So $\overline{\Lambda(V_\beta)} = \mathbb{I}$ iff $\beta\mathbf{x} = \mathbf{x}$, $\forall \mathbf{x} \in \Gamma$ and $J_\beta \restriction \Gamma = 1$, i.e., $V_\beta - \mathbb{I} \in \mathscr{D}_c$ iff $\beta\mathbf{x} = \mathbf{x}$, $\forall \mathbf{x} \in \Gamma$ and $J_\beta \restriction \Gamma = 1$.

Since $\kappa(\psi) = \psi \restriction \Gamma$ for $\psi \in C_c(\mathbb{R}^n)$, one might surmise that $V_\beta\Gamma \subseteq \Gamma$ iff $V_\beta \in \mathscr{O}_c$. However, the example (5.3) shows that it is not true that $\beta\Gamma \subseteq \Gamma \Rightarrow V_\beta \in \mathscr{O}_c$. For the converse, we have the following.

Lemma 5.7: If $V_\beta \in \mathscr{O}_c \cup \mathscr{O}_\varphi$, then $\beta\Gamma \subseteq \Gamma$.

Proof: Let $V_\beta \in \mathscr{O}_c$, hence V_β preserves $\mathrm{Ker}(\cdot,\cdot)_\Gamma \cap C_c(\mathbb{R}^n) = C_c(\mathbb{R}^n \backslash \Gamma)$.

This is equivalent to $\beta(\mathbb{R}^n \backslash \Gamma) \subseteq \mathbb{R}^n \backslash \Gamma$, which is equivalent to $\beta\Gamma \subseteq \Gamma$. This argument directly adapts to C_φ. ∎

Note that if Γ is curved and nonperiodic, then the translations will not preserve it, so $\exp(i\hat{\mathbf{p}} \cdot \mathbf{a}) \notin \mathscr{O}_c \cup \mathscr{O}_\varphi$, hence of the generating unitaries of $\overline{\Delta(\mathbb{R}^{2n})}$, only the commutative set $\{\exp(i\hat{\mathbf{q}} \cdot \mathbf{a}) \mid \mathbf{a} \in \mathbb{R}^n\}$ is in $\mathscr{O}_c \cup \mathscr{O}_\varphi$. This is why we consider the CCR algebra as too small a choice of field algebra for this type of constraining.

Theorem 5.8: *Given the notation above, we have*

$$V_\beta \in \mathscr{O}_c \cup \mathscr{O}_p \quad \textit{iff} \quad \beta\Gamma \subseteq \Gamma \quad \textit{and} \quad J_\beta(\mathbf{x}) = \mathbb{J}_\beta(\mathbf{x}), \quad \textit{for all} \quad \mathbf{x} \in \Gamma,$$

where J_β (resp., $\mathbb{J}_\beta$) is the Jacobian of β (resp., $\beta \restriction \Gamma$) with respect to μ (resp., γ).

Proof: Let $V_\beta \in \mathscr{O}_c \cup \mathscr{O}_\varphi$, so by Theorem 5.7, $\beta\Gamma \subseteq \Gamma$. Now, since $\Lambda(V_\beta^*) = \Lambda(V_\beta)^*$, we get

$$\Lambda(V_\beta)^*\Lambda(V_\beta)\kappa(\psi)=\Lambda(V_\beta)^*\kappa(V_\beta\psi)=\Lambda(V_\beta^*)\kappa(V_\beta\psi)=\kappa(V_\beta^*V_\beta\psi)=\kappa(\psi)$$
$$=\Lambda(V_\beta)\Lambda(V_\beta)^*\kappa(\psi),\quad \forall\,\psi\in C_c(\mathbb{R}^n)\quad\text{or}\quad C_\varphi.$$

Thus $\overline{\Lambda(V_\beta)}$ is unitary, so

$$(\psi,\psi)_\Gamma=(V_\beta\psi,\ V_\beta\psi)_\Gamma=(V_\beta\psi\restriction\Gamma,\ V_\beta\psi\restriction\Gamma)_{L^2(\Gamma)}=\int_\Gamma|(V_\beta\psi)(\mathbf{x})|^2d\gamma(\mathbf{x})$$
$$=\int_\Gamma J_\beta(\mathbf{x})\cdot|\psi(\beta\mathbf{x})|^2d\gamma(\mathbf{x})=\int_\Gamma J_\beta(\mathbf{x})\cdot\mathbb{J}_\beta^{-1}(\mathbf{x})|\psi(\beta\mathbf{x})|^2d\gamma(\beta\mathbf{x})$$
$$=\int_\Gamma J_\beta(\beta^{-1}\mathbf{x})\cdot\mathbb{J}_\beta^{-1}(\beta^{-1}\mathbf{x})\cdot|\psi(\mathbf{x})|^2d\gamma(\mathbf{x})=\int_\Gamma|\psi(\mathbf{x})|^2d\gamma(\mathbf{x}),$$

$$\forall\,\psi\in C_c(\mathbb{R}^n),\quad\text{or}\quad C_\varphi,$$

iff $J_\beta(\beta^{-1}\mathbf{x})\cdot\mathbb{J}_\beta^{-1}(\beta^{-1}\mathbf{x})=1$ for all $\mathbf{x}\in\Gamma$, i.e., $J_\beta(\mathbf{x})=\mathbb{J}_\beta(\mathbf{x})$ for all $\mathbf{x}\in\Gamma$.

Conversely, observe that $\beta\Gamma\subseteq\Gamma$ guarantees that both $\Lambda(V_\beta)$ and $\underline{\Lambda(V_\beta^*)}$ exist, so by the reversibility of the previous calculation when $J_\beta=\mathbb{J}_\beta$ on Γ, we see that $\overline{\Lambda(V_\beta)}$ is unitary, hence bounded, and similarly the same is true for $\underline{\Lambda(V_\beta^*)}$. Since Λ is a homomorphism and inverses are unique, we get that $\overline{\Lambda(V_\beta^*)}=\Lambda(V_\beta)^*$, i.e., $V_\beta\in\mathscr{O}_c\cup\mathscr{O}_\varphi$. ■

Remarks: (1) Note that if $\beta\in\mathrm{Diff}\,\mathbb{R}^n$ preserves all the level sets of φ we have $\varphi\circ\beta=\varphi$, so $[V_\beta,\hat{\varphi}]=0$. However, since we need not have $\mathbb{J}_\beta=J_\beta$ on Γ, there are certainly such β for which $V_\beta\notin\mathscr{O}_c$. Thus, $\mathscr{F}_c\cap\hat{\varphi}'\setminus\mathscr{O}_c\neq\emptyset$, i.e., Landsman[11] quantizes some operators that we have excluded from our observables. (Some of these can still be taken through Λ using Theorem 5.6, but they need not preserve the adjoint or boundedness). Nevertheless, we conclude that the field algebra $C_b(\mathbb{R}^n)\rtimes\mathrm{Diff}\,\mathbb{R}^n$ has ample elements in its physical algebras $\mathscr{R}_c$ or $\mathscr{R}_\varphi$.

(2) There is no reason, in general, to expect that the time evolutions will preserve $\mathscr{R}_S$, so we will need to extend it by taking the constrained field algebra as the C^* algebra generated in $\mathscr{B}(L^2(\Gamma))$ by $\mathscr{R}_S$ and the unitaries $\exp itH_\Gamma$, $t\in\mathbb{R}$.

(3) Recall that we consider the enforcement of secondary quantum constraints as the selection of the set $S=\mathscr{T}^{(t_0)}$ that the observables should preserve. Since this is an analogy to the classical procedure, it is natural to look for reasons to justify such a choice, and a first attempt may be to ask whether the choice of transverse states for S will make the Jacobian condition in Theorem 5.8 obsolete, i.e., whether for a $V_\beta\in\mathscr{F}_{\mathscr{T}^{(t)}}$ we have $V_\beta\in\mathscr{O}_{\mathscr{T}^{(t)}}$ iff $\beta\Gamma\subset\Gamma$. This is not true, as we can see by an easy counterexample. Continue the example (5.3) with the additional assumption that the Hamiltonian has $\mathrm{Dom}\,H=C_c^\infty(\mathbb{R}^2)$ and that $\beta\in\mathrm{Diff}\,\mathbb{R}^2$ is not the given one in (5.3), but $\beta(x_1,x_2)=(x_1,2x_2)$. Then both V_β and V_β^* preserve

$$\mathscr{T}^{(t_0)}=\left\{\psi\in C_c^\infty(\mathbb{R}^n)\;\middle|\;\frac{\partial\psi}{\partial x_2}(\mathbf{x})=0,\quad\forall\,\mathbf{x}\in S_{t_\psi},\ \ t_\psi<t_0\right\};$$

hence $V_\beta\in\mathscr{F}_{\mathscr{T}^{(t_0)}}$, and $\beta\Gamma=\Gamma$, $\beta\restriction\Gamma=\mathbb{I}$, $\mathbb{J}_\beta=1$, $J_\beta=2$; hence

$$\Lambda(V_\beta)^*=\sqrt{2}\mathbb{I}\neq\Lambda(V_\beta^*)=\frac{1}{\sqrt{2}}\,\mathbb{I},$$

so $V_\beta\notin\mathscr{O}_{\mathscr{T}^{(t_0)}}$.

Another possible reason one may want to use to justify the enforcement of secondary quantum constraints, is to produce a common dense invariant domain $\kappa(S)$ for the observables $\mathscr{R}_S$. However, for the choice $S=\mathscr{T}^{(t)}$ there is no reason why the Hamiltonian H_Γ should preserve $\kappa(\mathscr{T}^{(t)})$, so it will be unreasonable to require the observables to do so. So at this stage we fail to see why secondary quantum constraints should be imposed on the observables.

(4) It is interesting to observe that for any Hilbert space operator $K:\mathscr{H}_1\to\mathscr{H}_2$ with dense range, we can obtain the structure above. That is, given a dense space $S\subseteq\mathrm{dom}\,K$ for which $K(S)$

is dense in $\mathscr{H}_2$, we can define $\mathscr{T}_S$, $\mathscr{O}_S$, $\mathscr{D}_S$, $\mathscr{R}_S$ exactly as before by replacing $\mathscr{T}$ with $\mathscr{B}(\mathscr{H}_1)$, and κ by K. So every such operator K and space S defines a lifting problem, hence, a short exact sequence of $*$ algebras,

$$0\to\mathscr{D}_S\to\mathscr{O}_S\to\mathscr{R}_S\to 0.$$

This then produces a similar short exact sequence for the automorphism groups and their lifting through the factorization. In particular, for ordinary Dirac constraining, the operator K is the projection $P_{\text{phys}}:\mathscr{H}\to\mathscr{H}_{\text{phys}}$, the space S is $\mathscr{H}$, and $\mathscr{A}_S\cap\mathscr{T}_S$ is just $\mathscr{A}$, where $\mathscr{A}$ denotes either $\mathscr{O}$ or $\mathscr{D}$. This way of thinking nicely unifies the current construction (where $K=\kappa$) with that of the Dirac approach. The main difference is that P_{phys} is bounded while κ is unbounded and nonclosable.

VI. CONSTRAINING BY A GENERAL SELF-ADJOINT OPERATOR

For later reference, we start by summarizing the constraining algorithm developed in the preceding sections. Assume the following data: operators $\hat{\mathbf{p}}$, $\hat{\mathbf{q}}$, and H on $C_c^\infty(\mathbb{R}^n)\subset L^2(\mathbb{R}^n)$, a bounded $\varphi\in C^\infty(\mathbb{R}^n)$ such that $\Gamma=\varphi^{-1}(0)$ is a smooth $(n-1)$-dimensional submanifold, and, moreover, $\nabla\varphi$ is bounded and nonzero on a neighborhood of Γ and a unital field algebra $\mathscr{T}\subset\mathscr{B}(L^2(\mathbb{R}^n))$ containing $\hat{\varphi}$, $\exp i\hat{\mathbf{p}}\cdot\mathbf{a}$, $\exp i\hat{\mathbf{q}}\cdot\mathbf{a}$.

(1) Define $(\psi_1,\psi_2)_\Gamma:=\lim_{t\to 0}(1/2t)(\psi_1,\hat{h}P_t\psi_2)$, $\forall\psi_i\in C_\varphi(\mathbb{R}^n)$, $L^2(\Gamma)=[C_\varphi(\mathbb{R}^n)/\mathrm{Ker}(\cdot,\cdot)_\Gamma]^{-(\cdot,\cdot)_\Gamma}$, $\kappa:C_\varphi\to L^2(\Gamma)$ is the factorization map, and $L^2(\Gamma)$ is the constrained space.

(2) Let $\mathscr{T}_{t_0}:=\mathscr{H}_{t_0}^{\zeta}\cap C_\varphi\cap\mathrm{Dom}\,H$, check that $H\mathscr{T}_{t_0}\subset C_\varphi$ for t_0 small enough, and if so, define the constrained Hamiltonian H_Γ by $H_\Gamma\cdot\kappa(\psi):=\kappa(H\psi)$ for all $\psi\in\mathscr{T}_{t_0}$.

(3) Choose a space S in $\mathscr{H}$ for which $\kappa(S)$ is dense (e.g., C_φ), and define

$$\mathscr{T}_S=\{A\in\mathscr{T}\mid AS\subseteq S\supseteq A^*S\},$$

$$\mathscr{O}_S=\{A\in\mathscr{T}_S\mid(A\psi,A\psi)_\Gamma\leqslant M_A(\psi,\psi)_\Gamma\geqslant(A^*\psi,A^*\psi)_\Gamma,\quad\Lambda(A^*)\subseteq\Lambda(A)^*\},$$

where $\Lambda(A)$ denotes the closure of the operator defined by

$$\Lambda(A)\kappa(\psi)=\kappa(A\psi),\quad\forall\psi\in S.$$

Define $\mathscr{D}_S:=\{A\in\mathscr{O}_S\mid AS\subseteq\mathrm{Ker}\,\kappa\supseteq A^*S\}$; then $\Lambda(\mathscr{O}_S)\cong\mathscr{O}_S/\mathscr{D}_S=:\mathscr{R}_S$, and the algebra of the constrained observables on $L^2(\Gamma)$ is the C^* algebra generated by $\mathscr{R}_S$ and $\exp(i\mathbb{R}H_\Gamma)$.

In this section we want to generalize the method above to impose a constraint ''$C\psi=0$,'' where C is a general bounded self-adjoint operator on a Hilbert space $\mathscr{H}$ with zero in its continuous spectrum. [If we start with an unbounded self-adjoint operator C, we can, without loss of generality, convert the problem to a bounded one by replacing C with $f(C)$, where f is a continuous bounded real-valued function with $f(x)=x$ on a neighborhood of zero.] As before, we still assume that there is a unital field algebra $\mathscr{T}$ acting on $\mathscr{H}$, containing C, and that there is also a (possibly unbounded) Hamiltonian H given on $\mathscr{H}$, $\exp(itH)\in\mathscr{T}$ for all t. We will be concerned with the construction of three objects: the constrained Hilbert space (and the constraining map to it from the original space), the constrained Hamiltonian, and the algebra of constrained observables.

At the abstract C^* level, the kinematics part has already been solved,[9] but one obtained the set of all representations in which the constraint can be imposed as an eigenvalue condition. Here we want to build a particular concrete constrained system out of the given unconstrained one.

Now geometry was paramount in the analysis of the previous sections, in that we needed a metric (on an underlying space) to define gradients, norms of vectors, normals to surfaces and the Lebesgue measure. This vital piece of information is missing in the problem under consideration, and we somehow need to augment the given data $\{\mathscr{T},\mathscr{H},H,C\}$ in order to adapt the method previously found to this problem. The extra information we will assume is the following.

(i) A maximally commutative C^* algebra $\mathscr{A}\subset\mathscr{B}(\mathscr{H})$ containing C.

[Call $\mathscr{A}$ a *polarization*, and we know that it always has a cyclic and separating vector (Ref. 28, Proposition 2.5.3.]

(ii) A choice of a cyclic and separating vector Ω for $\mathscr{A}$. (Call Ω the vacuum.)

(iii) A choice of scaling operator $K\in\mathscr{A}_+$, Ker $K=\{0\}$.

(iv) A self-adjoint operator $\mathscr{P}_C$ such that $[\mathscr{P}_C,C]\psi=i\psi$ for all $\psi\in\mathscr{D}\equiv$ a dense invariant subspace of $P_{t_0}\mathscr{H}$, where P_t denotes the spectral projection of C of the interval $[-t,t]$. This is thought of as a ''local'' canonical momentum for C, which will define the normal direction to the constrained system.

Now define the space $\mathscr{L}:=\{A\in\mathscr{A}\mid \omega_0(A) \text{ exist}\}$, where

$$\omega_0(A):=\lim_{t\to 0}\frac{(P_t\Omega,\ AP_t\Omega)}{\|P_t\Omega\|^2}.$$

Since obviously $\mathbb{I}$ and $C\in\mathscr{L}$, this space is not zero. Moreover, the space is self-adjoint, and we also have that $|\omega_0(A)|\leqslant\|A\|$ for all $A\in\mathscr{L}$ because $|(P_t\Omega,\ AP_t\Omega)/\|P_t\Omega\|^2|\leqslant\|A\|$, and so ω_0 extends to the closure of $\mathscr{L}$. Now since ω_0 is obviously positive on the positive elements of $\mathscr{L}$, we can apply Ref. 29, Theorem 4.3.13 to conclude that ω_0 extends to a state on $\mathscr{A}$. Henceforth we fix a choice of extension and still denote it by ω_0.

Denote the GNS representation of ω_0 by $(\pi_0,\Omega_0,\mathscr{H}_0)$. Noting that $\omega_0(K)>0$, we define a state ω_K on $\mathscr{A}$ by

$$\omega_K(A):=\omega_0(KA)/\omega_0(K),\quad A\in\mathscr{A}.$$

Then, inspired by the following lemma and subsequent example, we identify the constrained Hilbert space with $\mathscr{H}_{\omega_K}$.

Lemma 6.1: ω_K is a ''Dirac state'' in the sense that $\omega_K(AC)=0$ for all $A\in\mathscr{A}$, i.e., $\pi_{\omega_K}(C)\Omega_{\omega_K}=0$.

Proof: It suffices to show that $\omega_K(C^2)=0$, since C is self-adjoint. So

$$\frac{\omega_0(KC^2)}{\omega_0(K)}=\lim_{t\to 0}\frac{(P_t\Omega,\ KC^2P_t\Omega)}{\|P_t\Omega\|^2\omega_0(K)}.$$

Now using the spectral decomposition $C=\int\lambda\,dP(\lambda)$, we have

$$\begin{aligned}|(KP_t\Omega,\ P_tC^2\Omega)|&\leqslant\|KC\|\cdot\|P_t\Omega\|\cdot\|P_tC\Omega\|\\&=\|KC\|\cdot\|P_t\Omega\|\cdot\left\|\int_{-t}^{t}\lambda\,dP(\lambda)\Omega\right\|\\&\leqslant\|KC\|\cdot\|P_t\Omega\|\cdot t\left\|\int_{-t}^{t}dP(\lambda)\Omega\right\|=t\|KC\|\cdot\|P_t\Omega\|^2.\end{aligned}$$

Hence $|\omega_K(C^2)|\leqslant[1/\omega_0(K)]\lim_{t\to 0}\ t\|KC\|=0$. ■

Remark: The proof above is easily adapted to show that ω_0 is also a Dirac state on $\mathscr{A}$. More precisely, we have for the left kernels that $N_{\omega_0}=N_{\omega_K}$ due to Ker $K=\{0\}$ and the fact that $\mathscr{A}$ is commutative. Hence we have an identification map $\theta:\mathscr{A}/N_{\omega_0}\to\mathscr{A}/N_{\omega_K}$ by $\theta(A+N_{\omega_0})=A+N_{\omega_K}$ and θ extends to a map $\theta:\mathscr{H}_{\omega_0}\to\mathscr{H}_{\omega_K}$ because

$$\begin{aligned}\|\theta(A+N_{\omega_0})\|_{\mathscr{H}_{\omega_K}}&=\omega_K(\theta(A+N_{\omega_0})^*\theta(A+N_{\omega_0}))^{1/2}\\&=\omega_K(A^*A)^{1/2}=\omega_0(KA^*A)^{1/2}\\&\leqslant\|K\|\cdot\omega_0(A^*A)^{1/2}=\|K\|\cdot\|A+N_{\omega_0}\|_{\mathscr{H}_0}.\end{aligned}$$

To define a constraining map $\kappa:\mathscr{H}\to\mathscr{H}_{\omega_K}$ from the unconstrained to the constrained space, recall that Ω separates $\mathscr{A}$; hence the map

$$\kappa(A\Omega):=\pi_{\omega_K}(A)\Omega_{\omega_K},\quad A\in\mathscr{A},$$

is well defined on the dense subspace $\mathscr{A}\Omega$ with a dense range. This will be our choice of constraining map for this context. Since $\|\kappa(A\Omega)\|^2=\omega_K(A^*A)$, we see that Ker $\kappa=N_{\omega_K}\Omega=N_{\omega_0}\Omega$.

Example: To motivate the preceding structures, and to see what is involved in the choices of $\mathscr{A}$, Ω, K, we now reconsider the constraint situation $\hat{\varphi}$, $L^2(\mathbb{R}^n)$ of the preceding sections.

Starting with $\hat{\varphi}=\varphi(\hat{\mathbf{q}})$, the natural choice of polarization is $\mathscr{A}:=\{f(\hat{\mathbf{q}})|f\in L^\infty(\mathbb{R}^n)\}=\{\exp(i\hat{\mathbf{q}}\cdot\mathbf{a})|\mathbf{a}\in\mathbb{R}^n\}''$, and for Ω we can then choose any positive nowhere vanishing L^2 function. Choose the Gaussian $\Omega(\mathbf{x})=\exp(-a|\mathbf{x}|^2)$, $a>0$ and note that $C_c(\mathbb{R}^n)=C_c(\mathbb{R}^n)\Omega$, hence $C_c(\mathbb{R}^n)\subset\mathscr{A}\Omega$. Now for K we must have $K\in\mathscr{A}_+$, so $K=k(\hat{\mathbf{q}})$ for some $k\in L^\infty_+(\mathbb{R}^n)$, $k^{-1}(0)=\varnothing$. For the moment we will choose k to be continuous, and then below deduce the precise choice that will correspond with the previous results for this situation. In particular, what we want to show is that

$$(\kappa(A\Omega),\kappa(B\Omega))_{\mathscr{H}_{\omega_K}}=b((A\Omega\restriction\Gamma),(B\Omega\restriction\Gamma))_{L^2(\Gamma)}, \qquad (*)$$

for all A, $B\in C_c(\mathbb{R}^n)$ for the right choice of K, where κ is the map defined in this section and b is a normalizing constant. Now

$$(\kappa(A\Omega),\kappa(B\Omega))_{\mathscr{H}_{\omega_K}}=\omega_K(A^*B)=\lim_{t\to 0}\frac{(A\Omega,KP_tB\Omega)}{\|P_t\Omega\|^2\omega_0(K)},$$

whenever $A^*B\in\mathscr{L}$ [which we will see below is all $C_c(\mathbb{R}^n)$], so if we write $A=f_A(\hat{\mathbf{q}})$, $B=f_B(\hat{\mathbf{q}})$ with f_A, $f_B\in C_c(\mathbb{R}^n)$ and remember that

$$(P_t\psi)(\mathbf{x})=\chi_{\varphi^{-1}[-t,t]}(\mathbf{x})\cdot\psi(\mathbf{x}),$$

we have

$$\frac{(A\Omega,\ KP_tB\Omega)}{\|P_t\Omega\|^2}=\frac{\int_{\varphi^{-1}[-t,t]}\overline{f_A}(\mathbf{x})k(\mathbf{x})f_B(\mathbf{x})\ \exp(-2a|\mathbf{x}|^2)d\mu(\mathbf{x})}{\int_{\varphi^{-1}[-t,t]}\exp(-2a|\mathbf{x}|^2)d\mu(\mathbf{x})}.$$

Now, recall that for $f\in C_c(\mathbb{R}^n)$ and small t, we have for a patch $U\cap\varphi^{-1}[-t,t]$ with local coordinates

$$\int_{U\cap\varphi^{-1}[-t,t]}f(\mathbf{x})d\mu(\mathbf{x})=\int_{-t}^{t}\left(\int\frac{f(\mathbf{y},\varphi)}{|\boldsymbol{\nabla}\varphi(\mathbf{y},\varphi)|}\,d\gamma_\varphi(\mathbf{y})\right)d\varphi$$
$$=2t\int_{U\cap\Gamma}\frac{f(\mathbf{y},0)}{|\nabla(\mathbf{y},0)|}\,d\gamma(\mathbf{y})+O(t)=2t\int_{U\cap\Gamma}(f/|\boldsymbol{\nabla}\varphi|)\restriction\Gamma\ d\gamma+O(t).$$

Thus

$$(\kappa(A\Omega),\kappa(B\Omega))_{\mathscr{H}_{\omega_K}}=\lim_{t\to 0}\frac{(A\Omega,\ KP_tB\Omega)}{\|P_t\Omega\|^2\omega_0(K)}=\frac{\int_\Gamma(\overline{f_A}kf_Be/|\boldsymbol{\nabla}\varphi|)\restriction\Gamma\ d\gamma}{\omega_0(K)\int_\Gamma(e/|\boldsymbol{\nabla}\varphi|)\restriction\Gamma\ d\gamma},$$

where e denotes the function $\exp(-2a|\mathbf{x}|^2)$. Now, since by a similar argument

$$\omega_0(K)=\lim_{t\to 0}\frac{(P_t\Omega,\ KP_t\Omega)}{\|P_t\Omega\|^2}=\frac{\int_\Gamma(ke/|\boldsymbol{\nabla}\varphi|)\restriction\Gamma\ d\gamma}{\int_\Gamma(e/|\boldsymbol{\nabla}\varphi|)\restriction\Gamma\ d\gamma}$$

[the existence of this limit shows $\mathscr{L}\supseteq C_c(\mathbb{R}^n)$], we have

$$(\kappa(A\Omega),\kappa(B\Omega))_{\mathscr{H}_{\omega_K}}=\frac{\int_\Gamma(\overline{f_A}kf_Be/|\nabla\varphi|)\restriction\Gamma\ d\gamma}{\int_\Gamma(ke/|\nabla\varphi|)\restriction\Gamma\ d\gamma}$$

$$=\frac{\int_\Gamma(\overline{f_A}f_Be)\restriction\Gamma\ d\gamma}{\int_\Gamma e\restriction\Gamma\ d\gamma}=\frac{((A\Omega\restriction\Gamma),(B\Omega\restriction\Gamma))_{L^2(\Gamma)}}{\|\Omega\restriction\Gamma\|^2_{L^2(\Gamma)}}$$

(where we made the choice $k=|\nabla\varphi|$), which is just the normalized inner product of $L^2(\Gamma)$, and this will produce the same κ that we had before.

If there is also a group of symmetries that needs to be unitarily implemented on the constrained Hilbert space $\mathscr{H}_{\omega_K}$, we can use this unitarity to determine K.

So now that we have the constraining map $\kappa:\mathscr{H}\to\mathscr{H}_{\omega_K}$ as above, we can proceed to constrain the dynamics. This is where we will use the assumed operator $\mathscr{P}_C$ in the role of the ''normal derivative $i(\partial/\partial\varphi)$ near Γ.'' Thus, start by selecting a space of transverse states by

$$\mathscr{H}^T_t:=\overline{\{P_t\psi\mid\psi\in\mathrm{Dom}\ \mathscr{P}_C,\ P_t\mathscr{P}_C\psi=0\}}$$

and

$$\mathscr{T}_t:=\{\psi\in\mathrm{Dom}\ H\mid P_t\psi\in\mathscr{H}^T_t\},$$

and note that $\mathscr{T}_t\subset\mathscr{T}_s$ if $t>s$. For a consistent constraining we need to assume there is a $t_0>0$ such that the set $\mathscr{S}_{t_0}:=\{\psi\in\mathscr{T}_{t_0}\mid H\psi\in\mathscr{A}\Omega\}$ satisfies $\mathrm{Ker}\ \kappa\cap\mathscr{S}_{t_0}=\{0\}$ and $\kappa(\mathscr{S}_{t_0})$ is dense in $\mathscr{H}_{\omega_K}$. Given this, we define the constrained Hamiltonian H_C on domain $\kappa(\mathscr{S}_{t_0})$ to be

$$H_C\cdot\kappa(\psi):=\kappa(H\psi),\quad\forall\psi\in\mathscr{S}_{t_0}.$$

Example: Continue the previous example with $C=\hat{\varphi}$ and the choice $K=|\nabla\varphi|$. Choose

$$\mathscr{P}_{\hat{\varphi}}\psi:=if(\varphi)\frac{\partial}{\partial\varphi}\psi,\quad\forall\psi\in C^\infty_c(\mathbb{R}^n),$$

where f is a smooth bump function that is unity on $[-t_0,t_0]$ and zero outside $[-t_0-\epsilon,\ t_0+\epsilon]$ for some $\epsilon>0$. Then

$$\mathscr{H}^T_{t_0}=\{\psi\in\mathscr{H}\mid\mathrm{supp}\ \psi\subset\varphi^{-1}([-t_0,t_0]),\quad\psi(\mathbf{y},\varphi)\ \text{independent of}\ \varphi\ \text{on}\ \varphi^{-1}[-\mathrm{t}_0,\mathrm{t}_0]\}.$$

If H is a differential operator with domain $C^\infty_c(\mathbb{R}^n)$, we have

$$\mathscr{T}_{t_0}=\{\psi\in C^\infty_c(\mathbb{R}^n)\mid\psi\restriction\varphi^{-1}((-t_0,t_0))\ \text{is constant in the direction}\ \nabla\varphi\}.$$

Since $\mathscr{H}^\zeta_{t_0}\cap C^\infty_c(\mathbb{R}^n)\subset\mathscr{T}_{t_0}$, we conclude that

$$H_{\hat{\varphi}}\kappa(\psi)=\kappa(H\psi),\quad\forall\psi\in\mathscr{T}_{t_0}$$

defines the same operator as before in Sec. IV.

Finally, to obtain the constrained kinematics as in Sec. V, let $S\subseteq\mathscr{A}\Omega$ be a subspace such that $\kappa(S)$ is dense in $\mathscr{H}_{\omega_K}$. Define, in complete analogy with Sec. V,

$$\mathscr{T}_S:=\{A\in\mathscr{T}\mid A\psi\in S\ni A^*\psi,\quad\forall\psi\in S\}$$

$$\mathscr{O}_S:=\{A\in\mathscr{T}_S\mid(A\psi,A\psi)_K\leqslant M_A\cdot(\psi,\psi)_K\geqslant(A^*\psi,A^*\psi)_K,\quad\forall\psi\in S,$$

$$M_A<\infty\quad\text{and}\ \Lambda(A^*)\subseteq\Lambda(A)^*\},$$

$$\mathscr{D}_S:=\{A\in\mathscr{O}_S\mid AS\subseteq\mathrm{Ker}\ \kappa\supseteq A^*S\},$$

where $\Lambda(A)\kappa(\psi):=\kappa(A\psi),\ \forall\psi\in S,\ A\in\mathscr{O}_S$.

The previous proofs carry over verbatim, so $\mathscr{D}_S = \mathrm{Ker}(\Lambda \restriction \mathscr{O}_S)$ and the algebra of observables acting on $\mathscr{H}_{\omega_K}$ is the C^* algebra generated by $\exp i\mathbb{R}H_C$ and

$$\mathscr{R}_S := \mathscr{O}_S / \mathscr{D}_S \cong \Lambda(\mathscr{O}_S) \subset \mathscr{B}(\mathscr{H}_{\omega_K}).$$

Example: In a continuation of the last example, it is obvious that if we take $\mathscr{F} = C_b(\mathbb{R}^n) \rtimes \mathrm{Diff}\ \mathbb{R}^n$ and $S = C_c(\mathbb{R}^n)$, then we will get the same observable algebra as before.

Remark: Another way to proceed could have been to extend the Dirac state ω_K on $\mathscr{A}$ to $\mathscr{F}$. However, this would have enlarged the GNS space (producing a wrong result for the example of this paper), and, in addition, there is the problem that the extension need not be unique.

VII. CONCLUSIONS AND DISCUSSION

To summarize, we took the problem of restricting a quantum particle in $\mathbb{R}^n$ to a lower-dimensional submanifold not conserved by the dynamics. We found a method to do the restriction, and this came in three parts—a map κ from a dense subspace of $L^2(\mathbb{R}^n)$ to the constrained Hilbert space $L^2(\Gamma)$, a method for constructing the constrained Hamiltonian from the unconstrained one, and a method for the construction of the algebra of observables $\mathscr{R}_\Gamma$ on $L^2(\Gamma)$. For each of these three parts there were choices to be made. For the first part we had to choose a domain for κ [$C_c(\mathbb{R}^n)$ and C_φ seem the canonical choices], for the second part the transverse space [here tangentiality of momentum to the level sets of φ near Γ seems to be the physically justified criterion], and for the third part the space S on which to reduce the observables [likely choices here are $C_c(\mathbb{R}^n)$, C_φ, or the transverse space used]. We regard these choices to be made as physical ones, and in the two examples, the choices made were evident, and produced results in agreement with the known solutions. The necessity of these choices should be compared with the choice of boundary conditions required in the constraining of a free quantum particle to a box.

There are mathematical pathologies associated with our proposed method, of which the central one is that the map κ is neither bounded nor even closable. As a consequence, the constraining of observables need not preserve boundedness or involution, so we had to restrict the method to those observables for which these pathologies do not occur. The method is also sensitive with respect to the original choice of field algebra, and may not provide enough observables for some choices.

While this method was developed in analogy with the classical constraint method, the analogy became quite vague at certain points, for instance, one can interpret the necessity for a choice of transverse space as an imposition of a secondary constraint, but this constraint could not be interpreted as obtained from a similar method as the classical one. Moreover, secondary constraints do not seem to be necessary for the constraining of the observables.

We expect from our work in Ref. 9 that the pathologies that occurred here can be circumvented by a suitable generalization to a C^*-algebra framework, insofar as the T procedure solves already without pathology the kinematics part of the question there; but this would involve losing the original representation, which may contain some physical information. The advantage of the current method is that it constructs the constrained system concretely from the given representation of the original system. Nevertheless, we intend to further pursue this line of thought.

de Rham cohomology of SO(n) and some related manifolds by supersymmetric quantum mechanics

Kazuto Oshima
Gunma College of Technology, Maebashi 371-8530, Japan

(Received 11 February 1998; accepted for publication 17 March 1998)

We study supersymmetric quantum mechanics on RP_n, $\mathrm{SO}(n)$, G_2, and $\mathrm{U}(2)$ to examine Witten's Morse theory concretely. We confirm the simple instanton picture of the de Rham cohomology that has been given in a previous paper. We use a reflection symmetry of each theory to select the true vacuums. The number of selected vacuums agrees with the de Rham cohomology for each of the above manifolds. © *1998 American Institute of Physics.* [S0022-2488(98)03206-X]

I. INTRODUCTION

In a previous paper,[1] the author has investigated Witten's Morse theory[2] for $\mathrm{SO}(n)$.[3] Instanton effects between adjacent classical vacuums have been studied. Using reflection symmetries of the theory, a selection rule for true vacuums has been given. This selection rule works well, at least for $n \leqslant 5$;[1] the number of selected vacuums agrees with the de Rham cohomology of $\mathrm{SO}(n)$. The main purpose of this paper is to show that the selection rule works well for arbitrary n. We also apply the selection rule to some related manifolds RP_n, G_2, and $\mathrm{U}(2)$; $\mathrm{RP}_1 \simeq \mathrm{SO}(2)$, $\mathrm{RP}_3 \simeq \mathrm{SO}(3)$, $\mathrm{G}_2 \subset \mathrm{O}(7)$, and $\mathrm{U}(2) \simeq \mathrm{SO}(2) \times \mathrm{SU}(2)$.

This paper is organized as follows: In Sec. II we review supersymmetric quantum mechanics on a manifold M. The selection rule for true vacuums is stated in this section. The manifold RP_n are studied in the third section. The manifold RP_n is simple, and this section will be helpful to understand the following sections. In Sec. IV the de Rham cohomology of $\mathrm{SO}(n)$ is derived for arbitrary n by the selection rule. The manifolds G_2 and $\mathrm{U}(2)$ are discussed in Secs. V and VI, respectively. The results are summarized in the last section.

II. SUPERSYMMETRIC QUANTUM MECHANICS ON A MANIFOLD

The supersymmetric Hamiltonian on a manifold with Morse function h is given by

$$\hat{H} = \tfrac{1}{2}(d_h d_h^\dagger + d_h^\dagger d_h), \tag{1}$$

where $d_h = e^{-h} d e^h$, $d_h^\dagger = e^h d^\dagger e^{-h}$, d is the exterior derivative, and $d^\dagger$ is its adjoint operator. In (any) coordinates $\{x^\mu\}$, the exterior multiplication e_{dx^μ} and the interior multiplication $i\partial/\partial x^\mu$ can be identified with the fermion creation operator $\hat{\psi}^{*\mu}$ and the annihilation operator $\hat{\psi}_\mu$, and we have

$$d = \hat{\psi}^{*\mu} \boldsymbol{\nabla}_\mu, \quad d^\dagger = g^{-1/2} \boldsymbol{\nabla}_\mu g^{1/2} g^{\mu\nu} \hat{\psi}_\nu, \tag{2}$$

where g is the determinant of the metric tensor $g_{\mu\nu}$ and $\boldsymbol{\nabla}_\mu$ is the covariant derivative,

$$\boldsymbol{\nabla}_\mu = \frac{\partial}{\partial x^\mu} - \Gamma^\lambda_{\mu\nu} \hat{\psi}^{*\nu} \hat{\psi}_\lambda . \tag{3}$$

The Hamiltonian $\hat{H}$ (1) takes the form

$$2\hat{H} = -g^{-1/2} \boldsymbol{\nabla}_\mu g^{1/2} g^{\mu\nu} \boldsymbol{\nabla}_\nu + R_{\mu\nu\sigma\tau} \hat{\psi}^\sigma \hat{\psi}^{*\tau} \hat{\psi}^{*\nu} \hat{\psi}^\mu + g^{\mu\nu} \frac{\partial h}{\partial x^\mu} \frac{\partial h}{\partial x^\nu} + H_{\mu\nu}[\hat{\psi}^{*\mu}, \hat{\psi}^\nu], \tag{4}$$

where $R_{\mu\nu\sigma\tau}$ is the Riemann tensor, and $H_{\mu\nu}$ is the Hessian matrix,

 © 1998 American Institute of Physics

$$H_{\mu\nu}=(\partial_\mu\partial_\nu-\Gamma^\lambda_{\mu\nu}\partial_\lambda)h. \tag{5}$$

The corresponding Lagrangian is

$$\mathscr{L}=\frac{1}{2}\,g_{\mu\nu}\,\frac{dx^\mu}{dt}\,\frac{dx^\nu}{dt}+\frac{1}{2}\,g^{\mu\nu}\,\frac{\partial h}{\partial x^\mu}\,\frac{\partial h}{\partial x^\nu}+\psi^{*\mu}\left(\frac{d}{dt}\,\psi_\mu-\Gamma^\lambda_{\mu\nu}\psi_\lambda\,\frac{dx^\nu}{dt}\right)$$
$$+H_{\mu\nu}\psi^{*\nu}\psi^\mu+\tfrac{1}{4}\,R_{\mu\nu\sigma\tau}\psi^\mu\psi^\nu\psi^{*\sigma}\psi^{*\tau}. \tag{6}$$

The gradient flow equation of (6) is

$$\frac{dx^\mu}{dt}=\pm g^{\mu\nu}\,\frac{\partial h}{\partial x^\nu}. \tag{7}$$

A relevant instanton solution satisfies (7) and connects adjacent critical points.

There is one classical vacuum for each critical point of h.[2] Around each critical point, h has the expansion

$$h=h_0+\sum_i\,\lambda_i\xi_i^2, \tag{8}$$

where λ_i are eigenvalues of the Hessian matrix and ξ_i are the corresponding local coordinates. The classical vacuum around a critical point corresponds to an l form:

$$|l\rangle=\prod_{\lambda_i<0}\,\hat{\psi}^*_{\xi_i}|0\rangle, \tag{9}$$

where l represents the number of the excited fermions (the negative eigenvalues) and $|0\rangle$ is the bosonic vacuum.

The true vacuums are determined by the quantum tunneling between adjacent classical vacuums (9). According to Witten,[2] one has

$$\langle l+1|d_h|l\rangle=\sum_\gamma\,n_\gamma e^{-(h(P^{(l+1)})-h(P^{(l)}))}, \tag{10}$$

where n_γ is an integer assigned for each instanton path γ from $P^{(l)}$ to $P^{(l+1)}$. If a state $|l\rangle$ does not couple with any adjacent classical vacuums, that is, if $d_h|l\rangle=0$ and $\langle l|d_h=0$, $|l\rangle$ is a true vacuum.

If there are plural instanton paths connecting a pair of adjacent critical points, it is not so easy to determine whether the matrix element (10) is zero or not, because of the notorious minus signs associated with fermions. In fact, for SO(n), there are exactly two instanton solutions between each pair of adjacent classical vacuum.[1] The selection rule given in Ref. 1 is as follows. Find a reflection transformation that leaves $h, d_h, d_h^\dagger$, and, consequently, $\hat{H}$ invariant, and that interchanges the two instanton paths. If the parities of a pair of adjacent classical vacuums are the same, the corresponding matrix element does not vanish, and the two classical vacuums are not true vacuums. If the parities of the two classical vacuums are different, the corresponding matrix element vanishes, and the two classical vacuums can be true vacuums. Repeat this for each pair of adjacent classical vacuums, and one obtains all true vacuums.

In the following sections, we apply this selection rule to SO(n) and some related manifolds. We see that the number of true vacuums agrees with the de Rham cohomology for each manifold.

III. RP_n

In this section, we discuss the real projective space RP_n, which is very simple but nontrivial. The manifold RP_n can be identified with $(n+1)\times(n+1)$ real matrices A with conditions $A^t=A$, $A^2=A$, and tr $A=1$.[4] Concretely, we have

$$A=(x_ix_j),\quad i,j=0,1,2,...,n, \tag{11}$$

where $\Sigma_{i=1}^{n} x_i^2 \leqslant 1$ and $x_0 = \sqrt{1-\Sigma_{i=1}^{n} x_i^2}$. Let us introduce the following polar coordinates:

$$x_1 = \sin\ \theta_1\ \cos\ \theta_2,$$

$$x_2 = \sin\ \theta_1\ \sin\ \theta_2\ \cos\ \theta_3,$$

$$\vdots$$

$$x_{n-2} = \sin\ \theta_1\ \sin\ \theta_2 \cdots \sin\ \theta_{n-2}\ \cos\ \theta_{n-1},$$

$$x_{n-1} = \sin\ \theta_1\ \sin\ \theta_2 \cdots \sin\ \theta_{n-2}\ \sin\ \theta_{n-1}\ \cos\ \theta_n,$$

$$x_n = \sin\ \theta_1\ \sin\ \theta_2 \cdots \sin\ \theta_{n-2}\ \sin\ \theta_{n-1}\ \sin\ \theta_n, \tag{12}$$

with $-\pi/2 \leqslant \theta_i \leqslant \pi/2$.

Fix real numbers $c_0, c_1, \ldots, c_n$ with $c_{i+1} > 2c_i > 0$. Then

$$h = \sum_{i=0}^{n} c_i x_i^2 \tag{13}$$

is a Morse function on RP_n[4] with critical points $P^{(l)}$,

$$P^{(l)} = \mathrm{diag}(0,0,\ldots,0,x_l^2 = 1,0,\ldots,0). \tag{14}$$

Around $P^{(l)}$, h has the expansion

$$h = (c_0 - c_l)(x_0 x_l)^2 + \cdots + (c_{l-1} - c_l)(x_{l-1} x_l)^2 + c_l + (c_{l+1} - c_l)(x_{l+1} x_l)^2 + \cdots + (c_n - c_l)(x_n x_l)^2. \tag{15}$$

The classical vacuum around $P^{(l)}$ is an l fermions excited state,

$$|l\rangle = \hat{\psi}_{0l}^* \hat{\psi}_{1l}^* \cdots \hat{\psi}_{l-1l}^* |0\rangle, \tag{16}$$

where $\hat{\psi}_{ij}^*$ is the fermionic mode corresponding to $x_i x_j$.

We introduce a metric on RP_n and find reflection symmetries of the theory and instanton solutions concretely. We introduce the following metric:

$$g_{ij} = \frac{1}{2}\ \mathrm{tr}\ \frac{\partial A^t}{\partial \theta_i}\ \frac{\partial A}{\partial \theta_j}. \tag{17}$$

The nonzero components of g_{ij} and Christoffel symbols are

$$\begin{gathered} g_{11} = 1, \quad g_{ii} = \sin^2\ \theta_1\ \sin^2\ \theta_2 \cdots \sin^2\ \theta_{i-1}, \quad i = 2,\ldots,n, \\ \Gamma_{ij}^{j} = \cot\ \theta_i, \quad i = 1,\ldots,n-1, \quad j = i+1,\ldots,n. \end{gathered} \tag{18}$$

The Morse function h (13), the metric g_{ij} and the corresponding supercharge,

$$d = \hat{\psi}^{*i} \nabla_i = \hat{\psi}^{*i} \left(\frac{\partial}{\partial \theta_i} - \cot\ \theta_i \sum_{j=i+1}^{n}\ \hat{\psi}^{*j} \hat{\psi}_j \right), \tag{19}$$

are invariant under the following transformations:

$$[i]: \quad \theta_i, \hat{\psi}^{*i}, \hat{\psi}_i \to -\theta_i, -\hat{\psi}^{*i}, -\hat{\psi}_i, \quad i = 1,\ldots,n. \tag{20}$$

Subsequently, the theory is invariant under these reflection transformations. Under the transformation $[i]$, x_j transform to $-x_j$ if $j \geqslant i$, and x_j are invariant if $j < i$. The fermionic modes $\hat{\psi}_{jk}^*$ have the same transformation properties as $x_j x_k$.

From the gradient flow equation (6), we have

$$\begin{aligned}\frac{d\theta_i}{dt}&=(c_0-c_{i-1}+(c_i-c_0)\cos^2\ \theta_{i+1}+(c_{i+1}-c_0)\sin^2\ \theta_{i+1}\ \cos^2\ \theta_{i+2}\\&\quad+\cdots+(c_n-c_0)\sin^2\ \theta_{i+1}\ \sin^2\ \theta_{i+2}\cdots\sin^2\ \theta_n)\sin 2\theta_i\,,\quad i=1,...,n-1,\\\frac{d\theta_n}{dt}&=(c_n-c_{n-1})\sin 2\theta_n\,.\end{aligned}\tag{21}$$

One finds that there are exactly a pair of instanton paths that connect $|l-1\rangle$ and $|l\rangle$ (16),

$$A=\begin{matrix}\\ l-1\\ l\end{matrix}\begin{matrix}\begin{matrix}\quad l-1 & \quad l\end{matrix}\\ \begin{pmatrix} 0 & & & & & & & \\ & \ddots & & & & & & \\ & & 0 & & & & & \\ & & & \cos^2\ \theta_l & \pm\sin\ \theta_l\ \cos\ \theta_l & & & \\ & & & \pm\sin\ \theta_l\ \cos\ \theta_l & \sin^2\ \theta_l & & & \\ & & & & & 0 & & \\ & & & & & & \ddots & \\ & & & & & & & 0\end{pmatrix}\end{matrix},\tag{22}$$

where $0\leqslant\theta_l\leqslant\pi/2$. Each of these two instanton solutions causes a nonzero instanton effect between $|l-1\rangle$ and $|l\rangle$.

Let us consider the transformation $[l]$. This transformation interchanges the two instanton paths. Under this transformation the two classical vacuums transform as

$$|l-1\rangle\to|l-1\rangle,\quad |l\rangle\to(-1)^l|l\rangle.\tag{23}$$

Thus, if l is even, the two classical vacuums $|l-1\rangle$ and $|l\rangle$ have the same parities, which means that the classical vacuums $|l-1\rangle$ and $|l\rangle$ are quantum mechanically coupled, and are not true vacuums.[1] If l is odd, the two classical vacuums $|l-1\rangle$ and $|l\rangle$ have the opposite parities and the two instanton effects cancel each other.

One obtains the following results. For $n=$even there is only one true vacuum $|0\rangle$, and for $n=$odd there are two true vacuums $|0\rangle$ and $|n\rangle$. These results agrees with the de Rham cohomology of RP_n; for $n=$even, there is one nonzero Betti number $b_0=1$, and for $n=$odd, there are two nonzero Betti numbers, $b_0=b_n=1$.

IV. SO(n)

In Ref. 1, all the classical vacuums, all the instanton solutions, and symmetry transformations are identified for a certain Morse function on SO(n). We review them to find true vacuums for arbitrary n.

Let $A=(a_{ij})$ be a group element of SO(n), and fix real numbers $c_1,c_2,\ldots,c_n$ with $c_i>2c_{i+1}>0$. Then

$$h=\sum_{i=1}^{n} c_i a_{ii}\,,\tag{24}$$

is a Morse function[4] on SO(n) with critical points $P^{(l)}$,

$$P^{(l)}=\mathrm{diag}(\epsilon_1,\epsilon_2,\ldots,\epsilon_n),\quad \epsilon_i=\pm1,\prod_i\ \epsilon_i=1.\tag{25}$$

The Morse index of $P^{(l)}$ is $\Sigma_{i=1}^{n}(n-i)[(1+\epsilon_i)/2]$. Around each critical point, h has the expansion

$$h=\sum_i \epsilon_i c_i+\sum_{i<j}(\lambda_{ij}\xi_{ij}^2+\mu_{ij}\eta_{ij}^2), \tag{26}$$

where

$$\lambda_{ij}=-\frac{\epsilon_j-\epsilon_i}{4}(c_j-c_i), \quad \xi_{ij}=a_{ij}+a_{ji}, \tag{27}$$

$$\mu_{ij}=-\frac{\epsilon_j+\epsilon_i}{4}(c_j+c_i), \quad \eta_{ij}=a_{ij}-a_{ji}. \tag{28}$$

A vacuum state that is localized around a critical point with the Morse index l is

$$|l\rangle=\prod_{i<j}\prod_{\epsilon_i=\epsilon_j=1}\hat{\psi}^*_{\eta_{ij}}\prod_{\epsilon_i>\epsilon_j}\hat{\psi}^*_{\xi_{ij}}|0\rangle. \tag{29}$$

There are exactly a pair of instanton solutions between the critical points $\mathrm{diag}(\epsilon_1,\epsilon_2,\ldots,\epsilon_{i-1},-1,1,\epsilon_{i+2},\ldots,\epsilon_n)$ and $\mathrm{diag}(\epsilon_1,\epsilon_2,\ldots,\epsilon_{i-1},1,-1,\epsilon_{i+2},\ldots,\epsilon_n)$:

$$\begin{pmatrix} \epsilon_1 & & & & & & & & \\ & \ddots & & & & & & & \\ & & \epsilon_{i-1} & & & & & & \\ & & & \cos\theta & \mp\sin\theta & & & & \\ & & & \mp\sin\theta & -\cos\theta & & & & \\ & & & & & \epsilon_{i+2} & & & \\ & & & & & & \ddots & & \\ & & & & & & & \epsilon_n & \end{pmatrix}. \tag{30}$$

Some changes of the signs are needed in (30) for the instanton solutions between the critical points $\mathrm{diag}(\epsilon_1,\epsilon_2,\ldots,\epsilon_{n-2},-1,-1)$ and $\mathrm{diag}(\epsilon_1,\epsilon_2,\ldots,\epsilon_{n-2},1,1)$.

The theory is invariant under each of the supersymmetric generalizations[1] of the following reflection transformations:

$$a_{ij}\to -a_{ij} \quad \text{and} \quad a_{ji}\to -a_{ji}, \quad j\neq i, i=2,3,\ldots,n, \tag{31}$$

and the transposition

$$a_{ij}\to a_{ji}. \tag{32}$$

We call the corresponding supersymmetric transformations as $[i]$ and $[t]$, respectively. Supersymmetric generalization means that the corresponding fermionic modes are also transformed. A transformation that is useful to elucidate true vacuums is the transformation that interchanges the two instanton solutions (30).

For the instanton process corresponding to (30), the transformation $[i]$ is relevant. From (29), one sees what kind of fermionic modes are newly excited or suppressed in this process. In this process, only the fermionic modes, including the indices i or $i+1$, can newly be exited or suppressed. At first, the fermionic modes $\hat{\psi}^*_{ki}$ and $\hat{\psi}^*_{ki+1}$, $k=1,\ldots,i-1$, are excited in the pair $\hat{\psi}^*_{\xi_{ki}}\hat{\psi}^*_{\eta_{ki+1}}$ if $\epsilon_k=1$. They change into $\hat{\psi}^*_{\eta_{ki}}\hat{\psi}^*_{\xi_{ki+1}}$ in this process, but do not cause any changes in their parities. In this process, the mode $\hat{\psi}_{\xi_{ii+1}}$ is newly exited. As for the fermionic modes $\hat{\psi}^*_{ik}$ and $\hat{\psi}^*_{i+1k}$, $k=i+1,\ldots,n$, the corresponding exited modes are $\hat{\psi}^*_{\eta_{i+1k}}$ and $\hat{\psi}^*_{\xi_{i+1k}}$, for $\epsilon_k=1$ and $\epsilon_k=-1$, respectively. In this process they change into $\hat{\psi}^*_{\eta_{ik}}$ and $\hat{\psi}^*_{\xi_{ik}}$, respectively. Thus, in this

process the number of the index i increases by $n-i$, and the number of the index $i+1$ diminishes by $n-i-2$ in the excited fermionic modes. The number of excited η modes does not change, so this process is not prohibited by the transformation $[t]$ [the instanton process below (30) is prohibited by $[t]$]. Taking the transformation $[i]$ or $[i+1]$ into consideration, we see that the two instanton effects cancel each other if $n-i$ is odd, and they add up if $n-i$ is even. Applying this simple rule to all the instanton solutions, one can easily select all true vacuums.

Let us first consider SO$(2n-1)$. We mark the elements of the critical points off two by two,

$$\mathrm{diag}(\epsilon_1,\epsilon_2|\epsilon_3,\epsilon_4|\cdots|\epsilon_{2n-3},\epsilon_{2n-2}|\epsilon_{2n-1}). \tag{33}$$

From the above rule, one sees that there are instanton effects between the two states around the following critical points:

$$\mathrm{diag}(\epsilon_1,\epsilon_2|\cdots|1,-1|\cdots|\epsilon_{2n-1})\leftrightarrow\mathrm{diag}(\epsilon_1,\epsilon_2|\cdots|-1,1|\cdots|\epsilon_{2n-1}). \tag{34}$$

On the contrary, if $\epsilon_{2i-1}=\epsilon_{2i}(i=1,2,...,n-1)$, the corresponding state is not affected by instanton effects, and it is decided to be a true vacuum. Thus, the critical points that correspond to true vacuums are

$$\mathrm{diag}(\epsilon_1,\epsilon_1|\epsilon_3,\epsilon_3|\cdots|\epsilon_{2n-3},\epsilon_{2n-3}|1). \tag{35}$$

Their Morse indices are $\Sigma_{i=\mathrm{odd}}^{2n-3}(4n-3-2i)\epsilon_i$. This formula agrees with the de Rham cohomology of SO$(2n-1)$:$\Lambda(x_3,x_7,\ldots,x_{4n-5})$.[5]

In the same way, for SO$(2n)$, the critical points that correspond to true vacuums are found to be

$$\mathrm{diag}(\epsilon_{2n-1}|\epsilon_1,\epsilon_1|\epsilon_3,\epsilon_3|\cdots|\epsilon_{2n-3},\epsilon_{2n-3}|\epsilon_{2n-1}). \tag{36}$$

Their Morse indices are $\Sigma_{i=\mathrm{odd}}^{2n-3}(4n-3-2i)\epsilon_i+(2n-1)[(\epsilon_{2n-1}+1)/2]$, which agrees with the de Rham cohomology of SO$(2n)$:$\Lambda(x_3,x_7,\ldots,x_{4n-5},x_{2n-1})$.[5]

V. G_2

The group G_2 is a 14-dimensional submanifold of O(7). An element A of G_2 is given by three seven-component vectors $a_i(i=1,2,4)$;

$$M(7,3;\mathbf{R})\supset \mathrm{G}_2\ni A=(a_1,a_2,a_4), \tag{37}$$

with conditions $|a_i|=1$ $(i=1,2,4)$ and $(a_1,a_2)=(a_1,a_4)=(a_2,a_4)=(a_1a_2,a_4)=0$. The inner product and the absolute value are defined by $(a_i,a_j)=\Sigma_{k=1}^{7}a_{ki}a_{kj}$, $|a_i|=\sqrt{(a_i,a_i)}$ and the products a_ia_j are defined using octonians (see the Appendix).

Fix real numbers c_1, c_2 and c_4 with $c_1>c_2>c_4>0$. Then

$$h=c_1a_{11}+c_2a_{22}+c_4a_{44} \tag{38}$$

is a Morse function on G_2.[4] This Morse function has eight critical points with the Morse indices $l=0$, 3, 5, 6, 8, 9, 11, and 14. We are interested in the following four classical vacuums $|5\rangle$, $|6\rangle$, $|8\rangle$, and $|9\rangle$ that are localized around the critical points $(a_{11},a_{22},a_{44})=(-1,1,-1)$, $(1,-1,-1)$, $(-1,1,1)$, and $(1,-1,1)$, respectively. Around each critical point $(\epsilon_1,\epsilon_2,\epsilon_4)$, h has the expansion[4]

$$\begin{aligned}h=&\sum_i \epsilon_ic_i+\frac{1}{2}\sum_{i<j}(\lambda_{ij}\xi_{ij}^2+\mu_{ij}\eta_{ij}^2)-\epsilon_1c_1(a_{31}^2+a_{51}^2+a_{71}^2)-\epsilon_2c_2(a_{32}^2+a_{62}^2+a_{72}^2)\\&-\epsilon_4c_4(a_{54}^2+a_{64}^2+a_{74}^2)-\tfrac{1}{9}(a_{34}\ \ a_{52}\ \ a_{61})B(a_{34}\ \ a_{52}\ \ a_{61})^t,\end{aligned} \tag{39}$$

where $i,j=1,2,4$, λ_{ij}, μ_{ij}, ξ_{ij}, and η_{ij} are defined by (27) and (28), and B is the following 3 $\times$3 matrix:

$$B=\begin{pmatrix} 4\epsilon_4c_4+\epsilon_2c_2+\epsilon_1c_1 & 2\epsilon_2c_4+2\epsilon_4c_2-\epsilon_1\epsilon_2\epsilon_4c_1 & 2\epsilon_1c_4-\epsilon_1\epsilon_2\epsilon_4c_2+2\epsilon_4c_1 \\ 2\epsilon_2c_4+2\epsilon_4c_2-\epsilon_1\epsilon_2\epsilon_4c_1 & \epsilon_4c_4+4\epsilon_2c_2+\epsilon_1c_1 & \epsilon_1\epsilon_2\epsilon_4c_4-2\epsilon_1c_2-2\epsilon_2c_1 \\ 2\epsilon_1c_4-\epsilon_1\epsilon_2\epsilon_4c_2+2\epsilon_4c_1 & \epsilon_1\epsilon_2\epsilon_4c_4-2\epsilon_1c_2-2\epsilon_2c_1 & \epsilon_4c_4+\epsilon_2c_2+4\epsilon_1c_1 \end{pmatrix}.$$

From (39), one finds classical vacuums as

$$\begin{aligned} |5\rangle &= |a_{32},a_{62},a_{72},a_{24}+a_{42},(a_{34},a_{52},a_{61})\rangle, \\ |6\rangle &= |a_{31},a_{51},a_{71},a_{12}+a_{21},a_{14}+a_{41},(a_{34},a_{52},a_{61})\rangle, \\ |8\rangle &= |a_{32},a_{62},a_{72},a_{24}-a_{42},(a_{34},a_{52},a_{61}),a_{54},a_{64},a_{74}\rangle, \\ |9\rangle &= |a_{31},a_{51},a_{71},a_{12}-a_{21},a_{14}-a_{41},(a_{34},a_{52},a_{61}),a_{54},a_{64},a_{74}\rangle, \end{aligned} \tag{40}$$

where the modes in the ket vectors denote excited fermionic modes and (a_{34},a_{52},a_{61}) represents a certain linear combination of a_{34}, a_{52}, and a_{61}.

Let us discuss instanton solutions of G_2. Embedding G_2 into O(7) (see the Appendix), we see that the critical points that correspond to $|5\rangle$, $|6\rangle$, $|8\rangle$, and $|9\rangle$ are elements of SO(7). The Morse function (38) will be obtained from (24) by imposing some restrictions on the coordinates for SO(7). Accordingly, instanton solutions of G_2 should be included in that of SO(7). Consider the pair $|5\rangle$ and $|6\rangle$. There are four instanton solutions of SO(7) that connect $(a_{11},a_{22},a_{44})=(-1,1,-1)$ and $(1,-1,-1)$ [these are diag$(-1,1,-1,-1,1,-1,1)$ and diag$(1,-1,-1,-1,-1,1,1)$ in SO(7), respectively]:

$$\begin{pmatrix} \cos\alpha & \pm\sin\alpha & & & & & & \\ \pm\sin\alpha & -\cos\alpha & & & & & & \\ & & -1 & & & & & \\ & & & -1 & & & & \\ & & & & -\cos\beta & \pm\sin\beta & & \\ & & & & \pm\sin\beta & \cos\beta & & \\ & & & & & & 1 & \end{pmatrix}. \tag{41}$$

Setting $\alpha=\beta$, Eq. (41) represents two paths in G_2 and gives two instanton solutions in G_2. Thus, we have found that there are exactly two instanton solutions in G_2 that connect $|5\rangle$ and $|6\rangle$. Under the transformation $a_{12}\to -a_{12}, a_{21}\to -a_{21}$, which induces the transformation $a_{56}\to -a_{56}$, $a_{65}\to -a_{65}$ in terms of O(7), the two instanton solutions are interchanged. We use this transformation to elucidate true vacuums. In the same way, one finds that there are two similar instanton solutions between $|8\rangle$ and $|9\rangle$.

We will determine whether there are instanton effects or not between the classical vacuums (40). A reflection transformation that is useful to this purpose is such transformation under which the following each set of modes (a_{12},a_{21}), (a_{34},a_{52},a_{61}), (a_{14},a_{41}), and (a_{24},a_{42}) has the same parities. For SO(n), we have seen that a reflection transformation that transform a group element to a group element makes the theory invariant.[1] As G_2 is a subgroup of O(7), some reflection symmetries for SO(n) will survive as symmetries for G_2 with suitable restrictions. For G_2, one finds eight reflection transformations that transform a group element to a group element. These eight transformations, which are certain combined transformations of $[i]$ for SO(n), will be symmetries of the theory. Among these eight transformations, the four transformations in Table I interchange the two instanton solutions (41) with $\alpha=\beta$.

The classical vacuums $|5\rangle$ and $|6\rangle$ have the same parities under each of the four transformations. Thus, the matrix element $\langle 6|d_h|5\rangle$ is nonvanishing, and $|5\rangle$ and $|6\rangle$ are not true vacuums. In the same way, one finds that $|8\rangle$ and $|9\rangle$ are not true vacuums. We have found that true vacuums are $|0\rangle$, $|3\rangle$, $|11\rangle$, and $|14\rangle$, in accordance with de Rham cohomology of G_2; $b_p=1$ for $p=0$, 3, 11, 14, and $b_p=0$ for the others.

TABLE I. Symmetry transformations that interchange the two instanton solutions (41) with $\alpha=\beta$. The minus signs mean that the corresponding elements a_{ki}, $i=1,...,4$, $k=1,...,7$, reverse the signs (a_3 is not independent).

VI. U(2)

In this section we discuss U(2), which is topologically identical with SO(2)×SU(2). We parametrize an element A of U(2) as

$$A=\begin{pmatrix} x_{11}+iy_{11} & x_{12}+iy_{12} \\ x_{21}+iy_{21} & x_{22}+iy_{22} \end{pmatrix}=\begin{pmatrix} \cos\ \theta e^{i(\alpha+\phi+\psi)} & -\sin\ \theta e^{i(\alpha+\phi-\psi)} \\ \sin\ \theta e^{i(\alpha-\phi+\psi)} & \cos\ \theta e^{i(\alpha-\phi-\psi)} \end{pmatrix},$$

$$0\leqslant\theta\leqslant\pi,\quad 0\leqslant\alpha,\phi,\psi\leqslant 2\pi. \tag{42}$$

Fix real numbers c_1, c_2 with $c_2>2c_1>0$. Then

$$h=c_1x_{11}+c_2x_{22}=(c_1\ \cos(\alpha+\phi+\psi)+c_2\ \cos(\alpha-\phi-\psi))\cos\ \theta \tag{43}$$

is a Morse function on U(2).[4] This Morse function has four critical points:

$$P^{(0)}=\begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix},\quad P^{(1)}=\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},\quad P^{(3)}=\begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix},\quad P^{(4)}=\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}. \tag{44}$$

We denote the corresponding classical vacuums as $|0\rangle$, $|1\rangle$, $|3\rangle$, and $|4\rangle$, respectively.

Around each critical point (ϵ_1,ϵ_2), h has the expansion

$$8h=(\epsilon_1c_1+\epsilon_2c_2)(8-(\epsilon_1x_{12}-\epsilon_2x_{21})^2-(\epsilon_1y_{12}+e_2y_{21})^2)-4\epsilon_1c_1y_{11}^2-4\epsilon_2c_2y_{22}^2. \tag{45}$$

From this expansion, one finds that

$$\begin{gathered} |0\rangle=|0\rangle,\quad |1\rangle=|\xi\rangle, \\ |3\rangle=|\eta,x_{12}+x_{21},y_{12}-y_{21}\rangle,\quad |4\rangle=|\xi,\eta,x_{12}-x_{21},y_{12}+y_{21}\rangle, \end{gathered} \tag{46}$$

where $\xi=\alpha+\phi+\psi$ and $\eta=\alpha-\phi-\psi$. We introduce the following metric:

$$g_{ij}=\frac{1}{2}\ \mathrm{tr}\ \frac{\partial A^\dagger}{\partial\theta^i}\frac{\partial A}{\partial\theta^j}, \tag{47}$$

where the indices i denote θ, α, ψ, and ϕ. The nonzero components of g_{ij} and Christoffel symbols are

$$\begin{gathered} g_{ii}=1,\quad g_{\phi\psi}=g_{\psi\phi}=\cos 2\theta, \\ \Gamma^0_{\phi\psi}=\Gamma^0_{\psi\phi}=\sin 2\theta,\quad \Gamma^\phi_{\theta\psi}=\Gamma^\psi_{\theta\phi}=-\frac{1}{\sin 2\theta}. \end{gathered} \tag{48}$$

The covariant derivatives are

$$\nabla_\alpha=\partial_\alpha,\quad \nabla_\theta=\partial_\theta+\frac{1}{\sin 2\theta}\,(\hat{\psi}^{*\phi}\hat{\psi}_\psi+\hat{\psi}^{*\psi}\hat{\psi}_\phi),$$

$$\nabla_\phi=\partial_\phi-\sin 2\theta\hat{\psi}^{*\psi}\hat{\psi}_\theta+\frac{1}{\sin 2\theta}\,\hat{\psi}^{*\theta}\hat{\psi}_\psi, \tag{49}$$

$$\nabla_\psi=\partial_\psi-\sin 2\theta\hat{\psi}^{*\phi}\hat{\psi}_\theta+\frac{1}{\sin 2\theta}\,\hat{\psi}^{*\theta}\hat{\psi}_\phi.$$

Consider the following simultaneous transformation:

$$\theta^i,\hat{\psi}^{*\theta^i},\hat{\psi}_{\theta^i}\to-\theta^i,-\hat{\psi}^{*\theta^i},-\hat{\psi}_{\theta^i},\quad \theta^i=\alpha,\psi,\phi, \tag{50}$$

which makes the Morse function h invariant. Under this transformation the covariant derivatives ∇_α, ∇_ψ, and ∇_ϕ reverse the sings, and ∇_θ is invariant. Accordingly, the supercharges $d_h, d_h^\dagger$, and the Hamiltonian is invariant under (50).

The gradient flow equations are

$$\frac{d\theta}{dt}=-(c_1\cos\xi+c_2\cos\eta)\sin\theta,$$

$$\frac{d\alpha}{dt}=-(c_1+c_2)\sin\theta\sin\alpha\cos(\phi+\psi)+(c_2-c_1)\cos\theta\cos\alpha\sin(\phi+\psi),$$

$$\frac{d\phi}{dt}=\frac{d\psi}{dt}=((c_2-c_1)\sin\alpha\cos(\phi+\psi)-(c_1+c_2)\cos\alpha\sin(\phi+\psi))\,\frac{\cos\theta}{1+\cos 2\theta}. \tag{51}$$

The degrees of the freedom has been reduced to three. Let us consider the equations in the (θ,η) plane. There are four fixed points $(\theta,\eta)=(0,0)$, $(0,\pi)$, $(\pi,0)$, and (π,π). Around these fixed points the gradient flow equations (51) become simple:

$$\begin{aligned}
&\theta\simeq 0,\quad \frac{d\eta}{dt}=-2c_2\sin\eta,\\
&\theta\simeq\pi,\quad \frac{d\eta}{dt}=2c_2\sin\eta,\\
&\eta\simeq 0,\quad \frac{d\theta}{dt}=-(c_2+c_1\cos\xi)\sin\theta,\\
&\eta\simeq\pi,\quad \frac{d\theta}{dt}=(c_2-c_1\cos\xi)\sin\theta.
\end{aligned} \tag{52}$$

One sees that $(\theta,\eta)=(0,0),(\pi,\pi)$ are stable fixed points and that $(\theta,\eta)=(0,\pi),(\pi,0)$ are unstable fixed points irrespective of the value of ξ.

The initial and the final conditions of a solution that connects $P^{(0)}$ and $P^{(1)}$ are both $\cos\theta\cos\eta=-1$. So, for solutions of (51) that connect $P^{(0)}$ and $P^{(1)}$, one concludes that $(\theta,\eta)\equiv(0,\pi)$ or $(\pi,0)$. Under these conditions, the gradient flow equation of ξ becomes

$$\frac{d\xi}{dt}=\pm 2c_1\sin\xi. \tag{53}$$

There are exactly two instanton solutions that connect $P^{(0)}$ and $P^{(1)}$,

TABLE II. Multiplication table of octonians e_j.

	e_1	e_2	e_3	e_4	e_5	e_6	e_7
e_1	-1	e_3	$-e_2$	e_5	$-e_4$	e_7	$-e_6$
e_2	$-e_3$	-1	e_1	$-e_6$	e_7	e_4	$-e_5$
e_3	e_2	$-e_1$	-1	e_7	e_6	$-e_5$	$-e_4$
e_4	$-e_5$	e_6	$-e_7$	-1	e_1	$-e_2$	e_3
e_5	e_4	$-e_7$	$-e_6$	$-e_1$	-1	e_3	e_2
e_6	$-e_7$	$-e_4$	e_5	e_2	$-e_3$	-1	e_1
e_7	e_6	e_5	e_4	$-e_3$	$-e_2$	$-e_1$	-1

$$A=\begin{pmatrix} e^{\pm i\xi} & 0 \\ 0 & -1 \end{pmatrix}, \quad 0\leqslant\xi\leqslant\pi. \tag{54}$$

For solutions that connect $P^{(3)}$ and $P^{(4)}$, one sees that $(\theta,\eta)\equiv(0,0)$ or (π,π) and that there are exactly two instanton solutions:

$$A=\begin{pmatrix} e^{\pm i\xi} & 0 \\ 0 & 1 \end{pmatrix}, \quad 0\leqslant\xi\leqslant\pi. \tag{55}$$

By the transformation (50), ξ reverses the sign and the two instanton solutions (54) [(55)] are interchanged with each other. Under this transformation $|0\rangle$ and $|3\rangle$ have even parities and $|1\rangle$ and $|4\rangle$ have odd parities. Therefore, there are not instanton effects in the processes $P^{(0)}\to P^{(1)}$ and $P^{(3)}\to P^{(4)}$. Our result for U(2) is that $|0\rangle$, $|1\rangle$, $|3\rangle$, and $|4\rangle$ are all true vacuums. This result agrees with the de Rham cohomology of U(2); $b_p=1$ for $p=0$, 1, 3, 4 and $b_p=0$ for the others. Our result is one of the examples of the Kunneth formula for a product manifold $M\times N$: $b_k(M\times N)=\Sigma_{p+q=k}\, b_p(M)b_q(N)$.

VII. SUMMARY

We have studied supersymmetric quantum mechanics on RP_n, $\mathrm{SO}(n)$, G_2, and U(2) as concrete examples of Witten's Morse theory. We have identified all the true vacuums for each theory. The number of the true vacuums agrees with the de Rham cohomology for each manifold. We have seen that the simple instanton picture that the author proposed for $\mathrm{SO}(n)^4$ holds for the above manifolds. For each pair of adjacent classical vacuums, there are exactly two instanton solutions that are interchanged by a reflection transformation of the theory. Owing to the reflection symmetry, it is easy to decide whether the two instanton effects cancel each other or not.

ACKNOWLEDGMENTS

The author thanks Dr. Y. Yasui for introducing him to this subject. The author thanks Dr. H. Usui for useful discussions.

APPENDIX: MULTIPLICATION RULE IN G_2 AND EMBEDDING

We note the multiplication rule in G_2. For elements a_i of G_2, the following expansions by octonians e_j are taken into account:

$$a_i=\sum_{j=1}^{7} a_{ji}e_j=\begin{pmatrix} a_{1i} \\ \vdots \\ a_{7i} \end{pmatrix}.$$

Note that $e_0=1$ does not appear in the expansion.

The multiplication rules of octonians are defined as usual (see Table II); for example, $e_1e_2=e_3$, $e_5e_3=-e_6$, and $e_i^2=-1$, $e_ie_j=-e_je_i$ $(i\neq j)$. Explicitly, $a_3=a_1a_2$ is given by

$$a_3=\begin{pmatrix} -a_{31}a_{22}+a_{21}a_{32}-a_{51}a_{42}+a_{41}a_{52}-a_{71}a_{62}+a_{61}a_{72} \\ a_{31}a_{12}-a_{11}a_{32}+a_{61}a_{42}-a_{41}a_{62}-a_{71}a_{52}+a_{51}a_{72} \\ -a_{21}a_{12}+a_{11}a_{22}-a_{71}a_{42}-a_{61}a_{52}+a_{51}a_{62}+a_{41}a_{72} \\ a_{51}a_{12}-a_{61}a_{22}+a_{71}a_{32}-a_{11}a_{52}+a_{21}a_{62}-a_{31}a_{72} \\ -a_{41}a_{12}+a_{71}a_{22}+a_{61}a_{32}+a_{11}a_{42}-a_{31}a_{62}-a_{21}a_{72} \\ a_{71}a_{12}+a_{41}a_{22}+a_{51}a_{32}-a_{21}a_{42}-a_{31}a_{52}-a_{11}a_{72} \\ -a_{61}a_{12}-a_{51}a_{22}-a_{41}a_{32}+a_{31}a_{42}+a_{21}a_{52}+a_{11}a_{62} \end{pmatrix}.$$

An element A of G_2 is embedded into O(7) as follows: $A=(a_1,a_2,a_4)\rightarrow(a_1,a_2,a_1a_2,a_4,a_1a_4,a_4a_2,a_1a_4a_2)\in \mathrm{O}(7)$.

Quantization of minisuperspaces as ordinary gauge systems

Claudio Simeone[a)]
Departamento de Física, Comisión Nacional de Energía Atómica, Av. del Libertador 8250, 1429 Buenos Aires, Argentina and Departamento de Física, Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, Ciudad Universitaria, Pabellón I, 1428, Buenos Aires, Argentina

(Received 24 November 1997; accepted for publication 17 March 1998)

Simple cosmological models are used to show that gravitation can be quantized as an ordinary gauge system if the Hamilton–Jacobi equation for the model under consideration is separable. In this situation, a canonical transformation can be performed such that in terms of the new variables the model has a linear and homogeneous constraint, and therefore canonical gauges are admissible in the path integral. This has the additional practical advantage that gauge conditions that do not generate Gribov copies are then easy to choose. © *1998 American Institute of Physics.* [S0022-2488(98)02906-5]

I. INTRODUCTION

The evolution of a cosmological model is given by the dynamics of the fields $g_{\mu\nu}(X)$ and of the matter field ϕ, which yield from the extremal condition imposed on the Einstein action. The change from the variables $g_{\mu\nu}$ to the set

$$g_{ab}(\mathbf{x},\tau),\ N(\mathbf{x},\tau),\ N^a(\mathbf{x},\tau)$$

where N and N^a are the lapse and shift functions defined by Kuchař[1] as a generalization of those introduced by Arnowitt, Deser and Misner,[2] $N=(-g^{00})^{-1/2}$, $N^a=g^{ab}g_{b0}$, gives the Einstein action the form[3]

$$S[g_{ab},p^{ab},N,N^a,\phi]=\int d\tau\int d^3x\ (p^{ab}\dot{g}_{ab}-N\mathcal{H}-N^a\mathcal{H}_a), \tag{1}$$

where the Hamiltonian and momentum constraints

$$\begin{aligned}\mathcal{H}&=\tfrac{1}{2}G_{abcd}\ p^{ab}p^{cd}-({}^3g)^{1/2}({}^3R-2\Lambda)+\mathcal{H}_{\mathrm{matt}}\approx 0,\\ \mathcal{H}_a&=-2\,g_{ac}\nabla_d\ p^{cd}+\mathcal{H}_{a,\mathrm{matt}}\approx 0\end{aligned} \tag{2}$$

reflect the general covariance of the theory.

The restriction to minisuperspace models and the choice of an homogeneous lapse and zero shift lead to a single constraint of the form[4]

$$H=\tfrac{1}{2}f_{ij}\ p^ip^j+V(q)\approx 0, \tag{3}$$

where f_{ij} is the reduced version of the DeWitt supermetric. The constraint H is a generator of gauge transformations giving rise to an infinite number of physically equivalent paths in phase space. If the action

$$S[q^i,p_i,N]=\int d\tau\ (p_i\dot{q}^i-NH) \tag{4}$$

a)Electronic mail: simeone@tandar.cnea.edu.ar

 © 1998 American Institute of Physics

is used to quantize the system by means of a path integral, the propagator diverges because of the sum over equivalent paths. This is solved by imposing a gauge condition that selects one path from each class of equivalent paths. Admissible gauge conditions are those which can be reached from any path by performing a gauge transformation that does not modify the action, so that a first restriction on admissible gauge conditions appears. A second—and general—condition is that gauge fixing must not generate Gribov copies, that is, the orbits (i.e., the points of the phase space connected by gauge transformations) must have no more than one intersection with the surface defined by the gauge.

Under the gauge transformation

$$\delta_\epsilon q^i = \epsilon(\tau)[q^i, H],\ \delta_\epsilon p_i = \epsilon(\tau)[p_i, H],\ \delta_\epsilon N = \dot{\epsilon}(\tau), \tag{5}$$

the action changes by

$$\delta_\epsilon S = \left[\epsilon(\tau) \left(p_i \frac{\partial H}{\partial p_i} - H \right) \right]_{\tau_1}^{\tau_2}, \tag{6}$$

so that for a quadratic Hamiltonian like that of Eq. (4) $\delta_\epsilon S$ vanishes only if

$$\epsilon(\tau_1) = 0 = \epsilon(\tau_2). \tag{7}$$

This introduces a restriction on admissible gauges: derivative gauge conditions like

$$\chi \dot{N} - \chi_0(q^i, p_i, N) = 0 \tag{8}$$

should be used,[5,6] reflecting a difference between gravitation and ordinary gauge systems, which have linear and homogeneous constraints so that $\delta_\epsilon S$ vanishes even if the boundaries are not mapped onto themselves, allowing then for canonical gauge conditions

$$\chi(q^i, p_i, \tau) = 0. \tag{9}$$

However, a system with a quadratic Hamiltonian can be made gauge invariant at the end points, improving the action with end point terms.[7] In a previous paper[8] we have shown that these terms can be seen as the result of a canonical transformation which identifies the constraint with one of the new momenta, yielding an action like that of an ordinary gauge system. In the present work we apply this idea to some minisuperspace models; we solve the Hamilton–Jacobi equation for them, and find the gauge-invariant action which makes simple canonical gauges admissible in the path integral. We show that this gauge fixing procedure makes it easy to avoid the Gribov problem, and, from a different point of view, we find that the path integral resulting after the gauge choice clearly manifests the (arbitrary) separation between true degrees of freedom and time.

II. GAUGE-INVARIANT ACTION

Let us consider the canonical transformation $(q^i, p_i) \to (\overline{Q}^i, \overline{P}_i)$ generated by the solution $W(q^i, \alpha_\mu, E)$ of the τ-independent Hamilton–Jacobi equation

$$H\left(q^i, \frac{\partial W}{\partial q^i} \right) = E, \tag{10}$$

matching the constants (α_μ, E) to the new momenta $(\overline{P}_\mu, \overline{P}_0)$. The new coordinates and momenta verify

$$\begin{aligned} [\overline{Q}^\mu, \overline{P}_0] &= [\overline{Q}^\mu, H] = 0, \\ [\overline{P}_\mu, \overline{P}_0] &= [\overline{P}_\mu, H] = 0, \\ [\overline{Q}^0, \overline{P}_0] &= [\overline{Q}^0, H] = 1. \end{aligned} \tag{11}$$

$\overline{Q}^{\mu}$ and $\overline{P}_{\mu}$ do not change under a gauge transformation and are then called observables, while $\overline{Q}^{0}$ has nonzero bracket with the constraint, suggesting its use to fix the gauge: In terms of the new variables the constraint is linear and homogeneous in the momenta, so that canonical gauges are admissible, and the condition that guarantees that the surface $\chi=0$ is not tangent to the orbits[9] (which will be used to ensure that it does not intersect them more than once) is fulfilled by $\chi \equiv \overline{Q}^{0}$:

$$\det([\chi,H])=[\overline{Q}^{0},H]\neq 0. \tag{12}$$

A second transformation, now in the space of observables, generated by

$$F=P_0\overline{Q}^{0}+f(\overline{Q}^{\mu},P_{\mu},\tau), \tag{13}$$

yields a new nonzero Hamiltonian

$$K=NP_0+\frac{\partial f}{\partial \tau}, \tag{14}$$

and a new set of nonconserved observables (Q^{μ},P_{μ}) that are therefore appropriate to characterize the trajectories in phase space. As a functional of Q^{i} and P_i the new gauge-invariant action reads

$$\mathcal{S}=\int_{\tau_1}^{\tau_2}\left(P_i\frac{dQ^{i}}{d\tau}-NP_0-\frac{\partial f}{\partial \tau}\right)d\tau, \tag{15}$$

so that the system is now an ordinary gauge system, i.e., one with a linear and homogeneous constraint $P_0\approx 0$ and a nonzero Hamiltonian $\partial f/\partial\tau$. The path integral then has the form

$$\int DQ^{0}\,DP_0\,DQ^{\mu}\,DP_{\mu}\,DN\;\delta(\chi)\;|[\chi,P_0]|\exp\left[i\int_{\tau_1}^{\tau_2}\left(P_i\frac{dQ^{i}}{d\tau}-NP_0-\frac{\partial f}{\partial\tau}\right)d\tau\right], \tag{16}$$

where $|[\chi,P_0]|$ is the Fadeev–Popov determinant and admits any canonical gauge. In terms of the original variables the gauge invariant action is written

$$\mathcal{S}=\int_{\tau_1}^{\tau_2}\left(p_i\frac{dq^{i}}{d\tau}-NH\right)d\tau+B \tag{17}$$

with[8]

$$B=[\overline{Q}^{i}\overline{P}_i-W+Q^{\mu}P_{\mu}-f]_{\tau_1}^{\tau_2}. \tag{18}$$

The existence of a gauge such that $\tau=\tau(q^{i})$ (intrinsic time)[10] and the vanishing of the end point terms B in that gauge and on the constraint surface assure that the new action $\mathcal{S}$ and the original one S weigh the paths in the same way.[8] This requirement determines the function f in Eq. (13).

III. MINISUPERSPACES

The procedure we have shown depends on the possibility of finding a solution to the Hamilton–Jacobi equation for the system. The separability of this equation and its application to cosmological models has been widely studied.[11,12] Here we will study simple models for which the Hamilton–Jacobi equation can be easily solved. Consider an isotropic and homogeneous Friedmann–Robertson–Walker (FRW) metric

$$ds^2=N^2d\tau^2-a^2(\tau)\left(\frac{dr^2}{1-kr^2}+r^2d\theta^2+r^2\,\sin^2\,\theta d\varphi^2\right).$$

The Hamiltonian constraint

$$H=\tfrac{1}{4}e^{-3\Omega}(\pi_\phi^2-\pi_\Omega^2)+\Lambda e^{3\Omega}\approx 0, \tag{19}$$

with $\Omega\sim\ln a(\tau)$ corresponds to a FRW metric with massless scalar field, nonzero cosmological constant and null curvature. The evolution is restricted to one of the two surfaces

$$\pi_\Omega=\pm\sqrt{\pi_\phi^2+4\Lambda e^{6\Omega}}$$

separated by $\pi_\Omega=0$; from a geometrical point of view this means that the topology of the surface where the gauge choice must select only one point from each orbit is that of half a plane. The τ-independent Hamilton–Jacobi equation has the solutions

$$W_\pm=\overline{P}\phi\pm\int d\Omega\sqrt{\overline{P}^2-4\overline{P}_0e^{3\Omega}+4\Lambda e^{6\Omega}}, \tag{20}$$

which are of the form

$$W=w(q^0,\overline{P}_0,\overline{P})+C(q^i)\overline{P}, \tag{21}$$

with $q^0=\Omega$, $q=\phi$. Fixing the gauge by means of the canonical condition

$$\chi\equiv\overline{Q}^0-g(\overline{P},T(\tau))=0 \tag{22}$$

with $T(\tau)$ a monotonous function of τ, as $\overline{Q}^0=\partial W_\pm/\partial\overline{P}_0=\overline{Q}^0(q^0,\overline{P}_0,\overline{P})$, if we choose

$$g(\overline{P},T(\tau))=\overline{Q}^0(q^0=T(\tau),\overline{P}_0=0,\overline{P})$$

in terms of the original variables we have

$$q^0=T(\tau). \tag{23}$$

The surface $\chi=0$ is thus a plane $\Omega=$constant for each value of τ. This guarantees that the gauge (22) does not produce Gribov copies, because if it did so at any τ, at another one it would be $[\chi,H]=0$, which is prevented by the gauge fixing procedure.

The additional end point terms B for the action of this system vanish in gauge (22) if

$$f=\overline{Q}P-w(T(\tau),\overline{P}_0=0,\overline{P}=P).$$

Thus, in this gauge and on the constraint surface we have

$$Q=\frac{\partial f}{\partial P}=C(q^i),$$

which together with Eq. (23) means that Q and τ define a hypersurface in the original configuration space. The Hamiltonian for the reduced system (Q,P) is

$$\frac{\partial f}{\partial\tau}=\mp\sqrt{P^2+4\Lambda e^{6T}}\,\frac{dT}{d\tau},$$

and it resembles that of a relativistic particle of T-dependent mass $m=2\Lambda^{1/2}e^{3T}$. In gauge (22) and on the constraint surface the path integral for the system then has the simple form

$$\langle\phi'',\Omega''|\phi',\Omega'\rangle=\int DQDP\exp\left[i\int_{T'}^{T''}(PdQ\pm\sqrt{P^2+4\Lambda e^{6T}}dT)\right], \tag{24}$$

where the endpoints are given by $T'=\Omega'$ and $T''=\Omega''$, while the paths go from $Q'=\phi'$ to $Q''=\phi''$.

Another easily solvable constraint is

$$H=\tfrac{1}{4}e^{-3\Omega}3(\pi_\phi^2-\pi_\Omega^2)+e^{3\Omega}V(\phi)\approx 0 \tag{25}$$

with $V(\phi)=\lambda e^{6\Omega}$, which corresponds to a FRW metric with a massless scalar field and an exponential potential which can reproduce an increasing cosmological constant. The topology is again like that of two disjoint planes. Multiplying by the positive-definite function $e^{3\Omega}$ an equivalent constraint is obtained:

$$H'=\tfrac{1}{4}(\pi_\phi^2-\pi_\Omega^2)+\lambda e^{6(\Omega+\phi)}\approx 0. \tag{26}$$

This is an example in which the new momentum $\overline{P}_0$ differs from the constraint H by a nonzero factor, so that the bracket of $\overline{Q}$ with the constraint is zero only on the constraint surface, but $\overline{Q}$ is still an observable. The solution of the τ-independent Hamilton–Jacobi equation is

$$W=\overline{P}(\phi-\Omega)+\frac{1}{\overline{P}}\left(\overline{P}_0(\phi+\Omega)-\frac{\lambda}{6}e^{6(\Omega+\phi)}\right) \tag{27}$$

and has the form (21) if $q^0=\phi+\Omega$ and $q=\phi-\Omega$. The canonical gauge

$$\chi\equiv\overline{Q}^0-\frac{T(\tau)}{\overline{P}}=0 \tag{28}$$

gives

$$q^0=\phi+\Omega=T(\tau),$$

corresponding to a plane $\phi+\Omega=$constant for each value of τ. This gauge does not generate Gribov copies, because if at any τ the plane intersected an orbit, at another τ they should be tangent, yielding $[\chi,H]=0$. As in the former example, with the choice of the function f such that the end points B vanish in gauge (28) the new coordinate Q and τ define a hypersurface in the original configuration space. The Hamiltonian for the reduced system described by Q and P is

$$\frac{\partial f}{\partial\tau}=\frac{\lambda}{P}e^{6T(\tau)}\frac{dT}{d\tau},$$

and the path integral in gauge (28) and on the constraint surface has the form

$$\langle\phi'',\Omega''|\phi',\Omega'\rangle=\int DQDP\exp\left[i\int_{T'}^{T''}\left(PdQ-\frac{\lambda}{P}e^{6T}dT\right)\right], \tag{29}$$

where $T'=\phi'+\Omega'$ and $T''=\phi''+\Omega''$, and the paths go from $Q'=\phi'-\Omega'$ to $Q''=\phi''-\Omega''$. As before, the evolution of the system described by the observables (Q,P) is given by a T-dependent Hamiltonian.

In a more general case,[8] whenever the Hamiltonian constraint has the form

$$H=G(\phi,\Omega)(\pi_\phi^2-\pi_\Omega^2)+V(\phi,\Omega)\approx 0 \tag{30}$$

with G and V positive definite functions such that $V(\phi,\Omega)/G(\phi,\Omega)=L_1(\phi+\Omega)L_2(\phi-\Omega)$ the change to the null coordinates

$$u=R_1(\phi-\Omega),\ \ v=R_2(\phi+\Omega)$$

with the choice $L_2(z)=R'(z)$ yields the equivalent constraint

$$H'=\pi_u\pi_v+\tfrac{1}{4}L(v) \tag{31}$$

related to H by $H=V(\phi,\Omega)H'$, with $L(v)\equiv L_1(v)/L_2(v)$. The generator function W which identifies the set $(\overline{Q}^i,\overline{P}_i)$ is

$$W=\overline{P}u+\frac{\overline{P}_0}{\overline{P}}v-\frac{1}{4\overline{P}}\int L(v)dv, \tag{32}$$

and has the form

$$W=w(v,\overline{P}_0,\overline{P})+C(u)\overline{P}. \tag{33}$$

The canonical gauge

$$\chi\equiv\overline{Q}^0-\frac{T(\tau)}{\overline{P}}=0 \tag{34}$$

is equivalent to

$$v=R_2(\phi+\Omega)=T(\tau).$$

The Gribov problem is avoided in the same way it was before, as the constraint hypersurface splits in

$$\pi_\Omega=\pm\sqrt{\frac{V(\phi,\Omega)}{G(\phi,\Omega)}+\pi_\phi^2}.$$

The generator function f giving the change to nonconserved observables is

$$f=\overline{Q}P+\frac{1}{4P}\int L(T)dT \tag{35}$$

and the new variables are related to the null ones by

$$\begin{gathered}Q^0=\frac{v}{P},\quad Q=u+\frac{v}{P^2}(1-P_0)-\frac{1}{4P^2}\int L(T)dT,\\ \pi_u=P,\quad \pi_v=\frac{P_0-L(v)}{P}.\end{gathered} \tag{36}$$

The system (Q,P) is governed by the nonzero Hamiltonian $\partial f/\partial\tau=(1/4P)\,L(T)\,dT/d\tau$, so that the path integral on the constraint surface and in gauge (34) is

$$\langle\phi'',\Omega''|\phi',\Omega'\rangle=\int DQDP\exp\left[i\int_{T'}^{T''}\left(PdQ-\frac{L(T)}{4P}dT\right)\right], \tag{37}$$

where $T'=R_2(\phi'+\Omega')$ and $T''=R_2(\phi''+\Omega'')$, and the paths go from $Q'=R_1(\phi'-\Omega')$ to $Q''=R_1(\phi''-\Omega'')$. The evolution of the reduced system is given by a T-dependent Hamiltonian. As in the preceding examples, this is nothing more, however, than a consequence of the fact that the gauge choice is not only a procedure to remove divergences from the path integral, but also a reduction procedure to physical degrees of freedom, giving rise to time and dynamical evolution.[3] This can soon be realized by examining the result of a ''wrong'' gauge choice, like a τ-independent one. We would then obtain a zero Hamiltonian for the reduced system, yielding no dynamical evolution.

IV. CONCLUSIONS

The presence of a quadratic constraint in the action of gravitation would make impossible, in principle, the quantization of cosmological models by means of the usual path integral procedure for gauge systems.[6] However, when the Hamilton–Jacobi equation for the system can be solved, this can mean nothing more than an inappropriate choice of coordinates and momenta. The change to variables such that the constraint is linear and homogeneous in the momenta provides the action

with invariance at the end points, making canonical gauges admissible in the path integral. In terms of the original variables the gauge-invariant action has additional end point terms, but these terms do not modify the dynamical trajectories of the system. The vanishing of the end point terms in a gauge that defines a hypersurface in the original configuration space guarantees that the improved action weighs the paths in the same way as the original one. However, because the new action is gauge invariant, the path integral can be computed in any canonical gauge. Canonical gauges make it easy to avoid Gribov copies, and also to define a global time.[3]

It should be emphasized that our procedure will only work in a limited class of minisuperspace models; even in the case of homogeneous and isotropic models, for an arbitrary potential $V(\phi,\Omega)$—yielding a topologically nontrivial constraint surface—it is most unlikely to work in general. However, the Hamilton–Jacobi equation is separable for constraints more general than those considered here: For example, solutions are known for models with more than one scalar field, or with a potential $V(\phi)\sim 1/\phi^2$, which reproduces an inflationary model with a decaying cosmological constant.[12] The existence of an intrinsic time and the possibility to avoid the Gribov problem in these and other separable models should be the object of a further analysis.

Low's well-known action principle for the Maxwell–Vlasov equations of ideal plasma dynamics was originally expressed in terms of a mixture of Eulerian and Lagrangian variables. By imposing suitable constraints on the variations and analyzing invariance properties of the Lagrangian, as one does for the Euler equations for the rigid body and ideal fluids, we first transform this action principle into purely Eulerian variables. Hamilton's principle for the Eulerian description of Low's action principle then casts the Maxwell–Vlasov equations into Euler–Poincaré form for right invariant motion on the diffeomorphism group of position-velocity phase space, $\mathbb{R}^6$. Legendre transforming the Eulerian form of Low's action principle produces the Hamiltonian formulation of these equations in the Eulerian description. Since it arises from Euler–Poincaré equations, this Hamiltonian formulation can be written in terms of a Poisson structure that contains the Lie–Poisson bracket on the dual of a semidirect product Lie algebra. Because of degeneracies in the Lagrangian, the Legendre transform is dealt with using the Dirac theory of constraints. Another Maxwell–Vlasov Poisson structure is known, whose ingredients are the Lie–Poisson bracket on the dual of the Lie algebra of symplectomorphisms of phase space and the Born–Infeld brackets for the Maxwell field. We discuss the relationship between these two Hamiltonian formulations. We also discuss the general Kelvin–Noether theorem for Euler–Poincaré equations and its meaning in the plasma context. © *1998 American Institute of Physics.* [S0022-2488(98)00506-4]

I. INTRODUCTION

A. Reduction of action principles

Due to their wide applicability, the Maxwell–Vlasov equations of ideal plasma dynamics have been studied extensively. In 1958 Low[1] wrote down an action principle for them in preparation for studying stability of plasma equilibria. Low's action principle is expressed in terms of a mixture of Lagrangian particle variables and Eulerian field variables.

Following the initiative of Arnold[2] and its later developments (see Ref. 3 for background), we start with a purely Lagrangian description of the plasma and investigate the invariance properties of the corresponding action. Using this setup and recent developments in the theory of the Euler–

Poincaré equations[4,5] due to Holm, Marsden, and Ratiu,[6] we are able to cast Low's action principle into a purely Eulerian description.

In this paper, we start with the *standard* form of Hamilton's variational principle (in the Lagrangian representation) and *derive* the new Eulerian action principle by a systematic reduction process, much as one does in the corresponding derivation of Poisson brackets in the Hamiltonian formulation of the Maxwell–Vlasov equations starting with the *standard canonical brackets* and proceeding by symmetry reduction (as in Ref. 7). In particular, the Eulerian action principle we obtain in this way is different from the ones found in Ye and Morrison[8] by *ad hoc* procedures. We also mention that the method of reduction of variational principles we develop naturally justifies constraints on the variations of the so-called ''Lin constraint'' form, well known in fluid mechanics.

The methods of this paper are based on reduction of variational principles, that is, on Lagrangian reduction (see Refs. 9–12). These methods have also been useful for systems with nonholonomic constraints. This has been demonstrated in the work of Bloch *et al.*,[13] who derived the reduced Lagrange d'Alembert equations for nonholonomic systems, which also have a constrained variational structure. The methods of the present paper should enhance the applicability of the Lagrangian reduction techniques for even wider classes of continuum systems.

B. Passage to the Hamiltonian formulation

The Hamiltonian structure and nonlinear stability properties of the equilibrium solutions for the Maxwell–Vlasov system have been thoroughly explored. Some of the key references are Iwínski and Turski,[14] Morrison,[15] Marsden and Weinstein,[7] and Holm, Marsden, Ratiu, and Weinstein.[16] See also the introduction and bibliography of Marsden *et al.*[17] for a guide to the history and literature of this subject.

In our approach, Lagrangian reduction leads to the Euler–Poincaré form of the equations, which is still in the Lagrangian formulation. Using this setup, one may pass from the Lagrangian to the Hamiltonian formulation of the Maxwell–Vlasov equations by Legendre transforming the action principle in the Eulerian description at either the level of the group variables (the level that keeps track of the particle positions), or at the level of the Lie algebra variables. One must be cautious in this procedure because the relevant Hamiltonian and Lagrangian are degenerate. We deal with this degeneracy by using a version of the Dirac theory of constraints.

Legendre transforming at the group level leads to a canonical Hamiltonian formulation and the latter leads to a new Hamiltonian formulation of the Maxwell–Vlasov equations in terms of a Poisson structure containing the Lie–Poisson bracket on the dual of a semidirect product Lie algebra. This new formulation leads us naturally to the starting point for Hamiltonian reduction used by Marsden and Weinstein[7] (see also Refs. 15 and 18).

C. Stability and asymptotics

The new Hamiltonian formulation of the Maxwell–Vlasov system places these equations into a framework in which one can use the energy-momentum and energy-Casimir methods for studying nonlinear stability properties of their relative equilibrium solutions. This is directly in line with Low's intended program, since the study of stability was Low's original motivation for writing his action principle. Sample references in this direction are Holm, Marsden, Weinstein, and Ratiu,[16] Morrison,[19] Morrison and Pfirsch,[20] Wan,[21] Batt and Rein[22] and Batt, Morrison, and Rein.[23] Other historical references for the Lagrangian approach to the Maxwell–Vlasov equations include Sturrock,[24] Galloway and Kim,[25] and Dewar.[26]

The Eulerian formulation of Low's action principle also casts it into a form that is amenable to asymptotic expansions and creation of approximate theories (such as guiding center theories) possessing the same mathematical structure arising from the Euler–Poincaré setting. See, for example, Ref. 27 for applications of this approach of Hamilton's principle asymptotics in geophysical fluid dynamics.

D. Comments on the Maxwell–Vlasov system

The rest of this paper will be concerned with variational principles for the Maxwell–Vlasov system of equations for the dynamics of an ideal plasma. These equations have a long history

dating back at least to Jeans,[28] who used them in a simpler form known as the Poisson–Vlasov system to study structure formation on stellar and galactic scales. Even before Jeans, Poincaré[4,29] had investigated the stability of equilibrium solutions of the Poisson–Vlasov system for the purpose of determining the stability conditions for steller configurations. The history of the efforts to establish stellar stability conditions using the Poisson–Vlasov system is summarized by Chandrasekhar.[30] The Poisson–Vlasov system is also used to describe the self-consistent dynamics of an electrostatic collisionless plasma, whereas the Maxwell–Vlasov system is used to describe the dynamics of a collisionless plasma evolving self-consistently in an electromagnetic field.

E. Organization of the paper

The paper is organized as follows. In Sec. II we introduce the Maxwell–Vlasov equations. In Sec. III we state the Euler–Poincaré theorem for Lagrangians depending on parameters along with the associated Kelvin–Noether theorem. This general theorem plays a key role in our analysis. In Sec. V we reformulate these equations in a purely Eulerian form and show how they satisfy the Euler–Poincaré theorem. The following section reviews some aspects of the Legendre transformation for degenerate Lagrangians. In Sec. IV we reprise Low's action principle for the Maxwell–Vlasov equations. In Sec. VII we cast the Euler–Poincaré formulation of the Maxwell–Vlasov equations into Hamiltonian form possessing a Poisson structure that contains a Lie–Poisson bracket. In Sec. VIII we summarize our conclusions.

II. THE MAXWELL–VLASOV EQUATIONS

The Maxwell–Vlasov system of equations describes the single particle distribution for a set of charged particles of one species moving self-consistently in an electromagnetic field. In this description, the Boltzmann function $f(\mathbf{x},\mathbf{v},t)$ is viewed as the instantaneous probability density function for the particle distribution, i.e., given a region Ω of phase space, the probability of finding a particle in that region is

$$\int_\Omega d\mathbf{x}\, d\mathbf{v} f(\mathbf{x},\mathbf{v},t), \tag{2.1}$$

where $\mathbf{x}$ and $\mathbf{v}$ are the current positions and velocities of the plasma particles. Thus, if the phase-space domain Ω is the whole $(\mathbf{x},\mathbf{v})$ space, the value of this integral at a certain time t is normalized to unity.

As is customary, we assume that the particles of the plasma obey dynamical equations and that the plasma density f is advected as a scalar along the particle trajectories in phase space, i.e.,

$$\frac{\partial f}{\partial t} + \dot{\mathbf{x}}\cdot\nabla_{\mathbf{x}} f + \dot{\mathbf{v}}\cdot\nabla_{\mathbf{v}} f = 0. \tag{2.2}$$

In this equation, and in the sequel, an overdot refers to a time derivative along a phase space trajectory, and $\nabla_{\mathbf{x}}$ and $\nabla_{\mathbf{v}}$ denote the gradient operators with respect to position and velocity, respectively. For pressureless motion in the electromagnetic field of the charged particle distribution, the acceleration of a particle is given by

$$\ddot{\mathbf{x}} = -\frac{q}{m}\left[\nabla_{\mathbf{x}}\Phi + \frac{\partial \mathbf{A}}{\partial t} - \mathbf{v}\times(\nabla_{\mathbf{x}}\times\mathbf{A})\right], \tag{2.3}$$

where (q/m) denotes the charge-to-mass ratio of an individual particle, Φ is the electric potential, and $\mathbf{A}$ is the magnetic vector potential. Substituting this expression for $\dot{\mathbf{v}}$ in Eq. (2.2) yields

$$\frac{\partial f}{\partial t} + \mathbf{v}\cdot\nabla_{\mathbf{x}} f - \frac{q}{m}\left[\nabla_{\mathbf{x}}\Phi + \frac{\partial \mathbf{A}}{\partial t} - \mathbf{v}\times(\nabla_{\mathbf{x}}\times\mathbf{A})\right]\cdot\nabla_{\mathbf{v}} f = 0. \tag{2.4}$$

This is the ***Vlasov equation*** (also called the collisionless Boltzmann, or Jeans equation). The system is completed by the Maxwell equations with sources:

$$\nabla_{\mathbf{x}}\cdot\mathbf{E} = \rho, \quad \nabla_{\mathbf{x}}\times\mathbf{B} = \frac{\partial \mathbf{E}}{\partial t} + \mathbf{j}, \tag{2.5}$$

where **E** and **B** are the electric and magnetic field variables, respectively, ρ is the charge density, and **j** is the current density. These quantities are expressed in terms of the Boltzmann function f and the Maxwell scalar and vector potentials Φ and **A** by

$$\mathbf{E}=-\nabla_{\mathbf{x}}\Phi-\frac{\partial \mathbf{A}}{\partial t},\quad \mathbf{B}=\nabla_{\mathbf{x}}\times\mathbf{A},$$
$$\rho(\mathbf{x},t)=q\int d\mathbf{v}\ f(\mathbf{x},\mathbf{v},t),\quad \mathbf{j}(\mathbf{x},t)=q\int d\mathbf{v}\ \mathbf{v}f(\mathbf{x},\mathbf{v},t). \tag{2.6}$$

By their definitions, **E** and **B** satisfy the kinematic Maxwell equations

$$\nabla_{\mathbf{x}}\cdot\mathbf{B}=0,\quad \nabla_{\mathbf{x}}\times\mathbf{E}=-\frac{\partial \mathbf{B}}{\partial t}. \tag{2.7}$$

Equations (2.4)–(2.7) comprise the ***Maxwell–Vlasov equations***. When **A** is absent, the field is electrostatic and one obtains the Poisson–Vlasov equations. The Poisson–Vlasov system can also be used to describe a self-gravitating collisionless fluid, and so it forms a model for the evolution of galactic dynamics (see, e.g., Ref. 31).

Note that the integral in (2.1) is independent of time (as the region and the function f evolve), since the vector field defining the motion of particles [see Eq. (2.3)] is divergence free with respect to the standard volume element on velocity phase space. Thus, one may interpret f either as a density or as a scalar. For our purposes later, we will need to be careful with the distinction, since the volume-preserving nature of the flow of particles will be a consequence of our variational principle and will not be imposed at the outset.

III. THE EULER–POINCARÉ EQUATIONS, SEMIDIRECT PRODUCTS, AND KELVIN'S THEOREM

A. The general Euler–Poincaré equations

Here we recall from Ref. 6 the general form of the Euler–Poincaré equations and their associated Kelvin–Noether theorem. In the next section, we will immediately specialize these statements for a general invariance group G to the case of plasmas when G is the diffeomorphism group, Diff($T\mathbb{R}^3$). We shall state the general theorem for right actions and right invariant Lagrangians, which is appropriate for the Maxwell–Vlasov situation. The notation is as follows.

(i) There is a *right* representation of the Lie group G on the vector space V and G acts in the natural way from the *right* on $TG\times V^*:(v_g,a)h=(v_gh,ah)$.

(ii) $\rho_v:\mathfrak{g}\to V$ is the linear map given by the corresponding right action of the Lie algebra on $V:\rho_v(\xi)=v\xi$, and $\rho_v^*:V^*\to\mathfrak{g}^*$ is its dual. The $\mathfrak{g}$–action on $\mathfrak{g}^*$ and V^* is defined to be *minus* the dual map of the $\mathfrak{g}$–action on $\mathfrak{g}$ and V, respectively, and is denoted by $\mu\xi$ and $a\xi$ for $\xi\in\mathfrak{g}$, $\mu\in\mathfrak{g}^*$, and $a\in V^*$. For $v\in V$ and $a\in V^*$, it will be convenient to write
$$v\diamond a=\rho_v^*a,\quad \text{i.e.,}\quad \langle v\diamond a,\xi\rangle=\langle a,v\xi\rangle=-\langle v,a\xi\rangle,$$
for all $\xi\in\mathfrak{g}$. Note that $v\diamond a\in\mathfrak{g}^*$.

(iii) Let $\mathcal{Q}$ be a manifold on which G acts *trivially* and assume that we have a function $L:TG\times T\mathcal{Q}\times V^*\to\mathbb{R}$ which is right G-invariant.

(iv) In particular, if $a_0\in V^*$, define the Lagrangian $L_{a_0}:TG\times T\mathcal{Q}\to\mathbb{R}$ by $L_{a_0}(v_g,u_q)=L(v_g,u_q,a_0)$. Then L_{a_0} is right invariant under the lift to $TG\times T\mathcal{Q}$ of the right action of G_{a_0} on $G\times\mathcal{Q}$.

(v) Right G-invariance of L permits us to define $l:\mathfrak{g}\times T\mathcal{Q}\times V^*\to\mathbb{R}$ by
$$l(v_gg^{-1},\ u_q,\ ag^{-1})=L(v_g,u_q,a).$$
Conversely, this relation defines for any $l:\mathfrak{g}\times T\mathcal{Q}\times V^*\to\mathbb{R}$ a right G-invariant function $L:TG\times T\mathcal{Q}\times V^*\to\mathbb{R}$.

(vi) For a curve $g(t)\in G$, let $\xi(t):=\dot{g}(t)g(t)^{-1}$ and define the curve $a(t)$ as the unique solution of the linear differential equation with time-dependent coefficients $\dot{a}(t)=-a(t)\xi(t)$

with initial condition $a(0)=a_0$. The solution can be equivalently written as $a(t)=a_0 g(t)^{-1}$.

Theorem 3.1: The following are equivalent:

(i) Hamilton's variational principle holds:

$$\delta\int_{t_1}^{t_2} L_{a_0}(g(t),\dot{g}(t),q(t),\dot{q}(t))\,dt=0, \tag{3.1}$$

for variations of g and q with fixed endpoints.

(ii) $(g(t),q(t))$ satisfies the Euler–Lagrange equations for L_{a_0} on $G\times Q$.

(iii) The constrained variational principle,[32]

$$\delta\int_{t_1}^{t_2} l(\xi(t),q(t),\dot{q}(t),a(t))\,dt=0, \tag{3.2}$$

holds on $\mathfrak{g}\times Q$, upon using variations of the form

$$\delta\xi=\frac{\partial\eta}{\partial t}-ad_\xi\eta=\frac{\partial\eta}{\partial t}-[\xi,\eta],\quad \delta a=-a\eta, \tag{3.3}$$

where $\eta(t)\in\mathfrak{g}$ vanishes at the endpoints and $\delta q(t)$ is unrestricted except for vanishing at the endpoints.

(iv) The following system of Euler–Poincaré equations (with a parameter) coupled with Euler–Lagrange equations holds on $\mathfrak{g}\times TQ\times V^*$:

$$\frac{\partial}{\partial t}\frac{\delta l}{\delta\xi}=-\mathrm{ad}^*_\xi\frac{\delta l}{\delta\xi}+\frac{\delta l}{\delta a}\diamond a \tag{3.4}$$

and

$$\frac{\partial}{\partial t}\frac{\partial l}{\partial\dot{q}^i}-\frac{\partial l}{\partial q^i}=0. \tag{3.5}$$

The strategy of the proof is simple: one just determines the form of the variations on the reduced space $\mathfrak{g}\times Q\times V^*$ that are induced by variations on the unreduced space $TG\times TQ$ and includes the relation of $a(t)$ to a_0. One then carries the variational principle to the quotient. See Ref. 6 for details. Here we have included the extra factor of Q which is needed in the present application; this will be the space of potentials for the Maxwell field. This extra factor does not substantively alter the arguments.

B. The Kelvin–Noether Theorem

We start with a Lagrangian L_{a_0} depending on a parameter $a_0\in V^*$ as above and introduce a manifold $\mathscr{C}$ on which G acts. We assume this is also a right action and suppose we have an equivariant map $\mathscr{K}:\mathscr{C}\times V^*\to\mathfrak{g}^{**}$.

In the case of continuum theories, the space $\mathscr{C}$ is chosen to be a loop space and $\langle\mathscr{K}(c,a),\mu\rangle$ for $c\in\mathscr{C}$ and $\mu\in\mathfrak{g}^*$ will be a circulation. This class of examples also shows why we *do not* want to identify the double dual $\mathfrak{g}^{**}$ with $\mathfrak{g}$.

Define the ***Kelvin–Noether quantity*** $I:\mathscr{C}\times\mathfrak{g}\times TQ\times V^*\to\mathbb{R}$ by

$$I(c,\xi,q,\dot{q},a)=\left\langle\mathscr{K}(c,a),\frac{\delta l}{\delta\xi}(\xi,q,\dot{q},a)\right\rangle. \tag{3.6}$$

Theorem 3.2 (Kelvin–Noether): Fixing $c_0\in\mathscr{C}$, let $\xi(t),q(t),\dot{q}(t),a(t)$ satisfy the Euler–Poincaré equations and define $g(t)$ to be the solution of $\dot{g}(t)=\xi(t)g(t)$ and, say, $g(0)=e$. Let $c(t)=g(t)^{-1}c_0$ and $I(t)=I(c(t),\xi(t),q(t),\dot{q}(t),a(t))$.

Then

$$\frac{d}{dt}I(t)=\left\langle \mathscr{K}(c(t),a(t)),\frac{\delta l}{\delta a}\diamond a\right\rangle. \tag{3.7}$$

The proof of this theorem is relatively straightforward; we refer to Ref. 6. We shall express the relation (3.7) explicitly for Maxwell–Vlasov plasmas at the end of Sec. VII.

IV. AN ACTION FOR THE MAXWELL–VLASOV EQUATIONS

A typical element of $T\mathbb{R}^3\cong\mathbb{R}^3\times\mathbb{R}^3$ will be denoted $\mathbf{z}=(\mathbf{x},\mathbf{v})$. We let $\pi_s:T\mathbb{R}^3\to\mathbb{R}^3$ and $\pi_v:T\mathbb{R}^3\to\mathbb{R}^3$ be the projections $\pi_s(\mathbf{z})=\mathbf{x}$ and $\pi_v(\mathbf{z})=\mathbf{v}$ onto the first and second factors, respectively.

A. Spaces of fields

We let $\mathrm{Diff}(T\mathbb{R}^3)$ denote the group of C^∞-diffeomophisms from $T\mathbb{R}^3$ onto itself. An element $\psi\in\mathrm{Diff}(T\mathbb{R}^3)$ maps plasma particles having initial position and velocity $(\mathbf{x}_0,\mathbf{v}_0)$ to their current position and velocity $(\mathbf{x},\mathbf{v})=\psi(\mathbf{x}_0,\mathbf{v}_0)$. This is the particle evolution map. We shall sometimes abbreviate $(\mathbf{x}_0,\mathbf{v}_0)=\mathbf{z}_0$, $(\mathbf{x},\mathbf{v})=\mathbf{z}$, etc. The spatial components of $\psi(\mathbf{x}_0,\mathbf{v}_0)$ are written as $\mathbf{x}(\mathbf{x}_0,\mathbf{v}_0)$ and the velocity components as $\mathbf{v}(\mathbf{x}_0,\mathbf{v}_0)$. We shall also use the following notation:

(i) $\mathscr{V}=C^\infty(\mathbb{R}^3,\mathbb{R})$ is the space of electric potentials $\Phi(\mathbf{x})$;
(ii) $\mathscr{A}$ is the space of magnetic potentials $A(\mathbf{x})$;
(iii) $\mathscr{F}=C^\infty(T\mathbb{R}^3,\mathbb{R})$ is the space of plasma densities $f(\mathbf{x},\mathbf{v})$;
(iv) $\mathscr{F}_0=C_0^\infty(T\mathbb{R}^3,\mathbb{R})$ is the space of plasma densities with compact support; and
(v) $\mathscr{D}_0=C_0^\infty(\mathbb{R}^3,\mathbb{R})$ is a space of test functions, denoted $\varphi(\mathbf{x})$.

The test functions $\varphi(\mathbf{x})$ are used to localize the variational principle. Thus, once one obtains Euler–Lagrange equations depending on f_0 and φ_0, if their validity can be naturally extended for any f_0 and φ_0, which will happen in our case, then we shall consider those extended equations to be the Euler–Lagrange equations of the system. We will usually be interested in the Euler–Lagrange equations for $f_0>0$ and $\varphi_0=1$.

B. The Lagrangian and the action

For each choice of the initial plasma distribution function f_0 and the test function φ_0, we define the Lagrangian

$$\begin{aligned}L_{f_0,\varphi_0}(\psi,\dot\psi,\Phi,\dot\Phi,\mathbf{A},\dot{\mathbf{A}})=&\int d\mathbf{x}_0\,d\mathbf{v}_0\,f_0(\mathbf{x}_0,\mathbf{v}_0)\Big(\frac{1}{2}m|\dot{\mathbf{x}}(\mathbf{x}_0,\mathbf{v}_0)|^2+\frac{1}{2}m|\dot{\mathbf{x}}(\mathbf{x}_0,\mathbf{v}_0)-\mathbf{v}(\mathbf{x}_0,\mathbf{v}_0)|^2\\&+q\dot{\mathbf{x}}(\mathbf{x}_0,\mathbf{v}_0)\cdot\mathbf{A}(\mathbf{x}(\mathbf{x}_0,\mathbf{v}_0))-q\Phi(\mathbf{x}(\mathbf{x}_0,\mathbf{v}_0))\Big)\\&+\frac{1}{2}\int d\mathbf{r}\,\varphi_0(\mathbf{r})\Big(\Big|\nabla_{\mathbf{r}}\Phi+\frac{\partial\mathbf{A}}{\partial t}(\mathbf{r})\Big|^2-|\nabla_{\mathbf{r}}\times\mathbf{A}(\mathbf{r})|^2\Big).\end{aligned} \tag{4.1}$$

This Lagrangian is the natural generalization of that for an N-particle system, with terms corresponding to kinetic energy, electric and magnetic field energy, the usual magnetic coupling term with coupling constant q (the electric charge), and a constraint that ties the Eulerian fluid velocity $\mathbf{v}$ to $\dot{\mathbf{x}}$, the material derivative of the Lagrangian particle trajectory. Here $\mathbf{x}$ and $\mathbf{v}$ are Lagrangian phase space variables, while $\mathbf{A}$ and Φ are Eulerian field variables. Thus, there should be no confusion created by the slight abuse of notation in abbreviating $\partial\mathbf{A}/\partial t$ and $\partial\Phi/\partial t$ as $\dot\Phi$ and $\dot{\mathbf{A}}$, respectively, in the arguments of the Lagrangian. This Lagrangian is inspired by Low.[1] However, we have added the term

$$\tfrac{1}{2}m|\dot{\mathbf{x}}(\mathbf{x}_0,\mathbf{v}_0)-\mathbf{v}(\mathbf{x}_0,\mathbf{v}_0)|^2,$$

which allows $\mathbf{v}$ to be varied independently in the variational treatment.

Consider the action

$$\mathfrak{S}=\int dt\; L_{f_0,\varphi_0}(\psi,\dot{\psi},\Phi,\dot{\Phi},\mathbf{A},\dot{\mathbf{A}}),$$

defined on the family of curves $(\psi(t),\Phi(t),\mathbf{A}(t))$ satisfying the usual fixed-endpoint conditions $(\psi(t_i),\Phi(t_i),\mathbf{A}(t_i))=(\psi_i,\Phi_i,\mathbf{A}_i)$, $i=1,2$. One now applies the standard techniques of the calculus of variations. In particular, integration by parts can be performed since f_0 and φ_0 have compact support. Moreover, once the Euler–Lagrange equations have been obtained, their validity can be easily extended in a natural way for $f_0>0$ and $\varphi_0=1$.

C. Derivation of the equations

To write the equations of motion, we need some additional notation. Consider the evolution map $\psi_t(\mathbf{x}_0,\mathbf{v}_0)=(\mathbf{x},\mathbf{v})$ so that ψ_t relates the initial positions and velocities of fluid particles to their positions and velocities at time t. Let $\mathbf{u}$ be the corresponding vector field:

$$\mathbf{u}(\mathbf{x},\mathbf{v}):=\dot{\psi}_t\circ\psi_t^{-1}(\mathbf{x},\mathbf{v})=:\dot{\mathbf{x}}\,\frac{\partial}{\partial\mathbf{x}}+\dot{\mathbf{v}}\,\frac{\partial}{\partial\mathbf{v}},$$

so the components of $\mathbf{u}$ are $(\dot{\mathbf{x}},\dot{\mathbf{v}})$. Recall that the transport of f_0 as a scalar is given by $f(\mathbf{x},\mathbf{v},t)=f_0\circ\psi_t^{-1}(\mathbf{x},\mathbf{v})$, which satisfies

$$\frac{\partial f}{\partial t}+\mathbf{u}\cdot\nabla_{\mathbf{z}}\,f=0, \tag{4.2}$$

where $\nabla_{\mathbf{z}}=(\nabla_{\mathbf{x}},\nabla_{\mathbf{v}})$ is the six-dimensional gradient operator in $(\mathbf{x},\mathbf{v})$ space. Let J_ψ be the Jacobian determinant of the mapping $\psi\in\mathrm{Diff}(T\mathbb{R}^3)$, that is, the determinant of the Jacobian matrix $\partial(\mathbf{x},\mathbf{v})/\partial(\mathbf{x}_0,\mathbf{v}_0)$.

Define $F(\mathbf{x},\mathbf{v},t)$ to be f_0, transported as a *density*:

$$F(\mathbf{x}(\mathbf{x}_0,\mathbf{v}_0),\mathbf{v}(\mathbf{x}_0,\mathbf{v}_0),t)J_\psi(\mathbf{x}_0,\mathbf{v}_0)=f_0(\mathbf{x}_0,\mathbf{v}_0),$$

so that

$$\frac{\partial F}{\partial t}+\nabla_{\mathbf{z}}\cdot(F\mathbf{u})=0. \tag{4.3}$$

Taking variations in our Lagrangian (4.1) and making use of the preceding equation for F, we obtain the following equations (taking $\varphi_0=1$):

$$\begin{aligned}
&\delta\mathbf{x}:\ \ m\ddot{\mathbf{x}}+m(\ddot{\mathbf{x}}-\dot{\mathbf{v}})=-q\nabla_{\mathbf{x}}\Phi-q\frac{\partial\mathbf{A}}{\partial t}+q\dot{\mathbf{x}}\times(\nabla_{\mathbf{x}}\times\mathbf{A}),\\
&\delta\mathbf{v}:\ \ \dot{\mathbf{x}}-\mathbf{v}=0,\\
&\delta\Phi:\ \ \nabla_{\mathbf{x}}\cdot\left(\nabla_{\mathbf{x}}\Phi+\frac{\partial\mathbf{A}}{\partial t}\right)=-q\int d\mathbf{v}\;F(\mathbf{x},\mathbf{v},t),\\
&\delta\mathbf{A}:\ \ \nabla_{\mathbf{x}}\times(\nabla_{\mathbf{x}}\times\mathbf{A})=-\frac{\partial}{\partial t}\left(\nabla_{\mathbf{x}}\Phi+\frac{\partial\mathbf{A}}{\partial t}\right)+q\int d\mathbf{v}\;\mathbf{v}F(\mathbf{x},\mathbf{v},t).
\end{aligned} \tag{4.4}$$

The second equation in (4.4) treats the Eulerian velocity $\mathbf{v}$ as a Lagrange multiplier, and ties its value to the fluid velocity $\dot{\mathbf{x}}$, hence $\dot{\mathbf{v}}=\ddot{\mathbf{x}}$ as well. The first two variational equations in the set (4.4) provide the desired relation for particle acceleration and the last two equations are the Maxwell equations with source terms. Thus, Hamilton's principle with Low's action provides the equations for self-consistent particle motion in an electromagnetic field, as required, and the description is completed by substituting

$$\left(\mathbf{v}, -\frac{q}{m}\left[\nabla_{\mathbf{x}}\Phi + \frac{\partial \mathbf{A}}{\partial t} - \mathbf{v}\times(\nabla_{\mathbf{x}}\times\mathbf{A})\right]\right)$$

for the components of $\mathbf{u}$ in the transport equation (4.2) to give the Vlasov equation (2.4).

V. THE MAXWELL–VLASOV SYSTEM AS EULER–POINCARÉ EQUATIONS

We will now specialize the general Euler–Poincaré theorem to the case of plasmas. The Lagrangian $L_{f_0,\varphi_0}(\psi,\dot{\psi},\Phi,\dot{\Phi},\mathbf{A},\dot{\mathbf{A}})$ in Eq. (4.1) has a right Diff$(T\mathbb{R}^3)$-symmetry. Let $\eta \in \mathrm{Diff}(T\mathbb{R}^3)$, $F \in \mathscr{F}$, and define the action of η on F by $F\eta = (F\circ\eta)J_\eta$ where, as above, J_η is the Jacobian determinant of η.

The symmetry of $L_{f_0,\varphi_0}(\psi,\dot{\psi},\Phi,\dot{\Phi},\mathbf{A},\dot{\mathbf{A}})$ is the property

$$L_{f_0\eta,\varphi_0}(\psi\eta,\dot{\psi}\eta,\Phi,\dot{\Phi},\mathbf{A},\dot{\mathbf{A}}) = L_{f_0,\varphi_0}(\psi,\dot{\psi},\Phi,\dot{\Phi},\mathbf{A},\dot{\mathbf{A}}),$$

for all $\eta \in \mathrm{Diff}(T\mathbb{R}^3)$.

A. Ingredients for Euler–Poincaré

Now we apply the general Euler–Poincaré Theorem 3.1, taking $G = \mathrm{Diff}(T\mathbb{R}^3)$ and $\mathscr{Q} = \mathscr{V}\times\mathscr{A}$ and the parameter $a_0 = f_0$. As we have explained before, φ_0 is an auxiliary quantity that will ultimately take the value unity. In the general Euler–Poincaré Theorem 3.1 we take

$$\delta\mathbf{u} = \frac{\partial \mathbf{w}}{\partial t} - \mathrm{ad}_{\mathbf{u}}\mathbf{w}, \quad \delta a = -\pounds_{\mathbf{w}} a, \tag{5.1}$$

where $\mathbf{w} \in \mathfrak{g}$ is a vector field on $T\mathbb{R}^3$, $\pounds_{\mathbf{w}}$ is the Lie derivative, and $\mathrm{ad}_{\mathbf{u}}\mathbf{w} = -[\mathbf{u},\mathbf{w}]$ defines $\mathrm{ad}_{\mathbf{u}}\mathbf{w}$ in terms of the Lie bracket of vector fields, $[\mathbf{u},\mathbf{w}]$. The Euler–Poincaré equations (3.4) are

$$\frac{\partial}{\partial t}\frac{\delta l}{\delta \mathbf{u}} = -a\,d^*_{\mathbf{u}}\frac{\delta l}{\delta \mathbf{u}} + \frac{\delta l}{\delta a}\diamond a, \tag{5.2}$$

where $\mathrm{ad}^*_{\mathbf{u}}$ is the dual of $\mathrm{ad}_{\mathbf{u}}$ and $\delta l/\delta \mathbf{u}$ is a one-form density. The one-form density $(\delta l/\delta a)\diamond a$ is defined by

$$\left\langle \frac{\delta l}{\delta a}\diamond a, \mathbf{w}\right\rangle = -\int \frac{\delta l}{\delta a}\cdot \pounds_{\mathbf{w}} a. \tag{5.3}$$

When the quantities a are tensor fields, $\delta l/\delta a$ will be elements of the dual space under the natural pairing.

We shall apply this result to obtain the Maxwell–Vlasov system (2.4)–(2.7) as Euler–Poincaré equations. We begin by recording a formula that will be needed later. Let $\mathbf{u},\mathbf{w}$ be two elements of $\mathfrak{g}$, the Lie algebra of vector fields for the diffeomorphism group on a manifold $\mathscr{M}$. Choose the one-form density $\mathbf{c} \in \mathfrak{g}^*$, and let the pairing $\langle \mathbf{c},\mathbf{u}\rangle : \mathfrak{g}^*\times\mathfrak{g}\to\mathbb{R}$ be given by

$$\langle \mathbf{c},\mathbf{u}\rangle = \int_{\mathscr{M}} d\mathbf{z}\ \mathbf{c}\cdot\mathbf{u} = \int_{\mathscr{M}} d\mathbf{z}\ c_j u^j, \tag{5.4}$$

where c_j and u^j, $j = 1,\ldots,n$, are components of $\mathbf{c}$ and $\mathbf{u}$ in $\mathbb{R}^n$ and $d\mathbf{z}$ is the volume form on $\mathscr{M}$. Then we can write the desired formula,

$$\begin{aligned}\langle \mathrm{ad}^*_{\mathbf{u}}\mathbf{c},\mathbf{w}\rangle &= \int d\mathbf{z}\ \mathrm{ad}^*_{\mathbf{u}}\mathbf{c}\cdot\mathbf{w}\\ &= \int d\mathbf{z}\ \mathbf{c}\cdot\mathrm{ad}_{\mathbf{u}}\mathbf{w}\\ &= -\int d\mathbf{z}\ c_i\left(u^j\frac{\partial w^i}{\partial z^j}-w^j\frac{\partial u^i}{\partial z^j}\right)\\ &= \int d\mathbf{z}\ w^i\left(c_j\frac{\partial u^j}{\partial z^i}+c_i(\nabla\cdot\mathbf{u})+(\mathbf{u}\cdot\nabla)c_i\right)=\langle \pounds_{\mathbf{u}}\mathbf{c},\mathbf{w}\rangle. \end{aligned} \tag{5.5}$$

Here $\pounds_{\mathbf{u}}\mathbf{c}$ is the Lie derivative of the the one-form density $\mathbf{c}$ with respect to the vector field $\mathbf{u}$, z^j is the coordinate chart, and c_j, u^j, w^j are the components of vectors in $\mathbb{R}^n$. Unless otherwise stated, we sum repeated indices over their range, $i,j=1,\ldots,n$, where n is the dimension of $\mathscr{M}$. We assume that the vector fields and one-form densities are defined so that integration by parts gives no contribution at the boundary (inclusion of nonzero boundary terms is straightforward). Formula (5.5) for $\mathrm{ad}^*_{\mathbf{u}}\mathbf{c}$ will be useful later.

By definition, $\mathbf{u}=(\dot{\mathbf{x}},\dot{\mathbf{v}})$; we will denote $\mathbf{u}_s=\dot{\mathbf{x}}$, the spatial part of the phase space velocity field.

B. The reduced action

We may transform the action (4.1) into the Eulerian description as the reduced action

$$\begin{aligned}\mathfrak{S}_{\mathrm{red}} &= \int dt\ l(\mathbf{u},\Phi,\dot{\Phi},\mathbf{A},\dot{\mathbf{A}})\\ &= \int dt\ \int d\mathbf{x}\ d\mathbf{v}\ F(\mathbf{x},\mathbf{v},t)\left(\frac{1}{2}m|\mathbf{u}_s|^2+\tfrac{1}{2}m|\mathbf{u}_s-\mathbf{v}|^2-q\Phi+q\mathbf{u}_s\cdot\mathbf{A}\right)\\ &\quad+\frac{1}{2}\int dt\int d\mathbf{x}\left|\nabla_{\mathbf{x}}\Phi+\frac{\partial\mathbf{A}}{\partial t}\right|^2-|\nabla_{\mathbf{x}}\times\mathbf{A}|^2. \end{aligned} \tag{5.6}$$

We vary this action with respect to $\mathbf{u}_s$, F, Φ and $\mathbf{A}$:

$$\begin{aligned}\delta\mathfrak{S}_{\mathrm{red}} &= \int dt\int d\mathbf{x}\ d\mathbf{v}\{F\,[(m\mathbf{u}_s+m(\mathbf{u}_s-\mathbf{v})+q\mathbf{A})\cdot\delta\mathbf{u}_s-q\,\delta\Phi+\mathbf{u}_s\cdot\delta\mathbf{A}]\\ &\quad+\delta F[\tfrac{1}{2}m|\mathbf{u}_s|^2+\tfrac{1}{2}m|\mathbf{u}_s-\mathbf{v}|^2-q\Phi+q\mathbf{u}_s\cdot\mathbf{A}]\}\\ &\quad+\int dt\int d\mathbf{x}\left(\nabla_{\mathbf{x}}\Phi+\frac{\partial\mathbf{A}}{\partial t}\right)\cdot\left(\nabla_{\mathbf{x}}\delta\Phi+\delta\frac{\partial\mathbf{A}}{\partial t}\right)-(\nabla_{\mathbf{x}}\times\mathbf{A})\cdot(\nabla_{\mathbf{x}}\times\delta\mathbf{A}). \end{aligned} \tag{5.7}$$

Stationary variations in Φ and $\mathbf{A}$ yield

$$\begin{aligned}\nabla_{\mathbf{x}}\cdot\left(\nabla_{\mathbf{x}}\Phi+\frac{\partial\mathbf{A}}{\partial t}\right)&=-q\int d\mathbf{v}\ F(\mathbf{x},\mathbf{v},t),\\ \nabla_{\mathbf{x}}\times(\nabla_{\mathbf{x}}\times\mathbf{A})&=-\frac{\partial}{\partial t}\left(\nabla_{\mathbf{x}}\Phi+\frac{\partial\mathbf{A}}{\partial t}\right)+q\int d\mathbf{v}\ F(\mathbf{x},\mathbf{v},t)\mathbf{u}_s. \end{aligned} \tag{5.8}$$

Thus, Maxwell's equations for the electromagnetic field of the plasma are recovered by requiring $\delta l=0$ for all variations of the field potentials Φ and $\mathbf{A}$. To continue toward the Euler–Poincaré form of the Maxwell–Vlasov equations, one must determine the forms of the variations $\delta\mathbf{u}_s$ and δF in (5.7).

According to the general theory, variations in the particle evolution map ψ lead to variations in the phase space velocity $\delta\mathbf{u}$ of the form

$$\delta\mathbf{u}=\frac{\partial\mathbf{w}}{\partial t}+[\mathbf{u},\mathbf{w}]\equiv\frac{\partial\mathbf{w}}{\partial t}-\mathrm{ad}_{\mathbf{u}}\mathbf{w}. \tag{5.9}$$

This Euler–Poincaré form of the variations may also be verified by a direct tensorial calculation, which is given in Ref. 6. The spatial part of this equation gives the variation of the spatial part of the field $\mathbf{u}$.

Variations of the field ψ also induce variations of the density F, in the same way as the parameter variations are induced in the general theory for the Euler–Poincaré equations [see Eq. (5.1)]. Either from that equation, or by direct calculations, these variations are computed to be

$$\delta F=-\nabla_{\mathbf{z}}\cdot(F\mathbf{w}), \tag{5.10}$$

which is equivalent to the formula

$$\delta(F\ d\mathbf{x}\ d\mathbf{v})=-\pounds_{\mathbf{w}}(F\ d\mathbf{x}\ d\mathbf{v}).$$

C. Computation of the variations

With these formulas for $\delta\mathbf{u}$ and δF in place, we compute

$$\begin{aligned}\delta\mathfrak{S}_{\mathrm{red}}=\int dt\int d\mathbf{x}\ d\mathbf{v}\ F\Big[&(m\mathbf{u}_s+m(\mathbf{u}_s-\mathbf{v})+q\mathbf{A})\cdot\left(\frac{\partial}{\partial t}\mathbf{w}+[\mathbf{u},\mathbf{w}]\right)\Big]\\&-\nabla_{\mathbf{z}}\cdot(F\mathbf{w})\left(\frac{1}{2}(m|\mathbf{u}_s|^2+m|\mathbf{u}_s-\mathbf{v}|^2)+q\mathbf{u}_s\cdot\mathbf{A}-q\Phi\right).\end{aligned} \tag{5.11}$$

Integrating by parts and dropping boundary terms gives

$$\begin{aligned}\delta\mathfrak{S}_{\mathrm{red}}=\int dt\int d\mathbf{x}\ d\mathbf{v}\ \mathbf{w}\cdot\Big[&-\frac{\partial}{\partial t}\left(Fm\left(\mathbf{u}_s+(\mathbf{u}_s-\mathbf{v})+\frac{q}{m}\mathbf{A}\right)\right)-\mathrm{ad}^*_{\mathbf{u}}\left(Fm\left(\mathbf{u}_s+(\mathbf{u}_s-\mathbf{v})+\frac{q}{m}\mathbf{A}\right)\right)\\&+F\nabla_{\mathbf{z}}\left(\frac{1}{2}m|\mathbf{u}_s|^2+\tfrac{1}{2}m|\mathbf{u}_s-\mathbf{v}|^2+q\mathbf{u}_s\cdot\mathbf{A}-q\Phi\right)\Big].\end{aligned} \tag{5.12}$$

Expanding the ad* term using formula (5.5) results in

$$\begin{aligned}\delta\mathfrak{S}_{\mathrm{red}}=\int dt\int d\mathbf{x}\ d\mathbf{v}\ \mathbf{w}\cdot\Big[&-\frac{\partial F}{\partial t}m\left(\mathbf{u}_s+(\mathbf{u}_s-\mathbf{v})+\frac{q}{m}\mathbf{A}\right)-Fm\frac{\partial}{\partial t}\left(\mathbf{u}_s+(\mathbf{u}_s-\mathbf{v})+\frac{q}{m}\mathbf{A}\right)\\&-(\mathbf{u}\cdot\nabla_{\mathbf{z}})\left(Fm\left(\mathbf{u}_s+(\mathbf{u}_s-\mathbf{v})+\frac{q}{m}\mathbf{A}\right)\right)-Fm\left(\mathbf{u}_s+(\mathbf{u}_s-\mathbf{v})+\frac{q}{m}\mathbf{A}\right)(\nabla_{\mathbf{z}}\cdot\mathbf{u})\\&-\left(Fm\left(\mathbf{u}_{sj}+(\mathrm{u}_{sj}-\mathrm{v}_j)+\frac{q}{m}\mathrm{A}_j\right)\right)\nabla_{\mathbf{z}}u^j+F\nabla_{\mathbf{z}}\left(\tfrac{1}{2}m|\mathbf{u}_s|^2+\tfrac{1}{2}m|\mathbf{u}_s-\mathbf{v}|^2+q\mathbf{u}_s\cdot\mathbf{A}-q\Phi\right)\Big].\end{aligned} \tag{5.13}$$

We expand the products to obtain

$$\begin{aligned}\delta\mathfrak{S}_{\mathrm{red}}=\int dt\int d\mathbf{x}\ d\mathbf{v}\ \mathbf{w}\cdot\Big\{&-m\left(\mathbf{u}_s+(\mathbf{u}_s-\mathbf{v})+\frac{q}{m}\mathbf{A}\right)\left(\frac{\partial F}{\partial t}+\mathbf{u}\cdot\nabla_{\mathbf{z}}F\right)\\&-Fm\left(\mathbf{u}_s+(\mathbf{u}_s-\mathbf{v})+\frac{q}{m}\mathbf{A}\right)(\nabla_{\mathbf{z}}\cdot\mathbf{u})-Fm\left[\left(\frac{\partial}{\partial t}+(\mathbf{u}\cdot\nabla_{\mathbf{z}})\right)\left(\mathbf{u}_s+(\mathbf{u}_s-\mathbf{v})+\frac{q}{m}\mathbf{A}\right)+\frac{q}{m}\nabla_{\mathbf{z}}\Phi\right]\\&-Fm\left(\mathrm{u}_{sj}+(\mathrm{u}_{sj}-\mathrm{v}_j)+\frac{q}{m}\mathrm{A}^j\right)\nabla_{\mathbf{z}}u^j+Fm\mathrm{u}_{sj}\nabla_{\mathbf{z}}\mathrm{u}_s^j+Fq\mathrm{A}^j\nabla_{\mathbf{z}}\mathrm{u}_{sj}\\&+Fm(\mathrm{u}_{sj}-\mathrm{v}_j)\nabla_{\mathbf{z}}(\mathrm{u}_s^j-\mathrm{v}_s^j)+Fq\mathrm{u}_{sj}\nabla_{\mathbf{z}}\mathrm{A}^j\Big\}.\end{aligned} \tag{5.14}$$

Consider the last two lines of Eq. (5.14). Upon writing $\mathbf{w}=(\mathbf{w}_1,\mathbf{w}_2)$, where $\mathbf{w}_1,\mathbf{w}_2\in\mathbb{R}^3$, these lines reduce to

$$\begin{aligned}
&-Fm(\mathbf{u}_s+(\mathbf{u}_s-\mathbf{v}))\cdot(\mathbf{w}_1\cdot\nabla_{\mathbf{x}}+\mathbf{w}_2\cdot\nabla_{\mathbf{v}})\mathbf{u}+Fm(\mathbf{u}_s+(\mathbf{u}_s-\mathbf{v}))\cdot(\mathbf{w}_1\cdot\nabla_{\mathbf{x}}+\mathbf{w}_2\cdot\nabla_{\mathbf{v}})\mathbf{u}_s\\
&\quad -Fq\mathbf{A}\cdot(\mathbf{w}_1\cdot\nabla_{\mathbf{x}}+\mathbf{w}_2\cdot\nabla_{\mathbf{v}})\mathbf{u}+Fq\mathbf{A}\cdot(\mathbf{w}_1\cdot\nabla_{\mathbf{x}}+\mathbf{w}_2\cdot\nabla_{\mathbf{v}})\mathbf{u}_s+Fq\mathbf{u}_s\cdot(\mathbf{w}_1\cdot\nabla_{\mathbf{x}}+\mathbf{w}_2\cdot\nabla_{\mathbf{v}})\mathbf{A}\\
&\quad -Fm(\mathbf{u}_s-\mathbf{v})\cdot(\mathbf{w}_1\cdot\nabla_{\mathbf{x}}+\mathbf{w}_2\cdot\nabla_{\mathbf{v}})\mathbf{v} \;=\; Fq\mathbf{u}_s(\mathbf{w}_1\cdot\nabla_{\mathbf{x}})\mathbf{A}-Fm(\mathbf{u}_s-\mathbf{v})\cdot\mathbf{w}_2. \qquad (5.15)
\end{aligned}$$

The first three lines cancel to zero because they only involve spatial velocity projections, where $\mathbf{u}=\mathbf{u}_s$. The last line follows upon using $\nabla_{\mathbf{x}}\mathbf{v}=0$ and $\nabla_{\mathbf{v}}\mathbf{A}=0$, which hold, respectively, because $\mathbf{v}$ is an independent coordinate and $\mathbf{A}$ is a function of space alone. Similarly, and under the additional observation that $\nabla_{\mathbf{z}}\Phi=(\nabla_{\mathbf{x}}\Phi,0)$ because the potential Φ also does not depend on velocity, the other three lines of Eq. (5.14) are purely spatial, i.e., the projection onto the last three coordinates would give zero, and hence the contribution to the variation of the action $\delta\mathfrak{S}_{\text{red}}$ from $\mathbf{w}_2$ comes only from the calculation in Eq. (5.15). Stationarity of the action under the velocity components of the variation, $\mathbf{w}_2$, then implies

$$Fm(\mathbf{u}_s-\mathbf{v})=0, \quad \text{i.e.,} \quad \mathbf{u}_s=\mathbf{v}. \qquad (5.16)$$

Consequently, in Eq. (5.14) we can write $\mathbf{u}$ as $(\mathbf{v},\mathbf{a})$ where $\mathbf{a}$ is yet to be determined, and we can also replace $\mathbf{u}_s-\mathbf{v}$ with zero. On doing this, the contribution to the variation of the action from $\mathbf{w}_1$ becomes

$$\begin{aligned}
\delta\mathfrak{S}_{\text{red}}=\int dt\int d\mathbf{x}\; d\mathbf{v}\;\mathbf{w}_1\cdot\Bigg[&-(m\mathbf{v}+q\mathbf{A})\left(\frac{\partial F}{\partial t}+\nabla_{\mathbf{z}}\cdot(F\mathbf{u})\right)\\
&-F\left(m\frac{\partial\mathbf{v}}{\partial t}+m(\mathbf{v}\cdot\nabla_{\mathbf{x}})\mathbf{v}+m(\mathbf{a}\cdot\nabla_{\mathbf{v}})\mathbf{v}+q\frac{\partial\mathbf{A}}{\partial t}+q\nabla_{\mathbf{x}}\Phi+q\mathbf{v}\times(\nabla_{\mathbf{x}}\times\mathbf{A})\right)\Bigg]. \qquad (5.17)
\end{aligned}$$

Here, we have used standard vector identities in obtaining the result

$$\mathbf{w}\cdot qF(\mathrm{u}_{sj}\nabla_{\mathbf{z}}\mathrm{A}_s^j-(\mathbf{u}\cdot\nabla_{\mathbf{z}})\mathbf{A})=qF\mathbf{w}_1\cdot(\mathbf{v}\times(\nabla_{\mathbf{x}}\times\mathbf{A})). \qquad (5.18)$$

Referring to the continuity equation (4.3) for F and using the identities $\partial\mathbf{v}/\partial t=0$ and $\nabla_{\mathbf{x}}\mathbf{v}=0$ reduces Eq. (5.17) to

$$\delta\mathfrak{S}_{\text{red}}=-\int dt\int d\mathbf{x}\; d\mathbf{v}\;\mathbf{w}_1\cdot F\left(m\mathbf{a}+q\nabla_{\mathbf{x}}\Phi+q\frac{\partial\mathbf{A}}{\partial t}-q\mathbf{v}\times(\nabla_{\mathbf{x}}\times\mathbf{A})\right).$$

Therefore, $\delta\mathfrak{S}_{\text{red}}=0$ implies that

$$m\mathbf{a}=-q\nabla_{\mathbf{x}}\Phi-q\frac{\partial\mathbf{A}}{\partial t}+q\mathbf{v}\times(\nabla_{\mathbf{x}}\times\mathbf{A}). \qquad (5.19)$$

Now consider what the invariance of the Boltzmann function f implies. By Eq. (4.2) and substitution for $\mathbf{u}=(\mathbf{v},\mathbf{a})$ we obtain

$$\frac{\partial f}{\partial t}+\mathbf{v}\cdot\nabla_{\mathbf{x}}f-\frac{q}{m}\left[\left(\nabla_{\mathbf{x}}\Phi+\frac{\partial\mathbf{A}}{\partial t}\right)-\mathbf{v}\times(\nabla_{\mathbf{x}}\times\mathbf{A})\right]\cdot\nabla_{\mathbf{v}}f=0, \qquad (5.20)$$

and so, along with Eqs. (5.8), we have recovered the full Maxwell–Vlasov system from stationarity of the action (5.6) entirely in the Eulerian description.

VI. THE GENERALIZED LEGENDRE TRANSFORMATION

A. Introduction

Before passing to the Hamiltonian description of the Maxwell–Vlasov equations, we pause to explain the theoretical background of how one does this when there are degeneracies. This section can be skipped if one is willing to simply take on faith that one should *do the Legendre transformation slowly and carefully* when there are degeneracies.

As explained in Ref. 3, one normally thinks of passing from Euler–Poincaré equations on a Lie algebra $\mathfrak{g}$ to Lie–Poisson equations on the dual $\mathfrak{g}^*$ by means of the Legendre transformation. In some situations involving the Euler–Poincaré equations, one starts with a Lagrangian on $\mathfrak{g}\times V^*$ and performs a *partial* Legendre transformation, in the variable ξ only, by writing

$$\mu=\frac{\delta l}{\delta \xi}, \quad h(\mu,a)=\langle \mu,\xi\rangle - l(\xi,a). \tag{6.1}$$

Since

$$\frac{\delta h}{\delta \mu}=\xi+\left\langle \mu,\frac{\delta \xi}{\delta \mu}\right\rangle-\left\langle \frac{\delta l}{\delta \xi},\frac{\delta \xi}{\delta \mu}\right\rangle=\xi, \tag{6.2}$$

and $\delta h/\delta a=-\delta l/\delta a$, we see that the Euler–Poincaré equations (3.4) for $\xi\in\mathfrak{g}$ and $\dot{a}(t)=-a(t)\xi(t)$ imply the Hamiltonian semidirect-product Lie–Poisson equations for $\mu\in\mathfrak{g}^*$. Namely,

$$\frac{\partial}{\partial t}\mu=-\mathrm{ad}^*_{(\delta h/\delta \mu)}\mu-\frac{\delta h}{\delta a}\diamond a=\{\mu,h\}_{LP}, \quad \frac{\partial}{\partial t}a=-a\,\frac{\delta h}{\delta \mu}=\{a,h\}_{LP}, \tag{6.3}$$

with $(+)$ Lie–Poisson bracket on $\mathfrak{g}^*\times V^*$ given by

$$\{g,h\}_{LP}=-\left\langle \mu,\mathrm{ad}_{(\delta h/\delta \mu)}\frac{\delta g}{\delta \mu}\right\rangle+\left\langle a,\frac{\delta g}{\delta a}\frac{\delta h}{\delta \mu}-\frac{\delta h}{\delta a}\frac{\delta g}{\delta \mu}\right\rangle. \tag{6.4}$$

If the Legendre transformation (6.1) is invertible, then one can also pass Lie–Poisson equations to the Euler–Poincaré equations together with the equations $\dot{a}(t)=-a(t)\xi(t)$.

It is important in this paper to give a detailed explanation that incorporates the degeneracy of the parameter-dependent system together with the role of symmetry. Unlike the examples considered in Ref. 6 such as compressible flow or MHD, in the case of the Maxwell–Vlasov system or even the Vlasov–Poisson system, the Lagrangian L_{a_0} corresponding to the action in Eq. (5.6) is *degenerate*, since it does not depend on the variables $\dot{\Phi}$ and $\dot{\mathbf{v}}$. In other words, *the degeneracy and corresponding constraints that appear in Vlasov plasmas are more serious than for fluids or the heavy top, etc*. To deal with this degeneracy, we shall use the generalized Legendre transformation in the context of Lagrangian submanifolds, as described in Ref. 32. This is also related to the Dirac theory of constraints (see Ref. 33). In particular, we shall take special care to ensure that the Hamiltonian formulation of the Maxwell–Vlasov system preserves the constraints associated with the degeneracy of its Lagrangian.

B. The general construction

Let Q be a manifold and $\pi:T^*Q\to Q$ be the cotangent bundle of Q. Then TT^*Q is a symplectic manifold with a symplectic form that can be written in two distinct ways as the exterior derivative of two intrinsic one-forms. These two one-forms are denoted λ and χ and are given in coordinates by

$$\lambda=\dot{p}\,dq+p\,d\dot{q} \tag{6.5}$$

and

$$\chi=\dot{p}\,dq-\dot{q}\,dp, \tag{6.6}$$

where (q,p) are coordinates for T^*Q and $(q,p,\dot{q},\dot{p})$ are the corresponding coordinates for TT^*Q. For the intrinsic definitions of these forms, see Ref. 33.

Let $L:J\to\mathbb{R}$ be a Lagrangian defined on a submanifold $J\subset TQ$ called the ***Lagrangian constraint***. The Legendre transformation is a procedure to obtain a Hamiltonian $H:K\to\mathbb{R}$ defined on a submanifold $K\subset T^*Q$, called the ***Hamiltonian constraint***. The Euler–Lagrange equations are

$$\lambda = dL \quad \text{on } J, \tag{6.7}$$

while the Hamilton equations are

$$\chi = -dH \quad \text{on } K. \tag{6.8}$$

The abbreviated expressions (6.7) and (6.8) stand for

$$\lambda = d(L\circ T\pi) \quad \text{on} \quad (T\pi)^{-1}(J) \tag{6.9}$$

and

$$\chi = -d(H\circ\tau^{-1}) \quad \text{on} \quad (\tau)^{-1}(K), \tag{6.10}$$

where τ is the canonical projection $\tau:TT^*Q\to T^*Q$, given in coordinates by $\tau(q,p,\dot{q},\dot{p}) = (q,p)$. The map $T\pi$ is given by $T\pi(q,p,\dot{q},\dot{p}) = (q,\dot{q})$.

Both the Euler–Lagrange and Hamilton equations define the same Lagrangian submanifold D of TT^*Q. The Lagrangian and Hamiltonian L and H are the generating functions with respect to the one-forms λ and χ, respectively.

The ***generalized Legendre transformation*** consists of the following steps:

Step 1: For each $(q,p)\in T^*Q$ define

$$K(q,p) = \left\{ (q,\dot{q}) \in T_qQ \,\middle|\, \frac{\partial}{\partial\dot{q}}(p\dot{q} - L(q,\dot{q})) = 0 \right\}, \tag{6.11}$$

and let

$$K = \{(q,p)\in T^*Q \,|\, K(q,p)\neq\varnothing\}. \tag{6.12}$$

Assumption: Assume that for each $(q,p)\in K$, the submanifold $K(q,p)$ is connected. This implies that the stationary value

$$\mathrm{stat}_{\dot{q}}(p\dot{q} - L(q,\dot{q})) \tag{6.13}$$

of $p\dot{q} - L(q,\dot{q})$ on $K(q,p)$ is uniquely defined; that is, it does not depend on $\dot{q}$.

Step 2: Define $H:K\to\mathbb{R}$ as follows:

$$H(q,p) = \mathrm{stat}_{\dot{q}}(p\dot{q} - L(q,\dot{q})). \tag{6.14}$$

C. The generalized Legendre transformation with parameters and symmetry

Now we adapt this methodology to the case of parameter-dependent Lagrangians with symmetry. Let $L_{a_0}:TG\times T\mathcal{Q}\to\mathbb{R}$ be a Lagrangian depending on a parameter $a_0\in V^*$. Assume that G acts on V^* on the right and denote by ag the action of $g\in G$ on $a\in V^*$. Assume also the following invariance property:

$$L_{ah}(gh,\dot{g}h,q,\dot{q}) = L_a(g,\dot{g},q,\dot{q}), \tag{6.15}$$

for all $g,h\in G$, all $(q,\dot{q})\in T\mathcal{Q}$, and all $a\in V^*$. A typical element of $T^*G\times T^*\mathcal{Q}$ will be denoted (g,α_g,q,ν_q) or simply (g,α,q,ν). For each $a_0\in V^*$ and $(g,\alpha)\in T^*G$, define

$$K_{a_0}(g,\alpha,q,\nu)=\left\{(g,\dot{g},q,\dot{q})\left|\frac{\partial}{\partial\dot{g}}(\alpha\dot{g}+\nu\dot{q}-L_{a_0}(g,\dot{g},q,\dot{q}))=0\right.\right.$$
$$\left.\left.\text{and }\frac{\partial}{\partial\dot{q}}(\alpha\dot{g}+\nu\dot{q}-L_{a_0}(g,\dot{g},q,\dot{q}))=0\right\}.\tag{6.16}$$

One can immediately check for any $a_0\in V^*$, $h\in G$, and $(g,\alpha,q,\nu)\in T^*G\times T^*\mathcal{Q}$ that $K_{a_0h}(gh,\alpha h,q,\nu)=K_{a_0}(g,\alpha,q,\nu)h$. Define

$$K_{a_0}=\{(g,\alpha,q,\nu)|K_{a_0}(g,\alpha,q,\nu)\neq\varnothing\}.\tag{6.17}$$

Then one can easily prove for any $h\in G$ that $K_{a_0h}=K_{a_0}h$. Define

$$K=\{(g,\alpha,q,\nu,a)|K_a(g,\alpha,q,\nu)\neq\varnothing\}.\tag{6.18}$$

Then $K\subset T^*G\times T^*\mathcal{Q}\times V^*$ is an invariant subset under the action of G given by $(g,\alpha,q,\nu,a)h=(gh,\alpha h,q,\nu,ah)$. Now for each $a_0\in V^*$ we define $H_{a_0}:K_{a_0}\to\mathbb{R}$ by

$$H_{a_0}(g,\alpha,q,\nu)=\alpha\dot{g}+\nu\dot{q}-L_{a_0}(g,\dot{g},q,\dot{q}),\tag{6.19}$$

for any $(g,\dot{g},q,\dot{q})\in K_{a_0}(g,\alpha,q,\nu)$. Then, according to the general theory explained above, Hamilton's equations are, for each $a_0\in V^*$, $-dH_{a_0}=\chi$ on K_{a_0}, where

$$\chi=\dot{\alpha}\,dg-\dot{g}\,d\alpha+\dot{\nu}\,dq-\dot{q}\,d\nu.\tag{6.20}$$

One can also easily prove, using the previous equalities, that $H_{a_0}(g,\alpha,q,\nu)$ has the following invariance property:

$$H_{a_0h}(gh,\alpha h,q,\nu)=H_{a_0}(g,\alpha,q,\nu).\tag{6.21}$$

Let $\mathfrak{s}^*$ be the dual of the semidirect product Lie algebra $\mathfrak{s}=\mathfrak{g}\circledS V$. Then define $\mathcal{K}\subset\mathfrak{s}^*\times T^*\mathcal{Q}$ by

$$\mathcal{K}=\{(\alpha,q,\nu,a)\in\mathfrak{s}^*\times T^*\mathcal{Q}|(e,\alpha,q,\nu,a)\in K\},$$

and the Hamiltonian $h_{\mathcal{K}}:\mathcal{K}\to\mathbb{R}$ by $h_{\mathcal{K}}(\alpha,a,q,\nu)=H_a(e,\alpha,q,\nu)$. Thus, $h_{\mathcal{K}}$ is the restriction to $\mathcal{K}\subset\mathfrak{s}^*$ of the right invariant Hamiltonian $H:K\to\mathbb{R}$ given by $H(g,\alpha,q,\nu,a)=H_a(g,\alpha,q,\nu)$. Then, by a natural generalization of semidirect product theory to include constrained Hamiltonian systems, we have that Hamilton's equations on $\mathcal{K}\subset\mathfrak{s}^*$ generated by $h_{\mathcal{K}}$ give the evolution of the system on $\mathcal{K}$ determined by the Poisson–Hamilton equations $\dot{f}=\{f,h_{\mathcal{K}}\}$ on the Poisson submanifold $\mathcal{K}\subset\mathfrak{s}^*\times T^*\mathcal{Q}$, where the Poisson structure is defined in a natural way. More precisely, we have the Dirac brackets on K (see, for instance, Ref. 34 or 3) which, by reduction, give the brackets on $\mathcal{K}$. This is the abstract procedure underlying the computations we do in the specific case of plasmas given in the next section.

VII. HAMILTONIAN FORMULATION

We now pass to the corresponding Hamiltonian formulation of the Maxwell–Vlasov system (2.4) and (2.5) in the Eulerian description by taking the Legendre transform of the reduced action (5.6).

A. The role of the general theory

From the geometrical point of view, we simply apply the generalized Legendre transformation described abstractly in Sec. VI to the degenerate Lagrangian

$$L_{f_0,\varphi_0}(\psi,\dot{\psi},\Phi,\dot{\Phi},\mathbf{A},\dot{\mathbf{A}}).$$

This Lagrangian is degenerate because it does not depend on the variables $\dot{\Phi}$ and $\dot{\mathbf{v}}$. The theory described in Sec. VI may be applied to this action on $T(\mathscr{F}\times\mathscr{V}\times\mathscr{A})$. The action of the group $\mathrm{Diff}(T\mathbb{R}^3)$ on the factor $\mathscr{F}$ for this Lagrangian is given as before, while the actions on the factors $\mathscr{V}$ and $\mathscr{A}$ are trivial. It is easy to see that the Hamiltonian constraint for each f_0 is $K_{f_0}\subset T^*(\mathrm{Diff}(T\mathbb{R}^3)\times\mathscr{V}\times\mathscr{A})$, defined by the conditions

$$\Psi=\frac{\delta L}{\delta\dot{\Phi}}=0 \quad \text{and} \quad \mathbf{m}_v=\frac{\delta L}{\delta\dot{\mathbf{v}}}=0.$$

These conditions impose constraints, which for consistency must be dynamically preserved.

B. Calculation of the transformed equations

We will perform the calculations in detail, working with the reduced Lagrangian rather than the Lagrangian

$$L_{f_0,\varphi_0}(\psi,\dot{\psi},\Phi,\dot{\Phi},\mathbf{A},\dot{\mathbf{A}})$$

and setting $\varphi_0=1$ as usual.

We start with the action (5.6) for the Maxwell–Vlasov system in the Eulerian description,

$$\mathfrak{S}_{\mathrm{red}}(\mathbf{u},\Phi,\dot{\Phi},\mathbf{A},\dot{\mathbf{A}})=\int dt\int d\mathbf{x}\,d\mathbf{v}F(\mathbf{x},\mathbf{v},t)\left(\frac{1}{2}m|\mathbf{u}_s|^2+\frac{1}{2}m|\mathbf{u}_s-\mathbf{v}|^2-q\Phi+q\mathbf{u}_s\cdot\mathbf{A}\right)$$
$$+\frac{1}{2}\int dt\int d\mathbf{x}\left|\nabla_{\mathbf{x}}\Phi+\frac{\partial\mathbf{A}}{\partial t}\right|^2-|\nabla_{\mathbf{x}}\times\mathbf{A}|^2. \tag{7.1}$$

This leads immediately to

$$\frac{\delta l}{\delta\dot{\mathbf{A}}}=\nabla_{\mathbf{x}}\Phi+\frac{\partial\mathbf{A}}{\partial t}=-\mathbf{E}, \tag{7.2}$$

and so (minus) the electric field variable $\mathbf{E}$ is the field momentum density canonically conjugate to the magnetic potential. Let us define the material momentum density in six dimensions,

$$\mathbf{m}\equiv\frac{\delta l}{\delta\mathbf{u}}. \tag{7.3}$$

We write $\mathbf{m}=(\mathbf{m}_s,\mathbf{m}_v)$, where $\mathbf{m}_s$ is the projection of $\mathbf{m}$ onto the first three coordinate positions, and $\mathbf{m}_v$ is the projection onto the last three places. We think of $\mathbf{m}_s$ and $\mathbf{m}_v$ also as vectors in six dimensions. From the Lagrangian we see that

$$\mathbf{m}_s=F(m\mathbf{u}_s+m(\mathbf{u}_s-\mathbf{v})+q\mathbf{A}) \quad \text{and} \quad \mathbf{m}_v=0. \tag{7.4}$$

Proceeding with the Legendre transform of our action (7.1) results in a corresponding (reduced) Hamiltonian function written in terms of the velocities,

$$h=\int d\mathbf{x}\,d\mathbf{v}\,F\left(m|\mathbf{u}_s|^2-\frac{1}{2}m|\mathbf{v}|^2+q\Phi\right)+\mathbf{m}_v\cdot\mathbf{a}+\frac{1}{2}\int d\mathbf{x}(|\mathbf{E}|^2+|\nabla_{\mathbf{x}}\times\mathbf{A}|^2+2\mathbf{E}\cdot\nabla_{\mathbf{x}}\Phi), \tag{7.5}$$

where $\mathbf{a}$ denotes the projection of $\mathbf{u}$ onto its last three entries. Transforming this to the momentum variables gives

$$h=\int d\mathbf{x}\; d\mathbf{v}\;\frac{1}{4Fm}|\mathbf{m}_s+mF\mathbf{v}-qF\mathbf{A}|^2-\frac{1}{2}mF|\mathbf{v}|^2+qF\Phi+\mathbf{m}_v\cdot\mathbf{a}$$
$$+\frac{1}{2}\int d\mathbf{x}\Big(|\mathbf{E}|^2+|\nabla_{\mathbf{x}}\times\mathbf{A}|^2+2\mathbf{E}\cdot\nabla_{\mathbf{x}}\Phi\Big). \tag{7.6}$$

The variation of this Hamiltonian with respect to **m**, **a**, **E**, **A**, F, and Φ is given by

$$\delta h=\int d\mathbf{x}\; d\mathbf{v}\Big[\mathbf{u}\cdot\delta\mathbf{m}+\mathbf{m}_v\cdot\delta\mathbf{a}-qF\mathbf{u}_s\cdot\delta\mathbf{A}+qF\,\delta\Phi-\Big(\frac{1}{2}m|\mathbf{u}_s|^2+\frac{1}{2}m|\mathbf{u}_s-\mathbf{v}|^2+q\mathbf{u}_s\cdot\mathbf{A}$$
$$-q\Phi\Big)\delta F\Big]+\int d\mathbf{x}(\mathbf{E}+\nabla_{\mathbf{x}}\Phi)\cdot\delta\mathbf{E}-(\nabla_{\mathbf{x}}\cdot\mathbf{E})\,\delta\Phi+\nabla_{\mathbf{x}}\times(\nabla_{\mathbf{x}}\times\mathbf{A})\cdot\delta\mathbf{A}. \tag{7.7}$$

This expression allows one to read off the evolution equations for the electromagnetic field:

$$\frac{\partial\mathbf{A}}{\partial t}=-\frac{\delta h}{\delta\mathbf{E}}=-\mathbf{E}-\nabla_{\mathbf{x}}\Phi,\quad \text{i.e.,}\quad \mathbf{E}=-\nabla_{\mathbf{x}}\Phi-\frac{\partial\mathbf{A}}{\partial t},$$

$$\frac{\delta h}{\delta\Phi}=0=-\nabla_{\mathbf{x}}\cdot\mathbf{E}+q\int d\mathbf{v}\;F,\quad \text{i.e.,}\quad \nabla_{\mathbf{x}}\cdot\mathbf{E}=q\int d\mathbf{v}F:=\rho, \tag{7.8}$$

$$\frac{\partial\mathbf{E}}{\partial t}=\frac{\delta h}{\delta\mathbf{A}}=\nabla_{\mathbf{x}}\times(\nabla_{\mathbf{x}}\times\mathbf{A})-q\int d\mathbf{v}\;F\mathbf{u}_s,\quad \text{i.e.,}\quad \frac{\partial\mathbf{E}}{\partial t}=\nabla_{\mathbf{x}}\times\mathbf{B}-\mathbf{j}.$$

Note that the constraint $\delta h/\delta\Phi=0$ (Gauss' law) arises from the absence of $\dot{\Phi}$ dependence in l.

The general theory of Sec. VI shows that F is an element of the second factor of the semi-direct product and so its evolution is given by Lie dragging as a density. Likewise, f is Lie dragged as a scalar and m_i satisfies a Lie–Poisson evolution equation:

$$\frac{\partial F}{\partial t}=-\nabla_{\mathbf{z}}\cdot(F\mathbf{u}),\quad \frac{\partial f}{\partial t}=-\mathbf{u}\cdot\nabla_{\mathbf{z}}\,f, \tag{7.9}$$

$$\frac{\partial m_i}{\partial t}=-\frac{\partial}{\partial z^j}m_iu^j-m_j\frac{\partial}{\partial z^i}u^j-F\frac{\partial}{\partial z^i}\frac{\delta h}{\delta F}.$$

The first two of these equations reflect the assumptions that were made in the definitions of f and F, while the last equation encodes the dynamics for the system. We first consider the case where the momentum component i takes the values 4,5,6. In this case,

$$-\frac{\partial m_i}{\partial t}=m_{sj}\frac{\partial}{\partial z^i}u^j+m_{vj}\frac{\partial}{\partial z^i}u^j-F\frac{\partial}{\partial z^i}\,(\tfrac{1}{2}m|\mathbf{u}_s|^2+\tfrac{1}{2}m|\mathbf{u}_s-\mathbf{v}|^2+q\mathbf{u}_s\cdot\mathbf{A}-q\Phi)$$
$$=m_{vj}\frac{\partial}{\partial z^i}u^j+Fm(u_{sj}-v_j)\,\frac{\partial u^j}{\partial z^i}-Fm(u_{sj}-v_j)\,\frac{\partial}{\partial z^i}(u_s^j-v_s^j)-qFu_{sj}\frac{\partial A_s^j}{\partial z^i}+Fq\frac{\partial}{\partial z^i}\Phi, \tag{7.10}$$

where $i=4,5,6$. In the second line of Eq. (7.10), we have substituted for $\mathbf{m}_s$ from Eq. (7.4) and rearranged terms. Here $\mathbf{m}_v=0$, because l does not depend on $\dot{\mathbf{v}}$. Setting $\mathbf{m}_v=0$ initially in Eq. (7.10) ensures that $\mathbf{m}_v\equiv0$ persists throughout the ensuing motion, for potentials Φ and **A** that are independent of **v** and provided the constraint holds that $\mathbf{u}_s=\mathbf{v}$, as in Eq. (5.16). Likewise, the Gauss' law constraint imposed by $\delta h/\delta\Phi=0$ also persists during the ensuing motion, as seen from the last equation of (7.8) and the first equation of (7.9), provided the constraint $\mathbf{u}_s=\mathbf{v}$ holds and F vanishes in the limit as $|\mathbf{v}|\to\infty$.

The spatial part of the evolution equation of **m** will produce the required single-particle dynamics. From Eq. (7.9), we have

$$\frac{\partial m_i}{\partial t} = -\frac{\partial}{\partial z^j} m_i u^j - m_j \frac{\partial}{\partial z^i} u^j - F \frac{\partial}{\partial z^i} \frac{\delta h}{\delta F}. \tag{7.11}$$

Setting $i=1,2,3$, in Eq. (7.11), then substituting for $\delta h/\delta F$ and using the relations

$$\mathbf{m}_s = F(m\mathbf{u}_s + m(\mathbf{u}_s - \mathbf{v}) + q\mathbf{A}), \quad \mathbf{m}_v \equiv 0,$$

and

$$\nabla_{\mathbf{v}}\Phi = 0, \quad \nabla_{\mathbf{v}}\mathbf{A} = 0,$$

yields the spatial components of the motion equation,

$$\frac{\partial m_{si}}{\partial t} = -\frac{\partial}{\partial z^j} m_{si} u^j - m_{sj} \frac{\partial}{\partial z^i} u^j - F \frac{\partial}{\partial z^i} \left(\frac{1}{2} m |\mathbf{u}_s|^2 + \frac{1}{2} m |\mathbf{u}_s - \mathbf{v}|^2 + q\mathbf{u}_s \cdot \mathbf{A} - q\Phi \right). \tag{7.12}$$

Substituting for $\mathbf{m}_s$ and then using the continuity relation $\partial F/\partial t + \nabla_{\mathbf{z}} \cdot (F\mathbf{u}) = 0$ gives

$$m \frac{\partial \mathrm{u}_{si}}{\partial t} + q \frac{\partial \mathrm{A}_{si}}{\partial t} = -u^j \frac{\partial}{\partial z^j} m\mathrm{u}_{si} - \mathrm{u}_s^j \frac{\partial}{\partial z^j} q\mathrm{A}_{si} - q\mathrm{A}_j \frac{\partial}{\partial z^i} u^j - q \frac{\partial \Phi}{\partial z^i} + q \frac{\partial}{\partial z^i} (\mathbf{u}_s \cdot \mathbf{A})$$
$$- \frac{1}{2} m \frac{\partial}{\partial z^i} |\mathbf{u}_s - \mathbf{v}|^2. \tag{7.13}$$

Rearranging this equation results in

$$m \left(\frac{\partial}{\partial t} + u^j \frac{\partial}{\partial z^j} \right) \mathbf{u}_s = q\mathbf{E} + q\mathbf{u}_s \times (\nabla_{\mathbf{x}} \times \mathbf{A}) - \frac{1}{2} m \frac{\partial}{\partial \mathbf{z}} |\mathbf{u}_s - \mathbf{v}|^2. \tag{7.14}$$

We may now evaluate this on the constraint set $\mathbf{u}_s = \mathbf{v}$ and thereby obtain the Lorentz force,

$$m\mathbf{a} = q(\mathbf{E} + \mathbf{v} \times \mathbf{B}), \tag{7.15}$$

where $\mathbf{a}$ is the acceleration of a fluid parcel [the last three components in $\mathbf{u} = (\mathbf{v}, \mathbf{a})$]. As we have seen, in this Hamiltonian formulation of the Maxwell–Vlasov equations in the Eulerian description, the acceleration $\mathbf{a}$ in $\mathbf{u}$ is a vector Lagrange multiplier which imposes $\mathbf{m}_v = 0$. Equation (7.15) provides an expression for this Lagrange multiplier in terms of known dynamical variables and, as a consequence, we regain the equation for the acceleration of a charged particle in an electromagnetic field. The momentum constraint $\mathbf{m}_v = 0$ remains invariant when the electromagnetic potentials are independent of the phase space velocity coordinate $\mathbf{v}$ and the velocity constraint $\mathbf{u}_s = \mathbf{v}$ holds. Perhaps not unexpectedly, one finds that $\nabla_{\mathbf{z}} \cdot \mathbf{u} = 0$. Also, (minus) the electric field is canonically conjugate to the vector potential, and the electrostatic potential Φ plays the role of a Lagrange multiplier which imposes Gauss's law. Thus, our Hamiltonian formulation augments the usual Maxwell–Vlasov description of plasma dynamics by self-consistently deriving the particle acceleration by the Lorentz force $m\mathbf{a} = q(\mathbf{E} + \mathbf{v} \times \mathbf{B})$ instead of assuming it *a priori*.

C. The Poisson Hamiltonian structure

The general theory outlined briefly in Sec. VI also leads to the Poisson bracket structure for the Maxwell–Vlasov theory on the Hamiltonian side. However, our Hamiltonian description has a redundancy, namely the information for the particle trajectories can be recovered from the spatial plasma density. Explicitly, if we let $H(f) = (1/2)|\mathbf{v}|^2 + \Phi_f(\mathbf{x})$ be the single-particle Hamiltonian determined by the plasma density f, then the flow of this Hamiltonian function can be identified with the particle evolution map ψ. We can also think of this as a constraint on the level of equations of motion, as the Hamiltonian vector field of $H(f)$ must equal the time derivative of the map ψ, i.e., the particle velocity field in phase space. In other words, as is well known, the particle dynamics is completely determined by the plasma density dynamics. This may be regarded as a

constraint on the system that leads to the elimination of the forward map as a dynamical variable. This ''redundancy'' is, of course, one of the sources of degeneracy of the Lagrangian and Hamiltonian structures.

Thus, the constraint of explicitly enforcing this consistency condition leads to a further ''reduction'' which again may be handled by the Dirac theory of constraints to arrive at the Hamiltonian structure in terms of the variables F (or equivalently f in view of the canonical nature of the particle transformations) and the electromagnetic potentials. The resulting Poisson bracket structure is given by the Lie–Poisson structure for the f's plus the canonical structure for the electromagnetic potentials, which was the starting point for Marsden and Weinstein,[7] who carried out the reduction of this bracket with respect to the action of the electromagnetic gauge group to obtain the final Maxwell–Vlasov bracket on the space with variables f, **E**, and **B**. This procedure was motivated by and corrected a bracket found by *ad hoc* methods in Ref. 15. We need not repeat this construction.

D. The Kelvin–Noether theorem

A final result worth mentioning is Kelvin's theorem for the Maxwell–Vlasov particle dynamics. These dynamics, given in the last equation in (7.9), may be rewritten as

$$\left(\frac{\partial}{\partial t}+\pounds_{\mathbf{u}}\right)\left(\frac{1}{F}m_i dz^i\right)+d\frac{\delta h}{\delta F}=0, \tag{7.16}$$

so that

$$\frac{d}{dt}\oint_{\gamma(t)}\frac{1}{F}m_i\,dz^i=0, \tag{7.17}$$

for a loop $\gamma(t)$ which follows the particle trajectories in phase space. The Kelvin circulation integral in phase space,

$$I=\oint_{\gamma(t)}\frac{1}{F}m_i\,dz^i, \tag{7.18}$$

may be evaluated on the invariant constraint manifold $\mathbf{m}_v=0$ as

$$I=\oint_{\gamma(t)}(mu_{si}+qA_i)dx^i. \tag{7.19}$$

We recognize this integral as the *Poincaré invariant* for the single-particle motion in phase space.

The above result follows from the abstract Kelvin–Noether theorem by letting $\mathscr{C}:=\{\gamma:S^1\to T\mathbb{R}^3|\,\gamma$ continuous$\}$ be the space of continuous loops in single-particle velocity phase space and letting the group $\mathrm{Diff}(T\mathbb{R}^3)$ act on $\mathscr{C}$ on the right by $(\eta,\gamma)\in\mathrm{Diff}(T\mathbb{R}^3)\times\mathcal{C}\mapsto\gamma\circ\eta\in\mathcal{C}$. The quantity $\mathscr{K}$ is chosen to be

$$\langle\mathscr{K}(\gamma,F),a\rangle=\oint_{\gamma}\frac{1}{F}a. \tag{7.20}$$

The abstract Kelvin–Noether theorem for the Maxwell–Vlasov equations in Euler–Poincaré form then reproduces the version of Kelvin's theorem given in (7.17).

VIII. CONCLUSION

In this paper we have cast Low's mixed Eulerian–Lagrangian action principle for Maxwell–Vlasov theory into a purely Eulerian description. In this description we find that Maxwell–Vlasov dynamics are governed by the Euler–Poincaré equations for right invariant motion on the diffeomorphism group of $\mathbb{R}^n$ ($n=6$ for three-dimensional Maxwell–Vlasov motion). These equations were recently discovered by Holm *et al.*[6] who investigated the class of Hamilton's principles which are right invariant under the subgroup of the diffeomorphisms which leaves invariant a set

$\mathscr{T}$ of tensor fields in the Eulerian variables. The Maxwell–Vlasov motions invariant under this subgroup are the steady Eulerian solutions, which, thus, are identified as relative equilibria. This identification of steady Eulerian Maxwell–Vlasov solutions as right invariant equilibria places these solutions into the Hamiltonian framework required for investigating their nonlinear stability characteristics using, e.g., the energy-Casimir method (see Ref. 16). It was this stated goal that first motivated Low to write his Lagrangian for Maxwell–Vlasov dynamics.

Thus, our formulation of a purely Eulerian action principle and its associated Euler–Poincaré equations and Hamiltonian framework advances Low's original intention of using his action principle for studying stability of plasma equilibria by placing the entire Maxwell–Vlasov equations (including the particle dynamics, field dynamics and probability distribution dynamics) into one self-consistent Hamiltonian picture in the Eulerian description. (As we discussed, Low used mixed aspects of both Eulerian and Lagrangian phase space descriptions in his action principle.)

Our Eulerian Hamilton's principle for Maxwell–Vlasov dynamics is constrained, and all of the corresponding Lagrange multipliers have been resolved. This Hamilton's principle is thus available for further approximations, e.g., by Hamilton's principle asymptotics (see, e.g., Ref. 27).

In summary, we have taken an existing action, due to Low,[1] for the Maxwell–Vlasov system of equations and demonstrated how to rederive this system as Euler–Poincaré equations. The Euler–Poincaré form emerges from Hamilton's principle for a system whose configuration space is a group and whose action is right invariant under a subgroup. This situation commonly appears in the Eulerian description of continuum mechanics. In the case of continuum mechanics, the dynamics takes place on the group of diffeomorphisms and the Eulerian variables are invariant under a subgroup of the diffeomorphism group. (This subgroup corresponds to steady Eulerian flows with nonzero velocity and vorticity.) We showed that this situation also occurs for the Maxwell–Vlasov equations of plasma dynamics in the Eulerian description, by showing that the variations considered take the appropriate form, and then deriving the Maxwell–Vlasov equations from the Hamilton's principle for the right invariant action (5.6) in Eulerian variables. We then passed to the Hamiltonian formulation of this system and found its Lie–Poisson structure.

As discussed in the Introduction, the Euler–Poincaré form of the dynamics is naturally adapted for applying Lagrange–D'Alembert methods for geometrical constraints and control as in Ref. 13. In future work, our Euler–Poincaré form of the Maxwell–Vlasov system shall be implemented to describe the control features of a plasma driven by an external antenna, following the lines of inquiry begun in the oscillation center approximation for plasmas by Similon *et al.*[35]

ACKNOWLEDGMENTS

We would all like to extend our gratitude to T. Ratiu for his time and invaluable input. Some early (unpublished) work by J. Marsden, P. Morrison, and H. Gumral on aspects of the problem addressed in this paper helped us in the formulation given here and is gratefully acknowledged. In addition, M. Hoyle would like to thank Dion Burns, Ion Georgiou, Don Korycansky, Shinar Kouranbaeva, Myung Kim and David Schneider for their time and the discussions which helped him understand this material. Work by D. Holm was conducted under the auspices of the US Department of Energy, supported (in part) by funds provided by the University of California for the conduct of discretionary research by Los Alamos National Laboratory. J. Marsden was partially supported by US Department of Energy Contract No. DE-FG0395-ER25251.

We show that, in conformally static spacetimes, Maxwell equations take their simplest form when written in terms of the so-called ''optical metric.'' © *1998 American Institute of Physics.* [S0022-2488(98)01006-8]

I. INTRODUCTION

In an inertial frame[1] of Minkowski spacetime, Maxwell equations take their simplest form:

$$\nabla\cdot\mathbf{B}=0, \tag{1.1}$$

$$\nabla\times\mathbf{E}+\frac{1}{c}\frac{\partial\mathbf{B}}{\partial t}=\mathbf{0}, \tag{1.2}$$

$$\nabla\cdot\mathbf{E}=4\pi\rho, \tag{1.3}$$

$$\nabla\times\mathbf{B}-\frac{1}{c}\frac{\partial\mathbf{E}}{\partial t}=\frac{4\pi}{c}\,\mathbf{j}. \tag{1.4}$$

In fact, one can define a notion of electromagnetically preferred frames as those in which Maxwell equations become simple, and then verify that such frames coincide with those identified by the other requirement, deriving from particle dynamics, that there are no ''apparent'' forces of inertial origin. Thus, mechanics and electromagnetism identify the same class of privileged frames in flat spacetime. Of course, these are nothing else than the inertial frames of special relativity.

An alternative way to characterize an inertial frame is to require that the family of observers associated with it be nonaccelerating, nonrotating, and nondeforming. This immediately creates a difficulty if one tries to carry over this notion to general relativity. Let n^a be a field of four-velocities, and $h_a{}^b:=\delta_a{}^b+n_a n^b$ the associated transverse projector.[2] One can define in a unique way the acceleration a_a, vorticity ω_{ab}, shear σ_{ab}, and expansion θ of the frame n^a, through the decomposition[3]

$$\nabla_b n_a=-n_b a_a+\omega_{ab}+\sigma_{ab}+\tfrac{1}{3}\theta h_{ab}. \tag{1.5}$$

For a nonaccelerating, nonrotating, and nondeforming frame, all the quantities a_a, ω_{ab}, σ_{ab}, and θ must vanish, which amounts to saying that $\nabla_a n^b=0$. However, it is not difficult to see[4] that vector fields satisfying this condition can only exist in the so-called ''ultrastatic'' spacetimes,[5] i.e., those whose metric admits the coordinate representation

$$g=-\mathrm{d}t^2+h_{ij}\mathrm{d}x^i\mathrm{d}x^j, \tag{1.6}$$

with i,j taking values from 1 to 3, and $\partial h_{ij}/\partial t=0$. These spacetimes are physically rather dull; they describe situations in which there are no gravitational forces, and differ from Minkowski spacetime only by having curved $t=$ const spatial sections. It seems therefore that no extension of the idea of inertial frames is possible in a general-relativistic context of physical interest.

Recently, however, a proposal has been made for a definition of inertial and gravitational forces in general relativity.[6–8] Contrary to what one might think at first, this idea is not at odds with the equivalence principle.[9,10] Furthermore, it has proved itself very useful for the analysis of several nontrivial general-relativistic effects.[11] Since the concept of inertial forces is associated with the one of deviation from inertial motion, it seems therefore that, at least in those spacetimes for which such forces can be defined, one should be able to introduce a concept of mechanically inertial frames.[9] Of course, the condition $\nabla_a n^b = 0$ must be replaced by a weaker one, in a way that we now briefly describe. A much more detailed discussion can be found in Refs. 8 and 9.

Let us first consider Newtonian mechanics in a static gravitational field with potential ϕ. An inertial observer at rest at a point $\mathbf{x}$ is subject to the gravitational force $-\nabla\phi(\mathbf{x})$, and therefore needs a thrust (i.e., a force of nongravitational origin) $\nabla\phi(\mathbf{x})$ per unit mass in order to remain at $\mathbf{x}$. This is exactly what happens, within a general-relativistic context, to static observers in a static spacetime $(\mathcal{M}, g_{ab})$. For, if we denote by η^a the timelike Killing vector field, the four-velocity of static observers is given by $n^a = \eta^a/(-\eta_b \eta^b)^{1/2}$, and one can easily check that their four-acceleration a_a (which is directly related to the thrust per unit mass that they need in order to remain static) can be expressed as $a_a = \nabla_a \Phi$, where

$$\Phi = \tfrac{1}{2} \ln(-\eta_a \eta^a) . \tag{1.7}$$

The function Φ can thus be thought of as a generalization of the Newtonian potential,[6,12] and the static frame as the counterpart of the Newtonian rest frame.[12] It is then reasonable to require that any definition of inertial observers should include the static ones as a particular case, in spite of the fact that they have $a_a \neq 0$. We now look for a property of the static frame n^a that could be taken as a more general characterization of inertial frames.

The vector field n^a has $\omega_{ab} = \sigma_{ab} = \theta = 0$, so that $\nabla_b n_a = -n_b \nabla_a \Phi$. Introducing the new metric

$$\tilde{g}_{ab} := e^{-2\Phi} g_{ab} , \tag{1.8}$$

which is of the ultrastatic type, this relationship can be reexpressed as $\tilde{\nabla}_a \tilde{n}^b = 0$, where $\tilde{\nabla}$ is the Riemannian connection associated to $\tilde{g}_{ab}$, and $\tilde{n}^a := e^{\Phi} n^a = \eta^a$ has unit norm with respect to $\tilde{g}_{ab}$. This suggests that $(\mathcal{M}, \tilde{g}_{ab})$, rather than the physical spacetime $(\mathcal{M}, g_{ab})$, is the natural structure to use in identifying inertial observers. Inspired by these heuristic remarks, we shall say that a frame n^a in $(\mathcal{M}, g_{ab})$ is inertial if there exists a conformally related $(\mathcal{M}, \tilde{g}_{ab})$ in which $\tilde{n}^a = e^{\Phi} n^a$ satisfies the condition $\tilde{\nabla}_a \tilde{n}^b = 0$.[13]

Of course, this definition allows one to define inertial frames only in spacetimes that are conformally static. A further generalization is possible;[6,9] however, as far as the present paper is concerned, we prefer to remain within a limited context, rather than introducing technical complications that would make the discussion less clear. Also, it must be pointed out that conformally static spacetimes already include several examples of great physical interest.

In a conformally static spacetime, g_{ab} admits at least one timelike conformal Killing vector field[3] η^a that satisfies the Frobenius condition, so that the inertial observers have $\tilde{n}^a = \eta^a$. In the ultrastatic spacetime $(\mathcal{M}, \tilde{g}_{ab})$, with $\tilde{g}_{ab}$ defined by Eqs. (1.7) and (1.8), the frame $\tilde{n}^a$ *is* indeed nonaccelerating, nonrotating, and nondeforming. The kinematical parameters of $\tilde{n}^a$ are related to those of n^a by the transformation:

$$\tilde{a}_a = a_a - h_a{}^b \nabla_b \Phi, \tag{1.9}$$

$$\tilde{\theta} = e^{\Phi}(\theta - 3\, n^a \nabla_a \Phi), \tag{1.10}$$

$$\tilde{\omega}_{ab} = e^{-\Phi} \omega_{ab} , \tag{1.11}$$

$$\tilde{\sigma}_{ab} = e^{-\Phi} \sigma_{ab} . \tag{1.12}$$

Therefore, in the physical spacetime $(\mathcal{M}, g_{ab})$, n^a has acceleration

$$a_a = h_a{}^b \nabla_b \Phi\,, \tag{1.13}$$

expansion

$$\theta = 3\, n^a \nabla_a \Phi\,, \tag{1.14}$$

and vanishing rotation and shear:

$$\omega_{ab} = \sigma_{ab} = 0\,. \tag{1.15}$$

Of course, the set of Eqs. (1.13)–(1.15) could also be taken as definition of the frame n^a and of the function Φ, but it is more convenient, in practice, to look simply for a conformal Killing vector field η^a.

This characterization of inertial frames may look somewhat artificial, as it requires one to introduce an unphysical spacetime $(\mathcal{M},\tilde{g}_{ab})$. Nevertheless, it is fully in line with the common ideas about what an inertial frame should be. In fact, when expressed in the frame $\tilde{n}^a$ in $(\mathcal{M},\tilde{g}_{ab})$, particle dynamics takes its simplest form, which closely mirrors Newtonian dynamics in an inertial frame.[6–9] In addition, the spatial trajectories of massless particles are geodesics of $\tilde{h}_{ab} = e^{-2\Phi} h_{ab}$.[6,7,9,14] Thus, light propagates along ''straight lines'' according to $\tilde{h}_{ab}$; for this reason, $\tilde{h}_{ab}$ is called the *optical metric*.[14]

Given the fact that one can successfully introduce a notion of mechanically inertial observers in conformally static spacetimes, it is natural to ask whether this is also true for electromagnetism; to wit, whether Maxwell equations also take a simpler form when expressed in the optical metric. In this article we show that this is indeed the case, i.e., that Maxwell equations, if written in terms of electric and magnetic fields, take their simplest form not in the physical spacetime $(\mathcal{M},g_{ab})$, but rather in $(\mathcal{M},\tilde{g}_{ab})$, when the fields are defined with respect to the frame $\tilde{n}^a$.

The presentation is organized as follows. In Sec. II we derive the form of Maxwell equations with respect to an arbitrary frame in the spacetime $(\mathcal{M},g_{ab})$. In Sec. III we do the same in $(\mathcal{M},\tilde{g}_{ab})$, and show that in this case one can choose the frame in such a way that Maxwell equations take the very simple form of Eqs. (1.1)–(1.4). In Sec. IV we consider two examples of physical interest, in order to show how problems that are otherwise complicated, simplify within this formalism. Section V contains some concluding remarks.

II. DECOMPOSITION OF MAXWELL EQUATIONS

In Minkowski spacetime, Maxwell equations

$$\nabla_{[a} F_{bc]} = 0 \tag{2.1}$$

and

$$\nabla^b F_{ba} = -4\pi J_a\,, \tag{2.2}$$

when decomposed in an inertial frame, take the familiar form of Eqs. (1.1)–(1.4).

In a general spacetime $(\mathcal{M},g_{ab})$, one can still define the electric and magnetic fields with respect to an arbitrary reference frame n^a as[3]

$$E_a := F_{ab} n^b \tag{2.3}$$

and

$$B^a := -\tfrac{1}{2} \epsilon^{abcd} n_b F_{cd}\,. \tag{2.4}$$

The electromagnetic tensor can then be expressed in the form[15]

$$F_{ab} = n_a E_b - n_b E_a + \epsilon_{abcd} n^c B^d. \tag{2.5}$$

This follows immediately on rewriting Eq. (2.4) as

$$\epsilon_{abcd}B^a=-\frac{1}{2}\,\epsilon_{abcd}\epsilon^{aefg}n_eF_{fg}=\frac{3!}{2}\,\delta^{[e}{}_b\delta^f{}_c\delta^{g]}{}_d n_eF_{fg}=n_bF_{cd}+n_dF_{bc}+n_cF_{db}\,, \tag{2.6}$$

and then contracting Eq. (2.6) with n^b, and using the definition (2.3) of E_a.

We now want to write differential equations for E_a and B^a. For this purpose, we must decompose Eqs. (2.1) and (2.2) in the frame n^a.

Let us begin by rewriting Eq. (2.1) in the form $\epsilon^{abcd}\nabla_bF_{cd}=0$. Using expression (2.5) for F_{cd} and the property

$$\epsilon^{abcd}\epsilon_{cdef}=2(\delta^a{}_f\delta^b{}_e-\delta^a{}_e\delta^b{}_f)\,, \tag{2.7}$$

we arrive at

$$\epsilon^{abcd}n_b(D_cE_d+a_cE_d)+\epsilon^{abcd}\omega_{bc}E_d+\nabla_bn^aB^b-\nabla_bn^bB^a+n^a\nabla_bB^b-n^b\nabla_bB^a=0\,. \tag{2.8}$$

Here, D denotes the transverse Riemannian connection associated with h_{ab},[3]

$$D_aT^{b_1\cdots b_r}{}_{c_1\cdots c_s}:=h_a{}^dh_{e_1}{}^{b_1}\cdots h_{e_r}{}^{b_r}h_{c_1}{}^{f_1}\cdots h_{c_s}{}^{f_s}\nabla_dT^{e_1\cdots e_r}{}_{f_1\cdots f_s} \tag{2.9}$$

(see the Appendix for the geometrical meaning of D when $\omega_{ab}\neq0$). Since

$$\nabla_bB^c=D_bB^c-n_bn^dh^c{}_e\nabla_dB^e-h_b{}^dn^cn_e\nabla_dB^e+n_bn^dn^cn_e\nabla_dB^e\,, \tag{2.10}$$

Eq. (2.8) can be rewritten as

$$\epsilon^{abcd}n_b(D_cE_d+a_cE_d)+\epsilon^{abcd}\omega_{bc}E_d+n^aD_bB^b-h^a{}_bn^c\nabla_cB^b+\omega^a{}_bB^b+\sigma^a{}_bB^b-\tfrac{2}{3}\,\theta B^a=0. \tag{2.11}$$

An expression similar to Eq. (2.11), with the roles of E_a and B^a exchanged, is easily obtained by substituting Eq. (2.5) into the left-hand side of Eq. (2.2), and using the analogue of Eq. (2.10) for E_a:

$$-\epsilon_{abcd}n^b(D^cB^d+a^cB^d)-\epsilon_{abcd}\omega^{bc}B^d+n_aD^bE_b-h_a{}^bn^c\nabla_cE_b+\omega_a{}^bE_b+\sigma_a{}^bE_b-\tfrac{2}{3}\theta E_a=4\pi J_a\,. \tag{2.12}$$

Now, on projecting Eqs. (2.11) and (2.12) along directions parallel and orthogonal to n^a, and defining the density of charge ρ and density of current j_a through $J_a=\rho\,n_a+j_a$, with $j_a:=h_a{}^bJ_b$, we finally obtain:

$$D_aB^a-\epsilon^{abcd}n_a\omega_{bc}E_d=0, \tag{2.13}$$

$$\epsilon^{abcd}n_b(D_cE_d+a_cE_d)-h^a{}_bn^c\nabla_cB^b+\omega^a{}_bB^b+\sigma^a{}_bB^b-\tfrac{2}{3}\theta B^a=0\,, \tag{2.14}$$

$$D^aE_a+\epsilon_{abcd}n^a\omega^{bc}B^d=4\pi\rho, \tag{2.15}$$

$$-\epsilon_{abcd}n^b(D^cB^d+a^cB^d)-h_a{}^bn^c\nabla_cE_b+\omega_a{}^bE_b+\sigma_a{}^bE_b-\tfrac{2}{3}\theta E_a=4\pi j_a\,. \tag{2.16}$$

As is obvious by inspection of Eqs. (2.13)–(2.16), the decomposition of Maxwell equations (2.1) and (2.2) with respect to a frame n^a does not produce, in general, a set of equations of the same form of Eqs. (1.1)–(1.4), because of the occurrence of extra terms arising from the derivatives of n^a. Also strictly related to this circumstance is the fact that charge is *apparently* not conserved in the frame n^a:

$$n^a\nabla_a\rho+D_aj^a=-\rho\,\theta-j^aa_a\,. \tag{2.17}$$

The additional terms in Eqs. (2.13)–(2.17) have exactly the same status of the so-called apparent forces that one must introduce when formulating dynamics in a noninertial reference

frame. Only if $\nabla_a n^b = 0$, does one recover the simple form of Eqs. (2.1)–(2.2) and of the continuity equation. However, this is possible only in the very special case of an ultrastatic spacetime.

III. OPTICAL GEOMETRY RECOVERED

It is a well-known property of conformal transformations that, in four spacetime dimensions,[3]

$$\tilde{\nabla}_{[a}F_{bc]} = \nabla_{[a}F_{bc]} \tag{3.1}$$

and

$$\tilde{\nabla}^b F_{ba} = e^{2\Phi}\nabla^b F_{ba}\,. \tag{3.2}$$

[Hereafter, indices of geometrical objects pertaining to the spacetime $(\mathcal{M},\tilde{g}_{ab})$ are raised and lowered by using $\tilde{g}_{ab}$ and its inverse $\tilde{g}^{ab}$. Thus we have, for example, $\tilde{X}^a := \tilde{g}^{ab}\tilde{X}_a$.] If we define $\tilde{J}_a := e^{2\Phi}J_a$, Eqs. (3.1) and (3.2) imply that Maxwell equations (2.1) and (2.2) hold in $(\mathcal{M},g_{ab})$ iff their counterparts

$$\tilde{\nabla}_{[a}F_{bc]} = 0 \tag{3.3}$$

and

$$\tilde{\nabla}^b F_{ba} = -4\pi\tilde{J}_a \tag{3.4}$$

hold in $(\mathcal{M},\tilde{g}_{ab})$. Notice that if we write $\tilde{J}_a = \tilde{\rho}\,\tilde{n}_a + \tilde{j}_a$, we have that $\tilde{\rho} = e^{3\Phi}\rho$; this is perfectly reasonable, if we think of $\tilde{\rho}$ as the electric charge per unit volume as measured according to the spatial metric $\tilde{h}_{ab}$. Similarly, we have $\tilde{j}_a = e^{2\Phi}j_a$, consistent with $\tilde{j}_a = \tilde{\rho}\tilde{v}_a$ for some three-velocity $\tilde{v}_a = e^{-\Phi}v_a$.

Since $\tilde{\epsilon}_{abcd} = e^{-4\Phi}\epsilon_{abcd}$, the electric and magnetic vectors in $(\mathcal{M},\tilde{g}_{ab})$ are

$$\tilde{E}_a := F_{ab}\tilde{n}^b = e^{\Phi}E_a \tag{3.5}$$

and

$$\tilde{B}^a := -\tfrac{1}{2}\tilde{\epsilon}^{abcd}\tilde{n}_b F_{cd} = e^{3\Phi}B^a\,. \tag{3.6}$$

Repeating the same procedure that led us to Eqs. (2.13)–(2.16), we write:

$$\tilde{D}_a\tilde{B}^a - \tilde{\epsilon}^{abcd}\tilde{n}_a\tilde{\omega}_{bc}\tilde{E}_d = 0\,, \tag{3.7}$$

$$\tilde{\epsilon}^{abcd}\tilde{n}_b(\tilde{D}_c\tilde{E}_d + \tilde{a}_c\tilde{E}_d) - h^a{}_b\tilde{n}^c\tilde{\nabla}_c\tilde{B}^b + \tilde{\omega}^a{}_b\tilde{B}^b + \tilde{\sigma}^a{}_b\tilde{B}^b - \tfrac{2}{3}\tilde{\theta}\tilde{B}^a = 0\,, \tag{3.8}$$

$$\tilde{D}^a\tilde{E}_a + \tilde{\epsilon}_{abcd}\tilde{n}^a\tilde{\omega}^{bc}\tilde{B}^d = 4\pi\tilde{\rho}, \tag{3.9}$$

$$-\tilde{\epsilon}_{abcd}\tilde{n}^b(\tilde{D}^c\tilde{B}^d + \tilde{a}^c\tilde{B}^d) - h_a{}^b\tilde{n}^c\tilde{\nabla}_c\tilde{E}_b + \tilde{\omega}_a{}^b\tilde{E}_b + \tilde{\sigma}_a{}^b\tilde{E}_b - \tfrac{2}{3}\tilde{\theta}\tilde{E}_a = 4\pi\tilde{j}_a\,. \tag{3.10}$$

If $(\mathcal{M},g_{ab})$ is conformally static with conformal Killing vector field η^a, we can choose Φ as in Eq. (1.7). It is then obvious that, in the reference frame $\tilde{n}^a = \eta^a$ in $(\mathcal{M},\tilde{g}_{ab})$, Eqs. (3.7)–(3.10) become:

$$\tilde{D}_a\tilde{B}^a = 0\,, \tag{3.11}$$

$$\tilde{\epsilon}^{abcd}\tilde{n}_b\tilde{D}_c\tilde{E}_d - \tilde{n}^b\tilde{\nabla}_b\tilde{B}^a = 0\,, \tag{3.12}$$

$$\tilde{D}^a\tilde{E}_a = 4\pi\tilde{\rho}\,, \tag{3.13}$$

$$-\tilde{\epsilon}_{abcd}\tilde{n}^b\tilde{D}^c\tilde{B}^d - \tilde{n}^b\tilde{\nabla}_b\tilde{E}_a = 4\pi\tilde{j}_a\,. \tag{3.14}$$

The second term of Eqs. (3.8) and (3.10) has been simplified by noticing that, e.g.,

$$h^a{}_b\tilde{n}^c\tilde{\nabla}_c\tilde{B}^b = \tilde{h}^a{}_b\tilde{n}^c\tilde{\nabla}_c\tilde{B}^b = \tilde{n}^c\tilde{\nabla}_c(\tilde{h}^a{}_b\tilde{B}^b) = \tilde{n}^b\tilde{\nabla}_b\tilde{B}^a\,, \tag{3.15}$$

because $\tilde{\nabla}_a\tilde{h}^b{}_c = 0$. These equations have exactly the same form as Eqs. (1.1)–(1.4). Also, in the frame $\tilde{n}^a$ charge conservation is expressed by the familiar continuity equation

$$\tilde{n}^a\tilde{\nabla}_a\tilde{\rho} + \tilde{D}_a\tilde{j}^a = 0\,, \tag{3.16}$$

without the ''apparent sources'' that are present in the right-hand side of Eq. (2.17). Therefore, in the reference frame $\tilde{n}^a$ of $(\mathcal{M},\tilde{g}_{ab})$, electromagnetism is described by the same equations that hold in an inertial frame of Minkowski spacetime.

IV. EXAMPLES

The formulation of particle dynamics in the optical geometry leads not only to a better intuitive understanding, but also to formal simplifications that allow one to have better control over complicated physical problems.[11] One expects that something similar should happen for electromagnetism as well. In this section we illustrate this point with the help of two simple examples, leaving the discussion of more technical problems for a future publication.

A. Magnetic field around a Schwarzschild black hole

Equations (3.11)–(3.14) allow one to introduce potentials exactly in the same way as is usually done in flat spacetime. We now present an example of a complicated problem that can be easily solved by this procedure.

Consider a Schwarzschild black hole immersed into an otherwise homogeneous, constant magnetic field. (We assume that the intensity of the latter is sufficiently low that it does not perturb spacetime appreciably.) We want to know how the field is modified by the presence of the black hole. This problem was solved by Wald in an indirect way,[16] and by Hanni and Ruffini through a rather lengthy calculation.[17]

For a general magnetostatic problem, Eq. (3.14) implies that, in a region in which there are no currents, one can express $\tilde{B}^a$ as the gradient of a scalar function ψ,

$$\tilde{B}^a = \tilde{D}^a\psi\,. \tag{4.1}$$

Substituting into Eq. (3.11), we see that ψ must be harmonic with respect to the optical metric:

$$\tilde{D}_a\tilde{D}^a\psi = 0\,. \tag{4.2}$$

In the particular case of Schwarzschild spacetime, $e^{\Phi} = (1-2M/r)^{1/2}$, and the optical metric is

$$\tilde{h} = \left(1-\frac{2M}{r}\right)^{-2}\mathrm{d}r^2 + \left(1-\frac{2M}{r}\right)^{-1} r^2(\mathrm{d}\vartheta^2 + \sin^2\vartheta\ \mathrm{d}\varphi^2)\,. \tag{4.3}$$

Orienting the coordinate system in such a way that the field at $r\to+\infty$ points in the azimuthal direction, ψ does not depend on φ, and Eq. (4.2) can be written explicitly as

$$\left(1-\frac{2M}{r}\right)\frac{\partial}{\partial r}\left(r^2\,\frac{\partial\psi}{\partial r}\right) + \frac{1}{\sin\vartheta}\,\frac{\partial}{\partial\vartheta}\left(\sin\vartheta\,\frac{\partial\psi}{\partial\vartheta}\right) = 0\,. \tag{4.4}$$

It is very easy to see that the solution of Eq. (4.4) which satisfies the asymptotic condition $\psi(r \to +\infty) \propto r\cos\vartheta$ is $\psi = K(r-2M)\cos\vartheta$, where K is a constant that represents the intensity of the field at infinity. The magnetic field B^a is then trivially found using Eqs. (4.1) and (3.6), and has the components:

$$B^r = K\left(1-\frac{2M}{r}\right)^{1/2}\cos\vartheta, \tag{4.5}$$

$$B^\vartheta = -K\left(1-\frac{2M}{r}\right)^{1/2}\frac{\sin\vartheta}{r}, \tag{4.6}$$

$$B^\varphi = 0. \tag{4.7}$$

B. Electromagnetism in FLRW cosmological models

Our second example is that of a Friedmann–Lemaitre–Robertson–Walker (FLRW) cosmological model, with metric

$$g = -\mathrm{d}t^2 + a(t)^2[\mathrm{d}\chi^2 + f(\chi)^2(\mathrm{d}\vartheta^2 + \sin^2\vartheta\ \mathrm{d}\varphi^2)], \tag{4.8}$$

where $a(t)$ depends on the particular matter content of the model, and $f(\chi)$ is either $\sin\chi$, $\sinh\chi$, or χ, according to whether the curvature of the spatial sections $t=$ const is positive, negative, or zero. It is obvious that this metric is conformally ultrastatic, with

$$\tilde{h} = \mathrm{d}\chi^2 + f(\chi)^2(\mathrm{d}\vartheta^2 + \sin^2\vartheta\ \mathrm{d}\varphi^2) \tag{4.9}$$

and $e^\Phi = a/a_0$, where $a_0 =$ const.

Suppose that we are given a configuration of charges and currents in a FLRW universe, and that we look for the electric and magnetic fields measured by the observers comoving with the cosmological fluid. Equations (3.11)–(3.14) tell us that we can consider a much simpler problem for the fields $\tilde{E}_a = (a/a_0)E_a$ and $\tilde{B}^a = (a/a_0)^3 B^a$, corresponding to the distribution of charges and currents described by $\tilde{\rho} = (a/a_0)^3\rho$ and $\tilde{j}_a = (a/a_0)^2 j_a$. In Eqs. (3.12) and (3.14), the terms $\tilde{n}^b\tilde{\nabla}_b\tilde{B}^a$ and $\tilde{n}^b\tilde{\nabla}_b\tilde{E}_a$ reduce to $\partial\tilde{B}^a/\partial t$ and $\partial\tilde{E}_a/\partial t$, respectively, so the only difference between Eqs. (1.1)–(1.4) and Eqs. (3.11)–(3.14) is that the latter are formulated in a curved space with the metric (4.9). This simplification might be of some help in investigations concerning the evolution of cosmic magnetic fields. Of course, in the particular case of a spatially flat model, Eqs. (3.11)–(3.14) exactly *coincide* with Eqs. (1.1)–(1.4); every problem can thus be mapped into a corresponding one formulated in Minkowski spacetime, as is already evident from Eqs. (3.1) and (3.2).

V. CONCLUSIONS

It is by now rather well established that the analysis of mechanical and optical phenomena in conformally static spacetimes can be greatly simplified working in the optical geometry.[6,7,11] In this article we have shown that the same happens for electromagnetism. *A posteriori*, this conclusion may perhaps sound not surprising, because electromagnetism (and, more generally, the physics of any massless field) must be consistent with the description of light propagation, and in particular with geometric optics.

Apart from its theoretical interest, the formulation of Maxwell equations in terms of the optical metric is potentially of practical usefulness, as we have argued in the previous section. The underlying reason for the simplification so achieved is that the influences of gravity and of the geometry of space on the electric and magnetic fields are separated out in this approach. In the ultrastatic spacetime $(\mathcal{M},\tilde{g}_{ab})$ there is no gravity, so Eqs. (3.11)–(3.14) just describe electromagnetism on a curved static space. It is the factors e^Φ in Eqs. (3.5) and (3.6) that account for the effect of gravity on E_a and B^a. In regions that do not contain charges or currents, this effect is simply a rescaling for the values of the fields, and does not alter the shape of the lines of force.

As we said at the beginning of the article, all this applies to conformally static spacetimes. The formalism can be generalized, e.g., by introducing a gravomagnetic field in addition to the potential Φ,[6,9] but this is beyond the scope of the present paper.

APPENDIX: TRANSVERSE COVARIANT DERIVATIVE

If the vector field n^a satisfies the Frobenius condition $n_{[a}\nabla_b n_{c]}=0$, i.e., if $\omega_{ab}=0$, there exist (at least locally) a family of hypersurfaces $\mathcal{S}$ orthogonal to n^a. In this case it is easy to show[3] that D_a defined by Eq. (2.9) coincides with the covariant derivative associated with the Riemannian connection induced on $\mathcal{S}$ by h_{ab}. The purpose of this appendix is to investigate the extent to which this situation is modified when $\omega_{ab}\neq 0$.

In this case the spaces of vectors orthogonal to n^a at different points of spacetime do not mesh in such a way as to coincide with the tangent spaces of any family of hypersurfaces, and there is no hope of defining a ''connection on a submanifold,'' because the submanifold simply does not exist. We can still look, however, for a transverse derivative that characterizes the rate of change of tensors as one moves along a spacelike direction. Of course, a first candidate is the projection of the Riemannian covariant derivative ∇_a associated with g_{ab}, defined by Eq. (2.9). It is straightforward to check that $D_a h_{bc}=0$, but also that for an arbitrary function f,

$$(D_aD_b-D_bD_a)f=-2\,\omega_{ab}n^c\nabla_c f\,. \tag{A1}$$

Thus, D_a does not define a connection, not even one with torsion. For if there were a torsion tensor $T^c{}_{ab}$ associated with D_a, the right-hand side of Eq. (A1) could be written as $-T^c{}_{ab}D_c f$, which is impossible unless $\omega_{ab}=T^c{}_{ab}=0$. This is unpleasant, and one might wonder whether another derivative exists that behaves in a more reasonable way. It is not difficult to see, however, that *no* derivative operator $\mathcal{D}_a$ can satisfy the following two requirements: (i) for any $T^{a_1\cdots a_r}{}_{b_1\cdots b_s}$ which is totally transverse (i.e., such that all its contractions with n^a vanish), $\mathcal{D}_c T^{a_1\cdots a_r}{}_{b_1\cdots b_s}$ is also totally transverse; (ii) there exists $T^c{}_{ab}$ such that $(\mathcal{D}_a\mathcal{D}_b-\mathcal{D}_b\mathcal{D}_a)f=-T^c{}_{ab}\mathcal{D}_c f$, $\forall f$. On the other hand, the notion of transverse derivative can be generalized on replacing (ii) by the weaker condition that there exist a *defect tensor* $\Delta^c{}_{ab}$,[18] such that

$$(\mathcal{D}_a\mathcal{D}_b-\mathcal{D}_b\mathcal{D}_a)f=-2\,\Delta^c{}_{ab}\nabla_c f\,, \tag{A2}$$

for any f. One can then define the torsion as twice the transverse part of the defect tensor, $T^c{}_{ab}:=2\,h^c{}_d\Delta^d{}_{ab}$, so that D_a turns out to be torsion-free (although its defect tensor is nonvanishing, equal to $2\,\omega_{ab}n^c$). It is then easy to prove that D_a is the only torsion-free derivative that satisfies (i), (ii), and which also preserves h_{ab}. We can thus regard it as the closest generalization of the notion of transverse Riemannian covariant derivative to the case in which the Frobenius condition fails to be satisfied.

[1] We adopt the following terminology. An *observer* is a future-directed, differentiable timelike curve. A *reference frame* is a congruence of observers, that can also be identified with the field of their four-velocities.

[2] We use latin indices a, b, ... from the beginning of the alphabet as abstract indices (see, e.g., Ref. 3), which just indicate the tensorial nature of an object without requiring the specification of a chart. We choose $+2$ as signature of the metric, $\epsilon_{0123}>0$ for the sign convention of the Levi–Civita tensor ϵ_{abcd}, and work in units in which $c=1$.

Microscopic dynamics from a coarsely defined solution to the protein folding problem

(Received 16 December 1997; accepted for publication 27 February 1998)

In this work we introduce a least-action formulation of the protein folding problem casted within a coarse description of the soft mode dynamics of the peptide chain. Ultimately, we show that this coarse variational approach can be lifted to yield the microscopic long-time torsional dynamics responsible for the actual folding process. As a first step, a binary coding of local topological constraints associated to each structural motif is introduced to coarsely mimic the long-time dynamics. Folding pathways are initially resolved as transitions between patterns of locally encoded structural signals. Our variational approach is aimed at identifying the most economic pathway with respect to the stepwise cost in conformational freedom. Our treatment allows us to account for the expediency of the process in proteins effectively capable of *in vitro* renaturation. We identify the dominant pathway by introducing a coarse version of Lagrangian microscopic dynamics. The coarse folding pathways are generated by a parallel search for structural patterns in a matrix of local topological constraints (LTM) of the chain. Each local topological constraint represents a coarse description of a local torsional state and each pattern is evaluated, translated, and finally recorded as a contact matrix (CM), an operation that is subject to a renormalization feedback loop. The renormalization operation periodically introduces long-range correlations on the LTM according to the latest CM generated by translation. Local topological constraints may form consensus regions in portions of the chain that translate as secondary structure motifs or tertiary interactions. Nucleation steps and cooperative effects are accounted for by means of the renormalization operation, which warrants the persistence of seeding patterns upon successive LTM evaluations. Relevant folding time scales beyond the realm of molecular dynamics simulations become accessible through the coarsely codified representation of local torsional constraints. The validity of our approach is tested *vis à vis* experimentally probed folding pathways generating tertiary interactions in proteins that may recover their active structure under *in vitro* renaturation conditions. We focus on determining significant folding intermediates and the late kinetic bottlenecks that occur within the first $\frac{1}{100}$ s of the renaturation process. After the computational accessibility of this coarse solution of the folding problem becomes apparent, we show how to lift our variational problem to microscopic dynamics of the peptide chain. The consistency of our approach is revealed by an actual generation of Newton's laws at the microscopic level through an inverse projection of the coarse dynamics originally generated through the pattern recognition computation. © *1998 American Institute of Physics.*

I. INTRODUCTION

This work is concerned with the theoretical underpinnings of the microscopic expedient by which natural proteins reach their active conformation under *in vitro* renaturation conditions. Specifically, we shall focus on proteins which recover their activity as a result of the actual dominance of robust folding pathways.[1–8] In this regard we shall concentrate on two critical

[a]Corresponding author; electronic mail: inmabb@criba.edu.ar

 © 1998 American Institute of Physics

aspects: (i) The *parallel* nature of the folding process, which implies that different portions of the chain might search *concurrently* for structural patterns, and (ii) the expediency of the folding process, which suggests the existence of a least-action principle underlying the parallel search for folding possibilities.

In general, the time scales involved in the folding process are incommensurably shorter than ergodic or thermodynamic time scales.[1–6] The question of how natural proteins fold as fast as they do remains elusive, mainly because most predictive approaches to the protein folding problem are rooted in the paradigm of equilibrium thermodynamics, which does not deal with the stringent timing of the process.[5]

We have asserted that the expediency of the folding process calls for a variational principle that should single out the dominant folding pathway.[9] But, how do we introduce such a principle for a process which is inherently parallel? This concurrence of folding events precludes any meaningful isolation of a single reaction coordinate at any given time. In order to address this question we shall first coarsely identify foldings of the protein as patterns of locally encoded signals. Within this frame, an underlying coarse Lagrangian or least-action formulation will be introduced over trajectories coarsely defined as sequences of pattern transitions. This Lagrangian will be conceived to single out the folding pathway that at each step minimizes the conformational entropy cost while maximizing the decrease in enthalpy. These tenets warrant a protein folding collapse following the most economic pathway.[1,9,10] Furthermore, even if a coarse description of conformation space might make longer time scales accessible to computation, ultimately, the problem of lifting the coarse dynamics to the level of actual torsional microscopic motions of the flexible chain should be addressed, as it is the case in this work.

The definition of the Lagrangian demands that we first introduce the appropriate coarse graining of conformation space upon which pathways are to be drawn. This leads to the first problem: The vast gap between the time scales accessible to molecular dynamics computations, typically in the range 10^{-12}–10^{-9} s, and those inherent to transitions between contact patterns (CPs) formed by the chain, typically in the range 10^{-4}–10^{3} s, suggests the need for a *semiempirical* model to elucidate the microscopic origin of the *expediency* of the folding process.[11,12] Then, our first problem becomes how to coarsely codify the local torsional states and local correlations and provide an effective dynamical picture introducing long-range correlations to account for the long-time behavior of the chain. Accordingly, the first goal of this work is to solve this problem by regarding foldings as patterns of locally encoded coarse structural signals.[13]

In consonance with this first goal, our working strategy may be sketched as follows.

(a) First, we introduce an ensemble of locally correlated two-state oscillators or spin flippers to coarsely simulate torsional isomerizations and search for *consensus* regions of torsional isomers along the chain. By consensus we simply mean regions of the chain where the local topological constraints associated to the formation of a particular folding are satisfied. In this way, a consensus window emerges as a pattern of structural signals encoded *locally* along the sequence. The broad latitude in local torsional coordinates within the Ramachandran, or local correlation maps of the protein chain,[14] and the vast structural distorsions it leads to implies that the binary codification cannot be implemented at the geometric level. Rather, the spin flippers are meant to mimic changes in the local topological constraints to which the flexible chain is subject in order to reach specific structural patterns.

(b) In a simplified version, a residue is classified using three information bits. The first two indicate the qualitative topographical features of its Ramachandran map,[14] defining the type of local torsional correlations (C), while the other bit indicates its hydrophobicity or polarity (h/p). This classification begets a fixed $3\times N$ matrix denoted the C-h/p matrix, with N being the length of the chain. Torsional topologies of an individual residue generated by the oscillators defined in (a) are rejected in the evaluation as part of the consensus if they are incompatible with the C class of the residue.

(c) We generate structural patterns as consensus regions within a matrix, the LTM, of local topological constraints (LTCs) of the peptide chain.

(d) We evaluate and translate such patterns into a contact matrix (CM) evolving within the time scale range 10^{-4}–10^{2} s. Thus, translation becomes a pattern recognition and, therefore, a *parallel* operation taking place at regular intervals. Each pattern within a LTM emerges with a certain probability that is effectively computed as the number of evaluations of the LTM that yield

the particular structural motif associated to the pattern divided by the total number of evaluations of the same LTM.

(e) The translation operation is subject to a feedback loop, whereby a renormalization operation readjusts the oscillator periods (or spin-flipping frequencies) according to the latest CP translated, and the contour ranges of intrachain interactions and contour distances are renormalized relative to the latest CP formed. In other words, *the renormalization operation introduces long-range correlations on the LTM* by slowing down or speeding up specific oscillators, depending on whether new interactions are formed or dismantled.

(f) Nucleation steps and the cooperativity in the formation of a secondary structure are accounted for by means of the renormalization operation: Suppose the LTM is evaluated at a given time and a short consensus region is detected. Then, the oscillators that generated this initial consensus window become endowed with frequencies that are lower than those of the neighboring residues and, consequently, the consensus region initially formed has a chance to grow upon successive evaluations of the LTM.

The fact that we characterize folding steps as CP transitions does not imply that any ''adiabatic assumption'' has been introduced *a priori*, in the sense that no enslavement or subordination of the fast-evolving microscopic degrees of freedom to CP transitions has been imposed.[15] Equivalently, CPs are not treated *a priori* as quasiequilibrium states by integrating out the relatively fast torsions as conformational entropy. Thus, the CM is generated by a parallel search for consensus windows in the LTM. In turn, the LTM is built upon the C-h/p matrix by adding two rows recording the phases of $2N$ two-state oscillators evolving within the broad period range 10^{-11}–10^{-3} s. Defined in this way, a LTM represents a coarse microscopic realization of a CP such that the consensus windows reflect the fulfillment of the LTCs determined by the CP. This sketch of the operational tenets reveals that, although advantage is taken of the fact that there exists a wide separation between characteristic time scales associated to folding events (typically in the range 10^{-4}–10^{3} s) and chain torsions (typically in the range 10^{-11}–10^{-7} s), no ''adiabatic assumption'' is introduced.

In this way, a computational strategy will be devised to provide theoretical underpinnings of the folding dynamics emerging as the evolution of patterns of locally encoded signals whose coherence reflects both cooperativity and nucleation effects. The key features of our approach are (a) the two-state coarse codification of local topological constraints of the flexible chain; (b) the renormalization of time scales for torsional isomerizations and their correlation decays relative to the successive stages of folding, thus introducing long-range correlations due to large-scale motions; (c) The identification of structural patterns with consensus regions in which specific topological constraints are fulfilled; and (d) the vast range of time scales 10^{-11}–10^{-2} s covered[2] (see Secs. III and IV) to account for the microscopic origin of cooperativity. In addition, our semiempirical approach has predictive potential, as revealed in Sec. IV, where we contrast a sequence of CP transitions with experimentally probed folding pathways involving secondary and tertiary interactions formed cooperatively.

At this point we may return to the original problem posed. Our representation of foldings as patterns of structural signals encoded locally along the peptide chain allows us to identify the most economic pathway defined as a sequence of CP transitions. This pathway entails at each step the minimal cost in conformational entropy while forming as many contacts as possible.[9,10] This fact will enable us to readily define a Lagrangian underlying the generation of trajectories regarded as sequences of LTM transitions. The variational perspective on the protein folding problem is developed in Sec. V. The LTM action leads naturally to a stochastic formulation of the problem, where the LTM transition probabilities are determined by the action, as indicated in Sec. V. This probability, in turn, begets a measure in pathway space that is typically very concentrated—almost Dirac delta-like—for folding chains that are the products of natural selection, as revealed in the detailed example expounded in Sec. IV. Furthermore, stochasticity is, in principle, inherent to our representational context of parallel computing, since different—and even conflicting—patterns in the same LTM may be simultaneously recognized by different processors, leading to competing folding pathways. The probability of recognizing a specific pattern is computed as the number of processors that recognize that pattern divided by the total number of processors involved in pattern recognition at that time.

Sections VI and VII are devoted to the elucidation of the microscopic torsional dynamics of

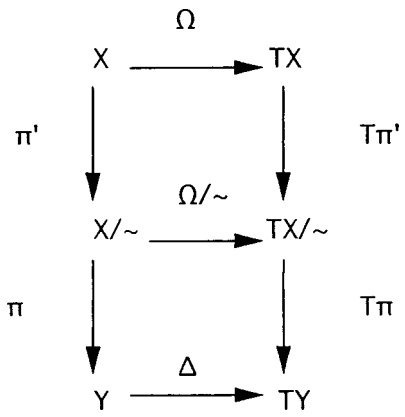

FIG. 1. Commutative scheme reflecting the compatibility of different coarse grainings of the folding dynamics.

the chain as stemming from the coarse solution to the folding problem. Thus, the coarse folding dynamics are lifted to the microscopic level, making the relevant long-time microscopic dynamics computationally accessible for the first time, at least to the best of our knowledge.

II. THE LEVELS OF COARSENING OF THE FOLDING DYNAMICS

The interplay between the different levels of coarseness with which the folding dynamics are simulated in this work require a clear representation scheme, such as the one presented in Fig. 1. Our main concern in this section is to rigorously define what is meant by a consistent treatment of the folding problem in which different coarse levels of description of the chain dynamics are compatible with each other. Standard notation has been adopted;[14] thus the conformation of each residue along the chain is specified by the two torsional or dihedral angular variables ϕ and ψ, each of which is taking values in a circle.

Let X denote the $2N$ torus (Cartesian product of $2N$ circles) corresponding to the full-detailed or (ϕ,ψ)-conformation space for a chain of length N. Then, at the richest level of the description, the chain dynamics is given by a map $\Omega: X \rightarrow TX$, where TX is the tangent space of X, that is, the space of all possible vector fields over X. Very limited time ranges for the full-detail dynamics (1–100 ps) have been explored by molecular dynamics (MD) simulations.[12] Since the time range effectively covered by MD is far shorter than the time ranges of interest to the folding context, we shall consistently introduce coarse descriptions of X, as indicated in Fig. 1. However, *our ultimate aim in this work is to define the dynamics over X. But we shall do so by first noting the existence of a variational principle at a coarser level of description, and, subsequently, lifting this variational formulation to X.*

Let $X/\sim$ be the quotient space consisting in the set of equivalence classes of (ϕ,ψ) isomers modulo a relation ''$\sim$,'' that is, conformations defined modulo their local torsional isomers, regardless of their difference at a finer level of detail. In accord with known stereochemical constraints, there are only two distinctive torsional species or isomers for each torsional variable. Two conformations of the entire chain are regarded as $\sim$ equivalent if their ϕ,ψ values for each residue lie within the same regions of the circle corresponding to the same local torsional isomers. Since there are two torsional isomers defined for each dihedral variable, $X/\sim$ may be represented as a lattice of $2\times 2N$ points drawn on the torus X. Actually, since each point represents one of the two basins of attraction in the unit circle, with each basin representing a torsional isomer, we get the isomorphism $X/\sim \approx (\mathbf{Z}_2)^{2N}$, where $\mathbf{Z}_2$ represents the cyclic field of integers modulo 2. This space is also isomorphic to the space of all possible LTMs, since local topological constraints are specified by regions within the circle for certain combinations of the canonical dihedral variables, as indicated in Sec. III. The dynamics at the LTM level are given by the projected map $\Omega/\sim: (\mathbf{Z}_2)^{2N} \rightarrow T(\mathbf{Z}_2)^{2N}$, where, as usual, ''$T$'' denotes the tangent space in this context.

Let Y denote an even coarser description of X. In this case, two conformations in X are regarded as equivalent if their respective CPs are identical, regardless of finer detail. Thus, at the CP level, the folding dynamics is given by a map $\Delta: Y \rightarrow TY$. Then, all three levels of description

of the folding dynamics are compatible with each other if and only if the diagram given in Fig. 1 is commutative. That means that the following relations between map compositions must hold:

$$\Delta\pi=(T\pi)(\Omega/\sim), \tag{1a}$$

$$(\Omega/\sim)\pi'=(T\pi')\Omega, \tag{1b}$$

where π is the canonical projection (in the computational context already described referred to as the translation operation) which associates to each LTM its equivalence class modulo CPs, π' is the canonical projection associating its LTM to each microscopic conformation belonging to X, and $T\pi$ and $T\pi'$ are their respective projections between tangent spaces, as indicated in Fig. 1.

The commutativity of the diagram would not hold valid unless the torsional variables divided in classes according to the potential basin where they belong (*cis-trans* isomers) are regarded as topological rather than geometric constraints: The vast latitude (30°–60°) in local torsional correlations within specific *cis* or *trans* basins[14] would lead otherwise to vast geometric distortions that would make specific structural motifs unrecognizable at a more detailed level. This point is developed in Sec. III. Likewise, excluded volume effects on the chain would lead to severe structural distortions for a putative element of a class modulo $\sim$, taking that microscopic realization to another $\sim$ class, and the diagram would fail to commute unless the elements of the space $X/\sim$ would again represent sets of topological rather than geometric constraints.

To summarize, the commutativity of the diagram displayed in Fig. 1 defines the consistent theoretical framework dealt with in this work: All three descriptions of conformation space, the one with the richest detail, X, the LTM description, $X/\sim$, and the CP description Y will represent mutually compatible frameworks within which the folding dynamics will be studied.

III. SIMULATING FOLDING DYNAMICS AT THE LTM LEVEL AND AT THE CP LEVEL

The essential operation in our parallel model and algorithm, the translation operation, lies within a renormalization feedback loop and consists in the transference of information cast in terms of the state of internal microscopic degrees of freedom into a coarser representation, a CP defined by a CM. Thus, patterns of locally encoded structural signals contained in the LTM are translated as foldings of the chain. The CM is, in turn, built upon the map of putative hydrophobic interactions, or h/p map. The algorithm and its underlying semiempirical model identify the CP class to which a LTM belongs at certain time intervals according to a set of renormalizable rules. The generation of the LTM is, in turn, affected by the last CP transition that has taken place, since a new set of constraints arises with each new CP formed, and the prescription for the evaluation operation itself is renormalized and thus depends on the last CP that has occurred. Prior to defining the folding process explicitly within our model, we must specify the basic representational elements and their interrelationships with regard to the basic operations:

A. The local topological two-state (or spin) variables η, ξ versus the geometric torsional variables ϕ,ψ

A basic tenet underlying our approach is that structural patterns are identified through the translation of consensus windows of a spin state matrix, the LTM. The consensus represents the fulfillment of local topological constraints required to form the structural pattern. In turn, the recognition of the structural pattern determines a renormalization of the LTM and of its evaluation code. Thus, it becomes convenient to define two-spin or two-state variables η, ξ defining local topological features. The identification of these variables requires a ribbon-like representation of the chain made up of tetragons with hinges at each α carbon (see Fig. 2), each of which contains the torsionally rigid CO–NH group in its planar trans conformation, a standard constraint of the system.[14]

The first variable η, also named the vertebral variable, is defined with respect to a specified *local* orientation, or + side, of the ribbon independently of twistings (see Fig. 2), so that $\eta_i=+1$ indicates local concavity at the ith α carbon of the chain (or hinge in the ribbon representation) with respect to the local + side of the ribbon, and $\eta_i=-1$, local convexity at the same contour location.

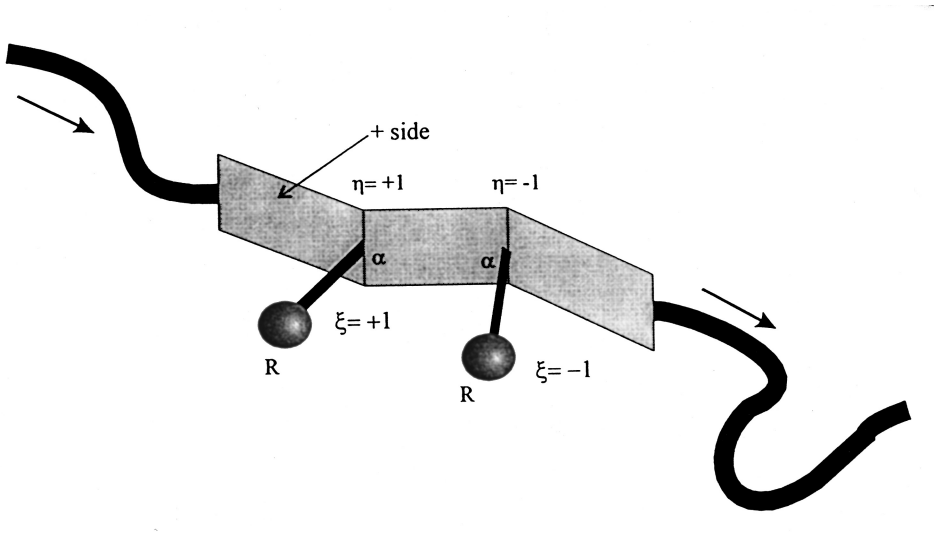

FIG. 2. Local topology of a ribbon-like model of the peptide chain, as represented by the two two-state variables η, ξ. The local + side of the ribbon faces the background and the balls labeled ''*R*'' represent the side chains attached to the hinge-like α carbons indicated by ''α.'' Each tetragon contains the torsionally rigid CO–NH group.

On the other hand, by spanning two adjacent tetragons into planes intersecting along a line containing the α carbon, two hinge regions are locally defined: an inner or concave domain and an outer or convex domain with respect to the + side. Thus, $\xi_i = +1$ indicates the fact that the side chain attached to the ith α carbon is contained in the convex region, while $\xi_i = -1$ indicates that it is contained in the concave domain, as indicated in Fig. 2.

B. The local topological matrix (LTM)

This two-state-entry matrix represented in Fig. 3 has five rows and N columns, with the ith column, $i = 1,2,...,N$, representing the residue with contour number i. The first two rows indicate, respectively, the local topological variables η, ξ. The correlation pattern C for each residue requires two bits of information and thus is indicated in the third and fourth rows, as indicated in Fig. 4. Thus, we get four kinds of correlation diagrams depending on the type of residue: one for glycine, one for proline, one for residues preceding a proline, except when that residue is glycine, and one for L-alanyl-like residues.[14] The hydrophobicity or polarity, denoted, respectively, with the $+1$ and -1 state, is indicated in the fifth row, which constitutes the h/p map. Conventionally,

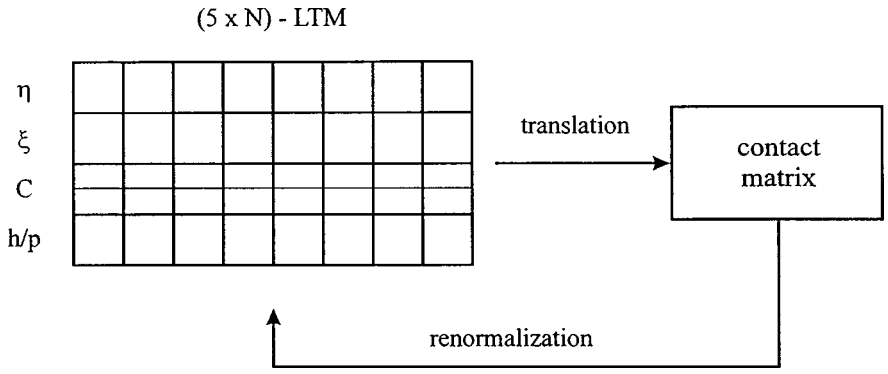

FIG. 3. The translation–renormalization feedback loop. It recognizes structural patterns as consensus windows in the local topological constraints matrix (LTM) and records them in the contact matrix (CM) as contact patterns (CPs). The LTM is built upon the primary sequence that determines its last three rows (the two C rows and the h/p row), which are fixed. The purpose of the renormalization operation is twofold: Taking a CM as input, it redistributes the frequency domain of the oscillators generating new LTMs and redefines contour distances *vis-à-vis* the latest CP generated, thus represcribing the evaluation of the LTM.

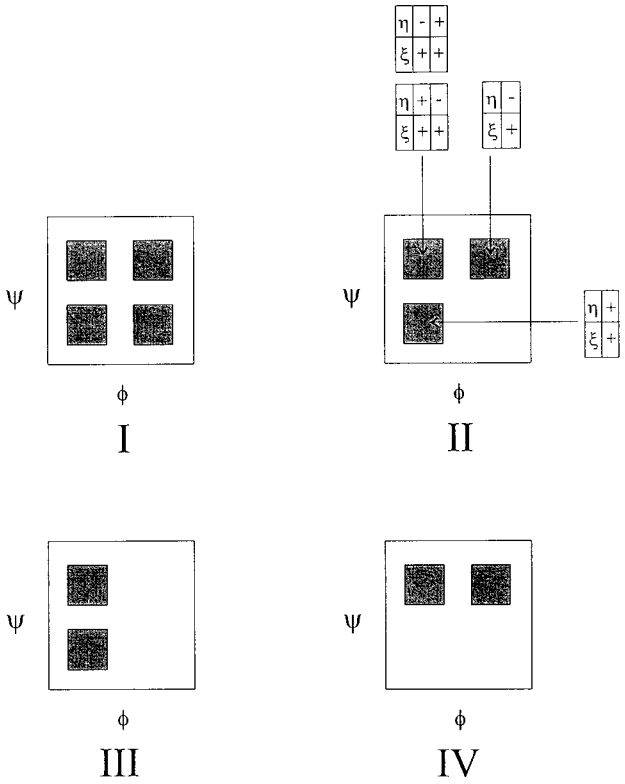

FIG. 4. Local topological constraints associated to the four classes of correlation diagrams based upon Ramachandran maps. In the caricatures, the regions of high probability have been shaded. The diagrams I–IV are labeled, respectively, $(-+)$, $(++)$, $(--)$, and $(+-)$ in the C representation. They correspond, respectively, to Gly, L-alanyl-like, Pro, and a residue preceding Pro different from Gly. Three of the plausible correlated zones correspond to structural motifs that may be characterized in terms of (η,ξ) states with $\xi=+1$. Thus, local torsional correlations are characterized by their local topological constraints.

a residue that is not hydrophobic is assigned the -1 sign. The structural patterns are progressively registered in the CM according to a renormalization feedback loop schematized in Fig. 3.

C. Folding as pattern recognition

The dominant secondary structure motifs can be identified in the LTM. Thus, the right-handed α helix requires a window of continuous concavity, that is, the vertebral variable should not change sign within the window, while the side chains are all oriented toward bulk solvent, or outward with respect to the helix interior. Without loss of generality and for the sake of notation, we shall identify this motif by a window of the LTM with $\eta=+1$, $\xi=+1$, while each local $\eta_i=+1$, $\xi_i=+1$ isomer is compatible with the ith Ramachandran correlation diagram C_i, and the h/p map shows a periodic $(i,i+3)$ or $(i,i+4)$ hydrophobicity [if $\text{sign(h/p)}_i=-1$, then the next residue for which $\text{sign(h/p)}=-1$ is $i+3$ or $i+4$]. Because of the highly helix-disruptive tendencies of glycine,[12,14] if its correlation diagram appears within a consensus window, the entire pattern is obliterated from the CM. The disrupting tendencies of the proline, on the other hand, do not require special instructions as the $(\eta_i=+1,\ \xi_i=+1)$ pattern is incompatible with a residue preceding proline, as shown in Fig. 4.

A consensus window translating into the α helix (R) is indicated in Fig. 5(a). Similarly, for a left-handed α helix, we must demand permanence of the -1 sign in the vertebral variable, while retaining all other conditions regarding side chain orientation, C compatibility, and hydrophobic periodicity.

Likewise, being pleated structures, β sheets are characterized by an alternation of the vertebral sign, while the side chain lies always within the convex region. In order to fulfill topological as well as h/p compatibilities, the η, ξ, and h/p sign pattern of a window must be preserved in other windows in a parallel or antiparallel fashion, depending on the relative orientation of the strands

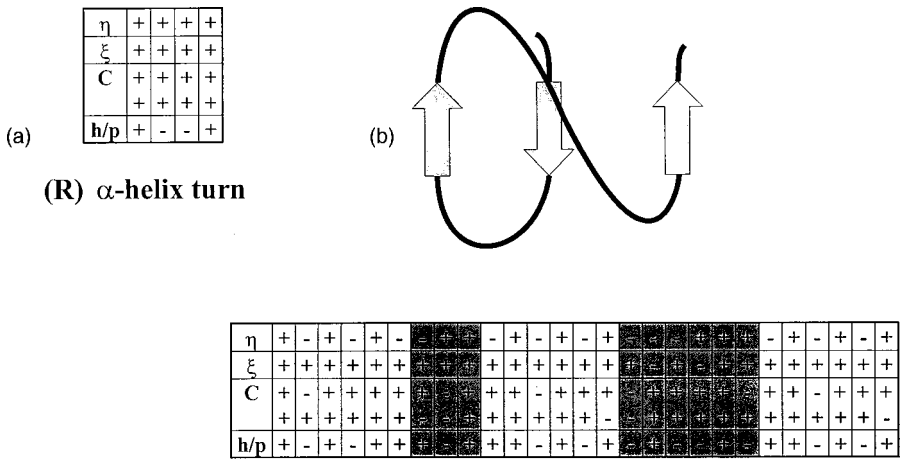

FIG. 5. (a) A consensus window for a right-handed α-helix turn. (b) A consensus window for the complex three-strand antiparallel β-sheet motif shown. The β bend and the turn consensus windows have been shaded in the LTM.

in the β sheet. For the sake of illustration, a three-strand β-sheet topology is displayed in Fig. 5(b), together with its LTM consensus pattern. A structural pattern in the same topology class[16] will be generated in our time-dependent simulation of the folding of bovine pancreatic trypsin inhibitor (BPTI),[17] as shown in Sec. IV.

Turns and bends may be a determinant of the β sheet or simply required to form hydrophobic contacts, thus, they will be treated generically, regardless of whether or not they realize β-sheet topologies. Should such motifs require closure of chain loops, they would pose demands in terms of LTM consensus, as indicated below.

Closure of a loop formed by a rod-like object determines two solvent environments: an inner cluster-like and an outer bulk-like domain. Since polar groups tend to be oriented toward the high dielectric medium, no orientational constraints are imposed upon loop closure when the inner cluster becomes like bulk solvent,[18] that is, it allows for four solvation layers on the polar groups.[19] Given the dimensions of the polypeptide chain, and the fact that the loop must accommodate seven water molecules across (the cluster diameter in a planar loop), a rough calculation gives a critical loop length of $N_c \approx 22$ for proteins. This means that a loop of size $N(\text{loop}) = N \geqslant 22$ poses no orientational demands on the polar groups.

These situations easily translate into patterns of the LTM. A bend or turn requiring loop closure is characterized by the following features: (1) a permanence of sign in the η row (this

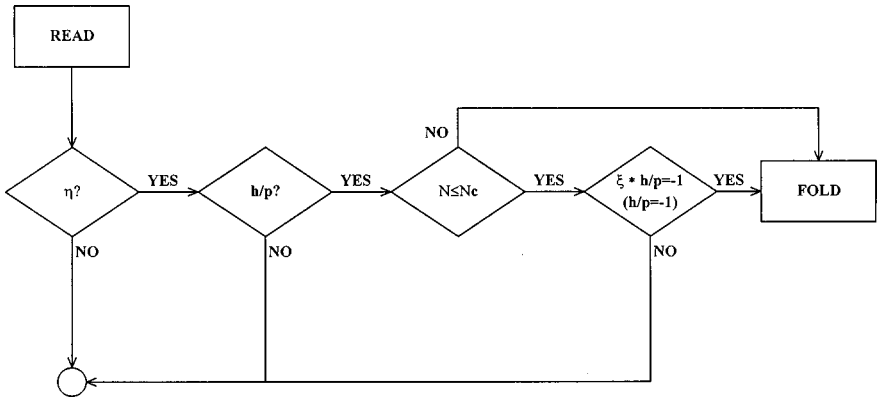

FIG. 6. The flow chart for evaluation of LTM-consensus representing a loop closure of the peptide chain. Evaluation asks first for fulfillment of vertebral constraints (η?), then for the possibility of hydrophobic contacts at the loop extremes (h/p?), then whether the size of the loop is larger or smaller than the critical size ($N \leqslant N_c$), and, finally, whether polar side chains are oriented toward bulk solvent for $N(\text{loop}) = N \leqslant N_c$ ($\xi \times (\text{h/p}) = -1$ for $(\text{h/p}) = -1$).

