λ_3 are unknown functions of (x,y), to be determined from the commutation relations. The coordinates of (2.1) are determined up to (1.13).

The fields $k_{(1)}$, $k_{(2)}$, and $k_{(3)}$ will form a Lie algebra if constants $a,\ldots,j$ exist such that

$$\begin{aligned} [k_{(1)},k_{(2)}] &= ak_{(1)} + bk_{(2)} + ck_{(3)}, \\ [k_{(1)},k_{(3)}] &= dk_{(1)} + ek_{(2)} + fk_{(3)}, \\ [k_{(2)},k_{(3)}] &= gk_{(1)} + hk_{(2)} + jk_{(3)}, \end{aligned} \tag{2.2}$$

Eqs. (2.2) are equivalent to the following set:

$$\phi_{,x} - y\phi_{,xy} = b(C_2 + \phi - y\phi_{,y}) + cC_3, \tag{2.3a}$$

$$\phi_{,xy} = a + b\phi_{,y}, \tag{2.3b}$$

$$\phi_{,xx} = b\phi_{,x}, \tag{2.3c}$$

$$\lambda_{2,x} = b\lambda_2 + c\lambda_3, \tag{2.3d}$$

$$e(C_2 + \phi - y\phi_{,y}) + fC_3 = 0, \tag{2.3e}$$

$$d + e\phi_{,y} = 0, \tag{2.3f}$$

$$e\phi_{,x} = 0, \tag{2.3g}$$

$$\lambda_{3,x} = e\lambda_2 + f\lambda_3, \tag{2.3h}$$

$$h(C_2 + \phi - y\phi_{,y}) + jC_3 = 0, \tag{2.3i}$$

$$g + h\phi_{,y} = 0, \tag{2.3j}$$

$$h\phi_{,x} = 0, \tag{2.3k}$$

$$\phi_{,y}\lambda_{3,x} - \phi_{,x}\lambda_{3,y} = h\lambda_2 + j\lambda_3. \tag{2.3l}$$

A few of these equations imply alternatives that will have to be considered separately. The alternatives will be organized into a binary tree and numbered in a positional system that will enable one to quickly identify complementary cases (see Fig. 1). Of the two alternatives implied by (2.3g) we choose for the beginning, the following.

Case 1: $\phi_{,x} \neq 0$.

This implies, from Eqs. (2.3g), (2.3k), (2.3f), and (2.3j)

$$e = h = d = g = 0. \tag{2.4}$$

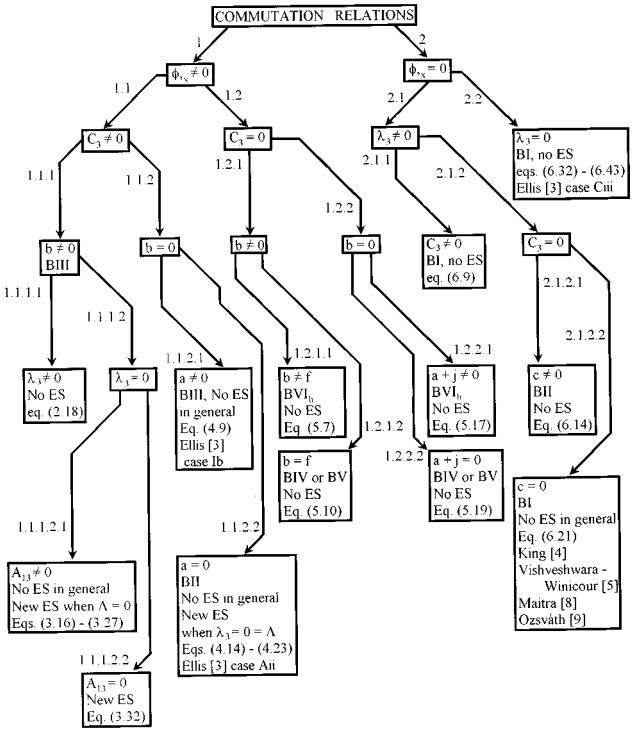

FIG. 1. The classes of metrics considered in the paper. Arrows point from more general classes to subclasses. The numbers at arrows are the case-numbers used in the text. The first entry in each rectangle is the property defining the case; all the symbols are introduced in Eqs. (2.1)–(2.3). The subsequent entries give the following information: 1. The Bianchi type of the corresponding algebra (2.2); 2. Information about the exact solutions (ES) known before or found in this paper; 3. The equation-numbers corresponding to the final result in the given case; 4. References to papers in which solutions of the given class were discussed.

Equations (2.3a)–(2.3d) survive unchanged, while the remaining ones simplify to

$$fC_3 = 0, \tag{2.5e}$$

$$\lambda_{3,x} = f\lambda_3, \tag{2.5h}$$

$$jC_3 = 0, \tag{2.5i}$$

$$\phi_{,y}\lambda_{3,x} - \phi_{,x}\lambda_{3,y} = j\lambda_3, \tag{2.5l}$$

other equations being fulfilled identically. Now we choose the following.

Case 1.1: $C_3 \neq 0$,

which implies, from (2.5),

$$f = j = 0, \tag{2.6}$$

$$\lambda_3 = \lambda_3(y), \tag{2.7h}$$

$$\phi_{,x}\lambda_{3,y} = 0. \tag{2.7l}$$

With (2.4) and (2.6), the second and third commutator in (2.2) are zero. Since in Case 1 $\phi_{,x} \neq 0$ by assumption, Eqs. (2.7h) and (2.7l) imply

$$\lambda_3 = \text{const}. \tag{2.8}$$

The solution of (2.3d) depends on whether $b=0$ or $b\neq 0$, so we follow now with case 1.1.1

Case 1.1.1: $b\neq 0$.

Then, from (2.3d),

$$\lambda_2=\beta(y)e^{bx}-c\lambda_3/b, \tag{2.9}$$

and from (2.3a)–(2.3c),

$$\phi=\alpha(y)e^{bx}-(a/b)y-C_2-(c/b)C_3, \tag{2.10}$$

where $\alpha(y)$ and $\beta(y)$ are arbitrary functions. The assumption $\phi_{,x}\neq 0$ implies $\alpha\neq 0$. The basis of the Killing vector fields can be changed to $k_{(1)}$, $k'_{(2)}=k_{(2)}+(c/b)k_{(3)}+(a/b)k_{(1)}$, and $k_{(3)}$. In the new basis,

$$k'^{\alpha}_{(2)}=e^{bx}[(\alpha-y\alpha_{,y})\delta^{\alpha}_0+\alpha_{,y}\delta^{\alpha}_1-b\alpha\delta^{\alpha}_2+\beta\delta^{\alpha}_3] \tag{2.11}$$

(i.e., by taking $k'_{(2)}$ instead of $k_{(2)}$, $c=0$ was achieved). The transformation (1.13) with $H=(1/b)\ln\alpha$, $T=(1/b)\int(\beta/\alpha)dy$ will now have the same effect as if $\beta=0$, $\alpha=1$. Finally, then, the following basis of the Killing vector fields resulted:

$$k^{\alpha}_{(1)}=\delta^{\alpha}_1, \quad k^{\alpha}_{(2)}=e^{bx}(\delta^{\alpha}_0-b\delta^{\alpha}_2), \quad k^{\alpha}_{(3)}=C_3\delta^{\alpha}_0+\lambda_3\delta^{\alpha}_3, \tag{2.12}$$

but from now on the transformations (1.13) are allowed only with H and T being constants. The commutation relations are

$$[k_{(1)},k_{(3)}]=[k_{(2)},k_{(3)}]=0, \quad [k_{(1)},k_{(2)}]=bk_{(2)}, \tag{2.13}$$

and they correspond to Bianchi type III. In virtue of the commutator $[k_{(1)},k_{(3)}]$ being zero, coordinates can be adapted to $k_{(1)}$ and $k_{(3)}$ simultaneously so that $k^{\alpha'}_{(1)}=\delta^{\alpha'}_1$, $k^{\alpha'}_{(3)}=\delta^{\alpha'}_0$. The transformation is

$$(t',x',y')=(t,x,y), \quad z'=-\lambda_3 t+C_3 z; \tag{2.14}$$

it is nonsingular because Case 1.1 was defined by $C_3\neq 0$, but it leads out of the Plebański class of coordinates used so far. In the new coordinates (primes dropped), the metric is independent of x and t, and

$$\begin{gathered} k^{\alpha}_{(2)}=e^{bx}(\delta^{\alpha}_0-b\delta^{\alpha}_2-\lambda_3\delta^{\alpha}_3), \\ u^{\alpha}=\delta^{\alpha}_0-\lambda_3\delta^{\alpha}_3, \quad w^{\alpha}=nC_3\delta^{\alpha}_3, \\ g_{00}=1+\lambda_3{}^2 g_{33}, \quad g_{01}=y+\lambda_3 g_{13}, \\ g_{02}=\lambda_3 g_{23}, \quad g_{03}=\lambda_3 g_{33}. \end{gathered} \tag{2.15}$$

Now the Killing equations involving $k_{(2)}$ have to be solved for the components of the metric tensor. For this purpose, two cases have to be considered separately: $\lambda_3\neq 0$ and $\lambda_3=0$.

Case 1.1.1.1: $\lambda_3\neq 0$.

It is convenient to change the coordinates yet again to

$$(t',x')=(t,x), \quad Y=\lambda_3 y+bz, \quad Z=\lambda_3 y-bz. \tag{2.16}$$

The vector fields u^{α}, w^{α}, and $k^{\alpha}_{(i)}$ become (primes dropped)

$$\begin{gathered} u^{\alpha}=\delta^{\alpha}_0-b\lambda_3(\delta^{\alpha}_2-\delta^{\alpha}_3), \quad w^{\alpha}=bC_3 n(\delta^{\alpha}_2-\delta^{\alpha}_3), \\ k^{\alpha}_{(1)}=\delta^{\alpha}_1, \quad k^{\alpha}_{(3)}=\delta^{\alpha}_0, \quad k^{\alpha}_{(2)}=e^{bx}(\delta^{\alpha}_0-2b\lambda_3\delta^{\alpha}_3), \end{gathered} \tag{2.17}$$

and the metric tensor, after the transformation (2.16) and after solving the Killing equations becomes (primes dropped again)

$$
\begin{aligned}
g_{00}&=1+(\lambda_3 b)^2(g_{22}+g_{33}-2g_{23}),\\
g_{01}&=\frac{1}{2\lambda_3}\,(Y+Z)-\frac{1}{2}\,b^2\lambda_3 Y(g_{22}-g_{33})+\lambda_3 h_{13},\\
g_{02}&=b\lambda_3(g_{22}-g_{23}),\quad g_{03}=b\lambda_3(g_{23}-g_{33}),\\
g_{11}&=\left(\frac{Y}{2\lambda_3}\right)^2+\frac{1}{2\lambda_3^2}\,YZ+\left(\frac{1}{2}\,bY\right)^2(g_{22}+g_{33}+2g_{23})-\frac{b}{\lambda_3}\,h_{12}Y+h_{11},\\
g_{12}&=-\frac{1}{2}\,bY(g_{22}+g_{23})+\frac{1}{2\lambda_3}\,h_{12}+\frac{1}{2b}\,h_{13},\\
g_{13}&=-\frac{1}{2}\,bY(g_{23}+g_{33})+\frac{1}{2\lambda_3}\,h_{12}-\frac{1}{2b}\,h_{13},
\end{aligned}
\tag{2.18}
$$

where $h_{11}(Z)$, $h_{12}(Z)$, $h_{13}(Z)$, $g_{22}(Z)$, $g_{23}(Z)$, and $g_{33}(Z)$ are functions to be determined from the Einstein equations.

No progress was made with the Einstein equations in full generality in this case. Progress may be possible with additional simplifying assumptions (e.g., orthogonality relations among the Killing fields).

No solutions belonging to this case have been identified in the existing literature.

III. CASE 1.1.1.2: $\lambda_3=0$

We go back to (2.15). With $\lambda_3=0$, the coordinates of (2.15) are still in the Plebański class [the factor C_3 in w^α is allowable because n is not defined uniquely by (1.5); see the comment after (1.7)]. The formulae (2.15) still apply, with $\lambda_3=0$, and the Killing equations involving $k_{(2)}$ are solved by

$$
\begin{aligned}
g_{11}&=y^2+(by)^2 g_{22}(z)-2byh_{12}(z)+h_{11}(z),\\
g_{12}&=-byg_{22}+h_{12},\quad g_{13}=-byg_{23}(z)+h_{13}(z),
\end{aligned}
\tag{3.1}
$$

the $h_{ij}(z)$, $g_{22}(z)$, $g_{23}(z)$, and $g_{33}(z)$ being arbitrary functions. The following inequalities hold:

$$
g_{33}<0,\quad g_{22}<0,\quad g_{33}-{g_{23}}^2/g_{22}:=h_{33}<0,
\tag{3.2}
$$

for the following reasons, respectively: (i) the rotation field must be spacelike everywhere; (ii) and (iii) the determinant of the metric $g<0$ or else the metric has an unphysical signature. In virtue of (3.2) one can define the functions K_{11},K_{22},K_{33} and H_{12},H_{13},H_{23} by

$$
\begin{aligned}
{K_{11}}^2&=h_{12}^2/g_{22}+(h_{13}-h_{12}g_{23}/g_{22})^2/h_{33}-h_{11},\\
{K_{22}}^2&=-g_{22},\quad {K_{33}}^2=-h_{33},\\
H_{12}&=h_{12}/g_{22},\quad H_{23}=g_{23}/g_{22},\\
H_{13}&=h_{13}/h_{33}-h_{12}g_{23}/(g_{22}h_{33}),
\end{aligned}
\tag{3.3}
$$

the appropriate sign of ${K_{11}}^2$ being guaranteed by the signature $(+---)$ assumed throughout. [Definitions analogous to (3.3) will be introduced in several other cases in this paper. In each case, the appropriate inequalities are fulfilled for the same reasons.] With these definitions, the metric form (2.15)–(3.1) may be written as

$$ds^2=(dt+ydx)^2-(K_{11}dx)^2-\{K_{22}[(-by+H_{12})dx+dy+H_{23}dz]\}^2-[K_{33}(H_{13}dx+dz)]^2. \tag{3.4}$$

Equation (3.4) defines the orthonormal tetrad used in this section, and the tetrad is comoving, i.e., the velocity field coincides with the tetrad vector #0: $u_\alpha={e^0}_\alpha$. Without loss of generality it may be assumed that

$$K_{33}=1, \tag{3.5}$$

because this result is achieved by the coordinate transformation $z'=\int K_{33}dz$ and redefinitions of H_{13} and H_{23}. The transformation leads to a rescaling of w^α in (2.15), but, taking into account the nonuniqueness of the definition of n through (1.5), the new coordinates are effectively still in the Plebański class.

The Einstein equation $G_{01}=0$ is now integrated with the result

$$H_{23}=A_{23}K_{11}/K_{22}, \tag{3.6}$$

(A and B with indices will denote arbitrary constants). Equation (3.6) substituted into $G_{03}=0$ implies $bA_{23}/(2K_{11}K_{22})=0$, and since this is within the case 1.1.1 defined by $b\neq 0$, the result is

$$A_{23}=0=H_{23}. \tag{3.7}$$

Now $G_{02}=0$ implies

$$H_{13}=A_{13}K_{11}K_{22}, \tag{3.8}$$

and $G_{12}=0$ implies

$$H_{12,z}=B_{12}K_{11}/{K_{22}}^3. \tag{3.9}$$

Using (3.7)–(3.9) in $G_{23}=0$ one obtains $bB_{12}/(K_{11}{K_{22}}^2)=0$, and so

$$B_{12}=0, \quad H_{12}=\text{const.} \tag{3.10}$$

The coordinate transformation $t=t'-H_{12}\,x/b$, $y=y'+H_{12}/b$ has the same effect as if

$$H_{12}=0, \tag{3.11}$$

which will be assumed from now on. [The transformation preserves $k^\alpha_{(2)}, k^\alpha_{(3)}, u^\alpha, w^\alpha$ and transforms $k^\alpha_{(1)}$ into ${k'}^\alpha_{(1)}=\delta^\alpha_1+(H_{12}/b)k^\alpha_{(3)}$, i.e., in the Killing fields $H_{12}=0$ can be achieved by a change of basis in the Lie algebra.] In a further analysis two subcases have to be considered separately.

Case 1.1.1.2.1: $A_{13}\neq 0$.

It is convenient to go over to the standard Bianchi-type coordinates in which $g_{33}=-1$ while $g_{03}=g_{13}=g_{23}=0$. The following transformations do it: in the first step we transform

$$t=T-F(z)Y, \quad x=X+[\ln(bF)]/b, \quad y=bYF, \tag{3.12}$$

where $F(z)$ is determined by

$$F_{,z}/F=-bA_{13}K_{22}/[K_{11}(1+A_{13}^2K_{22}^2)] \tag{3.13}$$

(the right-hand side is finite and nonzero because of assumptions made earlier). This leads to $g_{0a}=0$. Then we transform $z=H(Z)$, where

$$\frac{dH}{dZ}=(1+A_{13}{}^2K_{22}{}^2)^{1/2} \tag{3.14}$$

and thereby achieve $g_{33}=-1$. Denoting

$$L_{11}=K_{11}\frac{dH}{dZ}, \quad L_{22}=bFK_{22}, \tag{3.15}$$

we obtain the following metric form:

$$ds^2=[dT+F(Z)(bYdX-dY)]^2-[L_{11}(Z)dX]^2-[L_{22}(Z)(-bYdX+dY)]^2-dZ^2, \tag{3.16}$$

the coordinates no longer being in the Plebański class.

The Einstein equation $G_{02}=0$ implies

$$F_{,z}=AL_{22}/L_{11}, \tag{3.17}$$

where A is an arbitrary constant. Equation (3.17) can be integrated if the new variable z' is introduced by

$$z',_Z=L_{22}/L_{11}; \tag{3.18}$$

then

$$F(z')=Az'+B, \quad B=\text{const.} \tag{3.19}$$

With z' in place of Z, the equation $G_{13}=0$ is solved by

$$L_{11}=CL_{22}\exp\left[-\frac{1}{2}\int (AF/L_{22}{}^2)dz'\right]. \tag{3.20}$$

The only tetrad components of the Einstein tensor that are still nonzero are the diagonal ones. It may be verified that $G_{11}-G_{22}\equiv 0$ in virtue of (3.17)–(3.20), while $G_{11}-G_{33}=0$ follows by differentiation of $G_{33}=\Lambda$ in virtue of (3.20). Hence, the latter is the last equation to solve, and it is

$$(L_{22}L_{22,z'})^2-\tfrac{1}{2}AFL_{22}L_{22,z'}+(b^2+A^2/4)L_{22}{}^2-\tfrac{1}{4}(bF)^2=\Lambda(L_{11}L_{22})^2. \tag{3.21}$$

Equation (3.21) is an integro-differential equation. Substituting for L_{11} from (3.20) and differentiating by z', it can be changed into an ordinary second-order differential equation that determines $L_{22}(z')$, and then L_{11} can be (in principle) calculated from (3.20). No further progress in solving the Einstein equations was achieved in the general case.

The coordinates of (3.16) are still comoving, while the rotation vector field is

$$w^\alpha=L_{11}{}^{-2}(-A\delta_1^\alpha-bAY\delta_2^\alpha+bF\delta_3^\alpha). \tag{3.22}$$

The case $A=0$ that is seen to be simpler is equivalent [via (3.17) and (3.13)] to $A_{13}=0$ or $b=0$, and these were set aside for separate consideration. The matter density is

$$\kappa\epsilon = -3\Lambda + [bF/(L_{11}L_{22})]^2 + (A/L_{11})^2. \tag{3.23}$$

When $\Lambda = 0$, an elementary solution exists. Equation (3.21) has then the integral

$$L_{22}{}^2 = \tfrac{1}{4}\,[F^2 - (A^2 + 4b^2)(z' + D)^2], \tag{3.24}$$

where D is an arbitrary constant, and L_{11} is found from (3.20) to be

$$L_{11} = CW_1^{\alpha_1} W_2^{\alpha_2}, \tag{3.25}$$

where

$$\alpha_{1,2} = \frac{1}{8b^2}\,[(A^2 + 4b^2)^{1/2} \pm A]^2, \tag{3.26}$$

and W_1, W_2 are the two factors of (3.24):

$$W_{1,2} = \tfrac{1}{2}\,[F \mp (A^2 + 4b^2)^{1/2}(z' + D)]. \tag{3.27}$$

A (modestly thorough) search through the literature by this author has not turned up any rotating dust Bianchi-type III solution with the same configuration of the Killing, velocity, and rotation vector fields as here. (The method used in the search will be disclosed in Paper 3.) Hence, (3.16)–(3.27) is tentatively proposed as a new solution.

Case 1.1.1.2.2: $A_{13} = 0$.

The invariant meaning of $A_{13} = 0$ is that the Killing field $k^{\alpha}_{(1)}$ is everywhere orthogonal to the rotation field. We go back to (3.11). The equation $G_{13} = 0$ [in the coordinates of (3.4) with later simplifications] implies

$$K_{22} = A_{22}K_{11}. \tag{3.28}$$

The equation $G_{22} + G_{33} = 2\Lambda$ is integrated with the result

$$(K_{11}K_{11,z})^2 = \Lambda K_{11}{}^4 - bK_{11}{}^2 + C, \tag{3.29}$$

where C is an arbitrary constant. Using this result in $G_{22} = \Lambda$ we obtain

$$C = 1/(4A^2). \tag{3.30}$$

The case $K_{11,z} = 0$ leads to the Gödel solution.[2] When $K_{11,z} \neq 0$, the coordinate transformation,

$$K_{11}(z) = Z, \tag{3.31}$$

leads to the following solution:

$$ds^2 = (dt + ydx)^2 - (Zdx)^2 - [AZ(-bydx + dy)]^2 - [\Lambda Z^2 - b^2 + 1/(2AZ)^2]^{-1} dZ^2. \tag{3.32}$$

The matter–density is

$$\kappa\epsilon = -3\Lambda + 1/(A^2 Z^4). \tag{3.33}$$

With such a simple solution as (3.32) it is rather improbable that it could be still unknown. Nevertheless, the remark made after Eq. (3.27) applies also here.

The subcase $\Lambda = 0$ of (3.32) is a coordinate transform of the subcase $A = 0$ of (3.16)–(3.27).

IV. CASE 1.1.2: $b=0$

We go back to (2.8). From Eqs. (2.3)–(2.8) we have

$$\phi=axy+cC_3x+\alpha(y), \quad \lambda_2=c\lambda_3x+\beta(y), \tag{4.1}$$

where α and β are unknown functions and the other symbols are constants. Applying to the resulting Killing vector fields the change of basis $k'_{(2)}=k_{(2)}-(C_2/C_3)k_{(3)}$ and the coordinate transformation (1.13) with $H=\alpha/(ay+cC_3)$, $T_{,y}=(\beta-c\lambda_3H)/(ay+cC_3)$ (the denominators are nonzero because of the assumption $\phi_{,x}\neq 0$ defining case 1), we obtain the result

$$k^\alpha_{(2)}=cC_3x\,\delta^\alpha_0+ax\,\delta^\alpha_1-(ay+cC_3)\,\delta^\alpha_2+c\lambda_3x\,\delta^\alpha_3, \tag{4.2}$$

the other Killing fields being as in (2.1). The commutation relations are

$$[k_{(1)},k_{(2)}]=ak_{(1)}+ck_{(3)}, \quad [k_{(1)},k_{(3)}]=0=[k_{(2)},k_{(3)}]. \tag{4.3}$$

The Bianchi type of this algebra is III when $a\neq 0$ and II when $a=0\neq c$ ($a=c=0$ is excluded by the assumption $\phi_{,x}\neq 0$ made in case 1).

In order to adapt the coordinates to $k_{(1)}$ and $k_{(3)}$, the following coordinate transformation is now carried out:

$$(t',x',y')=(t,x,y), \quad z'=-\lambda_3t+C_3z, \tag{4.4}$$

after which (primes dropped)

$$u^\alpha=\delta^\alpha_0-\lambda_3\delta^\alpha_3, \quad k^\alpha_{(2)}=cx\,\delta^\alpha_0+ax\,\delta^\alpha_1-(ay+c)\,\delta^\alpha_2, \tag{4.5}$$

but for solving the Killing equations, the cases $a\neq 0$ and $a=0$ have to be considered separately. We first consider the following.

Case 1.1.2.1: $a\neq 0$.

Then the Killing equations imply

$$\begin{gathered}
g_{00}=1+\lambda_3{}^2g_{33}, \quad g_{01}=y+\lambda_3g_{13}, \quad g_{02}=\lambda_3g_{23}, \quad g_{03}=\lambda_3g_{33},\\
g_{11}=-\frac{2c}{a}\,y-\left(\frac{c}{a}\right)^2+\left(\frac{c\lambda_3}{a}\right)^2g_{33}-\frac{2c\lambda_3}{a}\,(ay+c)h_{13}+(ay+c)^2h_{11},\\
g_{12}=-\frac{c\lambda_3}{a(ay+c)}\,h_{23}+h_{12}, \quad g_{13}=-\frac{c\lambda_3}{a}\,g_{33}+(ay+c)h_{13},\\
g_{22}=h_{22}/(ay+c)^2, \quad g_{23}=h_{23}/(ay+c),
\end{gathered} \tag{4.6}$$

where $g_{33}(z)$ and all $h_{ij}(z)$ are arbitrary functions. In order to introduce an orthonormal tetrad, the following new functions are defined:

$$\begin{gathered}
K_{33}{}^2=-g_{33}, \quad H_{22}=h_{22}-h_{23}{}^2/g_{33}, \quad K_{22}{}^2=-H_{22},\\
H_{12}=(h_{12}-h_{13}h_{23}/g_{33})/H_{22},\\
K_{11}{}^2=1/a^2+h_{13}{}^2/g_{33}+H_{12}{}^2H_{22}-h_{11},\\
H_{13}=h_{13}/g_{33}, \quad H_{23}=h_{23}/g_{33}.
\end{gathered} \tag{4.7}$$

After the coordinate transformation,

$$t=T+cx/a, \quad y=(e^{aY}-c)/a, \quad (x',z')=(x,z), \tag{4.8}$$

the metric form becomes

$$ds^2=(dT+a^{-1}e^{aY}dx)^2-(K_{11}e^{aY}dx)^2-[K_{22}(e^{aY}H_{12}dx+dY)]^2-[K_{33}(\lambda_3 dT+H_{13}e^{aY}dx + H_{23}dY+dz)]^2, \tag{4.9}$$

and the Killing fields become

$$k^\alpha_{(1)}=\delta^\alpha_1, \quad k^\alpha_{(2)}=ax\,\delta^\alpha_1-\delta^\alpha_2, \quad k^\alpha_{(3)}=\delta^\alpha_0. \tag{4.10}$$

No progress was made with the Einstein equations for (4.9). However, a large subset of solutions by Ellis[3] is contained here when $0=\lambda_3=H_{13}=H_{23}=H_{12}$ (the first condition means that the velocity field is a Killing field; the next two conditions mean that the Killing fields $k^\alpha_{(1)}$ and $k^\alpha_{(2)}$ are orthogonal to rotation; the invariant interpretation of the last condition is unknown). It is the case Ib of Ellis, but not in full generality. Ellis' function t, when expressed as a function of Ellis' $y(x^2)$, obeys

$$2c^2(t^2)_{,yy}+K=0, \tag{4.11}$$

where c and K are constants [it is Ellis' Eq. (4.20), appropriately transformed]. The t^2 implied by (4.11) is a polynomial of second degree. Only when the discriminant Δ of the polynomial is zero will Ellis' case Ib be a subcase of (4.9). The reason for this is that with $\Delta\neq 0$ the Ellis case Ib has a four-dimensional symmetry group acting multiply transitively on 3-dimensional orbits, and the group has no 3-dimensional subgroups. Only with $\Delta=0$ a 3-dimensional subgroup exists.

Case 1.1.2.2: $a=0$

As stated before, the Bianchi type is now II. We go back to (4.5). With $a=0\neq c$, it can be assumed that $c=1$ with no loss of generality. The velocity field and the Killing fields are

$$u^\alpha=\delta^\alpha_0-\lambda_3\delta^\alpha_3, \quad k^\alpha_{(1)}=\delta^\alpha_1, \quad k^\alpha_{(2)}=x\,\delta^\alpha_0-\delta^\alpha_2, \quad k^\alpha_{(3)}=\delta^\alpha_0, \tag{4.12}$$

and the Killing equations imply

$$\begin{gathered} g_{00}=1+\lambda_3{}^2 g_{33}, \quad g_{01}=y+\lambda_3 g_{13}, \quad g_{02}=\lambda_3 g_{23}, \quad g_{03}=\lambda_3 g_{33}, \\ g_{11}=(1+\lambda_3{}^2 g_{33})y^2+2\lambda_3 y h_{13}+h_{11}, \\ g_{12}=\lambda_3 y g_{23}+h_{12}, \quad g_{13}=\lambda_3 y g_{33}+h_{13}, \end{gathered} \tag{4.13}$$

where $g_{22}(z)$, $g_{23}(z)$, $g_{33}(z)$ and the $h_{ij}(z)$ are arbitrary functions. The new functions K_{ii} and H_{ij} are defined by (4.7) with $a\to\infty$ and $h_{23}=g_{23}$. The metric is then

$$ds^2=(dt+ydx)^2-(K_{11}dx)^2-(H_{12}dx+K_{22}dy)^2-\{K_{33}[\lambda_3 dt+(\lambda_3 y+H_{13})dx+H_{23}dy+dz]\}^2. \tag{4.14}$$

Again, no progress with the Einstein equations was made at this level of generality. However, further progress was possible when

$$\lambda_3=0, \tag{4.15}$$

which means, from (4.12), that the velocity field itself becomes a Killing field. Then, by a transformation of z and a few redefinitions,

$$K_{33}=1 \tag{4.16}$$

can be achieved, and this will be assumed from now on. Some of the subcases implied by the Einstein equations turn out to be empty, so they will be mentioned only briefly. The first alternative is H_{23} being zero or nonzero. However, in both cases the Einstein equations together with coordinate transformations lead to the conclusion

$$H_{13}=0 \tag{4.17}$$

(which means $g_{\alpha\beta}k^{\alpha}_{(1)}w^{\beta}=0$). Then the equation $G_{01}=0$ is integrated with the result $H_{23}=A_{23}K_{11}K_{22}$ (the A_{ij} being arbitrary constants). Further integration of the Einstein equations must proceed separately for $A_{23}\neq 0$ and for $A_{23}=0$. However, the case $A_{23}\neq 0$ leads to a plain contradiction, and so the only case to consider is

$$H_{23}=0=A_{23} \tag{4.18}$$

(which means $g_{\alpha\beta}k^{\alpha}_{(2)}w^{\beta}=0$). The equation $G_{12}=0$ is then integrated with the result

$$H_{12,z}=H_{12}K_{22,z}/K_{22}+A_{12}K_{11}/K_{22}{}^2. \tag{4.19}$$

From $G_{11}-G_{22}$ we have

$$(K_{11}K_{22,z}-K_{22}K_{11,z})_{,z}-A_{12}{}^2K_{11}/K_{22}{}^3=0. \tag{4.20}$$

With the new variable $u(z)$ defined by

$$u_{,z}=K_{11}/K_{22}{}^3, \tag{4.21}$$

Eq. (4.20) can be integrated with the result

$$(K_{11}/K_{22})^2=-(A_{12}u)^2-2Bu+C:=W(u), \tag{4.22}$$

where B and C are arbitrary constants. With the help of (4.22), K_{11} is eliminated from the Einstein equations, and then $G_{33}=\Lambda$ remains as the only independent equation in the set. It may be written as

$$2WK_{22,u}/K_{22}=A_{12}{}^2u+B\pm(B^2+CA_{12}{}^2+1+4\Lambda WK_{22}{}^4)^{1/2}. \tag{4.23}$$

When $\Lambda=0$, this has simple elementary solutions, but several cases require separate treatment [$A_{12}\neq 0$ with $(B^2+CA_{12}{}^2)$ being positive, zero or negative, $A_{12}=0\neq B$], so (4.23) will be left as the most compact notation. This is again tentatively proposed as a new solution [the metric is defined by (4.14)–(4.19), (4.22), and (4.23)].

When $A_{12}=0$, these equations define a coordinate transform of Ellis' case Aii.[3] Then $H_{12}=B_{12}K_{22}$ from (4.19) and $B_{12}=0$ results by a coordinate transformation. The invariant meaning of the condition $A_{12}=0$ is not known to this author. With such an interpretation at hand, a new invariant definition of the Ellis case Aii would result.

V. CASE 1.2: $C_3=0$

We go back to Eqs. (2.3)–(2.5), and immediately have to consider separately the cases $b\neq 0$ and $b=0$. We take first the following.

Case 1.2.1: $b\neq 0$.

Equations (2.3a–2.3c) then imply

$$\phi=\alpha(y)e^{bx}-ay/b-C_2, \tag{5.1}$$

where α is an arbitrary function, $\alpha\neq 0$ because of the assumption $\phi_{,x}\neq 0$. Equation (2.5h) implies

$$\lambda_3=\mu(y)e^{fx}, \tag{5.2}$$

where μ is an arbitrary function; $\mu\neq 0$ because otherwise the symmetry group becomes two-dimensional. Equation (2.5l) then implies

$$\mu=B\alpha^{f/b}, \quad j=-af/b, \tag{5.3}$$

where B is an arbitrary constant. For further integration, the cases $f\neq b$ and $f=b$ have to be considered separately.

Case 1.2.1.1: $b\neq f$.

The Killing fields that result here, after a simplification of the basis by $k'_{(2)}=k_{(2)}-(a/b)k_{(1)}-[c/(f-b)]k_{(3)}$, are:

$$\begin{gathered} k^{\alpha}_{(1)}=\delta^{\alpha}{}_1, \quad k^{\alpha}_{(3)}=\alpha^{f/b}e^{fx}\delta^{\alpha}{}_3, \\ k^{\alpha}_{(2)}=e^{bx}[(\alpha-y\alpha_{,y})\delta^{\alpha}{}_0+\alpha_{,y}\delta^{\alpha}{}_1-b\alpha\delta^{\alpha}{}_2+\beta\delta^{\alpha}{}_3] \end{gathered} \tag{5.4}$$

(the basis change resulted in $a=c=0$). This algebra is of Bianchi type VI_h with the free parameter $b+f/b-f$. The Killing fields are further simplified by the coordinate transformation (1.13) with $H=b^{-1}\ln\alpha$, $T=\int(b\alpha)^{-1}\beta dy$, and by the subsequent transformation that leads out of the Plebański class:

$$t'=e^{-bx}t, \quad x'=x, \quad y'=bt+y, \quad z'=e^{-fx}z. \tag{5.5}$$

The result is (primes dropped):

$$\begin{gathered} k^{\alpha}_{(1)}=-bt\delta^{\alpha}{}_0+\delta^{\alpha}{}_1-fz\delta^{\alpha}{}_3, \quad k^{\alpha}_{(2)}=\delta^{\alpha}{}_0, \quad k^{\alpha}_{(3)}=\delta^{\alpha}{}_3, \\ u^{\alpha}=e^{-bx}\delta^{\alpha}{}_0+b\delta^{\alpha}{}_2, \quad w^{\alpha}=ne^{-fx}\delta^{\alpha}{}_3. \end{gathered} \tag{5.6}$$

The metric that results from the Killing equations is:

$$\begin{gathered} g_{00}=e^{2bx}(1+b^2h_{22}), \quad g_{01}=e^{bx}(y-bh_{12}), \quad g_{02}=-be^{bx}h_{22}, \\ g_{03}=-be^{(b+f)x}h_{23}, \quad g_{11}=h_{11}, \quad g_{12}=h_{12}, \quad g_{13}=e^{fx}h_{13}, \\ g_{22}=h_{22}, \quad g_{23}=e^{fx}h_{23}, \quad g_{33}=e^{2fx}h_{33}, \end{gathered} \tag{5.7}$$

where $h_{ij}(y), i,j=1,2,3$ are arbitrary functions. No progress with the Einstein equations was made here.

Case 1.2.1.2: $b=f$

The basis of the Killing fields is here:

$$\begin{gathered} k^{\alpha}_{(1)}=\delta^{\alpha}{}_1, \quad k^{\alpha}_{(3)}=B\alpha(y)e^{bx}\delta^{\alpha}{}_3, \\ k^{\alpha}_{(2)}=e^{bx}[(\alpha-y\alpha_{,y})\delta^{\alpha}{}_0+\alpha_{,y}\delta^{\alpha}{}_1-b\alpha\delta^{\alpha}{}_2+(cB\alpha x+\beta)\delta^{\alpha}{}_3] \end{gathered} \tag{5.8}$$

(as before, $a=0$ was achieved by a basis change). The Bianchi type is IV when $c\neq 0$ and V when $c=0$. To this basis we apply the transformation (1.13) with $H=b^{-1}\ln\alpha$, $T=\int b^{-1}(\beta e^{-bH}-cBH)dy$, and then the subsequent transformation:

$$t'=e^{-bx}t, \quad x'=x, \quad y'=bt+y, \quad z'=e^{-bx}(-ctx+z). \tag{5.9}$$

The result (i.e., the relevant vector fields and the metric that fulfills the Killing equations) is:

$$k^\alpha_{(1)}=-bt\delta^\alpha{}_0+\delta^\alpha{}_1-(ct+bz)\delta^\alpha{}_3,\quad k^\alpha_{(2)}=\delta^\alpha{}_0,\quad k^\alpha_{(3)}=\delta^\alpha{}_3,$$

$$u^\alpha=e^{-bx}\delta^\alpha{}_0+b\,\delta^\alpha{}_2-cxe^{-bx}\delta^\alpha{}_3,\quad w^\alpha=ne^{-bx}\delta^\alpha{}_3,$$

$$g_{00}=e^{2bx}(1+b^2h_{22}-2bcxh_{23}+c^2x^2h_{33}),\quad g_{01}=e^{bx}(y-bh_{12}+cxh_{13}),$$

$$g_{02}=e^{bx}(-bh_{22}+cxh_{23}),\quad g_{03}=e^{2bx}(-bh_{23}+cxh_{33}),$$

$$(g_{11},g_{12},g_{22})=(h_{11},h_{12},h_{22}),$$

$$(g_{13},g_{23})=e^{bx}(h_{13},h_{23}),\quad g_{33}=e^{2bx}h_{33},\tag{5.10}$$

where, as before, the h_{ij} are arbitrary functions of y. Also here, no progress was made with the Einstein equations.

Case 1.2.2: $b=0$.

Eqs. (2.3a)–(2.3c) and (2.3h) imply here

$$\phi=axy+\alpha(y),\quad \lambda_3=\mu(y)e^{fx},\tag{5.11}$$

where $\alpha(y)$ and $\mu(y)$ are arbitrary functions; $a\neq0$ because of the assumption defining case 1. In further integration, the cases $f\neq0$ and $f=0$ have to be considered separately. However, $f\neq0$ quickly leads to a contradiction with $a\neq0$, so the only case to consider is

$$f=0.\tag{5.12}$$

Then, from (2.3d),

$$\lambda_2=c\mu(y)x+\beta(y),\tag{5.13}$$

where β is an arbitrary function, and from (2.3l),

$$\mu=Ay^{-j/a},\tag{5.14}$$

where $A\neq0$ is an arbitrary constant. The transformation (1.13) with $H=\alpha/(ay)$, $T=\int[(\beta-cAHy^{-j/a})/(ay)]dy$ leads now to $\alpha=\beta=0$. With no loss of generality we can assume $A=1$. The coordinates will become adapted to $k_{(1)}$ and $k_{(3)}$ after the subsequent transformation:

$$z'=y^{j/a}z.\tag{5.15}$$

This leaves the metric u^α and w^α in the Plebański form (with rescaled n), while the Killing fields and the commutation relations become

$$\begin{gathered}k^\alpha_{(1)}=\delta^\alpha_1,\quad k^\alpha_{(2)}=C_2\delta^\alpha_0+ax\delta^\alpha_1-ay\delta^\alpha_2+(cx-jz)\delta^\alpha_3,\quad k^\alpha_{(3)}=\delta^\alpha_3,\\ [k_{(1)},k_{(2)}]=ak_{(1)}+ck_{(3)},\quad [k_{(1)},k_{(3)}]=0,\quad [k_{(2)},k_{(3)}]=jk_{(3)}.\end{gathered}\tag{5.16}$$

In solving the Killing equations the cases $a+j\neq0$ and $a+j=0$ have to be considered separately.

Case 1.2.2.1: $a+j\neq0$.

The algebra (5.16) is then of Bianchi type VI_h [the free parameter in the standard form of the commutation relations is $(1-j/a)/(1+j/a)$]. The Killing equations lead to the following metric form:

$$
\begin{gathered}
g_{00}=1, \quad g_{01}=y, \quad g_{02}=g_{03}=0, \\
g_{11}=C^2y^{-2j/a}h_{33}-2Cy^{1-j/a}h_{13}+y^2h_{11}, \\
g_{12}=-Cy^{-1-j/a}h_{23}+h_{12}, \quad g_{13}=-Cy^{-2j/a}h_{33}+y^{1-j/a}h_{13}, \\
g_{22}=h_{22}/y^2, \quad g_{23}=y^{-1-j/a}h_{23}, \quad g_{33}=y^{-2j/a}h_{33},
\end{gathered}
\tag{5.17}
$$

where the h_{ij} are functions of the variable u defined below, and C is the constant

$$
C=c/(a+j), \quad u=e^t y^{C_2/a}. \tag{5.18}
$$

The limit $C_2=0$ of (5.17) is an allowed subcase and does not require separate treatment. With $C_2=0$ all h_{ij} become functions of t alone, and this is the first instance where a proper spatially homogeneous (necessarily tilted) Bianchi-type model appears in this scheme.

No progress in solving the Einstein equations was achieved here.

Case 1.2.2.2: $a+j=0$.

The Bianchi type is IV when $c\neq 0$ and V when $c=0$. The Killing equations lead here to the metric

$$
\begin{gathered}
g_{00}=1, \quad g_{01}=y, \quad g_{02}=g_{03}=0, \\
g_{11}=\left(\frac{c}{a}\,y\,\ln y\right)^2 h_{33}+2\,\frac{c}{a}\,y^2\,\ln y h_{13}+y^2h_{11}, \\
g_{12}=\frac{c}{a}\,y h_{23}+h_{12}, \quad g_{13}=\frac{c}{a}\,y^2\,\ln y h_{33}+y^2h_{13}, \\
g_{22}=h_{22}/y^2, \quad g_{23}=h_{23}, \quad g_{33}=y^2h_{33},
\end{gathered}
\tag{5.19}
$$

where the h_{ij} are arbitrary functions of the same $u=e^t y^{C_2/a}$ as in (5.18).

No progress with the Einstein equations was made here, either.

VI. CASE 2: $\phi_{,x}=0$

We go back to Eqs. (2.3). Now $\phi_{,y}\neq 0$ can be assumed because with $\phi_{,x}=\phi_{,y}=0$ the Killing field $k^\alpha_{(2)}$ becomes spanned on u^α and w^α, and this situation was already considered in Paper 1.[1]

If $h\neq 0$, then (2.3j) implies $\phi=-(g/h)y+A$, $A=\text{const}$, and so $k^\alpha_{(2)}=(C_2+A)\delta^\alpha_0-(g/h)\delta^\alpha_1+\lambda_2\delta^\alpha_3$. Now $k'^\alpha_{(2)}=k^\alpha_{(2)}+(g/h)k^\alpha_{(1)}$ is spanned on u^α and w^α, and so we are again in the domain of Paper 1. Hence, $h=0$, and, from (2.3j), $g=0$. In the same way it follows from (2.3b) and (2.3f) that

$$
a=b=d=e=g=h=0. \tag{6.1}
$$

From here on, the cases $\lambda_3\neq 0$ and $\lambda_3=0$ have to be considered separately.

Case 2.1: $\lambda_3\neq 0$.

Using (2.3h) with (6.1) in (2.3l) we obtain $f\phi_{,y}=j$. In the same way as above, we conclude from here that

$$
f=j=0. \tag{6.2}
$$

Now from (2.3h) and (2.3d),

$$
\lambda_3=\lambda_3(y), \quad \lambda_2=c\lambda_3 x+\beta(y), \tag{6.3}
$$

where $\lambda_3(y)$ and β are arbitrary. The only equation that remains from the set (2.3) is now $cC_3=0$, and $\phi(y)$ is an arbitrary function. We first follow

Case 2.1.1: $C_3\neq 0$.

Then

$$c=0, \tag{6.4}$$

and the algebra becomes commutative (Bianchi type I). The transformation $z'=C_3z/\lambda_3(y)$ gives the same result as if $\lambda_3=C_3$, and then

$$C_3=\lambda_3=1 \tag{6.5}$$

may be assumed without loss of generality. The Killing fields are now

$$k^\alpha_{(1)}=\delta^\alpha_1, \quad k^\alpha_{(2)}=F\delta^\alpha_0+\phi_{,y}\delta^\alpha_1+\beta(y)\delta^\alpha_3, \quad k^\alpha_{(3)}=\delta^\alpha_0+\delta^\alpha_3, \tag{6.6}$$

where

$$F:=C_2+\phi-y\phi_{,y}. \tag{6.7}$$

The Killing equations for $k^\alpha_{(1)}$ and $k^\alpha_{(3)}$ imply that the metric tensor is independent of x and that it depends on t and z only through $u:=(t-z)/2$. It may be assumed that $\phi_{,yy}\neq 0\neq F-\beta$ because with $\phi_{,yy}=0$ the Killing field $k'^\alpha_{(2)}=k^\alpha_{(2)}-\phi_{,y}k^\alpha_{(1)}$ is spanned on u^α and w^α (this is the domain of Paper 1), while $F-\beta=0$ leads, through the Killing equations, to a singular metric [$\det(g_{\alpha\beta})=0$]. Knowing this, we can adapt coordinates to all three Killing vectors by the following transformation:

$$t=Ft'+z', \quad x=\phi_{,y}t'+x', \quad y=y', \quad z=\beta t'+z'. \tag{6.8}$$

In the new coordinates, all the metric components depend only on y'. With primes dropped, the Killing, velocity, and rotation fields and the metric tensor are as follows:

$$k^\alpha_{(1)}=\delta^\alpha_1, \quad k^\alpha_{(2)}=\delta^\alpha_0, \quad k^\alpha_{(3)}=\delta^\alpha_3, \quad u^\alpha=(F-\beta)^{-1}(\delta^\alpha_0-\phi_{,y}\delta^\alpha_1-\beta\delta^\alpha_3),$$

$$w^\alpha=\{C_3n/[\lambda_3(F-\beta)]\}(\delta^\alpha_0-\phi_{,y}\delta^\alpha_1-F\delta^\alpha_3),$$

$$g_{00}=F^2-\beta^2+2y\phi_{,y}(F-\beta)+\beta^2g_{33}+2\phi_{,y}\beta g_{13}+\phi^2_{,y}g_{11}, \tag{6.9}$$

$$g_{01}=y(F-\beta)+\phi_{,y}g_{11}+\beta g_{13},$$

$$g_{02}=\phi_{,y}g_{12}+Fg_{23}, \quad g_{03}=F-\beta+\beta g_{33}+\phi_{,y}g_{13},$$

and all the $g_{ij}(y)$, $i,j=1,2,3$ are arbitrary functions.

No progress with the Einstein equations was achieved in this case.

Case 2.1.2: $C_3=0$.

This means that the Killing field $k^\alpha_{(3)}$ is collinear with the rotation vector w^α. Now we have to consider separately the cases $c\neq 0$ and $c=0$.

Case 2.1.2.1: $c\neq 0$.

The Bianchi type of the algebra (2.2) is II in this case. The transformation (1.13) with $H=-\beta/(c\lambda_3)$ leads to

$$\beta=0. \tag{6.10}$$

It may be taken for granted that $F\neq 0$ [F is still given by (6.7)] because with $F=\beta=0$ the Killing equations imply $g_{13}=g_{23}=g_{33}=0$ and so $g_{03}=0$ from (6.9), i.e., $\det(g_{\alpha\beta})=0$. The transformation $z'=z/\lambda_3$ leads to the same result as

$$\lambda_3=1 \tag{6.11}$$

(in fact, the transformation reshuffles the components g_{2j}, $j=1,2,3$ among themselves, but formally the new metric still has the Plebański form). Hence (6.10) and (6.11) will be assumed. The subsequent transformation,

$$t=Ft',\quad x=\phi_{,y}t'+x',\quad y=y',\quad z=\tfrac{1}{2}\,c\phi_{,y}t'^2+z', \tag{6.12}$$

leads to (with primes dropped)

$$\begin{gathered} k^\alpha_{(1)}=\delta^\alpha_1,\quad k^\alpha_{(2)}=\delta^\alpha_0+cx\delta^\alpha_3,\quad k^\alpha_{(3)}=\delta^\alpha_3,\\ u^\alpha=F^{-1}(\delta^\alpha_0-\phi_{,y}\delta^\alpha_1-ct\phi_{,y}\delta^\alpha_3),\quad w^\alpha=(n/\lambda_3)\delta^\alpha_3. \end{gathered} \tag{6.13}$$

In the coordinates of (6.13) the Killing equations imply

$$\begin{gathered} g_{00}=(C_2+\phi)^2-(y\phi_{,y})^2+\phi^2_{,y}h_{11},\\ g_{01}=yF-ct\phi_{,y}h_{13}+\phi_{,y}h_{11},\quad g_{02}=\phi_{,y}h_{12},\quad g_{03}=\phi_{,y}h_{13},\\ g_{11}=(ct)^2g_{33}-2cth_{13}+h_{11},\quad g_{12}=-ctg_{23}+h_{12},\quad g_{13}=-ctg_{33}+h_{13}, \end{gathered} \tag{6.14}$$

where g_{22}, g_{23}, g_{33}, and the h_{ij} are arbitrary functions of y.

No progress with the Einstein equations was made.

Case 2.1.2.2: $c=0$.

We go back to Eqs. (6.1)–(6.3) with $c=C_3=0$. The algebra becomes commutative (Bianchi type I), but in contrast to Case 2.1.1 the Killing field $k^\alpha_{(3)}$ is here collinear with rotation. We have

$$\begin{gathered} \lambda_2=\beta(y),\quad \lambda_3=\lambda_3(y),\quad \phi=\phi(y),\quad k^\alpha_{(1)}=\delta^\alpha_1,\\ k^\alpha_{(2)}=F\delta^\alpha_0+\phi_{,y}\delta^\alpha_1+\beta\delta^\alpha_3,\quad k^\alpha_{(3)}=\lambda_3\delta^\alpha_3, \end{gathered} \tag{6.15}$$

where F is given by (6.7). Also here $F\neq 0$, or else we are back in the domain of Paper 1. Equation (6.11) applies here for the same reason as before, and the coordinates become adapted to the Killing fields after the transformation:

$$t=Ft',\quad x=\phi_{,y}t'+x',\quad y=y',\quad z=\beta t'+z'. \tag{6.16}$$

In the new coordinates (primes dropped)

$$\begin{gathered} k^\alpha_{(1)}=\delta^\alpha_1,\quad k^\alpha_{(2)}=\delta^\alpha_0,\quad k^\alpha_{(3)}=\delta^\alpha_3,\\ u^\alpha=F^{-1}(\delta^\alpha_0-\phi_{,y}\delta^\alpha_1-\beta\delta^\alpha_3),\quad w^\alpha=(n/\lambda_3)\delta^\alpha_3, \end{gathered} \tag{6.17}$$

and the Killing equations imply

$$\begin{gathered} g_{00}=(C_2+\phi)^2-(y\phi_{,y})^2+\phi^2_{,y}g_{11}+2\beta\phi_{,y}g_{13}+\beta^2g_{33},\\ g_{01}=yF+\phi_{,y}g_{11}+\beta g_{13},\quad g_{02}=\phi_{,y}g_{12}+\beta g_{23},\quad g_{03}=\phi_{,y}g_{13}+\beta g_{33}, \end{gathered} \tag{6.18}$$

where all $g_{ij}, i,j=1,2,3$ are arbitrary functions of y.

In general, no progress was made with the Einstein equations. However, a few authors have considered this case before, and a few simple exact solutions in this class are known. Therefore, we shall introduce the standard Bianchi-type coordinates in which $g_{02}=g_{12}=g_{23}=0$, $g_{22}=-1$ in order to facilitate the comparison. The transformation to coordinates in which $g_{i2}=0$, $i=0,1,3$, is

$$t=t'+F_0(y'), \quad x=x'+F_1(y'), \quad y=F_2(y')=y', \quad z=z'+F_3(y'), \tag{6.19}$$

where the functions $F_\alpha(y')$ obey

$$\sum_{\alpha=0}^{3} g_{\alpha i}F_{\alpha,y'}=0, \quad i=0,1,3. \tag{6.20}$$

The set (6.20) may be solved for $F_{0,y'}$, $F_{1,y'}$, and $F_{3,y'}$ and then finding the F_α only requires calculation of a few integrals (which are seen to exist, although the integrands are at this point not known as explicit functions of y'). Having achieved $g_{i2}=0$ in this way, we carry out the change of variable $y'=\int(-g_{22})^{1/2}dy$ [knowing that $g_{22}<0$ because of the signature and $g_{22}=g_{22}(y)$ because of the symmetries] that leads to $g_{2'2'}=-1$. The components g_{ij} in which $i\neq 2\neq j$, the velocity and the rotation do not change after (6.19). In the new coordinates, dropping primes,

$$ds^2=[(C_2+\phi)dt+Ydx]^2-[k_{11}(\phi_{,Y}dt+dx)]^2-dy^2-\{k_{33}[(\beta+h_{13}\phi_{,Y})dt+h_{13}dx+dz]\}^2, \tag{6.21}$$

where Y is the y-coordinate of (6.18), and

$$k_{11}{}^2=y^2-g_{11}+g_{13}{}^2/g_{33}, \quad k_{33}{}^2=-g_{33}, \quad h_{13}=g_{12}/g_{33}. \tag{6.22}$$

The subcase $\beta=h_{13}=0$ of (6.21) was first considered by King,[4] and it is known in the literature as ''stationary cylindrically symmetric.'' King demonstrated that, even in this subcase, the problem is underdetermined: one function in the metric may be chosen arbitrarily [in (6.21) it is k_{33}]. The limitation $\beta=h_{13}=0$ resulted from the reflection symmetries assumed in Ref. 4, that in the coordinates of (6.21) correspond to $z\to -z$ and $(t,x)\to(-t,-x)$. King's metric ansatz can be also derived from the following assumptions, as follows from the present consideration.

1. The manifold has a 3-dimensional symmetry group whose algebra is of the Bianchi type I.
2. One Killing field $(k^\alpha_{(3)})$ is collinear with rotation, the two others are linearly independent of u^α and w^α.
3. The velocity vector field is spanned on $k^\alpha_{(1)}$ and $k^\alpha_{(2)}$ (hence $\beta=0$).
4. The Killing fields $k^\alpha_{(1)}$ and $k^\alpha_{(2)}$ are both orthogonal to $k^\alpha_{(3)}$ (hence $h_{13}=0$).

A few examples of explicit solutions of the Einstein equations are given in Ref. 4, among them the solutions of Maitra (Ref. 8; see below) and of Lanczos (Ref. 10; this one goes by the name of ''Ehlers–van Stockum'' in Ref. 4). Vishveshwara and Winicour[5] derived the same metric form as King and provided another explicit example of a solution. The solution derived by Hoenselaers and Vishveshwara[6] that was supposed to be an example of the collection of Ref. 5, turned out to be a coordinate transform of the Gödel metric; see Ref. 7.

One more example was provided by Maitra.[8] In addition to the list above, it has the following invariant property.

5. The timelike Killing field $k_{(2)}$ has unit length so that $(C_2+\phi)^2-k_{11}{}^2\phi_{,Y}{}^2=1$.

The conditions 1–5 are still insufficient to reduce (6.21) to the Maitra solution; the following coordinate-dependent relations must hold in addition:

$$(C_2+\phi)Y-k_{11}{}^2\phi_{,Y}=m, \quad Y^2-k_{11}{}^2=m^2-r^2, \tag{6.23}$$

where $r(y)$ is a new coordinate defined by

$$\ln\left(\frac{dy}{dr}\right) = -\frac{1}{4u^2}\left\{(1+u^2)^{1/2} - 1 + \frac{1}{8} - \frac{1}{4}\ln\left[\frac{1}{2}(1+u^2)^{1/2} + \frac{1}{2}\right]\right\}$$

$$u := 2r/a, \quad a = \text{const}, \tag{6.24}$$

and $m(r)$ is the function

$$m = -\tfrac{1}{2}a\{(1+u^2)^{1/2} - 1 - \ln[\tfrac{1}{2}(1+u^2)^{1/2} + \tfrac{1}{2}]\}. \tag{6.25}$$

This author was not able to interpret (6.23) in invariant terms.

The first three of the six solutions by Ozsváth[9] also belong here, and they are subcases of the class considered by King. All of Ozsváth's solutions have 4-dimensional symmetry groups whose orbits are the whole 4-dimensional manifolds. In order to place specific Ozsváth's solutions in the classification considered here, one has to identify 3-dimensional subgroups of Ozsváth's groups. Examples can be spotted by inspection in Ref. 9 in which different non-isomorphic 3-dimensional subgroups are contained in the same 4-dimensional group. Hence, the same Ozsváth's solutions should come up as limits in different classes of the present investigation. For unique and complete identification, the formulae for group generators are necessary, and these are not given for most of Ozsváth's solutions.

Case 2.2: $\lambda_3 = 0$.

We go back to Eq. (6.1). Now necessarily $C_3 \neq 0$, so it may be assumed with no loss of generality that

$$C_3 = 1, \tag{6.26}$$

and then Eqs. (6.1) together with (2.3a), (2.3e), and (2.3i) imply

$$c = f = j = 0, \tag{6.27}$$

and (2.3d) implies

$$\lambda_2 = \beta(y). \tag{6.28}$$

In this case, necessarily $\beta \neq 0$ because with $\beta = 0$ the Killing equations imply that the determinant of the metric is zero. With (6.1) and (6.26)–(6.28) the whole set (2.3) is solved and the Killing fields are

$$k^\alpha_{(1)} = \delta^\alpha_1, \quad k^\alpha_{(2)} = F\delta^\alpha_0 + \phi_{,y}\delta^\alpha_1 + \beta\delta^\alpha_3, \quad k^\alpha_{(3)} = \delta^\alpha_0, \tag{6.29}$$

where F is still given by (6.7). It may be assumed with no loss of generality that

$$C_2 = 0, \tag{6.30}$$

because this is equivalent to changing the basis to $k'^\alpha_{(2)} = k^\alpha_{(2)} - C_2 k^\alpha_{(3)}$. The Killing fields all commute to zero, so the Bianchi type is I once more, but this time with a still different position of the orbits with respect to the hydrodynamical vector fields; now the velocity field is the Killing field $k^\alpha_{(3)}$, i.e., it is tangent to the orbits.

In order to adapt the coordinates to the Killing fields we carry out the transformation

$$t' = t - (F/\beta)z, \quad x' = x - (\phi_{,y}/\beta)z, \quad y' = y, \quad z' = z/\beta. \tag{6.31}$$

The Killing fields $k^\alpha_{(1)}$ and $k^\alpha_{(3)}$ do not change, while $k^\alpha_{(2)}$, the rotation and the metric acquire the form

$$k^\alpha_{(2)}=\delta^\alpha_3, \quad w^\alpha=(n/\beta)(F\delta^\alpha_0+\phi_{,y}\delta^\alpha_1-\delta^\alpha_3),$$
$$g_{00}=1, \quad g_{01}=y, \quad g_{02}=0, \quad g_{03}=\phi, \tag{6.32}$$

other components g_{ij} are arbitrary functions of y. Similarly as it was done in (6.19)–(6.21), we can transform the metric to the Bianchi-type coordinates in which $g_{02}=g_{12}=g_{23}=0$. Then

$$ds^2=(dt+ydx+\phi dz)^2-(k_{11}dx)^2-(k_{22}dy)^2-[k_{33}(h_{13}dx+dz)]^2, \tag{6.33}$$

where k_{11}, k_{22}, k_{33}, and h_{13} are functions of y. The transformation does not change (6.32). The Einstein equation $G_{01}=0$ then implies

$$h_{13}\phi_{,y}=1-Kk_{11}k_{22}/k_{33}, \tag{6.34}$$

where K is a constant. With this, $G_{03}=0$ implies

$$\phi_{,y}k_{11}/(k_{22}k_{33})-Kh_{13}=L=\text{const}, \tag{6.35}$$

and $G_{13}=0$ implies

$$-k_{33}{}^3h_{13,y}/(k_{11}k_{22})+K\phi=M=\text{const}. \tag{6.36}$$

Equations (6.34)–(6.36) can be used to elliminate all derivatives of ϕ and h_{13} from the Einstein tensor. This is done as follows.

(1) The derivative of (6.34) is used to eliminate $h_{13}\phi_{,yy}$.
(2) Equation (6.34) is used to eliminate $(h_{13}\phi_{,y})^2$, $h_{13}\phi_{,y}$ and $h_{13}\phi_{,y}{}^2$.
(3) From (6.35), $\phi_{,yy}$ is found and eliminated from the Einstein tensor completely.
(4) From (6.36), $h_{13,yy}$ is found and eliminated from the Einstein tensor.
(5) Equations (6.36) and (6.35) are used to eliminate $h_{13,y}$ and $\phi_{,y}$.

This procedure is designed so that the result of each step applies also in the limit $h_{13}=0$. After it is completed, the Einstein tensor is diagonal.

The equation $G_{11}-G_{33}=0$ is now

$$\tfrac{1}{2}(K/k_{33})^2+k_{22}{}^{-2}[-k_{22,y}k_{33,y}/(k_{22}k_{33})+k_{33,yy}/k_{33}+k_{11,y}k_{22,y}/(k_{11}k_{22})-k_{11,yy}/k_{11}]$$
$$-\tfrac{1}{2}[(Kh_{13}+L)/k_{11}]^2-(K\phi-M)^2/k_{33}{}^4=0. \tag{6.37}$$

In this, we replace one power of $(Kh_{13}+L)$ from (6.35), one power of $(K\phi-M)$ from (6.36), multiply the result by $k_{11}k_{22}k_{33}$ and use (6.34) to eliminate $Kk_{11}k_{22}/k_{33}$ from $K^2k_{11}k_{22}/k_{33}$. The result is then integrated, and the integral is

$$(k_{11}k_{33,y}-k_{33}k_{11,y})/k_{22}-K\phi h_{13}-\tfrac{1}{2}L\phi+Mh_{13}+\tfrac{1}{2}Ky=A=\text{const}. \tag{6.38}$$

The equation $G_{11}-G_{22}=0$ is

$$-\tfrac{1}{2}(Kh_{13}+L)^2+k_{22}{}^{-2}k_{33}{}^{-1}(-k_{22,y}k_{33,y}/k_{22}+k_{33,yy}-k_{11,y}k_{33,y}/k_{11})=0. \tag{6.39}$$

In this, we eliminate one power of $(Kh_{13}+L)$ using (6.35), then use (6.34) to eliminate $h_{13}\phi_{,y}$ from the result. The equation thus obtained is integrated to

$$k_{33,y}/(k_{11}k_{22})-\frac{1}{2}L\phi-\frac{1}{2}Ky+\frac{1}{2}K^2\int(k_{11}k_{22}/k_{33})dy=B=\text{const.} \tag{6.40}$$

Now we introduce the new variable $u(y)$ and the new functions $F(y)$ and $G(y)$ by

$$u_{,y}=k_{22}k_{33}/k_{11}, \quad F=Kh_{13}+L, \quad G=K\phi-M. \tag{6.41}$$

In these variables, Eqs. (6.35) and (6.36) may be rewritten as

$$G_{,u}=KF, \quad F_{,u}=K(k_{11}{}^2/k_{33}{}^4)G. \tag{6.42}$$

These can be separated when each is differentiated by u:

$$\begin{gathered} G_{,uu}-[(Kk_{11})^2/k_{33}{}^4]G=0, \\ F_{,uu}+(4k_{33,u}/k_{33}-2k_{11,u}/k_{11})F_{,u}-[(Kk_{11})^2/k_{33}{}^4]F=0. \end{gathered} \tag{6.43}$$

Equations (6.43) determine F and G as functions of the k_{ii} (k_{22} is hidden in the definition of u). Then, (6.34) implicitly defines k_{22} as a function of k_{11} and k_{33}. Next, (6.40) defines k_{33} as a function of k_{11}, and finally (6.38) defines $k_{11}(y)$. Hence, the set is in principle solvable. The one remaining Einstein equation is $G_{22}=\Lambda$. However, at this point it may be verified that $G_{22,y}=0$ in virtue of the other equations, so $G_{22}=\Lambda$ merely defines Λ in terms of the other constants. If $\Lambda=0$, then $G_{22}=0$ imposes an algebraic relation of the constants.

Suppose that $\phi=\text{const}$. Then the coordinate transformation $t=t'-\phi z$ leads to $\phi=0$ (which means $g_{\alpha\beta}k^{\alpha}_{(2)}k^{\beta}_{(3)}=0$). Then (6.34) implies $K\neq 0$, and so (6.35) implies $h_{13}=\text{const}$. Consequently, the transformation $z=z'-h_{13}x$ leads to $h_{13}=0$ (i.e., $g_{\alpha\beta}k^{\alpha}_{(1)}k^{\beta}_{(2)}=0$). With $\phi=h_{13}=0$ the metric (6.32)–(6.33) becomes identical to the metric ansatz of Lanczos,[10] and the Lanczos solution uniquely follows. In fact, with $\phi=\text{const}$, the Killing field $k^{\alpha}_{(2)}$ becomes the second Killing field spanned on u^{α} and w^{α}, and so we land in the domain of Paper 1. Hence, the definition of the Lanczos solution given above coincides with one of those from Paper 1.

The class defined by (6.32)–(6.43) contains the case Ciii of Ellis.[3]

At this point, the whole collection of metrics considered in this paper is exhausted.

VII. CONCLUDING REMARKS

In this paper, several classes of metrics were only derived. Investigation of their properties was postponed to separate projects; at this point it is not clear which of them would deserve further pursuit in the first turn, while investigating them all would expand the paper beyond acceptable limits.

All the cases considered here have the property that one of the Killing fields ($k_{(3)}$) is spanned on the fields of velocity u^{α} and rotation w^{α} of the source, while the other two are at every point linearly independent of u^{α} and w^{α}. In every case, the explicit formulae for the Killing fields were found, and the Killing equations were solved for the Killing fields were found, and the Killing equations were solved for the components of the metric tensor. Progress with solving the Einstein equations differed from case to case. The complete listing of nonempty cases is given in Fig. 1, and the results obtained are as follows.

(1) In case 1.1.1.1 (Bianchi type III) the final result is given by Eq. (2.18). No exact solutions are known and none were derived here.
(2) In case 1.1.1.2.1 (Bianchi type III) the final results are given by (3.16)–(3.27). A (most probably) new solution was found for the subcase $\Lambda=0$, given by Eqs. (3.16), (3.18), (3.19), and (3.24)–(3.27).

(3) In case 1.1.1.2.2 (Bianchi type III) a (most probably) new solution was derived here, given by Eq. (3.32).
(4) In case 1.1.2.1 (Bianchi type III) the final result is given by Eq. (4.9). No explicit solutions are known in general, but subcases of the case Ib of Ellis[3] belong here [see the paragraph after Eq. (4.10)].
(5) In case 1.1.2.2 (Bianchi type II) the final result is given by Eqs. (4.14)–(4.23). No explicit solutions are known in general, but with $\lambda_3 = 0 = \Lambda$, a new exact solution was derived here; see the comment after Eq. (4.23). The case Aii of Ellis[3] is a subcase here.
(6) In case 1.2.1.1 (Bianchi type VI_h) the final result is (5.6)–(5.7).
(7) In case 1.2.1.2 (Bianchi types IV and V) the final result is (5.10).
(8) In case 1.2.2.1 (Bianchi type VI_h), the final result is (5.17).
(9) In case 1.2.2.2 (Bianchi types IV and V), the final result is (5.19).
(10) In case 2.1.1 (Bianchi type I), the final result is (6.9).
(11) In case 2.1.2.1 (Bianchi type II), the final result is (6.14). No explicit solutions are known in points 6–11.
(12) In case 2.1.2.2 (Bianchi type I), the final result is (6.21). No explicit solutions are known in general, but a certain subcase (known as ''stationary cylindrically symmetric'') was considered by King[4] and Vishveshwara and Winicour.[5] Examples of explicit solutions were given in Refs. 4 and 5, and also by Maitra[8] and Ozsváth;[9] see the text after Eq. (6.25).
(13) In case 2.2 (Bianchi type I), the final result is given by Eqs. (6.32)–(6.43). No explicit solutions are known.

The Bianchi types do not uniquely identify the various cases because in each case the orbit of the symmetry group has a different position with respect to the velocity and rotation fields. This is why the same Bianchi types occur in inequivalent cases.

The collection of results corresponding to all three Killing vectors being at every point linearly independent of velocity and rotation will be presented in Paper 3 (now in preparation). Paper 3 will also contain an overview of literature on solutions of Einstein's equations with rotating fluid source.

ACKNOWLEDGMENT

Calculations for this paper were done with use of the algebraic computer program Ortocartan.[11,12]

(Received 7 July 1997; accepted for publication 9 September 1997)

A method has been recently proposed for defining an arbitrary number of differential calculi over a given noncommutative associative algebra. As an example a version of quantized space–time is considered here. It is found that there is a natural differential calculus over this version of quantized space–time using which the only possible torsion-free, metric-compatible, linear connection has zero curvature. It is then the noncummutative version of Minkowski space–time. Perturbations of this calculus are shown to give rise to nontrivial gravitational fields. © *1998 American Institute of Physics.* [S0022-2488(98)00601-X]

I. MOTIVATION AND NOTATION

Since the early days of quantum field theory physicists have been tempted to introduce some type of lattice structure on space–time to avoid the appearance of ultraviolet divergences, that is, to fix a natural value for an ultraviolet cut-off Λ. One of the disadvantages of these discrete structures is the fact that they destroy Lorentz invariance and they can hardly be considered in any respect as fundamental. It was Snyder[1] who first had the idea of using noncommuting coordinates to mimic a discrete structure in a covariant way. Since then several attempts have been made to continue this initial effort. We refer to Madore and Mourad[2] for a recent review with a historical perspective. One typically introduces four Hermitian generators q^μ of a noncommutative $*$-algebra $\mathscr{A}$ which satisfy commutation relations of the form

$$[q^\mu, q^\nu] = i\mu_P^{-2} q^{\mu\nu}. \tag{1.1}$$

The problem lies then with the interpretation of the right-hand side. One can define a succession of elements $q^{\lambda_1 \cdots \lambda_n}$ by the equations

$$[q^\lambda, q^{\mu\nu}] = i\mu_P^{-1} q^{\lambda\mu\nu}, \quad [q^\lambda, q^{\mu\nu\rho}] = i\mu_P^{-1} q^{\lambda\mu\nu\rho}, \tag{1.2}$$

and so forth. The structure of the algebra $\mathscr{A}$ is constrained by the value of these commutators. One possibility, considered by Snyder, is to choose them so as to form a representation of the Lie algebra of the de Sitter group. A second possibility, considered by Dubois-Violette and Madore,[3,4] is to choose them to form a representation of the conformal algebra. Recently Doplicher, Fredenhagen and Roberts[5,6] have argued that $q^{\mu\nu}$ should be chosen to lie in the center $\mathscr{Z}(\mathscr{A})$ of $\mathscr{A}$, that the q-tensors with more than 2 indices should vanish. We shall adopt this as a working hypothesis. There are 6 independent $q^{\mu\nu}$, which from (1.1) parameterize symplectic structures on space–time. In the commutative limit one obtains therefore a space of dimension greater than four except of course if the $q^{\mu\nu}$ are nilpotent. We shall not address here the question of the physical significance of the extra dimensions.

[a]Laboratoire associé au CNRS, URA D0063.

The idea that a noncommutative structure gives rise to an ultraviolet cut-off has been developed by several authors[6–8] since the original work of Snyder.[1,9] It is the right-hand arrow of the diagram

$$\begin{array}{ccc} \mathscr{A} & \Leftarrow & \Omega^*(\mathscr{A}) \\ \Downarrow & & \Uparrow \\ \text{Cut-off} & & \text{Gravity} \end{array}$$

The top arrow is a mathematical triviality; the $\Omega^*(\mathscr{A})$ is what gives a differential structure to the algebra. We shall define and discuss it in Section II. In Section IV we shall argue that each gravitational field is the unique ''shadow'' in the limit $\mu_P \to \infty$ of some differential structure over some non-commutative algebra. This would define the left-hand arrow of the diagram.

The composition of the three arrows is an expression of an old idea, due to Pauli and developed by Deser[10] and others,[11] that perturbative ultraviolet divergences will one day be regularized by the gravitational field. The possibility which we would like to defend is that the mechanism by which this works is through the introduction of non-commuting ''coordinates'' such as the q^μ. A hand-waving argument can be given[12] which allows one to think of the noncommutative structure of space–time as being due to quantum fluctuations of the light-cone in ordinary 4-dimensional space-time. This relies on the existence of quantum gravitational fluctuations. A purely classical argument based on the formation of black-holes has been also given.[6] In both cases the classical gravitational field is to be considered as regularizing the ultraviolet divergences through the introduction of the noncommutative structure of space–time. This can be strengthened as the conjecture that the classical gravitational field and the noncommutative nature of space–time are two aspects of the same thing. It is our purpose here to explore this relation.

In Section II we give a general prescription of how one defines differential calculi based on a set of derivations and we determine the conditions which the derivations must satisfy for the module of 1-forms to be a free module and for the module of 2-forms to be nontrivial. In Section III we associate a metric and a linear connection to each differential calculus and we argue that the association is unique. In Section IV we give the explicit calculations using a particularly simple set of derivations and we find that the associated gravitational field is trivial. In Sections V and VI we consider differential calculi which are, in a sense which we shall make precise, small perturbations of this basic differential calculus and we find that they lead to a rather simple but nontrivial gravitational field. In Section VII we consider a quotient algebra which could be considered as the noncommutative version of de Sitter space. Finally in Section VIII we discuss briefly the definition of ''gauge invariance.''

II. THE DIFFERENTIAL CALCULI

Let $\mathscr{A}$ be any unital associative $*$-algebra. Of the many differential calculi which can be constructed over $\mathscr{A}$ the largest is the differential envelope or universal differential calculus $(\Omega_u^*(\mathscr{A}), d_u)$. Every other differential calculus can be considered as a quotient of it. For the definitions we refer, for example, to the book by Connes.[13] Let $(\Omega^*(\mathscr{A}), d)$ be another differential calculus over $\mathscr{A}$. Then there exists a unique d_u-homomorphism ϕ,

$$\begin{array}{ccccccccc} \mathscr{A} & \overset{d_u}{\to} & \Omega_u^1(\mathscr{A}) & \overset{d_u}{\to} & \Omega_u^2(\mathscr{A}) & \overset{d_u}{\to} & \cdots \\ \| & & \phi_1 \downarrow & & \phi_2 \downarrow & & \\ \mathscr{A} & \overset{d}{\to} & \Omega^1(\mathscr{A}) & \overset{d}{\to} & \Omega^2(\mathscr{A}) & \overset{d}{\to} & \cdots \end{array} \tag{2.1}$$

of $\Omega_u^*(\mathscr{A})$ onto $\Omega^*(\mathscr{A})$. It is given by

$$\phi(d_u f\ ) = df. \tag{2.2}$$

The restriction ϕ_p of ϕ to each Ω_u^p is defined by

$$\phi_p(f_0 d_u f_1 \cdots d_u f_p) = f_0 df_1 \cdots df_p .$$

Consider a given algebra $\mathscr{A}$ and suppose that we know how to construct an $\mathscr{A}$-module $\Omega^1(\mathscr{A})$ and an application,

$$\mathscr{A} \overset{d}{\to} \Omega^1(\mathscr{A}). \tag{2.3}$$

Then using (2.1) there is a method of constructing $\Omega^p(\mathscr{A})$ for $p \geqslant 2$ as well as the extension of the differential. Since we know $\Omega_u^1(\mathscr{A})$ and $\Omega^1(\mathscr{A})$ we can suppose that ϕ_1 is given. It is the map such that

$$\Omega^1(\mathscr{A}) = \Omega_u^1(\mathscr{A})/\mathrm{Ker}\ \phi_1 .$$

We must construct $\Omega^2(\mathscr{A})$. The largest consistent choice would be to set

$$\Omega^2(\mathscr{A}) = \Omega_u^2(\mathscr{A})/\overline{d_u \mathrm{Ker}\ \phi_1}, \tag{2.4}$$

where

$$\overline{d_u \mathrm{Ker}\ \phi_1} = d_u \mathrm{Ker}\ \phi_1 + \Omega_u^1(\mathscr{A}) \otimes \mathrm{Ker}\ \phi_1 + \mathrm{Ker}\ \phi_1 \otimes \Omega_u^1(\mathscr{A})$$

is the bimodule generated by $d_u \mathrm{Ker}\ \phi_1$. Since

$$\Omega_u^2(\mathscr{A}) = \Omega_u^1(\mathscr{A}) \otimes_{\mathscr{A}} \Omega_u^1(\mathscr{A}),$$

we find that $\Omega^2(\mathscr{A})$ can be written also as

$$\Omega^2(\mathscr{A}) = \Omega^1(\mathscr{A}) \otimes_{\mathscr{A}} \Omega^1(\mathscr{A})/\mathscr{K}, \tag{2.5}$$

with

$$\mathscr{K} = (\phi_1 \otimes \phi_1)(\overline{d_u \mathrm{Ker}\ \phi_1}) = (\phi_1 \otimes \phi_1)(d_u \mathrm{Ker}\ \phi_1). \tag{2.6}$$

It can happen that $\mathscr{K} = \Omega^1(\mathscr{A}) \otimes_{\mathscr{A}} \Omega^1(\mathscr{A})$, in which case $\Omega^2(\mathscr{A}) = 0$.

Let π be the projection

$$\Omega^1(\mathscr{A}) \otimes_{\mathscr{A}} \Omega^1(\mathscr{A}) \overset{\pi}{\to} \Omega^2(\mathscr{A}). \tag{2.7}$$

Then π has a right inverse ι, a map

$$\Omega^2(\mathscr{A}) \overset{\iota}{\to} \Omega^1(\mathscr{A}) \otimes_{\mathscr{A}} \Omega^1(\mathscr{A}), \tag{2.8}$$

such that $\pi \circ \iota = 1$. This will allow us to identify $\Omega^2(\mathscr{A})$ as a submodule of $\Omega^1(\mathscr{A}) \otimes_{\mathscr{A}} \Omega^1(\mathscr{A})$. The map ϕ_2 is defined to be the projection of $\Omega_u^2(\mathscr{A})$ onto $\Omega^2(\mathscr{A})$ so defined. From the definition of π one sees that ϕ_2 is given by

$$\phi_2 = \pi \circ (\phi_1 \otimes \phi_1). \tag{2.9}$$

The wedge product of two elements ξ and η in $\Omega^1(\mathscr{A})$ is given by $\xi\eta=\pi(\xi\otimes\eta)$. Let ξ_u be an inverse image of ξ in $\Omega^1_u(\mathscr{A})$. Then the map d from $\Omega^1(\mathscr{A})$ to $\Omega^2(\mathscr{A})$ can be written in terms of d_u as

$$d(\phi_1(\xi_u))=\phi_2(d_u\xi_u). \tag{2.10}$$

Equation (2.4) defines the largest set of 2-forms consistent with the constraints on $\Omega^1(\mathscr{A})$. The procedure can be continued by iteration to arbitrary order in p. Define for this the map ψ_p,

$$\Omega^p_u(\mathscr{A})\xrightarrow{\psi_p}\bigotimes_1^p\Omega^1(\mathscr{A}), \tag{2.11}$$

given by $\psi_p=\phi_1\otimes\cdots\otimes\phi_1$ and define[13]

$$\Omega^p(\mathscr{A})=\Omega^p_u(\mathscr{A})/(\mathrm{Ker}\ \psi_p+d_u\mathrm{Ker}\ \psi_{p-1}). \tag{2.12}$$

We have then by definition

$$\mathrm{Ker}\ \phi_p=\mathrm{Ker}\ \psi_p+d_u\mathrm{Ker}\ \psi_{p-1}. \tag{2.13}$$

For example,

$$\mathrm{Ker}\ \psi_2=\Omega^1_u(\mathscr{A})\otimes\mathrm{Ker}\ \phi_1+\mathrm{Ker}\ \phi_1\otimes\Omega^1_u(\mathscr{A}), \tag{2.14}$$

and using (2.13) we find (2.4) as a particular case. Equation (2.12) can be rewritten as

$$\Omega^p(\mathscr{A})=\bigotimes_1^p\Omega^1(\mathscr{A})/\psi_p(d_u\mathrm{Ker}\ \psi_{p-1}),$$

or in the form

$$\Omega^p(\mathscr{A})=\bigotimes_1^p\Omega^1(\mathscr{A})/\mathscr{K}_p, \tag{2.15}$$

with the $\mathscr{K}_p$ defined by the recurrence relations

$$\mathscr{K}_p=\mathscr{K}_{p-1}\otimes\Omega^1(\mathscr{A})+\Omega^1(\mathscr{A})\otimes\mathscr{K}_{p-1},\quad \mathscr{K}_2=\mathscr{K}.$$

In particular we find the expression

$$\Omega^3(\mathscr{A})=\frac{\Omega^1(\mathscr{A})\otimes\Omega^1(\mathscr{A})\otimes\Omega^1(\mathscr{A})}{\mathscr{K}\otimes\Omega^1(\mathscr{A})+\Omega^1(\mathscr{A})\otimes\mathscr{K}} \tag{2.16}$$

for the module of 3-forms.

To initiate the above construction we define the 1-forms using a set of derivations. We shall suppose that they are interior and exclude therefore the case where $\mathscr{A}$ is commutative. For each integer n let λ_i be a set of n linearly independent anti-Hermitian elements of $\mathscr{A}$ and introduce the derivations $e_i=\mathrm{ad}\lambda_i$. In general the e_i do not form a Lie algebra but they do however satisfy commutation relations as a consequence of the commutation relations of $\mathscr{A}$. We shall suppose that if an element of $\mathscr{A}$ commutes with all of the λ_i then it is in the center $\mathscr{Z}(\mathscr{A})$ of $\mathscr{A}$: g,

$$e_if=0\Rightarrow f\in\mathscr{Z}(\mathscr{A}).$$

Define the map (2.3) by

$$df(e_i)=e_i f=[\lambda_i,f]. \tag{2.17}$$

We shall suppose that there exists a set of n elements θ^i of $\Omega^1(\mathscr{A})$ such that

$$\theta^i(e_j)=\delta^i_j. \tag{2.18}$$

In the examples which we consider we shall show that the θ^i exist by explicit construction. We shall refer to the set of θ^i as a frame or Stehbein. It commutes with the elements $f\in\mathscr{A}$,

$$f\theta^i=\theta^i f. \tag{2.19}$$

The $\mathscr{A}$-bimodule $\Omega^1(\mathscr{A})$ is generated by all elements of the form fdg or of the form $(df)g$. Because of the Leibniz rule these conditions are equivalent. By definition,

$$fdg(e_i)=fe_i g,\quad (dg)f(e_i)=(e_i g)f.$$

Using the frame we can write these as

$$fdg=(fe_i g)\theta^i,\quad (dg)f=(e_i g)f\theta^i. \tag{2.20}$$

The commutation relations of the algebra constrain the relations between fdg and $(dg)f$ for all f and g. Because of the commutation relations of the algebra or, equivalently, because of the kernel of ϕ_1 in the quotient (2.4) the θ^i satisfy in general commutation relations. With the identification ι we have

$$\pi(\theta^i\otimes\theta^j)=P^{ij}{}_{kl}\theta^k\otimes\theta^l,\quad P^{ij}{}_{kl}\in\mathscr{Z}(\mathscr{A}). \tag{2.21}$$

Since π is a projection we have

$$P^{ij}{}_{mn}P^{mn}{}_{kl}=P^{ij}{}_{kl}, \tag{2.22}$$

and the product $\theta^i\theta^j$ satisfies

$$\theta^i\theta^j=P^{ij}{}_{kl}\theta^k\theta^l. \tag{2.23}$$

The module $\mathscr{K}$ is generated by the elements $(\delta^i_k\delta^j_l-P^{ij}{}_{kl})\theta^k\otimes\theta^l$. In one important case which we shall consider the θ^i anticommute. This corresponds to

$$P^{ij}{}_{kl}=\frac{1}{2}(\delta^i_k\delta^j_l-\delta^j_k\delta^i_l). \tag{2.24}$$

Define $\theta=-\lambda_i\theta^i$. Then one sees that

$$df=-[\theta,f], \tag{2.25}$$

and it follows that as a bimodule $\Omega^1(\mathscr{A})$ is generated by one element. Under the condition (2.18) the $\Omega^1(\mathscr{A})$ is free of rank n as a left or right module. It can therefore be identified with the direct sum of n copies of $\mathscr{A}$:

$$\Omega^1(\mathscr{A})=\bigoplus_1^n\mathscr{A}. \tag{2.26}$$

In this representation θ^i is given by the element of the direct sum with the unit in the ith position and zero elsewhere.

Any element θ^i_u of $\Omega^1_u(\mathscr{A})$ can be written in the form

$$\theta_u^i = \sum_\alpha f_\alpha^{(i)} \otimes g_\alpha^{(i)}, \tag{2.27}$$

with the $f_\alpha^{(i)}$ and $g_\alpha^{(i)}$ elements of $\mathscr{A}$ such that

$$\sum_\alpha f_\alpha^{(i)} g_\alpha^{(i)} = 0. \tag{2.28}$$

Let θ^i be the images of θ_u^i in $\Omega^1(\mathscr{A})$. Then the condition (2.18) can be rewritten as

$$\sum_\alpha f_\alpha^{(i)} \lambda_j g_\alpha^{(i)} = \delta_j^i. \tag{2.29}$$

The assumption that $\Omega^1(\mathscr{A})$ is free then is equivalent to the assumption that these equations have a solution for $f_\alpha^{(i)}$ and $g_\alpha^{(i)}$.

The $f_\alpha^{(i)}$ and $g_\alpha^{(i)}$ can be used to give an explicit representation of $\mathscr{K}$. Introduce the notation

$$\mathscr{A}[\theta_u^i, \mathscr{A}] = \left\{ \sum_\alpha f_\alpha [\theta_u^i, g_\alpha] \,|\, f_\alpha, g_\alpha \in \mathscr{A} \right\}.$$

Then it is easily seen that

$$\text{Ker } \phi_1 = \sum_i \mathscr{A}[\theta_u^i, \mathscr{A}]. \tag{2.30}$$

If we define then the elements ν^i of $\Omega^1(\mathscr{A}) \otimes_{\mathscr{A}} \Omega^1(\mathscr{A})$ by

$$\nu^i = \sum_\alpha f_\alpha^{(i)} \theta \otimes \theta g_\alpha^{(i)}, \tag{2.31}$$

a short calculation yields the characterization

$$\mathscr{K} = \sum_i \mathscr{A}[\nu^i, \mathscr{A}]. \tag{2.32}$$

If we define $\lambda = (\lambda_1, \ldots, \lambda_n)$ then the condition (2.29) can be written in the form

$$\mathscr{A}[\lambda, \mathscr{A}] = \bigoplus_1^n \mathscr{A}. \tag{2.33}$$

More generally let $\mathscr{B}$ be an $\mathscr{A}$-bimodule and λ an element of $\mathscr{B}$. Define a map

$$\mathscr{A} \overset{d}{\longrightarrow} \mathscr{B}, \tag{2.34}$$

by $df = [\lambda, f]$. Then we can set

$$\Omega^1(\mathscr{A}) = \mathscr{A}[\lambda, \mathscr{A}] \subset \mathscr{B}. \tag{2.35}$$

The choice $\mathscr{B} = \mathscr{A} \otimes \mathscr{A}$ with $\lambda = 1 \otimes 1$ yields the universal calculus. We see from this example that λ itself need not be an element of $\Omega^1(\mathscr{A})$.

From (2.31) we see that $\pi(\nu^i)$ can be written as

$$\pi(\nu^i)=\sum_\alpha f_\alpha^{(i)}\lambda_j\lambda_k P^{jk}{}_{lm}g_\alpha^{(i)}\theta^l\otimes\theta^m. \tag{2.36}$$

But from the identity $[\pi(\nu^i),f]=0$ we see also that

$$\pi(\nu^i)=\frac{1}{2}F^i{}_{jk}\theta^j\theta^k, \tag{2.37}$$

with $F^i{}_{jk}$ elements in $\mathcal{Z}(\mathcal{A})$ such that

$$P^{jk}{}_{lm}F^i{}_{jk}=F^i{}_{lm}\,. \tag{2.38}$$

Using (2.29) it follows that

$$\sum_\alpha f_\alpha^{(i)}K_{jk}g_\alpha^{(i)}=0,$$

if we define K_{jk} by the equation

$$2\lambda_l\lambda_m P^{lm}{}_{jk}-\lambda_i F^i{}_{jk}-K_{jk}=0. \tag{2.39}$$

The exterior derivative of θ^i is given by

$$d\theta^i=\sum_\alpha df_\alpha^{(i)}dg_\alpha^{(i)}=-[\theta,\theta^i]-\pi(\nu^i). \tag{2.40}$$

The bracket is a graded bracket. Multiplying both sides of this equation by λ_i we find the identity

$$d\theta+\theta^2=-\theta^2+\pi(\nu^i\lambda_i).$$

Using (2.39) we find that this can be written in the form

$$d\theta+\theta^2=-\frac{1}{2}K_{ij}\theta^i\theta^j, \tag{2.41}$$

and if we take the exterior derivative of (2.25) we see immediately that the coefficients K_{ij} must lie in $\mathcal{Z}(\mathcal{A})$.

The structure elements $C^i{}_{jk}$ are defined by the equation

$$d\theta^i=-\frac{1}{2}C^i{}_{jk}\theta^j\theta^k. \tag{2.42}$$

From (2.40) it follows that

$$C^i{}_{jk}=F^i{}_{jk}-2\lambda_l P^{(li)}{}_{jk}\,. \tag{2.43}$$

We have started from an integer n and a set of λ_i. The necessary and sufficient conditions for the existence of the basis θ^i are expressed in Equation (2.29). If $\Omega^2(\mathcal{A})$ is nontrivial there exists $P^{ij}{}_{kl}\neq 0$ in $\mathcal{Z}(\mathcal{A})$ such that (2.22) and (2.23) are satisfied. Conversely we could have started from elements $P^{ij}{}_{kl}$, $F^i{}_{jk}$, K_{ij} in $\mathcal{Z}(\mathcal{A})$ and looked for a solution λ_i to Equation (2.39). Define

$$C^{ij}{}_{kl}=\delta^i_k\delta^j_l-2P^{ij}{}_{kl}\,. \tag{2.44}$$

Then from (2.22) we find that

$$C^{ij}{}_{kl}C^{kl}{}_{mn}=\delta^i_m\delta^j_n.$$

From the associativity rule for the product in $\Omega^3(\mathscr{A})$ one finds that $C^{ij}{}_{kl}$ must satisfy a weak form of the Yang–Baxter equation.

Quite generally let $\mathscr{V}$ be an $\mathscr{A}$-module and π a module morphism,

$$\mathscr{V}\otimes_{\mathscr{A}}\mathscr{V}\overset{\pi}{\to}\mathscr{V}\otimes_{\mathscr{A}}\mathscr{V}, \tag{2.45}$$

with $\pi^2=\pi$. This is the algebraic generalization of the product given by (2.7). The equivalent generalization of the product in the 3-forms is a module morphism,

$$\mathscr{V}\otimes_{\mathscr{A}}\mathscr{V}\otimes_{\mathscr{A}}\mathscr{V}\overset{\pi'}{\to}\mathscr{V}\otimes_{\mathscr{A}}\mathscr{V}\otimes_{\mathscr{A}}\mathscr{V}, \tag{2.46}$$

with $\pi'^2=\pi'$. One has then

$$\text{Ker }\pi'=\text{Ker }\pi\otimes\mathscr{V}+\mathscr{V}\otimes\text{Ker }\pi. \tag{2.47}$$

For the product to be nontrivial we must require that $\pi'\neq 0$. Since we have

$$\pi'(\text{Ker }\pi\otimes\mathscr{V})=0,\quad \pi'(\mathscr{V}\otimes\text{Ker }\pi)=0,$$

there must exist two morphisms ϕ', ϕ'' of $\mathscr{V}\otimes_{\mathscr{A}}\mathscr{V}\otimes_{\mathscr{A}}\mathscr{V}$ into itself such that

$$\pi'=\phi'\circ\pi_{12},\quad \pi'=\phi''\circ\pi_{23}.$$

We have here used the standard convention of setting $\pi_{12}=\pi\otimes 1$ and $\pi_{23}=1\otimes\pi$. The associativity rule becomes the compatibility condition

$$\phi'\circ\pi_{12}=\phi''\circ\pi_{23}. \tag{2.48}$$

In particular if $C^{ij}{}_{kl}$ satisfies the Yang–Baxter condition,

$$C_{23}\circ C_{12}\circ C_{23}=C_{12}\circ C_{23}\circ C_{12},$$

then one can set

$$\phi'=-\frac{1}{3}(1-4\pi_{12}\circ\pi_{23}),\quad \phi''=-\frac{1}{3}(1-4\pi_{23}\circ\pi_{12}). \tag{2.49}$$

However more general solutions to (2.48) do exist.

The $F^i{}_{jk}$ must satisfy a set of modified Jacobi identities. If we choose the λ_i so that the e_i are a basis of the Lie algebra of all derivations of a matrix algebra[14] then one can choose $P^{ij}{}_{kl}=\delta^i_k\delta^j_l$. If a smaller Lie algebra[4] is chosen then $P^{ij}{}_{kl}$ is given by (2.24), $K_{ij}=0$ and the $F^i{}_{jk}$ are equal to the structure constants of the Lie algebra. An example with $K_{ij}\neq 0$ can be found.[15] Examples with $F^i{}_{jk}=0$ and $K_{ij}=0$ have also been found.[16] If $P^{ij}{}_{kl}$ is given by (2.24) with a plus instead of a minus sign, n is even and $F^i{}_{jk}=0$ then a solution to (2.39) is given by Dirac matrices. If also $K_{ij}=0$ then a solution is given by ''super-coordinates.'' In these two cases the 1-forms θ^i commute.

III. THE LINEAR CONNECTIONS

The definition of a connection as a covariant derivative was given an algebraic form in the Tata lectures by Koszul[17] and generalized to noncommutative geometry by Karoubi[18] and

Connes.[19,13] We shall use here the expressions ''connection'' and ''covariant derivative'' synonymously. A ''bimodule connection'' is a connection on a general bimodule $\mathcal{M}$, which satisfies a left and right Leibniz rule. In the particular case where $\mathcal{M}$ is the module of 1-forms we shall speak of a ''linear connection.''

Let $\mathcal{A}$ be an arbitrary algebra and $(\Omega^*(\mathcal{A}),d)$ a differential calculus over $\mathcal{A}$. One defines a left $\mathcal{A}$-connection on a left $\mathcal{A}$-module $\mathcal{H}$ as a covariant derivative,

$$\mathcal{H}\overset{D}{\to}\Omega^1(\mathcal{A})\otimes_{\mathcal{A}}\mathcal{H}, \tag{3.1}$$

which satisfies the left Leibniz rule,

$$D(f\psi)=df\otimes\psi+fD\psi, \tag{3.2}$$

for arbitrary $f\in\mathcal{A}$. This map has a natural extension,

$$\Omega^*(\mathcal{A})\otimes_{\mathcal{A}}\mathcal{H}\overset{D}{\to}\Omega^*(\mathcal{A})\otimes_{\mathcal{A}}\mathcal{H}, \tag{3.3}$$

given, for $\psi\in\mathcal{H}$ and $\alpha\in\Omega^p(\mathcal{A})$, by

$$D(\alpha\psi)=d\alpha\otimes\psi+(-1)^p\alpha D\psi.$$

The operator D^2 is necessarily left-linear.

A covariant derivative on the module $\Omega^1(\mathcal{A})$ must satisfy (3.2). But $\Omega^1(\mathcal{A})$ has also a natural structure as a right $\mathcal{A}$-module and one must be able to write a corresponding right Leibniz rule in order to construct a bilinear curvature. Quite generally let $\mathcal{M}$ be an arbitrary bimodule. Consider a covariant derivative,

$$\mathcal{M}\overset{D}{\to}\Omega^1(\mathcal{A})\otimes_{\mathcal{A}}\mathcal{M}, \tag{3.4}$$

which satisfies both a left and a right Leibniz rule. In order to define a right Leibniz rule which is consistent with the left one, it was proposed[20–22] that one introduce a generalized permutation,

$$\mathcal{M}\otimes_{\mathcal{A}}\Omega^1(\mathcal{A})\overset{\sigma}{\to}\Omega^1(\mathcal{A})\otimes_{\mathcal{A}}\mathcal{M}.$$

The right Leibniz rule is given then as

$$D(\xi f\ )=\sigma(\xi\otimes df\ )+(D\xi)f, \tag{3.5}$$

for arbitrary $f\in\mathcal{A}$ and $\xi\in\mathcal{M}$. The purpose of the map σ is to bring the differential to the left while respecting the order of the factors. It is necessarily bilinear. Consider the case

$$\mathcal{M}=\Omega^1(\mathcal{A})$$

and let π be the projector defined by (2.7). It can be shown[20,23] that a necessary as well as sufficient condition for torsion to be right-linear is that σ satisfy the consistency condition,

$$\pi\circ(\sigma+1)=0. \tag{3.6}$$

We define a bimodule $\mathcal{A}$-connection to be the couple (D,σ). Using the fact that π is a projection one sees that the most general solution to the constraint (3.6) is given by

$$1+\sigma=(1-\pi)\circ\tau, \tag{3.7}$$

where τ is an arbitrary map,

$$\Omega^1(\mathscr{A})\otimes\Omega^1(\mathscr{A})\overset{\tau}{\to}\Omega^1(\mathscr{A})\otimes\Omega^1(\mathscr{A}). \tag{3.8}$$

If we choose $\tau=2$ then we find $\sigma=1-2\pi$ and $\sigma^2=1$. The eigenvalues of σ are then equal to ± 1.

There is at the moment no general consensus of the correct definition of the curvature of a bimodule connection. The problem is that the operator D^2 need not in general be right-linear. Nevertheless in the particular cases of interest to us here, with a module of 1-forms which is free and has a special basis such that (2.19) is satisfied, the ordinary definition of curvature is quite satisfactory.[15,16]

This general formalism can be applied in particular to the differential calculi which we have constructed in the previous section. Since $\Omega^1(\mathscr{A})$ is a free module the maps σ and τ can be defined by their action on the basis elements:

$$\sigma(\theta^i\otimes\theta^j)=S^{ij}{}_{kl}\theta^k\otimes\theta^l,\quad \tau(\theta^i\otimes\theta^j)=T^{ij}{}_{kl}\theta^k\otimes\theta^l. \tag{3.9}$$

By the sequence of identities,

$$fS^{ij}{}_{kl}\theta^k\otimes\theta^l=\sigma(f\theta^i\otimes\theta^j)=\sigma(\theta^i\otimes\theta^j f)=S^{ij}{}_{kl}f\theta^k\otimes\theta^l, \tag{3.10}$$

and the corresponding ones for $T^{ij}{}_{kl}$, we conclude that the coefficients $S^{ij}{}_{kl}$ and $T^{ij}{}_{kl}$ must lie in $\mathscr{Z}(\mathscr{A})$. From (3.7) the most general form for $S^{ij}{}_{kl}$ is

$$S^{ij}{}_{kl}=T^{ij}{}_{mn}(\delta^m_k\delta^n_l-P^{mn}{}_{kl})-\delta^i_k\delta^j_l. \tag{3.11}$$

Since $\Omega^1(\mathscr{A})$ is a free module, a covariant derivative can be defined by its action on the basis elements:

$$D\theta^i=-\omega^i{}_{jk}\theta^j\otimes\theta^k. \tag{3.12}$$

The coefficients here are elements of the algebra. The torsion 2-form is defined as usual as

$$\Theta^i=d\theta^i-\pi\circ D\theta^i.$$

There is a natural covariant derivative $D_{(0)}$ given by[15]

$$D_{(0)}\theta^i=-\theta\otimes\theta^i+\sigma(\theta^i\otimes\theta)-\nu^i, \tag{3.13}$$

which is torsion-free by (2.40). The corresponding coefficients are given by

$$\omega_{(0)}{}^i{}_{jk}=\lambda_l(S^{il}{}_{jk}-\delta^l_j\delta^i_k)+\frac{1}{2}F^i{}_{jk}. \tag{3.14}$$

The most general D is of the form

$$D=D_{(0)}+\chi, \tag{3.15}$$

where χ is an arbitrary bimodule morphism,

$$\Omega^1(\mathscr{A})\overset{\chi}{\to}\Omega^1(\mathscr{A})\otimes\Omega^1(\mathscr{A}). \tag{3.16}$$

If we write

$$\chi(\theta^i) = -\chi^i{}_{jk}\theta^j \otimes \theta^k, \tag{3.17}$$

then by an argument similar to (3.10) we conclude that

$$\chi^i{}_{jk} \in \mathcal{Z}(\mathcal{A}). \tag{3.18}$$

In general a covariant derivative is torsion-free provided the condition,

$$\omega^i{}_{lm} P^{lm}{}_{jk} = \frac{1}{2} C^i{}_{jk}, \tag{3.19}$$

is satisfied. The covariant derivative (3.15) is torsion free if and only if

$$\pi \circ \chi = 0. \tag{3.20}$$

One can define a metric by the condition

$$g(\theta^i \otimes \theta^j) = g^{ij}, \tag{3.21}$$

where the coefficients g^{ij} are elements of the algebra. To be well defined on all elements of the tensor product $\Omega^1(\mathcal{A}) \otimes_{\mathcal{A}} \Omega^1(\mathcal{A})$ the metric must be bilinear and by the sequence of identities,

$$f g^{ij} = g(f\theta^i \otimes \theta^j) = g(\theta^i \otimes \theta^j f) = g^{ij} f, \tag{3.22}$$

one concludes that the coefficients must lie in $\mathcal{Z}(\mathcal{A})$. This restriction plays an important role in the unicity argument which allows us to define the rightarrow of the diagram in Section 1. In the commutative limit the g^{ij} cannot be functions of the coordinates. In ordinary geometry an equivalence class of moving frames determines a metric and all equivalence classes correspond to the same differential calculus, the ordinary de Rham differential calculus. The choice of differential calculus does not fix the metric. In the noncommutative case on the other hand, as we have defined it, each differential calculus determines a Stehbein and thereby a metric. In the commutative limit all of the noncommutative differential calculi are either singular, if n is not equal to the classical dimension of the manifold, or have a common limit. The moving frame and the associated metric remain however as a shadow of the noncommutative structure.

The covariant derivative (3.12) is compatible with the metric if and only if [23]

$$\omega^i{}_{jk} + \omega_{kl}{}^m S^{il}{}_{jm} = 0. \tag{3.23}$$

When $F^i{}_{jk} = 0$ the condition that (3.14) be metric compatible can be written as

$$S^{im}{}_{ln} g^{np} S^{kj}{}_{mp} = g^{ik} \delta^j_l. \tag{3.24}$$

The metric we have chosen is not symmetric with respect to σ. That is

$$g^{ij} \neq S^{ij}{}_{kl} g^{kl},$$

in general. If one wishes to find a metric symmetric in the above sense then one must consider (3.24) as an equation for S and the metric and add the additional equation

$$g^{ij} = S^{ij}{}_{kl} g^{kl}. \tag{3.25}$$

The system (3.24), (3.25), if it has a solution, would yield a symmetric metric with a compatible connection.

Since we are primarily interested in the first-order effects in the commutative limit we can identify the curvature with the operator D^2. We then set as usual

$$D^2\theta^i = -\frac{1}{2}R^i{}_{jkl}\theta^k\theta^l\otimes\theta^j. \tag{3.26}$$

Since D^2 is not necessarily right-linear as an operator the last of the equivalent of the sequence of identities (3.10) is not valid and we cannot conclude that the coefficients $R^i{}_{jkl}$ necessarily lie in the center of the algebra.

IV. THE BASIC CALCULUS

In this section we shall return to the ''space–time'' algebra defined in Section I and we shall suppose, with Doplicher *et al.*, that the $q^{\mu\nu}$ lie in the center of the algebra. This permits us to suppose further that the matrix $q^{\mu\nu}$ has an inverse $q^{-1}_{\lambda\mu}$:

$$q^{-1}_{\lambda\mu}q^{\mu\nu} = \delta^\nu_\lambda.$$

We shall use this inverse to lower the indices of the generators q^μ:

$$\tilde{q}_\lambda = \mu_P^2 q^{-1}_{\lambda\mu}q^\mu.$$

A natural choice of n is $n=4$ and a natural choice of λ_μ is given by

$$\lambda_\mu = -i\tilde{q}_\mu. \tag{4.1}$$

The associated derivations defined in Section II satisfy then

$$e_\mu q^\lambda = \delta^\lambda_\mu, \tag{4.2}$$

and it follows that

$$[e_\mu, e_\nu] = 0. \tag{4.3}$$

From (4.2) it follows that

$$\theta^\lambda = dq^\lambda, \quad \theta = i\tilde{q}_\lambda dq^\lambda, \tag{4.4}$$

from which we deduce that

$$P^{\mu\nu}{}_{\rho\sigma} = \frac{1}{2}(\delta^\mu_\rho\delta^\nu_\sigma - \delta^\nu_\rho\delta^\mu_\sigma), \quad F^\lambda{}_{\mu\nu} = 0, \quad K_{\mu\nu} = i\mu_P^2 q^{-1}_{\mu\nu}. \tag{4.5}$$

One can interpret θ as a connection on a trivial bundle with the unitary elements of the algebra as a structural group.[14,24] We see from the above formula for $K_{\mu\nu}$ that $q^{\mu\nu}$ is related to the corresponding curvature. This is the noncommutative analogue of the classical result of mechanics which interprets the symplectic 2-form as the curvature of a line bundle.

From the commutation relations (2.19) one finds that the θ^λ anticommute. A possible form for σ is given therefore by

$$S^{\mu\nu}{}_{\rho\sigma} = \delta^\nu_\rho\delta^\mu_\sigma. \tag{4.6}$$

From (3.14) we see that in this case the coefficients of the connection necessarily lie in the center of the algebra. From (3.6) we see that the most general $S^{\mu\nu}{}_{\rho\sigma}$ must satisfy the constraint

$$S^{\mu\nu}{}_{[\rho\sigma]} + \delta^{\mu}_{[\rho}\delta^{\nu}_{\sigma]} = 0. \tag{4.7}$$

The most general σ is defined by a solution to Equations (3.24) and (4.7). If we restrict the $g_{\lambda\mu}$ to be the components of the Minkowski metric then the unique solution is given by (4.6). The Minkowski metric is then symmetric also with respect to σ. From (3.19) and (3.23) we see that if we require that the torsion vanish then we have

$$\omega^{\lambda}{}_{\mu\nu} = 0. \tag{4.8}$$

The space–time is therefore a noncommutative version of Minkowski space.

It is of interest to notice that Equation (4.2) defines a derivation of the algebra whatever the form of the matrix $q^{\mu\nu}$. The derivation is inner if the matrix is invertible; otherwise it is outer. Let θ^{λ} be a set of Grassmann variables. Define

$$q^{\lambda} = x^{\lambda} + \mu_P^{-1}\theta^{\lambda}, \quad q^{\mu\nu} = -2i\theta^{\mu}\theta^{\nu}. \tag{4.9}$$

Then (1.1) is satisfied and $q^{\mu\nu} \in \mathcal{Z}(\mathcal{A})$. In this case the matrix $q^{\mu\nu}$ is not invertible; it is in fact nilpotent.

Notice also that in this case the center $\mathcal{Z}(\mathcal{A})$ is nontrivial and in fact it is possible to impose that it be a smooth 6-dimensional manifold with the $q^{\mu\nu}$ as coordinates. We can, with Doplicher *et al.*, impose the conditions

$$q_{\mu\nu}q^{\mu\nu} = 0, \tag{4.10}$$

as well as

$$\epsilon_{\mu\nu\rho\sigma}q^{\mu\nu}q^{\rho\sigma} = 12,$$

which is equivalent to

$$q^{-1}_{\mu\nu} = -\frac{1}{3}\epsilon_{\mu\nu\rho\sigma}q^{\rho\sigma}. \tag{4.11}$$

The normalization is chosen for later convenience. The manifold can then be reduced to 4 dimensions. In the limit $\mu_P \to 0$ we have in fact a structure which can be regarded as a 4-dimensional manifold with a noncommutative extension à la Kaluza–Klein similar to the structures which are mentioned, for example, in Madore and Mourad.[2] In the limit $\mu_P \to \infty$ the structure can be considered to be that of an ordinary space–time with an extra 4- or 6-dimensional factor in which the Poisson structure defined by the commutator (1.1) takes its values.[25] An element of $\mathcal{Z}(\mathcal{A})$ can in no way correspond to a function on space–time in the commutative limit. Also if f is an element of $\mathcal{A}$ such that $e_{\mu}f = 0$ then we can only conclude that f is an arbitrary function of the $q^{\mu\nu}$; we cannot conclude that it is proportional to the identity. We regard the nontrivial center as something which is eventually to be eliminated, for example, by choosing $q^{\mu\nu}$ not to lie in the center. To simplify the calculations we shall suppose that the matrix of coefficients $g^{\mu\nu}$ of the metric is symmetric in the ordinary sense of the word we shall impose the condition that it be equal to the matrix of components of the ordinary Minkowski metric.

V. VARIATIONS OF THE CALCULUS

We shall now check the stability of the result (4.8) under the perturbation of the differential calculus. Introduce four arbitrary ''small'' elements f^{λ} of $\mathcal{A}$ and define

$$\tilde{f}_{\lambda} = \mu_P^2 q^{-1}_{\lambda\mu} f^{\mu}. \tag{5.1}$$

Then the elements

$$\lambda'_\mu = -i(\tilde{q}_\mu + \tilde{f}_\mu) \tag{5.2}$$

are ''near'' (4.1). In general, unless the condition (2.39) is satisfied, $\Omega^2(\mathscr{A})=0$ and the curvature will vanish. Impose the condition (2.39) and let $P^{\rho\sigma}_{(1)\mu\nu}$, $F^\lambda_{(1)\mu\nu}$ and $K_{(1)\mu\nu}$ be the first-order perturbations, respectively, of the coefficients. By simple dimensional arguments one can argue that $P^{\mu\nu}_{(1)\rho\sigma}$ must vanish. In fact it must tend to zero when the Planck mass tends to infinity but on the other hand it is without dimension and therefore cannot depend on the Planck mass. Therefore we set

$$P^{\mu\nu}_{(1)\rho\sigma}=0. \tag{5.3}$$

Using (4.5) we find that the linearization of (2.39) yields the equation

$$[\tilde{q}_\mu, \tilde{f}_\nu] - [\tilde{q}_\nu, \tilde{f}_\mu] = iF^\lambda_{(1)\mu\nu}\tilde{q}_\lambda - K_{(1)\mu\nu}. \tag{5.4}$$

Let k_μ be an arbitrary ''small'' 4-vector with the dimension of mass. Then a solution is given by

$$\tilde{f}_\lambda = k_\mu q^\mu \tilde{q}_\lambda \tag{5.5}$$

and

$$F^\lambda_{(1)\mu\nu} = k_{[\mu}\delta^\lambda_{\nu]} + 2q^{-1}_{\mu\nu}q^{\lambda\sigma}k_\sigma, \quad K_{(1)\mu\nu}=0. \tag{5.6}$$

The corresponding frame is given by

$$\theta'^\lambda = (1-k_\rho q^\rho)dq^\lambda + q^{\lambda\rho}k_\rho q^{-1}_{\mu\sigma}q^\sigma dq^\mu. \tag{5.7}$$

It will generate a new differential calculus $\Omega'^*(\mathscr{A})$ which will be in general different from $\Omega^*(\mathscr{A})$. Using (2.42) or (2.43) we find that

$$C^\lambda_{(1)\mu\nu} = F^\lambda_{(1)\mu\nu}. \tag{5.8}$$

The frame (5.7) explicitly breaks Lorentz invariance through the vector k_λ. This is quite natural since there is now present a gravitational field in the commutative limit. What is less desirable is the dependence on the extra ''coordinates'' $q^{\mu\nu}$. This dependence could perhaps be eliminated by averaging over the space of $q^{\mu\nu}$. Suppose there exists a Lorentz-invariant measure with

$$\langle q^{\mu\nu}q^{\rho\sigma}\rangle = \epsilon^{\mu\nu\rho\sigma}. \tag{5.9}$$

The normalization in (4.11) was chosen so that this equation is compatible with the condition $\langle 1\rangle = 1$. We have then

$$\langle \theta'^\lambda\rangle = dq^\lambda - q^\lambda k_\mu dq^\mu \tag{5.10}$$

and

$$\langle F^\lambda_{(1)\mu\nu}\rangle = -k_{[\mu}\delta^\lambda_{\nu]}. \tag{5.11}$$

The particular, simple form of (5.10) and (5.11) is due to the choice of normalization of the measure on the space of $q^{\mu\nu}$.

Let D' be a covariant derivative and define the coefficients $\omega'^\lambda{}_{\mu\nu}$ by the equation

$$D'\theta'^{\lambda} = -\omega'^{\lambda}{}_{\mu\nu}\theta'^{\mu}\otimes\theta'^{\nu},$$

equivalent to (3.12). Because of (4.8) we have $\omega'^{\lambda}{}_{\mu\nu} = \omega^{\lambda}_{(1)\mu\nu}$ and we can write to lowest order

$$D'\theta'^{\lambda} = -\omega^{\lambda}_{(1)\mu\nu}\theta'^{\mu}\otimes\theta'^{\nu}. \tag{5.12}$$

To extend the covariant derivative to the entire module of 1-forms we shall need the expression for the perturbed value σ' of σ. We define the coefficients $S'^{\mu\nu}{}_{\rho\sigma}$ by the equation

$$\sigma'(\theta'^{\mu}\otimes\theta'^{\nu}) = S'^{\mu\nu}{}_{\rho\sigma}\theta'^{\rho}\otimes\theta'^{\sigma},$$

equivalent to (3.12). We expand

$$S'^{\mu\nu}{}_{\rho\sigma} = \delta^{\nu}_{\rho}\delta^{\mu}_{\sigma} + S^{\mu\nu}_{(1)\rho\sigma}. \tag{5.13}$$

Each choice of $S^{\mu\nu}_{(1)\rho\sigma}$ corresponds to a definite choice of covariant derivative. As above, by simple dimensional arguments one can argue that

$$S^{\mu\nu}_{(1)\rho\sigma} = 0. \tag{5.14}$$

Therefore from (3.14) and a proper choice of χ so that (3.23) is satisfied we find that the torsion-free metric connection is given by

$$\omega^{\lambda}_{(1)\mu\nu} = \frac{1}{2}(F^{\lambda}_{(1)\mu\nu} - F_{(1)\mu\nu}{}^{\lambda} + F_{(1)\nu}{}^{\lambda}{}_{\mu}). \tag{5.15}$$

The curvature of the covariant derivative defined by this expression is essentially constant as far as ''space–time'' is concerned. From this point of view it is not particularly interesting. Using (5.11) we find that

$$\langle\omega^{\lambda}_{(1)\mu\nu}\rangle = \frac{1}{2}(k^{\lambda}g_{\mu\nu} - k_{\nu}\delta^{\lambda}_{\mu}). \tag{5.16}$$

To lowest order we find the expression

$$R^{\mu}{}_{\nu\rho\sigma} = \omega^{\mu}_{(1)\rho\tau}\omega^{\tau}_{(1)\sigma\nu} - \omega^{\mu}_{(1)\sigma\tau}\omega^{\tau}_{(1)\rho\nu} - \omega^{\mu}_{(1)\tau\nu}C^{\tau}_{(1)\rho\sigma}, \tag{5.17}$$

for the components of the curvature. It is not of particular interest to give an expression for the expectation value $\langle R^{\mu}{}_{\nu\rho\sigma}\rangle$ since it will depend critically on the probability measure. However the expectation value of the Einstein tensor must be of the form

$$\langle G_{\mu\nu}\rangle = ak_{\mu}k_{\nu} + bk^2 g_{\mu\nu}, \tag{5.18}$$

where a and b are dimensionless constants which depend on the details of the probability measure. At the present preliminary stage of the understanding of the relation between the differential calculus and the resulting curvature it is premature to consider this equation further.

VI. VARIATIONS OF THE ALGEBRA

Another way to obtain a nonvanishing gravitational field is to vary the structure of the algebra $\mathscr{A}$. We introduce 6 ''small'' elements $q^{\mu\nu}_{(1)}$ of $\mathscr{A}$ and define

$$q'^{\mu\nu} = q^{\mu\nu} + q^{\mu\nu}_{(1)}. \tag{6.1}$$

We have then

$$q'^{-1}_{\mu\nu} = q^{-1}_{\mu\nu} + q^{-1}_{\mu\rho} q^{-1}_{\nu\sigma} q^{\rho\sigma}_{(1)} . \tag{6.2}$$

Since we are here primarily interested in the effect of varying the structure of the algebra we keep the basic calculus and set

$$\lambda'_\mu = \lambda_\mu . \tag{6.3}$$

From (1.2) we find

$$[q^\lambda, q'^{\mu\nu}] = [q^\lambda, q^{\mu\nu}_{(1)}] = i\mu_P^{-1} q^{\lambda\mu\nu}_{(1)} .$$

The simplest generalization of the basic algebra is obtained by supposing that $q^{\lambda\mu\nu}_{(1)}$ lies in the center of $\mathscr{A}$. This is the extended model of Doplicher *et al.* If we impose this condition we can choose

$$q^{\mu\nu}_{(1)} = -\mu_P^{-1} q^{\lambda\mu\nu}_{(1)} \widetilde{q}_\lambda . \tag{6.4}$$

We have then

$$e'_\mu q'^\nu = e_\mu q^\nu = \delta^\nu_\mu + \mu_P^{-1} q^{-1}_{\mu\rho} q^{\nu\rho\sigma}_{(1)} \widetilde{q}_\sigma . \tag{6.5}$$

Using (4.5) we find that the linearization of (2.39) yields now the solution

$$F^\lambda_{(1)\rho\sigma} = \mu_P q^{-1}_{\rho\mu} q^{-1}_{\sigma\nu} (q^{\lambda\mu\nu}_{(1)} - q^{\mu\nu\lambda}_{(1)} + q^{\nu\mu\lambda}_{(1)}). \tag{6.6}$$

The corresponding frame is given by

$$\theta'^\lambda = dq^\lambda - \mu_P^{-1} q^{-1}_{\mu\rho} q^{\lambda\rho\sigma}_{(1)} \widetilde{q}_\sigma dq^\mu . \tag{6.7}$$

VII. de SITTER SPACE

To define a noncommutative version of a space which is not topologically trivial we shall use elementary techniques from classical geometry as well as from the quantum mechanics of constrained Hamiltonian systems. A nontrivial topological manifold V can be defined by its imbedding in a flat space of sufficiently high dimension. The algebra $\mathscr{B} = \mathscr{C}(V)$ of continuous functions on V can be identified with the algebra $\mathscr{A}$ of all continuous functions on the enveloping space modulo the ideal $\mathscr{I}$ of continuous functions which vanish on V: $\mathscr{B} = \mathscr{A}/\mathscr{I}$. As a first attempt to define a noncommutative version of de Sitter space we set $\mathscr{A}$ equal to a $*$-algebra generated by a set of elements q^i, $0 \leqslant i \leqslant 4$, which satisfy commutation relations similar to those given by (1.1):

$$[q^i, q^j] = i\mu_P^{-2} q^{ij} . \tag{7.1}$$

We introduce a Minkowski-signature metric with components g_{ij} and we define $\mathscr{I}$ to be the 2-sided ideal generated by the element

$$c_1 = g_{ij} q^i q^j - r^2 , \tag{7.2}$$

where r^2 is a real constant. Two problems present themselves immediately. The q^{ij} cannot be invertible; it would otherwise define a symplectic form on an odd-dimensional manifold. Using the commutation relations (7.1) one sees also that the 2-sided ideal generated by the element c_1 is the entire algebra and therefore $\mathscr{B} = 0$. We saw something similar to this in Section II where we noticed that the 2-sided ideal generated by the element θ is the entire algebra of forms. This second problem is connected with the fact that we are trying to define the manifold V exactly as a submanifold in spite of the fact that its ''points'' are fuzzy and only defined to within the

uncertainty μ_P^{-1}. As a solution to the first problem we add another dimension and we define V as a submanifold of a 6-dimensional space. We let then $0 \leqslant i \leqslant 5$ and we add a constraint

$$c_2 = q^5. \tag{7.3}$$

To circumvent the second problem we follow the example furnished by the quantization of constrained Hamiltonian systems. The two constraints are of second class and Dirac[26] has shown how in this case one can introduce a new bracket with respect to which they commute with each other and with the observables. One can similarly modify the commutation relations (7.1) so that c_1 commutes with the generators of $\mathscr{A}$ and thus with c_2. We introduce the components r^{ij} of an antisymmetric tensor and we set

$$[q^i, q^j]' = i\mu_P^{-2}(q^{ij} - r^{ij}). \tag{7.4}$$

From the condition $[q^i, c_2]' = 0$ we find that

$$r^{i5} = q^{i5}. \tag{7.5}$$

From the condition $[q^i, c_1]' = 0$ we find the equation

$$q_j r^{ij} + r^{ij} q_j = 2q^{ij} q_j, \tag{7.6}$$

for r^{ij}. Suppose that the element $q^{i5}q_i$ of $\mathscr{A}$ is invertible. The appropriate solution is given then by

$$r^{ij} = \frac{1}{2} q^{[ik} q^{j]5} [q_k, (q^{l5} q_l)^{-1}]_+, \tag{7.7}$$

which can also be written in the form

$$r^{ij} = q^{[ik} q^{j]5} q_k (q^{l5} q_l)^{-1} - \frac{i}{2}\, \mu_P^{-2} q^{[ik} q^{j]5} q_{kl} q^{l5} (q^{m5} q_m)^{-2}. \tag{7.8}$$

We define $\mathscr{T}$ to be the 2-sided ideal of $\mathscr{A}$ generated by the two elements c_1 and c_2. By modifying the original structure of the algebra we have obtained a nontrivial quotient algebra $\mathscr{B}$. The modification of the algebra is not ''small'' in the sense of the preceding section. We shall consider $\mathscr{B}$ as a possible noncommutative equivalent of de Sitter space. We refer to Masson[27] for some examples of quotient algebras defined without modification of the bracket.

We define $\widetilde{q}_i$ and λ_i as in Section IV. The associated derivations e_i satisfy then

$$e_i q^j = \delta_i^j - \frac{1}{2}[q_i q^{j5} - \delta_i^5 q^{jk} q_k, (q^{l5} q_l)^{-1}]_+, \tag{7.9}$$

and they no longer commute. They do not even close to form a Lie algebra:

$$[e_i, e_j] = i\mu_P^2 q_{ik}^{-1} q_{jl}^{-1} r^{kl}. \tag{7.10}$$

From the relations

$$e_i c_1 = 0, \quad e_i c_2 = 0, \tag{7.11}$$

it follows that the e_i can be considered as derivations of $\mathscr{B}$.

If we set

$$f_i{}^{jk} = \delta_i^{[j} q^{k]5} + \delta_i^5 q^{jk},$$

then in the commutative limit we can write

$$e_i = (q^{l5} q_l)^{-1} f_i{}^{jk} q_k \partial_j . \tag{7.12}$$

Since $f_i{}^{jk}$ is antisymmetric in the last 2 indices and since $f_i{}^{j5} = 0$ the e_i are vector fields on the de Sitter space. There are 6 of them and they satisfy 2 relations:

$$q_i q^{ij} e_j = 0, \quad q^{i5} e_i = 0. \tag{7.13}$$

We define a differential calculus as in Section IV. It follows from (7.11) and the construction of the differential that

$$dc_1 = 0, \quad dc_2 = 0. \tag{7.14}$$

The differential calculus can be considered then as a calculus $\Omega^*(\mathscr{B})$ over $\mathscr{B}$. It tends as it must in the commutative limit to the algebra of de Rham forms over de Sitter space. Classical de Sitter space is parallelizable but it is not obvious that $\Omega^1(\mathscr{B})$ is free as a left or right module. Because of the relations (7.13) the θ^i dual to the e_i cannot be constructed. Because of the factor $(q^{l5} q_l)^{-1}$ in the expression (7.7) the equation (2.39) has no solution for the λ_i which we have chosen.

VIII. GAUGE INVARIANCE

In (5.15) we calculated the connection associated to a perturbation of the basic differential calculus. One might have expected from the origin (5.2) of the perturbation that it would resemble rather a coordinate transformation and that the perturbed connection would vanish. The fact that this is not the case is due to the existence of the extra ''coordinates'' $q^{\mu\nu}$ which have been used to raise and lower indices. Our formalism is in fact analogous to that which can be used to describe a manifold V which is defined by its imbedding in a flat space of higher dimension so we mention this briefly. Let x^a be the coordinates of the imbedding space and y^α local coordinates of V. Then V is defined locally by functions of the form $x^a(y^\alpha)$. A variation of V to a surface V' is given by functions of the form $x'^a(y^\alpha) = x^a(y^\alpha) + h^a(y^\alpha)$. A variation of the coordinates of the imbedding space can be written in the form $x'^a = x^a + h^a(x^b)$. The most general variation of the metric on V is obtained by a variation $g'_{ab} = g_{ab} + \partial_{(a} h_{b)}$ of the components of the flat metric. In the commutative limit one can consider $(q^\lambda, q^{\mu\nu})$ as the ''coordinates'' of the imbedding space and the conditions $q^{\mu\nu} = 0$ the equations which define V.

Let V be a smooth manifold and ϕ a smooth map of V into itself. Then ϕ induces an automorphism ϕ^* of the algebra $\mathscr{C}(V)$ of smooth functions given by $\phi^* f = f \circ \phi$ and thereby a map ϕ_* of the derivations. If X is a derivation of $\mathscr{C}(V)$ then so is $\phi_* X = \phi^{*-1} \circ X \circ \phi^*$. The noncommutative equivalent of ϕ is an automorphism of the algebra $\mathscr{A}$. Consider the inner automorphism which acts on the generators by the transformation

$$q^\lambda \mapsto \mathrm{ad}\ U^{-1} q^\lambda, \quad q^{\mu\nu} \mapsto \mathrm{ad}\ U^{-1} q^{\mu\nu}. \tag{8.1}$$

Then it is obvious that $\lambda_\mu \to \mathrm{ad} U^{-1} \lambda_\mu$ and a solution to Equation (3.39) is transformed into another solution with the same values of $P^{\mu\nu}{}_{\rho\sigma}$, $F^\lambda{}_{\mu\nu}$ and $K_{\mu\nu}$. A derivation X is transformed into $X' = \mathrm{ad}\ U^{-1} \circ X \circ \mathrm{ad}\ U$ from which we deduce that

$$\theta^\alpha \mapsto \theta'^\alpha = \mathrm{ad} U \circ \theta^\alpha \circ \mathrm{ad} U^{-1}. \tag{8.2}$$

If the geometry of V is described (locally) by a moving frame θ^α then a change of moving frame is a map,

$$\theta^{\alpha} \mapsto \theta'^{\alpha} = \Lambda^{\alpha}_{\beta} \theta^{\beta}, \tag{8.3}$$

with Λ^{α}_{β} smooth functions of V. If the metric is to be left invariant then there are restrictions on the Λ^{α}_{β}:

$$\Lambda^{\alpha}_{\gamma} \Lambda^{\beta}_{\delta} g^{\gamma\delta} = g^{\alpha\beta}.$$

In the noncommutative case one could define a change of Stehbein using the same formula (8.3) but with Λ^{α}_{β} elements of the algebra $\mathscr{A}$. If $\Lambda^{\alpha}_{\beta} \in \mathscr{Z}(\mathscr{A})$ then the new Stehbein has the same status as the old; it is dual to a set of derivations. Otherwise the change is purely formal. From the left-linearity of D^2 we conclude that

$$D^2(\Lambda^{\alpha}_{\beta} \theta^{\beta}) = \Lambda^{\alpha}_{\beta} D^2 \theta^{\beta},$$

and so from (3.26) we find that

$$\Lambda^{\alpha}_{\lambda} R'^{\lambda}{}_{\beta\gamma\delta} = R^{\alpha}{}_{\lambda\mu\nu} \Lambda^{\lambda}_{\beta} \Lambda^{\mu}_{\gamma} \Lambda^{\nu}_{\delta}. \tag{8.4}$$

If we multiply this equation on both sides by $g^{\beta\gamma}$ and define the ''Ricci tensor'' as the map $\theta^{\alpha} \mapsto R^{\alpha}{}_{\delta} \theta^{\delta}$ defined by $R^{\alpha}{}_{\delta} = g^{\beta\gamma} R^{\alpha}{}_{\beta\gamma\delta}$ then we find the condition

$$\Lambda^{\alpha}_{\lambda} R'^{\lambda}{}_{\delta} = R^{\alpha}{}_{\nu} \Lambda^{\nu}_{\delta}. \tag{8.5}$$

The order of the factors is important here. There is no reason for the trace $R^{\alpha}{}_{\alpha}$ of $R^{\alpha}{}_{\delta}$ to be ''invariant'' except if $\Lambda^{\alpha}_{\beta} \in \mathscr{Z}(\mathscr{A})$. To define the analogue of the Einstein–Hilbert action one would also have to introduce a trace on the algebra such that

$$\mathrm{Tr}(R^{\alpha}{}_{\alpha}) \to \int_V R^{\alpha}{}_{\alpha},$$

in the commutative limit. There is no obvious way in which this can be done. We are therefore unable at the moment to propose a satisfactory definition of an action and indeed we are not in a position to argue that there is even a valid action principle. A discussion of this point has been made by Connes and coworkers in a series of articles[28–31] but the definition which these authors propose is valid only on the noncommutative generalizations of compact spaces with Euclidean-signature metrics. Cyclic homology groups have been proposed[19] as the appropriate generalization to noncommutative geometry of topological invariants; the appropriate definition of other, nontopological, invariants is not clear.

(Received 15 July 1997; accepted for publication 18 August 1997)

We apply the holonomy method to study the regularity of space-times whose initially open spatial sections are made compact. We restrict our attention to a set of different expressions of the anti-de Sitter space-time in $(2+1)$-dimensions. After we have computed the holonomy matrix to this set, we explicitly derive the regularity conditions for two elements of the set. The first expression, relevant to classical cosmology, will be regular if the periods of the compactified directions are 2π. The other expression, relevant to quantum cosmology, will be regular if the cosmological constant has a certain, well defined, discrete spectrum. © *1998 American Institute of Physics.* [S0022-2488(98)01901-X]

I. INTRODUCTION

The need for different types of space-times with closed spatial sections, in classical[1] and quantum[2] models of the Universe, has produced over the last years an increasing number of works where one turns to compact, or compactify, open manifolds.[3,4]

An interesting motivation, at the classical level, for the use of space-times whose initially open spatial sections were compactified, are the works by Fagundes.[3] There, he proposed an explanation to the so-called quasar redshift controversy (see Ref. 5 for a review) by means of multiple images of a single source produced in a universe with compact hyperbolic spatial sections.

Another motivation to consider space-times with compact spatial sections comes from quantum cosmology.[2] There one works with these space-times because one does not know, in the general case, how to treat the contributions coming from boundary terms at the spatial infinity.[2] However, we may mention a few attempts to write the quantum mechanics of gravitational systems with open spatial sections.[6]

The work of Louko and Ruback is an example, in quantum cosmology, where one has to compactify the initially open, flat, spatial sections of a set of space-times in order to compute the ''no-boundary'' wave-function[7] for certain universes.

An important property of the compactification process is that it may cause the development of singularities of conical, or even more complicate nature, in the resulting space-times.[4,8] And sometimes, as in the case of the space-times contributing to the ''no-boundary'' wave-function,[7] one is not interested in the presence of singularities. It means that it would be important to determine what the conditions are for one obtaining a regular space-time with compactified spatial sections.

Recently, a technique aimed at identifying, in a systematic way, the presence of conical singularities in a given space-time has been introduced. It is the so-called holonomy method.[9]

In the present paper, we would like to apply the holonomy method to investigate the regularity of space-times with spatial sections which are closed as the result of compactifications. The use of the holonomy method implies that we will treat here only the cases where after the compactifications the space-times may have, at most, conical singularities. In particular, we would like to

[a)]Present address: Departamento de Fisica Teorica, UERJ, Rua Sao Francisco Zavier 524, Maracana, CEP 20550-013, Rio de Janeiro, Brazil; electronic mail: no4c7@symbcomp.verj.br

determine if there are conditions on the physical constants describing these space-times, when we require them to be regular, and what these conditions are.

We may divide the space-times to be studied in two sets: the first with negatively curved spatial sections and the second with flat spatial sections. Here we shall consider only space-times of the first set, leaving the others, belonging to the second set, to a future work.

As a matter of simplicity we shall restrict our attention to space-times whose spatial sections have a constant negative curvature. In order to facilitate the calculations, we shall work in $(2+1)$-dimensions and comment, in Sec. V, on the modifications needed in order to treat $(3+1)$-dimensional space-times.

The next section, Sec. II, is devoted to the introduction of the particular space-time studied here. It is the $(2+1)$-dimensional anti-de Sitter space-time with compact spatial sections. We shall modify the usual anti-de Sitter metric by the introduction of an arbitrary and constant lapse function,[10] N, which will allow us to treat a certain set of cases.

In Sec. III, after demonstrating that the singularities that may be formed by the compactifications are, at most, conical, we apply the holonomy method to the anti-de Sitter space-time, written with an unspecified lapse function. Our final result in this section is a holonomy matrix whose elements depend on N, among other quantities.

In Sec. IV, we shall derive the regularity conditions for two elements of the set mentioned above.

The first case is treated in Sec. IV A. It is the usual expression for the anti-de Sitter space-time metric, with N equal to the identity, which is relevant to classical cosmology.[3] The regularity condition, in this case, is a constraint upon the periods of the parameters introduced to describe the compactified directions.

In Sec. IV B, we treat the second case where N is a given function of few constants present in the chosen space-time. As we shall see, in the Appendix, this space-time contributes at the semi-classical level to the ''no-boundary'' wave-function of a certain universe. It means that this case is relevant to quantum cosmology. Here, the regularity condition turns out to produce a transcendental equation for the only free physical parameter of the model, the cosmological constant Λ. For certain values of the integration constants, this equation has solutions which form a discrete and finite set.

Finally, in Sec. V, we conclude by outlining the main results of the paper and commenting on generalizations of the present analysis to other $(2+1)$ and $(3+1)$-dimensional anti-de Sitter space-times.

II. (2+1)-DIMENSIONAL ANTI-DE SITTER SPACE-TIME WITH COMPACT SPATIAL SECTIONS

In $(2+1)$-dimensions the anti-de Sitter space-time has the following metric:[11]

$$ds^2 = -N^2\, dt^2 + a^2(t)(d\chi^2 + \sinh^2\chi\, d\theta^2), \tag{1}$$

where

$$0 \leqslant t \leqslant 1, \quad 0 \leqslant \chi < \infty, \quad 0 \leqslant \theta \leqslant 2\pi, \tag{2}$$

$$a(t) = \pm\alpha \sin\left(\frac{Nt}{\alpha}\right), \qquad \text{and} \quad \alpha^2 = \frac{1}{|\Lambda|}. \tag{3}$$

in Eq. (3) Λ is the negative cosmological constant.

The presence of a constant and arbitrary lapse function in the metric (1) allows us to treat a set of different expressions of the anti-de Sitter space-time, each differing from the others by the value of N. Let us call this set ADS. The physical significance of the possible choices of N can be appreciated in Ref. 10.

From the literature,[12] we know that for fixed values of t the spatial sections of the anti-de Sitter space-time (1) are two-dimensional one-sheeted hyperboloids. The separation between the origin of the coordinate system and the pole of the one-sheeted hyperboloid is given by the scale factor, $a(t)$, at that instant. It means that the spatial sections are open. Therefore, since we are interested in the case where they are closed, we must compactify them.

In what follows, with the aid of a few mathematical results we shall introduce the relevant compact spatial sections.

The one-sheeted hyperboloid mentioned above is a representation of the two-dimensional hyperbolic space H^2. In two dimensions, every closed orientable surface of genus of at least two allows a geometric structure modeled on the H^2 (see the review article Ref. 13 for more details on this result due to Poincaré, among others). Based upon this result and in order to keep our treatment as simple as possible, let us choose our closed orientable surface to be a double torus. Then, the one-sheeted hyperboloid, which describes the spatial section of the space-time (1), will be compactified into a double torus.

One way to proceed is working in a projection of the H^2 onto a plane, which results in a disc called the Poincaré Disc (P.D.).[14] The conformal transformations which takes one from the coordinates (χ,θ) to the polar coordinates (r,θ) on the P.D. are

$$r=\sqrt{\alpha^2-v_0^2}\,\tanh(\chi/2), \quad \theta \text{ is unchanged}, \tag{4}$$

where

$$v_0=\sqrt{\alpha^2-a^2(t)}. \tag{5}$$

This mapping from the H^2 to the P.D. induces a non-trivial line element on the disc, given by

$$ds_{PD}^2=4(\alpha^2-v_0^2)^2\frac{(dr^2+r^2d\theta^2)}{(\alpha^2-v_0^2-r^2)^2}. \tag{6}$$

The next step in the compactification process is the selection of a fundamental region (in general a polygon) which tessellates[15] the P.D., and may be transformed into a double torus. Then, we shall take this fundamental region and construct the double torus, or in other words, the quotient surface H^2/Γ, where Γ is a certain symmetry transformation of the H^2.

In two dimensions, the unique symmetry transformations of the H^2 capable of generating compact surfaces are the hyperbolic ones,[16] in other words, Lorentzian boosts. Our compact surface will be fabricated by the identification of the sides, through the relevant boost transformations, of the above selected polygon.

The simplest fundamental region which gives rise to a double torus is the regular octagon.[14] If we now identify the opposite sides of this polygon, with the aid of four different boost transformations (one for each relevant direction), we obtain a representation of the desired compact surface.

Therefore, the spatial sections of our space-time will be given by the time evolution of a double torus with line element (6).

III. THE HOLONOMY MATRIX

We start by writing down the line element of the space-time described by the evolution of the double torus, in Cartesian coordinates, with the aid of Eqs. (1), (2) and (6),

$$ds^2=-N^2dt^2+\frac{4(\alpha^2-v_0^2)^2(dx^2+dy^2)}{(\alpha^2-v_0^2-x^2-y^2)^2}, \tag{7}$$

where the ranges of x and y will depend on the octagon dimensions, the opposite sides of the octagon are identified, and t has the range given in Eq. (2).

Observing Eqs. (1) and (3), we notice that the anti-de Sitter space-time has a singularity at $t=0$. This singularity can, at most, be conical. One can see it by noting that for Robertson-Walker space-times all the scalars, formed out of contractions of the Riemann tensor, are proportional to appropriate powers of the curvature scalar (R). From direct calculations one finds that our space-time has an everywhere constant curvature scalar,

$$R=-6|\Lambda|. \tag{8}$$

In fact, it is known that this singularity is a coordinate singularity.[12]

The same conclusion does not directly apply to the space-time with line element (7) because at the event $t=0$ $(v_0^2=\alpha^2)$, due to the identifications mentioned after Eq. (7), a conical singularity may have formed.

Let us, then, apply the holonomy method in order to investigate the presence, or not, of a conical singularity in the space-time with line element (7), at the event $t=0$.

Following the instructions of the holonomy method,[9] we start by writing down the parallel transport equations for a fiducial vector v, along a closed loop (to be specified), in the space-time represented by Eq. (7).

The easiest way to derive them, from Eq. (7), is by working on the orthonormal basis, defined by the transformations

$$w^t=dt, \quad w^i=\frac{2(\alpha^2-v_0^2)}{\alpha^2-v_0^2-x^2-y^2}dx_i, \tag{9}$$

where $i=x,y$ and $x_i=x,y$.

The non-vanishing connection coefficient components in this basis are

$$\Gamma_{txx}=\Gamma_{tyy}=\frac{-2\dot{v}_0 v_0(x^2+y^2)}{(\alpha^2-v_0^2)(\alpha^2-v_0^2-x^2-y^2)}=-\Gamma_{xtx}=-\Gamma_{yty}, \tag{10}$$

$$\Gamma_{ijj}=\frac{-x_i}{\alpha^2-v_0^2}=-\Gamma_{iji}, \tag{11}$$

where $j=x,y$; $i\neq j$, and i and x_i vary as in Eq. (9).

The parallel transport equation for the fidutial vector, v, is given by[9]

$$\frac{dv^\alpha}{d\lambda}+v^\beta\Gamma^\alpha_{\beta\gamma}\Omega^\gamma_\delta\frac{dx^\delta}{d\lambda}=0, \tag{12}$$

where λ is an affine parameter describing the curve, the Greek indices vary over all the coordinates, and the matrix Ω relates the non-coordinate basis with the coordinate one.

In order to obtain the explicit expression of Eq. (12), we have to introduce the closed loop around which we shall parallel transport v.

We start by noting that for a given instant t there are four independent, closed directions, one for each pair of opposite, identified, sides of the octagon. Each one of the four independent close, directions gives rise to a set of closed loops, which we shall call S_i $(i=1,\ldots,4)$. All closed loops which may be constructed, taking in account the identifications, are made up of at least one element of the four S_i. Therefore, since the space-time event under investigation is in the t direction, the simplest closed loops we can choose are the elements of the four S_i at constant and different values of t. These loops will collapse to $t=0$ when we take the limit $t\to 0$.

Then, the results derived by the use of the elements of the four S_i will be enough to draw conclusions about the regularity of our space-time.

In order to apply the holonomy method to one of the four S_i, we must choose an element of this set. Let us say the closed loop C, formed by joining the middle points of each of the opposite sides. Now, we orient our axes so that the x axis coincides with C. In terms of our coordinates, the parametric equation of C, for a certain instant of t, is

$$t=\text{constant}, \quad y=0\,, \quad x=g(\lambda), \tag{13}$$

where λ is a periodic parameter varying in the range $[\lambda_0,\lambda_f]$,$\lambda_f\equiv\lambda_0+p_\lambda$, and p_λ is the period of λ, and $g(\lambda)$ is a function of λ, to be specified, which describes x in terms of λ and varies between the extreme values of x, $[-x_0(t),x_0(t)]$. The extreme values of x are the following time dependent functions from Eq. (4):

$$x_0(t)=\sqrt{\alpha^2-v_0^2}\,\tanh(\chi_0/2), \quad \theta=0,\pi, \tag{14}$$

where χ_0 is one fixed value of χ.

So, with the aid of the relevant Ω components, we may write the parallel transport equations (12) for C [Eq. (13)]:

$$\frac{dv^y}{d\lambda}=0, \tag{15}$$

$$\frac{dv^t}{d\lambda}+\frac{4\gamma f^2(df/d\lambda)}{(1-f^2)^2}v^x=0, \tag{16}$$

$$\frac{dv^x}{d\lambda}+\frac{4\gamma f^2(df/d\lambda)}{(1-f^2)^2}v^t=0, \tag{17}$$

where,

$$f(\lambda)\equiv\frac{g(\lambda)}{\sqrt{\alpha^2-v_0^2}} \quad \text{and} \quad \gamma\equiv\frac{\dot{v}_0 v_0}{\sqrt{\alpha^2-v_0^2}}. \tag{18}$$

Observing Eq. (14), we note that the main motivation for the introduction of the new parametrization function $f(\lambda)$, Eq. (18), is to restrict all the time dependence of our subsequent results to be concentrated in γ [Eq. (18)].

The solution of Eq. (15) is given by

$$v^y=v_0^y, \tag{19}$$

where v_0^y is the value of $v^y(\lambda)$ for $\lambda=\lambda_0$. The two remaining equations, (16) and (17), form a coupled system of first order differential equations. In order to solve it we shall have to introduce the explicit value of $f(\lambda)$.

One of the simplest choices for $f(\lambda)$, which gives periodic solutions for the system (16) and (17), is obtained by demanding that

$$\frac{4f^2(df/d\lambda)}{(1-f^2)^2}=\cot(\gamma\lambda), \tag{20}$$

which gives, after an integration, the following implicit equation for f as a function of λ:

$$\left(\frac{1-f}{1+f}\right)^{\gamma}\exp\left(\frac{2f\gamma}{1-f^2}\right)=A\,\sin(\gamma\lambda), \tag{21}$$

where A is an integration constant.

Now, introducing our parametrization choice, Eq. (20), in the system (16) and (17) and solving it, we find the general solutions

$$v^t(\lambda)=\frac{D}{2}\left[\frac{B^2+\sin^2(\gamma\lambda)}{B\sin(\gamma\lambda)}\right] \quad \text{and} \quad v^x(\lambda)=\frac{D}{2}\left[\frac{B^2-\sin^2(\gamma\lambda)}{B\sin(\gamma\lambda)}\right], \tag{22}$$

where B and D are integration constants to be determined by the initial conditions.

Observing the solutions (22), we note that (for non-vanishing C and D) they are singular whenever $\lambda=2n\pi/\gamma$, n being an integer. This property comes directly from our choice for the parametrizing function $f(\lambda)$ [Eq. (20)]. This singularity of the solutions does not prevent us from using them in the holonomy method, because the holonomy matrix is computed by comparing the fiducial vector v at the same point,[9] before and after the parallel transport of v around the closed loop. Therefore, we must only avoid choosing as the initial point of the loop one of the singular points of the solutions (22).

For the initial conditions,

$$v^j(\lambda=\lambda_0)=v_0^j, \tag{23}$$

where $j=t,x$, and the solutions (19) and (22), we obtain the following holonomy matrix M:

$$\begin{pmatrix} v^t(\lambda_f) \\ v^x(\lambda_f) \\ v^y(\lambda_f) \end{pmatrix} = \begin{pmatrix} M_{tt} & M_{tx} & 0 \\ M_{xt} & M_{xx} & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} v_0^t \\ v_0^x \\ v_0^y \end{pmatrix}, \tag{24}$$

where

$$M_{tt}=M_{xx}=\frac{\sin^2(\gamma\lambda_0)+\sin^2(\gamma\lambda_f)}{2\sin(\gamma\lambda_0)\sin(\gamma\lambda_f)}\equiv M_+, \tag{25}$$

$$M_{tx}=M_{xt}=\frac{\sin^2(\gamma\lambda_0)-\sin^2(\gamma\lambda_f)}{2\sin(\gamma\lambda_0)\sin(\gamma\lambda_f)}\equiv M_-. \tag{26}$$

IV. REGULARITY CONDITIONS

The next step in the holonomy method is the determination of the limit of the holonomy matrix elements as the closed loops collapse to the event $t=0$. It means that we must take the limit of the non-trivial elements of M, given in Eqs. (25) and (26), as $t\to 0$.

The limits of M_+, Eq. (25), and M_-, Eq. (26), as $t\to 0$ are easy to determine because they depend on t only through γ. With the aid of Eqs. (5) and (18) we compute the limit of γ as

$$\lim_{t\to 0}\gamma=-N. \tag{27}$$

From Eq. (27), the desired limits of $M_\pm$ are

$$\lim_{t\to 0}M_\pm=\frac{\sin^2(N\lambda_0)\pm\sin^2(N\lambda_f)}{2\sin(N\lambda_0)\sin(N\lambda_f)}, \tag{28}$$

where the $+$ and $-$ signs on the right hand side of Eq. (28) are associated, respectively, with the limits of M_+ and M_-.

Since we would like to obtain the conditions to have regular space-times, following the holonomy method, we have to impose that the limits of M_+ and M_- are

$$\lim_{t\to 0} M_+ = 1 \quad \text{and} \quad \lim_{t\to 0} M_- = 0. \tag{29}$$

Before we impose that the limits of M_+ and M_- have the value given by Eq. (29), we must rewrite them in terms of the other free parameter (besides N) of the model. It is the period p_λ of the parameter λ which describes the closed loop C, Eq. (13).

Using the expression which relates λ_f with λ_0 and p_λ, shown just after Eq. (13), we may introduce p_λ in the limits of M_+ and M_-, Eq. (28). If, after doing that, we impose that the resulting expressions have the values given in Eq. (29), we obtain the following independent equations for generic values of λ_0:

$$\sin^2(Np_\lambda) = 0, \tag{30}$$

$$\sin(Np_\lambda)\ \cos(Np_\lambda) = 0, \tag{31}$$

$$\sin(Np_\lambda)[\cos(Np_\lambda) - 1] = 0, \tag{32}$$

$$\cos^2(Np_\lambda) - 2\cos(Np_\lambda) + 1 = 0. \tag{33}$$

The most general solution to this system of Equations (30)–(33), in the variables N and p_λ, is

$$Np_\lambda = 2\pi n, \tag{34}$$

where n is a non-zero, positive integer.

Let us now consider what conditions Eq. (34) will introduce for two elements of the ADS [Eq. (7)]. They will have definite values of the lapse function N.

A. The case relevant to classical cosmology

For this case, as mentioned in the Introduction, the lapse function is equal to the identity

$$N = 1. \tag{35}$$

It means that Eq. (34) is reduced to the following condition upon p_λ:

$$p_\lambda = 2\pi n. \tag{36}$$

From the discussion in Ref. 9, we know that the closed, or angular, direction must be defined in the range $[0,2\pi]$. Therefore, we can only accept the solution (36) for Eq. (34) such that

$$n = 1. \tag{37}$$

B. The case relevant to quantum cosmology

Here, as demonstrated in the Appendix, the lapse function has the following expression:

$$N = \alpha[\pi/2 \pm \arccos(a_1/\alpha)], \tag{38}$$

where a_1 is positive and is the value of the scale factor, $a(t)$, for $t = 1$.

In the present case we do not need to restrict n to be given by Eq. (37), because from Eq. (34) with N written above Eq. (38), we may still have the closed direction in the desired range for a generic value of n.

If we introduce N [Eq. (38)], in Eq. (34), we find the following equation for the variables p_λ and x:

$$a_1 x = \sin\left(\frac{2\pi n}{p_\lambda} x\right), \tag{39}$$

where x is related to the cosmological constant by

$$x = \sqrt{|\Lambda|} \tag{40}$$

and varies in the range $(0,1/a_1)$.

For given values of a_1 and n, Eq. (39) furnishes a relationship between p_λ and the cosmological constant. It is clear, then, that for a proper choice of p_λ one may derive from eq. (39) the allowed values of Λ such that the space-time is regular.

Suppose we adopt the same value of p_λ as in Sec. IV A, and for simplicity choose n to be given by Eq. (37). With these choices Eq. (39) reduces to

$$a_1 x = \sin x. \tag{41}$$

Equation (39) has solutions for $a_1 < 2/\pi$, and they form a discrete set. The number of solutions will depend on a_1 due to its presence in the superior limit of x.

We may write an approximate rule to the solutions of Eq. (39), if we separate them in two sets. The first set has the even order solutions and the second the odd order solutions.

Calling m the order of the solutions, we have the following approximate rules for the two sets of solutions,

$$\text{Even order: } |\Lambda|_k \approx (1-a_1)^2 (2k-1)^2 \pi^2, \quad k = 1,2,3,\ldots, \tag{42}$$

$$\text{Odd order: } \quad |\Lambda|_l \approx (1+a_1)^2 (2l\pi)^2, \quad l = 1,2,3,\ldots, \tag{43}$$

where $k = m/2$, $l = (m-1)/2$, and we have used Eq. (40). For values of n other than 1 we shall also have equations and solutions similar to Eqs. (41)–(43), respectively.

As we have discussed in Sec. III, the conditions (36), (37), (42) and (43) guarantee the regularity of the two expressions of the anti-de Sitter space-time, as investigated by using closed loops of one of the four S_i. Their regularity can only be assured if we repeat the above procedure to the other three S_i.

We start by choosing as the representative of each of the other three S_i, the closed loops which join the middle points of each remaining pairs of opposite identified sides, as we did for the S_i studied in Sec. III. In the next step, we simply rotate our (x,y) axes so that the x axis successively coincides with these three closed loops just introduced. Finally, we separately repeat the analysis from Secs. III and IV for each of the three cases.

The choice of the regular octagon as our fundamental region means that all four independent closed loops have the same length at any time. That property implies that after repeating the analysis above, we shall obtain the same regularity conditions (36), (37), (42) and (43), for each of the three independent loops above.

Therefore, we may conclude that those conditions guarantee the regularity of the two examples of different expressions of the anti-de Sitter space-time studied in this paper.

V. CONCLUSIONS

In the present paper we have applied the holonomy method to investigate the regularity of space-times whose spatial sections are closed as the result of compactifications. In particular we were interested in the conditions to obtain regular space-times.

As a matter of definiteness and simplicity we have studied a $(2+1)$-dimensional set of different expressions of the anti-de Sitter space-times (ADS). Each element of the set differs from the others by the value of a constant lapse function.

The holonomy matrix of that set was constructed in Sec. III. The regularity conditions for two particular elements of the ADS were derived in Sec. IV.

The first element of the ADS, relevant to classical cosmology,[3] will be regular only if the periods of the compactified directions are equal to 2π (Sec. IV A).

The second element of the ADS, relevant to quantum cosmology as shown in the Appendix, was studied in Sec. IV B. Here the space-time will be regular if, for given values of the initial conditions and two other free parameters, the negative cosmological constant present in the model has the discrete values of Eqs. (42) and (43).

It is important to add that the discrete spectrum for the cosmological constant has been derived just by demanding that the space-time be regular. This requirement, following Hartle and Hawking,[7] can be considered a first principle.

Our study, in the present paper, may be generalized to other cases. The most obvious generalization is to consider elements of the ADS (7), with values for N different from the two studied here.

One may also apply the above procedure to investigate the regularity of $(2+1)$-dimensional anti-de Sitter space-times whose closed spatial sections are negative curved surfaces of genus greater than two. It means that the fundamental regions are not octagons anymore. If the new polygons are regular, the analysis will be a repetition of what we did here for a greater number of independent closed loops. If, on the other hand, the polygons are not regular, we shall have to consider the regularity conditions derived for each independent closed loop, separately, and demand that they all agree.

Finally, the use of the holonomy method to examine the regularity of $(3+1)$-dimensional anti-de Sitter space-times with closed, negative curved, spatial sections follows directly from our work. The main differences are the possible uses of different projections of the H^3, and the presence of polyhedra, or complexes, as the fundamental regions.[8] It is not difficult to show that although we have the differences, mentioned above, between the $(2+1)$- and the $(3+1)$-dimensional cases, the line element (7) changes only by the straightforward introduction of an extra dimension, and the modification of the value of α.[17] Therefore, everything we did here may be generalized to this new situation.

ACKNOWLEDGMENTS

APPENDIX: ELEMENT OF THE ADS RELEVANT TO QUANTUM COSMOLOGY

In this Appendix, we would like to show that the anti-de Sitter space-time with line element (7), lapse function (38), compact spatial sections introduced in Sec. II, and regular as assured by the conditions (42) and (43), contributes at the semi-classical level to the ''no-boundary'' wavefunction of a certain universe.

The ''no-boundary'' conditions propose that only regular Euclidean space-times, with one single spacelike boundary, should contribute to the path integral leading to the desired wave-function. It means that in the semi-classical approximation the wave-function is given by the following expression:[18]

$$\Psi_{nb}[h_{ij}^{b},\varphi_{b}]=N_{0}\sum_{k}A_{k}\exp[-I_{k}], \tag{A1}$$

where N_0 is a normalization constant, I_k is the action of the k-th solution to the Euclidean-Einstein's field equations, and the sum is over these solutions. These solutions have a unique boundary which is compact, spacelike, and has the given three-metric h_{ij}^{b} and matter or gauge fields configuration φ_b on this boundary. The prefactors A_k are given by determinants of small fluctuations about the classical solutions.

We want to compute the ''no-boundary'' wave-function of a $(2+1)$-dimensional, homogeneous, isotropic, and constant negatively curved universe. For simplicity the only source of stress-energy is a negative cosmological constant. We shall restrict our attention to the semi-classical limit.

We start by proposing the Euclidean Friedmann–Robertson–Walker (F–R–W) metric ansatz, with the compact spatial sections introduced in Sec. II . In terms of the ADM formalism,[10] it is

$$ds^{2}=N^{2}(t)dt^{2}+a^{2}(t)(d\chi^{2}+\sinh^{2}\chi d\theta^{2}), \tag{A2}$$

where $N(t)$ is the lapse function, $a(t)$ is the scale factor, t and θ vary as in Eq. (2), Sec. II, and χ has a finite superior limit due to the compactifications.

Introducing Eq. (A2) in the general expression for the Euclidean action[19], we obtain the following result,

$$I[N,a(t)]=-\mathscr{A}\int[\dot{a}^{2}(t)-N^{2}-a^{2}(t)N^{2}\Lambda]\frac{1}{N}dt, \tag{A3}$$

where $\mathscr{A}$ is a finite defined number proportional to the volume of the compact, spatial sections, and we chose the gauge where N is a constant.

The variation of I, Eq. (A3), in terms of $a(t)$ and N, will produce the Euclidean-Einstein's equations. We shall solve these equations under the ''no-boundary'' conditions, suitably adapted for minisuperspaces.[7] For our case these conditions are the following.

(1) There must be an instant when the scale factor vanishes.
(2) The solution must have the scale factor specified at the boundary.
(3) The space-time must be regular.

We obtain two solutions satisfying the three conditions above.

The space-time which is important to the present study is the Lorentzian solution,

$$N=iN_{I},\ \text{where}\ \ N_{I}=\alpha\frac{\pi}{2}\pm\arccos\left(\frac{a_{1}}{\alpha}\right); \tag{A4}$$

$$a(t)=\pm\alpha\sin\left(N_{I}\frac{t}{\alpha}\right);\quad \alpha^{2}=\frac{1}{|\Lambda|}; \tag{A5}$$

valid for $a_1<\alpha$.

The solution Equations (A4) and (A5) satisfy all the three conditions above. More specifically it satisfies condition

(1) because $a(t)$ vanishes for $t=0$;

(2) because $a(t)$ is equal to the given value a_1 at the boundary, which is characterized by $t=1$;
(3) when the conditions (42) and (43), Sec. IV B, are valid.

Therefore, we conclude that the anti-de Sitter space-time with the line element (A2), lapse function (A4), scale factor (A5), compact spatial sections given in Sec. II, and for which conditions (42) and (43), Sec. IV B, are valid, contributes to the ''no-boundary'' wave-function (A1) of this universe.

In order to complete our proof, we must identify the above solution with the anti-de Sitter space-time introduced in Sec. IV B.

We start by renaming N_I in Eqs. (A4) and (A5), calling it N. It leads us to Eq. (38), Sec. IV B. This transformation also makes the scale factor Eq. (A5) identical to the one in Eq. (3), Sec. II. Then, we apply the coordinate transformations (4), Sec. II, to the line element (A2). Finally, we write the resulting line element in Cartesian coordinates which produces Eq. (7), Sec. III, concluding our demonstration.

The Dirac particle in the presence of the tensor wave on the background of gravitation

G. V. Shishkin[a] and W. H. Abdel Salam

(Received 31 December 1996; accepted for publication 10 April 1997)

In this paper new exact solutions for the Dirac equation are presented for the case of a particle in tensor wave field on the background of gravitation. Consideration is given to different configurations introducing the tensor interaction, which result in the required separation of variables by the algebraic method and lead to the derivation of exact solutions for the Dirac equation in the corresponding field situation. At the same time, most general metrics allowing for the exact solutions are given. The cases of zero and nonzero rest mass of a particle are with treated here. © *1998 American Institute of Physics.* [S0022-2488(97)03507-X]

I. INTRODUCTION

The present paper is a direct continuation of our previous one,[1] where exact solutions of the Dirac equation in the presence of scalar, vector, or pseudoscalar wave fields on the background of gravitation have been derived, and their associated matrices have been demonstrated. An analogous problem for the case of a tensor plane wave on the background of gravitation is presented here.

Investigation of the classical Volkov problem[2,3] (an electron in the field of a plane electromagnetic wave), which was the first solution for the nonstationary Dirac equation, was continued by several authors who have contributed to the further development of this problem: Bagrov *et al.* have studied the problem on the background of static electromagnetic fields.[4–10] These authors listed all possible configurations (geometry) of statical electric and magnetic fields allowing for exact solutions of the Volkov problem, and presented these solutions. Fedorov and his colleagues[11–20] have studied an analogous problem for the particle with different spins (0,1/2,1, 3/2,2), i.e., in their works consideration has been given to wave equations by Klein–Gordon, Dirac, Duffin–Kemmer, and others in the presence of a plane electromagnetic wave. The general approach to finding appropriate exact solutions turned out to be possible due to the method of projective operators proposed by Fedorov[11,21] and the universal notation for any wave equation in the general form put forward by Fedorov.[22,23] It should be particularly emphasized that in some solutions proposed by Fedorov *et al.* allowances are made for the anomalous particle moment, i.e., for the nonminimum interaction of particle with the electric field tensor.[13,15,20] The works of Ritus *et al.*[24,25] were the first to prove the fullness and orthonormality of the Volkov solution set.

In the works of Shishkin and co-authors[26–29] the Volkov problem is generalized for the case of wave fields having different tensor structure, i.e., exact solutions for the Dirac equations are found in the presence of scalar, vector, tensor, axial, pseudoscalar waves or waves of mixed types. In these works, the problem is considered for the plane Minkovsky space–time. Derivation of the appropriate exact solutions from the use of first- or second-order ordinary differential equations with and without separation of the variables is demonstrated in Refs. 28 and 29. In Ref. 29 it is pointed out that exact solutions of the Dirac equations are possible when the equation contains up to eight field functions (waves). This work also gives the first example of exact solutions for the generalized Volkov problem on the background of gravitation. The separation of variables, wher-

ever required, is performed by the algebraic method proposed in Refs. 30–32 and briefly outlined in our previous work.[1]

Thus in Ref. 1 we initiated a systematic study of the Volkov problem on the background of gravitation. The present work is a continuation of the study and is devoted to the possibility of obtaining exact solutions for the Dirac equation in the presence of a tensor wave on the background of gravitation.

II. EXACT SOLUTIONS

The physical meaning associated with tensor interaction is in direct relationship to the geometry in which such an interaction is realized. For example, the external field that is introduced by the term proportional to $\gamma^x\gamma^y\mathbf{T_{xy}}$ may be associated with the nonminimum interaction of the anomalous magnetic moment with the magnetic intensity of the electromagnetic field, i.e., with the electromagnetic field tensor. Similarly, the tensor structure proportional to $\gamma^x\gamma^t\mathbf{T_{xt}}$ is associated with nonminimum interaction of the particle electric dipole with the electric intensity of the electromagnetic field. Despite the fact the experimental data[33] point to the infinitesimal value of the electric dipole moment of elementary particles, the solutions associated with $\gamma^x\gamma^t\mathbf{T_{xt}}$ are of undoubted interest to mathematicians, if only for their substantial distinction from the corresponding solutions related to $\gamma^x\gamma^y\mathbf{T_{xy}}$. Specifically, for the zero-mass particle different additional exact solutions of the Dirac equation are available. Thus there is particular interest in the following variants when they introduce the tensor interaction and differ in geometry and physical meaning:

$$\gamma^x\gamma^y\mathbf{T_{xy}}(z-t), \quad \gamma^x\gamma^z\mathbf{T_{xz}}(z-t), \quad \gamma^x\gamma^t\mathbf{T_{xt}}(z-t), \quad \gamma^z\gamma^t\mathbf{T_{zt}}(z-t).$$

Here, for the sake of definiteness, it is assumed that the tensor wave is propagating along the z axis. The remaining variants of the tensor coupling realized for the Dirac particle are reduced to those enumerated above. It should be noted that the general introduction of a tensor field presupposes the presence of all the components of a $\mathbf{T_{ik}}$ tensor. In so doing, each specific physical realization is determined by the properties of the interacting particle itself. To illustrate, in the case of an electromagnetic field the particle may or may not have the nonzero electric charge and may or may not have the magnetic or electric moment. This will enable one to determine the type of interaction, namely, minimum, nonminimum, or mixed type.

Analysis of the Dirac equation for the separation of variables reveals that separation of variables is impossible in the cases $\gamma^x\gamma^z\mathbf{T_{xz}}$ and $\gamma^x\gamma^t\mathbf{T_{xt}}$, since the resultant systems of matrix separating equations have no solutions. It seems impossible to give some recommendations concerning the exact solutions in that even in the simplest situations with a particular relationship between field functions and the space and time variables one has to use the Riccati-type or still more complex equations. However, this does not rule out computerized numerical analysis. As regards to other variants being introducing, namely; $\gamma^x\gamma^y\mathbf{T_{xy}}$ and $\gamma^z\gamma^t\mathbf{T_{zt}}$, we have succeeded in specifying the matrices allowing for the separation of variables and exact solutions, and have managed to find these solutions.

A. The specific case of $\gamma^x\gamma^y\mathbf{T_{xy}}(z-t)$

In this case, the Dirac equation for the diagonal tetrad gauge takes the form:

$$\left\{\frac{\gamma^x}{a_x^{1/2}}\left(\frac{\partial}{\partial x}-\frac{\partial_x a_x}{4a_x}\right)+\frac{\gamma^y}{a_y^{1/2}}\left(\frac{\partial}{\partial y}-\frac{\partial_y a_y}{4a_y}\right)+\frac{\gamma^z}{a_z^{1/2}}\left(\frac{\partial}{\partial z}-\frac{\partial_z a_z}{4a_z}\right)+\frac{\gamma^t}{a_t^{1/2}}\left(\frac{\partial}{\partial t}-\frac{\partial_t a_t}{4a_t}\right)+m_0\right.$$
$$\left.+2ig\gamma^x\gamma^y\mathbf{T_{xy}}(z-t)\right\}\Psi=\{H\}\Psi=0. \tag{1}$$

Here $\mathbf{T_{xy}(z-t)}$ is the tensor wave, g is a magnetic moment of the particle (including the anomalous one), and $\mathbf{a_k(x,y,z,t)}$, $\mathbf{(k=x,y,z,t)}$ are gravitational field functions determining the space–time metric:

$$ds^2=a_x(dx)^2+a_y(dy)^2+a_z(dz)^2-a_t(dt)^2, \tag{2}$$

$$\{H\}\Psi=0\Rightarrow F\{H\}\Gamma\Gamma^{-1}\Psi=0\Rightarrow(\hat{K}_{xy}+\hat{K}_{zl})\Phi, \quad \Psi=\Gamma\Phi. \tag{3}$$

Hereafter the notation will be identical to that adopted in Ref. 1.

In compliance with Refs. 30–32, separation of variables is carried out as follows:

$$\hat{K}_{xy}\hat{K}_{zt}-\hat{K}_{zy}\hat{K}_{xy}=0, \tag{4}$$

$$a_k(x,y,z,t)=v_k(x,y)w(z,t), \tag{5}$$

where $\mathbf{F}$ is a scalar factor and $\mathbf{\Gamma}$ is a matrix 4×4, which provides a mean to satisfy commutation relation (4).

Directing our attention to the explicit form of Eq. (1), we write the operators $\hat{K}_{xy}$ and $\hat{K}_{zt}$ in the most general form,

$$\hat{\mathbf{K}}_{xy}=F\left\{\frac{\gamma^x}{\mathbf{a}_x^{1/2}}\left(\frac{\partial}{\partial\mathbf{x}}-\frac{\partial_x\mathbf{a}_x}{\mathbf{4a}_x}\right)+\frac{\gamma^y}{\mathbf{a}_y^{1/2}}\left(\frac{\partial}{\partial\mathbf{y}}-\frac{\partial_y\mathbf{a}_y}{\mathbf{4a}_y}\right)+\alpha\mathbf{m}_0\right\}\Gamma, \tag{6}$$

$$\hat{K}_{zt}=F\left\{\frac{\gamma^z}{a_z^{1/2}}\left(\frac{\partial}{\partial z}-\frac{\partial_z a_z}{4a_z}\right)+\frac{\gamma^t}{a_t^{1/2}}\left(\frac{\partial}{\partial t}-\frac{\partial_t a_t}{4a_t}\right)+(1-\alpha)m_0+2ig\gamma^x\gamma^yT_{xy}(z-t)\right\}\Gamma, \tag{7}$$

where $\boldsymbol{\alpha}$ is a number equal to 1 or 0.

The commutation requirement (4) as applied to operators (6) and (7) leads to the following system of reparating equations:

$$\gamma^x\Gamma\gamma^z-\gamma^z\Gamma\gamma^x=0, \quad \gamma^y\Gamma\gamma^z-\gamma^z\Gamma\gamma^y=0,$$

$$\gamma^x\Gamma\gamma^t-\gamma^t\Gamma\gamma^x=0, \quad \gamma^y\Gamma\gamma^t-\gamma^t\Gamma\gamma^y=0,$$

$$\gamma^x\Gamma\gamma^x\gamma^y-\gamma^x\gamma^y\Gamma\gamma^x=0, \quad \gamma^y\Gamma\gamma^x\gamma^y-\gamma^x\gamma^y\Gamma\gamma^y=0, \tag{7a}$$

$$\frac{\partial}{\partial x}\frac{F}{a_z^{1/2}}=0, \quad \frac{\partial}{\partial z}\frac{F}{a_x^{1/2}}=0, \quad \frac{\partial}{\partial x}\frac{F}{a_t^{1/2}}=0, \quad \frac{\partial}{\partial t}\frac{F}{a_x^{1/2}}=0,$$

$$\frac{\partial}{\partial y}\frac{F}{a_z^{1/2}}=0, \quad \frac{\partial}{\partial z}\frac{F}{a_y^{1/2}}=0, \quad \frac{\partial}{\partial y}\frac{F}{a_t^{1/2}}=0, \quad \frac{\partial}{\partial t}\frac{F}{a_y^{1/2}}=0,$$

$$\frac{\partial}{\partial\mathbf{x}}\frac{F}{\mathbf{a}_z^{1/2}}\frac{\partial_z\mathbf{a}_z}{\mathbf{4a}_z}=\mathbf{0}, \quad \frac{\partial}{\partial\mathbf{z}}\frac{F}{\mathbf{a}_x^{1/2}}\frac{\partial_x\mathbf{a}_x}{\mathbf{4a}_x}=\mathbf{0},$$

$$\frac{\partial}{\partial\mathbf{x}}\frac{F}{\mathbf{a}_t^{1/2}}\frac{\partial_t\mathbf{a}_t}{\mathbf{4a}_t}=\mathbf{0}, \quad \frac{\partial}{\partial\mathbf{t}}\frac{F}{\mathbf{a}_x^{1/2}}\frac{\partial_x\mathbf{a}_x}{\mathbf{4a}_x}=\mathbf{0}, \tag{7b}$$

$$\frac{\partial}{\partial\mathbf{y}}\frac{F}{\mathbf{a}_z^{1/2}}\frac{\partial_z\mathbf{a}_z}{\mathbf{4a}_z}=0, \quad \frac{\partial}{\partial\mathbf{z}}\frac{F}{\mathbf{a}_y^{1/2}}\frac{\partial_x\mathbf{a}_y}{\mathbf{4a}_y}=\mathbf{0},$$

$$\frac{\partial}{\partial \mathbf{y}}\frac{F}{\mathbf{a}_t^{1/2}}\frac{\partial_t \mathbf{a}_t}{\mathbf{4a}_t}=\mathbf{0}, \quad \frac{\partial}{\partial \mathbf{t}}\frac{F}{\mathbf{a}_y^{1/2}}\frac{\partial_x \mathbf{a}_y}{\mathbf{4a}_y}=\mathbf{0},$$

$$(\gamma^x\Gamma-\Gamma\gamma^x)(\mathbf{1}-\alpha)\mathbf{m}_0=\mathbf{0}, \quad (\gamma^y\Gamma-\Gamma\gamma^y)(\mathbf{1}-\alpha)\mathbf{m}_0=\mathbf{0},$$

$$(\gamma^z\Gamma-\Gamma\gamma^z)\alpha\mathbf{m}_0=\mathbf{0}, \quad (\gamma^t\Gamma-\Gamma\gamma^t)\alpha\mathbf{m}_0=\mathbf{0},$$

$$(\gamma^x\gamma^y\Gamma-\Gamma\gamma^x\gamma^y)\alpha\mathbf{m}_0=\mathbf{0}. \tag{7c}$$

Here, Eq. (7a) forms an independent subsystem of matrix equations solvable for

$$\Gamma=\gamma^x\gamma^y. \tag{8}$$

With the use of other equations of the system (7) we get:

$$\alpha=\mathbf{1}, \quad F=1, \tag{9}$$

$$a_x=v_x(x,y), \quad \mathbf{a}_z=\mathbf{w}_z(\mathbf{z},\mathbf{t}),$$

$$a_y=v_y(x,y), \quad \mathbf{a}_t=\mathbf{w}_t(\mathbf{z},\mathbf{t}), \tag{10}$$

In this manner, for the operators $\hat{K}_{xy}$ and $\hat{K}_{zt}$ we have the following:

$$\hat{K}_{xy}=\frac{\gamma^y}{v_x^{1/2}}\left(\frac{\partial}{\partial x}-\frac{\partial_x v_x}{4v_x}\right)-\frac{\gamma^x}{v_x^{1/2}}\left(\frac{\partial}{\partial y}-\frac{\partial_y v_y}{4v_y}\right)+\gamma^x\gamma^y m_0, \tag{11}$$

$$\hat{K}_{zt}=\frac{\gamma^z\gamma^y\gamma^z}{w_z^{1/2}}\left(\frac{\partial}{\partial z}-\frac{\partial_z w_z}{4w_z}\right)+\frac{\gamma^x\gamma^y\gamma^t}{w_t^{1/2}}\left(\frac{\partial}{\partial t}-\frac{\partial_t w_t}{4w_t}\right)-2ig\mathbf{T}_{\mathbf{xy}}(z-t). \tag{12}$$

Then turning our attention to the problem in eigenfunctions and eigenvalues in accordance with

$$\hat{\mathbf{K}}_{xy}\Phi=-\hat{\mathbf{K}}_{zt}\Phi=\mathbf{k}\Phi \tag{13}$$

and introducing the light-cone variables

$$u=z-t, \quad v=z+t \tag{14}$$

for the variables **u** and **v** with the use of Eq. (12) we derive the following equation:

$$\left\{\frac{\gamma^x\gamma^y\gamma^z}{w_z^{1/2}}\left(\partial_u+\partial_v-\frac{(\partial u+\partial v)w_z}{4w_z}\right)+\frac{\gamma^x\gamma^y\gamma^t}{w_t^{1/2}}\left(-\partial_u+\partial_v-\frac{(-\partial u+\partial v)}{4w_t}\right)-2ig\mathbf{T}_{\mathbf{xy}}(u)+k\right\}\Phi(u,v)=0. \tag{15}$$

In connection with this equation the following should be noted.

(1) In order for the variables **u** and **v** to be separated (see Refs. 1 and 30–32), it is required to assume that

$$w_z=c_z(z-t)d_z(z+t), \quad w_t=c_t(z-t)d_t(z+t). \tag{16}$$

(2) In order to use the advantages of a special representation for the degenerate matrices $\gamma^z \pm \gamma^t$ (see Refs. 26–29) we assume that

$$w_z = w_t = c(z-t)d(z+t). \tag{17}$$

(3) Finally, we assume the following so that the appearance of the Riccati-type equation in the variable **v** is obviated (see Ref. 1):

$$d(z+t)=1, \quad w_z = w_t = c(z-t) = c(u), \tag{18}$$

As a result, instead of Eq. (15) we get

$$\left\{ \frac{\gamma^x \gamma^y}{c^{1/2}} (\gamma^z - \gamma^t) \frac{\partial}{\partial u} - \frac{\gamma^x \gamma^y}{c^{1/2}} (\gamma^z - \gamma^t) \frac{\partial_u c}{4c} + \frac{\gamma^x \gamma^y}{c^{1/2}} (\gamma^z + \gamma^t) \frac{\partial}{\partial v} - 2ig\mathbf{T}_{\mathbf{xy}} + k \right\} \Phi(u,v) = 0. \tag{19}$$

Further, the following representation of the Dirac matrices is used:

$$\gamma^x = \begin{pmatrix} \mathbf{0} & \sigma_3 \\ \sigma_3 & \mathbf{0} \end{pmatrix}, \quad \gamma^y = \begin{pmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & -\mathbf{I} \end{pmatrix}, \quad \gamma^z = \begin{pmatrix} \mathbf{0} & \sigma_1 \\ \sigma_1 & \mathbf{0} \end{pmatrix}, \quad \gamma^t = \mathbf{i} \begin{pmatrix} \mathbf{0} & \sigma_2 \\ \sigma_2 & \mathbf{0} \end{pmatrix}. \tag{20}$$

Here, σ_k are the corresponding Pauli matrices,

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \mathbf{I} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}. \tag{21}$$

For the degenerate matrices $\gamma^z \pm \gamma^+$ we have, respectively,

$$\gamma^z + \gamma^t = \begin{pmatrix} \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{2} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{2} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} \end{pmatrix}, \quad \gamma^z - \gamma^t = \begin{pmatrix} \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{2} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{2} & \mathbf{0} & \mathbf{0} & \mathbf{0} \end{pmatrix}. \tag{22}$$

As Eq. (19) contains no field functions dependent on the variable **v**, we can assume the following:

$$\Phi \sim e^{ik_v v}. \tag{23}$$

Then Eq. (19) in the representation of Eq. (20) results in the following system of equations:

$$\begin{gathered} -\frac{2ik_v}{c^{1/2}} \Phi_2 - (2ig\mathbf{T}_{\mathbf{xy}} - k)\Phi_1 = 0, \\ \frac{2}{c^{1/2}} \left(\frac{\partial}{\partial u} - \frac{\partial_u c}{4c} \right) \Phi_1 - (2ig\mathbf{T}_{\mathbf{xy}} - k)\Phi_2 = 0, \\ \frac{2ik_v}{c^{1/2}} \Phi_4 - (2ig\mathbf{T}_{\mathbf{xy}} - k)\Phi_3 = 0, \\ -\frac{2}{c^{1/2}} \left(\frac{\partial}{\partial u} - \frac{\partial_u c}{4c} \right) \Phi_3 - (2ig\mathbf{T}_{\mathbf{xy}} - k)\Phi_4 = 0, \end{gathered} \tag{24}$$

when we have

$$\Phi_1 = \Phi_3, \quad \Phi_2 = -\Phi_4 \quad (\text{or } \Phi_1 = -\Phi_3, \quad \Phi_2 = \Phi_4). \tag{25}$$

The first pair of Eq. (24) gives the following:

$$\Phi_2 = -\frac{2ig\mathbf{T_{xy}}}{2ik_v}\, c^{1/2}\Phi_1, \tag{26}$$

and therefore in accordance with Eq. (25)

$$\left\{\frac{\partial}{\partial \mathbf{u}} - \frac{\partial_u \mathbf{c}}{\mathbf{4c}} + \frac{(\mathbf{2igT_{xy}} - \mathbf{k})}{\mathbf{4ik}_v}\, c\right\}\Phi_1 = \mathbf{0}, \tag{27}$$

$$\Phi_1 = \mathbf{c}^{1/4}\exp\left\{-\frac{\mathbf{1}}{\mathbf{4ik}_v}\int (\mathbf{2igT_{xy}} - \mathbf{k})^2 \mathbf{cdu}\right\}. \tag{28}$$

In such a manner we have established the dependence of the solution on variables **u** and **v**.

Let us now turn our attention to the operator $\hat{K}_{xy}$ [formula (11)] in order to obtain the corresponding equation:

$$\left\{\frac{\gamma^y}{v_x^{1/2}}\left(\frac{\partial}{\partial x} - \frac{\partial_x v_x}{4v_x}\right) - \frac{\gamma^x}{v_y^{1/2}}\left(\frac{\partial}{\partial y} - \frac{\partial_y v_y}{4v_y}\right) + \gamma^x\gamma^y m_0 - k\right\}\Phi(x,y) = 0, \tag{29}$$

where **x** and **y** appear symmetrically.

Separating the variables **x** and **y** according to the scheme

$$\{\mathbf{H_{x,y}}\}\Phi = \mathbf{0} \Rightarrow G\{\mathbf{H_{x,y}}\}\Lambda\Lambda^{-1}\Phi = \mathbf{0} \Rightarrow (\hat{\mathbf{K}}_\mathbf{x} + \hat{\mathbf{K}}_\mathbf{y})\Theta = \mathbf{0}, \quad \Phi = \Lambda\Theta, \tag{30}$$

$$\hat{\mathbf{K}}_\mathbf{x}\hat{\mathbf{K}}_\mathbf{y} - \hat{\mathbf{K}}_\mathbf{y}\hat{\mathbf{K}}_\mathbf{x} = \mathbf{0}, \tag{31}$$

$$v_x = \tilde{a}_x(x)\tilde{b}_x(y), \quad v_y = \tilde{a}_y(x)\tilde{b}_y(y), \tag{32}$$

and assuming

$$\hat{K}_x = \mathbf{G}\left\{\frac{\gamma^y}{\boldsymbol{\nu}_x^{1/2}}\left(\frac{\partial}{\partial x} - \frac{\partial_x \boldsymbol{\nu}_x}{\mathbf{4}\boldsymbol{\nu}_x}\right) + \gamma^x\gamma^y\mathbf{m}_0 - \alpha\mathbf{k}\right\}\Lambda, \tag{33}$$

$$\hat{K}_y = G\left\{-\frac{\gamma^x}{\nu_y^{1/2}}\left(\frac{\partial}{\partial y} - \frac{\partial_y \nu_y}{4\nu_y}\right) - (1-\alpha)k\right\}\Lambda, \tag{34}$$

we get the following system of separating equations:

$$\gamma^y\Lambda\gamma^x - \gamma^x\Lambda\gamma^y = \mathbf{0}, \quad \gamma^x\gamma^y\Lambda\gamma^x - \gamma^x\Lambda\gamma^x\gamma^y = \mathbf{0},$$

$$\partial_x\left(\frac{\mathbf{G}}{v_\mathbf{y}^{1/2}}\right) = \partial_y\left(\frac{\mathbf{G}}{v_x^{1/2}}\right) = \partial_x\left(\frac{\mathbf{G}}{v_\mathbf{y}^{1/2}}\frac{\partial_y v_y}{\mathbf{4}v_y}\right) = \partial_y\left(\frac{\mathbf{G}}{v_x^{1/2}}\frac{\partial_x v_x}{\mathbf{4}v_x}\right) = \mathbf{0}, \tag{35}$$

$$(\gamma^y\Lambda - \Lambda\gamma^y)(\mathbf{1}-\alpha)\mathbf{k} = \mathbf{0}, \quad (\gamma^x\gamma^y\Lambda - \Lambda\gamma^x\gamma^y)(\mathbf{1}-\alpha)\mathbf{k} = \mathbf{0},$$

$$(\gamma^x\Lambda - \Lambda\gamma^x)\alpha\mathbf{k} = \mathbf{0},$$

which gives

$$\Lambda = \gamma^x, \quad \alpha = \mathbf{1}, \quad \mathbf{G} = \tilde{\mathbf{a}}_y^{1/2}(\mathbf{x}), \tag{36}$$

$$v_x=\tilde{a}_x(x), \quad v_y=\tilde{a}_y(x)\tilde{b}_y(y), \tag{37}$$

$$\hat{K}_x=-\gamma^x\gamma^y\left(\frac{\tilde{a}_y}{\tilde{a}_x}\right)^{1/2}\left(\frac{\partial}{\partial x}-\frac{\partial_x\tilde{a}_x}{\mathbf{4}\tilde{a}_x}\right)-\gamma^y a_y^{1/2}\mathbf{m}_0-\gamma^x\,\tilde{a}_y^{1/2}\mathbf{k}, \tag{38}$$

$$\hat{K}_y=-\frac{1}{\tilde{b}_y^{1/2}}\left(\frac{\partial}{\partial y}-\frac{\partial_y\tilde{b}_y}{4\tilde{b}_y}\right). \tag{39}$$

And going over to the problem in eigenfunctions and eigenvalues

$$\hat{K}_x\Theta=\hat{K}_y\Theta=\tilde{\mathbf{k}}\Theta. \tag{40}$$

According to Eq. (38), for the variable **x** we get

$$\left\{\gamma^x\gamma^y\left(\frac{\tilde{a}_y}{\tilde{a}_x}\right)^{1/2}\left(\frac{\partial}{\partial\mathbf{x}}-\frac{\partial_x\tilde{a}_x}{\mathbf{4}\tilde{a}_x}\right)+\gamma^y a_y^{1/2}\mathbf{m}_0+\gamma^x\,\tilde{a}_y^{1/2}\mathbf{k}+\tilde{\mathbf{k}}\right\}\Theta=\mathbf{0}, \tag{41}$$

and from the representation of Eq. (20), we will get the following system;

$$\begin{aligned}
&\left\{-\left(\frac{\tilde{a}_y}{\tilde{a}_x}\right)^{1/2}\left(\frac{\partial}{\partial\mathbf{x}}-\frac{\partial_x\tilde{a}_x}{\mathbf{4}\tilde{a}_x}\right)+\tilde{a}_y^{1/2}\mathbf{k}\right\}\Theta_3+(\tilde{a}_y^{1/2}\mathbf{m}_0+\tilde{\mathbf{k}})\Theta_1=\mathbf{0},\\
&\left\{\left(\frac{\tilde{a}_y}{\tilde{a}_x}\right)^{1/2}\left(\frac{\partial}{\partial\mathbf{x}}-\frac{\partial_x\tilde{a}_x}{\mathbf{4}\tilde{a}_x}\right)-\tilde{a}_y^{1/2}\mathbf{k}\right\}\Theta_4+(\tilde{a}_y^{1/2}\mathbf{m}_0+\tilde{\mathbf{k}})\Theta_2=\mathbf{0},\\
&\left\{\left(\frac{\tilde{a}_y}{\tilde{a}_x}\right)^{1/2}\left(\frac{\partial}{\partial x}-\frac{\partial_x\tilde{a}_x}{4\tilde{a}_x}\right)+\tilde{a}_y^{1/2}k\right\}\Theta_1-(\tilde{a}_y^{1/2}m_0-\tilde{k})\Theta_3=0,\\
&\left\{-\left(\frac{\tilde{a}_y}{\tilde{a}_x}\right)^{1/2}\left(\frac{\partial}{\partial x}-\frac{\partial_x\tilde{a}_x}{4\tilde{a}_x}\right)-\tilde{a}_y^{1/2}k\right\}\Theta_2-(\tilde{a}_y^{1/2}m_0-\tilde{k})\Theta_4=0,
\end{aligned} \tag{42}$$

when we have

$$\Theta_1=\Theta_2, \quad \Theta_3=-\Theta_4, \tag{43}$$

In this case, believing

$$\Theta_v(x)=\tilde{a}_x^{1/4}\tilde{\Theta}_v(x), \quad v=1,2,3,4, \tag{44}$$

we will get

$$\begin{aligned}
&\left(-\frac{\partial}{\partial x}+\tilde{a}_x^{1/2}k\right)\tilde{\Theta}_3+\left(\tilde{a}_x^{1/2}m_0+\left(\frac{\tilde{a}_x}{\tilde{a}_y}\right)^{1/2}\tilde{k}\right)\tilde{\Theta}_1=0,\\
&\left(\frac{\partial}{\partial x}-\tilde{a}_x^{1/2}k\right)\tilde{\Theta}_4+\left(\tilde{a}_x^{1/2}m_0+\left(\frac{\tilde{a}_x}{\tilde{a}_y}\right)^{1/2}\tilde{k}\right)\tilde{\Theta}_2=0,\\
&\left(\frac{\partial}{\partial x}+\tilde{a}_x^{1/2}k\right)\tilde{\Theta}_1-\left(\tilde{a}_x^{1/2}m_0-\left(\frac{\tilde{a}_x}{\tilde{a}_y}\right)^{1/2}\tilde{k}\right)\tilde{\Theta}_3=0,
\end{aligned} \tag{45}$$

$$\left(-\frac{\partial}{\partial x}-\widetilde{a}_x^{1/2}k\right)\widetilde{\Theta}_2-\left(\widetilde{a}_x^{1/2}m_0-\left(\frac{\widetilde{a}_x}{\widetilde{a}_y}\right)^{1/2}\widetilde{k}\right)\widetilde{\Theta}_4=0.$$

At last, in order to avoid Riccati-type equations, we have to accept

$$\widetilde{\mathbf{a}}_y=\mathbf{1}. \tag{46}$$

By introducing an integral argument

$$\xi=\int \widetilde{\mathbf{a}}_x^{1/2}\mathbf{dx}\widetilde{\Theta}_\nu(\mathbf{x})\to\widetilde{\Theta}_\nu(\xi),\quad \nu=\mathbf{1,2,3,4}, \tag{47}$$

instead of Eq. (45) we have

$$\begin{aligned}
&\left(\frac{\partial}{\partial\xi}-k\right)\widetilde{\Theta}_3-(m_0+\widetilde{k})\widetilde{\Theta}_1=0,\\
&\left(\frac{\partial}{\partial\xi}-k\right)\widetilde{\Theta}_4+(m_0+\widetilde{k})\widetilde{\Theta}_2=0,\\
&\left(\frac{\partial}{\partial\xi}+k\right)\widetilde{\Theta}_1-(m_0-\widetilde{k})\widetilde{\Theta}_3=0,\\
&\left(\frac{\partial}{\partial\xi}+k\right)\widetilde{\Theta}_2+(m_0-\widetilde{k})\widetilde{\Theta}_4=0,
\end{aligned} \tag{48}$$

from which

$$\widetilde{\Theta}_1=\frac{\left(\frac{\partial}{\partial\xi}-k\right)\widetilde{\Theta}_3}{m_0+\widetilde{k}},\quad \widetilde{\Theta}_2=-\frac{\left(\frac{\partial}{\partial\xi}-k\right)\widetilde{\Theta}_4}{m_0+\widetilde{k}}. \tag{49}$$

For $\widetilde{\Theta}_1$ and $\widetilde{\Theta}_2$ we have now the following second-order equations:

$$\left(\frac{\partial^2}{\partial\xi^2}-\mathbf{m}_0^2+\widetilde{\mathbf{k}}^2-\mathbf{k}^2\right)\widetilde{\Theta}_3=\mathbf{0},\quad \left(\frac{\partial^2}{\partial\xi^2}-\mathbf{m}_0^2+\widetilde{\mathbf{k}}^2-\mathbf{k}^2\right)\widetilde{\Theta}_2=\mathbf{0}, \tag{50}$$

and the solution may be written exactly:

$$\widetilde{\Theta}_1=\widetilde{\Theta}_2=\exp\{\pm(m_0^2+k^2-\widetilde{k}^2)^{1/2}x\}=\exp\left\{\pm(m_0^2+k^2-\widetilde{k}^2)^{1/2}\int\widetilde{a}_x^{1/2}dx\right\}. \tag{51}$$

According to the definition of the operator $\hat{K}_y$ in Eq. (39), we can get the following for the variable **y**:

$$\left\{\frac{\mathbf{1}}{\widetilde{\mathbf{b}}_y^{1/2}}\left(\frac{\partial}{\partial\mathbf{y}}-\frac{\partial_{\mathbf{y}}\mathbf{b}_{\mathbf{y}}}{\mathbf{4b_y}}\right)-\widetilde{\mathbf{k}}\right\}\Theta_\nu(\mathbf{y})=\mathbf{0},\quad \nu=\mathbf{1,2,3,4}, \tag{52}$$

from where we obtain

$$\Theta_1(\mathbf{y})=\Theta_2(\mathbf{y})=\Theta_3(\mathbf{y})=\Theta_4(\mathbf{y})=\widetilde{\mathbf{b}}_y^{1/4}\exp\left\{\int \mathbf{b}_y^{1/2}(\mathbf{y})\mathbf{dy}\right\}. \tag{53}$$

Taking into consideration exact solutions for individual variables and explicit form of the matrices $\mathbf{\Gamma}$ and Λ, we finally have the following as a solution for the Dirac equation (1):

$$\Psi=\mathbf{e}^{ik_v(z+t)}\begin{pmatrix} -\Phi_1(\mathbf{z}-\mathbf{t})\Theta_3(\mathbf{x}) \\ \Phi_2(\mathbf{z}-\mathbf{t})\Theta_3(\mathbf{x}) \\ \Phi_1(\mathbf{z}-\mathbf{t})\Theta_1(\mathbf{x}) \\ \Phi_2(\mathbf{z}-\mathbf{t})\Theta_1(\mathbf{x}) \end{pmatrix}\Theta(\mathbf{y}). \tag{54}$$

This solution is possible for the metrics of the form

$$ds^2=\widetilde{a}_x(x)(dx)^2+\widetilde{b}(y)(dy)^2+c(z-t)(dz^2-dt^2). \tag{55}$$

It should be noted that the results (54) and (55) have been obtained for the particle with a nonzero rest mass ($\mathbf{m}\neq\mathbf{0}$), but they are true also for the case $\mathbf{m}_0=\mathbf{0}$.

However, in the case of zero rest mass of particle ($\mathbf{m}_0=\mathbf{0}$) an additional more general form of the metric makes it possible to find exact solutions for Eq. (1).

Actually, instead of Eq. (5), one could obtain the following:

$$\begin{aligned} &a_x=v_x(x,y)w_x(z,t), \quad a_z=w_z(z,t), \\ &a_y=v_y(x,y)w_y(z,t), \quad a_t=w_t(z,t). \end{aligned} \tag{56}$$

Equation (56) leads to the conditions

$$\begin{aligned} &a_x=v_x(x,y)\widetilde{c}(z-t), \\ &a_y=v_y(x,y)\widetilde{c}(z-t), \\ &w_z=w_t=c(z-t). \end{aligned} \tag{57}$$

Repeating all the above calculations, we come to the solution of the form (54), where instead of Eqs. (26) and (28) we get

$$\Phi_2=-\frac{(2ig\mathbf{T}_{\mathbf{xy}}-k)}{2ik_v}\left(\frac{c}{\widetilde{c}}\right)^{1/2}\Phi_1, \tag{58}$$

$$\Phi_1=c^{1/4}\exp\left\{-\frac{1}{4ik_v}\int(2ig\mathbf{T}_{\mathbf{xy}}-k)^2\,\frac{c}{\widetilde{c}}\,du\right\} \tag{59}$$

and instead of Eqs. (49) and (50) one should assume that

$$\widetilde{\Theta}_1=\frac{1}{\widetilde{k}}\left(\frac{\partial}{\partial\xi}-k\right)\widetilde{\Theta}_3, \quad \widetilde{\Theta}_2=-\frac{1}{\widetilde{k}}\left(\frac{\partial}{\partial\xi}-k\right)\widetilde{\Theta}_4, \tag{60}$$

$$\widetilde{\Theta}_1(x)=\widetilde{\Theta}_2(x)=\exp\left\{\pm(k^2-\widetilde{k}^2)^{1/2}\int \widetilde{a}_x^{1/2}dx\right\}. \tag{61}$$

Expression (53) still specifies the $\mathbf{y}$ dependence.

The most general form of the metrics allowing for the exact solutions for the case $\mathbf{m}_0=\mathbf{0}$ takes the form

$$ds^2=\widetilde{c}(z-t)\{\widetilde{a}_x(dx)^2+\widetilde{b}_y(dy)^2\}+c(z-t)\{(dz)^2-(dt)^2\}. \tag{62}$$

B. The specific case of $\gamma^z\gamma^t\mathbf{T}_{zt}(z-t)$

In this case the solution of the Dirac equation is quite similar to the previous one, except that the solution for $\mathbf{m}_0=\mathbf{0}$ here is a particular case of a more general solution for $\mathbf{m}_0\neq\mathbf{0}$ causing no differences in metrics [compare Eqs. (55) and (62)].

The Dirac equation takes the form

$$\left\{\frac{\gamma^x}{a_x^{1/2}}\left(\frac{\partial}{\partial x}-\frac{\partial_x a_x}{4a_x}\right)+\frac{\gamma^y}{a_y^{1/2}}\left(\frac{\partial}{\partial y}-\frac{\partial_y a_y}{4a_y}\right)+\frac{\gamma^z}{a_z^{1/2}}\left(\frac{\partial}{\partial z}-\frac{\partial_z a_z}{4a_z}\right)+\frac{\gamma^t}{a_t^{1/2}}\left(\frac{\partial}{\partial t}-\frac{\partial_t a_t}{4a_t}\right)\right.$$
$$\left.+m_0+2g\gamma^z\gamma^t\mathbf{T}_{zt}(z-t)\right\}\Psi=0. \tag{63}$$

Separating the variables according to Eqs. (3)–(5), we get the following:

$$\Gamma=\gamma^z\gamma^t,\quad \alpha=0,\quad F=w^{1/2}(z,t), \tag{64}$$

$$\begin{aligned} a_x&=v_x(x,y)w(z,t),\quad a_z=w_z(z,t),\\ a_y&=v_y(x,y)w(z,t),\quad a_t=w_t(z,t). \end{aligned} \tag{65}$$

In such, we get for the operators $\hat{K}_{xy}$ and $\hat{K}_{zt}$,

$$\hat{\mathbf{K}}_{xy}=\frac{\gamma^x\gamma^z\gamma^t}{v_x^{1/2}}\left(\frac{\partial}{\partial\mathbf{x}}-\frac{\partial v_x}{\mathbf{4}v_x}\right)+\frac{\gamma^y\gamma^z\gamma^t}{v_y^{1/2}}\left(\frac{\partial}{\partial\mathbf{y}}-\frac{\partial_y v_y}{\mathbf{4}v_y}\right), \tag{66}$$

$$\hat{K}_{zt}=\gamma^t\left(\frac{w}{w_z}\right)^{1/2}\left(\frac{\partial}{\partial z}-\frac{\partial_z w_z}{4w_z}\right)+\gamma^z\left(\frac{w}{w_t}\right)^{1/2}\left(\frac{\partial}{\partial t}-\frac{\partial_t w_t}{4w_t}\right)+\gamma^z\gamma^t w^{1/2}m_0+2gw^{1/2}T_{zt}(z-t). \tag{67}$$

Simplifications connected with the remarks in Sec. II A lead to

$$w=w(z-t),\quad w_z=w_t=c(z-t). \tag{68}$$

With the use of the representation (20) for the Dirac matrices we derive the following:

$$\Phi_1(z-t)=\Phi_3(z-t),\quad \Phi_2(z-t)=\Phi_4(z-t), \tag{69}$$

$$\Phi_4=\frac{w^{1/2}(m_0-2gT_{zt})-k}{2ik_\nu}\left(\frac{c}{w}\right)^{1/2}\Phi_1, \tag{70}$$

$$\Phi_1=c^{1/2}\exp\left\{\frac{1}{4ik_\nu}\int[wm_0^2-(2gw^{1/2}T_{zt}+k)^2]\frac{c}{w}\,du\right\}. \tag{71}$$

The explicit form of the operator $\hat{K}_{xy}$ (66) demonstrates that a symmetry about the substitution $\mathbf{x}\leftrightarrow\mathbf{y}$ exists between the variables $\mathbf{x}$ and $\mathbf{y}$.

When the separating of variables $\mathbf{x}$ from $\mathbf{y}$ in the operator $\hat{K}_{xy}$ is fulfilled, we have four solutions for the separating matrix, namely:

$$\Lambda=\gamma^y,\gamma^y\gamma^z\gamma^t,\gamma^x,\gamma^x\gamma^z\gamma^t. \tag{72}$$

In the process γ^y, $\gamma^y\gamma^z\gamma^t$, are equivalent to the solutions **x**, **xzt** in terms of **x**↔**y** symmetry. Because of this, it suffices to make an allowance, for example, the solutions γ^y and $\gamma^y\gamma^z\gamma^t$. Since the structure of the Dirac matrices γ^y and $\gamma^y\gamma^z\gamma^t$ is the same, specifically in the representation of Eq. (20), both matrices are the diagonal ones, systems of four equations correlated with the operators $\hat{K}_x$ and $\hat{K}_y$ will be of the same structure for both $\mathbf{\Gamma} = \gamma^y$, $\gamma^y\gamma^z\gamma^t$, and possibilities of the adequate exact solutions for the variables **x** and **y** will be associated with one and the same metric structure. Hence, we give here the results for the unique solution of Eq. (72), precisely: $\mathbf{\Gamma} = \gamma^y\gamma^z\gamma^t$.

As a result, we have the following for the operators $\hat{K}_x$ and $\hat{K}_y$:

$$\hat{\mathbf{K}}_{\mathbf{x}} = \gamma^x\gamma^y\left(\frac{\tilde{\mathbf{a}}_{\mathbf{y}}}{\tilde{\mathbf{a}}_{\mathbf{x}}}\right)^{1/2}\left(\frac{\partial}{\partial \mathbf{x}} - \frac{\partial_x \tilde{\mathbf{a}}_{\mathbf{x}}}{4\tilde{\mathbf{a}}_{\mathbf{x}}}\right) - \gamma^y\gamma^z\gamma^t \mathbf{k}\tilde{\mathbf{a}}_{\mathbf{y}}^{1/2}, \tag{73}$$

$$\hat{\mathbf{K}}_y = \frac{1}{\tilde{b}_y^{1/2}}\left(\frac{\partial}{\partial y} - \frac{\partial_y \tilde{b}_y}{4\tilde{b}_y}\right). \tag{74}$$

Here, **k** is the separation constant of **z**, **t** from **x**, **y**.

Calculations totally analogous to the previous ones give the following:

For the **x** variable:

$$\Theta_1(x) = \Theta_4(x), \quad \Theta_2(x) = \Theta_3(x),$$
$$\Theta_\nu(x) = a_\nu^{1/4}\tilde{\Theta}_\nu(x), \quad \nu = 1,2,3,4, \tag{75}$$

$$\tilde{\Theta}_1(x) = \frac{\dfrac{\partial}{\partial x}\tilde{\Theta}_3(x)}{k - \tilde{k}}, \quad \tilde{\Theta}_2(x) = \frac{\partial_x \tilde{\Theta}_4(x)}{k + \tilde{k}}, \tag{76}$$

$$\Theta_1(x) = \exp\left\{\pm(k^2 - \tilde{k}^2)\int \tilde{a}_x^{1/2} dx\right\}. \tag{77}$$

For the **y** variable:

$$\Theta_\nu(y) = \tilde{b}_y^{1/4}\exp\left\{-\tilde{k}\int \tilde{b}_y^{1/2} dy\right\}. \tag{78}$$

Here $\tilde{k}$ is constant of the separation **x** from **y**.

Considering Eqs. (64) and (72), for the solution we finally arrive to

$$\Psi = e^{ik_\nu(x+t)}\begin{pmatrix} \Phi_1(z-t)\Theta_1(x) \\ \Phi_2(z-t)\Theta_2(x) \\ -\Phi_1(z-t)\Theta_2(x) \\ -\Phi_2(z-t)\Theta_1(x) \end{pmatrix}\Theta(y). \tag{79}$$

These solutions are associated with the metric of the form

$$ds^2 = w(z-t)\{\tilde{a}_x(dx)^2 + \tilde{b}_y(dy)^2\} + c(z-t)\{(dz)^2 - (dt)^2\}. \tag{80}$$

III. CONCLUSIONS

This work as well as the previous one[1] presents a series of exact solutions for the Dirac equation in case of an external wave field in the background of gravitation. All the specific types of wave fields have been considered, namely: scalar, vector, axial, pseudoscalar,[1] and tensor fields (in this work).

All the solutions are characterized by the limit transition to the case without gravitation[26–29] and to the case of the free Dirac particle. Discussion of such limit transition is presented in Ref. 1.

Here we should also say some words about metrics associated with the exact solutions presented in the Ref. 1 and in the present article [see formulas (55), (62), (80) and also (3.52), (4.42), (7.40) in Ref. 1].

Naturally, the relevant metrics (55), (62), and (80) turned out to be the conformally plane-wave ones. By the appropriate transformation of coordinates these metrics are easily reduced to the plane-wave ones. It is natural, because the same Volkov problem proper without gravitation, is characterized by a plane symmetry, and therefore its exact solutions proved to be possible only in the Cartesian and light-cone (also ''plane'') variables. Introduction of gravitation into problems of this type should not ''impair'' the initial symmetry, otherwise, as has been demonstrated in our studies, e.g., Ref. 34, separation of variables would be impossible even in the case of the initial problem.

Note here, that plane metrics of the general relativity theory have been considered by a number of authors. Specifically, Taub[35] and McVittie[36] have demonstrated that nonpolarized plane gravitational waves are nonexistent. Bondi[37,38] has succeeded in showing that field equations permit the existence of ''plane'' wave zones having finite lengths between two regions of plane space–time. These metrics were deduced taking into account the general matric form proposed by Rosen.[39]

The metrics pointed out in the present work proved to be conformally similar in their structure and symmetry to the above-mentioned solutions.[35–39] It should be noted that a particular case of a plane nonwave gravitational metric ($d(z-t)=1$, $c(z-t)=1$), with a special selection of the functions $\tilde{a}_x(x)$ and $\tilde{b}_y(y)$ in the metrics specified by us in Eqs. (55), (62), (80) involves the degenerate case of the Kasner solution,[40] that is in agreement with a specific result of our work.[29]

Algebraic solutions for point groups: The tetrahedral group for the group chain $T \supset C_3$

Jin-Quan Chen[a] and Peng-Dong Fan
Department of Physics, Nanjing University, Nanjing, 210008, People's Republic of China

(Received 1 April 1997; accepted for publication 16 September 1997)

A new technique, the double-induced technique, is introduced for constructing irreducible symmetry operators (ISO's) adapted to the group chain $G \supset G(s)$. Simple algebraic expressions of irreducible matrices, the ISO's and symmetry adapted functions (SAF's) are derived for the group chain $T \supset C_3$ for both single-valued and double-valued representations in a unified way. The simplicity of the results lies in the fact that the ISO's and SAF's are functions of only the quatum numbers of the group chain [the analogy of (j,m) for the group chain $SO_3 \supset SO_2$], without involving any irreducible matrix elements. The symmetries of the SAF's are disclosed for the first time. © *1998 American Institute of Physics.*

I. INTRODUCTION

It is known that the group SO_3 has analytic solutions with the primitive character $\chi(\varphi)=\sin(j+\frac{1}{2})\varphi/\sin(\varphi/2)$ and irreducible matrices $D^j_{mm'}(\alpha,\beta,\gamma)$, the well known D-functions.[1] Although any point group is a subgroup of O_3, however until present all solutions to the point groups are numerical.[2–8] It means that the primitive characters, irreducible matrices, irreducible symmetry operators (ISO's), and symmetry adapted functions (SAF's) are usually tabulated for each irrep of each group, with pages and pages of tables. It is highly desirable to seek algebraic solutions for the point groups so that the characters, irreducible matrices, ISO's and SAF's all have closed and simple formulas.

Using the symmetrized boson representation, the algebraic expressions for the single-valued (s.v.) irreducible basis have been obtained for the groups O_h and I_h.[9,10] The advantages of the symmetrized boson representation are that it allows one to get the algebraic expression of the irreducible bases for all possible cases without projection and provides a concise and intuitive picture for the vibration modes of molecules. The shortcomings of the symmetrized boson representation method are that it is applicable only to the single-valued reps and the derivation is rather complicated.

Recently, using the newly discovered factorization lemma for the semi-direct product of two Abelian groups, unified algebraic expressions are obtained for both the s.v. and double-valued (d.v.) representations of the characters, irreducible matrices, ISO's and SAF's of all dihedral groups.[11,12]

The purpose in the present series of work is to develop a new technique, called the double-induced representation technique, which can be used for obtaining algebraic solutions of any point groups for both s.v. and d.v. reps, and for the s.v. reps it is equivalent to the symmetrized boson representation. In this paper the technique is applied to the tetrahedral group T. Algebraic expressions of the ISO's of T are derived for both single-valued and double-valued reps in a unified way without using any knowledge of the irreducible matrices. The algebraic expressions of the ISO's and SAF's are functions of the quantum numbers characterizing the irreducible basis vector, without involving any irreducible matrix elements.

The outline of the paper is as follows: The double-induced rep technique is introduced in Sec.

[a]Electronic mail: jqchen@chenwang.nju.edu.cn

II and a method for uniquely determining the Euler angles of a double point group is given in Sec. III. The algebraic solutions for the group chains $T \supset C_3$ (for both s.v. and d.v.) reps, are derived in Sec. IV, while the final section is a discussion and summary.

II. THE DOUBLE-INDUCED REPRESENTATION

Since we are dealing with both the s.v. and d.v. reps in a unified way, let us begin with a brief introduction of the double point group. Consider a point group G,

$$G=\{R_i : i=1,2,\ldots,|G|\}, R_i=R_{\mathbf{n}_i}(\omega_i), \tag{1a}$$

where $R_{\mathbf{n}_i}(\omega_i)$ denotes a rotation about the axis $\mathbf{n}_i$ through angle ω_i. The corresponding double point group is

$$G^{\dagger}=\{R_i, \widetilde{R}_i : i=1,2,\ldots,|G|\}, \widetilde{R}_i=R_{\mathbf{n}_i}(\omega_i+2\pi). \tag{1b}$$

In the single-valued (s.v.) reps, or the vector reps, $\widetilde{R}_i=R_i$, while in the double-valued (d.v.), or spinor reps, $\widetilde{R}_i=-R_i$. It is convenient to introduce an index θ for specifying the type of representations,

$$\widetilde{R}_i=\theta R_i, \theta=\begin{cases} 1, & \text{for s.v. reps,} \\ -1, & \text{for d.v. reps.} \end{cases} \tag{2}$$

In deriving an algebraic expression it is vital to use quantum numbers to label irreps. It is pointed out[7] that we can use the eigenvalue λ of the so called CSCO-I or CSCO (complete set of commuting operators) of G to label irreps. The CSCO of a finite group, denoted by C, is the analogy of the set of Casimir operators of a Lie group, and the CSCO of any pure rotation point group except for the dihedral groups consists of only a single class operator.[11] Since the dihedral groups have been discussed in Ref. 12, in the following we assume that C consists of only a single class operator, say the i-th class operator C_i. For example, the CSCO of T is $C=C_{31}^{+}+C_{32}^{+}+C_{33}^{+}+C_{34}^{+}$ in the notation of Ref. 3. The correspondence between the eigenvalue λ of $C=C_i$ and the conventional irrep label (the Mulliken notation or Koster notation) is easily obtained according to the following: The eigenvalue of the class operator $C=C_i$ in the irrep Γ, denoted by λ^{Γ}, is related to the character χ_i^{Γ} as (see p. 60 in the book of Ref. 7)

$$\lambda^{\Gamma}=\frac{g_i}{h_{\Gamma}}\chi_i^{\Gamma}, \tag{3}$$

where g_i is the number of elements in the i-th class and h_{Γ} is the dimension of the irrep Γ. Using (3) from the known characters one can know immediately λ^{Γ}, and thus the correspondence is easily established between the eigenvalue λ and the the conventional irrep label Γ. For the group T, the correspondence is shown in Table I between λ and the irrep label in Koster notation Γ_1–Γ_7,[2] as well as the modified Mulliken notation A_0, A_1, A_{-1}, F for the s.v. reps and $E_{\mu}, \mu=\frac{1}{2}, \frac{3}{2}, -\frac{3}{2}$ for the d.v. reps. As will be seen the modified Mulliken notation is most suitable for obtaining algebraic solutions. Henceforth, the eigenvalue λ of the CSCO of G is referred to as the *quantum number* of the group G.

It should be pointed out that using the double-induced rep technique we can derive *ab initio* everything, the irreducible characters and matrices, the ISO's and SAF's without borrowing any thing from other work. Using the known characters is only for identifying irreps.

TABLE I. The eigenvalues λ,ρ_μ of the CSCO-II, (C,C_{3z}), of T.

	A_0 Γ_1	A_1 Γ_2	A_{-1} Γ_3	F Γ_4	$E_{1/2}$ Γ_5	$E_{3/2}$ Γ_6	$E_{-3/2}$ Γ_7
λ	4	4ϵ	$4\epsilon^*$	0	2	2ϵ	$2\epsilon^*$
μ	0	1	-1	$(1,0,-1)$	$(\frac{1}{2},-\frac{1}{2})$	$(\frac{3}{2},\frac{1}{2})$	$(\frac{3}{2},-\frac{1}{2})$
$\rho_\mu=\exp\left(-\frac{2\pi\mu i}{3}\right)$	1	ϵ	ϵ^*	$(\epsilon,1,\epsilon^*)$			

[a] $\epsilon=\exp(-2\pi i/3)$.

A central task in the group representation theory is to find the irreducible symmetry operators (ISO's). Suppose that the ISO is symmetry adapted to a canonical subgroup chain $G\supset G(s)$. The normalized $G\supset G(s)$ ISO is defined as (the usual form of the ISO is denoted as $\mathscr{P}^{(\lambda)}_{\rho\rho}=\sqrt{h_\lambda/|G|}\,\mathscr{P}^{(\lambda)}_{\rho}{}^{\overline{\rho}}$)

$$\mathscr{P}^{(\lambda)}_{\rho}{}^{\overline{\rho}}=\sqrt{\frac{h_\lambda}{|G|}}\sum_{a=1}^{|G|}D^{(\lambda)}_{\rho\rho}(R_a)^*R_a, \tag{4}$$

where h_λ is the dimension of the irrep λ, $|G|$ the order of G, R_a the a-th group element, and $D^{(\lambda)}_{\rho\rho}(R_a)$ is the irreducible matrix element of R_a in the $G\supset G(s)$ basis,

$$D^{(\lambda)}_{\rho\rho}(R_a)=\langle\psi^\lambda_\rho|R_a|\psi^\lambda_\rho\rangle.$$

Applying $\mathscr{P}^{(\lambda)}_{\rho}{}^{\overline{\rho}}$ to a normalized generic wave function, we can get all the orthonormalized irreducible basis vectors.

The intrinsic operator $\overline{R}$ of the intrinsic group $\overline{G}=\{\overline{R},\overline{S},\overline{T},\ldots\}$ is defined by[7]

$$\overline{RS}=SR,\quad \text{for any}\quad S\in G. \tag{5}$$

Notice that the set of intrinsic operators $\{\overline{R_i}^{-1},i=1,2,\cdot,|G|\}$ form what is called the right regular representation of G.[13]

If $C(s)$ is the CSCO of the subgroup $G(s)$, then $\overline{C}(s)$ is the CSCO of the intrinsic subgroup $\overline{G}(s)$, where $\overline{C}(s)$ is obtained from $C(s)$ by replacing the elements R in it by $\overline{R}$. The set of operators $(C,C(s))$ and $(C,C(s),\overline{C}(s))$ are called the CSCO-II and CSCO-III of G, which are the analogies of (J^2,J_z) and $(J^2,J_z,\overline{J_z})$ for the rotation group. According to Ref. 9 the ISO's adapted to the group chain $G\supset G(s)$ can be obtained by finding the simultaneous eigenvectors of the CSCO-III of G,

$$\begin{pmatrix} C \\ C(s) \\ \overline{C}(s)\end{pmatrix}\mathscr{P}^{(\nu)}_{\rho}{}^{\overline{\rho}}=\begin{pmatrix}\lambda\\ \rho\\ \overline{\rho}\end{pmatrix}\mathscr{P}^{(\lambda)}_{\rho}{}^{\overline{\rho}}. \tag{6}$$

The ISO $\mathscr{P}^{(\lambda)}_{\rho}{}^{\overline{\rho}}$ is a $G\supset G(s)$ basis $|\lambda\rho\rangle$ and $\overline{G}\supset\overline{G}(s)$ basis $|\lambda\,\overline{\rho}\rangle$. The $\overline{\rho}$ and ρ will be referred to as the intrinsic and external quantum numbers, respectively.

The expression for the ISO (4) can be greatly simplified by using its double-coset factored form.[14,15] Suppose that G can be decomposed into p right cosets and $q-p$ double cosets with each element occurring only once either in a right coset or a double coset,

$$G=G(s)(e+k_2+\cdots+k_p)+G(s)(k_{p+1}+\cdots+k_q)G(s), \tag{7}$$

where k_i ($k_1\equiv e$) are coset generators. Furthermore, assume that $G(s)=\{s_i:\ i=1,2,...,|G(s)|\}$ is Abelian with the un-normalized projection operator $P^{\rho}=\sum_{i=1}^{|G(s)|}D^{(\rho)}(s_i)^*s_i$. Then it is easy to show that the ISO in (4) can be expressed as

$$\mathscr{P}_{\rho}^{(\lambda)\bar{\rho}}=\sqrt{\frac{h_\lambda}{|G|}}\left[\sum_{i=1}^{p}D_{\rho\rho}^{(\lambda)}(k_i)^*P^{\rho}k_i+\sum_{i=p+1}^{q}D_{\rho\rho}^{(\lambda)}(k_i)^*P^{\rho}k_iP^{\bar{\rho}}\right]. \tag{8}$$

The ISO in the factored form sums over only the q coset generators weighted by their matrix elements.

In the numerical approach to the eigenfunction method,[7] we diagonalize the CSCO-III in the $|G|$-dimensional group space and for each set of eigenvalues $(\lambda,\rho,\bar{\rho})$ we get one eigenvector $\mathscr{P}_{\rho}^{(\nu)\rho}$ in the original form (4). A packet of programs has been written for this purpose.[16] By inputing the names of the group G and its subgroup $G(s)$, the computer will generate the characters, irreducible matrices, the Clebsch–Gordan coefficients for any crystal point group.

Now our purpose is to obtain $\mathscr{P}_{\rho}^{(\nu)\rho}$ in the factored form (8) as an algebraic function of $(\lambda,\rho,\bar{\rho})$, and we have to change our strategy. The new strategy consists of the following steps

(1) Decompose the group G into double cosets with respect to the subgroup $G(s)$,

$$G=G(s)(e+k_2+k_3+\cdots+k_q)G(s). \tag{9a}$$

In this paper we only deal with the case when $G(s)$ is a cyclic group of order n with the generator C_{nz}. In the decomposition (9a) some double cosets, say the first p double cosets, are coincident with the right or left cosets,

$$k_iG(s)=G(s)k_i,\quad i=1,2,\ldots,p, \tag{9b}$$

and Eq. (9a) reduces to (7).

(2) Construct the orthonormal common eigenvectors $\varphi_{\rho\rho}^{i}$ of $C(s)$ and $\bar{C}(s)$ by applying the projection operator of the group $G(s)$ and $\bar{G}(s)$ to the double-coset generators k_i,

$$\varphi_{\rho\rho}^{i}=\text{const}\ P^{\rho}\bar{P}^{\bar{\rho}}k_i=\text{const}\ P^{\rho}k_iP^{\bar{\rho}}, \tag{9c}$$

where P^{ρ} is the projection operator of $G(s)$ with the eigenvalue ρ of its generator C_{nz} as its irrep label, and $\bar{P}^{\rho}$ is obtained from P^{ρ} by replacing the group element R with $\bar{R}$. For deriving (9c) the defining equation (5) for the intrinsic operator $\bar{R}$ has been used. The basis vectors $\varphi_{\rho\rho}^{i}$ form what is called the *double-induced representation*, which is a representation induced from the irreps $(\rho,\bar{\rho})$ of the group $G(s)\times\bar{G}(s)$. It is seen that the basis vectors $\varphi_{\rho\rho}^{i}$ are constructed by applying the projection operators P^{ρ} and $P^{\bar{\rho}}$ to the coset generator k_i from left and right, respectively, or in a manner of speaking, by sandwiching k_i between P^{ρ} and $P^{\bar{\rho}}$.

Notice that due to (9b) and the property of the projection operator, we have

$$k_iP^{\bar{\rho}}=P^{f_i(\bar{\rho})}k_i,\varphi_{\rho\rho}^{i}=\text{const}\ \delta_{\rho,f_i(\bar{\rho})}P^{\rho}k_i,\quad i=1,2,\cdots,p, \tag{9d}$$

where $f_i(\bar{\rho})$ is a simple function of $\bar{\rho}$. It is found that for all point groups $f_i(\bar{\rho})$ is either equal to $\bar{\rho}$ [evidently $f_1(\bar{\rho})\equiv\bar{\rho}$] or $\bar{\rho}^*$. Therefore there are only pn instead of pn^2 linearly independent basis vectors $\varphi_{\rho\rho}^{i}, i=1,2,\ldots,p$ and the total number of linearly independent basis vectors in the

double induced rep is $pn+(q-p)n^2$, which is just the order of the group G. It shows that although there are qn^2 elements in the double coset decompostion (9a), no double counting problem arises here.

It is also to be noticed that due to (9d) the dimension of the double-induced rep depends on the values of ρ and $\overline{\rho}$, and the maximum dimension is equal to q, the number of double cosets of G with respect to $G(s)$, which is usually much less than the order $|G|$.

(3) Construct the representation matrix, M, of the CSCO, C, in the double-induced rep,

$$M_{ij}=\langle \varphi^{i}_{\rho\rho}|C|\varphi^{j}_{\rho\rho}\rangle. \tag{9e}$$

Notice that the matrix $M\equiv M(\rho,\overline{\rho})$ depends on ρ and $\overline{\rho}$.

(4) Diagonalize C in the double-induced rep space $L_{\rho,\overline{\rho}}=\{\varphi^{i}_{\rho\overline{\rho}}: i=1,2,\ldots,q\}$ with the $\rho,\overline{\rho}$ as parameters. The ISO's can be expressed as

$$\mathscr{P}^{(\lambda)\overline{\rho}}_{\rho}=\sum_{i=1}^{q} u_i \varphi^{i}_{\rho\overline{\rho}}. \tag{9f}$$

The coefficients u_i are determined from the following matrix equation:

$$\tilde{M}\mathbf{u}=\lambda\mathbf{u}, \tag{9g}$$

where $\mathbf{u}=\{u_1,u_2,\ldots,u_q\}_{\text{column}}$ is a column vector.

Following the above four steps we can obtain a unified and compact expression of the ISO's $\mathscr{P}^{(\lambda)\overline{\rho}}_{\rho}$ as a function of all possible values of λ, ρ, and $\overline{\rho}$. The s.v. and d.v. reps are distinguished by the possible values of quantum numbers λ, ρ and $\overline{\rho}$, and are obtained simultaneously.

(5) According to Eq. (8), the coefficients in front of the coset generator k_i in the normalized ISO's are equal to $\sqrt{h_\lambda/|G|}$ times the complex conjugate of the matrix element of k_i. In this way we can obtain an algebraic expression of the irreducible matrices of all coset generators. The irreducible matrices of other elements are easily found from those of the coset generators.

(6) For an irrep of dimension h there are h sets of ISO's distinguished by the intrinsic quantum number $\overline{\rho}$ (or the column index in the conventional language). In many cases, for example, for obtaining the SAF's, only one set of the ISO's is sufficient and the normalization is unimportant. Therefore for each group we give the explicit expression for the chosen set of unnormalized ISO's, which are termed the generalized projection operators and designated by $\mathbf{P}^{(\Gamma)}_{\rho}$.

Up to this point, the coordinate system is irrelevant. For obtaining the SAF's, we need to specify the coordinate system, and determine the Euler angles of the double-coset generators in the coordinate system. Then we apply the generalized projection operators $\mathbf{P}^{(\Gamma)}_{\rho}$ to the eigenvector $|jm\rangle$ of angular momentum, and obtain algebraic expressions for the SAF's for both s.v. and d.v. reps.

Since the normalization of the ISO's are not important except for the case of reading out the irreducible matrix elements from the ISO's as stated in step (5), we are sloppy about the numerical factor for the ISO's in the process of derivation for the sake of clarity. The normalization is easily found according to the assumption that the scalar product of two elements is $(R_a,R_b)=\delta_{ab}$ and will be inserted into the final expression of the ISO's.

III. THE CONSTRUCTION OF THE GROUP TABLE OF $T^{\dagger}$

The starting point for finding algebraic solutions to the double point group $G^{\dagger}$ is constructing its group table. The group table of a double point group $G^{\dagger}$ is usually constructed in the following way: Find the Euler angles (α,β,γ), $0\leqslant\alpha,\gamma\leqslant 2\pi$, $0\leqslant\beta\leqslant\pi$, for each element of G, assign the

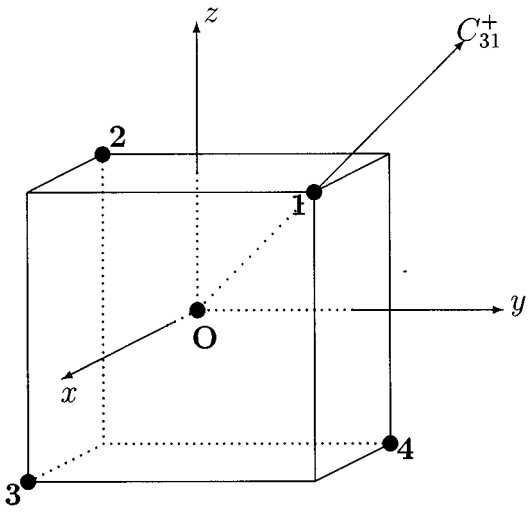

FIG. 1. The coordinate system xyz for $T \supset D_2$, with **1, 2, 3** and **4** indicating the four vertices of the tetrahedral.

matrices $\pm D^{1/2}(\alpha,\beta,\gamma)$ to the elements $(R,\widetilde{R})$, then by matrix multiplication we can form the group table of $G^{\dagger}$. However there is an ambiguity in the assignment (see p. 424 of Ref. 3): one could assign $R=D^{1/2}(\alpha,\beta,\gamma)$, $\widetilde{R}=-D^{1/2}(\alpha,\beta,\gamma)$ or $R=-D^{1/2}(\alpha,\beta,\gamma)$, $\widetilde{R}=D^{1/2}(\alpha,\beta,\gamma)$, and there is no definite rule for the assignment with the consequence that an inconsistency may arise. For example, in p. 422 of Ref. 3 the assignment is $C_{4z}=D^{1/2}(0,0,\pi/2)$, $C_{2z}=-D^{1/2}(0,0,\pi)$, which implies that $C_{4z}=\exp(-i(\pi/2)J_z)$, $C_{2z}=-\exp(-i\pi J_z)$ instead of $C_{2z}=C_{4z}^2=\exp(-i\pi J_z)$.