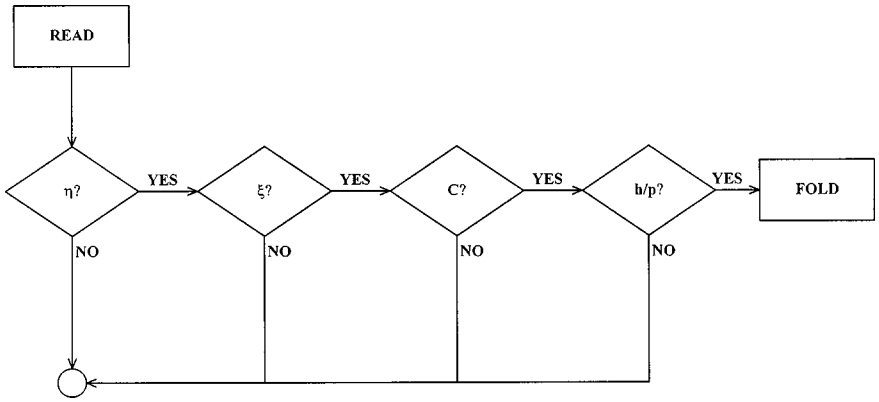

FIG. 7. The flow chart for the recognition of consensus windows as structural patterns. Evaluation asks first for fulfillment of a vertebral consensus (η?), then for the fulfillment of side-chain orientational constraints (ξ?), then for C compatibility (C?), and finally, for the occurrence of hydrophobic/polar periodicities or correspondences (h/p?).

condition may be somewhat relaxed for very large loops with $N(\text{loop}) \gg N_c$); (2) the outward orientation of polar groups in small loops becomes $[\text{sign(h/p)}]_i \times \xi_i = -1$ when $\text{sign(h/p)}_i = -1$ and $N(\text{loop}) < 22$; (3) the η,ξ patterns for individual residues must conform to their correlation diagrams when $\xi = +1$. On the other hand, crossover turns, such as the one featured in the complex β-sheet topology displayed in Fig. 5(b), pose no orientational demands on the polar groups, since they do not define local solvent environments. The only requirements of such turns are the sign inversion of the vertebral variable, which marks the existence of an inflection point [see Fig. 5(b)] and the C compatibility of the local topological patterns.

The structural patterns for bends and turns entailing loop closure are recognized according to the flow chart displayed in Fig. 6. On the other hand, once bends and turns have formed at the highest expense in conformational entropy (see below), the secondary structural patterns are identified according to the flow chart displayed in Fig. 7. This latter chart has been developed following all the operational tenets for the pattern identification described above.

D. The distribution of flipping periods in the generation of the LTM

In attempting to project torsions into the CP space, where the folding process is recorded, the time scale limitations of molecular dynamics simulations must be circumvented. This explains the need to introduce models in which activated molecular motions in the 10 ps to 1 MS range are considered.[12] Thus, faster diffusion-like unhindered torsions in a free residue are integrated out as conformational entropy of the state defined by the coarse LTM representation. Such motions, in the picosecond (ps) range, determine the rod-like shape of the protein molecule when viewed within the time scale window between two LTM states. Precisely, this interrelation between shape and time scale justifies the concept of the inner and outer solvent domain defined by an intramolecular loop, as put forth in our consensus analysis of the entropic cost of loop closure. Thus, the microscopic mean time range relevant to LTM transitions is 10^{-11}–10^{-3} s, covering the time scale for internal motions (10^{-11} s) of the order of the calculated diffusional displacements of flexible hinged domains,[12] and, at the other end of the spectrum, the limiting values (10^{-4}–10^{-3} s), typical mean time scales for the fast exchange between folded and unfolded states with respect to tertiary interactions engaging two secondary elements.[17] Within this range, we encompass the mean time frame of 10^{-7} s, typical for a localized helix-unwinding event leading to a bubble.[12]

These considerations lead us to define a temperature-dependent normalized distribution of periods, $w = w(\tau)$ for the independent $2N$ η,ξ oscillators. This distribution features three Gaussian peaks centered at characteristic periods 10^{-11}, 10^{-7}, and 10^{-3} s. The periods of the oscillators representing the topological *cis-trans* flipping or actually the characteristic times for changes in the local topological constraints, are assigned from this distribution in such a way that the effect of thermal fluctuations on the formation of consensus, and thus on structural transitions, is incor-

porated. Each Gaussian peak has a dispersion $\sigma^2 = gT$, where the constant g depends on the actual denaturation temperature $T(\text{denat.})$ and on the consensus interpretation of denaturation.

The period distribution allows us to classify residues in three classes: Class I contains all free residues, that is, residues not engaged in any structural motif, with mean period 10^{-11} s; class II contains all residues with mean period 10^{-7} s engaged in secondary structure but not in tertiary interactions; and class III contains all residues engaged in tertiary structure, whose mean period is 10^{-3} s. This classification of residues according to their inherent oscillator time scales is compatible with fluorescence depolarization probes for unhindered torsional motions,[12] with typical time scales for localized helix disruptions, and with diffusion–collision models,[20] in which secondary structure is stabilized further by forming tertiary contacts.[17]

In this way, long-wave or slower modes with mean frequencies in the range $10^7 - 10^3$ Hz result from the coupling of several local (η,ξ) modes which originally were high-frequency modes with a mean frequency of 10^{11} Hz. This is so since the formation of secondary or tertiary patterns involves the recognition of a consensus region, and thus the concurrent prescribed slowing down of the oscillators involved corresponds to the coupling associated to the consensus region.

Accordingly, the LTM evolves through a lottery from which periods of the oscillators for free residues are assigned from within a period range centered at 10 ps. A new period is assigned from the lottery to each oscillator each time a whole previously assigned period has been completed. The frequency $f = 1/\tau$ of an oscillator in the first two rows of the LTM corresponding to a residue not engaged in an intrachain interaction or loop satisfies the inequality

$$|f^{-1} - 10^{-11}\ \text{s}| \leqslant |\tau' - 10^{-11}\ \text{s}|, \quad \text{with } \tau' \text{ satisfying } w(\tau') = \text{Infimum}_{\tau}\{w(\tau) \geqslant 1/[2N]\}. \quad (2)$$

The condition yielding the extreme period τ' arises from the fact that there are, at most, $2N$ free oscillators in the peptide chain.

The other two peaks in the distribution correspond, respectively, to mean periods for residues in secondary and tertiary structural elements. Again, the same considerations apply in regards to the period assignment to oscillators for class II and class III residues. These rules imply that the residues in loops, bends, or turns concurrently formed with any secondary or tertiary structural element adopt the cadence of the structural element itself.

The mechanistic aspects of period distribution imply that this operation is subject to renormalization with each CP transition: A CP determines which columns in the LTM correspond to free or class I residues and that correspond to residues engaged in an intrachain interaction, or, equivalently, they belong to class II or III. Thus, since a CP transition reclassifies the residues, it also dictates the range from which new period assignments are drawn. The period range for a specific residue remains the same as before the CP transition if the transition does not alter the class of the residue, and changes if the CP transition transfers the residue to a different class. Thus, the renormalization operation is essentially the means by which long-range correlations in the LTM are introduced as a consequence of the latest large-scale motions.

E. The built-in internal clock

In order to satisfy the basic tenets of Shannon's information transmission while making all operations synchronized, the intrinsic beat period of the folding machine should be taken to represent $1/2\tau'$, one-half of the shortest possible period to be assigned to an oscillator. Since τ' depends on $w(\tau)$, it is itself T dependent. The time interval between two consecutive readings of the LTM, $\tau(\text{read})$, is taken as constant and, in order to lower the operational cost, it is fixed at the shortest time that a CP transition could possibly take. Thus, $\tau(\text{read}) = 2^{3+1}\tau' \approx 64$ ps at 298 K, the shortest time to close a three-loop with a single hydrophilic side chain in order to form a hydrophobic contact engaging the fastest oscillators at a typical folding temperature.

F. The temperature (T) in the semiempirical model

Secondary structure dismantling materializes and is recorded as such by deletion in the CM whenever a consensus bubble forms among class II residues engaged in the structure. By ''consensus bubble'' we mean that in any of the first two rows, a consecutive sequence of oscillators of length 30% of the total consensus window length[14] must be out of phase with the consensus

required values at the time when the reading of the LTM takes place. Because of the renormalization loop, this transition at the CM level immediately transfers a new set of constraints for the generation of new LTMs: The residues previously engaged in the structure and in its concurrent loops are reclassified, being transferred from class II to the higher-frequency class I.

Cooperative effects reflect themselves mechanistically in the formation of the consensus bubble: For instance, in the α-helix motif, the larger the helix, the more improbable to find a 30% out-of-phase subsequence of class II oscillators. Furthermore, these considerations enable us to estimate the constant g that determines the effect of thermal fluctuations on the period distribution: At the denaturation or melting temperature $T(\text{denat.})$, every helix formed must develop a consensus bubble evaluated and recorded with the next reading of the LTM. Thus, if σ is ''large enough,'' the period distribution in the helix is broad enough so that consensus cannot be preserved: The period range, of the order of σ, is such that a helix consensus cannot survive two consecutive readings. From these considerations, and taking into account our empirical estimate of the denaturation dispersion fixed at $\sigma = 10^{-8}$ s, and the typical experimental $T(\text{denat.}) = 303$ K for proteins such as the ones studied in this work[17]), we get $g \approx 3.2 \times 10^{-23}$ s^2/K.

G. Nucleation effects and protein folding cooperativity

Structural patterns such as the one presented in Fig. 5(b) do not result from all-or-none processes. Rather, a nucleating event involving the largest cost in conformational entropy takes place first and is subsequently followed by a sequence of folding events that seek to minimize additional losses in conformational entropy. Two theoretical approaches to biopolymer folding, the variational treatment rooted in the sequential minimization of entropy loss (SMEL),[9,21] and the theory of hydrophobic zippers,[10] take into account the cooperative nature of the formation of structural motifs triggered by nucleating events in their attempt to account for entropically driven pathways.

In our model, cooperativity and nucleation work through successive renormalization loops as expedients for the folding of peptide chains: Suppose a nucleating pattern has been identified in a reading of the LTM, be it a helix turn such as the one depicted in Fig. 5(a), or a turn involving a loop closure. Then, the residues engaged in the respective nucleating consensus window are automatically locked into lower frequencies of the order of 10^7 Hz ($1\ \text{Hz} = 1\ \text{s}^{-1}$) via the renormalization operation that immediately follows the translation of the nucleation pattern into a CP registered in the CM. Thus, the nucleation consensus will ''survive'' or be preserved for at least approximately 200 evaluations of the LTM, since the evaluation frequency is of the order of 10^9 Hz at 298 K [cf. Eq. (2)], the typical working temperature for *in vitro* folding of BPTI. This time span allows for a chance to enlarge the original consensus window by progressive torsional isomerizations of residues adjacent to those engaged in the nucleating step. Once adjacent residues form a consensus compatible with the original one in relation to a specific structural motif, they are also locked into the 10^7 Hz frequency domain and thus they contribute to the seeding process.

Formation of complex motifs such as the one shown in Fig. 5(b) might be triggered by more than one nucleating event taking place asynchronically, such as the closure of the two loops that ultimately generate the two pleated antiparallel pairings in this β-sheet topology. The asynchronous occurrence of more than one seeding event is compatible with the parallel nature of the renormalization operation, as illustrated in Sec. IV.

Summarizing, the key feature of renormalization that enables us to deal with cooperativity in the formation of a secondary structure is the survival of a nucleating pattern warranted by the reclassification of class I residues as class II residues once the nucleating pattern occurs. The argument holds *mutatis-mutandis* for tertiary interactions formed cooperatively from a secondary structure. In this case, the reclassification of class II residues as class III residues translates into a drastic shift in the oscillator frequency, from 10^7 to 10^3 Hz, thus warranting the survival of the respective nucleation pattern.

H. The renormalization operation and renormalized contour distances

As stated above, the renormalization operation is the expedient by which long-range correlations are introduced. It involves two concurrent roles: Redefining contour distances between different residues relative to the latest CP translated, thus determining how to read and evaluate

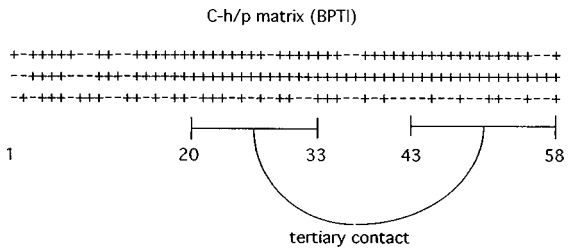

FIG. 8. The C-h/p matrix for a bovine pancreatic trypsin inhibitor (BPTI). The notation is consistent with that adopted in Figs. 3 and 5.

the LTM, and placing a new set of constraints on the generation of new LTMs after a CP transition has been recorded as a change in the CM. Both roles are specified at a given time according to the latest CP generated. The renormalization of constraints for the oscillators is articulated through the operational feedback loop (see Fig. 3), introducing the latest CP generated as input for the reclassification of residues. On the other hand, the renormalization of contour distances points to the root of cooperativity, since unfavorable long-range interactions with $N(\text{loop}) \approx 22$ or $N(\text{loop}) \gg 22$, might eventually materialize with lower entropic costs, as illustrated in Sec. III. Such situations take place when nucleating events bring the renormalized loop lengths, respectively, into the favorable ranges $N(\text{loop}) \ll 22$, or $22 < N(\text{loop}) < 30$, the upper bound being the critical size beyond which excluded-volume effects start becoming important.[19]

IV. RESULTS: THE CM PATHWAY FOR A BOVINE PANCREATIC TRYPSIN INHIBITOR (BPTI)

The aim of this section is to predict the dominant structural features of BPTI by a mechanistic analysis of its long-time dynamics, resulting from the simplified model of torsional motion at 298 K.[7,17,22] We shall focus on determining significant folding intermediates and the late kinetic bottlenecks that occur within the first 10^{-2} s of the renaturation process, a time span that requires 10^7 evaluations and renormalizations of the LTM. The C-h/p matrix for BPTI is displayed in Fig. 8. Our aim is to show how the dominant sequence of CM transitions for the BPTI describes the dominant folding kinetics, reproducing the essential cooperative features of the experimentally probed folding pathways, including the late scenario in which tertiary interactions direct and stabilize the native Cys–Cys (5,55) contact (cf. Refs. 7, 17). The actual refolding conditions involve special thiol and disulfide concentrations, so that the kinetics of formation, dismantling, and recombination of intrachain Cys–Cys disulfide bonds lies within the 10^{-5} s time scale,[7,22] and does not interfere with the folding process. This is so since the fastest Cys5–Cys30 interaction takes 4×10^{-5} s to form, as shown below.

In carrying out the simulation, special precautions have been taken to relax the conformational entropy demands associated with polar orientations in closed loops near the critical size. First of all, an operational definition of contact based on a proximity of 7 Å has been adopted in the CM development, in consonance with previous treatments.[10] Second, loops need not be, in general, planar, thus the orientational demands beyond the critical loop size must be relaxed smoothly and not abruptly: The entropic contribution, $-T\Delta S(\text{loop})$, will be linearly reduced in the interval $22 \leqslant N(\text{loop}) \leqslant 25$, so as to yield the following mean times of formation:

$$\tau(N(\text{loop}) = 22) = 2^{22 + N(\text{polar},22)} \times 10^{-11} \text{ s}, \tag{3a}$$

$$\tau(N(\text{loop}) = 25) = 2^{25} \times 10^{-11} \text{ s} \approx 3.2 \times 10^{-4} \text{ s}, \tag{3b}$$

where $N(\text{polar},22)$ is the number of polar side groups of a particular loop of size 22, and $\tau(N(\text{loop}))$ is the mean time of formation of a loop of size $N(\text{loop})$. Thus, the orientational demands are removed completely for $N(\text{loop}) > 25$, while they drop gradually and linearly within the interval $22 \leqslant N(\text{loop}) \leqslant 25$.

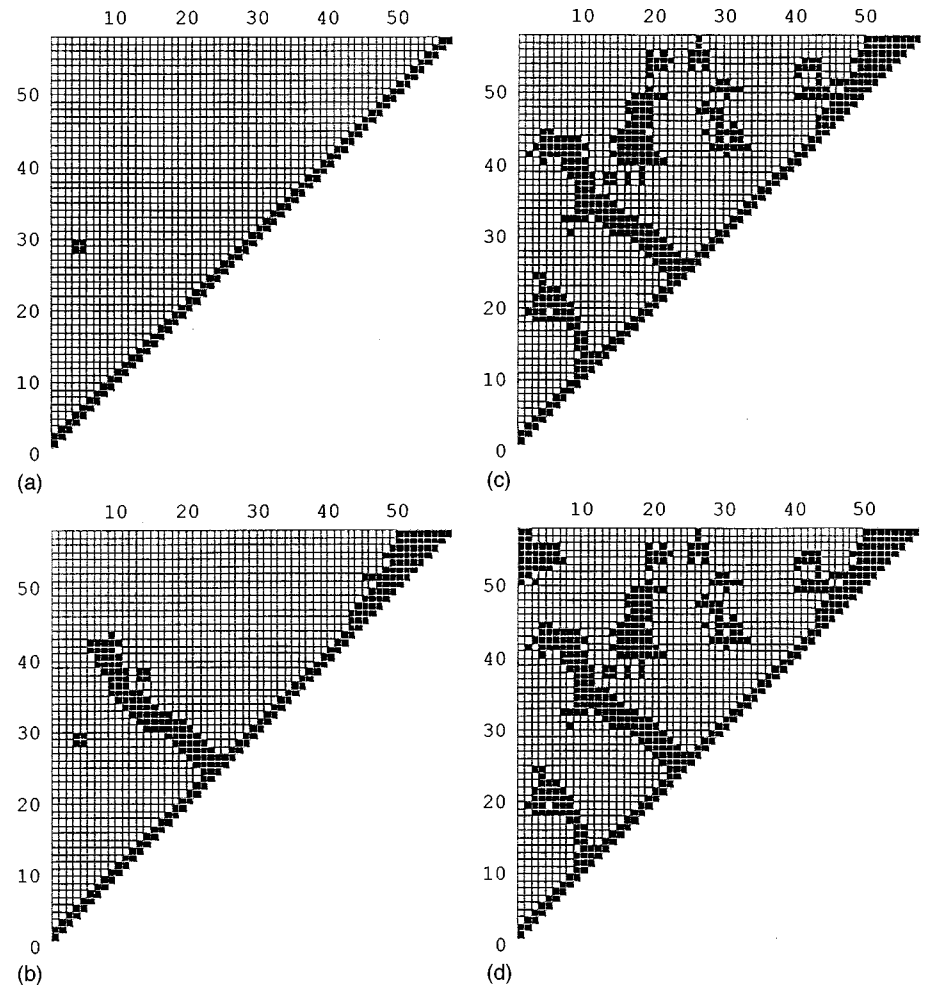

FIG. 9. (a)–(d). Four snapshots of the CM taken, respectively, at 3.2×10^{-4} s, 1.3×10^{-3} s, $1.3\times10^{-3}\,\mathrm{s}+3.2\times10^{-7}$ s, and $1.3\times10^{-3}\,\mathrm{s}+3.2\times10^{-7}\,\mathrm{s}+0.5\times10^{-2}$ s in the course of 10^7 translation–renormalization loops for the BPTI.

How does cooperativity operate in the folding of BPTI? To answer this question we can examine the estimated mean times to form native Cys–Cys disulfide contacts starting from a random coil conformation:

$$\tau(5,55)=2^{50}\times10^{-11}\ \mathrm{s}\approx10^{4}\ \mathrm{s};\quad \tau(30,51)=2^{21+13}\times10^{-11}\ \mathrm{s}\approx1.6\times10^{-1}\ \mathrm{s}, \tag{4}$$

where the number of polar side chains between residues 30 and 51 is $N(\mathrm{polar})=13$. Direct inspection of Eq. (4) reveals that such native contacts take a long time to form and can only be created cooperatively within the time scales under investigation. On the other hand, the third native Cys–Cys contact (14,38) may form directly within time scales commensurate with the occurrence of tertiary contacts:

$$\tau(14,38)\approx2^{24+1/3\times10}\times10^{-11}\ \mathrm{s}\approx1.3\times10^{-3}\ \mathrm{s}, \tag{5}$$

where $N(\mathrm{polar},(14,38))=10$ for the BPTI.

The actual sequence of CMs taken within the time span of 10^7 evaluations of the LTM is consistent with the previous analysis. Four significant snapshots of the time evolution of the CM have been taken and are displayed in Figs. 9(a)–9(d). The corresponding times are, respectively, 3.2×10^{-4} s, 1.3×10^{-3} s, $1.3\times10^{-3}\,\mathrm{s}+3.2\times10^{-7}$ s (the third snapshot is taken 320 LTM readings after the second), and $1.3\times10^{-3}\,\mathrm{s}+3.2\times10^{-7}\,\mathrm{s}+0.5\times10^{-2}$ s. A direct analysis of the CM evolution indicates that the non-native (5,30) disulfide bond forms first because a loop of size 25

poses no orientational constraints on its polar groups. Thus, we get the estimate $\tau(5,30) \approx 2^{25}\times 10^{-11}$ s$\approx 3.2\times 10^{-4}$ s. This is a good estimate, since the (5,30) contact indeed shows up on the CM snapshot taken precisely at that time, as featured in Fig. 9(a).

Nucleation windows of the form shown in Fig. 5(a) seeding the formation of an α helix appear in the (43–58) extreme of the molecule within the range of time scales 8.8×10^{-4}–9.8×10^{-4} s. The time scale of formation of (14,38) given in Eq. (5) is also a good estimate. The snapshot taken at 1.3×10^{-3} s [Fig. 9(b)] displays this native contact, as well as fully and partially developed secondary structure elements such as the α helix and a two-strand portion involving the contour region (20–33) of the β-sheet topology shown in Fig. 5(b). The nucleating events leading to the two-strand portion of the β-sheet topology take place in the (20–33) region of the chain within the same time interval as those triggering the formation of the helix.

Tertiary contacts between the α helix and the complex β sheet require the closure of the loop in the contour region (33–43) and start developing between the incomplete β sheet and the helix 320 LTM evaluations after the time when the last snapshot displayed in Fig. 9(b) was taken. This coincides precisely with the time estimation for closure of the ten loop with five polar groups within the (33–43) region of the BPTI:

$$\tau(\text{tertiary interaction}) \approx 2^{10+5}\times 10^{-11} \text{ s} \approx 3.2\times 10^{-7} \text{ s}. \tag{6}$$

We emphasize that this is a renormalized calculation that assumes the previous formation of a secondary structure.

At this point, the non-native (5,30) Cys–Cys bond is completely dismantled to give rise to the native (30–51) contact induced and stabilized by the tertiary interaction, as a direct observation of the third snapshot [Fig. 9(c)] reveals. This pathway reveals how the formation of (30,51) is expedited by cooperative folding, in agreement with recent findings.[7] Furthermore, during the time span of development of the first tertiary contact, the complex β-sheet motif continues to develop, fostering other tertiary interactions between the two dominant secondary structure elements. Since folding and unfolding of tertiary structure exchanges on the 10^{-3} s fast NMR time scale, the locking of oscillators at the mean 10^3 Hz frequency peak warrants the survival of the initial tertiary consensus while contact (30–51) forms and the β sheet is completed.

Finally, the (5,55) disulfide bond that would initially take a forbiddingly long time to form, now entails the closure of a complex 29 loop with no polar orientation demands: This loop is made up of the quasicoil (5–20) region, the β-sheet (20–30) region, and the quasicoil strand (51–55). Notice that the formation of the native (30,51) contact has short-circuited the loop closure for the (5,55) contact, so that the estimated time for this interaction is

$$\tau(5,55) \approx 2^{29}\times 10^{-11} \text{ s} \approx 0.5\times 10^{-2} \text{ s}. \tag{7}$$

This estimation of the rate-determining step in BPTI folding is corroborated by examination of the fourth snapshot [Fig. 9(d)], and confirms previous estimations,[7,17,22] in the sense that contact (30,51) occurs 10^5-fold more rapidly than (5,55).

Thus, the long-time dynamics obtained by means of our semiempirical microscopic model not only predicts with good accuracy the tertiary structural elements of the BPTI, but it also shows how cooperative effects can serve as an expedient to aid the formation of native interactions shaping the hydrophobic core.[17] A good agreement with experimental kinetic probes[7,17,22] has been found.

V. ($\pi-\rho$)-FOLDING PATHWAYS AND THE LEAST-ACTION PRINCIPLE

As indicated in the previous sections, structural patterns have been identified with consensus windows within which local topological constraints are fulfilled. It follows that the preferred folding pathway resolved as a sequence of CP transitions is the one for which each transition entails the minimal cost in conformational entropy, while maximizing the enthalpy decrease.[9] An example of such a pathway has been described in Sec. IV, where a single folding pathway happens to be dominant. On the other hand, the possibility of competing or multiple folding pathways is naturally incorporated in our computations, since different—and even conflictive—patterns may

be recognized in a single LTM. Thus, the probability of a single pattern is actually computed as the number of processors that recognize the pattern divided by the total number of processors involved in the evaluation of LTMs.

The highly dominant CM pathway computed in Sec. IV is the easiest to follow by the BPTI chain, and therefore by far the most probable as it entails the maximum economy of means for each step. This may be rationalized on account of two facts: (a) consensus, as identified in a LTM, implies the fulfillment of local topological constraints, which, in turn, determine the CP; (b) the enthalpic content is exclusively dependent on the contacts that have materialized.[9] Thus, whenever a single pathway dominates at the CM level, our semiempirical approach is compatible with the principle of sequential minimization of entropy loss (SMEL).[9,10,21]

In view of these facts, the following problem arises: Is it possible to define a Lagrangian L at the coarse microscopic level of LTM transitions that reproduces the SMEL behavior when a LTM trajectory is coarsely translated as a sequence of CP transitions? *In simple terms, is there a Lagrangian formulation to account for the expediency of the protein folding*? According to our treatment, the solution to this central problem involves determining $L=K-H$, where H is the enthalpy content, or potential in our context, and K is the ''kinetic energy'' of a LTM, $K=K(\mathrm{LTM})$, which must satisfy the following conditions.

(a) It must be uniquely defined for all LTMs associated to a specific CP, since otherwise many LTM trajectories, among which is the one singled out by L, would translate into the SMEL pathway.

(b) A CP transition is favored if it entails a minimal entropic cost; therefore its corresponding LTM transition must entail a minimization of the kinetic energy loss.

In accord with conditions (a) and (b), we define

$$K(\mathrm{LTM})=1/2\sum_{i=1,\ldots,2N} f_i^2, \tag{8}$$

where the f_i's, given in Hz, are the mean frequencies of the oscillators of the LTM and hence H must be given in Hz^2 units.

The choice given in Eq. (8) is a good one, as we shall demonstrate, making use of the fact that the oscillator frequencies of the LTM are determined by the renormalization operation: Let us suppose that a pattern of local signals has been identified and recorded in the CM at a given time by the translation operation. Then, the renormalization operation reclassifies the residues engaged in the latest CP generated, from class I into class II or, if a tertiary interaction has taken place, from class II into class III. The reader is reminded that residues belonging to loops whose closure is concurrent with secondary or tertiary interactions adopt the same cadence of those residues that form the respective contacts. Thus, *the loss in conformational entropy associated to the CP transition corresponds with a loss in kinetic energy of the LTM in such a way that a minimization of the entropy loss corresponds with a minimization of the loss in kinetic energy. This implies that the trajectory which maximizes the L action is the one that, projected onto CP space, represents the SMEL behavior*. For clarity, consider the possibility of two competitive interactions entailing closure of different size loops. Obviously, according to the SMEL principle, the interaction involving the formation of the smallest loop will be preferred. On the other hand, the closure of the smallest loop implies the slowing down of a smaller number of oscillators in the LTM, either from 10^{11} to 10^7 Hz or from 10^7 to 10^3 Hz, depending on whether a secondary or tertiary interaction has taken place. Thus, at the LTM level, the formation of the smallest loop is also selected by L, as it minimizes the kinetic energy loss with respect to the formation of the competing larger loop.

On the other hand, the renormalization operation warrants the uniqueness of K for every LTM, which translates into the same CP, since the renormalization operation establishes the new frequencies exclusively on the basis of the latest CP formed. By virtue of the renormalization operation, the occurrence of intrachain contacts is reflected as an alteration of oscillator frequencies. *This is the reason why the Lagrangian L underlies the coarse microscopic behavior which shows up at the level of CP transitions as the SMEL principle*.

In regards to the T dependence of K, we must take into account that at the denaturation T $(T(\mathrm{denat.}))$ consensus bubbles are created which dismantle every CP, as indicated in Sec. III. This is the result of a broad spreading of frequencies beyond the critical spreading value and the

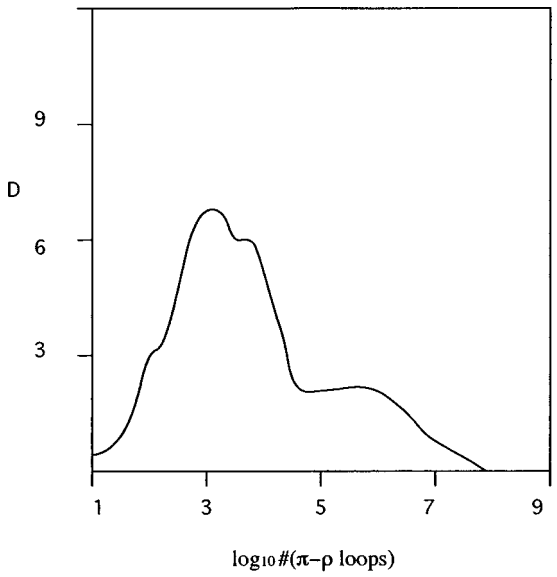

FIG. 10. Plot of the Hamming distance ($\times 100$) between consecutively evaluated LTMs along the folding pathway generated by iterating $(\pi-\rho)$ loops for BPTI.

concurrent impossibility of the preserving phase in consensus windows, as indicated in Sec. III. Thus, the renormalization operation near criticality will speed up all the oscillators for consensus windows where critical size bubbles occur, while such bubbles will become more and more ubiquitous as T approaches $T(\text{denat.})$. Then, K increases with T and the following relation holds as T approaches $T(\text{denat.})$ from below:

$$\lim_{T\to T(\text{denat.})^-} K=\text{Maximum } K=N\times 10^{22}\ \text{Hz}^2. \tag{9}$$

To conclude, we may state that the most economic folding pathway resolved at the coarse microscopic level, y^*, satisfies the following classical dynamics result:

$$L\ \text{action}(y^*)=\max_{\text{all LTM trajectories } y} L\ \text{action}(y). \tag{10}$$

Here ''L action(y)'' denotes the sum of all $L(\text{LTM}(i))$'s for all the LTM(i)'s, with i = discretized time index, along the trajectory y defined by mapping the previously allotted time interval over $(\mathbf{Z}_2)^{2N}$.

Without loss of generality we may assume that there exists a positive constant q so that $q+L=L'>0$. We may define a stochastic process Ξ at the semiempirical microscopic level of LTM transitions by defining transitional probabilities with respect to L':

$$p(V\to W)=[L'(W)-L'(V)]/[\Sigma_{W'}L'(W')-L'(V)], \tag{11}$$

where V, W, W' are LTMs, and the sum is extended over all W' states accessible from V within a predetermined Hamming distance $d=d(\text{max.})$ between LTM matrices (see Fig. 10). This distance is defined as

$$d(V,W)=(1/3N)\sum_{i,j}\Delta_{ij}(V,W),\quad \Delta_{ij}(V,W)=1\ \text{ if }\ V_{ij}\neq W_{ij},\quad \text{and}\quad =0\ \text{ otherwise.} \tag{12}$$

Prior to carrying out the stochastic computation using the Lagrangian, we determine the time dependence of $d(\text{max.})$ using the basic operational tenets defined in Sec. III. A $D-t$ plot ($D=100d(\text{max.})$) has been generated by performing 10^7 $(\pi-\rho$ loops) of the type indicated in Fig. 3, where π denotes translation and ρ renormalization. Thus, D is determined by computing after

every τ(read) interval the distance between two consecutive LTMs evaluated through two consecutive π operations. A computation for the BPTI is displayed in Fig. 10.

VI. THE LAGRANGIAN STRUCTURE OF THE $(\pi-\rho)$ LOOP COMPUTATION

This section is aimed at rigorously establishing the validity of the Lagrangian defined in Sec. V as the underlying functional selecting the optimal pathway among those generated by the $(\pi-\rho)$ loop iterative method. *We shall accomplish this by first noting that the Lagrangian-induced stochastic process* Ξ *and the stochastic process determined by an ensemble of realizations of the* $(\pi-\rho)$*-loop iterative computation are actually one and the same.*

The comparison between both processes requires a computation of the coarse informational entropy, $\sigma(t)$, and the computation of $\sigma_L(t)$, the informational entropy determined by the stochastic process Ξ. These quantities defined with respect to the CP partition of X, measure the spreading of probability in Shannon's sense due to the exploration of X that takes place during the folding process.[23,24] Thus, $\sigma=\sigma(t)$ is defined as follows:

$$\sigma(t)=-\sum_{j=1,\ldots,M} P_j(t)\ln P_j(t), \tag{13}$$

where M is the number of CP classes, and $P_j(t)$ is the probability that a $(\pi-\rho)$ loop computation reaches CP(j) at time t. Thus, this probability is evaluated as

$$P_j(t)=Q_j(t)/Q, \tag{14}$$

where $Q_j(t)$ is the number of $(\pi-\rho)$-loop pathways passing through CP(j) at time t and $Q\approx 100$ is the cardinal of the ensemble of $(\pi-\rho)$-loop pathways generated.

On the other hand, $\sigma_L(t)$ is defined as follows:

$$\sigma_L(t)=-\sum_{i=1,\ldots,M} \pi_t\mu\pi^{-1}\mathrm{CP}(i)[\ln(\pi_t\mu\pi^{-1}\mathrm{CP}(i))], \tag{15}$$

where π is the translation or projection of a LTM into its CP class, μ is the probability measure determined by Ξ over the space of LTM pathways, and $\pi_t\mu$ is the projection of μ over the time t replica of the LTM space. Thus, for a given CP, indicated by CP(i), the quantity $\pi_t\mu\pi^{-1}$ CP(i) is computed as follows:

$$\pi_t\mu\pi^{-1}\mathrm{CP}(i)=\#\{\Xi \text{ generated LTM trajectories intersecting } \pi^{-1}\ \mathrm{CP}(i) \text{ at time } t\}/\#\{\Xi \text{ generated LTM trajectories}\}. \tag{16}$$

Both coarse Shannon entropies defined, respectively, by Eqs. (13) and (15) are compared for the protein species BPTI (Fig. 11), giving a highly satisfactory agreement. Within the time scale range corresponding to the lifetime of the so-called molten globule intermediate[2] that corresponds to a plateau in the plots, the agreement is actually perfect. *We may conclude that the* $(\pi-\rho)$ *dynamics is underlied by the variational principle induced by the Lagrangian* L*, a result already implied in principle in Sec. V, and ultimately confirmed by the fact that both stochastic processes yield the same dispersion of probability at all times within relevant folding time scales.*

VII. GENERATING THE FOLDING DYNAMICS AT THE MICROSCOPIC LEVEL

The aim of this section is to determine the long-time microscopic dynamics of the chain torsional motion relevant to the folding process circumventing the computational limitations of Molecular Dynamics. This is done at the expense of approximating trajectories by coarse graining the time axis. Thus, in order to obtain the variational equations of microscopic motion, our strategy is to lift the coarsely defined Lagrangian introduced in Sec. V to the torus X. *Ultimately, we want to prove that the same coarse Lagrangian description that accounted for the SMEL, or maximum-economy-of-means behavior*[21] *at the level of contact pattern transitions, also yields Newton's equations of motion when carried over to the microscopic level.*

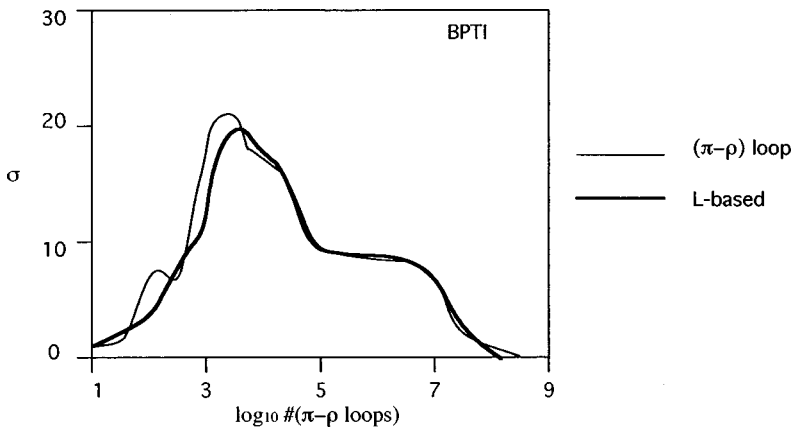

FIG. 11. Time dependence of the coarse information entropies $\sigma(t)$ and $\sigma_L(t)$ relative to the CP partition for BPTI. The abscissas indicate time in $\#(\pi-\rho)$ loop units.

To start with, the $(\pi-\rho)$ loop may be alternatively generated by a simulation of the continuous Φ, Ψ dynamics of the chain. Thus, if the dihedral torsions Φ_k, Ψ_k of the kth residue are modeled by oscillators with range $[0,2\pi]$, the LTM could simply be generated by transforming via a simple projection γ (see Fig. 12) the canonical torsional variables into the topological spin or two-state η, ξ variables used to define the LTM. This extended scheme of the $(\pi-\rho)$ loop is displayed in Fig. 12. One should notice that the computations using the extended scheme are actually identical to those using the scheme of Fig. 3, if the frequencies of the Φ, Ψ oscillators are taken to be exactly those of the η, ξ oscillators, and they are renormalized through the same rules via the map ρ.

Using the scheme of Fig. 12, the coarse Lagrangian defined in Sec. V may be now expressed in terms of the Φ, Ψ phase variables evaluated at time i on the microscopic conformation $\{\Phi_{k,i}, \Psi_{k,i}\}_k$ ($\Phi_{k,i}, \Psi_{k,i}$ denote the phases Φ_k, Ψ_k at time i):

$$L(\{\Phi_{k,i}, \Psi_{k,i}\}_k) = 1/2 \sum_{k=1,\ldots,2N} f_{k,i}^2 - H(\pi\gamma\{\Phi_{k,i}, \Psi_{k,i}\}_k), \tag{17}$$

where $f_{k,i}$ now represents the frequency of the Φ_k, Ψ_k phase oscillators at time i, which is identical to the frequency of the two-state η_k, ξ_k oscillators at time i, as indicated above. Thus, the following equations hold modulo 2π:

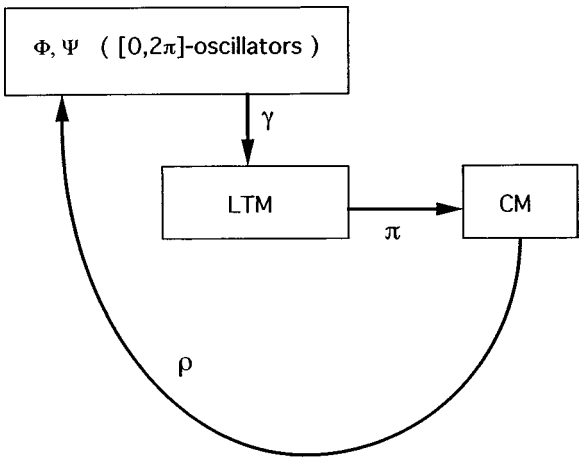

FIG. 12. Alternative scheme for the generation of $(\pi-\rho)$ loops using continuous oscillators with range $[0,2\pi]$ to mimic the Φ, Ψ torsions of the chain.

$$\Phi_{k,i+1}=\Phi_{k,i}+2\pi f_{k,i}h, \tag{18a}$$

$$\Psi_{k,i+1}=\Psi_{k,i}+2\pi f_{k,i}h, \tag{18b}$$

where $h=\tau'\approx 4$ ps at 298 °K ($\tau'=$minimum period, as defined in Sec. III) is a fixed time interval that enables us to discretize time so that we shall only consider the dynamics defined at multiples $t=ih$. The frequencies involved in Eqs. (18a) and (18b) are selected from the distribution ensemble whose width reflects the thermal fluctuations produced by the solvent environment, as indicated in Sec. III. With the time discretization, the variational calculus using L becomes an extremal problem in $2N\times J$ variables, with Jh being the time interval. The L action A reads as

$$A(\{\Phi_{k,i},\Psi_{k,i}\}_{k,i})=\sum_{i=1,\ldots,J} L(\{\Phi_{k,i},\Psi_{k,i}\}_k). \tag{19}$$

Thus, the pathway $\{\Phi_{k,i},\Psi_{k,i}\}_{k,i}$ realizing the extreme of A satisfies the following conditions:

$$\partial A/\partial\Phi_{k,i}=0; \quad \partial A/\partial\Psi_{k,i}=0; \quad k=1,\ldots,N; \quad i=1,\ldots,J. \tag{20}$$

These equations yield the following relations:

$$\rho(f_{k,i})=f_{k,i+1}=f_{k,i}-2\pi h[\partial H/\partial\Phi_k]_{i+1}, \tag{21a}$$

$$\rho(f_{k,i})=f_{k,i+1}=f_{k,i}-2\pi h[\partial H/\partial\Psi_k]_{i+1}. \tag{21b}$$

Since the reasoning is identical for both dihedral torsions, we shall henceforth focus only on Φ_k. In Eq. 21, $[\partial H/\partial\Phi_k]_{i+1}$ indicates that the derivative is evaluated at the conformation $\{\Phi_{k,i+1},\Psi_{k,i+1}\}_k$.

Equation (21) provides a thermodynamic interpretation of the $(\pi-\rho)$ loop dynamics whose characteristic period given by the time elapsed between one loop, and the next is $2^4h=64$ ps (see Sec. III). Thus, examining Eq. (21) once every 64 ps, we can identify the thermodynamic force—or torque—$[\partial H/\partial\Phi_k]_{i+1}$ as being the determinant of the frequency change. Thus, if a change of the phase $\Phi_{k,i}\rightarrow\Phi_{k,i+1}$ is responsible for an intrachain contact formation registered at the CP level, and thereby of a decrease in H, then the force $[\partial H/\partial\Phi_k]_{i+1}$ can only be positive or eventually zero, since the contact formed can only be dismantled $(\Delta H>0)$, or remain the same $(\Delta H=0)$ upon alterations of the phase Φ_k. Thus, the decrease in frequency that materializes upon the action of the renormalization at time $i+1$ is determined by the thermodynamic force $[\partial H/\partial\Phi_k]_{i+1}$ acting at time $i+1$. The stronger the contact formed as a result of the phase change $\Phi_{k,i}\rightarrow\Phi_{k,i+1}$, the bigger the decrease in frequency for the Φ_k oscillator.

One of the operational tenets of the $(\pi-\rho)$ loop is that if a transition $\Phi_{m,i}\rightarrow\Phi_{m,i+1}$ is responsible for the occurrence of an intrachain contact, with concurrent loop closure recorded as the CP$(i)\rightarrow$CP$(i+1)$ transition, then, *not only the frequency of the Φ_m oscillator is lowered upon renormalization, but also the f_k for any residue k within the loop*. This fact finds a natural interpretation once the thermodynamic forces governing the $(\pi-\rho)$ loop have been identified and Eq. (21) is used: *Only a Φ_k transition for a residue k within the loop can alter the contact formed*. Thus, all the f_k's in the loop are renormalized according to Eq. (21), while all other dihedrals retain their mean frequency because they cannot contribute to alter the contact in the CP(i) $\rightarrow$CP$(i+1)$ transition.

At this point we may obtain the microscopic equations of motion by combining Eqs. (18) and (21):

$$\Phi_{k,i+2}-2\Phi_{k,i+1}+\Phi_{k,i}=-4\pi^2h^2[\partial H/\partial\Phi_k]_{i+1}. \tag{22}$$

Since we can get the thermodynamic torques $[\partial H/\partial\Phi_k]_{i+1}$ by measuring the decrease in frequency using Eq. (18), together with the $(\pi-\rho)$ loop computation, *the folding dynamics have been essentially obtained at the microscopic level, except that we have coarse-grained time to multiples of 64h*.

Furthermore, Eq. (22) yields Newton's equations of motion at the microscopic level if we identify H with the potential and $(4\pi^2)^{-1}$ with the effective moment of inertia. Thus, in the limit $h \to 0$, Eq. (22) reads as

$$(4\pi^2)^{-1}\partial^2/\partial t^2 \Phi_k = -\partial H/\partial \Phi_k . \tag{23}$$

VIII. DISCUSSION

The semiempirical microscopic theory and its associated predictive algorithm expounded in this work provide the underpinnings to some issues that are central to the understanding of the long-time dynamics of a peptide chain in its relation to protein folding. Because our approach encompasses slower collective degrees of freedom than what detailed Molecular Dynamics computations may handle at present, we have initially dealt with a coarse description of the soft mode or manifold that nevertheless captures the dynamic hierarchy of torsional isomerization time scales. This has been done with the aim of eventually lifting the coarse dynamics to the level of soft-mode dynamics in a consistent manner.

In the first part of the work we obtain a coarse version of the soft-mode torsional dynamics of a peptide chain averaging out hard modes—stretching vibrations and planar angular vibrations,[25]—by means of a parallel computation which enabled us to penetrate into the time scale range of 1–10 ms, relevant to the protein folding process. Our treatment hinges upon a binary codification of local torsional isomerizations subject to the constraints imposed by both local and long-range correlations. In this way, patterns of locally encoded structural signals represent actual patterns of fulfilled local topological constraints that are recognized and translated as foldings of the chain. In turn, a feedback loop operates, whereby a new folding generated imposes new constraints upon the formation of patterns. Long-range intrachain contacts and secondary and tertiary interactions are induced by the drastic reduction in the available conformation space due to local correlations and by the solvent generation of local conformation-dependent dielectric environments. The actual time step of the parallel computation fixed at 64 ps is longer than that in previous treatments of the long-time torsional dynamics.[26] While such a long time step allows us to coarsely determine the microscopic origin of nucleation and cooperativity in the folding process by penetrating well into the 1–10 ms time range, it demands a more complex treatment of the solvent, which can no longer be treated as a hydrodynamic drag term: The recognition of a structural pattern becomes conditioned by the type of putative conformation-dependent dielectric domains that the solvent would determine if the corresponding folding would actually form.

Then, by introducing a variational principle underlying the generation of trajectories within our coarse microscopic description, we have reproduced and explained the expediency of the folding process at a meaningful level of understanding: The selected pathway reflects the maximum economy of each folding step. This nongeneric least-action formulation has been implemented, taking into account the inherently parallel nature of folding, demanding a concurrent evaluation of folding possibilities as consensus windows of locally encoded structural signals. The predictive potential of such an approach has been corroborated by contrasting the pathway singled out by the variational principle with the experimentally probed folding pathway.

The second aspect covered in this work has been to lift the coarse variational principle to the actual microscopic level of description of the long-time dynamics of chain torsions. The result reveal the consistency of our semiempirical variational approach, which becomes apparent by examining the $(\pi-\rho)$ loop dynamics at both ends of the spectrum of coarsenings of conformation space. Thus, at the finest level, we obtain Newton's equations of motion, while at the coarser level of contact patterns, we obtain a folding pathway entailing the maximum economy of means. The paramount advantage of our approach is given by the fact that we are able to actually compute ''relatively often'' (in a precise sense given in Sec. VII) the forces acting at the microscopic level and thus, elucidate the microscopic dynamics that project directly onto the dominant folding pathway.

ACKNOWLEDGMENTS

(Received 26 September 1996; accepted for publication 2 February 1998)

We analyze the number-theoretical spin chain with partition function $Z(\beta)=\zeta(\beta-1)/\zeta(\beta)$ using the polymer model technique. The finite (grand) canonical chains give bounds for the limit free energy and internal energy. The correlation functions for inverse temperature $\beta=-1$ are products of two-point functions. A combinatorial result for general interval graphs is derived. © *1998 American Institute of Physics.* [S0022-2488(98)00606-9]

I. INTRODUCTION

The simplest kind of number theory consists of adding integers and observing the regularities that arise. For example, one may add integers at neighboring positions in a row and write the results in the next row. If one starts with the row number $k=0$ containing a single one, then the result is Pascal's triangle [Fig. 1(a)], with the binomial coefficient $\binom{k}{l}$ at position (k,l). The defining relations of the binomial coefficients are thus

$$\binom{0}{l}:=\delta_0(l) \quad \text{and} \quad \binom{k+1}{l}:=\binom{k}{l-1}+\binom{k}{l}.$$

Although Pascal's triangle was already described in the 1303 book *The Precious Mirror of the Four Elements* by Chu Shih-chieh and thus has a rather long history, there are still many unsolved questions connected with it. Anybody who is now and then summing series knows some nontrivial identities met by the binomial coefficients.

Now we change the defining rule a bit. Instead of simply forgetting the values written in the kth row, we copy them to the row number $k+1$, thus obtaining *Pascal's triangle with memory.*

We want 2^k instead of $2^{k+1}-1$ entries in each row. Thus we consider these entries as being circularly ordered. For practical purposes we write a second copy of the first entry 1 at the end of the row but encircle it in order to mark its identification with the first entry [Fig. 1(b)].

The 2^k entries can be indexed by the base 2 k-digit numbers $0\ldots0$, $0\ldots01$, $\ldots$, $1\ldots1$, writing them in ascending order. Thus we may consider these entries as the values of a function $\mathbf{h}_k^C:\mathbf{G}_k\to\mathbb{N}$ with the k-fold Cartesian product group $\mathbf{G}_k:=\mathbb{Z}_2^k$, $\mathbb{Z}_2=(\{0,1\},+)$ being the two-element group in additive notation. A moment's thought shows that these functions can be defined by $\mathbf{h}_0^C:=1$,

$$\mathbf{h}_{k+1}^C(\sigma_1,\ldots,\sigma_{k+1}):=\mathbf{h}_k^C(\sigma_1,\ldots,\sigma_k)+\sigma_{k+1}\cdot\mathbf{h}_k^C(1-\sigma_1,\ldots,1-\sigma_k). \tag{1}$$

If one defines the *energy function* $\mathbf{H}_k^C:\mathbf{G}_k\to\mathbb{R}$ of the *canonical ensemble* by $\mathbf{H}_k^C=\ln(\mathbf{h}_k^C)$, then the functions

FIG. 1. Pascal's triangle (a) without memory and (b) with memory.

$$Z_k^C(\beta) := \sum_{\sigma \in \mathbf{G}_k} \exp(-\beta \mathbf{H}_k^C(\sigma))$$

can be interpreted as partition functions of a spin chain of length k, the superscript C referring to the canonical ensemble. Here the spins take the values $\sigma_i = 0,1$ instead of the more conventional choice $(-1)^{\sigma_i} = 1,-1$.

It turns out that they converge for $\mathrm{Re}(\beta) > 2$ to

$$Z(\beta) = \lim_{k \to \infty} Z_k^C(\beta)$$

which is the quotient

$$Z(\beta) := \frac{\zeta(\beta - 1)}{\zeta(\beta)} = \sum_{n=1}^{\infty} \varphi(n) \cdot n^{-\beta}$$

of Riemann zeta functions. Here $\varphi(n) := |\{l \in \{1, \ldots, n\} | \gcd(l,n) = 1\}|$ is Euler's totient function.

In Ref. 1 one of us showed that the interaction coefficients $j_k^C : \mathbf{G}_k \to \mathbb{R}$ with

$$\mathbf{H}_k^C(\sigma) = -\sum_{t \in \mathbf{G}_k^*} j_k^C(t) \cdot (-1)^{\sigma \cdot t}$$

are asymptotically translation invariant and saturate in the length k of the chain. Moreover, the effective interaction between spins at positions r and l was shown to decay like $1/(r-l)^2$.

This decay rate $\mathrm{dist}^{-\alpha}$ with $\alpha = 2$ is known to be the borderline case for phase transitions of a spin chain.

The dual group $\mathbf{G}_k^*$ of $\mathbf{G}_k$ being isomorphic to $\mathbf{G}_k$, the Fourier transform of $f : \mathbf{G}_k \to \mathbb{R}$ is given by

$$(\mathcal{F}_k f)(t) := 2^{-k} \sum_{\sigma \in \mathbf{G}_k} f(\sigma) \cdot (-1)^{\sigma \cdot t} \tag{2}$$

and thus $j_k^C = -\mathcal{F}_k \mathbf{H}_k^C$. In Ref. 1 the interaction was shown to be weakly ferromagnetic in the sense that $j_k^C(t) \geqslant 0$ for $t \neq 0$.

It turned out to be useful to introduce the *grand canonical* energy functions $\mathbf{H}_k^G : \mathbf{G}_k \to \mathbb{R}$, $\mathbf{H}_k^G := \ln(\mathbf{h}_k^G)$, the values

$$\mathbf{h}_k^G(\sigma) := \mathbf{h}_{k+1}^C(\sigma,1) \tag{3}$$

being the new elements appearing in each row of Fig. 1(b). They have the symmetries

$$\mathbf{H}_k^G(1-\sigma_1, \ldots, 1-\sigma_k) = \mathbf{H}_k^G(\sigma_1, \ldots, \sigma_k) = \mathbf{H}_k^G(\sigma_k, \ldots, \sigma_1).$$

In Ref. 2 the existence of the thermodynamic limit $F(\beta) := \lim_{k\to\infty} F_k^C(\beta)$ of the free energy $F_k^C(\beta) := -(\beta\cdot k)^{-1}\ln(Z_k^C(\beta))$ was shown (due to the lack of strict translation invariance of the interaction standard estimates cannot be applied here). Due to the long-range character of the interaction the chain is in a frozen state above the phase transition which gives rise to the somewhat unusual constancy of the free energy [$F(\beta)=0$ for $\beta\geqslant 2$].

In Ref. 3 thermodynamic expectations

$$\langle O\rangle_k^C(\beta) := \frac{\Sigma_{\sigma\in\mathbf{G}_k} O(\sigma)\exp(-\beta\mathbf{H}_k^C(\sigma))}{Z_k^C(\beta)}$$

of quantities like the internal energy $U_k^C := \langle (1/k)\mathbf{H}_k^C\rangle_k^C$ and magnetization $M_k := \langle (1/k)\times\Sigma_{l=1}^k(-1)^{\sigma_l}\rangle_k^C$ were analyzed. Due to the absolute convergence of the Dirichlet series $Z(\beta) = \Sigma_{n=1}^\infty \varphi(n) n^{-\beta}$ for $\mathrm{Re}(\beta)>2$ the limits $U(\beta) := \lim_{k\to\infty} U_k^C(\beta)$ and $M(\beta) := \lim_{k\to\infty} M_k(\beta)$ can be easily shown to have the values $U(\beta)=0$, $M(\beta)=1$ in the frozen low-temperature phase $\beta>2$.

In the high-temperature regime $\beta<2$ the estimates

$$\frac{\ln 2-\beta\,\ln(3/2)}{2-\beta} \leqslant U(\beta) \leqslant \ln(3/2) \tag{4}$$

were derived.

The corresponding grand canonical quantities are defined similarly.

In Ref. 4 it was shown that the values $\mathbf{H}_k^C(\sigma)$ of the canonical energy function can be naturally interpreted in terms of geodesics coming from and going to the cusp in the modular domain.

These geodesics are naturally organized in families of 2^k members and labelled by $\sigma\in\mathbf{G}_k$. Then $\mathbf{H}_k^C(\sigma)$ is the length difference between the geodesic with index σ and the shortest such geodesic (which carries index 0).

This related the spin chain to the quantum scattering theory in the modular domain, since these length differences arise naturally in the Wentzel–Kramers–Brilloin (WKB) expansion of the scattering matrix.

Moreover, numerical evidence was presented that the Riemann zeta function can be well approximated *within its critical strip* by statistical-mechanical expectations. The reasons for this observation are discussed in Ref. 5 by one of us.

In Ref. 6 Contucci and Knauf showed that there exists only one phase transition, at $\beta=2$. There the magnetization jumps from 1 to 0. The phase transition is at most of second order.

In Ref. 7 the relations between number theory and polymer models are treated.

The same partition function (but without the interpretation as coming from a spin chain) was discussed by Artuso *et al.* in Ref. 8. See also the related work by Feigenbaum[9] and the overview by Cvitanović.[10]

The study of the number-theoretical spin chain is mainly motivated by the idea that probabilistic properties of statistical mechanics, and in particular ferromagnetism, could be helpful in deriving new results in number theory (see Ref. 5).

For example, an interpretation of the functional equation of Z in terms of a Wannier-type duality of polymer model interpretations would be welcome.

In Sec. II we calculate the Fourier transforms of the functions $\mathbf{h}_k^C$ and $\mathbf{h}_k^G$. This leads directly to expressions for the correlation functions at $\beta=-1$.

The polymer model technique is then used in Sec. III in order to derive a formula for the interaction coefficients. They and not the free energy are described using connected multipolymers.

Like any Dirichlet series with a Euler product the number-theoretical spin chain itself has an interpretation as a polymer model (see Ref. 7), but this interpretation is not well adapted to the peculiarities of this chain. So, we would like to see another such interpretation in the spirit of Sec. III.

In Sec. IV we deal with general interval graphs, that is, graphs whose vertices correspond to intervals and which are connected by an edge if the corresponding intervals overlap. These types of graphs are used in our context.

In Sec. V the limit free energy is estimated from above and below using the k-spin (grand) canonical ensembles.

This result and a polymer inequality finally lead in Sec. VI to inequalities for the internal energy.

II. CORRELATION FUNCTIONS AT $\beta=-1$

In this section we analyze the Fourier transforms [see (2)] $J_k^C := \mathcal{F}_k(\mathbf{h}_k^C)$, $J_k^G := \mathcal{F}_k(\mathbf{h}_k^G)$ of the exponentiated (grand) canonical energy functions $\mathbf{h}_k^C$, resp. $\mathbf{h}_k^G$, inductively defined in (1) and (3). Using the shorthand $|s| := \Sigma_{i=1}^l s_i$ for $s \in \mathbf{G}_l$, we have the following.

Lemma 1: $J_0^C = 1$, and for $t = (t_1, \ldots, t_{k+1}) \in \mathbf{G}_{k+1}^*$

$$J_{k+1}^C(t_1, \ldots, t_{k+1}) = \tfrac{1}{2}(1 + (-1)^{t_{k+1}} + (-1)^{|t|}) J_k^C(t_1, \ldots, t_k). \tag{5}$$

The grand canonical Fourier coefficients are given by

$$J_{k+1}^G(t) = (1 + (-1)^{|t|}) J_k^C(t) \quad (t \in \mathbf{G}_k^*). \tag{6}$$

Proof: If $k=0$, then $|\mathbf{G}_k| = 1$ and $J_0^C = \mathbf{h}_0^C = 1$. To show the inductive formula (5), we use the abbreviation $t' := (t_1, \ldots, t_k) \in \mathbf{G}_k^*$. Then

$$\begin{aligned}
J_{k+1}^C(t) &= 2^{-k-1} \sum_{\sigma \in \mathbf{G}_{k+1}} \mathbf{h}_{k+1}^C(\sigma) \cdot (-1)^{\sigma \cdot t} \\
&= 2^{-k-1} \sum_{\sigma' \in \mathbf{G}_k} (\mathbf{h}_{k+1}^C(\sigma', 0) + (-1)^{t_{k+1}} \mathbf{h}_{k+1}^C(\sigma', 1)) \cdot (-1)^{\sigma' \cdot t'} \\
&= \frac{1}{2} 2^{-k} \sum_{\sigma' \in \mathbf{G}_k} \mathbf{h}_k^C(\sigma') \cdot (-1)^{\sigma' \cdot t'} + \frac{1}{2} (-1)^{t_{k+1}} 2^{-k} \sum_{\sigma' \in \mathbf{G}_k} (\mathbf{h}_k^C(\sigma') \\
&\quad + \mathbf{h}_k^C(1 - \sigma')) \cdot (-1)^{\sigma' \cdot t'} \\
&= \tfrac{1}{2}(1 + (-1)^{t_{k+1}} + (-1)^{|t|}) J_k^C(t'),
\end{aligned}$$

using the iterative definition (1) of $\mathbf{h}_k^C$ and the relation

$$\sum_{\sigma' \in \mathbf{G}_k} \mathbf{h}_k^C(1 - \sigma') \cdot (-1)^{\sigma' \cdot t'} = (-1)^{|t'|} \sum_{\sigma' \in \mathbf{G}_k} \mathbf{h}_k^C(\sigma') \cdot (-1)^{\sigma' \cdot t'}.$$

Equation (6) follows from the definition $\mathbf{h}_k^G(\sigma) = \mathbf{h}_{k+1}^C(\sigma, 1)$ of $\mathbf{h}_k^G$ and (5), since this implies

$$\begin{aligned}
J_k^G(t) &= 2^{-k} \sum_{\sigma \in \mathbf{G}_k} \mathbf{h}_{k+1}^C(\sigma, 1) \cdot (-1)^{\sigma \cdot t} \\
&= 2^{-k} \sum_{\sigma \in \mathbf{G}_k} (\mathbf{h}_k^C(\sigma) + \mathbf{h}_k^C(1 - \sigma)) \cdot (-1)^{\sigma \cdot t} \\
&= (1 + (-1)^{|t|}) J_k^C(t).
\end{aligned}$$

□

The above formulas allow us to write the Fourier coefficients as products over contributions from so-called polymers. The set

$$P_k := \{p_{l,r}, p_l \in \mathbf{G}_k^* \,|\, 1 \leqslant l, r \leqslant k;\ l < r\}$$

of *polymers* in $\mathbf{G}_k^*$ is given by

$$p_{l,r}(i) := \delta_l(i) + \delta_r(i), \quad p_l(i) := \delta_l(i) \quad (i = 1, \ldots, k). \tag{7}$$

We define their *support* by $\mathrm{supp}(p_{l,r}) := \{i \,|\, l \leqslant i \leqslant r\}$ for the *even* polymers and $\mathrm{supp}(p_l) := \{i \,|\, l \leqslant i \leqslant k\}$ for the *odd* ones. Two polymers $\gamma_1, \gamma_2 \in P_k$ are called overlapping or *incompatible* if $\mathrm{supp}(\gamma_1) \cap \mathrm{supp}(\gamma_2) \neq \varnothing$. So, in particular, all the odd polymers p_l, $1 \leqslant l \leqslant k$, are mutually incompatible.

Now an arbitrary group element $t = (t_1, \ldots, t_k) \in \mathbf{G}_k^*$ can be uniquely decomposed into the sum of $n := [\frac{1}{2}(|t| + 1)]$ compatible polymers:

$$t = \begin{cases} \displaystyle\sum_{i=1}^{n} p_{l_i, r_i}, & |t| \text{ even}, \\ \displaystyle\sum_{i=1}^{n-1} p_{l_i, r_i} + p_{l_n}, & |t| \text{ odd}, \end{cases} \tag{8}$$

whose indices l_i, r_i may be assumed to be increasing in i and are determined by $t_{l_i} = t_{r_i} = 1$. As an example $(0,1,0,1,1,0) = p_{2,4} + p_5 \in \mathbf{G}_6^*$.

We write this decomposition in the short form $t = \Sigma_{i=1}^{n} \gamma_i$ and set the activity of a polymer $\gamma \in \mathbf{G}_k^*$ equal to $z(\gamma) := -3^{-|\mathrm{supp}(\gamma)|}$.

Theorem 2: *With the above decomposition (8) of* $t \in \mathbf{G}_k^*$

$$J_k^C(t) = (3/2)^k \prod_{i=1}^{n} z(\gamma_i) \tag{9}$$

and

$$J_k^G(t) = (1 + (-1)^{|t|})(3/2)^k \prod_{i=1}^{n} z(\gamma_i). \tag{10}$$

Proof: We proceed by induction in the number k of spins. For $k = 0$, Eq. (9) gives $J_0^C = 1$, as in Lemma II.

(i) If $|t|$ is even and $t_{k+1} = 0$, then the polymers of the representation (8) of $(t_1, \ldots, t_{k+1})$ coincide with the polymers of $(t_1, \ldots, t_k)$. So, by (9), $J_{k+1}^C(t_1, \ldots, t_{k+1}) = \frac{3}{2} J_k^C(t_1, \ldots, t_k)$, in accordance with (5).

(ii) If $|t|$ is even and $t_{k+1} = 1$, then $(t_1, \ldots, t_{k+1})$ contains the additional polymer p_{k+1} so that both (5) and (9) imply

$$J_{k+1}^C(t_1, \ldots, t_{k+1}) = -\tfrac{1}{2} J_k^C(t_1, \ldots, t_k).$$

(iii) If $|t|$ is odd, then the odd polymer p_{l_n} in the decomposition (8) of $(t_1, \ldots, t_k)$ has activity $z(p_{l_n}) = -3^{l_n - k - 1}$. If $t_{k+1} = 0$, then the polymer decomposition for $(t_1, \ldots, t_{k+1})$ remains the same, but now $z(p_{l_n}) = -3^{l_n - k - 2}$. If $t_{k+1} = 1$, the odd polymer p_{l_n} is changed into the even polymer $p_{l_n, k+1}$ which, too, has activity $z(p_{l_n, k+1}) = -3^{l_n - k - 2}$. So both (5) and (9) predict $J_{k+1}^C(t_1, \ldots, t_{k+1}) = \frac{1}{2} J_k^C(t_1, \ldots, t_k)$, independent of whether $t_{k+1} = 0$ or 1.

The corresponding equation (10) for the grand canonical coefficients $J_k^G(t)$ follows directly from (9) and (6). □

Theorem 2 has the following corollary concerning the (grand) canonical expectations

$$\langle f\rangle_k^{C/G}(\beta)=\frac{\Sigma_{\sigma\in\mathbf{G}_k} f(\sigma)e^{-\beta\mathbf{H}_k^{C/G}(\sigma)}}{Z_k^{C/G}(\beta)}$$

of $f:\mathbf{G}_k\to\mathbb{R}$ at inverse temperature β:

Corollary 3: For $1\leqslant i_1<\cdots<i_{2l}\leqslant k$ *the even (grand) canonical correlation functions at inverse temperature* $\beta=-1$ *equal*

$$\left\langle \prod_{m=1}^{l}\sigma_{i_{2m-1}}\sigma_{i_{2m}}\right\rangle_k^{C/G}(-1)=\prod_{m=1}^{l}\langle\sigma_{i_{2m-1}}\sigma_{i_{2m}}\rangle_k^{C/G}(-1),$$

whereas the grand canonical correlation functions between an odd number of spins vanish for any $\beta\in\mathbb{R}$.

Proof: Using (9), resp. (10), we obtain for $|t|$ even the general identity

$$\left\langle \prod_{i:t_i=1}\sigma_i\right\rangle_k^{C/G}(-1)=\frac{J_k^{C/G}(t)}{J_k^{C/G}(0)}=\prod_{i=1}^{n}z(\gamma_i)$$

for the correlation functions, proving the product formula. The odd grand canonical correlation functions vanish identically since, by (10), $J_k^G(t)=0$ for $|t|$ odd. □

III. POLYMERS AND INTERACTION COEFFICIENTS

Now we will express the (grand) canonical interaction coefficients

$$\mathbf{j}_k^{C/G}(t)=-\mathcal{F}_k(\mathbf{H}_k^{C/G})(t)\quad(t\in\mathbf{G}_k^*)$$

in terms of the Fourier transforms $J_k^{C/G}(t)=\mathcal{F}_k(\mathbf{h}_k^{C/G})(t)$ of the exponentiated energy functions $\mathbf{h}_k^{C/G}=\exp(\mathbf{H}_k^{C/G})$ [observe that for historical reasons the $\mathbf{j}_k^{C/G}(t)$ are the *negative* Fourier coefficients].

Our motivation for considering that functional relationship is the existence of the explicit formulas (9) and (10) for J_k^C, resp. J_k^G.

The technique we apply stems from the theory of polymer models whose general setting we now recall (see, e.g., Refs. 11–13).

In an abstract setting one starts with a denumerable set P whose elements are called *polymers*. Two given polymers $\gamma_1,\gamma_2\in P$ may or may not overlap (be *incompatible*). Incompatibility is assumed to be a reflexive and symmetric relation on P.

Thus one may associate to a *k-polymer* $X:=(\gamma_1,\ldots,\gamma_k)\in P^k$ an undirected graph $G(X)=(V(X),E(X))$ without loops (edges connecting a vertex with itself) with vertex set $V(X):=\{1,\ldots,k\}$, vertices $i\neq j$ being connected by the edge $\{\gamma_i,\gamma_j\}\in E(X)$ if γ_i and γ_j are incompatible. Accordingly the k-polymer X is called *connected* if $G(X)$ is path-connected and *disconnected* if it has no edges $[E(X)=\emptyset]$.

The corresponding subsets of P^k are called C^k, resp. D^k, with $D^0:=P^0:=\{\emptyset\}$ consisting of a single element. Moreover $P^\infty:=\cup_{k=0}^\infty P^k$ with the subsets $D^\infty:=\cup_{k=0}^\infty D^k$ and $C^\infty:=\cup_{k=1}^\infty C^k$. We write $|X|:=k$ if $X\in P^k$.

Statistical weights or activities $z:P\to\mathbb{C}$ of the polymers are multiplied to give the activities $z^X:=\Pi_{i=1}^k z(\gamma_i)$ of k-polymers.

Finally, in order to work with finite sums, we use finite subsets $P_\Lambda\subset P$ of polymers, which are thought of as being geometrically enclosed in a finite region $\Lambda\subset S$.

A system of statistical mechanics is called a *polymer model* if its partition functions Z_Λ have the form

$$Z_\Lambda=\sum_{X\in D_\Lambda^\infty}\frac{z^X}{|X|!}. \tag{11}$$

Then, up the normalization factor $|\Lambda|^{-1}$, the free energy is given by

$$\ln(Z_\Lambda) = \sum_{X \in C_\Lambda^\infty} \frac{n(X)}{|X|!} z^X, \tag{12}$$

with $n(X) := n_+(X) - n_-(X)$, $n_\pm(X)$ being the number of subgraphs of $G(X)$ connecting the vertices of $G(X)$ with an even, resp. odd, number of edges (see Ref. 11).

In the present context we argue as follows: Our polymers are elements of the Abelian group

$$\mathbf{G}_\infty^* := \oplus_{n=1}^\infty \mathbb{Z}_2 \subset \otimes_{n=1}^\infty \mathbb{Z}_2,$$

which is the direct sum of the $\mathbb{Z}_2$ groups and thus consists of those infinite sequences $t = (t_1, t_2, \dots) \in \otimes_{n=1}^\infty \mathbb{Z}_2$ which have only finitely many entries $t_i \neq 0$. The set P of polymers and their supports is defined similarly to the set P_k [see (7)] except that now $k = \infty$.

This infinite volume case is then approximated by considering the set P_k of polymers in the finite subset $\Lambda = \{1, \dots, k\} \subset \mathbb{N}$. The group $\mathbf{G}_k^*$ is identified with the subgroup of those $t \in \mathbf{G}_\infty^*$ with $t_n = 0$ for $n > k$.

Then the map $D_k^\infty \to \mathbf{G}_k^*$, $(\gamma_1, \dots, \gamma_n) \mapsto \Sigma_{i=1}^n \gamma_i$ is an isomorphism between the disconnected multi-polymers in $\{1, \dots, k\}$ and the Abelian group $\mathbf{G}_k^*$.

We will now use this isomorphism to calculate the interaction coefficients.

For the canonical ensemble formula (9) in Theorem 2 implies

$$\begin{aligned} j_k^C(t) &= -2^{-k} \sum_{\sigma \in \mathbf{G}_k} \mathbf{H}_k^C(\sigma) \cdot (-1)^{\sigma \cdot t} \\ &= -2^{-k} \sum_{\sigma \in \mathbf{G}_k} \ln\left[\sum_{s \in \mathbf{G}_k^*} J_k^C(s) \cdot (-1)^{s \cdot \sigma} \right] \cdot (-1)^{\sigma \cdot t} \\ &= -\delta_{t,0} \cdot k \, \ln(3/2) - 2^{-k} \sum_{\sigma \in \mathbf{G}_k} \ln\left[\sum_{X \in D_k^\infty} \frac{\tilde{z}_\sigma^X}{|X|!} \right] \cdot (-1)^{\sigma \cdot t}, \end{aligned} \tag{13}$$

where the redefined single-polymer activities $\tilde{z}_\sigma(\gamma)$, $\gamma \in P_k$, are given by $\tilde{z}_\sigma(\gamma) := z_\sigma(\gamma) \cdot (-1)^{\sigma \cdot \gamma}$, that is

$$\tilde{z}_\sigma(p_{l,r}) := z(p_{l,r}) \cdot (-1)^{\sigma_l + \sigma_r}, \quad \tilde{z}_\sigma(p_l) := z(p_l) \cdot (-1)^{\sigma_l}.$$

By (12) we get

$$\begin{aligned} j_k^C(t) + \delta_{t,0} \cdot k \, \ln(3/2) &= -2^{-k} \sum_{\sigma \in \mathbf{G}_k} \sum_{X \in C_k^\infty} \frac{n(X)}{|X|!} \tilde{z}_\sigma^X \cdot (-1)^{\sigma \cdot t} \\ &= -\sum_{X = (\gamma_1, \dots, \gamma_{|X|}) \in C_k^\infty} \frac{n(X)}{|X|!} z^X \cdot 2^{-k} \sum_{\sigma \in \mathbf{G}_k} (-1)^{\sigma \cdot \left(t + \sum_{i=1}^{|X|} \gamma_i \right)} \\ &= -\sum_{\substack{X = (\gamma_1, \dots, \gamma_{|X|}) \in C_k^\infty \\ \sum_{i=1}^{|X|} \gamma_i = t}} \frac{n(X)}{|X|!} z^X, \end{aligned} \tag{14}$$

using the identity $\Sigma_{\sigma \in \mathbf{G}_k} (-1)^{\sigma \cdot s} = 2^k \delta_{s,0}$.

For the grand canonical ensemble $j_k^G(t)=0$ if $|t|$ is odd. If $|t|$ is even, then by (10) and a similar derivation as above

$$j_k^G(t)=-\delta_{t,0}\cdot(\ln(2)+k\ \ln(3/2))-\sum_{\substack{X=(\gamma_1,\ldots,\gamma_{|X|})\in C_k^{\infty,e}\\ \Sigma_{i=1}^{|X|}\gamma_i=t}}\frac{n(X)}{|X|!}z^X, \tag{15}$$

where now $C_k^{\infty,e}$ contains precisely those multi-polymers $X=(\gamma_1,\ldots,\gamma_{|X|})$ consisting only of even polymers γ_i of the form $p_{l,r}$ and not the odd polymers p_l.

IV. COMBINATORICS OF INTERVAL GRAPHS

The graphs $G(X)$ of the connected multi-polymers $X\in C_k^\infty$, resp. $C_k^{\infty,e}$, occurring in (14), resp. (15), have a special structure which enables us to obtain a simple explicit formula for the combinatorial factor $n(X)$.

The supports of the even polymers $p_{l,r}$ were of the form $\{l,\ldots,r\}$, whereas for the odd polymers p_l one had $\mathrm{supp}(p_l)=\{l,\ldots,k\}$. Polymers in P_k with overlapping supports were called incompatible.

These definitions imply that the graph $G(X)$ of a multi-polymer is a so-called interval graph. In general, a graph $G=(V,E)$ is called *interval graph* if there exists an isomorphism $I:V\to\overline{V}$ between the set V of vertices and a set $\overline{V}$ of intervals in $\mathbb{R}$ such that $v_i,v_j\in V$ are connected by the edge $\{v_i,v_j\}\in E$ precisely if the corresponding intervals $I(v_i)$ and $I(v_j)$ have nonempty intersection.

By renaming the vertices we can assume that $V=V_r:=\{v_1,\ldots,v_r\}$, $I(v_i)=[a_i,b_i]$, and $a_i\leqslant a_j$ for $i<j$. Then $G_i:=(V_i,E_i)$ with $E_i:=E\cap(V_i\times V_i)$ is the induced subgraph of G on the first i vertices, $1\leqslant i\leqslant r$.

Theorem 4: *For interval graphs G with the above notation*

$$n(G)=\prod_{i=1}^{r-1}(|E_i|-|E_{i+1}|).$$

Proof: We prove the formula by induction in the number $|V|$ of vertices.

If $|V|=1$, the index set of the product is empty so that the product gives 1. But $n(G)=n_+(G)-n_-(G)=1$, too, since $n_+(G)=1$ and $n_-(G)=0$.

The subgraphs G_i of G are themselves interval graphs. We assume that $n(G_{l-1})=\Pi_{i=1}^{l-2}(|E_i|-|E_{i+1}|)$ and show that

$$n(G_l)=\prod_{i=1}^{l-1}(|E_i|-|E_{i+1}|)=n(G_{l-1})\cdot(|E_{l-1}|-|E_l|)=-n(G_{l-1})\cdot|\hat{E}_l|, \tag{16}$$

where $\hat{E}_l:=E_l-E_{l-1}$ is the set of edges in G_l connecting the vertex v_l with the subgraph G_{l-1}. The set $\mathcal{C}_l$ of connected subgraphs of G_l is the disjoint union

$$\mathcal{C}_l=\dot{\cup}_{\hat{E}\subset\hat{E}_l}\mathcal{C}_l(\hat{E})$$

of $\mathcal{C}_l(\hat{E}):=\{(V_l,\tilde{E})\in\mathcal{C}_l|\tilde{E}\cap\hat{E}_l=\hat{E}\}$, i.e., the subsets of those connected graphs where the edges in $\hat{E}$ emanate from the vertex v_l. So

$$n(G_l)=\sum_{\hat{E}\subset\hat{E}_l}\ \sum_{(V_l,\tilde{E})\in\mathcal{C}_l(\hat{E})}(-1)^{|\tilde{E}|}. \tag{17}$$

We will show now that in fact

$$n(G_l)=\sum_{\substack{\hat{E}\subset\hat{E}_l\\ |\hat{E}|=1}}\ \sum_{(V_l,\tilde{E})\in\mathcal{C}_l(\hat{E})}(-1)^{|\tilde{E}|}, \tag{18}$$

that is, only subgraphs with exactly one edge adjacent to v_l contribute.

It is obvious that $\mathcal{C}_l(\varnothing)=\varnothing$, since in that case the vertex v_l is disconnected.

So we are left to show that terms in (17) with $|\hat{E}|\geqslant 2$ give no contribution.

We choose two different edges $\{v_x,v_l\},\{v_y,v_l\}\in\hat{E}$. Then the graph G_l contains the edge $e:=\{v_x,v_y\}$, as we show now. Namely the intervals $[a_x,b_x]=I(v_x)$ and $[a_y,b_y]=I(v_y)$ both intersect the interval $[a_l,b_l]=I(v_l)$ so that $a_l\leqslant b_x,b_y$, and they have the additional property $a_x,a_y\leqslant a_l$ since $x,y\leqslant l$. Thus $a_l\in[a_x,b_x]\cap[a_y,b_y]$ showing that these intervals intersect.

The set $A:=\{(V_l,\tilde{E})\in\mathcal{C}_l(\hat{E})\,|\,e\in\tilde{E}\}$ consists of the connected subgraphs containing the edge $e=\{v_x,v_y\}$. The map

$$J:A\to J(A),\quad (V_l,\tilde{E})\mapsto(V_l,\tilde{E}-\{e\}),$$

deletes the edge e and is obviously one-to-one. Moreover,

$$\mathcal{C}_l(\hat{E})=A\cup J(A),$$

since the graph $(V_l,\tilde{E}-\{e\})$ is still connected (v_x and v_y are connected by the edges $\{v_x,v_l\}$, $\{v_y,v_l\}$).

So if $|\hat{E}|\geqslant 2$, then

$$\sum_{(V_l,\tilde{E})\in\mathcal{C}_l(\hat{E})}(-1)^{|\tilde{E}|}=\sum_{(V_l,\tilde{E})\in A}((-1)^{|\tilde{E}|}+(-1)^{|\tilde{E}-\{e\}|})=0,$$

showing (18).

Now we resume (18):

$$n(G_l)=-\sum_{\hat{e}\in\hat{E}_l}\ \sum_{(V_l,\tilde{E})\in\mathcal{C}_l(\{\hat{e}\})}(-1)^{|\tilde{E}-\{\hat{e}\}|}.$$

However, the map K on $\mathcal{C}_l(\{\hat{e}\})$ given by $K((V_l,\tilde{E})):=(V_{l-1},\tilde{E}-\{\hat{e}\})$ is one-to-one and $K(\mathcal{C}_l(\{\hat{e}\}))=\mathcal{C}_{l-1}$, that is, its image consists of the connected subgraphs on the first $l-1$ vertices (by removing $\hat{e}$ we disconnect the vertex v_l from the vertices $v_1,\ldots,v_{l-1}$, but we do not disconnect any of these). Thus

$$n(G_l)=-\sum_{\hat{e}\in\hat{E}_l}\ \sum_{(V_{l-1},\tilde{E})\in\mathcal{C}_{l-1}}(-1)^{|\tilde{E}|}=-n(G_{l-1})\cdot|\hat{E}_l|,$$

proving (16). □

Remark: As the example of the graph $G=(V,E)$ of a square with $V:=\{v_1,v_2,v_3,v_4\}$ and $E:=\{\{v_1,v_2\},\{v_2,v_3\},\{v_3,v_4\},\{v_4,v_1\}\}$ shows, an analogous result does not hold for general graphs. Namely here $n(G_3)=1-0=1$ but $n(G)=1-4=-3$, although there are only two edges adjacent to the vertex v_4.

It was already shown in Ref. 1 that the (grand) canonical interaction is weakly ferromagnetic, i.e., that

$$j_k^C(t)\geqslant 0\quad\text{and}\quad j_k^G(t)\geqslant 0\quad\text{for}\quad t\in\mathbf{G}_k^*\backslash\{0\}.$$

That fact can now be easily seen to be a by-product of our above theorem for interval graphs $G=(V,E)$, since Theorem 4 implies

$$\operatorname{sign}(n(G))=\begin{cases}0, & G \text{ not connected},\\ -(-1)^{|V|}, & G \text{ connected}.\end{cases}$$

On the other hand, the sign of the activity of a multi-polymer X is $\operatorname{sign}(z^X)=(-1)^{|X|}$. Thus all connected multi-polymers give a positive contribution to the interaction coefficients (14) and (15).

By estimating the contribution of the simplest multi-polymers, we may obtain more precise lower bounds for the interaction coefficients. As in Ref. 1 we denote the positions of the first, resp. last, one in $t=(t_1,\ldots,t_k)\in\mathbf{G}_k^*\backslash\{0\}$ by

$$P_k^l(t):=\min\{i\in\{1,\ldots,k\}|t_i=1\}$$

and

$$P_k^r(t):=\max\{i\in\{1,\ldots,k\}|t_i=1\}.$$

Corollary 5: Let $t=(t_1,\ldots,t_k)\in\mathbf{G}_k^*\backslash\{0\}$.
(i) *If* $|t|$ *is odd, then* $j_k^G(t)=0$ *and* $j_k^C(t)\geqslant 3^{-2s}$, *with* $s:=k+1-P_k^l(t)$.
(ii) *If* $|t|$ *is even, then* $j_k^G(t)\geqslant 3^{-2s}$ *and* $j_k^C(t)\geqslant 3^{-2s}$, *with* $s:=P_k^r(t)+1-P_k^l(t)$.

The grand canonical interaction coefficients increase under concatenation, that is,

$$j_{k+l}^G(s,t)\geqslant \delta_{t,0}\cdot j_k^G(s)+\delta_{s,0}\cdot j_l^G(t)\quad (s\in\mathbf{G}_k^*,t\in\mathbf{G}_l^*). \tag{19}$$

Proof: We already stated that $j_k^G(t)=0$ for $|t|$ odd. The other lower bounds are achieved by first decomposing t according to (8) into disconnected polymers $t=\Sigma_{i=1}^n p_{l_i,r_i}$ for $|t|$ even, resp. $t=\Sigma_{i=1}^{n-1}p_{l_i,r_i}+p_{l_n}$ for $|t|$ odd. Then one remarks that for
(i) $|t|$ even the connected multi-polymer

$$X=(\gamma_1,\ldots,\gamma_n):=(p_{l_1,r_n},p_{r_1,l_2},\ldots,p_{r_{n-1},l_n})\in C_n^{\infty,e},$$

and for
(ii) $|t|$ odd the connected multi-polymer

$$X=(\gamma_1,\ldots,\gamma_n):=(p_{l_1},p_{r_1,l_2},\ldots,p_{r_{n-1},l_n})\in C_n^{\infty},$$

and their $n!$ different permutations have the property $\Sigma_{i=1}^n\gamma_i=t$. So they give contributions to $j_k^C(t)$ and $j_k^G(t)$ in (14) and (15).

The factor $|X|!=n!$ in the denominator is cancelled by the multiplicity of the permutations. The graphs $G(X)$ are trees, namely all γ_i, $i>1$, are only connected to γ_1. So, $n(X)\equiv n(G(X))=-(-1)^n$. The activities are $z^X=(-1)^n\cdot 3^{l_1-r_n-1}\cdot 3^{r_1-l_2-1}\cdots 3^{r_{n-1}-l_n-1}$ for $|t|$ even resp. $z^X=(-1)^n\cdot 3^{l_1-k-1}\cdot 3^{r_1-l_2-1}\cdots 3^{r_{n-1}-l_n-1}$ for $|t|$ odd. Thus multiplying these factors leads to the estimates of the corollary.

One obtains inequality (19) by noticing that in the grand canonical case the activities of the occurring (even) polymers are translation invariant. If both s and t are nonzero, then (19) simply states that $j_{k+l}^G(s,t)\geqslant 0$, i.e., the ferromagnetic property. If s or t is zero, then all connected multi-polymers contributing to the right-hand side of (19) contribute to the lhs, too (after a translation by k for the t-terms). □.

Remark: Proposition 3 of Ref. 2 says that, for nonzero $t\in\mathbf{G}_n^*$,

$$j_{n+1}^C(t,0)\leqslant j_n^C(t)\leqslant j_{n+1}^C(0,t).$$

This implies in particular that the canonical interaction coefficients neither increase nor decrease under concatenation.

V. ESTIMATES FOR THE FREE ENERGY

In this section we will show that the limit free energy is majorized by the canonical and minimized by the grand canonical k-spin free energies.

In order to derive these estimates, we compare the (grand) canonical energy values of the spin chain of length $k+l$ with the ones of the chains with lengths k and l. We state these inequalities for the exponentiated energies.

Lemma 6: For $\sigma \in \mathbf{G}_k$, $\tau \in \mathbf{G}_l$ *one has*

$$\mathbf{h}^G_{k+l}(\sigma,\tau) \leqslant \mathbf{h}^G_k(\sigma)\cdot \mathbf{h}^G_l(\tau), \tag{20}$$

$$\mathbf{h}^C_{k+l}(\sigma,\tau)+\mathbf{h}^C_{k+l}(1-\sigma,\tau)=(\mathbf{h}^C_k(\sigma)+\mathbf{h}^C_k(1-\sigma))\cdot \mathbf{h}^C_l(\tau) \tag{21}$$

and

$$|\mathbf{h}^C_{k+l}(\sigma,\tau)-\mathbf{h}^C_{k+l}(1-\sigma,\tau)| \leqslant |\mathbf{h}^C_k(\sigma)-\mathbf{h}^C_k(1-\sigma)|\cdot \mathbf{h}^C_l(\tau). \tag{22}$$

Proof: As in Ref. 1 we use the auxiliary functions $\mathbf{r}_k(s_0,s_1):\mathbf{G}_k \to \mathbb{R}$ with real parameters s_0,s_1 which are defined by $\mathbf{r}_1(s_0,s_1)(\sigma):=s_\sigma$ and

$$\mathbf{r}_{k+1}(s_0,s_1)(\sigma_1,\ldots,\sigma_{k+1}):=\mathbf{r}_k(s_0,s_1)(\sigma_1,\ldots,\sigma_k) + \sigma_{k+1}\cdot \mathbf{r}_k(s_0,s_1)(1-\sigma_1,\ldots,1-\sigma_k).$$

In particular we have $\mathbf{h}^C_k=\mathbf{r}_k(1,2)$, $k\in\mathbb{N}$, and $\mathbf{h}^G_k(\sigma)=\mathbf{h}^C_{k+1}(\sigma,1)=\mathbf{r}_{k+1}(1,2)(\sigma,1)$, $\sigma\in\mathbf{G}_k$.

By Lemma 4.6 of Ref. 1

$$\mathbf{r}_{k+l}(s_0,s_1)(\sigma,\tau)=\mathbf{r}_{l+1}(\mathbf{r}_k(s_0,s_1)(\sigma),\mathbf{r}_k(s_0,s_1)(1-\sigma))(0,\tau).$$

Moreover, we have for $\rho\in\mathbf{G}_l$

$$\mathbf{r}_{l+1}(s,s)(0,\rho)=\mathbf{r}_l(s,2s)(\rho),$$

since for $l=1$ both sides equal $s\cdot(1+\rho)$, whereas for $\rho'\in\mathbf{G}_l$, $\rho''\in\mathbf{G}_1$, and $\rho=(\rho',\rho'')\in\mathbf{G}_{l+1}$,

$$\begin{aligned}\mathbf{r}_{l+2}(s,s)(0,\rho)&=\mathbf{r}_{l+1}(s,s)(0,\rho')+\rho''\mathbf{r}_{l+1}(s,s)(1,1-\rho')\\ &=\mathbf{r}_l(s,2s)(\rho')+\rho''\mathbf{r}_{l+1}(s,s)(0,1-\rho')\\ &=\mathbf{r}_l(s,2s)(\rho')+\rho''\mathbf{r}_l(s,2s)(1-\rho')\\ &=\mathbf{r}_{l+1}(s,2s)(\rho).\end{aligned}$$

Now we apply these identities:

$$\begin{aligned}\mathbf{h}^G_{k+l}(\sigma,\tau)&=\mathbf{r}_{k+l+1}(1,2)(\sigma,\tau,1)\\ &=\mathbf{r}_{l+2}(\mathbf{r}_k(1,2)(\sigma),\mathbf{r}_k(1,2)(1-\sigma))(0,\tau,1)\\ &=\mathbf{r}_{l+2}(\mathbf{h}^C_k(\sigma),\mathbf{h}^C_k(1-\sigma))(0,\tau,1)\\ &=\mathbf{h}^C_k(\sigma)\cdot\mathbf{r}_{l+2}(1,0)(0,\tau,1)+\mathbf{h}^C_k(1-\sigma)\cdot\mathbf{r}_{l+2}(0,1)(0,\tau,1)\\ &\leqslant(\mathbf{h}^C_k(\sigma)+\mathbf{h}^C_k(1-\sigma))\cdot\mathbf{r}_{l+2}(1,1)(0,\tau,1)\\ &=\mathbf{h}^G_k(\sigma)\cdot\mathbf{r}_{l+2}(1,1)(0,\tau,1)\\ &=\mathbf{h}^G_k(\sigma)\cdot\mathbf{r}_{l+1}(1,2)(\tau,1)\\ &=\mathbf{h}^G_k(\sigma)\cdot\mathbf{h}^G_l(\tau),\end{aligned}$$

showing (20).

Similarly

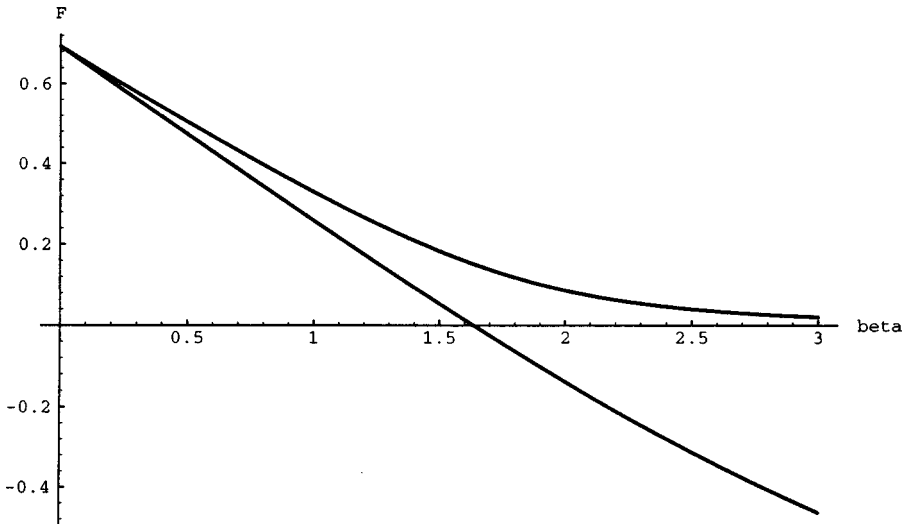

FIG. 2. Upper and lower bounds on the free energy $F(\beta)$.

$$\mathbf{h}^C_{k+l}(\sigma,\tau)=\mathbf{h}^C_k(\sigma)\cdot\mathbf{r}_{l+1}(1,0)(0,\tau)+\mathbf{h}^C_k(1-\sigma)\cdot\mathbf{r}_{l+1}(0,1)(0,\tau)$$

so that

$$\begin{aligned}\mathbf{h}^C_{k+l}(\sigma,\tau)+\mathbf{h}^C_{k+l}(1-\sigma,\tau)&=(\mathbf{h}^C_k(\sigma)+\mathbf{h}^C_k(1-\sigma))\cdot(\mathbf{r}_{l+1}(1,0)(0,\tau)+\mathbf{r}_{l+1}(0,1)(0,\tau))\\&=(\mathbf{h}^C_k(\sigma)+\mathbf{h}^C_k(1-\sigma))\cdot\mathbf{r}_{l+1}(1,1)(0,\tau)\\&=(\mathbf{h}^C_k(\sigma)+\mathbf{h}^C_k(1-\sigma))\cdot\mathbf{r}_l(1,2)(\tau),\end{aligned}$$

which implies (21).

The difference

$$\begin{aligned}|\mathbf{h}^C_{k+l}(\sigma,\tau)-\mathbf{h}^C_{k+l}(1-\sigma,\tau)|&=|\mathbf{h}^C_k(\sigma)-\mathbf{h}^C_k(1-\sigma)|\cdot|\mathbf{r}_{l+1}(1,0)(0,\tau)-\mathbf{r}_{l+1}(0,1)(0,\tau)|\\&\leqslant|\mathbf{h}^C_k(\sigma)-\mathbf{h}^C_k(1-\sigma)|\cdot\mathbf{h}^C_l(\tau),\end{aligned}$$

which is (22). □

Theorem 7: *For inverse temperature $\beta>0$ the limit free energy $F(\beta)$ is bounded by the k-spin free energies, $k\in\mathbb{N}$:*

$$F^C_k(\beta)\leqslant F(\beta)\leqslant F^G_k(\beta).$$

(*See Fig. 2, where* $k=15$).

Proof: We have for $n\in\mathbb{N}$

$$F^G_{nk}(\beta)=-\frac{1}{\beta k}\ln(Z^G_{nk}(\beta))^{1/n}\leqslant-\frac{1}{\beta k}\ln(Z^G_k(\beta))=F^G_k(\beta),$$

since by (20)

$$Z^G_{k+l}(\beta)=\sum_{\sigma\in\mathbf{G}_k}\sum_{\tau\in\mathbf{G}_l}(\mathbf{h}^G_{k+l}(\sigma,\tau))^{-\beta}$$

$$\geqslant\sum_{\sigma\in\mathbf{G}_k}\sum_{\tau\in\mathbf{G}_l}(\mathbf{h}^G_k(\sigma)\cdot\mathbf{h}^G_l(\tau))^{-\beta}$$

$$=Z^G_k(\beta)\cdot Z^G_l(\beta).$$

So $F(\beta)=\lim_{n\to\infty}F^G_{nk}(\beta)\leqslant F^G_k(\beta)$.

To show the lower estimate we need the converse inequality

$$Z^C_{k+l}(\beta)\leqslant Z^C_k(\beta)\cdot Z^C_l(\beta), \tag{23}$$

which then implies $F(\beta)=\lim_{n\to\infty}F^C_{nk}(\beta)\geqslant F^C_k(\beta)$.

To show (23), we use (21) and (22). For $a,b,c,d>0$, $a+b=c+d$, and $|a-b|\leqslant|c-d|$ the convexity of the function $x\mapsto x^{-\beta}$ implies $a^{-\beta}+b^{-\beta}\leqslant c^{-\beta}+d^{-\beta}$. Thus

$$(\mathbf{h}^C_{k+l}(\sigma,\tau))^{-\beta}+(\mathbf{h}^C_{k+l}(1-\sigma,\tau))^{-\beta}\leqslant(\mathbf{h}^C_k(\sigma)^{-\beta}+\mathbf{h}^C_k(1-\sigma)^{-\beta})\cdot\mathbf{h}^C_l(\tau)^{-\beta},$$

which after summation over σ and τ leads to (23). □

VI. THE INTERNAL ENERGY

From the estimates for the free energy we will derive upper and lower bounds for the internal energy per particle

$$U(\beta)=\lim_{k\to\infty}\frac{1}{k}\langle\mathbf{H}^C_k\rangle^C_k(\beta)=\lim_{k\to\infty}\frac{1}{k}\langle\mathbf{H}^G_k\rangle^G_k(\beta).$$

The first thing to say is that, in general, the k-spin energy expectation $\langle H_k\rangle(\beta)$ is *not* a monotone increasing function of the energy values $H_k(\sigma)$. But if

$$H_k(\sigma)=-\sum_{t\in\mathbf{G}^*_k}j(t)\cdot(-1)^{\sigma\cdot t}$$

is weakly ferromagnetic ($j(t)\geqslant 0$ for $t\neq 0_k$), then by the first and second GKS inequality for $\beta\geqslant 0$ and $s\in\mathbf{G}^*_k$

$$\frac{\partial\langle H_k\rangle}{\partial j(s)}=-\langle\chi_s\rangle-\beta\sum_{t\in\mathbf{G}^*_k}j(t)(\langle\chi_s\chi_t\rangle-\langle\chi_s\rangle\langle\chi_t\rangle)\leqslant 0 \tag{24}$$

with the character functions $\chi_s:\mathbf{G}_k\to\{-1,1\}$,

$$\chi_s(\sigma):=(-1)^{\sigma\cdot s}=\prod_{i:s_i=1}(-1)^{\sigma_i}.$$

Theorem 8: *For $\beta\geqslant 0$ and $k\in\mathbb{N}$*

$$U(\beta)\leqslant\frac{1}{k}\langle\mathbf{H}^G_k\rangle^G_k(\beta).$$

Proof: We start from the inequality (19),

$$j^G_{k+l}(s,t)\geqslant\delta_{t,0}\cdot j^G_k(s)+\delta_{s,0}\cdot j^G_l(t)\quad(s\in\mathbf{G}^*_k,t\in\mathbf{G}^*_l),$$

for the interaction coefficients. Thus by (24)

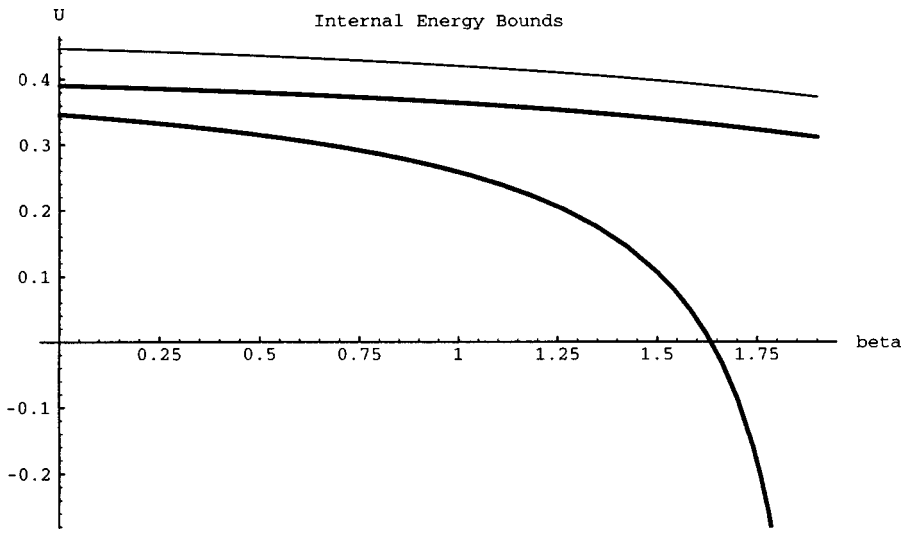

FIG. 3. Upper and lower bounds on the internal energy $U(\beta)$ (bold: Theorem 9).

$$\langle \mathbf{H}^G_{k+l}\rangle^G_{k+l} \leqslant \langle \mathbf{H}^G_k\rangle^G_k + \langle \mathbf{H}^G_l\rangle^G_l .$$

In particular we have $(1/n)\,\langle \mathbf{H}^G_{nk}\rangle^G_{nk} \leqslant \langle \mathbf{H}^G_k\rangle^G_k$ so that the theorem follows. □

We can also use the concavity of the function $\beta \mapsto \beta F(\beta)$ and our knowledge of the two values $\lim_{\beta \searrow 0} \beta F(\beta) = -\ln 2$ and $\beta_{\rm cr} F(\beta_{\rm cr}) = 0$ for the inverse critical temperature $\beta_{\rm cr} = 2$.

Theorem 9: *For* $0 < \beta < \beta_{\rm cr} = 2$ *and* $k \in \mathbb{N}$

$$\frac{-\beta F^G_k(\beta)}{2-\beta} \leqslant U(\beta) \leqslant \frac{\ln(2) + \beta F^G_k(\beta)}{\beta}.$$

Proof: In the above inverse temperature range the free energy is real-analytic, as shown in Ref. 6. Thus we can write the internal energy in the form

$$U(\beta) = \frac{d}{d\beta}(\beta F(\beta)).$$

By concavity of the function $\beta \mapsto \beta F(\beta)$ the derivative is bounded by the slope of the secants:

$$\frac{\beta_{\rm cr} F(\beta_{\rm cr}) - \beta F(\beta)}{\beta_{\rm cr} - \beta} \leqslant U(\beta) \leqslant \frac{\beta F^G_k(\beta) - (-\ln(2))}{\beta - 0}.$$

The bounds then follow from this and Theorem 7. □

In Fig. 3 we show the different bounds on the internal energy $U(\beta)$ for $k = 15$.

Although for this number k of spins Theorem 9 leads to a better upper bound than Theorem 8, only the latter estimate converges in the thermodynamic limit $k \to \infty$.

Since the methods used here are high-temperature expansions, the lower estimate for the internal energy derived in Ref. 6 is better near the critical temperature $\beta = 2$ but worse near $\beta = 0$.

Generalized similarity solutions for the type D fluid in five-dimensional flat space

O. P. Bhutani[a] and K. Singh[b]
Department of Mathematics, Indian Institute of Technology, Hauz Khas, New Delhi-110016, India

(Received 29 August 1997; accepted for publication 18 February 1998)

The partial differential equation corresponding to the metric function in a five-dimensional flat space describing the perfect fluid distribution has been examined for generalized symmetries via a new approach. It is shown that the approach utilized here has, besides providing generalized symmetries, for some particular values of the parameters involved, yielded new metrics and Petrov type D solutions. Further, for the general case the problem is reduced to the solution of an Abel's equation of second kind, which obviously generalizes the scope for new metrics and new Petrov type D solutions. © *1998 American Institute of Physics.* [S0022-2488(98)00306-5]

I. INTRODUCTION

This is a sequel to the paper by Bhutani and Kalra,[1] in which we demonstrated the efficacy and importance of the generalized symmetry approach. In fact, the said approach[2,3] combined with variational symmetry[4] has not only provided us a breakthrough in obtaining the exact solutions of the coupled system of nonlinear partial differential equations corresponding to Einstein exterior equations, which, in turn, yielded new solutions of Ernst form of Einstein equations, but has also enabled us to arrive at a generalized form of Weyl[5] and Schwarzschild[6] solutions.

Here, we have utilized the same technique for examining a problem from the realm of general relativity recently investigated[7] using the Lie continuous group of point transformation method.[8] More specifically, the authors[7] have derived solutions of type D for the perfect fluid distribution expressed by a five-dimensional flat metric of embedding class I. The carryover of the generalized symmetry technique has not only provided the generalized symmetries but has also enlarged the scope for the determination of type D solutions, the importance of which is well known.

The paper is structured as follows. The basic equations are briefly recalled in Sec. II. In Sec. III, the symmetries in the generalized form are derived, which are then used to reduce the main partial differential equation (pde) to a general second-order ordinary differential equation (ode). Some special cases are treated in Sec. IV. Section V is primarily devoted to determining the transformation group for a further reduction of second-order ode to a general first-order ode. We end this paper with some discussions. The detailed computations regarding the Fréchet derivative are shown in Appendix A.

II. RECALLING THE MAIN EQUATIONS

A five-dimensional flat metric,

$$ds^2=-(dx_1)^2-(dx_2)^2-(dx_3)^2+(dx_4)^2\pm(dx_5)^2, \tag{2.1}$$

on introducing the plane symmetry by

$$x_1=(t-r)\theta\cos\phi, \quad x_2=(t-r)\theta\sin\phi,$$

$$x_3=\frac{\theta^2}{2}(t-r)+r, \quad x_4=\frac{\theta^2}{2}(t-r)+t,$$

$$x_5=u(r,t), \tag{2.2}$$

assumes the following form:

$$ds^2=-t^2(d\theta^2+\theta^2 d\phi^2)+dt^2+2drdt-du^2. \tag{2.3}$$

The metric function $u(r,t)$ is governed by the differential equation,

$$L(u)\equiv -u_{rr}u_{tt}+u_{rt}^2+\frac{1}{t}u_r^3u_{tt}+\frac{2}{t}u_{rt}u_r(1-u_ru_t)$$

$$-\frac{1}{t}(1-u_t^2)u_ru_{rr}+\frac{1}{t^2}u_r^2(1-2u_ru_t+u_r^2)=0. \tag{2.4}$$

The associated expressions for pressure and density are given by

$$8\pi p=\frac{u_r^2}{mt^2}, \tag{2.5}$$

$$8\pi(\rho-p)=\frac{2(u_{rr}u_{tt}-u_{rt}^2)}{m^2}, \tag{2.6}$$

$$\text{where} \quad m=1+u_r^2-2u_ru_t. \tag{2.7}$$

For further details see Ref. 7.

III. DETERMINATION OF SYMMETRIES

Since for the case under consideration there is only one spatial variable, the symmetry operator has the form

$$S(u)=A(r,t,u)\frac{\partial u}{\partial t}+B(r,t,u)\frac{\partial u}{\partial r}+C(r,t,u). \tag{3.1}$$

Calculating the Fréchet derivative of L defined in Eq. (2.4), we get

$$F(L,u,\nu)=\nu_{tt}\left(\frac{u_r^3}{t}-u_{rr}\right)+\frac{2}{t}u_r\nu_t\left(u_tu_{rr}-u_ru_{rt}-\frac{1}{t}u_r^2\right)$$

$$+\frac{1}{t}\nu_r\left[3u_r^2u_{tt}+2u_{rt}-u_{rr}(1-u_t^2)+2u_r\left(\frac{1}{t}-2u_tu_{rt}\right)-\frac{2}{t}u_r^2(3u_t-2u_r)\right]$$

$$+2\nu_{rt}\left(u_{rt}+\frac{1}{t}u_r-\frac{1}{t}u_r^2u_t\right)-\nu_{rr}\left[u_{tt}+\frac{u_r}{t}(1-u_t^2)\right]. \tag{3.2}$$

On replacing ν by $S(u)$ in Eq. (3.2) and substituting the values of different derivatives of $S(u)$ in the resulting equation and collecting the coefficients of various powers of the derivatives of u in F, we get a polynomial expansion in u_r, u_t, u_ru_t,..., etc. On making use of Eq. (2.4) in the polynomial expression for F, rearranging the terms of various powers of derivatives of u, and equating them to zero, leads to the following determining equations (see Appendix A):

$$A_{rr}=0=A_u, \quad C_{rr}=0, \quad C_{rt}+\frac{1}{t}C_r=0,$$

$$C_{tt}+\frac{1}{t}C_r=0,\quad A_{uu}-\frac{1}{t}A_r=0,\quad A_{rt}+\frac{1}{t}A_r+C_{ru}=0,$$

$$A_{tt}+\frac{1}{t}A_r+2C_{tu}=0,\quad 2A_{tu}+C_{uu}-\frac{1}{t}C_r=0,\quad 2C_{ru}+B_{rr}-\frac{2}{t}A_r=0,$$

$$B_{tu}-\frac{1}{t}(B_u+A_u+C_t)=0,\quad B_{uu}-\frac{1}{t}B_r-\frac{2}{t}C_u-\frac{A}{t^2}=0,$$

$$C_{uu}+2B_{ru}-\frac{1}{t}(3C_r+2A_u)=0,\quad 2A_{tu}+\frac{2}{t}A_u-2C_{rt}-3B_{ru}=0,$$

$$B_{rt}+C_{tu}-\frac{1}{t}A_t-\frac{1}{t}A_r+\frac{A}{t^2}=0,\quad B_{tt}+\frac{1}{t}(B_r-2B_t-2A_t)+\frac{A}{t^2}=0,$$

$$A_{tt}-2B_{rt}+\frac{1}{t}(3A_r+2A_t)-\frac{2A}{t^2}=0,\quad C_{rt}-C_{uu}-B_{ru}-A_{tu}+\frac{1}{t}(A_u-3C_r)=0. \tag{3.3}$$

These equations, when solved, yield the following generalized Lie symmetries of the equation (2.4):

$$A=\alpha t,$$

$$B=b_1 r+\beta t^3+(1/2)(b_1-\alpha)t+\gamma, \tag{3.4}$$

$$C=-(1/2)(\alpha+b_1)u-\delta,$$

where α, β, γ, δ, and b_1 are arbitrary constants.

It is interesting to point out here that the case $b_1=\alpha$ corresponds to the symmetries that are reported in Ref. 7.

In our opinion it is a significant improvement in the available symmetries of the equation (2.4) as it involves an additional parameter and hence widens the scope of obtaining new possible metrics. In the next section it has been demonstrated through special cases, by way of generating a class of metrics belonging to Petrov type D. Before that, we determine the similarity variable $\xi=\xi(r,t)$ and new dependent variable $f(\xi)$, in terms of which Eq. (2.4) gets reduced to an ode, by solving, for the general case, the equations

$$\frac{dt}{\alpha t}=\frac{dr}{b_1 r+\beta t^3+(1/2)(b_1-\alpha)t+\gamma}=\frac{du}{(1/2)(b_1+\alpha)u+\delta}, \tag{3.5}$$

which yield

$$u=t^{(b_1+\alpha)/2\alpha}f(\xi)-\frac{2\delta}{b_1+\alpha}, \tag{3.6}$$

where

$$\xi(r,t)=t^{-b_1/\alpha}\left[r+\frac{\beta}{(b_1-3\alpha)}t^3+\frac{1}{2}t+\frac{\gamma}{b_1}\right]. \tag{3.7}$$

On substituting (3.6) in Eq. (2.4), we get

$$f''[(\alpha^2-b_1^2)f+(\alpha+b_1)^2 f^2 f'+4b_1(b_1-3\alpha)\xi f']$$
$$-4b_1(b_1-3\alpha)\xi f'^4+(\alpha+b_1)(3b_1-7\alpha)ff'^3+(b_1-3\alpha)^2 f'^2=0. \tag{3.8}$$

As Eq. (3.8) is highly nonlinear in character, it cannot be solved through available techniques for all values of the parameters involved in it. Consequently, some particular cases are in order.

IV. SOME SPECIAL CASES

A. Case (i) $b_1=-\alpha\neq 0$, $\delta\to 0$

For the case under consideration, ode (3.8) reduces to

$$\xi(f''-f'^3)+f'=0. \tag{4.1}$$

On solving the above equation, we get

$$f'(\xi)=\frac{\sqrt{c_0}}{\sqrt{(\xi+c_0)^2-c_0^2}}, \tag{4.2}$$

where c_0 is a positive constant.

Equation (4.2) readily yields

$$f(\xi)=\sqrt{c_0}\,\ln[\xi+c_0+\sqrt{\xi(\xi+2c_0)}]+d_0, \tag{4.3}$$

where d_0 is a constant.

Thus, we have obtained $u=f(\xi)$, with

$$\xi=\frac{t}{4b_1}(4b_1r+\beta t^3+2b_1t+4\gamma).$$

The metric (2.3) can now be evaluated as follows:

$$\begin{aligned}ds^2=&-\frac{16b_1^2c_0t}{(4b_1r+\beta t^3+2b_1+4\gamma)\{t(4b_1r+\beta t^3+2b_1t+4\gamma)+8c_0b_1\}}\,dr^2\\&+2\left[1-\frac{16b_1c_0(b_1r+\beta t^3+b_1t+\gamma)}{(4b_1r+\beta t^3+2b_1t+4\gamma)\{t(4b_1r+\beta t^3+2b_1t+4\gamma)+8c_0b_1\}}\right]dr\,dt\\&+\left[1-\frac{16c_0(b_1r+\beta t^3+b_1t+\gamma)^2}{t(4b_1r+\beta t^3+2b_1t+4\gamma)\{t(4b_1r+\beta t^3+2b_1t+4\gamma)+8c_0b_1\}}\right]dt^2\\&-t^2(d\theta^2+\theta^2d\phi^2).\end{aligned} \tag{4.4}$$

The corresponding expressions for pressure and density can be expressed as

$$8\pi p=\frac{16b_1^2c_0}{t^2[16b_1^2r^2+8b_1r(\beta t^3+2b_1t+4\gamma)+\beta^2t^6+4\beta b_1t^4+8\beta\gamma t^3+4b_1(b_1-6c_0\beta)t^2+16b_1\gamma t+16\gamma^2]} \tag{4.5}$$

and

$$8\pi(\rho-p)=\frac{32b_1^2c_0[16b_1^2r^2-16b_1r(\beta t^3-b_1t-2\gamma)-5\beta^2t^6-8\beta b_1t^4-16\beta\gamma t^3+4b_1(b_1-6c_0\beta)t^2+16b_1\gamma t+16\gamma^2]}{t^2[16b_1^2r^2+8b_1r(\beta t^3+2b_1t+4\gamma)+\beta^2t^6+4\beta b_1t^4+8\beta\gamma t^3+4b_1(b_1-6c_0\beta)t^2+16b_1\gamma t+16\gamma^2]^2}. \tag{4.6}$$

It is not difficult to see that the solution obtained is of Petrov type D. Further, it is shown in the later section that the metric (4.4) corresponds to nongeodesic flow.

B. Case (ii) $b_1=3\alpha\neq 0$, $\beta\to 0$

For this case, Eq. (3.8) assumes the following form:

$$f''-2ff'f''-f'^3=0. \tag{4.7}$$

On introducing $Z=f'$ in (4.7) and integrating the resulting equation, we get

$$Z^2 f = Z - a, \tag{4.8}$$

where ''a'' is a constant of integration.

(A) For the case when a is zero, Eq. (4.8) yields

$$f(\xi) = (2\xi + c_1)^{1/2}.$$

Thus, $u(r,t)$ assumes the following form:

$$u = t^2(2\xi + c_1)^{1/2} - \frac{\delta}{2\alpha}. \tag{4.9}$$

The corresponding metric, and the expressions for pressure and density, can be written as

$$ds^2 = -\frac{3\alpha t}{(6\alpha r + 3c_1\alpha t^3 + 3\alpha t + 2\gamma)}\,dr^2 + \frac{6(\alpha r - c_1\alpha t^3 - \gamma)}{(6\alpha r + 3c_1\alpha t^3 + 3\alpha t + 2\gamma)}\,dr dt + \left[1 - \frac{(3\alpha r + 6c_1\alpha t^3 + 3\alpha t + \gamma)^2}{3\alpha t(6\alpha r + 3c_1\alpha t^3 + 3\alpha t + 2\gamma)}\right]dt^2 - t^2(d\theta^2 + \theta^2 d\phi^2), \tag{4.10}$$

$$8\pi\rho = 3(8\pi p) = -\frac{1}{c_1 t^4}. \tag{4.11}$$

Clearly, (4.11) demands that $c_1 < 0$. The solution obviously belongs to Petrov type O.

(B) For $a \neq 0$, Eq. (4.8) can be written as

$$\frac{f\,df}{1 \pm \sqrt{1 - 4af}} = \frac{1}{2}\,d\xi, \tag{4.12}$$

which on integrating yields

$$6af \pm (1 - 4af)^{3/2} = 12a^2\xi + b. \tag{4.13}$$

On letting $f = (1 - q^2)/4a$, Eq. (4.13) can be expressed in the following convenient form:

$$q^2(\pm 2q - 3) = 24a^2\xi + 2b - 3. \tag{4.14}$$

In Eq. (4.14), ''b'' is a constant of integration.

The metric (2.3) in terms of implicit function $q = q(\xi)$ assumes the following forms:

$$ds^2 = -\frac{4a^2}{t^2(1 \mp q)^2}\,dr^2 + 2\left[1 - \frac{\{\alpha t^3(1 \mp q)^2(1 \pm q) - 4a^2(3\alpha r + \alpha t + \gamma)\}}{\alpha t^3(1 \mp q)^2}\right]dr dt + \left[1 - \frac{\{\alpha t^3(1 \mp q)^2(1 \pm q) - 4a^2(3\alpha r + \alpha t + \gamma)\}^2}{4a^2\alpha^2 t^4(1 \mp q)^2}\right]dt^2 - t^2(d\theta^2 + \theta^2 d\phi^2). \tag{4.15}$$

The pressure and density can be evaluated as

$$8\pi p = \frac{4a^2\alpha}{t[4a^2\alpha t - \alpha t^3(1 \mp q)^2(1 \pm 2q) + 8a^2(3\alpha r + \alpha t + \gamma)]}, \tag{4.16}$$

$$8\pi(\rho - p) = \frac{8a^2\alpha[4a^2(6\alpha r + 3\alpha t + 2\gamma) \mp \alpha t^3(1 \mp q)^2(1 \pm 2q)]}{tq[4a^2\alpha t - \alpha t^3(1 \mp q)^2(1 \pm 2q) + 8a^2(3\alpha r + \alpha t + \gamma)]^2}. \tag{4.17}$$

It is demonstrated in later sections that the metric (4.15) belongs to nongeodesic fluid distribution.

C. Case (iii) $\alpha \neq 0$, $b_1 = 0$, $\gamma \to 0$

The related ode for the case can be expressed as

$$ff'' + f^2 f' f'' - 7ff'^3 + 9f'^2 = 0. \tag{4.18}$$

Observing the invariance of (4.18) under the group of translation of independent variable ξ, we introduce $f' = \psi$ so that the equation (4.18) reduces to the following first-order equation:

$$\psi(9 - 7f\psi)df + f(1 + f\psi)d\psi = 0. \tag{4.19}$$

It can be easily integrated by multiplying with a suitable integrating factor to yield the following:

$$2f^9 f' = c(ff' - 1)^2, \tag{4.20}$$

where c is a positive constant. Equation (4.20) can be integrated further to give the following solution in the implicit form:

$$f^{10} + 5cf^2 \mp 10\int f^5 \sqrt{f^8 + 2c}\, df = 10c\xi + d. \tag{4.21}$$

As the algebra involved in evaluating the corresponding expressions for pressure, density, and metric turns out to be highly complex, we are leaving it for out later studies.

V. REDUCTION TO FIRST-ORDER ORDINARY DIFFERENTIAL EQUATION

As pointed out earlier, the main difficulty in solving Eq. (3.8) for all values of the parameters involved in it, is due to its intrinsic nonlinearity. To have an insight to it and for the sake of completeness, we have, here, using the Bluman–Cole technique,[8] made an attempt to determine a transformation group that leaves Eq. (3.8) invariant. This eventually helps to reduce it to a first-order differential equation.

To this effect we proceed as follows:

Consider the one-parameter transformation group,

$$\xi_1 = \xi + \epsilon\phi(\xi, f) + O(\epsilon^2), \quad f_1 = f + \epsilon\psi(\xi, f\ ) + O(\epsilon^2). \tag{5.1}$$

Invoking the invariance criteria as given in Ref. 8, Eq. (3.8), under the transformation (5.1), yields a highly overdetermined system of equations for the unknowns ϕ and ψ. Since the computations involved are too cumbersome but straightforward we, therefore, give the final results as under:

$$\phi(\xi, f) = 2k\xi, \quad \psi(\xi, f) = kf, \tag{5.2}$$

(one can also arrive at the same result via scale analysis) where k is an arbitrary constant.

In order to determine the invariants $x = x(\xi, f\ )$ and $y = y(\xi, f, f')$, we have to solve the following set of equations:

$$\frac{d\xi}{2k\xi} = \frac{df}{kf} = \frac{df'}{-kf'}, \tag{5.3}$$

which readily yields

$$x = \xi^{-1/2} f, \quad y = ff'.$$

In terms of the new independent variable x and the new dependent variable y, Eq. (3.8) assumes the following form:

$$x[(b_1^2-\alpha^2)x^4+2(\alpha^2+6\alpha b_1-3b_1^2)x^2y-(\alpha+b_1)^2x^4y$$
$$+2(\alpha+b_1)^2x^2y^2+8b_1(b_1-3\alpha)y^2]\frac{dy}{dx}=4y^2[2b_1(b_1-3\alpha)y(y+1)$$
$$+(\alpha+b_1)(4\alpha-b_1)x^2y-(4\alpha^2-3\alpha b_1+b_1^2)x^2]. \tag{5.4}$$

This is Abel's equation of the second kind, which is known, in general, to be not readily amenable to any of the standard devices of deriving the exact solutions available in the literature. The form of Eq. (5.4) suggests that it brings forth a tremendous scope. It generates an almost exhaustive class of solutions whenever a way of handling Abel's equation of the second kind, in general, is discovered.

For the sake of ready reference, a few special cases of Eq. (5.4) are listed below:

(i) $b_1=0, \quad \gamma\to 0,$

$$[x^3+(x^2-2)xy-2xy^2]\frac{dy}{dx}=16y^2(1-y), \tag{5.5}$$

(ii) $b_1=-\alpha, \quad \delta\to 0,$

$$x(x^2-2y)\frac{dy}{dx}=2y(x^2-y-y^2). \tag{5.6}$$

VI. DISCUSSIONS AND CONCLUSIONS

The study carried out above has established the superiority of the generalized symmetry approach utilized here over the Bluman and Cole technique used in Ref. 7 for the same problem. In short, the generalized symmetries arrived at in Eq. (3.4) have not merely provided, for some particular values of the parameters involved in it, new metrics [see (4.4) and (4.15)], but have also enlarged the scope for new metrics and Petrov type D solutions, the importance of which is well known.

Metric (4.4): As the reduction of it into normal form is rather difficult, the direct comparison with the most general metric due to Barnes[9] for geodesic flow is not possible.

Nevertheless, it can be shown that it possesses nonvanishing flow vector $(\nu^1,0,0,\nu^4)$:

$$\nu^1=-S\left[\frac{2\xi(\xi+2c_0)}{\{\xi(2b_1r-\beta t^3+b_1t+2\gamma)-3\beta c_0t^3\}(R+tPQ)}\right]^{1/2}$$

and

$$\nu^4=\frac{b_1}{2}(tP+T)\left[\frac{2\xi(\xi+2c_0)}{\{\xi(2b_1r-\beta t^3+b_1t+2\gamma)-3\beta c_0t^3\}}\right]^{1/2},$$

where

$$S=-b_1(2b_1r-\beta t^3+2\gamma)\xi^3-b_1c_0(4b_1r-5\beta t^3)\xi^2+c_0t\{(b_1r+\gamma)^2-t(b_1r+\gamma)(\beta t^2-b_1)$$
$$-2\beta t^4(\beta t^2+b_1)+6\beta b_1c_0t^2\}\xi-3\beta c_0^2t^4(b_1r+\beta t^3+b_1t+\gamma),$$

$$R=4b_1^3t^2\xi^6(\xi+6c_0)-4b_1^2c_0t^2(3b_1tr+3\beta t^4+2b_1t^2+3\gamma t-12b_1c_0)\xi^5$$
$$-16b_1^2c_0^2t^2(3b_1tr+3\beta t^4+2b_1t^2+3\gamma t-2b_1c_0)\xi^4+b_1c_0^2t^3\{b_1t(2b_1r-\beta t^3+b_1t+2\gamma)$$
$$-16b_1c_0(3b_1r+3\beta t^3+2b_1t+3\gamma)+8t(b_1r+\beta t^3+\gamma)^2+12b_1t^2(b_1r+\beta t^3+\gamma)$$
$$+4b_1^2t^3\}\xi^3+b_1c_0^3t^4\{b_1(4b_1r-5\beta t^3+2b_1t+4\gamma)+16(b_1r+\beta t^3+\gamma)^2$$
$$+24b_1t(b_1r+\beta t^3+\gamma)+8b_1^2t^2\}\xi^2-c_0^3t^4\{6\beta c_0b_1^2t^3$$
$$+(2b_1r-\beta t^3+b_1t+2\gamma)(b_1r+\beta t^3+b_1t+\gamma)^2\}\xi+3\beta c_0^4t^7(b_1r+\beta t^3+b_1t+\gamma)^2,$$

$$P^2=4b_1^2\xi^6+8b_1^2c_0\xi^5-4b_1c_0(2b_1tr+2\beta t^4+b_1t^2+2\gamma t-4b_1c_0)\xi^4$$
$$-8b_1c_0^2t(2b_1r+2\beta t^3+b_1t+2\gamma)\xi^3+c_0^2t^2(2b_1r-\beta t^3+b_1t+2\gamma)^2\xi^2$$
$$-6\beta c_0^3t^5(2b_1r-\beta t^3+b_1t+2\gamma)\xi+9\beta^2c_0^4t^8,$$

$$Q=2b_1^2\xi^4+8b_1^2c_0\xi^3-b_1c_0(4b_1tr+4\beta t^4+3b_1t^2+4\gamma t-8b_1c_0)\xi^2$$
$$-2b_1c_0^2t(4b_1r+4\beta t^3+3b_1t+4\gamma)\xi+c_0^2t^2(b_1r+\beta t^3+b_1t+\gamma)^2,$$

$$T=-2b_1t\xi^3-4b_1c_0t\xi^2+c_0t^3(3\beta t^2+b_1)\xi+3\beta c_0^2t^5,$$

and

$$\xi=(t/4b_1)(4b_1r+\beta t^3+2b_1t+4\gamma).$$

An attempt was made to calculate the corresponding acceleration vector $(\dot{\nu}^1,0,0,\dot{\nu}^4)$ too, but the algebra involved blew out of proportion, and hence we are omitting it. However, it is easily realizable that it would turn out to be nonvanishing. It can be concluded that the fluid distribution is with nongeodesic flow.

Metric (4.15): In this case the associated velocity and acceleration vectors are obtained as follows:

$$\nu^1=\frac{[\pm\alpha t^3q(1\mp q)^2-4a^2(3\alpha r+\alpha t+\gamma)]}{2a\alpha t[(4a^2/t)(6r+3t+2\gamma/\alpha)-t^2(1\mp q)^2(1\pm 2q)]^{1/2}},$$

$$\nu^2=\nu^3=0,$$

$$\nu^4=2a[(4a^2/t)(6r+3t+2\gamma/\alpha)-t^2(1\mp q)^2(1\pm 2q)]^{-1/2},$$

and the acceleration vectors $(\dot{\nu}^1,0,0,\dot{\nu}^4)$ are

$$\dot{\nu}^1=(1/2atq)[4a^2t(6r+3t+2\gamma/\alpha)-t^4(1\mp q)^2(1\pm 2q)]^{-3/2}[\pm t^6(1\pm 2q)q^2(1\mp q)^4$$
$$\pm 4a^2t^3(1\mp q)^2\{(1\pm q-4q^2)(3r+\gamma/\alpha)+t(1-7q^2)\}$$
$$\mp 16a^4(6r+3t+2\gamma/\alpha)\{(1\mp q)(3r+\gamma/\alpha)+t(1\mp 2q)\}],$$

and

$$\dot{\nu}^4=\frac{2at[t^3(1\pm 2q)(1\mp q)^2-4a^2(6r+3t+2\gamma/\alpha)]}{[4a^2t(6r+3t+2\gamma/\alpha)-t^4(1\mp q)^2(1\pm 2q)]^{3/2}}.$$

It is clear that velocity and acceleration vectors do not vanish and that the metric and hence the related fluid distribution is with nongeodesic flow.

ACKNOWLEDGMENTS

The second author (K.S.) is thankful to Dr. T. Gnana Bhaskar for his constant encouragement and interest in the preparation of this paper, and to the Council of Scientific and Industrial Research, India, for providing the financial support. Authors are also thankful to the referee for the constructive suggestions made on the earlier version of this paper.

APPENDIX A: FRECHET DERIVATIVE

On replacing ν by $S(u)$ in Eq. (3.5), we get

$$F(L,u,S(u))=[S(u)]_{tt}\left(\frac{u_r^3}{t}-u_{rr}\right)+\frac{2}{t}\,u_r\left(u_tu_{rr}-u_ru_{rt}-\frac{1}{t}\,u_r^2\right)[S(u)]_t$$
$$+\frac{1}{t}\left[3u_r^2u_{rt}+2u_{rt}-u_{rr}(1-u_t^2)-4u_tu_ru_{rt}+\frac{2}{t}\,u_r(1-3u_ru_t+2u_r^2)\right][S(u)]_r$$
$$+2\left(u_{rt}+\frac{1}{t}\,u_r-\frac{1}{t}\,u_r^2u_t\right)[S(u)]_{rt}-\left[u_{tt}+\frac{1}{t}\,u_r(1-u_t^2)\right][S(u)]_{rr}. \tag{A1}$$

Substituting the values of different derivatives of $S(u)$ in Eq. (A1) and collecting the coefficients of various powers of u_r, u_t, u_tu_r,..., etc., we get

$$F(L,u,S(u))=u_{rt}^2\Bigg[C_{rr}+A_{rr}u_t+\left(B_{uu}-\frac{1}{t}\,B_r-\frac{2}{t}\,C_u-\frac{A}{t^2}\right)u_r^3+\left(A_{uu}-\frac{1}{t}\,A_r\right)u_r^2u_t$$
$$+\left\{C_{uu}+2B_{ru}-\frac{1}{t}\,(3C_r+2A_u)\right\}u_r^2+\left(B_{rr}+2C_{ru}-\frac{2}{t}\,A_r\right)u_r+2A_{ru}u_ru_t\Bigg]$$
$$+2u_{rt}u_{rr}\Bigg[-\left(C_{rt}+\frac{1}{t}\,C_r\right)-\left(A_{rt}+C_{ru}+\frac{A_r}{t}\right)u_t-A_{ru}u_t^2+\left(\frac{1}{t}\,A_r-A_{uu}\right)u_t^2u_r$$
$$+\left\{\frac{1}{t}\,(A_u+B_u+C_t)-B_{tu}\right\}u_r^2+\left\{\frac{A}{t^2}+\frac{1}{t}\,(B_r+2C_u)-B_{uu}\right\}u_r^2u_t$$
$$+\left\{\frac{1}{t}\,(A_r+A_t)-\frac{A}{t^2}-B_{rt}-C_{tu}\right\}u_r+\left(\frac{1}{t}\,A_u-\frac{2}{t}\,C_r-A_{tu}-C_{uu}-B_{ru}\right)u_ru_t\Bigg]$$

(Received 13 June 1997; accepted for publication 15 October 1997)

Separability of bi-Hamiltonian finite-dimensional chains with two degenerated Poisson tensors, which have Pfaffian quasi-bi-Hamiltonian representation, is proved. © *1998 American Institute of Physics.* [S0022-2488(98)00106-6]

I. INTRODUCTION

In recent years considerable progress has been made in the construction of new integrable finite-dimensional dynamical systems showing bi-Hamiltonian property. The majority of them come from stationary flows, restricted flows, or nonlinearization of Lax equations of underlying soliton systems.[1–12] Although such constructed finite-dimensional systems are integrable, in principle, as follows from the existence of an appropriate number of integrals of motion, we still lack a general method of finding solutions given in the original variables. In this paper we announce significant progress in this direction. It is proved that most (perhaps all) bi-Hamiltonian finite-dimensional chains, which start with a Casimir of the first Poisson structure and terminate with a Casimir of the second Poisson structure, consist of nonlinear dynamical systems that are separable and, hence, through the solutions of the Hamilton–Jacobi equation, integrable by quadratures. Actually, first we consider in some phase space $M(\dim M=2n)$ so-called quasi-bi-Hamiltonian systems[13] that are Pfaffian, i.e., which in the Nijenhuis coordinates (λ,μ) (coordinates that diagonalize the appropriate Nijenhuis tensor) take the following form:

$$\begin{pmatrix}\lambda\\ \mu\end{pmatrix}_t=\begin{pmatrix}0 & I\\ -I & 0\end{pmatrix}\nabla H(\lambda,\mu;c)=\frac{(-1)^{n+1}}{\lambda_1\cdot\ \cdots\ \cdot\lambda_n}\begin{pmatrix}0 & \Lambda\\ -\Lambda & 0\end{pmatrix}\nabla F(\lambda,\mu;c), \tag{1}$$

where $\Lambda=\mathrm{diag}(\lambda_1,...,\lambda_n)$ and c is a constant parameter, or are inverse Pfaffian, i.e., in the Nijenhuis coordinates, take the form

$$\begin{pmatrix}\lambda\\ \mu\end{pmatrix}_t=\begin{pmatrix}0 & I\\ -I & 0\end{pmatrix}\nabla H(\lambda,\mu;c)=(-1)^{n+1}\lambda_1\cdot\ \cdots\ \cdot\lambda_n\begin{pmatrix}0 & \Lambda^{-1}\\ -\Lambda^{-1} & 0\end{pmatrix}\nabla F(\lambda,\mu;c), \tag{2}$$

where $\Lambda^{-1}=\mathrm{diag}(1/\lambda_1,\ldots,1/\lambda_n)$. Next, in both cases we prove the existence of n independent constants of motion $h_i(\lambda,\mu;c)$ $i=1,...,n$ all separable. The separability of $h_1(\lambda,\mu;c=0)\equiv H(\lambda,\mu)$ and $h_n(\lambda,\mu;c=0)\equiv F(\lambda,\mu)$ of the case (1) was recently proved in Ref. 14. Finally, we prove that most bi-Hamiltonian finite-dimensional systems with two degenerated Poisson tensors, the chain of which, in extended phase space $\bar{M}(\dim \bar{M}=2n+1)$, starts with the Casimir of the canonical (noncanonical) Poisson structure and terminates with the Casimir of the noncanonical (canonical) Poisson tensor, in the original phase space M and in Nijenhuis coordinates are equivalent to Pfaffian (inverse-Pfaffian) quasi-bi-Hamiltonian systems. Hence, they are separable! Moreover, a canonical transformation to the Nijenhuis coordinates is constructed in a very natural way. The procedure is applicable to all known bi-Hamiltonian systems being stationary flows, restricted flows, or nonlinearized spectral problems of underlying soliton systems. Few nontrivial examples illustrate the results.

II. PRELIMINARIES

Let us reexamine some facts about bi-Hamiltonian systems, both finite and infinite dimensional. We recall some definitions. Let M be a differentiable manifold, TM and T^*M its tangent and cotangent bundle. At any point $u \in M$, the tangent and cotangent spaces are denoted by T_uM and T_u^*M, respectively. The pairing between them is given by the map $\langle \cdot, \cdot \rangle : T_u^*M \times T_uM \to R$. For each smooth function $F \in C^\infty(M)$, dF denotes the differential of F (gradient ∇F for finite systems and variation δF for field systems). M is said to be a Poisson manifold if it is endowed with a Poisson bracket $\{\cdot, \cdot\} : C^\infty(M) \times C^\infty(M) \to C^\infty(M)$, degenerated in general. The related Poisson tensor θ is defined by $\{F,G\}_\theta(u) := \langle dG, \theta \circ dF \rangle(u) = \langle dG(u), \theta(u) dF(u) \rangle$. So, at each point u, $\theta(u)$ is a linear map $\theta(u) : T_u^*M \to T_uM$, which is skew symmetric and fulfills the Jacobi identity. Any function $c \in C^\infty(M)$, such that $dc \in \ker\theta$, is called a Casimir of θ. Let $\theta_0, \theta_1 : T^*M \to TM$ be two Poisson tensors on M. A vector field K is said to be a bi-Hamiltonian with respect to θ_0 and θ_1 if there exist two smooth functions $H, F \in C^\infty(M)$, such that

$$K = \theta_0 \circ dH = \theta_1 \circ dF. \tag{3}$$

Poisson tensors θ_0 and θ_1 are said to be compatible if the associated pencil $\theta^\epsilon = \theta_1 - \epsilon\theta_0$ is itself a Poisson tensor for any $\epsilon \in R$. Moreover, if θ_0 is invertible, the tensor $\Phi = \theta_1 \circ \theta_0^{-1}$, called a recursion operator, is a Nijenhuis (hereditary) tensor of such a property, that when it acts on a given bi-Hamiltonian vector field K, produces another bi-Hamiltonian vector field being a symmetry generator of K. Hence, having the Nijenhuis tensor, one can construct a hierarchy of Hamiltonian symmetries and related hierarchy of constants of the motion for underlying system, such as is important for its integrability. Finally, arbitrary tensor field $T^{(k,l)}$ is called a tensor invariant[15] of dynamical system $u_t = K(u)$ if

$$\left(\frac{\partial}{\partial t} + L_K \right) T^{(k,l)} = 0, \tag{4}$$

where L_K denotes the Lie derivative in the direction of vector field K. Examples of various tensor invariants are both Poisson tensors θ_1 and θ_2, the recursion operator Φ, symmetry generators $K_n = \Phi^n \circ K$, or conserved functions H and F.

Unfortunately, for a majority of bi-Hamiltonian finite-dimensional systems, both Poisson structures are degenerated, so one cannot construct the recursion Nijenhuis tensor inverting one of the Poisson structures. Nevertheless, due to the nonuniqueness of Hamiltonian functions, determined up to an appropriate Casimir function, it is always possible to construct a finite bi-Hamiltonian chain starting and terminating with Casimirs of θ_0 and θ_1, respectively. Actually, in the extended phase $\overline{M} \ni (q,p,c)$, where $q = (q_1, \ldots, q_n)^T$ and $p = (p_1, \ldots, p_n)^T$ are generalized coordinates and c is a Casimir coordinate; a typical bi-Hamiltonian chain reads as

$$\begin{aligned}
&\theta_0 \circ \nabla h_0 = 0, \\
&\theta_0 \circ \nabla h_1 = K_1 = \theta_1 \circ \nabla h_0, \\
&\theta_0 \circ \nabla h_2 = K_2 = \theta_1 \circ \nabla h_1, \\
&\qquad \vdots \\
&\theta_0 \circ \nabla h_n = K_n = \theta_1 \circ \nabla h_{n-1}, \\
&\qquad 0 = \theta_1 \circ \nabla h_n,
\end{aligned} \tag{5}$$

where $K \equiv K_1$, $H \equiv h_1$, $F \equiv h_0$, and $d \equiv \nabla$. A canonical θ_0 and noncanonical θ_1 Poisson structures (both degenerated) take the general form

$$\theta_0 = \begin{pmatrix} \theta_c & 0 \\ 0 & 0 \end{pmatrix}, \quad \theta_1 = \begin{pmatrix} \theta_{\mathrm{nc}} & K \\ -K^T & 0 \end{pmatrix}, \tag{6}$$

where

$$\theta_c=\begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}, \quad \theta_{\mathrm{nc}}=\begin{pmatrix} D & A \\ -A^T & B \end{pmatrix} \tag{7}$$

are a nondegenerated matrix from the space $M\ni(q,p)$, $K=K(q,p,c)\equiv K_1$ is an appropriate vector field from the hierarchy (5), and A,B,D are entries depending on generalized coordinates (q,p).

In our further considerations we shall concentrate on the following form of θ_{nc}:

$$\theta_{\mathrm{nc}}=\begin{pmatrix} 0 & A(q) \\ -A^T(q) & B(q,p) \end{pmatrix}. \tag{8}$$

It should be stressed that for all known examples of constrained flows of Lax equations and stationary flows in a Newton representation,[4,5,8,10,11,16,12,17] the matrix θ_{nc} takes the form (8), and for stationary flows in the Ostrogradsky representation[1,3,9] θ_{nc} can be put into the form (8) by an appropriate canonical transformation of variables. Moreover, for matrix θ_{nc} in the form (8), the Hamiltonians $h_r(q,p,c)$ take the general form

$$h_r(q,p,c)=h_r(q,p)+c\rho_\tau(q). \tag{9}$$

III. QUASI-BI-HAMILTONIAN SYSTEMS

For finite-dimensional systems the bi-Hamiltonian property is a very strong condition and, in fact, too restrictive for integrability. There are some physically interesting dynamical systems that in their natural phase space $M\ni(q,p)$ satisfy a weaker condition than the bi-Hamiltonian one. So, before we continue our considerations of bi-Hamiltonian chains we shall introduce the concept of quasi-bi-Hamiltonian systems.[13]

Definition 1: A vector field K is called a *quasi-bi-Hamiltonian* with respect to Poisson tensors θ_0 and θ_1 if there exist three smooth functions $\rho, H,F,$ such that

$$K=\theta_0\circ\nabla H=\frac{1}{\rho}\cdot\theta_1\circ\nabla F; \tag{10}$$

both Poisson matrix are compatible and nondegenerated (invertible). The function ρ is called the *integrating factor*.

To make this concept more familiar and relate it to the bi-Hamiltonian formalism let us review the well-known example of the integrable case of the Henon–Heiles system,[10,13]

$$q_{1tt}=-3q_1^2-\tfrac{1}{2}q_2^2, \qquad q_{2tt}=-q_1q_2, \tag{11}$$

which has two constants of motion of the form

$$\begin{aligned} H&=\tfrac{1}{2}p_1^2+\tfrac{1}{2}p_2^2+q_1^3+\tfrac{1}{2}q_1q_2^2, \\ F&=-2q_2p_1p_2+2q_1p_2^2-\tfrac{1}{4}q_2^4-q_1^2q_2^2, \end{aligned} \tag{12}$$

where $p_1=q_{1t}$ and $p_2=q_{2t}$. In the phase space $M\ni(q_1,q_2,p_1,p_2)$, the related vector fields admit the following quasi-bi-Hamiltonian formulations:

$$\begin{pmatrix} q_1 \\ q_2 \\ p_1 \\ p_2 \end{pmatrix}_{t_{\mathrm{H}}} = \begin{pmatrix} p_1 \\ p_2 \\ -3q_1^2-\tfrac{1}{2}q_2^2 \\ -q_1q_2 \end{pmatrix} \equiv K_H=\theta_0\circ\nabla H=-\frac{1}{q_2^2}\cdot\theta_1\circ\nabla F, \tag{13}$$

$$\begin{pmatrix} q_1 \\ q_2 \\ p_1 \\ p_2 \end{pmatrix}_{t_F} = \begin{pmatrix} -2q_2p_2 \\ -2q_2p_1+4q_1p_2 \\ 2q_1q_2^2-2p_2^2 \\ 2p_1p_2+q_2^3+2q_1^2q_2 \end{pmatrix} \equiv K_F = \theta_0 \circ \nabla F = -q_2^2 \cdot \theta_{-1} \circ \nabla H, \tag{14}$$

where

$$\theta_0 = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix}, \quad \theta_1 = \begin{pmatrix} 0 & 0 & q_1 & \frac{1}{2}q_2 \\ 0 & 0 & \frac{1}{2}q_2 & 0 \\ -q_1 & -\frac{1}{2}q_2 & 0 & \frac{1}{2}p_2 \\ -\frac{1}{2}q_2 & 0 & -\frac{1}{2}p_2 & 0 \end{pmatrix},$$

$$\theta_{-1} = \begin{pmatrix} 0 & 0 & 0 & 1/q_2 \\ 0 & 0 & 1/q_2 & -2q_1/q_2^2 \\ 0 & -1/q_2 & 0 & p_2/q_2^2 \\ -1/q_2 & 2q_1/q_2^2 & -p_2/q_2^2 & 0 \end{pmatrix}, \tag{15}$$

are appropriate compatible Poisson tensors. The Nijenhuis operator,

$$\Phi = \theta_1 \circ \theta_0^{-1}, \tag{16}$$

relates to both systems, i.e., applying Φ to Eq. (14) we get Eq. (13). Note that H, F, and θ_0 are tensor invariants of $u_t = K(u)$, but θ_1 and ρ are not. Hence, Φ is not a recursion operator.

Now, let us consider the first generalization of the Henon–Heiles system,

$$q_{1tt} = -3q_1^2 - \tfrac{1}{2}q_2^2 + c, \qquad q_{2tt} = -q_1q_2, \tag{17}$$

with the following constants of motion:

$$\overline{H} = \tfrac{1}{2}p_1^2 + \tfrac{1}{2}p_2^2 + q_1^3 + \tfrac{1}{2}q_1q_2^2 - cq_1,$$

$$-\tfrac{1}{4}\overline{F} = \tfrac{1}{2}q_2p_1p_2 - \tfrac{1}{2}p_1p_2^2 + \tfrac{1}{16}q_2^4 + \tfrac{1}{4}q_1^2q_2^2 - \tfrac{1}{4}q_2^2c, \tag{18}$$

$$\overline{G} = c.$$

In the extended phase space $\overline{M} \ni (q_1, q_2, p_1, p_2, c)$, the related dynamical systems admit the following bi-Hamiltonian formulations:

$$\begin{pmatrix} q_1 \\ q_2 \\ p_1 \\ p_2 \\ c \end{pmatrix}_{t_H} = \begin{pmatrix} p_1 \\ p_2 \\ -3q_1^2 - \frac{1}{2}q_2^2 + c \\ -q_1q_2 \\ 0 \end{pmatrix} \equiv \overline{K_{\overline{H}}} = \overline{\theta_0} \circ \overline{\nabla H} = \overline{\theta_1} \circ \overline{\nabla G}, \tag{19}$$

$$\begin{pmatrix} q_1 \\ q_2 \\ p_1 \\ p_2 \\ c \end{pmatrix}_{t_F} = \begin{pmatrix} \frac{1}{2} q_2 p_2 \\ \frac{1}{2} q_2 p_1 - q_1 p_2 \\ -\frac{1}{2} q_1 q_2^2 + \frac{1}{2} p_2^2 \\ -\frac{1}{2} p_1 p_2 - \frac{1}{4} q_2^3 - \frac{1}{2} q_1^2 q_2 + \frac{1}{2} q_2 c \\ 0 \end{pmatrix} \equiv \overline{K_F} = \overline{\theta_0} \circ \overline{\nabla} \left(-\frac{1}{4} \overline{F} \right) = \overline{\theta_1} \circ \overline{\nabla} \overline{H}, \tag{20}$$

where compatible Poisson tensors are of the following form:

$$\overline{\theta_0} = \begin{pmatrix} 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ -1 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$\overline{\theta_1} = \begin{pmatrix} 0 & 0 & q_1 & \frac{1}{2} q_2 & p_1 \\ 0 & 0 & \frac{1}{2} q_2 & 0 & p_2 \\ -q_1 & -\frac{1}{2} q_2 & 0 & \frac{1}{2} p_2 & -3q_1^2 - \frac{1}{2} q_2^2 + c \\ -\frac{1}{2} q_2 & 0 & -\frac{1}{2} p_2 & 0 & -q_1 q_2 \\ -p_1 & -p_2 & 3q_1^2 + \frac{1}{2} q_2^2 - c & q_1 q_2 & 0 \end{pmatrix}, \tag{21}$$

each degenerated. Note that $\overline{G}$ is a Casimir of $\overline{\theta_0}$ and $\overline{F}$ is a Casimir of $\overline{\theta_1}$.

Finally, let us consider the second generalized Henon–Heiles system in the form

$$q_{1tt} = -3q_1^2 - \tfrac{1}{2} q_2^2, \qquad q_{2tt} = -q_1 q_2 + \frac{d}{q_2^3}, \tag{22}$$

with the following constants of motion:

$$-2\overline{H} = -p_1^2 - p_2^2 - 2q_1^3 - q_1 q_2^2 - \frac{d}{q_2^2},$$

$$\overline{F} = -2q_2 p_1 p_2 + 2q_1 p_2^2 - \frac{1}{4} q_2^4 - q_1^2 q_2^2 + \frac{2dq_1}{q_2^2}, \tag{23}$$

$$\overline{G} = d.$$

In the extended phase space $\overline{M} \ni (q_1, q_2, p_1, p_2, d)$, the related dynamical systems admit the following bi-Hamiltonian formulations:

$$\begin{pmatrix} q_1 \\ q_2 \\ p_1 \\ p_2 \\ c \end{pmatrix}_{t_H} = \begin{pmatrix} -2p_1 \\ -2p_2 \\ 6q_1^2+q_2^2 \\ 2q_1q_2-2d/q_2^3 \\ 0 \end{pmatrix} \equiv \overline{K_H} = \overline{\theta}_0 \circ \overline{\nabla}(-2\overline{H}) = \overline{\theta}_{-1} \circ \overline{\nabla F}, \tag{24}$$

$$\begin{pmatrix} q_1 \\ q_2 \\ p_1 \\ p_2 \\ c \end{pmatrix}_{t_F} = \begin{pmatrix} -2q_2p_2 \\ -2q_2p_1+4q_1p_2 \\ 2q_1q_2^2-2p_2^2-2d/q_2^2 \\ 2p_1p_2+q_2^3+2q_1^2q_2+4dq_1/q_2^3 \\ 0 \end{pmatrix} \equiv \overline{K_F} = \overline{\theta}_0 \circ \overline{\nabla F} = \overline{\theta}_{-1} \circ \overline{\nabla G}, \tag{25}$$

where compatible Poisson tensors are $\overline{\theta}_0$ and

$$\overline{\theta}_{-1} = \begin{pmatrix} 0 & 0 & 0 & 1/q_2 & -2q_2p_2 \\ 0 & 0 & 1/q_2 & -2q_1/q_2^2 & -2q_2p_1+4q_1p_2 \\ 0 & -1/q_2 & 0 & p_2/q_2^2 & 2q_1q_2^2-2p_2^2-2d/q_2^2 \\ -1/q_2 & 2q_1/q_2^2 & -p_2/q_2^2 & 0 & 2p_1p_2+q_2^3+2q_1^2q_2+4dq_1/q_2^3 \\ * & * & * & * & 0 \end{pmatrix}, \tag{26}$$

again both degenerated. Stars in the last row mean matrix elements that make (26) skew symmetric. Notice that $\overline{G}$ and $\overline{H}$ from (23) are respective Casimirs of $\overline{\theta}_0$ and $\overline{\theta}_{-1}$.

The generalized Henon–Heiles systems (19) and (25) additionally have a quasi-bi-Hamiltonian representation. Actually, for the system (19) we find

$$\begin{pmatrix} q_1 \\ q_2 \\ p_1 \\ p_2 \end{pmatrix}_{t_H} = \begin{pmatrix} p_1 \\ p_2 \\ -3q_1^2-\frac{1}{2}q_2^2+c \\ -q_1q_2 \end{pmatrix} \equiv \overline{K_H} = \theta_0 \circ \overline{\nabla H} = -\frac{1}{q_2^2} \cdot \theta_1 \circ \overline{\nabla F}, \tag{27}$$

where Poisson tensors θ_0, θ_1 are given by (15) and conserved functions $\overline{H}, \overline{F}$ take the form (18), while for the system (25) its quasi-bi-Hamiltonian representation reads as

$$\begin{pmatrix} q_1 \\ q_2 \\ p_1 \\ p_2 \end{pmatrix}_{t_F} = \begin{pmatrix} -2q_2p_2 \\ -2q_2p_1+4q_1p_2 \\ 2q_1q_2^2-2p_2^2-2d/q_2^2 \\ 2p_1p_2+q_2^3+2q_1^2q_2+4dq_1/q_2^3 \end{pmatrix} \equiv \overline{K_F} = \theta_0 \circ \overline{\nabla F} = -q_2^2 \cdot \theta_{-1} \circ \overline{\nabla H}, \tag{28}$$

where conserved functions $\overline{H}, \overline{F}$ take the form (23). Hence, one concludes that quasi-bi-Hamiltonian representation survives the reduction $c=d=0$ (13), (14) while bi-Hamiltonian representation does not.

The Henon–Heiles example gave us some insight into the mutual relations between bi-Hamiltonian and quasi-bi-Hamiltonian representations. Now we shall pass to a more systematic treatment of the problem. In further considerations we shall only use the canonical coordinates (q,p) with respect to which θ_0 takes the canonical form $\theta_0=\theta_c$ (7). As θ_0 and θ_1 are compatible and invertible, the tensor $\Phi=\theta_1 \circ \theta_0^{-1}$ is the Nijenhuis (hereditary) tensor. As Φ is implectic–symplectic factorizable, all its eigenvalues have at least algebraic multiplicity 2.[18] Here, we assume the existence of an open set $U \subset M$ such that in U matrix Φ is maximal, i.e., has n distinct eigenvalues $\lambda=(\lambda_1,\ldots,\lambda_n)$. So, in a neighborhood of a regular point, where the eigenvalues λ are independent, one can construct a canonical transformation $(q,p) \to (\lambda,\mu)$ [(λ,μ) referred to as *Nijenhuis coordinates*], such that θ_1 and Φ take the Darboux form

$$\theta_1=\begin{pmatrix} 0 & \Lambda \\ -\Lambda & 0 \end{pmatrix}, \quad \Phi=\begin{pmatrix} \Lambda & 0 \\ 0 & \Lambda \end{pmatrix}, \quad \Lambda=\mathrm{diag}(\lambda_1,\ldots,\lambda_n). \tag{29}$$

Definition 2:

(i) A quasi-bi-Hamiltonian vector field (10) is said to be Pfaffian if, in Nijenhuis coordinates, it takes the form

$$\begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}\nabla H(\lambda,\mu)=\frac{(-1)^{n+1}}{\lambda_1\cdot\ \cdots\lambda_n}\begin{pmatrix} 0 & \Lambda \\ -\Lambda & 0 \end{pmatrix}\nabla F(\lambda,\mu), \tag{30}$$

i.e., the integrating factor ρ is the product of the eigenvalues of Φ,

$$\rho=(-1)^{n+1}\prod_{i=1}^{n}\lambda_i. \tag{31}$$

(ii) A quasi-bi-Hamiltonian vector field (10) is said to be inverse Pfaffian if in Nijenhuis coordinates if it takes the form

$$\begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}\nabla H(\lambda,\mu)=(-1)^{n+1}\lambda_1\cdot\ \cdots\ \cdot\lambda_n\begin{pmatrix} 0 & \Lambda^{-1} \\ -\Lambda^{-1} & 0 \end{pmatrix}\nabla F(\lambda,\mu), \tag{32}$$

where $\Lambda^{-1}=\mathrm{diag}(1/\lambda_1,\ldots,1/\lambda_n)$.

Notice that forms (31) and (32) are related by the Nijenhuis operator Φ (29) and its inverse Φ^{-1}.

Lemma 1: In the Pfaffian case (30) and in the inverse-Pfaffian case (32), the general solution of Eq. (10) is given by

$$H=\sum_{i=1}^{n}\frac{1}{\Delta_i}f_i(\lambda_i,\mu_i)+g_H(\lambda),$$

$$F=\sum_{i=1}^{n}\frac{\rho}{\lambda_i}\frac{1}{\Delta_i}f_i(\lambda_i,\mu_i)+g_F(\lambda), \tag{33}$$

where

$$\frac{\partial g_H}{\partial\lambda_i}=\frac{\lambda_i}{\rho}\frac{\partial g_F}{\partial\lambda_i}, \quad \Delta_i=\prod_{i\neq j}\lambda_{ij}, \quad \lambda_{ij}:=\lambda_i-\lambda_j, \tag{34}$$

and the n functions $f_i(\lambda_i,\mu_i)$ (each one depending on one pair of coordinates) are arbitrary smooth functions.

The proof for $g_H(\lambda)=g_F(\lambda)=0$ can be found in Ref. 14. Of course, the addition of an arbitrary function $g_H(\lambda)$ to $H=\Sigma_{i=1}^{n}(1/\Delta_i)f_i$, generates in $F=\Sigma_{i=1}^{n}(\lambda_i/\rho)(1/\Delta_i)f_i$ an additional function $g_F(\lambda)$ related to $g_H(\lambda)$ through relation (34).

Theorem 1: An arbitrary bi-Hamiltonian finite-dimensional system with two degenerated Poisson tensors of the form (6), where θ_{nc} takes the form (8), whose chain starts with a Casimir of the canonical Poisson structure and terminates with a Casimir of a noncanonical Poisson structure, is equivalent to a quasi-bi-Hamiltonian system, which in the Nijenhuis coordinates takes a Pfaffian form.

Proof: Let

$$\overline{\theta_0}\circ\overline{\nabla h_0}=0,$$
$$\overline{\theta_0}\circ\overline{\nabla h_1}=\overline{K_1}=\overline{\theta_1}\circ\overline{\nabla h_0},$$
$$\overline{\theta_0}\circ\overline{\nabla h_2}=\overline{K_2}=\overline{\theta_1}\circ\overline{\nabla h_1},$$

$$\vdots$$

$$\overline{\theta_0}\circ\overline{\nabla h_n}=\overline{K_n}=\overline{\theta_1}\circ\overline{\nabla h_{n-1}},$$
$$0=\overline{\theta_1}\circ\overline{\nabla h_n}, \tag{35}$$

be a bi-Hamiltonian chain on $U\subset\overline{M}\ni(q,p,c)$ with two degenerated Poisson structures, each with one Casimir, so that dim $\overline{M}=2n+1$ and rank $\overline{\theta_0}(\overline{\theta_1})=2n$, where

$$\overline{\theta_0}=\begin{pmatrix}0 & I & 0\\ -I & 0 & 0\\ 0 & 0 & 0\end{pmatrix},\quad \overline{\theta_1}=\begin{pmatrix}0 & A(q) & \dfrac{\partial\overline{h_1}}{\partial p}\\ -A^T(q) & B(q,p) & -\dfrac{\partial\overline{h_1}}{\partial q}\\ -\left(\dfrac{\partial\overline{h_1}}{\partial p}\right)^T & -\left(\dfrac{\partial\overline{h_1}}{\partial q}\right)^T & 0\end{pmatrix} \tag{36}$$

are compatible, $\overline{h_r}(q,p,c)=\overline{h_r}(q,p)+c\rho_r(q)$, and $\overline{\nabla}=(\partial/\partial q,\partial/\partial p,\partial/\partial c)^T$. In order to construct a bi-Hamiltonian hierarchy also in the original phase space $M\ni(q,p)$, one can try to project the chain (35) onto M. If $\pi:M\to M:(q,p,c)\to(q,p)$ is the projection map, the Hamiltonians h_r and the vector fields K_r cannot be projected onto M, because they depend on the fiber coordinate c. Instead, the Poisson tensors θ_0 and θ_1 are projected onto

$$\theta_0\equiv\theta_c=\pi'\circ\overline{\theta_0}\circ\pi'^T=\begin{pmatrix}0 & I\\ -I & 0\end{pmatrix},$$

$$\theta_1\equiv\theta_{\mathrm{nc}}=\pi'\circ\overline{\theta_1}\circ\pi'^T=\begin{pmatrix}0 & A\\ -A^T & B\end{pmatrix}, \tag{37}$$

with $A=A(q)$ and $B=B(q,p)$, where π' is the derivative of the map π. Because these Poisson tensors are compatible and invertible, one obtains the following Nijenhuis tensor:

$$\Phi=\theta_1\circ\theta_0^{-1}=\begin{pmatrix}A & 0\\ B & A^T\end{pmatrix}. \tag{38}$$

Nevertheless, as the Poisson tensor θ_1 is not invariant along the flows of vector fields K_r, where $\overline{K_r}=(K_r,0)^T$, so Φ is not a recursion operator for any K_r. However, vector fields K_r are still Hamiltonian with respect to θ_0, i.e.

$$K_r=\theta_0\circ\nabla h_r, \tag{39}$$

where $h_r=\overline{h_r}$, c is treated as a parameter, and $\nabla=(\partial/\partial q,\partial/\partial p)^T$.

Consider the last equation from the hierarchy (35): $0=\theta_1\circ\nabla h_n$. On M it reads as

$$\theta_1\circ\nabla h_n=-\rho_n K_1,\quad \rho_n=\frac{\partial h_n}{\partial c}. \tag{40}$$

As $h_0=c$, hence on M, $\nabla h_0=0$, and the hierarchy (35) turns into the form

$$\theta_0\circ\nabla h_1=K_1=-\frac{1}{\rho_n}\cdot\theta_1\circ\nabla h_n,$$

$$\theta_0\circ\nabla h_2=K_2=-\frac{\rho_1}{\rho_n}\cdot\theta_1\circ\nabla h_n+\theta_1\circ\nabla h_1,$$

$$\vdots$$

$$\theta_0 \circ \nabla h_n = K_n = -\frac{\rho_{n-1}}{\rho_n} \cdot \theta_1 \circ \nabla h_n + \theta_1 \circ \nabla h_{n-1}, \tag{41}$$

where $\rho_r = \partial h_r / \partial c$. The last equation in (41) terminates the sequence of vector fields K_r in the hierarchy, as for the next equation from the chain we have

$$\theta_0 \circ \nabla h_{n+1} = K_{n+1} = -\theta_1 \circ \nabla h_n + \theta_1 \circ \nabla h_n = 0. \tag{42}$$

Because of the form of the first equation from the hierarchy (41), vector field $K \equiv K_1$ is quasi-bi-Hamiltonian. Now, from the relation

$$\Phi \circ K_r = \theta_1 \circ \nabla h_r = K_{r+1} + \frac{\rho_r}{\rho_n} \cdot \theta_1 \circ \nabla h_n = K_{r+1} - \rho_r K_1, \tag{43}$$

one finds that

$$K_{r+1} = \Phi_r K_1, \quad \Phi_r = \sum_{i=0}^{r} \rho_{r-i} \Phi^i, \quad \rho_0 = 1, \quad r = 0,...,n-1, \tag{44}$$

and for $r = n$,

$$\Phi_n \circ K_1 = K_{n+1} = 0; \tag{45}$$

hence

$$\Phi^n + \rho_1 \Phi^{n-1} + \cdots + \rho_{n-1} \Phi + \rho_n I = 0. \tag{46}$$

In Nijenhuis coordinates, operator Φ is diagonal, so Eq. (46) is equivalent to the following system:

$$\begin{pmatrix} \lambda_1^{n-1} & \cdots & \lambda_1 & 1 \\ \lambda_2^{n-1} & \cdots & \lambda_2 & 1 \\ \vdots & & \vdots & \vdots \\ \lambda_n^{n-1} & \cdots & \lambda_n & l \end{pmatrix} \begin{pmatrix} \rho_1 \\ \rho_2 \\ \vdots \\ \rho_n \end{pmatrix} = \begin{pmatrix} -\lambda_1^n \\ -\lambda_2^n \\ \vdots \\ -\lambda_n^n \end{pmatrix}. \tag{47}$$

For all λ_i different, there is a unique solution to (47) in the form

$$\rho_r(q) = (-1)^r \sum_{\substack{j_1,..,j_r \\ j_1<..<j_r}} \lambda_{j_1} \cdot \cdots \cdot \lambda_{j_r} := \rho_r(\lambda), \quad r = 1,...,n. \tag{48}$$

So, the quasi-bi-Hamiltonian representation (41) for $K_1 \equiv K$ takes the Pfaffian form (30), where now $H = h_1$, $F = h_n$ and $\rho = -\rho_n$. □

The explicit form of the canonical transformation $(q,p) \to (\lambda,\mu)$ to the Nijenhuis coordinates is given in what follows. From relation (48) we get $q_k = \varphi_k(\lambda)$. Then, we introduce the generating function $S = \Sigma_{i=1}^n p_i \varphi_i(\lambda)$, such that

$$q_i = \frac{\partial S}{\partial p_i}, \quad \mu_i = \frac{\partial S}{\partial \lambda_i}. \tag{49}$$

The first equation reconstructs $q_k = \varphi_k(\lambda)$ and solving the second one with respect to p_k, we get the missing part of the canonical transformation in the form $p_k = \psi_k(\lambda,\mu)$.

Theorem 2: An arbitrary bi-Hamiltonian finite-dimensional system with two degenerated Poisson tensors of the form (6), where θ_{nc} takes the form (8), whose chain starts with a Casimir of

a noncanonical Poisson structure and terminates with a Casimir of the canonical structure, is equivalent to a quasi-bi-Hamiltonian system, which in the Nijenhuis coordinates takes an inverse-Pfaffian form.

Proof: Let

$$\begin{aligned}
&\overline{\theta}_{-1}\circ\overline{\nabla h_1}=0,\\
&\overline{\theta}_{-1}\circ\overline{\nabla h_2}=\overline{K}_1=\overline{\theta}_0\circ\overline{\nabla h_1},\\
&\overline{\theta}_{-1}\circ\overline{\nabla h_3}=\overline{K}_2=\overline{\theta}_0\circ\overline{\nabla h_2},\\
&\qquad\vdots\\
&\overline{\theta}_{-1}\circ\overline{\nabla h_{n+1}}=\overline{K}_n=\overline{\theta}_0\circ\overline{\nabla h_n},\\
&\qquad 0=\overline{\theta}_0\circ\overline{\nabla h_{n+1}}
\end{aligned}\tag{50}$$

be a bi-Hamiltonian chain on $U\subset\overline{M}\ni(q,p,c)$ with two degenerated Poisson tensors, each with one Casimir, so that $\dim\overline{M}=2n+1$ and $\operatorname{rank}\overline{\theta}_0(\overline{\theta}_{-1})=2n$, where

$$\overline{\theta}_{-1}=\begin{pmatrix} 0 & A(q) & \dfrac{\partial\overline{h}_n}{\partial p}\\ -A^T(q) & B(q,p) & -\dfrac{\partial\overline{h}_n}{\partial q}\\ -\left(\dfrac{\partial\overline{h}_n}{\partial p}\right)^T & -\left(\dfrac{\partial\overline{h}_n}{\partial q}\right)^T & 0\end{pmatrix},\quad \overline{\theta}_0=\begin{pmatrix} 0 & I & 0\\ -I & 0 & 0\\ 0 & 0 & 0\end{pmatrix},\tag{51}$$

are compatible and where $\overline{h}_r(q,p,c)=\overline{h}_r(q,p)+c\tilde{\rho}_r(q)$. Like in the previous case (Theorem 6.4), in the original phase space $M\ni(q,p)$, $\theta_c=\theta_0$ and $\theta_{\mathrm{nc}}=\theta_{-1}$ constitute a compatible pair of Poisson tensors, but as in the previous case, the tensor θ_{-1} is not invariant along any flow of K_r. Because θ_0 is invertible, hence $\Phi^{-1}=\theta_{-1}\circ\theta_0^{-1}$ is the inverse of the Nijenhuis operator Φ but is not a recursion operator for K_r.

Consider the first equation from the hierarchy (50): $\overline{\theta}_{-1}\circ\overline{h}_1=0$. On M it reads as

$$\theta_{-1}\circ\nabla h_1=-\tilde{\rho}_1K_n,\quad \tilde{\rho}_1=\frac{\partial h_1}{\partial_c},\tag{52}$$

and the whole hierarchy turns into

$$\begin{aligned}
&-\frac{1}{\tilde{\rho}_1}\cdot\theta_{-1}\circ\nabla h_1=K_n=\theta_0\circ\nabla h_n,\\
&\theta_{-1}\circ\nabla h_n-\frac{\tilde{\rho}_n}{\tilde{\rho}_1}\cdot\theta_{-1}\circ\nabla h_1=K_{n-1}=\theta_0\circ\nabla h_{n-1},\\
&\qquad\vdots\\
&\theta_{-1}\circ\nabla h_2-\frac{\tilde{\rho}_2}{\tilde{\rho}_1}\cdot\theta_{-1}\circ\nabla h_1=K_1=\theta_0\circ\nabla h_1,
\end{aligned}\tag{53}$$

where $\tilde{\rho}_r=\partial h_r/\partial c$, $\tilde{\rho}_{n+1}=1$, $h_r=\overline{h}_r$, and $\overline{K}_r=(K_r,0)^T$. The last equation terminates the sequence of vector fields K_r in the hierarchy; as for the next equation from the chain we have

$$\theta_{-1}\circ\nabla h_1-\theta_{-1}\circ\nabla h_1=K_0=0.\tag{54}$$

Because of the form of the first equation from the hierarchy (53), the vector field $K \equiv K_n$ is called quasi-bi-Hamiltonian. Now, from the relation

$$\Phi^{-1} \circ K_r = \theta_{-1} \circ \nabla h_r = K_{r-1} + \frac{\tilde{\rho}_r}{\tilde{\rho}_1} \cdot \theta_{-1} \circ \nabla h_1 = K_{r-1} - \tilde{\rho}_r K_n, \tag{55}$$

one finds that

$$K_{n-r} = \Phi_r^{-1} \circ K_n = \sum_{i=0}^{r} \tilde{\rho}_{r+1-i} \Phi^{-r+i} \circ K_n, \tag{56}$$

and for $r=n$,

$$K_0 = \Phi_n^{-1} K_n = \sum_{i=0}^{n} \tilde{\rho}_{n+1-i} \Phi^{-n+i} \circ K_n = 0; \tag{57}$$

hence

$$\Phi^{-n} + \tilde{\rho}_n \Phi^{-n+1} + \cdots + \tilde{\rho}_2 \Phi^{-1} + \tilde{\rho}_1 I = 0. \tag{58}$$

In Nijenhuis coordinates we have

$$\theta_0 = \begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}, \quad \theta_{-1} = \begin{pmatrix} 0 & \Lambda^{-1} \\ -\Lambda^{-1} & 0 \end{pmatrix}, \quad \Phi^{-1} = \begin{pmatrix} \Lambda^{-1} & 0 \\ 0 & \Lambda^{-1} \end{pmatrix}, \tag{59}$$

where $\Lambda^{-1} = \mathrm{diag}(1/\lambda_1, \ldots, 1/\lambda_n)$, and for all λ_i different there is a unique solution to Eq. (58) in the form

$$\tilde{\rho}_{n+1-k} = (-1)^k \sum_{\substack{j_1,\ldots,j_k \\ j_1 < \ldots < j_k}} \frac{1}{\lambda_{j_1} \cdot \cdots \cdot \lambda_{j_k}}, \quad k = 1,\ldots,n. \tag{60}$$

So, the first equation (53) takes the inverse-Pfaffian form (32), where now $H = h_n$, $F = h_1$, and $\rho = -\tilde{\rho}_1$. □

IV. SEPARABILITY OF BI-HAMILTONIAN AND QUASI-BI-HAMILTONIAN SYSTEMS

In the previous section we introduced the notion of quasi-bi-Hamiltonian systems, their Pfaffian, and inverse-Pfaffian forms. Moreover, we proved that each bi-Hamiltonian system with two degenerated Poisson tensors always has a quasi-bi-Hamiltonian representation. In the following section we consider the inverse statement, which says that each Pfaffian or inverse-Pfaffian quasi-bi-Hamiltonian system with $c \neq 0$ has a bi-Hamiltonian representation with a bi-Hamiltonian chain, and, moreover, we prove the separability of such a class of dynamical systems.

Theorem 3: For a quasi-bi-Hamiltonian system, the Hamiltonian functions H and F, written in terms of the Nijenhuis coordinates (λ_i, μ_i) in the form (33), are separable for each n-ple of functions $f_i(\lambda_i, \mu_i)$ when

$$g_H(\lambda) = 0 \quad \text{and} \quad g_F(\lambda) = 0,$$

$$g_H(\lambda) = c(\lambda_1 + \cdots + \lambda_n) \quad \text{and} \quad g_F(\lambda) = c\rho,$$

$$g_H(\lambda) = \frac{c}{\rho} \quad \text{and} \quad g_F(\lambda) = c\left(\frac{1}{\lambda_1} + \cdots + \frac{1}{\lambda_n}\right), \tag{61}$$

where c is an arbitrary constant.

Proof: The Hamilton–Jacobi equation for H is separable iff H verifies the Levi-Civita condition. It is in the form of a set of nonlinear partial differential equations,

$$\frac{\partial H}{\partial \lambda_i}\frac{\partial H}{\partial \lambda_j}\frac{\partial^2 H}{\partial \mu_i \partial \mu_j}+\frac{\partial H}{\partial \mu_i}\frac{\partial H}{\partial \mu_j}\frac{\partial^2 H}{\partial \lambda_i \partial \lambda_j}-\frac{\partial H}{\partial \lambda_i}\frac{\partial H}{\partial \mu_j}\frac{\partial^2 H}{\partial \mu_i \partial \lambda_j}-\frac{\partial H}{\partial \mu_i}\frac{\partial H}{\partial \lambda_j}\frac{\partial^2 H}{\partial \lambda_i \partial \mu_j}=0, \tag{62}$$

for all pairs (i,j), $i\neq j$. Applying the relations

$$\frac{\partial}{\partial \lambda_i}\frac{1}{\Delta_i}=-\frac{1}{\Delta_i}\sum_{\alpha\neq i}\frac{1}{\lambda_{i\alpha}},\quad \frac{\partial}{\partial \lambda_\beta}\frac{1}{\Delta_i}=-\frac{1}{\Delta_i}\frac{1}{\lambda_{i\beta}},\quad \beta\neq i, \tag{63}$$

one directly verifies the relation (62) for $H(\lambda,\mu)$ and $F(\lambda,\mu)$. □

The case $g_H(\lambda)=g_F(\lambda)=0$ was proved for the first time in Ref. 14.

Theorem 4:

(i) An arbitrary quasi-bi-Hamiltonian system, which in Nijenhuis coordinates has the Pfaffian form (30), has n independent constants of motion of the form

$$h_r=\sum_{i=1}^{n}\frac{\rho_{r-1}^{i}}{\Delta_i}f_i(\lambda_i,\mu_i)+c\rho_r,\quad r=1,...,n, \tag{64}$$

where

$$\Delta_i=\prod_{j\neq i}\lambda_{ij},\quad \lambda_{ij}=\lambda_i-\lambda_j,$$
$$\rho_r^i:=(-1)^r\sum_{\substack{j_1,...,j_r\\ j_1<..<j_r\\ j_1\neq i,..,j_r\neq i}}\lambda_{j_1}\cdot\ \cdots\ \cdot\lambda_{j_r}, \tag{65}$$

ρ_r are defined by (48), and n functions f_i are arbitrary smooth functions.

(ii) Arbitrary function h_r is separable for each n-ple of functions $f_i(\lambda_i,\mu_i)$, that is, an appropriate Hamilton–Jacobi equation can be solved.

(iii) On the phase space $M\ni(\lambda,\mu)$, functions h_k, $k=1,...,n$, are in involution with respect to Poisson tensors,

$$\theta_0=\begin{pmatrix}0 & I\\ -I & 0\end{pmatrix},\quad \theta_1=\begin{pmatrix}0 & \Lambda\\ -\Lambda & 0\end{pmatrix}.$$

(iv) On the extended phase space $\overline{M}\ni(\lambda,\mu,c)$, functions h_r with $c\neq 0$ form a bi-Hamiltonian chain with respect to degenerated Poisson tensors,

$$\overline{\theta_0}=\begin{pmatrix}0 & I & 0\\ -I & 0 & 0\\ 0 & 0 & 0\end{pmatrix},\quad \overline{\theta_1}=\begin{pmatrix}0 & \Lambda & \dfrac{\partial h_1}{\partial \mu}\\ -\Lambda & 0 & -\dfrac{\partial h_1}{\partial \lambda}\\ -\left(\dfrac{\partial h_1}{\partial \mu}\right)^T & \left(\dfrac{\partial h_1}{\partial \lambda}\right)^T & 0\end{pmatrix}.$$

The chain starts with the Casimir $h_0=c$ of the first Poisson tensor $\overline{\theta_0}$ and terminates with the Casimir h_n of the second Poisson tensor $\overline{\theta_1}$.

Proof:

(iii) Let $\gamma_r=\nabla h_r$; then by direct calculations one can verify that

$$\gamma_{r+1}=\Phi^{\dagger}\gamma_r+\rho_r\gamma_1, \tag{66}$$

where

$$\Phi^{\dagger}=\theta_0^{-1}\circ\theta_1=\begin{pmatrix}\Lambda & 0\\ 0 & \Lambda\end{pmatrix},$$

and ρ_r is given by Eq. (48). In the calculus the following relations are helpful:

$$\frac{\partial\rho_r}{\partial\lambda_i}=-\rho^i_{r-1},\quad \lambda_i\frac{\partial\rho_r}{\partial\lambda_i}=\rho_r-\rho^i_r,\quad \lambda_i\rho^i_{r-1}=-\rho_r+\rho^i_r,$$

$$\frac{\partial\rho^k_r}{\partial\lambda_i}=-\rho^{ki}_{r-1},\quad \lambda_i\frac{\partial\rho^k_r}{\partial\lambda_i}=\rho^k_r-\rho^{ki}_r,\quad \lambda_i\rho^{ki}_{r-1}=-\rho^k_r+\rho^{ki}_r, \tag{67}$$

$$\rho^{ki}_r:=(-1)^r\sum_{\substack{j_1,\ldots,j_r\\ j_1<\ldots<j_r\\ j_1\neq i,k,\ldots,j_r\neq i,k}}\lambda_{j_1}\cdot\ \cdots\ \cdot\lambda_{j_r},$$

as well as relations (63). From (66), it follows that

$$\gamma_{r+1}=\Phi^{\dagger}_r\circ\gamma_1=\sum_{i=0}^{r}\rho_{r-i}(\Phi^{\dagger})^i\circ\gamma_1,$$

and thus, because $\theta_0\circ\Phi^{\dagger}=\Phi\circ\theta_0$, we have

$$\begin{aligned}\{h_l,h_k\}_{\theta_0}&=\langle\nabla h_k,\theta_0\circ\nabla h_l\rangle\\ &=\sum_{i=0}^{l}\sum_{j=0}^{k}\rho_{r-i}\rho_{k-j}\langle\Phi^{\dagger j}\circ\gamma_1,\theta_0\circ\Phi^{\dagger i}\circ\gamma_1\rangle\\ &=\sum_{i=0}^{l}\sum_{j=0}^{k}\rho_{r-i}\rho_{k-j}\langle\gamma_1,\Phi^{i+j}\circ\theta_0\circ\gamma_1\rangle=0,\end{aligned}$$

where the last equality follows from skew symmetry of the tensor $\Phi^m\circ\theta_0$ for any m. As $\theta_1=\Phi\circ\theta_0$ we have

$$\begin{aligned}\{h_l,h_k\}_{\theta_1}&=\langle\nabla h_k,\theta_k,\theta_1\circ\nabla h_l\rangle\\ &=\sum_{i=0}^{l}\sum_{j=0}^{k}\rho_{r-i}\rho_{k-j}\langle\Phi^{\dagger j}\circ\gamma_1,\theta_1\circ\Phi^{\dagger i}\circ\gamma_1\rangle\\ &=\sum_{i=0}^{l}\sum_{j=0}^{k}\rho_{r-i}\rho_{k-j}\langle\gamma_1,\Phi^{i+j}\circ\theta_1\circ\gamma_1\rangle\\ &=\sum_{i=0}^{l}\sum_{j=0}^{k}\rho_{r-i}\rho_{k-j}\langle\gamma_1,\Phi^{i+j+1}\circ\theta_0\circ\gamma_1\rangle=0.\end{aligned}$$

□

(i) Follows immediately from (iii) as

$$L_K h_{r+1}=\langle\nabla\gamma_{r+1},\theta_0\circ\gamma_1\rangle=0.$$

□

(ii) We prove the statement by direct verification of the Levi-Civita condition (62) for each h_r. Notice that $h_1=H$ and $h_n=F$, where H and F are given in Lemma 1, as $\rho^i_0=1$ and $\rho^i_{n-1}=-\rho_n/\lambda_i=\rho/\lambda_i$. □

(iv) The relation $\overline{\theta_0}\circ\nabla h_{r+1}=\overline{\theta_1}\circ\nabla h_r$ is equivalent to the following equalities:

$$\frac{\partial h_{r+1}}{\partial \mu_i}=\lambda_i \frac{\partial h_r}{\partial \mu_i}+\rho_r \frac{\partial h_1}{\partial \mu_i},$$

$$\frac{\partial h_{r+1}}{\partial \lambda_i}=\lambda_i \frac{\partial h_r}{\partial \lambda_i}+\rho_r \frac{\partial h_1}{\partial \lambda_i}, \quad i=1,...,n,$$

$$\left(\frac{\partial h_1}{\partial \lambda}\right)^T \frac{\partial h_r}{\partial \mu}-\left(\frac{\partial h_1}{\partial \mu}\right)^T \frac{\partial h_r}{\partial \lambda}=0.$$

The first two are equivalent to the relation (66) while the last one is equal to $\{h_r,h_1\}_{\theta_0}=0$.□

Theorem 5:

(i) An arbitrary quasi-bi-Hamiltonian system, which in Nijenhuis coordinates has the inverse-Pfaffian form (32), has n independent constants of motion of the form

$$h_r=\sum_{i=1}^{n} \frac{\rho_{r-1}^i}{\Delta_i} f_i(\lambda_i,\mu_i)+c\tilde{\rho}_r, \quad r=1,...,n, \tag{68}$$

where Δ_i, ρ_r^i, and f_i are the same as in Theorem 4.

(ii) Arbitrary function h_r is separable for each n-ple of functions $f_i(\lambda_i,\mu_i)$, that is, an appropriate Hamilton–Jacobi equation can be solved.

(iii) On the phase space $M\ni(\lambda,\mu)$, functions h_k, $k=1,...,n$, are in involution with respect to Poisson tensors,

$$\theta_0=\begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}, \quad \theta_{-1}=\begin{pmatrix} 0 & \Lambda^{-1} \\ -\Lambda^{-1} & 0 \end{pmatrix}. \tag{69}$$

(iv) On the extended phase space $\overline{M}\ni(\lambda,\mu,c)$, h_r functions with $c\neq 0$ form a bi-Hamiltonian chain with respect to degenerated Poisson tensors,

$$\overline{\theta}_0=\begin{pmatrix} 0 & I & 0 \\ -I & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \overline{\theta}_{-1}=\begin{pmatrix} 0 & \Lambda^{-1} & \dfrac{\partial h_n}{\partial \mu} \\ -\Lambda^{-1} & 0 & -\dfrac{\partial h_n}{\partial \lambda} \\ -\left(\dfrac{\partial h_n}{\partial \mu}\right)^T & \left(\dfrac{\partial h_n}{\partial \lambda}\right)^T & 0 \end{pmatrix}. \tag{70}$$

The chain starts with the Casimir h_1 of the noncanonical Poisson tensor $\overline{\theta}_{-1}$ and terminates with the Casimir $h_{n+1}=c$ of the canonical Poisson tensor $\overline{\theta}_0$.

Proof: The proof is analogous to the one of Theorem 4, where we additionally use the relation $\tilde{\rho}_r=-\rho_{r-1}/\rho_n$.

V. EXAMPLES

The theory developed in previous sections will be illustrated by a few representative examples. We start with the Henon–Heiles system introduced in the beginning of this paper.

Example 1: Separability of the Henon–Heiles system and its generalizations.

For the first generalization of the Henon–Heiles system (17)–(21), we find

$$\frac{\partial h_1}{\partial c}=\frac{\partial \overline{H}}{\partial c}=-q_1=-\lambda_1-\lambda_2,$$

$$\frac{\partial h_2}{\partial c}=\frac{\partial\left(-\frac{1}{4}\overline{F}\right)}{\partial c}=-\frac{1}{4}q_2^2=\lambda_1\lambda_2, \tag{71}$$

and hence

$$q_1=\lambda_1+\lambda_2, \quad q_2=2\sqrt{-\lambda_1\lambda_2}. \tag{72}$$

From the generating function $S=p_1(\lambda_1+\lambda_2)+2p_2\sqrt{-\lambda_1\lambda_2}$, we get the conjugate momenta

$$p_1=\sqrt{-\lambda_1\lambda_2}\left(\frac{\mu_1}{\Delta_1}+\frac{\mu_2}{\Delta_2}\right), \quad p_2=\frac{\lambda_1\mu_1}{\Delta_1}+\frac{\lambda_2\mu_2}{\Delta_2}, \tag{73}$$

where $\Delta_1=-\Delta_2=\lambda_1-\lambda_2$. In Nijenhuis coordinates, the conserved functions read as

$$\begin{aligned} h_1&=\frac{\lambda_1(\mu_1^2+2\lambda_1^3)}{2\Delta_1}+\frac{\lambda_2(\mu_2^2+2\lambda_2^3)}{2\Delta_2}-c(\lambda_1+\lambda_2),\\ h_2&=-\frac{\lambda_2\lambda_1(\mu_1^2+2\lambda_1^3)}{2\Delta_1}-\frac{\lambda_1\lambda_2(\mu_2^2+2\lambda_2^3)}{2\Delta_2}+c\lambda_1\lambda_2. \end{aligned} \tag{74}$$

The Hamilton–Jacobi equations $h_i(\lambda,\partial W_i/\partial\lambda)=E_i$, $i=1,2$, are separable and have the complete integrals $W_i=\Sigma_{k=1}^2 W_i^{(k)}(\lambda_k;c_0,c_1)$, where $W_i^{(k)}$ are solutions of the following equations:

$$\frac{dW_i^{(k)}}{d\lambda_k}=\left[\frac{1}{\lambda_k}\,(-2\lambda_k^4+c\lambda_k^2+c_1\lambda_k+c_0)\right]^{1/2}, \quad c_{2-i}=2E_i, \quad i,k=1,2. \tag{75}$$

For the second generalized Henon–Heiles representation (22)–(26), from the relations

$$\begin{aligned} \frac{\partial h_1}{\partial d}&=\frac{\partial(-2\overline{H})}{\partial d}=-\frac{1}{q_2^2}=\frac{1}{\lambda_1\lambda_2},\\ \frac{\partial h_2}{\partial d}&=\frac{\partial\overline{F}}{\partial d}=\frac{2q_1}{q_2^2}=-\frac{1}{\lambda_1}-\frac{1}{\lambda_2}, \end{aligned} \tag{76}$$

we find the following Nijenhuis coordinates:

$$\begin{aligned} q_1&=\frac{1}{2}\,(\lambda_1+\lambda_2), \quad q_2=\sqrt{-\lambda_1\lambda_2},\\ p_1&=2\sqrt{-\lambda_1\lambda_2}\left(\frac{\mu_1}{\Delta_1}+\frac{\mu_2}{\Delta_2}\right), \quad p_2=2\left(\frac{\lambda_1\mu_1}{\Delta_1}+\frac{\lambda_2\mu_2}{\Delta_2}\right), \end{aligned} \tag{77}$$

and the following conserved functions:

$$\begin{aligned} h_1&=-\frac{\lambda_1(16\mu_1^2+\lambda_1^3)}{4\Delta_1}-\frac{\lambda_2(16\mu_2^2+\lambda_2^3)}{4\Delta_2}+\frac{d}{\lambda_1\lambda_2},\\ h_2&=\frac{\lambda_2\lambda_1(16\mu_1^2+\lambda_1^3)}{4\Delta_1}+\frac{\lambda_1\lambda_2(16\mu_2^2+\lambda_2^3)}{4\Delta_2}-d\left(\frac{1}{\lambda_1}+\frac{1}{\lambda_2}\right). \end{aligned} \tag{78}$$

Again, the Hamilton–Jacobi equations $h_i(\lambda,\partial W_i/\partial\lambda)=E_i$, $i=1,2$, are separable and have the complete integrals $W_i=\Sigma_{k=1}^2 W_i^{(k)}(\lambda_k;c_0,c_1)$, where $W_i^{(k)}$ are solutions of the following equations:

$$\frac{dW_i^{(k)}}{d\lambda_k}=\left[\frac{1}{\lambda_k}\left(-16\lambda_k^4-c_1\lambda_k-c_0-\frac{4d}{\lambda_k}\right)\right]^{1/2}, \quad c_{2-i}=4E_i, \quad i,k=1,2. \tag{79}$$

Example 2: Separability of the second Newton representation for the stationary flow of the Harry Dym equation.

Newton dynamics,

$$q_{1_{xx}}=8q_1^{-5}q_2, \qquad q_{2_{xx}}=-2q_1^{-4}-d, \tag{80}$$

is another example of a bi-Hamiltonian system recently derived in Ref. 12. With $p_1=q_{1_x}$ and $p_2=q_{2_x}$ the related bi-Hamiltonian chain (35) is given by Hamiltonian functions

$$\begin{aligned} h_0&=d,\\ h_1&=\tfrac{1}{2}p_1^2+\tfrac{1}{2}p_2^2+2q_1^{-4}q_2+dq_2,\\ h_2&=\tfrac{1}{2}q_2p_1^2-\tfrac{1}{2}q_1p_1p_2+\tfrac{1}{2}q_1^{-2}+2q_1^{-4}q_2^2-\tfrac{1}{4}dq_1^2, \end{aligned} \tag{81}$$

canonical Poisson tensor $\overline{\theta_0}$, and the noncanonical one,

$$\overline{\theta_1}=\begin{pmatrix} 0 & 0 & 0 & -\frac{1}{2}q_1 & p_1\\ 0 & 0 & -\frac{1}{2}q_1 & -q_2 & p_2\\ 0 & \frac{1}{2}q_1 & 0 & \frac{1}{2}q_1 & -8q_1^{-5}q_2\\ \frac{1}{2}q_1 & q_2 & -\frac{1}{2}q_1 & 0 & 2q_1^{-4}+d\\ -p_1 & -p_2 & 8q_1^{-5}q_2 & -2q_1^{-4}-d & 0 \end{pmatrix}. \tag{82}$$

Hence, we have

$$\rho_1=\frac{\partial h_1}{\partial d}=q_2=-\lambda_1-\lambda_2, \qquad \rho_2=\frac{\partial h_2}{\partial d}=-\tfrac{1}{4}q_1^2=\lambda_1\lambda_2, \tag{83}$$

and then

$$q_1=2\sqrt{-\lambda_1\lambda_2}, \quad q_2=-\lambda_1-\lambda_2. \tag{84}$$

Introducing a generating function $S=2p_2\sqrt{-\lambda_1\lambda_2}-p_2(\lambda_1+\lambda_2)$ and inverting the system $\mu=\partial S/\partial\lambda$, we get the second part of the canonical transformation,

$$p_1=\sqrt{-\lambda_1\lambda_2}\left(\frac{\mu_1}{\Delta_1}+\frac{\mu_2}{\Delta_2}\right), \quad p_2=-\lambda_1\frac{\mu_1}{\Delta_1}-\lambda_2\frac{\mu_2}{\Delta_2}, \tag{85}$$

and hence

$$\begin{aligned} h_1&=\frac{\lambda_1(4\mu_1^2+\lambda_1^{-3})}{8\Delta_1}+\frac{\lambda_2(4\mu_2^2+\lambda_2^{-3})}{8\Delta_2}-d(\lambda_1+\lambda_2),\\ h_2&=-\frac{\lambda_2\lambda_1(4\mu_1^2+\lambda_1^{-3})}{8\Delta_1}-\frac{\lambda_1\lambda_2(4\mu_2^2+\lambda_2^{-3})}{8\Delta_2}+d\lambda_1\lambda_2. \end{aligned} \tag{86}$$

The Hamilton–Jacobi equations $h_i(\lambda,\partial W_i/\partial\lambda)=E_i$, $i=1,2$, are separable and have the complete integrals $W_i=\Sigma_{k=1}^{2}W_i^{(k)}(\lambda_k;c_0,c_1)$, where $W_i^{(k)}$ are solutions of the following equations:

$$\frac{dW_i^{(k)}}{d\lambda_k}=\left[\frac{1}{4\lambda_k}\left(-\lambda_k^{-2}+4d\lambda_k^2+c_1\lambda_k+c_0\right)\right]^{1/2},\quad c_{2-i}=8E_i,\quad i,k=1,2. \tag{87}$$

Example 3: Separability of the first Newton representation of the seventh-order stationary flow of the KdV.

We consider a Newton system,

$$\begin{aligned}0&=r_{1_{xx}}+10r_1^2-4r_2,\\ 0&=r_{2_{xx}}+16r_1r_2-10r_1^3-4r_3,\\ 0&=r_{3_{xx}}+20r_1r_3+8r_2^2-30r_1^2r_2+15r_1^4-c,\end{aligned} \tag{88}$$

with a related bi-Hamiltonian chain given by the conserved functions

$$\begin{aligned}h_0&=c,\\ h_1&=s_1s_3+\tfrac{1}{2}s_2^2+10r_1^2r_3-4r_2r_3+8r_1r_2^2-10r_1^3r_2+3r_1^5-cr_1,\\ h_2&=\tfrac{1}{2}r_3s_3^2-\tfrac{1}{2}r_1s_2^2+\tfrac{1}{2}r_2s_2s_3-\tfrac{1}{2}s_1s_2-\tfrac{1}{2}r_1s_1s_3+2r_1^2r_2^2+\tfrac{5}{2}r_1^4r_2-\tfrac{5}{4}r_1^6-2r_2^3+r_3^2-6r_1r_2r_3\\ &\quad+\tfrac{1}{4}cr_1^2+\tfrac{1}{2}cr_2,\\ h_3&=\tfrac{1}{8}r_2^2s_3^2+\tfrac{1}{8}r_1^2s_2^2+\tfrac{1}{8}s_1^2+\tfrac{1}{4}r_1s_1s_2+\tfrac{1}{4}r_2s_1s_3-\tfrac{1}{4}r_1r_2s_2s_3-\tfrac{1}{2}r_3s_2s_3-3r_1^3r_2^2+r_1r_2^3+\tfrac{5}{4}r_1^5r_2\\ &\quad+2r_3^2r_1+\tfrac{5}{4}r_1^4r_3+r_2^2r_3-r_1^2r_2r_3-\tfrac{1}{4}cr_1r_2-\tfrac{1}{4}cr_3,\end{aligned} \tag{89}$$

with the 7×7 Poisson matrices $\overline{\theta_0}$ and $\overline{\theta_1}$, where

$$\overline{\theta_1}=\begin{pmatrix}0&0&0&r_1/2&-1/2&0&s_3\\ 0&0&0&r_2/2&0&-1/2&s_2\\ 0&0&0&r_3&r_2/2&r_1/2&s_1\\ -r_1/2&-r_2/2&-r_3&0&s_2/2&s_3/2&c-\partial V/\partial r_1\\ 1/2&0&-r_2/2&-s_2/2&0&0&-\partial V/\partial r_2\\ 0&1/2&-r_1/2&-s_3/2&0&0&-\partial V/\partial r_3\\ -s_3&-s_2&-s_1&\partial V/\partial r_1-c&\partial V/\partial r_2&\partial V/\partial r_3&0\end{pmatrix}, \tag{90}$$

and $V(r)=10r_1^2r_3-4r_2r_3+8r_1r_2^2-10r_1^3r_2+3r_1^5$. This bi-Hamiltonian chain contains three nontrivial vector fields that commute in pairs. Integrals of motion also commute and are functionally independent, since the Jacobian $\det[\partial(h_1,h_2,h_3)/\partial(s_1,s_2,s_3)]$ does not vanish. Hence, we have

$$\begin{aligned}\rho_1&=\frac{\partial h_1}{\partial c}=-r_1=-\lambda_1-\lambda_2-\lambda_3,\\ \rho_2&=\frac{\partial h_2}{\partial c}=\frac{1}{4}r_1^2+\frac{1}{2}r_2=\lambda_1\lambda_2+\lambda_1\lambda_3+\lambda_2\lambda_3,\\ \rho_3&=\frac{\partial h_3}{\partial c}=-\frac{1}{4}r_1r_2-\frac{1}{4}r_3=-\lambda_1\lambda_2\lambda_3\end{aligned} \tag{91}$$

and then

$$r_1=\lambda_1+\lambda_2+\lambda_3,$$

$$r_2=(\lambda_1\lambda_2+\lambda_1\lambda_3+\lambda_2\lambda_3)-\tfrac{1}{2}(\lambda_1^2+\lambda_2^2+\lambda_3^2), \tag{92}$$

$$r_3=4\lambda_1\lambda_2\lambda_3+\tfrac{1}{3}(\lambda_1+\lambda_2+\lambda_3)[4(\lambda_1\lambda_2+\lambda_1\lambda_3+\lambda_2\lambda_3)-\tfrac{1}{3}(\lambda_1^2+\lambda_2^2+\lambda_3^2)].$$

From the appropriate generating function, we calculate

$$s_1=-\frac{1}{8}\left\{[(-3\lambda_1^2+\lambda_2^2+\lambda_3^2)+2(\lambda_1\lambda_2+\lambda_1\lambda_3-\lambda_2\lambda_3)]\,\frac{\mu_1}{\Delta_1}+\text{c.p.}\right\},$$

$$s_2=\frac{1}{4}\left[(-\lambda_1+\lambda_2+\lambda_3)\,\frac{\mu_1}{\Delta_1}+(\lambda_1-\lambda_2+\lambda_3)\,\frac{\mu_2}{\Delta_2}+(\lambda_1+\lambda_2-\lambda_3)\,\frac{\mu_3}{\Delta_3}\right], \tag{93}$$

$$s_3=\frac{1}{4}\left(\frac{\mu_1}{\Delta_1}+\frac{\mu_2}{\Delta_2}+\frac{\mu_3}{\Delta_3}\right),$$

where $\Delta_1=(\lambda_1-\lambda_2)(\lambda_1-\lambda_3),\ldots,$ and c.p. stands for cyclic permutations of the indices 1,2,3, in λ, μ, and Δ. The three Hamiltonians in the Nijenhuis coordinates take the form

$$h_1=\frac{f_1}{\Delta_1}+\frac{f_2}{\Delta_2}+\frac{f_3}{\Delta_3}-c(\lambda_1+\lambda_2+\lambda_3),$$

$$h_2=-\frac{(\lambda_2+\lambda_3)f_1}{\Delta_1}-\frac{(\lambda_1+\lambda_3)f_2}{\Delta_2}-\frac{(\lambda_1+\lambda_2)f_3}{\Delta_3}+c(\lambda_1\lambda_2+\lambda_1\lambda_3+\lambda_2\lambda_3), \tag{94}$$

$$h_3=\frac{\lambda_2\lambda_3 f_1}{\Delta_1}+\frac{\lambda_1\lambda_3 f_2}{\Delta_2}+\frac{\lambda_1\lambda_2 f_3}{\Delta_3}-c\lambda_1\lambda_2\lambda_3,$$

where $f_i(\lambda_i,\mu_i)=\frac{1}{8}(\mu_i^2+128\lambda_i^7)$. The appropriate Hamilton–Jacobi equations $h_i(\lambda,\partial W_i/\partial\lambda)=E_i$ are separable and have the complete integrals

$$W_i=\sum_{k=1}^{3} W_i^{(k)}(\lambda_k;c_0,c_1,c_2),\quad i=1,2,3, \tag{95}$$

with $W_i^{(k)}$ being solutions of the following equations:

$$\frac{dW_i^{(k)}}{d\lambda_k}=(-128\lambda_k^7+8c\lambda_k^3+c_2\lambda_k^2+c_1\lambda_k+c_0)^{1/2},\quad c_{3-i}=8E_i. \tag{96}$$

Example 4: Separability of the second Newton representation of the seventh-order stationary flow of the KdV.

Let us consider a Newton system,[12]

$$0=q_{1_{xx}}+10q_1^2-4q_2,$$

$$0=q_{2_{xx}}+20q_1q_2-10q_1^3+2q_3, \tag{97}$$

$$0=q_{3_{xx}}+4q_1q_3-dq_3^{-3}.$$

The related bi-Hamiltonian chain takes the form (50); h_r and $\overline{\theta}_{-1}$ are

$$h_1=-2p_1p_2-2p_3^2-20q_1^2q_2+4q_2^2+5q_1^4-4q_1q_3^2-dq_3^{-2},$$

$$h_2=-p_1^2-2q_1p_1p_2+2q_2p_2^2-2q_1p_3^2+2q_3p_2p_3+2q_1^2q_3^2-4q_2q_3^2-16q_1q_2^2+4q_1^5-2dq_2q_3^{-2},$$

$$h_3=-q_3^2p_2^2+2q_3p_1p_3+2q_1q_3p_2p_3-q_1^2p_3^2+8q_2p_3^2+q_3^4$$

$$+8q_1q_2q_3^2-4q_1^3q_3^2-dq_1^2q_3^{-2}-2dq_2q_3^{-2},$$

$$h_4=d, \tag{98}$$

and

$$\overline{\theta}_{-1}=\begin{pmatrix} 0 & 0 & 0 & 0 & 0 & -1/q_3 & A_1 \\ 0 & 0 & 0 & 1 & 0 & -q_1/q_3 & A_2 \\ 0 & 0 & 0 & -q_1/q_3 & -1/q_3 & B_1 & A_3 \\ 0 & -1 & q_1/q_3 & 0 & 0 & B_2 & A_4 \\ 0 & 0 & 1/q_3 & 0 & 0 & -p_3/q_3^2 & A_5 \\ 1/q_3 & q_1/q_3 & -B_1 & -B_2 & p_3/q_3^2 & 0 & A_6 \\ -A_1 & -A_2 & -A_3 & -A_4 & -A_5 & -A_6 & 0 \end{pmatrix}, \tag{99}$$

where

$$p_1=q_{2_x}, \quad p_2=q_{1_x}, \quad p_3=q_{3_x}, \quad (A_1,\ldots,A_6,0)^T=\overline{\theta}_0\circ\nabla h_3,$$

$$B_1=(q_1^2+2q_2)/q_3^2, \quad B_2=(q_3p_2-q_1p_3)/q_3^2.$$

Hence, we find

$$\begin{aligned} \tilde{\rho}_1&=-q_3^{-2}=-\frac{1}{\lambda_1\lambda_2\lambda_3}, \\ \tilde{\rho}_2&=-2q_1q_3^{-2}=\frac{1}{\lambda_1\lambda_2}+\frac{1}{\lambda_1\lambda_3}+\frac{1}{\lambda_2\lambda_3}, \\ \tilde{\rho}_3&=-q_1^2q_3^{-2}-2q_2q_3^{-2}=-\frac{1}{\lambda_1}-\frac{l}{\lambda_2}-\frac{1}{\lambda_3}, \end{aligned} \tag{100}$$

and then the Nijenhuis map

$$\begin{aligned} q_1&=-\tfrac{1}{2}(\lambda_1+\lambda_2+\lambda_3), \\ q_2&=\tfrac{1}{2}(\lambda_1\lambda_2+\lambda_1\lambda_3+\lambda_2\lambda_3)-\tfrac{1}{8}(\lambda_1+\lambda_2+\lambda_3)^2, \\ q_3&=(\lambda_1\lambda_2\lambda_3)^{1/2}, \\ p_1&=\lambda_1(-\lambda_1+\lambda_2+\lambda_3)\frac{\mu_1}{\Delta_1}+\lambda_2(\lambda_1-\lambda_2+\lambda_3)\frac{\mu_2}{\Delta_2}+\lambda_3(\lambda_1+\lambda_2-\lambda_3)\frac{\mu_3}{\Delta_3}, \\ p_2&=-2\left(\lambda_1\frac{\mu_1}{\Delta_1}+\lambda_2\frac{\mu_2}{\Delta_2}+\lambda_3\frac{\mu_3}{\Delta_3}\right), \\ p_3&=2(\lambda_1\lambda_2\lambda_3)^{1/2}\left(\frac{\mu_1}{\Delta_1}+\frac{\mu_2}{\Delta_2}+\frac{\mu_3}{\Delta_3}\right). \end{aligned} \tag{101}$$

The three Hamiltonians (98) in the Nijenhuis coordinates take the form

$$h_1=\frac{f_1}{\Delta_1}+\frac{f_2}{\Delta_2}+\frac{f_3}{\Delta_3}-d\,\frac{1}{\lambda_1\lambda_2\lambda_3},$$

$$h_2=-\frac{(\lambda_2+\lambda_3)f_1}{\Delta_1}-\frac{(\lambda_1+\lambda_3)f_2}{\Delta_2}-\frac{(\lambda_1+\lambda_2)f_3}{\Delta_3}+d\left(\frac{1}{\lambda_1\lambda_2}+\frac{1}{\lambda_1\lambda_3}+\frac{1}{\lambda_2\lambda_3}\right), \tag{102}$$

$$h_3=\frac{\lambda_2\lambda_3 f_1}{\Delta_1}+\frac{\lambda_1\lambda_3 f_2}{\Delta_2}+\frac{\lambda_1\lambda_2 f_3}{\Delta_3}-d\left(\frac{1}{\lambda_1}+\frac{1}{\lambda_2}+\frac{1}{\lambda_3}\right),$$

where $f_i(\lambda_i,\mu_i)=\lambda_i(\lambda_i^5-4\mu_i^2)$. The appropriate Hamilton–Jacobi equations $h_i(\lambda,\partial W_i/\partial\lambda)=E_i$ are separable and have the complete integrals

$$\frac{dW_i^{(k)}}{d\lambda_k}=\left[\frac{1}{4\lambda_k}\left(\lambda_k^6-c_2\lambda_k^2-c_1\lambda_k-c_0-\frac{d}{\lambda_k}\right)\right]^{1/2},\quad c_{3-i}=E_i,\quad k=1,2,3. \tag{103}$$

Example 5: A bi-Hamiltonian formulation for *elliptic separable potentials*. Present results allow us to reexamine the theory of classical Hamiltonian systems with separable potentials in the frame of the bi-Hamiltonian theory. In Refs. 19 and 20, there has been formulated and proved a theorem that says that the Hamilton–Jacobi equation for a natural Hamiltonian system $H=T+V(q)$ is separable in generalized elliptic coordinates if it has N functionally independent and commuting integrals of motion of the form

$$K_i(q,p)=\frac{1}{2}\sum_{j=1,j\neq i}^{N}(\alpha_i-\alpha_j)^{-1}l_{ij}^2+p_i^2+V_i(q)=P_i(q,p)+V_i(q), \tag{104}$$

where q_i,p_i are canonically conjugated variables, $l_{ij}=q_ip_j-q_jp_i$ $(i,j=1,...,N)$ are angular momenta, α_i are different, positive constants, and $V_i(q)$ are functions of $q=(q_1,\ldots,q_N)$ such that the Poisson brackets $\{H,K_i\}=0$, $i=1,...,N$. The Hamiltonian is given as

$$H=\frac{1}{2}\sum_{i=1}^{N}K_i(q,p)=\frac{1}{2}(p,p)+\sum_{i=1}^{N}\frac{1}{2}V_i(q)=T+V(q). \tag{105}$$

Then, in Ref. 17, a theorem was proved that says that every natural Hamiltonian system $H=T+V(q)$ separable in generalized elliptic coordinates admits, in the extended phase space of variables (q,p,c), the bi-Hamiltonian formulation

$$\begin{pmatrix} q\\ p\\ c\end{pmatrix}_t=\theta_0\circ\nabla h_1=\theta_1\circ\nabla h_0,\quad \theta_0=\begin{pmatrix}0 & I & 0\\ -I & 0 & 0\\ 0 & 0 & 0\end{pmatrix},$$
$$\theta_1=\begin{pmatrix}0 & A-\frac{1}{2}q\otimes q & q_t\\ -A+\frac{1}{2}q\otimes q & \frac{1}{2}p\otimes q-\frac{1}{2}q\otimes p & p_t\\ -q_t & -p_t & 0\end{pmatrix}, \tag{106}$$

where $A=\mathrm{diag}(\alpha_1,...,\alpha_N)$, $h_0=c$, $h_1=H+\frac{1}{2}c(q,q)$, and in the remaining column and row of θ_1 $q_t=\partial h_1/\partial p=p$, $p_t=-\partial h_1/\partial q=-\partial(V+\frac{1}{2}cq^2)/\partial q$ denote the components of the Hamiltonian vector field. The potential V satisfies the equations

$$0=(\alpha_i-\alpha_r)\frac{\partial^2 V}{\partial q_i\partial q_r}+\frac{3}{2}\left(q_r\frac{\partial V}{\partial q_i}-q_i\frac{\partial V}{\partial q_r}\right)+\frac{1}{2}\sum_{j=1}^{N}\left(q_jq_r\frac{\partial^2 V}{\partial q_i\partial q_j}-q_iq_j\frac{\partial^2 V}{\partial q_j\partial q_r}\right),\quad i,r=1,...,N, \tag{107}$$

which are the iff condition for θ_1 to fulfill the Jacobi identity.

This bi-Hamiltonian formulation generates an infinite chain of commuting bi-Hamiltonian vector fields,

$$\theta_0 \circ \nabla h_0 = 0, \ldots, \theta_0 \circ \nabla h_{r+1} = \theta_1 \circ \nabla h_r, \ldots, \quad r = 0,1,2,\ldots, \tag{108}$$

with $h_0 = c$ and

$$h_r = \frac{1}{2} \sum_{i=1}^{N} \alpha_i^{r-1} \tilde{K}_i = \frac{1}{2} \sum_{i=1}^{N} \alpha_i^{r-1} K_i + \frac{1}{2} c(q, A^{r-1} q), \quad r = 1,2,\ldots, \tag{109}$$

where $\tilde{K}_i = K_i + c q_i^2$ and K_i are given by (104). Moreover, we can define new Hamiltonians,

$$\tilde{h}_r = h_r + \sum_{k=1}^{r} \beta_{N-k} h_{r-k}, \quad r = 0,\ldots,N, \tag{110}$$

where β_r are solutions of the set of linear equations,

$$\alpha_i^N + \sum_{r=0}^{N-1} \beta_r \alpha_i^r = 0, \tag{111}$$

so that the new chain starts with $\tilde{h}_0 = h_0 = c$, a Casimir of θ_0, and terminates with

$$\tilde{h}_N = \beta_0 \left(\frac{1}{2} \sum_{i=1}^{N} \alpha_i^{-1} \tilde{K}_i - c \right), \tag{112}$$

which is a Casimir of θ_1.

Here we prove the inverse statement that each bi-Hamiltonian chain (106) is separable in generalized elliptic coordinates. Let us construct the Nijenhuis coordinates. The solution to the set of equations (111) takes the form

$$\beta_{N-r} = (-1)^r \sum_{\substack{j_1,\ldots,j_r \\ j_1 < \ldots < j_r}} \alpha_{j_1} \cdot \cdots \cdot \alpha_{j_r} := \rho_r(\alpha), \quad \beta_N = 1. \tag{113}$$

Hence, the c-dependent part of

$$\tilde{h}_r(q,p,c;\alpha) = \tilde{h}_r(q,p;\alpha) + c \rho_r(q;\alpha) \tag{114}$$

reads as

$$\rho_r(q;\alpha) = \beta_{N-r} + \frac{1}{2} \sum_{k=0}^{r-1} \beta_{N-k}(q, A^{r-k-1} q), \tag{115}$$

and defines the Nijenhuis coordinates (48) through the relation

$$\rho_r(\alpha) + \frac{1}{2} \sum_{k=0}^{r-1} \rho_k(\alpha)(q, A^{r-k-1} q) = \rho_r(\lambda). \tag{116}$$

But so defined Nijenhuis coordinates are just the generalized elliptic coordinates. Indeed, the generalized elliptic coordinates $\lambda_1, \ldots, \lambda_N$ defined by the relation[20]

$$1 + \frac{1}{2} \sum_{k=1}^{N} \frac{q_k^2}{z - \alpha_k} = \frac{\Pi_{j=1}^{N} (z - \lambda_j)}{\Pi_{k=1}^{N} (z - \alpha_k)}, \tag{117}$$

are equivalent to the Nijenhuis coordinates defined by relations (116). To see this let

$$A(z) := \prod_{k=1}^{N} (z - \alpha_k) = \sum_{r=0}^{N} \rho_r(\alpha) z^{N-r},$$

$$\Lambda(z) := \prod_{k=1}^{N} (z-\lambda_k) = \sum_{r=0}^{N} \rho_r(\lambda) z^{N-r}, \tag{118}$$

$$A_k(z) := \frac{A(z)}{z-\alpha_k} = \sum_{r=1}^{N} \rho_{r-1}^{k}(\alpha) z^{N-r},$$

where

$$\rho_r^i(\alpha) = (-1)^r \sum_{\substack{j_1,\ldots,j_r \\ j_1<\ldots<j_r \\ j_1\neq i,\ldots,j_r\neq i}} \alpha_{j_1} \cdot \cdots \cdot \alpha_{j_r}.$$

From (117), it follows that

$$\begin{aligned}\Lambda(z) = A(z) + \sum_{k=1}^{N} A_k(z) q_k^2 &= \sum_{r=0}^{N} \rho_r(\alpha) z^{N-r} + \frac{1}{2} \sum_{k=1}^{N} \sum_{r=1}^{N} \rho_{r-1}^{k}(\alpha) z^{N-r} q_k^2 \\ &= z^N + \sum_{r=1}^{N} \left[\rho_r(\alpha) + \frac{1}{2} \sum_{k=1}^{N} \rho_{r-1}^{k}(\alpha) q_k^2 \right] z^{N-r}. \end{aligned} \tag{119}$$

Comparing the coefficients standing by the same powers of z and applying the relation

$$\sum_{l=0}^{r} \rho_l(\alpha) \alpha_i^{r-l} = \rho_r^i(\alpha), \tag{120}$$

we get

$$\begin{aligned}\rho_r(\lambda) = \rho_r(\alpha) + \frac{1}{2} \sum_{k=1}^{N} \rho_{r-1}^{k}(\alpha) q_k^2 &= \rho_r(\alpha) + \frac{1}{2} \sum_{k=1}^{N} \sum_{l=0}^{r-1} \rho_l(\alpha) \alpha_k^{r-l-1} q_k^2 \\ &= \rho_r(\alpha) + \frac{1}{2} \sum_{l=0}^{r-1} \rho_l(\alpha) (q, A^{r-l-1} q), \end{aligned} \tag{121}$$

that is, relation (116).

The basic example here is the Garnier system, with the potential $V^{(2)}(q) = \frac{1}{4}(q,q)^2 + \frac{1}{2}(q,Aq)$. Its bi-Hamiltonian formulation with the bi-Hamiltonian infinite chain is the special case of the system (106) and the chain (108), (109). This potential is a member of an infinite family of permutationally symmetric potentials separable in generalized elliptic coordinates that were found and characterized recursively in Ref. 20. This family contains, for instance, $V^{(3)}(q) = \frac{1}{8}(q,q)^3 - \frac{1}{2}(q,q)(q,Aq) + \frac{1}{2}(q,A^2q)$ and $V^{(-1)}(q) = [1 - \frac{1}{2}(q,A^{-1}q)]^{-1}$. All these potentials come up as constraint spectral problems of the coupled KdV systems and their bi-Hamiltonian formulation has been initially derived in Ref. 5. Nevertheless, all potentials, not necessarily related to the coupled KdV hierarchies, which have the bi-Hamiltonian formulation given in (106), are separable in generalized elliptic coordinates (117).

(Received 20 May 1997; accepted for publication 2 February 1998)

Solutions of a nonlinear system of differential partial equations in two-dimensional space are studied. We prove that the considered system is fully integrable and that its solutions determine an infinite class of mappings of the space of curvilinear axially symmetric coordinates onto the space of cylindric coordinates. The corresponding family of reverse transformations is found in a closed form. An infinite number of the first integrals of the nonlinear system is obtained. Symmetries of a class of electrostatic systems associated with the considered family of curvilinear coordinates are discussed. © *1998 American Institute of Physics.*

I. INTRODUCTION

The theory of the solvable nonlinear partial differential equations have been initiated by finding analytic solutions of the Korteweg–de Vries's equation.[1] General tools for the investigation of solvable nonlinear systems have been found.[2–4] Actually, there is a rich literature discussing a large number of interesting examples of solvable nonlinear partial equations and presenting the application of these systems to studying solitons dynamics and the theory of instantons.[3–9]

The main aim of this work is the investigation of the possibility of applying Lax's formalism to the study of a space of the axially symmetric surfaces in the three-dimensional space. In particular, we want to answer the following two questions: (a) Does there exist the Poisson action for which we can find a complete system of mutually commuting functionals? (b) Is it possible to distinguish a class of the curvilinear coordinates that are a geometric generalization of the spherical ones?

The solution of these problems appears to be related with the discussion of the following equation:

$$\partial_q{}^2 \ln \rho^2 + \partial_c{}^2 \rho^2 = 0, \tag{1.1}$$

where ρ is the real function of coordinates $(q,c) \in M$:

$$M = \{(q,c), \infty > q \geqslant 0, |c| \leqslant 1\}. \tag{1.2}$$

Space S_ρ of the solution of Eq. (1.1) that we will investigate is defined as follows:

$$\rho \in S_\rho: \ \rho^2(q,c) = \frac{1-c^2}{q^2}\, w(q,c), \quad w(q,c) = 1 + \sum_{n=1}^{\infty} w_n(c) q^n, \tag{1.3}$$

where functions $w_n(c)$ are polynomials. Equation (1.1) formulates the condition of integrability for differential form dz given by the relation

$$dz(q,c) = \rho \rho_{,c}\, dq - (\rho_{,q}/\rho) dc. \tag{1.4}$$

Denoting $\partial_q f = \dot{f}$ and $\partial_c f = f'$, we immediately see that the pair of functions z, ρ results from the system of equations

 © 1998 American Institute of Physics

$$\dot{z}=\rho\rho', \quad \dot{\rho}=-\rho z'. \tag{1.5}$$

An essential point of the discussion of solution S: $\rho\in S_\rho$ is based on the Lax's theory, and it is presented in Sec. III. The result of this section proves that system (1.5) can be presented as an infinite-dimensional Hamiltonian system for which the pair of functions $(z(c),\rho(c))$ plays the role of canonical coordinates while variable q is the evolution parameter giving a mapping $q\mapsto(z(c,q),\rho(c,q))$. This Hamiltonian system is fully integrable. We will prove this by constructing an infinite set of commuting functionals $H_n:(z,\rho)=G\mapsto J_n=J_n(G)\in R$, $n=1,2,...$, $J=(J_1,J_2,\ldots)$.

One of the possible interpretations of functions z,ρ and coordinates q,c is shortly discussed below and will be studied in Sec. II. In Sec. II we will show that interpretation results from the considering classes of axially symmetric curvilinear coordinates in R^3 space. We will call them q coordinates and let $\mathbf{q}_f=(q_f,c_f,\varphi)$ be some elements of this class. The space of q coordinates is obtained by considering the following conditions:

$$\mathbf{q}_f\in N=M\times(0,2\pi), \tag{1.6a}$$

$$*dq_f=dc_f\wedge d\varphi, \tag{1.6b}$$

where $*$ is the Hodge isomorphism (see Sec. II). For all q coordinates the metric tensor g and the volume element $d\mu(q,c,\varphi)$ have a very specific simple form:

$$g(q,c,\varphi)=\mathrm{diag}(g_q,g_q/\rho^2,\rho^2), \quad g_q(q,c)=\rho_{,q}^2+(\rho\rho_{,c})^2, \tag{1.7}$$

$$d\mu(q,c,\varphi)=g_q(q,c)dqdcd\varphi, \tag{1.8}$$

where functions $\rho(q,c)\in\overline{S_\rho}\subset S_\rho$, and for simplicity, label f has been omitted.

Simultaneously, if coordinates z,ρ,φ are interpreted as standard cylindric coordinates then elements $(z(q,c),\rho(q,c))$ define the coordinates transformation G,

$$G: \quad N\ni(q,c,\varphi)\mapsto(z,\rho,\varphi)\in D, \tag{1.9}$$

where D denotes the space of cylindrical coordinates. The simplest example of q coordinates is obtained through substitution:

$$q_e=r^{-1}=\frac{1}{\sqrt{\rho^2+z^2}}, \quad c_e=z/r, \quad \varphi=\arctan(y/x). \tag{1.10}$$

Here, x,y,z are Cartesian coordinates. The latter coordinates are called nondeformed q coordinates and they are an elementary modification of spherical coordinates. For all other q coordinates the solution of equation $q_f=\mathrm{const}$ leads to families of an axially symmetric closed surface prolate—deformed along the z axis.

The problem of consistency of condition (1.6a) with condition (1.6b) is not trivial and it is studied in Sec. II. This consistency is the result of an explicit construction of an infinite set of mappings F_f, $f\in\mathscr{F}$, of space D onto space N:

$$F_f: \quad D\ni(z,\rho,\varphi)\mapsto(q,c,\varphi)\in N. \tag{1.11}$$

Specific properties of the family of q coordinates are revealed under their application to studying the Poisson equation.

Let $\Psi(z,\rho)$ be the electric potential in the cylindrical frame, (f,ϕ)—the subspace of electrostatic states where $\phi(\mathbf{q})\equiv\phi(q)$ is the potential in the q frame of coordinates, while f determines the transformation F_f of $D\mapsto N$, i.e., let us have $\Psi=\phi\circ F_f$. Considering the integral of Coulomb energy for state (f,ϕ) and performing the transformation of coordinates to q coordinates, one finds

$$\mathscr{E}(f,\phi)=\frac{1}{8\pi}\int_{R^3}d^3x\mathbf{E}^2(\mathbf{x})=\frac{1}{8\pi}\int_N d\mu(q,c,\varphi)g^{qq}[\phi'(q)]^2=\frac{1}{2}\int_0^\infty dq[\phi'(q)]^2. \tag{1.12}$$

For all (f,ϕ) states this integral is factorized into the ''radial part''×''angular part.'' The angular factor is equal to 4π. Coulomb energy depends on the choice of function ϕ only. Thus, Coulomb energy is an invariant of transformations: $(f,\phi)\mapsto(\overline{f},\phi)$.

There is one more interesting and rather unexpected symmetry of (f,ϕ) states that stems from the hidden symmetry of equations (1.5). Consider spherical moments of charge density $\varrho_f(\mathbf{q})$. From the Poisson equation and Eq. (1.7), we get

$$\varrho_f(\mathbf{q})=-\frac{1}{4\pi\sqrt{|g|}}\frac{\partial}{\partial q^\alpha}g^{\alpha\beta}\sqrt{|g|}\frac{\partial}{\partial q^\beta}\phi_f(q)=-\frac{1}{4\pi g_q}\phi_f''(q). \tag{1.13}$$

Let $\mathscr{Q}_l(f,\phi)$ denote moments associated with spherical functions: $Q_l=r^lP_l(\cos\theta)$, and $\overline{h_l}(z,\rho)$ be homogeneous polynomials of degree n obtained by the transformation of coordinates:

$$\overline{h_l}(z,\rho)=r^l(z,\rho)P_l(z/r(z,\rho)). \tag{1.14}$$

Then, in the frame of cylindrical coordinates we have

$$\mathscr{Q}_l(f,\phi)=2\pi\int_{-\infty}^\infty\int_0^\infty dzd\rho\rho\overline{h_l}(z,\rho)(\varrho_f\circ F_f)(z,\rho), \tag{1.15}$$

and changing the latter into $\mathbf{q}_f$ [see Eqs. (1.8) and (1.13)], we get

$$\mathscr{Q}_l(f,\phi)=-\frac{1}{2}\int_0^\infty dq\,\phi_f''(q)\times H_l(G_f), \tag{1.16}$$

where

$$H_l(G_f)=\int_{-1}^1 dc(\overline{h_l}\circ G_f)(q,c),\quad G_f\in\{G\}:G_f\circ F_f=\mathrm{id}. \tag{1.17}$$

In Sec. III we will prove that $H_l(G_f)$ are just invariant functionals of the Lax's system (1.5); thus they are independent of coordinate q. Hence, integrals $\mathscr{Q}_l(\varrho_f)$ are also factorized into the ''radial part''×''angular part.''

In the same section we find too that $H_0(G_f)\equiv 2$; hence the total charge Q_0 is equal to $\mathscr{Q}_0(\phi)=\phi'(0)-\phi'(\infty)$, and we can rewrite Eq. (1.16) in the form

$$\mathscr{Q}_l(f,\phi)=\tfrac{1}{2}H_l(G_f)Q_0(\phi). \tag{1.18}$$

As we can see, only constant Q_0 depends on potential functions ϕ, so if $Q_0(\phi)=Q_0(\overline{\phi})$ then $\mathscr{Q}_l$ are invariants of the transformations $(f,\phi)\mapsto(f,\overline{\phi})$.

In the Appendix we discuss solutions for polynomials $w_n(c)$ [see Eq. (1.3)], and we find the recurrence algorithm for obtaining them. Coefficients of polynomials $w_n(c)$ are functions of some constants $I_2,I_3,\ldots,I_n$. We present explicit expressions for a few lowest polynomials and we find values of functionals H_n for a few lowest values of parameter n.

II. THE CLASS OF q COORDINATES

The Hodge isomorphism * in the three-dimensional space associates the space of one-forms with the space of two-forms. For basis one-forms dq^i, we have

$$*dq^i=\frac{1}{2}\sqrt{|g|}(g)^{ij_1}\epsilon_{j_1j_2j_3}dq^{j_2}\wedge dq^{j_3}, \tag{2.1}$$

where $g=g(\mathbf{q})$ is a matrix of the metric tensor and $(g)^{ij}$ are elements of the reverse matrix $(g)^{-1}$. In the frame of cylindrical coordinates the metric tensor $g_{\mathrm{cyl}}(z,\rho,\varphi)=\mathrm{diag}(1,1,\rho^2)$; hence, for the squared length element we get

$$ds^2(dz,d\rho,d\varphi)=dz^2+d\rho^2+\rho^2 d\varphi^2, \tag{2.2}$$

Considering transformations G of q coordinates into cylindrical coordinates, we obtain

$$(G^*ds^2)(dq,dc,d\varphi)=g_{ij}(\mathbf{q})dq^i dq^j=(z_{,q}^2+\rho_{,q}^2)dq^2+2(z_{,q}z_{,c}+\rho_{,q},\rho_{,c})dqdc + (z_{,c}^2+\rho_{,c}^2)dc^2+\rho^2 d\varphi^2, \tag{2.3}$$

Applying the last formula to Eq. (2.1), we find

$$^*dq=\frac{\rho}{|z_{,q}\rho_{,c}-z_{,c}\rho_{,q}|}\,[(z_{,c}^2+\rho_{,c}^2)dq^{c\varphi}-(z_{,q}z_{,c}+\rho_{,q}\rho_{,c})dq^{\varphi q})], \tag{2.4}$$

where, for brevity, we denoted $dq^i\wedge dq^j=dq^{ij}$. Comparing this result with condition in Eq. (1.6b), we get

$$\frac{\rho(z_{,c}^2+\rho_{,c}^2)}{|z_{,q}\rho_{,c}-z_{,c}\rho_{,q}|}=1, \quad z_{,q}z_{,c}+\rho_{,q},\rho_{,c}=0, \tag{2.5}$$

and after eliminating function $z_{,q}$ from the latter equation we arrive at

$$0=\rho_{,q}\rho_{,c}^2/\rho+\rho_{,c}^2 z_{,c}+(\rho_{,q}/\rho)z_{,c}^2+z_{,c}^3=(z_{,c}+\rho_{,q}/\rho)(z_{,c}^2+\rho_{,c}^2). \tag{2.6}$$

Hence, because the second factor is positive we obtain the pair of Eqs. (1.5): $\rho_{,q}=-\rho z_{,c}$, $z_{,q}=\rho\rho_{,c}$. This proves immediately the validity of Eqs. (1.1,1.4) and (1.7). Considering reverse transformations F described by functions $q(z,\rho)$ and $c(z,\rho)$ and the rules of composition for matrices describing the tangent transformations dF and dG, we get

$$\frac{q_{,z}}{c_{,\rho}}=\frac{\rho_{,c}}{z_{,q}}=\frac{1}{\rho}, \quad \frac{q_{,\rho}}{c_{,z}}=\frac{z_{,c}}{\rho_{,q}}=-\frac{1}{\rho}\,; \tag{2.7}$$

hence,

$$\rho q_{,z}-c_{,\rho}=0, \quad \rho q_{,\rho}+c_{,z}=0, \tag{2.8}$$

which lead to the system of differential equations,

$$dq(z,\rho)=\frac{1}{\rho}\,(c_{,\rho}dz-c_{,z}d\rho), \tag{2.9}$$

$$dc(z,\rho)=-\rho(q_{,\rho}dz-q_{,z}d\rho). \tag{2.10}$$

Let us consider the conditions of integrability of differentials dz and dq. They read as

$$0=\frac{1}{\rho}\,(c_{,zz}+c_{,\rho\rho}-c_{,\rho}/\rho), \tag{2.11a}$$

$$0=\rho(q_{,zz}+q_{,\rho\rho}+q_{,\rho}/\rho). \tag{2.11b}$$

Equation (2.11b) is fulfilled identically for $\rho=0$. For the $\rho>0$ function q has to satisfy the three-dimensional cylindrical Laplace equation. Thus, function $q(z,\rho)$ is electrical potential that we obtain by considering a charged string placed along the z axis: $\varrho_e(x,y,z)=\delta(x)\delta(y)f(z)$. It enables us to write a complete solution of system (2.9),(2.10) in the following form:

$$q_f(z,\rho)=q(z,\rho)=\int_{-\infty}^{\infty} dtf(t)\ \frac{1}{\sqrt{(z-t)^2+\rho^2}}, \tag{2.12}$$

$$c_f(z,\rho)=c(z,\rho)=\int_{-\infty}^{\infty} dtf(t)\ \frac{z-t}{\sqrt{(z-t)^2+\rho^2}}. \tag{2.13}$$

Let us consider functions (q_f,ρ_f) as elements of a family of transformation F_f, $f\in\mathscr{F}$, where $\mathscr{F}$ is define as follows: (a) $f>0$, (b) $\int_R f=1$, and (c) supp $f=\cup_{i=1}^{p}[a_i,b_i]$, $a_i<b_i<a_{i+1}$, (support).

Introducing the notation $Z(m)=\{(z,\rho),z\in m,\rho=0\}$, $M(h,g)=\{(q,c),q\in h,c\in g\}$ and taking into account the formula

$$c(z,0)=\lim_{\rho\to 0} c(z,\rho)=\int_R dtf(l)\mathrm{sgn}(z-t)=-1+2\int_{-\infty}^{z} dtf(t), \tag{2.14}$$

we find that F_f are one-to-one mappings of the following sets:

$$D_1=Z(\{z,z<a_1\})\leftrightarrow M(R^+,-1)=M_1, \tag{2.15}$$

$$D_2=Z(\text{supp } f)\leftrightarrow M(\infty,[-1,1])=M_2, \tag{2.16}$$

$$D_3=Z(\{z,z>b_p\})\leftrightarrow M(R^+,-1)=M_3, \tag{2.17}$$

$$D_4=\lim_{r\to\infty}\{(z,\rho),z^2+\rho^2=r^2\}\leftrightarrow M(0,[-1,1])=M_4. \tag{2.18}$$

For Jacobian $J(z,\rho)$ of transformations F_f, we find

$$J(z,\rho)=q_{,z}c_{,\rho}-q_{,\rho}c_{,z}=\rho(q_{,z}^2+q_{,\rho}^2),\quad J>0 \quad \text{if } \rho>0; \tag{2.19}$$

hence, if $p=1$ then F_f: $\partial D\mapsto\partial M$ and F_f are one-to-one transformations of the space of cylindrical coordinates D onto M [see Eq. (1.2)].

Let us consider the case $p>1$. Then, in each interval $b_i\leqslant a_{i+1}$ there exists a single point z_i: $q_{,z}(z_i,0)=q_{,\rho}(z_i,0)=0$, $F_f(z_i,0)=(q_i,c_i)$. Using formula (2.14) we get

$$F_f(Z([b_i,z_i]))=F_f(Z([z_i,a_{i+1}])=M([q_i,\infty],c_i)=N_i, \tag{2.20}$$

which shows that functions $z(q,c)$ are discountinous at points of one-dimensional set $N=\cup_{i=1}^{p-1}N_i$. All other conclusions about transformations F_f and F_f^{-1} remain unchanged, hence points (a)–(c) and Eqs. (2.12) and (2.13) define a class of coordinates $\mathbf{q}_f$ that were postulated in (1.6a) and (1.6b).

III. LAX'S SYSTEM

The class of q coordinates studied in the previous section forms an infinite family. Below we will discuss a family of reverse transformations G: $(q,c)\to(z,\rho)$. Functions (z,ρ) describing these transformations obey a pair of nonlinear partial equations (1.5). Because set $\{G\}$ must also consist of an infinite family we can expect that these equations are integrable.

Below we develop Lax's formalism for discussing this question. The basic point of this idea is determining a Poisson algebra for functions z,ρ and then obtaining Eq. (1.5) as a pair of Hamiltonian equations, i.e., let us have

$$\dot{z}=\{z,H\},\quad \dot{\rho}=\{\rho,H\}, \tag{3.1}$$

and let Poisson brackets be defined by the following relations:

$$\{z(c),z(\overline{c})\}=\{\rho(c),\rho(\overline{c})\}=0, \tag{3.2}$$

$$\{\rho(c),z(\overline{c})\}=\rho(c)\,\delta'(\overline{c}-c), \tag{3.3a}$$

$$\{z(c),\rho(\overline{c})\}=\rho(\overline{c})\,\delta'(\overline{c}-c), \tag{3.3b}$$

where $\delta'(x)\equiv-\delta'(-x)$ denotes derivative of Dirac distribution. The introduced Poisson brackets obey Jacobi conditions: $W(A,B,C)=0$ for arbitrary elements A,B,C, where

$$W(A,B,C)=\{A,\{B,C\}\}+\{B,\{C,A\}\}+\{C,\{A,B\}\}. \tag{3.4}$$

Indeed, we have

$$W(z(a),z(b),\rho(c))=\rho(c)\,\delta'(b-c)[\,\delta'(a-c)+\delta'(c-a)\,]=0, \tag{3.5}$$

while all remaining Jacobi conditions are fulfilled trivially. The physics interpretation of Eqs. (3.1) is to be found through considering the space of curves (or axially symmetric surfaces) $\{\Gamma\}$, $\Gamma=\{[-1,1]\ni c\mapsto(z(c),\rho(c))\}$. For given $\Gamma_0=\Gamma(q_0)$ they determine the evolution of this curve: $q\mapsto\Gamma(q)$.

Theorem 1: (a) *Let* $\{\overline{\Gamma}\}$ *denote subspace of a set* $\{\Gamma\}$ *of curves* Γ: $[-1,1]\in c\to(z(c),\rho(c))$ *for which* $\rho(\pm1)=0$, $\mathscr{H}=\{H_n(\Gamma)\}$ *is a set of functionals:*

$$H_l(\Gamma)=\int_{-1}^{1}dc(h_l\circ\Gamma)(c),\quad l=0,1,2,..., \tag{3.6}$$

$$h_l(z,\rho)=\sum_{m=0}^{[l/2]}h_{lm}z^{l-2m}\rho^{2m},\quad h_{lm}=\frac{(-4)^{-m}l!}{(l-2m)!m!^2}, \tag{3.7}$$

and let $A=(\mathscr{H},\{,\})$ *denote the algebra of a group of transformations of* $\{\overline{\Gamma}\}$.

(a) $\{\overline{\Gamma}\}$ *is an A-invariant subspace of* $\{\Gamma\}$; (b) *algebra A is Abelian on* $\{\overline{\Gamma}\}$; (c) *Eqs. (1.5) and (3.1) coincide if*

$$H=\frac{1}{2}H_2=\frac{1}{4}\int_{-1}^{1}d\overline{c}[2z^2(\overline{c})-\rho^2(\overline{c})]; \tag{3.8}$$

(d) *for* $\Gamma_q=G(q,c)$ *being a solution of Eqs. (1.5) integrals* $H_l(\Gamma_q)$ *do not depend on q.*

Proof: Functions $h_n(z,\rho)$ obey the following relations:

$$h_{n,z}=nh_{n-1},\quad \rho h_{n,\rho}=n(h_n-zh_{n-1}), \tag{3.9}$$

$$(n+1)h_{n+1}-(2n+1)zh_n+n(z^2+\rho^2)h_{n-1}=0. \tag{3.10}$$

For functionals

$$A=\int_{-1}^{1}dca(z,\rho), \tag{3.11}$$

Poisson brackets $\{x^i(c),A\}$, $(x^1=z,\ x^2=\rho)$, are obtained from the textbook expression

$$\{x^i(c),A\}=\sum_j\int_{-1}^{1}d\overline{c}a_{,j}(\mathbf{x}(\overline{c}))\{x^i(c),x^j(\overline{c})\}. \tag{3.12}$$

Hence,

$$\{z(c),H_k\}=\int_{-1}^{1}d\overline{c}.\mathscr{H}_{k,\rho}(\overline{c})\rho(\overline{c})\,\delta'(\overline{c}-c)=-(d_c\rho.\mathscr{H}_{k,\rho})(c), \tag{3.13}$$

$$\{\rho(c),H_k\}=\rho(c)\int_{-1}^{1}d\overline{c}.\mathscr{H}_{k,z}(\overline{c})\,\delta'(\overline{c}-c)=-(\rho d_c.\mathscr{H}_{k,z})(c), \tag{3.14}$$

where $d_c = z' d_z + \rho' d_\rho$ and $\mathscr{H}_{l,i}(c) = (h_{l,i} \circ \Gamma)(c)$. While arriving at the last formulas, we used integration by parts and the fact that function ρ vanishes at the integration boundary. Using relations (3.9) we can present this result in the form

$$\begin{pmatrix} \{z, H_k\} \\ \{\rho, H_k\} \end{pmatrix} = -k\rho \begin{pmatrix} h_{k-1,\rho} & -h_{k-1,z} \\ h_{k-1,z} & h_{k-1,\rho} \end{pmatrix} \begin{pmatrix} z' \\ \rho' \end{pmatrix}, \tag{3.15}$$

from which we immediately see the equivalence of Eq. (1.5) and Eqs. (3.1) and (3.8). Next, we have

$$\{h_l, H_k\} = h_{l,z}\{z(c), H_k\} + h_{l,\rho}\{\rho(c), H_k\} = -(k-1)kl(A_{lk} z' + B_{lk} \rho'), \tag{3.16}$$

where

$$A_{lk} = h_{k-1} h_{l-1} - 2h_{k-2} h_{l-1} z + h_{k-2} h_{l-1}, \tag{3.17}$$

$$B_{lk} = \frac{1}{\rho} [h_{k-1} h_l - z(h_{k-1} h_{l-1} + h_{k-2} h_l) + (z^2 - \rho^2) h_{k-2} h_{l-1}], \tag{3.18}$$

and where A_{lk} as well as B_{lk} are polynomials of variables z, ρ. If we define

$$\Omega_{lk} = \rho(\partial_\rho A_{lk} - \partial_z B_{lk}), \tag{3.19}$$

then, with the help of formulas (3.9), we arrive at

$$\begin{aligned} \Omega_{lk} &= (k+1) h_{k+1} h_l + (l+1) h_k h_{l+1} - 2(k+l+1) z h_k h_l + (z^2 + \rho^2)(l h_k h_{l-1} + k h_{k-1} h_l) \\ &= h_k[(l+1) h_{l+1} - (2l+1) z h_l + l(z^2 + \rho^2) h_{l-1}] \\ &\quad + h_l[(k+1) h_{k+1} - (2k+1) z h_k + k(z^2 + \rho^2) h_{k-1}] \\ &= 0. \end{aligned}$$

In the last step we used Eq. (3.10). This result proves that the two terms on the right-hand side of formula (3.16) give derivative d_c, i.e. we have

$$\{h_l, H_k\} = \frac{d}{dc} U_{lk}(z, \rho), \tag{3.20}$$

where functions U_{lk} are homogeneous polynomials of variables z, ρ obtained from the formula

$$U_{lk}(z, \rho) = -(k-1)kl\left(\int_a^z ds A_{lk}(s, \rho) + \int_0^\rho dt B_{lk}(a, t) \right), \tag{3.21}$$

We have $h_l(z,0) = z^l$, $A_{lk}(z,0) = 0$; hence $U_{lk}(z,0) = 0$. Integrating formula (3.20), we get

$$\{H_l, H_k\} = \int_{-1}^{1} dc \{h_l, H_k\} = U_{lk}(z, \rho) \Big|_{c=-1}^{c=1} = U_{lk}(z,0)|_{c=-1}^{c=1} = 0, \tag{3.22}$$

which completes the proof point (c). Then we get immediately point (d): $2\dot{H}_m = \{H_m, H_2\} = 0$. The second equation in formulas (3.15) has the following form: $\dot{\rho} = \rho F_n$. Hence, if $\Gamma(q_0) \in \{\Gamma\}$ then all derivatives $(d_q^p \rho)(\pm 1)$ must vanish and for all q: $\Gamma(q) \in \{\Gamma\}$; thus the point (a) is fulfilled too.

Below we present the result of explicit calculation of the values of integrals H_n. They are obtained using the solution given in the Appendix. H_n are functions of a set of constants I. Let H_n' be the value of H_n for $I_1 = 0$. Then we have

$$H_0' = 2, \quad H_1' = 0, \quad H_2' = I_2, \quad H_3' = \tfrac{3}{2} I_3, \quad H_4' = I_2^2 + 2I_4, \quad H_5' = 5I_2 I_3 + \tfrac{5}{2} I_5,$$

$$H_6'=I_2^3+\frac{9}{2}I_3^2+6I_2I_4+3I_6, \quad H_7'=\frac{21}{2}I_2^2I_3+\frac{63}{5}I_3I_4+\frac{21}{2}I_2I_5+\frac{7}{2}I_7,$$

and

$$H_n(I)=\sum_{k=0}^{n}\binom{n}{k}H'_{n-k}(I_1)^k. \tag{3.23}$$

The structure of these relations is very simple: $H_l=\gamma_k I_k+\psi_k(I_1,\ldots,I_{k-1})$. Mappings $H_l\to c^l H_l$, $I_l\to c^l I_l$ are symmetry transformations of Eq. (3.23). The one nontrivial observation results from the above numerical calculus: $\gamma_l=l/2\neq 0$. The nonvanishing of coefficients γ_l leads immediately to one-to-one correspondence between the elements of set I and between the elements of set of constants $H=\{H_1,H_2,\ldots\}$. Hence, H is the complete set of the first integrals of equations (1.5) in respect to the considered class of solutions.

The proof of this fact for all n results from noticing that in Eq. (A8) only the first term in round parentheses gives contributions to function ρ, which are proportional to I_n, and that the appropriate numerical coefficients are known. However, details of this proof will not be discussed here.

Polynomials $h_n(z,\rho)$ are homogeneous functions of degree n. The recurrence relation (3.10) shows that $h_n(x,\sqrt{1-x^2})=P_n(x)$; hence h_n and polynomials h_n appearing in Eq. (1.14) coincide. This conclusion proves the validity of formulas (1.14)–(1.18).

Formula (1.18) shows that the spherical moments $\mathcal{O}(f,\phi)$ are invariants of transformations $(f,\phi)\mapsto(f,\tilde{\phi})$: $Q_0(\phi)=Q_0(\tilde{\phi})$. Taking into account the above fact and noticing that for $\tilde{\phi}(q)=q$ we have $\rho(f,\tilde{\phi})(z,\rho)=f(z)\delta(\rho)/(2\pi\rho)$, we can change $\phi\to Q_0(\phi)q$ and calculate moments $\mathcal{O}_l$ in an elementary way in the frame of cylindrical coordinates. We get

$$\mathcal{O}_l(f,\phi)=\mathcal{O}_l(f,Q_0(\phi)q)=f_l(f)Q_0(\phi), \quad f_l(f)=\int_{-\infty}^{\infty}dt\,t^l f(t). \tag{3.24}$$

Comparing this result to formula (1.18), we find

$$f_l=\tfrac{1}{2}H_l(I), \quad l=0,1,\ldots. \tag{3.25}$$

The last formula enables us to express parameters of the solution for functions z,ρ by moments f_n describing transformation F_f. This means that for all q-coordinates $\mathbf{q}_f(z,\rho,\varphi)$ we can find reverse transformations G_f: $G_f\circ F_f=\mathrm{id}$, and we can calculate elements of the metric tensor $g(\mathbf{q}_f)$ [see Eq. (1.7)].

APPENDIX: DERIVATION OF POLYNOMIALS *w*

We will study a class of solutions of the system (1.5) for which function ρ fulfills the condition (1.3). Substituting Eq. (1.3) to Eq. (1.1) and changing variables (q,c) into (x,y), we obtain the equation for function w,

$$x^2(ww_{,xx}-w_{,x}^2)+w^2[-2(w-1)+(1-y^2)w_{,yy}-4yw_{,y}]=0. \tag{A1}$$

Searching w in the form of a power series,

$$w(x,y)=\sum_{n=0}^{\infty}w_n(y)x^n, \tag{A2}$$

one gets the following system for function coefficients $w_n(y)$:

$$\sum_p [p(2p-n-1)+2]w_p w_{n-p} - \sum_{p,r} w_p w_r (2w_{n-p-r} + 4y w'_{n-p-r} - (1-y^2) w''_{n-p-r}) = 0, \tag{A3}$$

valid for $n=0,1,2,\ldots$. It can be rewritten in the form

$$w_0^2\{(1-y^2)w''_n - 4y w'_n\} + \gamma_n w_n + d_n(y) = 0, \tag{A4}$$

where

$$d_0(y)=0, \quad \gamma_0 = 2w_0(1-w_0), \quad \gamma_n = [n(n-1)+4]w_0 - 6w_0^2, \quad n \geqslant 1, \tag{A5}$$

$$d_n(y) = \sum_{i=1}^{n-1} \{i(2i-n-1)w_{n-i}w_i - [d_i/w_0 + i(i-1)w_i]g_{n-i}/w_0\} + \gamma_0 \overline{d}_n(y), \tag{A6}$$

$$g_k(y) = \sum_{i=0}^{k} w_{k-i} w_i .$$

If we put $w_0(y)=1$, $w_1(y)=0$ then $\gamma_0=0$, $\gamma_n=(n-2)(n+1)$ and functions $w_n(y)$, $d_n(y)$ are polynomials of parity $(-1)^n$,

$$w_n(y) = \sum_{k \in Z_n} w_{nk} y^k, \quad d_n(y) = \sum_{k \in Z_{n-2}} d_{nk} y^k, \tag{A7}$$

where $Z_n = n-2, n-4, \ldots, 0, (1)$. We get coefficients w_{nk}, $n \geqslant 2$ with the help of Eq. (A4),

$$w_{nk} = \frac{(n+k-1)!!}{k!(n-k-2)!!} \left((-1)^{(n-k)/2} I_n + \sum_{p=0,2,\ldots,}^{2[k/2]-2} (-1)^{p/2+1} \mathscr{N}^n_{kp} d_{nk-p-2} \right), \tag{A8}$$

$$\mathscr{N}^n_{kp} = \frac{(k-p-2)!(n-k+p-2)!!}{(n+k-2p-1)!!}. \tag{A9}$$

Here, $[n/m]$ is an integer quotation and $I=\{I_2, I_3, \ldots\}$ is an infinite set of integration constants. Because $\gamma_0=0$, Eqs. (A6) and (A8) determine the recurrence algorithm with respect to index n. Using it, one obtains

$$\begin{aligned} w(x,y) = 1 &- I_2 x^2 - 3I_3 y x^3 + [(-2^{-1}3\ 5 I_4 + 3I_{2^2})y^2 + 2^{-1}3 I_4]x^4 + [(-2^{-1}5\ 7 I_5 + 2\ 5 I_{32})y^3 \\ &+ 2^{-1}3\ 5 I_5 y]x^5 + [(2^{-1}3\ 5\ 7 I_{42} + 2^{-2}3^2 5 I_{3^2} - 2^{-3}3^2 5\ 7 I_6 - 3\ 5 I_{2^3})y^4 \\ &+ (-2^{-1}3^2 5 I_{42} + 2^{-2}3\ 5\ 7 I_6 + 5 I_{2^3})y^2 - 2^{-3}3\ 5\ I_6]x^6 + [(2^{-1}3^2 5^{-1}7\ 13 I_{43} \\ &+ 2^{-1}3^3 7 I_{52} - 2^{-3}3^2 7\ 11 I_7 - 3^2 7 I_{32^2})y^5 + (-2^{-1}3^2 7 I_{43} - 2^{-1}3\ 5\ 7 I_{52} + 2^{-2}3^2 5\ 7 I_7 \\ &+ 3\ 7 I_{32^2})y^3 - 2^{-3}3\ 5\ 7 I_7 y]x^7 + \cdots, \end{aligned} \tag{A10}$$

where $I_{p_1{}^{k_1},\ldots p_s{}^{k_s}}$ denote $\Pi_{i=1}^s I_{p_i}{}^{s_i}$. We find function $z(x,y)$ we by integrating of formula (1.4):

$$z(x,y) = I_1 + \frac{y}{x} + \frac{y}{2x} \sum_{n=2}^{\infty} \sum_{k \in Z_n} \frac{k+2}{n-1} (w_{nk+2} - w_{nk}) x^n y^k, \tag{A11}$$

The potential constraints of the complex (1+2)-dimensional soliton systems and related Hamiltonian equations

Deng-yuan Chen
Department of Mathematics, Shanghai University, Shanghai 201800, People's Republic of China

(Received 15 January 1997; accepted for publication 6 November 1997)

Potential complete constraints (symmetric and nonsymmetric) of the complex KP and MKP systems are derived by using the general theory for a nonlinear equation to be a Hamiltonian system. All the complex Hamiltonian equations corresponding to this kind of constraint are obtained, which contain the famous nonlinear Schrödinger equations and several new Hamiltonian equations. In addition, the classical Kaup–Newell system and the Heisenberg system are also led by a new reduction approach from the MKP system. © *1998 American Institute of Physics.* [S0022-2488(98)01406-6]

I. INTRODUCTION

It is well known that many $(1+1)$-dimensional soliton equations can arise as the nonlinearization of real linear problems of a $(1+2)$-dimensional integrable system. In the nonlinearized procedure, potential symmetric constraints play crucial roles.[1–4] For example, by restricting the potential u to the symmetry $\phi\psi$ of the Kadomtsev–Petviashvili (KP) system, the associated real linear problem for ϕ and its adjoint for ψ are reduced to the first two equations of the famous AKNS hierarchy. As a result, one can obtain solutions for the KP equation by solving the lower-dimensional constrained equations.

Recently, a new notion called the potential complete constraint (contains symmetric and nonsymmetric) of the $(1+2)$-dimensional integrable system was introduced by this author with N. S. Zhu and M. Zhu.[5] Based on the idea that the linear problem and its adjoint must be restricted to an infinite-dimensional real Hamilton equation, we derived the concrete expressions of the complete constraint of the KP system[5] and modified Kadomtesev–Petviashvili (MKP) system,[6] and obtained further some new Hamiltonian equations.

In this paper, we would like to extend the method of finding the complete constraint to a high-dimensional integrable system associated with a complex linear problem (named complex integrable system for short). To this end, we first need to establish the theory of the Hamiltonian equation on the linear space constructed by complex vector fields. Then, along the line provided in Ref. 5, we derive the potential complete constraints for the complex KP and MKP systems and the related Hamiltonian equation. Consequently, the famous nonlinear Schrödinger (NS) equations and several other new complex Hamiltonian equations are deduced as particular examples. Finally, by the new nonlinearized method of linear problem of the complex MKP system, we obtain the classical Kaup–Newell (KN) equations and Heisenberg (HB) equations and give their Hamiltonian structures.

The organization of the paper is as follows. In Sec. II we give some notions of the Gateaux derivative and the functional derivative and prove a fundamental theorem of the complex Hamiltonian equation. In Sec. III we deduce the potential constraints of the complex KP system and related Hamiltonian equations. (The detailed computation is given in the Appendix.) We also discuss the potential constraints of the complex MKP system by a particular reduction approach in Sec. IV.

II. GATEAUX DERIVATIVE, FUNCTIONAL DERIVATIVE, AND COMPLEX HAMILTONIAN EQUATION

Let $t\in R$, $x\in R^n$, $\phi=\phi(t,x)=(\phi_1,\phi_2,\ldots,\phi_s)^T$, and for any fixed $t,\phi_j=\phi_j(t,x)$ $(j=1,2,\ldots,s)$ belong to the space $S(R^n)$ of the rapidly decreasing complex-valued functions. For two

 © 1998 American Institute of Physics

series of non-negative integers $\alpha=(\alpha_1,\alpha_2,\ldots,\alpha_n)$ and $\beta=(\beta_1,\beta_2,\ldots,\beta_n)$, we write $D^\alpha=D_1^{\alpha_1}D_2^{\alpha_2}\cdots D_n^{\alpha_n}$, $\alpha=\Sigma_{j=1}^n\alpha_j$, and $I^\beta=I_1^{\beta_1}I_2^{\beta_2}\cdots I_n^{\beta_n}$, $\beta=\Sigma_{j=1}^n\beta_j$, where $D_j=\partial/\partial x_j$, $I_j=\frac{1}{2}(I_j^- -I_j^+)$, $I_j^-=\int_{-\infty}^{x_j}dx_j$, $I_j^+=\int_{x_j}^{+\infty}dx_j$, and $D_jI_j=I_jD_j=1$, $(j=1,2,...,n)$. Suppose $f=f(t,x,\phi)=(f_1,f_2,\ldots,f_m)^T$ is a complex smooth vector field with the components of $f_j=f_j(t,x,D\phi,\ldots,D^\alpha\phi,I\phi,\ldots,I^\beta\phi)$ $(j=1,2,...,m)$, which, together with all its partial derivatives, tends to be zero fast enough. $V^{(m)}$ denotes the complex linear space constructed by these vector fields. For two arbitrary vector fields f and g in $V^{(m)}$, we define their real inner product,[7]

$$\langle f,g\rangle=\frac{1}{2}\int_{-\infty}^{\infty}(f\cdot\overline{g}+\overline{f}\cdot g)dx, \tag{2.1}$$

where $f\cdot g=\Sigma_{j=1}^m f_jg_j$, and the overbar denotes the complex conjugate. Thus it can be seen that inner product (2.1) is commutative,

$$\langle f,g\rangle=\langle g,f\rangle. \tag{2.2}$$

Let $Q^{(m)}$ denote a set composed of all the linear operators $L=L(t,x,\phi)$ on $V^{(m)}$ into $V^{(m)}$ that are infinitely differentiable with respect to x and smooth with respect to ϕ.

Definition 1: Let θ be an operator in $Q^{(m)}$. If there exists another operator $J\in Q^{(m)}$ such that

$$\langle\theta f,g\rangle=\langle f,Jg\rangle, \tag{2.3}$$

for any $f,g\in V^{(m)}$, then J is named the conjugate operator of θ and denoted as θ^*. It is named a self-conjugate operator if $\theta^*=\theta$, while an anti-self-conjugate operator if $\theta^*=-\theta$.

Obviously, the differential operator D_j, integral operator I_j, and complex matrix

$$\sigma=\begin{pmatrix}-i & 0\\ 0 & i\end{pmatrix}\in Q^{(2)}, \tag{2.4}$$

are all anti-self-conjugate operators.

Definition 2: Let $f\in V^{(m)}$, $h\in V^{(s)}$, and ϵ is an arbitrary complex number; then

$$f'[h]=f'(\phi)[h]=\frac{d}{d\epsilon}f(\phi+\epsilon h)\big|_{\epsilon=0} \tag{2.5}$$

is named the Gateaux derivative of the complex vector field f in the direction h.

By simple calculation, we obtain easily that f' is a linear operator on $V^{(s)}$ into $V^{(m)}$ containing differential operator D_j and integrable operator I_j. In fact, if we set

$$f'_{l\phi_j}=\sum_\alpha\frac{\partial f_l}{\partial(D^\alpha\phi_j)}D^\alpha+\sum_\beta\frac{\partial f_l}{\partial(I^\beta\phi_j)}I^\beta, \tag{2.6}$$

we have

$$f'=(f'_{l\phi_j})_{m\times s}. \tag{2.7}$$

For an operator $L\in Q^{(m)}$, we can also define their Gateaux derivative operator L' on $V^{(s)}$ into $Q^{(m)}$ and the Leibniz formula holds.

Concerning the high-order Gateaux derivative, we have the following relation.

Lemma 1: Let $f,g\in V^{(s)}$ and $L\in Q^{(m)}$; then

$$(L')'[f]g=(L')'[g]f; \tag{2.8a}$$

$$(L'[f])'[g]-(L'[g])'[f]=L'[[\![f,g]\!]], \tag{2.8b}$$

where $[\![f,g]\!]=f'[g]-g'[f]$ is the commutator of f and g.

Definition 3: If $\theta=\theta(t,x,\phi)\in Q^{(s)}$ is an anti-self-conjugate operator and satisfies the identity

$$\langle f,\theta'[\theta g]h\rangle+\langle g,\theta'[\theta h]f\rangle+\langle h,\theta'[\theta f]g\rangle=0, \tag{2.9}$$

for any $f,g,h\in V^{(s)}$, then θ is named an implectic operator.

Clearly, the above D_j, I_j, and σ are all implectic operators.

Definition 4: For a given real-valued functional $H=H(t,x,\phi)$, if there exits a complex vector field $f\in V^{(s)}$ satisfying

$$H'[h]=\langle f,h\rangle, \tag{2.10}$$

for any $h\in V^{(s)}$, then f is named functional derivative or Gradient of H and is denoted as

$$\frac{\delta H}{\delta\phi}=\text{grad } H=f. \tag{2.11}$$

The above Gateaux derivative and functional derivative also have a similar close relationship to the real vector fields.

Theorem 1: Suppose that a complex vector field $f\in V^{(s)}$ is the functional derivative of a real-valued functional w, i.e., $f=\delta w/\delta\phi$, then the Gateaux derivative of f is a self-conjugate operator. Inversely, if $f'=f'^*$, then f is the functional derivative of the functional,

$$w=\int_0^1\langle f(\rho\phi),\phi\rangle d\rho. \tag{2.12}$$

Proof: Let f be the functional derivative of w; then for any complex vector field $g,h\in V^{(s)}$, we have

$$w'[g]=\langle f,g\rangle,\quad w'[h]=\langle f,h\rangle. \tag{2.13}$$

It follows that

$$(w'[g])'[h]=\langle f'[h],g\rangle+\langle f,g'[h]\rangle \tag{2.14}$$

and

$$(w'[h])'[g]=\langle f'[g],h\rangle+\langle f,h'[g]\rangle. \tag{2.15}$$

Using the formula (2.8b), from (2.14) and (2.15), we obtain

$$w'[[\![g,h]\!]]=\langle f'[h],g\rangle-\langle f'[g],h\rangle+\langle f,[[\![g,h]\!]]\rangle, \tag{2.16}$$

which leads to

$$\langle g,f'[h]\rangle=\langle f'[h],g\rangle=\langle f'[g],h\rangle, \tag{2.17}$$

i.e., f' is a self-conjugate operator.

On the other hand, calculating the Gateaux derivative of (2.12) in the direction $h\in V^{(s)}$ and noting $\phi'[h]=h$, we obtain

$$w'[h]=\int_0^1(\langle\rho f'(\rho\phi)[h],\phi\rangle+\langle f(\rho\phi),h\rangle)d\rho. \tag{2.18}$$

According to the hypothesis $f'=f'^*$, the above equality can also be read as

$$w'[h]=\int_0^1\langle\rho f'(\rho\phi)[\phi]+f(\rho\phi),h\rangle d\rho. \tag{2.19}$$

Because

$$f'(\rho\phi)[\phi]=\frac{d}{d\epsilon}f(\rho\phi+\epsilon\phi)|_{\epsilon=0}=\frac{d}{d\rho}f(\rho\phi), \tag{2.20}$$

we finally have

$$w'[h]=\int_0^1\left\langle\frac{d}{d\rho}\rho f(\rho\phi),h\right\rangle d\rho=\langle f,h\rangle, \tag{2.21}$$

which is just the desired result.

Definition 5: Suppose that there is a complex nonlinear equation,

$$\phi_t=\theta(\phi)f(t,x,\phi), \tag{2.22}$$

if $\theta(\phi)\in Q^{(s)}$ is an implectic operator and $f(t,x,\phi)\in V^{(s)}$ is a functional derivative of some real-valued functional $w=w(t,x,\phi)$; then (2.22) is called a Hamiltonian equation and w is called its Hamiltonian functional.

In light of Theorem 1, we have immediately the following corollary.

Corollary: Let $\theta(\phi)\in Q^{(s)}$ be an implectic operator; then the sufficient and necessary condition for (2.22) to be a Hamiltonian equation is that the Gateaux derivative of f is a self-conjugate operator,

$$f'=f'^*, \tag{2.23}$$

and the corresponding Hamiltonian functional is given by (2.12).

III. COMPLETE CONSTRAINTS OF THE COMPLEX KP SYSTEM

Consider the linear problem of the complex KP system,

$$i\phi_y=\phi_{xx}+2u\phi, \tag{3.1a}$$

$$\phi_t=\phi_{xxx}+3u\phi_x+\tfrac{3}{2}u_x\phi+\tfrac{3}{2}i(Iu_y)\phi; \tag{3.1b}$$

and its conjugate linear problem,

$$i\psi_y=-\psi_{xx}-2v\psi, \tag{3.2a}$$

$$\psi_t=\psi_{xxx}+3v\psi_x+\tfrac{3}{2}v_x\psi-\tfrac{3}{2}i(Iv_y)\psi, \tag{3.2b}$$

where u and $v=\overline{u}$ both satisfy the KP equation,

$$q_t=\tfrac{1}{4}q_{xxx}+3qq_x-\tfrac{3}{4}Iq_{yy}, \tag{3.3}$$

$\psi=\overline{\phi}$, $i^2=-1$, and

$$I=\frac{1}{2}(I^--I^+),\quad I^-=\int_{-\infty}^{x}dx,\quad I^+=\int_x^{\infty}dx. \tag{3.4}$$

If the potentials u and v are constrained to the symmetry $\phi\psi$ of the complex KP system, i.e., $u=v=\phi\psi$, then (3.1a) and (3.2a) become[1]

$$i\phi_y=\phi_{xx}+2\phi^2\psi, \tag{3.5a}$$

$$i\psi_y=-\psi_{xx}-2\phi\psi^2, \tag{3.5b}$$

which is the NS equation. Also, (3.1b) and (3.2b) become

$$\phi_t=\phi_{xxx}+6\phi\psi\phi_x, \tag{3.6a}$$

$$\psi_t=\psi_{xxx}+6\phi\psi\psi_x, \tag{3.6b}$$

which is the first high-order NS equation.

In order to derive other nonsymmetric constraints of the complex KP system, we choose the implectic operator σ and rewrite the linear problems (3.1) and (3.2) as the vector form

$$\omega_y=\sigma f; \tag{3.7a}$$

$$\omega_t=\sigma g, \tag{3.7b}$$

where $\omega,f,g\in V^{(2)}$ and

$$\omega=\begin{pmatrix}\phi\\ \psi\end{pmatrix},\quad f=\begin{pmatrix}f_1\\ f_2\end{pmatrix}=\begin{pmatrix}\phi_{xx}+2u\phi\\ \psi_{xx}+2v\psi\end{pmatrix}; \tag{3.8a}$$

$$g=\begin{pmatrix}g_1\\ g_2\end{pmatrix}=\begin{pmatrix} i\phi_{xxx}+3iu\phi_x+\frac{3}{2}iu_x\phi-\frac{3}{2}(Iu_y)\phi\\ -i\psi_{xxx}-3iv\psi_x-\frac{3}{2}iv_x\psi-\frac{3}{2}(Iv_y)\psi\end{pmatrix}. \tag{3.8b}$$

Now, let the general form of the potential constraint of the complex KP system be

$$(u,v)=(u(\phi,\psi,\phi_x,\psi_x),v(\phi,\psi,\phi_x,\psi_x)); \tag{3.9}$$

then the sufficient and necessary conditions for (3.7a) and (3.7b) to be Hamiltonian equations are

$$f'=f'^*; \tag{3.10a}$$

$$g'=g'^*, \tag{3.10b}$$

where

$$f'=\begin{pmatrix}f'_{1,\phi} & f'_{1,\psi}\\ f'_{2,\phi} & f'_{2,\psi}\end{pmatrix},\quad f'^*=\begin{pmatrix}f'^*_{1,\phi} & f'^*_{2,\phi}\\ f'^*_{1,\psi} & f'^*_{2,\psi}\end{pmatrix}; \tag{3.11a}$$

$$g'=\begin{pmatrix}g'_{1,\phi} & g'_{1,\psi}\\ g'_{2,\phi} & g'_{2,\psi}\end{pmatrix},\quad g'^*=\begin{pmatrix}g'^*_{1,\phi} & g'^*_{2,\phi}\\ g'^*_{1,\psi} & g'^*_{2,\psi}\end{pmatrix}. \tag{3.11b}$$

From (3.10), one can obtain by direct computation (see the Appendix)

$$u=-ia\psi\phi_x+\alpha\phi\psi+\beta, \tag{3.12a}$$

$$v=ia\phi\psi_x+\alpha\phi\psi+\beta, \tag{3.12b}$$

where a, α, and β are three arbitrary real constants. Therefore we have the following.

Theorem 2: Assume that the complex vector fields f and g of (3.8) belong to $V^{(2)}$; then the necessary and sufficient condition for (3.7) to be Hamiltonian equations is that the potential constraints take the form of (3.12).

Substituting the potential (3.12) into (3.7a) and (3.7b), respectively, gives

$$\begin{pmatrix}\phi\\ \psi\end{pmatrix}_y=\sigma\begin{pmatrix}\phi_{xx}-2(ia\psi\phi_x-\alpha\phi\psi-\beta)\phi\\ \psi_{xx}+2(ia\phi\psi_x+\alpha\phi\psi+\beta)\psi\end{pmatrix}, \tag{3.13a}$$

$$\begin{pmatrix}\phi\\ \psi\end{pmatrix}_t=\sigma\begin{pmatrix} i\phi_{xxx}+3a\psi(\phi\phi_x)_x-3ia^2(\phi\psi)^2\phi_x+3a\alpha(\phi\psi)^2\phi+6i\alpha\phi\psi\phi_x+3i\beta\phi_x\\ -i\psi_{xxx}+3a\phi(\psi\psi_x)_x+3ia^2(\phi\psi)^2\psi_x+3a\alpha(\phi\psi)^2\psi-6i\alpha\phi\psi\psi_x-3i\beta\psi_x\end{pmatrix}, \tag{3.13b}$$

which are Hamiltonian equations, and the corresponding Hamiltonian functionals are

$$w_1=\int_{-\infty}^{\infty}[\tfrac{1}{2}(\psi\phi_{xx}+\phi\psi_{xx})+\tfrac{1}{2}ia\phi\psi(\phi\psi_x-\psi\phi_x)+\alpha(\phi\psi)^2+2\beta\phi\psi]dx, \tag{3.14a}$$

$$w_2=\int_{-\infty}^{\infty}\{\tfrac{1}{2}i(\psi\phi_{xxx}-\phi\psi_{xxx})+\tfrac{3}{4}a[\psi^2(\phi\phi_x)_x+\phi^2(\psi\psi_x)_x]$$
$$+a\alpha(\phi\psi)^3-\tfrac{1}{2}i(a^2\phi^2\psi^2-3\alpha\phi\psi-3\beta)(\psi\phi_x-\phi\psi_x)\}dx. \tag{3.14b}$$

In particular, let $\alpha=1$ and $a=\beta=0$; the potential (3.12) becomes the well-known symmetry constraint of the linear problem of the complex KP system. Equations (3.13a) and (3.13b) become the NS equations (3.5) and (3.6), respectively, and the corresponding Hamiltonian functionals are

$$w_1=\frac{1}{2}\int_{-\infty}^{\infty}(\psi\phi_{xx}+\phi\psi_{xx}+2\phi^2\psi^2)dx, \tag{3.15a}$$

$$w_2=\frac{1}{2}i\int_{-\infty}^{\infty}[\psi\phi_{xxx}-\phi\psi_{xxx}+3\phi\psi(\psi\phi_x-\phi\psi_x)]dx. \tag{3.15b}$$

Let $a=1$ and $\alpha=\beta=0$; the potential (3.12) is

$$(u,v)=(-i\psi\phi_x,i\phi\psi_x), \tag{3.16}$$

and (3.13a) and (3.13b) give, respectively,

$$\begin{pmatrix}\phi\\ \psi\end{pmatrix}_y=\sigma\begin{pmatrix}\phi_{xx}-2i\phi\psi\phi_x\\ \psi_{xx}+2i\phi\psi\psi_x\end{pmatrix}, \tag{3.17a}$$

$$\begin{pmatrix}\phi\\ \psi\end{pmatrix}_t=\sigma\begin{pmatrix}i\phi_{xxx}+3\psi(\phi\phi_x)_x-3i(\phi\psi)^2\phi_x\\ -i\psi_{xxx}+3\phi(\psi\psi_x)_x+3i(\phi\psi)^2\psi_x\end{pmatrix}, \tag{3.17b}$$

which are new Hamiltonian equations. To our knowledge, their integrabilities have not been reported in any literature. The corresponding Hamiltonian functionals are

$$w_1=\frac{1}{2}\int_{-\infty}^{\infty}[\psi\phi_{xx}+\phi\psi_{xx}+i\phi\psi(\phi\psi_x-\psi\phi_x)]dx, \tag{3.18a}$$

$$w_2=\frac{1}{2}i\int_{-\infty}^{\infty}\{\psi\phi_{xxx}-\phi\psi_{xxx}-\tfrac{3}{2}i[\psi^2(\phi\phi_x)_x+\phi^2(\psi\psi_x)_x]-\phi^2\psi^2(\psi\phi_x-\phi\psi_x)\}dx. \tag{3.18b}$$

IV. THE REDUCTION TECHNIQUE OF THE COMPLEX MKP SYSTEM

For the sake of finding more $(1+1)$-dimensional integrable systems, in this section we would like to consider the potential constraints and the new reduction method of the complex MKP system.

It is known that the linear problem of the complex MKP system is

$$i\phi_y=\phi_{xx}+2iu\phi_x, \tag{4.1a}$$

$$\phi_t=\phi_{xxx}+3iu\phi_{xx}+\tfrac{3}{2}(iu_x-u^2-Iu_y)\phi_x; \tag{4.1b}$$

and the conjugate linear problem is

$$i\psi_y=-\psi_{xx}+2iv\psi_x, \tag{4.2a}$$

$$\psi_t=\psi_{xxx}-3iv\psi_{xx}-\tfrac{3}{2}(iv_x+v^2+Iv_y)\psi_x, \tag{4.2b}$$

where u and $v=\overline{u}$ both satisfy the MKP equation,

$$q_t=\tfrac{1}{4}q_{xxx}+\tfrac{3}{2}q^2q_x-\tfrac{3}{2}q_xIq_y-\tfrac{3}{4}Iq_{yy}, \tag{4.3}$$

and $\psi=\overline{\phi}$.

If the potentials u and v are constrained into the symmetry of the MKP system, i.e., $u=v=-\phi\psi$, then (4.1a) and (4.2a) become the integrable equation (3.17a). Also, (4.1b) and (4.2b) become a high-order integrable equation (3.17b).

Generally, if we write the linear problems (4.1) and (4.2) as the vector form (3.7), where

$$f=\begin{pmatrix} f_1 \\ f_2 \end{pmatrix}=\begin{pmatrix} \phi_{xx}+2iu\phi_x \\ \psi_{xx}-2iv\psi_x \end{pmatrix}, \tag{4.4a}$$

$$g=\begin{pmatrix} g_1 \\ g_2 \end{pmatrix}=\begin{pmatrix} i\phi_{xxx}-3u\phi_{xx}-\frac{3}{2}(u_x+iu^2+iIu_y)\phi_x \\ -i\psi_{xxx}-3v\psi_{xx}-\frac{3}{2}(v_x-iv^2-iIv_y)\psi_x \end{pmatrix}, \tag{4.4b}$$

then, using the approach ($f'=f'^*$, $g'=g'^*$) provided in the previous section, we can deduce the potential complete constraint of the MKP system.

Theorem 3: Assume the vector fields f and g in (4.4) belong to $V^{(2)}$; then the necessary and sufficient condition for corresponding (3.7) to be Hamiltonian equations is that the complete constraint takes the functional form

$$u=v=\alpha\phi\psi+\beta\phi+\gamma\psi+\delta, \tag{4.5}$$

where α and δ are the real constants and β and $\gamma=\overline{\beta}$ are the conjugate complex numbers. Substituting (4.5) into (3.7a) and (3.7b) yields

$$\begin{pmatrix} \phi \\ \psi \end{pmatrix}_y=\sigma\begin{pmatrix} \phi_{xx}+2i(\alpha\phi\psi+\beta\phi+\gamma\psi+\delta)\phi_x \\ \psi_{xx}-2i(\alpha\phi\psi+\beta\phi+\gamma\psi+\delta)\psi_x \end{pmatrix}; \tag{4.6a}$$

$$\begin{pmatrix} \phi \\ \psi \end{pmatrix}_t=\sigma\begin{pmatrix} i\phi_{xxx}-3(\alpha\phi\psi+\beta\phi+\gamma\psi+\delta)\phi_{xx}-3[\alpha\psi\phi_x+\beta\phi_x+i(\alpha\phi\psi+\beta\phi+\gamma\psi+\delta)^2]\phi_x \\ -i\psi_{xxx}-3(\alpha\phi\psi+\beta\phi+\gamma\psi+\delta)\psi_{xx}-3[\alpha\phi\psi_x+\gamma\psi_x-i(\alpha\phi\psi+\beta\phi+\gamma\psi+\delta)^2]\psi_x \end{pmatrix}, \tag{4.6b}$$

which are the Hamiltonian equations, and the corresponding Hamiltonian functionals are

$$w_1=\int_{-\infty}^{\infty}\{\tfrac{1}{2}(\psi\phi_{xx}+\phi\psi_{xx})+i[\tfrac{1}{2}\alpha\phi\psi+\tfrac{2}{3}(\beta\phi+\gamma\psi)+\delta](\psi\phi_x-\phi\psi_x)\}dx; \tag{4.7a}$$

$$\begin{aligned} w_2=\int_{-\infty}^{\infty}\{&\tfrac{1}{2}i(\psi\phi_{xxx}-\phi\psi_{xxx})-\tfrac{3}{4}\alpha[\psi^2(\phi\phi_x)_x+\phi^2(\psi\psi_x)_x]-(\beta\phi+\gamma\psi+\tfrac{3}{2}\delta) \\ &\times(\psi\phi_{xx}+\phi\psi_{xx})-\beta\psi\phi_x^2-\gamma\phi\psi_x^2+i[\tfrac{1}{2}\alpha^2\phi^2\psi^2+\tfrac{6}{5}\alpha\phi\psi(\beta\phi+\gamma\psi) \\ &+\tfrac{3}{4}(\beta\phi+\gamma\psi)^2+\tfrac{3}{2}\alpha\delta\phi\psi+2\delta(\beta\phi+\gamma\psi)+\tfrac{3}{2}\delta^2](\phi\psi_x-\psi\phi_x)\}dx. \end{aligned} \tag{4.7b}$$

Specially, if we set $\alpha=-1$, $\beta=\delta=0$, then (4.6a) and (4.6b) become (3.17a) and (3.17b), and the Hamilton functionals (4.7a) and (4.7b) become (3.18a) and (3.18b). If we set $\beta=1$, $\alpha=\delta=0$, then (4.6a) and (4.6b) become

$$\begin{pmatrix} \phi \\ \psi \end{pmatrix}_y=\sigma\begin{pmatrix} \phi_{xx}+2i(\phi+\psi)\phi_x \\ \psi_{xx}-2i(\phi+\psi)\psi_x \end{pmatrix}; \tag{4.8a}$$

$$\begin{pmatrix}\phi\\ \psi\end{pmatrix}_t=\sigma\begin{pmatrix} i\phi_{xxx}-3(\phi+\psi)\phi_{xx}-3[\phi_x+i(\phi+\psi)^2]\phi_x\\ -i\psi_{xxx}-3(\phi+\psi)\psi_{xx}-3[\psi_x-i(\phi+\psi)^2]\psi_x\end{pmatrix}, \tag{4.8b}$$

which are new Hamiltonian equations. The corresponding Hamiltonian functionals are

$$w_1=\int_{-\infty}^{\infty}[\tfrac{1}{2}(\psi\phi_{xx}+\phi\psi_{xx})+\tfrac{2}{3}i(\phi+\psi)(\psi\phi_x-\phi\psi_x)]dx; \tag{4.9a}$$

$$w_2=\int_{-\infty}^{\infty}[\tfrac{1}{2}i(\psi\phi_{xxx}-\phi\psi_{xxx})-(\phi+\psi)(\psi\phi_{xx}+\phi\psi_{xx}) -(\psi\phi_x^2+\phi\psi_x^2)+\tfrac{3}{4}i(\phi+\psi)^2(\phi\psi_x-\psi\phi_x)]dx. \tag{4.9b}$$

Similarly, if setting $\beta=i$, $\alpha=\delta=0$, from (4.6), we can obtain another new Hamilton equation,

$$\begin{pmatrix}\phi\\ \psi\end{pmatrix}_y=\sigma\begin{pmatrix}\phi_{xx}-2(\phi-\psi)\phi_x\\ \psi_{xx}+2(\phi-\psi)\psi_x\end{pmatrix}; \tag{4.10a}$$

$$\begin{pmatrix}\phi\\ \psi\end{pmatrix}_t=\sigma\begin{pmatrix} i\phi_{xxx}-3i(\phi-\psi)\phi_{xx}-3i[\phi_x-(\phi-\psi)^2]\phi_x\\ -i\psi_{xxx}-3i(\phi-\psi)\psi_{xx}+3i[\psi_x-(\phi-\psi)^2]\psi_x\end{pmatrix}, \tag{4.10b}$$

the corresponding Hamilton functionals are

$$w_1=\int_{-\infty}^{\infty}[\tfrac{1}{2}(\psi\phi_{xx}+\phi\psi_{xx})-\tfrac{2}{3}(\phi-\psi)(\psi\phi_x-\phi\psi_x)]dx; \tag{4.11a}$$

$$w_2=\int_{-\infty}^{\infty}[\tfrac{1}{2}i(\psi\phi_{xxx}-\phi\psi_{xxx})-i(\phi-\psi)(\psi\phi_{xx}+\phi\psi_{xx}) -i(\psi\phi_x^2-\phi\psi_x^2)-\tfrac{3}{4}i(\phi-\psi)^2(\phi\psi_x-\psi\phi_x)]dx. \tag{4.11b}$$

In what follows, we shall propose a new reduction approach that can generate the KN equations and the HB equations from the linear problem of the complex MKP system.

Differentiating (4.1a) and (4.2a) with respect to x and replacing ϕ_x and ψ_x by ϕ and ψ, we have

$$i\phi_y=(\phi_x+2iu\phi)_x, \tag{4.12a}$$

$$i\psi_y=(-\psi_x+2iv\psi)_x. \tag{4.12b}$$

If the potentials u and v are both constrained to the symmetry $\phi\psi$, i.e., $u=v=\phi\psi$, then (4.12) becomes the KN equation,[8,9]

$$i\phi_y=(\phi_x+2i\phi^2\psi)_x, \tag{4.13a}$$

$$i\psi_y=(-\psi_x+2i\phi\psi^2)_x, \tag{4.13b}$$

which is a Hamiltonian equation,

$$\omega_y=Df=D\frac{\delta w_1}{\delta\omega}, \tag{4.14a}$$

where $f\in V^{(2)}$,

$$f=\begin{pmatrix}f_1\\ f_2\end{pmatrix}=\begin{pmatrix}-i\phi_x+2\phi^2\psi\\ i\psi_x+2\psi^2\phi\end{pmatrix}, \tag{4.14b}$$

and w_1 is a Hamiltonian functional,

$$w_1=\frac{1}{2}\int_{-\infty}^{\infty}[i(\phi\psi_x-\psi\phi_x)+2\phi^2\psi^2]dx. \tag{4.14c}$$

Still applying the same operation to (4.1b) and (4.2b) i.e., differentiating (4.1a) and (4.2b) and replacing ϕ_x, ψ_x by ϕ, ψ, yields easily

$$\phi_t=[\phi_{xx}+3iu\phi_x+\tfrac{3}{2}(iu_x-u^2-Iu_y)\phi]_x, \tag{4.15a}$$

$$\psi_t=[\psi_{xx}-3iv\psi_x-\tfrac{3}{2}(iv_x+v^2+Iv_y)\psi]_x. \tag{4.15b}$$

Setting $u=v=\phi\psi$ and noticing $Iu_y=Iv_y=i(\phi\psi_x-\psi\phi_x)+3\phi^2\psi^2$, we can derive the high-order KN equation,[8,9]

$$\phi_t=(\phi_{xx}+6i\phi\psi\phi_x+6\phi^3\psi^2)_x, \tag{4.16a}$$

$$\psi_t=(\psi_{xx}-6i\phi\psi\psi_x+6\phi^2\psi^3)_x, \tag{4.16b}$$

which is also a Hamiltonian equation,

$$\omega_t=Dg=D\frac{\delta w_2}{\delta\omega}, \tag{4.17a}$$

where $g\in V^{(2)}$,

$$g=\begin{pmatrix}g_1\\g_2\end{pmatrix}=\begin{pmatrix}\phi_{xx}+6i\phi\psi\phi_x+6\phi^3\psi^2\\ \psi_{xx}-6i\phi\psi\psi_x+6\phi^2\psi^3\end{pmatrix}, \tag{4.17b}$$

and w_2 is a Hamiltonian functional,

$$w_2=\frac{1}{2}\int_{-\infty}^{\infty}[\psi\phi_{xx}+\phi\psi_{xx}+3i\phi\psi(\psi\phi_x-\phi\psi_x)+4\phi^3\psi^3]dx. \tag{4.17c}$$

In (4.12) and (4.15), we introduce a new real function ν satisfying

$$\nu^2+\phi\psi=1, \tag{4.18}$$

and set the potential constraints to be

$$u=\frac{1}{2}i\left(\nu_x+\frac{1}{1+\nu}\psi\phi_x\right), \tag{4.19a}$$

$$v=-\frac{1}{2}i\left(\nu_x+\frac{1}{1+\nu}\phi\psi_x\right); \tag{4.19b}$$

then (4.12a) and (4.12b) become

$$\phi_y=i(\phi\nu_{xx}-\nu\phi_{xx}), \tag{4.20a}$$

$$\psi_y=i(\nu\phi_{xx}-\psi\nu_{xx}), \tag{4.20b}$$

$$\nu_y=\tfrac{1}{2}i(\psi\phi_{xx}-\phi\psi_{xx}), \tag{4.20c}$$

which is the HB equation.[10]

Inserting (4.19a) and (4.19b) into (4.15a) and (4.15b), respectively, and noticing

$$Iu_y=-\frac{1}{4}\left(3\phi_x\psi_x+3\nu_x^2+2\nu_{xx}+\frac{2}{1+\nu}\psi\phi_{xx}\right), \tag{4.21a}$$

$$Iv_y=-\frac{1}{4}\left(3\phi_x\psi_x+3\nu_x^2+2\nu_{xx}+\frac{2}{1+\nu}\,\phi\psi_{xx}\right), \tag{4.21b}$$

we obtain

$$\phi_t=\phi_{xxx}+\tfrac{3}{2}[(\phi_x\psi_x+\nu_x^2)\phi]_x, \tag{4.22a}$$

$$\psi_t=\psi_{xxx}+\tfrac{3}{2}[(\phi_x\psi_x+\nu_x^2)\psi]_x, \tag{4.22b}$$

$$\nu_t=\nu_{xxx}+\tfrac{3}{2}[(\phi_x\psi_x+\nu_x^2)\nu]_x, \tag{4.22c}$$

which is the high-order HB equation.[10] Equations (4.20b) and (4.22b) are both the Hamiltonian equations. But here the differential operator D is not their implectic operator. Consider the $V^{(2)}$'s linear subspace $V_0^{(2)}$ constructed by all vector fields (f_1,f_2) with $f_2=f_1$ and the complex function matrix

$$\theta=\sigma\nu=\begin{pmatrix}-i\nu & 0\\ 0 & i\nu\end{pmatrix}, \tag{4.23}$$

with $\nu=\sqrt{1-\phi\psi}$. It is easy to check that θ is an anti-Hermite matrix, and for any $f,g,h\in V_0^{(2)}$, θ satisfies (2.9); therefore it is the implectic operator.

Now we rewrite the equations (4.20b) and (4.22b) as the vector form

$$\omega_y=\theta f,\quad f=\begin{pmatrix}f_1\\ f_2\end{pmatrix}=\frac{1}{\nu}\begin{pmatrix}\nu\phi_{xx}-\phi\nu_{xx}\\ \nu\psi_{xx}-\psi\nu_{xx}\end{pmatrix}, \tag{4.24a}$$

$$\omega_t=\theta g,\quad g=\begin{pmatrix}g_1\\ g_2\end{pmatrix}=\frac{i}{\nu}\begin{pmatrix}\phi_{xxx}+\tfrac{3}{2}[(\phi_x\psi_x+\nu_x^2)\phi]_x\\ -\psi_{xxx}-\tfrac{3}{2}[(\phi_x\psi_x+\nu_x^2)\psi]_x\end{pmatrix}, \tag{4.24b}$$

where f and g belong to $V_0^{(2)}$. By direct computation, we can verify that $f'=f'^*$ and $g'=g'^*$. Consequently, (4.24a) and (4.24b) are both the Hamiltonian equations, and the corresponding Hamiltonian functionals are

$$w_1=\int_{-\infty}^{\infty}\left[\frac{1}{2}\,(\phi\psi)_x(\ln\,\nu)_x-\phi_x\psi_x\right]dx, \tag{4.25a}$$

$$w_2=\int_{-\infty}^{\infty}\left\{\frac{i}{1+\nu}\,(\psi\phi_{xxx}-\phi\psi_{xxx})+\frac{i}{2(1+\nu)^2}\,(\psi\phi_x-\phi\psi_x)\left[(\nu+2)\phi_x\psi_x+\frac{\nu(\nu+3)}{1+\nu}\,\nu_x^2\right]\right\}dx. \tag{4.25b}$$

This is a new result. To our knowledge, the Hamiltonian property of the HB equations have not been reported in any literature.

For a complex operator, $T=\Sigma a_{ijk}(u,v)\partial_x^i\partial_y^j\partial_t^k$; according to Definition 1, its conjugate (adjoint) operator is $T^*=\Sigma(-1)^{i+j+k}\partial_x^i\partial_y^j\partial_t^k\overline{a_{ijk}(u,v)}$; then we find easily that (4.12a), (4.15a) and (4.12b), (4.15b) are just the adjoints of the linear problems (4.1) and (4.2), respectively. Therefore, the new reduction approach is substantially to nonlinearize the adjoint linear problems of the MKP system. (These adjoint linear problems are completely different from the adjoint of the real MKP system defined by Cheng *et al.* in Ref. 3.)

ACKNOWLEDGMENT

The author's sincere thanks are extended to the referees who have offered me valuable suggestions. The author also thanks Da-jun Zhang and Hong-wei Xin for their helpful discussions and careful verifications to all the results.

APPENDIX: PROOF OF CONSTRAINED FORMULAS OF COMPLEX KP SYSTEM

In the Appendix, we will prove the formulas (3.12).

From (3.8a) and (3.9), by using (2.6), it is easily calculated that

$$f'_{1,\phi}=D^2+2\frac{\partial\phi u}{\partial\phi_x}D+2\frac{\partial\phi u}{\partial\phi},\quad f'_{1,\psi}=2\phi\left(\frac{\partial u}{\partial\psi_x}D+\frac{\partial u}{\partial\psi}\right),$$
$$f'_{2,\phi}=2\psi\left(\frac{\partial v}{\partial\phi_x}D+\frac{\partial v}{\partial\phi}\right),\quad f'_{2,\psi}=D^2+2\frac{\partial\psi v}{\partial\psi_x}D+2\frac{\partial\psi v}{\partial\psi}. \tag{A1}$$

Thus, we have

$$f'^{*}_{1,\phi}=D^2-2D\frac{\partial\psi v}{\partial\psi_x}+2\frac{\partial\psi v}{\partial\psi},\quad f'^{*}_{2,\phi}=-2\left(D\phi\frac{\partial u}{\partial\psi_x}-\phi\frac{\partial u}{\partial\psi}\right),$$
$$f'^{*}_{1,\psi}=-2\left(D\psi\frac{\partial v}{\partial\phi_x}-\psi\frac{\partial v}{\partial\phi}\right),\quad f'^{*}_{2,\psi}=D^2-2D\frac{\partial\phi u}{\partial\phi_x}+2\frac{\partial\phi u}{\partial\phi}. \tag{A2}$$

Substituting (A1) and (A2) into (3.10a) and comparing the coefficients of D and the functional term of the corresponding elements leads to

$$\phi\frac{\partial u}{\partial\phi_x}=-\psi\frac{\partial v}{\partial\psi_x}, \tag{A3a}$$

$$\frac{\partial u}{\partial\psi_x}=0,\quad \frac{\partial v}{\partial\phi_x}=0, \tag{A3b}$$

$$\frac{\partial\phi u}{\partial\phi}=-\left(\psi\frac{\partial v}{\partial\psi_x}\right)_x+\frac{\partial\psi v}{\partial\psi}, \tag{A3c}$$

$$\frac{\partial\psi v}{\partial\psi}=-\left(\phi\frac{\partial u}{\partial\phi_x}\right)_x+\frac{\partial\phi u}{\partial\phi}. \tag{A3d}$$

From Eqs. (A3), we have immediately

$$u=-ia(\phi,\psi)\psi\phi_x+b_1(\phi,\psi); \tag{A4a}$$

$$v=ia(\phi,\psi)\phi\psi_x+b_2(\phi,\psi), \tag{A4b}$$

where a is the real function of ϕ and ψ, $b_2=\overline{b_1}$ and

$$\frac{\partial\phi b_1}{\partial\phi}=\frac{\partial\psi b_2}{\partial\psi}. \tag{A5}$$

In order to determine the unknown function $a(\phi,\psi)$ and $b_1(\phi,\psi)$, we have to use the equality (3.10b).

It follows from (3.8b), (A4), and (2.6) that

$$g'_{1,\phi}=iD^3+3iuD+3i\phi_x\left(\frac{\partial u}{\partial\phi_x}D+\frac{\partial u}{\partial\phi}\right)+\frac{3}{2}i\phi D\left(\frac{\partial u}{\partial\phi_x}D+\frac{\partial u}{\partial\phi}\right)+\frac{3}{2}iu_x-\frac{3}{2}\phi I(u_y)'_\phi-\frac{3}{2}Iu_y. \tag{A6}$$

Noticing the following equalities:

$$\frac{\partial u_y}{\partial\phi_{xxx}}=-i\frac{\partial u}{\partial\phi_x},\quad \frac{\partial u_y}{\partial\phi_{xx}}=-i\frac{\partial u}{\partial\phi}-2i\phi\left(\frac{\partial u}{\partial\phi_x}\right)^2, \tag{A7}$$

we calculate easily

$$\phi I(u_y)'_\phi = -i\left\{ D\phi\,\frac{\partial u}{\partial \phi_x}\,D + 2\phi\,\frac{\partial u}{\partial \phi_x}\,D\phi\,\frac{\partial u}{\partial \phi_x} - \left[\phi_x\,\frac{\partial u}{\partial \phi_x} + 2\phi\left(\frac{\partial u}{\partial \phi_x}\right)_x - \phi\,\frac{\partial u}{\partial \phi}\right]D + \phi\left(\frac{\partial u}{\partial \phi_x}\right)_{xx} - 4\phi\,\frac{\partial u}{\partial \phi_x}\left(\phi\,\frac{\partial u}{\partial \phi_x}\right)_x - 2\phi^2\,\frac{\partial u}{\partial \phi_x}\left(\frac{\partial u}{\partial \phi_x}\right)_x - \phi\left(\frac{\partial u}{\partial \phi}\right)_x \right\} + \phi\,\frac{\partial u_y}{\partial \phi_x} + \phi I\,\frac{\delta u_y}{\delta \phi}, \tag{A8}$$

where

$$\frac{\delta u_y}{\delta \phi} = \frac{\partial u_y}{\partial \phi} - \left(\frac{\partial u_y}{\partial \phi_x}\right)_x + \left(\frac{\partial u_y}{\partial \phi_{xx}}\right)_{xx} - \left(\frac{\partial u_y}{\partial \phi_{xxx}}\right)_{xxx}. \tag{A9}$$

Then (A6) can be rewritten as

$$\begin{aligned} g'_{1\phi} = {} & iD^3 + 3iD\phi\,\frac{\partial u}{\partial \phi_x}\,D + 3i\phi\,\frac{\partial u}{\partial \phi_x}\,D\phi\,\frac{\partial u}{\partial \phi_x} + 3i\left[u - \phi\left(\frac{\partial u}{\partial \phi_x}\right)_x + \phi\,\frac{\partial u}{\partial \phi}\right]D \\ & + 3i\phi_x\,\frac{\partial u}{\partial \phi} + \frac{3}{2}\,i\phi\left(\frac{\partial u}{\partial \phi_x}\right)_{xx} - 6i\phi\,\frac{\partial u}{\partial \phi_x}\left(\phi\,\frac{\partial u}{\partial \phi_x}\right)_x \\ & - 3i\phi^2\,\frac{\partial u}{\partial \phi_x}\left(\frac{\partial u}{\partial \phi_x}\right)_x - \frac{3}{2}\,\phi\,\frac{\partial u_y}{\partial \phi_x} + \frac{3}{2}\,iu_x - \frac{3}{2}\,Iu_y - \frac{3}{2}\,\phi I\,\frac{\delta u_y}{\delta \phi}. \end{aligned} \tag{A10}$$

Furthermore, we have

$$\begin{aligned} g'^{*}_{1\phi} = {} & iD^3 - 3iD\psi\,\frac{\partial v}{\partial \psi_x}\,D + 3i\psi\,\frac{\partial v}{\partial \psi_x}\,D\psi\,\frac{\partial v}{\partial \psi_x} + 3i\left[v - \psi\left(\frac{\partial v}{\partial \psi_x}\right)_x + \psi\,\frac{\partial v}{\partial \psi}\right]D - 3i\psi_x\,\frac{\partial v}{\partial \psi} \\ & - \frac{3}{2}\,i\psi\left(\frac{\partial v}{\partial \psi_x}\right)_{xx} + 6i\psi\,\frac{\partial v}{\partial \psi_x}\left(\psi\,\frac{\partial v}{\partial \psi_x}\right)_x + 3i\psi^2\,\frac{\partial v}{\partial \psi_x}\left(\frac{\partial v}{\partial \psi_x}\right)_x - 3i\left[\psi\left(\frac{\partial v}{\partial \psi_x}\right)_x\right]_x \\ & + 3i\left(\psi\,\frac{\partial v}{\partial \psi}\right)_x - \frac{3}{2}\,\psi\,\frac{\partial v_y}{\partial \psi_x} + \frac{3}{2}\,iv_x - \frac{3}{2}\,Iv_y + \frac{3}{2}\,\frac{\delta v_y}{\delta \psi}\,I\psi. \end{aligned} \tag{A11}$$

In $g'_{1\phi} = g'^{*}_{1\phi}$, using the formula

$$Ir = \sum_{k=0}^{\infty} (-1)^k r^{(k)} I^{k+1}, \quad r^{(k)} = \frac{\partial^k r}{\partial x^k}, \tag{A12}$$

and comparing the coefficients of the same powers of D or I lead to

$$u - \phi\left(\frac{\partial u}{\partial \phi_x}\right)_x + \phi\,\frac{\partial u}{\partial \phi} = v - \psi\left(\frac{\partial v}{\partial \psi_x}\right)_x + \psi\,\frac{\partial v}{\partial \psi}, \tag{A13a}$$

$$\begin{aligned} & 2\phi_x\,\frac{\partial u}{\partial \phi} + \phi\left(\frac{\partial u}{\partial \phi_x}\right)_{xx} - 4\phi\,\frac{\partial u}{\partial \phi_x}\left(\phi\,\frac{\partial u}{\partial \phi_x}\right)_x - 2\phi^2\,\frac{\partial u}{\partial \phi_x}\left(\frac{\partial u}{\partial \phi_x}\right)_x + i\phi\,\frac{\partial u_y}{\partial \phi_x} + u_x + iIu_y \\ & = -2\psi_x\,\frac{\partial v}{\partial \psi} - \psi\left(\frac{\partial v}{\partial \psi_x}\right)_{xx} + 4\psi\,\frac{\partial v}{\partial \psi_x}\left(\psi\,\frac{\partial v}{\partial \psi_x}\right)_x + 2\psi^2\,\frac{\partial v}{\partial \psi_x}\left(\frac{\partial v}{\partial \psi_x}\right)_x \\ & \quad - 2\left[\psi\left(\frac{\partial v}{\partial \psi_x}\right)_x\right]_x + 2\left(\psi\,\frac{\partial v}{\partial \psi}\right)_x + i\psi\,\frac{\partial v_y}{\partial \psi_x} + v_x + iIv_y, \end{aligned} \tag{A13b}$$

$$\phi \frac{\partial^k}{\partial x^k} \frac{\delta u_y}{\delta \phi} = - \frac{\delta v_y}{\delta \psi} \frac{\partial^k \psi}{\partial x^k}, \quad k = 0,1,2,\ldots . \tag{A13c}$$

Inserting the expressions (A4) into (A13a), we obtain easily $a_x = 0$, which means a is a real constant. So

$$\begin{aligned} u_y = {} & a(\phi_x \psi_x - \psi \phi_{xx})_x + 2ia^2(\phi \psi^2 \phi_x)_x - 4ab_{1x}\phi\psi + 2a(b_2 - b_1)\psi\phi_x \\ & - i\left[(\phi_{xx} + 2b_1\phi)\frac{\partial}{\partial \phi} - (\psi_{xx} + 2b_2\psi)\frac{\partial}{\partial \psi}\right] b_1, \end{aligned} \tag{A14a}$$

and

$$\begin{aligned} v_y = {} & a(\phi_x \psi_x - \phi \psi_{xx})_x - 2ia^2(\phi^2 \psi \psi_x)_x - 4ab_{2x}\phi\psi + 2a(b_1 - b_2)\phi\psi_x \\ & - i\left[(\phi_{xx} + 2b_1\phi)\frac{\partial}{\partial \phi} - (\psi_{xx} + 2b_2\psi)\frac{\partial}{\partial \psi}\right] b_2. \end{aligned} \tag{A14b}$$

It follows that (A13b) is

$$\begin{aligned} & 2\phi_x \frac{\partial b_1}{\partial \phi} - 2\psi\left(\frac{\partial b_2}{\partial \psi}\right)_x + (b_1 - b_2)_x - 6ia(b_1 - b_2)\phi\psi \\ & + I\left\{\left[(\phi_{xx} + 2b_1\phi)\frac{\partial}{\partial \phi} - (\psi_{xx} + 2b_2\psi)\frac{\partial}{\partial \psi}\right](b_1 - b_2) - 2ia(b_1 - b_2)_x\phi\psi\right\} = 0. \end{aligned} \tag{A15}$$

Differentiating the above equality with respect to x, we have

$$\begin{aligned} & 2\phi_{xx}\frac{\partial b_1}{\partial \phi} + 2\phi_x\left(\frac{\partial b_1}{\partial \phi}\right)_x - 2\psi_x\left(\frac{\partial b_2}{\partial \psi}\right)_x - 2\psi\left(\frac{\partial^2 b_2}{\partial \phi \partial \psi}\phi_x + \frac{\partial^2 b_2}{\partial \psi^2}\psi_x\right)_x \\ & + \left(\frac{\partial (b_1 - b_2)}{\partial \phi}\phi_x + \frac{\partial (b_1 - b_2)}{\partial \psi}\psi_x\right)_x - 6ia[(b_1 - b_2)\phi\psi]_x \\ & + \left[(\phi_{xx} + 2b_1\phi)\frac{\partial}{\partial \phi} - (\psi_{xx} + 2b_2\psi)\frac{\partial}{\partial \psi}\right](b_1 - b_2) - 2ia(b_1 - b_2)_x\phi\psi = 0. \end{aligned} \tag{A16}$$

In (A16), setting the coefficients of ϕ_{xx} and ψ_{xx} to be zero, we obtain

$$\frac{\partial b_1}{\partial \phi} - \psi \frac{\partial^2 b_2}{\partial \phi \partial \psi} + \frac{\partial (b_1 - b_2)}{\partial \phi} = 0, \tag{A17a}$$

$$\frac{\partial^2 b_2}{\partial \psi^2} = 0, \tag{A17b}$$

and combining (A17a) and (A5), we also have

$$\frac{\partial^2 b_1}{\partial \phi^2} = 0. \tag{A18}$$

Furthermore, setting the coefficients of ϕ_x^2, $\phi_x\psi_x$, and ψ_x^2 to be zero yields

$$\frac{\partial^2 b_1}{\partial \psi^2} = 0, \quad \frac{\partial^2 (b_1 - b_2)}{\partial \phi \partial \psi} = 0, \quad \frac{\partial^2 b_2}{\partial \phi^2} = 0. \tag{A19}$$

Setting the coefficients of ϕ_x and ψ_x to be zero, if $a \neq 0$ we obtain

$$4\phi\,\frac{\partial(b_1-b_2)}{\partial\phi}+3(b_1-b_2)=0, \tag{A20a}$$

$$4\psi\,\frac{\partial(b_1-b_2)}{\partial\psi}+3(b_1-b_2)=0. \tag{A20b}$$

At last, setting the sum of the remaining items to be zero gives

$$\phi b_1\,\frac{\partial(b_1-b_2)}{\partial\phi}-\psi b_2\,\frac{\partial(b_1-b_2)}{\partial\psi}=0. \tag{A21}$$

Equation (A20) coupled with (A21) implies $b_1=b_2=b$, i.e., b is a real function. Thus, from (A18), (A19), and (A5), we obtain

$$b=\alpha\phi\psi+\beta, \tag{A22}$$

where α and β are real constants.

If $a=0$, one also obtains (A22) from (A17b), (A18), (A19), (A21) and (A5).

Hence, the formulas (3.12) are derived. Then, it is easy to verify that (3.12) satisfy (A13) and (3.10b). So we have proved the desired result completely.

(Received 5 February 1998; accepted for publication 16 March 1998)

For slowly rotating fluids, we establish the existence of a critical point similar to the one found for nonrotating systems. As the fluid approaches the critical point, the effective inertial mass of any fluid element decreases, vanishing at that point and changing sign beyond it. This result implies that the first-order perturbative method is not always reliable to study dissipative processes occurring before relaxation. Physical consequences that might follow from this effect are commented on. © *1998 American Institute of Physics.* [S0022-2488(98)03406-9]

I. INTRODUCTION

An alternative path to the study of self-gravitating systems, which avoids the use of numerical procedures and/or the introduction of too restrictive simplifying assumptions, consists in perturbing the system, compelling it to withdraw from an equilibrium state. Then, evaluating it after its departure from equilibrium, it is possible to study the tendency of the evolution of the object. This is usually done following a first-order perturbative method that neglects quadratic and higher terms in the perturbed quantities. This applies whenever the relevant processes occurring in the self-gravitating object take place on time scales that are of the order of, or smaller than, the hydrostatic time scale. In this case the quasistatic approximation fails[1] (e.g., during the quick collapse phase preceding neutron star formation), and the system is evaluated immediately after its departure from equilibrium, where *immediately* means on a time scale of the order of relaxation times.

Recently, it has been shown[2–5] that, for systems out of a quasistatic approximation, a first-order perturbative theory is not always satisfactory. In fact, there exist systems for which this method seems to be inadequate, however small is the perturbation. These are those for which the parameter

$$\alpha = \frac{\kappa T}{\tau(\rho + p)}$$

is close to, or beyond the so-called critical point ($\alpha = 1$). This combination of the temperature T, the heat conduction coefficient κ, the relaxation time τ, the energy density ρ, and the pressure p, has been found to be the same in spherically symmetric systems,[2,3] and axially symmetric systems with reflection symmetry.[5] Also, the viscous spherically symmetric case has been studied with similar results.[4]

The astrophysical interest of the study of relativistic rotating fluids is past all doubt. Therefore, it seems important to establish, for such systems, the existence, or not, of a critical point as described above. With this aim, we assume that, initially, a nonviscous slowly rotating object is close to the hydrostatic equilibrium (along the r coordinate) and nearly to thermal adjustment [the so-called *complete equilibrium* (Ref. 1, p. 66)], as measured by a local Minkowskian observer.

Therefore, the time derivatives of the radial velocity and heat flow can be neglected. At that time, we perturb the radial velocity and the heat flow, and we evaluate conservation equations and the heat transport equation just after the perturbation takes place, neglecting quadratic and higher terms in the perturbed quantities. Here *just after the perturbation* means on a time scale that is of the order of the relaxation time. This is necessary if the relevant processes take place on time scales that are of the order of, or smaller than, the hydrostatic time scale. This meaning of *just after the perturbation* implies that physical quantities remain unchanged, but not the time derivatives of the perturbed quantities. These are still small, but they cannot be neglected since the system is departing from the complete equilibrium.

As has been mentioned above, it is necessary to use a heat transport equation, together with the conservation equations, to find out the existence, or not, of the critical point. In order to keep clear of inconsistencies, the heat transport equation cannot be the well-known Eckart one,[6,7] because it assumes a vanishing relaxation time. Furthermore, this theory suffers from two importants drawbacks: Noncausality (the thermal signals propagate at infinite speed), and unstability (all the predicted equilibrium states are unstable). Fortunately, there exist well physically founded thermodynamical theories that avoid these problems and that can deal with prerelaxation processes.[8–11] In this work, we shall use the Israel–Stewart heat transport equation. Nevertheless, it is important to emphasize that, as in Refs. 2–5, the results found are also valid in the context of the *Extended Irreversible Thermodynamics*.[10,11]

The paper is organized as follows. The next section is devoted to introduce the interior and exterior metrics used, and to construct the stress–energy tensor. Also, the validity of the slow rotating limit is discussed. In Sec. III, the conservation equations and heat transport equation are evaluated just after perturbation, and we find the expression for the critical point. Finally, we discuss the results in the last section.

We adopt metric of signature -2 and geometrized units $c=G=1$. The quantities subscripted with r_1 denote that they are evaluated at the surface of the object, whereas a partial derivative with respect time is denoted by subscript 0.

II. ENERGY–MOMENTUM TENSOR

We consider a nonstatic and axisymmetric distribution of matter and radiation. Let us assume that the interior metric is given by[12]

$$ds^2=Y^2du^2+2\frac{Y}{X}\,dudr+2a\,\sin^2\,\theta\left(\frac{Y}{X}-Y^2\right)dud\phi-2a\,\sin^2\,\theta\left(\frac{Y}{X}\right)drd\phi-R^2d\theta^2$$
$$-\sin^2\,\theta\left[r^2+a^2\,\cos^2\,\theta+2a^2\,\sin^2\,\theta\left(\frac{Y}{X}-\frac{Y^2}{2}\right)\right]d\phi^2, \tag{1}$$

where $u=x^0$ is a time-like coordinate, $r=x^1$ is the null coordinate, and $\theta=x^2$ and $\phi=x^3$ are the usual angle coordinates. Here $R^2=r^2+a^2\,\cos^2\,\theta$, a is the angular momentum per unit mass in the weak field limit—the Kerr parameter—and X and Y are arbitrary functions of u, r, and θ. The u-coordinate is related to retarded time in a flat space–time, and therefore, u-constant surfaces are null cones open to the future. In these coordinates r-constant surfaces are oblate spheroids.

The energy–momentum tensor may be expressed in the above coordinates (1). Nevertheless, the physical quantities appearing in it will be those measured by a local Minkowskian observer comoving with the fluid. Thus, it is necessary to introduce the local Minkowski coordinates (t,x,y,z) related to these by

$$dt=Ydu+\frac{dr}{X}+a\,\sin^2\,\theta\left(\frac{1}{X}-Y\right)d\phi,$$

$$dx=\frac{dr}{X}+\frac{a\,\sin^2\,\theta}{X}\,d\phi,$$

$$dy=(r^2+a^2\cos^2\theta)^{1/2}d\theta,$$
$$dz=(r^2+a^2\cos^2\theta]^{1/2}\sin\theta d\phi. \tag{2}$$

The radial velocity of matter is given by

$$\frac{dr}{du}=\frac{XYR\omega_x-Ya\omega_z\sin\theta}{R(1-\omega_x)+Ya\omega_z\sin\theta}, \tag{3}$$

and the orbital velocity is

$$\Omega=\frac{d\phi}{du}=\frac{Y\omega_z}{R\sin\theta(1-\omega_x)+Ya\omega_z\sin^2\theta}, \tag{4}$$

where ω_x and ω_z are the corresponding components of the velocity of a fluid element as measured in the locally Minkowski frame.

In the slow rotating limit, $a\ll 1$, and consequently $\Omega\ll 1$. Thus, from (4),

$$\omega_z=\frac{\Omega R\sin\theta(1-\omega_x)}{Y(1-\Omega a\sin^2\theta)}=\frac{\Omega r\sin\theta(1-\omega_x)}{Y}+\mathcal{O}(\Omega^2),$$

and ω_z is also much less than unity. Note that in the static case (i.e., $\omega_x=0$), and for a local Minkowskian observer (i.e., $Y=1$); this means that every fluid element must move at a nonrelativistic velocity.[13] A simple calculus shows that this condition is accomplished by most of the known pulsars (Ref. 14, p. 146).

The interior metric (1) can be matched to the Kerr–Vaidya exterior metric,[15]

$$ds^2=\left(1-\frac{2mr}{\tilde{R}^2}\right)du^2+2dudr+\frac{4mr\tilde{a}\sin^2\theta}{\tilde{R}^2}dud\phi-2\tilde{a}\sin^2\theta drd\phi-\tilde{R}^2d\theta^2$$
$$-\sin^2\theta\left(r^2+\tilde{a}^2+\frac{2mr\tilde{a}^2\sin^2\theta}{\tilde{R}^2}\right)d\phi, \tag{5}$$

where $\tilde{R}=r^2+\tilde{a}^2\cos^2\theta$, $\tilde{a}$ is the exterior Kerr parameter, and m is the total mass. It is worth mentioning at this point that the metric above is not a pure radiation solution and may be interpreted as such only asymptotically.[16] A pure rotating radiation solution may be found in Ref. 17. However, although the interpretation of the Carmeli–Kaye metric is not completely clear, the appearance of the critical point is independent of the shape and the intensity of the emission pulse, and will be put in evidence for small values of luminosity (see below).

A particular solution can be found in Ref. 12. Nevertheless, in this work we shall not restrict ourselves to a particular solution, and we shall go on using the unknown functions $X(u,r,\theta)$ and $Y(u,r,\theta)$. These are constrained by the following junction conditions at the surface $(r=r_1)$,[12]

$$X_{r=r_1}=Y_{r=r_1}=\left(1-\frac{2mr}{R^2}\right)^{1/2}_{r=r_1},$$
$$\left(\frac{\partial X}{\partial\theta}\right)_{r=r_1}=\left(\frac{\partial Y}{\partial\theta}\right)_{r=r_1}=-\left(\frac{mra^2\sin(2\theta)}{X(r^2+a^2\cos^2\theta)^2}\right)_{r=r_1}, \tag{6}$$
$$\left(\frac{\partial X}{\partial r}\right)_{r=r_1}=\left(\frac{\partial Y}{\partial r}\right)_{r=r_1}=-\left(\frac{m(r^4-a^4\cos^2\theta+2r^2a^2\cos^2\theta)}{X(r^2-a^2\cos^2\theta)(r^2+a^2\cos^2\theta)^2}\right)_{r=r_1}.$$

Next, we assume that, for a local Minkowskian observer, comoving with the fluid, the space–time contains the following.

(1) An anisotropic fluid of density $\rho^{\rm mat}$, radial pressure $p^{\rm mat}$, and tangential pressure $p_\perp^{\rm mat}$.
(2) A radiation field of specific intensity $I(x,t;\mathbf{n},\nu)$, radiation energy flow q, radiation energy density $\rho^{\rm rad}$, and radiation pressure $p^{\rm rad}$.

The specific intensity of the radiation field $I(x,t;\mathbf{n},\nu)$, is measured at the position x and time t, traveling in the direction $\mathbf{n}$ with a frequency ν. The moments of $I(x,t;\mathbf{n},\nu)$ for a planar geometry can be written as[18]

$$\rho^{\rm rad}=\frac{1}{2}\int_0^\infty d\nu\int_{-1}^1 d\mu I(x,t;\mathbf{n},\nu), \tag{7}$$

$$q=\frac{1}{2}\int_0^\infty d\nu\int_{-1}^1 d\mu\mu I(x,t;\mathbf{n},\nu), \tag{8}$$

and

$$p^{\rm rad}=\frac{1}{2}\int_0^\infty d\nu\int_{-1}^1 d\mu\mu^2 I(x,t;\mathbf{n},\nu), \tag{9}$$

where $\mu=\cos\theta$. In classical radiative transfer theory, the specific intensity of the radiation field, $I(x,t;\mathbf{n},\nu)$, at the position x and time t, traveling in the direction $\mathbf{n}$ with a frequency ν, is defined so that

$$d\mathscr{E}=I(x,t;\mathbf{n},\nu)dS\cos\alpha d\vartheta d\nu dt, \tag{10}$$

is the energy crossing a surface element dS, into solid angle $d\vartheta$ around $\mathbf{n}$ (α is the angle between $\mathbf{n}$ and the normal to dS), transported by radiation of frequencies $(\nu,\nu+d\nu)$, in time dt (see Ref. 18 for details).

For a nonrotating observer, the radiation portion of the stress–energy tensor reads as[18,19]

$$\hat{T}^R_{\mu\nu}=\begin{pmatrix}\rho^{\rm rad} & -q & 0 & 0\\ -q & p^{\rm rad} & 0 & 0\\ 0 & 0 & \frac{1}{2}(\rho^{\rm rad}-p^{\rm rad}) & 0\\ 0 & 0 & 0 & \frac{1}{2}(\rho^{\rm rad}-p^{\rm rad})\end{pmatrix}. \tag{11}$$

The radiation part of the energy momentum tensor as seen by an observer comoving with the fluid can be found by means of a local rotation to (11),

$$\hat{T}^R_{\mu\nu}=\begin{pmatrix}\rho^{\rm rad}+D^2p_\perp^{\rm rad} & -q & 0 & DG\\ -q & p^{\rm rad} & 0 & -Dq\\ 0 & 0 & p_\perp^{\rm rad} & 0\\ DG & -Dq & 0 & D^2\rho^{\rm rad}+p_\perp^{\rm rad}\end{pmatrix}, \tag{12}$$

where D is an unknown function of u, r and θ associated with the local dragging of inertial frames effect, $p_\perp^{\rm rad}=\frac{1}{2}(\rho^{\rm rad}-p^{\rm rad})$, and $G=\frac{1}{2}(3\rho^{\rm rad}-p^{\rm rad})$.

The material part of the energy–momentum tensor for this observer is given by

$$\hat{T}^{\rm M}_{\mu\nu}=(\rho_{\rm M}+p_\perp)\hat{U}_\mu\hat{U}_\nu-p_\perp\eta_{\mu\nu}+(p-p_\perp)\hat{s}_\mu\hat{s}_\nu, \tag{13}$$

where the Minkowski metric is denoted by $\eta_{\mu\nu}$, $\hat{s}_\mu=\delta^x_\mu$, and $\hat{U}_\mu=\delta^t_\mu$. Thus, the energy–momentum tensor, as seen by a Minkowskian observer comoving with the fluid, can be written as

$$\hat{T}_{\mu\nu}=\hat{T}^R_{\mu\nu}+\hat{T}^{\rm M}_{\mu\nu}. \tag{14}$$

In the slow rotation limit D is taken up to first order. Thus, in virtue of (12) and (13), (14) $\hat{T}_{\mu\nu}$ can be expressed as

$$\hat{T}_{\mu\nu}=(\rho+p_\perp)\hat{U}_\mu\hat{U}_\nu-P_\perp\eta_{\mu\nu}+(p-p_\perp)\hat{s}_\mu\hat{s}_\nu+2\hat{q}_{(\mu}\hat{U}_{\nu)}+2\hat{q}_{(\mu}\hat{D}_{\nu)}+2G\hat{U}_{(\mu}\hat{D}_{\nu)}, \tag{15}$$

where $\hat{q}_\mu=-q\hat{s}_\mu$, $\hat{D}_\mu=D\delta^z_\mu$, $\rho=\rho^{\rm rad}+\rho^{\rm mat}$ is the total energy density, and $p=p^{\rm mat}+p^{\rm rad}$ and $p_\perp=p_\perp^{\rm mat}+p_\perp^{\rm rad}$ are the total radial pressure and the total tangential pressure, respectively.

It remains to express the energy–momentum tensor in curvilinear coordinates (1), as seen by an observer at rest with respect to the Minkowskian coordinates given by (2). Thus, we apply a Lorentz boost and the coordinate transformation defined in (2). The boost velocity is, in the rotating case, $\boldsymbol{\omega}=(\omega_x,0,\omega_z)$—see Ref. 20 for details. Assuming a slow rotation limit, D, a, and ω_z are taken up to first order. Thus,

$$T_{\mu\nu}=(\rho+p_\perp)U_\mu U_\nu-p_\perp g_{\mu\nu}+(p-p_\perp)s_\mu s_\nu+2q_{(\mu}U_{\nu)}+2q_{(\mu}D_{\nu)}+2GU_{(\mu}D_{\nu)}, \tag{16}$$

where $g_{\mu\nu}$ is given by (1),

$$U_\mu=\gamma Y\delta^u_\mu+\frac{\gamma(1-\omega_x)}{X}\,\delta^r_\mu+\gamma\left[a\,\sin^2\,\theta\left(\frac{1-\omega_x}{X}-Y\right)-\omega_z r\,\sin\,\theta+\mathcal{O}(\omega_z^2)\right]\delta^\phi_\mu, \tag{17}$$

$$\begin{aligned}s_\mu=&-\gamma\omega_x Y\delta^u_\mu+\left(\frac{\gamma(1-\omega_x)}{X}+\mathcal{O}(\omega_z^2)\right)\delta^r_\mu\\&+\left[r\,\sin\,\theta\,\frac{\omega_z}{\omega_x}\,(\gamma-1)+\frac{\gamma a\,\sin^2\,\theta}{X}\,[1-\omega_x(1-YX)]+\mathcal{O}(\omega_z^2)\right]\delta^\phi_\mu,\end{aligned} \tag{18}$$

$$q_\mu=-qs_\mu, \tag{19}$$

$$D_\mu=\mathcal{O}(\omega_z^2)\,\delta^u_\mu+\mathcal{O}(\omega_z^2)\,\delta^r_\mu+[Dr\,\sin\,\theta+\mathcal{O}(\omega_z^2)]\delta^\phi_\mu, \tag{20}$$

$$\omega=\sqrt{\omega_x^2+\omega_z^2}=\omega_x+\mathcal{O}(\omega_z^2),$$

and

$$\gamma=\frac{1}{\sqrt{1-\omega^2}}=\frac{1}{\sqrt{1-\omega_x^2}}+\mathcal{O}(\omega_z^2). \tag{21}$$

Here, $\mathcal{O}(\omega_z^2)$ corresponds to quadratic and higher terms in ω_z, D, and a.

III. DEPARTURE FROM COMPLETE EQUILIBRIUM

As has been mentioned in the Introduction, we assume that, before perturbation, the slowly rotating system is evolving along a sequence of states in which it is close complete equilibrium. Therefore, u derivatives of ω_x and q can be neglected because it is close to hydrostatic equilibrium (along the r coordinate) and nearly thermally adjusted. A system that is thermally adjusted changes its properties considerably only within a time scale $\tau_{\rm cha}$ that is large as compared with the Kelvin–Helmholtz time scale $\tau_{\rm KH}$ (Ref. 1, p. 66). Thus, before perturbation we can assume that the u derivatives of ρ, p, and $p_\perp$ are small, and consequently ω_x too (i.e., we can neglect quadratic and higher terms in ω_x). On the other hand, if the system is close to hydrostatic equilibrium, then the hydrostatic time scale $\tau_{\rm hyd}\sim\sqrt{r^3/m}$ is much shorter than the Kelvin–Helmholtz time scale $\tau_{\rm KH}\sim m^2/2rl$, and inertial terms in the equation of motion $T^\mu_{r;\mu}=0$ can be ignored. This condition will be accomplished for small values of luminosity l, and consequently for small values of q. Thus, before perturbation $q\sim\mathcal{O}(\omega_x)$.

We shall evaluate the system just after perturbation. Where, as stated before, *just after perturbation* means on a time scale of the order of the relaxation time. Physically, this implies that the

perturbed quantities (ω_x and q) are still much less than unity. Nevertheless, the system is departing form complete equilibrium and the u derivatives of ω_x and q must be small but different from zero [i.e., $q_{,0}\sim\omega_{x,0}\sim\mathscr{O}(\omega_x)$].

Thus, the system is characterized by the following: Before perturbation,

$$\rho_{,0}\sim p_{,0}\sim p_{\perp,0}\sim\omega_x\sim q\sim\mathscr{O}(\omega_x), \tag{22}$$

$$\omega_{x,0}\sim q_{,0}\sim\mathscr{O}(\omega_x^2); \tag{23}$$

after perturbation,

$$\rho_{,0}\sim p_{,0}\sim p_{\perp,0}\sim\omega_x\sim q\sim\omega_{x,0}\sim q_{,0}\sim\mathscr{O}(\omega_x). \tag{24}$$

In order to clarify the existence of a critical point in slowly rotating fluids, we shall use conservation equations ($T^{\mu}_{\nu;\mu}=0$).

A. Conservation equations

Before perturbation, conservation equations read as

$$R_\nu := T^{\mu}_{\nu;\mu}=0. \tag{25}$$

After perturbation, physical quantities contained in (16) remain unchanged since we are evaluating the system on a time scale of the order of the relaxation time. Therefore, the only new terms appearing in conservation equations are those containing u derivatives of ω_x and q, and conservation equations can be written as

$$\tilde{T}^{\mu}_{\nu;\mu}=\tilde{R}_\nu+\tilde{\omega}_{x,0}\mathscr{F}_\nu+\tilde{q}_{,0}\mathscr{G}_\nu=0, \tag{26}$$

where an overtilde denotes that the quantity is evaluated after perturbation, and $\mathscr{F}_\nu$ and $\mathscr{G}_\nu$ do not depend on ω_x, q, or u derivatives of physical variables, since we are applying first-order perturbation theory. The only terms that can contain $\tilde{\omega}_{x,0}$ and $\tilde{q}_{,0}$ in $\tilde{T}^{\mu}_{\nu;\mu}=0$ are of the form $\tilde{T}^{0}_{\nu,0}$. By means of (1), (17–20), and (16), we find four equations of the form (26)—see Appendix A for details—

$$\begin{aligned}
\tilde{R}_u&=(\rho+p)\tilde{\omega}_{x,0}+\tilde{q}_{,0},\\
\tilde{R}_r&=\frac{2}{XY}\left[(\rho+p)\tilde{\omega}_{x,0}+\tilde{q}_{,0}\right],\\
\tilde{R}_\theta&=0,\\
\tilde{R}_\phi&=0.
\end{aligned} \tag{27}$$

Note that $\tilde{R}_\phi$ is not the total meridional force acting on a given fluid element since it contains terms in $\tilde{\omega}_{z,0}$. Nevertheless, $\tilde{R}_r$ does not contain u-derivatives of physical variables. Thus, $\tilde{R}_r>0$ is the total outward force (pressure gradient+gravitational) along the r-coordinate acting on a given fluid element after perturbation.

The u derivative of the heat flow $\tilde{q}_{,0}$ can be connected with $\tilde{\omega}_{x,0}$ by means of an adequate heat transport equation.

B. Heat transport equation

As it is well known, the Eckart–Landau transport equation[6,7] assumes a vanishing relaxation time. This fact leads to undesirable predictions: An infinite speed for the propagation of the thermal signals and unstable equilibrium states.[21] Thus, it is necessary to adopt a relativistic thermodynamic theory leading to a hyperbolic equation for the propagation of thermal signals. On

the other hand, we are evaluating the system *just after* its departure form hydrostatic equilibrium and thermal adjustment (in the sense described above). Thus, to be consistent with this choice we must use a heat transport equation with a nonvanishing relaxation time.

We shall use the Israel–Stewart relativistic transport equation.[8,9] For viscous free fluid distributions, this one can be written as[22]

$$\tau h^{\mu\nu}U^{\alpha}q_{\nu;\alpha}+q^{\mu}=\kappa h^{\mu\nu}(T_{,\nu}-TU^{\alpha}U_{\nu;\alpha})-\frac{1}{2}\,\kappa T^{2}\left(\frac{\tau}{\kappa T^{2}}\,U^{\beta}\right)_{;\beta}q^{\mu}+\tau\omega^{\mu\nu}q_{\nu}, \tag{28}$$

where κ, τ, and T denote thermal conductivity, thermal relaxation time, and temperature, respectively, $h^{\mu\nu}=U^{\mu}U^{\nu}-g^{\mu\nu}$ is the projector onto the hypersurface orthogonal to U^{μ} and $\omega_{\mu\nu}=h^{\alpha}_{\mu}h^{\beta}_{\nu}U_{[\alpha;\beta]}$ is the vorticity.

Before perturbation, transport equations (28) can be symbolized as

$$\mathscr{H}^{\mu}=0. \tag{29}$$

Just after perturbation, (28) can be written as

$$\tilde{\mathscr{H}}^{\mu}+\tilde{\omega}_{x,0}\mathscr{T}^{\mu}+\tilde{q}_{,0}\mathscr{T}^{\mu}=0. \tag{30}$$

Nevertheless, physical quantities contained on $\mathscr{H}^{\mu}$ do not change just after perturbation, and $\tilde{\mathscr{H}}^{\mu}=\mathscr{H}^{\mu}$. Thus, from (29), expression (30) takes the form

$$\tilde{\omega}_{x,0}\mathscr{T}^{\mu}+\tilde{q}_{,0}\mathscr{T}^{\mu}=0. \tag{31}$$

Vectors $\mathscr{T}^{\mu}$ and $\mathscr{T}^{\mu}$, as $\mathscr{T}_{\nu}$ and $\mathscr{G}_{\nu}$ in the preceding section, do not depend on ω_x, q, or u derivatives of physical variables.

The components of (28) containing u-derivatives of q and ω_x up to first order are

$$\tau h^{\mu\nu}U^{\alpha}q_{\nu;\alpha} \tag{32}$$

and

$$-\kappa T h^{\mu\nu}U^{\alpha}U_{\nu;\alpha}. \tag{33}$$

Therefore, the heat transport equation (28) just after perturbation is given by—see Appendix B for details—

$$\tilde{q}_{,0}=-\frac{\kappa T}{\tau}\,\tilde{\omega}_{x,0}, \tag{34}$$

for any value of μ.

C. Equation of motion

We are now in a position to find the equation of motion just after perturbation. From (27) and (34), we can write

$$\tilde{R}_{r}=\frac{2(\rho+p)}{XY}\,(1-\alpha)\tilde{\omega}_{x,0}, \tag{35}$$

where

$$\alpha=\frac{\kappa T}{\tau(\rho+p)}. \tag{36}$$

As it has been noted in Sec. III A, $\tilde{R}_{r}>0$ is the total outward force along the r-coordinate acting on a given fluid element. Note that it vanishes for $\alpha=1$ (the critical point). This fact has an important consequence: For $\alpha=1$, $\tilde{R}_{r}$ vanishes, even though the u-derivative of the radial velocity

is different from zero. This method also predicts an anomalous behavior beyond the critical point—Eq. (35). If $\alpha>1$, then an outward force ($\tilde{R}_r>0$) implies an inward acceleration ($\tilde{\omega}_{x,0}<0$). Therefore, it seems that, for systems out of the quasistatic approximation, first-order perturbation theory cannot be applied close to the critical point or beyond it.

On the other hand, (35) may be compared with the Newtonian form

$$Force = mass \times acceleration, \tag{37}$$

where here, the term

$$\frac{2(\rho+p)}{XY}(1-\alpha), \tag{38}$$

stands for the *effective inertial mass*. Below the critical point, this *inertial mass* decreases as α grows up. This seems to be connected with the dynamical stability of the system, leading to a minimum stability for $\alpha=1$.[23]

IV. CONCLUSIONS

In this paper we have studied the departure, of a slowly rotating fluid distribution, from a state close to hydrostatic equilibrium (along the r coordinate) and nearly thermally adjusted. Our aim has been to elucidate the existence of a critical point similar to that found for nonrotating systems.[2–5] The existence of this critical point implies that the first-order perturbative method is not always satisfactory to study prerelaxation processes (i.e., processes that take place on time scales smaller than the hydrostatic time scale).

We have found that, also in this case, there exists such a critical point. This one is given by the condition

$$\alpha=\frac{\kappa T}{\tau(\rho+p)}=1, \tag{39}$$

and it coincides with this one found in a spherically symmetric case[2–4] and in an axially symmetric case.[5] Therefore, condition $\alpha=1$ establishes an upper limit for which prerelaxation processes can be studied by means of a first-order perturbative method. This result is also valid if the initial system configuration is strictly in complete equilibrium and radially static (i.e., $\omega_x=\omega_{x,0}=q=q_{,0}=0$).

Note that this method predicts, for values of α less than unity, that the effective inertial mass decreases as α grows. Intuitively, this means that the departure from equilibrium or quasiequilibrium will be steeper for larger α's, or, in other words, that the smaller the α, the larger the dynamical stability. This point has been recently illustrated, by means of an expression for the active gravitational mass in terms of α.[23] It is interesting to emphasize that, at least in nonrotating configurations, causality and stability conditions[21] do not always forbid the existence of the critical point.[3,4]

Finally, it is also worth noticing that the critical point and the inflationary equation of state for nondissipative systems ($p=-\rho$) are similar, in that they imply the vanishing of the inertial mass term. Therefore one might wonder about the plausibility of an inflationary scenario in a Universe at, or close to, the critical point.

APPENDIX A: CONSERVATION EQUATIONS JUST AFTER PERTURBATION

In the slow rotating limit, U^μ, s^μ, and D^μ read as

$$U^\mu=\left(\frac{\gamma(1-\omega_x)}{Y}+\mathcal{O}(\omega_z^2)\right)\delta^\mu_u+[\omega_x X+\mathcal{O}(\omega_z^2)]\delta^\mu_r+\left(\frac{\omega_z}{r\ \sin\ \theta}+\mathcal{O}(\omega_z^2)\right)\delta^\mu_\phi, \tag{A1}$$

$$s^\mu=\left(\frac{\gamma(1-\omega_x)}{Y}+\mathcal{O}(\omega_z^2)\right)\delta^\mu_u+[-\gamma X+\mathcal{O}(\omega_z^2)]\delta^\mu_r+\left[-\frac{\omega_z}{r\ \sin\ \theta}\left(\frac{\gamma-1}{\omega_x}\right)+\mathcal{O}(\omega_z^2)\right]\delta^\mu_\phi, \tag{A2}$$

$$D^\mu=\mathcal{O}(\omega_z^2)\,\delta^\mu_u+\mathcal{O}(\omega_z^2)\,\delta^\mu_r+\left(-\frac{D}{r\ \sin\ \theta}+\mathcal{O}(\omega_z^2)\right)\delta^\mu_\phi, \tag{A3}$$

and $q^\mu=-qs^\mu$. From (16) the only terms that contain u derivatives of ω_x and q (up to first order in ω_x and ω_z) in conservation equations $T^\mu_{\nu;\mu}=0$ are of the form $T^0_{\nu,0}$. In particular,

$$\begin{aligned}
(\rho+p_\perp)(U^0U_\nu)_{,0}&=(\rho+p_\perp)\left(\frac{\gamma(1-\omega_x)}{Y}\,U_\nu\right)_{,0},\\
(p-p_\perp)(s^0s_\nu)_{,0}&=(p-p_\perp)\left(\frac{\gamma(1-\omega_x)}{Y}\,s_\nu\right)_{,0},\\
G(U^0D_\nu+U_\nu D^0)_{,0}&=G\left(\frac{\gamma(1-\omega_x)}{Y}\,D_\nu\right)_{,0},\\
(q^0U_\nu+q^0D_\nu+q_\nu U^0+q_\nu D^0)_{,0}&=-q_{,0}\left(\frac{\gamma(1-\omega_x)}{Y}\,(U_\nu+D_\nu+s_\nu)\right)\\
&\quad-q\left(\frac{\gamma(1-\omega_x)}{Y}\,(U_\nu+D_\nu+s_\nu)\right)_{,0}.
\end{aligned} \tag{A4}$$

Thus, from (17)–(20), (21), (A4), and following the definition of $\mathcal{F}_\nu$ and $\mathcal{G}_\nu$ given in (26), we find, up to first order in ω_x,

$$\begin{aligned}
\omega_{x,0}\mathcal{F}_u&=(\rho+p_\perp)\left(\frac{1}{1+\omega_x}\right)_{,0}-(p-p_\perp)\left(\frac{\omega_x}{1+\omega_x}\right)_{,0}-q\left(\frac{1-\omega_x}{1+\omega_x}\right)_{,0}=-\omega_{x,0}(\rho+p),\\
\omega_{x,0}\mathcal{F}_r&=\left(\frac{\rho+p-2q}{XY}\right)\left(\frac{1-\omega_x}{1+\omega_x}\right)_{,0}=-\omega_{x,0}\,\frac{2(\rho+p)}{XY},\\
\omega_{x,0}\mathcal{F}_\theta&=0,\quad \omega_{x,0}\mathcal{F}_\phi=0,
\end{aligned} \tag{A5}$$

$$\begin{aligned}
q_{,0}\mathcal{G}_u&=-q_{,0},\quad q_{,0}\mathcal{G}_r=-q_{,0}\,\frac{2}{XY},\\
q_{,0}\mathcal{G}_\theta&=0,\quad q_{,0}\mathcal{G}_\phi=0,
\end{aligned} \tag{A6}$$

where we have neglected in $\omega_{x,0}\mathcal{F}_\phi$ terms of the form $\omega_{x,0}D$, $\omega_{x,0}a$, and $\omega_{x,0}\omega_z$, and in $q_{,0}\mathcal{G}_\phi$ terms of the form $q_{,0}D$, $q_{,0}a$, and $q_{,0}\omega_z$. Thus,

$$\mathcal{F}_\mu=-(\rho+P)(1,2/XY,0,0), \tag{A7}$$

and

$$\mathcal{G}_\mu=-(1,2/XY,0,0). \tag{A8}$$

The expression of conservation equations can be found by means of (26):

$$\tilde{R}_\nu=[(\rho+p)\tilde{\omega}_{x,0}+\tilde{q}_{,0}](1,2/XY,0,0). \tag{A9}$$

APPENDIX B: HEAT TRANSPORT EQUATION JUST AFTER PERTURBATION

The right-hand terms in (28),

$$-\frac{1}{2}\kappa T^2\left(\frac{\tau}{\kappa T^2}U^\beta\right)_{;\beta}q^\alpha,$$

and

$$\tau\omega^{\mu\nu}q_\nu,$$

contain factors of the form $\omega_{x,0}q$, that are of second order. Therefore, the only terms in (28) that contain u derivatives of ω_x and q up to first order are of the form

$$\tau h^{\mu\nu}U^0q_{\nu,0} \tag{B1}$$

and

$$-\kappa T h^{\mu\nu}U^0U_{\nu,0}. \tag{B2}$$

Using (A1), (18), and (19) in (B1) and (B2),

$$\begin{aligned}\tau h^{\mu\nu}U^0q_{\nu,0}&=\frac{\gamma(1-\omega_x)}{Y}\tau h^{\mu\nu}(-q_{,0}s_\nu-qs_{\nu,0}),\\ -\kappa T h^{\mu\nu}U^0U_{\nu,0}&=-\frac{\gamma(1-\omega_x)}{Y}\kappa T h^{\mu\nu}U_{\nu,0}.\end{aligned} \tag{B3}$$

Vectors $\mathscr{T}^\mu$ and $\mathscr{T}^\mu$ (31) do not depend on ω_x, q, and their u derivatives because we are using first-order perturbation theory. Thus, from (B3),

$$\tilde{\omega}_{x,0}\mathscr{T}^\mu=\tilde{\omega}_{x,0}\frac{\kappa T}{XY}h^{\mu r}, \tag{B4}$$

and

$$\tilde{q}_{,0}\mathscr{T}^\mu=\tilde{q}_{,0}\frac{\tau}{XY}h^{\mu r}, \tag{B5}$$

where we have neglected terms of the form $\tilde{q}_{,0}a$. Therefore, from (B4) and (B5), expression (31) takes the form

$$\tilde{q}_{,0}=-\frac{\kappa T}{\tau}\tilde{\omega}_{x,0}, \tag{B6}$$

which is valid for any μ.

(Received 25 November 1997; accepted for publication 6 February 1998)

In a recent paper [Zhijun Qiao and Ruguang Zhou, Phys. Lett. A **235**, 35 (1997)], the amazing fact was reported that a discrete and a continuous integrable system share the same r-matrix with the interesting property of being nondynamical. Now, we present three further pairs of different continuous integrable systems sharing the same r-matrix again being nondynamical. The first pair is the finite-dimensional constrained system (FDCS) of the famous AKNS hierarchy and the Dirac hierarchy; the second pair is the FDCS of the well-known geodesic flows on the ellipsoid and the Heisenberg spin chain hierarchy; and the third pair is the FDCS of one hierarchy studied by Xianguo Geng [Phys. Lett. A **162**, 375 (1992)] and another hierarchy proposed by Zhijun Qiao [Phys. Lett. A **192**, 316 (1994)]. All those FDCSs possess Lax representations and from the viewpoint of r-matrix can be shown to be completely integrable in Liouville's sense. © *1998 American Institute of Physics.* [S0022-2488(98)02506-7]

I. INTRODUCTION

The well-known nonlinearization method[1] is a powerful tool to generate completely integrable finite-dimensional Hamiltonian systems (CIFDHSs) from the eigenvalue problems or Lax pairs of nonlinear evolution equations (NLEEs). With the help of this method many new CIFDHSs have been successively found, and solutions to NLEEs have been given by involutive or parametric representations.[2–12] The r-matrix[13] method is quite an effective approach to the Lie–Poisson structure in $1+1$-dimensional space,[14,15] providing fundamental commutator relations in the quantum inversing scattering.[16] Recently, the study of CIFDHSs admitting an r-matrix has already received attention.[17–22] It has been shown that r-matrices play a very important part in proving the integrability of CIFDHSs. Besides, the Lax matrix associated with the r-matrix of a CIFDHS can be applied for obtaining algebraic–geometric solutions of soliton equations or NLEEs.[23]

In a recent paper,[24] we reported an interesting and surprising result: a discrete and a continuous integrable system possess the same nondynamical r-matrix being independent from the dynamical variables p,q. The question of whether there are other pairs of continuous or discrete finite-dimensional integrable systems sharing the same r-matrix which should be nondynamical arises. In the present paper, on the basic idea of Ref. 24 we have considered a wide class of 2×2 spectral problems and finally succeeded in finding three other pairs of different continuous integrable systems with the common nondynamical r-matrix. The first pair is formed by the finite-dimensional constrained system (FDCS) of the famous AKNS and Dirac hierarchies; the second pair is formed by the FDCS of the well-known geodesic flow on the ellipsoid and the Heisenberg spin chain hierarchy; while the third pair consists of the FDCS of a hierarchy studied by Xianguo Geng[7] and a hierarchy proposed by Zhijun Qiao.[11] All of these FDCSs possess Lax representations, and by using the r-matrix approach can be shown to be completely integrable in Liouville's sense.

Before displaying these results, let us first introduce some basic symbols and notations. Let $(R^{2N},dp\wedge dq)$ stand for the standard symplectic structure in the Euclidic space $R^{2N}=\{(p,q)|p=(p_1,\ldots,p_N),\ q=(q_1,\ldots,q_N)\}$, where p_i,q_i $(i=1,...,N)$ are N pairs of canonical coordinates. The standard inner product in R^N will be denoted by $\langle\cdot,\cdot\rangle$ and the Poisson bracket of two Hamiltonian functions F,G is given through[25]

$$\{F,G\}=\sum_{i=1}^{N}\left(\frac{\partial F}{\partial q_i}\frac{\partial G}{\partial p_i}-\frac{\partial F}{\partial p_i}\frac{\partial G}{\partial q_i}\right)=\left\langle\frac{\partial F}{\partial q},\frac{\partial G}{\partial p}\right\rangle-\left\langle\frac{\partial F}{\partial p},\frac{\partial G}{\partial q}\right\rangle.$$

With N arbitrary distinct constants $\lambda_1,\ldots,\lambda_N$ we form the diagonal matrix $\Lambda=\mathrm{diag}(\lambda_1,...,\lambda_N)$, while λ, μ are used for two different spectral parameters. By $C^\infty(R)$ we denote the set of all functions on real field R being infinitely many times differentiable. Finally, x stands for the spatial continuous variable.

II. THE CONSTRAINED AKNS AND DIRAC (D) SYSTEM

We consider the following two 2×2 traceless Lax matrices:

$$L^{\mathrm{AKNS}}=L^{\mathrm{AKNS}}(\lambda)=\begin{pmatrix}1&0\\0&-1\end{pmatrix}+\sum_{j=1}^{N}\frac{1}{\lambda-\lambda_j}\begin{pmatrix}p_jq_j&-q_j^2\\p_j^2&-p_jq_j\end{pmatrix}\equiv\begin{pmatrix}A_{\mathrm{AKNS}}(\lambda)&B_{\mathrm{AKNS}}(\lambda)\\C_{\mathrm{AKNS}}(\lambda)&-A_{\mathrm{AKNS}}(\lambda)\end{pmatrix},\tag{1}$$

$$L^{D}=L^{D}(\lambda)=\begin{pmatrix}0&1\\-1&0\end{pmatrix}+\sum_{j=1}^{N}\frac{1}{\lambda-\lambda_j}\begin{pmatrix}p_jq_j&-q_j^2\\p_j^2&-p_jq_j\end{pmatrix}\equiv\begin{pmatrix}A_D(\lambda)&B_D(\lambda)\\C_D(\lambda)&-A_D(\lambda)\end{pmatrix}.\tag{2}$$

Let us choose two 2×2 matrices M_{AKNS} and M_D:

$$M_{\mathrm{AKNS}}=\begin{pmatrix}\lambda&-\langle q,q\rangle\\\langle p,p\rangle&-\lambda\end{pmatrix},\tag{3}$$

$$M_D=\begin{pmatrix}\langle p,q\rangle&\lambda+\frac{1}{2}(\langle p,p\rangle-\langle q,q\rangle)\\-\lambda+\frac{1}{2}(\langle p,p\rangle-\langle q,q\rangle)&-\langle p,q\rangle\end{pmatrix}.\tag{4}$$

Then we have the following.

Theorem 1: The Lax equations

$$L_x^{\mathrm{AKNS}}=[M_{\mathrm{AKNS}},L^{\mathrm{AKNS}}],\tag{5}$$

$$L_x^{D}=[M_D,L^{D}],\tag{6}$$

respectively describe the following finite-dimensional Hamiltonian systems (FDHSs) (H_{AKNS}) and (H_D),

$$(H_{\mathrm{AKNS}}):\begin{cases}q_x=-\langle q,q\rangle p+\Lambda q=\dfrac{\partial H_{\mathrm{AKNS}}}{\partial p},\\[2ex]p_x=\langle p,p\rangle q-\Lambda p=-\dfrac{\partial H_{\mathrm{AKNS}}}{\partial q};\end{cases}\tag{7}$$

$$(H_D):\begin{cases}q_x=\langle p,q\rangle q+\frac{1}{2}(\langle p,p\rangle-\langle q,q\rangle)p+\Lambda p=\dfrac{\partial H_D}{\partial p},\\[2ex]p_x=-\langle p,q\rangle p-\frac{1}{2}(\langle p,p\rangle-\langle q,q\rangle)q-\Lambda q=-\dfrac{\partial H_D}{\partial q},\end{cases}\tag{8}$$

with Hamiltonian functions

$$H_{\mathrm{AKNS}}=\langle \Lambda q,p\rangle-\tfrac{1}{2}\langle p,p\rangle\langle q,q\rangle, \tag{9}$$

$$H_D=\tfrac{1}{2}(\langle \Lambda p,p\rangle+\langle \Lambda q,q\rangle)+\tfrac{1}{2}(\langle p,q\rangle^2-\langle q,q\rangle\langle p,p\rangle)+\tfrac{1}{8}(\langle p,p\rangle+\langle q,q\rangle)^2. \tag{10}$$

Proof: By direct calculation.

Through setting

$$u=-\langle q,q\rangle,\quad v=\langle p,p\rangle, \tag{11}$$

Eq. (7) becomes

$$\begin{aligned} q_{jx}&=\lambda_j q_j+up_j,\quad j=1,...,N,\\ p_{jx}&=vq_j-\lambda_j p_j,\quad j=1,...,N, \end{aligned} \tag{12}$$

which is nothing other than the well-known Zakharov–Shabat–AKNS spectral problem (ZS-AKNSSP)[26]

$$y_x=\begin{pmatrix}\lambda & u\\ v & -\lambda\end{pmatrix}y \tag{13}$$

where $\lambda=\lambda_j$, $y=(q_j,p_j)^T$. The potentials u,v defined by Eq. (11) are correspond exactly to the Bargmann–Garnier constraint[1(b)]

$$G_0=(v,u)^T=\sum_{j=1}^{N}\left(\frac{\delta\lambda_j}{\delta u},\frac{\delta\lambda_j}{\delta v}\right)^T \tag{14}$$

of ZS-AKNSSP (13), where $\delta\lambda_j/\delta u$, $\delta\lambda_j/\delta v$ are the two spectral gradients of spectral parameters λ_j with respect to the potentials u and v. Therefore Eq. (7) coincides with the constrained AKNS system (c-AKNSS).

Similarly, after setting

$$u=-\tfrac{1}{2}(\langle p,p\rangle-\langle q,q\rangle),\quad v=-\langle p,q\rangle, \tag{15}$$

it is easily seen that Eq. (8) becomes the Dirac spectral problem (DSP)[27]

$$y_x=\begin{pmatrix}-v & \lambda-u\\ -\lambda-u & v\end{pmatrix}y \tag{16}$$

with $\lambda=\lambda_j$, $y=(q_j,p_j)^T$. Thus, Eq. (8) is the constrained Dirac system (c-DS).

Let us return to the Lax matrix (1) and (2). By a simple calculation we obtain the following.

Proposition 1: For $J=\mathrm{AKNS}$ and $J=D$ the following holds:

$$\begin{aligned} &\{A_J(\lambda),A_J(\mu)\}=\{B_J(\lambda),B_J(\mu)\}=\{C_J(\lambda),C_J(\mu)\}=0,\\ &\{A_J(\lambda),B_J(\mu)\}=\frac{2}{\mu-\lambda}(B_J(\mu)-B_J(\lambda)),\\ &\{A_J(\lambda),C_J(\mu)\}=\frac{2}{\mu-\lambda}(C_J(\lambda)-C_J(\mu)),\\ &\{B_J(\lambda),C_J(\mu)\}=\frac{4}{\mu-\lambda}(A_J(\mu)-A_J(\lambda)). \end{aligned} \tag{17}$$

Set $L_1^J(\lambda)=L^J(\lambda)\otimes I$, $L_2^J(\mu)=I\otimes L^J(\mu)$, where I is the 2×2 unit matrix. Then the above proposition yields the following.

Theorem 2: The Lax matrices $L^J(\lambda)$ ($J=$AKNS,D) defined by Eqs. (1) and (2) satisfy the fundamental Poisson bracket

$$\{L_1^J(\lambda)\overset{\otimes}{,}L_2^J(\mu)\}=[r_{12}(\lambda,\mu),L_1^J(\lambda)]-[r_{21}(\mu,\lambda),L_2^J(\mu)]. \tag{18}$$

Here $\{L_1^J(\lambda)\overset{\otimes}{,}L_2^J(\mu)\}$ is a 4×4 matrix,[14] $[\cdot,\cdot]$ is the usual commutator of the matrix, and the r-matrices $r_{12}(\lambda,\mu)$, $r_{21}(\mu,\lambda)$ are exactly given by the following standard r-matrices:

$$r_{12}(\lambda,\mu)=\frac{2}{\mu-\lambda}P,\quad r_{21}(\mu,\lambda)=Pr_{12}(\mu,\lambda)P, \tag{19}$$

$$P=\begin{pmatrix}1&0&0&0\\0&0&1&0\\0&1&0&0\\0&0&0&1\end{pmatrix}=\frac{1}{2}\left(I+\sum_{i=1}^{3}\sigma_i\otimes\sigma_i\right) \tag{20}$$

(here σ_i are the Pauli matrices).

So, the c-AKNSS (7) and c-DS (8) share the same standard r-matrix (19), which is obviously nondynamical.

Remark 1: In fact, since the r-matrix relation (18) is concerned only with the commutator, the r-matrix $r_{12}(\lambda,\mu)$ satisfying (18) in the case of the c-AKNSS (7) and c-DS (8) can be also chosen as

$$r_{12}(\lambda,\mu)=\frac{2}{\mu-\lambda}P+I\otimes\tilde{S},\quad \tilde{S}=\begin{pmatrix}a&b\\c&d\end{pmatrix}, \tag{21}$$

where the elements a,b,c,d can be arbitrary functions $a(\lambda,\mu,p,q)$, $b(\lambda,\mu,p,q)$, $c(\lambda,\mu,p,q)$, $d(\lambda,\mu,p,q)\in C^\infty(R)$ with respect to the spectral parameters λ, μ and the dynamical variables p,q. This shows that for a given Lax matrix, the associated r-matrix is not uniquely defined (there are even infinitely many r-matrices possible). Here we give the simplest case: $a=b=c=d=0$, i.e., the standard r-matrix (19).

III. THE CONSTRAINED HARRY–DYM (HD) AND HEISENBERG SPIN CHAIN (HSC) SYSTEM

The constrained Harry–Dym (HD) system describes the geodesic flow on an ellipsoid and shares the same r-matrix with the constrained Heisenberg spin chain (HSC).

To see this, we follow the process given in Sec. II, considering the following Lax matrices:

$$\begin{aligned}L^{\mathrm{HD}}=L^{\mathrm{HD}}(\lambda)&=\begin{pmatrix}-\langle p,q\rangle\lambda^{-1}&\lambda^{-2}+\langle q,q\rangle\lambda^{-1}\\-\langle p,p\rangle\lambda^{-1}&\langle p,q\rangle\lambda^{-1}\end{pmatrix}+\sum_{j=1}^{N}\frac{1}{\lambda-\lambda_j}\begin{pmatrix}p_jq_j&-q_j^2\\p_j^2&-p_jq_j\end{pmatrix}\\&\equiv\begin{pmatrix}A_{\mathrm{HD}}(\lambda)&B_{\mathrm{HD}}(\lambda)\\C_{\mathrm{HD}}(\lambda)&-A_{\mathrm{HD}}(\lambda)\end{pmatrix},\end{aligned} \tag{22}$$

$$\begin{aligned}L^{\mathrm{HSC}}=L^{\mathrm{HSC}}(\lambda)&=\begin{pmatrix}-\langle p,q\rangle\lambda^{-1}&\langle q,q\rangle\lambda^{-1}\\-\langle p,p\rangle\lambda^{-1}&\langle p,q\rangle\lambda^{-1}\end{pmatrix}+\sum_{j=1}^{N}\frac{1}{\lambda-\lambda_j}\begin{pmatrix}p_jq_j&-q_j^2\\p_j^2&-p_jq_j\end{pmatrix}\\&\equiv\begin{pmatrix}A_{\mathrm{HSC}}(\lambda)&B_{\mathrm{HSC}}(\lambda)\\C_{\mathrm{HSC}}(\lambda)&-A_{\mathrm{HSC}}(\lambda)\end{pmatrix}.\end{aligned} \tag{23}$$

Set

$$M_{\mathrm{HD}}=\begin{pmatrix} 0 & 1 \\ -\dfrac{\langle \Lambda p,p\rangle}{\langle \Lambda^2 q,q\rangle}\lambda & 0 \end{pmatrix}, \tag{24}$$

$$M_{\mathrm{HSC}}=\begin{pmatrix} -i\lambda\langle \Lambda p,q\rangle & i\lambda\langle \Lambda q,q\rangle \\ -i\lambda\langle \Lambda p,p\rangle & i\lambda\langle \Lambda p,q\rangle \end{pmatrix}, \quad i^2=-1. \tag{25}$$

Then a direct calculation leads to the following theorem.

Theorem 3: The Lax representations

$$L_x^{\mathrm{HD}}=[M_{\mathrm{HD}},L^{\mathrm{HD}}], \tag{26}$$

$$L_x^{\mathrm{HSC}}=[M_{\mathrm{HSC}},L^{\mathrm{HSC}}], \tag{27}$$

respectively give the following FDHS:

$$(H_{\mathrm{HD}}):\begin{cases} q_x=p=\dfrac{\partial H_{\mathrm{HD}}}{\partial p}\Big|_{TQ^{N-1}}, \\ p_x=-\dfrac{\langle \Lambda p,p\rangle}{\langle \Lambda^2 q,q\rangle}\Lambda q=-\dfrac{\partial H_{\mathrm{HD}}}{\partial q}\Big|_{TQ^{N-1}}, \\ \langle \Lambda q,q\rangle=1; \end{cases} \tag{28}$$

$$(H_{\mathrm{HSC}}):\begin{cases} q_x=i\langle \Lambda q,q\rangle\Lambda p-i\langle \Lambda p,q\rangle\Lambda q=\dfrac{\partial H_{\mathrm{HSC}}}{\partial p}, \\ p_x=i\langle \Lambda p,q\rangle\Lambda p-i\langle \Lambda p,p\rangle\Lambda q=-\dfrac{\partial H_{\mathrm{HSC}}}{\partial q}, \end{cases} \tag{29}$$

with the Hamiltonian functions

$$H_{\mathrm{HD}}=\frac{1}{2}\langle p,p\rangle-\frac{\langle \Lambda p,p\rangle}{2\langle \Lambda^2 q,q\rangle}(\langle \Lambda q,q\rangle-1), \tag{30}$$

$$H_{\mathrm{HSC}}=\tfrac{1}{2}\,i\langle \Lambda p,p\rangle\langle \Lambda q,q\rangle-\tfrac{1}{2}\,i\langle \Lambda p,q\rangle^2. \tag{31}$$

Here, in Eq. (28) TQ^{N-1} is a tangent bundle in R^{2N}:

$$TQ^{N-1}=\{(p,q)\in R^{2N}|F\equiv\langle \Lambda q,q\rangle-1=0,G\equiv\langle \Lambda p,q\rangle=0\}. \tag{32}$$

Obviously, Eq. (28) is equivalent to

$$q_{xx}+\frac{\langle \Lambda q_x,q_x\rangle}{\langle \Lambda^2 q,q\rangle}\Lambda q=0, \quad \langle \Lambda q,q\rangle=1, \tag{33}$$

which is nothing but the equation of the geodesic flow on the surface $\langle \Lambda q,q\rangle=1$ in R^N space.[3,22] On the other hand, by setting

$$u=\frac{\langle \Lambda q_x,q_x\rangle}{\langle \Lambda^2 q,q\rangle}, \tag{34}$$

Eq. (33) becomes the well-known Harry–Dym spectral problem

$$y_{xx}+\lambda uy=0 \tag{35}$$

with $\lambda=\lambda_j$, $y=q_j$, $j=1,...,N$. Simultaneously, Eq. (34) gives the constraint condition considered by Cao,[3] so that Eq. (28) coincides with the constrained HD system (c-HDS).

In addition, after setting

$$u=-\langle \Lambda q,q\rangle, \quad v=\langle \Lambda p,p\rangle, \quad w=-\langle \Lambda p,q\rangle, \tag{36}$$

we can see that Eq. (29) becomes the Heisenberg spin chain spectral problem[28]

$$y_x=\begin{pmatrix} -i\lambda w & -i\lambda u \\ -i\lambda v & i\lambda w \end{pmatrix} y, \quad i^2=-1, \tag{37}$$

with $\lambda=\lambda_j$, $y=(q_j,p_j)^T$. Thus, Eq. (29) reads as the constrained Heisenberg spin chain system (c-HSCS). The constraint defined by Eq. (36) has been studied and applied to obtaining involutive solutions for the Heisenberg spin chain equations in Ref. 29. However, the r-matrix was not given.

Now, we construct the r-matrix of c-HDS (28) and c-HSCS (29). Their Lax matrices (22) and (23) share all elements except one, namely

$$\begin{pmatrix} 0 & \lambda^{-2} \\ 0 & 0 \end{pmatrix}.$$

Since this element does not affect the calculations concerning the fundamental Poisson bracket $\{L_1^J(\lambda)\overset{\otimes}{,}L_2^J(\mu)\}$, one can readily deduce that the c-HDS and c-HSCS possess the same r-matrix.

Theorem 4: The Lax matrix $L^J(\lambda)$ ($J=$HD,HSC) defined by Eqs. (22) and (23) satisfies the fundamental Poisson bracket (18) with the common nondynamical r-matrix

$$r_{12}(\lambda,\mu)=\frac{2\lambda}{\mu(\mu-1)}P, \quad r_{21}(\mu,\lambda)=Pr_{12}(\mu,\lambda)P. \tag{38}$$

Apparently the r-matrix (38) solves the classical Yang–Baxter equation (CYBE)

$$[r_{ij},r_{ik}]+[r_{ij},r_{jk}]+[r_{kj},r_{ik}]=0, \quad i,j,k=1,2,3. \tag{39}$$

Remark 2: The r-matrix $r_{12}(\lambda,\mu)$ satisfying Eq. (18) in the case of c-HDS (28) and c-HSCS (29) can also be chosen as

$$r_{12}(\lambda,\mu)=\frac{2\lambda}{\mu(\mu-\lambda)}P+I\otimes\tilde{S}. \tag{40}$$

Evidently, Eq. (38) is the simplest case: $\tilde{S}=0$ of Eq. (40).

IV. THE CONSTRAINED *G* AND *Q* SYSTEM

In this section, we introduce the following Lax matrices:

$$\begin{aligned} L^G=L^G(\lambda)&=\begin{pmatrix} (\frac{1}{2}+\langle p,q\rangle)\lambda^{-1} & \langle q,q\rangle\lambda^{-1} \\ 0 & -(\frac{1}{2}+\langle p,q\rangle)\lambda^{-1} \end{pmatrix}+\sum_{j=1}^{N}\frac{1}{\lambda-\lambda_j}\begin{pmatrix} p_jq_j & -q_j^2 \\ p_j^2 & -p_jq_j \end{pmatrix} \\ &\equiv\begin{pmatrix} A_G(\lambda) & B_G(\lambda) \\ C_G(\lambda) & -A_G(\lambda) \end{pmatrix}, \end{aligned} \tag{41}$$

$$L^Q=L^Q(\lambda)=\begin{pmatrix} -\lambda^{-1} & \langle q,q\rangle\lambda^{-1} \\ 0 & \lambda^{-1} \end{pmatrix}+\sum_{j=1}^{N}\frac{1}{\lambda-\lambda_j}\begin{pmatrix} p_jq_j & -q_j^2 \\ p_j^2 & -p_jq_j \end{pmatrix}\equiv\begin{pmatrix} A_Q(\lambda) & B_Q(\lambda) \\ C_Q(\lambda) & -A_Q(\lambda) \end{pmatrix}. \tag{42}$$

If we set

$$M_G=\begin{pmatrix} -\frac{1}{\alpha}\lambda & \frac{1}{\alpha}(\langle p,p\rangle-\langle q,q\rangle)-1 \\ \frac{1}{\alpha}(\langle p,p\rangle-\langle q,q\rangle+1)\lambda & \frac{1}{\alpha}\lambda \end{pmatrix}, \tag{43}$$

$$M_Q=\begin{pmatrix} \lambda+\frac{1}{2\beta^2}\langle \Lambda q,q\rangle\langle p,p\rangle & \frac{1}{\beta}\langle \Lambda q,q\rangle \\ -\frac{1}{\beta}\langle p,p\rangle\lambda & -\lambda-\frac{1}{2\beta^2}\langle \Lambda q,q\rangle\langle p,p\rangle \end{pmatrix}, \tag{44}$$

with

$$\alpha=\sqrt{(\langle p,p\rangle-\langle \Lambda q,q\rangle)^2-4\langle \Lambda q,p\rangle},\quad \beta=1-\langle p,q\rangle,$$

then, by a lengthy and straightforward calculation we obtain the following.

Theorem 5: The following Lax representations,

$$L_x^G=[M_G,L^G] \tag{45}$$

and

$$L_x^Q=[M_Q,L^Q], \tag{46}$$

where the first one is restricted to the surface $\Gamma=\{(p,q)\in R^{2N}|\langle p,q\rangle=0,\langle \Lambda q,q\rangle\langle p,p\rangle+\langle \Lambda q,p\rangle=0\}$ in the space R^{2N}, respectively produce the finite-dimensional systems

$$\begin{aligned} q_x&=\frac{1}{\alpha}(-\Lambda q+(\langle p,p\rangle-\langle \Lambda q,q\rangle)p)-p,\\ p_x&=\frac{1}{\alpha}(\Lambda p+(\langle p,p\rangle-\langle \Lambda q,q\rangle)\Lambda q)+\Lambda q, \end{aligned} \tag{47}$$

and

$$\begin{aligned} q_x&=\Lambda q+\frac{1}{\beta}\langle \Lambda q,q\rangle p+\frac{1}{2\beta^2}\langle p,p\rangle\langle \Lambda q,q\rangle q,\\ p_x&=-\Lambda p-\frac{1}{\beta}\langle p,p\rangle\Lambda q-\frac{1}{2\beta^2}\langle p,p\rangle\langle \Lambda q,q\rangle p. \end{aligned} \tag{48}$$

In Eqs. (47) and (48), respectively insert

$$\begin{aligned} u&=\frac{1}{\alpha}=\frac{1}{\sqrt{(\langle p,p\rangle-\langle \Lambda q,q\rangle)^2-4\langle \Lambda q,p\rangle}},\\ v&=\frac{\langle p,p\rangle-\langle \Lambda q,q\rangle}{\alpha}=\frac{\langle p,p\rangle-\langle \Lambda q,q\rangle}{\sqrt{(\langle p,p\rangle-\langle \Lambda q,q\rangle)^2-4\langle \Lambda q,p\rangle}}; \end{aligned} \tag{49}$$

and

$$\begin{aligned} u&=\frac{\langle \Lambda q,q\rangle}{\beta}=\frac{\langle \Lambda q,q\rangle}{1-\langle q,p\rangle}\\ v&=\frac{-\langle p,p\rangle}{\beta}=-\frac{\langle p,p\rangle}{1-\langle q,p\rangle}. \end{aligned} \tag{50}$$

Then, Eqs. (47) and (48) turn out to become the spectral problem studied by Geng (simply called G-spectral problem),[7]

$$y_x=\begin{pmatrix} -\lambda u & v-1 \\ \lambda(v+1) & \lambda u \end{pmatrix} y, \tag{51}$$

with $\lambda=\lambda_j$, $y=(q_j,p_j)^T$, and the spectral problem proposed by Qiao (simply called Q-spectral problem),[11]

$$y_x=\begin{pmatrix} \lambda-\frac{1}{2}uv & u \\ \lambda v & -\lambda+\frac{1}{2}uv \end{pmatrix} y, \tag{52}$$

with $\lambda=\lambda_j$, $y=(q_j,p_j)^T$, respectively. So, Eqs. (47) and (48) are nothing but the constrained Geng system (c-GS) and constrained Qiao system (c-QS) under the constraint conditions (49) and (50). Since the Lax equation (45) gives the c-GS (47) on the surface Γ, the Lax matrix L^G should become

$$L_\Gamma^G=L_\Gamma^G(\lambda)=\begin{pmatrix} \frac{1}{2}\lambda^{-1} & \langle q,q\rangle\lambda^{-1} \\ 0 & -\frac{1}{2}\lambda^{-1} \end{pmatrix}+\sum_{j=1}^{N}\frac{1}{\lambda-\lambda_j}\begin{pmatrix} p_jq_j & -q_j^2 \\ p_j^2 & -p_jq_j \end{pmatrix}, \tag{53}$$

which is almost the same as L^Q. Hence, through calculating the fundamental Poisson bracket and commutator we have the following theorem.

Theorem 6: For the c-GS (47) and c-QS (48), their Lax matrices $L_\Gamma^G(\lambda)$ and $L^Q(\lambda)$ satisfy the fundamental Poisson bracket (18) with the same nondynamical r-matrix:

$$r_{12}(\lambda,\mu)=\frac{2}{\mu-\lambda}P-\frac{2}{\mu}S,\quad S=\begin{pmatrix} 0&0&0&0\\ 0&0&0&0\\ 0&1&0&0\\ 0&0&0&0 \end{pmatrix}=\sigma_-\otimes\sigma^+. \tag{54}$$

We can easily show that Eq. (54) satisfies the CYBE (39).

Remark 3: The r-matrix $r_{12}(\lambda,\mu)$ in Theorem 6 can be also chosen as

$$r_{12}(\lambda,\mu)=\frac{2}{\mu-\lambda}P-\frac{2}{\mu}S+I\otimes\tilde{S}. \tag{55}$$

Equation (54) is the simplest case: $\tilde{S}=0$ of Eq. (55).

V. CONCLUSION

In this article, we present three pairs of different finite-dimensional constrained systems with common nondynamical r-matrices. Along the discrete Toda symplectic map and continuous constrained c-KdV system discovered in Ref. 24 these three pairs form (to the authors' knowledge), the only four examples of pairs of different finite-dimensional integrable systems possessing the above property. The question of whether or not there are any other pairs like them arises. It seems that this is not the case.

From Remarks 1–3, we see that the r-matrix $r_{12}(\lambda,\mu)$ satisfying the fundamental Poisson bracket (18) is composed of two parts, the first one being their main term, and the second one being the common term $I\otimes\tilde{S}$ of Eqs. (21), (40), and (55). Usually when proving the integrability of FDHS we choose their main term as the simplest nondynamical one in order to reduce the calculations.

Apparently, the r-matrix is not uniquely defined. In fact, there are infinitely many r-matrices since the elements a,b,c,d in the matrix $\tilde{S}$ of Eqs. (21), (40), and (55) can be arbitrarily chosen, and they may be constants as well as functions with respect to the spectral parameters λ, μ and the dynamical variables p,q. For a given Lax matrix $L^J(\lambda)$, our r-matrices formulas (21),

(40), and (55) admit an infinite set of solutions $r_{12}(\lambda,\mu)$ of Eq. (18), which includes both the dynamical case [as $a=a(\lambda,\mu,p,q)$, $b=b(\lambda,\mu,p,q)$, $c=c(\lambda,\mu,p,q)$, $d=d(\lambda,\mu,p,q)\in C^{\infty}(R)$] and the nondynamical or constant case [as $a=a(\lambda,\mu)$, $b=b(\lambda,\mu)$, $c=c(\lambda,\mu)$, $d=d(\lambda,\mu)$, or $a,b,c,d=\text{const}$].

In analogy to the first author's thesis,[30] we can further discuss the involutive sets, integrability, separation of variables, and algebraic–geometric solutions for these constrained FDHSs by using the determinant of Lax matrix, r-matrix relation, Poisson bracket, and further modern algebraic–geometric tools.

ACKNOWLEDGMENTS

The first author would like to express his sincere thanks to Prof. Gu Chaohao and Prof. Hu Hesheng for their enthusiastic instructions and help. The last two sections of this work were finished when the first author visited Gh-Kassel University, Germany in 1997. He is very grateful to Prof. Strampp, Prof. Blum, and Prof. Barner for their friendly help and warm invitations. Fluid space–times and conharmonic symmetries

Abdussattar and Babita Dwivedi
Department of Mathematics, Banaras Hindu University, Varanasi 221 005, India

(Received 29 January 1997; accepted for publication 27 January 1998)

The conharmonic curvature tensor is considered as an invariant of the conharmonic transformation defined by Ishii and the necessary and sufficient conditions for the conharmonic curvature tensor in a perfect fluid space–time to be divergence free has been obtained. Conharmonic motion, conharmonic collineation, and conharmonic curvature collineation are introduced as subcases of conformal motion, conformal collineation, and Weyl conformal collineation, respectively, and relations of conharmonic symmetries with inheriting symmetries are investigated. In the case of an existing conharmonic Killing vector along the flow vector, along the anisotropy vector, and perpendicular to both in an anisotropic fluid space–time it is found that no equation of state is singled out unless the conharmonic Killing vector is also a curvature inheritance vector. Conditions are obtained for the symmetries of the anisotropic fluid space–time admitting a conharmonic Killing vector to be inherited. In the case of a conharmonic symmetric space–time and also in the case of a space–time with a divergence-free conharmonic curvature tensor it is found that if the space–time admits an infinitesimal conharmonic Killing vector then the scalar curvature of the space–time vanishes and the space–time is either conharmonically flat or has four distinct principal null directions. © *1998 American Institute of Physics.* [S0022-2488(98)02605-X]

I. INTRODUCTION

Katzin *et al.*[1] initiated the study of a fundamental symmetry property of the space–time of general relativity defined by the vanishing Lie deformation of the Riemann curvature tensor. A vector ξ is said to define a ''curvature collineation'' (CC) if $L_\xi R^h_{ijk}=0$, where R^h_{ijk} is the Riemann curvature tensor of the Riemannian V_4 and L_ξ denotes the Lie derivative with respect to an infinitesimal vector ξ. The contraction of CC, i.e., $L_\xi R_{ij}=0$, where R_{ij} is the Ricci tensor, defines ''Ricci collineation'' (RC). Further studies on CC (including RC) indicated that their relations with conformal and projective symmetries are restricted to a rare special case. In order to get rid of this situation, Duggal[2] modified the concept of CC suitable for proper conformal and other related symmetries and introduced another symmetry called ''curvature inheritance'' (CI). A V_4 is said to admit curvature inheritance along a vector ξ if

$$L_\xi R^h_{ijk}=2\alpha R^h_{ijk}, \tag{1.1}$$

where α is a scalar function of space–time coordinates. The ''Ricci inheritance'' (RI) is similarly defined by

$$L_\xi R_{ij}=2\alpha R_{ij}. \tag{1.2}$$

We also have

$$L_\xi R^j_k=2\alpha R^j_k-R^i_k h^j_i \tag{1.3}$$

and

$$L_\xi R=2\alpha R-R_{ij}h^{ij}, \tag{1.4}$$

where

 © 1998 American Institute of Physics

$$h_{ij} \equiv L_{\xi} g_{ij} = \xi_{i;j} + \xi_{j;i}, \tag{1.5}$$

The existence of symmetry vectors is of interest in the study of exact solutions of Einstein field equations and in the determination of related conservation laws.[3–13] In particular a number of recent articles[14–17] have been concerned with conformal killing vectors (CKVs) in fluid space–times. Much of the analysis that has been done in the subject of CKVs concerns special conformal killing vectors (SCKVs).[18–21]

Ishii[22] introduced the conharmonic transformation as a subgroup of the conformal transformation

$$\overline{g_{ij}} = e^{2\sigma} g_{ij}, \tag{1.6}$$

where σ is a scalar function, satisfying the condition

$$\sigma^{i}_{;i} + \sigma_{;i}\sigma^{i}_{;} = 0. \tag{1.7}$$

A fourth-rank tensor Z^{h}_{ijk} which remains invariant under conharmonic transformation is given by

$$Z^{h}_{ijk} = R^{h}_{ijk} + \tfrac{1}{2}(\delta^{h}_{j} R_{ik} - \delta^{h}_{k} R_{ij} + g_{ik} R^{h}_{j} - g_{ij} R^{h}_{k}) \tag{1.8}$$

and its contraction

$$Z_{ij} = -\tfrac{1}{2} R g_{ij} \tag{1.9}$$

is also invariant under (1.7). It may be noted that the conharmonic curvature tensor Z^{h}_{ijk} and the Riemann curvature tensor R^{h}_{ijk} become identical in an empty space–time ($R_{ij} = 0$). The conformal curvature tensor

$$C^{h}_{ijk} = R^{h}_{ijk} + \tfrac{1}{2}(\delta^{h}_{j} R_{ik} - \delta^{h}_{k} R_{ij} + g_{ik} R^{h}_{j} - g_{ij} R^{h}_{k}) + \frac{R}{6}(\delta^{h}_{k} g_{ij} - \delta^{h}_{j} g_{ik}) \tag{1.10}$$

may be expressed in terms of conharmonic curvature tensor Z^{h}_{ijk} and its contraction Z_{ij} as

$$C^{h}_{ijk} = Z^{h}_{ijk} - \tfrac{1}{3}(\delta^{h}_{k} Z_{ij} - \delta^{h}_{j} Z_{ik}). \tag{1.11}$$

The two tensors C^{h}_{ijk} and Z^{h}_{ijk} become identical if the space–time is with zero scalar curvature. Recently we have obtained a spherically symmetric conharmonically flat space–time

$$ds^2 = \frac{[f(r-t) + F(r+t)]^2}{r^2}[dr^2 + r^2\, d\theta^2 + r^2 \sin^2\theta\, d\phi^2 - dt^2], \tag{1.12}$$

which is found to describe the gravitational field due to a distribution of pure radiation in the presence of disordered radiation.[23]

The plan of the present paper is as follows. In Sec. II a perfect fluid space–time is considered with a divergence-free conharmonic curvature tensor and it is found that if the conharmonic curvature tensor is divergence-free then either $(\mu + p) = 0$ or the fluid is shear-free, vorticity-free, acceleration-free, and the energy density and isotropic pressure are constant over the spacelike hypersurface orthogonal to the fluid four-velocity vector. Conharmonic motion (Conh M), conharmonic collineation (Conh C), and conharmonic curvature collineation (Conh CC) are defined as subcases of conformal motion (Conf M), conformal collineation (Conf C), and Weyl conformal collineation (W Conf C) respectively, in Sec. III. It is shown that if a space–time admits a proper curvature inheritance vector (CIV) which is also a conharmonic killing vector (Conh KV), then the space–time is necessarily conharmonically flat and if a space–time admits a proper Ricci inheritance vector (RIV) which is also a Conh KV, then the scalar-curvature of the space–time vanishes. In Sec. IV an anisotropic fluid space–time admitting a Conh KV is considered and the equation of state is determined in three special cases of the Conh KV which is also a CIV. In Sec. V, a proper Conh KV is studied in two different space–times—one with a symmetric conharmonic curvature tensor and the other with a divergence-free conharmonic curvature tensor. In both cases

it is found that the scalar curvature of the space–time vanishes and the space–time is either conharmonically flat or of type N, i.e., has four distinct principal null directions.

II. PERFECT FLUID SPACE–TIME WITH A DIVERGENCE-FREE CONHARMONIC CURVATURE TENSOR

The energy momentum tensor for a perfect-fluid distribution is given by

$$T_{ij}=(\mu+p)u_iu_j+pg_{ij}, \tag{2.1}$$

where μ is the energy density, p is the isotropic pressure, and u^i is the fluid four-velocity vector. We consider a perfect fluid space–time which has a divergence-free conharmonic curvature tensor. If the divergence of the conharmonic curvature tensor vanishes, i.e., $Z^h_{ijk;h}=0$, we obtain from Eq. (1.8)

$$(R_{ij}-\tfrac{1}{2}Rg_{ij})_{;k}=(R_{ik}-\tfrac{1}{2}Rg_{ik})_{;j}. \tag{2.2}$$

From the field equations

$$R_{ij}-\tfrac{1}{2}Rg_{ij}=T_{ij}, \tag{2.3}$$

Eq. (2.2) may be expressed as

$$T_{ij;k}=T_{ik;j}. \tag{2.4}$$

Substituting for T_{ij} from Eq. (2.1) in Eq. (2.4) we get

$$\begin{aligned}&[\langle\mu+p\rangle_{;k}u_iu_j+(\mu+p)u_{i;k}u_j+(\mu+p)u_{j;k}u_i+p_{;k}g_{ij}]\\&\quad-[\langle\mu+p\rangle_{;j}u_iu_k+(\mu+p)u_{i;j}u_k+(\mu+p)u_{k;j}u_i+p_{;j}g_{ik}]=0.\end{aligned} \tag{2.5}$$

Contraction by u^k yields

$$(\mu+p)^{\cdot}u_iu_j+(\mu+p)\dot{u}_iu_j+(\mu+p)\dot{u}_ju_i+\dot{p}g_{ij}+(\mu+p)_{;j}u_i+(\mu+p)u_{i;j}-p_{;j}u_i=0. \tag{2.6}$$

Here and in what follows an overhead dot denotes the covariant derivative along the fluid flow vector.

From the conservation equation $T^{ij}_{;j}=0$ we get

$$(\mu+p)\dot{u}_i=-p_{;i}-\dot{p}u_i \quad \text{(force equation)}, \tag{2.7}$$

$$\text{and}\quad \dot{\mu}=-(\mu+p)\theta \quad \text{(energy equation)}, \tag{2.8}$$

where $\theta\equiv u^i_{;i}$ is the expansion scalar. The covariant derivative of the unit flow vector may be decomposed as

$$u_{i;j}=\sigma_{ij}+w_{ij}+\tfrac{1}{3}\theta(g_{ij}+u_iu_j)-\dot{u}_iu_j, \tag{2.9}$$

where σ_{ij} is the shear, w_{ij} is the rotation, and $\dot{u}_i$ is the acceleration of the congruence of the fluid flow vector. Equation (2.6) with the help of Eq. (2.7) takes the form

$$(\mu-p)^{\cdot}u_iu_j+(\mu-p)_{;j}u_i-p_{;i}u_j+\dot{p}g_{ij}+(\mu+p)u_{i;j}=0. \tag{2.10}$$

Contracting by u^i we get

$$(\mu-p)_{;j}=-(\mu-p)^{\cdot}u_j. \tag{2.11}$$

Making use of Eq. (2.7) we get Eq. (2.11)

$$(\mu+p)\dot{u}_i=-\mu_{;i}-\dot{\mu}u_i. \tag{2.12}$$

Equation (2.10) in view of Eq. (2.11) reduces to

$$-p_{;i}u_j+\dot{p}g_{ij}+(\mu+p)u_{i;j}=0. \tag{2.13}$$

Contracting by g^{ij} we get

$$\dot{p}=-\tfrac{1}{3}(\mu+p)\,\theta. \tag{2.14}$$

In view of Eq. (2.8) this equation yields

$$\dot{\mu}=3\dot{p}. \tag{2.15}$$

Equation (2.13) with the help of Eq. (2.7) may be written as

$$(\mu+p)\dot{u}_iu_j+\dot{p}(g_{ij}+u_iu_j)+(\mu+p)u_{i;j}=0. \tag{2.16}$$

Using Eq. (2.14) in Eq. (2.16) we get

$$(\mu+p)[\dot{u}_iu_j-\tfrac{1}{3}\theta(g_{ij}+u_iu_j)+u_{i;j}]=0. \tag{2.17}$$

This suggests that either

$$(\mu+p)=0 \tag{2.18}$$

or

$$u_{i;j}=\tfrac{1}{3}\theta(g_{ij}+u_iu_j)-\dot{u}_iu_j\,. \tag{2.19}$$

If $(\mu+p)=0$ we have either $\mu=0$, $p=0$ (empty space–time) or the perfect fluid may be regarded as if endowed with a vacuumlike equation of state.[24]

Comparing Eq. (2.19) with Eq. (2.9) we get

$$\sigma_{ij}+\omega_{ij}=0. \tag{2.20}$$

That is, $\sigma_{ij}=\omega_{ij}=0$. Making use of Eqs. (2.12) and (2.19), Eq. (2.5) becomes

$$\begin{aligned}&[p_{;k}-(\mu+p)\dot{u}_k]u_iu_j+\tfrac{1}{3}(\mu+p)\,\theta u_jg_{ik}-(\mu+p)\dot{u}_ju_ku_i+p_{;k}g_{ij}\\&\quad-[p_{;i}-(\mu+p)\dot{u}_j]u_iu_k-\tfrac{1}{3}(\mu+p)\,\theta g_{ij}u_k+(\mu+p)\dot{u}_ku_iu_j-p_{;j}g_{ik}=0.\end{aligned} \tag{2.21}$$

This equation with the help of Eqs. (2.7) and (2.14) may be written as

$$p_{;k}u_iu_j-p_{;j}u_iu_k-(\mu+p)\dot{u}_kg_{ij}+(\mu+p)\dot{u}_jg_{ik}-(\mu+p)\dot{u}_ku_iu_j+(\mu+p)\dot{u}_ju_iu_k=0. \tag{2.22}$$

Contracting by g^{ij} and making use of Eq. (2.7), Eq. (2.22) yields

$$(\mu+p)\dot{u}_k=0, \tag{2.23}$$

i.e.,

$$\dot{u}_k=0 \quad (\text{since } \mu+p\neq 0). \tag{2.24}$$

In view of this equation, Eqs. (2.7) and (2.12) yield

$$\mu_{;i}=-\dot{\mu}u_i \tag{2.25}$$

and

$$p_{;i}=-\dot{p}u_i\,. \tag{2.26}$$

From these equations and Eq. (2.15) we obtain

$$\mu-3p=\text{constant}. \tag{2.27}$$

Thus if $(\mu+p)\neq 0$, then the fluid is shear-free, vorticity-free, acceleration-free, and the energy density and pressure are constant over the spacelike hypersurface orthogonal to the fluid four-velocity vector. These are precisely the conditions for the space–time to be FRW.

Conversely, if the perfect fluid does not have a vacuumlike equation of state and $(\mu+p)=0$ (i.e., $\mu=0$, $p=0$), then obviously the conharmonic curvature tensor of the space–time is divergence-free. Also if the fluid is shear-free, vorticity-free, acceleration-free, and the energy density and pressure are constant over the spacelike hypersurface orthogonal to the fluid four-velocity vector, from Eq. (2.1) we see that

$$T_{ij;k}-T_{ik;j}=[(\mu+p)u_iu_j+pg_{ij}]_{;k}-[(\mu+p)u_iu_k+pg_{ik}]_{;j}. \tag{2.28}$$

Using Eqs. (2.19), (2.24), (2.25), and (2.26) in Eq. (2.28) we get Eq. (2.4), i.e., the divergence of the conharmonic curvature tensor vanishes. Thus we may state the following theorem.

Theorem (2.1): The conharmonic curvature tensor of a perfect-fluid space–time will be divergence-free if and only if either $(\mu+p)=0$ (which is not really a perfect fluid but is an Einstein space) or the space–time is a FRW model satisfying $(\mu-3p)=$constant.

III. CONHARMONIC SYMMETRIES AND THE RELATION OF CONH KV WITH INHERITING SYMMETRIES

A V_4 is said to admit a Conf M generated by a conformal Killing vector (CKV) ξ if

$$h_{ij}\equiv L_\xi g_{ij}=2\psi g_{ij}, \tag{3.1}$$

where ψ is a scalar function of the space–time coordinates given by $\psi=\frac{1}{4}\xi^k_{;k}$. In particular ξ is called a special conformal Killing vector (SCKV) if $\psi_{;ij}=0$, $\psi_{,i}\neq 0$. Other subcases of CKV are the homothetic vector (HV) if $\psi_{,i}=0$, $\psi\neq 0$ and the Killing vector (KV) if $\psi=0$.

A V_4 is said to admit a conformal collineation (Conf C) if there exists a vector ξ such that

$$L_\xi\Gamma^i_{jk}=\delta^i_j\psi_{;k}+\delta^i_k\psi_{;j}-g_{jk}g^{im}\psi_{;m} \tag{3.2}$$

and V_4 admits a Weyl conformal collineation (W Conf C) along the vector field ξ if

$$L_\xi C^h_{ijk}=0. \tag{3.3}$$

It follows that every Conf M is a Conf C and W Conf C but the converse is not necessarily true.

Now we define another subcase of conformal symmetries called conharmonic symmetries. A Conf M is defined as conharmonic motion (Conh M) if

$$\Box\psi\equiv g^{ij}\psi_{;ij}=0,\quad \psi_{;ij}\neq 0. \tag{3.4}$$

A Conf C is similarly defined as Conh C if Eq. (3.2) holds together with condition (3.4). A V_4 is said to admit a conharmonic curvature collineation (Conh CC) if there exists a vector ξ which satisfies

$$L_\xi Z^h_{ijk}=0. \tag{3.5}$$

Obviously every conharmonic motion is necessarily a Conh C and Conh CC but the converse is not necessarily true. From Eq. (1.11) it is clear that every Conh CC is a W Conf C. Every Conh M must also satisfy

$$L_\xi R^h_{ijk}=\delta^h_j\psi_{;ik}-\delta^h_k\psi_{;ij}+\psi^h_{;j}g_{ik}-\psi^h_{;k}g_{ij}, \tag{3.6}$$

$$L_\xi R_{ij}=-2\psi_{;ij}, \tag{3.7}$$

$$L_\xi R^j_k=-2\psi^j_{;k}-2\psi R^j_k, \tag{3.8}$$

and

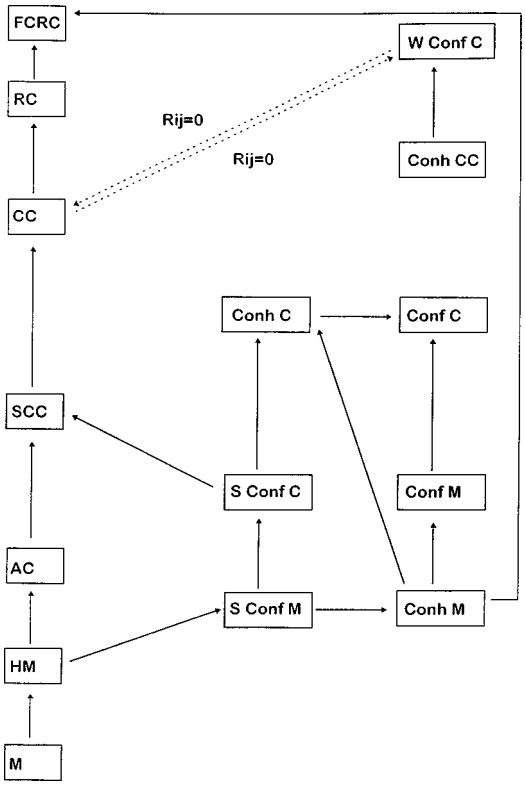

FIG. 1. Relation between conharmonic and other space–time symmetries.

$$L_\xi R = -2\psi R. \tag{3.9}$$

From Eq. (3.7)—in view of Eq. (3.4)—we observe that

$$g^{ij} L_\xi R_{ij} = 0, \tag{3.10}$$

showing that every Conh M is a contracted Ricci collineation but the converse is not necessarily true. Consequently, the existence of a Conh KV ξ also gives rise to a conservation law generator of the form[25]

$$[\sqrt{-g}(T_i^j - \tfrac{1}{2}\delta_i^j T)\xi^i]_{;j} = 0. \tag{3.11}$$

A block diagram (Fig. 1) is constructed showing the relation of conharmonic symmetries with some other well-known symmetries. Now we have the following theorems based upon the relation of Conh KV with inheriting symmetries.

Theorem 3.1: A V_4, which admits a Conh KV and also a proper CIV, is necessarily a conharmonically flat space.

Proof: Taking the Lie derivative of (1.8) and making use of Eqs. (1.1), (1.2), (1.3), and (1.8) we get

$$L_\xi Z_{ijk}^h = 2\alpha Z_{ijk}^h + E_{ijk}^h, \tag{3.12}$$

where

$$E_{ijk}^h = \tfrac{1}{2}[h_{ik}R_j^h - h_{ij}R_k^h + g_{ij}R_k^m h_m^h - g_{ik}R_j^m h_m^h]. \tag{3.13}$$

Using Eq. (3.1) in Eq. (3.13) we get

$$E_{ijk}^h = 0. \tag{3.14}$$

In view of Eqs. (3.5) and (3.14), Eq. (3.12) gives

$$Z^h_{ijk}=0 \quad [\text{since } \alpha\neq 0), \tag{3.15}$$

showing that V_4 is conharmonically flat.

In order to illustrate this theorem we consider a plane symmetric perfect fluid cosmological model obtained by Singh and Singh[26] which is of class one but not conformal to flat space–time. The geometry of the model is described by the metric

$$ds^2=(1+at)^2(-dt^2+dx^2+dy^2)+(1+bt)dz^2, \tag{3.16}$$

where a and b are either both positive or both negative arbitrary constants. The space–time (3.16) is found to admit a Conh KV $\xi^i=(A/a)\delta^i_0$, which is also a CIV only when $a=b$ with $\psi=-\alpha=A/(1+at)$, where A is an arbitrary constant. However, when $a=b$ the model becomes conharmonic to flat space–time and reduces to a special case $(k=0)$ of the FRW model representing a universe filled with disordered radiation.

Theorem 3.2: If ξ is a RIV as well as a Conh KV in a V_4 then

$$L_\xi R^h_{ijk}=2\alpha(R^h_{ijk}-Z^h_{ijk}). \tag{3.17}$$

Proof: Taking the Lie derivative of Eq. (1.8) and then using Eqs. (1.2), (1.3), (3.1), and (3.5) we get

$$L_\xi R^h_{ijk}+\alpha(\delta^h_j R_{ik}-\delta^h_k R_{ij}+g_{ik}R^h_j-g_{ij}R^h_k)=0. \tag{3.18}$$

Using Eq. (1.8) in Eq. (3.18) we get the following result.

Corollary: If ξ is a RIV as well as a Conh KV in a conharmonically flat space–time then the symmetry of the Riemann tensor of the space–time is inherited.

Proof: Proof is obvious from Eq. (3.17).

Remark: In the conharmonically flat cosmological model of Singh and Singh given by Eq. (3.16) with $a=b$, $\xi^i=(A/a)\delta^i_0$ being a Conh KV and RIV with $\psi=-\alpha=A/(1+at)$ is found to be a CIV also.

Theorem 3.3: If ξ is a proper RIV as well as a Conh KV in a V_4 then the scalar curvature of the space–time vanishes and if the Riemann curvature tensor of the space–time is divergence-free then we have

$$(\alpha+\psi)_{;j}R^j_k=0. \tag{3.19}$$

Proof: Equations (1.2) and (3.7) give

$$\alpha R_{ij}=-\psi_{;ij}. \tag{3.20}$$

Contracting by g^{ij} and using (3.4) we get

$$\alpha R=0, \tag{3.21}$$

that is, the scalar curvature R of the space–time vanishes (since $\alpha\neq 0$). Differentiating (3.20) covariantly we get

$$\alpha_{;k}R_{ij}+\alpha R_{ij;k}=-\psi_{;ijk}. \tag{3.22}$$

Antisymmetrizing this equation with respect to j and k and making use of the divergence-free condition of the Riemann tensor,

$$R^h_{ijk;h}\equiv R_{ij;k}-R_{ik;j}=0, \tag{3.23}$$

and the identity

$$\psi_{;ikj}-\psi_{;ijk}=\psi_{;h}R^h_{ijk}, \tag{3.24}$$

we get

$$[\alpha_{;k}R_{ij}-\alpha_{;j}R_{ik}]=\psi_{;h}R^{h}_{ijk}. \tag{3.25}$$

Contracting this equation by g^{ij} and making use of the fact that $R=0$ we get the theorem.

Corollary: If a space–time V_4, with perfect fluid distribution admits a RIV which is also a Conh KV, then this space–time necessarily admits a distribution of disordered radiation or photon fluid. Also if the Riemann curvature tensor of the space–time is divergence free then we have $(\alpha+\psi)=$constant.

Proof: From Eqs. (2.1), (2.3), and the fact that $R=0$ we get the first part of the corollary with

$$R_{ij}=\frac{\mu}{3}(4u_iu_j+g_{ij}). \tag{3.26}$$

In view of Eq. (3.26), Eq. (3.19) yields

$$\frac{\mu}{3}[4(\alpha+\psi)^{\cdot}u_k+(\alpha+\psi)_{;k}]=0. \tag{3.27}$$

Contracting Eq. (3.27) with u_k we get

$$(\alpha+\psi)^{\cdot}=0 \quad (\text{if } \mu\neq 0), \tag{3.28}$$

that is

$$(\alpha+\psi)=\text{constant}. \tag{3.29}$$

Remark: In the plane symmetric model of Singh and Singh given by Eq. (3.16), $\xi^i=A/a\,\delta^i_0$ is a Conh KV and a RIV leads to $R=0$. Since the model is filled with a perfect fluid distribution, in this situation $(R=0)$ it represents a distribution of disordered radiation.

We now consider a static spherically symmetric metric in curvature coordinates

$$ds^2=-e^{\nu}dt^2+e^{\lambda}dr^2+r^2(d\theta^2+\sin^2\theta\,d\phi^2), \tag{3.30}$$

where λ and ν are functions of r alone. If this space–time is admitting a one parameter group of Conf M defined by Eq. (3.1) with ψ as a function of r alone, then we have[18,27,28]

$$e^{\nu}=a^2r^2, \tag{3.31}$$

$$e^{\lambda}=b^2/\psi^2, \tag{3.32}$$

and

$$\xi^i=\psi r\,\delta^i_1, \tag{3.33}$$

where a and b are arbitrary constants.

In order that the metric (3.30) may admit a one parameter group of Conh M, the function ψ should satisfy Eq. (3.4), which gives

$$\psi_{,rr}+\psi^2_{,r}/\psi+3\psi_{,r}/r=0. \tag{3.34}$$

Integrating Eq. (3.34) we get

$$\psi^2=A/r^2+B, \tag{3.35}$$

where A and B are arbitrary constants. The line-element (3.30) admitting a one parameter group of Conh M is obtained as

$$ds^2=-a^2r^2dt^2+b^2(A/r^2+B)^{-1}dr^2+r^2(d\theta^2+\sin^2\theta\,d\phi^2). \tag{3.36}$$

This space–time is obviously found to admit contracted Ricci collineation defined by Eq. (3.10) along the Conh KV $\xi^i=(A/r^2+B)^{1/2}r\,\delta^i_1$. The scalar curvature R of the space–time (3.36) vanishes if we take $B=b^2/3$. The space–time with scalar curvature $R=0$ is admitting a Conh KV $\xi^i=(A/r^2+b^2/3)^{1/2}r\,\delta^i_1$ but it is verified that this ξ^i is not a RIV, showing that the converse of the first part of theorem (3.3) is not necessarily true.

IV. ANISOTROPIC FLUID SPACE–TIMES ADMITTING CONH KV

Harrera *et al.*[18] initiated the study of Conf M for anisotropic matter in the context of general relativity. Maartens *et al.*[20] examined in detail the kinematic and dynamic properties of anisotropic fluids that admit a Conf M. The relations of energy density with the anisotropic pressure components have been explicitly obtained by considering the conformal killing vector to be special and parallel to u^i, parallel to n^i, and perpendicular to u^i and n^i. They have further extended their results to a fluid with arbitrary stress tensor and with vanishing energy flux vector. In this section we consider the anisotropic fluid space–time to admit a Conh KV which is also a ClV and study its consequences.

If ξ is a CKV and X^i is any non-null unit vector, then Maartens *et al.*[20] have shown that

$$L_\xi X^i=-\psi X^i+Y^i \tag{4.1}$$

and

$$L_\xi X_i=\psi X_i+Y_i, \tag{4.2}$$

where Y^i is a vector perpendicular to X^i. Making use of these results for a timelike unit vector u^i and spacelike unit vector n^i we get

$$L_\xi u^i=-\psi u^i+v^i, \tag{4.3}$$

$$L_\xi u_i=\psi u_i+v_i, \tag{4.4}$$

where $u_iv^i=0$ and

$$L_\xi n^i=-\psi n^i+m^i, \tag{4.5}$$

$$L_\xi n_i=\psi n_i+m_i, \tag{4.6}$$

where $n_im^i=0$. These vectors u^i and n^i are identified as the unit fluid four-velocity vector and the unit anisotropy vector in the energy momentum tensor for a fluid with anisotropic pressure. It is clear from Eqs. (4.3) and (4.6) that if $n_iu^i=0$ then we have

$$n_iv^i+u^im_i=0. \tag{4.7}$$

Maartens *et al.*[20] have shown that (i) if a CKV ξ is parallel to u^i, i.e., $\xi^i=\lambda u^i$, then

$$\psi=\dot\lambda+\dot u_i\xi^i \tag{4.8}$$

and

$$v_i=2\omega_{ij}\xi^j+\lambda[\dot u_i+(\log\lambda^{-1})_{;j}h^j_i], \tag{4.9}$$

where $\lambda=-\xi_iu^i$ is a scalar function, ω_{ij} is the vorticity tensor, $\dot u_i$ is the four-acceleration vector, and $h_{ij}=g_{ij}+u_iu_j$ is the projection tensor. (ii) If ξ is perpendicular to u^i, i.e., $\xi_iu^i=0$, then

$$\psi=\dot u_i\xi^i, \tag{4.10}$$

$$v_i=2\omega_{ij}\xi^j. \tag{4.11}$$

The expression for the energy–momentum tensor of an anisotropic fluid is given by

$$T_{ij}=\mu u_i u_j+P_{11}n_i n_j+p_1 p_{ij}, \tag{4.12}$$

where μ is the total energy density as measured by an observer with four-velocity u^i, n^i is a unit spacelike vector of anisotropy orthogonal to u^i, p_{11} and p_1 are the components of the anisotropic pressure parallel to and perpendicular to n^i, and $p_{ij}=g_{ij}+u_i u_j-n_i n_j$ is the projection tensor onto the two plane orthogonal to u^i and n^i. We substitute for T_{ij} from Eq. (4.12) in Eq. (2.3) and then take the Lie derivative. This gives, on making use of Eqs. (3.1), (3.7), (3.9), (4.4), and (4.6),

$$\begin{aligned}-2\psi_{;ij}=&(L_\xi\mu+2\psi\mu)u_i u_j+(L_\xi p_{11}+2\psi p_{11})n_i n_j+(L_\xi p_1+2\psi p_1)p_{ij}\\&+2(\mu+p_1)u_{(i}v_{j)}+2(p_{11}-p_1)n_{(i}m_{j)}.\end{aligned} \tag{4.13}$$

Contractions by $u^i u^j$, $n^i n^j$, p^{ij}, $u^i n^j$, $u^i p^{jk}$, $n^i p^{jk}$, and $p^{ik}p^{jl}-\frac{1}{2}p^{ij}p^{kl}$, respectively, yield

$$L_\xi\mu+2\psi\mu=-2\psi_{;ij}u^i u^j, \tag{4.14}$$

$$L_\xi p_{11}+2\psi p_{11}=-2\psi_{;ij}n^i n^j, \tag{4.15}$$

$$L_\xi p_1+2\psi p_1=-\psi_{;ij}p^{ij}, \tag{4.16}$$

$$(\mu+p_{11})n^j v_j=2\psi_{;ij}u^i n^j, \tag{4.17}$$

$$(\mu+p_1)p^{jk}v_j=2\psi_{;ij}u^i p^{jk}, \tag{4.18}$$

$$(p_1-p_{11})p^{jk}m_j=2\psi_{;ij}n^i p^{jk}, \tag{4.19}$$

$$\psi_{;ij}p^{ik}p^{jl}-\tfrac{1}{2}(\psi_{;ij}p^{ij})p^{kl}=0. \tag{4.20}$$

With the help of Eqs. (4.14)–(4.20) we see that if ξ is a Conh KV of an anisotropic fluid space–time which is parallel to u^i, parallel to n^i, and perpendicular to u^i and n^i, then no equation of state is singled out. However, when we take ξ to be a CIV also then it may be possible to get an equation of state. If ξ is a CKV of a space–time of general relativity with anisotropic fluid given by (4.12), which is also a CIV, and if $(\mu+p_{11})\neq 0$ and $(\mu+p_1)\neq 0$ then Duggal[2] has obtained the following inheritance equations:

$$L_\xi\mu=2(\alpha-\psi)\mu, \tag{4.21a}$$

$$L_\xi p_{11}=2(\alpha-\psi)p_{11}, \tag{4.21b}$$

$$L_\xi p_1=2(\alpha-\psi)p_1, \tag{4.21c}$$

$$L_\xi u_i=\psi u_i(\text{i.e., } v_i=0). \tag{4.21d}$$

A CKV ξ satisfies[20]

$$(R^{ij}\xi_j)_{;i}=-3\Box\psi. \tag{4.22}$$

For a Conh KV ξ this reduces to

$$(R^{ij}\xi_j)_{;i}=0. \tag{4.23}$$

If ξ is a Conh KV which is also a CIV of the space–time then from theorem (3.3) we have in the case of anisotropic fluid

$$\mu=2p_1+p_{11}. \tag{4.24}$$

Since the scalar curvature of the space–time is zero; we may write Eq. (4.23) with the help of Eqs. (2.3) and (4.12) as

$$[(\mu u^i u^j+p_{11}n^i n^j+p_1 p^{ij})\xi_j]_{;i}=0. \tag{4.25}$$

From (3.1) we get

$$\xi^i_{;i}=4\psi. \tag{4.26}$$

Now we consider three special cases of the vector ξ: (i) ξ parallel to n^i, (ii) ξ parallel to u^i, and (iii) ξ perpendicular to u^i and n^i.

Case (i): Using $\xi^i=\lambda n^i$ in (4.25) we get

$$[p_{11}\xi^i]_{;i}=0. \tag{4.27}$$

With the help of Eqs. (4.21b) and (4.26), Eq. (4.27) obtains

$$(\alpha+\psi)p_{11}=0. \tag{4.28}$$

If $(\alpha+\psi)\neq 0$, then $p_{11}=0$. Thus Eq. (4.24) gives

$$\mu=2p_1. \tag{4.29}$$

Case (ii): Using $\xi^i=\lambda u^i$ in (4.25) we get

$$[\mu\xi^i]_{;i}=0. \tag{4.30}$$

With the help of Eqs. (4.21a) and (4.26), Eq. (4.30) obtains

$$(\alpha+\psi)\mu=0. \tag{4.31}$$

Since $(\alpha+\psi)\neq 0$ we get $\mu=0$ and Eq. (4.24) reduces to

$$2p_1+p_{11}=0. \tag{4.32}$$

Case (iii): Using $\xi^i u_i=\xi^i n_i=0$ in (4.25) we get

$$(p_1\xi^i)_{;i}=0. \tag{4.33}$$

With the help of Eqs. (4.21c) and (4.26), Eq. (4.33) gives

$$(\alpha+\psi)p_1=0. \tag{4.34}$$

Since $(\alpha+\psi)\neq 0$ we get $p_1=0$ and Eq. (4.24) gives

$$\mu=p_{11}. \tag{4.35}$$

Remark: In the case of a perfect fluid distribution (i.e., when $p_1=p_{11}$) cases (i) and (iii) give the stiff equation of state and case (ii) leads to an empty space–time.

Now we consider the case of an anisotropic fluid with arbitrary stress tensor π^{ij} ($\pi^{ij}u_j=0$, $\pi^i_i=0$) given by

$$T^{ij}=\mu u^i u^j+ph^{ij}+\pi^{ij}, \tag{4.36}$$

where p is the isotropic pressure. Taking the Lie derivative of Eq. (2.3) with T_{ij} given by (4.36) and making use of Eqs. (3.1), (3.7), (3.9), and (4.4) we get

$$-2\psi_{;ij}=(L_\xi\mu+2\psi\mu)u_iu_j+(L_\xi p+2\psi p)h_{ij}+L_\xi\pi_{ij}. \tag{4.37}$$

Contracting Eq. (4.37) by u^iu^j, h^{ij}, $u^ih^j_k$, and $h^i_kh^j_l-\frac{1}{3}h^{ij}h_{kl}$, respectively, we get

$$L_\xi\mu+2\psi\mu=-2\psi_{;ij}u^iu^j, \tag{4.38}$$

$$L_\xi p+2\psi p=-\tfrac{2}{3}\psi_{;ij}u^iu^j, \tag{4.39}$$

$$u^ih^j_kL_\xi\pi_{ij}=-2\psi_{;ij}u^ih^j_k, \tag{4.40}$$

$$\pi_{ik}v^i = -2\psi_{;ij}(h^i_k h^j_l - \tfrac{1}{3}h^{ij}h_{kl}). \tag{4.41}$$

Using Eqs. (2.3) and (4.36) in Eq. (4.23) we get

$$\left[(\mu+p)u^i(u^j\xi_j)+\left(\frac{\mu}{2}-\frac{p}{2}\right)\xi^i+\pi^{ij}\xi_j\right]_{;i}=0. \tag{4.42}$$

Considering $\xi_i\, u^i=0$ and making use of Eq. (4.26), Eq. (4.42) yields

$$\left(\frac{\mu}{2}-\frac{p}{2}\right)_{;i}\xi^i+2\psi(\mu-p)+\pi^{ij}_{;i}\xi_j=0. \tag{4.43}$$

With the help of Eqs. (4.38) and (4.39), Eq. (4.43) takes the form

$$\psi(\mu-p)+\pi^{ij}_{;i}\xi_j=\tfrac{2}{3}\psi_{;ij}u^iu^j. \tag{4.44}$$

For the T^{ij} given by (4.36) the momentum conservation equation is obtained as

$$(\mu+p)\dot{u}^i=-h^{ik}(p_{;k}+\pi^j_{k;j}). \tag{4.45}$$

Multiplying Eq. (4.45) by ξ_i and making use of Eqs. (4.39) and (4.44) we get

$$(\mu+p)[\dot{u}^i\xi_i-\psi]=0. \tag{4.46}$$

In view of Eq. (4.10), Eq. (4.46) is identically satisfied for any μ and p.

When we choose ξ parallel to u^i then Eq. (4.42) is the same as in the case of perfect fluid distribution because $u_i\pi^{ij}=0$. Thus in this case the equation of state may be singled out only when ξ is also a CIV and this leads to an empty space–time.

The space–time symmetries of a CKV ξ are said to be inherited[29] if fluid flow lines are mapped conformally by ξ, i.e., if Eq. (4.21d) holds. We find that the space–time symmetries are not inherited in the case of Conh KV ξ in general but when we take u_i as an eigenvector of $\psi_{;ij}$, i.e.,

$$\psi_{;ij}u^j=\nu u_i, \tag{4.47}$$

where ν is a scalar function then Eqs. (4.17) and (4.18) are reduced to

$$(\mu+p_{11})n^jv_j=0 \tag{4.48}$$

and

$$(\mu+p_1)p^{jk}v_j=0. \tag{4.49}$$

Now if $(\mu+p_{11})\neq 0$ and $(\mu+p_1)\neq 0$, then Eqs. (4.48) and (4.49) give

$$n^jv_j=0 \tag{4.50}$$

and

$$p^{jk}v_j=0. \tag{4.51}$$

Using Eq. (4.50) in Eq. (4.51) and remembering the fact that $u^iv_i=0$, we get

$$v_i=0. \tag{4.52}$$

Thus the Conh KV symmetries of the fluid space–time are inherited when u_i is an eigenvector of $\psi_{;ij}$.

Recently, Coley and Tupper[30] have investigated all the spherically symmetric space–times representing an anisotropic fluid and admitting a proper inheriting conformal Killing vector (ICKV). We consider the case of class B2S space–times,

$$ds^2=S^{-2}(r)(-dt^2+dr^2+d\theta^2+\sin^2\ \theta d\phi^2) \tag{4.53}$$

with $\xi^i=\delta^i_1$ and $\psi=-S^{-1}S,r$. In order that the space–time (4.53) may admit a proper inheriting conharmonic Killing vector (I Conh KV), ψ should satisfy Eq. (3.4), which gives

$$\psi_{,rr}+2\psi\psi_{,r}=0. \tag{4.54}$$

Integrating Eq. (4.54) we get

$$\psi_{,r}+\psi^2=K, \tag{4.55}$$

where K is an arbitrary constant. The solution of Eq. (4.55) is obtained as

$$\psi=\frac{\sqrt{K}(1-Ce^{-2\sqrt{K}r})}{(1+Ce^{-2\sqrt{K}r})}, \tag{4.56}$$

where C is an arbitrary constant. Consequently a spherically symmetric static metric representing an anisotropic fluid and admitting a proper inheriting Conh KV $\xi^i=\delta^i_1$ is obtained as

$$ds^2=(Ae^{\sqrt{K}r}+Be^{-\sqrt{K}r})^2[-dt^2+dr^2+d\theta^2+\sin^2\ \theta\ d\phi^2], \tag{4.57}$$

where A and B are arbitrary constants satisfying $B=AC$.

The expressions for μ, p_{11}, and p_1 in this model are obtained as

$$\mu=(Ae^{\sqrt{K}r}+Be^{-\sqrt{K}r})^{-2}\left[1-2K+K\left\{\frac{Ae^{\sqrt{K}r}-Be^{-\sqrt{K}r}}{Ae^{\sqrt{K}r}+Be^{-\sqrt{K}r}}\right\}^2\right], \tag{4.58}$$

$$p_{11}=(Ae^{\sqrt{K}r}+Be^{-\sqrt{K}r})^{-2}\left[-1+3K\left\{\frac{Ae^{\sqrt{K}r}-Be^{-\sqrt{K}r}}{Ae^{\sqrt{K}r}+Be^{-\sqrt{K}r}}\right\}^2\right], \tag{4.59}$$

and

$$p_1=(Ae^{\sqrt{K}r}+Be^{-\sqrt{K}r})^{-2}\left[2K-K\left\{\frac{Ae^{\sqrt{K}r}-Be^{-\sqrt{K}r}}{Ae^{\sqrt{K}r}+Be^{-\sqrt{K}r}}\right\}^2\right]. \tag{4.60}$$

The equation of state satisfied by the anisotropic fluid in this model is obtained as

$$\mu=\frac{p_{11}+4p_1-6Kp_1}{(6K-1)}. \tag{4.61}$$

It may be noted that when we take $K=1/3$ then

$$\mu=p_{11}+2p_1. \tag{4.62}$$

V. SOME SPACE–TIMES WITH PROPER CONHARMONIC SYMMETRY

A. Conharmonic symmetric space–times

Sharma[31] has studied the proper conformal symmetries of conformal symmetric space–times defined by[32]

$$C_{hijk;l}=0. \tag{5.1}$$

It is shown that conformal symmetric space–times, admitting an infinitesimal conformal symmetry, are either of type O or N. Those of type N represent plane gravitational waves with parallel rays, provided the Einstein tensor is invariant of the infinitesimal conformal symmetry. In this section we consider a conharmonic symmetric space–time defined by

$$Z_{hijk;l}=0 \tag{5.2}$$

and study the consequences of an existing Conh KV. The commutation formula[33] for the conharmonic curvature tensor gives

$$L_\xi(Z^h_{ijk;l})-(L_\xi Z^h_{ijk})_{;l}=(L_\xi\Gamma^h_{lm})Z^m_{ijk}-(L_\xi\Gamma^m_{li})Z^h_{mjk}-(L_\xi\Gamma^m_{lj})Z^h_{imk}-(L_\xi\Gamma^m_{lk})Z^h_{ijm}. \tag{5.3}$$

Using Eqs. (3.2), (3.5), and (5.2) in Eq. (5.3) we get

$$\begin{aligned}&(\delta^h_l\psi_{;m}+\delta^h_m\psi_{;l}-g_{lm}\psi^h_{;})Z^m_{ijk}-(\delta^m_l\psi_{;i}+\delta^m_i\psi_{;l}-g_{li}\psi^m_{;})Z^h_{mjk}\\&\quad-(\delta^m_l\psi_{;j}+\delta^m_j\psi_{;l}-g_{lj}\psi^m_{;})Z^h_{imk}-(\delta^m_l\psi_{;k}+\delta^m_k\psi_{;l}-g_{lk}\psi^m_{;})Z^h_{ijm}=0.\end{aligned} \tag{5.4}$$

Contracting the above equation at h and l we get

$$\psi_{;m}Z^m_{ijk}-\psi_{;m}(Z^m_{ijk}+Z^m_{kij}+Z^m_{jki})+\psi_{;j}Z_{ik}-\psi_{;k}Z_{ij}=0. \tag{5.5}$$

From Eq. (1.8) it may be seen that

$$Z^m_{\{ijk\}}=0. \tag{5.6}$$

Thus Eq. (5.5) reduces to

$$\psi_{;m}Z^m_{ijk}+\psi_{;j}Z_{ik}-\psi_{;k}Z_{ij}=0. \tag{5.7}$$

Contracting by g^{ij} and then making use of Eq. (1.9) we get

$$R\psi_{;k}=0. \tag{5.8}$$

Since ξ is a proper conharmonic vector field we have $\psi_{;i}\neq 0$ and Eq. (5.8) leads to $R=0$. Consequently, Eq. (1.9) gives

$$Z_{ij}=0 \tag{5.9}$$

and from Eq. (1.11) the conharmonic curvature tensor and the conformal curvature tensor become identical. Equation (5.7) now takes the form

$$\psi_{;m}Z^m_{ijk}=0. \tag{5.10}$$

Making use of Eq. (5.10) in Eq. (5.4) and then multiplying the obtained equation by $\psi^l_{;}$ we get

$$\psi_{;l}\psi^l_{;}Z^h_{ijk}=0. \tag{5.11}$$

In view of the above equation, either $Z^h_{ijk}=0$, i.e., the space–time is conharmonically flat or $\psi^l_{;}\,\psi_{;l}=0$. Since space–time admits proper conharmonic vector field ξ, $\psi^l_{;}\neq 0$, therefore, if $\psi^l_{;}\psi_{;l}=0$ then $\psi^l_{;}$ must be null. Thus from Eq. (5.10) the space–time is of type N and the four repeated principal null directions of the conharmonic curvature tensor are given by $\psi^l_{;}$. Thus we may state the following theorem.

Theorem 5.1: If a conharmonic symmetric space–time admits a proper conharmonic killing vector field ξ, then the scalar curvature of the space–time vanishes and the space–time is either conharmonically flat or of type N.

B. Space–times admitting a divergence-free conharmonic curvature tensor

Sharma[34] has shown that if ξ is a CKV of a space–time admitting a divergence-free conformal curvature tensor then this space–time will be either conformally flat or of type N. We have studied the above case when ξ is a Conh KV of a space–time with a divergence-free conharmonic curvature tensor. From Eq. (1.8) we obtain

$$Z^h_{ijk;l}+Z^h_{ikl;j}+Z^h_{ilj;k}=\tfrac{1}{2}[\,\delta^h_j(R_{ik;l}-R_{il;k})+\delta^h_k(R_{il;j}-R_{ij;l})+\delta^h_l(R_{ij;k}-R_{ik;j}) +g_{ik}(R^h_{j;l}-R^h_{l;j})+g_{il}(R^h_{k;j}-R^h_{j;k})+g_{ij}(R^h_{l;k}-R^h_{k;l})]. \tag{5.12}$$

The divergence-free condition of the conharmonic curvature tensor given by Eq. (2.2) reduces Eq. (5.12) to

$$Z^h_{ijk;l}+Z^h_{ikl;j}+Z^h_{ilj;k}=\tfrac{1}{2}[\,\delta^h_j(R_{;l}g_{ik}-R_{;k}g_{il})+\delta^h_k(R_{;j}g_{il}-R_{;l}g_{ij})+\delta^h_l(R_{;k}g_{ij}-R_{;j}g_{ik})]. \tag{5.13}$$

Now taking the Lie derivative of Eq. (5.13) we get

$$\begin{aligned}L_\xi[Z^h_{ijk;l}+Z^h_{ikl;j}+Z^h_{ilj;k}]&=\psi[\,\delta^h_j(R_{;l}g_{ik}-R_{;k}g_{il})+\delta^h_k(R_{;j}g_{il}-R_{;l}g_{ij})+\delta^h_l(R_{;k}g_{ij}-R_{;j}g_{ik})]\\&\quad+\tfrac{1}{2}[\,\delta^h_j\{(L_\xi R)_{;l}g_{ik}-(L_\xi R)_{;k}g_{il}\}+\delta^h_k\{(L_\xi R)_{;j}g_{il}-(L_\xi R)_{;l}g_{ij}\}\\&\quad+\delta^h_l\{(L_\xi R)_{;k}g_{ij}-(L_\xi R)_{;j}g_{ik}\}].\end{aligned} \tag{5.14}$$

With the help of Eq. (3.9), Eq. (5.14) takes the form

$$L_\xi(Z^h_{ijk;l}+Z^h_{ikl;j}+Z^h_{ilj;k})=-R[\,\delta^h_j(\psi_{;l}g_{ik}-\psi_{;k}g_{il})+\delta^h_k(\psi_{;j}g_{il}-\psi_{;l}g_{ij})+\delta^h_l(\psi_{;k}g_{ij}-\psi_{;j}g_{ik})]. \tag{5.15}$$

In view of Eq. (5.3) we may write two more equations,

$$L_\xi(Z^h_{ikl;j})-(L_\xi Z^h_{ikl})_{;j}=(L_\xi\Gamma^h_{jm})Z^m_{ikl}-(L_\xi\Gamma^m_{ji})Z^h_{mkl}-(L_\xi\Gamma^m_{jk})Z^h_{iml}-(L_\xi\Gamma^m_{jl})Z^h_{ikm} \tag{5.16}$$

and

$$L_\xi(Z^h_{ilj;k})-(L_\xi Z^h_{ilj})_{;k}=(L_\xi\Gamma^h_{km})Z^m_{ilj}-(L_\xi\Gamma^m_{ki})Z^h_{mlj}-(L_\xi\Gamma^m_{kl})Z^h_{imj}-(L_\xi\Gamma^m_{kj})Z^h_{ilm}. \tag{5.17}$$

Adding Eqs. (5.3), (5.16), and (5.17) and making use of Eqs. (3.2), (3.5), and (5.15) we get

$$\begin{aligned}&-R[\,\delta^h_j(\psi_{;l}g_{ik}-\psi_{;k}g_{il})+\delta^h_k(\psi_{;j}g_{il}-\psi_{;l}g_{ij})+\delta^h_l(\psi_{;k}g_{ij}-\psi_{;j}g_{ik})]\\&=(\delta^h_l\psi_{;m}+\delta^h_m\psi_{;l}-g_{lm}\psi^h_{;})Z^m_{ijk}-(\delta^m_l\psi_{;i}+\delta^m_i\psi_{;l}-g_{li}\psi^m_{;})Z^h_{mjk}\\&\quad+(\delta^h_j\psi_{;m}+\delta^h_m\psi_{;j}-g_{jm}\psi^h_{;})Z^m_{ikl}-(\delta^m_j\psi_{;i}+\delta^m_i\psi_{;j}-g_{ji}\psi^m_{;})Z^h_{mkl}\\&\quad+(\delta^h_k\psi_{;m}+\delta^h_m\psi_{;k}-g_{km}\psi^h_{;})Z^m_{ilj}-(\delta^m_k\psi_{;i}+\delta^m_i\psi_{;k}-g_{ki}\psi^m_{;})Z^h_{mlj}.\end{aligned} \tag{5.18}$$

A straightforward contraction of the above equation at h and l with the help of Eq. (5.6) yields

$$\psi_{;m}Z^m_{ijk}+g_{ij}\psi^m_{;}Z_{mk}-g_{ki}\psi^m_{;}Z_{mj}=2R(\psi_{;i}g_{ik}-\psi_{;k}g_{ij}). \tag{5.19}$$

Again contracting the above equation by g^{ij} and making use of Eq. (1.9) we get $R=0$ (since $\psi_{;i}\neq 0$) and hence Eq. (1.9) gives $Z_{ij}=0$. Making use of these facts in Eq. (5.19) we get Eq. (5.10) and consequently Eq. (5.18) leads to

$$\psi_{,h}Z_{lijk}+\psi_{;i}Z^h_{ljk}=0. \tag{5.20}$$

Multiplying this equation by $\psi^l_{;}$ we get Eq. (5.11). Thus we may state the following theorem.

Theorem 5.2: If ξ is a proper Conh KV of a space–time with divergence-free conharmonic curvature tensor then the scalar curvature of the space–time vanishes and the space–time becomes either conharmonically flat or of type N.

Corollary 1: If ξ is a proper Conh KV in a space–time with a divergence-free conharmonic curvature tensor then we have

$$Z^h_{ijk;l}+Z^h_{ikl;j}+Z^h_{ilj;k}=0. \tag{5.21}$$

Proof: Proof is obvious from Eq. (5.13) and the fact that $R=0$.

Corollary 2: If a space–time V_4 has a divergence-free conharmonic curvature tensor and ξ is a proper Conh KV of the space–time, then the space–time must have a divergence-free Riemann curvature tensor.

Proof: Making use of the fact that $R=0$ in Eq. (2.2) we get Eq. (3.23) and hence the corollary.

Relativistic spin networks and quantum gravity

John W. Barrett[a)]

(Received 3 November 1997; accepted for publication 27 January 1998)

Relativistic spin networks are defined by considering the spin covering of the group SO(4), SU(2)×SU(2). Relativistic quantum spins are related to the geometry of the two-dimensional faces of a 4-simplex. This extends the idea of Ponzano and Regge that SU(2) spins are related to the geometry of the edges of a 3-simplex. This leads us to suggest that there may be a four-dimensional state sum model for quantum gravity based on relativistic spin networks that parallels the construction of three-dimensional quantum gravity from ordinary spin networks. © *1998 American Institute of Physics.* [S0022-2488(98)01005-6]

I. INTRODUCTION

In Refs. 1 and 2, it was proposed that the quantum theory of gravity could take the form of a very special type of discrete model on a triangulated 4-manifold, which has the property that the propagation of physical states does not depend on the choice of triangulation. Such a model is called a topological state sum.

Topological state sums are closely related to topological quantum field theories. Arguments that the quantum theory of gravity should be closely related to a topological quantum field theory are given in Ref. 3.

In Ref. 4, a specific family of four-dimensional topological state sums were constructed. It was suggested in Refs. 1 and 2 that the topological state sum of Ref. 4 might be a representation of a topological state for the quantum theory of gravity, and that the physical hypothesis that the universe is in that state could be studied.

Ooguri,[5] and, more recently, Baez[6] have argued that the topological state sum of Ref. 4 (reformulated in Ref. 7), which is a precise realization of Ref. 5, is a construction of the quantum theory of the BF Lagrangian.

In fact, the Plebanski Lagrangian[8,9] for general relativity has the form of BF theory[10] with gauge group $\mathrm{SL}(2,C)$, with an added term that is a constraint. Smolin[11] has argued that for general relativity with a cosmological constant the constraint vanishes for the self-dual sector. This suggests[1,2] that the self-dual sector can be identified with the topological state sum of Ref. 4.

The purpose of this paper is to outline a new state sum model, which is a sort of constrained doubling of the topological state sum of Ref. 4. This constraint is a quantum version of the Plebanski constraint.

In three dimensions, quantum gravity is constructed by the Ponzano–Regge state sum model in which representations of SU(2) label edges.[12] This corresponds to a path integral in which the metric is the variable. However, this model can also be understood as a path integral in the first-order formalism using a frame field and connection form.[13]

It is worth pursuing the link with the classical frame field to get a heuristic understanding of the discrete models. Integrating the frame field e, an $\mathbb{R}^3$-valued 1-form, along an edge, gives a vector in $\mathbb{R}^3$. This can also be regarded as an element of the dual of the Lie algebra so(3).

The idea is that to pass from three dimensions to four dimensions one has to replace SO(3) with SO(4), or its spin covering, SU(2)×SU(2).

The topological home for this spin is now on triangles. This is in accord with the assignment of spins to triangles in Ref. 4, which can be regarded as a special case of $SU(2)\times SU(2)$, where one of the copies of $SU(2)$ acts trivially, thus rendering all variables self-dual. We are also making contact with the loop variables picture of Rovelli and Smolin,[14] in which the fundamental operators live on surfaces. The relation of the loop variables to state sum models, and the difference between BF theory and gravity in this context, was investigated in Refs. 15 and 16.

In a BF theory, the B field is an $so(4)^*$-valued 2-form, which can be integrated on a triangle to give an element of $so(4)^*$, the dual of the Lie algebra $so(4)$. However, in Einstein gravity it is important that $so(4)^*$ is identified with $\mathbb{R}^4\wedge\mathbb{R}^4$, as B is constrained to be of the form $B=*e\wedge e$, where e is a vector-valued one-form. In this formula, $e\wedge e$ is an $\mathbb{R}^4\wedge\mathbb{R}^4$-valued 2-form, and $*$ is the Hodge $*:\mathbb{R}^4\wedge\mathbb{R}^4\to\mathbb{R}^4\wedge\mathbb{R}^4$.

Assuming the frame field gives a linear embedding of the triangle in $\mathbb{R}^4$, the integral over this triangle,

$$\int e\wedge e,$$

is a *simple* bivector, i.e., of the form $f\wedge g\in\mathbb{R}^4\wedge\mathbb{R}^4$. Thus, the essential constraint that marks Einstein gravity from BF theory is the simplicity of bivectors.

This remark is the key to our construction of the discrete model, even though we do not have a classical frame field in the construction. The discrete models and the path integral formalism with classical frame fields do have close parallels, however.

A discretization of the classical Einstein gravity using bivectors on triangles that are constrained to be simple was previously studied in Refs. 17 and 18. Some related discrete classical models with self-dual bivectors, rather than simple bivectors, were studied in Refs. 18 and 19.

The new state sum model gives a quantum mechanical version of these constraints. The translation is to replace bivectors with bivector operators. The simplicity condition is then translated into a condition in the representation theory for these operators.

At present, we have an axiomatic description of the space of vertices, but not an explicit construction. If the only allowable vertex is the one we explicitly construct, then the state sum does not seem to give a topological invariant of manifolds. Thus, the relationship of our new state sum to topology is still unclear.

However, it is already very close to a topological theory, in that the deviation from the topological theory[4] is only in the imposed constraints. This should make an investigation of its ''ultraviolet'' behavior much simpler than for a continuum theory. Our hope is that the ''doubling'' of the topological state sum of Ref. 4 should allow us to pass from the self-dual sector to the full quantum theory of gravity.

The new state sum has a very natural relationship with Regge calculus in a new formulation, in that the classical version of the theory has the metric as its variable in the same way as Regge calculus. We believe, though do not have a complete argument, that it will contain ''local degrees of freedom'' as does general relativity, and that propagating plane waves will occur in a linearization of the theory, as in Refs. 20 and 21. However, we do not yet have an analog of the Ponzano–Regge asymptotic formula that would give a direct link with the Einstein action.

The heart of our construction is a reformulation of the geometry of simplexes in Euclidean (or Minkowski) 4-space in terms of variables on their 2-subsimplexes. This paper, accordingly, begins with a theorem in classical four-dimensional Euclidean geometry. The theorem allows us to describe 4-simplexes in terms of oriented area variables on 2-simplexes, giving a more precise version of the idea in Ref. 17. The constraints on the variables have a very elegant form, which can be carried over to the quantum theory.

Having discovered this form for the quantum constraints, it then becomes relatively straightforward to produce a new state sum.

II. BIVECTOR GEOMETRY OF A 4-SIMPLEX

An abstract 4-simplex is determined by an ordered set of five points, which we denote (01234). The faces of the abstract 4-simplex are just the subsets of this set.

A geometric 4-simplex is the convex hull of 5 points in $\mathbb{R}^4$. This embedding is required to be nondegenerate, i.e., the five points do not lie in any hyperplane. To each face now corresponds an affine subspace in $\mathbb{R}^4$, and also a linear subspace through the origin in $\mathbb{R}^4$ that is parallel to it. In particular, each triangle (2-simplex) determines a plane through the origin.

An embedding of an abstract 4-simplex in $\mathbb{R}^4$ is simply the set of position coordinates $x_0,x_1,x_2,x_3,x_4\in\mathbb{R}^4$ that determine the vertices of a geometric 4-simplex. The ordering of the vertices also determines an orientation for the simplex.

An oriented triangle in $\mathbb{R}^4$ determines a bivector. The position coordinates $x_0,x_1,x_2\in\mathbb{R}^4$ determine the displacement vectors for the edges $e_{01}=x_0-x_1$, $e_{02}=x_0-x_2$ and hence the bivector $b=\frac{1}{2}e_{01}\wedge e_{02}\in\mathbb{R}^4\wedge\mathbb{R}^4$. This bivector is invariant under an even permutation of the vertices but changes sign for an odd permutation.

In this way, a geometric 4-simplex determines a set of ten bivectors, one for each triangle. We show that the bivectors characterize the geometric 4-simplex uniquely, and give the conditions that an assignment of ten bivectors to the triangles of an abstract 4-simplex determines an embedding.

The properties of the bivectors for a 4-simplex are the following.

(1) The bivector changes sign if the orientation of the triangle is changed.

(2) Each bivector is simple, i.e., of the form $b=f\wedge g$.

(3) If two triangles share a common edge, then the sum of the two bivectors is also simple.

(4) The sum of the four bivectors corresponding to the faces of a tetrahedron is zero. This sum is calculated using the orientation of the triangles given by the boundary of the tetrahedron.

(5) The assignment of bivectors is nondegenerate. This means that for six triangles sharing a common vertex, the six bivectors are linearly independent.

(6) Using the Euclidean metric, the bivectors can be considered as linear operators. Then for three triangles meeting at a vertex of a tetrahedron, $\mathrm{Tr}\, b_1[b_2,b_3]>0$. The sign in this formula is determined by a convention relating a choice for the orientation for the boundary of the tetrahedron to the order in which the three bivectors appear in this formula.

Conditions (2), (3), and (4) were introduced in Ref. 17. We are indebted to John Baez,[22] who pointed out the necessity of (6) and the inversion ambiguity in the theorem that were missing in our first version of this paper.

Theorem: *Each geometric 4-simplex determines a set of bivectors satisfying these conditions, and each set of bivectors satisfying these conditions determines a geometric 4-simplex unique up to parallel translation and inversion through the origin.*

Proof: A simple bivector determines a plane (of dimension 2) through the origin in $\mathbb{R}^4$. Two simple bivectors b_1,b_2 determine two planes lying in a hyperplane (of dimension 3) if and only if b_1+b_2 is simple. If the planes lie in a hyperplane, this is clear because all bivectors are simple in three dimensions. Conversely, the simplicity condition can be understood as $b\wedge b=0$. Then

$$0=(b_1+b_2)\wedge(b_1+b_2)=2b_1\wedge b_2.$$

If $b_1=x\wedge y$, $b_2=z\wedge t$, then $0=x\wedge y\wedge z\wedge t$ implies a linear relation between x,y,z,t. This calculation also shows that (3) is insensitive to the orientation of the triangles.

For the bivectors for a geometric 4-simplex (4) is satisfied by Stokes' theorem. Condition (5) is true because the edges meeting at a vertex can be taken as axes for $\mathbb{R}^4$, and then the bivectors are clearly linearly independent. Condition (6) follows from the calculation $\mathrm{Tr}\, b_1[b_2,b_3]=\frac{9}{8}V^2$, where V is the volume of the tetrahedron.[23] This completes the proof that the conditions are satisfied by a geometric 4-simplex.

Now suppose a set of bivectors b_i satisfies (1)–(6). The simplicity conditions and the nondegeneracy imply that the planes corresponding to the four faces of a tetrahedron either all lie in a common hyperplane or share a common direction. However, if the bivectors share a common direction, then $\mathrm{Tr}\, b_1[b_2,b_3]=0$, contradicting (6). Therefore the four planes for a tetrahedron lie in a hyperplane. Furthermore, each plane is determined as the intersection of two of these hyperplanes, as each triangle is contained in two tetrahedra. The nondegeneracy condition implies that the five hyperplanes intersect generically, that is, any four of them intersect at a point.

To construct the geometric 4-simplex, shift one of the five hyperplanes away from the origin by parallel translation. The hyperplanes now bound a geometric 4-simplex, with two-dimensional faces parallel to the planes corresponding to the original bivectors b_i, $i=1,...,10$. This simplex has

ten bivectors, $b_i' = \lambda_i b_i$, for some ten scalars, $\lambda_i \neq 0 \in \mathbb{C}$. Condition (4) is the only linear relation on the bivectors for the faces of a tetrahedron. This implies that the λ_i are all equal for the faces of a tetrahedron, and hence are all equal for all ten triangles.

The geometric 4-simplex can be scaled by moving the hyperplane. If its distance from the origin is scaled by a parameter μ, then the bivectors all scale as μ^2. Therefore the λ_i can be scaled so that they are all equal to 1 or all equal to -1. Then the area bivectors b_i' of the reconstructed 4-simplex are either exactly equal to the original b_i, or all equal to $-b_i$. However, the b_i' also satisfy (6) as they are the bivectors of a geometric 4-simplex. Hence, the inequality in (6) forces the b_i' to be exactly equal to the b_i and not to their negatives.

The scaling parameter μ is only determined up to a sign, and so the geometric 4-simplex is determined up to inversion about the origin. This operation does not affect the area bivectors.

Metric geometry. Now introduce the standard Euclidean metric on $\mathbb{R}^4$ (one could also use the standard Minkowski metric). If the bivectors are replaced by their duals, $*b$, then conditions (1)–(5) are still satisfied, but $\mathrm{Tr}\, b_1[b_2, b_3] = 0$. This duality interchanges a set of planes lying in a hyperplane with a set of planes sharing a common direction.

The bivectors can be identified with elements of the Lie algebra so(4). (Also, it may be profitable to think of them as the elements of the dual of this Lie algebra.) The splitting $\mathrm{so}(4) \simeq \mathrm{su}(2) \oplus \mathrm{su}(2)$ is then the same as the splitting of the space of bivectors into self-dual and anti-self-dual parts, $\mathbb{R}^4 \wedge \mathbb{R}^4 = \Lambda^2_+ \oplus \Lambda^2_-$. The condition that a bivector b is simple is

$$0 = \langle b, *b \rangle = \langle b^+, b^+ \rangle - \langle b^-, b^- \rangle,$$

so that the norm of the self-dual and anti-self-dual parts is equal. The area A of the triangle is determined by

$$A^2 = \langle b, b \rangle = \langle b^+, b^+ \rangle + \langle b^-, b^- \rangle.$$

A geometric simplex has a metric geometry, which is determined by the lengths of its ten edges. Thus, two geometric 4-simplexes have the same edge lengths if and only if they are related by an isometry of $\mathbb{R}^4$. Therefore the bivector data determines a set of edge lengths. Two sets of bivector data determine the same edge lengths if and only if the bivectors are all transformed simultaneously by an orthogonal rotation.

By contrast, specifying the ten areas does not specify the metric geometry uniquely,[24] although it does for almost all configurations. However, giving the areas of the four faces of a tetrahedron does not specify the geometry of the tetrahedron uniquely, so that two 4-simplexes cannot be glued together by specifying the areas of the 16 triangles in their union.[25] For this reason, we decided that the theory should be based on bivectors rather than areas.

III. RELATIVISTIC SPIN NETWORKS

In the theory of spin networks, using the Lie group SU(2), each representation determines a map from vectors in $\mathbb{R}^3$ to operators in the representation space, namely the representation of the Lie algebra. In quantum physics, these are called vector operators. The intuition is that in the classical limit, when the representation is ''large,'' these behave as ordinary vectors in three-dimensional space, with probability near 1.

Given three irreducible representations on spaces V_a, V_b, V_c, the spin network trivalent vertex is a uniquely determined element of

$$V_a \otimes V_b \otimes V_c.$$

In a three-dimensional theory, this is the vertex for a triangle. This element is invariant under the group action. The corresponding vector operators satisfy

$$J_a + J_b + J_c = 0,$$

when applied to this state, as a consequence. This is the relation for the edge vectors of a triangle, or, equivalently, the bivectors in $\mathbb{R}^3$ that are dual to the edge vectors. Note that for other groups,

the space of vertices may form a vector space of dimension greater than unity. In these cases, it is necessary to pick a basis for these spaces and sum over the basis in a state sum model.

To define a theory of relativistic spin networks, we label the edges of a graph with irreducible representations of $SU(2)\times SU(2)$. These are pairs (j,k) of representations of $SU(2)$. Then the representation of the Lie algebra gives bivector operators, by analogy with the preceding case. The condition that these are simple bivectors can be transcribed into the quantum theory by requiring that $j=k$. This is the correct condition because classically it is requiring the self-dual and anti-self-dual parts to have the same norm.

We also have in mind using the q deformation of spin networks.[26] This is algebraically very similar to the undeformed case, with the advantage that the computations can be made finite by the choice of a root of unity. A disadvantage is the loss of the simple geometrical picture of bivectors. Also, the representations are braided. We take the braiding for the two copies of $SU(2)$ to be opposite, i.e., related by an orientation reversing map.

Now in the relativistic case, the theory is for four-dimensional manifolds and the relativistic spin network vertices reside in a tetrahedron. There will be one bivector operator for each face of a tetrahedron, and so this will be a four-valent vertex. The idea for relating spins on faces to the geometry of a tetrahedron is from Barbieri,[23] who considered a single $SU(2)$ spin.

The labeling of a 4-simplex is as follows. The triangles are labeled with representations of $SU(2)\times SU(2)$, and each tetrahedron is labeled with a tensor in the product of the four spaces on its faces.

(1) Changing the orientation of a triangle changes the representation to its dual.

(2) The representations on the triangles are of the form (j,j). These are called simple representations.

(3) For any pair of faces of a tetrahedron, the pair of representations can be decomposed into its Clebsch–Gordan series for $SU(2)\times SU(2)$. Under this isomorphism, the tensor for the tetrahedron decomposes into summands that are nonzero only for the simple representations of $SU(2)\times SU(2)$.

(4) The tensor for the tetrahedron is an invariant tensor.

These conditions are the quantum analogs of the properties (1)–(4) of bivectors on a 4-simplex given earlier. For the first condition, note that in the case of a classical Lie algebra, the action of the Lie algebra in the dual representation is minus the adjoint of the original action. We have not analyzed the inequalities (5) and (6), but note that a simple operator analog of (6) seems feasible. Operator versions of the expression in (6) are considered in the context of canonical quantization in Ref. 27.

We do not have a description of a basis for the space of vertices. However we can show that the space is nonempty in many cases, by exhibiting a canonical element. This vertex is defined by

$$\sum_j \dim j \;\rangle\!\!-\!\!\langle$$

where the middle edge is labeled by (j,j), and $\rangle\!-$ is the usual $SU(2)$ vertex doubled.

This looks unsymmetric because the faces of the tetrahedron have been split into two pairs. Each term in the sum obviously satisfies (2) and (4), and satisfies (3) for the two preferred pairs. The sum of the bivector operators for a pair is equal to the bivector operator for the middle edge in the vertex. This is a simple bivector operator because only simple representations of the form (j,j) appear.

However, the pairs can be switched by fusion, with the coefficients determined by the $6j$ symbol. The orthogonality relation of the $6j$ symbol shows that the vertex is given by the same formula if the top two and bottom two pairs are chosen. For the third splitting, the braidings of self-dual and anti-self-dual pieces cancel, so the same remark applies.

The classical limit. The simple representations of $SU(2)\times SU(2)$ occur as the summands of the Hilbert space of functions on S^3, which has the obvious action of $SO(4)$. The corresponding classical phase space is therefore the cotangent space T^*S^3. A Lie algebra element $l\in so(4)$ acts on functions on S^3 by the formula

$$l = l^{\mu\nu} x_\mu \frac{\partial}{\partial x^\nu}.$$

The corresponding momentum in the classical case is $l^{\mu\nu} x_\mu p_\nu$, for a point $(x,p) \in T^*S^3$. This is the dual pairing of so(4) with the simple bivector $x \wedge p$ in $\mathbb{R}^4$, which explains how simple bivectors are associated to triangles.

This phenomenon is familiar from the standard relativistic angular momentum theory, where the failure of simplicity of the angular momentum is associated with intrinsic spin. In our picture, intrinsic spin occurs for nonsimple representations, which would arise from sections of spinor bundles over S^3.

IV. THE NEW MODEL

It is easy to see how to transform the state sum of Ref. 4 to create a quantum version of summation over all assignments of bivector data to the 2-simplexes of a triangulated 4-manifold. We pick labelings of the 2-simplex of the triangulation by irreducible representations of $U_q(SU_2)$, just as in Ref. 4. For each such labeling of the 2-simplexes, we label the tetrahedra in each 4-simplex by elements of a basis for the vector space of vertices defined in the previous section (so that each tetrahedron in the interior of the manifold is labeled twice). In Ref. 4, a basis for the space of vertices was determined by specifying a labeling of the tetrahedron by a spin j. In the new model, each basis vertex will be a certain linear combination of the $\rangle\!\!-\!\!\langle$ labeled on the middle edge with (j,j).

There are two slightly different possibilities here. The first is to label tetrahedra in each 4-simplex with vertices as just described. The second possibility is to label the tetrahedron in the manifold with $\rangle\!\!-\!\!\langle$ labeled on the middle edge with (j,j) and use this in each of the two 4-simplexes it shares. The extra label j is then summed with the same weights as given by the vertex. The second sum is thus the ''diagonal'' subset of the first. Thus, we actually have two slightly different models, both of which deserve careful study. If vertices other than the canonical vertex exist, there will be still other variant state sums to consider.

In either case, a weight (in $\mathbb{C}$) is defined for the labeling, and the state sum model determines a number by summing the weights over all labelings.

For each 4-simplex, a weight is determined by taking the product of all the vertices for its tetrahedra to form a closed relativistic spin network. The weight for the manifold is determined by taking the product of all these weights with correction factors for the simplexes of dimension less than four. For example, on a tetrahedron, this is the inner product between the basis elements in the vector spaces of vertices for the tetrahedron in each of the two 4-simplexes it shares. This ensures that the state sum does not depend on the choice of basis for the space of vertices on tetrahedra in the interior. The lower-dimensional corrections would be analogous to the ones in Ref. 4, but modified to take into account the fact that we are quantum tracing over two copies of each representation at each step.

In Ref. 4 we combined the 15 spins on each 4-simplex into a diagram called a $15j$-q symbol that depended on the orientation of the 4-simplex. Since reversing orientation switches self-dual with anti-self-dual bivectors, in the new state sum the weights are linear combinations of the product of two $15j$-q symbols with identical representations but opposite orientation for each 4-simplex of the triangulated 4-manifold. Thus, the model is a ''constrained'' doubling of the Crane–Yetter model.

V. CONCLUSIONS

The one issue that still needs to be addressed in order for the state sum we are proposing to be a candidate for a quantum theory of gravity is how probability amplitudes computed with it behave as we refine the triangulation. This is analogous to the ultraviolet problems long familiar to quantum field theory and quantum gravity. It is important to note, however, that the nature of the problem has changed, since we no longer have a continuum metric. Instead of short distance behavior, we are concerned with fluctuations within fluctuations, with each fluctuation having a characteristic Planck length ''size.'' This at any rate is the most natural interpretation of the labelings in our state sum.

There are several possible avenues for constructing a finite theory from our state sum. The most elegant solution would be if there is topological invariance. It will take a good deal of careful calculation of relativistic spin networks to determine if this is the case.

Another possibility is to consider the possibility that below a certain subdivision the universe is in a self-dual, i.e., topological, state. However, this would require relaxing the constraints to allow self-dual states in the model. We could think of this hypothesis as related to the idea that the universe began in a topological state.[28]

Another possibility is to try to imitate our construction using either the category of representations of a larger quantum group or possibly a quantum supergroup. It is plausible that the sort of cancellations familiar from supergravity and supersymmetry will reappear in our context, and give us a finite theory. The advantage of this line of development over superstring theory is that if the cancellations do give a finite theory, it will be an exact theory rather than a perturbative expansion to something more mysterious.

It is interesting that the sort of tensor categories that go into the state sum we are proposing are so similar to the ones invented in constructing string theories.[29] Terms in our state sum can be interpreted as diagrams in string perturbation theory, by connecting together the diagrams we are associating to the 4-simplexes, and interpreting elements in the representations as string states.

At this point, perhaps the strongest thing that we can say of our model is that it transforms a number of important and familiar questions into statements about finite calculations that are well defined and can be investigated. We believe that this is a good sign in itself.

Effects of spin-torsion in gauge theory gravity

Chris Doran,[a] Anthony Lasenby, Anthony Challinor, and Stephen Gull
MRAO, Cavendish Laboratory, Madingley Road, Cambridge CB3 0HE, United Kingdom

(Received 5 February 1997; accepted for publication 17 February 1998)

The spin-torsion sector of a new gauge-theoretic formulation of gravity is analyzed and the relationship to the Einstein–Cartan–Kibble–Sciama theory of gravity is discussed. The symmetries of the Riemann tensor and the conservation laws of the theory are derived. This formalism is applied to the problem of a Dirac field coupled self-consistently to gravity. The equations derived from a minimally coupled gauge-invariant Lagrangian naturally give the gauge-theoretic analogs of the Einstein–Cartan–Dirac equations. Finally, a semiclassical model for a spinning point-particle moving in a gravitational background with torsion is considered. © *1998 American Institute of Physics.* [S0022-2488(98)00706-3]

I. INTRODUCTION

The problem of formulating gravity as a gauge theory has been considered by many authors (see Refs. 1–8 for a representative sample). The gauge-theoretic approach leads naturally to an extension of general relativity known as spin-torsion theory.[9] Such theories build upon Cartan's suggestion[10] that torsion (the antisymmetric part of the connection) should be identified as a possible physical field. The connection between torsion and quantum spin emerged later[2,11,12] when it was realized that the stress-energy tensor for a massive fermion field was asymmetric.[13,14]

A new approach to gauge theory gravity (GTG) was developed in Refs. 15 and 16. In this approach, gravitational effects are described by a pair of gauge fields defined over a flat Minkowski background space–time. The gauge fields ensure the invariance of the theory under arbitrary local displacements and rotations in the background spacetime. All physical predictions are extracted in a gauge-invariant manner, which ensures that the background space–time plays no dynamic role in the physics. Most of the discussion in Ref. 15 was simplified by setting the torsion to zero. Even if the torsion does vanish, differences between GTG and general relativity still arise over global issues such as the role of topology and horizons. These differences are highlighted by the discussion of the Kerr singularity in Doran *et al.*[17–19] Further applications of GTG to situations with vanishing torsion can be found in Ref. 20.

In this paper we consider the spin-torsion sector of GTG in more detail. This is important both for theoretical considerations, such as spinor-driven inflationary models, and for comparisons with possible experiments or observations. Within GTG, torsion is viewed as a physical field derived from the gravitational gauge fields. This viewpoint has some conceptual advantages over that used in differential geometry, where torsion is regarded as a property of a non-Riemannian manifold. A further feature of the GTG approach is that the type of torsion which can arise physically is constrained.[15] This constraint follows from the requirement that minimally coupled equations for the matter fields should be derivable from a minimally coupled, gauge-invariant action.

The paper is arranged as follows. We begin with an introduction to the ''spacetime algebra.''[21,22] This algebraic structure is well suited to many aspects of relativistic physics, enabling manipulations to be carried out in a coordinate-free manner. The theory developed in Ref. 15 takes on its most compelling form when written in the space–time algebra, so we employ it here. One aim of this paper is to advertise the advantages of the algebraic techniques provided by space–time algebra, which extends the language of differential forms to incorporate spinors and quaternions, and provides very clean and clear methods for encoding rotations. These advantages are perhaps not as widely known as they deserve to be. The relations derived in this paper may be

translated into more conventional languages using the schemes described in Appendix D and in Ref. 15.

We next introduce the equations of GTG and discuss the relationship between GTG and the Einstein–Cartan–Kibble–Sciama (ECKS) theory of gravity. We then proceed to a covariant expression for the Riemann tensor in the presence of torsion. From this we are able to relate the Riemann tensor, and its contractions, to the equivalent tensors in the absence of torsion. We then consider the symmetries of the Riemann tensor and the gauge theory version of the Bianchi identity. As is well known, much of the symmetry of the Riemann tensor is lost when torsion is included.

The Dirac field coupled self-consistently to gravity provides an example of a system with torsion, which may be relevant to discussions of the early universe. The equations for this setup are derived from a minimally coupled, gauge-invariant action. The resulting equations are the GTG analogs of the Einstein–Cartan–Dirac equations. Appendix A contains a number of results for the gravitational fields particular to the case of spin generated by a single Dirac fermion. The analogs of the Einstein–Dirac equations are also given. These equations describe the Dirac field coupled to gravity via the (symmetric) stress-energy tensor only. In this arrangement the torsion vanishes. The Einstein–Dirac equations can also be derived from an action, but only if one is prepared to sacrifice the gauge structure of the theory. In Appendix B we give the GTG proof of the useful result, first given by Seitz,[23] relating solutions of the Einstein–Cartan–Dirac equations and solutions of the Einstein–Dirac equations.

Finally, we consider a simple, semiclassical model for a spin-1/2 point-particle moving in a gravitational background with torsion, which builds upon the model discussed in Ref. 15. This displays a coupling of the particle's motion to the torsion, unlike some previous models.[24] This model is used in a separate paper[25] to discuss the anisotropy of a new cosmological solution of the Einstein–Cartan–Dirac equations. Throughout the main part of this paper we assume that the spin tensor has a vanishing contraction, which is necessary for consistency with the minimal coupling procedure. Results for the case where the contraction of the spin tensor does not vanish are contained in Appendix C.

Natural units ($G=c=\hbar=1$) are used throughout this paper.

II. GAUGE THEORY GRAVITY

We begin with a brief introduction to the ''spacetime algebra''—the geometric (or Clifford) algebra of space–time. This is familiar to physicists in the guise of the algebra generated from the Dirac γ-matrices. Further details may be found in Refs. 21 and 22. The spacetime algebra (STA) is generated by four vectors $\{\gamma_\mu\}$, $\mu=0,\ldots,3$, equipped with an associative (Clifford) product, denoted by juxtaposition. The symmetrized and antisymmetrized products define the inner and outer products between vectors, denoted by a dot and a wedge, respectively:

$$\gamma_\mu\cdot\gamma_\nu\equiv\tfrac{1}{2}(\gamma_\mu\gamma_\nu+\gamma_\nu\gamma_\mu)=\eta_{\mu\nu}=\text{diag}(+---), \tag{1}$$

$$\gamma_\mu\wedge\gamma_\nu\equiv\tfrac{1}{2}(\gamma_\mu\gamma_\nu-\gamma_\nu\gamma_\mu). \tag{2}$$

The outer product of two vectors defines a bivector — a directed plane segment, representing the plane including the two vectors.

A full basis for the STA is provided by the set

1	$\{\gamma_\mu\}$	$\{\sigma_k, i\sigma_k\}$	$\{i\gamma_\mu\}$	i
1 scalar	4 vectors	6 bivectors	4 trivectors	1 pseudoscalar
grade 0	grade 1	grade 2	grade 3	grade 4

(3)

where $\sigma_k\equiv\gamma_k\gamma_0, k=1\ldots3$, and $i\equiv\gamma_0\gamma_1\gamma_2\gamma_3=\sigma_1\sigma_2\sigma_3$. The pseudoscalar i squares to -1 and anticommutes with all odd-grade elements. The $\{\sigma_k\}$ generate the geometric algebra of Euclidean 3-space which will be familiar as the algebra of the Pauli spin matrices. An arbitrary real super-

position of the basis elements (3) is called a ''multivector,'' and these inherit the associative Clifford product of the $\{\gamma_\mu\}$ generators. For a grade-r multivector A_r and a grade-s multivector B_s we define the inner and outer products via

$$A_r \cdot B_s \equiv \langle A_r B_s \rangle_{|r-s|}, \quad A_r \wedge B_s \equiv \langle A_r B_s \rangle_{r+s}, \tag{4}$$

where $\langle M \rangle_r$ denotes the grade-r part of M. The subscript 0 is dropped when denoting the scalar part of a multivector, $\langle M \rangle = \langle M \rangle_0$. We shall also make use of the commutator product,

$$A \times B \equiv \tfrac{1}{2}(AB - BA). \tag{5}$$

The operation of reversion, denoted by a tilde, is defined by

$$(AB)^{\sim} \equiv \tilde{B}\tilde{A}, \tag{6}$$

and the rule that vectors are unchanged under reversion. We adopt the convention that, in the absence of brackets, inner, outer, and commutator products take precedence over Clifford products.

Vectors are usually denoted in lower case Latin or Greek for a frame of orthonormal vectors. Let $\{e_\mu\}$ be an arbitrary basis for the grade-1 vector space. The reciprocal basis, denoted by $\{e^\mu\}$, satisfies $e_\mu \cdot e^\nu = \delta_\mu^\nu$. The vector derivative $\partial_a F$ of a multivector-valued function $F(a)$, with respect to the vector argument a, is defined by

$$\partial_a F(a) \equiv e^\mu e_\mu \cdot \partial_a F(a), \tag{7}$$

with the directional derivative operator $e_\mu \cdot \partial_a$ defined by the limit

$$e_\mu \cdot \partial_a F(a) \equiv \lim_{\epsilon \to 0} \left(\frac{F(a + \epsilon e_\mu) - F(a)}{\epsilon} \right). \tag{8}$$

We shall use the symbol ∇ for the vector derivative with respect to space–time position, so that $\nabla \equiv \partial_x$.

Linear functions mapping vectors to vectors are usually denoted with an underbar, $\underline{f}(a)$ (where a is the vector argument). The adjoint function $\overline{f}(a)$ satisfies

$$\underline{f}(a) \cdot b = a \cdot \overline{f}(b). \tag{9}$$

Linear functions extend to act on multivectors via the rule

$$\underline{f}(a \wedge b \wedge \cdots \wedge c) \equiv \underline{f}(a) \wedge \underline{f}(b) \wedge \cdots \wedge \underline{f}(c), \tag{10}$$

which defines a grade-preserving linear operation. The determinant of a linear function is defined by

$$\underline{f}(i) \equiv \det(\underline{f}) i. \tag{11}$$

Contractions of a linear function may be written as $\partial_a \cdot \underline{f}(a)$, and the protraction of a linear function is defined to be $\partial_a \wedge \underline{f}(a)$. Throughout, the argument of a linear function is assumed to independent of position, unless stated otherwise.

Gravitational effects are introduced via two gauge fields, $\overline{h}(a) = \overline{h}(a,x)$ and $\Omega(a) = \Omega(a,x)$, where x is the STA position vector $x = x^\mu \gamma_\mu$ and the dependence on x is often left implicit. The first of these, $\overline{h}(a)$, is a position-dependent linear function mapping the vector argument a to vectors. The gauge-theoretic purpose of $\overline{h}(a)$ is to ensure covariance of the equations under arbitrary local displacements of the matter fields in the background space–time.[15,16] The second gauge field, $\Omega(a)$, is a position-dependent linear function which maps the vector a onto the space of bivectors. Its introduction ensures covariance of the equations under local (Lorentz) rotations of fields, at a point, in the background space–time. It is useful to define another gauge field $\omega(a)$ by

$$\omega(a,x)\equiv\Omega(\underline{h}(a),x), \tag{12}$$

which also maps vectors to bivectors. This field has the advantage of transforming covariantly under position-gauge transformations $x\mapsto x'$:

$$\omega(a,x)\mapsto\omega'(a,x)\equiv\omega(a,x'). \tag{13}$$

From these gauge fields we assemble the covariant derivative $\mathcal{D}$, whose action on a multivector M is given by

$$\begin{aligned}\mathcal{D}M&\equiv\partial_a a\cdot\mathcal{D}M\\ &=\partial_a(a\cdot\overline{h}(\nabla)M+\omega(a)\times M),\end{aligned} \tag{14}$$

which also defines the operator $a\cdot\mathcal{D}$. We shall also make use of the operator $\mathcal{D}_a$ defined by

$$\mathcal{D}_a M\equiv a\cdot\nabla M+\Omega(a)\times M. \tag{15}$$

The covariant derivative contains a grade-raising and -lowering component, so that we may write

$$\mathcal{D}M=\mathcal{D}\cdot M+\mathcal{D}\wedge M, \tag{16}$$

where

$$\mathcal{D}\cdot M\equiv\partial_a\cdot(a\cdot\mathcal{D}M),\quad \mathcal{D}\wedge M\equiv\partial_a\wedge(a\cdot\mathcal{D}M). \tag{17}$$

The field strength corresponding to the $\Omega(a)$ gauge field is defined by

$$R(a\wedge b)\equiv a\cdot\nabla\Omega(b)-b\cdot\nabla\Omega(a)+\Omega(a)\times\Omega(b). \tag{18}$$

From this we define the covariant Riemann tensor

$$\mathcal{R}(a\wedge b)\equiv R[\underline{h}(a\wedge b)]. \tag{19}$$

The Ricci tensor, Ricci scalar and Einstein tensor are formed from contractions of the Riemann tensor:

$$\text{Ricci tensor:}\quad \mathcal{R}(a)=\partial_b\cdot\mathcal{R}(b\wedge a), \tag{20}$$

$$\text{Ricci scalar:}\quad \mathcal{R}=\partial_a\cdot\mathcal{R}(a), \tag{21}$$

$$\text{Einstein tensor:}\quad \mathcal{G}(a)=\mathcal{R}(a)-\tfrac{1}{2}a\mathcal{R}. \tag{22}$$

In any expression containing the symbol $\mathcal{R}$ the argument determines whether the Riemann or Ricci tensors, or Ricci scalar is implied.

Differential operators act on the multivector to their immediate right unless brackets are present. When acting on multivectors to which they are not immediately adjacent, the ''overdot'' notation is employed to denote the scope of a differential operator, so that

$$\dot{\nabla}A\dot{B}=\partial_a A a\cdot\nabla B. \tag{23}$$

As an example, Leibniz' rule can be written

$$\nabla(AB)=\nabla AB+\dot{\nabla}A\dot{B}. \tag{24}$$

The overdot notation extends to covariant derivatives. For example, for a general multivector-valued tensor $T(b,\ldots c)$ we define

$$a\cdot\dot{\mathcal{D}}\dot{T}(b,\ldots c)\equiv a\cdot\mathcal{D}T(b,\ldots c)-T(a\cdot\mathcal{D}b,\ldots c)-\cdots-T(b,\ldots a\cdot\mathcal{D}c). \tag{25}$$

The resultant object $a\cdot\dot{\mathcal{D}}\dot{T}(b,\ldots c)$ is also a covariant tensor. The utility of the $a\cdot\dot{\mathcal{D}}$ operator for tensors is that it commutes with contractions and protractions. The proof is straightforward, involving only the results that

$$\partial_b a\cdot\mathcal{D}\dot{T}(b,c,\ldots d)=a\cdot\dot{\mathcal{D}}\dot{T}'(c,\ldots d)-\omega(a)\cdot\partial_b T(b,c,\ldots d)-\partial_b T(\omega(a)\cdot b,c,\ldots d), \tag{26}$$

where $T'(c,\ldots d)\equiv\partial_b T(b,c,\ldots d)$, and

$$\partial_b\cdot\omega(a)T(b,\ldots)-\partial_b T(\omega(a)\cdot b,\ldots)=\partial_b T((\omega(a)\cdot b)\cdot\partial_e e,\ldots)-\partial_b T(\omega(a)\cdot b,\ldots)=0. \tag{27}$$

The field equations are obtained from variation of a suitable gauge-invariant action with respect to the gravitational gauge fields and the matter fields.[15] Varying with respect to the $\overline{h}$-field leads to the GTG analog of the Einstein equation:

$$\mathcal{G}(a)=\kappa\mathcal{T}(a), \tag{28}$$

where $\mathcal{T}(a)$ is the covariant matter stress-energy tensor (which need not be symmetric if spin is present) and $\kappa\equiv 8\pi$. On varying the $\Omega(a)$-field we find that

$$\mathcal{D}\wedge\overline{h}(a)=\kappa\mathcal{S}[\overline{h}(a)]+\tfrac{1}{2}\kappa[\partial_b\cdot\mathcal{S}(b)]\wedge\overline{h}(a), \tag{29}$$

where $\mathcal{S}(a)$ is the covariant spin tensor and a is independent of position. The definition of $\mathcal{S}(a)$ in terms of the matter Lagrangian is given in Ref. 15 and for the Dirac field it is discussed in Sec. V below.

The variation principle leading to (29) is different from that usually considered in the context of Poincaré gauge theory.[5,26] There one varies the action with respect to the metric and the torsion tensors, which are considered as separate dynamical variables. In GTG we vary with respect to the $\overline{h}(a)$ and $\Omega(a)$ gauge fields, the latter of which contains information about both the Christoffel connection and the torsion. In this respect the GTG approach is closer to the Palatini principle. The fact that $\Omega(a)$ is bivector valued and coordinate free removes the problems with the Palatini approach in ECKS theory first discussed by Sandberg.[27] This is because the ''projective transformation'' discussed in Ref. 27 is not a permissible transformation in GTG. Treating $\Omega(a)$ as a separate dynamical variable also recovers the link with a genuine gauge theory since it is the full $\Omega(a)$ that appears in the expression for minimal coupling to a Dirac wave function.

An important consequence of Eq. (29) is that minimally coupled equations for the matter fields are obtained from a minimally coupled Lagrangian only if the contraction of the spin tensor vanishes, that is, if

$$\partial_a\cdot\mathcal{S}(a)=0. \tag{30}$$

This is because Eq. (29) implies

$$\mathcal{D}_a[\overline{h}(\partial_a)\det(\underline{h})^{-1}]=-\tfrac{1}{2}\kappa\partial_a\cdot\mathcal{S}(a), \tag{31}$$

and the left-hand side must vanish for the minimally coupled equations to arise from the minimally coupled action. Minimal coupling at the level of the field equations is crucial in ensuring that GTG incorporates the equivalence principle (both classical and quantum). Minimal coupling at the level of the action, on the other hand, ensures that one has a genuine gauge theory and is important for constructing a quantum field theory. We therefore believe that Eq. (30) is a necessary requirement of all physical fields and this condition is assumed throughout the main part of this paper. Results for the case when $\partial_a\cdot\mathcal{S}(a)$ is not zero are given in Appendix C. For scalar fields and Yang–Mills gauge fields the spin tensor vanishes. For spin-1/2 fields the spin tensor is of the form

$$\mathcal{S}(a)=T\cdot a, \tag{32}$$

where T is the spin trivector. This form necessarily has vanishing contraction. The picture is slightly more complicated for spin-1 and spin-3/2 matter fields, where there is some freedom in the equations that one can work with. In both these cases, however, it is possible to construct theories in which Eq. (30) does hold. This work will be presented elsewhere.

Given that the spin tensor satisfies Eq. (30), Eq. (29) reduces to the ''wedge'' equation

$$\mathcal{D}\wedge\bar{h}(a)=\partial_b\wedge[b\cdot\mathcal{D}\bar{h}(a)]=\kappa\mathcal{S}[\bar{h}(a)], \tag{33}$$

or, in the case where a is position dependent,

$$\mathcal{D}\wedge\bar{h}(a)=\bar{h}(\nabla\wedge a)+\kappa\mathcal{S}[\bar{h}(a)]. \tag{34}$$

We refer to the left-hand side of Eq. (33) as the torsion. In the spin-torsion extension of general relativity, the torsion is measured by the antisymmetric part of the connection (the symmetric part is fixed by the requirement of metric compatibility) on the space–time manifold. The relationship between these two expressions is described in Appendix D.

The criterion that led us to restrict the torsion type also constrains the Lagrangian for the free gravitational field. In particular, it rules out the quadratic curvature terms in the Lagrangian often considered in the context of Poincaré gauge theory[5,28–30] This is because the higher-order terms in the field equations prevent one from deriving $\mathcal{D}_a\bar{h}(\partial_a\det(\underline{h})^{-1})=0$. The only additional terms that can be added to the Lagrangian are quadratic in the torsion.[5,31] Such terms contain derivatives of the $\bar{h}$-field, however, and so considerably complicate the theory. Indeed, the theory looks so simple and compelling with no derivatives of the $\bar{h}$-function present that it is tempting to view their absence as suggestive of a deeper principle. We discuss some ways that derivatives of the $\bar{h}$-field can be incorporated into the action in Sec. V, however, and it is a simple matter to adapt the present work for the presence of quadratic torsion terms.

Equations (28) and (29) are locally the same as those of ECKS theory. This can be made clear by introducing a coordinate frame and following the scheme described in Appendix D. Globally, however, the theories are not equivalent. This is because GTG is explicitly constructed as a gauge theory in a flat space–time and there is no possibility of the fields altering the topology of this background space–time. This leads to a number of differences between the two theories,[15,17,18] though these differences are not the subject of the present paper. Our aim here is to show that GTG, together with the techniques of space–time algebra, simplify many otherwise difficult derivations required in all of GTG, ECKS theory and general relativity.

This completes the definitions of the quantities required in this paper. Further details may be found in Ref. 15.

III. THE RIEMANN TENSOR

The definition (19) for the Riemann tensor can be manipulated into a manifestly covariant form. We begin by introducing the derivatives

$$L_a\equiv a\cdot\bar{h}(\nabla) \tag{35}$$

and writing

$$\mathcal{R}(a\wedge b)=L_a\omega(b)-L_b\omega(a)-\omega[\underline{h}^{-1}(L_a\underline{h}(b)-L_b\underline{h}(a))]+\omega(a)\times\omega(b), \tag{36}$$

where in this section the vectors a,b, etc. are assumed to be arbitrary functions of position. To eliminate the derivatives of the $\underline{h}$-function, we first write the ''wedge'' Eq. (33) in the form

$$\bar{h}(\dot{\nabla})\wedge\dot{\bar{h}}(c)=-\partial_d\wedge[\omega(d)\cdot\bar{h}(c)]+\kappa\mathcal{S}[\bar{h}(c)]$$

$$\Rightarrow\quad\langle b\wedge a\ \bar{h}(\dot{\nabla})\wedge\dot{\bar{h}}(c)\rangle=-\langle b\wedge a\ \partial_d\wedge[\omega(d)\cdot\bar{h}(c)]\rangle+\kappa\langle b\wedge a\ \mathcal{S}[\bar{h}(c)]\rangle$$

$$\Rightarrow\quad[\dot{L}_a\dot{\underline{h}}(b)-\dot{L}_b\dot{\underline{h}}(a)]\cdot c=[a\cdot\omega(b)-b\cdot\omega(a)]\cdot\bar{h}(c)-\kappa\bar{\mathcal{S}}(a\wedge b)\cdot\bar{h}(c), \tag{37}$$

where overdots denote the scope of the differential operator and $\overline{\mathcal{S}}(a)$ is the adjoint to the spin tensor, defined by

$$\overline{\mathcal{S}}(B)\cdot a = B\cdot\mathcal{S}(a), \tag{38}$$

for an arbitrary vector a and bivector B. The adjoint function $\overline{\mathcal{S}}(B)$ is a vector-valued linear function of its bivector argument B. It follows that

$$\begin{aligned}\underline{h}^{-1}(L_a\underline{h}(b)-L_b\underline{h}(a)) &= L_a b - L_b a + a\cdot\omega(b) - b\cdot\omega(a) - \kappa\overline{\mathcal{S}}(a\wedge b)\\ &= a\cdot\mathcal{D}b - b\cdot\mathcal{D}a - \kappa\overline{\mathcal{S}}(a\wedge b).\end{aligned} \tag{39}$$

If we denote the right-hand side of (39) by c, then we can write the Riemann tensor as

$$\mathcal{R}(a\wedge b) = L_a\omega(b) - L_b\omega(a) + \omega(a)\times\omega(b) - \omega(c), \tag{40}$$

which only differs from the torsion-free expression given in Ref. 15 by the definition of the vector c.

Evaluating the commutator of L_a and L_b gives

$$[L_a, L_b] = [L_a\underline{h}(b) - L_b\underline{h}(a)]\cdot\nabla = c\cdot\overline{h}(\nabla) = L_c, \tag{41}$$

where c is given by the right-hand side of (39). This bracket structure summarizes the content of the ''wedge'' equation (33) in a form that is independent of the torsion. The structure is essentially that of the Lie bracket, though its use in GTG is somewhat different. A new method of solving the field equations, which exploits this bracket structure, was given in Ref. 15. This ''intrinsic'' method has the advantage of yielding a set of first-order equations which, although still nonlinear, are generally more tractable than their second-order counterparts in general relativity.

When solving the field equations in the presence of torsion it proves useful to introduce the new field

$$\omega'(a) = \omega(a) + \kappa\mathcal{S}(a) - \tfrac{3}{2}\kappa a\cdot T, \tag{42}$$

where

$$T \equiv \tfrac{1}{3}\partial_a\wedge\mathcal{S}(a) \tag{43}$$

is the spin trivector. The $\omega'(a)$-field satisfies the equation

$$\mathcal{D}'\wedge\overline{h}(a) \equiv \partial_b\wedge(\dot{L}_b\dot{\overline{h}}(a) + \omega'(b)\cdot\overline{h}(a)) = 0 \tag{44}$$

and is the ω-function in the absence of torsion. We can derive an expression for $\omega'(a)$ in terms of the $\overline{h}$-function alone by inverting (44) to yield[15]

$$\omega'(a) = -H(a) + \tfrac{1}{2}a\cdot(\partial_b\wedge H(b)), \tag{45}$$

where

$$H(a) \equiv \overline{h}(\nabla\wedge\overline{h}^{-1}(a)) = -\overline{h}(\dot{\nabla})\wedge\dot{\overline{h}}(\overline{h}^{-1}(a)). \tag{46}$$

In GTG, $\omega'(a)$ plays the same role as the Christoffel symbol (the symmetric part of the connection) in the spin-torsion extension of general relativity.

On defining

$$\varpi(a) \equiv \omega(a) - \omega'(a) = -\kappa\mathcal{S}(a) + \tfrac{3}{2}\kappa a\cdot T, \tag{47}$$

we see that the Riemann tensor can be written as

$$\mathcal{R}(a\wedge b)=\mathcal{R}'(a\wedge b)+a\cdot\dot{\mathcal{D}}'\dot{\varpi}(b)-b\cdot\dot{\mathcal{D}}'\dot{\varpi}(a)+\varpi(a)\times\varpi(b), \tag{48}$$

where the primes denote the equivalent quantities in the absence of torsion. (In the literature these are often denoted with a pair of curly braces to denote the use of the Christoffel connection.)

On contracting Eq. (48) with ∂_a we find the following expression for the Ricci tensor:

$$\begin{aligned}\mathcal{R}(b)&=\mathcal{R}'(b)+\dot{\mathcal{D}}'\cdot\dot{\varpi}(b)-b\cdot\mathcal{D}'[\partial_a\cdot\varpi(a)]+\partial_a\cdot[\varpi(a)\times\varpi(b)]\\&=\mathcal{R}'(b)-\kappa\dot{\mathcal{D}}'\cdot\dot{\mathcal{S}}(b)-\tfrac{3}{2}\kappa b\cdot(\mathcal{D}'\cdot T)+\langle\partial_a\varpi(a)\varpi(b)\rangle_1-\partial_a\,\varpi(a)\cdot\varpi(b)\\&=\mathcal{R}'(b)-\kappa\dot{\mathcal{D}}'\cdot\dot{\mathcal{S}}(b)-\tfrac{3}{2}\kappa b\cdot(\mathcal{D}'\cdot T)-\kappa^2\overline{\mathcal{S}}[\mathcal{S}(b)]+\tfrac{3}{2}\kappa^2\overline{\mathcal{S}}(b\cdot T),\end{aligned} \tag{49}$$

where again $\mathcal{R}'(a)$ is the Ricci tensor in the absence of torsion and we have assumed a vanishing contraction of the torsion tensor. Finally, we make a further contraction to obtain the following expression for the Ricci scalar:

$$\mathcal{R}=\mathcal{R}'+\tfrac{9}{2}\kappa^2T^2-\kappa^2\mathcal{S}(\partial_a)\cdot\mathcal{S}(a). \tag{50}$$

No derivatives of $\mathcal{S}(a)$ appear in this expression, which is a feature of assuming that the spin tensor has a zero contraction.[5,31]

IV. SYMMETRIES AND CONSERVATION LAWS

In this section we discuss some of the symmetries of the Riemann tensor and conservation laws of GTG when torsion is present. These have already been given in Ref. 15, for the case of vanishing torsion. The zero torsion results may be combined with the expressions of the previous section to extend them to the torsion sector. However, for reasons of completeness, we shall not follow this route but shall give derivations from ''first principles.'' Many of these results have immediate counterparts in differential geometry, though the conciseness of their derivations here compares favorably with tensor-calculus techniques.

Our starting point is the equation

$$\mathcal{D}\wedge\overline{h}(c)=\kappa\mathcal{S}[\overline{h}(c)], \tag{51}$$

where c is independent of position. Taking the covariant exterior derivative of this equation gives

$$\mathcal{D}\wedge(\mathcal{D}\wedge\overline{h}(c))=\kappa\mathcal{D}\wedge\mathcal{S}[\overline{h}(c)]. \tag{52}$$

However,

$$\begin{aligned}\mathcal{D}\wedge(\mathcal{D}\wedge\overline{h}(c))&=\overline{h}(\partial_a)\wedge\mathcal{D}_a[\overline{h}(\partial_b)\wedge(\mathcal{D}_b\overline{h}(c))]\\&=[\mathcal{D}\wedge\overline{h}(\partial_b)]\wedge[\mathcal{D}_b\overline{h}(c)]+\overline{h}(\partial_a)\wedge\overline{h}(\partial_b)\wedge[\mathcal{D}_a\mathcal{D}_b\overline{h}(c)]\\&=\kappa\mathcal{S}[\overline{h}(\partial_b)]\wedge[\mathcal{D}_b\overline{h}(c)]+\tfrac{1}{2}\overline{h}(\partial_a)\wedge\overline{h}(\partial_b)\wedge[R(a\wedge b)\cdot\overline{h}(c)],\end{aligned} \tag{53}$$

so that

$$\begin{aligned}(2\kappa)^{-1}\partial_a\wedge\partial_b\wedge[\mathcal{R}(a\wedge b)\cdot\overline{h}(c)]&=\mathcal{D}\wedge\mathcal{S}[\overline{h}(c)]-\mathcal{S}[\overline{h}(\partial_b)]\wedge[\mathcal{D}_b\overline{h}(c)]\\&=\dot{\mathcal{D}}\wedge\dot{\mathcal{S}}[\overline{h}(c)]+\partial_a\wedge\mathcal{S}[a\cdot\mathcal{D}\overline{h}(c)]-\mathcal{S}(\partial_b)\wedge[b\cdot\mathcal{D}\overline{h}(c)].\end{aligned} \tag{54}$$

The final two terms on the right-hand side of Eq. (54) are

$$\begin{aligned}\partial_a\wedge\mathcal{S}\,[a\cdot\mathcal{D}\bar{h}(c)]-\mathcal{S}(\partial_b)\wedge[b\cdot\mathcal{D}\bar{h}(c)]&=\mathcal{S}(\partial_a)\wedge[\partial_b\ a\cdot(b\cdot\mathcal{D}\bar{h}(c))-a\cdot\mathcal{D}\bar{h}(c)]\\&=-\mathcal{S}(\partial_a)\wedge[a\cdot(\mathcal{D}\wedge\bar{h}(c))]\\&=-\kappa\mathcal{S}(\partial_a)\wedge[a\cdot\mathcal{S}(\bar{h}(c))],\end{aligned}\tag{55}$$

so Eq. (54) reduces to the covariant equation

$$\partial_a\wedge\partial_b\wedge[\mathcal{R}(a\wedge b)\cdot c]=2\kappa\dot{\mathcal{D}}\wedge\dot{\mathcal{S}}(c)-2\kappa^2\mathcal{S}(\partial_a)\wedge[a\cdot\mathcal{S}(c)].\tag{56}$$

Protracting Eq. (56) with ∂_c yields

$$\partial_a\wedge\partial_b\wedge\mathcal{R}(a\wedge b)=3\kappa\mathcal{D}\wedge T+\kappa^2\mathcal{S}(\partial_a)\wedge\mathcal{S}(a),\tag{57}$$

and dotting back with c gives

$$2\partial_b\wedge\mathcal{R}(c\wedge b)-\partial_a\wedge\partial_b\wedge[\mathcal{R}(a\wedge b)\cdot c]=3\kappa c\ \mathcal{D}\wedge T+\kappa^2 c\ \mathcal{S}(\partial_a)\wedge\mathcal{S}(a).\tag{58}$$

Hence, applying Eq. (56) again, we find that

$$\partial_a\wedge\mathcal{R}(a\wedge b)=-\kappa[\dot{\mathcal{D}}\wedge\dot{\mathcal{S}}(b)+\tfrac{3}{2}b\ \mathcal{D}\wedge T]+\kappa^2\mathcal{S}(\partial_a)\wedge[a\cdot\mathcal{S}(b)]-\tfrac{1}{2}\kappa^2 b\ \mathcal{S}(\partial_a)\wedge\mathcal{S}(a).\tag{59}$$

In the absence of spin the right-hand side of (59) vanishes, leaving the simple equation $\partial_a\wedge\mathcal{R}(a\wedge b)=0$ which, as noted in Ref. 15, encodes all the symmetries of the Riemann tensor in the absence of torsion.

The adjoint function to $\mathcal{R}(B)$ is written $\bar{\mathcal{R}}(B)$ and is defined by

$$A\cdot\mathcal{R}(B)=B\cdot\bar{\mathcal{R}}(A)\tag{60}$$

for any two bivectors A and B. The Riemann tensor and its adjoint are related by

$$\mathcal{R}(B)-\bar{\mathcal{R}}(B)=-\partial_b\wedge[B\cdot(\partial_a\wedge\mathcal{R}(a\wedge b))]+\tfrac{1}{2}B\ \partial_b\wedge\partial_a\wedge\mathcal{R}(a\wedge b)\tag{61}$$

and Eq. (59) can be used to express the right-hand side in terms of the spin. Clearly a vanishing spin tensor implies that $\mathcal{R}(B)=\bar{\mathcal{R}}(B)$, though the relation $\partial_a\wedge\mathcal{R}(a\wedge b)=0$ contains more information and is more useful in practice.

Returning to Eq. (59) and contracting with ∂_b we obtain

$$\partial_a\wedge\mathcal{R}(a)=\partial_a\wedge\mathcal{G}(a)=-\kappa\dot{\mathcal{S}}(\dot{\mathcal{D}})+\kappa^2[\partial_b\cdot\mathcal{S}(\partial_a)]\wedge[a\cdot\mathcal{S}(b)],\tag{62}$$

and the same expression must hold for the matter stress-energy tensor. The final term can be simplified by noting that

$$i\bar{\mathcal{S}}(iB)=i\partial_a\langle iB\mathcal{S}(a)\rangle=\mathcal{S}(a)\wedge(\partial_a\cdot B)\tag{63}$$

[since $\partial_a\cdot\mathcal{S}(a)=0$]. We can therefore write

$$[\partial_b\cdot\mathcal{S}(\partial_a)]\wedge[a\cdot\mathcal{S}(b)]=\partial_b\cdot[i\bar{\mathcal{S}}(i\mathcal{S}(b))]=-i\partial_b\wedge\bar{\mathcal{S}}(i\mathcal{S}(b)).\tag{64}$$

The gauge theory version of the Bianchi identity follows from the Jacobi identity applied to covariant derivatives of an arbitrary multivector M:

$$[\mathcal{D}_a,[\mathcal{D}_b,\mathcal{D}_c]]M+\text{ cyclic permutations}=0.\tag{65}$$

Evaluating the commutators we find that

$$\mathcal{D}_a R(b\wedge c)+\text{ cyclic permutations}=0,\tag{66}$$

which we want to replace by a covariant expression. We first extend to the case where a,b and c are position dependent:

$$\mathcal{D}_a R(b\wedge c)-R[(a\cdot\nabla b-b\cdot\nabla a)\wedge c]+\text{ cyclic permutations}=0. \tag{67}$$

Next, we replace a with $\underline{h}(a)$, etc. to find

$$a\cdot\mathcal{D}\mathcal{R}(b\wedge c)-\mathcal{R}[(\underline{h}^{-1}L_a\underline{h}(b)-\underline{h}^{-1}L_b\underline{h}(a))\wedge c]+\text{ cyclic permutations}=0. \tag{68}$$

Recalling Eq. (39), Eq. (68) becomes

$$a\cdot\mathcal{D}\mathcal{R}(b\wedge c)-\mathcal{R}[(a\cdot\mathcal{D}b-b\cdot\mathcal{D}a)\wedge c]+\kappa\mathcal{R}[\overline{\mathcal{S}}(a\wedge b)\wedge c]+\text{ cyclic permutations}=0, \tag{69}$$

which simplifies to give

$$a\cdot\dot{\mathcal{D}}\dot{\mathcal{R}}(b\wedge c)+\kappa\mathcal{R}[\overline{\mathcal{S}}(a\wedge b)\wedge c]+\text{ cyclic permutations}=0. \tag{70}$$

The adjoint form of this equation is

$$\partial_c\wedge\partial_b\wedge\partial_a\langle a\cdot\dot{\mathcal{D}}\dot{\mathcal{R}}(b\wedge c)B\rangle=-\kappa\partial_c\wedge\partial_b\wedge\partial_a\langle\mathcal{R}[\overline{\mathcal{S}}(a\wedge b)\wedge c]B\rangle, \tag{71}$$

where B is an arbitrary bivector. Equation (71) evaluates to

$$\dot{\mathcal{D}}\wedge\dot{\overline{\mathcal{R}}}(B)=\kappa\partial_a\ \mathcal{S}(a)\wedge\overline{\mathcal{R}}(B), \tag{72}$$

or, alternatively,

$$\partial_a\wedge[a\cdot\mathcal{D}\overline{\mathcal{R}}(B)-\overline{\mathcal{R}}(a\cdot\mathcal{D}B)]=\kappa\partial_a\ \mathcal{S}(a)\wedge\overline{\mathcal{R}}(B), \tag{73}$$

which is our gauge theory version of the Bianchi identity.

On contracting Eq. (72) we obtain

$$(\partial_a\wedge\partial_b)\cdot[\dot{\mathcal{D}}\wedge\dot{\overline{\mathcal{R}}}(a\wedge b)]=\kappa(\partial_a\wedge\partial_b\wedge\partial_c)\ \mathcal{S}(c)\wedge\overline{\mathcal{R}}(a\wedge b),$$

$$\Rightarrow\quad 2b\cdot\dot{\mathcal{D}}\ \dot{\overline{\mathcal{R}}}(\partial_b)-\mathcal{D}\mathcal{R}=\kappa(\partial_a\wedge\partial_b\wedge\partial_c)\ \mathcal{S}(c)\wedge\overline{\mathcal{R}}(a\wedge b), \tag{74}$$

which may be written as

$$\dot{\overline{\mathcal{G}}}(\dot{\mathcal{D}})\equiv a\cdot\dot{\mathcal{D}}\dot{\overline{\mathcal{G}}}(\partial_a)=-\kappa\partial_a\cdot\overline{\mathcal{R}}[\mathcal{S}(a)]+\kappa\partial_a\cdot\mathcal{S}[\overline{\mathcal{R}}(a)]. \tag{75}$$

Taking the inner product with an arbitrary vector b, we obtain the adjoint form

$$\dot{\mathcal{D}}\cdot\dot{\mathcal{G}}(a)=\kappa\mathcal{S}(\partial_b)\cdot\mathcal{R}(b\wedge a)-\kappa[a\cdot\mathcal{S}(\partial_b)]\cdot\mathcal{R}(b). \tag{76}$$

In the absence of torsion, we obtain the simple result

$$\dot{\mathcal{G}}(\dot{\mathcal{D}})=0, \tag{77}$$

which is the GTG version of covariant conservation of the Einstein tensor.

V. THE SELF-CONSISTENT DIRAC FIELD

A simple way to produce gauge fields with torsion is to consider matter described by a Dirac spinor field $|\psi(x)\rangle$. In the STA, it is convenient to represent such a spinor by an even multivector ψ (see Refs. 32 and 33 for an explicit map for the Dirac–Pauli representation). The $\{\hat{\gamma}_\mu\}$ operators, and the conventional unit scalar imaginary j, have actions which are represented by

$$\begin{aligned}\hat{\gamma}_\mu|\psi\rangle&\leftrightarrow\gamma_\mu\psi\gamma_0\quad(\mu=0\ldots3),\\ j|\psi\rangle&\leftrightarrow\psi i\sigma_3.\end{aligned} \tag{78}$$

In this manner, all matrix manipulations are eliminated, and the geometric content of the Dirac theory is made manifest.[34]

Spinors transform single sidedly under Lorentz rotations, which leads to the introduction of the spinor covariant derivative $D\psi \equiv \partial_a a \cdot D\psi$ where

$$a \cdot D\psi \equiv L_a \psi + \tfrac{1}{2}\omega(a)\psi. \tag{79}$$

The equations of motion for the Dirac field and the gauge fields are derived from the minimally coupled action,[15]

$$S_{\mathrm{ECD}} = \int |d^4x| \det(\underline{h})^{-1} \left[\tfrac{1}{2}\mathcal{R} - \kappa\langle D\psi i\gamma_3\tilde{\psi} - m\psi\tilde{\psi}\rangle\right], \tag{80}$$

where m is the mass of the particle. Varying with respect to ψ and the gravitational gauge fields leads to the system of equations

$$\begin{aligned} &\text{``wedge'':} && \mathcal{D}\wedge\overline{h}(a) = \kappa T \cdot \overline{h}(a) \\ &\text{Einstein:} && \mathcal{G}(a) = \kappa\mathcal{T}(a), \\ &\text{Dirac:} && D\psi i\sigma_3 = m\psi\gamma_0, \end{aligned} \tag{81}$$

where

$$T \equiv \tfrac{1}{2}\psi i\gamma_3\tilde{\psi} \tag{82}$$

is the spin trivector, and the matter stress-energy tensor $\mathcal{T}(a)$ is given by[15]

$$\mathcal{T}(a) = \langle a \cdot D\psi i\gamma_3\tilde{\psi}\rangle_1. \tag{83}$$

These equations are the gauge theory equivalents of the Einstein–Cartan–Dirac equations. The ''wedge'' equation summarizes Cartan's suggestion[10] that the torsion be identified with the spin of the matter present. Note that the minimally coupled Lagrangian has given rise to the minimally coupled Dirac equation, on variation of ψ. As noted in the Introduction, this is because ''trivector'' spin of the type $\mathcal{S}(a) = T \cdot a$ automatically has a vanishing contraction. A number of results for the gravitational field particular to this case of trivector spin are contained in Appendix A.