For avoiding this inconsistency, we enlarge the domain of the Euler angles as

$$0\leqslant\alpha\leqslant 2\pi, 0\leqslant\gamma\leqslant 4\pi, 0\leqslant\beta\leqslant\pi,$$

and determine the Euler angles for the rotation through angle ω about the axis **n** with azimuthal angles θ,φ, $R_{\mathbf{n}(\theta\varphi)}(\omega)$, uniquely by the formula[14]

$$\begin{pmatrix} e^{-(i/2)(\alpha+\gamma)}\cos\dfrac{\beta}{2}, & -e^{-(i/2)(\alpha-\gamma)}\sin\dfrac{\beta}{2} \\ e^{(i/2)(\alpha-\gamma)}\sin\dfrac{\beta}{2}, & e^{(i/2)(\alpha+\gamma)}\cos\dfrac{\beta}{2} \end{pmatrix} = \begin{pmatrix} \cos\dfrac{\omega}{2}-in_z\sin\dfrac{\omega}{2}, & -(n_y+in_x)\sin\dfrac{\omega}{2} \\ (n_y-in_x)\sin\dfrac{\omega}{2}, & \cos\dfrac{\omega}{2}+in_z\sin\dfrac{\omega}{2} \end{pmatrix}, \tag{10}$$

where

$$n_z=\cos\,\theta,\quad n_x=\sin\,\theta\,\cos\varphi,\quad n_y=\sin\,\theta\,\sin\,\varphi.$$

With the following unique assignment:

$$R_i=D^{1/2}(\alpha_i,\beta_i,\gamma_i),\quad \widetilde{R}_i=-D^{1/2}(\alpha_i,\beta_i,\gamma_i),$$

and using the D-function[17] given in the left hand side of (10) we can construct the group table for any double point group.

The coordinate system for the group T is usually chosen as in Fig. 1. The Euler angles for T and the group table of $T^{\dagger}$ are listed in Table II and Table III.

TABLE II. The Euler angles for $T^{\dagger}$ in the coordinate system of Fig. 1.

Element	α	β	γ	Element	α	β	γ
E	0	0	0	C_{2x}	0	π	π
C_{2y}	0	π	0	C_{2z}	0	0	π
C_{31}^{+}	0	$\frac{\pi}{2}$	$\frac{\pi}{2}$	C_{32}^{+}	π	$\frac{\pi}{2}$	$\frac{7\pi}{2}$
C_{33}^{+}	π	$\frac{\pi}{2}$	$\frac{5\pi}{2}$	C_{34}^{+}	0	$\frac{\pi}{2}$	$\frac{7\pi}{2}$
C_{31}^{-}	$\frac{\pi}{2}$	$\frac{\pi}{2}$	3π	C_{32}^{-}	$\frac{3\pi}{2}$	$\frac{\pi}{2}$	2π
C_{33}^{-}	$\frac{\pi}{2}$	$\frac{\pi}{2}$	0	C_{34}^{-}	$\frac{3\pi}{2}$	$\frac{\pi}{2}$	3π

Remark 1: It is found that the new group table has the desired feature that the elements $R,S,T,\ldots,$ belong to the same class and $\widetilde{R},\widetilde{S},\widetilde{T},\ldots,$ belong to a different class, instead of a mix up of tilded and untilded elements in the same class.

Remark 2: The Euler angles in Table II are different from those given in p. 54 by Bradley and Cracknell[3] (notice that the definition of the Euler angles α and γ in Ref. 3 is opposite to what is used here).

In later developments we need to use different quantization axes for different subgroup chains and it is important to know the relation between the Euler angles of the same operator in two different coordinates systems. Suppose that the new coordinate system $x'y'z'$ is obtained from the original one xyz by a rotation $R(\phi,\theta,\zeta)$, i.e., $xyz \xrightarrow{R(\phi,\theta,\zeta)} x'y'z'$, then the Euler angles (α',β',γ') of an operator in the new system is determined by

$$D^{1/2}(\alpha',\beta',\gamma')=D^{1/2}(-\zeta,-\theta,-\phi)D^{1/2}(\alpha,\beta,\gamma)D^{1/2}(\phi,\theta,\zeta). \tag{11}$$

In passing we note that through out the paper we will use the Condon–Shortley definition for $|jm\rangle$. When $j=l$, l being an integer,

$$|lm\rangle \equiv Y_{lm},$$

TABLE III. The group table of $T^{\dagger}$.

where the spherical harmonic Y_{lm} is defined in accordance with Rose.[17] The following properties of the D-function[17] are useful for deriving the SAF's and their symmetries,

$$C_{2x}|jm\rangle=(-)^{-j}|j-m\rangle,\quad C_{2y}|jm\rangle=(-)^{j-m}|j-m\rangle,\qquad C_{2z}|jm\rangle=(-)^{m}|jm\rangle, \tag{12a}$$

$$d^j_{mm'}(\beta)=(-1)^{m-m'}d^j_{m',m}(\beta)=(-1)^{m-m'}d^j_{-m-m'}(\beta),\qquad d^j_{mm'}\left(\frac{\pi}{2}\right)=(-1)^{j-m'}d^j_{-m',m}\left(\frac{\pi}{2}\right)=(-1)^{j-m'}d^j_{-m,m'}\left(\frac{\pi}{2}\right), \tag{12b}$$

where $d^j_{mm'}(\beta)=\langle jm|e^{-i\beta J_y}|jm'\rangle$.

IV. THE GROUP CHAIN $T\supset C_3$

The CSCO of T is

$$C=C_{31}^{+}+C_{32}^{+}+C_{33}^{+}+C_{34}^{+}=\mathbf{5}+\mathbf{6}+\mathbf{7}+\mathbf{8}, \tag{13}$$

where and in the following we use a bold face integer to denote the group element listed in Table III, e.g., **5** represents the element $R_5=C_{31}^{+}$.

From the known characters of the group T and Eq. (3) one can know immediately that C has seven distinct eigenvalues $(4,4\epsilon,4\epsilon^*,0)$, and $(2,2\epsilon,2\epsilon^*)$, $\epsilon=e^{-2\pi i/3}$, corresponding to the seven irreps; in our notation they are the s.v. reps (A_0,A_1,A_{-1},F) and the d.v. reps $(E_{1/2},E_{3/2},E_{-3/2})$; see Table I.

A. The C_3 double-induced representation

It is known that C_3 is a canonical subgroup of T for both the s.v. and d.v. reps and its CSCO can be chosen as $C(s)=C_{31}^{+}$. Choosing the axis of C_{31}^{+} as the quantization axis, the operator C_{31}^{+} can be written as

$$C_{31}^{+}=\exp\left(-\frac{2\pi J_z i}{3}\right). \tag{14}$$

Its eigenvalue is denoted by $\rho\equiv\rho_\mu$,

$$\rho=\rho_\mu=\exp\left(-\frac{2\pi\mu i}{3}\right),\mu=\begin{cases}0,\pm1, & \text{for s. v. reps},\\ \pm\ \frac{1}{2},\ \frac{3}{2}, & \text{for d. v. reps.}\end{cases} \tag{15}$$

As in Ref. 5 we use μ as the label of the irreps of C_3. Notice that the irreps $\frac{3}{2}$ and $-\frac{3}{2}$ of C_3 are equivalent, $-\frac{3}{2}\cong\frac{3}{2}$, and

$$C_{31}^{3+k}=\theta C_{31}^{k},\quad (\rho)^{3+k}=\theta\rho^{k}, \tag{16}$$

where θ is the index introduced in (2).

The CSCO-II of T is (C,C_{31}^{+}), and each irreducible basis vectors of T can be uniquely labeled by the eigenvalues of the CSCO-II, as shown in Table I. For the d.v. reps, it is more convenient to use the value μ instead of the value $\rho_\mu=\exp(-2\pi\mu i/3)$ as the component label.

We begin with the construction of the eigenvectors $\varphi^{i}_{\rho\rho}$—of C_{31}^{+} and $\overline{C_{31}^{+}}$ in the group space. The projection operator of C_3 is defined as

$$P^{\mu}\equiv P^{\rho_\mu}=(P^{\mu})^{\dagger}=\frac{1}{2}\sum_{k=0}^{5}(\rho_{\mu}^{*})^{k}(C_{31})^{k}. \tag{17}$$

Regarding P^{ρ} as a vector in the group space, we have

$$(P^{\rho})^{*}=P^{\rho *},\quad (P^{\mu})^{*}=P^{-\mu},\quad P^{3/2}=P^{-3/2}. \tag{18}$$

Due to (16), for both s.v. and d.v. reps we have

$$P^{\rho}=P^{\mu}=e+\rho C_{31}^{-}+\rho^{*}C_{31}^{+}=\mathbf{1}+\rho\mathbf{9}+\rho^{*}\mathbf{5}. \tag{19}$$

The double coset decomposition of the group T with respect to C_3 is

$$T=C_3(e+C_{2z})C_3. \tag{20}$$

Notice that any member in a coset can be chosen as the coset generator, but once chosen, it should be kept fixed. Here we choose e and C_{2z} as the coset generators.

According to (9c), sandwiching the two coset generators (e,C_{2z}) between P^{ρ} and $P^{\overline{\rho}}$, and inserting normalization coefficients we get two common eigenvectors of C_{31}^{+} and $\overline{C_{31}^{+}}$,

$$\varphi^{1}_{\rho,\overline{\rho}}=\frac{1}{3\sqrt{3}}P^{\rho}eP^{\overline{\rho}},\quad \varphi^{2}_{\rho,\overline{\rho}}=\tfrac{1}{3}P^{\rho}C_{2z}P^{\overline{\rho}}. \tag{21a}$$

Using $P^{\rho}P^{\rho'}=3\delta_{\rho,\rho'}P^{\rho}$ it is easy to show that

$$\varphi^{1}_{\rho\overline{\rho}}=\delta_{\rho\overline{\rho}}\varphi^{1}_{\rho},\quad \varphi^{1}_{\rho}=\frac{1}{\sqrt{3}}P^{\rho},$$

$$\varphi^{2}_{\rho\overline{\rho}}=\tfrac{1}{3}P^{\rho}C_{2z}P^{\overline{\rho}}=\frac{1}{\sqrt{3}}[\rho^{*}\overline{\rho}\,\varphi^{2}_{\rho}+\rho\overline{\rho^{*}}\varphi^{3}_{\rho}+\varphi^{4}_{\rho}], \tag{21b}$$

where φ^{i}_{ρ} are eigenvectors of C_{3z},

$$\varphi^{1}_{\rho}=\frac{1}{\sqrt{3}}P^{\rho},\quad \varphi^{2}_{\rho}=\varphi^{1}_{\rho}C_{2x},\quad \varphi^{3}_{\rho}=\varphi^{1}_{\rho}C_{2y},\quad \varphi^{4}_{\rho}=\varphi^{1}_{\rho}C_{2z}. \tag{21c}$$

The two basis vectors $\varphi^{1}_{\rho\overline{\rho}}$, $\varphi^{2}_{\rho\overline{\rho}}$—form the double-induced rep. Recall what was mentioned in Sec. II that there are only $12=1\times3+1\times3^{2}$ linearly independent basis vectors in (21b).

Using the group table, the two common eigenvectors of C_{31}^{+} and $\overline{C_{31}^{+}}$ can be written explicitly,

$$\varphi^{1}_{\rho}=\frac{1}{\sqrt{3}}[\mathbf{1}+\rho\mathbf{9}+\rho^{*}\mathbf{5}],$$

$$\varphi^{2}_{\rho\overline{\rho}}=\tfrac{1}{3}[(\mathbf{4}+\rho\mathbf{11}+\theta\rho^{*}\mathbf{8})+\overline{\rho}(\mathbf{12}+\rho\mathbf{6}+\rho^{*}\mathbf{2})+\theta\overline{\rho^{*}}(\mathbf{7}+\theta\rho\mathbf{3}+\rho^{*}\mathbf{10})]. \tag{22}$$

For later convenience, one element in each of the basis vectors of the double-induced rep is chosen as its representative. Although any element in a basis vector can be chosen as its representative, the simplest choice here is to choose the element **1** and **4** as the representatives of φ^{1} and φ^{2}.

The task of finding the eigenvectors of the CSCO-III in the 12-dimensional group space of T is reduced to finding the eigenvector of the CSCO in the two-dimensional double-induced rep space $L_{\rho\bar{\rho}}=\{\varphi^i_{\rho\bar{\rho}}: i=1,2\}$. Since $\rho\equiv\rho_\mu=\exp(-2\pi\mu i/3)$, the basis vectors $\varphi^i_{\rho\bar{\rho}}$ can be written as $\varphi^i_{\mu\bar{\mu}}$, $\mu,\bar{\mu}=0,\pm\frac{1}{2},\pm 1,\frac{3}{2}$.

The next step is to find the representation matrix M of the operator C in the double-induced representation. A key point for finding the matrix elements M_{ji} in $C\varphi^i_{\rho\bar{\rho}}=\Sigma_j M_{ji}\varphi^j_{\rho\bar{\rho}}$, is that we only need to find the coefficients in front of the representatives of $\varphi^1_{\rho\bar{\rho}}$ and $\varphi^2_{\rho\bar{\rho}}$, i.e., in front of **1** and **4**. This can be accomplished by the following procedure: (1). Highlight the elements **1** and **4** in rows 5–8 (which correspond to the elements $C^+_{31}-C^+_{34}$) of the group table of $T^\dagger$. (2) Collecting the highlighted numbers in each column, we obtain the following table:

R_i	**9**	**10**	**11**	**12**
CR_i	**1** $+\theta$**4**	**1**$+\theta$**4**	**1**+**4**	**1** +**4**

The table shows, e.g., $CR_9=R_1+\theta R_4+\cdots$. The terms involving elements other than R_1 and R_4 are ignored. Using the above table and (22) we have

$$C\varphi^1_\rho=\frac{1}{\sqrt{3}}[\rho(\mathbf{1}+\theta\mathbf{4})]=\rho\varphi^1_\rho+\sqrt{3}\,\theta\rho\varphi^2_{\rho\bar{\rho}},$$
$$C\varphi^2_{\rho\bar{\rho}}=\tfrac{1}{3}[\rho(\mathbf{1}+\mathbf{4})+\bar{\rho}(\mathbf{1}+\mathbf{4})+\theta(\bar{\rho}\rho)^*(\mathbf{1}+\theta\mathbf{4})]=\sqrt{3}\rho\varphi^1_\rho\delta_{\rho\bar{\rho}}+(\rho+\bar{\rho}+\rho^*\bar{\rho}^*)\varphi^2_{\rho\bar{\rho}}, \tag{23}$$

where $\rho^{*2}=\theta\rho$ has been used.

From (23) we obtain the transpose of the rep matrix M of C,

$$\tilde{M}=\begin{pmatrix}\rho\delta_{\rho\bar{\rho}}, & \sqrt{3}\rho\delta_{\rho\bar{\rho}}\\ \sqrt{3}\theta\rho\delta_{\rho\bar{\rho}}, & \rho+\bar{\rho}+(\rho\bar{\rho})^*\end{pmatrix}. \tag{24}$$

The diagonalization of the matrix $\tilde{M}$ in (24) is carried out separately for two cases.

Case (i) $\rho\neq\bar{\rho}$

When $\rho\neq\rho$, or $\bar{\mu}\neq\mu$, M shrinks into one-dimensional and there is only one non-vanishing vector, $\varphi^2_{\mu\bar{\mu}}$, which is necessarily an eigenvector of the operator C with the eigenvalue $\lambda=M_{22}=\rho_\mu+\rho_{\bar{\mu}}+(\rho_\mu\rho_{\bar{\mu}})^*$,

$$\lambda=\begin{cases}0,\\ 2,\\ 2\epsilon, & \text{for}(\mu,\bar{\mu})\ \text{or}(\bar{\mu},\mu)=\begin{cases}(1,-1),(0,1),(0,-1),\\ (\frac{1}{2}-\frac{1}{2}),\\ (\frac{3}{2},\frac{1}{2}),\\ (\frac{3}{2},-\frac{1}{2}),\end{cases}\\ 2\epsilon^*,\end{cases} \tag{25a}$$

where

$$\epsilon=\rho_1=\exp\left(-\frac{2\pi i}{3}\right). \tag{25b}$$

Consulting Table I we know that the four eigenvalues $0,2,2\epsilon,2\epsilon^*$ of λ in (25a) correspond to the four irreps $F,E_{1/2},E_{3/2}$, and $E_{-3/2}$, respectively. Hence we have the basis vectors

$$\mathscr{P}_{\mu}^{(F)\overline{\mu}}=\varphi^{2}_{\mu\overline{\mu}},\quad \mu\neq\overline{\mu}=0,\pm1, \tag{26a}$$

$$\mathscr{P}_{\mu}^{(E_\nu)\overline{\mu}}=\varphi^{2}_{\mu\overline{\mu}},\quad (\mu,\overline{\mu})\ \text{or}(\overline{\mu},\mu)=\begin{cases}(\frac{1}{2},-\frac{1}{2}),\\ (\frac{3}{2},\frac{1}{2}),\\ (\frac{3}{2},-\frac{1}{2}),\end{cases}\quad \text{for}\quad \nu=\begin{cases}\frac{1}{2}\\ \frac{3}{2}\\ -\frac{3}{2}\end{cases}. \tag{26b}$$

Case (ii) $\overline{\rho}=\rho$

For $\rho=\overline{\rho}$, the matrix $\widetilde{M}$ is simplified as

$$\widetilde{M}=\rho_\mu\begin{pmatrix}1, & \sqrt{3}\\ \theta\sqrt{3}, & \theta+2\end{pmatrix}. \tag{27}$$

The eigenvector is

$$\mathscr{P}_{\mu}^{(\lambda)\mu}=N_{\lambda\mu}\left[\varphi^{1}_{\mu}-\frac{1}{\sqrt{3}}(1-\lambda\rho_{-\mu})\varphi^{2}_{\mu\mu}\right]. \tag{28}$$

For each μ, the matrix $\widetilde{M}$ in (27) has two eigenvalues, which are easily found as

$$\lambda=(0,4\rho_\mu),\quad \mu=0,\pm1,\quad \text{for s.v.}, \tag{29a}$$

$$\lambda=2\rho_{\mu\mp1/2}=\begin{cases}(2,2\epsilon)=(\lambda^{E_{1/2}},\lambda^{E_{3/2}}), & \mu=\frac{1}{2},\\ (2\epsilon^*,2)=(\lambda^{E_{-3/2}},\lambda^{E_{1/2}}), & \mu=-\frac{1}{2},\\ (2\epsilon,2\epsilon^*)=(\lambda^{E_{3/2}},\lambda^{E_{-3/2}}), & \mu=\frac{3}{2}.\end{cases} \tag{29b}$$

The eigenvalue $\lambda=4\rho_\mu$ corresponds to the one-dimensional irreps $A_\mu,\mu=0,\pm1$.

B. The $T\supset C_3$ ISO's

Substituting the eigenvalues (29) into (28), we can get the ISO's.

(1) The $T\supset C_3$ s.v. reps:

$$\begin{cases}\mathscr{P}^{(A_\mu)}=\frac{1}{2}(\varphi^{1}_{\mu}+\sqrt{3}\varphi^{2}_{\mu\mu}),\\ \mathscr{P}^{(F)\mu}_{\mu}=\frac{1}{2}(\sqrt{3}\varphi^{1}_{\mu}-\varphi^{2}_{\mu\mu}),\end{cases}\quad \mu=0,\pm1. \tag{30}$$

From (21), (30), and (26a) we get all the $T\supset C_3$ s.v. ISO's

$$\begin{cases} \mathscr{P}^{(A_\mu)} = \dfrac{1}{\sqrt{12}}[P^\mu + P^\mu C_{2z} P^\mu], \\ \mathscr{P}_\mu^{(F)\mu} = \frac{1}{2}[P^\mu - \frac{1}{3} P^\mu C_{2z} P^\mu], \quad \mu = 1,0,-1, \\ \mathscr{P}_\mu^{(F)\overline{\mu}} = \frac{1}{3} P^\mu C_{2z} P^{\overline{\mu}}, \quad \overline{\mu} \neq \mu. \end{cases} \tag{31}$$

Using the fact that

$$P^{\rho_\mu} C_{2z} P^{\rho_\mu} = P^{\rho_\mu}(C_{2x} + C_{2y} + C_{2z}), \tag{32}$$

$\mathscr{P}^{A_\mu}$ can be rewritten as

$$\mathscr{P}^{A_\mu} = \frac{1}{\sqrt{12}} P^{\rho_\mu} \wp^{++}, \tag{33}$$

with $\wp^{++} = 1 + C_{2x} + C_{2y} + C_{2z}$.

(2) The $T \supset C_3$ d.v. reps

For d.v. reps, (28) can be simplified as

$$\mathscr{P}_\mu^{(\lambda)\mu} = \frac{1}{\sqrt{2}}(\varphi_\mu^1 \mp i \varphi_{\mu\mu}^2), \lambda = 2\rho_{\mu \pm 1/2}, \mu = \tfrac{3}{2}, \pm \tfrac{1}{2}. \tag{34}$$

Combining it with (26b) we get the $T \supset C_3$ ISO's,

$$\begin{cases} \mathscr{P}_\mu^{(E_{1/2})\mu} = \dfrac{1}{\sqrt{6}}\left(P^\mu + \dfrac{(-1)^\mu}{\sqrt{3}} P^\mu C_{2z} P^\mu \right), \\ \mathscr{P}_\mu^{(E_{1/2})\overline{\mu}} = -\dfrac{i}{3} P^\mu C_{2z} P^{\overline{\mu}}, \overline{\mu} \neq \mu = \pm \tfrac{1}{2}, \end{cases} \tag{35a}$$

$$\begin{cases} \mathscr{P}_\mu^{(E_{3/2})\mu} = \dfrac{1}{\sqrt{6}}\left(P^\mu - \dfrac{(-1)^\mu}{\sqrt{3}} P^\mu C_{2z} P^\mu \right), \\ \mathscr{P}_\mu^{(E_{3/2})\overline{\mu}} = -\dfrac{i}{3} P^\mu C_{2z} P^{\overline{\mu}}, \overline{\mu} \neq \mu = \tfrac{3}{2}, \tfrac{1}{2}, \end{cases} \tag{35b}$$

where the phase factor $-i$ is chosen for convenience. The ISO's for $E_{-3/2}$ are obtained from the complex conjugation [for a definition see (18)] of the ISO's of $E_{3/2}$ as

$$\mathscr{P}_{-\mu}^{(E_{-3/2})-\overline{\mu}} = (\mathscr{P}_\mu^{(E_{3/2})\overline{\mu}})^*. \tag{36}$$

Notice that $C_{2z}^{-1} = \theta C_{2z}$ and the ISO's obey the condition

$$(\mathscr{P}_\mu^{(E_\nu)\overline{\mu}})^\dagger = \mathscr{P}_{\overline{\mu}}^{(E_\nu)\mu}.$$

C. The $T \supset C_3$ irreducible matrices

The operator C_{31}^{+} is diagonal and its representation matrix is readily known. The representation matrices of the coset generator C_{2z} are obtained in the following way: by comparing (31) and (35) with (8) we know that the coefficients of $P^{\mu}C_{2z}P^{\overline{\mu}}$ in (31) and (35) are equal to $\sqrt{h_\lambda/|G|}D^{\Gamma}_{\mu\overline{\mu}}(C_{2z})^*$. Consequently from (31) we immediately get $T \supset C_3$ s.v. matrix elements of C_{31}^{+} and C_{2z}, $D^{F}_{\mu\mu'}(C_{31}^{+}) = \delta_{\mu\mu'}\rho_\mu$, $D^{F}_{\mu\mu'}(C_{2z}) = \frac{2}{3} - \delta_{\mu\mu'}$, or in the matrix form

$$D^{F}(C_{31}^{+}) = \begin{pmatrix} \rho_1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \rho_{-1} \end{pmatrix}, D^{F}(C_{2z}) = \begin{pmatrix} -\frac{1}{3} & \frac{2}{3} & \frac{2}{3} \\ \frac{2}{3} & -\frac{1}{3} & \frac{2}{3} \\ \frac{2}{3} & \frac{2}{3} & -\frac{1}{3} \end{pmatrix}. \tag{37}$$

Similarly from (35) we get the $T \supset C_3$ d.v. irreducible matrices:

$$D^{E_{1/2}}(C_{31}^{+}) = \begin{pmatrix} \rho_{1/2} & 0 \\ 0 & \rho_{-1/2} \end{pmatrix}, D^{E_{3/2}}(C_{31}^{+}) = \begin{pmatrix} \rho_{3/2} & 0 \\ 0 & \rho_{1/2} \end{pmatrix}, \tag{38a}$$

$$D^{E_{1/2}}(C_{2z}) = D^{E_{3/2}}(C_{2z}) = i\begin{pmatrix} -\sqrt{\frac{1}{3}} & \sqrt{\frac{2}{3}} \\ \sqrt{\frac{2}{3}} & \sqrt{\frac{1}{3}} \end{pmatrix}. \tag{38b}$$

The irreducible matrices of the irreps $E_{-3/2}$ and $E_{3/2}$ are complex conjugate to each other,

$$D^{E_{-3/2}}(R_a) = D^{E_{3/2}}(R_a)^*.$$

The matrices of other elements are easily obtained by

$$D^{(\lambda)}_{\mu\overline{\mu}}(C_{31}^{j}C_{2z}C_{31}^{k}) = \rho_\mu^{j} D^{(\lambda)}_{\mu\overline{\mu}}(C_{2z})\rho_{\overline{\mu}}^{k} = \epsilon^{\mu j + \overline{\mu k}} D^{(\lambda)}_{\mu\overline{\mu}}(C_{2z}), \tag{39}$$

where $C_{31}^{j} \equiv (C_{31}^{+})^{j}$.

Using the group table of $T^{\dagger}$ we can obtain the pair of index (j,k) for each element of $T^{\dagger}$, as shown below:

(j,k)	(00)	(01)	(02)	(10)	(11)	(12)	(20)	(21)	(22)
$C_{31}^{j}C_{2z}C_{31}^{k}$	C_{2z}	$\tilde{C}_{33}^{+}$	$\tilde{C}_{34}^{-}$	$\tilde{C}_{34}^{+}$	$\tilde{C}_{32}^{-}$	$\tilde{C}_{2x}$	$\tilde{C}_{33}^{-}$	$\tilde{C}_{2y}$	C_{32}^{+}

Equation (39) shows that the irreducible matrix elements of all elements in the same double coset differ from that of the coset generator only by a phase factor $\epsilon^{\mu j + \overline{\mu k}}$. Equations (37)–(39) are the algebraic expressions for the irreducible matrices of $T^{\dagger}$.

D. The $T \supset C_3$ generalized projection operators

To obtain the SAF's, the normalization of the ISO's is unimportant and for each irrep we only need one set of the ISO's. We collect these chosen unnormalized ISO's below, and call them the generalized projection operators.

1. $T \supset C_3$ s.v. generalized projection operators

Taking $\overline{\mu}=0$ for the irrep F from (31) we have

$$\begin{cases} \mathbf{P}^{A}{}_{\mu}=P^{\mu}+P^{\mu}C_{2z}P^{\mu}, \\ \\ \mathbf{P}^{F}_{\mu}=3P^{\mu}\delta_{\mu 0}-(-1)^{\mu}P^{\mu}C_{2z}P^{\overline{\mu=0}}, \end{cases} \qquad \mu=1,0,-1. \tag{40a}$$

2. $T \supset C_3$ d.v. generalized projection operators

For the irrep E_{μ}, there are two sets of the ISO's distinguished by $\overline{\mu}=(\frac{1}{2},-\frac{1}{2}),(\frac{1}{2},\frac{3}{2})$, and $(-\frac{1}{2},-\frac{3}{2})$ for the irreps $E_{1/2}, E_{3/2}$, and $E_{-3/2}$, respectively. Taking $\overline{\mu}=\frac{1}{2},\frac{3}{2}$, and $-\frac{3}{2}$ for the irreps $E_{1/2}$, $E_{3/2}$, and $E_{-3/2}$, respectively, from (35) we have:

$$\mathbf{P}^{E_{\nu}}_{\mu}=\sqrt{3}P^{\mu}\delta_{\mu\nu}+(-1)^{\mu-\frac{1}{2}+|\nu|}P^{\mu}C_{2z}P^{\nu},$$

$$\nu=\tfrac{1}{2},\ \tfrac{3}{2},\ \mu=\nu,\ \nu-1;\nu=-\tfrac{3}{2},\ \mu=\nu,\ \nu+1. \tag{40b}$$

Equation (40) is the algebraic expression for the generalized projection operator, and they are all we need for constructing the s.v. and d.v. SAF's of $T^{\dagger}$. Compared to the double-coset factored form (8), it represents a great simplification in that it is merely a function of only two quantum numbers ν and μ instead of all the irreducible matrix elements of the coset generators.

E. The $T \supset C_3$ SAF's

Up to now the coordinate system has not been specified explicitly. For obtaining the SAF's we need to introduce the coordinate system. The usual coordinate system for the group T is shown in Fig. 1, which is suitable for the group chain $T \supset D_2$. For the group chain $T \supset C_3$, we choose the coordinate system $x'y'z'$ as shown in Fig. 2, with z' as the axis of C_{31}^{+}. The coordinate system $x'y'z'$ is obtained from the system xyz in Fig. 1 by a rotation $R(\omega)$,

$$xyz \overset{R(\omega)}{\rightarrow} x'y'z', R(\omega)\equiv R\left(0,\ \cos^{-1}\frac{1}{\sqrt{3}},\ \frac{\pi}{4}\right). \tag{41}$$

Notice that $\cos^{-1}(1/\sqrt{3})$ is the angle between the z axis and the axis of C_{31}^{+} in Fig. 1. Using (11) and Table II we obtain the Euler angles in the system $x'y'z'$ for the coset generator C_{2z}, $C_{2z}=R(\pi,\cos^{-1}(-\frac{1}{3}),0)$.

The projection operator method with the projection operator in its original form (4) is quite tedious, but it becomes very efficient with the algebraic form in (40). For example, applying (40a) to $|jm\rangle$ and using

$$P^{\mu}|j\overline{m}\rangle=3\,\delta_{\mu,\overline{m}(\mathrm{mod}\ 3)}|j\overline{m}\rangle, C_{2z}|j\overline{m}\rangle=\sum_{m}\ e^{-im\pi}d^{j}_{m\overline{m}}(\beta_0)|jm\rangle, \beta_0=\cos^{-1}(-\tfrac{1}{3}), \tag{42}$$

we immediately obtain the $T \supset C_3$ s.v. SAF:

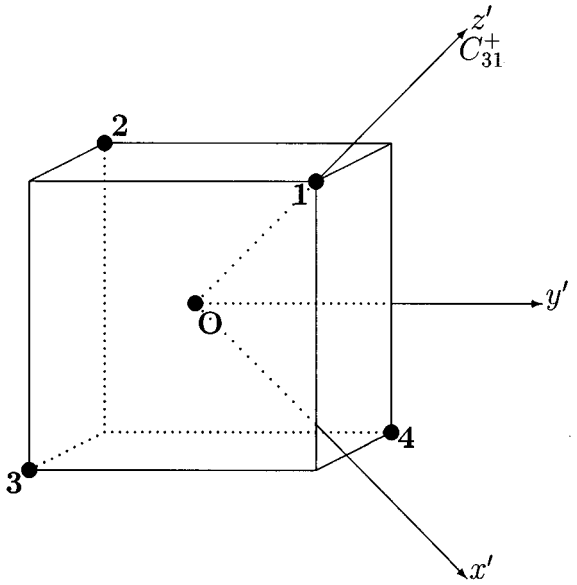

FIG. 2. The coordinate system $x'y'z'$ for $T\supset C_3$, $xyz \overset{R(\omega)}{\rightarrow} x'y'z'$, $R(\omega)\equiv R(0,\cos^{-1}(1/\sqrt{3}),\ \pi/4)$.

1. One-dimensional s.v. irreps

$$\psi^{(A_\mu)\overline{m}}=Y_{l\overline{m}}+3\sum_{m=\mu}^{(3)}(-1)^m d^l_{m\overline{m}}(\beta_0)Y_{lm},$$
$$\overline{m}=\mu(\ \mathrm{mod}\ 3),\quad \mu=0,\pm 1, \tag{43a}$$

where the normalization factor is suppressed for simplicity and the summation symbol stands for

$$\sum_{m=\mu}^{(n)}\equiv\sum_{m=\mu,\mu+n,\mu-n,\ldots}.$$

2. Three-dimensional s.v. irreps

$$\psi_\mu^{(F)\overline{m}}=Y_{l\overline{m}}\delta_{\mu 0}-(-1)^\mu\sum_{m=\mu}^{(3)}(-1)^m d^l_{m\overline{m}}(\beta_0)Y_{lm},$$
$$\overline{m}=0(\mathrm{mod}\ 3),\mu=0,\pm 1. \tag{43b}$$

It is easily found that

$$\begin{cases}\langle\psi^{(A_\mu)\overline{m}}|lm\rangle=(-1)^{m+\overline{m}}\langle\psi^{(A_{-\mu})-\overline{m}}|l-m\rangle,\\ \langle\psi_\mu^{(F)\overline{m}}|lm\rangle=(-1)^{m+\overline{m}}\langle\psi_{-\mu}^{(F)-\overline{m}}|l-m\rangle,\end{cases}\qquad \mu=0,\pm 1, \tag{44a}$$

where the SAF's ψ_μ^Γ are, of course, supposed to have been normalized.

Therefore for multiplicity free case the SAF's in (43) for A_0 and F have the symmetries

$$\langle \psi^{A_0}|lm\rangle=(-1)^m\langle \psi^{A_0}|l-m\rangle,$$
$$\langle \psi^{F}_{\mu}|lm\rangle=(-1)^m\langle \psi^{F}_{-\mu}|l-m\rangle, \quad \mu=0,\pm 1. \tag{44b}$$

However, for the non-multiplicity free case, the above symmetries no longer hold. Since the intrinsic quantum number is irrelevant, we can use the following as the new SAF's:

$$\psi'^{(\Gamma)\overline{m}}_{\mu}=\frac{1}{\sqrt{2}}(\psi^{(\Gamma)\overline{m}}_{\mu}\pm\psi^{(\Gamma)-\overline{m}}_{\mu}), \quad \Gamma=A_0,F, \tag{45}$$

where the ''+'' and ''−'' signs are taken for $\overline{m}>0$ and $\overline{m}<0$, respectively. Using (43) we get the new SAF's for $T\supset C_3$,

$$\psi'^{(A_0)\overline{m}}=Y_{l\overline{m}}\pm Y_{l-\overline{m}}+3\sum_{m=0}^{(3)}(-1)^m[d^l_{m\overline{m}}(\beta_0)\pm d^l_{m-\overline{m}}(\beta_0)]Y_{lm}, \tag{46a}$$

$$\psi'^{(F)\overline{m}}_{\mu}=(Y_{l\overline{m}}\pm Y_{l-\overline{m}})\delta_{\mu,0}-(-1)^{\mu}\sum_{m=\mu}^{(3)}(-)^m[d^l_{m\overline{m}}(\beta_0)\pm d^l_{m-\overline{m}}(\beta_0)]Y_{lm}, \tag{46b}$$

where $\overline{m}=0 \pmod 3$, $\mu=0,\pm 1$. The SAF's for $A_{\pm 1}$ are still given by (43a), i.e.,

$$\psi'^{(A_\mu)\overline{m}}=Y_{l\overline{m}}+3\sum_{m=\mu}^{(3)}(-1)^m d^l_{m\overline{m}}(\beta_0)Y_{lm}, \overline{m}=\mu(\mathrm{mod}\ 3), \mu=\pm 1. \tag{46c}$$

The SAF's ψ' have the desired symmetries:

$$\langle \psi'^{(A_0)\overline{m}}|lm\rangle=(-1)^{m+\overline{m}}\,\mathrm{sign}(\overline{m})\langle \psi'^{(A_0)\overline{m}}|l-m\rangle,$$
$$\langle \psi'^{(A_\mu)\overline{m}}|lm\rangle=(-1)^{m+\overline{m}}\langle \psi'^{(A_{-\mu})-\overline{m}}|l-m\rangle, \mu=\pm 1, \tag{47}$$
$$\langle \psi'^{(F)\overline{m}}_{\mu}|lm\rangle=(-1)^{m+\overline{m}}\,\mathrm{sign}(\overline{m})\langle \psi'^{(F)\overline{m}}_{-\mu}|l-m\rangle, \mu=0,\pm 1.$$

Notice that the index $\overline{m}$ in (46) serves as the multiplicity label. In general the SAF's $\psi^{(\Gamma)\overline{m}}_{\mu}$ with different $\overline{m}$ may be neither orthogonal nor linearly independent. With these algebraic expressions, it is easy to find the exact numerical expression of the SAF's $\psi^{(\Gamma)\overline{m}}_{\mu}$ for any l with the help of some software, say the Maple software. The multiplicity or frequency τ^l_Γ for the occurrence of the irrep Γ of T in the subduced rep $l\downarrow\Gamma$ is calculated first and used as a control parameter for the calculation: If the multiplicity τ^l_Γ is equal to one, then for obtaining the SAF's from the expressions (46) one only needs to let $\overline{m}$ take the lowest possible value, i.e., zero for the irrep A_0 or F, and ± 1 and for the irrep $A_{\pm 1}$. Otherwise one should let $\overline{m}$ take τ^l_Γ different values: $0,3,-3,6,-6,...$, for A_0 or F, $1,-2,4,-5,\ldots$, for A_1 and $-1,2,-4,5,\ldots$, for A_{-1}. The linear independence of the SAF's $\psi^{(\Gamma)\overline{m}}_{\mu}$ with different $\overline{m}$ is checked in each step. No orthogonal procedure is included for keeping the simplicity of the algebraic expression of the SAF's. The $T\supset C_3$ SAF's for $j=1$–3, and a part for $j=6,8$ are listed in Table IV.

Applying (40b) to $|jm\rangle$ we obtain the $T\supset C_3$ d.v. SAF:

TABLE IV. The $T \supset C_3$ s.v. SAF's. The superscript is the multiplicity label. For $l=6$ and 8 only the SAF's with multiplicity are listed.

$\overline{m}=0$ $|F\,-1\rangle = -|1\,-1\rangle$

$|F0\rangle = |10\rangle$

$|F1\rangle = |11\rangle$

$\overline{m}=-1 \quad |A_{-1}\rangle = \frac{\sqrt{2\cdot 3}}{3}|2\,-1\rangle - \frac{\sqrt{3}}{3}|22\rangle$

$\overline{m}=1 \quad |A_1\rangle = \frac{\sqrt{3}}{3}|2\,-2\rangle + \frac{\sqrt{2\cdot 3}}{3}|21\rangle$

$\overline{m}=0 \quad |F\,-1\rangle = \frac{\sqrt{3}}{3}|2\,-1\rangle + \frac{\sqrt{2\cdot 3}}{3}|22\rangle$

$|F0\rangle = |20\rangle$

$|F1\rangle = \frac{\sqrt{2\cdot 3}}{3}|2\,-2\rangle - \frac{\sqrt{3}}{3}|21\rangle$

$\overline{m}=0$

$|A_0\rangle = -\frac{\sqrt{2}}{3}|3\,-3\rangle + \frac{\sqrt{5}}{3}|30\rangle + \frac{\sqrt{2}}{3}|33\rangle$

$\overline{m}=0$

$|F\,-1\rangle^1 = \frac{\sqrt{2\cdot 3}}{6}|3\,-1\rangle - \frac{\sqrt{2\cdot 3\cdot 5}}{6}|32\rangle$

$|F0\rangle^1 = \frac{\sqrt{2\cdot 5}}{6}|3\,-3\rangle + \frac{2}{3}|30\rangle - \frac{\sqrt{2\cdot 5}}{6}|33\rangle$

$$-\frac{\sqrt{3\cdot5\cdot11\cdot13}}{81}|85\rangle+\frac{\sqrt{2\cdot3\cdot7\cdot11\cdot13}}{324}|88\rangle$$

3. Two-dimensional d.v. irreps

$$\psi_{\mu}^{(E_\nu)\overline{m}}=\frac{1}{\sqrt{3}}\delta_{\mu\nu}|j\overline{m}\rangle+(-1)^{|\nu|-1/2}\sum_{m=\mu}^{(3)}(-1)^{m-\mu}d^{j}_{m\overline{m}}(\beta_0)|jm\rangle,\overline{m}=\nu(\mathrm{mod}\ 3),$$
$$\nu=\tfrac{1}{2},\ \tfrac{3}{2},\ \mu=\nu,\ \nu-1;\nu=-\tfrac{3}{2},\ \mu=\nu,\ \nu+1. \tag{48}$$

Using (12b) it can be shown that the SAF's for $E_{\pm3/2}$ have the symmetry

$$\langle\psi_{\mu}^{(E_{3/2})\overline{m}}|\,jm\rangle=(-1)^{m-\overline{m}}\langle\psi_{-\mu}^{(E_{-3/2})-\overline{m}}|\,j-m\rangle,\mu=\tfrac{1}{2},\tfrac{3}{2}, \tag{49}$$

while from the numerical values of (48) it is known that the SAF's for $E_{1/2}$ in the multiplicity free case have the symmetry

$$\langle\psi_{1/2}^{(E_{1/2})}\,|\,jm\rangle=\pm\langle\psi_{-1/2}^{(E_{1/2})}\,|j-m\rangle,$$

however for the non-multiplicity free case they do not have such a symmetry. The lack of symmetry for the SAF $\psi^{(E_{1/2})}$ is due to the lack of symmetry of the ISO's in (35a). Since the intrinsic quantum number $\overline{\mu}$ is irrelevant for obtaining the SAF's, we can choose the following as the generalized projection operator:

$$\mathbf{P}'^{(E_{1/2})}_{\mu}=\mathscr{P}^{(E_{1/2})(1/2)}_{\mu}+\mathscr{P}^{(E_{1/2})-1/2}_{\mu}. \tag{50a}$$

Applying (50a) to the trial state $(|j\overline{m}\rangle+|j-\overline{m}\rangle)$, we obtain the new SAF's for the irrep $E_{1/2}$,

$$\psi'^{(E_{1/2})\overline{m}}_{1/2}=|j\overline{m}\rangle+\sqrt{3}\sum_{m=1/2}^{(3)}(-)^{m-1/2}[d^{j}_{m\overline{m}}(\beta_0)-\sqrt{2}d^{j}_{m-\overline{m}}(\beta_0)]|jm\rangle,$$
$$\psi'^{(E_{1/2})\overline{m}}_{-1/2}=|j-\overline{m}\rangle+\sqrt{3}\sum_{m=-1/2}^{(3)}(-)^{m+1/2}[d^{j}_{m-\overline{m}}(\beta_0)+\sqrt{2}d^{j}_{m\overline{m}}(\beta_0)]|jm\rangle, \tag{50b}$$

where $\overline{m}=\frac{1}{2}$ (mod 3). The SAF's in (50b) have the desired symmetry:

$$\langle \psi'^{(E_{1/2})\overline{m}}_{\mu} | jm\rangle = (-)^{m-\overline{m}} \langle \psi'^{(E_{1/2})\overline{m}}_{-\mu} | j-m\rangle. \tag{50c}$$

Hence we see that the symmetries of the SAF's for the non-multiplicity free case depend on the choice of the intrinsic quantum number and the trial state to be projected.

Using (48) for $E_{\pm 3/2}$ and (50b) for $E_{1/2}$, we can find the exact numerical expression of the SAF's $\psi^{(\Gamma)\overline{m}}_{\mu}$ for any j. The SAF's for $j=\frac{1}{2}-\frac{9}{2}$ are listed in Table V. It should be mentioned that the symmetrization of the SAF's as indicated in (47) and (50c) leads to simpler numerical results.

V. DISCUSSIONS

A. The left-, right-, and double-induced representations

There are three possible ways to construct an induced representation of a group G from the ISO's P^{ρ} of its subgroup $G(s)$. We first deompose G into left-, right-, and double-cosets as

$$\begin{aligned} G &= (e + \not{c}_2 + \not{c}_3 + \cdots) G(s) \\ &= G(s)(e + r_2 + r_3 + \cdots) \\ &= G(s)(e + k_2 + k_3 + \cdots) G(s). \end{aligned} \tag{51}$$

Then the three sets of the basis vectors $\{\not{c}_i P^{\rho}\}$, $\{P^{\rho} r_i\}$, and $\{P^{\rho} k_i P^{\overline{\rho}}\}$ form the left-, right-, and double-induced representations of G, respectively. The conventionally called induced representation[3] is the left-induced representation. If $G(s)$ is an invariant subgroup of G, then the double-induced representation is reduced to the left- or the right-induced representation, which are equivalent to one another. Therefore, the double-induced representation is a generalization of the conventional induced representation.

B. The induction method for finding irreps

Since the induction technique is the pillar for finding irreps of point groups in traditionally group rep theory, it is worth showing the difference between the technique proposed in this paper and the usual induction technique. To show the difference, in this subsection we first sketch the induction method for finding irreps of a group G from irreps of its maximal invariant subgroup.[3] Recall that an invariant subgroup of G is called maximal if it is not a subgroup of another invariant subgroup of G. Assume that H is a maximal invariant subgroup of G and C_q is a cyclic group of prime order q,

$$G = H \wedge C_q, C_q = \{s^n : n = 0,1,\ldots,q-1\}.$$

We can factorize G into left cosets in the form of

$$G = (e + s + s^2 + \cdots + s^{q-1}) H.$$

Suppose that $D^{(\mu,0)} \equiv D^{(\mu)}$ is an irrep of H of dimension $|\mu|$ with basis vectors $\psi^{(\mu)}_{0m}$,

$$h \psi^{(\mu)}_{0m} = \sum_{m'} D^{(\mu)}_{m'm}(h) \psi^{(\mu)}_{0m'}.$$

Define

$$\psi^{(\mu)}_{nm} = s^n \psi^{(\mu)}_{0m}, \quad n = 0,1,\ldots,q-1,$$

which span the induced rep of G. For given n, the basis vectors $\psi^{(\mu)}_{nm}$ carry the representation $D^{(\mu,n)}$ of H,

TABLE V. The $T \supset C_3$d.v. SAF's. The superscript is the multiplicity label. For $j=\frac{9}{2}$ only the SAf's with multiplicity are listed.

TABLE V. *(Continued).*

$\overline{m}=\frac{3}{2}$

$$|E_{-\frac{3}{2}}\ -\tfrac{1}{2}\rangle^1=-\frac{2\sqrt{11}}{11}|\tfrac{9}{2}-\tfrac{1}{2}\rangle-\frac{\sqrt{7\cdot 11}}{11}|\tfrac{9}{2}\tfrac{5}{2}\rangle$$

$$|E_{-\frac{3}{2}}\ -\tfrac{3}{2}\rangle^1=\frac{8\sqrt{7\cdot 11}}{99}|\tfrac{9}{2}-\tfrac{9}{2}\rangle+\frac{2\sqrt{2\cdot 3\cdot 11}}{99}|\tfrac{9}{2}-\tfrac{3}{2}\rangle+\frac{\sqrt{3\cdot 11}}{9}|\tfrac{9}{2}\tfrac{3}{2}\rangle+\frac{2\sqrt{2\cdot 7\cdot 11}}{99}|\tfrac{9}{2}\tfrac{9}{2}\rangle$$

$$h\psi_{nm}^{(\mu)}=hs_n\psi_{0m}^{(\mu)}=s_nh'\psi_{0m}^{(\mu)}=s^n\sum_{m'}D_{m'm}^{(\mu)}(h')\psi_{0m'}^{(\mu)}=\sum_{m'}D_{m'm}^{(\mu,n)}(h)\psi_{nm'}^{(\mu)}, \tag{52}$$

with

$$D^{(\mu,n)}(h)=D^{(\mu)}(s^{-n}hs^n),\quad n=0,1,\ldots,q-1.$$

Case (i)

If the representations $D^{(\mu,n)}(H),n=0,1,\ldots,q-1$, are mutually inequivalent, then the induced rep $\mu\uparrow G$ is irreducible. The typical example is $D^{A_{\pm 1}}(T)\uparrow O=D^E$.

Case (ii)

If the representations $D^{(\mu,n)}(H),n=0,1,\ldots,q-1$, are mutually equivalent, then the induced rep $\mu\uparrow G$ is reducible. It can be reduced into q mutually inequivalent irreps $\mathscr{D}^{(\mu_n)},n=0,1,\ldots(q-1)$, of G each of dimension $|\mu|$, with the irreducible matrices,

$$\mathscr{D}^{(\mu_n)}(h)=D^{(\mu)}(h),\quad \mathscr{D}^{(\mu_n)}(s)=\exp(2\pi ni/q)M,$$

while the matrix M is decided from the following matrix equations:

$$D^{(\mu)}(s^{-1}hs)=M^{-1}D^{(\mu)}(h)M, \tag{53a}$$

$$M^n=I, \tag{53b}$$

where h in (53a) runs over all generators of H and I is a unit matrix.

The typical example is $D^{A_0}(T)\uparrow O=D^{A_1}\oplus D^{A_2},D^F(T)\uparrow O=D^{F_1}\oplus D^{F_2}$.

C. Comparison between the two induction techniques

The shortcomings of the induction method are as follows. (1) The theory is applicable only to the case when H is a maximal invariant subgroup of G. (2) The procedure is laborious. We need to solve a set of matrix equations (53) to get the matrix M. (3) Only numerical solutions for the irreps of G are found.

Folland proposed an improved induction method,[18] which is also applicable only to the case when $G(s)$ is an invariant subgroup of G.

Some special features of the double-induced technique are the following.

1. The ISO's are obtained by seeking the eigenvectors of the CSCO of G in the double-induced rep in a unified way regardless of the induced representations are reducible or irreducible, regardless they are s.v. or d.v., and regardless the subgroup is invariant or non-invariant.

2. All are derived *ab initio*. Only for identifying the irreps obtained by the eigenfunction method, do we need to consult the character table.

3. *Algebraic* instead of numerical solutions for the ISO's and irreducible matrices are found.

4. The present approach allows a high level of flexibility in choosing both the subgroup $G(s)$ according to the physical problem under consideration and the intrinsic subgroup $\overline{G(s')}$ according to the symmetrization requirement for the SAF's in the non-multiplicity case.

5. With the algebraic expression for the SAF's we are able for the first time to derive many symmetries of the SAF's, which are otherwise hidden in the numerical tables.

6. The algebraic expressions are functions of only the quantum numbers of the chosen group chain, while the ISO's in the coset factored form are functions of all the matrix elements of the coset generators.

Damhus *et al.*[19] gave the $T \supset C_3$ for $j=0, \frac{1}{2}, 1, \frac{3}{2}, 2$. Our results differ from Ref. 19 in phases.

Summary: The algebraic expression of the generalized projection operator greatly simplifies the projection operator method, enabling us to obtain a simple algebraic expression for the SAF's and thereby make the extensive tabulation of the SAF's obsolete.

The group chain $T \supset D_2 \supset C_2$ can be treated similarly and will be reported elsewhere. The application of this approach to the octahedral group and the icosahedral group as well as the relation between the double-induced representation and the symmetrized boson representation will be addressed in subsequent papers.[20]

(Received 8 November 1996; accepted for publication 15 September 1997)

The standard and antistandard ordered operators acting on two-dimensional q-deformed phase space are shown to satisfy algebras which can be called $q-W_\infty$. q-star products and q-Moyal brackets corresponding to these algebras are constructed. Some applications like defining q-classical mechanics and q-path integrals are discussed. © *1998 American Institute of Physics.*

I. INTRODUCTION

A way of visualizing quantum mechanics as $\hbar$-deformation of the classical case is to utilize symbols of operators, star products and Moyal brackets.[1] If we denote the symbol map by $\mathcal{S}_O^{(\hbar)}$, to an operator $\hat{f}$ there corresponds a c-number object $f_O^{(\hbar)}$,

$$S_O^{(\hbar)}(\hat{f})=f_O^{(\hbar)},$$

where the subscript O denotes the operator ordering adopted. Noncommutativity of quantum mechanics is taken into account in terms of the star product defined such that

$$\mathcal{S}_O^{(\hbar)}(\hat{f}\hat{g})=\mathcal{S}_O^{(\hbar)}(\hat{f})\star_O^{(\hbar)}\mathcal{S}_O^{(\hbar)}(\hat{g})$$

and the symbol corresponding to the commutator (divided by $\hbar$) of the operators $\hat{f}$ and $\hat{g}$ is the Moyal bracket (or $\star^\hbar$-bracket):

$$\{f_O^{(\hbar)}(p,x),g_O^{(\hbar)}(p,x)\}_M\equiv\frac{1}{i\hbar}\,(f_O^{(\hbar)}(p,x)\star_O^\hbar g_O^{(\hbar)}(p,x)-g_O^{(\hbar)}(p,x)\star_O^\hbar f_O^{(\hbar)}(p,x)), \tag{1}$$

where p and x are classical phase space variables.

Recently $\star$-products and Moyal brackets are used in some diverse context such as constructing a representation of noncommuting forms[2] and they appeared in the formulation of two-dimensional area-preserving diffeomorphisms.[3] The latter is closely related to the quantum Hall effect which also exhibits a q-deformed structure where q is related to filling fraction.[4] Hence, understanding q-deformations in terms of symbols of the q-deformed operators may shed light on some aspects of the quantum Hall effect. Although the quantum Hall effect is a many-body problem, it is based on a field theory which is given in a two-dimensional phase space when it is restricted to the lowest Landau level. Hence, understanding q-deformed star products and Moyal brackets in a two-dimensional phase space is the first step in this direction.

One of the essential properties of the ordinary star product is its associativity. In this case it is known that the unique deformation of the Poisson bracket is the Moyal bracket (1).[5] On the other hand it was shown that it is impossible to deform Heisenberg dynamics by keeping the algebra of the observables associative.[6] Hence, to obtain a nontrivial deformation of the quantum mechanics we should sacrifice associativity of the star product. In fact, q-deformed algebras are not associative, so that a q-deformed star product leading to them should also be nonassociative.

a)Electronic mail: dayi@mam.gov.tr

Here, after deriving the algebras of the standard (or XP) and the antistandard (or PX) ordered operators q-deformed star products and Moyal brackets corresponding to them are constructed and the obstacles in generalizing Weyl ordering to the q-deformed operators are emphasized.

Once a q-Moyal bracket is obtained an immediate application is to define q-classical mechanics in terms of q-Poisson brackets. This and some other applications like classical as well as quantum mechanical properties of q-canonical transformations and a definition of q-path integrals on general grounds are briefly discussed.

II. ORDINARY SYMBOLS AND STAR PRODUCTS

In the two-dimensional phase space given in terms of the ordinary ($\hbar$-deformed) canonical operators

$$[P_\hbar,\ X_\hbar]=i\hbar, \tag{2}$$

an operator $\mathscr{O}$ can be written as

$$\mathscr{O}=\sum_{(m,n)>0}\mathscr{O}_{m,n}g(P_\hbar^m,X_\hbar^n), \tag{3}$$

where $g(P_\hbar^m,X_\hbar^n)$ are some functions of $P_\hbar^m$, $X_\hbar^n$ and $\mathscr{O}_{m,n}$ are some constant coefficients depending on the operator ordering scheme adopted. Hence, it is sufficient to deal with the monomials $g(P_\hbar^m,X_\hbar^n)$ as far as the algebraic properties of the operators are concerned. We are interested in the following three different ordering schemes which constitute complete basis.

Standard (or XP) ordering: In this scheme one deals with the monomials $X_\hbar^nP_\hbar^m$. They satisfy the Lie algebra[7]

$$[X_\hbar^nP_\hbar^m,\ X_\hbar^kP_\hbar^l]=\sum_{r=1}^{\infty}(i\hbar)^r r!\left\{\binom{k}{r}\binom{m}{r}-\binom{n}{r}\binom{l}{r}\right\}X_\hbar^{n+k-r}P_\hbar^{l+m-r}. \tag{4}$$

Antistandard (or PX) ordering: the suitable monomials $P_\hbar^nX_\hbar^m$, can be shown to satisfy[7]

$$[P_\hbar^nX_\hbar^m,\ P_\hbar^kX_\hbar^l]=\sum_{r=1}^{\infty}(-i\hbar)^r r!\left\{\binom{k}{r}\binom{m}{r}-\binom{n}{r}\binom{l}{r}\right\}P_\hbar^{n+k-r}X_\hbar^{l+m-r}. \tag{5}$$

The algebras (4) and (5) are called W_∞.[3]

Weyl ordering: The monomials

$$T_{m,n}^{(\hbar)}=\exp\left(P_\hbar\frac{\partial}{\partial\mathscr{P}}+X_\hbar\frac{\partial}{\partial\mathscr{Q}}\right)\mathscr{P}^m\mathscr{Q}^n|_{\mathscr{P}=|\mathscr{Q}=0}, \tag{6}$$

where $\mathscr{P}$ and $\mathscr{Q}$ are c-number variables, constitute a complete basis, and satisfy the Lie algebra[8,9]

$$[T_{m,n}^{(\hbar)},\ T_{k,l}^{(\hbar)}]=\sum_{a=0}^{b}(i\hbar)^{2a+l}B_{mnkl}^aT_{m+k-2a-l,n+l-2a-1}^{(\hbar)}, \tag{7}$$

where $b=\min\{[(m+k-1)/2,(n+l-1)/2]\}$. $B_{00kl}=B_{mn00}\equiv 0$ and for the other values of the indices

$$B_{mnkl}^a\equiv\sum_{c=0}^{2a+1}\frac{(-1)^c m!n!k!l!}{(2a+1-b)!b!(m+c-2a-1)!(n-c)!(k-c)!(l+c-2a-1)!}. \tag{8}$$

For our purposes it is sufficient to deal with the symbols of the monomials in each ordering scheme, which are given by

$$\mathscr{S}_S^{(\hbar)}[X_h^m P_h^n]=\mathscr{S}_A^{(\hbar)}[P_\hbar^m X_\hbar^n]=\mathscr{S}_W^{(h)}[T_{m,n}^{(h)}]=p^m x^n, \tag{9}$$

where p and x are c-number variables.

Related star products are[1,7]

$$\star_S^h \equiv \exp(i\hbar \overleftarrow{\partial}_p \vec{\partial}_x), \tag{10}$$

$$\star_A^\hbar \equiv \exp(-ih \overleftarrow{\partial}_x \vec{\partial}_p), \tag{11}$$

$$\star_W^\hbar \equiv \exp\left[\frac{-i\hbar}{2}(\overleftarrow{\partial}_x \vec{\partial}_p - \overleftarrow{\partial}_p \vec{\partial}_x)\right]. \tag{12}$$

We used $\partial/\partial x \equiv \partial_x$; $\partial/\partial p \equiv \partial_p$. One of them can be utilized in the Moyal bracket (1) in terms of the related symbols. Observe that $\star^\hbar$-products are associative,[1] so that the algebraic properties of the commutators are preserved.

III. CLASSICAL ($\hbar=0$) q-DEFORMED SYMBOLS, STAR PRODUCTS, AND MOYAL BRACKETS

Classical ($\hbar=0$) q-deformed canonical operators are defined as

$$P_q X_q - q X_q P_q = 0. \tag{13}$$

Now, the monomials of the different ordering schemes are equivalent up to an overall q-dependent factor. Thus it is sufficient to consider the algebra

$$q^{nk} T_{m,n}^{(q)} T_{k,l}^{(q)} - q^{ml} T_{k,l}^{(q)} T_{m,n}^{(q)} = 0, \tag{14}$$

where $T_{m,n}^{(q)} \equiv P_q^m X_q^n$. They give a complete basis in P_q, X_q space and the basis operators in another ordering scheme are equal to $T_{m,n}^{(q)}$ up to an overall q-dependent constant.

Symbols of the operators $T_{m,n}^{(q)}$ are

$$\mathscr{S}^{(q)} T_{m,n}^{(q)} = p^m x^n. \tag{15}$$

It is possible to define associative $\star^q$-products

$$\star_S^q \equiv \exp(\nu \overleftarrow{\partial}_p p x \vec{\partial}_x), \tag{16}$$

$$\star_A^q \equiv \exp(-\nu \overleftarrow{\partial}_x x p \vec{\partial}_p), \tag{17}$$

$$\star_W^q \equiv \exp\left[\frac{-\nu}{2}(\overleftarrow{\partial}_x x p \vec{\partial}_p - \overleftarrow{\partial}_p p x \vec{\partial}_x)\right], \tag{18}$$

where $\nu \equiv \ln q$ and the subscripts denote the resemblance to the ordinary star products (10)–(12). In fact, (16)–(18) can be obtained from (10)–(12) by a canonical transformation in accord with the fact that there exists a unique deformation of the Poisson bracket if the star product is associative.

The symbols defined in (15) satisfy

$$q^{nk} p^m x^n \star^q p^k x^l - q^{ml} p^k x^l \star^q p^m x^n = 0, \tag{19}$$

for any $\star^q$-product (16)–(18).

IV. q-SYMBOLS, q-STAR! q-SYMBOLS, q-STAR PRODUCTS AND q-MOYAL q-MOYAL BRACKETS

q-deformed ($\hbar \neq 0$) canonical variables satisfy

$$PX - qXP = i\hbar. \tag{20}$$

To reproduce (14) in $\hbar = 0$ limit we define the q-commutator as

$$[t(P^m,X^n),\ t(P^k,X^l)]_q \equiv q^{nk} t(P^m,X^n) t(P^k,X^l) - q^{ml} t(P^k,X^l) t(P^m,X^n), \tag{21}$$

where $t(P^m,X^n)$ is a function of P^m and X^n, depending on the operator ordering scheme adopted. Observe that the weights of the q-commutator (21) change according to the operators which are considered.

As one can easily see, the standard or the antistandard ordered monomials form a complete basis in the q-phase space given by P and X.

By explicit calculations q-algebra satisfied by the standard ordered monomials $X^n P^m$ can be derived:

$$[X^n P^m,\ X^k P^l]_q = \sum_{r=1}^{\infty} (i\hbar)^r [r]! \left\{ q^{(k-r)(n-r)+ml} \begin{bmatrix} k \\ r \end{bmatrix} \begin{bmatrix} m \\ r \end{bmatrix} - q^{(m-r)(l-r)+nk} \begin{bmatrix} n \\ r \end{bmatrix} \begin{bmatrix} l \\ r \end{bmatrix} \right\} X^{n+k-r} P^{l+m-r}, \tag{22}$$

where we used the definitions of the q-factorial

$$[n]! \equiv \left(\frac{1-q^n}{1-q} \right)! \equiv [1][2]\cdots[n-1][n],$$

and the q-binomial coefficient

$$\begin{bmatrix} n \\ r \end{bmatrix} \equiv \frac{[n]!}{[n-r]![r]!}.$$

Similarly we see that in the antistandard ordering scheme the monomials $P^m X^n$ satisfy the q-algebra

$$[P^n X^m,\ P^k X^l]_q = \sum_{r=1}^{\infty} (-i\hbar)^r q^{r(r-1)/2} [r]! \left\{ \begin{bmatrix} k \\ r \end{bmatrix} \begin{bmatrix} m \\ r \end{bmatrix} - \begin{bmatrix} n \\ r \end{bmatrix} \begin{bmatrix} l \\ r \end{bmatrix} \right\} P^{n+k-r} X^{m+l-r}. \tag{23}$$

The q-deformed algebras (22) and (23) can be called q-W_∞. For other definitions of q-W_∞ algebra see Ref. 10.

Symbol maps for the standard and antistandard orderings are defined like the ordinary case:

$$\mathscr{S}_S(X^m P^n) = \mathscr{S}_A(P^m X^n) = p^m x^n. \tag{24}$$

As emphasized before, the ordinary star products should be associative so that the Moyal bracket satisfies an identity corresponding to the Jacobi identity satisfied by the ordinary operators. However, now the situation is altered drastically: we do not any more deal with the commutators which are not aware of their entries but with the q-commutators (21) which change according to their entries, i.e., the underlying algebraic structure is nonassociative. Thus the associativity condition cannot be preserved and we can obtain a nontrivial deformation of the Poisson bracket other than $\hbar$-deformation.

In terms of the q-derivative

$$D_z f(z) \equiv \frac{f(z)-f(qz)}{(1-q)z}, \tag{25}$$

we can construct q-star products for the standard and antistandard orderings as

$$\star_S \equiv \sum_{r=0}^{\infty} \frac{(i\hbar)^r}{[r]!} \overleftarrow{D}_p^r \exp(\nu \overleftarrow{\partial}_p p x \vec{\partial}_x) \vec{D}_x^r, \tag{26}$$

$$\star_A \equiv \sum_{s=0}^{\infty} (-\nu \overleftarrow{\partial}_x x)^s \sum_{r=0}^{\infty} \frac{(-i\hbar)^r q^{r(r-1)/2}}{[r]!} \overleftarrow{D}_x^r \vec{D}_p^r (p \vec{\partial}_p)^s. \tag{27}$$

One can see that if the q-Moyal bracket is defined as

$$\{p^m x^n, p^k x^l\}_{q-M} \equiv \frac{1}{i\hbar} (q^{nk} p^m x^n \star p^k x^l - q^{ml} p^k x^l \star p_m x^n), \tag{28}$$

by using the symbols (24) and the q-star products (26)–(27), q-Moyal algebras corresponding to (22) and (23) are obtained. In Ref. 11 another q-star product is defined by using the coherent states maps, however it does not lead to the algebras which we deal within (22) and (23).

Generalization of the Weyl ordering (6) to the q-phase space is not obvious: a term of a monomial can be generalized by assuming that it is weighted with a factor q^γ, where γ is a number depending on the term under consideration. To emphasize the difficulties related to this ordering procedure, let us suppose that there exist operators $T_{m,n}$ leading to the ordinary Weyl ordered operators in the $q=1$ limit, satisfying

$$[T_{m,n},\ T_{k,l}]_q = \sum_{r,s=0}^{A,B} \mathscr{C}_{mnkl}^{rs}(\hbar,q) T_{r,s}, \tag{29}$$

where for obtaining the correct classical limit $\mathscr{C}$ should satisfy

$$\mathscr{C}_{mnkl}^{(K)rs}(0,q) = 0. \tag{30}$$

An operator algebra is proposed in Ref. 9 as a generalization of (7) by replacing the factorial terms with the q-factorials:

$$[T_{m,n}^{(GF)}, T_{k.l}^{(GF)}]_q = \sum_{a=0}^{b} \sum_{c=0}^{2a+1} \frac{(-1)^c [m]![n]![k]![l]!}{[2a+1-b]![b]![m+c-2a-1]![n-c]![k-c]![l+c-2a-1]!} \times (i\hbar)^{2a+1} T_{m+k-2a-1,n+l-2a-1}^{(GF)}, \tag{31}$$

where b is given as in (7). The symbol map independent of the definition of the q-Weyl ordered operators is

$$S_W T_{m,n}^{(GF)} = p^m x^n, \tag{32}$$

so that the $\star$-product reproducing (31), in terms of the q-Moyal bracket (28), is

$$\star^W \equiv \sum_{M=0}^{\infty} (-\nu/2)^M \sum_{L=0}^{M} \frac{(-1)^L}{(M-L)!L!} (\overleftarrow{\partial}_x x)^{M-L} (\overleftarrow{\partial}_p p)^L \sum_{\alpha=0}^{\infty} (-i\hbar/2)^\alpha$$
$$\times \sum_{\beta=0}^{\alpha} \frac{(-1)^\beta}{[\alpha-\beta]![\beta]!} \overleftarrow{D}_x^{\alpha-\beta} \overleftarrow{D}_p^{\beta} \vec{D}_p^{\alpha-\beta} \vec{D}_x^{\beta} (p\vec{\partial}_p)^{M-L} (x\vec{\partial}_x)^L. \tag{33}$$

Obviously, independent of how the generalization is done, we have

$$T_{m,0} = P^m, \quad T_{0,m} = X^m. \tag{34}$$

Hence, by studying the q-commutators $[P^m, X^m]_q$ one can try to reach to the other q-weighted monomials: e.g.,

$$P^2X^2 - q^4X^2P^2 = i\hbar[2](PX + q^2XP) \tag{35}$$

suggests that $T_{1,1} \approx (PX + q^2XP)$. Similarly, explicit calculation gives

$$P^2X^3 - q^6X^3P^2 = [2](PX^2 + q^4X^2P + q^2XPX), \tag{36}$$

yielding $T_{1,2} \approx (PX^2 + q^4X^2P + q^2XPX)$. However, the q-commutator of this operator with P,

$$P(PX^2 + q^4X^2P + q^2XPX) - q^2(PX^2 + q^4X^2P + q^2XPX)P = i\hbar(1 + q + q^2)(PX + q^3XP), \tag{37}$$

suggests $T_{1,1} \approx (PX + q^3XP)$, which is in contradiction with the one suggested by (35).

In fact, having obstacles in defining q-Weyl ordering is not surprising. If one considers monomials reproducing the Weyl ordered ones in the $q=1$ limit with a definite q weight, they cannot constitute a complete basis. For having a complete basis one should have monomials with all possible q weights.

V. APPLICATIONS

In terms of the q-star products and the related q-Moyal brackets (26)–(28), one can study quantum as well as classical dynamics on general grounds.

If we deal with the $\star s$-product, q-classical dynamics can be given in terms of the q-Poisson bracket defined for the observables $f(p,x) = \Sigma_i f_i(p,x)$ and $g(p,x) = \Sigma_j g_j(p,x)$ where f_i and g_j are monomials in p, x, as

$$\{f(x,p), g(x,p)\}_{q-P} \equiv \lim_{\hbar \to 0} \{f(x,p), g(x,p)\}_{q-M}$$
$$= \sum_{i,j} [q^{\alpha(f_i, g_j)} (D_p f_i) \exp(\nu \overleftarrow{\partial}_p p x \overleftarrow{\partial}_x)(D_x g_j)$$
$$- q^{\alpha(g_j, f_i)} (D_p g_j) \exp(\nu \overleftarrow{\partial}_p p x \overleftarrow{\partial}_x)(D_x f_i)], \tag{38}$$

where $\alpha(p^m x^n, p^k x^l) = nk$. Thus, if $H = \Sigma_k H_k$ is the classical Hamiltonian where H_k are monomials, the equation of motion of the observable $f(p,x)$ is

$$\tau_q(f) = \{H, f\}_{q-P}, \tag{39}$$

where $\lim_{q \to 1} \tau_q = d/dt$. Now, observe that in general

$$\{H, fg\}_{q-P} \neq f\{H, g\}_{q-P} + g\{H, f\}_{q-P}, \tag{40}$$

which leads to

$$\tau_q(fg) \neq \tau(f)g + f\tau(g). \tag{41}$$

Obviously, there are some exceptions like f or g is constant. One may think that $\star s$ of f and g should be considered on the left-hand side of (41). However, in the limit $\hbar \to 0$ the q-star product will yield $\star_S^{(q)}$ (16), and $f \star_S^{(q)} g = q^{\alpha(f,g)} fg$, so that there is not any difference.

In the ordinary classical mechanics canonical transformations leave the basic Poisson brackets invariant. One of these is the point transformation defined as

$$u = f(x); \quad p_u = (\partial_x f(x))^{-1} p, \tag{42}$$

where f is an invertible function. For the q-classical mechanics point transformation can be defined as

$$u = f(x); \quad p_u = (D_x f(x))^{-1} p. \tag{43}$$

Now, in terms of the q-Poisson bracket (38) one can observe that

$$\{u, p_u\}_{q-P} = -q^{\alpha(u,p_u)j} \quad \{p_u, u\}_{q-P} = 1, \tag{44}$$

instead of the ones satisfied by p,x:

$$\{x,p\}_{q-P} = -q; \quad \{p,x\}_{q-P} = 1. \tag{45}$$

In (44) $\alpha(u,p_u) = x\partial_x \log f(x)$, which is a number. Let us have an example where $f(x) = \sqrt{x}$:

$$u = \sqrt{x}; \quad p_u = \left[\frac{1}{2}\right]^{-1} \sqrt{x} p, \tag{46}$$

so that

$$\{u, p_u\}_{q-P} = -q^{1/2}; \quad \{p_u, u\}_{q-P} = 1. \tag{47}$$

In fact, the transformation (46) was studied in Ref. 12 and it was found that it is a q-canonical transformation if the phase space operators satisfy

$$\hat{p}\hat{x} - q\hat{x}\hat{p} = i\hbar, \tag{48}$$

$$\hat{p}_u \hat{u} - \sqrt{q}\hat{u}\hat{p}_u = i\hbar, \tag{49}$$

which are consistent with (45) and (47).

When we deal with q-quantum mechanics in the Heisenberg picture, time evolution of an observable f is given by

$$\tau(f) = \{H,f\}_{q-M} = \frac{1}{i\hbar} \sum_{i,j} (q^{\alpha(H_i, f_j)} H_i \star f_j - q^{\alpha(f_j, H_i)} f_j \star H_i). \tag{50}$$

Here $\star$ indicates one of the q-star products (26) and (27).

In the Schrödinger picture time evolution of a time-dependent state vector ψ is given by

$$i\hbar\, \tau(\psi(t)) = \hat{H}\psi(t), \tag{51}$$

where $\hat{H}$ is the q-Hamiltonian operator, i.e., $\mathscr{S}(\hat{H}) = H$.

Contrary to the ordinary quantum mechanics, in the q-deformed case the relation between the Schrödinger picture (51) and the Heisenberg picture (50) is not clear. The unique common feature

of the deformed and nondeformed cases is the fact that in both of the cases symbols of the monomials are the same, namely, $p^m x^n$. The difference lies in the definition of the related star products. Thus we may still assume that the symbol of the evolution operator $\hat{U}(t)$ is

$$U(t)=\mathscr{S}(\hat{U}(t))=e^{(it/h)H}. \tag{52}$$

Then we can adopt the definition of the path integral of the ordinary time evolution given in terms of the star products and symbols in Ref. 13 to define the q-path integral as

$$G(t)=\lim_{N\to\infty} U\left(\frac{t}{N}\right)\star\cdots\star U\left(\frac{t}{N}\right). \tag{53}$$

When the canonical transformation (42) is performed there will be some q-quantum corrections in the transformed Hamiltonian. The kinetic term including the q-quantum corrections can be studied in terms of the $\star s$-product similar to the ordinary case[7] by defining the transformed kinetic term as

$$\tilde{H}_0=(D_x f)^{-1/2}\star_s p\star_s (D_x f)^{-2}\star_s D_x f\star_s p\star_s (D_x f)^{-1/2}. \tag{54}$$

Because of the nonassociativity of the q-star product we should specify in which order the multiplications will be performed in (54). However, we do not possess a general procedure.

As it is briefly illustrated, q-star products and q-Moyal brackets are very useful in studying several aspects of q- deformations on general grounds. However, the relations to the other formulations of q-dynamics (e.g., see Ref. 14) and q- path integral definitions[15] should be studied.

(Received 19 November 1996; accepted for publication 15 July 1997)

A class of classical relativistic nonlinear field models has been recently introduced by two of us [A. Degasperis and F. Tinebra, J. Math. Phys. **34**, 2950 (1993)]; they are solvable by an explicit mapping to free field equations. Here we show the behavior of particular solutions of these models for both scalar and spinor fields. In the real spectrum we find brachion and tachion localized solutions, and we show the large-time behavior of wave packets, while in the complex spectrum we prove that the asymptotic states may contain solitons, antisolitons, and point-like charged particles (''pointons''). We report on several processes such as soliton–antisoliton pair creation and annihilation, and pointon decay in two solitons. © *1998 American Institute of Physics.* [S0022-2488(98)02701-7]

I. INTRODUCTION

A new class of relativistic field equations has been recently introduced by two of us.[1] Two simple instances of them are the following nonlinear versions of the Klein–Gordon equation:

$$\Box Q+[m^2-2\epsilon^{\mu\nu}\ \mathrm{Im}(Q^*_{,\mu}Q_{,\nu})-g^{\mu\nu}\ \mathrm{Im}(Q^*Q_{,\mu})\mathrm{Im}(Q^*Q_{,\nu})]Q=0, \tag{1.1}$$

and of the Dirac equation

$$\gamma^\mu\phi_{,\mu}+(im-\epsilon_{\mu\nu}\gamma^\mu\overline{\phi}\gamma^\nu\phi)\phi=0. \tag{1.2}$$

While being invariant with respect to the Lorentz group of coordinate transformations, these PDE's possess the nice property of being solvable by a transformation of the field variable which maps them into their linearized form. The price we pay to buy this virtue is that they are constrained to live in a 1+1 dimensional space–time. For motivations and further observations, together with reference to the literature, the reader is referred to Ref. 1, where the method of construction, based on charge conservation, of our relativistic models is detailed (for charge conservation combined with gauge transformation in a nonrelativistic context, see Ref. 2). In fact, in Ref. 1 the attention is mainly devoted to deriving the general class of solvable PDE's, for both scalar and spinor fields, together with systems of coupled equations, and only marginal results are given on general properties and solutions.

The purpose of this paper is to present special classes of solutions whose explicit expression obtains by mapping simple linear combinations of exponential solutions of the free field. According to whether these exponentials are everywhere bounded (real spectrum) or unbounded (complex spectrum), the corresponding solutions of our nonlinear model show different behaviors. The resulting phenomenology is better described by the charge density rather than by the field itself. Thus, in the real part of spectrum, we prove the existence of brachion and tachion-type solutions

with power-localization in the spatial coordinate, and we show that nonlinear wavepackets have a boomerang behavior. As for the complex spectrum, both scalar and spinor solitons show up with a rich phenomenology, including pair-production and annihilation. Of course, in contrast with the scalar case, where one can use terms borrowed from elementary particle physics, in the spinor case this is not possible since classical spinor variables commute rather than anticommute, this leading to the fact that all states have positive charge.

The derivation of our results is elementary, though actual computations are rather lenghty. Our presentation is not always aimed to generality, and we content ourselves with pointing out behaviors of simple solutions. Throughout the paper, we present results in relativistically invariant form. To this aim, for the benefit of the reader, we introduce here our notation, and, for future reference, few useful formulas.

Space–time coordinates are equivalently denoted

$$z=(x^0,x^1)=(t,x)=x^\mu, \tag{1.3}$$

according to convenience. The light speed is set equal to unity, $c=1$, and greek indices take the values 0 and 1, while two equal indices are meant to be summed over these values. Lorentz transformations

$$x^\mu \to x'^\mu = L^\mu_\nu x^\nu \tag{1.4}$$

are defined by the 2×2 matrix L^μ_ν, which may be given the following equivalent expressions:

$$L^\mu_\nu = \gamma \begin{pmatrix} 1 & \beta \\ \beta & 1 \end{pmatrix}, \quad \gamma \equiv (1-\beta^2)^{-1/2}, \quad -1<\beta<1, \tag{1.5a}$$

$$L^\mu_\nu = \begin{pmatrix} \cosh\,\alpha & \sinh\,\alpha \\ \sinh\,\alpha & \cosh\,\alpha \end{pmatrix}, \quad -\infty<\alpha<+\infty, \tag{1.5b}$$

where $\beta=\mathrm{tgh}\,\alpha$; in this second notation, the group property is more transparent, as it reads $L(\alpha_1)L(\alpha_2)=L(\alpha_1+\alpha_2)$, and the Lorentz matrix takes the exponential expression

$$L^\mu_\nu = L(\alpha) = \exp(\alpha\sigma_1), \tag{1.6}$$

σ_1 being the Pauli matrix $\sigma_1=\left(\begin{smallmatrix}0&1\\1&0\end{smallmatrix}\right)$. The metric tensor

$$g_{\mu\nu} = \mathrm{diag}(1,-1) = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \tag{1.7}$$

and the skew-symmetric Ricci tensor

$$\epsilon_{\mu\nu} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \tag{1.8}$$

are left unchanged by a Lorentz transformation, so that, with any pair of vectors a^μ and b^μ, the following expressions:

$$g_{\mu\nu}a^\mu b^\nu = a^0b^0 - a^1b^1, \quad \epsilon_{\mu\nu}a^\mu b^\nu = a^0b^1 - a^1b^0, \tag{1.9}$$

are Lorentz-invariant. We also note that

$$g^{\mu\nu}=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix},\quad \epsilon^{\mu\nu}=\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix},\quad \epsilon_{\mu\alpha}\epsilon_{\nu\beta}g^{\alpha\beta}=-g_{\mu\nu}. \tag{1.10}$$

With two given vectors a^μ and b^μ there can be associated, at most, three independent invariants, so that the following four invariants:

$$I_a\equiv g_{\mu\nu}a^\mu a^\nu,\quad I_b\equiv g_{\mu\nu}b^\mu b^\nu,\quad I\equiv g_{\mu\nu}a^\mu b^\nu,\quad \tilde{I}\equiv\epsilon_{\mu\nu}a^\mu b^\nu, \tag{1.11}$$

are not independent, namely,

$$I^2=I_aI_b+\tilde{I}^2. \tag{1.12}$$

The basic ingredient of the solutions of linear differential equations is the exponential, $\exp(g_{\mu\nu}u^\mu x^\nu)$, where u^μ is a complex vector with fixed norm,

$$g_{\mu\nu}u^\mu u^\nu=m^2, \tag{1.13}$$

where the mass m is a given (positive) real number. This complex vector u^μ is parametrized in the following way:

$$u^\mu=\eta\ \cos\ \theta k^\mu+i\tau\ \sin\ \theta\epsilon^{\mu\nu}k_\nu, \tag{1.14}$$

where the scalars η and τ are sign parameters,

$$\eta=\pm 1,\quad \tau=\pm 1,$$

and are referred to as, respectively, ''charge'' and ''chirality'' (see below). The ''spectral angle'' parameter θ is a scalar to be taken in the interval

$$0\leqslant\theta\leqslant\frac{\pi}{2}, \tag{1.15}$$

and the real vector k^μ is defined as

$$k^\mu=(\omega,k),\quad \omega=+\sqrt{m^2+k^2}, \tag{1.16}$$

the wave number k being a real parameter, $-\infty<k<+\infty$, the associated frequency ω being positive definite, $m\leqslant\omega$. An alternative parametrization of the real vector k^μ may be

$$k^\mu=m(\cosh\ \alpha,\sinh\ \alpha),\quad -\infty<\alpha<+\infty, \tag{1.17}$$

namely $\omega=m\ \cosh\alpha$ and $k=m\ \sinh\alpha$. The expression (1.14), together with (1.16), justifies the introduction of the following notation:

$$E(k,\eta,\theta,\tau)\equiv\exp(-iu^\mu x_\mu). \tag{1.18}$$

For future reference, we note that, if u_n^μ and u_m^μ are any two vectors satisfying condition (1.13), then (an asterisk stands for complex conjugation) the vector $u_n^{\mu *}-u_m^\mu$ is orthogonal to the vector $u_n^{\mu *}+u_m^\mu$, and, therefore,

$$\epsilon^{\mu\nu}(u_{n\nu}^*+u_{m\nu})=[\lambda_{nm}/(m^2-\mu_{nm})](u_n^{\mu *}-u_m^\mu), \tag{1.19a}$$

$$\epsilon^{\mu\nu}(u_{n\nu}^*-u_{m\nu})=-[\lambda_{nm}/(m^2+\mu_{nm})](u_n^{\mu *}+u_m^\mu), \tag{1.19b}$$

where we have introduced the two invariants

$$\mu_{nm} \equiv g_{\mu\nu} u_n^{\mu *} u_m^{\nu}, \quad \lambda_{nm} \equiv \epsilon_{\mu\nu} u_n^{\mu *} u_m^{\nu}, \tag{1.20}$$

which, because of (1.12), satisfy the relation

$$\mu_{nm}^2 = m^4 + \lambda_{nm}^2. \tag{1.21}$$

As for spinors, our notation is the following. The Dirac vector $\gamma^\mu = (\gamma^0, \gamma^1)$ is

$$\gamma^0 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \gamma^1 = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \tag{1.22}$$

which satisfies the usual condition $\{\gamma^\mu, \gamma^\nu\} = 2g^{\mu\nu}$. If φ is the spinor

$$\varphi = \begin{pmatrix} \varphi_1 \\ \varphi_2 \end{pmatrix}, \tag{1.23}$$

then the corresponding bar-conjugated spinor is defined as

$$\overline{\varphi} = \varphi^+ \gamma^0 = (\varphi_1^* \quad -\varphi_2^*). \tag{1.24}$$

The transformation of spinors that corresponds to the Lorentz transformation (1.4) reads

$$\varphi \to \varphi' = \wedge \varphi, \tag{1.25}$$

where the 2×2 matrix $\wedge$ takes the expression

$$\wedge = (1 + \gamma + \beta\gamma\sigma_1)/\sqrt{2(1+\gamma)} = \exp\left(\frac{\alpha}{2}\,\sigma_1\right), \tag{1.26}$$

α, β, and γ being the same as in (1.5) and (1.6). Thus, if φ and ψ are two spinors, then $\overline{\varphi\psi}$ and $\overline{\varphi}\gamma^\mu\psi$ are, respectively, scalar and vector with respect to Lorentz transformations. As basic spinors, we use the following expressions:

$$\mathscr{E}(k, \eta, \theta, \tau) = E(k, \eta, \theta, \tau)\chi(k, \eta, \theta, \tau), \tag{1.27}$$

where the exponential function $E(k, \eta, \theta, \tau)$ is defined by (1.18), (1.14), and (1.16), and the constant spinor $\chi(k, \eta, \theta, \tau)$ has the expression

$$\chi(k, \eta, \theta, \tau) \equiv \frac{1}{2}\sqrt{m\cos\theta}[1 + \eta + (1-\eta)\gamma^1]\exp\left[\frac{1}{2}(\eta\alpha + i\tau\theta)\sigma_1\right]\begin{pmatrix} 1 \\ 0 \end{pmatrix}, \tag{1.28}$$

with α such that $k = m \sinh\alpha$, and with the normalization

$$\overline{\chi}\chi = \eta m \cos^2\theta. \tag{1.29}$$

The spinor (1.28) obtains by applying the Lorentz transformation (1.25), with (1.26), to the spinor $\chi(0, \eta, \theta, \tau)$ in the rest reference frame (i.e., for $k = 0$).

For future reference, we report here, without proof, few properties of the basic spinor (1.28). To this aim, we first introduce the following simplifying notation:

$$\chi_n = \chi(k_n, \eta_n, \theta_n, \tau_n), \quad n = 1,2,..., \tag{1.30}$$

$$\overline{\chi_n}\chi_m \equiv S_{nm}\,, \quad \overline{\chi_n}\gamma^\mu\chi_m \equiv V^\mu_{nm}\,. \tag{1.31}$$

Since the vector V^μ_{nm} satisfies the equation

$$\epsilon_{\mu\nu}V^\mu_{nm}(u^{\nu *}_n + u^\nu_m) = 0, \tag{1.32}$$

its expression has to be of the form

$$V^\mu_{nm} = \Gamma_{nm}(u^{\mu *}_n + u^\mu_m). \tag{1.33}$$

Moreover, we find that

$$\Gamma_{nm} = [m/(m^2+\mu_{nm})]S_{nm}\,, \tag{1.34}$$

where the two invariants μ_{nm} and S_{nm} are defined by (1.20) and, respectively, (1.31). The explicit expression of S_{nm} follows from its definition, together with (1.28), and turns out to read

$$S_{nm} = \eta_n[\cos\,\theta_n\,\cos\,\theta_m(m^2+\mu_{nm})/2]^{1/2}, \quad \eta_n\eta_m = 1, \tag{1.35a}$$

$$S_{nm} = \eta_n\lambda_{nm}[\cos\,\theta_n\,\cos\,\theta_m/2(m^2-\mu_{nm})]^{1/2}, \quad \eta_n\eta_m = -1. \tag{1.35b}$$

We note that the space component of the complex wave vector u^μ, see (1.14), can be any complex number, and plays the role of the spectral variable. Bounded free field solutions obtain only if the spectral variable is real ($\theta=0$), where sums of exponentials provide periodic or quasi-periodic solutions, and integrals over k yield wave packet solutions. Complex u^μ solutions are exponentially unbounded; however, they are still of interest as they may be mapped into bounded solutions of the nonlinear field equations. Because of this, we discuss below the two cases separately, namely, after a short presentation of the models given in Sec. II, in Sec. III we deal with the real spectrum and in Sec. IV with the complex spectrum. Section V is devoted to conclusions.

II. MODELS AND LINEARIZATION

Here we shortly review the linearization method, and discuss few general properties of the mapping which takes solutions of the linear (free-field) equation into solutions of the nonlinear equation. Let us consider first the complex scalar field $q(z)$ which satisfies the Klein–Gordon equation (m is a real constant),

$$\Box q + m^2 q = 0, \tag{2.1}$$

and, consequently, the conservation law,

$$j^\mu{}_{,\mu} = 0, \tag{2.2}$$

for the current

$$j_\mu = \mathrm{Im}(q q^*_{,\mu}). \tag{2.3}$$

In the following method, it is convenient to introduce, together with the field $q(z)$, an associated real scalar field $v(z)$ with the property of satisfying the field equation

$$v_{,\mu} = \epsilon_{\mu\nu}j^\nu, \tag{2.4}$$

which is certainly integrable because of the conservation law (2.2). Thus, from now on, the pair of fields $q(z)$ and $v(z)$ are the dynamical variables of the model.

Consider now the mapping $q \to Q$, $v \to V$ as defined by the formulas

$$Q=q\ \exp[f(v)],\quad V=g(v), \tag{2.5}$$

with the condition of being invertible, namely

$$q=Q\ \exp[-F(V)],\quad v=G(V). \tag{2.6}$$

At this point, f and g are arbitrary real functions of a real variable (except for the obvious requirement that the operations below be meaingful), while F and G obtain via the invertibility condition,

$$F(g(v))=f(v),\quad G(g(v))=v. \tag{2.7}$$

We note that, because of the reality of the function f, the transformation (2.5), just in contrast with respect to the local SU(1) gauge transformation, changes the amplitude of the field value q, but not its phase. Moreover, its dependence on the real field v, together with the field equation (2.4), guarantees that also the current associated with the new field Q,

$$J_\mu=\mathrm{Im}(QQ^*_{,\mu}), \tag{2.8}$$

is conserved, i.e.,

$$J^\mu_{,\mu}=0. \tag{2.9}$$

This property of our mapping, which is basic in the present approach, directly follows from the transformation rule

$$J_\mu=j_\mu\ \exp[2f(v)] \tag{2.10}$$

and Eq. (2.4).

Let us look now at the equations satisfied by the new fields Q and V. For the latter one, the equation reads

$$V_{,\mu}=H(V)\epsilon_{\mu\nu}J^\nu,\ \ H(V)\equiv\exp[-2F(V)]/G'(V), \tag{2.11}$$

and it is evident that, with no loss of generality (it is just a matter of a change of the variable V), one can ask that $H(V)=1$, so that V formally satisfies the same equation as v, that is

$$V_{,\mu}=\epsilon_{\mu\nu}J^\nu. \tag{2.12}$$

On the contrary, the equation for Q is no more linear and comes out to be

$$\Box Q+[m^2+(F''-F'^2)J_\alpha J^\alpha+2F'\epsilon^{\alpha\beta}\ \mathrm{Im}(Q^*_{,\alpha}Q_{,\beta})]Q=0. \tag{2.13}$$

We first observe that with the choice $H(V)=1$, see (2.11), $F(V)$ and $G(V)$ are related to each other by

$$G(V)=\Gamma+\int_0^V dV'\ \exp[-2F(V')], \tag{2.14}$$

where Γ is an integration constant. As a consequence of the inversion formulas (2.7), also the function $g(v)$ is no more arbitrary, as it is given by the expression

$$g(v)=\gamma+\int_0^v dv'\ \exp[2f(v')], \tag{2.15}$$

γ being an arbitrary constant. Therefore, the mapping $q \to Q$ is characterized by a function $f(v)$ and a real parameter γ, while $F(V)$ and Γ are consequently determined by the inversion condition (2.7).

Before proceeding further, it is worth pointing out that the class of mappings $M(\gamma,f):(q,v)\to(Q,V)$ under consideration, can be restricted by using an equivalence relation according to the following definition. Two mappings $M(\gamma,f)$ and $M(\tilde{\gamma},\tilde{f})$ are equivalent to each other if, for any solution (q,v) of (2.1) and (2.4) there exists another solution of the same equations, say $(\tilde{q},\tilde{v})$, such that the corresponding transformed fields are the same: $M(\gamma,f):(q,v)\to(Q,V)$ and $M(\tilde{\gamma},\tilde{f}):(\tilde{q},\tilde{v})\to(Q,V)$. This means that the two corresponding nonlinear equations, say (2.13) with F and $\tilde{F}$, have the same manifold of solutions and, therefore, do not deserve separate analysis. In particular, it is easily proved that, if $u:(q,v)\to(\tilde{q},\tilde{v})$ is a transformation which leaves the free field Eqs. (2.1) and (2.4) invariant, and if the composed map $M(\gamma,f)\star u$ is of the same type, i.e., $M(\gamma,f)\star u = M(\tilde{\gamma},\tilde{f})$, then $M(\gamma,f)$ and $M(\tilde{\gamma},\tilde{f})$ are equivalent. A simple application of this result is the following. Consider the two parameter transformation $u:(q,v)\to(\tilde{q},\tilde{v})$ with

$$\tilde{q}=aq, \quad \tilde{v}=a^2v+b, \tag{2.16}$$

where a and b are real parameters; then, given a mapping $M(\gamma,f):q\to Q$, the composed mapping $M(\tilde{\gamma},\tilde{f})=M(\gamma,f)\star u$ is readly found to correspond to

$$\tilde{f}(v)=f(a^2v+b)+\ln a, \quad \tilde{\gamma}=\gamma+\int_0^b dv\ \exp[2f(v)]. \tag{2.17}$$

Therefore, we conclude that, by choosing b and a so that

$$\int_0^b dv\ \exp[2f(v)]=-\gamma, \tag{2.18}$$

and

$$a=\exp[-f(b)], \tag{2.19}$$

within the class of equivalence of any mapping $M(\gamma,f)$, there exists a mapping $M(\tilde{\gamma},\tilde{f})$ such that $\tilde{\gamma}=0$ and $\tilde{f}(0)=0$. This observation gives us the possibility to consider, without loss of generality, only mappings of the form $M(0,f(v))$, with the additional property $f(0)=0$. It is also easy to see that the inverse mapping, characterized by the function $F(V)$ and the paramter Γ, satisfies the same condition, say $\Gamma=F(0)=0$. In conclusion, here and below we confine our attention to invertible mappings $q\leftrightarrow Q$, $v\leftrightarrow V$ of the form (2.5) and (2.6) with

$$g(v)=\int_0^v dv'\ \exp[2f(v')], \quad G(V)=\int_0^V dV'\ \exp[-2F(V')], \tag{2.20}$$

which are characterized by one real function $f(v)$ (or, equivalently, $F(V)$, see (2.7)) with the property

$$f(0)=0 \quad (\text{or } F(0)=0). \tag{2.21}$$

Once $f(v)$ (and, therefore, $F(V)$) is fixed, the nonlinear field equations of interest are (2.13) and (2.12); we note that the nonlinearity in the complex scalar field Q in (2.13) is only cubic and quintic for any choice of the function $F(V)$.

It is obvious that our mapping, see (2.5), (2.6), and (2.20), translates whatever property of the free field equations into the corresponding one for the nonlinear Eqs. (2.12) and (2.13). Instances of interesting properties are the transformations which map a solution (Q,V) into another solution $(\widetilde{Q},\widetilde{V})$, and the nonlinear superposition principle. The formal way to construct the relevant formulas is simple. Suppose $M:(q,v)\to(Q,V)$ is the mapping, and $u:(q,v)\to(\widetilde{q},\widetilde{v})$ is a transformation which leaves the free field equations invariant, then the transformation $U:(Q,V)\to(\widetilde{Q},\widetilde{V})$, with $U=M\star u\star M^{-1}$, maps solutions of the nonlinear field equations into solutions of the same equations. For example the transformation u (2.16) yields the transformation U given by the explicit expressions,

$$\widetilde{Q}=aQ\ \exp[f(a^2G(V)+b)-F(V)],\quad \widetilde{V}=g(a^2G(V)+b). \tag{2.22}$$

As for the nonlinear superposition principle, the way to proceed is similar; suppose (Q_j,V_j), $j=1,2,...,N$, are N solutions of the nonlinear field equations, and $q_j=Q_j\ \exp[-F(V_j)]$ the corresponding solutions of the K-G equation (2.1), then let q be the linear superposition, $q=\Sigma_j\ a_jq_j$, where the a_j's are arbitrary complex numbers and v is the corresponding solution of (2.4), with (2.3), then the new solution (Q,V) given by the nonlinear superposition of the (Q_j,V_j)'s reads

$$Q=\sum_j\ a_jQ_j\ \exp[F(V)-F(V_j)],\quad V=g(v). \tag{2.23}$$

Deriving a more explicit expression of this formula is a simple task, and is left to the interested reader.

Models for spinor fields can be similarly constructed.[1] Since the formulas for the linearizing transformation are the same as before, we confine ourselves to report below the basic equations. The free field $\varphi(z)=\binom{\varphi_2}{\varphi_1}$ satisfies the Dirac equation (see Sec. I for the notation)

$$\gamma^\mu\varphi_{,\mu}+im\varphi=0, \tag{2.24}$$

while the corresponding current

$$j^\mu=\overline{\varphi}\gamma^\mu\varphi,\quad \overline{\varphi}\equiv\varphi^\dagger\gamma^0 \tag{2.25}$$

satisfies the conservation law (2.2).

Again, it is convenient to introduce the associated scalar field $v(z)$, which satisfies the field equation (2.4). Then, for a given function $f(v)$, with $f(0)=0$, we associate to the free field variables φ and v the new fields ϕ and V through the transformation formulas

$$\phi=\exp[f(v)]\varphi,\quad V=g(v), \tag{2.26}$$

while the inverse transformation reads (compare with (2.5) and (2.6))

$$\varphi=\exp[-F(V)]\phi,\quad v=G(V). \tag{2.27}$$

As before, the four functions f, F, g, and G are related to each other by Eqs. (2.20), together with the condition (2.21), and the new scalar field V satisfies again Eq. (2.12), with $J^\mu=\overline{\phi}\gamma^\mu\phi$, or more explicitly,

$$V_{,\mu}=\epsilon_{\mu\nu}\overline{\phi}\gamma^\nu\phi. \tag{2.28}$$

The field equation for the new spinor ϕ is nonlinear, and takes the expression

$$\gamma^{\mu}\phi_{,\mu}+[im-F'(V)\epsilon_{\mu\nu}\gamma^{\mu}\overline{\phi}\gamma^{\nu}\phi]\phi=0, \tag{2.29}$$

with a cubic nonlinearity in the spinor field. Of course, a two-parameter family of transformations which map a given solution (ϕ,V) of the field equations (2.29) and (2.28) into a new solution $(\tilde{\phi},\tilde{V})$ of the same equations can be found in exactly the same way as for the scalar case, and it looks as in (2.22), namely

$$\tilde{\phi}=a\phi\ \exp[f(a^2G(V)+b)-F(V)], \quad \tilde{V}=g(a^2G(V)+b). \tag{2.30}$$

The same holds for the nonlinear superposition formula of solutions of (2.28) and (2.29), whose derivation does not need to be repeated here.

The generalization of this approach to systems of coupled equations for scalar and spinor fields has been given in Ref. 1. Here, we shortly report on few examples of particular field models, which correspond to simple choices of the function $f(v)$ [or, equivalently, $F(V)$ or $g(v)$ or $G(V)$] which defines the linearizing transformation. First, we observe that a preliminary requirement is that all the four functions f, g, F, and G be explicitly expressed in terms of elementary functions. Second, apart from obvious simplicity criteria, we ask that the mapping $q\to Q$ be either nonsingular or have a simple singularity structure. This point is particularly relevant in the context of the scalar field, as contrasted with the nonrelativistic case, because the scalar function v, which enters in the transformations (2.5) and (2.26), can assume any real value. In fact, modulo an additive constant of integration, v is the (space) integral of the charge density, $v_x=-j_0$, which is definite positive in the nonrelativistic case, $v_x=|\psi|^2>0$, while in the relativistic case $v_x=\mathrm{Im}(q^*q_t)$ may take any real value (see also below). However, in the case of the spinor field, the charge density $j_0=|\varphi_1|^2+|\varphi_2|^2$ is positive and the discussion of the problem of avoiding singularities of the nonlinear field ϕ is simpler than in the scalar one. In order to clearly show the singularities in the variable v, it is convenient to introduce the real function

$$D(v)=\exp[-2f(v)]=1/g'(v) \tag{2.31}$$

so that the transformation of the charge density reads [see (2.10)]

$$J_0=j_0/D(v);$$

in this notation, the singularities of J_0 may arise only from the zeros of the function $D(v)$ whenever j_0 is nonsingular. We also point out that, because of (2.21), $D(v)$ should be chosen so as to satisfy the condition

$$D(0)=1. \tag{2.32}$$

Example A: $D(v)$ has only one zero,

$$D(v)=(1+av)^{\alpha/a}, \quad a\alpha>0, \tag{2.33}$$

$$f(v)=-\frac{\alpha}{2a}\ln(1+av), \quad g(v)=\frac{1}{a-\alpha}[(1+av)^{1-\alpha/a}-1], \tag{2.33a}$$

$$F(V)=-\frac{\alpha}{2(a-\alpha)}\ln[1+(a-\alpha)V], \quad G(V)=\frac{1}{a}\{[1+(a-\alpha)V]^{a/(a-\alpha)}-1\}, \tag{2.33b}$$

$$F'(V)=-\frac{\alpha}{2}[1+(a-\alpha)V]^{-1}, \quad F''(V)-(F'(V))^2=\frac{\alpha}{4}(2a-3\alpha)[1+(a-\alpha)V]^{-2}. \tag{2.33c}$$

Example A_1: this is the $a \to 0$ limit of Example A, $D(v)$ has no zero for finite v,

$$D(v) = \exp(\alpha v), \tag{2.34}$$

$$f(v) = -\frac{\alpha}{2} v, \quad g(v) = -\frac{1}{\alpha} [\exp(-\alpha v) - 1], \tag{2.34a}$$

$$F(V) = \frac{1}{2} \ln(1 - \alpha V), \quad G(V) = -\frac{1}{\alpha \ln(1 - \alpha V)}, \tag{2.34b}$$

$$F'(V) = -\frac{\alpha}{2} (1 - \alpha V)^{-1}, \quad F''(V) - (F'(V))^2 = -\frac{3}{4} \alpha^2 (1 - \alpha V)^{-2}. \tag{2.34c}$$

Example A_2: this is the $a \to \alpha$ limit of Example A,

$$D(v) = 1 + av, \tag{2.35}$$

$$f(v) = -\frac{1}{2} \ln(1 + av), \quad g(v) = \frac{1}{a} \ln(1 + av), \tag{2.35a}$$

$$F(V) = -\frac{a}{2} V, \quad G(V) = \frac{1}{a} [\exp(aV) - 1], \tag{2.35b}$$

$$F'(V) = -\frac{a}{2}, \quad F''(V) - (F'(V))^2 = -\frac{a^2}{4}. \tag{2.35c}$$

Example B_1: $D(v)$ has two complex zeros,

$$D(v) = (a^2 v^2 + 1)^{1/2}, \quad a > 0, \tag{2.36}$$

$$f(v) = -\frac{1}{4} \ln(a^2 v^2 + 1), \quad g(v) = \frac{1}{a} \ln \sqrt{1 + a^2 v^2} + av), \tag{2.36a}$$

$$F(V) = -\frac{1}{2} \ln[\cosh(aV)], \quad G(V) = \frac{1}{a} [\sinh(aV)], \tag{2.36b}$$

$$F'(V) = -\frac{a}{2} \operatorname{tgh}(aV), \quad F''(V) - (F'(V))^2 = -\frac{a^2}{4} [2 - \operatorname{tgh}^2(aV)]. \tag{2.36c}$$

Example B_2: $D(v)$ has two complex zeros,

$$D(v) = (a^2 v^2 + 1), \tag{2.37}$$

$$f(v) = -\frac{1}{2} \ln(a^2 v^2 + 1), \quad g(v) = \frac{1}{a} \operatorname{arctg}(av), \tag{2.37a}$$

$$F(V) = \ln \cos(aV), \quad G(V) = \frac{1}{a} \operatorname{tg}(aV), \tag{2.37b}$$

$$F'(V) = -\operatorname{atg}(aV), \quad F''(V) - (F'(V))^2 = -a^2 [1 + 2 \operatorname{tg}^2(aV)]. \tag{2.37c}$$

Example B_3: $D(v)$ has two complex zeros,

$$D(v)=(a^2v^2+1)^{3/2}, \tag{2.38}$$

$$f(v)=-\frac{3}{4}\ln(a^2v^2+1), \quad g(v)=\frac{v}{\sqrt{a^2v^2+1}}, \tag{2.38a}$$

$$F(V)=\frac{3}{4}\ln(1-a^2V^2), \quad G(V)=\frac{V}{\sqrt{1-a^2V^2}}, \tag{2.38b}$$

$$F'(V)=-\frac{3}{2}a^2V/(1-a^2V^2), \quad F''(V)-(F'(V))^2=-\frac{3a^2}{2}\left(1+\frac{5}{2}a^2V^2\right)\Big/(1-a^2V^2)^2. \tag{2.38c}$$

It should be noted that only in the models A and A_2, $D(v)$ vanishes on the real axis, i.e., for $v=-1/a$, and that only with the choice A_2 the field equations (2.13) in the scalar case, and (2.29) in the spinor case, are not coupled to the scalar field V; these equations coincide with (1.1) and (1.2) for $a=-2$ i.e., $F'(V)=1$).

III. SPECIAL SOLUTIONS-REAL SPECTRUM

In this section we describe few properties of particular solutions of the nonlinear field equations introduced in the previous section. The main emphasis here is on our capability to write down explicit expressions of solutions of nonlinear PDEs by transforming explicit expressions of the linear free field, whose building blocks are, of course, the elementary exponential solutions. Before proceeding to this task, however, we briefly look at the initial value problem associated with our field equations.

For the free scalar field, this is the problem of computing the solution $q(x,t)$ of the K-G equation (2.1), and the solution $v(x,t)$ of the auxiliary equation (2.4), which satisfy the conditions

$$q(x,0)=q_0(x), \quad q_t(x,0)=q_1(x), \quad x\epsilon\Re, \tag{3.1a}$$

$$v(x,0) \xrightarrow[x\to-\infty]{} l; \tag{3.1b}$$

both choices of the initial time $t=0$, and of the point $x=-\infty$ in (3.1b), are made for the sake of convenience. If $q_0(x)$ and q_1 are assumed to be in $L^2(\Re)$, then the solution $q(x,t)$ has the Fourier integral representation

$$q(x,t)=\int_{-\infty}^{+\infty}\frac{dk}{\sqrt{2\pi}}\{q+(k)\exp[i(kx-\omega t)]+q-(k)\exp[i(kx+\omega t)]\}, \tag{3.2}$$

where the complex amplitudes $q\pm(k)$ are easily expressed in terms of the Fourier transforms of the initial values (3.1a). Once the spectral integral (3.2) is performed, the potential function $v(x,t)$ obtains by quadrature, namely,

$$v(x,t)=\int_{-\infty}^{x}dx'\ \mathrm{Im}[q^*(x',t)q_t(x',t)]+l. \tag{3.3}$$

The point we wish to make here is that the similar initial value problem for the transformed nonlinear equation (2.13) cannot, in general, be mapped into the problem (3.1) with L^2 initial values (3.1a). Indeed, consider the problem of finding the solutions $Q(x,t)$ and $V(x,t)$ of, respectively, (2.13) and (2.12) with the initial values

$$Q(x,0)=Q_0(x), \quad Q_t(x,0)=Q_1(x), \quad x\epsilon\mathfrak{R} \tag{3.4a}$$

in $L^2(\mathfrak{R})$, and the condition

$$V(x,0) \xrightarrow[x\to-\infty]{} L. \tag{3.4b}$$

Then, these conditions can be mapped in conditions for the corresponding free field q according to the transformation (2.6), namely,

$$\begin{aligned} q_0(x)&=Q_0(x)\exp[-F(V_0(x))], \\ q_1(x)&=[Q_1(x)-F'(V_0(x))V_1(x)Q_0(x)]\exp[-F(V_0(x))], \end{aligned} \tag{3.5}$$

where we have set, for notational convenience,

$$\begin{aligned} V_0(x)&=V(x,0)=L+\int_{-\infty}^{x} dx'\ \mathrm{Im}[Q_0^*(x')Q_1(x')], \\ V_1(x)&=V_t(x,0)=\mathrm{Im}[Q_0^*(x)Q_{0x}(x)]. \end{aligned} \tag{3.6}$$

As it will be shown below, even if the initial values Q_0 and Q_1 are L^2 functions, the transformation factor $\exp[-F(V_0)]$, see (3.5), may well be singular as $|x|\to\infty$ so that the spectral representation (3.2) of the corresponding free field is not valid. This property of integrable nonlinear equations is well-known to occurr in both cases of S-integrability and C-integrability.[1] The obvious reason for this property is that there may exist solutions of the free field q whose spectral representation is given by an integral in the spectral variable k which runs, in contrast with the Fourier case (3.2), off the real axis, while yielding, via the mapping (2.5), L^2 solutions Q. A detailed discussion of this problem has been given in Ref. 3 for the Eckhaus equation, which is the nonrelativistic analog of the scalar equation (1.1), and it is not repeated here. Similar considerations apply also to the spinor field, namely, to Eq. (2.29).

At any rate, the method of solution of initial value problems is outside the scope of this paper, and, in fact, it requires separate consideration of each of the field models described in the previous section.

We now turn our attention to the simpler task of constructing solutions of the nonlinear equations by transforming known solutions of the free field. Moreover, in the following, the properties of a given nonlinear field will be described by considering the associated charge density, both in the scalar and spinor case, rather than the field solution itself. This is particularly justified whenever we show plots of x-profiles. If the integrals defining the total charge c of the free field,

$$c=\int_{-\infty}^{+\infty} dx j_0(x,t) \tag{3.7}$$

and the total charge C of the nonlinear field,

$$C=\int_{-\infty}^{+\infty} dx J_0(x,t), \tag{3.8}$$

exist, then the relevant formulas follow from (2.4) and (2.12), and read

$$c=l-r, \quad C=L-R=g(l)-g(r), \tag{3.9}$$

where we use the asymptotic conditions (3.1b) and (3.4b), together with the notation

$$v(x,t) \xrightarrow[x\to+\infty]{} r, \quad V(x,t) \xrightarrow[x\to+\infty]{} R, \tag{3.10}$$

which defines the constants r and R, and the relation $V=g(v)$ (see (2.5) or (2.26)). In this respect, we also note that it may well happen that the free field charge c is infinite, while the corresponding charge C is finite (see below).

Because of linearity, the free field solutions are combinations of the elementary solutions (1.18), which, on the real spectrum ($\theta=0$), read

$$E(k,\eta)=\exp(-i\eta k^{\mu}x_{\mu})=\exp[i\eta(kx-\omega t)], \quad \eta=\pm 1, \tag{3.11}$$

for the scalar field equation (2.1), and (1.27) (with $\theta=0$)

$$\epsilon(k,\eta)=E(k,\eta)\chi(k,\eta), \quad \eta=\pm 1, \tag{3.12a}$$

$$\chi(k,\eta)=\frac{1}{\sqrt{8}}[(1+\eta)+(1-\eta)\gamma^{1}]\begin{pmatrix}\sqrt{\omega+m}\\ \eta k/\sqrt{\omega+m}\end{pmatrix}, \quad \eta=\pm 1, \tag{3.12b}$$

for the spinor field equation (2.4); here k^{μ} is the timelike vector (1.16).