Protracting the stress-energy tensor (83) with ∂_a, we find that

$$\begin{aligned} \partial_a \wedge \mathcal{T}(a) &= \partial_a \wedge \langle a \cdot D\psi i\gamma_3\tilde{\psi}\rangle_1 \\ &= \tfrac{1}{2}\langle D\psi i\gamma_3\tilde{\psi} - \partial_a\psi i\gamma_3(a \cdot D\psi)^{\sim}\rangle_2. \end{aligned} \tag{84}$$

However, the Dirac equation implies that $\langle D\psi i\gamma_3\tilde{\psi}\rangle_2 = 0$, so we can write

$$\partial_a \wedge \mathcal{T}(a) = -\tfrac{1}{2}\langle \partial_a[a \cdot D\psi i\gamma_3\tilde{\psi} + \psi i\gamma_3(a \cdot D\psi)^{\sim}]\rangle_2 = -\langle \partial_a(a \cdot \mathcal{D}T)\rangle_2 = -\mathcal{D} \cdot T. \tag{85}$$

This demonstrates that the Dirac equation and the definition (83) for the stress-energy tensor are consistent with Eq. (62), since the final term on the right-hand side of Eq. (62) vanishes for the case of trivector spin. It can also be shown that the Dirac equation is consistent with the contracted Bianchi identity (75). The proof of this is simplified by employing the results of Appendix A. A new, exact solution to the Einstein–Cartan–Dirac equations in GTG, describing an almost homogeneous universe with a spin-induced anisotropy, is given in Ref. 25.

The gauge-invariant action (80) naturally gives rise to a spin-torsion theory, with the torsion (measured by the left-hand side of the ''wedge'' equation) given by the spin of the matter. Such an interaction is inevitable if the gravitational fields are introduced via a gauge theoretic route. This is good reason to prefer the Einstein–Cartan–Dirac equations over the Einstein–Dirac equa-

tions, which result from coupling the Dirac equation with the torsion-free space–time of general relativity. However, as most of the literature focuses on solutions of the Einstein–Dirac equations (see, for example, Refs. 35–38), it is interesting to see how the present techniques can be adapted to such a setup. We start by replacing $\omega(a)$ in the action by the equivalent expression in terms of $\overline{h}(a)$ and its derivatives. The action then becomes

$$S_{\mathrm{ED}}=\int |d^4x|\det(\underline{h})^{-1}\,[\tfrac{1}{2}\mathcal{R}'-\kappa\langle\overline{h}(\nabla)\psi i\gamma_3\tilde{\psi}+\tfrac{1}{4}\partial_a\wedge H(a)\psi i\gamma_3\tilde{\psi}-m\psi\tilde{\psi}\rangle], \tag{86}$$

where $H(a)$ is as defined in Eq. (46) and $\mathcal{R}'$ is now a function of $\overline{h}(a)$ and its first and second derivatives. The dynamical variables are now $\overline{h}(a)$ and ψ, with the ''wedge'' equation replaced by the identity

$$\mathcal{D}'\wedge\overline{h}(a)=0. \tag{87}$$

Variation with respect to ψ produces the equation

$$D'\psi i\sigma_3=m\psi\gamma_0, \tag{88}$$

where the prime again denotes that the covariant derivative does not contain a contribution from the spin. Variation with respect to $\overline{h}(a)$ yields

$$\mathcal{G}'(a)=\kappa\mathcal{T}'(a), \tag{89}$$

where $\mathcal{T}'(a)$ is obtained by variation of the matter action with respect to $\overline{h}(a)$. The derivation of $\mathcal{T}'(a)$ is more complicated now due to the presence of derivatives of the $\overline{h}(a)$-function in the matter Lagrangian. The calculations are not too difficult, however, and yield

$$\mathcal{T}'(a)=\langle a\cdot D'\psi i\gamma_3\tilde{\psi}\rangle_1+\tfrac{1}{2}a\cdot(\mathcal{D}'\cdot T). \tag{90}$$

Satisfyingly $\mathcal{T}'(a)$ is a symmetric tensor, which it has to be since $\mathcal{G}'(a)$ is automatically symmetric. The pair of equations (88) and (89) constitute the GTG version of the Einstein–Dirac equations. These are usually obtained from the system (81) by the Belifante–Rosenfield procedure.[39,40] It is perhaps surprising that to derive the equations rigorously from an action involves replacing the symmetric metric tensor $g_{\mu\nu}$ with $\overline{h}(a)$ as the dynamical variable, since it is the latter that unambiguously yields a symmetric stress-energy tensor.

Despite the neat features of the GTG derivation of the Einstein–Dirac set of equations, there are still good reasons to prefer the Einstein–Cartan–Dirac set, though of course no experiment has yet been devised which could distinguish between them. The key reason, as stated earlier, is that the Einstein–Cartan–Dirac set maintains the link with gauge theories, which is lost if one pushes the Riemannian geometry viewpoint of the Einstein–Dirac set. Such considerations are clearly important in attempting to construct a fully quantum theory. Furthermore, the clean separation into the $\overline{h}(a)$ and $\Omega(a)$ gauge fields of the GTG approach is particularly appealing in looking for extensions to a multiparticle quantum theory of gravity.

It is worth pointing out that if $\overline{h}(a),\omega(a)$ and ψ satisfy Eq. (81), then the fields $\overline{h}(a),\omega'(a)$ and ψ satisfy Eqs. (88) and (89) if the condition

$$T\psi=\tfrac{1}{2}\psi i\gamma_3\tilde{\psi}\psi=0 \tag{91}$$

is satisfied. It is a simple matter to show that this is equivalent to the condition[21]

$$\tilde{\psi}\psi=\psi\tilde{\psi}=0. \tag{92}$$

The proof of the analogous result between Einstein–Dirac and Einstein–Cartan–Dirac theory was given by Seitz in Ref. 23. The gauge theory proof is given in Appendix B. Condition (92) is always satisfied for neutrino solutions.

VI. SPINNING POINT-PARTICLE MODELS

In recent years there has been considerable interest in obtaining semiclassical equations describing the dynamics of a fermion, while maintaining the concept of a definite particle trajectory $x(\lambda)$ (see, for example, Refs. 41 and 42). One of the aims of this work is to obtain a quantum theory via a path-integral quantization of a suitable classical model.[43,44] In Ref. 15, an action was proposed to describe the dynamics of a spin-1/2 particle in a gravitational background, but the resulting equations were only given in a full classical approximation, which neglected the spin. In this section we derive the semiclassical equations of motion resulting from this action, including the effects of torsion in the gravitational background.

The action is given by

$$S=\int d\lambda \left\langle \dot{\Psi} i\sigma_3\tilde{\Psi}+\frac{1}{2}\Omega(\dot{x})\Psi i\sigma_3\tilde{\Psi}+p(v-m_p e\Psi\gamma_0\tilde{\Psi})+m_p^2 e\right\rangle, \tag{93}$$

where $v\equiv \underline{h}^{-1}(\dot{x})$ is the covariant tangent vector to the trajectory and, for this section, overdots denote differentiation with respect to λ. The Lagrange multiplier p is identified with the momentum of the particle (which has mass m_p) and an einbein e is included to ensure invariance of the equations under reparametrization of the path. The spinor $\Psi(\lambda)$ contains information about the spin and velocity of the particle. In general, p and v will not be collinear. The dynamical variables are $x(\lambda),\Psi(\lambda),p(\lambda)$ and $e(\lambda)$. Varying Ψ,p and e gives the equations

$$\dot{\Psi} i\sigma_3+\tfrac{1}{2}\omega(v)\Psi i\sigma_3=m_p ep\Psi\gamma_0, \tag{94}$$

$$v=m_p e\Psi\gamma_0\tilde{\Psi}, \tag{95}$$

$$p\cdot v=em_p^2. \tag{96}$$

Equation (94) may be written in manifestly covariant form

$$v\cdot D\Psi i\sigma_3=m_p ep\Psi\gamma_0. \tag{97}$$

Equations of motion for v and the spin bivector $S\equiv\Psi i\sigma_3\tilde{\Psi}$ follow from (94). We find that

$$ev\cdot\mathcal{D}(v/e)=-2m_p^2e^2p\cdot S, \tag{98}$$

$$v\cdot\mathcal{D}S=2p\wedge v. \tag{99}$$

In the presence of trivector type torsion the geodesic equation reduces to $v\cdot\mathcal{D}v=0$, where v is the unit tangent vector to the path (this is not true for more general types of torsion, in which case it is necessary to distinguish between geodesics and auto-parallels). It follows from (98) that, in general, the motion is not geodesic. Furthermore, if we construct the unit spin vector along $\Psi\gamma_3\tilde{\Psi}$, we find that this is not Fermi transported in general. These effects, which are present even in the absence of gravitation,[33] were present in the classical dipole model of Papapetrou.[45]

The equation of motion for p is obtained by variation of x. We find that

$$\partial_\lambda\overline{h}^{-1}(p)+\tfrac{1}{2}\partial_\lambda\partial_a(\Omega(a)\cdot S)=\overset{*}{\nabla}(\dot{x}\overset{*}{\overline{h}}^{-1}(p))+\tfrac{1}{2}\partial_a\langle a\cdot\overset{*}{\nabla}\overset{*}{\Omega}(\dot{x})S\rangle, \tag{100}$$

where, for this section, we employ overstars in place of overdots for the scope of a differential operator. This equation yields

$$\begin{aligned}\overline{h}^{-1}(\dot{p})+\underline{h}(v)\cdot(\overset{*}{\nabla}\wedge\overset{*}{\overline{h}}^{-1}(p))&=\tfrac{1}{2}\partial_a\langle(a\cdot\overset{*}{\nabla}\overset{*}{\Omega}(\dot{x})-\dot{x}\cdot\overset{*}{\nabla}\overset{*}{\Omega}(a))S-\Omega(a)\dot{S}\rangle\\&=\tfrac{1}{2}\overline{h}^{-1}[v\cdot\overline{\mathcal{R}}(S)]-\tfrac{1}{2}\partial_a\,\Omega(a)\cdot[\dot{S}+\omega(v)\times S].\end{aligned} \tag{101}$$

We now employ Eq. (99) on the right-hand side of (101) to find (after application of $\overline{h}$ to both sides)

$$\dot{p}-v\cdot[\overline{h}(\overset{*}{\nabla})\wedge\overset{*}{\overline{h}}(\overline{h}^{-1}(p))]=\tfrac{1}{2}v\cdot\overline{\mathcal{R}}(S)-\partial_a\,\omega(a)\cdot(p\wedge v). \tag{102}$$

Hence, recalling Eq. (33), we find the manifestly covariant equation of motion for p

$$v\cdot\mathcal{D}p=\tfrac{1}{2}v\cdot\overline{\mathcal{R}}(S)+\kappa v\cdot\mathcal{S}(p). \tag{103}$$

The presence of $\overline{\mathcal{R}}(S)$ and $\mathcal{S}(p)$ in this equation implies a coupling of the particle to the torsion, unlike some previous models.[24] We exploit this coupling in another paper[25] to discuss the torsion-induced anisotropy of a cosmological solution for a self-consistent Dirac field. We can use Eq. (99) to substitute for p in (103). This gives the equation

$$v\cdot\mathcal{D}\left(\frac{em_p^2v}{v^2}-\frac{v\cdot(v\cdot\mathcal{D}S)}{2v^2}\right)=\frac{1}{2}v\cdot\overline{\mathcal{R}}(S)+\kappa v\cdot\mathcal{S}(p), \tag{104}$$

which is the analog of the result found by Papapetrou[45] in the absence of torsion [his equation (5.7)].

The constraint equation (96) is consistent with the equations of motion for v and p since

$$\partial_\lambda(p\cdot v)=(v\cdot\mathcal{D}p)\cdot v+p\cdot(v\cdot\mathcal{D}v)=(\dot{e}/e)p\cdot v$$

$$\Rightarrow(p\cdot v)/e=\text{ constant}. \tag{105}$$

We thus have a complete, consistent set of semiclassical equations describing the dynamics of a massive spin-1/2 point-particle in a gravitational background. The equations are under-determined until a choice is made for the einbein. A convenient choice for comparison to classical models is to take $v^2=1$, so that λ is the proper time for the particle.

VII. CONCLUSIONS

In this paper we have discussed the symmetry of the Riemann tensor and the conservation laws of GTG in the presence of torsion. This extends many of the results discussed in Ref. 15, where the effects of torsion were not considered. Many of the results presented here have counterparts in the standard tensor-calculus formulation of ECKS theory. A full translation between the two approaches is contained in Appendix D.

As an example of a model with torsion, we considered the Dirac field coupled self-consistently to gravity. A minimally coupled gauge-invariant Lagrangian leads to the GTG version of the Einstein–Cartan–Dirac equations. The Einstein–Dirac equations may also be formulated consistently but they cannot be derived from minimal coupling and gauge-theoretic arguments alone. This is a consequence of the natural association of torsion with the spin of the matter field which arises in GTG. Finally, we considered a semiclassical model for a massive spinning point-particle, moving in a gravitational background with torsion. This showed that the motion is not generally geodesic, the spin vector is not Fermi-transported and the particle couples to the torsion.

In a separate paper[25] we apply much of this formalism to obtain a new self-consistent cosmological solution describing a universe arising from a massive Dirac field. This solution provides a counterexample to the claim of Ref. 26 that Einstein–Cartan theories of gravity and general relativity are observationally equivalent. The model presented in Ref. 25 contains an isotropic line element, but spinning point particles see a preferred direction in space due to the spin of the matter field. It is certainly true that for every solution of the Einstein–Cartan (or GTG) equations there is an equivalent solution in general relativity. There must be because every metric gives a solution to the Einstein field equations; the matter distribution is whatever the Einstein tensor dictates. This misses the point, however, that in theories with spin there are extra physical fields present which have observable consequences. These cannot just be hidden in an effective stress-energy tensor.

APPENDIX A: RESULTS FOR TRIVECTOR SPIN

The specialization of the results in the main text to the case of trivector spin is useful for studying the Einstein–Cartan–Dirac set of equations. In this setup the spin tensor is given entirely by

$$\mathcal{S}(a)=T\cdot a, \tag{A1}$$

where T is the spin trivector. First we have the following expressions for the Riemann tensor:

$$\mathcal{R}(a\wedge b)=\mathcal{R}'(a\wedge b)+\tfrac{1}{4}\kappa^2(a\wedge b)\cdot T\ T-\tfrac{1}{2}\kappa[(a\wedge b)\cdot\partial_c]\cdot(c\cdot\mathcal{D}T), \tag{A2}$$

with the prime denoting the equivalent tensor in the absence of spin. Contracting Eq. (A2) we obtain expressions for the Ricci tensor and scalar:

$$\mathcal{R}(a)=\mathcal{R}'(a)+\tfrac{1}{2}\kappa^2(a\cdot T)T-\tfrac{1}{2}\kappa a\cdot(\mathcal{D}\cdot T), \tag{A3}$$

$$\mathcal{R}=\mathcal{R}'+\tfrac{3}{2}\kappa^2T^2. \tag{A4}$$

These expressions are equivalent to those used in Ref. 23, but express the intrinsic content in a coordinate-free fashion.

The protraction of the Riemann tensor is

$$\partial_a\wedge\mathcal{R}(a\wedge b)=-\kappa(b\cdot\mathcal{D}T+\tfrac{1}{2}b\ \mathcal{D}\wedge T), \tag{A5}$$

which produces an antisymmetric term of

$$\overline{\mathcal{R}}(B)-\mathcal{R}(B)=\kappa(B\cdot\mathcal{D})\cdot T-\tfrac{1}{2}\kappa B\ \mathcal{D}\wedge T. \tag{A6}$$

Equation (A5) contracts to give

$$\partial_a\wedge\mathcal{R}(a)=\partial_a\wedge\mathcal{G}(a)=-\kappa\mathcal{D}\cdot T, \tag{A7}$$

so the antisymmetric part of the Einstein tensor is determined by the covariant divergence of the spin trivector.

The Bianchi identity simplifies to

$$\dot{\mathcal{D}}\wedge\dot{\overline{\mathcal{R}}}(B)=-\kappa\overline{\mathcal{R}}(B)\times T. \tag{A8}$$

The contracted result is

$$\dot{\overline{\mathcal{G}}}(\dot{\mathcal{D}})=\tfrac{1}{2}\kappa(\partial_b\wedge\partial_a)\cdot[\overline{\mathcal{R}}(a\wedge b)\times T]. \tag{A9}$$

Taking the inner product with an arbitrary vector b, we obtain the adjoint form

$$\dot{\mathcal{D}}\cdot\dot{\mathcal{G}}(b)=\tfrac{1}{2}\kappa(\partial_c\wedge\partial_a)\cdot\mathcal{R}[(a\wedge b\wedge c)\times T]. \tag{A10}$$

Equation (A9) may be written as

$$\dot{\overline{\mathcal{G}}}(\dot{\mathcal{D}})=\kappa i\partial_a\wedge\mathcal{R}(a\wedge(iT)), \tag{A11}$$

which, when combined with (A5) gives

$$\dot{\overline{\mathcal{G}}}(\dot{\mathcal{D}})=-\tfrac{1}{2}\kappa^2(s\mathcal{D}\cdot s+2s\cdot\mathcal{D}s), \tag{A12}$$

where the ''Pauli–Lubansky'' vector $s\equiv -iT$ is the dual of the spin trivector. Equation (A12) shows that $\dot{\overline{\mathcal{G}}}(\dot{\mathcal{D}})$ is second order in the spin.

APPENDIX B: SOLUTIONS OF THE EINSTEIN–CARTAN–DIRAC EQUATIONS AND THE EINSTEIN–DIRAC EQUATIONS

In this appendix we give the GTG proof that solutions of the equations (81) satisfying condition (92) are also solutions of the pair of equations (88) and (89). The proof is similar to that of Seitz.[23]

Assume that $\overline{h}(a), \omega(a)$, and ψ satisfy (81) and define $\omega'(a)$ via Eq. (45). The Dirac stress-energy tensor $\mathcal{T}(a)$, defined in Eq. (83), decomposes as follows:

$$\mathcal{T}(a)=\langle a\cdot D\psi i\gamma_3\tilde{\psi}\rangle_1=\langle a\cdot D'\psi i\gamma_3\tilde{\psi}\rangle_1+\tfrac{1}{2}\langle\varpi(a)\psi i\gamma_3\tilde{\psi}\rangle_1$$
$$=\mathcal{T}'(a)+\tfrac{1}{2}\kappa^2(a\cdot T)\cdot T-\tfrac{1}{2}\kappa a\cdot(\mathcal{D}\cdot T). \tag{B1}$$

We next use Eqs. (A3) and (A4) to write

$$\mathcal{G}(a)=\mathcal{G}'(a)-\tfrac{1}{2}\kappa a\cdot(\mathcal{D}\cdot T)+\tfrac{1}{2}\kappa^2(a\cdot T)\cdot T-\tfrac{3}{4}\kappa^2 aT^2. \tag{B2}$$

So, given that $\mathcal{G}(a)=\kappa\mathcal{T}(a)$, the equivalent equation for the primed tensors will also be satisfied provided that $T^2=0$. This holds if and only if $T\psi=0$.

It remains to consider the Dirac equation. Noting that

$$D'\psi=D\psi-\tfrac{1}{4}\kappa\partial_a a\cdot T\psi=D\psi-\tfrac{3}{4}\kappa T\psi, \tag{B3}$$

we see that Eq. (88) will also be satisfied provided that the condition $T\psi=0$ is satisfied. This completes the proof. Clearly, the converse is also true.

APPENDIX C: RESULTS FOR ARBITRARY SPIN TENSORS

In this Appendix we generalize the main results of this paper to a general spin tensor $\mathcal{S}(a)$ which is not required to have a vanishing contraction. The results are quoted without proof since the derivations follow those given in the main text.

For consistency with the previous results, we continue to denote the protraction of $\mathcal{S}(a)$ by $3T$. The contraction of the spin tensor is denoted t, so we have

$$\partial_a\mathcal{S}(a)=\partial_a\cdot\mathcal{S}(a)+\partial_a\wedge\mathcal{S}(a)=t+3T. \tag{C1}$$

Equation (39) generalizes to

$$\underline{h}^{-1}(L_a\underline{h}(b)-L_b\underline{h}(a))=a\cdot\mathcal{D}b-b\cdot\mathcal{D}a-\kappa\overline{\mathcal{S}}(a\wedge b)-\tfrac{1}{2}\kappa(a\wedge b)\cdot t, \tag{C2}$$

where $\overline{\mathcal{S}}(a)$ is the adjoint to the spin tensor, as defined at Eq. (38). The right-hand side of (C2) now defines the vector c which appears in the covariant expression (40) for the Riemann tensor. The $\omega'(a)$ field (the equivalent field in the absence of torsion) is given by

$$\omega'(a)=\omega(a)+\kappa\mathcal{S}(a)-\tfrac{1}{2}\kappa(3a\cdot T+a\wedge t). \tag{C3}$$

The Riemann tensor is still given by Eq. (48). On contracting we arrive at the following expression for the Ricci tensor:

$$\mathcal{R}(a)=\mathcal{R}'(a)-\kappa\dot{\mathcal{D}}'\cdot\dot{\mathcal{S}}(a)-\tfrac{3}{2}\kappa a\cdot(\mathcal{D}'\cdot T)-\tfrac{1}{2}\kappa a\mathcal{D}'\cdot t$$
$$-\kappa^2\overline{\mathcal{S}}(\mathcal{S}(a))+\tfrac{3}{2}\kappa^2\overline{\mathcal{S}}(a\cdot T)+\tfrac{1}{2}\kappa^2\overline{\mathcal{S}}(a\wedge t), \tag{C4}$$

which is the generalization of (49). Contracting this expression with ∂_a, we find the generalization of (50):

$$\mathcal{R}=\mathcal{R}'-\kappa\mathcal{D}'\cdot t+\tfrac{9}{2}\kappa^2T^2-\tfrac{1}{2}\kappa^2t^2-\kappa^2\mathcal{S}(\partial_a)\cdot\mathcal{S}(a). \tag{C5}$$

Of the full spin tensor $\mathcal{S}(a)$ only t is differentiated in this expression, though the corresponding term in the action is a total divergence, and so does not contribute to the field equations.

The protraction of the Riemann tensor [Eq. (59)] is given by

$$\partial_a \wedge \mathcal{R}(a \wedge b) = -\tfrac{1}{2}\kappa(b \wedge \mathcal{D} \wedge t + 2\dot{\mathcal{D}} \wedge \dot{\mathcal{S}}(b) + 3b\ \mathcal{D} \wedge T) + \tfrac{1}{4}\kappa^2(4i\overline{\mathcal{S}}[i\mathcal{S}(b)] - 2b\ \mathcal{S}(\partial_a) \wedge \mathcal{S}(a) + 2b \wedge \mathcal{S}(t) - 2\mathcal{S}(b) \wedge t + 3b\ T \wedge t). \tag{C6}$$

The protraction of the Ricci tensor [Eq. (62)] generalizes to

$$\partial_a \wedge \mathcal{R}(a) = -\kappa\dot{\mathcal{S}}(\dot{\mathcal{D}}) + \kappa^2 \partial_a \cdot (i\overline{\mathcal{S}}[i\mathcal{S}(a)]) - \tfrac{1}{2}\kappa^2 \mathcal{S}(t). \tag{C7}$$

For general torsion, the Bianchi identity is still given by the compact expression (72). The contracted Bianchi identity now becomes

$$\dot{\overline{\mathcal{G}}}(\dot{\mathcal{D}}) = \kappa[\overline{\mathcal{G}}(t) - \partial_a \cdot \overline{\mathcal{R}}(\mathcal{S}(a)) + \partial_a \cdot \mathcal{S}(\overline{\mathcal{R}}(a))]. \tag{C8}$$

Taking the inner product with a vector a gives the adjoint relation

$$\dot{\mathcal{D}} \cdot \dot{\mathcal{G}}(a) = \kappa[t \cdot \mathcal{G}(a) + \mathcal{S}(\partial_b) \cdot \mathcal{R}(b \wedge a) - (a \cdot \mathcal{S}(\partial_b)) \cdot \mathcal{R}(b)]. \tag{C9}$$

APPENDIX D: THE RELATION WITH TENSOR CALCULUS

In this appendix we relate the frame-free approach of GTG to the standard approaches of tensor calculus. These results extend those given in Appendix C of Ref. 15. Throughout this Appendix we follow the conventions of Ref. 9.

We start with a set of coordinates $\{x^\mu\}$ and introduce the vectors

$$e_\mu \equiv \frac{\partial x}{\partial x^\mu}, \quad e^\mu \equiv \nabla x^\mu. \tag{D1}$$

From these we construct the vectors

$$g_\mu \equiv \underline{h}^{-1}(e_\mu), \quad g^\mu \equiv \overline{h}(e^\mu). \tag{D2}$$

These vectors satisfy the relation

$$g_\mu \cdot g^\nu = e_\mu \cdot e^\nu = \delta_\mu^\nu. \tag{D3}$$

The metric is given by the 4×4 matrix

$$g_{\mu\nu} \equiv g_\mu \cdot g_\nu. \tag{D4}$$

If the x dependence in $g_{\mu\nu}$ is replaced by dependence on the coordinates $\{x^\mu\}$ alone, then Riemann–Cartan geometry is recovered.

The connection is defined by

$$\mathcal{D}_\mu g_\nu = \Gamma^\alpha_{\mu\nu} g_\alpha, \tag{D5}$$

so that

$$\Gamma^\lambda_{\mu\nu} = g^\lambda \cdot (\mathcal{D}_\mu g_\nu). \tag{D6}$$

Unlike the coordinate-free object $\Omega(a)$, the connection contains artifacts from the chosen coordinate frame. Since

$$\partial_\mu g_{\nu\lambda} = (\mathcal{D}_\mu g_\nu) \cdot g_\lambda + g_\nu \cdot (\mathcal{D}_\mu g_\lambda), \tag{D7}$$

we find that

$$\partial_\mu g_{\nu\lambda} = \Gamma^\alpha_{\mu\nu} g_{\alpha\lambda} + \Gamma^\alpha_{\mu\lambda} g_{\alpha\nu}, \tag{D8}$$

which recovers ''metric compatibility'' of the connection. The covariant derivative of a covariant vector $\mathcal{A} = A^\alpha g_\alpha = A_\alpha g^\alpha$ is

$$\mathcal{D}_\mu \mathcal{A} = \mathcal{D}_\mu (A^\alpha g_\alpha) = (\partial_\mu A^\alpha) g_\alpha + A^\alpha \Gamma^\beta_{\mu\alpha} g_\beta = (\partial_\mu A^\alpha + \Gamma^\alpha_{\mu\beta} A^\beta) g_\alpha, \tag{D9}$$

as expected.

Equation (D8) inverts to show that the connection contains a component given by the standard Christoffel symbol and a ''contorsion'' term

$$\Gamma^\nu_{\lambda\mu} = \{^\nu_{\lambda\mu}\} - K_{\lambda\mu}{}^\nu. \tag{D10}$$

The components of the contorsion tensor are given by

$$\begin{aligned} K_{\lambda\mu}{}^\nu = \{^\nu_{\lambda\mu}\} - g^\nu \cdot (\mathcal{D}_\lambda g_\mu) &= g^\nu \cdot [(\omega'(g_\lambda) - \omega(g_\lambda)) \cdot g_\mu] \\ &= \kappa (g^\nu \wedge g_\mu) \cdot [\mathcal{S}(g_\lambda) - \tfrac{3}{2} g_\lambda \cdot T - \tfrac{1}{2} g_\lambda \wedge t]. \end{aligned} \tag{D11}$$

The torsion tensor is defined by the antisymmetric part of the connection:

$$\begin{aligned} S_{\lambda\mu}{}^\nu = \tfrac{1}{2}(\Gamma^\nu_{\lambda\mu} - \Gamma^\nu_{\mu\lambda}) &= \tfrac{1}{2} g^\nu \cdot (\mathcal{D}_\lambda g_\mu - \mathcal{D}_\mu g_\lambda) \\ &= -\tfrac{1}{2}[g_\mu \cdot (\mathcal{D}_\lambda g^\nu) - g_\lambda \cdot (\mathcal{D}_\mu g^\nu)] \\ &= -\tfrac{1}{2}(g_\mu \wedge g_\lambda) \cdot (\mathcal{D} \wedge g^\nu) = \tfrac{1}{2}(g_\lambda \wedge g_\mu) \cdot [\mathcal{S}(g^\nu) + \tfrac{1}{2} t \wedge g^\nu], \end{aligned} \tag{D12}$$

and the modified torsion tensor is defined by

$$\begin{aligned} T_{\lambda\mu}{}^\nu &= S_{\lambda\mu}{}^\nu + \delta^\nu_\lambda S_{\mu\alpha}{}^\alpha - \delta^\nu_\mu S_{\lambda\alpha}{}^\alpha \\ &= \tfrac{1}{2}\kappa (g_\lambda \wedge g_\mu) \cdot \mathcal{S}(g^\nu). \end{aligned} \tag{D13}$$

For covariant quantities such as the Riemann tensor the translation to tensor calculus is straightforward:

$$R^\mu{}_{\nu\rho\sigma} = (g^\mu \wedge g_\nu) \cdot \mathcal{R}(g_\sigma \wedge g_\rho). \tag{D14}$$

A vierbein $e_\mu{}^i$ (essentially an orthonormal tetrad) is given by

$$e_\mu{}^i = g_\mu \cdot \gamma^i, \quad e^\mu{}_i = g^\mu \cdot \gamma_i, \tag{D15}$$

where $\{\gamma^i\}$ is a fixed orthonormal frame. Any position dependence in the $\{\gamma^i\}$ is eliminated with a suitable rotor transformation.

(Received 24 March 1997; accepted for publication 12 March 1998)

The dynamical process following the breaking of Weyl geometry to Riemannian geometry is considered by studying the motion of de Sitter bubbles in a Weyl vacuum. The bubbles are given in terms of an exact, spherically symmetric thin shell solution to the Einstein equations in a Weyl–Dirac theory with a time-dependent scalar field of the form $\beta=f(t)/r$. The dynamical solutions obtained lead to a number of possible applications. An important feature of the thin shell model is the manner in which β provides a connection between the interior and exterior geometries since information about the exterior geometry is contained in the boundary conditions for β. © *1998 American Institute of Physics.* [S0022-2488(98)02806-0]

I. INTRODUCTION

The success of models like the Glashow–Weinberg–Salam electroweak model have provided strong motivation for believing that symmetries of nature that were once manifest are no longer directly observable; one must extrapolate backwards from our broken symmetry state to the symmetric state that is described by the Lagrangian. The ultimate success of the standard model is contingent upon the existence of the Higgs particle—unless an additional degree of symmetry is broken.[1] This latter possibility, which involves the breaking of Weyl's scale invariance, has recently received further consideration.[2] While the topic of breaking Weyl geometry to Riemannian geometry has a relatively long history (see, e.g., Ref. 3), the analysis of the dynamics of thin shells that form in this process has been neglected. This problem is considered here by studying the dynamical properties of spherically symmetric thin-shell solutions to Einstein's equations with Weyl's scale invariance broken in the interior of the bubble.[4]

Shortly after Einstein presented his general theory of relativity, Weyl[5] attempted to unify the electromagnetic and gravitational fields within a geometrical framework. Einstein had shown that the rotation of a vector under parallel transport was related to the gravitational field; Weyl argued that the electromagnetic field would acquire a similar geometric status if the length of the vector was also allowed to vary according to $\delta\ell=\ell\kappa_\mu\delta x^\mu$. The covector field κ_μ, together with the metric tensor $g_{\mu\nu}$ that is defined modulo an equivalence class, comprised the fundamental fields of the new geometry. Weyl's geometry was rejected at the time because it did not permit an atomic standard of length. In more recent years, Weyl's theory has been reconsidered from several points of view (see, e.g., Refs. 4 and 6–11). Of particular interest here is the suggestion that atomic standards of length are introduced into a pure Weyl geometry through a symmetry breaking process.

The possibility that regions of space–time with broken scale invariance can coexist within regions of unbroken scale invariance has been demonstrated[4] by applying the Gauss–Mainardi–Codazzi (GMC) formalism in Weyl geometry to a Weyl–Dirac theory with a real scalar field β. The surface tension of the resulting static, spherically symmetric bubble arose from the boundary conditions imposed on the normal component of the derivative of the field β. In this way, a stable ''particle'' was constructed entirely from the fields $g_{\mu\nu}$, κ_μ, and β. By setting $\kappa_\mu=0$ and

 © 1998 American Institute of Physics

$\beta=$ constant in the interior space, the conformal invariance is broken and an ''atomic'' scale can be introduced into the theory. Generalizations of this model have been considered,[9–11] including the development of a geometric formulation of the causal interpretation of quantum mechanics[10] where β is a complex scalar field. In the present work, β is taken to be real and of the form $\beta(r,t)=f(t)/r$ in the exterior space V^E. This choice is useful in focusing on the dynamical properties of bubbles after they emerge in the ambient Weyl geometry.

The absence of a generalized Birkhoff theorem in Weyl space allows dynamical solutions to exist in the spherically symmetric case in the model under consideration. The analysis of exact, time-dependent solutions to the radial equation of motion shows that spherically symmetric bubbles that form in the ambient Weyl vacuum may, depending on the circumstances, collapse, remain at a fixed radius, oscillate indefinitely, or diverge to infinity. The spherically symmetric solution to the Einstein equations for the ansatz $\beta(r,t)=f(t)/r$ is presented in Sec. II. The analysis of the radial motion of the thin shell is provided in Sec. III and some concluding remarks are given in Sec. IV.

II. THE SPHERICALLY SYMMETRIC SOLUTION

The GMC formalism is here applied to the Weyl–Dirac theory given by

$$I_D=\int\left\{-\frac{1}{4}f_{\mu\nu}f^{\mu\nu}+\beta^2R+6\beta_{,\mu}\beta^{,\mu}-\lambda\beta^4\right\}\sqrt{-g}\;d^4x, \tag{2.1}$$

where $f_{\mu\nu}=\kappa_{\nu,\mu}-\kappa_{\mu,\nu}$. This action was introduced by Dirac[6] in order to study his Large Numbers hypothesis within the context of a theory of gravitation. Dirac's eloquent reasoning led him to propose a two-metric view that served to revive interest in Weyl's geometry. Generalizations of Dirac's action were subsequently proposed (see, e.g., Ref. 7) which accommodated Weyl's geometric interpretation of the electromagnetic field within a single-metric theory. This latter view is also maintained in the present paper.

The field equations that follow from (2.1) are the Maxwell and Einstein equations

$$\Box_\nu f^{\mu\nu}=0 \tag{2.2}$$

and

$$G_{\mu\nu}=\frac{1}{2\beta^2}E_{\mu\nu}+I_{\mu\nu}+\frac{1}{2}\lambda g_{\mu\nu}\beta^2\equiv T_{\mu\nu}, \tag{2.3}$$

where $E_{\mu\nu}$ is the usual Maxwell tensor and $\Box$ is the Riemannian covariant derivative,

$$I_{\mu\nu}=\frac{2}{\beta}(\Box_\nu\Box_\mu\beta-g_{\mu\nu}\Box_\alpha\Box^\alpha\beta)-\frac{1}{\beta^2}(4\beta_{,\mu}\beta_{,\nu}-g_{\mu\nu}\beta_{,\alpha}\beta^{,\alpha}), \tag{2.4}$$

and the field equation for β is identically the trace of (2.3).

For simplicity, the GMC formalism is applied to a spherically symmetric shell. The most general line element is then given by[12]

$$ds^2=-e^{\nu(r,t)}\,dt^2+e^{\mu(r,t)}\,dr^2+r^2(d\theta^2+\sin^2\theta\,d\phi^2). \tag{2.5}$$

The exterior and interior geometries are distinguished by writing $t_{E,I}$, $\nu_{E,I}$ and $\mu_{E,I}$ in the exterior and interior space–times $V^{E,I}$, respectively. It will be assumed here that the bubbles which form in the symmetry breaking process have interior geometries with $\kappa_\mu=0$ (which establishes length integrability in the region of space–time occupied by the bubble) and $\beta=\beta_0$ (which breaks the conformal invariance and fixes the scale in V^I according to the value of the constant β_0). Due to their continuity properties, $\kappa_\mu=0$ and $\beta=\beta_0$ on the thin shell Σ as well.[4] With the Maxwell tensor and $I_{\mu\nu}$ vanishing in V^I, the interior stress-energy tensor reduces to

$$T^I_{\mu\nu}=\tfrac{1}{2}\lambda g_{\mu\nu}\beta_0^2. \tag{2.6}$$

In what follows, λ will be taken to be negative. For this choice, and assuming no additional matter sources in V^I, the tensor (2.6) represents a de Sitter space and the interior metric is given by

$$e^{-\mu_I}=1+\tfrac{1}{6}\lambda\beta_0^2r^2=e^{\nu_I}, \tag{2.7}$$

with a horizon at $r=\beta_0^{-1}\sqrt{6/|\lambda|}\equiv r_h^I$.

In the exterior geometry V^E, β is expressed in the form

$$\beta(r,t)=f(t)/r, \tag{2.8}$$

where $f(t)$ is an arbitrary dimensionless function of t, and where $t\equiv t_E$ here and henceforth. Normally, one would proceed in applying the GMC formalism by solving the Einstein equations in V^E for the ansatz (2.8) and then using the resulting solution to obtain the equation of motion for the thin shell. In the present model a number of possible exterior metrics are known to exist. However, the condition that $\beta=\beta_0$ in V^I together with the boundary condition that β be continuous across Σ for all t requires that β also be a constant with respect to the intrinsic time τ of the thin shell defined at $r=R(\tau)$. That is,

$$\left.\frac{d\beta}{d\tau}\right|_{r=R}=\beta_{,t}X_E+\beta'\dot{R}=0, \tag{2.9}$$

where $X_E\equiv dt/d\tau$ and the prime and dot denote differentiation with respect to r and τ, respectively. The resulting condition,

$$X_E=-\frac{\beta'}{\beta_{,t}}\dot{R}, \tag{2.10}$$

leads to a restriction on the set of possible solutions to (2.3) in V^E. In effect, the condition (2.10) establishes a relationship between the radial and time derivatives of β at Σ that constrains the exterior metric since it is a functional of β. This constraint is satisfied when the exterior metric takes the form (see the Appendix)

$$e^{\nu_E}=-\frac{\beta_{,t}^2}{\beta'^2(1+\tfrac{1}{6}\lambda\beta^2r^2)} \tag{2.11}$$

and

$$e^{\mu_E}=-\frac{1+\tfrac{1}{6}\lambda\beta^2r^2}{\gamma^2\beta^2r^4}, \tag{2.12}$$

where γ is an arbitrary constant with dimension (length)$^{-1}$. If one assumes that the sign of the constant λ does not change during the formation of the bubble, then it must be taken to be negative to ensure the correct signature of the metric (see Ref. 4 for the conventions used here). For this choice, the signature $(-,+,+,+)$ is preserved for $r^2<(r_h^I)^2$ in V^I and for $r^2>(r_h^I)^2\beta_0^2/\beta^2$ in V^E. For the ansatz (2.8) this latter condition becomes $f^2(t)>(r_h^I)^2\beta_0^2$, so that the possibility of a time-dependent change of signature exists.

It is interesting to note that, in the spherically symmetric case with β of the form given in (2.8), the Einstein equations (2.3) also support the time-dependent solution

$$e^{\nu_E}=-\frac{\beta_{,t}^2}{\beta'^2(1+\tfrac{1}{6}\lambda\beta^2r^2+q^2/4\beta^2r^2)} \tag{2.13}$$

and

$$e^{\mu_E} = -\frac{1+\frac{1}{6}\lambda\beta^2 r^2 + q^2/4\beta^2 r^2}{\gamma^2\beta^2 r^4}. \tag{2.14}$$

However, when the exterior metric is matched onto the thin shell via the field β, the boundary conditions lead to the requirement that $q=0$. This suggests that, in the time-dependent, spherically symmetric case, a charged particle solution is not allowed. In contrast, the surface charge was an integral component of the static solution presented in Ref. 4.

III. THE MOTION OF THE THIN SHELL

With the interior and exterior metrics in hand, it is now possible to study the motion of the thin shell. In the GMC formalism, the equation of motion follows from the jump in the $\theta\theta$-component of the extrinsic curvature $K_{\mu\nu}$ across Σ. In terms of the interior metric (2.7) together with the ansatz (2.8), this equation can be expressed in the form [see (A12)]

$$1+\dot{R}^2+\frac{1}{6}\lambda\beta_0^2 R^2 = e^{(\mu-\nu)_E}\frac{\dot{R}^4}{X_E^2}. \tag{3.1}$$

Substituting (A8) for X_E^2 into (3.1) yields

$$1+\dot{R}^2+\frac{1}{6}\lambda\beta_0^2 R^2 = \frac{\dot{R}^4}{\dot{R}^2+e^{-\mu_E}}. \tag{3.2}$$

Using (2.12) at $r=R$ (with $\beta=\beta_0$) and solving for $\dot{R}^2$, one finds

$$\dot{R}^2 = \frac{a^2(1-R^2/R_{eq}^2)}{(R_{eq}^2/R^2-1)^2-a^2}, \tag{3.3}$$

where $a^2=\gamma^2\beta_0^2 R_{eq}^4$ and

$$R_{eq} = \frac{1}{\beta_0}\sqrt{\frac{6}{|\lambda|}} = r_h^I \tag{3.4}$$

results when $\dot{R}=0$. It is possible to obtain an analytical description of the radial motion from (3.3). The analysis of the motion of the thin shell is facilitated by breaking the problem into the following two cases.

A. Case 1: $R<R_{eq}$

The situation considered here applies to the case where a bubble of Riemannian geometry with $R<R_{eq}$ forms in the ambient Weyl space. In this case, the substitution of variables given by

$$x \equiv \frac{R_{eq}^2}{R^2} - 1 \tag{3.5}$$

allows (3.3) to be transformed into the integral form

$$I_1 \equiv \int \frac{1}{1+x}\sqrt{\frac{x^2-a^2}{x}}dx = \pm 2\gamma\beta_0 R_{eq}\tau. \tag{3.6}$$

Setting $x=\cosh p \equiv \mathrm{ch}p$, the integral I_1 becomes

$$I_1 = \frac{1}{\sqrt{a}}\left[\int \frac{(a\,\mathrm{ch}p-1)}{\sqrt{\mathrm{ch}p}}dp + (1-a^2)\left(\int \frac{dp}{\sqrt{\mathrm{ch}p}} - a\int \frac{\sqrt{\mathrm{ch}p}}{a\,\mathrm{ch}p+1}dp\right)\right]. \tag{3.7}$$

Expressing the three integrals in (3.7) in terms of elliptic integrals [see Eqs. (2.464.9), (2.464.10) and (2.464.15) in Ref. 13], one has

$$I_1=\sqrt{2a}\left\{\sqrt{2}\frac{\mathrm{sh}p}{\sqrt{\mathrm{ch}p}}-2E\left(\alpha,\frac{1}{\sqrt{2}}\right)+(1-a)\left[F\left(\alpha,\frac{1}{\sqrt{2}}\right)-\Pi\left(\alpha,\frac{1}{a+1},\frac{1}{\sqrt{2}}\right)\right]\right\}, \tag{3.8}$$

where $p\neq 0$, $\mathrm{sh}p\equiv\sinh p$, and

$$\alpha\equiv\arcsin\sqrt{\frac{\mathrm{ch}p-1}{\mathrm{ch}p}}=\arcsin\sqrt{\frac{R_{eq}^2-2R^2}{R_{eq}^2-R^2}}. \tag{3.9}$$

The case $a=1$ can be investigated easily because it involves only the elliptic integral of the second kind $E(\alpha,1/\sqrt{2})$. This choice does not represent a serious limitation due to the arbitrariness of the parameters γ and β_0 that appear in a. With this choice, Eq. (3.6) becomes

$$-\sqrt{2}E\left(\alpha,\frac{1}{\sqrt{2}}\right)+\frac{\mathrm{sh}p}{\sqrt{\mathrm{ch}p}}=\pm\frac{\tau}{R_{eq}}, \tag{3.10}$$

which is valid for $0<R<R_{eq}/\sqrt{2}$. For $R=0$ ($\alpha=\pi/2$, $\mathrm{ch}p=\infty$) the second term in (3.10) diverges, while $R=R_{eq}/\sqrt{2}$ leads to $\alpha=0$ and $\mathrm{ch}p=1$ that invalidate the integrations leading to (3.8). While R cannot be set equal to the endpoints of the interval over which it is defined (for $a=1$), it is of interest to consider the properties of the thin shell in the neighborhood of these points by means of expansions. To this end, it is useful to first invert (3.9), so that

$$\frac{R}{R_{eq}}=\sqrt{\frac{1-\sin^2\alpha}{2-\sin^2\alpha}}, \tag{3.11}$$

and to choose units for which $R_{eq}=1$.

1. Upper limit: $R\approx R_{eq}/2^{1/2}$

This limit corresponds to $\alpha\approx 0$. The expansion of (3.10) to third order in α yields

$$\pm\frac{\tau}{2}-\frac{\alpha^3}{3}\left(\frac{1}{4}+\frac{1}{2^{3/2}}\right)=0, \tag{3.12}$$

which has the solutions $\alpha=\pm 1.52042\tau^{1/3}$. Substituting this result into (3.11), one obtains an oscillatory motion with a period that increases with τ and that has a maximum amplitude $R\sim R_{eq}/\sqrt{2}$.

2. Lower limit: $R\approx 0$

This limit corresponds to $\alpha\approx\pi/2$. Expanding (3.10) to second order in $\alpha-\pi/2$ for the $+$ sign on the right-hand side, one obtains

$$-\frac{1}{\alpha-\pi/2}+\tau E\left(\frac{1}{\sqrt{2}}\right)+\left(\sqrt{1-\frac{1}{\sqrt{2}}}-\frac{1}{3(2)^{3/2}}\right)\left(\alpha-\frac{\pi}{2}\right)=0, \tag{3.13}$$

where $E(1/\sqrt{2})$ is the complete elliptic integral of the second type. The two solutions of (3.13), which are given by

$$\alpha=0.109314-0.835143\tau\pm 0.835143\sqrt{5.45723+3.4996\tau+\tau^2},$$

also lead to oscillatory motion when they are substituted into (3.11).

The expansion for the $-$ sign on the right-hand side of (3.10) leads to the two solutions

$$\alpha = 0.109314 + 0.835143\tau \pm 1.67249\sqrt{1.36071 - 0.872685\tau + 0.249342\tau^2}.$$

Of these, the one with the + sign in front of the square root yields oscillatory motion. The other solution, on the contrary, expands from $R \sim 0.4R_{eq}$ at $\tau = 0$ to the maximum $R \sim R_{eq}$ at $\tau \sim 1.5$, and then decreases asymptotically to $R = 0$.

In summary, it is has been shown that bubbles which are created in the Weyl vacuum with initial radii near either of the endpoints of the interval $0 < R < R_{eq}/\sqrt{2}$ exist indefinitely with a finite radius or else collapse to $R = 0$.

B. Case 2: $R > R_{eq}$

The situation considered here applies to the case where a bubble of Riemannian geometry with $R > R_{eq}$ is formed in the ambient Weyl vacuum. The substitution of variables given by

$$y \equiv 1 - \frac{R_{eq}^2}{R^2} \tag{3.14}$$

leads to the equation

$$I_2 \equiv \int \frac{1}{1-y}\sqrt{\frac{a^2-y^2}{y}}\, dy = \mp \frac{2a}{R_{eq}}\tau. \tag{3.15}$$

1. Upper limit: $R^2 \gg R_{eq}^2$

This limit corresponds to $y \sim 1$. Expanding the integrand of I_2 about this upper limit to order $(y-1)^{-1}$ one obtains

$$I_2 \sim \int \left[\frac{a^2+1}{2\sqrt{a^2-1}} - \frac{\sqrt{a^2-1}}{y-1}\right] dy = \mp \frac{2a}{R_{eq}}\tau. \tag{3.16}$$

Integration of (3.16) yields the result

$$y = 1 + \exp\left[\frac{a^2+1}{2(a^2-1)}y \pm \frac{2a\tau}{R_{eq}\sqrt{a^2-1}}\right]. \tag{3.17}$$

For sufficiently large values of τ, the result with the + sign leads to values of $y \gg 1$ (for $a^2 \neq 1$) which invalidates the approximation, whereas $y \to 1$ ($R \to \infty$) exponentially as $\tau \to \infty$ for the − sign in (3.17).

2. Lower limit: $R \approx R_{eq}$

By expanding the integrand of I_2 in the neighborhood of $y = 0$ to lowest order and integrating, one obtains

$$y^{1/2}\left(1 + \frac{y}{3}\right) \simeq \mp \frac{\tau}{R_{eq}}. \tag{3.18}$$

This equation has the solutions

$$y = 0 \quad \text{and} \quad y = -3 \pm 3\sqrt{1 + \left(\frac{\tau}{R_{eq}}\right)^2}. \tag{3.19}$$

The case $y = 0$ is trivial: if the bubble is created at $\tau = 0$ with $R = R_{eq}$, it will remain at the stable radius forever. The solution with the lower negative sign requires $y < 0$ and is unphysical in the present case ($0 < y < 1$). The remaining solution leads to

$$\frac{R_{eq}^2}{R^2} = 4 - 3\sqrt{1 + \left(\frac{\tau}{R_{eq}}\right)^2}. \tag{3.20}$$

In this case, a bubble that has a radius $R \gtrsim R_{eq}$ at $\tau = 0$ will expand to $R = \infty$ in a time $\tau = \sqrt{7/9} R_{eq}$.

3. Special case: a=1

In this case I_2 can be integrated exactly and yields [see Eq. (2.618.2) in Ref. 13]

$$I_2 = -2\sqrt{2} E\left(\alpha, \frac{1}{\sqrt{2}}\right) = \mp \frac{2\tau}{R_{eq}}, \tag{3.21}$$

where $\sqrt{2}\sin\varphi/2 = R_{eq}/R$, $0 < \varphi \leqslant \pi/2$ $(0 < R_{eq}/R \leqslant 1)$, and $\alpha = \arcsin(\sqrt{2}\sin\varphi/2)$. To second order in α, Eq. (3.21) becomes

$$\alpha = \mp \frac{\tau}{\sqrt{2} R_{eq}} \text{ or } \frac{R}{R_{eq}} = \mp \frac{1}{\sin(\tau/\sqrt{2} R_{eq})}.$$

In this case, R diverges whenever $\tau = n\pi\sqrt{2} R_{eq}$, and has minima of $R = R_{eq}$ for $\tau = (2n + 1)\pi^2/\sqrt{2}$.

In summary, bubbles that are created in the Weyl vacuum with an initial radius greater than R_{eq} appear to be unstable in all cases, except the trivial case of $R = R_{eq}$.

IV. DISCUSSION

It has been suggested, in the spirit of the electroweak model, that Weyl geometry should be considered a more fundamental geometry than Riemannian geometry since the latter represents a state of broken scale invariance. The feasibility of this proposal has been explored here by considering a Weyl–Dirac theory that supports a dynamical thin-shell solution to the Einstein equations. The fields that occur in the conformally invariant action are the source of the spherically symmetric bubbles that are posited; the geometric fields are the fabric from which the ''particles'' are constructed. The conformal symmetry is broken in the interior de Sitter geometry, and the surface tension is provided by the scalar field β. In principle, the bubbles could be associated with microscopic particles (see Ref. 10), perhaps born in a transition phase in the early universe, or they could be viewed on the cosmological scale. In the latter case, one could consider a single bubble of Riemannian geometry as representing our observable universe. In either case, the extrapolation backwards from our present state of broken scale invariance to the pre-particle Weyl vacuum lies within the domain of cosmology.

A common feature of the most successful cosmological theories is the presence of an inflationary epoch. An outstanding problem in such theories concerns the period of transition from the initial inflationary stage to the final stage of decelerating Friedmann–Robertson–Walker expansion. This transition is often described in terms of a first-order phase transition of the vacuum, wherein true vacuum bubbles are created and expand, leaving isolated regions of false vacuum. However, the precise physical process involved in the transition remains poorly understood. Kodama *et al.*[14] provided one of the earliest models of the transition phase in which an infinite number of true vacuum bubbles are nucleated simultaneously on a sphere, forming a shell-like true vacuum region around a de Sitter bubble. They showed that the trapped false vacuum domain either disappears leaving a black hole, or else remains as an ever-expanding domain connected with the outer region through a wormhole. However, it has been shown that the formation of bubbles in this manner is highly improbable.[15] Furthermore, Linde has pointed out[16] that the constant vacuum energy of de Sitter space, which has traditionally been viewed as necessarily leading to inflation (see, e.g., Ref. 17), can support other interpretations depending upon one's choice of coordinates. In the context of the present model, it is of interest to note that a variety of radial motions are possible, including an exponentially expanding solution. However, it remains an open question as to what interpretation should be given with regard to the identification of ''true'' and ''false'' vacua in the present model. Also, the precise conditions that precipitate the symmetry breaking process require further study.

In recent years, it has become popular to consider inflationary scenarios within the context of conformally invariant scalar field theories. In this paper, a theory of this type has been used to

study the dynamical properties of a bubble once it has formed in the Weyl vacuum. The development of the bubble model in the time-dependent case places a significant constraint on the set of possible spherically symmetric solutions to Einstein's equations. This constraint strongly links the properties of the thin shell to those of the exterior geometry. In the microscopic interpretation, a similar link has been shown[10] to lead to the guiding force postulated in the causal interpretation of quantum mechanics. In the cosmological interpretation, such a link is of interest because it allows for the possibility that information about the external metric may be available to an internal observer. This could prove to be of significance in the problem of boundary conditions of the universe.

The analysis of the radial equation of motion of the thin shell revealed the following results. Bubbles that emerge in the Weyl vacuum with $R>R_{eq}$ are unstable (except the trivial static case of $R=R_{eq}$) as they variously diverge to $R=\infty$. For bubbles with $R<R_{eq}$ initially, a number of possibilities exist. Of particular interest are those oscillatory solutions for which the radius remains finite. The freedom allowed by the parameters in the theory permit the scale associated with these bubbles to take on any value from the microscopic to the cosmological. In the first case, the results obtained here may prove to be of interest in the geometric causal interpretation of Ref. 10. In the latter case, one may find the present model useful in addressing some of the unresolved issues in inflationary cosmology. Indeed, the intimate relationship between particle physics and cosmology suggests that we should be considering theories of the very early universe that find application at any scale.

This work was supported in part by the Natural Sciences and Engineering Research Council of Canada. One of the authors (G.P.) wishes to thank Dr. K. Denford, Dean of Science, University of Regina, for continued research support.

APPENDIX A: THE TIME-DEPENDENT MODEL

A time-dependent, spherically symmetric solution to the Einstein field equations (2.3) is, in general, obtained by solving the three equations

$$\frac{d}{dr}\,(re^{-\mu})=1+r^2\left[-\frac{q^2}{4\beta^2 r^4}-e^{-\mu}\left(2\frac{\beta''}{\beta}-\frac{\beta'^2}{\beta^2}-\mu'\frac{\beta'}{\beta}+\frac{4}{r}\frac{\beta'}{\beta}\right)\right.$$
$$\left.+e^{-\nu}\left(\mu_{,t}\frac{\beta_{,t}}{\beta}+3\frac{\beta_{,t}^2}{\beta^2}\right)+\frac{1}{2}\lambda\beta^2\right], \tag{A1}$$

$$\frac{d}{dr}\,(\mu+\nu)=r\left[2\frac{\beta''}{\beta}-4\frac{\beta'^2}{\beta^2}-(\mu'+\nu')\frac{\beta'}{\beta}\right]+re^{\mu-\nu}\left[2\frac{\beta_{,tt}}{\beta}-4\frac{\beta_{,t}^2}{\beta^2}-(\mu+\nu)_{,t}\frac{\beta_{,t}}{\beta}\right], \tag{A2}$$

and

$$\frac{d}{dt}\,(e^{-\mu})=-re^{-\mu}\left(2\frac{\beta'_{,t}}{\beta}-\nu'\frac{\beta_{,t}}{\beta}-\mu_{,t}\frac{\beta'}{\beta}-4\frac{\beta'}{\beta}\frac{\beta_{,t}}{\beta}\right). \tag{A3}$$

The solutions to these equations in the interior and exterior spaces are then generally used in determining the equation of motion $r=R(\tau)$ for the thin shell in the frame comoving with the thin shell with proper time τ. In the GMC formalism, one introduces the spherically symmetric intrinsic metric

$$ds_\Sigma^2=-d\tau^2+R^2(\tau)(d\theta^2+\sin^2\theta\,d\phi^2) \tag{A4}$$

and the extrinsic curvature[4]

$$K_{\mu\nu}=-\tfrac{1}{2}n^\alpha h_{\mu\nu,\alpha}, \tag{A5}$$

where n^μ is the unit spacelike vector field normal to Σ and $h_{\mu\nu}$ are the coefficients of the intrinsic metric on Σ. The equation of motion of the thin shell can be obtained from the jump in the $\theta\theta$-component of the extrinsic curvature:[4]

$$(K^\theta_{\ \theta})^E-(K^\theta_{\ \theta})^I=\sigma, \tag{A6}$$

where 2σ is the surface energy density of the thin shell,

$$(K^\theta_{\ \theta})^{E,I}=-\frac{1}{R}e^{-\mu_{E,I}}X_{E,I}, \tag{A7}$$

and

$$X^2_{E,I}=e^{(\mu-\nu)_{E,I}}\dot{R}^2+e^{-\nu_{E,I}}. \tag{A8}$$

The surface energy σ is generally taken to be an arbitrary parameter in models involving domain walls. However, by identifying this surface energy with the discontinuity in the normal derivative of the field β across Σ, the ''particle'' proposed in Ref. 4 was shown to be an entity that is derived entirely from the fields in the theory.

In the time-dependent, spherically symmetric theory under consideration, the scalar field β establishes an intimate link between V^I, the thin shell, and V^E. The dynamical implications of this link can be seen as follows. In the time-dependent case,

$$n^\mu=e^{(\mu+\nu)/2}(e^{-\nu}\dot{R},e^{-\mu}X,0,0) \tag{A9}$$

and

$$\sigma=e^{-(\mu+\nu)_E/2}\frac{\omega}{X_E}, \tag{A10}$$

where $\omega\equiv(\beta'/\beta)|_{r=R}$. Equation (A10) provides a correction to (4.3) in Ref. 11 where n^μ was not normalized to unity. Using (A9) and (A10), the equation of motion (A6) for the thin shell becomes

$$e^{(\nu-\mu)_I/2}X_I=e^{(\nu-\mu)_E/2}X_E+e^{-(\mu+\nu)_E/2}\frac{\omega R}{X_E}. \tag{A11}$$

For $\beta(t,r)=f(t)/r$, it follows that $\omega R=-1$. Using this, together with the interior metric (2.7), the square of (A11) becomes

$$1+\dot{R}^2+\frac{1}{6}\lambda\beta_0^2R^2=e^{(\mu-\nu)_E}\frac{\dot{R}^4}{X_E^2}. \tag{A12}$$

Now, there are two distinct expressions for X_E^2 in the present model. First, there is (A8) that follows from the form of $dt/d\tau$ in the spherically symmetric case. Then there is (2.10) that follows from the choice of boundary conditions for β. In general, there is no guarantee that the two equations of motion that result when these two expressions for X_E^2 are substituted into (A12) will be consistent with each other. Of course, the form of the equation of motion also depends on the form of the solutions for e^{μ_E} and e^{ν_E}. Clearly then, this model is rather tightly constrained. Indeed, the equation of motion of the thin shell could be viewed as being somewhat prescriptive of the nature of the exterior geometry. In other words, the intimate link between the thin shell and the exterior geometry suggests that the properties of the thin shell may provide information regarding properties of the exterior geometry. This in fact is the case. Equating the two expressions for X_E^2 given in (A8) and (2.10) one finds

$$e^{(\mu-\nu)_E}\dot{R}^2+e^{-\nu_E}=\frac{\beta'^2}{\beta_{,t}^2}\dot{R}^2. \tag{A13}$$

Substitution of $e^{(\mu-\nu)_E}\dot{R}^2$ from (A13) into the equation of motion (A12) leads to the result

$$e^{\nu_E} = -\frac{\beta_{,t}^2}{\beta'^2(1+\frac{1}{6}\lambda\beta_0^2R^2)}. \tag{A14}$$

Hence, the equation of motion, which applies only at $r=R$, leads to an algebraic expression for $e^{\nu_E}|_{r=R}$. One may view (A14) as a necessary condition for the projection of $e^{\nu_E}(r)$ onto Σ in order for the present model to be internally consistent. Adopting this viewpoint, the most obvious form for $e^{\nu_E}(r)$ to satisfy this condition is

$$e^{\nu_E} = -\frac{\beta_{,t}^2}{\beta'^2(1+\frac{1}{6}\lambda\beta^2r^2)}. \tag{A15}$$

For this choice, the Einstein equations (A1)–(A3) are satisfied when

$$e^{\mu_E} = -\frac{1+\frac{1}{6}\lambda\beta^2r^2}{\gamma^2\beta^2r^4}, \tag{A16}$$

where γ is an arbitrary constant with dimensions $(\text{length})^{-1}$. In the present model of a spherically symmetric region of Riemannian space in an exterior Weyl geometry, the equations of the dynamical model will be self-consistent provided the exterior metric is of the form given in (A15) and (A16) (the time-dependent solution presented in Ref. 11 satisfies this condition for $c_1 = -c_2^2$ and $q=0$. However, the oscillatory nature of the thin shell solution given in that paper is superseded by the results contained herein).

Stable singularities of wave-fronts in general relativity

Robert Low[a)]
Department of Mathematics, Coventry University, Coventry CV1 5FB, United Kingdom

(Received 23 December 1997; accepted for publication 23 February 1998)

A wave-front in a space-time $\mathcal{M}$ is a family of null geodesics orthogonal to a smooth spacelike two-surface in $\mathcal{M}$; it is of some interest to know how a wave-front can fail to be a smoothly immersed surface in $\mathcal{M}$. In this paper we see that the space of null geodesics $\mathcal{N}$ of $\mathcal{M}$, considered as a contact manifold, provides a natural setting for an efficient study of the stable singularities arising in the time evolution of wave-fronts. © *1998 American Institute of Physics.*
[S0022-2488(98)03506-3]

Consider a smooth spacelike two-surface in a space-time $\mathcal{M}$. Associated with this two-surfaces are two families of null geodesics, the ingoing and the outgoing null congruence. Congruences of this form are called wave-fronts, and it is of some interest to analyze the behavior of the evolution of these surfaces. In particular, we wish to know in what ways the surface can fail to be smoothly immersed, at least generically. For example, information gained from such an analysis is relevant to the consideration of images formed by gravitational lenses.

Analyses of the singularities of evolving wave-fronts in GR have already been presented in the literature.[1,2] This analysis differs from earlier work on the problem in that it automatically considers variations through wave-fronts, and requires no noncanonical choices, thereby facilitating a geometrical understanding of the situation. It also establishes a framework in which the application of Arnol'd's classification of stable singularities of Legendre mappings can be applied without the need for a great deal of intervening analysis.

We will begin by reviewing the differentiable and contact structures of the space of null geodesics, $\mathcal{N}$, for a strongly causal space-time, $\mathcal{M}$, and in particular for the case when $\mathcal{M}$ is globally hyperbolic. We then go on to see how to use the contact geometry to characterize wave-fronts and the stable singularities arising in their evolution, making heavy use of the analysis Arnol'd carried out for wave-fronts in flat space.[3]

So let $\mathcal{M}$ be a strongly causal space-time, and let $T^{*\prime}\mathcal{M}$ be the cotangent bundle of $\mathcal{M}$, minus the zero section. Take local coordinates (x^a,p_a) on $T^{*\prime}\mathcal{M}$. Then $T^{*\prime}\mathcal{M}$ has two natural forms defined on it, the canonical one-form θ given locally by $p_a dx^a$ and the symplectic form $\omega = d\theta = dp_a \wedge dx^a$.

In addition to these two differential forms, there are a couple of vector fields on $T^{*\prime}\mathcal{M}$ that we will need.

The first of these is the Euler field Δ, given by $\Delta = p_a(\partial/\partial p_a)$, which generates dilatations on each fiber of the cotangent bundle.

The second is the geodesic flow on the (reduced) cotangent bundle, defined by the Lorentz metric on $\mathcal{M}$ as follows: the Hamiltonian is defined by $H(x^a,p_a) = \frac{1}{2}g^{ab}p_a p_b = \frac{1}{2}p^a p_a$, and the geodesic spray is the vector field X_G on $T^{*\prime}\mathcal{M}$ defined by $X_G \lrcorner \omega + dH = 0$, or, in coordinates,

$$X_G = p^a \frac{\partial}{\partial x^a} - \Gamma_{abc} p^a p^b \frac{\partial}{\partial p_c},$$

where $\Gamma_{abc} = g_{ad}\Gamma^d{}_{bc}$ and $\Gamma^d{}_{bc}$ is the usual Christoffel symbol. We note also that $\mathcal{L}_\Delta X_G = X_G$.

Now, to construct $\mathcal{N}$, the space of null geodesics, we restrict our attention to $N'\mathcal{M}$, the bundle of (future pointing) null vectors, i.e., that part of $T^{*\prime}\mathcal{M}$ given by $p^a p_b = 0$ with p^a future pointing. Furthermore, since Δ and X_G are linearly independent and $[\Delta, X_G] = X_G$, the two-surfaces ele-

ments defined at each point by these two vector fields form an integral distribution. We could consider the space of null geodesics of $\mathcal{M}$ as the quotient manifold of leaves of this distribution.

It is sometimes more useful to consider taking the quotient by each vector field in turn. We could take the quotient by the Euler field, to obtain the space of unscaled null geodesics of $\mathcal{M}$ lifted to $N'\mathcal{M}$; since the Lie derivative of X_G along Δ is just X_G again, although X_G does not project to a vector field on this space, it still gives a one dimensional distribution on the resulting space. The integral curves of this distribution form a regular distribution[4] if $\mathcal{M}$ is strongly causal, and so the resulting space, $\mathcal{N}$, is a manifold. We could equally carry out these two identifications in the other order, with the same result.

It is also worth noting that under a conformal transformation of the metric, $N'\mathcal{M}$ is unchanged, and the restriction of the geodesic spray, X_G, to $N'\mathcal{M}$ is simply rescaled, so that all the geometry we are considering is conformally invariant.

As a notational convention, we will use lower-case Greek letters to represent points of $\mathcal{N}$ and the corresponding upper-case Greek letters to represent the corresponding subset of $\mathcal{M}$.

Lemma 1: If $\mathcal{M}$ is a globally hyperbolic space-time, and $\mathcal{S}$ is any smooth Cauchy surface for $\mathcal{M}$, then $\mathcal{N}$, the space of null geodesics of $\mathcal{M}$, is diffeomorphic to $T_1^*\mathcal{S}$, the cotangent sphere bundle of $\mathcal{S}$.

Proof: Give $\mathcal{S}$ coordinates, x_α, where α runs from 1 to 3, and let h be the Riemannian metric on $\mathcal{S}$ induced by g, the Lorentz metric on $\mathcal{M}$. Then a unit covector at x in $\mathcal{S}$ can be identified with a future pointing codirection at x in $\mathcal{M}$, by adding the unit future pointing timelike conormal to $\mathcal{S}$ at x, and then identifying this covector with all its positive multiples. Thus $T_1^*\mathcal{S}$ may be identified with the restriction to $\mathcal{S}$ of $N'\mathcal{M}$.

This gives us a bijection from $\mathcal{N}$ to $T_1^*\mathcal{S}$, by mapping any null geodesic γ in $\mathcal{N}$ to (x,v) where x is the point at which γ meets $\mathcal{S}$ and v is the unit covector in $T\mathcal{S}$ associated with the future pointing cotangent to Γ at x. It remains only to show that this bijection is a diffeomorphism. However, this now follows immediately from the fact that $T_1^*\mathcal{S}$ gives a slice of the foliation of $N'\mathcal{M}$ provided by the null geodesics, and thus defines the differentiable structure of $\mathcal{N}$.[4] □

Given two Cauchy surfaces, $\mathcal{S}_1$ and $\mathcal{S}_2$, the geodesic flow on $T^{*\prime}\mathcal{M}$ defines a function $f_g: T_1^*\mathcal{S}_1 \to T_1^*\mathcal{S}_2$ by mapping the point (x_1,v_1) to the point (x_2,v_2) where the null geodesic through $x_1 \in \mathcal{S}_1$ with a cotangent specified by v_1 meets $\mathcal{S}_2$ at x_2 with cotangent specified by v_2.

Corollary 1: If $\mathcal{S}_1$ and $\mathcal{S}_2$ are any Cauchy surfaces of $\mathcal{M}$, then $f_g: T_1^*\mathcal{S}_1 \to T_1^*\mathcal{S}_2$ is a diffeomorphism. □

We can now see how the canonical form on $T^{*\prime}\mathcal{M}$ gives a contact structure on $\mathcal{N}$. To this end it is convenient to list some relationships between the Euler and geodesic vector fields and the canonical and symplectic forms,

$$\Delta \lrcorner \theta = 0, \quad \Delta \lrcorner \omega = \theta, \quad X_G \lrcorner \theta = 2H,$$

$$X_G \lrcorner \omega = -dH, \quad \mathcal{L}_\Delta \theta = \theta, \quad \mathcal{L}_\Delta \omega = \omega,$$

$$\mathcal{L}_{X_G} \theta = dH, \quad \mathcal{L}_{X_G} \omega = 0.$$

First, we restrict everything to $N'\mathcal{M}$. This is the surface $H=0$ in $T^{*\prime}\mathcal{M}$, and on this surface we observe that $X_G \lrcorner \theta$, $X_G \lrcorner \omega$, $\mathcal{L}_{X_Q}\theta$ and $\mathcal{L}_{X_G}\omega$ are all zero. It follows that if we simply take the quotient space of integral curves of the geodesic spray restricted to $N'\mathcal{M}$, θ will project to the resulting space of scaled null geodesics.

But we also want to quotient out by the action of the Euler field. θ cannot be projected to this quotient: however, it is homogeneous, and the distribution of planes that it defines does project. θ thus defines a 2-form on $\mathcal{N}$ only up to scale. Denote this object by $[\theta]$. The distribution of planes defined by the vanishing of $[\theta]$ gives a geometric structure on $\mathcal{N}$ which is well defined, even though θ itself need not be globally defined by this procedure. We now have to show that we do indeed have a contact structure.

So let S be a two-surface in $\mathcal{N}$. Then S defines Σ, a two-parameter family of null geodesics in $\mathcal{M}$, i.e., a three-surface $\tilde{S}$ in $\mathcal{M}$ which is ruled by null geodesics. This surface will, in general, have self-intersections and singularities, but will not, in general, be a wave-front.

Lemma 2: The tangent plane to S lies in the kernel of $[\theta]$ at each point of S iff the corresponding family of null rays Σ in $\mathcal{M}$ forms a wave-front, i.e., it comprises the outgoing (or ingoing) null congruence to some spacelike two-surface Σ.

Proof: The tangent place to S lies in the kernel of $[\theta]$ at each point iff θ vanishes on Σ, which is well known to be equivalent to Σ being orthogonal to any spacelike slice.[5] □

Lemma 3: The planes so defined on $\mathcal{N}$ are precisely the contact planes of $T_1^*\mathcal{S}$.

Proof: The contact form on $T_1^*\mathcal{S}$ is simply the restriction to $T_1^*\mathcal{S}$ of the canonical form on $T\mathcal{S}$. A Legendre manifold of $T_1^*\mathcal{S}$ is therefore a manifold L such that for any point $(q,v)\in L$, the projection map carries v to a vector orthogonal to the projection of L. But on identifying $T_1^*\mathcal{S}$ with N, we see that these are precisely the wave-fronts, and so $[\theta]$ defines a contact structure on $\mathcal{N}$. □

Corollary 2: The mapping $f_g: T_1^*\mathcal{S}_1 \to T_1^*\mathcal{S}_2$ is a contact mapping. □

Note that in the case where $\mathcal{M}$ is static, and $\mathcal{S}_1$ and $\mathcal{S}_2$ are both hypersurfaces orthogonal to the timelike Killing vector, this is essentially a statement of Huygens' principle; the above corollary is then a generalization of Huygens' principle to a nonstatic space-time.

Corollary 3: The Legendre sub-manifolds of $\mathcal{N}$ are precisely those families of null geodesics which form wave-fronts. □

A particularly important example of this is when $\tilde{S}$ consists of all those null geodesics which pass through some point, say p, of $\mathcal{M}$. In this case, one can show[6,7] that S is a smooth S^2 in $\mathcal{N}$, called the sky of p and denoted P. Thus a special case of what we will consider is the evolution of the light cone of a point.

We can now use this framework to provide the classification on the stable singularities of wave-fronts,[1,2] with a considerable saving of labor.

Theorem 1: Generically, wave-fronts will contain only singular points of types A_2 and A_3. At isolated instants, they will also contain transitions of type A_4 and D_4.

Proof: This now follows immediately from the classifications of Legendre mappings given in Ref. 3. □

Since the Legendre manifolds of $\mathcal{N}$ are precisely the lifts of wave-fronts, we immediately see that this resolution of singularities is obtained by perturbation through Legendre sub-manifolds of wave-fronts, so that singularities may be resolved by a small perturbation of the surface in which a wave-front intersects any Cauchy surface. This provides some saving of labor over the space-time approach, such as is provided in Ref. 2; the analysis presented therein may be related to this one by the observation that the conical Lagrange manifolds of $T^{*\prime}\mathcal{M}$ are precisely those which project to Legendre manifolds of $\mathcal{N}$.

Finally, we should note that although the analysis carried out above has been presented for the case where $\mathcal{M}$ is globally hyperbolic, this classification of stable singularities holds in rather greater generality. If, now, Γ is some generator of a wave-front, we can consider the intersection of some neighborhood of Γ in the wave-front with $\mathcal{S}$, a small portion of the spacelike surface through which Γ passes. We continue to require that $\mathcal{M}$ be strongly causal; first, so that $\mathcal{N}$ will retain its structure as a contact manifold, and second, so that we can guarantee that by taking $\mathcal{S}$ sufficiently small, no null geodesic in our neighborhood of Γ will intersect $\mathcal{S}$ more than once. Then by the same argument as before, wave-fronts are precisely the Legendre submanifolds of $\mathcal{N}$. Furthermore, if we consider the projection of a neighborhood of Γ to $\mathcal{S}$, then the classification of stable singularities will be exactly as before.

ACKNOWLEDGMENTS

The field equations for cylindrically symmetric perfect fluid models with a non-scale invariant equation of state where the energy density is linearly related to the pressure are rewritten as a set of first order coupled ordinary differential equations. Variables are chosen such that the resulting phase space is compact and everywhere regular. The dynamical systems approach, used in the past mainly for scale invariant matter sources, is subsequently used to gain qualitative information about the space of solutions. It leads to a simple way of demonstrating the existence and properties of interior sources for cylindrically symmetric vacuum solutions. The models are shown to exhibit asymptotic scale invariance. © *1998 American Institute of Physics.* [S0022-2488(98)00605-7]

I. INTRODUCTION

There has been a continuing interest in cylindrically symmetric models since the first vacuum solution was found by Weyl and Levi-Civita in 1917–1918. This is despite the fact that it is hard to find any natural phenomena which could give rise to this particular geometry. Instead, cylindrical symmetry can be used as a probe to examine what features survive when generalizing spherical symmetry to axial symmetry as the infinite cylinder is the simplest axially symmetric system possible. Thin shells can be used as sources, which was shown by Wang *et al.*[1] Philbin[2] recently found an exact perfect fluid source but the equation of state is somewhat complicated. Stela and Kramer[3] have studied the case of static models with an incompressible fluid, i.e., constant energy density, numerically using the formulation of Kramer.[4]

In this paper we will use the dynamical systems approach which has been used with great success for over twenty years now in spatially homogeneous cosmology where considerable qualitative information has been gained, see, e.g., Ref. 5 and references therein. Usually one has considered scale invariant matter sources. For a perfect fluid this implies an equation of state where the pressure is directly proportional to the energy-density. In this paper we will give an example of a source which is not scale invariant and show that the dynamical system can be used to study such sources as well.

The matter source is assumed to be a perfect fluid with a stress-energy tensor of the form

$$T_{ab}=\mu u_a u_b+p(g_{ab}+u_a u_b), \tag{1}$$

where μ, p and u^a are the energy density, the pressure and the 4-velocity of the fluid, respectively. The equation of state is assumed to be of the form $\mu=\mu_0+(\eta-1)p$, where η and μ_0 are constants. The incompressible fluid case is given by $\eta=1$ and $\mu_0>0$. The case $\eta>1$ and $\mu_0 \geqslant 0$ yields a ''generalized barotropic'' equation of state where the genuine barotropic case is found by setting $\mu_0=0$. The equation of state for this case is often written in the form $p=(\gamma-1)\mu$, resulting in the relationship $\eta=\gamma/(\gamma-1)$. The physical range of γ is $1<\gamma\leqslant 2$, which corresponds to $2\leqslant\eta<\infty$ ($\gamma=1\Leftrightarrow\eta=\infty$). The choice of equation of state includes the explicitly solvable case of Evans,[6] $\eta=6$ ($\gamma=\frac{6}{5}$), which was also studied by Stela and Kramer.[3]

The static cylindrically symmetric models are a subclass of the more general static Bianchi type I models. The general line element of these models is

 © 1998 American Institute of Physics

$$ds^2 = -C_1(\rho)^2 dt^2 + d\rho^2 + C_2(\rho)^2 d\varphi + C_3(\rho)^2 dz^2, \tag{2}$$

with the 4-velocity of the fluid given by $u^a = C_1^{-1}(1,0,0,0)$.

For a solution to be cylindrically symmetric it has to have flat geometry in the vicinity of the central axis (pages 192 and 217 in Ref. 7). In the present case this implies that the above metric coefficients satisfy the following conditions:

$$\lim_{\rho\to 0} C_{1,3} = \lim_{\rho\to 0} \rho^{-1} C_2 = 1. \tag{3}$$

Thus one might expect that in order to distinguish a particular solution as cylindrically symmetric or not, the metric functions must be known explicitly in order to check the above limits. However, in Ref. 8 it was shown that the dynamical systems approach to the field equations yields a very simple way of implementing the above constraint. In the present paper we will study a relatively simple class of models. We thus hope that the presentation will not be clouded by too many technical details. We will return to possible generalizations in the discussion at the end of the paper.

The outline of the paper is as follows. In section II we write the field equations so that the phase space of the equations becomes compact and everywhere regular. In section III we perform a local analysis of the dynamical system. In section IV the different invariant boundary submanifolds of the phase space are discussed and the corresponding phase portraits are given. In section V we show how an interior solution is matched with the vacuum solution while in section VI we examine the cylindrically symmetric submanifold explicitly. In section VII we focus on the incompressible fluid while the more general models are investigated in section VIII. We end with a discussion in section IX. In Appendix A we discuss the Levi-Civita vacuum models while Appendix B gives the relation to the variables used by Kramer[4] and Stela and Kramer.[3]

II. THE DYNAMICAL SYSTEM

We will now rewrite the field equations in an autonomous form with variables adapted to the normal congruence associated with the symmetry surfaces $\rho = \text{const}$. Note that this congruence is spacelike. Misner has introduced a convenient parametrization of the metric coefficients in the context of spatially homogeneous cosmology.[9] Here we use an analogous parametrization. The metric functions C_1, C_2 and C_3 can be written as

$$C_1 = e^{\beta^0 - 2\beta^+}, \quad C_2 = e^{\beta^0 + \beta^+ + \sqrt{3}\beta^-}, \quad C_3 = e^{\beta^0 + \beta^+ - \sqrt{3}\beta^-}. \tag{4}$$

The variables β^0, $\beta^\pm$ are related to the kinematics of the normal congruence of the symmetry surfaces,

$$\theta = 3\dot{\beta}^0, \quad \sigma_+ = 3\dot{\beta}^+, \quad \sigma_- = 3\dot{\beta}^-, \tag{5}$$

where θ is the expansion and $\sigma_\pm$ describes the shear. A dot indicates $d/d\rho$. The field equations $G_{ab} = T_{ab}$ can now be written as the following:

Evolution equations:

$$\dot{\theta} = -\theta^2 - \frac{1}{2}(\mu - 5p), \tag{6}$$

$$\dot{\sigma}_+ = -\theta\sigma_+ - (\mu + p), \tag{7}$$

$$\dot{\sigma}_- = -\theta\sigma_-. \tag{8}$$

Defining equation for p:

$$p = \tfrac{1}{3}\theta^2 - \tfrac{1}{3}\sigma_+^2 - \tfrac{1}{3}\sigma_-^2. \tag{9}$$

The spacetime is fully described by the variables θ and $\sigma_{\pm}$, which can be understood by either studying the automorphism group[10] or using the equivalence problem approach.[11,12] However, the variables β^0 and $\beta^{\pm}$, and thus the metric variables C_1, C_2 and C_3, can be found in terms of quadratures using the decoupled equations in Eq. (5) when θ and $\sigma_{\pm}$ are known.

The equations of motion for the fluid, $\nabla_a T^{ab}=0$, yield an evolution equation for the pressure p, which also can be found by differentiating Eq. (9),

$$\dot{p}=-\tfrac{1}{3}(\theta-2\sigma_+)(\mu+p). \tag{10}$$

For the purpose of this paper it is more useful to examine instead the evolution equation for the variable $w=\mu+p$. Without specifying an equation of state, we obtain

$$\dot{w}=(v_s^{-2}+1)\dot{p}=-\tfrac{1}{3}(\theta-2\sigma_+)(v_s^{-2}+1)w, \tag{11}$$

where $v_s^2=dp/d\mu$ is the square of the sound velocity in the fluid. This velocity is assumed to be a real quantity. We now make the assumption that $w=\mu+p\geqslant 0$. This is just the weak energy condition[13] and w can be interpreted as a ''weak energy variable.'' Thus, as $w=0$ is an invariant submanifold of the system of differential equations, it is obvious that w is an important dynamical quantity. For the models considered in this paper, the evolution equation for w becomes

$$\dot{w}=-\tfrac{1}{3}\eta(\theta-2\sigma_+)w. \tag{12}$$

Note that the above equations also can be found by specializing the equations of Ref. 14 to the static Bianchi type I case. We can now write Eq. (9) as

$$\frac{3w}{\eta}=\theta^2+\frac{3\mu_0}{\eta}-\sigma_+^2-\sigma_-^2. \tag{13}$$

As w is assumed positive, we see that the $D=\sqrt{\theta^2+3\mu_0/\eta}$ is a ''dominant quantity.'' By introducing new bounded variables according to

$$Q=\frac{\theta}{D},\quad \Sigma_+=\frac{\sigma_+}{D},\quad \Sigma_-=\frac{\sigma_-}{D},\quad W=\frac{3w}{\eta D^2}, \tag{14}$$

along with a new independent variable ξ,

$$3d\xi=Dd\rho, \tag{15}$$

the system of differential equations can be written as the following.

Evolution equations:

$$Q'=-\tfrac{1}{2}(1-Q^2)(6+(\eta-6)W), \tag{16}$$

$$\Sigma_+'=-\tfrac{1}{2}(2\eta-(\eta-6)Q\Sigma_+)W, \tag{17}$$

$$\Sigma_-'=\tfrac{1}{2}(\eta-6)Q\Sigma_-W. \tag{18}$$

Defining equation for W:

$$W=1-\Sigma_+^2-\Sigma_-^2, \tag{19}$$

where a prime denotes $d/d\xi$. The μ_0-terms have been eliminated using

$$\frac{3\mu_0}{\eta D^2}=1-Q^2. \tag{20}$$

The above system of differential equations is invariant under the discrete symmetry

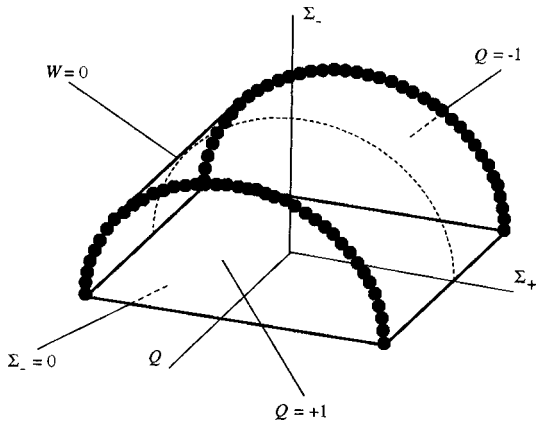

FIG. 1. The structure of the phase space with the different boundaries indicated.

$$(Q,\Sigma_+,\Sigma_-,\eta)\rightarrow -(Q,\Sigma_+,\Sigma_-,\eta). \tag{21}$$

This transformation can be achieved by choosing $D=-\sqrt{\theta^2+3\mu_0/\eta}$ instead of $D=\sqrt{\theta^2+3\mu_0/\eta}$. The line element is invariant under this discrete symmetry and solutions are thus represented by two orbits in the phase space related by the above discrete symmetry. The system is also invariant under the discrete symmetry

$$(Q,\Sigma_+,\Sigma_-)\rightarrow(Q,\Sigma_+,-\Sigma_-), \tag{22}$$

which corresponds to the discrete isometry $z\leftrightarrow\varphi$ in the line element [see Eq. (2)]. Knowing the structure of the phase space for $\Sigma_-\geqslant 0$ means that by using the above discrete symmetry, the structure of the phase space where $\Sigma_-\leqslant 0$ is easily found. For convenience and without loss of generality we will choose $\Sigma_-\geqslant 0$. The boundary of the reduced phase space is given by a number of invariant submanifolds. They are (i) $W=1-\Sigma_+^2-\Sigma_-^2=0$, (ii) $\Sigma_-=0$ and (iii) $Q=\pm 1$.

From Eq. (16), it follows that Q is a decreasing monotone function in phase space except on the boundaries $Q=\pm 1$. This prevents the existence of periodic orbits, recurrent orbits and homoclinic orbits as well as equilibrium points anywhere in phase space except on the $Q=\pm 1$ boundaries.[5] Therefore the only equilibrium points of the system of differential equations must lie on the boundary submanifolds $Q=\pm 1$. The structure of the phase space is given in Fig. 1 where we also indicate the different boundary submanifolds.

III. A LOCAL ANALYSIS OF THE DYNAMICAL SYSTEM

Here we give the equilibrium points of the system together with their eigenvalues. The value of W is also given as it shows if the point is on the boundary $W=0$ or not. As stated earlier, all equilibrium points are located on the $Q=\pm 1$ boundaries and thus have two eigenvectors which are associated with directions within the $Q=\pm 1$ submanifold while the third direction is directed away from this submanifold. We refrain from giving the explicit eigenvectors but the eigenvalues are ordered so that the first two are associated with directions within the $Q=\pm 1$ submanifolds while the third eigenvalue corresponds to a direction pointing out of these submanifolds.

The equilibrium points $K^{\pm}$:

$$Q=\pm 1,\quad \Sigma_+^2+\Sigma_-^2=1,\quad W=0; \tag{23}$$

$$0,2\eta\Sigma_+\pm(6-\eta),\pm 6. \tag{24}$$

The zero eigenvalue indicates that this is a line of equilibrium points. The eigenvector direction which points out of the $Q=\pm 1$ boundaries lies in the $W=0$ submanifold. There is one special point, denoted T, for which $Q=1$, $\Sigma_+=\frac{1}{2}$ and $\Sigma_-=\sqrt{3}/2$. It corresponds to flat space written on the so called Taub form, $ds^2=-dt^2+d\rho^2+\rho^2 d\varphi^2+dz^2$, which is explicitly cylindrically symmetric. It corresponds to the choice $m=0$ in the Levi-Civita line element, see Appendix A. Orbits

which start from this point will therefore correspond to solutions which are cylindrically symmetric. By only studying orbits starting from this point we have thus ''automatically'' satisfied the constraint equation (3), (see Ref. 8 for a more detailed discussion). There is of course a corresponding point on the $Q=-1$ boundary, but using the discrete symmetry [Eq. (21)] we only need to study the $Q=+1$ case. Being of such importance, we will give the eigenvalues and eigenvectors for T explicitly. They are

$$0, \quad (0,-\sqrt{3},1); \quad 6, \quad (0,-\sqrt{3}(2+\eta),\eta-6); \quad 6, \quad (1,0,0). \tag{25}$$

The equilibrium points $B^{\pm}$:

$$Q=\pm 1, \quad \Sigma_+=\pm\frac{2\eta}{\eta-6}, \quad \Sigma_-=0, \quad W=\frac{3(2-\eta)(6+\eta)}{(\eta-6)^2}; \tag{26}$$

$$\pm\frac{3(2-\eta)(\eta+6)}{2(\eta-6)}, \quad \pm\frac{3(2-\eta)(\eta+6)}{2(\eta-6)}, \quad \mp\frac{3(2+\eta)}{\eta-6}. \tag{27}$$

The point $B^+(B^-)$ exists only for $1\leqslant\eta<2$ ($\gamma>2$). At $\eta=2$ ($\gamma=2$) the point $B^+(B^-)$ coincides with a point on the line $K^+(K^-)$. The eigenvector directions which point out of the $Q=\pm 1$ boundary submanifolds lie in the $\Sigma_-=0$ submanifold.

IV. BOUNDARY SUBMANIFOLDS

When studying the orbits in the interior of phase space it is always advantageous to know the dynamics of the boundary. The different invariant boundary submanifolds were given in section II but are discussed here in more detail.

A. The scale invariant submanifolds

The invariant submanifolds $Q=\pm 1$ correspond to $\mu_0/D^2=0$, implying that μ_0 is dynamically unimportant. For $\eta\neq 1$ the ''effective'' equation of state is $\mu=(\eta-1)p$, i.e., $p=(\gamma-1)\mu$ which is *scale invariant*. Such models, with $1<\gamma<2$, were studied in Ref. 8. For the incompressible fluid, $\eta=1$, one has a perfect fluid with vanishing energy-density but non-zero pressure. Although being physically questionable, this type of source is also scale invariant. There is a bifurcation at $\eta=\gamma=2$ when the points $B^{\pm}$ leave the phase space. The general solution for the $Q=\pm 1$ submanifolds is

$$\Sigma_+=\frac{2\eta Q}{\eta-6}(1-A_0\Sigma_-), \quad \eta\neq 6, \tag{28}$$

where A_0 is a constant. When $\eta=6$, the general solution is instead $\Sigma_-=\text{const}$. The phase portraits for the $Q=1$ submanifold is given in Fig. 2(a)–2(d). The corresponding phase portraits for the $Q=-1$ submanifold can be found by using the discrete symmetries Eq. (21) and Eq. (22).

B. The ''weak-energy condition'' submanifold

The dynamics on the $W=0$ boundary is independent of the parameter η and the solution is

$$\Sigma_+=s_+, \quad \Sigma_-=s_-, \tag{29}$$

where s_+ and s_- are constants satisfying $s_+^2+s_-^2=1$. The phase portrait is given in Fig. 2(e).

C. The LRS submanifold

The submanifold $\Sigma_-=0$ corresponds to locally rotationally symmetric (LRS) solutions of Petrov type D (see e.g., Ref. 7). For these models the metric variables C_2 and C_3 in Eq. (2) can be chosen to be equal. There is a bifurcation at $\eta=\gamma=2$ resulting from $B_{\pm}$ leaving the phase space. The phase portraits are given in Fig. 2(f) and 2(g).

When $\mu_0\neq 0$ the source of the field equations is no longer scale invariant. Therefore the equations only allow self-similar solutions when $\mu_0=0$. The situation is similar to that of cos-

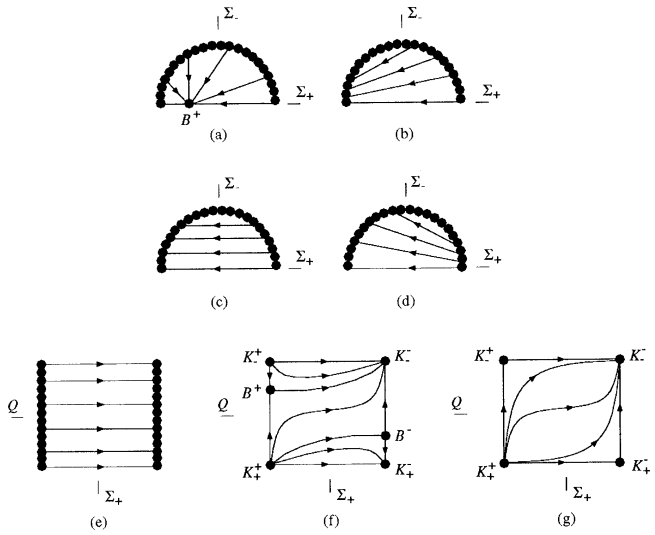

FIG. 2. The structure of the various boundary submanifolds for different values of the parameter η when (a) $Q=1$ and $1\leqslant\eta<2$, (b) $Q=1$ and $2\leqslant\eta<6$, (c) $Q=1$ and $\eta=6$, (d) $Q=1$ and $\eta>6$, (e) $W=0$, (f) $\Sigma_-=0$ and $1\leqslant\eta<2$ and (g) $\Sigma_-=0$ and $\eta\geqslant 2$. The dynamics on the boundary $Q=-1$ can be found by applying the discrete symmetries Eq. (21) and Eq. (22).

mology where a non-zero cosmological constant forbids the existence of self-similar solutions. As there exists a monotone function everywhere in phase space except on the $Q=\pm 1$ submanifolds there can be no complicated attractors inside phase space. Therefore all orbits end at equilibrium points which are characterized by a scale invariant matter source yielding an asymptotic scale invariance for the models. Also, as long as orbits in phase space are ''shadowing'' the $Q=\pm 1$ submanifolds, they will behave effectively as having a scale invariant perfect fluid source.

V. MATCHING WITH THE VACUUM SOLUTION

A source to the vacuum solution is characterized by a positive pressure p which vanishes on a surface at a finite distance from the center. On this surface the interior solution is matched with the vacuum solution. This is analogous to a spherically symmetric star where the interior solution is matched with the Schwarzschild solution. The continuity of the metric and its first derivatives is equivalent to the continuity of the variables θ, σ_+ and σ_- on the boundary. From Eq. (9) it follows that $p=0$ implies

$$Q^2-\Sigma_+^2-\Sigma_-^2=0. \tag{30}$$

This is a surface in the reduced phase space which is not an invariant submanifold, as is easily seen by differentiating the above expression. It divides the phase space into disjoint parts characterized by $p>0$ and $p<0$, respectively (see Fig. 3). Physical solutions are represented by orbits starting from an equilibrium point in a direction which corresponds to positive pressure. Cylindrically symmetric models start at the equilibrium point T. Instead of continuing the orbits through the surface $p=0$, they are stopped at the $p=0$ surface and the explicit values of the phase space variables there serve as ''initial'' data for the vacuum equations.

The matching conditions on the surface $p=0$ implies that we have to match the interior solution with a vacuum solution described by

$$\sigma_+=\frac{\Sigma_+^{(\mathrm{B})}}{Q^{(\mathrm{B})}}\,\theta, \quad \sigma_-=\theta\sqrt{1-\left(\frac{\Sigma_+^{(\mathrm{B})}}{Q^{(\mathrm{B})}}\right)^2}, \tag{31}$$

where $\Sigma_+^{(\mathrm{B})}$ and $Q^{(\mathrm{B})}$ are the values of the solutions in the limit $p\to 0$. The ''mass-parameter'' m of the Levi-Civita line element (see Appendix A) is related explicitly to the boundary values $\Sigma_\pm^{(\mathrm{B})}$ and $Q^{(\mathrm{B})}$ by

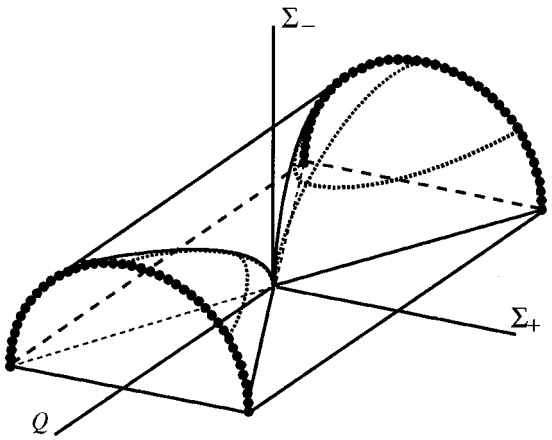

FIG. 3. The surfaces $p=0$. The scale of Q has been exaggerated for visual reasons. The region beneath the paraboloid is characterized by $p>0$.

$$m=\frac{2Q^{(\mathrm{B})}-\Sigma_{+}^{(\mathrm{B})}-\sqrt{3}\Sigma_{-}^{(\mathrm{B})}}{Q^{(\mathrm{B})}-2\Sigma_{+}^{(\mathrm{B})}}, \tag{32}$$

showing that m is manifestly constant. As orbits corresponding to physical sources are stopped at some finite ξ_0 and not at an equilibrium point of the system, it follows from the above expression and the differential equation for Q that all cylinders have a finite size. The proper radius R of the cylinder can be found by integrating Eq. (15),

$$R=3\int \frac{d\xi}{D}=\sqrt{\frac{3\eta}{\mu_0}}\int_{-\infty}^{\xi_0}\sqrt{1-Q^2}\,d\xi. \tag{33}$$

VI. THE CYLINDRICALLY SYMMETRIC SUBMANIFOLD

Within the general class of static Bianchi type I models there exists a particularly interesting subclass of solutions, namely the cylindrically symmetric solutions. As discussed previously, all the cylindrically symmetric solutions correspond to orbits starting from the point T. As this point is a source; there will always be a one-parameter set of orbits entering the interior phase space. Using the eigenvectors given in Eq. (25), we can write the linearized solution near the point T as

$$Q=1-\epsilon_Q e^{6\xi}, \tag{34}$$

$$\Sigma_{+}=\tfrac{1}{2}-\sqrt{3}\,\epsilon_\Sigma(2+\eta)e^{6\xi}, \tag{35}$$

$$\Sigma_{-}=\frac{\sqrt{3}}{2}+\epsilon_\Sigma(\eta-6)e^{6\xi}, \tag{36}$$

where $\epsilon_Q,\epsilon_\Sigma$ are small positive parameters. A translation of the parameter ξ just leads to a rescaling of the parameters $\epsilon_Q,\epsilon_\Sigma$. The quotient p/μ at the center $\rho=0$ of the cylinder is given by

$$\left.\frac{p}{\mu}\right|_{\xi\to-\infty}=\frac{4\sqrt{3}(\epsilon_\Sigma/\epsilon_Q)-1}{\eta+(\eta-1)[4\sqrt{3}(\epsilon_\Sigma/\epsilon_Q)-1]}, \tag{37}$$

which implies that orbits corresponding to solutions with positive pressure have $\epsilon_\Sigma/\epsilon_Q>1/4\sqrt{3}$ (assuming $\eta\geqslant 1$). Orbits with $\epsilon_\Sigma/\epsilon_Q<1/4\sqrt{3}$ have negative pressure while if $\epsilon_\Sigma/\epsilon_Q=1/4\sqrt{3}$ the orbits start out exactly in the $p=0$ surface. Enforcing the energy condition $p/\mu\leqslant 1$ at the center of the cylinder implies that for $1\leqslant\eta<2$ we must also have $\epsilon_\Sigma/\epsilon_Q\leqslant 1/(2\sqrt{3}[2-\eta])$. For $\eta\geqslant 2$

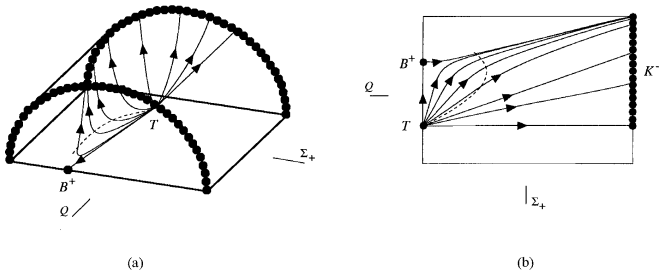

FIG. 4. The cylindrically symmetric submanifold for the case $\eta=1$, the incompressible fluid, as (a) a surface of solutions in the full phase space and (b) the surface of solutions projected onto $\Sigma_-=0$. The dashed line indicates where orbits pass through the $p=0$ surface.

this condition puts no extra limits on the choice of $\epsilon_\Sigma/\epsilon_Q$. If the direction of an orbit is close to the boundary $Q=1$, i.e., $\epsilon_Q \ll \epsilon_\Sigma$, it follows from Eq. (37) above that (excluding the case $\eta=1$)

$$\left.\frac{p}{\mu}\right|_{\xi\to-\infty} \approx \frac{1}{\eta-1}, \tag{38}$$

which is an aspect of the previously discussed asymptotic scale invariance of the source.

It follows that models with an initial positive pressure will reach a point where $p=0$ at a finite value of the independent variable. At this point they can then be matched with a cylindrically symmetric vacuum solutions as described in the previous section.

VII. THE INCOMPRESSIBLE FLUID

The incompressible fluid is characterized by a constant energy density $\mu=\mu_0$ which is equivalent to setting $\eta=1$. The cylindrically symmetric submanifold is a 2-dimensional surface in phase space spanned by the two eigenvectors corresponding to the non-zero eigenvalues of the point T. The structure of this submanifold is given in Fig. 4(a). The assumption of positivity of the pressure near the center of the cylinder yields the restriction $\epsilon_\Sigma/\epsilon_Q > 1/4\sqrt{3}$. The conditions $p/\mu \leqslant 1$ and $p>0$ at the center of the cylinder (i.e., the conditions Stela and Kramer[3] use), lead to $1/4\sqrt{3} < \epsilon_\Sigma/\epsilon_Q \leqslant 1/2\sqrt{3}$. This means that we cannot choose initial data such that the resulting orbit shadows the scale invariant boundary $Q=1$ (with the exception of the point T). This will be true for all models with $1 \leqslant \eta < 2$. In Fig. 4(b) the surface of solutions is projected onto the $\Sigma_-=0$ plane. The curve where the cylindrically symmetric submanifold passes through the surface $p=0$ is indicated in Fig. 4 by the dashed line.

VIII. GENERAL FEATURES

If we allow η to vary, it is clear that models with $1<\eta<2$ have the same qualitative behavior as the incompressible fluid, e.g., the point B^+ describes the intermediate state of the model for many of the orbits. As the point B^+ leaves the phase space at $\eta=2$, this intermediate behavior is instead described by a point on the line of equilibrium points K^+ whose values of the phase space variables is a function of η. As an example of this generic behavior for models with $\eta \geqslant 2$, the cylindrically symmetric submanifold for the case $\eta=4$ ($\gamma=\frac{4}{3}$) is shown in Fig. 5. For $\eta \geqslant 2$ we can always choose initial data so that the resulting solution ''shadows'' the scale invariant boundary $Q=1$, independently of the specific value of η.

We remark finally on models with $\eta=6$, which implies an equation of state of the form $\mu=\mu_0+5p$. In this case the equations simplify and can be solved exactly. The solution is characterized by the integrals

$$\frac{(1+Q)(1-2\Sigma_+)}{(1-Q)(1+2\Sigma_+)}=\text{const.}, \quad \Sigma_-=\text{const.} \tag{39}$$

All the dynamics of the cylindrically symmetric models therefore will take place in the plane $\Sigma_-=\sqrt{3}/2$. This feature, that the cylindrically symmetric submanifold coincides with a known

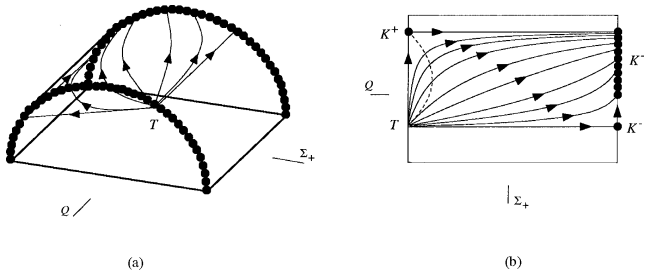

FIG. 5. The cylindrically symmetric submanifold for the case $\eta=4$, the incompressible fluid, as (a) a surface of solutions in the full phase space and (b) the surface of solutions projected onto $\Sigma_-=0$. The dashed line in (b) indicates where orbits pass through the $p=0$ surface. Different points on the line of equilibrium points K^- are denoted by simply K^- as their exact value is of lesser interest.

submanifold of the system of differential equations, exists only for the case $\eta=6$. The phase portrait is given in Fig. 6. The corresponding exact solution was found by Evans.[6]

A numerical study shows that the mass parameter m of the Levi-Civita line element takes values in the range $0<m<1$ although the exact values depend on the choice of η.

IX. DISCUSSION

In this paper we have shown that by an appropriate choice of variables the phase space of the field equations for static Bianchi type I perfect fluid models with an equation of state $\mu=\mu_0+(\eta-1)p$ can be made compact and everywhere regular. This together with the existence of a monotone function indicate that the global structure of the phase space can be well understood. We have also shown that these models are asymptotically scale invariant.

Even though the source is not scale invariant the dynamical systems approach has turned out to be a very useful tool. It constitutes a very simple way of implementing the otherwise rather cumbersome cylindrically symmetric constraint on the more general static Bianchi type I models and thus finding the cylindrically symmetric submanifold. All orbits describing cylindrically symmetric solutions start from a single point in phase space and can be parametrized by the quotient $\epsilon_\Sigma/\epsilon_Q$, where ϵ_Σ and ϵ_Q are the parameters of the local linearized solution of the field equations near the center of the cylinder. By following only orbits corresponding to positive pressure near the center of the cylinder, the physically reasonable interior solutions are easily singled out. These orbits are then stopped as the pressure of the fluid vanishes and it is shown that the corresponding solution with $\mu_0\neq 0$ can be matched at a finite radius with a Levi-Civita vacuum solution. This is in stark contrast with the case $\mu_0=0$ see Ref. 8, where such matching is impossible.

The present approach can easily be applied to static spherically symmetric models with the same equation of state. As this class of models have been studied extensively in the literature over the years it is unlikely that the dynamical systems approach would yield any new results. However, there are some other natural generalizations of the models in this paper. If the fluid is allowed to rotate without shear, i.e., making the models stationary rigidly rotating, the generali-

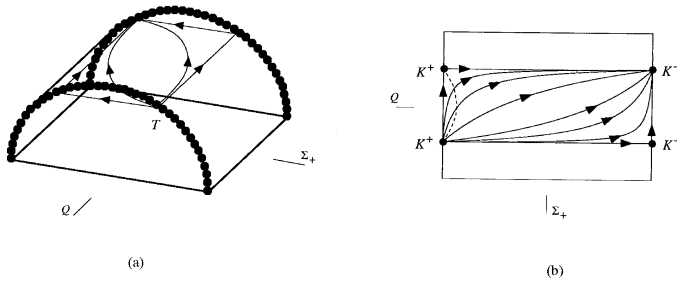

FIG. 6. The cylindrically symmetric submanifold for the case $\eta=6$ as (a) a surface of solutions in the full phase space and (b) the surface of solutions projected onto $\Sigma_-=0$. In (b) the dashed line indicates where the orbits pass the surface $p=0$.

zation is straightforward. The addition of rotation adds one dimension to the phase space, making the visualization somewhat more complicated, but the approach to proving the existence of interior solutions is still valid. A further generalization is to let the rotation be non-rigid. This is equivalent to a non-vanishing fluid shear. These models will contain an arbitrary function, e.g. the fluid shear, making the system of differential equations undetermined. Therefore they are not well-suited for the dynamical systems approach. One can of course define the functional dependence of the fluid shear, thus making the system determined again and then study that particular class of models. Another way of generalizing the models is by introducing a more general equation of state, $p=p(\mu)$. For these models the choice of variables in this paper will not be appropriate as they will not result in a compact phase space. But by making a slightly different choice and imposing the weak energy condition on the fluid, a compact phase space can be found. The question of existence of interior solutions with, e.g., a polytropic perfect fluid, can then be studied.

APPENDIX A: THE LEVI-CIVITA SOLUTION

The general static cylindrically symmetric solution is the Levi-Civita solution,[7]

$$ds^2=-r^{2m}dt^2+r^{-2m}(r^{2m^2}(dr^2+dz^2)+r^2d\varphi^2), \tag{40}$$

where m is a constant of referred to as the ''mass parameter.'' Introducing a new radial variable, $\rho=\rho(r)$, the above metric can be written in the form of (2),

$$ds^2=-\rho^{2m/A}dt^2+d\rho^2+\rho^{2(1-m)/A}d\varphi^2+\rho^{2m(m-1)/A}dz^2, \tag{41}$$

where $A=m(m-1)+1$. The kinematical quantities are

$$\theta=1/\rho, \tag{42}$$

$$\sigma_+=\frac{m^2-4m+1}{2A\rho}, \tag{43}$$

$$\sigma_-=\frac{\sqrt{3}(1-m^2)}{2A\rho}. \tag{44}$$

APPENDIX B: COMPARISON WITH KRAMER

In Ref. 7 Kramer introduced the variables y and z which are used for the numerical calculation in Ref. 3. They are defined in terms of the variables used in this paper according to

$$y=\frac{2\theta-\sigma_+-\sqrt{3}\sigma_-}{\theta-2\sigma_+}=\frac{2Q-\Sigma_+-\sqrt{3}\Sigma_-}{Q-2\Sigma_+}, \tag{45}$$

$$z=\frac{2\theta-\sigma_++\sqrt{3}\sigma_-}{\theta-2\sigma_+}=\frac{2Q-\Sigma_++\sqrt{3}\Sigma_-}{Q-2\Sigma_+}. \tag{46}$$

We easily see that the variable z becomes infinite at the point T, i.e., at the center of the cylinder, while the linear solution, Eqs. (34)–(36), implies that

$$y=\frac{2-8\sqrt{3}(\epsilon_\Sigma/\epsilon_Q)}{1-2\sqrt{3}(2+\eta)(\epsilon_\Sigma/\epsilon_Q)}, \tag{47}$$

at the point T. At the boundary of the cylinder the equality $y=1/z$ holds which is equivalent to Eq. (32).

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 39, NUMBER 6 JUNE 1998

Closed formula for the matrix elements of the volume operator in canonical quantum gravity

T. Thiemann[a)]
Physics Department, Harvard University, Cambridge, Massachusetts 02138

(Received 15 May 1997; accepted for publication 16 February 1998)

We derive a closed formula for the matrix elements of the volume operator for canonical Lorentzian quantum gravity in four space–time dimensions in the continuum in a spin-network basis. We also display a new technique of regularization which is state dependent but we are forced to it in order to maintain diffeomorphism covariance and in that sense it is natural. We arrive naturally at the expression for the volume operator as defined by Ashtekar and Lewandowski up to a state-independent factor. © *1998 American Institute of Physics.*

I. INTRODUCTION

The volume functional V for Lorentzian canonical quantum gravity plays a quite important role in the quantization process: if one follows the approach advertized in Ref. 1 and chooses a representation in which traces of the holonomy along closed loops for a certain SU(2) A_a^i connection can be promoted to basic configuration operators, then it becomes technically very hard to define physically interesting operators such as the Euclidean and Lorentzian Hamiltonian constraint operators, an operator corresponding to the length of a curve, an operator corresponding to the ADM (Arnowitt–Deser–Misner) energy, matter Hamiltonian operators, and so forth. The common reason is that all these operators involve only the co-triad e_a^i of the intrinsic metric of the initial data hypersurface Σ polynomially which, however, cannot be written as a polynomial in the momentum conjugate to A_a^i and therefore does not seem to make any sense as a quantum operator.

Fortunately, there is a trick available: as proved in Refs. 2 and 3, the total volume of Σ is the generating functional of the co-triad meaning that one gets e_a^i from V essentially by functional derivation. Therefore, if we write $\delta t \dot{s}^a e_a^i \propto \{h_s, V\} + o(\delta t^2)$, where s is an edge with parameter length δt, h_s is the holonomy along s, and $\{.,.\}$ denotes Poisson brackets, then it would be sufficient to quantize V in such a way that (gauge-invariant) functions of a finite number of holonomies form a dense domain. Such a satisfactory quantization of V which has precisely this property was indeed given already in the literature. The first paper on the quantization of the volume was Ref. 4. Another quantization of the volume was later mentioned for the first time in Ref. 1 and supplemented recently by a detailed paper (second reference in Ref. 5). After Refs. 1 and 4, another paper (first reference in Ref. 6) appeared which focuses on the quantization on a lattice while Refs. 1 and 4 deal with the continuum formulation.

Therefore, the strategy outlined above and in Refs. 2 and 3 can be implemented and, in particular, was successfully employed to construct various operators listed above.[2,3,7–9] However, the explicit computation of the spectrum of most of those operators was not performed so far. The reason is that the spectra of all these operators are clearly largely determined by the spectrum of the volume operator whose precise spectrum is fairly unknown except for the most simple situations. (In Ref. 10 a general four-valent case in the continuum is considered while in Ref. 6 a general six-valent case, the maximum valence of a vertex in a hyper-cubic lattice, is considered. In Ref. 7 the extension to non-gauge-invariant states of the volume operator published first in the present paper is applied to compute the spectrum of a length operator in a general four-valent case and in Ref. 11 the same extension is employed to compute the matrix elements of the operator

constructed in Refs. 2 and 3 for a general three-valent vertex. See below for the meaning of ''valence'' and ''vertex'' in the theories under consideration.)

The present paper is devoted to the derivation of the complete set of matrix elements of this operator in closed form in terms of known quantities from which the spectrum can be obtained, in principle, straightforwardly although only numerically in general. A similar formula has been derived earlier in Ref. 12 by De Pietri and Rovelli. The difference between Ref. 12 and the present paper is twofold: First of all, we work with the operator introduced by Ashtekar and Lewandowski[5] while Ref. 12 works with the operator introduced earlier by Rovelli and Smolin.[4] These two operators agree only on vertices of valence smaller than or equal to four. Second and more importantly, we prefer to employ the connection representation of quantum gravity which leads to the, to our mind, quite compact invariant vector field calculus whereas Ref. 12 employs the loop representation which leads to *a*, to our mind, quite cumbersome, partly graphical notation. While both representations were proved to be unitarily equivalent in Ref. 13 (see Ref. 14 for a later proof) the (inverse) loop transformation that maps them into each other is rather complicated and thus a full proof that both formulas as well as the methods to arrive at them are identical is lacking at the moment (a proof exists for the case of a single nonplanar four-valent vertex[10]).

In Sec. III, after introducing the notation in Sec. II, we develop a novel technique to regularize the volume operator which is state dependent very much in the same way as the regularization displayed in the second reference of Ref. 5. This part of the paper is a continuation of the work on the point-splitting regularizations of the volume and area operators as displayed in Refs. 1 and 5. The derivation is rather short and gives a diffeomorphism covariant end result. We are unambiguously led to the Ashtekar–Lewandowski volume operator defined in Ref. 15.

In Sec. IV we repeat the argument given in Refs. 5 and 10 which shows that the spectrum is discrete and that its computation reduces to linear algebra, in the sense that we just need to determine separately the eigenvalues of an infinite number of finite-dimensional, positive semidefinite and symmetric real-valued matrices.

Finally, in Sec. V we derive the explicit formula for an arbitrary matrix element in a spin-network basis and compute the eigenvalues of the associated matrices in a number of simple cases. It should be noted that the formulas obtained, albeit quite complicated, are the starting point for a numerical evaluation of the spectrum and are in particular useful to determine the large spin behavior of the volume operator.

II. NOTATION

Let us first introduce the notation. We consider the Hamiltonian formulation of the Palatini action of four-dimensional Lorentzian vacuum gravity.

Denote by q_{ab} the intrinsic metric on the initial data hypersurface Σ and let e_a^i be its co-triad where $i,j,k,\ldots$ denote su(2) indices. The densitized triad $E_i^a := \det((e_b^j))e_i^a$ multiplied by $1/\kappa$, κ being Newton's constant, is the momentum conjugate to $K_a^i := \mathrm{sgn}(\det((e_c^j)))K_{ab}e_i^b$ where K_{ab} is the extrinsic curvature of Σ. Notice that usually the term ''densitized triad'' is used for the quantity $\sqrt{\det(q)}e_i^a$ which differs (possibly) by a sign from the above definition.

Upon performing a canonical point transformation discovered by Ashtekar[16] on the phase space of general relativity (of which we use its real Lorentzian variant; the real variant for Euclidean signature was first described in Ref. 17 and for the Lorentzian one later in Ref. 18) coordinated by $(K_a^i, E_i^a/\kappa)$ we arrive at the chart $(A_a^i/\kappa := (\Gamma_a^i + K_a^i)/\kappa, E_i^a)$, where Γ_a^i is the spin connection of e_a^i. It is easy to see that the configuration variable A_a^i is an su(2) connection. The reason for modifying the definition of the densitized triad is that only with our choice the above transformation is a symplectomorphism as explained in more detail in Ref. 3.

The virtue of casting general relativity into a connection dynamics formulation initialized by Ashtekar is as follows.

(1) First of all, the phase space of general relativity is now embedded into that of an su(2) gauge theory, thereby opening access to a wealth of techniques that have been proving useful in quantizing those theories. Probably the most important technique is the use of traces of the holonomy along piecewise analytic loops in Σ, so-called Wilson-loop functionals, to coordi-

natize the space of smooth connections modulo gauge transformations $\mathcal{A}/\mathcal{G}$. For gauge theories that have been emphasized, for instance, in Refs. 19 and 20 and for quantum gravity in Ref. 21.

(2) Using those Wilson loop functionals one can construct[22–24] a quantum configuration space of generalized connection modulo gauge transformations $\overline{\mathcal{A}/\mathcal{G}}$ and find natural, σ-additive, diffeomorphism invariant, regular Borel probability measures μ_0 thereon which equips us with a Hilbert space structure $\mathcal{H}:=L(\overline{\mathcal{A}/\mathcal{G}},d\mu_0)$. Of course, for this to make sense we have to make the following assumption: Wilson loop functionals continue to make sense as operators in the quantum theory. We will adopt this viewpoint in the sequel in the hope of capturing one of the physically interesting phases of quantum general relativity. The interested reader is referred to Ref. 1 and references therein for further details.

The following paragraph is meant to equip the reader with a working knowledge of the tools associated with $\overline{\mathcal{A}/\mathcal{G}}$.

We begin by defining cylindrical functions. Since the gauge-invariant information contained in a connection is captured by finite linear sums of products of Wilson loop functionals we may label gauge-invariant functions by piecewise analytic graphs γ which are just the union of the loops involved. Such a graph consists of maximally analytic pieces, called the edges e of γ, and the edges meet in the vertices v of γ. A function f on $\overline{\mathcal{A}/\mathcal{G}}$ is said to be cylindrical with respect to a graph γ iff it can be written as $f=f_\gamma\circ p_\gamma$, where $p_\gamma(A)=(h_{e_1}(A),\ldots,h_{e_n}(A))$ and where $e_1,\ldots,e_n$ are the edges of γ. Here $h_e(A)$ is the holonomy along e evaluated at $A\in\overline{\mathcal{A}/\mathcal{G}}$ and f_γ is a complex-valued function on $\mathrm{SU}(2)^n$. Since a function cylindrical with respect to a graph γ is automatically cylindrical with respect to any graph bigger than γ, a cylindrical function is actually given by a whole equivalence class of functions f_γ. In the sequel we will not distinguish between this equivalence class and one of its representatives.

We say that a function cylindrical with respect to a graph γ is of class C^n if it is of class C^n with respect to the standard differentiable structure of $\mathrm{SU}(2)^n$ and denote this class of functions by $\mathrm{Cyl}^n_\gamma(\overline{\mathcal{A}/\mathcal{G}})$, $\mathrm{Cyl}^n(\overline{\mathcal{A}/\mathcal{G}}):=\cup_{\gamma\in\Gamma}\mathrm{Cyl}^n_\gamma(\overline{\mathcal{A}/\mathcal{G}})$, where Γ is the set of piecewise analytic graphs in Σ. Thus we have a differential calculus[15] on $\overline{\mathcal{A}/\mathcal{G}}$.

Finally, the measure μ_0 is the faithful projective limit[25,26] of the self-consistent projective family $(\mu_{0,\gamma})_{\gamma\in\Gamma}$ defined by

$$\int_{\overline{\mathcal{A}/\mathcal{G}}} d\mu_0(A) f(A) := \int_{\overline{\mathcal{A}/\mathcal{G}}} d\mu_{0,\gamma}(A) f_\gamma(p_\gamma(A)) := \int_{SU(2)^n} d\mu_H(g_1)\cdots d\mu_H(g_n) f_\gamma(g_1,\ldots,g_n),$$

where $g_I:=h_{e_I}(A)$. This equips us with an integral calculus on $\overline{\mathcal{A}/\mathcal{G}}$.

III. REGULARIZATION OF THE VOLUME OPERATOR

In this section we present a new regularization of the volume operator which uses the methods derived by Abhay Ashtekar and Jurek Lewandowski in Refs. 5, 10, and 15. Most of the issues involved in the regularization as presented here are borrowed from their work.

The advantage of our procedure is that it is rather short and compact.

Let $R\subset\Sigma$ be an open, connected region of Σ. We have the identity

$$\frac{1}{3!}\,\epsilon_{abc}\epsilon^{ijk}E^a_iE^b_jE^c_k=\det((E^a_i))=\det((q_{ab}))=[\det((e^i_a))]^2=:\det(q)\geqslant 0 \tag{III.1}$$

and can thus write the volume of the region R as measured by the metric q_{ab} as follows:

$$V(R):=\int_R d^3x\sqrt{\det(q)}=\sqrt{\frac{1}{3!}\,\epsilon_{ijk}\epsilon^{abc}E^a_iE^b_jE^c_k}. \tag{III.2}$$

The next step is to smear the fields E^a_i. Let $\chi_\Delta(p,x)$ be the characteristic function in the coordinate x of a cube with center p spanned by the three vectors $\mathbf{\Delta}_i=\Delta_i\mathbf{n}_i(\Delta)$ where $\mathbf{n}_i$ is a normal vector in the frame under consideration and which has coordinate volume, vol

$=\Delta_1\Delta_2\Delta_3\ \det(\mathbf{n}_1,\mathbf{n}_2,\mathbf{n}_3)$ (we assume the three normal vectors to be right oriented). In other words, $\chi_\Delta(p,x)=\Pi_{i=1}^3\theta(\Delta_i-|\langle n_i,x-p\rangle|)$ where $\langle .,.\rangle$ is the standard Euclidean inner product and $\theta(y)=1$ for $y>0$ and zero otherwise.

We consider the smeared quantity

$$E(p,\Delta,\Delta',\Delta'')\coloneqq\frac{1}{\mathrm{vol}(\Delta)\mathrm{vol}(\Delta')\mathrm{vol}(\Delta'')}\int_\Sigma d^3x\int_\Sigma d^3y\int_\Sigma d^3z\ \chi_\Delta(p,x)\chi_{\Delta'}\left(p,\frac{x+y}{2}\right)$$
$$\times\chi_{\Delta''}\left(p,\frac{x+y+z}{3}\right)\frac{1}{3!}\,\epsilon_{abc}\epsilon^{ijk}E_i^a(x)E_j^b(y)E_k^c(z). \tag{III.3}$$

Notice that if we take the limits $\Delta_i,\Delta_i',\Delta_i''\to 0$ in any combination and in any rate with respect to each other then we get back to (III.1) evaluated at the point p. This holds for any choice of linearly independent normal vectors $\mathbf{n}_i,\mathbf{n}_i',\mathbf{n}_i''$. The strange argument $(x+y+z)/3$ will turn out to be very crucial in obtaining a manifestly diffeomorphism covariant result. We will see this in a moment.

Then it is easy to see that the classical identity

$$V(R)=\lim_{\Delta\to 0}\lim_{\Delta'\to 0}\lim_{\Delta''\to 0}\int_R d^3p\sqrt{|E(p,\Delta,\Delta',\Delta'')|} \tag{III.4}$$

holds. We could introduce absolute values because we have the classical identity $\det(q)=|\det(q)|$ and the modulus is necessary for the regulated quantity (III.3) is not non-negative anymore. This continues to hold in the quantum theory and it is an open question whether one should impose the anholonomic constraint $\det(q)\geqslant 0$ in the quantum theory.[27] Also, observe that (III.3) is not gauge invariant any longer in contrast to $V(R)$, however, we will be interested only in the limit of shrinking all Δ to points and, as it turns out, recover gauge invariance also in the quantum theory.

The virtue of introducing the quantities (III.3) is that they enable us to define operators corresponding to $V(R)$, in the limit that all Δ shrink to a point, and which have the dense domain $\mathrm{Cyl}^3(\overline{\mathscr{A}/\mathscr{G}})$. To see this, notice that due to the canonical brackets $\{A_a^i(x),E_j^b(y)\}=\kappa\delta_a^b\delta_j^i\delta^{(3)}(x,y)$ we are naturally led to represent the operator corresponding to E_i^a by $\hat{E}_i^a(x)=-i\ell_p^2\delta/\delta A_a^i(x)$ where $\ell_p=\sqrt{\hbar\kappa}$ is the Planck length.

Now let a graph γ be given. In order to simplify the notation, we subdivide each edge e with endpoints v,v' which are vertices of γ into two segments s,s' where $e=s\circ(s')^{-1}$ and s has an orientation such that it is *outgoing* at v while s' has an orientation such that it is *outgoing* at v'. This introduces new vertices $s\cap s'$ which we will call pseudo-vertices because they are not points of nonanalyticity of the graph. Let $E(\gamma)$ be the set of these segments of γ but $V(\gamma)$ the set of true (as opposed to pseudo) vertices of γ. Let us now evaluate the action of $\hat{E}_i^a(p,\Delta)\coloneqq 1/\mathrm{vol}(\Delta)\int_\Sigma d^3x\chi_\Delta(p,x)\hat{E}_i^a(x)$ on a function $f=p_\gamma^* f_\gamma$ cylindrical with respect to γ. We find $\{e:[0,1]\to\Sigma;\ t\to e(t)$ being a parametrization of the edge $e\}$

$$\hat{E}_i^a(p,\Delta)f=-\frac{i\ell_p^2}{\mathrm{vol}(\Delta)}\sum_{e\in E(\gamma)}\int_0^1 dt\chi_\Delta(p,e(t))\dot{e}^a(t)\,\frac{1}{2}\,\mathrm{tr}\left(h_e(0,t)\tau_i h_e(t,1)\,\frac{\partial}{\partial h_e(0,1)}\right)f_\gamma. \tag{III.5}$$

Here we have used (1) the fact that a cylindrical function is already determined by its values on $\mathscr{A}/\mathscr{G}$ rather than $\overline{\mathscr{A}/\mathscr{G}}$ so that it makes sense to take the functional derivative, (2) the definition of the holonomy as the path-ordered exponential of $\int_e A$ with the smallest parameter value to the left, (3) $A=dx^a\,A_a^i\tau_i/2$ where $\mathrm{SU}(2)\ni\tau_j=-i\sigma_j$, σ_i being the usual Pauli matrices, so that $[\tau_i/2,\tau_j/2]=\epsilon_{ijk}\tau_k/2$, and (4) we have defined $\mathrm{tr}(h\partial/\partial g)=h_{AB}\partial/\partial g_{AB}$, $A,B,C,\ldots$ being SU(2) indices. The state that appears on the right-hand side of (III.5) is actually well defined, in the sense of functions of connections, only when A is smooth for otherwise the integral over t does not exist.[28] However, we will be interested only in quantities constructed from operators of the form (III.5) and for which the limit of shrinking $\Delta\to 0$ to a point has a meaning in the sense of $\mathscr{H}=L_2(\overline{\mathscr{A}/\mathscr{G}},d\mu_0)$ and therefore will not be concerned with the actual range of the operator (III.5).

We now wish to evaluate the whole operator $\hat{E}(p,\Delta,\Delta',\Delta'')$ on f. It is clear that we obtain three types of terms: the first type comes from all three functional derivatives acting on f only, the second type comes from two functional derivatives acting on f and the remaining one acting on the trace appearing in (III.5), and, finally, the third type comes from only one derivative acting on f_γ and the remaining two acting on the trace. Explicitly we find [we mean by $\theta(t,t')$ the theta function which is unity if $0<t<t'<1$ and zero otherwise and likewise $\theta(t,t',t'')$ is 1 if $0<t<t'<t''<1$ and zero otherwise]

$$

\end{aligned}
$$

$$\times \mathrm{tr}\left(h_e(0,t)\,\tau_i h_e(t,1)\,\frac{\partial}{\partial h_e(0,1)}\right)$$

$$+\sum_{e''\in E(\gamma)} \dot{e}''(t)^a \dot{e}''(t')^b \dot{e}''(t'')^c \chi_\Delta(p,e''(t))\chi_{\Delta'}\left(p,\frac{e''(t)+e''(t')}{2}\right)$$

$$\times \chi_{\Delta''}\left(p,\frac{e''(t)+e''(t')+e''(t'')}{3}\right)$$

$$\times\Bigg[\theta(t,t',t'')\mathrm{tr}\left(h_{e''}(0,t)\,\tau_i h_{e''}(t,t')\,\tau_j h_{e''}(t',t'')\,\tau_k h_{e''}(t'',1)\,\frac{\partial}{\partial h_{e''}(0,1)}\right)$$

$$+\theta(t,t'',t')\mathrm{tr}\left(h_{e''}(0,t)\,\tau_i h_{e''}(t,t'')\,\tau_k h_{e''}(t'',t')\,\tau_j h_{e''}(t',1)\,\frac{\partial}{\partial h_{e''}(0,1)}\right)$$

$$+\theta(t',t'',t)\mathrm{tr}\left(h_{e''}(0,t')\,\tau_j h_{e''}(t',t'')\,\tau_k h_{e''}(t'',t)\,\tau_i h_{e''}(t,1)\,\frac{\partial}{\partial h_{e''}(0,1)}\right)$$

$$+\theta(t',t,t'')\mathrm{tr}\left(h_{e''}(0,t')\,\tau_j h_{e''}(t',t)\,\tau_i h_{e''}(t,t'')\,\tau_k h_{e''}(t'',1)\,\frac{\partial}{\partial h_{e''}(0,1)}\right)$$

$$+\theta(t'',t,t')\mathrm{tr}\left(h_{e''}(0,t'')\,\tau_k h_{e''}(t'',t)\,\tau_i h_{e''}(t,t')\,\tau_j h_{e''}(t',1)\,\frac{\partial}{\partial h_{e''}(0,1)}\right)$$

$$+\theta(t'',t',t)\mathrm{tr}\left(h_{e''}(0,t'')\,\tau_k h_{e''}(t'',t')\,\tau_j h_{e''}(t',t)\,\tau_i h_{e''}(t,1)\,\frac{\partial}{\partial h_{e''}(0,1)}\right)\Bigg]\Bigg\} f_\gamma$$

$$=:[\hat{O}_{1,2,3}+\hat{O}_{2,31}+\hat{O}_{12,3}+\hat{O}_{1,23}+\hat{O}_{123}]f_\gamma. \tag{III.6}$$

The fact that the integrand of the terms involved in $\hat{O}_{12,3}$, $\hat{O}_{1,23}$, $\hat{O}_{2,31}$, and $\hat{O}_{123}$ vanishes if either of the cases $0<t=t'<1$, $0<t'=t''<1$, $0<t=t'=t''<1$ occurs is due to the fact that in this case in $\hat{O}_{12,3}$, $\hat{O}_{1,23}$, $\hat{O}_{2,31}$, and $\hat{O}_{123}$ we get a trace which contains $\tau_{(i}\tau_{j)}$, $\tau_{(j}\tau_{k)}$, and $\tau_{(k}\tau_{i)}$ contracted with ϵ^{ijk} which vanishes. {To see this recall that the functional derivative is

$$\delta h_e(A)/\delta A^i_a(x)=\frac{1}{2}\int_0^1 dt\Bigg[\frac{1}{2}\,\delta^{(3)}(e(t+),x)\dot{e}(t+)^a h_e(0,t)\,\tau_i h_e(t,1)$$

$$+\frac{1}{2}\,\delta^{(3)}(e(t-),x)\dot{e}(t-)^a h_e(0,t)\,\tau_i h_e(t,1)\Bigg]$$

(one sided derivatives and δ distributions). This expression is also correct if x is an endpoint of e [in which case there is only one term which survives in (III.7)], which results in the case that we consider $h_{e_1}\tau_j h_{e_2}$ instead of h_e, $e=e_1\circ e_2$, $x=e_1\cap e_2$ a point of analyticity, in a term involving $\tau_{(i}\tau_{j)}$.}

Given a triple e,e',e'' of (not necessarily distinct) edges of γ, consider the functions

$$x_{ee'e''}(t,t',t''):=\frac{e(t)+e'(t')+e''(t'')}{3}. \tag{III.7}$$

This function has the interesting property that the Jacobian is given by

$$3^3\,\det\left(\frac{\partial(x^1_{ee'e''},x^2_{ee'e''},x^3_{ee'e''})(t,t',t'')}{\partial(t,t',t'')}\right)=\epsilon_{abc}\dot{e}(t)^a\dot{e}'(t')^b\dot{e}''(t'')^a, \tag{III.8}$$

which is precisely the form of the factor that enters all the integrals in (III.6). This is why we have introduced the strange argument $(x+y+z)/3$.

We now consider the limit $\Delta_i,\Delta_i',\Delta_i''\to 0$. The idea is that all quantities in (III.6) are meaningful in the sense of functions on smooth connections and thus limits of functions as $\Delta\to 0$ are to be understood with respect to any Sobolev topology. The miracle is that the final function is again cylindrical and thus the operator that results in the limit has an extension to all of $\overline{\mathscr{A}/\mathscr{G}}$.

Lemma III.1: For each triple of edges e,e',e'' there exists a choice of vectors $\mathbf{n}_i,\mathbf{n}_i',\mathbf{n}_i''$ and a way to guide the limit $\Delta_i,\Delta_i',\Delta_i''\to 0$ such that

$$\int_{[0,1]^3} \det\left(\frac{\partial(x^a_{ee'e''})}{\partial(t,t',t'')}\right)\chi_\Delta(p,e)\chi_{\Delta'}(p,(e+e')/2)\chi_{\Delta''}(p,(e+e'+e'')/3)\hat{O}_{ee'e''} \qquad \text{(III.9)}$$

vanishes

(a) *if e,e',e'' do not all intersect p or*
(b) $\det(\partial(x^a_{ee'e''})/\partial(t,t',t''))_p=0$ *(which is a diffeomorphism invariant statement).*

Otherwise it tends to $1/8\,\mathrm{sgn}(\det(\partial(x^a_{ee'e''})/\partial((t,t',t'')))_p\hat{O}_{e,e',e''}(p)\Pi_{i=1}^3\Delta_i''$. *Here we have denoted by $\hat{O}_{ee'e''}(t,t',t'')$ the trace(s) involved in the various terms of (III.6).*

Remark: The idea that one should adapt the regularization to each triple of edges was first communicated to the author by Jurek Lewandowski. Its justification relies on the fact that the classical expression does not depend on the way we regularize. What is new here is to introduce even more parameters than in Ref. 10 to be adapted to a triple which simplifies the proofs. What is also new is that we introduced the $(x+y+z)/3$ argument which makes the proof especially clear. It should be mentioned, however, that different regularization schemes result in different operators (see, e.g., Ref. 4); on the other hand, the requirement of consistency of the dynamics of the theory as defined in Refs. 2 and 3 rules out the operator of Ref. 4.

Proof: If at least one of e,e',e'' does not intersect p, then, if we choose Δ_i, etc. smaller than some finite number Δ_0, (III.9) vanishes identically since the support of the characteristic functions is in a neighborhood around p which shrinks to zero with the Δ_i, etc.

So let us assume that all of e,e',e'' intersect p at parameter value t_0,t_0',t_0'' (this value is unique because the edges are not self-intersecting). Then we can write $e(t)=p+c(t-t_0)$, where c is analytic and vanishes at $\tau=t-t_0=0$. We have the case subdivision:
Case I: $\det(\partial(x^a_{ee'e''})/\partial(t,t',t''))_{t_0}=0$.
Case I(a): All of $\dot{c}(0),\dot{c}'(0),\dot{c}''(0)$ are colinear.
Case I(b): Two of $\dot{c}(0),\dot{c}'(0),\dot{c}''(0)$ are colinear and the third is linearly independent of them.
Case I(c): No two of $\dot{c}(0),\dot{c}'(0),\dot{c}''(0)$ are colinear.
Case II: $\det(\partial(x^a_{ee'e''})/\partial(t,t',t''))_{t_0}\neq 0$.
Notice that all vectors $\dot{c}(0),\dot{c}'(0),\dot{c}''(0)$ are nonvanishing by the definition of a curve.

We consider first case I. We exclude the trivial case that all three curves lie in a coordinate plane or line such that the determinant already vanishes for all finite values of the Δ's. Therefore there exist linearly independent unit vectors u,v,w (not necessarily orthogonal) in terms of which we may express c,c',c''.

In case I(a) we have an expansion of the form

$$\begin{aligned}
c(t)&=au(t+o(t''))+bv(t^m+o(t^{m+1}))+cw(t^n+o(t^{n+1})),\\
c'(t)&=au(t+o(t^2))+b'v(t^{m'}+o(t^{m'+1}))+c'w(t^{n'}+o(t^{n'+1})),\\
c''(t)&=a''u(t+o(t^2))+b''v(t^{m''}+o(t^{m''+1}))+c''w(t^{n''}+o(t^{n''+1})),
\end{aligned} \qquad \text{(III.10)}$$

where $a,b,c,a',b',c',a'',b'',c''$ are real numbers with $aa'a''\neq 0$ and at least one of the b's and c's being different from zero (also not for instance $b=c=b'=c'=0$). Furthermore, $m,m',m'',n,n',n''\geqslant 2$. The characteristic functions have support in coordinate cubes spanned by the vectors $\mathbf{n}_i,\mathbf{n}_i',\mathbf{n}_i''$. Now, since u,v,w are linearly independent, we may simply *choose*, for instance, $\mathbf{n}_i:=u$, $\mathbf{n}_i':=v$, $\mathbf{n}_i'':=w$. It follows then and from the fact that $0\leqslant\chi\leqslant 1$ that

$$\begin{aligned}
&\chi_\Delta(p,e)\chi_{\Delta'}(p,(e+e')/2)\chi_{\Delta''}(p,(e+e'+e'')/3)\\
&\quad=\tilde{\chi}_\Delta(0,c)\tilde{\chi}_{\Delta'}(0,(c+c')/2)\tilde{\chi}_{\Delta''}(0,(c+c'+c'')/3)\\
&\quad\leqslant\theta_{\Delta_1}(\langle c,u\rangle)\,\theta_{\Delta_1'}(\langle(c+c')/2,v\rangle)\,\theta_{\Delta_1''}(\langle(c+c'+c'')/3,w\rangle).
\end{aligned}\tag{III.11}$$

From the explicit expansions of c,c',c'' we conclude that (III.11) has the bound

$$\theta_{\delta_1\Delta_1}(t)\,\theta_{\delta_1'\Delta_1'}(t')\,\theta_{\delta_1''\Delta_1''}(t'')\tag{III.12}$$

for some sufficiently large numbers $\delta_1,\delta_1',\delta_1''$. On the other hand we also see from the explicit expansion of $|\det(\partial(x^a_{ee'e''})/\partial(t,t',t''))|$ around t_0 that it is bounded by $M(|t|^k+|t'|^k+|t''|^k)$ where M is a positive number and where $k=\min(m+n',m+n'',m'+n,m'+n'',m''+n,m''+n')-2\geqslant 2$.

The prescription of how to guide the limit in case I(a) is then to synchronize $\Delta_1=\Delta_1'=\Delta_1''=\Delta$ and to take the limit $\Delta\to 0$ first. The integral is at least of order Δ^5 while we divide only by an order of Δ^3 so that the result vanishes.

In case I(b) we have an expansion of the form (let w.l.g. c,c' have collinear tangents)

$$\begin{aligned}
c(t)&=au(t+o(t^2))+bv(t^m+o(t^{m+1}))+cw(t^n+o(t^{n+1})),\\
c'(t)&=au(t+o(t^2))+b'v(t^{m'}+o(t^{m'+1}))+c'w(t^{n'}+o(t^{n'+1})),\\
c''(t)&=a''v(t+o(t^2))+b''u(t^{m''}+o(t^{m''+1}))+c''w(t^{n''}+o(t^{n''}+1)).
\end{aligned}\tag{III.13}$$

We now argue as above and find that the product of the characteristic functions can be estimated by

$$\theta_{\delta_1\Delta_1}(t)\,\theta_{\delta_1'\Delta_1'}(t')\,\theta_{\delta_2''\Delta_2''}(t'')$$

while the determinant can be estimated as above just that k is now given by $k=\min(m,m',m'',n,n',n'')-1\geqslant 1$.

The prescription is now $\Delta_1=\Delta_1'=\Delta_2'':=\Delta\to 0$ first and we conclude that the integral is at least of order Δ^4 while we divide again only by Δ^3 such that the limit vanishes.

In case I(c) finally we have an expansion of the form

$$\begin{aligned}
c(t)&=au(t+o(t^2))+bv(t^m+o(t^{m+1}))+cw(t^n+o(t^{n+1})),\\
c'(t)&=av(t+o(t^2))+b'v(t^{m'}+o(t^{m'+1}))+c'w(t^{n'}+o(t^{n'+1})),\\
c''(t)&=a''u(t+o(t^2))+b''v(t+o(t^2))+c''w(t^{n''}+o(t^{n''+1})).
\end{aligned}\tag{III.14}$$

This time we estimate the product of the characteristic functions for instance by

$$\theta_{\delta_1\Delta_1}(t)\,\theta_{\delta_2'\Delta_2'}(t')\,\theta_{\delta_2''\Delta_2''}(t''),$$

while the determinant can be estimated as above and k is given by $k=\min(m,m',n,n',n'')-1\geqslant 1$ so that we have actually the same situation as in case I(b) upon synchronizing this time $\Delta_1=\Delta_2'=:\Delta_2''=:\Delta\to 0$.

As for case II we observe that the nonvanishing of the functional determinant at p implies that the map $x_{ee'e''}$ is actually invertible in a neighborhood of p by the inverse function theorem. In other words, there is only one point (t_0,t_0',t_0'') such that $x_{ee'e''}(t_0,t_0',t_0'')=p$. Moreover, since the determinant is nonvanishing at p, all three edges must be distinct from each other. It follows now from our choice of edges that p must be a vertex $v=e\cup e'\cup e''$ of γ in order that the result is nonvanishing and thus from the choice of parametrization $t_0=t_0'=t_0''=0$.

Therefore, if we take the limit $\Delta_i''\to 0$ first in any order, then the condition $\chi_{\Delta''}(p,x_{ee'e''})=1$ will actually imply $\chi_\Delta(p,e)=\chi_{\Delta'}(p,(e+e')/2)=1$ for small enough Δ_i'' so that we can take

these characteristic functions out of the integral and replace them by 1 if p is a common vertex of all three edges. Also we can replace the operator $\hat{O}_{ee'e''}(t,t',t'')$ by $\hat{O}_{ee'e''}(v)$. This holds only if the triple intersects in p.

If not all of e,e',e'' intersect in p, then the limit will vanish anyway if we take a suitable limit of the Δ_i as we have shown before. We can account for that case by replacing $\chi_\Delta(p,e),\chi_{\Delta'}(p,(e+e')/2)$ by $\chi_\Delta(p,v)\chi_{\Delta'}(p,v)$. Here v is the common vertex at which the distinct e,e',e'' must be incident, otherwise they could not even pass through a small enough neighborhood of p. We can also assume that all three edges have linearly independent tangents at v and expand still around $t=0$. The remaining integral divided by $\Delta_1''\Delta_2''\Delta_3''$ then tends to

$$\int_{[0,1]^3} d^3t\ \det\left(\frac{\partial x_{ee'e''}}{\partial t}\right)\delta^{(3)}(p,x_{ee'e''})=s(e,e',e'')\int_{C_{ee'e''}} d^3x\ \delta^{(3)}(p,x)=\frac{1}{8}\,s(e,e',e''), \tag{III.15}$$

where

$$s(e,e',e'')_v:=\mathrm{sgn}(\det(\dot{e}(0),\dot{e}'(0),\dot{e}''(0))). \tag{III.16}$$

The factor $\frac{1}{8}$ is due to the fact that in the limit $\Delta''\to 0$ we obtain an integral over $C(e,e',e'')$, the cone based at p and spanned by $\dot{e}(0),\dot{e}'(0),\dot{e}''(0)$ where the orientation is taken to be positive. This integral just equals $\int_{\mathbb{R}^3_+} d^3t\ \delta(0,t)\,\delta(0,t')\,\delta(0,t'')=\frac{1}{8}$ as one can easily check. This furnishes the proof. □

We conclude that (III.6) reduces to (in particular, the operators $\hat{O}_{12,3}\hat{O}_{1,23}\hat{O}_{2,31}\hat{O}_{123}$ drop out)

$$\lim_{\Delta''\to 0}\hat{E}(p,\Delta,\Delta',\Delta'')f=\sum_{e,e',e''}\frac{il_p^6 s(e,e',e'')_v}{8\cdot 3!\ \mathrm{vol}(\Delta)\mathrm{vol}(\Delta')}\,\chi_\Delta(p,v)\chi_{\Delta'}(p,v)\hat{O}_{e,e',e''}(0,0,0),$$

where v on the right-hand side is the intersection point of the triple of edges and it is understood that we only sum over such triples of edges which are incident at a common vertex. There is no factor of 3^3 missing because it cancels against a similar factor in $\mathrm{vol}(\Delta'')$. Moreover,

$$\hat{O}_{e,e',e''}(0,0,0)=\epsilon_{ijk}X^i_{e''}X^j_{e'}X^k_e \quad\text{and}\quad X^i_e:=X^i(h_e(0,1)):=\mathrm{tr}\left(\tau_i h_e(0,1)\,\frac{\partial}{\partial h_e(0,1)}\right) \tag{III.17}$$

is a right invariant vector field in the τ_i direction of su(2), that is, $X(hg)=X(h)$ (This important observation, which is fundamental for all that follows, is due to Abhay Ashtekar and Jurek Lewandowski.) We also have extended the values of the sign function to include 0, which takes care of the possibility that one has triples of edges with linearly dependent tangents.

The final step consists in choosing $\Delta=\Delta'$ and taking the square root of the modulus. We replace the sum over all triples incident at a common vertex $\Sigma_{e,e',e''}$ by a sum over all vertices followed by a sum over all triples incident at the same vertex $\Sigma_{v\in V(\gamma)}\Sigma_{e\cap e'\cap e''=v}$. Now, for small enough Δ and given p, at most one vertex contributes, that is, at most one of $\chi_\Delta(v,p)\neq 0$ because all vertices have finite separation. Then we can take the relevant $\chi_\Delta(p,v)=\chi_\Delta(p,v)^2$ out of the square root and take the limit which results in

$$\begin{aligned}
\hat{V}(R)_\gamma&=\int_R d^3p\,\widehat{\sqrt{\det(q)(p)}}_\gamma=\int_R d^3p\ \hat{V}(p)_\gamma,\\
\hat{V}(p)_\gamma&=l_p^3\sum_{v\in V(\gamma)}\delta^{(3)}(p,v)\hat{V}_{v,\gamma},\\
\hat{V}_{v,\gamma}&=\sqrt{\left|\frac{i}{3!\cdot 8}\sum_{e,e',e''\in E(\gamma),e\cap e'\cap e''=v}s(e,e',e'')q_{ee'e''}\right|},\\
q_{ee'e''}&=\epsilon_{ijk}X^i_eX^j_{e'}X^k_{e''},
\end{aligned} \tag{III.18}$$

where we could switch the order of the X's because a triple contributes only if the corresponding edges are distinct and so the X's commute.

Expression (III.18) is the final expression for the volume operator and coincides precisely with the expression found in Refs. 5 and 10 while it is genuinely different from the one found in Ref. 4 as pointed out in Ref. 10. Note that the final expression is manifestly diffeomorphism covariant. Although the procedure of adapting the limiting to a given triple of edges is somewhat nonstandard, there is an argument in favor of such a procedure: the discussion in Lemma III.1 reveals that any other regularization which would result in a finite contribution for the case where $s(e,e'e'')$ is zero would necessarily depend on the higher-order intersection characteristics of a triple of edges. However, since such a quantity is not diffeomorphism covariant, which is inacceptable, the dependence must be trivial, that is, a constant [this is precisely what happens in (III.4) according to (III.11)]. While there is no *a priori kinematical* reason to prefer one operator over the other, there is a *dynamical* reason: the volume operator can be seen as an essential ingredient in the regularization of the Lorentzian Wheeler–DeWitt constraint operator.[2,3] The fact that (III.18) contains $s(e,e',e'')$ is the precise reason for this operator to be anomaly free! Therefore, the regularization leading to (III.18) is the one singled out by the dynamics of the theory!

IV. SPECTRAL ANALYSIS

In this section we summarize a number of results due to Abhay Ashtekar and Jurek Lewandowski obtained in their series of papers.[5,10,15] We have included them here for the sake of self-containedness of the present paper. More specifically, the cylindrical consistency of the family of volume operators $\hat{V}_\gamma$ as defined in Ref. 15 and in the present paper, the self-adjointness of the corresponding projective limit, and the fact that the spectrum of the volume operator is discrete were first observed in Ref. 10. The proof of these properties given in Ref. 10 uses methods developed in Refs. 1, 5, 10, and 15.

This section is subdivided into three parts. First we prove that the family of operators derived in (III.18) defines a linear unbounded operator on $\mathscr{H}$. Next we show that the operator is symmetric, positive semi-definite, and admits self-adjoint extensions, and finally we show that its spectrum is discrete and that the operator so defined is anomaly free.

A. Cylindrical consistency

What we have obtained in (III.18) is a family of operators $(\hat{V}(R)_\gamma, D_\gamma)_{\gamma\in\Gamma}$. That is not enough to show that this family of cylindrical projections ''comes from'' a linear operator on $\mathscr{H}$. As proved in Ref. 15 for this to be the case we need to check that whenever $\gamma\subset\gamma'$, then we have the following.

(1) $p^*_{\gamma\gamma'} D_\gamma \subset D_{\gamma'}$, where $p_{\gamma\gamma'}$ is the restriction from γ' to γ. This condition makes sure that the operator defined on bigger graphs can be applied to functions defined on smaller graphs.
(2) $(\hat{V}(R)_{\gamma'})_{|\gamma} = \hat{V}(R)_\gamma$. This is the condition of cylindrical consistency and says that the operator on bigger graphs equals the operator on smaller graphs when restricted to functions thereon.

A graph $\gamma\subset\gamma'$ can be obtained from a bigger graph γ' by a finite series of steps consisting of the following basic ones:

(i) remove an edge from γ',
(ii) join two edges e',e'', such that $e'\cap e''$ is a point of analyticity, to a new edge $e=e'\circ(e'')^{-1}$, and
(iii) reverse the orientation of an edge.

Clearly, a dense domain for $\hat{V}(R)_\gamma$ is given by $D_\gamma := \mathrm{Cyl}^3_\gamma(\overline{\mathscr{A}/\mathscr{G}})$. This choice trivially satisfies requirement (1) since functions which just do not depend on some arguments or only on special combinations $h_e = h_{e'} h_{e''}$, $h_{e'} = h_e^{-1}$ are still thrice continuously differentiable if the original function was [here we have used the fact that SU(2) is a Lie group, that is, group multiplication and taking inverses is an analytic map].

Next, let us check cylindrical consistency. Consider first the case (i) that γ does not depend on an edge e on which γ' does. Then clearly $X_e^i f_\gamma = 0$ for any function cylindrical with respect to γ and so in the sum over triples over vertices in (III.18) the terms involving e drop out.

Next consider the case (ii). If $e = e' \circ (e'')^{-1}$ is an edge of γ and e', e'' are edges of γ' where $v := e' \cap e''$ is a point of analyticity for γ while for γ' it is not, then while v is a vertex for γ', it is only a pseudo-vertex for γ, and so in $\hat{V}(D)_\gamma$ there is no term corresponding to v. On the other hand, since the vertex v is a pseudo vertex for γ, it is in particular only two-valent and so the corresponding term in $\hat{V}(D)_{\gamma'}$ drops out. Likewise, if v is a vertex for γ at which the outgoing edge e is incident, then from right invariance of the vector field we have $X_e = X_{e' \circ (e'')^{-1}} = X_{e'}$ and so at vertices that belong to both γ and γ' the corresponding vertex operators coincide.

Finally, case (iii) is actually excluded by our unambiguous choice of orientation.

We conclude that there exists an operator $(\hat{V}(R), D)$ on $\mathscr{H}$ which is densely defined on $D = \mathrm{Cyl}^3(\overline{\mathscr{A}/\mathscr{G}})$.

B. Symmetry, positivity, and self-adjointness

Notice that the vector field iX_e is symmetric on $\mathscr{H}_\gamma$, the completion of $\mathrm{Cyl}^1_\gamma(\overline{\mathscr{A}/\mathscr{G}})$ with respect to $\mu_{0,\gamma}$, e an edge of γ, because the Haar measure is right invariant. It follows from the explicit expression (III.18) in terms of the iX_e that all the projections $\hat{V}(R)_\gamma$ are symmetric. In this special case (namely, the volume operator leaves the space D_γ invariant) this is enough to show that $\hat{V}(R)$ is symmetric on D.

Furthermore, all $\hat{V}(R)_\gamma$ are positive semi-definite by inspection so that $\hat{V}(R), D$ is a densely defined, positive semi-definite, and symmetric operator. It follows that it has self-adjoint extensions, for instance, its Friedrich extension.

C. Discreteness and anomaly-freeness

The operator $\hat{V}(D)$ has the important property that it leaves the dense subset $\mathrm{Cyl}^\infty_\gamma(\overline{\mathscr{A}/\mathscr{G}}) \subset \mathscr{H}$ invariant, separately for each $\gamma \in \Gamma$. Moreover, recall that $\mathscr{H}$ possesses a convenient basis, called the spin-network basis in the sequel.[29,30,13]

Let us recall the most important features of that basis. Given a graph γ, let us associate with each edge $e \in E(\gamma)$ a spin quantum number $j_e > 0$. Also, with each vertex $v \in V(\gamma)$ we associate a certain contraction matrix c_v as follows: if π_j is the irreducible representation of SU(2) corresponding to spin j, then form the tensor product $\otimes_{e \in E(\gamma)} \pi_{j_e}(h_e)$ and for each vertex v contract the indices A of the matrices $\pi_{j_e}(h_e)_{AB}$ for all e incident at v in a gauge-invariant fashion. We obtain a gauge-invariant function $T_{\gamma,\mathbf{j},\mathbf{c}}(A)$ called a spin-network function. It turns out that, given $\gamma, \mathbf{j}$, there are only a finite number of linearly independent $\mathbf{c}$ compatible with $\gamma, \mathbf{j}$. Moreover, one can show that spin-network functions defined on different graphs are orthogonal and even on the same graph they are orthogonal whenever the vectors $\mathbf{j}$ do not equal each other. It follows that there is an orthonormal basis

$$\langle T_{\gamma,\mathbf{j},\mathbf{c}}, T_{\gamma',\mathbf{j}',\mathbf{c}'} \rangle = \delta_{\gamma,\gamma'} \delta_{\mathbf{j},\mathbf{j}'} \delta_{\mathbf{c},\mathbf{c}'} .$$

Now it is obvious that the operator $\hat{V}(R)$ leaves the finite-dimensional vector space $U_{\gamma,\mathbf{j}}$ spanned by spin-network states compatible with $\gamma, \mathbf{j}$ invariant. The matrix

$$(V(R)_{\gamma\mathbf{j}})_{\mathbf{c},\mathbf{c}'} := \langle T_{\gamma,\mathbf{j},\mathbf{c}} | \hat{V}(R) | T_{\gamma,\mathbf{j},\mathbf{c}'} \rangle \tag{IV.1}$$

is therefore finite dimensional, positive semi-definite, and symmetric. The task of computing its eigenvalues therefore becomes a problem in linear algebra!

Next, since from (III.18)

$$\hat{V}(R)_\gamma = l_p^3 \sum_{v \in V(\gamma) \cap R} \hat{V}_{v,\gamma}, \tag{IV.2}$$

and since $\hat{V}_{v,\gamma}$ involves only those $e \in E(\gamma)$ with $v \in e$, we find that $\hat{V}_{v,\gamma}$ can only change the entry c_v in $\mathbf{c}$. In other words, $[\hat{V}_{v,\gamma}, \hat{V}_{v',\gamma}] = 0$ and each $\hat{V}_{v,\gamma}$ can be diagonalized separately.

Finally, since the spins j_e only take discrete values, it follows that $\mathscr{H}_\gamma$ has a countable basis and the spectrum that $\hat{V}(R)$ attains on D_γ is therefore pure point. Let us check whether this is the complete spectrum. Assume it was not and let $\hat{P}$ be the spectral projection on the rest of the spectrum [the existence of the spectral projections relies on the fact that $\hat{V}(R)$ is self-adjoint and not only symmetric]. It follows that $u=\hat{P}v$ is orthogonal to D_γ where v is any vector in $\mathscr{H}_\gamma$. But D_γ is dense in $\mathscr{H}_\gamma$ and so we find for every $\epsilon>0$ a $\phi\in D_\gamma$ with $\|u-\phi\|<\epsilon$. Now we have from orthogonality $\epsilon^2>\|u-\phi\|^2=\|u\|^2+\|\phi\|^2>\|u\|^2$ and so $u=0$. This shows that the complete spectrum is already attained on D_γ. It is purely discrete as well in the physical sense that it is attained on a countable basis so that the eigenvalues only comprise a countable set. In a mathematical sense one would need to check that there are no accumulation points and no eigenvalues of infinite multiplicity. To settle this question it would be enough to show that the formula for the eigenvalue is an unbounded function of $j:=\Sigma_{e\in E(\gamma)}j_e$ because every countably infinite set of j's corresponding to different choices of **j** diverges. This is one possible future application of the explicit matrix element formulas which we derive in the next section.

Last, we wish to show that the volume operators are anomaly free (given the fact that we have largely adapted our regularization to a graph, this statement is far from trivial). By this we mean the following: given any two open sets $R_1,R_2\subset\Sigma$ we have vanishing Poisson brackets $\{V(R_1),V(R_2)\}=0$ because the functionals $V(R)$ depend on the momentum variable $E^a_i(x)$ only. Now, given a function f cylindrical with respect to a graph γ, it is not at all obvious any more that $[\hat{V}(R_1),\hat{V}(R_2)]f=0$ for any such f. Fortunately, given the above characterization of the spectrum, the commutator can be easily proved to vanish on cylindrical functions. To see this, note that the above results imply that if we choose any region $R(\gamma)$ such that $\gamma\subset R(\gamma)$, then there exists an eigenbasis of $\mathscr{H}_\gamma$ of $\hat{V}(R(\gamma))$. Now consider any region R. Since all regions are open by construction, all regions fall into equivalence classes with respect to γ: R,R' are equivalent if they contain the same vertices of γ (any vertex either has a neighborhood which lies completely inside R or it lies outside). Therefore any two $\hat{V}(R),\hat{V}(R')$ differ at most by some of the $\hat{V}_{v,\gamma}$, all of which are contained in the expression for $\hat{V}(R(\gamma))$. Since the $\hat{V}_{v,\gamma}$ commute, the eigenbasis of $\hat{V}(R(\gamma)$ is a simultaneous eigenbasis of all $\hat{V}_{v,\gamma}$ for all $v\in V(\gamma)$ and so this eigenbasis is a simultaneous eigenbasis of all $\hat{V}(R)_\gamma$. Since all $\mathscr{H}_\gamma$ are orthogonal, we have a simultaneous eigenbasis for all $\hat{V}(R)$.

While it is in general not enough to verify that two self-adjoint, unbounded operators commute on a dense domain (rather, by definition, we have to check that the associated spectral projections commute), in our case we are done because the spectral projections *are* the projections on the various D_γ because the point spectrum is already the complete spectrum. Thus we have verified that the commutator algebra mirrors the classical Poisson algebra.

V. THE COMPLETE SET OF MATRIX ELEMENTS

In this final section we are going to compute (IV.1) in a spin-network basis for each $\gamma,\mathbf{j},\mathbf{c},\mathbf{c}',R$. The advantage of our approach as compared to the ones proposed already in the literature[6] will be obvious: in Ref. 6 one works with an overcomplete and nonorthogonal set of states. This prevents one from giving a unified treatment as it is done here and only allowed one to find a formula for the eigenvalues in a few simple cases. More generally, one has to check all the time the linear independence of the states and can compute the matrix elements only in a case-by-case analysis.

In the next subsection we show in more detail a result which follows immediately from Refs. 1, 5, and 10: namely, that the problem of computing the matrix elements of the volume operator reduces to that of computing the matrix elements of a homogeneous polynomial of degree three of spin operators for a spin system.

This opens access to powerful techniques well known from the quantum theory of angular momentum for spin systems. Then we will show how the actual computation can be done by viewing the problem as a task in spin recoupling theory and that all the matrix elements can be written as algebraic functions of $6j$-symbols for which a closed formula exists (Racah formula). Finally we will diagonalize the volume operator for an infinite number of (very special) graphs.

A. The left regular representation and the spin-network representation

Consider a spin-network state $T_{\gamma,\mathbf{j},\mathbf{c}}(A)$. This is a state for the connection representation $L_2(\overline{\mathscr{A}/\mathscr{G}},d\mu_0)$ in the sense that the (equivalence classes modulo gauge transformations of) connection operators are diagonal in this representation. Notice that a spin-network state is gauge invariant so that it can be viewed alternatively as a function of $[A]$, the gauge equivalence class of A. Here we will use the fact that $d\mu_0$ extends to $\overline{\mathscr{A}}$ (Ref. 26) and reduces to the measure indicated in the Introduction when integrating gauge-invariant functions. Consider the usual Dirac (generalized) states δ_A defined by $\overline{\delta_A}(A'):=\delta_{\mu_0}(A,A')$ where δ_{μ_0} is the δ distribution with respect to μ_0 (Ref. 13) and $A,A'\in\overline{\mathscr{A}}$. We define the *spin-network representation* by

$$\delta_A(T_{\gamma,\mathbf{j},\mathbf{c}}):=\int_{\overline{\mathscr{A}}} d\mu_0(A')\,\overline{\delta_A(A')}\,T_{\gamma,\mathbf{j},\mathbf{c}}(A')=T_{\gamma,\mathbf{j},\mathbf{c}}(A)=:\langle A|\gamma,\mathbf{j},\mathbf{c}\rangle. \tag{V.1}$$

So far this is only notation. The advantage of this notion will become transparent upon proving that the states $|\gamma,\mathbf{j},\mathbf{c}\rangle$ are nothing else than the usual angular momentum states associated with an abstract spin system.

To see this, let v be a vertex of γ and $e_1,\ldots,e_n$ be the edges of γ incident at v, and we have chosen orientations such that all of them are outgoing at v. The spin-network state $T_{\gamma,\mathbf{j},\mathbf{c}}(A)$ can be written

$$T_{\gamma,\mathbf{j},\mathbf{c}}(A)=(c_v)_{m_1\ldots m_n}\prod_{i=1}^{n}(\pi_{j_{e_i}}(h_{e_i}(A)))_{m_i m_i'}(M_v)_{m_1'\ldots m_n'}=\mathrm{tr}\left(c_v\cdot\bigotimes_{i=1}^{n}\pi_{j_{e_i}}(h_{e_i}(A))\cdot M_v\right), \tag{V.2}$$

where c_v is the vertex contractor corresponding to v which contracts the indices corresponding to the starting points of the e_i and M_v contracts the indices corresponding to the endpoints (recall that the holonomy is a path-ordered exponential with the smallest parameter value to the left). Note that c_v is $\mathbb{C}$-valued while M_v still depends on the rest of the graph.

Consider a local gauge transformation at v, that is, $h_{e_i}\to g h_{e_i}$ for some $g\in\mathrm{SU}(2)$. Then (V.2) becomes $\mathrm{tr}(c_v\cdot\otimes_{i=1}^{n}\pi_{j_{e_i}}(g)\cdot\otimes_{i=1}^{n}\pi_{j_{e_i}}(h_{e_i}(A))\cdot M_v)$. In order for this to be gauge invariant, notice that the tensor product representation $\otimes_i\pi_{j_{e_i}}(g)$ can be written as a direct sum of orthogonal irreducible representations $\pi_j(g)$, and so we just need to choose c_v to be proportional to one of the various equivalent (but orthogonal) trivial representations $\pi_0(g)=\pi_0(1)$ contained in that decomposition (see Ref. 13 for more details) in order for (V.2) to be gauge invariant. This is precisely what a spin-network state is.

The point is now that

$$\prod_{i=1}^{n}(\pi_{j_{e_i}}(h_{e_i}(A)))_{m_i m_i'}=:\langle A|(m_1,j_1),\ldots,(m_n,j_n);m_1',\ldots,m_n'\rangle \tag{V.3}$$

transforms *precisely* as the usual angular momentum eigenstates

$$|(m_1,j_1),\ldots,(m_n,j_n);k_1,\ldots,k_m\rangle:=\prod_{i=1}^{n}|m_i,j_i;k_1,\ldots,k_m\rangle$$

of an abstract spin system of n spins $j_1,\ldots,j_n$ under rotations (see, e.g., Ref. 31). This is because $|(m,j);k\rangle$ transforms as $\hat{U}(g)|(m,j);k\rangle=\pi_j(g)_{m,m'}|(m',j);k\rangle$ by definition, where $\hat{U}(g)$ is a unitary representation of the rotation group. Here $k_1,\ldots,k_m$ are some additional quantum numbers of observables commuting with the operators $\hat{J}_i$ which in our case coincide with the $m_1',\ldots,m_n'$. In other words, the left regular representation $L_g f(h_e)=f(gh_e)$ that we are dealing with in the connection representation can be seen to be equivalent with the representation $\hat{U}(g)$ of the spin-network representation.

Let us now couple the spins $j_1,\ldots,j_n$ to resulting spin $j=0$ and denote a particular state with zero angular momentum by $|0\rangle$. We claim that up to a constant

$$(c_v)_{m_1..m_n}=\langle (m_1,j_1),\ldots,(m_n,j_n);k_1,\ldots,k_m|0\rangle, \tag{V.4}$$

where the inner product is now to be understood in the angular momentum Hilbert space of the abstract spin system. In other words, the c_v are just usual Clebsh–Gordan coefficients. The proof is easy. We have

$$\begin{aligned}(c_v)_{m_1\cdots m_n}\prod_{i=1}^{n}\pi_{j_i}(g)_{m_i m_i'}(g)&=\langle \hat{U}(g)((m_1',j_1),\ldots,(m_n',j_n);k_1,\ldots,k_m)|0\rangle\\ &=\langle (m_1',j_1),\ldots,(m_n',j_n);k_1,\ldots,k_m|\hat{U}(g^{-1})0\rangle=(c_v)_{m_1'\cdots m_n'},\end{aligned}$$

where we have used unitarity of the group and of the representation and that $\hat{U}(g)|0\rangle=|0\rangle$ is rotation invariant. The factor of proportionality is seen to equal unity because $c_v^2=1$ and since $\Sigma_{m_1\cdots m_n}|(m_1,j_1)\cdots(m_n,j_n);k_1\cdots k_m\rangle\langle(m_1,j_1)\cdots(m_n,j_n);k_1\cdots k_m|=1$ due to completeness and the Wigner–Eckart theorem.[31]

Next, consider the self-adjoint right invariant vector fields $Y_e:=-i/2X_e$. We have $[X^i,X^j]=-2\epsilon^{ijk}X^k$ and so $[Y^i,Y^j]=i\epsilon^{ijk}Y^k$, which is the usual angular momentum algebra. It follows that [we use a dual interpretation of the SU(2) indices $A,B,C,\ldots$, which we may choose to take values $\pm\frac{1}{2}$ and so can be interpreted to be the eigenvalues of the three-component of angular momentum]

$$\begin{aligned}\langle j=\tfrac{1}{2},C|Y_e^j h_e(A)_{CD}&=\langle j=\tfrac{1}{2},C|(-i/2)(\tau_j h_e(A))_{CD}\\ &=(i/2)\langle(\tau_j)_{EC}(\tfrac{1}{2},C)|h_e(A))_{ED}\\ &=(i/2)\,\frac{d}{dt_{t=0}}\langle\hat{U}(\exp(t\tau_j))(\tfrac{1}{2},E)|h_e(A))_{ED}\\ &=\langle\tfrac{1}{2},E|J_j h_e(A)_{ED},\end{aligned} \tag{V.5}$$

and so by multilinearity of the tensor product representation we find due to self-adjointness of J_I (set $Y_I:=Y_{e_I}$)

$$\begin{aligned}Y_I^j T_{\gamma,\mathbf{j},\mathbf{c}}(A)&=\frac{i}{2}\,\frac{d}{dt_{t=0}}\langle A|\gamma,\mathbf{j},\mathbf{m};\mathbf{m}'\rangle\langle\mathbf{j},\mathbf{m}|\hat{U}(\exp(-t\tau_j))_I 0\rangle(M_v)_{m_1'\cdots m_n'}\\ &=\langle A|\gamma,\mathbf{j}_v,\mathbf{m};\mathbf{m}'\rangle\langle\mathbf{j}_v,\mathbf{m}|J_I^j 0\rangle(M_v)_{m_1'\cdots m_n'},\end{aligned} \tag{V.6}$$

where $\mathbf{j}_v$ comprises the components of $\mathbf{j}$ which correspond to the edges incident at v.

Since spin-network states are thus characterized by the various zero-angular momentum eigenstates $|0\rangle$ of the abstract spin system, there is a one-to-one correspondence between the possible choices of c_v and $|0\rangle$. So let $|0\rangle$ correspond to c_v and $|0'\rangle$ to c_v'. Let $p(\mathbf{Y})$ be any polynomial of the Y_I^i corresponding to the vertex v. Then we have for its matrix elements

$$\begin{aligned}\langle T_{\gamma,\mathbf{j},\mathbf{c}}|p(\mathbf{Y})|T_{\gamma,\mathbf{j},\mathbf{c}'}\rangle&=\int_{\mathcal{M}\mathcal{G}}d\mu_0(A)\overline{\langle\mathbf{j}_v,\mathbf{m}|0\rangle\langle A|\gamma,\mathbf{j}_v,\mathbf{m};\mathbf{m}'\rangle(M_v)_{m_1'\cdots m_n'}}\langle\mathbf{j}_v,\overline{\mathbf{m}}|p(\mathbf{J})0'\rangle\\ &\quad\times\langle A|\gamma,\mathbf{j}_v,\overline{\mathbf{m}};\overline{\mathbf{m}}'\rangle(M_v)_{\overline{m}_1'\cdots\overline{m}_n'}\\ &=\overline{\langle\mathbf{j}_v,\mathbf{m}|0\rangle}\langle\mathbf{j}_v,\mathbf{m}|p(\mathbf{J})^\dagger 0'\rangle\prod_{v'\neq v}\delta_{c_{v'},c_{v'}'}\\ &=\langle 0|p(\mathbf{J})^\dagger 0'\rangle\prod_{v'\neq v}\delta_{c_{v'},c_{v'}'}=\langle p(\mathbf{J})0|0'\rangle\prod_{v'\neq v}\delta_{c_{v'},c_{v'}'}.\end{aligned} \tag{V.7}$$

Here we have used (V.6) in the first step, the orthonormality of the spin-network states in the second step, and in the last step we have again recalled that $\Sigma_{\mathbf{m}}|\mathbf{j}_v,\mathbf{m}\rangle\langle\mathbf{j}_v,\mathbf{m}|=1$ is the identity on the abstract angular momentum Hilbert space labeled by the spins $\mathbf{j}_v$ [completeness, notice that we sum over $\mathbf{m}$ in (V.7)].

Expression (V.7) is a huge simplification: in order to compute the matrix elements of the volume operator it is enough to compute the matrix elements of the angular momentum operator polynomial $\epsilon_{ijk}J^i_e J^j_{e'} J^k_{e''}$ between states that have zero angular momentum coming from $\mathbf{j}_v$. The next subsection is devoted to this task.

B. Recoupling theory for *n* angular momenta

The first task is to label all the linearly independent states $|0\rangle$ which correspond to the coupling of n angular momenta $j_1,\ldots,j_n$ to zero angular momentum. This is a well-known problem in the quantum theory of angular momentum and runs under the name recoupling theory. We review here what we need for our computation.

The states $|\mathbf{j},\mathbf{m}\rangle$ are a complete basis for a spin system consisting of n angular momenta. In this basis the $2n$ mutually commuting operators $(J^i_I)^2, J^3_I$ are diagonal with eigenvalues $j_I(j_I+1), m_I$.

We are obviously interested in a basis in which the square of the operator of total angular momentum $J:=J_1+\cdots+J_n$ and its three-component are diagonal with eigenvalues $j(j+1), m$. In order to label that basis we need $2(n-1)$ more quantum numbers of mutually commuting operators and commuting with J^2, J_3. The n operators J^2_I are readily verified to satisfy these conditions but we need $n-2$ more. In order to motivate our choice notice that $\hat{V}_{v,\gamma}$ is the square root of the modulus of $i(\frac{3}{2})^3\frac{1}{4}\Sigma_{I<J<K}\epsilon(e_I,e_J,e_K)q_{IJK}$ where

$$\tfrac{1}{4}q_{IJK}:=\tfrac{1}{8}\epsilon_{ijk}X^i_I X^j_J X^k_K=[Y^i_I Y^i_J,\ Y^j_J Y^j_K]=\tfrac{1}{4}[(Y^i_{IJ})^2,(Y^j_{JK})^2],$$

where $Y_{IJ}:=Y_I+Y_J$. Here we have used total antisymmetry of $\epsilon(e_I,e_J,e_K)$, $\hat{q}_{IJK}$ and the fact that $[X_I,\ X_J]=0$, $I\neq J$, in order to get rid of 3! and in order to sum only over $I<J<K$. This observation {i.e., the fact that the third-order polynomial $\mathrm{tr}(X_I[X_J,\ X_K])$ in the X can be written as a commutator of two second-order polynomials $\mathrm{tr}(X_I X_J)$ which are gauge invariant, also made independently by Abhay Ashtekar and Jurek Lewandowski} urges us to study the operator

$$\hat{q}_{IJK}:=[J^2_{IJ},\ J^2_{JK}],\quad \text{where}\quad J_{IJ}=J_I+J_J, \tag{V.8}$$

and thus it would be convenient if we could work in a basis in which the J_{IJ} also were diagonal. Clearly we cannot achieve this for all $n(n-1)/2$ operators J_{IJ}, but we can work in different bases adapted to $\hat{q}_{IJK}$ for a particular triple $I<J<K$ and expand them in terms of each other.

We will develop a theory of recoupling schemes here which is somewhat different from the one encountered in the standard literature and we also consider arbitrary n. The following paragraphs will therefore be somewhat detailed.

Definition V.1: A coupling scheme based on a pair $1\leqslant I<J\leqslant n$ *is an orthonormal basis* $|\mathbf{g}(IJ),\mathbf{j},j,m\rangle$, *diagonalizing besides* J^2, J_3, J^2_I, $I=1,\ldots,n$ *the squares of the additional* $n-2$ *operators* $G_2,\ldots,G_{n-1}$, *where*

$$G_1:=J_I,\quad G_2:=G_1+J_J,\quad G_3:=G_2+J_1,\quad G_4:=G_3+J_2,\ldots,$$

$$G_{I+1}:=G_I+J_{I-1},\quad G_{I+2}:=G_{I+1}+J_{I+1},\quad G_{I+3}:=G_{I+2}+J_{I+2},\ldots,$$

$$G_J:=G_{J-1}+J_{J-1},\quad G_{J+1}:=G_J+J_{J+1},\quad G_{J+2}:=G_{J+1}+J_{J+2},\ldots,$$

$$G_n:=G_{n-1}+J_n=J.$$

The vector $\mathbf{g}(IJ):=(g_2(IJ),\ldots,g_{n-1}(IJ))$ *denotes the eigenvalues of the squares of* $G_2,\ldots,G_{n-1}$. *We will call the coupling scheme based on the pair (12) the standard basis.*

Let us check that the G_I satisfy the angular momentum algebra and that the squares of the operators J, J_I, G_I and the operator J^3 are mutually commuting: for this it will be enough to check that the operators for the standard basis are mutually commuting since there is a relabeling of indices such that any coupling scheme becomes the standard basis. Since $[J_I,\ J_J]=0$, $I\neq J$, we find $[G^i_I,\ G^j_I]=\Sigma^P_{J=1}[J^i_J,\ J^j_J]=i\epsilon_{ijk}\Sigma^I_{J=1}J_J=i\epsilon_{ijk}G^k_I$, which implies that G^2_I has spectrum $g_I(g_I+1)$ with g_I integral or half-integral.

Let $I<J$. Then we can write $G_J=G_I+(J_{I+1}+\cdots+J_J)=:G_I+G'_I$ so that $[G_I,\ G'_I]=0$ because G_I,G'_I involve disjoint sets of J_K's and so $[G_J^2,\ G_I^2]=[G_I^2+(G'_I)^2,\ G_I^2]+2(G'_I)^i\{G_I^j[G_I^i,G_I^j]+[G_I^i,G_I^j]G_I^j\}=2i(G'_I)\epsilon_{ijk}\{G_I^jG_I^k+G_I^kG_I^j\}=0$. The same argument can be used for the other commutators.

The virtue of this definition is the following: we have now a neat labeling of the vectors $|0\rangle$ referred to in the previous subsection. We can choose them to be the vectors of the standard basis corresponding to $j=0$, that is, they are just the vectors $|\mathbf{g}(12),\mathbf{j},j=0,m=0\rangle$ ($m=0$ is forced by $j=0$) and the different vertex contractors just correspond to the various possible values of the intermediate (or so-called recoupling) vectors $G_2,\ldots,G_{n-1}$. We will therefore compute the matrix elements of $\hat{q}_{IJK}$ in this basis. In what follows we will drop the indices $\mathbf{j},j=0$, $m=0$ since they are the same in every coupling scheme, and, since $\hat{q}_{IJK}$ commutes with $J^2,J_I^2,(J)^3$, matrix elements between vectors with different values of these operators therefore vanish anyway. We will also write $\mathbf{g}$ instead of $\mathbf{g}(12)$.

After these long preparations we are now in the position to complete the derivation. We use completeness of the bases $|\mathbf{g}(IJ),\mathbf{j},j,m\rangle$ and have

$$\begin{aligned}\langle\mathbf{g}|\hat{q}_{IJK}|\mathbf{g}'\rangle&=\sum_{\mathbf{g}(IJ)}g_2(IJ)(g_2(IJ)+1)[\langle\mathbf{g}|\mathbf{g}(IJ)\rangle\langle(\mathbf{g}_{IJ})|J_{JK}^2|\mathbf{g}'\rangle-\langle\mathbf{g}|J_{JK}^2|\mathbf{g}_{IJ}\rangle\langle\mathbf{g}(IJ)|\mathbf{g}'\rangle]\\&=\sum_{\mathbf{g}(IJ),\mathbf{g}(JK),\mathbf{g}''}g_2(IJ)(g_2(IJ)+1)g_2(JK)(g_2(JK)+1)\langle\mathbf{g}(IJ)|\mathbf{g}''\rangle\langle\mathbf{g}(JK)|\mathbf{g}''\rangle\\&\quad\times[\langle\mathbf{g}(IJ)|\mathbf{g}\rangle\langle\mathbf{g}(JK)|\mathbf{g}'\rangle-\langle\mathbf{g}(JK)|\mathbf{g}\rangle\langle\mathbf{g}(IJ)|\mathbf{g}'\rangle],\end{aligned}\tag{V.9}$$

where we have used that the so-called $3nj$-*symbols* $\langle\mathbf{g}(IJ)|\mathbf{g}(JK)\rangle$ are real [also $\langle\mathbf{g}(IJ)|\mathbf{g}(KL)\rangle$ for any $I<J,K<L$ are real]. To see this, insert a unit in terms of the basis $|\mathbf{j},\mathbf{m}\rangle$ which allows us to write the $3nj$-symbol in terms of Clebsh–Gordan coefficients which are real.[31] It is understood that in (V.9) and in what follows the summation extends only over the allowed values of $\mathbf{g}$, etc., which are purely fixed by the values of $j_1,\ldots,j_n$.

The task left is to write the $3nj$-symbols of the form $\langle\mathbf{g}(IJ)|\mathbf{g}'\rangle$ in terms of known quantities. We will derive below a formula which expresses it in terms of the $6j$-symbol for which a closed formula (the Racah formula[31]) exists.

We will denote $\mathbf{g}(IJ)=(g_2(j_I,j_J),g_3(g_2,j_1),\ldots,g_{I+1}(g_I,j_{I-1}),g_{I+2}(g_{I+1},j_{I+1}),\ldots,g_J(g_{J-1},j_{J-1}),g_{J+1}(g_J,j_{J+1}),\ldots,g_{n-1}(g_{n-2},j_{n-1}))$, where the notation $j''(j,j')$ means that we couple J,J' to resulting spin j'' of J'', thereby keeping explicit track of the coupling scheme. The following two elementary lemmata will be crucial in computing the $3nj$-symbols.

Lemma V.1:

$$\begin{aligned}\langle\mathbf{g}(IJ)|\mathbf{g}'\rangle=\langle g_2(j_I,j_J),g_3(g_2,j_1),\ldots,g_{I+1}(g_I,j_{I-1}),g_{I+2}(g_{I+1},j_{I+1}),\ldots,g_J(g_{J-1},j_{J-1})|\\\times|g'_2(j_1,j_2),g'_3(g'_2,j_3),\ldots,g'_J(g'_{J-1},j_J)\rangle\delta_{g,J,g'_J}\cdots\delta_{g_{n-1},g'_{n-1}},\end{aligned}$$

where on the right-hand side we consider a spin system consisting of spins $J_1,\ldots,J_J$ and total spin quantum number g_J.

Proof: Since $G_J(12)^2,\ldots,G_{n-1}(12)^2$ are diagonal on both vectors it is immediately clear that the $3nj$-symbol must be proportional to the Kronecker delta δ_{g_K,g'_K} for $K=J,\ldots,n-1$. To get the factor of proportionality we expand both vectors in terms of the basis $|\mathbf{j},\mathbf{m}\rangle$ and Clebsh–Gordan coefficients. To do this, note that by definition

$$\begin{aligned}&\langle g_2(j_1,j_2),\ldots,g_{n-2}(g_{n-3},j_{n-2});g_{n-1}m\\&\quad-m_n,j_nm_n|g_2(j_1,j_2),\ldots,g_{n-2}(g_{n-3},j_{n-2}),g_{n-1}(g_{n-2},j_{n-1}),j(g_{n-1},j_n),m\rangle\\&\quad=\langle g_{n-1}(g_{n-2},j_{n-1})m-m_n,j_nm_n|j,m;g_{n-1},j_n\rangle,\end{aligned}$$

where on the right-hand side we have the standard Clebsh–Gordan coefficient. Here

$$|g_2(j_1,j_2),\ldots,g_{n-2}(g_{n-3},j_{n-2});g_{n-1}m-m_n,j_nm_n\rangle$$
$$:=|g_2(j_1,j_2),\ldots,g_{n-2}(g_{n-3},j_{n-2}),g_{n-1}(g_{n-2},j_{n-1}),m-m_n\rangle\otimes|j_nm_n\rangle.$$

We can now iterate this procedure and obtain

$$|g'_2(j_1,j_2),\ldots,g'_{n-2}(g'_{n-3},j_{n-2}),g'_{n-1}(g'_{n-2},j_{n-1}),j(g'_{n-1},j_n),m\rangle$$
$$=\sum_{m_J+\cdots+m_n=m}\langle g'_{n-1}m-m_n,j_nm_n|jm\rangle\langle g'_{n-2}m-m_n-m_{n-1},j_{n-1}m_{n-1}|g'_{n-1}m-m_n\rangle\cdots$$
$$\langle g'_Jm_J,j_{J+1}m_{J+1}|g'_{J+1},m_J+m_{J+1}\rangle|g'_2(j_1,j_2),\ldots,g'_J(g'_{J-1},j_J),m_J\rangle\otimes|j_{J+1},m_{J+1}\rangle\otimes\cdots$$
$$\otimes|j_n,m_n\rangle.$$

Similarly we have

$$|g_2(j_I,j_J),\ldots,g_{n-2}(g_{n-3},j_{n-2}),g_{n-1}(g_{n-2},j_{n-1}),j(g_{n-1},j_n),m\rangle$$
$$=\sum_{m_J+\cdots+m_n=m}\langle g_{n-1}m-m_nj_nm_n|jm\rangle\langle g_{n-2}m-m_n-m_{n-1},j_{n-1}m_{n-1}|g_{n-1}m-m_n\rangle\cdots$$
$$\langle g_Jm_J,j_{J+1}m_{J+1}|g_{J+1},m_J+m_{J+1}\rangle|g_2(j_I,j_J),\ldots,g_J(g_{j-1},j_{J-1}),m_J\rangle$$
$$\otimes|j_{J+1},m_{J+1}\rangle\otimes\cdots\otimes|j_n,m_n\rangle.$$

Thus we have the inner product

$$\begin{aligned}\langle\mathbf{g}(IJ)|\mathbf{g}'\rangle=&\sum_{m_J+\cdots+m_n=m}\langle g_2(j_I,j_J),\ldots,g_J(g_{J-1},j_{J-1}),m_J|g'_2(j_1,j_2),\ldots,g'_J(g'_{J-1},j_J),m_J\rangle\\
&\times\langle g'_{n-1}m-m_n,j_nm_n|jm\rangle\langle g'_{n-2}m-m_n-m_{n-1},j_{n-1}m_{n-1}|g'_{n-1}m-m_n\rangle\cdots\\
&\langle g'_Jm_J,j_{J+1}m_{J+1}|g'_{J+1},m_J+m_{J+1}\rangle\\
&\times\langle g_{n-1}m-m_n,j_nm_n|jm\rangle\langle g_{n-2}m-m_n-m_{n-1},j_{n-1}m_{n-1}|g_{n-1}m-m_n\rangle\cdots\\
&\langle g_Jm_J,j_{J+1}m_{J+1}|g_{J+1},m_J+m_{J+1}\rangle\\
=&\langle g_2(j_I,j_J),\ldots,g_J(g_{J-1},j_{J-1}),\tilde{m}|g'_2(j_1,j_2),\ldots,g'_J(g'_{J-1},j_J),\tilde{m}\rangle\\
&\times\sum_{m_{J+1},\ldots,m_n}\langle g'_{n-1}m-m_n,j_nm_n|jm\rangle\\
&\times\langle g'_{n-2}m-m_n-m_{n-1},j_{n-1}m_{n-1}|g'_{n-1}m-m_n\rangle\cdots\\
&\langle g'_Jm_J,j_{J+1}m_{J+1}|g'_{J+1},m_J+m_{J+1}\rangle\langle g_{n-1}m-m_n,j_nm_n|jm\rangle\\
&\times\langle g_{n-2}m-m_n-m_{n-1},j_{n-1}m_{n-1}|g_{n-1}m-m_n\rangle\cdots\\
&\langle g_Jm_J,j_{J+1}m_{J+1}|g_{J+1},m_J+m_{J+1}\rangle\\
=&\langle g_2(j_I,j_J),\ldots,g_J(g_{J-1},j_{J-1}),\tilde{m}|g'_2(j_1,j_2),\ldots,g'_J(g'_{J-1},j_J),\tilde{m}\rangle\delta_{g_J,g'_J}\cdots\delta_{g_{n-1},g'_{n-1}},\end{aligned}$$

where in the second step we have used the fact that the $3nj$-symbols are independent of m. [This is an extension of the usual Wigner–Eckart theorem which we shortly outline here: Let us expand $|\mathbf{g}(IJ)\rangle=\Sigma_{\mathbf{g}(KL)}\langle\mathbf{g}(KL);j,m|\mathbf{g}(IJ);j,m\rangle|\mathbf{g}(KL);j,m\rangle$ where we assume that $m<j$ w.l.g. Now apply the ladder operator $J^\dagger$ to both sides of this equation. We find $J^\dagger|\mathbf{g}(MN);j,m\rangle=c(j,m)|\mathbf{g}(MN);j,m+1\rangle$ for any $K<L$ where the coefficient only depends on j,m. Comparing coefficients we find $\langle\mathbf{g}(KL);j,m|\mathbf{g}(IJ);j,m\rangle=\langle\mathbf{g}(KL);j,m+1|\mathbf{g}(IJ);j,m+1\rangle$, that is, the $3nj$-symbols are rotation invariant. □

Thus, $\tilde{m}$ is arbitrary and in the last step we have used the sum rule for the Clebsh–Gordan coefficients, that is, $\Sigma_{m_1+m_2=m}(\langle j_1m_1,j_2m_2|jm\rangle)^2=1$. □

Lemma V.2:

$$\langle g_2(j_1,j_2),\ldots,g_K(g_{K-1},j_K),g_{K+1}(g_K,j_{K+1},g_{K+2}(g_{K+1},j_{K+2});m|$$
$$\times|g_2(j_1,j_2),\ldots,g_K(g_{K-1},j_K),g'_{K+1}(g_K,j_{K+2}),g'_{K+2}(g'_{K+1},j_{K+1});m\rangle$$
$$=\langle g_{K+1}(g_K,j_{K+1}),g_{K+2}(g_{K+1},j_{K+2});m|g'_{K+1}(g_K,j_{K+2}),g_{K+2}(g'_{K+1},j_3);m\rangle.$$

Proof: Again we expand

$$|g_2,\ldots,g_{K=2};m\rangle=\sum_{m_{K+1},m_{K+2}}\langle g_K m-m_{K+1}-m_{K+2},j_{K+1}m_{K+1}|g_{K+1}m-m_{K+2}\rangle$$
$$\times\langle g_{K+2}m-m_{K+2},j_{K+2}m_{K+2}|g_{K+2}m-m_{K+2}\rangle$$
$$\times|g_2,\ldots,g_k;m-m_{K+1}-m_{K+2}\rangle\otimes|j_{K+1}m_{K+1},j_{K+2}m_{K+2}\rangle$$

and

$$|g_2,\ldots,g_K,g'_{K+1},g_{K+2};m\rangle=\sum_{m_{K+1},m_{K+2}}\langle g_K m-m_{K+1}-m_{K+2},j_{K+2}m_{K+2}|g'_{K+1}m-m_{K+1}\rangle$$
$$\times\langle g_{K+2}m-m_{K+1},j_{K+1}m_{K+1}|g_{K+2}m-m_{K+1}\rangle|g_2,\ldots,g_k;m$$
$$-m_{K+1}-m_{K+2}\rangle\otimes|j_{K+1}m_{K+1},j_{K+2}m_{K+2}\rangle.$$

We find for the inner product of these states due to the normalization just

$$\sum_{m_{K+1},m_{K+2}}\langle g_K m-m_{K+1}-m_{K+2},j_{K+1}m_{K+1}|g_{K+1}m-m_{K+2}\rangle\langle g_{K+2}m$$
$$-m_{K+2},j_{K+2}m_{K+2}|g_{K+2}m-m_{K+2}\rangle\langle g_K m-m_{K+1}-m_{K+2},j_{K+2}m_{K+2}|g'_{K+1}m-m_{K+1}\rangle$$
$$\times\langle g_{K+2}m-m_{K+1},j_{K+1}m_{K+1}|g_{K+2}m-m_{K+1}\rangle$$
$$\equiv\langle g_{K+1}(g_K,j_{K+1}),g_{K+2}(g_{K+1},j_{K+2});m|g'_{K+1}(g_K,j_{K+2}),g_{K+2}(g'_{K+1},j_3);m\rangle$$

as claimed. □

We are now ready to reduce out the general $3nj$-symbol. We assume that $g_K=g'_K$, $K=J,\ldots,n-1$, as otherwise we get zero by Lemma V.1. Upon repeatedly using the completeness relations of the coupling scheme bases we first shift j_J and then j_I to the right in the matrix element

$$\langle\mathbf{g}(IJ),\mathbf{g}'\rangle=_{V.1}\langle g_2(j_I,j_J),g_3(g_2,j_1),\ldots,g_{I+1}(g_I,j_{I-1}),g_{I+2}(g_{I+1},j_{I+1}),\ldots,g_J(g_{J-1},j_{J-1})|$$
$$\times|g'_2(j_1,j_2),g'_3(g'_2,j_3),\ldots,g'_{J-1}(g'_{J-2},j_{J-1}),g_J(g'_{J-1},j_J)\rangle$$

$$=_{V.1}\sum_{h_2}\langle g_2(j_I,j_J),g_3(g_2,j_1),g_4,\ldots,g_J|h_2(j_I,j_1),g_3(h_2,j_J),g_4,\ldots,g_J\rangle$$
$$\times\langle h_2(j_I,j_1),g_3(h_2,j_J),g_4,\ldots,g_J|g'_2(j_1,j_2),g'_3(g'_2,j_3),\ldots,g'_{J-1},g_J\rangle$$

$$=_{V.1}\sum_{h_2}\langle g_2(j_I,j_J),g_3(g_2,j_1)|h_2(j_I,j_1),g_3(h_2,j_J)\rangle$$
$$\times\sum_{h_3}\langle h_2(j_I,j_1),g_3(h_2,j_J),g_4(g_3,j_2),g_5,\ldots,g_J$$
$$\times|h_2(j_I,j_1),h_3(h_2,j_2),g_4(h_3,j_J),g_5,\ldots,g_J\rangle$$
$$\times\langle h_2(j_I,j_1),h_3(h_2,j_2),g_4(h_3,j_J),g_5,\ldots,g_J|g'_2(j_1,j_2),g'_3(g'_2,j_3),\ldots,g'_{J-1},g_J\rangle$$

$$=_{V.1,V.2}\sum_{h_2}\langle g_2(j_I,j_J),g_3(g_2,j_1)|h_2(j_I,j_1),g_3(h_2,j_J)\rangle$$

$$
\begin{aligned}
&\times\sum_{h_3}\langle g_3(h_2,j_J),g_4(g_3,j_2)|h_3(h_2,j_2),g_4(h_3,j_J)\rangle\\
&\times\langle h_2(j_I,j_1),h_3(h_2,j_2),g_4(h_3,j_J),g_5,\ldots,g_J|g_2'(j_1,j_2),g_3'(g_2',j_3),\ldots,g_{J-1}',g_J\rangle\\
=&\cdots\\
=&\sum_{h_2}\langle g_2(j_I,j_J),g_3(g_2,j_1)|h_2(j_I,j_1),g_3(h_2,j_J)\rangle\\
&\times\sum_{h_3}\langle g_3(h_2,j_J),g_4(g_3,j_2)|h_3(h_2,j_2),g_4(h_3,j_J)\rangle\cdots\\
&\times\sum_{h_I}\langle g_I(h_{I-1},j_J),g_{I+1}(g_I,j_{I-1})|h_I(h_{I-1},j_{I-1}),g_{I+1}(h_I,j_J)\rangle\\
&\times\sum_{h_{I+1}}\langle g_{I+1}(h_I,j_J),g_{I+2}(g_{I+1},j_{I+1})|h_{I+1}(h_I,j_{I+1}),g_{I+2}(h_{I+1},j_J)\rangle\\
&\times\sum_{h_{I+2}}\langle g_{I+2}(h_{I+1},j_J),g_{I+3}(g_{I+2},j_{I+2})|h_{I+2}(h_{I+1},j_{I+2}),g_{I+3}(h_{I+2},j_J)\rangle\cdots\\
&\times\sum_{h_{J-1}}\langle g_{J-1}(h_{J-2},j_J),g_J(g_{J-1},j_{J-1})|h_{J-1}(H_{J-2},j_{J-1}),g_J(h_{J-1},j_J)\rangle\\
&\times\langle h_2(j_I,j_1)h_3(h_2,j_2),\ldots,h_I(h_{I-1},j_{I-1}),h_{I+1}(h_I,j_{I+1}),\ldots,h_{J-1}(h_{J-2},j_{J-1}),\\
&\times g_J(h_{J-1},j_J)||g_2'(j_1,j_2),\ldots,g_I'(g_{I-1}',j_I),g_{I+1}'(g_I',j_{I+1}),\ldots,g_J'(g_{J-1}',j_J)\rangle.
\end{aligned}
\tag{V.10}
$$

Now the last matrix element in the last line of (V.10) is different from zero only for $h_K=g_K'$, $K=I,\ldots,J-1$ by Lemma V.1 (we have $g_J=g_J'$ already) and in that case reduces by the same reasoning to

$$
\begin{aligned}
&\langle h_2(j_I,j_1)h_3(h_2,j_2),\ldots,h_{I-1}(h_{I-2},j_{I-2}),g_I(h_{I-1},j_{I-1})|g_2'(j_1,j_2),\ldots,g_I'(g_{I-1}',j_I)\rangle\\
&=\sum_{k_2}\langle h_2(j_I,j_1),h_3(h_2,j_2)|k_2(j_1,j_2),h_3(k_2,j_I)\rangle\\
&\times\sum_{k_3}\langle h_3(k_2,j_I),h_4(h_3,j_3)|k_3(k_2,j_3),h_3(k_3,j_I)\rangle\cdots\\
&\times\sum_{k_{I-1}}\langle h_{I-1}(k_{I-2},j_I),h_I(h_{I-1},j_{I-1})|k_{I-1}(k_{I-2},j_{I-1}),g_I'(k_{I-1},j_I)\rangle\\
&\times\langle k_2(j_1,j_2),k_3(k_2,j_3),\ldots,k_{I-1}(k_{I-2},j_{I-1}),g_I'(k_{I-1},j_I)\\
&\times|g_2'(j_1,j_2),g_3'(g_2',j_3),\ldots,g_I'(g_{I-1}',j_I)\rangle
\end{aligned}
\tag{V.11}
$$

and the last matrix element in the last line of (V.11) is just given by $\Pi_{K=2}^{I-1}\delta_{k_K,g_K'}$ so that the summation drops out. So, altogether, there are only the $I-3$ summation variables $h_2,\ldots,h_{I-1}$.

Equations (V.10) and (V.11) demonstrate that we manage to reduce the $3nj$-symbol under investigation to a polynomial of matrix elements of the structure

$$
\begin{aligned}
&\text{type I: } \langle j_{12}(j_1,j_2),j(j_{12},j_3)|j_{13}(j_1,j_3),j(j_{13},j_2)\rangle \text{ or}\\
&\text{type II: } \langle j_{12}(j_1,j_2),j(j_{12},j_3)|j_{23}(j_2,j_3),j(j_{23},j_1)\rangle.
\end{aligned}
\tag{V.12}
$$

In fact, all matrix elements in (V.10) are of type I and all matrix elements in (V.11) are of type I, except for the first factor after the first equality which is of type II.

The point is now that both matrix elements are related to the $6j$-symbol.[31] The $6j$-symbol is defined through the type II matrix element, namely

$$\langle j_{12}(j_1,j_2),j(j_{12},j_3)|j_{23}(j_2,j_3),j(j_{23},j_1)\rangle =: \sqrt{(2j_{12}+1)(2j_{23}+1)}(-1)^{j_1+j_2+j_3+j}\begin{Bmatrix} j_1 & j_2 & j_{12} \\ j_3 & j & j_{23}\end{Bmatrix}. \tag{V.13}$$

In order to relate the type I matrix element to the $6j$-symbol we need to use the following identity for the CG (Clebsh–Gordan) coefficients

$$\langle j_1m_1,j_2m_2|jm\rangle=(-1)^{j_1+j_2-j}\langle j_2m_2,j_1m_1|jm\rangle, \tag{V.14}$$

which is a consequence of the choice of phases for the CG coefficients in order to have them real valued.[31] Let us now set $j_1':=j_2$, $j_2':=j_1$, $j_3':=j_3$, $j_{12}':=j_{12}$, $j_{23}':=j_{13}$, and $j':=j$. Then we obtain

$$\langle j_{12}(j_1,j_2),j(j_{12},j_3)|j_{13}(j_1,j_3),j(j_{13},j_2)\rangle=\langle j_{12}'(j_2',j_1'),j'(j_{12}',j_3')|j_{23}'(j_2',j_3'),j'(j_{23}',j_1')\rangle,$$

which is almost the standard form except for the wrong order of j_1',j_2' in the first entry. Using the expansion

$$|j_{12}'(j_2',j_1'),j'(j_{12}',j_3');m'\rangle \sum_{m_1+m_2+m_3=m'}\langle j_2'm_2,j_1'm_1|j_{12}'m_1+m_2\rangle\langle j_{12}'m_1+m_2,j_3'm_3|j'm'\rangle|j_1'm_1,\ldots,j_3'm_3'\rangle$$

and (V.14) we therefore find

$$\langle j_{12}'(j_2',j_1'),j'(j_{12}',j_3')|j_{23}'(j_2',j_3'),j'(j_{23}',j_1')\rangle =(-1)^{j_1'+j_2'-j_{12}'}\langle j_{12}'(j_1',j_2'),j'(j_{12}',j_3')|j_{23}'(j_2',j_3'),j'(j_{23}',j_1')\rangle$$

and so we have for the type I matrix element

$$\langle j_{12}(j_1,j_2),j(j_{12},j_3)|j_{13}(j_1,j_3),j(j_{13},j_2)\rangle =(-1)^{j_1+j_2-j_{12}}\sqrt{(2j_{12}+1)(2j_{13}+1)}(-1)^{j_1+j_2+j_3+j}\begin{Bmatrix} j_2 & j_1 & j_{12} \\ j_3 & j & j_{13}\end{Bmatrix}. \tag{V.15}$$

Finally, for the benefit of the reader, we note the Racah formula,[31]

$$\begin{Bmatrix} j_1 & j_2 & j_{12} \\ j_3 & j & j_{23}\end{Bmatrix}=\Delta(j_1,j_2,j_{12})\Delta(j_1,j,j_{23})\Delta(j_3,j_2,j_{23})\Delta(j_3,j,,j_{12})w\begin{Bmatrix} j_1 & j_2 & j_{12} \\ j_3 & j & j_{23}\end{Bmatrix},$$

$$\Delta(a,b,c)=\sqrt{\frac{(a+b-c)!(a-b+c)!(-a+b+c)!}{(a+b+c+1)!}}, \tag{V.16}$$

$$w\begin{Bmatrix} j_1 & j_2 & j_{12} \\ j_3 & j & j_{23}\end{Bmatrix}=\sum_n (-1)^n(n+1)! \times[(n-j_1-j_2-j_{12})!(n-j_1-j-j_{23})!(n-j_3-j_2-j_{23})!(n-j_3-j-j_{12})!]^{-1} \times[(j_1+j_2+j_3+j-n)!(j_2+j_{12}+j+j_{23}-n)!(j_{12}+j_1+j_{23}+j_3-n)!]^{-1},$$

and the sum extends over all positive integers such that no factorial in the denominator has a negative argument. In conclusion, formulas (V.9)–(V.11) provide us with the general expression for the matrix elements of the operator $\hat{q}_{IJK}$ in the standard basis where it is understood that all occurring matrix elements are known in terms of $j_1,\ldots,j_n$ via (V.13), (V.15), and (V.16).

Let us call $M_{v,IJK}(\mathbf{g},\mathbf{g}'):=\langle\mathbf{g}|\hat{q}_{IJK}|\mathbf{g}'\rangle$. Then we have the matrix

$$M_v(\mathbf{g},\mathbf{g}')=\left(\frac{3}{2}\right)^3\frac{i}{4}\sum_{I<J<K}\epsilon(I,J,K)M_{v,IJK}(\mathbf{g},\mathbf{g}'),\tag{V.17}$$

which by inspection of (V.9) is a Hermitian matrix of a special kind, namely, it is of the form of i times a real-valued skew matrix. Its eigenvalues therefore come in pairs $\pm\lambda,\lambda>0$ or are zero. The eigenvalues of the positive semidefinite matrix $M_v^\dagger M_v$ are therefore $|\lambda|^2$ or 0 where λ is an eigenvalue of M_v. We conclude that the eigenvalues of $\hat{V}_{v,\gamma}$ are given by $l_p^3\sqrt{|\lambda|}$ or 0 where both eigenvectors of M_v corresponding to eigenvalues $\pm\lambda$ produce the same eigenvalue $l_p^3\sqrt{|\lambda|}$ of $\hat{V}_{v,\gamma}$. We see that the problem of diagonalizing the volume operator becomes equivalent to diagonalizing the matrices M_v which can be done for each $v\in V(\gamma)$ separately.

In the next subsection we will derive the spectrum in the most simple cases.

Remark: We have nowhere made use of the fact that we are only interested in gauge-invariant functions. Therefore, our results carry over, word by word, to the case of non-gauge-invariant functions provided we use the notion of an extended spin-network state.

Definition V.2: An extended spin-network state is a state of the form $T_{\gamma,\mathbf{j},\mathbf{c}}$ as before just that the vertex contractors now are Clebsh–Gordan coefficients of the form $\langle j_1m_1,\ldots,j_nm_n|j_1,\ldots,j_n,g_2,\ldots,g_{n-1},j\rangle$, where j may be different from zero.

This is important for applications in quantum gravity[2,3] and for the length operator[7] where we need the action of the volume operator on non-gauge-invariant functions in an intermediate step.

C. Examples

Given a vertex v and a vector of spins $\mathbf{j}$ coloring the edges incident at v, let us denote by $d(\mathbf{j},v)$ the number of linearly independent vectors $|\mathbf{g}\rangle$ compatible with $\mathbf{j}$. This number is the dimension of a vector space of vertex contractors associated with v and it is given purely algebraically as the number of linearly independent trivial representations which appear in the decomposition into irreducibles of the tensor product representation $\pi_{j_1}\otimes\cdots\otimes\pi_{j_n}$. One can determine this number for each case at hand by repeated application of the usual Clebsh–Gordan theorem $\pi_j\otimes\pi_{j'}=\pi_{j+j'}\oplus\pi_{j+j'-1}\oplus\cdots\oplus\pi_{|j-j'|}$ and counting all the trivial representation of spin 0 that appear. Notice that the sum is direct so that all the representations are orthogonal and therefore linearly independent. What one would like to have is a closed formula for $d(\mathbf{j},v)$, but that seems to be a complicated combinatorical problem. To our knowledge, such a dimension formula is only known for the case of an n-fold tensor product of fundamental representations $j_1=\cdots=j_n=\frac{1}{2}$ for the groups GL(N), U(N), and SU(N).[32] We will not deal with this problem in the present paper.

First of all, whenever $d(\mathbf{j},v)=1$, then 0 is the only possible eigenvalue (this observation was made first in Ref. 6 for the case of a trivalent graph in which the vertex contractors span only a one-dimensional vector space). More generally, whenever $d(\mathbf{j},v)$ is odd, we know that 0 is an eigenvalue of multiplicity at least 1.

Since M_v is a $d\times d$ skew matrix its characteristic polynomial has the structure $t^k(t^2-\lambda_1^2)\cdots(t^2-\lambda_{(d-k)/2}^2)=t^kp_{(d-k)/2}(t^2)$, where $0\leqslant k\leqslant d$ for d even and $1\leqslant k\leqslant d$ for d odd. It follows from Galois theory that we can determine the spectrum by quadratures exactly in general whenever $d(\mathbf{j},v)\leqslant 9$ and in fortunate cases (whenever 0 has multiplicity at least $d-8$) up to arbitrarily high dimension. In the most general case, however, a numerical evaluation is the only possible approach.

We consider the first nontrivial cases $d(\mathbf{j},v)\leqslant 9$ for an arbitrary valence n of the vertex. We may label the spins in such a way that $0<j_1\leqslant\cdots\leqslant j_n$. We may parametrize the situation by the non-negative number $k:=j_1+\cdots+j_{n-1}-j_n$ (there is no contractor for $k<0$). If k is low valued, then it is clear from Clebsh–Gordan theory that $d(\mathbf{j},v)$ will be low valued. Specifically, if $k=0$, then the first $n-1$ spins have to add up to maximum spin and thus $d=1$; the spectrum is only the point 0 irrespective of the value of n. In the following we will assume that $2j_1\geqslant k$, otherwise the discussion requires a case division. If $k=1$, then one sees readily that $d=n-1$: the only irreducible representations contained in $j_1\otimes j_2$ that can possibly add up with $j_3,\ldots,j_{n-1}$ to j_n are j_1+j_2,j_1+j_2-1. Repeating the argument, the assertion follows.

Let in general $c_k(n)$ be the number of representations with weight $j_1+\cdots+j_n-k$ contained in $j_1\otimes\cdots\otimes j_n$ for $j_{n+1}=j_1+\cdots+j_n-k$ to couple to angular momentum 0 where $j_1\leqslant,\ldots,\leqslant j_n$ and where we assume that $j_2-j_1\leqslant j_1+j_2-k$, that is $k\leqslant 2j_1$. We wish to show that $c_k(n)=(n+k$

$-2,k)$ where (n,k) is the usual binomial coefficient. Since $c_0(n)=1$ as we showed above, the induction is started. Now suppose we know all coefficients up to k for each n and start deriving those for $k+1$. We can assume that we know them already up to $n-1$ since $c_k(2)=1$ for all k is trivial to see since we have made the assumption $2j_1 \geqslant k$. Then we have the recursion $c_{k+1}(n-1)+c_k(n)=c_{k+1}(n)$ which follows from the fact that if we have the tensor product $j_1 \otimes \cdots \otimes j_{n-1}$, then there are $c_l(n-1)$ representations with weight $j_1+\cdots+j_{n-1}-l, 0 \leqslant l \leqslant k+1$. However, if we now form the tensor product with all of them with j_n, then the number of times that $j_1+\cdots+j_n-k$ arises from those with weight $j_1+\cdots+j_{n-1}-l, 0 \leqslant l \leqslant k$, which is given by $c_k(n)$, is equal to the number of times that $j_1+\cdots+j_n-(k+1)$ arises from them. In addition we have $c_{k+1}(n-1)$ terms coming from the representation $j_1+\cdots+j_{n-1}-(k+1)$ itself. It is now readily verified that $c_k(n)$ solves the recursion.

Notice that $n+1$ is the valence of the vertex. So we get back the result that in the trivalent case we have $d=c_k(2)=(k,k)=1$. We can now ask for which combinations of k,n we have $c_k(n) \leqslant 9$. Notice that $c_k(3)=k+1$:

Case $k=0$: n arbitrary.

Case $k=1$: $n-1 \leqslant 9$ so $n \leqslant 10$.

Case $k=2$: $n(n-1)/2 \leqslant 9$ so $n \leqslant 4$.

Case $3 \leqslant k \leqslant 8$: $n \leqslant 3$.

Case $k>8$: $n \leqslant 2$.

Reverse question (only $n \geqslant 2$ makes sense since we need valence at least 3 for the volume operator not to vanish trivially):

Case $n=2$: k arbitrary.

Case $n=3$: $k+1 \leqslant 9$ so $k \leqslant 8$.

Case $n=4$: $(k+1)(k+2)/2 \leqslant 9$ so $k \leqslant 2$.

Case $5 \leqslant n \leqslant 10$: $k \leqslant 1$.

Case $n>10$: $k=0$.

So, for instance we can treat the general four-valent case under the restriction that $j_4=j_1+j_2+j_3-k, 0 \leqslant k \leqslant 8$, for $j_3 \geqslant j_2 \geqslant j_1 \geqslant k/2$ in which case $d=k+1$. As the formulas already get quite involved, we will only discuss the cases $k=1,2,3$ explicitly.

Notice first of all that due to gauge invariance $J_1+J_2+J_3+J_4|0\rangle=0$ so that we can substitute for J_4. Thus, for instance, $\hat{q}_{124}|0\rangle=-(\hat{q}_{121}+\hat{q}_{122}+\hat{q}_{123})|0\rangle$ and it is easily verified that the operator identity $\hat{q}_{122}+\hat{q}_{121}=0$ holds. It follows that

$$M_v=\left(\frac{3}{4}\right)^3 \frac{i}{4}\,[\epsilon(1,2,3)-\epsilon(1,2,4)+\epsilon(1,3,4)-\epsilon(2,3,4)]\hat{q}_{123}=:\sigma\hat{q}_{123},$$

which simplifies the discussion tremendously since we just need to compute the matrix elements of the single operator $\hat{q}_{123}$. We have to compute the $k(k+1)/2$ matrix elements

$$\langle j_{12}|\hat{q}_{123}|j'_{12}\rangle=[j_{12}(j_{12}+1)-j'_{12}(j'_{12}+1)]\sum_{j_{23}} j_{23}(j_{23}+1)\langle j_{12}|j_{23}\rangle\langle j'_{12}|j_{23}\rangle$$

for $j_{12}, j'_{12}=j_1+j_2-l$, $l=0,\ldots,k$, and the sum extends over $j_{23}=j_2+j_3-l$, $l=0,\ldots,k$, which requires the computation of $(k+1)^2$ $6j$-symbols for $j_{123}=j=j_1+j_2+j_3-k=j_4$. The computation is rather tedious. We will display only a few intermediate calculational results before giving the eigenvalue λ_k.

Let $j_{12}:=j_1+j_2, j_{23}:=j_2+j_3$ and $J=2(j_1+j_2+j_3)$.

Case $k=1$: The $6j$-symbols are

$$\begin{aligned}\langle j_{12}|j_{23}\rangle&=-\langle j_{12}-1|j_{23}-1\rangle=\sqrt{\frac{j_1 j_3}{j_{12}j_{23}}},\\ \langle j_{12}-1|j_{23}\rangle&=\langle j_{12}|j_{23}-1\rangle=\sqrt{\frac{j_2 J}{2j_{12}j_{23}}},\end{aligned} \tag{V.18}$$

and so we have the only nonvanishing matrix element

$$\langle j_{12}|\hat{q}_{123}|j_{12}-1\rangle = 4\sqrt{j_1 j_2 j_3 (j_1+j_2+j_3)}. \tag{V.19}$$

The corresponding eigenvalue of the volume operator is

$$\lambda_1 = 2 l_p^3 \sqrt{|\sigma|}\sqrt[4]{j_1 j_2 j_3 (j_1+j_2+j_3)}. \tag{V.20}$$

This result, formula (V.20), was obtained before by Jurek Lewandowski using an independent method (also using gauge invariance $J_1+J_2+J_2+J_3=0$).

Case $k=2$: The $6j$-symbols are

$$\begin{aligned}
\langle j_{12}|j_{23}\rangle &= \sqrt{\frac{j_1(2j_1-1)j_3(2j_3-1)}{j_{12}(2j_{12}-1)j_{23}(2j_{23}-1)}},\\
\langle j_{12}-1|j_{23}\rangle &= \sqrt{2\frac{(2j_1-1)j_2 j_3(J-1)}{j_{12}(2j_{12}-2)j_{23}(2j_{23}-1)}},\\
\langle j_{12}-2|j_{23}\rangle &= \sqrt{\frac{j_2(2j_2-1)(J-1)(J-2)}{(2j_{12}-1)(2j_{12}-2)j_{23}(2j_{23}-1)}},\\
\langle j_{12}|j_{23}-1\rangle &= \sqrt{2\frac{j_1 j_2(2j_3-1)(J-1)}{j_{12}(2j_{12}-1)j_{23}(2j_{23}-2)}},\\
\langle j_{12}|j_{23}-2\rangle &= \sqrt{\frac{j_2(2j_2-1)(J-1)(J-2)}{j_{12}(2j_{12}-1)(2j_{23}-1)(2j_{23}-2)}},\\
\langle j_{12}-1|j_{23}-1\rangle &= \frac{(2j_2-1)(J-1)-(2j_1-1)(2j_3-1)}{2\sqrt{j_{12}(2j_{12}-2)j_{23}(2j_{23}-2)}},\\
\langle j_{12}-2|j_{23}-1\rangle &= -\sqrt{2\frac{(2j_1-1)(2j_2-1)j_3(J-2)}{(2j_{12}-1)(2j_{12}-2)j_{23}(2j_{23}-2)}},\\
\langle j_{12}-1|j_{23}-2\rangle &= -\sqrt{2\frac{j_1(2j_2-1)(2j_3-1)(J-2)}{j_{12}(2j_{12}-2)(2j_{23}-1)(2j_{23}-2)}},\\
\langle j_{12}-2|j_{23}-2\rangle &= 2\sqrt{\frac{j_1(2j_1-1)j_3(2j_{23}-1)}{(2j_{12}-1)(2j_{12}-2)(2j_{23}-1)(2j_{23}-2)}},
\end{aligned} \tag{V.21}$$

and we find then the matrix elements

$$\begin{aligned}
\langle j_{12}|\hat{q}_{123}|j_{12}-1\rangle &= \sqrt{\frac{2j_1 2j_2(2j_3-1)(J-1)}{2(2j_{12}-1)(2j_{12}-2)}}\frac{1}{2(2j_{23}-1)}\,[(2j_1-1)[6j_3+2j_{23}-1]+(2j_2-1)\\
&\quad\times[3J+2j_{23}-7]],\\
\langle j_{12}|\hat{q}_{123}|j_{12}-2\rangle &= 0,\\
\langle j_{12}-1|\hat{q}_{123}|j_{12}-2\rangle &= \sqrt{\frac{(2j_1-1)(2j_2-1)2j_3(J-2)}{2(2j_{12})(2j_{12}-1)}}\frac{1}{2(2j_{23}-1)}\\
&\quad\times[(J-1)[6j_2+2j_{23}-1]+(2j_3-1)[6j_1-2j_{23}+1]],
\end{aligned} \tag{V.22}$$

and since the eigenvalues of any 3×3 skew matrix with entries a,b,c are given by 0, $\pm i\sqrt{a^2+b^2+c^2}$, we find the eigenvalues $0,\lambda_2$ where

$$\lambda_2 = l_p^3\sqrt{|\sigma|}\sqrt[4]{\langle j_{12}|\hat{q}_{123}|j_{12}-1\rangle^2+\langle j_{12}-1|\hat{q}_{123}|j_{12}-2\rangle^2}. \tag{V.23}$$

Case $k=3$: We will refrain from displaying the $6j$-symbols explicitly in terms of the j_I. Rather, we consider them as given through the formulas of the previous section. Now it is easy to check that the eigenvalues of a 4×4 skew matrix with entries a,b,c,d,e,f are given by i times

$$t=\pm\frac{1}{\sqrt{2}}\sqrt{a^2+b^2+c^2+d^2+e^2+f^2\pm\sqrt{[(a+f)^2+(c+d)^2+(e-f)^2]\times[(a-f)^2+(c-d)^2+(e+f)^2]}}$$

and notice that the argument of the inner square root can be written as $(a^2+b^2+c^2+d^2+e^2+f^2)-4(af+cd-eb)^2$, which shows that t is purely real. Substituting the matrix elements $\langle j_{12}-l|\hat{q}_{123}|j_{12}-l'\rangle, 0\leqslant l<l,\leqslant 3$ for a,b,c,d,e,f we obtain

$$\lambda_3=l_p^3\sqrt{|\sigma|}\sqrt{|t|}. \tag{V.24}$$

The reader should now have a feeling of how to compute the spectrum analytically. The formulas derived can serve for analytical estimates as well as the starting point for the implementation of an appropriate computer code for an algebraic manipulation program.

A length operator for canonical quantum gravity

T. Thiemann[a)]
Physics Department, Harvard University, Cambridge, Massachusetts 02138

(Received 15 May 1997; accepted for publication 16 January 1998)

We construct an operator that measures the length of a curve in four-dimensional Lorentzian vacuum quantum gravity. We work in a representation in which an SU(2) connection is diagonal and it is therefore surprising that the operator obtained after regularization is densely defined, does not suffer from factor ordering singularities, and does not require any renormalization. We show that the length operator admits self-adjoint extensions and compute part of its spectrum which, like its companions, the volume and area operators already constructed in the literature, is purely discrete and roughly quantized in units of the Planck length. The length operator contains full and direct information about all the components of the metric tensor which facilitates the construction of so-called weave states which approximate a given classical three-geometry. © *1998 American Institute of Physics.* [S0022-2488(98)02406-2]

I. INTRODUCTION

It is by now widely believed that perturbative quantization of gravity is impossible. Among the nonperturbative approaches, the canonical approach[1] has the advantage of not requiring any extra structure beyond classical general relativity and the principles of quantum theory which is in contrast, for instance, to string theory.

Roughly speaking (for details see, e.g., Ref. 2), in the canonical approach one splits the four-dimensional, Lorentzian space–time manifold M into time and space, that is, M has the topology $M=\mathbb{R}\times\Sigma$, where Σ is a Riemannian three-manifold of arbitrary topology, and writes the Einstein–Hilbert action in Hamiltonian form with respect to this $3+1$ split. One finds that the pull-back q_{ab}, $a=1,2,3$, to Σ of the four-dimensional metric $g_{\mu\nu}$, $\mu,\nu=0,...,3$, is one of the canonical coordinates and it is therefore of particular interest to construct an operator in the quantum theory that measures $q_{ab}(x)$ for all $x\in\Sigma$.

A natural classical phase space functional of q_{ab} which contains full and direct information about this positive definite three-metric is, of course, the length of an arbitrary piecewise smooth curve c in Σ. The classical length of c is defined by $L(c):=\int_0^1 dt\sqrt{q_{ab}(c(t))\dot{c}^a(t)\dot{c}^b(t)}$, where $[0,1]\to c$ is a parametrization of the curve and it is understood that one sums over smooth segments of c. This object should also play an important role in the quantum theory due to its intuitive physical meaning.

Here a word of caution is in order:

Due to its four-dimensional diffeomorphism invariance, canonical general relativity is subject to four constraints corresponding to infinitesimal diffeomorphisms of M.[2] Obviously then, the length $L(c)$ is not a Dirac observable, i.e., it has nonvanishing Poisson brackets with the constraint functionals because it is, in particular, not invariant under diffeomorphisms of Σ. This means that part of the information contained in $L(c)$, as we vary c, is actually gauge and thus not physically relevant. On the other hand, it is mathematically difficult to extract the ''relevant'' information from $L(c)$ and therefore we will, in the present paper, consider all $L(c)$ since it is at least an overcomplete set of data from which q_{ab} can be reconstructed.

The problem in quantizing the length functional is, of course, that q_{ab} turns into an operator and experience from, say, scalar field theories, raises the worry that this operator must be ill defined in the quantum theory for it is smeared only in one direction: it is well known that a scalar

 © 1998 American Institute of Physics

field $\phi(x)$, even for free-field theory, is an operator-valued distribution which turns into a densely defined operator on the Hilbert space (Fock space) only when smearing it in three dimensions.

If one was working in a representation of canonical quantum gravity for which the intrinsic metric q_{ab} of an initial data hypersurface Σ was the configuration variable, then the operator corresponding to the length of a curve would be fairly easy to construct because it would act by multiplication and so there would be no immediate problem, even if q_{ab} would take values in a set of distributions rather than in the set of smooth functions of Σ.

However, in this so-called geometrodynamic representation[2] one of the most important operators, the Wheeler–DeWitt constraint operator, adopts an algebraic form which is so difficult that almost half a century after its discovery it is still unknown how to rigorously define it and much less how to solve it (compare Ref. 1 for a detailed analysis).

Fortunately, there is an alternative, called the connection representation, in which the Wheeler–DeWitt operator adopts a polynomial form after multiplying it by $\sqrt{\det((q_{ab}))}$.[3] In the Lorentzian signature, if one insists on a polynomial Wheeler–DeWitt constraint, the underlying connection is complex valued,[3] which renders the task of incorporating the correct reality conditions on the classical phase space variables at the quantum level into a difficult one. However, these complications can be overcome in two different ways:

(a) The first possibility is to start with Euclidean gravity and real connection variables in which the Wheeler–DeWitt constraint is also a polynomial[4] and to Wick rotate the Euclidean theory into the Lorentzian regime[5] (see also Ref. 6).
(b) The second possibility arises from the recent discovery[7,8] that by employing a certain novel technique it is indeed possible to obtain a finite, densely defined (and symmetric) operator corresponding to the original Wheeler–DeWitt constraint directly in the Lorentzian regime in terms of real-valued su(2) connection variables A_a^i and without multiplying by a power of $\sqrt{\det(q)}$.

The idea to use real connection variables for *Lorentzian* gravity rather than for Euclidean gravity was clearly spelled out for the first time in Ref. 9; in particular, it was pointed out there that, despite the algebraically complicated structure of the Wheeler–DeWitt constraint, the techniques associated with $\overline{\mathcal{A}/\mathcal{G}}$ as discussed below can be employed. The technique advertised in Refs. 7 and 8 is, however, independent of the one described in Ref. 9 which was restricted to the classical case and unavoidably is doomed to produce a highly singular Hamiltonian constraint operator (compare Ref. 10 where this singularity is discussed in the restricted context of lattice quantum gravity). In contrast, the one proposed in Refs. 7 and 8 is perfectly finite everywhere on the Hilbert space. Also, it is independent of the technique used in Ref. 11 which suffers from other problems that have to do with taking the square root of a nonpositive and not self-adjoint operator besides being a quantization of the Euclidean constraint operator only.

Summarizing, it seems then that we are forced to quantize the length functional in this real connection representation which we will use in the sequel. The problem then is that the metric depends on the momentum E_i^a canonically conjugate to the connection only, and it depends on it in a nonpolynomial fashion. Specifically, $q_{ab}=\det((E_i^a))E_a^iE_b^i$ where E_a^i is the *inverse* of the matrix E_i^a. It is therefore much harder to define a well-defined operator corresponding to it. In fact, that is why only volume and area operators could be constructed so far.[12,13] It turns out that the same novel technique introduced in Refs. 7 and 8 can be used to derive a completely well-defined operator corresponding to the length of a curve which is the content of the present paper. The paper is organized as follows:

In Sec. II we fix the notation and define the real connection representation (see Ref. 14 for a more detailed review and references therein). We recall the necessary information about the underlying Hilbert space and the techniques that come with the space of (generalized) connections modulo gauge transformations $\overline{\mathcal{A}/\mathcal{G}}$. This Hilbert space can be roughly thought of as the completion of a space Φ which is spanned by finite sums of finite products of traces of the holonomy of the connection around closed loops, also called the Wilson loop functional. The completion is with respect to a measure which, roughly speaking, reduces on functions of n independent Wilson loop variables to the n-fold product Haar measure on $\mathrm{SU}(2)^n$. A genuine state in Φ can then roughly be thought of as a functional of the connection labeled by a collection of loops, that is, a graph.

In Sec. III we derive the length operator and show that it is an unbounded, non-negative and symmetric operator on the full Hilbert space with dense domain and that it has self-adjoint extensions. The construction involves several steps:

(a) First one has to regularize the naive expression for the length operator, that is, one derives an operator which depends on a specific parametrization and a specific partition into segments of the curve in question. The regulator is characterized by the maximal interval length of that partition.
(b) Next, one takes the regulator to zero and observes that on each state from a dense subset Φ of the Hilbert space there exists a value ϵ_0 of the regulator such that for any $\epsilon < \epsilon_0$ the operator remains the same. The result is a family of regulator-independent operators, one for each state $\psi \in \Phi$.
(c) Finally, one confirms that this family of operators qualifies as the set of projections to the one-dimensional spaces spanned by states from Φ of a state-independent operator on the Hilbert space which has domain and range in the dense set Φ.

In Sec. IV we derive several properties of its spectrum and compute it for some simple situations. In particular, it is shown that the spectrum is purely discrete. With the techniques that are introduced to establish this result it is actually possible to show that the length operator so obtained is an essentially self-adjoint operator on the Hilbert space so that its self-adjoint extension is unique. It turns out that the length operator is indeed diagonal on the ''spin-network states'' introduced by Penrose[15] (see Sec. II).

Finally, in Sec. V we comment on how one can construct ''weave states'' which approximate a given classical geometry as defined by the length operator. We need to consider weave states which are more general than most of the ones previously considered in the literature in the sense that they necessarily involve intersections and overlappings of the loops involved and should therefore be called ''lattice states.'' This section, in contrast to the previous ones, is less precise and contains several heuristic elements which is due to the following issue:

Surprisingly, the length operator cannot be directly employed in order to construct weave states: This has to do with the fact that a curve is a very singular object in the sense that the length operator acts on a state nontrivially only if the graph on which the state depends intersects the curve. This has the striking consequence that, given some region occupied by some genuine loop configuration, the quantum volume of that region is positive while the length of ''almost any'' curve that penetrates the same region is zero. The conclusion is that a one-dimensional curve is a mathematical abstraction of a physical curve which should have a finite ''thickness,'' that is, on a macroscopic scale the curve looks one-dimensional but microscopically it looks rather like a solid tube. This is, of course, motivated by the general rule in quantum field theory that the excitations of the quantum field cannot be measured in a point but only in a ''smeared'' region.

We construct, directly from the length operator, an associated ''tube operator'' which is nothing else than a certain sum of length operators for a congruence of curves whose union is (piecewise) a solid cylinder. One difficulty that has to be overcome is that one has to define what it means that a tube is ''thin,'' i.e., that it should look one-dimensional on a macroscopic scale. We define a notion of ''quantum thinness,'' again by means of the length operator, roughly by requiring that the thickness of the tube should be of the order of the Planck length. Of course, the tube will be thin only on certain states. The length of a tube is, roughly speaking, the sum of the lengths of the length operators from which it is constructed. A weave state that approximates a classical metric is then a state with respect to which the tube is thin and such that the length of the tube agrees up to quantum corrections with the length of the ''central curve'' of the tube as measured by the classical metric. Using the calculations from Sec. IV we explicitly construct a weave state that approximates the length of a tube as measured by any slowly varying classical three-metric.

II. THE REAL CONNECTION REPRESENTATION

Let q_{ab} be the intrinsic metric of an initial data hypersurface Σ and let K_{ab} be its extrinsic curvature. Introduce a triad field e^i_a which transforms like a one-form under diffeomorphisms of Σ and according to the adjoint representation of SU(2) so that $q_{ab} = \delta_{ij} e^i_a e^j_b$. Let e^a_i be its inverse

and define $K_a^i := \mathrm{sgn}(\det((e_b^j)))K_{ab}e_i^b$ and $E_i^a := \det((e_b^j))e_i^a$. Then one can show that $(K_a^i/\kappa, E_i^a)$ is a canonical pair for Lorentzian four-dimensional canonical gravity, where κ is Newton's constant.

Now consider the spin-connection Γ_a^i, that is, the unique connection which annihilates the triad e_a^i. One can define an SU(2) connection $A_a^i := \Gamma_a^i + K_a^i$ which has the correct dimension of an inverse length. Then one can show that the so-called real Ashtekar variables given by $A_a^i/\kappa, E_i^a$ define a canonical pair. In retrospect, since this real connection formulation does not simplify the Wheeler–DeWitt constraint too much while the complex formulation suffers from the other problems mentioned in the Introduction, the virtue of using a connection dynamics formulation rather than a geometrodynamical one is the following: one can use techniques normally employed in Yang–Mills theory. In particular, one can use Wilson loop variables which serve as good coordinates on $\mathcal{A}/\mathcal{G}$, the space of smooth connections modulo gauge transformations. The use of loops to probe connections is radical: those Wilson loop variables can become well-defined operators only if the excitations of geometry are stringlike rather than bubblelike. On the other hand, given that assumption, it is possible to explicitly characterize the quantum configuration space $\overline{\mathcal{A}/\mathcal{G}}$ of *generalized* connections modulo gauge transformations. This is the precise analog, in the connection representation, of ''Wheeler's superspace'' in the metric formulation which, to the best of our knowledge, was never specified precisely.

One can show that the elements of $\overline{\mathcal{A}/\mathcal{G}}$ are in one-to-one correspondence with the set of all homomorphisms from the group of holonomically equivalent loops in Σ into SU(2)/Ad.[16] Moreover, there is a σ-additive, faithful, and diffeomorphism-invariant probability measure μ_0 on $\overline{\mathcal{A}/\mathcal{G}}$ which equips us with a Hilbert space structure $\mathcal{H} := L_2(\overline{\mathcal{A}/\mathcal{G}}, d\mu_0)$. This measure is defined as follows:

In the sequel we will denote by γ a closed graph, that is, a collection of analytic edges e which intersect in vertices v such that each vertex is at least two-valent. A function f on $\overline{\mathcal{A}/\mathcal{G}}$ is said to be cylindrical with respect to γ iff it is of the form $f(A) = (f_\gamma \circ p_\gamma)(A) = f_\gamma(h_{e_1}(A), \ldots, h_{e_n}(A))$, where $e_1, \ldots, e_n$ are the edges of γ, h_e is the holonomy along e_i, and f_γ is a complex-valued function on $\mathrm{SU}(2)^n$ which is gauge invariant. So each cylindrical function is determined through a graph γ and such an f_γ and one says that f_γ and f'_γ are equivalent whenever their pullbacks agree, that is $p_\gamma^* f_\gamma = p_{\gamma'}^* f_{\gamma'}$. Let us denote by $\mathrm{Cyl}_\gamma(\overline{\mathcal{A}/\mathcal{G}})$ the collection of functions cylindrical with respect to γ modulo cylindrical equivalence and denote by $\mathrm{Cyl}(\overline{\mathcal{A}/\mathcal{G}}) := \cup_\gamma \mathrm{Cyl}_\gamma(\overline{\mathcal{A}/\mathcal{G}})$ the set of all cylindrical functions. The measure (μ_0) can now be seen as the σ-additive extension[17] of the following self-consistent family of measures $(\mu_{0,\gamma})_\gamma$.[18] Let $f \in \mathrm{Cyl}_\gamma(\overline{\mathcal{A}/\mathcal{G}})$. Then

$$\int_{\overline{\mathcal{A}/\mathcal{G}}} d\mu(A) f(A) := \int_{\overline{\mathcal{A}/\mathcal{G}}} d\mu_{0,\gamma}(A) f(A) := \int_{SU(2)^n} d\mu_H(g_1) \cdots d\mu_H(g_n) f_\gamma(g_1, \ldots, g_n), \tag{II.1}$$

where μ_H is the Haar measure on SU(2) and $g_I = h_{e_I}(A)$. In other words, everything is reduced to finite-dimensional integrals over SU(2). One can show that $\mathrm{Cyl}(\overline{\mathcal{A}/\mathcal{G}})$ is dense in $\mathcal{H}$.

Thus integral calculus is introduced on $\overline{\mathcal{A}/\mathcal{G}}$. One can even develop differential calculus on $\overline{\mathcal{A}/\mathcal{G}}$:[19] a differentiable cylindrical function is simply a differentiable function on $\mathrm{SU}(2)^n$. Functional derivatives can be evaluated on differentiable elements of $\mathrm{Cyl}(\overline{\mathcal{A}/\mathcal{G}})$ because on a finite graph a distributional connection can be replaced by a smooth one.[16,18] One sees that differential and integral calculus is inherited from the one on $\mathrm{SU}(2)^n$. Finally, let us define the spaces $\mathrm{Cyl}_\gamma^n(\overline{\mathcal{A}/\mathcal{G}})$, $\mathrm{Cyl}^n(\overline{\mathcal{A}/\mathcal{G}}) = \cup_\gamma \mathrm{Cyl}_\gamma^n(\overline{\mathcal{A}/\mathcal{G}})$, of differentiable cylindrical functions of order $n = 0,1,\ldots,\infty$. Each of $\mathrm{Cyl}^n(\overline{\mathcal{A}/\mathcal{G}})$ is dense in $\mathcal{H}$.

III. THE LENGTH OPERATOR

The stage is now set to derive the length operator. Before we do that we wish to comment on why it was impossible up to now to define this operator rigorously on $\mathcal{H}$ and why it was possible to define volume and area operators.

Consider for instance the volume of a region $R \subset \Sigma$,

$$V(R) := \int_R d^3x \sqrt{|\det(q)|} = \int_R d^3x \sqrt{\left|\frac{1}{3!}\,\epsilon_{abc}\epsilon^{ijk}E^a_i E^b_j E^c_k\right|}, \tag{III.1}$$

where ϵ_{abc} carries density weight -1. We see that this functional involves the square root of a *polynomial* in E^a_i. This is important because, according to the canonical commutation relations, we are supposed to replace E^a_i by $\hat{E}^a_i = -i\ell_p^2\delta/\delta A^i_a$, where $\ell_p := \sqrt{k\hbar}$ is the Planck length. Now one tries to regularize the polynomial and defines its square root by its spectral resolution. This has been done successfully in the literature.[12,13]

We know how to regularize a polynomial in the basic operators A, E, but certainly we do not know how to define a nonpolynomial function. This is precisely the case for

$$q_{ab} = \epsilon_{acd}\epsilon_{bef}\epsilon^{ijk}\epsilon^{imn}\,\frac{E^c_j E^d_k E^e_m E^f_n}{4\det((E^g_l))^2}. \tag{III.2}$$

Even if one could define it, it is by now well known that the operator version of the denominator of (III.2) has a huge kernel so that it could not be defined on a dense domain. This is the reason why a quantization of the length of a piecewise differentiable curve $c:[0,1]\to\Sigma;\ t\to c(t)$ given classically by

$$L(c) := \int_{[0,1]} dt \sqrt{\dot{c}^a(t)\dot{c}^b(t)q_{ab}(c(t))} \tag{III.3}$$

has escaped its quantization in the representation $\mathscr{H}$ so far. Note that no absolute value signs are necessary in (III.3) under the square root since $\dot{c}^a\dot{c}^b q_{ab} = (\dot{c}^a e^i_a)(\dot{c}^b e^j_b)\,\delta_{ij} \geqslant 0$.

A. Regularization of the length operator

The regularization of (III.3) is based on two *key* observations:

Observation 1: The triad is integrable with generating functional $V := V(\Sigma)$, the total volume of Σ. More precisely we have $e := \mathrm{sgn}(\det((e^i_a)))$,

$$\frac{\delta V}{\delta E^a_i} = e\,\frac{e^i_a}{2} = \frac{1}{\kappa}\,\{A^i_a, V\}, \tag{III.4}$$

which can be verified immediately.

Observation 2: The total volume can be quantized in a mathematically rigorous way. Its action on sufficiently differentiable cylindrical functions is given by (we follow Ref. 13)

$$\hat{V}f = l_p^3\hat{v}f = \ell_p^3 \sum_{v\in V(\gamma)} \hat{V}_v f_\gamma = \ell_p^3 \sum_{v\in V(\gamma)} \sqrt{\left|\frac{i}{8\cdot 3!}\sum_{e_I\cup e_J\cup e_K = v} \epsilon(e_I,e_J,e_K)\epsilon_{ijk}X^i_I X^j_J X^k_K\right|} f_\gamma. \tag{III.5}$$

Here $g_I = h_{e_I}(A)$, $X_I = X(g_I)$, and $X^j(g) := \mathrm{tr}(g[-i\sigma_j/2]\partial_g)$ are the components of the right invariant vector field on SU(2) (σ_j are Pauli matrices) where we have assumed that the edges are outgoing at a vertex. Here $V(\gamma)$ is the set of vertices of γ and finally $\epsilon(e_I,e_J,e_K) = \mathrm{sgn}(\det(\dot{e}_I(0),\dot{e}_J(0),\dot{e}_K(0)))$. Note that $\hat{v}$ is a dimensionless operator. One can show that (III.5) has dense domain $\mathrm{Cyl}^3(\mathscr{A}/\mathscr{G})$ and is an essentially self-adjoint operator on $\mathscr{H}$ with a purely discrete spectrum (compare the second paper of Ref. 13).

These two observations motivate the following regularization strategy.

Choose the basis in su(2) given by $\tau_j = -i\sigma_j/2$ and write $e_a = e^i_a\tau_i$, $A_a = A^i_a\tau_i$ so that for smooth A we have $h_e(A) = 1 + A(e) + o(A(e)^2)$, where $A(e) = \int_e A$. Then, according to (III.4),

$$q_{ab} = -2\,\mathrm{tr}(e_a e_b) = -\frac{8}{\kappa^2}\,\mathrm{tr}(\{A_a,V\}\{A_b,V\}). \tag{III.6}$$

Clearly we now are going to replace the integral in (III.3) by a Riemann sum and take the limit. So, let $t_0=0<t_1<\cdots<t_n=1$ be a partition of $[0,1]$ such that points t of nondifferentiability of c are among the values t_i and let $\Delta_i:=t_i-t_{i-1}$. It is understood that in the limit $n\to\infty$ also $\delta:=\max((\Delta_i)_{i=1}^n)\to 0$. Consider then the following quantity:

$$L_n(c):=\frac{1}{\kappa}\sum_{i=1}^{n}\sqrt{2\,\mathrm{tr}(\{h_c(t_{i-1},t_i),V\}\{h_c(t_{i-1},t_i)^{-1},V\})}. \tag{III.7}$$

Here $h_c(s,t)$ denotes the holonomy of A along c from the parameter value $s\to t$. It is easy to see that for a classical (that is, smooth) connection we have $\{h_c(t_{i-1},t_i)^{\pm 1},V\}=\pm\Delta_i\dot{c}^a(\tilde{t}_i)\{A_a(c(\tilde{t}_i)),V\}+o(\Delta_i^2)$, where $\tilde{t}_i$ is some value of $t\in[t_{i-1},t_i]$. Therefore (III.7) converges, in the sense of smooth functions, classically to (III.3) in the limit $n\to\infty$. Note that the argument of the square root is manifestly gauge invariant. The motivation to replace the A's by holonomies of course comes from the fact that $\hat{V}$ has finite action on holonomies as seen from (III.5).

The final step is to replace V by $\hat{V}$ and Poisson brackets by commutators times $1/i\hbar$. The result is

$$\hat{L}_n(c):=\ell_p\sum_{i=1}^{n}\sqrt{-8\,\mathrm{tr}([h_c(t_{i-1},t_i),\hat{v}][h_c(t_{i-1},t_i)^{-1},\hat{v}])}. \tag{III.8}$$

To complete the definition of the length operator we now define for each thrice differentiable cylindrical function $f\in \mathrm{Cyl}^3(\overline{\mathcal{A}/\mathcal{G}})$

$$\hat{L}(c)f:=\lim_{n\to\infty}[\hat{L}_n(c)f]. \tag{III.9}$$

As it stands, (III.9) does not make sense yet because we have not shown that the limit exists and it may matter how to choose the partition $(t_i)_{i=0}^n$. Also, it is far from obvious that the square root is well defined because we did not show that its argument is a positive and self-adjoint operator. These issues will be settled in the next subsections.