A. Brachions and tachions

Let us consider first the scalar field. The simplest solutions of the K-G equation (2.1) obtain as linear combinations of a finite number of exponentials of the form (3.11). However, the corresponding nonlinear field solutions may be singular as a consequence of the particular mapping (2.5) one considers. Therefore, for this class of solutions, we limit our consideration to the models B_2 and B_3 we have previously introduced (see (2.37) and (2.38)), since these are the only ones to possess regular and finite-charge solutions. Moreover, in order to show the main features of these solutions, it is sufficient to consider the sum of two exponentials, namely,

$$q(z)=a_1E(k_1,\eta_1)+a_2E(k_2,\eta_2), \tag{3.13}$$

because the extension to the generic sum of N exponentials does not take into play any novel feature. The scalar field $v(z)$ corresponding to (3.13) obtains by integrating the differential equation (2.4), where the current j^{μ} is given by (2.3), i.e.,

$$j^{\mu}(z)=k^{\mu}+(\eta_1k_1^{\mu}+\eta_2k_2^{\mu})\mathrm{Re}[a_1a_2^{*}E(k_1,\eta_1)E^{*}(k_2,\eta_2)], \tag{3.14}$$

and it is easily found to have the expression

$$v(z)=\epsilon_{\mu\nu}x^{\mu}k^{\nu}+\sigma[(\mu+m^2)/(\mu-m^2)]^{1/2}\,\mathrm{Im}[a_1a_2^{*}E(k_1;\eta_1)E^{*}(k_2,\eta_2)]+\overline{v,} \tag{3.15}$$

where we have introduced the vector

$$k^{\mu}=\eta_1|a_1|^2k_1^{\mu}+\eta_2|a_2|^2k_2^{\mu}, \tag{3.16}$$

the relativistic invariant

$$\mu=\eta_1\eta_2g_{\mu\nu}k_1^{\mu}k_2^{\nu} \tag{3.17}$$

and the sign $\sigma, \sigma^2 = 1$, according to the formulas

$$\lambda = \eta_1 \eta_2 \epsilon_{\mu\nu} k_1^\mu k_2^\nu, \quad \sigma = \text{sign } \lambda, \tag{3.18}$$

while $\overline{v}$ is a real integration constant. The derivation of expression (3.15) comes from the observation that, for any two real vectors k_1^μ and k_2^μ on the same branch of the mass-shell, see (1.16), the relation $\mu^2 = \lambda^2 + m^4$ holds together with the identity

$$\epsilon_{\mu\nu}(\eta_1 k_1^\nu + \eta_2 k_2^\nu) = \sigma[(\mu + m^2)/(\mu - m^2)]^{1/2}(\eta_2 k_{2\mu} - \eta_1 k_{1\mu}), \tag{3.19}$$

which is a special case of (1.19a) (i.e., for $\theta_1 = \theta_2 = 0$). The nonlinear equations are (2.12) and (2.13), with the specifications (2.37c) for the model B_2 and (2.38c) for the model B_3. The corresponding expressions for the nonlinear fields Q and V explicitly read

$$Q = q/(1 + a^2 v^2)^{1/2}, \quad V = \frac{1}{a} \operatorname{arctg}(av), \tag{3.20}$$

for B_2, and

$$Q = q/(1 + a^2 v^2)^{3/4}, \quad V = v/(1 + a^2 v^2)^{1/2}, \tag{3.21}$$

for B_3, while the current J^μ (see (2.8)) is given by the general formula

$$J^\mu = j^\mu / D(v), \tag{3.22}$$

see (2.10) and (2.31), with the specifications (2.37) and (2.38) for, respectively, B_2 and B_3.

Let us consider first the simpler case in which only one exponential is present in (3.13), namely let us set $a_1 = A$, $a_2 = 0$, $k_1^\mu = k^\mu$, $\eta_1 = \eta$. Moreover, since k^μ is time-like, by performing a Lorentz transformation we can set $k = 0$, i.e., $k^\mu = (m, 0)$, without loss of generality. In this case, also the currents j^μ and J^μ are time-like, and the charge density of the nonlinear field is

$$J^0 = \eta m |A|^2 / D(v), \tag{3.23}$$

with

$$v(x,t) = -\eta m |A|^2 x + \overline{v}. \tag{3.24}$$

The corresponding charge readily obtains from the general formula (3.9) (with $l = \eta\infty$ and $r = -\eta\infty$), and reads

$$C = \eta C_0, \tag{3.25}$$

where the elementary charge C_0 takes the values

$$C_0 = \frac{\pi}{a} \quad \text{for } B_2, \quad C_0 = \frac{2}{a} \quad \text{for } B_3. \tag{3.26}$$

Since the current J^μ is conserved, and it vanishes as $x \to \pm\infty$ for any fixed value of t and in any frame of reference, the charge C is relativistically invariant. We conclude, therefore, that this solution of the nonlinear field models B_2 and B_3 describes a (algebraically) localized object, whose (''quantized'') charge may have two apposite values that, remarkably enough, do not depend on the amplitude A and are given only in terms of the structure constant a of the model.

We consider next the generic solution corresponding to the free field (3.13). In this case the norm of the vector k^μ, see (3.16), may take any value, according to the value of the invariant μ given by (3.17). In fact, since

$$k^\mu k_\mu = m^2(\alpha_1^2+\alpha_2^2)+2\mu\alpha_1\alpha_2, \quad \alpha_j \equiv |a_j|^2, \tag{3.27}$$

and

$$\mu = \eta_1\eta_2(\omega_1\omega_2 - k_1k_2), \tag{3.28}$$

it is convenient to separate the case in which the two exponentials in (3.13) are in the same branch, namely $\eta_1\eta_2=1$, from that in which they are in different branches, namely $\eta_1\eta_2=-1$.

In the first case, let us set $\eta_1=\eta_2=\eta$; then

$$\mu = \omega_1\omega_2 - k_1k_2 \geqslant m^2 \tag{3.29}$$

and the vector k^μ is time-like for any choice of k_1, k_2, a_1, and a_2. Therefore, without loss of generality, we can choose a frame of reference in which $\alpha_1k_1+\alpha_2k_2=0$, or, equivalently, $k^\mu = \eta(\alpha_1\omega_1+\alpha_2\omega_2,0)$ so that the scalar field v takes the expression

$$v(x,t) = -\eta(\alpha_1\omega_1+\alpha_2\omega_2)x + \sigma[\alpha_1\alpha_2(\mu+m^2)/(\mu-m^2)]^{1/2}\cos\,\theta(x,t)+\overline{v}, \tag{3.30}$$

where the explicit expression of the phase $\theta(x,t)$ can be easily derived from (3.15). Since also in this case we have that $l=\eta\infty$ and $r=-\eta\infty$, for the same argument as before, the corresponding charge is again relativistically invariant and has the same value (3.25). Moreover, as it is easily verified, there are values of the parameters k_1, k_2, a_1, a_2, and η such that the currents j^μ, and, therefore, J^μ, are time-like in the whole space-time, or time-like in some regions and space-like in other regions (but, for no choice of the parameters, space–like in the whole space-time). Our conclusion on this case is that this solution is again algebraically confined in space, with a parameter-independent charge which may take the two values (3.25). Adding one exponential to the previous free field q has, therefore, given only some internal motion through the time-dependence of the phase function θ that appears in the expression (3.30) (yielding a sort of breather). A plot of the corresponding charge density J^0 (see (3.14) and (3.22)) for the model B_2 is provided in Fig. 1.

In the second case, i.e. for $\eta_1=-\eta_2=\eta$, since

$$\mu = -(\omega_1\omega_2 - k_1k_2) \geqslant -m^2, \tag{3.31}$$

the vector k^μ (see (3.16)) is time-like if

$$-m^2\left(\frac{\alpha_1^2+\alpha_2^2}{2\alpha_1\alpha_2}\right) < \mu, \tag{3.32}$$

and is space-like if

$$\mu < -m^2\left(\frac{\alpha_1^2+\alpha_2^2}{2\alpha_1\alpha_2}\right). \tag{3.33}$$

If the parameters a_1, a_2, k_1, and k_2 are chosen so as to satisfy (3.32), then the vector $\epsilon_{\mu\nu}\,k^\nu$, which is orthogonal to the time-like vector k^μ, is, of course, space-like, and the corresponding nonlinear field solution has the same properties as in the previous case; there exist a frame of reference in which $k^\mu=\eta(\alpha_1\omega_1-\alpha_2\omega_2,0)$, the total charge is invariant and takes two values according to the formula

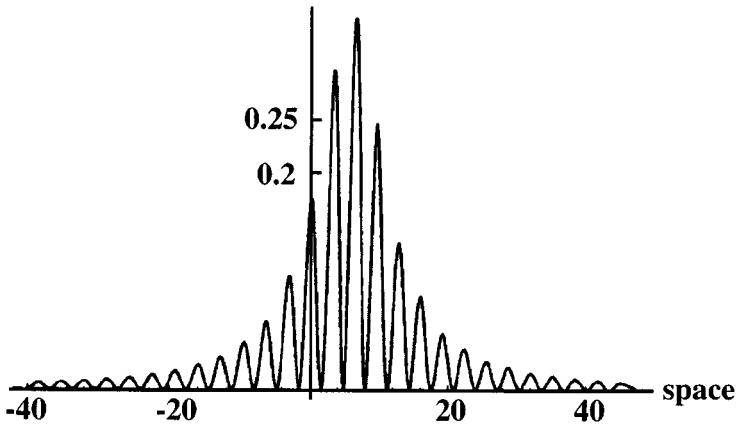

FIG. 1. Brachion profile. The charge density $J^0(x,t)$ is plotted against the space coordinate x at $t=10$ for the scalar model B_2 with $a=1$, $m=1$. The parameters are $\eta_1=\eta_2=1$, $\tau_1=-\tau_2=1$, $\theta_1=\theta_2=0$, $\beta_1=-\beta_2=7/10$, $a_1=a_2=0.1$, $\overline{v}=0$ and the charge takes the elementary value $C_0=\pi$.

$$C=\eta C_0\ \mathrm{sign}(\alpha_1\omega_1-\alpha_2\omega_2). \tag{3.34}$$

The only difference, with respect to the previous case, is that the sign of the charge depends on the relative amplitude $|a_1|^2/|a_2|^2$ and on the spectral variable, say k_1, as explicitely shown in (3.34). Again, for any value of the invariant μ and amplitudes $|a_1|$ and $|a_2|$, there are space–time regions (which may invade the whole space–time) where the current J^μ (and, of course, j^μ, see (3.22)) is time-like.

Let us finally choose k_1 and k_2 so as to satisfy the inequality (3.33). Now the vector k^μ is space-like while $\epsilon_{\mu\nu}k^\nu$ is time-like, and this implies that, in a generic frame of reference, the localized profile of $J^0(x,t)$ moves with the velocity

$$\beta=(\alpha_1k_1-\alpha_2k_2)/(\alpha_1\omega_1-\alpha_2\omega_2), \tag{3.35}$$

whose modulus is larger than the speed of light,

$$|\beta|>1. \tag{3.36}$$

We may call this solution a ''tachion'' and the previous solutions (with velocity smaller than the light-speed) ''brachions,'' just to emphasize the difference between these two classes of solutions. Tachions behave very differently with respect to ordinary particles. In the present example, there is a frame of reference in which the tachion moves with infinite speed, this being the case when (see (3.35)),

$$\alpha_1\omega_1=\alpha_2\omega_2. \tag{3.37}$$

Moreover, in this coordinate system the tachion is completely delocalized since the function $v(x,t)$ becomes periodic in the spatial variable x,

$$v(x,t)=\eta(\alpha_1k_1-\alpha_2k_2)t+\sqrt{\alpha_1\alpha_2}[(m^2+\mu)/\lambda]\cos\ \theta(x,t)+\overline{v}. \tag{3.38}$$

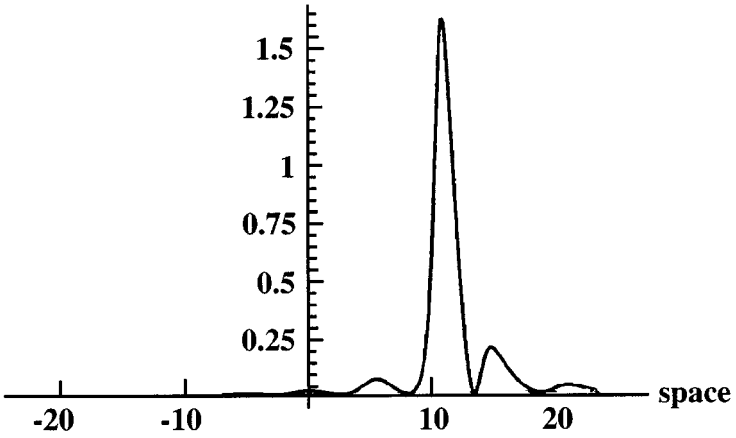

FIG. 2. Tachion profile. The charge density $J^0(x,t)$ is plotted against the space coordinate x at $t=4$ for the scalar model B_2 with $a=1$, $m=1$. The parameters are $\eta_1=-\eta_2=1$, $\tau_1=-\tau_2=1$, $\theta_1=\theta_2=0$, $\beta_1=\sqrt{3}/2$, $\beta_2=-1/2$, $a_1=a_2=1$, $\overline{v}=0$. The absolute value of the charge is $C_0=\pi$ and the tachion velocity is $\beta=2.732$.

Because of this property, the corresponding current does not asymptotically vanish as $x\to\pm\infty$ in all frames of reference, and, therefore, the total charge is no more relativistically invariant. Indeed, while the charge C takes only the two elementary values $\pm C_0$, according to the general formula (3.34), its sign depends on the particular frame of reference since the quantity $\alpha_1\omega_1-\alpha_2\omega_2$ may change its sign by a Lorentz transformation. In fact, the jump of the charge sign obtains by a Lorentz transformation that changes the sign of the tachion velocity (compare (3.35) with (3.34)). The profile of a tachion is plotted in Fig. 2.

This analysis can be easily extended to solutions originated by a sum of N, rather than just two (see (3.3)), exponentials. The following general conclusion can be drawn by looking at the vector $k^\mu\equiv\Sigma\,\eta_n|a_n|^2k_n^\mu$; the corresponding nonlinear field solutions are localized brachions if the vector k^μ is time-like, and tachions if, instead, k^μ is space-like. For the tachion solutions, the charge density profile is localized, with the exception of the frame of reference in which it moves infinitely fast, where it is quasiperiodic in the coordinate x. The absolute value of the charge of all these solutions is always $|C_0|$, independently of N and their associated parameters a_n, k_n, η_n, while the charge itself is Lorentz invariant only for brachions. We finally observe that the associated scalar field $V(x,t)=g(v)$, for the models under consideration B_2 and B_3, has the shape of a modulated kink whose jump $V(-\infty,t)-V(+\infty,t)$ is the total charge C, see (3.9).

Nonlinear spinor fields corresponding to sums of elementary solutions (3.12) can be similarly constructed. We now briefly report on this class of solutions by pointing out the main difference with respect to the scalar case. This stems from the fact that the charge density j^0, and therefore J^0, is positive definite for any solution $\varphi=\binom{\varphi_2}{\varphi_1}$ of the Dirac equation (2.24), namely,

$$j^0=|\varphi_1|^2+|\varphi_2|^2, \tag{3.39}$$

and, therefore, all finite charge solutions of spinor field equations have positive charge. The point here is that our spinor field is a classical commuting variable and, in contrast with the quantized theory of anticommuting fields, there is no spin-statistics relation.

Let us start again with the free field solution [see (3.12) and (3.11)]

$$\varphi(z)=a_1E(k_1,\eta_1)\chi(k_1,\eta_1)+a_2E(k_2,\eta_2)\chi(k_2,\eta_2), \tag{3.40}$$

whose corresponding current (see (2.25)) has the expression

$$j^\mu(z)=k^\mu+2V^\mu\ \mathrm{Re}[a_1a_2^*E(k_1,\eta_1)E^*(k_2,\eta_2)]. \tag{3.41}$$

Here the vector k^μ takes the expression

$$k^\mu=|a_1|^2k_1^\mu+|a_2|^2k_2^\mu; \tag{3.42}$$

as it follows from the fact that the spinor $\chi(k,\eta)$ has been defined by (3.12) so as to satisfy the normalization condition (see Sec. I),

$$\overline{\chi(}k,\eta)\gamma^\mu\chi(k,\eta)=k^\mu=(\omega,k). \tag{3.43}$$

Moreover, the vector V^μ in (3.41), that is

$$V^\mu=\overline{\chi(}k_1,\eta_1)\gamma^\mu\chi(k_2,\eta_2), \tag{3.44}$$

has the following expression [as a special case of formula (1.33)],

$$V^\mu=m[2(m^2+\mu)]^{-1/2}(k_1^\mu+k_2^\mu),\quad \text{if}\ \ \eta_1=\eta_2=\eta, \tag{3.45a}$$

$$V^\mu=(m/\lambda)[(m^2-\mu)/2]^{1/2}(k_2^\mu-k_1^\mu),\quad \text{if}\ \ \eta_1=-\eta_2=\eta, \tag{3.45b}$$

where the relativistic invariants μ and λ are defined by (3.17) and (3.18).

Finally, integrating Eq. (2.4), with (3.41), yields the scalar field

$$v(z)=\epsilon_{\mu\nu}\,x^\mu k^\nu+\eta(m/\lambda)[2(m^2+\mu)]^{1/2}\ \mathrm{Im}[a_1a_2^*E(k_1,\eta_1)E^*(k_2,\eta_2)]+\overline{v},\quad \text{if}\ \ \eta_1=\eta_2=\eta, \tag{3.46a}$$

$$v(z)=\epsilon_{\mu\nu}\,x^\mu k^\nu-\eta m[2/(m^2-\mu)]^{1/2}\ \mathrm{Im}[a_1a_2^*E(k_1,\eta_1)E^*(k_2,\eta_2)]+\overline{v},\quad \text{if}\ \ \eta_1=-\eta_2=\eta, \tag{3.46b}$$

where $\overline{v}$ is an integration constant.

Similarly to the scalar case, finite charge solutions, corresponding to the free field (3.40), are obtained for the nonlinear models B_2 and B_3 only. Therefore we consider the nonlinear equations (2.28) and (2.29), with (2.37c) for B_2 and (2.38c) for B_3, whose solutions are explicitly given by the transformation

$$\phi=\varphi/(1+a^2v^2)^{1/2},\quad V=\frac{1}{a}\,\mathrm{arctg}(av), \tag{3.47}$$

and, respectively,

$$\phi=\varphi/(1+a^2v^2)^{3/4},\quad V=v/(1+a^2v^2)^{1/2}, \tag{3.48}$$

while the current J^μ is provided by (3.22), with (2.37) for B_2 and (2.38) for B_3.

The properties of these solutions are rather simple, since the vector k^μ, in contrast with the scalar field models, is timelike for any choice of the parameters a_1, a_2, k_1, k_2, η_1, and η_2. As a consequence, there exists a frame of reference in which

$$k^\mu=(|a_1|^2\omega_1+|a_2|^2\omega_2,0), \tag{3.49}$$

and the spinor field ϕ models a localized object at rest.

This is easily shown by the expression of the charge density $J^0=j^0/D(v)$, where the field v is of the form

$$v(x,t)=-x(|a_1|^2\omega_1+|a_2|^2\omega_2)+\alpha\ \cos\ \theta(x,t)+\overline{v}, \tag{3.50}$$

the expressions of the constant α, and of the phase function $\theta(x,t)$, being easily derived from formulas (3.46). Thus we conclude that these solutions describe an elementary spinorial object (namely no break-up process occurs during the time evolution) which travels no faster than light (brachions) with the same positive elementary, relativistically invariant, charge C_0 given by (3.26) (the localized x-profile of the charge density looks as in Fig. 1). Indeed, these same conclusions hold for solutions corresponding to a sum of any finite number of elementary spinors (3.12), these being localized brachions with the parameter-independent elementary charge C_0.

B. Wave packets

Here we consider the nonlinear field solutions which obtain by transforming the wave packet solutions of the free field. The following analysis is aimed to provide few asymptotic properties of such solutions as $t\to\pm\infty$. In particular, we will focus our attention on the asymptotic expression of the velocity of the center of charge, and on the leading term of the charge density $J^0(x,t)$ in the direction $x=\beta t$, with $-1\leqslant\beta\leqslant 1$. Since the computational technique, which is based on the Fourier analysis of the free field solutions, is standard, the derivation of the final expression is not detailed.

Let us consider first the scalar field. The free field wave packet is given by the integral (3.2) in terms of two complex amplitudes $q_+(k)$ and $q_-(k)$, which we assume to be rapidly decreasing functions of the real variable k. These amplitudes are, respectively, related to the positive and negative charge components of the field, as shown by the integral expression of the total charge c, see (3.7), that is

$$c=\int_{-\infty}^{+\infty}dk\ \omega(k)[|q_+(k)|^2-|q_-(k)|^2]. \tag{3.51}$$

The behavior of the free field is well-known to be simple. In fact, the center of charge, with coordinate $x_c(t)$, defined by the formula

$$cx_c(t)=\int_{-\infty}^{+\infty}dx\ xj^0(x,t), \tag{3.52}$$

moves with the velocity $\dot{x}_c(t)\equiv s(t)$, whose expression is provided by the conservation law (2.2), and reads

$$cs(t)=\int_{-\infty}^{+\infty}dx\ j^1(x,t). \tag{3.53}$$

The right-hand side integral can be easily related to the Fourier amplitudes, so that the center of charge velocity takes the alternative expression

$$cs(t)=\int_{-\infty}^{+\infty}dk\ k\{(|q_+(k)|^2+|q_-(k)|^2)+2\ \mathrm{Re}[q_+^*(k)q_-(k)\exp(2i\omega t)]\}. \tag{3.54}$$

It then follows that the free field wave packet asymptotically moves with the same velocity s_a,

$$s_a=\frac{1}{c}\int_{-\infty}^{+\infty} dk\ k[|q_+(k)|^2+|q_-(k)|^2], \tag{3.55}$$

both in the past ($t\to-\infty$) and in the future ($t\to+\infty$). This is not so for the corresponding nonlinear field wave packet, which may indeed display a boomerang behavior as its asymptotic velocities $S_{\text{in}}(t=-\infty)$ and $S_{\text{out}}(t=+\infty)$ have apposite sign. In order to show this effect, let us give first the asymptotic behaviors of the current $j^\mu(x,t)$, and of the associated scalar field $v(x,t)$, as $t\to\pm\infty$ in the direction $x=\beta t$, with $-1<\beta<1$. These can be derived from the well-known leading term of the free field, that is

$$q(\beta t,t)\xrightarrow[t\to\pm\infty]{} (m|t|)^{-1/2} q^{\text{out}}_{\text{in}}(\beta,t), \tag{3.56a}$$

$$q^{\text{out}}_{\text{in}}(\beta,t)=m\gamma^{3/2}[q_+(m\beta\gamma)\exp(-i\alpha_\pm)+q_-(-m\beta\gamma)\exp(i\alpha_\pm)], \tag{3.56b}$$

$$\alpha_\pm=mt/\gamma\pm\frac{\pi}{4},\quad \gamma=(1-\beta^2)^{-1/2}. \tag{3.56c}$$

In fact, inserting these expressions into the definition (2.3), we obtain the leading term of the current j^μ, namely,

$$j^\mu(\beta t,t)\xrightarrow[t\to\pm\infty]{} |t|^{-1} j^\mu_a(\beta), \tag{3.57a}$$

$$j^\mu_a(\beta)=m^2\gamma^4[|q_+(m\beta\gamma)|^2-|q_-(-m\beta\gamma)|^2](1,\beta), \tag{3.57b}$$

in the usual notation $j^\mu=(j^0,j^1)$. As for the scalar field $v(x,t)$, its expression in terms of the Fourier amplitudes of the free field obtains by inserting (3.2) in (3.3); we leave out the simple, and tedious, steps of this computation and display only the following asymptotic formula

$$v(\beta t,t)\xrightarrow[t\to\pm\infty]{} v^{\text{out}}_{\text{in}}(\beta), \tag{3.58a}$$

$$v^{\text{out}}_{\text{in}}(\beta)=\mp\frac{1}{2}\int_{-\infty}^{+\infty} dk\ \omega\left[\operatorname{sign}\left(\beta-\frac{k}{\omega}\right)|q_+(k)|^2-\operatorname{sign}\left(\beta+\frac{k}{\omega}\right)|q_-(k)|^2\right]+\overline{v}. \tag{3.58b}$$

For the sake of completeness, we note that the integration constant $\overline{v}$, which appears in this expression, is related to the asymptotic constants l and r, see (3.3) and (3.10), by the equations

$$l=\tfrac{1}{2}c+\overline{v},\quad r=-\tfrac{1}{2}c+\overline{v}. \tag{3.59}$$

Therefore, the total charge C, see (3.8), of the nonlinear field can be conveniently computed via (3.9), namely,

$$C=g(\tfrac{1}{2}c+\overline{v})-g(-\tfrac{1}{2}c+\overline{v}). \tag{3.60}$$

We are now in the position to derive the asymptotic behaviors of both the current $J^\mu(\beta t,t)$ of the nonlinear field in the direction $x=\beta t$, and the velocity of the center of charge, whose position $X_c(t)$ is, of course,

$$X_c(t)=\frac{1}{C}\int_{-\infty}^{+\infty} dx\ xJ^0(x,t). \tag{3.61}$$

In fact, the general transformation law (3.22), together with (3.57) and (3.58), imply that

$$J^{\mu}(\beta t,t) \xrightarrow[t\to\pm\infty]{} |t|^{-1} J^{\mu}_{\substack{\text{out}\\ \text{in}}}(\beta), \tag{3.62a}$$

$$J^{\mu}_{\substack{\text{out}\\ \text{in}}}(\beta) = j^{\mu}_{a}(\beta)/D(v^{\text{out}}_{\text{in}}), \tag{3.62b}$$

whereas the asymptotic values of the nonlinear wave packet velocity $S(t)\equiv \dot{X}_c(t)$, whose expression is (compare with (3.53))

$$CS(t) = \int_{-\infty}^{+\infty} dx J^1(x,t), \tag{3.63}$$

can be derived as follows. We rewrite this last equation as

$$CS(t) = \int_{-\infty}^{-|t|} dx J^1(x,t) + \int_{|t|}^{+\infty} dx J^1(x,t) + |t| \int_{-1}^{1} d\beta J^1(\beta t,t), \tag{3.64}$$

and take the limits as $t\to\pm\infty$; then, using (3.62) yields the formula

$$S(t) \xrightarrow[t\to\pm\infty]{} S^{\text{out}}_{\text{in}} = \frac{1}{C} \int_{-1}^{1} d\beta j^1_a(\beta)/D(v^{\text{out}}_{\text{in}}). \tag{3.65a}$$

For computational purpose, we deem it convenient to rewrite some of the expressions given above in the following alternative forms:

$$j^{\mu}_{a}(\beta) = \frac{\omega^3}{m^2} [|q_+(k)|^2 - |q_-(-k)|^2](\omega,k), \tag{3.57c}$$

$$v^{\text{out}}_{\text{in}}(\beta) = \mp\frac{1}{2} \left(\int_{-\infty}^{k} dk' - \int_{k}^{+\infty} dk' \right) \omega(k')[|q_+(k')|^2 + |q_-(-k')|^2] + \overline{v}, \tag{3.58c}$$

$$S^{\text{out}}_{\text{in}} = \frac{1}{C} \int_{-\infty}^{+\infty} dk k[|q_+(k)|^2/D(v^{\text{out}}_{\text{in}}(\beta)) + |q_-(k)|^2/D(v^{\text{out}}_{\text{in}}(-\beta))], \tag{3.65b}$$

with the obvious relation between the variables β and k

$$k = m\gamma\beta, \quad \omega(k) = m\gamma, \quad \beta = k/\omega. \tag{3.66}$$

As already pointed out, we note also here that even a well-behaved free field wave packet q, see (3.2), may yield a singular nonlinear field Q. The singularities correspond, of course, to the zeros of the function $D(v)$, see (3.22). For the sake of simplicity, we avoid this problem by considering only those models whose corresponding function $D(v)$ has no finite real zero; these are the models A_1, see (2.34), B_1, see (2.36), B_2, see (2.37) and B_3, see (2.38). For these models, to any free field wave packet there corresponds a nonsingular, finite charge, solution of the nonlinear field equations. Let us now show the boomerang effect. Consider a free field solution in the frame of reference in which the velocity of its center of charge asymptotically vanishes as $t\to\pm\infty$. This is the case if we assume that

$$|q_{\pm}(-k)|^2 = |q_{\pm}(k)|^2, \tag{3.67}$$

as this implies that $s_a=0$, see (3.55). It is then convenient to rewrite the expression (3.58c) in the following form

$$v_{\text{in}}^{\text{out}}=\overline{v\mp}\,\omega(k), \tag{3.68}$$

with, by taking into account (3.67),

$$w(k)=\frac{1}{2}\left(\int_{-\infty}^{k}dk'-\int_{k}^{+\infty}dk'\right)\omega(k')[|q_+(k')|^2+|q_-(k')|^2]. \tag{3.69}$$

We note now that the parity property (3.67) implies that the function $w(k)$ be odd,

$$w(-k)=-w(k); \tag{3.70}$$

it then follows that, by using (3.65b), the asymptotic velocities S_{out} and S_{in} of the nonlinear wave packet turn out to take the expressions

$$S_{\text{in}}^{\text{out}}=\frac{1}{C}\int_{-\infty}^{+\infty}dk\;k[|q_+(k)|^2/D(\overline{v\mp}w(k))+|q_-(k)|^2/D(\overline{v\pm}w(k))], \tag{3.71}$$

with the consequence, because of (3.67) and (3.70), that

$$S_{\text{out}}=-S_{\text{in}}, \tag{3.72}$$

and this proves that the nonlinear field wave packet behaves like a boomerang.

A similar analysis can be carried on for the spinor field. Here below we just report the relevant formulas. Again, two complex rapidly decreasing Fourier amplitudes, $\varphi_+(k)$ and $\varphi_-(k)$, completely characterize the free spinor field (see (3.12)),

$$\varphi(x,t)=\int_{-\infty}^{+\infty}\frac{dk}{\sqrt{2\pi}}[\varphi_+(k)\mathscr{E}(k,+)+\varphi_-(k)\mathscr{E}(k,-)], \tag{3.73}$$

whose charge c, see (3.7) and (3.39), is the positive quantity

$$c=\int_{-\infty}^{+\infty}dk\;\omega(k)[|\varphi_+(k)|^2+|\varphi_-(k)|^2]. \tag{3.74}$$

Of course, the center of charge coordinate x_c and velocity s are still given by (3.52) and, respectively, (3.53), while the Fourier integral representation of the velocity now reads

$$cs(t)=\int_{-\infty}^{+\infty}dk\{k[|\varphi_+(k)|^2-|\varphi_-(k)|^2]+2m\;\text{Re}[\varphi_+^*(k)\varphi_-(k)\exp(2i\omega t)]\}. \tag{3.75}$$

In order to derive this expression we have taken into account the definition (3.12) of the spinor $\chi(k,\eta)$, together with Eq. (3.44), (3.45), and (3.19). In the limit as $t\to\pm\infty$, this velocity takes the asymptotic value s_a,

$$s_a=\frac{1}{c}\int_{-\infty}^{+\infty}dk\;k[|\varphi_+(k)|^2-|\varphi_-(k)|^2], \tag{3.76}$$

which is the same in the past and in the future. Similarly to the scalar field, the behavior of the nonlinear wave packet is quite different. In order to obtain the asymptotic values S_{out} and S_{in} of the

velocity of the center of charge $S(t)$, as defined by (3.63), as $t\to+\infty$ and $t\to-\infty$, respectively, it is convenient to derive first the asymptotic behavior of the free-field current $j^\mu(\beta t,t)$,

$$j^\mu(\beta t,t)\xrightarrow[t\to\pm\infty]{}|t|^{-1}[j_a^\mu(\beta)+j_\pm^\mu(\beta,t)], \tag{3.77}$$

where

$$j_a^\mu(\beta)=m^2\gamma^4[|\varphi_+(m\gamma\beta)|^2+|\varphi_-(-m\gamma\beta)|^2](1,\beta), \tag{3.78a}$$

$$j_\pm^\mu(\beta,t)=2m^2\gamma^4\ \mathrm{Re}[\varphi_+^*(m\gamma\beta)\varphi_-(-m\gamma\beta)\exp(2i\alpha_\pm)](\beta,1), \tag{3.78b}$$

with $\alpha_\pm(\beta,t)$ as defined by (3.54c). These formulas follow from the asymptotic behavior,

$$\varphi(\beta t,t)\xrightarrow[t\to\pm\infty]{}(m|t|)^{-1/2}\varphi_{\text{in}}^{\text{out}}(\beta,t), \tag{3.79a}$$

$$\varphi_{\text{in}}^{\text{out}}(\beta,t)=m\gamma^{3/2}[\varphi_+(m\gamma\beta)\chi(m\gamma\beta_1,+)\exp(-i\alpha_\pm)+\varphi_-(-m\gamma\beta)\chi(-m\gamma\beta,-)\exp(i\alpha_\pm)], \tag{3.79b}$$

together with the expression (2.25) of the current. Next we obtain the asymptotic behavior of the scalar field $v(x,t)$, namely the functions $v_{\text{out}}(\beta)$ and $v_{\text{in}}(\beta)$ as defined by (3.58a). The lines of computation are the same as in the scalar case, and are not repeated. The resulting expressions are

$$v_{\text{in}}^{\text{out}}(\beta)=\mp\frac{1}{2}\int_{-\infty}^{+\infty}dk\ \omega\left[\operatorname{sign}\left(\beta-\frac{k}{\omega}\right)|\varphi_+(k)|^2+\operatorname{sign}\left(\beta+\frac{k}{\omega}\right)|\varphi_-(k)|^2\right]+\overline{v}, \tag{3.80a}$$

or, equivalently (see (3.66)),

$$v_{\text{in}}^{\text{out}}(\beta)=\mp\frac{1}{2}\left(\int_{-\infty}^{k}dk'-\int_{k}^{+\infty}dk'\right)\omega(k')[|\varphi_+(k')|^2-|\varphi_-(-k')|^2]+\overline{v}. \tag{3.80b}$$

The expression of the total charge C, see (3.8), is, of course, given again by Eq. (3.60), and also Eq. (3.62), (3.63), and (3.64) are still holding. It is also easy to ascertain the validity of the asymptotic formula (3.65) where now the expressions (3.58a) and (3.80) have to be considered, so as to yield the integral representation

$$S_{\text{in}}^{\text{out}}=\frac{1}{C}\int_{-\infty}^{+\infty}dk k[|\varphi_+(k)|^2/D(v_{\text{in}}^{\text{out}}(\beta))-|\varphi_-(k)|^2/D(v_{\text{in}}^{\text{out}}(-\beta))]. \tag{3.81}$$

The observation about the boomerang effect we have already made for the scalar field applies without any change also to the present case and its proof does not need to be repeated.

IV. SPECIAL SOLUTIONS-COMPLEX SPECTRUM

We consider now those nonlinear field solutions which correspond to linear combinations of finitely many exponential solutions of the free field, where the wave vector u^μ, see (1.18), is complex. According to our parametrization (1.14) of u^μ, this clearly amounts to requiring that the spectral angle θ be nonvanishing, $\theta\neq0$, with the further implication that, in contrast with the solutions discussed in the previous section, also the sign parameter $\tau=\pm1$ comes into play (see (1.14)).

Let us look first at the scalar field models. In this case, the generic free field solution is

$$q=\sum_{n=1}^{N} A_n E_n, \tag{4.1}$$

where N is a positive integer, A_n is an arbitrary complex number and, in the notation (1.18) for exponentials, E_n shortly stands for the expression,

$$E_n \equiv E(k_n, \eta_n, \theta_n \tau_n), \quad \theta_n \neq 0, \quad n=1,2,...,N. \tag{4.2}$$

We note that the generic exponential $E(k,\eta,\theta,\tau)=\exp(-iu_\mu x^\mu)$ is not bounded, since, as shown by the explicit expression

$$E(k,\eta,\theta,\tau)=\exp[i\eta\ \cos\ \theta(kx-\omega t)]\exp[-\tau\ \sin\ \theta(\omega x-kt)], \tag{4.3}$$

it diverges to the left (i.e., as $x\to-\infty$) if $\tau=+1$ and to the right (i.e., as $x\to+\infty$) if $\tau=-1$. Just because of this property, it seems appropriate to refer to τ as ''chirality.''

Since we prefer to deal with the current j^μ, see (2.3), rather than with the field q, we introduce the N-dimensional vector, and matrix, notation. Thus, the current associated with the scalar field solution (4.1) takes the following expression:

$$j^\mu=(\mathbf{E},\mathbf{G}^\mu\mathbf{E}), \tag{4.4}$$

where $\mathbf{E}$ is the vector,

$$\{\mathbf{E}\}_n=A_n E_n, \tag{4.5}$$

$\mathbf{G}^\mu$ is the Hermitian matrix whose entries are

$$\{\mathbf{G}^\mu\}_{nm}=\tfrac{1}{2}(u_n^{\mu *}+u_m^\mu), \tag{4.6}$$

and the scalar product is defined as

$$(\mathbf{A},\mathbf{B})=\sum_{n=1}^{N} A_n^* B_n. \tag{4.7}$$

In this notation, and by taking into account the relation (1.19a), the differential equation (2.4) is easily integrated to yield the auxiliary scalar field

$$v=(\mathbf{E},\mathbf{M}\mathbf{E})+\overline{v}, \tag{4.8}$$

where $\overline{v}$ is an integration constant and the entries of the Hermitian matrix $\mathbf{M}$ are given in terms of the invariants μ_{nm} and λ_{nm}, see (1.20),

$$\{\mathbf{M}\}_{nm}=M_{nm}=\frac{1}{2i}\,\lambda_{nm}/(m^2-\mu_{nm}). \tag{4.9}$$

These formulas are the basic tools for the construction of the nonlinear field solutions. Indeed our task here is to discuss the properties of the current (2.8) of the nonlinear field corresponding to (4.1) via the transformation (2.5), namely of the explicit expression (see (3.22) and (4.4)),

$$J^\mu=(\mathbf{E},\mathbf{G}^\mu\mathbf{E})/D(v), \tag{4.10}$$

where v is given by (4.8) and (4.9). Moreover, in order to guarantee that generic solutions be singularity free, in this section we confine our attention to model B_2, see (2.37), so that the expression (4.10) specializes to

$$J^{\mu}=(\mathbf{E},\mathbf{G}^{\mu}\mathbf{E})/[1+a^2((\mathbf{E},\mathbf{M}\mathbf{E})+\overline{v})^2], \tag{4.11}$$

with (4.6) and (4.9).

Let us consider first the total charge C corresponding to the current (4.11); this is given by the general formula (3.9), that presently reads (see (2.37a)),

$$C=\frac{1}{a}\,[\operatorname{arctg}(al)-\operatorname{arctg}(ar)], \tag{4.12}$$

where l and r are, respectively, the asymptotic values $v(-\infty,t)$ and $v(+\infty,t)$ of $v(x,t)$ (see (3.3) and (3.10)). Since these asymptotic values depend on the chirality of the exponentials E_n, it is convenient to specify, without any loss of generality, that the first p exponentials have positive chirality, while the remaining $N-p$ chiralities are negative, i.e.,

$$\tau_1,\tau_2,\ldots,\tau_p>0,\quad \tau_{p+1},\tau_{p+2},\ldots,\tau_N<0, \tag{4.13}$$

where, of course, $p=0$ if all chiralities are negative, and, vice versa, $p=N$ if they are all positive. Moreover, it is expedient to label the exponentials E_n so as to order their rate of growth within each chirality group in the following way:

$$\omega_1 \sin\theta_1<\cdots<\omega_p \sin\theta_p,\quad \omega_{p+1}\sin\theta_{p+1}>\cdots>\omega_N\sin\theta_N. \tag{4.14}$$

These assumptions, together with the expression

$$M_{nn}=\tfrac{1}{2}\tau_n\eta_n \operatorname{cotg}\theta_n, \tag{4.15}$$

which follows from (4.9), (1.20), and (1.14), imply the asymptotic values

$$l=\eta_p\infty,\quad r=-\eta_{p+1}\infty \quad \text{if } 1\leqslant p\leqslant N-1, \tag{4.16a}$$

$$l=\overline{v},\quad r=-\eta_1\infty \quad \text{if } p=0, \tag{4.16b}$$

$$l=\eta_N\infty,\quad r=\overline{v} \quad \text{if } p=N. \tag{4.16c}$$

The implication of the expression (4.12) of the charge C is therefore that, if the state contains both chiralities, the charge is either vanishing or takes the elementary values $\pm C_0=\pm\pi/a$ (see (3.26)) according to the formula,

$$C=\frac{\pi}{2a}\,(\eta_p+\eta_{p+1}),\quad 1\leqslant p\leqslant N-1, \tag{4.17a}$$

while if the chiralities are all positive, or all negative, the total charge can take any value between $-C_0$ and $+C_0$, i.e., $-C_0<C<+C_0$, depending on the integration constant $\overline{v}$, the explicit expressions being [the arctg function is evaluated in the interval $(-\pi/2),(\pi/2)$]

$$C=\frac{\pi}{2a}\,\eta_1+\frac{1}{a}\operatorname{arctg}(a\overline{v}),\quad \text{if } p=0, \tag{4.17b}$$

$$C=\frac{\pi}{2a}\,\eta_N-\frac{1}{a}\operatorname{arctg}(a\overline{v}),\quad \text{if } p=N. \tag{4.17c}$$

Here, and in the following, we omit to consider states with degeneracies such as, for instance, $\omega_p \sin\theta_p=\omega_{p-1}\sin\theta_{p-1}$, and we strictly stick to the condition (4.14).

Let us proceed now to the analysis of the x-profile of the current J^μ, and to its asymptotic evolution at very large time both in the past and in the future. Since the expression (4.11) of the current is a rational function of exponentials of the form (4.3), it is easily seen that, at any fixed time t, J^μ has an exponentially localized profile in the space coordinate x, which, however complicate it may look, shows (see the orderings (4.13) and (4.14), together with (4.6) and (4.15)) the exponential tails

$$J^\mu \to \frac{4}{a^2}\ \eta_{p+1}\ \sin\ \theta_{p+1} \mathrm{tg}\theta_{p+1} k^\mu_{p+1}\ \exp[-2\ \sin\ \theta_{p+1}(\omega_{p+1}x - k_{p+1}t)], \quad x \to +\infty, \tag{4.18a}$$

$$J^\mu \to \frac{4}{a^2}\ \eta_p\ \sin\ \theta_p \mathrm{tg}\theta_p k^\mu_p\ \exp[2\ \sin\ \theta_p(\omega_p x - k_p t)], \quad x \to -\infty. \tag{4.18b}$$

These formulas hold if $1 \leqslant p \leqslant N-1$. In the case $p=0$ (all chiralities are negative, $\tau_n = -1$), the index p in (4.18b) should be replaced with N, while, if $p=N$ (all chiralities are positive, $\tau_n = +1$), the index p in (4.18a) should be formally vanished.

More interesting is the dynamical problem of the time evolution of this profile, and, particularly, the large time behavior and the breaking up processes. Our approach is standard, and we look at the asymptotic y-profile of the current $J^\mu(y+\beta t, t)$, as $t \to \pm\infty$, in a frame of reference moving with velocity β. To this aim, it is convenient to introduce the characteristic velocities

$$\beta_n = k_n/\omega_n, \quad n = 1,...,N, \tag{4.19}$$

so that the modulus of the exponentials (4.2), according to (4.3), depend on the new coordinate y and velocity β as follows:

$$|E_n| = \exp(-\tau_n \omega_n\ \sin\ \theta_n y)\exp[-\tau_n \omega_n\ \sin\ \theta_n(\beta - \beta_n)t]; \tag{4.20}$$

therefore, we conclude that, if β do not coincide with any of the characteristic velocities β_n, $n=1,2,...,N$, then the current $J^\mu(y+\beta t, t)$ [see (4.11)] vanishes as $t \to \pm\infty$ for almost all values of y. This implies that no smooth profile, with traveling speed β, shows up at large time. On the other hand, if β equals one of the velocities β_n, see (4.19), which we assume to be all different from each other for the sake of simplicity, i.e.,

$$\beta_n \neq \beta_m \quad \text{if } n \neq m, \tag{4.21}$$

then the limit state

$$J^\mu_\pm(y) = \lim_{t \to \pm\infty} J^\mu(y+\beta t, t) \tag{4.22}$$

does not vanish if β is such that either the condition

$$\tau_n(\beta - \beta_n) \geqslant 0, \quad n = 1,2,...,N \tag{4.23}$$

holds, as for the $t \to +\infty$ limit, or the condition

$$\tau_n(\beta - \beta_n) \leqslant 0, \quad n = 1,2,...,N, \tag{4.24}$$

is satisfied so as to guarantee the existence of the $t \to -\infty$ limit. In order to investigate on the existence of a velocity β which satisfies condition (4.23) or condition (4.24), we conveniently split the set $\{\beta_n\}$ of the characteristic velocities into two subsets B_+ and B_- according to their corresponding chiralities,

$$B_+ = \{\beta_n : \tau_n = +1\}, \quad B_- = \{\beta_n : \tau_n = -1\}, \tag{4.25}$$

to say that $\beta_1, \ldots, \beta_p \in B_+$ and $\beta_{p+1}, \ldots, \beta_N \in B_-$, as it follows from our ordering (4.13). In fact, it can be readily proved that, for the existence of a solution β of condition (4.23) or condition (4.24), it is necessary and sufficient, that the two sets B_+ and B_- be disjoined in the following sense. Let $\beta^{\pm}_{\max}$ and $\beta^{\pm}_{\min}$ be defined as

$$\beta^{\pm}_{\max} = \mathrm{Max}\{\beta_n\}, \quad \beta^{\pm}_{\min} = \min\{\beta_n\}, \quad \beta_n \epsilon B_{\pm}, \tag{4.26}$$

then either

$$\beta^{+}_{\max} < \beta^{-}_{\min} \quad \text{or} \quad \beta^{-}_{\max} < \beta^{+}_{\min}. \tag{4.27}$$

If this condition is not met by the set of velocities β_n, then no asymptotic profile $J^{\mu}_{\pm}(y)$, see (4.22), exists as an ordinary function of y, though an asymptotic state may appear as a Dirac distribution (see also below). In the following, we discuss only those solutions J^{μ} for which the condition (4.27) for the existence of asymptotic profiles is satisfied.

Consider first the case in which both chiralities enter in the solution, namely, $1 \leqslant p \leqslant N-1$. Assume also that, of the two possibilities (4.27), the condition

$$\beta^{+}_{\max} < \beta^{-}_{\min} \tag{4.28}$$

is satisfied. Then, while the inequality (4.24) has no solution β, both $\beta = \beta^{+}_{\max}$ and $\beta = \beta^{-}_{\min}$ satisfy the inequality (4.23). Moreover, to simplify our discussion, we can change the frame of reference by a Lorentz transformation so as to have

$$\beta^{+}_{\max} = -\overline{\beta}, \quad \beta^{-}_{\min} = \overline{\beta}, \quad \overline{\beta} > 0. \tag{4.29}$$

According to our previous considerations, we conclude that, in the present case, no y-profile asymptotically shows up at $t \to -\infty$, while, as $t \to +\infty$, two profiles separate from each other traveling with opposite velocities $\overline{\beta}$ and $-\overline{\beta}$. Since these two profiles clearly obtain from the general expression (4.11) when all exponentials, but one, disappear, at this point it is convenient to write down the expression of the current J^{μ} for $N=1$, namely the 1-soliton profile. By dropping the unnecessary index, and using the notation (1.14) and the formula (4.15), the one-soliton expression of the current (4.11) reads

$$J^{\mu}(k, \eta, \theta, \tau) = \eta \frac{\sin\,\theta}{a} k^{\mu} / (\sqrt{1 + a^2 \overline{v}^2}\, \cosh\, \xi + \eta \tau a \overline{v}), \tag{4.30}$$

where $k^{\mu} = (\omega, \kappa)$, $\omega = \sqrt{m^2 + k^2}$,

$$\xi \equiv 2\tau \sin\,\theta \epsilon_{\mu\nu} k^{\mu} (x^{\nu} - \overline{x^{\nu}}) = 2\tau \sin\,\theta\, [\omega(x - \overline{x}) - k(t - \overline{t})] = 2\tau\omega \sin\,\theta\, [x - \overline{x} - \beta(t - \overline{t})], \tag{4.31}$$

and

$$\exp(2\tau \sin\,\theta \epsilon_{\mu\nu} k^{\mu} \overline{x^{\nu}}) = \frac{a}{2} \mathrm{cotg}\,\theta |A|^2 / \sqrt{1 + a^2 \overline{v}^2}. \tag{4.32}$$

It should be noted that the profile of solitons with the same spectral parameters k and θ and integration constant $\overline{v}$ may still look different because of the relative sign $\eta\tau$ of charge and chirality, as shown by the expression of the denominator.

The total charge C of the soliton is given by the general expression (4.17), which presently reads

$$C=\frac{\pi}{2a}\,\eta-\frac{\tau}{a}\,\mathrm{arctg}(a\overline{v}), \tag{4.33}$$

while we note that, because of the arbitrariness of the parameter $\overline{v}$, the amplitude and size of the soliton are independent from each other.

Going back to our asymptotic analysis, if $1\leqslant p\leqslant N-1$, and the condition (4.28) is satisfied, see (4.29), then, as $t\to+\infty$, the nonlinear field solution breaks up into two one-soliton states,

$$J^{\mu}\to J^{\mu}(-\overline{k},\eta_{+},\theta_{+},1)+J^{\mu}(\overline{k},\eta_{-},\theta_{-},-1),\quad t\to+\infty, \tag{4.34}$$

where (see (4.19))

$$\overline{k}=m\overline{\beta}/\sqrt{1-\overline{\beta}^{2}}, \tag{4.35}$$

and η_{+}, $\theta_{+}(\eta_{-},\theta_{-})$ are the charge and spectral angle associated with the particular exponential corresponding to $-k(k)$ (note that the chiralities are, by construction, $\tau_{+}=+1$ and $\tau_{-}=-1$).

A peculiar outcome of this analysis is that the charge C does not necessarily coincide with the sum of the charges of the asymptotic one-soliton states into which the N-exponential solution (4.11) breaks. Indeed, while the total charge in the case we are considering is given by (4.17a), the sum of the charges of the two one-soliton states which appear at $t\to+\infty$, see (4.34) and (4.33), is

$$C_{+\infty}=\frac{\pi}{2a}\,(\eta_{+}+\eta_{-}), \tag{4.36}$$

$\eta+\,+\eta-$ being not necessarily equal to $\eta_{p}+\eta_{p+1}$ for $N\geqslant 3$, and on the other hand, no solitons states exist in the limit as $t\to-\infty$. This property, which is obviously due to the fact that the two limit operations as $|x|\to\infty$ and $|t|\to\infty$ do not commute with each other, does not contradict the charge conservation law as it is shown below while considering particularly simple solutions. Here we limit ourselves to noticing that a picture of the evolution of the charge density $J^{0}(x,t)$ would look like the process of creation of a couple of solitons.

The evolution is quite different if we assume instead that all chiralities are equal, say positive, so that $p=N$ (see (4.13)), while still keeping the assumption (4.14). In fact, in this case, both inequalities (4.23) and (4.24) have one, and only one, solution, namely $\beta=\beta^{+}_{\max}$ satisfies (4.23) and $\beta=\beta^{+}_{\min}$ satisfies (4.24). It is convenient to take again advantage of a Lorentz transformation to set, without any loss of generality,

$$\beta^{+}_{\min}=-\overline{\beta},\quad \beta^{+}_{\max}=\overline{\beta}>0, \tag{4.37}$$

and to use the same notation as before (and note that now the chiralities are positive, $\tau_{+}=\tau_{-}=1$). Therefore, we conclude that the two limits

$$J^{\mu}_{\pm}(y)=\lim_{t\to\pm\infty}J^{\mu}(y\pm\overline{\beta}t,t) \tag{4.38}$$

exist, and are the one-soliton solution (see (4.30))

$$J^{\mu}_{\pm}=J^{\mu}(\pm\overline{k},\eta_{\pm},\theta_{\pm},1), \tag{4.39}$$

with charge

$$C_{\pm}=\frac{\pi}{2a}\,\eta_{\pm}-\frac{1}{a}\,\mathrm{arctg}(a\overline{v}). \tag{4.40}$$

Again, we note that the charge $C_{\pm}$ of the asymptotic states may not equal the charge of the nonlinear field solution, which, according to (4.17c), reads

$$C=\frac{\pi}{2a}\,\eta_N-\frac{1}{a}\,\mathrm{arctg}(a\overline{v}). \tag{4.41}$$

Indeed, this happens if η_+ and/or η_- do not coincide with η_N, and the way the charge conservation law is not broken is discussed below. It should be also pointed out that, because of the opposite sign of the velocities of the in and out-soliton states, the nonlinear field solution pictures an object which moves like a boomerang. The dynamics in the alternative case in which all chiralities are negative, say $p=0$ (see (4.13)), looks very much the same (i.e., it describes a boomerang-type object) and does not need to be detailed.

The remaining case, in which the inequality

$$\beta^{-}_{\max}<\beta^{+}_{\min} \tag{4.42}$$

holds, instead of (4.28), is easily seen to correspond to a situation in which time is reversed. Indeed, in this case, only the condition (4.24), which implies the existence of asymptotic solitons as $t\to-\infty$, has solutions, namely $\beta=\beta^{-}_{\max}$ and $\beta=\beta^{+}_{\min}$, while the opposite condition (4.23), for the existence of solitons at $t=+\infty$, has no solution. The resulting process can be roughly described as the annihilation of two solitons. Since the analysis of this nonlinear field solution is similar to that of the creation process described above, we deem it unnecessary to discuss it any further. It is more instructive to detail the behavior of a few particularly simple solutions.

Let us consider first the zero-charge $N=2$ solution which describes the soliton–antisoliton annihilation (solitons and antisolitons are defined by the expression (4.30) with $\eta=1$ and, respectively, $\eta=-1$, so that their charge densities are positive and, respectively, negative). This is the case with $p=1$, i.e., $\tau_1=1$ and $\tau_2=-1$, and $\eta_1+\eta_2=0$ so as to have $C=0$ (see (4.17a)). The annihilation process is implied by the condition (4.42), which is satisfied with the choice

$$\beta_2=-\overline{\beta},\quad \beta_1=\overline{\beta}>0; \tag{4.43}$$

the evolution is shown in Fig. 3. The plot in Fig. 4 shows instead the soliton–antisoliton creation [with, of course, $\beta_1=-\beta$ and $\beta_2=\beta>0$, see condition (4.28)].

More illuminating, with respect to the asymptotic behavior, is the nonvanishing charge $N=2$ solution, with opposite chiralities, i.e., $p=1$. Just to be definite, let us set $\eta_1=\eta_2=1$ so that the total charge takes the elementary value, $C=C_0=(\pi/a)$ [see (4.17a)], and let us take the velocities β_1 and β_2 as in (4.43), so that the two solitons have a head-on collision and disappear since no soliton profile is found as $t\to+\infty$. Let us choose, for simplicity, the following values of the parameters: $\theta_1=\theta_2=\theta$, $A_1=A_2=1$, and note that the profiles of the two incoming solitons are different because $\eta_1\tau_1=1$ and $\eta_2\tau_2=-1$ [see (4.30)]. Then, let us compute the corresponding charge density $J^0(x,t)$, see (4.11) with (4.6) and (4.9),

$$J^0=\frac{2\overline{\omega}\cos\,\overline{\theta}(\cosh\,\xi+\cos\,\varphi)\exp(2\overline{k}\,\sin\,\overline{\theta t})}{\left\{1+a^2\left[\overline{v}+\left(\cot\mathrm{g}\,\overline{\theta}\,\sinh\,\xi+\frac{\overline{\omega}}{k}\sin\,\varphi\right)\exp(2\overline{k}\,\sin\,\overline{\theta t})\right]^2\right\}}, \tag{4.44a}$$

where we have set $(\overline{k}=\overline{\beta}\,\overline{\omega})$,

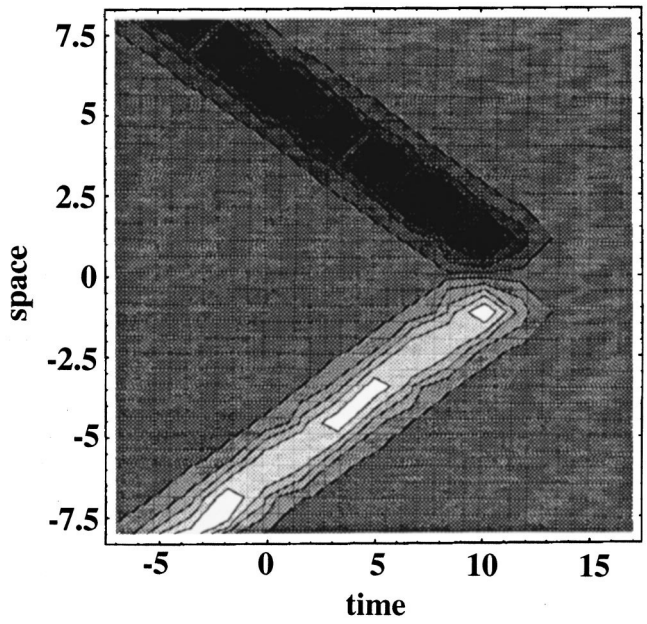

FIG. 3. Soliton–antisoliton annihilation. Contour plot of the charge density $J^0(x,t)$ for the scalar model B_2 with $a=1$, $m=1$. The parameters are $\eta_1=-\eta_2=1$, $\tau_1=-\tau_2=1$, $\theta_1=\theta_2=\pi/6$, $\beta_1=-\beta_2=2/3$, $a_1=a_2=0.8$, $\overline{v}=0$. The soliton and antisoliton have opposite charge, as shown by the grey level.

$$\xi=2\overline{\omega}\sin\overline{\theta x},\quad \varphi=2\overline{k}\cos\overline{\theta x}. \tag{4.44b}$$

It is now easy to derive from this explicit expression the asymptotic limit of $J^0(x,t)$ as $t\to+\infty$, where no soliton exists. In fact, since the function $\operatorname{cotg}\theta\sinh\xi+(\overline{\omega}/\overline{k})\sin\varphi$ in the denominator of the right-head side of (4.44a) is monotonically increasing with just one (simple) zero at $x=0$, it follows by direct computation that this limit exists as a Dirac distribution, and it is found to be

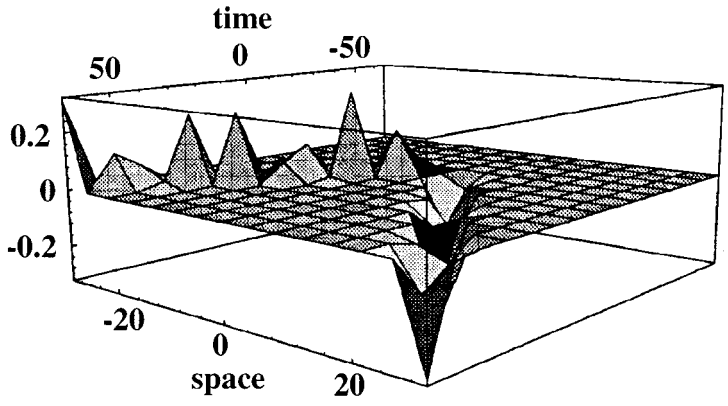

FIG. 4. Soliton–antisoliton creation. Three-dimensional plot of the charge density $J^0(x,t)$ for the scalar model B_2 with $a=1$, $m=1$. The parameters are $\eta_1=-\eta_2=-1$, $\tau_1=-\tau_2=1$, $\theta_1=\theta_2=\pi/4$, $\beta_1=-\beta_2=-1/3$, $a_1=a_2=10$, $\overline{v}=0$.

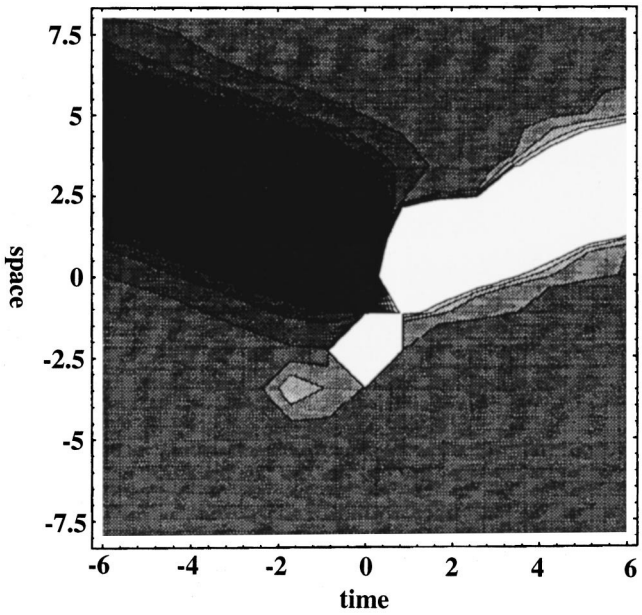

FIG. 5. Pointon absorption. Contour plot of the charge density $J^0(x,t)$ for the scalar model B_2 with $a=1$, $m=1$. Since the pointon tends to a Dirac distribution as $t\to-\infty$, its track is not visible back far in the past because of low numerical resolution. The parameters are $\eta_1=-\eta_2=1$, $\tau_1=\tau_2=1$, $\theta_1=\pi/6$, $\theta_2=\pi/3$, $\beta_1=-\beta_2=1/2$, $a_1=a_2=2$, $\overline{v}=0$. The charge of the incoming soliton is $-\pi/2$, that of the outgoing soliton is $\pi/2$, and the pointon charge is π.

$$\lim_{t\to+\infty} J^0(x,t)=\frac{\pi}{a}\,\delta(x)=C_0\delta(x). \tag{4.45}$$

This result shows that, after the collision of the two solitons, an elementary charged particle is left at rest in the origin with the remarkable property of becoming point-like as $t\to+\infty$. This mechanism of creation (annihilation) of charged point-like particles, whenever the in and out-soliton states have different charges, is quite general, and we have explicity shown it in this simple case just to avoid complicated expressions.

There are two different kinds of elementary objects in this field model, which show themselves as asymptotic states; these are the soliton, and the point-like particle, which we call ''pointon'' to stress their point-size structure. The current J^μ associated with a pointon is simply a Dirac distribution,

$$J^\mu(x,t)=\eta C_0 v^\mu \delta(\epsilon_{\alpha\beta}v^\alpha x^\beta), \tag{4.46}$$

where v^μ is its velocity vector, namely, $v^\mu=(\gamma,\beta\gamma)$ with $-1<\beta<1$ and $v^\mu\nu_\mu=1$. Of course, $\eta=1$ for pointons and $\eta=-1$ for antipointons. The process we have described above is therefore the formation of a standing pointon at the origin as a result of a two-soliton collision. The opposite process, in which two solitons appears as $t\to+\infty$, while a pointon was at the origin at $t=-\infty$, pictures instead the decay of a pointon in two solitons.

Although we leave to the interested reader the task to explore more complex solutions of our nonlinear field model, we conclude from our findings that the complex spectrum solutions break up at large $|t|$ into systems which generically may contain solitons and antisolitons together with pointons and antipointons. Two examples are shown in Figs. 5 and 6.

A quite similar analysis of complex-spectrum solutions of the spinor field models goes as well along the same lines. Since only few obvious modifications of the scalar field results are required,

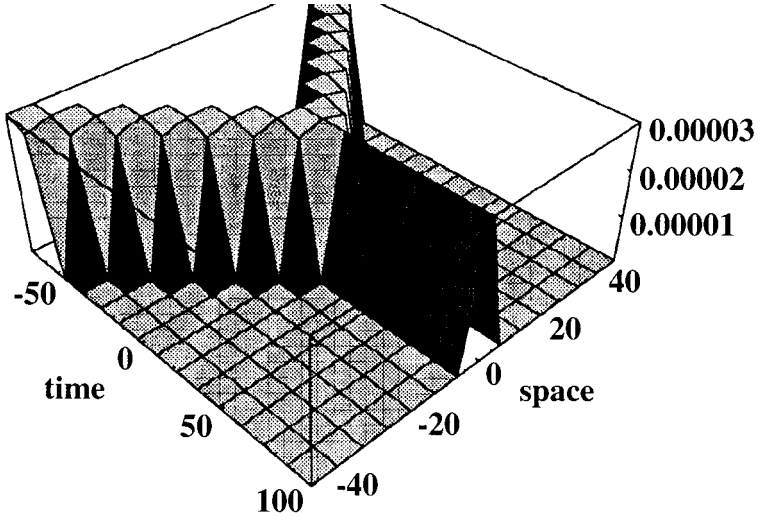

FIG. 6. Pointon creation. Three-dimensional plot of the charge density $J^0(x,t)$ for the scalar model B_2 with $a=1$, $m=1$. The charge of the two incoming solitons is $\pi/2$, and the pointon charge is π. The parameters are $\eta_1=\eta_2=1$, $\tau_1=-\tau_2=1$, $\theta_1=\theta_2=\pi/4$, $\beta_1=-\beta_2=1/2$, $a_1=a_2=0.03$, $\overline{v}=0$.

our discussion of the spinor field given below is very terse with emphasis only on the main changes. Again we consider only solutions of the model B_2, see (2.37), for which the expression of the current J^μ is still given by (4.11) with the following specifications. The spinor free field to start with is

$$\varphi=\sum_{n=1}^{N} A_n \mathscr{E}_n, \tag{4.47}$$

where A_n is an arbitrary complex number, and the elementary spinor $\mathscr{E}_n$ stands, according to our notation (1.27) with (1.18), for

$$\mathscr{E}_n=\mathscr{E}(k_n,\eta_n,\theta_n,\tau_n)=E_n\chi_n, \tag{4.48}$$

where the exponential E_n is (4.2) and χ_n is the spinor (1.28), namely,

$$\chi_n=\chi(k_n,\eta_n,\theta_n,\tau_n). \tag{4.49}$$

The free field current j^μ is easily computed, and it can be given again the expression (4.4) in vector notation, where, however, the $N\times N$ matrix $\mathbf{G}^\mu$ takes now the following form:

$$\{\mathbf{G}^\mu\}_{nm}=\Gamma_{nm}(u_n^{\mu *}+u_m^\mu), \tag{4.50}$$

where the scalar Γ_{nm} comes from the general formula (1.33), with (1.31), and its expression obtains by combining (1.34) with (1.35),

$$\Gamma_{nm}=m\,\eta_n[\cos\,\theta_n\,\cos\,\theta_m/2(m^2+\mu_{nm})]^{1/2}, \quad \eta_n\eta_m=1, \tag{4.51a}$$

$$\Gamma_{nm}=m\,\eta_n[\lambda_{nm}/(m^2+\mu_{nm})][\cos\,\theta_n\,\cos\,\theta_m/2(m^2-\mu_{nm})]^{1/2}, \quad \eta_n\eta_m=-1. \tag{4.51b}$$

Again, the relation (1.19a) leads to the integration of the differential equation (2.4), whose solution has the same expression as (4.8), where the $N\times N$ matrix $\mathbf{M}$ in the present case reads

$$\{\mathbf{M}\}_{nm}=M_{nm}=\frac{1}{i}\,\Gamma_{nm}\lambda_{nm}/(m^2-\mu_{nm}). \tag{4.52}$$

Having established these basic formulas, the following analysis of the solution (4.11) parallels that one discussed for the scalar case. Indeed, all arguments and reasonings are exactly the same, the only difference being due to the introduction of the factor Γ_{nm} in (4.50) and (4.52) (note that replacing Γ_{nm} with 1/2 reproduces the scalar field results).

The total charge is again provided by the expression (4.12); in order to evaluate the asymptotic values l and r we assume the labeling (4.13) of the chiralities τ_n, with the ordering (4.14), and we use the expression

$$M_{nn}=\tfrac{1}{2}\tau_n\ \mathrm{cotg}\ \theta_n, \tag{4.53}$$

which follows from (4.52), the previous formula (4.15), and the equality $\Gamma_{nn}=\eta_n/2$. The resulting limit values are

$$l=+\infty,\quad r=-\infty,\quad \text{if } 1\leqslant p\leqslant N-1, \tag{4.54a}$$

$$l=\overline{v},\quad r=-\infty,\quad \text{if } p=0, \tag{4.54b}$$

$$l=+\infty,\quad r=\overline{v},\quad \text{if } p=N. \tag{4.54c}$$

As a consequence of (4.12), we find that the charge of the spinor field solution is

$$C=C_0=\frac{\pi}{a},\quad 1\leqslant p\leqslant N-1 \tag{4.55a}$$

if both positive and negative chiralities are present, while in the opposite two cases

$$C=\frac{\pi}{2a}+\frac{1}{a}\,\mathrm{arctg}(a\overline{v}),\quad p=0, \tag{4.55b}$$

$$C=\frac{\pi}{2a}-\frac{1}{a}\,\mathrm{arctg}(a\overline{v}),\quad p=N. \tag{4.55c}$$

As expected from the positiveness of the charge density J^0, the total charge (4.55) is always positive. The exponential tails of the profile at fixed t, and at the leading order, are

$$J^\mu\to\frac{4}{a^2}\sin\theta_{p+1}tg\,\theta_{p+1}k^\mu_{p+1}\exp[-2\sin\theta_{p+1}(\omega_{p+1}x-k_{p+1}t)],\quad x\to+\infty, \tag{4.56a}$$

$$J^\mu\to\frac{4}{a^2}\sin\theta_p tg\,\theta_p k^\mu_p\exp[2\sin\theta_p(\omega_p x-k_p t)],\quad x\to-\infty. \tag{4.56b}$$

These expressions are valid if $1\leqslant p\leqslant N-1$. In the case $p=0$ all chiralities are negative and the index p in (4.56b) should be replaced by N; instead, if $p=N$, the asymptotic expression (4.56a) holds if one formally sets $p=0$.

The investigation of the evolution of the N-exponential solution (4.47) through the large-time asymptotic behavior of the corresponding current J^μ is the same as in the scalar case, and it is not repeated. Again, we limit our analysis to those solutions with characteristic velocities β_n which satisfy the important condition (4.27). In these cases, the asymptotic states may contain solitons

and pointons, as shown for scalar fields. As a difference with respect to scalar solitons, we note that the spinor soliton profile do not depend on the sign parameter η, its expression being

$$J^{\mu}(k,\theta,\tau)=\frac{\sin\,\theta}{a}\,k^{\mu}/(\sqrt{1+a^2\overline{v^2}}\,\cosh\,\xi+\tau a\overline{v}), \tag{4.57}$$

where ξ is specified by (4.31) and (4.32); this, of course, implies that also the charge does not depend on η,

$$C=\frac{\pi}{2a}-\frac{\tau}{a}\,\mathrm{arctg}(a\overline{v}). \tag{4.58}$$

As already pointed out, the fact that the charge has only one sign (positive) is a consequence of the commutativity of our spinor field variables, as contrasted with the theory of quantized fields.

Therefore, in the spinor field model, since only positively charged states exist, the elementary objects, which show up at large time are solitons and pointons. With the exception of those processes corresponding to solutions with vanishing charge, such as soliton–antisoliton creation and annihilation, all other reactions occurred in the scalar case such as pointon decay and formation, do also exist for spinor field solutions, and can be easily investigated by analogy.

V. CONCLUSIONS

The field models we have introduced are C-integrable, $U(1)$ invariant and relativistically invariant, and the conserved Noether current is local. The special solutions we have explicitly constructed are sufficiently representative of the main features of the models. Some of the field equations we have explicitly displayed have been chosen because their discrete spectrum solutions are free of singularities. In particular, the solutions of the model B_2 [see (2.37)] for the scalar fields $Q(x,t)$ and $V(x,t)$,

$$\Box Q+\{m^2-a^2[1+2tg^2(aV)]J_{\alpha}\,J^{\alpha}+2a\;\;\mathrm{tg}(aV)\,\epsilon^{\alpha\beta}\,\mathrm{Im}(Q_{,\alpha}Q^{*}_{,\beta})\}Q=0, \tag{5.1a}$$

$$V_{,\mu}=\epsilon_{\mu\nu}J^{\nu},\quad J_{\mu}\equiv\mathrm{Im}(QQ^{*}_{,\mu}), \tag{5.1b}$$

have been discussed in detail. In fact, each model can be given both a scalar version and a spinor version. Thus, for instance the model B_2 for the spinor field ϕ and the scalar field V is obtained by replacing Eq. (5.1) with

$$\gamma^{\mu}\phi_{,\mu}+[im+a\;\;\mathrm{tg}(aV)\,\epsilon_{\mu\nu}\gamma^{\mu}\overline{\phi}\gamma^{\nu}\phi]\phi=0, \tag{5.2a}$$

$$V_{,\mu}=\epsilon_{\mu\nu}\overline{\phi}\gamma^{\nu}\phi. \tag{5.2b}$$

The most remarkable properties of these models appear when looking at nondispersive localized solutions. Their total charge is independent on amplitude and phase, and its absolute value C_0 is characteristic of the model; for instance, for (5.1) and (5.2), $C_0=\pi/a$. Moreover, in the scalar case, the large time asymptotic analysis in the solitonic sector shows that, in addition to smooth, exponentially localized, profiles, there may appear point-like states described by Dirac distributions (pointons and antipointons). The charge carried by pointons (antipointons) turns out to be the elementary charge $C_0(-C_0)$ of the model. The dynamics described by these solutions is rather rich, and we have displayed simple instances of processes such as pair creation and annihilation, as well as pointon absorption and emission. In this respect, we find it remarkable that in our models, smooth initial conditions for the fields evolve, in the limit as $t\to\infty$, to asymptotic states containing point-like particles, whereas these objects are usually considered as foreign to field theory.

We finally observe that the class of nonlinear field models considered here, is still integratable when a parametric forcing is introduced. Indeed, in this case the nonlinear equations are mapped into linear equations with a potential term. It would therefore be of interest to introduce, both in the scalar and in the spinor case, some particular form of external potential, and to analyze the asymptotic properties of the solutions. We expect that, in analogy with the nonrelativistic case,[4] such properties should be strongly influenced by the parametric forcing. We leave this matter to future investigation.

(Received 20 October 1996; accepted for publication 10 September 1997)

We compute the functional determinant for a Dirac operator in the presence of an Abelian gauge field on a bidimensional disk, under global boundary conditions of the type introduced by Atiyah–Patodi–Singer. We also discuss the connection between our result and the index theorem. © *1998 American Institute of Physics.* [S0022-2488(97)03312-4]

I. INTRODUCTION

The wide application of functional determinants in Quantum and Statistical Physics is by now a well known fact. Typically, one is faced with the necessity of defining a regularized determinant for elliptic differential operators, among which the Dirac first order one plays a central role. An interesting related problem is the modification of physical quantities due to the presence of boundaries. The study of boundary effects has lately received much attention,[1–9] since it is of importance in many different situations, like effective models for strong interactions, quantum cosmology and application of QFT to statistical systems, among others.

In previous work,[10,11] we have studied elliptic Dirac boundary problems in the case of local boundary conditions. In particular, we have developed for this case a scheme for evaluating determinants from the knowledge of the associated Green's function, based on Seeley's theory of complex powers.[12]

Another type of boundary conditions extensively studied in the literature are global ones, of the type introduced by Atiyah, Patodi and Singer (APS)[13] in connection with the index theorem for manifolds with boundaries (see, Ref. 14, for a review.) Other motivations for considering these global (or spectral) conditions are their consistency with charge conjugation and chiral invariance, and the presence of topological obstructions for the chiral Dirac operator under local boundary conditions (although this restriction no longer holds when considering the whole Dirac operator[10]).

In this paper we present the complete evaluation of the determinant of the Dirac operator on a disk, in the presence of an axially symmetric Abelian flux, under spectral boundary conditions (see Refs. 15, 16 and references therein for related work), chosen so that they make self adjoint the operator under consideration.

In Section II we establish our conventions and set the problem to be considered.

In Section III we study zero modes and obtain the projector on the null space of the operator.

Section IV is devoted to the evaluation of the Green's function of the problem in the subspace orthogonal to such null space. The knowledge of this Green's function is necessary in the evaluation of the determinant, which is done in Section V. This evaluation is performed in two steps. The first one involves the consideration of the quotient of determinants with and without gauge field, under a fixed boundary condition. For this situation, we grow the field along a continuous path through a parameter α, and perform a point splitting regularization of the α-derivative of the logarithm of the quotient of determinants, written in terms of the Green's function.

The second step amounts to the evaluation, via ζ-function, of the quotient of the free operators under different global boundary conditions, which is possible thanks to the explicit determination of their eigenfunctions and corresponding eigenvalues.

The use of a different regularization in each step is enforced for the following reasons: In the first place, a construction of complex powers is not available for the case of spectral boundary conditions (see Ref. 18). As regards the Green's function approach, it cannot be applied to the

0022-2488/98/39(1)/532/13/$15.00
© 1998 American Institute of Physics

second step, because there is no smooth path connecting both boundary conditions.

In Section VI we discuss the application of the APS index theorem to our example, with emphasis on the effect of the boundary isomorphism σ appearing in the Dirac operator.

Finally, Section VII contains our conclusions.

II. SETTING OF THE PROBLEM

We will evaluate the determinant of the operator $D=i\not{\partial}+\not{A}$ acting on functions defined on a two dimensional disk of radius R, under APS boundary conditions.

We take A_μ to be an Abelian gauge field. As it is well known, it can be written as $A_\mu=\epsilon_{\mu\nu}\partial_\nu\phi+\partial_\mu\eta$ ($\epsilon_{01}=-\epsilon_{10}=1$). We set $\eta\equiv 0$, thus choosing the Lorentz gauge. For ϕ we take a smooth (real) bounded function $\phi=\phi(r)$; then $A_r=0$ and $A_\theta(r)=-\partial_r\phi(r)=-\phi'(r)$. We call

$$\kappa=\frac{\Phi}{2\pi}=\frac{1}{2\pi}\oint_{r=R}A_\theta R\,d\theta=-R\phi'(R). \tag{1}$$

Our convention for two dimensional Dirac matrices is

$$\gamma_0=\begin{pmatrix}0&1\\1&0\end{pmatrix},\quad \gamma_1=\begin{pmatrix}0&-i\\i&0\end{pmatrix},\quad \gamma_5=\begin{pmatrix}1&0\\0&-1\end{pmatrix}, \tag{2}$$

which satisfy

$$\gamma_\mu\gamma_\nu=\delta_{\mu\nu}I+i\epsilon_{\mu\nu}\gamma_5. \tag{3}$$

Therefore, the free Dirac operator can be written as

$$i\not{\partial}=i(\gamma_0\partial_0+\gamma_1\partial_1)=2i\begin{pmatrix}0&\dfrac{\partial}{\partial X}\\[2ex]\dfrac{\partial}{\partial X^*}&0\end{pmatrix}, \tag{4}$$

where $X=x_0+ix_1$ and $X^*=x_0-ix_1$ or, in polar coordinates

$$i\not{\partial}=i\left(\gamma_r\partial_r+\frac{1}{r}\gamma_\theta\partial_\theta\right), \tag{5}$$

with

$$\gamma_r=e^{-i\gamma_5\theta}\gamma_0=\begin{pmatrix}0&e^{-i\theta}\\e^{i\theta}&0\end{pmatrix},\quad \gamma_\theta=e^{-i\gamma_5\theta}\gamma_1=\begin{pmatrix}0&-ie^{-i\theta}\\ie^{i\theta}&0\end{pmatrix}. \tag{6}$$

With these conventions, the full Dirac operator can be written as

$$D=e^{-\gamma_5\phi(r)}\,i\not{\partial}e^{-\gamma_5\phi(r)}=\begin{pmatrix}0&\sigma^{-1}(\partial_r+B)\\\sigma(-\partial_r+B)&0\end{pmatrix}, \tag{7}$$

with

$$\sigma=-ie^{i\theta}, \tag{8}$$

and

$$B(r)=-\frac{i}{r}\partial_\theta+\partial_r\phi(r). \tag{9}$$

At the boundary, the self adjoint operator $B(r)$ becomes

$$B\equiv B(R)=-\frac{1}{R}[i\partial_\theta+\kappa], \tag{10}$$

with eigenvectors $e^{in\theta}$ and eigenvalues $(1/R)(n-\kappa)$. We take the radial variable to be conveniently adimensionalized through multiplication by a fixed constant with dimensions of mass.

We will consider the action of the differential operator D on the space of functions satisfying global boundary conditions, characterized by

$$(\mathscr{P}_{\geqslant}\quad \sigma(1-\mathscr{P}_{\geqslant})\sigma^*)\begin{pmatrix}\varphi(R,\theta)\\ \chi(R,\theta)\end{pmatrix}=0, \tag{11}$$

with

$$\mathscr{P}_{\geqslant}=\frac{1}{2\pi}\sum_{n\geqslant k+1} e^{in\theta}\langle e^{in\theta},\cdot\rangle, \tag{12}$$

where k is the integer such that $k<\kappa\leqslant k+1$. Notice that

$$\sigma(1-\mathscr{P}_{\geqslant})\sigma^*=\sigma\,\mathscr{P}_{<}\,\sigma^*=\frac{1}{2\pi}\sum_{n\leqslant k+1} e^{in\theta}\langle e^{in\theta},\cdot\rangle=\mathscr{P}_{\leqslant} \tag{13}$$

and the operator so defined, $(D)_\kappa$, turns out to be self adjoint. The presence of σ as in (11) has a relevant consequence on the boundary conditions for the lower components. As we will discuss later, this also reflects on the form of the index theorem for the present situation.

Our aim is to compute the quotient of the determinants of the operators $(D)_\kappa$ and $(i\not\partial)_{\kappa=0}$. Since the global boundary conditions in Eq. (11) depend on the flux Φ as a step function, there is no continuous family connecting both operators. So, we will proceed in two steps:

$$(D)_\kappa\rightarrow(i\not\partial)_\kappa\rightarrow(i\not\partial)_{\kappa=0}. \tag{14}$$

In the first step, where there is no change of boundary conditions, we can grow the gauge field by varying α from 0 to 1 in

$$D_\alpha=i\not\partial+\alpha\not{A}=e^{-\alpha\gamma_5\phi(r)}i\not\partial e^{-\alpha\gamma_5\phi(r)},\ \text{ with }\ 0\leqslant\alpha\leqslant1, \tag{15}$$

thus going smoothly from the free to the full Dirac operator. The explicit knowledge of the Green's function will allow us to perform the calculation of this step, where we will use a gauge invariant point splitting regularization of the α-derivative of the determinant. The second step will be achieved by using a ζ-function regularization, after explicitly computing the spectra.

But this is not the whole story: As we are going to see, these global boundary conditions give rise to the presence of zero modes, which must be taken into account.

III. ZERO MODES

We will here show that the operator $(D_\alpha)_\kappa$ has $|k+1|$ zero modes.

From (7), we get

$$D_\alpha\psi=0\Leftrightarrow\not\partial e^{-\alpha\gamma_5\phi(r)}\psi=0, \tag{16}$$

or, equivalently

$$\begin{pmatrix} 0 & e^{-i\theta}\left(\partial_r - \frac{i}{r}\partial_\theta\right) \\ e^{i\theta}\left(\partial_r + \frac{i}{r}\partial_\theta\right) & 0 \end{pmatrix} \begin{pmatrix} e^{-\alpha\phi(r)} & 0 \\ 0 & e^{\alpha\phi(r)} \end{pmatrix} \begin{pmatrix} \varphi(r,\theta) \\ \chi(r,\theta) \end{pmatrix} = 0. \tag{17}$$

Now, we introduce the expansions

$$\varphi(r,\theta) = \sum_{n=-\infty}^{\infty} \varphi_n(r) e^{in\theta}, \quad \chi(r,\theta) = \sum_{n=-\infty}^{\infty} \chi_n(r) e^{in\theta}. \tag{18}$$

The solutions are thus given by

$$\varphi_n(r) = a_n r^n e^{\alpha\phi(r)}, \quad \chi_n(r) = b_n r^{-n} e^{-\alpha\phi(r)}, \tag{19}$$

where the coefficients a_n and b_n are to be determined from the regularity requirement at the origin and the boundary conditions at $r=R$, Eq. (11). Thus

$$\begin{aligned} \varphi(r,\theta) &= e^{\alpha\phi(r)} \sum_{n=0}^{k} a_n r^n e^{in\theta}, \quad \text{for } k \geqslant 0, \\ \chi(r,\theta) &= e^{-\alpha\phi(r)} \sum_{n=0}^{-k-2} b'_n r^n e^{-in\theta}, \quad \text{for } k < -1. \end{aligned} \tag{20}$$

Then, there are $|k+1|$ zero modes which, once normalized, are given by

$$\begin{aligned} &\frac{e^{\alpha\phi(r)}}{\sqrt{2\pi q_n(R;\alpha)}} \begin{pmatrix} X^n \\ 0 \end{pmatrix}, \quad \text{for } 0 \leqslant n \leqslant k, \quad \text{if } k \geqslant 0; \\ &\frac{e^{-\alpha\phi(r)}}{\sqrt{2\pi p_n(R;\alpha)}} \begin{pmatrix} 0 \\ X^{*n} \end{pmatrix}, \quad \text{for } 0 \leqslant n \leqslant -k-2, \quad \text{if } k < -1. \end{aligned} \tag{21}$$

Here, the normalization factors are

$$q_n(u;\alpha) = \int_0^u e^{2\alpha\phi(r)} r^{2n+1} dr, \quad p_n(u;\alpha) = \int_0^u e^{-2\alpha\phi(r)} r^{2n+1} dr. \tag{22}$$

Notice that, for $k=-1$ (in particular, when $\Phi=0$), there is no zero mode.

So, the kernel of the orthogonal projector on $\mathrm{Ker}(D_\alpha)_\kappa$ is

$$\begin{aligned} P_\alpha(x,y) &= \sum_{n=0}^{k} \frac{e^{\alpha[\phi(|X|)+\phi(|Y|)]}}{2\pi q_n(R;\alpha)} \begin{pmatrix} (XY^*)^n & 0 \\ 0 & 0 \end{pmatrix}, \quad \text{if } k \geqslant 0, \\ P_\alpha(x,y) &= \sum_{n=0}^{-k-2} \frac{e^{-\alpha[\phi(|X|)+\phi(|Y|)]}}{2\pi p_n(R;\alpha)} \begin{pmatrix} 0 & 0 \\ 0 & (X^*Y)^n \end{pmatrix}, \quad \text{if } k < -1. \end{aligned} \tag{23}$$

Since P_α is an orthogonal projector, $P_\alpha^2 = P_\alpha$, we have

$$(\partial_\alpha P_\alpha)(1-P_\alpha) = P_\alpha(\partial_\alpha P_\alpha). \tag{24}$$

Being $(D_\alpha+P_\alpha)_\kappa$ invertible, we can define

$$\mathrm{Det}'(D_\alpha)_\kappa \equiv \mathrm{Det}(D_\alpha+P_\alpha)_\kappa, \tag{25}$$

and write

$$\frac{\mathrm{Det}'(D)_\kappa}{\mathrm{Det}(i\partial\!\!\!/)_{\kappa=0}} = \frac{\mathrm{Det}(D+P_1)_\kappa}{\mathrm{Det}(i\partial\!\!\!/+P_0)_\kappa}\,\frac{\mathrm{Det}(i\partial\!\!\!/+P_0)_\kappa}{\mathrm{Det}(i\partial\!\!\!/)_{\kappa=0}}. \tag{26}$$

As mentioned above, we can compute

$$\frac{\partial}{\partial\alpha}[\ln\,\mathrm{Det}(D_\alpha+P_\alpha)_\kappa] = \mathrm{Tr}[(\mathcal{A}+\partial_\alpha P_\alpha)G_\alpha], \tag{27}$$

after determining the Green's function $G_\alpha(x,y)$ satisfying

$$(D_\alpha+P_\alpha)G_\alpha(x,y)=\delta(x,y), \quad (\mathscr{P}_{\geqslant} \quad \mathscr{P}_{\leqslant})G_\alpha(x,y)\big|_{r=R}=0, \tag{28}$$

and applying a regularization prescription to the trace in (27). Then, by integrating in α from 0 to 1 we will get the first quotient in the r.h.s. of (26).

The computation of this Green's function will be the subject of the next section.

IV. CALCULATION OF THE GREEN'S FUNCTION

Notice that, since $(D_\alpha)_\kappa$ is self adjoint, we can write

$$G_\alpha=(1-P_\alpha)\mathscr{G}_\alpha(1-P_\alpha)+P_\alpha, \tag{29}$$

where $\mathscr{G}_\alpha(x,y)$ is the kernel of the right-inverse of $(D_\alpha)_\kappa$ on the orthogonal complement of $Ker(D_\alpha)_\kappa$. From Eq. (7), it is easy to see that $\mathscr{G}_\alpha(x,y)$ can be obtained by solving the differential equation

$$i\partial\!\!\!/\begin{pmatrix}\varphi\\ \chi\end{pmatrix}=\begin{pmatrix}f\\ g\end{pmatrix}, \tag{30}$$

for $\binom{\chi}{\varphi}$ satisfying

$$(\mathscr{P}_{\geqslant} \quad \mathscr{P}_{\leqslant})e^{\alpha\gamma_5\phi(R)}\begin{pmatrix}\varphi\\ \chi\end{pmatrix}=0. \tag{31}$$

Let us start by considering functions f and g identically vanishing in a neighbourhood of $r=0$. We expand

$$\begin{aligned}\varphi(r,\theta)&=\sum\ \varphi_n(r)e^{in\theta}, \quad \chi(r,\theta)=\sum\ \chi_n(r)e^{in\theta}\\ f(r,\theta)&=\sum\ f_n(r)e^{in\theta}, \quad g(r,\theta)=\sum\ g_n(r)e^{in\theta}.\end{aligned} \tag{32}$$

Equation (30) together with the boundary conditions at $r=R$ (Eq. (31)) and at $r=0$ (regularity), univocally determine the φ_n's (χ_n's) in terms of the f_n's (g_n's), except for $|k+1|$ of them, which correspond to the zero modes of the system. We chose the particular solution

$$\varphi(r,\theta)=i\sum_{n\geqslant k+1}e^{in\theta}r^n\int_r^R dr'(r')^{-n}g_{n+1}(r')-i\sum_{n\leqslant k}e^{in\theta}r^n\int_0^r dr'(r')^{-n}g_{n+1}(r')$$
$$=\frac{i}{2\pi}\int_r^R dr'\int_0^{2\pi}d\theta'\sum_{n\geqslant k+1}e^{in(\theta-\theta')}\left(\frac{r}{r'}\right)^n e^{-i\theta'}g(r',\theta')$$
$$-\frac{i}{2\pi}\int_0^r dr'\int_0^{2\pi}d\theta'\sum_{n\leqslant k}e^{in(\theta-\theta')}\left(\frac{r}{r'}\right)^n e^{-i\theta'}g(r',\theta'),\tag{33}$$

and

$$\chi(r,\theta)=\frac{i}{2\pi}\int_r^R dr'\int_0^{2\pi}d\theta'\sum_{n\leqslant k+1}e^{in(\theta-\theta')}\left(\frac{r'}{r}\right)^n e^{i\theta'}f(r',\theta')$$
$$-\frac{i}{2\pi}\int_0^r dr'\int_0^{2\pi}d\theta'\sum_{n\geqslant k+2}e^{in(\theta-\theta')}\left(\frac{r'}{r}\right)^n e^{i\theta'}f(r',\theta').\tag{34}$$

Therefore, calling

$$\mathscr{G}^{(0)}(x,y)=\frac{1}{2\pi i}\begin{pmatrix}0 & \dfrac{1}{X-Y}\left(\dfrac{X}{Y}\right)^{k+1}\\ \dfrac{1}{X^*-Y^*}\left(\dfrac{Y^*}{X^*}\right)^{k+1} & 0\end{pmatrix},\tag{35}$$

we have

$$\begin{pmatrix}\varphi\\ \chi\end{pmatrix}(x)=\int d^2y\,\mathscr{G}^{(0)}(x,y)\begin{pmatrix}f\\ g\end{pmatrix}(y).\tag{36}$$

The particular solution in (33) and (34) makes $\mathscr{G}^{(0)}(x,y)$ Hermitian (although this will prove to be not essential).

Notice that $\binom{\varphi}{\chi}$ so constructed, satisfying Eq.(31), is neither in $[\mathrm{Ker}((D_\alpha)_\kappa e^{\alpha\gamma_5\phi})]^\perp$, nor in L_2 for arbitrary $\binom{f}{g}$ (as expected from the existence of zero modes).

Restricting $\binom{\varphi}{\chi}$ to $[\mathrm{Ker}((D_\alpha)_\kappa e^{\alpha\gamma_5\phi})]^\perp$ and $\binom{f}{g}$ to $[\mathrm{Ker}((D_\alpha)_\kappa e^{-\alpha\gamma_5\phi})]^\perp$ corresponds to the composition

$$\mathscr{G}_\alpha=(1-P_\alpha)e^{\alpha\gamma_5\phi}\mathscr{G}^{(0)}e^{\alpha\gamma_5\phi}(1-P_\alpha),\tag{37}$$

which is an integral operator with locally integrable kernel (an anti-diagonal matrix whose only singularity is at $Y=X$). It is worth to stress that, due to the presence of the projector $(1-P_\alpha)$, $\mathscr{G}_\alpha$ is independent of the particular choice made in (33) and (34).

The addition of P_α [Eq. (23)] leads, for $k\geqslant 0$, to

$$G_\alpha(x,y)$$
$$=\frac{1}{2\pi i}\begin{pmatrix}ie^{\alpha[\phi(|X|)+\phi(|Y|)]}\displaystyle\sum_{n=0}^{k}\frac{(XY^*)^n}{q_n(R;\alpha)} & e^{\alpha[\phi(|X|)-\phi(|Y|)]}\left[\dfrac{1}{X-Y}+\dfrac{1}{Y}\displaystyle\sum_{n=0}^{k}\left(\frac{X}{Y}\right)^n\frac{q_n(|Y|;\alpha)}{q_n(R;\alpha)}\right]\\ e^{-\alpha[\phi(|X|)-\phi(|Y|)]}\left[\dfrac{1}{X^*-Y^*}-\dfrac{1}{X^*}\displaystyle\sum_{n=0}^{k}\left(\frac{Y^*}{X^*}\right)^n\frac{q_n(|X|;\alpha)}{q_n(R;\alpha)}\right] & 0\end{pmatrix},\tag{38}$$

which is the inverse of $(D_\alpha+P_\alpha)_\kappa$, as can be easily verified by direct inspection. For the $k<-1$ case, we get

$$G_\alpha(x,y) = \frac{1}{2\pi i}\begin{pmatrix} 0 & e^{\alpha[\phi(|X|)-\phi(|Y|)]}\left[\frac{1}{X-Y}-\frac{1}{X}\sum_{n=0}^{-k-2}\left(\frac{Y}{X}\right)^n\frac{p_n(|X|;\alpha)}{p_n(R;\alpha)}\right] \\ e^{-\alpha[\phi(|X|)-\phi(|Y|)]}\left[\frac{1}{X^*-Y^*}+\frac{1}{Y^*}\sum_{n=0}^{-k-2}\left(\frac{X^*}{Y^*}\right)^n\frac{p_n(|Y|;\alpha)}{p_n(R;\alpha)}\right] & ie^{-\alpha[\phi(|X|)+\phi(|Y|)]}\sum_{n=0}^{-k-2}\frac{(X^*Y)^n}{p_n(R;\alpha)} \end{pmatrix}. \tag{39}$$

V. EVALUATION OF THE DETERMINANT

Now we have all the necessary elements to compute the first quotient in the r.h.s. of Eq. (26). In fact, from Eqs. (29) and (24)

$$\mathrm{Tr}[(\partial_\alpha P_\alpha)G_\alpha]=0. \tag{40}$$

So, Eq. (27) becomes

$$\frac{\partial}{\partial\alpha}[\ln\,\mathrm{Det}(D_\alpha+P_\alpha)_\kappa]=\mathrm{Tr}[\not{A}G_\alpha]. \tag{41}$$

As usual, the kernel of the operator inside the trace is singular at the diagonal, so we must introduce a regularization. We will employ a point-splitting one where, following Schwinger,[17] we will introduce a phase factor in order to preserve gauge invariance. For $k\geqslant 0$, from (38), we take

$$\begin{aligned}\mathrm{Tr}[\not{A}G_\alpha] &\equiv \mathrm{Reg.Part}\left\{\int_{r<R} d^2x\ \mathrm{tr}[\not{A}(x)G_\alpha(x,x+\epsilon)e^{i\alpha(\epsilon_r A_r(x)+\epsilon_\theta A_\theta(x))}]\right\}_{\epsilon\to 0}\\ &= -\frac{1}{2\pi}\mathrm{Reg.Part}\int_{r<R} d^2x\ \phi'(r)\left\{e^{-i\theta}e^{\alpha\phi'(r)[\epsilon_r-i\epsilon_\theta]}\left[\frac{e^{i\theta}}{\epsilon_r-i\epsilon_\theta}+\frac{1}{X^*}\sum_{n=0}^{k}\frac{q_n(|X|;\alpha)}{q_n(R;\alpha)}\right.\right.\\ &\quad\left.+O(\epsilon)\right]+e^{i\theta}e^{-\alpha\phi'(r)[\epsilon_r+i\epsilon_\theta]}\left[-\frac{e^{-i\theta}}{\epsilon_r+i\epsilon_\theta}+\frac{1}{X}\sum_{n=0}^{k}\frac{q_n(|X|;\alpha)}{q_n(R;\alpha)}+O(\epsilon)\right]\Bigg\}_{\epsilon\to 0}\\ &= \mathrm{Reg.Part}\left\{-\left[\frac{2i\epsilon_\theta}{\epsilon_r^2+\epsilon_\theta^2}\right]\int_0^R dr\ r\phi'(r)-\frac{\alpha}{\pi}\int_{r<R} d^2x\phi'^2-2(k+1)\phi(R)\right.\\ &\quad\left.+\sum_{n=0}^{k}\frac{\partial}{\partial\alpha}\ln[q_n(R;\alpha)]\right\}_{\epsilon\to 0}.\end{aligned} \tag{42}$$

The regular part at $\epsilon=0$ drops out the first term and, integrating in α from 0 to 1, we get

$$\ln\left[\frac{\mathrm{Det}(D+P_1)_\kappa}{\mathrm{Det}(i\not{\partial}+P_0)_\kappa}\right]=-\frac{1}{2\pi}\int_{r<R} d^2x\phi'^2-2(k+1)\phi(R)+\sum_{n=0}^{k}\ln\left[2(n+1)\frac{q_n(R;1)}{R^{2(n+1)}}\right]. \tag{43}$$

When there are no zero modes ($k+1=0$) only the first term in the r.h.s. survives. For $k<-1$, from (40), one gets a similar expression where the sum runs from 0 to $-k-2=|k+1|-1$, and the norms q_n are replaced by p_n, defined in Eq. (22). This result can also be obtained by performing the change $\phi\to-\phi$ and $k+1\to-(k+1)$. Moreover, as expected from (7), this expression is invariant under the shift $\phi(r)\to\phi(r)+\epsilon$, for any constant ϵ.

In the following, we will obtain the second quotient of determinants in Eq. (26) by computing explicitly the spectra of the free Dirac operators and using a ζ-function regularization. The equation to be solved is

$$i\not{\partial}\psi=\lambda\psi, \tag{44}$$

or, explicitly

$$i\begin{pmatrix} 0 & e^{-i\theta}\left(\partial_r-\frac{i}{r}\partial_\theta\right) \\ e^{i\theta}\left(\partial_r+\frac{i}{r}\partial_\theta\right) & 0 \end{pmatrix}\begin{pmatrix}\varphi(r,\theta)\\ \chi(r,\theta)\end{pmatrix}=\lambda\begin{pmatrix}\varphi(r,\theta)\\ \chi(r,\theta)\end{pmatrix}. \tag{45}$$

Now, by expanding

$$\varphi(r,\theta)=\sum_{n=-\infty}^{\infty}\varphi_n(r)e^{in\theta},\quad \chi(r,\theta)=\sum_{n=-\infty}^{\infty}\chi_n(r)e^{in\theta}, \tag{46}$$

we get

$$\begin{aligned} i\varphi_n'(z)-i\frac{n}{z}\varphi_n(z)&=\frac{\lambda}{|\lambda|}\chi_{n+1}(z),\\ i\chi_{n+1}'(z)+i\frac{(n+1)}{z}\chi_{n+1}(z)&=\frac{\lambda}{|\lambda|}\varphi_n(z), \end{aligned} \tag{47}$$

where $z=|\lambda|r$. So, $\varphi_n(z)$ satisfies

$$\varphi_n''(z)+\frac{1}{z}\varphi_n'(z)+\left(1-\frac{n^2}{z^2}\right)\varphi_n(z)=0. \tag{48}$$

Therefore, the general solution of Eq. (46) is

$$\psi(r,\theta)=\sum_{n=-\infty}^{\infty}\psi_n\begin{pmatrix} J_n(|\lambda|r)e^{in\theta}\\ -i\frac{|\lambda|}{\lambda}J_{n+1}(|\lambda|r)e^{i(n+1)\theta}\end{pmatrix}. \tag{49}$$

Now, by imposing the global boundary conditions given in Eq. (11), it follows that: If $n\geqslant k+1$, the upper component must vanish at the boundary, which implies $\lambda=\pm j_{n,l}/R$ ($j_{n,l}$ is the l-th zero of $J_n(z)$). Analogously, if $n\leqslant k$, it is the lower component which must vanish, and so $\lambda=\pm j_{n+1,l}/R$. Therefore, the eigenvalues are

$$\lambda_{n,l}=\pm j_{n,l}/R,\quad \text{for } n=0,\pm1,\pm2,\ \ldots \quad \text{and } l=1,2,\ \ldots\ . \tag{50}$$

Notice that $j_{-n,l}=j_{n,l}$, and that, for $n=k+1$ the eigenvalues appear twice, once for an eigenfunction with vanishing upper component at the boundary, and once for another one with vanishing lower component.

From these eigenvalues we can construct the ζ-function

$$\zeta_{(i\not{\partial}+P_0)_\kappa}(s)=|k+1|+(1+e^{-i\pi s})\left\{\sum_{n=-\infty}^{n=\infty}\sum_{l=1}^{\infty}\left(\frac{j_{n,l}}{R}\right)^{-s}+\sum_{l=1}^{\infty}\left(\frac{j_{|k+1|,l}}{R}\right)^{-s}\right\}. \tag{51}$$

The first term, $|k+1|$, is the multiplicity of the 0-eigenvalue of $(i\partial\!\!\!/)_\kappa$. It is also interesting to note that the double sum in the r.h.s. (which is independent of k) corresponds to the ζ-function of the Laplacian on a disk with Dirichlet boundary conditions, thus being analytic at $s=0$.[12] The second sum, to be explicitly computed below, is regular at $s=0$. Then $\zeta_{(i\partial\!\!\!/+P_0)_\kappa}(s)$ is regular at the origin. As far us we know, the regularity of the ζ at the origin for non local boundary conditions has not been established in general.[18]

From (52), we can write

$$\begin{aligned}\ln\left[\frac{\mathrm{Det}(i\partial\!\!\!/+P_0)_\kappa}{\mathrm{Det}(i\partial\!\!\!/)_{\kappa=0}}\right] &= -\frac{d}{ds}[\zeta_{(i\partial\!\!\!/+P_0)_\kappa}(s)-\zeta_{(i\partial\!\!\!/)_{\kappa=0}}(s)]_{s=0}\\ &= -\frac{d}{ds}\left[(1+e^{-i\pi s})R^s\left\{\sum_{l=1}^{\infty}(j_{|k+1|,l})^{-s}-\sum_{l=1}^{\infty}(j_{0,l})^{-s}\right\}\right]_{s=0}\\ &= -2\left[f'_{|k+1|}(0)-f'_0(0)+\left(\ln R-\frac{i\pi}{2}\right)[f_{|k+1|}(0)-f_0(0)]\right],\end{aligned} \tag{52}$$

where the function f is defined as

$$f_\nu(s)\equiv\sum_{l=1}^{\infty}(j_{\nu,l})^{-s}. \tag{53}$$

Taking into account the asymptotic expansion for the zeros of Bessel functions[19]

$$(j_{\nu,l})^{-s}-(l\pi)^{-s}+s\left(\frac{2\nu-1}{4}\right)\pi(l\pi)^{-s-1}\sim sO(l^{-s-2}), \tag{54}$$

we can write

$$f_\nu(s)=\sum_{l=1}^{\infty}\left[(j_{\nu,l})^{-s}-(l\pi)^{-s}+s\left(\frac{2\nu-1}{4}\right)\pi(l\pi)^{-s-1}\right]+\pi^{-s}\left[\zeta(s)-s\left(\frac{2\nu-1}{4}\right)\zeta(s+1)\right], \tag{55}$$

where $\zeta(s)$ is Riemann's ζ-function. By (55), the first series converges for Re $s>-1$, and equals 0 at $s=0$. Thus

$$f_\nu(0)=-\frac{\nu}{2}-\frac{1}{4}, \tag{56}$$

and

$$f'_\nu(0)=-\frac{1}{2}\ln 2+\left(\frac{2\nu-1}{4}\right)(\ln\pi-\gamma)-\sum_{l=1}^{\infty}\ln\left[\frac{j_{\nu,l}}{l\pi}e^{-([2\nu-1/4l])}\right], \tag{57}$$

where γ is Euler's constant. By replacing Eqs. (57) and (58) into Eq. (53), we get

$$\ln\left[\frac{\mathrm{Det}(i\partial\!\!\!/+P_0)_\kappa}{\mathrm{Det}(i\partial\!\!\!/)_{\kappa=0}}\right]=-|k+1|\left[\frac{i\pi}{2}-\gamma-\ln\left(\frac{R}{\pi}\right)\right]+2\sum_{l=1}^{\infty}\ln\left[\frac{j_{|k+1|,l}}{j_{0,l}}e^{-([|k+1|/2l])}\right]. \tag{58}$$

Finally, adding (44) and (59), and taking into account that we have used a gauge invariant procedure, we obtain for the quotient in the l.h.s. of (26)

$$\ln\left[\frac{\mathrm{Det}(D+P_1)_\kappa}{\mathrm{Det}(i\partial\!\!\!/)_{\kappa=0}}\right]=-\frac{1}{2\pi}\int_{|x|<R}\int_{|y|<R}d^2x\ d^2y A_\mu(x)[\delta_{\mu\nu}\delta(x-y)-\partial_\mu\partial_\nu\partial^{-2}(x-y)]A_\nu(y)$$
$$-2(k+1)\phi(R)+\sum_{n=0}^{k}\ln\left[2(n+1)\frac{q_n(R;1)}{R^{2(n+1)}}\right]-|k+1|\left[\frac{i\pi}{2}-\gamma-\ln\left(\frac{R}{\pi}\right)\right]$$
$$+2\sum_{l=1}^{\infty}\ln\left[\frac{j_{|k+1|,l}}{j_{0,l}}e^{-(|k+1|/2l)}\right]. \tag{59}$$

The first term is the integral on the disk of the same expression appearing in the well-known result for the boundaryless case.[20] Note that this final result is also invariant under the transformation: $\phi\to\phi+\epsilon$ for any constant ϵ.

Now, a comment is in order concerning global axial transformations and their relationship to zero modes. Under such a transformation, with constant ϵ,

$$e^{-\gamma_5\epsilon}(i\partial\!\!\!/)_{\kappa=0}e^{-\gamma_5\epsilon}=(i\partial\!\!\!/)_{\kappa=0} \tag{60}$$

is invariant. Moreover

$$e^{-\gamma_5\epsilon}(D+P_1)_\kappa e^{-\gamma_5\epsilon}=(D+e^{-\gamma_5\epsilon}P_1e^{-\gamma_5\epsilon})_\kappa, \tag{61}$$

while its inverse has the structure

$$G^{(\epsilon)}(x,y)=(1-P_1)\mathcal{G}(x,y)(1-P_1)+e^{\gamma_5\epsilon}P_1\ e^{\gamma_5\epsilon}. \tag{62}$$

Therefore, since γ_5 leaves Ker $(D)_\kappa$ invariant,

$$\frac{\partial}{\partial\epsilon}\ln\left[\frac{\mathrm{Det}(e^{-\gamma_5\epsilon}(D+P_1)_\kappa e^{-\gamma_5\epsilon})}{\mathrm{Det}(e^{-\gamma_5\epsilon}(i\partial\!\!\!/)_{\kappa=0}e^{-\gamma_5\epsilon})}\right]=-\mathrm{Tr}[e^{-\gamma_5\epsilon}\{\gamma_5,P_1\}e^{-\gamma_5\epsilon}G^{(\epsilon)}]$$
$$=-2\ \mathrm{Tr}[\gamma_5P_1]=-2(N_+-N_-), \tag{63}$$

where $N_{+(-)}$ is the number of positive(negative) chirality zero modes.

It can be verified that our strategy leads to the correct result for the index of $(D)_\kappa$. By following the same procedure that lead to Eq. (60), we can compute the quotient of determinants in the l.h.s of (64). In fact, using Eq. (63) instead of Eq. (29), the only difference appears in the first term of the r.h.s. of (52), where a factor $e^{\pm 2\epsilon s}$ arises. Thus, after performing the ϵ-derivative

$$N_+-N_-=k+1, \tag{64}$$

which agrees with our previous result for the number of zero modes.

For the sake of completeness, in the next section we will show how the presence of the σ's in (7) and (11) affects the index theorem.

VI. RELATION TO THE INDEX THEOREM

Here we will reobtain the index by following the Atiyah–Patodi–Singer approach.[13]

The Dirac operator in polar coordinates can also be written as[15,16]

$$D=\frac{1}{\sqrt{r}}\begin{pmatrix}0 & e^{-i\theta/2}(\partial_r+B)e^{-i\theta/2}\\ e^{i\theta/2}(-\partial_r+B)e^{i\theta/2} & 0\end{pmatrix}\sqrt{r}, \tag{65}$$

subject to the boundary conditions in Eq. (11). It is to be stressed that the presence of the factors $e^{\pm i\theta/2}$ coming from the σ's will produce a departure from the index formula in Ref. 13.

To be be consistent with (11) we call $\mathscr{D}$ the differential operator $(-\partial_r+B)$ acting on functions

$$f(r,\theta)=\sum_{n=-\infty}^{\infty} f_n(r)e^{i(n+1/2)\theta} \tag{66}$$

satisfying

$$\mathscr{P}_{\geqslant}[e^{-i\theta/2}f(R,\theta)]=0. \tag{67}$$

Its adjoint, $\mathscr{D}^+$, is the differential operator (∂_r+B) defined on the space of functions

$$g(r,\theta)=\sum_{n=-\infty}^{\infty} g_n(r)e^{i(n-1/2)\theta} \tag{68}$$

satisfying

$$\mathscr{P}_{\leqslant}[e^{i\theta/2}g(R,\theta)]=0. \tag{69}$$

Then $D^+D=(1/\sqrt{r})\,e^{-i\theta/2}\,\mathscr{D}^+\mathscr{D}\,e^{i\theta/2}\sqrt{r}$, where $\mathscr{D}^+\mathscr{D}=-\partial_r^2+B^2$ acting on functions satisfying

$$\begin{cases}\mathscr{P}_{\geqslant}[e^{-i\theta/2}f(R,\theta)]=0,\\ \mathscr{P}_{\leqslant}[e^{i\theta/2}\mathscr{D}f(R,\theta)]=0,\end{cases} \tag{70}$$

or, equivalently,

$$\begin{cases} f_n(R)=0, & \text{for } n\geqslant k+1\\ -f_n'(R)+\dfrac{n+1/2-\kappa}{R}f_n(R)=0, & \text{for } n\leqslant k.\end{cases} \tag{71}$$

Similarly, $\mathscr{D}\mathscr{D}^+=-\partial_r^2+B^2$ acting on functions $g(r,\theta)$ satisfying

$$\begin{cases} g_n(R)=0, & \text{for } n\leqslant k+1\\ g_n'(R)+\dfrac{n+1/2-\kappa}{R}g_n(R)=0, & \text{for } n\geqslant k+2.\end{cases} \tag{72}$$

Now, we have for the heat kernels

$$\mathrm{Tr}\{e^{-tD^+D}\}-\mathrm{Tr}\{e^{-tDD^+}\}=\mathrm{Tr}\{e^{-t\mathscr{D}^+\mathscr{D}}\}-\mathrm{Tr}\{e^{-t\mathscr{D}\mathscr{D}^+}\}. \tag{73}$$

When written in this fashion, the boundary contribution to the r.h.s. in (73), $K(t)$, can be easily constructed from Eqs. (2.16) and (2.17) in Ref. 13, thus getting

$$K(t)=\frac{1}{2}\,\mathrm{erfc}\left(-\left(k+\frac{1}{2}-\kappa\right)\sqrt{t}\,\right)-\sum_{n\neq k}\frac{\mathrm{sig}(n+\frac{1}{2}-\kappa)}{2}\,\mathrm{erfc}\left(\left|\,n+\frac{1}{2}-\kappa\right|\,\sqrt{t}\,\right). \tag{74}$$

Taking into account that

$$\lim_{t\to\infty} K(t) = m(\kappa) = \begin{cases} 0 & \text{for } k+\frac{1}{2} < \kappa \leqslant k+1 \\ \frac{1}{2} & \text{for } \kappa = k+\frac{1}{2}, \\ 1 & \text{for } k < \kappa < k+\frac{1}{2} \end{cases} \tag{75}$$

we obtain

$$\int_0^\infty dt\ t^{s-1}\{K(t)-m(\kappa)\} = \frac{-\Gamma(s+1/2)}{2s\sqrt{\pi}}\,\eta_{(B+\,1/2R)}(2s), \tag{76}$$

where

$$\eta_{(B+\,1/2R)}(s) = R^s \sum_{n\neq\kappa-\,1/2} \mathrm{sig}\left(n+\frac{1}{2}-\kappa\right)\left|n+\frac{1}{2}-\kappa\right|^{-s}. \tag{77}$$

In particular

$$\eta_{(B+\,1/2R)}(0) = \begin{cases} 2(\kappa-k-1) & \text{for } k+\frac{1}{2} < \kappa \leqslant k+1 \\ 0 \quad \text{for } \kappa = k+\frac{1}{2} \\ 2(\kappa-k) & \text{for } k < \kappa < k+\frac{1}{2} \end{cases}. \tag{78}$$

Finally, taking into account that, for $k<\kappa\leqslant k+1$,

$$m(\kappa) - \tfrac{1}{2}\eta_{(B+\,1/2R)}(0) = k+1-\kappa = \tfrac{1}{2}[1-h(B)-\eta_{(B)}(0)], \tag{79}$$

where $h(B)=\dim\ker(B)$, and from the asymptotic expansion[13] of the heat kernels in (74), we have

$$\text{index } D = \kappa + \frac{[1-h(B)-\eta_{(B)}(0)]}{2} = k+1, \tag{80}$$

in agreement with (64). The first term in the intermediate expression is the well known contribution from the bulk.[20] The second one is the boundary contribution of APS, shifted by 1/2. This correction, due to the presence of the factor σ in (7), has already been obtained in[15] with slightly different spectral boundary conditions.

VII. CONCLUSIONS

In this paper we have achieved the complete evaluation of the determinant of the Dirac operator on a disk, in the presence of an axially symmetric flux, under global boundary conditions of the type intoduced by Atiyah, Patodi, and Singer.[13] To this end, we have proceeded in two steps: In the first place, we have grown the gauge field while keeping the boundary condition fixed. This calculation was possible thanks to the exact knowledge of the zero modes and the Green's function (in the complement of the null space.) Here, a gauge invariant point splitting regularization was employed. In references[10,11] we developed, for the case of local boundary conditions, a regularization scheme based on Seeley's complex powers.[12] Its application to the present problem leads to the same result as the point splitting we used here, even though its relation to the ζ-function is not guaranteed. In fact, as far as we know, the construction of complex powers for elliptic boundary problems with global boundary conditions is still under study.[18]

In the second step, we have explicitly obtained the eigenvalues of $(i\partial\!\!\!/ + P_0)_\kappa$. We have shown that the corresponding ζ-function is regular at the origin and we have evaluated the quotient of the free Dirac operators for two different global boundary conditions.

We have verified that our complete result is in agreement with the APS index theorem, adapted to our example.

ACKNOWLEDGMENT

We thank María Amelia Muschietti and Jorge Solomin for valuable discussions. This work was partially supported by CONICET, Argentina.

(Received 4 April 1997; accepted for publication 17 September 1997)

Dedicated to the memory of Gerda Dorfmeister.

Different finite difference replacements for the derivative are analyzed in the context of the Heisenberg commutation relation. The type of the finite difference operator is shown to be tied to whether one can naturally consider D and X to be self-adjoint and skew self-adjoint or whether they have to be viewed as creation and annihilation operators. The first class, generalizing the central difference scheme, is shown to give unitary equivalent representations. For the second case we construct a large class of examples, generalizing previously known difference operator realizations of $[D, X] = \mathrm{Id}$. © *1998 American Institute of Physics.* [S0022-2488(98)01001-9]

I. INTRODUCTION

The idea of discrete physics and discrete space–time is a very old one. To the best of our knowledge, the oldest references in a physical journal are Refs. 1 and 2, and it has been reconsidered many times in the past (see Ref. 3 for an extensive bibliographical review on the subject). The basic motivations for all those efforts were: (a) the presence of ultraviolet infinities in the standard quantum field theory, and (b) understanding the origin of the fundamental length (mass) scale in the Einstein's general relativity theory.

In recent years there has been a growing number of attempts to find an underlying discrete structure of space–time. At the same time interesting discrete structures have surprisingly emerged within originally continuous models. The most interesting examples can be found in string theory,[4] Roger Penrose's spin network calculus,[5] the loop representation of quantum gravity[6] (see also Ref. 7), the Bekenstein black hole entropy problem,[8–12] or the recent approach advocated by G. t' Hooft.[13–15] Also, it is interesting to mention in this context the old work by Aharonov *et al.*,[16] where the modular variables for the coordinate and momentum operators were introduced to describe an infinite slit experiment with magnetic field.

Increasing popularity of discrete models in theoretical physics has been stimulated by several successful attempts to discretize continuous models for technical reasons. This has advanced our understanding of discrete techniques. Here, the best examples are the lattice QCD[17] and the Regge calculus in classical gravity.[18]

On the other hand, there have been several attempts to incorporate discrete space–time at the *kinematical* level and to investigate its physical consequences.[19,20] This line of research can be also associated with the q-deformations of the Poincare group.[21] Another interesting approach has been recently proposed by Mazur,[12,22] who has given additional physical arguments in favor of space–time discreteness.

We assume a discrete coordinate space (see also Ref. 23) and investigate its consequences for the Heisenberg commutation relations. This approach is purely kinematical, as the Heisenberg relations are, and does not depend on the details of the underlying dynamics. Such ''unusual'' realizations of the Heisenberg algebra have also been found in 2D gravity.[24] These representations are not unitarily equivalent to the Schrödinger representation. In particular, they cannot be exponentiated to the Weyl form of the canonical commutation relation.

To motivate our discussion we first consider the standard quantum mechanical representation of the momentum operator:

$$p_\mu = -i\hbar \frac{\partial}{\partial x^\mu}. \tag{1.1}$$

Hence, the coordinate discretization can be implemented through a derivative discretization:

$$\frac{d}{dx} \to D_{\Delta x}, \tag{1.2}$$

where $D_{\Delta x}$ is a discretized derivative (difference) operator and Δx is the discretization parameter (usually a fixed coordinate spacing). Even though we will call $D_{\Delta x}$ a discretized derivative it should be noted at this point that initially this is just some difference operator acting, for example, on the space of smooth functions on $\mathbb{R}$. However, such operators can be naturally restricted to act on the space of functions on $\Delta x \times \mathbb{Z}$. It is in this sense that we talk about a discrete derivative.

We will consider a wide class of possible derivative discretization schemes of the form

$$D_{\Delta x}(M+N+1) \equiv D_{\Delta x} \equiv \sum_{k=-M}^{+N} \alpha_k E_{\Delta x}^k, \tag{1.3}$$

where α_k are real constant coefficients and M and N are integer indices corresponding to the lowest and highest nonzero terms (hence, $\alpha_{-M} \cdot \alpha_N \neq 0$). We take the coefficients α_k to be constant as one would like to have the same definition of the discrete derivative at all points in the coordinate space. The expression will be called n-point for $n=M+N+1$. For convenience, let us define the shift operator $E_{\Delta x}^n$ as

$$E_{\Delta x}^n \, f(x) \equiv E^n f(x) = f(x+n\Delta x). \tag{1.4}$$

One can easily check that this operator fulfills the following commutation relations:

$$\begin{aligned} [E^m, E^n] &= 0, \\ [E^m, x] &= m\Delta x E^m, \\ [E^m, xE^n] &= m\Delta x E^{m+n}, \\ [E^m, E^n x] &= m\Delta x E^{m+n}. \end{aligned} \tag{1.5}$$

Several authors have used a purely imaginary Δx and α_k. This case is not addressed in the present paper and our methods are not directly applicable to it.

In addition, the formal continuum limit reads

$$\lim_{\Delta x \to 0} E_{\Delta x}^n = 1. \tag{1.6}$$

In the simplest case, $N=M=1$ the difference operator can be expressed by the Heine bracket $[\cdot]_q$ defined for the dimensionless variables $P.q$ as (see Appendix A for its basic properties)

$$H(P,q)\equiv[P]_q=\frac{q^P-q^{-P}}{q-q^{-1}}, \tag{1.7}$$

where $q=e^i$ and $P=-i(\partial/\partial x)$. This notation is widely used in the context of q-deformations and, in particular, to define the q-deformed Poincaré group[21] (see also Ref. 22).

This paper is organized as follows. In Sec. II we investigate the basic properties of the difference operator (1.3). Section III is devoted to a construction of the Heisenberg algebra for the operator (1.3) and its conjugate operator $X_{\Delta x}$ when the latter is a bounded operator (finite series). In Sec. IV we consider the case of unbounded operators. In Sec. V we introduce the momentum formulation of our problem and within this representation we complete our proofs in the unbounded case in Sec. VI. Section VII contains the summary of our results.

II. THE DISCRETE DERIVATIVE

In this section we shall investigate the general properties of the discretized derivative (1.3) and the corresponding momentum operator. We would like to be able to talk about the convergence of discretized operators to the ordinary ones when the parameter Δx tends to zero and whenever we can make sense of this limit we will call it *the classical limit*. In particular, we stipulate that for analytic functions

$$D_{\Delta x}\, f(x)\to\frac{d}{dx}\, f(x), \quad \Delta x\to 0, \tag{2.1}$$

holds pointwise in x. Consequently, by writing (2.1) in terms of the translation operator $\epsilon^{k\Delta x}d/dx$ we obtain

$$D_{\Delta x}\, f(x)\equiv\sum_{k=-M}^{+N}\alpha_k\, e^{k\Delta x d/dx}f(x). \tag{2.2}$$

Applying the Taylor expansion to (1.3) at $x=x_i$, we have

$$D_{\Delta x}\, f(x_i)=f(x_i)\sum_{k=-M}^{+N}\alpha_k+\frac{1}{1!}\frac{df(x_i)}{dx}\sum_{k=-M}^{+N}\alpha_k\, k\Delta x+\cdots+\frac{1}{n!}\, f^{(n)}(x_i)\sum_{k=-M}^{+N}\alpha_k k^n\Delta x^n+\cdots . \tag{2.3}$$

From (2.3), we then get the following two conditions for the coefficients α_k to fulfill (2.1):

$$\sum_{k=-M}^{+N}\alpha_k=0, \quad \sum_{k=-M}^{+N}k\alpha_k=\frac{1}{\Delta x}. \tag{2.4}$$

We may also sharpen the notion of a classical limit by specifying the accuracy of the discretization scheme. For example, the coefficients α_k can be chosen to give the best fit to the ordinary derivative by requiring that all terms in (2.3) vanish up to the order Δx^{M+N}. As a result, in addition to (2.4), the following set of algebraic equations for the coefficients must be satisfied:

$$\sum_{k=-M}^{k=+N}k^n\alpha_k=0 \quad \text{for } n=2,3,...,(M+N), \tag{2.5}$$

and we get instead of (2.3) the following approximation for the derivative:

TABLE I. Values of the lowest optimal α coefficients.

$N=M$	α_1	α_2	α_3	α_4	α_5	α_6
1	1/2					
2	2/3	−1/12				
3	3/4	−3/20	1/60			
4	4/5	−1/5	4/105	−1/280		
5	5/6	−5/21	5/84	−5/504	1/1260	
6	6/7	−15/56	5/63	−1/56	1/385	−1/5544

$$D_{\Delta x}f(x_i)=f'(x_i)+\frac{\Delta x^{M+N+1}}{(M+N+1)!}\,f^{(M+N+1)}(x_i)\sum_{k=-M}^{+M}\alpha_k k^{M+N+1}+o(\Delta x^{M+N+1}). \tag{2.6}$$

Equations (2.4) and (2.5) comprise the set of $M+N+1$ linear equations for $M+N+1$ coefficients α_k and they can be solved explicitly. The corresponding determinant is the *Vandermonde* determinant and its value is $\det\|A\|=1!\cdot 2!\cdot\cdots\cdot(2N)!\neq 0$. Consequently, there exists a unique solution. Its form is given by the following:

Theorem 1: *The discrete derivative of the form (1.3) gives the best fit to the ordinary derivative, i.e., it has expansion (2.3) with the first nonvanishing coefficient for* Δx^{M+N+1}*, if and only if the coefficients* α_k *are of the following form*:

$$\begin{aligned}\alpha_0&=\frac{-1}{\Delta x}\left[\sum_{k=1}^{N}\frac{1}{k}-\sum_{k=1}^{M}\frac{1}{k}\right],\\ \alpha_k&=\frac{(-1)^{k+1}}{\Delta x}\,\frac{M!N!}{k(M+k)!(N-k)!}.\end{aligned} \tag{2.7}$$

Higher-order terms in the expansion (2.3) cannot vanish, as the system would become overdetermined.

In the symmetric case, i.e., when $M=N$, Theorem 1 implies the symmetry between forward and backward terms. Indeed, in this case the coefficients (2.7) have the following simple properties:

$$\alpha_k(\Delta x)=-\alpha_{-k}(\Delta x)=\alpha_{-k}(-\Delta x). \tag{2.8}$$

Moreover, for a fixed k,

$$\lim_{N\to\infty}\alpha_k(\Delta x)=(-1)^{k+1}\,\frac{1}{(\Delta x)k},\quad k\neq 0. \tag{2.9}$$

The meaning of (2.9) is explained in Appendix B. Moreover, Eq. (2.8) implies the symmetry of the discrete derivative:

$$D_{\Delta x}=+D_{-\Delta x}. \tag{2.10}$$

The operator $D_{\Delta x}$ satisfying (2.10) we shall call **symmetric** (in Δx). Later on we shall limit ourselves to this case as it preserves the parity symmetry. Discretization schemes and corresponding coefficients satisfying, in addition to (2.4), (2.5) and symmetric we shall call **optimal**. In fact, in the special symmetric case $N=1$, (2.8) implies that the derivative is optimal and we obtain the well-known central difference scheme. The numerical values of the optimal α-coefficients for the lowest $(2N+1)$-point schemes are given in Table I.

In analogy to (2.2), the optimal derivative can be rewritten as

$$D_{\Delta x}f(x)\equiv 2\sum_{k=1}^{N}\alpha_k \sinh\left(k\Delta x\,\frac{d}{dx}\right)f(x). \tag{2.11}$$

In particular, for the optimal three-point (=central difference) discretization scheme we have

$$D_{\Delta x}f(x)=\frac{1}{\Delta x}\sinh\left(\Delta x\,\frac{d}{dx}\right)f(x)=\frac{1}{i\Delta x}\sin\left(i\Delta x\,\frac{d}{dx}\right)f(x). \tag{2.12}$$

The representation (2.12) is exactly the derivative represented by the Heine symbol (1.7).[21,22]

Originally, Heisenberg introduced his matrix mechanics by postulating that mathematical operations in classical equations of motion should be reinterpreted (that led to the correspondence principle). In this spirit Dirac postulated that the ''quantum differentiation'' must satisfy the additivity and the Leibniz rule. From this he obtained the fundamental (Heisenberg) commutation relations for coordinates and momenta.[25] We would like to proceed in an analogous way. However, in our case not all general rules for derivatives are satisfied by (1.3), subject to (2.4). The basic properties of the ordinary derivative are listed below along with some comments on how those properties change if one uses $D_{\Delta x}$ instead of d/dx:

(1) Additivity. Ordinary and discrete derivative are both linear:

$$D_{\Delta x}[f(x)+g(x)]=D_{\Delta x}f(x)+D_{\Delta x}g(x).$$

(2) Leibniz rule. The rule for differentiation of the product is not satisfied exactly by (1.3). The deviation is of order $O(\Delta x)$ and for the optimal scheme of order $O(\Delta x^{2N})$.[26]

(3) Derivative of the composite function. The same result as for the Leibniz rule holds for the derivative of a composite function: $D_{\Delta x}[f\circ g(x)]=D_{\Delta x}f(g(x))\times D_{\Delta x}g(x)+O(\Delta x^{2N})$.

(4) Derivative of monomials. Discrete derivative of the monomial x^n is identical to the ordinary derivative if the discretization scheme is optimal and the exponent $n\leqslant 2N$. In general, assuming (2.4) and (2.8), we have

$$D_{\Delta x}(N)x^n=nx^{n-1}+\sum_k\sum_{i=2}^{n}\alpha_k k^i\binom{n}{k}\Delta x^i x^{n-i}. \tag{2.13}$$

(5) Heisenberg commutation relation. This will be the subject of the following sections. We shall present a construction of the discrete counterpart of the Schrödinger couple x and d/dx satisfying a discrete analog of the continuous Heisenberg commutation relation: $[d/dx, x]f(x)=f(x)$. Naively, that is, by replacing only d/dx with $D_{\Delta x}$ and using (1.3), we get

$$[D_{\Delta x}, x]f(x)=\Delta x\sum_k k\,\alpha_k\, f(x+k\Delta x). \tag{2.14}$$

For the optimal discretization we will construct a position operator called X which together with $D_{\Delta x}$ forms a conjugate pair, that is the relation $[D_{\Delta x}, X]=I$ holds on a dense domain in a Hilbert space.

(6) Hermiticity. In the symmetric case we have a natural Hermitian conjugation induced from the relation $(E_{\Delta x}^n)^\dagger=E_{\Delta x}^{-n}$. The operator $D_{\Delta x}$, like the operator d/dx, is formally anti-Hermitian if $M=N$ and $\alpha_k(\Delta x)=-\alpha_{-k}(\Delta x)$ and we have

$$\int (D_{\Delta x}f(x))g(x)\,dx=-\int f(x)(D_{\Delta x}g(x))\,dx. \tag{2.15}$$

A more detailed analysis will be given in the subsequent sections.

III. LIE ALGEBRAIC DISCRETIZATION

The notion of the *Lie algebraic discretization* has been introduced in Ref. 27. It can be described as a special case of representation theory of the enveloping algebra of the Heisenberg algebra in which at least one of the generators is a difference operator. As a result, some linear difference equations have a representation theoretic meaning similar to the D-module interpretation of linear differential equations [see Ref. 28, in particular Sec. VI]. The most important application seems to be to describe quasi-polynomial solutions to a certain class of difference equations. On the other hand the whole procedure has certain appeal of *déjà vu* in the context of basic quantum mechanics and from this point of view one can regard the authors' concept of the Lie algebraic discretization as a quantization procedure.

Following Ref. 27, we start with (1.1) and we look for a conjugate operator $X\equiv X_{\Delta x}$ that satisfies

$$[D_{\Delta x}, X]=1, \tag{3.1}$$

with the additional condition ('classical limit')

$$\lim_{\Delta x\to 0} X_{\Delta x}=x. \tag{3.2}$$

In Ref. 27, only the special cases of the forward and backward *Euler schemes* that are not symmetric under reflections (2.10) have been discussed. This can be improved in two ways. First, we can start with the more general discretization scheme (1.3). Second, we can require that $D_{\Delta x}$ be formally skew-Hermitian whereas $X_{\Delta x}$ be formally Hermitian relative to some $\star$ anti-involution to ensure a natural physical interpretation.

In Ref. 27 it has been shown that for derivatives in the form

$$D^{+}_{\Delta x}f(x)\equiv\frac{f(x+\Delta x)-f(x)}{\Delta x},\quad D^{-}_{\Delta x}f(x)\equiv\frac{f(x)-f(x-\Delta x)}{\Delta x}, \tag{3.3}$$

we get the Heisenberg algebra for D^{+} and $x(1-\Delta x D^{-})$:

$$[D^{+}, x(1-\Delta x D^{-})]=1. \tag{3.4}$$

However, as has been mentioned in Sec. II, we are not satisfied with the Euler forms of the discrete derivative (3.3), as these schemes are not optimal and symmetric with respect to reflections.[29] In particular, this form of the discrete derivative does not seem to be skew-Hermitian with respect to any natural Hermitian structure. Also, the central difference scheme (and optimal, in general) was shown to enable a consistent formulation of the action principle and the Euler–Lagrange equations in the classical theory.[30] Another possibility would be that the pair $D_{\Delta x}, X$ is a pair of conjugate operators (annihilation and creation operators). But here again, no natural Hermitian structure on the Hilbert space of states seems to induce that.

First, we take up a question of generalizing the results of Ref. 27 to a wider class of discrete operators. As the starting point we generalize the form of the coordinate operator used in Ref. 27, stipulating the following Ansatz:

$$X\equiv\sum_{k=-N}^{M}\beta_k\, x\, E^{k}, \tag{3.5}$$

subject to the condition (continuous limit)

$$\sum_{k=-N}^{M} \beta_k = 1. \tag{3.6}$$

In fact, one can add to (3.5) two additional terms without changing the conclusions. Thus X might be taken to be of the form

$$X \equiv \sum_{k=-N}^{M} \beta_k \, x \, E^k + \sum_{k=-N}^{M} \beta_k' E^k x + \sum_{k=-N}^{M} \beta_k'' E^k. \tag{3.7}$$

The last term commutes with the derivative $D_{\Delta x}$ and does not change commutation relation (3.1). It changes, however, condition (3.6), replacing it with

$$\sum_{k=-N}^{M} (\beta_k + \beta_k') = 1, \quad \sum_{k=-N}^{M} \beta_k'' = 0. \tag{3.8}$$

The second term on the right-hand side of (3.7), due to (1.5), has the same commutation relation as (3.5), leading to the substitution

$$\beta_k \to \beta_k + \beta_k' . \tag{3.9}$$

From now on, we restrict our attention to (3.5). From (3.1) we get the following conditions for the β's:

$$\begin{aligned} &\sum_{k=-N}^{M} \beta_k = 1, \\ &\Delta x \sum_{\substack{k=-M \\ -N \leqslant n-k \leqslant M}}^{N} \alpha_k \, \beta_{n-k} \, k = \delta_{n0}, \end{aligned} \tag{3.10}$$

where n goes from $-(M+N)$ to $+(M+N)$. Here, (3.10) is a set of $(2M+2N+2)$ equations for $(2M+2N+2)$ coefficients α_k, β_k plus two additional equations (2.4). Hence, the system is formally overdetermined. Let us start with the second equation above (set of $2N+2M+1$ equations) and rewrite it as two separate sets, each of size $M+N+1$, corresponding to $n \leqslant 0$ and $0 \leqslant n$, respectively. For simplicity we introduce matrix notation in the $(M+N+1)$-dimensional space of coefficients. Let us define vectors

$$\beta = \begin{bmatrix} \beta_{-N} \\ \beta_{-N+1} \\ \vdots \\ \beta_M \end{bmatrix}, \quad b = \begin{bmatrix} 1/\Delta x \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \tag{3.11}$$

and two $(N+M+1) \times (N+M+1)$ matrices:

$$A_-=\begin{bmatrix} N\alpha_N & \dots & \dots & -M\alpha_{-M} \\ (N-1)\alpha_{N-1} & \dots & -M\alpha_{-M} & 0 \\ \dots & \dots & \dots & \dots \\ -M\alpha_{-M} & 0 & \dots & 0 \end{bmatrix},$$
$$A_+=\begin{bmatrix} N\alpha_N & \dots & \dots & -M\alpha_{-M} \\ 0 & N\alpha_N & \dots & (-M+1)\alpha_{-M+1} \\ \dots & \dots & \dots & \dots \\ 0 & \dots & 0 & N\alpha_N \end{bmatrix}. \tag{3.12}$$

Now, our equations can be rewritten as two sets of equations for the coefficients β_k in the following simple form:

$$A_-\ \beta=b, \quad A_+\ \beta=b, \tag{3.13}$$

where the first equations in both sets are identical. The determinants of the systems (3.13) are

$$\det\|A_-\|=(-M\alpha_{-M})^{M+N+1}, \quad \det\|A_+\|=(N^{M+N+1}\alpha_N)^{M+N+1}, \tag{3.14}$$

and (3.13) can be solved explicitly. Indeed, there are three possibilities to consider: (1) Both determinants are nonzero (i.e., $M\cdot N\neq 0$); (2) one of the determinants is zero, then either $M=0$ or $N=0$; or (3) both determinants are zero ($M=N=0$). In the last case the derivative expansion (1.3) consists of one nonzero term ($\alpha_0 E_0$) only and the second condition of (2.4) cannot be fulfilled. In the first case, using Cramer's rule, we get two different solutions to (3.13), hence the system is inconsistent. The only nontrivial possibility is to have the second case. Let us assume that $\alpha_N\neq 0$. Then from the second equation of (3.13) we get the following (unique) solution for β's:

$$\beta_{-N}=\frac{1}{N\alpha_N\Delta x}, \quad \beta_{-N+1}=\cdots=\beta_M=0, \tag{3.15}$$

and the first equation of the set (3.10) implies: $\beta_{-N}=1$ and $\alpha_N=1/(N\Delta x)$. Now, consistency of the first equation of (3.13) implies that the only nonzero α's can be α_0 and α_N. Finally, Eqs. (2.4) are satisfied as well if $\alpha_0=-\alpha_N$. An identical solution can be found for $\alpha_{-M}\neq 0$. Hence, we have the following.

Theorem 2: *For the discretized derivative operator (1.3) satisfying (2.4) and the coordinate operator in the form (3.5) with condition (3.2) to satisfy Heisenberg commutation relation (3.1) the coefficients α_k, β_k must be either in the forward Euler form:*

$$\alpha_k\equiv\alpha_k^F=-\frac{1}{N\Delta x}\ \delta_{k0}+\frac{1}{N\Delta x}\ \delta_{N,k}, \quad \beta_k\equiv\beta_k^F=+\delta_{-N,k}, \tag{3.16}$$

or in the backward Euler form:

$$\alpha_k\equiv\alpha_k^B=\frac{1}{M\Delta x}\ \delta_{k0}-\frac{1}{M\Delta x}\ \delta_{-M,k}, \quad \beta_k\equiv\beta_k^B=+\delta_{-M,k}. \tag{3.17}$$

Thus, for X of the form (3.5) the only way to satisfy (3.1) is to take $D_{\Delta x}$ as the Euler derivatives (3.3). In this case the coordinate operators are

$$X^{B,F}=x(1-\Delta x D_{N\Delta x}^{\mp})=xE_{\Delta x}^{\pm N}. \tag{3.18}$$

This proves that the Turbiner–Smirnov discretization scheme is unique under conditions (3.1), (3.2), and (3.5). Hence, an optimal derivative with the discretized coordinate operator of the form (3.5) cannot satisfy the Heisenberg commutation relation. In fact, this is impossible for any symmetric discretization scheme with finite series in (3.5).

IV. TRANSCENDENTAL OPERATORS X

In the previous section we have limited our considerations to the coordinate operators (3.5) in the form of a finite series. However, there is still a possibility of having the Heisenberg algebra with the discrete derivative of the form (1.3) and an infinite series for X. We shall investigate the algebraic aspects of this problem in this section and a complete, rigorous solution of the problem will be given in Sec. VI. We should mention that the operator X is always unbounded and eventually special care needs to be exercised when dealing with any expressions involving X. In this section we study only formal aspects of our problem, leaving aside important questions like the domain of the definition of X or in what sense we understand expressions below involving infinite sums. We will come back to those questions in Secs. V and VI.

In the present section we postulate that our coordinate operator has the following form:

$$X=x\sum_{k=-\infty}^{\infty}\beta_m E_{\Delta x}^m, \tag{4.1}$$

and we have an infinite set of linear algebraic equations (3.10) for $n=0,\pm 1,\pm 2,\pm 3,\ldots$. In addition, the continuous limit condition (3.6) is tentatively taken to mean

$$\sum_{k=-\infty}^{+\infty}\beta_k=1. \tag{4.2}$$

Eventually, we will have to regularize this condition since in many examples a direct evaluation of this limit does not make sense.

We define infinite-dimensional matrices and vectors analogous to (3.11) and (3.12):

$$\beta_+=\begin{bmatrix}\beta_{-N}\\ \beta_{-N+1}\\ \beta_{-N+2}\\ \vdots\end{bmatrix}\quad \beta_-=\begin{bmatrix}\beta_M\\ \beta_{M-1}\\ \beta_{M-2}\\ \vdots\end{bmatrix},\quad b=\begin{bmatrix}1/\Delta x\\ 0\\ 0\\ \vdots\end{bmatrix}, \tag{4.3}$$

$$A_+=\begin{bmatrix}N\alpha_N & \cdots & -M\alpha_{-M} & 0 & \cdots & \cdots\\ 0 & N\alpha_N & \cdots & -M\alpha_{-M} & 0 & \cdots\\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots\end{bmatrix},$$
$$A_-=\begin{bmatrix}-M\alpha_{-M} & \cdots & N\alpha_N & 0 & \cdots & \cdots\\ 0 & -M\alpha_{-M} & \cdots & N\alpha_N & 0 & \cdots\\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots\end{bmatrix}. \tag{4.4}$$

Formally, we get, instead of (3.13), the following two sets of equations:

$$A_+\beta_+=b,\quad A_-\beta_-=b. \tag{4.5}$$

In both sets the first equation is identical and relates at most $(M+N+1)$ coefficients β_m. Each next equation involves one more (higher-order) coefficient that can be explicitly computed.

Hence, our system has $(M+N)$ free parameters. In the special case, when $M\cdot N=0$, the first or last element in each row in (4.4) vanishes and we have $(M+N-1)$ free parameters. This implies for the kernel of operators A_+, A_-

$$D\equiv \dim \ker A_+ = \dim \ker A_- = M+N-\delta_{MN,0}. \tag{4.6}$$

Hence, we have proven the following.

Theorem 3: *For operator X in the form of infinite series (4.1) there is an* $(M+N-\delta_{MN,0})$*-parameter family of formal solutions to the Heisenberg relation (3.1).*

Remark: We do not claim at this point that any of the formal solutions satisfy (4.2).

In the case $M\cdot N\neq 0$, Eqs. (4.5) imply one algebraic condition for the coefficients $\{\beta_{-N},\ldots,\beta_M\}$:

$$\sum_{k=-M}^{+N} k\ \alpha_k\ \beta_{-k}=\frac{1}{\Delta x}, \tag{4.7}$$

and the higher coefficients β_k $(k>M$ or $k<-N)$ can be uniquely determined from

$$\beta_{M+i}=\frac{-1}{M\alpha_{-M}}\sum_{k=-M+1}^{+N} k\ \alpha_k\ \beta_{i-k},$$

$$\beta_{-(N+i)}=\frac{-1}{N\alpha_N}\sum_{k=-M}^{N-1} k\ \alpha_k\ \beta_{-(i+k)}, \tag{4.8}$$

where $i=1,2,\ldots$ with additional condition (4.2).

In the remainder of this section we shall assume that the coefficients α_k are optimal and the coefficients β_k have the symmetry

$$\beta_k=\beta_{-k}, \quad -N\leqslant k\leqslant N. \tag{4.9}$$

This implies the symmetry of the discrete coordinate operator with respect to the Δx reflections:

$$X_{\Delta x}=X_{-\Delta x}, \tag{4.10}$$

in analogy to the discrete derivative operator (2.10).

Indeed, now we have $N+1$ β-parameters $\{\beta_0,\beta_1,\beta_2,\ldots,\beta_N\}$ subject to

$$\sum_{k=1}^{N} k\ \alpha_k\ \beta_k=\frac{1}{2\Delta x}. \tag{4.11}$$

The higher-order coefficients (β_k for $|k|>N$) are uniquely determined from

$$\beta_{N+i}=\frac{-1}{N\alpha_N}\sum_{k=1}^{N} k\ \alpha_k\ \beta_{i-k}-\frac{1}{N\alpha_N}\sum_{k=1}^{N-1} k\ \alpha_k\ \beta_{i+k}, \quad i=1,2,\ldots. \tag{4.12}$$

Using induction on i and (4.7), we obtain the claim

$$\beta_{-(N+i)}=\beta_{N+i}. \tag{4.13}$$

We remark that the normalization condition (4.2) can be rewritten as

$$2\sum_{k=1}^{+\infty}\beta_k = 1-\beta_0, \tag{4.14}$$

i.e., we are left with $(N-1)$ free parameters β. All considerations in this section were rather formal as we deal with infinite series whose convergence is unclear. In fact, as we shall see below the series might diverge in the usual sense. We discuss in detail a concrete example to illustrate this point.

In the case $N=1$, (4.12) implies the following condition for the β-coefficients:

$$\beta_{i+2}=\beta_i, \quad i=0,1,2,\ldots . \tag{4.15}$$

Hence, we have two free parameters: β_0 and β_1. The latter can be determined from (4.11), giving

$$\beta_1=+1. \tag{4.16}$$

This provides an exact formula for all odd coefficients in the following compact form:

$$\begin{aligned}\beta_{2k+1}&=(-1)^k, \quad k=0,1,2,\ldots,\\ \beta_{-(2k+1)}&=\beta_{2k+1},\end{aligned} \tag{4.17}$$

and for even coefficients we have

$$\beta_{2k}=(-1)^k\beta_0. \tag{4.18}$$

It is clear from (4.17) that our series is indeed divergent and we must redefine the classical limit to make sense of the summation in (4.1). There is no unique way of doing that. We will say more about this in the next section.

At the moment, we are still left with one free parameter, β_0, and one equation, the normalization condition (4.14). As a special case we can put

$$\beta_0=0. \tag{4.19}$$

Hence, a formal solution for the discretized coordinate operator, X, in the $N=1$ case is (4.1) with β-coefficients given by

$$\begin{aligned}\beta_{2k}&=0 \quad \forall k\\ \beta_{2k+1}&=(-1)^k, \quad k=0,1,2,\ldots,\\ \beta_{-(2k+1)}&=\beta_{2k+1}, \quad k=0,1,2,\ldots .\end{aligned} \tag{4.20}$$

Now, this solution can be compared with the solution found by Frappat and Sciarino.[31] Their solution, after restricting it to one dimension, reads

$$X=x\,\frac{1}{E+E^{-1}}+\frac{1}{E+E^{-1}}\,x. \tag{4.21}$$

There is a formal analogy between their solution and (4.20). To see that analogy one expands the first term in (4.21) at $E=0$ and the second one at $E^{-1}=0$. There is, however, an important difference between the approach of the present paper and that of Ref. 31. In their approach, the discretization parameter Δx is purely imaginary. As a consequence, the shift operator E is formally Hermitian and positive definite, while the momentum operator corresponding to our $D_{\Delta x}$ is unbounded. Moreover, since the shift is in the imaginary direction it is hard to see what this has

to do with a discrete space–time. By contrast, we are treating the shift as a unitary operator, thus retaining the real discretization parameter, which, in turn, ensures that the momentum is bounded.

V. MOMENTUM FORMULATION

In this section we reformulate some of the results obtained earlier as well as clarify some of the points left obscure in our discussion of Eq. (4.21).

The basic idea is to realize the algebra of shift operators as an algebra of multiplication operators on the Hilbert space of square integrable functions on the circle. One can also view this realization as the momentum space counterpart of the content of the preceding sections. Throughout this section $\Delta x=1$.

At the core of the idea of discretization is that in all operations one proceeds by performing a sequence of discrete steps of size, in this section, 1. This calls for bringing the Fourier transform into the picture. To this end we will first reinterpret (1.5). Our setup is as follows. We consider the unit circle,

$$S^1=\{z\in\mathbb{C}:\ |z|=1\}, \tag{5.1}$$

and the Hilbert space $H=L^2(S^1)$. We recall

$$L^2(S^1)=\left\{ f=\sum_{-\infty}^{\infty} a_n z^n\ :\ \sum_{-\infty}^{\infty} |a_n|^2<\infty \right\}. \tag{5.2}$$

We use the following parametrization of the circle S^1: $z=\exp i\theta$, $\theta\in\mathbb{R}$ (mod 2π). Thus a function $f\in L^2(S^1)$ can be written as

$$f(e^{i\theta})=\sum_{n\in\mathbb{Z}} a_n\, e^{in\theta}, \tag{5.3}$$

and a_n are the Fourier coefficients of f. Since the shift operator E defined in (1.4) corresponds to the elementary step of unit size we postulate that $E=T_z$, where T_z is the operator of multiplication by z. We will say more about multiplication operators towards the end of this section. Till further notice we also suppress writing T. Thus we set

$$E^n=z^n, \quad x=-z\,\frac{d}{dz}, \quad n\in\mathbb{Z}. \tag{5.4}$$

It is routine to check that (1.5) holds. Furthermore we define

$$D(z)\ :=\sum_{k=-M}^{N} \alpha_k\, z^k. \tag{5.5}$$

In other words the difference operator becomes now a multiplication by a Laurent polynomial in z. We might observe that the operator x above is one of the generators of the Virasoro algebra (with the trivial central term), called L_0. Now we reinterpret Eqs. (2.4) and (2.5). We see that (2.4) goes into

$$D(z=1)=0, \quad (L_0 D)(z=1)=-1. \tag{5.6}$$

Similarly, (2.5) goes into

$$(L_0^n D)(z=1)=0 \quad \text{for } n=2,3,\ldots,(M+N). \tag{5.7}$$

Now, it is immediate that the coordinate operator X should be sought [see (3.4)] in the form

$$X=-z\sum_{n=-\infty}^{\infty}\beta_n\frac{d}{dz}z^n, \tag{5.8}$$

where

$$\sum_{n=-\infty}^{\infty}\beta_n=1. \tag{5.9}$$

Let us now, at least formally, introduce the function $h(z)=\Sigma_{-\infty}^{\infty}\beta_n z^n$. From the above condition we get that $h(1)=1$. Moreover X can be written

$$X(z)=L_0h(z)=-zh(z)\frac{d}{dz}-zh'(z). \tag{5.10}$$

As was already explained earlier, we can in fact ignore the second part and look for X in the form

$$X(z)=-f(z)\frac{d}{dz},\quad f(1)=1. \tag{5.11}$$

Thus X is formally an element of the Virasoro algebra. We want that

$$[D(z), X(z)]=\left[f(z)\frac{d}{dz},D(z)\right]=1, \tag{5.12}$$

where $D(z)$ is a function (Laurent polynomial) defined previously. We therefore obtain that

$$f(z)D'(z)=1, \tag{5.13}$$

which formally implies

$$f(z)=\frac{1}{D'(z)}. \tag{5.14}$$

We note that the condition $f(1)=1$ is automatically satisfied as a consequence of the second condition imposed on D. However, it is important to underscore the fact that the latter expression can only be understood formally at this stage of our analysis. Yet, there are some special cases when we do not expect to have any difficulties. For example, if $D(z)=A+Bz$, that is $M=0$, $N=1$. Then we impose the following conditions:

$$D(1)=0,\quad D'(1)=1, \tag{5.15}$$

which gives $D(z)=z-1$ and, consequently, $f(z)=1$. Thus we get the pair $D(z)=z-1$, $X(z)=-d/dz$, which clearly satisfies (5.12). Using (5.10) we get that in this case $h(z)=1/z$. Hence $\beta_{-1}=1$ and $\beta_i=0$, $i\neq -1$. Going back to the difference operator realization we get that $D=E-I$, $X=xE^{-1}$, which is the pair found in Ref. 27 for $\Delta x=1$. We can contrast this example with that of the symmetric discretization scheme for which $D(z)=\frac{1}{2}(z-z^{-1})$. In that case $f(z)=2z^2/(1+z^2)$, which is not bounded on the unit circle, and, consequently, $f(z)$ is not a multiplier [that is the multiplication by f is not a bounded operator on $L^2(S^1)$]. This example is explained in detail in the next section.

However, there are many cases for which f is a multiplication operator on the circle. We present now a general construction of X for which f is a multiplier. One can view this construction as a generalization of Ref. 27.

First, we review a few elementary facts from the theory of doubly infinite Toeplitz operators.[32] Initially, we can consider a vector space of sequences $a=\{a_n\}_{n\in\mathbb{Z}}$ such that $\Sigma_{n\in\mathbb{Z}}|a_n|^2<\infty$. This space, called ℓ^2, is isomorphic to $L^2(S^1)$, the fact well known from the theory of Fourier series. On ℓ^2 we introduce a linear operator T_c,

$$a_m\to\sum_{n\in\mathbb{Z}} c_{m-n}a_n, \tag{5.16}$$

where $c=\{c_n\}_{n\in\mathbb{Z}}$ is a sequence of numbers. It is known that T_c is a bounded operator on ℓ^2 iff c is a sequence of the Fourier coefficients of an essentially bounded function on S^1. We recall that $\phi(\theta)$ is an essentially bounded function on S^1 if it is bounded almost everywhere there. The isomorphism between ℓ^2 and L^2 allows one to study the Toeplitz operator T_c as acting on $L^2(S^1)$. We will say that $\phi(\theta)$ is a symbol of T_c if under this isomorphism T_c acts on $L^2(S^1)$ as

$$(T_c f\,)(\theta)=\phi(\theta)f(\theta),\quad f\in L^2(S^1). \tag{5.17}$$

Because of this relation we often write T_ϕ to denote the Toeplitz operator with the symbol ϕ. We will need in this section one more result from the theory of Toeplitz operators. The result below gives a complete description, in terms of symbols, of invertible Toeplitz operators.

Lemma 1: T_ϕ is invertible if and only if $1/\phi$ is essentially bounded. If this holds, $T_\phi^{-1}=T_{1/\phi}$.

Now we apply this lemma to our problem. Let us first consider a Laurent polynomial $g(z)$ such that $\mathrm{Res}_{z=0}\, g=0$ and g is nowhere zero on S^1. We can normalize such a g to satisfy $g(1)=1$. Now we define

$$D(e^{i\theta}):=i\int_0^\theta e^{it}g(e^{it})dt, \tag{5.18}$$

where we used $dz=ie^{i\theta}d\theta$. Observe that since there is no z^{-1} in g, $D(z)$ is again a Laurent polynomial satisfying (5.6). Now we set $f(z)=1/g(z)$. We see that $f(z)$ is bounded on S^1, so, by the lemma above, T_f is then the bounded inverse of T_g. Now we define the operator $X(z)=-T_f\partial/\partial z$: $C^\infty(S^1)\to C^\infty(S^1)$. By exactly the same computation as the one leading up to (5.5) we obtain that on $C^\infty\subset L^2(S^1)$, $X(z)$ and $D(z)$ so defined satisfy the Heisenberg commutation relation as well as (5.6).

Our original setup has been formulated in terms of the ℓ^2 space. Now we would like to return to it. The map which maps back $L^2(S^1)$ to ℓ^2 is given by the Fourier series method: $f\to\{\hat{f}(n)\}_{n\in z}$, where $\hat{f}(n)$ is the nth Fourier coefficient of f. We recall that using (5.10) we can describe the coefficients β_n as

$$\beta_n=\hat{f}(n+1),\quad n\in\mathbb{Z}. \tag{5.19}$$

Example: $g(z)=a+bz^{-2}$, $|a/b|\neq 1$. The condition $g(1)=1$ gives $a+b=1$. Thus $D(z)=az+(1-2a)+(a-1)z^{-1}$, $|a/(1-a)|\neq 1$. We have two cases to consider depending on whether $|a/(1-a)|<1$ (case 1) or $|a/(1-a)|>1$ (case 2).

Case 1: $f(z)=z^2\{1/[az^2+(1-a)]\}$.

We observe that f is analytic inside the unit circle S^1 and thus its Fourier expansion coincides with its Taylor expansion around $z=0$. We obtain

$$\hat{f}(n)=\begin{cases}\dfrac{(-1)^{(n-2)/2}}{1-a}\left(\dfrac{a}{1-a}\right)^{(n-2)/2}, & \text{if } n\geqslant 2 \text{ and } n \text{ is even;}\\ 0, \quad \text{otherwise.}\end{cases} \tag{5.20}$$

Thus

$$\beta_n=\begin{cases}\dfrac{(-1)^{(n-1)/2}}{1-a}\left(\dfrac{a}{1-a}\right)^{(n-1)/2}, & \text{if } n\geqslant 1 \text{ and } n \text{ is odd;}\\ 0, \quad \text{otherwise.}\end{cases} \tag{5.21}$$

Case 2: $f(z)=\{1/[a+(1-a)z^{-2}]\}$, $|a/(1-a)|>1$.

We observe that f is analytic outside of the unit circle S^1 and thus its Fourier expansion coincides with its Taylor expansion around $z=\infty$. We obtain

$$\hat{f}(n)=\begin{cases}\dfrac{(-1)^{n/2}}{a}\left(\dfrac{1-a}{a}\right)^{(-n)/2}, & \text{if } n\leqslant 0 \text{ and } n \text{ is even;}\\ 0, \quad \text{otherwise.}\end{cases} \tag{5.22}$$

Consequently,

$$\beta_n=\begin{cases}\dfrac{(-1)^{(n+1)/2}}{a}\left(\dfrac{1-a}{a}\right)^{(-n-1)/2}, & \text{if } n\leqslant -1 \text{ and } n \text{ is odd;}\\ 0, \quad \text{otherwise.}\end{cases} \tag{5.23}$$

This example illustrates very well the fact that the optimal discretization is special even from the point of view of the Heisenberg commutation relations. Indeed the case excluded from the example is $a=\frac{1}{2}$ which is precisely the optimal case. We can get, however, some information about this case making a approach $\frac{1}{2}$. This allows us to discuss the formal solution (4.20). One way of interpreting this solution relies on a regularization of D which essentially amounts to moving the zeros of D' off the unit circle. We now present a simple example of such a regularization. First we set $a=\frac{1}{2}-\epsilon$, $\epsilon>0$. We observe that $|a/(1-a)|<1$, so, we are dealing with the first case above. Directly from (5.21) we obtain

$$\beta_n(\epsilon)=\begin{cases}\dfrac{(-1)^{(n-1)/2}}{1/2-\epsilon}\left(\dfrac{1/2-\epsilon}{1/2+\epsilon}\right)^{(n-1)/2}, & \text{if } n\geqslant 1 \text{ and } n \text{ is odd;}\\ 0, \quad \text{otherwise.}\end{cases} \tag{5.24}$$

It is interesting to note that

$$\beta_n(0)=\begin{cases}2(-1)^{(n-1)/2}, & \text{if } n\geqslant 1 \text{ and } n \text{ is odd;}\\ 0, \quad \text{otherwise.}\end{cases} \tag{5.25}$$

This is a formal solution to (4.7) and (4.8), with no symmetry condition imposed on β's. It has exactly the same status as the symmetric solution (4.20). Thus we see that the formal solutions of Sec. V can be justified through an appropriate regularization. In addition we have to properly interpret (4.2) (classical limit). It makes sense to consider this expression for $\epsilon\neq 0$. Then, as it is easy to check,

$$\sum_{k=-\infty}^{\infty}\beta_k(\epsilon)=1. \tag{5.26}$$

The same expression does not make sense for $\epsilon=0$, clearly indicating that one cannot interchange $\lim_{\epsilon-0}$ with Σ.

The final item we would like to discuss in this section is the question of Hermiticity or rather lack thereof. In our formulation the pair D and X may not necessarily consist of (even formally) Hermitian or adjoint elements. This is plain, for example, if one looks at the pair $D=E-1$ and $X=xE^{-1}$ or even more general pairs found above. One could, however, make this pair adjoint to each other, thus turning D and X into a pair consisting of a creation and an annihilation operator, by constructing a proper representation space. One possibility would be to consider a Fock representation, which carries an essentially unique Hermitian form. Thus, for the last example, the completion of the space span $\{e_n=X^n 1,\ n\geqslant 0\}$ with respect to the inner product $\langle e_m,e_n\rangle = \delta_{m,n},n!$ gives us a Fock space on which D acts as an annihilation operator and X acts as a creation operator, respectively, and both act as difference operators. Another possibility is to consider a coherent representation, i.e., such that is generated from the vector v: $Dv=\lambda v$, $\lambda \in \mathbb{C}$, whose special case is the Fock representation obtained for $\lambda=0$. In the case of $D=E-1$ the vacuum state v is a quasiperiodic function satisfying $v(x+1)=(\lambda+1)v(x)$. One obtains the representation space as the span $\{\epsilon_n=X^n v,\ n\geqslant 0\}$ and the unique Hermitian form is defined by $\langle v,v\rangle=1$ and $\langle e_m,e_n\rangle=\langle v,D^m X^n v\rangle$, where in the last expression one moves X to the left and D to the right making use of (5.12), the formula $\langle u,X^n w\rangle=\langle D^n u,w\rangle$, and $Dv=\lambda v$.

In the next section we study the optimal discretization for which we show that one can construct pairs of Hermitian (self-adjoint) operators D and X.

VI. MOMENTUM FORMULATION APPROACH TO OPTIMAL DISCRETIZATION

Now we take on the case of the optimal discretization. Thus $M=N$ throughout this section. Also, in this section we are interested in self-adjoint pairs X, P relative to the standard inner product on $L^2(S^1)$. For convenience we multiply D from previous sections by $1/i$ and denote the resulting function by D_N.

The problem of classifying the pairs of operators satisfying Heisenberg commutation relations under an additional assumption that one of the operators be bounded was considered in Ref. 33. Since our difference operators are bounded, we are studying a special case of that classification, included in Ref. 33, in particular in Theorem 8.5 therein. The approach below is direct, however, and can be used as an introduction to a more encompassing treatment of Ref. 33 (see also Refs. 34 and 35). Moreover, we have a different physical motivation. Our interest lies in concrete bounded operators explicitly given by difference operators, reflecting the underlying assumption that the coordinate space is discrete. We recall some basic definitions from Ref. 33. Let H denote a separable Hilbert space over $\mathbb{C}$.

Definition: Let P,Q be operators in H, and Ω a dense subspace of H. We call (P,Q) a conjugate pair on Ω iff

(K1) *P and Q are symmetric, $\Omega\subset D(P)\cap D(Q)$,*

(K2) *$P\Omega\subset\Omega$, $Q\Omega\subset\Omega$,*

(K3) *$P=\overline{P/\Omega}$, $Q=\overline{Q/\Omega}$,*

(K4) *Q is bounded,*

(K5) *P has a self-adjoint extension.*

In this section we essentially show that our X and D_N form a conjugate pair in the above sense.

We start with the following.

Lemma 2: Let $D_N(z)$ be optimal. Then $D_N'(z)$ has two simple roots on the circle S^1.

Proof: Since $z=e^{i\theta}$, $0\leqslant\theta<2\pi$, we want to show that $(d/d\theta)D_N\equiv D_N'(\theta)$ has exactly two zeros for $\theta\in[0.2\pi)$.

To derive $D_N'(\theta)$ we first compute $D_N(\theta)$. We find that

$$D_N(\theta)=2\sum_{k=1}^{N}\frac{(-1)^{k+1}}{k}\frac{(N!)^2}{(N+k)!(N-k)!}\sin k\theta.$$

Hence,

$$D_N'(\theta)=2\sum_{k=1}^{N}(-1)^{k+1}\frac{(N!)^2}{(N+k)!(N-k)!}\cos k\theta$$

or, in terms of z,

$$D_N'(\theta)=\sum_{\substack{k=-N\\k\neq 0}}^{N}\frac{(-1)^{k+1}(N!)^2}{(N+k)!(N-k)!}z^k=\frac{(-1)^{N+1}(N!)^2}{(2N)!}z^{-N}\sum_{\substack{k=-N\\k\neq 0}}^{N}(-1)^k\binom{2N}{N}z^k$$
$$=\frac{(-1)^{N+1}(N!)^2}{(2N)!}z^{-N}\left[(1-z)^{2N}-(-1)^N\binom{2N}{N}z^N\right].$$

Thus it suffices to show that the polynomial $(1-z)^{2N}-(-1)^N\binom{2N}{N}z^N$ has exactly two zeros for $z\in S^1$. Indeed, we obtain $[(1-z)^2/z]^N=(-1)^N\binom{2N}{N}$ or $\sin^2\theta/2=\frac{1}{4}\sqrt[N]{\binom{2N}{N}}$ This equation has two solutions, provided $\frac{1}{4}\sqrt[N]{\binom{2N}{N}}<1$ and $N\geqslant 1$.

Indeed, for $N=1$ we get $\frac{1}{4}\cdot 2<1$ and there are two roots, $\theta=\pi/2,\frac{3}{2}\pi$. Now, we proceed by induction. First we observe that the above inequality is equivalent to $\binom{2N}{N}<4^N$. We already proved it for $N=1$. We note that

$$\binom{2N+2}{N+1}=\binom{2N}{N}\frac{(2N+1)(2N+2)}{(N+1)^2}=\binom{2N}{N}\frac{2(2N+1)}{(N+1)},$$

and we use the induction hypothesis to prove the claim.

To prove that the zeros are simple, we show that $d/dz[(1-z)^{2N}-(-1)^N\binom{2N}{N}z^N]$ is not zero there. Using that $(1-z)^{2N}-(-1)^N\binom{2N}{N}z^N=0$, we obtain that this derivative can be zero if and only if $2z^2-2z-1=0$. Since this equation has two real zeros not equal to ± 1 we conclude that the zeros of $D_N'(\theta)$ are simple. ■

Now, we turn to the problem of the localization of those zeros. We will show that both zeros move towards $\theta=\pi$ as $N\to\infty$. First we prove three technical lemmas.

Lemma 3:

$$\frac{\left(1+1/2N\right)}{\left(1+1/N\right)}<\frac{1+\dfrac{1}{2(N+1)}}{1+1/(N+1)},\quad N\geqslant 1.$$

Proof: Consider

$$\left(1+\frac{1}{2N}\right)\left(1+\frac{1}{N+1}\right)=\frac{2N^2+5N+2}{2N(N+1)}\quad\text{and}\quad\left(1+\frac{1}{N}\right)\left(1+\frac{1}{2(N+1)}\right)=\frac{2N^2+5N+3}{2N(N+1)}.$$

Hence,

$$\left(1+\frac{1}{2N}\right)\left(1+\frac{1}{N+1}\right)<\left(1+\frac{1}{N}\right)\left(1+\frac{1}{2(N+1)}\right),$$

which implies the claim. ■

TABLE II. Roots of D'_N.

N	1	10	100	2500	10 000
root 1	$\frac{1}{2}\pi$	2.32	2.80	3.06	3.10
root 2	$\frac{3}{2}\pi$	3.96	3.48	3.27	3.19

The next lemma improves on the estimate used in the course of the proof of Lemma 2.
Lemma 4:

$$\binom{2N}{N}<4^N\left[\frac{(1+1/2N)}{(1+1/N)}\right]^N, \quad N\geqslant 1.$$

Proof: The proof goes by induction on N. The only nontrivial step is to observe that

$$\binom{2(N+1)}{N+1}=\binom{2N}{N}\frac{4(1+1/2N)}{(1+1/N)},$$

which, by the induction hypotheses, implies

$$\binom{2(N+1)}{N+1}<4^{N+1}\left[\frac{\left(1+1/2N\right)}{\left(1+1/N\right)}\right]^{N+1}.$$

Now, the claim follows from Lemma 3. ■

Finally, we have the following.
Lemma 5: The sequence $a_N=1/4\sqrt[N]{\binom{2N}{N}}$, $N=1,2,...,$ *is increasing and* $\lim_{N-\infty} a_N=1$.
Proof: By Lemma 4, $a_N<(1+1/2N)/(1+1/N)$. Hence.

$$4\binom{2N}{N}a_N<4\binom{2N}{N}\frac{(1+1/2N)}{(1+1/N)}.$$

The left-hand side equals $\binom{2N}{N}^{(N+1)/N}$, from which we get $\binom{2N}{N}^{(N+1)/N}<\binom{2(N+1)}{(N+1)}$, which implies that $a_N<a_{N+1}$. To compute $\lim_{N\to\infty} a_N$ we observe that $\lim_{N\to\infty}\exp(1/N)[\ln(2N)!-2\ln(N)!]$ can be computed using the Stirling formula:

$$\Gamma(x)=e^{-x}x^{x-1/2}(2\pi)^{1/2}\left[1+\frac{1}{12x}+\cdots\right],$$

valid for large x. Thus

$$\lim_{N\to\infty} a_N=\frac{1}{4}\lim_{N\to\infty}\exp\frac{1}{N}\left[\ln(2N+1)^{2N+1/2}-2\ln(N+1)^{N+1/2}\right]=\frac{1}{4}\lim_{N\to\infty} e^{2\ln((2N+1)(N+1))}=1,$$

thus completing the proof. ■

To find the roots of $D'_N(\theta)$ we solve $\sin^2(\theta_N/2)=a_N$. By Lemma 5 we see that θ_N's are approaching π as N increases. Table II illustrates this phenomenon numerically.

Let us denote by θ_N^+, and θ_N^- the zeros of $D'_N(\theta), \theta_N^{\pm}\in[0,2\pi]$. Then on the intervals $I_N^1=(\theta_N^- -2\pi,\theta_N^+)$, and $I_N^2=(\theta_N^+,\theta_N^-)$, $D_N(\theta)$ is monotone and thus $D_N(\theta)$ has an inverse which

we denote by ϕ_N^1 and ϕ_N^2, respectively. Now, we observe that the Hilbert space $H=L^2(S^1)$ $\simeq L^2([\theta_N^- - 2\pi, \theta_N^-])$ admits the direct sum decomposition: $H=L^2(I_N^1)\oplus L^2(I_N^2)$. Moreover, we have

$$L^2(I_N^i)\simeq L^2(D_N(\mathrm{I}_N)), \quad \tau_i:\ \psi(\theta)\to|(D_N'\circ\phi_N^i)(y)|^{-1/2}\psi(\phi_N^i(y)),$$

where $y=D_N(\theta)$ and $i=1,2$. Now we show that τ is a unitary isomorphism.

Lemma 6: τ_i is a unitary isomorphism, $i=1,2$.

Proof:

$$\langle\psi_1|\psi_2\rangle=\int_{I_N^i}\overline{\psi_1(\theta)}\psi_2(\theta)d\theta=\int_{D_N(I_N^i)}\overline{\psi_1(\phi_N^i(y))}\psi_2(\phi_N^i(y))\left|\frac{dy}{d\theta}\right|^{-1}dy.$$

Observe, however, that $|dy/d\theta|=|(D_N'\circ\phi_N^i)(y)|$. Hence,

$$\langle\psi_1|\psi_2\rangle_{L^2(I_N^i)}=\int_{D_N(I_N^i)}(\overline{\tau_i\psi_1})(y)(\tau_i\psi_2)(y)\ dy=\langle\tau_i\psi_1|\tau_i\psi_2\rangle_{L^2(D_N(I_N^i))},$$

which ends the proof. ■

We will need an explicit form of the inverse of τ_i. A simple computation yields

$$\tau_i^{-1}:\ \phi\to|D_N'(\theta)|^{1/2}\phi(D_N(\theta)), \quad \theta\in I_N^i, \quad \phi\in L^2(D_N(I_N^i)).$$

Now, we want to define the skew-Hermitian part of the operator $[1/D_N'(\theta)](d/d\theta)[1/D_N'(\theta)]$ on $L^2(D_N)$. It is easier, however, to consider first its push-forward under τ:

$$\begin{aligned}
&\frac{1}{2}\,\tau_i\circ\left[\frac{1}{D_N'(\theta)}\frac{d}{d\theta}+\frac{d}{d\theta}\frac{1}{D_N'(\theta)}\right]\circ\tau_i^{-1}\phi(y)\\
&\quad=\frac{1}{2}\,\tau_i\circ\left[\frac{1}{D_N'(\theta)}\frac{d}{d\theta}+\frac{d}{d\theta}\frac{1}{D_N'(\theta)}\right](\mathrm{sign}(D_N'(\theta))D_N'(\theta))^{1/2}\phi(D_N(\theta))\\
&\quad=\frac{1}{2}\,\tau_i\circ\left[\frac{1}{D_N'(\theta)}\,\phi(D_N(\theta))+2\frac{\mathrm{sign}\,D_N'(\theta)}{(\mathrm{sign}(D_N'(\theta))D_N'(\theta))^{1/2}}\,\partial_\theta\phi(D_N(\theta))\right]\\
&\quad=\tau_i\circ\frac{\mathrm{sign}\,D_N'(\theta)}{(\mathrm{sign}(D_N'(\theta))D_N'(\theta))^{1/2}}\,\partial_\theta\phi(D_N(\theta))\\
&\quad=|D_N'\circ\varphi_N^i(y)|^{-1/2}\frac{(\mathrm{sign}(D_N'(\theta))\circ\varphi_N^i)(y)}{|D_N'(\theta)\circ\varphi_N^i(y)|^{1/2}}\frac{\partial}{\partial\varphi_N^i(y)}\,\phi(y)=\frac{1}{D_N'\circ\varphi_N^i(y)}\frac{\partial}{\partial\varphi_N^i(y)}\,\phi(y).
\end{aligned}$$

Since $\partial/\partial y=[\partial\varphi_N^i(y)/\partial y][\partial/\partial\varphi_N^i(y)]$ we need to compute $\partial\varphi_N^i(y)/\partial y$. To this end we simply observe that $(\varphi_N^i\circ D_N)(\theta)=\theta$. Hence,

$$\frac{d\varphi_N^i}{dy}=\frac{1}{D_N'(\theta)}=\frac{1}{(D_N'\circ\varphi_N^i)(y)}.$$

This implies

$$\left(\tau_1\circ\frac{1}{2}\left[\frac{1}{D_N'(\theta)}\frac{d}{d\theta}+\frac{d}{d\theta}\frac{1}{D_N'(\theta)}\right]\circ\tau_1^{-1}\right)(y)=\frac{\partial}{\partial y}, \quad y\in D_N(I_N^i).$$

We thus have the following important theorem.

Theorem 4: *Let*

$$X_N=\frac{i}{2}\left[\frac{1}{D_N'(\theta)}\frac{d}{d\theta}+\frac{d}{d\theta}\frac{1}{D_N'(\theta)}\right]$$

be defined on a dense set $S\in L^2(S^1)$. Then X_N is unitary equivalent to $i\partial/\partial y|_{L^2(D_N(I_N^1))} \oplus i\partial/\partial y|_{L^2(D_N(I_N^2))}$, *defined on the dense space* $\tau_1(S\cap L^2(I_N^1))+\tau_2(S\cap L^2(I_N^2))$.

We can prove a similar statement for $D_N(\theta)$. We have: $\tau_i\circ D_N(\theta)\circ\tau_i^{-1}\phi(y)=\tau_1 \circ D_N(\theta)|D_N'(\theta)|^{1/2}\phi(D_N(\theta))=|D_N'\circ\varphi^i(y)|^{-1/2}D_N\circ\varphi^i(y)|D_N'\circ\varphi^i(y)|^{1/2}\phi(D_N\circ\varphi^i)(y)=y\phi(y), \quad y \in D_N(I_N^i)$. Hence we have the following.

Theorem 5: *Let* P_N *be the operator of multiplication by the function* D_N. *Then* P_N *is unitary equivalent to* $y|_{L^2(D_N(I_N^1))}\oplus y|_{L^2(D_N(I_N^2))}$.

Corollary: The pair $Q=D_N$ and $P=-X_N$ is a conjugate pair on Ω, where $\Omega=\tau^{-1}(S_1) \oplus\tau^{-1}(S_2)$, $S_i=\{f\in L^2(D_N(I_N^i))$, f is absolutely continuous, $f=0$ on the boundary of $D_N\}$, $i=1,2$.

Remark: Observe that X_N is closed and symmetric on Ω. We discuss its self-adjoint extensions below.

First, however, we determine the spectrum of D_N or to be more precise T_{D_N}. By the well-known theorem on Toeplitz operators,[32] Spec $(T_{D_N})=$ essential range of $D_N=$ range of D_N, where the latter is a consequence of continuity. Because X_N decomposes into a direct sum of operators of the type id/dy on the finite intervals $D_N(I_N^i)$ we present a brief description of basic features of such operators. For convenience we take a finite interval $[-1,1]$. The following discussion is based on Ref. 36 and all the details can be found there. The operator id/dy is known to have a one-parameter family of self-adjoint extensions. More precisely, let us set $id/dy=T_\alpha$, defined on $D(T_\alpha)=\{\varphi:\varphi$ is absolutely continuous and $\varphi(-1)=\alpha\varphi(1)\}$, where $\alpha\in\mathbb{C}$, $|\alpha|=1$.

To interpret α we solve the eigenvalue problem: $i(d/dy)\psi=\lambda\psi$ with $\psi(-1)=\alpha\psi(1) =e^{i\varphi_0}\psi(1)$, $\alpha=e^{i\varphi_0}$, $\varphi_0\in[0,2\pi)$. Thus we obtain; $\psi(y)=e^{i\lambda y}$ and $e^{-i\lambda}=e^{i\varphi_0}e^{i\lambda}$ from which it follows that $2\lambda+\varphi_0=2\pi n$, $n\in\mathbb{Z}$. Hence, $\lambda=\lambda_n=n\pi-\varphi_0/2$, $n\in Z$. The appearance of π is accidental and can easily be removed by rescaling T_α. The spectrum of T_α is a lattice of physical positions. We would like to point out that there is no canonical way of identifying this lattice with the lattice we have started with. It seems to be compelling in fact to consider as a real physical space the lattice of eigenvalues of T_α and the corresponding Hilbert space $L^2(D_N(I_N^1))$, for example. Thus we would, so to speak, avoid the ''spectrum doubling'' problem by decree. On the other hand, this would have to be interpreted quantum mechanically as saying that the process of quantization amounts in this case to finding an irreducible representation of the Heisenberg commutation relations subject to the condition that the spectrum of the position operator be discrete. This representation would then have a relation to the calculus of difference operators as described above, yet the physical Hilbert space would be only ''half'' of the Hilbert space that naturally carries the action of difference operators.

To close this section we would like to mention that the optimal discretization has a very nice property that $\lim_{N\to\infty} D_N(\theta)=\theta$. This fact is proven in Appendix B. It is only in this case that we get an irreducible representation of the Heisenberg commutation relations in the case of the optimal discretization.

VII. SUMMARY AND CONCLUSIONS

In this paper we have investigated a wide class of discretization schemes for the derivative and/or momentum operator defined by (1.3). The optimal subclass of these schemes has been distinguished. These schemes give the best fit to the continuous operators and are symmetric with respect to the space reflections. The particular form of those schemes has been determined in Sec.

II. It has been shown that the solution found in Ref. 27 is the only solution in the form of finite series for the operator X. We also have determined that the commutation relation for the annihilation–creation-type of operators can be satisfied for a large class of difference operators, thus extending the result of Ref. 27, if one admits X in a form of an infinite series in E.

Our analysis in Sec. VI has shown that upon quantization the classically different optimal discretization schemes are all unitary equivalent. As a result, the number of points used to ''delocalize'' d/dx is unessential. For a fixed number of these points, say $2N+1$, the representation of the canonical commutation relations is reducible. Furthermore, by the result of Appendix B its irreducible components are unitary equivalent to the case with an infinite ($N\to\infty$) number of points.

Further extensions of this work can be done in several directions. First, one can investigate the case of an imaginary shift, as has been mentioned in Sec. I. Second, more general ansatz for the P and X operators can be analyzed. In particular, we suggest that the representation used in Ref. 24 can be included into our scheme by considering operator X being a nonlinear function of x. Finally, it would be interesting to study simple quantum mechanical systems within our approach.

It was brought to our attention that the so-called umbral calculus[37] rests on the same principle as our work. Umbral calculus is specifically designed to deal with representations of the canonical commutation relations on spaces of polynomials. Even though we do not make this assumption we recognize the evident similarity between the umbral calculus and our work. This deserves further study (for a very readable introduction to umbral calculus see also Ref. 38 where some physical aspects of umbral calculus are discussed).

ACKNOWLEDGMENTS

We are greatly indebted to P. O. Mazur for his insightful comments and constant encouragement. Also, we thank A. Herdegen for many illuminating suggestions regarding the content of Sec. VI. We also would like to thank the referee for pointing out to us the relevance of umbral calculus to the present work. The authors gratefully acknowledge the support of the State Committee for Scientific Research Republic Poland (KBN) 2 P03B 140 10 and the Natural Sciences and Engineering Research Council of Canada. AZG would like to thank the Kościuszko Foundation (NY) for the financial support and the Department of Physics, University of South Carolina, for hospitality.

APPENDIX A: HEINE SYMBOLS

The Heine symbol defined by (1.7) exhibit many interesting features. The deformation parameter $q\geqslant 0$ is usually bound to the (complex) region: $|q|\leqslant 1$ and it is parametrized exponentially by a (dimensionless) physical parameter l:

$$q=\exp\left(\frac{il}{2}\right). \tag{A1}$$

The above parametrization allows us to rewrite the Heine symbol (1.7) in the following widely used form:

$$[P]_q\equiv\frac{\sin(lP/2)}{\sin(l/2)}=\frac{\sinh(ilP/2)}{\sinh(il/2)}. \tag{A2}$$

Function $H(P,q)$ is antisymmetric in P:

$$H(P,q)=-H(-P,q). \tag{A3}$$

Also, it has the following limits for fixed q:

$$\lim_{P\to 0} H(P,q)=0,$$

$$\lim_{P\to 1} H(P,q)=1, \tag{A4}$$

$$\lim_{P\to\infty} H(P,q)=\infty, \quad q\neq 0,1.$$

As a function of q the function $H(P,q)$ is invariant under the transformation

$$q\to q'\equiv\frac{1}{q}. \tag{A5}$$

For $P=1$ it is constant: $H(1,q)=1$ and for $P<1$ $(P>1)$ it has maximum (minimum) at $q=1$ equal to P. The point $P=q=1$ is singular and the limits $\lim_{q\to 1}$ and $\lim_{P\to 1}$ do not commute. Also, the limit $\lim_{q\to 0}$ is singular—it is equal to 0 for $P\in[0,1)$, equal to 1 for $P=1$, and undefined for $P>1$.

APPENDIX B: A REMARK ABOUT D_N

Let us consider the function $f(\theta)=\theta$, $-\pi<\theta<\pi$. This function has the Fourier expansion

$$\theta=\sum_{n=1}^{\infty} b_n \sin n\theta,$$

where

$$b_n=\frac{2(-1)^n}{n}.$$

Let us recall that

$$D_N(\theta)=i\sum_{n=1}^{N} \frac{2(-1)^{n+1}(N!)^2}{n(N+n)!(N-n)!}\sin n\theta.$$

The main idea now is to compare the Nth partial sum S_N of $if(\theta)$ with the above sum. Clearly,

$$S_N(\theta)=i\sum_{n=1}^{N} \frac{2(-1)^{n+1}}{n}\sin n\theta.$$

The two sums look alike; the difference is the factor $(N!)^2/(N-n)!(N+n)!$.

We claim that $D_N(\theta)$ is an approximation to $i\theta$, i.e., $\lim_{N\to\infty} D_N(\theta)=i\theta$ in $(-\pi,\pi)$. This approximation is a result of a specific method of summation of the Fourier series, similar to the Fejer method of arithmetic means. Let us briefly review this subject. We refer the reader to Ref. 39 for more details. Given an infinite matrix $a=[a_{ij}:i,j=0,1,...]$ and a sequence $\{S_n:n=0,1,...\}$ we define a new sequence σ_n, $n=0,1,...$, by

$$\sigma_N=\sum_{n=0}^{\infty} a_{Nn}S_n.$$

We require that a satisfy the following conditions:

(i) $\lim_{N\to\infty} a_{Nn}=0$.
(ii) $B_N:=\Sigma_{n=0}^{\infty}|a_{Nn}|$ exists for every $N=0,1,...$, and the set $\{B_N:N=0,1,...\}$ is bounded.
(iii) $\lim_{N\to\infty}\Sigma_{n=0}^{\infty}a_{Nn}=1$.

If the σ_N have a limit s, then we say that the sequence of partial sums S_N is *a-summable* to the limit s. The most important fact for us is the following:

Theorem B1:[39] *If a satisfies (i), (ii), and (iii) and if S_N tends to a finite limit s, then* $\lim_{N\to\infty}\sigma_N=s$.

We claim that D_N are precisely the linear means σ_N for an appropriate choice of a. We define

$$a_{Nn}=\begin{cases}\dfrac{(2n+1)(N!)^2}{(N-n)!(N+n+1)!}, & \text{if } 0<n\leqslant N\\ 0, & \text{otherwise}\end{cases}.$$

It is easy to check that a so defined satisfy (i) and (ii). To see that (iii) is satisfied as well we observe that $a_N n$ satisfy

$$\sum_{m=n}^{N} a_{Nm}=\frac{(N!)^2}{(N-n)!(N+n)!},\quad 0\leqslant n\leqslant N.$$

In particular, for $n=1$ we obtain

$$\sum_{n=1}^{N} a_{Nn}=\frac{(N!)^2}{(N-1)!(N+1)!}=\frac{N}{N+1}.$$

By taking the limit $N\to\infty$ we obtain (iii). To prove our claim we need to show that $D_N=\sigma_N$. This follows from (B1). Finally, applying Theorem B1 we conclude that $\lim_{N\to\infty} D_N(\theta)=i\theta$.

Lattice functions, wavelet aliasing, and SO(3) mappings of orthonormal filters

Sarah John
Department of Physics and Astronomy, University of Missouri, Columbia, Missouri 65211

(Received 2 June 1997; accepted for publication 15 September 1997)

A formulation of multiresolution in terms of a family of dyadic lattices $\{S_j; j \in Z\}$ and filter matrices $M_j \subset \mathrm{U}(2) \subset \mathrm{GL}(2,C)$ illuminates the role of aliasing in wavelets and provides exact relations between scaling and wavelet filters. By showing the $\{DN; N \in Z_+\}$ collection of compactly supported, orthonormal wavelet filters to be strictly $\mathrm{SU}(2) \subset \mathrm{U}(2)$, its representation in the Euler angles of the rotation group SO(3) establishes several new results: a 1:1 mapping of the $\{DN\}$ filters onto a set of orbits on the SO(3) manifold; an equivalence of $D\infty$ to the Shannon filter; and a simple new proof for a criterion ruling out pathologically scaled nonorthonormal filters. © *1998 American Institute of Physics.* [S0022-2488(98)00301-6]

I. INTRODUCTION

The theory of wavelets, developed in recent years,[1–12] has found widespread applications in several areas in science and technology. Among their useful features are the phase space structure, which allows simultaneous windowing in the spatial and frequency domains, and their scale transformations, which allows microscopic focusing as well as zooming to examine spectral details both at the local as well as global scales. Wavelets, therefore, are more versatile than the fixed scale Wigner or Gabor phase space transforms, or the strictly global Fourier transforms.

Wavelets are either continuous or discrete. Continuous wavelets have a high degree of redundancy when spanning $L^2(R)$, thereby allowing discretization without loss of information. The discretized wavelets constitute frames or unconditional (Riesz) basis for $L^2(R)$ and is the basis for multiresolution analysis introduced by Mallat.[2,3] A particular collection of compactly supported orthonormal wavelets $\{DN; N \in Z_+\}$ first constructed by Daubechies,[1] which include the Haar and Daubechies wavelets, has proven useful in wavelet applications, its members mainly characterized by their finite interval of support and the order of differentiability. Another distinction between members of this collection relates to aliasing, a phenomenon associated with undersampling that would be particularly relevant in the selection of an optimal wavelet for any given application. For instance, in zoom, aliasing artifacts can seriously degrade the quality of reconstruction at any given scale, and in this case the Shannon wavelet would be perfect with unaliased subspaces but has the shortcoming of unbounded support. Again, in ill-posed inverse problems,[13] with noise, bandlimiting, and other signal distortions, a more rigorous information theoretic analysis is needed to determine optimized wavelets.[14,15]

This paper emphasizes the role of aliasing in multiresolution.[2] A key development is the use of the lattice or ''comb'' function $S_0(x)$, consisting of a train of Dirac deltas, to represent a unit lattice in the multiresolution subspace V_0, together with all the scaled lattices $\{S_j; j \in Z\}$ obtained by dyadic scale transformations acting on S_0. The algebra relating S_j at different scales is derived and the structure of 2×2 filter matrices $M_j \subset \mathrm{GL}(2,C)$ determined from two simultaneous linear equations representing aliased information.[16] Here $\mathrm{GL}(2,C)$ is the group of invertible 2×2 matrices. This approach may be compared to the linear phase filter theory[10,11] that by contrast relates only to unitary filter matrices, $M_j \subset \mathrm{U}(2)$, whereas the present formalism is more general, starting with $M_j \subset \mathrm{GL}(2,C)$, and eventually restricting to unitary matrices, $M_j \subset \mathrm{U}(2) \subset \mathrm{GL}(2,C)$ for multiresolution analysis. Related approaches using sampling may be found in the texts by Kaiser[7] and Holschneider.[9] Some well-known results, see for example the excellent texts by Chui,[5]

Daubechies,[6] and the more recent book by Hernandez and Weiss,[12] are rederived to illustrate the useful role of the lattice functions S_j, while other results are considered in greater detail, for instance, distinct representations of unitary matrices are written down explicitly to show how exact relations between scaling and wavelet filters may be obtained.

Several new results are also derived. It is shown that the relevant group for the $\{DN\}$ family is SU(2)⊂U(2). As SU(2) has a 2:1 homomorphism into the rotation group SO(3), a representation of the SU(2) group elements in the three Euler angles provides a framework for mapping the $\{DN\}$ filters onto a collection of closed orbits on the SO(3) manifold. The filters can then be viewed as being related to each other via rotations in three-dimensional space. This is distinct from the usual one-parameter representation of the filters that can only be representative of the U(1) group and not of the full structure of the non-Abelian SU(2) Lie group requiring three continuous parameters. The Euler angle representation also leads to a proof relating $D\infty$ to the Shannon filter and yields a simple new proof for a criterion ruling out pathologically scaled nonorthonormal filters.[17–19]

The paper is divided into the following sections. Section II briefly reviews continuous and discrete wavelets, and multiresolution.

In Sec. III a family of dyadic lattices $\{S_j\}$ and its algebra are derived and their role in multiresolution established. A derivation of the dilation equation is included to illustrate the useful role of lattice functions S_j. Although sampling is implicitly incorporated in all earlier works, the explicit use of lattice functions is new here.

In Sec. IV some well-known concepts on sampling and aliasing are discussed and a technique for the removal of aliasing provides the structure of 2×2 filter matrices $M_j\subset \mathrm{GL}(2,C)$. With $M_j\subset \mathrm{U}(2)$, exact relations between multiresolution filter elements are deduced from the general structure of unitary matrices. Further, a representation of the SU(2) group elements in the Euler angles leads to a heuristic derivation of the Haar filter.

In Sec. V the relevant group for the $\{DN\}$ filters is shown to be SU(2). Its representation in the Euler angles provides a 1:1 mapping of the filters onto a collection of orbits on the SO(3) manifold, and leads to a proof relating $D\infty$ to the Shannon filter.

Section VI discusses pathologically scaled filters with a criterion to eliminate them and an elementary new proof for it is given using the Euler angles.

Finally, Sec. VII gives a brief summary and outlook.

II. REVIEW

A brief review of continuous and discrete wavelet transforms as well as multiresolution is included for completeness and to establish notations and conventions.

A. Continuous wavelets

A continuous wavelet transform $W_f(a,b)$ of a function $f\in L^2(R^1)\cap L^1(R^1)$ is defined as a cross correlation between f and the conjugate of a continuous wavelet family

$$\left\{ \psi_{ab}:\psi_{ab}(x)=a^{-1/2}\psi\left(\frac{x-b}{a}\right);\ a\in R^1_+,\ b\in R^1 \right\} \tag{2.1}$$

and is given by

$$W_f(a,b)=\int_{-\infty}^{\infty} dx\ f(x)a^{-1/2}\overline{\psi\left(\frac{x-b}{a}\right)} \tag{2.2}$$

with Fourier transform,

$$\hat{W}_f(a,\omega)=a^{1/2}\hat{f}(\omega)\overline{\hat{\psi}(a\omega)}. \tag{2.3}$$

Their inverse transforms are given by the Grossmann–Morlet formulas,

$$f(x)=\frac{1}{C_\psi}\int_0^\infty da\ a^{-2}\int_{-\infty}^{\infty} db\ W_f(a,b)a^{-1/2}\psi\left(\frac{x-b}{a}\right) \tag{2.4}$$

and

$$\hat{f}(\omega)=\frac{1}{C_\psi}\int_0^\infty da\ a^{-2}\hat{W}_f(a,\omega)a^{1/2}\hat{\psi}(a\omega), \tag{2.5}$$

respectively. Here, the constant

$$C_\psi=\int_0^\infty (d\xi/\xi)|\hat{\psi}(\xi)|^2 \tag{2.6}$$

with the requirement

$$0<C_\psi<\infty \tag{2.7}$$

sets an admissibility condition on ψ, that ψ must have mean zero,

$$\int_{-\infty}^{\infty} dx\ \psi(x)=\hat{\psi}(0)=0, \tag{2.8}$$

indicating oscillations in the function.

Two completeness relations are implicit in the inverse transforms. From Eq. (2.5) one obtains

$$1=\frac{1}{C_\psi}\int_0^\infty da\ a^{-1}|\hat{\psi}(a\omega)|^2 \tag{2.9}$$

and from Eq. (2.4) the Grossmann–Morlet reproducing kernel $K(x,x')$ defined via

$$f(x)=\int_{-\infty}^{\infty} dx'\ K(x,x')f(x') \tag{2.10}$$

and given by

$$K(x,x')=\frac{1}{C_\psi}\int_0^\infty da\ a^{-3}\int_{-\infty}^{\infty} db\,\psi\left(\frac{x-b}{a}\right)\overline{\psi\left(\frac{x'-b}{a}\right)} \tag{2.11}$$

obtains a completeness relation in Hilbert space,

$$I=\int_0^\infty da\ a^{-2}\int_{-\infty}^{\infty} db|\psi_{ab}\rangle\langle\psi_{ab}|, \tag{2.12}$$

as can be seen in an expansion for $f(x)$ in the form

$$f(x)=\langle x|f\rangle=\int_0^\infty da\ a^{-2}\int_{-\infty}^\infty db\int_{-\infty}^\infty dx'\langle x|\psi_{ab}\rangle\langle\psi_{ab}|x'\rangle\langle x'|f\rangle,$$

where $\langle x|\psi_{ab}\rangle=\psi_{ab}(x)$ as given by Eq. (2.1).

B. Discrete wavelets

A continuous wavelet family, expressed in two continuous variables, has high redundancy when spanning a one-dimensional function space $L^2(R^1)$ and this in turn allows a discretization of the variables without loss of information. A discrete wavelet family, such as a dyadic family, given by

$$\{\psi_{jk}:\psi_{jk}(x)=2^{j/2}\psi(2^jx-k);\ j,k\in Z\},\tag{2.13}$$

constitutes a frame, or more restrictively, an unconditional (Riesz) basis for $L^2(R^1)$, depending on the wavelet ψ. Frames allow linear dependence among its elements implying redundancy, whereas Riesz bases constitute a subset of frames with linearly independent elements and no redundancy.

The Riesz coefficient R_{jk} for $f\in L^2(R^1)$ is defined as a cross correlation, or equivalently as an inner product $\langle\psi_{jk}|f\rangle$ given by

$$R_{jk}=\int_{-\infty}^\infty dx'\ 2^{j/2}\overline{\psi(2^jx'-k)}f(x').\tag{2.14}$$

A simple inversion formula is obtained in terms of its dual family $\{\tilde{\psi}_{jk}:j,k\in Z\}$, and is given by

$$f(x)=\sum_{j,k}\ R_{jk}\tilde{\psi}_{jk}.\tag{2.15}$$

For an orthonormal family, $\tilde{\psi}=\psi$ and one may deduce a discrete reproducing kernel $K_d(x,x')$ from Eqs. (2.14) and (2.15) by writing

$$f(x)=\int_{-\infty}^\infty dx'\ K_d(x,x')f(x')\tag{2.16}$$

with

$$K_d(x,x')=\sum_{j,k}\ 2^j\psi(2^jx-k)\overline{\psi(2^jx'-k)},\tag{2.17}$$

which gives a completeness relation in Hilbert space of the form

$$\sum_{j,k}\ |\psi_{jk}\rangle\langle\psi_{jk}|=I.\tag{2.18}$$

To generate multiresolution, on the other hand, the discrete *wavelet* coefficient C_{jk} must be defined as a convolution with an orthonormal wavelet family $\{\psi_j:\psi_j(x)=2^{j/2}\psi(2^jx);j\in Z\}$ followed by sampling on a scaled lattice. With convolution defined by

$$C_j(x)=\int_{-\infty}^\infty dx'\ f(x')2^{j/2}\psi(2^j(x-x')),$$

sampling on the scaled lattice gives

$$C_{jk}=\int_{-\infty}^{\infty} dx'\ f(x')2^{j/2}\psi(k-2^j x'). \tag{2.19}$$

This definition is necessary for multiresolution, as made clear in the derivation of the dilation equation (see Sec. III E). The wavelet coefficients may also be viewed as Riesz coefficients in the wavelet basis $\{\psi^{-}{}_{jk}:\psi^{-}{}_{jk}=2^{j/2}\psi(k-2^j x);j,k\in Z\}$, where the negative sign in the superscript indicates an inversion $2^j x-k\rightarrow-(2^j x-k)$ compared to the basis given by Eq. (2.13).

C. Multiresolution

A discrete wavelet family generates multiresolution,[2,3] which leads to an approximation theory for analyzing a function $f\in L^2(R^1)$ at distinct scales. The underlying concept in multiresolution is a nested sequence of closed subspaces $\{V_j:V_j\subset V_{j+1};j\in Z\}$, which has the following properties for dyadic scaling:

(i) $f(2x)\in V_{j+1}\leftrightarrow f(x)\in V_j$,
(ii) $\cup_{j\in Z}V_j$ is dense in $L^2(R^1)$, $\cap_{j\in Z}V_j=\{0\}$,
(iii) $V_{j+1}=V_j\oplus W_j$, $V_j\perp W_j$, and $L^2(R^1)=\oplus_{j\in Z}W_j$,
(iv) there exist related pairs of functions $\phi,\psi\in V_0$ such that $\{\phi_{jk}:\phi_{jk}=2^{j/2}\phi(2^j x-k);k\in Z\}$ forms an orthonormal basis for V_j, $\{\psi_{jk}:\psi_{jk}=2^{j/2}\psi(2^j x-k);k\in Z\}$ an orthonormal basis for W_j, and $\{\psi_{jk};j,k\in Z\}$ an orthonormal basis for $L^2(R^1)$. ϕ is the scaling function and ψ is the wavelet.

The spaces ν_j, w_j of $2^{j+1}\pi$ periodic functions, with $\nu_j\oplus w_j=\nu_{j+1}$ are defined by

$$\nu_j=\{\hat{m}_j;\forall\hat{m}_j(\omega)\in L^2[-2^j\pi,2^j\pi]\}, \tag{2.20}$$

$$w_j=\{\hat{m}_j;\forall\hat{m}_j(\omega)\in L^2[-2^{j+1}\pi,-2^j\pi;2^j\pi,2^{j+1}\pi]\}, \tag{2.21}$$

where w_j obviously is a translation of ν_j space and

$$\hat{m}_j(\omega)=\sum_k m_k e^{-i2^{-j}\omega k},\quad m_k\in C. \tag{2.22}$$

A necessary condition for multiresolution is the dilation equation,

$$2^{1/2}\hat{\phi}_j(2\omega)=\hat{m}_j(\omega)\hat{\phi}_j(\omega), \tag{2.23}$$

where $\hat{m}_j(\omega)\in\nu_j$. For $j=0$ and with $\hat{m}'(\omega)=2^{-1/2}\hat{m}_0(\omega)$, iteration ''constructs'' $\hat{\phi}=\hat{\phi}_0$,

$$\hat{\phi}(\omega)=\Pi_{n=1}^{\infty}\hat{m}'(2^{-n}\omega). \tag{2.24}$$

The constraints placed on $\hat{m}=\hat{m}_0$ to obtain an orthonormal basis for V_0, $\{\phi_{0k};k\in Z\}$, is the unitarity relation

$$|\hat{m}(\omega)|^2+|\hat{m}(\omega-\pi)|^2=2 \tag{2.25}$$

with $\hat{m}(0)=2^{1/2}$ implying that only a subset of ν_j qualify as multiresolution filters.

Multiresolution subspaces V_j and W_j consisting of $f_j\in L^2$ are defined by

$$V_j=\{\hat{f}_j:\hat{f}_j(\omega)=\hat{m}_j(\omega)\hat{\phi}_j(\omega);\quad\forall\hat{m}_j\in\nu_j\}, \tag{2.26}$$

$$W_j=\{\hat{f}_j:\hat{f}_j(\omega)=\hat{m}_j(\omega)\hat{\psi}_j(\omega);\quad\forall\hat{m}_j\in\nu_j\}, \tag{2.27}$$

which basically implies an expansion in the orthonormal basis of the subspace. For example,

$$f_j(x)=\sum_k m_k \phi_{jk}(x), \quad f_j \in V_j . \tag{2.28}$$

III. LATTICE FUNCTIONS AND WAVELET THEORY

In this section a family of dyadically scaled lattice functions $\{S_j ; j \in Z\}$ is introduced and their algebra derived. Following a well-known method, these functions derive expressions for a sequence $\{f_n\}$ as a continuous variable in x. Their useful role in multiresolution analysis is exemplified by a derivation of the dilation equation. As the δ function plays a pivotal role in the formulation, a few of its properties are now delineated.

A. The δ function and its properties

The Dirac δ function is defined by

$$\int_{-\infty}^{\infty} \delta(x)\ dx=1, \tag{3.1}$$

with

$$\delta(x)=0, \quad x \neq 0. \tag{3.2}$$

Strictly, this definition precludes δ from the L^2 space, as it must assume an infinite value at $x=0$ and therefore is to be considered as a ''generalized'' function, the definition also providing the following rule:

$$\delta(a^j x)=|a|^{-j}\delta(x). \tag{3.3}$$

A family of scaled deltas $\{\delta_j(x); j \in Z\}$ is now introduced, with

$$\delta_j(x)=a^{j/2}\delta(a^j x), \quad a \in R^1_+,$$

which on applying the rule [Eq. (3.3)] may be written as

$$\delta_j(x)=a^{-j/2}\delta(x). \tag{3.4}$$

These scaled deltas are to be viewed as existing in a scaled space. This allows one to define unit L^p norm, $1 \leqslant p < \infty$, by associating a factor $a^{j/2}$ for each delta in the measure, and is given by

$$\int_{-\infty}^{\infty} |\delta_j(x)|^p a^{jp/2}\ dx=\int_{-\infty}^{\infty} |\delta(x)|^p\ dx=1.$$

Then it follows that

$$\int_{-\infty}^{\infty} \delta_j(\cdot-m_1)\,\delta_j(\cdot-m_2)\cdots\delta_j(\cdot-m_p)a^{jp/2}\ dx=\delta_{m_1,m_2\cdots m_p}, \tag{3.5}$$

where $\delta_j(\cdot-m_1)=a^{j/2}\delta(a^j x-m_1)$, etc.

One very useful property of the delta function is the linear functional

$$\int_{-\infty}^{\infty} f(x')\,\delta(x-x')dx'=f(x), \tag{3.6}$$

which picks out the value of f at a given value x.

An integral representation for the delta function given by

$$\delta(x)=(2\pi)^{-1}\int_{-\infty}^{\infty}e^{ikx}\,dk \tag{3.7}$$

is useful in proving results in Sec. III B.

B. Lattice functions: S_j

A unit lattice is represented by the comb or lattice function S_0 consisting of a train of Dirac deltas

$$S_0(x)=\sum_n\ \delta(x-n) \tag{3.8}$$

with Fourier transform,

$$\hat{S}_0(\omega)=\sum_k\ e^{-ik\omega}=2\pi\sum_n\ \delta(\omega-2\pi n), \tag{3.9}$$

where the second equality follows from the Poisson summation formula written in the form

$$\sum_k\ F(k)=\sum_n\ \left\{\int_{-\infty}^{\infty}e^{2\pi inx}\ F(x)\ dx\right\}, \tag{3.10}$$

with $F(x)=e^{-ix\omega}$, and an application of Eq. (3.7).

A family of dyadically scaled lattices $\{S_j;j\in Z\}$ is now introduced, with

$$S_j(x)=2^{j/2}\ S_0(2^jx)=2^{j/2}\sum_n\ \delta(2^jx-n)=\sum_n\ \delta_j(x,n), \tag{3.11}$$

where

$$\delta_j(x,n)=2^{j/2}\delta(2^jx-n). \tag{3.12}$$

Their Fourier transforms are given by

$$\hat{S}_j(\omega)=2^{-j/2}\hat{S}_0(2^{-j}\omega)=2^{-j/2}2\pi\sum_n\ \delta(2^{-j}\omega-2\pi n). \tag{3.13}$$

Applying Eq. (3.3) to the preceding equations obtains the following forms:

$$S_j(x)=2^{-j/2}\sum_n\ \delta(x-2^{-j}n), \tag{3.14}$$

$$\hat{S}_j(\omega)=2^{j/2}\ 2\pi\sum_n\ \delta(\omega-2^{j+1}\pi n). \tag{3.15}$$

The following properties of the lattice functions are easily proved,

$$S_j^2(x)=S_j(x), \tag{3.16}$$

$$S_j(x)S_{j-1}(x)=S_{j-1}(x). \tag{3.17}$$

A relation between S_j and S_{j+1}, deduced from the defining equation (3.11) is given by

$$S_{j+1}(x)=2^{1/2}S_j(2x), \tag{3.18}$$

with Fourier transform

$$\hat{S}_{j+1}(\omega)=2^{-1/2}\hat{S}_j(\omega/2). \tag{3.19}$$

Similarly, Eq. (3.15) obtains a relation between S_j and S_{j-1} as follows:

$$\begin{aligned}\hat{S}_{j-1}(\omega)&=2^{(j-1)/2}2\pi\sum_n \delta(\omega-2^j\pi n)\\ &=2^{(j-1)/2}2\pi\sum_{n\ \text{even}}[\delta(\omega-2^j\pi n)+\delta(\omega-2^j\pi(n+1))]\\ &=2^{-1/2}[S_j(\omega)+S_j(\omega-2^j\pi)]\end{aligned} \tag{3.20}$$

with inverse Fourier transform given by

$$S_{j-1}(x)=2^{-1/2}S_j(x)[1+e^{i2^j\pi x}], \tag{3.21}$$

which is easily verified for $j=0$ when

$$S_{-1}(x)=2^{-1/2}S_0(x)[1+e^{i\pi x}]=2^{1/2}\sum_{n\ \text{even}}\delta(x-n)=2^{1/2}\sum_n \delta(x-2n). \tag{3.22}$$

C. Sampling

Sampling constitutes a mapping of $f\in L^2(R^1)$ onto a sequence $\{f_n\}$ with the map invertible for Shannon or sufficient sampling. The following proposition extends to dyadic lattices a well-known representation of a sampled sequence $\{f_n\}$ written as a generalized function, one advantage being that conversion formulas such as $f*g\leftrightarrow\hat{f}\hat{g}$ valid for continuous functions can now be readily adapted.

Note: In the following $f_{S_j}\in\nu_j$, the space of $2^{j+1}\pi$ periodic functions, and $f\in L^2$.

Proposition 3.1: A sequence $\{f_k=f(2^{-j}k)\}$ obtained by sampling $f\in L^2$ on a lattice S_j has representation

$$f_{S_j}(x)=f(x)S_j(x) \tag{3.23}$$

with Fourier transform represented in either form

$$\hat{f}_{S_j}(\omega)=2^j\sum_n \hat{f}(\omega-2^{j+1}\pi n) \tag{3.24}$$

or

$$\hat{f}_{S_j}(\omega)=\sum_n f(2^{-j}n)e^{-i2^{-j}n\omega}. \tag{3.25}$$

Proof: Equation (3.23) provides the required sampled sequence $\{f_k=f(2^{-j}k)\}$ since

$$f_{S_j}(x)=f(x)\sum_n 2^{j/2}\delta(2^j x-n)$$

and (including a factor 2^j to the measure for the two deltas in the integrand)

$$\begin{aligned} f_{S_j}(k)&=\int_{-\infty}^{\infty} f_{S_j}(x)\,\delta_j(x,k)2^j\,dx \\ &=\sum_n 2^{2j}\int_{-\infty}^{\infty} f(x)\,\delta(2^j x-n)\,\delta(2^j x-k)dx \\ &=\sum_n f(2^{-j}n)\,\delta_{k,n} \\ &=f(2^{-j}k). \end{aligned}$$

One method for obtaining the Fourier transform of Eq. (3.23) is by applying the convolution formula $f*g\leftrightarrow\hat{f}\hat{g}$,

$$\begin{aligned} \hat{f}_{S_j}(\omega)&=\hat{f}(\omega)*\hat{S}_j(\omega) \\ &=2^j\,2\pi\sum_n\int_{-\infty}^{\infty}(2\pi)^{-1}\,d\omega'\,\hat{f}(\omega')\,\delta(\omega-\omega'-2^{j+1}\pi n) \\ &=2^j\sum_n\hat{f}(\omega-2^{j+1}\pi n). \end{aligned}$$

Note the use of phase-space measure $(2\pi)^{-1}dx\,d\omega$, which implies $d\omega\rightarrow(2\pi)^{-1}\,d\omega$. Alternatively, by performing a direct Fourier transform,

$$\hat{f}_{S_j}(\omega)=\int_{-\infty}^{\infty}f(x)S_j(x)e^{-i\omega x}2^{j/2}\,dx=\sum_n f(2^{-j}n)e^{-i2^{-j}n\omega}.$$

The equivalence of the two forms can also be established directly by the Poisson summation formula. □

D. Multiresolution and lattice functions

The space ν_j of all $2^{j+1}\pi$ periodic functions is equivalent to the space of sampled sequences of f on S_j, $\forall f\in L^2$, that is,

$$\nu_j\equiv\{\hat{f}_{S_j}:\hat{f}_{S_j}(\omega)=\hat{f}(\omega)*\hat{S}_j(\omega);\ \ \forall f\in L^2\}\equiv\{\hat{m}_j;\forall\hat{m}_j(\omega)\in L^2[-2^j\pi,2^j\pi]\},\tag{3.26}$$

and therefore V_j as specified by Eq. (2.26) can be expressed in terms of S_j in the form

$$V_j=\{\hat{f}_j:\hat{f}_j(\omega)=\hat{f}(\omega)*\hat{S}_j(\omega)\,\hat{\phi}_j(\omega);\ \ \forall\hat{f}\in L^2\}.\tag{3.27}$$

The multiresolution subspaces for the Shannon wavelet have a particularly simple structure with $\hat{\phi}_j(\omega)=\chi_j(\omega)$, where the characteristic function χ_j is defined by

$$\chi_j(\omega)=\begin{cases}1, & 0\leqslant|\omega|<\Omega_j\\ 0, & \text{otherwise,}\end{cases}\tag{3.28}$$

and where $\Omega_j = 2^j \pi$ is the Nyquist bandwidth of S_j. In this case,

$$V_j = \{\hat{f}_j : \hat{f}_j(\omega) = \hat{f}_{S_j}(\omega)\chi_j(\omega);\ \ \forall \hat{f} \in L^2\} \tag{3.29}$$

and the orthogonal wavelet subspaces W_j, $L^2 = \oplus_{j \in Z} W_j$ form a union of disjoint regions in the frequency domain. All multiresolution properties are then immediately apparent since Ω_j spans V_j exactly, and consequently,

(i) $\Omega_j < \Omega_{j+1} \rightarrow V_j \subset V_{j+1}$,
(ii) $\hat{f}_j(\omega) \in V_j \leftrightarrow \hat{f}_j(2\omega) \in V_{j-1}$,
(iii) $\Omega_{j \rightarrow \infty} = \infty \rightarrow \cup_{j \in Z} V_j = V_{j \rightarrow \infty} = \infty$ is dense in $L^2(R_1)$,
(iv) $\Omega_{j \rightarrow -\infty} = 0 \rightarrow \cap_{j \in Z} V_j = V_{j \rightarrow -\infty} = \{0\}$,
(v) $\chi_j \in V_j$ generates an orthonormal basis for V_j.

E. Dilation equation using S_j

Wavelet theory formulated in terms of a sequence of sampled values $\{f_n\}$ has the drawback that mathematical operations such as convolution and sampling are not expressed symbolically, and consequently many of the underlying concepts are not evident per se in the equations. By using lattice functions S_j to represent $\{f_n\}$ as a distribution, the expressions attain a more obvious interpretation while also simplifying mathematical operations in symbolic manipulations. As an illustration, a derivation of the dilation equation,

$$\hat{\phi}_j(2\omega) = 2^{-1/2} \hat{m}_{S_j}(\omega) \hat{\phi}_j(\omega) \tag{3.30}$$

follows incorporating the lattice functions S_j.

There are two distinct methods for obtaining the scaling and wavelet coefficients. For instance, the scaling coefficients D_{jk} may be obtained either via a direct convolved projection of $f \in L^2$ into ν_j or alternatively via successive multiresolution decomposition in the form $\nu_{j+1} \rightarrow \nu_j \oplus w_j$. The first method is the true wavelet analysis, where f is convolved with $\{\phi_j(x) = 2^{j/2}\phi(2^j x); j \in Z\}$ followed by sampling on $\{S_j; j \in Z\}$, obtaining

$$D_{S_j}(x) = (f * \phi_j(x)) S_j(x) \quad \in \nu_j = L^2[-2^j\pi, 2^j\pi], \tag{3.31}$$

$$D_{S_{j-1}}(x) = (f * \phi_{j-1}(x)) S_{j-1}(x) \quad \in \nu_{j-1} = L^2[-2^{j-1}\pi, 2^{j-1}\pi], \tag{3.32}$$

with the scaling coefficients given by $\{D_{jk}\} \equiv \{D_{S_j}(k); k \in Z\}$.

The second method is the multiresolution analysis, with a successive projection from $\nu_j \rightarrow \nu_{j-1}$. This is achieved by convolving sequence $\{D_{jk}; k \in Z\}$ with masking coefficients $\{m_k; k \in Z\}$, $\hat{m}_{S_j}(\omega) \in \nu_j$, followed by 2:1 downsampling, obtaining

$$D_{S_{j-1}}(x) = (m_{S_j}(x) * D_{S_j}(x)) S_{j-1}(x) \in \nu_{j-1}, \tag{3.33}$$

where on substituting for $D_{S_j}(x)$ and $D_{S_{j-1}}(x)$ from Eqs. (3.31) and (3.32)

$$f * \phi_{j-1}(x) S_{j-1}(x) = m_{S_j}(x) * f * \phi_j(x) S_j(x) S_{j-1}(x) = m_{S_j}(x) * f * \phi_j(x) S_{j-1}(x) \tag{3.34}$$

and therefore

$$f * \phi_{j-1}(x) = m_{S_j}(x) * f * \phi_j(x) \tag{3.35}$$

with Fourier transform

$$\hat{f}(\omega)\hat{\phi}_{j-1}(\omega)=\hat{m}_{S_j}(\omega)\hat{f}(\omega)\hat{\phi}_j(\omega). \tag{3.36}$$

On substituting $\hat{\phi}_{j-1}(\omega)=2^{1/2}\hat{\phi}_j(2\omega)$ one obtains the dilation equation

$$\hat{\phi}_j(2\omega)=2^{-1/2}\hat{m}_{S_j}(\omega)\hat{\phi}_j(\omega), \quad \hat{m}_{S_j}(\omega)\in\nu_j \tag{3.37}$$

with inverse Fourier transform

$$\phi_j(x/2)=2^{1/2}\sum_n m_n\phi_j(x-2^{-j}n). \tag{3.38}$$

The wavelet coefficients C_{jk} are similarly obtained, with the ''wavelet'' projection from L^2 given by

$$C_{S_{j-1}}(x)=(f*\psi_{j-1}(x))S_{j-1}(x)\in w_{j-1} \tag{3.39}$$

and ''multiresolution'' from $\nu_j\rightarrow w_{j-1}$ with masking sequence $\{m^1{}_k:k\in Z\}$, $\hat{m}^1{}_{S_j}(\omega)\in w_j$, given by

$$C_{S_{j-1}}(x)=(m^1{}_{S_j}(x)*D_{S_j}(x))S_{j-1}(x) \quad \in w_{j-1}, \tag{3.40}$$

obtaining

$$\hat{\psi}_j(2\omega)=2^{-1/2}\hat{m}^1{}_{S_j}(\omega)\hat{\phi}_j(\omega), \quad \hat{m}^1{}_{S_j}(\omega)\in w_j. \tag{3.41}$$

IV. WAVELET ALIASING

Multiresolution analysis, first introduced by Mallat[2,3] for two-dimensional image processing, has the desirable feature of reconstructing images in increasing resolution as higher scales are incorporated. Some of these added details arise from the unfolding of aliased frequencies that were present in a blurred form at lower scales. An important distinction between various multiresolutions obtained from distinct wavelet families relates to the amount of aliasing present in the wavelet coefficients. In this section some well-known concepts of sampling and aliasing are discussed and a general formalism for removal of aliasing forms the framework for understanding how multiresolution subspaces arise, the approach also clearly revealing the way aliasing gets incorporated into wavelet coefficients. Also, exact relations between wavelet and scaling filters are obtained and a representation of the filters in the Euler angles provides a heuristic derivation of the Haar filter.

A. Aliasing

For a given lattice S_j with sampling interval $\Delta_j=2^{-j}$, the Nyquist bandwidth $\Omega_j=2\pi(2\Delta_j)^{-1}=2^j\pi$ corresponds to the maximum frequency that can be accurately sampled on that lattice. Therefore, a function $f\in L^2$ bandlimited to $[-\Omega,\Omega]$ when sampled on a lattice S_j with bandwidth $\Omega_j<\Omega$ results in a summing of frequencies beyond Ω_j with those within the passband $[-\Omega_j,\Omega_j]$ giving rise to the phenomenon of aliasing. A familiar example is the Moire patterns seen in a rotating fan, where a low frequency rotation appears superimposed on the actual high frequency rotation due to the insufficient sampling rate of the eye. Aliasing is more easily analyzed in the frequency domain where the Fourier transform of a sampled function is given by

$$\hat{f}_{S_j}(\omega)=2^j\sum_n \hat{f}(\omega-2\Omega_j n), \quad \Omega_j=2^j\pi \tag{4.1}$$

and on multiplying both sides by the characteristic filter $\chi_j(\omega)$ [given by Eq. (3.28)] one obtains the passband frequencies given by

$$\hat{g}(\omega)=\hat{f}_{S_j}(\omega)\chi_j(\omega)=2^j\sum_n \hat{f}(\omega-2^{j+1}\pi n)\chi_j(\omega). \tag{4.2}$$

One particular reconstruction for f from its sampled values is obtained by taking the inverse Fourier transform of the first equality obtaining

$$g(x)=f_{S_j}(x)*(\mathscr{F}^{-1}\chi_j)(x)=f_{S_j}(x)*2^j\ \mathrm{sinc}(2^j\pi x), \tag{4.3}$$

where $\mathrm{sinc}(x)=\sin(x)/x$. In the case of either sufficient or oversampling, when $\Omega_j\geqslant\Omega$, there are no overlap of the translates in Eq. (4.2) into the passband region, and the filter χ picks out only one term, namely, $\hat{g}(\omega)=2^j\hat{f}(\omega)$, with inverse Fourier transform

$$g(x)=2^jf(x)=\sum_n \int_{-\infty}^{\infty} f(x')2^{-j/2}\delta(x'-2^{-j}n)2^j\ \mathrm{sinc}(2^j\pi(x-x'))2^{j/2}\,dx',$$

obtaining the famous *Whittacker–Shannon–Kotel'nikov* interpolation formula for exact reconstruction from sampled values $f(\Delta_j n)$,

$$f(x)=\sum_n f(\Delta_j n)\mathrm{sinc}(\Omega_j(x-\Delta_j n)). \tag{4.4}$$

For insufficient sampling, when $\Omega_j<\Omega$, the translates in the summation in Eq. (4.2) overlap producing aliasing (Fig. 1). This precludes reconstruction of $f(x)$ from a single sampled sequence $\{f_n\}$. In signal processing, techniques for removal of aliasing, that unfold both high and low frequency components from subsampled data, such as the filter bank and subband coding techniques, rely on several distinct subsampled sequences obtained by phase filtering and processed simultaneously. In image processing, distinct subsampled sets may be obtained by varying the optical transfer function, effected by changing the width of the camera lens.[16]

Wavelet aliasing also has its origin in undersampling as a wavelet coefficient C_{jk} is obtained by convolving $f\in L^2$ with wavelet ψ_j followed by sampling on S_j, given by

$$C_j(x)=f(x)*\psi_j(x)S_j(x)\in w_j, \tag{4.5}$$

with Fourier transform

$$\hat{C}_j(\omega)=\hat{f}\hat{\psi}_j*\hat{S}_j(\omega)=2^j\sum_n \hat{f}(\omega-2^{j+1}\pi n)\hat{\psi}_j(\omega-2^{j+1}\pi n). \tag{4.6}$$

Now if the bandwidth of the convolved function $\hat{f}\hat{\psi}_j$ exceeds the passband Ω_j of the sampling lattice, adjacent, possibly several translates overlap producing aliased coefficients $C_{jk}=C_j(k)$.

In dyadic multiresolution, C_{jk} is obtained via successive 2:1 downsampling, with aliasing occurring at most from one adjacent translate at each scale, thereby enabling the much simpler algorithm used in practice for successive reconstruction and removal of aliasing.

B. Removal of aliasing

As an approximation theory, multiresolution pertains to a reconstruction sequence $\{f^j;j\in Z\}\rightarrow f$, obtained by incorporating successively higher scales $\nu_{j-1}\oplus w_{j-1}\rightarrow\nu_j$, which improves sharpness and fidelity by incorporating higher frequencies while simultaneously unfolding aliased frequencies. The formulation for the removal of aliasing starts with a more general class of

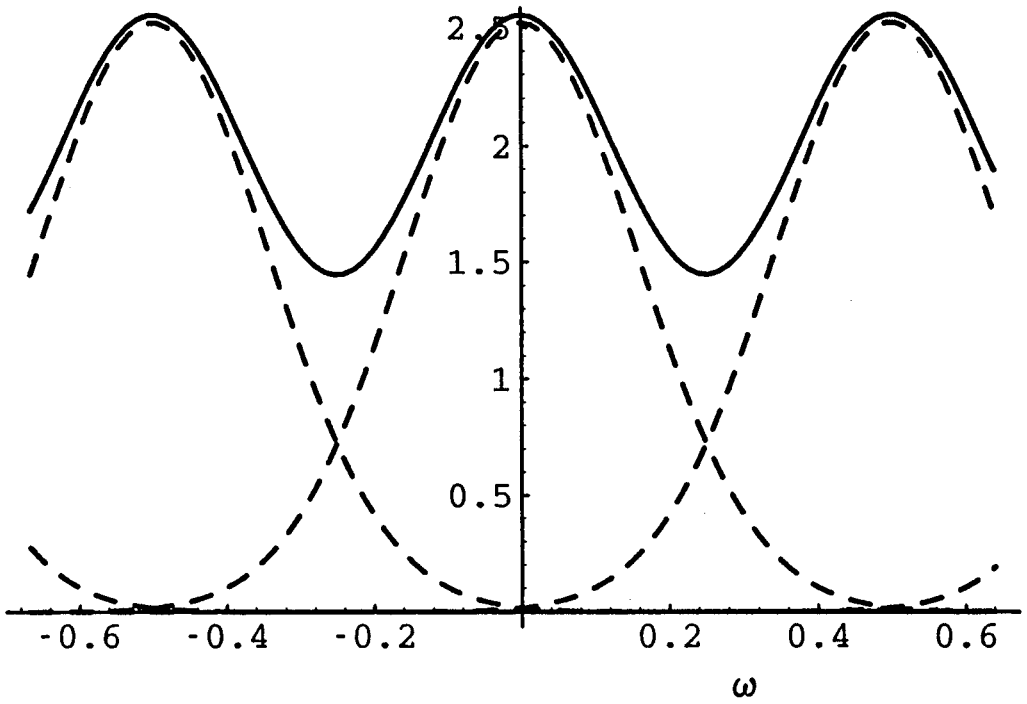

FIG. 1. Aliasing due to undersampling. The figure plots Eq. (4.1) for $j=-1$. The dotted lines are the translated functions $\frac{1}{2}\hat{f}(\omega-\pi n)$ and the solid line is their sum, representing the sampled function. Aliasing arises from the overlapping regions of the translates (ω is in units of 2π).

masking coefficients $\{m_k\}\in C$ than indicated for multiresolution, and subsequently restricted to obey orthonormality relations. The following proposition indicates that in dyadic multiresolution, at each 2:1 downsampling, aliasing accumulates from overlap of a single nearest translate.