B. Finiteness and choice of the partition adapted to a graph

Let f be a function cylindrical with respect to a graph γ and let s be one of the segments of c into which we have partitioned it. We wish to study the action of the operator

$$\hat{l}_s^2:=-8\,\mathrm{tr}([h_s,\hat{v}][h_s^{-1},\hat{v}]) \tag{III.10}$$

on f. By choosing n in (III.9) large enough we may assume without loss of generality that s and γ are either disjoint, intersect at, at most one point, or s is contained in γ [here we have made use of the piecewise analyticity of γ (Ref. 18)]. Further we adapt the partition to the graph in the following way: (a) if s and γ intersect in a point, then this point is a boundary point of s, and (b) if s is contained in γ, then it is contained in an edge of γ. This is a choice that we have to make in order to achieve independence of the partition. The resulting operator is different if one assumes that s and γ do not intersect at an endpoint of s.

We have in general $V(s\cup\gamma)=V(\gamma)\cup V(s)\cup V(\gamma\cap s)=V(\gamma)\cup V(\gamma\cap s)$. The volume operator applied to a graph is a sum of the $\hat{V}_v$ for each vertex of the graph and $\hat{V}_v$ only depends on those edges of the graph which are incident at v as follows from (III.5). Therefore $h_s\hat{V}_v=\hat{V}_v h_s$ if s is not incident at v. It follows that

$$[h_s^{-1},\hat{v}]f=\sum_{v\in V(\gamma)}h_s^{-1}\hat{V}_v f-\sum_{v\in V(\gamma\cup_s)}\hat{V}_v h_s^{-1}f=\sum_{v\in V(\gamma)\cap\partial s}[h_s^{-1},\hat{V}_v]f-\sum_{v\in V(\gamma\cap s)-V(\gamma)}\hat{V}_v h_s^{-1}f, \tag{III.11}$$

and both sums in the last line have at most one nonvanishing term corresponding to an endpoint of s intersecting γ.

Case 1: $\gamma\cap s=\varnothing$. Then $\hat{l}_s^2 f=0$ as is immediate from (III.11).

Case 2: $p \in \gamma \cap s$. Subcase (a): p is neither a vertex of γ nor a kink of c and so only the second term in (III.11) survives. This implies that p is a trivalent vertex with only two independent tangent directions of the edges of γ and the segment s incident at p. The properties of the volume operator now imply that the contribution $\hat{V}_p$ of $\hat{v}$ vanishes and therefore $\hat{l}_p^2 f = 0$.

Subcase (b): p is not a vertex of γ but a kink of c. Since s is only one of the segments of c incident at p this case is not different from (a).

Subcase (c): p is a vertex of γ but not a kink of c. Now the result can be nonvanishing. We have for a vertex $p=v$ of γ that $\hat{l}_s^2 f = -8\,\mathrm{tr}([h_s, \hat{V}_v][h_s^{-1}, \hat{V}_v])f$, that is, only the first term in (III.11) survives. That the volume operator in the second commutator also reduces to $\hat{V}_v$ follows by a similar argument.

Subcase (d): p is both a vertex of γ and a kink of s. Again, this case does not differ from (c) for the same reason as (b) was equal to (a).

So we conclude that for large enough n the operator (III.8) reduces to

$$\hat{L}_n(c) := \not{\ell}_p \sum_{v \in V(\gamma)} \sum_{v \in s_i} \sqrt{-8\,\mathrm{tr}([h_{s_i}, \hat{V}_v][h_{s_i}^{-1}, \hat{V}_v])}, \tag{III.12}$$

where we have denoted the segment $s_i := c([\mathbf{t}_{i-1}, t_i])$. This demonstrates that $\hat{L}_n(c)$ is a finite operator for each n because there are at most $|V(\gamma)|$ terms in the sum (III.12). The next question is whether the limit $n \to \infty$ exists.

C. Existence of the limit $n \to \infty$

We now show that (III.12) is actually independent of the s_i so that the limit $n \to \infty$ is already taken and the limit therefore exists trivially.

In fact, s_i can be an arbitrarily ''short'' (we put this term in quotation marks because there is no background metric available with respect to which we could measure the length of s_i) segment of c starting at one and only one vertex v of γ.

Let us first recall the notion of a spin-network state.[20–22] We use the notation of Ref. 22: Label the edges e of a graph γ with nontrivial irreducible representations of SU(2), that is, assign to each of them a spin quantum number $j_e > 0$. If π_j is an irreducible representation of SU(2) with weight (or spin) j, then the spin-network state depends on $\pi_{j_e}(h_e)$. Further, assign to each vertex v of γ a contractor matrix m_v which contracts the matrix elements of the tensor product (over the set of edges e incident at v) of the $\pi_{j_e}(h_e)$ in such a way that the resulting state is gauge invariant. We label these spin-network states by $T_{\gamma,\mathbf{j},\mathbf{m}}$. One can show that spin-network states form an orthonormal basis of $\mathscr{H}$. Consider first the case that γ and $s := s_i$ intersect at only one point. Since $\hat{l}_s^2$ is gauge invariant, the result of applying $\hat{l}_s^2$ to a gauge-invariant cylindrical function must be a gauge-invariant cylindrical function f' which depends on the graph $s \cup \gamma$. Let us decompose f' into a basis of spin-network states. Since f did not depend on s, the spin assigned to s for a particular term T in the spin-network decomposition of f' can only be $j = \pm 1, 0$. In the case $j = 0$ the state T does not depend on s at all. In case that $j = \pm 1$, then T would be a spin-network state which contains an univalent vertex, namely the endpoint of s distinct from v, and there is only one edge, namely s, incident at it and colored with $j \neq 0$. Such a state is not gauge invariant. Therefore the case $j \neq 0$ does not appear.

Now consider the case that $s := s_i$ is contained in an edge e of γ and starts at a vertex v of γ. By choosing n high enough we may assume that s is properly contained in e, that is, $e' := e - s \neq \emptyset$. Without loss of generality we may assume that f is a spin-network state and thus e carries spin $j > 0$. Then in the spin-network decomposition of f' a particular term depends on $\gamma = \gamma \cup s$ in which the spins of all the edges of γ distinct from e are unchanged while e' carries spin j and s carries spin $j' \in \{j, j \pm 1\}$. Consider the divalent ''vertex'' $p = s \cap e'$ of γ. In the case that $j' = j$, then T depends on all of e with the same spin, i.e., it does not depend on s and e' with different spins. The only gauge-invariant way to contract the corresponding matrix elements at p is such that the resulting state depends on s, e' only through their product $e = s \circ e'$. In the case that $j' = j \pm 1$, then p is a two-valent vertex at which two edges e', s with distinct spins $j, j' = j \pm 1$ are incident. There exists no vertex contractor that makes such a state gauge invariant; therefore this case cannot appear.

This furnishes the proof that for a spin-network state f the function $\hat{L}_n(c)f$ still depends on all of the edges of γ if f did and that there is no dependence on the segments of the partition of c, which is to be expected since the classical length of a curve is a functional of E^a_i only. Thus, the limit $n\to\infty$ is already taken in (III.12).

D. Cylindrical consistency

Since we have adapted our partition to the graph on which a cylindrical function depends, although the operator (III.12) was derived, it is not obvious any more that the family of operators $(\hat{L}_\gamma(c))$ constructed actually line up and qualify as the projections of an operator on $\mathscr{H}$. So let $\gamma\subset\gamma'$. We need to show that (1) $(\hat{L}_{\gamma'}(c))_{|\gamma}=\hat{L}_\gamma(c)$, that is, the restriction of a projection to a smaller graph actually coincides with the projection to the smaller graph, and (2) the domain of $\hat{L}_\gamma(c)$ is contained in that of $\hat{L}_{\gamma'}(c)$. Issue (2) follows trivially by inspection if we choose the domain of $\hat{L}_\gamma(c)$ to be $\mathrm{Cyl}^3_\gamma(\overline{\mathscr{A}/\mathscr{G}})$, which we can since the volume operator has that domain. Issue (1) follows immediately: Given a curve c, the actions of $\hat{L}_\gamma(c)$ and $\hat{L}_{\gamma'}(c)$ on a function f cylindrical with respect to γ differ if either (a) γ' has more vertices intersecting c than γ or (b) there are additional edges of γ' incident at a common vertex of γ and γ' intersecting c. This follows directly by inspection from (III.12). So first let v be a vertex of γ' but not of γ and s be a segment of c incident of v. Then $[h_s^{-1},\ \hat{V}_v]f=-f\hat{V}_v h_s^{-1}=0$ and so this term in the sum (III.12) does not contribute. Now if case (b) occurs, then the cylindrical consistency of the volume operator assures that the edges of $\gamma'-\gamma$ incident at v do not contribute.

This furnishes the proof that (III.12) is consistently defined.

E. Symmetry and positivity

We wish to show that (1) every projection $\hat{L}_\gamma(c)$ is a symmetric operator on $\mathscr{H}$ with domain $\mathrm{Cyl}^3_\gamma(\overline{\mathscr{A}/\mathscr{G}})$ and (2) the family of projections $((\hat{L}_\gamma(c))_\gamma)$ comes from a positive semi-definite symmetric operator on $\mathscr{H}$ with domain $\mathrm{Cyl}^3(\overline{\mathscr{A}/\mathscr{G}})$.

Lemma III.1: Every projection $\hat{L}_\gamma(c)$ defines a symmetric and positive semi-definite operator on $\mathscr{H}$ with domain $\mathscr{D}_\gamma:=\mathrm{Cyl}^3_\gamma(\overline{\mathscr{A}/\mathscr{G}})$.

Proof: Let us begin with $\hat{l}_s^2$. Since $\hat{V}_v$ is a symmetric operator on $\mathscr{H}$ we find for the adjoint of $[h_s^{-1},\ \hat{V}_v]$ using the unitarity of SU(2)

$$[h_s,\ \hat{V}_v]^\dagger=[\hat{V}_v,\ \overline{h_s}]=-[(h_s^{-1})^T,\ \hat{V}_v], \tag{III.13}$$

where $(.)^T$ denotes the transpose of (.). It follows that

$$\hat{l}_s^2:=+8\sum_{A,B}\hat{K}_{AB}(s)^\dagger\hat{K}_{AB}(s),\quad \text{where}\ \ \hat{K}_{AB}(s)=[(h_s^{-1})_{AB},\ \hat{V}], \tag{III.14}$$

which shows that $\hat{l}_s^2$ is a symmetric and positive semi-definite operator on $\mathscr{H}$ and therefore possesses a square root $\hat{l}_s$. The statement about the domain is a consequence of the fact that $\hat{L}_\gamma(c)$ is defined in terms of the spectral projections of $\hat{V}_\gamma$ which has domain $\mathscr{D}_\gamma$. □

Let us derive a more convenient expression for (III.12):

By means of the basic SL(2,ℂ) formula $g^{-1}_{AB}=\epsilon_{AC}\epsilon_{BD}g_{DC}$ we readily derive that $\hat{l}_s=\hat{l}_{s^{-1}}$. This motivates the following notation:

Let there be given an oriented curve c and a vertex v of γ that intersects it. If v is an interior point of c, consider any two segments $s^\pm_v$ of c which start at v and are ''short'' enough as not to intersect γ at any other of its vertices. If v is an endpoint of c, we need only one such segment $s^+_v=s^-_v$ starting at v. In (III.12) the segments s_i of c starting at vertices of γ come with the orientation of c. However, as we just showed, the operator $\hat{l}_s$ is invariant under reversal of the orientation of s and the result of applying it to a gauge-invariant function is independent of the choice of s as long as it is ''short'' enough. Therefore, let

$$N(v,c)=\begin{cases}0, & v\notin c,\\ \frac{1}{2}, & v \text{ is an point of } c,\\ 1, & v \text{ is an interior point of } c,\end{cases} \tag{III.15}$$

and define $\hat{L}_v^{\pm}(c):=\hat{l}_{s_v^{\pm}}(c)$. Then the length operator can be conveniently written

$$\hat{L}_\gamma(c)=\sum_{v\in V(\gamma)} N(v,c)[\hat{L}_v^+(c)+\hat{L}_v^-(c)]. \tag{III.16}$$

Theorem III.1: *The family* $(\hat{L}_\gamma(c),\mathscr{D}_\gamma)$ *defines a positive semi-definite symmetric operator on* $\mathscr{D}:=\mathrm{Cyl}^3(\overline{\mathscr{A}/\mathscr{G}})$.

Proof: So far we have demonstrated $\hat{L}_\gamma(c)$ is a symmetric and positive semi-definite operator for each γ with domain $\mathscr{D}_\gamma=\mathrm{Cyl}^3_\gamma(\overline{\mathscr{A}/\mathscr{G}})$. However, to qualify as a symmetric projection of a symmetric operator requires more:

Let $\hat{S}$ be a symmetric operator on $\mathscr{H}$ with symmetric projections $\hat{S}_\gamma$. Let $f=p^*_\gamma f_\gamma$ and $g=p^*_{\gamma'}g_{\gamma'}$ be cylindrical functions. Then

$$\langle g,\hat{S}f\rangle=\langle g,\hat{S}_\gamma f\rangle=\langle \hat{S}_\gamma g,f\rangle\overset{!}{=}\langle \hat{S}g,f\rangle=\langle \hat{S}_{\gamma'}g,f\rangle. \tag{III.17}$$

Condition (III.17) is necessary and sufficient for a family of self-consistent symmetric projections to come from a symmetric operator. Let us check that (III.17) is satisfied for $\hat{L}(c)$ for each curve c.

It is sufficient to check it for the case that f,g are spin-network states. Now since $\hat{L}_\gamma(c)$ does not change the graph γ on which f depends nontrivially, it follows that $\langle g,\hat{L}_\gamma(c)f\rangle$ is nonvanishing if and only if $\gamma=\gamma'$ because spin-network states depending on different graphs are orthogonal.[20–22] The same holds for $\langle \hat{L}_{\gamma'}(c)g,f\rangle$. Symmetry now follows from the cylindrical consistency and the statement about the domain is because $\hat{V}$ has this domain. □

F. Self-adjointness

Although the expression of $\hat{L}_\gamma(c)f$ does not depend on the $s_v^{\pm}$ such that there must be a way to write purely in terms of the right invariant vector fields X_I very much like in the case of the volume operator (III.5), it is not clear to us how to do that. We can therefore not employ the essential self-adjointness of iX_I with core $\mathrm{Cyl}^1(\overline{\mathscr{A}/\mathscr{G}})$ in order to show that $\hat{L}_\gamma(c)$ is essentially self-adjoint as well with core $\mathrm{Cyl}^3(\overline{\mathscr{A}/\mathscr{G}})$.

An independent proof which demonstrates that there exist self-adjoint extensions goes as follows:

Theorem III.2: *The operator* $(\hat{L}(c),\mathscr{D})$ *admits self-adjoint extensions on* $\mathscr{H}$.

Proof: The expression of $\hat{L}(c)$ is purely real and symmetric. Therefore it commutes with the antiunitary operator of complex conjugation. The assertion now follows from von Neumann's theorem (Ref. 23, p. 143). □

A possible choice of extension is given by its Friedrichs extension.

IV. SPECTRAL ANALYSIS OF THE LENGTH OPERATOR

A. Discreteness

The important feature of $\hat{L}_\gamma(c)$ is that it changes neither the graph γ on which a cylindrical function depends nor the irreducible representations of the corresponding spin-network states into which a cylindrical function f can be decomposed. Since the number of spin-network states associated with a fixed graph and a fixed coloring of its edges by irreducible representations is finite dimensional,[22] it follows that the length operator on each such subspace of $\mathscr{D}$ is just a symmetric, positive semi-definite, finite-dimensional matrix. Its eigenvalues are real and are given by certain non-negative functions $\lambda(\{j_I\})$ of the spins j_I associated with the edges of γ. Since spin

networks span $\mathcal{D}_\gamma$ and provide a countable basis for its completion $\mathcal{H}_\gamma$ (with respect to $\mu_{0,\gamma}$) it follows that there exists a countable basis of eigenvectors for $\mathcal{H}_\gamma$. The corresponding eigenvalues therefore form a countable set and lie in the point spectrum of $\hat{L}_\gamma(c)$.

Recall that a point in the spectrum is said to be in the discrete spectrum if it is an isolated point and an eigenvalue of finite multiplicity (clearly 0 has infinite multiplicity; all functions cylindrical with respect to graphs not intersecting the curve c are annihilated). In order to show that the point spectrum that $\hat{L}_\gamma(c)$ attains on $\mathcal{D}_\gamma$ is discrete it would be sufficient to show that $\lambda(\{j_I\})$ diverges whenever $j:=j_1+\cdots+j_n$, n being the number of edges of γ, diverges. Namely, if there was a finite condensation point in the point spectrum, then an infinite number of different n-tuples would give an eigenvalue which lies in a finite neighborhood of that condensation point but necessarily the corresponding values of j must diverge which would be a contradiction. The same argument shows that there would not be an eigenvalue of infinite multiplicity.

Looking at the eigenvalue formulas derived below for some simple graphs, such a behavior of λ is plausible because $\hat{L}_\gamma(c)$ is an unbounded operator; however, a strict proof is missing at this point.

Discreteness of the spectrum of $\hat{L}_\gamma(c)$ would follow immediately if we could prove it for the volume operator. An elegant method of proof would be to show that $\hat{V}$ is (a positive root of) an elliptic operator. Since this operator acts on the compact manifold $\mathrm{SU}(2)^n$, standard results form harmonic analysis would imply that its spectrum is discrete. Unfortunately this does not work: the volume operator is easily seen to be the fourth root of the operator $\hat{q}^\dagger\hat{q}$, $\hat{q}=\Sigma_{IJK}\epsilon_{IJK}\hat{q}_{IJK}$ (compare Ref. 7) and so is a sixth-order homogenous polynomial in the derivative operators X_I. Its principal symbol can be seen to be a non-negative function with an at least two-dimensional kernel and therefore is far from being invertible. Indeed, it is by now well known that the volume operator has a kernel which includes all divalent and trivalent graphs.

Summarizing, we have shown that $\hat{L}_\gamma(c)$ has pure point spectrum when restricted to $\mathcal{D}_\gamma$. Now consider the complete spectrum of $\hat{L}_\gamma(c)$ on all of $\mathcal{H}_\gamma$. Since $\hat{L}_\gamma(c)$ is a self-adjoint (not only symmetric) operator, it has spectral projections which are orthogonal for disjoint subsets of its spectrum. It follows that if I is a subset of the real numbers not contained in the part of the spectrum that $\hat{L}_\gamma(c)$ attains on $\mathcal{D}_\gamma$, and if $\hat{P}_I$ is the corresponding spectral projection, then $\mathcal{H}'_\gamma:=\hat{P}_I\mathcal{H}_\gamma$ and $\mathcal{D}_\gamma$ are orthogonal. However, $\mathcal{D}_\gamma$ is dense in $\mathcal{H}_\gamma$, therefore for each $v\in\mathcal{H}'_\gamma$, $\epsilon>0$ we find $f\in\mathcal{D}_\gamma$ such that $\|v-f\|<\epsilon$. On the other hand, by orthogonality $\|v-f\|\geqslant\|v\|$, which is a contradiction unless $v=0$. Therefore the complete spectrum of $\hat{L}_\gamma(c)$ is already attained on $\mathcal{D}_\gamma$ and it has no continuous part very much like its companions, the area and volume operators.[12,13] Thus, the spectrum on $\mathcal{H}_\gamma$ is discrete in the sense that it does not have a continuous part.

Similarly, it follows that the spectrum of $\hat{L}(c)$ is attained on $\mathcal{D}$ and also does not have a continuous part (this property is shared by all three operators, length, area, and volume): Although the set of piecewise analytic graphs is uncountable, the matrix elements of the length operator in a spin-network basis do not depend on the graph, they only depend on the quantum numbers **j**, **m** *and are therefore diffeomorphism invariant*. Therefore, the spectrum attained on $\mathcal{D}_\gamma$ and $\mathcal{D}_{\varphi(\gamma)}$, $\varphi\in\mathrm{Diff}(\Sigma)$ an analyticity preserving diffeomorphism, is identical. Moreover, the spectrum does not depend on whether two curves touch each other in a C^m or C^n fashion for any $1\leqslant m<n$. It follows that the spectrum only depends on the C^∞ properties of the diffeomorphism class of a graph, that is, all that matters is whether two edges are distinct or coincide. In other words, all we need to know about a graph is

(a) the number N of its vertices,
(b) the valence $n(v)$ of each vertex v, and
(c) the topologically different ways of connecting edges incident at different vertices in a C^∞ manner which is a finite number.

Thus, since this characterization of a graph depends on discrete labels and the union of countable sets is a countable set, it follows that the spectrum is still discrete in the sense that it does not have a continuous part. On the other hand, we see that every eigenvalue of the length, area, or volume operators is of uncountably infinite multiplicity when we consider all of $\mathcal{H}$.

Given the results stated in this section we can now establish that the length operator is even essentially self-adjoint with core $\mathrm{Cyl}^3(\overline{\mathcal{A}/\mathcal{G}})$. To see this we note that the Hilbert space is the completion of an uncountable direct sum

$$\mathcal{H}=\overline{\oplus_{\gamma,\mathbf{j}}\mathcal{H}_{\gamma,\mathbf{j}}},$$

where the sum is over all graphs and all colorings of the edges of the graph. As said above, each $\mathcal{H}_{\gamma,\mathbf{j}}$ is finite dimensional and each $\hat{L}_\gamma$ is self-adjoint on $\mathcal{H}_{\gamma,\mathbf{j}}$ so that $\hat{L}_\gamma \pm i$ id has dense range $D_{\gamma,\mathbf{j}}=\mathcal{H}_{\gamma,\mathbf{j}}$. We now compute

$$[\hat{L}(c)\pm \mathrm{iid}](\oplus_{\gamma,\mathbf{j}}\mathcal{H}_{\gamma,\mathbf{j}})=\oplus_{\gamma,\mathbf{j}}[\hat{L}_\gamma(c)\pm \mathrm{iid}].\mathcal{H}_{\gamma,\mathbf{j}}=\oplus_{\gamma,\mathbf{j}}\mathcal{H}_{\gamma,\mathbf{j}}\subset[\hat{L}(c)\pm \mathrm{iid}].\mathcal{H}.$$

However, the left-hand side is dense in $\mathcal{H}$. So, $\hat{L}(c)$ satisfies the basic criterion for essential self-adjointness. Actually this result follows trivially from general results on cylindrically consistent families of essentially self-adjoint operators[19] where the cylindrical subspaces are now labeled by γ, $\mathbf{j}$.

B. Eigenvalues

By inspection, the task of giving a closed formula for the eigenvalues of the length operator requires having a closed formula for the spectrum of the volume operator at one's disposal which we lack, however, at the present stage (see, however, Refs. 24 and 25 for a closed formula for its matrix elements). We will therefore restrict ourselves here to computing the spectrum for some simple types of graphs and thereby obtain the quantum of length.

Specifically, it is comparatively simple to compute the spectrum of the length operator when restricted to at most trivalent graphs, thus including the classical spin networks which were introduced in Ref. 15 and whose vertices are all precisely trivalent. Since for trivalent graphs the vertex contractors of a spin network are unique and since the result of applying the length operator to a spin-network state is a spin-network state on the same graph and with the same spin, it follows that all spin-network states on trivalent graphs are eigenvectors of the length operator. We will see that the corresponding eigenvalues are nonvanishing in general. This is an astonishing feature because the volume operator is known to vanish on trivalent graphs. Now, classically the volume of a region is known if one can measure the lengths of arbitrary curves through that region and so nonvanishing lengths of curves result in nonvanishing volume. This indicates that trivalent graphs are rather special and are insufficient to construct weave states that approximate a given classical geometry.

The computations are largely governed by the properties of the $6j$-symbol of the recoupling theory of angular momentum which we recall in the Appendix. The way the recoupling theory of spin systems enters the stage is as follows: in our computations we evaluate the volume operator at a given vertex v on functions f which transform according to an irreducible representation j of SU(2) under gauge transformations at v. This j is nothing other than the resulting total angular momentum to which the angular momenta j_I (which color the edges e_I incident at v) couple. There are different ways to couple angular momenta j_I to resulting spin j, and this freedom is determined by the recoupling quantum numbers $j_{IJ}, j_{IJK},\ldots$ (compare the Appendix) and results in different contractors of the not necessarily gauge-invariant (or extended) spin networks. Here we mean by an extended spin network just any function that depends on the edges of a graph through the matrix elements of irreducible representations of SU(2) evaluated at the holonomy of the corresponding edge and transforms at each vertex according to an irreducible representation of SU(2) under gauge transformations. The point is now that the function f is easily seen to be in the left regular representation of $\mathrm{SU}(2)^n$, n being the valence of the vertex v, defined by $\hat{R}(g_1,\ldots,g_n)f(h_1,\ldots,h_n)=f(g_1h_1,\ldots,g_nh_n)$. On the other hand, the connection with the abstract angular momentum Hilbert space where SU(2) acts by the abstract unitary representation $\hat{U}(g)$ and which is spanned by the vectors of the form $|(j_1,m_1),\ldots,(j_n,m_m);k_1,\ldots,k_n\rangle=|j_1,m_1;k_1\rangle \otimes\cdots\otimes|j_n,m_n;k_n\rangle$, where k_I are certain additional quantum numbers, is made as follows: Consider the special functions $(\pi_j(h))_{m,m'}$ given by the matrix elements of the jth irreducible representation of SU(2), $m,m'\in\{-j,-j+1,\ldots,j\}$. Consider the Hilbert space $L_2(\mathrm{SU}(2),d\mu_H)$ and let $|g\rangle$ be the usual Dirac generalized eigenstates of the multiplication operator $\hat{g}$. Then

$(\pi_j(h))_{m,m'}=\langle h|j,m;m'\rangle$. The proof is by checking the representation property $\hat{R}(g)(\pi_j(h))_{m,m'}=(\pi_j(gh))_{m,m'}=(\pi_j(g))_{m,\tilde{m}}(\pi_j(h))_{\tilde{m},m'}=\langle h|\hat{U}(g)|j,m;m'\rangle$ by definition of the states $|j,m;m'\rangle$. The reader is referred to Ref. 25 for more details.

It follows from these considerations that instead of doing tedious computations within the left regular representation (spin-network states or traces of the holonomy around closed loops[10]), it is far easier to do them in the abstract representation which allows the use of the powerful Clebsh–Gordan theory of angular momentum. We will do that in what follows. In particular, it follows immediately that the right invariant vector field X_I is identified with $2iJ_I$, where J_I is the angular momentum operator of the spin associated with the Ith edge which is the self-adjoint generator of the unitary group $\hat{U}(g)$.

We are now in the position to compute the spectrum of the length operator on trivalent graphs γ. First we cast the volume operator in the more convenient form

$$\hat{V}=\not{\sum}_p^3\hat{v}f=\not{\sum}_p^3\sum_{v\in V(\gamma)}\hat{V}_v \quad \text{where} \quad \hat{V}_v:=\sqrt{\left|\frac{i}{32}\hat{q}_v\right|},$$
$$\hat{q}_v=\sum_{e_I\cup e_J\cup e_K=v,I<J<K}\epsilon(e_I,e_J,e_K)\hat{q}_{IJK}, \quad \text{where} \quad \hat{q}_{IJK}:=[J_{IJ}^2,J_{JK}^2]. \tag{IV.1}$$

To arrive at this expression one only has to use elementary angular momentum algebra. Expression (IV.1) captures a neat interpretation of the volume operator: it measures the difference between recoupling schemes of n angular momenta based on J_{IJ} and J_{JK}, respectively. This is why the recoupling theory is important and the matrix elements of the volume operator can be given purely in terms of polynomials of $6j$-symbols.[25]

Now let v be a vertex of γ which intersects c. From (III.16) we find $[h:=h_{s_v^\pm},\ \hat{L}_v(c):=\hat{L}_v^\pm(c)]$

$$\tfrac{1}{8}\hat{L}_v(c)^2=-[\mathrm{tr}(h^{-1}\hat{V}h)\hat{V}+\hat{V}\,\mathrm{tr}(h^{-1}\hat{V}h)]+2\hat{V}^2+\mathrm{tr}(h^{-1}\hat{V}^2h), \tag{IV.2}$$

and the simplification that occurs on trivalent graphs is that the first three terms vanish identically. We have two possibilities:

case A: s_v lies within an edge of γ incident at v or

case B: s_v is not contained in an edge of γ.

We will discuss both cases separately.

1. Case A

We may without loss of generality assume that s_v coincides with one, say e_3, of the three edges of γ incident at v. This is because (1) if $e=s_v\circ e'$, then for any irreducible representation π_j of SU(2) we have $\pi_j(h_e)=\pi_j(h_{s_v})\pi_j(h_{e'})$ so a spin-network state also depends on s_v through π_j and (2) for a right invariant vector field $X(h_{s_v})=X(h_{s_v}h_{e'})=X(h_e)$ by definition of right invariance. Therefore the volume operator (IV.1) contains only one term $\hat{q}_{123}$.

Consider a trivalent spin-network function $f=T_{\gamma,\mathbf{j}}$ with spins j_1,j_2,j_3 assigned to e_1,e_2,e_3 (we have suppressed the contractor matrices $\mathbf{m}$ since they are unique for trivalent spin networks). Then $h_{e_3}f$ can be decomposed into extended spin network functions with total angular momentum $j=\frac{1}{2}$ and edge spins $j_1'=j_1,j_2'=j_2,j_3'=j_3\pm\frac{1}{2}$ by usual Clebsh–Gordan representation theory. Let us determine the precise coefficients of that decomposition.

Lemma IV.1: Let $n=2j$ so that $\pi_j(g)_{A_1,\ldots,A_n;B_1,\ldots,B_n}=g_{(A_1,B_1}\cdots g_{A_n),B_n}$ where the round bracket means total symmetrization in the A indices. Then

$$g_{A_0,B_0}\pi_j(g)_{A_1,\ldots,A_n;B_1,\ldots,B_n}=\pi_{j+1/2}(g)_{A_0,\ldots,A_n;B_0,\ldots,B_n}$$
$$-\frac{n}{n+1}\epsilon_{A_0(A_1}\pi_{j-1/2}(g)_{A_2,\ldots,A_n);(B_2,\ldots,B_n}\epsilon_{B_1)B_0}. \tag{IV.3}$$

Proof: Elementary linear algebra. □

We now multiply each of the two terms in (IV.3) with $g^{-1}_{B_0,A_0}$ and sum over A_0, B_0. The result is

$$g^{-1}_{B_0,A_0}\pi_{j+1/2}(g)_{A_0;\ldots,A_n;B_0,\ldots,B_n}=\frac{n+2}{n+1}\,\pi_j(g)_{A_1,\ldots,A_n;B_1,\ldots,B_n},$$
$$g^{-1}_{B_0,A_0}\epsilon_{A_0(A_1}\pi_{j-1/2}(g)_{A_2,\ldots,A_n);(B_n,\ldots,B_n}\epsilon_{B_1)B_0}=-\pi_j(g)_{A_1,\ldots,A_n;B_1,\ldots,B_n}. \tag{IV.4}$$

Formulas (IV.4) illustrate the computational reason for why the edge s_v does not appear in a gauge invariant function f after evaluating $\hat{L}(c)f$ on it. We now can write $h_{e_3}f=f_+ +[n_3/(n_3+1)]f_-$ where, according to (IV.3), the vectors f_+ and f_- respectively are proportional to the vectors $|j_{12}=j_3,j=\frac{1}{2};j_1,j_2,j_3+\frac{1}{2}\rangle$ and $|j_{12}=j_3,j=\frac{1}{2};j_1,j_2,j_3-\frac{1}{2}\rangle$, respectively, on the abstract angular momentum Hilbert space. That in both vectors j_{12} still equals j_3 follows from the fact that we did not change the way the matrices are contracted in f in multiplying it by h_{e_3}.

The space of states V_+ with total angular momentum $j=\frac{1}{2}$ and spins $j_1,j_2,j_3'=j_3+\frac{1}{2}$ is two-dimensional: it is spanned by $|j_{12}=j_3,j=\frac{1}{2};j_1,j_2,j_3+\frac{1}{2}\rangle$ and $|j_{12}=j_3+1,j=\frac{1}{2};j_1,j_2,j_3+\frac{1}{2}\rangle$, respectively. Likewise, the span of the space of states V_- with total angular momentum $j=\frac{1}{2}$ and spins $j_1,j_2,j_3'=j_3-\frac{1}{2}$ is given by $|j_{12}=j_3,j=\frac{1}{2};j_1,j_2,j_3-\frac{1}{2}\rangle$ and, provided that $j_3\geqslant 1$, $|j_{12}=j_3-1,j=1/2;j_1,j_2,j_3-\frac{1}{2}\rangle$, respectively. The volume operator leaves these two spaces separately invariant and the operator $\hat{q}_{123}$, being antisymmetric on $\mathscr{H}$, reduces to an antisymmetric 2×2 matrix on V_+ and to an antisymmetric 2×2 matrix on V_- if $j_3\geqslant 1$ and to the zero matrix if $j_3<1$. Let the matrix elements different from zero of these matrices be denoted by $\pm\mu_+$, $\pm\mu_-$, respectively. Then, since we take the modulus of the square root of $\hat{q}_{123}$ it follows that $f_\pm$ are already eigenvectors of $\hat{V}$ with eigenvalues $\lambda_\pm:=\sqrt{|\mu_\pm|}/4\sqrt{2}$. It follows then from (IV.4) and $h^{-1}\hat{V}^2h=(h^{-1}\hat{V}h)^2$ that our spin-network state is an eigenfunction of the length operator $\hat{L}_v(c)$ with eigenvalue $(\ell_p/2)\sqrt{[1/(n_3+1)][(n_3+2)\lambda_+^2+n_3\lambda_-^2]}$.

It remains to compute the matrix elements $\mu_\pm$ of $\hat{q}_{123}=[J^2_{12},J^2_{23}]$. We have

$$\begin{aligned}\mu_+&:=\langle j_{12}'=j_3+1,j=\tfrac{1}{2};j_1,j_2,j_3'=j_3+\tfrac{1}{2}|\hat{q}_{123}|j_{12}=j_3,j=\tfrac{1}{2};j_1,j_2,j_3'=j_3+\tfrac{1}{2}\rangle\\
&=[(j_3+1)(j_3+2)-j_3(j_3+1)]\langle j_{12}'=j_3+1,j=\tfrac{1}{2}|J^2_{23}|j_{12}=j_3,j=\tfrac{1}{2}\rangle\\
&=2(j_3+1)\sum_{j_{23}=j_1\pm 1/2}j_{23}(j_{23}+1)\langle j_{12}'=j_3+1,j=\tfrac{1}{2}|j_{23},j=\tfrac{1}{2}\rangle\times\langle j_{23},j=\tfrac{1}{2}|j_{12}=j_3,j=\tfrac{1}{2}\rangle,\end{aligned} \tag{IV.5}$$

where we have suppressed $j_1,j_2,j_3'=j_3+\frac{1}{2}$. In the last step we have inserted a complete 1 in form of the coupling scheme $(j_2,j_3')\to j_{23}$, $(j_1,j_{23})\to j$ and realized that the only possible values for j_{23} in order to couple to spin $j=\frac{1}{2}$ with j_1 are the ones displayed. Completely analogously we find

$$\begin{aligned}\mu_-&:=\langle j_{12}'=j_3-1,j=\tfrac{1}{2};j_1,j_2,j_3'=j_3-\tfrac{1}{2}|\hat{q}_{123}|j_12=j_3,j=\tfrac{1}{2};j_1,j_2,j_3'=j_3-\tfrac{1}{2}\rangle\\
&=[(j_3-1)j_3-j_3(j_3+1)]\langle j_{12}'=j_3-1,j=\tfrac{1}{2}|J^2_{23}|j_{12}=j_3,j=\tfrac{1}{2}\rangle\\
&=-2j_3\sum_{j_{23}=j_1\pm 1/2}j_{23}(j_{23}+1)\langle j_{12}'=j_3-1,j=\tfrac{1}{2}|j_{23},j=\tfrac{1}{2}\rangle\langle j_{23},j=\tfrac{1}{2}|j_{12}=j_3,j=\tfrac{1}{2}\rangle.\end{aligned} \tag{IV.6}$$

We now use the formulas given in the Appendix to compute the eight remaining matrix elements in terms of $6j$-symbols and evaluate the latter by means of the Racah formula. The result is

$$\mu_+ = \sqrt{(a+b+c)(a+b-c)(b+c-a)(c+a-b)},$$
$$\text{where } a=j_1=\tfrac{1}{2}, b=j_2+\tfrac{1}{2}, \text{ and } c=j_3+1,$$
$$\mu_- = -\sqrt{(a+b+c)(a+b-c)(b+c-a)(c+a-b)}, \tag{IV.7}$$
$$\text{where } a=j_1+\tfrac{1}{2}, b=j_2+\tfrac{1}{2}, c=j_3.$$

The final result is thus given by the following theorem.

Theorem IV.1: *The eigenvalue* λ *of* $\hat{L}_v(c)$ *for a trivalent spin-network state* T_γ *with vertex at* v *such that* c *and* γ *share a segment incident at* v *is given by* ($j_3 \in \{j_1+j_2, j_1+j_2-1, \ldots, |j_1-j_2|\}$)

$$\lambda = \frac{l_p}{2\sqrt{j_3+1/2}} \sqrt{(j_3+1)\sqrt{(j_1+j_2+j_3+2)(j_1+j_2-j_3)(j_2+j_3-j_1+1)(j_3+j_1-j_2+1)}}$$
$$\overline{+ j_3\sqrt{(j_1+j_2+j_3+1)(j_1+j_2-j_3+1)(j_2+j_3-j_1)(j_3+j_1-j_2)}}, \tag{IV.8}$$

provided the edges e_1, e_2, e_3 *of* γ *incident at* v *do not have colinear tangents at* v, *otherwise* $\lambda = 0$.

The formula for λ simplifies if we take v to be a divalent vertex not sharing a segment with c. Then $j_3=0$ and necessarily $j_1=j_2=j_0$, and we find simply

$$\lambda(j_0) = l_p \sqrt[4]{j_0(j_0+1)}$$

which for large spin grows as $\sqrt{j_0}$. In other words, the warping of Σ when the gravitational field is in the spin-network state labelled by j_0 grows with the spin j_0 since one and the same curve c appears longer the more spin j_0 we have in a neighborhood of it.

The quantum of length is achieved for $j_0=\frac{1}{2}$ and is given by

$$\frac{1}{\sqrt{2}} \sqrt[4]{3} l_p .$$

The length can change only in packets of $\Delta L \approx \pm \frac{1}{2}\sqrt{1/j_0} l_p$, which approaches zero for large spin so that for high spin the length looks like a continuous operator.

2. Case B

As this is actually a four-valent problem, the computations will be much more elaborate than in the previous case since we now have to couple four angular momenta which will necessarily invoke the $9j$-symbol. Fortunately one can reduce the $3(n-1)j$-symbol to a polynomial in $6j$-symbols, n the valence of the vertex.

The segment $e_4 := s_v$ carries spin $j_4=\frac{1}{2}$. First we note that if again f is a spin-network state with vertex v intersecting c, then we have [$\epsilon_{IJK} := \epsilon(e_I, e_J, e_K)$]

$$\hat{q}_v h_{e_4} f = [\epsilon_{124}\hat{q}_{124} + \epsilon_{234}\hat{q}_{234} + \epsilon_{314}\hat{q}_{314}] h_{e_4} f + h_{e_4}\epsilon_{123}\hat{q}_{123} f = [\epsilon_{124}+\epsilon_{234}+\epsilon_{124}]\hat{q}_{124} h_{e_4} f, \tag{IV.9}$$

where in the second step we exploited gauge invariance of f, that is, in infinitesimal form $[X_1 + X_2 + X_3] f = 0$.

The extended spin-network function $h_{e_4} f$ is represented on the abstract angular momentum Hilbert space by a vector proportional to $\psi := |j_{12}=j_3, j_{123}=0, j=\frac{1}{2}; j_1, j_2, j_3, j_4=\frac{1}{2}\rangle$, where the notation means that the operator $[(J_1+J_2+J_3)^i]^2$ is diagonal as well, the coupling scheme being given by $(j_1, j_2) \to j_{12}$, $(j_{12}, j_3) \to j_{123}$, $(j_{123}, j_4) \to j$.

The space of states with given values $j_1, j_2, j_3, j_4 = j = \frac{1}{2}$ is easily seen to be three-dimensional and is spanned by ψ, ψ_+, ψ_-, where $\psi_\pm = |j_{12}=j_3 \pm 1, j_{123}=1, j=\frac{1}{2}; j_1, j_2, j_3, j_4=\frac{1}{2}\rangle$. This is because $j=1/2$ requires $j_{123}=0,1$ and $j_{123}=0$ enforces $j_{12}=j_3$ while $j_{123}=1$ enforces $j_{12}=j_3 \pm 1$ by

the usual Clebsh–Gordan decomposition into irreducibles $(j)\otimes(j')=(j+j')\oplus(j+j'-1)\oplus\cdots\oplus(|j-j'|)$. The task left to do is to compute the matrix elements of $\hat{q}_v$ between $\psi,\psi_\pm$. Notice that the simplification that occurred in the second step of (IV.9) does not apply to the states $\psi_\pm$ because $j_{123}\neq 0$, so we need to use the full expression of $\hat{q}_v$ for the matrix element between ψ_+,ψ_- while for the other two we just need $q_{124}=[J_{12}^2, J_{24}^2]$. Let us begin with $\hat{q}_{124}$. In the following computation we are going to insert a complete 1 in the form of the basis corresponding to the coupling scheme $(j_2,j_4)\to j_{24}$, $(j_1,j_{24})\to j_{124}$, $(j_{124},j_3)\to j$ in order to evaluate J_{24}^2. We abbreviate $|j_{12}=j_3,j_{123}=0,j=\frac{1}{2};j_1,j_2,j_3,j_4=\frac{1}{2}\rangle=:|j_{12},j_{123}\rangle$, etc., and have for any values of the various j's

$$\begin{aligned}\langle j'_{12},j'_{123}|\hat{q}_{124}|j_{12},j_{123}\rangle&=[j'_{12}(j'_{12}+1)-j_{12}(j_{12}+1)]\langle j'_{12},j'_{123}|J_{24}^2|j_{12},j_{123}\rangle\\&=[j'_{12}(j'_{12}+1)-j_{12}(j_{12}+1)]\\&\quad\times\sum_{j_{24},j_{124}} j_{24}(j_{24}+1)\langle j'_{12},j'_{123}|j_{24},j_{124}\rangle\langle j_{24},j_{124}|j_{12},j_{123}\rangle,\end{aligned}\tag{IV.10}$$

where the allowed values for j_{24},j_{124} are $j_{124}=j_3\pm\frac{1}{2}$ in order to couple with j_3 the resulting $j=\frac{1}{2}$, and $j_{24}=j_2\pm\frac{1}{2}$ are the possible irreducible representations contained in $(j_2)\otimes(j_4)$. The next step is to reduce the matrix elements to $6j$-symbols. Note that the matrix elements are not of the standard textbook form $\langle j_{12},j_{34}|j_{13},j_{24}\rangle$ so that we need to invent a new reduction of the $9j$-symbol as a product of $6j$-symbols. Upon inserting a complete 1 corresponding to a basis of yet another coupling scheme we have

$$\begin{aligned}\langle j_{12},j_{123}|j_{24},j_{124}\rangle&\equiv\langle j_{12}(j_1,j_2),j_{123}(j_{12},j_3),j(j_{123},j_4)|j_{24}(j_2,j_4),j_{124}(j_1,j_{24}),j(j_{124},j_3)\rangle\\&=\sum_{j'_{124}}\langle j_{12}(j_1,j_2),j_{123}(j_{12},j_3),j(j_{123},j_4)\|j_{12}(j_1,j_2),j'_{124}(j_{12},j_4),j(j_{124},j_3)\rangle\\&\quad\times\langle j_{12}(j_1,j_2),j'_{124}(j_{12},j_4),j(j_{124},j_3)|j_{24}(j_2,j_4),j_{124}(j_1,j_{24}),j(j_{124},j_3)\rangle\\&=\langle j_{123}(j_{12},j_3),j(j_{123},j_4)\|j_{124}(j_{12},j_4),j(j_{124},j_3)\rangle\\&\quad\times\langle j_{12}(j_1,j_2),j_{124}(j_{12},j_4)|j_{24}(j_2,j_4),j_{124}(j_1,j_{24})\rangle.\end{aligned}\tag{IV.11}$$

In going from the third equality to the fourth equality, two things happened: (a) Because j_{124} is diagonal on the vectors involved in the second scalar product factor in the third line, the sum reduces to only one term $j'_{124}=j_{124}$, and (b) we used the Wigner–Eckart theorem to reduce the matrix elements,[26] that is, we could get rid of the first entry of the vectors involved in the first scalar product factor and of the last entry in the second, both in the third line. Equation (IV.11) is the form that allows us to express everything in terms of $6j$-symbols. Namely we have

$$\begin{aligned}&\langle j_{123}(j_{12},j_3),j(j_{123},j_4)|j_{124}(j_{12},j_4),j(j_{124},j_3)\rangle\\&\quad=(-1)^{j_1+j_2+j_4+j_{124}}\sqrt{(2j_{12}+1)(2j_{124}+1)}\begin{Bmatrix}j_1 & j_2 & j_{12}\\ j_4 & j_{124} & j_{24}\end{Bmatrix},\end{aligned}\tag{IV.12}$$

$$\begin{aligned}&\langle j_{12}(j_1,j_2),j_{124}(j_{12},j_4)|j_{24}(j_2,j_4),j_{124}(j_1,j_{24})\rangle\\&\quad=(-1)^{2(j_3+j_{12})+j_4+j-j_{123}}\sqrt{(2j_{123}+1)(2j_{124}+1)}\begin{Bmatrix}j_3 & j_{12} & j_{123}\\ j_4 & j & j_{124}\end{Bmatrix}.\end{aligned}\tag{IV.13}$$

In order to see this we do the following: In (IV.12) set $j'_1:=j_1$, $j'_2:=j_2$, $j'_3:=j_4$, $j':=j_{124}$, $j'_{12}:=j_{12}$, $j'_{23}:=j_{24}$ and use the standard formula (A1) for the $6j$-symbol given in the Appendix in terms of the primed j's. In (IV.13) we first set $j'_1:=j_3$, $j'_2:=j_{12}$, $j'_3:=j_4$, $j':=j$, $j'_{12}:=j_{123}$, $j'_{23}:=j_{124}$ and secondly recall the identity $|j_{12}(j_2,j_1),j\rangle=(-1)^{j_1+j_2-j_{12}}|j_{12}(j_1,j_2),j\rangle$ in order to apply the standard formula in terms of the primed j's.

As the whole expression becomes rather lengthy we refrain from writing the matrix elements (IV.10) out explicitly in terms of j_1,j_2,j_3. Rather, we consider them as known through (IV.10)–(IV.14) (and similar relations for the other $\hat{q}_{IJK}$) and define

$$a:=\langle\psi|\hat{q}_v|\psi_+\rangle,\quad b:=\langle\psi|\hat{q}_v|\psi_-\rangle,\quad c:=\langle\psi_+|\hat{q}_v|\psi_-\rangle. \tag{IV.14}$$

So, $\hat{q}_v$ reduces to an antisymmetric 3×3 matrix with nonvanishing off-diagonal entries $\pm a$, $\pm b,\pm c$, eigenvalues $0,\pm i\mu$ where $\mu=\sqrt{a^2+b^2+c^2}$ and eigenvectors $\psi^0,\psi^\pm$ which are chosen to be

$$\psi^0=c\psi-b\psi_++a\psi_-,\quad \psi^\pm=[\mp ib\mu-ac]\psi+[-\mp ic\mu+ab]\psi_++[b^2+c^2]\psi_-, \tag{IV.15}$$

and inverted:

$$\psi_-=\frac{1}{2\mu^2}[\psi^++\psi^-+2a\psi^0],$$

$$-[b^2+c^2]\psi_+=\frac{b}{\mu^2}[(b^2+c^2)\psi^0-(\psi^++\psi^-)/2]+\frac{ib}{2\mu}[\psi^+-\psi^-], \tag{IV.16}$$

$$+[b^2+c^2]\psi=\frac{c}{\mu^2}[(b^2+c^2)\psi^0-(\psi^++\psi^-)/2]-\frac{ic}{2\mu}[\psi^+-\psi^-].$$

Now let $\sigma:=\sqrt{\mu/32}$, σ being the eigenvalue of $\hat{V}$ on both $\psi^\pm$ while it vanishes on ψ^0. It is then straightforward to check that

$$\hat{V}\psi=\sigma\left[\psi-\frac{c}{\mu^2}\,\psi^0\right]=\sigma\,\frac{a^2+b^2}{\mu^2}\,\psi+\text{terms}\propto\psi_\pm. \tag{IV.17}$$

We now translate this result back into the representation $L_2(\overline{\mathscr{A}/\mathscr{G}},d\mu_0)$, multiply by $h_{e_4}^{-1}$, and take the trace. The result must be a gauge-invariant vector with no dependence on e_4, that is, $j=j_4=0$. It follows that $\mathrm{tr}(h_{e_4}\psi_\pm)=0$ because in writing $h_{e_4}\psi_\pm$ in terms of extended spin-networks we cannot get $j=0$ since the contractor corresponding to $j_{123}=1$ is unchanged. Therefore, we have the following.

Theorem IV.2: *The eigenvalue of $\hat{L}_v(c)$ on a trivalent spin-network state T_γ with vertex v such that c and γ do not share a segment incident at v is given by*

$$\hat{L}_v(c)T_\gamma=l_p\sqrt{\mu}\,\frac{a^2+b^2}{2\mu^2}\,T_\gamma,\quad \mu:=\sqrt{a^2+b^2+c^2}, \tag{IV.18}$$

where a,b,c are given through (IV.10)–(IV.14).

V. TUBE OPERATOR AND WEAVES

The length operator has a strange feature unshared by the area and volume operators: Ultimately, in a semiclassical approximation, one wishes to construct states which approximate a fixed classical three-geometry (Σ,q_{ab}). Such eigenstates have been called ''weaves'' in the literature (see, for instance, Ref. 27). Most of these eigenstates typically only involve linked, rather than intersecting, loops, and since the length and volume operators automatically annihilate those states, we need to construct more general weave states for which the name ''lattice states'' is more appropriate.

It is clear that a state that approximates such a geometry has to be defined on a (infinite, in case Σ is not compact) graph filling all of Σ in the following sense: consider a parameter ϵ which we may think of as a lattice spacing and which characterizes the average distance (as measured by q_{ab}) between neighboring vertices of the graph. In order to serve as a good approximation, the parameter needs to be small as compared to the scales of macroscopic objects. Consider any

macroscopic volume or area in Σ. It follows that the graph necessarily intersects these objects provided that ϵ is small enough and it intersects it the more often the smaller ϵ is. Each intersection makes a contribution no matter whether the intersection point is a vertex or not. On the other hand, even for the most random distribution of vertices with mean separation ϵ, even if ϵ is much smaller than the length of a given curve, the curve genuinely almost never intersects the graph at a vertex and so the quantum length of the curve would be always much smaller than its classical length.

This is obviously not what we want and so the length operator constructed cannot be directly associated with the length of a given classical curve. Following the old physical argument that an object always has to have an extension of at least one Planck volume in order not to form a black hole, the conclusion is that a one-dimensional curve cannot correspond to a physical object. This motivates the following definition.

Definition V.1: A tube C with a curve c as center is a two-parameter congruence of curves $C:(r,s)\in[0,1]\times[-\pi.\pi]\to C_{r,s}$ *such that* $C_{0,s}=c\forall s\in[-\pi,\ \pi]$.

So, the picture is that we have a congruence of curves, all of which look like c and which fill a three-dimensional region in Σ homeomorphic to a solid cylinder.

We are now ready to define a tube operator.

Definition V.2: The tube operator is given by

$$\hat{L}(C):=\sum_{(r,s)\in[0,1]\times[-\pi,\pi]}\hat{L}(C_{r,s}). \tag{V.1}$$

Notice that there is an uncountable sum involved in (V.1).

We would like to assign a length to a tube C that is associated somehow with the length of its central curve c. The basic problem is that it makes sense to speak of a length of a three-dimensional object only if it is in some sense one-dimensional. In terms of a tube, one would like to say that it is ''thin'' in the sense that the curves transversal to the central curve have small length as compared to the central one. Obviously, the concept of thinness then depends on the state, and while the tube operator is state independently defined its expectation value will be a good estimate of the length of the central curve only for states for which it is thin.

Let us make precise what we have just said.

Definition V.3: (i) Given a tube C and a state ψ *we define a real-valued function* $L(C,\psi,.)$ *on* $[0,1]$ *given by*

$$L(C,\psi,t):=\sum_{r,s}\ \frac{\langle\psi,\hat{L}(C_{r,s}([0,t]))\psi\rangle}{\|\psi\|^2},$$

where $C_{r,s}([0,t])$ *is the curve* $C_{r,s}$ *followed only until parameter value* t.

(ii) The function $L(C,\psi,.)$ *has discontinuities at a finite number n of points* $0\leqslant t_1<t_2<\cdots<t_n\leqslant 1$ *corresponding to the fact that new vertices of the graph* γ *underlying* ψ *enter the region filled by the* $C_{r,s}([0,t])$ *for all* r,s *as we increase* t. *The number n is finite as otherwise the state* ψ *will not be in the domain of the volume operator. Upon varying the parametrization of the tube we can arrange that at each* t_k *precisely one new vertex enters the tube chopped at value* t_k *and so n equals the number of vertices of* γ *that lie in the tube. Denote by* $p=\{p_i\}_{i=0}^n$ *a partition adapted to these discontinuities in the sense that* $0=p_0\leqslant t_1<p_1<t_2<p_2<\cdots<p_{n-1}<t_n\leqslant p_n=1$.

(iii) Given p, consider the family of n cylinders

$$C_k(C,\psi,p):=C([0,1]\times[-\pi,\pi]\times[p_{k-1},p_k]),\quad k=1,\ldots,n,$$

and let $S_k(C,\psi,p)$ *be the set of smooth curves e satisfying*

(a) *e is not self-intersecting,*
(b) *e lies in the cylinder* C_k, *that is,* $e\subset C_k(C,\psi,p)$, *and*
(c) *e starts and ends on the boundary of the cylinder* C_k, *that is,* $\partial e\subset\partial C_k(C,\psi,p)$.

(iv) Finally we define the following quantities,

$$\Delta_k(C,\psi) := \sup_p \sup_{e \in S_k(C,\psi,p)} \frac{\langle \psi, \hat{L}(e)\psi\rangle}{\|\psi\|^2},$$

$$\delta(C,\psi) := \inf_k \Delta_k(C,\psi), \tag{V.2}$$

$$\Delta(C,\psi) := \sup_k \Delta_k(C,\psi),$$

where the supremum in the first line of (V.2) is taken with respect to all partitions adapted to $t_1,..,t_n$ *which depend only on* C, ψ.

Let us explain the meaning of the quantities (V.2):

The partition p chops the tube into n cylinders C_k, each of which contains precisely one vertex of the graph γ underlying ψ. The number Δ_k is the maximal length of any curve that lies in C_k and starts and ends on the boundary of C_k and for any of the possible choppings. We restrict the curves e to be non-self-intersecting such that they cannot pass through vertices more than once. Finally, the numbers δ, Δ are just the minimum and maximum of the Δ_k.

The idea is to use δ, Δ to decide whether a tube is thin or not for a given state.

Definition V.4: A tube C *is said to be thin in the state* ψ *provided that*

(1) $0 < \delta(C,\psi) < o(l_p)$,
(2) $\delta(C,\psi)/\Delta(C,\psi) = o(1)$, *and*
(3) $n \gg 1$.

Condition (1) says that the cylinder of shortest length has nonzero length and is also not too long as compared to the Planck length. Condition (2) means that the longest cylinder is not much longer than the shortest one. Since the length Δ_k is in particular a measure for the transversal length of the tube, (1) and (2) imply that the tube has a transversal extension of order l_p. Moreover, it means that the regions C_k have approximately the same length. Finally, (3) means that the quantum length of the tube as defined below is macroscopic.

Definition V.5: (i) The length of the tube C *in the state* ψ *is defined by*

$$L(C,\psi) := \sum_{r,s} \frac{\langle \psi, \hat{L}(C_{r,s})\psi\rangle}{\|\psi\|^2}. \tag{V.3}$$

(ii) The physical length $L_{\rm phys}(c,\psi)$ *of a curve* c *in the state* ψ *is given by the length of* $L(C,\psi)$ *where* C *is any tube with central curve* c *and which is thin for* ψ.

Note that this definition of quantum length of a curve c in a state ψ does not refer to any background structure; it involves only the length operator.

Let us see whether that this makes mathematical sense and does give the correct answer for semi-classical considerations.

Since the tube is a *congruence* of curves $C_{r,s}$, each vertex of γ lies on at most one of the curves $C_{r,s}$ and, for a genuine distribution of vertices, each curve intersects at most one vertex. It follows that only a finite number of curves contribute for a finite number of times in (V.1) and so the tube operator is densely defined on $\mathscr{D}$ and it is trivial to see that it is positive semi-definite, symmetric, and possesses self-adjoint extensions. Since the length operators $\hat{L}(s_v)$ commute for distinct vertices v, it follows that all contributing length operators can be simultaneously diagonalized.

Next, let c be a smooth curve and q_{ab} some classical metric which is slowly varying in an open region containing c. We wish to construct a weave state ψ_q which approximates the classical length of c as measured by q_{ab}. For simplicity we consider a weave state ψ defined by a trivalent lattice so that all length operators are automatically diagonal. To simplify life further, let us assume that all edges have equal spin j_0, which implies that j_0 is integral. Let $\lambda(j_0)$ be the corresponding eigenvalue of (IV.18) (almost never will the lattice have a segment in common with one of the contributing curves so that we need to consider only case B of Sec. IV B). Let C be a tube thin for this weave with central curve c. Then we have $\delta(C,\psi) = \Delta(C,\psi) = \lambda(j_0) l_p$. If

length of the central curve of the tube and mean separation between vertices of the state as measured by q_{ab} are denoted as $L(c)$ and ϵ, respectively, then it follows that we obtain for the expectation value of the tube operator.

$$L(C)=l_p\,\frac{L(c)}{\epsilon}\,\lambda(j_0)(1+o(\epsilon/L(c))) \tag{V.4}$$

because, since C is thin for ψ, the number of vertices contained in the region filled by the tube is given by $n\approx L(c)/\epsilon$ (here we used that q_{ab} is slowly varying). It follows that in order for this quantity to equal $L(c)$ we must choose $\epsilon=\lambda(j_0)l_p$. As a consistency check, this means that the tube is also classically considered thin with respect to q_{ab} because the fact that there is only one vertex per unit $\delta(C,\psi)=\lambda(j_0)l_p:=\epsilon$ contained in the tube means that its transversal extension is also of order ϵ.

A few remarks are in order:

(1) Notice that λ is a monotonously increasing function of j_0 so that the lattice can be chosen coarser the more spin it carries in order to still approximate the same geometry [since then $\epsilon\propto\lambda(j_0)$].
(2) The limit $\epsilon\to 0$ blows up. It is physically meaningless to consider lattices with mean distance of vertices smaller than Planck scale which, as already stated in the literature, hints at a discrete structure.
(3) The limit $\epsilon\to\infty$ gives a zero eigenvalue because Σ becomes more and more empty.
(4) We see that there are weave states $\Psi(q_{ab},j_0;\delta(j_0))$ which approximate q_{ab} where we have considered j_0 as a free parameter. Notice that there is a large number of weave states corresponding to the various values of j_0 such that the same geometry is approximated [we cannot, however, let $j_0\to\infty$ because of the condition $\delta(C,\psi)=o(l_p)$ above]. Also observe that we use here weave states which necessarily involve intersecting and overlapping ($j_0>\frac{1}{2}$), rather than only linked, loops.[27]
(5) On the other hand, we can fix ϵ, vary j_0, and ask which classical geometry is being approximated. Since one and the same curve appears longer, according to (V.3), the more spin the lattice carries, we see that the corresponding q_{ab} must be warped as compared to δ_{ab}. This gives rise to the speculation that the spin of the lattice must have something to do with the curvature which in turn has to do with the local energy distribution of the gravitational field. Indeed, the spin characterizes the eigenvalue of the ADM Hamiltonian.[8,28]
(6) To summarize, the tube operator is state-independently defined; however, its expectation value for a given state can be associated with the length of its central curve only if it is thin, which is a state-dependent notion. On the other hand, the definition of ''thin'' involves only the length operator, so it is really quantum thinness that we are talking about; that is, rather than taking a weave that is supposed to approximate a geometry q_{ab} and saying that the transversal length of the tube should be of order l_p as measured by q_{ab}, we take it to be of order l_p as measured by the length operator for the given state. In fact, the notion of thinness applies to any state, not only to a weave state.

VI. SUMMARY

(i) A satisfactory quantization of the length of a piecewise smooth curve was given. The length operator leaves the piecewise analytic graph of a cylindrical function invariant (in particular, analytic), therefore it is proper to allow the curve to be only piecewise smooth rather than piecewise analytic. It is gauge invariant and diffeomorphism covariantly defined.
(ii) The length operator is an unbounded, self-adjoint, positive semi-definite operator with domain $\mathrm{Cyl}^3(\overline{\mathscr{A}/\mathscr{G}})$.
(iii) The spectral analysis turns out to be tedious but straightforward. In particular, the methods displayed here reveal that the complete spectrum can be found by writing a suitable computer code. This also is true for the volume operator.[25]
(iv) The spectrum is entirely discrete, the quantum of the length being given by $\sqrt[4]{3}l_p/\sqrt{2}$. In particular, all spin-network states on graphs with valence not bigger than 3 are eigenvectors of the length operator with, in general, nonvanishing eigenvalue.

(v) In order to approximate a three-geometry a tube operator has to be constructed. One can build intersecting and overlapping weave states which are such that they reproduce the classical length of the tubes given a classical geometry.

(vi) An interesting issue is the following: We could try to define the length of a tube in an alternative way which does not refer to a length operator at all: As a tube is a three-dimensional object it has a quantum volume and its $t=\text{const}$ discs do have a quantum area. We could say that a tube is thin for a state provided that each such disc has an area which is bounded from below and above by its infimum $a>0$ and supremum A as t varies and define $L=2V/(A+a)$ where V is the expectation value of the volume. Interestingly, these two notions of length do not seem to be closely related as the latter would be zero for any state based on a trivalent graph while the operator defined here would have a nonzero expectation value. This is not unexpected for two reasons: First of all, the ''formula'' length times area equals volume only holds in Euclidean space and, second, our length operator is at best a very different operator ordering of that ''formula'' as it involves commutators with holonomies which are absent in the definition of area and volume operators.

APPENDIX: THE 6*j*-SYMBOL

The following can be found in any textbook on the recoupling theory of angular momenta (for instance, Ref. 26).

Consider the coupling of three angular momenta of some spin system consisting of three independent subsystems with angular momenta j_I, $I=1,2,3$. Since the three systems are independent of each other, the operators J_I^i, J_J^j, $I\neq J$, mutually commute. We are interested in states that are labeled by the quantum numbers of a maximal set of mutually commuting observables which includes the square of the total angular momentum $J^i=J_1^i+J_2^i+J_3^i$ of this system. It is easy to see that the set consisting of j_1,j_2,j_3,j,m (where m is the eigenvalue of J^3) is insufficient because j_i,m_i is a set consisting of six rather than five quantum numbers. The missing quantum number is any choice of J_{IJ}, $I<J$, which labels the eigenvalue of the square of $J_{IJ}:=J_I+J_J$. It is easy to see that J,J_{IJ} satisfy the angular momentum algebra.

Denote an orthonormal basis of states so constructed by $|j_{IJ},j;j_1,j_2,j_3\rangle$ where it is understood that one first couples j_I,j_J to resulting spin j_{IJ} and then j_{IJ},j_K to the resulting total spin j. Any choice of such a recoupling scheme leads to an orthonormal basis and thus the transformation between these bases must be unitary. The matrix elements of this transformation were explicitly computed by Racah. In particular we have

$$\langle j_{12},j;j_1,j_2,j_3|j_{23},j;j_1,j_2,j_3\rangle:=(-1)^{j_1+j_2+j_3+j}\sqrt{(2j_{12}+1)(2j_{23}+1)}\begin{Bmatrix} j_1 & j_2 & j_{12} \\ j_3 & j & j_{23}\end{Bmatrix}, \tag{A1}$$

where the 2×3 matrix on the right-hand side is the so-called $6j$-symbol for which a closed formula exists.[26]

There exists a choice of phases for the basis vectors such that all the $6j$-symbols are real. With this choice they enjoy a large number of symmetries of which we just need two:

(1) it is invariant under an arbitrary permutation of its columns and
(2) it is crossing symmetric, that is,

$$\begin{Bmatrix} j_1 & j_2 & j_3 \\ j_4 & j_5 & j_6\end{Bmatrix}=\begin{Bmatrix} j_1 & j_6 & j_5 \\ j_4 & j_3 & j_2\end{Bmatrix}. \tag{A2}$$

For the purposes of this paper it is sufficient to table the value of the $6j$-symbol for the special case that one of j_I,j_{IJ},j takes the value $\frac{1}{2}$. Then we have the special values

$$\left\{\begin{array}{ccc} a & b & c \\ \frac{1}{2} & c-\frac{1}{2} & b+\frac{1}{2} \end{array}\right\} = (-1)^{a+b+c} \sqrt{\frac{(a+c-b)(a+b-c+1)}{(2b+1)(2b+2)(2c)(2c+1)}}, \tag{A3}$$

$$\left\{\begin{array}{ccc} a & b & c \\ \frac{1}{2} & c-\frac{1}{2} & b-\frac{1}{2} \end{array}\right\} = (-1)^{a+b+c} \sqrt{\frac{(a+b+c+1)(b+c-a)}{(2b)(2b+1)(2c)(2c+1)}}. \tag{A4}$$

This is all one needs to know in order to verify the eigenvalue calculations of the present paper. How to generalize the recoupling theory for any number of spins is clear.

(Received 23 December 1997; accepted for publication 12 February 1998)

As a basis for electronic structure calculations, Gaussians are inconvenient because they show unsuitable behavior at larger distances, while Hankel functions are singular at the origin. This paper discusses a new set of special functions which combine many of the advantageous features of both families. At large distances from the origin, these ''smoothed Hankel functions'' resemble the standard Hankel functions and therefore show behavior similar to that of an electronic wave function. Near the origin, the functions are smooth and analytical. Analytical expressions are derived for two-center integrals for the overlap, the kinetic energy, and the electrostatic energy between two such functions. We also show how to expand such a function around some point in space and discuss how to evaluate the potential matrix elements efficiently by numerical integration. This supplies the elements needed for a practical application in an electronic structure calculation. © *1998 American Institute of Physics.* [S0022-2488(98)02206-3]

I. INTRODUCTION

The calculation of the electronic structure of molecules and crystals is becoming increasingly important as a means to understand phenomena on a microscopic level and to supply data which are inaccessible to experiment.[1] The approaches range from Hartree–Fock and configuration-interaction methods to density-functional calculations and the Car–Parrinello method for quantum-mechanical molecular dynamics. In all these approaches, the wave functions must be represented in an accurate but easily handled manner and several central quantities, such as the expectation values for a potential of general shape, must be evaluated. The choice of the basis set used in the representation has a large influence on the calculational efficiency, the numerical stability, and the effort of implementation. In this paper, we present a new set of analytical functions which were designed to optimize these aims.

In general, most applications use one of the following three approaches: (1) an expansion in plane waves, equivalent to a numerical representation on a real-space mesh, (2) an expansion in some kind of analytical basis set centered on the atoms, or (3) an expansion in numerical atomic functions such as the orbitals of a free atom. The expansion in plane waves is extremely popular, thanks to the simple formulation, general flexibility, and numerical robustness. This approach is often used for norm-conserving[2] or ultrasoft[3] pseudopotentials as well as in the linear augmented plane-wave (LAPW) method.[4] These successful methods rely heavily on fast-Fourier-transform algorithms for efficient execution. Unfortunately, plane waves treat all parts of space in the same way, even though more detail is needed close to the atoms. Depending on the system, a large

 © 1998 American Institute of Physics

number of basis functions are needed, leading to slow program execution and large storage requirements.

In contrast, representations using some kind of atom-centered local functions generally involve considerably fewer basis functions, with the potential of large savings in computer time and storage. Whether these gains are realized depends on the type of function used. For example, a basis of Gaussian functions leads to simple algorithms since most operations can be done analytically. Unfortunately, the behavior of the true wave functions is closer to exponential than Gaussian. Consequently several basis functions must be contracted to form chemical basis sets and numerical stability becomes an issue. These problems are avoided by Hankel or Slater functions, for example, in the linear-muffin-tin orbital (LMTO) method[4] which uses a basis of augmented Hankel functions centered on the atoms. The cost for this type of approach is that the mathematical operations are more complicated, making it difficult to implement essential features such as the forces on the atoms. Furthermore, due to the inherent simplicity of the plane-wave methods, their execution speeds are quite difficult to match in practice despite the smaller function set. Finally, Hankel functions are singular near the nucleus. This restricts their use to augmentation methods which replace each function by a numerical representation near the atom.

The new functions presented here are intended to combine as far as possible the positive features of Hankel functions and Gaussians. In essence, they are Hankel functions from which the singularities have been removed, leading to smooth functions which are analytical in all of space. They have the following advantages. Since their behavior at larger radii is that of Hankel functions, they are similar to the true wave functions and avoid the need for basis contractions and stability problems. The degree of smoothing can be tuned, making it possible to optimize the basis so that fewer functions are needed for an accurate representation. Because these functions are analytical, numerical operations on a real-space mesh can be done reasonably efficiently. In addition, many important operations (for example, all relevant two-center integrals) can be done analytically. Finally, since the functions are nonsingular and smooth over all of space they seem predestined for an implementation of pseudopotential methods using local orbitals.

An implementation of density-functional program, based on these functions and using augmentation to supply local atomic detail, has recently been completed.[5] In this paper, we present the mathematical properties of these new ''smoothed Hankel functions.'' Our aim is to supply those properties and equations which are needed for an electronic structure calculation. Ultimately, for any selected basis set $\{\varphi_i(\mathbf{r})\}$ the tasks are to evaluate the overlap matrix

$$S_{i,j}=\int \varphi_i(\mathbf{r})^*\varphi_j(\mathbf{r})d^3r, \tag{1.1}$$

the matrix of the kinetic energy

$$T_{i,j}=\int \varphi_i(\mathbf{r})^*(-\Delta)\varphi_j(\mathbf{r})d^3r, \tag{1.2}$$

and the matrix of the potential energy

$$V_{i,j}=\int \varphi_i(\mathbf{r})^*V(\mathbf{r})\varphi_j(\mathbf{r})d^3r \tag{1.3}$$

to high accuracy and reasonably efficiently, and to assemble the charge density out of the products

$$\rho_{ij}(\mathbf{r})=\varphi_i(\mathbf{r})^*\varphi_j(\mathbf{r}) \tag{1.4}$$

in a form which can be used in the further steps of the calculation. More specifically, we would like to evaluate the simpler terms such as S_{ij} and T_{ij} analytically. If the potential matrix element is to be calculated numerically, the functions must be easy to generate on a mesh. For realistic descriptions involving either augmentation or nonlocal pseudopotentials, it is necessary to expand each function locally in the vicinity of an atom. Finally, for the application to crystals, all these steps must be done for Bloch sums of the original functions. These points are addressed in the following.

The rest of this paper is organized as follows. In the following Secs. II and III we define some useful differential operators and collect some results concerning Fourier transforms which are needed in the following sections. In Sec. IV, we present a family of functions $F_L(\mathbf{r})$ of which the smoothed Hankel functions $H_L(\mathbf{r})$ and the related generalized Gaussians $G_{pL}(\mathbf{r})$ are special cases. Following this we introduce the functions $G_{pL}(\mathbf{r})$ and $H_L(\mathbf{r})$ in Secs. V and VI.

One pleasant feature of the smoothed Hankels is that the matrix elements Eqs. (1.1), (1.2) can be expressed analytically, using the functions $H_L(\mathbf{r})$ themselves, their energy derivatives $\dot{H}_L(\mathbf{r})$, and related functions $W_{pL}(\mathbf{r})$. These are discussed in Sec. VII. Sections VIII–X give expressions for the matrix elements in the nonperiodic case, show how to evaluate the Bloch sums of the $H_L(\mathbf{r})$, and how to obtain the matrix elements for the Bloch-periodic case.

In Secs. XI and XII we show how to evaluate Coulomb integrals involving the $H_L(\mathbf{r})$ (Sec. XI) and how to expand the functions around an arbitrary site, using a convenient technique which can be used for any type of smooth function (Sec. XII). Finally, in the Appendix, we give an integral representation of the $H_L(\mathbf{r})$ and elucidate the connection to the well-known Ewald summation method for lattice sums.

II. SPHERICAL HARMONICS $Y_L(\hat{\mathbf{r}})$ AND $\mathscr{Y}_L(\mathbf{r})$

In the following sections we shall be working with real valued spherical harmonics, labeled with the compound index $L=(\ell,m_\ell)$:

$$Y_L(\hat{\mathbf{r}}) := Y^{m}_{\ell}(\hat{\mathbf{r}}) \tag{2.1}$$

as given in (59:14:8) of Ref. 6 and with the spherical harmonic polynomials

$$\mathscr{Y}_L(\mathbf{r}) := r^{\ell} Y_L(\hat{\mathbf{r}}). \tag{2.2}$$

The $\mathscr{Y}_L(\mathbf{r})$ are real polynomials in the Cartesian coordinates x,y,z of $\mathbf{r}$. Therefore we can use expressions such as

$$\mathscr{Y}_L(i\mathbf{r}) \quad \text{or} \quad \mathscr{Y}_L(-\nabla) \tag{2.3}$$

obtained by substituting ix, iy, and iz and $-\partial/\partial x$, $-\partial/\partial y$, and $-\partial/\partial z$, respectively, for x, y, and z in the polynomial $\mathscr{Y}_L(\mathbf{r})$. Furthermore each additive term of the polynomial $\mathscr{Y}_L$ is a product of a real valued coefficient and exactly ℓ variables. Hence we obtain in particular

$$\mathscr{Y}_L(a\mathbf{g}) = a^{\ell}\mathscr{Y}_L(\mathbf{g}), \tag{2.4}$$

where a is any complex number and $\mathbf{g}$ is any possible argument for $\mathscr{Y}_L$ with three components which commute with the complex numbers.

Let S denote the unit sphere surface. The $Y_L(\hat{\mathbf{r}})$ form a complete orthonormal basis of $\mathscr{L}_2(S)$, i.e., of the set of all complex valued functions $f(\hat{\mathbf{r}})$ with

$$\int_0^{2\pi}\int_0^{\pi} |f(\hat{\mathbf{r}})|^2 \sin\theta d\theta d\varphi < \infty. \tag{2.5}$$

Since the $Y_L(\hat{\mathbf{r}})$ are bounded on the unit sphere surface, we can consequently write

$$Y_K(\hat{\mathbf{r}})Y_L(\hat{\mathbf{r}}) = \sum_M a_M Y_M(\hat{\mathbf{r}}) \tag{2.6}$$

and using the orthonormality of the $Y_L(\hat{\mathbf{r}})$ we see

$$a_M = C_{KLM}, \tag{2.7}$$

where the C_{KLM} denote the real Gaunt integrals (or Clebsch–Gordan coefficients)

$$C_{KLM}=\int_0^{2\pi}\int_0^{\pi} Y_K(\hat{\mathbf{r}})Y_L(\hat{\mathbf{r}})Y_M(\hat{\mathbf{r}})\sin\,\theta d\theta d\varphi. \tag{2.8}$$

By multiplying both sides of (2.6) with $r^{k+\ell}$ and using (2.2) we obtain the corresponding expression for the spherical harmonic polynomials:

$$\mathscr{Y}_K(\mathbf{r})\mathscr{Y}_L(\mathbf{r})=\sum_M C_{KLM}(x^2+y^2+z^2)^{(k+\ell-m)/2}\mathscr{Y}_M(\mathbf{r}), \tag{2.9}$$

where $K=(k,m_k)$, $L=(\ell,m_\ell)$, and $M=(m,m_m)$. According to the selection rules for the Gaunt integrals, $k+l-m$ is a non-negative even integer when C_{KLM} is nonzero.

III. FOURIER TRANSFORMS

Here we list some results from the theory of Fourier transformation and Fourier series expansion which we require later on. We shall apply Fourier transformation to elements of the class $\mathscr{S}(\mathscr{R}^3)$ of *rapidly decreasing functions* on $\mathscr{R}^3$ only, where $\mathscr{S}(\mathscr{R}^3)$ is defined by

$$\mathscr{S}(\mathscr{R}^3):=\left\{\sigma:\mathscr{R}^3\to\mathscr{C}\,\middle|\,\begin{array}{c}\sigma\in C^\infty(\mathscr{R}^3)\ \text{ and }\ \sup_{\mathbf{r}}|\mathbf{r}^\alpha D^\beta\sigma(\mathbf{r})|<\infty\ \text{ for all multi-indices}\\ \alpha=(\alpha_1,\alpha_2,\alpha_3),\beta=(\beta_1,\beta_2,\beta_3)\in\mathscr{N}_0^3\end{array}\right\}, \tag{3.1}$$

$$\mathbf{r}^\alpha:=x^{\alpha_1}y^{\alpha_2}z^{\alpha_3}, \tag{3.2}$$

$$D^\beta\sigma(\mathbf{r}):=\frac{\partial^{|\beta|}}{\partial x^{\beta_1}\partial y^{\beta_2}\partial z^{\beta_3}}\sigma(\mathbf{r}), \tag{3.3}$$

$$|\beta|:=\beta_1+\beta_2+\beta_3 \tag{3.4}$$

(see Definition 17.1 in Ref. 7), i.e., $\mathscr{S}(\mathscr{R}^3)$ is the class of all functions $\sigma:\mathscr{R}^3\to\mathscr{C}$ with the properties that σ is arbitrarily often differentiable, is continuous together with all its derivatives, and that σ and all its derivatives go to zero faster than the inverse of any polynomial as $|\mathbf{r}|\to\infty$. Obviously $\mathscr{S}(\mathscr{R}^3)$ is a linear space over the complex numbers $\mathscr{C}$.

We denote the Fourier transform of a rapidly decreasing function $\sigma(\mathbf{r})\in\mathscr{S}(\mathscr{R}^3)$ by $\hat{\sigma}(\mathbf{q})$ and define it by

$$\hat{\sigma}(\mathbf{q}):=\int_{\mathscr{R}^3} e^{-i\mathbf{q}\cdot\mathbf{r}}\sigma(\mathbf{r})d^3r. \tag{3.5}$$

In the following we shall simply write $\int$ for $\int_{\mathscr{R}^3}$.

A central theorem ensures that $\hat{\sigma}$ belongs to $\mathscr{S}(\mathscr{R}^3)$ for all $\sigma\in\mathscr{S}(\mathscr{R}^3)$ and that the Fourier transformation $\sigma\mapsto\hat{\sigma}$ is an isomorphism from $\mathscr{S}(\mathscr{R}^3)$ onto $\mathscr{S}(\mathscr{R}^3)$ (cf. Theorem 17.3 in Ref. 7). One can reconstruct $\sigma(\mathbf{r})$ from $\hat{\sigma}(\mathbf{q})$ by

$$\sigma(\mathbf{r})=\frac{1}{(2\pi)^3}\int e^{i\mathbf{q}\cdot\mathbf{r}}\hat{\sigma}(\mathbf{q})d^3q \tag{3.6}$$

(cf. Theorem 17.2 in Ref. 7).

Concerning the interrelationship between Fourier transformation and derivation, one has the following general results for $\sigma(\mathbf{r})\in\mathscr{S}(\mathscr{R}^3)$:

$$D_{\mathbf{q}}^\beta\hat{\sigma}(\mathbf{q})=\widehat{((-i\mathbf{r})^\beta\sigma(\mathbf{r}))}(\mathbf{q}), \tag{3.7}$$

$$\widehat{(D_{\mathbf{r}}^\beta\sigma)}(\mathbf{q})=(i\mathbf{q})^\beta\hat{\sigma}(\mathbf{q}) \tag{3.8}$$

(cf. pp. 146, 142 of Ref. 7) whereby $D_{\mathbf{q}}$ and $D_{\mathbf{r}}$ denote the differentiation with respect to $\mathbf{q}$ and $\mathbf{r}$, respectively.

If we consider a function $\sigma(\mathbf{r}) \in \mathscr{S}(\mathscr{R}^3)$ which can be separated into a radial and an angular part according to

$$\sigma(\mathbf{r}) = \frac{u(r)}{r} Y_L(\hat{\mathbf{r}}), \tag{3.9}$$

then the corresponding Fourier transform $\hat{\sigma}(\mathbf{q})$ is given by

$$\hat{\sigma}(\mathbf{q}) = \frac{v(q)}{q} Y_L(\hat{\mathbf{q}}), \tag{3.10}$$

where

$$v(q) = 4\pi(-i)^{\ell} \int_0^{\infty} u(r) j_{\ell}(qr) qr dr, \tag{3.11}$$

$$u(r) = \frac{4\pi i^{\ell}}{(2\pi)^3} \int_0^{\infty} v(q) j_{\ell}(qr) qr dq \tag{3.12}$$

(cf. pp. 35/36 of Ref. 8), whereby the j_{ℓ} denote the spherical Bessel functions (see 10.1.1 in Ref. 9).

Further useful relationships are (cf. Eq. (17.11) in Ref. 7)

$$\widehat{(e^{-a^2 r^2})}(\mathbf{q}) = \left(\frac{\pi}{a^2}\right)^{3/2} e^{-q^2/4a^2} \tag{3.13}$$

and for any $\sigma, \rho \in \mathscr{S}(\mathscr{R}^3)$:

$$\widehat{(\sigma(\mathbf{r}-\mathbf{R}))}(\mathbf{q}) = \hat{\sigma}(\mathbf{q}) e^{-i\mathbf{q}\cdot\mathbf{R}} \tag{3.14}$$

(obvious from (3.5)), and

$$\int \sigma(\mathbf{r})^* \rho(\mathbf{r}) d^3 r = \frac{1}{(2\pi)^3} \int \hat{\sigma}(\mathbf{q})^* \hat{\rho}(\mathbf{q}) d^3 q \tag{3.15}$$

(cf. Exercise 1 on p. 153 in Ref. 7).

Next, consider a Bloch sum

$$K^b(\mathbf{r}) = \sum_{\mathbf{R}} e^{i\mathbf{k}\cdot\mathbf{R}} K(\mathbf{r}-\mathbf{R}) = e^{i\mathbf{k}\cdot\mathbf{r}} \sum_{\mathbf{R}} e^{-i\mathbf{k}\cdot(\mathbf{r}-\mathbf{R})} K(\mathbf{r}-\mathbf{R}) \tag{3.16}$$

for some rapidly decreasing function $K(\mathbf{r}) \in \mathscr{S}(\mathscr{R}^3)$ where $\mathbf{R}$ runs over the Bravais vectors of some lattice. Since the function $\mathbf{r} \mapsto \Sigma_{\mathbf{R}} e^{-i\mathbf{k}\cdot(\mathbf{r}-\mathbf{R})} K(\mathbf{r}-\mathbf{R})$ is periodic in direct space and has the translational symmetry of the Bravais lattice, it can be expanded as a Fourier series in terms of the plane waves $e^{i\mathbf{G}\cdot\mathbf{r}}$ associated with the reciprocal lattice vectors $\mathbf{G}$:

$$\sum_{\mathbf{R}} e^{-i\mathbf{k}\cdot(\mathbf{r}-\mathbf{R})} K(\mathbf{r}-\mathbf{R}) = \frac{1}{\Omega} \sum_{\mathbf{G}} \hat{K}(\mathbf{k}+\mathbf{G}) e^{i\mathbf{G}\cdot\mathbf{r}} \tag{3.17}$$

(cf. Appendix D in Ref. 10) where Ω is the volume of a direct lattice unit cell. From (3.16) we therefore obtain

$$K^b(\mathbf{r}) = \frac{1}{\Omega} \sum_{\mathbf{G}} \hat{K}(\mathbf{k}+\mathbf{G}) e^{i(\mathbf{k}+\mathbf{G})\cdot\mathbf{r}}. \tag{3.18}$$

Starting from a second Bloch sum for some function $L(\mathbf{r}) \in \mathscr{S}(\mathscr{R}^3)$ with the same vector $\mathbf{k}$ as in the case of $K^b(\mathbf{r})$,

$$L^b(\mathbf{r}) = \sum_{\mathbf{R}} e^{i\mathbf{k}\cdot\mathbf{R}} L(\mathbf{r}-\mathbf{R}) \tag{3.19}$$

we obtain from (3.18) and

$$\int_{\mathrm{UC}} e^{i(\mathbf{G}-\mathbf{G}')\cdot\mathbf{r}} d^3r = \Omega\, \delta_{\mathbf{G}\mathbf{G}'} \tag{3.20}$$

(cf. Appendix D (D3)–(D5) in Ref. 10) the expression

$$\int_{\mathrm{UC}} K^b(\mathbf{r})^* L^b(\mathbf{r}) d^3r = \frac{1}{\Omega} \sum_{\mathbf{G}} \hat{K}(\mathbf{k}+\mathbf{G})^* \hat{L}(\mathbf{k}+\mathbf{G}). \tag{3.21}$$

In these equations, $\int_{\mathrm{UC}}$ denotes the integration over a unit cell.

IV. PROPERTIES OF THE FUNCTIONS $F_L(\mathbf{r}) := \mathscr{Y}_L(-\nabla) f(r)$

In this section we introduce a general method for creating families of functions (cf. Ref. 11) and present some properties which all these families have in common. Among others, the families G_L of generalized Gaussians and H_L of smoothed Hankels to be introduced in the Secs. V and VI are specific instances of such families.

Let $f(r) = f(|\mathbf{r}|)$ be a function defined in three-dimensional space which depends only on $r = |\mathbf{r}|$ and is an element of the linear space $\mathscr{S}(\mathscr{R}^3)$ of Eq. (3.1). In particular $f(r)$ is arbitrarily often differentiable and we can define a family of functions $F_L(\mathbf{r}) \in \mathscr{S}(\mathscr{R}^3)$ by

$$F_L(\mathbf{r}) := \mathscr{Y}_L(-\nabla) f(r). \tag{4.1}$$

Applying (3.8), (2.4), and (2.2) we see that the Fourier transform of F_L is given by

$$\widehat{F_L}(\mathbf{q}) = \mathscr{Y}_L(-i\mathbf{q})\widehat{f(r)}(\mathbf{q}) = (-i)^\ell q^\ell \widehat{f(r)}(\mathbf{q}) Y_L(\hat{\mathbf{q}}). \tag{4.2}$$

Since $f(r)$ depends on $\mathbf{r}$ only through $|\mathbf{r}| = r$, we obtain from Corollary 20.6 in Ref. 7 that $\widehat{f(r)}(\mathbf{q})$ depends on $\mathbf{q}$ only through $|\mathbf{q}| = q$. Therefore, $\widehat{F_L}(\mathbf{q})$ is of the form (3.10) and from (3.9)–(3.12) we can conclude that

$$F_L(\mathbf{r}) = f_\ell(r) Y_L(\hat{\mathbf{r}}), \tag{4.3}$$

where

$$f_\ell(r) = \frac{4\pi}{(2\pi)^3} \int_0^\infty q^{\ell+2} \widehat{f(r)}(\mathbf{q}) j_\ell(qr) dq. \tag{4.4}$$

By noting that $\mathscr{Y}_0(\mathbf{r}) = Y_0(\hat{\mathbf{r}}) = 1/\sqrt{4\pi}$ and comparing (4.3) with (4.1) we obtain

$$f_0(r) = f(r). \tag{4.5}$$

From (4.4) we see that $f_\ell(r)$ depends on r only through the spherical Bessel function j_ℓ. From the recurrence relation

$$j_\ell(qr) = \frac{1}{q}\left[-\frac{\partial}{\partial r} + \frac{\ell-1}{r}\right] j_{\ell-1}(qr) \quad \text{for } \ell \geqslant 1 \tag{4.6}$$

for the j_ℓ (cf. 10.1.22 in Ref. 9) we consequently get a recurrence relation for the f_ℓ:

$$f_\ell(r)=\left[-\frac{\partial}{\partial r}+\frac{\ell-1}{r}\right]f_{\ell-1}(r) \quad \text{for } \ell\geqslant 1. \tag{4.7}$$

Using (4.7) and (4.5) one can prove by induction over ℓ

$$f_\ell(r)=r^\ell\left(-\frac{1}{r}\frac{\partial}{\partial r}\right)^\ell f(r) \quad \text{for all } \ell\in\mathcal{N}_0 \tag{4.8}$$

(see p. 39 in Ref. 8). We see from (4.8) that we can write $f_\ell(r)$ in the form

$$f_\ell(r)=r^\ell\chi_\ell(r), \tag{4.9}$$

where $\chi_\ell(r)$ is given by

$$\chi_0(r)=f_0(r)=f(r), \tag{4.10}$$

$$\chi_\ell(r)=\left(-\frac{1}{r}\frac{\partial}{\partial r}\right)^\ell f(r) \quad \text{for all } \ell\in\mathcal{N}_0, \tag{4.11}$$

$$\chi_\ell(r)=-\frac{1}{r}\frac{\partial}{\partial r}\chi_{\ell-1}(r) \quad \text{for } \ell\geqslant 1. \tag{4.12}$$

To conclude this section, we derive a recurrence relation for the radial functions $\chi_\ell(r)$ for the special case that $f(r)$ fulfills

$$\Delta f(r)=p(\mathbf{r}) \tag{4.13}$$

for some known function $p(\mathbf{r})$.

For any $f(r)\in\mathcal{S}(\mathbb{R}^3)$ we have $\Delta f(r)=p(\mathbf{r})\in\mathcal{S}(\mathbb{R}^3)$. By writing the Laplacian operator Δ in polar coordinates (see, e.g., p. 32 in Ref. 12) we see that the function $\Delta f(r)$ also depends only on $r=|\mathbf{r}|$, i.e.,

$$p(\mathbf{r})=p(r). \tag{4.14}$$

By applying the operator $\mathcal{Y}_L(-\nabla)$ to both sides of (4.13) we obtain

$$\Delta F_L(\mathbf{r})=P_L(\mathbf{r}), \tag{4.15}$$

where

$$P_L(\mathbf{r})=\mathcal{Y}_L(-\nabla)p(r)=p_\ell(r)Y_L(\hat{\mathbf{r}}). \tag{4.16}$$

Next, we write the Laplacian in polar coordinates in the form

$$\Delta=\frac{1}{r}\frac{\partial^2}{\partial r^2}(r\cdot)-\frac{\widehat{\ell^2}}{r^2\hbar^2}, \tag{4.17}$$

where

$$\widehat{\ell^2}Y_L(\hat{\mathbf{r}})=\ell(\ell+1)\hbar^2Y_L(\hat{\mathbf{r}}) \tag{4.18}$$

(cf. pp. 32, 150, 151 in Ref. 12). This lets us derive from (4.15) the following relationship between $f_\ell(r)$ and $p_\ell(r)$:

$$\frac{\partial^2}{\partial r^2}f_\ell(r)+\frac{2}{r}\frac{\partial}{\partial r}f_\ell(r)-\frac{\ell(\ell+1)}{r^2}f_\ell(r)=p_\ell(r). \tag{4.19}$$

Applying (4.8) we can obtain from this equation

$$-p_{\ell-1}(r)=\left[\frac{\partial}{\partial r}+\frac{\ell+1}{r}\right]f_\ell(r) \quad \text{for } \ell\geqslant 1. \tag{4.20}$$

Together with (4.7) this leads to

$$f_{\ell+1}(r)=\frac{2\ell+1}{r}f_\ell(r)+p_{\ell-1}(r) \quad \text{for } \ell\geqslant 1, \tag{4.21}$$

which by virtue of (4.9) is equivalent to

$$r^2\chi_{\ell+1}(r)=(2\ell+1)\chi_\ell(r)+r^{-(\ell-1)}p_{\ell-1}(r) \quad \text{for } \ell\geqslant 1. \tag{4.22}$$

Since $\chi_0(r)$ equals $f(r)$, relationship (4.22) can be used to calculate the $\chi_\ell(r)$ for higher angular momenta by recursion, assuming that the $p_\ell(r)$ are known and that $\chi_1(r)$ has already been obtained. For example, $\chi_1(r)=-(1/r)(\partial/\partial r)\chi_0(r)$ can be used to do this (cf. (4.12)). The functions $f_\ell(r)=r^\ell\chi_\ell(r)$ are then also supplied, giving a method to calculate the functions of the family F_L in practical applications. Note, however, that a power series expansion is more stable numerically for small values of r.

V. THE GENERALIZED GAUSSIANS

In this section, we introduce functions G_L and G_{pL} which will be needed in the succeeding sections as part of recurrence relations, for the evaluation of the Hamiltonian and overlap matrix elements between smoothed Hankel functions, for the evaluation of Coulomb integrals, and in the expansion of smoothed Hankel functions around a chosen site.

The functions G_L are generalized Gaussians used in standard quantum mechanical molecular orbital approaches[13] defined for some energy parameter $\varepsilon=-\kappa^2\leqslant 0$ $(\kappa\geqslant 0)$ and an additional parameter $a>0$ by

$$G_L(\mathbf{r}):=\mathscr{Y}_L(-\nabla)g(r), \tag{5.1}$$

where

$$g(r):=\left(\frac{a^2}{\pi}\right)^{3/2}e^{\varepsilon/4a^2}e^{-a^2r^2}=\left(\frac{a^2}{\pi}\right)^{3/2}e^{\gamma\varepsilon}e^{-a^2r^2}, \tag{5.2}$$

$$\gamma:=\frac{1}{4a^2}. \tag{5.3}$$

The root function $g(r)$ is a normalized Gaussian of width $1/a$, multiplied by the factor $e^{\gamma\epsilon}$ for convenience in later expressions. Obviously $g(r)$ is an element of $\mathscr{S}(\mathscr{R}^3)$ and hence

$$G_L(\mathbf{r})\in\mathscr{S}(\mathscr{R}^3) \quad \text{for all } L. \tag{5.4}$$

From our general results of the last section it follows that

$$G_L(\mathbf{r})=g_\ell(r)Y_L(\hat{\mathbf{r}})=r^\ell\mu_\ell(r)Y_L(\hat{\mathbf{r}}) \tag{5.5}$$

with

$$\mu_\ell(r)=\left(-\frac{1}{r}\frac{\partial}{\partial r}\right)^\ell g(r)=(2a^2)^\ell g(r)=\left(\frac{a^2}{\pi}\right)^{3/2}e^{\gamma\varepsilon}(2a^2)^\ell e^{-a^2r^2}. \tag{5.6}$$

Consequently we can write in closed form

$$G_L(\mathbf{r})=\left(\frac{a^2}{\pi}\right)^{3/2}e^{\gamma\varepsilon}(2a^2)^\ell e^{-a^2r^2}r^\ell Y_L(\hat{\mathbf{r}}). \tag{5.7}$$

The following sections also require the Fourier transform $\widehat{G_L}$ of G_L which by (5.1), (3.8), (5.2), (5.3) and (3.13) can easily be determined to be

$$\widehat{G_L}(\mathbf{q}) = \mathscr{Y}_L(-i\mathbf{q}) e^{\gamma(\varepsilon - q^2)}. \tag{5.8}$$

The second set of functions to be introduced in this section are the functions G_{pL}, obtained by repeatedly applying the Laplace operator to the G_L defined above:

$$G_{pL}(\mathbf{r}) := \Delta^p G_L(\mathbf{r}) = \Delta^p(\mathscr{Y}_L(-\nabla) g(r)) = \mathscr{Y}_L(-\nabla)(\Delta^p g(r)). \tag{5.9}$$

To evaluate these functions in practice, a recurrence relation (in p) for the G_{pL} can be derived as follows. Due to

$$g(r) \in \mathscr{S}(\mathscr{R}^3) \Rightarrow \Delta^p g(r) \in \mathscr{S}(\mathscr{R}^3) \tag{5.10}$$

we can apply our general results of Sec. IV [cf. (4.3)] and introduce radial functions $g_{p\ell}(r)$, $\mu_{p\ell}(r)$, and $\varphi_{p\ell}(r)$ such that

$$G_{pL}(\mathbf{r}) = g_{p\ell}(r) Y_L(\hat{\mathbf{r}}) = \mu_{p\ell}(r) r^\ell Y_L(\hat{\mathbf{r}}) = \varphi_{p\ell}(r) \left(\frac{a^2}{\pi}\right)^{3/2} e^{\gamma\varepsilon} e^{-a^2 r^2} r^\ell Y_L(\hat{\mathbf{r}}). \tag{5.11}$$

We proceed by deriving a recurrence relation in p for the $\varphi_{p\ell}(r)$. Due to $G_{p+1,L}(\mathbf{r}) = \Delta G_{pL}(\mathbf{r})$ and the definition (5.11) of the $\varphi_{p\ell}(r)$ we have

$$\varphi_{p+1,\ell}(r) \left(\frac{a^2}{\pi}\right)^{3/2} e^{\gamma\varepsilon} e^{-a^2 r^2} r^\ell Y_L(\hat{\mathbf{r}}) = \Delta\left[\varphi_{p\ell}(r) \left(\frac{a^2}{\pi}\right)^{3/2} e^{\gamma\varepsilon} e^{-a^2 r^2} r^\ell Y_L(\hat{\mathbf{r}})\right]. \tag{5.12}$$

Using the Laplacian Δ in polar coordinates (4.17)/(4.18), this leads to

$$\varphi_{p+1,\ell}(r) = \frac{\partial^2}{\partial r^2}\varphi_{p\ell}(r) + \left[\frac{2(\ell+1)}{r} - 4a^2 r\right]\frac{\partial}{\partial r}\varphi_{p\ell}(r) + [4a^4 r^2 - 2a^2(2\ell+3)]\varphi_{p\ell}(r). \tag{5.13}$$

A comparison of the definition (5.11) of $\varphi_{p\ell}(r)$ with the explicit expression (5.7) for $G_L(\mathbf{r}) = G_{0L}(\mathbf{r})$ shows that

$$\varphi_{0\ell}(r) = (2a^2)^\ell \quad \text{for all } \ell \in \mathscr{N}_0. \tag{5.14}$$

From (5.13) we then obtain

$$\varphi_{1\ell}(r) = (2a^2)^{\ell+1}(2a^2 r^2 - (2\ell+3)) \quad \text{for all } \ell \in \mathscr{N}_0 \tag{5.15}$$

and that the $\varphi_{p\ell}(r)$ are of the form

$$\varphi_{p\ell}(r) = a_0 + a_2 r^2 + \ldots + a_{2p} r^{2p}. \tag{5.16}$$

Following (5.9), (5.8), and (3.8), the Fourier transform of $G_{pL}(\mathbf{r})$ is given by

$$\widehat{G_{pL}}(\mathbf{q}) = (-q^2)^p \mathscr{Y}_L(-i\mathbf{q}) e^{\gamma(\varepsilon - q^2)}. \tag{5.17}$$

Using this and relation (3.7), one can prove the following recurrence relation for the $G_{pL}(\mathbf{r})$ (by showing the equality of the Fourier transforms of the right- and left-hand sides):

$$G_{pL}(\mathbf{r}) = 4a^4 r^2 G_{p-1,L}(\mathbf{r}) - 2a^2(4p + 2\ell - 1) G_{p-1,L}(\mathbf{r}) - 8a^4(p-1)(2p+2\ell-1) G_{p-2,L}(\mathbf{r}) \tag{5.18}$$

for $p \geqslant 2$. Finally, from (5.18) and the definition (5.11) of $\varphi_{p\ell}(r)$ we immediately obtain the desired recurrence relation, which enables us to calculate the $\varphi_{p\ell}(r)$ for $p \geqslant 2$:

$$\varphi_{p\ell}(r)=4a^4r^2\varphi_{p-1,\ell}(r)-2a^2(4p+2\ell-1)\varphi_{p-1,\ell}(r)-8a^4(p-1)(2p+2\ell-1)\varphi_{p-2,\ell}(r). \tag{5.19}$$

Together with the explicit expressions for $\varphi_{0\ell}(r)$ and $\varphi_{1\ell}(r)$ given above, all required functions $\varphi_{p\ell}(r)$ can now be evaluated.

VI. UNSMOOTHED AND SMOOTHED HANKEL FUNCTIONS

In this section we present our convention for the (ordinary) Hankel functions $\check{H}_L$, define the smoothed Hankel functions H_L, derive a recurrence relation that allows the evaluation of the $H_L(\mathbf{r})$, and compare the smoothed Hankels H_L with the unsmoothed Hankels $\check{H}_L$. Next, we introduce the functions $H_{pL}(\mathbf{r}):=\Delta^p H_L(\mathbf{r})$ which are needed in recurrence relations, in the evaluation of the Hamiltonian and overlap matrix elements, and for the calculation of Coulomb integrals. Finally we give a recurrence relation for the calculation of the $H_{pL}(\mathbf{r})$ and obtain their Fourier transform $\widehat{H_{pL}}(\mathbf{q})$.

We start with the definition of the unsmoothed Hankels $\check{H}_L$ for the energy parameter $\varepsilon=-\kappa^2<0$ $(\kappa>0)$. They are singular at $\mathbf{r}=\mathbf{0}$ and are generated from a root function as discussed above:

$$\check{H}_L(\mathbf{r}):=\mathscr{Y}_L(-\nabla)\check{h}(r), \tag{6.1}$$

where

$$\check{h}(r):=\frac{e^{-\kappa r}}{r}. \tag{6.2}$$

The usual spherical Hankel functions of the first kind, $h^{(1)}_\ell(r)$, (see 10.1.1 in Ref. 9) and the $\check{H}_L$ are related by

$$\check{H}_L(\mathbf{r})=-i^\ell\kappa^{\ell+1}h^{(1)}_\ell(i\kappa r)Y_L(\hat{\mathbf{r}}). \tag{6.3}$$

The smoothed Hankel functions $H_L(\mathbf{r})$ with energy parameter $\varepsilon=-\kappa^2<0$ $(\kappa>0)$ and an additional ''smoothing'' parameter $a>0$ are defined in a similar way, starting from a modified root function $h(r)$:

$$H_L(\mathbf{r}):=\mathscr{Y}_L(-\nabla)h(r), \tag{6.4}$$

where

$$h(r):=\frac{1}{2r}(u_+(r)-u_-(r)), \tag{6.5}$$

$$u_\pm(r):=e^{\mp\kappa r}\left[1-\mathrm{erf}\left(\frac{\kappa}{2a}\mp ar\right)\right], \tag{6.6}$$

where erf(z) is the error function (cf. 7.1.1 in Ref. 9). It will be seen below that $h(r)$ is similar to $\check{h}(r)=\exp(-\kappa r)/r$ but is nonsingular. The function $h(r)$ is arbitrarily often continuously differentiable at every point in $\mathscr{R}^3$ including zero, i.e.,

$$h(r)\in C^\infty(\mathscr{R}^3), \tag{6.7}$$

and can be represented by a power series

$$\sum_{j=0}^{\infty}a_jr^{2j} \tag{6.8}$$

containing only even powers of r (cf. pp. 48/49 in Ref. 8). Using Eqs. (6.5)/(6.6) together with the property

$$\lim_{x\to\infty} \operatorname{erf}(\pm x) = \pm 1 \tag{6.9}$$

and the rule of de l'Hospital to determine $\lim_{r\to\infty} u_-(r)$ one can see:

$$h(r) \text{ behaves like } \frac{e^{-\kappa r}}{r} \text{ for large } r. \tag{6.10}$$

This fact together with (6.7) allows the conclusion

$$h(r) \in \mathscr{S}(\mathscr{R}^3) \tag{6.11}$$

[see (3.1) for the definition of $\mathscr{S}(\mathscr{R}^3)$].

Using the Laplacian Δ written in polar coordinates [Eq. (4.17)], one can prove by explicit calculation that $h(r)$ satisfies the following differential equation:

$$(\Delta+\varepsilon)h(a,\varepsilon;r) = -4\pi g(a,\varepsilon;r), \tag{6.12}$$

where we have noted the parameters a and ε of $h(r)$ [Eq. (6.5)] and of $g(r)$ [Eq. (5.2)] explicitly. Applying the operator $\mathscr{Y}_L(-\nabla)$ to both sides of (6.12) we obtain by means of (6.7), (6.4), and (5.1) the relation

$$(\Delta+\varepsilon)H_L(a,\varepsilon;\mathbf{r}) = -4\pi G_L(a,\varepsilon;\mathbf{r}). \tag{6.13}$$

To understand the relation between the smoothed and unsmoothed Hankel functions, it is useful to digress briefly into a formulation which involves distributions (avoided in the rest of this paper). It can be shown[11] that the corresponding differential equation for the unsmoothed Hankel functions is

$$(\Delta+\varepsilon)\check{H}_L(\varepsilon;\mathbf{r}) = -4\pi D_L(\mathbf{r}), \tag{6.14}$$

where

$$D_L(\mathbf{r}) = \mathscr{Y}_L(-\nabla)\,\delta(\mathbf{r}). \tag{6.15}$$

Comparing this with (6.13), we interpret the result as follows. The distribution $D_L(\mathbf{r})$ is a point multipole centered at the origin. The standard Hankel function $\check{H}_L(r)$ is the response of the Helmholtz operator $\Delta+\varepsilon$ to this singular source term. Our smoothed Hankel function $H_L(\mathbf{r})$ is the response of the same operator to a smeared-out version of the point multipole. This smooth multipole is the Gaussian $G_L(a,\varepsilon;\mathbf{r})$ which converges to $D_L(\mathbf{r})$ as $a\to\infty$. Since the source term is now smooth and analytical, the same is true for the function H_L itself. At large distances, the smooth Gaussians and the point multipoles are indistinguishable and the two types of functions coincide, by virtue of our definition of G_L involving an energy-dependent factor $e^{\gamma\varepsilon}$.

Still using distributions for now, the equations above are especially clear in Fourier space. Differential equation (6.13) translates to

$$(-q^2+\varepsilon)\widehat{H_L}(\mathbf{q}) = -4\pi\mathscr{Y}_L(-i\mathbf{q})e^{\gamma(\varepsilon-q^2)} \tag{6.16}$$

from which we deduce that the Fourier transform of the smoothed Hankel function is

$$\widehat{H_L}(\mathbf{q}) = \frac{-4\pi}{\varepsilon-q^2}\,\mathscr{Y}_L(-i\mathbf{q})e^{\gamma(\varepsilon-q^2)}. \tag{6.17}$$

These two equations apply to the standard Hankel function $\check{H}_L$ if γ is set to zero. The right-hand side of (6.16) then is $-4\pi\mathscr{Y}_L(-i\mathbf{q})$, which is the Fourier transform of the distribution $D_L(\mathbf{r})$ giving the point multipole.

Next, we derive a recurrence relation for the smoothed Hankel functions to permit their evaluation in practice. Due to (6.11) and $\Delta h(r) = -\varepsilon h(r) - 4\pi g(r)$ we can apply the results (4.3), (4.9), (4.10), (4.12), and (4.13)–(4.22) from Sec. IV. Using in addition the explicit formulas (6.5)/(6.6) for $h(r)$ and (5.6) for $\mu_\ell(r)$ we obtain

$$H_L(\mathbf{r}) = h_\ell(r) Y_L(\hat{\mathbf{r}}) = \chi_\ell(r) r^\ell Y_L(\hat{\mathbf{r}}), \tag{6.18}$$

$$\chi_0(r) = \frac{1}{2r}(u_+(r) - u_-(r)), \tag{6.19}$$

$$\chi_1(r) = \frac{1}{2r^3}(u_+(r) - u_-(r)) + \frac{\kappa}{2r^2}(u_+(r) + u_-(r)) - \frac{2a}{\sqrt{\pi} r^2} e^{\varepsilon/4a^2} e^{-a^2 r^2}, \tag{6.20}$$

$$\chi_{\ell+1}(r) = \frac{2\ell+1}{r^2}\chi_\ell(r) - \frac{\varepsilon}{r^2}\chi_{\ell-1}(r) - \frac{4\pi}{r^2}\left(\frac{a^2}{\pi}\right)^{3/2} e^{\varepsilon/4a^2}(2a^2)^{\ell-1} e^{-a^2 r^2} \quad \text{for } \ell \geqslant 1. \tag{6.21}$$

Equations (6.19)–(6.21) cannot directly be applied for $\mathbf{r} = \mathbf{0}$. For this point, using the rule of de l'Hospital we obtain

$$\chi_0(0) = -\kappa\left[1 - \operatorname{erf}\left(\frac{\kappa}{2a}\right)\right] + \frac{2a}{\sqrt{\pi}} e^{\varepsilon/4a^2} \tag{6.22}$$

and hence from (6.18) and $Y_0(\hat{\mathbf{r}}) = 1/\sqrt{4\pi}$,

$$H_0(\mathbf{0}) = -\frac{\kappa}{\sqrt{4\pi}}\left[1 - \operatorname{erf}\left(\frac{\kappa}{2a}\right)\right] + \frac{a}{\pi} e^{\varepsilon/4a^2}. \tag{6.23}$$

As we shall see below, the χ_ℓ are nonsingular for $r \to 0$ and therefore we have from (6.18)

$$H_L(\mathbf{0}) = 0 \quad \text{for all } \ell \neq 0. \tag{6.24}$$

In the following, we compare the behavior of the smoothed Hankel functions H_L with that of the unsmoothed Hankel functions $\check{H}_L$ in more detail. Considering first the radial parts of the functions near $r = 0$, note that we can represent $h(r)$ by a power series in r containing only even powers of r [see (6.8)]. Therefore we conclude from (4.10) and (4.12) that this is also true for all the $\chi_\ell(r)$. Furthermore, since $h_\ell(r)$ equals $\chi_\ell(r) r^\ell$ we can represent $h_\ell(r)$ by a power series in r which starts with a term proportional to r^ℓ. Hence the radial part $h_\ell(r)$ of $H_L(\mathbf{r})$ behaves as r^ℓ for small r, whereas the radial part of $\check{H}_L(\mathbf{r})$ behaves as $1/r^{\ell+1}$ (see p. 7127 in Ref. 14). In summary, $h_\ell(r)$ bends over near the origin and approaches 0 as r^ℓ whereas the radial part of $\check{H}_L(\mathbf{r})$ diverges when 0 is approached.

In Fig. 1 this behavior can be seen. For large values of r, the radial parts of H_L and $\check{H}_L$ become identical since from (6.10), (6.2), (6.4), and (6.1) we have

$$\lim_{|\mathbf{r}| \to \infty} H_L(a, \varepsilon; \mathbf{r}) = \check{H}_L(\varepsilon; \mathbf{r}). \tag{6.25}$$

Furthermore, from the definition (6.5)/(6.6) of $h(r)$ one can conclude

$$\lim_{a \to \infty} h(r) = \frac{e^{-\kappa r}}{r}. \tag{6.26}$$

Therefore we obtain from (6.2), (6.4), and (6.1) the relationship

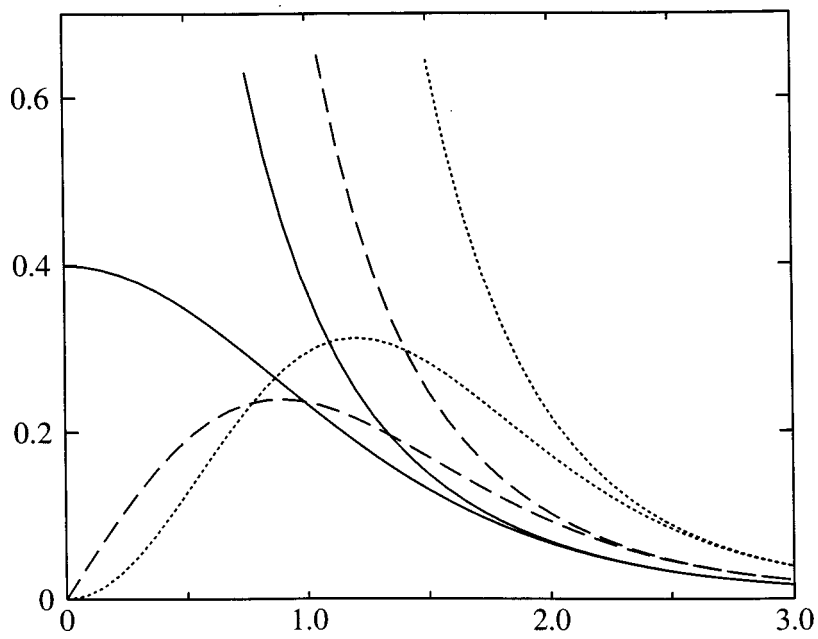

FIG. 1. Comparison of the radial parts of smoothed and unsmoothed Hankel functions for $\ell=0$ (continuous lines), $\ell=1$ (dashed lines) and $\ell=2$ (dotted lines). The energy parameter ε equals -1 in all cases and the smoothing parameter a for the smoothed Hankels equals 1.

$$\lim_{a\to\infty} H_L(a,\varepsilon;\mathbf{r})=\check{H}_L(\varepsilon;\mathbf{r}). \tag{6.27}$$

Consequently, as the parameter a is increased, the function $H_L(a,\varepsilon;\mathbf{r})$ becomes less and less ''smooth'' near the origin and begins to resemble the unsmoothed Hankel function. This motivates the name ''smoothing'' parameter for a. For large radii, the Gaussian source term in (6.13) is negligible and the differential equations (6.13) and (6.14) for the two types of functions H_L and $\check{H}_L$, respectively, are essentially the same.

Let us point out one important motivation of using the smoothed Hankel functions as basis functions in place of the normal unsmoothed functions. In the interstitial region close to muffin-tin spheres, the smoothed Hankel functions H_L show more resemblance to true wave functions than do the $\check{H}_L$. It follows that one can restrict oneself to substantially smaller basis sets with a corresponding gain in efficiency. To understand this, note that a true wave function ψ is a solution of Schrödinger's equation (here presented in atomic units):

$$\Delta\psi(\mathbf{r})=(-E+V(\mathbf{r}))\psi(\mathbf{r}). \tag{6.28}$$

The unsmoothed Hankel function $\check{H}_L(\varepsilon)$ with energy parameter $\varepsilon<0$ satisfies for $\mathbf{r}\neq\mathbf{0}$ the differential equation

$$\Delta\check{H}_L(\varepsilon;\mathbf{r})=-\varepsilon\check{H}_L(\varepsilon;\mathbf{r}) \tag{6.29}$$

(cf. p. 7130 in Ref. 14), i.e., it is a solution of Schrödinger's equation for energy $\varepsilon<0$ and $V(\mathbf{r})\equiv 0$. In comparison, according to (6.13) the smoothed Hankel function $H_L(a,\varepsilon)$ satisfies the differential equation

$$\Delta H_L(a,\varepsilon;\mathbf{r})=\left(-\varepsilon-4\pi\frac{G_L(a,\varepsilon;\mathbf{r})}{H_L(a,\varepsilon;\mathbf{r})}\right)H_L(a,\varepsilon;\mathbf{r}), \tag{6.30}$$

which is Schrödinger's equation for energy $\varepsilon<0$ and the potential

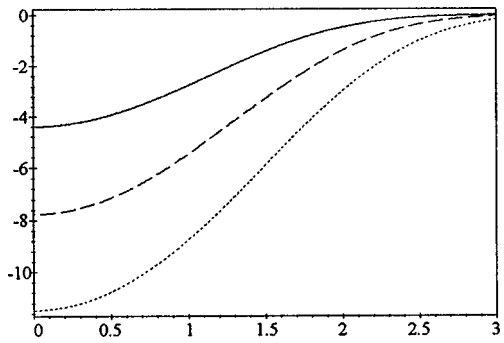

FIG. 2. The function $-4\pi G_L(a,\varepsilon;\mathbf{r})/H_L(a,\varepsilon;\mathbf{r})$ which plays the role of the potential when the differential equation (6.30) is interpreted as the Schrödinger equation, plotted along an arbitrary straight line starting from the origin for the case $\varepsilon=-1$, $a=1$ for $\ell=0$ (continuous line), $\ell=1$ (dashed) and $\ell=2$ (dotted). At intermediate distances outside the muffin-tin sphere, the functions can be adjusted to mimic the shape of the true potential which decreases as the Coulomb attraction of the screened nucleus becomes noticeable. This leads to a substantial reduction in the required basis size.

$$V(\mathbf{r})=-4\pi\frac{G_L(a,\varepsilon;\mathbf{r})}{H_L(a,\varepsilon;\mathbf{r})}. \tag{6.31}$$

This quantity is similar to a realistic potential at intermediate distances since it mimics the decrease of the screened Coulomb potential as the nucleus is approached (Fig. 2). In other words, a true wave function ''bends over'' as r becomes smaller and the potential drops below the absolute value of the energy because then the curvature (i.e., the second derivative) becomes negative. Such behavior is built into the smoothed Hankel functions but is not displayed by the normal Hankel functions. In practice, the shape of a wave function can be reasonably accurately represented by a single smoothed Hankel function outside the muffin-tin sphere or the core region if the two parameters ε and a are chosen appropriately, while a single standard Hankel function is generally inadequate.

To conclude this section, later on we will require the functions

$$H_{pL}(\mathbf{r}):=\Delta^p H_L(\mathbf{r}) \tag{6.32}$$

for which one can prove [by induction over p and using (6.13)] the following recurrence relation:

$$H_{0L}(a,\varepsilon;\mathbf{r})=H_L(a,\varepsilon;\mathbf{r}), \tag{6.33}$$

$$H_{p+1,L}(a,\varepsilon;\mathbf{r})=-\varepsilon H_{pL}(a,\varepsilon;\mathbf{r})-4\pi G_{pL}(a,\varepsilon;\mathbf{r}) \quad \text{for all } p\geqslant 0. \tag{6.34}$$

These equations enable one to calculate the $H_{pL}(\mathbf{r})$ in practice, whereby the $H_L(a,\varepsilon;\mathbf{r})$ are obtained from (6.18) to (6.24) and the $G_{pL}(a,\varepsilon;\mathbf{r})$ are obtained from (5.11), (5.14), (5.15), and (5.19). The Fourier transforms $\widehat{H_{pL}}$ follow from (6.32), (3.8), (6.13), and (5.8) and are given by

$$\widehat{H_{pL}}(\mathbf{q})=-\frac{4\pi}{\varepsilon-q^2}\,\mathscr{Y}_L(-i\mathbf{q})(-q^2)^p e^{\gamma(\varepsilon-q^2)}. \tag{6.35}$$

When p is set to zero, this expression gives the Fourier transform for the smoothed Hankel function $H_L(\mathbf{r})$. Since a product in reciprocal space corresponds to a convolution of the original functions, the following interesting interpretation arises. The smoothed Hankel function $H_L(\mathbf{r})$ can be seen as the convolution of the standard singular Hankel function $\check{H}_L$ [with Fourier transform $-4\pi\mathscr{Y}_L(-i\mathbf{q})/(\varepsilon-q^2)$] and a Gaussian (with Fourier transform $e^{-\gamma q^2}$), multiplied by our chosen normalization factor $e^{\gamma\varepsilon}$. Alternatively, it can up to a constant factor $1/\sqrt{4\pi}$ be considered the convolution of the generalized Gaussian G_L with the standard Hankel function of angular momentum zero. The two relevant length scales are the ''smoothing radius'' $R_{\mathrm{sm}}=1/a$ and the decay length $D=1/\kappa=1/\sqrt{-\varepsilon}$. These specify the width of the Gaussian and the Hankel functions,

respectively. If $R_{\mathrm{sm}} \ll D$, the smoothed Hankel function approaches the standard Hankel function, while a Gaussian is reproduced if $R_{\mathrm{sm}} \gg D$. Thus the smoothed Hankel functions interpolate between the two families and combine the features of both.

VII. THE FUNCTIONS $\dot{H}_L(\mathbf{r})$ AND $W_{pL}(\mathbf{r})$

To evaluate the elements of the kinetic energy and the overlap matrix we will need a further type of related functions, namely, the W_{pL} defined below. To calculate these explicitly we require the energy derivatives of the H_L, $\dot{H}_L$, which we consider first.

We denote the energy derivative of an arbitrary function f which depends on the energy parameter ε by $\dot{f}$ and we are interested here in the specific case

$$\dot{H}_L(\mathbf{r}) := \frac{\partial H_L(\mathbf{r})}{\partial \varepsilon}. \tag{7.1}$$

From (6.18) we have

$$\dot{H}_L(\mathbf{r}) = \dot{h}_\ell(r) Y_L(\hat{\mathbf{r}}) = \dot{\chi}_\ell(r) r^\ell Y_L(\hat{\mathbf{r}}). \tag{7.2}$$

To calculate $\dot{\chi}_\ell(r)$ we can derive a simple expression. Due to $\varepsilon = -\kappa^2$ we have

$$\frac{\partial}{\partial \varepsilon} = -\frac{1}{2\kappa}\frac{\partial}{\partial \kappa} \tag{7.3}$$

and from this we can obtain using (6.19)–(6.21) and (6.6)

$$\dot{\chi}_0(r) = \frac{1}{4\kappa}(u_+(r) + u_-(r)). \tag{7.4}$$

By induction over $\ell \in \dot{\mathcal{N}}_0$ it can be shown that

$$\dot{\chi}_{\ell+1}(r) = \tfrac{1}{2}\chi_\ell(r) \quad \text{for all } \ell \in \dot{\mathcal{N}}_0 \tag{7.5}$$

(cf. pp. 56/57 in Ref. 8). Therefore, we can calculate $\dot{H}_L(\mathbf{r})$ in the form (7.2) by calculating $\dot{\chi}_0(r)$ directly from (7.4) and obtaining the $\dot{\chi}_{\ell+1}(r)$ for $\ell \geqslant 0$ from (7.5). Hereby the $\chi_\ell(r)$ are obtained recursively from (6.19) to (6.21). For the special case $\mathbf{r} = \mathbf{0}$ we use

$$\dot{H}_0(\mathbf{0}) = \dot{\chi}_0(0)\frac{1}{\sqrt{4\pi}}, \tag{7.6}$$

$$\dot{H}_L(\mathbf{0}) = \lim_{\mathbf{r}\to\mathbf{0}} \dot{\chi}_\ell(r) r^\ell Y_L(\hat{\mathbf{r}}) = 0 \quad \text{for } \ell > 0. \tag{7.7}$$

Next, we turn to the $W_{pL}(\mathbf{r})$ mentioned above. As usual, they are generated from a root function $w(r)$ as

$$W_{pL}(\mathbf{r}) = \Delta^p \mathscr{Y}_L(-\nabla) w(r). \tag{7.8}$$

Here $w(r) \in \mathscr{S}(\mathscr{R}^3)$ with parameters $\varepsilon = -\kappa^2 < 0$ $(\kappa > 0)$ and $a > 0$ is defined by its Fourier transform $\widehat{w(r)}(\mathbf{q})$:

$$\widehat{w(r)}(\mathbf{q}) := \frac{4\pi e^{\gamma(\varepsilon - q^2)}}{(\varepsilon - q^2)^2}, \tag{7.9}$$

where γ equals $1/4a^2$ as before. According to (3.8) the Fourier transform of $W_{pL}(\mathbf{r})$ is

$$\widehat{W_{pL}}(\mathbf{q}) = \frac{4\pi}{(\varepsilon - q^2)^2}\, \mathscr{Y}_L(-i\mathbf{q})(-q^2)^p e^{\gamma(\varepsilon - q^2)}. \tag{7.10}$$

Comparison with (6.35) reveals that the derivative of W_{pL} with respect to γ is the negative of H_{pL}. Using (6.35) to write $H_L(\mathbf{r})$ in the form (3.6) we can get

$$\dot{H}_L(\mathbf{r}) = \frac{1}{(2\pi)^3} \int e^{i\mathbf{q}\cdot\mathbf{r}} \left[\frac{4\pi}{(\varepsilon - q^2)^2}\, \mathscr{Y}_L(-i\mathbf{q}) e^{\gamma(\varepsilon - q^2)} + \gamma \frac{-4\pi}{\varepsilon - q^2}\, \mathscr{Y}_L(-i\mathbf{q}) e^{\gamma(\varepsilon - q^2)} \right] d^3q. \tag{7.11}$$

By comparing this with (7.10) and (6.35) we obtain

$$W_{0L}(\mathbf{r}) = \dot{H}_L(\mathbf{r}) - \gamma H_L(\mathbf{r}). \tag{7.12}$$

Furthermore, one can prove the relation

$$W_{p+1,L}(\mathbf{r}) = -\varepsilon W_{pL}(\mathbf{r}) - H_{pL}(\mathbf{r}) \quad \text{for } p \geqslant 0 \tag{7.13}$$

by using (6.35) and (7.10) to show that the Fourier transforms of the right- and left-hand sides are equal. In sum, the $W_{pL}(\mathbf{r})$ can be obtained recursively from (7.12) and (7.13) if the $\dot{H}_L(\mathbf{r})$ and $H_{pL}(\mathbf{r})$ are calculated from (7.2) to (7.7) and (6.33)/(6.34), respectively.

VIII. OVERLAP AND HAMILTONIAN INTEGRALS IN THE NONPERIODIC CASE

In this section we discuss for the nonperiodic case the calculation of the overlap, kinetic energy, and potential integrals which are needed to evaluate the overlap and Hamiltonian matrix elements for the smoothed Hankel functions. As mentioned in Sec. I, these are the critical quantities when using the smoothed Hankel functions as basis set in any type of electronic structure calculation.

As preparation, we note the following important relationship. Let $P(\mathbf{r})$ and $Q(\mathbf{r})$ be two functions belonging to $\mathscr{S}(\mathscr{R}^3)$. Using Green's second identity (see, e.g., p. 350 in Ref. 15) for the case of a sphere around the origin and letting the radius of the sphere go to infinity shows

$$0 = \int [P(\mathbf{r})\Delta Q(\mathbf{r}) - Q(\mathbf{r})\Delta P(\mathbf{r})] d^3r. \tag{8.1}$$

In the following we treat the H_L and G_L as complex functions although they are actually real. We use this notation in order to be able to treat periodic structures involving Bloch sums of H_L and G_L in an analogous way as in the nonperiodic case. Moreover, where it is helpful we explicitly note the parameters $\gamma = 1/4a^2$ and $\varepsilon = -\kappa^2$ which define the Hankels and Gaussians.

First we consider the overlap integral $\int H_{L_1}(\gamma_1, \varepsilon_1; \mathbf{r} - \mathbf{R}_1)^* H_{L_2}(\gamma_2, \varepsilon_2; \mathbf{r} - \mathbf{R}_2) d^3r$ where H_{L_1} and H_{L_2} are smoothed Hankel functions centered at $\mathbf{R}_1$ and $\mathbf{R}_2$, respectively, and $\varepsilon_1 \neq \varepsilon_2$. Due to (6.11) and (6.4), both $H_L(\mathbf{r})$ and $H_L(\mathbf{r} - \mathbf{R})$ belong to $\mathscr{S}(\mathscr{R}^3)$. By applying (8.1) and using (6.13) we obtain

$$\begin{aligned} &\int H_{L_1}(\gamma_1, \varepsilon_1; \mathbf{r} - \mathbf{R}_1)^* H_{L_2}(\gamma_2, \varepsilon_2; \mathbf{r} - \mathbf{R}_2) d^3r \\ &\quad = \frac{4\pi}{\varepsilon_1 - \varepsilon_2} \left\{ \begin{array}{l} \displaystyle\int H_{L_1}(\gamma_1, \varepsilon_1; \mathbf{r} - \mathbf{R}_1)^* G_{L_2}(\gamma_2, \varepsilon_2; \mathbf{r} - \mathbf{R}_2) d^3r \\ \displaystyle -\int G_{L_1}(\gamma_1, \varepsilon_1; \mathbf{r} - \mathbf{R}_1)^* H_{L_2}(\gamma_2, \varepsilon_2; \mathbf{r} - \mathbf{R}_2) d^3r \end{array} \right\}. \end{aligned} \tag{8.2}$$

The integral over a smoothed Hankel function times a Gaussian can be evaluated using (3.15), (3.14), (6.35), (5.8), (2.4), (2.9), (3.6) and again (6.35). The idea is to perform the integral in reciprocal space, by rewriting the product of the Fourier transforms of the two factors as a sum of Fourier transforms of smoothed Hankel functions. The phase factors for the positions $\mathbf{R}_1$ and $\mathbf{R}_2$ combine and we are left with back transforms at the vector $\mathbf{R}_1 - \mathbf{R}_2$. In detail:

$$\int H_{L_1}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^* G_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)d^3r$$

$$= \frac{1}{(2\pi)^3}\int \frac{-4\pi}{\varepsilon_1-q^2}(-1)^{\ell_1}\mathcal{Y}_{L_1}(-i\mathbf{q})e^{\gamma_1(\varepsilon_1-q^2)}e^{i\mathbf{q}\cdot\mathbf{R}_1}\mathcal{Y}_{L_2}(-i\mathbf{q})e^{\gamma_2(\varepsilon_2-q^2)}e^{-i\mathbf{q}\cdot\mathbf{R}_2}d^3q$$

$$= e^{\gamma_2(\varepsilon_2-\varepsilon_1)}(-1)^{\ell_1}\frac{1}{(2\pi)^3}\int \frac{-4\pi}{\varepsilon_1-q^2}e^{(\gamma_1+\gamma_2)(\varepsilon_1-q^2)}e^{i\mathbf{q}\cdot(\mathbf{R}_1-\mathbf{R}_2)}$$

$$\times\sum_M C_{L_1L_2M}(-q^2)^{(\ell_1+\ell_2-m)/2}\mathcal{Y}_M(-i\mathbf{q})d^3q$$

$$= e^{\gamma_2(\varepsilon_2-\varepsilon_1)}(-1)^{\ell_1}\sum_M C_{L_1L_2M}H_{(\ell_1+\ell_2-m)/2,M}(\gamma_1+\gamma_2,\varepsilon_1;\mathbf{R}_1-\mathbf{R}_2) \tag{8.3}$$

and similarly

$$\int G_{L_1}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^* H_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)d^3r$$

$$= e^{\gamma_1(\varepsilon_1-\varepsilon_2)}(-1)^{\ell_1}\sum_M C_{L_1L_2M}H_{(\ell_1+\ell_2-m)/2,M}(\gamma_1+\gamma_2,\varepsilon_2;\mathbf{R}_1-\mathbf{R}_2). \tag{8.4}$$

These two relations also hold for $\varepsilon_1=\varepsilon_2$. From (8.2) to (8.4) we obtain the final result that the overlap integral for $\varepsilon_1\neq\varepsilon_2$ is given in closed form as

$$\int H_{L_1}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^* H_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)d^3r$$

$$= 4\pi(-1)^{\ell_1}\sum_M C_{L_1L_2M}\left\{\begin{array}{l} \dfrac{e^{\gamma_2(\varepsilon_2-\varepsilon_1)}}{\varepsilon_1-\varepsilon_2}H_{(\ell_1+\ell_2-m)/2,M}(\gamma_1+\gamma_2,\varepsilon_1;\mathbf{R}_1-\mathbf{R}_2) \\ +\dfrac{e^{\gamma_1(\varepsilon_1-\varepsilon_2)}}{\varepsilon_2-\varepsilon_1}H_{(\ell_1+\ell_2-m)/2,M}(\gamma_1+\gamma_2,\varepsilon_2;\mathbf{R}_1-\mathbf{R}_2)\end{array}\right\}. \tag{8.5}$$

The values of the $H_{(\ell_1+\ell_2-m)/2,M}$ can be calculated from (6.33) and (6.34) because

$$C_{L_1L_2M} \text{ vanishes unless } \frac{\ell_1+\ell_2-m}{2}\in\mathcal{N}_0. \tag{8.6}$$

Equations (8.3), (8.4), and (8.5) are examples of an important general property: *Two-center integrals involving any combination of smoothed Hankel functions and Gaussians can be expressed analytically using functions of the same families, evaluated for the connecting vector between the two centers.* This is still the case when the kinetic energy operator or a Coulomb kernel is included in the integral. Furthermore, the analytical expressions are equally valid for Bloch-summed functions. These points are discussed below and in Sec. XI.

We still need the overlap integral in the case $\varepsilon_1=\varepsilon_2=:\varepsilon$ which involves, not surprisingly, the energy derivatives. It can be obtained by using (3.15), (3.14), (6.35), (2.4), (2.9), (3.6), and (7.10):

$$\int H_{L_1}(\gamma_1,\varepsilon;\mathbf{r}-\mathbf{R}_1)^* H_{L_2}(\gamma_2,\varepsilon;\mathbf{r}-\mathbf{R}_2)d^3r$$

$$= \frac{1}{(2\pi)^3}\int \frac{(4\pi)^2}{(\varepsilon-q^2)^2}e^{(\gamma_1+\gamma_2)(\varepsilon-q^2)}(-1)^{\ell_1}\mathcal{Y}_{L_1}(-i\mathbf{q})e^{i\mathbf{q}\cdot\mathbf{R}_1}\mathcal{Y}_{L_2}(-i\mathbf{q})e^{-i\mathbf{q}\cdot\mathbf{R}_2}d^3q$$

$$= (-1)^{\ell_1}\frac{4\pi}{(2\pi)^3}\int \frac{4\pi e^{(\gamma_1+\gamma_2)(\varepsilon-q^2)}}{(\varepsilon-q^2)^2}e^{i\mathbf{q}\cdot(\mathbf{R}_1-\mathbf{R}_2)}\sum_M C_{L_1L_2M}(-q^2)^{(\ell_1+\ell_2-m)/2}\mathcal{Y}_M(-i\mathbf{q})d^3q$$

$$= 4\pi(-1)^{\ell_1}\sum_M C_{L_1L_2M}W_{(\ell_1+\ell_2-m)/2,M}(\gamma_1+\gamma_2,\varepsilon;\mathbf{R}_1-\mathbf{R}_2). \tag{8.7}$$

The functions $W_{(\ell_1+\ell_2-m)/2,M}$ can be calculated from (7.12) and (7.13).

Next, the kinetic energy integrals follow almost immediately from our previous results. Using (6.13) we obtain

$$\begin{aligned}\int & H_{L_1}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^*(-\Delta)H_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)d^3r \\ &= \varepsilon_2\int H_{L_1}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^*H_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)d^3r + 4\pi \\ &\times\int H_{L_1}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^*G_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)d^3r \end{aligned} \tag{8.8}$$

as well as an equivalent expression obtained when the Laplace operator is moved to the first function in the integrand. This reduces the integral to cases which have already been handled in (8.2)–(8.7).

Finally, we discuss the potential integrals $\int H_{L_1}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^*V(\mathbf{r})H_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)d^3r$ where $V(\mathbf{r})$ is a smooth potential. In an augmentation method, this will be the interstitial potential, extended smoothly through the muffin-tin spheres. In a pseudopotential method, it might be a smooth local potential defined in all of space to which nonlocal atomic terms are added later on. The evaluation of these integrals cannot be discussed before the representation of the potential has been chosen, but in any case will require careful thought. One sensible approach is to represent the smooth potential on a real-space mesh and to evaluate the integrals numerically. This exploits the advantage that realistic basis functions are often strongly smoothed, so that a relatively coarse mesh is adequate. For crystals, this approach has been successfully implemented as described in Ref. 5. A key step is to evaluate the smoothed Hankel functions efficiently on the real-space mesh. This is done by setting up the Fourier transforms (6.35) and applying a fast Fourier transform routine. In a similar manner, the output density can be calculated.

IX. EVALUATION OF BLOCH SUMS

In this section, we discuss the evaluation of the Bloch sums

$$H^b_{pL}(\gamma,\varepsilon;\mathbf{r}) := \sum_{\mathbf{R}} e^{i\mathbf{k}\cdot\mathbf{R}}H_{pL}(\gamma,\varepsilon;\mathbf{r}-\mathbf{R}), \tag{9.1}$$

$$W^b_{pL}(\gamma,\varepsilon;\mathbf{r}) := \sum_{\mathbf{R}} e^{i\mathbf{k}\cdot\mathbf{R}}W_{pL}(\gamma,\varepsilon;\mathbf{r}-\mathbf{R}), \tag{9.2}$$

where H_{pL} and W_{pL} have been introduced in the Secs. VI and VII, respectively, and $\mathbf{r}$ is some point in $\mathscr{R}^3$. These Bloch sums will be needed in Sec. X for the evaluation of the overlap and Hamiltonian matrix elements involving Bloch versions of smoothed Hankel functions.

As we will see below, for the calculation of the $H^b_{pL}(\gamma,\varepsilon;\mathbf{r})$ we also need the Gaussian Bloch sums

$$G^b_{pL}(\gamma,\varepsilon;\mathbf{r}) := \sum_{\mathbf{R}} e^{i\mathbf{k}\cdot\mathbf{R}}G_{pL}(\gamma,\varepsilon;\mathbf{r}-\mathbf{R}), \tag{9.3}$$

where the G_{pL} were defined in Sec. V. These can be evaluated by direct summation, whereby the $G_{pL}(\gamma,\varepsilon;\mathbf{r}-\mathbf{R})$ are obtained from (5.11), (5.14), (5.15), and (5.19). The sums converge rapidly because the G_{pL} are well-localized functions and therefore only a few terms in the sum (9.3) must be included.

The basic idea for the evaluation of the more slowly convergent sums is Ewald summation: Each term is split into a localized and a smooth part, and the corresponding sums are done in real

and reciprocal space, respectively. In the present case, the sum over the smoothed Hankels H_L [Eq. (9.1) for the case $p=0$] can by virtue of (3.18) and (6.35) be written as

$$H_L^b(\gamma,\varepsilon;\mathbf{r}) = H_L^b(\gamma',\varepsilon;\mathbf{r}) + (H_L^b(\gamma,\varepsilon;\mathbf{r}) - H_L^b(\gamma',\varepsilon;\mathbf{r}))$$
$$= \frac{1}{\Omega}\sum_{\mathbf{G}} \frac{-4\pi}{\varepsilon-|\mathbf{k}+\mathbf{G}|^2}\mathscr{Y}_L(-i(\mathbf{k}+\mathbf{G}))e^{\gamma'(\varepsilon-|\mathbf{k}+\mathbf{G}|^2)}e^{i(\mathbf{k}+\mathbf{G})\cdot\mathbf{r}}$$
$$+\sum_{\mathbf{R}} e^{i\mathbf{k}\cdot\mathbf{R}}(H_L(\gamma,\varepsilon;\mathbf{r}-\mathbf{R}) - H_L(\gamma',\varepsilon;\mathbf{r}-\mathbf{R})). \tag{9.4}$$

Here $\gamma'>\gamma$ is chosen to enable the rapid convergence of both $\Sigma_{\mathbf{G}}$ and $\Sigma_{\mathbf{R}}$ simultaneously. The first sum converges rapidly if γ' is large enough for a fast decay of the factor $e^{\gamma'(\varepsilon-|\mathbf{k}+\mathbf{G}|^2)}$ in reciprocal space. Convergence of the second sum comes about because the function $H_L(\gamma,\varepsilon;\mathbf{r})-H_L(\gamma',\varepsilon;\mathbf{r})$ is localized, since $H_L(\gamma,\varepsilon;\mathbf{r})$ and $H_L(\gamma',\varepsilon;\mathbf{r})$ coincide as soon as $|\mathbf{r}|$ becomes moderately large. The $H_L(\gamma,\varepsilon;\mathbf{r}-\mathbf{R})$ and $H_L(\gamma',\varepsilon;\mathbf{r}-\mathbf{R})$ in (9.4) are evaluated using (6.18)–(6.24). The values of the $H_{pL}^b(\gamma,\varepsilon;\mathbf{r})$ [Eq. (9.1)] for all $p\in\mathscr{N}_0$ can then be obtained from the recurrence relation

$$H_{0L}^b(\gamma,\varepsilon;\mathbf{r}) = H_L^b(\gamma,\varepsilon;\mathbf{r}), \tag{9.5}$$

$$H_{p+1,L}^b(\gamma,\varepsilon;\mathbf{r}) = -\varepsilon H_{pL}^b(\gamma,\varepsilon;\mathbf{r}) - 4\pi G_{pL}^b(\gamma,\varepsilon;\mathbf{r}) \tag{9.6}$$

following directly from the recurrence relation (6.33)/(6.34) for the H_{pL}, where the G_{pL}^b are obtained from (9.3).

In order to calculate W_{pL}^b of Eq. (9.2), we will require Bloch sums of the energy derivative:

$$\dot{H}_L^b(\gamma,\varepsilon;\mathbf{r}) := \sum_{\mathbf{R}} e^{i\mathbf{k}\cdot\mathbf{R}}\dot{H}_L(\gamma,\varepsilon;\mathbf{r}-\mathbf{R}) \tag{9.7}$$

[see (7.1)] which can be evaluated by choosing a suitable parameter $\gamma'>\gamma$ in the Ewald sum

$$\dot{H}_L^b(\gamma,\varepsilon;\mathbf{r}) = \frac{1}{\Omega}\sum_{\mathbf{G}} \frac{4\pi}{\varepsilon-|\mathbf{k}+\mathbf{G}|^2}\left(\frac{1}{\varepsilon-|\mathbf{k}+\mathbf{G}|^2}-\gamma'\right)\mathscr{Y}_L(-i(\mathbf{k}+\mathbf{G}))e^{\gamma'(\varepsilon-|\mathbf{k}+\mathbf{G}|^2)}e^{i(\mathbf{k}+\mathbf{G})\cdot\mathbf{r}}$$
$$+\sum_{\mathbf{R}} e^{i\mathbf{k}\cdot\mathbf{R}}(\dot{H}_L(\gamma,\varepsilon;\mathbf{r}-\mathbf{R}) - \dot{H}_L(\gamma',\varepsilon;\mathbf{r}-\mathbf{R})). \tag{9.8}$$

This formula can be obtained by taking the derivative of formula (9.4) with respect to the energy parameter ε. Again, if γ' is chosen suitably, both sums in (9.8) converge rapidly. The energy derivatives $\dot{H}_L(\mathbf{r}-\mathbf{R})$ are evaluated according to (7.2)–(7.7).

After this preparation, we obtain W_{pL}^b from the recurrence relation

$$W_{0L}^b(\gamma,\varepsilon;\mathbf{r}) = \dot{H}_L^b(\gamma,\varepsilon;\mathbf{r}) - \gamma H_L^b(\gamma,\varepsilon;\mathbf{r}), \tag{9.9}$$

$$W_{p+1,L}^b(\gamma,\varepsilon;\mathbf{r}) = -\varepsilon W_{pL}^b(\gamma,\varepsilon;\mathbf{r}) - H_{pL}^b(\gamma,\varepsilon;\mathbf{r}), \tag{9.10}$$

which follows from (7.12)/(7.13), whereby the $H_{pL}^b(\gamma,\varepsilon;\mathbf{r})$ are calculated using (9.4)–(9.6).

X. OVERLAP AND HAMILTONIAN INTEGRALS IN THE PERIODIC CASE

In this section we show how to calculate the overlap and kinetic energy integrals for Bloch sums H_L^b of smoothed Hankel functions. As was discussed in Sec. VIII, the evaluation of the potential matrix elements is a separate problem which can, for example, be treated reasonably efficiently by numerical integration. This will not be considered further here. Exactly as in the nonperiodic case, two-center integrals can be expressed analytically using functions evaluated for the connecting vector between the centers. We recover the same expressions as before except that all appearing functions are now Bloch sums with the same wave vector **k**.

We require some preliminary considerations: Let

$$K^b(\mathbf{r}) = \sum_{\mathbf{R}} e^{i\mathbf{k}\cdot\mathbf{R}} K(\mathbf{r}-\mathbf{R}) \tag{10.1}$$

and

$$L^b(\mathbf{r}) = \sum_{\mathbf{R}} e^{i\mathbf{k}\cdot\mathbf{R}} L(\mathbf{r}-\mathbf{R}) \tag{10.2}$$

be Bloch sums for the same wave vector $\mathbf{k}$ where $K(\mathbf{r})$ and $L(\mathbf{r}) \in \mathscr{S}(\mathscr{R}^3)$. According to Green's second identity (see, e.g., p. 350 of Ref. 15) we have

$$\int_{\mathrm{UC}} (K^b(\mathbf{r})^* \Delta L^b(\mathbf{r}) - L^b(\mathbf{r}) \Delta K^b(\mathbf{r})^*) d^3r = \int_{\partial(\mathrm{UC})} \left(K^b(\mathbf{r})^* \frac{\partial}{\partial n} L^b(\mathbf{r}) - L^b(\mathbf{r}) \frac{\partial}{\partial n} K^b(\mathbf{r})^* \right) d^2r, \tag{10.3}$$

where the first integral is taken over a unit cell of the direct lattice and the second integral is taken over its surface, and where $\partial/\partial n$ denotes derivation in the direction of the outer normal on the unit cell surface. To every point $\mathbf{r}_0$ on the unit cell surface (with the exception of a finite number of vertex points) there corresponds some point

$$\mathbf{r}' = \mathbf{r}_0 + \mathbf{R}' \tag{10.4}$$

on the unit cell surface for a suitable direct lattice vector $\mathbf{R}' \neq \mathbf{0}$, such that the outer normal at $\mathbf{r}'$ is the negative of that in $\mathbf{r}_0$. This is a consequence of the fact that a unit cell, when translated through all direct lattice vectors, fills all of the space without either overlapping periodic images of itself or leaving voids. From (10.1) and (10.2) we have the Bloch property

$$K^b(\mathbf{r}+\mathbf{R}') = e^{i\mathbf{k}\cdot\mathbf{R}'} K^b(\mathbf{r}), \tag{10.5}$$

$$L^b(\mathbf{r}+\mathbf{R}') = e^{i\mathbf{k}\cdot\mathbf{R}'} L^b(\mathbf{r}) \tag{10.6}$$

for all $\mathbf{r} \in \mathscr{R}^3$. Consequently the contributions from opposite parts of the unit cell surface cancel in the right-hand side of (10.3), giving

$$\int_{\mathrm{UC}} K^b(\mathbf{r})^* \Delta L^b(\mathbf{r}) d^3r = \int_{\mathrm{UC}} L^b(\mathbf{r}) \Delta K^b(\mathbf{r})^* d^3r. \tag{10.7}$$

We are now able to proceed in straightforward analogy to the nonperiodic case [see (8.2)–(8.8)] whereby we use (10.7) in place of (8.1), (3.21) in place of (3.15), and (3.18) in place of (3.6). The two functions in question are again centered at the points $\mathbf{R}_1$ and $\mathbf{R}_2$ [not to be confused with the lattice vectors $\mathbf{R}$ used to write out Bloch sums as in (10.1)]. We obtain

$$\int_{\mathrm{UC}} H^b_{L_1}(\gamma_1, \varepsilon_1; \mathbf{r}-\mathbf{R}_1)^* G^b_{L_2}(\gamma_2, \varepsilon_2; \mathbf{r}-\mathbf{R}_2) d^3r$$

$$= (-1)^{\ell_1} e^{\gamma_2(\varepsilon_2-\varepsilon_1)} \sum_M C_{L_1 L_2 M} H^b_{(\ell_1+\ell_2-m)/2, M}(\gamma_1+\gamma_2, \varepsilon_1; \mathbf{R}_1-\mathbf{R}_2), \tag{10.8}$$

$$\int_{\mathrm{UC}} G^b_{L_1}(\gamma_1, \varepsilon_1; \mathbf{r}-\mathbf{R}_1)^* H^b_{L_2}(\gamma_2, \varepsilon_2; \mathbf{r}-\mathbf{R}_2) d^3r$$

$$= (-1)^{\ell_1} e^{\gamma_1(\varepsilon_1-\varepsilon_2)} \sum_M C_{L_1 L_2 M} H^b_{(\ell_1+\ell_2-m)/2, M}(\gamma_1+\gamma_2, \varepsilon_2; \mathbf{R}_1-\mathbf{R}_2), \tag{10.9}$$

giving the overlap integral in the case $\varepsilon_1 \neq \varepsilon_2$:

$$\int_{\mathrm{UC}} H^b_{L_1}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^* H^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)\,d^3r$$

$$= 4\pi(-1)^{\ell_1}\sum_M C_{L_1L_2M}\left(\begin{array}{l} \dfrac{e^{\gamma_2(\varepsilon_2-\varepsilon_1)}}{\varepsilon_1-\varepsilon_2} H^b_{(\ell_1+\ell_2-m)/2,M}(\gamma_1+\gamma_2,\varepsilon_1;\mathbf{R}_1-\mathbf{R}_2) \\ + \dfrac{e^{\gamma_1(\varepsilon_1-\varepsilon_2)}}{\varepsilon_2-\varepsilon_1} H^b_{(\ell_1+\ell_2-m)/2,M}(\gamma_1+\gamma_2,\varepsilon_2;\mathbf{R}_1-\mathbf{R}_2) \end{array}\right). \tag{10.10}$$

The overlap integral in the case $\varepsilon_1=\varepsilon_2=:\varepsilon$ is given by:

$$\int_{\mathrm{UC}} H^b_{L_1}(\gamma_1,\varepsilon;\mathbf{r}-\mathbf{R}_1)^* H^b_{L_2}(\gamma_2,\varepsilon;\mathbf{r}-\mathbf{R}_2)\,d^3r$$

$$= 4\pi(-1)^{\ell_1}\sum_M C_{L_1L_2M} W^b_{(\ell_1+\ell_2-m)/2,M}(\gamma_1+\gamma_2,\varepsilon;\mathbf{R}_1-\mathbf{R}_2). \tag{10.11}$$

The required Bloch sums H^b_{pM} and W^b_{pM} can be evaluated as described in the preceding section. Finally, the kinetic energy integral is

$$\int_{\mathrm{UC}} H^b_{L_1}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^*(-\Delta) H^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)\,d^3r$$

$$= \varepsilon_2 \int_{\mathrm{UC}} H^b_{L_1}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^* H^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)\,d^3r$$

$$+ 4\pi \int_{\mathrm{UC}} H^b_{L_1}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^* G^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)\,d^3r. \tag{10.12}$$

XI. COULOMB INTEGRALS

Up to now, the smoothed Hankel functions were mainly considered as a basis to represent the wave function. Once a localized representation is available, these functions are also useful to describe other quantities. For example, the implementation of Ref. 5 uses a combination of smoothed Hankel functions and Gaussians to represent the charge density of an atomic core. One important task is then to calculate the associated Coulomb integrals. That is, we need the integrals $\int\int P(\mathbf{r})Q(\mathbf{r}')/|\mathbf{r}-\mathbf{r}'|\,d^3r\,d^3r'$ where $P(\mathbf{r})Q(\mathbf{r}')$ is any combination of Gaussians and smoothed Hankels. We first discuss this problem for the nonperiodic case, then for periodic functions. The latter case is not fundamentally different but somewhat more complicated because of the long-range nature of the Coulomb interaction.

We are interested in Coulomb integrals of the following general form (written in atomic Rydberg units):

$$U = \int\int \frac{n_1(\mathbf{r})n_2(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}\,d^3r\,d^3r' \tag{11.1}$$

where n_1 and n_2 are two charge densities. We can rewrite U as

$$U = \frac{1}{2}\int n_1(\mathbf{r})\phi_2(\mathbf{r})\,d^3r = \frac{1}{2}\int \phi_1(\mathbf{r})n_2(\mathbf{r})\,d^3r, \tag{11.2}$$

where $\phi_j(\mathbf{r})$ is the potential generated at point $\mathbf{r}$ by the charge distribution n_j, given by Coulomb's law as

$$\phi_j(\mathbf{r}) = 2\int \frac{n_j(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}\,d^3r'. \tag{11.3}$$

This potential satisfies Poisson's equation

$$\Delta \phi_j(\mathbf{r}) = -8\pi n_j(\mathbf{r}). \tag{11.4}$$

Turning to the nonperiodic case first, our aim is to calculate the integral

$$U_{PQ} = \int\int \frac{P_{L_1}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^* Q_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}'-\mathbf{R}_2)}{|\mathbf{r}-\mathbf{r}'|} d^3r d^3r' \tag{11.5}$$

for all combinations $P,Q \in \{G,H\}$. We will do this using the potential generated by one of the two functions as in (11.2). To determine this potential, we first note that according to (6.13) and (5.7) we have

$$\Delta H_L(\gamma,\varepsilon;\mathbf{r}) = -4\pi e^{\gamma\varepsilon} G_L(\gamma,0;\mathbf{r}) - \varepsilon H_L(\gamma,\varepsilon;\mathbf{r}), \tag{11.6}$$

$$\Delta H_L(\gamma,0;\mathbf{r}) = -4\pi G_L(\gamma,0;\mathbf{r}). \tag{11.7}$$

Here $G_L(\gamma,0;\mathbf{r})$ denotes the function $G_L(\gamma,\varepsilon;\mathbf{r})$ for $\varepsilon=0$ and $H_L(\gamma,0;\mathbf{r})$ denotes the function $\lim_{\varepsilon\to 0} H_L(\gamma,\varepsilon;\mathbf{r})$. We see that the two potentials of interest are

$$\phi_{G_L}(\gamma,\varepsilon;\mathbf{r}) = 2e^{\gamma\varepsilon} H_L(\gamma,0;\mathbf{r}), \tag{11.8}$$

$$\phi_{H_L}(\gamma,\varepsilon;\mathbf{r}) = \frac{8\pi}{\varepsilon}(H_L(\gamma,\varepsilon;\mathbf{r}) - e^{\gamma\varepsilon} H_L(\gamma,0;\mathbf{r})) \tag{11.9}$$

since these functions satisfy Poisson's equation for the corresponding densities and go to zero at infinity. Inserting these expressions in (11.2) yields

$$U_{GG} = e^{\gamma_1\varepsilon_1} \int H_{L_1}(\gamma_1,0;\mathbf{r}-\mathbf{R}_1)^* G_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2) d^3r, \tag{11.10}$$

$$U_{GH} = e^{\gamma_1\varepsilon_1} \int H_{L_1}(\gamma_1,0;\mathbf{r}-\mathbf{R}_1)^* H_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2) d^3r, \tag{11.11}$$

$$U_{HH} = \frac{4\pi}{\varepsilon_1}\left\{ \begin{array}{l} \displaystyle\int H_{L_1}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^* H_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2) d^3r \\ \displaystyle -e^{\gamma_1\varepsilon_1}\int H_{L_1}(\gamma_1,0;\mathbf{r}-\mathbf{R}_1)^* H_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2) d^3r \end{array} \right\}. \tag{11.12}$$

This reduces all three Coulomb integrals to the integrals over products of Gaussians and smoothed Hankels for which we can use the expressions (8.3), (8.7), and (8.5), whereby the necessary values of the type $H_{pM}(\gamma,0;\mathbf{r}) = \lim_{\varepsilon\to 0} H_{pM}(\gamma,\varepsilon;\mathbf{r})$ occurring therein can be evaluated from:

$$H_{0M}(\gamma,0;\mathbf{r}) = H_M(\gamma,0;\mathbf{r}) = \left(\lim_{\varepsilon\to 0} \chi_m(\gamma,\varepsilon;r)\right) r^m Y_M(\hat{\mathbf{r}}), \tag{11.13}$$

$$\lim_{\varepsilon\to 0} \chi_0(\gamma,\varepsilon;r) = \frac{\mathrm{erf}(ar)}{r}, \tag{11.14}$$

$$\lim_{\varepsilon\to 0} \chi_1(\gamma,\varepsilon;r) = \frac{\mathrm{erf}(ar)}{r^3} - \frac{2a}{\sqrt{\pi} r^2} e^{-a^2r^2}, \tag{11.15}$$

$$\lim_{\varepsilon\to 0} \chi_{m+1}(\gamma,\varepsilon;r) = \frac{2m+1}{r^2} \lim_{\varepsilon\to 0} \chi_m(\gamma,\varepsilon;r) - \frac{4\pi}{r^2}\left(\frac{a^2}{\pi}\right)^{3/2} (2a^2)^{m-1} e^{-a^2r^2} \quad \text{for } m \geqslant 1, \tag{11.16}$$

for $\mathbf{r}\neq\mathbf{0}$,

$$H_M(\gamma,0;\mathbf{0}) = \frac{a}{\pi}\delta_{M0} \tag{11.17}$$

[cf. (6.18)–(6.21), (6.23), (6.24)] and

$$H_{p+1,M}(\gamma,0;\mathbf{r}) = -4\pi G_{pM}(\gamma,0;\mathbf{r}) \quad \text{for } p\geqslant 0 \tag{11.18}$$

[cf. (6.34)].

In the remainder of this section, we discuss the Coulomb integrals involving smoothed Hankels and Gaussians for the periodic case. Because of the long-ranged nature of the electrostatic potential, we must be careful about the way in which the limit $\varepsilon\to 0$ is done. We introduce new functions $F^b_{pL}(\gamma;\mathbf{r})$ by subtracting a homogeneous background from the Bloch function before taking the limit:

$$F^b_L(\gamma;\mathbf{r}) := \lim_{\varepsilon\to 0}\{H^b_L(\gamma,\varepsilon;\mathbf{r}) - \overline{H}^b_L(\gamma,\varepsilon)\}, \tag{11.19}$$

$$F^b_{pL}(\gamma;\mathbf{r}) := \Delta^p F^b_L(\gamma;\mathbf{r}), \tag{11.20}$$

where H^b_L is the previously defined Bloch sum of smoothed Hankels for the case $\mathbf{k}=\mathbf{0}$ and $\varepsilon<0$:

$$H^b_L(\gamma,\varepsilon;\mathbf{r}) := \sum_{\mathbf{R}} H_L(\gamma,\varepsilon;\mathbf{r}-\mathbf{R}) \tag{11.21}$$

and the constant $\overline{H}^b_L$ is the average value of this Bloch sum over a unit cell:

$$\overline{H}^b_L(\gamma,\varepsilon) := \frac{1}{\Omega}\int_{\mathrm{UC}} H^b_L(\gamma,\varepsilon;\mathbf{r})d^3r. \tag{11.22}$$

In other words, we define the function $F^b_L(\gamma;\mathbf{r})$ by subtracting the average value from the Bloch sum over the smooth Hankels when $\varepsilon<0$ and then taking the limit for $\varepsilon\to 0$. In a representation as a Fourier sum over the reciprocal lattice, this is equivalent to simply leaving away the divergent term for $\mathbf{G}=\mathbf{0}$ and setting ε to zero in all others: Following (11.21), (3.18), and (6.35) the Fourier series for H^b_L is

$$H^b_L(\gamma,\varepsilon;\mathbf{r}) = \frac{1}{\Omega}\sum_{\mathbf{G}} \frac{-4\pi}{\varepsilon-G^2}\mathscr{Y}_L(-i\mathbf{G})e^{\gamma(\varepsilon-G^2)}e^{i\mathbf{G}\cdot\mathbf{r}} \tag{11.23}$$

and hence we obtain from (11.22) and (3.20) the average value

$$\overline{H}^b_L(\gamma,\varepsilon) = \frac{1}{\Omega}\widehat{H_L}(\mathbf{0}) = \frac{-4\pi}{\Omega}\frac{e^{\gamma\varepsilon}}{\varepsilon}Y_0\delta_{L0} = \frac{-\sqrt{4\pi}}{\Omega}\frac{e^{\gamma\varepsilon}}{\varepsilon}\delta_{L0}. \tag{11.24}$$

The factor δ_{L0} arises from $\mathscr{Y}_L(-i\mathbf{G}) = (-i)^{\ell}G^{\ell}Y_L(\mathbf{G})$, which is zero whenever $\mathbf{G}=\mathbf{0}$ and $L\neq 0$. From (11.19), (3.18), (11.24), and (6.35) we obtain the Fourier series for F^b_L:

$$F^b_L(\gamma;\mathbf{r}) = \frac{1}{\Omega}\sum_{\mathbf{G}\neq\mathbf{0}} \frac{4\pi}{G^2}\mathscr{Y}_L(-i\mathbf{G})e^{-\gamma G^2}e^{i\mathbf{G}\cdot\mathbf{r}}. \tag{11.25}$$

We see from (11.19), (11.21), (11.24), (11.25) that we can evaluate $F^b_L(\gamma;\mathbf{r})$ by Ewald summation in practice, using the formula

$$F_L^b(\gamma;\mathbf{r}) = F_L^b(\gamma';\mathbf{r}) + (F_L^b(\gamma;\mathbf{r}) - F_L^b(\gamma';\mathbf{r}))$$
$$= \frac{1}{\Omega}\sum_{\mathbf{G}\neq\mathbf{0}} \frac{4\pi}{G^2}\,\mathscr{Y}_L(-i\mathbf{G})e^{-\gamma' G^2}e^{i\mathbf{G}\cdot\mathbf{r}}$$
$$+\sum_{\mathbf{R}} (H_L(\gamma,0;\mathbf{r}-\mathbf{R}) - H_L(\gamma',0;\mathbf{r}-\mathbf{R})) + \frac{\sqrt{4\pi}}{\Omega}(\gamma-\gamma')\,\delta_{L0} \tag{11.26}$$

with some suitable $\gamma' > \gamma$. Here the last term is obtained from $\lim_{\varepsilon\to 0}\{\bar{H}_L^b(\gamma',\varepsilon) - \bar{H}_L^b(\gamma,\varepsilon)\}$ [cf. (11.24)] using the rule of de l'Hospital. The preceding expression involves terms of the type $H_L(\gamma,0,\mathbf{r}) = \lim_{\varepsilon\to 0} H_L(\gamma,\varepsilon,\mathbf{r})$, to be calculated according to (11.13)–(11.17).

Finally, to obtain the $F_{pL}^b(\gamma;\mathbf{r})$ for $p>0$ we first note that due to (11.20), (11.19), (6.13) and (11.23) we have

$$F_{1L}^b(\gamma;\mathbf{r}) = \lim_{\varepsilon\to 0}\{-\varepsilon H_L^b(\gamma,\varepsilon;\mathbf{r}) - 4\pi G_L^b(\gamma,\varepsilon;\mathbf{r})\} = \frac{\sqrt{4\pi}}{\Omega}\delta_{L0} - 4\pi G_L^b(\gamma,0;\mathbf{r}), \tag{11.27}$$

where G_L^b denotes the Bloch sum of the G_L for $\mathbf{k}=\mathbf{0}$. Using (11.27) we immediately get the result

$$F_{p+1,L}^b(\gamma,\mathbf{r}) = -4\pi G_{pL}^b(\gamma,0;\mathbf{r}) \quad \text{for } p\geqslant 1. \tag{11.28}$$

The $G_{pL}^b(\gamma,0;\mathbf{r})$ for $p\in\mathscr{N}_0$ are evaluated by direct summation as described in (9.3) with $\mathbf{k}$ set to zero. Using (11.26), (11.27), and (11.28), the $F_{pL}^b(\gamma;\mathbf{r})$ for all $p\in\mathscr{N}_0$ can be calculated.

After this somewhat tedious excursion to define the functions F_{pL}^b and to supply a method to calculate them, we can return to the Coulomb integrals in the case of periodic systems. For their evaluation we will need the integrals

$$\int_{\mathrm{UC}} F_{L_1}^b(\gamma_1;\mathbf{r}-\mathbf{R}_1)^* G_{L_2}^b(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)\,d^3r, \tag{11.29}$$

$$\int_{\mathrm{UC}} G_{L_1}^b(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^* F_{L_2}^b(\gamma_2;\mathbf{r}-\mathbf{R}_2)\,d^3r, \tag{11.30}$$

and

$$\int_{\mathrm{UC}} F_{L_1}^b(\gamma_1;\mathbf{r}-\mathbf{R}_1)^* H_{L_2}^b(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)\,d^3r, \tag{11.31}$$

which are discussed next. For the evaluation of (11.29) and (11.30) we use Eq. (11.25) for F_L^b, proceed in the same manner as in Sec. X to evaluate the integrals (10.8) and (10.9), and obtain the first two integrals in closed form:

$$\int_{\mathrm{UC}} F_{L_1}^b(\gamma_1;\mathbf{r}-\mathbf{R}_1)^* G_{L_2}^b(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)\,d^3r$$
$$= e^{\gamma_2\varepsilon_2}(-1)^{\ell_1}\sum_M C_{L_1L_2M} F^b_{(\ell_1+\ell_2-m)/2,M}(\gamma_1+\gamma_2;\mathbf{R}_1-\mathbf{R}_2), \tag{11.32}$$

$$\int_{\mathrm{UC}} G_{L_1}^b(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^* F_{L_2}^b(\gamma_2;\mathbf{r}-\mathbf{R}_2)\,d^3r$$
$$= e^{\gamma_1\varepsilon_1}(-1)^{\ell_1}\sum_M C_{L_1L_2M} F^b_{(\ell_1+\ell_2-m)/2,M}(\gamma_1+\gamma_2;\mathbf{R}_1-\mathbf{R}_2). \tag{11.33}$$

Since H_L^b and F_L^b are Bloch functions for the same wave vector $\mathbf{k}=\mathbf{0}$ we have following (10.7) the relation

$$\int_{\mathrm{UC}} F^b_{L_1}(\gamma_1;\mathbf{r}-\mathbf{R}_1)^* \Delta H^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)d^3r = \int_{\mathrm{UC}} H^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)\Delta F^b_{L_1}(\gamma_1;\mathbf{r}-\mathbf{R}_1)^* d^3r. \tag{11.34}$$

As before, we use this expression to reduce the third required integral (11.31) to the previous cases. Applying (6.13) and (11.27) gives

$$\int_{\mathrm{UC}} F^b_{L_1}(\gamma_1;\mathbf{r}-\mathbf{R}_1)^* H^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)d^3r$$

$$= \frac{1}{\varepsilon_2}\left\{ \begin{array}{c} 4\pi \int_{\mathrm{UC}} G^b_{L_1}(\gamma_1,0;\mathbf{r}-\mathbf{R}_1)^* H^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)d^3r \\ -4\pi \int_{\mathrm{UC}} F^b_{L_1}(\gamma_1;\mathbf{r}-\mathbf{R}_1)^* G^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)d^3r \\ -(\sqrt{4\pi}/\Omega)\,\delta_{L_1 0}\int_{\mathrm{UC}} H^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)d^3r \end{array} \right\}. \tag{11.35}$$

From (3.18), (3.20), (6.35) we see

$$\int_{\mathrm{UC}} H^b_L(\gamma,\varepsilon;\mathbf{r}-\mathbf{R})d^3r = \widehat{H_L}(\mathbf{0}) = -\sqrt{4\pi}\,\frac{e^{\gamma\varepsilon}}{\varepsilon}\,\delta_{L0} \tag{11.36}$$

giving the final expression for the integral (11.31) in terms of the previous cases (10.9) and (11.32):

$$\int_{\mathrm{UC}} F^b_{L_1}(\gamma_1;\mathbf{r}-\mathbf{R}_1)^* H^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)d^3r$$

$$= \frac{4\pi}{\varepsilon_2}\left\{ \begin{array}{c} \int_{\mathrm{UC}} G^b_{L_1}(\gamma_1,0;\mathbf{r}-\mathbf{R}_1)^* H^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)d^3r \\ -\int_{\mathrm{UC}} F^b_{L_1}(\gamma_1;\mathbf{r}-\mathbf{R}_1)^* G^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)d^3r \\ +\frac{1}{\Omega}\,\frac{e^{\gamma_2\varepsilon_2}}{\varepsilon_2}\,\delta_{L_1 0}\delta_{L_2 0} \end{array} \right\}. \tag{11.37}$$

Finally, the two-center Coulomb integrals for the periodic case can be formulated. As before, we want to calculate the potential for one of the factors, then integrate over the product with the other factor. However, if $P(\mathbf{r})$ is any function representing a periodic charge density, then we can find a *periodic* potential ϕ_P satisfying $\Delta\phi_P = -8\pi P$ only if the neutrality condition is satisfied:

$$\int_{\mathrm{UC}} P(\mathbf{r})d^3r = 0. \tag{11.38}$$

Therefore, a sensible aim is to derive expressions for the integrals

$$\int_{\mathrm{UC}}\int_{\mathrm{UC}} \frac{\tilde{P}_{L_1}(\mathbf{r}-\mathbf{R}_1)^* \tilde{Q}_{L_2}(\mathbf{r}'-\mathbf{R}_2)}{|\mathbf{r}-\mathbf{r}'|} d^3r d^3r', \tag{11.39}$$

where $P(\mathbf{r})$ and $Q(\mathbf{r})$ are Bloch sums of smoothed Hankels or Gaussians, and $\tilde{P}$ and $\tilde{Q}$ are the corresponding functions with a possible constant term subtracted:

$$\tilde{P}_L(\mathbf{r}) := P_L(\mathbf{r}) - \frac{1}{\Omega}\int_{\mathrm{UC}} P_L(\mathbf{r})d^3r, \tag{11.40}$$

$$\tilde{Q}_L(\mathbf{r}) := Q_L(\mathbf{r}) - \frac{1}{\Omega}\int_{\mathrm{UC}} Q_L(\mathbf{r})d^3r. \tag{11.41}$$

In a properly formulated application of the resulting expressions, the various additional homogeneous terms will cancel in the final result. Our plan is therefore to calculate the integral

$$U = \frac{1}{2}\int_{\mathrm{UC}} \phi_{\tilde{P}_{L_1}}(\mathbf{r}-\mathbf{R}_1)^* \tilde{Q}_{L_2}(\mathbf{r}-\mathbf{R}_2)d^3r, \tag{11.42}$$

where $\phi_{\tilde{P}_L}(\mathbf{r})$ satisfies Poisson's equation

$$\Delta\phi_{\tilde{P}_L}(\mathbf{r}) = -8\pi\tilde{P}_L(\mathbf{r}). \tag{11.43}$$

Of course, the potential $\phi_{\tilde{P}_L}$ is determined only up to an additive constant. But since $\tilde{Q}_{L_2}(\mathbf{r})$ satisfies the neutrality condition by construction, adding an arbitrary constant to $\phi_{\tilde{P}_L}$ will not change the value of the integral (11.42). We therefore need not impose any additional condition besides (11.43) on $\phi_{\tilde{P}_L}$ in order to obtain the correct value of U.

First, we subtract the average values from G_L^b and H_L^b to make functions which satisfy the neutrality condition [cf. (3.18), (3.20), (5.8) and (11.36)]:

$$\tilde{G}_L^b(\gamma,\varepsilon;\mathbf{r}) = G_L^b(\gamma,\varepsilon;\mathbf{r}) - \frac{1}{\Omega}\frac{e^{\gamma\varepsilon}}{\sqrt{4\pi}}\delta_{L0} \tag{11.44}$$

and

$$\tilde{H}_L^b(\gamma,\varepsilon;\mathbf{r}) = H_L^b(\gamma,\varepsilon;\mathbf{r}) + \frac{\sqrt{4\pi}}{\Omega}\frac{e^{\gamma\varepsilon}}{\varepsilon}\delta_{L0}. \tag{11.45}$$

Next, we obtain two potentials which satisfy the Poisson equation for G_L^b and H_L^b, using (11.27), (5.7), (11.44) for the first and (6.13), (11.27), (5.7), (11.45) for the second:

$$\phi_{\tilde{G}_L^b}(\gamma,\varepsilon;\mathbf{r}) = 2e^{\gamma\varepsilon}F_L^b(\gamma;\mathbf{r}), \tag{11.46}$$

$$\phi_{\tilde{H}_L^b}(\gamma,\varepsilon;\mathbf{r}) = \frac{8\pi}{\varepsilon}(H_L^b(\gamma,\varepsilon;\mathbf{r}) - e^{\gamma\varepsilon}F_L^b(\gamma;\mathbf{r})). \tag{11.47}$$

Finally, we exploit that $F_L^b(\gamma;\mathbf{r})$ satisfies the neutrality condition according to the definition (11.19) and assemble the final expressions for the two-center Coulomb integrals by means of (11.42), the previous equations, and (11.36):

$$\begin{aligned} U_{GG} &= \int_{\mathrm{UC}}\int_{\mathrm{UC}} \frac{\tilde{G}_{L_1}^b(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^*\tilde{G}_{L_2}^b(\gamma_2,\varepsilon_2;\mathbf{r}'-\mathbf{R}_2)}{|\mathbf{r}-\mathbf{r}'|}d^3r\,d^3r' \\ &= \frac{1}{2}\int_{\mathrm{UC}} \phi_{\tilde{G}_{L_1}^b}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^*\left(G_{L_2}^b(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2) - \frac{1}{\Omega}\frac{e^{\gamma_2\varepsilon_2}}{\sqrt{4\pi}}\delta_{L_20}\right)d^3r \\ &= e^{\gamma_1\varepsilon_1}\int_{\mathrm{UC}} F_{L_1}^b(\gamma_1;\mathbf{r}-\mathbf{R}_1)^* G_{L_2}^b(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2)d^3r, \end{aligned} \tag{11.48}$$

$$U_{GH} = \int_{\mathrm{UC}}\int_{\mathrm{UC}} \frac{\tilde{G}_{L_1}^b(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^*\tilde{H}_{L_2}^b(\gamma_2,\varepsilon_2;\mathbf{r}'-\mathbf{R}_2)}{|\mathbf{r}-\mathbf{r}'|}d^3r\,d^3r'$$

$$= \frac{1}{2} \int_{\mathrm{UC}} \phi_{\tilde{G}^b_{L_1}}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^* \left(H^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2) + \frac{\sqrt{4\pi}}{\Omega} \frac{e^{\gamma_2\varepsilon_2}}{\varepsilon_2} \delta_{L_2 0} \right) d^3r$$

$$= e^{\gamma_1\varepsilon_1} \int_{\mathrm{UC}} F^b_{L_1}(\gamma_1;\mathbf{r}-\mathbf{R}_1)^* H^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2) d^3r, \tag{11.49}$$

$$U_{HH} = \int_{\mathrm{UC}} \int_{\mathrm{UC}} \frac{\tilde{H}^b_{L_1}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^* \tilde{H}^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}'-\mathbf{R}_2)}{|\mathbf{r}-\mathbf{r}'|} d^3r d^3r'$$

$$= \frac{1}{2} \int_{\mathrm{UC}} \phi_{\tilde{H}^b_{L_1}}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^* \left(H^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2) + \frac{\sqrt{4\pi}}{\Omega} \frac{e^{\gamma_2\varepsilon_2}}{\varepsilon_2} \delta_{L_2 0} \right) d^3r$$

$$= \frac{4\pi}{\varepsilon_1} \left\{ \begin{array}{c} \displaystyle\int_{\mathrm{UC}} H^b_{L_1}(\gamma_1,\varepsilon_1;\mathbf{r}-\mathbf{R}_1)^* H^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2) d^3r \\ \displaystyle -e^{\gamma_1\varepsilon_1} \int_{\mathrm{UC}} F^b_{L_1}(\gamma_1;\mathbf{r}-\mathbf{R}_1)^* H^b_{L_2}(\gamma_2,\varepsilon_2;\mathbf{r}-\mathbf{R}_2) d^3r \end{array} \right\}$$

$$- \frac{\Omega}{\varepsilon_1} \frac{4\pi e^{\gamma_1\varepsilon_1}}{\Omega\varepsilon_1} \frac{4\pi e^{\gamma_2\varepsilon_2}}{\Omega\varepsilon_2} \delta_{L_1 0} \delta_{L_2 0}. \tag{11.50}$$

As usual, the integrals in these expressions can be calculated using functions evaluated for the connecting vector $\mathbf{R}_1 - \mathbf{R}_2$. The relevant equations are (11.32), (11.37), (10.10), and (10.11).

XII. EXPANSION OF A SMOOTH FUNCTION AROUND A SITE

Modern electronic structure calculations often use either augmentation or nonlocal pseudopotentials to introduce atomic detail at the atomic sites. In either approach it is neccessary to expand the basis functions as a sum of angular-momentum components around the various atomic sites. In this section, we present a method to do this, based on biorthogonal polynomials to the Gaussian family $G_{kL}(\mathbf{r})$. This approach can be applied to any smooth function, in particular to the smoothed Hankel functions and to plane waves. The result will be to approximate a given smooth function $F(\mathbf{r})$ by a finite expansion of the form

$$F(\mathbf{r}) \sim \sum_{kL} a_{kL} P_{kL}(\mathbf{r}). \tag{12.1}$$

The expansion functions P_{kL} are polynomials in x, y, and z which will be defined using the radial functions $\varphi_{k\ell}$ of the generalized Gaussians (5.11). The advantage over a Taylor series is that the expansion (12.1) converges evenly over some chosen range, making it significantly more useful in practical applications.

In Sec. V, the Gaussians $G_{kL}(\gamma,\varepsilon;\mathbf{r})$ were defined with an energy-dependent factor $e^{\gamma\varepsilon}$ in order to simplify expressions involving Gaussians and smoothed Hankel functions. Throughout this section, ε is zero and will be suppressed in the notation. Gaussians are therefore specified by one parameter γ which gives the decay of the functions as $e^{-a^2r^2}$ with $a^2 = 1/(4\gamma)$. Equivalently, we speak of the smoothing radius $R_{\mathrm{sm}} = 1/a$ which is the width of the Gaussian. As preparation, we prove two relationships for the functions G_{kL}.

(a) The radial functions $\varphi_{k\ell}(r)$ which define the generalized Gaussians as in (5.11) by

$$G_{kL}(\gamma;\mathbf{r}) = \varphi_{k\ell}(r) \left(\frac{a^2}{\pi} \right)^{3/2} e^{-a^2r^2} r^\ell Y_L(\hat{\mathbf{r}}) \tag{12.2}$$

are related to the generalized Laguerre polynomials $L_n^{(\alpha)}(x)$ (see Chapter 22 in Ref. 9) by

$$\varphi_{k\ell}(r) = (-1)^k (2a^2)^{k+\ell} 2^k k! L_k^{(\ell+1/2)}(a^2r^2). \tag{12.3}$$

Proof: We proceed by induction over $k \in \mathcal{N}_0$. For $k \leqslant 1$, Eq. (12.3) can be confirmed by comparing the explicit expressions for $L_0^{(\ell+1/2)}(x)$ and $L_1^{(\ell+1/2)}(x)$ (see 22.3.9 in Ref. 9) with expressions (5.14) and (5.15) for $\varphi_{0\ell}(r)$ and $\varphi_{1\ell}(r)$, respectively. Assume we have already shown (12.3) for all $k<k_0$ where $k_0 \geqslant 2$. By applying the recurrence relation for $L_n^{(\alpha)}(a^2r^2)$ (22.7.12 in Ref. 9) and the induction hypothesis, the right-hand side of (12.3) for $k=k_0$ is transformed into the right-hand side of the recurrence relation for the $\varphi_{p\ell}(r)$ (Eq. (5.19)) with p replaced by k_0. This completes the proof for all $k \in \mathcal{N}_0$. ◇

(b) The functions G_{kL} are orthogonal in both k and L in the following sense:

$$\int G_{kL}(\gamma;\mathbf{r}) G_{k'L'}(\gamma;\mathbf{r}) e^{a^2r^2} d^3r = \frac{1}{4\pi}\left(\frac{a^2}{\pi}\right)^{3/2} (2a^2)^{2k+\ell} 2^k k!(2k+2\ell+1)!!\,\delta_{kk'}\delta_{LL'}. \tag{12.4}$$

Proof: In the case $L \neq L'$ the orthogonality follows immediately from (12.2) and the orthogonality of the spherical harmonics $Y_L(\hat{\mathbf{r}})$. For the case $L=L'$, the result is obtained using (12.2), Eq. (2.9) for the case $K=L$, the orthogonality of the $Y_M(\hat{\mathbf{r}})$, $C_{LL0}=1/\sqrt{4\pi}$, (12.3) and the orthogonality relation of the generalized Laguerre polynomials

$$\int_0^\infty e^{-u} u^{\ell+1/2} L_k^{(\ell+1/2)}(u) L_{k'}^{(\ell+1/2)}(u)\,du = \frac{\Gamma(k+\ell+3/2)}{k!}\,\delta_{kk'} \tag{12.5}$$

(cf. 22.2.12 in Ref. 9) with the substitution $u=a^2r^2$. ◇

Returning to the desired expansion (12.1), we define the polynomials $P_{kL}(\gamma;\mathbf{r})$ by scaling $\varphi_{k\ell}(r)$ in a convenient way:

$$P_{kL}(\gamma;\mathbf{r}) = p_{k\ell}(\gamma;r) Y_L(\hat{\mathbf{r}}), \tag{12.6}$$

$$p_{k\ell}(\gamma;r) = \varphi_{k\ell}(r)\,\frac{a^\ell (2\ell+1)!!}{(2a^2)^{k+\ell}(2k+2\ell+1)!!}\,r^\ell. \tag{12.7}$$

The radial functions $\varphi_{k\ell}$ [see (5.16)] as well as the $r^\ell Y_L(\hat{\mathbf{r}}) = \mathscr{Y}_L(\mathbf{r})$ are polynomials in x,y,z. Therefore, we see that the P_{kL} are indeed polynomials in the Cartesian coordinates of $\mathbf{r}$. The $P_{kL}(\gamma;\mathbf{r})$ are biorthogonal to the G_{kL} as follows from Eqs. (12.6)/(12.7), (12.2), and (12.4):

$$\int G_{kL}(\gamma;\mathbf{r}) P_{k'L'}(\gamma;\mathbf{r})\,d^3r = \frac{1}{4\pi}(2a^2)^k a^\ell 2^k k!(2\ell+1)!!\,\delta_{kk'}\delta_{LL'}. \tag{12.8}$$

The significance of the biorthogonality is that, in order to expand a function as a linear combination of the P_{kL}, we can use the Gaussians G_{kL} to project out the coefficients. Consider some function $F(\mathbf{r})$ and assume that

$$\int_0^{2\pi}\int_0^{\pi} |F(r,\theta,\varphi)|^2 \sin\theta\, d\theta\, d\varphi < \infty \quad \text{for all } r \geqslant 0. \tag{12.9}$$

Such a function can be written in the form

$$F(\mathbf{r}) = \sum_L f_L(r) r^\ell Y_L(\hat{\mathbf{r}}) \tag{12.10}$$

because the $Y_L(\hat{\mathbf{r}})$ form a complete basis of $\mathscr{L}_2(S)$ [cf.(2.5)]. Now, if $f_L(r)$ satisfies the condition

$$\int_0^\infty e^{-u} u^{\ell+1/2}\left[f_L\left(\frac{\sqrt{u}}{a}\right)\right]^2 du < \infty$$

$$\text{where } u=a^2r^2, \tag{12.11}$$

we can expand $f_L(r)$ in terms of the generalized Laguerre polynomials $L_k^{(\ell+1/2)}(u)$ by using (12.5):

$$f_L\left(\frac{\sqrt{u}}{a}\right)\sim\sum_{k=0}^{\infty} c_{kL}(\gamma)L_k^{(\ell+1/2)}(u), \tag{12.12}$$

$$c_{kL}(\gamma)=\frac{k!}{\Gamma(k+\ell+3/2)}\int_0^\infty e^{-u}u^{\ell+1/2}f_L\left(\frac{\sqrt{u}}{a}\right)L_k^{(\ell+1/2)}(u)du. \tag{12.13}$$

For a finite approximation obtained by truncating the sum at some $n\in\mathcal{N}_0$ we have the property

$$\int_0^\infty e^{-u}u^{\ell+1/2}\left[f_L\left(\frac{\sqrt{u}}{a}\right)-\sum_{k=0}^{n} c_{kL}(\gamma)L_k^{(\ell+1/2)}(u)\right]^2du=\min_{\zeta\in\Pi_n}\int_0^\infty e^{-u}u^{\ell+1/2}\left[f_L\left(\frac{\sqrt{u}}{a}\right)-\zeta(u)\right]^2du, \tag{12.14}$$

where Π_n is the set of all polynomials of degree $\leqslant n$ (see, e.g., pp. 98–101 in Ref. 16). Using (12.3) and (12.7), expansion (12.12) translates to a linear combination of the radial functions $p_{k\ell}(r)$:

$$f_L(r)r^\ell\sim\sum_{k=0}^{\infty} a_{kL}(\gamma)p_{k\ell}(\gamma;r) \tag{12.15}$$

for suitable coefficients $a_{kL}(\gamma)$. By multiplying through with $Y_L(\hat{\mathbf{r}})$ we obtain the desired expansion (12.1) of $F(\mathbf{r})$, which is valid provided (12.11) holds for all angular-momentum components L. Because of the biorthogonality relation (12.8), the expansion coefficients $a_{kL}(\gamma)$ can be obtained by integration:

$$a_{kL}(\gamma)=\frac{4\pi}{(2a^2)^k a^\ell 2^k k!(2\ell+1)!!}\int G_{kL}(\gamma;\mathbf{r})F(\mathbf{r})d^3r. \tag{12.16}$$

As a specific instance, the aim might be to expand the smoothed Hankel function $H_{L'}(\gamma',\varepsilon';\mathbf{r}-\mathbf{R}')$ centered at $\mathbf{R}'$ around some other site $\mathbf{R}$. We obtain an expansion in the polynomials $P_{kL}(\gamma;\mathbf{r}-\mathbf{R})$ centered at $\mathbf{R}$:

$$H_{L'}(\gamma',\varepsilon';\mathbf{r}-\mathbf{R}')\sim\sum_{k,L} a_{kL}(\gamma,\mathbf{R}-\mathbf{R}')P_{kL}(\gamma;\mathbf{r}-\mathbf{R}) \tag{12.17}$$

whereby the coefficients are

$$\begin{aligned}a_{kL}(\gamma,\mathbf{R}-\mathbf{R}')&=\frac{4\pi}{(2a^2)^k a^\ell 2^k k!(2\ell+1)!!}\int G_{kL}(\gamma;\mathbf{r}-\mathbf{R})H_{L'}(\gamma',\varepsilon';\mathbf{r}-\mathbf{R}')d^3r\\&=\frac{4\pi}{(2a^2)^k a^\ell 2^k k!(2\ell+1)!!}e^{-\gamma\varepsilon'}(-1)^\ell\\&\quad\times\sum_M C_{LL'M}H_{(\ell+\ell'-m)/2+k,M}(\gamma+\gamma',\varepsilon';\mathbf{R}-\mathbf{R}')\end{aligned} \tag{12.18}$$

[compare (8.4)], i.e., the involved integral reduces to a sum of smoothed Hankel functions of the connecting vector $\mathbf{R}-\mathbf{R}'$. Altogether we obtain an analytical expansion theorem for the smoothed Hankel functions around an arbitrary point in space. In contrast to the well-known structure-constant expansion[17] for the standard Hankel functions, the present expression can be applied even when point $\mathbf{R}$ lies close to or is identical with the center of the function at $\mathbf{R}'$. Furthermore, analogous expressions can be used to expand a Bloch-summed function $H^b_{L'}(\gamma',\varepsilon';\mathbf{r}-\mathbf{R}')$. Hereby the integral over all space as in (12.18) is reduced to an integral over the unit cell which

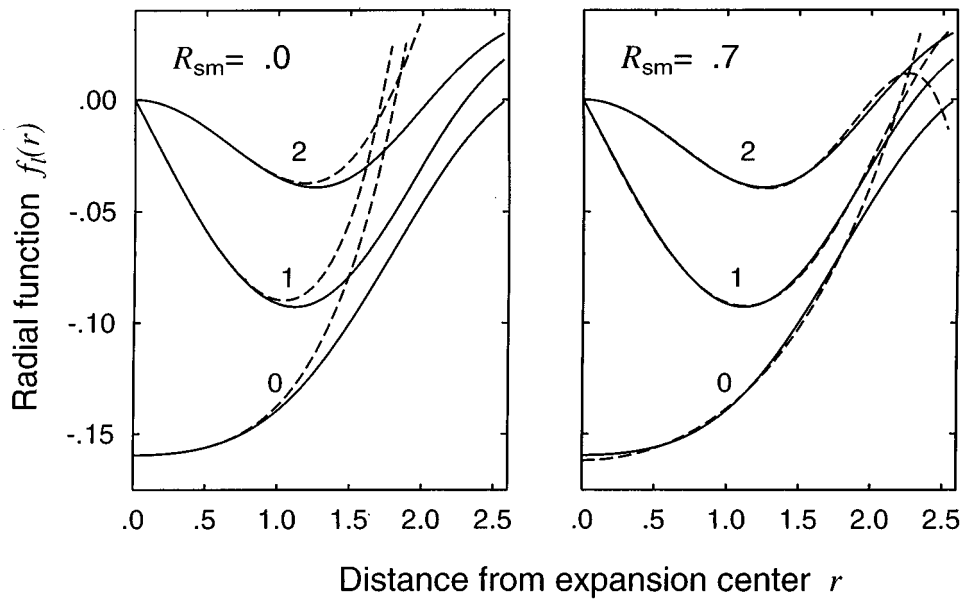

FIG. 3. Expansion of a smoothed Hankel function centered at point $\mathbf{R}'=(0,0,2)$ as a sum of the polynomials P_{kL} around the origin. The Hankel function has angular momentum $(\ell',m_{\ell'})=(1,0)$, energy $\varepsilon'=-1$, and smoothing radius $R'_{\rm sm}=1/a'=1$. Shown are the radial components for $(\ell,m_\ell)=(0,0)$, (1,0), and (2,0) for two choices of the smoothing radius $R_{\rm sm}=1/a$ when expanded up to $k_{\max}=2$. For $R_{\rm sm}=0$, the expansion reduces to a Taylor series, which is accurate near the center but deviates in an uncontrolled manner already at moderate distances. For $R_{\rm sm}=0.7$ the error in the expansion is spread evenly over the range where the Gaussian is large, here approximately to $r=1.5$.

is then evaluated analytically following (10.9). On the other hand, if the aim is to expand a plane wave, the coefficients are given by integrals over the plane wave times $G_{kL}(\gamma;\mathbf{r}-\mathbf{R})$. This simply picks out the corresponding Fourier coefficient of G_{kL}.

For a discussion of the convergence of the expansion (12.1), the central quantity is the width $R_{\rm sm}$ of the underlying Gaussian $g_0(r)=e^{-a^2r^2}=e^{-r^2/R_{\rm sm}^2}$ which defines the family $G_{kL}(\mathbf{r})$. By calculating the expansion coefficients according to (12.16), we are projecting out information about the function $F(\mathbf{r})$ in that part of volume where g_0 is non-negligible. Correspondingly, we obtain a representation which is accurate there but deviates where g_0 is small. When the extent of g_0 is made larger by increasing $R_{\rm sm}$, the resulting expansion is valid over a larger part of space but is less accurate overall for a fixed level of truncation. This is in contrast to a Taylor series, which places all emphasis on the (comparatively irrelevant) point at the center of expansion. Figure 3 illustrates the dependence of the convergence on the smoothing radius.

In order to formalize the discussion of convergence, we have chosen the normalization of the functions P_{kL} (12.6)/(12.7) such that

$$|p_{k\ell}(\gamma;r)|\leqslant 1 \quad \text{for all} \quad r\leqslant R_{\rm sm}$$

and

$$|p_{0\ell}(\gamma;R_{\rm sm})|=1. \tag{12.19}$$

Typical radial functions $p_{k\ell}(r)$ are shown in Fig. 4. The characteristic behavior is that the polynomials oscillate in a well-behaved manner up to a range of approximately $R_{\rm sm}$ and somewhat beyond, then quickly increase to large values. If we truncate (12.15) in order to approximate $f_L(r)r^\ell$ by the finite sum $\Sigma_{k\leqslant k_{\max}}a_{kL}(\gamma)p_{k\ell}(\gamma;r)$, then an upper bound for the approximation error on $r\leqslant R_{\rm sm}$ is given by

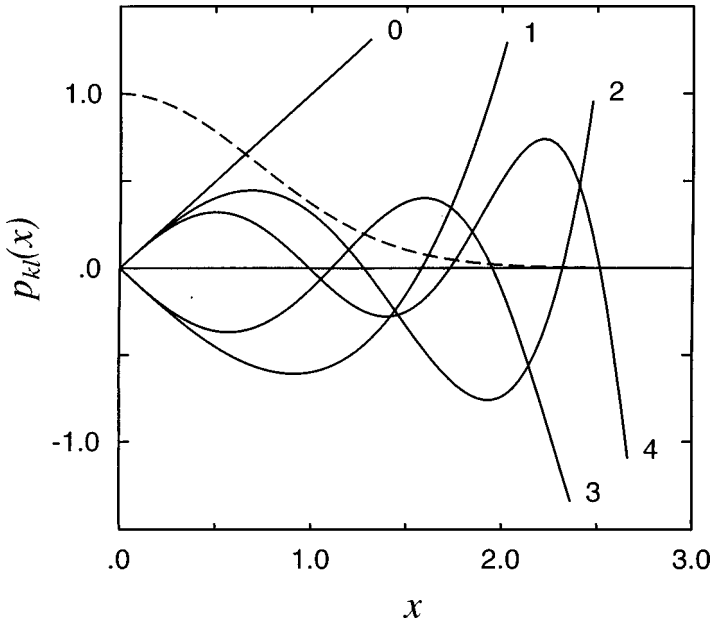

FIG. 4. Radial polynomials $p_{k\ell}(r)$ for $\ell=1$ and $R_{\rm sm}=1/a=1.0$, plotted for $0\leqslant k\leqslant 4$. The Gaussian $g_0(r)=\exp(-r^2/R_{\rm sm}^2)$ is also shown (dashed line). Note that the polynomials are well-behaved where g_0 is large, then increase rapidly outside this range.

$$\left| f_L(r) r^{\ell} - \sum_{k\leqslant k_{\max}} a_{kL}(\gamma) p_{k\ell}(\gamma;r) \right| = \left| \sum_{k>k_{\max}} a_{kL}(\gamma) p_{k\ell}(\gamma;r) \right| \leqslant \sum_{k>k_{\max}} |a_{kL}(\gamma)|. \quad (12.20)$$

In close analogy to the expansion of a function over a finite interval using Chebyshev poynomials,[18] the absolute values of the expansion coefficients generally decrease rapidly by orders of magnitude. The approximation error on $r\leqslant R_{\rm sm}$ is then bounded by the coefficient of the first neglected term, i.e.,

$$\left| f_L(r) r^{\ell} - \sum_{k\leqslant k_{\max}} a_{kL}(\gamma) p_{k\ell}(\gamma;r) \right| \leqslant |a_{k_{\max}+1,L}(\gamma)|. \quad (12.21)$$

XIII. SUMMARY

In this paper, we have presented a set of functions which combine many of the best features of Hankel functions and Gaussians as a basis for electronic structure calculations. These ''smoothed Hankel functions'' equal the standard Hankel functions at large distances, showing the same exponential decay. At smaller radii, the functions bend over smoothly until they approach the origin as $r^{\ell} Y_L(\hat{\mathbf{r}})$. The resulting object is nonsingular and analytical in all parts of space. The shape of each function is characterized by two separate parameters. The first is an energy which defines the decay at large distances, exactly as in the case of the standard Hankel functions. The second parameter is a smoothing radius which determines how strongly the singularity has been smoothed out, i.e., at what distance the smoothed Hankel function starts to deviate significantly from the standard function. A major advantage is that by adjusting these two parameters, basis functions can be made which closely resemble the true wave function outside the core regime. This is an improvement over both Gaussians and standard Hankel functions. A second advantage is that the resulting basis set is reasonably well suited to a direct numerical evaluation of the unavoidable three-center integrals, since a coarse mesh can be used. Furthermore, Bloch sums of the functions can be handled in a very similar way, leading to a unified description for crystals and molecules. In Ref. 5, a successful implementation of a density-functional crystal program based on these features was presented.

To use a given set of functions as a basis set, a number of calculational steps must be performed. To provide the neccessary formalism for the smoothed Hankel functions, we have first

introduced some families of auxiliary functions. These as well as the smoothed Hankel functions themselves are generated in compact form from simple root functions by differential operators. Using these results, we have derived analytical expressions for overlap and kinetic-energy two-center matrix elements as well as Coulomb integrals involving two such functions. To evaluate the expressions in practice, suitable recurrence relations were found. Finally, we have presented a general procedure by which an arbitrary smooth function can be expanded as a sum of polynomials around some point in space, whereby the approximation converges evenly over a chosen range as higher terms are included. Such a local representation is a necessary step when the functions are used in the context of augmentation methods or norm-conserving pseudopotentials. In sum, we believe the functions presented here have a high potential as a local basis set in electronic structure calculations and have derived expressions to perform the various calculational steps needed for such an application.

APPENDIX A: DERIVATION OF AN EXPLICIT INTEGRAL REPRESENTATION FOR THE $\chi_\ell(r)$

Here, we make the connection to an explicit integral representation for the radial functions $\chi_\ell(r)$, related to the smoothed Hankel functions by $H_L(\mathbf{r})=\chi_\ell(r)r^\ell Y_L(\hat{\mathbf{r}})$ [see Eq. (6.18)]. Such representations are used in standard formulations of Ewald summation[19] and in Ref. 20. This representation is mainly of theoretical interest; for the calculation of the χ_ℓ it is more efficient to use the recurrence relations (6.19)–(6.21).

For $\chi_0(r)$ we obtain from (6.19) and (6.6) the representation

$$\chi_0(r)=\frac{1}{2r}\left[e^{-\kappa r}\frac{2}{\sqrt{\pi}}\int_{(\kappa/2a)-ar}^{\infty}e^{-t^2}dt-e^{\kappa r}\frac{2}{\sqrt{\pi}}\int_{(\kappa/2a)+ar}^{\infty}e^{-t^2}dt\right]. \tag{A1}$$

By making the substitutions

$$\xi=\frac{-t+\sqrt{t^2+2\kappa r}}{2r},\quad t=\frac{\kappa}{2\xi}-r\xi,\quad \frac{dt}{d\xi}=-\frac{\kappa}{2\xi^2}-r, \tag{A2}$$

and

$$\xi=\frac{t-\sqrt{t^2-2\kappa r}}{2r},\quad t=\frac{\kappa}{2\xi}+r\xi,\quad \frac{dt}{d\xi}=-\frac{\kappa}{2\xi^2}+r \tag{A3}$$

in the first and second integral, respectively, we obtain

$$\begin{aligned}\chi_0(r)&=\frac{1}{2r}\frac{2}{\sqrt{\pi}}\left[\int_a^0 e^{-\kappa^2/4\xi^2}e^{-r^2\xi^2}\left(-\frac{\kappa}{2\xi^2}-r\right)d\xi-\int_a^0 e^{-\kappa^2/4\xi^2}e^{-r^2\xi^2}\left(-\frac{\kappa}{2\xi^2}+r\right)d\xi\right]\\&=\frac{2}{\sqrt{\pi}}\int_0^a e^{\varepsilon/4\xi^2}e^{-r^2\xi^2}d\xi.\end{aligned} \tag{A4}$$

Finally, by applying (4.10) and (4.11) we see that

$$\chi_\ell(r)=\frac{2}{\sqrt{\pi}}2^\ell\int_0^a \xi^{2\ell}e^{\varepsilon/4\xi^2}e^{-r^2\xi^2}d\xi\quad\text{for all }\ell\in\mathcal{N}_0. \tag{A5}$$

APPENDIX B: EVALUATION OF BLOCH SUMS OF ORDINARY (UNSMOOTHED) HANKEL FUNCTIONS

The standard Ewald method[19] for evaluating lattice sums of Hankel functions is equivalent to splitting off a smoothed-Hankel part which is summed in reciprocal space. Here, we show how to do this in our formalism, whereby the inconvenient integrals to represent $\chi_\ell(r)$ are avoided (see Appendix A).

The aim is the evaluation of the Bloch sum

$$\check{H}_L^b(\varepsilon;\mathbf{r}) := \sum_{\mathbf{R}} e^{i\mathbf{k}\cdot\mathbf{R}} \check{H}_L(\varepsilon;\mathbf{r}-\mathbf{R}) \tag{B1}$$

of unsmoothed Hankel functions at some point $\mathbf{r}$. This point cannot be a direct lattice point $\mathbf{R}'$ since $\check{H}_L^b(\mathbf{r})$ is undefined there. For a suitable parameter $\gamma>0$, we split (B1) up into two parts, which are evaluated as sums over reciprocal and direct space lattice vectors, respectively:

$$\begin{aligned}\check{H}_L^b(\varepsilon;\mathbf{r}) &= H_L^b(\gamma,\varepsilon;\mathbf{r}) + (\check{H}_L^b(\varepsilon;\mathbf{r}) - H_L^b(\gamma,\varepsilon;\mathbf{r})) \\ &= \frac{1}{\Omega}\sum_{\mathbf{G}} \frac{-4\pi}{\varepsilon-|\mathbf{k}+\mathbf{G}|^2}\, \mathscr{Y}_L(-i(\mathbf{k}+\mathbf{G}))\, e^{\gamma(\varepsilon-|\mathbf{k}+\mathbf{G}|^2)} e^{i(\mathbf{k}+\mathbf{G})\cdot\mathbf{r}} \\ &\quad + \sum_{\mathbf{R}} e^{i\mathbf{k}\cdot\mathbf{R}} (\check{H}_L(\varepsilon;\mathbf{r}-\mathbf{R}) - H_L(\gamma,\varepsilon;\mathbf{r}-\mathbf{R}))\end{aligned} \tag{B2}$$

[cf. (3.18), (6.35)]. In the real-space sum, the values $H_L(\gamma,\varepsilon;\mathbf{r}-\mathbf{R})$ can be calculated from (6.18) to (6.24). Furthermore, the values $\check{H}_L(\varepsilon;\mathbf{r}-\mathbf{R})$ can be obtained as follows in view of (6.27) and (6.18)–(6.24):

$$\check{H}_L(\mathbf{r}) = \check{\chi}_\ell(r) r^\ell Y_L(\hat{\mathbf{r}}), \tag{B3}$$

$$\check{\chi}_0(r) = \frac{e^{-\kappa r}}{r}, \tag{B4}$$

$$\check{\chi}_1(r) = \frac{e^{-\kappa r}}{r^3} + \frac{\kappa e^{-\kappa r}}{r^2}, \tag{B5}$$

$$\check{\chi}_{\ell+1}(r) = \frac{2\ell+1}{r^2}\,\check{\chi}_\ell(r) - \frac{\varepsilon}{r^2}\,\check{\chi}_{\ell-1}(r) \quad \text{for } \ell \geqslant 1. \tag{B6}$$

(Received 27 January 1997; accepted for publication 9 February 1998)

A noncommutative differential calculus on the h-superplane is presented via a contraction of the q-superplane. An R-matrix which satisfies both ungraded and graded Yang–Baxter equations is obtained and a new deformation of the $(1+1)$-dimensional classical phase space (the super-Heisenberg algebra) is introduced. © *1998 American Institute of Physics.* [S0022-2488(98)02305-6]

I. INTRODUCTION

A possible approach to quantum groups is obtained by deforming the coordinates of a linear space to be noncommuting objects.[1] In this scheme the quantum group structure appears if one considers linear transformations which preserve the algebraic properties of the algebra of coordinates. A natural and physically interesting question is whether one can define differentials and derivatives corresponding to these noncommuting variables. A general answer to this question was given by Connes,[2] who considered the differential algebra for non-commutative algebras. Differential geometry of Lie groups and supergroups plays an important role in the mathematical modeling of physical theories. Since a (graded) Hopf algebra or quantum (super) group can be regarded as a generalization of the notion of a (super) group, it is tempting to also generalize the corresponding notions of differential geometry.[3]

Recently Wess and Zumino[4] have shown that a consistent quantum deformation of the differential calculus is satisfied by an R-matrix which can be any solution of the quantum Yang–Baxter equation. The noncommutative plane has been studied in the course of the last few years[5] in that the geometry underlying the above-mentioned plane has a deep connection with the Yang–Baxter equation, which is important in two-dimensional exactly soluble statistical models. The quantum (super) plane was generalized to the supersymmetric quantum (super) plane[6,7] and it was shown that the quantum superplane is related to the graded Yang–Baxter equation.

The h-deformation of the supergroup $\mathrm{GL}(1|1)$ is given by Dabrowski and Parashar,[8] via a contraction of $\mathrm{GL}_q(1|1)$. They have also introduced a differential calculus on the h-superplane which is related to $\mathrm{GL}_h(1|1)$ via the Wess–Zumino formulas.

This paper considers an alternative approach where instead of adopting the Wess–Zumino calculus from the start, the R-matrix is obtained using the consistency conditions. This leads to a consistent exterior derivative. We start by introducing a noncommutative differential calculus on the h-superplane via a contraction of the q-superplane. We define derivatives and differentials on the h-superplane of noncommuting coordinates and give their commutation rules. We note the role of the graded Yang–Baxter equation and the connection to the quantum supergroup. We give a new deformation of the $(1+1)$-dimensional classical phase space. Finally we show that the q-deformed super-oscillator algebra satisfies the undeformed (classical) super-oscillator algebra when objects are transformed into new objects such that they are singular for certain values of the deformation parameter.

II. A DIFFERENTIAL CALCULUS ON *h*-SUPERPLANE

In this work we denote q-deformed objects by primed quantities. Unprimed quantities represent transformed coordinates. As usual, we assume that even (bosonic) objects commute with everything and odd (Grassmann) objects anticommute among themselves.

 © 1998 American Institute of Physics

A. Quantum *h*-superplane

We begin by considering the quantum superplane which is defined by Manin.[9] The commutation relation between the even coordinate x' and the odd (Grassmann) coordinate θ' of the quantum superplane is in the form

$$x'\theta' - q\theta' x' = 0, \tag{1}$$

where q is a complex deformation parameter.

We now introduce new coordinates x and θ, in terms of x' and θ' as

$$x = x', \quad \theta = \theta' - \frac{h}{q-1}x', \tag{2}$$

as in Ref. 10. This transformation is singular in the $q \to 1$ limit. Using relation (1), it is easy to verify that

$$x\theta = q\theta x + hx^2, \tag{3}$$

where the new deformation parameter h commutes with the coordinate x. Also, since the Grassmann coordinate θ' satisfies

$$\theta'^2 = 0$$

one obtains

$$\theta^2 = -h\theta x, \tag{4}$$

where h anti-commutes with θ and

$$h^2 = 0, \tag{5}$$

that is, the new deformation parameter h is a Grassmann number.[8] Taking the $q \to 1$ limit we obtain the following relations which define the h-superplane:

$$x\theta = \theta x + hx^2, \quad \theta^2 = -h\theta x. \tag{6}$$

B. Relations of coordinates and differentials

To establish a noncommutative differential calculus on the quantum h-superplane, we assume that the commutation relations between the coordinates and their differentials are in the following form:

$$\begin{aligned} x'\mathrm{d}x' &= A\mathrm{d}x'x' \\ x'\mathrm{d}\theta' &= F_{11}\mathrm{d}\theta' x' + F_{12}\mathrm{d}x'\theta', \\ \theta'\mathrm{d}x' &= F_{21}\mathrm{d}x'\theta' + F_{22}\mathrm{d}\theta' x', \\ \theta'\mathrm{d}\theta' &= B\mathrm{d}\theta'\theta'. \end{aligned} \tag{7}$$

We demand an exterior differential d obeying the condition:

$$\mathrm{d}^2 = 0, \tag{8}$$

and the graded Leibniz rule

$$\mathrm{d}(fg) = (\mathrm{d}f)g + (-1)^{\hat{f}} f(\mathrm{d}g), \tag{9}$$

where $\hat{f}$ is the Grassmann degree of f (recall that d should be odd), that is, $\hat{f}=0$ for even variables and $\hat{f}=1$ for odd variables. Considering the differential of a function and differentiating (2) we have

$$\mathrm{d}x=\mathrm{d}x', \quad \mathrm{d}\theta=\mathrm{d}\theta'+\frac{h}{q-1}\mathrm{d}x'. \tag{10}$$

Substituting (2) and (10) into (7) one has

$$\begin{aligned} x\mathrm{d}x &= A\mathrm{d}xx, \\ x\mathrm{d}\theta &= F_{11}\mathrm{d}\theta x+F_{12}\mathrm{d}x\theta+\frac{h}{q-1}(A-F_{11}-F_{12})\mathrm{d}xx, \\ \theta\mathrm{d}x &= F_{21}\mathrm{d}x\theta+F_{22}\mathrm{d}\theta x-\frac{h}{q-1}(A+F_{21}+F_{22})\mathrm{d}xx, \\ \theta\mathrm{d}\theta &= B\mathrm{d}\theta\theta-\frac{h}{q-1}[(B+F_{12}+F_{21})\mathrm{d}x\theta-(B-F_{11}-F_{22})\mathrm{d}\theta x]. \end{aligned} \tag{11}$$

These relations are slightly different from the results of Dabrowski and Parashar.[8] The reason for this difference is that in Ref. 8, the commutation relations among the matrix elements of a matrix belonging to $\mathrm{GL}_h(1|1)$ were obtained via the use of commutation relations of the dual *exterior* superplane. On the other hand we use the commutation relations of the dual superplane as in Ref. 3. The commutation relations among the matrix elements are the same in both approaches. However the commutation relations involving the differentials turn out not to be the same.

We know that the quantum supermatrices of the quantum $\mathrm{GL}_q(1|1)$ supergroup can be defined as linear transformations of the variables x' and θ', which preserve the commutation relation (1) and their duals,[9] that is, the quantum supergroup $\mathrm{GL}_q(1|1)$ acts as a linear transformation on the quantum superplane, which preserves (1) and the relations

$$\varphi'^2=0, \quad \varphi' y'-q^{-1}y'\varphi'=0. \tag{12}$$

In extending this property of covariance under the coaction of $\mathrm{GL}_q(1|1)$, from the superplane to its calculus, it will be assumed that the deformed group structure implies and is implied by invariance of the intermediary relations (7) under linear transformations of the quantum superplane. In the present work, this will be applied to the h-deformed superplane.

The coefficients A, B and F_{ij} given in (11) can be related to q by the consistency of calculus. Thus we apply the exterior derivative d to the relation (3). From the consistency condition

$$\mathrm{d}(x\theta-q\theta x-hx^2)=0 \tag{13}$$

we find

$$F_{11}=q(1-F_{22}), \quad F_{12}=-(1+qF_{21}). \tag{14a}$$

Applying the exterior derivative d on the second and third relations of (11) and using the definitions (8), (9) one finds

$$F_{12}=qF_{11}-1, \quad F_{21}=q(F_{22}-1). \tag{14b}$$

Similarly from the last relation of (11) we get

$$F_{12}+F_{21}=q(F_{11}+F_{22})-(1+q)B. \tag{14c}$$

On the other hand, using relation (4) we obtain

$$\theta\mathrm{d}\theta=\mathrm{d}\theta\theta+hF_{21}\mathrm{d}x\theta-h(1-F_{22})\mathrm{d}\theta x \tag{15}$$

$$= \mathrm{d}\theta\theta - \frac{h}{q}[F_{11}\mathrm{d}\theta x + (1+F_{12})\mathrm{d}x\theta].$$

Thus we have

$$\begin{gathered} B=1,\ \ F_{12}+F_{21}+1=(1-q)F_{21}, \\ 1-F_{11}-F_{22}=(1-q)(1-F_{22}). \end{gathered} \tag{14d}$$

To find the commutation relation between differentials, say $\mathrm{d}x$ and $\mathrm{d}\theta$, we apply the exterior derivative d on the first two relations of (11) and use the nilpotency of d [Eq. (8)]. Then it is easy to see that

$$\mathrm{d}x\mathrm{d}\theta = \frac{1}{q}\mathrm{d}\theta\mathrm{d}x, \quad (\mathrm{d}x)^2 = 0. \tag{16}$$

Solving the system (14) we now get

$$\begin{gathered} A \ \text{ undetermined}, \ \ F_{11}=q, \\ F_{12}=q^2-1, \ \ F_{21}=-q, \ \ F_{22}=0. \end{gathered} \tag{17}$$

We choose A equal to q^2, since this leads to the standard R-matrix [Eq. (38)] in the $h\to 0$ limit. We are thus led to the following deformed relations containing q and h

$$\begin{gathered} x\mathrm{d}x = q^2\mathrm{d}xx, \\ x\mathrm{d}\theta = q\mathrm{d}\theta x - h\mathrm{d}xx + (q^2-1)\mathrm{d}x\theta, \\ \theta\mathrm{d}x = -q\mathrm{d}x\theta - qh\mathrm{d}xx, \\ \theta\mathrm{d}\theta = \mathrm{d}\theta\theta - h(q\mathrm{d}x\theta + \mathrm{d}\theta x). \end{gathered} \tag{18}$$

Note that although in the $q\to 1$ limit the transformations (2) and (10) are ill behaved, the resulting commutation relations are well defined. We shall not use the limit process, yet.

C. Relations of derivatives and variables

First, we wish to construct the curl of any one-form $w(x',\theta')$. To this end let us denote the partial derivatives with respect to x' and θ' as

$$\partial_{x'} = \frac{\partial}{\partial x'}, \quad \partial_{\theta'} = \frac{\partial}{\partial \theta'}, \tag{19}$$

respectively, and introduce the super-gradient operator in vector notation

$$\nabla = (\partial_{x'}, \partial_{\theta'}). \tag{20}$$

We define the vectors $X'=(x',\theta')$ and $\mathrm{d}X'=(\mathrm{d}x',\mathrm{d}\theta')$. Then we can write the differential d as

$$\mathrm{d} = \mathrm{d}x'\partial_{x'} + \mathrm{d}\theta'\partial_{\theta'} = \mathrm{d}X'.\nabla, \tag{21}$$

where the dot denotes the inner product. If we write $w(x',\theta')$ in the basis $\mathrm{d}X'$ as

$$w(x',\theta') = \mathrm{d}x' w_1(x',\theta') + \mathrm{d}\theta' w_2(x',\theta') \tag{22}$$

where w_1 and w_2 are smooth functions of the variables then we get

$$\mathrm{d}w(x',\theta') = \mathrm{d}x'\mathrm{d}\theta'[q\partial_{x'}w_2(x',\theta') - \partial_{\theta'}w_1(x',\theta')]. \tag{23}$$

Thus the curl of the one-form $w(x',\theta')=(w_1(x',\theta'),w_2(x',\theta'))$ is given by

$$\nabla\times w(x',\theta')=q\partial_{x'}w_2(x',\theta')-\partial_{\theta'}w_1(x',\theta'). \tag{24}$$

Now we can find the commutation rules of the derivatives, once we obtain the derivatives ∂_x and ∂_θ. For this if we demand the chain rule on the expressions (2) we find

$$\partial_x=\partial_{x'}+\frac{h}{q-1}\partial_{\theta'},\quad \partial_\theta=\partial_{\theta'}. \tag{25}$$

It is easy to see that in the case of (25) the differential d given in (21) preserves its form

$$\mathrm{d}=\mathrm{d}x\partial_x+\mathrm{d}\theta\partial_\theta. \tag{26}$$

If we now put $w(x,\theta)=\mathrm{d}f(x,\theta)$ then we conclude that ∂_x and ∂_θ generate a non-commutative algebra with the commutation relations

$$\partial_\theta\partial_x=q\partial_x\partial_\theta,\quad \partial_\theta^2=0. \tag{27}$$

From (26)

$$\mathrm{d}f(x,\theta)=\mathrm{d}x\partial_x f+\mathrm{d}\theta\partial_\theta f, \tag{28}$$

so that replacing f with xf and θf we arrive at the following commutation relations between derivatives and variables:

$$\begin{aligned}
\partial_x x&=1+Ax\partial_x+F_{12}\theta\partial_\theta-\frac{h}{q-1}(A-F_{11}-F_{12})x\partial_\theta,\\
\partial_x\theta&=-F_{21}\theta\partial_x-\frac{h}{q-1}[(A+F_{21}+F_{22})x\partial_x+(1+F_{12}+F_{21})\theta\partial_\theta],\\
\partial_\theta x&=F_{11}x\partial_\theta,\\
\partial_\theta\theta&=1-\theta\partial_\theta-F_{22}x\partial_x-\frac{h}{q-1}(1-F_{11}-F_{22})x\partial_\theta.
\end{aligned} \tag{29}$$

These commutation relations are well defined in the limit $q\to 1$. This can be checked using (17).

The covariant differential structure which is obtained so far is a concrete example of non-commutative differential geometry. The complete framework of the differential calculus requires commutation relations of the exterior differentials with derivatives.

D. Relations of differentials with derivatives

Finally we shall find the commutation relations between differentials and derivatives. We assume that they have the following form in terms of primed quantities

$$\begin{aligned}
\partial_{x'}\mathrm{d}x'&=A_{11}\mathrm{d}x'\partial_{x'}+A_{12}\mathrm{d}\theta'\partial_{\theta'},\\
\partial_{x'}\mathrm{d}\theta'&=A_{21}\mathrm{d}\theta'\partial_{x'}+A_{22}\mathrm{d}x'\partial_{\theta'},\\
\partial_{\theta'}\mathrm{d}x'&=B_{11}\mathrm{d}x'\partial_{\theta'}+B_{12}\mathrm{d}\theta'\partial_{x'},\\
\partial_{\theta'}\mathrm{d}\theta'&=B_{21}\mathrm{d}\theta'\partial_{\theta'}+B_{22}\mathrm{d}x'\partial_{x'}.
\end{aligned} \tag{30}$$

Using (25) and (10), these commutation rules can be written as

$$\begin{aligned}
\partial_x \mathrm{d}x &= A_{11}\mathrm{d}x\partial_x + \frac{h}{q-1}(A_{11}-A_{12}+B_{11})\mathrm{d}x\partial_\theta + A_{12}\mathrm{d}\theta\partial_\theta + \frac{h}{q-1}B_{12}\mathrm{d}\theta\partial_x,\\
\partial_x \mathrm{d}\theta &= A_{21}\mathrm{d}\theta\partial_x + \frac{h}{q-1}(A_{11}-A_{21}+B_{22})\mathrm{d}x\partial_x + \frac{h}{q-1}(A_{12}-A_{21}+B_{12})\mathrm{d}\theta\partial_\theta,\\
\partial_\theta \mathrm{d}\theta &= B_{21}\mathrm{d}\theta\partial_\theta + \frac{h}{q-1}(B_{22}-B_{21}-B_{11})\mathrm{d}x\partial_\theta + B_{22}\mathrm{d}x\partial_x - \frac{h}{q-1}B_{12}\mathrm{d}\theta\partial_x,\\
\partial_\theta \mathrm{d}x &= B_{11}\mathrm{d}x\partial_\theta + B_{12}\mathrm{d}\theta\partial_x - \frac{h}{q-1}B_{12}(\mathrm{d}\theta\partial_\theta + \mathrm{d}x\partial_x).
\end{aligned} \tag{31}$$

Finding the coefficients A_{ij} and B_{ij} from these equations we get

$$\begin{aligned}
\partial_x \mathrm{d}x &= q^2\mathrm{d}x\partial_x - h\mathrm{d}x\partial_\theta + (q^2-1)\mathrm{d}\theta\partial_\theta,\\
\partial_x \mathrm{d}\theta &= q\mathrm{d}\theta\partial_x + qh(\mathrm{d}x\partial_x + \mathrm{d}\theta\partial_\theta),\\
\partial_\theta \mathrm{d}x &= -q\mathrm{d}x\partial_\theta,\\
\partial_\theta \mathrm{d}\theta &= \mathrm{d}\theta\partial_\theta + h\mathrm{d}x\partial_\theta.
\end{aligned} \tag{32}$$

Here, in order to obtain these relations we used that the exterior differential d (anti-) commutes with the differentials, that is,

$$\mathrm{d}(\mathrm{d}x) = -(\mathrm{d}x)\mathrm{d}, \quad \mathrm{d}(\mathrm{d}\theta) = (\mathrm{d}\theta)\mathrm{d} \tag{33}$$

and the relation

$$\partial_i(X^j \mathrm{d}X^k) = \delta^i{}_j \delta^k{}_l \mathrm{d}X^k, \tag{34}$$

where $\partial_1 = \partial_x$, $\partial_2 = \partial_\theta$, $X^1 = x$, and $X^2 = \theta$. Again, the relations (32) are well defined in the limit $q \to 1$.

E. The R-matrix formalism

We now shall obtain the R-matrix satisfying the graded Yang–Baxter equations

$$R_{12}R_{13}R_{23} = R_{23}R_{13}R_{12}, \tag{35}$$

$$\hat{R}_{12}\hat{R}_{23}\hat{R}_{12} = \hat{R}_{23}\hat{R}_{12}\hat{R}_{23}. \tag{36}$$

For this we define the commutation relations between variables and their differentials [see Eq. (18)] in the following form

$$X^i \mathrm{d}X^j = q(-1)^{\hat{i}(\hat{j}+1)} K^{ji}{}_{kl} \mathrm{d}X^k X^l \tag{37}$$

where $K \in End(\mathscr{C} \otimes \mathscr{C})$. Comparing (37) with (18) we have

$$K_{h,q} = \begin{pmatrix} q & 0 & 0 & 0 \\ h & 1 & 0 & 0 \\ -q^{-1}h & q-q^{-1} & 1 & 0 \\ 0 & -h & -q^{-1}h & q^{-1} \end{pmatrix} = (K^{ij}{}_{kl}). \tag{38}$$

If we define

$$K_h = \lim_{q \to 1} K_{h,q}, \tag{39}$$

$$\hat{K}_h = \lim_{q\to 1}(K_{h,q}P), \tag{40}$$

where P is the super permutation matrix, that is,

$$P^{ij}{}_{kl} = (-1)^{\hat{i}\hat{j}}\delta^i{}_l\delta^j{}_k,$$

we have

$$K_h = \begin{pmatrix} 1 & 0 & 0 & 0 \\ h & 1 & 0 & 0 \\ -h & 0 & 1 & 0 \\ 0 & -h & -h & 1 \end{pmatrix}, \quad \hat{K}_h = \begin{pmatrix} 1 & 0 & 0 & 0 \\ h & 0 & 1 & 0 \\ -h & 1 & 0 & 0 \\ 0 & -h & -h & -1 \end{pmatrix}. \tag{41}$$

Here the matrix $\hat{K}_h$ coincides with the $\hat{R}_h$ matrix of Ref. 8. We know from Ref. 8 that the matrix $\hat{K}_h$ satisfies Equation (36) with the grading

$$(\hat{K}_{12})^{abc}{}_{def} = \hat{K}^{ab}{}_{de}\delta^c{}_f,$$

$$(\hat{K}_{13})^{abc}{}_{def} = (-1)^{b(c+f)}\hat{K}^{ac}{}_{df}\delta^b{}_e, \tag{42}$$

$$(\hat{K}_{23})^{abc}{}_{def} = (-1)^{a(b+c+e+f)}\hat{K}^{bc}{}_{ef}\delta^a{}_d.$$

Also, the R-matrix

$$R_h = P\hat{K}_h \tag{43}$$

obeys both the ungraded and the graded Yang–Baxter equations with the grading again given by (42). This is due to the odd character of h. As a consequence,

$$K_h = R_h^{-1} \tag{44}$$

so that K_h has the same properties as R_h.

We note that the equation

$$\hat{K}_h T_1 T_2 = T_1 T_2 \hat{K}_h \tag{45}$$

is satisfied for the h-deformed supergroup GL(1|1). Here T is a supermatrix in $\mathrm{GL}_h(1|1)$ and $T_1 = T\otimes I$, $T_2 = I\otimes T$. It is assumed that the tensor product is graded, that is,

$$(T_1)^{ij}{}_{kl} = T^i{}_k\delta^j{}_l, \quad (T_2)^{ij}{}_{kl} = (-1)^{\hat{i}(\hat{j}+\hat{l})}T^j{}_l\delta^i{}_k.$$

It is well-known that a supermatrix has the form

$$T = \begin{pmatrix} a & \beta \\ \gamma & d \end{pmatrix}$$

with two even (Latin letters) and two Grassmann (Greek letters) matrix elements. Equation (45) explicitly reads

$$a\beta=\beta a,\quad a\gamma=\gamma a+h(a^2+\gamma\beta-ad),$$

$$d\beta=\beta d,\quad d\gamma=\gamma d-h(d^2-\gamma\beta-da),$$

$$\beta^2=0,\quad \gamma^2=h\gamma(d-a), \tag{46}$$

$$\beta\gamma=-\gamma\beta+h\beta(d-a),$$

$$ad=da+h\beta(a-d).$$

Using the K_h matrix, we now formulate the differential calculus on the h-superplane. The commutation relations between variables and their differentials are

$$X^i\mathrm{d}X^j=(-1)^{\hat{i}(\hat{j}+1)}K^{ji}{}_{kl}\mathrm{d}X^kX^l. \tag{47}$$

The commutation relations between variables and derivatives are

$$\partial_jX^i=\delta^i{}_j+(-1)^{\hat{i}\hat{j}}K^{ik}{}_{lj}X^l\partial_k, \tag{48}$$

and the relations between differentials and derivatives are

$$\partial_j\mathrm{d}X^i=(-1)^{\hat{i}(\hat{j}+1)}(K^{-1})^{ik}{}_{lj}\,\mathrm{d}X^l\partial_k. \tag{49}$$

Note that the commutation relations between variables can be expressed using the $\hat{K}$ matrix as

$$X^iX^j=\hat{K}^{ij}{}_{kl}X^kX^l, \tag{50}$$

and the relations between derivatives as

$$\partial_i\partial_j=\hat{K}^{kl}{}_{ji}\partial_l\partial_k. \tag{51}$$

F. The commutation relations

We would like to discuss the meaning of covariance in a graded version of non-commutative differential calculus of Wess–Zumino.[4] Before proceeding, we define the dual quantum h-superplane. For this we interpret the differentials $\mathrm{d}x$ and $\mathrm{d}\theta$, as the coordinates of the dual superplane as follows [see Eq. (12)]

$$\mathrm{d}x=\varphi,\quad \mathrm{d}\theta=y. \tag{52}$$

We now formulate the differential calculus on the h-superplane as follows.

The commutation relations of variables and their differentials are

$$x\theta=\theta x+hx^2,\quad \theta^2=-h\theta x,$$

$$\varphi y=y\varphi,\quad \varphi^2=0. \tag{53a}$$

Note that if we assume that the relations (53a) have to be covariant under the coaction

$$\delta(x)=a\otimes x+\beta\otimes\theta,\quad \delta(\theta)=\gamma\otimes x+d\otimes\theta,$$

and that β, γ anticommute with θ, φ and h we get anew the relations (46).

The commutation relations among the derivatives are

$$\partial_x\partial_\theta=\partial_\theta\partial_x,\quad \partial_\theta^2=0, \tag{53b}$$

and those between variables and derivatives are

$$\partial_x x = 1 + x\partial_x + hx\partial_\theta, \quad \partial_\theta x = x\partial_\theta,$$
$$\partial_x \theta = \theta\partial_x - h(x\partial_x + \theta\partial_\theta), \quad \partial_\theta \theta = 1 - \theta\partial_\theta + hx\partial_\theta. \tag{53c}$$

The commutation relations of variables with their differentials are

$$x\mathrm{d}x = \mathrm{d}x x, \quad \theta\mathrm{d}\theta = \mathrm{d}\theta\theta - h(\mathrm{d}x\theta + \mathrm{d}\theta x),$$
$$x\mathrm{d}\theta = \mathrm{d}\theta x - h\mathrm{d}x x, \quad \theta\mathrm{d}x = -\mathrm{d}x\theta - h\mathrm{d}x x. \tag{54}$$

The commutation relations between derivatives and differentials are

$$\partial_x \mathrm{d}x = \mathrm{d}x\partial_x - h\mathrm{d}x\partial_\theta, \quad \partial_\theta \mathrm{d}\theta = \mathrm{d}\theta\partial_\theta + h\mathrm{d}x\partial_\theta,$$
$$\partial_x \mathrm{d}\theta = \mathrm{d}\theta\partial_x + h(\mathrm{d}x\partial_x + \mathrm{d}\theta\partial_\theta), \quad \partial_\theta \mathrm{d}x = -\mathrm{d}x\partial_\theta. \tag{55}$$

Note that the simple relations involving the differentials φ and y in (53) are not obtained using the R-matrix $\hat{K}_h$. Instead the $q \to 1$ limit of (16) has been used.

The exterior differential

$$\mathrm{d} = \varphi\partial_x + y\partial_\theta \tag{56}$$

satisfies the usual properties such that

$$\mathrm{d}x - x\mathrm{d} = \varphi, \quad \mathrm{d}\theta + \theta\mathrm{d} = y, \tag{57a}$$

as expected. The relations of the exterior differential d with ∂_x and ∂_θ are

$$\mathrm{d}\partial_x = \partial_x \mathrm{d}, \quad \mathrm{d}\partial_\theta = -\partial_\theta \mathrm{d} \tag{57b}$$

and those with differentials φ and y

$$\mathrm{d}\varphi = -\varphi\mathrm{d}, \quad \mathrm{d}y = y\mathrm{d}. \tag{57c}$$

Thus the basic requirement for the exterior derivative is quite consistent:

$$\begin{aligned} \mathrm{d}^2 &= \mathrm{d}(\varphi\partial_x + y\partial_\theta) \\ &= -\varphi\mathrm{d}\partial_x + y\mathrm{d}\partial_\theta \\ &= -(\varphi\partial_x + y\partial_\theta)\mathrm{d} = -\mathrm{d}^2 \end{aligned}$$

so that d^2 must vanish.

As we understand from the language of Wess–Zumino,[4] covariance here means that all the relations between coordinates x, θ, differentials $\mathrm{d}x$, $\mathrm{d}\theta$ and derivatives ∂_x, ∂_θ, etc., must preserve their form when one changes the coordinates by

$$x \to ax + \beta\theta,$$
$$\theta \to \gamma x + d\theta, \tag{58a}$$

where the matrix $T = (T^i_j)$ is an element of the quantum supergroup acting on the quantum superspace. Therefore we change the differentials by

$$\mathrm{d}x \to a\mathrm{d}x - \beta\mathrm{d}\theta,$$
$$\mathrm{d}\theta \to -\gamma\mathrm{d}x + d\mathrm{d}\theta. \tag{58b}$$

This is consistent since the exterior differential d anticommutes with the Grassmann variables as mentioned before. Covariance can be maintained if one defines the transformation law of the partial derivatives as follows:

$$\partial_x \to (a^{-1} - a^{-1}\gamma d^{-1}\beta a^{-1})\partial_x - a^{-1}\gamma d^{-1}\partial_\theta,$$
$$\partial_\theta \to (d^{-1} - d^{-1}\beta a^{-1}\gamma d^{-1})\partial_\theta + d^{-1}\beta a^{-1}\partial_x. \tag{58c}$$

Hence the differentials transform under the action of supertranspose of supertranspose of T, $(T^{st})^{st}$, whereas the derivatives transform under the inverse of the supertranspose of T, $(T^{st})^{-1}$.

III. A NEW DEFORMATION OF CLASSICAL PHASE SPACE

We now shall obtain a new deformation of the $(1+1)$-dimensional super-Heisenberg algebra (the classical phase space). We denote the algebra (53) generated by coordinates x,θ and the derivatives ∂_x and ∂_θ by $\mathscr{B}_h$. It is interesting to note that simply identifying ∂_x and ∂_θ with ip_x and p_θ is not compatible with the hermiticity of coordinates and momenta. In other words, the algebra $\mathscr{B}_h$ cannot be interpreted as a deformation of the $(1+1)$-dimensional super-Heisenberg algebra. In order to identify ∂_x and ∂_θ with the momenta ip_x and p_θ, one must take care of Hermiticity of coordinates and momenta. To this end, let us define the Hermitian conjugation of the coordinates x and θ, respectively, as

$$x^+ = x, \quad \theta^+ = \theta + 2hx. \tag{59}$$

It is then easy to see that the deformation parameter of the algebra (53) becomes a pure imaginary parameter:

$$\overline{h} = -h, \tag{60}$$

where the bar denotes complex conjugation. In this case, the Hermitian conjugation of the derivatives ∂_x and ∂_θ are

$$\partial_x^+ = -\partial_x + 2h\partial_\theta, \quad \partial_\theta^+ = \partial_\theta. \tag{61}$$

Note that the definitions (59) and (61) for the classical case are obtained in the $h \to 0$ limit.

The relations (53) are now invariant under definitions (59)–(61). The above involution allows us to define the Hermitian operators

$$\hat{x} = x, \quad \hat{\theta} = \theta + hx, \tag{62}$$

and

$$\hat{p}_x = i(\partial_x - h\partial_\theta), \quad \hat{p}_\theta = \partial_\theta. \tag{63}$$

The final form of the h-deformed super-Heisenberg algebra is

$$\hat{x}\hat{\theta} = \hat{\theta}\hat{x} + h\hat{x}^2, \quad \hat{\theta}^2 = -h\hat{\theta}\hat{x},$$
$$\hat{p}_x\hat{p}_\theta = \hat{p}_\theta\hat{p}_x, \quad \hat{p}_\theta^2 = 0,$$
$$\hat{p}_x\hat{x} = \hat{x}\hat{p}_x + i(1 + h\hat{x}\hat{p}_\theta), \quad \hat{p}_\theta\hat{x} = \hat{x}\hat{p}_\theta, \tag{64}$$
$$\hat{p}_x\hat{\theta} = \hat{\theta}\hat{p}_x - h(\hat{x}\hat{p}_x + i\hat{\theta}\hat{p}_\theta), \quad \hat{p}_\theta\hat{\theta} = 1 - \hat{\theta}\hat{p}_\theta + h\hat{x}\hat{p}_\theta.$$

IV. A COMMENT ON SUPER-OSCILLATORS

We know that introducing one ''bosonic'' and one ''fermionic'' oscillator, A and B, respectively, and making the usual identification

$$x' \leftrightarrow A^+, \quad \theta' \leftrightarrow B^+,$$
$$\partial_{x'} \leftrightarrow A, \quad \partial_{\theta'} \leftrightarrow B, \tag{65}$$

one constructs the quantum super-oscillator algebra which is covariant under the quantum supergroup $\mathrm{GL}_q(1|1)$. Under identification (25) and (2) give

$$x \leftrightarrow A^+, \quad \partial_x \leftrightarrow A + \frac{h}{q-1} B,$$
$$\partial_\theta \leftrightarrow B, \quad \theta \leftrightarrow B^+ - \frac{h}{q-1} A^+, \tag{66}$$

where q is a real number. Substituting (66) into (29) and using (17), surprisingly all h-dependence cancels and one obtains the usual q-deformed super-oscillator algebra[11]

$$AA^+ = 1 + q^2 A^+ A + (q^2 - 1) B^+ B,$$
$$BB^+ = 1 - B^+ B, \quad B^2 = 0 = B^{+2}, \tag{67}$$
$$AB^+ = q B^+ A, \quad AB = q^{-1} BA.$$

In the $q \to 1$ limit, we get undeformed super-oscillator algebra.

An interesting problem is the construction of a differential calculus on the (h_1, h_2)-superplane using the methods of this paper. A differential calculus on this superplane using the Wess–Zumino formulas has been given in Ref. 12.

Deforming maps for Lie group covariant creation and annihilation operators

Gaetano Fiore[a)]
Sektion Physik der Ludwig-Maximilians-Universität München, Theoretische Physik—Lehrstuhl Professor Wess, Theresienstrasse 37, 80333 München, Germany

(Received 21 April 1997; accepted for publication 1 December 1997)

Any deformation of a Weyl or Clifford algebra $\mathscr{A}$ can be realized through a ''deforming map,'' i.e., a formal change of generators in $\mathscr{A}$. This is true in particular if $\mathscr{A}$ is covariant under a Lie algebra $\mathbf{g}$ and its deformation is induced by some triangular deformation $U_h\mathbf{g}$ of the Hopf algebra $U\mathbf{g}$. We propose a systematic method to construct all the corresponding deforming maps, together with the corresponding realizations of the action of $U_h\mathbf{g}$. The method is then generalized and explicitly applied to the case that $U_h\mathbf{g}$ is the quantum group $\mathscr{U}_h\mathrm{sl}(2)$. A preliminary study of the status of deforming maps at the representation level shows in particular that ''deformed'' Fock representations induced by a compact $U_h\mathbf{g}$ can be interpreted as standard ''undeformed'' Fock representations describing particles with ordinary Bose or Fermi statistics. © *1998 American Institute of Physics.* [S0022-2488(98)02105-7]

I. INTRODUCTION

In recent years the idea of non-cocommutative Hopf algebras[1] (in particular quantum groups[2]) as candidates for generalized symmetry transformations in quantum physics has raised an increasing interest. One way to implement this idea in quantum field theory or condensed matter physics would be to deform the canonical commutation relations (CCR) of some system of mode creators/annihilators, covariant under the action of a Lie algebra $\mathbf{g}$, in such a way that they become covariant under the action of a non-cocommutative deformation $U_h\mathbf{g}$ (with deformation parameter h) of the cocommutative Hopf algebra $U\mathbf{g}$, as it has been done, e.g., in Refs. 3 and 4 for the $\mathscr{U}_h\mathrm{sl}(N)$ covariant Weyl algebra in N dimensions.

As a toy model for these deformations one can consider the deformed Weyl algebra $\mathscr{A}_h$ in one dimension[5] with generators fulfilling the ''quantum'' commutation relation (QCR)

$$\tilde{A}\tilde{A}^+ = \mathbf{1} + q^2\tilde{A}^+\tilde{A} \tag{I.1}$$

with $q=e^h$. When $q=1$ the above reduces to the classical Weyl algebra $\mathscr{A}$,

$$aa^+ = \mathbf{1} + a^+a. \tag{I.2}$$

If we define $n := a^+a$, $(x)_z=(z^x-1)/(z-1)$, and[6]

$$A := a\sqrt{\frac{(n)_{q^2}}{n}}, \quad A^+ := \sqrt{\frac{(n)_{q^2}}{n}}\,a^+, \tag{I.3}$$

we find out that A, A^+ fulfill the QCR (I.1); hence we can define an algebra homomorphism $f:\mathscr{A}_h \to \mathscr{A}[[h]]$, or ''deforming map'' (in the terminology of Refs. 7 and 8), starting from

$$f(\tilde{A}) = A, \quad f(\tilde{A}) = A^+. \tag{I.4}$$

The right-hand sides of (I.3) have to be understood as formal power series in the deformation parameter h.

 © 1998 American Institute of Physics

We are interested in deformed multidimensional Weyl or Clifford algebras A_h where the QCR:

(1) keep a quadratic structure as in Eq. (I.1), so that one can represent the generators as creation or annihilation operators; and
(2) are covariant under the action $\widetilde{\triangleright}_h$ of $U_h\mathbf{g}$.

More precisely, the generators $\tilde{A}_i^+$, $\tilde{A}^i$ should transform linearly under the action of $\widetilde{\triangleright}_h$,

$$x\widetilde{\triangleright}_h\tilde{A}_i^+=\tilde{\rho}\,^j_i(x)A_j^+, \tag{I.5}$$

$$x\widetilde{\triangleright}_h\tilde{A}^i=\tilde{\rho}^{\vee\,i}_j(x)A^j, \tag{I.6}$$

with $\tilde{\rho}^{\vee}$ being the contragradient representation of the representation $\tilde{\rho}$ of $U_h\mathbf{g}$ ($\tilde{\rho}^{\vee}=\tilde{\rho}^{T}\circ S_h$, where S_h is the antipode of $U_h\mathbf{g}$ and ^{T} is the operation of matrix transposition).

In this work we essentially stick to the case that $U_h\mathbf{g}$ is *triangular*; we treat the general quasitriangular case in Ref. 9. In the former case one can show easily that, for arbitrary $\tilde{\rho}$, $U_h\mathbf{g}$-covariant QCR are given by

$$\tilde{A}^i\tilde{A}_j=\pm R^{ij}_{vu}\tilde{A}^u\tilde{A}^v, \tag{I.7}$$

$$\tilde{A}_i^+\tilde{A}_j^+=\pm R^{vu}_{ij}\tilde{A}_u^+\tilde{A}_v^+, \tag{I.8}$$

$$\tilde{A}^i\tilde{A}_j^+=\delta^i_j\mathbf{1}_{\mathscr{A}}\pm R^{ui}_{jv}\tilde{A}_u^+\tilde{A}^v; \tag{I.9}$$

here the sign $\pm$ refers to the Weyl/Clifford case, respectively, and R is the corresponding ''R-matrix'' of $U_h\mathbf{g}$. [One just has to note that $R=(\tilde{\rho}\otimes\tilde{\rho})\mathscr{R}$, where $\mathscr{R}$ is the universal triangular structure of H_h, and that $\tau\circ\Delta_h(x)=\mathscr{R}\Delta_h(x)\mathscr{R}^{-1}$ (τ denotes the flip operator).]

Here $\mathscr{A}_h$ is a left-module algebra of $U_h\mathbf{g}$: the ''quantum'' action $\widetilde{\triangleright}_h$ is extended to products of the generators as a left-module algebra map $\widetilde{\triangleright}_h: U_h\times\mathscr{A}_h\to\mathscr{A}_h$ (i.e., consistently with the QCR) using the coproduct $\Delta_h(x)=\Sigma_\mu\, x^\mu_{(1)}\otimes x^\mu_{(2)}$ of $U_h\mathbf{g}$,

$$x\widetilde{\triangleright}_h(a\cdot b)=\sum_\mu\,(x^\mu_{(1)}\widetilde{\triangleright}_h a)\cdot(x^\mu_{(2)}\widetilde{\triangleright}_h b), \tag{I.10}$$

because the (I.8) are covariant under (i.e., compatible with) $\widetilde{\triangleright}_h$.

The existence of deforming maps for arbitrary (i.e., not necessarily of the kind described above) deformations of Weyl (or Clifford) algebras is a consequence[10] of a theorem[11] asserting the triviality of the cohomology groups of the latter. (See Refs. 12 and 9 for effective and concise presentations of these results. See also Ref. 13, where the problem of stability of quantum mechanics under deformations was addressed for the first time.) However, no general method for their explicit construction is available. Actually, using cohomological arguments, one can also easily show that deforming maps are unique up to an inner automorphism,

$$f\to f_\alpha:=\alpha f(\cdot)\alpha^{-1},\quad \alpha=\mathbf{1}_{\mathscr{A}}+O(h); \tag{I.11}$$

therefore it is enough to construct one to find all of them.

In this work we present a general method which allows us, given a triangular Hopf algebra $U_h\mathbf{g}$ and any $U_h\mathbf{g}$-covariant deformed Weyl or Clifford algebra, to explicitly construct the corresponding deforming maps f and the corresponding realizations $\triangleright_h$ of $\widetilde{\triangleright}_h$ [$\triangleright_h$ is defined by $\triangleright_h:=(\mathrm{id}\otimes f)\circ\widetilde{\triangleright}_h\circ(\mathrm{id}\otimes f^{-1})$]. In a first attempt to generalize our construction procedure to *quasitriangular* $U_h\mathbf{g}$, we also generalize the construction to the case that $U_h\mathbf{g}$ is the quantum group $\mathscr{U}_h\mathrm{sl}(2)$ and $\tilde{\rho}$ is its fundamental representation. Finally we investigate on the status of deforming maps at the representation-theoretic level.

The construction method is based (Sec. II A) on use of the Drinfel'd–Reshetikhin twist $\mathscr{F}$,[14,15] intertwining between the coproducts of $U\mathbf{g}$ and $U_h\mathbf{g}$, and on the fact that within $\mathscr{A}[[h]]$ one can

realize both the action $\triangleright$ of $U_h\mathbf{g}$ (Sec. II A) and the action $\triangleright_h$ in an ''adjointlike'' way. We show first (Sec. III) that $\mathscr{F}$ can be used in a *universal* way to construct, within $\mathscr{A}_h$, $U_h\mathbf{g}$-tensors out of $U\mathbf{g}$-tensors, and in particular out of a_i^+, a^i objects A_i^+, A^i that transform under $\triangleright_h$ as in formula (I.6). Then (Sec. IV) we verify that the objects A_i^+, A^j really satisfy the QCR (I.8). In Sec. V we generalize our construction (by means of the Drinfel'd twist[16]) to the case of deformed Weyl and Clifford algebras with generators belonging to the fundamental representation of the quantum group $\mathscr{U}_h\mathrm{sl}(2)$; the deforming map is again completely explicit thanks to the semiuniversal expression[8] for $\mathscr{F}$. We compare our deforming map with the one previously found in Ref. 17. At the representation-theoretic level it would be natural to interpret deforming maps as ''operator maps,'' in other words as intertwiners between the representations of $\mathscr{A}$ and $\mathscr{A}_h$. However, we have to expect that, in the role of intertwiners, deforming maps may become singular at $h=0$, because the representation theories of $\mathscr{A}$, $\mathscr{A}_h$ are in general rather different. In Sec. VI we show that there is always a $*$-representation of $\mathscr{A}_h$ which is intertwined by f with the Fock representation of $\mathscr{A}$; this allows us to interpret $\tilde{A}^i, \tilde{A}_i^+$ as ''composite'' operators on a classical Fock space describing ordinary bosons and fermions. We also explicitly show that f^{-1} is ill defined as an intertwiner from the remaining (if any) unitarily inequivalent $*$-representations of $\mathscr{A}_h$.

On the basis of the above result we conclude that also at the quantization-of-field level noncommutative Hopf algebra symmetries are not necessarily incompatible with Bose or Fermi statistics (contrary to what is often claimed). We arrived at the same conclusion at the first-quantization level in Refs. 18 and 19, where the initial motivation for the present work originated. The connection between the two approaches through second quantization will be described elsewhere.

II. PRELIMINARIES AND NOTATION

A. Twisting groups into quantum groups

Let $H=(U\mathbf{g}, m, \Delta, \varepsilon, S)$ be the cocommutative Hopf algebra associated to the universal enveloping (UE) algebra $U\mathbf{g}$ of a Lie algebra $\mathbf{g}$. The symbol m denotes the multiplication [in the sequel it will be dropped in the obvious way $m(a\otimes b)\equiv ab$, unless explicitly required], whereas Δ, ε, and S are the comultiplication, counit, and antipode, respectively.

Let $\mathscr{F}\in U\mathbf{g}[[h]]\otimes U\mathbf{g}[[h]]$ (we will write $\mathscr{F}=\mathscr{F}^{(1)}\otimes\mathscr{F}^{(2)}$, in a Sweedler's notation with *upper* indices; on the rhs a sum $\Sigma_i \mathscr{F}_i^{(1)}\otimes\mathscr{F}_i^{(2)}$ of many terms is implicitly understood) be a ''twist,'' i.e., an element satisfying the relations

$$(\varepsilon\otimes\mathrm{id})\mathscr{F}=\mathbf{1}=(\mathrm{id}\otimes\varepsilon)\mathscr{F}, \tag{II.1}$$

$$\mathscr{F}=\mathbf{1}\otimes\mathbf{1}+O(h) \tag{II.2}$$

($h\in\mathbf{C}$ is the ''deformation parameter,'' and $\mathbf{1}$ the unit in $U\mathbf{g}$; from the second condition it follows that $\mathscr{F}$ is invertible as a power series). It is well known[14] that if $\mathscr{F}$ also satisfies the relation

$$(\mathscr{F}\otimes\mathbf{1})[(\Delta\otimes\mathrm{id})(\mathscr{F})]=(\mathbf{1}\otimes\mathscr{F})[(\mathrm{id}\otimes\Delta)(\mathscr{F})], \tag{II.3}$$

and $(U_h\mathbf{g}, m_h)$ is an algebra isomorphic to $U\mathbf{g}[[h]]$ with isomorphism, say, $\varphi_h: U_h\mathbf{g}\to U\mathbf{g}[[h]]$ (in particular, if $U_h\mathbf{g}=U\mathbf{g}[[h]]$ and $\varphi_h=\mathrm{id}\ (\mathrm{mod}\ h)$, or even $\varphi_h=\mathrm{id}$), then one can construct a triangular non-cocommutative Hopf algebra $H_h=(U_h\mathbf{g}, m_h, \Delta_h, \varepsilon_h, S_h, \mathscr{R})$ having an isomorphic algebra structure $[m_h=\varphi_h^{-1}\circ m\circ(\varphi_h\otimes\varphi_h)]$, an isomorphic counit $\varepsilon_h:=\varepsilon\circ\varphi_h^{-1}$, comultiplication and antipode defined by

$$\Delta_h(a)=(\varphi_h^{-1}\otimes\varphi_h^{-1})\{\mathscr{F}\Delta[\varphi_h(a)]\mathscr{F}^{-1}\},\quad S_h(a)=\varphi_h^{-1}\{\gamma^{-1}S[\varphi_h(a)]\gamma\}, \tag{II.4}$$

where

$$\gamma:=S\mathscr{F}^{-1(1)}\cdot\mathscr{F}^{-1(2)},\quad \gamma^{-1}=\mathscr{F}^{(1)}\cdot S\mathscr{F}^{(2)}, \tag{II.5}$$

and (triangular) universal R-matrix

$$\mathscr{R}:=[\varphi_h^{-1}\otimes\varphi_h^{-1}](\mathscr{F}_{21}\mathscr{F}^{-1}),\quad \mathscr{F}_{21}:=\mathscr{F}^{(2)}\otimes\mathscr{F}^{(1)}. \tag{II.6}$$

Condition (II.3) ensures that Δ_h is coassociative as Δ. The inverse of S_h is given by $S_h^{-1}(a) = \varphi_h^{-1}\{\gamma' S[\varphi_h(a)]\gamma'^{-1}\}$, where

$$\gamma' := \mathscr{F}^{(2)} \cdot S\mathscr{F}^{(1)}, \quad \gamma'^{-1} = S\mathscr{F}^{-1(2)} \cdot \mathscr{F}^{-1(1)}; \tag{II.7}$$

$\gamma^{-1}\gamma' \in \mathrm{Centre}(U\mathbf{g})$, and $S\gamma = \gamma'^{-1}$.

Conversely, given an h-deformation $H_h = (U_h\mathbf{g}, m_h, \Delta_h, \varepsilon_h, S_h, \mathscr{R})$ of H in the form of a triangular Hopf algebra, one can find[14] an isomorphism $\varphi_h : U_h \to U\mathbf{g}[[h]]$ and an invertible $\mathscr{F}$ satisfying conditions (II.1)–(II.3) such that H_h can be obtained from H through formulas (II.4), (II.5), and (II.7).

Examples of $\mathscr{F}$'s satisfying conditions (II.3), (II.1), and (II.2) are provided, e.g., by the so-called ''Reshetikhin twists'' [15]

$$\mathscr{F} := e^{h\omega_{ij} h_i \otimes h_j}, \tag{II.8}$$

where $\{h_i\}$ is a basis of the Cartan subalgebra of $\mathbf{g}$ and $\omega_{ij} = -\omega_{ji} \in \mathbf{C}$. A less obvious example is, for instance, the ''Jordanian'' deformation of Ref. 20.

A similar result to the above holds for genuine quantum groups. A well-known theorem by Drinfel'd, Proposition 3.16 in Ref. 16, proves, for any quasitriangular deformation $H_h = (U_h\mathbf{g}, m_h, \Delta_h, \varepsilon_h, S_h, \mathscr{R})$[2,21] of $U\mathbf{g}$, with $\mathbf{g}$ a simple finite-dimensional Lie algebra, the existence of an algebra isomorphism $\varphi_h : U_h\mathbf{g} \to U\mathbf{g}[[h]]$ and an invertible $\mathscr{F}$ satisfying condition (II.1) such that H_h can be obtained from H through formulas (II.4), (II.5), and (II.7), as well. This $\mathscr{F}$ does not satisfy condition (II.18); however, the (nontrivial) coassociator

$$\phi := [(\Delta \otimes \mathrm{id})(\mathscr{F}^{-1})](\mathscr{F}^{-1} \otimes \mathbf{1})(\mathbf{1} \otimes \mathscr{F})[(\mathrm{id} \otimes \Delta)(\mathscr{F})] \tag{II.9}$$

still commutes with $\Delta^{(2)}(U\mathbf{g})$,

$$[\phi, \Delta^{(2)}(U\mathbf{g})] = 0, \tag{II.10}$$

thus explaining why Δ_h is coassociative in this case, too. The corresponding universal (quasitriangular) R-matrix $\mathscr{R}$ is related to $\mathscr{F}$ by

$$\mathscr{R} = [\varphi_h^{-1} \otimes \varphi_h^{-1}](\mathscr{F}_{21} q^{t/2} \mathscr{F}^{-1}), \tag{II.11}$$

where $t := \Delta(\mathscr{C}) - \mathbf{1} \otimes \mathscr{C} - \mathscr{C} \otimes \mathbf{1}$ is the canonical invariant element in $U\mathbf{g} \otimes U\mathbf{g}$ ($\mathscr{C}$ is the quadratic Casimir). The twist $\mathscr{F}$ is defined (and unique) up to the transformation

$$\mathscr{F} \to \mathscr{F} T, \tag{II.12}$$

where T is a $\mathbf{g}$-invariant [i.e., commuting with $\Delta(U\mathbf{g})$] element of $U\mathbf{g}[[h]]^{\otimes^2}$ such that

$$T = \mathbf{1} \otimes \mathbf{1} + O(h), \quad (\varepsilon \otimes \mathrm{id})T = \mathbf{1} = (\mathrm{id} \otimes \varepsilon)T. \tag{II.13}$$

A function

$$T = T(\mathbf{1} \otimes \mathscr{C}_i, \mathscr{C}_i \otimes \mathbf{1}, \Delta(\mathscr{C}_i)) \tag{II.14}$$

of the Casimirs $\mathscr{C}_i \in U\mathbf{g}$ of $U\mathbf{g}$ and of their coproducts clearly is $\mathbf{g}$ invariant.

In general, as a consequence of the existence of an isomorphism φ_h, representations $\tilde{\rho}$, ρ of deformed and undeformed algebras are in one-to-one correspondence (except for special values of h making it singular) through

$$\rho = \tilde{\rho} \circ \varphi_h. \tag{II.15}$$

A special case of interest is when $U\mathbf{g}$ is a $*$-Hopf algebra and $\mathscr{F}$ is unitary,

$$\mathscr{F}^{*\otimes *} = \mathscr{F}^{-1}; \tag{II.16}$$

note that in this case

$$\gamma' = \gamma^*. \tag{II.17}$$

One can show[22] that $\mathscr{F}$ can always be made unitary if $\mathbf{g}$ is compact.

We will often use a ''tensor notation'' for our formulas: Eq. (II.3) will read

$$\mathscr{F}_{12}\mathscr{F}_{12,3} = \mathscr{F}_{23}\mathscr{F}_{1,23}, \tag{II.18}$$

and definition (II.9) will read $\phi \equiv \phi_{123} = \mathscr{F}_{12,3}^{-1}\mathscr{F}_{12}^{-1}\mathscr{F}_{23}\mathscr{F}_{1,23}$, for instance; the comma separates the tensor factors *not* stemming from the coproduct. For practical purposes it will be often convenient in the sequel to use the Sweedler's notation with *lower* indices $\Delta(x) \equiv x_{(1)} \otimes x_{(2)}$ for the cocommutative coproduct (on the rhs a sum $\Sigma_i x^i_{(1)} \otimes x^i_{(2)}$ of many terms is implicitly understood); similarly, we will use the Sweedler's notation $\Delta^{(n-1)}(x) \equiv x_{(1)} \otimes \cdots \otimes x_{(n)}$ for the $(n-1)$-fold coproduct. For the non-cocommutative coproducts Δ_h, instead, we will use a Sweedler's notation with barred indices: $\Delta_h(x) \equiv x_{(\bar{1})} \otimes x_{(\bar{2})}$.

B. Classical *U*g-covariant creators and annihilators

Let $\mathscr{A}$ be the unital algebra generated by $\mathbf{1}_{\mathscr{A}}$ and elements $\{a_i^+\}_{i \in I}$ and $\{a^j\}_{j \in I}$ satisfying the (anti)commutation relations

$$[a^i,\ a^j]_\pm = 0, \quad [a_i^+,\ a_j^+]_\pm = 0, \tag{II.19}$$

$$[a^i,\ a_j^+]_\pm = \delta^i_j \mathbf{1}_{\mathscr{A}}$$

(the $\pm$ sign denotes commutators and anticommutators, respectively), belonging respectively to some representation ρ and to its contragradient $\rho^\vee = \rho^T \circ S$ of H (^{T} is the transpose):

$$\begin{aligned} x \triangleright a_i^+ &= \rho(x)^l_i a_l^+, \\ x \triangleright a^i &= \rho(Sx)^i_l a^l, \end{aligned} \quad x \in U\mathbf{g}, \quad \rho(x)^i_j \in \mathbf{C}. \tag{II.20}$$

Equivalently, one says that a_i^+, a^i are ''covariant'' under $\triangleright$, or that they span two (left) modules of $U\mathbf{g}$:

$$(xy) \triangleright a = x \triangleright (y \triangleright a), \quad x,y \in U\mathbf{g}, \tag{II.21}$$

with either $a = a^i$ or a_i^+.

Here $\mathscr{A}$ is a (left) module algebra of $(H, \triangleright)$, if the action $\triangleright$ is extended on the whole $\mathscr{A}$ by means of the (cocommutative) coproduct

$$x \triangleright (ab) = (x_{(1)} \triangleright a)(x_{(2)} \triangleright b). \tag{II.22}$$

Then property (II.21) holds for all $a \in \mathscr{A}$.

Setting

$$\sigma(X) := \rho(X)^i_j a_i^+ a^j \tag{II.23}$$

for all $X \in \mathbf{g}$, one finds that σ: $\mathbf{g} \to \mathscr{A}$ is a Lie algebra homomorphism, so that σ can be extended to all of $U\mathbf{g}$ as an algebra homomorphism σ: $U\mathbf{g} \to \mathscr{A}$; on the unit element we set $\sigma(\mathbf{1}_{U\mathbf{g}}) := \mathbf{1}_{\mathscr{A}}$. σ can be seen as the generalization of the Jordan–Schwinger realization of $\mathbf{g} = \mathrm{su}(2)$ [formula (V.8)].[23]

Then it is easy to check the following.

Proposition 1: The (left) action $\triangleright: U\mathbf{g} \times \mathscr{A} \to \mathscr{A}$ can be realized in an ''adjointlike'' way:

$$x \triangleright a = \sigma(x_{(1)}) a \sigma(Sx_{(2)}), \quad x \in U\mathbf{g}, \quad a \in \mathscr{A}. \tag{II.24}$$

In the specially interesting case of a compact section $\mathbf{g}$ (with $*$-structure ''$*$'') one can introduce in $\mathscr{A}$ a $*$-structure, the ''Hermitian conjugation'' (which we will denote by $\star$), such that

$$(a^i)^\star = a_i^+. \tag{II.25}$$

Correspondingly, ρ is a $*$-representation ($\rho\circ\star=*\circ\rho^T$) and σ becomes a $*$-homomorphism, i.e., $\sigma\circ *=\star\circ\sigma$.

III. QUANTUM COVARIANT CREATORS AND ANNIHILATORS

Let H_h and φ_h be as in Sec. II A. Clearly, $\sigma_{\varphi_h}:=\sigma\circ\varphi_h$ is an algebra homomorphism σ_{φ_h}: $U_h\mathbf{g}\to\mathscr{A}[[h]]$. Inspired by Proposition 3 we are led to define

$$x\triangleright_h a := \sigma_{\varphi_h}(x_{(\bar{1})})\,a\,\sigma_{\varphi_h}(S_h x_{(\bar{2})}). \tag{III.1}$$

Using the Hopf algebra axioms it is straightforward to prove the relations [cf. relations (I.10)]

$$\begin{aligned}&(xy)\triangleright_h a = x\triangleright_h(y\triangleright_h a),\\ &x\triangleright_h(ab)=(x_{(\bar{1})}\triangleright_h a)(x_{(\bar{2})}\triangleright_h b),\end{aligned}\qquad \forall x,y\in U\mathbf{g}[[h]],\quad \forall a,b\in\mathscr{A}[[h]]. \tag{III.2}$$

In other words, we have the following.

Proposition 2. The definition (III.1) realizes $\triangleright_h$ *(the left action of* H_h*) on the algebra* $\mathscr{A}[[h]]$.

However, a_i^+, a^j are *not* covariant w.r.t. to $\triangleright_h$. One may ask whether there exist some objects A_i^+, $A^j\in\mathscr{A}$ that *are* covariant under $\triangleright_h$ and transform as in Eq. (I.8).

The answer comes from the following crucial proposition.

Proposition 3: The elements

$$A_i^+ := \sigma(\mathscr{F}^{(1)})\,a_i^+\,\sigma(S\mathscr{F}^{(2)}\gamma)\in\mathscr{A}[[h]], \tag{III.3}$$

$$A^i := \sigma(\gamma' S\mathscr{F}^{-1(2)})\,a^i\,\sigma(\mathscr{F}^{-1(1)})\in\mathscr{A}[[h]] \tag{III.4}$$

are "covariant" under $\triangleright_h$*, more precisely belong respectively to the representation* $\tilde{\rho}$ *and to its quantum contragredient* $\tilde{\rho}^\vee=\tilde{\rho}^T\circ S_h$ *of* $U_h\mathbf{g}$ *acting through* $\triangleright_h$:

$$x\triangleright_h A_i^+=\tilde{\rho}(x)_i^l A_l^+,\quad x\triangleright_h A^i=\tilde{\rho}(S_h x)_m^i A^m. \tag{III.5}$$

Proof: Due to relation (II.4), $\mathscr{F}$ is an intertwiner between Δ_h and Δ (in this proof we drop the symbol φ_h):

$$x_{(\bar{1}')}\mathscr{F}^{(1)}\otimes x_{(\bar{2}')}\mathscr{F}^{(2)}=\mathscr{F}^{(1)}x_{(1')}\otimes\mathscr{F}^{(2)}x_{(2')}. \tag{III.6}$$

Applying $\mathrm{id}\otimes S$ on both sides of the equation and multiplying the result by $\mathbf{1}\otimes\gamma$ from the right we find [with the help of relation (II.5)]

$$x_{(\bar{1}')}\mathscr{F}^{(1)}\otimes(S\mathscr{F}^{(2)})\,\gamma S_h x_{(\bar{2}')}=\mathscr{F}^{(1)}x_{(1')}\otimes(Sx_{(2')})(S\mathscr{F}^{(2)})\,\gamma. \tag{III.7}$$

Applying $\sigma\otimes\sigma$ to both sides and sandwiching a_i^+ between the two tensor factors we find

$$\sigma(x_{(\bar{1}')})A_i^+\,\sigma(S_h x_{(\bar{2}')})=\sigma(\mathscr{F}^{(1)})\,\sigma(x_{(1')})\,a_i^+\,\sigma(Sx_{(2')})\,\sigma[(S\mathscr{F}^{(2)})\,\gamma], \tag{III.8}$$

which, in view of formula (III.1), proves the first relation.

To prove the second relation, let us note that relation (II.4) implies an analogous relation

$$\Delta_h(a)\tilde{\mathscr{F}}=\tilde{\mathscr{F}}\Delta(a),\quad \text{with } \tilde{\mathscr{F}}:=[\gamma' S\mathscr{F}^{-1\ (2)}\otimes\gamma' S\mathscr{F}^{-1\ (1)}]\Delta(S\gamma). \tag{III.9}$$

This can be shown by applying in order the following operations to both sides of Eq. (II.4): multiplying by $\mathscr{F}^{-1}$ from the left and from the right, applying $S\otimes S$, multiplying by $\gamma'\otimes\gamma'$ from the left and by $\Delta(S\gamma)$ from the right, replacing $a\to S_h x$, and using the properties (II.4) and $(S_h\otimes S_h)\circ\Delta_h=\tau\circ\Delta_h\circ S_h$. Next, we observe that A^i can be rewritten as

$$A^i=\sigma[\tilde{\mathscr{F}}^{(1)}S(\gamma^{-1})_{(1)}]\,a^i\,\sigma[(\gamma^{-1})_{(2)}S\tilde{\mathscr{F}}^{(2)}\gamma]=\sigma(\tilde{\mathscr{F}}^{(1)})\,a^l\,\sigma(S\tilde{\mathscr{F}}^{(2)}\gamma)\,\rho(\gamma^{-1})_l^i; \tag{III.10}$$

where, reasoning as for the first relation,

$$\sigma(x_{(1')})A^i\sigma(S_h x_{(2')}) \overset{(III.10)}{=} \sigma(\tilde{\mathscr{F}}^{(1)})\sigma(x_{(1')})a^l\sigma(Sx_{(2')})\sigma[(S.\tilde{\mathscr{F}}^{(2)})\gamma]\rho(\gamma^{-1})^i_l$$

$$\overset{(II.24)}{=} \sigma(\tilde{\mathscr{F}}^{(1)})a^l\sigma[(S.\tilde{\mathscr{F}}^{(2)})\gamma]\rho(\gamma^{-1}Sx)^i_l$$

$$\overset{(II.4)}{=} \sigma(\tilde{\mathscr{F}}^{(1)})a^l\sigma[(S.\tilde{\mathscr{F}}^{(2)})\gamma]\rho(S_h x\cdot\gamma^{-1})^i_l$$

$$\overset{(III.10)}{=} \rho(S_h x)^i_l A^l,$$

which proves the second relation. □

Remark 1: The proposition clearly holds even if one chooses in formulas (III.3) and (III.4) two $\mathscr{F}$'s differing by a tranformation (II.12). We shall exploit this freedom when $U_h\mathbf{g}$ is genuinely quasitriangular.

Remark 2: Note that in the $*$-Hopf algebra case Eqs. (II.25), (II.16), and (II.17) imply

$$(A^i)^\star = A^+_i . \tag{III.11}$$

Remark 3: Under the right action $\triangleleft_h$ ($a\triangleleft_h x := (S_h^{-1}x)\triangleright_h a$ with $a\in\mathscr{A}$, $x\in U\mathbf{g}$) the covariance properties of A^i, A^+_i read

$$A^i\triangleleft_h x = \rho(x)^i_l A^l, \quad A^+_i\triangleleft_h x = \rho(S_h^{-1}x)^m_i A^+_m . \tag{III.12}$$

Remark 4: σ_{φ_h} is not the only algebra homomorphism $U_h\mathbf{g}\to\mathscr{A}[[h]]$. For any $\alpha = \mathbf{1}_{\mathscr{A}} + O(h)$ we find a new one by setting

$$\sigma_{\varphi_h,\alpha}(x) = \alpha\sigma_{\varphi_h}(x)\alpha^{-1}; \tag{III.13}$$

correspondingly, we can define a new realization of $\tilde{\triangleright}_h$ by

$$x\triangleright_{h,\alpha} a := \sigma_{\varphi_h,\alpha}(x_{(1)})a\sigma_{\varphi_h,\alpha}(S_h x_{(2)}). \tag{III.14}$$

Covariant objects under $\triangleright_{h\alpha}$ will be given by

$$A^+_{i,\alpha} := \alpha A^+_i\alpha^{-1}, \quad A^{i,\alpha} := \alpha A^i\alpha^{-1}. \tag{III.15}$$

If relations (III.11) hold, we can preserve them by choosing $\alpha^\star = \alpha^{-1}$.

To conclude this section, let us give useful alternative expressions for A^+_i, A^i by ''moving'' to the right/left past a^+_i, a^i the expressions $\sigma(\cdot)$ lying at their left/right in definitions (III.3) and (III.4).

Lemma 1: If $\mathscr{T}\in U\mathbf{g}[[h]]^{\otimes^3}$ *is* $\mathbf{g}$ *invariant* (*i.e.*, $[\mathscr{T}, U\mathbf{g}[[h]]^{\otimes^3}]=0$), *then* $m_{ij}S_i.\mathscr{T}$, $m_{ij}S_j.\mathscr{T}$ ($i,j=1,2,3$, $i\neq j$) *are* $\mathbf{g}$ *invariants belonging to* $U\mathbf{g}[[h]]^{\otimes^2}$.

(Here S_i denotes S acting on the ith tensor factor, and m_{ij} multiplication of the ith tensor factor by the jth from the right.)

Proof: For instance,

$$\mathscr{T}^{(1)}x_{(1)}\otimes.\mathscr{T}^{(2)}x_{(2)}\otimes.\mathscr{T}^{(3)}x_{(3)}\otimes x_{(4)} = x_{(1)}.\mathscr{T}^{(1)}\otimes x_{(2)}.\mathscr{T}^{(2)}\otimes x_{(3)}.\mathscr{T}^{(3)}\otimes x_{(4)}$$

$$\Downarrow (m_{23})^2\circ S_3$$

$$\mathscr{T}^{(1)}x_{(1)}\otimes.\mathscr{T}^{(2)}x_{(2)}Sx_{(3)}S.\mathscr{T}^{(3)}x_{(4)} = x_{(1)}.\mathscr{T}^{(1)}\otimes x_{(2)}.\mathscr{T}^{(2)}S.\mathscr{T}^{(3)}Sx_{(3)}x_{(4)}$$

for any $x\in U\mathbf{g}[[h]]$, whence (because of $a_{(1)}Sa_{(2)} = \varepsilon(a) = Sa_{(1)}a_{(2)}$)

$$\mathscr{T}^{(1)}x_{(1)}\otimes.\mathscr{T}^{(2)}S.\mathscr{T}^{(3)}x_{(2)} = x_{(1)}.\mathscr{T}^{(1)}\otimes x_{(2)}.\mathscr{T}^{(2)}S.\mathscr{T}^{(3)}, \tag{III.16}$$

so that $.\mathscr{T}^{(1)}\otimes.\mathscr{T}^{(2)}S.\mathscr{T}^{(3)}\in U\mathbf{g}[[h]]^{\otimes^2}$ is $\mathbf{g}$ invariant. □

Proposition 4: If H_h is triangular, the definitions (III.3) and (III.4) amount to

$$A_i^+=a_l^+\sigma(.\mathscr{T}^{-1(2)})\rho(.\mathscr{T}^{-1(1)})_i^l, \tag{III.17a}$$

$$A_i^+=\rho(S.\mathscr{T}^{(1)}\gamma'^{-1})_i^l\sigma(.\mathscr{T}^{(2)})a_l^+, \tag{III.17b}$$

$$A^{\ i}=\rho(.\mathscr{T}^{(1)})_l^i\sigma(.\mathscr{T}^{(2)})a^l, \tag{III.17c}$$

$$A^i=a^l\sigma(.\mathscr{T}^{-1(2)})\rho(\gamma^{-1}S.\mathscr{T}^{-1(1)})_l^i. \tag{III.17d}$$

If H_h is quasitriangular, the same formulas hold with in general four different $\mathscr{T}$'s [related to each other by transformations (II.12)].

Proof: Observing that

$$\sigma(x)a=\sigma(x_{(1)})a\,\sigma(Sx_{(2)}\cdot x_{(3)}), \tag{III.18}$$

$$a\,\sigma(x)=\sigma(x_{(3)}Sx_{(2)})a\,\sigma(x_{(1)}), \tag{III.19}$$

for all $x\in U\mathbf{g}$, $a\in\mathscr{A}$, we find from relations (III.3), (III.4), and (II.20)

$$A_i^+=a_l^+\sigma(.\mathscr{T}^{(1)}_{(2)}S.\mathscr{T}^{(2)}\gamma)\rho(.\mathscr{T}^{(1)}_{(1)})_i^l, \tag{III.20}$$

$$A^i=\sigma(\gamma'S.\mathscr{T}^{-1(2)}\cdot.\mathscr{T}^{-1(1)}_{(2)})\rho(.\mathscr{T}^{-1(1)}_{(1)})_l^iA^l. \tag{III.21}$$

On the other hand, applying the previous lemma to $.\mathscr{T}=\phi$ [formula (II.9)] we find that

$$T:=m_{23}(\mathrm{id}\otimes\mathrm{id}\otimes S)\phi\overset{(II.5)}{=}(.\mathscr{T}^{-1(1)}_{(1)}\otimes.\mathscr{T}^{-1(1)}_{(2)}).\mathscr{T}^{-1}(\mathbf{1}\otimes\gamma^{-1}S.\mathscr{T}^{-1(2)})$$

is $\mathbf{g}$ invariant, where one easily finds the relation

$$.\mathscr{T}^{(1)}_{(1)}\otimes.\mathscr{T}^{(1)}_{(2)}S(.\mathscr{T}^{(2)})\gamma=T^{-1}.\mathscr{T}^{-1}\equiv.\mathscr{T}'^{-1}, \tag{III.22}$$

after noting that $[T,.\mathscr{T}^{\pm1(1)}_{(1)}\otimes.\mathscr{T}^{\pm1(1)}_{(2)}]=0$. Replacing in Eq. (III.20) one finds relation (III.17a). In the triangular case $\phi\equiv\mathbf{1}^{\otimes^3}$, implying $T\equiv\mathbf{1}^{\otimes^2}$ and $\mathscr{T}'=\mathscr{T}$. Similarly one proves the other relations. Relations (III.17c) and (III.17d), can be found also more directly starting from relations (III.17a) and (III.17b) by observing that in the unitary-$\mathscr{T}$ case they follow from the latter two by applying the $*$-conjugation. □

IV. QUANTUM COMMUTATION RELATIONS: THE TRIANGULAR CASE

Theorem 1: *If the non-cocommutative Hopf algebra H_h is triangular [i.e., the twist $\mathscr{T}$ satisfies Eq. (II.1)], then A^i,A_j^+ close the quadratic commutation relations*

$$A^iA_j^+=\delta_j^i\mathbf{1}_{\mathscr{A}}\pm R_{jv}^{ui}A_u^+A^v, \tag{IV.1}$$

$$A^iA^j=\pm R_{vu}^{ij}A^uA^v, \tag{IV.2}$$

$$A_i^+A_j^+=\pm R_{ij}^{vu}A_u^+A_v^+, \tag{IV.3}$$

where R is the (numerical) quantum R-matrix of $U\mathbf{g}$ in the representation ρ,

$$R_{hk}^{ij}:=[(\rho\otimes\rho)(.\mathscr{R})]_{hk}^{ij}. \tag{IV.4}$$

Proof: Beside Eqs. (III.17), we will need their ''inverse'' relations:

$$a_l^+=A_i^+\sigma(.\mathscr{T}^{(2)})\rho(.\mathscr{T}^{(1)})_l^i,$$

$$a_l^+ = \rho(\gamma S.\mathscr{F}^{-1(1)})_l^i \sigma(.\mathscr{F}^{-1(2)}) A_i^+ ,$$
$$a^l = \rho(.\mathscr{F}^{-1(1)})_i^l \sigma(.\mathscr{F}^{-1(2)}) A^i,$$
$$a^l = A^i \sigma(.\mathscr{F}^{(2)}) \rho(S.\mathscr{F}^{(1)} \cdot \gamma)_i^l . \tag{IV.5}$$

Using Eqs. (III.17),

$$A^i A_j^+ \overset{(III.17)}{=} \rho(.\mathscr{F}^{(1)})_l^i \sigma(.\mathscr{F}^{(2)}) a^l a_m^+ \sigma(.\mathscr{F}^{-1(2')}) \rho(.\mathscr{F}^{-1(1')})_j^m$$

$$\overset{(II.19)}{=} \rho(.\mathscr{F}^{(1)})_l^i \sigma(.\mathscr{F}^{(2)}) [\delta_m^l \pm a_m^+ a^l] \sigma(.\mathscr{F}^{-1(2')}) \rho(.\mathscr{F}^{-1(1')})_j^m$$

$$\overset{(III.19)(II.20)}{=} (\rho_j^i \otimes \sigma)[.\mathscr{F}\mathscr{F}^{-1}] \pm \rho(.\mathscr{F}^{(1)}_{(1')} \mathscr{F}^{-1(2')})_l^i a_m^+ \sigma(.\mathscr{F}^{(2)}_{(2)} \mathscr{F}^{-1(2')}_{(2')}) a^l \rho(.\mathscr{F}^{(2)}_{(1)} \mathscr{F}^{-1(1')})_j^m$$

$$\overset{(IV.5)}{=} \delta_j^i \mathbf{1}_{\mathscr{A}} \pm \rho(G^{(1)})_j^m A_m^+ \sigma(G^{(2)}) A^l \rho(G^{(3)})_l^i , \tag{IV.6}$$

where $G := .\mathscr{F}_{12}.\mathscr{F}_{23,1}.\mathscr{F}^{-1}_{1,23}.\mathscr{F}^{-1}_{32}$. On the other hand, applying to Eq. (II.18) the permutations $\tau_{23} \circ \tau_{12}$ and τ_{23} we obtain, respectively,

$$.\mathscr{F}_{12}.\mathscr{F}_{23,1} = .\mathscr{F}_{31}(.\mathscr{F}^{(1)}_{(1)} \otimes .\mathscr{F}^{(2)} \otimes .\mathscr{F}^{(1)}_{(2)}), \tag{IV.7}$$

$$.\mathscr{F}^{-1}_{1,23}.\mathscr{F}^{-1}_{32} = (.\mathscr{F}^{(1)}_{(1)} \otimes .\mathscr{F}^{(2)} \otimes .\mathscr{F}^{(1)}_{(2)})^{-1} .\mathscr{F}^{-1}_{13}, \tag{IV.8}$$

which, replaced in the definition of G [using the definition (II.6)], gives $G = \mathscr{R}_{13}$; this proves Eq. (IV.1).

As for relation (IV.2),

$$A^i A^j \overset{(III.17)}{=} \rho(.\mathscr{F}^{(1)})_l^i \sigma(.\mathscr{F}^{(2)}) a^l a^m \sigma(.\mathscr{F}^{-1(2')}) \rho(\gamma^{-1} S.\mathscr{F}^{-1(1')})_m^j$$

$$\overset{(II.19)}{=} \pm \rho(.\mathscr{F}^{(1)})_l^i \sigma(.\mathscr{F}^{(2)}) a^m a^l \sigma(.\mathscr{F}^{-1(2')}) \rho(\gamma^{-1} S.\mathscr{F}^{-1(1')})_m^j$$

$$\overset{(II.20)}{=} \pm \rho(.\mathscr{F}^{(1)}.\mathscr{F}^{-1(2')}_{(2')})_l^i a^m \sigma(.\mathscr{F}^{(2)}_{(1)} \mathscr{F}^{-1(2')}_{(1')}) a^l \rho(\gamma^{-1} S.\mathscr{F}^{-1(1')} \cdot S.\mathscr{F}^{(2)}_{(2)})_m^j$$

$$\overset{(IV.5)}{=} \pm \rho(.\mathscr{F}^{(1)}.\mathscr{F}^{-1(2')}_{(2')}.\mathscr{F}^{-1(\bar{1})})_l^i A^m \sigma(.\mathscr{F}^{(2'')}.\mathscr{F}^{(2)}_{(1)}.\mathscr{F}^{-1(2')}_{(1')}.\mathscr{F}^{-1(\bar{2})}) \times A^l \rho[\gamma^{-1} S(.\mathscr{F}^{(1'')}.\mathscr{F}^{(2)}_{(2)}.\mathscr{F}^{-1(1')}) \gamma]_m^j$$

$$\overset{(II.4)}{=} \pm \rho(G^{-1(1)})_l^i A^m \sigma(G^{-1(2)}) A^l \rho[S_h(G^{-1(3)}]_m^j . \tag{IV.9}$$

However, we have already shown that $G = .\mathscr{R}_{13}$; by recalling that $(\mathrm{id} \otimes S_h).\mathscr{R}^{-1} = .\mathscr{R}$, relation (IV.2) follows.

Similarly one can prove relation (IV.3), which can be found also more directly by observing that in the unitary-$\mathscr{F}$ case it follows from the previous one by applying the $*$-conjugation and by noting that $\bar{R} = R_{21}$. □

Remark 5: It is interesting to ask how the invariants which can be constructed from A^i, A_j^+ are related to the ones which can be constructed from a^i, a_j^+. It is straightforward to prove that, e.g., any invariant of the form $I_h^n := A_{i_1}^+ \ldots A_{i_n}^+ A^{i_n} \ldots A^{i_1}$, coincides with the invariant of the form

$I^n := a^+_{i_1}\dots a^+_{i_n}, a^{i_n}\dots a^{i_1}$ (in particular, so is $I^2 \equiv N := A^+_i A^i = n$). One can show[9] the equality $P(A^i, A^+_j) = P(a^i, a^+_j)$ for all polynomial invariants $P(\tilde{A}^i, \tilde{A}^+_j)$. This is no longer true if H_h is genuinely quasitriangular.

V. QUANTUM COMMUTATION RELATIONS: THE $\mathscr{U}_h$sl(2) CASE

It is now tempting to consider the quasitriangular case and ask whether a transformation such as in Remark 1 can map a^i, a^+_j into $U_h\mathbf{g}$-covariant A^i, A^+_j satisfying relations of the type found in Refs. 3 and 4. We will stick here to the case $\mathbf{g} = \mathrm{sl}(2,\mathbf{C})$, $\rho \equiv$ fundamental representation, directing the reader to Ref. 9 for the general case.

We fix our conventions as follows. As ''classical'' generators of Usl(2) we choose $j_0, j_+, j_- \in \mathbf{g}$,

$$[j_0,\, j_\pm] = \pm j_\pm, \quad [j_+,\, j_-] = 2j_0, \tag{V.1}$$

$$\Delta(x) = \mathbf{1}\otimes x + x\otimes \mathbf{1}, \quad x = j_0, j_+, j_- . \tag{V.2}$$

As generators of $\mathscr{U}_h$sl(2) we choose J_0, J^+, J^- satisfying

$$[J_0,\, J_\pm] = \pm J_\pm, \quad [J_+,\, J_-] = \frac{q^{2J_0} - q^{-2J_0}}{q - q^{-1}}, \tag{V.3}$$

$$\Delta_h(J_0) = \mathbf{1}\otimes J_0 + J_0\otimes \mathbf{1}, \quad \Delta_h(J_\pm) = J_\pm \otimes q^{-J_0} + q^{J_0}\otimes J_\pm . \tag{V.4}$$

{Let us recall incidentally that the mapping $\varphi_h : \mathscr{U}_h\mathrm{sl}(2) \to U\mathrm{sl}(2)[[h]]$, up to an inner automorphism $\varphi_h \to \varphi_{h,v} := v\,\varphi_h(\cdot)v^{-1}$ is given by[7]

$$\varphi_h(J_0) = j_0, \quad \varphi_h(J_\pm) = \sqrt{\frac{[j \pm j_0]_q [1 + j \mp j_0]_q}{(j \pm j_0)(1 + j \mp j_0)}}\, j_\pm , \tag{V.5}$$

where j is the positive root of the equation $j(j+1) - \mathscr{C} = 0$, $\mathscr{C} = j_- j_+ + j_0(j_0+1)$ is the Casimir, $q = e^h$, and $[x]_q := (q^x - q^{-x})/(q - q^{-1})$.}

At the coalgebra level, the universal $\mathscr{F}$ [connecting Δ to Δ_h in formula (II.4)] is not explicitly known; however the Usl(2)[[h]]-valued matrix $F := (\rho\otimes \mathrm{id})\mathscr{F}$ has been determined in Ref. 8 and reads

$$F = \begin{Vmatrix} a(j,j_0) & b(j,j_0) j_- \\ -j_+ b(j,j_0) & a(j,j_0 - 1) \end{Vmatrix}, \quad F^{-1} = \begin{Vmatrix} a(j,j_0) & -b(j,j_0) j_- \\ j_+ b(j,j_0) & a(j,j_0 - 1) \end{Vmatrix}, \tag{V.6}$$

where

$$a(j,j_0) := \frac{q^{(j-j_0)/q}}{\sqrt{(1+2j)[1+2j]_q}} \left[\sqrt{(1 + j + j_0)[1 + j + j_0]_q} + q^{-(1+2j)/2} \sqrt{(j - j_0)[j - j_0]_q} \right],$$
$$b(j,j_0) := \frac{q^{(j-j_0)/2}}{\sqrt{(1+2j)[1+2j]_q}} \left[\sqrt{\frac{[1 + j + j_0]_q}{1 + j + j_0}} - q^{-(1+2j)/2} \sqrt{\frac{[j - j_0]_q}{j - j_0}} \right]; \tag{V.7}$$

the matrix elements in Eq. (V.6) are w.r.t. the orthonormal basis $\{|\uparrow\rangle, |\downarrow\rangle\}$ (spin up, spin down) of eigenstates of j_0 with eigenvalues $\pm\frac{1}{2}$. $a^+_\uparrow|0\rangle = |\uparrow\rangle$, etc. All indices in the sequel will run over $\{\uparrow,\downarrow\}$. F is unitary w.r.t. the su(2) $*$-structure $j_0^* = j_0$, $(j_+)^* = j_-$.

[See formulas (3.1) and (3.30) in Ref. 8. To match our conventions with theirs, one has to rescale $j_\pm$ by $\sqrt{2}$ and note that the right correspondence between our notation and theirs is $\mathscr{F} \equiv \mathscr{F}_q \leftrightarrow U_{q^{-1}}$, what is needed to match the coproducts.]

The homorphism σ in this case coincides with the well-known Jordan–Schwinger realization of sl(2) (Ref. 23) and reads

$$\sigma(j_+)=a_\uparrow^+a^\downarrow,\quad \sigma(j_-)=a_\downarrow^+a^\uparrow,\quad \sigma(j_0)=\tfrac{1}{2}(a_\uparrow^+a^\uparrow-a_\downarrow^+a^\downarrow), \tag{V.8}$$

implying in particular

$$\sigma(j)=n/2, \tag{V.9}$$

where $n:=a_i^+a^i$ is the ''classical number of particles'' operator. The $\mathscr{U}_h$su(N)-covarient Weyl algebra (with $N\geqslant 2$, $q=e^h$ real and positive) was introduced by Pusz and Woronowicz;[3] independently, Wess and Zumino[4] introduced its $\mathscr{U}_h$sl(N)-covariant generalization (arbitrary complex q) in R-matrix notation. One can consider also its Clifford version.[24] In the R-matrix notation[4] the QCR of the generators (which we will denote here by $\tilde{A}^i,\tilde{A}_j^+$) read

$$\tilde{A}^i\tilde{A}^j=\pm q^{\mp 1}R^{ij}_{vu}\tilde{A}^u\tilde{A}^v, \tag{V.10}$$

$$\tilde{A}_i^+\tilde{A}_j^+=\pm q^{\mp 1}R^{vu}_{ij}\tilde{A}_u^+\tilde{A}_v^+, \tag{V.11}$$

$$\tilde{A}^i\tilde{A}_j^+=\mathbf{1}_{\mathscr{A}}\delta_j^+\pm q^{\pm 1}R^{ui}_{jv}\tilde{A}_u^+\tilde{A}^v, \tag{V.12}$$

where $i,\ j=1,...,N$, $R=(\rho_d\otimes\rho_d)\mathscr{R}$ is the R-matrix of $\mathscr{U}_h$sl(N) in the defining representation ρ_d, and the sign $\pm$ refers to Weyl and Clifford, respectively. [The ''braiding'' (V.12) between $\tilde{A}^i,\tilde{A}_j^+$ could be also replaced by the inverse one: $\tilde{A}^i\tilde{A}_j^+=\mathbf{1}_{\mathscr{A}}\delta_j^i\pm q^{\mp}R^{-1\,ui}_{\ \ jv}\tilde{A}_u^+\tilde{A}^v$. For a comprehensive introduction to braiding, see Ref. 25.] Both have been treated subsequently by many other authors. They are related, but should not be confused, with the celebrated Biedenharn–Macfarlane–Hayashi q-oscillator (super)algebras.[5,26] [The generators α^i,α_j^+ of the latter fulfill ordinary (anti)commutation relations, except for the q-(anti)commutation relations $\alpha^i\alpha_i^+\mp q^2\alpha_i^+\alpha^i$ and are *not* $U_h\mathbf{g}$ covariant (in spite of the fact that they are usually used to construct a generalized Jordan–Schwinger realization of $U_h\mathbf{g}$). It is of interest to note that, however, the generators α^i,α_j^+ can be typically realized as algebraic ''functions'' of $\tilde{A}^i,\tilde{A}_i^+$,[17] whereas the generators A^i,A_i^+ can be typically realized only as *trascendental* ''functions'' of $\tilde{A}^i,\tilde{A}_i^+$.] When $q>0$ the QCR of the generators are compatible with the $*$-structure[3] of annihilators and creators,

$$A_i^+=(A^i)^\star. \tag{V.13}$$

When $N=2$ we will pick up $i,j,\ldots=\uparrow,\downarrow$; the R-matrix will read

$$R\equiv\|R^{ij}_{hk}\|:=\begin{Vmatrix} q & & & \\ & 1 & & \\ & (q-q^{-1}) & 1 & \\ & & & q \end{Vmatrix}, \tag{V.14}$$

where the row and columns of the matrix (V.14) are ordered in the usual way: $\uparrow\uparrow$, $\uparrow\downarrow$, $\downarrow\uparrow$, $\downarrow\downarrow$ from left to right and from up to down.

More explicitly, the Weyl QCR (V.10)–(V.12) read

$$\begin{aligned}
\tilde{A}^\uparrow\tilde{A}_\uparrow^+&=\mathbf{1}_{\mathscr{A}}+q^2\tilde{A}_\uparrow^+\tilde{A}^\uparrow+(q^2-1)\tilde{A}_\downarrow^+\tilde{A}^\downarrow,\\
\tilde{A}^\downarrow\tilde{A}_\downarrow^+&=\mathbf{1}_{\mathscr{A}}+q^2\tilde{A}_\downarrow^+A^\downarrow,\\
\tilde{A}^\uparrow\tilde{A}_\downarrow^+&=q\tilde{A}_\downarrow^+\tilde{A}^\uparrow,\quad \tilde{A}^\downarrow\tilde{A}_\uparrow^+=qA_\uparrow^+\tilde{A}^\downarrow,
\end{aligned} \tag{V.15}$$

$$\tilde{A}^\downarrow\tilde{A}^\uparrow=q\tilde{A}^\uparrow\tilde{A}^\downarrow,\quad \tilde{A}_\uparrow^+\tilde{A}_\downarrow^+=q\tilde{A}_\downarrow^+\tilde{A}_\uparrow^+ \tag{V.16}$$

and the Clifford

$$\tilde{A}^\uparrow\tilde{A}_\uparrow^+=\mathbf{1}_{\mathscr{A}}-\tilde{A}_\uparrow^+\tilde{A}^\uparrow+(q^{-2}-1)\tilde{A}_\downarrow^+\tilde{A}^\downarrow,$$

$$\tilde{A}^{\downarrow}\tilde{A}^{+}_{\downarrow}=\mathbf{1}_{\mathscr{A}}-\tilde{A}^{+}_{\downarrow}\tilde{A}^{\downarrow},\quad \tilde{A}^{\uparrow}\tilde{A}^{+}_{\downarrow}=-q^{-1}\tilde{A}^{+}_{\downarrow}\tilde{A}^{\uparrow},\tag{V.17}$$

$$\tilde{A}^{\downarrow}\tilde{A}^{+}_{\uparrow}=-q^{-1}\tilde{A}^{+}_{\uparrow}\tilde{A}^{\downarrow},$$

$$\tilde{A}^{\downarrow}\tilde{A}^{\uparrow}=-q^{-1}\tilde{A}^{\uparrow}\tilde{A}^{\downarrow},\quad \tilde{A}^{\uparrow}\tilde{A}^{\uparrow}=0,\quad \tilde{A}^{\downarrow}\tilde{A}^{\downarrow}=0;\tag{V.18}$$

$$\tilde{A}^{+}_{\uparrow}\tilde{A}^{+}_{\downarrow}=-q^{-1}\tilde{A}^{+}_{\downarrow}\tilde{A}^{+}_{\uparrow},\quad \tilde{A}^{+}_{\uparrow}\tilde{A}^{+}_{\uparrow}=0,\quad \tilde{A}^{+}_{\downarrow}\tilde{A}^{+}_{\downarrow}=0.\tag{V.19}$$

Now we try to construct the A^{+}_{i},A^{i}. The ansatz of Proposition 4 is equivalent to

$$A^{+}_{i}=a^{+}_{l}\sigma(\mathscr{F}^{-1(2)})\rho(\mathscr{F}^{-1(1)})^{l}_{i}f(n),$$
$$A^{i}=g(n)\rho(\mathscr{F}^{(1)})^{i}_{l}\sigma(\mathscr{F}^{(2)})a^{l},\tag{V.20}$$

with the same $\mathscr{F}$ and two invertible functions f,g. {In fact, in $T=K[\mathscr{C}\otimes\mathbf{1},\mathbf{1}\otimes\mathscr{C},\Delta(\mathscr{C})]$ the dependence on the last argument results only in a numerical factor, because of Eqs. (II.20) and (II.24). The $\mathscr{C}\otimes\mathbf{1}$ and $\mathbf{1}\otimes\mathscr{C}$ dependences can be replaced by the n dependence, since it is easy to prove that $\sigma(\mathscr{C})=(n/2)(n/2+1)$; the latter can be concentrated either at the left or at the right of a^{i},a^{+}_{j}, upon using the commutation relations $[n,\,a^{+}_{i}]=a^{+}_{i}$, $[n,\,a^{i}]=-a^{i}$.} The product fg is determined by requiring that the commutation relation between $N:=A^{+}_{i}A^{i}$ and A^{i},A^{+}_{j} are the same as those between $\tilde{N}:=\tilde{A}^{+}_{i}\tilde{A}^{i}$ and $\tilde{A}^{i}$,$\tilde{A}^{+}_{j}$:

$$NA^{+}_{i}=A^{+}_{i}(1+q^{\pm 2}N),\quad NA^{i}=A^{i}q^{\mp 2}(N-1);\tag{V.21}$$

one easily finds

$$gf(x)=\sqrt{\frac{(x+1)_{q^{\pm 2}}}{(x+1)}}.\tag{V.22}$$

If $q\in\mathbf{R}^{+}$ and we wish that $A^{+}_{i}=(A^{i})^{\star}$, we need to choose

$$g(x)=f(x)=\sqrt{\frac{(x+1)_{q^{\pm 2}}}{(x+1)}}.\tag{V.23}$$

This is nothing else but the already encountered function (I.3)[6] needed to transform the classical creation/annihilation operators in one dimension a^{+},a into the quantum ones A^{+},A.

If we are interested in Fock space representations, $A^{+}_{i}|0\rangle=a^{+}_{i}|0\rangle$, stating that the quantum and classical one-particle states coincide, is automatically satisfied, because $f(0)=1$.

Now one can express the rhs of (V.20) thoroughly in terms of a^{i},a^{+}_{j}. It is convenient to introduce the up–down ''number of particle'' operators $n^{\uparrow}$,$n^{\downarrow}$ ($n^{\uparrow}+n^{\downarrow}=n$) by

$$n^{\uparrow}:=a^{+}_{\uparrow}a^{\uparrow},\quad n^{\downarrow}:=a^{+}_{\downarrow}a^{\downarrow}.\tag{V.24}$$

Using Eqs. (V.6), (V.7), (V.8), and (V.20), it is easy algebra to prove the following. (In the fermionic case one has to fully exploit the nilpotency of a^{i},a^{+}_{j}.)

Proposition 5: Equations (V.20) amount, in the Weyl case, to

$$A^{+}_{\uparrow}=\sqrt{\frac{(n^{\uparrow})_{q^2}}{n^{\uparrow}}}\,q^{n^{\downarrow}}a^{+}_{\uparrow},\quad A^{+}_{\downarrow}=\sqrt{\frac{(n^{\downarrow})_{q^2}}{n^{\downarrow}}}\,a^{+}_{\downarrow},$$
$$A^{\uparrow}=a^{\uparrow}\sqrt{\frac{(n^{\uparrow})_{q^2}}{n^{\uparrow}}}\,q^{n^{\downarrow}},\quad A^{\downarrow}=a^{\downarrow}\sqrt{\frac{(n^{\downarrow})_{q^2}}{n^{\downarrow}}},\tag{V.25}$$

and, in the Clifford one, to

$$A^{+}_{\uparrow}=q^{-n^{\downarrow}}a^{+}_{\uparrow},\quad A^{+}_{\downarrow}=a^{+}_{\downarrow},\quad A^{\uparrow}=a^{\uparrow}q^{-n^{\downarrow}},\quad A^{\downarrow}=a^{\downarrow}.\tag{V.26}$$

We are ready for the main theorem of this section (the proof is a straightforward computation).

Theorem 2: *The elements $A^iA_j^+\in\mathscr{A}$ ($\mathscr{A}$ Weyl or Clifford) defined in formulas (V.20) and (V.23) satisfy the QCR (V.12) and (V.11).*

Let us compare the map (V.25) (for the Weyl algebra) with the one found in Ref. 17. That map, in our notation, would read

$$A_\uparrow^+=q^{n^\uparrow}a_\uparrow^+,\quad A_\downarrow^+=a_\downarrow^+,$$
$$A^\uparrow=a^\uparrow\,\frac{(n^\uparrow)_{q^2}}{n^\uparrow}\,q^{n^\downarrow},\quad A^\downarrow=a^\downarrow\,\frac{(n^\downarrow)_{q^2}}{n^\downarrow} \tag{V.27}$$

[clearly, it is not compatible with the $*$-structure $A_{i,\alpha}^+=(A^{i,\alpha})^\star$]. It is straightforward to check that the element $\alpha\in\mathscr{A}[[h]]$ needed to transform A_i^+,A^i into $A_{i,\alpha}^+,A^{i,\alpha}$ [formulas (III.15)] is

$$\alpha:=\sqrt{\frac{\Gamma(n^\uparrow+1)\Gamma(n^\downarrow+1)}{\Gamma_{q^2}(n^\uparrow+1)\Gamma_{q^2}(n^\downarrow+1)}}, \tag{V.28}$$

where Γ is the Euler Γ-function and Γ_{q^2} its q-deformation[27] satisfying the property

$$\Gamma_q(a+1)=(a)_q\Gamma_q(a). \tag{V.29}$$

The corresponding realization of $\tilde{\triangleright}_h$ is obtained through relation (III.14).

VI. REPRESENTATION THEORY

In this section we compare representations of $\mathscr{A}$ with representations of $\mathscr{A}_h$ and investigate whether the deforming maps found in the preceding sections can be interpreted as intertwiners between them.

We start with a general remark. At least perturbatively in h, we expect that, for any given representation π of $\mathscr{A}$ on some space V, the objects $\pi(A_{i,\alpha}^+),\pi(A^{i,\alpha})$ are well-defined operators on V, since $A_{i,\alpha}^+=a_i^++O(h)$, $A^{i,\alpha}=a^i+O(h)$; consequently, $\pi\circ f_\alpha$ is a representation of $\mathscr{A}_h$ on V. Let us prove this statement more rigorously for some specific kind of representations.

If **g** is compact, we can choose ρ to be a unitary representation; the **g**-covariant CCR will admit the $*$-relations (II.25). Assuming the latter, the Stone–Von Neumann theorem (or its Clifford counterpart) applies: there exists a ''$*$-representation'' π of Eqs. (II.19) and (II.25) on a separable Hilbert space $\mathscr{H}$, i.e., a π fulfilling the following properties:

(1) $\pi(a^i),\pi(a_i^+)$ are closed;
(2) $\pi(a_i^+)\subset[\pi(a^i)]^\dagger$;
(3) there exists a dense linear subset $\mathscr{D}\subset\mathscr{H}$ contained in the domain of the product of any two operators $\pi(a^i),\pi(a_i^+)$;
(4) the CCR (II.19) hold on $\mathscr{D}$;
(5) the non-negative definite operator $\pi(n):=\pi(a_i^+a^i)$ is essentially self-adjoint on $\mathscr{D}$.

Moreover, the irreducible components $(\pi_l,\mathscr{H}_l)$ of $(\pi,\mathscr{H})$ are, up to a unitary transformation $U_l:\mathscr{H}\to\mathscr{H}$, Fock space representations, i.e., there exist ''ground states'' $|0\rangle_l\in\mathscr{H}_l$:

$$\pi(a^i)|0\rangle_l=\mathbf{0}. \tag{VI.1}$$

One can choose the dense set $\mathscr{D}$ as the linear span of all the analytic vectors of the form $\pi(a_{i_1}^+\cdots a_{i_k}^+)|0\rangle_l$.

In the case under consideration, choosing $\mathscr{F}$ unitary [so that relation (III.11) holds] and setting $\Pi:=\pi\circ f$, one can easily realize that Π is a $*$-representation of the QCR [(I.8) or (V.10)–(V.12)] on $\mathscr{H}$, i.e., it fulfills conditions analogous to (1)–(5), with $\tilde{A}^i,\tilde{A}_i^+$ in the place of a^i,a_i^+.

The reason is essentially the following. Assume first that π and ρ are irreducible, and let $\mathscr{H}^{(k)}:=\mathrm{Span}_{\mathbf{C}}\{\pi(a_{i_1}^+\cdots a_{i_k}^+)|0\rangle\}$; $\mathscr{H}^{(k)}$ is a finite-dimensional eigenspace of $\pi(n)$, because ρ is finite-dimensional and, therefore, $\mathscr{A}$ has a finite number of generators. From Eqs. (III.17) and the

relation $[\sigma(U\mathbf{g}),\, n]=0$ it follows that $\pi(A^i),\pi(A_i^+)$ differ from $\pi(a^i),\pi(a_i^+)$ just by operators mapping each $\mathscr{H}^{(k)}$ into itself. [Incidentally, from relation (II.1) it follows in particular $\pi(A^i)|0\rangle=\mathbf{0}$ and $\pi(A_i^+)|0\rangle=\pi(a_i^+)|0\rangle$.] Therefore all the properties (1)–(5) are inherited by $\pi(A^i),\pi(A_i^+)$ as well. The same result holds for $\Pi_\alpha:=\pi\circ f_\alpha$ if $\alpha^\star=\alpha^{-1}$, because $\pi(\alpha)$ can be absorbed in the unitary transformation U. Finally, the result extends by linearity and orthogonality also to the case that π and/or ρ are reducible.

Summing up, f_α is an intertwiner between the $*$-representation of the CCR and a $*$-representation of the QCR. In other words, we can represent the objects $\tilde{A}^i,\tilde{A}_i^+$ [fulfilling the QCR and the $*$-relations (III.11)] as composite operators acting on the Fock space $\mathscr{H}$, as anticipated in the Introduction. The latter can be used to describe ordinary bosons and fermions. This disproves the quite common belief that non-cocommutative Hopf algebra symmetries are necessarily incompatible with ordinary Bose and Fermi statistics.

Let us analyze now a different situation. Let $\mathbf{g}=\mathrm{sl}(2)$, $\mathscr{A}$ be the corresponding two-dimensional Weyl algebra, and (π,V) be the Fock space representation of the latter (with ground state $|0\rangle$). Let $\mathscr{A}_h$ be the deformation of $\mathscr{A}$ considered in Sec. V with $q^2=e^{2h}$ a root of unity, i.e., $q^{2p}=1$, $q^{2k}\neq 1$ with $p,k\in\mathbf{N}$ and $k<p$. It is easy to realize that $\pi[(n_i)_{q^2}(a_i^+)^{mp}(a_{-i}^+)^l]|0\rangle=\mathbf{0}$ for $l,m=0,1,...$; consequently, $A^\uparrow,A^\downarrow$ annihilate all the vectors of the form $|m,n\rangle := \pi[(a_\uparrow^+)^{mp}(a_\downarrow^+)^{np}|0\rangle$ $(n,m=0,1,...)$. Although (π,V) was irreducile as a representation of $\mathscr{A}$, it is reducile as a representation of the subalgebra of $\mathscr{A}$ generated by A^i,A_j^+; the irreducible components $V_{m,n}$ are isomorphic and p^2-dimensional, and are obtained by applying A_i^+'s to the cyclic vectors $|m,n\rangle$. $V_{m,n}$ is also a (reducible) representation of $\mathscr{U}_h\mathrm{sl}(2)$ and may be called (with an abuse of terminology, since we have not introduced any spatial degrees of freedom) an ''anyonic space.'' Thus, f can be seen as an intertwiner from the classical bosonic Fock representation onto a direct sum of ''anyonic'' representations of $\mathscr{A}_h$.

Whenever some class P of representations of $\mathscr{A}_h$ is ''larger'' than the corresponding class p of representations of the CCR, then f_α^{-1} can of course be well defined (as an intertwiner between P and p) only on some proper subset of P; on its complement it must be singular.

It is instructive to see whether and how this phenomenon occurs in some concrete example, e.g., for the class of $*$-representations considered above. Both a deformed algebra $\mathscr{A}_h$ covariant under some triangular Hopf algebra H_h of the type (II.8) (with $\mathscr{F}$ unitary) and the deformed Clifford algebra of Sec. V are not good for this purpose, because P is as large as p. {For the latter algebra this was shown in Ref. 24. For the former this can be understood as follows. In the present case $\mathscr{R}=\mathscr{F}^{-2}$. Given any representation ρ of $U\mathbf{g}$ and the corresponding representation $\tilde{\rho}$ of $U_h\mathbf{g}$, let us choose a basis of eigenvectors $|l\rangle$ of the Cartan subalgebra. In this basis $R:=(\tilde{\rho}\otimes\tilde{\rho})\mathscr{R}$ will be diagonal, and, in particular, it will be $R_{ll}^{ll}=1$ as a consequence of the antisymmetry of $\omega_{ij}(h_i\otimes h_j)$. The QCR (I.8) will imply in particular

$$\tilde{A}^i\tilde{A}_i^+=\mathbf{1}_{\mathscr{A}}\pm\tilde{A}_i^+\tilde{A}^i \quad (\text{no sum over } i), \tag{VI.2}$$

and, setting $\tilde{N}_i := A_i^+\tilde{A}^i$ (no sum over i),

$$[\tilde{N}_i,\,\tilde{N}_j]=0,\quad [\tilde{N}_i,\,\tilde{A}_j^+]=\delta_{ij}\tilde{A}_j^+,\quad [\tilde{N}_i,\,\tilde{A}^j]=-\delta_i^j\tilde{A}^j. \tag{VI.3}$$

Let us denote by $\mathscr{A}_h^{(i)}$ the subalgebra generated by $\tilde{A}^i,\tilde{A}_i^+$. Each $\mathscr{A}_h^{(i)}$ separately is isomorphic to a classical one-dimensional Weyl/Clifford algebra, and therefore admits, up to unitary equivalences, a unique $*$-representation in the form of a Fock representation with level N_i. Because of the relations (VI.3), we can choose $\{N_i\}_{i\in I}$ as a complete set of commuting observables, where the uniqueness, up to unitary equivalences, of the $*$-representation of $\mathscr{A}_h$ follows immediately.} On the contrary, it was proved in Ref. 3 that there are many unitarily nonequivalent $*$-representations on separable Hilbert spaces of the $\mathscr{U}_h\mathrm{su}(2)$-covariant $(q\in\mathbf{R}^+)$ deformed Weyl algebra. [Incidentally, even one-dimensional deformed Heisenberg algebras may have more unitarily inequivalent representations.[28] Moreover, within each representation one has still some freedom in the ''physical'' interpretation of the observables, e.g., what are the ''right'' momentum/position observables (see, e.g., Ref. 29).]

Sticking to the case $0<q<1$, one can parametrize the Woronowicz–Pusz[3] unitarily inequivalent irreducible $*$-representations of this algebra by three parameters E, r, s, where $q^2<E<1$, and r, s are non-negative integers with $r+s\leqslant 2$. We shall denote the corresponding Hilbert space by $\mathscr{H}_{E,r,s}$. We divide them in the following classes for clarity:

(1) In the representation $s=2$ (and $r=0$, the value E is irrelevant) one parametrizes the vectors of an orthonormal basis of $\mathscr{H}_{E,0,2}$ by $\{|q^{2m_1}/(q^2-1),q^{2m_2}/(q^2-1)\rangle\}$.
(2) In the representations with $s=1=r$, one parametrizes the vectors of an orthonormal basis of $\mathscr{H}_{E,1,1}$ by $\{|q^{2n_1}E,q^{2m_1}/(q^2-1)\rangle\}$.
(3) In the representations with $s=1$ and $r=0$, one parametrizes the vectors of an orthonormal basis of $\mathscr{H}_{E,0,1}$ by $\{|0,q^{2m_1}/(q^2-1)\rangle\}$ (the value E is irrelevant).
(4) In the representations with $s=0$ and $r=2$, one parametrizes the vectors of an orthonormal basis of $\mathscr{H}_{E,2,0}$ by $\{|q^{2n_1}E,q^{2n_2}E\rangle\}$.
(5) Finally, in the representations with $s=0$ and $r=1$, one parametrizes the vectors of an orthonormal basis of $\mathscr{H}_{E,1,0}$ by $\{|q^{2n_1}E,0\rangle\}$.

Here n_1,n_2; m_1,m_2 denote integers, with $m_1\geqslant m_2\geqslant 0$, $n_1<n_2$. Only representations (1) and (3) have a ground state; but representation (3) is degenerate.

In the rest of this section we drop the symbols Π to avoid a too heavy notation. On the vectors $|\eta_\uparrow,\eta_\downarrow\rangle$ of the above basis of any $\mathscr{H}_{E,r,s}$, $\tilde{A}^i,\tilde{A}_i^+$, $i=\uparrow,\downarrow$, are defined (modulo a possible but here irrelevant phase in the case $r+s<2$) by

$$\tilde{A}^\uparrow|\eta,\eta_\downarrow\rangle=\sqrt{\eta-\eta_\downarrow}|q^{-2}\eta,\eta_\downarrow\rangle,\quad \tilde{A}^\downarrow|\eta,\eta_\downarrow\rangle=\sqrt{\eta_\downarrow-\frac{1}{q^2-1}}\,|q^{-2}\eta,q^{-2}\eta_\downarrow\rangle,$$
$$\tilde{A}_\uparrow^+|\eta,\eta_\downarrow\rangle=\sqrt{q^2\eta-\eta_\downarrow}|q^2\eta,\eta_\downarrow\rangle,\quad \tilde{A}_\downarrow^+|\eta,\eta_\downarrow\rangle=\sqrt{q^2n_\downarrow-\frac{1}{q^2-1}}\,|q^2\eta,q^2\eta_\downarrow\rangle. \tag{VI.4}$$

Hence, setting $\tilde{N}^\uparrow:=\tilde{A}_\uparrow^+\tilde{A}^\uparrow$, $\tilde{N}^\downarrow:=\tilde{A}_\downarrow^+\tilde{A}^\downarrow$, and $\tilde{N}:=\tilde{N}^\uparrow+\tilde{N}^\downarrow$, we find that $|\eta,\eta_\downarrow\rangle$ are eigenvectors of the following operators:

$$\tilde{N}^\uparrow|\eta,\eta_\downarrow\rangle=(\eta-\eta_\downarrow)|\eta,\eta_\downarrow\rangle,$$
$$\tilde{N}^\downarrow|\eta,\eta_\downarrow\rangle=\left(\eta_\downarrow-\frac{1}{q^2-1}\right)|\eta,\eta_\downarrow\rangle,$$
$$[1+(q^2-1)\tilde{N}^\downarrow]|\eta,\eta_\downarrow\rangle=(q^2-1)\eta_\downarrow|\eta,\eta_\downarrow\rangle, \tag{VI.5}$$
$$[1+(q^2-1)\tilde{N}]|\eta,\eta_\downarrow\rangle=(q^2-1)\eta|\eta,\eta_\downarrow\rangle.$$

Formally, the inverse of the transformation (V.25) reads

$$f^{-1}(\tilde{A}_\downarrow^+):=\tilde{a}_\downarrow^+=\sqrt{\frac{\log[1+(q^2-1)\tilde{N}^\downarrow]}{2\tilde{N}^\downarrow\log q}}\,\tilde{A}_\downarrow^+,$$
$$f^{-1}(\tilde{A}_\uparrow^+):=\tilde{a}_\uparrow^+=\sqrt{\frac{1+(q^2-1)\tilde{N}^\downarrow}{2\tilde{N}^\uparrow\log q}\log\left[\frac{1+(q^2-1)\tilde{N}}{1+(q^2-1)\tilde{N}^\downarrow}\right]}\tilde{A}_\uparrow^+, \tag{VI.6}$$
$$f^{-1}(\tilde{A}^\downarrow):=\tilde{a}^\downarrow=\tilde{A}^\downarrow\sqrt{\frac{\log[1+(q^2-1)\tilde{N}^\downarrow]}{2\tilde{N}^\downarrow\log q}},$$
$$f^{-1}(\tilde{A}^\uparrow):=\tilde{a}^\uparrow=\tilde{A}^\uparrow\sqrt{\frac{1+(q^2-1)\tilde{N}^\downarrow}{2\tilde{N}^\uparrow\log q}\log\left[\frac{1+(q^2-1)\tilde{N}}{1+(q^2-1)\tilde{N}^\downarrow}\right]}.$$

A glance at formula (VI.5) shows that the arguments of both logarithms in the inverse transformation (VI.6) are positive definite on representation (1), whereas at least one of the arguments of the two logarithms is negative on any representation (2), (3), (4), or (5) [in the representation (3) the other argument vanishes]. This makes f^{-1} ill-defined on all representations (2), (3), (4), or (5).

We conclude that representation (1) is the one intertwined by f^{-1} to the standard bosonic Fock representation of the su(2)-covariant Weyl algebra $\mathscr{A}$, whereas the representations of the classes (2), (4), and (5) have no classical analog, and representation (3) reduces to the representation of a one-dimensional Weyl algebra.

We construct and classify superconformally covariant differential operators defined on $N=2$ super Riemann surfaces. By contrast to the $N=1$ theory, these operators give rise to partial rather than ordinary differential equations which leads to novel features for their matrix representation. The latter is applied to the derivation of $N=2$ super W-algebras in terms of $N=2$ superfields. © *1998 American Institute of Physics.* [S0022-2488(98)01606-5]

I. INTRODUCTION

In the context of two-dimensional conformal field theories and integrable models, an important role is played by conformally covariant differential operators in one complex variable:[1] these linear, n-th order operators have the general form $L^{(n)}=\partial^n+a_1^{(n)}\partial^{n-1}+\cdots+a_n^{(n)}$ where $\partial \equiv \partial/\partial z$ denotes the derivative with respect to local complex coordinates z parametrizing a compact Riemann surface and conformal covariance means that the coefficient functions $a_k^{(n)}(z)$ transform in such a way under local conformal changes of coordinates $z\to z'(z)$ that $L^{(n)}$ maps conformal fields to conformal fields. Any such differential operator can be reparametrized in the following way in terms of a projective connection and $n-2$ conformal fields:

$$L^{(n)}=L_n+M_{w_3}^{(n)}+\cdots+M_{w_n}^{(n)}.$$

Here, L_n is the so-called *Bol operator* of order n,[1] i.e., the conformally covariant version of the differential operator $\partial^n=(\partial/\partial z)^n$. The simplest examples are given by

$$L_0=1, \qquad L_1=\partial, \qquad L_2=\partial^2+\tfrac{1}{2}R, \tag{1}$$

$$L_3=\partial^3+2R\partial+(\partial R),$$

$$L_4=\partial^4+5R\partial^2+5(\partial R)\partial+\tfrac{3}{2}[(\partial^2 R)+\tfrac{3}{2}R^2],$$

where $R=R_{zz}(z)$ denotes a projective connection, i.e., a locally holomorphic field transforming with the Schwarzian derivative under a conformal change of coordinates $z\to z'(z)$:

$$R'(z')=(\partial z')^{-2}[R(z)-S(z',z)], \quad \text{where } S(z',z)=\partial^2 \ln \partial z'-\tfrac{1}{2}(\partial \ln \partial z')^2. \tag{2}$$

Each of the lower order operators $M_{w_k}^{(n)}$ $(k=3,\ldots,n)$ is also conformally covariant and depends linearly on a conformal field w_k of weight k, e.g.,

[a)]Alexander von Humboldt Fellow on leave of absence from the Université Claude Bernard.

 © 1998 American Institute of Physics

$$M^{(n)}_{w_n}=w_n, \quad M^{(n)}_{w_{n-1}}=w_{n-1}\partial+\tfrac{1}{2}(\partial w_{n-1}),$$
$$M^{(n)}_{w_{n-2}}=w_{n-2}\left[\partial^2-\frac{1-n}{2}R\right]+(\partial w_{n-2})\partial+\frac{n-1}{2(2n-3)}[\partial^2-(n-2)R]w_{n-2}. \tag{3}$$

The operators L_n and $M^{(n)}_{w_k}$ can both be obtained from Möbius covariant operators and admit a matrix representation which is related to the principal embedding of $sl(2)$ into $sl(n)$.[2] As we already mentioned, all of these covariant operators admit numerous applications[1] to integrable models (Lax pairs, Poisson operators) and to conformal models (conformal Ward identity, diffeomorphism anomaly, Krichever-Novikov algebra, Wess-Zumino-Witten model), in particular to the theory of W-algebras. Their $N=1$ supersymmetric generalization has been worked out in references[1,3] (see also Ref. 4) and the present paper is devoted to their $N=2$ supersymmetric generalization.

There is a new feature in $N=2$ superspace geometry which makes this theory considerably richer and more complicated: the ''square root'' of the translation generator ∂ is not given by a single odd operator as in $N=1$ supersymmetry ($D^2=\partial$), but it involves two odd operators ($\{D,\overline{D}\}=\partial$). Therefore, one has to deal with partial differential equations (involving D and $\overline{D}$) rather than ordinary differential equations (only involving D). Another aspect of the algebra $\{D,\overline{D}\}=\partial$ consists of the fact that it introduces a $U(1)$ symmetry into the theory: after projection from the super Riemann surface to the underlying ordinary Riemann surface, one thereby recovers $U(1)$-transformations in addition to the familiar conformal transformations. Henceforth, the Bol operators (1) acting on $U(1)$-neutral fields are to be generalized to conformally covariant operators acting on $U(1)$-charged fields. The latter as well as the original operators (1) arise from different types of $N=2$ super Bol operators which are constructed and classified in section IV. In particular, one is led to introduce operators which relate the chiral and anti-chiral subspaces of superconformal fields (section IV B). It is only for these so-called ''sandwich operators'' that we will be able to give a matrix representation (section VI). The latter provides a connection field with values in the Lie superalgebra $sl(n+1|n)$ and the associated $N=2$ super W_n-algebra[5] can be constructed by imposing zero curvature conditions on this connection (section VII).

To keep supersymmetry manifest, all considerations will be carried out in superspace while the projection to ordinary space will be indicated in each case. The passage from the $N=2$ to the $N=1$ superfield formalism will also be discussed so as to make contact with previous work which mostly uses the latter description. Applications of our results will be mentioned in the text and in the concluding remarks.

II. GEOMETRIC FRAMEWORK

In this section, we recall some definitions (following Ref. 6 and references therein) and we introduce some tools which are needed in the sequel.

A. Notation and basic relations

We will work on a compact $N=2$ super Riemann surface (SRS) locally parametrized by coordinates

$$(\mathbf{z};\overline{\mathbf{z}})\equiv(z,\theta,\overline{\theta};\overline{z},\theta^-,\overline{\theta^-})\equiv(x^{++},\theta^+,\overline{\theta^+};x^{--},\theta^-,\overline{\theta^-}), \tag{4}$$

with $z,\overline{z}$ even and $\theta,\overline{\theta},\theta^-,\overline{\theta^-}$ odd. The variables are complex and related by complex conjugation (denoted by *):

$$z^*=\overline{z}, \quad (\theta^+)^*=\theta^-, \quad (\overline{\theta^+})^*=\overline{\theta^-}.$$

As indicated in (4), we will omit the plus-indices of θ^+ and $\overline{\theta^+}$ to simplify the notation.

The canonical basis of the tangent space is defined by $(\partial,D,\overline{D};\overline{\partial},D_-,\overline{D}_-)$ with

$$\partial=\frac{\partial}{\partial z},\quad D=\frac{\partial}{\partial\theta}+\frac{1}{2}\overline{\theta}\partial,\quad \overline{D}=\frac{\partial}{\partial\overline{\theta}}+\frac{1}{2}\theta\partial$$
$$\overline{\partial}=\frac{\partial}{\partial\overline{z}},\quad D_-=\frac{\partial}{\partial\theta^-}+\frac{1}{2}\overline{\theta^-}\overline{\partial},\quad \overline{D}_-=\frac{\partial}{\partial\overline{\theta^-}}+\frac{1}{2}\theta^-\overline{\partial}. \tag{5}$$

The graded Lie brackets between these vector fields are given by

$$\{D,\overline{D}\}=\partial,\quad \{D_-,\overline{D}_-\}=\overline{\partial}, \tag{6}$$

all others brackets being zero, in particular,

$$D^2=0=\overline{D}^2,\quad (D_-)^2=0=(\overline{D}_-)^2. \tag{7}$$

For later reference, we note that this set of equations implies

$$[D,\overline{D}]^2=\partial^2,\quad [D_-,\overline{D}_-]^2=\overline{\partial}^2. \tag{8}$$

B. Superconformal transformations

By definition of the SRS, any two sets of local coordinates, say $\mathbf{z}$ and $\mathbf{z}'$, are related by a *superconformal transformation*, i.e., a smooth mapping satisfying three conditions:

(i) $\mathbf{z}'=\mathbf{z}'(\mathbf{z})\Leftrightarrow D_-\mathbf{z}'=0=\overline{D}_-\mathbf{z}'$,

$\overline{\mathbf{z}'}=\overline{\mathbf{z}}'(\overline{\mathbf{z}})\Leftrightarrow D\overline{\mathbf{z}'}=0=\overline{D}\overline{\mathbf{z}'}$;

(ii) $D\overline{\theta'}=0=\overline{D}\,\theta'$; (9)

(iii) $Dz'=\frac{1}{2}\overline{\theta'}D\theta',\quad \overline{D}z'=\frac{1}{2}\theta'\overline{D\theta'}$,

$D_-\overline{z'}=\frac{1}{2}\overline{\theta^-}'D_-\theta^-{}',\quad \overline{D}_-\overline{z'}=\frac{1}{2}\theta^-{}'\overline{D}_-\overline{\theta^-}'$.

These relations imply that D and $\overline{D}$ separately transform into themselves,

$$D'=e^{w}D,\quad \overline{D}'=e^{\overline{w}}\overline{D}, \tag{10}$$
$$\partial'=\{D',\overline{D}'\}=e^{w+\overline{w}}[\partial+(\overline{D}w)D+(D\overline{w})\overline{D}],$$

where

$$e^{-w}\equiv D\theta',\quad Dw=0,\quad e^{-\overline{w}}\equiv\overline{D\theta'},\quad \overline{Dw}=0, \tag{11}$$

and

$$e^{-w-\overline{w}}=\partial z'+\tfrac{1}{2}\,\overline{\theta}'\partial\theta'+\tfrac{1}{2}\theta'\partial\overline{\theta}'. \tag{12}$$

Note that eqs. (10), (11) imply $(D\theta')(D'\theta)=1=(\overline{D\theta'})(\overline{D}'\overline{\theta})$ and that analogous equations hold in the $\overline{z}$-sector.

C. $U(1)$ symmetry

Equation (12) determines the product of $D\theta'$ and $\overline{D\theta'}$, but not their quotient which is related to the $U(1)$ automorphism group of the $N=2$ supersymmetry algebra. To introduce $U(1)$-*transformations* parametrized by a superanalytic superfield K, we decompose eq. (12) in a symmetric way,

$$D\theta' = e^{+K/2}(\partial z' + \tfrac{1}{2}\overline{\theta'}\partial\theta' + \tfrac{1}{2}\theta'\partial\overline{\theta'})^{1/2},$$
$$\overline{D\theta'} = e^{-K/2}(\partial z' + \tfrac{1}{2}\overline{\theta'}\partial\theta' + \tfrac{1}{2}\theta'\partial\overline{\theta'})^{1/2}, \tag{13}$$

which implies $K=\ln(D\theta'/\overline{D\theta'})$.

D. Superconformal fields

In the following, we will consider *superconformal fields* $C_{p,q}(\mathbf{z},\overline{\mathbf{z}})$ transforming like

$$C'_{p,q} = e^{pw+q\overline{w}}C_{p,q} \quad (p,q\in\mathbf{Z}/2, \quad p+q\in\mathbf{Z}), \tag{14}$$

and which are supposed to have Grassmann parity $(-)^{p+q}$. The space of these fields will be denoted by $\mathcal{F}_{p,q}$. The pair (p,q) will be called the *superconformal weight* of $C_{p,q}$ while $\frac{1}{2}(p+q)$ and $\frac{1}{2}(p-q)$ will be referred to as its *conformal* and $U(1)$ *weight* (or *charge*), respectively—see eq. (18) below. Thus, $C_{p,q}$ is *neutral* with respect to $U(1)$ if $p=q$. Fields with another index structure (transforming also with $w^-,\overline{w^-}$) can be defined in an analogous way.

From the transformation properties of derivatives and fields, it follows that the following chirality conditions are superconformally covariant:

$$DC_{p,0}=0 \quad \text{or} \quad \overline{D}C_{0,p}=0. \tag{15}$$

The space of these so-called *chiral* and *anti-chiral* fields will be denoted by $\mathcal{F}^c_{p,0}$ and $\mathcal{F}^a_{0,p}$, respectively.

Note that the quadratic constraints $D\overline{D}C_{0,-1}=0$ and $\overline{D}DC_{-1,0}=0$ are also covariant.

E. Projection to component fields

A generic $N=2$ superfield admits the θ-expansion,

$$C(\mathbf{z},\overline{\mathbf{z}}) = c+\theta\psi+\overline{\theta\eta}+\theta\overline{\theta}d+\theta^-[\gamma+\theta e+\overline{\theta}f+\theta\overline{\theta}\delta]+\overline{\theta}^-[\epsilon+\theta g+\overline{\theta}h+\theta\overline{\theta}\tau]$$
$$+\theta^-\overline{\theta}^-[m+\theta\varphi+\overline{\theta\chi}+\theta\overline{\theta}n] \tag{16}$$

where the component fields $c,\ldots,n$ depend on z and $\overline{z}$. Equivalently, these space-time fields can be introduced by means of projection,

$$C|=c, \quad DC|=\psi, \quad \overline{D}C|=\overline{\eta}, \quad [D,\overline{D}]C|=-2d,\ldots,$$

where the bar denotes the projection onto the lowest component of the corresponding superfield.

Conformal and $U(1)$-transformations are related to the expressions

$$(w+\overline{w})| = -\ln\,\partial z',$$
$$(w-\overline{w})| = -\ln\left|\frac{D\theta'}{\overline{D\theta'}}\right| = -K|\equiv -k. \tag{17}$$

Here and in all following space-time equations, z' stands for the lowest component of the superfield $z'(\mathbf{z})$ and the *fermionic contributions are never spelled out.*

If $C=C_{p,q}$ belongs to $\mathcal{F}_{p,q}$, then its transformation law (14) can be projected down to ordinary space by taking into account eqs. (13), (17):

$$c'_{p,q} = (\partial z')^{-(1/2)(p+q)}e^{-(1/2)(p-q)k}c_{p,q}. \tag{18}$$

Obviously, $\frac{1}{2}(p+q)$ [resp., $\frac{1}{2}(p-q)$] is the conformal [resp., $U(1)$] weight of the ordinary conformal field $c_{p,q}(z,\overline{z})$.

Whereas $C_{p,q}|$ transforms homogeneously under conformal and $U(1)$-transformations, the (bosonic) space-time field $[D,\overline{D}]C_{p,q}|$ does not unless $p=0=q$. In fact, $[D,\overline{D}]C_{p,q}$ is not a superconformal field. The remedy to this problem consists of adding an appropriate term to the projection operator $[D,\overline{D}]$ which eliminates the unwanted contribution in the transformation law of $[D,\overline{D}]C_{p,q}|$—see section III C.

F. From $N=2$ to $N=1$ formalism

Since $N=2$ theories are often formulated in terms of $N=1$ superfields, we will outline how the latter are extracted from $N=2$ superfields.

A generic $N=2$ superfield (16) can be written in terms of the odd coordinates,

$$\theta_1=(\theta+\overline{\theta})/2, \quad \theta_2=(\theta-\overline{\theta})/2, \tag{19}$$

and the complex conjugate variables $\overline{\theta_1}=(\theta_1)^*, \overline{\theta_2}=(\theta_2)^*$ which give rise to the $N=1$ derivative

$$D_1\equiv\frac{\partial}{\partial\theta_1}+\theta_1\partial=D+\overline{D}, \quad (D_1)^2=\partial \quad \text{(and c.c.)}. \tag{20}$$

Indeed, one finds

$$C(z,\overline{z},\theta_1,\overline{\theta_1},\theta_2,\overline{\theta_2})=a+\theta_2\alpha+\overline{\theta_2}\beta+\theta_2\overline{\theta_2}b, \tag{21}$$

where $a,b(\alpha,\beta)$ represent even (odd) $N=1$ superfields depending on the variables $z,\overline{z},\theta_1,\overline{\theta_1}$.

III. DERIVATIVES, CONNECTIONS AND COVARIANT OPERATORS

Along the lines of the $N=1$ theory,[1] we now introduce the necessary ingredients for the construction and description of covariant operators.

A. Schwarzian derivative

The *super Schwarzian derivative*[7,1] associated to a superconformal change of coordinates $\mathbf{z}\to\mathbf{z}'(\mathbf{z})$ is defined by

$$\begin{aligned}-\mathcal{S}(\mathbf{z}',\mathbf{z})&=2e^{-(1/2)(w+\overline{w})}[D,\overline{D}]e^{(1/2)(w+\overline{w})}\\&=[D,\overline{D}](w+\overline{w})+D(w+\overline{w})\overline{D}(w+\overline{w})\\&=\partial(w-\overline{w})+(D\overline{w})(\overline{D}w)\\&=\frac{\partial\overline{D\theta'}}{\overline{D\theta'}}-\frac{\partial D\theta'}{D\theta'}+\frac{\partial\overline{\theta'}}{\overline{D\theta'}}\frac{\partial\theta'}{D\theta'}.\end{aligned} \tag{22}$$

It satisfies the ''chain rule,''

$$\mathcal{S}(\mathbf{z}'',\mathbf{z})=e^{-(w+\overline{w})}\mathcal{S}(\mathbf{z}'',\mathbf{z}')+\mathcal{S}(\mathbf{z}',\mathbf{z}). \tag{23}$$

From eqs. (22), (12), we can extract the bosonic component fields of $\mathcal{S}$:

$$\begin{aligned}\mathcal{S}(\mathbf{z}',\mathbf{z})|&=\partial k,\\[\mathcal{S}(\mathbf{z}',\mathbf{z})|&=S(z',z)+\tfrac{1}{2}(\partial k)^2.\end{aligned} \tag{24}$$

Here, $S(z',z)$ denotes the ordinary Schwarzian derivative (2): it represents the ''conformal part'' of $\mathcal{S}$ while ∂k represents its ''$U(1)$ part.''

B. Projective coordinates

A *superprojective (super Möbius) mapping* is a superconformal change of coordinates $\mathbf{Z}=(Z,\Theta,\overline{\Theta})\to\mathbf{Z}'(\mathbf{Z})$ satisfying $\mathcal{S}(\mathbf{Z}',\mathbf{Z})=0$. By virtue of (22), this condition is equivalent to the relation

$$(D_\Theta\Theta')(D_{\overline{\Theta}}\overline{\Theta}')=(cZ+d+\Theta\overline{\gamma}+\overline{\Theta}\gamma)^{-2}, \tag{25}$$

where c and d (γ and $\overline{\gamma}$) are Grassmann even (odd) constants. This condition can be solved so as to obtain the general expression of a superprojective mapping $\mathbf{Z}\to\mathbf{Z}'$: by taking into account the conditions $D_\Theta\overline{\Theta}'=0=D_{\overline{\Theta}}\Theta'$ and $D_\Theta Z'=\frac{1}{2}\overline{\Theta}'D_\Theta\Theta'$, $D_{\overline{\Theta}}Z'=\frac{1}{2}\Theta' D_{\overline{\Theta}}\overline{\Theta}'$, one finds

$$\begin{aligned}
\Theta'(\mathbf{Z})&=e^{+h}\left\{-2\frac{\alpha Z+\beta}{cZ+d}+\frac{\Theta}{cZ+d}\left[1+2\frac{\overline{\alpha}Z+\overline{\beta}}{cZ+d}\gamma\right]-\frac{\Theta\overline{\Theta}}{(cZ+d)^2}\gamma\right\},\\
\overline{\Theta}'(\mathbf{Z})&=e^{-\overline{h}}\left\{-2\frac{\overline{\alpha}Z+\overline{\beta}}{cZ+d}+\frac{\overline{\Theta}}{cZ+d}\left[1-2\frac{\alpha Z+\beta}{cZ+d}\overline{\gamma}\right]+\frac{\Theta\overline{\Theta}}{(cZ+d)^2}\overline{\gamma}\right\},\\
Z'(\mathbf{Z})&=\frac{aZ+b}{cZ+d}[1+2(\alpha\overline{\beta}+\overline{\alpha}\beta)+8\alpha\overline{\beta}\alpha\overline{\beta}]-\frac{\Theta(\overline{\alpha}Z+\overline{\beta})+\overline{\Theta}(\alpha Z+\beta)}{(cZ+d)^2}\\
&\quad\times[1+2(\alpha\overline{\beta}+\overline{\alpha}\beta)]+\Theta\overline{\Theta}\partial\left[\frac{\alpha Z+\beta}{cZ+d}\frac{\overline{\alpha}Z+\overline{\beta}}{cZ+d}\right].
\end{aligned} \tag{26}$$

Here $h,\overline{h},a,b$ ($\alpha,\beta,\overline{\alpha},\overline{\beta}$) are Grassmann even (odd) constants which satisfy the conditions

$$\begin{aligned}
\alpha d-\beta c=\gamma,\quad ad-bc=1,\\
\overline{\alpha}d-\overline{\beta}c=\overline{\gamma},\quad 2(\alpha\overline{\beta}+\overline{\alpha}\beta)=h-\overline{h}.
\end{aligned} \tag{27}$$

The lowest order component of Z' represents an ordinary projective transformation: $Z'|=(aZ|+b)(cZ|+d)^{-1}$.

A *superprojective structure* is an atlas of local coordinates for which all changes of charts $\mathbf{Z}\to\mathbf{Z}'$ are superprojective mappings.

A *quasi-primary superfield* $\mathcal{C}_{p,q}(\mathbf{Z},\overline{\mathbf{Z}})$ of superconformal weight (p,q) transforms according to the rule

$$\mathcal{C}'_{p,q}(\mathbf{Z}',\overline{\mathbf{Z}}')=(cZ+d+\Theta\overline{\gamma}+\overline{\Theta}\gamma)^{p+q}e^{-(p-q)H}\mathcal{C}_{p,q}(\mathbf{Z},\overline{\mathbf{Z}}), \tag{28}$$

with

$$H(\mathbf{Z})=h+\frac{1}{cZ+d}\left[2(\overline{\alpha}Z+\overline{\beta})+\Theta\overline{\gamma}-\overline{\Theta}\gamma+\frac{1}{2}\Theta\overline{\Theta}c\right]$$

under a superprojective change of coordinates $\mathbf{Z}\to\mathbf{Z}'$.

C. Projective connection

A *superprojective (super Schwarzian) connection* is a collection $\mathcal{R}\equiv\mathcal{R}_{\theta\overline{\theta}}$ of superfields (one for each coordinate patch) which are locally superanalytic (i.e., $D_-\mathcal{R}=0=\overline{D}_-\mathcal{R}$) and which transform under a superconformal change of coordinates according to

$$\mathcal{R}'(\mathbf{z}')=e^{w+\overline{w}}[\mathcal{R}(\mathbf{z})-\mathcal{S}(\mathbf{z}',\mathbf{z})]. \tag{29}$$

The existence of such connections on compact SRS's of arbitrary genus can be proven along the lines of the $N=0$ and $N=1$ theories.[1]

If $\mathbf{Z}$ belongs to a projective atlas, then the super Schwarzian derivative of the superconformal mapping $\mathbf{z}\to\mathbf{Z}$ represents a projective connection,

$$\mathcal{R}(\mathbf{z})=\mathcal{S}(\mathbf{Z},\mathbf{z}). \tag{30}$$

In fact, eq. (23) then implies the transformation law (29) and it ensures that the expression (30) is inert under a projective change of coordinates $\mathbf{Z}\to\mathbf{Z}'$. The relation (30) establishes the equivalence between projective structures and projective connections.

The superfield $\mathcal{R}$ admits the θ-expansion

$$\mathcal{R}_{\theta\bar{\theta}}(\mathbf{z})=\rho_z+\theta\eta_{\theta z}+\overline{\theta\eta_{\bar{\theta}z}}+\theta\bar{\theta}[-\tfrac{1}{2}r_{zz}].$$

The component fields $\rho=\mathcal{R}|,\ldots,r=[D,\bar{D}]\mathcal{R}|$ are locally holomorphic ($0=\bar{\partial}\rho=\cdots=\bar{\partial}r$) and the bosonic components have the transformation laws

$$\begin{aligned}\rho'&=(\partial z')^{-1}[\rho-\partial k],\\ r'&=(\partial z')^{-2}[r-S-(\rho-\tfrac{1}{2}\partial k)\partial k].\end{aligned} \tag{31}$$

From these equations, we conclude that the quantity $R=r-\frac{1}{2}\rho^2$ transforms like (2), i.e., like an ordinary projective connection while ρ represents a $U(1)$-connection.

Using a superprojective connection, we can define the second order operator

$$\mathcal{D}_{p,q}=p\bar{D}D-qD\bar{D}+pq\mathcal{R}, \tag{32}$$

which projects out an ordinary conformal field from the superconformal field $C_{p,q}$:

$$(\mathcal{D}_{p,q}C_{p,q})'|=e^{-(k/2)(p-q)}(\partial z')^{-(1/2)(p+q+2)}(\mathcal{D}_{p,q}C_{p,q})|.$$

D. Affine connection, covariant derivative and Miura transformation

A *superaffine connection* is a collection $B\equiv B_\theta,\bar{B}\equiv\bar{B}_{\bar{\theta}}$ of superfields (one for each coordinate patch) which are locally superanalytic, which satisfy the chirality conditions $DB=0=\overline{DB}$ and which transform under a superconformal change of coordinates according to

$$\begin{aligned}B'(\mathbf{z}')&=e^{w}[B(\mathbf{z})+D\bar{w}],\\ \bar{B}'(\mathbf{z}')&=e^{\bar{w}}[\bar{B}(\mathbf{z})+\bar{D}w].\end{aligned} \tag{33}$$

The only compact SRS's which admit a globally defined affine connection are those of genus one.[1] Nevertheless, these quantities can always be introduced locally and they represent extremely useful computational tools for deriving globally well-defined results.

Using an affine connection we can introduce *supercovariant derivatives*,

$$\begin{aligned}\nabla_{p,q}&=D-qB:\mathcal{F}_{p,q}\to\mathcal{F}_{p+1,q},\\ \bar{\nabla}_{p,q}&=\bar{D}-p\bar{B}:\mathcal{F}_{p,q}\to\mathcal{F}_{p,q+1}.\end{aligned} \tag{34}$$

Products of covariant derivatives are defined by taking into account the weights, e.g.,

$$\nabla\bar{\nabla}\nabla C_{p,q}=\nabla_{p+1,q+1}\bar{\nabla}_{p+1,q}\nabla_{p,q}C_{p,q}.$$

From the very definitions, it then follows that

$$\nabla^2=0=\bar{\nabla}^2. \tag{35}$$

Locally, we can express B and $\bar{B}$ as

$$B=DQ, \quad \overline{B}=\overline{D}Q, \tag{36}$$

with

$$Q=\ln(D\Theta\overline{D}\overline{\Theta})=\ln\Big(\partial Z+\tfrac{1}{2}\,\Theta\partial\overline{\Theta}+\tfrac{1}{2}\,\overline{\Theta}\partial\Theta\Big), \tag{37}$$

where Θ and $\overline{\Theta}$ belong to an atlas of superprojective coordinates $\mathbf{Z}$. Then, we have the operatorial expressions

$$\begin{aligned}\nabla_{p,q}&=(\overline{D}\overline{\Theta})^q\cdot D\cdot(\overline{D}\overline{\Theta})^{-q},\\ \overline{\nabla}_{p,q}&=(D\Theta)^p\cdot\overline{D}\cdot(D\Theta)^{-p}.\end{aligned} \tag{38}$$

Affine and projective connections are related by the *super Miura transformation*,

$$\mathcal{R}=D\overline{B}-\overline{D}B-B\overline{B}=[D,\overline{D}]Q-(DQ)(\overline{D}Q). \tag{39}$$

This formula follows from the expression of the projective connection in terms of the Schwarzian derivative [eq. (30)] or, equivalently, by comparing the expressions equations (53) and (52) below for the conformally covariant operator $\mathcal{L}_1$.

From eq. (39) we can determine explicit expressions for the component fields $[D,\overline{D}]\mathcal{R}|=r=R+\frac{1}{2}\rho^2$ and $\mathcal{R}|=\rho$. In fact, by taking into account (37), one recovers the ordinary Miura transformation for the projective connection R and an explicit expression for ρ:

$$\begin{aligned}R&=\partial^2\,\ln\,\partial Z|-\tfrac{1}{2}(\partial\,\ln\,\partial Z|)^2,\\ \rho&=([D,\overline{D}]\ln\,\partial Z)|.\end{aligned} \tag{40}$$

Furthermore, from eqs. (36) and (37), we conclude that

$$\begin{aligned}b\equiv\overline{D}B|&=\tfrac{1}{2}(\partial\,\ln\,\partial Z|-\rho),\\ \overline{b}\equiv D\overline{B}|&=\tfrac{1}{2}(\partial\,\ln\,\partial Z|+\rho).\end{aligned} \tag{41}$$

From these expressions, we obtain the *conformally and $U(1)$-covariant space-time derivative*,

$$\{\nabla,\overline{\nabla}\}C_{p,q}|=\left[\tilde{\partial}_{p,q}-\frac{p+q}{2}(\partial\,\ln\,\partial Z|)\right]c_{p,q},\ \text{ with }\quad \tilde{\partial}_{p,q}\equiv\partial-\frac{p-q}{2}\rho. \tag{42}$$

Here, $\tilde{\partial}_{p,q}$ denotes the $U(1)$-covariant derivative associated to the $U(1)$-connection ρ [cf. eq. (31)] and the local expression $\partial\,\ln\,\partial Z|$ transforms like an affine connection with respect to a conformal change of coordinates $z\to z'(z)$.[1]

E. Determination of conformally covariant operators

We are interested in superconformally covariant differential operators which are globally defined on compact SRS's of any genus. In order to construct these quantities, we start from an operator $\mathcal{L}$ which is a differential polynomial in the covariant derivatives $\nabla,\overline{\nabla}$ and require that it only depends on the affine connections $B,\overline{B}$ through the particular combination $\mathcal{R}=D\overline{B}-\overline{D}B-B\overline{B}$ (which is globally defined): using a variational argument,[8,2] one imposes $\delta\mathcal{L}=0$ while varying $B,\overline{B}$ subject to the condition that $\mathcal{R}$ is fixed,

$$0=\delta\mathcal{R}=D\,\delta\overline{B}-\overline{D}\,\delta B-\delta B\overline{B}-B\,\delta\overline{B}.$$

The latter relation can be rewritten as

$$\nabla\delta\overline{B}=\overline{\nabla}\delta B, \tag{43}$$

and the nilpotency of $\nabla,\overline{\nabla}$ then yields

$$\overline{\nabla}\nabla\delta\overline{B}=0=\nabla\overline{\nabla}\delta B, \tag{44}$$

while the chirality properties of $B,\overline{B}$ imply

$$\nabla\delta B=0=\overline{\nabla}\delta\overline{B}. \tag{45}$$

There are two basic classes of covariant differential operators: besides the super Bol operators (which only depend on a projective structure or equivalently on a projective connection), one can introduce operators which also depend linearly on a conformal field. These two classes will be determined in sections IV and V, respectively, and at the end of section V, we will show that the most general covariant operator can be written as a sum of these.

IV. SUPER BOL OPERATORS

We successively discuss the cases where the differential operator $\mathcal{L}$ contains an even and odd number of derivatives $\nabla,\overline{\nabla}$. All operators discussed in this section are supposed to be *normalized* in the sense that the coefficients of the highest order derivatives are constant.

A. Even number of derivatives

The general form of a normalized covariant operator involving an even number of derivatives is

$$\mathcal{L}_n^{even}=\alpha(\nabla\overline{\nabla})^n+\beta(\overline{\nabla}\nabla)^n \quad [n\in\mathbf{N}^*,(\alpha,\beta)\neq(0,0)], \tag{46}$$

and such that

$$\mathcal{L}_n^{even}:\mathcal{F}_{p,q}\to\mathcal{F}_{p+n,q+n}, \quad \text{for some } (p,q). \tag{47}$$

Thus, the operator does not modify the $U(1)$ charge of the fields. In order to simplify the notation, we do not spell out the dependence of $\mathcal{L}$ on p and q.

Imposing $\delta\mathcal{L}_n^{even}=0$ and using eqs. (43)–(45), one finds that p,q and n are related: the general solution reads as

$$\begin{aligned}\mathcal{L}_n^{even}&=q(\nabla\overline{\nabla})^n-p(\overline{\nabla}\nabla)^n, \quad \text{with } p+q=-n,\\ &=\{\nabla,\overline{\nabla}\}^{n-1}(q\nabla\overline{\nabla}-p\overline{\nabla}\nabla).\end{aligned} \tag{48}$$

Here and in the following, the constant overall factor of $\mathcal{L}$ has been chosen in a convenient way. For $n=1$ and $n=2$, we have the explicit expressions

$$\begin{aligned}\mathcal{L}_1^{even}&=qD\overline{D}-p\overline{D}D-pq\mathcal{R}, \quad \text{with } p+q=-1,\\ &=\frac{p+q}{2}\mathcal{L}_1^{sym}-\frac{p-q}{2}\left(\partial-\frac{p-q}{2}\mathcal{R}\right),\end{aligned}$$

$$\mathcal{L}_2^{even}=\frac{p+q}{2}\mathcal{L}_2^{sym}-\frac{p-q}{2}\Big(\partial^2-\mathcal{R}[D,\overline{D}]-2\frac{p-q}{2}\mathcal{R}\partial+(\overline{D}\mathcal{R})D$$
$$-(D\mathcal{R})\overline{D}-\frac{p-q}{2}\partial\mathcal{R}-pq\mathcal{R}^2\Big),\quad \text{with}\quad p+q=-2, \tag{49}$$

where $\mathcal{L}_1^{sym}$ and $\mathcal{L}_2^{sym}$ denote the symmetric solution ($p=q$); see eq. (53) below. Thus, the covariant operator $\mathcal{L}_n^{even}$ has a conformal part (a multiple of $\mathcal{L}_n^{sym}$) and a $U(1)$ part, each of which is proportional to the corresponding weight.

Projection to components is achieved by virtue of the operator $\mathcal{D}_{p,q}$ introduced in eq. (32):

$$(\mathcal{D}_{p+n,q+n}\mathcal{L}_n^{even}C_{p,q})|=pqL_{n+1}^{p,q}c_{p,q}\,. \tag{50}$$

Here, $L_n^{p,q}$ denotes the *generalization of the usual Bol operator* L_n (depending on the ordinary projective connection $R=r-\frac{1}{2}\rho^2$) *to charged conformal fields*: it amounts to replacing the ordinary partial derivative (acting on $c_{p,q}$) by the $U(1)$-covariant derivative $\tilde{\partial}_{p,q}$ introduced in eq. (42), e.g.,

$$L_2^{p,q}=\tilde{\partial}_{p,q}^2+\tfrac{1}{2}R,\quad \text{with}\ \ p+q=-1\,,$$
$$L_3^{p,q}=\tilde{\partial}_{p,q}^3+2R\tilde{\partial}_{p,q}+(\partial R),\quad \text{with}\ \ p+q=-2. \tag{51}$$

Obviously, the general solution (48) involves two different classes of solutions: the *symmetric solution* ($p=q$) for which the operator acts on neutral fields and the *asymmetric solutions* ($p\neq q$) among which we find as particular cases the *chiral* ($p=0$) and *anti-chiral* ($q=0$) *solutions*.

1. Symmetric solution

The symmetric solution $\mathcal{L}_n^{sym}:\mathcal{F}_{-n/2,-n/2}\to\mathcal{F}_{n/2,n/2}$ has the general form

$$\mathcal{L}_n^{sym}=(\nabla\overline{\nabla})^n-(\overline{\nabla}\nabla)^n=\partial^{n-1}[D,\overline{D}]+\frac{n}{2}\mathcal{R}\partial^{n-1}+\cdots, \tag{52}$$

and the simplest examples are

$$\mathcal{L}_1^{sym}=[D,\overline{D}]+\tfrac{1}{2}\mathcal{R},$$
$$\mathcal{L}_2^{sym}=\partial[D,\overline{D}]+\mathcal{R}\partial-(D\mathcal{R})\overline{D}-(\overline{D}\mathcal{R})D+(\partial\mathcal{R}), \tag{53}$$
$$\mathcal{L}_3^{sym}=\partial^2[D,\overline{D}]+\tfrac{3}{2}\mathcal{R}\partial^2-3(D\mathcal{R})\partial\overline{D}-3(\overline{D}\mathcal{R})\partial D+3(\partial\mathcal{R})\partial+(\tfrac{1}{2}[D,\overline{D}]\mathcal{R}-\tfrac{1}{4}\mathcal{R}^2)[D,\overline{D}]$$
$$-(2\partial D\mathcal{R}+\tfrac{1}{4}D\mathcal{R}^2)\overline{D}-(2\partial\overline{D}\mathcal{R}-\tfrac{1}{4}\overline{D}\mathcal{R}^2)D$$
$$+\tfrac{3}{2}(\partial^2\mathcal{R}+\tfrac{1}{2}\mathcal{R}[D,\overline{D}]\mathcal{R}-\tfrac{1}{4}\mathcal{R}^3-2(D\mathcal{R})(\overline{D}\mathcal{R})),$$

$$\mathcal{L}_4^{sym}=\partial^3[D,\overline{D}]+2\mathcal{R}\partial^3-6(\overline{D}\mathcal{R})\partial^2 D-6(D\mathcal{R})\partial^2\overline{D}+6\partial\mathcal{R}\partial^2+(2([D,\overline{D}]\mathcal{R})-\mathcal{R}^2)\partial[D,\overline{D}]$$
$$-(8\partial\overline{D}\mathcal{R}-2\mathcal{R}\overline{D}\mathcal{R})\partial D-(8\partial D\mathcal{R}+2\mathcal{R}D\mathcal{R})\partial\overline{D}+(6\partial^2\mathcal{R}+4\mathcal{R}[D,\overline{D}]\mathcal{R}-15D\mathcal{R}\overline{D}\mathcal{R}$$
$$-2\mathcal{R}^3)\partial+(\partial[D,\overline{D}]\mathcal{R}-\mathcal{R}\partial\mathcal{R})[D,\overline{D}]-(3\partial^2\overline{D}\mathcal{R}-\mathcal{R}\partial\overline{D}\mathcal{R}-\tfrac{3}{2}\overline{D}\mathcal{R}\partial\mathcal{R}+\tfrac{9}{2}\overline{D}\mathcal{R}[D,\overline{D}]\mathcal{R}$$
$$-2\mathcal{R}^2\overline{D}\mathcal{R})D-(3\partial^2 D\mathcal{R}+\mathcal{R}\partial D\mathcal{R}+\tfrac{3}{2}D\mathcal{R}\partial\mathcal{R}+\tfrac{9}{2}D\mathcal{R}[D,\overline{D}]\mathcal{R}-2\mathcal{R}^2 D\mathcal{R})\overline{D}$$
$$+2\mathcal{R}\partial[D,\overline{D}]\mathcal{R}-10D\mathcal{R}\partial\overline{D}\mathcal{R}+10\overline{D}\mathcal{R}\partial D\mathcal{R}+4\partial\mathcal{R}[D,\overline{D}]\mathcal{R}-4\mathcal{R}^2\partial\mathcal{R}+2\partial^3\mathcal{R},$$

where the derivatives only act on the field to their immediate right. Note that the result for $\mathcal{L}_1^{sym}$ is nothing but the Miura transformation (39). The operator $\mathcal{L}_n^{sym}$ has the hermiticity property

$$\int dzd\theta d\overline{\theta} f\mathcal{L}_n^{sym}g=(-1)^{n+1}\int dzd\theta d\overline{\theta}(\mathcal{L}_n^{sym}f)g, \quad \text{for } f,g\in\mathcal{F}_{-n/2,-n/2}.$$

The operators (53) play the role of Poisson (Hamiltonian) operators in the description of super-integrable models—see section VII.

2. Chiral and anti-chiral solutions

The anti-chiral ($q=0$) and chiral ($p=0$) solutions read as

$$\mathcal{L}_n^{anti}=(\overline{\nabla}\overline{\nabla})^n=\overline{D}(\nabla\overline{\nabla})^{n-1}D:\mathcal{F}_{-n,0}\to\mathcal{F}_{0,n}^a,$$
$$\mathcal{L}_n^{chir}=(\nabla\overline{\nabla})^n=D(\overline{\nabla}\overline{\nabla})^{n-1}\overline{D}:\mathcal{F}_{0,-n}\to\mathcal{F}_{n,0}^c. \tag{54}$$

For these operators, the target spaces are the anti-chiral and chiral subspaces, respectively, since $\overline{D}\mathcal{L}_n^{anti}=0$ and $D\mathcal{L}_n^{chir}=0$. Both classes of operators are related by Hermitian conjugation:

$$\int dzd\theta d\overline{\theta} f\mathcal{L}_n^{chir}g=\int dzd\theta d\overline{\theta}(\mathcal{L}_n^{anti}f)g, \quad \text{for } f\in\mathcal{F}_{-n,0}, g\in\mathcal{F}_{0,-n}.$$

Differential operators of this type have been introduced in reference 9: they occur as Lax operators in the $N=2$ supersymmetric KdV and KP hierarchies[10,9,11] —see section V.

Since q and p vanish for $\mathcal{L}_n^{anti}$ and $\mathcal{L}_n^{chir}$, respectively, the r.h.s. of eq. (50) vanishes for both of these operators: we will discuss their relation with ordinary Bol operators in the next section.

B. Sandwich operators

Before considering operators involving an odd number of derivatives, it is worthwhile to have another look at the chiral and anti-chiral solutions.

The anti-chiral solution (54) has the form

$$\mathcal{L}_n^{anti}C_{-n,0}=\overline{D}(\nabla\overline{\nabla})^{n-1}DC_{-n,0}\equiv\overline{D}\mathcal{K}_{n-1}DC_{-n,0}, \tag{55}$$

where $\mathcal{K}_n$ will be referred to as a ''*sandwich operator*'' for obvious reasons. Since $DC_{-n,0}\equiv\Phi_{-n+1,0}$ represents a chiral field, we have obtained a new conformally covariant operator,

$$\overline{D}\mathcal{K}_{n-1}=\overline{D}(\nabla\overline{\nabla})^{n-1}:\mathcal{F}_{-n+1,0}^c\to\mathcal{F}_{0,n}^a. \tag{56}$$

Although $\mathcal{K}_{n-1}$ formally coincides with $\mathcal{L}_{n-1}^{chir}=(\nabla\overline{\nabla})^{n-1}$, it does not represent the same operator, because it does not act on the same space. We have the operatorial relations

$$\overline{D}\mathcal{K}_1=\overline{D}[D\overline{D}+\mathcal{R}]=\overline{D}[\partial+\mathcal{R}],$$
$$\overline{D}\mathcal{K}_2=\overline{D}[\partial^2+3\mathcal{R}\partial+(\overline{D}D\mathcal{R})+2(D\overline{D}\mathcal{R})+2\mathcal{R}^2]. \tag{57}$$

Note that the operator $\mathcal{K}_n$ can be written in different forms since it is only defined as ''sandwiched'' between $\overline{D}$ and D.

The projection to component field expressions is simply done by applying D to $\overline{D}\mathcal{K}_n$:

$$(D\overline{D}\mathcal{K}_n C)|=L_{n+1}^{-n,0}c, \quad \text{for } C\in\mathcal{F}^c_{-n,0}. \tag{58}$$

Here, $C|=c$ and $L_n^{p,q}$ denotes the generalization of the Bol operator L_n to charged conformal fields; see eq. (51). This shows that $\mathcal{L}_n^{anti}$ also represents a supersymmetric generalization of the Bol operators, though the latter have to be projected out according to the procedure (58) rather than (50).

Of course, one can apply the same line of reasoning to the chiral solution for which

$$\mathcal{L}_n^{chir}C_{0,-n}=D(\overline{\nabla}\nabla)^{n-1}\overline{D}C_{0,-n}\equiv D\overline{\mathcal{K}}_{n-1}\overline{D}C_{0,-n} \tag{59}$$

and

$$D\overline{\mathcal{K}}_{n-1}:\mathcal{F}^a_{0,-n+1}\to\mathcal{F}^c_{n,0}. \tag{60}$$

C. Odd number of derivatives

The general form of a normalized covariant operator involving an odd number of derivatives is

$$\mathcal{L}_n^{odd}=\overline{\nabla}(\nabla\overline{\nabla})^n,$$

or

$$\overline{\mathcal{L}}_n^{odd}=\nabla(\overline{\nabla}\nabla)^n, \quad \text{with } n=0,1,2,\ldots, \tag{61}$$

acting on $\mathcal{F}_{p,q}$. These operators modify the $U(1)$ charge of the fields.

For $n=0$, the condition of covariance $\delta\mathcal{L}_n=0$ leads to the explicit results

$$\begin{aligned}\mathcal{L}_0^{odd}C_{0,q}&=\overline{\nabla}C_{0,q}=\overline{D}C_{0,q}\\ \overline{\mathcal{L}}_0^{odd}C_{p,0}&=\nabla C_{p,0}=DC_{p,0}.\end{aligned} \tag{62}$$

For $n\geqslant 1$, we find

$$\mathcal{L}_n^{odd}=\overline{D}(\nabla\overline{\nabla})^n:\{C\in\mathcal{F}_{-n,0}/\mathcal{L}_n^{anti}C=0\}\to\mathcal{F}^{\,a}_{0,n+1}, \tag{63}$$

the simplest examples being

$$\begin{aligned}\mathcal{L}_1^{odd}C_{-1,0}&=\overline{D}[\partial+\mathcal{R}]C_{-1,0},\\ \mathcal{L}_2^{odd}C_{-2,0}&=\overline{D}[\partial^2+3\mathcal{R}\partial-(\overline{D}\mathcal{R})D+(\overline{D}D\mathcal{R})+2(D\overline{D}\mathcal{R})+2\mathcal{R}^2]C_{-2,0},\end{aligned} \tag{64}$$

with

$$\begin{aligned}0&=\mathcal{L}_1^{anti}C_{-1,0}=\overline{D}DC_{-1,0},\\ 0&=\mathcal{L}_2^{anti}C_{-2,0}=\overline{D}[\partial+\mathcal{R}]DC_{-2,0}.\end{aligned} \tag{65}$$

If $C_{-n,0}$ is a chiral field, it automatically satisfies $\mathcal{L}_n^{anti}C_{-n,0}=0$, henceforth

$$\mathcal{F}^{\,c}_{-n,0}\subset\{C\in\mathcal{F}_{-n,0}/\mathcal{L}_n^{anti}C=0\}.$$

By comparing eqs. (56) and (63), we conclude that $\mathcal{L}_n^{odd}=\overline{D}(\nabla\overline{\nabla})^n$ is an extension (in the functional analytic sense[12]) of the operator $\overline{D}\mathcal{K}_n=\overline{D}(\nabla\overline{\nabla})^n$: both operators differ by their domain of definition and act in the same way on the smaller domain, i.e., on $\mathcal{F}^{\,c}_{-n,0}$. The Bol operator $L^{-n,0}_{n+1}$ acting on $c=C|$ is extracted in the same manner from $\mathcal{L}_n^{odd}C$ and $\overline{D}\mathcal{K}_nC$, i.e., according to eq. (58).

D. Comments

1. Super Bol operators in projective coordinates

The Bol operator L_n is most directly obtained from the Möbius covariant operator ∂_Z^n (acting on quasi-primary fields of appropriate weight) by going over from the projective coordinates Z to a generic system of conformal coordinates z by a conformal transformation (see Ref. 1 and references therein). Proceeding in the same way in the $N=2$ supersymmetric case, we start from the differential operator $\partial_Z^{n-1}[D_\Theta,D_{\overline{\Theta}}]=(D_\Theta D_{\overline{\Theta}})^n-(D_{\overline{\Theta}}D_\Theta)^n$ which transforms homogeneously under a superprojective change of coordinates $\mathbf{Z}\to\mathbf{Z}'$ when acting on quasi-primary fields of appropriate weight [see eq. (28)]:

$$(\partial_Z^{n-1}[D_\Theta,D_{\overline{\Theta}}]\mathcal{C}_{-n/2,-n/2})'=(cZ+d+\Theta\overline{\gamma}+\overline{\Theta}\gamma)^n\partial_Z^{n-1}[D_\Theta,D_{\overline{\Theta}}]\mathcal{C}_{-n/2,-n/2}. \tag{66}$$

By passing over from the projective coordinates $\mathbf{Z}$ to generic conformal coordinates $\mathbf{z}$ by a superconformal transformation, the operator $\partial_Z^{n-1}[D_\Theta,D_{\overline{\Theta}}]$ becomes the super Bol operator $\mathcal{L}_n^{sym}$: we have

$$\partial_Z^{n-1}[D_\Theta,D_{\overline{\Theta}}]\mathcal{C}_{-n/2,-n/2}\equiv(D\Theta\overline{D}\overline{\Theta})^{-n/2}\mathcal{L}_n^{sym}C_{-n/2,-n/2}, \tag{67}$$

where $\mathcal{C}$ and C are related by

$$\mathcal{C}_{-n/2,-n/2}(\mathbf{Z},\overline{\mathbf{Z}})\equiv(D\Theta\overline{D}\overline{\Theta})^{n/2}C_{-n/2,-n/2}(\mathbf{z},\overline{\mathbf{z}}). \tag{68}$$

In operatorial form, eq (67) reads as

$$\mathcal{L}_n^{sym}=(D\Theta\overline{D}\overline{\Theta})^{n/2}\cdot\partial_Z^{n-1}[D_\Theta,D_{\overline{\Theta}}]\cdot(D\Theta\overline{D}\overline{\Theta})^{n/2}, \tag{69}$$

which means that $\mathcal{L}_n^{sym}$ represents the superconformally covariant version of the differential operator $\partial^{n-1}[D,\overline{D}]$ acting on $U(1)$-neutral superfields.

The same line of arguments applies to the sandwich operator $\mathcal{K}_n$ acting on chiral fields. In fact, $DC_{-n,0}=0$ is equivalent to $D_\Theta\mathcal{C}_{-n,0}=0$ where $\mathcal{C}_{-n,0}\equiv(D\Theta)^nC_{-n,0}$ and for such fields one has

$$D_{\overline{\Theta}}\partial_Z^n\mathcal{C}_{-n,0}=(\overline{D\Theta})^{-(n+1)}\overline{D}\mathcal{K}_nC_{-n,0}. \tag{70}$$

2. Recursion and factorization relations

The super Bol operators can be determined by using a *recursion relation*,[1] e.g., if $\psi\in\mathcal{F}_{-1/2,-1/2}$ is assumed to be Grassmann even, then

$$\mathcal{L}_1^{sym}\psi=0\Rightarrow\mathcal{L}_n^{sym}\psi^n=0. \tag{71}$$

Thus, one can determine the explicit form of $\mathcal{L}_2^{sym}$ by applying $\partial[D,\overline{D}]$ to ψ^2 while using $\mathcal{L}_1^{sym}\psi=0$ (i.e., $[D,\overline{D}]\psi=-\frac{1}{2}\mathcal{R}\psi$) and so on for $\mathcal{L}_3^{sym},\ldots$. The proof of (71) consists of going over to superprojective coordinates.

The operators $\overline{D}\mathcal{K}_n$ can be determined in the same way: if $\psi\in\mathcal{F}^{c}_{-1,0}$ is Grassmann even, then

$$\overline{D}\mathcal{K}_1\psi=0\Rightarrow\overline{D}\mathcal{K}_n\psi^n=0. \tag{72}$$

If the super Bol operators are defined by virtue of Möbius covariant operators as in eq. (69), their expressions in terms of covariant derivatives [eq. (52)] represent *factorization formulae*. The latter may then be proven by going over to projective coordinates for which ∇ and $\overline{\nabla}$ reduce to D_Θ and $D_{\bar{\Theta}}$, respectively.[1]

3. From N=2 to N=1 operators

An $N=2$ superfield F can be projected to an $N=1$ superfield $F|_{N=1}$ by evaluating it at $\theta=\overline{\theta},\theta^-=\overline{\theta^-}$. By virtue of this projection, one finds that the quantity $\mathcal{R}_1\equiv\frac{1}{2}(D-\overline{D})\mathcal{R}|_{N=1}$ transforms like an $N=1$ superprojective connection, i.e., according to $\mathcal{R}_1'=e^{3W}(\mathcal{R}_1-\mathcal{S}_1)$ where $W\equiv w|_{N=1}=\overline{w}|_{N=1}$ and where $\mathcal{S}_1\equiv\mathcal{S}|_{N=1}$ denotes the $N=1$ super Schwarzian derivative.

Since sandwich operators act on chiral fields C, we have $\overline{D}C=(D+\overline{D})C\equiv D_1C$ where $D_1=D+\overline{D}$ denotes the basic $N=1$ derivative introduced in section II F. For the simplest sandwich operator, we thus obtain the expression

$$(\overline{D}\mathcal{K}_1C)|_{N=1}=([D_1^3+(\overline{D}\mathcal{R})+\mathcal{R}D_1]C)|_{N=1},$$

which represents a $U(1)$-covariant version of the $N=1$ super Bol operator $D_1^3+\mathcal{R}_1$.

V. COVARIANT OPERATORS INVOLVING CONFORMAL FIELDS

In this section, we introduce covariant operators $\mathcal{M}^{(n)}_{\mathcal{W}_{p,q}}$ which depend on a projective connection $\mathcal{R}$ and, in a linear way, on a superconformal field $\mathcal{W}_{p,q}$. We restrict our attention to the case of sandwich operators since these are the only ones for which we will be able to give a matrix representation.

Thus, we try to construct a covariant operator which acts between the same spaces as $\mathcal{K}_n$ [cf. eq. (56)]:

$$\overline{D}\mathcal{M}^{(n)}_{\mathcal{W}_{p,q}}:\mathcal{F}^{\ c}_{-n,0}\rightarrow\mathcal{F}^{\ a}_{0,n+1}.$$

To do so, we proceed as before and first write $\mathcal{M}^{(n)}_{\mathcal{W}_{p,q}}$ as a differential polynomial in the nilpotent operators ∇ and $\overline{\nabla}$. It turns out that a covariant operator can only be obtained in the case of neutral superfields $\mathcal{W}_{k,k}$ of conformal weight $k\in\mathbf{N}$ with $1\leqslant k\leqslant n$: the corresponding operator reads as

$$\mathcal{M}^{(n)}_{\mathcal{W}_{k,k}}=\sum_{l=0}^{n-k}\{a^{(n)}_{kl}[(\nabla\overline{\nabla})^l\mathcal{W}_{k,k}]+b^{(n)}_{kl}[(\overline{\nabla}\nabla)^l\mathcal{W}_{k,k}]\}(\nabla\overline{\nabla})^{n-k-l},\tag{73}$$

with constant coefficients $a^{(n)}_{kl}$ and $b^{(n)}_{kl}$ (with $l=0,...,k$) to be determined by imposing the condition $\delta\overline{D}\mathcal{M}^{(n)}_{\mathcal{W}_{k,k}}=0$ and using eqs. (43)–(45). This leads to the following result (which is unique up to a global factor):

$$a^{(n)}_{kl}=\frac{\binom{n-k}{l}\binom{k+l}{l}}{\binom{2k+l}{l}}\quad,\qquad b^{(n)}_{kl}=\frac{\binom{n-k}{l}\binom{k+l-1}{l}}{\binom{2k+l}{l}},\tag{74}$$

for $l=1,\ldots,n-k$ and $a^{(n)}_{k0}+b^{(n)}_{k0}=1$. For instance,

$$\mathcal{M}^{(n)}_{\mathcal{W}_{n,n}}=\mathcal{W}_{n,n}$$

$$\mathcal{M}^{(n)}_{\mathcal{W}_{n-1,n-1}}=\mathcal{W}_{n-1,n-1}\partial+\frac{n-1}{2n-1}(D\mathcal{W}_{n-1,n-1})\overline{D}+\frac{n}{2n-1}(D\overline{D}\mathcal{W}_{n-1,n-1})$$
$$+\frac{n^2}{2n-1}\mathcal{R}\mathcal{W}_{n-1,n-1},\tag{75}$$

where we recall that sandwich operators can be cast into different forms since they are only defined as sandwiched between $\overline{D}$ and D. Component field results are recovered by applying the derivative D and subsequently projecting to the lowest component:

$$(D\overline{D}\mathcal{M}^{(n)}_{\mathcal{W}_{k,k}}C_{-n,0})|=\left[\widetilde{M}^{(n+1)}_{w_k}-\frac{n+k+1}{2k(2k+1)}\,\widetilde{M}^{(n+1)}_{v_{k+1}}\right]c_{-n,0}, \tag{76}$$

with $w_k=\mathcal{W}_{k,k}|$ and $v_{k+1}=(\mathcal{D}_{k,k}\mathcal{W}_{k,k})|$ where $\mathcal{D}_{k,k}$ denotes the second order operator (32). Here, $\widetilde{M}^{(n)}_{w_k}$ is the $U(1)$-covariant generalization of the operator $M^{(n)}_{w_k}$ mentioned in the Introduction—see eq. (3).

The *most general* normalized superconformally covariant sandwich operator of order n has the form

$$\begin{aligned}&\mathcal{L}^{(n)}:\mathcal{F}^{\ c}_{-n,0}\to\mathcal{F}^{\ a}_{0,n+1},\\ &C_{-n,0}\mapsto\mathcal{L}^{(n)}C_{-n,0}=\overline{D}[\partial^n+a^{(n)}_1\partial^{n-1}+a^{(n)}_2\partial^{n-2}+\ldots+a^{(n)}_n]C_{-n,0},\end{aligned} \tag{77}$$

with even coefficient functions $a^{(n)}_k(\mathbf{z})$ transforming in an appropriate way under superconformal changes of coordinates—see Refs. 2,1 and 3 for the $N=0$ and $N=1$ supersymmetric theories, respectively. It can be expressed as a sum of the previously introduced operators,

$$\mathcal{L}^{(n)}=\overline{D}\left[\mathcal{K}_n+\sum_{k=2}^{n}\mathcal{M}^{(n)}_{\mathcal{W}_{k,k}}\right]=\overline{D}\left[\partial^n+\frac{n(n+1)}{2}\,\mathcal{R}\partial^{n-1}+\ldots\right], \tag{78}$$

i.e., it can be parametrized in terms of a projective connection $\mathcal{R}$ and $n-1$ neutral superconformal fields $\mathcal{W}_{2,2},\ldots,\mathcal{W}_{n,n}$. The relation between these fields and the coefficients $a^{(n)}_k$ is invertible and given by differential polynomials.

Operators of the form (77) with $C_{-n,0}=D\Phi$ occur as Lax operators, e.g., $\mathcal{L}^{(1)}$ and $\mathcal{L}^{(2)}$ give rise to the $N=2$ super KdV and Boussinesq equations, respectively.[9,11]

VI. MATRIX REPRESENTATION OF COVARIANT OPERATORS

In this section, we discuss the matrix representation of the sandwich operators (78) while starting with the particular case of the super Bol operator,

$$\overline{D}\mathcal{K}_n=\overline{D}(\nabla\overline{\nabla})^n=\overline{D}[D-nB][\overline{D}+\overline{B}][D-(n-1)B][\overline{D}+2\overline{B}]\cdots[D-B][\overline{D}+n\overline{B}]. \tag{79}$$

The two conformally covariant differential equations,

$$Df=0,\quad \overline{D}\mathcal{K}_nf=0\quad (f\in\mathcal{F}_{-n,0}), \tag{80}$$

are equivalent to two systems of first order differential equations which can be cast into matrix form:

$$Q^{fac}_n\vec{f}=\vec{0},\quad \overline{Q}^{fac}_n\vec{f}=\vec{0}. \tag{81}$$

Here, $\vec{f}=(f_1,f_2,\ldots,f_{2n},f)^t$ and $Q^{fac}_n,\overline{Q}^{fac}_n$ denote the $(2n+1)\times(2n+1)$ matrix operators

$$Q^{fac}_n=-\mu_-+D\mathbf{1}-BH,\quad \overline{Q}^{fac}_n=-\overline{\mu}_-+\overline{D}\mathbf{1}-\overline{BH}, \tag{82}$$

where $\mu_-,\overline{\mu}_-,H,\overline{H}$ belong to the superprincipal embedding $sl(2|1)_{\text{pal}}\subset sl(n+1|n)$ of the Lie superalgebra $sl(2|1)$ into the Lie superalgebra $sl(n+1|n)$—see eqs. (A3) of Appendix A. We note that the operators (82) can be rewritten in the form

$$Q^{fac}_n=D\mathbf{1}-A^{fac}_\theta,\quad \overline{Q}^{fac}_n=\overline{D}\mathbf{1}-A^{fac}_{\overline{\theta}}, \tag{83}$$

where A_θ^{fac} and $\overline{A}_\theta^{fac}$ are to be interpreted as components of a $sl(2|1)_{\text{pal}}$-valued connection—a viewpoint which will be further developed in the next section.

While Q_n^{fac} and $\overline{Q}_n^{fac}$ describe the *factorized form* (79) *of the super Bol operator*, one obtains an equivalent matrix representation for this operator by conjugation with a group element $N \in SL(2|1)_{\text{pal}} \subset SL(n+1|n)$,

$$Q_n = \hat{N}^{-1} \cdot Q_n^{fac} \cdot N, \quad \overline{Q}_n = \hat{N}^{-1} \cdot \overline{Q}_n^{fac} \cdot N, \tag{84}$$

where N is an upper triangular matrix with entries 1 on the diagonal.[13,3] [The matrix equations (81) then become $Q_n \vec{f}\,' = \vec{0}, \overline{Q}_n \vec{f}\,' = \vec{0}$ with $\vec{f}\,' \equiv N^{-1}\vec{f} = (f_1', \ldots, f_{2n}', f)$, i.e., the component f of $\vec{f}$ is not modified which explains why Q_n and $\overline{Q}_n$ still represent the scalar equations (80).] The hatted group element $\hat{N} = \exp \hat{M}$ follows from $N = \exp M$ by changing the sign of the anticommuting part of the Lie superalgebra element M.[14,3]

By using the gauge freedom (84), we find a form of Q_n and $\overline{Q}_n$ which makes the dependence on the superprojective structure manifest:

$$\begin{aligned} Q_n &= -\mu_- + D\mathbf{1} - \tfrac{1}{2}[\mathcal{R}\overline{\mu}_+ + (D\mathcal{R})E_{++}], \\ \overline{Q}_n &= -\overline{\mu}_- + \overline{D}\mathbf{1} + \tfrac{1}{2}[\mathcal{R}\mu_+ + (\overline{D}\mathcal{R})E_{++}]. \end{aligned} \tag{85}$$

This matrix representation of $\overline{D}\mathcal{K}_n$ in which $\mu_\pm, \overline{\mu}_\pm$ and $E_{++} \equiv -\{\mu_+, \overline{\mu}_+\}$ belong to the Lie superalgebra $sl(2|1)_{\text{pal}}$ exhibits most clearly the underlying algebraic structure which is due to the covariance with respect to super Möbius transformations. By unraveling the matrix equations $Q_n \vec{f}\,' = \vec{0}, \overline{Q}_n \vec{f}\,' = \vec{0}$, one recovers our results (57) for the operator $\overline{D}\mathcal{K}_n$.

The matrix representation (85) can be extended to the sandwich operators involving superconformal fields that we discussed in section V:

$$\begin{aligned} Q_n &= -\mu_- + D\mathbf{1} - \frac{1}{2}\sum_{i=1}^{n} [i\mathcal{V}_{i,i}\overline{\mu}_+ + (D\mathcal{V}_{i,i})E_{++}]E_{++}^{i-1}, \\ \overline{Q}_n &= -\overline{\mu}_- + \overline{D}\mathbf{1} + \frac{1}{2}\sum_{i=1}^{n} [i\mathcal{V}_{i,i}\mu_+ + (\overline{D}\mathcal{V}_{i,i})E_{++}]E_{++}^{i-1}. \end{aligned} \tag{86}$$

Here, $\mathcal{V}_{1,1} \equiv \mathcal{R}$ and $\mathcal{V}_{i,i}$ is a superconformal field for $i \geqslant 2$. Then $\mathcal{V}_{i,i}$ $(i = 1, \ldots, n)$ can be expressed in terms of the projective connection $\mathcal{R}$ and the conformal fields $\mathcal{W}_{k,k}$ $(k = 2, \ldots, n)$ appearing in the expression (78) by means of invertible relations involving differential polynomials. Henceforth, the expressions (86) provide a matrix representation for the most general sandwich operator. Thanks to this result, explicit expressions for covariant operators can be derived in a straightforward way.

If the sandwich operators are parametrized in the form (77), their matrix realization reads as

$$\begin{aligned} Q_n^{hor} &= -\mu_- + D\mathbf{1}, \\ \overline{Q}_n^{hor} &= -\overline{\mu}_- + \overline{D}\mathbf{1} + \sum_{i=1}^{n} [\lambda_i a_i^{(n)} E_{1,2i} + \mu_i (\overline{D} a_i^{(n)}) E_{1,2i+1}], \end{aligned} \tag{87}$$

where E_{ij} are the matrices with entries $(E_{ij})_{kl} = \delta_{ik}\delta_{jl}$ and

$$\lambda_i = \frac{(n-i)!}{n!(i-1)!}, \quad \mu_i = \frac{(n-i)!}{n!\,i!}.$$

This gauge choice is referred to as the *horizontal gauge*[15] while (85), (86) is known as the $osp(1|2)$ *highest weight gauge*. In fact, as we will now verify, the combination $Q_n + \overline{Q}_n$ leads to

the matrix representation of $N=1$ superconformally covariant differential operators in terms of highest weight generators of $osp(1|2)_{\rm pal}\subset sl(2|1)_{\rm pal}$ (see Appendix A for the algebraic details).

By adding the expressions (86), we find

$$Q_n+\overline{Q}_n=-\kappa_-+(D+\overline{D})\mathbf{1}+\frac{1}{2}\sum_{i=1}^{n}[i\mathcal{V}_{i,i}M_{2i-1}-(D-\overline{D})\mathcal{V}_{i,i}M_{2i}].$$

Here, $\kappa_-\equiv\mu_-+\overline{\mu}_-\in osp(1|2)_{\rm pal}$ and $M_k\equiv(\mu_+-\overline{\mu}_+)^k$ are highest weight generators of $osp(1|2)_{\rm pal}$ while $D+\overline{D}=D_1$ denotes the basic $N=1$ derivative. By projecting from $N=2$ to $N=1$ superfields along the lines of section IV D 3, we get

$$Q_n^{(N=1)}\equiv(Q_n+\overline{Q}_n)|_{N=1}=-\kappa_-+D_1\mathbf{1}+\sum_{k=1}^{2n}V_{k+1}M_k, \tag{88}$$

with

$$V_{2i}=\frac{i}{2}\,\mathcal{V}_{i,i}\Big|_{N=1},\quad V_{2i+1}=-\frac{1}{2}(D-\overline{D})\mathcal{V}_{i,i}\Big|_{N=1}\qquad(i=1,\ldots,n).$$

The expression (88) coincides with the $N=1$ matrix representation found in Refs. 3,16 up to the fact that it involves a different (though equivalent) realization of the superprincipal embedding of $osp(1|2)_{\rm pal}$ in $sl(n+1|n)$. The same realization can be obtained by choosing Q_n and $\overline{Q}_n$ along the lines of Ref. 15:

$$\begin{aligned}Q_n'&=-\tilde{\mu}_++D\mathbf{1}+\frac{1}{2}\sum_{i=1}^{n}[(D\mathcal{V}_{i,i})\tilde{E}^i_{--}-\mathcal{V}_{i,i}[\tilde{\mu}_+,\tilde{E}^i_{--}]],\\ \overline{Q}_n'&=+\tilde{\overline{\mu}}_++\overline{D}\mathbf{1}-\frac{1}{2}\sum_{i=1}^{n}[(\overline{D}\mathcal{V}_{i,i})\tilde{E}^i_{--}+\mathcal{V}_{i,i}[\tilde{\overline{\mu}}_+,\tilde{E}^i_{--}]].\end{aligned} \tag{89}$$

Here, the tilde denotes the transposed matrix and the common structure of the results (86) and (89) becomes apparent if one takes into account the identities

$$[\mu_-,E^i_{++}]=-i\overline{\mu}_+E^{i-1}_{++},\quad [\overline{\mu}_-,E^i_{++}]=-i\mu_+E^{i-1}_{++}. \tag{90}$$

VII. WARD IDENTITIES AND *W*-ALGEBRAS FROM A ZERO CURVATURE CONDITION

The highest weight matrix representation (86) of covariant sandwich operators has the form

$$Q_n=D\mathbf{1}-A_\theta,\quad \overline{Q}_n=\overline{D}\mathbf{1}-A_{\bar\theta}, \tag{91}$$

where A_θ and $A_{\bar\theta}$ can be interpreted as the spinorial components of a connection with values in the Lie superalgebra $sl(2|1)_{\rm pal}\subset sl(n+1|n)$. The spinorial components can be supplemented with spatial components A_z and $A_{\bar z}$ represented by generic elements of $sl(n+1|n)$. Altogether these fields represent the fundamental variables for the superspace formulation of a (2,0)-supersymmetric gauge theory based on graded Lie algebras. (For the general framework of such theories, we refer to Ref. 16.)

Within the $N=1$ superfield formalism, it has been shown[16] that classical super W-algebras can be constructed in the following way: in the z-sector, one considers the highest weight gauge for the spinorial components of the connection [i.e., eqs. (86) in the present case], all entries of the connection components $A_z,A_{\bar z},A_\theta,\ldots$, are supposed to be smooth superfields and zero curvature conditions are imposed on the connection. We will now apply this procedure to the $N=2$ theory.

The integrability conditions for the system of differential equations $\vec{0}=Q_n\vec{f}=\overline{Q}_n\vec{f}=(\overline{\partial}-A_{\bar z})\vec{f}$ are the *zero curvature conditions*

$$
\begin{aligned}
&0 = DA_\theta - \hat{A}_\theta A_\theta, \quad 0 = \overline{D}A_{\bar{\theta}} - \hat{A}_{\bar{\theta}} A_{\bar{\theta}}, \\
&A_z = DA_{\bar{\theta}} + \overline{D}A_\theta - \hat{A}_\theta A_{\bar{\theta}} - \hat{A}_{\bar{\theta}} A_\theta, \\
&0 = DA_{\bar{z}} - \overline{\partial}A_\theta - A_\theta A_{\bar{z}} + \hat{A}_{\bar{z}} A_\theta, \\
&0 = \overline{D}A_{\bar{z}} - \overline{\partial}A_{\bar{\theta}} - A_{\bar{\theta}} A_{\bar{z}} + \hat{A}_{\bar{z}} A_{\bar{\theta}},
\end{aligned}
\tag{92}
$$

where the hat again denotes the automorphism of the Lie superalgebra which reverses the signs of all odd elements. As may be verified explicitly, the expressions (86) (involving smooth superfields $\mathcal{V}_{i,i}$) verify the constraints of the first line. The second line is simply a redefinition constraint which determines the component A_z in terms of the variables A_θ and $A_{\bar{\theta}}$. Finally, A_θ and $A_{\bar{\theta}}$ having the form (86), the last two conditions represent constraints for the entries of the matrix $A_{\bar{z}}$. Actually, most of these constraints are algebraic equations which allow us to express the entries of $A_{\bar{z}}$ in terms of other fields while the other ones represent partial differential equations for the independent fields. These differential equations are the Ward identities for the super W_n-algebras.

In the simplest case ($n=1$), the matrix $A_{\bar{z}}$ only contains one independent superfield H satisfying the differential equation

$$
\mathcal{L}_2^{sym} H = \overline{\partial}\mathcal{R}, \tag{93}
$$

where $\mathcal{L}_2^{sym}$ denotes the symmetric super Bol operator (53). This relation is nothing but the (2,0) *superconformal Ward identity*,[6] the superfield $H \equiv H_{\bar{z}}^{\ z}$ being interpreted as the Beltrami superfield (in the so-called restricted geometry) and the superprojective connection $\mathcal{R}$ as the stress-energy tensor. It expresses the superdiffeomorphism invariance of the generating functional $Z_c[H]$ in superconformal field theory.

For $n=2$, $A_{\bar{z}}$ contains two independent superfields $H \equiv H_{\bar{z}}^{\ z}$ and $G \equiv G_{\bar{z}}^{\ zz}$ which are associated to $\mathcal{R}$ and $\mathcal{V} \equiv \mathcal{V}_{2,2}$, respectively. These variables satisfy the system of differential equations

$$
\begin{aligned}
\overline{\partial}\mathcal{R} &= \mathcal{L}_2^{sym} H + [2\mathcal{V}\partial - (\overline{D}\mathcal{V})D - (D\mathcal{V})\overline{D} + 2(\partial\mathcal{V})]G, \\
\overline{\partial}\mathcal{V} &= \frac{-1}{16}[\mathcal{L}_4^{sym} + 4\mathcal{M}_{\mathcal{V}}^{(4)sym}]G + [2\mathcal{V}\partial - (\overline{D}\mathcal{V})D - (D\mathcal{V})\overline{D} + (\partial\mathcal{V})]H,
\end{aligned}
\tag{94}
$$

where $\mathcal{M}_{\mathcal{V}}^{(4)sym}$ is the following superconformally covariant operator. (This operator is an example of a covariant operator involving a conformal superfield and generalizing the symmetric Bol operators of section IV A 1. These operators can be determined in a systematic way along the lines of section V.)

$$
\begin{aligned}
\mathcal{M}_{\mathcal{V}}^{(4)sym} = {} & 5\mathcal{V}\partial[D,\overline{D}] + 5D\mathcal{V}\partial\overline{D} - 5\overline{D}\mathcal{V}\partial D + \tfrac{5}{2}\partial\mathcal{V}\,[D,\overline{D}] \\
& + (\tfrac{3}{2}[D,\overline{D}]\mathcal{V} + 7\mathcal{R}\mathcal{V})\partial + (3\partial D\mathcal{V} + \mathcal{R}D\mathcal{V} - 9D\mathcal{R}\mathcal{V})\overline{D} - (3\partial\overline{D}\mathcal{V} - \mathcal{R}\overline{D}\mathcal{V} + 9\overline{D}\mathcal{R}\mathcal{V})D \\
& + \partial[D,\overline{D}]\mathcal{V} + 3\mathcal{R}\partial\mathcal{V} - 5\overline{D}\mathcal{R}D\mathcal{V} - 5D\mathcal{R}\overline{D}\mathcal{V} + 8\partial\mathcal{R}\mathcal{V}.
\end{aligned}
$$

The relations (94) generalize the Ward identity (93) which is recovered for $\mathcal{V}=0=G$. They represent the *Ward identities associated to the $N=2$ super W_3-algebra* and they are manifestly covariant since all differential operators occurring on their r.h.s. are superconformally covariant when acting on the given fields.

As a matter of fact, the Ward identities (94) are equivalent to the *Poisson bracket algebra* (commutation relations)

$$
\begin{aligned}
[\mathcal{R}_2, \mathcal{R}_1] &= (\mathcal{L}_2^{sym})_1 \delta^{(3)}(\mathbf{z}_2, \mathbf{z}_1), \\
[\mathcal{R}_2, \mathcal{V}_1] &= (2\mathcal{V}\partial - (\overline{D}\mathcal{V})D - (D\mathcal{V})\overline{D} + (\partial\mathcal{V}))_1 \delta^{(3)}(\mathbf{z}_2, \mathbf{z}_1),
\end{aligned}
\tag{95}
$$

$$[\mathcal{V}_2,\mathcal{V}_1]=-\tfrac{1}{16}\,(\mathcal{L}_4^{sym}+4\mathcal{M}_{\mathcal{V}}^{(4)sym})_1\delta^{(3)}(\mathbf{z}_2,\mathbf{z}_1),$$

for which we used the notation $\mathcal{R}_i\equiv\mathcal{R}(\mathbf{z}_i)$ and $\mathcal{V}_i\equiv\mathcal{V}(\mathbf{z}_i)$. By spelling out all expressions on the r.h.s. of eqs. (95), one finds that this result exactly coincides with the one found in Ref. 17 by applying quite different methods (see also Refs. 9,18 as well as Ref. 11 for a general formula). The introduction of covariant operators not only allows us to cast the results in a compact form, it also helps to exhibit the conformal symmetry which plays a crucial role in the formulation of integrable models. In fact, the covariant operators occurring in eqs. (94), (95) yield the second Hamiltonian structure for the $N=2$ super Boussinesq equation.[17–19] We note that the algebra (95) can be rewritten in terms of $N=1$ superfields[18] in which case all $N=2$ covariant operators reduce to $N=1$ covariant ones (see Ref. 3 for the latter operators and the corresponding algebra).

By integrating the Ward identities (94), one can deduce the operator product expansions (OPE) of the spin 1 and spin 2 supercurrents $\mathcal{R}$ and $\mathcal{V}$. To do so, one proceeds along the lines of Ref. 16 and defines $\mathcal{R}$ and $\mathcal{V}$ as derivatives of a generating functional $Z_c=Z_c[H,G]$,

$$\mathcal{R}=-\left.\frac{\delta Z_c}{\delta H}\right|_{H=0,G=0},\qquad \mathcal{V}=-\left.\frac{\delta Z_c}{\delta G}\right|_{H=0,G=0}. \tag{96}$$

By using eqs. (B1) and (B4) of Appendix B, one obtains the (singular parts of the) *OPE of the classical $N=2$ super W_3-algebra*:[19] in terms of the notation $\mathcal{R}_i\equiv\mathcal{R}(\mathbf{z}_i)$ and $\mathcal{V}_i\equiv\mathcal{V}(\mathbf{z}_i)$, we have

$$\mathcal{R}_2\mathcal{R}_1=\frac{2}{z_{12}^2}+\left[\frac{\overline{\theta}_{12}\theta_{12}}{z_{12}^2}+\frac{\overline{\theta}_{12}}{z_{12}}\overline{D}-\frac{\theta_{12}}{z_{12}}D-\frac{\overline{\theta}_{12}\theta_{12}}{z_{12}}\partial\right]\mathcal{R}_1,$$

$$\mathcal{R}_2\mathcal{V}_1=\left[2\frac{\overline{\theta}_{12}\theta_{12}}{z_{12}^2}+\frac{\overline{\theta}_{12}}{z_{12}}\overline{D}-\frac{\theta_{12}}{z_{12}}D-\frac{\overline{\theta}_{12}\theta_{12}}{z_{12}}\partial\right]\mathcal{V}_1, \tag{97}$$

$$\begin{aligned}-16\mathcal{V}_2\mathcal{V}_1=&\frac{12}{z_{12}^4}+12\,\frac{\overline{\theta}_{12}\theta_{12}\mathcal{R}_1}{z_{12}^4}+12\,\frac{(\overline{\theta}_{12}\overline{D}-\theta_{12}D-\overline{\theta}_{12}\theta_{12}\partial)\mathcal{R}_1}{z_{12}^3}\\&+\frac{2(20\mathcal{V}_1+2[D,\overline{D}]\mathcal{R}_1-\mathcal{R}_1^2)-(\overline{\theta}_{12}\overline{D}+\theta_{12}D)(20\mathcal{V}_1+8[D,\overline{D}]\mathcal{R}_1-\mathcal{R}_1^2)}{z_{12}^2}\\&+\frac{\overline{\theta}_{12}\theta_{12}(6[D,\overline{D}]\mathcal{V}_1+6\partial^2\mathcal{R}_1+U_1)}{z_{12}^2}-\frac{\partial(20\mathcal{V}_1+2[D,\overline{D}]\mathcal{R}_1-\mathcal{R}_1^2)}{z_{12}}\\&+\frac{\overline{\theta}_{12}(12\partial\overline{D}\mathcal{V}_1+3\partial^2\overline{D}\mathcal{R}_1+\overline{\psi}_1)+\theta_{12}(12\partial D\mathcal{V}_1-3\partial^2 D\mathcal{R}_1+\psi_1)}{z_{12}}\\&-\frac{1}{4}\,\overline{\theta}_{12}\theta_{12}\frac{16\partial[D,\overline{D}]\mathcal{V}_1+8\partial^3\mathcal{R}_1+\partial[D,\overline{D}]\mathcal{R}_1^2+2(\partial\mathcal{U}_1-\overline{D}\psi_1+D\overline{\psi}_1)}{z_{12}},\end{aligned}$$

which expressions involve the composite supercurrents $\mathcal{R}^2$ and $\mathcal{U},\overline{\psi},\psi$ defined by

$$\mathcal{U}=28\mathcal{R}\mathcal{V}+4\mathcal{R}[D,\overline{D}]\mathcal{R}-15D\mathcal{R}\overline{D}\mathcal{R}-2\mathcal{R}^3,$$

$$\overline{\psi}=-4\mathcal{R}\overline{D}\mathcal{V}+36\overline{D}\mathcal{R}\mathcal{V}-\mathcal{R}\partial\overline{D}\mathcal{R}-\tfrac{3}{2}\,\partial\mathcal{R}\overline{D}\mathcal{R}+\tfrac{9}{2}[D,\overline{D}]\mathcal{R}\overline{D}\mathcal{R}-2\mathcal{R}^2\overline{D}\mathcal{R},$$

$$\psi=4\mathcal{R}D\mathcal{V}-36D\mathcal{R}\mathcal{V}-\mathcal{R}\partial D\mathcal{R}-\tfrac{3}{2}\,\partial\mathcal{R}D\mathcal{R}-\tfrac{9}{2}[D,\overline{D}]\mathcal{R}D\mathcal{R}+2\mathcal{R}^2D\mathcal{R}.$$

In conclusion, we note that one can explicitly derive the Poisson brackets (95) from the OPE (97) by applying the supersymmetric version of Cauchy's theorem (Appendix B).[16]

VIII. CONCLUDING REMARKS

Interestingly enough, the zero curvature conditions provide a link between two different classes of $N=2$ superconformally covariant operators: by starting from the matrix representation of sandwich operators, one obtains Ward identities involving symmetric covariant operators.

Concerning the matrix representation of covariant operators which are not of sandwich type we remark the following: if one disregards the covariance properties and considers $\mathcal{L}_n^{sym}$ as sandwiched between $\overline{D}$ and D, it has the form (77) and equation (87) with properly chosen coefficients $a_i^{(n)}$ then provides a matrix representation. However, this result is neither satisfactory nor complete, since it does not properly take into account conformal symmetry and since the scalar operator $\mathcal{L}_n^{sym}$ can only be recovered from this matrix representation up to contributions $\mathcal{L}_a$ satisfying $\overline{D}\mathcal{L}_a D=0$.

The expression $\mathcal{M}_{\mathcal{W}}^{(n)}C$ may be viewed as the result of a bilinear and covariant map J, i.e., $\mathcal{M}_{\mathcal{W}}^{(n)}C=J(\mathcal{W},C)$ which is known as the super Gordan transvectant.[1–3] Such bilinear as well as trilinear covariant operators[3] can be constructed along the lines of section III E. These operators occur in particular in the Poisson brackets of super W-algebras.[3]

There is a remarkable relationship between the matrix representation of conformally covariant operators and the general formula determining the singular vectors of the Virasoro algebra—see the second of Refs. 2. This relationship generalizes to the $N=1$ supersymmetric theory[3] and our results concerning $N=2$ covariant operators should also allow us to draw close parallels to the recent study of singular vectors of the $N=2$ superconformal algebra.[20]

Apart from the Gelfand-Dickey derivation of (super) W-algebras and the zero curvature construction that we discussed here, various other approaches have been considered in the literature—see for instance Refs. 21,22. The tools developed in the present work should provide the necessary ingredients for generalizing these constructions to the $N=2$ theory.

Finally, we note that our results can be extended—along the lines of Refs. 4 and 23—to the case of pseudo-differential operators which appear for instance as Lax operators in superintegrable models.[24]

Note added in proof: As we realized after completion of the present work, a first attempt to construct $N=2$ superconformally covariant operators has been made some time ago by Mathieu:[25] in particular, this author found the form of the lowest order, symmetric super Bol operators in a nonchiral basis of $N=2$ superspace.

ACKNOWLEDGMENTS

We wish to thank François Delduc for informing us about their results prior to publication, for numerous stimulating discussions and precious advice. F.G. acknowledges financial support by the Alexander von Humboldt-Foundation and expresses his gratitude to Stefan Theisen for the hospitality extended to him in Munich at the final stage of this work.

APPENDIX A: NONSTANDARD MATRIX REALIZATION OF $sl(n+1|n)$

$sl(n+1|n)$ is the graded Lie algebra of $(2n+1)\times(2n+1)$ matrices with a vanishing supertrace. It admits a purely *fermionic* system of simple roots.

We will consider a nonstandard matrix realization of $sl(n+1|n)$ which is referred to as the *diagonal representation*.[3,16] It consists of assigning a $\mathbf{Z}_2$-grading $i+j\,(\mathrm{mod}\ 2)$ to a matrix element M_{ij}, defining the supertrace by the alternating sum

$$\mathrm{str}\ M=\sum_{i=1}^{2n+1}(-1)^{i+1}M_{ii},$$

and the graded commutator by

$$[M,N\}_{ik}=\sum_{j=1}^{2n+1}(M_{ij}N_{jk}-(-1)^{(i+j)(j+k)}N_{ij}M_{jk}).$$

In the Serre-Chevalley basis, the basic commutation relations of $sl(n+1|n)$ read as

$$[h_i,h_j]=0, \quad [h_i,e_j]=+a_{ij}e_j,$$

$$\{e_i,f_j\}=\delta_{ij}h_j, \quad [h_i,f_j]=-a_{ij}f_j, \quad \text{for } i,j\in\{1,..,2n\}.$$

Here, the h_i belong to the Cartan subalgebra, the e_i denote the fermionic simple roots, f_i the associated negative roots and the a_{ij} are the elements of the Cartan matrix:

$$a_{ij}=\delta_{i+1,j}-\delta_{i,j+1}. \tag{A1}$$

In the diagonal representation, the Serre-Chevalley generators can be represented by the matrices

$$h_i=E_{i,i}+E_{i+1,i+1}, \quad e_i=E_{i,i+1}, \quad f_i=E_{i+1,i}, \tag{A2}$$

where E_{ij} denotes the $(2n+1)\times(2n+1)$ matrix with entries $(E_{ij})_{kl}=\delta_{ik}\delta_{jl}$.

The superprincipal embedding of $sl(2|1)$ in $sl(n+1|n)$ is denoted by $sl(2|1)_{\text{pal}}\subset sl(n+1|n)$ and is defined as follows:[15]

$$H=\sum_{i=1}^{n}(n-i+1)h_{2i-1}, \quad \bar{H}=-\sum_{i=1}^{n} ih_{2i},$$

$$\mu_+=\sum_{i=1}^{n} e_{2i-1}, \quad \bar{\mu}_+=-\sum_{i=1}^{n} e_{2i}, \tag{A3}$$

$$\mu_-=\sum_{i=1}^{n}(n-i+1)f_{2i-1}, \quad \bar{\mu}_-=\sum_{i=1}^{n} if_{2i}.$$

Here, $H,\bar{H}$ represent the Cartan generators of $sl(2|1)$, $\mu_+,\bar{\mu}_+$ the fermionic simple roots and $\mu_-,\bar{\mu}_-$ the associated negative roots. The nonvanishing commutators of these generators read as

$$[H,\bar{\mu}_\pm]=\pm\bar{\mu}_\pm, \quad [\bar{H},\mu_\pm]=\pm\mu_\pm,$$

$$\{\mu_+,\mu_-\}=H, \quad \{\bar{\mu}_+,\bar{\mu}_-\}=\bar{H}, \tag{A4}$$

$$\{\mu_+,\bar{\mu}_+\}\equiv -E_{++}, \quad \{\mu_-,\bar{\mu}_-\}\equiv -E_{--},$$

where E_{++} and E_{--} correspond to the bosonic roots of $sl(2|1)$.

The Lie superalgebra $sl(2|1)_{\text{pal}}$ contains the superprincipal embedding of $osp(1|2)$ into $sl(n+1|n)$, i.e., $osp(1|2)_{\text{pal}}\subset sl(2|1)_{\text{pal}}\subset sl(n+1|n)$: this embedding is defined by the combinations

$$J_0=H+\bar{H}, \quad \kappa_+=\mu_++\bar{\mu}_+, \quad \kappa_-=\mu_-+\bar{\mu}_-,$$
$$J_+=E_{++}, \quad J_-=-E_{--}, \tag{A5}$$

which satisfy the commutation relations

$$[J_0,\kappa_\pm]=\pm\kappa_\pm, \quad \{\kappa_+,\kappa_-\}=J_0, \quad \{\kappa_\pm,\kappa_\pm\}=\pm 2J_\pm. \tag{A6}$$

Here, J_0 is the Cartan generator and κ_+ the fermionic simple root. The highest weight generators M_k of $osp(1|2)_{\text{pal}}$ are defined by the relations

$$[J_0,M_k]=kM_k, \quad [\kappa_+,M_k\}=0 \quad (k=1,2,\ldots,2n), \tag{A7}$$

which are solved by

$$M_k=M_1^k, \quad \text{with } M_1=\mu_+-\bar{\mu}_+. \tag{A8}$$

APPENDIX B: SOME DISTRIBUTIONAL RELATIONS

In this appendix, we gather some distributional relations which hold in $d=2, N=2$ superspace and we use them to determine the correspondence rules between supercurrent OPE's and commutation relations.

Let $(\mathbf{z}_i,\overline{\mathbf{z}_i})\equiv(z_i,\theta_i,\overline{\theta_i};\overline{z_i},\theta_i^-,\overline{\theta_i^-})$ with $i=1,2$ denote the local coordinates of two points on a $N=2$ SRS. We then define the relative coordinates,

$$\theta_{12}=\theta_1-\theta_2,\quad \overline{\theta}_{12}=\overline{\theta_1}-\overline{\theta_2},\quad z_{12}=z_1-z_2-\tfrac{1}{2}(\theta_1\overline{\theta_2}+\overline{\theta_1}\theta_2). \tag{B1}$$

For a superanalytic superfield F (i.e., a field depending only on $\mathbf{z}$), one has the following Cauchy formulas[26,9] ($n\in\mathbf{N}$):

$$\int d^3\mathbf{z}_1(\overline{\theta}_{12}\theta_{12},\theta_{12},\overline{\theta}_{12},1)\frac{F(\mathbf{z}_1)}{z_{12}^{n+1}}=\left(1,-\overline{D},D,\frac{1}{2}[D,\overline{D}]\right)\frac{\partial^n F(\mathbf{z}_2)}{n!}. \tag{B2}$$

Here, $d^3\mathbf{z}$ denotes the measure $(2\pi i)^{-1}dz\,d\theta\,d\overline{\theta}$ with respect to which the Dirac distribution takes the form

$$\delta^{(3)}(\mathbf{z}_1,\mathbf{z}_2)=\delta^{(1)}(z_1-z_2)(\overline{\theta_1}-\overline{\theta_2})(\theta_1-\theta_2)=\frac{1}{z_{12}}\,\overline{\theta}_{12}\theta_{12}. \tag{B3}$$

The integration of Ward identities is performed by means of the Dirac distribution with respect to the measure $d^4\mathbf{z}=(2\pi i)^{-1}d\overline{z}dz\,d\theta\,d\overline{\theta}$:

$$\delta^{(4)}(\mathbf{z}_1,\mathbf{z}_2)=\delta^{(2)}(z_1-z_2,\overline{z_1}-\overline{z_2})(\overline{\theta_1}-\overline{\theta_2})(\theta_1-\theta_2)=\partial_{z_1}^-\frac{1}{z_{12}}\,\overline{\theta}_{12}\theta_{12}. \tag{B4}$$

A general OPE of two supercurrents $A(\mathbf{z}_2)$ and $B(\mathbf{z}_1)$ can be written in the form

$$A(\mathbf{z}_2)B(\mathbf{z}_1)=\sum_{n\in\mathbf{N}}\frac{a_n(\mathbf{z}_1)+\overline{\theta}_{12}\alpha_n(\mathbf{z}_1)+\theta_{12}\beta_n(\mathbf{z}_1)+\overline{\theta}_{12}\theta_{12}b_n(\mathbf{z}_1)}{z_{21}^{n+1}}+\text{regular terms}, \tag{B5}$$

and by virtue of the relations (B2), this OPE is equivalent to the commutation relation

$$[A(\mathbf{z}_2),B(\mathbf{z}_1)]=\sum_{n\in\mathbf{N}}\frac{1}{n!}\left(\frac{a_n(\mathbf{z}_1)}{2}[D,\overline{D}]+\alpha_n(\mathbf{z}_1)D-\beta_n(\mathbf{z}_1)\overline{D}+b_n(\mathbf{z}_1)\right)\partial_1^n\delta^{(3)}(\mathbf{z}_2,\mathbf{z}_1). \tag{B6}$$

Anti-isospectral transformations, orthogonal polynomials, and quasi-exactly solvable problems

Avinash Khare[a] and Bhabani Prasad Mandal[b]
Institute of Physics, Sachivalaya Marg, Bhubaneswar-751005, India

(Received 1 December 1997; accepted for publication 23 December 1997)

We consider the double sinh-Gordon potential which is a quasi-exactly solvable problem and show that in this case one has two sets of Bender–Dunne orthogonal polynomials. We study in some detail the various properties of these polynomials and the corresponding quotient polynomials. In particular, we show that the weight functions for these polynomials are *not* always positive. We also study the orthogonal polynomials of the double sine-Gordon potential which is related to the double sinh-Gordon case by an anti-isospectral transformation. Finally we discover a new quasi-exactly solvable problem by making use of the anti-isospectral transformation. © *1998 American Institute of Physics.* [S0022-2488(98)03205-8]

I. INTRODUCTION

Recently, in an interesting paper, Krajewska *et al.*[1] have introduced an anti-isospectral transformation (which they also called duality transformation). In particular, using this transformation they relate the spectra of quasi-exactly solvable (QES) potentials V_1 and V_2 given by

$$V_1(x)=x^2(ax^2+b)^2-\hbar a(2M+3)x^2, \tag{1.1}$$

$$V_2(x)=x^2(ax^2-b)^2-\hbar a(2M+3)x^2, \tag{1.2}$$

where $a,b>0$ and M is non-negative integer. It may be noted here that the duality property does not hold for other (exactly non-calculable) levels. It is clearly of great interest to understand this new transformation in some detail and explore its various consequences. For example, one would like to know whether one can discover new QES problems by using this transformation. Second, are the QES levels of the dual potentials related even if they are valid over different domain? Further, whether the number of QES levels in the two cases are identical or not.

Another recent development is the work of Bender–Dunne[2] where they have shown that the eigenfunctions of the Schrödinger equation for a quasi-exactly solvable (QES) problem is the generating function for a set of orthogonal polynomials $\{P_n(E)\}$ in the energy variable E. It was further shown in one specific example that these polynomials satisfy the three-term recursion relation

$$P_n(E)=EP_{n-1}(E)+C_nP_{n-2}(E), \tag{1.3}$$

where C_n is E independent quantity. Using the well known theorem,[3,4] ''the *necessary and sufficient* condition for a family of polynomials $\{P_n\}$ (with degree $P_n=n$) to form an orthogonal polynomial system is that $\{P_n\}$ satisfy a three-term recursion relation of the form

$$P_n(E)=(A_nE+B_n)P_{n-1}(E)+C_nP_{n-2}(E), \quad n\geqslant 1, \tag{1.4}$$

where the coefficients A_n, B_n, and C_n are independent of E, $A_n\neq 0$, $C_1=0$, $C_n\neq 0$ for $n\geqslant 1$,'' it then followed that $\{P_n(E)\}$ for this problem forms an orthogonal set of polynomials with respect to some weight function, $w(E)$. Recently several authors have studied the Bender–Dunne polynomials in detail.[1,4–6] In fact it has been claimed that the Bender–Dunne construction is quite universal and valid for any quasi-exactly solvable model in both one as well as multi-dimensions.

However, in a recent note[7] we have discussed three QES problems for all of which the Schrödinger equation can be transformed to Heun's equation and further in all these cases the three-term recursion relation satisfied by the Bender–Dunne polynomials is not of the form as given by Eq. (1.4) and hence does not form an orthogonal set. It is worth pointing out that in all these cases the Hamiltonian cannot be written in terms of quadratic generator of the Sl(2) algebra. We suspect that this may be the reason why the polynomials in these examples do not form an orthogonal set.

The question which we would like to raise and study in this paper is regarding the properties of the Bender–Dunne polynomials in case they form an orthogonal set. For example, in the example discussed by Bender–Dunne (as well as in most other QES examples discussed so far), for a given potential, the QES states have either even or odd number of nodes. The question is what happens in a QES problem if one can obtain states with even as well as odd number of nodes. In particular, do the polynomials corresponding to the even and odd number of nodes together form an orthogonal set or if the polynomials corresponding to even number of nodes form one orthogonal set and polynomials with odd number of nodes form a separate orthogonal set? Second, how universal are the properties of Bender–Dunne orthogonal polynomials in such cases? For example, are the weight functions always positive? Do the moments of weight function have pure power growth?[4]

The purpose of this note is to explore in some detail the various issues raised above. In particular, in Sec. II, we discuss the double sinh-Gordon (DSHG) model which is an QES problem but where states with odd as well as even number of nodes are known for a given potential. We show that in this case there are two sets of orthogonal polynomials with polynomials corresponding to even number of nodes forming one orthogonal set while the polynomials corresponding to odd number of nodes forming another orthogonal set. We study the properties of these polynomials as well as the corresponding quotient polynomials in detail and show that in many respect they are similar to the Bender–Dunne polynomials. However, unlike the Bender–Dunne case, the weight functions are not always positive for either of the orthogonal polynomial sets. In Sec. III, we discuss several consequences of the duality symmetry in the context of the QES problems. In particular, we study two QES problems, in both of which the domain of validity of the potential and it's dual are different. As a result we show that in the case of the double sine-Gordon (DSG) potential, the number of QES levels are almost half of those in the double sinh-Gordon case (which is dual to it). However, even then many of the predictions about their corresponding Bender–Dunne polynomials still go through. For example, the QES levels of DSG are still related to the corresponding levels of DSGH case. Further, the weight functions here are also not always positive. Finally using duality, we discover a new QES problem which has so far not been discussed in the literature. Section IV is reserved for discussions.

II. DSHG SYSTEM AND ORTHOGONAL POLYNOMIALS

The DSHG system is one of the few double well problems in quantum mechanics which is quasi-exactly solvable.[8,9] This double well system has found application in several different branches of physics starting from the theory of diffusion in bistable field,[10] quantum theory of instantons,[11,12] quantum theory of molecules and also as a model for nonlinear coherent structure.[13,14] The Hamiltonian for this case is given by (we shall assume $\hbar=2m=1$ throughout this paper)

$$H=-\frac{d^2}{dx^2}+(\zeta\cosh 2x-M)^2, \tag{2.1}$$

where ζ is a positive parameter. The value of M is not restricted in principle but it has been shown[8] that the solutions for first M levels are exactly known in case M is a positive integer. Note further that for $M>\zeta$, this potential has a double well structure with the two minima lying at $\cosh 2x_0=M/\zeta$. Let us now derive the three-term recursion relation in this case. On substituting

$$\psi(x)=e^{-(\zeta/2)\cosh 2x}\phi(x) \tag{2.2}$$

in the Schrödinger equation $H\psi=E\psi$ with H as given by Eq. (2.1) we obtain

$$\phi''(x)-2\zeta\ \sinh 2x\ \phi'(x)+[(E-M^2-\zeta^2)+2(M-1)\zeta\ \cosh 2x]\phi(x)=0. \tag{2.3}$$

On further substituting

$$z=\cosh 2x-1; \quad \phi=z^s\sum_{n=0}^{\infty}\ \frac{R_n(E)}{n!}\left(\frac{z+2}{2}\right)^{n/2} \tag{2.4}$$

we obtain the three-term recursion relation ($n\geqslant 0$).

$$R_{n+2}(E)-[n^2+4(s+\zeta)n+4s^2+E-M^2-\zeta^2-2(M-1)\zeta]R_n(E)$$
$$-4\zeta[M+1-2s-n]n(n-1)R_{n-2}(E)=0 \tag{2.5}$$

provided $2s^2=s$, i.e., either $s=0$ or $s=\frac{1}{2}$. Thus we have two sets of independent solutions: the even states (i.e., states with even number of nodes) for $s=0$ and the odd states for $s=\frac{1}{2}$. Note that unlike the Bender–Dunne (or most other QES) cases, s is not contained in the potential and this is perhaps related to the fact that for any integer M ($\geqslant 2$) the QES solutions corresponding to both even and odd states are obtained. From Eq. (2.5) we observe that the even and odd polynomials $R_n(E)$ do not mix with each other and hence we have two separate three-term recursion relations depending on whether n is odd or even. In particular, it is easily shown that the three-term recursion relations corresponding to the even and odd n cases, respectively, are given by ($n\geqslant 1$)

$$P_n(E)-[4n^2+8n(s+\zeta-1)+4s^2-8s+4-6\zeta+E-(M+\zeta)^2]P_{n-1}(E)$$
$$-8\zeta(n-1)(2n-3)(M+3-2s-2n)P_{n-2}=0, \tag{2.6}$$

$$Q_n(E)-[4n^2+4n(2s+2\zeta-1)+4s^2-4s+1-2\zeta+E-(M+\zeta)^2]Q_{n-1}(E)$$
$$-8\zeta(n-1)(2n-1)(M+2-2s-2n)Q_{n-2}=0, \tag{2.7}$$

with $P_0(E)=1$, $Q_0(E)=1$. These recursion relations generate a set of monic polynomials, of which the first few are

$$P_0(E)=1, \quad P_1(E)=\mathscr{E}+4s^2+2\zeta, \tag{2.8}$$

$$P_2(E)=\mathscr{E}^2+\mathscr{E}[8s^2+8s+12\zeta+4]+(4s^2+4s+10\zeta+4)(4s^2+2\zeta)+8\zeta(M-2s-1),$$

and

$$Q_0(E)=1, \quad Q_1(E)=\mathscr{E}+4s^2+4s+1+6\zeta, \tag{2.9}$$

$$Q_2(E)=\mathscr{E}^2+\mathscr{E}[8s^2+8s+20\zeta+10]+(4s^2+4s+6\zeta+1)(4s^2+4s+14\zeta+9)$$
$$+24\zeta(M-2s-2),$$

where

$$\mathscr{E}\equiv E-(M+\zeta)^2. \tag{2.10}$$

Note that unlike the Bender–Dunne case, the polynomials $P_n(E)$ and $Q_n(E)$ are not eigenfunctions of parity. It is easily seen that when M is a positive integer, exact solutions for first M levels are obtained. In particular, if M is odd (even) integer, then solutions with even number of nodes ($s=0$) are obtained when the coefficient of $P_{n-2}(Q_{n-2})$ vanishes. Similarly if M is odd (even) integer, the solutions with odd number of nodes ($s=\frac{1}{2}$) are obtained when the coefficient of $Q_{n-2}(P_{n-2})$ vanishes. Further for M even (say $2k+2$, $k=0,1,2,...$), half the levels, i.e., $(k+1)$ levels are obtained each from the zeros of the orthogonal polynomials $P_{k+1}(E)$ and $Q_{k+1}(E)$. On the other hand, when M is odd (say $2k+1$, $k=0,1,...$) then $k+1$ and k levels are obtained from the zeros of the orthogonal polynomials $P_{k+1}(E)$ and $Q_k(E)$, respectively.

We have studied the properties of the polynomial sets $\{P_n(E)\}$ and $\{Q_n(E)\}$ and we find that many of their properties are almost the same and in turn they are similar to the Bender–Dunne polynomials. In particular, since in both the cases the recursion relations are similar to those given by Eq. (1.4), hence for all values of the parameters M and s, they form an orthogonal set. Second, the wave function $\psi(x,E)$ is the generating function for the polynomials $P_n(E)$ as well as $Q_n(E)$. Third, when M is a positive integer, both of these polynomials exhibit factorization property whose precise form depends on whether M is even or odd. In particular, if $M=2k+1$, $k=0,1,2,...$ then one has $(n\geqslant 0)$

$$P_{k+1+n}(E)=P_{k+1}(E)\overline{P}_n(E),$$
$$Q_{k+n}(E)=Q_k(E)\overline{Q}_n(E). \tag{2.11}$$

On the other hand, if $M=2k+2$, $k=0,1,2,...$, then

$$P_{k+1+n}(E)=P_{k+1}(E)\overline{R}_n(E),$$
$$Q_{k+1+n}(E)=Q_{k+1}(E)\overline{S}_n(E), \tag{2.12}$$

where $\overline{P}_0(E)=\overline{Q}_0(E)=\overline{R}_0(E)=\overline{S}_0(E)=1$. Following Ref. 5, it is easily shown that the polynomial sets $\{P_n(E)\}$, $\{Q_n(E)\}$, $\{R_n(E)\}$ and $\{S_n(E)\}$ correspond to the non-exact spectrum for this problem.

To illustrate this factorization we list in factored form, the first few polynomials of both the types in case $M=3$ and $M=4$.

$$M=3:$$
$$P_0(E)=1,$$
$$P_1(E)=\mathscr{E}+2\zeta,$$
$$P_2(E)=\mathscr{E}^2+\mathscr{E}[12\zeta+4]+20\zeta^2+24\zeta, \tag{2.13}$$
$$P_3(E)=[\mathscr{E}+18\zeta+16]P_2(E),$$
$$P_4(E)=[\mathscr{E}^2+\mathscr{E}(46\zeta+52)+(36+28\zeta)(16+18\zeta)-240\zeta]P_2(E).$$

$$Q_0(E)=1,$$
$$Q_1(E)=\mathscr{E}+6\zeta+4,$$
$$Q_2(E)=\left[\mathscr{E}+14\zeta+\frac{35}{2}\right]Q_1(E), \tag{2.14}$$
$$Q_3(E)=[\mathscr{E}^2+\mathscr{E}(36\zeta+52)+(36+22\zeta)(16+14\zeta)-160\zeta]Q_1(E),$$

where $\mathscr{E}$ is given by Eq. (2.6). Let us notice that in this case $P_2(E)$, is a common factor of $P_n(E)$ for $n\geqslant 2$. The zeros of $P_2(E)$ are at

$$E_0=7+\zeta^2-2\sqrt{1+4\zeta^2},$$
$$E_2=7+\zeta^2+2\sqrt{1+4\zeta^2}, \tag{2.15}$$

which give the ground and second excited state eigenvalues for the potential when $M=3$. On the other hand $Q_1(E)$ is a common factor of $Q_n(E)$ for $n\geqslant 1$. The zeros of $Q_1(E)$ are at

$$E_1=\zeta^2+5, \tag{2.16}$$

which give the first excited state eigenvalue for the same potential (i.e., when $M=3$). In this way for $M=3$ one obtains exact energy eigenvalues for the first three levels.

$$M=4:$$

$$P_0(E)=1,$$

$$P_1(E)=\mathscr{E}+2\zeta+1,$$

$$P_2(E)=\mathscr{E}^2+\mathscr{E}[12\zeta+10]+20\zeta^2+44\zeta+9, \tag{2.17}$$

$$P_3(E)=[\mathscr{E}+18\zeta+25]P_2(E),$$

$$P_4(E)=[\mathscr{E}^2+\mathscr{E}(46\zeta+64)+(28\zeta+49)(18\zeta+25)-240\zeta]P_2(E).$$

$$Q_0(E)=1,$$

$$Q_1(E)=\mathscr{E}+6\zeta+1,$$

$$Q_2(E)=\mathscr{E}^2+\mathscr{E}[20\zeta+10]+84\zeta^2+116\zeta+9, \tag{2.18}$$

$$Q_3(E)=[\mathscr{E}+22\zeta+25]Q_2(E),$$

$$Q_4(E)=[\mathscr{E}^2+\mathscr{E}(52\zeta+74)+(30\zeta+49)(22\zeta+25)-336\zeta]Q_2(E).$$

In this case $P_2(Q_2)$ is a common factor of $P_n(Q_n)$ for $n\geqslant 2$. The zeros of $P_2(E)$ are at

$$\begin{aligned} E_1&=\zeta^2+2\zeta+11-4\sqrt{\zeta^2+\zeta+1},\\ E_3&=\zeta^2+2\zeta+11+4\sqrt{\zeta^2+\zeta+1}, \end{aligned} \tag{2.19}$$

which give the first and the third excited state energies for the potential when $M=4$. On the other hand the zeros of $Q_2(E)$ are at

$$\begin{aligned} E_0&=\zeta^2-2\zeta+11-4\sqrt{\zeta^2-\zeta+1},\\ E_2&=\zeta^2-2\zeta+11+4\sqrt{\zeta^2-\zeta+1}, \end{aligned} \tag{2.20}$$

which give the ground and the second excited state energies for the same potential ($M=4$). The corresponding eigenfunctions can be easily obtained by evaluating $\psi(x)$ in Eq. (2.4) at these values of E and not surprisingly they are the same as given by Razavy[8] (with appropriate change of parameters).

The norms (squared) of the orthogonal set of polynomials $P_n(E)$ and $Q_n(E)$ can be easily determined by using the recursion relations and we find (assuming $\gamma_0^{(p)}=\gamma_0^{(q)}=1$)

$$\begin{aligned} \gamma_n^{(p)}&=(-8\zeta)^n n!\prod_{k=1}^{n}[(2k-1)(M-2s-2k+1)],\\ \gamma_n^{(q)}&=(-8\zeta)^n n!\prod_{k=1}^{n}[(2k+1)(M-2s-2k)]. \end{aligned} \tag{2.21}$$

We observe from here that $\gamma_n^{(p)}$ vanishes for $2n\geqslant M-2s+1$ while $\gamma_n^{(q)}$ vanishes for $2n\geqslant M-2s$ provided M is a positive integer and as remarked by Bender–Dunne, this vanishing of norm is an alternative characterization of the QES problem. It may be noted that unlike the Bender–Dunne case, the norms are alternative in sign for $2n<M-2s+1$ or $2n<M-2s$ depending on the set $\{P_n(E)\}$, or $\{Q_n(E)\}$, respectively.

Using the factorization property as given by Eqs. (2.11) and (2.12) and using the recursion relations (2.6) and (2.7) satisfied by P_n and Q_n, it is easily shown that $P_n Q_n R_n$ and S_n satisfy the following recursion relations:

$$\begin{aligned}
\overline{P}_n(E) &= [(M+1+2n)^2+4(M+1+2n)(s+\zeta-1)+4s^2-8s+4-6\zeta+\mathscr{E}]\overline{P}_{n-1}(E) \\
&\quad +4\zeta(M-1+2n)(M+2n-2)[2-2s-2n]\overline{P}_{n-2}(E), \\
\overline{Q}_n(E) &= [(M-1+2n)^2+2(M-1+2n)(2s+2\zeta-1)+4s^2-4s+1-2\zeta+\mathscr{E}]\overline{Q}_{n-1}(E) \\
&\quad +4\zeta(M-3+2n)(M+2n-2)[3-2s-2n]\overline{Q}_{n-2}(E), \\
\overline{R}_n(E) &= [(M+2n)^2+4(M+2n)(s+\zeta-1)+4s^2-8s+4-6\zeta+\mathscr{E}]\overline{R}_{n-1}(E)+4\zeta(M-1+2n) \\
&\quad \times(M+2n-3)[3-2s-2n]\overline{R}_{n-2}(E), \\
\overline{S}_n(E) &= [(M+2n)^2+2(M+2n)(2s+2\zeta-1)+4s^2-4s+1-2\zeta+\mathscr{E}]\overline{S}_{n-1}(E) \\
&\quad +4\zeta(M-2+2n)(M+2n-1)[2-2s-2n]\overline{S}_{n-2}(E).
\end{aligned} \tag{2.22}$$

Using these recursion relations, it is straightforward to obtain the norms of theses polynomials and show that they are all positive. In particular, we obtain

$$\begin{aligned}
\overline{\gamma}_n^P &= (4\zeta)^n \prod_{k=1}^{n} [(M+2k+1)(M+2k)(2k+2s)], \\
\overline{\gamma}_n^Q &= (4\zeta)^n \prod_{k=1}^{n} [(M+2k)(M+2k-1)(2k+2s-1)], \\
\overline{\gamma}_n^R &= (4\zeta)^n \prod_{k=1}^{n} [(M+2k+1)(M+2k-1)(2k+2s-1)], \\
\overline{\gamma}_n^S &= (4\zeta)^n \prod_{k=1}^{n} [(M+2k+1)(M+2k)(2k+2s)].
\end{aligned} \tag{2.23}$$

Note that in Eqs. (2.22) and (2.23) M and s take only specific values. For example, in the case of $\overline{P}_n(E)M$ is odd and $s=0$, while in the case of $Q_n(E)$ M is odd and $s=\frac{1}{2}$. On the other hand, in the case of $\overline{R}_n(E)$ M is even and $s=\frac{1}{2}$ while in the case of $S_n(E)$ M is even but $s=0$.

Finally, we can also obtain the weight function $w(E)$ for our polynomials $\{P_n(E)\}$ and $\{Q_n(E)\}$ by using the expression as derived by Krajewska *et al.*[5] In particular, the weight function $w^{(p)}(E)$ can be written as

$$w^{(p)}(E) = \sum_{k=1}^{M} w_k^{(p)} \delta(E-E_k), \tag{2.24}$$

where the numbers $w_k^{(p)}$ satisfy the algebraic equation

$$\sum_{k=1}^{M} P_n(E_k) w_k^{(p)} = \delta_{n0}. \tag{2.25}$$

A similar relation also exists for the weight function of the Q polynomials.

As an illustration we have computed the weight functions $w_n^{(p)}$ and $w_n^{(q)}$ in case $M=3$ and 4. For example, when $M=3$, using Eqs. (2.24) to (2.25) and (2.13) we find that

$$w_0^{(p)}=\frac{1}{2}-\frac{2\zeta+1}{2\sqrt{1+4\zeta^2}},\quad w_2^{(p)}=\frac{1}{2}+\frac{2\zeta+1}{2\sqrt{1+4\zeta^2}},\quad w_1^{(q)}=1. \tag{2.26}$$

On the other hand, when $M=4$, using Eqs. (2.24), (2.25), (2.17), and (2.18) we find

$$\begin{aligned} w_0^{(q)}&=\frac{1}{2}-\frac{\zeta+1}{2\sqrt{\zeta^2-\zeta+1}},\quad w_1^{(p)}=\frac{1}{2}-\frac{\zeta+1}{2\sqrt{\zeta^2+\zeta+1}},\\ w_2^{(q)}&=\frac{1}{2}+\frac{\zeta+1}{2\sqrt{\zeta^2-\zeta+1}},\quad w_3^{(p)}=\frac{1}{2}+\frac{\zeta+1}{2\sqrt{\zeta^2+\zeta+1}}. \end{aligned} \tag{2.27}$$

As a cross check on our calculation of weight functions, we have calculated the norm of the polynomials by using the basic relations

$$\gamma_n^{(p)}=\int dE w^{(p)}(E)[P_n(E)]^2;\quad \gamma_n^{(q)}=\int dE w^{(q)}(E)[Q_n(E)]^2 \tag{2.28}$$

and for $M=3$ as well as 4 we have verified that we get the same answer as given by Eq. (2.21). It is worth pointing out that unlike the Bender–Dunne example, in none of our cases the weight functions are always positive. Actually this is not all that surprising. As has been proved by Finkel *et al.*,[4] if the three-term recursion relation is of the form

$$\hat{P}_{k+1}=(E-b_k)\hat{P}_k-a_k\hat{P}_{k-1},\quad k\geqslant 0 \tag{2.29}$$

with $a_0=0$ and $a_{n+1}=0$, then the weight functions are all positive if b_k is real for $0\leqslant k\leqslant n$ and $a_k>0$ for $1\leqslant k\leqslant n$. On comparing Eq. (2.29) with our recursion relation (2.6) and (2.7) we find that in both of our cases, a_k is in fact <0 for $1\leqslant k\leqslant n$.

Once the weight function is known, then one can also calculate the moments of $w(E)$, defined by

$$\mu_n=\int dE\ w(E)E^n. \tag{2.30}$$

Since in our case, the polynomials $\{P_n(E)\}$ and $\{Q_n(E)\}$ are not eigenfunctions of parity, hence unlike the Bender–Dunne case, odd moments do not vanish in our case. For example, the first few moments in our case for $M=3$ are (we choose $\mu_0^{(p)}=\mu_0^{(q)}=1$ without any loss of generality)

$$\begin{aligned} \mu_1^{(p)}&=(3+\zeta)^2-2\zeta;\quad \mu_2^{(p)}=-16\zeta+[(3+\zeta)^2-2\zeta]^2;\\ \mu_1^{(q)}&=(3+\zeta)^2-6\zeta-4;\quad \mu_2^{(q)}=[(3+\zeta)^2-6\zeta-4]^2. \end{aligned} \tag{2.31}$$

Following Finkel *et al.*,[4] we can also calculate the growth rate of the moments. In particular, since in both of our cases, $a_k\neq 0$ for $1\leqslant k<n$ where a_k as given by Eqs. (2.29), (2.6) and (2.7), hence following their discussion it is easily shown that for large n, to leading order

$$\mu_n^{(p)},\quad \mu_n^{(q)}\sim(M+\zeta)^{2n}. \tag{2.32}$$

Thus in our case the moments have a pure power growth.

III. NEW QES POTENTIALS FROM ANTI-ISOSPECTRAL TRANSFORMATIONS

In an interesting paper, Krajewska *et al.*[1] have recently discussed the consequences of the anti-isospectral transformation (also termed as duality transformation) in the context of the QES problems. In particular, they have shown that under the transformations $x\rightarrow ix=y$, if a potential $V(x)$ goes to $\overline{V}(y)$, i.e.,

$$V(x)\rightarrow\overline{V}(y) \tag{3.1}$$

then the QES levels of the two are also related. In particular, they have shown that if M levels of the potential $V(x)$ are QES levels with energy eigenvalues and eigenfunctions $E_k(k=0,1,...,M-1)$ and $\psi_k(x)$ respectively then the energy eigenfunctions of $\bar{V}(y)$ are given by

$$\bar{E}_k = -E_{M-1-k}, \quad \bar{\psi}_k(y) = \psi_{M-1-k}(ix). \tag{3.2}$$

As an illustration, these authors have discussed the x^6 potentials as given by Eqs. (1.1) and (1.2) and explained in details how the eigen spectra of these two dual potentials are related. However, in this particular case, the domain of x and y are the same.

The purpose of this section is to explore the consequences of this symmetry when the domain of validity of $V(x)$ and $\bar{V}(y)$ are different and to see how many of the results derived in Ref. 1 go through in this case. In particular, do $V(x)$ and $\bar{V}(y)$, hold the same number of bound states? Are the bound states of the two potentials still related by Eq. (3.2)? To begin with, we would also like to comment that, the duality symmetry is only useful in case the potential $V(x)$ is symmetric in x as otherwise the dual potential $\bar{V}(y)$ will be a complex potential.

A. DSG example

Let us consider the potential corresponding to the DSHG case, and try to explore the consequences of the duality symmetry in this case. On applying the duality transformation $x \to i\theta$ to the Schrödinger equation $H\psi = E\psi$ with H as given by Eq. (2.1) we obtain the following Schrödinger equation for the DSG equation:

$$\left[-\frac{d^2}{d\theta^2} - (\zeta \cos 2\theta - M)^2 \right] \psi(\theta) = \hat{E}\psi(\theta), \quad \hat{E} = -E. \tag{3.3}$$

Note that whereas the domain of x in DSHG equation is $-\infty \leqslant x \leqslant \infty$ in the DSG case, the domain is $0 \leqslant \theta \leqslant 2\pi$ provided we are solving the problem on a circle as we do here. As a result, unlike the DSHG case, in the DSG case due to the periodicity constraint, one has to demand that the wave function $\psi(\theta)$ must be invariant under $\theta \to \theta + \pi$, i.e.,

$$\psi(\theta + \pi) = \psi(\theta). \tag{3.4}$$

Looking at the QES eigenfunctions of the DSHG case, it is easy to see that when M is even (i.e., $M = 2,4,...$) then the eigenfunctions of the DSG case do not remain invariant under $\theta \to \theta + \pi$ but they change sign. As a result, the QES levels of DSG when M is even must be rejected. Thus on physical ground, we find that in case the domain of $V(x)$ and $\bar{V}(y)$ are different then the number of QES levels of $V(x)$ and $\bar{V}(y)$ need not be identical. In particular, boundary conditions may forbid some wave functions to be eigenfunctions. For example, for $M = 2$, naively one would have two exact energy eigenstates of DSG equation as given by

$$\begin{aligned} \psi_0^{\mathrm{DSG}}(\theta) &= \sin\ \theta e^{-(\zeta/2)\cos 2\theta}, \\ \psi_2^{\mathrm{DSG}}(\theta) &= \cos\ \theta e^{-(\zeta/2)\cos 2\theta}. \end{aligned} \tag{3.5}$$

However, both of these are unacceptable eigenfunctions of DSG, being odd under $\theta \to \theta + \pi$. Thus we have shown that even though DSG and DSHG are dual system, DSG equation has approximately only half the number of QES levels compared to the DSHG case. In particular, when M is an odd integer ($M = 1,3,5,...$) only then the DSG is a QES system and in that case the first M levels are exactly known, and in fact they can be immediately obtained from the corresponding DSHG case by making use of the duality relation (3.2). For example, for $M = 1$ the ground state of the above DSG is given by

$$\hat{E}_0 = -(1 + \zeta^2), \quad \psi_0 = e^{-(\zeta/2)\cos 2\theta}. \tag{3.6}$$

On the other hand, for $M = 3$, the first 3 levels of the DSG equation are are given by

$$\hat{E}_0 = -7 - \zeta^2 - 2\sqrt{1 + 4\zeta^2}; \quad \psi_0 = [2\zeta - \{\sqrt{1 + 4\zeta^2} - 1\}\cos 2\theta] e^{-(\zeta/2)\cos 2\theta};$$

$$\hat{E}_1 = -\zeta^2 - 5; \quad \psi_1 = \sin 2\theta e^{-(\zeta/2)\cos 2\theta}; \tag{3.7}$$

$$\hat{E}_2 = -7 - \zeta^2 + 2\sqrt{1+4\zeta^2}; \quad \psi_2 = [2\zeta + \{\sqrt{1+4\zeta^2}+1\}\cos 2\theta] e^{-(\zeta/2)\cos 2\theta}.$$

The energy eigenstates of the DSG equation have recently been obtained by Habib *et al.*[9] and not surprisingly our results are the same as obtained by them.

One can now study the Bender–Dunne polynomials of the DSG equation and it is easy to see that most of the discussion of the last section (for the DSHG case) also goes through in this case except that now only odd values of M give us a QES system. For example, the recursion relations for P_n and Q_n as given in the last section are also valid in this case provided we replace E by $-E$. Thus the three-term recursion relation for P_n as given by Eq. (2.6) with E changed to $-E$ will give an exact solution for the DSG case only if $s=0$ while the three-term recursion relation for Q_n as given by Eq. (2.7) (with E changed to $-E$) will give an exact solution only if $s=\frac{1}{2}$. Most of the other properties in the last section continue to be valid in the DSG case also (with the obvious replacement of E by $-E$) except now only $\bar{P}_n(E)$ and $\bar{Q}_n(E)$ exist while $\bar{R}_n(E)$ and $\bar{S}_n(E)$ as given by Eq. (2.22) do not exist (Note that P_n and Q_n do not give QES solution if M is even integer.) In particular, we want to emphasize that the norms of the polynomial sets $\{P_n(E)\}$, $\{Q_n(E)\}$, $\{\bar{P}_n(E)\}$ and $\{\bar{Q}_n(E)\}$ are unchanged from those of the DSHG case. However, the weight functions get interchanged. For example for $M=3$ the weight functions for the DSG case are

$$w_0^{(p)} = \frac{1}{2} + \frac{2\zeta+1}{2\sqrt{1+4\zeta^2}}, \quad w_2^{(p)} = \frac{1}{2} - \frac{2\zeta+1}{2\sqrt{1+4\zeta^2}}, \quad w_1^{(q)} = 1. \tag{3.8}$$

Thus even in this case, the weight function are *not* always positive. Finally, it is easily shown that the moments for the DSG and DSHG cases are related by

$$\mu_n^{(p,q)}|_{\mathrm{DSG}} = (-1)^n \mu_n^{(p,q)}|_{\mathrm{DSHG}} \tag{3.9}$$

so that for large n, to leading order, the DSG moments also have a pure power growth rate as given by

$$\mu_n \sim (-1)^n (M+\zeta)^{2n}. \tag{3.10}$$

B. New QES potential

We shall now point out a nontrivial application of the duality symmetry. In particular, using this, we obtain an entirely new QES potential which has so far not been discussed in the literature.[15]

Consider the following potential

$$V(x) = \frac{\mu^2[8\sinh^4(\mu x/2) - 4(5/\epsilon^2 - 1)\sinh^2(\mu x/2) + 2(1/\epsilon^4 - 1/\epsilon^2 - 2)]}{8[1 + (1/\epsilon^2) + \sinh^2(\mu x/2)]^2} \tag{3.11}$$

which is obtained in the context of the stability analysis of the ϕ^6-kink solution in $1+1$ dimensions.[12] As has been shown before, in this case the Schrödinger equation can be converted to Heun's equation with four regular singular points. Further, for any ϵ, the ground stat of the Schrödinger equation corresponding to this potential is given by ($\hbar = 2m = 1$)

$$\psi_0 = N_0 \left[\frac{\epsilon^2+1}{\epsilon^2+1+\epsilon^2\sinh^2(\mu x/2)}\right]\left[\frac{\epsilon^2\sinh^2(\mu x/2)}{\epsilon^2+1+\epsilon^2\sinh^2(\mu x/2)} + \frac{1}{2}\right]^{1/2}, \quad E_0 = 0. \tag{3.12}$$

Further for the special case of, $\epsilon^2 = \frac{1}{2}$, the second excited state is also analytically known and given by

$$\psi_2 = N_2\left[\frac{3}{3+\sinh^2(\mu x/2)}\right]\left[\frac{\sinh^2(\mu x/2)}{3+\sinh^2(\mu x/2)} - \frac{1}{4}\right], \quad E_2 = \frac{3}{4}\,\mu^2. \tag{3.13}$$

Thus for $\epsilon^2 = \frac{1}{2}$ this is a QES system. It may be noted that even though it is a QES system in one dimension, the Hamiltonian can not be written in this case in terms of the quadratic generators of Sl(2).[16] Further, as shown by us recently,[7] in this case the Bender–Dunne polynomials do not form an orthogonal set. We shall now apply the duality transformation and obtain a new QES system which has not been discussed before.

On considering the duality transformation $x \to i\theta$ in the Schrödinger equation $H\psi = E\psi$ corresponding to the potential (3.11), we find that we have a new periodic potential

$$\overline{V}(\theta) = -\frac{\mu^2[8\sin^4(\mu\theta/2) + 4(5/\epsilon^2 - 1)\sin^2(\mu\theta/2) + 2(1/\epsilon^4 - 1/\epsilon^2 - 2)]}{8[1 + 1/\epsilon^2 - \sin^2(\mu\theta/2)]^2}. \tag{3.14}$$

Notice that the domain of $V(x)$ and $\overline{V}(\theta)$ are very different, i.e., whereas $-\infty \leqslant \mu x \leqslant \infty$, $0 \leqslant \mu\theta \leqslant 2\pi$. However, the predictions of duality symmetry as given by Eq. (3.2) are still valid. In particular, using Eq. (3.2) we predict that the potential $V(\theta)$ as given above is a QES system in case $\epsilon^2 = \frac{1}{2}$ and it's ground and second excited states energy eigenvalues are given by

$$\begin{aligned} E_0 &= -\frac{3}{4}\,\mu^2, \quad \psi_0 = N_3\left[\frac{3}{3-\sin^2(\mu\theta/2)}\right]\left[\frac{1}{4} + \frac{\sin^2(\mu\theta/2)}{3-\sin^2(\mu\theta/2)}\right], \\ E_2 &= 0, \quad \psi_2 = N_4\left[\frac{\epsilon^2+1}{\epsilon^2+1-\epsilon^2\,\sin^2(\mu\theta/2)}\right]\left[\frac{1}{2} - \frac{\epsilon^2\,\sin^2(\mu\theta/2)}{\epsilon^2+1-\epsilon^2\,\sin^2(\mu\theta/2)}\right]. \end{aligned} \tag{3.15}$$

In particular, we would like to emphasize that for the QES potential (3.14), the second excited state ψ_2 is known at all real values of ϵ, while ψ_0 is only known at $\epsilon^2 = \frac{1}{2}$. One can solve the Schrödinger equation explicitly for the potential (3.14) and check that indeed these are the energy eigenstates of the system. In particular, note that both ψ_0 and ψ_2 are invariant under $\mu\theta \to \mu\theta + 2\pi$, i.e., $\psi(\mu\theta + 2\pi) = \psi(\mu\theta)$. It is really remarkable that using duality we are able to obtain a new QES system. In this case one can also obtain the three-term recursion relation for the Bender–Dunne polynomials[2] and show that they do not form an orthogonal set. This is related to the fact that the corresponding Schrödinger equation can be converted to Heun's equation with four regular singular points.

It may be worthwhile to look at all known QES systems and see if the corresponding dual systems have already been discussed in the literature or not. In this way one may discover some more QES systems.

IV. DISCUSSIONS

In this paper we have analyzed in some detail a QES system for which the energy eigenstates for levels with odd as well as even number of nodes are known for a given potential. We have seen that in this case one obtains two independent sets of orthogonal polynomials. Further, we have also seen that the weight functions in this case are not necessarily positive. It will be interesting to study a few other examples of the same type and enquire if in those cases, too, one obtains two sets of orthogonal polynomials or not and further, whether the weight functions in such cases are always positive or not. We have also compared the spectrum of two dual potentials in case their domain of validity are quite different. We have seen in one case that because of different boundary conditions, the QES spectrum of the dual potentials is not the same. It will be interesting to study several such QES dual potentials and see if some general conclusions can be obtained in these cases.

Finally, it would be really interesting if one can discover some new QES potentials by making use of the duality symmetry.

Generalized Lie algebras of type A_n

Volodymyr Lyubashenko[a] and Anthony Sudbery
Department of Mathematics, University of York, Heslington, York, England YO1 5DD, United Kingdom

(Received 9 April 1997; accepted for publication 10 December 1997)

It is shown that the quantized enveloping algebra of $\mathfrak{sl}(n)$ contains a generalized Lie algebra, defined by means of axioms similar to Woronowicz's. This gives rise to Lie algebra-like generators and relations for the locally finite part of the quantized enveloping algebra, and suggests a canonical Poincaré–Birkhoff–Witt basis.
© *1998 American Institute of Physics.* [S0022-2488(98)01705-8]

I. INTRODUCTION

There have been several proposals[1–3] for a definition of a ''quantum Lie algebra,'' something which should bear the same relation to the quantized enveloping algebra $U_q(\mathfrak{g})$ as the classical Lie algebra $\mathfrak{g}$ bears to its enveloping algebra. Properties of the classical Lie algebra which are retained in one or more of these proposals include the following.

(1) The quantum Lie algebra $\mathfrak{g}_q$ should be a vector space of the same dimension as the classical Lie algebra $\mathfrak{g}$.
(2) It should be a deformation of $\mathfrak{g}$, i.e., the classical Lie algebra should be recovered in the limit $q\to 1$.
(3) It should have a binary operation, the *quantum Lie bracket*.
(4) The quantum Lie bracket should be a bilinear map from $\mathfrak{g}\times\mathfrak{g}$ to $\mathfrak{g}$.
(5) It should satisfy a Jacobi identity and an antisymmetry axiom.
(6) These axioms should be stated in terms of the quantum Lie bracket alone (i.e., without reference to a pre-existing enveloping algebra).
(7) The quantum Lie algebra should appear as a subspace of the quantized enveloping algebra, the bracket $[x,y]$ being given by the Hopf algebra adjoint action of x on y.
(8) It should be possible to define the relations of the enveloping algebra in terms of the quantum Lie bracket, by interpreting the bracket as a quadratic expression like a commutator.
(9) There should be a Poincaré–Birkhoff–Witt theorem stating that the quantized enveloping algebra has a basis consisting of ordered monomials in the Lie algebra elements.

It seems to be impossible to meet all these requirements simultaneously. We might expect to have to modify them, indeed some of them can be seen to be unrealistic, but none of the proposed definitions satisfies them all, even in modified form. In this paper we describe a form of quantum Lie algebra having a subset of the above properties which is sufficient for the formulation of a gauge theory based on a quantum group.[4] To avoid confusion with the other senses of quantum Lie algebra defined in the literature, we call our system a ''generalized Lie algebra'' (we are grateful to Delius for this suggestion).

The essential properties of our definition, its relation to other definitions and the ways in which it fails to meet the specifications set out above are as follows.

1. Our generalized Lie algebra is a vector space with a bilinear bracket operation satisfying versions of anticommutativity and the Jacobi identity which are formulated with the aid of an auxiliary structure, a generalized antisymmetrizer. This structure is close to that found by Woronowicz[5] in his theory of non-commutative differential geometry on quantum groups. However, Woronowicz's Lie algebra has the additional property that its generalized antisymmetrizer

[a]Current address: Department of Mathematics, Kansas State University, 137 Cardwell Hall, Manhattan, Kansas 66506-2602.

 © 1998 American Institute of Physics

satisfies the braid relation. Ours does not have this property. It may be that some property similar to this is needed for a fully satisfactory theory, but we have not yet succeeded in identifying it. The quantum Lie algebra of Delius *et al.*[2,3] does not satisfy a Jacobi identity, and the antisymmetry of their Lie bracket can only be defined if the field of scalars is considered to be the field of rational functions in an indeterminate q; it is not a property of the algebra for a specific value of q. The Jacobi identity for Majid's quantum Lie algebra is formulated with reference to the enveloping algebra which contains it, not intrinsically; and he has no antisymmetry axiom.

2. With the help of the generalized antisymmetrizer we can define the enveloping algebra of a generalized Lie algebra, which is not possible for a general algebra. Thus we start with the generalized Lie algebra and construct the enveloping algebra around it, unlike Delius *et al.* and Majid who start with the quantized enveloping algebra and find the quantum Lie algebra inside it. The relations of our enveloping algebra, as in the classical case, are quadratic-linear (generalized commutator=Lie bracket). However, this enveloping algebra cannot be directly identified with the quantized enveloping algebra which is (roughly speaking—see the next paragraph) generated by the generalized Lie algebra but with homogeneous quadratic relations, the right-hand side containing an extra central element as a factor. To put it another way, the structure constants in the quantized enveloping algebra are multiples of a function of the Casimirs. This is an interesting feature; it means that the PBW theorem leads to a description of the vector space structure of the enveloping algebra as a space of polynomial functions not on a flat space (namely the Lie algebra) but on a hypersurface of the same dimension. Thus quantization gives rise to curvature of the enveloping algebra.

3. The algebra generated by our generalized Lie algebra cannot be expected to be the same size as the quantized enveloping algebra, since this differs from the classical enveloping algebra in containing infinite power series (specifically, exponentials) in the generators. On the other hand, if, as is common in the mathematical literature, one takes the generators of the quantized enveloping algebra to be q^{H_i} in place of the Cartan subalgebra elements H_i, then one loses the polynomials in the H_i. It is a remarkable fact[6] that the quantized enveloping algebra so defined contains a subalgebra, its locally finite part, which has the same structure as the classical enveloping algebra and is a large part of the quantized enveloping algebra. It seems likely that the enveloping algebra of the generalized Lie algebra, as defined in this paper, coincides with the locally finite part of the quantized enveloping algebra. Here we prove this for the case of $\mathfrak{sl}(2)$.

4. The construction of a generalized Lie algebra given here makes sense for any simple Lie algebra, but it is only for the Lie algebras of type A_n that it yields a system with the same dimension as the classical Lie algebra. Thus it is only in these cases that a PBW theorem is likely to hold. Even here, we have no general proof of the theorem; it can be checked by an explicit calculation for A_1 and A_2.

On this question of dimension our construction is similar to that of Majid, which yields (or can be adapted to yield) a quantum Lie algebra of dimension n^2-1 where n is the dimension of any representation of the classical Lie algebra. Woronowicz's theory yields a satisfactory deformation of the classical Lie algebra only in the case of general linear groups;[7–9] in all other cases (see Refs. 10–13) the generalized Lie algebra has dimension n^2 where n is the dimension of a particular representation.

5. As indicated above, the commutator-like relations obtained from the generalized Lie algebra are not the only relations in the quantized enveloping algebra; there is also a relation between central elements, giving the extra (non-classical) central generator in terms of more familiar Casimir elements which are polynomials in Lie algebra elements. The existence of this extra relation is at present only a conjecture in all cases except $\mathfrak{sl}(2)$, for which it can be explicitly demonstrated.

The organization of the paper is as follows. The next section contains the definition of a generalized Lie algebra and the proof that such a system can be found inside the quantized enveloping algebra. This relies heavily on the theorems of Joseph and Letzter[6] concerning the locally finite part of a quantized enveloping algebra. In section III we complete the theory for $\mathfrak{sl}(2)_q$, proving the Poincaré–Birkhoff–Witt theorem, determining the extra relation between central elements, and proving that the algebra defined by the generalized Lie algebra relations, together with the extra relation, is the locally finite part of the quantized enveloping algebra.

Section IV contains some material on the generalized Lie algebra $\mathfrak{sl}(3)_q$, with formulae for the Lie brackets and a discussion of the rather surprising symmetry properties of the enveloping algebra.

Notation: We use the usual notation for coproducts in a Hopf algebra:

$$\Delta(x)=\sum x_{(1)}\otimes x_{(2)},$$

$$(\Delta\otimes\mathrm{id})\circ\Delta(x)=\sum x_{(1)}\otimes x_{(2)}\otimes x_{(3)},\ \text{etc.},$$

and for the q-analogue function:

$$[x]_q=\frac{q^x-q^{-x}}{q-q^{-1}}.$$

II. GENERALIZED LIE ALGEBRAS

Definition 2.1: A *generalized Lie algebra* over a field $\mathbb{K}$ is a $\mathbb{K}$-vector space L together with linear maps $\beta: L\otimes L\to L$ (the generalized Lie bracket, written as $x\otimes y\mapsto[x,y]$) and $\gamma: L\otimes L\to L\otimes L$ (the generalized antisymmetrizer) satisfying the following.

1. Generalized antisymmetry: For $t\in L\otimes L$,

$$\gamma(t)=0\Rightarrow\beta(t)=0. \tag{2.1}$$

2. The generalized Jacobi identity: For $x\in L$, define $\mathrm{ad}x: L\to L$ by $\mathrm{ad}x(y)=[x,y]$. Then

$$\mathrm{ad}[x,y]=m\circ(\mathrm{ad}\otimes\mathrm{ad})\circ\gamma(x\otimes y), \tag{2.2}$$

where $m:\mathrm{End}\,L\otimes\mathrm{End}\,L\to\mathrm{End}\,L$ denotes multiplication of linear maps on L.

Definition 2.2: A generalized Lie algebra is *balanced* if it satisfies a second Jacobi identity.

3. The right generalized Jacobi identity: For $x\in L$, define $\mathrm{rad}x: L\to L$ by $\mathrm{rad}x(y)=[y,x]$. Then

$$\mathrm{rad}[x,y]=\tilde{m}\circ(\mathrm{rad}\otimes\mathrm{rad})\circ\gamma(x\otimes y), \tag{2.3}$$

where $\tilde{m}:\mathrm{End}\,L\otimes\mathrm{End}\,L\to\mathrm{End}\,L$ denotes the opposite multiplication of linear maps: $\tilde{m}(A\otimes B)=BA$.

If γ is the usual antisymmetrization map, $\gamma(x\otimes y)=x\otimes y-y\otimes x$, the above become the usual antisymmetry and Jacobi axioms for a Lie algebra. These generalized axioms were found by Woronowicz to hold for the geometrical Lie bracket of left-invariant vector fields on a quantum Lie group;[5] he also found that in this case the generalized antisymmetrizer was of the form $\gamma=1-\sigma$ where σ satisfies the braid relation. This is not true of the generalized Lie algebras described in this paper; we do not know if there is a weaker axiom of this type that they satisfy.

Woronowicz included only one Jacobi identity among his axioms; the geometrical construction does not obviously yield a balanced generalized Lie algebra. This is also, at first sight, true of the construction from universal enveloping algebras to be described in this paper. However, inspection of the generalized Lie algebra $\mathfrak{sl}(2)_q$ reveals that it is in fact balanced, and it seems likely that this is true more generally.

Definition 2.3: A *representation* of a generalized Lie algebra (L,β,γ) is a linear map $\rho: L\to\mathrm{End}\,V$ for some vector space V, such that

$$\rho\circ\beta=m_V\circ(\rho\otimes\rho)\circ\gamma: L\otimes L\to\mathrm{End}\,V, \tag{2.4}$$

where m_V denotes multiplication of linear operators on V.

Then the Jacobi identity (2.3) states that ad is a representation of L in $\mathrm{End}_{\mathbb{K}}V$, as with classical Lie algebras.

Definition 2.4: The *universal enveloping algebra* of a generalized Lie algebra (L,β,γ) is the quotient of the tensor algebra of L by the ideal generated by $(\beta-\gamma)(V\otimes V)$. Then every representation of L automatically generates a representation of its universal enveloping algebra.

Let $x_1,\ldots,x_n$ be a basis for L, and let γ_{ij}^{kl} be the matrix elements of γ with respect to the basis $x_i\otimes x_j$ of $L\otimes L$; in the classical case,

$$\gamma_{ij}^{kl}=\delta_i^k\delta_j^l-\delta_i^l\delta_j^k.$$

Then the Jacobi identity can be written as

$$[[x_i,x_j],x_k]=\gamma_{ij}^{lm}[x_l,[x_m,x_k]],$$

the right Jacobi identity as

$$[x_i,[x_j,x_k]]=\gamma_{jk}^{lm}[[x_i,x_l],x_m],$$

the representation property as

$$\rho([x_i,x_j])=\gamma_{ij}^{kl}\rho(x_k)\rho(x_l),$$

and the relations in the universal enveloping algebra as

$$\gamma_{ij}^{kl}x_kx_l=[x_i,x_j]=\beta_{ij}^kx_k,$$

where β_{ij}^k are the structure constants of L (i.e., the matrix elements of β).

Let q be a fixed element of the ground field $\mathbb{K}$, $\mathfrak{g}$ a simple Lie algebra over $\mathbb{K}$, and let $\mathcal{U}=\overline{U}_q(\mathfrak{g})$ be the simply-connected quantized enveloping algebra of $\mathfrak{g}$, which is defined as follows. $\mathcal{U}$ contains a copy of the group algebra of the weight lattice of $\mathfrak{g}$ (with basis elements denoted by q^λ where λ is an integral weight of $\mathfrak{g}$ with respect to a Cartan subalgebra $\mathfrak{h}$) and generators $E_1,\ldots,E_r,F_1,\ldots,F_r$ corresponding to fundamental roots $H_1,\ldots,H_r$ of $\mathfrak{g}$, with relations

$$q^\lambda E_iq^{-\lambda}=q^{\langle H_i,\lambda\rangle}E_i,$$

$$q^\lambda F_iq^{-\lambda}=q^{-\langle H_i,\lambda\rangle}F_i,$$

$$E_iF_j-F_jE_i=\delta_{ij}\left(\frac{q^{2H_i}-q^{-2H_i}}{q_i-q_i^{-1}}\right),$$

$$[E_i,[E_i,\ldots,[E_i,E_j]_{q_i^{-n+1}}]_{q_i^{-n+3}}\cdots]_{q_i^{n-1}}=0,$$

$$[F_i,[F_i,\ldots,[F_i,F_j]_{q_i^{-n+1}}]_{q_i^{-n+3}}\cdots]_{q_i^{n-1}}=0,$$

where $\langle,\rangle$ denotes the Killing form in the Cartan subalgebra $\mathfrak{h}$ (which we do not distinguish from its dual $\mathfrak{h}^*$),

$$q_i=q^{\langle H_i,H_i\rangle},$$

$$n=\frac{2\langle H_i,H_j\rangle}{\langle H_i,H_i\rangle}=\text{number of roots } H_j+kH_i \text{ with } k>0,$$

and

$$[X,Y]_p=pXY-p^{-1}YX.$$

Then $\mathcal{U}$ is a Hopf algebra with comultiplication

$$\Delta(E_i)=E_i\otimes q^{-H_i}+q^{H_i}\otimes E_i,$$

$$\Delta(F_i)=F_i\otimes q^{-H_i}+q^{H_i}\otimes F_i,$$

$$\Delta(q^\lambda)=q^\lambda\otimes q^\lambda,$$

and antipodes

$$S(E_i)=-q_i^{-1}E_i,\quad S(F_i)=-q_iF_i,\quad S(q^\lambda)=q^{-\lambda}.$$

As in any Hopf algebra, we have the adjoint representation of $\mathcal{U}$ on itself, given by $x\mapsto \mathrm{ad}\ x\in \mathrm{End}_{\mathbb{K}}\ \mathcal{U}$ where

$$\mathrm{ad}\ x(y)=\sum\ x_{(1)}yS(x_{(2)}),\quad \text{if}\ \ \Delta(x)=\sum\ x_{(1)}\otimes x_{(2)}.$$

This is a representation:

$$\mathrm{ad}(xy)=\mathrm{ad}\ x\cdot\mathrm{ad}\ y, \tag{2.5}$$

and each ad x is a generalized derivation of $\mathcal{U}$, in the sense that

$$\mathrm{ad}\ x\ \ (yz)=\sum\ \ \mathrm{ad}\ x_{(1)}(y)\cdot\mathrm{ad}\ x_{(2)}(z). \tag{2.6}$$

The adjoint action of the generators of $\mathcal{U}$ is given by

$$\begin{aligned}\mathrm{ad}\ E_i(x)&=E_ixq^{H_i}-q^{H_i-1}xE_i,\\ \mathrm{ad}\ F_i(x)&=F_ixq^{H_i}-q^{H_i+1}xF_i,\\ \mathrm{ad}\ q^\lambda(x)&=q^\lambda xq^{-\lambda}.\end{aligned} \tag{2.7}$$

We use the adjoint representation to define a bracket on $\overline{U}_q(\mathfrak{g})$, defining

$$[x,y]=\mathrm{ad}\ x(y). \tag{2.8}$$

Each ad x is also a generalized derivation of this bracket:

$$[x,[y,z]]=\sum\ [[x_{(1)},y],[x_{(2)},z]]. \tag{2.9}$$

This is a kind of Jacobi identity for the adjoint bracket. The representation property gives another kind of Jacobi identity:

$$[[x,y],z]=\sum\ [x_{(1)},[y,[x_{(2)},z]]]. \tag{2.10}$$

Both of these are valid in any Hopf algebra.[1] However, they are not suitable as replacements for the Jacobi identity in defining a notion of generalized Lie algebra, as the ad-invariant subspaces of quantized enveloping algebras which are candidates for generalized Lie algebras are not usually subcoalgebras, and so the coproduct which is required to formulate the above Jacobi identities is not an intrinsic notion. That is why we are interested in the third kind of Jacobi identity, of the form (2.3), which is specific to quantized enveloping algebras.

The vector space $\overline{U}_q(\mathfrak{g})$ does not split up nicely into irreducible ad-invariant subspaces; strictly speaking it is not a direct sum of such spaces, for there are elements with components in an infinite number of them. The *locally finite part* of $\mathcal{U}=\overline{U}_q(\mathfrak{g})$ is the set of elements for which this is not true, i.e.,

$$\mathcal{F}=\mathrm{LF}\overline{U}_q(\mathfrak{g})=\{x\in\mathcal{U}:\ \text{ad}\,\mathcal{U}(x)\ \text{ is finite-dimensional}\}. \tag{2.11}$$

The discovery of Joseph and Letzter was that $\mathcal{F}$ is easily described, and has the same composition as the classical enveloping algebra $U(\mathfrak{g})$.

Theorem 2.1 (Joseph and Letzter[6])**:** *Let* λ *be a dominant integral weight of* $\mathfrak{g}$, V_λ *the simple* $\mathfrak{g}$*-module with highest weight* λ; V_λ *can also be regarded as a simple* $\mathcal{U}$*-module where* $\mathcal{U}=\overline{U}_q(\mathfrak{g})$, *and* $\mathrm{End}_{\mathbb{K}}\,V_\lambda$ *is a* $\mathcal{U}$*-module by conjugation [i.e., if* $x\in\mathcal{U}$ *acts on* V_λ *by* $\rho(x)$, *it acts on* $\mathrm{End}_{\mathbb{K}}\,V_\lambda$ *by* $T\mapsto\Sigma\rho(x_{(1)})T\rho(Sx_{(2)})$*]. Then we have the following.*

(1) $E_\lambda=\text{ad}\,\mathcal{U}(q^{-4\lambda})$ *is a finite-dimensional* ad*-invariant subspace of* $\mathcal{U}$, *isomorphic to* $\mathrm{End}_{\mathbb{K}}\,V_\lambda$ *as a* $\mathcal{U}$*-module.*

(2) *The locally finite part of* $\mathcal{U}$ is

$$\mathcal{F}=\sum_\lambda E_\lambda, \tag{2.12}$$

where the sum extends over all dominant integral weights of $\mathfrak{g}$.

For a dominant integral weight λ, we write $N_\lambda=\dim_{\mathbb{K}}V_\lambda$. Then our result on the existence of generalized Lie algebras in $\overline{U}_q(\mathfrak{g})$ is the following.

Theorem 2.2: *For each dominant integral weight* λ, $\overline{U}_q(\mathfrak{g})$ *contains an* (N_λ^2-1)*-dimensional* ad*-invariant subspace* L_λ, *a linear map* $\sigma:L_\lambda\otimes L_\lambda\to L_\lambda\otimes L_\lambda$, *and a central element* $C_\lambda\in\overline{U}_q(\mathfrak{g})$ *such that*

$$xy-m\circ\sigma(x\otimes y)=C_\lambda[x,y]\quad(x,y\in L_\lambda), \tag{2.13}$$

i.e.,

$$x_ix_j-\sigma_{ij}^{kl}x_kx_l=C_\lambda[x_i,x_j], \tag{2.14}$$

where m *denotes multiplication in* $\overline{U}_q(\mathfrak{g})$, $[,]$ *is the adjoint bracket, and* $\{x_i\}$ *is a basis of* L_λ.

Proof: Writing $\mathcal{U}=\overline{U}_q(\mathfrak{g})$, let $\overline{L}=\text{ad}\,\mathcal{U}(q^{-4\lambda})$. Then $\overline{L}$ is invariant under ad $\mathcal{U}$, and by Theorem 2.1 it is isomorphic as a $\mathcal{U}$-module to $\mathrm{End}_{\mathbb{K}}\,V_\lambda$. This contains a one-dimensional submodule (spanned by the identity of $\mathrm{End}_{\mathbb{K}}\,V_\lambda$) and so by complete reducibility of representations of $\overline{U}_q(\mathfrak{g})$ (Ref. 14, p. 324) we can write

$$\overline{L}=\mathbb{K}C_\lambda\oplus L,$$

as a $\mathcal{U}$-module, for some $C_\lambda\in\overline{L}$. Then C_λ carries the trivial representation of $\mathcal{U}$:

$$\text{ad}\,x(C_\lambda)=\varepsilon(x)C_\lambda,\quad\forall x\in\mathcal{U}.$$

Hence C_λ is a central element of $\mathcal{U}$, for

$$xC_\lambda=\sum x_{(1)}C_\lambda Sx_{(2)}x_{(3)}=\sum\ \text{ad}\,x_{(1)}(C_\lambda)x_{(2)}=\sum\varepsilon(x_{(1)})C_\lambda x_{(2)}=C_\lambda x.$$

Now $\overline{L}$ is a left coideal of $\mathcal{U}$:

$$\begin{aligned}x\in\overline{L}&\Rightarrow x=\text{ad}\,u(q^{-4\lambda}),\quad\text{for some}\ u\in\mathcal{U}\\&\Rightarrow\Delta(x)=\sum\Delta(u_{(1)})\Delta(q^{-4\lambda})\Delta(Su_{(2)})\\&=\sum(u_{(1)}\otimes u_{(2)})(q^{-4\lambda}\otimes q^{-4\lambda})(Su_{(4)}\otimes Su_{(3)})\\&\in\mathcal{U}\otimes\overline{L}.\end{aligned} \tag{2.15}$$

Hence for any $x \in L$ we can write

$$\Delta(x) = x_0 \otimes C_\lambda + \sum u' \otimes x',$$

with $x_0, u' \in \mathcal{U}$ and $x' \in L$. In fact we can choose C_λ so that $x_0 = x$: for if $q^{-4\lambda} = C_\lambda + w$ with $w \in L$ and if $x = \mathrm{ad}\, u(q^{-4\lambda})$, then from (2.15),

$$\begin{aligned}\Delta(x) &= \sum u_{(1)} q^{-4\lambda} S u_{(3)} \otimes \mathrm{ad}\, u_{(2)}(C_\lambda + w) \\ &= \sum u_{(1)} q^{-4\lambda} S u_{(3)} \otimes (\varepsilon(u_{(2)}) C_\lambda + \mathrm{ad}\, u_{(2)}(w)) \\ &= u_{(1)} q^{-4\lambda} S u_{(2)} \otimes C_\lambda + \sum u_{(1)} q^{-4\lambda} S u_{(3)} \otimes \mathrm{ad}\, u_{(2)}(w),\end{aligned}$$

but $\mathrm{ad}\, u_{(2)}(w) \in L$ since L is invariant under $\mathrm{ad}\, \mathcal{U}$, and the first term is $x \otimes C_\lambda$.

In L we have the bracket $[x,y] = \mathrm{ad}\, x(y)$. Define $\sigma: L \otimes L \to L \otimes L$ by

$$\sigma(x \otimes y) = \sum \mathrm{ad}\, u'(y) \otimes x', \quad \text{where } \Delta(x) = x \otimes C_\lambda + \sum u' \otimes x', \tag{2.16}$$

i.e.,

$$\sigma(x \otimes y) = \sum \mathrm{ad}\, x_{(1)}(y) \otimes x_{(2)} - [x,y] \otimes C_\lambda. \tag{2.17}$$

Then

$$m \circ \sigma(x \otimes y) = \sum x_{(1)} y(S x_{(2)}) x_{(3)} - [x,y] C_\lambda = xy - [x,y] C_\lambda.$$

Since C_λ is central, this establishes the theorem. □

The existence of a generalized Lie algebra in $U_q(\mathfrak{sl}(n))$ follows immediately.

Theorem 2.3: *If q is not a $2n$th root of unity nor a primitive twelfth root of unity, $U_q(\mathfrak{sl}(n))$ contains an (n^2-1)-dimensional generalized Lie algebra with the adjoint bracket.*

Proof: In Theorem 2, take $\mathfrak{g} = \mathfrak{sl}(n)$ and λ the highest weight of the n-dimensional (defining) representation. Then L_λ carries an irreducible representation of $U_q(\mathfrak{g})$ [a deformation of the adjoint representation of $\mathfrak{sl}(n)$]. Since C_λ is central, $\mathrm{ad}\, C_\lambda$ acts on L_λ as a multiple of the identity; in a lemma we will show that this multiple is $q^2 - 1 + q^{-2}$ (which vanishes only if q is a primitive 12th root of unity). Assuming this for the moment, we apply ad to (2.14) and restrict to $L = L_\lambda$ to obtain

$$\mathrm{ad}_L[x_i, x_j] = \gamma_{ij}^{kl}\, \mathrm{ad}_L\, x_k \cdot \mathrm{ad}_L\, x_l, \tag{2.18}$$

where

$$\gamma = \frac{1 - \sigma}{q^2 - 1 + q^{-2}}.$$

Thus the generalized Jacobi identity is satisfied in L by the adjoint bracket. Also, from (2.13),

$$\gamma\left(\sum x \otimes y\right) = 0 \Rightarrow \sigma\left(\sum x \otimes y\right) = \sum x \otimes y \Rightarrow C_\lambda \sum [x,y] = 0 \Rightarrow \sum [x,y] = 0,$$

since $\overline{U}_q(\mathfrak{g})$ contains no zero divisors.[6] Thus the adjoint bracket restricted to L_λ has the antisymmetry property with respect to the generalized antisymmetrizer γ.

Completion of the proof now needs the following lemmas.

Lemma 2.1: The central element in $\overline{L}$ is given by

$$C_\lambda = \sum_{r=0}^{n-1} (-1)^r \frac{[n-r]_q}{[n]_q} K_r, \tag{2.19}$$

where K_r is defined recursively by

$$K_r = \mathrm{ad}(F_r E_r) K_{r-1}, \quad K_0 = q^{-4\lambda}. \tag{2.20}$$

Lemma 2.2: The adjoint action of the central element on L is

$$\mathrm{ad}\ C_\lambda(x) = (q^2 - 1 + q^{-2})x, \quad \text{for } x \in L. \tag{2.21}$$

The proofs, both unenlightening calculations, are relegated to an appendix. □

Although the antisymmetrizer γ in this Lie algebra is not of the Woronowicz form $\gamma = 1 - \sigma$ where σ satisfies the braid relation, it is of a related form. According to (2.18) and (2.17), γ is a scalar multiple of $1 - \sigma$ where

$$\sigma(x \otimes y) = \overline{\sigma}(x \otimes y) - [x,y] \otimes C_\lambda,$$

and $\overline{\sigma}: \overline{L} \otimes \overline{L} \to \overline{L} \otimes \overline{L}$ is given by

$$\overline{\sigma}(x \otimes y) = \sum \mathrm{ad}\ x_{(1)}(y) \otimes x_{(2)}.$$

It is a straightforward exercise in Hopf algebra manipulation[15] to show that $\overline{\sigma}$ satisfies the braid relation.

III. THE GENERALIZED LIE ALGEBRA $\mathfrak{sl}(2)_q$

In the case of $\mathfrak{g} = \mathfrak{sl}(2)$, the simply connected quantized enveloping algebra is generated by E, F, and $q^{\pm(1/2)H}$ with relations

$$q^H E q^{-H} = qE,$$

$$q^H F q^{-H} = q^{-1} F,$$

$$EF - FE = \frac{q^{2H} - q^{-2H}}{q - q^{-1}}.$$

The highest weight of the fundamental two-dimensional representation is (i.e., corresponds via the Killing form to) $\lambda = \frac{1}{2}H$, so in the notation of Lemma 2.1 we have

$$K_0 = q^{-4\lambda} = q^{-2H},$$

$$K_1 = \mathrm{ad}(FE) K_0 = -(q - q^{-1})(qEF - q^{-1}FE).$$

Hence, according to Lemma 2.1, the central element is

$$C = q^{-2H} + \left(\frac{q - q^{-1}}{q + q^{-1}}\right)(qEF - q^{-1}FE). \tag{3.1}$$

A basis for the generalized Lie algebra is $(X_\pm, X_0)$ where

$$X_+ = \frac{\operatorname{ad} E(q^{-2H})}{q-q^{-1}} = q^{-H}E,$$

$$X_- = -\frac{\operatorname{ad} F(q^{-2H})}{q-q^{-1}} = q^{-H}F, \tag{3.2}$$

$$X_0 = -\frac{\operatorname{ad}(FE)q^{-2H}}{q^2-q^{-2}} = \frac{qEF-q^{-1}FE}{q+q^{-1}} = \frac{C-q^{-2H}}{q-q^{-1}}.$$

The adjoint brackets of these basis elements can be calculated to be

$$[X_+,X_+]=0, \quad [X_+,X_0]=-q^{-1}X_+, \quad [X_+,X_-]=(q+q^{-1})X_0,$$

$$[X_0,X_+]=qX_+, \quad [X_0,X_0]=(q-q^{-1})X_0, \quad [X_0,X_-]=-q^{-1}X_-, \tag{3.3}$$

$$[X_-,X_+]=-(q+q^{-1})X_0, \quad [X_-,X_0]=qX_-, \quad [X_-,X_-]=0.$$

The generalized Lie algebra $\mathfrak{sl}(2)_q$ is defined by these brackets together with the generalized antisymmetrizer $\gamma=(q^2-1+q^{-2})^{-1}\gamma'$ where

$$\gamma'(X_\pm\otimes X_\pm)=0,$$

$$\gamma'(X_\pm\otimes X_0)=q^{\mp 2}X_\pm\otimes X_0-X_0\otimes X_\pm,$$

$$\gamma'(X_0\otimes X_\pm)=q^{\pm 2}X_0\otimes X_\pm-X_\pm\otimes X_0,$$

$$\gamma'(X_+\otimes X_-)=X_+\otimes X_--X_-\otimes X_++(q^2-q^{-2})X_0\otimes X_0, \tag{3.4}$$

$$\gamma'(X_-\otimes X_+)=-\gamma'(X_+\otimes X_-),$$

$$\gamma'(X_0\otimes X_0)=(q-q^{-1})^2X_0\otimes X_0+\left(\frac{q-q^{-1}}{q+q^{-1}}\right)(X_+\otimes X_--X_-\otimes X_+)=\left(\frac{q-q^{-1}}{q+q^{-1}}\right)\gamma'(X_+\otimes X_-).$$

We note the following properties of $\mathfrak{sl}(2)_q$.

Proposition 1: 1. $\mathfrak{sl}(2)_q$ *is a balanced generalized Lie algebra.*

2. The generalized antisymmetrizer γ *is essentially idempotent:*

$$\gamma^2=\left(\frac{q^2+q^{-2}}{q^2-1+q^{-2}}\right)\gamma.$$

Proof: By calculation. □

The second of these properties is peculiar to $\mathfrak{sl}(2)_q$, reflecting the simple structure of its representations, as will become apparent when we consider $\mathfrak{sl}(3)_q$. The first, however, may be more general.

The enveloping algebra of the generalized Lie algebra $U(\mathfrak{sl}(2)_q)$—not to be confused with the quantized enveloping algebra $U_q(\mathfrak{sl}(2))$—is defined by means of the brackets (3.3) and the antisymmetrizer (3.4). By redefining the generators to absorb the factor q^2-1+q^{-2}, it can be presented as the associative algebra generated by three elements $Y_0, Y_\pm$ with relations

$$qY_0Y_+-q^{-1}Y_+Y_0=Y_+,$$

$$q^{-1}Y_0Y_--qY_-Y_0=-Y_-, \tag{3.5}$$

$$Y_+Y_--Y_-Y_++(q^2-q^{-2})Y_0^2=(q+q^{-1})Y_0.$$

On the other hand, as elements of the quantized enveloping algebra $U_q(\mathfrak{sl}(2))$ the generators $X_\pm$, X_0 and the central element C satisfy (by Theorem 2.2)

$$q^2X_0X_+ - X_+X_0 = qCX_+ ,$$

$$q^{-2}X_0X_- - X_-X_0 = -q^{-1}CX_- , \tag{3.6}$$

$$X_+X_- - X_-X_+ + (q^2 - q^{-2})X_0^2 = (q + q^{-1})CX_0 ,$$

and

$$CX_m = X_mC \quad (m = 0, \pm 1).$$

However, the central element C is not independent of the other generators X_m: there is a further relation,

$$C^2 = (q - q^{-1})^2\left(X_0^2 + \frac{qX_-X_+ + q^{-1}X_+X_-}{q + q^{-1}} \right) + 1, \tag{3.7}$$

as can be verified by direct calculation.

The main results of this section are that the locally finite part of $\overline{U}_q(\mathfrak{g})$ is isomorphic, as an algebra, to the algebra with generators X_0, $X_\pm$, C, and relations (3.6), and as a vector space to the algebra of polynomials in four commuting variables X_0, $X_\pm$, C subject to the relation (3.7). We use the following notation for the various algebras:

$\mathcal{A}$ = enveloping algebra of the generalized Lie algebra $\mathfrak{sl}(2)_q$
= algebra generated by $Y_\pm$, Y_0 with relations (3.5),

$\mathcal{B}$ = algebra generated by $X_\pm$, X_0, C with relations (3.6),

$\mathcal{C}$ = algebra generated by $X_\pm$, X_0, C with relations (3.6) and (3.7),

$\mathcal{F}$ = locally finite part of $\overline{U}_q(\mathfrak{g})$.

Then $\mathcal{A}$, $\mathcal{B}$, and $\mathcal{C}$ are related by homomorphisms

$$\varphi: \mathcal{B} \to \mathcal{A} \quad \text{with} \quad \varphi(C) = 1,$$

$$\psi: \mathcal{B} \to \mathcal{C} \quad \text{enforcing} \quad (3.7).$$

Lemma 3.1: The algebra $\mathcal{A}$ has a basis of ordered monomials $Y_-^l Y_0^m Y_+^n$ where l,m,n are non-negative integers.

Proof: It is evident that the commutation relations (3.5) allow any product of Y's to be expressed as a combination of ordered monomials. We have only to show that these monomials are independent. According to the diamond lemma,[16] this will follow if it can be shown that the two methods of reducing $Y_+Y_0Y_-$ to a combination of ordered monomials both lead to the same result. This is easily checked using (3.5). □

Lemma 3.2: The algebra $\mathcal{B}$ has a basis of ordered monomials $C^kX_-^lX_0^mX_+^n$.

Proof: $\mathcal{A} \otimes \mathbb{K}[C]$ contains an isomorphic copy of $\mathcal{B}$ generated by C and $X_m = CY_m$. This is spanned by monomials $C^kX_-^lX_0^mX_+^n = C^{k+l+m+n}Y_-^lY_0^mY_+^n$ and by Lemma 3.1 these are independent. □

Lemma 3.3: The algebra $\mathcal{C}$ is isomorphic as a vector space to the space of polynomials in four commuting variables C, X_0, X_+, X_- subject to the relation (3.7).

Proof: Let

$$C_2 = (q + q^{-1})X_0^2 + qX_-X_+ + q^{-1}X_+X_- .$$

Using (3.6), it can be checked that C_2 commutes with X_0, X_+, and X_-. Hence the two-sided ideal I generated by $(q + q^{-1})(C^2 - 1) - (q - q^{-1})^2C_2$ [i.e., the kernel of the relation (3.7)] is the same as the left ideal generated by it. It follows that the monomials $X_-^lX_0^mX_+^n$ and $CX_-^lX_0^mX_+^n$ are independent modulo I, and therefore form a basis of $\mathcal{C}$. But these monomials also form a basis of the commutative algebra described in the theorem. □

Theorem 3.1: *The locally finite part of $\overline{U}_q(\mathfrak{sl}(2))$ is isomorphic to $\mathcal{C}$.*

Proof: By Theorem 2.1, the locally finite part of $\mathcal{U} = \overline{U}_q(\mathfrak{g})$ is

$$\mathcal{F}=\sum_{n=0}^{\infty} V_n, \quad \text{where } V_n=\mathrm{ad}\,\mathcal{U}(q^{-2nH}).$$

Since $\frac{1}{2}nH$ is the highest weight of the $(n+1)$-dimensional representation of $\mathcal{U}$, $\dim V_n=(n+1)^2$. By the derivation property (2.6) of the adjoint action,

$$V_{m+n}\subseteq V_m V_n.$$

Hence

$$V_n\subseteq V_1^n.$$

Let $\mathcal{U}'$ be the subalgebra of $\mathcal{U}$ generated by V_1, i.e., by C, X_-, X_+, and X_0. Since the relations (3.6) and (3.7) hold in $\mathcal{U}$, $\mathcal{U}'$ is a quotient of $\mathcal{C}$ and therefore, by Lemma 3.3, is spanned by monomials $X_-^k X_0^l X_+^m$ and $CX_-^k X_0^l X_+^m$. Let W_n be the subspace spanned by monomials $X_-^k X_0^l X_+^m$ with $k+l+m=n$. Then

$$V_1^{n+2}=V_1^n+CW_{n+1}+W_{n+2}, \tag{3.8}$$

as can be proved by induction, using

$$V_1 W_r=CW_r+W_{r+1}$$

and

$$C^2W_r+W_{r+2}=W_r+W_{r+2},$$

which follows from (3.7). But

$$\dim W_r\leqslant\frac{1}{2}(r+1)(r+2), \tag{3.9}$$

so

$$\dim(V_1^{n+2})\leqslant\dim(V_1^n)+(n+3)^2.$$

We can now prove by induction that

$$V_1^n=V_n\oplus V_{n-2}\oplus\cdots\oplus(V_0 \text{ or } V_1).$$

For if this is true, then from (3.8) we have

$$V_1^{n+2}\supseteq V_{n+2}\oplus V_n\oplus\cdots,$$

since the V_n are known to be complementary in $\mathcal{U}$.[6] By dimensions the inclusion must be equality, so the sum in (3.8) is direct and also (3.9) must be equality. It follows that the monomials $X_-^k X_0^l X_+^m$ and $CX_-^k X_0^l X_+^m$ are independent and form a basis of $\Sigma V_n=\mathcal{F}$. By Lemma 3.3, $\mathcal{F}$ is isomorphic to $\mathcal{C}$. □

In one sense, the locally finite part of the quantized enveloping algebra is the same size as the classical enveloping algebra of $\mathfrak{sl}(2)$. Both can be written as $Z\otimes\mathcal{U}_0$ where Z, the center, is a polynomial algebra in one variable and $\mathcal{U}_0$ has the same decomposition into simple modules under the adjoint action in both cases. However, the above shows that it is more appropriate to regard the locally finite part of $\overline{U}_q(\mathfrak{sl}(2))$ as twice as big as the classical enveloping algebra. In the classical case the center is generated by a Casimir element which is a polynomial in the Lie algebra generators; in the generalized case the center is generated by a square root of such a polynomial, tending to 1 in the classical limit.

IV. THE GENERALIZED LIE ALGEBRA $\mathfrak{sl}(3)_q$

This section contains some details of and observations on the generalized Lie algebra of type A_2. All were established by mindless calculation.

We take λ to be the highest weight of the triplet representation,

$$\lambda=\frac{1}{3}(2H_1+H_2)$$

(identifying weights with elements of the Cartan subalgebra by means of the Killing form, and taking H_1 and H_2 to have unit length). A convenient basis for the generalized Lie algebra $\mathfrak{sl}(3)_q$ is the following, consisting of two elements T_1,T_2 (scalar multiples of the K_1,K_2 defined in Lemma 2.1) and elements $X_\alpha=X_{\pm1},X_{\pm2},X_{\pm12}$ corresponding to the roots $\alpha=\pm H_1,\pm H_2,\pm(H_1+H_2)$ of $\mathfrak{sl}(3)$:

$$T_1=\frac{\mathrm{ad}(F_1E_1)q^{-4\lambda}}{q-q^{-1}}=q^{-(2/3)(H_1+2H_2)}(qE_1F_1-q^{-1}F_1E_1),$$

$$T_2=\mathrm{ad}(F_2E_2)T_1,$$

$$X_1=\frac{\mathrm{ad}\ E_1(q^{-4\lambda})}{q-q^{-1}}=q^{-(1/3)(5H_1+4H_2)}E_1,$$

$$X_{12}=\mathrm{ad}\ E_2(X_1)=q^{-(1/3)(5H_1+H_2)}(E_2E_1-q^{-1}E_1E_2),$$

$$X_2=\mathrm{ad}\ F_1(X_{12}),$$

$$X_{-1}=\frac{\mathrm{ad}\ F_1(q^{-4\lambda})}{q-q^{-1}}=-q^{-(1/3)(5H_1+4H_2)}F_1,$$

$$X_{-12}=\mathrm{ad}\ F_2(X_{-1})=q^{-(1/3)(5H_1+H_2)}(qF_1F_2-F_2F_1),$$

$$X_{-2}=-\mathrm{ad}\ E_1(X_{-12}).$$

The adjoint action of $\overline{U_q}(\mathfrak{g})$ on these basis elements is

$$\mathrm{ad}(q^{H_i})T_j=T_j;$$

$$\mathrm{ad}(q^{H_i})X_{\pm j}=\begin{cases}q^{\pm1}X_{\pm j}, & \text{if } i=j,\\ q^{\mp1/2}X_{\pm j}, & \text{if } i\neq j;\end{cases}$$

$$\mathrm{ad}(q^{H_i})X_{\pm12}=q^{\pm1/2}X_{\pm12};$$

$$\mathrm{ad}\ E_i(X_\alpha)=\begin{cases}X_{\alpha+H_i}, & \text{if } \alpha+H_i \text{ is a root},\\ T_i, & \text{if } \alpha=-H_i,\\ 0, & \text{otherwise};\end{cases}$$

$$\mathrm{ad}\ F_i(X_\alpha)=\begin{cases}X_{\alpha-H_i}, & \text{if } \alpha-H_i \text{ is a root},\\ T_i, & \text{if } \alpha=H_i,\\ 0, & \text{otherwise};\end{cases}$$

$$\mathrm{ad}\ E_i(T_j)=\begin{cases}(q+q^{-1})X_i, & \text{if } i=j,\\ X_{12}, & \text{if } i\neq j;\end{cases}$$

	T_1	T_2	X_1	X_{-1}
T_1	$-(q^2-q^{-2})T_1$	$-(q-q^{-1})T_1$	$-q(q+q^{-1})$	$q^{-1}(q+q^{-1})$

X_{12}	0	$-q^{-5/2}$	0	$-q^{-1}T_1+T_2$
X_{-12}	$q^{5/2}$	0	qT_1-T_2	0

FIG. 1. The brackets of $\mathfrak{sl}(3)_q$.

$$\text{ad } F_i(T_j)=\begin{cases}(q+q^{-1})X_{-i}, & \text{if } i=j,\\ X_{-12}, & \text{if } i\neq j.\end{cases}$$

From this the adjoint brackets between the basis elements can be calculated; the result is given in Fig. 1, in which $[X,Y]$ is given in the row labelled by X and the column labelled by Y. If $\alpha+\beta\neq 0$, $[X_\alpha,X_\beta]=c_{\alpha\beta}X_{\alpha+\beta}$ is represented by the coefficient $c_{\alpha\beta}$; similarly, $[T_i,X_\alpha]=b_{i\alpha}X_\alpha$ is represented by $b_{i\alpha}$.