Proposition 4.1: Aliasing in 2:1 *downsampling of a sequence* $\{f_k=f(2^{-j}k);k\in Z\}$ *arises from overlap of a single nearest translate, with*

$$\hat{f}_{S_{j-1}}(\omega)=2^{-1/2}[\hat{f}_{S_j}(\omega)+\hat{f}_{S_j}(\omega-2^j\pi)]. \tag{4.7}$$

Proof: From Proposition (3.1) the sequence has representation $f_{S_j}(x)$ with 2:1 downsampling given by

$$f_{S_{j-1}}(x)=f_{S_j}(x)S_{j-1}(x) \tag{4.8}$$

with Fourier transform

$$\begin{aligned}\hat{f}_{S_{j-1}}(\omega)&=\hat{f}_{S_j}(\omega)*\hat{S}_{j-1}(\omega)\\&=\hat{f}_{S_j}(\omega)*2^{-1/2}[\hat{S}_j(\omega)+\hat{S}_j(\omega-2^j\pi)]\\&=2^{-1/2}[\hat{f}_{S_j}(\omega)+\hat{f}_{S_j}(\omega-2^j\pi)],\end{aligned} \tag{4.9}$$

where the second equality follows from Eq. (3.20) and the last from the equivalence

$$f_{S_j}(x)S_j(x)\equiv f_{S_j}(x). \tag{4.10}$$

□

Evidently, the original sequence cannot be recovered directly from the downsampled sequence. However, consider the following. Generate a sequence $\{g^0{}_k; k \in Z\}$ by convolving $\{f_k; k \in Z\}$ with a masking sequence $\{m^0{}_k; k \in Z\}$ followed by a 2:1 downsampling, obtaining the sequence $\{g^0{}_k; k \in 2Z\}$. Then from Proposition (4.1)

$$\hat{g}^0{}_{S_{j-1}}(\omega) = 2^{-1/2}[\hat{g}^0{}_{S_j}(\omega) + \hat{g}^0{}_{S_j}(\omega - 2^j\pi)], \tag{4.11}$$

where

$$\hat{g}^0{}_{S_j}(\omega) = \hat{m}^0{}_{S_j}(\omega)\hat{f}_{S_j}(\omega). \tag{4.12}$$

This suggests that to recover f_k a second equation may be set up with a different masking sequence $\{m^1{}_k\}$, with the two equations written out explicitly in the form

$$\hat{g}^0{}_{S_{j-1}}(\omega) = 2^{-1/2}[\hat{m}^0{}_{S_j}(\omega)\hat{f}_{S_j}(\omega) + \hat{m}^0{}_{S_j}(\omega - 2^j\pi)\hat{f}_{S_j}(\omega - 2^j\pi)], \tag{4.13}$$

$$\hat{g}^1{}_{S_{j-1}}(\omega) = 2^{-1/2}[\hat{m}^1{}_{S_j}(\omega)\hat{f}_{S_j}(\omega) + \hat{m}^1{}_{S_j}(\omega - 2^j\pi)\hat{f}_{S_j}(\omega - 2^j\pi)]. \tag{4.14}$$

Solving for $\hat{f}_{S_j}$, one obtains

$$\mathbf{F}_j(\omega) = M_j^{-1}(\omega)\mathbf{G}_{j-1}(\omega), \tag{4.15}$$

where

$$\mathbf{F}_j(\omega) = \begin{pmatrix} \hat{f}_{S_j}(\omega) \\ \hat{f}_{S_j}(\omega - 2^j\pi) \end{pmatrix}, \quad \mathbf{G}_{j-1}(\omega) = \begin{pmatrix} \hat{g}^0{}_{S_{j-1}}(\omega) \\ \hat{g}^1{}_{S_{j-1}}(\omega) \end{pmatrix} \tag{4.16}$$

and

$$M_j(\omega) = 2^{-1/2}\begin{pmatrix} \hat{m}^0{}_{S_j}(\omega) & \hat{m}^0{}_{S_j}(\omega - 2^j\pi) \\ \hat{m}^1{}_{S_j}(\omega) & \hat{m}^1{}_{S_j}(\omega - 2^j\pi) \end{pmatrix}, \tag{4.17}$$

the only requirement for a solution being that M_j be invertible, that is, $M_j \in \mathrm{GL}(2,C)$, the general linear group of 2×2 invertible matrices. The components of $\mathbf{F}_j$ are defined in orthogonal intervals within the passband of S_j, the upper component $\hat{f}_{S_j}(\omega)$ in $0 \leqslant |\omega| < \Omega_j/2$ and the lower component $\hat{f}_{S_j}(\omega - 2^j\pi)$ being the same as $\hat{f}_{S_j}(\omega)$ in the interval $\Omega_j/2 \leqslant |\omega| < \Omega_j$. The components of $\mathbf{G}_{j-1}$ are defined on S_{j-1}, each representing distinct aliased information. A solution in the interval $0 \leqslant |\omega| \leqslant \Omega_j/2$ unfolds the aliasing obtaining $\hat{f}_{S_j}(\omega)$ in $0 \leqslant |\omega| < \Omega_j$.

C. Unitary groups and multiresolution

Most of the results in this section are implicit in earlier works. In general, the only requirement on $M_j \in \mathrm{GL}(2,C)$ is that $\det M_j \neq 0$ in the interval $0 \leqslant |\omega| \leqslant \Omega_j/2$ for a solution to exist. A further restriction of M_j to the unitary group, $M_j \subset \mathrm{U}(2)$ has $M_j{}^\dagger M_j = I$ and

$$\mathbf{G}_{j-1}{}^\dagger \mathbf{G}_{j-1} = (M_j\mathbf{F}_j)^\dagger M_j\mathbf{F}_j = \mathbf{F}_j{}^\dagger \mathbf{F}_j \tag{4.18}$$

preserves norm and orthogonality. This corresponds to multiresolution and one may now identify the components of $\mathbf{F}_j$ to be specified in ν_j and that of $\mathbf{G}_{j-1}$ in orthonormal subspaces $\nu_{j-1} \oplus w_{j-1}$. The sequences $\{m^0{}_k\}, \{m^1{}_k\}$ are now the scaling and wavelet masking coefficients and the components of $\mathbf{G}_{j-1}$ the scaling and wavelet coefficients.

Note: To simplify notation only the $j=0$ case will be considered in the rest of the paper and the subscript S_j will be dropped.

The next proposition derives exact relations between scaling and wavelet filters from the general structure of U(2) matrices.

Proposition 4.2: Let $M_U \in \mathrm{U}(2)$ *and* $M_S \in \mathrm{SU}(2)$ *with* $M_U = e^{i\theta} M_S$, $\theta \in R$, *and where* U(2) *and* SU(2) *are the unitary and the special unitary groups. Then the elements* $\hat{m}^0(\omega), \hat{m}^1(\omega)$ *of* $M_j \in \mathrm{U}(2)$ *are uniquely related as*

$$\hat{m}^0(\omega) = e^{i2\theta} \hat{m}^{1*}(\omega - \pi), \tag{4.19}$$

$$\hat{m}^1(\omega) = -e^{i2\theta} \hat{m}^{0*}(\omega - \pi), \tag{4.20}$$

obtaining the unitarity relation

$$2^{-1}(|\hat{m}^0(\omega)|^2 + |\hat{m}^0(\omega - \pi)|^2) = 1. \tag{4.21}$$

Proof: A general representation for $M_S \in \mathrm{SU}(2)$ is given by

$$M_S = \begin{pmatrix} \xi & \eta \\ -\eta^* & \xi^* \end{pmatrix}, \tag{4.22}$$

where $\eta, \xi \in C$. The requirement $\det M_S = |\eta|^2 + |\xi|^2 = 1$ reduces the number of independent variables to three. A subset of the unitary group $M_U \subset \mathrm{U}(2)$ that represent M_j may be parametrized in ω and equated to M_j,

$$e^{i\theta(\omega)} \begin{pmatrix} \xi(\omega) & \eta(\omega) \\ -\eta^*(\omega) & \xi^*(\omega) \end{pmatrix} = 2^{-1/2} \begin{pmatrix} \hat{m}^0(\omega) & \hat{m}^0(\omega - \pi) \\ \hat{m}^1(\omega) & \hat{m}^1(\omega - \pi) \end{pmatrix}. \tag{4.23}$$

Comparing ξ, ξ^* with corresponding elements on the right-hand side proves Eq. (4.19), and a similar comparison of η, η^* proves Eq. (4.20). These relations together with $\det M_S = 1$ obtain the unitarity relation. □

Corollary: For $M_S \in M_j \subset \mathrm{SU}(2)$, η, ξ are related as

$$\eta(\omega) = \xi(\omega - \pi), \tag{4.24}$$

obtained by comparing the top rows of Eq. (4.23).

D. Euler angle representation of $M_j \subset$ SU(2)

A useful representation of $M_S \in \mathrm{SU}(2)$ is in the three Euler angles of rigid body rotations given by

$$M_S{}^E = \begin{pmatrix} e^{i(\alpha+\gamma)/2} \cos(\beta/2) & ie^{-i(\alpha-\gamma)/2} \sin(\beta/2) \\ ie^{-i(\alpha-\gamma)/2} \sin(\beta/2) & e^{-i(\alpha+\gamma)/2} \cos(\beta/2) \end{pmatrix} \tag{4.25}$$

and exhibits 4π periodicity in the Euler angles. This corresponds to a 2:1 homomorphism with the rotation group SO(3), with two group elements $\pm M_S \in \mathrm{SU}(2)$ mapping onto a single group element in SO(3). Substituting into the left-hand side of Eq. (4.23) and also including an ω dependency for the Euler angles $(\alpha(\omega), \beta(\omega), \gamma(\omega))$ to indicate the subset of SU(2) matrices representing M_j yields the following relations:

$$2^{-1/2} \hat{m}^0(\omega) = e^{i(\alpha(\omega)+\gamma(\omega))/2} \cos(\beta(\omega)/2), \tag{4.26}$$

$$2^{-1/2}\hat{m}^1(\omega)=e^{-i(\alpha(\omega)-\gamma(\omega)-\pi)/2}\sin(\beta(\omega)/2). \tag{4.27}$$

This form permits a mapping of the SU(2) filters onto orbits on the SO(3) manifold. The SO(3) manifold consists of all points within a sphere of radius π,[20] with each point mapping to a specific Euler set (α, β, γ). The frequency dependent Euler set $(\alpha(\omega), \beta(\omega), \gamma(\omega))$ representing a particular filter therefore traces a continuous orbit on the SO(3) group manifold as a function of ω.

In the following proposition, relations between Euler angles at ω and $\omega-\pi$ are given, that obtains a heuristic derivation of the Haar filter.

Proposition 4.3: The Euler angles (α,β,γ) *at* ω *and* $\omega-\pi$ *are related as*

$$\alpha(\omega-\pi)=\alpha(\omega)+\pi,\quad \beta(\omega-\pi)=\beta(\omega)-\pi,$$
$$\gamma(\omega-\pi)=-\gamma(\omega). \tag{4.28}$$

Proof: Since $\hat{m}^0(\omega-\pi)=-\hat{m}^{1*}(\omega)$ from Eq. (4.20), then from Eqs. (4.26) and (4.27),

$$e^{i(\alpha(\omega-\pi)+\gamma(\omega-\pi))/2}\cos(\beta(\omega-\pi)/2)=e^{i(\alpha(\omega)-\gamma(\omega)+\pi))/2}\sin(\beta(\omega)/2) \tag{4.29}$$

and the results are deduced by comparing the Euler angles on both sides. □

E. Haar filter

One particular guess for the Euler angles that checks with Eqs. (4.28) is

$$\alpha(\omega)=-\omega,\quad \beta(\omega)=\omega,\quad \gamma(\omega)=0, \tag{4.30}$$

and results in the Haar filter matrix M_H [substituting in Eq. (4.25)],

$$M_H=\begin{pmatrix} e^{-i\omega/2}\cos(\omega/2) & ie^{-i\omega/2}\sin(\omega/2) \\ ie^{i\omega/2}\sin(\omega/2) & e^{i\omega/2}\cos(\omega/2)\end{pmatrix}. \tag{4.31}$$

Therefore one may infer

$$\hat{m}^0(\omega)=2^{1/2}e^{-i\omega/2}\cos(\omega/2)=2^{-1/2}(1+e^{-i\omega}) \tag{4.32}$$

and the masking coefficients for $\hat{m}^0(\omega)=\Sigma_n m_n e^{-i\omega n}$ are read off as $\{m^0{}_k\}=\{2^{-1/2},2^{-1/2}\}$. There also exists a second possibility $(\alpha(\omega),\beta(\omega),\gamma(\omega))\equiv(\omega+2\pi,\omega,0)$ and this corresponds to the other 2:1 map giving $-M_H$ and is typical for 2:1 homomorphism.

V. ORTHONORMAL FILTERS

It is shown that the underlying group structure for the $\{DN\}$ collection of orthonormal filters is SU(2). Using the Euler angle representation for SU(2) the filters are then expressed in terms of the three Euler angles. Also a proof relating $D\infty$ to Shannon filter is established.

A. SU(2) structure of $\{DN\}$ filters

A systematic construction of orthonormal scaling filters assumes the following unitarity and admissibility relations:

$$|\hat{m}^0(\omega)|^2+|\hat{m}^0(\omega-\pi)|^2=2, \tag{5.1}$$

$$\hat{m}^0(0)=2^{1/2}. \tag{5.2}$$

The pioneering work by Daubechies[1] paved the way for several construction procedures, and the version by Strichartz[21] will be followed here. In this section it will be shown that the relevant group structure for the $\{DN\}$ filters is SU(2)⊂U(2).

The Strichartz method consists in the binomial expansion of

$$[\cos^2(\omega/2)+\sin^2(\omega/2)]^{2N-1}=1 \tag{5.3}$$

written in the form of the unitarity relation [Eq. (5.1)]

$$Q_1(\omega)+Q_2(\omega)=1, \tag{5.4}$$

where

$$x=\cos(\omega/2). \tag{5.5}$$

Q_1, Q_2 are given by

$$Q_1(\omega)=2^{-1}|\hat{m}^0(\omega)|^2=x^{2N}\sum_{k=0}^{N-1}\binom{2N-1}{k}x^{2N-2-2k}(1-x^2)^k, \tag{5.6}$$

$$Q_2(\omega)=Q_1(\omega-\pi)=2^{-1}|\hat{m}^0(\omega-\pi)|^2=(1-x^2)^N\sum_{k=0}^{N-1}\binom{2N-1}{k}(1-x^2)^{N-1-k}x^{2k}. \tag{5.7}$$

Further, using the Riesz lemma, Q_1 and Q_2 are expressed as polynomials in $Z=e^{-i\omega}$,[1]

$$Q_1(\omega)=|x^N e^{i\omega(N-1)/2}R_{N-1}(Z)|^2, \tag{5.8}$$

$$Q_2(\omega)=|(1-x^2)^{N/2}e^{i(\omega-\pi)(N-1)/2}R_{N-1}(-Z)|^2, \tag{5.9}$$

with

$$R_{N-1}(Z)=\sum_{n=0}^{N-1}b_n e^{-i\omega n}, \quad b_n\in R^1, \tag{5.10}$$

and

$$\sum_{n=0}^{N-1}b_n=1. \tag{5.11}$$

The unitarity relation therefore takes the form

$$x^{2N}|e^{i\omega(N-1)/2}R_{N-1}(Z)|^2+(1-x^2)^N|e^{i(\omega-\pi)(N-1)/2}R_{N-1}(-Z)|^2=1 \tag{5.12}$$

and this clearly indicates that the ''regularity'' term x^{2N} cannot be factored out from Q_1 (or from $\hat{m}_0$), while still maintaining the unitarity relation, thereby implying regularity to be an intrinsic feature of multiresolution.

Substituting for $x=\cos(\omega/2)$ in Eqs. (5.8) and (5.9), Q_1 and Q_2 take the form

$$Q_1(\omega)=|e^{i\omega(2N-1)/2}P_{2N-1}(Z)|^2, \tag{5.13}$$

$$Q_2(\omega)=|e^{i(\omega-\pi)(2N-1)/2}P_{2N-1}(-Z)|^2, \tag{5.14}$$

where

$$P_{2N-1}(Z)=2^{-N}(1+e^{-i\omega})^N\sum_{n=0}^{N-1} b_n e^{-i\omega n},\quad b_n\in R^1 \tag{5.15}$$

is a $(2N-1)$th polynomial in Z. From Eqs. (5.6), (5.13), and (4.23) relations between the filter, the binomial expansion series, and the variables of unitary matrices is obtained,

$$2^{-1/2}\hat{m}^0(\omega)=e^{i\omega(2N-1)/2}P_{2N-1}(Z)=e^{i\theta(\omega)}\xi(\omega) \tag{5.16}$$

and on comparing the second equality,

$$\theta(\omega)=\omega(2N-1)/2,\quad \xi(\omega)=P_{2N-1}(Z). \tag{5.17}$$

The filter $\hat{m}^0(\omega)$ represents an orthonormal scaling filter and its companion wavelet filter is obtained from $\hat{m}^1(\omega)=-e^{i2\theta}\hat{m}^{0*}(\omega-\pi)$, yielding

$$2^{-1/2}\hat{m}^1(\omega)=-e^{i(\omega+\pi)(2N-1)/2}P^*_{2N-1}(-Z). \tag{5.18}$$

Together, these filters define a unitary filter matrix,

$$M_j=e^{i\omega(2N-1)/2}\begin{pmatrix} P_{2N-1}(Z) & ie^{-i\pi N}P_{2N-1}(-Z)\\ ie^{i\pi N}P^*_{2N-1}(-Z) & P^*_{2N-1}(Z)\end{pmatrix}. \tag{5.19}$$

A comparison with the unitary matrix in the form $M_U=e^{i\theta}M_S$ obtains $\theta=\omega(2N-1)/2\in R^1$ and M_S given by the matrix in Eq. (5.19), with $\xi(\omega)=P_{2N-1}(Z)$ and $\eta(\omega)=ie^{-i\pi N}P_{2N-1}(-Z)$.

By definition the $\{DN\}$ filters are

$$2^{-1/2}\hat{m}^0(\omega)=P_{2N-1}(Z), \tag{5.20}$$

$$2^{-1/2}\hat{m}^1(\omega)=-P^*_{2N-1}(-Z), \tag{5.21}$$

where the wavelet filter is obtained from $\hat{m}^1(\omega)=-\hat{m}^{0*}(\omega-\pi)$ and compares with M_S in Eq. (5.19) except for a constant phase factor. This shows that a conventional $\{DN\}$ filter has only an underlying SU(2) group structure. These filters can therefore be expressed entirely in the Euler angles.

B. Euler angle representation of $\{DN\}$ filters

SU(2) is 2:1 homomorphic to the rotation group SO(3) [there are two group elements, $\pm M_S\in \mathrm{SU}(2)$ that map to a single element in SO(3)]. A parametrization of SU(2) in terms of the rotation angles, in particular, the three Euler angles, provides a graphic portrayal of the $\{DN\}$ filters as a collection of orbits on the SO(3) manifold, with the members related via rotations in three-dimensional space. The transformation into the Euler representation may be accomplished by writing

$$P(Z)=e^{i\phi_1(\omega)/2}|P(Z)|, \tag{5.22}$$

$$P(-Z)=e^{i\phi_2(\omega)/2}|P(-Z)|, \tag{5.23}$$

and therefore Eqs. (5.20) and (5.21) become

$$2^{-1/2}\hat{m}^0(\omega)=P_{2N-1}(Z)=e^{i\phi_1(\omega)/2}|P_{2N-1}(Z)|, \tag{5.24}$$

$$2^{-1/2}\hat{m}^1(\omega)=-P^*_{2N-1}(-Z)=e^{-i(\phi_2(\omega)-2\pi)/2}|P_{2N-1}(-Z)|. \tag{5.25}$$

On comparing with Eqs. (4.26) and (4.27)

$$e^{i(\alpha(\omega)+\gamma(\omega))/2}\cos(\beta(\omega)/2)=e^{i\phi_1(\omega)/2}|P_{2N-1}(Z)|, \tag{5.26}$$

$$e^{-i(\alpha(\omega)-\gamma(\omega)-\pi)/2}\sin(\beta(\omega)/2)=e^{-i(\phi_2(\omega)-2\pi)/2}|P_{2N-1}(-Z)|. \tag{5.27}$$

One may then deduce from these equations,

$$\phi_1(\omega)=\alpha(\omega)+\gamma(\omega), \tag{5.28}$$

$$\phi_2(\omega)=\alpha(\omega)-\gamma(\omega)+\pi, \tag{5.29}$$

$$\cos(\beta(\omega)/2)=|P_{2N-1}(Z)|, \tag{5.30}$$

and on solving for α, γ, we obtain

$$\alpha(\omega)=(\phi_1(\omega)+\phi_2(\omega)-\pi)/2, \tag{5.31}$$

$$\gamma(\omega)=(\phi_1(\omega)-\phi_2(\omega)+\pi)/2. \tag{5.32}$$

The transformation is particularly simple for $N=1$ when Eq. (5.15) gives

$$P_1(Z)=2^{-1}(1+e^{-i\omega})=e^{-i\omega/2}\cos(\omega/2), \tag{5.33}$$

$$P_1(-Z)=2^{-1}(1-e^{-i\omega})=e^{-i(\omega-\pi)/2}\sin(\omega/2) \tag{5.34}$$

and comparing with Eqs. (5.22) and (5.23) one obtains $\phi_1(\omega)=-\omega$, $\phi_2(\omega)=-\omega+\pi$ and $|P_1(Z)|=\cos(\omega/2)$. Substituting in Eqs. (5.30)–(5.32),

$$\alpha(\omega)=-\omega,\quad \beta(\omega)=\omega,\quad \gamma(\omega)=0, \tag{5.35}$$

to be compared with Eq. (4.30) obtained heuristically for the Haar filter.

C. Shannon filter: $D\infty$

The $\{DN\}$ collection is a denumerable set of compactly supported orthonormal filters with increasing support. At one extreme is the Haar filter $(D1)$ with minimal support, while in the $N\to\infty$ limit, as will be shown in this section, $D\infty$ corresponds to the Shannon filter with noncompact support but having well-defined bandlimiting properties. An indication toward this limiting trend can be seen in Fig. 2, a plot for $|\hat{m}^0(\omega)|$ vs ω for $N=1,2,10$; the figure also revealing a qualitative measure for aliasing, dependent on the width of the filter, indicating maximum aliasing for Haar filter, and totally aliasing free for Shannon filter. In the following proposition it is shown that the Shannon filter corresponds to $D\infty$.

Proposition 5.1: $D\infty$ is equivalent to the Shannon filter as defined by

$$|\hat{m}^0(\omega)|=\begin{cases}1, & 0\leqslant|\omega|<\dfrac{\pi}{2}\\[2ex] 0, & \dfrac{\pi}{2}\leqslant|\omega|<\pi.\end{cases} \tag{5.36}$$

Proof: Since from Eqs. (5.24) and (5.30)

$$2^{-1/2}|\hat{m}^0(\omega)|=|P_{2N-1}(Z)|=|\cos(\beta(\omega)/2)|, \tag{5.37}$$

the following equivalent statement holds true for $N\to\infty$,

$$\beta(\omega)\to 0,\quad 0\leqslant|\omega|<\pi/2, \tag{5.38}$$

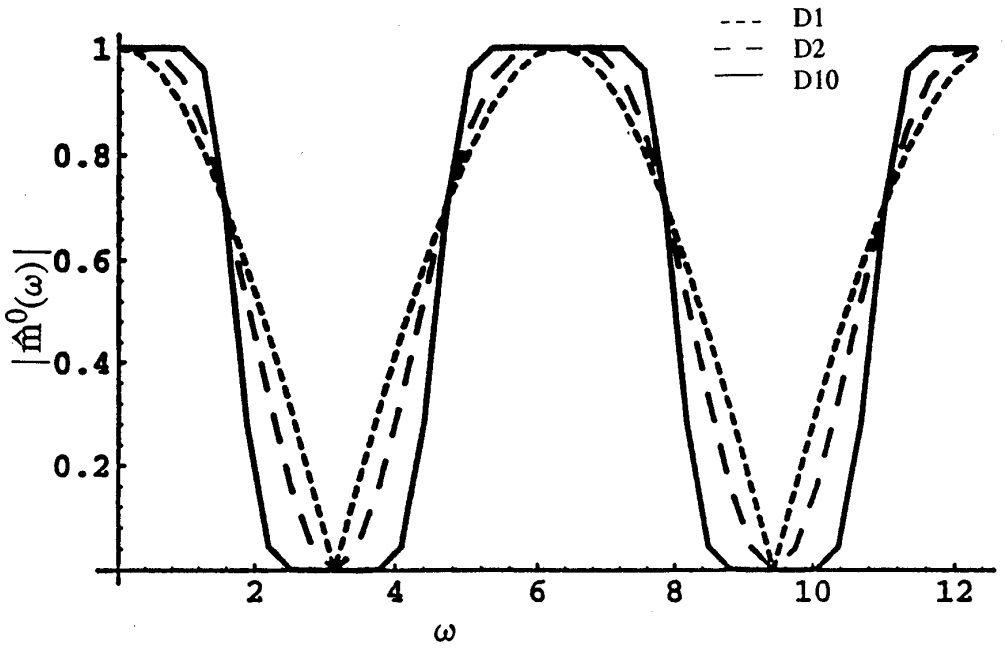

FIG. 2. The 2π periodic filter $|\hat{m}^0(\omega)|$ vs ω for $D1$, $D2$, $D10$. The first zero is at $\omega=\pi$. In 2:1 downsampling this figure is overlayed with one shifted by π, producing aliasing from overlapping regions that vanishes in the limiting case $D\infty$.

$$\beta(\omega)\to\pi, \quad \pi/2\leqslant|\omega|<\pi \tag{5.39}$$

and is proved using the De Moivre–Laplace theorem. The theorem states that the binomial function $f_M(k)$ defined by

$$f_M(k)=\binom{M}{k}q^k p^{M-k}, \tag{5.40}$$

p,q positive, $p+q=1$, $(M,k\in Z_+)$, approaches a normal or Gaussian distribution $g_M(k)$ in the limit $Mpq\gg 1$, centered at mean Mq and width $(Mpq)^{1/2}$, that is,

$$f_M(k)\to g_M(k), \quad Mpq\gg 1, \tag{5.41}$$

where

$$g_M(k)=(2\pi Mpq)^{-1/2}e^{-(k-Mq)^2/(2Mpq)}. \tag{5.42}$$

To prove Eq. (5.38), let

$$p=\cos^2(\omega/2), \quad q=\sin^2(\omega/2), \tag{5.43}$$

then for $0\leqslant|\omega|<\pi/2$, one has $1\leqslant p<\frac{1}{2}$ and $0\leqslant q<\frac{1}{2}$. From Eqs. (5.6) and (5.37),

$$\cos^2(\beta(\omega)/2)=Q_1(\omega)=\sum_{k=0}^{N-1}\binom{2N-1}{k}p^{2N-1-k}q^k=\sum_{k=0}^{N-1}f_M(k), \tag{5.44}$$

where $M=2N-1$. In the limit $N\to\infty$, $Mpq\gg 1$, the stated theorem has $f_M(k)\to g_M(k)$ and also replacing the sum by an integration over k, Eq. (5.44) becomes

$$I=\cos^2(\beta(\omega)/2)\approx\int_0^N g_M(k)dk. \tag{5.45}$$

Now for $0\leqslant q<\frac{1}{2}$ one has $0\ll Mq\ll N$, showing the upper limit to be well beyond the mean of the Gaussian $g_M(k)$. Similarly with the width $(Mpq)^{1/2}\ll Mq$, one may conclude that the significant contribution from the integrand lies well within the limits of integration [a rough estimate requires $M^{1/2}(\frac{1}{2}-q)>3(pq)^{1/2}$], whence it follows $I\approx 1$ and therefore in the limit $N\to\infty$,

$$\cos(\beta(\omega)/2)\to 1 \tag{5.46}$$

or

$$\beta(\omega)\to 0,\quad 0\leqslant|\omega|<\pi/2 \tag{5.47}$$

proves Eq. (5.38).

A similar argument holds for Eq. (5.39) with $\pi/2\leqslant|\omega|<\pi$ and $\frac{1}{2}\leqslant p<0$, $\frac{1}{2}\leqslant q<1$. Now $Mq\gg N$ and with $(Mpq)^{1/2}\ll Mq-N$ the integrand is well outside the integration limits and hence $I\approx 0$ and in the limit $N\to\infty$,

$$\beta(\omega)\to\pi,\quad \pi/2\leqslant|\omega|<\pi \tag{5.48}$$

completes the proof. □

VI. SCALED FILTERS

Filters satisfying both unitarity and admissibility relations do not necessarily produce orthonormal basis.[17–19] Dlin and Madych[19] gave nontrivial examples of such filters. An additional sufficiency relation to ensure orthonormality of the scaling function ϕ is stated as

$$|\hat{m}^0(\omega)|\neq 0,\quad 0\leqslant|\omega|\leqslant\pi/3 \tag{6.1}$$

and follows from a corollary to Cohen's theorem[17] (see also in Ref. 6, Corollary 6.3.2). Lawton's criterion,[18] requires nondegeneracy on the eigenvalue 1 of a $(2K-1)\times(2K-1)$ matrix $\mathbf{A}$ defined by

$$A_{lk}=\sum_{n=0}^{K} m(n)\overline{m}(k-2l+n),\quad -K+1\leqslant l,\ k\leqslant K-1,$$

where $m(n)=0$ if $n<0$ or $n>K$. That both Cohen's and Lawton's conditions are equivalent (see Ref. 6) allows one to focus on Eq. (6.1). A rather elegant new proof for this criterion is given here in the Euler angle representation, but first, the cause for lack of sufficiency of the unitarity relation is examined in the next two propositions.

Proposition 6.1: Let

$$\hat{m}^0(\omega)=\sum_n m(n)e^{-i\omega n} \tag{6.2}$$

represent an orthonormal filter for V_0 with periodicity 2π. Then their scaled versions

$$\hat{m}^0{}_N(\omega)=\sum_n m(n)e^{-i\omega nN}, \quad N \text{ odd integer} \tag{6.3}$$

also satisfy the unitarity relation but with a reduced periodicity $2\pi/N$ *that preclude them from generating an orthonormal basis for* V_0.

Proof: The unitarity relation gives

$$|\hat{m}^0(N\omega)|^2+|\hat{m}^0(N\omega-\pi)|^2=2$$

and since $\hat{m}^0(\omega)$ is 2π periodic in ω, for N odd one may write,

$$|\hat{m}^0(N\omega)|^2+|\hat{m}^0(N(\omega-\pi))|^2=2. \tag{6.4}$$

Scaled filters $\hat{m}^0{}_N(\omega)$ are defined by (note that this is not dyadic scaling, but will be termed pathological scaling)

$$\hat{m}^0{}_N(\omega)=\hat{m}^0(N\omega)=\sum_n m(n)e^{-i\omega nN}=\sum_n m_N(n)e^{-i\omega n} \tag{6.5}$$

with the new coefficients defined by $m_N(Nn)=m(n)$, $n\in Z$, and 0 otherwise. Substituting in Eq. (6.4) it is seen that the scaled filters satisfy the unitarity relation (for N even the equation does not reduce to this form),

$$|\hat{m}^0{}_N(\omega)|^2+|\hat{m}^0{}_N(\omega-\pi)|^2=2 \tag{6.6}$$

but with a reduced periodicity $2\pi/N$ that preclude them from being an orthonormal filter for V_0. □

Next it is shown that the orthonormality condition

$$\sum_k |\hat{\phi}(\omega-2\pi k)|^2=1 \tag{6.7}$$

derives a series of dyadically scaled relations that are not necessarily unitarity relations.

Proposition 6.2: If $\{\phi(x-n);n\in Z\}$ *is an orthonormal basis for* V_0 *such that* $\langle\phi(0),\phi(n)\rangle=\delta_{n,0}$ *and* $\hat{m}^0(\omega)$ *an orthonormal filter for* V_0, *then the relations*

$$\sum_k |\hat{\phi}(\omega-2^{j+1}\pi k)|^2=2^{-j}, \quad \forall j\in Z \tag{6.8}$$

are satisfied, and they derive the relation

$$|\hat{m}_j^0(\omega)|^2+|\hat{m}_j^0(\omega-\pi)|^2=2, \quad j\geqslant 0 \tag{6.9}$$

with $\hat{m}_j^0(\omega)$ *denoting dyadic scaling. Since for* $j\neq 0$ *these do not represent unitarity relations, they cannot be considered as a sufficient condition on an orthonormal filter.*

Proof: To prove Eq. (6.8) define

$$|\hat{\phi}(2^j(\omega'-2\pi k))|^2=\hat{f}(\omega'-2\pi k), \tag{6.10}$$

where $\omega'=2^{-j}\omega$. Then, since

$$\mathscr{F}^{-1}[\hat{\phi}(2^j(\omega'-2\pi k))]=2^{-j}e^{-i2\pi kx}\phi(2^{-j}x), \tag{6.11}$$

the inverse Fourier transform of Eq. (6.10) is obtained as

$$f(n)=2^{-2j}e^{-i2\pi kn}\int_{-\infty}^{\infty}\phi(2^{-j}x')\phi^*(2^{-j}(n-x'))dx'=2^{-j}e^{-i2\pi kn}\delta_{n,0}, \tag{6.12}$$

where the last equality follows from the orthonormality $\langle\phi(0),\phi(n)\rangle=\delta_{n,0}$. Application of the Poisson summation formula,

$$\sum_k \hat{f}(\omega'-2k\pi)=\sum_n f(n)e^{i\omega' n}=2^{-j}, \tag{6.13}$$

proves Eq. (6.8).

Next, as in the standard method, using the dilation equation to write

$$\hat{\phi}(2\omega-2^{j+1}\pi k)=\hat{m}^0(\omega-2^j\pi k)\hat{\phi}(\omega-2^j\pi k)$$

and expanding the following summation in even and odd integers,

$$2^{-j}=\sum_k |\hat{\phi}(2\omega-2^{j+1}\pi k)|^2=2^{-1}(|\hat{m}^0(\omega)|^2+|\hat{m}^0(\omega-2^j\pi)|^2)\sum_k |\hat{\phi}(\omega-2^{j+1}\pi k)|^2, \tag{6.14}$$

obtains the following relations for $j\leqslant 0$:

$$|\hat{m}^0(\omega)|^2+|\hat{m}^0(\omega-2^j\pi)|^2=2,$$

which implies Eq. (6.9) using the transformation $\omega\rightarrow 2^j\omega$. For $j\neq 0$ these are not unitarity relations, the requirement then being

$$|\hat{m}^0{}_j(\omega)|^2+|\hat{m}^0{}_j(\omega-2^j\pi)|^2=2. \tag{6.15}$$

□

Both foregoing propositions indicate the possibility of obtaining scaled versions of a true orthonormal filter if only the unitarity relation and the condition on a scaling filter $\hat{m}_0(0)=2^{1/2}$ are employed for construction. Both emphasize exact 2π periodicity for orthonormal filters. For dyadic scaling, the $j>0$ filters are eliminated by the admissibility condition on wavelets. For pathological scaling, a well-known sufficiency relation must be satisfied. The following proposition gives the necessary and sufficient conditions on orthonormal filters.

Proposition 6.3: The necessary and sufficient conditions on a filter $\hat{m}^0(\omega)$ *to represent an orthonormal filter for* V_0 *are*:

(i) *the unitarity relation*: $|\hat{m}^0(\omega)|^2+|\hat{m}^0(\omega-\pi)|^2=2$,
(ii) *the scaling filter condition*: $\hat{m}^0(0)=2^{1/2}$,
(iii) *the wavelet admissibility condition*: $\hat{m}^0(\pi)=0$,
(iv) *a sufficiency relation eliminating pathological scaling*: $\hat{m}^0(\omega)\neq 0;\ 0\leqslant|\omega|\leqslant\pi/3$.

Proof: To prove the sufficiency relation, first it will be shown that for a valid filter $\hat{m}^0(\omega)$ there can be no zeros in $0\leqslant|\omega|<\pi$ and next, for the lowest order scaling at $N=3$, the first zero appears at $\omega=\pi/3$. The first condition is easily established in the Euler angle representation, where

$$2^{-1/2}|\hat{m}^0(\omega)|=|\cos(\beta(\omega)/2)| \tag{6.16}$$

evidently has no zero in the interval $0\leqslant|\beta(\omega)|<\pi$ because the right-hand side does not. A valid filter has a 1:1 mapping between ω and $\beta(\omega)$ since $|\cos(\beta(\omega)/2)|$ is 2π periodic in β, and $|\hat{m}^0(\omega)|$, 2π periodic in ω, giving the simultaneous intervals

$$0\leqslant|\beta(\omega)|<\pi,\quad 0\leqslant|\omega|<\pi \tag{6.17}$$

and so it may be concluded that there is no zero for $\hat{m}^0(\omega)$ as well in $0 \leqslant |\omega| < \pi$. The first zero appears at $\omega = \pi$ as can also be seen from

$$\hat{m}^0(\pi) = \sum_{n \text{ even}} m(n) - \sum_{n \text{ odd}} m(n) = -\hat{m}^{1*}(0) = 0, \tag{6.18}$$

where the last equality follows from the required admissibility condition on a wavelet filter. This less restrictive interval $[-\pi, \pi]$ was first given by Mallat (see also Fig. 2).

Next, for the $N=3$ scaled version given by Eq. (6.5) one has at $\omega = \pi/3$,

$$\hat{m}^0{}_3(\pi/3) = \hat{m}^0(3(\pi/3)) = 0, \tag{6.19}$$

showing the first zero to be at $\omega = \pi/3$ for the lowest scaling. The nonzero interval for β remains invariant for the cosine function, and one has

$$0 \leqslant |\beta(\omega)| < \pi, \quad 0 \leqslant |\omega| < \pi/3, \tag{6.20}$$

implying multiple mapping from $\beta(\omega)$ to ω in the interval $0 \leqslant |\omega| < \pi$. □

VII. SUMMARY AND OUTLOOK

This paper formulates wavelet theory in terms of a family of dyadically scaled lattice functions S_j and its algebra. A set of linear equations representing convolution and sampling determines the structure of a 2×2 filter matrix $M_j \subset \mathrm{GL}(2,C)$ defined via

$$\mathbf{G}_{j-1} = M_j \mathbf{F}_j,$$

where $\mathbf{F}_j, \mathbf{G}_{j-1}$ are vectors with components defined on S_j and S_{j-1} lattices, respectively. When $M_j \subset \mathrm{U}(2)$, the projections from S_j to S_{j-1} preserve norm and orthogonality and correspond to the multiresolution decomposition $\nu_j \rightarrow \nu_{j-1} \oplus w_{j-1}$, the components of M_j then constituting wavelet and scaling filters. This allows exact relations between the filters to be deduced from the general structure of a unitarity matrix.

The underlying group for the $\{DN\}$ filters is shown to be SU(2), with its representation in the Euler angles revealing several interesting properties. These include, a mapping to a set of orbits on the SO(3) manifold with members related to each other by three-dimensional rotations; an equivalence of $D\infty$ to Shannon filter; and a simple new proof for a sufficiency relation ruling out nonorthonormal pathological scaling. The amount of aliasing in multiresolution filters is delineated qualitatively as shown in Fig. 2, with the Haar filter producing maximum aliasing, while the Shannon filter is completely aliasing free.

The formulation for dyadic scaling can be extended directly to (N)th order scaled lattices resulting in $N \times N$ filter matrix $M_j \subset \mathrm{U}(N)$, M_j now defining N orthonormal filters and a multiresolution decomposition $\nu_{j+1} \rightarrow \nu_j \oplus w_j^1 \oplus \cdots \oplus w_j^{N-1}$. As in dyadic scaling it should be possible to relate the various filters, but the complexity increases with increasing N.

Spectrum of the Dirac operator on $Gr_2(\mathbb{C}^{m+2})$

(Received 1 July 1997; accepted for publication 23 July 1997)

The spectrum of the Dirac operator, acting on the quaternion-Kähler spin symmetric space $Gr_2(\mathbb{C}^{m+2})$, is explicitly computed by harmonic analysis methods: in particular ''branching rules'' for irreducible representations of the Lie group $\mathrm{SU}(m+2)$ and its subgroup $\mathrm{S}(\mathrm{U}(m)\times\mathrm{U}(2))$, are given. © *1998 American Institute of Physics.* [S0022-2488(98)02401-3]

I. INTRODUCTION

In the study of the relations between the spectrum of the Dirac operator and the geometry of a compact spin manifold, it is natural to consider symmetric spaces corresponding to the geometry. Indeed, for these manifolds, the spectrum of the Dirac operator can be (theoretically) computed by classical harmonic analysis methods.

In this paper, we compute the Dirac spectrum of $Gr_2(\mathbb{C}^{m+2})$. This is motivated by results of Refs. 1 and 2 about the determination of a lower bound for the square of the first eigenvalue of the Dirac operator, acting on a compact spin quaternion-Kähler manifold with positive scalar curvature. Symmetric spaces with this geometry are known: the only compact quaternion-Kähler symmetric spaces are, besides five exceptional cases, the quaternionic projective space $\mathbb{H}P^m$, the Grassmannians $Gr_2(\mathbb{C}^{m+2})$ and $\widetilde{Gr_4}(\mathbb{R}^{m+4})$.[3] In fact, these spaces are the only known examples of compact quaternion-Kähler manifolds, see Ref. 4. Furthermore, the quaternionic projective space is spin, but the last two Grassmannians are spin only for m even.[5] It is then interesting to study the Dirac operator on these three families of Grassmannians. The spectrum of the Dirac operator on $\mathbb{H}P^m$ was given in Ref. 6. Here, we consider the case of the Grassmannian $Gr_2(\mathbb{C}^{m+2})=G/K$, with $G=\mathrm{SU}(m+2)$ and $K=\mathrm{S}(\mathrm{U}(m)\times\mathrm{U}(2))$.

For symmetric spaces, the spectrum of the Dirac operator D is totally determined by the spectrum of its square. Eigenvalues of D^2 are related to irreducible G-modules V_G, whose decomposition under the action of K, has an irreducible K-module occurring in the corresponding decomposition of the spinor space.[7–10] They have the following form[10]:

$$\lambda = c(V_G) + \frac{S}{8},$$

where $c(V_G)$ is the eigenvalue of the Casimir operator of V_G.

In the following, we give the ''branching rules'' for $G=\mathrm{SU}(m+2)$ and $K=\mathrm{S}(\mathrm{U}(m)\times\mathrm{U}(2))$ (see Proposition 2 below), the decomposition into irreducible K-modules of the spinor space (Proposition 3), which enables us to compute the spectrum:

Proposition 1: *On the compact spin Riemannian symmetric space* $Gr_2(\mathbb{C}^{m+2}) \simeq \mathrm{SU}(m+2)/\mathrm{S}(\mathrm{U}(m)\times\mathrm{U}(2))$, *m even, endowed with the metric induced from the Killing form sign-changed, the spectrum of the square of the Dirac operator is*

$$k\geqslant 1 \ \ if\ \ q\leqslant m/2+p-1.$$

II. THE GRASSMANNIAN $Gr_2(\mathbb{C}^{m+2})$

We *denote* by $M_{p,q}(\mathbb{C})$ the space of $p\times q$ matrices with complex coefficients.
Let $G=\mathrm{SU}(m+2)=\{A\in M_{m+2}(\mathbb{C}); {}^t\overline{A}A=I_{m+2}; \det A=1\}$ and

$$K=\mathrm{S}(\mathrm{U}(m)\times\mathrm{U}(2))=\left\{A=\begin{pmatrix}B & 0\\ 0 & C\end{pmatrix}; \begin{cases}B\in U(m),\\ C\in U(2),\end{cases} \det A=1\right\}.$$

The quotient space G/K, identified with the Grassmannian $Gr_2(\mathbb{C}^{m+2})$, is a compact simply connected irreducible symmetric space of ''type I.''[11] The symmetric space structure is given by the involutive automorphism $\sigma: G\to G$, $A\to SAS^{-1}$, where $S=\left(\begin{smallmatrix}I_m & 0\\ 0 & -I_2\end{smallmatrix}\right)$, since $K=\{A\in G;\sigma(A)=A\}$. Let $\mathfrak{G}$ (resp. $\mathfrak{K}$) be the Lie algebra of G (respective of K) and let $\mathfrak{G}=\mathfrak{K}\oplus\mathfrak{P}$ be the Lie algebras decomposition induced by the involution σ_*. One has

$$\mathfrak{P}=\{X\in\mathfrak{G};\sigma_*(X)=-X\}=\left\{X_U=\begin{pmatrix}0 & U\\ -{}^t\overline{U} & 0\end{pmatrix}; U\in M_{m,2}(\mathbb{C})\right\}.$$

Restricted to K, the adjoint representation Ad_G of G acts on $\mathfrak{P}\simeq M_{m,2}(\mathbb{C})$ by

$$Ad_G\left(\begin{pmatrix}B & 0\\ 0 & C\end{pmatrix}\right)\cdot U=BU{}^t\overline{C}. \tag{1}$$

Since this representation is irreducible, all G-invariant metrics on G/K are homothetic. We consider the G-invariant metric g induced by the restriction to $\mathfrak{P}$ of the sign-changed Killing form of $\mathfrak{G}$. The symmetric space G/K is Einstein[4] and, with this metric, its scalar curvature is $S=2m$.

Let $(1,i,j,k)$ be the standard basis of $\mathbb{H}$. We identify $\mathbb{H}$ with $\mathbb{C}\oplus j\mathbb{C}$ and $\mathbb{H}^m$ with $\mathbb{C}^m\oplus j\mathbb{C}^m$ ($\mathbb{H}$ acts on the right). In the following, we identify $M_{m,2}(\mathbb{C})\simeq\mathfrak{P}$ with $\mathbb{H}^m\simeq\mathbb{R}^{4m}$ by

$$U=(\xi_1,\xi_2)\in M_{m,2}(\mathbb{C})\to\xi=\xi_1+j\overline{\xi_2}\in\mathbb{C}^m\oplus j\mathbb{C}^m, \tag{2}$$

and *denote* by α the homomorphism $K\to\mathrm{SO}(4m)$; $k\to Ad(k)_{|\mathfrak{P}}$. The group $\alpha(K)$ is a subgroup of $\mathrm{Sp}(m)\mathrm{Sp}(1)$ so the $4m$-dimensional manifold $(G/K,g)$ has a quaternion-Kähler structure.[12,13]

Finally let us recall that the Killing form of $\mathfrak{G}$ is given by $B(X,Y)=2(m+2)\Re[\mathrm{Tr}(XY)]$, so restriction of B to $\mathfrak{P}$ is

$$B(X_U,X_V)=-4(m+2)\Re(\xi_U,\xi_V), \tag{3}$$

where ξ_U (respectively ξ_V) are the elements of $\mathbb{H}^m$ corresponding to X_U (X_V) by the isomorphism given in (2), and where $(,)$ denotes the usual symplectic product on $\mathbb{H}^m$.

III. SPIN STRUCTURE AND DIRAC OPERATOR ON $Gr_2(\mathbb{C}^{m+2})$

The symmetric space $(G/K,g)$ has a spin structure (necessarily unique because it is simply connected) if there is a lift to $Spin(4m)$ of the homomorphism $\alpha: K\to\mathrm{SO}(4m)$, $k\to Ad(k)_{|\mathfrak{P}}$, (see Sec. II), hence if m is even.[5] Henceforward, except in Sec. IV, m is assumed to be even. The

lift of α is *denoted* by $\tilde{\alpha}$. The complex Clifford algebra $\mathbb{C}\ell_{4m}$, admits, up to equivalence, a unique irreducible representation $\rho:\mathbb{C}\ell_{4m}\to Hom_{\mathbb{C}}(\Sigma,\Sigma)$. The induced representation $Spin(4m)\to Hom_{\mathbb{C}}(\Sigma,\Sigma)$ will be also denoted by ρ.

For the definition and properties of the Dirac operator D on a spin symmetric space see Refs. 7–10. Here, all we need to know is the following: the spectrum of the Dirac operator D is $Spec(D,Gr_2(\mathbb{C}^{m+2}))=\{\pm\sqrt{\lambda};\lambda\in Spec(D^2,Gr_2(\mathbb{C}^{m+2}))\}$, with[10]

$$Spec(D^2,Gr_2(\mathbb{C}^{m+2}))=\left\{c_{[\alpha]}+\frac{S}{8};[\alpha]\in[G],m([\alpha]_{|K},\Sigma_i)\geqslant 1\right\}, \tag{4}$$

where (i) $[G]$ is the set of equivalence classes of unitary irreducible representations of G; (ii) $\Sigma=\oplus_{i=1}^{n}\Sigma_i$, the decomposition of Σ into irreducible K-modules under the action of K by the representation $\rho\circ\tilde{\alpha}$; (iii) $m([\alpha]_{|K},\Sigma_i)$ the multiplicity of the K-module Σ_i in the decomposition into irreducible K-modules of a G-module representing $[\alpha]$; (iv) $c_{[\alpha]}$ the eigenvalue of the Casimir operator of the representation $[\alpha]$.

Hence we are lead to state the ''branching rules'' giving the decomposition of an irreducible G-module into irreducible K-modules, give the decomposition (ii), determine the $[\alpha]$'s such that $m([\alpha]_{|K},\Sigma_i)\geqslant 1$, compute the corresponding eigenvalues with the help of Freudenthal's formula.

IV. BRANCHING RULES OF SU($m+2$) UNDER THE ACTION OF S(U(m)×U(2))

For results on representation theory, we refer to Refs. 14–17.

Let $T=\{$ diag. matrix $(e^{i\beta_1},\ldots,e^{i\beta_{m+2}});\beta_1,\ldots,\beta_{m+2}\in\mathbb{R}\}$, the usual maximal torus of U$(m+2)$. Its Lie algebra is $\mathfrak{T}=\{$ diag. matrix $(i\beta_1,\ldots,i\beta_{m+2});\beta_1,\ldots\beta_{m+2}\in\mathbb{R}\}$. We *denote* by $(y_1,\ldots,y_{m+2})$ the basis of the dual $\mathfrak{T}^*$ given by

$$y_k[\text{ diag. matrix }(i\beta_1,\ldots,i\beta_{m+2})]=\beta_k. \tag{5}$$

Let $T'=T\cap \mathrm{SU}(m+2)$. This is a maximal common torus of G and K. Its Lie algebra is $\mathfrak{T}'=\{$ diag. matrix $(i\beta_1,\ldots,i\beta_{m+2});\beta_1,\ldots\beta_{m+2}\in\mathbb{R},\Sigma_{k=1}^{m+2}\beta_k=0\}$. We *denote* by $(x_1,\ldots,x_{m+1})$ the basis of the dual $\mathfrak{T}'^*$ given by

$$x_k[\text{ diag. matrix }(i\beta_1,\ldots,i\beta_{m+2})]=\beta_k. \tag{6}$$

A weight $\mu\in i\mathfrak{T}'^*$ such that $\mu=\Sigma_{k=1}^{m+1}\lambda_k\hat{x}_k$, in the basis $(\hat{x}_k\equiv ix_k)_{k=1,\ldots,m+1}$, is *denoted* by

$$\mu=(\lambda_1,\ldots,\lambda_{m+1}). \tag{7}$$

We can also express μ in the basis $(\hat{y}_k\equiv iy_k)_{k=1,\ldots,m+2}$, of $i\mathfrak{T}^*$: $\mu=\Sigma_{k=1}^{m+2}\mu_k\hat{y}_k$; $\Sigma_{k=1}^{m+2}\mu_k=0$. In this case we *denote* μ by

$$\mu=[\mu_1,\ldots,\mu_{m+2}]. \tag{8}$$

The correspondence between the two expressions (7), (8) is

$$\lambda_i=\mu_i-\mu_{m+2}\Leftrightarrow\begin{cases}\mu_i=\lambda_i+\lambda_0\\ \mu_{m+2}=\lambda_0:=-\dfrac{1}{m+2}\displaystyle\sum_{i=1}^{m+1}\lambda_i,\end{cases}\qquad i=1,\ldots,m+1. \tag{9}$$

In the following, we consider the invariant scalar product on $\mathfrak{T}'$ given by $\langle X,Y\rangle = -\Re[\mathrm{Tr}(XY)] = -1/2(m+2)B(X,Y), \forall X,Y \in \mathfrak{T}'$, where B is the Killing form of $\mathfrak{G}$ (see Sec. II). We also *denote* by $\langle,\rangle$ its extension to $i\mathfrak{T}'^*$. Then for $\mu=[\mu_1,\ldots,\mu_{m+2}]$ and $\mu' = [\mu'_1,\ldots,\mu'_{m+2}] \in i\mathfrak{T}'^*$, we get

$$\langle \mu,\mu'\rangle = \sum_{i=1}^{m+2} \mu_i \mu'_i . \tag{10}$$

A. Determination of [*G*]

As G is simply connected, every class in $[G]$ corresponds to a dominant weight and conversely.

Lemma 1: *A weight of* G, $\beta=(k_1,\ldots,k_{m+1})=[p_1,\ldots,p_{m+2}]$ *is dominant iff*

$$\begin{cases} k_i \in \mathbb{N}, i=1,\ldots,m+1, \\ k_1 \geqslant k_2 \geqslant \cdots \geqslant k_{m+1}, \end{cases} \Leftrightarrow \begin{cases} (p_i - p_{i+1}) \in \mathbb{N}, \\ i=1,\ldots,m+1 . \end{cases}$$

Proof: We choose as positive roots $\hat{x}_i - \hat{x}_j, 1 \leqslant i < j \leqslant m+1$; $\hat{x}_1+\hat{x}_2+\cdots+2\,\hat{x}_i+\cdots+\hat{x}_{m+1}, i=1,\ldots,m+1$, such that the simple roots are $\theta_k = \hat{x}_k - \hat{x}_{k+1}; 1 \leqslant k \leqslant m$; $\theta_{m+1} = \hat{x}_1+\hat{x}_2+\cdots+2\,\hat{x}_{m+1}$. The conditions for β to be a dominant weight are $2\langle\beta,\theta_k\rangle/\langle\theta_k,\theta_k\rangle \in \mathbb{N}$, $k=1,\ldots,m+1$. Hence the result. ■

The Weyl group W_G of G is generated by the reflections across $\theta_k^{\perp}$. Hence it acts on $i\mathfrak{T}'^*$ by

$$\mu=[\mu_1,\ldots,\mu_{m+2}] \rightarrow [\mu_{\sigma(1)},\ldots,\mu_{\sigma(m+2)}], \sigma \in \mathfrak{S}_{m+2}. \tag{11}$$

B. Determination of [K]

We choose as positive roots for K, $\hat{x}_i - \hat{x}_j, 1 \leqslant i < j \leqslant m$; $\hat{x}_1+\hat{x}_2+\cdots+2\,\hat{x}_{m+1}$, such that the simple roots are

$$\theta'_k = \hat{x}_k - \hat{x}_{k+1}; 1 \leqslant k \leqslant m-1, \theta'_m = \hat{x}_1+\hat{x}_2+\cdots+2\,\hat{x}_{m+1}. \tag{12}$$

The Weyl group W_K of K is generated by the reflections across $\theta'^{\perp}_k$. Hence it acts on $i\mathfrak{T}'^*$ by

$$\mu=[\mu_1,\ldots,\mu_{m+2}] \rightarrow [\mu_{\sigma(1)},\ldots,\mu_{\sigma(m)},\mu_{s(m+1)},\mu_{s(m+2)}], \quad \begin{cases} \sigma \in \mathfrak{S}_m, \\ s \in \mathfrak{S}_2. \end{cases} \tag{13}$$

Conditions for a weight $\beta \in \mathfrak{T}'^*$ to be dominant are $2\langle\beta,\theta'_k\rangle/\langle\theta'_k,\theta'_k\rangle \in \mathbb{N}$, $k=1,\ldots,m$, so we get

Lemma 2: *A weight of* K, $\beta=(l_1,\ldots,l_{m+1})=[q_1,\ldots,q_{m+2}]$ *is dominant iff*

$$\begin{cases} (l_i - l_{i+1}) \in \mathbb{N}, i=1,\ldots,m-1, \\ l_{m+1} \in \mathbb{N}, \end{cases} \Leftrightarrow \begin{cases} (q_i - q_{i+1}) \in \mathbb{N}, \\ i=1,\ldots,m-1\ ,\ i=m+1. \end{cases}$$

Every class $[\alpha]$ in $[K]$ is related to a dominant weight of K, but the converse is not true as K is not semi-simple. Indeed, dominant weights induce possibly multivalued representations, so we determine those giving a single-valued representation.

Lemma 3: *A dominant weight of* K, $\beta=(l_1,\ldots,l_{m+1})=[q_1,\ldots,q_{m+2}]$ *induces a single-valued representation iff*

$$l_i \in \mathbb{Z} \Leftrightarrow q_i - q_{m+2} \in \mathbb{Z}, i=1,\ldots,m-1.$$

Such weights are *called* analytically dominant weights.

Proof: The center of the Lie algebra $\mathfrak{K}$ is $\mathfrak{C}=\mathbb{R}$. diag. matrix$(i,\ldots,i,-im/2,-im/2)$. As $\mathfrak{K}$ is of compact type, one has the decomposition $\mathfrak{K}=\mathfrak{C}\oplus\mathfrak{C}^{\perp}$, where $\mathfrak{C}^{\perp}\simeq\mathfrak{su}(m)\oplus\mathfrak{su}(2)$ is semi-simple. This decomposition induces $\mathfrak{T}'=\mathfrak{C}\oplus\mathfrak{T}''$, where $\mathfrak{T}''=\mathfrak{C}^{\perp}\cap\mathfrak{T}'$, and

$$i\mathfrak{T}'^{*}=i\mathfrak{C}^{*}\oplus i\mathfrak{T}''^{*}. \tag{14}$$

Let $\beta=(l_1,\ldots,l_{m+1})=[q_1,\ldots,q_{m+2}]$, a dominant weight of K. By (14), one has the decomposition $\beta=\gamma+\delta$, with $\gamma=n(1,1,\ldots,1,0)\in i\mathfrak{C}^{*}$, $n=1/m\Sigma_{i=1}^{m}l_i-1/2l_{m+1}$, and $\delta=(l_1',\ldots,l_{m+1}')\in i\mathfrak{T}''^{*}$,

$$\begin{cases} l_i'=l_i-n, & i=1\ldots,m,\\ l_{m+1}'=l_{m+1}. \end{cases}$$

Let

$$H=\left\{A=\begin{pmatrix} B & 0\\ 0 & C\end{pmatrix};B\in \mathrm{SU}(m);C\in \mathrm{SU}(2)\right\}.$$

This is a compact simply connected subgroup of K with Lie algebra $\mathfrak{C}^{\perp}$. The weight δ is dominant for H: indeed, relative to the maximal torus $T''=T'\cap H$, positive roots can be chosen such that the simple roots are restrictions of the θ_k' (12), hence conditions for a weight in $i\mathfrak{T}''^{*}$ to be dominant are the same as in lemma 2. Since H is simply connected, there exists, up to equivalence, a unique irreducible representation of H corresponding to the weight δ. Let $\rho:H\to Gl_{\mathbb{C}}(V)$, such a representation.

Now, for any

$$A=\begin{pmatrix} B & 0\\ 0 & C\end{pmatrix}\in K,$$

let $B'=(\det B)^{-1/m}B\in \mathrm{SU}(m)$ and $C'=(\det C)^{-1/2}C\in \mathrm{SU}(2)$. Of course, B' is defined up to an m-root of the unity, and C' is defined up to ± 1. Let $\tilde{\rho}$ the possibly multivalued representation $K\to Gl_{\mathbb{C}}(V)$,

$$\tilde{\rho}(A)=(\det B)^{n}\rho\left(\begin{pmatrix} B' & 0\\ 0 & C'\end{pmatrix}\right).$$

We claim that this is an irreducible (possibly multivalued) representation of K with dominant weight β:

Irreducibility comes from the fact that the restriction of $\tilde{\rho}$ to H is the (single-valued) irreducible representation ρ of H seen before. Furthermore, because $\tilde{\rho}_{*}[X=\text{ diag. matrix}(i\beta_1,\ldots,i\beta_{m+2})]\cdot v=\beta(X)v$, β is the dominant weight of $\tilde{\rho}$. Finally, as $\det B=e^{i\theta}$, where θ is defined up to $2\pi\mathbb{Z}$, a necessary and sufficient condition for $\tilde{\rho}$ to be single valued is $(e^{2k\pi i})^{n}\rho[\text{diag. matrix}(\exp(-2k\pi i/m),\ldots,\exp(-2k\pi i/m),e^{k\pi i},e^{k\pi i})]\cdot v=v,\forall k\in\mathbb{Z}$. This is equivalent to: $l_m\in\mathbb{Z}$, hence to: $l_i\in\mathbb{Z},i=1,\ldots,m-1$, because of the dominance conditions of lemma 2. ■

C. Branching rules of *G* under the action of *K*

We state the branching rules, following very closely the computation methods (based on Weyl's formula for characters) of Ref. 18.

Proposition 2: *Let $\beta_G=[p_1,\ldots,p_{m+2}]$ the dominant weight of an irreducible G-*module V_G *(see Lemma 1). The decomposition of V_G into irreducible K-modules contains the K-*module V_K *of dominant weight $\beta_K=[q_1,\ldots,q_{m+2}]$, (see lemmas 2, 3), if and only if the following three conditions are satisfied:*

(i) $(q_{m+2}-p_{m+2})\in\mathbb{Z}$,

(ii) $p_{i+2}\leqslant q_i\leqslant p_i$, $1\leqslant i\leqslant m$,

(iii) in the (finite) power series expansion in X of $(X-X^{-1})^{-m}\Pi_{i=1}^{m+1}(X^{r_i+1}-X^{-(r_i+1)})$, *where*

$$\begin{cases} r_1=p_1-\max(q_1,p_2), \\ r_i=\min(q_{i-1},p_i)-\max(q_i,p_{i+1}), \quad 2\leqslant i\leqslant m, \\ r_{m+1}=\min(q_m,p_{m+1})-p_{m+2}, \end{cases}$$

the coefficient of $X^{(q_{m+1}-q_{m+2}+1)}$ does not vanish. Moreover, the value of this coefficient is the multiplicity of the K-module V_K.

Remark 1: *Note that by (i) and the conditions of Lemmas 1, 2, 3, the r_i in (iii) are integers. Furthermore, by (ii) these integers are non-negative. Hence, the coefficient of X^k, $k>0$, in the expansion of condition (iii) is a non-negative integer. Moreover, the coefficient of X^{-k} is equal to the opposite coefficient of X^k.*

Proof. Let $\beta_G=(k_1,\ldots,k_{m+1})=[p_1,\ldots,p_{m+2}]$ be the dominant weight of an irreducible G-module V_G. By Weyl's formula, the character of the corresponding representation is $\chi_G(\beta_G)=J_G(\beta_G+\delta_G)/J_G(\delta_G)$, where $J_G(\beta)=\Sigma_{w\in W_G}(\det w)e^{w\cdot\beta}$, and where δ_G *is* the half-sum of the positive roots of G.

The corresponding notions for K are *denoted* by χ_K, J_K, δ_K respectively.

Let $S(\beta_G)$ the finite set of dominant weights of K, counted with their multiplicity, corresponding to the irreducible K-modules occurring in the decomposition of V_G. One has

$$\chi_G(\beta_G)=\sum_{\beta_K\in S(\beta_G)}\chi_K(\beta_K). \tag{15}$$

By Weyl's formula, (15) is equivalent to

$$J_G(\beta_G+\delta_G)\frac{J_K(\delta_K)}{J_G(\delta_G)}=\sum_{\beta_K\in S(\beta_G)}J_K(\beta_K+\delta_K). \tag{16}$$

The proof consists in dividing $J_G(\beta_G+\delta_G)$ by $J_G(\delta_G)/J_K(\delta_K)$, and trying to set the result in the form $\Sigma J_K(\beta_K+\delta_K)$, where β_K are analytically dominant weights of K. Since in this case the $J_K(\beta_K+\delta_K)$ are linearly independent, we thus obtain the decomposition (16).

Let Φ_G^+ (respectively Φ_K^+) be the set of positive roots of G (respective of K). It's a general result that $J_G(\delta_G)=\Pi_{\alpha\in\Phi_G^+}(e^{\alpha/2}-e^{-(\alpha/2)})$, $J_K(\delta_K)=\Pi_{\alpha\in\Phi_K^+}(e^{\alpha/2}-e^{-(\alpha/2)})$. Since $\Phi_K^+\subset\Phi_G^+$, we get $J_K(\delta_K)/J_G(\delta_G)=\Pi_{\alpha\in\Phi_G^+\setminus\Phi_K^+}(e^{\alpha/2}-e^{-(\alpha/2)})^{-1}$. One has $\Phi_G^+\setminus\Phi_K^+=\{\hat{x}_i-\hat{x}_{m+1},\hat{x}_i-\hat{x}_{m+2},\ 1\leqslant i\leqslant m\}$, where $\hat{x}_{m+2}$ *denotes* the restriction of $\hat{y}_{m+2}$ to $i\mathfrak{T}'^*$. Thus we get

$$\frac{J_K(\delta_K)}{J_G(\delta_G)}=\prod_{i=1}^{m}e^{(\hat{z}_i+\hat{z}_i')/2}(e^{\hat{z}_i}-1)^{-1}(e^{\hat{z}_i'}-1)^{-1}, \tag{17}$$

with the following *notations*: $\hat{z}_i:=\hat{x}_i-\hat{x}_{m+1}$, $\hat{z}_i':=\hat{x}_i-\hat{x}_{m+2}$. Since

$$\delta_G=\sum_{i=1}^{m+1}(m+2-i)\hat{x}_i=\frac{1}{2}\sum_{i=1}^{m+2}(m+3-2i)\hat{y}_i, \tag{18}$$

we have $\beta_G+\delta_G=(k'_1,\ldots,k'_{m+1})=[p'_1,\ldots,p'_{m+2}]$, where $k'_i:=k_i+(m+2-i)$, $i=1,\ldots,m+1$. Hence, by the description of the Weyl group W_G (see (11)), we get

$$J_G(\beta_G+\delta_G)=\det[e^{p'_i\hat{x}_j}]_{1:m+2}. \tag{19}$$

Here and in the following we *denote* by $[a_{ij}]_{p:q}$ a square matrix whose suffixes i,j range from p to q.

The half-sum of the positive roots δ_K is $\delta_K=\frac{1}{2}(\Sigma_{i=1}^{m}(m+2-2i)\hat{x}_i+2\,\hat{x}_{m+1})$. If $\beta_K=(l_1,\ldots,l_{m+1})=[q_1,\ldots,q_{m+2}]$ is an analytically dominant weight of K, then $\beta_K+\delta_K=(l'_1,\ldots,l'_{m+1})=[q'_1,\ldots,q'_{m+2}]$, where $l'_i:=l_i+1/2\,(m+2-2i)$, $i=1,\ldots,m$, $l'_{m+1}:=l_{m+1}+1$. By the description of the Weyl group W_K (13), we get $J_K(\beta_K+\delta_K)=\det[e^{q'_i\hat{x}_j}]_{1:m}\det[e^{q'_i\hat{x}_j}]_{m+1:m+2}$. Since $l'_{m+1}=q'_{m+1}-q'_{m+2}$, we have $\det[e^{q'_i\hat{x}_j}]_{m+1:m+2}=e^{q'_{m+2}(\hat{x}_{m+1}+\hat{x}_{m+2})}(e^{l'_{m+1}\hat{x}_{m+1}}-e^{l'_{m+1}\hat{x}_{m+2}})$, hence since $\hat{x}_{m+1}+\hat{x}_{m+2}=-\Sigma_{i=1}^{m}\hat{x}_i$, and $l'_i=q'_i-q'_{m+2}$, $i=1,\ldots,m$, we get

$$J_K(\beta_K+\delta_K)=\mu(l'_{m+1})\det[e^{l'_i\hat{x}_j}]_{1:m}. \tag{20}$$

Here and in the following, we *set* $\mu(k)=e^{k\hat{x}_{m+1}}-e^{k\hat{x}_{m+2}}$. In (19), multiplying each column C_i by $e^{-p'_{m+2}\hat{x}_i}$, we get, since $\Sigma_{i=1}^{m+2}\hat{x}_i=0$,

$$J_G(\beta_G+\delta_G)=\det[e^{k'_i\hat{x}_j}]_{1:m+2}\quad\text{with}\quad k'_{m+2}=0\ .$$

Subtracting the $(m+2)$th line multiplied by $e^{k'_i\hat{x}_{m+2}}$ from the ith line, $i=1,\ldots,m+1$, then developing relatively to the last column we get

$$J_G(\beta_G+\delta_G)=\det[e^{k'_i\hat{x}_j}-e^{k'_i\hat{x}_{m+2}}]_{1:m+1}.$$

Subtracting the $(i+1)$th line multiplied by $\mu(k'_i)/\mu(k'_{i+1})$, from the ith line, $i=1,\ldots,m$, then developing relatively to the last column we get

$$J_G(\beta_G+\delta_G)=\left(\prod_{i=1}^{m-1}\mu(k'_{i+1})^{-1}\right)\det[a_{ij}]_{1:m},$$

where

$$a_{ij}=\mu(k'_{i+1})(e^{k'_i\hat{x}_j}-e^{k'_i\hat{x}_{m+2}})-\mu(k'_i)(e^{k'_{i+1}\hat{x}_j}-e^{k'_{i+1}\hat{x}_{m+2}}).$$

Because of the expression of $J_K(\delta_K)/J_G(\delta_G)$ (17), we divide a_{ij} by $(e^{\hat{z}_j}-1)(e^{\hat{z}'_j}-1)$, the result is $\mu(1)^{-1}\Sigma_{h\in\mathbb{N}}P_i(h)e^{h\hat{x}_j}$, where

$$P_i(h)=\begin{cases}-e^{(k'_{i+1}+1)(\hat{x}_{m+1}+\hat{x}_{m+2})}\mu(k'_i-k'_{i-1})\mu(-(h+1)) & \text{if } 0\leqslant h<k'_{i+1},\\ e^{(\hat{x}_{m+1}+\hat{x}_{m+2})}\mu(k'_{i+1})\mu(k'_i-(h+1)) & \text{if } k'_{i+1}\leqslant h<k'_i-1\ ,\\ 0 \quad otherwise.\end{cases}$$

Since we have $\hat{z}_i+\hat{z}'_i=2\,\hat{x}_i-(\hat{x}_{m+1}+\hat{x}_{m+2})$, we get

$$J_G(\beta_G+\delta_G)\frac{J_K(\delta_K)}{J_G(\delta_G)}=\frac{e^{-m/2\,(\hat{x}_{m+1}+\hat{x}_{m+2})}}{\mu(1)^m(\Pi_{i=2}^m\mu(k_i'))}\det\left[\sum_{h\in\mathbb{N}}P_i(h)e^{(h+1)\hat{x}_j}\right]_{1:m},$$

$$=\frac{e^{m/2\,(\hat{x}_{m+1}+\hat{x}_{m+2})}}{\mu(1)^m(\Pi_{i=2}^m\mu(k_i'))}\det\left[\sum_{h\in\mathbb{N}}Q_i(h)e^{h\hat{x}_j}\right]_{1:m},$$

where

$$Q_i(h)=\begin{cases}-e^{k_{i+1}'(\hat{x}_{m+1}+\hat{x}_{m+2})}\mu(k_i'-k_{i-1}')\mu(-h) & if\ 1\leqslant h\leqslant k_{i+1}',\\ \mu(k_{i+1}')\mu(k_i'-h) & if\ k_{i+1}'<h<k_i',\\ 0 & otherwise.\end{cases}$$

By properties of the determinant, we can write

$$J_G(\beta_G+\delta_G)\frac{J_K(\delta_K)}{J_G(\delta_G)}=\frac{e^{m/2(\hat{x}_{m+1}+\hat{x}_{m+2})}}{\mu(1)^m(\Pi_{i=2}^m\mu(k_i'))}\sum_{h_i'\in\mathbb{N}}\left(\prod_{i=1}^m Q_i(h_i')\right)\det[e^{h_i'\hat{x}_j}]_{1:m}. \tag{21}$$

Since $\det[e^{h_i'\hat{x}_j}]_{1:m}=0$, if $h_i'=h_j'$, $i\neq j$, the h_i' in the sum (21) can be assumed all distinct. Then, always by the properties of the determinant, we can write

$$J_G(\beta_G+\delta_G)\frac{J_K(\delta_K)}{J_G(\delta_G)}=\frac{e^{m/2(\hat{x}_{m+1}+\hat{x}_{m+2})}}{\mu(1)^m(\Pi_{i=2}^m\mu(k_i'))}\Sigma\det[Q_i(h_j')]_{1:m}\det[e^{h_i'\hat{x}_j}]_{1:m},$$

where the sum is taken over all of the m-tuples $(h_1',\ldots,h_m')$ of integers satisfying

$$h_1'>h_2'>\cdots>h_m'>0\ . \tag{22}$$

If such an $(h_1',\ldots,h_m')$ does not satisfy

$$k_{i+2}'<h_i'<k_i',\ i=1,\ldots,m, \tag{23}$$

then $\det[Q_i(h_j')]_{1:m}$ vanishes. Indeed, if $h_m'\geqslant k_m'$, then $h_i'\geqslant k_m'$, so $Q_m(h_i')=0$ and all the entries of the last line are 0. If $h_j'\geqslant k_j'$, for some $j=1,\ldots,m-1$, then $\det[Q_i(h_j')]_{1:m}=\det[Q_i(h_j')]_{1:j}\det[Q_i(h_j')]_{j+1:m}$, with $\det[Q_i(h_j')]_{1:j}=0$, because all the entries of the last line are 0. If $h_j'\leqslant k_{j+2}'$, for some $j=1,\ldots,m-1$, then we transform $\det[Q_i(h_j')]_{1:m}$ by subtracting the jth column, multiplied by $\mu(-h_k')/\mu(-h_j')$, from the kth column, $k=j+1,\ldots,m$. The result is $\det[Q_i(h_j')]_{1:m}=\det[Q_i(h_j')]_{1:j}\det[b_{ij}]_{j+1:m}$, where all the entries of the first line of $[b_{ij}]_{j+1:m}$ are 0. Hence, we get

$$J_G(\beta_G+\delta_G)\frac{J_K(\delta_K)}{J_G(\delta_G)}=\frac{e^{m/2(\hat{x}_{m+1}+\hat{x}_{m+2})}}{\mu(1)^m(\Pi_{i=2}^m\mu(k_i'))}\sum{}'\det[Q_i(h_j')]_{1:m}\det[e^{h_i'\hat{x}_j}]_{1:m}, \tag{24}$$

where Σ' means that the sum is taken over all of the m-tuples $(h_1',\ldots,h_m')$ satisfying (22) and (23).

Assuming that the h_i' satisfy (22) and (23), we compute $\det[Q_i(h_j')]_{1:m}$ by subtracting the $(j-1)$th column, multiplied by $\mu(-h_j')/\mu(-h_{j-1}')$, from the jth column, $j=m,m-1,\ldots,2$. The resulting matrix $[c_{ij}]_{1:m}$ is a tridiagonal matrix such that $c_{j,j+1}c_{j+1,j}=0$, $j=1,\ldots,m-1$, hence its determinant is the product of the diagonal elements. So we get

$$\det[Q_i(h'_j)]_{1:m}=Q_1(h'_1)\prod_{i=2}^{m}\left(Q_i(h'_i)-\frac{\mu(-h'_i)}{\mu(-h'_{i-1})}Q_i(h'_{i-1})\right). \tag{25}$$

Now every $\mu(k'_i)$ factors through c_{ii}: $c_{ii}=\mu(k'_i)e^{(k'_{i+1}-s'_{i-1})(\hat{x}_{m+1}+\hat{x}_{m+2})}\mu(r'_i)\mu(-s'_i)/\mu(-s'_{i-1})$, with

$$r'_i:=\min(h'_{i-1},k'_i)-\max(h'_i,k'_{i+1}),\quad i=1,\ldots,m,\quad h'_0\equiv k'_1,$$
$$s'_i:=\min(h'_i,k'_{i+1}),\quad i=0,\ldots,m.$$

Hence (25) gives

$$\det[Q_i(h'_j)]_{1:m}=\left(\prod_{i=1}^{m}\mu(k'_i)e^{(k'_{i+1}-s'_{i-1})(\hat{x}_{m+1}+\hat{x}_{m+2})}\mu(r_i')\right)\frac{\mu(-s'_m)}{\mu(-s'_0)}.$$

Now, since $\mu(-k)=-\mu(k)e^{-k(\hat{x}_{m+1}+\hat{x}_{m+2})}$, $\forall k\in\mathbb{Z}$, we obtain, *setting* $r'_{m+1}:=s'_m$, $\det[Q_i(h'_j)]_{1:m}=e^{P(\hat{x}_{m+1}+\hat{x}_{m+2})}(\Pi_{i=2}^{m}\mu(k'_i))(\Pi_{i=1}^{m+1}\mu(r'_i))$, where $P:=\Sigma_{i=0}^{m}(k'_{i+1}-s'_i)$. So (24) gives

$$J_G(\beta_G+\delta_G)\frac{J_K(\delta_K)}{J_G(\delta_G)}=\sum{}'e^{(P+m/2)(\hat{x}_{m+1}+\hat{x}_{m+2})}\frac{\Pi_{i=1}^{m+1}\mu(r'_i)}{\mu(1)^m}\det[e^{h'_i\hat{x}_j}]_{1:m}. \tag{26}$$

With (16) and (20) in mind, we write the second part of equality (26)

$$\sum{}'\sum_{l'_{m+1}\in\mathbb{N}^*}e^{(P+m/2)(\hat{x}_{m+1}+\hat{x}_{m+2})}\frac{\Pi_{i=1}^{m+1}\mu(r'_i)}{\mu(1)^m\mu(l'_{m+1})}\mu(l'_{m+1})\det[e^{h'_i\hat{x}_j}]_{1:m}. \tag{27}$$

Let $X:=\exp((\hat{x}_{m+1}-\hat{x}_{m+2})/2)$. One has $\mu(k)=\exp(k(\hat{x}_{m+1}+\hat{x}_{m+2})/2)(X^k-X^{-k})$, $\forall k\in\mathbb{Z}$. Then the sum in (27) is equal to

$$\sum{}'\sum_{l'_{m+1}\in\mathbb{N}^*}\frac{\Pi_{i=1}^{m+1}(X^{r'_i}-X^{-r'_i})}{(X-X^{-1})^m(X^{l'_{m+1}}-X^{-l'_{m+1}})}\mu(l'_{m+1})\det[e^{l_i'\hat{x}_j}]_{1:m},$$

where

$$l'_i:=h'_i-M/2,\quad M:=\left(\sum_{i=1}^{m+1}k'_i-\sum_{i=1}^{m}h'_i-l'_{m+1}\right). \tag{28}$$

Now, we look for conditions on l'_{m+1}, such that $\mu(l'_{m+1})\det[e^{l_i'\hat{x}_j}]_{1:m}=J_K(\beta_K+\delta_K)$, where β_K is an analytically dominant weight of K, (see (20)). Let

$$\begin{cases} l_i:=l'_i-m/2+i-1, & i=1,\ldots,m,\\ l_{m+1}:=l'_{m+1}-1\ . \end{cases} \tag{29}$$

We have $l_{m+1}\in\mathbb{N}$ and by (22), $l_i-l_{i+1}\in\mathbb{N}$, $i=1,\ldots,m-1$, hence $\beta_K=(l_1,\ldots,l_{m+1})$ is a dominant weight for K (see lemma 2). Furthermore it is an analytically dominant weight iff

$$(M+m)/2\in\mathbb{Z}, \tag{30}$$

From (28) and (29), we get $M=2/(m+2)\,\Sigma_{i=1}^{m+1}(k_i-l_i)+m$, so the condition (30) is equivalent to

$$h_0:=\frac{1}{m+2}\sum_{i=1}^{m+1}(k_i-l_i)\in\mathbb{Z}. \tag{31}$$

Let $h_i:=l_i+h_0$, $i=1,\ldots,m$, then (23) gives

$$\begin{cases} k_{i+2}\leqslant h_i\leqslant k_i, & i=1,\ldots,m-1,\\ 0\leqslant h_m\leqslant k_m. \end{cases} \tag{32}$$

Furthermore, we have

$$\begin{cases} r_1'=k_1-\max(h_1,k_2)+1,\\ r_i'=\min(h_{i-1},k_i)-\max(h_i,k_{i+1})+1, & i=2,\ldots,m,\\ r_{m+1}'=\min(h_m,k_{m+1})+1. \end{cases} \tag{33}$$

Now, since each analytically dominant weight $\beta_K=(l_1,\ldots,l_{m+1})$ satisfying conditions (31), (32), corresponds by (28), (29) to a unique $(m+1)$-tuple $(h_1',\ldots,h_m',l_{m+1}')$ of positive integers satisfying conditions (22), (23) and (30), we can write (26) as

$$J_G(\beta_G+\delta_G)\frac{J_K(\delta_K)}{J_G(\delta_G)}=\sum\frac{\Pi_{i=1}^{m+1}(X^{r_i'}-X^{-r_i'})}{(X-X^{-1})^m(X^{(l_{m+1}+1)}-X^{-(l_{m+1}+1)})}J_K(\beta_K+\delta_K), \tag{34}$$

where the sum is taken over all the analytically dominant weights $\beta_K=(l_1,\ldots,l_{m+1})$ satisfying (31), (32), and the following condition:

In (34), the coefficient of $X^{(l_{m+1}+1)}$ in the power series expansion in X of $(X-X^{-1})^m\Pi_{i=1}^{m+1}(X^{r_i'}-X^{-r_i'})$, does not vanish.

This gives the decomposition (16). Now it's easy to see from (9), that for a weight $\beta_K=(l_1,\ldots,l_{m+1})=[q_1,\ldots,q_{m+1}]$ conditions (31), (32), and the last condition obtained are respectively equivalent to conditions (i), (ii), (iii) of the Proposition 2. Hence the result. ■

V. DECOMPOSITION OF THE SPINOR SPACE Σ UNDER THE ACTION OF K.

Notations are those of Secs. II and III. We henceforward assume that m is even. We consider the same spinor representation as in Ref. 19:

Let $(X_k)_{1\leqslant k\leqslant 4m}$ be the orthonormal basis of $\mathfrak{P}\simeq M_{m,2}(\mathbb{C})$ given by

$$\begin{cases} X_{4k-3}=\dfrac{1}{2\sqrt{m+2}}E_{k,1}\\ X_{4k-2}=-i\dfrac{1}{2\sqrt{m+2}}E_{k,1}\\ X_{4k-1}=-\dfrac{1}{2\sqrt{m+2}}E_{k,2}\\ X_{4k}=-i\dfrac{1}{2\sqrt{m+2}}E_{k,2} \end{cases},\quad 1\leqslant k\leqslant m,$$

where E_{ij} *denotes* the usual basis of $M_{m,2}(\mathbb{C})$. Under the identification $\mathfrak{P}\simeq\mathbb{H}^m$ given in (2), this basis corresponds to the orthonormal basis $\mathscr{B}=(e_k, Ie_k, Je_k, Ke_k)$, $1\leqslant k\leqslant m$, of $\mathbb{R}^{4m}$ used in Ref. 19. The following vectors

$$\begin{cases} x_k=\frac{1}{2}(e_k+iIe_k), & \overline{x_k}=\frac{1}{2}(e_k-iIe_k), \\ y_k=\frac{1}{2}(Je_k+iKe_k), & \overline{y_k}=\frac{1}{2}(Je_k-iKe_k), \end{cases}$$

form a Witt basis of $\mathbb{C}^{4m}$: one has $(x_k,x_l)=(\overline{x_k},\overline{x_l})=(y_k,y_l)=(\overline{y_k},\overline{y_l})=0$,$(x_k,\overline{x_l})=(y_k,\overline{y_l})=\frac{1}{2}\delta_{kl}$, where $(,)$ is the complex bilinear extension to $\mathbb{C}^{4m}$ of the usual scalar product of $\mathbb{R}^{4m}$.

Let $\Phi=\overline{x_1}\cdot\overline{x_2}\cdots\overline{x_m}\cdot\overline{y_1}\cdot\overline{y_2}\cdots\overline{y_m}\in\mathbb{C}l_{4m}$. (Clifford multiplication is *denoted* by a centered dot). The vector space $\Sigma=\mathbb{C}l_{4m}\cdot\Phi$, is of complex dimension 4^m. Indeed a basis is given by

$$\varphi_{IJ}=x_{i_1}\cdot x_{i_2}\cdots x_{i_p}\cdot y_{j_1}\cdot y_{j_2}\cdots y_{j_q}\cdot\Phi,$$

where

$$\begin{cases} I=(i_1,\ldots,i_p), & 0\leqslant i_1<\cdots<i_p\leqslant m, \\ J=(j_1,\ldots,j_q), & 0\leqslant j_1<\cdots<j_q\leqslant m, \end{cases}$$

with the convention $x_0=\overline{x_0}=1$.

The spin representation is then defined by

$$\rho:\mathbb{C}\!\not{l}_{4m}\to Hom_{\mathbb{C}}(\Sigma,\Sigma),\varphi\to(\rho(\varphi):\psi\cdot\Phi\to\varphi\cdot\psi\cdot\Phi).$$

Let $X=\text{diag. matrix}(i\beta_1,\ldots,i\beta_{m+1},i\beta_{m+2})\in\mathfrak{T}'$, $\Sigma_{k=1}^{m+2}\beta_k=0$. By the results of the end of Sec. II, we have

$$\tilde{\alpha}_*(X)=\frac{1}{2}\sum_{k=1}^{m}(\beta_{m+1}-\beta_k)e_k\cdot Ie_k+\frac{1}{2}\sum_{k=1}^{m}(\beta_k-\beta_{m+2})Je_k\cdot Ke_k.$$

Hence from the relations

$$\begin{cases} e_k\cdot Ie_k\cdot\varphi_{IJ}=i\varphi_{IJ} & if \quad k\notin I, \\ e_k\cdot Ie_k\cdot\varphi_{IJ}=-i\varphi_{IJ} & if \quad k\in I, \\ Je_k\cdot Ke_k\cdot\varphi_{IJ}=i\varphi_{IJ} & if \quad k\notin J, \\ Je_k\cdot Ke_k\cdot\varphi_{IJ}=-i\varphi_{IJ} & if \quad k\in J, \end{cases}$$

we get

$$(\rho_*\circ\tilde{\alpha}_*)(X)\cdot\varphi_{IJ}=i\left(\sum_{k=1}^{p}\beta_{i_k}-\sum_{k=1}^{q}\beta_{j_k}+\left(\frac{m}{2}-p\right)\beta_{m+1}+\left(q-\frac{m}{2}\right)\beta_{m+2}\right)\varphi_{IJ}. \tag{35}$$

So, under the action of the maximal torus T', the spinor space splits into the direct sum of the $\mathbb{C}\varphi_{IJ}$, with corresponding weights $[\varepsilon_1,\ldots,\varepsilon_m,(m/2-p),(q-m/2)]$, $\varepsilon_k=-1,0,$ or 1. Hence from lemma 2, we deduce

Proposition 3: *The spinor space* Σ *splits into the direct sum of* $[(m+1)(m/2+1)]$ *irreducible K-modules* $\Sigma_{p,q}$, $0\leqslant p+q\leqslant m$, *with dominant weight*

$$\beta_{p,q}=[\underbrace{1,\ldots,1}_{p},0,\ldots,0,\underbrace{-1,\ldots,-1}_{q},(m/2-p),(q-m/2)].$$

Furthermore the multiplicity is 1.

Proof: By Weyl's dimension formula, one has

$$n_{p,q}:=\dim\Sigma_{p,q}=\frac{(m-(p+q)+1)^2}{m+1}\binom{m+1}{p}\binom{m+1}{q},$$

and a proof by induction shows that $\Sigma_{0\leqslant p+q\leqslant m}n_{p,q}=4^m=\dim\Sigma$, so, the multiplicity is 1. ■

VI. SPECTRUM OF D^2

A. Determination of the $[\alpha]$'s in $[G]$ such that $m([\alpha]_{|K},\Sigma_{p,q})\geqslant 1$

From Propositions 2 and 3, we get, after some tedious computations:

Proposition 4: *Let* $\beta_G=[p_1,\ldots,p_{m+2}]$ *the dominant weight of an irreducible G-module* V_G. *Then the decomposition of* V_G *into irreducible K-modules contains a K-module isomorphic to* $\Sigma_{p,q}$ *if and only if* β_G *is of the following form*:

(i) If $m=2$,

$$\beta_G=[k+l,k,-k,-(k+l)],\quad k,l\in\mathbb{N},\quad (k,l)\neq(0,0),$$
$$\beta_G=[k+l+2,k,-(k+1),-(k+l+1)],\quad k,l\in\mathbb{N},$$
$$\beta_G=[k+l+1,k+1,-k,-(k+l+2)],\quad k,l\in\mathbb{N}.$$

(ii) If $m\geqslant 4$,

$$\begin{cases}\beta_G=[k+l+n+m/2-(p'+2),\underbrace{k,1,\ldots,1}_{p'},0,\ldots,0,\underbrace{-1,\ldots,-1}_{q},-(k+n),-(k+l+m/2-(q'+2))],\\ \quad 0\leqslant p'\leqslant m/2-2,\ 0\leqslant q'\leqslant m/2-2,\ k,l,n\in\mathbb{N},\ s.t.0\leqslant n\leqslant m/2-(q'+2)\quad and\\ \quad k\geqslant 1\ \ if\ p'\geqslant 1\ ,\\ \quad (k,l)\neq(0,0)\ \ if\ p'=0\quad and\ \ 1\leqslant n\leqslant m/2-(q'+2),\\ \quad (k,l)\neq(0,0)\quad and\ \ (k,l)\neq(0,1)\ \ if\ p'=q'=n=0,\\ \beta_G=[k+l+m/2-(p'+2),k+n,\underbrace{1,\ldots,1}_{p'},0,\ldots,0,\underbrace{-1,\ldots,-1}_{q'},-k,-(k+l+n+m/2-(q'+2))],\\ \quad 0\leqslant p'\leqslant m/2-2,\ 0\leqslant q'\leqslant m/2-2,\ k,l,n\in\mathbb{N},\ s.t.0\leqslant n\leqslant m/2-(p'+2)\quad and\\ \quad k\geqslant 1\ \ if\ q'\geqslant 1,\\ \quad (k,l)\neq(0,0)\ \ if\ q'=0\quad and\ \ 1\leqslant n\leqslant m/2-(p'+2),\\ \quad (k,l)\neq(0,0)\quad and\ \ (k,l)\neq(0,1)\ \ if\ p'=q'=n=0,\end{cases}\tag{36}$$

$$\begin{cases}\beta_G=[k+l+n+1,k+1,\underbrace{1,\ldots,1}_{p'},0,\ldots,0,\underbrace{-1,\ldots,-1}_{q'},-(k+n-m/2+p'+3),-(k+l+m/2-(q'+1))],\\ \quad m/2-2\leqslant p'\leqslant m-4,\ 0\leqslant q'\leqslant m-(p'+4),\ k,l,n\in\mathbb{N},\ s.t.0\leqslant n\leqslant m-(p'+q'+4),\\ \beta_G=[k+l+m/2-(p'+1),k+n-m/2+p'+3,\underbrace{1,\ldots,1}_{p'},0,\ldots,0,\underbrace{-1,\ldots,-1}_{q'},-(k+1),-(k+l+n+1)],\\ \quad m/2-2\leqslant q'\leqslant m-4,\ 0\leqslant p'\leqslant m-(q'+4),\ k,l,n\in\mathbb{N},\ s.t.0\leqslant n\leqslant m-(p'+q'+4),\end{cases}\tag{37}$$

$$\begin{cases} \beta_G=[k+l+1,k+1,\underbrace{1,\ldots,1}_{p'},0,\ldots,0,\underbrace{-1,\ldots,-1}_{q'},-(k-m/2+p'+2),-(k+l+m/2-q')], \\ \quad m/2-1\leqslant p'\leqslant m-2,\ 0\leqslant q'\leqslant m-(p'+2),\ \ k,l\in\mathbb{N}, \\ \beta_G=[k+l+m/2-p',k-m/2+q'+2,\underbrace{1,\ldots,1}_{p'},0,\ldots,0,\underbrace{-1,\ldots,-1}_{q'},-(k+1),-(k+l+1)], \\ \quad m/2-1\leqslant q'\leqslant m-2,\ 0\leqslant p'\leqslant m-(q'+2),\ \ k,l\in\mathbb{N}, \end{cases} \tag{38}$$

$$\begin{cases} \beta_G=[k+l+1,k+1,\underbrace{1,\ldots,1}_{p'},0,\ldots,0,\underbrace{-1,\ldots,-1}_{q'},-(k-m/2+p'+1),-(k+l+m/2-q'+1)], \\ \quad m/2\leqslant p'\leqslant m-2,\ 0\leqslant q'\leqslant m-(p'+2),\ \ k,l\in\mathbb{N}, \\ \beta_G=[k+l+m/2-p'+1,k-m/2+q'+1,\underbrace{1,\ldots,1}_{p'},0,\ldots,0,\underbrace{-1,\ldots,-1}_{q'},-(k+1),-(k+l+1)], \\ \quad m/2\leqslant q'\leqslant m-2,\ 0\leqslant p'\leqslant m-(q'+2),\ \ k,l\in\mathbb{N}, \end{cases} \tag{39}$$

$$\begin{cases} \beta_G=[k+l+m/2-p',k+m/2-p',\underbrace{1,\ldots,1}_{p'},0,\ldots,0,\underbrace{-1,\ldots,-1}_{q'},-k,-(k+l+m-(p'+q'))], \\ \quad 0\leqslant p'\leqslant m/2-1,\ 0\leqslant q'\leqslant m-(p'+2),\ \ k,l\in\mathbb{N},\ \ s.t.k\geqslant 1\ \ if\ q'\geqslant 1\ , \\ \beta_G=[k+l+m-(p'+q'),k,\underbrace{1,\ldots,1}_{p'},0,\ldots,0,\underbrace{-1,\ldots,-1}_{q'},-(k+m/2-q'),-(k+l+m/2-q')], \\ \quad 0\leqslant q'\leqslant m/2-1,\ 0\leqslant p'\leqslant m-(q'+2),\ \ k,l\in\mathbb{N},\ \ s.t.k\geqslant 1\ \ if\ p'\geqslant 1, \end{cases} \tag{40}$$

$$\begin{cases} \beta_G=[k+l+m/2-(p'+1),k+m/2-(p'+1),\underbrace{1,\ldots,1}_{p'},0,\ldots,0,\underbrace{-1,\ldots,-1}_{q'},-k,-(k+l+m-(p'+q'+2))], \\ \quad 0\leqslant p'\leqslant m/2-2,\ 0\leqslant q'\leqslant m-(p'+2),\ \ k,l\in\mathbb{N},\ \ s.t.k\geqslant 1\ \ if\ q'\geqslant 1, \\ \beta_G=[k+l+m-(p'+q'+2),k,\underbrace{1,\ldots,1}_{p'},0,\ldots,0,\underbrace{-1,\ldots,-1}_{q'},-(k+m/2-(q'+1)),-(k+l+m/2-(q'+1))], \\ \quad 0\leqslant q'\leqslant m/2-2,\ 0\leqslant p'\leqslant m-(q'+2),\ \ k,l\in\mathbb{N},\ \ s.t.k\geqslant 1\ \ if\ p'\geqslant 1, \end{cases} \tag{41}$$

B. Computation of the eigenvalues

From (4) and since $S=2^m$ (see Sec. II), eigenvalues of D^2 are obtained from the list of dominant weights occurring in Proposition 4 by the formula

$$\lambda(\beta_G)=c(\beta_G)+\frac{m}{4},$$

where $c(\beta_G)$ is the eigenvalue of the Casimir operator of the representation corresponding to β_G. By Freudenthal's formula we have

$$c(\beta_G)=\frac{1}{2(m+2)}\langle\beta_G,\beta_G+2\delta_G\rangle, \tag{42}$$

where $\langle,\rangle$ is the scalar product (10), and δ_G the half-sum of the positive roots of G, see (18). Note that if $\beta_G=[p_1,\ldots,p_{m+2}]$ is a dominant weight of G, so is $\beta'_G=[-p_{m+2},-p_{m+1},\ldots,-p_1]$, and it is easily verified that $\langle\beta_G,\beta_G+2\delta_G\rangle=\langle\beta'_G,\beta'_G+2\delta_G\rangle$. Hence the two types of dominant weights occurring in (36), (41) respectively, give the same eigenvalue. Computation of (42) for each of these cases leads to Proposition 1. In case $m=2$, we recover, up to a homothetic change of the metric, a result of Strese on the Dirac spectrum of the Grassmannian $Gr_4(\mathbb{R}^6)\simeq Gr_2(\mathbb{C}^4)$.[20]

Because of the expression of the eigenvalues of D^2, it is easy to see that the lowest one is $\mu_{0,1}=3/2$, if $m=2$, and $\lambda_{1,0,0,0,0}=\mu_{0,0,0,m/2-2,m/2-2}=m(m+4)/(2(m+2))$, if $m\geqslant 4$. Hence the square of the first eigenvalue of the Dirac operator is $\lambda^2=m(m+4)/(2(m+2))$. So the ratio $\nu:=\lambda^2/S$ of the square of the first eigenvalue by the scalar curvature is

$$\nu=\frac{m+4}{4\,(m+2)}>\nu_0=\frac{m+3}{4\,(m+2)}$$

where ν_0 is the corresponding ratio for the quaternionic projective space. Thus the conjecture of Ref. 1 is verified for the Grassmannian $Gr_2(\mathbb{C}^{m+2})$.

Furthermore, the following characterization of the first eigenvalue can be given:

Let $\Sigma(G/K)$ the spinor bundle of $Gr_2(\mathbb{C}^{m+2})=G/K$. From the results of Ref. 2, the space $\Sigma^\lambda(G/K)=\{\psi\in\Gamma(\Sigma(G/K));D^2\psi=\lambda^2\psi\}$, splits into the orthogonal decomposition

$$\Sigma^\lambda(G/K)=\bigoplus_{k=0}^{m}\Sigma^\lambda_k(G/K), \tag{43}$$

where $\Sigma^\lambda_k(G/K)=\{\psi\in\Sigma^\lambda(G/K);\Omega\cdot\psi=(6m-4k(k+2))\psi\}$, Ω being the fundamental 4-form given by the quaternion-Kähler structure of G/K.

Proposition 5: *If λ is the first eigenvalue of the Dirac operator, then there exists a non trivial spinor field in $\Sigma^\lambda_0(G/K)$.*

Proof: From Propositions 1 and 4, the lowest eigenvalue corresponds to the weight $\beta_G=[\underbrace{1,\ldots,1}_{m/2},0,0,\underbrace{-1,\ldots,-1}_{m/2}]$. From Proposition 2, the (up to equivalence) G-module V_G corresponding to β_G contains in its decomposition under the action of K, a K-module V_K isomorphic to $\Sigma_{m/2,m/2}$. Indeed, the dominant weight of $\Sigma_{m/2,m/2}$ is $\beta_{m/2,m/2}=[\underbrace{1,\ldots,1}_{m/2},\underbrace{-1,\ldots,-1}_{m/2},0,0]$. Conditions (i) and (ii) are easily verified. The expansion of condition (iii) equals $(X-X^{-1})$, so the condition (iii) is also verified. Furthermore the multiplicity of V_K is 1.

From (35), the vector of Σ, $\varphi=x_1\cdot x_2\cdots x_{m/2}\cdot y_1\cdot y_2\cdots y_{m/2}\cdot\Phi$, is a weight-vector for the weight $\beta_{m/2,m/2}$.

Now, from the general description of the spectrum of the Dirac operator on a symmetric space (see Refs. 5, 7, 9, 10), a spinor field $\psi\in\Sigma^\lambda(G/K)$ can be constructed as follows:

Let $\hat\rho$ be the representation $G\to Hom_{\mathbb{C}}(V_G,V_G)$. The condition that V_G contains an irreducible K-module isomorphic to $\Sigma_{m/2,m/2}$ is equivalent to the existence of a K-equivariant homomorphism $L:V_G\to\Sigma$, such that $L_{|V_K}$ is the isomorphism $V_K\simeq\Sigma_{m/2,m/2}$. The spinor bundle of G/K is isomorphic to $G\times_K\Sigma\to G/K$, $[g,\phi]\to[g]$, where K acts on the left on Σ by the representation $\rho\circ\widetilde{\alpha}$ of Sec. III. Then, the spinor field ψ defined by $\psi:[g]\to[g,(L\circ\hat\rho(g^{-1}))\cdot v]$, with $L(v)=\varphi$, belongs to $\Sigma^\lambda(G/K)$.

Under the decomposition (43), the spinor field ψ splits into $\psi=\Sigma_{k=0}^m\psi_k$. Now, from results of Ref. 19, the action of the fundamental 4-form Ω on ψ is

$$(\Omega\cdot\psi)([g])=[g,\mathbf{\Omega}\cdot(L\circ\hat\rho(g^{-1}))(v)],$$

where $\mathbf{\Omega}=\Sigma_{c.p.I,J,K}\mathbf{\Omega}_I\cdot\mathbf{\Omega}_I-6m$, with $\mathbf{\Omega}_I=\Sigma_{i=1}^{m}(e_i\cdot Ie_i+Je_i\cdot Ke_i)$, (e_i,Ie_i,Je_i,Ke_i), being the orthonormal basis of $\mathbb{R}^{4m}$ introduced in Sec. V.

If e denotes the neutral element in G, we get $(\Omega\cdot\psi)([e])=[e,\mathbf{\Omega}\cdot\varphi]$. From the result of page 331 in Ref. 19 we have $\mathbf{\Omega}\cdot\varphi=6m\varphi$. Hence $\psi_0([e])=\psi([e])\neq 0$, and ψ_0 is a non-trivial vector of $\Sigma_0^{\lambda}(G/K)$. Hence the result. ■

ACKNOWLEDGMENT

Representation properties, Racah sum rule, and Biedenharn–Elliott identity for $U_q(\mathrm{osp}(1|2))$

Pierre Minnaert and Marek Mozrzymas[a)]
Centre de Physique Théorique et Modélisation,[b)] *Université Bordeaux I, France*[c)]

(Received 11 July 1997; accepted for publication 5 August 1997)

It is shown that the universal R matrix in the tensor product of two irreducible representation spaces of the quantum superalgebra $U_q(\mathrm{osp}(1|2))$ can be expressed by Clebsch–Gordan coefficients. The Racah sum rule satisfied by $U_q(\mathrm{osp}(1|2))$ Racah coefficients and $6-j$ symbols is derived from the properties of the universal R matrix in the tensor product of three representation spaces. Considering the tensor product of four irreducible representations, it is shown that Biedenharn–Elliott identity holds for $U_q(\mathrm{osp}(1|2))$ Racah coefficients and $6-j$ symbols. A recursion relation for $U_q(\mathrm{osp}(1|2))$ $6-j$ symbols is derived from the Biedenharn–Elliott identity. © *1998 American Institute of Physics.* [S0022-2488(97)03011-9]

I. INTRODUCTION

In three previous papers, Refs. 1–3, we have studied the properties of irreducible representations of the quantum superalgebra $U_q(\mathrm{osp}(1|2))$. It was shown that it is possible to construct Racah–Wigner calculus for this quantum superalgebra, in a completely similar way as in the classical algebra su(2)[4] and the quantum algebra $U_q(\mathrm{su}(2))$[5–7] cases. In this paper, in order to complete our study of the representations of this simple quantum superalgebra, we shall consider the properties of its universal R matrix in the tensor product of irreducible representations.

The universal R matrix for $U_q(\mathrm{osp}(1|2))$ has been derived and its basic properties have been exhibited in Ref. 8. It was also considered in the construction of vertex model solutions of the graded Yang–Baxter equation in Ref. 9. In the present paper we study the properties of the universal R matrix in the tensor product of two irreducible $U_q(\mathrm{osp}(1|2))$ representations. We give explicit formulas for the matrix representation of the universal R matrix in different bases of the tensor product of representations. In particular, we show that matrix elements of the universal R matrix in the reduced basis of the tensor product of two representations can be expressed with $U_q(\mathrm{osp}(1|2))$ Clebsch–Gordan coefficients (denoted sq-CGc). Analytic expressions for sq-CGc of any tensor product of irreducible representations are known,[1,10,11] therefore the matrix representation of the universal R matrix can be calculated for any tensor product.

In Ref. 2, we have defined and studied properties of Racah coefficients (denoted $sqRc$) and $6-j$ symbols (denoted $sq6-j$) for the quantum superalgebra $U_q(\mathrm{osp}(1|2))$. In particular, it was shown that, as in the classical case, $sq6-j$ symbols satisfy not only the usual tetrahedral symmetry but present also an additional symmetry of the Regge type. Another property satisfied by $sqRc$ and $sq6-j$ symbols is the pseudo-orthogonality relation. This relation can be considered an algebraic relation satisfied by $sqRc$ and $sq6-j$ symbols. It is known that in the classical Racah–Wigner calculus for su(2) or $U_q(\mathrm{su}(2))$, Racah coefficients and $6-j$ symbols satisfy, besides orthogonality relations, other algebraic relations, namely the Racah sum rule and the Biedenharn–Elliott identity. These algebraic identities have been extended to the corresponding features of the superalgebra osp(1|2), Ref. 12. In this paper we extend the Racah sum rule and the Biedenharn–Elliott identity for $sqRc$ and $sq6-j$ symbols. In both cases, the structure of these relations is

completely similar to the corresponding classical ones, the only difference concerns the phases that are more complicated in the case of $U_q(\mathrm{osp}(1|2))$. As in the classical cases, we also derive from the Biedenharn–Elliott identity a three-term recurrence relation between $sq6-j$ symbols.

This paper is organized in the following way: in Sec. II we study the properties of the universal R matrix in the tensor product of irreducible representations of $U_q(\mathrm{osp}(1|2))$. In Sec. III, considering the tensor product of three $U_q(\mathrm{osp}(1|2))$ representations, we derive the Racah sum rule for $sqRc$ and $sq6-j$ symbols and we derive a simple algebraic identity following from the sum rule. Finally, in Sec. IV, we prove the Biedenharn–Elliott identity for $sq6-j$ symbols and the three-term recurrence relation.

II. PROPERTIES OF THE UNIVERSAL R MATRIX IN THE IRREDUCIBLE REPRESENTATIONS OF THE QUANTUM SUPERALGEBRA $U_q(\mathrm{osp}(1|2))$

A. The $U_q(\mathrm{osp}(1|2))$ universal R matrix

The quantum superalgebra $U_q(\mathrm{osp}(1|2))$ is generated by four elements: $\mathbf{1}$, H (even) and $v_\pm$ (odd) with the following (anti)commutation relations:

$$[H,v_\pm]=\pm\frac{1}{2}v_\pm, \quad [v_+,v_-]_+=-\frac{\sinh(\eta H)}{\sinh(2\eta)}, \tag{2.1}$$

where the deformation parameter η is real and $q=e^{-\eta/2}$ (we choose $\eta>0$ so that $q<1$). The quantum superalgebra $U_q(\mathrm{osp}(1|2))$ is a Hopf algebra with the following coproduct Δ^q and antipode S:

$$\Delta^q(v_\pm)=v_\pm\otimes q^H+q^{-H}\otimes v_\pm, \tag{2.2}$$

$$\Delta^q(H)=H\otimes\mathbf{1}+\mathbf{1}\otimes H, \quad \Delta^q(\mathbf{1})=\mathbf{1}\otimes\mathbf{1}, \tag{2.3}$$

$$S(H)=-H, \quad S(v_\pm)=-q^{\pm 1/2}v_\pm. \tag{2.4}$$

One can consider another coalgebra structure and antipode defined by

$$\Delta'^q(v_\pm)=v_\pm\otimes q^{-H}+q^H\otimes v_\pm, \tag{2.5}$$

$$S'(H)=-H, \quad S'(v_\pm)=-q^{\mp 1/2}v_\pm, \tag{2.6}$$

which, together with relations (2.1), define another Hopf algebra structure that we denote $U'_q(\mathrm{osp}(1|2))$. Both Hopf algebra structures are related by

$$U'_q(\mathrm{osp}(1|2))=U_{q^{-1}}(\mathrm{osp}(1|2)). \tag{2.7}$$

It is known[8] that a canonical element $R^q\in U_q(\mathrm{osp}(1|2))\otimes U_q(\mathrm{osp}(1|2))$ exists, called the universal R matrix, that defines a similarity relation between Δ'^q and Δ^q:

$$R^q\Delta^q=\Delta'^qR^q. \tag{2.8}$$

This universal R matrix is

$$R^q=q^{4H\otimes H}\sum(-1)^k q^{k(k-1)/4}\frac{(1+q^{-1})^k}{[k]!\,\gamma^k}(q^Hv_+)^k\otimes(q^Hv_-)^k, \tag{2.9}$$

and it satisfies the following relations:

$$R^{q13}R^{q23}=(\Delta\otimes id)R^q\equiv R^{q12,3}, \tag{2.10}$$

$$R^{q13}R^{q12}=(id\otimes\Delta)R^q\equiv R^{q1,23}, \tag{2.11}$$

where the indices $i,j=1,2,3$, $i\neq j$, in R^{qij} show the embeding of $R^q=\Sigma r_n\otimes r'_n$ into the tensor product $U_q(\mathrm{osp}(1|2))\otimes U_q(\mathrm{osp}(1|2))\otimes U_q(\mathrm{osp}(1|2))$. The above relations imply the Yang–Baxter equation for the universal R matrix,

$$R^{q12}R^{q13}R^{q23}=R^{q23}R^{q13}R^{q12}. \tag{2.12}$$

In the following we will consider the properties of the universal R matrix in the tensor product of irreducible representations of the quantum superalgebra $U_q(\mathrm{osp}(1|2))$.

B. The $U_q(\mathrm{osp}(1|2))$ finite-dimensional representations

A representation of a quantum superalgebra $U_q(\mathrm{osp}(1|2))$ in a finite-dimensional graded space V is a homomorphism $T:U_q(\mathrm{osp}(1|2))\to L(V,V)$ of the associative graded algebra $U_q(\mathrm{osp}(1|2))$ into the associative graded algebra $L(V,V)$ of linear operators in V, such that

$$[T(H),T(v_\pm)]=\pm\frac{1}{2}\,T(v_\pm),\quad [T(v_+),T(v_-)]_+=-\frac{\sinh(\eta T(H))}{\sinh(2\eta)}. \tag{2.13}$$

Let us recall the main results concerning these representations, Ref. 1. Any finite-dimensional grade star representation of $U_q(\mathrm{osp}(1|2))$ is characterized by four parameters: the highest weight l (a non-negative integer), the parity λ of the highest weight vector in the representation space, and the signature parameters $\varphi,\psi=0,1$ of the Hermitian form in the representation space V. The parity λ and the signature φ define the class $\epsilon=0,1$ of the grade star representation by the relation $\epsilon=\lambda+\varphi+1 \pmod 2$. The irreducible representation space of highest weight $l, V=V^l(\lambda)$ is a graded vector space of dimension $2l+1$ with basis $e^{lq}_m(\lambda)$, where $-l<m<l$, the parameter $\lambda=0,1$ is the parity of the highest weight vector $e^l_l(\lambda)$, and $\deg(e^l_m(\lambda))=l-m+\lambda \pmod 2$. The vectors $e^{lq}_m(\lambda)$ are constructed from the vector $e^l_l(\lambda)$ in a standard way so they depend on q via the normalization factor. The vectors $e^{lq}_m(\lambda)$ are pseudo-orthogonal with respect to a Hermitian form in the representation space, denoted $(\,,\,)$, and their normalization is determined by the signature parameters φ,ψ:

$$(e^{lq}_m(\lambda),e^{lq}_{m'}(\lambda))=(-1)^{\varphi(l-m)+\psi}\delta_{mm'}. \tag{2.14}$$

The operators $T(v_\pm)$ and $T(H)$ act on the basis $e^{lq}_m(\lambda)$ in the following way:

$$T(H)e^{lq}_m(\lambda)=\frac{m}{2}\,e^{lq}_m(\lambda),$$

$$T(v_+)e^{lq}_m(\lambda)=(-1)^{l-m}\sqrt{[l-m][l+m+1]\gamma}\;e^{lq}_{m+1}(\lambda),$$

$$T(v_-)e^{lq}_m(\lambda)=\sqrt{[l+m][l-m+1]\gamma}\;e^{lq}_{m-1}(\lambda), \tag{2.15}$$

where the symbol $[n]$ is the graded quantum symbol defined by

$$[n]=\frac{q^{-n/2}-(-1)^n q^{n/2}}{q^{-1/2}+q^{1/2}}, \tag{2.16}$$

and $\gamma=\cosh(\eta/4)/\sinh(2\eta)$. Note that although the symbol $[n]$ is not invariant under the exchange $q\leftrightarrow q^{-1}$, the relations (2.15) are invariant with respect to this substitution. Furthermore, it follows from the explicit formulas for $e^{lq}_m(\lambda)$, Ref. 11, that

$$e_m^{lq}(\lambda)=e_m^{lq^{-1}}(\lambda), \tag{2.17}$$

thus both quantum algebras $U_q(osp(1|2))$ and $U_{q^{-1}}(osp(1|2))$ define the same basis in the representation space $V^l(\lambda)$. In the next section, we shall see that this is no longer true when we consider tensor product of representation spaces.