The entries which are too long to fit into the table are

$$[T_2,T_2]=-(q^2-q^{-2})T_1+(q^3-q^{-3})T_2,$$

$$[X_2,X_{-2}]=q^{-1}(q-q^{-1})T_1-qT_2,$$

$$[X_{-2},X_2]=q(q-q^{-1})T_1+q^{-1}T_2.$$

Notice that if L is regarded as a module over $\mathbb{K}[q,q^{-1}]$ then, with this basis, the brackets exhibit the simple antisymmetry which was also found by Delius and Hüffmann. Define a map of *q-conjugation* on L, $X\to X^{\blacktriangledown}$, by the requirements that it leaves the above basis elements fixed and that $\{f(q)X\}^{\blacktriangledown}=f(q^{-1})X^{\blacktriangledown}$. Then it is apparent from the table that

$$[Y,X]=-[X,Y]^{\blacktriangledown}, \quad \text{for all } X,Y\in L. \tag{4.1}$$

The generalized antisymmetrizer of $\overline{U}_q(\mathfrak{g})$ can be described as follows. The generalized Lie algebra $L=\mathfrak{sl}(3)_q$ carries an irreducible representation of $\overline{U}_q(\mathfrak{g})$; as in the classical case, $L\otimes L$ splits into irreducible representations as

$$L\otimes L=M_{27}\oplus M_{10}\oplus M_{10}^{*}\oplus M_8^{\mathrm{a}}\oplus M_8^{\mathrm{s}}\oplus M_1,$$

where the numerical labels 27, 10, 8, 1 indicate the dimensions of the simple modules. These are completely defined by their highest-weight elements:

$$\begin{aligned}
W_{27}&=X_{12}\otimes X_{12},\\
W_{10}&=q^{1/2}X_1\otimes X_{12}-q^{1/2}X_{12}\otimes X_1,\\
W_{10}^{*}&=q^{1/2}X_2\otimes X_{12}-q^{-1/2}X_{12}\otimes X_2,\\
W_8^{\mathrm{s}}&=\{q^{5/2}(q+q^{-1})+q^{-5/2}\}X_1\otimes X_2+\{q^{-5/2}(q+q^{-1})+q^{5/2}\}X_2\otimes X_1\\
&\quad-(q^4T_1+q^{-1}T_2)\otimes X_2-X_2\otimes(q^{-4}T_1+qT_2),\\
W_8^{\mathrm{a}}&=q^{3/2}X_1\otimes X_2-q^{-3/2}X_2\otimes X_1-q(qT_1-T_2)\otimes X_{12}+q^{-1}X_{12}\otimes(q^{-1}T_1-T_2),
\end{aligned} \tag{4.2}$$

$$\begin{aligned}
W_1&=T_1\otimes T_2+T_2\otimes T_1-(q+q^{-1})(T_1\otimes T_1+T_2\otimes T_2)+(q^2+1+q^{-2})(q^{-1}X_1\otimes X_{-1}+qX_{-1}\otimes X_1\\
&\quad+q^{-1}X_2\otimes X_{-2}+qX_{-2}\otimes X_2-q^{-2}X_{12}\otimes X_{-12}-q^2X_{-12}\otimes X_{12}).
\end{aligned}$$

Let Π_{27}, Π_{10}, Π_{10}^{*}, Π_8^{s}, Π_8^{a}, and Π_1 denote the projectors onto these simple modules. Then we have the following.

Lemma 4.1: The generalized antisymmetrizer of $\overline{U}_q(\mathfrak{g})$ *is*

$$\gamma=\frac{(q^2+1)\Pi_{10}^{*}+(q^2+q^{-2})\Pi_8^{a}+(1+q^{-2})\Pi_{10}}{q^2-1+q^{-2}}. \tag{4.3}$$

Proof: Straightforward Hopf-algebra manipulations show that γ commutes with the diagonal adjoint action of $\mathcal{U}=U_q(\mathfrak{sl}(3))$ on $L\otimes L$, i.e., with $(\mathrm{ad}\otimes\mathrm{ad})\circ\Delta(u)$ for all $u\in\mathcal{U}$. Thus it is only necessary to calculate the action of γ on the highest-weight elements listed above. This is not too laborious for the cases of W_{10}, W_{10}^{*}, and W_{27}. For the octets the relevant highest-weight elements (eigenvectors of γ) and the eigenvalues can be determined from the Jacobi identity: in the two-dimensional space of highest-weight octet vectors [elements of $L\otimes L$ with weight H_1+H_2 which are annihilated by $(\mathrm{ad}\otimes\mathrm{ad})\circ\Delta(E_1)$ and $(\mathrm{ad}\otimes\mathrm{ad})\circ\Delta(E_2)$], the eigenvectors of γ are the relative eigenvectors of $\mathrm{ad}\circ\beta$ and $m\circ(\mathrm{ad}\otimes\mathrm{ad})$.

The eigenvalue 0 for the singlet can be verified in a similar way. We find that $\beta(W_1)=0$ but $m\circ(\mathrm{ad}\otimes\mathrm{ad})(W_1)\neq 0$. Since $\mathrm{ad}\circ\beta(W_1)=m\circ(\mathrm{ad}\otimes\mathrm{ad})\circ\gamma(W_1)$ and $\gamma(W_1)$ must be a multiple of W_1, it follows that $\gamma(W_1)=0$. □

The quantized enveloping algebra $\mathcal{U}=\overline{U}_q(\mathfrak{sl}(3))$ has a symmetry between (E_1,F_1,H_1) and (E_2,F_2,H_2) corresponding to the outer automorphism of $\mathfrak{sl}(3)$ which comes from the symmetry of the Dynkin diagram ∘—∘. The generalized Lie algebra $\mathcal{L}=\mathfrak{sl}(3)_q=\mathrm{ad}\mathcal{U}(q^{-4\lambda})$ is not invariant under this automorphism of $\mathcal{U}$. Indeed, the weight diagram of the 3-dimensional representation is taken by this symmetry to that of the conjugate representation, with highest weight $\lambda^{*}\neq\lambda$. This gives another generalized Lie algebra $L^{*}\subset\mathrm{ad}\mathcal{U}(q^{-4\lambda^{*}})$ with $L^{*}\neq L$. This is another octet (under

the adjoint representation) which also generates the locally finite part of $\mathcal{U}$. It is interesting to express the elements of L^* in terms of those of L and to compare this situation with the classical one.

In the classical enveloping algebra the octets are the Lie algebra itself, one which is quadratic in the generators, and multiples of these by functions of the Casimirs. The outer automorphism acts linearly on the generators. In the locally finite part of the quantized enveloping algebra we have the same general structure;[6] the quadratic octet has highest-weight element obtained by multiplying the factors of the tensor W_8^s in (4.2). The highest-weight element of the octet L is X_{12}. Let X_{12}^* be the highest-weight element of L^*, and let $Y_{12}=m(W_8^s)$. Then a calculation gives

$$X_{12}^*=\frac{q^{1/2}(q+q^{-1})CX_{12}+q(q-q^{-1})Y_{12}}{(q^{1/2}+q^{-1/2})(q^2+1+q^{-2})}. \tag{4.4}$$

Thus the elements of L^* are quadratic in the generators L, and the quantum counterpart of the outer automorphism is a nonlinear symmetry of $\overline{U}_q(\mathfrak{sl}(3))$.

APPENDIX: PROOFS OF LEMMAS 2.1 AND 2.2

Lemma 2.1: The central element in $\overline{L}$ is given by

$$C_\lambda=\sum_{r=0}^{n-1}(-1)^r\frac{[n-r]_q}{[n]_q}K_r, \tag{2.19}$$

where K_r is defined recursively by

$$K_r=\mathrm{ad}(F_rE_r)K_{r-1},\quad K_0=q^{-4\lambda}. \tag{2.20}$$

Proof: Let C be defined by (2.19). Since this has zero weight for the Cartan algebra generated by $H_1,\ldots,H_{n-1}$ [i.e., ad $q^{H_i}(C)=C$], in order to show that it is central it is sufficient to show that ad $E_i(C)=0$ for $i=1,\ldots,n-1$. We calculate ad $E_i(K_j)$.

Since ad $\overline{U}_q(\mathfrak{g})(q^{-4\lambda})$ is the direct sum of the q-analogues of the scalar and the adjoint modules of $\mathfrak{sl}(n)$, the structure of the roots of $\mathfrak{sl}(n)$ gives

$$\mathrm{ad}\,E_j\ \mathrm{ad}\,E_i\ \mathrm{ad}\,E_{i-1}\cdots\mathrm{ad}\,E_1(q^{-4\lambda})=0\quad\text{unless}\quad j=i+1. \tag{A1}$$

Hence

$$\mathrm{ad}\,E_j(K_i)=0\quad\text{if}\quad j>i+1\quad\text{and}\quad i>0.$$

This also holds if $i=0$ since $q^{-4\lambda}$ commutes with E_j for $j>1$.

For $i=j$ we have

$$\mathrm{ad}\,E_i(K_i)=\mathrm{ad}(F_iE_i+[2H_i]_q)\mathrm{ad}\,E_i(K_{i-1})=[\langle 2H_i,H_i\rangle]_q\ \mathrm{ad}\,E_i(K_{i-1})=[2]_q\ \mathrm{ad}\,E_i(K_{i-1}),$$

since

$$\begin{aligned}(\mathrm{ad}\,E_i)^2K_{i-1}&=\mathrm{ad}\,F_{i-1}\cdots\mathrm{ad}\,F_1(\mathrm{ad}\,E_i)^2\ \mathrm{ad}\,E_{i-1}\cdots\mathrm{ad}\,E_1(q^{-4\lambda})\\&=0\quad\text{by (A1).}\end{aligned}$$

For $j=i-1$ we have

$$\begin{aligned}\mathrm{ad}\,E_j(K_{j+1})&=\mathrm{ad}\,F_{j+1}\ \mathrm{ad}(F_jE_j+[2H_j])\mathrm{ad}\,E_{j+1}\ \mathrm{ad}\,E_j(K_{j-1})\\&=\mathrm{ad}([2H_j-1]_q)\mathrm{ad}\,F_{j+1}\ \mathrm{ad}\,E_{j+1}\ \mathrm{ad}\,E_j(K_{j-1})\\&=\mathrm{ad}(F_{j+1}E_{j+1}E_j)K_{j-1}\ \text{ since }\ [2\langle H_j,H_j\rangle-1]_q=1\\&=\mathrm{ad}[(E_{j+1}F_{j+1}-[2H_{j+1}]_q)E_j]K_{j-1}\end{aligned}$$

$$= \operatorname{ad} E_j(K_{j-1}), \tag{A2}$$

since $\operatorname{ad} F_{j+1} \operatorname{ad} E_j(K_{j-1}) = 0$ by the structure of the roots of $\mathfrak{sl}(n)$.

For $j < i-1$,

$$\begin{aligned}
\operatorname{ad} E_j(K_i) &= \operatorname{ad}(F_i \cdots F_{j+1} E_j F_j \cdots F_1 E_i \cdots E_1) q^{-4\lambda} \\
&= \operatorname{ad}[F_i \cdots F_{j+1}(F_j E_j + [2H_j]_q) F_{j-1} \cdots F_1 E_i \cdots E_1] q^{4\lambda} \\
&= [\langle 2H_j, H_{j+1} + \cdots + H_i \rangle]_q \operatorname{ad}(F_i E_i \cdots F_{j+1} E_{j+1} E_j) K_{j-1} \quad \text{by (A1)} \\
&= -\operatorname{ad}(F_i E_i \cdots F_{j+2} E_{j+2} E_j) K_{j-1} \quad \text{by (A2)} \\
&= 0 \quad \text{by (5.1)}.
\end{aligned}$$

To summarize,

$$\operatorname{ad} E_j(K_i) = 0 \quad \text{if } i < j-1 \text{ or } i > j+1,$$

$$\operatorname{ad} E_j(K_{j+1}) = \operatorname{ad} E_j(K_{j-1}), \tag{A3}$$

and

$$\operatorname{ad} E_j(K_j) = [2]_q \operatorname{ad} E_j(K_{j-1}).$$

Hence for $j = 1, \ldots, n-2$,

$$\begin{aligned}
\operatorname{ad} E_j(C) &= \frac{(-1)^{j-1}}{[n]_q}([n-j-1]_q - [2]_q[n-j]_q + [n-j+1]_q) \operatorname{ad} E_j(K_{j-1}) \\
&= 0,
\end{aligned}$$

while

$$\operatorname{ad} E_{n-1}(C) = \frac{(-1)^{n-1}}{[n]_q}([2]_q - [2]_q[1]_q) = 0.$$

Thus C is a highest-weight vector in the module $\overline{L}$. Since its weight is zero, it follows that C is an invariant element [$\operatorname{ad} x(C) = \varepsilon(x)C$ for all $x \in \mathcal{U}$] and therefore central. It is therefore a multiple of C_λ. But $C = q^{-4\lambda} + w$ with $w \in L$; hence $C = C_\lambda$. □

Lemma 2.2: The adjoint action of the central element on L is

$$\operatorname{ad} C_\lambda(x) = (q^2 - 1 + q^{-2})x, \quad \text{for } x \in L. \tag{A4}$$

Proof: It follows from Lemma 2.1 by Schur's lemma that $\operatorname{ad} C_\lambda$ acts as a multiple of the identity on the irreducible component L. To find the multiple we calculate $\operatorname{ad} C_\lambda(X_1)$ for $X_1 = \operatorname{ad} E_1(q^{-4\lambda})$. We use

$$\operatorname{ad} E_r(X_1) = 0 \quad \text{unless } r = 2,$$

$$\operatorname{ad} F_r(X_1) = 0 \quad \text{unless } r = 1,$$

$$\operatorname{ad} F_1(X_1) = K_1.$$

Then we have

$$\operatorname{ad} K_0(X_1) = q^{-\langle 4\lambda, H_1 \rangle} X_1 = q^{-2} X_1.$$

Now

$$\operatorname{ad} E_1(q^{-4\lambda}) = (q - q^{-1}) q^{-4\lambda + H_1} E_1,$$

so

$$\begin{aligned} K_1 &= (q-q^{-1})\,\mathrm{ad}\,F_1(q^{-4\lambda+H_1}E_1) \\ &= -(q-q^{-1})q^{-4\lambda+2H_1}(qE_1F_1-q^{-1}F_1E_1) \\ &= (q-q^{-1})^2 q^{-4\lambda+2H_1}F_1E_1 - q.q^{-4\lambda}(q^{4H_1-1}). \end{aligned} \tag{A5}$$

Therefore

$$\mathrm{ad}\,K_1(X_1) = -q(q^{\langle -4\lambda+4H_1,H_1\rangle}-q^{\langle -4\lambda,H_1\rangle})X_1 = -q(q^2-q^{-2})X_1. \tag{A6}$$

To calculate ad $K_2(X_1)$, note that

$$\mathrm{ad}\,E_2(K_1) = E_2K_1q^{H_2}-q^{H_2-1}K_1E_2 = q^{H_2-1}(E_2K_1-K_1E_2).$$

Since ad $F_2(X_1)=0$, we have

$$\mathrm{ad}\,K_2(X_1) = \mathrm{ad}[F_2\cdot \mathrm{ad}\,E_2(K_1)\cdot q^{H_2}]X_1 = \mathrm{ad}[q^{2H_2}F_2(E_2K_1-K_1E_2)]X_1.$$

Using (A6) and the fact that ad $F_2(X_1)=0$,

$$\mathrm{ad}[q^{2H_2}F_2K_1E_2]X_1 = -q\ \mathrm{ad}[q^{2H_2}(E_2F_2-[2H_2]_q)]X_1 = -(q^2-q^{-2})X_1;$$

using (A5) and the fact that $\mathrm{ad}(E_1E_2)X_1=0$,

$$\begin{aligned} \mathrm{ad}[q^{2H_2}F_2K_1E_2]X_1 &= -q\ \mathrm{ad}[q^{2H_2}F_2q^{-4\lambda}(q^{4H_1}-1)E_2]X_1 \\ &= -q\ \mathrm{ad}[q^{2H_2-4\lambda}(q^{4H_1-2}-1)(E_2F_2-[2H_2]_q)]X_1 \\ &= -q^{-2}(q^2-1)X_1; \end{aligned}$$

$$\text{therefore}\ \ \mathrm{ad}\,K_2(X_1) = -(q^2-1)X_1.$$

We now have that K_3 is a sum of products of ad E_3 and ad F_3, both of which annihilate X_1, and operators of which X_1 is an eigenvector; it follows that ad $K_3(X_1)=0$. Similarly ad $K_r(X_1)=0$ for $r>3$; hence

$$\mathrm{ad}\,C_\lambda(X_1) = \left(q^{-2}+q(q-q^{-1})\,\frac{(q+q^{-1})[n-1]_q-[n-2]_q}{[n]_q}\right)X_1 = (q^2-1+q^{-2})X_1.$$

Symmetry classification and exact solutions of the Kramers equation

Stanislav Spichak and Valerii Stognii
Institute of Mathematics of the National Academy of Sciences of Ukraine, 3 Tereshchenkivs'ka Street, Kyiv 4, Ukraine, and Kyiv Polytechnical Institute, 37 Pobedy Avenue, Kyiv, Ukraine

(Received 15 April 1997; accepted for publication 16 September 1997)

The complete classification of Lie symmetries for the Kramers equation is described. Group invariance under infinitesimal transformations is used to generate a wide class of exact solutions. Some of the known solutions are obtained as particular cases. The general results can also be used to solve some types of moving-boundary problems. We researched some Q-conditional symmetry properties of this equation. © *1998 American Institute of Physics.* [S0022-2488(98)01505-9]

I. INTRODUCTION

The one-dimensional Fokker–Planck equation has the form (see Ref. 1)

$$\frac{\partial u(x,t)}{\partial t} = -\frac{\partial}{\partial x}[A(x,t)u(x,t)] + \frac{1}{2}\frac{\partial^2}{\partial x^2}[B(x,t)u(x,t)],$$

where $u=u(t,x)$ is a probability density and A and B are differential functions. This is the basic equation in the theory of continuous Markovian process and serves as a mathematical model for a number of problems in physical and biological sciences (see Refs. 1–10).

In the case of several space variables, the Fokker–Planck equation describes many more different complex processes then the one-dimensional equation. In the general case, the Fokker–Planck equation can be written in the form

$$\frac{\partial u(x,t)}{\partial t} = -\sum_{i=1}^{n}\frac{\partial}{\partial x_i}[A_i(x,t)u(x,t)] + \frac{1}{2}\sum_{i,j=1}^{n}\frac{\partial^2}{\partial x_i \partial x_j}[B_{ij}u(x,t)],$$

where $x=(x_1,\ldots,x_n)$, the coefficient of drift $A(x,t)$, and coefficient of diffusion $B(x,t)$ are defined as the vector and matrix,

$$A(x,t)=(A_1(x,t),\ldots,A_n(x,t)), \quad B(x,t)=\|B_{ij}(x,t)\|, \quad i,j=1,\ldots,n, \tag{1}$$

correspondingly. Now consider the two-dimensional Fokker–Planck equation that describes the motion of a particle in a fluctuating medium (see Ref. 1):

$$\frac{\partial u}{\partial t} = -\frac{\partial}{\partial x}(yu) + \frac{\partial}{\partial y}(V'(x)u) + \gamma\frac{\partial}{\partial y}\left(yu + \frac{\partial u}{\partial y}\right), \tag{2}$$

where $u=u(t,x,y)$ is a probability density, γ is a constant, and $V(x)$ is an external potential. The equation (2) is known as Kramers equation. The coefficients of drift and diffusion (1) can be written in the form

$$A(t,x,y)=(y,-V'(x)-\gamma y), \quad B(t,x,y)=\begin{pmatrix}0 & 0\\ 0 & 2\gamma\end{pmatrix}.$$

II. LIE'S SYMMETRY ANALYSIS

We investigate symmetry properties of the equation (2) for different potentials under the infinitesimal local operators,

 © 1998 American Institute of Physics

$$Q=\xi^0(t,x,y,u)\,\frac{\partial}{\partial t}+\xi^1(t,x,y,u)\,\frac{\partial}{\partial x}+\xi^2(t,x,y,u)\,\frac{\partial}{\partial y}+\eta(t,x,y,u)\,\frac{\partial}{\partial u}. \tag{3}$$

Theorem 1: *The maximal invariance local group of the free Kramers equation (2) [with* $V'(x)=0$*] is the six-dimensional Lie group generated by the following operators:*

$$\begin{gathered}P_0=\partial_t=\frac{\partial}{\partial t},\quad P_1=\partial_x=\frac{\partial}{\partial x},\quad I,G_1=t\partial_x+\partial_y+\frac{1}{2}\,(y+\gamma x),\\ S_1=\exp(\gamma t)\left(\frac{1}{\gamma}\,\partial_x+\partial_y+y\right),\quad T_1=\exp(-\gamma t)\left(\frac{1}{\gamma}\,\partial_x-\partial_y\right).\end{gathered} \tag{4}$$

Proof: Applying the Lie's algorithm (see Refs. 11 and 12) to the equation (2), we find that

$$\begin{gathered}\xi^0=F(t),\quad \xi^1=\frac{3}{2}\,xF'(t)+G(t),\quad \xi^2=\frac{1}{2}\,yF'+\frac{3}{2}\,xF''+G',\\ \eta=-\frac{1}{2\gamma}\left[(2F''+\gamma F')\,\frac{y^2}{2}+y\left(\frac{3}{2}\,x(F'''+\gamma F'')+G''+\gamma G'+\frac{3}{2}\,xF'V''+V''G+\frac{1}{2}\,V'F'\right)\right.\\ \left.+\Theta(t,x),\right.\end{gathered} \tag{5}$$

with $F(t)$, $G(t)$, and $\Theta(t,x)$ satisfying the equations

$$\begin{gathered}5F'''-2\gamma^2F'+4V''F'+3xV'''F'+2V'''G=0,\\ \Theta_x+\tfrac{3}{2}\,x(-F''''+\gamma^2F'')-\tfrac{3}{2}\,xV''F''+\tfrac{3}{2}\,\gamma xV''F'+\tfrac{3}{2}\,V'F''+\tfrac{3}{2}\,\gamma V'F'-G'''+\gamma^2G'-V''G'\\ +\gamma V''G=0,\\ \Theta_t+V'(\tfrac{3}{2}\,x(F'''+\gamma F'')+(G''+\gamma G')+\tfrac{3}{2}\,xV''F'+V''G+\tfrac{1}{2}\,V'F')+2\gamma F''-\gamma^2F'=0.\end{gathered} \tag{6}$$

Let us put in (5), (6), $V'(x)=0$. Solving this equation we obtain from (3) and (5) the operators (4).

Remark 1: The change of variables,

$$u=w(\tau,\xi,\eta),\quad \tau=t,\quad \xi=x-\left(\frac{c}{\gamma}\right)t,\quad \eta=y-\frac{c}{\gamma},$$

reduces the equation (2) with $V'(x)=C=\text{const}$ to the free Kramers equation.

Remark 2: The change of variables,

$$u=w(\tau,\xi,\eta),\quad \tau=t,\quad \xi=x+\frac{c}{k},\quad \eta=y,\quad k\neq 0,$$

reduces the equation (2) with $V'(x)=kx+C$ to the equation (2) with $V'(x)=kx$.

Theorem 2: *The maximal invariance local group of the equation (2) with* $V'(x)=kx$ *when* $k\neq-\frac{3}{4}\gamma^2$, $\frac{3}{16}\gamma^2$ *is the six-dimensional Lie group.*

(a) *In the case* $k<\gamma^2/4$, *the correspondent symmetry operators are*

$$P_0,I,X_i=\exp(\lambda_i t)\left(\frac{\partial}{\partial x}+\lambda_i\,\frac{\partial}{\partial y}+\frac{1}{2\gamma}\,[(\lambda_i^2+\gamma\lambda_i+k)y+(-\lambda_i^3+\gamma^2\lambda_i-k\lambda_i+\gamma k)x]\right), \tag{7}$$

$i=1,2,3,4$,
where λ_i *are the roots of the equation*

$$\lambda^4+(2k-\gamma^2)\lambda^2+k^2=0. \tag{8}$$

(b) *In the case* $k>\gamma^2/4$ *the corresponding operators are*

$$P_0, I, Y_i, \quad k=1,2,3,4, \tag{9}$$

where $Y_1=\mathrm{Re}\, X_1$, $Y_2=\mathrm{Im}\, X_1$, $Y_3=\mathrm{Re}\, X_3$, $Y_4=\mathrm{Im}\, X_3$, X_i, *and the operators* X_i *are those in (7);* λ_i *are complex roots of the equation (8).*

(c) *In the case* $k=\gamma^2/4$, *the corresponding operators are*

$$\begin{gathered} P_0, I, X_i=\exp(\lambda_i t)\left(\frac{\partial}{\partial x}+\lambda_i\frac{\partial}{\partial y}+\frac{\gamma y}{2}+\frac{\gamma^2}{4}x\right), \quad i=1,3, \\ X_i=\exp(\lambda_i t)\left(t\frac{\partial}{\partial x}+(1+\lambda_i t)\frac{\partial}{\partial y}+\left(\frac{\gamma t}{2}+1\right)y+\frac{\gamma^2}{2}tx\right), \quad i=2,4, \end{gathered} \tag{10}$$

where $\lambda_2=\lambda_1$, $\lambda_3=\lambda_4=-\lambda_1$, λ_1 *are the roots of the equation (8).*

Theorem 3: *The maximal invariance local group of the equation (2) with* $V'(x)=kx$ *when* $k=-\frac{3}{4}\gamma^2$ *and* $k=\frac{3}{16}\gamma^2$ *is the eight-dimensional Lie group generated by the operators (7) and in addition the following operators: (a) in the case* $k=-\frac{3}{4}\gamma^2$,

$$\begin{gathered} N_1=\exp(\gamma t)\left(\partial_t+\frac{3}{2}\gamma x\partial_x+\frac{\gamma}{2}(3\gamma x+y)\partial_y+\frac{3}{4}\gamma y^2+\frac{3}{4}\gamma^2 xy-\frac{9}{16}\gamma^3x^2+\frac{\gamma}{2}\right), \\ N_2=\exp(-\gamma t)\left(\partial_t+\frac{3}{2}\gamma x\partial_x+\frac{\gamma}{2}(3\gamma x-y)\partial_y+\frac{1}{4}\gamma y^2+\frac{3}{4}\gamma^2 xy+\frac{9}{16}\gamma^3x^2-\frac{3}{2}\gamma\right); \end{gathered} \tag{11}$$

(b) in the case $k=\frac{3}{16}\gamma^2$,

$$\begin{gathered} N_1=\exp\left(\frac{1}{2}\gamma t\right)\left(\partial_t+\frac{3}{4}\gamma x\partial_x+\frac{\gamma}{4}\left(\frac{3}{2}\gamma x+y\right)\partial_y+\frac{1}{4}\gamma y^2+\frac{3}{8}\gamma^2 xy+\frac{9}{64}\gamma^3x^2\right), \\ N_2=\exp\left(-\frac{1}{2}\gamma t\right)\left(\partial_t-\frac{3}{4}\gamma x\partial_x+\frac{\gamma}{4}\left(\frac{3}{2}\gamma x-y\right)\partial_y+\gamma\right). \end{gathered} \tag{12}$$

Theorem 4: *The maximal invariance local group of the equation (2) with* $V'(x)\neq kx+c$ *is a two-dimensional Lie group generated by the operators* $P_0=\partial t, I$.

The proofs of Theorems 2, 3, and 4 follow from the solutions of the equations (5),(6) for correspondent potentials.

III. *Q*-CONDITIONAL SYMMETRY

In this section we present some results on Q-conditional symmetry of the Kramers equation. The term and the concept of Q-conditional symmetry of an equation was introduced in Refs. 12, 13, and 14.

Let us consider the operator (3) and the additional condition

$$Qu=0. \tag{13}$$

We say that the equation (2) is Q-conditionally invariant if the system (2), (13) is invariant under the operator (3). In particular, the Lie symmetry operator Q is a Q-conditional symmetry. The Q-conditional symmetry operator always leads to a reduction of an initial equation as well as a Lie symmetry one. So the possibility of finding exact solutions is expanded.

For example, let us consider the equation (2) with the potential

$$V'=kx^{-1/3}+\tfrac{3}{16}\gamma^2x, \quad k\neq 0. \tag{14}$$

The operator,

$$Q=\partial_t-\tfrac{3}{4}\gamma x\partial_x+\left(\tfrac{3}{8}\gamma^2-\tfrac{1}{4}\gamma y\right)\partial_y+\gamma u\partial_u, \tag{15}$$

is not a Lie symmetry operator of the equations (2), (14), as follows from Theorem 4. However, the operator (15) gives the invariant solution (ansatz)

$$u(t,x,y)=\exp(\gamma t)\varphi(\omega_1,\omega_2),\quad \omega_1=\exp(\tfrac{3}{4}\gamma t)x,\quad \omega_2=x^{-1/3}y+\tfrac{3}{4}\gamma x^{2/3},\tag{16}$$

which reduces the equation. Indeed, substituting (16) into (2), (14) we obtain the reduced equation,

$$\omega_2\varphi_1-\left(\frac{\omega_2^2}{2}+k\right)\omega_1^{-1}\varphi_2-\gamma\omega_1^{-1}\varphi_{22}=0,\quad \varphi_i=\frac{\partial\varphi}{\partial\omega_i},\quad \varphi_{22}=\frac{\partial^2\varphi}{\partial\omega_2\partial\omega_2}.$$

This equation may be integrated, in particular, when $\varphi=\varphi(\omega_2)$.

Remark 3: If Q is a Q-conditional operator for a PDE, then the equation is $\overline{Q}$-conditionally invariant under $\overline{Q}=f(x,u)Q$, where $f(x,u)$ is an arbitrary function of the independent and dependent variables. We say that Q and $\overline{Q}$ are equivalent operators. Then we may consider $\xi^0=1$ in (2) if $\xi^0\not\equiv 0$.

Theorem 5: *All Q-conditional operators of the equation (2) with $V'\neq kx^{-1/3}+\frac{3}{16}\gamma^2 x$, kx are equivalent to ∂_t, I.*

Theorem 6: *The equations (2) and (14) have the following Q-conditional symmetry operators*:

$$Q=\partial_t+F(t)x\partial_x+(\tfrac{1}{3}F(t)y+F'(t)x+\tfrac{2}{3}F^2x)\partial_y+fu\partial_u,$$

where $F(t)$ is an arbitrary solution of the equation

$$F''+2FF'+\tfrac{4}{9}F^3-\tfrac{1}{4}\gamma^2F=0,$$

$$2\gamma f=-y^2\left(\frac{2}{3}F'+\frac{4}{9}F^2+\frac{1}{3}\gamma F\right)-yx\left(\gamma F'+\frac{2}{3}\gamma F^2+\frac{1}{2}\gamma^2F\right)-x^2\left(\frac{3}{8}\gamma^2F'+\frac{1}{4}\gamma^2F^2+\frac{3}{16}\gamma^3F\right)-x^{2/3}k\left(2F'+\frac{4}{3}F^2+\gamma F\right)+C\exp\left\{-\frac{2}{3}\int F\,dt\right\}-\frac{4}{3}\gamma F+\gamma^2,$$

*where $C=$*const.

Theorem 7: *All Q-conditional symmetry operators $(\xi^0=1)$ of the equation (2) with $V'=kx$,* and $k\neq-\frac{1}{4}\gamma^2$, $\frac{3}{16}\gamma^2$ *are equivalent to the Lie symmetry operators given in (7), (9), or (10).*

Theorem 8: *All Q-conditional symmetry operators $(\xi^0=1)$ of the equation (2) with $V'=kx$, $k=-\frac{1}{4}\gamma^2$, $\frac{3}{16}\gamma^2$ (including those equivalent to Lie symmetry operators) have the following form*:

$$Q=\partial_t+(F(t)x+G(t))\partial_x+[\tfrac{1}{3}F(t)y+(F'(t)+\tfrac{2}{3}F(t)^2)x+G'(t)+\tfrac{2}{3}F(t)G(t)]\partial_y+f(t,x,y)u\partial_u.$$

Here the functions $F(t)$, $G(t)$ satisfy the following equations:

$$F''+2FF'+\tfrac{4}{9}F^3+(\tfrac{4}{5}k-\tfrac{2}{5}\gamma^2)F=0,$$

$$G''+\tfrac{4}{3}FG'+\tfrac{2}{3}F'G+\gamma G'+\tfrac{2}{3}\gamma FG+\tfrac{4}{9}F^2G+kG=h(t),$$

where $h(t)$ satisfies the equation

$$h''+(\tfrac{4}{3}F-\gamma)h'+(k+\tfrac{2}{3}F'+\tfrac{4}{9}F^2-\tfrac{2}{3}\gamma F)h=0.$$

The function $f(t,x,y)$ is

(a) $k=-\frac{3}{4}\gamma^2$, $2\gamma f=-y^2(\frac{2}{3}F'+\frac{4}{9}F^2+\frac{1}{3}\gamma F)-y[x(\gamma F'+\frac{2}{3}\gamma F^2)+h]$

$$+\tfrac{3}{4}\gamma^3x^2F+x(h'-\gamma h+\tfrac{2}{3}Fh)+s(t),$$

(b) $k=\tfrac{3}{16}\gamma^2$, $2\gamma f=-y^2(\tfrac{2}{3}F'+\tfrac{4}{9}F^2+\tfrac{1}{1}\gamma F)-y[x(\gamma F'+\tfrac{2}{3}\gamma F^2+\tfrac{1}{2})+h]$

$$-x^2(\tfrac{3}{16}\gamma^3F+\tfrac{3}{8}\gamma^2F'+\tfrac{1}{4}\gamma^2F^2)+x(h'-\gamma h+\tfrac{2}{3}Fh)+s(t),$$

where in both (a) and (b) the function $s(t)$ satisfies the equation

$$s'+\tfrac{2}{3}Fs=-2\gamma(\tfrac{2}{3}F'+\tfrac{4}{9}F^2+\tfrac{1}{3}\gamma F)+\tfrac{4}{3}\gamma^2F.$$

In conclusion, we consider the example Q_1-, Q_2-conditional symmetry of the Kramers equation with an arbitrary potential. It is easy to show that this equation is invariant under the two operators,

$$Q_1=\partial_x+V'(x),\quad Q_2=\partial_y+y,$$

under the additional conditions $Q_1u=Q_2u=0$. It turned out that the solution,

$$u=\exp\left\{-\frac{y^2}{2}-V(x)\right\}$$

[the well-known Boltzmann solution (see Ref. 1)], of the stationary Kramers equation (2) ($u_t=0$) with an arbitrary potential, is invariant under these operators.

From the above examples we see that further work on finding Q- and Q_1-, Q_2-conditional symmetry operators is of great interest.

IV. SOME EXACT SOLUTIONS

Now we consider the algorithms (see Refs. 11, 15, 16, and 17) of the construction of exact solutions of the Kramers equation (2).

Let us write down the final transformations generated by operators (7) ($k<\gamma^2/4$). The operator P_0 generates translation on variable t, I generates the identical transformation, X_i generates

$$t'=t,\quad x'=x+a_i\exp\{\lambda_i t\},\quad y'=y+a_i\lambda_i\exp\{\lambda_i t\},$$

$$u'(t',x',y')=\exp\left(-\frac{e^{\lambda_i t}}{2\gamma}\left[(\lambda_i^2+\gamma\lambda_i+k)ya_i+\frac{a_i^2}{2}\lambda_ie^{\lambda_i t}+(-\lambda_i^3+\gamma^2\lambda_i-k\lambda_i+\gamma k)xa_i+\frac{a_i^2}{2}e^{\lambda_i t}\right]\right)u(t,x,y), \tag{17}$$

where a_i are group parameters, and λ_i are roots of the equation (8).

It is appropriate to write here the corresponding formulas of generating solutions that follow from (17):

$$u_{\mathrm{II}}(t,x,y)=\exp\left\{\frac{e^{\lambda_i t}}{2\gamma}\left[(\lambda_i^2+\gamma\lambda_i+k)ya_i+\frac{a_i^2}{2}\lambda_ie^{\lambda_i t}+(-\lambda_i^3+\gamma^2\lambda_i-k\lambda_i+\gamma k)xa_i+\frac{a_i^2}{2}e^{\lambda_i t}\right]\right\}u_{\mathrm{I}}(t',x',y'), \tag{18}$$

where t',x',y' are given in (17), respectively.

A well-known solution of the stationary Kramers equation (2) is the Boltzman distribution,

$$u(x,y)=N\exp\{-V(x)-\tfrac{1}{2}y^2\} \tag{19}$$

(N is a normalization constant). Applying formulas (18) to (19) with $V'(x)=kx$, $k<\gamma^2/4$, one can easily obtain a nonstationary solution of the equation (2).

Now consider the free Kramers equation $[V'(x)=0]$ (see Ref. 18). Let us consider the operator from (4),

$$S_1=\exp(\gamma t)\left(\frac{1}{\gamma}\,\partial_x+\partial_y+y\right).$$

We find the invariants

$$\omega_1=t,\quad \omega_2=\gamma x-y,\quad \omega_3+\frac{y^2}{2}+\ln u,$$

and build anzatz

$$u(t,x,y)=\exp\left\{-\frac{y^2}{2}\right\}\varphi(\omega_1,\omega_2),\quad \omega_1=t,\quad \omega_2=\gamma x-y. \tag{20}$$

Substitution of (20) into the free Kramers equation gives rise to the heat equation,

$$\frac{\partial\varphi}{\partial\omega_1}-\gamma\,\frac{\partial^2\varphi}{\partial\omega_2^2}=0.$$

It is clear that by using solutions of the heat equation and the anzatz (20) one can construct many partial solutions.

A great number of partial solutions of the equation (2) can be found by means of the method described in Ref. 15. So, if $u_0(t,x,y)$ is a solution of the equation, then the functions Qu_0, $Q^2u_0,\ldots$ will also be solutions with any symmetry operator Q. For example, by means of the operators X_i (7) for the equation (2) with $V'(x)=kx$, $(k<\gamma^2/4)$, we find exact solutions beginning with $u_0=e^{\gamma t}$.

(Received 22 January 1997; accepted for publication 4 February 1997)

[S0022-2488(98)01706-X]

By following the steps indicated in Ref. 1 after Eq. (11), one actually finds that $F_{\mu\nu}$ also satisfies the source-free Maxwell equations in the background metric $\tilde{g}_{\mu\nu}$ without any further condition. Therefore, Eq. (12) should not appear. This fact does not affect the results of the paper.

Analytic regularization of the $(\bar{\psi}_i\psi_i)^2_D$ model at finite temperature and density

G. N. J. Añaños, A. P. C. Malbouisson, and N. F. Svaiter[a)]
Centro Brasileiro de Pesquisas Fisicas-CBPF, Rua Dr. Xavier Sigaud 150, Rio de Janeiro, RJ 22290-180 Brazil

(Received 17 November 1997; accepted for publication 3 March 1998)

Simultaneously using the dimensional and analytic regularization methods we reexamine the Gross–Neveu model at finite temperature and density (chemical potential) in a D-dimensional space–time. The regularized effective potential is presented at the $1/N$ (large N) approximation. It is found that in $D=3$ the effective potential is finite. © *1998 American Institute of Physics.*

I. INTRODUCTION

Besides computer simulations on the lattice, there have been many attempts over the years to go beyond the limitations of perturbative renormalizability in quantum field theory in the framework of continuous space–time formulation. For instance, much work has been done in the context of constructive field theory.[1] For scalar models, 't Hooft and Rivasseau[2] presented a construction of the ultraviolet limit for a massive Euclidean planar $(\lambda\varphi^4)_4$ model with the ''wrong'' sign of the coupling constant (yielding the loss of physical positivity). Since the number of planar graphs does not grow factorially with the perturbation order in λ (just a power behavior) the construction in this case can be done in a purely perturbative way. Only Feynman amplitudes matter for estimations. This result has been extended to the nonplanar case in the infrared region. Feldman *et al.* and Gawedzki and Kupianen[3] treated the model with a fixed ultraviolet cutoff and with the coupling constant with the ''good'' sign (leading to infrared asymptotic freedom), and showed that the model exists in the case of vanishing renormalized mass. There, the use of nonperturbative techniques such as polymer expansions and constructive renormalization have been applied to surmount the perturbative lack of convergence generated by ''instanton'' and ''renormalon'' singularities. These are, respectively, the factorial growth of the number of Feynman graphs and the factorial growth of a single renormalized amplitude due to renormalization of divergent subgraphs.

Also if an N-component (''colors'') field with a quartic coupling of intensity λ is considered, the introduction of an ultralocal intermediate field leads to the possibility of the summation of an infinite number of Feynman diagrams with an effective three-body coupling constant $\lambda/\sqrt{N}$ in the large-N limit. In this case, some of the more divergent diagrams are suppressed and an effective complete propagator is obtained. This is the basic idea underlying the so-called $1/N$ expansion. A well-known example where this idea is implemented is the four-fermion self-interaction model $(\bar{\psi}_i\psi_i)^2$, the Gross–Neveu model.[4] Although the Gross–Neveu model is perturbatively nonrenormalizable in $D=3$, at leading order in $1/N$, the resulting effective theory shares some of the basic requirements for a constructively renormalizable theory. This is due to the remarkable property of asymptotic safeness.[5] In other words, the effective coupling constant obtained from the effective propagator does not decrease to zero at high momenta: the model is not asymptotically free. Instead, it presents a nontrivial stable ultraviolet fixed point. Then by choosing N large enough de Calan *et al.*[5] have been able to show that there exist an N-independent λ^* such that $\lim_{N\to\infty}\lambda^*(N)=\lambda^*$. Based on this property it is possible to perform *convergent* phase space expansions for the Schwinger functions of a genuine nonrenormalizable model, although at the present time nothing can be said about whether or not these Schwinger functions verify the Osterwalder–Schrader axioms. From the point of view of the renormalization group, the model

a)Electronic mail: nfuxsvai@lafex.cbpf.br

 © 1998 American Institute of Physics

has been studied by many authors.[6] In this case it may be noted that, in general, associating an effective coupling constant which vanishes in some region of momentum space, asymptotic freedom prevents renormalon-like singularities to be present in the interesting part of the Borel plane. This means that the general summations of contributions defining the perturbative expansions can be done and the construction program can be carried out and, sometimes, Borel summability can be achieved giving *a posteriori* sense to perturbation methods.

In $D=2$, the massless model is asymptotically free and in any space–time dimension $D<4$ a chiral symmetry may be spontaneously broken with dynamical generation of mass. In the absence of chemical potential and at finite temperature the spontaneous broken symmetry may be restored via a second-order phase transition. For $D=2$ the condensation of kinks means that the phase transition may occur at any nonzero temperature. The question that is raised is whether the presence of the chemical potential changes the order of the phase transition.[7] In the literature there is no agreement on the subject since some results from lattice calculation indicate that for nonzero chemical potential the transition is of first order, while it is of second order for vanishing chemical potential.[8] Wolf obtained a different result in $D=2$, with a tricritical point separating second-order phase transition from first-order one. Recently, the four fermion model was investigated by Barducci *et al.*[9] where an explicitly broken chiral symmetry introduced by a fermionic mass term in the Lagrangian density was analyzed. These authors suggest that, depending on the value of the fermion mass, the transition could be of first or of second order. Also, indications for the existence of a tricritical phenomenon were found.

The main goal of this note is to investigate at the $(1/N)$ (large N) approximation the finite temperature behavior of the effective potential of the Gross–Neveu model. For more generality, we treat the model in arbitrary space–time dimension D, and to exhibit the analytic structure of the effective potential we use a mix between dimensional and zeta function analytic regularization methods. We determine that the regularized effective potential is free of any ultraviolet singularity in odd space–time dimensions. In the case of the Yukawa model the same kind of mathematical phenomenon was found in Ref. 10. This somewhat surprising result is to be compared to those obtained in the case of the calculation of the Casimir energy using similar regularization methods. As was suggested in Ref. 10, we also generalize in this note the analytical regularization procedure to the case of nonzero chemical potential. Recently Daicic and Frankel[11] investigated the magnetic properties of a Bose gas using very similar techniques. They investigated a Bose gas in the relativistic and nonrelativistic regime using a Mellin integral transform method to analyze the analytic structure of the thermodynamic potential. These authors claim that in this approach it is possible to present new results for a broad range of physical parameters such as temperature, field strength, etc., not revealed using another approach. We use the same methods to investigate the model in the case of nonzero chemical potential.

The outline of the paper is as follows: In Sec. II we briefly review the formalism of the effective potential, and the effective potential is obtained at zero and nonzero chemical potential. Conclusions are given in Sec. III. In this paper we use $\hbar=k_B=c=1$.

II. THE 1/*N* (LARGE *N*) EFFECTIVE POTENTIAL OF THE GROSS–NEVEU MODEL AT ZERO AND FINITE TEMPERATURE

Let us consider a system consisting of fermion fields in thermal equilibrium with a reservoir at temperature β^{-1}. They are defined on a $D=d+1$ dimensional flat space–time with trivial topology of the spacelike sections. The Gross–Neveu model is described in terms of a U(N) symmetric action for a set of N massless fermions

$$S(\bar{\psi},\psi)=\int d^Dx\left(\bar{\psi}(i\not{\partial})\psi+\frac{\lambda}{2N}(\bar{\psi}\psi)^2\right). \tag{1}$$

The symmetry which prevents the fermions from acquiring a mass in perturbation theory is

$$\psi\rightarrow\gamma^5\psi. \tag{2}$$

In an even dimension space–time the above transformation defines a discrete chiral symmetry. In an odd dimensional space–time a fermionic mass violates space parity.

The Green's functions of the model are generated by the generating functional

$$Z[\eta,\bar{\eta}]=c\int \mathscr{D}\psi\mathscr{D}\bar{\psi}\,\exp\left\{\int d^Dx(\mathscr{L}+\bar{\psi}\eta+\bar{\eta}\psi)\right\}, \tag{3}$$

where $\bar{\psi}(x)$, $\psi(x)$, $\bar{\eta}(x)$, and $\eta(x)$ are elements of a Grassmann algebra. The analysis of the symmetry behavior of the model is simplified by the introduction of a constraint field $\varphi(x)$ in the Lagrangian density, which becomes

$$\mathscr{L}'(\varphi,\psi,\bar{\psi})=\mathscr{L}(\psi,\bar{\psi})-\frac{1}{2}\left(\varphi+\left(\frac{\lambda}{N}\right)^{1/2}\bar{\psi}\psi\right)^2=\bar{\psi}(i\partial\!\!\!/)\psi-\left(\frac{\lambda}{N}\right)^{1/2}\varphi\bar{\psi}\psi-\frac{1}{2}\varphi^2. \tag{4}$$

Then we may write the generating functional given by Eq. (3) equivalently as

$$Z(\eta,\bar{\eta})=c'\int \mathscr{D}\psi\mathscr{D}\bar{\psi}\mathscr{D}\varphi\ \exp\, i\int d^Dx(\mathscr{L}'+\bar{\psi}\eta+\bar{\eta}\psi), \tag{5}$$

where $\mathscr{L}'(\varphi,\psi,\bar{\psi})$ is given by Eq. (4). To determine the equilibrium value of $\varphi(x)$ we define the generating functional of the connected Green functions $W(J)$ by

$$e^{iW(J)}=\int \mathscr{D}\psi\mathscr{D}\bar{\psi}\mathscr{D}\varphi\ \exp\left\{i\int d^Dx(\mathscr{L}'+J\varphi\right\}, \tag{6}$$

from which we get by a Legendre transform the effective action $\Gamma(\varphi_0)$,

$$\Gamma(\varphi_0)=\int d^Dx(\varphi_0(x)J(x)-W(J)) \tag{7}$$

where

$$\varphi_0(x)=\frac{\delta W(J)}{\delta J(x)}. \tag{8}$$

If we assume translational invariance the effective potential is given by

$$V(\varphi_0)=-\sum_n^{\infty}\ \frac{1}{n!}\,\tilde{\Gamma}^{(n)}(0,0,..0)(\varphi_0-\varphi_{\min})^n \tag{9}$$

or

$$V(\varphi_0)=\frac{1}{2}\,\varphi_0^2-iN\sum_{s=1}^{\infty}\int\ \frac{d^Dk}{(2\pi)^D}\,\frac{1}{s}\left(\frac{\lambda\varphi_0^2}{Nk^2}\right)^s. \tag{10}$$

As is well known, at zero temperature the minimum of the effective potential is not at the origin, there is a spontaneous symmetry breaking with a dynamical generation of mass associated to a bound state. To allow comparison with the results that we will get in the case of nonzero chemical potential, let us briefly review some basic features of the model at zero chemical potential.

If we assume that the system is in thermal equilibrium with a reservoir at temperature β^{-1} we may use the Matsubara formalism. In this case we have to perform the replacements $\omega\to\omega_n=2\pi/\beta(n+\frac{1}{2})$ and $(1/2\pi)\int dq_E^0=(1/\beta)\Sigma_n$. Defining $(\lambda/N)^{1/2}=g$, and using dimensional regularization to deal with ultraviolet divergences associated with the continuous Euclidean momenta, it is possible to obtain the effective potential in the form of a sum of Hurwitz zeta functions. In this case the effective potential is given by

$$V(\varphi_0,\beta)=\frac{1}{2}\,\varphi_0^2+2N\sum_{s=1}^{\infty}\,p(D,s)(g\varphi_0)^{2s}\beta^{2s-D}\zeta\left(2s-d,\,\frac{1}{2}\right), \tag{11}$$

where $p(D,s)$ is given by

$$p(D,s)=\frac{\pi^{d/2}}{\Gamma(s+1)}\,\Gamma\left(s-\frac{d}{2}\right)\,\frac{(-1)^s}{(2\pi)^{2s}}, \tag{12}$$

and the Hurwitz zeta function being defined by

$$\zeta(z,q)=\sum_{n=0}^{\infty}\,\frac{1}{(n+q^z)}, \tag{13}$$

which is analytic for $\mathrm{Re}(z)>1$.

Note that the effective potential is not yet well defined since the Hurwitz zeta function is defined only in an open connected set of points in the s complex plane. By a standard procedure it is possible to find the analytic extension of the Hurwitz zeta function to the whole s plane. To perform the analytic continuation of the Hurwitz zeta function we go along the following steps: first we use the Euler representation for the gamma function to express the Hurwitz zeta function as

$$\zeta(z,q)=\frac{1}{\Gamma(z)}\,\int_0^{\infty}dt\;t^{z-1}\,\frac{e^{-tq}}{1-e^{-t}}. \tag{14}$$

Next we split the integral from zero to infinity in two integrals from zero to one and from one to infinity. The second one is an analytic function, the divergences being associated with the zero limit of the first integration. Then using a Bernoulli representation for the integrand it is possible to get the following expression to the analytic extension of $\zeta(z,\frac{1}{2})$:

$$\zeta\left(z,\,\frac{1}{2}\right)=\frac{1}{\Gamma(z)}\,g_1\left(z,\,\frac{1}{2}\right)+\frac{1}{\Gamma(z)}\,\sum_{n=0}^{\infty}\,\frac{B_n(\frac{1}{2})}{n!}\,\frac{1}{(z+n-1)}, \tag{15}$$

where $g_1(z,\frac{1}{2})$ is given by

$$g_1\left(z,\,\frac{1}{2}\right)=\int_1^{\infty}dt\;t^{z-1}\,\frac{e^{t/2}}{e^t-1}, \tag{16}$$

and $B_n(x)$ are the Bernoulli polynomials. Taking $z=2s-d$ and defining $c_n=(B_n/n!)((1/2^{n-1})-1)$ we replace this analytic extension in the effective potential $V(\varphi_0,\beta)$. A straightforward calculation gives

$$V(\varphi_0,\beta)=\frac{1}{2}\,\varphi_0^2+2N\sum_{s=1}^{\infty}\,q(D,s)\left(g_1\left(2s-d,\,\frac{1}{2}\right)+\sum_{n=0}^{\infty}\,\frac{c_n}{2s-D+n}\right)(g\varphi_0)^{2s}\beta^{2s-D}, \tag{17}$$

where $q(D,s)$ is given by

$$q(D,s)=\frac{(-1)^s}{\Gamma(s+1)}\,\frac{1}{\Gamma(s-D/2+1)}\,\frac{1}{(4\pi)^{2s}-(D/2)}. \tag{18}$$

A direct consequence of the regularization method employed is the following: we see from the above equation that $V(\varphi_0,\beta)$ has no singularities for odd D and integer s. This means that for odd D at the $1/N$ (large N) approximation the regularized effective potential is finite. No renormalization procedure is needed. It is interesting to note that this fact is analogous from a mathematical point of view to similar situations in the Casimir effect and for anomalies in unbounded odd dimensional space–times.[12] For even D, the regularized effective potential has poles, as we

expected. On more physical grounds we remember that to exhibit the singularity structure of the effective potential at finite temperature is important for several reasons, including dimensional reduction. As explicitly pointed out by Landsman,[13] the possibility of dimensionally reducing a thermal field theory depends on whether we are able to find thermal counterterms that cancel the divergent contributions as $\beta\to 0$ comes from the integration of nonzero Matsubara frequencies. These temperature-dependent counterterms should be controlled by a thermal renormalization group and fixed by the imposition of renormalization conditions on Feynman diagrams computed with the aid of some regularization scheme. In spite of regularization being purely an intermediary tool in the process of renormalizing a quantum field theory, we know that dimensional reduction is scheme dependent,[14,15] being optimal in BPHZ (Bogoliubov–Panasiuk–Hepp–Zimmermann) subtractions at zero momenta and temperature β^{-1}. By analytical continuation of the Hurwitz zeta function we have the exact form of the polar terms that appear in the expansion of the effective potential in the framework of dimensional regularization. These will command the counterterms needed for renormalization. It would be interesting to see how dimensional reduction works in this case, as compared to the behavior obtained from other regularization methods. For a recent discussion of these subjects see, for example, Ref. 16.

Now we perform the same analysis in the case of nonzero chemical potential. Thus, let us introduce a chemical potential μ and define

$$\sigma=\frac{\mu\beta}{2\pi}. \tag{19}$$

It is well known that the effect of the chemical potential is to shift the energy levels by μ. Then following the same steps as before it is possible to show that the only change in Eq. (11) is that instead of $\zeta(z,\frac{1}{2})$, we have to analytically extend $\zeta(z,\frac{1}{2}+i\sigma)$. Let us first write an integral representation of the Hurwitz zeta function as follows:

$$\zeta\left(z,\frac{1}{2}+i\sigma\right)=\frac{1}{\Gamma(z)}\int_0^\infty dt\ t^{z-1}\frac{e^{-t(1/2+i\sigma)}}{1-e^{-t}}. \tag{20}$$

Proceeding as we have done to get Eq. (15) above, the integrand of Eq. (20) may be expressed in terms of the Bernoulli polynomials. Using the following expansion,

$$B_n(x+h)=\sum_{k=0}^{n} C_n^k B_k(x)h^{n-k}, \tag{21}$$

we have

$$B_n\left(\frac{1}{2}-i\sigma\right)=\sum_{k=0}^{n} A_{nk}\sigma^{n-k} \tag{22}$$

where

$$A_{nk}=-(-i)^{n-k}C_n^k(1-2^{1-k})B_k, \tag{23}$$

and B_k are the Bernoulli numbers.[17] Substituting Eqs. (21)–(23) in Eq. (20) we have for the analytic extension

$$\left(2s-d,\frac{1}{2}+i\sigma\right)=\frac{1}{\Gamma(2s-d)}g_2\left(2s-d,\frac{1}{2}-i\sigma\right)+\frac{1}{\Gamma(2s-d)}\sum_{n=0}^{\infty}\sum_{k=0}^{n}\frac{A_{nk}}{(2s-D+n)}\sigma^{n-k} \tag{24}$$

where $g_2(2s-d,\frac{1}{2}+i\sigma)$ is given by

$$g_2\left(2s-d,\frac{1}{2}+i\sigma\right)=\int_1^\infty dt\ t^{2s-D}\frac{e^{t(1/2-i\sigma)}}{e^t-1}. \tag{25}$$

The effective potential is then expressed as

$$V(\varphi_0,\beta)=\frac{1}{2}\,\varphi_0^2+2N\sum_{s=1}^{\infty}p(D,s)\left(\zeta\left(2s-d,\,\frac{1}{2}+i\sigma\right)\right)+\left(\zeta\left(2s-d,\,\frac{1}{2}-i\sigma\right)\right)(g\varphi_0)^{2s}\beta^{2s-D}, \tag{26}$$

where $p(D,s)$ is given by Eq. (12) and the Hurwitz zeta function is given by Eq. (24). Some comments are in order. It is known that a dimensional regularization method fails for massless fields. Note we are using this method only in a $D-1$ dimensional integral, and the Matsubara frequencies play the role of masses. Consequently we must restrict ourselves to nonzero temperatures. Also since Eq. (26) is a Laurent series in β^{-1} our expansion is suitable for high temperatures. It may be seen from Eq. (26) that since we have the sum of two Hurwitz zeta functions (whose arguments have chemical potentials with opposite signs) the regularized effective potential remains real in the case of nonzero chemical potential. This means that at least at the one-loop approximation there are no indications for a first-order phase transition.

III. CONCLUSION

We obtained in this paper that the $1/N$ (large N) approximation effective potential is finite in any odd dimensional space–time, in particular in $D=3$. There are no ultraviolet divergences. In the Yukawa model the same mathematical phenomenon has been shown.[10] This situation is very similar to the one encountered in the calculation of the renormalized vacuum energy of scalar fields confined in boxes (Casimir energy).[18] Dolan and Nash used the zeta function analytic regularization method to obtain the Casimir energy of conformally coupled scalar field confined in odd and even dimensional spheres.[19] They obtained that for odd dimensional spheres (even space–time dimension) there is a pole in the point of interest, being necessary for the introduction of a counterterm, while for even dimensional spheres (odd dimensional space–time) the result obtained is naturally finite. No renormalization is needed. The question that we have to answer is the link between the one-loop effective energy and the Casimir energy. This problem has been studied by some authors where it was proved that the effective energy and the Casimir energy differ, but this is an inherent renormalization-scheme ambiguity.[20] We conjecture that the absence of singularities for the thermal regularized effective potential in odd-dimensional space–time is an artifact of our approximation. In any case we hope that this note could help further investigations on the subject.

(Received 21 January 1997; accepted for publication 25 February 1998)

Applying the doublet representation we analyze the solutions of a Hamiltonian system which has eigenstates with complex eigenvalues. The example of the Friedrichs model allows us to show how the appearance of solutions with non-Hilbert initial conditions is linked to the energy degeneration of the Hamiltonian spectrum. We discuss the difficulties of giving a physical meaning to the growing or decaying non-Hilbert solutions. We also suggest a way to circumvent the problem of the anomalous probabilities related to both complex energy eigenvalues and degeneration of the spectrum. © *1998 American Institute of Physics.* [S0022-2488(98)02307-X]

I. INTRODUCTION

The doublet representation[1] offers a useful way to study the dynamical evolution of both Hilbert and non-Hilbert solutions of a Hamiltonian system. In the scheme of this formalism any physical system is represented, not only by its wave functions $\varphi(\omega)$ but also by a partner $\varphi^{\star}(\omega)$. These two functions allow us to construct an invariant scalar that, in case of Hilbert states, becomes the probability of the appearance of the corresponding state. For non-Hilbert solutions, the product of the wave function and its partner remains an invariant scalar, but its probabilistic interpretation is under discussion. Precisely in this work we apply the doublet representation to show the difficulties of giving a physical interpretation to non-Hilbert solutions and we analyze the relation between energy degeneration and the appearance of complex eigenvalues. The explicit computations performed in the frame of the Friedrichs model allow us to study the conditions that the interaction Hamiltonian must satisfy to keep the spectrum in the real domain. In the other case we show how to circumvent the problem of badly behaved probabilities by means of defining a ''reduced'' space that solves the degeneration problem.

The paper is organized as follows: in Sec. II we make a brief review of Ref. 1. In Sec. III we analyze which initial conditions correspond to states in Hilbert space $\mathscr{H}$ and which ones correspond to non-Hilbert states. Section IV is devoted to the study of the anomalous behavior of probabilities and mean values for non-Hilbert states. The conditions that the interaction must satisfy in order to obtain a real spectrum are studied in Sec. V. In Sec. VI we find a basis of the reduced space where the energy degeneration is removed. Finally, in Sec. VII we draw our main conclusions.

II. THE DOUBLET REPRESENTATION

Hamiltonian equations have, in general, well-defined continuous solutions $\varphi(\omega)$ that may or may not belong to $\mathscr{H}$. But in both cases it is possible to define a ''partner'' of the wave function, namely $\varphi^{\star}(\omega)$, that is not necessarily the complex conjugate of $\varphi(\omega)$.[1] Then, solutions of the Hamiltonian equations will be represented by the ''doublet'' $(\varphi,\varphi^{\star})$. In the particular case where

$\varphi \in \mathscr{H}$, solutions satisfy $\varphi^\star = \varphi^*$, where φ^* is the complex conjugate of φ. In Ref. 1 we have applied this formalism to study the Friedrichs Hamiltonian and we have obtained that the field equations in the doublet representation read as

$$\omega_0 \varphi_1 + \lambda \int_0^\infty g(\omega)\varphi(\omega)d\omega = i\dot{\varphi}_1, \tag{1}$$

$$\omega\varphi(\omega) + \lambda g(\omega)\varphi_1 = i\dot{\varphi}(\omega), \tag{2}$$

$$\omega_0 \varphi_1^\star + \lambda \int_0^\infty g(\omega)\varphi^\star(\omega)d\omega = -i\dot{\varphi}_1^\star, \tag{3}$$

$$\omega\varphi^\star(\omega) + \lambda g(\omega)\varphi_1^\star = -i\dot{\varphi}^\star(\omega), \tag{4}$$

where $\varphi_1, \varphi_1^\star, \varphi(\omega), \varphi^\star(\omega)$ are the wave functions of the doublet representation (the first two for the discrete mode), $\lambda \in \Re$ is the coupling constant, $\omega_0 \in \Re^+$ is the discrete eigenvalue of the free Hamiltonian, $0 \leqslant \omega < \infty$ is the continuous spectrum, and $g(\omega) = g^*(\omega)$ stands for the interaction function.

We demand that wave functions satisfy the following natural conditions:

$$\varphi_1\varphi_1^\star + \int_0^\infty \varphi(\omega)\varphi^\star(\omega)d\omega < \infty, \tag{5}$$

$$(\varphi_1^\star)^\star = \varphi_1, \quad [\varphi^\star(\omega)]^\star = \varphi(\omega). \tag{6}$$

With these conditions, the solution to system (1)–(4) is

$$\varphi_1(t) = \frac{1}{\sqrt{\alpha'(z_0)}}\,\tilde{\varphi}_1 e^{-iz_0 t} + \int_0^\infty \frac{\lambda g(\tilde{\omega})}{\alpha(\tilde{\omega})}\,\tilde{\varphi}(\tilde{\omega})e^{-i\omega t}d\tilde{\omega}, \tag{7}$$

$$\varphi_1^\star(t) = \frac{1}{\sqrt{\alpha'(z_0)}}\,\tilde{\varphi}_1^\star e^{+iz_0 t} + \int_0^\infty \frac{\lambda g(\tilde{\omega})}{\alpha(\tilde{\omega})}\,\tilde{\varphi}^\star(\tilde{\omega})e^{+i\omega t}d\tilde{\omega}, \tag{8}$$

$$\varphi(\omega,t) = \frac{1}{\sqrt{\alpha'(z_0)}}\,\frac{\lambda g(\omega)}{z_0-\omega}\,\tilde{\varphi}_1 e^{-iz_0 t} + \tilde{\varphi}(\omega)e^{-i\omega t} + \int_0^\infty \frac{\lambda^2 g(\omega)g(\tilde{\omega})}{(\tilde{\omega}-\omega)\alpha(\tilde{\omega})}\,\tilde{\varphi}(\tilde{\omega})e^{-i\tilde{\omega}t}d\tilde{\omega}, \tag{9}$$

$$\varphi^\star(\omega,t) = \frac{1}{\sqrt{\alpha'(z_0)}}\,\frac{\lambda g(\omega)}{z_0-\omega}\,\tilde{\varphi}_1^\star e^{+iz_0 t} + \tilde{\varphi}^\star(\omega)e^{+i\omega t} + \int_0^\infty \frac{\lambda^2 g(\omega)g(\tilde{\omega})}{(\tilde{\omega}-\omega)\alpha(\tilde{\omega})}\,\tilde{\varphi}^\star(\tilde{\omega})e^{+i\tilde{\omega}t}d\tilde{\omega}, \tag{10}$$

where

$$z_0(\lambda) = \omega_0 + \lambda^2 \int_0^\infty \frac{g^2(\omega)}{(z_0(\lambda)-\omega)}\,d\omega, \tag{11}$$

$$\alpha(z) = \omega_0 - z - \lambda^2 \int_0^\infty \frac{g^2(\omega)}{z-\omega}\,d\omega, \tag{12}$$

$\alpha' = d\alpha/dz$, and $(\tilde{\varphi}_1, \tilde{\varphi}(\tilde{\omega}))$, $(\tilde{\varphi}_1^\star, \tilde{\varphi}^\star(\tilde{\omega}))$ are the eigenfunctions of the free plus the interaction Hamiltonians. The singularities in $\tilde{\alpha}(\tilde{\omega})$ and $(\tilde{\omega}-\omega)^{-1}$ must be avoided making the shift $\pm i\epsilon$. We do not write it explicitly in order not to complicate the notation. A main characteristic of the solutions (7)–(10) is that they behave in a continuous way when the coupling constant λ goes to zero.

When $(\varphi_1, \varphi(\omega))$ belongs to $\mathscr{H}$, we have

$$\varphi_1^\star = \varphi_1^* \quad \text{and} \quad \varphi^\star(\omega) = \varphi^*(\omega).$$

In this particular case, Eq. (5) implies that

$$0 \leqslant \varphi_1 \varphi_1^\star \leqslant 1,$$

$$0 \leqslant \int_{\omega_1}^{\omega_2} \varphi(\omega)\varphi^*(\omega)d\omega \leqslant 1.$$

If $[\omega_1, \omega_2]$ is any nonempty interval, the last integral corresponds to a well-defined probability.

III. NON-HILBERT INITIAL CONDITIONS

From Eqs. (7)–(10) we can see that $\varphi^\star$ equals φ^* when $z_0 \in \Re$. In this case, the solutions belong to $\mathscr{H}$. But as we can obtain Hilbert solutions, even for those Hamiltonians that have complex eigenvalues, we are now interested in determining, for nonreal z_0, which initial conditions correspond to those states.

Initial conditions in $\mathscr{H}$ imply that $\varphi_1^\star(t=0) = \varphi_1^*(t=0)$ and $\varphi^\star(\omega, t=0) = \varphi^*(\omega, t=0)$. When analyzing the solutions (7)–(10) to the equations of motion, we see that this relation of conjugation holds true for any time value if the first terms of the rhs in (7)–(10) cancel with the corresponding residue evaluated in z_0. It is easy to see that these four conditions reduce to the following two:

$$2\pi i \ \mathrm{Res}\left[\frac{\lambda g(\omega)}{\alpha(\omega)} \ \tilde{\varphi}(\omega), z_0\right] = -\frac{1}{\sqrt{\alpha'(z_0)}} \ \tilde{\varphi}_1, \tag{13}$$

$$2\pi i \ \mathrm{Res}\left[\frac{\lambda g(\omega)}{\alpha(\omega)} \ \tilde{\varphi}^\star(\omega), z_0\right] = -\frac{1}{\sqrt{\alpha'(z_0)}} \ \tilde{\varphi}_1^\star. \tag{14}$$

An illustrative example with initial conditions in $\mathscr{H}$ that satisfy (13) and (14) is the general state whose initial conditions coincide with the discrete eigenstate of the free Hamiltonian H_0:

$$\varphi_1(t=0) = \varphi_1^\star(t=0) = 1, \quad \varphi(\omega, t=0) = \varphi^\star(\omega, t=0) = 0,$$

and evolve with the complete Hamiltonian H. Indeed, performing the change of basis (7)–(10), we obtain that

$$\tilde{\varphi}(\omega) = \frac{\lambda g(\omega)}{\alpha(\omega)},$$

and replacing it in Eq. (13), we see that

$$\begin{aligned} 2\pi i \ \mathrm{Res}\left[\frac{\lambda g(\omega)}{\alpha(\omega)} \ \tilde{\varphi}(\omega), z_0\right] &= 2\pi i \ \mathrm{Res}\left[\frac{\lambda^2 g^2(\tilde{z})}{\alpha^2(\tilde{z})}, \tilde{z} = z_0\right] \\ &= 2\pi i \ \mathrm{Res}\left[\frac{-i}{2\pi} \frac{1}{\alpha(\tilde{z})}, \tilde{z} = z_0\right] \\ &= -\frac{1}{\alpha'(z_0)} = -\frac{1}{\sqrt{\alpha'(z_0)}} \ \tilde{\varphi}_1, \end{aligned} \tag{15}$$

which is precisely that condition. This is also true for condition (14). Here we have used

$$\alpha_+(\omega) - \alpha_-(\omega) = -2\pi i \lambda^2 g^2(\omega).$$

On the other hand, one state whose initial values satisfy neither condition (13) nor condition (14) is, for example, the discrete eigenstate of the Hamiltonian,

$$\tilde{\varphi}_1 = \tilde{\varphi}_1^\star = 1 \quad \text{and} \quad \tilde{\varphi}(\omega) = \tilde{\varphi}^\star(\omega) = 0,$$

that it is obviously out of $\mathscr{H}$.

Finally, we note that there are initial conditions which satisfy either (13) or (14) but not both, and other ones which satisfy neither, but are not eigenstates of H. Nevertheless, all of them obey the ''normalization'' condition (5).

IV. PROBABILITY BEHAVIOR OUT OF HILBERT

To characterize the physical behavior of non-$\mathscr{H}$ states, we should not consider the temporal evolution of the wave functions only, since each one alone does not provide information either about transition probabilities or about the mean values. For example, the discrete eigenstate $(\tilde{\varphi}_1, \tilde{\varphi}_1^\star)$ whose components evolve with $e^{-iz_0 t}$ and $e^{iz_0 t}$, respectively, must not be interpreted as two decaying and growing states, because, in spite of the fact that they seem to be so, they are one single stationary state satisfying

$$\tilde{\varphi}_1(t)\tilde{\varphi}_1^\star(t) = \tilde{\varphi}_1(0)\tilde{\varphi}_1^\star(0) = 1,$$

$$\tilde{\varphi}(\tilde{\omega},t)\tilde{\varphi}^\star(\tilde{\omega},t) = \tilde{\varphi}(\tilde{\omega},0)\tilde{\varphi}^\star(\tilde{\omega},0) = 0,$$

as it may be seen from Eqs. (7)–(10).

Nevertheless, when evaluating probabilities for a general non-Hilbert state, including stationary ones, we see that—even though total ''probability'' is normalized to unity [see Eq. (5)]—the partial probability of finding the state in a bounded interval of energy may be out of the interval [0,1] or be a complex number. To investigate the nature of this problem let us consider an example. From Eqs. (7)–(10), the ''probability'' of being in the discrete eigenstate of H is

$$\varphi_1 \varphi_1^\star = \frac{1}{\alpha'}, \tag{16}$$

and the ''probability density'' of finding the system with continuous energy ω is

$$\varphi(\omega)\varphi^\star(\omega) = \frac{1}{\alpha'} \frac{\lambda^2 g^2(\omega)}{(z_0 - \omega)^2}. \tag{17}$$

Expanding the probability of finding the system in the discrete state up to the second order in the interaction constant λ, we find

$$\varphi_1 \varphi_1^\star = 1 - \lambda^2 \int_0^\infty \frac{g^2(\omega)}{(\omega_0 - \omega)^2}\, d\omega, \tag{18}$$

whereas for the probability density of finding it with a continuous energy ω, we obtain

$$\varphi(\omega)\varphi^\star(\omega) = \lambda^2 \frac{g^2(\omega)}{(\omega_0 - \omega)^2}. \tag{19}$$

So in this approximation we have

$$\varphi_1 \varphi_1^\star + \int_0^\infty \varphi(\omega)\varphi^\star(\omega) d\omega = 1.$$

We want to point out some features from the previous expressions

(1) Probability densities obey the condition expressed in (5).
(2) The probability density (19) has a pole in $\omega = \omega_0$.
(3) This pole produces complex ''probabilities'' in general and the ''probability density'' may be complex or greater than unity in its neighborhood.

Statements (1), (2), and (3) show us the nature of the problem and suggest a way to circumvent it. In fact, when we find ω_0 as the result of a measurement of the energy of the system, we do not know whether the corresponding state is the discrete eigenvector, the continuous vector with the same eigenvalue, or a linear combination of both. Then, it seems that we are not allowed to treat them as separated states assigning different probabilities to them because we cannot distinguish these states through energy measurements. But if we compute the probability to obtain ω_0 as the probability of the system to be in the discrete state plus the probability of the system to be in the continuum in a neighborhood of ω_0, the problem gets solved by itself because the infinite terms involving ω_0 cancel each other in the λ^2 approximation, i.e.,

$$\begin{aligned}\mathscr{P}[\omega_0-\Delta,\omega_0+\Delta] &= \varphi_1\varphi_1^\star + \int_{\omega_0-\Delta}^{\omega_0+\Delta} \varphi(\omega_0)\varphi^\star(\omega_0)\,d\omega \\ &= 1-\lambda^2\int_0^{\omega_0-\Delta} \frac{g^2(\omega)}{(\omega_0-\omega)^2}\,d\omega - \lambda^2\int_{\omega_0+\Delta}^{\infty} \frac{g^2(\omega)}{(\omega_0-\omega)^2}\,d\omega,\end{aligned}$$

does not have the problems mentioned in the above statements (2) and (3).

Nevertheless, this is only a second-order solution. It can be seen after a straightforward computation that in the next step of the expansion (fourth-order) complex contributions reappear from each term of the probability densities and do not cancel each other. This is so because, as we will see, this is not the right way to solve the problem.

Due to the bad behavior of probabilities out of $\mathscr{H}$, we have studied the behavior of another meaningful magnitude: the mean value. In the frame of the doublet representation we can generalize the expression of the free Hamiltonian mean value in any state as

$$\begin{aligned}\langle H_0(t)\rangle &= \omega_0\varphi_1(t)\varphi_1^\star(t) + \int_0^\infty \omega\varphi(\omega,t)\varphi^\star(\omega,t)\,d\omega \\ &= \omega_0\Bigg[\frac{1}{\sqrt{\alpha'(z_0)}}\,\tilde{\varphi}_1 e^{-iz_0t} + \int_0^\infty \frac{\lambda g(\tilde{\omega})}{\alpha_+(\tilde{\omega})}\,\tilde{\varphi}(\tilde{\omega})e^{-i\tilde{\omega}t}d\tilde{\omega}\Bigg] \\ &\quad\cdot\Bigg[\frac{1}{\sqrt{\alpha'(z_0)}}\,\tilde{\varphi}_1^\star e^{+iz_0t} + \int_0^\infty \frac{\lambda g(\tilde{\omega})}{\alpha_-(\tilde{\omega})}\,\tilde{\varphi}^\star(\tilde{\omega})e^{+i\tilde{\omega}t}d\tilde{\omega}\Bigg] \\ &\quad+\int_0^\infty\Bigg[\frac{1}{\sqrt{\alpha'(z_0)}}\,\frac{\lambda g(\omega)}{z_0-\omega}\,\tilde{\varphi}_1 e^{-iz_0t} + \lambda^2 g(\omega) \\ &\quad\times\int_0^\infty \frac{g(\tilde{\omega})}{\alpha_+(\tilde{\omega})(\tilde{\omega}-\omega)}\,\tilde{\varphi}(\tilde{\omega})e^{-i\tilde{\omega}t}d\tilde{\omega} + \tilde{\varphi}(\omega)e^{-i\omega t}\Bigg] \\ &\quad\times\Bigg[\frac{1}{\sqrt{\alpha'(z_0)}}\,\frac{\lambda g(\omega)}{z_0-\omega}\,\tilde{\varphi}_1^\star e^{+iz_0t} + \lambda^2 g(\omega) \\ &\quad\times\int_0^\infty \frac{g(\tilde{\omega})}{\alpha_-(\tilde{\omega})(\tilde{\omega}-\omega)}\,\tilde{\varphi}^\star(\tilde{\omega})e^{+i\tilde{\omega}t}d\tilde{\omega} + \tilde{\varphi}^\star(\omega)e^{+i\omega t}\Bigg]\omega\,d\omega,\end{aligned}$$

whose instabilities come from the real contributions of exponentials $e^{\pm iz_0t}$. That is to say, the mean value has oscillating terms (which correspond to real frequencies ω) and growing or decaying waves coming from the imaginary contribution of the ''frequency'' z_0. These instabilities do not cause problems to Hilbert states because they satisfy conditions (13) and (14), so the complex exponentials cancel each other and do not produce vanishing or indefinitely growing terms. On the other hand, non-$\mathscr{H}$ states will have anomalous terms in the mean values of the Hamiltonian which diverge for growing time values, except when they are eigenstates of H. So here we also have a problem for the mean values evaluated in non-$\mathscr{H}$ states.

In conclusion, we point out that, in spite of the fact that it is possible to find the dynamical evolution for any doublet, it is difficult to assign probabilities or mean values (i.e., to give physical meaning) to them. In the next section we show that this problem is linked to the fact that the probability of measuring energy ω_0 has contributions coming from the discrete state plus contributions from any interval around ω_0, belonging to the continuum.

V. INTERACTIONS THAT GENERATE REAL z_0

In the previous sections we have identified the appearance of anomalous probabilities with z_0 being a nonreal number. Now we will show that the problems created by this complex quantity arise from the fact that the improper integrals around ω_0 yield a complex eigenvalue of the complete Hamiltonian. To show the explicit limit between complex and real eigenvalues, we make use of the solutions (7)–(10) which are continuous in λ (see Ref. 1). Thus, we can suppose that z_0 in expression (11) can be expanded as a power series of λ, taking $z_0|_{\lambda=0}=\omega_0$,

$$z_0=\omega_0+\lambda^2\int_0^\infty \frac{g^2(\omega)}{(\omega_0-\omega)}\,d\omega-\frac{2}{3}\lambda^4\int_0^\infty \frac{g^2(\omega)}{(\omega_0-\omega)}\,d\omega\int_0^\infty \frac{g^2(\omega')}{(\omega_0-\omega')^2}\,d\omega'+\cdots . \tag{20}$$

As we can see, improper integrals appear in the expansion of z_0. A generic coefficient in the series always contains a factor like

$$\frac{g^2(\omega)}{(\omega_0-\omega)^n},$$

implying the appearance of poles in the function under integration which—when computed in the complex plane—give imaginary contributions to z_0. These divergences point out the influence of the degeneration in the free Hamiltonian spectrum: when the eigenstate that corresponds to the discrete eigenvalue of the free Hamiltonian interacts with the eigenstate of the continuum with energy ω_0 and its neighborhood, complex eigenvalues of the complete Hamiltonian appear. As it has been shown in Ref. 2, the reality of the discrete eigenvalue z_0 is related to $g(\omega)$ evaluated in the eigenvalue.

Expression (20) tells us that, if we confine ourselves to the second-order expansion, z_0 is real when $g(\omega_0)=0$. This is in accordance with well-known results that establish that

$$g(\omega_0)=0\Rightarrow\Gamma^{(2)}=\pi\lambda^2 g^2(\omega_0)=0,$$

where $\Gamma^{(2)}$ is the second order in λ contribution to half the inverse of time life.[3–5] But this is not true for higher orders in the λ expansion because the condition $g^2(\omega_0)=0$ is not sufficient to guarantee that the whole integral be nondivergent.

From the previous results, we conclude that the condition that $g(\omega)$ must satisfy in order to obtain a real spectrum is

$$\lim_{\lambda\to 0}\frac{g^2(\omega)}{(z_0(\lambda)-\omega)^n}<\infty,\quad \forall n\in\mathcal{N}, \tag{21}$$

for any ω belonging to an interval that contains ω_0 because, when performing the expansion (20), condition (21) guarantees the reality of the expansion. This is equivalent to requesting that

$$\lim_{\lambda\to 0} z(\lambda)=\omega_0$$

does not belong to the support of $g(\omega)$.

A trivial example of interaction satisfying (21) is the Ohmic interaction $g(\omega)=\omega$ with a cutoff that leaves ω_0 out of the integration interval. In fact, any interaction that vanishes over a finite interval around ω_0 is a trivial example.

A nontrivial interaction satisfying (21) is

$$g(\omega)=\begin{cases}\exp(\omega_0-\omega)^{-1}, & \text{if } \omega_0<\omega;\\ 0, & \text{if } \omega_0=\omega;\\ \exp-(\omega_0-\omega)^{-1}, & \text{if } \omega_0>\omega,\end{cases} \tag{22}$$

which removes, in a continuous way, the interaction between the degenerate states of the free Hamiltonian.

For interactions satisfying condition (21), the spectrum of the complete Hamiltonian is real, no pathologies appear in the evaluation of probabilities, and the whole problem can be formulated in Hilbert space with no need of enlarging the state space to the doublet one in order to diagonalize H.

VI. A REDUCED SPACE

In general cases in which $g(\omega)$ does not satisfy condition (21) and z_0 is not necessarily a real number, we may remove the degeneration that causes anomalous probabilities defining a new basis with the following procedure (which we will develop in Dirac notation because it is clearer in this case).

To exclude the continuous eigenvalue ω_0 from the continuous spectrum (thus removing the degeneration) we define the set

$$\mathscr{C}=\{\omega/0\leqslant\omega\leqslant\omega_0-a \quad \text{or} \quad \omega_0+a\leqslant\omega\}, \tag{23}$$

with $a\in\Re$, $a>0$. Next, we define the orthogonal basis:

$$|\Lambda\rangle=\Lambda_1|1\rangle+\int_{\omega_0-a}^{\omega_0+a}\lambda(\omega)|\omega\rangle d\omega\,\epsilon\mathscr{H}, \tag{24}$$

$$\{|\omega_r\rangle\}=\{|\omega\rangle/\omega\in\mathscr{C}\}, \tag{25}$$

where the basis vectors satisfy

$$\begin{aligned}&\langle\Lambda|\Lambda\rangle=\Lambda_1\Lambda_1^*+\int_{\omega_0-a}^{\omega_0+a}\Lambda(\omega)\Lambda^*(\omega)d\omega=1,\\ &\langle\omega_r|\Lambda\rangle=\langle\Lambda|\omega_r\rangle=0 \quad \text{and} \quad \langle\omega_r|\omega_r'\rangle=\delta(\omega_r-\omega_r').\end{aligned} \tag{26}$$

In this basis the matrix elements of H are

$$\begin{aligned}\langle\Lambda|H|\Lambda\rangle&=\omega_0\Lambda_1\Lambda_1^*+\lambda\int_{\omega_0-a}^{\omega_0+a}g(\omega)[\Lambda_1^*\Lambda(\omega)+\Lambda_1\Lambda^*(\omega)]d\omega\\ &+\int_{\omega_0-a}^{\omega_0+a}\omega\Lambda(\omega)\Lambda^*(\omega)d\omega\equiv\Lambda(\lambda),\end{aligned} \tag{27}$$

$$\langle\omega_r'|H|\omega_r\rangle=\omega_r\delta(\omega_r'-\omega_r), \tag{28}$$

$$\langle\omega_r|H|\Lambda\rangle=\lambda\Lambda_1 g(\omega_r). \tag{29}$$

With them, we can define the Hamiltonian $\tilde{H}$ which acts on the ''reduced'' space as

$$\tilde{H}=\Lambda(\lambda)|\Lambda\rangle\langle\Lambda|+\int_{\mathscr{C}}\omega|\omega\rangle\langle\omega|d\omega+\int_{\mathscr{C}}\lambda g(\omega)[\Lambda_1|\Lambda\rangle\langle\omega|+\Lambda_1^*|\omega\rangle\langle\Lambda|]d\omega. \tag{30}$$

Diagonalizing $\tilde{H}$, we obtain that its discrete eigenvalue satisfies the following recursive equation:

$$\tilde{\Lambda}(\lambda)=\Lambda(\lambda)+\lambda^2\int_{\mathscr{C}}\frac{\Lambda_1\Lambda_1^* g^2(\omega)}{(\tilde{\Lambda}(\lambda)-\omega)}\,d\omega. \tag{31}$$

Taking into account the results of Sec. V, we have that $\tilde{\Lambda}(\lambda)$ will be real (and the probability well defined) if $\lim_{\lambda\to 0}\tilde{\Lambda}(\lambda)$ does not belong to the support of $g(\omega)$, i.e., if

$$\lim_{\lambda\to 0}\tilde{\Lambda}(\lambda)=\lim_{\lambda\to 0}\Lambda(\lambda)=\omega_0+\int_{\omega_0-a}^{\omega_0+a}(\omega-\omega_0)\Lambda(\omega)\Lambda^*(\omega)d\omega \tag{32}$$

does not belong to the continuous set $\{\omega_r\}$ [we have used the normalization condition (26)]. As the function under integration in (32) is small enough near ω_0, it will be always possible to define some real number a near ω_0 to satisfy

$$\omega_0-a\leqslant\Lambda(\lambda=0)\leqslant\omega_0+a.$$

Then, we conclude that H has a real spectrum, the wave functions belong to $\mathscr{H}$, and the probabilities are well defined in the reduced space spanned by the basis (24)–(25).

We also notice that the reality of $\tilde{\Lambda}(\lambda)$ in (31) is guaranteed from a sufficiently small value of (ω_0-a) and it remains in the $a\to 0$ limit. In this case

$$\lim_{a\to 0}\tilde{\Lambda}\equiv W_0\in\Re,$$

and the spectrum remains nondegenerated because the continuous ω_0 energy value has been removed from the continuous spectrum. So, the eigenfunction which evolves with $\exp(iz_0t)$ becomes the Hilbert eigenfunction which evolves with $\exp(iW_0t)$ defined in the reduced space.

VII. CONCLUSIONS

We have shown that the states which do not satisfy conditions (13) and (14) do not belong to $\mathscr{H}$. So, even though we can predict their temporal evolution, it is impossible to define either well-behaved probabilities or nondivergent mean values for them. Non-Hilbert states are useful to describe the dynamical evolution of physical wave functions, but they cannot be considered as having the same physical nature as those of Hilbert space (the same as plane waves do not have the same physical nature as ordinary Hilbert states).

Taking into account that the existence of non-Hilbert states is linked to the appearance of nonreal eigenvalues and that these eigenvalues are related to the degeneration of the Hamiltonian spectrum, we have shown how to solve the problem. To do so we define a reduced basis that generates wave functions which represent states with well-defined probabilities and mean values.

Multicomponent Wentzel–Kramers–Brillouin approximation on arbitrary symplectic manifolds: A star product approach

C. Emmrich and H. Römer
Fakultät für Physik, Universität Freiburg, Hermann-Herder-Strasse 3, 79104 Freiburg, Germany

(Received 20 February 1997; accepted for publication 28 May 1997)

It is known that in the Wentzel–Kramers–Brillouin approximation of multicomponent systems like the Dirac equation or Born–Oppenheimer approximation, an additional phase appears apart from the Berry phase. So far, this phase was only examined in special cases, or under certain restrictive assumptions, namely, that the eigenspaces of the matrix or endomorphism valued symbol of the Hamiltonian form trivial bundles. We give a completely global derivation of this phase which does not depend on any choice of local trivializing sections. This is achieved using a star product approach to quantization. Furthermore, we give a systematic and global approach to a reduction of the problem to a problem defined completely on the different ''polarizations.'' Finally, we discuss to what extent it is actually possible to reduce the problem to a really scalar one, and make some comments on obstructions to the existence of global quasiclassical states. © *1998 American Institute of Physics.* [S0022-2488(98)03106-5]

I. INTRODUCTION

Whereas the semiclassical and Wentzel–Kramers–Brillouin (WKB) approximation of systems with Hamiltonians whose symbol is a scalar function is very well understood both on a local and a global level,[1–4] this is not the case to the same extent for systems with Hamiltonians whose symbols are matrix valued functions on a symplectic manifold, or sections in the endomorphism bundle of a vector bundle over a symplectic manifold M.

Such Hamiltonians appear in many places in physics: Examples are the Dirac equation, multicomponent wave equations like electrodynamics in media and Yang–Mills theories, and the Born–Oppenheimer approximation in molecular physics.

In the scalar case, a nice geometric interpretation of the semiclassical states as half densities on Lagrangian submanifolds invariant under the Hamiltonian flow exists, and discrete spectra may be computed using the Bohr–Sommerfeld condition, taking into account the Maslov correction.

In the multicomponent case, the analogous structures are not known: There exist many results on a local level, but on a global level results are only known either for special examples, or under the very restrictive assumption that the eigenspaces of the symbol of the Hamiltonian form trivial bundles over the symplectic base manifold M.[1,5–7].

Locally, the WKB ansatz for multicomponent systems still is

$$\Psi(x)=a(x,\hbar)\exp(iS(x)/\hbar),$$

with $a(x,\hbar)=a_0(x)+a_1(x)\hbar+\cdots$. Here, the $a_i(x)$ are now vector valued functions.[8,9,1]

In lowest order in $\hbar$ the time independent Schrödinger equations yields

$$[H_0(x,dS(x))-E]a_0(x)=0,$$

i.e., $a_0(x)$ has to be an eigenvector of the matrix valued principal symbol $H_0(x,p)$ at the point $p=dS(x)$. Denoting by $\lambda_\alpha(x,p)$ the α-th eigenvalue of the matrix $H_0(x,p)$ at the point (x,p), the phase $S(x)$ has to satisfy the Hamilton–Jacobi-equation for one of the eigenvalue functions λ_α: $\lambda_\alpha(x,dS)-E=0$, and one obtains a separate phase function for each ''polarization'' α.

 © 1998 American Institute of Physics

The equation of order $\hbar$ has a more complicated structure than in the scalar case: The absolute value of the amplitude still fulfills the usual transport equation, but the vector a_0 satisfies a more complicated equation which contains a Berry phase term,[10] and an additional term without an obvious geometric meaning.[11,7,9]

There exist some functional analytically rigorous results on the WKB approximation for special systems in the literature.[1,6] However, no analog of the Bohr–Sommerfeld quantization condition is known in general, and all those results have the common feature that they are based on the assumption that the bundles of eigenvectors of the symbol of the Hamiltonian are trivial, at least on the ''classically allowed region'' $\lambda_\alpha < \tilde{E}$ for an $\tilde{E} > E$. This assumption is not always fulfilled: Nontrivial eigenspace bundles do in fact occur in many physical situations. One immediate example is Dirac's equation for a field of spin 1/2 on a nontrivial space time manifold M, either Riemannian or pseudo-Riemannian, where the eigenbundles depend on the global structure of M (and the spin structure.) But even for the Born–Oppenheimer approximation the phenomenon of nontrivial eigenspace bundles may arise due to the phenomenon of level crossing, i.e., the possibility of two eigenvalues becoming equal in certain points on phase space: The degeneracy increases in those points. For the WKB approximation one has to cut out those points and to treat them separately. This may lead to the appearance of nontrivial bundles, and as a matter of fact, it is well known that nontrivial bundles play a role in real molecular systems.

In Ref. 7 a Bohr–Sommerfeld condition could be derived for systems whose symbol has nondegenerate eigenvalues, using the Moyal product on matrix valued symbols in order to reduce this case to the WKB approximation for a scalar system. To this end, a formally unitary $U = U_0 + U_1\hbar + \cdots$ was introduced such that

$$U^\dagger * H * U = \Lambda,$$

for some diagonal matrix valued symbol Λ. This approach has been further refined in Ref. 12.

However, this method has several disadvantages: First, considering this equation at zeroth order, one concludes that the columns of U_0 are eigenvectors of H_0. Hence, this method may again be applied globally only if the eigenvector bundles are trivial. Moreover, it is not possible to generalize this method to the case of degenerate eigenvalues with constant degeneracies. In this case, it is in general not possible to diagonalize the Hamiltonian globally (even if the eigenvector bundles are trivial), but only to block-diagonalize it. Finally, this approach is not natural from a geometric point of view: The Moyal product is defined only on trivial bundles over $\mathbb{R}^{2n}$, hence it is not possible to stick with the Moyal product if one wants to reduce the problem in a global way to a problem defined on the respective eigenbundles. In particular, it will become obvious that this method, if generalized to the degenerate case, will correspond to a quantization based on a noncanonical and unnatural choice of a connection: The choice of U_0 implies, as mentioned above, a choice of trivializing sections of the eigenbundles. In a sense to become clear in section IV, the quantization achieved by this process corresponds to a connection with respect to which the chosen set of trivializing sections is covariantly constant. Such a connection is obviously geometrically meaningless, since it depends on the choice of those sections.

Our goal in this article is to reduce the problem of WKB for endomorphism valued symbols ''as far as possible'' to the scalar case, using only globally defined methods: Apart from being an important progress in a geometric understanding of a multicomponent WKB approximation, this is an important step towards a Bohr–Sommerfeld like condition, since the latter is necessarily global in nature.

For this reduction of the problem, the notion of star products on arbitrary endomorphism bundles proves to be particularly useful, since we have to deal with nontrivial bundles. Such star products are known to exist on arbitrary endomorphism bundles over a symplectic manifold, as has been shown by Fedosov.[13] His method is particularly adapted to our purposes, since his proof of existence is constructive in nature, and there exist explicit formulas for the isomorphisms of different star products. Although we will restrict ourselves to formal star products, i.e., to formal power series in $\hbar$, the method can in principle be translated into operator language using the notion of asymptotic operator representations, which are, in a suitable sense, representations up to order $O(\hbar^\infty)$ of the star product algebra. Such representations are known to exist if certain quantization condition are satisfied.[14]

The main idea of the paper is to give a ''basis independent and geometrically natural version of the diagonalization procedure of.[7] '' What is meant by this becomes more apparent if one observes that essentially all additional complications in the WKB approximation of multicomponent systems are due to the fact that the projection operators onto the eigenspaces of the principal symbol of H are in general not constant. If one could replace ordinary derivatives by covariant derivatives with respect to which the projections are covariantly constant, the problem would be considerably simplified. However, as we assume that we are studying a given definite quantum mechanical system, we cannot simply replace ordinary derivatives by covariant derivatives ''by hand,'' as we do not want to change the physics of the system.

Here, the use of Fedosov's star product proves to be particularly powerful: His construction of a star product depends on the choice of a symplectic connection on the base space and a connection on the endomorphism bundle. Nevertheless, the different star products are isomorphic. Hence, if we interpret the choice of the connection as defining a definite quantization procedure, then we may change this connection without changing physics if we apply at the same time the corresponding isomorphism. This means that we are allowed to change the connection in order to simplify the problem, if we consistently correct the symbols of the Hamiltonian and all interesting observables at the same time.

Indeed, this additional freedom (which is completely missing if one restricts oneself to the Moyal product) may be used to simplify the problem considerably: One may find an $\hbar$-dependent connection, $\hbar$-dependent projections, and a corrected symbol such that all these structures are compatible in an obvious sense. An important feature of Fedosov's product is that the star product constructed from these data is compatible with the projections as well, i.e., if A and B are observables such that there corrected symbols commute with the projections, then the corresponding star product $A*B$ commutes with the projections as well. Hence, the different blocks defined by the projections are decoupled for a suitable set of observables.

Using these techniques, we will be lead to a geometrical interpretation of the additional phases appearing in the WKB approximation at order $\hbar$ as formed from the Poisson-curvature and an analog of the second fundamental form of a Berry-type connection. We will show that this even holds if one chooses a different connection for computing the correction. Hence, the Berry-type connection is distinguished among the set of all compatible connections.

The paper is organized as follows: In the next section we give a short overview over Fedosov's construction of star products on arbitrary endomorphism bundles to the extent needed for our applications. The main fact will be that a modification of the connection on the endomorphism bundle at some order $O(\hbar^k)$ induces an isomorphism of the corresponding star product algebras which implies corrections only at higher order $O(\hbar^{k+1})$. This will allow the use of inductive methods in the main part of the paper, and to compute the corrections iteratively order by order in $\hbar$.

In Section III, we show how one may use the freedom of choosing the connection in order to block-diagonalize the system, i.e., to find a decomposition of the vector bundle such that the Hamiltonian and a large class of observables preserve this decomposition at the quantum mechanical level. Furthermore, we will show that for a suitable class of observables, a formal Heisenberg equation of motion may be defined.

In Section IV we compute the correction of the symbol of H at order $\hbar$ for all compatible connections, thus reproducing in particular the additional phase observed in special cases before. We give a geometric interpretation of these terms, and show that a certain adapted connection which is of ''Berry type'' is distinguished among all adapted connections.

In Section V we discuss some physical aspects of the assumptions and results of the previous analysis.

Finally, in Section VI we examine to what extent it is actually possible to reduce the problem to a scalar one, and discuss some aspects connected to a Bohr–Sommerfeld like quantization condition.

II. STAR PRODUCTS ON ENDOMORPHISM BUNDLES

In this section we give a short introduction to Fedosov's beautiful construction of star products on arbitrary symplectic manifolds,[13] as needed for our purposes, and we prove three lemmas needed in Section III.

We assume the reader to be familiar with the general ideas of deformation quantization. For the deformation quantization program, we refer to Ref. 15. For an alternative, less explicit proof of existence of star products on arbitrary symplectic manifolds, see Ref. 16.

We denote the Moyal product, which is the star product on $\mathbb{R}^{2n}$ corresponding to Weyl ordering, by $\diamondsuit$:

$$(a \diamondsuit b)(x) = (e^{(i\hbar/2)\omega^{kl}(\partial/\partial x^k)(\partial/\partial y^l)} a(x)b(y))|_{x=y},$$

where ω^{kl} are the components of the Poisson tensor. The algebra $\mathcal{F}(\mathbb{R}^{2n})\otimes\mathbb{C}[[\hbar]]$ with the product $\diamondsuit$ is called the Weyl algebra over $\mathbb{R}^{2n}$. [Here, $\mathcal{F}(\mathbb{R}^{2n})$ denotes the algebra of smooth functions on $\mathbb{R}^{2n}$.]

Let M be a symplectic manifold with symplectic form ω and a symplectic connection ∂_s (such a connection always exists), and let V be a Hermitian vector bundle over M with Hermitian connection $\mathbf{\nabla}$. We consider the bundle $V[[\hbar]] = V\otimes\mathbb{C}[[\hbar]]$ which is a fiber bundle over M whose fiber over a point $q\in M$ is the $\mathbb{C}[[\hbar]]$ module $V_q[[\hbar]] = V_q\otimes\mathbb{C}[[\hbar]]$. Let $E[[\hbar]] = \cup_{q\in M} \mathrm{End}(V_q)\otimes\mathbb{C}[[\hbar]]$ be the bundle of endomorphisms of the fibers of $V[[\hbar]]$.

We may define a star product on the endomorphism $\Gamma(E[[\hbar]])$ of the bundle $V[[\hbar]]$ by Fedosov's construction.[13] To this end one considers the algebra,

$$\mathcal{A} = \Gamma(E[[\hbar]]\otimes W),$$

where W is the Weyl algebra bundle over M (i.e., the bundle over M whose fiber over q consists of Weyl algebra on the symplectic vector space T_qM).

$\mathcal{A}$ is graded as a vector space, with a degree defined by

$$\deg(\hbar) = 2, \quad \deg(y^i) = 1,$$

where the (y^i) are coordinates on the fiber T_qM. Defining $\mathcal{A}_i$ as the set of all $\hat{X}\in\mathcal{A}$ which are sums of terms of degree larger or equal i, $\mathcal{A}$ becomes a filtered algebra:

$$\mathcal{A} = \mathcal{A}_0 \supset \mathcal{A}_1 \supset \cdots .$$

The Hermitian connection $\mathbf{\nabla}$ on V induces a connection on $E[[\hbar]]$ which we denote by ∇ as well. Together with the symplectic connection ∂_s on M this defines a connection $\partial = 1\otimes\partial_s + \mathbf{\nabla}\otimes 1$ on $E[[\hbar]]\otimes W$.

One may construct by an iterative procedure, starting with ∂, an exterior covariant derivative D on $\mathcal{A}\otimes\Omega(M)$, the forms on M with values in $\mathcal{A}$, such that we have the following

(1) $D^2 = 0$.
(2) The space of covariant constant elements in $\mathcal{A} \hat{=} \mathcal{A}\otimes\Omega_0(M) \subset \mathcal{A}\otimes\Omega(M)$ is isomorphic as a vector space to $E[[\hbar]]$.
(3) D acts as a derivation on $\mathcal{A}\otimes\Omega(M)$ (with the product induced by the Moyal product on $\mathcal{A}$).

These properties guarantee that the covariant constant sections form a subalgebra and allow us to use the vector space isomorphism of 2 between the covariant constant elements in $\mathcal{A}$ and $E[[\hbar]]$ to define the star product on $\Gamma(E[[\hbar]])$ by pull back of the product on $\mathcal{A}$. More precisely, if we denote the isomorphism from $\Gamma(E[[\hbar]])$ to the covariantly constant elements in $\mathcal{A}$ by $\mathcal{Q}$, and its inverse by σ, the star product on $E[[\hbar]]$ is given by

$$a * b = \sigma(\mathcal{Q}(a) \diamondsuit \mathcal{Q}(b)),$$

for $a,b\in\Gamma(E[[\hbar]])$.

To give an explicit expression for this flat derivative, we introduce operators δ and δ^{-1} on $\mathcal{A}\otimes\Omega(M)$:

$$\delta = dx^i \wedge \frac{\partial}{\partial y^i}$$

and

$$\delta^{-1}a=\frac{1}{p+q}\,i_{y^i(\partial/\partial x^i)}a,$$

if a is a q-form that is homogeneous of degree p in the fiber coordinate y, $p+q\neq 0$, and $\delta^{-1}a=0$ if $p=q=0$. These operators have the important property that for any $\hat{X}\in\Omega(M)\otimes\mathcal{A}$:

$$\hat{X}=\hat{X}_{00}+(\delta^{-1}\delta+\delta\delta^{-1})\hat{X}.$$

Here, $\hat{X}_{00}$ denotes the part of $\hat{X}$ that is a zero form of degree 0 in y.

The ansatz,

$$D=-\delta+\partial+\left[\frac{i}{\hbar}\,r,\ \ \right],$$

for a one form r with values in $\mathcal{A}$, the flatness condition $D^2=0$ together with a ''normalization condition'' $\delta^{-1}r=0$ lead to the condition

$$r=\delta^{-1}\tilde{R}+\delta^{-1}\left(\partial r+\frac{i}{\hbar}\,r^2\right)-\delta^{-1}\Omega, \tag{1}$$

for a power series $\Omega=\Sigma_{i=1}^{\infty}\hbar^i\omega_i$ with coefficients ω^i in the closed 2-forms on M, by which r is uniquely defined and may be computed iteratively. Here, $\tilde{R}$ is the curvature of the connection ∂, considered as a two form with values in $\mathcal{A}$, acting on $\mathcal{A}$ as $(i/\hbar)[\tilde{R},\cdot\,]$: If R^E is the curvature of ∇ and R^s is the curvature of ∂_s, then $\tilde{R}$ is locally given by

$$\tilde{R}=-i\,\frac{\hbar}{2}\,R^E_{ij}dx^i\wedge dx^j+1\otimes\frac{1}{4}\,\omega_{ij}(R^s)^i_{klm}y^jy^kdx^l\wedge dx^m.$$

The freedom of choosing Ω comes from the fact that the curvature of D is not necessarily zero, but it is sufficient if it is a central 2-form, i.e., one commuting with all elements in $\mathcal{A}\otimes\Omega(M)$. Whereas the zeroth order term in $\hbar$ is always the symplectic form, the higher order terms may be chosen as arbitrary closed 2-forms. It is known that different choices of Ω lead in general to inequivalent star products, i.e., inequivalent quantizations.[17,18] Two star products are equivalent iff the Ω's differ by a power series with values in the exact 2-forms. Thus, the equivalence classes are parametrized by power series with coefficients in the second de Rham cohomology class of M.

For our considerations, this simply means that we have to stick with a fixed choice of Ω: All the statements below are true, as long as we do not change Ω (or rather its cohmology class.) Different choices of Hermitian connections will lead to equivalent star products, as long as Ω is not changed, and all formulas derived below will hold. We do not claim that any of the possible choices is *a priori* preferable. Rather, our approach is to assume that we are given a definite physical system, including the physically correct quantization, and we do not try to find a distinguished quantization on *a priori* reasons. Thus, we assume that we are given a definite Ω from the very beginning, and we will never change it throughout our analysis, in order not to change physics.

We note that in spite of the factor $1/\hbar$ in (1) the solution of this equation is a power series in $\hbar$, containing no negative powers.

With r determined, the covariantly constant continuation $\mathcal{Q}(a)$ of a in $\mathcal{A}$ is given by the unique solution to the equation,

$$\mathcal{Q}(a)=a_0+\delta^{-1}\left(\partial\mathcal{Q}(a)+\left[\frac{i}{\hbar}\,r,\mathcal{Q}(a)\right]\right), \tag{2}$$

which may again be solved iteratively.

Different choices of ∇ will yield different star products. However, they are equivalent in the following sense.

Given two Hermitian connections $\nabla^{(1)},\nabla^{(2)}$ and two symplectic connections $\partial_s^{(1)},\partial_s^{(2)}$ with corresponding derivatives $D^{(1)},D^{(2)}$, there is a formally unitary,

$$U_{(12)}=\exp_\diamond\left(\frac{i}{\hbar}A_{(12)}\right),$$

for some $A\in\mathcal{A}$ such that

$$D^{(1)}\hat{X}=0\Rightarrow D^{(2)}(U_{(12)}\diamond\hat{X}\diamond U_{(12)}^{-1})=0,$$

for any $\hat{X}\in\Gamma(\mathcal{A})$. (Here, $\exp_\diamond$ denotes the exponential with respect to the fiberwise Moyal product $\diamond$.)

Furthermore, letting $\mathcal{Q}^{(i)}(X)$ denote the covariant constant continuation of $X\in\Gamma(E[[\hbar]])$ with respect to $D^{(i)}$, and $\sigma^{(i)}$ denote the inverse of $\mathcal{Q}^{(i)}$ $(i=1,2)$, we have an isomorphism of the different star products given by

$$\phi(X)\overset{\text{def}}{=}\sigma^{(2)}(U_{(12)}\diamond\mathcal{Q}^{(1)}(X)\diamond U_{(12)}^{-1}).$$

To check this statement one simply has to compute

$$\begin{aligned}\phi(X*_1Y)&=\sigma^{(2)}(U_{(12)}\diamond\mathcal{Q}^{(1)}(X*_1Y)\diamond U_{(12)}^{-1})\\&=\sigma^{(2)}(U_{(12)}\diamond\mathcal{Q}^{(1)}(X)\diamond\mathcal{Q}^{(1)}(Y)\diamond U_{(12)}^{-1})\\&=\sigma^{(2)}((U_{(12)}\diamond\mathcal{Q}^{(1)}(X)\diamond U_{(12)}^{-1})\diamond(U_{(12)}\diamond\mathcal{Q}^{(1)}(Y)\diamond U_{(12)}^{-1}))\\&=\sigma^{(2)}(\mathcal{Q}^{(2)}(\phi(X))\diamond\mathcal{Q}^{(2)}(\phi(Y)))=\phi(X)*_2\phi(Y).\end{aligned}$$

We note that, in general, $\phi(X)\neq X$. This is precisely what was meant in the introduction by the statement that we can change the quantization procedure without changing physics, if we consistently correct the symbols of the Hamiltonian and the relevant observables at the same time.

We may express $U_{(12)}\diamond\hat{X}\diamond U_{(12)}^{-1}$ directly in terms of $A_{(12)}$ as

$$U_{(12)}\diamond\hat{X}\diamond U_{(12)}^{-1}=\sum_{k=0}^{\infty}\left(\frac{i}{\hbar}\right)^k\frac{1}{k!}[A_{(12)},[\underbrace{A_{(12)},\ldots}_{k\text{-times}}[A_{(12)},\hat{X}]\ldots]]. \tag{3}$$

For $A_{(12)}$, one may derive the following equation which defines it iteratively:[13]

$$A_{(12)}=\delta^{-1}\left(\frac{ad\left(\frac{i}{\hbar}A_{(12)}\right)}{\exp_\diamond\left(ad\left(\frac{i}{\hbar}A_{(12)}\right)\right)-1}(\Delta\gamma)_{(12)}+(D+\delta)A_{(12)}\right). \tag{4}$$

Here, $(\Delta\gamma)_{(12)}$ denotes the one form on M with values in $\mathcal{A}$ (acting by $(i/\hbar)[(\Delta\gamma)_{(12)}\cdot]$) which is induced by the difference of the two connection forms corresponding to $\partial^{(i)}=1\otimes\partial_s^{(i)}+\nabla^{(i)}\otimes 1$, $i=1,2$ on $E[[\hbar]]\otimes W$. (The difference of two connection forms is tensorial and hence defines a one form on M.) If $\nabla^{(i)}$ is locally given by $\partial/\partial x^i+\Gamma_i$, and the Christoffel symbols corresponding to $\partial_s^{(i)}$ are given by $(\Gamma_s^{(i)})_{lm}^k$; then $(\Delta\gamma)_{(12)}$ is locally given by

$$(\Delta\gamma)_{12}=-i\hbar(\Gamma_i^{(2)}-\Gamma_i^{(1)})dx^i+1\otimes\tfrac{1}{2}\,\omega_{ij}((\Gamma_s^{(2)})_{kl}^i-(\Gamma_s^{(1)})_{kl}^i)y^jy^kdx^l. \tag{5}$$

In particular, it is obvious from this expression that $A_{(12)}$ does not contain any negative powers of $\hbar$.

Remarks:

(1) Though U does contain inverse powers of $\hbar$, $U_{(12)} \diamond \hat{X} \diamond U_{(12)}^{-1}$ is again a power series in $\hbar$ for all $\hat{X} \in \Gamma(\mathcal{A})$ with $D^{(1)}\hat{X}=0$. This is shown in Ref. 13 by showing first that $D^{(2)} \times (U_{(12)} \diamond \hat{X} \diamond U_{(12)}^{-1})=0$ in an enlarged algebra W^+ whose elements may contain negative powers of $\hbar$ in some specified way, and then showing that any $Y \in W^+$ such that $D^{(2)}Y=0$ and such that $\sigma^{(2)}(Y)$ is a power series in $\hbar$, lies in the subalgebra W itself.

(2) The mappings $\sigma^{(i)}$ may be considered as the restriction of one mapping σ from $\mathcal{A}$ to $\Gamma(E[[\hbar]])$. This mapping is simply given by setting y to zero, i.e., it picks out the part of $\hat{X} \in \mathcal{A}$ not depending on y. We will use the notions of Ref. 13 and call $\sigma(\hat{X})$ the symbol of $\hat{X} \in \mathcal{A}$.

From now on we will restrict ourselves to one fixed symplectic connection ∂_s on M and will only modify the connection $\boldsymbol{\nabla}$ on V. We will prove two lemmas which will be essential in the following sections.

Lemma 1: Let $\boldsymbol{\nabla}^{(1)}$ and $\boldsymbol{\nabla}^{(2)}$ be connections on $E[[\hbar]]$, ∂_s a fixed symplectic connection, and let $D^{(1)}, D^{(2)}$ denote the corresponding flat Fedosov connections, and $U_{(12)}$ the corresponding automorphism. Assume that the difference of the two connections $\boldsymbol{\nabla}^{(1)}$ and $\boldsymbol{\nabla}^{(2)}$ is of order $O(\hbar^m)$ for some m. Then

$$\sigma(U_{(12)} \diamond \hat{X} \diamond U_{(12)}^{-1}) = \sigma(\hat{X}) + O(\hbar^{(m+1)}),$$

for any $\hat{X} \in \mathcal{A}$ which is covariantly constant with respect to $D^{(1)}$.

Proof: By (5), $A_{(12)}$ is contained in $\mathcal{A}_{2m+3}$. Hence, using (3), we may conclude that $U_{(12)} \diamond \hat{X} \diamond U_{(12)}^{-1} - \hat{X} \in \mathcal{A}_{2m+1}$, and the symbols $\sigma(U_{(12)} \diamond \hat{X} \diamond U_{(12)}^{-1}), \sigma(\hat{X})$ may differ only by a term of order $O(\hbar^{m+1})$. Q.E.D.

If we consider three different connections, $U_{(13)}$ is not necessarily the same as the composition $U_{(23)} \diamond U_{(12)}$ of $U_{(12)}$ and $U_{(23)}$, but $U_{(13)}^{-1} \diamond U_{(23)} \diamond U_{(12)}$ defines an automorphism of the elements in $\mathcal{A}$ covariantly constant with respect to $D^{(1)}$. Although this automorphism in general is not simply the identity, we have the following lemma.

Lemma 2: Let $\boldsymbol{\nabla}^{(1)}$, $\boldsymbol{\nabla}^{(2)}$, and $\boldsymbol{\nabla}^{(3)}$ be connections on $E[[\hbar]]$, ∂_s a fixed symplectic connection, and let $D^{(i)}$ denote the corresponding flat Fedosov connections and $U_{(ik)}$ the corresponding automorphisms of $\mathcal{A}$ mapping covariant constant sections with respect to $D^{(i)}$ to covariant constant sections with respect to $D^{(k)}$. Assume that the difference of the two connections $\boldsymbol{\nabla}^{(2)}$ and $\boldsymbol{\nabla}^{(3)}$ is of order $O(\hbar^m)$ for some m. Then

$$\sigma(U_{(13)} \diamond \hat{X} \diamond U_{(13)}^{-1}) = \sigma((U_{(23)} \diamond U_{(12)}) \diamond \hat{X} \diamond (U_{(23)} \diamond U_{(12)})^{-1}) + O(\hbar^{(m+2)}),$$

for any $\hat{X} \in \mathcal{A}$ which is covariantly constant with respect to $D^{(1)}$.

Proof: By the Baker–Campbell–Hausdorff formula, $U_{(23)} \diamond U_{(12)}$ may be written as $\exp_\diamond((i/\hbar)A)$ with $A = A_{(12)} + A_{(23)} + C$, where C is the sum of multiple commutators of $(1/\hbar)A_{(12)}$ and $(1/\hbar)A_{(23)}$ multiplied by $\hbar$. From formulas (4) and (5) it is obvious that A does not contain negative powers of $\hbar$.

Now, by assumption and (4), (5), $A_{(23)}$ is contained in $\mathcal{A}_{2m+3}$, and is of the special form

$$A_{23} = \hbar^{m+1} T^1_{(23)} + \hbar^m T^2_{(23)} + T^3_{(23)},$$

where $T^1_{(23)}$ contains only terms at least of degree 1 in the fiber coordinate y, $T^2_{(23)}$ contains only terms at least of degree 3 in y, and $T^3_{(23)} \in \mathcal{A}_{2m+4}$.

Similarly, $A_{12} = \hbar T^1_{12} + T^2_{12} + T^3_{12}$ with $T^1_{(12)}$ containing only terms at least of degree 1 in the fiber coordinate y, $T^2_{(12)}$ containing only terms at least of degree 3 in y, and $T^3_{(12)} \in \mathcal{A}_4$. Now, since all other terms in the Baker–Cambell–Hausdorff formula will be contained in $\mathcal{A}_{2m+5}$, we may conclude that

$$C = \frac{1}{\hbar}[\hbar T^1_{12} + T^2_{12}, \hbar^{m+1} T^1_{12} + \hbar^m T^2_{12}] + \cdots,$$

where the missing terms denoted by dots are in $\mathcal{A}_{2m+5}$. An inspection of each term, using the fact that T^2_{12}, T^2_{23} are scalar, finally shows that C is of the form

$$C=\hbar^m C^1+\hbar^{m+1}C^2+\hbar^{m+2}C^3+C^4,$$

where C^1 only contains terms at least quadratic in y, C^2 only terms at least of degree 1 in y, and $C^4\in\mathcal{A}_{2m+5}$. Since C^1 and C^2 contain no terms independent of y, they may contribute to the symbol of $\sigma((U_{(23)}\diamond U_{(12)})\diamond\hat{X}\diamond(U_{(23)}\diamond U_{(12)})^{-1})$ only through higher order terms of the Moyal product. Hence, the whole contribution of C to the symbol is of order $\hbar^{m+2}$.

On the other hand, we see from (4) and $(\Delta\gamma)_{(13)}=(\Delta\gamma)_{(12)}+(\Delta\gamma)_{(23)}$ that $A_{(13)}=A_{(12)}+A_{(13)}+\tilde{C}$, where $\tilde{C}\in\mathcal{A}_{2m+4}$ as well. A close inspection of the possible term in $\tilde{C}$ shows again that it contributes to the symbol of $U_{(13)}\diamond\hat{X}\diamond(U_{(13)})^{-1}$ only at order $\hbar^{m+2}$. Thus, the difference of the two symbols is of order $\hbar^{m+2}$. Q.E.D.

Let $\tilde{\nabla}$ be an arbitrary (possibly $\hbar$-dependent) connection on $V[[\hbar]]$, and π_α a set of projection valued sections in $E[[\hbar]]$ with $\pi_\alpha\pi_\beta=\delta_{\alpha\beta}\pi_\alpha$, $\Sigma_\alpha\pi_\alpha=id$. Define $\nabla=\Sigma_\alpha\pi_\alpha\circ\tilde{\nabla}\circ\pi_\alpha$ as a ''Berry-type connection.'' Then $\nabla\pi_\alpha=0$, and we have the following lemma.

Lemma 3: With the notations above, and a fixed symplectic connection ∂_s, let $*$ denote the Fedosov star product corresponding to ∇. Then, π_α are ''quantum projections,'' i.e., $\pi_\alpha*\pi_\beta=\delta_{\alpha\beta}\pi_\alpha$.

Proof: We will show $\pi_\alpha*\pi_\beta=\pi_\alpha\cdot\pi_\beta$. We first note that, since $\nabla\pi_\alpha=0$, $\forall\alpha$, it follows from (1) that $[r,\pi_\alpha]=0$, $\forall\alpha$. (Since π_α does not depend on y, there is no difference between $\diamond$-commutator and ordinary matrix commutator.) Then, from (2), $\mathcal{Q}(\pi_\alpha)=\pi_\alpha$ for all α. But then we have $\pi_\alpha*\pi_\beta=\pi_\alpha\cdot\pi_\beta=\delta_{\alpha\beta}\pi_\alpha$. Q.E.D.

III. BERRY CONNECTIONS AND ''BLOCK DIAGONALIZATION''

After the technical preliminaries of the last section, we are now in the position to address the actual problem of this paper.

We consider a Hamiltonian which is a section in the bundle $E[[\hbar]]$:

$$H=H_0+\hbar H_1+\cdots.$$

We assume that the eigenvalues $\lambda_\alpha(x)$ of $H_0(x)$ $(\alpha=1,...,r)$, have constant multiplicities m_α throughout phase space. We denote by $\pi_\alpha^{(0)}(x)$ the projections of V_x onto the α-th eigenspace of $H_0(x)$. Under the regularity assumptions above, these eigenspaces form smooth vector bundles over M.

We assume that we are given a Hermitian connection on V and a symplectic connection on M, which together define a star product; in many applications there is a distinguished choice of connections and quantization. For example, in the case of the Born-Oppenheimer approximation, one may start with a symplectic manifold which is just the nuclear phase space $\mathbb{R}^{2N}$ where N is three times the number of nuclei in the molecule. In this case, there is a distinguished quantization prescription, namely Weyl ordering, which corresponds to the choice of the trivial connection on the trivial bundle V.

Hence, we assume that we are given a definite quantization. As we allow the symbols of the observables to depend on $\hbar$, one may alternatively interpret this as the choice of a definite symbol calculus.

Nevertheless, we still have the freedom of changing the connection defining our star product without changing the physics, if we apply the corresponding isomorphism of the resulting algebras at the same time, i.e., we have to correct the symbol H by applying the isomorphism ϕ introduced above. We can use this freedom to reduce the problem to a simpler one, which is closer to the scalar case. That this is possible indeed is the content of the next theorem.

Theorem 4: *There exists a formally orthogonal decomposition $V[[\hbar]]=\oplus_{\alpha=1}^r V_\alpha$, $\dim(V_\alpha)=m_\alpha$ with corresponding quantum projections $\pi_\alpha^{(\infty)}$ (i.e., $\pi_\alpha^{(\infty)}*_\infty\pi_\beta^{(\infty)}=\delta_{\alpha\beta}\pi_\alpha^{(\infty)}$), and a compatible connection $\nabla^{(\infty)}$ [i.e., $\nabla^{(\infty)}\pi_\alpha^{(\infty)}=0$, $\forall\alpha$] such that the corrected symbol H_{corr} preserves the decomposition: $[H_{corr},\pi_\alpha^{(\infty)}]=0$ for $\alpha=1,...,r$. (Here, [,] denotes the $*_\infty$ commutator.)*

Proof: We show the theorem by induction on the order in $\hbar$.

For the connections $\nabla^{(k)}$ to be constructed below we denote by ϕ_k the isomorphism of the algebras $\Gamma(E[[\hbar]])$ with star products $*,*_k$ constructed from ∇ and $\nabla^{(k)}$, respectively: $\phi_k(X*Y)=\phi_k(X)*_k\phi_k(Y)$.

Let $\pi_\alpha^{(1)}(x) \overset{\text{def}}{=} \pi_\alpha^{(0)}(x)$ denote the projection onto the i-th eigenspace of $H_0(x)$ (i.e., of the zeroth order term of the original Hamiltonian H), and define $\nabla^{(1)}$ as the Berry-type connection:

$$\nabla^{(1)}\psi \overset{\text{def}}{=} \sum_\alpha \pi_\alpha^{(1)} \nabla(\pi_\alpha^{(1)}\psi).$$

The difference between the corrected Hamiltonian $H^{(1)} = \phi_1(H)$, which is obtained from H by applying the isomorphism corresponding to the change of the connection from ∇ to $\nabla^{(1)}$ is of order $O(\hbar)$ by Lemma 1. Hence, $\nabla^{(1)}\pi_\alpha^{(1)} \equiv 0$ by construction, and $[H^{(1)}, \pi_\alpha^{(1)}] = O(\hbar)$ for all α.

Now assume that we have found (formally orthogonal) projections $\pi_\alpha^{(k)}$ with $\pi_\alpha^{(k)} = \pi_\alpha^{(0)} + O(\hbar)$ with a corresponding Berry-type connection,

$$\nabla^{(k)}\psi \overset{\text{def}}{=} \sum_\alpha \pi_\alpha^{(k)} \nabla(\pi_\alpha^{(k)}\psi),$$

such that the corrected Hamiltonian $H^{(k)} = \phi_k(H)$, satisfies $[H^{(k)}, \pi_\alpha^{(k)}] = O(\hbar^k)$. We will construct new orthogonal projections $\pi_\alpha^{(k+1)}$ satisfying the requirement

$$[H^{(k)}, \pi_\alpha^{(k+1)}] = O(\hbar^{k+1}), \quad \forall \alpha. \tag{6}$$

To this end, we make the ansatz:

$$\pi_\alpha^{(k+1)} = \exp(i\hbar^k A)\, \pi_\alpha^{(k)}\, \exp(-i\hbar^k A), \tag{7}$$

for a fixed A independent of α. If we can find such an A, equation (7) automatically defines new formally orthogonal projections (i.e., $\pi_\alpha^{(k+1)} *_{k+1} \pi_\beta^{(k+1)} = \pi_\alpha^{(k+1)} \pi_\beta^{(k+1)} = \delta_{\alpha\beta}\pi_\alpha^{(k+1)}$, according to lemma 3). With this ansatz $\pi_\alpha^{(k+1)}$ is given up to order $O(\hbar^{k+1})$ by

$$\pi_\alpha^{(k+1)} = \pi_\alpha^{(k)} + i\hbar^k [A, \pi_\alpha^{(k)}] + O(\hbar^{k+1}).$$

Hence, equation (6) yields up to order $O(\hbar^{k+1})$ the condition

$$[H^{(k)}, \pi_\alpha^{(k)}] + i\hbar^k [H_0, [A, \pi_\alpha^{(0)}]] = O(\hbar^{k+1}), \quad \forall \alpha.$$

As the $\pi_\alpha^{(k)}$ are projections, we may write

$$H^{(k)} = \sum_\alpha \pi_\alpha^{(k)} H^{(k)} \pi_\alpha^{(k)} + \hbar^k W,$$

where the first term on the right hand side commutes with $\pi_\alpha^{(k)}$ and

$$\hbar^k W = \sum_{\beta \neq \gamma} \pi_\beta^{(k)} H^{(k)} \pi_\gamma^{(k)} = \sum_{\beta \neq \gamma} \pi_\beta^{(k)} [H^{(k)}, \pi_\gamma^{(k)}] \pi_\gamma^{(k)}.$$

As the commutator on the right hand side is of order $O(\hbar^k)$ the left hand side is of the same order. Hence, we have to solve

$$\hbar^k [W, \pi_\alpha^{(0)}] + i\hbar^k [H_0, [A, \pi_\alpha^{(0)}]] = O(\hbar^{k+1}), \quad \forall \alpha.$$

Note that in this equation only the projections $\pi_\alpha^{(0)}$ $(\alpha = 1, \ldots, r)$ appear. A solution to this equation is given by

$$A = i \sum_{\alpha \neq \beta} \frac{\pi_\alpha^{(k)} W \pi_\beta^{(k)}}{\lambda_\alpha - \lambda_\beta},$$

as may be easily verified using $\pi_\alpha^k W \pi_\alpha^k = 0$ for all α by construction of W.

Using the new projections we may define a new Berry-type connection $\nabla^{(k+1)}$ which preserves the decomposition defined by the projections even to arbitrary order in $\hbar$. As the difference of the projections is of order $O(\hbar^k)$, the difference of the connections $\nabla^{(k)}$ and $\nabla^{(k+1)}$ is of the same order, and hence, by Lemmas 1 and 2, the corrected symbol $H^{(k+1)}=\phi_{k+1}(H)$ differs from $H^{(k)}$ only at order $O(\hbar^{k+1})$ Thus, by (6), $H^{(k+1)}$ is compatible with the decomposition up to $O(\hbar^{k+1})$: $[H^{(k+1)},\pi_\alpha^{(k+1)}]=O(\hbar^{k+1})$.

As $\nabla^{(k)}$ and $\nabla^{(k+1)}$ differ only at order $O(\hbar^k)$, the connections $\nabla^{(k)}$ have a well defined limit ∇^∞, which by induction fulfills the assertions of the theorem. Q.E.D.

The importance of theorem 4 lies in the following two corollaries, which are a kind of generalization to our much more general setting of the results of the paper,[19] which deals only with the Dirac equation on flat space-time.

Corollary 5: Let $X,Y\in\Gamma E[[\hbar]]$ such that $[X,\pi_\alpha^{(\infty)}]=[Y,\pi_\alpha^{(\infty)}]=0$ for all α. Let $*_\infty$ denote the star product constructed from $\nabla^{(\infty)}$ by Fedosov's construction. Then $[X*_\infty Y,\pi_\alpha^{(\infty)}]=0$ for all α.

Proof: As $\nabla^{(\infty)}\pi_\alpha^{(\infty)}=0$, the curvature of $\nabla^{(\infty)}$ commutes with $\pi_\alpha^{(\infty)}$. As δ^{-1} only acts on the second factor of $\mathcal{A}=\Gamma(E[[\hbar]]\otimes W)$ and the Moyal product $\diamond$ only involves derivatives with respect to the fiber coordinates y, we may conclude from (1) by induction on the total degree that r commutes with $\pi_\alpha^{(\infty)}$. (Observe that we may write the term $r^2=r\diamond r$ as $1/2[r,r]_\diamond$.)

Now, the covariant constant continuation $\hat{X}=\mathcal{Q}^{(\infty)}(X)$ of X is given by[13]

$$\hat{X}=X+\delta^{-1}\left(\partial\hat{X}+\left[\frac{i}{\hbar}\,r,\hat{X}\right]_\diamond\right), \tag{8}$$

and we may again conclude inductively, $[\hat{X},\pi_\alpha^{(\infty)}]=0$, and similarly for $\hat{Y}$.

Using again the fact that the Moyal product $\diamond$ on $\mathcal{A}$ only involves derivatives with respect to y, it follows that $\hat{X}\diamond\hat{Y}$ commutes with $\pi_\alpha^{(\infty)}$ for all α. Hence, by taking the symbol, i.e., by setting $y=0$, we get the assertion of the corollary. Q.E.D.

Corollary 6: Denote by ϕ_∞ the isomorphism of the algebras $\Gamma(E[[\hbar]])$ with products $*$ and $*_\infty$. Let

$$\mathcal{O}\overset{\text{def}}{=}\{\phi_\infty^{-1}(\tilde{X})\,|\,\tilde{X}\in\Gamma(E[[\hbar]]),[\tilde{X},\pi_\alpha^{(\infty)}]=0,\forall\,\alpha\}.$$

Then, $\mathcal{O}$ is a subalgebra of $\Gamma(E[[\hbar]])$ for which the Heisenberg time evolution,

$$\dot{X}=\frac{1}{i\hbar}\,[H,X]_*,$$

is a well defined differential equation.

Proof: $\mathcal{O}$ is a subalgebra of $\Gamma(E[[\hbar]])$ by the preceding corollary. We only have to show that $[H,X]_*=O(\hbar)$, since then there will be no negative powers of $\hbar$ in the Heisenberg time evolution.

Denoting again $\phi_\infty(H)$ by H_{corr}, we know that H_{corr} is of the form $\Sigma_\alpha\lambda_\alpha\pi_\alpha^{(\infty)}+O(\hbar)$.

Now, by (1), r is of the form $r=1\otimes\hat{r}+O(\hbar)$ for a scalar one-form $\hat{r}$. From this one may conclude that the covariantly constant continuation $\mathcal{Q}^{(\infty)}(H_{corr})$ of H_{corr} is of the form $\Sigma_\alpha\rho_\alpha\pi_\alpha^{(\infty)}+O(\hbar)$ for some scalar ρ_α. Thus, since $\tilde{X}$ commutes with $\pi_\alpha^{(\infty)}$, we may conclude that the classical matrix commutator does not contribute to $[H_{corr},\tilde{X}]_{*_\infty}$ at zeroth order in $\hbar$. Hence, the commutator is of order $\hbar$. Applying ϕ_∞^{-1}, the corollary follows. Q.E.D.

IV. CORRECTION AT ORDER $\hbar$

In the previous section we have achieved a complete reduction of the multicomponent WKB problem to a set of different polarizations. In this section, we will explicitly compute the corrections to the symbol of the Hamiltonian at order $\hbar$. Thus, this section will generalize the results of Ref. 7, and give a completely geometric derivation of the results derived there for trivial bundles only. We achieve this by first using the Berry-type connection as in the proof of theorem 4 in the

previous section. However, the connection is not uniquely defined by the compatibility conditions: Hence, in the second subsection, we will investigate the dependence of the structure of this phase on the choice of a compatible connection (in the sense of theorem 4). It will turn out that it is unique up to a Berry-type phase, and that the Berry-type connection considered so far is geometrically distinguished among all compatible connections.

A. Berry-type connection

To compute the correction of the symbol H at order $\hbar$, we only have to carry out the first two steps of the iterative procedure in the proof of the previous theorem. Actually, it is not necessary to compute $H^{(2)}$, but it is sufficient to compute the ''block diagonal'' part of $H^{(1)}$ since

$$\begin{aligned} H_{corr} &= H^{(2)} + O(\hbar^2) \\ &= \sum_\alpha \pi_\alpha^{(2)} H^{(1)} \pi_\alpha^{(2)} + O(\hbar^2) \\ &= \sum_\alpha \exp(i\hbar A)\,\pi_\alpha^{(1)} \exp(-i\hbar A) H^{(1)} \exp(i\hbar A)\,\pi_\alpha^{(1)} \exp(-i\hbar A) \\ &= \sum_\alpha \exp(i\hbar A)\,\pi_\alpha^{(1)} (H^{(1)} + i\hbar [H^{(1)}, A])\,\pi_\alpha^{(1)} \exp(-i\hbar A) + O(\hbar^2) \\ &= \sum_\alpha \exp(i\hbar A)\,\pi_\alpha^{(0)} H^{(1)} \pi_\alpha^{(0)} \exp(-i\hbar A) + O(\hbar^2), \end{aligned}$$

with A as defined in the proof of theorem 4, and $\pi_\alpha^{(1)} = \pi_\alpha^{(0)}$.

Here, we used the fact that the zeroth degree part $H_0^{(1)}$ of $H^{(1)}$ is just $H_0^{(0)}$, and that $\pi^{(0)}$ is the projection onto the eigenspaces of $H_0^{(0)}$. Hence, in order to determine the correction of the symbol at order $\hbar$ up to a unitary rotation, we only have to compute $\pi_\alpha^{(0)} H^{(1)} \pi_\alpha^{(0)}$ for all α.

Defining $\gamma_l \overset{\text{def}}{=} \Sigma_\alpha \pi_\alpha^{(0)} (\nabla_l \pi_\alpha^{(0)})$ we get by formulas (3), (4):

$$\begin{aligned} \pi_\alpha^{(0)} H^{(1)} \pi_\alpha^{(0)} &= \pi_\alpha^{(0)} (H^{(0)} + \sigma([\gamma_l y^l, \nabla_\alpha H_0^{(0)} y^i]_\diamond) + \tfrac{1}{2}\,\sigma([\gamma_l y^l, [\gamma_m y^m, H_0^{(0)}]_{\mathrm{cl}}]_\diamond)\,\pi_\alpha^{(0)} + O(\hbar^2) \\ &= \pi_\alpha^{(0)} H^{(0)} \pi_\alpha^{(0)} + \pi_\alpha^{(0)} \left(\omega^{il} \frac{i\hbar}{2} (\gamma_i \nabla_l H_0^{(0)} - \nabla_i H_0^{(0)} \gamma_l) \right) \pi_\alpha^{(0)} \\ &\quad + \pi_\alpha^{(0)} \frac{i\hbar}{4} \omega^{il} (\gamma_i [\gamma_l, H_0^{(0)}]_{\mathrm{cl}} - [\gamma_i, H_0^{(0)}]_{\mathrm{cl}} \gamma_l)\,\pi_\alpha^{(0)} + O(\hbar^2). \end{aligned} \tag{9}$$

Here, $[\cdot,\cdot]_{\mathrm{cl}}$ denotes the usual matrix commutator, and $[\cdot,\cdot]_\diamond$ the Moyal product commutator.

In the computation, the following relations (following trivially from the projection property) prove to be useful:

$$\pi_\alpha^{(0)} (\nabla \pi_\beta^{(0)})\,\pi_\alpha^{(0)} = 0, \quad \forall\, \alpha, \beta,$$

$$\pi_\alpha^{(0)} (\nabla \pi_\beta^{(0)})\,\pi_\beta^{(0)} = \pi_\alpha^{(0)} (\nabla \pi_\beta^{(0)}), \quad \pi_\beta^{(0)} (\nabla \pi_\beta^{(0)})\,\pi_\alpha^{(0)} = (\nabla \pi_\beta^{(0)})\,\pi_\alpha^{(0)}, \quad \forall\, \alpha \neq \beta.$$

Using $H_0^{(0)}(x) = \Sigma_\alpha \lambda_\alpha(x)\,\pi_\alpha^{(0)}(x)$, we get for the second term on the right hand side of the last equation in (9):

$$\frac{i\hbar}{2}\,\omega^{il}\Bigg(\sum_{\beta}\ \pi_\alpha^{(0)}(\nabla_i\pi_\alpha^{(0)})\nabla_l(\lambda_\beta\pi_\beta^{(0)})\pi_\alpha^{(0)}-\sum_{\beta,\gamma}\ \pi_\alpha^{(0)}\nabla_i(\lambda_\beta\pi_\beta^{(0)})\pi_\gamma^{(0)}(\nabla_l\pi_\gamma^{(0)})\pi_\alpha^{(0)}\Bigg)$$

$$=\frac{i\hbar}{2}\,\omega^{il}\Bigg(\lambda_\alpha\pi_\alpha^{(0)}(\nabla_i\pi_\alpha^{(0)})(\nabla_l\pi_\alpha^{(0)})-\sum_{\beta}\ \lambda_\beta\pi_\alpha^{(0)}(\nabla_i\pi_\alpha^{(0)})\pi_\beta^{(0)}(\nabla_l\pi_\alpha^{(0)})$$

$$-\sum_{\beta}\ \lambda_\beta\pi_\alpha^{(0)}(\nabla_i\pi_\beta^{(0)})\pi_\alpha^{(0)}(\nabla_l\pi_\alpha^{(0)})+\sum_{\beta,\gamma}\ \lambda_\beta\pi_\alpha^{(0)}\nabla_i(\pi_\beta^{(0)})\pi_\gamma^{(0)}(\nabla_l\pi_\alpha^{(0)})\Bigg)$$

$$=i\hbar\,\omega^{il}\sum_{\beta}\ \lambda_\beta\pi_\alpha^{(0)}(\nabla_i\pi_\beta^{(0)})(\nabla_l\pi_\alpha^{(0)}).$$

For the last term in (9) we get

$$\frac{i\hbar}{4}\,\omega^{il}\Bigg(\sum_{\beta,\gamma}\ \pi_\alpha^{(0)}(\nabla_i\pi_\alpha^{(0)})[\pi_\beta^{(0)}\nabla_l\pi_\beta^{(0)},\lambda_\gamma\pi_\gamma^{(0)}]_{\mathrm{cl}}\pi_\alpha^{(0)}$$

$$-\sum_{\beta,\gamma,\rho}\ \pi_\alpha^{(0)}[\pi_\beta^{(0)}(\nabla_i\pi_\beta^{(0)}),\lambda_\gamma\pi_\gamma^{(0)}]_{\mathrm{cl}}\pi_\rho^{(0)}(\nabla_l\pi_\rho^{(0)})\pi_\alpha^{(0)}\Bigg)$$

$$=\frac{i\hbar}{4}\,\omega^{il}\Bigg(\lambda_\alpha\sum_{\beta}\ \pi_\alpha^{(0)}(\nabla_i\pi_\alpha^{(0)})\pi_\beta^{(0)}(\nabla_l\pi_\beta^{(0)})\pi_\alpha^{(0)}-\sum_{\gamma}\ \lambda_\gamma\pi_\alpha^{(0)}(\nabla_i\pi_\alpha^{(0)})\pi_\gamma^{(0)}(\nabla_l\pi_\gamma^{(0)})\pi_\alpha^{(0)}$$

$$-\sum_{\gamma}\ \lambda_\gamma\pi_\alpha^{(0)}(\nabla_i\pi_\alpha^{(0)})\pi_\gamma^{(0)}(\nabla_l\pi_\gamma^{(0)})\pi_\alpha^{(0)}+\sum_{\rho}\ \lambda_\alpha\pi_\alpha^{(0)}(\nabla_i\pi_\alpha^{(0)})\pi_\rho^{(0)}(\nabla_l\pi_\rho^{(0)})\pi_\alpha^{(0)}\Bigg)$$

$$=-\frac{i\hbar}{2}\,\omega^{il}\sum_{\gamma}\ \lambda_\gamma\pi_\alpha^{(0)}(\nabla_i\pi_\gamma^{(0)})(\nabla_l\pi_\alpha^{(0)}).$$

Thus, we finally get

$$\pi_\alpha^{(0)}H^{(1)}\pi_\alpha^{(0)}=\pi_\alpha^{(0)}H^{(0)}\pi_\alpha^{(0)}+\frac{i\hbar}{2}\,\omega^{il}\sum_{\gamma}\ \lambda_\gamma\pi_\alpha^{(0)}(\nabla_i\pi_\gamma^{(0)})(\nabla_l\pi_\alpha^{(0)})$$

$$=\pi_\alpha^{(0)}H^{(0)}\pi_\alpha^{(0)}+\frac{i\hbar}{2}\,\omega^{il}\lambda_\alpha\pi_\alpha^{(0)}(\nabla_i\pi_\alpha^{(0)})(\nabla_l\pi_\alpha^{(0)})$$

$$+\frac{i\hbar}{2}\,\omega^{il}\sum_{\gamma\neq\alpha}\ \lambda_\gamma\pi_\alpha^{(0)}(\nabla_i\pi_\gamma^{(0)})\pi_\gamma^{(0)}(\nabla_l\pi_\alpha^{(0)}).$$

In order to give a geometric interpretation of the correction terms we compute the curvature of the Berry connection:

$$F^B\psi=\sum_{\alpha}\ \pi_\alpha^{(0)}\circ\nabla\circ\pi_o^{(0)}\nabla\,\pi_\alpha^{(0)}\psi$$

$$=\sum_{\alpha}\ \pi_\alpha^{(0)}\nabla^2\pi_\alpha^{(0)}+\sum_{\alpha}\ \pi_\alpha^{(0)}(\nabla\,\pi_\alpha^{(0)})(\nabla\,\pi_\alpha^{(0)})$$

$$=\sum_{\alpha}\ \pi_\alpha^{(0)}F^o\pi_\alpha^{(0)}+\sum\ \pi_\alpha^{(0)}(\nabla\,\pi_\alpha^{(0)})\wedge(\nabla\,\pi_\alpha^{(0)}),$$

where F^o denotes the curvature of the original connection ∇, and the covariant derivatives have to be interpreted as covariant exterior derivatives, acting on forms.

Hence, the coefficient of λ_α of the α-th block in the correction at order $\hbar$ is $\omega^{-1}(\pi_\alpha^{(0)}F^B\pi_\alpha^{(0)}-\pi_\alpha^{(0)}F^0\pi_\alpha^{(0)})$. Here, ω^{-1} is the Poisson tensor. The curvature of the Berry connection is block diagonal by construction, the effect of the projection operators on both sides is just to pick out the right block, corresponding to α. In particular, if the original connection is flat, the coefficient of λ_α on the α-th block of the correction is exactly the Poisson curvature of the Berry connection, i.e., the contraction of the curvature with the Poisson tensor.

In order to interpret the remaining terms we define a vector bundle analog of the second fundamental form for embedded submanifolds:

For arbitrary $\beta\neq\alpha$ set

$$\widetilde{S}^{\beta\alpha}:\quad \Gamma(V_\alpha^{(1)})\to\Gamma(V_\beta^{(1)})\otimes\Gamma(\Lambda^1(M)),$$

$$\psi\mapsto\pi_\beta^{(1)}\circ\nabla\circ\pi_\alpha^{(1)}\psi=\pi_\beta^{(1)}(\nabla\pi_\alpha^{(1)})\psi.$$

$\widetilde{S}^{\beta\alpha}$ obviously is tensorial for $\beta\neq\alpha$; hence it induces a mapping $S^{\alpha\beta}:V_\alpha^{(1)}\to V_\beta^{(1)}\otimes\Lambda^1(M)$ which is a vector bundle analog of the second fundamental form: It measures the extent to which parallel transport with respect to ∇ tends to rotate a vector from a given eigenspace into the others.

For fixed $\alpha\neq\beta$, we may form $S^{\beta\alpha}\wedge S^{\alpha\beta}$, which is a two-form with values in the endomorphims of V_α, and hence may be contracted with the Poisson tensor to define an endomorphism of V_α, which is just the coefficient of λ_β in the α-th block of the first order correction of H.

B. Arbitrary compatible connection

For an arbitrary connection $\widetilde{\nabla}$ which is compatible in the sense of theorem 4 up to some order $\hbar^k$, we first consider the correction at order $\hbar$. By lemma 2, we may compute the correction at order $\hbar$ by first going over to the Berry connection, and then in a second step to the connection $\widetilde{\nabla}$, as the the corrected symbol obtained in this way differs from the one obtained by going over directly from ∇ to $\widetilde{\nabla}$ is of order $O(\hbar^2)$.

As both $\nabla^{(1)}$ and $\widetilde{\nabla}$ are compatible with the projections $\pi_\alpha^{(0)}$ up to $O(\hbar)$, the difference $\Delta\gamma$ of the respective connection forms commutes with $\pi_\alpha^{(0)}$ and $H^{(0)}$ up to order $O(\hbar)$. Hence, denoting the corrected symbol corresponding to the new connection $\widetilde{\nabla}$ by $\widetilde{H}$ we get by formulas (3) and (4),

$$\begin{aligned}\pi_\alpha^{(0)}\widetilde{H}\pi_\alpha^{(0)}&=\pi_\alpha^{(0)}(H^{(1)}+\sigma([(\Delta\gamma)_l y^l,\nabla_i^{(1)}H_0^{(0)}y^i]_\diamond)+\tfrac{1}{2}\,\sigma([(\Delta\gamma)_l y^l,[(\Delta\gamma)_m y^m,H_0^{(0)}]_{\mathrm{cl}}]_\diamond)\pi_\alpha^{(0)}\\&\quad+O(\hbar^2)\\&=\pi_\alpha^{(0)}H^{(1)}\pi_\alpha^{(0)}+\pi_\alpha^{(0)}\omega^{il}\frac{i\hbar}{2}((\Delta\gamma)_i\nabla_l H_0^{(0)}-\nabla_i H_0^{(0)}(\Delta\gamma)_l)\pi_\alpha^{(0)}+O(\hbar^2)\\&=\pi_\alpha^{(0)}H^{(1)}\pi_\alpha^{(0)}+\pi_\alpha^{(0)}\omega^{il}i\hbar((\Delta\gamma)_i(\partial_l\lambda_\alpha))\pi_\alpha^{(0)}+O(\hbar^2)\\&=\pi_\alpha^{(0)}H^{(1)}\pi_\alpha^{(0)}+\pi_\alpha^{(0)}i\hbar(\Delta\gamma)(X_{\lambda_\alpha})\pi_\alpha^{(0)}+O(\hbar^2).\end{aligned}$$

Here, X_{λ_α} denotes the Hamiltonian vector field corresponding to λ_α.

Hence, we see that for an arbitrary connection compatible with $\pi_\alpha^{(0)}$ the lowest order corrections differ just by a Berry phase term. The additional geometric term involving the eigenvalues themselves and not their derivatives are unique and always contain the Poisson curvature and the second fundamental form of the Berry connection and not the Poisson curvature of the chosen connection. Hence, the Berry connection is distinguished among all connections satisfying theorem 4.

V. PHYSICAL DISCUSSION

The effects described in the preceding sections owe their existence to the space time dependence of the eigenspaces of the symbol H associated to the wave equation under consideration. The elements of the eigenspaces are physically interpreted as generalized polarization states.

One example is polarization effects for light propagation in nonisotropic and nonhomogeneous media. Such effects may survive even in the classical limit, as evident from the existence of precession effects for a top in an external gravitational field. The details of the effect depend on the concrete wave equation and its symbol, or, stated differently, on the quantization. We do not know about any general principle dictating in every case the ''correct'' choice of one out of the infinity of *a priori* possible quantizations.

Sometimes, however, the situation is more favorable: For the motion of a particle of spin 1/2 in an external gravitational and/or gauge field, the correct quantization is believed to be given by Dirac's equation. Also, for a molecular system in the Born–Oppenheimer approximation, one normally has a unique quantization procedure.

When no unique evident quantization procedure is available, one would like to trace the influence of a change of quantization. This can be done rather efficiently in the global star product approach adopted in this work. The main tool is Fedosov's star product, and one essential piece of data entering into its construction, and hence also in the determination of the quantization, is a Hermitian connection ∇ which, in addition, also allows to measure the space-time dependence of eigenvectors and eigenspaces. In particular, nonvanishing of any characteristic class which can be constructed in terms of the curvature of the Hermitian connection will imply nontriviality of eigenbundles.

The global star product approach is already quite convenient for studying different quantizations for contractable phase space $\mathbb{R}^{2n}$ when all eigenbundles are necessarily trivial. Globalization becomes indispensible for nontrivial space time and eigenbundles. Examples for such a situation have already been mentioned in the introduction.

Even for known prescribed quantization (and Hermitian connection ∇) it turned out to be advantageous to perform a transformation from ∇ to a new connection ∇' leaving the eigenspaces of the symbol fixed. Supplementing the resulting change of the star product quantization by the corresponding isomorphism of observables leaves physics unchanged, but casts it into a form which can be interpreted more readily.

Among the Hermitian connections ∇' compatible with the eigenbundle decomposition, the Berry connection ∇'_B is distinguished in the following way:

For a section ϕ of an eigenbundle, $\nabla'_B\phi$ is obtained by simply projecting $\nabla\phi$ back onto the eigenspace, without additional rotation. The curvature and second fundamental forms thus arising enjoy a privileged status.

Of course, a global approach can always be replaced by a local procedure, supplemented by rules for changing coordinate patches, but conceptually, a genuinely global scheme is preferable.

Nontrivial base manifolds for the quantization bundles can also effectively arise if one considers parametrized systems of linear differential operators with a parameter λ varying in some manifold Λ. In this case, one considers the projection $p: M\times\Lambda\to M$, and the discussion of parametrized systems is performed in terms of a single differential operator on the pulled back bundle of the quantum bundle to $M\times\Lambda$ by means of p. The ordinary Berry phase, for instance, can be obtained by taking $\Lambda = S^1$.

Considering the additional phase appearing in addition to the Berry-type phase, no general intuitive interpretation is known to us. However, this phase does have physical consequences, e.g., the eigenvalues for WKB states are modified by this additional phase. In Ref. 11 a simple example with a 2×2-matrix valued symbol has been analyzed in detail, using more elementary techniques. This model could both be solved analytically, and using the WKB approximation. The same additional phase was observed there for this special example, and it could be shown that this additional phase does change the eigenvalues of the Hamiltonian in the WKB approximation, and that it is needed to get the correct eigenvalues in the WKB approximation.

Let us finally mention that the obstructions against the existence of global WKB amplitudes to be discussed in the next section are of global character and are inaccessable to local considerations.

VI. OUTLOOK

In the preceding sections, we have achieved a complete block diagonalization of the considered problem: We have found a decomposition of $V[[\hbar]]$ into subspaces, such that the symbol of

the Hamiltonian and the connection are compatible with this decomposition. Furthermore, we have found a maximal set of observables which is compatible with this decomposition as well in that sense, that their time evolution does not contain any negative powers of $\hbar$. Hence, for the purposes of WKB approximation, one may treat each block separately.

However, the problem of multicomponent WKB has not been completely reduced to a scalar problem. In this section, we will show that it can still be reduced closer to a purely scalar one, but only at the price of noncanonical choices of a connection. Nevertheless, this further reduction proves to be useful for a discussion of obstructions to a complete reduction to a scalar problem. Furthermore, for this discussion, only parallel transport along the Hamiltonian vector field will play a role, which does not depend on the choices made in the connection.

We have seen in the last section that the choice of a different connection leads at order $\hbar$ to the addition of a Berry-phase term $\gamma(X_{\lambda_\alpha})$ to the α-th block of the corrected symbol. We may use the Berry-phase term to simplify the problem by choosing the connection such that this term just compensates the remaining terms at order $\hbar$, so that the Hamiltonian is reduced to a set of scalar Hamiltonians up to order $O(\hbar^2)$ on the α-th block. This is always possible as long as the eigenvalue functions have no critical points, where their Hamiltonian vector fields vanish. In practice this means that one has to cut out those points. However, this is not a real problem if one has applications to WKB in mind, as the Lagrangian submanifolds relevant to the WKB approximation lie in level sets of the eigenvalue functions and hence will generically not intersect the critical points. It is possible to iterate the procedure above, which gives the following theorem.

Theorem 7: *Let $\tilde{M}$ be any open submanifold of M not containing critical points of the eigenvalue functions λ_α. Denote the embedding of $\tilde{M}$ by i, and let $\tilde{V}$ be the pull back bundle $i^*(V)$, i.e., the subbundle of V obtained by restricting V to $\tilde{M}$. Then there is an ($\hbar$ dependent) connection $\tilde{\boldsymbol{\nabla}}^\infty$ and a decomposition $\tilde{V}[[\hbar]]=\oplus_{\alpha=1}^m \tilde{V}_\alpha$ fulfilling theorem 4 such that the corrected Hamiltonian restricted to $\tilde{V}_\alpha$ is scalar, namely, the eigenvalue function λ_α of $H^{(0)}$ for each α.*

As stated before, the connection defined in this way is far from unique: Only the partial connection for each block, giving covariant derivatives in the direction of the respective Hamiltonian vector field, is uniquely defined by the iteration procedure above. However, we may always find a continuation of this partial connection to a connection on the whole bundle.

The result of theorems 4 and 7 is optimal in the following sense: We started from a decomposition of V into the bundles of eigenvectors of H_0. However, due to the higher order corrections, the eigenvalues of the quantum mechanical Hamiltonian operator will in general have lower degeneracy than the eigenvalues of the principal symbol H_0. One might hope to find a finer decomposition of the vector bundle $V[[\hbar]]$, so that one ends up with one dimensional subbundles and ''formal $U(1)$-connections.'' However, this is not possible in general, not even at order $O(\hbar^2)$: The connection constructed in the previous theorem has in general a $U(m_1)\times\cdots\times U(m_r)$ holonomy and cannot be replaced by a connection with a $U(1)\times\cdots\times U(1)$ holonomy without destroying the block-diagonality of the corrected symbol of the Hamiltonian.

To understand this fact better, we first consider the case of a two-dimensional phase space as base space.[20] In this special case it is always possible to reduce the problem to one-dimensional subbundles, at least in a tubular neighborhood of any energy level set $\lambda_\alpha^{-1}(E)$ for a noncritical value E:

To show the existence of such a decomposition and a compatible connection we start with a connection $\tilde{\boldsymbol{\nabla}}^\infty$ for which the Hamiltonian is scalar on each block, as in theorem 7. As the connection to be defined will respect the block structure, we may restrict ourselves to one block α and only need to consider the corresponding eigenvalue function λ_α.

If $\lambda_\alpha^{-1}(E)$ is diffeomorphic to $\mathbb{R}$, we may choose a transversal manifold S at some point $p\in\lambda_\alpha^{-1}(E)$. Choosing an arbitrary decomposition into one-dimensional subbundles on S, we may define a decomposition on a whole tubular neighborhood of $\lambda_\alpha^{-1}(E)$ by parallel transport along the Hamiltonian flow of λ_α. Denoting by $\tilde{\pi}_k$ the corresponding one-dimensional projections, we define a new connection $\hat{\boldsymbol{\nabla}}$ as $\Sigma_k \pi_k\circ\tilde{\boldsymbol{\nabla}}^\infty\circ\pi_k$. Since we have a set of trivializing sections covariantly constant along the Hamiltonian flow both for $\tilde{\boldsymbol{\nabla}}^\infty$ and for $\hat{\boldsymbol{\nabla}}$, it follows that

$$\hat{\boldsymbol{\nabla}}_{X_{\lambda_\alpha}} u=\tilde{\boldsymbol{\nabla}}^\infty_{X_{\lambda_\alpha}} u,$$

for any section u in the the α-th block, and hence the corrected symbol is not modified at order $\hbar$ by going over to the new connection. Hence, the Hamiltonian is still scalar [at least up to order $O(\hbar^2)$], and we have found the connection and decomposition we are looking for up to the same order. This procedure can be iterated again, and we can thus reduce the problem to a purely scalar one.

If $\lambda_\alpha^{-1}(E)$ is diffeomorphic to S^1, then the situation is a bit more involved: Due to the periodicity of the flow, we cannot simply define a decomposition into subbundles on a complete tubular neighborhood of the level set by parallel transport of an arbitrary decomposition on a transversal submanifold S. Instead, defining $U(p)$ as the holonomy for $\tilde{\nabla}^\infty$ along one period of the Hamiltonian flow line starting at the point $p \in S$, we choose the complex eigenspaces of $U(p)$ (which always exist as U is unitary) on S and parallel transport these along the Hamiltonian flow of λ_α. (If the eigenspaces of U are not one-dimensional then we have to choose one-dimensional subspaces in a smooth way along S.) We may define $\tilde{\nabla}$ as before and get a connection with the desired properties.

We note that we can even modify the connection further by adding a $u(1)\times u(1)$ valued one-form to the connection form such that the holonomy along the Hamiltonian flow vanishes and the symbol of the Hamiltonian is modified without destroying diagonality: The corresponding phase is moved in this way from the connection to the symbol.

These observations explain the special role of two-dimensional phase spaces for a multicomponent WKB approximation. Now, an analogous construction obviously does not work generally if the underlying phase space is more than two-dimensional: Even if the Hamiltonian system defined by λ_α is integrable, the flow will generically be only quasiperiodic. This does not only imply that the above construction does not work, but even that such a decomposition into one-dimensional subbundles with a compatible connection and scalar symbols do not exist.

Namely, assume such a decomposition would exist. Let γ denote the integral curve of X_{λ_α} through a fixed point p. Then (pulling back the respective bundles with the inclusion map $i:\gamma \to M$) we first claim that the decomposition of $i^*V[[\hbar]]$ into one-dimensional subbundles is uniquely determined by the decomposition at the point p and the requirement that the corrected symbol is diagonal with respect to the decomposition. To see this, we first note that given any such decomposition with compatible connection, it is determined by the decomposition at P through parallel transport. Hence, if there are several such decompositions, they must correspond to different connections.

However, we may modify any such connection without changing the decomposition by adding a $u(1)\times\cdots\times u(1)$ valued one-form to the connection form. By a proper choice, we may achieve that the corrected symbol on the α-th block is simply λ_α. Now assume that we are given two different decompositions with corresponding (properly modified) connections which coincide at the point p. Then, as the corrected symbols simply is λ_α in both cases, the difference of the connection forms of the two connections (modified as above) must vanish on X_{λ_α}, hence parallel transport along γ coincides for both connections. As the decomposition has to be invariant under parallel transport, the two decomposition must coincide over γ.

Hence, there is at most one such decomposition, and it is determined by parallel transport with the connection in theorem 7. Now, due to the quasiperiodicity, the curve γ comes arbitrarily close to p for certain arbitrarily large times T_i. However, there will generically be no one-dimensional subspace W_p in the fiber V_p over p which, when parallel transported along γ, will be in a suitable sense close to W_p for all the times T_i. Hence, there cannot exist a continuous decomposition into one-dimensional subspaces with the desired properties which is defined in a whole neighborhood of γ.

The difference to the situation in perturbation theory comes from the Berry-phase term. Hence, if one tries to completely diagonalize the corrected symbol, one has to solve a differential equation along the flow of λ_α, and not just simply to diagonalize a matrix. Thus, although it is always possible to completely diagonalize the symbol locally, this is not possible in general globally.

QED in external field with space–time uniform invariants: Exact solutions

S. P. Gavrilov,[a] D. M. Gitman,[b] and A. E. Gonçalves[c]
Departamento de Física, CCET, Universidade Federal de Sergipe, 49000-000 Aracaju, SE, Brazil

(Received 21 October 1997; accepted for publication 28 January 1998)

We study exact solutions of Dirac and Klein–Gordon equations and Green functions in d-dimensional QED and in an external electromagnetic field with constant and homogeneous field invariants. The cases of even and odd dimensions are considered separately; they are essentially different. We direct attention to the asymmetry of the quasienergy spectrum, which appears in odd dimensions. The in and out classification of the exact solutions as well as the completeness and orthogonality relations is strictly proven. Different Green functions in the form of sums over the exact solutions are constructed. The Fock–Schwinger proper time integral representations of these Green functions are found. As physical applications, we consider the calculations of different quantum effects related to the vacuum instability in the external field. For example, we present mean values of particles created from the vacuum, the probability of the vacuum remaining a vacuum, the effective action, and the expectation values of the current and energy-momentum tensor. © *1998 American Institute of Physics.* [S0022-2488(98)02607-3]

I. INTRODUCTION

Exact solutions of the relativistic wave equations (Klein–Gordon or Dirac equation) in an external electromagnetic field as well as Green functions of those equations are very important in QED with such a field. Special complete sets of the exact solutions and special kinds of Green functions allow one to calculate different quantum effects, for example, particle scattering, pair creation and so on, in zero order with respect to the radiative corrections, but taking the interaction with the external field into account exactly.[1–3] They may serve also as a basis for the perturbation theory with respect to the radiative interaction, in which the external field is taken into account exactly (so-called generalized Furry picture).[4,5] In four-dimensional space–time the above exact solutions were studied for different configurations of the external field in numerous papers and books (see, for example, Refs. 3 and 6). Among all the configurations of the external electromagnetic fields, which admit the exact solutions in $d=4$, one is especially important due to the fact that it corresponds to a wide class of real physical situations. It is a combination of constant uniform electric and magnetic fields and a plane wave field. The exact solutions can be found if there exists a reference frame in which the constant electric and magnetic fields, and the wave 3-vector are collinear. First, the exact solutions of Klein–Gordon and Dirac equation in such a configuration were found in Ref. 7. Some of the Green functions of scalar field in the same configuration were studied in other papers.[8] Using those exact solutions and Green functions different quantum effects were calculated.[9] Calculation of Green functions of spinor field was not present in the literature. Moreover, lately, field theoretical models in dimensions different from $d=4$ attract attention due to various reasons. One can mention here models in $2+1$ dimensions which probably describe planar physical phenomenon, and models in $d>4$ dimensions in connection with Kaluza–Klein ideas (see, e.g., Ref. 10). That is why in the present article we are going to study exact solutions and Green functions (both scalar and spinor case) in d-dimensional QED

with an external electromagnetic field, which may be considered as a generalization of the above mentioned special configuration in four dimensions. At the same time we also present new results in four dimensions. A general definition of such a configuration valid for any dimensions of space–time is the following: an external electromagnetic field with constant and homogeneous field invariants. Also, an important motivation to consider in exact solutions and Green functions in such a configuration of the external electromagnetic field is the fact that formally problems in some configurations of an external gravitational field lead to the same kind of equations, so that the former exact solutions can be used in the latter case after some simple identifications. Such a reduction may be done, for example, for De Sitter and FRW metrics,[11,12] for four fermionic models in an external field and so on.

In a sense, the paper can be considered as a continuation and generalization of Ref. 13, where only an electriclike external field was considered. The latter paper can help the reader to better understand the logic of the exact solutions constructed in this more complicated present case. Thus, here we sometimes omit technical details and explanations which can be extracted from the above mentioned previous paper.

The paper is organized as follows: In Sec. II we describe first the external electromagnetic field under consideration. Then, we present the so-called in and out complete sets of exact solutions of Dirac and Klein–Gordon equations in the external field. The cases of even and odd dimensions have to be considered separately; they are essentially different. We attract attention to the asymmetry of the quasienergy spectrum, which appears in odd dimensions. We spend enough time to prove strictly the in and out classification of the exact solutions as well as to prove the completeness and orthogonality relations. Then in Sec. III we construct different Green functions in the form of sums over the exact solutions and present them in the form of contour integrals over the Fock–Schwinger proper time. Among them are the causal Green function, in–in and out–out Green functions, the commutator function and so on. One ought to say that the spinor case is treated first, even in $d=4$ dimensions. As physical applications, we consider in Sec. III the calculations of different quantum effects related to the vacuum instability in the external field. For example, we present mean values of particles created from the vacuum, the probability for the vacuum remaining a vacuum, the effective action, the expectation values of the current and energy-momentum tensor. We calculate the latter quantities by means of both in and out sets of the exact solutions.

II. COMPLETE SETS OF EXACT SOLUTIONS

The Dirac equation in an external electromagnetic field with potentials $A_\mu(x)$ in d dimensions has the form ($\hbar=c=1$)

$$(\mathscr{P}_\mu\gamma^\mu-m)\psi(x)=0, \quad \mathscr{P}_\mu=i\partial_\mu-qA_\mu(x), \tag{1}$$

where $\psi(x)$ is a $2^{[d/2]}$-component column, γ^μ are γ-matrices in d dimensions,[14]

$$[\gamma^\mu,\gamma^\nu]_+=2\eta^{\mu\nu}, \quad \eta^{\mu\nu}=\mathrm{diag}(\underbrace{1,-1,-1,...}_{d}), \quad d=D+1,$$

and $x=(x^\mu)=(x^0,\mathbf{x})$, $\mathbf{x}=(x^i)$, $\mu=0,1,...,D$, $i=1,...,D$. The time-independent scalar product of the solutions of the Dirac equation may be chosen in the conventional form

$$(\psi,\psi')=\int \bar{\psi}(x)\gamma^0\psi'(x)d\mathbf{x}. \tag{2}$$

As usual, it is convenient to present $\psi(x)$ in the form

$$\psi(x)=(\mathscr{P}_\mu\gamma^\mu+m)\phi(x). \tag{3}$$

Then the functions ϕ have to obey the squared Dirac equation in d dimensions,

$$\left(\mathscr{P}^2-m^2-\frac{q}{2}\sigma^{\mu\nu}\mathscr{F}_{\mu\nu}\right)\phi(x)=0, \quad \mathscr{F}_{\mu\nu}=\partial_\mu A_\nu(x)-\partial_\nu A_\mu(x), \quad \sigma^{\mu\nu}=\frac{i}{2}[\gamma^\mu,\gamma^\nu]. \tag{4}$$

To construct the above mentioned generalized Furry picture in QED with an external field, one has to find special sets of exact solutions of Eq. (1), namely, two complete and orthonormal sets of solution: $\{{}_{\pm}\psi_{\{n\}}(x)\}$ which describes particles $(+)$ and antiparticles $(-)$ in the initial time instant $(x^0\to-\infty)$, and $\{{}^{\pm}\psi_{\{n\}}(x)\}$ which describes particles $(+)$ and antiparticles $(-)$ in the final time instant $(x^0\to+\infty)$. According to the general approach,[5] such solutions obey the following asymptotic conditions:

$$H_{\text{o.p.}}(x^0)\,{}_{\zeta}\psi_{\{n\}}(x)={}_{\zeta}\epsilon\,{}_{\zeta}\psi_{\{n\}}(x),\quad \operatorname{sgn}{}_{\zeta}\epsilon=\zeta,\quad x^0\to-\infty,$$
$$H_{\text{o.p.}}(x^0)\,{}^{\zeta}\psi_{\{l\}}(x)={}^{\zeta}\epsilon\,{}^{\zeta}\psi_{\{l\}}(x),\quad \operatorname{sgn}{}^{\zeta}\epsilon=\zeta,\quad x^0\to+\infty, \tag{5}$$

where $\zeta,\{n\}$ and $\zeta,\{l\}$ are complete sets of quantum numbers which characterize solutions ${}_{\zeta}\psi_{\{n\}}(x)$ and ${}^{\zeta}\psi_{\{l\}}(x)$, respectively, $H_{\text{o.p.}}=\gamma^0(m-\gamma^i\mathscr{P}_i)$ is a one-particle Dirac Hamiltonian in convenient external field gauge $A_0(x)=0$; ${}^{+}\epsilon$, ${}_{+}\epsilon$ are particle quasienergies and $|{}^{-}\epsilon|$ and $|{}_{-}\epsilon|$ are antiparticles quasienergies. All the information about the processes of particle scattering and creation by an external field (in zeroth order with respect to the radiative corrections) can be extracted from the decomposition coefficients (matrices) $G({}_{\zeta}|{}^{\zeta'})$,

$${}^{\zeta}\psi(x)={}_{+}\psi(x)G({}_{+}|{}^{\zeta})+{}_{-}\psi(x)G({}_{-}|{}^{\zeta}). \tag{6}$$

The matrices $G({}_{\zeta}|{}^{\zeta'})$ obey the following relations:

$$G({}_{\zeta}|{}^{+})G({}_{\zeta}|{}^{+})^{\dagger}+G({}_{\zeta}|{}^{-})G({}_{\zeta}|{}^{-})^{\dagger}=\mathbf{I},$$
$$G({}_{+}|{}^{+})G({}_{-}|{}^{+})^{\dagger}+G({}_{+}|{}^{-})G({}_{-}|{}^{-})^{\dagger}=0, \tag{7}$$

where $\mathbf{I}$ is the identity matrix.

Let us describe the external electromagnetic field in which we are going to construct the exact solutions. Such a field is a generalization of the corresponding field in $d=4$, which is a combination of the constant uniform field with the plane wave field and which admits there exact solutions. One can describe such a field in $d=4$ in arbitrary reference frame saying that both its field invariants do not depend on space–time coordinates. In $d>4$ there exist, generally speaking, more independent field invariants. Besides $I_1=1/2\mathscr{F}_{\mu\nu}\mathscr{F}^{\mu\nu}$, those are all possible independent invariant combinations which may be constructed from the field tensor $\mathscr{F}_{\mu\nu}$ and Levi-Civita tensor. It is easy to see that there exist $[d/2]$ such invariants. We define the external field under consideration in arbitrary dimensions in the same manner; all its field invariants have to be constant and uniform. One can see that such a field is a combination of a constant uniform field $F_{\mu\nu}$ and a plane-wave field $f_{\mu\nu}(nx)$

$$\mathscr{F}_{\mu\nu}=F_{\mu\nu}+f_{\mu\nu}(nx), \tag{8}$$

where n_μ is a real isotropic vector, $n_\mu n^\mu=0$. It is an eigenvector of the tensor $F_{\mu\nu}$, $F_{\mu\nu}n^\nu=\mathscr{E}n_\mu$, and $f_{\mu\nu}(nx)$ is a transverse field with respect to n_μ, $n^\mu f_{\mu\nu}(nx)=f_{\mu\nu}(nx)n^\nu=0$. If all of the invariants are equal to zero (it is only possible for $d>2$), only a plane-wave field configuration is possible. If some of the invariants are not equal to zero, then a constant, uniform component $F_{\mu\nu}$, is not zero. The field (8) is free. Such a field is of special interest due to the fact that QED with a free classical field can be treated as exact QED (without external fields) but with some special (coherent) initial photon states.[15,3]

If the eigenvalue $\mathscr{E}$ is not zero, the external field violates the vacuum stability (creating particles). One can find an inertial frame where the matrix $\mathscr{F}_{\mu\nu}$ has a simple form

$$F_{\mu\nu}=F^{\perp}_{\mu\nu}+F^{\|}_{\mu\nu},$$

$$F^{\|}_{\mu\nu}=E(\delta^0_\mu\delta^D_\nu-\delta^D_\mu\delta^0_\nu),$$

$$f_{\mu\nu}(nx)=\sum_{k=1}^{D-1}(n_\mu\delta^k_\nu-n_\nu\delta^k_\mu)\dot f_k(x_-),\quad \dot f_k(x_-)=\frac{df_k(x_-)}{dx_-},\tag{9}$$

$$n_\mu=\delta^0_\mu-\delta^D_\mu,\quad x_-=nx=x^0-x^D.$$

If $d>2$ is even then

$$F^{\perp}_{\mu\nu}=\sum_{j=1}^{(d-2)/2}H_j(\delta^{2j}_\mu\delta^{2j-1}_\nu-\delta^{2j}_\nu\delta^{2j-1}_\mu),$$

and if $d=2$ the fields $F^{\perp}_{\mu\nu}$ and $f_{\mu\nu}(nx)$ are absent. In the case of d is odd, and $\mathscr{E}\neq 0$,

$$F^{\perp}_{\mu\nu}=\sum_{j=1}^{(d-3)/2}H_j(\delta^{2j}_\mu\delta^{2j-1}_\nu-\delta^{2j}_\nu\delta^{2j-1}_\mu)\quad\text{if } d>3,\ \text{and } F^{\perp}_{\mu\nu}=0\quad\text{if } d=3.$$

The same formula is valued if $\mathscr{E}=0$, but at least one of the imaginary eigenvalues of $F_{\mu\nu}$ is zero. Here $f_k(x_-)$ are arbitrary functions of x_-. If $\mathscr{E}=0$, and all imaginary eigenvalues of $F_{\mu\nu}$ are not equal to zero (all field invariants are not equal to zero) we have

$$E=0,\quad F^{\perp}_{\mu\nu}=\sum_{j=1}^{(d-1)/2}H_j(\delta^{2j}_\mu\delta^{2j-1}_\nu-\delta^{2j}_\nu\delta^{2j-1}_\mu),\quad f_k(x_-)=0\ \text{ for all }\ k.$$

In the reference frame under consideration $\mathscr{E}=E$.

To realize the external electromagnetic field of the above form, we select the following potentials:

$$A_\mu(x)=A^E_\mu(x)+A^H_\mu(x)+f_\mu(x_-),$$

$$A^E_\mu(x)=Ex^0\delta^D_\mu,\quad A^H_i=-H_jx_{i+1}\delta_{i,2j-1},\quad j=1,...,[d/2]-1,\quad i=1,...,D-1,\tag{10}$$

$$f_\mu(x_-)=0\quad\text{if }\ \mu=0,D.$$

Below we present linearly independent sets of solutions of the squared Dirac equation, which correspond to the particles in the initial time instance and to the antiparticles in the final time instant:

$$\overset{-}{+}\phi_{p_-,n,\xi,r}(x)=\overset{-}{+}\phi_{p_-,n,r}(x^0,x^D)\overset{-}{+}u_{\xi,r}(x_-)\phi_{n,r}(x_\perp),$$

$$\phi_{n,r}(x_\perp)=\phi_{p_1,n_1}(x_1,x_2)\phi_{p_3,n_2}(x_3,x_4)\dots\phi_{p_{d-3},n_{(d-2)/2}}(x_{D-2},x_{D-1}),\quad\text{if } d \text{ is even},$$

$$\phi_{n,r}(x_\perp)=\phi_{p_1,n_1}(x_1,x_2)\phi_{p_3,n_2}(x_3,x_4)\dots\phi_{p_{d-2},n_{(d-3)/2}}(x_{D-3},x_{D-2})(2\pi)^{-1/2}$$
$$\times\exp(-ip_{D-1}x^{D-1})\quad\text{if } d \text{ is odd and } H_{(d-1)/2}=0,$$

$$\overset{-}{+}\phi_{p_-,n,r}(x^0,x^D)=(4\pi)^{-1/2}$$
$$\times\exp\left\{\frac{i}{2}(qE(x^2_-/2-x^2_D)-p_-x_++\lambda\ \ln(\mp\tilde\pi_-))+\overset{-}{+}J(x_-)-\overset{-}{+}K^\mu(x_-)\pi_{\perp\mu}\right\},\tag{11}$$

$$
{}^{-}_{+}J(x_-)=-\frac{1}{2qE}\int_{\mp\infty}^{\pi_-}qf\left(\frac{p_--\tau}{qE}\right)\left[qf\left(\frac{p_--\tau}{qE}\right)+qF{}^{-}_{+}K\left(\frac{p_--\tau}{qE}\right)\right]\tau^{-1}d\tau,
$$

$$
{}^{-}_{+}K(x_-)=-\frac{1}{qE}\int_{\mp\infty}^{\pi_-}\exp\left\{-\frac{F}{E}\ln\frac{\pi_-}{\tau}\right\}qf\left(\frac{p_--\tau}{qE}\right)\tau^{-1}d\tau,
$$

$$
{}^{-}_{+}u_{\xi,r}(x_-)=\mp\left(\frac{1}{2\pi_-}(1+\gamma^0\gamma^D)+\frac{1}{2}(1-\gamma^0\gamma^D)+\frac{1}{2\pi_-}(\gamma^0-\gamma^D)\gamma qf(x_-)\right)v_{\xi,r},
$$

$$
x_+=x^0+x^D,\quad \tilde{\pi}_-=\pi_-/\sqrt{qE},
$$

where p_-, $n=(n_1,n_2,\ldots,n_{[d/2]-1};p_1,p_3,\ldots,p_{2[(d-1)/2]-1})$, ξ and $r=(r_1,r_2,\ldots,r_{[d/2]-1})$ is a complete set of quantum numbers. Among them p_-, p_j are momenta of the continuous spectrum, n_j are integer quantum numbers, $\xi=\pm1$ and $r_j=\pm1$ are spin quantum numbers; the momentum p_- is the eigenvalue of the operator $2i(\partial/\partial x_+)$; if $qE>0$ is chosen then the signs $\mp$ assigned to the functions ${}^{-}_{+}\phi_{p_-,n,\xi,r}(x)$ are matched with those of the kinetic momentum $\pi_-=p_--qEx_-$ at $x_-\to\pm\infty$, and

$$
\begin{gathered}
x^\mu_\perp=0\quad\text{if}\quad\mu=0,D,\quad x^\mu_\perp=x^\mu\quad\text{if}\quad\mu=1,\ldots,D-1,\\
\pi_{\perp\mu}=0\quad\text{if}\quad\mu=0,D,\quad \pi_{\perp\mu}=i\frac{\partial}{\partial x^\mu}-qA^H_\mu(x)\quad\text{if}\quad\mu=1,\ldots,D-1,\\
qE\lambda=m^2+\sum_{j=1}^{[d/2]-1}\omega_j+\omega_0,\quad \omega_0=\begin{cases}0, & d\ \text{is even},\\ p^2_{d-2}, & d\ \text{is odd},\end{cases}\\
\omega_j=\begin{cases}|qH_j|(2n_j+1-r_j), & H_j\neq0,\\ p^2_{2j-1}+p^2_{2j}, & H_j=0.\end{cases}
\end{gathered}
\tag{12}
$$

Each function $\phi_{p_{2j-1},n_j}(x_{2j-1},x_{2j})$ obeys the following equations:

$$
(\pi^2_{\perp 2j-1}+\pi^2_{\perp 2j}-\omega_j)\phi_{p_{2j-1},n_j}(x_{2j-1},x_{2j})=0,
$$

$$
(\pi_{\perp 2j-1}-p_{2j-1})\phi_{p_{2j-1},n_j}(x_{2j-1},x_{2j})=0.
$$

If $H_j\neq0$, a solution of these equations is

$$
\begin{aligned}
\phi_{p_{2j-1},n_j}(x_{2j-1},x_{2j})=&\left(\frac{\sqrt{|qH_j|}}{2^{n_j+1}\pi^{3/2}n_j!}\right)^{1/2}\exp\left\{-ip_{2j-1}x^{2j-1}-\frac{|qH_j|}{2}\left(x^{2j}+\frac{p^{2j-1}}{qH_j}\right)^2\right\}\\
&\times\mathscr{H}_{n_j}\left[\sqrt{|qH_j|}\left(x^{2j}+\frac{p^{2j-1}}{qH_j}\right)\right],
\end{aligned}
$$

where $\mathscr{H}_{n_j}(x)$ is the Hermite polynomial with integer $n_j=0,1,\cdots$. If $H_j=0$, the discrete quantum numbers n_j have to be replaced by the momenta p_{2j}, and the corresponding function has the form

$$
\phi_{p_{2j-1},p_{2j}}(x_{2j-1},x_{2j})=(2\pi)^{-1}\exp\{-i(p_{2j-1}x^{2j-1}+p_{2j}x^{2j})\}.
$$

The symbol $\ln(\mp\tilde{\pi}_-)$ means the principal branch of the logarithm, $\ln(\mp\tilde{\pi}_-)=\ln|\tilde{\pi}_-|+i\pi\Theta(\pm\tilde{\pi}_-)$, while the integration paths in the τ-plane, as well as the arguments π_-, are shown in Figs. 1 and 2 for the functions ${}_{+}K(x_-)$, ${}_{+}J(x_-)$ and ${}^{-}K(x_-)$, ${}^{-}J(x_-)$, respectively.

One assumes the functions $f_k(x_-)$ obey the requirement that ${}^{-}_{+}K(x_-)$ and ${}^{-}_{+}J(x_-)$ are analytic functions, and in particular, the functions $f_k(x_-)$ vanish at $x_-\to\pm\infty$ quite rapidly.

The solution has a different form if d is odd, $\mathscr{E}=0$, and all the imaginary eigenvalues of $F_{\mu\nu}$ are not equal to zero (in this case a plane-wave field is absent),

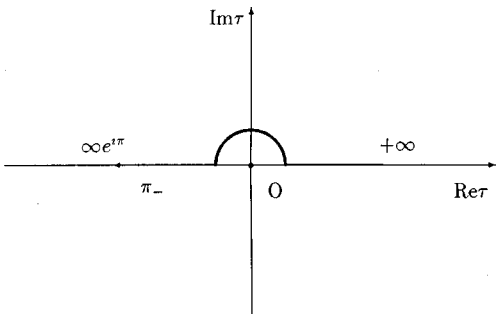

FIG. 1. Path of integration in ${}_+K(x_-)$ and ${}_+J(x_-)$ integrals.

$$
\begin{aligned}
&{}^-_+\phi_{n,\xi,r}(x)={}^-_+\phi_{n,r}(x^0)\,\phi_{n,r}(\mathbf{x})\,v_{\xi,r}\,,\\
&\phi_{n,r}(\mathbf{x})=\phi_{p_1,n_1}(x_1,x_2)\,\phi_{p_3,n_2}(x_3,x_4)\ldots\phi_{p_{d-2},n_{(d-1)/2}}(x_{D-1},x_D),\\
&{}^-_+\phi_{n,r}(x^0)=c\,\exp(\pm i|{}_\mp\epsilon_{nr}|x^0),\quad |{}_\mp\epsilon_{nr}|=\sqrt{m^2+\sum_{j=1}^{(d-1)/2}\omega_j},
\end{aligned}
\tag{13}
$$

where c is a normalization constant.

Here $v_{\xi,\tau}$ are some constant orthonormal spinors, $v^\dagger_{\xi,r}v_{\xi,r'}=\delta_{r,r'}$. Equation (4) allows one to subject these spinors to some supplementary conditions,

$$
\Xi_\pm v_{\mp 1,r}=0,\ \ \Xi_\pm=\tfrac{1}{2}(1\pm\gamma^0\gamma^D),\quad \text{rank}\ \ \Xi_\pm=J_{(d)}=2^{[d/2]-1};
\tag{14}
$$

$$
R_j v_{\xi,r}=r_j v_{\xi,r},\quad d\geqslant 4,\quad R_j=i\gamma^{2j-1}\gamma^{2j}.
\tag{15}
$$

If $d=2,3$, the independent quantum number r does not appear.

One can verify the solutions of the Dirac equation with different ξ, namely, $(\mathscr{P}_\mu\gamma^\mu+m)_+\phi_{p_-,n,+1,r}(x)$ and $(\mathscr{P}_\mu\gamma^\gamma+m)_+\phi_{p_-,n,-1,r}(x)$, or $(\mathscr{P}_\mu\gamma^\gamma+m)^-\phi_{p_-,n,+1,r}(x)$, and $(\mathscr{P}_\mu\gamma^\mu+m)^-\phi_{p_-,n,-1,r}(x)$, are linearly dependent for each sign ''+'' or ''−''. It means, in fact, that the spin projections of a particle $(+)$ and an antiparticle $(-)$ can take on only $J_{(d)}$ values. Thus to construct the complete sets, it is sufficient to use only the following solutions:

$$
{}^-_+\psi_{p_-,n,r}(x)=(\mathscr{P}_\mu\gamma^\mu+m)\,{}^-_+\phi_{p_-,n,+1,r}(x).
\tag{16}
$$

In particular, if $d=2,3$, there is only one spin projection, with only one spinor $v_{+1,r}=(1/\sqrt{2})\binom{1}{i}$. To get the case where $E=0$, one has to consider a limit in the solution ${}^-_+\psi_{p_-,n,r}(x)$, such that $-(qE)^{-1}\ln(\mp\tilde{\pi}_-)\to x_-/p_-$, and $p_->0$ for $\{{}_+\psi_{p_-,n,r}(x)\}$, whereas $p_-<0$ for $\{{}^-\psi_{p_-,n,r}(x)\}$.

Using solutions (13) we may construct the Dirac spinors in a slightly different way,

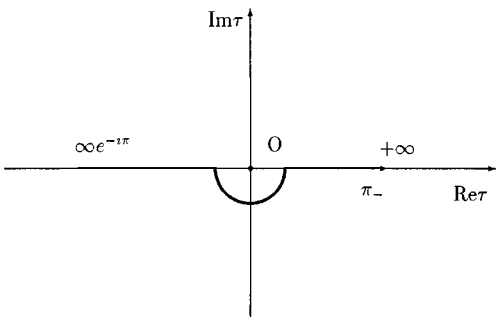

FIG. 2. Path of integration in ${}^-K(x_-)$ and ${}^-J(x_-)$ integrals.

$$
{}^{-}_{+}\psi_{n,\bar{r}}(x)=(\mathscr{P}_{\mu}\gamma^{\mu}+m){}^{-}_{+}\phi_{n,\bar{r}}(x),
$$

$$
{}^{-}_{+}\phi_{n,\bar{r}}(x)=({}^{-}_{+}\phi_{n,+1,r}(x)+\mathrm{sgn}(qH_{(d-1)/2}){}^{-}_{+}\phi_{n,-1,r}(x)), \tag{17}
$$

$$
\bar{r}=(r_1,r_2,\ldots,r_{(d-3)/2},\quad \mathrm{sgn}(qH_{(d-1)/2})),
$$

where

$$
R_j{}^{-}_{+}\phi_{n,\bar{r}}(x)=\bar{r}_j{}^{-}_{+}\phi_{n,\bar{r}}(x),\quad j=1,2,\ldots,(d-1)/2,
$$

and ${}^{-}_{+}\phi_{n,\bar{r}}(x)$ are eigenvectors of the time-independent operator $m^2-\mathscr{P}^i\mathscr{P}_i+(q/2)\sigma^{\mu\nu}F_{\mu\nu}$.

The solutions ${}_{+}\psi_{n,\bar{r}}(x)$ from (17) describe particles $(+)$ and ${}^{-}\psi_{n,\bar{r}}(x)$ describe antiparticles $(-)$ in any time instant. They form a complete and orthonormal set of solutions. There is an interesting asymmetry in energy spectrums of such particles and antiparticles in odd dimensions. If all quantum numbers $n_j=0$, and $r_j=\mathrm{sgn}(qH_j)$, then $\gamma\mathbf{P}{}^{-}_{+}\psi_{n,\bar{r}}(x)=0$, and the ground state of the particle has energy ${}_{+}\epsilon_0=m$, but the energy of the ground state of the antiparticle is dependent of the magnetic field and different: $|{}^{-}\epsilon_0|=\sqrt{m^2+2\min|qH_j|}$.

In the $d=4$ case, the solutions similar to (16) were found first in Ref. 7. In the case $E=0$, they coincide with ones in Ref. 16, and if $H=0$ they coincide with well-known Wolkov form.[17] In the case $E=0$, the solutions form a complete and orthonormal set, moreover ${}_{+}\psi_{p_-,n,r}(x)$ describe particles and ${}^{-}\psi_{p_-,n,r}(x)$ describe antiparticles in any time instant. It is no longer true if $E\neq 0$. However, solutions (16) can be used to construct new complete sets which can be classified by the correct way.

One can form two complete and orthonormal sets of the solutions: $\{{}_{\pm}\psi_{p_-,n,r}(x)\}$ and ${}^{\pm}\psi_{p_-,n,r}(x)$ using (16) and additional sets

$$
\begin{aligned}
{}^{+}\psi_{p_-,n,r}(x)&=\Theta(\pi_-)({}_{+}\psi(x)G({}_{+}|{}^{+}))_{p_-,n,r},\\
{}_{-}\psi_{p_-,n,r}(x)&=\Theta(-\pi_-)({}^{-}\psi(x)G({}_{-}|{}^{-})^{\dagger})_{p_-,n,r},
\end{aligned} \tag{18}
$$

where $G({}_{\zeta}|{}^{\zeta'})$ obeys relations (7) and, in particular, $G({}_{+}|{}^{-})$ are decomposition coefficients of ${}^{-}\psi_{p_-,n,r}(x)$ solutions in ${}_{+}\psi_{p_-,n,r}(x)$ solutions,

$$
G({}_{+}|{}^{-})_{p_-,n,r,p'_-,n',r'}=({}_{+}\psi_{p_-,n,r},{}^{-}\psi_{p'_-,n',r'}). \tag{19}
$$

The corresponding Klein–Gordon solutions follow from (11) by the replacement $u_{\xi,r}(x_-)=\exp\{-(1/2)\ln(\mp\tilde{\pi}_-)\}$.

The orthonormality of all the solutions can be verified by using the following integral transformations:

$$
{}_{\pm}\psi_{p_-,n,r}(x)=(2\pi qE)^{-1/2}\int_{-\infty}^{+\infty}M^*(p_D,p_-){}_{\pm}\psi_{p_D,n,r}(x)dp_D, \tag{20}
$$

$$
{}_{\pm}\psi_{p_D,n,r}(x)=(2\pi qE)^{-1/2}\int_{-\infty}^{+\infty}M(p_D,p_-){}_{\pm}\psi_{p_-,n,r}(x)dp_-,
$$

$$
M(p_D,p_-)=\exp\left\{-\frac{i}{4qE}\left((p_--2p_D)^2-2(p_D)^2\right)\right\}, \tag{21}
$$

$$
\int_{-\infty}^{+\infty}M^*(p_D,p'_-)M(p_D,p_-)dp_D=2\pi qE\,\delta(p_--p'_-).
$$

The same relation is valid for functions with $(\pm)$ indices above.

The saddle points $\pi_-=-2(qEx_0-p_D)$ give the main contribution to integrals (21) with ${}^{-}_{+}\psi_{p_-,n,r}(x)$ functions at $x_0\to\pm\infty$ (this was first found in Ref. 18 for the $d=4$ case without a

magnetic field). Since the plane wave vanishes in ${}^{-}_{+}\psi_{p_-,n,r,}(x)$ at $\pi_- \to \pm\infty$, relations (21) reduce at $x_0 \to \pm\infty$ to the space–time uniform field case and can be presented by use of formulas from Ref. 19 as follows:

$$
\begin{gathered}
{}^{-}_{+}\psi_{p_D,n,r}(x) = (\mathscr{P}_\mu \gamma^\mu + m)\,{}^{-}_{+}\phi_{p_D,n,r}(x), \quad x_0 \to \pm\infty, \\
{}^{-}_{+}\phi_{p_D,n,r}(x) = {}^{-}_{+}\phi_{n,r}(x^0)\exp(-ip_D x^D)\,\phi_{n,r}(x_\perp)v_{+1,r}, \\
{}^{-}_{+}\phi_{n,r}(x^0) = CD_{\nu-1}[\pm(1-i)\xi], \\
\xi = (qEx^0 - p_D)/\sqrt{qE}, \quad \nu = i\lambda/2, \quad C = (4\pi qE)^{-1/2}\exp\{(-\pi/2 + i\,\ln 2)\lambda/4\}(-i),
\end{gathered}
\tag{22}
$$

where the function $\phi_{n,r}(x_\perp)$ was defined in (11), and, $D_\nu(z)$ is the Weber parabolic cylinder function.[20] Such solutions were discussed in Ref. 13. One can now verify the orthonormality relations of the sets $\{{}_{+}\psi_{p_D,n,r}(x)\}$ and $\{{}^{-}\psi_{p_D,n,r}(x)\}$. Using transformation (20) one gets the orthonormality relations of sets $\{{}_{+}\psi_{p_-,n,r}(x)\}$ and $\{{}^{-}\psi_{p_-,n,r}(x)\}$ as well. Using the explicit forms of solutions, (16), (18), and relations (7) one can derive the following relations:

$$
\begin{gathered}
{}^{+}\psi(x)G({}_{+}|{}^{+})^\dagger = {}_{+}\psi(x) - {}^{-}\psi(x)G({}_{+}|{}^{-})^\dagger, \\
{}_{-}\psi(x)G({}_{-}|{}^{-}) = {}^{-}\psi(x) - {}_{+}\psi(x)G({}_{+}|{}^{-}).
\end{gathered}
\tag{23}
$$

By means of the latter one can get the orthonormality relations for both sets of the solutions,

$$
\begin{gathered}
({}_{\zeta}\psi_{p_-,n,r},\ {}_{\zeta'}\psi_{p'_-,n',r'}) = \delta_{\zeta\zeta'}\delta_{rr'}\delta_{nn'}\delta(p_- - p'_-), \\
({}^{\zeta}\psi_{p_-,n,r},\ {}^{\zeta'}\psi_{p'_-,n',r'}) = \delta_{\zeta\zeta'}\delta_{rr'}\delta_{nn'}\delta(p_- - p'_-),
\end{gathered}
\tag{24}
$$

where $\zeta, \zeta' = \pm$, $\delta_{nn'}$ is the Kronecker symbol for the discrete spectrum and the δ-function for the continuous one. Here $r = r' = +1$ if $d = 2,3$.

To solve a problem of the $(\pm)$ classification of the solutions, one needs to study their asymptotic behavior at $x_0 \to \pm\infty$. From the asymptotic forms (22) it follows[13] that the asymptotic of the quasienergies of these solutions, ${}_{+}\epsilon = -qEx^0$, is positive and ${}^{-}\epsilon = -qEx^0$ is negative. Thus the solutions ${}_{+}\psi_{p_D,n,r}(x)$ describe particles at $x_0 \to -\infty$, and the solutions ${}^{-}\psi_{p_D,n,r}(x)$ describe antiparticles at $x_0 \to +\infty$. Since the solutions ${}_{-}\psi_{p_-,n,r}(x)$ are orthogonal to ${}_{+}\psi_{p_-,n,r}(x)$, they describe antiparticles at $x_0 \to -\infty$, and solutions ${}^{+}\psi_{p_-,n,r}(x)$ describe particles at $x_0 \to +\infty$ since they are orthogonal to ${}^{-}\psi_{p_-,n,r}(x)$. One can verify this by taking into account that the main contribution to integrals (21) at $x_0 \to \pm\infty$ for ${}^{+}_{-}\psi_{p,r}(x)$ is given by point $\pi_- = 0$. In this limit the contribution of the plane wave does not depend on x and the results of transformation (21) are proportional to a superposition of the solutions in a constant uniform field,[20]

$$
\begin{gathered}
{}^{+}_{-}\psi_{p_D,n,r}(x) = \sum_{n,r} a_{n'r'}(\mathscr{P}_\mu \gamma^\mu + m)\,{}^{+}_{-}\phi_{p_D,n',r'}(x), \quad x_0 \to \pm\infty, \\
{}^{+}_{-}\phi_{p_D,n,r}(x) = {}^{+}_{-}\phi_{n,r}(x^0)\exp(-ip_D x^D)\,\phi_{n,r}(x_\perp)v_{+1r}, \\
{}^{+}_{-}\phi_{n,r}(x^0) = CD_{-\nu}[\pm(1+i)\xi],
\end{gathered}
\tag{25}
$$

where a_{nr} are some coefficients dependent on the plane-wave form. From the asymptotic representations (25), one can see[13] that the asymptotic of the quasienergies of these solutions ${}^{+}\epsilon = qEx^0$ is positive and ${}_{-}\epsilon = qEx^0$ is negative.

Both sets $\{{}_{\pm}\psi_{p_-,n,r}(x)\}$ and $\{{}^{\pm}\psi_{p_-,n,r}(x)\}$ are orthonormal and complete at any time instant. The form of the commutation function, which will be present in the next section, can serve as

direct proof of the last statement. In $d=4$ such complete sets of the solutions, were first found in Ref. 8. If the plane wave is absent and $E=0$, one can get the solutions with defined energies from ${}^{-}_{+}\psi_{p_D,n,r}(x)$ (22) considering the next limit in ${}^{-}_{+}\phi_{n,r}(x^0)$:

$$ {}^{-}_{+}\phi_{n,r}(x^0)\to[{}_{\mp}\epsilon_{nr}({}_{\mp}\epsilon_{nr}+p_D)]^{-1}\ \exp(\pm i|{}_{\mp}\epsilon_{nr}|x^0), $$

$$ |{}_{\mp}\epsilon_{nr}|=\sqrt{m^2+\sum_{j=1}^{[(d-1)/2]}\omega_j+\omega_0'},\quad \omega_0'=\begin{cases}p_D^2, & d \text{ is even},\\ 0, & d \text{ is odd},\end{cases} $$

where ω_j is defined in (12). In this case one can choose ${}^{+}\psi_{p_D,n,r}(x)={}_{+}\psi_{p_D,n,r}(x)$ and ${}_{-}\psi_{p_D,n,r}(x)={}^{-}\psi_{p_D,n,r}(x)$.

Let us select some important properties of the solution. One can see that the matrix elements $G({}_{\zeta}|{}^{\zeta'})$ are diagonal with respect to continuous quantum numbers and spin quantum numbers,

$$ G({}_{\zeta}|{}^{\zeta'})_{p_-,n,r,p'_-,n',r'}=\delta_{rr'}\delta(p_--p'_-)\delta(p_1-p'_1)\cdots\delta(p_{2[(d-1)/2]-1}-p'_{2[(d-1)/2]-1})g({}_{\zeta}|{}^{\zeta'})_{nn'}. \tag{26} $$

The solutions ${}^{-}_{+}\psi_{p_-,n,r}(x)$ satisfy the orthonormality conditions on the null-plane,

$$ \int\ {}^{-}_{+}\overline{\psi}_{p_-,n,r}(x)\Xi_-\ {}^{-}_{+}\psi_{p'_-,n',r'}(x)dx_+\ dx^1\cdots dx^{D-1}=\delta_{rr'}\delta_{nn'}\delta(p_--p'_-),\quad \mp\pi_->0. \tag{27} $$

Since ${}^{+}\psi_{p_-,n,r}(x)=0$ for $\pi_-<0$ and relations (23) take place, one gets the following representations for $G({}_{+}|{}^{-})G({}_{+}|{}^{-})^{\dagger}$ and $G({}_{+}|{}^{-})G^{\dagger}G({}_{+}|{}^{-})$ matrices:

$$ \begin{aligned}(G({}_{+}|{}^{-})G({}_{+}|{}^{-})^{\dagger})_{p_-,n,r,p'_-,n',r'}&=\int\ {}_{+}\overline{\psi}_{p_-,n,r}(x)\Xi_-\ {}_{+}\psi_{p'_-,n',r'}(x)dx_+dx^1\cdots dx^{D-1},\\ &\pi_-<0,\\ (G({}_{+}|{}^{-})^{\dagger}G({}_{+}|{}^{-}))_{p_-,n,r,p'_-,n',r'}&=\int\ {}^{-}\overline{\psi}_{p_-,n,r}(x)\Xi_-\ {}^{-}\psi_{p'_-,n',r'}(x)dx_+dx^1\cdots dx^{D-1},\\ &\pi_->0.\end{aligned} \tag{28} $$

Thus one can calculate ${}_{+}\mathscr{D}=g({}_{+}|{}^{-})g({}_{+}|{}^{-})^{\dagger}$ and ${}^{-}\mathscr{D}=g({}_{+}|{}^{-})^{\dagger}g({}_{+}|{}^{-})$ matrices using the following integrals with the solutions of the squared Dirac equation:

$$ {}^{-}_{+}\mathscr{D}_{nn'}=\int\ {}^{-}_{+}\phi^{\dagger}_{p_-,n,+1,r}(x){}^{-}_{+}\phi_{p_-,n',+1,r}(x)dx^2\ dx^4\cdots dx^{2[(d-1)/2]},\quad \mp\pi_-<0. \tag{29} $$

III. GREEN FUNCTIONS

The perturbation theory with respect to the radiative interaction for the matrix elements of the processes also has the usual Feynman structure in an external field creating pairs.[5,21,3] The Feynman diagrams have to be calculated by means of the causal propagator

$$ S^c(x,x')=c_v^{-1}i\langle 0,out|T\psi(x)\overline{\psi}(x')|0,in\rangle,\quad c_v=\langle 0,out|0,in\rangle, \tag{30} $$

where $\psi(x)$ is quantum spinor field in the generalized Furry representation, satisfying the Dirac equation (1), $|0,in\rangle$ and $|0,out\rangle$ are the initial and the final vacuum in this representation, and c_v is the vacuum to vacuum transition amplitude. The propagator $S^c(x,x')$ obeys the equation

$$ (\mathscr{P}_\mu\gamma^\mu-m)S^c(x,x')=-\delta^{(d)}(x-x'), \tag{31} $$

and is a Green function of the equation. Another important singular function is the commutation function

$$S(x,x')=i[\psi(x),\bar{\psi}(x')]_+ . \tag{32}$$

It obeys the homogeneous Dirac equation (1) and the initial condition

$$S(x,x')|_{x_0=x_0'}=i\gamma^0\delta(\mathbf{x}-\mathbf{x}'). \tag{33}$$

The commutation function $S(x,x')$ is, at the same time, the propagation function of the Dirac equation, i.e., it connects solutions of the equation in two different time instants.

QED with unstable vacuum has a number of peculiarities. Thus, for instance, in the calculation of the expectation values and the total probabilities Green functions of different types from (30) appear:[5,21,3]

$$\begin{aligned}
S^c_{in}(x,x')&=i\langle 0,in|T\psi(x)\bar{\psi}(x')|0,in\rangle,\\
S^-_{in}(x,x')&=i\langle 0,in|\psi(x)\bar{\psi}(x')|0,in\rangle,\\
S^+_{in}(x,x')&=i\langle 0,in|\bar{\psi}(x')\psi(x)|0,in\rangle,\\
S^{\bar{c}}_{in}(x,x')&=i\langle 0,in|\psi(x)\bar{\psi}(x')T|0,in\rangle,\\
S^c_{out}(x,x')&=i\langle 0,out|T\psi(x)\bar{\psi}(x')|0,out\rangle,
\end{aligned} \tag{34}$$

where the symbol of the T-product acts on both sides: It orders the field operators to the right and antiorders them to the left. The function $S^c_{\rm in}(x,x')$, $S^c_{\rm out}(x,x')$ obeys Eq. (31), $S^{\mp}(x,x')$ satisfies Eq. (1), and $S^{\bar{c}}_{\rm in}(x,x')$ obeys the equation

$$(\mathscr{D}_\mu\gamma^\mu-m)S^{\bar{c}}_{in}(x,x')=\delta^{(d)}(x-x'). \tag{35}$$

As well, all these different kinds of the Green functions are used to represent various matrix elements of operators of the current and energy-momentum tensor, and effective action beginning with zeroth order with respect to radiative interaction.

Solutions (16) and (18) with quantum number p_- are especially adapted to calculate all the Green functions. One can express the Green functions via solutions (16) and (18)[5,21,3]

$$S^c(x,x')=\theta(x_0-x_0')S^-(x,x')-\theta(x_0'-x_0)S^+(x,x'), \tag{36}$$

$$S(x,x')=S^-(x,x')+S^+(x,x'), \tag{37}$$

$$\begin{aligned}
S^-(x,x')&=i\int_{-\infty}^{+\infty}dp_-\sum_{nr\{n_j'\}}{}^+\psi_{p_-,n,r}(x)g({}_+|^+)^{-1}_{nn'}\,{}^+\bar{\psi}_{p_-,n',r}(x'),\\
S^+(x,x')&=i\int_{-\infty}^{+\infty}dp_-\sum_{nr\{n_j'\}}{}^-\psi_{p_-,n,r}(x)[g({}_-|^-)^{-1}]^*_{nn'}\,{}^-\bar{\psi}_{p_-,n',r}(x'),
\end{aligned} \tag{38}$$

$$S^c_{in}(x,x')=\theta(x_0-x_0')S^-_{in}(x,x')-\theta(x_0'-x_0)S^+_{in}(x,x'), \tag{39}$$

$$S^{\bar{c}}_{in}(x,x')=\theta(x_0'-x_0)S^-_{in}(x,x')-\theta(x_0-x_0')S^+_{in}(x,x'), \tag{40}$$

$$S^{\mp}_{in}(x,x')=i\int_{-\infty}^{+\infty}dp_-\sum_{nr}{}^{\pm}\psi_{p_-,n,r}(x)\,{}^{\pm}\bar{\psi}_{p_-,n,r}(x'), \tag{41}$$

$$S^c_{out}(x,x')=\theta(x_0-x_0')S^-_{out}(x,x')-\theta(x_0'-x_0)S^+_{out}(x,x'), \tag{42}$$

$$S^{\mp}_{out}(x,x')=i\int_{-\infty}^{+\infty}dp_-\sum_{nr}{}^{\pm}\psi_{p_-,n,r}(x)\,{}^{\pm}\bar{\psi}_{p_-,n,r}(x'), \tag{43}$$

where all $p_j'=p_j$, the symbol Σ_{nr} means the summation over all discrete quantum numbers n_j, r_j and the integration over all continuous p_j, and the symbol $\Sigma_{\{n_j\}}$ means the summation over all discrete quantum numbers n_j only. Using the relations between the Green functions and between the matrices $G(_\zeta|^{\zeta'})$ one can present the functions $S^{\mp}$, $S_{in}^{\mp}$ and $S_{out}^{\mp}$ as follows:

$$\pm S^{\mp}(x,x')=S^c(x,x')\pm\theta(\mp(x_0-x_0'))S(x,x'), \tag{44}$$

$$\pm S_{in}^{\mp}(x,x')=S_{in}^c(x,x')\pm\theta(\mp(x_0-x_0'))S(x,x'), \tag{45}$$

$$\pm S_{out}^{\mp}(x,x')=S_{out}^c(x,x')\pm\theta(\mp(x_0-x_0'))S(x,x'), \tag{46}$$

$$S_{in}^c(x,x')=S^c(x,x')-S^a(x,x'), \tag{47}$$

$$S_{out}^c(x,x')=S^c(x,x')-S^p(x,x'), \tag{48}$$

$$S^a(x,x')=-i\int_{-\infty}^{+\infty}dp_-\sum_{nr\{n_j'\}}{}_-\psi_{p_-,n,r}(x)[g(_+|^-)g(_-|^-)^{-1}]^{\dagger}_{nn'}{}_+\overline{\psi}_{p_-,n',r}(x'), \tag{49}$$

$$S^p(x,x')=i\int_{-\infty}^{+\infty}dp_-\sum_{nr\{n_j'\}}{}^+\psi_{p_-,n,r}(x)[g(_+|^+)^{-1}g(_+|^-)]_{nn'}{}^-\overline{\psi}_{p_-,n',r}(x'). \tag{50}$$

To calculate all the types of Green functions it is sufficient to take sums in $S^{\pm}(x,x')$ and $S^{a,p}(x,x')$ only. That will be done below.

It follows from (18)

$$S^{\pm}(x,x')=\int_{-\infty}^{+\infty}\Theta(\mp\pi_-){}_+^-Y(x,x',p_-)dp_-, \tag{51}$$

$${}_+^-Y(x,x',p_-)=i\sum_{nr}{}_+^-\psi_{p_-,n,r}(x){}_+^-\overline{\psi}_{p_-,n,r}(x'). \tag{52}$$

Also taking into account Eqs. (23) one gets

$$\begin{aligned}S^a(x,x')&=-\int_{-\infty}^{+\infty}\Theta(-\pi_-){}_+Y(x,x',p_-)dp_-,\\ S^p(x,x')&=\int_{-\infty}^{+\infty}\Theta(\pi_-){}^-Y(x,x',p_-)dp_-.\end{aligned} \tag{53}$$

Due to the fact that ${}_+\psi_{p_-,n,r}(x)$ and ${}^-\psi_{p_-,n,r}(x)$ have similar form (16), the sums in (52) can be taken in the same way. Since

$$\sum_r v_{+1,r}v^+_{+1,r}=\Xi_+ \quad \text{if } d>3, \text{ and } v_{+1}v^+_{+1}=\Xi_+ \quad \text{if } d=2,3,$$

the summation over the spin quantum numbers can be done in (52) to get

$$\begin{aligned}{}_+^-Y(x,x',p_-)=&\left[\gamma^0+(\gamma_\perp\mathscr{P}_\perp+m)\frac{1}{\pi_-}\right]\Xi_+\exp\left(-i\frac{q}{2}\sigma^{\mu\nu}F^\perp_{\mu\nu}{}_+^-a\right)\\ &\times\left[\gamma^0+(-\gamma_\perp\mathscr{P}_\perp'{}^*+m)\frac{1}{\pi_-'}\right]\gamma^0\exp\left\{\frac{1}{2}[\ln(\mp\tilde{\pi}_-)+(\ln(\mp\tilde{\pi}_-'))^*]\right\}\\ &\cdot\sqrt{qE}{}_+^-\tilde{f}^{(0)}(x,x',p_-),\end{aligned} \tag{54}$$

$$ {}^{-}_{+}\tilde{f}^{(0)}(x,x',p_-)=i\sum_n {}^{-}_{+}\varphi_{p_-,n,r}(x)\,{}^{-}_{+}\varphi^{*}_{p_-,n,r}(x'), \tag{55} $$

$$ {}^{-}_{+}\varphi_{p_-,n,r}(x)=\exp\{-\tfrac{1}{2}\ln(\mp\tilde{\pi}_-)\}\,{}^{-}_{+}\phi_{p_-,n,r}(x^0,x^D)\,\phi_{n,r}(x_\perp), $$

$$ {}^{-}_{+}a=(2qE)^{-1}[(\ln(\mp\tilde{\pi}'_-))^*-\ln(\mp\tilde{\pi}_-)], \tag{56} $$

$$ \tilde{\pi}'_-=\tilde{\pi}_-+\sqrt{qE}\,y_-,\ \ y_\mu=x_\mu-x'_\mu, $$

$$ \mathscr{P}_{\perp\mu}=0 \quad \text{if } \mu=0,D,\ \ \mathscr{P}_{\perp\mu}=\mathscr{P}_\mu \quad \text{if } k=1,\ldots,D-1, $$

$$ \mathscr{P}'^{*}_{\mu}=-i\,\frac{\partial}{\partial x'^{\mu}}-qA_\mu(x'). $$

It is convenient to make the replacement

$$ u=(2qE)^{-1}[(\ln(\mp\tilde{\pi}'_-))^*-\ln(\mp\tau)] $$

in the functions ${}^{-}_{+}K(x_-)$ and ${}^{-}_{+}J(x_-)$, and the one

$$ u=(2qE)^{-1}[(\ln(\tilde{\pi}'_-))^*-\ln\,\tau] $$

in the functions ${}^{-}_{+}K^*(x'_-)$ and ${}^{-}_{+}J^*(x'_-)$ [from ${}^{-}_{+}\phi_{p_-,n,r}(x^0,x^D)$ and ${}^{-}_{+}\phi^{*}_{p_-,n,r}(x'^0,x'^D)$ defined in (11)]. We do not discuss the integration paths over the variable u, since it is natural to consider the plane-wave potential $f(x_-)$ to be an entire function on x_-, in that case the integrals ${}^{-}_{+}K(x_-)$, ${}^{-}_{+}J(x_-)$, ${}^{-}_{+}K^*(x'_-)$ and ${}^{-}_{+}J^*(x'_-)$ are well defined by the integration limits. For different forms of the plane-wave potential, the integration paths over u are no longer arbitrary, however, they easily are extracted from the integration paths shown in Figs. 1 and 2. Then, one can present some combinations involved in (55) in the following way:

$$ {}^{-}_{+}K(x_-)-{}^{-}_{+}K^*(x'_-)=l({}^{-}_{+}a)+2(e^{2qF\,{}^{-}_{+}a}-1)\int_{{}^{-}_{+}b}^{0}e^{-2qFu}qf(x_-(u))du, $$

$$ {}^{-}_{+}K(x_-)+{}^{-}_{+}K^*(x'_-)=l({}^{-}_{+}a)+2(e^{2qF\,{}^{-}_{+}a}+1)\int_{{}^{-}_{+}b}^{0}e^{-2qFu}qf(x_-(u))du, \tag{57} $$

$$ {}^{-}_{+}J(x_-)-{}^{-}_{+}J^*(x'_-)=\Phi({}^{-}_{+}a)+2\int_0^{{}^{-}_{+}a}qf(x_-(u))e^{2qFu}\,du\ qF\int_{{}^{-}_{+}b}^{0}e^{-2qFu'}qf(x_-(u'))du', $$

where

$$ \Phi({}^{-}_{+}a)=\int_0^{{}^{-}_{+}a}qf(x_-(u))[qf(x_-(u))+qFl(u)]du, $$

$$ l(u)=2\int_0^u e^{2qF(u-u')}qf(x_-(u'))du', \tag{58} $$

$$ {}^{-}_{+}b=-\infty-i\pi/(2qE)\Theta(\mp\pi'_-),\ \ x_-(u)=x'_-+y_-\,\frac{1-\exp\{-2qEu\}}{1-\exp\{-2qE\,{}^{-}_{+}a\}}. $$

The summation over n_j in (55) can be performed using the Möller formula.[20] After integration over p_j in (55), applying the operators $\exp\{-i\,{}^{-}_{+}K(x_-)\pi_\perp\}$ and $\exp\{-i\,{}^{-}_{+}K(x_-)\pi'_\perp\}^*$, and using relations (57), we obtain

$$ {}^{-}_{+}\tilde{f}^{(0)}(x,x',p_-)=\exp\left\{ iq\Lambda - im^2 {}^{-}_{+}a - \frac{1}{2}\left[\ln(\mp\tilde{\pi}_-)+(\ln(\mp\tilde{\pi}'_-))^*\right] - i\,\frac{\pi_- + \pi'_-}{4}\,y_+ \right\} h({}^{-}_{+}a), \tag{59} $$

$$ h({}^{-}_{+}a)=\exp\left\{ i\Phi({}^{-}_{+}a) - i\,\frac{1}{4}\,(y+l({}^{-}_{+}a))qF^{\perp}\,\coth(qF^{\perp}\,{}^{-}_{+}a)(y+l({}^{-}_{+}a)) + \frac{i}{2}\,yqF^{\perp}l(s) \right\} Z_{(d)}, \tag{60} $$

where

$$ \begin{aligned} Z_{(d)} &= c_d \prod_{j=1}^{(d-2)/2} \left(\frac{qH_j}{\sin(qH_j s)} \right), \quad d \text{ is even}, \\ Z_{(d)} &= c_d s^{-1/2} \prod_{j=1}^{(d-3)/2} \left(\frac{qH_j}{\sin(qH_j s)} \right), \quad d \text{ is odd}, \\ c_d &= (4\pi)^{-d/2} \exp\{-i\pi(d-4)/4\}, \end{aligned} \tag{61} $$

and

$$ \Lambda = -\int_{x'}^{x} (A^E_\mu + A^H_\mu)\,dx^\mu. \tag{62} $$

Here $A^E_\mu + A^H_\mu$ is a potential of the constant uniform field $F_{\mu\nu}$, and the integral is taken along the line.

Let us remark that the functions ${}^{-}_{+}\tilde{f}^{(0)}(x,x',p_-)$ are special solutions of the Klein–Gordon equation,

$$ \left(\pi_- 2i\,\frac{\partial}{\partial x_-} - iqE + \mathscr{P}^2_\perp - m^2 \right) {}^{-}_{+}\tilde{f}^{(0)}(x,x',p_-)=0. \tag{63} $$

Taking into account the relations

$$ \begin{aligned} \pi_\perp e^{iq\Lambda} &= e^{iq\Lambda}\left(i\,\frac{\partial}{\partial x_\perp} + \frac{1}{2}\,qFy_\perp \right), \\ \pi'^{*}_\perp e^{iq\Lambda} &= e^{iq\Lambda}\left(-i\,\frac{\partial}{\partial x'_\perp} - \frac{1}{2}\,qFy_\perp \right), \end{aligned} \tag{64} $$

$$ \begin{aligned} \exp(-iq\sigma^{0D}F_{0D}\,{}^{-}_{+}a) &= \cosh(qE\,{}^{-}_{+}a) - i\sigma^{0D}\,\sinh(qE\,{}^{-}_{+}a), \\ \exp\left(-i\,\frac{q}{2}\,\sigma^{\mu\nu}F^{(j)}_{\mu\nu}\,{}^{-}_{+}a \right) &= \cos(qH_j\,{}^{-}_{+}a) + iR_j\,\sin(qH_j\,{}^{-}_{+}a), \end{aligned} \tag{65} $$

where

$$ F^{(j)}_{\mu\nu} = H_j(\delta^{2j}_\mu \delta^{2j-1}_\nu - \delta^{2j}_\nu \delta^{2j-1}_\mu), $$

and matrix R_j is defined by (15), one can get relation

$$ \begin{aligned} &\exp\left(-i\,\frac{q}{2}\,\sigma^{\mu\nu}F^{\perp}_{\mu\nu}\,{}^{-}_{+}a \right) \gamma\pi'^{*}_\perp\, {}^{-}_{+}\tilde{f}^{(0)}(x,x',p_-) \\ &\quad = (\gamma\pi_\perp + \gamma qF^{\perp}l({}^{-}_{+}a))\exp\left(-i\,\frac{q}{2}\,\sigma^{\mu\nu}F^{\perp}_{\mu\nu}\,{}^{-}_{+}a \right) {}^{-}_{+}\tilde{f}^{(0)}(x,x',p_-). \end{aligned} \tag{66} $$

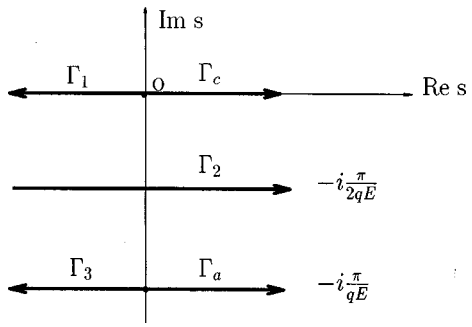

FIG. 3. Contours of integration $\Gamma_1,\Gamma_2,\Gamma_3,\Gamma_c,\Gamma_a$.

By using formulas (65), (66) and Eq. (63) one can transform expression (54) to the following form:

$$\bar{}_{+}Y(x,x',p_-)=\mp(\gamma\mathscr{P}+m)\bar{}_{+}\tilde{f}(x,x',p_-), \tag{67}$$

$$\bar{}_{+}\tilde{f}(x,x',p_-)=\left[\exp\left(-i\frac{q}{2}\sigma^{\mu\nu}F_{\mu\nu}\bar{}_{+}a\right)\mp\frac{1}{2}(\gamma^0-\gamma^D)\gamma\int_0^{\bar{}_{+}a}e^{qF(\bar{}_{+}a-2u)}q\frac{df(x_-(u))}{du}du\right.$$
$$\left.\times\exp\left\{-\frac{1}{2}[\ln(\mp\tilde{\pi}_-)+(\ln(\mp\pi'_-))^*]\right\}\right]\bar{}_{+}\tilde{f}^{(0)}(x,x',p_-). \tag{68}$$

In the external field under consideration the real proper time S is a function of π_- and π'_- because the classical equation of motion has a form $\pi_-^{-1}dx_-=m^{-1}dS$. Thus if $y_-\neq 0$, one can transform the p_- integration in Green functions into integration over the Fock–Schwinger proper time by making the change of the variable,

$$s=\bar{}_{+}a. \tag{69}$$

Then, one gets the following representations for the Green functions:

$$S^{\mp,a,p}(x,x')=(\gamma\mathscr{P}+m)\Delta^{\mp,a,p}(x,x'),$$

$$\mp\Delta^{\pm}(x,x')=\int_{\Gamma_c}f(x,x',s)ds-\Theta(\pm y_-)\int_{\Gamma_c-\Gamma_2-\Gamma_1}f(x,x',s)ds, \tag{70}$$

$$\Delta^a(x,x')=\int_{\Gamma_a}f(x,x',s)ds+\Theta(y_-)\int_{\Gamma_2+\Gamma_3-\Gamma_a}f(x,x',s)ds, \tag{71}$$

$$\Delta^p(x,x')=\int_{\Gamma_a}f(x,x',s)ds+\Theta(-y_-)\int_{\Gamma_1^a}f(x,x',s)ds. \tag{72}$$

All the contours of the integrals are shown in Fig. 3.
The contours Γ_c and Γ_1 are placed below the singular points on the real axis everywhere outside of the origin, and

$$f(x,x',s)=\left[\exp\left(-i\frac{q}{2}\sigma^{\mu\nu}F_{\mu\nu}s\right)+(n\gamma)\gamma\right.$$
$$\left.\times\int_0^s e^{qF(s-2u)}\frac{df((nx(u)))}{du}du\,\frac{\sinh(qEs)}{E(ny)}\right]f^{(0)}(x,x',s), \tag{73}$$

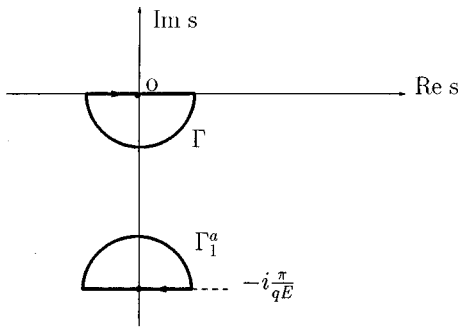

FIG. 4. Contours of integration Γ, Γ_1^a.

$$f^{(0)}(x,x',s)=\exp\{iq\Lambda\}\,\frac{qE}{\sinh(qEs)}$$
$$\times\exp\left\{-im^2s+i\Phi(s)-i\,\frac{1}{4}\,(y+l(s))qF\,\coth(qFs)(y+l(s))+\frac{i}{2}\,yqFl(s)\right\}Z_{(d)}, \tag{74}$$

where $Z_{(d)}$ is defined in (61). The function $f^{(0)}(x,x',s)$ has two singular points on the complex region between the contours $\Gamma_c-\Gamma_1$ and $\Gamma_a-\Gamma_3$. They are situated at the imaginary axis: $s_0=0$, and $qEs_1=-i\pi$. One can transform the contours $\Gamma_c-\Gamma_2-\Gamma_1$ into Γ and $\Gamma_2+\Gamma_3-\Gamma_a$ into Γ_1^a (see Fig. 4) with radii tending to zero. Since

$$\int_\Gamma f(x,x',s)ds=0 \quad \text{if } y_\mu y^\mu<0, \quad \int_{\Gamma_1^a} f(x,x',s)ds=0 \quad \text{if } y_0^2>y_D^2,$$

one can rewrite (70), (71) and (72) as follows:

$$S^{\mp}(x,x')=(\gamma\mathscr{P}+m)\Delta^{\mp}(x,x'), \tag{75}$$

$$\mp\Delta^{\pm}(x,x')=\int_{\Gamma^c} f(x,x',s)ds-\Theta(\pm y_0)\int_\Gamma f(x,x',s)ds,$$

$$S^{a,p}(x,x')=(\gamma\mathscr{P}+m)\Delta^{a,p}(x,x'), \tag{76}$$

$$\Delta^a(x,x')=\int_{\Gamma^a} f(x,x',s)ds+\Theta(-y^D)\int_{\Gamma_1^a} f(x,x',s)ds,$$

$$\Delta^p(x,x')=\int_{\Gamma^a} f(x,x',s)ds+\Theta(y^D)\int_{\Gamma_1^a} f(x,x',s)ds,$$

one can check that these expressions are valid for arbitrary x and x'. To prove this, one needs to verify that the functions $S^{\pm}(x,x')$ and $S^{a,p}(x,x')$, which are presented via integrals (75) and (76), and by means of representations (51) and (53), are the same solutions of the Dirac equation for any x and x'. Thus it is enough to check first that expressions (75) and (76) obey the Dirac equation for any x and x'. Then, one has to prove that the Cauchy conditions for distributions (75) and (76) coincide at $x_0=x_0'$ with (51) and (53), respectively. As to $S^{\pm}(x,x')$, one can use the proper time representations for $S^c(x,x')$ and $S(x,x')$ functions, which follow from (75), (36) and (37),

$$S^c(x,x')=(\gamma\mathscr{P}+m)\Delta^c(x,x'),$$

$$\Delta^c(x,x')=\int_{\Gamma_c} f(x,x',s)ds, \tag{77}$$

$$S(x,x')=(\gamma\mathscr{P}+m)\Delta(x,x'),$$

$$\Delta(x,x')=\mathrm{sign}(x_0-x_0')\int_{\Gamma} f(x,x',s)ds. \tag{78}$$

One can see that $f(x,x',s)$ obeys the following equations,

$$-i\frac{d}{ds}f(x,x',s)=\left(\mathscr{P}^2-m^2-\frac{q}{2}\sigma^{\mu\nu}\mathscr{F}_{\mu\nu}\right)f(x,x',s), \tag{79}$$

$$\lim_{s\to+0} f(x,x',s)=i\delta^{(d)}(x-x'). \tag{80}$$

Thus $f(x,x',s)$ is the Fock–Schwinger function.[22,23] So, representation (77) of causal Green function has the well-known Schwinger form.[22] The concrete representation (78) of the commutation function has the same form as the general representation.[24] Similar to Ref. 24, one can select all singularities of this function and see that it is continuous at x_0-x_0'. In the $d=4$ case one can transform this representation to the Fock form.[23] The analysis of space-time singularities in integrals (76) over the contour Γ_1^a can be done in a similar manner to Ref. 24. In the $d=4$ the representations, (75)–(78) coincide with the ones found in Ref. 8. To find the proper time representation we used the special behavior of solutions (16). But one has the different form of solutions (17) if d is odd, $E=0$ and all the imaginary eigenvalues H_j of the field tensor are not equal to zero. In this case since solutions (17) can represent a special case of the $d+1$ general form (16), one does not need to calculate Green functions of the case independently and representations (75), (77) and (78) are valid if one puts $E=0$, $f((nx))=0$ and replaces $qE/\sinh(qEs)$ $\to qH_{(d-1)/2}/\sin(qH_{(d-1)/2})$ in formulas (73) and (74) [the functions $S^{a,p}(x,x')$ are equal to zero].

IV. SOME PHYSICAL APPLICATIONS

All the information about the processes of particle creation, annihilation, and scattering in an external field (without radiative corrections) can be extracted from the matrices $G(_{\zeta}|^{\zeta'})$ (6). These matrices define a canonical transformation between in and out creation and annihilation operators in the generalized Furry representation,[5,3]

$$\begin{aligned} a^\dagger(out)&=a^\dagger(in)G(_+|^+)+b(in)G(_-|^+),\\ b(out)&=a^\dagger(in)G(_+|^-)+b(in)G(_-|^-). \end{aligned} \tag{81}$$

Here $a^\dagger_{\{n\}}(in)$, $b^\dagger_{\{n\}}(in)$, $a_{\{n\}}(in)$, $b_{\{n\}}(in)$ are creation and annihilation operators of in-particles and antiparticles, respectively, and $a^\dagger_{\{n\}}(out)$, $b^\dagger_{\{n\}}(out)$, $a_{\{n\}}(out)$, $b_{\{n\}}(out)$ are ones of out-particles and antiparticles; $\{n\}$ are possible quantum numbers. For example, let us calculate the mean numbers of antiparticles created (which are also equal to the number of pairs created) by the external field from the in-vacuum $|0,in\rangle$ with a given quantum number p_D,n,r. By using relations (81) and (21) one finds representation of this quantity

$$N_{p_D,n,r}=\langle 0,in|b^\dagger_{p_D,n,r}(out)b_{p_D,n,r}(out)|0,in\rangle=(G(_+|^-)^\dagger G(_+|^-))_{p_D,n,r,p_D',n',r}|_{p_D=p_D',n=n'}, \tag{82}$$

$$(G(_+|^-)^\dagger G(_+|^-))_{p_D,n,r,p_D',n',r}$$

$$= \int_{-\infty}^{+\infty} (G(_+|^-)G(_+|^-)^\dagger)_{p_-,n,r,p_-,n',r} M^*(p_D,p_-)M(p_D',p_-)\,\frac{dp_-}{2\pi qE}, \tag{83}$$

where the standard space coordinate volume regularization was used, so that $\delta(p_j-p_j')\to\delta_{p_j,p_j'}$. Then, by using formulas (28) and (29) one gets

$$N_{p_D,n,r} = \int_{-\infty}^{+\infty} {}^-\mathscr{D}_{nn} M^*(p_D,p_-)M(p_D',p_-)\frac{dp_-}{2\pi qE}\bigg|_{p_D=p_D'}. \tag{84}$$

If L_D is the length of the correspondent edge of the space box, then the maximum wave length of the plane wave is $2L_D$. Thus using the Fourier-series expansion of ${}^-\mathscr{D}$ one gets

$$N_{p_D,n,r} = \frac{1}{L_D}\int_0^{L_D} {}^-\mathscr{D}_{nn}\, dp_-. \tag{85}$$

One can calculate the quantities ${}^-_+\mathscr{D}_{nn'}$, given by Eq. (29), taking into account that the operator $\pi_\perp$ is Hermitian, and

$$e^{iK^*\pi_\perp}e^{-iK\pi_\perp} = \exp\left\{-\frac{i}{2}K^*qFK - i(K-K^*)\pi_\perp\right\}.$$

Then all the integrals over x^j in form (29) can be expressed in terms of the Laguerre polynomials.[25] In the special case when $n=n'$ one has

$${}^-\mathscr{D}_{nn} = \exp\left\{-\pi\lambda - \mathrm{Im}\ {}^-K(x_-)(qf(p_-/qE)+qF\ \mathrm{Re}\ {}^-K(x_-)) - \sum_{j=1}^{[d/2]-1} h_j\right\}\prod_{j=1}^{[d/2]-1} L_{n_j}(2h_j), \tag{86}$$

$$h_j = -|qH_j|((\mathrm{Im}\ {}^-K_{2j-1}(x_-))^2+(\mathrm{Im}\ {}^-K_{2j}(x_-))^2), \quad \pi_-\gt 0.$$

Remember that we are discussing the case in which the constant electric field acts for an infinite time. However, one can analyze the problem in finite times $T=x^0_{out}-x^0_{in}$, acting similar to Ref. 13. Then the mean number of pairs created by the external field $N_{p_D,n,r}$ is the same if time T is large enough: $\sqrt{qE}T\gg 1$, $\sqrt{qE}T\gg\lambda$ and $qET\gg|p_D|$.

Summing over the quantum numbers in (85), one can find the total number of pairs created from the vacuum. Using standard regularization with respect to the $(d-1)$-dimensional spatial volume $V_{(d-1)}$ and special regularization with respect to time T of acting of a constant electric field,[13] where $\int dp_D\, N_{p_D,n,r} = qETN_{p_D,n,r}$, one gets

$$N = V_{(d-2)}n^{cr},$$

$$n^{cr} = J_{(d)}\,\frac{Tm^2\beta(1)}{2^{(d-1)}\pi^{d/2}}\,\frac{E}{E_c}\exp\left\{-\pi\,\frac{E_c}{E}\right\}, \tag{87}$$

where n^{cr} is the number density of the created pairs for time T, and the coefficient $\beta(1)$ is defined by the next formula as a special case on $l=1$

$$\beta(l) = \prod_{j=1}^{(d-2)/2}\{qH_j\coth(l\pi H_j/E)\}, \quad d \text{ is even},$$

$$\beta(l) = \left(\frac{m^2E}{n\pi E_c}\right)^{1/2}\prod_{j=1}^{(d-3)/2}\{qH_j\coth(l\pi H_j/E)\}, \quad d \text{ is odd}. \tag{88}$$

Here, $E_c=m^2/|q|$ is the characteristic value of a constant electric field strength. This quantity N does not depend on the parameters of plane-wave field and is the same as the number of pairs created in a constant and uniform field.[13] The corresponding formulas for the $d=4$ case were first written in Ref. 26, and, in fact, can be derived easily from the Schwinger formulas.[22]

By using proper-time kernel $f(x,x',s)$ (73), one can construct the d-dimensional form of the Schwinger $out-in$ effective action[22]

$$\Gamma_{out-in}=\frac{1}{2}\,\mathrm{tr}\left\{\int dx\int_0^\infty s^{-1}f(x,x,s)ds\right\}. \tag{89}$$

It is not dependent on the parameters of the plane-wave field. And it is not amazing because the effective action is a function of the field invariants only which do not depend on the plane wave. Taking into account formulas (65) one can find the trace in (89) representation

$$\rho(s)=\mathrm{tr}\left\{\exp\left(-i\,\frac{q}{2}\,\sigma^{\mu\nu}F_{\mu\nu}s\right)\right\}=2^{[d/2]}\cosh(qEs)\prod_{j=1}^{[(d-2)/2]}\cos(qH_js). \tag{90}$$

Then, one calculates the probability for a vacuum to remain a vacuum by using the Schwinger method,[22]

$$\begin{gathered}P_v=\exp(-2\,\mathrm{Im}\,\Gamma_{out-in})=\exp\{-\mu N\},\\ \mu=\sum_{l=0}^{\infty}\frac{\beta(l+1)}{(l+1)\beta(1)}\exp\left\{-l\pi\,\frac{E_c}{E}\right\},\end{gathered} \tag{91}$$

where $\beta(l)$ is defined by (88). This result coincides with the result from Ref. 13, and in $d=4$ the results coincide with Refs. 22 and 26.

Let the operator of the current of the Dirac field operator $\psi(x)$ have the form

$$j_\mu=\frac{q}{2}\,[\bar{\psi}(x),\gamma_\mu\psi(x)], \tag{92}$$

and operator of metric energy-momentum tensor (EMT) of the Dirac field operator have the form

$$\begin{gathered}T_{\mu\nu}=\tfrac{1}{2}\,(T^{\mathrm{can}}_{\mu\nu}+T^{\mathrm{can}}_{\nu\mu}),\\ T^{\mathrm{can}}_{\mu\nu}=\tfrac{1}{4}\,\{[\bar{\psi}(x),\gamma_\mu\mathscr{P}_\nu\psi(x)]+[\mathscr{P}^*_\nu\bar{\psi}(x),\gamma_\mu\psi(x)]\},\end{gathered} \tag{93}$$

where $T^{\mathrm{can}}_{\mu\nu}$ is the canonical EMT operator. We are going to discuss the following matrix elements with these operators:

$$\langle j_\mu\rangle^c=\langle 0,out|j_\mu|0,in\rangle c_v^{-1}, \tag{94}$$

$$\langle T_{\mu\nu}\rangle^c=\langle 0,out|T_{\mu\nu}|0,in\rangle c_v^{-1}, \tag{95}$$

$$\langle j_\mu\rangle^{in}=\langle 0,in|j_\mu|0,in\rangle, \tag{96}$$

$$\langle T_{\mu\nu}\rangle^{in}=\langle 0,in|T_{\mu\nu}|0,in\rangle, \tag{97}$$

$$\langle j_\mu\rangle^{out}=\langle 0,out|j_\mu|0,out\rangle, \tag{98}$$

$$\langle T_{\mu\nu}\rangle^{out}=\langle 0,out|T_{\mu\nu}|0,out\rangle. \tag{99}$$

Using the Green functions which were found before, one can present these matrix elements in the following form:

$$\langle j_\mu\rangle^c=iq\;\mathrm{tr}\{\gamma_\mu S^c(x,x)\}=iq\;\;\mathrm{tr}\{\gamma_\mu\gamma^k\mathscr{P}_\kappa\Delta^c(x,x')\}|_{x=x'}, \tag{100}$$

$$\langle T_{\mu\nu}\rangle^c = i/4\ \mathrm{tr}\{(\gamma_\mu(\mathscr{P}_\nu+\mathscr{P}'^*_\nu)+\gamma_\nu(\mathscr{P}_\mu+\mathscr{P}'^*_\mu))S^c(x,x')\}|_{x=x'} = i\ \mathrm{tr}\{B_{\mu\nu}\Delta^c(x,x')\}|_{x=x'}, \tag{101}$$

$$\langle j_\mu\rangle^{in} = \langle j_\mu\rangle^c - \langle j_\mu\rangle^a, \tag{102}$$

$$\langle j_\mu\rangle^{out} = \langle j_\mu\rangle^c - \langle j_\mu\rangle^p, \tag{103}$$

$$\langle T_{\mu\nu}\rangle^{in} = \langle T_{\mu\nu}\rangle^c - \langle T_{\mu\nu}\rangle^a, \tag{104}$$

$$\langle T_{\mu\nu}\rangle^{out} = \langle T_{\mu\nu}\rangle^c - \langle T_{\mu\nu}\rangle^p, \tag{105}$$

$$\langle j_\mu\rangle^{(a,p)} = iq\ \mathrm{tr}\{\gamma_\mu\gamma^\kappa\mathscr{P}_\kappa\Delta^{a,p}(x,x')\}|_{x=x'}, \tag{106}$$

$$\langle T_{\mu\nu}\rangle^{(a,p)} = i\ \mathrm{tr}\{B_{\mu\nu}\Delta^{a,p}(x,x')\}|_{x=x'}, \qquad B_{\mu\nu} = 1/4\{\gamma_\mu(\mathscr{P}_\nu+\mathscr{P}'^*_\nu)+\gamma_\nu(\mathscr{P}_\mu+\mathscr{P}'^*_\mu)\}\gamma^\kappa\mathscr{P}_\kappa, \tag{107}$$

where the Green functions are given by Eqs. (76), (77) and the relation

$$\Delta^c(x,x) = \tfrac{1}{2}[\Delta^-(x,x)-\Delta^+(x,x)]$$

is used. It is convenient to represent $\langle j_\mu\rangle^{a,p}$ and $\langle T_{\mu\nu}\rangle^{a,p}$ as follows:

$$-\langle j_\mu\rangle^a = \langle j_\mu\rangle^{(1)} + \langle j_\mu\rangle^{(2)}, \tag{108}$$

$$-\langle j_\mu\rangle^p = \langle j_\mu\rangle^{(1)} - \langle j_\mu\rangle^{(2)}, \tag{109}$$

$$-\langle T_{\mu\nu}\rangle^a = \langle T_{\mu\nu}\rangle^{(1)} + \langle T_{\mu\nu}\rangle^{(2)}, \tag{110}$$

$$-\langle T_{\mu\nu}\rangle^p = \langle T_{\mu\nu}\rangle^{(1)} - \langle T_{\mu\nu}\rangle^{(2)}, \tag{111}$$

where

$$\langle j_\mu\rangle^{(1)} = iq\ \mathrm{tr}\{\gamma_\mu\gamma^\kappa\mathscr{P}_\kappa\Delta^{(1)}(x,x')\}|_{x=x'}, \tag{112}$$

$$\langle T_{\mu\nu}\rangle^{(1)} = i\ \mathrm{tr}\{B_{\mu\nu}\Delta^{(1)}(x,x')\}|_{x=x'}, \tag{113}$$

$$\Delta^{(1)}(x,x') = -\frac{1}{2}\int_{\Gamma_3+\Gamma_2+\Gamma_a} f(x,x',s)ds, \tag{114}$$

and all contributions with derivatives of $\Theta(\pm y^D)$ functions, which are formally divergent, are included in terms $\langle j_\mu\rangle^{(2)}$ and $\langle T_{\mu\nu}\rangle^{(2)}$. The nature of such divergences is connected with infinite time T of acting of a constant electric field and was discussed in Ref. 13 (see also below).

The components $\langle j_\mu\rangle^{(1,2)}$ and $\langle T_{\mu\nu}\rangle^{(1,2)}$ cannot be calculated in the framework of the perturbation theory with respect to the external background or in the framework of the WKB method. Among them only the term $\langle j_\mu\rangle^{in}$ was calculated before in $d=4$.[3] Only expression (101) for $\langle T_{\mu\nu}\rangle^c$ has to be regularized and renormalized because of the ultraviolet divergences. Expression (100) for the term $\langle j_\mu\rangle^c$ is finite after the regularization lifting and equal to zero. The terms $\langle j_\mu\rangle^{(1)}$ and $\langle T_{\mu\nu}\rangle^{(1)}$ are also finite, and $\langle j_\mu\rangle^{(1)}=0$. The terms $\langle j_\mu\rangle^{(2)}$ and $\langle T_{\mu\nu}\rangle^{(2)}$ have to be regularizated with respect to time T of acting of a constant electric field[13] and do not have standard ultraviolet divergences. That is consistent with the fact that the ultraviolet divergences have a local nature and result (as in the theory without an external field) from the leading local terms at $s\to+0$. The nonzero contributions to the expressions $\langle j_\mu\rangle^{(2)}$ and $\langle T_{\mu\nu}\rangle^{(1,2)}$ are related to global features of the theory and indicate the vacuum instability.

At asymptotic region $x_0=T/2\to+\infty$, the densities of current and the EMT of particles created

are

$$j_\mu^{\rm cr}=\frac{\int d\mathbf{x}(\langle j_\mu\rangle^{in}-\langle j_\mu\rangle^{out})}{\int d\mathbf{x}}, \tag{115}$$

$$T_{\mu\nu}^{\rm cr}=\frac{\int d\mathbf{x}(\langle T_{\mu\nu}\rangle^{in}-\langle T_{\mu\nu}\rangle^{out})}{\int d\mathbf{x}}, \tag{116}$$

according to definitions (96)–(99).

Then, using representations (102)–(107), and taking into account terms $\langle j_\mu\rangle^{(2)}$ and $\langle T_{\mu\nu}\rangle^{(2)}$ which are uniform, one gets from (115) and (116),

$$j_\mu^{\rm cr}=2\langle j_\mu\rangle^{(2)}, \tag{117}$$

$$T_{\mu\nu}^{\rm cr}=2\langle T_{\mu\nu}\rangle^{(2)}. \tag{118}$$

Using special regularization with respect to time T of acting of a constant electric field,[13] one can interpret these divergent terms and get

$$\langle j_\mu\rangle^{\rm cr}=2|q|n^{\rm cr}\delta_\mu^D, \tag{119}$$

$$\langle T_{00}\rangle^{\rm cr}=\langle T_{33}\rangle^{\rm cr}=qETn^{\rm cr}, \tag{120}$$

and other components of $\langle T_{\mu\nu}\rangle^{\rm cr}$ are equal to zero.