C. Tensor product of representations and the $\mathscr{T}$ matrix

In the following, the representation T of class ϵ that acts in the representation space $V^l(\lambda)$ is denoted by T^l. The generators $v_\pm$ and H are represented in the tensor product of two irreducible representations of the same class, $T^{l_1}\otimes T^{l_2}$ by the operators

$$v_\pm^{\otimes}(1,2)=(T^{l_1}\otimes T^{l_2})(\Delta(v_\pm))=T^{l_1}(v_\pm)\otimes q^{T^{l_2}(H)}+q^{-T^{l_1}(H)}\otimes T^{l_2}(v_\pm), \tag{2.18}$$

$$H^{\otimes}(1,2)=(T^{l_1}\otimes T^{l_2})(\Delta(H))=T^{l_1}(H)\otimes T^{l_2}(\mathbf{1})+T^{l_1}(\mathbf{1})\otimes T^{l_2}(H). \tag{2.19}$$

The tensor product $T^{l_1}\otimes T^{l_2}$ is simply reducible. The standard basis $e_{m_1}^{l_1q}(\lambda_1)\otimes e_{m_2}^{l_2q}(\lambda_2)$ and reduced basis $e_m^{lq}(l_1,l_2,\lambda)$ of the representation space $V^{l_1}(\lambda_1)\otimes V^{l_2}(\lambda_2)$ are related by Clebsch–Gordan coefficients in the following way:

$$e_m^{lq}(l_1,l_2,\lambda)=\sum_{m_1,m_2}(l_1m_1\lambda_1,l_2m_2\lambda_2|lm\lambda)_q\, e_{m_1}^{l_1q}(\lambda_1)\otimes e_{m_2}^{l_2q}(\lambda_2), \tag{2.20}$$

or equivalently,

$$\sum_{l,m}(-1)^{(l-m)L}(l_1m_1\lambda_1,l_2m_2\lambda_2|lm\lambda)_q e_m^{lq}(l_1,l_2,\lambda)=(-1)^{(l_1-m_1)(l_2-m_2)}e_{m_1}^{l_1q}(\lambda_1)\otimes e_{m_2}^{l_2q}(\lambda_2), \tag{2.21}$$

where $m_1+m_2=m$, $L=l_1+l_2+l$, and l is an integer satisfying the conditions

$$|l_1-l_2|\leqslant l\leqslant l_1+l_2,\quad \lambda=L+\lambda_1+\lambda_2(\mathrm{mod}\ 2). \tag{2.22}$$

Both bases $e_{m_1}^{l_1q}(\lambda_1)\otimes e_{m_2}^{l_2q}(\lambda_2)$ and $e_m^{lq}(l_1,l_2,\lambda)$ are orthogonal but not positive definite, i.e., we have

$$(e_{m_1}^{l_1q}(\lambda_1)\otimes e_{m_2}^{l_2q}(\lambda_2),e_{m_1'}^{l_1q}(\lambda_1)\otimes e_{m_2'}^{l_2q}(\lambda_2))=(-1)^{(l_1-m_1+\lambda_1)(l_2-m_2+\lambda_2)}\delta_{m_1m_1'}\delta_{m_2m_2'}, \tag{2.23}$$

$$(e_m^{lq}(l_1,l_2,\lambda),e_{m'}^{l'q}(l_1,l_2,\lambda))=\delta_{ll'}\delta_{mm'}(-1)^{\varphi(l-m)+\psi}, \tag{2.24}$$

where

$$\varphi=L+\lambda_1+\varphi_2(\mathrm{mod}\ 2),\quad \psi=(L+\lambda_2)\lambda_1+\varphi_2L+\psi_1+\psi_2(\mathrm{mod}\ 2). \tag{2.25}$$

We may consider also another reduced basis built with the basis $e_m^{lq^{-1}}(\lambda)$:

$$e_m^{lq^{-1}}(l_1,l_2,\lambda)=\sum_{m_1,m_2}(l_1m_1\lambda_1,l_2m_2\lambda_2|lm\lambda)_{q^{-1}}e_{m_1}^{l_1q^{-1}}(\lambda_1)\otimes e_{m_2}^{l_2q^{-1}}(\lambda_2), \tag{2.26}$$

$$=\sum_{m_1,m_2}(l_1m_1\lambda_1,l_2m_2\lambda_2|lm\lambda)_{q^{-1}}e_{m_1}^{l_1q}(\lambda_1)\otimes e_{m_2}^{l_2q}(\lambda_2), \tag{2.27}$$

where the second line is deduced from Eq. (2.17). This basis is normalized in the same way (2.24) as the basis $e_m^{lq}(l_1,l_2,\lambda)$, but the two reduced bases are different because we have, in general,

$$(l_1m_1\lambda_1,l_2m_2\lambda_2|lm\lambda)_{q^{-1}}\neq(l_1m_1\lambda_1,l_2m_2\lambda_2|lm\lambda)_q. \tag{2.28}$$

Thus, there exists an automorphism $\mathscr{T}^q(l_1,l_2)$ of the space $V^{l_1}(\lambda_1)\otimes V^{l_2}(\lambda_2)$ that relates both bases:

$$\mathscr{T}^q(l_1,l_2)(e_m^{lq}(l_1,l_2,\lambda))=e_m^{lq^{-1}}(l_1,l_2,\lambda).$$

Using the orthogonality relations (2.20), (2.21), one can show that this operator has the following matrix form in the basis $e_m^{lq}(l_1,l_2,\lambda)$:

$$[\mathscr{T}^q(l_1,l_2)]_{l'm',lm}=(-1)^{(l_1+l_2+l')(l'-m')}\sum_{m_1m_2}(-1)^{(l_1-m_1)(l_2-m_2)}\times(l_1m_1\lambda_1,l_2m_2\lambda_2|l'm'\lambda')_q(l_1m_1\lambda_1,l_2m_2\lambda_2|lm\lambda)_{q^{-1}}. \tag{2.29}$$

From this expression it follows that $[\mathscr{T}^q(l_1,l_2)]^{-1}=\mathscr{T}^{q^{-1}}(l_1,l_2)$. Note also that the matrix $\mathscr{T}^q(l_1,l_2)$ is diagonal in the indices m',m but it is not diagonal in the indices l',l. The symmetries of Clebsch–Gordan coefficients imply the following properties for the matrix elements $[\mathscr{T}^q(l_1,l_2)]_{l'm',lm}$:

$$[\mathscr{T}^q(l_1,l_2)]_{lm,l'm'}=(-1)^{(l_1+l_2+l'+l+m)(l'+l)}[\mathscr{T}^{q^{-1}}(l_1,l_2)]_{l'm',lm}, \tag{2.30}$$

$$[\mathscr{T}^{q^{-1}}(l_1,l_2)]_{l'm',lm}=(-1)^{m(l'+l)}(-1)^{(1/2)l(l-1)+(1/2)l'(l'-1)}[\mathscr{T}^q(l_1,l_2)]_{l'-m',l-m}, \tag{2.31}$$

$$[\mathscr{T}^q(l_2,l_1)]_{l'm',lm}=(-1)^{(l_1+l_2+\lambda_1+\lambda_2)(l'+l)}(-1)^{(1/2)l(l-1)+(1/2)l'(l'-1)}[\mathscr{T}^{q^{-1}}(l_1,l_2)]_{l'm',lm} \tag{2.32}$$

D. The permutation operator τ and the universal R matrix

We shall now consider the tensor product of the previous irreducible representations in reverse order, namely $T^{l_2}\otimes T^{l_1}$. For this we introduce the permutation operator τ acting in any graded tensor product space as follows:

$$\tau(a\otimes b)=(-1)^{\deg(a)\deg(b)}(b\otimes a). \tag{2.33}$$

Therefore, for the quantum superalgebra $U_q(\mathrm{osp}(1|2))$ we have

$$\tau\Delta^q(v_\pm)=\Delta^{q^{-1}}(v_\pm)=R^q\Delta^q(v_\pm)(R^q)^{-1}, \tag{2.34}$$

$$\tau\Delta^q(H)=\Delta^{q^{-1}}(H)=R^q\Delta^q(H)(R^q)^{-1}, \tag{2.35}$$

which means that the action of the operator τ for the coproduct of generators of $U_q(\mathrm{osp}(1|2))$ coïncides with the action of the universal R matrix. The action of the operator τ in the tensor product of representations $T^{l_1}\otimes T^{l_2}$ reverse the order of the tensor product, and we have

$$\tau(e_{m_1}^{l_1q}(\lambda_1)\otimes e_{m_2}^{l_2q}(\lambda_2))=(-1)^{(l_1-m_1+\lambda_1)(l_2-m_2+\lambda_2)}e_{m_2}^{l_2q}(\lambda_2)\otimes e_{m_1}^{l_1q}(\lambda_1), \tag{2.36}$$

and

$$\tau v_{\pm}^{\otimes q}(l_1,l_2)\tau^{-1}=v_{\pm}^{\otimes q^{-1}}(l_2,l_1), \tag{2.37}$$

$$\tau H^{\otimes q}(l_1,l_2)\tau^{-1}=H^{\otimes q^{-1}}(l_2,l_1). \tag{2.38}$$

Using the following symmetry property of Clebsch–Gordan coefficients,[1]

$$\begin{aligned}(l_1m_1\lambda_1,l_2m_2\lambda_2|lm\lambda)_q=&(-1)^{(l_1-m_1+\lambda_1)(l_2-m_2+\lambda_2)}(-1)^{(l_1+l_2+l)(\lambda_1+\lambda_2)+\lambda_1\lambda_2}\\&\times(-1)^{(1/2)(l_1+l_2-l)(l_1+l_2-l+1)}(l_2m_2\lambda_2,l_1m_1\lambda_1|lm\lambda)_{q^{-1}},\end{aligned} \tag{2.39}$$

one can check that the action of τ on the reduced basis reads as

$$\tau(e_m^{lq}(l_1,l_2,\lambda))=(-1)^{(l_1+l_2+l+\lambda_1)(l_1+l_2+l+\lambda_2)}(-1)^{(1/2)(l_1+l_2-l)(l_1+l_2-l-1)}e_m^{lq^{-1}}(l_2,l_1,\lambda). \tag{2.40}$$

Thus the operator τ that relates the bases $e_m^{lq}(l_1,l_2,\lambda)$ and $e_m^{lq^{-1}}(l_2,l_1,\lambda)$ is a representation isomorphism:

$$\tau:(T^{l_1}\otimes T^{l_2})(\mathrm{U}_q(\mathrm{osp}(1|2)))\to(T^{l_2}\otimes T^{l_1})(\mathrm{U}_{q^{-1}}(\mathrm{osp}(1|2))). \tag{2.41}$$

The operator R^q in the representation $T^{l_1}\otimes T^{l_2}$ will be denoted $R^q(l_1,l_2)\equiv R^q(1,2)$. In such a representation its action is

$$R^q(1,2)v_{\pm}^{\otimes q}(l_1,l_2)R^q(1,2)^{-1}=v_{\pm}^{\otimes q^{-1}}(l_1,l_2), \tag{2.42}$$

$$R^q(1,2)H^{\otimes q}(l_1,l_2)R^q(1,2)^{-1}=H^{\otimes q^{-1}}(l_1,l_2). \tag{2.43}$$

Since $R^q(1,2)$ does not exchange the two spaces, in this case the action of the operator τ does not coïncide with the action of $R^q(1,2)$.

1. Matrix elements of $R^q(1,2)$ in the tensor product basis

Using relations (2.15) one can show that, in the standard basis $e_{m_1}^{l_1q}(\lambda_1)\otimes e_{m_2}^{l_2q}(\lambda_2)$, the operator $R^q(1,2)$ has the following matrix form:

$$\begin{aligned}[\mathbb{R}^q(1,2)]_{m_1m_2,n_1n_2}=&(-1)^{k(\lambda_1+1)+(1/2)k(k-1)}q^{(1/4)k(3k+1)}q^{(1/2)k(n_1-n_2)+(n_1+k)(n_2-k)}\\&\times\frac{(1+q^{-1})^k}{[k]!}\left(\frac{[l_1-n_1]![l_1+n_1+k]![l_2+n_2]![l_2-n_2+k]!}{[l_1+n_1]![l_1-n_1-k]![l_2-n_2]![l_2+n_2-k]!}\right)^{1/2}\\&\times\delta_{m_1,n_1+k}\delta_{m_2,n_2-k}.\end{aligned} \tag{2.44}$$

For the simplest case when $l_1=l_2=1$, $R^q(1,2)_{m_1m_2,n_1n_2}$ has the following form:

$$[\mathscr{R}^q(1,1)]_{m_1m_2,n_1n_2}=\begin{pmatrix} q & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & a & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & q^{-1} & 0 & b & 0 & e & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & c & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & d & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & q^{-1} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & q \end{pmatrix}, \tag{2.45}$$

where

$$a=d=(-1)^{\lambda_1}(q-q^{-1}), \quad c=b=q^{-1/2}a, \quad e=(-1)^{\lambda_1}(1+q^{-1})a. \tag{2.46}$$

When $\lambda_1=0$, this matrix coïncides with the corresponding matrix given in Ref. 8.

2. Matrix elements of $R^q(1,2)$ and $R^{q^{-1}}(1,2)$ in the reduced bases

Relations (2.42), (2.43) suggest that the vector $e_m^{lq^{-1}}(l_1,l_2,\lambda)$ is proportional to the vector $R^q(1,2)e_m^{lq}(l_1,l_2,\lambda)$. In the Appendix we prove that indeed we have

$$R^q(1,2)e_m^{lq}(l_1,l_2,\lambda)=q^{(1/2)(l(l+1)-l_1(l_1+1)-l_2(l_2+1))}e_m^{lq^{-1}}(l_1,l_2,\lambda). \tag{2.47}$$

From this relation it follows that

$$[R^q(1,2)]^{-1}=R^{q^{-1}}(1,2). \tag{2.48}$$

Furthermore, formula (2.47) allows one to calculate the matrix elements of the operators $R^q(1,2)$ and $R^{q^{-1}}(1,2)$ in the reduced bases $e_m^{lq}(l_1,l_2,\lambda)$ and $e_m^{lq^{-1}}(l_1,l_2,\lambda)$. Let us introduce the following notation: $\mathbb{R}_e^q(\mathbb{R}_e^{q^{-1}})$ is the matrix of the operator $R^q(1,2)(R^{q^{-1}}(1,2))$ in the basis $e_m^{lq}(l_1,l_2,\lambda)$, $\mathbb{R}_{\underline{e}}^q(\mathbb{R}_{\underline{e}}^{q^{-1}})$ is the matrix of the operator $R^q(1,2)(R^{q^{-1}}(1,2))$ in the basis $e_m^{lq^{-1}}(l_1,l_2,\lambda)$, and let $\mathbb{D}^q$ be a diagonal matrix of the form

$$[\mathbb{D}^q]_{lm,l'm'}=q^{(1/2)(l(l+1)-l_1(l_1+1)-l_2(l_2+1))}\delta_{l,l'}\delta_{m,m'}. \tag{2.49}$$

Using relation (2.47) and the orthogonality relations (2.20), (2.21) for sq-CGc, one can derive the following matrix relations:

$$\mathbb{R}_e^q=\mathscr{T}^q\mathbb{D}^q, \quad \mathbb{R}_e^{q^{-1}}=\mathbb{D}^{q^{-1}}\mathscr{T}^{q^{-1}}, \tag{2.50}$$

$$\mathbb{R}_{\underline{e}}^q=\mathbb{D}^q\mathscr{T}^q, \quad \mathbb{R}_{\underline{e}}^{q^{-1}}=\mathscr{T}^{q^{-1}}\mathbb{D}^{q^{-1}}, \tag{2.51}$$

where $\mathscr{T}^q$ is the matrix given by the formula (2.29). In particular, for the first relation we have

$$[\mathbb{R}_e^q]_{l'm',lm}=q^{(1/2)(l(l+1)-l_1(l_1+1)-l_2(l_2+1))}(-1)^{(l_1+l_2+l')(l'-m')}\sum_{m_1m_2}(-1)^{(l_1-m_1)(l_2-m_2)}$$
$$\times(l_1m_1\lambda_1,l_2m_2\lambda_2|l'm'\lambda')_q(l_1m_1\lambda_1,l_2m_2\lambda_2|lm\lambda)_{q^{-1}}, \tag{2.52}$$

i.e., the matrix elements of the operator $R^q(1,2)$ can be expressed in terms of sq-CGc. The values of the sq-CGc for an arbitrary tensor product of irreducible representations can be calculated from the analytical expression given in Refs. 2, 10, and 11, therefore the matrix elements of $R^q(1,2)$ in any tensor product of irreducible representations can be deduced from formula (2.52). For example, calculating the values of corresponding sq-CGc for $l_1=l_2=1$, we get from formula (2.52),

$$[\mathbb{R}^q_e]_{l'm',lm}=\begin{pmatrix} q^{-2}a & 0 & 0 & 0 & 0 & 0 & qc & 0 & 0 \\ 0 & q^{-1}b & 0 & 0 & 0 & qd & 0 & 0 & 0 \\ 0 & 0 & q^{-1} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & q^{-1}b & 0 & 0 & 0 & -qd & 0 \\ 0 & 0 & 0 & 0 & q & 0 & 0 & 0 & 0 \\ 0 & -q^{-1}d & 0 & 0 & 0 & qb & 0 & 0 & 0 \\ -q^{-2}c & 0 & 0 & 0 & 0 & 0 & qa & 0 & 0 \\ 0 & 0 & 0 & q^{-1}d & 0 & 0 & 0 & qb & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & q \end{pmatrix}, \tag{2.53}$$

where

$$a=\frac{q}{q^2-q+1}, \quad b=\frac{2q}{q^2+1}, \quad c=\frac{q^3-q^2+q-1}{\sqrt{q^2+1}(q^2-q+1)}, \quad d=(-1)^{\lambda_1}\frac{q^2-1}{q^2+1}. \tag{2.54}$$

From expressions (2.42), (2.43), and (2.47), it follows that the operator $R^q(1,2)$ yields an isomorphism of two representations:

$$R^q(1,2):(T^{l_1}\otimes T^{l_2})(U_q(osp(1|2)))\rightarrow(T^{l_1}\otimes T^{l_2})(U_{q^{-1}}(osp(1|2))). \tag{2.55}$$

E. The operator $\mathscr{R}^q$

Finally, in the following we will use the operator $\mathscr{R}^q$ that is a composition of the operators τ and R^q:

$$\mathscr{R}^q=\tau\circ R^q. \tag{2.56}$$

Properties of the operators τ and R^q, in particular, the Yang–Baxter equation (2.12) satisfied by R^q, implies that $\mathscr{R}^q$ satisfies the following relation:

$$(\mathscr{R}^q\otimes id)(id\otimes\mathscr{R}^q)(\mathscr{R}^q\otimes id)=(id\otimes\mathscr{R}^q)(\mathscr{R}^q\otimes id)(id\otimes\mathscr{R}^q). \tag{2.57}$$

Further, from relations (2.10) we get the relations

$$(\mathscr{R}^q\otimes id)(id\otimes\mathscr{R}^q)=\tau(12,3)R^{q}{}_{12,3}\equiv\mathscr{R}^{q}{}^{12,3}, \tag{2.58}$$

$$(id\otimes\mathscr{R}^q)(\mathscr{R}^q\otimes id)=\tau(1,23)R^{q}{}_{1,23}\equiv\mathscr{R}^{q}{}^{1,23}, \tag{2.59}$$

where

$$\tau(12,3)=(\tau\otimes id)(id\otimes\tau), \quad \tau(1,23)=(id\otimes\tau)(\tau\otimes id). \tag{2.60}$$

In the tensor product $T^{l_1}\otimes T^{l_2}$ the operator $\mathscr{R}^q$ is represented by the operator

$$\mathscr{R}^q(1,2)=\tau\circ R^q(1,2),$$

and formulas (2.58), (2.59) take the form

$$(\mathscr{R}^q(1,3)\otimes id(2))(id(1)\otimes\mathscr{R}^q(2,3))=\mathscr{R}^{q12,3}(12,3), \tag{2.61}$$

$$(id(2)\otimes\mathscr{R}^q(1,3))(\mathscr{R}^q(1,2)\otimes id(3))=\mathscr{R}^{q1,23}(1,23). \tag{2.62}$$

Using relations (2.40), (2.47) we derive immediately the action of $\mathscr{R}^q(1,2)$ on the reduced basis,

$$\begin{aligned}\mathscr{R}^q(1,2)e^{lq}_m(l_1,l_2,\lambda)=&(-1)^{(l_1+l_2+l+\lambda_1)(l_1+l_2+l+\lambda_2)}\\&\times(-1)^{(1/2)(l_1+l_2-l)(l_1+l_2-l-1)}\\&\times q^{(1/2)[l(l+1)-l_1(l_1+1)-l_2(l_2+1)]}e^{lq}_m(l_2,l_1,\lambda),\end{aligned} \tag{2.63}$$

and its action on the operators $v^{\otimes q}_{\pm}(l_1,l_2)$, $H^{\otimes q}(l_1,l_2)$ reads as

$$\mathscr{R}^q(1,2)v^{\otimes q}_{\pm}(l_1,l_2)\mathscr{R}^q(1,2)^{-1}=v^{\otimes q}_{\pm}(l_2,l_1), \tag{2.64}$$

$$\mathscr{R}^q(1,2)H^{\otimes q}(l_1,l_2)\mathscr{R}^q(1,2)^{-1}=H^{\otimes q}(l_2,l_1), \tag{2.65}$$

where

$$\mathscr{R}^q(1,2)^{-1}=R^{q^{-1}}(1,2)\circ\tau. \tag{2.66}$$

The operator $\mathscr{R}^q(1,2)$ defines then an isomorphism of representations,

$$\mathscr{R}^q(1,2):(T^{l_1}\otimes T^{l_2})(U_q(osp(1|2)))\rightarrow(T^{l_2}\otimes T^{l_1})(U_q(osp(1|2))). \tag{2.67}$$

The universal R matrix is the appropriate tool for obtaining numerous relations between Racah coefficients and $sq6\text{-}j$ symbols. In the following section we shall first use it to derive the Racah sum rule for $sq6\text{-}j$ symbols.

III. RACAH SUM RULE FOR THE sq-6j SYMBOLS

In order to derive the Racah sum rule, we will consider the action of the operator $\mathscr{R}^q$ on the reduced bases of the tensor product of three irreducible representations of the same class $T^{l_1}\otimes T^{l_2}\otimes T^{l_3}$. The operators $H,v_{\pm}$ are represented in this tensor product by

$$v^{\otimes}_{\pm}(1,2,3)=(T^{l_1}\otimes T^{l_2}\otimes T^{l_3})((\Delta\otimes id)\Delta(v_{\pm})), \tag{3.1}$$

$$H^{\otimes}(1,2,3)=(T^{l_1}\otimes T^{l_2}\otimes T^{l_3})((\Delta\otimes id)\Delta(H)). \tag{3.2}$$

The reduction of the tensor product $V^{l_1}(\lambda_1)\otimes V^{l_2}(\lambda_2)\otimes V^{l_3}(\lambda_3)$ of representation spaces can be done, as in the classical case, in two different schemes:

$$T^l\subset((T^{l_1}\otimes T^{l_2})\otimes T^{l_3}),\quad T^l\subset(T^{l_1}\otimes(T^{l_2}\otimes T^{l_3})). \tag{3.3}$$

The bases $e^{lq}_m(l_1,l_{23},\lambda)$ and $e^{lq}_m(l_{12},l_3,\lambda)$ corresponding to these reduction schemes are orthogonal and normalized in the following way:

$$(e^{lq}_m(l_{12},l_3,\lambda),e^{l'q}_{m'}(l'_{12},l_3,\lambda))=(-1)^{\varphi_{12,3}(l-m)+\psi_{12,3}}\delta_{ll'}\delta_{mm'}\delta_{l_{12}l'_{12}}\equiv g_{ll_{12}m,l'l'_{12}m'}, \tag{3.4}$$

$$(e^{lq}_m(l_1,l_{23},\lambda),e^{l'q}_{m'}(l_1,l'_{23},\lambda))=(-1)^{\varphi_{1,23}(l-m)+\psi_{1,23}}\delta_{ll'}\delta_{mm'}\delta_{l_{23}l'_{23}}\equiv g_{ll_{23}m,l'l'_{23}m'}, \tag{3.5}$$

where

$$\varphi_{1,23}=\varphi_{12,3}=\mathscr{S}+\lambda_1+\lambda_2+\varphi_3(\mathrm{mod}\ 2), \tag{3.6}$$

$$\psi_{12,3}=(l_1+l_2+l_{12})(\mathscr{S}+1)+(\lambda_1+\lambda_3+\varphi_2)\mathscr{S}+\sum_{i<j}\lambda_i\lambda_j+\sum_{i=1}^{3}\psi_i\ (\mathrm{mod}\ 2), \tag{3.7}$$

$$\psi_{1,23}=(l_2+l_3+l_{23})(\mathscr{S}+1)+(\lambda_1+\lambda_3+\varphi_2)\mathscr{S}+\sum_{i<j}\lambda_i\lambda_j+\sum_{i=1}^{3}\psi_i\ (\mathrm{mod}\ 2), \tag{3.8}$$

with

$$\mathscr{S}=l_1+l_2+l_3+l,\quad \lambda=\sum_{i=1}^{3}(\lambda_i+l_i)+l. \tag{3.9}$$

The sqRacah coefficients $U^s(l_1,l_2,l_3,l,l_{12},l_{23},q)$ of the quantum superalgebra $\mathrm{U}_q(\mathrm{osp}(1|2))$ are defined, in the standard way, as the coefficients that relate reduced bases in two different reduction schemes,[2]

$$e_m^{lq}(l_{12},l_3,\lambda)=\sum_{l_{23}}(-1)^{(l_2+l_3+l_{23})(\mathscr{S}+1)}U^s(l_1,l_2,l_3,l,l_{12},l_{23},q)e_m^{lq}(l_1,l_{23},\lambda), \tag{3.10}$$

or equivalently,

$$e_m^{lq}(l_1,l_{23},\lambda)=\sum_{l_{12}}(-1)^{(l_1+l_2+l_{12})(\mathscr{S}+1)}U^s(l_1,l_2,l_3,l,l_{12},l_{23},q)e_m^{lq}(l_{12},l_3,\lambda). \tag{3.11}$$

We have the following relation between $sqRc$ and $sq6-j$ symbols:[2]

$$\begin{aligned}U^s(l_1,l_2,l_3,l,l_{12},l_{23},q)=&(-1)^{(\lambda_2+1)(l_2+l+l_{23}+l_{12})}(-1)^{(l_1+l_2+l_3)(l+1)}(-1)^{l_{12}(l_1+l_{23}+l)}\\&\times(-1)^{l_{23}(l_{12}+l_3+l)}(-1)^{\mathscr{S}(\mathscr{S}-1)/2}\sqrt{[2l_{12}+1][2l_{23}+1]}\\&\times\begin{Bmatrix}l_1 & l_2 & l_{12}\\ l_3 & l & l_{23}\end{Bmatrix}_q^s.\end{aligned} \tag{3.12}$$

Let us consider the matrix $W_{l'm',lm}$ of the operator $id(1)\otimes\mathscr{R}^q(3,2)$ in the bases $e_m^{lq}(l_{12},l_3,\lambda)$ and $e_m^{lq}(l_{13},l_2,\lambda)$,

$$W_{l'm',lm}=g_{l'l'_{12}m',l''l''_{12}m''}(e_{m''}^{l''q}(l''_{12},l_3,\lambda),id(1)\otimes\mathscr{R}^q(3,2)e_m^{lq}(l_{13},l_2,\lambda)) \tag{3.13}$$

Using relations (2.20), (3.10), and (2.63), one obtains

$$\begin{aligned}&id(1)\otimes\mathscr{R}^q(3,2)e_m^{lq}(l_{13},l_2,\lambda)\\&=\sum_{l_{12},l_{23}}(-1)^{(l_1+l_3+l_{12}+l_{23})(\mathscr{S}+1)}(-1)^{(l_2+l_3+l_{23}+\lambda_2)(l_2+l_3+l_{23}+\lambda_3)}\\&\quad\times(-1)^{(1/2)(l_2+l_3-l_{23})(l_2+l_3-l_{23}-1)}q^{(1/2)[l_{23}(l_{23}+1)-l_2(l_2+1)-l_3(l_3+1)]}\\&\quad\times U^s(l_1,l_3,l_2,l,l_{13},l_{23},q)U^s(l_1,l_2,l_3,l,l_{12},l_{23},q)e_m^{lq}(l_{12},l_3,\lambda)\end{aligned} \tag{3.14}$$

Therefore, the matrix $W_{l'm',lm}$ has the form

$$W_{l'm',lm}=\sum_{l_{23}}(-1)^{(l_1+l_3+l_{12}+l_{23})(\mathscr{S}+1)}(-1)^{(l_2+l_3+l_{23}+\lambda_2)(l_2+l_3+l_{23}+\lambda_3)}$$
$$\times(-1)^{(1/2)(l_2+l_3-l_{23})(l_2+l_3-l_{23}-1)}q^{(1/2)[l_{23}(l_{23}+1)-l_2(l_2+1)-l_3(l_3+1)]}$$
$$\times U^s(l_1,l_3,l_2,l,l_{13},l_{23},q)U^s(l_1,l_2,l_3,l,l_{12},l_{23},q)\delta_{l',l}\delta_{m',m}. \tag{3.15}$$

It is diagonal and it does not depend on m.

On the other hand, we have

$$id(1)\otimes\mathscr{R}^q(3,2)e^{lq}_m(l_{13},l_2,\lambda)=([\mathscr{R}^q(1,2)]^{-1}\otimes id(3))(\mathscr{R}^q(1,2)\otimes id(3))$$
$$\times(id(1)\otimes\mathscr{R}^q(3,2))e^{lq}_m(l_{13},l_2,\lambda), \tag{3.16}$$
$$=(-1)^{(l_2+l_{13}+l+\lambda_2)(l_2+l_{13}+l+\lambda_{13})}$$
$$\times(-1)^{(1/2)(l_2+l_{13}-l)(l_2+l_{13}-l-1)}q^{(1/2)[l(l+1)-l_2(l_2+1)-l_{13}(l_{13}+1)]}$$
$$\times([\mathscr{R}^q(1,2)]^{-1}\otimes id(3))e^{lq}_m(l_2,l_{13},\lambda), \tag{3.17}$$

where we have used relations (2.61), (2.63). Applying further relations (2.20), (3.10), and (2.63), we find that

$$([\mathscr{R}^q(1,2)]^{-1}\otimes id(3))e^{lq}_m(l_2,l_{13},\lambda)$$
$$=\sum_{l_{12}}(-1)^{(l_1+l_2+l_{12})(\mathscr{S}+1)}(-1)^{(l_1+l_2+l_{12}+\lambda_1)(l_1+l_2+l_{12}+\lambda_2)}$$
$$\times(-1)^{(1/2)(l_1+l_2-l_{12})(l_1+l_2-l_{12}-1)}q^{-(1/2)[l_{12}(l_{12}+1)-l_1(l_1+1)-l_2(l_2+1)]}$$
$$\times U^s(l_2,l_1,l_3,l,l_{12},l_{13},q)e^{lq}_m(l_{12},l_3,\lambda). \tag{3.18}$$

Substitution of this relation into (3.16) and of the resulting formula into relation (3.13) yields another expression for the matrix $W_{l'm',lm}$,

$$W_{l'm',lm}=(-1)^{(l_2+l_{23}+l+\lambda_2)(l_2+l_{13}+l+\lambda_{13})}(-1)^{(l_1+l_2+l_{12}+\lambda_1)(l_1+l_2+l_{12}+\lambda_2)}(-1)^{(l_1+l_2+l_{12})(\mathscr{S}+1)}$$
$$\times(-1)^{(1/2)(l_2+l_{13}-l)(l_2+l_{13}-l-1)}(-1)^{(1/2)(l_1+l_2-l_{12})(l_1+l_2-l_{12}-1)}$$
$$\times q^{(1/2)[l(l+1)-l_2(l_2+1)-l_{13}(l_{13}+1)]}q^{-(1/2)[l_{12}(l_{12}+1)-l_1(l_1+1)-l_2(l_2+1)]}$$
$$\times U^s(l_2,l_1,l_3,l,l_{12},l_{13},q)\delta_{l',l}\delta_{m',m}. \tag{3.19}$$

Comparison of this expression with relation (3.15) furnishes the Racah sum rule for $U_q(\mathrm{osp}(1|2))$ Racah coefficients:

$$\sum_{l_{23}}(-1)^{(l_2+l_3+l_{23})(\mathscr{S}+1)}(-1)^{(l_2+l_3+l_{23}+\lambda_2)(l_2+l_3+l_{23}+\lambda_3)}$$
$$\times(-1)^{(1/2)(l_2+l_3-l_{23})(l_2+l_3-l_{23}-1)}q^{(1/2)[l_{23}(l_{23}+1)-l_2(l_2+1)-l_3(l_3+1)]}$$
$$\times U^s(l_1,l_3,l_2,l,l_{13},l_{23},q)U^s(l_1,l_2,l_3,l,l_{12},l_{23},q)$$
$$=(-1)^{(l_2+l_{23}+l+\lambda_2)(\mathscr{S}+\lambda_1+\lambda_3)}(-1)^{(l_1+l_2+l_{12}+\lambda_1)(l_1+l_2+l_{12}+\lambda_2)}(-1)^{(1/2)(l_2+l_{13}-l)(l_2+l_{13}-l-1)}$$
$$\times(-1)^{(1/2)(l_1+l_2-l_{12})(l_1+l_2-l_{12}-1)}q^{(1/2)[l(l+1)+l_1(l_1+1)-l_{12}(l_{12}+1)-l_{13}(l_{13}+1)]}$$
$$\times U^s(l_2,l_1,l_3,l,l_{12},l_{13},q). \tag{3.20}$$

Substituting in this expression relation (3.12) that relates sqRacah coefficients and $sq6-j$ symbols, we derive the Racah sum rule satisfied by the latter:

$$\sum_{l_{23}} (-1)^{(l_1+l_2+l_{13}+l_{23})(\mathscr{L}+1)+\mathscr{L}l}(-1)^{(l_2+l_3+l_{23})l_{23}+(l_1+l_2+l_{12})l_{12}+(l_1+l_3+l_{13})l_{13}}(-1)^{\mathscr{L}(\mathscr{L}+1)/2}$$
$$\times(-1)^{(1/2)(l_2+l_3-l_{23})(l_2+l_3-l_{23}-1)}(-1)^{(1/2)(l_1+l_2-l_{12})(l_1+l_2-l_{12}-1)}$$
$$\times(-1)^{(1/2)(l_2+l_{13}-l)(l_2+l_{13}-l-1)}q^{(1/2)[l_{23}(l_{23}+1)+l_{12}(l_{12}+1)+l_{13}(l_{13}+1)]}[2l_{23}+1]$$
$$\times\begin{Bmatrix} l_1 & l_2 & l_{12} \\ l_3 & l & l_{23} \end{Bmatrix}_q^s \begin{Bmatrix} l_1 & l_3 & l_{13} \\ l_2 & l & l_{23} \end{Bmatrix}_q^s = q^{(1/2)[l(l+1)+l_1(l_1+1)+l_2(l_2+1)+l_3(l_3+1)]} \begin{Bmatrix} l_2 & l_1 & l_{12} \\ l_3 & l & l_{13} \end{Bmatrix}_q^s . \tag{3.21}$$

Using the orthogonality relation for the $sq6-j$ symbols,

$$\sum_{l_{12}} (-1)^{(l_1+l_2+l_{12})(\mathscr{L}+1)}[2l_{12}+1][2l_{23}+1] \begin{Bmatrix} l_1 & l_2 & l_{12} \\ l_3 & l & l_{23} \end{Bmatrix}_q^s \begin{Bmatrix} l_1 & l_2 & l_{12} \\ l_3 & l & l'_{23} \end{Bmatrix}_q^s$$
$$= (-1)^{(l_2+l_3+l_{23})(\mathscr{L}+1)} \delta_{l_{23},l'_{23}}, \tag{3.22}$$

one can rewrite the Racah sum rule (3.21) in the following form:

$$\sum_{l_{13}} (-1)^{\Theta} q^{-(1/2)[l_{23}(l_{23}+1)+l_{12}(l_{12}+1)+l_{13}(l_{13}+1)]}[2l_{13}+1] \begin{Bmatrix} l_2 & l_1 & l_{12} \\ l_3 & l & l_{13} \end{Bmatrix}_q^s \begin{Bmatrix} l_1 & l_3 & l_{13} \\ l_2 & l & l_{23} \end{Bmatrix}_q^s$$
$$= q^{-(1/2)[l(l+1)+l_1(l_1+1)+l_2(l_2+1)+l_3(l_3+1)]} \begin{Bmatrix} l_1 & l_2 & l_{12} \\ l_3 & l & l_{23} \end{Bmatrix}_q^s , \tag{3.23}$$

where the phase argument Θ is

$$\Theta = \tfrac{1}{2}(l_2+l_3-l_{23})(l_2+l_3-l_{23}-1)+\tfrac{1}{2}(l_1+l_2-l_{12})(l_1+l_2-l_{12}-1)$$
$$+\tfrac{1}{2}(l_2+l_{13}-l)(l_2+l_{13}-l-1)+\tfrac{1}{2}\mathscr{L}(\mathscr{L}+1)+\mathscr{L}l+(l_2+l_3+l_{23})l_{23}$$
$$+(l_1+l_2+l_{12})l_{12}+(l_1+l_3+l_{13})l_{13}. \tag{3.24}$$

In the limit $q\to 1$ this formula becomes the Racah sum rule for the $6-j$ symbols for the superalgebra osp(1|2) and it takes the form given in Ref. 12.

If $l_{12}=0$ and $l_1=l_2$, $l_3=l$, then the Racah sum rule (3.23) leads to the summation formula

$$\sum_{l_{13}} (-1)^{(l_1+l_3)(l_{13}+l'_{13})+l'_{13}} q^{-(1/2)[l_{13}(l_{13}+1)+l'_{13}(l'_{13}+1)]}[2l_{13}+1] \begin{Bmatrix} l_1 & l_3 & l_{13} \\ l_1 & l_3 & l'_{13} \end{Bmatrix}_q^s$$
$$= q^{-(1/2)[l_1(l_1+1)+l_3(l_3+1)]}. \tag{3.25}$$

IV. BIEDENHARN–ELLIOTT IDENTITY FOR THE QUANTUM SUPERALGEBRA $U_q(\mathrm{osp}(1|2))$

The tensor product $T^{l_1}\otimes T^{l_2}\otimes T^{l_3}\otimes T^{l_4}$ of four irreducible representations of the same class can be reduced into irreducible representations according to one of the following five reduction schemes:

$$[(T^{l_1}\otimes T^{l_2})\otimes T^{l_3}]\otimes T^{l_4}, \tag{4.1}$$

$$[T^{l_1}\otimes (T^{l_2}\otimes T^{l_3})]\otimes T^{l_4}, \tag{4.2}$$

$$T^{l_1}\otimes [(T^{l_2}\otimes T^{l_3})\otimes T^{l_4}], \tag{4.3}$$

$$T^{l_1}\otimes [T^{l_2}\otimes (T^{l_3}\otimes T^{l_4})], \tag{4.4}$$

$$(T^{l_1}\otimes T^{l_2})\otimes (T^{l_3}\otimes T^{l_4}). \tag{4.5}$$

The Biedenharn–Elliott identity is concerned with the relation between the schemes (4.1) and (4.4). One can go from one to the other either by the chain

$$(4.1)\rightarrow(4.2)\rightarrow(4.3)\rightarrow(4.4), \tag{4.6}$$

or by the chain

$$(4.1)\rightarrow(4.5)\rightarrow(4.4), \tag{4.7}$$

each step involving sqRacah coefficients. Since the overall matrices that connect the two reduction schemes, (4.1) and (4.4), must be independent of the chain, there must exist a relation between combinations of products of three sqRacah coefficients for the first chain and combinations of products of two sqRacah coefficients for the second chain. This is precisely the Biedenharn–Elliott identity. Writing down the equality of corresponding matrix elements, the Biedenharn–Elliott identity for sqRacah coefficients reads as

$$\begin{aligned}
&\sum_{l_{23}} (-1)^{(l_2+l_3+l_{23})(l_2+l_3+l_4+l_{234}+1)}(-1)^{(l_1+l_2+l_{12})(l_1+l_2+l_3+l_{123}+1)}\\
&\quad\times(-1)^{(l_1+l_{23}+l_{123})(l_1+l_{23}+l_4+l+1)}U^s(l_1,l_2,l_3,l_{123},l_{12},l_{23},q)U^s(l_1,l_{23},l_4,l,l_{123},l_{234},q)\\
&\quad\times U^s(l_2,l_3,l_4,l_{234},l_{23},l_{34},q)\\
&\quad=(-1)^{(l_1+l_2+l_{12})(l_1+l_2+l_{34}+l+1)}(-1)^{(l_{12}+l_3+l_{123})(l_{12}+l_3+l_4+l+1)}\\
&\qquad\times U^s(l_{12},l_3,l_4,l,l_{123},l_{34},q)U^s(l_1,l_2,l_{34},l,l_{12},l_{234},q).
\end{aligned} \tag{4.8}$$

For $sq6$-j symbols it is rewritten as

$$\begin{aligned}
&\sum_{l_{13}} (-1)^{\Theta}[2l_{23}+1]\begin{Bmatrix} l_1 & l_2 & l_{12}\\ l_3 & l_{123} & l_{23}\end{Bmatrix}_q^s\begin{Bmatrix} l_1 & l_{23} & l_{123}\\ l_4 & l & l_{234}\end{Bmatrix}_q^s\begin{Bmatrix} l_2 & l_3 & l_{23}\\ l_4 & l_{234} & l_{34}\end{Bmatrix}_q^s\\
&\quad=\begin{Bmatrix} l_{12} & l_3 & l_{123}\\ l_4 & l & l_{34}\end{Bmatrix}_q^s\begin{Bmatrix} l_1 & l_2 & l_{12}\\ l_{34} & l & l_{234}\end{Bmatrix}_q^s,
\end{aligned} \tag{4.9}$$

where the phase argument Θ is given by

$$\begin{aligned}
\Theta=&\frac{1}{2}\left(\sum_{all} l_i\right)\left(\sum_{all} l_i-1\right)+l_{23}(l+l_{12}+l_{34})+(l_4+l_{234})(l_3+l+l_{123}+l_{34})\\
&+(l_3+l_{12}+l_{123})(l_3+l_2+l+l_{12}+l_{34})+(l_1+l_2+l_{12})(l_1+l_3+l_4+l_{34}+l+l_{234})\\
&+l_2+l_4+l+l_{34}+l_{123}+l_{234},
\end{aligned} \tag{4.10}$$

where $\Sigma_{all}\, l_i$ means summation over all 10 arguments appearing in $sq6\text{-}j$ symbols. Similarly, as in the cases of $su(2)$ and $u_q(su(2))$ the three-term recurrence relation for $sq6\text{-}j$ symbols follows from the Biedenharn–Elliott identity (4.9). Putting $l=1$ into this identity and using the known analytical expressions of the $sq6\text{-}j$ symbols with one argument equal to 1 (see the table in Ref. 3), we derive a recurrence relation that can be written, after a change in the notation,

$$A\begin{Bmatrix} a & b & e \\ c & d & f-1 \end{Bmatrix}_q^s + B\begin{Bmatrix} a & b & e \\ c & d & f \end{Bmatrix}_q^s + C\begin{Bmatrix} a & b & e \\ c & d & f+1 \end{Bmatrix}_q^s = 0, \tag{4.11}$$

where

$$A=(-1)^{a+d+f+1}[2][2f+2]([a+d+f+1][a-d+f][a+d-f+1][-a+d+f][b+c+f+1] \times[b-c+f][b+c-f+1][-b+c+f])^{1/2}, \tag{4.12}$$

$$B=(-1)^{a+c+f+1}[2f+1]([a-d+f][a+d-f]+(-1)^{a+b+f}[-a+d+f][a+d+f+2]) \times([b+c-f][b-c+f]+(-1)^{b+c+f}[-b+c+f][b+c+f+2])+(-1)^{\Psi}[2f][2f+1] \times[2f+2]([e+c-d][e-c+d]+(-1)^{e+c+d}[-e+c+d][e+c+d+2]), \tag{4.13}$$

$$C=(-1)^{b+c+f}[2][2f]([a+d+f+2][a-d+f+1][a+d-f][-a+d+f+1] \times[b+c+f+2][b-c+f+1][b+c-f][-b+c+f+1])^{1/2}, \tag{4.14}$$

and

$$\Psi=(a+b+e)(a+b+c+d)+(d+e+c)(b+d+e+f)+(a+d+f)(a+c+e+f)+c+d. \tag{4.15}$$

APPENDIX: ACTION OF THE UNIVERSAL *R* MATRIX ON THE REDUCED BASIS $e_m^{lq}(l_1,l_2,\lambda)$

In this appendix we prove the relation (2.47). For this, we recall that the vector $e_m^{lq}(l_1,l_2,\lambda)$ can be expressed in the form (Ref. 1)

$$e_m^{lq}(l_1,l_2,\lambda)=\frac{1}{(N(l,m,q))^{1/2}}\,P_{ml}^{lq\otimes}(1,2)e_{l_1}^{l_1q}(\lambda_1)\otimes e_{l-l_1}^{l_2q}(\lambda_2), \tag{A1}$$

where

$$P_{ml}^{lq\otimes}(1,2)=\left(\frac{[l+m]!}{[2l]![l-m]!}\,\gamma^{-(l-m)}\right)^{1/2} v_-^{\otimes q}(l_1,l_2)^{l-m}P^{lq\otimes}(1,2), \tag{A2}$$

$$P^{lq\otimes}(1,2)=(T^{l_1}\otimes T^{l_2})(\Delta(P^{lq}))=\sum_{r=0}^{\infty} c_r(l)(v_-^{\otimes}(1,2))^r(v_+^{\otimes}(1,2))^r, \tag{A3}$$

and P^{lq} is the projection operator on the highest weight vector of weight l. The coefficients $c_r(l)$ are of the form

$$c_r(l)=\frac{[2l+1]!}{[2l+r+1]![r]!\,\gamma^r}. \tag{A4}$$

The value of the normalization factor $N(l,m,q)$ is given by the formula

$$N(l,m,q)=q^{(1/2)(l_1+l_2-l)(l_1+l_2-l-1)}\,\frac{[2l+1]![2l_1]!}{[l_1+l_2+l]![l_1+l_2+l+1]!}. \tag{A5}$$

From relations (2.42) and (A2), (A3) it follows that

$$R^q(1,2)P^{lq\otimes}_{ml}(1,2)R^{q^{-1}}(1,2)=P^{lq^{-1}\otimes}_{ml}(1,2),$$

and one deduces successively the relations

$$R^q(1,2)e^{lq}_m(l_1,l_2,\lambda)=(N(l,m,q))^{-1/2}R^q(1,2)P^{lq\otimes}_{lm}(1,2)R^{q^{-1}}(1,2)R^q(1,2)e^{l_1q}_{l_1}(\lambda_1)\otimes e^{l_2q}_{l-l_1}(\lambda_2), \tag{A6}$$

$$=(N(l,m,q))^{-1/2}q^{l_1(l-l_1)}P^{lq^{-1}\otimes}_{ml}(1,2)e^{l_1q}_{l_1}(\lambda_1)\otimes e^{l_2q}_{l-l_1}(\lambda_2), \tag{A7}$$

$$=\left(\frac{N(l,m,q^{-1})}{N(l,m,q)}\right)^{1/2}q^{l_1(l-l_1)}e^{lq^{-1}}_m(l_1,l_2,\lambda). \tag{A8}$$

The norm ratio $N(l,m,q^{-1})/N(l,m,q)$ is calculated from the definition (A5), and one gets finally the action of the universal R-matrix on the reduced basis $e^{lq}_m(l_1,l_2,\lambda)$:

$$R^q(l_1,l_2)e^{lq}_m(l_1,l_2,\lambda)=q^{(1/2)[l(l+1)-l_1(l_1+1)-l_2(l_2+1)]}e^{lq^{-1}}_m(l_1,l_2,\lambda). \tag{A9}$$

Unobstructedness of Calabi–Yau orbi-Kleinfolds

Z. Ran[a)]
Department of Mathematics, University of California, Riverside, California 92521

(Received 29 August 1997; accepted for publication 4 September 1997)

We show that Calabi–Yau spaces with certain types of hypersurface-quotient singularities have unobstructed deformations. This applies in particular to all Calabi–Yau orbifolds nonsingular in codimension 2.
© *1998 American Institute of Physics.* [S0022-2488(98)02501-8]

I. INTRODUCTION

In recent years Calabi–Yau manifolds have attracted a great deal of attention, motivated both by their role in classification theory and by their connections with physics, in particular the phenomenon of mirror symmetry. Both the classification theory and physics viewpoints suggest looking more generally at a suitable class of *singular* Calabi–Yau spaces, e.g., most known mirror symmetry constructions involve forming a quotient under a finite group action, thus leading naturally to Calabi–Yau *orbifolds* and families of such.

Now a basic result about Calabi–Yau manifolds X is the theorem of Bogomolov–Tian–Todorov asserting that X has unobstructed deformations. Some extensions of this theorem to the case of singular X have been considered in Refs. 1–4. However,these extensions do not cover, e.g., the case of orbifolds. Thus one is naturally led to ask, as did Morrison, whether unobstructedness holds for Calabi–Yau orbifolds, say nonsingular in codimension 2. Our purpose here is to answer this question affirmatively and, in fact, to prove a rather more general statement which at the same time generalizes the reuslt of Ref. 2, allowing (local) quotients of Kleinfolds, whence the term ''orbi-Kleinfolds.''

The proof is particularly easy in the orbifold case, requiring little more than a simple combination of (either form of) the ''dual unobstructedness criterion'' of Ref. 5 with the ideas surrounding Schlessinger's rigidity theorem.[6] The more general orbi-Kleinfold case requires more work, which we feel is justified by the interest of the result.

II. SOME DEFINITIONS

We begin by recalling that a *Kleinian* singularity is an isolated simple hypersurface singularity. These are classified by Arnold into types $A–D–E$ (cf. Ref. 7, p. 132). We generalize this notion as follows.

Definition 1: An isolated hypersurface singularity (X,p) is said to be weakly Kleinian *provided.*

(i) *X is cDV (i.e., a general surface section through p is a DuVal or Kleinian singularity*);
(ii) *X admits a* $\mathbb{C}^*$ *action with positive weights*;
(iii) *for a resolution* $\widetilde{X}\to X$*, all components of the exceptional locus are smooth divisors E with* $H^{p,q}(E)=0$ *for* $p\neq q$.

Remark: Note that (i) implies that X is a rational singularity, hence $H^{p,0}(E)=0$, $p>0$. In particular, in dimension 3, (i) implies (iii).

Next recall from Ref. 2 that an isolated singularity (X,p) is said to be *good* if for a resolution

a)Electronic mail: ziv@ucrmath.ucr.edu

$\tilde{X}\to X$ and $\hat{\tilde{X}}$ the formal neighborhood of the exceptional locus, the map induced by exterior derivative

$$d:H^i(\Omega^j_{\tilde{X}})\to H^i(\Omega^{j+1}_{\tilde{X}})$$

is injective in the range $i,j>0$, $i\neq j$, $i+j<\dim X$. All threefold rational singularities, and A_1 singularities in all dimensions are good. Presumably all Kleinian singularities are good, but this is unproven. The unobstructedness result of Ref. 2 as stated allowed good Kleinian singularities, but it was remarked by Namikawa in Ref. 4 that the proof covers the good weakly Kleinian case as well.

Definition 2: An analytic variety X is said to be a (weak) orbi-Kleinfold *if X is locally of the form V/G, where V has good (weak) Kleinian singularities and G is a finite group acting on V which is ''small'' in that for all* $g\in G$, $p\in V^g$, *the induced action of g on the Zariski tangent* T_pV *has no eigenspace of codimension exactly 1.*

Remarks:

(1) All orbifolds are orbi-Kleinfolds (cf. Ref. 8).
(2) In dimension 3, all terminal singularities are, by Mori's classification (cf. Ref. 9) (cyclic) quotients of isolated cDV points, hence ''almost'' weakly orbi-Kleinian; thus the class of weak orbi-Kleinfolds is rather more general than that of orbifolds.
(3) All orbi-Kleinfolds are Cohen–Macaulay, because a finite quotient of a CM variety is CM [cf. Eagon–Hochster, ''Cohen–Macaulay rings, invariant theory, and the generic perfection of determinantal loci,'' Am J. Math (1971); indeed this follows easily by observing that CM is equivalent to an arbitrary system of parameters being regular, i.e., having trivial Koszul homology, and the fact that Koszul homology commutes with the averaging (or Reynolds) operator; I am indebted to M. Hochster for this remark].
(4) If $X=V/G$ is a local weak orbi-Kleinfold, then V admits a G-equivariant resolution $\tilde{V}$, yielding an orbifold $X_{\text{orb}}=V/G$ with a birational morphism to X. This construction clearly globalizes, yielding an ''orbifold resolution'' $X_{\text{orb}}\to X$ for any weak orbi-Kleinfold, which is an isomorphism off the (discrete) nonorbifold locus of X.

Definition 3: A Calabi–Yau (weak) orbi-Kleinfold *is a compact irreducible (weak) orbi-Kleinfold X such that*

(i) *X admits a resolution of singularities by a Kähler manifold*;
(ii) *the dualizing sheaf* $\omega_X\cong\mathscr{O}_X$:

III. THEOREM AND PROOF

Our main result is the following:

Theorem 4: Any Calabi–Yau weak orbi-Kleinfold nonsingular in codimension 2 has unobstructed deformations.

Remark: This generalizes Theorem 1 of Ref. 2. In dimension 3, unobstructedness of Calabi–Yau spaces with terminal singularities has been proven by Namikawa,[4] but not all weak orbi-Kleinfolds are terminal, nor conversely.

Proof of theorem: Let X be a Calabi–Yau weak orbi-Kleinfold of dimension n, $\Theta=\mathscr{H}om(\Omega^1_X,\mathscr{O}_X)$ its tangent sheaf, and $j:X_{\text{reg}}\to X$ the inclusion of the open subset of regular points. In view of our depth hypothesis, results of Schlessinger,[6] as exposed in Ref. 10, Secs. I 9–10, show that we have an isomorphism of deformation functors

$$\text{Def}(X)\xrightarrow{\sim}\text{Def}(X_{\text{reg}}).$$

In particular the first-order deformation group

$$T^1(X)=\mathrm{Ext}^1(\Omega^1_X,\mathscr{O}_X)\cong H^1(X_{\mathrm{reg}},\Theta),$$

and, more importantly for us obstructions to deforming X may be taken in the group $H^2(X_{\mathrm{reg}},\Theta)$. The following is in essence due to Schlessinger (and is valid more generally for quotients, nonsingular in codimension 2, of isolated hypersurface singularities).

Lemma 5: (i) $R^1j_*\Theta_{X_{\mathrm{reg}}}$ is supported in the nonorbifold locus of X; (ii) $R^2j_*\Theta_{X_{\mathrm{reg}}}=0$.

Proof: We work locally on a small open set $U=V/G\subset X$, where V is a local hypersurface with one (possibly) singular point p. Put

$$V_0=V-\{p\},$$

$$V_{00}=\text{subset of } V_0 \text{ where } G \text{ acts freely.}$$

Note that $V-V_{00}$ has codimension $\geqslant 3$ in X and $U_{\mathrm{reg}}=V_{00}/G$. As in Ref. 10, we have

$$H^i(V_{\mathrm{reg}},\Theta)=H^i(V_{00},\Theta_{V_{00}})^G=H^i(V_0,\Theta_{V0})^G,\quad i=1,2,$$

and $H^i(V_0,\Theta_{V_0})$ coincides with $T^i_{V,p}$ and in particular vanishes if p is regular or $i=2$. □

Now put

$$\widetilde{\Omega}_X=j_*\Omega_{X_{\mathrm{reg}}}.$$

This is a complex of reflexive sheaves on X and by Lemma 2 we have

$$H^2(X_{\mathrm{reg}},\Theta_{X_{\mathrm{reg}}})=H^2(X,j_*\Theta_{X_{\mathrm{reg}}})\hookrightarrow\mathrm{Ext}^2(\widetilde{\Omega}^1_X,\mathscr{O}_X),$$

hence the latter group is an obstruction group for deformations of X. By Grothendieck duality, $\mathrm{Ext}^2(\widetilde{\Omega}^1_X,\mathscr{O}_X)=\mathrm{Ext}^2(\widetilde{\Omega}^1_X,\omega_X)$ is dual to $H^{n-2}(\widetilde{\Omega}^1_X)$. Now the following result generalizes simultaneously results of Steenbrink[8] and Ref. 2, Proposition 4.

Proposition 6: Let X be a compact weak orbi-Kleinfold of dimension $n\geqslant 2$, $\pi_0:X_{orb}\to X$ an orbifold resolution $\pi_1:\widetilde{X}\to X_{orb}$ a resolution of singularities with $\widetilde{X}$ Kähler. Then

(i) $\widetilde{\Omega}^{\cdot}_X=\pi_{0*}\widetilde{\Omega}^{\cdot}_{X_{\mathrm{orb}}}=(\pi_0\circ\pi_1)_*\Omega^{\cdot}_{\widetilde{X}}$;

(ii) *$\widetilde{\Omega}^{\cdot}_X$ is a resolution of the constant sheaf $\mathbb{C}_X$;*

(iii) *the Hodge–De Rham spectral sequence*

$$E_1^{p,q}=H^q(X,\widetilde{\Omega}^p)\Rightarrow H^{p,q}(X,\mathbb{C})$$

degenerates at E_1 in degrees $\leqslant n-1$.

The argument that Proposition 6 implies Theorem 4, based on the ''T^2-injecting criterion'' (Theorem 1.1, (ii) of Ref. 5) is identical to the corresponding argument in Ref. 2. In the case of orbifolds, Proposition 6 is due to Steenbrink[8] (and consequently the reader only interested in orbifolds may stop reading here). Our proof of the Proposition combines ideas from Refs. 8 and 2.

Proof of Proposition 6: (i) The assertion is local, and at orbifold points has been proven by Steenbrink (Ref. 8), Lemma 1.11). For the nonorbifold points, consider

$$U=V/G\subset X,$$

$$\omega\in\Gamma(U,\widetilde{\Omega}^i_X)=\Gamma(U_{\mathrm{reg}},\Omega^i_{\mathrm{reg}}).$$

By Ref. 8, Lemma 1.8, ω lifts to $\tilde{\omega}\in\Gamma(V_{\text{reg}},\Omega^i_{V_{\text{reg}}})$. We may assume our desingularization of X is locally over U of the form $\tilde{V}/G$ where $\tilde{V}\to V$ is some desingularization (which will also blow up the nonfree locus of G, in addition to sing V). By Ref. 2, Proposition 4, (i), $\tilde{\omega}$ extends holomorphically to $\tilde{V}$ and being G-invariant descends to $\tilde{V}/G$, as required. (ii) This is a consequence of Ref. 8, Lemma 1.8, Ref. 2, Proposition 4, and exactness of the functor of G-invariants. (iii) We prove the vanishing of the differentials d_1^{ij}, $i+j<n$, the case of d_r^{ij}, $r\geqslant 2$, being similar. Denote by $\tilde{\Omega}^j_X\subset\tilde{\Omega}^j_X$ the subsheaf of closed forms and similarly for $\tilde{\Omega}^j_{X_{\text{orb}}},\tilde{\Omega}^j_{\tilde{X}}$. Consider the Leray spectral sequence

$$E_2^{p,q}=H^p(X,R^q\pi_{0*}\tilde{\Omega}^j_{X_{\text{orb}}})\Rightarrow H^i(X_{\text{orb}},\tilde{\Omega}^j_{X_{\text{orb}}})$$

and the anlogous one for $\tilde{\Omega}^j_{X_{\text{orb}}}$. Using that π_0 is an isomorphism off the finite nonorbifold locus of X, we get a diagram

$$H^0(R^{i-1}\pi_{0*}\tilde{\Omega}^j_{X_{\text{orb}}})\to H^0(R^{i-1}\pi_{0*}\tilde{\Omega}^{j+1}_{X_{\text{orb}}})\overset{\beta_{ij}}{\to}H^0(R^{i-1}\pi_{0*}\tilde{\Omega}^{j+1})$$

$$(*)H^i(\overset{\downarrow}{\tilde{\Omega}^j_X})\to H^i(\overset{\downarrow}{\hat{\Omega}^{j+1}_X})\to H^i(\overset{\downarrow}{\tilde{\Omega}^{j+1}_X})$$

$$H^i(\overset{\downarrow}{\tilde{\Omega}^j_{X_{\text{orb}}}})\overset{\alpha_{ij}}{\to}H^i(\overset{\downarrow}{\hat{\Omega}^{j+1}_{X_{\text{orb}}}})\to H^i(\overset{\downarrow}{\tilde{\Omega}^{j+1}_{X_{\text{orb}}}})L$$

in which the composite of the middle-row arrow coincides with d_1^{ij}. by Steenbrink,[8] we have

$$H^i(\tilde{\Omega}^{j+1}_{X_{\text{orb}}})=\mathbb{H}^i(F^{j+1}\tilde{\Omega}^{\cdot}_{X_{\text{orb}}})=F^{j+1}\mathbb{H}^{i+j+1}(\tilde{\Omega}^{\cdot}_{X_{\text{orb}}}),$$

where F denotes the Hodge (or stupid) filtration, and it follows easily that α_{ij} vanishes. To prove $d_1^{ij}=0$ for $i+j<n$, $j\neq i-2$, it will suffice, by $(*)$, to prove the vanishing of β_{ij} in this range. For this we use our goodness hypothesis. Let $\hat{X}_{\text{orb}}$ be the formal neighborhood of the exceptional locus of π_0 and similarly for $\hat{\tilde{X}}$. Then we have a diagram

$$H^{i-1}(\hat{X}_{\text{orb}},\hat{\Omega}^{j+1}_{X_{\text{orb}}})\overset{\hat{\beta}_{ij}}{\to}H^{i-1}(\hat{X}_{\text{orb}},\Omega^{j+1}_{\text{orB}})$$

$$(**)H^{i-1}(\hat{\tilde{X}},\hat{\Omega}^{j+1}_{\tilde{X}})\overset{\tilde{\beta}_{ij}}{\to}H^{i-1}(\hat{X},\Omega^{j+1}_{X}),$$

where $\hat{\beta}_{ij},\tilde{\beta}_{ij}$ are the obvious maps. By goodness, $\tilde{\beta}_{ij}$ vanishes whenever $i-1\neq j+1$, because the supposedly injective exterior-derivative map vanishes on its image. If we can prove the vertical maps π^* in $(**)$ are injective, it then follows that $\hat{\beta}_{ij}$, hence β_{ij}, vanishes. But the injectivity of π^* follows from Steenbrink's duality argument (Ref. 8, Proof of Theorem 1.12), applied on the formal scheme $\hat{X}_{\text{orb}}$.

Finally, it remains to prove the vanishing of $d_1^{i,i-2}$, $2\leqslant i\leqslant(n+1)/2$. This is done just as in Ref. 2, comparing $H^{\cdot}(X,\mathbb{C})$ with $H^{\cdot}(X_{\text{orb}},\mathbb{C})$ and using the fact that the component of the exceptional locus of π_0 are quotients of manifolds with only (p,p) cohomology, hence by Steenbrink's theory are themselves orbifolds with all their cohomology of type (p,p), hence contribute via Gysin only (p,p) classes to $H^{\cdot}(X_{\text{orb}})$. □

Remark: After this was written, the author became aware of Fujiki's paper,[11] which contains numerous results on symplectic orbifolds and their deformations, but not including unobstructedness, which Fujiki includes as an hypothesis in some statements. In particular, in his Theorem 4.8, p. 116, the hypothesis ''$\mathscr{S}$ is smooth'' holds automatically.

ACKNOWLEDGMENTS

We are grateful to Professor D. R. Morrison for suggesting the problem of unobstructedness of Calabi–Yau orbifolds.

Using the concept of irreducible tensor basis and the properties of irreducible tensor operator, we give all $O(N)\supset O(N-1)$ reduction factors for $(m_1m_2m_30\cdot 0)\otimes(100\cdot 0)$. © *1998 American Institute of Physics.* [S0022-2488(97)00712-3]

I. INTRODUCTION

Reduction factors are very useful in many physical problems. For example, in algebraic models of atomic[1,2] and nuclear[3–5] physics, in order to classify wave-functions and to gain the analytic formulae for the electric and magnetic transition rates, one needs to know the algebraic expressions for reduction factors (reduced Wigner coefficients).

$O(N)\supset O(N-1)$ reduction factors have been studied by many authors. For $N=3$, they are the well-known Clebsch–Gordon coefficients of $O(3)$.[6,7] $O(4)\supset O(3)$ reduction factors in the $O(4)\supset O(3)\supset O(2)$ basis were first obtained by Biedenharn.[8] For some special reduction factors of $O(N)\supset O(N-1)$, Gavrilik[9] considered the case of coupling $l_1\otimes l_2$ to (L_1L_2) with all three symmetric irreducible representations (i.e., with $L_2=0$). Later Ališauskas *et al.*[10–12] derived the algebraic expressions for the coupling $l_1\otimes l_2$ to (L_1L_2) by use of the substitution group technique of $SP_4(O_5)$ and Pan *et al.*[13] discussed the case of the coupling $(w_1w_2)\otimes(w_30)$ to $(w_1'w_1')$ with $w_1+w_2+w_3=w_1'+w_2'$ in terms of $\mathrm{SU}(N)\supset\mathrm{SU}(N-1)\supset O(N-1)$. However, these results are very complicated and since they only considered the less than two-rowed irreducible representations for $O(N)$ and $O(N-1)$, from these results, one can not obtain all $O(6)\supset O(5)$ reduction factors for $(m_{16}m_{26}m_{36})\otimes(1\,0\,0)$, with $m_{36}\neq 0$, which are very important in the $O(6)$ limit case in the interacting boson model (IBM).[3,4]

In the 1960's an effective method—irreducible tensor basis method, was put forward by Baird *et al.*[14] and Sun.[15] This method relies on the concept of an irreducible tensor basis, that is, the generators of group G are composed of the generators of its subgroup G' and the irreducible tensor operators of G'. So it can lead to the recurrent relations for the irreducible representations and for the reduction factors easily and naturally, which can reduce the amount of calculation largely. The method has been applied widely.[14–23] In this paper, we will use the irreducible tensor basis method to calculate the reduction factors of $O(N)\supset O(N-1)$ for the three-rowed irreducible representations of $O(N)$ and $O(N-1)$.

This paper is arranged as follows. In Section II, the basic results of $O(3)$ are reviewed. In Section III, the irreducible tensor basis of $O(4)$ is constructed. In Section IV, the irreducible representations of $O(4)$ are derived. In Section V, the reduction factors of $O(4)\supset O(3)$ are evaluated. In Section VI, further calculations are discussed and the reduction factors of $O(N)\supset O(N-1)$ for the three-rowed irreducible representations of $O(N)$ and $O(N-1)$ are obtained. A brief conclusion is given in the final section.

II. BASIC RESULTS OF $O(3)$

In fact, the irreducible tensor basis method is very parallel to the treatment of the quantum theory of angular momentum, where the groups of interest are $O(3)$ and $SU(2)$.[6,7] In the framework of the irreducible tensor basis method, some important concepts and tools in the theory of angular momentum such as irreducible tensor operator and the Wigner–Eckart theorem, which are very useful for evaluating the matrix elements of physical quantities and the Clebsch–Gordon coefficients of $O(3)$, will be extended and then be used to discuss the groups $O(N)$ $(N>3)$. To this end, we first have to construct the new basis for $O(N)$ $(N\geqslant 3)$—the irreducible tensor basis, from their old generators I_{pq}, then can apply the (generalized) Wigner–Eckart theorem to evaluating the irreducible representations of $O(N)$ and $O(N)\supset O(N-1)$ reduction factors. In order to see clearly how to construct the irreducible tensor basis for the orthogonal groups, and how to utilize the irreducible tensor basis method, let us begin with the simplest case—$O(3)$.

It is well known that the generators $I_{pq}(p>q)$ of $O(N)$ satisfy the commutation relations[24,16]

$$[I_{pq},I_{rs}]=\delta_{ps}I_{qr}+\delta_{qr}I_{ps}-\delta_{pr}I_{qs}-\delta_{qs}I_{pr},$$

$$p,q,r,s=1,2,...,N, \tag{1}$$

where $I_{pq}=E_{pq}-E_{qp}$ and E_{pq} is a $N\times N$ matrix with only one nonzero element 1 in the pth row and qth column position,

$$E_{pq}=\begin{bmatrix} 0 & \cdot & 0 & 0 & 0 & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & \cdot & 0 & 0 & 0 & \cdot & 0 \\ 0 & \cdot & 0 & 1 & 0 & \cdot & 0 \\ 0 & \cdot & 0 & 0 & 0 & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & \cdot & 0 & 0 & 0 & \cdot & 0 \end{bmatrix} \leftarrow p\text{th row}.$$

$$\uparrow$$

$$q\text{th column}$$

When $N=3$, Eq. (1) gives the commutation relations satisfied by the generators $\{I_{32},I_{31},I_{21}\}$ of $O(3)$.

First, it is convenient to replace the three linearly independent generators $\{I_{32},I_{31},I_{21}\}$ of $O(3)$ by their linear combinations. This can be done by defining[16]

$$L_0=iI_{21},\quad L_{\pm 1}=-\frac{1}{\sqrt{2}}(I_{31}\pm iI_{32}). \tag{2}$$

They satisfy

$$[L_0,L_{\pm 1}]=\pm L_{\pm 1},\quad [L_{+1},L_{-1}]=L_0. \tag{3}$$

The above equations are the usual definition of angular momentum operator **L** in the quantum mechanics,[6,7] and L_0 and $L_{\pm 1}$ are the three spherically harmonic components of **L**.

TABLE I. The Clebsch–Gordon coefficients of $O(3)\left[\begin{smallmatrix} l & 1 \\ m' & q \end{smallmatrix}\middle| \begin{smallmatrix} l' \\ m \end{smallmatrix}\right]$.

m'	$q \backslash l'$	$l+1$	l	$l-1$
$m-1$	1	$\sqrt{\frac{(l+m)(l+m+1)}{(2l+1)(2l+2)}}$	$-\sqrt{\frac{(l+m)(l-m+1)}{2l(2l+1)}}$	$-\sqrt{\frac{(l-m)(l-m+1)}{2l(l+1)}}$
m	0	$\sqrt{\frac{(l-m+1)(l+m+1)}{(l+1)(2l+1)}}$	$\frac{m}{\sqrt{l(l+1)}}$	$\sqrt{\frac{(l-m)(l+m)}{l(2l+1)}}$
$m+1$	-1	$\sqrt{\frac{(l-m)(l-m+1)}{(2l+1)(2l+2)}}$	$\sqrt{\frac{(l-m)(l+m+1)}{2l(l+1)}}$	$-\sqrt{\frac{(l+m)(l+m+1)}{2l(2l+1)}}$

Take the Gel'fand–Tsetlin basis $\left|\begin{smallmatrix} l \\ m \end{smallmatrix}\right]$ as the basis vectors carrying the irreducible representations of $O(3)$, where l labels the irreducible representations of $O(3)$ while m labels those of $O(2)$. (In the quantum theory of angular momentum, $|lm\rangle \equiv \left|\begin{smallmatrix} l \\ m \end{smallmatrix}\right]$ are the common eigenvectors of $\{\mathbf{L}^2, L_0\}$.) As the components of l for distinguishing the individual basis vectors, m must obey the constraint $-l \leqslant m \leqslant l$. Thus, by means of the standard treatment of quantum theory of angular momentum,[6,7] we have immediately the irreducible representations of $O(3)$,

$$\begin{aligned} &\left[\begin{matrix} l \\ m' \end{matrix}\middle| L_0 \middle| \begin{matrix} l \\ m \end{matrix}\right] = m\,\delta(m'm), \\ &\left[\begin{matrix} l \\ m' \end{matrix}\middle| L_{\pm 1} \middle| \begin{matrix} l \\ m \end{matrix}\right] = \mp \sqrt{\frac{1}{2}(l \mp m)(l \pm m + 1)}\,\delta(m' m \pm 1), \end{aligned} \tag{4}$$

and the Clebsch–Gordon coefficients of $O(3)$ (the case of $l \times 1$ considered in this paper are given in Table I).

Here, we have chosen the phase conventions for the Clebsch–Gordon coefficients (Table I) of $O(3)$,

$$\begin{aligned} &\left[\begin{matrix} l & 1 \\ l & 0 \end{matrix}\middle| \begin{matrix} l' \\ l \end{matrix}\right] > 0, \\ &\left[\begin{matrix} l & 1 \\ m & q \end{matrix}\middle| \begin{matrix} l' \\ m' \end{matrix}\right] = \left[\begin{matrix} 1 & l \\ q & m \end{matrix}\middle| \begin{matrix} l' \\ m' \end{matrix}\right]. \end{aligned} \tag{5}$$

Note that in later calculations of the reduction factors of $O(N)\supset O(N-1)(N>3)$, we will choose the phase conventions consistent with Eq. (5).

Finally, in order to construct the irreducible tensor basis of $O(4)$ in the next section, let us review the usual definition of an irreducible tensor operator of $O(3)$, employed by Racah[25] initially. The set $\mathbf{T}^{(3)}(l)$ is called the irreducible tensor operator of rank l of $O(3)$, if its linearly independent components $T^{(3)}\left(\begin{smallmatrix} l \\ m \end{smallmatrix}\right)$ satisfy

$$\begin{aligned} &\left[L_i,\ T^{(3)}\begin{pmatrix} l \\ m \end{pmatrix}\right] = \sum_{m'} T^{(3)}\begin{pmatrix} l \\ m' \end{pmatrix}\left[\begin{matrix} l \\ m' \end{matrix}\middle| L_i \middle| \begin{matrix} l \\ m \end{matrix}\right], \\ &i = 0, \pm 1; \quad m, m' = -l, -l+1, \ldots, l-1, l, \end{aligned} \tag{6}$$

where $[{}^{l}_{m'}|L_i|^{l}_{m}]$ are the irreducible representation matrices of $O(3)$. Equation (6) shows that under the operations of $O(3)$ the irreducible tensor operator $\mathbf{T}^{(3)}(l)$ transforms according to the irreducible representations l of $O(3)$. The number of components $T^{(3)}({}^{l}_{m})$ is equal to the dimension $2l+1$ of the irreducible representations l of $O(3)$.

The definition of the irreducible tensor operator of $O(3)$ has been generalized to $O(N)(N>3)$ (see Appendix A).

III. THE IRREDUCIBLE TENSOR BASIS OF $O(4)$

In order to apply the irreducible tensor basis method to $O(4)$, we first have to construct the irreducible tensor basis of $O(4)$ by combining its old generators $\{I_{43},I_{42},I_{41},I_{32},I_{31},I_{21}\}$. Observe that some of them, $\{I_{32},I_{31},I_{21}\}$, in fact are the generators of the subgroup $O(3)$ of $O(4)$, which have been combined to the angular momentum operators $\mathbf{L}$ [see Eq. (2)] of $O(3)$ in the last section. Then the remaining three generators, $\{I_{43},I_{42},I_{41}\}$, can be conveniently grouped to display their transformation properties under the subgroup $O(3)$. Defining

$$\begin{aligned} T^{(3)}\begin{pmatrix}1\\0\end{pmatrix}&\equiv iI_{43},\\ T^{(3)}\begin{pmatrix}1\\+1\end{pmatrix}&\equiv\sqrt{\frac{1}{2}}\,(I_{42}-iI_{41}),\\ T^{(3)}\begin{pmatrix}1\\-1\end{pmatrix}&\equiv\sqrt{\frac{1}{2}}\,(I_{42}+iI_{41}),\end{aligned} \tag{7}$$

it is checked easily that they satisfy Eq. (6). Hence, $T^{(3)}({}^{1}_{q})$ $(q=-1,0,1)$, as three components form an irreducible tensor operator $\mathbf{T}^{(3)}(1)$ of rank 1 of $O(3)$.

Hence, the generators of $O(4)$ are composed of the generators $\mathbf{L}$ of the subgroup $O(3)$ and the irreducible tensor operator $\mathbf{T}^{(3)}(1)$ of rank 1 of $O(3)$. Note that since we seek unitary representations, in Eq. (7), we have so defined the irreducible tensor operator $\mathbf{T}^{(3)}(1)$ that

$$T^{(3)\dagger}\begin{pmatrix}1\\q\end{pmatrix}=(-)^{q}T^{(3)}\begin{pmatrix}1\\-q\end{pmatrix}. \tag{8}$$

Then the commutation relations satisfied by the generators of $O(4)$ are the following.

(1) The commutation relations of $O(3)$ [Eq. (3)].
(2) The commutation relations between the generators $\mathbf{L}$ of $O(3)$ and the irreducible tensor operator $\mathbf{T}^{(3)}(1)$ of $O(3)$ [Eq. (6)].
(3) The commutation relations between the components of $\mathbf{T}^{(3)}(1)$. Using Eq. (1), we get immediately

$$\begin{aligned}\left[T^{(3)}\begin{pmatrix}1\\0\end{pmatrix},\quad T^{(3)}\begin{pmatrix}1\\\pm1\end{pmatrix}\right]&=\pm L_{\pm1},\\ \left[T^{(3)}\begin{pmatrix}1\\+1\end{pmatrix},\quad T^{(3)}\begin{pmatrix}1\\-1\end{pmatrix}\right]&=-L_0.\end{aligned} \tag{9}$$

We have also found from the commutation relations of $O(4)$ that, in the irreducible tensor basis of $O(4)$, Cartan's subalgebra of $O(4)$ is

$$H_1=L_0, \quad H_2=T^{(3)}\begin{pmatrix}1\\0\end{pmatrix}. \tag{10}$$

IV. THE IRREDUCIBLE REPRESENTATIONS OF $O(4)$

Take the Gel'fand–Tsetlin basis,[24]

$$\begin{vmatrix} v_1 & v_2 \\ l & \\ m & \end{vmatrix}, \tag{11}$$

as the basis vectors carrying the irreducible representations (v_1v_2) of $O(4)$. All the entries in the Gel'fand pattern (11) must obey the following betweenness relations:

$$v_1\geqslant l\geqslant|v_2|\geqslant 0, \quad l\geqslant|m|\geqslant 0. \tag{12}$$

Hence, evaluating the irreducible representations of $O(4)$ is to evaluate the matrix elements of all generators of $O(4)$ in the Gel'fand–Tsetlin basis (11). Fortunately, owing to the fact that the irreducible representations of the subgroup $O(3)$ in the Gel'fand–Tsetlin basis have been given in the last section, now we need only to evaluate the matrix elements of the remaining generators, the irreducible tensor operator $\mathbf{T}^{(3)}(1)$, of $O(4)$. Furthermore, by means of the Wigner–Eckart theorem,

$$\begin{bmatrix} v_1 & v_2 \\ l' & \\ m' & \end{bmatrix} T^{(3)}\begin{pmatrix}1\\q\end{pmatrix} \begin{bmatrix} v_1 & v_2 \\ l & \\ m & \end{bmatrix} = \begin{bmatrix} v_1 & v_2 \\ l' & \end{bmatrix} T^{(3)}(1) \begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix} \begin{bmatrix} l & 1 & l' \\ m & q & m' \end{bmatrix}, \tag{13}$$

we can simplify the problem of calculating the matrix representations of $\mathbf{T}^{(3)}(1)$ into that of evaluating the $T^{(3)}(1)$ reduced matrix elements,

$$\begin{bmatrix} v_1 & v_2 \\ l' & \end{bmatrix} T^{(3)}(1) \begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix}, \quad l'=l,\ l\pm 1. \tag{14}$$

We begin with calculating the matrix elements of Eq. (8): it follows that

$$\begin{bmatrix} v_1 & v_2 \\ l' & \\ m' & \end{bmatrix} T^{(3)\dagger}\begin{pmatrix}1\\q\end{pmatrix} \begin{bmatrix} v_1 & v_2 \\ l & \\ m & \end{bmatrix} = (-)^q \begin{bmatrix} v_1 & v_2 \\ l' & \\ m' & \end{bmatrix} T^{(3)}\begin{pmatrix}1\\-q\end{pmatrix} \begin{bmatrix} v_1 & v_2 \\ l & \\ m & \end{bmatrix}. \tag{15}$$

We square Eq. (15), apply the Wigner–Eckart theorem, and then run over l', l, m', m, and q using the orthogonality of the Clebsch–Gordon coefficients, to obtain the symmetry relation satisfied by the $T^{(3)}(1)$ reduced matrix elements,

$$\begin{bmatrix} v_1 & v_2 \\ l' & \end{bmatrix} T^{(3)}(1) \begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix} = \sqrt{\frac{2l+1}{2l'+1}} \begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix} T^{(3)}(1) \begin{bmatrix} v_1 & v_2 \\ l' & \end{bmatrix}. \tag{16}$$

Here, we have chosen the phase conventions for the $T^{(3)}(1)$ reduced matrix elements,

$$\begin{bmatrix} v_1 & v_2 \\ l' & \end{bmatrix}\left\| T^{(3)}(1) \right\|\begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix}\geqslant 0, \quad l'\neq l. \tag{17}$$

In later calculations of the reduced matrix elements of the irreducible tensor operators $\mathbf{T}^{(N)}\times(10\cdot 0)$ of rank $(10\cdot 0)$ of $O(N)$ $(N>3)$, we will choose the phase conventions consistent with Eq. (17).

Next calculate the matrix elements of a commutation relation,

$$\left[T^{(3)}\begin{pmatrix} 1 \\ +1 \end{pmatrix}, \quad T^{(3)}\begin{pmatrix} 1 \\ -1 \end{pmatrix}\right]=-L_0. \tag{18}$$

By virtue of the Wigner–Eckart theorem, together with the Clebsch–Gordon coefficients (Table I) of $O(3)$ and the symmetry relation Eq. (16), it is straightforward to obtain the following two equations satisfied by the $T^{(3)}(1)$ reduced matrix elements:

$$\begin{bmatrix} v_1 & v_2 \\ l-1 & \end{bmatrix}\left\| T^{(3)}(1) \right\|\begin{bmatrix} v_1 & v_2 \\ l-1 & \end{bmatrix}=\sqrt{\frac{l+1}{l-1}}\begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix}\left\| T^{(3)}(1) \right\|\begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix}, \tag{19}$$

and

$$\begin{aligned}\frac{2l-1}{2l+1}\begin{bmatrix} v_1 & v_2 \\ l-1 & \end{bmatrix}\left\| T^{(3)}(1) \right\|\begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix}^2 &= l-\frac{1}{l+1}\begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix}\left\| T^{(3)}(1) \right\|\begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix}^2 \\ &\quad +\frac{1}{l+1}\begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix}\left\| T^{(3)}(1) \right\|\begin{bmatrix} v_1 & v_2 \\ l+1 & \end{bmatrix}^2.\end{aligned} \tag{20}$$

We observe that Eq. (19) is a recurrent equation and Eq. (20) is an inhomogeneous recurrent equation.

Now evaluate the matrix elements of $T^{(3)}(\begin{smallmatrix}1\\0\end{smallmatrix})$ in the highest weight basis vector. It follows, using Eq. (10) and the highest weight theorem,[2,16] that

$$\begin{bmatrix} v_1 & v_2 \\ \hat{l} & \\ \hat{m} & \end{bmatrix}\left| T^{(3)}\begin{pmatrix} 1 \\ 0 \end{pmatrix} \right|\begin{bmatrix} v_1 & v_2 \\ \hat{l} & \\ \hat{m} & \end{bmatrix}=\begin{bmatrix} v_1 & v_2 \\ v_1 & \\ v_1 & \end{bmatrix}\left| T^{(3)}\begin{pmatrix} 1 \\ 0 \end{pmatrix} \right|\begin{bmatrix} v_1 & v_2 \\ v_1 & \\ v_1 & \end{bmatrix}=v_2, \tag{21}$$

where $\hat{l}$ stands for the highest weight representation (i.e., the allowed maximum of l) of $O(3)$ contained in (v_1v_2) of $O(4)$, so $\hat{l}=v_1$. $\hat{m}$ has the similar definition. Application of the Wigner–Eckart theorem and the Clebsch–Gordon coefficients (Table I) of $O(3)$ to the above equation gives rise to

$$\begin{bmatrix} v_1 & v_2 \\ \hat{l} & \end{bmatrix}\left\| T^{(3)}(1) \right\|\begin{bmatrix} v_1 & v_2 \\ \hat{l} & \end{bmatrix}=v_2\sqrt{\frac{v_1+1}{v_1}}. \tag{22}$$

Then inserting it into the recurrent equation (19) and utilizing Eq. (19) repeatedly we can obtain, in light of mathematical induction,

$$\begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix}\left\| T^{(3)}(1) \right\|\begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix}=\frac{(v_1+1)v_2}{\sqrt{l(l+1)}}. \tag{23}$$

Inserting the above equation into Eq. (20), and from the highest weight state, utilizing Eq. (20) repeatedly, we can obtain, by mathematical induction,

$$\begin{bmatrix} v_1 & v_2 \\ l-1 & \end{bmatrix} \left\| T^{(3)}(1) \right\| \begin{matrix} v_1 & v_2 \\ l & \end{matrix} = \sqrt{\frac{(v_1+l+1)(v_1-l+1)(v_2+l)(l-v_2)}{l(2l-1)}}. \tag{24}$$

By virtue of the symmetry relation (16), and replacing l by $l+1$, we then get

$$\begin{bmatrix} v_1 & v_2 \\ l+1 & \end{bmatrix} \left\| T^{(3)}(1) \right\| \begin{matrix} v_1 & v_2 \\ l & \end{matrix} = \sqrt{\frac{(v_1+l+2)(v_1-l)(v_2+l+1)(l-v_2+1)}{(l+1)(2l+3)}}. \tag{25}$$

Equation (23), Eq. (24), and Eq. (25) give all the reduced matrix elements of $\mathbf{T}^{(3)}(1)$. Thus we obtain the irreducible representations of $O(4)$.

V. $O(4)\supset O(3)$ REDUCTION FACTORS

In terms of the concept of coupling coefficients, the coupled Gel'fand–Tsetlin basis of $O(4)$ constructed from two Gel'fand–Tsetlin bases distinguished by a single prime and two primes may be written as

$$\begin{aligned} \begin{vmatrix} v_1 & v_2 \\ l & \\ m & \end{vmatrix} &= \Sigma \begin{vmatrix} v_1' & v_2' & v_1'' & v_2'' \\ l' & & l'' & \\ m' & & m'' & \end{vmatrix} \begin{bmatrix} v_1' & v_2' & v_1'' & v_2'' \\ l' & & l'' & \\ m' & & m'' & \end{bmatrix} \begin{vmatrix} v_1 & v_2 \\ l & \\ m & \end{vmatrix} \\ &= \Sigma \begin{vmatrix} v_1' & v_2' & v_1'' & v_2'' \\ l' & & l'' & \\ m' & & m'' & \end{vmatrix} \begin{bmatrix} v_1' & v_2' & v_1'' & v_2'' \\ l' & & l'' & \end{bmatrix} \begin{vmatrix} v_1 & v_2 \\ l & \end{vmatrix} \begin{bmatrix} l' & l'' \\ m' & m'' \end{vmatrix} \begin{matrix} l \\ m \end{matrix}. \end{aligned} \tag{26}$$

where

$$\begin{bmatrix} v_1' & v_2' & v_1'' & v_2'' \\ l' & & l'' & \\ m' & & m'' & \end{bmatrix} \begin{vmatrix} v_1 & v_2 \\ l & \\ m & \end{vmatrix}$$

are the coupling coefficients of $O(4)$. In order to gain the second equation, we have used Racah's factorization lemma,[25,2] which decompose the coupling coefficients of $O(4)$ into the product of the Clebsch–Gordon coefficients of the subgroup $O(3)$ and factor

$$\begin{bmatrix} v_1' & v_2' & v_1'' & v_2'' \\ l' & & l'' & \end{bmatrix} \begin{vmatrix} v_1 & v_2 \\ l & \end{vmatrix}.$$

This factor is referred to as the $O(4)\supset O(3)$ reduction factor, whose value depends only on the irreducible representations of $O(4)$ and $O(3)$.

Consider a coupled irreducible tensor of rank 1 of $O(3)$,

$$T^{(3)}\begin{pmatrix} 1 \\ 0 \end{pmatrix} = T^{(3)\prime}\begin{pmatrix} 1 \\ 0 \end{pmatrix} + T^{(3)\prime\prime}\begin{pmatrix} 1 \\ 0 \end{pmatrix}. \tag{27}$$

It is worthy of reminding the reader that all the three irreducible tensor operators in Eq. (27) are the generators of $O(4)$. Now calculate the matrix element of Eq. (27) in the coupled Gel'fand–Tsetlin basis (26) with $(v_1'' \; v_2'')=(1\;0)$, $l''\equiv\beta$ and $m''=0$, where $T^{(3)\prime}(\begin{smallmatrix}1\\0\end{smallmatrix})$ and $T^{(3)\prime\prime}(\begin{smallmatrix}1\\0\end{smallmatrix})$ act on the Gel'fand–Tsetlin basis of a single prime and two primes, respectively. It follows, in light of the Wigner–Eckart theorem, that we can obtain the following equation satisfied by $O(4)\supset O(3)$ reduction factors,

$$\sum_{\tilde{l}} C_1(\tilde{l})\begin{bmatrix} v_1' & v_2' & 1 & 0 \\ \tilde{l}' & & \beta & \end{bmatrix}\begin{bmatrix} v_1 & v_2 \\ \tilde{l} & \end{bmatrix}=\sum_{\tilde{l}} C_2(\tilde{l})\begin{bmatrix} v_1' & v_2' & 1 & 0 \\ \tilde{l} & & \beta & \end{bmatrix}\begin{bmatrix} v_1 & v_2 \\ \tilde{l} & \end{bmatrix}$$
$$+\sum_{\tilde{\beta}} C_3(\tilde{\beta})\begin{bmatrix} v_1' & v_2' & 1 & 0 \\ l' & & \tilde{\beta} & \end{bmatrix}\begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix}, \tag{28}$$

where the three known coefficients are

$$C_1(\tilde{l})=\begin{bmatrix} \tilde{l}' & \beta & \tilde{l} \\ m & 0 & m \end{bmatrix}\begin{bmatrix} l & 1 & \tilde{l} \\ m & 0 & m \end{bmatrix}\begin{bmatrix} v_1 & v_2 \\ \tilde{l} & \end{bmatrix}\Big\| T^{(3)}(1)\Big\|\begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix},$$
$$C_2(\tilde{l})=\begin{bmatrix} \tilde{l} & \beta & \tilde{l} \\ m & 0 & m \end{bmatrix}\begin{bmatrix} \tilde{l} & 1 & \tilde{l}' \\ m & 0 & m \end{bmatrix}\begin{bmatrix} v_1' & v_2' \\ l' & \end{bmatrix}\Big\| T^{(3)}(1)\Big\|\begin{bmatrix} v_1' & v_2' \\ \tilde{l} & \end{bmatrix}, \tag{29}$$
$$C_3(\tilde{\beta})=\begin{bmatrix} l' & \tilde{\beta} & l \\ m & 0 & m \end{bmatrix}\begin{bmatrix} \tilde{\beta} & 1 & \beta \\ 1 & 0 & 0 \end{bmatrix}\begin{bmatrix} 1 & 0 \\ \beta & \end{bmatrix}\Big\| T^{(3)}(1)\Big\|\begin{bmatrix} 1 & 0 \\ \tilde{\beta} & \end{bmatrix}.$$

Therefore, inserting the needed Clebsch–Gordon coefficients (Table I) of $O(3)$ and the irreducible representations [Eqs. (23)–(25)] of $O(4)$ obtained previously into Eq. (29), we can solve Eq. (28) to obtain, by mathematical induction, all $O(4)\supset O(3)$ reduction factors,

$$\begin{bmatrix} v_1' & v_2' & 1 & 0 \\ l' & & q & \end{bmatrix}\begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix}, \quad q=0,1. \tag{30}$$

Using the method of highest weight decomposition or Schur function method,[2,16] we can get the selection rules for $O(4)\supset O(3)$ reduction factors, Eq. (30), that is, for a fixed $(v_1\ v_2)$, $(v_1'v_2')$, in Eq. (30) is allowed to take $(v_1\pm 1 v_2)$ and $(v_1 v_2\pm 1)$ only, and similarly, for a fixed l, l' in Eq. (30) is allowed to take l only for $q=0$, and to take l, $l\pm 1$ only for $q=1$. In order to be consistent with Eq. (5) here, we have adopted the following phase conventions for $O(4)\supset O(3)$ reduction factors:

$$\begin{bmatrix} v_1' & v_2' & 1 & 0 \\ \hat{l} & & 0 & \end{bmatrix}\begin{bmatrix} v_1 & v_2 \\ \hat{l} & \end{bmatrix}>0,$$
$$\begin{bmatrix} v_1' & v_2' & 1 & 0 \\ l' & & q & \end{bmatrix}\begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix}=\begin{bmatrix} 1 & 0 & v_1' & v_2' \\ q & & l' & \end{bmatrix}\begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix}. \tag{31}$$

The algebraic expressions for all $O(4)\supset O(3)$ reduction factors for $(v_1 v_2)\otimes(10)$, as a special case of $N=4$, are given in Table III.

In fact, in the process of solving Eq. (28), we have reduced the amount of computation due to the following equation:

$$\begin{bmatrix} v_1' & v_2' & 1 & 0 \\ l' & & 1 & \end{bmatrix}\begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix}=\begin{bmatrix} v_1' & v_2' & 1 & 0 \\ l' & & 0 & \end{bmatrix}\begin{bmatrix} v_1 & v_2 \\ l' & \end{bmatrix}\begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix}\Big\| T^{(3)}(1)\Big\|\begin{bmatrix} v_1 & v_2 \\ l' & \end{bmatrix}$$
$$-\begin{bmatrix} v_1' & v_2' & 1 & 0 \\ l & & 0 & \end{bmatrix}\begin{bmatrix} v_1 & v_2 \\ l & \end{bmatrix}\begin{bmatrix} v_1' & v_2' \\ l & \end{bmatrix}\Big\| T^{(3)}(1)\Big\|\begin{bmatrix} v_1' & v_2' \\ l' & \end{bmatrix}, \tag{32}$$

which can be obtained easily by taking $\beta=0$ in Eq. (28). Equation (32) gives a relation between the reduction factors

$$\begin{bmatrix} v_1' & v_2' & 1 & 0 \\ l' & & 1 & \end{bmatrix} \begin{vmatrix} v_1 & v_2 \\ l & \end{vmatrix}$$

and the simpler ones

$$\begin{bmatrix} v_1' & v_2' & 1 & 0 \\ l & & 0 & \end{bmatrix} \begin{vmatrix} v_1 & v_2 \\ l & \end{vmatrix}.$$

Since

$$\begin{bmatrix} v_1' & v_2' \\ l & \end{bmatrix} \left\| T^{(3)}(1) \right\| \begin{bmatrix} v_1' & v_2' \\ l' & \end{bmatrix}$$

have been gained in the last section, we need merely to calculate the simpler reduction factors

$$\begin{bmatrix} v_1' & v_2' & 1 & 0 \\ l & & 0 & \end{bmatrix} \begin{vmatrix} v_1 & v_2 \\ l & \end{vmatrix}.$$

By means of Eq. (32), we can also obtain the symmetry relation satisfied by the $O(4)\supset O(3)$ reduction factors,

$$\begin{bmatrix} v_1 & v_2 & 1 & 0 \\ l & & q & \end{bmatrix} \begin{vmatrix} v_1' & v_2' \\ l' & \end{vmatrix} = (-1)^q \sqrt{\frac{d(v_1'v_2')d(l)}{d(v_1v_2)d(l')}} \begin{bmatrix} v_1' & v_2' & 1 & 0 \\ l' & & q & \end{bmatrix} \begin{vmatrix} v_1 & v_2 \\ l & \end{vmatrix}, \tag{33}$$

where $d(v_1v_2)$ and $d(l)$ stand for the dimensions of the irreducible representations (v_1v_2) of $O(4)$ and l of $O(3)$, respectively, namely,

$$\begin{aligned} d(v_1v_2)&=(v_1-v_2+1)(v_1+v_2+1), \\ d(l)&=2l+1. \end{aligned} \tag{34}$$

The symmetry relation, Eq. (33), can further reduce the amount of calculation required to construct tables of $O(4)\supset O(3)$ reduction factors greatly.

VI. FURTHER CALCULATIONS

From Section II to Section V, we have observed that the irreducible tensor basis method is a kind of recurrent method. That is, for the case in this paper, in terms of the Clebsch–Gordon coefficients of $O(3)$ for $l\otimes 1$, we first gain the irreducible representations (v_1v_2) of $O(4)$; then using the obtained irreducible representations of $O(4)$, we obtain all $O(4)\supset O(3)$ reduction factors for $(v_1v_2)\otimes(1\ 0)$. This method may go further to $O(5), O(6), \ldots$. We have calculated up to $O(6)$, and obtained the irreducible representations of $O(6)$ and the $O(6)\supset O(5)$ reduction factors, however, for economical pages, the procedure is no longer repeated here. Some important concepts and tools needed in the further evaluation of the irreducible representations and the reduction factors, such as the definition of an irreducible tensor operator, the generalized Wigner–Eckart theorem, and the explicit construction of the irreducible tensor bases of $O(5)$ and $O(6)$, are given in Appendices A, B, and C, respectively.

From the calculated results of $O(6)$, We have also found that there exists a very simple relation depending on rank N for both irreducible representations and reduction factors, therefore,

TABLE II. The Irreducible representations of $O(N)$.

n_1'	n_2'	n_3'	$\begin{bmatrix} m_1 & m_2 & m_3 & 0 & \cdot & 0 \\ n_1 & n_2 & n_3 & 0 & \cdot & \end{bmatrix} \Big\| T^{(N-1)} \Big\| \begin{bmatrix} m_1 & m_2 & m_3 & 0 & \cdot & 0 \\ n_1' & n_2' & n_3' & 0 & \cdot & \end{bmatrix}$
n_1+1	n_2	n_3	$\left\{\frac{(n_1-5+N)(m_1-n_1)(m_1+n_1-2+N)(n_1-m_2+1)(n_1+m_2-3+N)(n_1-m_3+2)(n_1+m_3-4+N)}{(2n_1-3+N)(n_1-n_2+1)(n_1+n_2-4+N)(n_1-n_3+2)(n_1+n_3-5+N)}\right\}^{1/2}$
n_1-1	n_2	n_3	$\left\{\frac{(n_1+2)(m_1-n_1+1)(m_1+n_1-3+N)(n_1-m_2)(n_1+m_2-4+N)(n_1-m_3+1)(n_1+m_3-5+N)}{(2n_1-3+N)(n_1-n_2+1)(n_1+n_2-4+N)(n_1-n_3+2)(n_1+n_3-5+N)}\right\}^{1/2}$
n_1	n_2+1	n_3	$\left\{\frac{(n_2-6+N)(m_1-n_2+1)(m_1+n_2-3+N)(m_2-n_2)(m_2+n_2-4+N)(n_2-m_3+1)(n_2+m_3-5+N)}{(2n_2-5+N)(n_1-n_2+1)(n_1+n_2-4+N)(n_2-n_3+1)(n_2+n_3-6+N)}\right\}^{1/2}$
n_1	n_2-1	n_3	$\left\{\frac{(n_2+1)(m_1-n_2+2)(m_1+n_2-4+N)(m_2-n_2+1)(m_2+n_2-5+N)(n_2-m_3)(n_2+m_3-6+N)}{(2n_2-5+N)(n_1-n_2+1)(n_1+n_2-4+N)(n_2-n_3+1)(n_2+n_3-6+N)}\right\}^{1/2}$
n_1	n_2	n_3+1	$\left\{\frac{(n_3-7+N)(m_1-n_3+2)(m_1+n_3-4+N)(m_2-n_3+1)(m_2+n_3-5+N)(m_3-n_3)(m_3+n_3-6+N)}{(2n_3-7+N)(n_1-n_3+2)(n_1+n_3-5+N)(n_2-n_3+1)(n_2+n_3-6+N)}\right\}^{1/2}$
n_1	n_2	n_3-1	$\left\{\frac{n_3(m_1-n_3+3)(m_1+n_3-5+N)(m_2-n_3+2)(m_2+n_3-6+N)(m_3-n_3+1)(m_3+n_3-7+N)}{(2n_3-7+N)(n_1-n_3+2)(n_1+n_3-5+N)(n_2-n_3+1)(n_2+n_3-6+N)}\right\}^{1/2}$

we can extend easily the irreducible representations of $O(6)$ for $(m_{16}m_{26}m_{36})$ and the reduction factors of $O(6)\supset O(5)$ for $(m_{16}m_{26}m_{36})\otimes(1\,0\,0)$ to the case of $O(N)$ but for the three-rowed irreducible representations. Thus we can gain by mathematical induction the irreducible representations of $O(N)$ for $(m_1m_2m_30\cdot0)$,

$$\begin{bmatrix} m_1 & m_2 & m_3 & 0 & \cdot & 0 \\ n_1 & n_2 & n_3 & 0 & \cdot & \end{bmatrix} \Big\| T^{(N-1)} \Big\| \begin{bmatrix} m_1 & m_2 & m_3 & 0 & \cdot & 0 \\ n_1' & n_2' & n_3' & 0 & \cdot & \end{bmatrix},$$

and all $O(N)\supset O(N-1)$ reduction factors for $(m_1m_2m_30\cdot0)\otimes(1\,0\cdot0)$,

$$\left[\begin{array}{cccccc|cccccc} m_1 & m_2 & m_3 & 0 & \cdot & 0 & 1 & m_1' & m_2' & m_3' & 0 & \cdot & 0 \\ n_1' & n_2' & n_3' & 0 & \cdot & & q & n_1 & n_2 & n_3 & 0 & \cdot & \end{array}\right], \quad q=0,1,$$

where $(m_1m_2m_30\cdot0)$ labels the three-rowed irreducible representations of $O(N)$ while $(n_1n_2n_30\cdot)$ labels the three-rowed irreducible representations of $O(N-1)$, and $(1)\equiv(1\,0\cdot0)$, $(q)\equiv(q0\cdot)$.

Of course, we can obtain directly the selection rules for the irreducible representations of $O(N)$ and $O(N)\supset O(N-1)$ reduction factors by use of the method of highest weight decomposition of Shur function method.[2,16] The selection rules for the irreducible representations of $O(N)$ are the following: for a fixed $(n_1n_2n_30\cdot0)$, $(n_1'n_2'n_3'0\cdot0)$ is allowed to take $(n_1\pm1n_2n_30\cdot0)$, $(n_1n_2\pm1n_30\cdot0)$ and $(n_1n_2n_3\pm10\cdot0)$. The selection rules for $O(N)\supset O(N-1)$ reduction factors are the following: for a fixed $(m_1m_2m_30\cdot0)$, $(m_1'm_2'm_3'0\cdot0)$ is allowed to take $(m_1\pm1m_2m_30\cdot0)$, $(m_1m_2\pm1m_30\cdot0)$ and $(m_1m_2m_3\pm10\cdot0)$, and for a fixed $(n_1n_2n_30\cdot0)$, $(n_1'n_2'n_3'0\cdot0)$ is allowed to take $(n_1n_2n_30\cdot0)$ for $q=0$, and to take $(n_1\pm1n_2n_30\cdot0)$, $(n_1n_2\pm1n_30\cdot0)$ and $(n_1n_2n_3\pm10\cdot0)$ for $q=1$.

Similarly, the irreducible representations of $O(N)$ for $(m_1m_2m_30\cdot0)$ and $O(N)\supset O(N-1)$ reduction factors for $(m_1m_2m_30\cdot0)\otimes(1\,0\cdot0)$ have similar phase conventions as the irreducible representations $(m_{16}m_{26}m_{36})$ of $O(6)$ and $O(6)\supset O(5)$ reduction factors for $(m_{16}m_{26}m_{36})\otimes(1\,0\,0)$, respectively. In fact, all of them are consistent with the phase conventions of $O(3)$.

TABLE III. The reduction factors of $O(N)\supset O(N-1)$.

(a) n_1'	n_2'	n_3'	q	$\begin{bmatrix} m_1 & m_2 & m_3 & 0 & \cdot & 0 & 1 \\ n_1' & n_2' & n_3' & 0 & \cdot & & q \end{bmatrix} \begin{vmatrix} m_1+1 & m_2 & m_3 & 0 & \cdot & 0 \\ n_1 & n_2 & n_3 & 0 & \cdot & \end{vmatrix}$

The algebraic expressions for the irreducible representations of $O(N)$ for $(m_1m_2m_30\cdot 0)$ are given in Table II, and the algebraic expressions for $O(N)\supset O(N-1)$ reduction factors for $(m_1m_2m_30\cdot 0)\otimes(1\,0\cdot 0)$ are given in Table III. The orthonormality conditions satisfied by reduction factors have been checked by virtue of software ''MATHEMATICA.''

VII. CONCLUSION

Using the irreducible tensor basis method, we obtain, by a recurrent approach, the algebraic expressions for the irreducible representations of $O(N)$ for $(m_1m_2m_30\cdot 0)$ and all reduction factors of $O(N)\supset O(N-1)$ for $(m_1m_2m_30\cdot 0)\otimes(1\,0\cdot 0)$. These results are elegant and practical. The irreducible spinor representations of $O(N)$ and corresponding reduction factors of $O(N)\supset O(N-1)$ will be given elsewhere.

Compared with other methods, the irreducible tensor basis method in this paper is simple and distinct. This method can not only be generalized to the more general cases of $O(N)$ but also be used to discuss the classical Lie algebras systematically. This is being studied.

APPENDIX A: THE IRREDUCIBLE TENSOR OPERATOR OF $O(N)$

We denote the generators of $O(N)$ by $X_k^{(N)}$ $(k=1,2,...,N(N-1)/2)$. The set $\mathbf{T}^{(N)}(\Gamma_N)$ is said to be an irreducible tensor operator of rank Γ_N of $O(N)$, if under the operations of $O(N)$ its linearly independent components $T^{(N)}\binom{\Gamma_N}{\gamma_N}$ transform according to the irreducible representations Γ_N of $O(N)$, that is,

$$\left[X_k^{(N)},\ T^{(N)}\begin{pmatrix}\Gamma_N\\ \gamma_N\end{pmatrix}\right]=\sum_{\gamma_N'} T^{(N)}\begin{pmatrix}\Gamma_N\\ \gamma_N'\end{pmatrix}\begin{bmatrix}\Gamma_N\\ \gamma_N'\end{bmatrix} X_k^{(N)}\Bigg|\begin{matrix}\Gamma_N\\ \gamma_N\end{matrix}\Bigg],$$

where

$$\begin{bmatrix}\Gamma_N\\ \gamma_N'\end{bmatrix} X_k^{(N)}\Bigg|\begin{matrix}\Gamma_N\\ \gamma_N\end{matrix}\Bigg]$$

is the representation matrix of $O(N)$ and γ_N stands for the components of Γ_N. It can also be shown that the number of components of $\mathbf{T}^{(N)}(\Gamma_N)$ is equal to the dimension $d\Gamma_N$ of the irreducible representation Γ_N of $O(N)$.[14,2,16]

APPENDIX B: THE GENERALIZED WIGNER–ECKART THEOREM

For the typical case in this paper, we have to evaluate the matrix elements of the irreducible tensor operator $\mathbf{T}^{(N-1)}(\widetilde{\Gamma}_{N-1})$ of rank $\widetilde{\Gamma}_{N-1}$ of $O(N-1)$ in the Gel'fand–Tsetlin basis of $O(N)$.[24] Application of the generalized Wigner–Eckart theorem to the matrix elements of $\mathbf{T}^{(N-1)}\times(\widetilde{\Gamma}_{N-1})$, whose components have been conveniently labeled by the Gel'fand pattern of $O(N-1)$, gives rise to

$$\left[\begin{array}{c|c|c} \Gamma_N & \widetilde{\Gamma}_{N-1} & \Gamma_N \\ \Gamma_{N-1} & \widetilde{\Gamma}_{N-2} & \Gamma'_{N-1} \\ \Gamma_{N-2} & \cdot & \Gamma'_{N-2} \\ \cdot & \widetilde{\Gamma}_2 & \cdot \\ \Gamma_2 & & \Gamma'_2 \end{array}\right] T^{(N-1)} = \left[\begin{array}{c|c|c} \Gamma_N & \widetilde{\Gamma}_{N-1} & \Gamma_{N-1} \\ \Gamma_{N-1} & \widetilde{\Gamma}_{N-2} & \Gamma_{N-2} \\ \cdot & \cdot & \cdot \\ \Gamma'_2 & \widetilde{\Gamma}_2 & \Gamma_2 \end{array}\right],$$

where Γ_N stands for the irreducible representations of $O(N)$, Γ_{N-1} stands for those of $O(N-1)$, and so forth. Here

$$\left[\begin{array}{c} \Gamma_N \\ \Gamma_{N-1} \end{array}\right\| T^{(N-1)}(\widetilde{\Gamma}_{N-1}) \left\|\begin{array}{c} \Gamma_N \\ \Gamma'_{N-1} \end{array}\right]$$

are the $T^{(N-1)}(\widetilde{\Gamma}_{N-1})$ reduced matrix elements and

$$\left[\begin{array}{c|c|c} \Gamma'_{N-1} & \widetilde{\Gamma}_{N-1} & \Gamma_{N-1} \\ \Gamma'_{N-2} & \widetilde{\Gamma}_{N-2} & \Gamma_{N-2} \\ \cdot & \cdot & \cdot \\ \Gamma'_2 & \widetilde{\Gamma}_2 & \Gamma_2 \end{array}\right]$$

are the coupling coefficients of $O(N-1)$. Using Racah's factorization lemma,[25,2] the coupling coefficients of $O(N-1)$ can be decomposed into a product of $N-3$ reduction factors of $O(i)\supset O(i-1)$ $(i=3,4,...,N-1)$.

APPENDIX C: THE IRREDUCIBLE TENSOR BASIS OF $O(5)$ AND $O(6)$

1. The irreducible tensor basis of $O(5)$

The irreducible tensor basis of $O(5)$ includes the following two parts: (1) The generators $X_p^{(4)}$ $(p=1,2,...,6)$ of $O(4)$; (2) a set of irreducible tensors of rank (1 0) of $O(4)$, $\mathbf{T}^{(4)}(1\,0)$, with components

$$T^{(4)}(\beta_{-1}) = -i\sqrt{\tfrac{1}{2}}\,(I_{52}+iI_{51}), \quad T^{(4)}(\beta_{+1}) = -i\sqrt{\tfrac{1}{2}}\,(I_{52}-iI_{51}),$$

$$T^{(4)}(\beta_3) = I_{53}, \quad T^{(4)}(\beta_4) = iI_{54},$$

where β_i $(i=-1,+1,3,4)$ are the Gel'fand patterns labeling the basis vectors carrying the basic representations (1 0) of $O(4)$,

$$\beta_{-1} = \begin{array}{ccc} 1 & & 0 \\ & 1 & \\ -1 & & \end{array}, \quad \beta_{+1} = \begin{array}{ccc} 1 & & 0 \\ & 1 & \\ & 1 & \end{array},$$

$$\beta_3 = \begin{array}{ccc} 1 & & 0 \\ & 1 & \\ 0 & & \end{array}, \quad \beta_4 = \begin{array}{ccc} 1 & & 0 \\ & 0 & \\ & 0 & \end{array}.$$

Thus, the commutation relations of the generators of $O(5)$ are the following.

(1) The commutation relations of the generators $X_p^{(4)}$ of $O(4)$.
(2) The commutation relations between $X_p^{(4)}$ and $\mathbf{T}^{(4)}(1\,0)$. According to the definition of irreducible tensor of $O(4)$ they are

$$[X_p^{(4)},\ T^{(4)}(\beta_i)]=\sum_j T^{(4)}(\beta_j)[\beta_j|X_p^{(4)}|\beta_i].$$

The basic representation matrix, $[\beta_j|X_p^{(4)}|\beta_i]$, of $O(4)$ have been obtained in Section IV.

(3) The commutation relations between the components of $\mathbf{T}^{(4)}(1\ 0)$. Using Eq. (1), we can obtain immediately

$$[T^{(4)}(\beta_{-1}),\ T^{(4)}(\beta_{+1})]=-L_0,\quad [T^{(4)}(\beta_{-1}),\ T^{(4)}(\beta_3)]=-L_{-1},$$
$$[T^{(4)}(\beta_{-1}),\ T^{(4)}(\beta_4)]=T^{(3)}_{-1};\quad [T^{(4)}(\beta_{+1}),\ T^{(4)}(\beta_3)]=L_{+1},$$
$$[T^{(4)}(\beta_{+1}),\ T^{(4)}(\beta_4)]=T^{(3)}_{+1};\quad [T^{(4)}(\beta_3),\ T^{(4)}(\beta_4)]=T^{(3)}_0.$$

2. The irreducible tensor basis of $O(6)$

The irreducible tensor basis of $O(6)$ includes the following two parts: (1) The generators $X_q^{(5)}$ $(q=1,2,...,10)$ of $O(5)$; (2) a set of irreducible tensors of rank $(1\ 0)$ of $O(5)$, $\mathbf{T}^{(5)}(1\ 0)$, with components

$$T^{(5)}(\gamma_{-1})=-\sqrt{\tfrac{1}{2}}\,(I_{62}+iI_{61}),\quad T^{(5)}(\gamma_{+1})=-\sqrt{\tfrac{1}{2}}\,(I_{62}-iI_{61}),$$

$$T^{(5)}(\gamma_3)=-iI_{63},\quad T^{(5)}(\gamma_4)=I_{64},\quad T^{(5)}(\gamma_5)=iI_{65},$$

where γ_i $(i=-1,+1,3,4,5)$ are the Gel'fand patterns labeling the basis vectors carrying the basic representation $(1\ 0)$ of $O(5)$, namely,

$$\gamma_{-1}=\begin{matrix}1&0\\1&0\\1&\\-1&\end{matrix},\quad \gamma_{+1}=\begin{matrix}1&0\\1&0\\1&\\1&\end{matrix},\quad \gamma_3=\begin{matrix}1&0\\1&0\\1&\\0&\end{matrix},$$

$$\gamma_4=\begin{matrix}1&0\\1&0\\0&\\0&\end{matrix},\quad \gamma_5=\begin{matrix}1&0\\0&0\\0&\\0&\end{matrix}.$$

Thus, the commutation relations of the generators of $O(6)$ are the following.

(1) The commutation relations of the generators $X_q^{(5)}$ of $O(5)$.

(2) The commutation relations between $X_q^{(5)}$ and $\mathbf{T}^{(5)}(1\ 0)$. According to the definition of the irreducible tensor of $O(5)$, they are

$$[X_q^{(5)},\ T^{(5)}(\gamma_i)]=\sum_j T^{(5)}(\gamma_j)[\gamma_j|X_q^{(5)}|\gamma_i].$$

(3) The commutation relations between the components of $\mathbf{T}^{(5)}(1\ 0)$. By direct calculation, we have

$$[T^{(5)}(\gamma_{-1}),\ T^{(5)}(\gamma_{+1})]=L_0,\quad [T^{(5)}(\gamma_{-1}),\ T^{(5)}(\gamma_3)]=-L_{-1},$$
$$[T^{(5)}(\gamma_{-1}),\ T^{(5)}(\gamma_4)]=-T^{(3)}_{-1},\quad [T^{(5)}(\gamma_{-1}),\ T^{(5)}(\gamma_5)]=T^{(4)}(\beta_{-1});$$
$$[T^{(5)}(\gamma_{+1}),\ T^{(5)}(\gamma_3)]=L_{+1},\quad [T^{(5)}(\gamma_{+1}),\ T^{(5)}(\gamma_4)]=-T^{(3)}_{+1},$$
$$[T^{(5)}(\gamma_{+1}),\ T^{(5)}(\gamma_5)]=T^{(4)}(\beta_{+1});\quad [T^{(5)}(\gamma_3),\ T^{(5)}(\gamma_4)]=-T^{(3)}_0$$
$$[T^{(5)}(\gamma_3),\ T^{(5)}(\gamma_5)]=T^{(4)}(\beta_3),\quad [T^{(5)}(\gamma_4),\ T^{(5)}(\gamma_5)]=T^{(4)}(\beta_4).$$

(Received 11 December 1996; accepted for publication 16 September 1997)

Two outer automorphisms of the space of infinite-dimensional representations of $sl(2)$ algebra are considered. The similar constructions for the loop algebras and Yangians are presented. The corresponding linear and quadratic R-brackets include the dynamical r-matrices. © *1998 American Institute of Physics.* [S0022-2488(98)00701-4]

I. INTRODUCTION

We are concerned with the representation theory of loop algebras and Yangians and with the method of separation of variables in framework of the inverse scattering method. Our aim is to apply the representation theory of $sl(2)$ and $sl(N)$ algebras into the r-matrix formalism.

Let us start with the following Levi-Civita theorem:[1] if the Hamilton–Jacobi equation associated with Hamiltonian,

$$H=g^{ij}(x_1,\ldots,x_n)p_ip_j+h^j(x_1,\ldots,x_n)p_j+U(x_1,\ldots,x_n),\quad \{p_i,x_j\}=\delta_{ij}, \tag{I.1}$$

can be integrated by separation of variables then the equation is integrated with $U=0$ (I.1), i.e., in the absence of a force, in the same system of coordinates.

This paper is devoted to the similar problem. Consider a classical Hamiltonian system completely integrable on a $2n$-dimensional symplectic manifold D. It means that the system possesses n independent integrals $I_1,\ldots,I_n$ in the involution,

$$\{I_i(x,p),I_j(x,p)\}=0,\quad i,j=1,\ldots,n,$$

where $\{x_j,p_j\}_{j=1}^n$ is some coordinate system in D.

Introduce the following mapping:

$$I_j\to I'_j=\sum_i^n a_{ij}(x,p)\cdot[I_i+v_i(x,p)], \tag{I.2}$$

here a_{ij} and v_j are certain functions on D. In contrast with the Calogero and Toda models[2] we shall consider special mappings (I.2), which preserve the phase space of initial integrable model.

Under the suitable conditions for functions a_{ij} and v_j, the mapping (I.2) could define a new integrable system on D with independent integrals $I'_1,\ldots,I'_n$ in the involution

$$\{I'_i(x,p),I'_j(x,p)\}=0,\quad i,j=1,\ldots,n,$$

and could preserve the property of separability in the same coordinate system.

Remember that systems discovered by Stäckel (see Ref. 2) have the similar properties. Their integrals are

$$I_j=\sum_{i=1}^{n} a_{ij}(x_1,\ldots,x_n)[p_i^2+v_i(x_i)], \tag{I.3}$$

with the special functions $a_{ij}(x_1,\ldots,x_n)$ and the arbitrary functions $v_i(x_i)$.

We try to make a first step to understand the algebraic roots of constraints on the functions a_{ij} and v_j, which guarantee the properties of integrability and separability for mapping (I.2) in the framework of the inverse scattering method.

II. OUTER AUTOMORPHISMS OF REPRESENTATIONS OF $SL(2)$

Let W be an infinite-dimensional representation of the Lie algebra $sl(2)$ in linear space V defined in the Cartan–Weyl basis $\{s_3,s_\pm\}\in \mathrm{End}(V)$ equipped with the natural bracket,

$$[s_3,s_\pm]=\pm s_\pm, \quad [s_+,s_-]=2s_3, \tag{II.4}$$

and the single Casimir operator,

$$\mathbf{\Delta}=s_3^2+\frac{1}{2}(s_+s_-+s_-s_+). \tag{II.5}$$

If operator s_+ is invertible in $\mathrm{End}(V)$ then the mapping

$$\begin{aligned} &s_3\to s_3'=s_3, \quad s_+\to s_+'=s_+,\\ &s_-\to s_-'=s_-+fs_+^{-1}, \quad f\in\mathbb{C}, \end{aligned} \tag{II.6}$$

is an outer automorphism of the space of infinite-dimensional representations of $sl(2)$ in V. The mapping (II.6) shifts the spectrum of $\mathbf{\Delta}$ on the parameter f,

$$\Delta\to\Delta'=\Delta+f. \tag{II.7}$$

Let us call the mapping (II.6) an additive automorphism.

Assuming in addition the value of Casimir operator $\mathbf{\Delta}$ is equal to zero $\Delta=0$ in W, then the mapping

$$\begin{aligned} &s_j\to s_j'=s_j\cdot(1-fs_+^{-1}), \quad j=\pm,3, \quad f\in\mathbb{C},\\ &\mathbf{\Delta}\to\mathbf{\Delta}'=\mathbf{\Delta}\cdot(1-fs_+^{-1})^2, \quad \Delta=\Delta'=0, \end{aligned} \tag{II.8}$$

is another outer automorphism of representation W. Let us call the mapping (II.8) a multiplicative automorphism.

These special infinite-dimensional representations W could be obtained by using the previous additive automorphism (II.6). Notice that the similar representations with $\Delta=0$ are well known in the quantum conformal field theory.[3]

We can suppose that additive (II.6) and multiplicative (II.8) automorphisms define the one-parametric realizations $W(f)$ of $sl(2)$.

For instance, the realization of $sl(2)$ with one free parameter f in the classical mechanics is given by

$$s_3=\frac{xp}{2}, \quad s_+=\frac{x^2}{2}, \quad s_-=-\frac{p^2}{2}+\frac{f}{x^2}, \quad \Delta'=f, \tag{II.9}$$

where (x,p) is a pair of canonical coordinate and momenta with the classical Poisson bracket $\{p,x\}=1$. Similar realization of generators s_j as the differential operators in quantum case is

$$s_3=x\partial_x-l, \quad s_+=x, \quad s_-=x\partial_x^2-2l\partial_x+\frac{f}{x}, \quad \Delta'=l(l+1)+f. \tag{II.10}$$

For the quantum Calogero system the more sophisticated representation of $sl(2)$ is equal to

$$s_3=\frac{1}{4}\sum_{k=1}^{N}(x_kD_k+D_kx_k), \quad s_+=2\sum_{k=1}^{N}x_k^2, \quad s_-=-2\sum_{k=1}^{N}D_k^2,$$

where x_k are coordinates and D_k are the corresponding Dunkl operators.[4]

Using the inner automorphisms of $sl(2)$ the one parametric mappings (II.6) and (II.8) can be generalized. Let W be an infinite-dimensional representation of $sl(2)$ in V defined by operators $s_j\in\mathrm{End}(V)$ with the standard bracket and the single quadratic Casimir operator $\mathbf{\Delta}$,

$$[s_i,s_j]=\varepsilon_{ijk}s_k, \quad \mathbf{\Delta}=s_1^2+s_2^2+s_3^2. \tag{II.11}$$

Introduce the general linear operator $b\in\mathrm{End}(V)$ as

$$b=\alpha_1s_1+\alpha_2s_2+\alpha_3s_3, \quad \alpha_j\in\mathbb{C}, \tag{II.12}$$

where α_j are three arbitrary parameters. If b is invertible operator, then the mapping

$$s_j\to s_j'=s_j+\alpha_jb^{-1} \tag{II.13}$$

is an outer automorphism of the space of infinite-dimensional representations of $sl(2)$ in V, if the parameters α_j lie on the cone

$$\alpha_1^2+\alpha_2^2+\alpha_3^2=0. \tag{II.14}$$

For this mapping the spectrum of the Casimir operator $\mathbf{\Delta}$ (II.11) is additively shifted on the parameter $f=\Sigma\alpha_j$,

$$\Delta\to\Delta'=\Delta+f=\Delta+\sum_{j=1}^{3}\alpha_j. \tag{II.15}$$

If the value of the Casimir operator $\mathbf{\Delta}$ is equal to zero $\Delta=0$ and the general linear operator $b\in\mathrm{End}(V)$ (II.12) is invertible, then the mapping,

$$s_j\to s_j'=s_j(1-b^{-1}), \quad \mathbf{\Delta}\to\mathbf{\Delta}'=\mathbf{\Delta}\cdot(1-b^{-1})^2, \tag{II.16}$$

is an outer multiplicative automorphism of representation W.

Automorphisms (II.13) and (II.16) define the general two- and three-parametric realizations $W(\alpha_j)$ of $sl(2)$.

For the $sl(N)$ algebra the similar additive automorphism shifted the highest central element of N-th order can be taken in the form

$$s_{ij}\to s_{ij}'=s_{ij}+\frac{A_{ij}^{(m-1)}}{B^{(m)}}, \quad s_{ij}\in\mathrm{End}(V), \quad m=N(N-1)/2. \tag{II.17}$$

In operators s_{ij} functions $B^{(m)}$ and $A_{ij}^{(m-1)}$ are certain polynomials of degrees m and $m-1$. Here we shall not go into details of this problem, one example related to $sl(3)$ will be presented in Section IV.

Motivated by realization (II.9) we present one application of automorphism (II.6) in the theory of integrable systems. Consider a classical Hamiltonian system completely integrable on the phase space $D=\mathbb{R}^{2n}$ with the natural Hamiltonian,

$$H=\sum_{j=1}^{n} p_j^2+V(x_1,\ldots,x_n).$$

Let the phase space be identified completely or partially with the m coadjoint orbits in $sl(2)^*$ as (II.9). Then the mapping,

$$H\to H'=H+\sum_{j=1}^{m}\frac{f_j}{x_j^2},\quad f_j\in\mathbb{R}, \tag{II.18}$$

preserves the properties of integrability and separability. The list of such systems can be found in Ref. 2.

Our main aim is to develop similar constructions for the loop algebras and Yangians. Some examples of the integrable systems related with this approach have been considered in Refs. 5–7.

III. DYNAMICAL *R*-MATRICES ASSOCIATED TO $\widetilde{SL(2)}$

All details of the general r-matrix scheme can be found in a review[8] and in references therein. We recall briefly necessary elements of r-matrix scheme for loop algebra $\mathfrak{g}=\widetilde{sl(2)}$ to assume the standard identification of the dual spaces.

The loop algebra $\mathfrak{g}=\widetilde{sl(2)}$ consists of Laurent polynomials $s_j(\lambda)=\Sigma_k s_j\lambda^k$, $j=1,2,3$ of a spectral parameter λ with coefficients in $\mathfrak{a}=sl(2)$ and commutator $[s_i\lambda^l,s_j\lambda^m]=\varepsilon_{ijk}s_k\lambda^{l+m}$. The standard R-bracket associated with loop algebra $\mathfrak{g}$ is defined by the following decomposition of $\mathfrak{g}$ into a linear sum of two subalgebras:

$$\mathfrak{g}=\mathfrak{g}_+\dot{+}\mathfrak{g}_-,\quad \mathfrak{g}_+=\oplus_{i\geqslant 0}\mathfrak{a}\lambda^i,\quad \mathfrak{g}_-=\oplus_{i<0}\mathfrak{a}\lambda^i,\quad R=P_+-P_-. \tag{III.1}$$

Here R is a standard r-matrix and $P_\pm$ means the projection operators onto $\mathfrak{g}_\pm$ parallel $\mathfrak{g}_\mp$.

The Lax equation may be presented in the form

$$\frac{dL(\lambda)}{dt}=-\mathrm{ad}^*_{\mathfrak{g}}M\cdot L,\quad M=\frac{1}{2}R(dP(L)), \tag{III.2}$$

where the Lax matrix $L(\lambda)$ belongs to $\mathfrak{g}^*$, P is an ad*-invariant polynomial on $\mathfrak{a}^*$. For an algebra $\widetilde{sl(2)}$ polynomial $P(L)$ is a function of the unique invariant polynomial $\Delta(\lambda)=\Sigma_{j=1}^{3}s_j^2(\lambda)$. Let $P(L)=\phi(\lambda)\Delta(\lambda)$, where ϕ is a function of λ. The integrals of motion I_k related to flow (III.2) are

$$I_k(L)=\mathrm{Res}_{\lambda=0}(\phi_k(\lambda)\Delta(\lambda)), \tag{III.3}$$

where $\phi_k(\lambda)$ are various functions of spectral parameter defining a complete set of integrals of motion.[8]

The Lax matrix $L(\lambda)$ (III.2) is defined on the whole infinite-dimensional phase space $\mathfrak{g}^*$. It is well known that the standard R-bracket associated with (III.1) has also a large collection of finite-dimensional Poisson (ad^*_R-invariant) subspaces,[8]

$$\mathscr{L}_{M,N}=\oplus_{j=-M}^{N}\mathfrak{a}^{*}\lambda^{j}, \quad \text{provided } M\geqslant 0;\ N\geqslant 1, \tag{III.4}$$

and, as a rule, the concrete physical systems are related to the restrictions of the flow (III.2) to certain low-dimensional Poisson submanifolds $\mathscr{L}_{M,N}$ (III.4).

The r-matrix scheme is extended easily to the twisted subalgebras of loop algebra $\mathfrak{g}$ and corresponding r-matrices have rational, trigonometric and elliptic dependence on the spectral parameter. We shall work with a tensor form of the Lax equations and R-bracket on $\widetilde{sl(2)}$, that allows us to consider all the r-matrices simultaneously. In addition, for brevity, we shall consider the $\widetilde{sl(2,\mathbb{R})}$ only.

The Lax matrix $L(\lambda)$ (III.2) associated to the Hamiltonian (III.3) is given by

$$L(\lambda)=\sum_{k=1}^{3} s_k(\lambda)\sigma_k, \quad \Delta(\lambda)=\frac{1}{2}\,\mathrm{tr}L^{2}(\lambda)=-\det L(\lambda), \tag{III.5}$$

where σ_j are Pauli matrices. The R-bracket related to decomposition (III.1) take the following form:

$$\{\overset{1}{L}(\lambda),\overset{2}{L}(\mu)\}=[r_{12}(\lambda,\mu),\overset{1}{L}(\lambda)]-[r_{21}(\lambda,\mu),\overset{2}{L}(\mu)], \tag{III.6}$$

where the standard notations are introduced:

$$\begin{gathered}\overset{1}{L}(\lambda)=L(\lambda)\otimes I, \quad \overset{2}{L}(\mu)=I\otimes L(\mu),\\ r_{12}(\lambda,\mu)=\sum_{k=1}^{3} w_k(\lambda,\mu)\cdot\sigma_k\otimes\sigma_k, \quad r_{21}(\lambda,\mu)=\Pi r_{12}(\mu,\lambda)\Pi.\end{gathered} \tag{III.7}$$

Here Π is the permutation operator of auxiliary spaces and $w_k(\lambda,\mu)$ are certain functions of spectral parameters only. Their explicit dependence on λ,μ is not important for the moment.

Returning now to the additive automorphism of representations of $sl(2)$ (II.13) we introduce the related mappings on the loop algebras $\mathfrak{g}=\widetilde{sl(2,\mathbb{R}}$ or $\mathfrak{g}=\oplus^{n}\widetilde{sl(2,\mathbb{R}}$.

The entries of the Lax matrix are Laurent polynomials with coefficients in $sl(2)$. Let us consider the mapping transforming these coefficients. If parameters a_j lie on the cone (II.14), then the first mapping similar to the automorphism (II.13),

$$s_j(\lambda)=\sum_k s_j\lambda^{k}\to s_j'(\lambda)=\sum_k [s_j+\alpha_j b^{-1}]\lambda^{k}, \quad b=\sum_{j=1}^{3}\alpha_j s_j, \tag{III.8}$$

is a canonical change of variables on $sl(2)$. This mapping is defined for the infinite-dimensional representations of $sl(2)$ and mapping (III.8) is a Poisson map with respect to the first natural Lie–Poisson bracket and to the second linear Lie–Poisson bracket associated with the standard R-matrix (III.1) on $\widetilde{sl(2)}$. For the certain Lax representation $L(\lambda)$ mapping (III.8) transforms the integrals of motion I_k similar to (II.18).

Let us introduce the general linear operator $b(\lambda)\in\widetilde{sl(2)}$,

$$b(\lambda)=\sum_{j=1}^{3}\alpha_j(\lambda)s_j(\lambda), \tag{III.9}$$

where $\alpha_j(\lambda)$ are functions of spectral parameter and of central elements on $\widetilde{sl(2)}$. If functions $\alpha_j(\lambda)$ lie on the cone,

$$\alpha_1^2(\lambda)+\alpha_2^2(\lambda)+\alpha_3^2(\lambda)=0, \tag{III.10}$$

then the second mapping similar to the automorphism (II.13),

$$s_j(\lambda)\to s_j'(\lambda)=s_j(\lambda)+\alpha_j(\lambda)b^{-1}(\lambda), \tag{III.11}$$

is a Poisson map with respect to the first natural Lie–Poisson bracket. For the mapping (III.11) the Lax matrix (III.5), the invariant polynomial $\Delta(\lambda)$ and integrals of motion I_k (III.3) are additively shifted,

$$L(\lambda)\to L'(\lambda)=L(\lambda)+\sum_{k=1}^{3}\alpha_k\sigma_k\cdot b^{-1}(\lambda), \tag{III.12}$$

$$\Delta(\lambda)\to\Delta'(\lambda)=\Delta(\lambda)+V(\lambda)=\Delta(\lambda)+\sum_{k=1}^{3}\alpha_k(\lambda), \tag{III.13}$$

$$I_k\to I_k'=I_k+U_k,\quad U_k=\mathrm{Res}_{\lambda=0}(\phi_k(\lambda)V(\lambda))\in\mathbb{C}. \tag{III.14}$$

Restriction (III.10) guarantees that initial integrals of motion I_k (III.3) transform by some constants $U_k\in\mathbb{C}$ (I.2). Hence, two Lax matrices $L(\lambda)$ and $L'(\lambda)$ [the original and the image of mapping (III.11)] correspond to the same integrable system.

The entries of the initial matrix $L(\lambda)$ belong to $\mathfrak{g}^*$. The entries of the matrix $L'(\lambda)$ are the Laurent polynomials of spectral parameter λ with coefficients from the universal enveloping algebra of $\mathfrak{a}^*$. So, to begin with the element of the loop algebra we construct special element of the universal enveloping algebra $U(\mathfrak{g}^*)$ defined by the following algebra homomorphism:

$$U(\mathfrak{g}^*)\to\mathbb{C}[\lambda,\lambda^{-1}]\otimes U(\mathfrak{a}^*).$$

Nevertheless, the second Poisson bracket $\{L'(\lambda),L'(\mu)\}$ can be directly calculated, because of all the necessary Poisson brackets between $s_j(\lambda)$ and $b(\lambda)$ are preassigned by (III.6).

Further we consider a special class of the linear dynamical R-bracket related to $\widetilde{sl(2)}$ and defined by the following second restriction on coefficients $\alpha_j(\lambda)$:

$$\{b(\lambda),b(\mu)\}=g(\lambda,\mu)b(\lambda)-g(\mu,\lambda)b(\mu),\quad \lambda,\mu\in\mathbb{C}, \tag{III.15}$$

or, that is equivalent,

$$w_j(\lambda,\mu)\alpha_j(\mu)\alpha_i(\lambda)-w_i(\lambda,\mu)\alpha_i(\mu)\alpha_j(\lambda)=g(\lambda,\mu)\cdot\alpha_k(\lambda), \tag{III.16}$$

where (j,i,k) are cyclic permutations of indices (1,2,3) and the scale function $g(\lambda,\mu)$ depends on the spectral parameters only. This restriction is closely related with the separation of variables method. It guarantees that all zeroes of $b(\lambda)$ are mutually commuting. Below we assume that both conditions (III.10) and (III.15) are always fulfilled for the mapping (III.11).

In this case we get the Lax matrix $L'(\lambda)$; (III.12) obeys the linear R-bracket (III.6), where constant r_{ij}-matrices substituted by r'_{ij}-matrices depending on dynamical variables,

$$r_{12}(\lambda,\mu)\to r'_{12}=r_{12}+\sum_{i,j=1}^{3}\alpha_{ij}(\lambda,\mu)\sigma_i\otimes\sigma_j, \tag{III.17}$$

with coefficients α_{ij} being

$$\alpha_{ij}(\lambda,\mu)=g(\lambda,\mu)\,\frac{\alpha_j(\mu)\alpha_i(\mu)w_i(\lambda,\mu)}{b^2(\mu)}-g(\mu,\lambda)\,\frac{\alpha_i(\lambda)\alpha_j(\lambda)w_j(\lambda,\mu)}{b^2(\lambda)}. \qquad \text{(III.18)}$$

For the proof see Ref. 9.

Dynamical matrices $r'_{jk}(\lambda,\mu)$ (III.17) obey the classical dynamical Yang–Baxter equation,

$$[r'_{12}(\lambda,\mu),r'_{13}(\lambda,\nu)]+[r'_{12}(\lambda,\mu),r'_{23}(\mu,\nu)]+[r'_{32}(\nu,\mu),r'_{13}(\lambda,\nu)]+[L'_2(\mu),r'_{13}(\lambda,\nu)]$$
$$-[L'_3(\nu),r'_{12}(\lambda,\mu)]+[X_{123}(\lambda,\mu,\nu),L'_2(\mu)-L'_3(\nu)]=0, \qquad \text{(III.19)}$$

where an explicit expression of the tensor $X(\lambda,\mu,\nu)$ is not important for the moment (see Refs. 5, 9, and 10). This equation is the image of a standard 2-cocycle in the universal enveloping algebra of the loop algebra, which consists of Laurent polynomials of spectral parameter λ with coefficients from the corresponding universal enveloping algebra of the Lie algebra.

We can suppose that mapping (III.11) defines a family of Lax matrices $L'(\lambda)$ and dynamical r-matrices (III.17) with a fixed set of parameters $\alpha_j(\lambda)$ for certain integrable system. Thus, the Lax matrix $L(\lambda)$ (III.2), the constant r-matrices (III.7) and the standard classical Yang–Baxter equation on $\widetilde{sl(2)}$ are the limits of the dynamical ones at $\alpha_j(\lambda)=0$.

The mapping (III.11) allows us to construct an infinite set of the Lax matrices associated to the loop algebra $\widetilde{sl(2)}$, which correspond to different integrable systems. According to Ref. 9 we introduce an infinite set of mappings,

$$s_j(\lambda)\to s'_j(\lambda)=s_j(\lambda)+[\alpha_j(\lambda)b^{-1}(\lambda)]_{M_jN_j}, \qquad \text{(III.20)}$$

where $[z]_{MN}$ means the restriction of z onto the certain Poisson subspace $\mathscr{S}_{MN}$ (III.4) of the standard R-bracket (III.1).

As an example, we can use the linear combinations of the following Laurent and Fourier projections:

$$[z]_{MN}=\left[\sum_{k=-\infty}^{+\infty} z_k\lambda^k\right]_{MN}\equiv\sum_{k=-M}^{N} z_k\lambda^k,$$
$$[z]_{MN}=\left[\sum_{k=-\infty}^{+\infty} z_k\exp(k\cdot\lambda)\right]_{MN}\equiv\sum_{k=-M}^{N} z_k\exp(k\cdot\lambda), \qquad \text{(III.21)}$$

if the corresponding r-matrices have rational or trigonometric dependence on a spectral parameter.[9]

Generally speaking, we can not describe now all the possible restrictions of the mapping (III.11) to certain low-dimensional submanifolds, which allow us to define the second Poisson bracket on $\widetilde{sl(2)}$. However, for a fairly large class of properly defined projections (III.21) the mappings (III.20) are the Poisson maps with respect to the second R-bracket and the corresponding dynamical r-matrices obey the dynamical Yang–Baxter equation (III.19).

For instance, an application of projections (III.21) yields dynamical r-matrices,

$$r_{12}(\lambda,\mu)\to r'_{12}=r_{12}+\sum_{i,j=1}^{3}\alpha_{ij}(\lambda,\mu)\sigma_i\otimes\sigma_j, \qquad \text{(III.22)}$$

with the following coefficients:

$$\alpha_{ij}(\lambda,\mu)=g(\lambda,\mu)w_i(\lambda,\mu)\left[\frac{\alpha_j(\mu)\alpha_i(\mu)}{b^2(\mu)}\right]_{MN}-g(\mu,\lambda)w_j(\lambda,\mu)\left[\frac{\alpha_i(\lambda)\alpha_j(\lambda)}{b^2(\lambda)}\right]_{MN}. \tag{III.23}$$

The essential feature of the restricting mappings (III.20) is, in comparison with the mapping (III.11), that the invariant polynomial $\Delta(\lambda)$ and all integrals of motion I_k are shifted now on the items depending on dynamical variables,

$$\begin{aligned}\Delta(\lambda)&\to\Delta_{MN}(\lambda)=\Delta(\lambda)+V_{MN}(s_j,\alpha_j,\lambda),\\ I_k&\to I_k'=I_k+\mathrm{Res}_{\lambda=0}(\phi_k(\lambda)V_{MN}(s_j,\alpha_j,\lambda)),\end{aligned} \tag{III.24}$$

with V_{MN} being

$$V_{MN}(s_j,\alpha_j,\lambda)=\sum_{k=1}^{3}(2s_k(\lambda)+[a_j(\lambda)b^{-1}(\lambda)]_{MN})[a_j(\lambda)b^{-1}(\lambda)]_{MN}. \tag{III.25}$$

Hence, images of integrals of motion I_k' of the mapping (III.20) are functionally different from the original ones I_k.

The second feature of the mapping (III.20) is that it can be also applied to the finite-dimensional representations of $sl(2)$. Consider the multipole Lax matrices related to the rational r-matrix.[8] Let $\mathfrak{g}=\oplus^n\widetilde{sl(2,\mathbb{R}}$ and elements of mapping (III.11) are

$$\alpha_1=1,\quad \alpha_2=i,\quad \alpha_3=0,\quad b(\lambda)=\sum_{k=1}^{n}\frac{s_+^{(k)}}{\lambda-e_k},\quad e_j\neq e_k\in\mathbb{R}. \tag{III.26}$$

The Taylor projection of $b^{-1}(\lambda)$ is determined by the following recurrence relations:[5]

$$[b^{-1}(\lambda)]_{MN}|_{M=0}=\sum_{k=0}^{N}\mathscr{T}_k\lambda_{N-k},\quad \mathscr{T}_k=\sum_{i=1}^{n}\left(s_+^{(i)}\sum_{j=0}^{k-1}\mathscr{T}_{k-1-j}e_i^j\right),\quad \mathscr{T}_0=1. \tag{III.27}$$

The Taylor projection (III.27) is the well-defined polynomial of the nilpotent operators $s_+^{(k)}$ without the negative powers, which can also be used for finite-dimensional representations of $sl(2)$.

Once again, the mappings (III.20) are not just isomorphisms of the Lax matrices $L(\lambda)$ and $L'(\lambda)$, in contrast with mapping (III.11), but they also preserve the second Poisson R-bracket together with all the commuting integrals of motion I_k', i.e., preserve the properties of integrability and separability.

Thus, the mappings (III.20) play the role of a dressing procedure allowing one to construct the Lax matrices $L'_{MN}(\lambda)$ for an infinite set of new integrable systems starting from the single known Lax matrix $L(\lambda)$ associated to one integrable model. Many well-known integrable mechanical systems, such as Henon–Heiles, Garnier, Neumann (and many others) can be embedded into the proposed scheme.[5,6,9,10]

Now we shall briefly discuss the second multiplicative automorphism (II.16). Let us start with some Lax matrix $L(\lambda)\in\widetilde{sl(2)}^*$. This matrix relates to the integrable system with the Lax representation (III.2) and with the following integrals of motion (III.3):

$$I_k=\mathrm{Res}_{\lambda=0}(\phi_k(\lambda)\Delta(\lambda)).$$

Recall that the multiplicative automorphism (II.16) of $sl(2)$ transforms the Casimir operator by the rule

$$\mathbf{\Delta}\to\mathbf{\Delta}'=\mathbf{\Delta}\cdot\varphi(b)=\mathbf{\Delta}\cdot(1-b^{-1})^2.$$

Motivated by this transformation we consider the new set of integrals I'_k [see (I.2)] defined by

$$I'_k = \mathrm{Res}_{\lambda=0}(\varphi_k(b,\lambda)\cdot\Delta(\lambda)), \tag{III.28}$$

where $\varphi_k(b,\lambda)$ are certain functions of $b(\lambda)$ (III.9) and of the spectral parameter λ. The involution conditions,

$$\{I'_i, I'_j\}=0, \quad i,j=1,\ldots,n,$$

yield the set of equations in $\varphi_k(b,\lambda)$,

$$\mathrm{Res}_{\lambda\mu=0}\{\Delta(\lambda),b(\mu)\}\varphi_j(\lambda)\varphi_k(\mu)\left(\frac{\partial \ln \varphi_j}{\partial b}(\lambda)\Delta(\lambda)-\frac{\partial \ln \varphi_k}{\partial b}(\mu)\Delta(\mu)\right)=0.$$

New integrals of motion I'_j could be functionally different from the original ones I_j.

In the quantum case the Poisson brackets should be replaced by the standard commutator relations on $sl(2)$ and the non-dynamical linear R-matrix bracket (III.6) becomes the following commutator relations:

$$[\overset{1}{L}(\lambda),\overset{2}{L}(\mu)]=[\mathfrak{r}_{12}(\lambda,\mu),\overset{1}{L}(\lambda)]-[\mathfrak{r}_{21}(\lambda,\mu),\overset{2}{L}(\mu)], \quad \mathfrak{r}(\lambda,\mu)=-i\hbar r(\lambda,\mu). \tag{III.29}$$

The theory of the general quantum linear or quadratic R-bracket with dynamical r-matrices is not well developed yet, but a nice feature of the presented special Poisson mappings (III.11) and (III.20) is that it admits a natural quantization. All the necessary commutator relations between operators $s_j(\lambda)$ and the linear invertible operator $b(\lambda)$ (III.9) are preassigned by (III.29) and, therefore, the introduction of the quantum dynamical r-matrices (III.17) is a straightforward calculation in this particular case. A similar calculation yields the direct quantum counterpart of the dynamical Yang–Baxter equation.

IV. DYNAMICAL *R*-MATRICES AND SEPARATION OF VARIABLES

The presented algebraic constructions are intimately connected with the method of separation of variables in classical mechanics. We shall use the technique developed by Sklyanin in the framework of an r-matrix formalism and based on the application of the Baker–Akhiezer function.[11] Recall, that the Baker–Akhiezer function $\Psi(\lambda)$ is the eigenvector of the Lax matrix,

$$L(\lambda)\Psi(\lambda)=z(\lambda)\Psi(\lambda),$$

corresponding to the eigenvalue $z(\lambda)$, which has certain analyticity properties. Since an eigenvector is defined up to a scalar factor, to exclude the ambiguity in the definition of $\Psi(\lambda)$ one has to fix a normalization of $\Psi(\lambda)$ imposing a linear constraint,

$$\sum_{j=1}^{N}\beta_j(\lambda)\Psi_j(\lambda)=1.$$

The main purpose of this Section is to find a correspondence between the outer automorphisms of infinite-dimensional representations of $sl(2)$ and the normalization of the Baker–Akhiezer function.

According to the Sklyanin recipe the variables of separation (x_j,p_j) are defined by the poles of the properly normalized Baker–Akhiezer function $\Psi(\lambda)$ and the corresponding eigenvalues $z(\lambda)$ of the Lax matrix.[11] For the Lax matrix $L(\lambda)\in\widetilde{sl(2)}^*$ the poles x_j of $\Psi(\lambda)$ are zeroes of the following function:

$$B(\lambda,\beta_1,\beta_2)=\beta_1^2(\lambda)s_+(\lambda)-\beta_2^2(\lambda)s_-(\lambda)-2\beta_1(\lambda)\beta_2(\lambda)s_3(\lambda). \tag{IV.1}$$

Introduce functions $\alpha_j(\lambda)$ as

$$\alpha_1(\lambda)=[(\beta_1^2-\beta_2^2)f](\lambda),\quad \alpha_2(\lambda)=i[(\beta_1^2+\beta_2^2)f](\lambda),\quad \alpha_3=-2[\beta_1\beta_2 f](\lambda), \tag{IV.2}$$

where $f(\lambda)$ is a certain common function of a spectral parameter only. The coefficients $\alpha_j(\lambda)$ lie on the cone (III.10) and define the linear operator $b(\lambda,\alpha_j)=B(\lambda,\beta_1,\beta_2)$ (III.9) for the mappings (III.11) and (III.20). The second restriction (III.15) on $\alpha_j(\lambda)$ guarantees that all zeroes x_j of $b(\lambda)$ are mutually commuting $\{x_j,x_k\}=0$.

For the linear R-bracket the eigenvalues $z(\lambda)$ of the Lax matrix $L(\lambda)$ corresponding to zeroes x_j are canonically conjugated momenta p_j. The pairs of variables (x_j,p_j) lie on the spectral curve,

$$W(p_j,x_j)=0,\quad W(z,\lambda)=\det(z-L(\lambda))=z^2-\Delta(\lambda), \tag{IV.3}$$

which fits exactly to separated equations.[11] The mappings (III.20) change the separated equations (IV.3) as

$$p_j^2-\Delta(x_j,I_k)=0\to p_j^2-\Delta'(x_j,I_k')=0, \tag{IV.4}$$

where $\Delta'(\lambda)$ and new integrals of motion I_k' are given by (III.24). Thus, by taking the single Lax matrix $L(\lambda)$ associated to some integrable system, which can be integrated by separation of variables in coordinates $\{x_j,p_j\}$, we get an infinite set of completely integrable systems determined by the mappings (III.20), which are separable in the same variables $\{x_j,p_j\}$.

The linear operator $b(\lambda)$ (III.9) is a symmetric function of its zeroes $\{x_j\}_{j=1}^n$ and dynamical r-matrices (III.17) depends of the spectral parameters and only half of the dynamical variables $\{x_j\}_{j=1}^n$. Moreover, if normalization $\beta(\lambda)$ of $\Psi(\lambda)$ is given by an arbitrary constant numeric vector, then three functions $\alpha_j(\lambda)$ (IV.2) differ by certain numeric constants β_j,

$$\alpha_j(\lambda)=\beta_j f(\lambda),\quad \beta_j\in\mathbb{C},\quad \sum \beta_j^2=0. \tag{IV.5}$$

Then by (IV.5) the invariant polynomial $\Delta(\lambda)$ and all the integrals of motion I_k (III.3) are shifted on items said to be potentials depending on separated coordinates x_j (I.2):

$$\begin{aligned}\Delta'&=\Delta+V_{MN}(x_1,\ldots,x_n)=\Delta+2b(x_j,\lambda)\left[\frac{f(\lambda)}{b(x_j,\lambda)}\right]_{MN},\\ I_k'&=I_k+U_k(x_1,\ldots,x_n)=I_k+\mathrm{Res}_{\lambda=0}(\phi_k(\lambda)V_{MN}(x_1,\ldots,x_n)).\end{aligned} \tag{IV.6}$$

Thus, all integrable systems related to the mappings (III.20) with the constant normalization of the corresponding Baker–Akhiezer function obey to the Levi-Civita theorem[1] (I.1).

Integrals of motion I_j' (III.28) associated to the multiplicative automorphism (II.16) could be different from original ones on certain functions $a_{ij}(x_1,\ldots,x_n)$ of only half of the dynamical variables $\{x_j\}_{j=1}^n$ [see (I.2) and the Stäckel systems (I.3)]. Here functions a_{ij} are defined by (III.28) for any concrete representation.

The method of separation of variables for the Lax matrices $L(\lambda)\in\widetilde{sl(N)}^*$ was studied in Ref. 11. The separated coordinates are obtained as zeroes of the certain polynomial $B(\lambda)$ of degree $N(N-1)/2$ in components of $L(\lambda)$. The spectral curve $W(z,\lambda)=\det(z-L(\lambda))$ is a nonhyperellip-

tic algebraic curve for $N>2$ and the Levi-Civita theorem can not be applied directly to this case. Still the polynomial $B(\lambda)$ depending on separated coordinates can be used to construct a counterpart of the mappings (III.11) and (III.20) for $\widetilde{sl(N)}$.

Consider, for instance, the loop algebra $\widetilde{sl(3)}$. Let the Lax matrix $L(\lambda)\in\widetilde{sl(3)}^*$ obey the standard linear R-bracket (III.6) with the rational r-matrix $r_{12}=(\lambda-\mu)^{-1}\Pi$, where Π is the permutation operator: $\Pi x\otimes y=y\otimes x, x,y\in\mathbb{C}^3$. The entries $s_{ij}(\lambda)$ of the Lax matrix $L(\lambda)$ are constructed in variables s_{ij} $(i,j=1,2,3.\ \Sigma s_{ii}=0)$ with the following standard Poisson brackets:

$$\{s_{ij},s_{km}\}=s_{im}\delta_{jk}-s_{kj}\delta_{im},$$

which define the natural Lie–Poisson bracket on $\widetilde{sl(3)}^*$. According to Ref. 11, the simplest choice of normalization $\beta(\lambda)$ of $\Psi(\lambda)$ is

$$\beta_1=\beta_2=0,\quad \beta_3=1, \tag{IV.7}$$

then the polynomial $B(\lambda)$ is given by

$$B(\lambda)=s_{32}(\lambda)u_{13}(\lambda)-s_{31}(\lambda)u_{23}(\lambda), \tag{IV.8}$$

where $u_{ij}(\lambda)$ is (ij)-cofactor of the determinant of $L(\lambda)$. The polynomial $B(\lambda)$ (IV.8) allows us to introduce the following mapping:

$$\begin{aligned} &s_{ij}\to s'_{ij}=s_{ij},\quad (ij)\neq(13),(23),\\ &s_{13}\to s'_{13}=s_{13}+s_{32}f(\lambda)B^{-1}(\lambda),\\ &s_{23}\to s'_{23}=s_{23}-s_{31}f(\lambda)B^{-1}(\lambda), \end{aligned} \tag{IV.9}$$

as an analog of the mapping (III.11) with the normalization (IV.7). This mapping leaves fixed the spectral invariants τ_1 and τ_2 and shifts the third invariant polynomial τ_3,

$$\begin{aligned} &\tau_1(\lambda)=\mathrm{tr}L(\lambda)=0\to\tau'_1(\lambda)=\tau_1(\lambda)=0,\\ &\tau_2(\lambda)=\mathrm{tr}L^2(\lambda)\to\tau'_2(\lambda)=\tau_2(\lambda),\\ &\tau_3(\lambda)=\det L(\lambda)\to\tau'_3(\lambda)=\tau_3(\lambda)+f(\lambda). \end{aligned}$$

The general Lax matrix $L'(\lambda)$ defined by (IV.9) obeys the linear R-bracket with the dynamical r-matrices.

So, we can apply the known polynomials $B(\lambda)$ and the method of separation of variables to construct the analogs of mappings (III.11) and (III.20) for the loop algebra $\widetilde{sl(N)}$. It would be interesting to find the general counterparts of outer automorphisms (II.13) and (II.16) for infinite-dimensional representations of $sl(N)$ and to consider the inverse problem of choosing the correct normalization of Baker–Akhiezer function by using these automorphisms. A similar, but more difficult problem arises for the simple Lie algebras other than $sl(N)$.

V. DYNAMICAL *R*-MATRICES AND QUADRATIC *R*-BRACKET

Now we consider analogs of the additive and multiplicative automorphisms of $sl(2)$ (II.6)–(II.8) for the quadratic R-bracket in classical mechanics.

Introduce the formal particular mapping,

$$T(u)=\begin{pmatrix} A & B \\ C & D \end{pmatrix}(u)\to T'(u)=\begin{pmatrix} A+fD^{-1} & B \\ C & D \end{pmatrix}(u). \tag{V.1}$$

If the initial matrix $T(u)$ obeys the standard quadratic R-bracket,

$$\{\overset{1}{T}(u),\overset{2}{T}(v)\}=[r(u-v),\overset{1}{T}(u)\overset{2}{T}(v)], \quad \text{with } r=(u-v)^{-1}\Pi, \tag{V.2}$$

then the image $T'(u)$ of mapping (V.1) obeys the dynamical quadratic R-bracket,

$$\{\overset{1}{T'}(u),\overset{2}{T'}(v)\}=[r(u-v),\overset{1}{T'}(u)\overset{2}{T'}(v)]+\overset{2}{T'}(v)s_{21}\overset{1}{T'}(u)-\overset{1}{T'}(u)s_{12}\overset{2}{T'}(v). \tag{V.3}$$

Here dynamical matrices s_{jk} are given by

$$s_{12}(u,v)=\frac{1}{u-v}\left[\frac{f(u)}{D^2(u)}-\frac{f(v)}{D^2(v)}\right]\cdot\sigma_-\otimes\sigma_+,$$
$$s_{21}(u,v)=\Pi s_{12}(v,u)\Pi. \tag{V.4}$$

In contrast to the linear case, the mapping (V.1) related to additive automorphism (II.6) changes the form of the R-bracket. However, if the functions $D(u)$ and $f(u)$ (V.1) are independent of spectral parameter u, then the dynamical matrices s_{jk} in (V.3) go to zero.[6] Moreover, in this case, we can use the more general mapping [see (V.1)],

$$A(u)\to A'(u)=A(u)+g(D),$$

where $g(D)$ is an arbitrary function on entry D. This mapping changes the standard R-bracket (V.2) to the dynamical bracket (V.3), but it preserves the property of integrability,

$$\{\mathrm{tr}T'(u),\mathrm{tr}T'(v)\}=0.$$

We have to emphasize that additive and multiplicative automorphisms of $sl(2)$ (II.6)–(II.8) give rise to the integrable systems associated to the two root systems BC_n and D_n, respectively.[6] Consider the special solutions,

$$U_A(u)=\begin{pmatrix} A(u) & B(u) \\ C(u) & -A(-u) \end{pmatrix}, \tag{V.5}$$

of the classical reflection equation,

$$\{\overset{1}{U}(u),\overset{2}{U}(v)\}=[r(u-v),\overset{1}{U}(u)\overset{2}{U}(v)]+\overset{1}{U}(u)r(u+v)\overset{2}{U}(v)-\overset{2}{U}(v)r(u+v)\overset{1}{U}(u). \tag{V.6}$$

with the rational $r=(u-v)^{-1}\Pi$ r-matrix. An application of the additive and multiplicative automorphisms of $sl(2)$ (II.6)–(II.8) is more tricky in the quadratic case.

If the entry $B(u)$ is independent of spectral parameter u, i.e. $\partial B/\partial u=0$, we can construct the new solution of the reflection equation (V.6),

$$U_C=U_A+\begin{pmatrix} 0 & 0 \\ \gamma B^{-1} & 0 \end{pmatrix}, \quad \gamma\in\mathbb{R}. \tag{V.7}$$

Assuming in addition that entry $A(u)$ is a linear function of u, i.e. $A(u)=ua_1+a_2$, let us introduce the second bounary matrix,

$$U_{BC}=U_C+\begin{pmatrix} \dfrac{\alpha}{u}+\beta & 0 \\ \left[\dfrac{\alpha}{u}(A(u)-A(-u))+\beta(A(u)+A(-u))\right]B^{-1} & \dfrac{\alpha}{u}-\beta \end{pmatrix},$$

$$\alpha,\beta,\in\mathbb{R}, \tag{V.8}$$

which is a new solution of the reflection equation (V.6). These solutions U_C (V.7) and U_{BC} (V.8) could be associated with the additive automorphism (II.6).

If the central element $\Delta=\det U_A(u)=0$ is equal to zero and $\partial B/\partial u=0$ the third boundary matrix,

$$U_D=\begin{pmatrix} A(u)-A(-u)B^{-1} & B\cdot(1-B^{-1})^2 \\ C(u) & -A(-u)+A(u)B^{-1} \end{pmatrix}, \tag{V.9}$$

is a solution of the reflection equation (V.6). This solution could be associated with the multiplicative automorphism (II.8).

The reflection equation (V.6) has an important covariance property: if $T(u)$ and $U(u)$ satisfy the relations (V.2) and (V.6), then the matrix

$$U'(u)=T(u)K(u)T^{-1}(-u), \tag{V.10}$$

is also a solution of the reflection equation provided that the Poisson brackets between the entries of initial matrices are equal to zero $\{K_{ij}(u),T_{km}(u)\}=0$. Using this property the special solution $U_A(u)$ (V.5) is given by

$$U_A(u)=T(u)\sigma_{\pm}T^{-1}(-u), \quad \Delta=\det U_A(u)=0, \tag{V.11}$$

$$\sigma_+=\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad \sigma_-=\begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}.$$

If the entry $T_{12}(u)$ $(T_{21}(u))$ is independent of the spectral parameter u, the entry U_{12} (U_{21}) is independent too. The list of the models with such matrices $T(u)$ includes the Heizenberg magnets, the nonlinear Schrödinger equation, the Toda lattices and many others.

Of course, taking another initial constant solution of the reflection equation in (V.11) the boundary matrices U_{BC} can be obtained by the usual rule[6] (V.10). However, the boundary matrix $U_D(u)$ can not be expanded on simplest factors.

As an example, here we consider the Toda lattices. The initial boundary matrix $U_A(u)$ is given by

$$U_A(u)=\begin{pmatrix} (u-p)\exp(q) & \exp(2q) \\ u^2-p^2 & (u+p)\exp(q) \end{pmatrix}, \tag{V.12}$$

where (q,p) is a pair of canonically conjugate variables $\{p,q\}=1$. According to Ref. 6 matrices U_A, U_{BC} and U_D correspond to the Toda lattices associated with the Lie algebras of the A_n, $B_n(\beta=\gamma=0)$, $C_n(\alpha=\beta=0)$ and D_n series, respectively. Among the Hamiltonians, in comparison with (I.2), there are

$$H_A=\frac{1}{2}\sum_{j=1}^{n} p_j^2+\sum_{j=1}^{n-1} \exp(x_{j+1}-x_j),$$

$$H_{BC}=H_A+\gamma \exp(-2x_1)+(2\alpha+2\beta p_1)\exp(-x_1),$$

$$H_D=H_A+\exp(-x_1-x_2).$$

In classical and quantum mechanics the boundary matrices (V.8) and (V.9) have been used for the relativistic Toda lattices and for the Heisenberg XXX and XXZ models in Ref. 6.

The more complicated dynamical quadratic R-bracket has been introduced in Ref. 7 for the Neumann top, Kowalewski top and Toda lattice associated to the Lie algebra G_2.

VI. CONCLUSIONS

The outer automorphisms of an infinite-dimensional representation of $sl(2)$ gives the possibility of constructing new Lax matrices. The corresponding linear and quadratic R-brackets include the dynamical r-matrices, which obey the dynamical Yang–Baxter equations.

For the loop algebras as a second step we applied the certain projection of a general Lax matrix onto the low-dimensional subspaces, which preserve the R-bracket. Thus, the set of the Lax matrices associated to the different integrable systems can be obtained.

Another natural way to understand the origin of dynamical r-matrices is to consider the reduction procedure. In this approach we start with some integrable system on the rich initial phase space supplied with a symplectic action of a symmetry group. By using a relatively simple invariant Hamiltonian and factorizing the corresponding dynamics by the symmetry group we get a smaller phase space with a nontrivial dynamic. Then the dynamical r-matrices describe the Poisson–Dirac brackets on reduced phase space. Of course, the automorphisms of the Lie algebras play an important role in this approach too.

In a proposed scheme we also begin with some integrable system and then construct another integrable system by using the automorphisms of Lie algebras. However, in contrast with Calogero models, the initial phase space is the same space for all considered systems. To apply the outer automorphisms of Lie algebras we construct Poisson mappings from one special representation of the loop algebra to special representations of the corresponding universal enveloping algebra. So, we preserve the phase space, but transform representations of algebras in the same linear space.

The similar dynamical deformations of quadratic R-bracket has been applied for the construction of Lax matrix for integrable systems associated to the root systems BC_n and D_n.

Among the known and possible examples there is a wide class of the Stäckel systems; the integrable extensions of the classical tops—Euler top, Manakov and Steklov tops, Lagrange and Goryachev–Chaplygin top; generalizations of the Heisenberg and Gaudin magnets.

The following problems, however, remain open. We have not an exhaustive description of outer automorphisms of infinite-dimensional representations of simple Lie algebras and of the all admissible low-dimensional submanifolds, which allow a well-defined restriction to the corresponding linear classical and quantum R-brackets.

Demazure characters and WZW fusion rules

Mark A. Walton[a)]
Department of Physics, University of Lethbridge, Lethbridge, Alberta T1K 3M4, Canada

(Received 2 July 1997; accepted for publication 15 August 1997)

The Demazure character formula is applied to the Verlinde formula for the fusion rules of Wess–Zumino–Witten (WZW) models. We follow Littelmann's derivation of a generalized Littlewood–Richardson rule that computes tensor products for simple Lie algebras. A combinatorial rule for WZW fusions does not result, however. Only a modified version of the Littlewood–Richardson rule is obtained that computes an (old) upper bound on the fusion coefficients of A_r WZW models. We argue that this is because the characters of simple Lie algebras appear in this treatment, instead of the corresponding affine characters. The Bruhat order on the affine Weyl group must be implicated in any combinatorial rule for WZW fusions; the Bruhat order on subgroups of this group (such as the finite Weyl group) does not suffice. © *1998 American Institute of Physics.* [S0022-2488(97)02612-1]

I. INTRODUCTION

The fusion coefficients $N_{l,m}^n \in \mathbf{Z}_{\geqslant 0}$ of a rational conformal field theory (RCFT) may be defined by[1]

$$\frac{S_{l,p}}{S_{0,p}}\frac{S_{m,p}}{S_{0,p}} = \sum_{n\in\Phi} N_{l,m}^n \frac{S_{n,p}}{S_{0,p}}, \quad \forall p \in \Phi. \tag{1}$$

Here, the indices $l,m,n,p,\ldots \in \Phi$ label the primary fields of the RCFT, with the index 0 specifying the identity field. $S_{i,j}$ denotes an element of the matrix describing the transformation of the characters of the primary fields under the change of torus modulus $\tau \to -1/\tau$.

We will restrict attention to those RCFTs realizing an affine Kac–Moody algebra $X_{r,k}$ that is the central extension at fixed level k of the loop algebra of the simple Lie algebra X_r of rank r. These are often called Wess–Zumino–Witten (WZW) models.[2]

If the chiral algebra is not extended, the primary fields of such theories are in one-to-one correspondence with the integrable highest-weight representations of $X_{r,k}$. The set of highest weights of these affine representations can therefore be used to label the primary fields. Alternatively, we can label the primary fields using the following set of dominant weights of X_r:

$$P_{\geqslant}(X_{r,k}) := \left\{ \lambda = \sum_{i=1}^{r} \lambda_i \omega^i \;\middle|\; \lambda_i \in \mathbf{Z}_{\geqslant 0},\ \sum_{i=1}^{r} \lambda_i a_i^\vee \leqslant k \right\}. \tag{2}$$

ω^i denotes the ith fundamental weight of X_r, and $a_i^\vee$ is the corresponding comark, so that $1 + \Sigma_{i=1}^r a_i^\vee = h^\vee$, the dual Coxeter number. $F(X_r)$ will stand for the set of fundamental weights of X_r. The WZW fusion rules may be written as

$$\frac{S_{\lambda,\zeta}}{S_{0,\zeta}}\frac{S_{\mu,\zeta}}{S_{0,\zeta}} = \sum_{\nu\in P_{\geqslant}(X_{r,k})} N_{\lambda,\mu}^{\nu} \frac{S_{\nu,\zeta}}{S_{0,\zeta}}, \quad \forall \zeta \in P_{\geqslant}(X_{r,k}). \tag{3}$$

[a)]Supported in part by NSERC. Electronic mail: walton@hg.uleth.ca

The ratios of matrix elements of S appearing in (3) are intimately related to the characters of representations of X_r.[3] Let $R(\lambda)$ be the integrable representation of X_r with highest weight λ, and let $P(\lambda)$ denote the set of its weights. If

$$P(X_r) := \left\{ \lambda = \sum_{i=1}^{r} \lambda_i \omega^i \mid \lambda_i \in \mathbf{Z} \right\} \tag{4}$$

is the set of integral weights of X_r, we have $P(\lambda) \subset P(X_r)$. Let e^λ denote the formal exponential of the weight λ, with the property $e^\lambda e^\mu = e^{\lambda+\mu}$. The formal character of $R(\lambda)$ may be written as

$$\mathrm{ch}_\lambda := \sum_{\sigma \in P(\lambda)} \mathrm{mult}_\lambda(\sigma) e^\sigma, \tag{5}$$

where $\mathrm{mult}_\lambda(\sigma)$ is the multiplicity of the weight σ in the representation $R(\lambda)$, and $\rho = \sum_{i=1}^{r} \omega^i$ is the Weyl vector.

Define

$$e^\sigma(\zeta) := \exp\left[\frac{-2\pi i}{k+h^\vee} \, \sigma \cdot (\zeta + \rho) \right]. \tag{6}$$

Kac and Peterson showed that

$$\frac{S_{\lambda,\zeta}}{S_{0,\zeta}} = \mathrm{ch}_\lambda(\zeta) \quad (\lambda, \zeta \in P_{\geqslant}(X_{r,k})). \tag{7}$$

This result allows us to relate the WZW fusion coefficients $N_{\lambda,\mu}^{\nu}$ to the coefficients appearing in the decomposition of a tensor product of two representations of X_r. Let

$$P_{\geqslant}(X_r) := \left\{ \lambda = \sum_{i=1}^{r} \lambda_i \omega^i \middle| \lambda_i \in \mathbf{Z}_{\geqslant 0} \right\} \tag{8}$$

be the set of dominant weights of X_r. Then, if the tensor product coefficients $T_{\lambda,\mu}^{\nu}$ are defined by

$$R(\lambda) \otimes R(\mu) = \bigoplus_{\nu \in P_{\geqslant}(X_r)} T_{\lambda,\mu}^{\nu} R(\nu), \tag{9}$$

the corresponding characters obey

$$\mathrm{ch}_\lambda \ \mathrm{ch}_\mu = \sum_{\nu \in P_{\geqslant}(X_r)} T_{\lambda,\mu}^{\nu} \ \mathrm{ch}_\nu . \tag{10}$$

The Weyl character formula is

$$\mathrm{ch}_\lambda = \frac{\Sigma_{w \in W} (\det w) e^{w(\lambda+\rho)}}{\Sigma_{w \in W} (\det w) e^{w\rho}}, \tag{11}$$

where W is the Weyl group of X_r. Therefore,

$$\mathrm{ch}_\lambda(\zeta) = \frac{\Sigma_{w \in W} (\det w) \zeta^{w(\lambda+\rho)}}{\Sigma_{w \in W} (\det w) \zeta^{w\rho}}, \tag{12}$$

where we have defined

$$\zeta^{\sigma} := e^{\sigma}(\zeta), \tag{13}$$

for notational convenience. The Weyl formula makes manifest the Weyl symmetry of the characters:

$$\mathrm{ch}_{\lambda}(\zeta) = (\det w)\mathrm{ch}_{w.\lambda}(\zeta) = \mathrm{ch}_{\lambda}(w.\zeta), \quad \forall w \in W(\zeta \in P_{\mathbf{R}}(X_r)), \tag{14}$$

where $w.\lambda := w(\lambda+\rho)-\rho$ denotes the shifted action of the Weyl group element w, and $P_{\mathbf{R}}(X_r) := \{\lambda = \Sigma_{i=1}^{r}\lambda_i\omega^i | \lambda_i \in \mathbf{R}\}$. When $\zeta \in P(X_r)$, this symmetry can be extended to include the elements of the Weyl group of $X_{r,k}$, the so-called affine Weyl group $\hat{W}$:

$$\mathrm{ch}_{\lambda}(\zeta) = (\det w)\mathrm{ch}_{w.\lambda}(\zeta) = \mathrm{ch}_{\lambda}(w.\zeta), \quad \forall w \in \hat{W} \quad (\zeta \in P(X_r)). \tag{15}$$

Let $S(X_r)$ signify the set of simple roots of X_r. W is generated by the primitive reflections r_{α},

$$r_{\alpha}\lambda := \lambda - (\lambda \cdot \alpha^{\vee})\alpha, \quad \alpha \in S(X_r), \tag{16}$$

where $\alpha^{\vee}$ is the simple coroot dual to the simple root α. $\hat{W}$ has one additional generator r_{α_0} corresponding to the zeroth affine simple root $\alpha_0 = \delta - \theta$.[4] Here θ is the highest root of X_r, and δ is the imaginary root of the affine algebra that yields $\delta \cdot \lambda = k$ for any level k weight λ (and $\delta \cdot \beta = 0$ for any root β). The action of r_{α_0} in (15) is therefore

$$r_{\alpha_0}.\lambda = r_{\theta}.\lambda + (k+h^{\vee})(\theta - \delta). \tag{17}$$

Since ζ corresponds to a level k weight, and ρ to a level $h^{\vee}$ one, we have $\zeta^{\delta} = 1$. Then the identity,

$$\zeta^{r_{\alpha_0}.\lambda} = \zeta^{r_{\theta}.\lambda + (k+h^{\vee})\theta} = \zeta^{r_{\theta}.\lambda}, \tag{18}$$

leads to the full affine Weyl invariance of (15).

Comparing Eqs. (3) and (10), taking into account the Kac–Peterson relation[3] and the affine Weyl symmetry (15), one finds[5,4,6,7]

$$N_{\lambda,\mu}^{\nu} = \sum_{w \in \hat{W}} (\det w) T_{\lambda,\mu}^{w.\nu}. \tag{19}$$

Using the well-known connection between multiplicities and tensor product coefficients,

$$T_{\lambda,\mu}^{\nu} = \sum_{w \in W} (\det w)\mathrm{mult}_{\mu}(w.\nu - \lambda), \tag{20}$$

we can also write

$$N_{\lambda,\mu}^{\nu} = \sum_{w \in \hat{W}} (\det w)\mathrm{mult}_{\mu}(w.\nu - \lambda). \tag{21}$$

These formulas make it clear that the WZW fusion coefficients are integers, while it is not evident from the form of the matrix S in (3). They do not, however, confirm that the fusion coefficients are non-negative integers, as must be.

That the tensor product coefficients are non-negative is made manifest by rules for their computation that reduce to *counting* certain objects, usually Young tableaux (see Ref. 8, for

example). The most famous is the Littlewood–Richardson rule that computes the tensor product coefficients of the simple Lie algebra A_r. Such rules do not involve overcounting and cancellations, and will be called combinatorial rules.

Algorithms like the Littlewood–Richardson rule involve Young tableaux. The action of the affine Weyl group on the Young tableaux for classical simple Lie algebras can be simply described. So, (19) allows the combinatorial methods for computing tensor products to be adapted to the computation of WZW fusion rules.[9] The adaptation is not combinatorial, however; the factor $\det w = \pm 1$ in (19) means the adapted methods involve overcounting and cancellations.

Can one find a purely combinatorial method for the computation of WZW fusion rules? To the best of our knowledge, no such rule is known. (Of course, for sufficiently large level k, when the fusion coefficient coincides with the corresponding tensor product coefficient, we can use the combinatorial rules for tensor products.) Such a rule, if it exists, should find wide application, much as the original Littlewood–Richardson rule has. It could, for example, settle the conjecture of a *threshold level* for WZW fusions.[10,11] More importantly, however, it would provide a constructive mathematical proof that fusion coefficients are non-negative integers, something that is obvious and necessary from a physical point of view. It may also deepen our understanding of WZW fusions; perhaps it will provide a definition of WZW fusion expressed solely in terms of standard (integrable, highest weight, positive integer level) representations, analogous to that for simple Lie algebra tensor products.

We may try to use (19) as a guide to a combinatorial rule. The problem with (19), however, is the factor $\det w = \pm 1$, inherited from the Weyl character formula (11). So, perhaps a non-negative character formula can lead to a combinatorial rule. The Demazure character formula[12,13] is such a non-negative formula, and Littelmann[14] has derived the Littlewood–Richardson rule and generalizations from it. In this work, we adapt his methods to the computation of WZW fusion rules, in an attempt to find a purely combinatorial rule. Although our results are only valid for $X_r = A_r$, we use universal language appropriate to all simple Lie algebras (and their untwisted affine analogs) whenever possible. This reflects our hope that a universal result, valid for all $X_{r,k}$, will eventually be found.

As far as we know, this work is the first direct application of Demazure character formulas to WZW fusions. In light of Littelmann's results, this is a natural attempt at finding a combinatorial rule for WZW fusions. Unfortunately, no such rule is obtained. Our effort does make it clear why, however. We hope it will therefore help as a stepping stone to a combinatorial rule for WZW fusions.

II. DEMAZURE CHARACTER FORMULAS

Introduce the primitive Demazure operators D_α:

$$D_\alpha(e^\mu) := \frac{e^\mu - e^{r_\alpha \cdot \mu}}{1 - e^{-\alpha}}, \tag{22}$$

for all $\alpha \in S(X_r)$. These linear operators are associated with the primitive reflections of the Weyl group W of X_r, and are defined for all $\mu \in P(X_r)$. More explicitly,

$$D_\alpha(e^\mu) = \begin{cases} e^\mu + \cdots + e^{\mu - (\mu\cdot\alpha^\vee)\alpha}, & \mu\cdot\alpha^\vee \geqslant 0; \\ 0, \quad \mu\cdot\alpha^\vee = -1; \\ -e^{\mu+\alpha} - \cdots - e^{\mu + (-\mu\cdot\alpha^\vee - 1)\alpha}, & \mu\cdot\alpha^\vee \leqslant -2. \end{cases} \tag{23}$$

A Demazure operator can also be associated to every element of the Weyl group of X_r. Suppose $w = r_{\beta_1} r_{\beta_2} \cdots r_{\beta_l}$, with all $\beta_i \in S(X_r)$, is a decomposition of $w \in W$. Such a decomposition is said to have length l. For fixed $w \in W$, any decomposition of minimum length is called a reduced

decomposition. The length $l(w)$ of any reduced decomposition of $w \in W$ is known as the length of w. Now, if $w = r_{\beta_1} r_{\beta_2} \cdots r_{\beta_l}$ is a reduced decomposition of $w \in W$, then we define

$$D_w := D_{\beta_1} \circ D_{\beta_2} \circ \cdots \circ D_{\beta_l}. \tag{24}$$

It makes sense to label these operators with the Weyl group element w, since they do not depend on which reduced decomposition is used. It is important, however, that a *reduced* decomposition be used in the definition of D_w; we have $r_\alpha^2 = \mathrm{id}$, but

$$D_\alpha(D_\alpha(e^\mu)) = D_\alpha(e^\mu). \tag{25}$$

This last relation follows from the more general one:

$$D_\alpha(e^\lambda D_\alpha(e^\mu)) = D_\alpha(e^\lambda) D_\alpha(e^\mu). \tag{26}$$

The Weyl group of any simple Lie algebra contains a unique element of maximum length. If w_L symbolizes the longest element of the Weyl group W, we have the following Demazure character formula:

$$\mathrm{ch}_\lambda = D_{w_L}(e^\lambda). \tag{27}$$

It is also useful to introduce other primitive Demazure operators related to the D_α:

$$d_\alpha(e^\mu) := (D_\alpha - id)(e^\mu) = \frac{e^{\mu-\alpha} - e^{r_\alpha \cdot \mu}}{1 - e^{-\alpha}}, \tag{28}$$

for all $\alpha \in S(X_r)$. More explicitly,

$$d_\alpha(e^\mu) = \begin{cases} e^{\mu-\alpha} + \cdots + e^{\mu-(\mu\cdot\alpha^\vee)\alpha}, & \mu \cdot \alpha^\vee \geqslant 1; \\ 0, \quad \mu \cdot \alpha^\vee = 0; \\ -e^\mu - \cdots - e^{\mu-(\mu\cdot\alpha^\vee+1)\alpha}, & \mu \cdot \alpha^\vee \leqslant -1. \end{cases} \tag{29}$$

These operators can also be generalized to d_w, for each $w \in W \backslash id$, in a way similar to that defining the D_w. For later convenience, we also define $d_{id}(e^\lambda) := e^\lambda$.

To write other Demazure character formulas, we need the Bruhat partial order on the elements of the Weyl group W. Let r_α be the Weyl reflection across the hyperplane in weight space normal to the root α, i.e. $r_\alpha \lambda = \lambda - (\lambda \cdot \alpha^\vee)\alpha$. The length $l(w)$ of a Weyl group element w is defined as the number of primitive reflections in a reduced decomposition of the element. For $v_1, v_2 \in W$, we write $v_1 \leftarrow v_2$ if and only if both $v_1 = r_\alpha v_2$ for some positive root α, and $l(v_1) = l(v_2) + 1$. Then for $w, \widetilde{w} \in W$, the Bruhat order is defined by $w > \widetilde{w}$ if $w \leftarrow v_1 \leftarrow v_2 \leftarrow \cdots \leftarrow v_n \leftarrow \widetilde{w}$, for some $v_1, v_2, \ldots, v_n \in W$.

Another formula for the character of the representation $R(\lambda)$ is

$$\mathrm{ch}_\lambda = \sum_{v \in W} d_v(e^\lambda). \tag{30}$$

A generalization is

$$D_w(e^\lambda) = \sum_{v \leq w} d_v(e^\lambda). \tag{31}$$

The formula

$$D_\alpha(d_{r_\alpha v}(e^\mu))=d_{r_\alpha v}(e^\mu)+d_v(e^\mu), \quad \text{if } r_\alpha v\prec v, \quad \alpha\in S(X_r), \tag{32}$$

makes explicit the relation between the two types of Demazure operators. Using (28) this translates into

$$d_v(e^\mu)=d_\alpha\circ d_{r_\alpha v}(e^\mu), \quad \text{if } r_\alpha v\prec v, \quad \alpha\in S(X_r). \tag{33}$$

III. TABLEAUX AND THE WEYL GROUP

In order to relate the Demazure formulas to the Littlewood–Richardson rule, the Weyl group must be related to Young tableaux and standard tableaux. This is done by recognizing certain sequences of elements of W as the appropriate generalizations of standard tableaux. The so-called minimal defining chains (MDCs) of Weyl group elements are in one-to-one correspondence with certain vectors of fixed weight that form a basis of the irreducible representation $R(\lambda)$ of X_r.[15,16] For the algebra A_r, it is well known that such vectors are in one-to-one correspondence with standard tableaux. MDCs are what work for all simple Lie algebras X_r.

Suppose μ is the highest weight of an integrable representation $R(\mu)$ of X_r. Such a weight can be expressed as a sum of fundamental weights $\mu=\nu^1+\nu^2+\cdots+\nu^n$, where $\nu^j\in F(X_r)$, $1\leqslant j\leqslant n$. If we fix an order $>$ on the elements of $F(X_r)$, so that we can also impose $\nu^i\geqslant\nu^{i+1}$ on the sum, the expression is unique. Now consider a sequence $c=(w_1,w_2,\ldots,w_n)$ of n Weyl group elements $w_i\in W$. The sequence, or chain, is a defining chain if it respects the Bruhat order: $w_1\preceq w_2\preceq\cdots\preceq w_n$. A sequence of weights of fundamental representations corresponding to each defining chain and weight μ is given by

$$P_\mu(c):=(w_1\nu^1,w_2\nu^2,\ldots,w_n\nu^n). \tag{34}$$

Different defining chains, however, lead to the same weight sequence. A unique *minimal defining chain* (MDC) can be associated with the weight sequence: $c=(w_1,\ldots,w_n)$ is a minimal defining chain if for any other defining chain $\tilde{c}=(\tilde{w}_1,\ldots,\tilde{w}_n)$ satisfying $P_\mu(c)=P_\mu(\tilde{c})$, we have $w_j\preceq\tilde{w}_j$, for all $1\leqslant j\leqslant n$.

Define the μ-weight $p_\mu[c]$ of the MDC c as

$$p_\mu[c]=p_\mu[(w_1,\ldots,w_n)]:=w_1\nu^1+\cdots+w_n\nu^n. \tag{35}$$

Let $\mathscr{C}_\mu[\sigma]$ be the set of MDCs with μ-weight σ, and let $\mathscr{C}_\mu(w)$ denote the set of MDCs with the last element equal to $w\in W$. The weights of a representation $R(\mu)$ and those of MDCs are related:

$$\mathrm{mult}_\mu(\sigma)=|\mathscr{C}_\mu[\sigma]|, \tag{36}$$

so that

$$\mathrm{ch}_\mu=\sum_{\sigma\in P(\mu)}\sum_{c\in\mathscr{C}_\mu[\sigma]}e^{p_\mu[c]}. \tag{37}$$

Also relevant here is the connection with Demazure operators:

$$d_w(e^\lambda)=\sum_{c\in\mathscr{C}_\lambda(w)}e^{p_\lambda[c]}. \tag{38}$$

In the case $X_r=A_r$, the usual standard tableaux are recovered as follows. Let $\{e_i|i=1,\ldots,r+1;\ e_i\cdot e_j=\delta_{i,j}\}$ be an orthonormal basis of $\mathbf{R}^{r+1}$. The fundamental weights can be chosen to be $\omega^i=e_1+e_2+\cdots+e_i-i\psi/(r+1)$, with $\psi=\Sigma_{i=1}^{r+1}e_i$.[17] The Weyl group of A_r acts as the group of permutations on the e_i. Therefore the weights $w_j\nu^j$ $[w_j\in W,\ \nu^j\in F(A_r)]$ in the weight sequence

$P_\mu(c)=(w_1\nu^1, w_2\nu^2, \ldots, w_n\nu^n)$ of a MDC c can be associated with a column of boxes, with numbers from 1 to $r+1$ in each, increasing down the column. A box $\boxed{2}$, say, corresponds to a summand e_2 in the expression for the weight, modulo multiples of ψ. If the fundamental weights of A_r are ordered $\omega^1<\omega^2<\cdots<\omega^r$, then if the columns of boxes corresponding to the weights in the weight sequence of a MDC are assembled into a tableaux, the columns will have heights that do not increase from left to right. Furthermore, the Bruhat order imposed on a MDC ensures that the numbers in the rows of the tableau also do not increase from left to right. But these are precisely the defining properties of a standard tableau for A_r. (These are sometimes called semi-standard tableaux, when standard tableaux designate those with numbers increasing in both rows and columns.) [The further *minimal* property of the MDCs is necessary for (36) and (38).]

The MDCs, corresponding weight sequences, and standard tableaux associated with vectors in the A_2 representation $R(2,1)$ of highest weight $2\omega^1+\omega^2=:(2,1)$ are given as an example in Table I. There we use the shorthand notation $r_{\alpha_i}=:r_i$.

If a standard tableau corresponds to a weight sequence $P_\mu(c)$ of the MDC c, then we say that it has shape μ. The shape of a standard tableau is determined by the configuration of its boxes, and not by the numbers therein. If the numbers are removed from a standard tableau of shape μ, a Young tableau of shape μ results. Young tableaux also enter into the Littlewood–Richardson rule.

It will be useful to define subchains obtained from other chains by keeping the last i elements on the right, and also by keeping the first $n-i$ elements on the left. If $c=(w_1, w_2, \ldots, w_n)$ is a defining chain, we define

$$R_i(c):=(w_{n-i+1}, w_{n-i+2}, \ldots, w_n) \quad \text{and} \quad L_i(c):=(w_1, w_2, \ldots, w_{n-i}). \tag{39}$$

If $\mu=\nu^1+\nu^2+\cdots+\nu^n\in P_{\geqslant}(X_{\tau r})$, we also define

$$R_i(\mu):=\nu^{n-i+1}+\nu^{n-i+2}+\cdots+\nu^n \quad \text{and} \quad L_i(\mu):=\nu^1+\nu^2+\cdots+\nu^{n-i}. \tag{40}$$

IV. LITTELMANN'S GENERALIZATION OF THE CLASSICAL LITTLEWOOD–RICHARDSON RULE

From (10) and the Weyl character formula (11), we have

$$\sum_{w\in W}(\det w)e^{w(\lambda+\rho)}\ \mathrm{ch}_\mu=\sum_{\nu\in P_{\geqslant}(X_r)}T^{\nu}_{\lambda,\mu}\sum_{w\in W}(\det w)e^{w(\nu+\rho)}. \tag{41}$$

Defining the linear operator Θ by

$$\Theta(e^\lambda):=\sum_{w\in W}(\det w)e^{w(\lambda+\rho)}, \tag{42}$$

this can be rewritten as

$$\Theta(e^\lambda\ \mathrm{ch}_\mu)=\Theta\left(\sum_{\nu\in P_{\geqslant}(X_r)}T^{\nu}_{\lambda,\mu}e^\nu\right). \tag{43}$$

What Littelmann showed was that the left-hand side simplifies because it contains terms of the form

$$\Theta(e^\kappa d_v(e^\gamma))=0, \quad \text{for } r_\alpha v\prec v\in W, \quad \kappa\cdot\alpha^\vee=0, \quad \alpha\in S(X_r). \tag{44}$$

To see why these contributions vanish, first note that by the definition (42), we get

$$\Theta(e^{w\cdot\gamma})=(\det w)\Theta(e^\gamma), \quad \forall w\in W, \tag{45}$$

so that

$$\Theta(D_\alpha(e^\gamma))=\Theta(e^\gamma), \quad \forall\alpha\in S(X_r). \tag{46}$$

Equation (26) above then gives

$$\Theta(e^\kappa D_\alpha(e^\gamma))=\Theta(D_\alpha(e^\kappa D_\alpha(e^\gamma)))=\Theta(D_\alpha(e^\kappa)D_\alpha(e^\gamma))=\Theta(D_\alpha(e^\kappa)e^\gamma), \tag{47}$$

for any simple root $\alpha\in S(X_r)$. This implies

$$\Theta(e^\kappa d_\alpha(e^\gamma))=\Theta(d_\alpha(e^\kappa)e^\gamma), \tag{48}$$

by the definition (28) of the operators d_α. From (33) we then get

$$\Theta(e^\kappa d_v(e^\gamma))=\Theta(d_\alpha(e^\kappa)d_{r_\alpha v}(e^\gamma)), \quad \text{for } r_\alpha v\prec v. \tag{49}$$

But since $d_\alpha(e^\kappa)=0$ for $\kappa\cdot\alpha^\vee=0$, (44) is proved.

The vanishing contributions to the tensor product $R(\lambda)\otimes R(\mu)$ encoded in (44) can be identified easily using the MDCs. From (37), the left-hand side of (43) contains expressions of the form

$$\Theta(e^{\lambda+p_\mu[c]})=\Theta(e^{[\lambda+p_{R_i(\mu)}[R_i(c)]]+p_{L_i(\mu)}[L_i(c)]}), \tag{50}$$

where $1\leqslant i\leqslant n$. Suppose that for the particular MDC under consideration,

$$\lambda + p_{R_i(\mu)}[R_i(c)] \in P_{\geqslant}(X_r), \quad \text{for } i = 1,...,l < n;$$

$$\lambda + p_{R_{l+1}[\mu]}(R_{l+1}(c)) \notin P_{\geqslant}(X_r). \tag{51}$$

For $X_r = A_r$, we have $w\nu \cdot \alpha^\vee \in \{-1,0,1\}$, for all $\alpha \in S(X_r)$ and $\nu \in F(X_r)$. With $c = (w_1,\ldots,w_n)$ and $P_\mu(c) = (w_1\nu^1,\ldots,w_n\nu^n)$, (51) implies that $(\lambda + p_{R_l(\mu)}[R_l(c)]) \cdot \alpha^\vee = 0$ and $(\lambda + p_{R_{l+1}(\mu)} \times [R_{l+1}(c)]) \cdot \alpha^\vee = -1$, for some simple root $\alpha \in S(X_r)$. This means that $(w_{n-l}\nu^{n-l}) \cdot \alpha^\vee = -1$ and that $r_\alpha w_{n-l} \prec w_{n-l}$.

By (38) then, the expression in (50) is contained in

$$\Theta(e^{\lambda + p_{R_l(\mu)}[R_l(c)]} d_{w_{n-l}}(e^{\mu - R_l(\mu)})), \tag{52}$$

which vanishes by (44). The Bruhat order obeyed by the elements of minimal defining chains, and their connection with Demazure characters, ensures that all terms in (52) of the form (50) obeying (51) are present on the left-hand side of (43), if one is.

A minimal defining chain c is called λ dominant if

$$\lambda + p_{R_i(\mu)}[R_i(c)] \in P_{\geqslant}(X_r), \quad \text{for all } 0 \leqslant i \leqslant n. \tag{53}$$

So, only the λ-dominant MDCs can contribute to the left-hand side of (43). Define $\mathscr{C}_{\lambda,\mu}[\sigma]$ to be the set of λ-dominant MDCs of μ weight σ. Then, once the terms of the form (52) are eliminated from the left-hand side of (43), we are left with

$$\Theta\left(\sum_{\nu \in P_{\geqslant}(X_r)} \dim\, \mathscr{C}_{\lambda,\mu}[\nu - \lambda] e^\nu \right) = \Theta\left(\sum_{\nu \in P_{\geqslant}(X_r)} T^\nu_{\lambda,\mu} e^\nu \right). \tag{54}$$

But, it is easy to see that

$$\Theta\left(\sum_{\mu \in P_{\geqslant}(X_r)} a_\mu e^\mu \right) = \Theta\left(\sum_{\nu \in P_{\geqslant}(X_r)} b_\nu e^\nu \right) \Rightarrow a_\mu = b_\mu, \quad \forall \mu \in P_{\geqslant}(X_r). \tag{55}$$

Littelmann's generalization of the Littlewood–Richardson rule then follows:

$$\boxed{T^\nu_{\lambda,\mu} = |\mathcal{C}_{\lambda,\mu}[\nu - \lambda]|} \ . \tag{56}$$

In the case $X_r = A_r$, the classical Littlewood–Richardson rule is recovered. Let a standard tableau be called λ dominant if the corresponding MDC is λ dominant. To find the tensor product coefficient $T^\nu_{\lambda,\mu}$, one simply counts the number of λ-dominant standard tableaux of shape μ and weight $\nu - \lambda$. These can be found by taking each standard tableau of shape μ and weight $\nu - \lambda$ and adding the weights of its columns, from right to left, to λ. If the addition of the weight of one of the columns results in a nondominant weight, no contribution results. If this does not happen, the standard tableau contributes 1 to $T^\nu_{\lambda,\mu}$.

The rule is most easily implemented by adding the columns directly to the Young tableau of shape λ, to form a mixed tableau. The shape of the mixed tableau is similar to the shape of a Young tableau. One takes the columns of the standard tableau, and any box $\boxed{3}$, e.g., to the third row of the Young tableau, etc. If the addition in this manner of any column results in a mixed tableau of nondominant shape, the standard tableau does not contribute.

For example, consider the decomposition of the tensor product of A_2 representations: $R(2,0)\otimes R(2,1)=R(0,3)\oplus R(1,1)\oplus R(2,2)\oplus R(3,0)\oplus R(4,1)$, where $R(\lambda_1,\lambda_2)$ means $R(\lambda)$ with $\lambda=\lambda_1\omega^1+\lambda_2\omega^2$. We have $T^{(3,0)}_{(2,0),(2,1)}=1$ while there are two standard tableaux of shape (2,1) and of the appropriate weight $(3,0)-(2,0)=(1,0)$:

$$\begin{array}{|c|c|c|}\hline 1&1&2\\\hline 3\\\cline{1-1}\end{array}\ ,\quad \begin{array}{|c|c|c|}\hline 1&1&3\\\hline 2\\\cline{1-1}\end{array}\ . \tag{57}$$

Only the first standard tableau contributes because by adding its columns, from right to left, to the Young tableau $\square\square$ of shape (2,0), we obtain the following sequence of mixed tableaux:

$$\begin{array}{|c|c|}\hline \ &\ \\\hline 2\\\cline{1-1}\end{array}\ ,\quad \begin{array}{|c|c|c|}\hline \ &\ &1\\\hline 2\\\cline{1-1}\end{array}\ ,\quad \begin{array}{|c|c|c|c|}\hline \ &\ &1&1\\\hline 2\\\cline{1-1}3\\\cline{1-1}\end{array}\ , \tag{58}$$

each of which has a dominant shape. In attempting to do the same for the second standard tableau, we immediately encounter

$$\begin{array}{|c|c|}\hline \ &\ \\\hline 3\\\cline{1-1}\end{array}\ . \tag{59}$$

This mixed tableau is clearly not dominant, and so does not contribute to the tensor product.

Only five tableaux from Table I contribute to the tensor product $R(2,0)\otimes R(2,1)$. The rest must result in terms of the form (44). For example, the five tableaux,

$$\begin{array}{|c|c|c|}\hline 1&1&3\\\hline 2\\\cline{1-1}\end{array}\ ,\quad \begin{array}{|c|c|c|}\hline 1&2&3\\\hline 2\\\cline{1-1}\end{array}\ ,\quad \begin{array}{|c|c|c|}\hline 1&1&3\\\hline 3\\\cline{1-1}\end{array}\ ,\quad \begin{array}{|c|c|c|}\hline 1&3&3\\\hline 2\\\cline{1-1}\end{array}\ ,\quad \begin{array}{|c|c|c|}\hline 1&3&3\\\hline 3\\\cline{1-1}\end{array}\ , \tag{60}$$

furnish together such a form, with $\kappa=(2,0)$, $\gamma=(2,1)$, and $v=r_2r_1$.

The form of the Littlewood–Richardson rule just described differs from the original, in which the only numbered tableau that enters is

$$\begin{array}{|c|c|c|}\hline 1&1&1\\\hline 2\\\cline{1-1}\end{array}\ . \tag{61}$$

But the translation is simple, and is described explicitly in Ref. 18. The version involving standard tableaux is the most convenient, since it can be directly related to vectors in representations of X_r.

V. MODIFIED LITTLEWOOD–RICHARDSON RULES FOR FUSIONS

In this section we will follow Littelmann's derivation of a generalized Littlewood–Richardson rule,[14] as outlined in the previous section, and attempt to find a combinatorial rule for WZW fusions.

From (3) and (7), we can follow steps in the previous section to arrive at

$$\Theta(e^{\lambda}\ \mathrm{ch}_{\mu})(\sigma)=\Theta\left(\sum_{\nu\in P_{\geqslant}(X_{r,k})} N^{\nu}_{\lambda,\mu}e^{\nu}\right)(\sigma), \tag{62}$$

where λ, μ, σ are elements of $P_{\geqslant}(X_{r,k})$.

From (19) it is clear that the Weyl group $\hat{W}$ of $X_{r,k}$ must be implicated. Using the action (17) of the $\hat{W}$ generator r_{α_0} that is additional to the generators of W, it is simple to show that

$$\Theta(e^{w\cdot\gamma})(\sigma)=(\det w)\Theta(e^{\gamma})(\sigma), \quad \forall w\in\hat{W}, \tag{63}$$

when σ, $\gamma\in P(X_r)$. But another ingredient in Littelmann's derivation of a generalized Littlewood–Richardson rule is the Demazure character formulas for $\mathrm{ch}_\mu(\sigma)$ that involve the Bruhat order on W. We know of no way to write a similar formula for $\mathrm{ch}_\mu(\sigma)$ involving the Bruhat order on the full affine Weyl group $\hat{W}$. Formulas involving the Bruhat order on subgroups of $\hat{W}$ *can* be written, however, as we now demonstrate.

In order to use the affine Weyl symmetry (63), the weights involved must have level k: $\delta\cdot\gamma=k$ is required. If two such weights are added, however, we get level $2k$. Let ω^0 be the zeroth affine fundamental weight, so that $\delta\cdot\omega^0=1$. If ξ, ϕ have level k, i.e. $\delta\cdot\phi=\delta\cdot\xi=k$, define $\bar{\phi}:=\phi-k\omega^0$. Then $\delta\cdot(\xi+\bar{\phi})=k$. Notice that $\sigma^{\omega^0}=1$, so that we are able to interpret the weight μ on the left-hand side of (62) above as $\bar{\mu}$, in order to exploit the affine symmetry (63).

With $w=r_{\alpha_0}$ in (63), it is easy to show that

$$\Theta(d_{\alpha_0}(e^{\gamma}))(\sigma)=0, \tag{64}$$

for $\delta\cdot\gamma=k$, with $\gamma\in P(X_r)$, if d_{α_0} is defined by (28) with $\alpha=\alpha_0$. From this,

$$\Theta(e^{\gamma}d_{\alpha_0}(e^{\bar{\phi}}))(\sigma)=0, \quad \text{if } \gamma\cdot\alpha_0=k-\theta\cdot\gamma=0 \tag{65}$$

follows, since $\gamma+r_{\alpha_0}\cdot\bar{\phi}=r_{\alpha_0}\cdot(\gamma+\bar{\phi})$ in that case. Finally then, if we define Demazure operators d_u for any $u\in\hat{W}$ by the reduced decomposition of u, we find

$$\Theta(e^{\gamma}d_u(e^{\bar{\phi}}))(\sigma)=0, \quad \text{if } k-\theta\cdot\gamma=0 \quad \text{and} \quad r_{\alpha_0}u\prec u, \tag{66}$$

where now $\prec$ indicates the Bruhat order on $\hat{W}$.

For $X_r=A_r$, let W^m denote the subgroup of $\hat{W}$ generated by all the affine primitive reflections except r_{α_m}:

$$W^m=\langle r_{\alpha_i} \mid i\in\{0,1,2,\ldots,r\}\setminus m\rangle. \tag{67}$$

So all $W^m\cong W$, and $W^0=W$. Denote by $x\in W$ the Weyl group element that permutes the simple roots of A_r and $-\theta$ in a cyclic manner:

$$x(-\theta,\alpha_1,\alpha_2,\ldots,\alpha_r)=(\alpha_1,\alpha_2,\ldots,\alpha_r,-\theta). \tag{68}$$

Using these definitions we can write a modified Demazure character formula,

$$\boxed{\mathrm{ch}_{\bar{\mu}}(\sigma) \;=\; \sum_{v\in W^m} d_v(e^{x^m\bar{\mu}})(\sigma)} \quad , \tag{69}$$

involving the subgroup W^m of the affine Weyl group $\hat{W}$.

Defining chains and corresponding tableaux can also be associated to the affine subgroups W^m. The highest weight μ of an integrable representation $R(\mu)$ can be expressed uniquely as a sum $\mu = x^m\nu^1 + x^m\nu^2 + \cdots + x^m\nu^n$, where $\nu^j \in F(A_r)$, and the order $\nu^i \geqslant \nu^{i+1}$ has been fixed. A sequence $c=(w_1,w_2,\ldots,w_n)$ of elements of W^m can be associated with such a weight. If $w_j \preceq w_{j+1}$, the chain is a defining chain. If it is also the minimal defining chain corresponding to the following sequence of weights:

$$P^m_\mu(c) := (w_1x^m\nu^1, w_2x^m\nu^2, \ldots, w_nx^m\nu^n), \tag{70}$$

we will call it an m-MDC.

Define the μ weight $p_{\mu,m}[c]$ of the m-MDC c as

$$p_{\mu,m}[c] = p_{\mu,m}[(w_1,w_2,\ldots,w_n)] := w_1x^m\nu^1 + \cdots + w_nx^m\nu^n. \tag{71}$$

Let $\mathscr{C}^m_\mu[\phi]$ be the set of m-MDCs with μ weight ϕ, and let $\mathscr{C}^m_\mu(w)$ denote the set of m-MDCs with the last element equal to $w \in W^m$. The weights of a representation $R(\mu)$ and those of m-MDCs are related:

$$\mathrm{mult}_\mu(\phi) = |\mathscr{C}^m_\mu[\phi]|, \tag{72}$$

so that

$$\mathrm{ch}_{\overline{\mu}}(\sigma) = \sum_{\phi \in P(\mu)} \sum_{c \in \mathscr{C}^m_\mu[\phi]} e^{p_{\mu,m}[c]}(\sigma). \tag{73}$$

The relevant connection with Demazure operators is given by

$$d_w(e^\lambda)(\sigma) = \sum_{c \in \mathscr{C}^m_\lambda(w)} e^{p_{\lambda,m}[c]}. \tag{74}$$

The previous two equations are valid for any $\sigma \in P(A_r)$, and the previous three are consequences of the Weyl invariance of characters.

A minor variation of the usual standard tableaux associated to $X_r = A_r$ can encode the m-MDCs. In terms of the orthonormal basis $\{e_i\}$ of $\mathbf{R}^{r+1}$ related to the usual standard tableaux, the action of $x \in W$ is very simple:

$$x(e_1,e_2,\ldots,e_{r+1}) = (e_2,e_3,\ldots,e_{r+1},e_1). \tag{75}$$

Using the same ordering of fundamental weights: $\omega^r > \omega^{r-1} > \cdots > \omega^1$, we can define m-standard tableaux as the numbered tableaux of shape μ with numbers appearing in the order

$$(m+1, m+2, \ldots, r+1, 1, 2, \ldots, m), \tag{76}$$

from left to right in its rows, and from top to bottom with no repetitions in its columns. [Other tableaux, with orderings that are noncyclic permutations of (76), can also be defined. Their relation to fusion coefficients, however, is not clear.] Notice that 0-standard tableaux are the usual standard tableaux.

As an example, consider again the A_2 representation of highest weight $2\omega^1 + \omega^2 = (2,1)$. For A_2, $x = r_{\alpha_1}r_{\alpha_2}$, and the corresponding 1-MDCs, and 1-standard tableaux are shown in Table II.

The derivation of a modified Littlewood–Richardson rule from (62), (66), (73), and (74) follows the derivation of the classical Littlewood–Richardson rule outlined in the previous section. To state the result, we define c, an m-MDC of length n, to be (λ,k) dominant if

TABLE II. Minimal defining chains and corresponding 1-standard tableaux for the A_2 representation of highest weight $2\omega^1+\omega^2=:(2,1)$, using the affine Weyl subgroup $W^1=\langle r_0, r_2\rangle$.

$$\lambda + p_{R_i(\mu)}[R_i(c)] \in P_{\geqslant}(X_{r,k}), \quad \text{for all } 0 \leqslant i \leqslant n. \tag{77}$$

Let $\mathscr{C}^{m,k}_{\lambda,\mu}[\sigma]$ denote the set of (λ,k)-dominant m-MDCs of μ weight σ. The modified Littlewood–Richardson rule for $A_{r,k}$ fusions is then

$$\boxed{N^{\nu}_{\lambda,\mu} \;\leq\; |\mathcal{C}^{m,k}_{\lambda,\mu}[\nu-\lambda]| \;\; \forall\; 0 \leq m \leq r\ .} \tag{78}$$

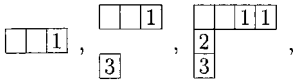
Let an m-standard tableau be called (λ,k) dominant if the corresponding m-MDC is (λ,k) dominant. To treat the fusion coefficient $N^{\nu}_{\lambda,\mu}$ for $A_{r,k}$, one simply counts the number of (λ,k)-dominant m-standard tableaux of shape μ and weight $\nu-\lambda$. These can be found by taking each m-standard tableau of shape μ and weight $\nu-\lambda$ and adding the weights of its columns, from right to left, to λ. If the addition of the weight of one of the columns results in a nondominant weight $\notin P_{\geqslant}(A_{r,k})$, no contribution results. If this does not happen, the m-standard tableau contributes 1 to the upper bound on $N^{\nu}_{\lambda,\mu}$.

The modified rule is easily implemented by adding the columns directly to the Young tableau of shape λ, to form a mixed tableau. If the addition in this manner of any column results in a mixed tableau of shape $\notin P_{\geqslant}(A_{r,k})$, the m-standard tableau does not contribute. As an example, consider the $A_{2,k=3}$ fusion rule: $R(2,0)\otimes_3 R(2,1)=R(1,1)\oplus R(0,3)$. Choosing $m=1$ as in Table

II, we can explain $N^{(3,0)}_{(2,0),(2,1)}=0$ (for $k=3$). From Table II we read that the two 1-standard tableaux of shape (2,1) and of the appropriate weight $(3,0)-(2,0)=(1,0)$ are

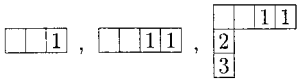
(79)

Neither of these tableaux contribute. The first does not, because by adding its columns, from right to left, to the Young tableau $\square\square$ of shape (2,0), we obtain the following sequence of mixed tableaux:



(80)

the second of which has shape $\notin P_{\geqslant}(A_{2,3})$. For the second standard tableau, we find



(81)

Again, the second mixed tableau has a shape $\notin P_{\geqslant}(A_{2,3})$ this time because it has a number of columns (of less than three boxes) greater than $k=3$. In a similar fashion, the complete fusion rule is found correctly, at level 3 and all higher levels.

If we compare the noncombinatorial expressions for tensor product coefficients (21), and for fusion coefficients (20), it is clear that the modified Littlewood–Richardson rule (78) calculates the right-hand side of

$$N^{\nu}_{\lambda,\mu} \leqslant T^{(m)\nu}_{\lambda,\mu} := \sum_{w\in W^m} (\det w)\,\mathrm{mult}_{\mu}(w.\nu-\lambda). \tag{82}$$

We conjecture that

$$\boxed{N^{\nu}_{\lambda,\mu} \;=\; T^{(m)\nu}_{\lambda,\mu} \quad \text{when} \quad \mathrm{mult}_{\mu}(r_{\alpha_m}.\nu-\lambda)=0} \quad . \tag{83}$$

It is not hard to find an example when the bound (78) is not saturated. Consider the $A_{4,4}$ fusion $R(1,1,1,1)\otimes_4 R(1,1,1,1)$, with decomposition containing four copies of $R(1,1,1,1)$, so that $N^{(1,1,1,1)}_{(1,1,1,1),(1,1,1,1)}=4$. The modified Littlewood–Richardson rule gives $T^{(m)(1,1,1,1)}_{(1,1,1,1),(1,1,1,1)}=16, 6, 5, 5, 6,$ for $m=0,1,2,3,4$, respectively.

The $A_{4,4}$ fusion coefficient $N^{(1,1,1,1)}_{(1,1,1,1),(1,1,1,1)}=4$ *can* be recovered from the Littlewood–Richardson rule, however, if level-rank duality[19] is used. But this fix is not general. If the level is increased by one, it fails: the $A_{4,5}$ fusion coefficient $N^{(1,1,1,1)}_{(1,1,1,1),(1,1,1,1)}=14$ cannot be recovered using (78) and level-rank duality. The problem is deeper than that, as we discuss in the next section.

We now show that the modified Littlewood–Richardson rule (78) gives a known upper bound on WZW A_r fusion coefficients. Let J denote the diagram outer automorphism of $P_{\geqslant}(A_{r,k})$, with action

$$J\lambda = J\left(\sum_{i=1}^{r} \lambda_i \omega^i\right) = \left(k - \sum_{i=1}^{r} \lambda_i\right)\omega^1 + \sum_{i=2}^{r} \lambda_{i-1}\omega^i. \tag{84}$$

What we will show is that

$$T^{\nu}_{\lambda,\mu} = T^{(0)\nu}_{\lambda,\mu} = T^{(m)J^m\nu}_{J^m\lambda,\mu}. \tag{85}$$

From (20) we can write

$$T^{(m)J^m\nu}_{J^m\lambda,\mu} = \sum_{w\in W^m} (\det w)\,\mathrm{mult}_{\mu}(J^m((J^{-m}wJ^m)(\nu+\rho)-(\lambda+\rho))), \tag{86}$$

using $J^m\rho=\rho$. But for $w\in W^m$, we have $J^{-m}wJ^m\in W$. Furthermore, if σ is any weight satisfying $\sigma\cdot\delta=0$, then $J^m\sigma=x^m\sigma$. The Weyl invariance of the multiplicities then establishes (85).

The bound computed by (78) is just (82), or

$$N^{\nu}_{\lambda,\mu} \leqslant T^{J^{-m}\nu}_{J^{-m}\lambda,\mu}. \tag{87}$$

But it is well known that

$$N^{\nu}_{\lambda,\mu} = N^{J^{-m-n}\nu}_{J^{-m}\lambda,J^{-n}\mu}, \tag{88}$$

for all m,n. And with $N^{\nu}_{\lambda,\mu}\leqslant T^{\nu}_{\lambda,\mu}$, we obtain

$$N^{\nu}_{\lambda,\mu} \leqslant T^{J^{-m-n}\nu}_{J^{-m}\lambda,J^{-n}\mu}. \tag{89}$$

This last result is even stronger than the upper bound (82). It was originally conjectured to be saturated for all triples $\lambda,\mu,\nu\in P_{\geqslant}(A_{r,k})$, for some choice of m and n.[6]

VI. DISCUSSION

The classical Littlewood–Richardson rule for A_r tensor products, and generalizations for other simple Lie algebras [see (56)], can be derived from Demazure character formulas, as Littelmann demonstrated.[14] Here we wrote Demazure character formulas (69) for ratios of elements of the modular S matrices of affine Kac–Moody algebras. These were then used in the Verlinde formula in an attempt to derive a combinatorial rule for WZW A_r fusion rules.

The resulting modified Littlewood–Richardson rule (78), however, only provides an upper bound on the fusion coefficients. The basic reason is the use of the subgroups W^m of the affine Weyl group in the Demazure character formula (69), instead of the full affine Weyl group and its Bruhat order. The cancellations in (20) can be ordered systematically using the Bruhat order on the finite Weyl group W, so that a combinatorial rule results from (30) and (38). The affine Bruhat order is needed, however, to order all the cancellations in (21) in a similar way. But we were unable to write a character formula for the relevant quantities (7) that involves the Bruhat order on the full affine Weyl group.

Perhaps such a character formula can be written. On the other hand, a different derivation of the Littlewood–Richardson rule suggests that it may be difficult. Let $R(\mu;\phi)$ denote the subspace of the representation $R(\mu)$ consisting of vectors of weight ϕ. Then (see Ref. 20, Thm. 4, Sec. 78, for example)

$$T^{\nu}_{\lambda,\mu} = \dim\{V\in R(\mu;\nu-\lambda) \mid E(-\alpha_i)^{\nu_i+1}V=0, \quad \forall i\in\{1,2,..,r\}\}, \tag{90}$$

where $E(-\alpha_i)$ is the generator of X_r in the Cartan–Weyl basis that decreases the weight of a vector by α_i. So-called ''good'' bases for the representations of X_r exist[21] that result in combinatorial rules when used in (90). In particular, such a good basis for $X_r = A_r$ can be labelled by the standard tableaux (or, equivalently, by Gelfand–Tsetlin patterns[22]), so that the classical Littlewood–Richardson rule results. The modified Littlewood–Richardson rule (78) corresponds to

$$T^{(m)\nu}_{\lambda,\mu} = \dim\{V \in R(\mu;\nu-\lambda) \mid E(-\alpha_i)^{\nu_i+1} V = 0, \quad \forall i \in \{0,1,2,...,r\}\backslash m\}, \tag{91}$$

where we identify $E(-\alpha_0) := E(+\theta)$. A Weyl-transformed version of the good basis of Ref. 22 exists, and the rule involving the m-standard tableaux results. However, a natural generalization of the last two relations is

$$N^{\nu}_{\lambda,\mu} = \dim\{V \in R(\mu;\nu-\lambda) \mid E(-\alpha_i)^{\nu_i+1} V = 0, \quad \forall i \in \{0,1,2,...,r\}\}. \tag{92}$$

This equation was conjectured in Ref. 11, and was motivated by the depth rule of Ref. 2. But no basis of representations of X_r exists that is good with respect to (92),[11] as can be verified explicitly for $X_r = A_r$ using the results of Ref. 22.

It seems then that a different approach is required, one relating fusions more directly to affine representations. This would allow the use of good bases for affine representations, or formulas for their characters involving the affine Bruhat order. In this context, we should mention the more recent work of Littelmann: in Ref. 16 the generalized Littlewood–Richardson rule of (78) was further generalized to a rule for tensor products of all symmetrizable Kac–Moody algebras, and the language of minimal defining chains was upgraded to one of certain paths.

(Received 2 January 1995; accepted for publication 3 September 1997)

We discuss hypersurface motions in Riemannian manifolds whose normal velocity is a function of the induced hypersurface volume element and derive a second-order partial differential equation for the corresponding time function $\tau(x)$ at which the hypersurface passes the point x. Equivalently, these motions may be described in a Hamiltonian formulation as the singlet sector of certain diffeomorphism-invariant field theories. At least in some (infinite class of) cases, which could be viewed as a large-volume limit of Euclidean M-branes moving in an arbitrary $M+1$-dimensional Riemannian manifold, the models are integrable: In the time-function formulation the equation becomes linear [with $\tau(x)$ a harmonic function on the embedding Riemannian manifold]. We explicitly compute solutions to the large volume limit of Euclidean membrane dynamics in $\mathbb{R}^3$ by methods used in electrostatics and point out an additional gradient flow structure in $\mathbb{R}^n$. In the Hamiltonian formulation we discover infinitely many hierarchies of integrable, multidimensional, N-component theories possessing infinitely many diffeomorphism invariant, Poisson commuting, conserved charges. © *1998 American Institute of Physics.* [S0022-2488(97)00912-2]

I. INTRODUCTION

In physics, and mathematics, surface motions are usually considered independent of the parametrization, the most prominent example perhaps being the ''flow by mean curvature,'' which has been of intense mathematical interest[1] as well as of physical importance.[2] When studying the dynamics of relativistic membranes, on the other hand, one encounters[3] in a partially gauge-fixed formulation, a very interesting equation (describing the time evolution of a two-dimensional surface in $\mathbb{R}^3$) that is parametrization *dependent:* this means that different parametrizations of the initial surface Σ_0 generically lead to geometrically different shapes Σ_t at later times, t. In the case at hand, there is a residual symmetry group of area-preserving diffeomorphisms, but any reparametrization whose Jacobi determinant is different from 1 will generically change the motion. Alternatively, the equation (though first order in time) may be viewed as requiring the initial unparametrized shape Σ_0 *and* the initial unparametrized normal velocity field on Σ_0 as initial conditions (the parametrization of Σ_0, and of Σ_t, then follows, up to area-preserving diffeomorphisms of Σ_0—that do not change the geometry of the motion—from the equation). Moreover, it was shown in Ref. 4 that this parametrization-dependent equation also arises when studying a diffeomorphism-invariant field theory and restricting to the zero levels of certain constraints [such as Eq. (34) in Sec. IV of this paper]. In Ref. 5, on the other hand, some surface motions in $\mathbb{R}^3$ were shown to be best described by a (second-order partial differential) equation for $\tau(\mathbf{x})$, the time at which Σ_t contains $\mathbf{x}$.

In this paper, we significantly generalize this situation (to higher dimensions, curved embedding spaces, and more general dynamics) by considering a rather general class of parametrization-

dependent hypersurface motions in Riemannian manifolds that are first order in time, viz. Eq. (1) in Sec. II. For these type of hypersurface motions we shall derive in Sec. II a second-order partial differential equation for the time-function $\tau(x)$, which in some cases (that may be viewed as large-volume limits of Euclidean M-branes or, equivalently, as highly generalized, multilinear, field theoretic extensions of Nahm's matrix equations[6]) turns out to simply be $\Delta\tau=0$, where Δ is the Laplacian of the embedding Riemannian manifold in which the motion takes place. The fact that the evolution (1) is not purely geometric, but requires the initial surface *and* its initial normal velocity (which is also reflected in the fact that the equation for the time function is second order) can be understood from a Hamiltonian point of view: we shall give an equivalent diffeomorphism-invariant (constrained) Hamiltonian formulation of these evolutions in Sec. IV. As an example, we consider the particular case of three-dimensional Euclidean space in Sec. III: the solution of the Laplace equation for the time function becomes easy to handle thanks to the formal equivalence with the potential equation of electrostatics: we compute explicit solutions of these surface motions determined by singular one-dimensional membranes at $t=-\infty$ and $t=+\infty$ (corresponding to negatively and positively charged composed loops of wire, respectively) between which two-dimensional surfaces develop in time.

Finally, and perhaps most importantly, we are led to an infinite set of hierarchies of multidimensional integrable diffeomorphism-invariant N-component field theories for which we are able to provide a complete set of Poisson-commuting, diffeomorphism-invariant, conserved charges (Sec. IV).

II. SOME HYPERSURFACE MOTIONS IN RIEMANNIAN MANIFOLDS AND THEIR TIME FUNCTIONS

Let Σ be an orientable compact connected manifold of dimension M with a fixed volume form ρ. We shall denote coordinates on Σ by $\varphi^r, 1\leqslant r\leqslant M$. Let $(\mathcal{N},\zeta)$ be an orientable Riemannian manifold of dimension $N=M+1$ on which we shall denote coordinates by $x^i, 1\leqslant i\leqslant M+1$ and whose volume form induced by ζ will be denoted by ω_ζ. Consider the set of smooth immersions $x:\Sigma\to\mathcal{N}$, $\mathrm{imm}(\Sigma,\mathcal{N})$. For each immersion x there is a unique outward normal field $n[x]:\Sigma\to T\mathcal{N}$ (depending on x and its first derivatives) attached to the parametrized hypersurface $x:\Sigma\to\mathcal{N}$. Moreover, let $x^*\zeta$ denote the Riemannian metric on Σ obtained by pulling back ζ to Σ by x and denote by $\omega_{x^*\zeta}$ the corresponding volume form on Σ. It follows that there is a unique smooth positive function $\sqrt{g[x]}/\rho:\Sigma\to\mathbb{R}$ depending on x, its first derivatives, and the reference volume form ρ such that $\omega_{x^*\zeta}=(\sqrt{g[x]}/\rho)\rho$. Finally, let α be a positive smooth function on (a suitable open interval of) the positive real line with a nowhere vanishing derivative. Consider now the hypersurface motion $(-\epsilon,\epsilon)\to\mathrm{imm}(\Sigma,\mathcal{N}):t\mapsto x(t)$ in $\mathcal{N}$ described by the following differential equation:

$$\dot{x}:=\frac{\partial x}{\partial t}=\alpha(\sqrt{g[x]}/\rho)n[x]. \tag{1}$$

In local coordinates this equation looks as follows: writing

$$g_{rs}=\frac{\partial x^i}{\partial\varphi^r}\,\frac{\partial x^j}{\partial\varphi^s}\,\zeta_{ij}(x), \tag{2}$$

for the induced metric $x^*\zeta$, we get

$$\dot{x}^i=\alpha(\sqrt{\det(g_{rs})}/\rho)\,\frac{1}{M!\sqrt{\det(g_{rs})}}\,\zeta^{ij}(x)\sqrt{\det(\zeta_{kl})}(x)\,\epsilon_{ji_1\cdots i_M}\epsilon^{r_1\cdots r_M}\,\frac{\partial x^{i_1}}{\partial\varphi^{r_1}}\cdots\frac{\partial x^{i_M}}{\partial\varphi^{r_M}}. \tag{3}$$

The following choices of α are of particular interest:

$$\text{Lorentzian } M\text{-brane:}\quad \dot{x}=\sqrt{1-(\sqrt{g[x]}/\rho)^2}\,n[x], \tag{4}$$

$$\text{Euclidean } M\text{-brane:}\quad \dot{x}=\sqrt{(\sqrt{g[x]}/\rho)^2-1}\,n[x], \tag{5}$$

and the large-volume limit of (5),

$$\dot{x} = (\sqrt{g[x]}/\rho) n[x]. \tag{6}$$

The small-volume limit of (4),

$$\dot{x} = n[x] \tag{7}$$

(which may be called the *Optical model*) is not contained in this class (since the prefactor α of the normal is constant). Nevertheless, it can be solved directly since (7) is easily seen to imply the following equation of free motion:

$$\frac{\partial^2 x^i}{\partial t^2} + \Gamma^i_{jk}(x) \frac{\partial x^j}{\partial t} \frac{\partial x^k}{\partial t} = 0 \tag{8}$$

(where Γ^i_{jk} denote the Christoffel symbols of ζ), which can be solved as soon as the geodesic flow of $(\mathcal{N},\zeta)$ is explicitly known (e.g., for flat $\mathbb{R}^N$, the N-sphere, etc.). Some of the following results will also remain true for (7).

As in Ref. 5 we are trying to derive a differential equation for the time function.

Theorem II. 1: *Let Σ, ρ, $\mathcal{N}$, ζ and α be defined as above.*

(1) Suppose that there is a positive real number ϵ and a solution x of the above equation (1) such that the map $x:(-\epsilon,\epsilon)\times\Sigma\to\mathcal{N}:(t,\varphi)\mapsto x(t,\varphi)$ is a diffeomorphism onto its image, $\mathcal{N}_\epsilon$, which is an open neighborhood of the initial hypersurface $x(0,\Sigma)$.

Then the first component of the inverse map $x^{-1}:\mathcal{N}_\epsilon\to(-\epsilon,\epsilon)\times\Sigma$ that we shall call the time function *τ satisfies the following equations where $\nabla\tau := \zeta^{\#}(d\tau)$ ($\nabla^i\tau = \zeta^{ij}\,\partial_j\tau$) denotes the gradient of τ, $|v| := \sqrt{\zeta(v,v)} = \sqrt{\zeta_{ij}v^i v^j}$ for any tangent vector v to $\mathcal{N}$, and the symbol ";" stands for the covariant derivative,*

$$n[x] = \frac{\nabla\tau}{|\nabla\tau|}(x), \tag{9}$$

$$|\nabla\tau|(x) = \frac{1}{\alpha(\sqrt{g[x]}/\rho)}, \tag{10}$$

$$0 = |\nabla\tau|^2 \zeta^{ij}\tau_{;ij} + (\tilde{\beta}(|\nabla\tau|) - 1)\,\tau_{;ij}\,\nabla\tau^i\,\nabla\tau^j, \tag{11}$$

where $\tilde{\beta}$ is defined by

$$\tilde{\beta}(z) := -z\,\frac{\partial}{\partial z}\log(\alpha^{-1}(1/z)). \tag{12}$$

Equations (9) and (10) *remain true for positive α, whose derivative may vanish.*

(2) Conversely, suppose that the smooth function $\tau:\mathcal{N}\to\mathbb{R}$ is a solution of the second-order partial differential equation (11) and that there is a positive real number ϵ such that all its level surfaces $\tau = c$ for $c\in(-\epsilon,\epsilon)$ are diffeomorphic to Σ.

Then there is a parametrization of the zero level surface Σ_0 of τ, $x_0:\Sigma\to\Sigma_0$ and a positive real number r, such that Eq. (10) is satisfied for x_0 and $r\rho$. Moreover, let Φ_t denote the flow of the vector field $X := \nabla\tau/|\nabla\tau|^2$, i.e. the solution of the ordinary differential equation $\partial\Phi_t(x)/\partial t = X(\Phi_t(x))$ with initial condition $\Phi_0(x) = x$. Then for each parametrization x_0 of the zero level surface that satisfies the above condition (10) the map $x:(-\epsilon,\epsilon)\times\Sigma\to\mathcal{N}$, defined by

$$x(t,\varphi) := \Phi_t(x_0(\varphi)), \tag{13}$$

satisfies Eq. (1) (with ρ replaced by $r\rho$) with initial condition x_0.

Proof: 1. It is obvious that the gradient of τ will be orthogonal on the surfaces of constant time whence the gradient of τ is proportional to the surface normal $n[x]$ that gives (9). Using the inverse function theorem