To study the backreaction of particles created on the electromagnetic field and metrics one needs the expressions $\langle j_\mu\rangle^{in}$ and $\langle T_{\mu\nu}\rangle^{in}$. We found the form of $\langle j_\mu\rangle^{in}=\langle j_\mu\rangle^{(2)}=1/2\langle j_\mu\rangle^{\rm cr}$ and $\langle T_{\mu\nu}\rangle^{(2)}=1/2\langle T_{\mu\nu}\rangle^{\rm cr}$. Let us calculate other terms in expressions (104). By using formulas (65) one can find traces in (101) and (107) representations. One has the next nonzero traces: one presented by expression (90) and

$$\begin{aligned}&{\rm tr}\left\{\gamma^0\gamma^D\,\exp\left(-i\,\frac{q}{2}\,\sigma^{\mu\nu}F_{\mu\nu}s\right)\right\}=\tanh(qEs)\rho(s),\\ &{\rm tr}\left\{\gamma^{2j}\gamma^{2j-1}\,\exp\left(-i\,\frac{q}{2}\,\sigma^{\mu\nu}F_{\mu\nu}s\right)\right\}=-\tan(qH_js)\rho(s).\end{aligned} \tag{121}$$

Then

$$\langle T_{\mu\nu}\rangle^c=\int_{\Gamma_c}\tau_{\mu\nu}(s)ds, \tag{122}$$

$$\begin{aligned}&\langle T_{\mu\nu}\rangle^{(1)}=-\frac{1}{2}\int_{\Gamma_3+\Gamma_2+\Gamma_a}\tau_{\mu\nu}(s)ds,\\ &\tau_{\mu\nu}(s)=b_\mu(s)\rho(s)f^{(0)}(x,x,s)\ \ \text{if}\ \ \mu=\nu,\\ &\tau_{0D}(s)=-b_D(s)\tanh(qEs)\rho(s)f^{(0)}(x,x,s),\\ &\tau_{\mu\nu}(s)=-b_{2j}(s)\tan(qH_js)\rho(s)f^{(0)}(x,x,s)\quad \text{if}\ \ \mu=2j,\quad \nu=2j-1,\quad j=1,2,...,[d/2]-1,\\ &b_D(s)=-b_0(s)=\frac{qE}{2}\coth(qEs),\quad b_{2j}(s)=b_{2j-1}(s)=\frac{qH_j}{2}\cot(qH_js).\end{aligned} \tag{123}$$

Exponential stability for the energy exchange dynamics of the Holstein model

D. Hennig
Freie Universität Berlin, Fachbereich Physik, Institut für Theoretische Physik, Arnimallee 14, 14195 Berlin, Germany

(Received 30 April 1997; accepted for publication 15 April 1998)

We investigate the dynamics of the energy exchange between excitonic and vibrational degrees of freedom in the context of the Holstein model. Using Nekhoroshev-type arguments we derive bounds on the energy exchange for weak exciton–vibron coupling. It is shown that for large differences of the excitonic and vibronic frequencies the energy exchange is suppressed up to times growing exponentially with the ratio of the frequencies. Although the excitonic and vibronic energies are each for itself conserved there is equipartition of the excitonic energy among all lattice sites entailing an extended exciton. However, in the limit of large exciton–vibron coupling the excitonic actions are frozen separately, which leads to exciton localization. The action freezing is reflected in breather solutions. © *1998 American Institute of Physics.* [S0022-2488(98)01907-0]

I. INTRODUCTION

In their pioneering studies Fermi, Pasta, and Ulam (FPU)[1] showed that in the presence of nonlinearity the energy exchange between coupled systems may be suppressed, a behavior which is in contrast to the sharing of energy in linear models. In particular for systems of harmonic oscillators interacting via nonlinear springs they demonstrated numerically that the dispersion of the excitation energy can be inhibited, an effect which is also called self-trapping. The question of whether there appears equipartition of excitation energy is still an actual topic in various fields of physical significance. We quote here the energy exchange between excitonic and vibronic parts in the context of the Holstein model[2] and note that self-trapping of excitation energy plays an important role for optical storage patterns in nonlinear fibers, condensed matter physics, and biophysics.

With regard to the Holstein model we remark that weak exciton–vibron interactions allow a perturbational treatment of the corresponding system of coupled equations and that one can use ideas and techniques from classical mechanics. In the case of a finite number of degrees of freedom (DOF) application of perturbational methods lead to an understanding of stability phenomena in the energy exchange dynamics. Preservation of tori for all times provided the initial data lie in resonance free regions of phase space is assured by the Kolmogorov–Arnold–Moser theorem.[3] With the help of Nekhoroshev's arguments for nearly integrable systems, the stability of motion up to finite times growing exponentially with some power of the inverse of the perturbation strength is guaranteed[3–5] and the result holds for open sets of initial data. The energy exchange problem in the Holstein model can be formulated as a stability question in the sense of Nekhoroshev and one can derive estimates of the time interval during which the exciton–vibron energy exchange remains small. On the other hand, one has to be aware that the estimates of Nekhoroshev contain a dependence on the number of DOF such that the analytical stability results cannot be maintained in the thermodynamic limit when the number of DOF approaches infinity.[5,6] Bambusi and Giorgilli developed a general perturbational scheme making the extension of the Nekhoroshev statement to infinite lattices possible when the unperturbed motion has only a finite number of frequencies.[7] They applied their theory to a modified FPU chain and a system of weakly coupled rotators. The modified FPU lattice consists of particles having alternating light and heavy masses. The spectrum of the system is divided into a high frequency optical branch and an acoustic branch of low frequencies. The uncoupled system is decomposed into two sets of harmonic oscillators with a clear frequency separation between them. In the weak coupling limit

 © 1998 American Institute of Physics

it has been proven that there is little energy exchange between the optical and acoustical subsystems up to times growing exponentially with the frequency ratio. Suppression of the energy exchange does not mean that the individual actions associated with the two subsystems do not vary in time. However, such a situation seems to be unlikely since the optical modes are almost completely resonant. In the case of the lattice model of infinitely many weakly coupled rotators it has been proven that for localized initial conditions, i.e., if only a finite number of rotators is excited, such states are stable up to times which increase exponentially with a power of the inverse of the perturbation strength. In this case each action is separately frozen.[7]

In the present paper we investigate for the Holstein model the energy exchange between the excitonic and vibrational subsystems, respectively. Different energy sharing phenomena resulting from pronounced exchange, inhibition of exchange, and even strong quasiparticle localization are observed upon changes of the parameters of the system. In particular, when the uncoupled excitonic system and vibrational system evolve on distinct time scales we prove exponential inhibition of the energy exchange for weak exciton–vibron coupling and give quantitative statements on the stability properties of the coupled motion. Increasing the strength of the exciton–vibron interaction a transition to self-trapping of the excitonic energy appears for which the excitonic actions become separately frozen. In the extreme case even strong localization for which virtually the total excitonic energy is stored at a single lattice site is possible. The localization effect can be interpreted in terms of the discrete self-trapping (DST) model which arises after elimination of the vibronic DOF from the original Holstein system. The DST system exhibits a breather solution for which the action variables deviate only by a small amount from their initial values. In the case of static breathers the action variables are completely frozen and thus always stay at their initial values. Some aspects have already been discussed in Ref. 8.

II. THE HOLSTEIN MODEL

The Holstein model describes the movement of a single exciton along a one-dimensional molecular chain while interacting with intramolecular Einstein-type oscillators.[2] The Hamiltonian is given by

$$H = H_{\mathrm{exc}} + H_{\mathrm{vib}} + H_{\mathrm{int}}, \tag{1}$$

with

$$H_{\mathrm{exc}} = \epsilon \sum_n |c_n|^2 + V \sum_n |c_n - c_{n-1}|^2, \tag{2}$$

$$H_{\mathrm{vib}} = \sum_n \left(\frac{1}{2} p_n^2 + \frac{1}{2} \omega^2 q_n^2 \right), \tag{3}$$

$$H_{\mathrm{int}} = \alpha \sum_n q_n |c_n|^2. \tag{4}$$

The complex variable c_n is the excitonic occupation amplitude at a molecular site with index n, ϵ is the on-site energy, and V is the transfer matrix element due to dipole–dipole interaction. The vibrational part H_{vib} is given by the energy of a set of local harmonic oscillators corresponding to the intramolecular vibrations of the molecules where q_n and p_n are the coordinate and momentum, respectively. The exciton–vibron coupling is linear in the vibronic coordinate q_n and the latter couples to the excitonic occupation $|c_n|^2$. The strength of the coupling is regulated by α. The exciton–vibron interaction can be thought of as a modulation of the excitonic energy by the intramolecular vibrations.

The Holstein system can be cast into the form of a FPU model. To this end we perform a transformation from the excitonic variables c_n to pairs of momentum and coordinate variables (y_n, x_n), respectively, given by

$$c_n=\frac{1}{\sqrt{2}}\,(x_n+iy_n). \tag{5}$$

The transformed excitonic and interaction parts of the Hamiltonian then read as

$$H_{\mathrm{exc}}=\frac{1}{2}\,\epsilon\sum_n\,[x_n^2+y_n^2]+\frac{1}{2}\,V\sum_n\,[(x_n-x_{n-1})^2+(y_n-y_{n-1})^2], \tag{6}$$

$$H_{\mathrm{int}}=\frac{1}{2}\,\alpha\sum_n\,q_n(x_n^2+y_n^2). \tag{7}$$

For vanishing exciton–vibron coupling, i.e., $\alpha=0$, the system of (3), (6), and (7) decouples into two integrable systems, namely, the set of uncoupled intramolecular harmonic oscillators and the linear excitonic chain where both H_{vib} and H_{exc} are conserved quantities. When $\alpha\neq 0$ energy exchange between the two subsystems is possible due to the cubic interaction. It is the cubic coupling term which brings nonlinearity into play and in this sense the Holstein model represents a FPU system. We remark that the excitonic part H_{exc} can be brought into the form of a set of uncoupled harmonic oscillators through a transformation to normal coordinates. However, when dealing with the excitonic transfer it is more appropriate to use the coupled (nondiagonal) form of (6).

III. EXPONENTIAL BOUND ON THE ENERGY EXCHANGE

In this section we prove that for weak coupling $\alpha\ll 1$ and small ratio V/ω the energy exchange between the excitonic and vibronic DOF, respectively, is bounded up to exponentially long times. The proof is due to a Nekhoroshev-type argument and relies on a classical perturbation scheme developed by Bambusi and Giorgilli.[7] To be precise, we state the following theorem.

Theorem: Consider the Cauchy problem for the Hamiltonian (3), (6), (7) with initial data $\{p(0),q(0)\}$ and $\{x(0),y(0)\}$. The total energy $E(0)$ of the unperturbed (excitonic and vibronic) parts is given by

$$E(0)=\frac{1}{2}\,\epsilon\sum_n\,[(x_n(0))^2+(y_n(0))^2]+\sum_n\,\left(\frac{1}{2}\,(p_n(0))^2+\frac{1}{2}\,\omega^2(q_n(0))^2\right). \tag{8}$$

If it holds that

$$E(0)\leqslant\frac{1}{2^6}\left(\frac{\omega\epsilon}{\alpha}\right)^2, \tag{9}$$

and if the dimensionless parameter

$$\mu=2^9 3^2\left(\frac{V}{\omega}+\frac{\alpha}{\omega}\,\sqrt{E(0)}\left[\frac{1}{\omega^2}+\frac{1}{4\epsilon^2}\right]^{1/2}\right) \tag{10}$$

satisfies $\mu<1$ then the following estimate is true

$$\frac{|H_{\mathrm{vib}}(t)-H_{\mathrm{vib}}(0)|}{E(0)}\leqslant\mu, \tag{11}$$

for all times with

$$t\leqslant\frac{1}{\omega\mu}\,\exp\left(\frac{1}{\mu}\right). \tag{12}$$

Proof: The proof of the above theorem relies on the normal form results of Ref. 7. Before proceeding we set up the phase space, a symplectic form on it, and a norm for points in phase space. The phase space $\mathscr{P}:=l^2\times l^2\times l^2\times l^2$ with l^2 being the space of square summable sequences. The symplectic form Ω is defined as

$$\Omega(((p^1,q^1),(y^1,x^1)),((p^2,q^2),(y^2,x^2)))=\sum_k [(p_k^1 q_k^2-p_k^2 q_k^1)]+[(y_k^1 x_k^2-y_k^2 x_k^1)]. \tag{13}$$

The norm of a point $\xi=(p,q,x,y)\in\mathscr{P}$ is conveniently taken as the sum of the excitonic and vibronic partial energies, respectively:

$$\|\xi\|_{\mathscr{P}}^2=H_{\mathrm{exc}}(\xi)+H_{\mathrm{vib}}(\xi)=\frac{1}{2}\,\epsilon\sum_n [|x_n|^2+|y_n|^2]+\sum_n \left(\frac{1}{2}\,|p_n|^2+\frac{1}{2}\,\omega^2|q_n|^2\right). \tag{14}$$

In Ref. 7 an abstract scheme was introduced to develop a normal form theory for Hamiltonian systems defined on a generic Banach space. In particular, all the quantitative estimates obtained in the framework of this theory are then independent of the number of DOF. Here we apply this perturbation theory to bring the system (15) into normal form up to an exponentially small remainder.

We consider the real Hamiltonian function $H:\mathscr{G}\to R$ and decompose H as follows:

$$H=H_{\mathrm{vib}}+H_{\mathrm{exc}}+H_{\mathrm{int}}, \tag{15}$$

with H_{exc} and H_{int} being of class $C^\infty(\mathscr{P})$ and their symplectic gradients are defined for all $\xi\in\mathscr{P}$. For quantitative perturbational computation we consider the domain $\mathscr{G}=\{0\}\subset\mathscr{P}$ and its complex extension $\mathscr{G}_R=\mathscr{P}^{\mathscr{C}}$ is defined via the positive parameters R and $d<1$, yielding the complex ball B centered at the origin of phase space:

$$\mathscr{G}_{R,d}=B(\xi=0,R(1-d)). \tag{16}$$

(The parameter R will be fixed later.) Apparently, H_{vib} can be extended to a complex analytic function on $\mathscr{G}_{R,d}$. H_{vib} is considered as the unperturbed system. The main point is that the system H_{vib} generates a periodic continuous flow Φ_t on $\mathscr{P}^{\mathscr{C}}$ with period $T=2\pi/\omega$. It is readily seen that for every $d<1$ the complex domain $\mathscr{G}_{R,d}$ is invariant for Φ_t. With regard to the smoothness of Φ_t one has that the map Φ_t is of class $C^1(\mathscr{P}^{\mathscr{C}},\mathscr{P}^{\mathscr{C}})$ for every fixed t and the time derivative $d\Phi_t(\xi)/dt$ exists for every $\xi\in D$, where D is a flow-invariant dense subset of $\mathscr{P}^{\mathscr{C}}$. Finally, it holds $\forall t\in R$ that $\|\Phi_t'\|_{\mathscr{P},\mathscr{P}}<K$ for some $K>0$. With these smoothness conditions for the flow Φ_t related to H_{vib} the perturbation theory of Ref. 7 can be applied.

H_{vib} and H_{exc} represent two integrable subsystems if $\alpha=0$. For $\alpha\neq 0$ they interact through H_{int}. Moreover, the systems H_{vib} and H_{ext} commute, that is $\{H_{\mathrm{vib}},H_{\mathrm{exc}}\}=0$. Thus H_{exc} is already in normal form with respect to H_{vib}. Further we assume that $\nabla^\Omega H_{\mathrm{exc}}$ and $\nabla^\Omega H_{\mathrm{int}}$ can be extended to complex analytic functions from $\mathscr{G}_{R,0}$ to $\mathscr{P}^{\mathscr{C}}$ fulfilling the inequalities

$$\omega_0\geqslant\frac{1}{R}\sup\|\nabla^\Omega H_{\mathrm{exc}}(\xi)\|,\quad \omega_1\geqslant\frac{1}{R}\sup\|\nabla^\Omega H_{\mathrm{int}}(\xi)\|, \tag{17}$$

for $\xi\in\mathscr{G}_{R,0}$ and constants $\omega_{0,1}$. Provided the number μ given by

$$\mu=\frac{24}{d}\,e\pi\left(\frac{\omega_0+\omega_1}{\omega}\right), \tag{18}$$

satisfies $\mu<1$ for $0<d\leqslant 1/4$ then there exists an analytical canonical transformation $\mathscr{T}:\mathscr{G}_{R,2d}\to\mathscr{G}_{R,d}$ such that $H\circ\mathscr{T}$ takes the form

$$H(\mathscr{T}(\xi))=H_{\mathrm{vib}}(\xi)+H_{\mathrm{exc}}(\xi)+\mathscr{Z}(\xi)+\mathscr{R}(\xi). \tag{19}$$

Moreover, the following bound is valid for the symplectic gradient of $\mathscr{R}$:

$$\frac{1}{R}\sup_{\xi\in\mathcal{G}_{R,2d}}\|\nabla^{\Omega}\mathcal{R}(\xi)\|\leqslant 3(e+1)\omega_1\mu\,\exp\left(-\frac{1}{\mu}\right). \tag{20}$$

Furthermore, $\mathcal{Z}$ is in normal form with respect to H_{vib}, i.e., $\{H_{\mathrm{vib}},\mathcal{Z}\}=0$. Finally, for any analytic function $g:\mathcal{G}_{R,0}\to\mathcal{B}$, with $\mathcal{B}$ a generic Banach space, one obtains

$$\sup_{\xi\in\mathcal{G}_{R,2d}}\|g(\xi)-g(\mathcal{T}(\xi)\|_{\mathcal{B}}\leqslant\frac{2\pi(e+1)}{d}\,\frac{\omega_1}{\omega}\sup_{\xi\in\mathcal{G}_{R,d}}\|g(\xi)\|_{\mathcal{B}}. \tag{21}$$

With the help of quantitative estimates resulting from the normal form computations one derives an upper bound on the variation of the harmonic energy H_{vib} up to exponentially long times (See corollary 4.2 of Ref. 7). One infers that along the solutions of the Cauchy problem of (15) it holds that

$$|H_{\mathrm{vib}}(t)-H_{\mathrm{vib}}(0)|\leqslant\frac{6\pi(e+1)}{d}\,\frac{\omega_1}{\omega}\sup_{\xi\in\mathcal{G}_{R,d}}|H_{\mathrm{vib}}(\xi)|, \tag{22}$$

The inequality (22) is valid for all times $t\leqslant\min(T_0,T_*)$, where T_0 is the time it takes for the solution to escape from the domain $\mathcal{G}_{R,2d}$, and

$$T_*=\frac{2\pi}{3}\,\frac{1}{\omega\mu}\,\exp\left(\frac{1}{\mu}\right). \tag{23}$$

The proof of the normal form statement is based on a recursive algorithm which is equivalent to the Lie transform method used to perform consecutive canonical changes to give a (perturbed) Hamiltonian system a normal form. In this case one seeks to find normal forms in the neighborhood of an unperturbed periodic orbit. The scheme of the proof is presented in Ref. 7. In finite dimension the procedure goes essentially along the lines given in Ref. 9. In achieving the normal form one has to define a suitable norm for functions in order to obtain estimates for the Poisson brackets and the homological equation in terms of this norm. The extension of the method for the normal form computation to infinite dimensional systems requires a proper implementation of the the averaging procedure to derive estimates for the solution of the homological equation. According to Ref. 10 the averaging is performed over a periodic orbit of the unperturbed system. That the treatment of the periodic case does not impose restrictions on the analysis and involves the quasiperiodic orbits as well can be seen by noting that (in finite dimensions) all the frequencies are in a sense close to a resonance. In fact, according to Lochak any quasiperiodic motion can be approximated by a periodic one exploiting a theorem of Dirichlet.[11]

In order to verify the statement of the theorem we need the estimates of $\omega_{0,1}$ for $\xi\in\mathcal{G}_{R,0}$. Computation of ω_1 requires the expressions for the components of the symplectic gradient of H_{int}, which are given by

$$(\nabla^{\Omega}H_{\mathrm{int}})_{p_k}=-\frac{\partial H_{\mathrm{int}}}{\partial q_k}=-\frac{1}{2}\,\alpha(x_k^2+y_k^2), \tag{24}$$

$$(\nabla^{\Omega}H_{\mathrm{int}})_{q_k}=\frac{\partial H_{\mathrm{int}}}{\partial p_k}=0, \tag{25}$$

$$(\nabla^{\Omega}H_{\mathrm{int}})_{y_k}=-\frac{\partial H_{\mathrm{int}}}{\partial x_k}=-\alpha q_k x_k\,, \tag{26}$$

$$(\nabla^{\Omega}H_{\mathrm{int}})_{x_k}=\frac{\partial H_{\mathrm{int}}}{\partial y_k}=\alpha q_k y_k\,. \tag{27}$$

We derive

$$\|(\nabla^{\Omega}H_{\mathrm{int}})_p\|^2=\frac{1}{8}\,\alpha^2\sum_n\,(|x_n|^2+|y_n|^2)^2\leqslant\frac{1}{8}\,\alpha^2\left(\frac{2}{\epsilon}\right)^2\|\xi\|^4. \tag{28}$$

Furthermore, we get

$$\|(\nabla^{\Omega}H_{\mathrm{int}})_x\|^2+\|(\nabla^{\Omega}H_{\mathrm{int}})_y\|^2\leqslant\alpha^2\,\frac{2}{\omega^2}\,\|\xi\|^4. \tag{29}$$

Finally, we obtain

$$\omega_1=\alpha\left[\frac{2}{\omega^2}+\frac{1}{2\epsilon^2}\right]^{1/2}R. \tag{30}$$

With concern to ω_0 we need the gradients

$$(\nabla^{\Omega}H_{\mathrm{exc}})_{y_k}=-\frac{\partial H_{\mathrm{exc}}}{\partial x_k}=-V(x_k-x_{k-1})+V(x_{k+1}-x_k), \tag{31}$$

$$(\nabla^{\Omega}H_{\mathrm{exc}})_{x_k}=\frac{\partial H_{\mathrm{exc}}}{\partial y_k}=V(y_k-y_{k-1})-V(y_{k+1}-y_k). \tag{32}$$

We then estimate

$$\|(\nabla^{\Omega}H_{\mathrm{exc}})_x\|^2+\|(\nabla^{\Omega}H_{\mathrm{exc}})_y\|^2\leqslant\frac{1}{2}\,\epsilon\sum_n\,4V^2[|x_n-x_{n-1}|^2+|y_n-y_{n-1}|^2]\leqslant16V^2\|\xi\|^2, \tag{33}$$

and obtain eventually,

$$\omega_0=4V. \tag{34}$$

To arrive at the bound of the variation of $|H_{\mathrm{vib}}(t)-H_{\mathrm{vib}}(0)|$ given in the theorem above we have to assure that the orbit does not escape from the domain $\mathcal{G}_{R,2d=(1/2)}$ where we choose $d=1/4$. Exploiting the conservation of energy we can take R such that the escape time actually becomes infinite.[7] With the choice of the norm of a point ξ as the sum of the partial energies $H_{\mathrm{vib}}(t)+H_{\mathrm{exc}}(t)\equiv E(t)$ one has

$$\|\xi\|^2=E(t)\leqslant E(0)+|H_{\mathrm{int}}(0)|+|H_{\mathrm{int}}(t)|. \tag{35}$$

The size of the interaction can be bounded by $|H_{\mathrm{int}}|\leqslant\sqrt{2}\alpha/(\omega\epsilon)R^3$. If the right-hand side of (35) is less than or equal to $R^2/4$ then the solutions remain trapped inside the domain $\mathcal{G}_{R,(1/2)}$. From the latter condition follows the inequality

$$E(0)+2\alpha\,\frac{\sqrt{2}}{\omega\epsilon}\,R^3-\frac{R^2}{4}\leqslant0, \tag{36}$$

which can be satisfied for $R=\sqrt{8E(0)}$ provided

$$E(0)\leqslant\frac{1}{2^6}\left(\frac{\omega\epsilon}{\alpha}\right)^2, \tag{37}$$

yielding the inequality (9) from the theorem. Combining (30) and (34) readily gives μ as stated in the theorem which completes the proof. □

The above theorem tells us that if the (uncoupled) excitonic and vibronic partial dynamics of the Holstein lattice evolve on different time scales then there will be little energy exchange between the two subsystem up to times growing exponentially with the frequency separation between them. The frequency separation is determined by the ratio of ω/V, and thus for fixed V the vibronic frequency ω has to be large enough. It is worth mentioning that all the estimates

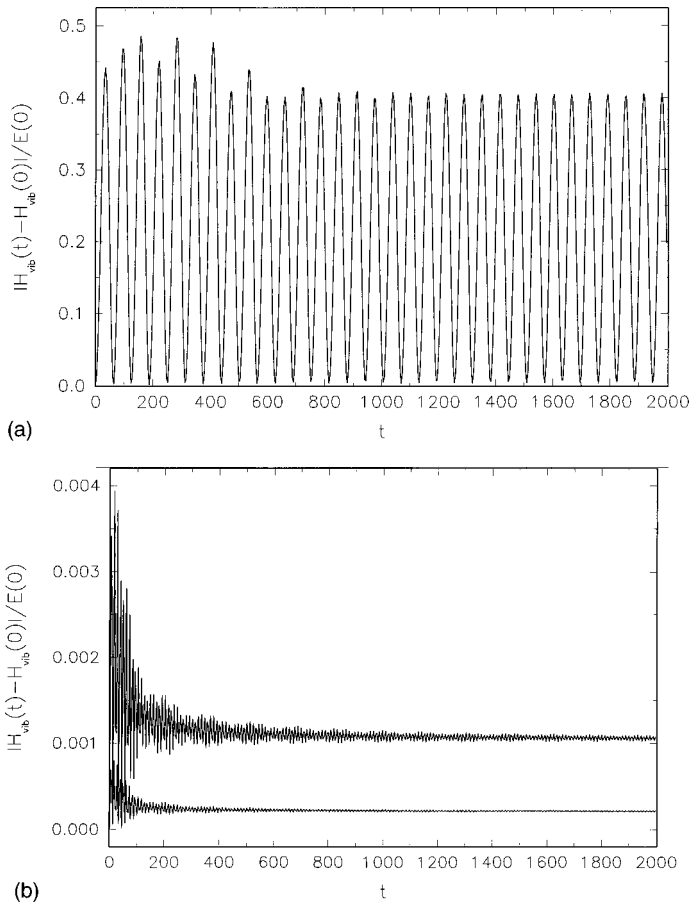

FIG. 1. Dynamics of the exchange between excitonic energy and vibronic energy in the Holstein model. (a) Time evolution of the energy ratio $|H_{\mathrm{vib}}(t)-H_{\mathrm{vib}}(0)|/E(0)$ for a chain consisting of $N=500$ sites. The excitonic energy is initially localized at the three central lattice sites, i.e., $x_{248\,250}(0)=y_{248\,250}(0)=0.5/3$, and $x_{249}(0)=y_{249}(0)=0.5$ and the remaining sites of $n\neq 248$, 249, 250 are unexcited. Parameters: $\omega^2=0.01$, $V=0.01$, and $\alpha=0.1$. (b) The same as in (a) but for increased frequency $\omega=1$. Upper curve $\epsilon=1$ and lower curve $\epsilon=5$.

entering the above theorem on stability are independent of the chain length N and thus the results on the bound of the energy exchange can be extended to the case of $N\to\infty$. In the present study the Nekhoroshev theorem does not separately control as usual the variations of the individual actions; it rather provides a bound on the energy exchange between the two subsystems of the Holstein lattice, namely the excitonic and vibronic parts, respectively. Nevertheless, the freezing of the separate excitonic actions is of considerable physical interest since it could lead to localization of the quasiparticle if the excitonic energy becomes stored at only a few lattice sites or even at a single site.

In order to illustrate the stability phenomenon expressed by the above theorem we show in Figs. 1(a) and 1(b) the temporal evolution of the energy exchange rate $|H_{\mathrm{vib}}(t)-H_{\mathrm{vib}}(0)|/E(0)$. For a lattice of length $N=500$ we used localized initial conditions for which only the central three sites contain solely excitonic energy and the remainder of the chain is kept unexcited. The duration of the integration interval is up to 10^{10} times the period $T=2\pi/\omega$ of an (uncoupled) vibronic oscillator. Figure 1(a) shows the evolution of the energy ratio for a frequency $\omega^2=0.01$. Obviously there is a pronounced energy exchange between the two subsystems. Due to the statement of the theorem increasing the frequency to $\omega^2=1$ results in a suppression of the energy exchange and each partial energy becomes virtually conserved as seen in Fig. 1(b). The upper and lower curves belong to an on-site energy $\epsilon=1$ and $\epsilon=5$, respectively. According to the estimate (11) it holds that the larger the on-site energy ϵ the more diminished the energy exchange, which is confirmed in the numerical investigations. However, the conservation of the excitonic energy does not lead necessarily to a freezing of the exchange among the various excitonic DOF in the sense that all

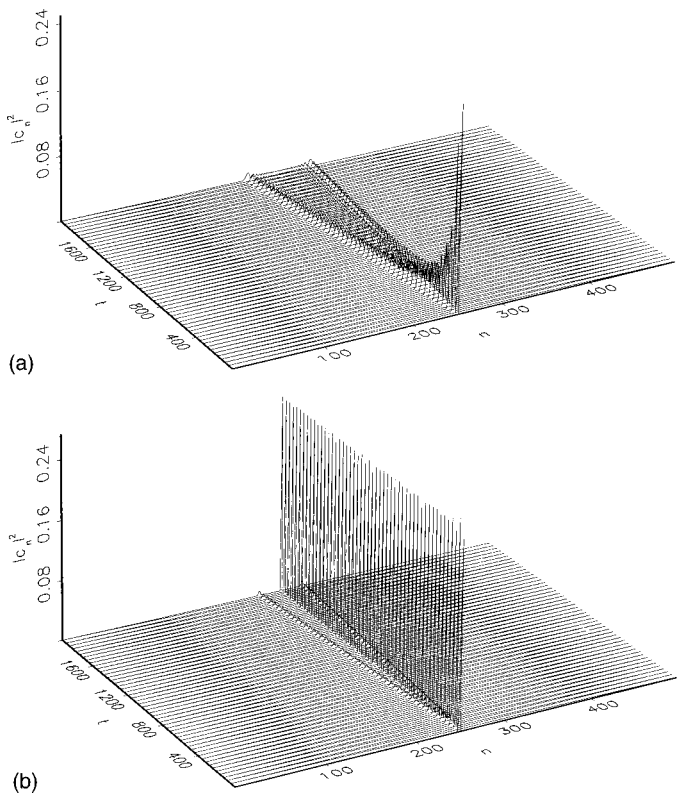

FIG. 2. Amplitude profile of the excitonic occupations (actions) $|c_n(t)|^2$ for the Holstein system. Initial data as in Fig. 1. (a) Equipartition of the excitonic energy among the molecular lattice sites. Parameters $\omega^2=0.5$, $\epsilon=1$, $V=0.01$, and $\alpha=0.1$. (b) Localization of the excitonic energy. Parameters as in (a) except for enlarged coupling $\alpha=1$. An equal picture of excitonic localization results from the DST system with $\gamma\equiv\alpha^2/\omega^2=2$.

individual excitonic occupations (actions) $|c_n(t)|^2$ stay close to their initial values $|c_n(0)|^2$. The latter behavior becomes apparent from Fig. 2(a) where the spreading of the excitonic actions $|c_n(t)|^2$ over the lattice in course of time is shown. Interestingly, when the exciton–vibron coupling is enlarged then the excitonic energy becomes highly localized around a single lattice site as Fig. 2(b) reveals. In Sec. IV we characterize this localized excitation pattern as a single site breather solution.

IV. THE DST SYSTEM, BREATHER SOLUTIONS, AND FREEZING OF THE ACTIONS

The results of Sec. III have shown that for weak coupling α (and by fixed V as well as ϵ) the exciton–vibron energy exchange is suppressed up to times growing exponentially with the vibron frequency ω. On the other hand between the individual DOF of the exciton subsystem we observe an energy exchange manifested in equipartition of the excitonic energy among the molecular lattice sites.

However, when α is increased one notices that not only the energy exchange between the two subsystems is suppressed but also the excitonic actions $|c_n|^2$ stay close to their initial values and exhibit less variations from constancy. In other words the exciton actions become (almost) conserved, which is also called freezing of the actions.[5]

The latter freezing effect can be understood in a heuristic way by considering the equations of motion for the coupled exciton–vibron system:

$$\ddot{q}_n=-\omega^2 q_n-\alpha|c_n|^2, \tag{38}$$

$$i\dot{c}_n=V[c_{n+1}+c_{n-1}-2c_n]+\epsilon c_n+\alpha q_n c_n\,. \tag{39}$$

In the limit of large frequency ω as well as large coupling α the terms on the right-hand side of (38) dominate the second derivative of $q_n(t)$ on the left-hand side giving $q_n=-\alpha/\omega^2|c_n|^2$

$\equiv \tilde{q}_n$, implying that the q coordinate is enslaved to $q_n = \tilde{q}_n$ as long as the ratio ω^2/α is of the order one. Inserting the instantaneous shift $q_n = \tilde{q}_n$ into Eq. (39) one obtains a closed equation in the excitonic occupations c_n in the form of a nonlinear discrete Schrödinger equation,

$$i\dot{c}_n = V[c_{n+1} + c_{n-1} - 2c_n] + \epsilon c_n - \gamma |c_n|^2 c_n , \tag{40}$$

which is called the discrete self-trapping (DST) equation.[12] Concerning the localization properties we remark that the DST system (with nonlinearity strength $\gamma = \alpha/\omega^2$) and the Holstein system (with α and ω) produce equal excitonic localization patterns $|c_n(t)|^2$. Thus the DST system serves to explain the localization behavior of the Holstein system from which the vibronic DOF are eliminated. In the following we briefly review the self-trapping properties of the DST system related to breather solutions. The stationary exciton localization pattern illustrated in Fig. 2(b) resembles a DST breather solution of the form $c_n = \phi_n \exp(i\Omega t)$. This solution is time independent in a rotating frame of frequency Ω and its spatial amplitudes ϕ_n decay exponentially with increasing distance from the central excitation peak at site $n = 250$. A characteristic feature of the single frequency DST breathers is that the excitonic occupations (actions) are completely frozen, i.e., $|c_n(t)|^2 = |c_n(0)|^2$. The linear stability of such an excitation pattern strongly localized around a single lattice site is readily demonstrated (see Ref. 13).

In Ref. 14 the existence of breather solutions for general networks of (weakly) coupled anharmonic oscillators has been proven by means of the anti-integrable limit. These authors suggested also the application of the anti-integrable limit to prove the existence of breather solutions for the DST system (cf. Sec. 9 of Ref. 14). The question then is whether such localized breather solutions are stable in the sense of Nekhoroshev, i.e., if one starts μ-close (the small parameter μ measures the deviation from integrability) within such localized periodic solutions does one stay then within $\mathcal{O}(\mu)$ at least for a time interval of the order of $C_1 \exp(-C_2/\mu^k)$ for some positive constants $C_{1,2}$ and k? That such solutions cannot be Lyapunov stable becomes clear by the fact that the Arnold web permeates the phase space densely. Recently Bambusi assured stability of breather solutions of general Hamiltonian networks for exponentially long time scales.[15] The DST system represents such a Hamiltonian lattice and the exponential stability of its localized periodic solutions corresponding to localized initial conditions can be proven with a Nekhoroshev-type argument using the theory developed in Ref. 15. In this way one can show that the situation of initially localized excitations changes little in course of time yielding exponentially stable breather states.

We give the construction of quantum Lax equations for IRF models and the difference version of the Calogero–Moser–Sutherland model introduced by Ruijsenaars. We solve the equations using factorization properties of the underlying face Hopf algebras/elliptic quantum groups. This construction is in the spirit of the Adler–Kostant–Symes method and generalizes our previous work to the case of face Hopf algebras/elliptic quantum groups with dynamical R matrices. © *1998 American Institute of Physics.* [S0022-2488(98)03306-4]

I. INTRODUCTION

Face Hopf algebras[1] have been found to be the algebraic structure that underlies some particularly interesting integrable models of statistical physics. They generalize Hopf algebras and quantum groups. Another closely related generalization of quantum groups, the so-called elliptic quantum groups, were introduced by Felder[2] in the context of IRF (face) models.[3] Face Hopf algebras and elliptic quantum groups play the same role for face models as quantum groups do for vertex models. The R matrices are now replaced by dynamical R matrices, which first appeared in the context of Liouville string field theory;[4] they can be understood as a reformulation of the Boltzmann weights in Baxters solutions of the face-type Yang–Baxter equation. A partial classification of the dynamical R matrices is given in Ref. 5. Recently, another type of integrable quantum systems, known as Ruijsenaars models,[6] and their various limiting cases have been shown to be connected to quantum groups and elliptic quantum groups[7–11] through different approaches.

The Calogero–Moser–Sutherland class of integrable models describes the motion of particles on a one-dimensional line or circle interacting via pairwise potentials that are given by Weierstrass elliptic functions and their various degenerations. The simplest case is an inverse r^2 potential. The Ruijsenaars–Schneider model is a relativistic generalization, whose quantum mechanical version, the Ruijsenaars model, is the model that we are interested in here.

The Hamiltonian of the Ruijsenaars model for two particles with coordinates x_1 and x_2 has the form

$$\mathcal{H}=\left\{\frac{\theta\big(c\,\eta/2-\lambda\big)}{\theta(-\lambda)}\,t_1^{(\lambda)}+\frac{\theta\big(c\,\eta/2+\lambda\big)}{\theta(\lambda)}\,t_2^{(\lambda)}\right\},$$

where $\lambda=x_1-x_2$. Here $c\in\mathbb{C}$ is the coupling constant, η is the relativistic deformation parameter, the θ function is given in (27); we have set $\hbar=1$. The Hamiltonian acts on a wave function as

$$\mathcal{H}\psi(\lambda)=\frac{\theta(c\,\eta/2-\lambda)}{\theta(-\lambda)}\,\psi(\lambda-\eta)+\frac{\theta(c\,\eta/2+\lambda)}{\theta(\lambda)}\,\psi(\lambda+\eta);$$

the $t_i^{(\lambda)}$ that appear in the Hamiltonian are hence shift operators in the variable λ; in the present case of two particles they generate a one-dimensional graph:

Relative to a fixed vertex λ the vertices of this graph are at points $\eta \cdot \mathbb{Z} \in \mathbb{R}$, the (ordered) paths connect neighboring vertices and are hence intervals in $\mathbb{R}$. There are two paths per interval, one in the positive and one in the negative direction.

Now consider an N-particle Ruijsenaars model: The graph relative to a fixed λ is then a $N-1$-dimensional hypercubic lattice. Relative to $\lambda \in \mathbb{R}^{N-1}$, the vertices are at points $(\eta \cdot \mathbb{Z})^{\times(N-1)}$. This picture can obviously be generalized, and in the following we shall consider an arbitrary ordered graph.

Remark: For the Ruijsenaars system λ can take any value in $\mathbb{R}^{N-1}$, so we are *a priori* let to a huge graph that consists of a continuous family of disconnected graphs. Since the graphs are disconnected, it is sufficient to consider one. Later, we will, in fact, write all expressions with respect to one fixed vertex λ. This will lead to equations containing explicit shifts on the graph and thus to dynamical R-matrices. Apart from the physical interpretation there is *a priori* no reason to restrict the values of particle coordinates at the level of the shift operator to $\mathbb{R}$. We can and shall everywhere in the following take $\mathbb{C}$ instead of $\mathbb{R}$.

A. Face algebras

The Hilbert space of the model will be built from vector spaces on paths of fixed length. As we shall argue in the following, the operators on this Hilbert space can be chosen to be elements of a Face Algebra F[1] (or weak C^*-Hopf algebras,[12,13] which is essentially the same with a*-structure).

There are two commuting projection operators e^i, $e_i \in F$ for each vertex of the graph (projectors onto bra's and ket's corresponding to vertex i):

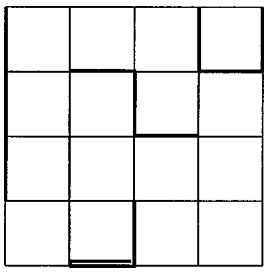
$$e_i e_j = \delta_{ij} e_i, \quad e^i e^j = \delta_{ij} e^i, \quad \Sigma e_i = \Sigma e^i = 1. \tag{1}$$

F shall be equipped with a coalgebra structure such that the combination $e^i_j \equiv e^i e_j = e_j e^i$ is a corepresentation:

$$\Delta(e^i_j) = \Sigma_k e^i_k \otimes e^k_j, \quad \epsilon(e^i_j) = \delta_{ij}. \tag{2}$$

It follows that $\Delta(1) = \Sigma_k e_k \otimes e^k \neq 1 \otimes 1$ (unless the graph has only a single vertex)—this is a key feature of face algebras (and weak C^*-Hopf algebras).

So far we have considered matrices with indices that are vertices, i.e., paths of length zero. In the given setting it is natural to also allow paths of fixed length on a finite oriented graph $\mathcal{G}$ as matrix indices. To illustrate this, here are some paths of length 3 on a graph that is a square lattice, e.g., on part of a graph corresponding to a particular Ruijsenaars system:



We shall use capital letters to label paths. A path P has an origin (source) $\cdot P$, an end (range) $P \cdot$, and a length $\sharp P$. Two paths Q, P can be concatenated to form a new path $Q \cdot P$, if the end of the first path coincides with the start of the second path, i.e., if $Q \cdot = \cdot P$ (this explains our choice of notation).

The important point is, that the symbols T^A_B, where $\sharp A=\sharp B\geqslant 0$, with relations

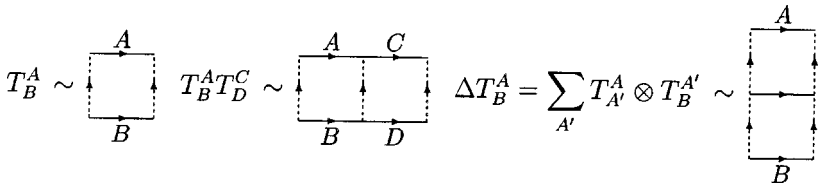
$$\Delta(T^A_B)=\sum_{A'} T^A_{A'}\otimes T^{A'}_B \quad (\sharp A=\sharp A'=\sharp B), \tag{3}$$

$$\epsilon(T^A_B)=\delta_{AB}, \tag{4}$$

$$T^A_B T^C_D=\delta_{A\cdot,\cdot C}\delta_{B\cdot,\cdot D}T^{A\cdot C}_{B\cdot D}, \tag{5}$$

span an object that obeys the axioms of a face algebra. Relations (3) and (4) make T^A_B a corepresentation; (5) is the rule for combining representations. The axioms of a face algebra can be found in Refs. 1, 14.

Pictorial representation:



The dashed paths indicate the F space(s); their orientation is from the lower to upper ''index.'' Inner paths are summed over.

Often it is convenient not to consider a particular representation, i.e., T matrices corresponding to paths of a given fixed length but rather an abstract, universal T. Heuristically one can think of the universal T as an abstract matrix or group element, but it does, in fact, simply provide an alternative to the usual Hopf algebra notation: T, $T_1\otimes T_1$, T_1T_2, e.g., correspond to the identity map, coproduct map, and multiplication map of F, respectively. (More details are given in the Appendix.) Keeping this in mind we shall—without loss of generality—nethertheless, use a formal notation that treats T as if it was the canonical element T_{12} of $U\otimes F$, where U is the dual of F via the pairing $\langle,\rangle$

$$\langle T,f\rangle=f, \quad \langle T_1\otimes T_1,f\rangle=\Delta f, \quad \langle T_1T_2,f\otimes g\rangle=fg; \quad f,g\in F.$$

Here and in the following, we shall frequently suppress the the second index of T; it corresponds to the F-space. The displayed expressions are short for $\langle T_{12},f\otimes \mathrm{id}\rangle=f\in F$, $\langle T_{12}T_{13},f\otimes \mathrm{id}\otimes \mathrm{id}\rangle=\Delta f\in F\otimes F$, and $\langle T_{13}T_{23},f\otimes g\otimes \mathrm{id}\rangle=fg\in F$.

A face *Hopf* algebra has an antialgebra and anticoalgebra endomorphism, called the antipode and denoted by S or—in the universal tensor formalism—by $\tilde{T}$: $\langle\tilde{T},f\rangle=S(f)$. The antipode satisfies some compatibility conditions with the coproduct that is given in the Appendix.

Remark: In the limit of a graph with a single vertex a face Hopf algebra is the same as a Hopf algebra. Ordinary matrix indices correspond to closed loops in that case.

B. Boltzmann weights

By dualization we can describe a coquasitriangular structure of F by giving a quasitriangular structure for U. The axioms[1] for a quasitriangular face algebra are similar to those of a quasitriangular Hopf algebra; there is a universal $R\in U\otimes U$ that controls the noncocommutativity of the coproduct in U and the noncommutativity of the product in F,

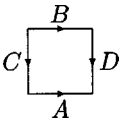
$$RT_1T_2=T_2T_1R, \quad \tilde{R}T_2T_1=T_1T_2\tilde{R}, \quad \tilde{R}\equiv(S\otimes \mathrm{id})(R), \tag{6}$$

however, the antipode of R is no longer the inverse of R, but rather

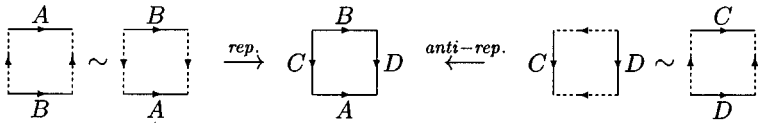
$$\tilde{R}R=\Delta(1), \quad R\tilde{R}=\Delta'(1). \tag{7}$$

The numerical ''R matrix'' obtained by contracting R with two face corepresentations is given by the face Boltzmann weight W:

$$\langle \mathcal{R}, T^A_B \otimes T^C_D \rangle = R^{AC}_{BD} \equiv W\left(C \begin{smallmatrix} B \\ A \end{smallmatrix} D\right) \sim$$



The pictorial representation makes sense since the Boltzmann weight is zero unless $C \cdot A$ and $B \cdot D$ are valid paths with a common source and range, as will be discussed in more detail below. Also note that $T^A_B \mapsto \langle \mathcal{R}, T^A_B \otimes T^C_D \rangle$ is a *representation* of the matrix elements of (T^A_B) while $T^C_D \mapsto \langle \mathcal{R}, T^A_B \otimes T^C_D \rangle$ is an *antirepresentation*. Consistent with our pictorial representation for the T matrices, we see that the orientation of the paths in F-space remain the same for the first case but are reversed for the latter:



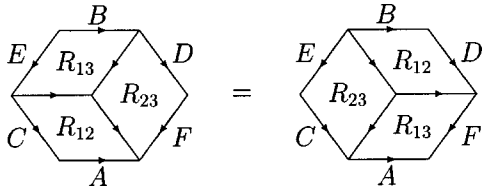
Definition: For $f \in F$ we can define two algebra homomorphisms $F \to U$:

$$R^+(f) = \langle R, f \otimes \mathrm{id} \rangle, \quad R^-(f) = \langle \tilde{R}, \mathrm{id} \otimes f \rangle. \tag{8}$$

Yang–Baxter Equation: As a consequence of the axioms of a quasitriangular face Hopf algebra, R satisfies the Yang–Baxter Equation,

$$R_{12} R_{13} R_{23} = R_{23} R_{13} R_{12} \in U \otimes U \otimes U. \tag{9}$$

Contracted with $T^A_B \otimes T^C_D \otimes T^E_F$, this expression yields a numerical Yang–Baxter equation with the following pictorial representation:[3]



The inner edges are paths that are summed over. Moving along the outer edges of the hexagon, we will later read of the shifts in the Yang–Baxter equation for dynamical R matrices.

So far we have argued heuristically that the Ruijsenaars system naturally leads to graphs and face algebras. The formal relation between face Hopf algebras and oriented graphs, it is established by a lemma of Hayashi (Lemma 3.1 of Ref. 14), which says that any right or left comodule M of a face Hopf algebra F decomposes in a natural way as a linear space to a direct sum $M = \oplus_{i,j} M_{ij}$, with indices i, j running over all vertices. So we can naturally associate paths from j to i to any pair of indices, such that $M_{ij} \neq \varnothing$. So we may speak (and we really do in the paper) of the vectors of a comodule or a module as of paths. As the dual object U to a face Hopf algebra is again a face Hopf algebra characterized by the same set of vertices,[14] the same applies to its comodules. It is convenient to choose the orientation of paths appearing in the decomposition of a comodule of U (and hence in the module of F) opposite to the convention that one uses in the case of F.

Particularly, we have for any matrix corepresentation T^A_B of F with symbols A, B used to label some linear basis in M, the linear span $\langle T^A_B \rangle$ of all T^A_B decomposes as linear space (bicomodule of the face Hopf algebra) as a direct sum,

$$\bigoplus_{i,j,k,l} \langle e^i e_j T^A_B e^k e_l \rangle = \langle T^A_B \rangle,$$

i.e., a sum over paths with fixed starting and ending vertices. The upper indices i and k fix the beginning and the end of the path A and the lower indices j and l fix the beginning and the end of the path B.

Let us assume that the matrix elements T^A_B of a corepresentation of F act in a module of paths that we shall label by greek characters α, β, etc. The definition of the dual face Hopf algebra implies that the matrix element $(T^A_B)^\alpha_\beta$ is nonzero only if $\cdot\alpha=\cdot B$, $\cdot A=\alpha\cdot$, $B\cdot=\cdot\beta$, and $A\cdot=\beta\cdot$, i.e., if paths $\alpha\cdot A$ and $B\cdot\beta$ have common starting and end points. This justifies the pictorial representation used in the paper. It also follows immediately that in the case of a coquasitriangular Face Hopf algebra $\langle\mathcal{R},T^A_B\otimes T^C_D\rangle=R^{AC}_{BD}\equiv W(\,{}^B_{C\,D}{}_A)$ is zero unless $\cdot C=\cdot B$, $B\cdot=\cdot D$, $C\cdot=\cdot A$, and $A\cdot=D\cdot$.

To make contact with the Ruijsenaars type of models, we have to assume that the (coquasitriangular) face Hopf algebra F is generated by the matrix elements of some fundamental corepresentation of it. We shall postulate the paths of the corresponding corepresentation to be of length 1. The paths belonging to the n-fold tensor product of the fundamental corepresentation are then, by definition, of length n. Taking an infinite tensor product of the fundamental corepresentation, we get a graph that corresponds to the one generated by the shift operators of the related integrable model.

In the next section we are going to formulate a quantum version of the so-called main theorem, which gives the solution by factorization of the Heisenberg equations of motion. For this construction F needs to have a coquasitriangular structure—this will also fix its algebra structure.

II. QUANTUM FACTORIZATION

The cocommutative functions in F are of particular interest to us since they form a set of mutually commutative operators. We shall pick a Hamiltonian from this set. Cocommutative means that the result of an application of comultiplication Δ is invariant under exchange of the two resulting factors. The typical example is a trace of the T matrix. The following theorem gives for the case of face Hopf algebras what has become known as the ''main theorem'' for the solution by factorization of the equations of motion.[15–19] The following theorem is a direct generalization of our previous results for Hopf algebras/Quantum Groups.[20,21]

Theorem 0.1 (the main theorem for face algebras)**:**

(i) The set of cocommutative functions, denoted I, is a commutative subalgebra of F.

(ii) The Heisenberg equations of motion defined by a Hamiltonian $\mathcal{H}\in I$ are of Lax form,

$$i\,\frac{dT}{dt}=[M^\pm,T], \tag{10}$$

with $M^\pm=1\otimes\mathcal{H}-m_\pm\in U_\pm\otimes F$, $m_\pm=R^\pm(\mathcal{H}_{(2)})\otimes\mathcal{H}_{(1)}$; see (8).

(iii) Let $g_\pm(t)\in U_\pm\otimes F$ be the solutions to the factorization problem,

$$g_-^{-1}(t)g_+(t)=\exp(it(m_+-m_-))\in U\otimes F; \tag{11}$$

then

$$T(t)=g_\pm(t)T(0)g_\pm(t)^{-1} \tag{12}$$

solves the Lax equation (10); $g_\pm(t)$ are given by

$$g_\pm(t)=\exp(-it(1\otimes h))\exp(it(1\otimes h-M^\pm(0))), \tag{13}$$

and are the solutions to the differential equation

$$i\,\frac{d}{dt}\,g_\pm(t)=M^\pm(t)g_\pm(t),\quad g_\pm(0)=1. \tag{14}$$

Proof: The proof is similar to the one given in Ref. 21 for factorizable quasitriangular Hopf algebras. Here we shall only emphasize the points that are different because we are now dealing with face algebras. An important relation that we shall use several times in the proof is

$$\Delta(1)T_1T_2=T_1T_2=T_1T_2\Delta(1). \tag{15}$$

[Note that the generalization is not trivial since now $\Delta(1)\neq1\otimes1$ in general.]

(i) Let $f,g\in I\subset F$; then $fg\in I$. Let us show that f and g commute:

$$fg=\langle T_1T_2,f\otimes g\rangle=\langle\Delta(1)T_1T_2,f\otimes g\rangle=\langle\tilde{R}RT_1T_2,f\otimes g\rangle=\langle\tilde{R}T_2T_1R,f\otimes g\rangle=\langle T_2T_1R\tilde{R},f\otimes g\rangle$$
$$=\langle T_2T_1\Delta'(1),f\otimes g\rangle=\langle T_2T_1,f\otimes g\rangle=gf.$$

[$\tilde{R}\equiv(S\otimes\mathrm{id})(R)$ can be commuted with T_2T_1R in the fifth step because f and g are both cocommutative.]

(ii) We need to show that $[R^{\pm}(\mathcal{H}_{(2)})\otimes\mathcal{H}_{(1)},T]=0$. This follows from the cocommutativity of $\mathcal{H}$ and (6):

$$\langle T_1R^{\pm}_{21}T_2,\mathcal{H}\otimes\mathrm{id}\rangle=\langle R^{\pm}_{21}T_1T_2,\mathcal{H}\otimes\mathrm{id}\rangle=\langle T_2T_1R^{\pm}_{21},\mathcal{H}\otimes\mathrm{id}\rangle.$$

(iii) We need to show that $[m_+,m_-]=0$; then the proof of Ref. 21 applies,

$$m_+m_-=\langle T_1R_{13}T_2\tilde{R}_{32},\mathcal{H}\otimes\mathcal{H}\otimes\mathrm{id}\rangle\equiv\langle T_1T_2R_{13}\tilde{R}_{32},\mathcal{H}\otimes\mathcal{H}\otimes\mathrm{id}\rangle=\langle\tilde{R}_{12}T_2T_1R_{12}R_{13}\tilde{R}_{32},\mathcal{H}\otimes\mathcal{H}\otimes\mathrm{id}\rangle$$
$$=\langle\tilde{R}_{12}T_2T_1\tilde{R}_{32}R_{13}R_{12},\mathcal{H}\otimes\mathcal{H}\otimes\mathrm{id}\rangle=\langle R_{12}\tilde{R}_{12}T_2T_1\tilde{R}_{32}R_{13},\mathcal{H}\otimes\mathcal{H}\otimes\mathrm{id}\rangle$$
$$=\langle\Delta'(1)T_2T_1\tilde{R}_{32}R_{13},\mathcal{H}\otimes\mathcal{H}\otimes\mathrm{id}\rangle=\langle T_2\tilde{R}_{32}T_1R_{13},\mathcal{H}\otimes\mathcal{H}\otimes\mathrm{id}\rangle=m_-m_+.$$

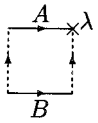
Remark: The objects in this theorem $[M^{\pm},m_{\pm},g_{\pm}(t),T(t)]$ can be interpreted (a) as elements of $U\otimes F$, (b) as maps $F\to F$, or (c) when a representation of U is considered, as matrices with F-valued matrix elements.

III. DYNAMICAL OPERATORS

In the main theorem we dealt with expressions that live in $U\otimes F$ (and should be understood as maps from F into itself). In this section we want to write expressions with respect to one fixed vertex. Like we mentioned in the Introduction, we are particularly interested in the action of the Hamiltonian with respect to a fixed vertex. Since the Hamiltonian is an element of F, we shall initially fix the vertex in this space; due to the definition of the dual face Hopf algebra U this will also fix a corresponding vertex in that space. We shall proceed as follows: We will fix a vertex in the T-matrix with the help of $e^{\lambda},e_{\lambda}\in F$ and will also introduce the corresponding universal $T(\lambda)$. Next, we will construct dynamical R matrices $R^{\pm}(\lambda)$ as $R^{\pm}(T(\lambda))$—this is an algebra homomorphism—and will give the Yang–Baxter and RTT equations with shifts as an illustration. Finally, we shall plug everything into the main theorem.

Convention for corepresentation T with respect to a fixed vertex: $T(\lambda)^A_B$ is zero unless the range (end) of path A is equal to the fixed vertex λ. Such a T will map the vector space spanned by vectors v^A with $A\cdot=\lambda$ fixed to itself. With the help of the projection operator $e^{\lambda}\in F$ we can give the following explicit expression:

$$T(\lambda)^A_B \;=\; T^A_B\,e^{\lambda} \quad\sim$$



(16)

The universal $T(\lambda)$ is an abstraction of this and is defined analogously,

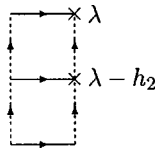
$$T_{12}(\lambda) \;=\; T_{12}\,(e^{\lambda})_2 \quad\sim$$

(17)

Coproducts of T: Expressions for the coproducts $\Delta_1T(\lambda)$ and $\Delta_2T(\lambda)$ follow either directly from the definition of $T(\lambda)$ or can be read of the corresponding pictorial representations.

(i) Coproduct in F-space:[2]

$$\Delta_2 T(\lambda) \;=\; T_{12}(\lambda)T_{13}(\lambda-h_2) \quad\sim\quad$$



(18)

The shift operator h in F-space that appears here is

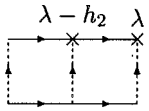
$$h_{(F)}=\sum_{\eta,\mu}\,(\mu-\eta)e^{\mu}_{\eta}\in F, \tag{19}$$

where we assume some appropriate (local) embedding of the vertices of the underlying graph in $\mathbb{C}^n$ so that the difference of vertices makes sense.

Proof: $\Delta_2 T_{12}(e^{\lambda})_2=\Sigma_{\eta}T_{12}T_{13}(e^{\lambda}_{\eta})_2(e^{\eta})_3=\Sigma_{\eta,\mu}T_{12}(e^{\lambda}e^{\mu})_2(e_{\eta})_2T_{13}(e^{\eta})_3=\Sigma_{\eta,\mu}T_{12}(\lambda)\times(e^{\mu}_{\eta})_2T_{13}(\lambda+\eta-\mu)=T_{12}(\lambda)T_{13}(\lambda-h_2)$. In the second and third step we used $e^{\lambda}e^{\mu}\propto\delta_{\lambda,\mu}$.

(ii) Coproduct in U-space (gives multiplication in F):

$$\Delta_1 T(\lambda) \;=\; T_{13}(\lambda-h_2)T_{23}(\lambda) \quad\sim\quad$$



(20)

This time we have a shift operator in U-space:

$$h_{(U)}=\sum_{\eta,\mu}\,(\mu-\eta)E_{\mu}E^{\eta}\in U. \tag{21}$$

The proof is a little more involved than the one given for the F-case above and uses $(e^{\eta})_2T_{12}=(E^{\eta})_1T_{12}$ and $T_{12}(e^{\mu})_2=(E_{\mu})_1T_{12}$, which follow from $T\tilde{T}T=T$, $\tilde{T}T\tilde{T}=\tilde{T}$ and $T\tilde{T}=\Sigma_{\xi}E^{\xi}\otimes e^{\xi}$.

Dynamical R-matrix: Using the fact that $f\mapsto R^{+}(f)\equiv\langle R,f\otimes\mathrm{id}\rangle$ is an algebra homomorphism, we define

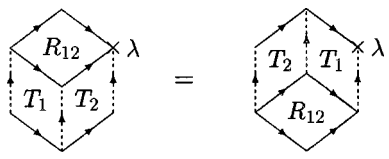
$$R_{12}(\lambda)\equiv\langle R,T_1(\lambda)\otimes T_2\rangle. \tag{22}$$

The numerical R-matrix is defined analogously: $R(\lambda)^{AC}_{BD}=\langle R,T(\lambda)^{A}_{B}\otimes T^{C}_{D}\rangle$. In the pictorial representation this fixes the one vertex of R that is only the end point to paths.

Dynamical RTT equation: From the coproduct $\Delta_1 T$ and $R\Delta(x)=\Delta'(x)R$ for all $x\in U$ follows:[2]

$$R_{12}(\lambda)T_1(\lambda-h_2)T_2(\lambda)=T_2(\lambda-h_1)T_1(\lambda)R_{12}(\lambda-h_3). \tag{23}$$

Pictorially,

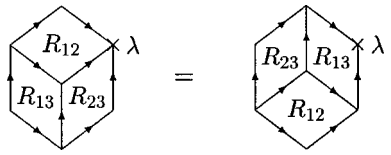


Shifts h_1,h_2 are in U-space, shift h_3 is in F-space. Twice contracted with R, the dynamical RTT-equation yields the dynamical Yang–Baxter equation:

Dynamical Yang–Baxter equation:[4]

$$R_{12}(\lambda)R_{13}(\lambda-h_2)R_{23}(\lambda)=R_{23}(\lambda-h_1)R_{13}(\lambda)R_{12}(\lambda-h_3). \tag{24}$$

Pictorially,



Hamiltonian and Lax operators in dynamical setting: The Hamiltonian $\mathcal{H}$ should be a cocommutative element of F. In the case of the Ruijsenaars model, it can be chosen to be the trace of a T-matrix, i.e., the U-trace of T in an appropriate representation ρ: $\mathcal{H}=\mathrm{tr}_1^{(\rho)}T_1$. This can be written as a sum over vertices λ of operators that act in the respective subspaces corresponding to paths ending in the vertex λ:

$$\mathcal{H}=\sum_{Q,\#Q\text{fixed}} T_Q^Q=\sum_{\lambda}\mathcal{H}(\lambda), \tag{25}$$

with $\mathcal{H}(\lambda)=\mathcal{H}e^{\lambda}=\Sigma T(\lambda)_Q^Q$. The pictorial representation of the Hamiltonian is two closed dashed paths (F-space) connected by paths Q of fixed length that are summed over. In $\mathcal{H}(\lambda)$, the end of path Q is fixed. When we look at a representation on Hilbert space, the paths Q with end point λ that appear in the component $\mathcal{H}(\lambda)$ of the Hamiltonian $\mathcal{H}$ will shift the argument of a state $\psi(\lambda)$ corresponding to the vertex λ to a new vertex, corresponding to the starting point of the path Q. In the next section we will see in detail how this construction is applied to the Ruijsenaars system. For this we will have to take a representation of the face Hopf algebra F. We shall then denote the resulting Lax operator by L. The Hamiltonian will contain a sum (coming from the trace) over shift operators.

For the Lax operators it is convenient to fix two vertices, λ and μ, corresponding to paths from μ to λ. (We did not need to do this for the Hamiltonian since it acts only on closed paths.) The T that appears in the Lax equation (10) becomes

$$T_{12}(\lambda,\mu)=T_{12}(e_\mu e^{\lambda})_2=(E_\lambda)_1T_{12}(E_\mu)_1;$$

it should be taken in some representation of F on the appropriate Hilbert space. On space U we are interested in a finite-dimensional representation that is going to give us matrices. Both is done in the next section and we shall call the resulting operator $L(\lambda,\mu)$. Similarly, we proceed with the other two Lax operators $M^{\pm}$:

$$M^{\pm}(\lambda,\mu)\equiv(E_\lambda\otimes 1)M^{\pm}(E_\mu\otimes 1)=E_\lambda\delta_{\lambda,\mu}\otimes\mathcal{H}-m_{\pm}(\lambda,\mu).$$

(Recall that $E_\lambda E_\mu=E_\lambda\delta_{\lambda,\mu}$.) If we define $M_{012}^{\pm}=T_{02}(1-R_{01}^{\pm})$, then $M_{12}^{\pm}=\langle M_{012}^{\pm},\mathcal{H}\otimes\mathrm{id}^2\rangle$ and we can write dynamical Lax equations in an obvious notation as

$$i\frac{dT(\lambda,\mu)}{dt}=\langle M_{012}^{\pm}(\lambda,\lambda-h_0)T_{12}(\lambda-h_0,\mu)-T_{12}(\lambda,\mu-h_0)M_{012}^{\pm}(\mu-h_0,\mu),\mathcal{H}\otimes\mathrm{id}^2\rangle, \tag{26}$$

where $h_0=\Sigma_{\alpha,\beta}(\alpha-\beta)E_\alpha^\beta$ is the shift operator in the space contracted by the Hamiltonian. If the Hamiltonian is a trace we shall find a sum over shifts.

Remark: There is another possible choice of conventions for the fixed vertex. We could have worked with $T_{12}\{\nu\}=(e_\nu)_2T_{12}$ instead of $T_{12}(\lambda)=T_{12}(e^{\lambda})_2$. This would have fixed the lower left vertex in the pictorial representation of T_B^A and the vertex that is *starting* point for all paths in $R\{\nu\}$. The dynamical equations would, of course, look a little different from the ones that we have given.

IV. THE LAX PAIR

Here we give as an example the Lax pair for the case of the N-particle quantum Ruijsenaars model. We may think of the face Hopf algebra F as of the elliptic quantum group associated to $sl(N)$ introduced by Felder.[2] We will continue to use the symbol F for it. In that case there is an additional spectral parameter entering all relations in the same way as it is in the case of ordinary quantum groups.

Let h be the Cartan subalgebra of $sl(N)$ and h^* its dual. The actual graph related to the elliptic quantum group F is $h^* \sim \mathbb{C}^{N-1}$. This is the huge graph of the remark made in the Introduction. However, it decomposes into a continuous family of disconnected graphs, each one isomorphic to $-\eta.\Lambda$, the $-\eta \in \mathbb{C}$ multiple of the weight lattice Λ of $sl(N)$, and we can restrict ourselves to this one component for simplicity. Correspondingly, the shifts in all formulas are rescaled by a factor $-\eta$. The space $h^* \sim \mathbb{C}^{N-1}$ itself will be considered as the orthogonal complement of $\mathbb{C}^N = \oplus_{i=1,\ldots,N} \mathbb{C}\varepsilon_i$, $\langle \varepsilon_i, \varepsilon_j \rangle = \delta_{ij}$ with respect to $\Sigma_{i=1,\ldots,N}\varepsilon_i$. We write the orthogonal projection $\epsilon_i = \varepsilon_i - 1/N \Sigma_k \varepsilon_k$ for the generator of h^*; $\langle \epsilon_i, \epsilon_j \rangle = \delta_{ij} - 1/N$. The points of the lattice $\eta.\Lambda$ will be denoted by greek characters λ, μ, etc.

The elliptic quantum group is defined by the matrix elements of the ''fundamental corepresentation.'' This is described with the help of the paths of length 1 in the following way: Let us associate a one-dimensional linear space $V_{\rho,\lambda} \sim \mathbb{C}\eta.\epsilon_k$ and a corresponding path of length 1 to any pair $\lambda, \rho \in \eta.\Lambda$, such that $\rho - \lambda = \eta\epsilon_k$, for some $k = 1,\ldots,N$. We let $V_{\rho,\lambda} = \varnothing$ for all other pairs of vertices. The vector space V of the fundamental corepresentation is formed by all paths of length 1,

$$V = \bigoplus_{\lambda,\rho} V_{\rho,\lambda} \quad \sim \quad \bigoplus_{\lambda,\rho} \rho \longleftarrow \lambda \quad = \quad \bigoplus_{\lambda,i} \lambda + \eta\epsilon_i \longleftarrow \lambda$$

As all spaces $V_{\rho,\lambda}$ are at most one dimensional, we can characterize the numerical R-matrix R^{AC}_{BD} in the fundamental corepresentation by just four indices referring to the vertices of the ''square'' defined by paths A,B,C,D in the case of nonzero matrix element R^{AC}_{BD}. Let us set $\cdot B = \cdot C = \nu$, $\cdot D = B\cdot = \mu$, $D\cdot = A\cdot = \lambda$ and $\cdot A = C\cdot = \rho$, and also

$$R^{AC}_{BD} = W\left(C \begin{matrix} B \\ A \end{matrix} D\right) \equiv W\begin{pmatrix} \nu & \mu \\ \rho & \lambda \end{pmatrix} \quad \sim \quad \begin{array}{ccc} \nu & \longrightarrow & \mu \\ \uparrow & & \downarrow \\ \rho & \longrightarrow & \lambda \end{array}.$$

Then the nonzero Boltzmann weights as given by Ref. 22 are ($i \neq j$)

$$W\begin{pmatrix} \lambda + 2\eta\epsilon_i & \lambda + \eta\epsilon_i \\ \lambda + \eta\epsilon_i & \lambda \end{pmatrix} \Big| u = 1 \quad \sim \quad \Longrightarrow \lambda,$$

$$W\begin{pmatrix} \lambda + \eta(\epsilon_i + \epsilon_j) & \lambda + \eta\epsilon_i \\ \lambda + \eta\epsilon_i & \lambda \end{pmatrix} \Big| u = \frac{\theta(\eta)\theta(-u + \lambda_{ij})}{\theta(u + \eta)\theta(\lambda_{ij})} \quad \sim \quad \begin{array}{cc} \Downarrow & \\ \Longrightarrow & \lambda \end{array},$$

and

$$W\begin{pmatrix} \lambda + \eta(\epsilon_i + \epsilon_j) & \lambda + \eta\epsilon_j \\ \lambda + \eta\epsilon_i & \lambda \end{pmatrix} \Big| u = \frac{\theta(u)\theta(\eta + \lambda_{ij})}{\theta(u + \eta)\theta(\lambda_{ij})} \quad \sim \quad \begin{array}{cc} \rightarrow & \\ \square & \\ & \lambda \end{array}.$$

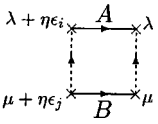
Here $\lambda_{ij} \equiv \lambda_i - \lambda_j = \langle \lambda, \epsilon_i - \epsilon_j \rangle$, $\theta(u)$ is the Jacobi theta function,

$$\theta(u) = \sum_{j \in \mathbb{Z}} e^{\pi i (j+1/2)^2 \tau + 2\pi i (j+1/2)(u+1/2)}, \tag{27}$$

$u \in \mathbb{C}$ is the spectral parameter, and τ is the elliptic modulus parameter. The matrix element $T^A_B(\lambda|u)$ (now depending also on the spectral parameter u, which also enters all previous expressions in the standard way) in the fundamental corepresentation, is also uniquely determined by the value of the vertices that fix the length-1 paths A and B. Let us use the following notation for it

$(i,j=1,...,N)$:

$$T_B^A(\lambda|u)=\sum_\mu L_j^i(\mu,\lambda|u)e_\mu \quad \sim$$



where $\mu=B\cdot$, $\lambda=A\cdot$, $\mu+\eta\epsilon_j=\cdot B$, $\lambda+\eta\epsilon_i=\cdot A$.

As the lattice $\eta.\Lambda$ that we consider is just one connected component of a continuous family of disconnected graphs, the vertices $\lambda,\mu,...$, are allowed to take any values in $\mathbb{C}^{(N-1)}$. This will be assumed implicitly in the rest of this section. Now we need to specify the appropriate representation of F that can be read from Ref. 7. We can characterize it by its path decomposition. To any pair of vertices λ, μ we associate a one-dimensional vector space $\tilde{V}_{\lambda,\mu}\sim\mathbb{C}$ (the path from μ to λ). The representation space $\tilde{V}$ is then

$$\tilde{V}=\bigoplus_{\lambda,\mu\in h^*}\tilde{V}_{\lambda,\mu}.$$

The matrix element $T_B^A(\lambda)\equiv L_j^i(\lambda,\mu|u)$ for fixed A, B and hence also with fixed i,j,λ,μ is obviously nonzero only if restricted to act from $\tilde{V}_{\lambda,\mu}$ to $\tilde{V}_{\lambda+\eta\epsilon_i,\mu+\eta\epsilon_j}$, in which case it acts as multiplication by

$$L_j^i(\lambda,\mu|u)=\frac{\theta\big(c\,\eta/N+u+\lambda_i-\mu_j\big)}{\theta(u)}\prod_{k\neq i}\frac{\theta\big(c\,\eta/N+\lambda_k-\mu_j\big)}{\theta(\lambda_k-\lambda_i)}. \tag{28}$$

Here we used notation $\lambda_i=\langle\lambda,\epsilon_i\rangle$ for $\lambda\in h^*$. $c\in\mathbb{C}$ will play the role of the coupling constant.

The Hamiltonian is chosen in accordance with Sec. III as $\mathcal{H}=\Sigma_P T_P^P$, i.e., the trace in the ''fundamental'' corepresentation. In accordance with the discussion of the previous sections, it is nonzero only when acting on the diagonal subspace (closed paths),

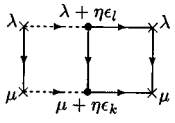
$$H=\bigoplus_{\lambda\in h^*}H_\lambda\equiv\bigoplus_{\lambda\in h^*}\tilde{V}_{\lambda,\lambda},$$

of $\tilde{V}$. So this is the actual state space of the integrable system under consideration. The Lax operator $M^\pm$ acts from $\tilde{V}_{\lambda,\mu}$ to $\tilde{V}_{\lambda+\eta\epsilon_i,\mu+\eta\epsilon_j}$ as multiplication by $M_k^{\pm l}(\lambda,\mu|u,v)=(1\otimes\mathcal{H})_k^l(\lambda,\mu|v)-m_{\pm k}^l(\lambda,\mu|u,v)$ with

$$(1\otimes\mathcal{H})_k^l(\lambda,\mu|v)=\delta_{\lambda,\mu}\delta_k^l\frac{\theta\big(c\,\eta/N+v\big)}{\theta(v)}\prod_{j'\neq i}\frac{\theta\big(c\,\eta/N+\lambda_{j',i}\big)}{\theta(\lambda_{j',i})}, \tag{29}$$

$$m_k^{+l}(\lambda,\mu|u,v)=\delta_{\epsilon_i+\epsilon_k,\epsilon_j+\epsilon_l}\delta_{\lambda,\mu+\eta\epsilon_j}\sum_{i,j}L_j^i(\mu+\eta\epsilon_k,\ \mu|v)W\left(\begin{matrix}\lambda+\eta\epsilon_l & \lambda\\ \mu+\eta\epsilon_k & \mu\end{matrix}\middle|v-u\right) \tag{30}$$

$$\sim$$



m^- is given by a similar formula with the inverse Boltzmann weight.

Dynamical Lax Equation:

$$i\frac{dL_k^i(\lambda,\mu|u)}{dt}=\sum_{j,\nu}M_j^{\pm i}(\lambda,\nu|u,v)L_k^j(\nu,\mu|u)-L_j^i(\lambda,\nu|u)M_k^{\pm j}(\nu,\mu|u,v).$$

The Hamiltonian $\mathcal{H}$ maps the component $H_\lambda \sim \mathbb{C}.|\lambda\rangle$ into the component $H_{\lambda+\eta\epsilon_i} \sim \mathbb{C}.|\lambda + \eta\epsilon_i\rangle$. Obviously, $\tilde{V}$ can be understood as the complex vector space of all functions in λ, μ as well as H can be understood as the complex vector space of all functions in λ. In that case the Hamiltonian $\mathcal{H}$ given by (29) is proportional to a difference operator in variable $\lambda \in h^*$,

$$\mathcal{H} \propto \sum_i t_i^{(\lambda)} \prod_{j \neq i} \frac{\theta(c\,\eta/N + \lambda_{j,i})}{\theta(\lambda_{j,i})}, \tag{31}$$

where $t_i^{(\lambda)}$ has an obvious meaning of the shift operator by $-\eta\epsilon_i$ in the variable λ. This is equivalent[23] to the Ruijsenaars Hamiltonian.[6] It follows from Ref. 7 that in the same way we can obtain the higher-order Hamiltonians concerning traces in properly fused ''fundamental representations.''

APPENDIX: UNIVERSAL *T*

For many reasons it is very convenient to use a formalism based on the so-called universal T. The expressions formally resemble those in a matrix representation but give, nevertheless, general face Hopf algebra statements. This greatly simplifies notation but also the interpretation and application of the resulting expressions. When we are dealing with quantizations of the functions on a group, we need to keep track both of the noncommutativity of the quantized functions and the residue of the underlying group structure. Both these structures can be encoded in algebraic relations for the universal T, which easily allows us to control two noncommutative structures. In fact, T can be regarded as a universal group element. Universal tensor expressions can *formally* be read in two ways: Either as ''group'' operations (or rather operations in U) or as the corresponding pull-back maps in the dual space. This simplifies the heuristics of ''dualizing and reversing arrows'' and allows us to keep track of the classical limit. Example: Multiplication in U, $x \otimes y \mapsto xy$: The corresponding pull-back map in the dual space F is the coproduct Δ. Both operations are summarized in the same universal expression $T_{12}T_{13}$.

Sometimes T can be realized as the canonical element $U \otimes F$, but we do not need to limit ourselves to these cases and will instead define T as the identity map from F to itself and will use the same symbol for the identity map $U \to U$.

For the application of this identity map to an element of F we shall nevertheless use the same bracket notation as we would for a true canonical element in the finite case, i.e., $f \equiv \langle \mathrm{id}, f\rangle = \langle T_{12}, f \otimes \mathrm{id}\rangle$. This notation is very convenient—like inserting the unity in quantum mechanics. The identity map on a product is given by $ab \mapsto a \cdot b$ or

$$\langle T_{12}, ab \otimes \mathrm{id}\rangle = \langle T_{13}T_{23}, a \otimes b \otimes \mathrm{id}\rangle = a \cdot b.$$

We shall write $\Delta_1 T_{12} = T_{13}T_{23}$ to express this fact—this is hence the universal-T notation for the multiplication map in F (and the coproduct map in U). The coproduct map in F (multiplication map in U) is $T_{12}T_{13}$:

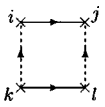
$$f \mapsto \langle T_{12}T_{13}, f \otimes \mathrm{id} \otimes \mathrm{id}\rangle = \Delta(f).$$

The antipode map is $\tilde{T}: f \mapsto S(f)$, the contraction map $x \otimes 1$ with $x \in U = F^*$ maps $f \in F$ to $1\langle x, f\rangle$, the counit map is $1 \otimes 1$, etc. For face algebras the counit is not an algebra homomorphism, but rather $\Delta 1_F = \Sigma_k e_k \otimes e^k$ and $\Delta 1_U = \Sigma_k E_k \otimes E^k$, where $\langle E_k, f\rangle = \epsilon(fe_k)$ and $\langle E^k, f\rangle = \epsilon(e^k f)$. Therefore $\epsilon(ab) = \Sigma_k \epsilon(ae_k)\epsilon(e^k b)$. This is one of the face algebra axioms. It differs from the corresponding ordinary Hopf algebra axiom [there: $\epsilon(ab) = \epsilon(a)\epsilon(b)$]. Some important relations involving the coproduct and antipode maps are

$$\tilde{T}T = \sum_i E_i \otimes e_i, \quad T\tilde{T} = \sum_i E^i \otimes e^i, \quad \tilde{T}T\tilde{T} = \tilde{T}, \quad T\tilde{T}T = T.$$

In the pictorial representation these relations imply that the vertices of the paths in U and F that form T match to give a closed ''square.'' They also give us two ways to fix the four vertices of T:

$$(1\otimes e^i_k)T(1\otimes e^j_l) \;=\; (E^i_j\otimes 1)T(E^k_l\otimes 1) \quad \sim$$



Further useful relations can be obtained from this by summing over some of the indices and using $\Sigma_i e^i_j = e_j$, $\Sigma_j e_j = 1$, etc.

On infravacua and superselection theory

Walter Kunhardt[a)]
Institut für Theoretische Physik der Universität Göttingen, Bunsenstrasse 9, 37073 Göttingen, Germany

(Received 9 September 1997; accepted for publication 18 March 1998)

In the Doplicher, Haag, and Roberts theory of superselection sectors, one usually considers states which are local excitations of some vacuum state. Here, we extend this analysis to local excitations of a class of ''infravacuum'' states appearing in models with massless particles. We show that the corresponding superselection structure, the statistics of superselection sectors and the energy-momentum spectrum are the same as with respect to the vacuum state. (The latter result is obtained with a novel method of expressing the shape of the spectrum in terms of properties of local charge transfer cocycles.) These findings provide evidence to the effect that infravacua are a natural starting point for the analysis of the superselection structure in theories with long-range forces. © *1998 American Institute of Physics.* [S0022-2488(98)01107-4]

I. INTRODUCTION

The description of the superselection structure of theories with long-range interactions such as quantum electrodynamics (QED) is a long-standing problem in the algebraic approach to quantum field theory. As a characteristic feature, such theories contain charges which obey Gauss's law and thus do not fit into the framework of superselection sectors as described by Doplicher, Haag, and Roberts.[1]

Focusing (mainly for definiteness) on QED, Gauss's law has the following three consequences: First, since every charge is accompanied by an electromagnetic field, an operator ψ_c which describes the creation of an electric charge in a gauge-invariant way in the ''physical'' Hilbert space, cannot be local. There is, however, the possibility of localizing the charge and (the Cauchy data of) its field in a spacelike cone $\mathscr{C}$ (as a simple example of a region extending to spacelike infinity). In this case, the charge cannot be detected by measurements in the spacelike complement $\mathscr{C}'$ of that cone.

Second, the configuration of the asymptotic electric flux at spacelike infinity is a classical observable whose values label an uncountable number of superselection sectors in the physical Hilbert space. Among these is the vacuum sector, but also the sector generated from the vacuum by the operator ψ_c. The former is identified with the vacuum representation π_0 of the observables, the latter with the representation $\pi_0 \circ \gamma_{\mathscr{C}}$, where $\gamma_{\mathscr{C}} \equiv \mathrm{Ad}\psi_c^*$. Obviously, the spacelike direction of $\mathscr{C}$ can be determined by measurements of the asymptotic flux distribution in the sector $\pi_0 \circ \gamma_{\mathscr{C}}$. This implies that the representations π_0 and $\pi_0 \circ \gamma_{\mathscr{C}}$, equal by construction when restricted to $\mathscr{C}'$, will not be equivalent in restriction to the spacelike complement $\mathscr{C}_1'$ of some arbitrary spacelike cone $\mathscr{C}_1$.

Third, Gauss's law lies at the origin of what is called the infraparticle problem: electrons are infraparticles, i.e., they do not correspond to eigenvalues of the mass operator. The physical picture for this is that every electron is accompanied by a cloud of low-energy photons. Related to this is the emission of bremsstrahlung in collisions of charged particles. The creation of infinitely many photons in such a process manifests itself on the mathematical side in the fact that the representations of the incoming and the outgoing free photon fields cannot both be Fock representations. However, this does not preclude that both representations can be equivalent, as is indeed the case for certain representations constructed by Kraus, Polley, and Reents.[2] Therefore these so-called KPR representations are interpreted as a background radiation field which is

a)Electronic mail: kunhardt@theorie.physik.uni-goettingen.de

 © 1998 American Institute of Physics

sufficiently chaotic in the sense that the addition of bremsstrahlung only amounts to a slight perturbation of them.

Motivated by this picture, Buchholz has pointed out in Ref. 3 that in front of such a background the spacelike direction of the localization cone $\mathscr{C}$ of ψ_c should not be detectable any more. In mathematical terms, the representations π_I and $\pi_I \circ \gamma_{\mathscr{C}}$ (where π_I corresponds to the KPR-like background) are expected to satisfy the so-called BF (Buchholz–Fredenhagen) criterion, i.e., they should become unitarily equivalent in restriction to the spacelike complement of *any* spacelike cone $\mathscr{C}_1$, in contrast to the situation prevailing in front of the vacuum.

Thus, trading the vacuum π_0 for a background π_I is expected to lead to an important improvement of the localizability properties of the charged states and should therefore permit one to carry through the BF variant of the Doplicher, Haag, and Roberts (DHR) analysis[4,5] in this case too.

In this perspective, the aim of the present contribution is to provide a consistency check of these ideas for the case of (massless) theories with DHR-like charges. We will show that in such theories, a DHR analysis can be based on a wide class of background representations π_I and that the main results of this analysis are invariant with respect to the choice of that background. More importantly, also the sets of sectors satisfying Borchers's criterion are invariant.

These results provide a justification for viewing such representations as a background and corroborate the hope that, in theories with long-range interactions, the superselection structure may indeed be described more easily in relation to such a background rather than to the vacuum. Recent results[6] obtained in the framework of the simple model of Ref. 7 also point into this direction.

We end this introduction by explaining the main assumptions and some notation. The starting point of the following analysis will be a quantum field theory given in its vacuum representation. More specifically, let $(\mathscr{H}_0, U_0, \Omega_0)$ be a vacuum Hilbert space, that is a Hilbert space $\mathscr{H}_0$ which carries a strongly continuous unitary representation U_0 of the translation group $\mathbf{R}^{1+s}$ (of $(1+s)$-dimensional Minkowski space, also denoted by $\mathbf{R}^{1+s}$) whose spectrum is contained in the forward lightcone $\overline{\mathbf{V}_+} \subset \mathbf{R}^{1+s}$ and such that the translation invariant subspace of $\mathscr{H}_0$ is spanned by a single unit vector Ω_0. Assume further that we are given a Haag–Kastler net

$$\mathscr{O} \mapsto \mathscr{A}(\mathscr{O})$$

of von Neumann algebras on $\mathscr{H}_0$, i.e., an isotonous mapping from the bounded regions $\mathscr{O} \subset \mathbf{R}^{1+s}$ to the von Neumann subalgebras of $\mathscr{B}(\mathscr{H}_0)$ which satisfies locality [i.e., $\mathscr{A}(\mathscr{O}_1) \subset \mathscr{A}(\mathscr{O}_2)'$ if $\mathscr{O}_1 \subset \mathscr{O}_2'$, in standard notation], translation covariance with respect to $\alpha_x := \mathrm{Ad}U_0(x)$ [i.e., $\alpha_x(\mathscr{A}(\mathscr{O})) = \mathscr{A}(\mathscr{O}+x)$] and weak additivity. The quasilocal algebra $\overline{\cup_{\mathscr{O}} \mathscr{A}(\mathscr{O})}^{\|\cdot\|}$ is also denoted by $\mathscr{A}$ and is assumed to act irreducibly. It will be of crucial importance later on that one can conclude from these assumptions that the net $\mathscr{A}$ has Borchers's property B and that the C^*-algebra $\mathscr{A}$ is simple.[8] (These conclusions do not, in fact, rely on the existence and/or uniqueness of the vacuum vector Ω_0.)

It is customary to introduce the following notations at this point: the identical representation $\pi_0 : \mathscr{A} \to \mathscr{B}(\mathscr{H}_0)$ is called the vacuum representation; it is the Gel'fand–Naïmark–Segal (GNS) representation of the vacuum state $\omega_0 = (\Omega_0, \cdot\, \Omega_0)$. The spectral family associated with the translations U_0 is denoted by E_0.

II. ENERGY COMPONENTS

In this section, we will present certain folia of states, namely energy components of positive energy representations. This notion has been introduced by Borchers and Buchholz[9] and discussed further by Wanzenberg.[10] We begin this section by recalling some details which are relevant in the present context.

For the whole of this section, let $(\mathscr{H}, \pi)$ be a positive energy representation of $(\mathscr{A}, \alpha)$. This means that there exists, on the Hilbert space $\mathscr{H}$, a strongly continuous representation U_π of the translations such that

$$\pi \circ \alpha_x = \mathrm{Ad}U_\pi(x) \circ \pi, \quad \mathrm{sp}U_\pi \subset \overline{\mathbf{V}_+}.$$

It is then known[11] that the operators $U_\pi(x)$ can be chosen such that $U_\pi(x) \in \pi(\mathcal{A})''$, and it is a remarkable fact[9] that there is a unique choice for which, on any subspace $\mathcal{H}' \subset \mathcal{H}$ which is invariant under $\pi(\mathcal{A})$, the spectrum $\mathrm{sp}U_\pi|_{\mathcal{H}'}$ has Lorentz-invariant lower boundary. From now on, U_π will always denote this canonical implementation of the translations and E_π the associated spectral family.

The notion of energy contents of π-normal states can now be introduced. To this end, denote by

$$\mathcal{S}_\pi(\Delta) := \{\mathrm{tr}\rho\pi(\cdot) | \rho \in \mathcal{T}_1(\mathcal{H}), \quad \rho \geqslant 0, \quad \mathrm{tr}\rho = 1, \quad \rho E_\pi(\Delta) = \rho\}$$

the set of all π-normal states which have energy-momentum in Δ. [In the present and in the next section, Δ always stands for a compact subset of $\overline{\mathbf{V}_+}$. Moreover, we will use the notation $\Delta_q := \overline{\mathbf{V}_+} \cap (q - \overline{\mathbf{V}_+})$ for the double cone in momentum space with apices 0 and $q \in \mathbf{V}_+$.] Then $\mathcal{S}_\pi = \cup_\Delta \mathcal{S}_\pi(\Delta)^{\|\cdot\|}$ is just the folium of π. Another set $\tilde{\mathcal{S}}_\pi$ of states, called the *energy component* of π, is defined by

$$\tilde{\mathcal{S}}_\pi := \overline{\cup_\Delta \tilde{\mathcal{S}}_\pi(\Delta)}^{\|\cdot\|},$$

where $\tilde{\mathcal{S}}_\pi(\Delta)$ denotes the set of all locally π-normal states in the weak closure of $\mathcal{S}_\pi(\Delta)$. Of course, $\mathcal{S}_\pi \subset \tilde{\mathcal{S}}_\pi$, and one can show that $\tilde{\mathcal{S}}_\pi$ is a folium, too. Physically, it is interpreted as the set of states which can be reached from the folium of π by operations requiring only a finite amount of energy. Some important properties of the elements of $\tilde{\mathcal{S}}_\pi$ are collected in the following Lemma, parts 2 and 3 of which are due to Wanzenberg.[10]

Lemma 2.1: Let $\omega \in \tilde{\mathcal{S}}_\pi$ and denote by $(\mathcal{H}_\omega, \pi_\omega, \Omega_\omega)$ its GNS triple.

(1) Then $(\mathcal{H}_\omega, \pi_\omega)$ is a locally π-normal positive energy representation of $(\mathcal{A}, \alpha)$.
(2) Moreover, if $\omega \in \tilde{\mathcal{S}}_\pi(\Delta_q)$ for some $q \in \mathbf{V}_+$, then one has $\Omega_\omega \in E_{\pi_\omega}(\Delta_q)\mathcal{H}_\omega$.
(3) In the situation of 2, one has $\tilde{\mathcal{S}}_{\pi_\omega}(\Delta) \subset \tilde{\mathcal{S}}_\pi(\Delta + \Delta_q - \Delta_q)$ for any Δ.

Proof: Using the positivity of the energy in the representation π, part 1 follows from the fact that ω is locally π-normal by arguments similar to those in Ref. 12. (In Ref. 12, these arguments are only applied to states $\omega \in \tilde{\mathcal{S}}_\pi(\Delta_q)$, but they carry over to norm limits of such states as well.)

For simplicity, part 2 will only be proved in the case that π_ω is factorial. For the general case, see Ref. 10. Let Δ_q be given. Then the idea is to show that Ω_ω does not have momentum outside Δ_q. To this end, fix some $p \in \overline{\mathbf{V}_+} \setminus \Delta_q$ and choose a neighborhood $\mathcal{N}_p \subset \overline{\mathbf{V}_+} \setminus \Delta_q$ of p and an open set $\mathcal{N} \subset \mathrm{sp}U_{\pi_\omega}$ such that

$$(\Delta_q + \mathcal{N} - \mathcal{N}_p) \cap \overline{\mathbf{V}_+} = \varnothing.$$

(Such a choice is always possible because the lower boundary of $\mathrm{sp}U_{\pi_\omega}$ is Lorentz invariant.) Now choose a test function f satisfying $\mathrm{supp}\, \tilde{f} \subset \mathcal{N} - \mathcal{N}_p$ and take an arbitrary $A \in \mathcal{A}$. Then, $A(f) := \int dx f(x) \alpha_x(A)$ is an element of $\mathcal{A}$ and satisfies $\pi(A(f))E_\pi(\Delta_q)\mathcal{H}_\pi = \{0\}$. Since $\omega \in \tilde{\mathcal{S}}_\pi(\Delta_q)$, this implies $\omega(A(f)^* A(f)) = 0$, hence $\pi_\omega(A(f))\Omega_\omega = 0$. This means that Ω_ω is orthogonal to

$$\mathcal{D} := \mathrm{span}\{\pi_\omega(A(f))^* \Psi | \Psi \in \mathcal{H}_\omega, A \in \mathcal{A}, \mathrm{supp}\, \tilde{f} \subset \mathcal{N} - \mathcal{N}_p\}.$$

Since π_ω is factorial and $\mathcal{N} - \mathcal{N}_p$ is open, it follows by an argument explained in Ref. 4 (see, in particular, the proof of Prop. 2.2 therein) that the closure of $\mathcal{D}$ equals $E_{\pi_\omega}(\mathrm{sp}U_{\pi_\omega} + \mathcal{N}_p - \mathcal{N})\mathcal{H}_\omega$. Thus, $\Omega_\omega \in \mathcal{D}^\perp$ yields

$$\{\Omega_\omega\}^\perp \supset \mathcal{D}^{\perp\perp} = \overline{\mathcal{D}} = E_{\pi_\omega}(\mathrm{sp}U_{\pi_\omega} + \mathcal{N}_p - \mathcal{N})\mathcal{H}_\omega \supset E_{\pi_\omega}(\mathcal{N}_p)\mathcal{H}_\omega,$$

where the last inclusion holds because $\mathrm{sp}U_{\pi_\omega} - \mathcal{N} \ni 0$. From this, we get $E_{\pi_\omega}(\mathcal{N}_p)\Omega_\omega = 0$ or, as $p \in \overline{\mathbf{V}_+} \setminus \Delta_q$ was arbitrary, $\Omega_\omega \in E_{\pi_\omega}(\Delta_q)\mathcal{H}_\omega$.

To prove part 3, let $\Psi \in E_{\pi_\omega}(\Delta)\mathscr{H}_\omega$. Part 2 and the cyclicity of Ω_ω imply that there exists in $\mathscr{A}$ a sequence $(A_n)_{n\in\mathbf{N}}$ of operators with energy-momentum support in $\Delta-\Delta_q$ such that $\Psi = \lim_{n\to\infty}\pi_\omega(A_n)\Omega_\omega$. From $\omega \in \widetilde{\mathscr{S}}_\pi(\Delta_q)$ follows $\omega(A_n^*\cdot A_n)\in\widetilde{\mathscr{S}}_\pi(\Delta_q+(\Delta-\Delta_q))=\widetilde{\mathscr{S}}_\pi(\Delta+\Delta_q-\Delta_q)$, i.e.,

$$\langle\Psi,\pi_\omega(\cdot)\Psi\rangle = \lim_{n\to\infty}\omega(A_n^*\cdot A_n)\in\widetilde{\mathscr{S}}_\pi(\Delta+\Delta_q-\Delta_q).$$

Thus any vector state from $\mathscr{S}_{\pi_\omega}(\Delta)$ lies in $\widetilde{\mathscr{S}}_\pi(\Delta+\Delta_q-\Delta_q)$. One now gets the assertion by taking convex combinations, norm limits and locally normal w^* limits. ■

The preceding lemma has shown that positivity of the energy is a property which ''survives'' the process of going from the representation π to the GNS representation of a state in $\widetilde{\mathscr{S}}_\pi$. Other properties survive as well, as for instance the compactness condition $C_\sharp$ of Fredenhagen and Hertel[13,14] which can be formulated as follows:

Definition: Condition $C_\sharp$ is said to be satisfied in the (positive energy) representation π if, for any Δ and any bounded region $\mathscr{O}\subset\mathbf{R}^{1+s}$, the set

$$\mathscr{S}_\pi(\Delta)|_{\mathscr{A}(\mathscr{O})}\equiv\{\omega|_{\mathscr{A}(\mathscr{O})}|\,\omega\in\mathscr{S}_\pi(\Delta)\}$$

is contained in a $\|\cdot\|$-compact subset of $\mathscr{A}(\mathscr{O})^*$.

This condition controls the infrared properties of the model under consideration, cf. Ref. 14. It has been established in the theory of a massive free particle (in any space-time dimension) and in the theory of a massless (scalar or vector) particle in at least $1+3$ space-time dimensions[15,14] and is believed to hold in QED as well. In the present context, it will play a technical role in the proof of Theorem 3.2 since it allows (by part 1 of the following lemma) a simplification in the definition of $\widetilde{\mathscr{S}}_\pi(\Delta)$ given above.

Lemma 2.2: Let $C_\sharp$ be satisfied in the representation π and let ω be a state in the weak closure of $\mathscr{S}_\pi(\Delta)$. Then

(1) ω is locally π-normal, i.e., $\omega\in\widetilde{\mathscr{S}}_\pi(\Delta)$;

(2) $C_\sharp$ is satisfied in the GNS representation of ω.

Proof: Both parts follow from the fact that, in restriction to $\mathscr{A}(\mathscr{O})$, any w^* limit of $\mathscr{S}_\pi(\Delta)$ is, as a consequence of $C_\sharp$, even a $\|\cdot\|$-limit of $\mathscr{S}_\pi(\Delta)$. Part 1 now follows directly. For part 2, we note that the above fact implies $\widetilde{\mathscr{S}}_\pi(\Delta)|_{\mathscr{A}(\mathscr{O})}\subset\overline{\mathscr{S}_\pi(\Delta)|_{\mathscr{A}(\mathscr{O})}}^{\|\cdot\|}$, which, in view of Lemma 2.1(3) yields the assertion. ■

III. INFRAVACUUM REPRESENTATIONS

Intuitively, an infrared cloud (in QED) can be split, given any energy threshold $\epsilon>0$, into a finite number N_ϵ of ''hard'' photons and infinitely many ''soft'' photons whose total energy is less than ϵ. As the creation of hard photons can be described by a quasilocal operation, this picture motivates the following mathematical notion.

Definition: An irreducible representation $(\mathscr{H}_I,\pi_I)$ of $\mathscr{A}$ is called an *infravacuum representation* if, for any $q\in\mathbf{V}_+$, the set $\widetilde{\mathscr{S}}_{\pi_0}(\Delta_q)$ contains some π_I-normal state.

With any arbitrarily small amount of energy, one can thus create from the vacuum representation some state in an infravacuum representation. In the terms of Ref. 10, this means that the transition energy between the sectors π_0 and π_I vanishes (cf. Theorem 3.2 below). As an example for infravacuum representations, we mention the KPR representations, i.e., a class of non-Fock representations (of the free asymptotic electromagnetic field) devised by Kraus, Polley and Reents,[2] cf. also Ref. 16, so as to be stable (up to unitary equivalence) under the bremsstrahlung produced in typical collision processes of charged particles. We note that with the above definition, the vacuum π_0 itself is an infravacuum representation, which will be convenient in the sequel. However, the notion of infravacuum representations is tailored to theories with massless particles in the sense that in a purely massive theory, π_0 would be the only infravacuum representation.

The following lemma collects some basic properties of any infravacuum representation.

Lemma 3.1: Let π_I be an infravacuum representation. Then

(1) for any $q \in \mathbf{V}_+$, $\tilde{\mathscr{S}}_{\pi_0}(\Delta_q)$ contains a *pure* π_I-normal state;

(2) π_I is a locally normal positive energy representation of $(\mathscr{A},\alpha)$;

(3) for any bounded $\mathscr{O}$, the restriction of $\pi_I : \mathscr{A}(\mathscr{O}) \to \pi_I(\mathscr{A}(\mathscr{O}))$ to uniformly bounded subsets of $\mathscr{A}(\mathscr{O})$ is a homeomorphism with respect to the weak operator topologies.

Proof: Choose, for some $q \in \mathbf{V}_+$, a state $\omega \in \mathscr{S}_{\pi_I} \cap \tilde{\mathscr{S}}_{\pi_0}(\Delta_q)$ and let $(\mathscr{H},\pi,\Omega)$ be its GNS triple. Since $\omega \in \mathscr{S}_{\pi_I}$, π is quasi-equivalent to the irreducible representation π_I. This implies that $\pi(\mathscr{A})'$ is a type I factor and thus contains some minimal projection P. Obviously, $\pi|_{P\mathscr{H}} \cong \pi_I$, which implies assertion 2 by Lemma 2.1(1). Moreover, recalling $\Omega \in E_\pi(\Delta_q)\mathscr{H}$, it also implies that the pure π_I-normal state $\omega_P := (P\Omega, \pi(\cdot)P\Omega)/\|P\Omega\|^2$ fulfills

$$\omega_P \in \mathscr{S}_{\pi_I}(\Delta_q) \subset \mathscr{S}_{\pi}(\Delta_q) \subset \tilde{\mathscr{S}}_{\pi}(\Delta_q) \subset \tilde{\mathscr{S}}_{\pi_0}(2\Delta_q).$$

Since q was arbitrary, this proves part 1. Finally, part 3 follows by applying Corollary 7.1.16. of Ref. 17 to the maps $\pi_I : \mathscr{A}(\mathscr{O}) \to \pi_I(\mathscr{A}(\mathscr{O}))$ which are isomorphisms of von Neumann algebras since π_I is faithful and locally normal. ■

Let us remark that one can even establish local unitary equivalence between π_0 and π_I under the additional assumption that π_I satisfies weak additivity. [If additivity and not merely weak additivity were assumed for π_0, additivity and hence weak additivity would follow for π_I by local normality.] The reasoning for this goes along the following line: According to the arguments collected nicely in Ref. 8, there exist Reeh–Schlieder vectors in $\mathscr{H}_0$ and $\mathscr{H}_I$, i.e., the von Neumann algebras $\mathscr{A}(\mathscr{O})$ and $\pi_I(\mathscr{A}(\mathscr{O}))$ possess cyclic and separating vectors. From this, one obtains local unitary equivalence by applying Theorem 7.2.9. of Ref. 17. We recall, however, that an attempt to establish unitary implementability of π_I on an algebra pertaining to an unbounded region (such as $\mathscr{O}'$) would fail because π_I need not be normal on such a region. Indeed, the interesting case will be the situation in which π_I does *not* fulfill the DHR criterion with respect to π_0.

To conclude this section about general properties of infravacuum representations, we want to compare the nets $\tilde{\mathscr{S}}_{\pi_0}$ and $\tilde{\mathscr{S}}_{\pi_I}$ of states. In the next theorem, we will have to make the additional assumption that the vacuum state is unique in the sense that, for some $q \in \mathbf{V}_+$, ω_0 is the only vacuum state in $\tilde{\mathscr{S}}_{\pi_0}(\Delta_q)$.

Theorem 3.2: Let π_I be an infravacuum representation. Then we have, for any Δ and any $q \in \mathbf{V}_+$:

$$\tilde{\mathscr{S}}_{\pi_I}(\Delta) \subset \tilde{\mathscr{S}}_{\pi_0}(\Delta + \Delta_q - \Delta_q).$$

If, moreover, the defining representation π_0 satisfies $C_\sharp$ and if the vacuum state is unique in the sense explained above, then also the converse is true, namely

$$\tilde{\mathscr{S}}_{\pi_0}(\Delta) \subset \tilde{\mathscr{S}}_{\pi_I}(\Delta + \Delta_q - \Delta_q).$$

Proof: Using Lemma 3.1(1), the first statement follows immediately from Lemma 2.1(3). To prove the second statement, we will first use the two additional assumptions to show $\omega_0 \in \tilde{\mathscr{S}}_{\pi_I}(\Delta_q)$ for any Δ_q. This is done as follows. Take some $\omega \in \mathscr{S}_{\pi_I} \cap \tilde{\mathscr{S}}_{\pi_0}(\Delta_q)$. It is easy to see that $\omega \in \tilde{\mathscr{S}}_{\pi_I}(\Delta_q)$. Now consider the family $(\omega_L)_{L>0}$ of states defined by $\omega_L := (1/|V_L|)\int_{V_L} d^{1+s}x\, \omega \circ \alpha_x$, where $V_L := [-L,L]^{(1+s)} \subset \mathbf{R}^{1+s}$. Since $\omega_L \in \tilde{\mathscr{S}}_{\pi_I}(\Delta_q)$, any w^* limit $\tilde{\omega}$ of this family is a w^* limit of $\tilde{\mathscr{S}}_{\pi_I}(\Delta_q)$. Now π_I satisfies $C_\sharp$ by Lemma 2.2(2), so Lemma 2.2(1) can be applied to $\tilde{\omega}$ and yields $\tilde{\omega} \in \tilde{\mathscr{S}}_{\pi_I}(\Delta_q)$. In particular, $\tilde{\omega}$ has positive energy. On the other hand, $\tilde{\omega}$ is translation invariant by construction, i.e., it is a vacuum state. Moreover, by the first part of the present theorem, $\tilde{\omega} \in \tilde{\mathscr{S}}_{\pi_0}(2\Delta_q)$. Now if q is sufficiently small, the uniqueness assumption yields $\tilde{\omega} = \omega_0$ whence $\omega_0 \in \tilde{\mathscr{S}}_{\pi_I}(\Delta_q)$. Trivially, this conclusion remains true for any q. With this information, the second statement follows again from Lemma 2.1(3). ■

We remark, in addition, that the previous theorem does not, in general, entail that one of the sets $\tilde{\mathscr{S}}_{\pi_0}(\Delta)$ and $\tilde{\mathscr{S}}_{\pi_I}(\Delta)$ is contained in the other because the nets $\Delta \mapsto \tilde{\mathscr{S}}_{\pi}(\Delta)$ ($\pi = \pi_0$ or π_I)

need not be regular from the outside [which would mean $\tilde{\mathscr{S}}_\pi(\Delta)=\tilde{\tilde{\mathscr{S}}}_\pi(\Delta):=\cap_q\tilde{\mathscr{S}}_\pi(\Delta+\Delta_q)$], but the outer regularized nets $\tilde{\tilde{\mathscr{S}}}_\pi$ coincide. We note, as an aside, that the nets $\mathscr{S}_{\pi_0}$ and $\mathscr{S}_{\pi_I}$, in contrast, are regular from the outside, as follows from the continuity of the spectral families E_0 and E_{π_I}.

IV. THE DHR CRITERION

In the spirit of the theory of superselection sectors of Doplicher, Haag and Roberts,[1] it is natural to consider, for any infravacuum representation π_I, the set of representations

$$\mathrm{DHR}(\pi_I):=\{\pi|\,\pi|_{\mathscr{A}(\mathscr{O}')}\cong\pi_I|_{\mathscr{A}(\mathscr{O}')},\forall\mathscr{O}\in\mathscr{K}\}$$

(where $\mathscr{K}$ denotes the set of all double cones in $\mathbf{R}^{1+s}$). The well-known DHR analysis can be carried through under one additional assumption, namely that of Haag duality. Thus, we will restrict our attention in the sequel to those infravacuum representations which have this property, i.e.,

$$\pi_I(\mathscr{A}(\mathscr{O}'))'=\pi_I(\mathscr{A}(\mathscr{O})),\quad\forall\mathscr{O}\in\mathscr{K}.$$

We mention as an aside that Haag duality has been established for KPR representations (cf. Sec. III) if the net of observables fulfills an additional condition corresponding to an algebraic version of Gauss's law.[16,18]

Instead of $\mathrm{DHR}(\pi_I)$, one can now study the set

$$\Delta_{\pi_I,t}:=\bigcup_{\mathscr{O}\in\mathscr{K}}\Delta_{\pi_I,t}(\mathscr{O})$$

of transportable localized endomorphisms of the C^*-algebra $\pi_I(\mathscr{A})$, where $\Delta_{\pi_I,t}(\mathscr{O})$ denotes the subset of all such endomorphisms which act trivially on the subalgebra $\pi_I(\mathscr{A}(\mathscr{O}'))$. Transportability means that, for any $x\in\mathbf{R}^{1+s}$, the endomorphisms ρ_I and $\rho_{I,x}$ are unitarily equivalent in $\mathscr{H}_{\pi_I}$, where $\rho_{I,x}$ is given by the action of the translations

$$\Delta_{\pi_I,t}(\mathscr{O})\to\Delta_{\pi_I,t}(\mathscr{O}+x):\rho_I\mapsto\rho_{I,x}:=\mathrm{Ad}\,U_{\pi_I}(x)\circ\rho_I\circ\mathrm{Ad}\,U_{\pi_I}(x)^*.$$

We recall that $\Delta_{\pi_I,t}$ can be viewed as the set of objects of a tensor C^*-category with subobjects and finite direct sums,[19] also denoted by $\Delta_{\pi_I,t}$, whose morphisms $T\in I_{\pi_I}(\sigma_I,\rho_I)$ from σ_I to ρ_I are the intertwining operators $T\in\mathscr{B}(\mathscr{H}_{\pi_I})$ from $\sigma_I\circ\pi_I$ to $\rho_I\circ\pi_I$. It is a crucial consequence of Haag duality that the intertwiners are again local observables:

$$I_{\pi_I}(\sigma_I,\rho_I)\subset\pi_I(\mathscr{A}(\mathscr{O}))\quad\text{if }\sigma_I,\rho_I\in\Delta_{\pi_I,t}(\mathscr{O}).$$

[Comment on the notation: Viewing the index I as a label which distinguishes different infravacuum representations, we let for clarity all objects of $\Delta_{\pi_I,t}$ carry an index I. In particular, I may take on the value 0, then referring to the vacuum.] One eventually has to pass from $\Delta_{\pi_I,t}$ to the full subcategory $\Delta_{\pi_I,f}$ of objects with finite statistical dimension, which is a tensor C^*-category with conjugates. Its importance resides in the fact that it is possible to recover from it (by a deep result of Doplicher and Roberts[5]) a compact gauge group and a field net with normal commutation relations whose gauge invariant part contains all finite-dimensional DHR sectors of $\pi_I(\mathscr{A})$.

Though not explicitly stated in the literature, it is well-known that the above-mentioned notions do not depend on the choice of the infravacuum representation π_I. In fact, a slightly more general result is true:

Theorem 4.1: Let π_I be an irreducible, locally normal representation of $\mathscr{A}$ and assume that π_0 and π_I satisfy Haag duality. Then, a bijective functor

$$F:\Delta_{\pi_0,t}\to\Delta_{\pi_I,t}$$

is defined by the actions (on objects respectively, on morphisms)

$$F(\rho_0) := \pi_I \circ \pi_0^{-1} \circ \rho_0 \circ \pi_0 \circ \pi_I^{-1}, \quad \rho_0 \in \Delta_{\pi_0,t},$$

$$F(T) := \pi_I \circ \pi_0^{-1}(T), \quad T \in I_{\pi_0}.$$

This functor restricts to an isomorphism $F:\Delta_{\pi_0,f} \to \Delta_{\pi_I,f}$ of the corresponding tensor C^*-categories with conjugates.

Proof: As the algebra $\mathscr{A}$ is simple, any representation is faithful, so $\pi_I \circ \pi_0^{-1}: \pi_0(\mathscr{A}) \to \pi_I(\mathscr{A})$ is bijective. Disregarding for a moment the question of transportability, this means that F, as defined above, is well-defined on the objects ρ_0 and remembering $I_{\pi_0} \subset \pi_0(\mathscr{A})$, also on the morphisms. Obviously, F is bijective. One checks that $F(\rho_0)$ is localized in $\mathscr{O}$ iff ρ_0 is, which implies that $F(\rho_0)$ is transportable iff ρ_0 is. Since the statistical dimension of an object is a purely algebraic notion,[20] F clearly restricts to the subcategories of finite statistical dimension. As any bijective functor, F preserves all algebraic structures involved, such as subobjects, direct sums, conjugates and the symmetries. ■

Obviously, what lies at the heart of this proof is that $\pi_I \circ \pi_0^{-1}$ is a net isomorphism. The additional property of this isomorphism of being bicontinuous (with respect to the weak operator topologies) in restriction to norm-bounded subsets of local algebras [cf. Lemma 3.1(3)] has not been exploited yet but will play an essential role in Sec. VI.

We should emphasize that the above theorem and its proof remain valid if π_0 also is replaced by an irreducible, locally normal representation of $\mathscr{A}$ which satisfies Haag duality. In particular, the spectral properties of this representation do not enter into the argument.

As straightforward as the foregoing theorem may be, as important is its interpretation: It shows that replacing the vacuum π_0 by an infravacuum π_I does not affect the superselection structure of the theory. Not only the charges of the theory remain the same, but also their fusion structure, their statistics, their localization and their transportability properties. In more pictorial terms, an infravacuum is suited as well as the ''empty'' vacuum as a background in front of which DHR theory can take place.

V. COCYCLES AND THEIR SPECTRAL PROPERTIES

We have seen in the previous section that the DHR superselection structure of a theory does not depend on the infravacuum with respect to which it is defined. In elementary particle physics, physically meaningful (DHR) representations should, however, also fulfill what is called Borchers's criterion, i.e., have positive energy. In the next two sections, we want to convince ourselves that this additional property too is independent of the infravacuum representation chosen.

It is well-known[1] that Borchers's criterion is fulfilled for all $\rho_0 \in \Delta_{\pi_0,f}$ since the subcategory of finite-dimensional objects is closed under conjugates. However, it is important to note that the proof of this theorem, in relying on the additivity of the energy, makes crucial use of the fact that π_0 is a vacuum representation and thus fails when π_0 is replaced by π_I. Yet, any $\rho_I \in \Delta_{\pi_I,f}$ actually *does* fulfill Borchers's criterion, as follows from Theorem 6.3 below.

Leaving DHR theory for a moment, we first discuss a mathematical notion whose relevance will soon become clear. Thus, let $(\mathscr{H}_I, U_I)$ be a pair consisting of a Hilbert space $\mathscr{H}_I$ and a strongly continuous unitary representation U_I of $\mathbf{R}^{1+s}$ whose spectral family will be denoted by E_I. Note that no condition is imposed on its spectrum at this stage.

Definition: A strongly continuous function $\Gamma:\mathbf{R}^{1+s} \to \mathscr{U}(\mathscr{H}_I)$ is called a *cocycle over* $(\mathscr{H}_I, U_I)$ if it fulfills the cocycle equation

$$\Gamma(x)\mathrm{Ad}\, U_I(x)(\Gamma(y)) = \Gamma(x+y).$$

A cocycle is called *C-spectral*, where C is some closed subset of $\mathbf{R}^{1+s}$, if it complies with the following condition: for any compact $\Delta \subset \mathbf{R}^{1+s}$, one has

$$\mathrm{sp}(\Gamma(\cdot)E_I(\Delta)) \subset C - \Delta.$$

Here, the spectrum sp A of a uniformly bounded, strongly continuous operator-valued function $A:\mathbf{R}^{1+s} \to \mathscr{B}(\mathscr{H}_I)$ is, by definition, the support of its Fourier transform in the sense of operator-

valued distributions. In particular, one has $\int dx f(x)A(x)=0$ for any test function f with supp $\tilde{f}\cap \mathrm{sp}\, A=\varnothing$. Of course, if $A=U:\mathbf{R}^{1+s}\to\mathscr{U}(\mathscr{H}_I)$ is a group homomorphism, sp $A=$ sp U coincides with the common spectrum of the generators of the group.

The notion of spectral cocycles does not seem to have appeared in the literature. The idea of applying it to the above-mentioned problem and the main part of Theorem 5.2 are due to Buchholz.

The following basic properties of the spectrum will be important in the sequel:

Lemma 5.1: Let A, A_1 and A_2 be uniformly bounded, strongly continuous operator-valued functions on $\mathbf{R}^{1+s}$. Then, one has

(1) sp $A^*=-$ sp A, where $A^*(x)=(A(x))^*$;

(2) $\mathrm{sp}(A_1+A_2)\subset \mathrm{sp}\, A_1\cup \mathrm{sp}\, A_2$;

(3) $\mathrm{sp}(A_1A_2)\subset \mathrm{sp}\, A_1+\mathrm{sp}\, A_2$ if sp A_1 or sp A_2 is bounded.

Proof: Parts 1 and 2 are elementary, whereas part 3 can be obtained, by considering matrix elements, from the corresponding property of scalar-valued functions which in turn is the contents of Secs. 1,2 and Théorème II of Ref. 21, Chap. IV. ■

Theorem 5.2: A bijective correspondence between strongly continuous unitary representations $V:\mathbf{R}^{1+s}\to\mathscr{U}(\mathscr{H}_I)$ and cocycles Γ over $(\mathscr{H}_I,U_I)$ is given by

$$\Gamma(x)=V(x)U_I(x)^*.$$

Moreover, sp $V\subset C$ iff Γ is C-spectral.

Proof: The first assertion is obvious. As to the second one, let V satisfy sp $V\subset C$. Making use of the previous Lemma, one then has, for any compact $\Delta\subset\mathbf{R}^{1+s}$,

$$\mathrm{sp}(\Gamma(\cdot)E_I(\Delta))=\mathrm{sp}(V(\cdot)U_I^*(\cdot)E_I(\Delta))\subset \mathrm{sp}\, V-\mathrm{sp}(E_I(\Delta)U_I(\cdot))\subset C-\Delta$$

which shows that Γ is C-spectral. To prove the converse, let Γ be C-spectral. Let $\Delta\subset\mathbf{R}^{1+s}$ be compact and choose a cover of Δ by a finite number of pairwise disjoint Borel sets $(\Delta_j)_{j=1,\ldots,N}$. Then, again by Lemma 5.1, one gets

$$\mathrm{sp}(V(\cdot)E_I(\Delta))\subset \mathrm{sp}\left(V(\cdot)\sum_j E_I(\Delta_j)\right)=\mathrm{sp}\sum_j (\Gamma(\cdot)E_I(\Delta_j)E_I(\Delta_j)U_I(\cdot))$$

$$\subset \bigcup_j (\mathrm{sp}(\Gamma(\cdot)E_I(\Delta_j))+\mathrm{sp}(E_I(\Delta_j)U_I(\cdot)))\subset \bigcup_j (C-\Delta_j+\Delta_j)$$

$$=C+\bigcup_j(\Delta_j-\Delta_j).$$

Since the cover may be chosen such that the maximal diameter of the sets Δ_j is arbitrarily small, this implies $\mathrm{sp}(V(\cdot)E_I(\Delta))\subset C$ for any compact $\Delta\subset\mathbf{R}^{1+s}$, which, in view of $s-\lim_{\Delta\nearrow\mathbf{R}^{1+s}} E_I(\Delta)=\mathbf{1}_{\mathscr{H}_I}$, finally yields sp $V(\cdot)\subset C$. ■

VI. BORCHERS'S CRITERION AND INFRAVACUA

Let us now return to DHR theory. If π_I is an infravacuum representation of $\mathscr{A}$, the role of what was denoted by $(\mathscr{H}_I,U_I)$ in the previous section is of course taken over by $(\mathscr{H}_{\pi_I},U_{\pi_I})$. For any object $\rho_I\in\Delta_{\pi_I,t}$, the following set Z^{ρ_I} of cocycles is of interest:

$$Z^{\rho_I}:=\{\Gamma^{\rho_I}|\Gamma^{\rho_I}\ \text{is a cocycle over}\ (\mathscr{H}_{\pi_I},U_{\pi_I})\ \ \text{and}\ \Gamma^{\rho_I}(x)\in I_{\pi_I}(\rho_{I,x},\rho_I)\}.$$

An object ρ_I is called covariant if there exists a strongly continuous unitary representation $V_{\rho_I}:\mathbf{R}^{1+s}\to\mathscr{U}(\mathscr{H}_{\pi_I})$ which implements the translations in the representation $\rho_I\circ\pi_I$. [Such a representation will be called an *implementation* and denoted with the symbol V_{ρ_I} in order to avoid confusion with the unique *canonical* implementation U_π introduced in Sec. II for the positive energy representations π of $\mathscr{A}$.]

By relating V_{ρ_I} and Γ^{ρ_I} as in Theorem 5.2, we easily obtain the following result:

Lemma 6.1: Z^{ρ_I} is nonempty iff $\rho_I \in \Delta_{\pi_I,t}$ is covariant.

In the rest of this section, we will study the behavior of the cocycles introduced above under the bifunctor $F:\Delta_{\pi_0,t}\to\Delta_{\pi_I,t}$ described in Theorem 4.1. We now have cocycles $\Gamma^{\rho_0}\in Z^{\rho_0}$ and $\Gamma^{\rho_I}\in Z^{\rho_I}$ which take on values in the groups of local and unitary elements of $\pi_0(\mathscr{A})$ respectively $\pi_I(\mathscr{A})$. As a consequence, not only they are in the domain of F (which equals $\pi_I\circ\pi_0^{-1}$ on intertwiners) respectively F^{-1}, but we even have because of the continuity properties of F established in Lemma 3.1(3) (whose proof only relies on local normality—cf. also the remark after Theorem 4.1.):

Lemma 6.2: Let $\rho_0\in\Delta_{\pi_0,t}$, $\rho_I:=F(\rho_0)$. Then the functor F maps Z^{ρ_0} onto Z^{ρ_I}.

In other words, ρ_0 is covariant iff ρ_I is. [We will stick to the notation $\rho_I:=F(\rho_0)$ in the sequel.] Moreover, an elementary calculation shows that, in this case, implementations V_{ρ_0}, respectively, V_{ρ_I} of the translations for $\rho_0\circ\pi_0$, respectively, $\rho_I\circ\pi_I$ can be obtained from each other by the formula

$$V_{\rho_I}(x)=\pi_I\circ\pi_0^{-1}(V_{\rho_0}(x)U_{\pi_0}(x)^*)U_{\pi_I}(x). \tag{1}$$

We will now investigate in what extent the functor F also respects spectral properties. The inclusions obtained in Theorem 3.2 are taken as a starting point, but we will comment on more general situations at the end of this section.

Theorem 6.3: Let π_I be an irreducible, locally normal positive energy representation of $\mathscr{A}$ and assume that π_0 and π_I satisfy Haag duality. Denote by

$$F:\Delta_{\pi_0,t}\to\Delta_{\pi_I,t}$$

the bifunctor of Theorem 4.1. If both inclusions of Theorem 3.2 are valid, then one obtains for any covariant object $\rho_0\in\Delta_{\pi_0,t}$:

(1) F maps the C-spectral cocycles in Z^{ρ_0} onto the C-spectral ones in Z^{ρ_I};

(2) if V_{ρ_0} and V_{ρ_I} are related by (1) then $\mathrm{sp}\ V_{\rho_0}=\mathrm{sp}\ V_{\rho_I}$;

(3) ρ_0 has positive energy iff ρ_I has;

(4) if ρ_0 and ρ_I have positive energy and are finite direct sums of irreducibles, then the respective canonical implementations $U_{\rho_0\circ\pi_0}$ and $U_{\rho_I\circ\pi_I}$ of the translations are related by Eq. (1); in particular, their spectra coincide:

$$\mathrm{sp}\ U_{\rho_0\circ\pi_0}=\mathrm{sp}\ U_{\rho_I\circ\pi_I}.$$

Proof: 1. Let $\Gamma^{\rho_0}\in Z^{\rho_0}$ be C-spectral and let $\Gamma^{\rho_I}(x):=F(\Gamma^{\rho_0}(x))$. It will be shown in the next lemma that this entails, for any compact set Δ,

$$\mathrm{sp}(\Gamma^{\rho_I}(\cdot)E_I(\Delta))\subset\bigcap_{\Delta_0}\{C-\Delta_0|\tilde{\mathscr{S}}_{\pi_I}(\Delta)\subset\tilde{\mathscr{S}}_{\pi_0}(\Delta_0)\}.$$

As a consequence of the first inclusion of Theorem 3.2, Δ_0 can be chosen to be any neighborhood of Δ. This implies that the right-hand side reduces to $C-\Delta$, i.e., Γ^{ρ_I} is C-spectral. The converse is proved along the same lines, now using the second inclusion of Theorem 3.2.

2. Due to (1), part 1 applies to the cocycles $\Gamma^{\rho_0}(x):=V_{\rho_0}(x)U_0(x)^*$ and $\Gamma^{\rho_I}(x):=V_{\rho_I}(x)U_I(x)^*$. Using Theorem 5.2, this yields for any closed $C\subset\mathbf{R}^{1+s}$:

$$\mathrm{sp}\ V_{\rho_0}\subset C\ \text{iff}\ \mathrm{sp}\ V_{\rho_I}\subset C,$$

which immediately gives the assertion. From this, part 3 follows directly.

As to part 4, we first consider the special case when ρ_0 (and therefore also ρ_I) is irreducible. Then all implementations of the translations coincide up to a one-dimensional one, i.e., a phase factor. Together with part 2, this yields the following equivalences:

$$V_{\rho_0}=U_{\rho_0\circ\pi_0}\Leftrightarrow\ \mathrm{sp}\ V_{\rho_0}\ \text{has Lilb}\Leftrightarrow\ \mathrm{sp}\ V_{\rho_I}\ \text{has Lilb}\Leftrightarrow V_{\rho_I}=U_{\rho_I\circ\pi_I}$$

(where ''Lilb'' means ''Lorentz-invariant lower boundary''). Applying part 2 again gives all of the assertion in this case. In the general case of reducible ρ_0, we prove $V_{\rho_0}=U_{\rho_0\circ\pi_0}\Leftrightarrow V_{\rho_I}=U_{\rho_I\circ\pi_I}$ as follows: if $W_j\in I_{\pi_0}(\rho_{0,j},\rho_0)$ denote intertwiners which perform the decomposition of ρ_0 into irreducibles $\rho_{0,j}$, then $F(W_j)$ decompose ρ_I into irreducibles $\rho_{I,j}=F(\rho_{0,j})$. The implementations V_{ρ_0} and V_{ρ_I} decompose into subrepresentations $W_j^*V_{\rho_0}(x)W_j$ and $F(W_j^*)V_{\rho_I}(x)F(W_j)$ on the corresponding subspaces and these subrepresentations can be seen to be related by (1) iff V_{ρ_0} and V_{ρ_I} are. Since the latter are, by definition, canonical iff all their subrepresentations are, the assertion follows from the special case discussed first. ■

Lemma 6.4: Let Γ^{ρ_0} be C-spectral. Then we have for any compact Δ:

$$\mathrm{sp}(\Gamma^{\rho_I}(\cdot)E_I(\Delta))\subset\bigcap_{\Delta_0}\{C-\Delta_0\,|\,\tilde{\mathscr{S}}_{\pi_I}(\Delta)\subset\tilde{\mathscr{S}}_{\pi_0}(\Delta_0)\}.$$

Proof: Let Δ_0 be such that $\tilde{\mathscr{S}}_{\pi_I}(\Delta)\subset\tilde{\mathscr{S}}_{\pi_0}(\Delta_0)$ and let f be a test function satisfying $\mathrm{supp}\,\tilde{f}\cap(C-\Delta_0)=\varnothing$. Setting $\Gamma^{\rho_0}(f):=\int dx f(x)\Gamma^{\rho_0}(x)$, we obtain $\Gamma^{\rho_0}(f)E_0(\Delta_0)=\int dx f(x)\Gamma^{\rho_0}(x)E_0(\Delta_0)=0$ since Γ^{ρ_0} is C-spectral. This means $\omega(\pi_0^{-1}(\Gamma^{\rho_0}(f)^*\Gamma^{\rho_0}(f)))=0$ for any vector state $\omega\in\mathscr{S}_{\pi_0}(\Delta_0)$, hence (by weak continuity) for any $\omega\in\tilde{\mathscr{S}}_{\pi_0}(\Delta_0)$ and in particular for any $\omega\in\tilde{\mathscr{S}}_{\pi_I}(\Delta)$. We thus have $\pi_I\circ\pi_0^{-1}(\Gamma^{\rho_0}(f))E_I(\Delta)=0$ and hence by local normality $\int dx f(x)(\pi_I\circ\pi_0^{-1}(\Gamma^{\rho_0}(x))E_I(\Delta)=0$. [For this argument, one has to realize that f can be approximated in $L^1(\mathbf{R}^{1+s})$ by test functions with compact support.] As this holds for any f with $\mathrm{supp}\,\tilde{f}\cap(C-\Delta_0)=\varnothing$, it follows that $\mathrm{sp}(\pi_I\circ\pi_0^{-1}(\Gamma^{\rho_0}(\cdot))E_I(\Delta))\subset C-\Delta_0$. This yields the assertion. ■

The inclusions of Theorem 3.2 played a crucial role in the previous theorem. However, partial results remain valid if less information about the relation between $\tilde{\mathscr{S}}_{\pi_I}$ and $\tilde{\mathscr{S}}_{\pi_0}$ is available. For instance, let us merely assume (instead of these inclusions) that there exists a compact neighborhood $\mathscr{N}$ of 0 such that [cf. Lemma 2.1(3)]

$$\tilde{\mathscr{S}}_{\pi_I}(\Delta)\subset\tilde{\mathscr{S}}_{\pi_0}(\Delta+\mathscr{N})\quad\text{for all compact sets }\Delta.$$

In this case, we obtain with the same arguments as above that the cocycle $\Gamma^{\rho_I}:=F(\Gamma^{\rho_0}(\cdot))$ is $(C-\mathscr{N})$-spectral if Γ^{ρ_0} is C-spectral. In terms of V_{ρ_0} and V_{ρ_I}, this means

$$\mathrm{sp}\,V_{\rho_I}\subset\mathrm{sp}\,V_{\rho_0}-\mathscr{N}.$$

In general, all detailed information on the shape of sp V_{ρ_I} (such as the size of possible mass gaps) is lost, but what can easily be seen is that ρ_I has positive energy if ρ_0 has. The canonical implementations of the translations need, in general, not be related by (1) any more. A similar reasoning applies if the roles of π_0 and π_I are exchanged.

VII. CONCLUSION AND OUTLOOK

We have seen that, as far as DHR theory is concerned, the role of the vacuum representation π_0 can be taken over by any locally normal representation π_I satisfying Haag duality. Moreover, we have given sufficient conditions on π_I which ensure that the class of representations fulfilling Borchers's criterion is independent of π_I. These representations may be interpreted as background fields whose interaction with the charged particles of the model is weak.

Natural candidates for states describing such a background were elements of the energy component of the vacuum. The latter notion, introduced in Ref. 9, deserves some more interest on its own, and one might ask in the spirit of Sec. III under which circumstances other properties such as, e.g., Haag duality carry over from π_0 to π_I.

It seems thus that for most purposes, the characteristic feature of a vacuum representation, namely the existence of a translation invariant vector in the representation Hilbert space, is not an essential property. However, we recall that this property plays a crucial role for proving that the energy-momentum spectra are additive under the fusion of covariant sectors:

$$\mathrm{sp}\ U_{\rho_1\circ\rho_2\circ\pi_0}\supset \mathrm{sp}\ U_{\rho_1\circ\pi_0}+\mathrm{sp}\ U_{\rho_2\circ\pi_0}.$$

Trivially, using the results of Theorem 6.3, this yields

$$\mathrm{sp}\ U_{F(\rho_1\circ\rho_2)\circ\pi_I}\supset \mathrm{sp}\ U_{F(\rho_1)\circ\pi_I}+\mathrm{sp}\ U_{F(\rho_2)\circ\pi_I},$$

but it would of course be interesting to know under which assumptions the latter inclusion can be derived without relying on the vacuum sector.

Finally, returning to Buchholz's proposal of reconciling QED with superselection theory, several interesting questions arise. First, it has to be clarified which parts of the present work (in particular of Secs. IV and VI) can be generalized from DHR-like localized charges to charges localized in spacelike cones. Second, it will be important to check in specific models whether there exist backgrounds which permit better localization properties of charges of electric type than the vacuum does. In fact, this question could be answered affirmatively[6] for a simple model[7] recently introduced by Buchholz *et al.* Another candidate for such a model with the advantage of being closer to QED, might be the one proposed by Herdegen.[22]

ACKNOWLEDGMENTS

I am deeply indebted to Professor D. Buchholz for numerous helpful discussions and constant interest in this work. Financial support from the Deutsche Forschungsgemeinschaft (''Graduiertenkolleg Theoretische Elementarteilchenphysik'' at Hamburg University) is also gratefully acknowledged.

An increasing entropy for a free quantum particle

Clasine van Winter
Department of Mathematics and Department of Physics and Astronomy, University of Kentucky, Lexington, Kentucky 40506

(Received 14 November 1995; accepted for publication 24 April 1998)

For a quantum-mechanical particle without interaction, a linear manifold of states is identified that has a preferred time direction pointing to the future. States with the broken time-reversal symmetry are singled out by their behavior under dilations. At positive times such states can be described in terms of a density operator with the property that the trace of its square decreases as the time increases. This density operator determines an entropy that approaches its least upper bound when the time tends to infinity. The expectation value of the dilation operator was negative in the distant past and will be positive in the remote future. This is the irreversible aspect of the time evolution that causes the entropy to increase, although there is no approach to equilibrium. The density operator with increasing entropy is obtained from the usual density operator by an invertible transformation that is compared with the Λ-transformation in the Prigogine theory of irreversible behavior in K-systems and large Hamiltonian systems with many resonances. © *1998 American Institute of Physics.* [S0022-2488(98)03307-6]

I. INTRODUCTION

Let $\rho(t)$ be the density operator of a quantum system with Hamiltonian H. Following Von Neumann, one defines the entropy[1–3]

$$S[\rho(t)] = -\operatorname{Tr} \rho(t) \ln \rho(t). \tag{1.1}$$

If H is self-adjoint, the entropy $S[\rho(t)]$ is constant in time. The interpretation is that there is no irreversible behavior at the microscopic level.

The present paper examines one particle without interaction. For this case an invertible operator L is identified such that any ρ in the domain of L gives rise to a density operator $\sigma(t) := L\rho(t)$ $(t \geqslant 0)$ with the property that $S[\sigma(t)]$ increases between times $t=0$ and $t \to \infty$.

Units are chosen so that the time evolution takes the form

$$\rho(t) = \exp(-iH_0 t)\rho \exp(iH_0 t)$$

with $\rho = \rho(0)$. In the momentum representation the free Hamiltonian H_0 acts on $L^2(\mathbb{R}^3)$ as multiplication by k^2.

Let D be the dilation operator. This is the self-adjoint operator which acts on C_0^∞-functions $f(\mathbf{k}) \in L^2(\mathbb{R}^3)$ as

$$D = \frac{i}{2} (\mathbf{k}\cdot\boldsymbol{\nabla}_k + \boldsymbol{\nabla}_k \cdot \mathbf{k}). \tag{1.2}$$

Define $J := \exp(-\pi D/2)$. The operator J is self-adjoint but not bounded. Suppose that ρ is of the form

$$\rho = (1+J^2)^{-1/2} R (1+J^2)^{-1/2} \tag{1.3}$$

with some positive operator R in the trace class. If this condition is satisfied, the closure of $J\rho(t)J$ belongs to the trace class if $t \geqslant 0$, but not necessarily if $t < 0$. Hence states ρ satisfying Eq. (1.3) have a preferred time direction pointing to the future. For $t \geqslant 0$ only, define

 © 1998 American Institute of Physics

$$\sigma(t) := \rho(t) + J\rho(t)J. \tag{1.4}$$

According to Theorem 6.1

$$\text{Tr } \sigma(t) = \text{Tr } \sigma. \tag{1.5}$$

By general entropy inequalities[4]

$$S[\sigma(t)] \leqslant S[\rho(t)] + S[J\rho(t)J], \tag{1.6}$$

with equality if and only if

$$\rho(t)J\rho(t)J = 0, \quad J\rho(t)J\rho(t) = 0. \tag{1.7}$$

Typically Eq. (1.7) is not satisfied, but the relation becomes true as $t \to \infty$. By Lemma 7.2 the operators in Eq. (1.7) tend to 0 in the trace norm as $t \to \infty$. The right-hand side of Eq. (1.6) is equal to its value at $t=0$ by Lemma 7.1. Theorem 7.5 states that $S[\sigma(t)]$ tends to $S(\rho)+S(J\rho J)$ as $t \to \infty$. Hence the entropy increases between times $t=0$ and $t \to \infty$. Except in case ρ is of rank 1, it is an open problem whether the entropy increase is monotone.

Let P_+ and P_- be the spectral projections onto the subspaces of $L^2(\mathbb{R}^3)$ in which the dilation operator D is positive and negative, respectively. The proof that $S[\sigma(t)]$ tends to its least upper bound as $t \to \infty$ is based on the relations[5,6]

$$\begin{aligned} &\lim_{t\to\infty} \| P_- \exp(-iH_0 t) f \| = 0, \\ &\lim_{t\to-\infty} \| P_+ \exp(-iH_0 t) f \| = 0. \end{aligned} \tag{1.8}$$

As Eq. (1.2) indicates, D is the quantum analog of the scalar product $\mathbf{x}\cdot\mathbf{k}$, with $\mathbf{x}$ the position and $\mathbf{k}$ proportional to the momentum of the particle being considered. Intuitively, one expects that $\mathbf{x}\cdot\mathbf{k}$ was negative in the distant past and will be positive in the remote future. This notion is confirmed by Eq. (1.8). It represents an irreversible aspect of the time evolution, although there is no approach to equilibrium.

Due to Eq. (1.8), any $\rho(t)$ in the trace class tends in the trace norm to $P_+\rho(t)P_+$ as $t \to \infty$. Since JP_+ is bounded,

$$(1+J^2)^{1/2} P_+ \rho(t) P_+ (1+J^2)^{1/2}$$

belongs to the trace class. This means that $P_+\rho(t)P_+$ has the form of Eq. (1.3). Hence any $\rho(t)$ tends to a limit to which this paper applies.

Equation (1.4) identifies the operator L taking $\rho(t)$ into $\sigma(t)$. Theorem 6.3 states that L has an inverse such that $L^{-1}\sigma(t) = \rho(t)$. Let ρ be normalized such that Tr $\rho = 1$. Let A be a bounded operator on $L^2(\mathbb{R}^3)$. By Theorem 6.4 there exists an operator AL^{-1} taking the range of L into the trace class on $L^2(\mathbb{R}^3)$ in such a way that the expectation value of A at time $t \geqslant 0$ is given by

$$\langle A(t) \rangle = \text{Tr } A\rho(t) = \text{Tr}(AL^{-1})\sigma(t). \tag{1.9}$$

Hence $\sigma(t)$ can be used as a density operator to evaluate expectation values.

The notion of a transformation taking the usual density operator into a density operator with increasing entropy, has long been advocated by Prigogine and coauthors,[7,8] although not for a single quantum particle without interaction. Section II gives a brief overview of some of their work. The dilation operator and the operator J are discussed in Sec. III. It is of practical importance that functions in the domain of J are boundary values of analytic functions. This aspect of the dilation operator is the subject of Sec. IV. Section V is devoted to lemmas that characterize the behavior of $J\rho(t)J$ and related quantities as functions of t. This prepares for Sec. VI in which it is shown that Tr $\sigma(t)$ is constant and Tr $\sigma^2(t)$ decreasing. The construction of the operator L^{-1} is also in Sec. VI. Section VII is devoted to the entropy, including the proof that $S[\sigma(t)]$ tends to its least upper bound as $t \to \infty$. If ρ is of rank 1, the entropy increase is monotone by Sec. VIII.

Since ρ is supposed to be positive, σ defined by Eq. (1.4) is positive, but it is not true that every positive operator in the trace class is a σ generated by a positive ρ. This follows from examples in the Appendix. It is one of the reasons why it is an open problem whether the entropy increase is monotone in case the rank of ρ is larger than 1, as explained in Sec. VIII.

II. THE PRIGOGINE ENTROPY OPERATOR

The operator L has a role similar to the Λ-transformation in numerous papers by Prigogine and co-workers.[7–9] Their objective is a unified formulation of dynamics and thermodynamics, including a description of irreversible behavior at the microscopic level. The procedure is to find a transformation Λ which breaks the time-reversal symmetry in the sense that $\Lambda\rho(t)$ is defined only for $t\geqslant 0$ and evolves in time according to a semigroup. In quantum mechanics the transformed probability density $\Lambda\rho(t)$ has to be such that the quantity

$$\Omega(t) := \mathrm{Tr}\ \rho^*(t)\Lambda^*\Lambda\rho(t) \quad (t\geqslant 0) \tag{2.1}$$

is a monotone decreasing function of t. The operator $\Lambda^*\Lambda$ is called the microscopic entropy operator. The classical counterpart of the function $\Omega(t)$ is obtained if the trace in Eq. (2.1) is replaced by integration over the phase space. In agreement with Eq. (2.1), Theorem 6.2 states that the operator $\sigma(t)$ defined by Eq. (1.4) does have the property that $\mathrm{Tr}\ \sigma^2(t)$ is decreasing on $t \geqslant 0$.

Systems investigated by the Prigogine group divide into two categories calling for entirely different methods of analysis: classical dynamical systems[10] and large Hamiltonian systems, including quantum systems, with a continuous energy spectrum and infinitely many resonances.[11] We do not know of ideas in the literature that could be used to find an entropy operator for a single quantum particle without interaction.

In the context of classical dynamical systems, entropy operators were constructed explicitly for the baker map[12,13] and other Bernoulli systems,[14] as well as for K-flows.[15] This work has inspired many papers.[16–27] For an entropy operator $\Lambda^*\Lambda$ in a classical dynamical system to exist, it is necessary[28] that the time evolution of nonequilibrium states is generated by an operator whose spectrum is absolutely continuous, of uniform multiplicity, and running from $-\infty$ to ∞. Due to this condition, constructions for classical dynamical systems cannot be used in quantum mechanics.

In a quantum system with bound states, one could imagine an entropy that is defined only on the absolutely continuous subspace of the Hamiltonian, but this does not solve the problem that the spectrum of the Hamiltonian is bounded below. As outlined at the end of Sec. VIII, our operator $\sigma(t)$ can be viewed as a partial trace of a density operator $\tilde{\rho}(t)$ that changes in time according to a semigroup of isometries $\{U(t)|0\leqslant t<\infty\}$ with a generator whose spectrum consists of the lower half-plane plus the entire real axis.

Historically the Λ-transformation was first proposed for large Hamiltonian systems with many resonances.[7] The first example of this kind[7,29–32] was the Friedrichs model,[33] in which a discrete state embedded in a continuum disappears as the result of a perturbation. While the Friedrichs model may be solved explicitly, typical large Hamiltonian systems exhibit a high level of complexity. The existence of an operator Λ is closely related to the validity of kinetic equations that govern the relaxation of the system to equilibrium. To derive a kinetic theory, the Prigogine group uses the theory of subdynamics[7,34–39] which aims at constructing a complete set of projection operators that commute with the Liouville operator. This corresponds to identifying a complete set of subspaces in which time evolutions are mutually independent, hence the name subdynamics. It is an essential point in this theory that the Hamiltonian be decomposed into an unperturbed term plus a perturbation. The Λ-operator transforms unperturbed into perturbed projections.

One difficulty is that the perturbed subspaces do not belong to the unperturbed Hilbert space. Recent papers[32,40,41] therefore use Gel'fand triplets, as in the theory of rigged Hilbert spaces.[42–44] This amounts to including resonances in the spectral decomposition.[45] Closely related is an approach which treats decaying states as generalized eigenvectors with complex eigenvalues.[46] Either way, the time evolution is governed by unstable states. In the subdynamics theory irreversible behavior is due to resonances. A recent alternative[47–49] to the subdynamics theory is formulated entirely in terms of density operators because the dynamics cannot be implemented by wave functions. How this is related to the Λ-transformation is described in the original papers.[47,49]

Systems investigated by the Prigogine group are entirely different from the free particle in this paper, calling for entirely different methods of investigation. Yet a fundamental observation by Prigogine and coauthors[8,50] remains unchanged. They pointed out that any quantum operator $\Lambda^*\Lambda\rho$ cannot be written in the form $\Lambda^*\Lambda\rho = A_1\rho A_2$, where A_1 and A_2 are operators acting on the same Hilbert space as ρ. If $\Lambda^*\Lambda\rho$ did have this form, the transformation Λ would take wave functions into wave functions, hence pure states would go into pure states. In other words, states satisfying $\rho = \rho^2$ would go into states satisfying $\Lambda\rho = (\Lambda\rho)^2$, so that $\Omega(t)$ in Eq. (2.1) would not decrease as required. It follows that any operator Λ needs to act on operators and cannot act on wave functions. Our operator L taking ρ into σ agrees with this prediction.

III. THE DILATION OPERATOR

Recall that the Hamiltonian H_0 acts on $f(\mathbf{k}) \in L^2(\mathbb{R}^3)$ as multiplication by k^2. We write $|\mathbf{k}| = k$ and introduce two spherical polar coordinates ω. Identifying $f(\mathbf{k})$ and $f(k,\omega)$, we write L^2 instead of $L^2(\mathbb{R}^3)$.

The Mellin transform

$$Mf(k,\omega) = f\#(u,\omega)$$

defined by

$$f\#(u,\omega) = (2\pi)^{-1/2} \int_0^\infty k f(k,\omega) k^{iu-1/2} dk \tag{3.1}$$

is a unitary map taking L^2 onto the space $L^2(\mathbb{R}\times S^2)$ consisting of functions $f\#(u,\omega)$ with inner product

$$(f\#, g\#) = \int_{S^2} \int_{-\infty}^{\infty} f\#(u,\omega) \overline{g\#}(u,\omega) du\, d\omega.$$

We denote this space by ML^2. The inverse $M^{-1} f\#(u,\omega)$ is determined by

$$k f(k,\omega) = (2\pi)^{-1/2} \int_{-\infty}^{\infty} f\#(u,\omega) k^{-iu-1/2} du. \tag{3.2}$$

If we define $z := \ln k$ and

$$F(z,\omega) := f(e^z,\omega) e^{3z/2},$$

it follows from Eq. (3.2) that

$$F(z,\omega) = (2\pi)^{-1/2} \int_{-\infty}^{\infty} f\#(u,\omega) e^{-izu} du. \tag{3.3}$$

Hence many properties of the Mellin transform can be derived from properties of the Fourier transform. For example, if $f\# \in C_0^\infty(\mathbb{R}\times S^2)$, then F is in the domain of $i\partial/\partial z$. Applying $i\partial/\partial z$ to F corresponds to multiplying $f\#$ by u. Since $\partial/\partial z = k\partial/\partial k$, it is easy to verify that

$$i \frac{\partial}{\partial z} F(z,\omega) = k^{3/2} \left[ik \frac{\partial}{\partial k} + 3i/2 \right] f(k,\omega). \tag{3.4}$$

The operator in square brackets on the right is equal to the dilation operator D introduced by Eq. (1.2). Multiplying Eq. (3.4) by $k^{-1/2}$ and using Eq. (3.3) therefore gives

$$kDf(k,\omega) = (2\pi)^{-1/2} \int_{-\infty}^{\infty} u f\#(u,\omega) k^{-iu-1/2} du. \tag{3.5}$$

Up to this point, multiplication by u is restricted to C_0^∞ and D acts as a differential operator. We now extend multiplication by u from C_0^∞ to the set $\mathrm{Dom}(u) \in ML^2$ consisting of all $f\#(u,\omega) \in ML^2$ with the property that $uf\#(u,\omega) \in ML^2$. The operator u so defined is self-adjoint and has an absolutely continuous spectrum from $-\infty$ to ∞. As a result, D extends to a self-adjoint operator on L^2 with domain $\mathrm{Dom}(D) = M^{-1}\mathrm{Dom}(u)$ and the same spectrum as u. It follows from Eq. (3.5) that $D = M^{-1}uM$.

Once the self-adjoint operator D is available, we can define the positive operator $e^{\phi D}$ on L^2. Its domain $\mathrm{Dom}(e^{\phi D})$ is given by $M^{-1}\mathrm{Dom}(e^{\phi u})$, the inverse Mellin transform of the set of all $f\#(u,\omega) \in ML^2$ with the property that $e^{\phi u} f\#(u,\omega) \in ML^2$. Taking $\phi = -\pi/2$, we define

$$J := \exp(-\pi D/2) = M^{-1} \exp(-\pi u/2) M. \tag{3.6}$$

The set of all $f \in L^2$ with the property that $Jf \in L^2$ is denoted by K^2.

IV. ANALYTIC FUNCTIONS

For a description of the set K^2 we examine the class of all functions $f(ke^{i\phi},\omega)$ which are analytic in the sector $-\pi/2 < \phi < 0$ for almost every $\omega \in S^2$ and have the property that the integral

$$\int_{S^2} \int_0^\infty |ke^{i\phi} f(ke^{i\phi},\omega)|^2 dk d\omega$$

is bounded uniformly in the sector. It is known[51–53] that functions in this class have mean-square boundary values $f(k,\omega)$ and $f(ke^{-i\pi/2},\omega)$. Under the inner product

$$\langle f,g\rangle = \int_{S^2} \int_0^\infty [f(k,\omega)\overline{g}(k,\omega) + f(ke^{-i\pi/2},\omega)\overline{g}(ke^{-i\pi/2},\omega)]k^2 dk d\omega$$

the class is a Hilbert space which we denote by G^2.

For $f \in G^2$, we consider the Mellin transform

$$f\#(u,\omega,\phi) = (2\pi)^{-1/2} \int_0^\infty ke^{i\phi} f(ke^{i\phi},\omega) k^{iu-1/2} dk$$

and its inverse

$$ke^{i\phi} f(ke^{i\phi},\omega) = (2\pi)^{-1/2} \int_{-\infty}^\infty f\#(u,\omega,\phi) k^{-iu-1/2} du. \tag{4.1}$$

It is known[51–53] that a function f belongs to G^2 if and only if its Mellin transform is of the form

$$f\#(u,\omega,\phi) = e^{\phi u - i\phi/2} f\#(u,\omega,0) \tag{4.2}$$

with some function $f\#(u,\omega,0)$ satisfying

$$\int_{S^2} \int_{-\infty}^\infty (1+e^{-\pi u}) |f\#(u,\omega,0)|^2 du d\omega < \infty. \tag{4.3}$$

Given $f\#(u,\omega,0)$ satisfying Eq. (4.3), we can construct $f\#(u,\omega,\phi)$ according to Eq. (4.2). Since $f\#(u,\omega,0)$ is the same as the Mellin transform $f\#(u,\omega)$ of $f(k,\omega)$, it follows that $f(k,\omega)$ has an analytic continuation $f(ke^{i\phi},\omega) \in G^2$ if and only if its Mellin transform $f\#(u,\omega)$ satisfies Eq. (4.3). The condition expressed by Eq. (4.3) is that $f(k,\omega)$ and $Jf(k,\omega)$ belong to L^2. Hence $f(k,\omega) \in K^2$ if and only if $f(k,\omega)$ is the boundary value of a function $f(ke^{i\phi},\omega) \in G^2$.

Comparing Mellin transforms with the help of Eqs. (4.1) and (4.2) shows that

$$e^{\phi D} f(k,\omega) = e^{3i\phi/2} f(ke^{i\phi},\omega). \tag{4.4}$$

Taking $\phi = -\pi/2$ gives

$$Jf(k,\omega)=e^{-3i\pi/4}f(ke^{-i\pi/2},\omega). \tag{4.5}$$

If $-\pi/2<\phi<0$, then $\exp(-ik^2e^{2i\phi}t)$ is bounded if and only if $t\geqslant 0$. Hence, if $f\in G^2$, then $\exp(-ik^2e^{2i\phi}t)f\in G^2$ if $t\geqslant 0$ but not necessarily if $t<0$. In terms of boundary values at $\phi=0$, it follows that $f\in K^2$ has the property that $\exp(-ik^2t)f\in K^2$ if $t\geqslant 0$ but not necessarily if $t<0$. The set K^2 has a broken time-reversal symmetry. For $f\in K^2$, it follows from Eq. (4.5) that

$$J\ \exp(-ik^2t)f(k,\omega)=\exp(ik^2t)Jf(k,\omega)\quad (t\geqslant 0). \tag{4.6}$$

Unless stated otherwise, t is assumed to be non-negative in all of the following.

V. THE DENSITY OPERATOR ρ

This section uses Eq. (4.6) to derive identities satisfied by $J\rho(t)J$ and related operators. The results are used in Secs. VI and VII to study the density operator $\sigma(t)$ and the entropy $S[\sigma(t)]$ as functions of t.

Lemma 5.1: The density operator ρ is of the form (1.3) if and only if ρ and $J\rho$ belong to the trace class and ρJ and $J\rho J$ have closures in the trace class.

Proof: Suppose ρ has the form of Eq. (1.3). Since R is in the trace class by assumption and $(1+J^2)^{-1/2}$ and $J(1+J^2)^{-1/2}$ are bounded, ρ and $J\rho$ belong to the trace class. By the same token

$$(1+J^2)^{-1/2}RJ(1+J^2)^{-1/2}\ \text{ and }\ J(1+J^2)^{-1/2}RJ(1+J^2)^{-1/2} \tag{5.1}$$

belong to the trace class. On $f\in K^2$, these operators act as ρJ and $J\rho J$, respectively. Since K^2 is dense in L^2, it follows that ρJ and $J\rho J$ have closures given by expression (5.1). These closures belong to the trace class.

Now suppose that ρ, $J\rho$, and the closures of ρJ and $J\rho J$ belong to the trace class. Define

$$T:=(1+J)\rho(1+J). \tag{5.2}$$

This operator has domain K^2. By assumption, its closure $\overline{T}$ belongs to the trace class. Since J is positive, $(1+J^2)^{1/2}(1+J)^{-1}$ is bounded. Hence

$$R:=(1+J^2)^{1/2}(1+J)^{-1}\overline{T}(1+J^2)^{1/2}(1+J)^{-1}$$

belongs to the trace class. Solving for $\overline{T}$ gives

$$\overline{T}=(1+J)(1+J^2)^{-1/2}R(1+J)(1+J^2)^{-1/2}.$$

Hence

$$\rho=(1+J)^{-1}\overline{T}(1+J)^{-1}=(1+J^2)^{-1/2}R(1+J)(1+J^2)^{-1/2}(1+J)^{-1}=(1+J^2)^{-1/2}R(1+J^2)^{-1/2}. \tag{5.3}$$

This shows that ρ has the desired form, with R in the trace class.

If R is positive, then ρ is positive. Now suppose that ρ is positive. By Eq. (5.3) $(Rg,g)\geqslant 0$ whenever g is of the form $(1+J^2)^{-1/2}f$ with $f\in L^2$. Since the set of functions g is dense in L^2, it follows that R is positive. □

In case there is no danger of confusion, we henceforth write ρJ, $J\rho J$, and $J\rho(1+J^2)^{1/2}$ when we actually mean closures.

If ρ satisfies Eq. (1.3),

$$\begin{aligned}\mathrm{Tr}(1+J^2)^{1/2}\rho(1+J^2)^{1/2}&=\mathrm{Tr}(1+J^2)^{-1/2}\rho(1+J^2)^{1/2}+\mathrm{Tr}\ J^2(1+J^2)^{-1/2}\rho(1+J^2)^{1/2}\\&=\mathrm{Tr}\ \rho+\mathrm{Tr}\ J\rho J.\end{aligned}$$

Lemma 5.2: If ρ is of the form (1.3) and $t\geqslant 0$,

$$J\rho(t)=\exp(iH_0t)J\rho\ \exp(iH_0t). \tag{5.4}$$

If closures of all operators are understood,

$$\rho(t)J=\exp(-iH_0t)\rho J\ \exp(-iH_0t), \tag{5.5}$$

$$J\rho(t)J=\exp(iH_0t)J\rho J\ \exp(-iH_0t). \tag{5.6}$$

Proof: According to Lemma 5.1, ρ and $J\rho$ are bounded. Hence the range of ρ belongs to K^2. Equation (5.4) follows from Eq. (4.6). For any $f\in K^2$,

$$\rho(t)Jf=\exp(-iH_0t)\rho J\ \exp(-iH_0t)f.$$

The right-hand side can be extended to all $f\in L^2$ if ρJ is replaced by its closure identified in expression (5.1). It follows that $\rho(t)J$ is closable with closure in the trace class, the closure satisfying Eq. (5.5). To prove Eq. (5.6) we consider

$$J\rho(t)Jf=\exp(iH_0t)J\rho\ \exp(iH_0t)Jf=\exp(iH_0t)J\rho J\ \exp(-iH_0t)f.$$

According to expression (5.1) the operator on the right has a closure in the trace class. Hence, so does $J\rho(t)J$, and the two closures are equal. □

Corollary 5.3: If ρ is of the form (1.3) and $t>0$, there exists an operator $R(t)$ in the trace class such that $\rho(t)$ satisfies Eq. (1.3) with $R(t)$ instead of R.

Proof: Due to Lemma 5.2, $\rho(t)$, $J\rho(t)$, $\rho(t)J$, and $J\rho(t)J$ have closures in the trace class. Hence $R(t)$ in the trace class can be constructed following the second part of the proof of Lemma 5.1. □

Lemma 5.4: If ρ is of the form (1.3), $J^{1/2}\rho$ belongs to the trace class. The operators $\rho J^{1/2}$ and $J^{1/2}\rho J^{1/2}$ have closures in the trace class. If $t\geqslant 0$ and closures of all operators are understood

$$J^{1/2}\rho(t)=\exp(-H_0t)J^{1/2}\rho\ \exp(iH_0t), \tag{5.7}$$

$$\rho(t)J^{1/2}=\exp(-iH_0t)\rho J^{1/2}\ \exp(-H_0t), \tag{5.8}$$

$$J^{1/2}\rho(t)J^{1/2}=\exp(-H_0t)J^{1/2}\rho J^{1/2}\ \exp(-H_0t). \tag{5.9}$$

Proof: Because $J^{1/2}(1+J^2)^{-1/2}$ is bounded, the first part of the lemma can be proved in much the same way as the first part of Lemma 5.1. Taking $\phi=-\pi/4$ in Eq. (4.4) gives

$$J^{1/2}\ \exp(-ik^2t)f(k,\omega)=\exp(-k^2t)J^{1/2}f(k,\omega)\quad (t\geqslant 0) \tag{5.10}$$

for every $f\in K^2$. Since the range of ρ belongs to K^2 by Lemma 5.1, Eq. (5.7) follows.

Applying $J^{1/2}$ to Eq. (5.10) and using Eq. (4.6) gives

$$\exp(ik^2t)Jf(k,\omega)=J\ \exp(-ik^2t)f(k,\omega)=J^{1/2}\ \exp(-k^2t)J^{1/2}f(k,\omega),$$

hence

$$\exp(iH_0t)J^{1/2}g=J^{1/2}\ \exp(-H_0t)g \tag{5.11}$$

for every g of the form $g=J^{1/2}f$, with $f\in K^2$.

We claim that the set of functions g being considered in Eq. (5.11) is dense in L^2. Indeed, for f to belong to K^2, it is sufficient that the Mellin transform $f\#$ is of the form $(1+e^{-\pi u/2})^{-1}h\#$ with $h\#\in ML^2$. Hence it is sufficient that $g\#$ is of the form

$$g\#=e^{-\pi u/4}(1+e^{-\pi u/2})^{-1}h\#=[2\cosh(\pi u/4)]^{-1}h\#. \tag{5.12}$$

Suppose N exists such that $g\#(u,\omega)=0$ if $|u|>N$. Solving Eq. (5.12) for $h\#$ gives $h\#\in ML^2$, hence $g\#$ is of the desired form. Since the set of all $g\#$ with compact support is dense in ML^2, it follows that Eq. (5.11) is true on a dense set, as claimed.

Applying $\exp(-iH_0t)\rho$ to Eq. (5.11) gives

$$\rho(t)J^{1/2}g=\exp(-iH_0t)\rho J^{1/2}\ \exp(-H_0t)g. \tag{5.13}$$

Replacing $\rho J^{1/2}$ by its closure constructed as in the proof of Lemma 5.1, we can extend the right-hand side of Eq. (5.13) to all of L^2. Hence $\rho(t)J^{1/2}$ is closable with closure in the trace class satisfying Eq. (5.8). The proof of Eq. (5.9) is similar. □

Lemma 5.5: If ρ is of the form (1.3), the operator $J\rho J^{1/2}$ is closable. Its closure belongs to the trace class. If $t \geqslant 0$ and closures of operators are understood

$$J\rho(t)J\rho(t) = \exp(iH_0t)J\rho J^{1/2} \exp(-2H_0t)J^{1/2}\rho \exp(iH_0t). \tag{5.14}$$

Proof: Given the proofs of Lemmas 5.1 and 5.4, the statement about $J\rho J^{1/2}$ is easy to verify. Thus, the closures of $\rho J^{1/2}$ and $J\rho J^{1/2}$ are bounded. This means that the range of $\rho J^{1/2}$ belongs to K^2. Hence

$$J \exp(-iH_0t)\rho J^{1/2} = \exp(iH_0t)J\rho J^{1/2}.$$

Applying $J \exp(-iH_0t)\rho$ to Eq. (5.11) gives

$$J\rho(t)J^{1/2}g = J \exp(-iH_0t)\rho J^{1/2} \exp(-H_0t)g = \exp(iH_0t)J\rho J^{1/2} \exp(-H_0t)g \tag{5.15}$$

on a dense set of functions g. As in Lemmas 5.2 and 5.4, the operators in Eq. (5.15) have closures that are equal. Applying these to $J^{1/2}\rho(t)$ and using Eq. (5.7) gives the desired relation (5.14).□

VI. THE DENSITY OPERATOR σ

Theorem 6.1: *If ρ is of the form (1.3), the operator $\sigma(t)$ defined by Eq. (1.4) is positive and belongs to the trace class. Its trace satisfies Eq. (1.5).*

Proof: The operator $\sigma(t)$ belongs to the trace class due to Lemma 5.1 and Eq. (5.6). By the same token, Tr $\sigma(t)$ is constant on $t \geqslant 0$. That $\sigma(t)$ is positive follows from the assumption that R is positive. □

The next theorem states that Tr $\sigma^2(t)$ is decreasing, like the entropy operator (2.1) in the Prigogine theory.

Theorem 6.2: *If ρ is of the form (1.3), the operator $\sigma(t)$ defined by Eq. (1.4) has the property that*

$$\text{Tr } \sigma^2(s) > \text{Tr } \sigma^2(t) \quad \text{if } 0 \leqslant s < t, \tag{6.1}$$

$$\lim_{t\to\infty} \text{Tr } \sigma^2(t) = \text{Tr } \rho^2 + \text{Tr}(J\rho J)(J\rho J). \tag{6.2}$$

Proof: Due to Lemmas 5.2, 5.4, and 5.5,

$$\begin{aligned}
\text{Tr } \rho(t)[J\rho(t)J] &= \text{Tr}[J\rho(t)J]\rho(t) \\
&= \text{Tr}[J\rho(t)J^{1/2}][J^{1/2}\rho(t)] \\
&= \text{Tr}[J^{1/2}\rho(t)][J\rho(t)J^{1/2}] \\
&= \text{Tr}[J^{1/2}\rho(t)J^{1/2}][J^{1/2}\rho(t)J^{1/2}] \\
&= \text{Tr}[\exp(-H_0t)J^{1/2}\rho J^{1/2} \exp(-2H_0t)J^{1/2}\rho J^{1/2} \exp(-H_0t)].
\end{aligned} \tag{6.3}$$

Let T be the closure of $J^{1/2}\rho J^{1/2}$. Then

$$\begin{aligned}
&\text{Tr}[\exp(-H_0s)T \exp(-2H_0s)T \exp(-H_0s)] - \text{Tr}[\exp(-H_0t)T \exp(-2H_0t)T \exp(-H_0t)] \\
&\quad = \text{Tr}\{\exp(-H_0s)T[\exp(-2H_0s) - \exp(-2H_0t)]T \exp(-H_0s)\} \\
&\qquad + \text{Tr}\{\exp(-H_0t)T[\exp(-2H_0s) - \exp(-2H_0t)]T \exp(-H_0t)\}.
\end{aligned} \tag{6.4}$$

If $0 \leqslant s < t$, the operator $[\exp(-2H_0s) - \exp(-2H_0t)]$ is strictly positive. The trace is faithful. Hence the right-hand side of Eq. (6.4) is the sum of two positive traces. It follows that

$$\text{Tr } \rho(s)J\rho(s)J > \text{Tr } \rho(t)J\rho(t)J \quad \text{if } 0 \leqslant s < t.$$

By the definition of $\sigma(t)$ and Eq. (5.6)

$$\mathrm{Tr}\ \sigma^2(t)=\mathrm{Tr}\ \rho^2+\mathrm{Tr}\ \rho(t)J\rho(t)J+\mathrm{Tr}\ J\rho(t)J\rho(t)+\mathrm{Tr}(J\rho J)(J\rho J). \tag{6.5}$$

Terms one and four on the right do not depend on t while terms two and three are decreasing. This proves Eq. (6.1).

Recall that the operator T belongs to the trace class. Since $\exp(-H_0t)$ is bounded and tends to 0 strongly as $t\to\infty$, the operator $\exp(-H_0t)T\exp(-H_0t)$ tends to 0 in the trace norm as $t\to\infty$. It follows with Eq. (6.3) that $\mathrm{Tr}\ \rho(t)J\rho(t)J$ tends to 0 as $t\to\infty$. Equation (6.2) now follows from Eq. (6.5). □

We proceed to show how $\rho(t)$ can be recovered if Eq. (1.3) is true and $\sigma(t)$ is known. To simplify the notation, we first examine ρ and σ at $t=0$.

Since the trace class is a subset of the Schmidt class, its members are integral operators. The integral kernel of ρ is a $L^2\times L^2$-function $\rho(k,\omega;k',\omega')$. The Mellin transform $\rho\#:=M\rho M^{-1}$ is an integral operator with $ML^2\times ML^2$-kernel $\rho\#(u,\omega;v,\omega')$. By Eq. (3.6) MJM^{-1} acts as multiplication by $\exp(-\pi u/2)$. Hence $MJ\rho JM^{-1}$ has integral kernel

$$\exp(-\pi u/2)\rho\#(u,\omega;v,\omega')\exp(-\pi v/2).$$

Theorem 6.3: *Let L be a linear operator whose domain consists of all operators ρ of the form (1.3). Let L act according to*

$$L\rho=\rho+J\rho J.$$

Define $\rho\#:=M\rho M^{-1}$. Let $L\#$ act according to

$$L\#\rho\#=\rho\#+MJ\rho JM^{-1},$$

where the domain of $L\#$ consists of all operators $\rho\#$ with the property that $M^{-1}\rho\#M$ is of the form (1.3). If ρ is of the form (1.3), σ defined by Eq. (1.4) equals $L\rho$. Its Mellin transform $\sigma\#:=M\sigma M^{-1}$ equals $L\#\rho\#$. The operator $L\#$ transforms integral kernels according to

$$\sigma\#(u,\omega;v,\omega')=(L\#\rho\#)(u,\omega;v,\omega')=\{1+\exp[-\pi(u+v)/2]\}\rho\#(u,\omega;v,\omega'). \tag{6.6}$$

There is an inverse $(L\#)^{-1}$ defined on the range of $L\#$. It recovers the integral kernel of $\rho\#$ according to

$$\rho\#(u,\omega;v,\omega')=[(L\#)^{-1}\sigma\#](u,\omega;v,\omega')=\{1+\exp[-\pi(u+v)/2]\}^{-1}\sigma\#(u,\omega;v,\omega'). \tag{6.7}$$

The relations (6.6) and (6.7) remain true when ρ and σ are replaced by $\rho(t)$ and $\sigma(t)$, respectively.

Proof: Lemma 5.1 states that Eq. (1.3) is sufficient for ρ and $J\rho J$ to belong to the trace class. Since M is unitary, $M\rho M^{-1}$ and $MJ\rho JM^{-1}$ belong to the trace class. Hence L and $L\#$ are well defined. It is easy to see that σ equals $L\rho$ and $\sigma\#$ equals $L\#\rho\#$. These operators belong to the trace class. This leads to Eq. (6.6) as explained above. Since $\{1+\exp[-\pi(u+v)/2]\}^{-1}$ is a bounded function of u and v, Eq. (6.7) follows immediately.

If ρ is of the form (1.3), then $\rho(t)$ is of this form for all $t>0$. This is the statement of Corollary 5.3. Since L and the Mellin transform do not depend on t, the reasoning that proved Eqs. (6.6) and (6.7) can be repeated for every $t>0$. □

The next theorem shows that the operator $\sigma(t)$ can be used to calculate expectation values of observables.

Theorem 6.4: *Let A be a bounded operator on $L^2(\mathbb{R}^3)$. Under the assumptions of Theorem 6.3 there is an operator AL^{-1} defined on the range of L. If $\sigma(t)$ belongs to the range of L, then $(AL^{-1})\sigma(t)$ is in the trace class and Eq. (1.9) is satisfied.*

Proof: Let $A\#$ be the Mellin transform of A and define

$$(AL^{-1})\#:=A\#\{1+\exp[-\pi(u+v)/2]\}^{-1}.$$

Due to Eq. (6.6) $(AL^{-1})\#\sigma\#=A\#\rho\#$, hence $M^{-1}(AL^{-1})\#M$ satisfies the conditions of the theorem. □

Although ρ can be recovered from σ and σ can be used to calculate expectation values of observables, it is clear that ρ and σ are not equivalent as density operators. Indeed, our objective is to show that $\sigma(t)$ gives rise to an increasing entropy, while $\rho(t)$ does not. Theorem 6.2 states that Tr $\sigma^2(t)$ is decreasing while Tr $\rho^2(t)$ is not. Theorem 6.4 implies another distinction. To represent an observable, A must be self-adjoint on $L^2(\mathbb{R}^3)$. The operator AL^{-1} does not act on wave functions in $L^2(\mathbb{R}^3)$ but on operators in the range of L. For AL^{-1} to represent an observable, the obvious condition is that $(AL^{-1})L$ be self-adjoint on $L^2(\mathbb{R}^3)$.

VII. THE ENTROPY

Let A be a positive compact operator. We denote by $\gamma_n(A)$ the nth largest eigenvalue of A, counting multiplicity. If ρ satisfies Eq. (1.3), ρ and $J\rho J$ belong to the trace class. Hence

$$\sum_n \gamma_n(\rho)<\infty, \quad \sum_n \gamma_n(J\rho J)<\infty. \tag{7.1}$$

Referring to Eq. (1.1) we define

$$s(\gamma):=\begin{cases} -\gamma \ln \gamma & \text{if } \gamma>0 \\ 0 & \text{if } \gamma=0 \end{cases}$$

and assume

$$\begin{aligned} S(\rho)&:=\sum_n s[\gamma_n(\rho)]<\infty, \\ S(J\rho J)&:=\sum_n s[\gamma_n(J\rho J)]<\infty. \end{aligned} \tag{7.2}$$

Lemma 7.1: If ρ is of the form (1.3), Eq. (7.2) is satisfied, and $t\geqslant 0$, then

$$S[\rho(t)]=S(\rho), \quad S[J\rho(t)J]=S(J\rho J).$$

Proof: This follows from Eq. (5.6) and the fact that $\exp(-iH_0t)$ is unitary. □

Due to Eq. (7.1), at most a finite number of eigenvalues γ_n may exceed 1. Hence the sums in Eq. (7.2) converge absolutely. With Eq. (1.6) and Lemma 7.1, $S[\sigma(t)]$ is bounded above. To show that $S[\sigma(t)]$ is bounded below, we define

$$\nu(t):=\sigma(t)/\text{Tr } \sigma(t). \tag{7.3}$$

This gives

$$S[\sigma(t)]=[\text{Tr } \sigma(t)]\{S[\nu(t)]-\ln \text{Tr } \sigma(t)\}. \tag{7.4}$$

Since $\nu(t)$ is positive with Tr $\nu(t)=1$, all eigenvalues of $\nu(t)$ lie in the interval $[0,1]$, hence $S[\nu(t)]\geqslant 0$. By Theorem 6.1 Tr $\sigma(t)$ is a finite positive constant Tr σ. Hence

$$S[\sigma(t)]\geqslant -(\text{Tr } \sigma)\ln \text{Tr } \sigma.$$

We know from the proof of Theorem 6.2 that Tr $\rho(t)\ J\rho(t)J$ tends to 0 as $t\to\infty$. The next result is significant in view of the necessary and sufficient condition (1.7) for the entropy $S[\sigma(t)]$ to take its maximum possible value.

Lemma 7.2: If ρ is of the form (1.3), $\rho(t)\ J\rho(t)J$ and $J\rho(t)\ J\rho(t)$ tend to 0 in the trace norm as $t\to\infty$.

Proof: By Lemma 5.4 $J^{1/2}\rho$ belongs to the trace class. The operator $\exp(-2H_0t)$ is bounded if $t\geqslant 0$ and tends to 0 strongly as $t\to\infty$. Hence $\exp(-2H_0t)\ J^{1/2}\rho$ tends to 0 in the trace norm. With $J\rho J^{1/2}$ in the trace class by Lemma 5.5, $J\rho(t)\ J\rho(t)$ tends to 0 in the trace norm by Eq. (5.14). So does its adjoint $\rho(t)\ J\rho(t)J$. □

We proceed to prove two lemmas that will be used to show that the entropy $S[\sigma(t)]$ tends to its least upper bound $S(\rho)+S(J\rho J)$ as $t\to\infty$.

Lemma 7.3: Define

$$\pi_+(t):=P_+\rho(t)P_+, \quad \pi_-(t):=P_-J\rho(t)JP_-,$$

where P_+ and P_- are the spectral projections onto the subspaces of L^2 in which the dilation operator D is positive and negative, respectively. If ρ is of the form (1.3), the set of all nonvanishing eigenvalues $\gamma_k[\pi_+(t)+\pi_-(t)]$ $(k=1,2,...)$ is equal to the union of the sets of all nonvanishing $\gamma_n[\pi_+(t)]$ and $\gamma_m[\pi_-(t)]$ $(m,n=1,2,...)$.

Proof: To simplify the notation, we give the proof for $t=0$. The proof for $t>0$ is similar.

Let ψ_+ be an eigenvector of π_+ with eigenvalue $\gamma\neq 0$. Then $\psi_+=P_+\psi_+$, hence

$$(\pi_++\pi_-)\psi_+=\pi_+\psi_+=\gamma\psi_+.$$

Similarly, an eigenvector ψ_- of π_- with eigenvalue $\gamma\neq 0$ is an eigenvector of $\pi_++\pi_-$ with the same eigenvalue. If γ has multiplicity M_+ as eigenvalue of π_+ and multiplicity M_- as eigenvalue of π_-, the eigenvectors ψ_+ and ψ_- yield a set of M_++M_- linearly independent eigenvectors of $\pi_++\pi_-$. Hence γ is an eigenvalue of $\pi_++\pi_-$ with multiplicity $M\geqslant M_++M_-$.

Now suppose ψ is an eigenvector of $\pi_++\pi_-$ with eigenvalue γ. Then

$$\pi_+P_+\psi=(\pi_++\pi_-)P_+\psi=P_+(\pi_++\pi_-)\psi=\gamma P_+\psi. \tag{7.5}$$

Hence $P_+\psi$ and $P_-\psi$ are eigenvectors of $\pi_++\pi_-$. Let γ have multiplicity M as eigenvalue of $\pi_++\pi_-$ and suppose there are m linearly independent eigenvectors $P_+\psi$. Then $0\leqslant m\leqslant M$ and $\pi_++\pi_-$ has $M-m$ eigenvectors $P_-\psi$. Due to Eq. (7.5) γ is an eigenvalue of π_+ with multiplicity $M_+\geqslant m$. By the same token, γ is an eigenvalue of π_- with multiplicity $M_-\geqslant M-m$. Hence $M_++M_-\geqslant M$. By the first part of the proof $M\geqslant M_++M_-$. Hence $M=M_++M_-$. There is a one-to-one correspondence, counting multiplicity, between nonvanishing eigenvalues $\gamma_k[\pi_++\pi_-]$ on the one hand and nonvanishing γ in the union of all $\gamma_n[\pi_+]$ and $\gamma_m[\pi_-]$ on the other. □

Lemma 7.4: Let ρ be of the form (1.3). Let λ_k $(k=1,2,...)$ be the kth largest number, counting multiplicity, in the set consisting of all nonvanishing eigenvalues $\gamma_n(\rho)$ and $\gamma_m(J\rho J)$ $(m,n=1,2,...)$. In terms of the notation introduced in Lemma 7.3

$$\lim_{t\to\infty}\gamma_k[\pi_+(t)+\pi_-(t)]=\lambda_k. \tag{7.6}$$

Proof: If A and B are compact and positive[54]

$$|\gamma_n(A)-\gamma_n(B)|\leqslant\|A-B\|. \tag{7.7}$$

Since $P_-\exp(-iH_0t)$ tends to 0 strongly as $t\to\infty$, by Eq. (1.8), $P_-\rho(t)$ tends to 0 in the trace norm. The trace norms of $P_-\rho(t)$ and its adjoint are equal. Hence $\rho(t)P_-$ tends to 0 in the trace norm. Denoting the trace norm of an operator C in the trace class by $\|C\|_1$, we find

$$\lim_{t\to\infty}\|\pi_+(t)-\rho(t)\|_1=0. \tag{7.8}$$

Hence, given $\epsilon>0$, there exists $T>0$, not depending on n, such that

$$|\gamma_n[\pi_+(t)]-\gamma_n(\rho)|<\epsilon \quad \text{if} \quad t>T. \tag{7.9}$$

By a similar argument, T may be chosen so large that also

$$|\gamma_m[\pi_-(t)]-\gamma_m(J\rho J)|<\epsilon \quad \text{if} \quad t>T. \tag{7.10}$$

According to Lemma 7.3, $\gamma\neq 0$ is an eigenvalue of $\pi_+(t)+\pi_-(t)$ if and only if γ is an eigenvalue of $\pi_+(t)$ and/or $\pi_-(t)$. This suggests that each $\gamma[\pi_+(t)+\pi_-(t)]\neq 0$ tends to some λ_k as $t\to\infty$. Since Lemma 7.3 states that multiplicities match, λ_k with multiplicity M should be

the limit of M eigenvalues $\gamma[\pi_+(t)+\pi_-(t)]$. It is a complication, however, that graphs of eigenvalues $\gamma_n[\pi_+(t)]$ and $\gamma_m[\pi_-(t)]$ may intersect. Thus, for instance, it could happen that $\gamma_1[\pi_+(t)+\pi_-(t)]$ equals $\gamma_1[\pi_+(t)]$ at time t_1, but $\gamma_1[\pi_-(t)]$ at time t_2. To cope with this difficulty, we choose any integer l with the property that $\lambda_{l+1}<\lambda_l$. The sequence $\lambda_1,\lambda_2,\ldots,\lambda_l$ will contain i eigenvalues $\gamma_n(\rho)$ and j eigenvalues $\gamma_m(J\rho J)$, with $i+j=l$. These eigenvalues are the limits of i eigenvalues $\gamma_n[\pi_+(t)]$ and j eigenvalues $\gamma_m[\pi_-(t)]$. We claim that T may be chosen so large that the graphs of this set of $i+j$ eigenvalues do not intersect at times $t>T$, except, possibly, for intersections of graphs that tend to the same limit λ_k $(k=1,2,\ldots,l)$.

To prove this, we choose ϵ so small that the difference between successive λ's in the sequence $\lambda_1,\lambda_2,\ldots,\lambda_{l+1}$ exceeds 2ϵ. By Eq. (7.9) T exists such that at $t>T$ each $\gamma_n[\pi_+(t)]$ is within ϵ from some λ_q, and similarly for each $\gamma_m[\pi_-(t)]$ $(n,m=1,2,\ldots)$. In particular, the eigenvalues $\gamma_n[\pi_+(t)]$ and $\gamma_m[\pi_-(t)]$ that tend to λ_q with $q=l+1,\ l+2,\ldots$ do not exceed $\lambda_{l+1}+\epsilon<\lambda_l-\epsilon$ when $t>T$. This leaves precisely l eigenvalues in the intervals $(\lambda_k-\epsilon,\ \lambda_k+\epsilon)$ with $k=1,2,\ldots,l$. By the choice of ϵ, the ϵ-intervals centered at distinct λ_k $(k=1,2,\ldots,l)$ are disjoint. Hence the l eigenvalues being considered do not change intervals when $t>T$. Graphs of eigenvalues that tend to different limits λ_k $(k=1,2,\ldots,l)$ do not intersect when $t>T$. If λ_k is simple, the ϵ-interval centered at λ_k contains precisely one eigenvalue $\gamma_n[\pi_+(t)]$ or $\gamma_m[\pi_-(t)]$. By Lemma 7.3, this is a $\gamma_p[\pi_+(t)+\pi_-(t)]$. In this case p equals k. If λ_k is repeated M times, $\lambda_k=\lambda_{k+1}=\cdots=\lambda_{k+M-1}$, the ϵ-interval centered at λ_k contains M eigenvalues $\gamma_p[\pi_+(t)+\pi_-(t)]$. If at any time $t>T$ the M eigenvalues are ordered, they receive labels $k,\ k+1,\ldots,k+M-1$. In the course of time the ordering within the group of M may change, but it remains true that

$$|\gamma_{k+r}[\pi_+(t)+\pi_-(t)]-\lambda_{k+r}|<\epsilon \quad \text{if} \quad t>T, \quad r=0,1,\ldots,M-1.$$

Summarizing, choose l with the property that $\lambda_{l+1}<\lambda_l$. Choose ϵ so small that the difference between successive distinct λ's in the sequence $\lambda_1,\lambda_2,\ldots,\lambda_{l+1}$ exceeds 2ϵ. Now T exists such that Eqs. (7.9) and (7.10) are true when $t>T$. By what we have shown

$$|\gamma_k[\pi_+(t)+\pi_-(t)]-\lambda_k|<\epsilon \quad \text{if} \quad t>T, \quad k=1,2,\ldots,l.$$

Hence Eq. (7.6) is true. Since ϵ depends on l, the convergence is not uniform in k. It is uniform on any finite set $k=1,2,\ldots,l$. □

Theorem 7.5: *Let $\sigma(t)$ be defined by Eq. (1.4). Let $S[\sigma(t)]$ be defined as in Eq. (1.1). If ρ is of the form (1.3) and Eq. (7.2) is satisfied*

$$\lim_{t\to\infty} S[\sigma(t)]=S(\rho)+S(J\rho J). \tag{7.11}$$

Proof: By Eq. (7.8) and the corresponding equation with $\pi_-(t)$ and $J\rho(t)J$

$$\lim_{t\to\infty}\|\pi_+(t)+\pi_-(t)-\sigma(t)\|_1=0.$$

Due to Eqs. (7.6) and (7.7)

$$\lim_{t\to\infty}\gamma_k[\sigma(t)]=\lim_{t\to\infty}\gamma_k[\pi_+(t)+\pi_-(t)]=\lambda_k.$$

By Eq. (7.2) and the definition of λ_k in Lemma 7.4

$$\sum_k s(\lambda_k)=S(\rho)+S(J\rho J).$$

To prove Eq. (7.11), let us adopt the convention that $0\ln 0=0$. Then it is sufficient to show that

$$\lim_{t\to\infty}\sum_k \gamma_k[\sigma(t)]\ln\gamma_k[\sigma(t)]=\sum_k \lambda_k\ln\lambda_k, \tag{7.12}$$

hence that on the left the sum over k and the limit with respect to t may be interchanged. Our proof uses the dominated convergence theorem for sums. This requires a suitable estimate on $\gamma_k[\sigma(t)]$.

If A and B are compact and positive

$$\gamma_{i+j+1}(A+B) \leqslant \gamma_{i+1}(A) + \gamma_{j+1}(B) \quad (i,j=0,1,2,...).$$

This is a special case of an inequality due to Fan.[54,55] Take $A=\rho(t)$, $B=J\rho(t)J$, so that $A+B=\sigma(t)$. Take $i+j=k$. Suppose the sequence $\lambda_1,\ldots,\lambda_k$ contains i eigenvalues $\gamma_n(\rho)$ and j eigenvalues $\gamma_m(J\rho J)$. Then $\gamma_{i+1}(\rho) \leqslant \lambda_k$ and $\gamma_{j+1}(J\rho J) \leqslant \lambda_k$, so that $\gamma_{k+1}[\sigma(t)] \leqslant 2\lambda_k$. Since $\Sigma_k\, \lambda_k$ converges by Eq. (7.1), there is a finite N such that $\lambda_k \leqslant 1/2e$ when $k \geqslant N$. Since the function $-x\, \ln x$ is nondecreasing on $[0,1/e]$, it follows that

$$0 \leqslant -\gamma_{k+1}[\sigma(t)] \ln\, \gamma_{k+1}[\sigma(t)] \leqslant -2\lambda_k\, \ln 2\lambda_k \quad (k \geqslant N).$$

By Eq. (7.1) and assumption (7.2) the sum $-\Sigma_k\, \lambda_k \ln 2\lambda_k$ converges. Dominated convergence therefore assures that

$$\lim_{t\to\infty} \sum_{k=N}^{\infty} = \sum_{k=N}^{\infty} \lim_{t\to\infty}$$

on the left in Eq. (7.12). Adding the limits of the terms with $k=1,2,...,N-1$ gives the desired result (7.12). This completes the proof of Eq. (7.11). □

Theorem 7.6: *If the data are as in Theorem 7.5, the entropy $S[\sigma(t)]$ tends to its maximum possible value as $t\to\infty$.*

Proof: The proposition follows from Theorem 7.5 with Eq. (1.6) and Lemma 7.1. □

VIII. DISCUSSION

Let σ be equal to $L\rho$ as in Theorem 6.3. If ρ is a positive operator, so is σ. Given $\sigma\# = L\#\rho\#$, the operator $(L\#)^{-1}$ correctly recovers the positive operator $\rho\#$.

Now choose a positive operator σ in the trace class and construct

$$\tau\#(u,\omega;v,\omega') = \{1+\exp[-\pi(u+v)/2]\}^{-1}\sigma\#(u,\omega;v,\omega'). \tag{8.1}$$

This is the integral kernel of a bounded operator $\tau\#$. The Appendix gives examples in which the operator $\tau\#$ is not positive. Thus there is a distinction between ρ and σ not unlike a distinction between ρ and $\Lambda\rho$ in the Prigogine theory. Among other requirements, Λ must be positivity preserving, in order that densities are transformed into densities. For classical dynamical systems on a measure space with an invariant measure, it was shown that Λ^{-1} is not positivity preserving.[56]

It will be understood that this paper is meant only for operators σ of the form $L\rho$ with positive ρ satisfying Eq. (1.3). Let us call this the allowed class. If c is a positive constant and σ belongs to the allowed class, so does $c\sigma$. If σ_1 and σ_2 belong to the allowed class, so does $\sigma_1+\sigma_2$. Hence the allowed class is a cone in the trace class.

In published examples of entropy operators for classical dynamical systems,[12–15] the phase space is compact and there is a uniform equilibrium density ρ_0. The Λ-operator has the property that $\|\Lambda\rho(t)-\rho_0\|$ is strictly monotonically decreasing to 0 as $t\to\infty$, for all initial densities $\rho(0) \neq \rho_0$. The authors referred to strong Markov semigroups[12,13] or monotonic Markov semigroups.[14,15] These semigroups give rise to nondecreasing entropies[57–60] that tend to their maximal values of zero[61] as $t\to\infty$.

That an entropy may exhibit fluctuations is illustrated by computer calculations to determine the Boltzmann H-function for a system of two-dimensional hard disks.[7,8,62] For the entropy to increase, the H-function has to decrease, but under suitable conditions it was found to increase over limited periods of time.

Another example[59,60] is provided by the quadratic map $f(x)=4x(1-x)$ with phase space $[0,1]$. The Perron–Frobenius operator P for this map can be determined in closed form. Taking $\rho(x)=1$ as initial density, one finds $P\rho(x)=[4(1-x)]^{-1/2}$ with entropy

$$S(P\rho) = -\int_0^1 [P\rho(x)]\ln[P\rho(x)]dx = -1 + \ln 2.$$

This is less than the initial entropy $S(\rho)=0$. The equilibrium density in this example is given by $\rho_0(x)=[\pi^2 x(1-x)]^{-1/2}$. Essential for the example is that ρ_0 is not the uniform density and that the map is not invertible.[59,60]

As for the entropy in the present paper, we do not know whether $S[\sigma(t)]$ is a monotone function of t. First suppose that $\rho(t)$ is of rank 1, so that $\sigma(t)$ is of rank 2. Denote the eigenvalues of $\sigma(t)$ by $\lambda_1(t)$ and $\lambda_2(t)$. By Theorems 6.1 and 6.2, $\lambda_1(t)+\lambda_2(t)$ is constant while $\lambda_1^2(t)+\lambda_2^2(t)$ is decreasing. This requires that $[\lambda_1(t)-\lambda_2(t)]^2$ be decreasing. One implication is, that $\lambda_1(t)$ must not be equal to $\lambda_2(t)$ at any finite time. Thus, an operator of rank 2 with equal eigenvalues does not belong to the allowed class. Suppressing the variable t, we label the eigenvalues so that $\lambda_1>\lambda_2$. In terms of $\lambda:=(\lambda_1+\lambda_2)/2$ and $\mu:=(\lambda_1-\lambda_2)/2$, the entropy takes the form

$$S[\sigma(t)] = -(\lambda+\mu)\ln(\lambda+\mu) - (\lambda-\mu)\ln(\lambda-\mu).$$

Since λ is constant and μ decreasing, the entropy is an increasing function of t on $t\geqslant 0$.

It is an open problem whether the foregoing result generalizes to density operators of higher rank. Suppose $0\leqslant s\leqslant t$ and compare $\sigma(s)$ with $\sigma(t)$. There exist several conditions[63] that are necessary and sufficient in order that

$$\mathrm{Tr}\ f[\sigma(t)] \geqslant \mathrm{Tr}\ f[\sigma(s)]$$

for every concave function f. These conditions are difficult to verify, however. They may be stronger than required for the entropy to be non-decreasing.

Theorems 6.1 and 6.2 state that the trace norm of $\sigma(t)$ is constant in time while the Schmidt norm is decreasing. The normalized operator $\nu(t)$ defined in Eq. (7.3) has the same properties. Suppose we could extend the two theorems to all operators of finite rank. Then we could use the Calderón–Lions theorem to interpolate between the trace and the Schmidt norms,[64] showing that $\mathrm{Tr}[\nu(\tau)]^\alpha$ is a nonincreasing function of $t\geqslant 0$ for fixed α with $1\leqslant\alpha\leqslant 2$. As a result the Rényi entropies, often called α-entropies,[65]

$$S_\alpha[\nu(t)] := (1-\alpha)^{-1}\ \ln\ \mathrm{Tr}[\nu(t)]^\alpha\ (1<\alpha\leqslant 2)$$

would be nondecreasing. Since $S_\alpha[\nu(t)]$ tends to $S[\nu(t)]$ as α tends to 1, the entropy $S[\nu(t)]$ would be nondecreasing. By Eq. (7.4), this result would carry over to $S[\sigma(t)]$. In a time-independent setting a similar reasoning has been used to study the change in entropy when a measurement is performed on a quantum system.[66]

While the Rényi entropy $S_2[\sigma(t)]$ is increasing by Theorem 6.2, the interpolation method does not apply in this paper because Theorem 6.1 does not generalize well beyond the allowed class of operators σ determined by positive ρ. To see what may happen, consider a spherically symmetric situation and take

$$\sigma\#(u,v) = \exp(-3\pi|u|/4)\exp(-3\pi|v|/4).$$

This is the kernel of a positive operator. By Example (A2) in the appendix, $\sigma\#$ determines an operator $\tau\#$, according to Eq. (8.1), which is not positive. It is easy to verify that τ, $J\tau$, τJ, and $J\tau J$ belong to the Schmidt class. Whether these operators belong to the trace class would be difficult to determine. There is a sufficient condition for a function to be the integral kernel of an operator in the trace class, but it requires that the operator be positive.[67,68] In any case, there is no difficulty constructing $\tau(t)$ and

$$J\tau(t)J = \exp(iH_0t)J\tau J\ \exp(-iH_0t).$$

These operators determine $\sigma(t)$ according to

$$\sigma(t) = \tau(t) + J\tau(t)J.$$

There are spectral decompositions

$$\tau=\tau_+ + \tau_-, \quad J\tau J=(J\tau J)_+ +(J\tau J)_-$$

in terms of positive and negative parts in the Schmidt class.[69] To make σ positive, $(J\tau J)_+$ must cancel τ_- while τ_+ must cancel $(J\tau J)_-$. Since τ and $J\tau J$ have different time evolutions, however, their negative parts are unlikely to be canceled at later times. Hence $\sigma(t)$ is unlikely to be positive. Assuming that τ and $J\tau J$ have finite traces, Tr$\sigma(t)$ is equal to Tr σ, but if $\sigma(t)$ is not positive, Tr $\sigma(t)$ is not equal to the trace norm $\|\sigma(t)\|_1$ required to interpolate between trace and Schmidt norms.

Recall that the allowed class of operators σ is a cone in the trace class. There is an abstract interpolation theory for cones,[70,71] but its interpolating norms are difficult to identify. We do not know whether this is an avenue for further progress.

Summarizing, $S[\sigma(t)]$ is increasing if $\rho(t)$ is of rank 1. For $\rho(t)$ of higher rank it is an open problem whether $S[\sigma(t)]$ may exhibit fluctuations. An example to this effect would be very interesting. In any case $S[\sigma(t)]$ tends to its least upper bound as $t\to\infty$.

To complete this section, we summarize what made us introduce the density operator $\sigma(t)$. Let f belong to the set K^2 described in Sec. IV. Define the two-component quantity $\tilde{f}:=\{f,Jf\}$ with inner product

$$\langle\tilde{f},\tilde{g}\rangle := (f,g)+(Jf,Jg). \tag{8.2}$$

It can be shown that the set of all $\tilde{f}$ determined by $f\in K^2$ is complete under the inner product (8.2), hence a Hilbert space. We denote the Hilbert space by $\tilde{K}^2$. Given a complete orthonormal set $\{\phi_n\}$ $(n=1,2,...)$ in L^2, define

$$\psi_n:=(1+J^2)^{-1/2}\phi_n, \quad \tilde{\psi}_n:=\{\psi_n, J\psi_n\}.$$

This determines a complete orthonormal set $\{\tilde{\psi}_n\}$ $(n=1,2,...)$ in $\tilde{K}^2$.

A positive trace class operator $\tilde{\rho}$ on $\tilde{K}^2$ has to act according to

$$\tilde{\rho}\tilde{f}=\sum_n \mu_n\tilde{\psi}_n\langle\tilde{f},\tilde{\psi}_n\rangle$$

with some orthonormal set $\{\tilde{\psi}_n\}$ and positive eigenvalues μ_n satisfying $\Sigma_n\ \mu_n<\infty$. If $\tilde{f}$ is written as a column with elements $\tilde{f}_0=f$ and $\tilde{f}_1=Jf$, then $\tilde{\rho}$ takes the form of a 2×2 matrix with elements

$$\tilde{\rho}_{00}=\rho, \quad \tilde{\rho}_{01}=\rho J, \quad \tilde{\rho}_{10}=J\rho, \quad \tilde{\rho}_{11}=J\rho J.$$

Here ρ acts as

$$\rho f=\sum_n \mu_n\psi_n(f,\psi_n)=\sum_n \mu_n(1+J^2)^{-1/2}\phi_n(f,[1+J^2]^{-1/2}\phi_n).$$

Hence ρ is of the form (1.3) with Tr $R=\Sigma_n\ \mu_n$.

The transformation $U(t)$ defined by

$$U(t)\tilde{f}:=\{\exp(-iH_0t)f, \quad J\ \exp(-iH_0t)f\} \quad (t\geqslant 0)$$

is an isometry on $\tilde{K}^2$. The family $\{U(t)|0\leqslant t<\infty\}$ is a contraction semigroup. Denote its generator by T and let λ be a complex number. The operator T is closed and symmetric. In the momentum representation its resolvent acts according to

$$(T-\lambda)^{-1}\tilde{f}=\{(k^2-\lambda)^{-1}f(k,\omega), \quad J(k^2-\lambda)^{-1}f(k,\omega)\}.$$

By Sec. IV, $f(k,\omega)\in K^2$ if and only if $f(k,\omega)$ is the boundary value of a function $f\in G^2$. Hence the operator $(T-\lambda)^{-1}$ on $\tilde{K}^2$ is bounded if and only if $(k^2e^{2i\phi}-\lambda)^{-1}f(ke^{i\phi},\omega)\in G^2$ whenever $f(ke^{i\phi},\omega)\in G^2$. Thus $(T-\lambda)^{-1}$ is bounded if and only if Im $\lambda>0$. In other words, while the time evolution on L^2 is generated by the operator H_0 with spectrum $[0,\infty)$, on $\tilde{K}^2$ we have a generator whose spectrum includes the entire real axis $(-\infty,\infty)$. This is interesting because for a classical dynamical system to have a Prigogine entropy operator, it is necessary[28] that the spectrum of the generator of the time evolution runs from $-\infty$ to ∞.

Let $U^*(t)$ be the adjoint of $U(t)$ on $\tilde{K}^2$ and let $\tilde{\rho}(t)$ denote $U(t)\tilde{\rho}U^*(t)$. Since $U(t)$ is an isometry, the entropy $S[\tilde{\rho}(t)]$ is constant in time on $t\geqslant 0$. Notice, however, that if $\tilde{\rho}(t)$ is written as a 2×2 matrix, the sum of its diagonal elements is

$$\tilde{\rho}_{00}(t)+\tilde{\rho}_{11}(t)=\rho(t)+J\rho(t)J=\sigma(t).$$

The motivation to focus on $S[\sigma(t)]$ as an entropy came from publications by Mackey[59,72] in which he showed that taking a trace of a classical dynamical system with constant entropy may give rise to an entropy that increases. As examples he referred to the constructions of $\Lambda\rho(t)$ for the baker map[13] and for K-flows.[15] Recall that $\Lambda\rho(t)$ in these cases evolves in time according to a strong[12,13] (or monotonic[14,15]) Markov semigroup. Mackey[59,72] quoted a theorem due to Rohlin,[73] which essentially says that every such Markov semigroup is a trace of a K-system. Besides coarse graining, taking a trace appears to be one of very few procedures that may generate a system with increasing entropy.

APPENDIX: COUNTEREXAMPLES

Let $\sigma\#$ be a positive operator in the trace class on ML^2. Transformation (8.1) takes $\sigma\#$ into $\tau\#$. The integral kernel of $\tau\#$ is square-integrable. Hence $\tau\#$ belongs to the Schmidt class. This appendix gives examples in which the operator $\tau\#$ is not positive. The implication is that the underlying operator σ is not of the form $\rho+J\rho J$ with positive ρ. Hence σ does not belong to the allowed class to which this paper applies.

For the sake of simplicity the examples consider operators σ of rank 1 or 2 with integral kernels that do not depend on angular variables. There are many possibilities for generalizations. With a slight change of notation, it is sufficient to construct operators $\sigma\#$ in the trace class on $L^2(\mathbb{R})$ such that

$$I:=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\overline{f}(u)(1+e^{-u-v})^{-1}\sigma\#(u,v)f(v)\,du\,dv<0 \tag{A1}$$

for some $f(u)\in L^2(\mathbb{R})$.

Example A1: Suppose $\sigma\#(u,v)=g(u)\overline{g}(v)$ and

$$\overline{f}(u)g(u)=\begin{cases}-\alpha e^{-u} & \text{if } u>0\\ e^{u} & \text{if } u<0,\end{cases}$$

with some real constant α to be determined later. In the first quadrant of the uv-plane we introduce new integration variables $x=e^{-u}$, $y=e^{-v}$, in the second quadrant $x=e^{u}$, $y=e^{-v}$, and so on. This gives

$$I=1-\alpha+(\alpha^2-1)\int_0^1\int_0^1(1+xy)^{-1}dx\,dy.$$

Now

$$\int_0^1(1+xy)^{-1}dx=y^{-1}\ln(1+y)$$

and

$$\int_0^1 y^{-1}\ln(1+y)dy=\sum_{n=1}^{\infty}(-1)^{n-1}n^{-2}=\zeta(2)/2=\pi^2/12.$$

Hence consider

$$I_1(\alpha)=1-\alpha+(\alpha^2-1)(\pi^2/12).$$

This function has zeros $\alpha_1=12\pi^{-2}-1$ and $\alpha_2=1$. It is negative when $\alpha_1<\alpha<\alpha_2$. Given $\alpha\in(\alpha_1,\alpha_2)$, there are many ways in which $f(u)g(u)$ can be factorized into $f(u)$ and $g(u)$. Hence there are many operators $\sigma\#$ of rank 1 resulting in operators $\tau\#$ that are not positive. □

Example A2: For an example in which $\sigma\#$ has rank 2, we first examine $\sigma\#(u,v)=h(u)h(v)$ with

$$\overline{f}(u)h(u)=\begin{cases}-\beta e^{-2u} & \text{if } u>0\\ e^{2u} & \text{if } u<0.\end{cases}$$

Evaluating the integral in Eq. (A1) with the help of the integration variables x and y of Example A1 gives

$$I_2(\beta)=\frac{1}{4}-\frac{1}{4}\beta+(\beta^2-1)\int_0^1\int_0^1 xy(1+xy)^{-1}dxdy=\frac{1}{4}-\frac{1}{4}\beta+\beta^2-1-(\beta^2-1)(\pi^2/12).$$

This function has zeros $\beta_1=(\pi^2-9)(12-\pi^2)^{-1}$ and $\beta_2=1$. It is negative when $\beta_1<\beta<\beta_2$. With a view to the following we note that β_1 is close to 0.4 and α_1 close to 0.2. In any case $\alpha_1<\beta_1$.

We now pick positive numbers a and b, then choose

$$g(u)=\begin{cases}ae^{-u/2},\\ ae^{u/2},\end{cases}\quad h(u)=\begin{cases}be^{-3u/2} & \text{if } u>0\\ be^{3u/2} & \text{if } u<0.\end{cases}\tag{A2}$$

This makes

$$\sigma\#(u,v)=g(u)\overline{g}(v)+h(u)\overline{h}(v)$$

the kernel of a positive operator of rank 2. Notice that $\sigma\#(u,v)$ is well behaved in the sense of being continuous and positive as a function of u, v. However, if $\beta_1<\gamma<1$ and

$$f(u)=\begin{cases}-\gamma e^{-u/2} & \text{if } u>0\\ e^{u/2} & \text{if } u<0,\end{cases}\tag{A3}$$

then the integral I of Eq. (A1) is negative. □

Example A3: Returning to $\sigma\#(u,v)=g(u)\overline{g}(v)$ of rank 1, with $g(u)$ as in Eq. (A2), we let $f_1(u)$ be equal to $f(u)$ defined in Eq. (A3). As noted before, this makes I negative. We also choose

$$f_2(u)=\begin{cases}-\gamma e^{-3u/2} & \text{if } u>0\\ e^{3u/2} & \text{if } u<0.\end{cases}$$

Again I is negative. Hence we have identified linearly independent functions f_1 and f_2 for which I is negative. □

Similar to the Beltrami parametrization of complex structures on a (compact) Riemann surface, we use in this paper the Kodaira-Spencer deformation theory of complex structures on a (compact) complex manifold of higher dimension. According to the Newlander-Nirenberg theorem, a smooth change of local complex coordinates is implemented with respect to an integrable complex structure parametrize by a Beltrami differential. The question of constructing a local field theory on a complex compact manifold is addressed and the action of smooth diffeomorphisms is studied in the BRS algebraic approach. The BRS cohomology for the diffeomorphisms gives generalized Gel'fand-Fuchs cocycles provided that the Kodaira-Spencer integrability condition is satisfied. The diffeomorphism anomaly is computed and turns out to be holomorphically split as in the bidimensional Lagrangian conformal models. Moreover, its algebraic structure is much more complicated than the one proposed in a recent paper [Losev *et al.* Nuc. Phys. B **484**, 196 (1997)]. © *1998 American Institute of Physics.* [S0022-2488(98)00807-X]

I. INTRODUCTION

A class of bidimensional conformal models, thanks to the equivalence between conformal and complex structures on a 2-D manifold, has been suitably incorporated in the framework of the local field theory upon using the Beltrami parametrization of complex structures. Moreover, in this parametrization the holomorphic factorization of the partition functions of these Lagrangian conformal models (free bosonic string, bc system possibly coupled to Yang-Mills gauge fields) has been proved.[2–4]

In a real even dimensions larger than two, the equivalence between conformal and complex structures is no longer valid. However, complex structures on a complex manifold are still parametrized by a vector-valued (0,1)-form fulfilling both an integrability and algebraic conditions. This is the Kodaira-Spencer deformation theory of complex structures on a manifold thus generalizing the Beltrami parametrization to larger dimensions. While in two-(real) dimensions, the Beltrami differential has been used in the study of some bidimensional Lagrangian conformal models on a (compact) Riemann surface, the Kodaira-Spencer deformation of complex structures has occurred in theoretical physics in the context of mirror symmetry in string field models with values in some target Kähler manifold.[5–8]

Quite recently, the holomorphicity of the partition function for chiral lagrangian of higher dimensional bc systems on a Kähler manifold has been considered in Ref. 1, but only with respect to the so-called ''chiral diffeomorphisms.'' It is a restriction which does not represent the whole problem of symmetry under arbitrary reparametrization. Moreover, this *a priori* holomorphicity in

the Beltrami differential defining an (integrable) complex structure is put by hand, and it is not straightforward to decide whether a higher dimensional analog of the *bc* system actually enjoys the holomorphic factorization property. Moreover, the proposed ''chiral anomaly'' in Ref. 1 turns out to be much more complicated as it will be shown in this work.

In the present work, we simply address the question whether this parametrization might give rise to interesting features for possible local field theories on a compact complex manifold, for instance, whether the Beltrami differential may play a role at the field level. In particular, we have in mind the four-(real) dimensional interesting case and possible links with the recent work.[9] For other noteworthy implications of the holomorphicity in the Beltrami differential the reader is referred to Ref. 1.

Following closely the bidimensional approach where smooth diffeomorphisms connected to the identity map make up the ''gauge group,'' the action of smooth diffeomorphisms (and not chiral diffeomorphisms as considered in Ref. 1) is studied in the BRS formulation. Furthermore, the BRS cohomology for diffeomorphisms is analyzed along the lines developed in Refs. 10–12, and allows one to compute the local expression of a diffeomorphism anomaly. A few possible Lagrangian models will be investigated. The first part of the present paper is devoted to the notation and, according to the book[13] by Kodaira, we will introduce the parametrization of complex structures on a compact manifold by vector-valued (0,1)-forms, the higher dimensional analogs of the Beltrami differentials. We shall concentrate on the generalized matter fields considered as usual tensors.

The main part of the paper is based on the study of the diffeomorphism cohomology and the finding of anomalies under the locality principle. The cohomology can be carried out for the BRS operator of the diffeomorphisms which is nilpotent under the restriction that the complex structure is integrable.

II. BASIC IDEA FOR THE PERTURBATION OF COMPLEX STRUCTURES

Consider a complex compact manifold of complex dimension n according to a finite complex analytic covering $\{(U_\alpha, z_\alpha)\}$ with $M=\cup_\alpha U_\alpha$ and $z_\alpha: U_\alpha \to \mathbf{C}^n$, the local complex coordinate mapping, $z\equiv(z^1,\ldots,z^n)=(z^k)$, with biholomorphic transition functions

$$\text{in } U_\alpha \cap U_\beta \neq \varnothing: \quad z_\alpha = f_{\alpha\beta}(z_\beta), \tag{II.1}$$

for any point in the intersection. When the underlying smooth structure is considered (thus M is viewed as a real smooth manifold of dimension $2n$), the complex conjugate coordinates $\overline{z}\equiv(\overline{z^1},\ldots,\overline{z^n})=(\overline{z^k})$ is regarded as independent with respect to z.

Partial derivatives will be shortly denoted as $\partial/\partial z^k \equiv \partial_k$ and $\partial/\partial \overline{z^j} \equiv \partial_{\overline{J}}$. We shall denote by $T^{1,0}$ the holomorphic tangent bundle of M, and ∂ will stand for the natural frame on $T^{1,0}$ associated with the local background complex coordinates $(z,\overline{z})$. Similarly, dz will be the natural dual basis in the holomorphic cotangent space $(T^{1,0})^*$,

$$\partial \equiv \begin{pmatrix} \partial_1 \\ \vdots \\ \partial_n \end{pmatrix}, \quad \overline{\partial} \equiv \begin{pmatrix} \partial_{\overline{1}} \\ \vdots \\ \partial_{\overline{n}} \end{pmatrix}, \quad dz \equiv (dz^1,\ldots,dz^n), \quad d\overline{z} \equiv (d\overline{z^1},\ldots,d\overline{z^n}), \tag{II.2}$$

while we have for the external derivative (denoted here by a boldface symbol)

$$d = \boldsymbol{\partial} + \overline{\boldsymbol{\partial}} = dz\cdot\partial + d\overline{z}\cdot\overline{\partial} = dz^k\partial_k + d\overline{z^j}\partial_{\overline{J}}, \quad d^2 = \boldsymbol{\partial}^2 = \overline{\boldsymbol{\partial}}^2 = \{\boldsymbol{\partial}, \overline{\boldsymbol{\partial}}\} = 0. \tag{II.3}$$

This given system of local complex coordinates (which is fixed once and for all) will serve as a background for the perturbation implemented by modifying transition functions, according to the Kodaira-Spencer's approach, as follows. On any overlapping $U_\alpha \cap U_\beta \neq \varnothing$, of the finite covering, the background transition function $f_{\alpha\beta}(z_\beta)$ is replaced by another function $f_{\alpha\beta}(z_\beta,t)$, such that $f_{\alpha\beta}(z_\beta,0)=f_{\alpha\beta}(z_\beta)$, and where t is a complex parameter belonging to some domain of $\mathbf{C}^m$ containing the origin. One can thus get a complex analytic family parametrized by t of complex compact manifolds. It turns out that the infinitesimal deformation of M can be represented by an

element of the cohomology group $H^1(M,\Theta)$ of M with coefficients in the sheaf Θ of germs of holomorphic vector fields on M. In most cases, the Kodaira-Spencer's conjecture holds, dim $H^1(M,\Theta)=m$ would give the dimension of the moduli space of M when the number of moduli can be defined. A question of primary importance is to know whether it is always possible to deform a complex manifold. A partial answer is given, for instance, in Ref. 13: It is always possible to deform the complex structure on any complex compact manifold. Furthermore, all the complex compact manifolds belonging to the same complex analytic family are all diffeomorphic since they are subordinated to the same smooth structure underlying the background complex structure. This situation allows one to tackle the deformation problem by parametrizing the complex structures by a vector-valued (0,1)-form on M which extends to the higher dimensional case the well-known Beltrami parametrization of complex structures on a Riemann surface.

A. The Newlander-Nirenberg theorem and the Kodaira-Spencer integrability condition

Let $\boldsymbol{\mu}$ be a vector-valued (0,1)-form, a smooth section of $T^{1,0}\otimes(T^{0,1})^*$ and then locally represented as

$$\boldsymbol{\mu}(z,\bar{z})=d\bar{z}\cdot\mu(z,\bar{z})\cdot\partial=\mu^k_J(z,\bar{z})d\bar{z}^J\otimes\partial_k,\quad \mu=(\mu^k_J). \tag{II.4}$$

This object generalizes the usual Beltrami differential but will be subject to an integrability condition as stated below.

Theorem: (Newlander-Nirenberg[13]) For a given smooth vector-valued (0,1)-form, $\boldsymbol{\mu}$, viewed as a differential operator of first order and locally defined on M by Eq. (II.4), consider the following partial differential operator of first order:

$$\boldsymbol{\mathcal{L}}=\bar{\boldsymbol{\partial}}-\boldsymbol{\mu}=d\bar{z}\cdot(\bar{\partial}-\mu\cdot\partial)=d\bar{z}^i\mathcal{L}_{\bar{\imath}}=d\bar{z}^i(\partial_{\bar{\imath}}-\mu^k_{\bar{\imath}}\partial_k). \tag{II.5}$$

Next suppose that $\boldsymbol{\mu}$ obeys the following two conditions:

$$\det(I-\mu\bar{\mu})\neq 0,\quad \text{and}\quad \boldsymbol{\mathcal{L}}\boldsymbol{\mu}=\bar{\boldsymbol{\partial}}\boldsymbol{\mu}-\boldsymbol{\mu}^2=\bar{\boldsymbol{\partial}}\boldsymbol{\mu}-\tfrac{1}{2}[\boldsymbol{\mu},\boldsymbol{\mu}]=0, \tag{II.6}$$

where the graded bracket reflects the bracket of vector fields.

Hence, the differential operators $\mathcal{L}_{\bar{1}},\ldots,\mathcal{L}_{\bar{n}},\bar{\mathcal{L}}_1,\ldots,\bar{\mathcal{L}}_n$ are linearly independent and they fulfill the condition

$$\boldsymbol{\mathcal{L}}^2=0\Leftrightarrow[\mathcal{L}_{\bar{\imath}},\mathcal{L}_{\bar{J}}]=0,\quad \bar{\imath},\bar{J}=1,\ldots,n. \tag{II.7}$$

Moreover, the system of n PDE's

$$\boldsymbol{\mathcal{L}}f=0\Leftrightarrow\mathcal{L}_{\bar{\imath}}f=0,\quad \bar{\imath}=1,\ldots,n, \tag{II.8}$$

has locally n linearly independent smooth solutions $Z=(Z^1(z,\bar{z}),\ldots,Z^n(z,\bar{z}))$, i.e., the Jacobian never vanishes,

$$\mathcal{J}\equiv\frac{\partial(Z,\bar{Z})}{\partial(z,\bar{z})}=|\det\lambda|^2\det(I-\mu\bar{\mu})\neq 0\Rightarrow\det\lambda\neq 0, \tag{II.9}$$

where $\lambda=(\partial_i Z^k)$ is the (half)-Jacobian matrix.

B. The smooth change of local complex coordinates

Furthermore, the solution Z provides a new system of complex coordinates on M, that is a new integrable complex structure parametrized by μ. The new complex structure $(Z,\bar{Z})$ on M can be seen as a deformation of the background complex structure $(z,\bar{z})$, and each such μ determines an integrable complex structure on M.

Remark: The coordinates Z local solutions of system (II.8) are defined up to an holomorphic function $F(Z)$. Also, when $\mu=(\mu_1^k)\equiv 0$ the change of local coordinates becomes holomorphic so that $\mu\equiv 0$ corresponds to the complex structure given by z. Moreover, one has $\det \lambda \neq 0$.

The Newlander-Nirenberg theorem infers a *smooth* change of local complex coordinates in $\mathbf{C}^n$, $(z,\bar{z})\to(Z,\bar{Z})$. These complex coordinates Z can be reobtained by the following row-vector of 1-forms:

$$dZ=\boldsymbol{\partial} Z+\boldsymbol{\mu} Z=(dz+d\bar{z}\cdot\mu)\cdot\lambda. \tag{II.10}$$

One accordingly gets the following integrability conditions, on the one hand $\lambda=(\partial_i Z^k)$, $\det \lambda \neq 0$,

$$\bar{\boldsymbol{\partial}}\boldsymbol{\partial} Z+\boldsymbol{\partial}(\boldsymbol{\mu} Z)=0\Leftrightarrow\bar{\partial}\lambda-\partial(\mu\cdot\lambda)=0, \tag{II.11}$$

and the other hand, the necessary integrability condition (II.6) on $\boldsymbol{\mu}$. Therefore, the defining system of n PDE's (II.8) for Z, namely,

$$\boldsymbol{\mathcal{L}} Z=(\bar{\boldsymbol{\partial}}-\boldsymbol{\mu})Z=0, \quad \boxed{\bar{\boldsymbol{\partial}}\boldsymbol{\mu}-\boldsymbol{\mu}^2=0,}$$

is the analog of the Beltrami equation but with in addition an integrability condition. The latter looks like the vanishing of a curvature. One may also assume that $\det(I-\mu\bar{\mu})>0$ and $\det \lambda >0$, when orientation-preserving coordinate transformations are in order.

According to definition (II.10) and its complex conjugate, one can write in matrix notation

$$(dZ,d\bar{Z})=(dz,d\bar{z})\begin{pmatrix} I & \bar{\mu} \\ \mu & I \end{pmatrix}\begin{pmatrix} \lambda & 0 \\ 0 & \bar{\lambda} \end{pmatrix}, \tag{II.13}$$

so that by duality

$$\begin{pmatrix} \partial_Z \\ \partial_{\bar{Z}} \end{pmatrix}=\begin{pmatrix} \lambda & 0 \\ 0 & \bar{\lambda} \end{pmatrix}^{-1}\begin{pmatrix} I & \bar{\mu} \\ \mu & I \end{pmatrix}^{-1}\begin{pmatrix} \partial_z \\ \partial_{\bar{z}} \end{pmatrix}. \tag{II.14}$$

One explicitly finds

$$\begin{pmatrix} \partial_Z \\ \partial_{\bar{Z}} \end{pmatrix}=\begin{pmatrix} \lambda^{-1}\cdot(I-\bar{\mu}\cdot\mu)^{-1}\cdot(\partial_z-\bar{\mu}\cdot\partial_{\bar{z}}) \\ \bar{\lambda}^{-1}\cdot(I-\mu\cdot\bar{\mu})^{-1}\cdot(\partial_{\bar{z}}-\mu\cdot\partial_z) \end{pmatrix}\equiv\begin{pmatrix} \lambda^{-1}\cdot\nabla \\ \bar{\lambda}^{-1}\cdot\bar{\nabla} \end{pmatrix}. \tag{II.15}$$

III. THE DIFFEOMORPHISM ACTION

By computing the pull-back of the 1-form (II.10) under any smooth diffeomorphism φ, $\varphi^* dZ=d\varphi^* Z=(d\varphi^* w+d\varphi^*\bar{w})\cdot(\varphi^*\mu))\cdot(\varphi^*\lambda)=(dz+d\bar{z}\cdot(\mu^\varphi))\cdot(\lambda^\varphi)$, where $(z,\bar{z})$ are coordinates in the source chart of φ and $(w,\bar{w})=\varphi(z,\bar{z})$ in the target chart, the finite diffeomorphism transformation of the matrices of basic geometric objects reads

$$\begin{aligned} \lambda^\varphi&=(\partial\varphi+\partial\bar{\varphi}\cdot(\mu\circ\varphi))\cdot(\lambda\circ\varphi), \\ \mu^\varphi&=(\bar{\partial}\varphi+\overline{\partial\varphi}\cdot(\mu\circ\varphi))\cdot(\partial\varphi+\partial\bar{\varphi}\cdot(\mu\circ\varphi))^{-1}. \end{aligned} \tag{III.1}$$

Thus, as a vector-valued $(0,1)$-form,

$$\boldsymbol{\mu}^\varphi=d\bar{z}\cdot\mu^\varphi\cdot\partial=(\bar{\boldsymbol{\partial}}\varphi+\overline{\boldsymbol{\partial}\varphi}\cdot(\mu\circ\varphi))\cdot(\partial\varphi+\partial\bar{\varphi}\cdot(\mu\circ\varphi))^{-1}\cdot\partial. \tag{III.2}$$

We arrive at the equivalence problem between integrable complex structures. Consider two copies of the compact complex manifold M with local background complex coordinates $(z,\bar{z})$ and let φ be any smooth diffeomorphism homotopic to the identity map. Given a vector-valued

(0,1)-form, $\boldsymbol{\mu}$, submitted to the condition $\overline{\boldsymbol{\partial}}\boldsymbol{\mu}-\boldsymbol{\mu}^2=0$, let $(Z,\overline{Z})$ be the local complex coordinates at the point $(w,\overline{w})=\varphi(z,\overline{z})$ solving the system of n PDE's (II.12), then one can merely show that the integrability condition is preserved by diffeomorphisms (as will be explicitly proved in Appendix A and also below for the infinitesimal version)

$$\overline{\boldsymbol{\partial}}\boldsymbol{\mu}-\boldsymbol{\mu}^2=0\Rightarrow\overline{\boldsymbol{\partial}}\boldsymbol{\mu}^{\varphi}-(\boldsymbol{\mu}^{\varphi})^2=0, \tag{III.3}$$

and thanks to the Newlander-Nirenberg theorem there are local complex coordinates Z^{φ} pertaining to the integrable complex structure parametrized by $\boldsymbol{\mu}^{\varphi}$; hence one has

$$(\overline{\boldsymbol{\partial}}-\boldsymbol{\mu}^{\varphi})Z^{\varphi}=0. \tag{III.4}$$

The problem is to see whether the mapping $(Z^{\varphi},\overline{Z^{\varphi}})\rightarrow(Z,\overline{Z})$ is indeed biholomorphic. If it is so, then $\boldsymbol{\mu}$ and $\boldsymbol{\mu}^{\varphi}$ define equivalent integrable complex structures which thus correspond to the same point t in the moduli space. The situation is the same as for Riemann surfaces, that is the mapping $(Z^{\varphi},\overline{Z^{\varphi}})\rightarrow(Z,\overline{Z})$ is actually biholomorphic. $\boldsymbol{\mu}$ and $\boldsymbol{\mu}^{\varphi}$ defining equivalent integrable complex structures. The reader is referred to Appendix B for the details.

The infinitesimal action given by the (graded) Lie derivative, $s\equiv L_{\mathbf{c}}=i_{\mathbf{c}}d-di_{\mathbf{c}}$ and, thanks to (II.10), writes locally in each open set U,

$$sZ=L_{\mathbf{c}}Z=i_{\mathbf{c}}dZ=(c+\overline{c}\cdot\mu)\cdot\lambda\equiv C\cdot\lambda\equiv\Upsilon, \tag{III.5}$$

where $\boldsymbol{c}=c\cdot\partial+\overline{c}\cdot\overline{\partial}=\Upsilon\cdot\partial_Z+\overline{\Upsilon}\cdot\partial_{\overline{Z}}$ is the (smooth) Faddeev-Popov ghost vector field expressed, respectively, in the holomorphic coordinates z and Z, and C reflects a change of basis in the Lie algebra of diffeomorphisms leading to the holomorphic factorization property of bidimensional conformal models.[14,15,3,4] Here, in matrix notation, we have

$$(C,\overline{C})=(c,\overline{c})\begin{pmatrix} I & \overline{\mu} \\ \mu & I \end{pmatrix},\quad (\Upsilon,\overline{\Upsilon})=(C,\overline{C})\begin{pmatrix} \lambda & 0 \\ 0 & \overline{\lambda} \end{pmatrix}, \tag{III.6}$$

the latter being the BRS counterpart of Eq. (II.13).

On the one hand, the infinitesimal version of (III.1) can be expressed in terms of the nilpotent BRS operation, $s^2=0$, as

$$\begin{aligned} s\lambda&=\boldsymbol{c}\lambda+(\partial c+\partial\overline{c}\cdot\mu)\cdot\lambda,\\ s\mu&=\boldsymbol{c}\mu+(\overline{\partial}-\mu\cdot\partial)c+(\overline{\partial}-\mu\cdot\partial)\overline{c}\cdot\mu,\\ s\boldsymbol{c}&=\tfrac{1}{2}[\boldsymbol{c},\boldsymbol{c}],\quad \boldsymbol{c}=c\cdot\partial+\overline{c}\cdot\overline{\partial}, \end{aligned} \tag{III.7}$$

where the graded bracket is that of vector fields. Note that the variation of μ is nonlinear in μ. Moreover, we know that the integrability condition (II.6) is s-invariant thanks to Appendix A.

On the other hand, with respect to the integrable complex structure defined by μ, the infinitesimal action of diffeomorphisms on the complex coordinate Z writes locally in U, with $s^2=0$,

$$\begin{aligned} &sZ\equiv\boldsymbol{c}Z=\Upsilon,\quad s\Upsilon=0,\\ &s\boldsymbol{d}+\boldsymbol{d}s=0\Rightarrow[s,\partial_Z]=-\partial_Z\boldsymbol{c}. \end{aligned} \tag{III.8}$$

Accordingly, one has the following remarkable identities, together with their complex conjugate:

$$[s-\boldsymbol{c},\partial_Z]=0,\quad s\boldsymbol{\partial}+\boldsymbol{\partial}s=\boldsymbol{\partial}\overline{\Upsilon}\cdot\partial_{\overline{Z}}-\overline{\boldsymbol{\partial}}\,\Upsilon\cdot\partial_Z. \tag{III.9}$$

By computing directly $s\ dZ=-ds\ Z$, one finds,

$$s\lambda=\partial(C\cdot\lambda),$$

$$s\boldsymbol{\mu}=-\overline{\boldsymbol{\partial}}(C\cdot\partial)+[\boldsymbol{\mu},C\cdot\partial],\quad \boldsymbol{\mu}=d\overline{z}\cdot\mu\cdot\partial, \tag{III.10}$$

$$s(C\cdot\partial)=\tfrac{1}{2}[C\cdot\partial,C\cdot\partial]=(C\cdot\partial C)\cdot\partial,$$

where the component C of the vector field $C\cdot\partial$, a smooth section of the holomorphic tangent bundle $T^{1,0}$,[13] is defined by (III.6).

The reader's attention is drawn to the fact that, these two systems of infinitesimal variations for $\boldsymbol{\mu}$ and λ, (III.7) and (III.10), are equivalent only upon the use of both the integrability conditions (II.6) and (II.11). The former represents the true infinitesimal action of diffeomorphisms, while the latter, which holds only in the case of an integrable complex structure, will govern the holomorphic factorization property. In the integrable case, the system (III.10) will also represent the infinitesimal action of diffeomorphisms, and the integrability condition (II.6) is seen to be stable under diffeomorphisms by

$$\overline{\boldsymbol{\partial}}\boldsymbol{\mu}-\boldsymbol{\mu}^2=0\Rightarrow s(\overline{\boldsymbol{\partial}}\boldsymbol{\mu}-\boldsymbol{\mu}^2)=[C\cdot\partial,\overline{\boldsymbol{\partial}}\boldsymbol{\mu}-\boldsymbol{\mu}^2]=0. \tag{III.11}$$

IV. FIELDS AND LAGRANGIANS

According to what has been done in the two dimensional case,[16,17,3,4,11] one can take advantage of the complex coordinate system Z pertaining to an integrable complex structure μ, in order to exhibit some simple Lagrangians built on a n-dimensional complex manifold.

Before going further, one presumes that a classical action Γ_0^{Cl} has to be well defined on the complex manifold M, i.e.,

$$\Gamma_0^{\mathrm{Cl}}=\int_M dZ^{A_n}\wedge d\overline{Z}^{\overline{A}_n}L_{A_n\overline{A}_n}(Z,\overline{Z}), \tag{IV.1}$$

where in the integrand a multi-index notation has been used; see Eq. (V.26) below, with $|A_n|=|\overline{A}_n|=n$. This means that the Lagrangian density is a skew-symmetric covariant tensorial density under holomorphic change of local coordinates $Z\to Z'(Z)$,

$$L_{A'_n\overline{A}'_n}(Z',\overline{Z}')=\left|\frac{\partial(Z'^1,\ldots,Z'^n)}{\partial(Z^1,\ldots,Z^n)}\right|^{-2}L_{A_n\overline{A}_n}(Z,\overline{Z}),\quad |A_n|=|A'_n|=|\overline{A}_n|=|\overline{A}'_n|=n. \tag{IV.2}$$

For instance, one may ask whether analog Lagrangians of the bc-systems as well as a generalization of the bosonic string can be obtained over such a higher dimensional complex manifold, and what is the role of the complex structure.

Our purpose is first to use the holomorphic coordinates Z and then to make explicit the coupling of matter fields with the integrable complex structure μ.

The simplest higher-dimensional analog of the bidimensional bc-system[3,4] is constructed by considering a holomorphic vector bundle E over M and the fields Ψ as a smooth section of $T^{k,0*}\otimes E$, $0\leqslant k\leqslant n-1$, and Ψ^* a smooth section of $T^{n-k,n-1*}\otimes E^*$. Our choice for the bc fields is rather different from the one written in Ref. 1 and reduces to the usual bc-system for $n=1$. One has following well-defined action:

$$S_{bc}=\int_M \Psi^*\wedge(\overline{\boldsymbol{\partial}}+\overline{\boldsymbol{A}})\Psi, \tag{IV.3}$$

where the (0,1)-connection form $\overline{\boldsymbol{A}}$ parametrizes the holomorphic structure on E provided the integrability condition, $\overline{\boldsymbol{\partial}\boldsymbol{A}}+\overline{\boldsymbol{A}}^2=0$, is satisfied.[18]

The natural generalization of the free bosonic string action reads

$$S(\Phi)=\int_M \overline{\boldsymbol{\partial}}\Phi\wedge\overline{(\overline{\boldsymbol{\partial}}\Phi)}, \tag{IV.4}$$

where in a multi-index notation $\Phi=\Phi_I\,dZ^I$ is a smooth complex-valued $(n-1,0)$-form which can be chosen to be real only in the case $n=1$.

One can see that it is not possible to consider scalar fields in such a complex model unless there exists a Hermitian metric g on M.

In any case, the important point is that the above Lagrangian densities depend locally on the integrable complex structure μ. One can directly check that the two above actions are actually local in μ. Indeed, defining the following change of field variables $(\lambda^I_J)\Phi_I=\phi_J$, with $(\lambda^I_J)=\lambda^{i_1}_{j_1}\cdots\lambda^{i_{n-1}}_{j_{n-1}}$, according to the form degree, then action (IV.4) reads

$$S(\phi,\mu,\overline{\mu})=\int_M \det(I-\mu\cdot\overline{\mu})(\overline{\nabla}\phi+\imath(\boldsymbol{\tau})\phi)\wedge\overline{(\overline{\nabla}\phi+\imath(\boldsymbol{\tau})\phi)}, \tag{IV.5}$$

where $\nabla=dz\cdot\nabla$ [∇ defined in (II.15)] and $\imath(\boldsymbol{\tau})\phi=(n-1)\tau^r\wedge\phi_r$ is a $(n-1,1)$-form given by the inner product on the $(n-1,0)$-form $\phi=\phi_I\,dz^I$ with respect to the vector-valued $(1,1)$-form $\boldsymbol{\tau}=d\overline{z}\cdot(I-\mu\overline{\mu})^{-1}\wedge\boldsymbol{\partial}\mu\cdot\partial$. In the course of the calculation, condition (II.11) on the integrating factor has been used.

Similarly, for the bc-system the action takes the following local expression in μ:

$$S_{bc}(\psi,\psi^*,\mu,\overline{\mu})=\int_M \det(I-\mu\cdot\overline{\mu})\,\psi^*\wedge(\overline{\nabla}+\imath(\boldsymbol{\tau})+d\overline{z}\cdot(I-\mu\overline{\mu})^{-1}\cdot\overline{a})\psi, \tag{IV.6}$$

with $\imath(\boldsymbol{\tau})\psi=k\tau^r\wedge\psi_r$ is a $(k,1)$-form with values (as well ψ) in a copy of the holomorphic vector bundle E with respect to the complex analytic coordinates z, and where we have set for the components of the $(0,1)$-type connection $A_{\overline{Z}}=\lambda^{-1}\cdot(I-\mu\overline{\mu})^{-1}\cdot\overline{a}$. In this framework, (integrable) complex structures on E are parametrized by μ and $\overline{a}$ upon the integrability conditions $\overline{\boldsymbol{\mathcal{L}}}\boldsymbol{\mu}=0$ and $\overline{\boldsymbol{\mathcal{L}}}\overline{\boldsymbol{a}}+\overline{\boldsymbol{a}^2}=0$, respectively. However, the obvious holomorphic factorization property in μ for $n=1$, $(\psi^*\wedge(\overline{\boldsymbol{\partial}}-\boldsymbol{\mu}+\overline{\boldsymbol{a}})\psi)$ (Ref. 4) is spoiled, and the action S_{bc} strongly differs from the one proposed in) Ref. 1 which is assumed to enjoy that property in any dimension.

The action of diffeomorphisms gives rise, for instance, to the following local (in μ) transformation laws on the $(n-1,0)$-form ϕ and on the bc fields ψ and ψ^*:

$$s\phi=\boldsymbol{c}\phi+\imath(\tilde{\boldsymbol{\Omega}})\phi,\quad s\psi=\boldsymbol{c}\psi+\imath(\tilde{\boldsymbol{\Omega}})\psi,\quad s\psi^*=\boldsymbol{c}\psi^*+\imath(\tilde{\boldsymbol{\Omega}})\psi^*+\imath(\overline{\tilde{\boldsymbol{\Omega}}})\psi^*, \tag{IV.7}$$

where we have introduced the following vector-valued $(1,0)$-form carrying ghost grading one $\tilde{\boldsymbol{\Omega}}=dz\cdot(\partial c+\partial\overline{c}\cdot\mu)\cdot\partial$ which governs the parallel transport along the ghost vector field $\boldsymbol{c}$.

V. STUDY OF POSSIBLE DIFFEOMORPHISM ANOMALIES

From now on, since matter fields have not been specified, they will be collectively denoted by ϕ, and together with the integrable complex structure μ, one introduces the short-hand notation $f_0\equiv\{\phi,\psi,\psi^*,\mu^k_{\overline{i}},\overline{\mu^j_l}\}$, and for the diffeomorphism ghost fields as well $f_1\equiv\{c^i,\overline{c^l}\}$, and $f\equiv f_0\cup f_1$. In order to suppress the index summation and the integration over the manifold M as well, we also introduce the dual contraction by the bracket $\langle,\rangle$, defined as

$$\langle\tilde{f},f\rangle\equiv\int_M dz^n\wedge d\overline{z}^n\langle\tilde{f}(z,\overline{z}),f(z,\overline{z})\rangle. \tag{V.1}$$

The diffeomorphism symmetry (III.7) can be encoded in the following nilpotent BRS functional operator:

$$\delta_0=\sum_f\left\langle sf,\frac{\delta}{\delta f}\right\rangle,\quad sf(z,\overline{z})=\boldsymbol{c}f(z,\overline{z})+V(f,c,\overline{c})(z,\overline{z}), \tag{V.2}$$

where V is a local differential polynomial. The diffeomorphism invariance of the classical theory is stated in a Ward identity, $\delta_0\Gamma_0^{\mathrm{Cl}}[f_0]=0$, together with the integrability condition on the μ's, which may be seen as a local constraint,

$$[\mathcal{L}_{\bar{\imath}},\mathcal{L}_{\bar{J}}]=(\mathcal{L}_{\bar{\imath}}\mu_{\bar{J}}^{k}-\mathcal{L}_{\bar{J}}\mu_{\bar{\imath}}^{k})\partial_k\equiv F_{\bar{\imath}\bar{J}}^{k}(\mu)\partial_k,\quad \text{with}\quad F_{\bar{\imath}\bar{J}}^{k}(\mu)=0, \tag{V.3}$$

with of course the complex conjugate expression. According to the diffeomorphism invariance of the integrability condition, one has

$$\delta_0 F_{\bar{\imath}\bar{J}}^{k}(\mu)=0=\delta_0\bar{F}_{ij}^{\bar{l}}(\bar{\mu}). \tag{V.4}$$

Following the spirit of Ref. 15, in the vacuum sector ($\phi\equiv 0$), we can rephrase the Ward identity in terms of local Ward operators with respect to the ghost (parameter) fields, c's, as

$$\begin{aligned}W_k(z,\bar{z})\Gamma_0^{\mathrm{Cl}}[\mu,\bar{\mu}]\equiv&\left(\partial_k\mu_{\bar{\imath}}^{r}\frac{\delta}{\delta\mu_{\bar{\imath}}^{r}}-\partial_{\bar{\imath}}\frac{\delta}{\delta\mu_{\bar{\imath}}^{k}}+\partial_r\left(\mu_{\bar{\imath}}^{r}\frac{\delta}{\delta\mu_{\bar{\imath}}^{k}}\right)\right.\\&\left.+\bar{\mu}_k^{\bar{s}}\left(\partial_{\bar{s}}\bar{\mu}_{\bar{l}}^{\bar{J}}\frac{\delta}{\delta\bar{\mu}_{\bar{l}}^{\bar{J}}}+\partial_{\bar{J}}\left(\bar{\mu}_{\bar{l}}^{\bar{J}}\frac{\delta}{\delta\bar{\mu}_{\bar{l}}^{\bar{s}}}\right)\right)+\bar{F}_{kl}^{\bar{J}}(\bar{\mu})\frac{\delta}{\delta\bar{\mu}_{\bar{l}}^{\bar{J}}}\right)(z,\bar{z})\Gamma_0^{\mathrm{Cl}}[\mu,\bar{\mu}]=0,\end{aligned} \tag{V.5}$$

together with the complex conjugate expression $\bar{W}_{\bar{J}}\Gamma_0^{\mathrm{Cl}}[\mu,\bar{\mu}]=0$. One can directly check that the combination

$$\begin{aligned}(W_k-\bar{\mu}_k^{\bar{l}}\bar{W}_{\bar{l}})(z,\bar{z})\Gamma_0^{\mathrm{Cl}}[\mu,\bar{\mu}]=&\left(\bar{F}_{kl}^{\bar{J}}(\bar{\mu})\frac{\delta}{\delta\bar{\mu}_{\bar{l}}^{\bar{J}}}-\bar{\mu}_k^{\bar{l}}F_{\bar{l}\bar{\imath}}^{r}(\mu)\frac{\delta}{\delta\mu_{\bar{\imath}}^{r}}+(I-\bar{\mu}\cdot\mu)_k^{t}\right.\\&\left.\times\left(\partial_r\mu_{\bar{\imath}}^{r}\frac{\delta}{\delta\mu_{\bar{\imath}}^{t}}-\partial_{\bar{\imath}}\frac{\delta}{\delta\mu_{\bar{\imath}}^{t}}+\mu_{\bar{\imath}}^{r}\partial_r\frac{\delta}{\delta\mu_{\bar{\imath}}^{t}}+\partial_t\mu_{\bar{\imath}}^{r}\frac{\delta}{\delta\mu_{\bar{\imath}}^{r}}\right)\right)(z,\bar{z})\Gamma_0^{\mathrm{Cl}}[\mu,\bar{\mu}]\\=&0,\end{aligned} \tag{V6}$$

no longer depends on the $\bar{\mu}$'s if the integrability conditions $F(\mu(z,\bar{z}))=\bar{F}(\bar{\mu}(z,\bar{z}))=0$ are taken into account. With these constraints one obtains a new local Ward operator

$$\begin{aligned}\mathcal{W}_k(z,\bar{z})\Gamma_0^{\mathrm{Cl}}[\mu,\bar{\mu}]\equiv&([(I-\bar{\mu}\cdot\mu)^{-1}]_k^{t}(W_t-\bar{\mu}_t^{\bar{l}}\bar{W}_{\bar{l}}))(z,\bar{z})\Gamma_0^{\mathrm{Cl}}[\mu,\bar{\mu}]\\=&\left(\partial_r\mu_{\bar{\imath}}^{r}\frac{\delta}{\delta\mu_{\bar{\imath}}^{k}}-\partial_{\bar{\imath}}\frac{\delta}{\delta\mu_{\bar{\imath}}^{k}}+\mu_{\bar{\imath}}^{r}\partial_r\frac{\delta}{\delta\mu_{\bar{\imath}}^{k}}+\partial_k\mu_{\bar{\imath}}^{r}\frac{\delta}{\delta\mu_{\bar{\imath}}^{r}}\right)(z,\bar{z})\Gamma_0^{\mathrm{Cl}}[\mu,\bar{\mu}],\end{aligned} \tag{V.7}$$

which reflects the linear change of parameter $C^k=c^k+\mu_{\bar{\imath}}^{k}\bar{c}^{\bar{\imath}}$ corresponding to the variation (III.10) of μ. Recall that the latter is equivalent to the Lie derivative of μ only if the integrability condition is considered.

On the physical side, the meaning of the geometrical quantity

$$\Theta_k^{\bar{l}}(z,\bar{z})\equiv\frac{\delta\Gamma_0^{\mathrm{Cl}}}{\delta\mu_{\bar{\imath}}^{k}(z,\bar{z})}$$

is still lacking. It does not correspond to the energy-momentum tensor as in the bidimensional case since the equivalence between conformal and integrable complex structures no longer holds in higher dimensions. Moreover, the μ's which serve as classical source for the components of Θ are not all independent of each other due to the integrability condition. The question whether the latter induces some constraints on the theory is not yet under control. Nevertheless, one may write down the classical Ward identity (V.7) in the vacuum sector with respect to the ghost C, as

$$\left(\mathcal{L}_i^{\bar{}}(z,\bar{z}) \frac{\delta}{\delta \mu_i^k(z,\bar{z})} - \partial_r \mu_i^r(z,\bar{z}) \frac{\delta}{\delta \mu_i^k(z,\bar{z})} - \partial_k \mu_i^r(z,\bar{z}) \frac{\delta}{\delta \mu_i^r(z,\bar{z})} \right) \Gamma_0^{\mathrm{Cl}}[\mu,\bar{\mu}] = 0. \quad \text{(V.8)}$$

Geometrically, when passing to the $(Z,\bar{Z})$ complex coordinates, Θ behaves like a $(T^{1,0})^* \otimes (T^{0,1})$-valued density according to the following transformation law:

$$\vartheta(Z,\bar{Z}) \equiv \frac{1}{\mathcal{J}} \lambda^{-1} \cdot \Theta(z,\bar{z}) \cdot (I - \mu \cdot \bar{\mu}) \cdot \bar{\lambda}, \quad \text{(V.9)}$$

where $\mathcal{J}$ is the Jacobian defined in (II.9). In terms of the $(Z,\bar{Z})$ complex coordinates, the classical Ward identities (V.8) translate to the vanishing of the following divergences (see Appendix C for some computational details):

$$\partial_{Z^r} \bar{\vartheta}_k^r = 0. \quad \text{(V.10)}$$

Note that for $n=1$, (V.9) reduces to the transformation law of a quadratic differential.[17]

We now introduce external fields $\beta \equiv \beta_{-1} \cup \beta_{-2} \equiv \{\gamma, \eta_k^{\bar{}}, \bar{\eta}_J^{\bar{}}\} \cup \{\zeta_i, \bar{\zeta}_i^{\bar{}}\}$, with an assigned (negative) ghost grading, respectively, coupled to the BRS variation of the fields $f \equiv \{\phi, \mu_i^k, \bar{\mu}_l^{\bar{}}, c^i, \bar{c}^{i\bar{}}\}$, in order to have a Φ-Π neutral action, written in a shorthand notation as

$$\Gamma_1^{\mathrm{Cl}}[\beta,f] = \sum_f \langle \beta, sf \rangle. \quad \text{(V.11)}$$

One has $\delta_0 \Gamma_1^{\mathrm{Cl}}[\beta,f] = 0$ thanks to $s^2 = 0$. Within the following enlarged classical action, $\Gamma^{\mathrm{Cl}}[\beta,f] = \Gamma_0^{\mathrm{Cl}}[f_0] + \Gamma_1^{\mathrm{Cl}}[\beta,f]$, the BRS functional operator writes:

$$\delta_0 = \sum_f \left\langle \frac{\delta \Gamma^{\mathrm{Cl}}}{\delta \beta}, \frac{\delta}{\delta f} \right\rangle \quad \text{(V.12)}$$

and the diffeomorphism invariance of Γ^{Cl} simplifies into the so-called Slavnov identity[19]

$$\delta_0 \Gamma^{\mathrm{Cl}}[\beta, f] = 0. \quad \text{(V.13)}$$

In order to preserve the classical diffeomorphism invariance on the functional Γ^{Cl}, the BRS operation can be extended to the classical sources β, either trivially by saying that these external fields are s-invariant, or by defining

$$\begin{aligned} s\beta_{-1}(z,\bar{z}) &= \frac{\delta \Gamma^{\mathrm{Cl}}[\beta,f]}{\delta f_0(z,\bar{z})} = \frac{\delta \Gamma_0^{\mathrm{Cl}}[f_0]}{\delta f_0(z,\bar{z})} + \boldsymbol{c}\beta_{-1}(z,\bar{z}) + \tilde{V}(\beta_{-1}, f_1)(z,\bar{z}), \\ s\beta_{-2}(z,\bar{z}) &= \frac{\delta \Gamma^{\mathrm{Cl}}[\beta,f]}{\delta f_1(z,\bar{z})} = \boldsymbol{c}\beta_{-2}(z,\bar{z}) + \tilde{V}(\beta_{-2}, f_1)(z,\bar{z}) + X(f_0, \beta_{-1})(z,\bar{z}), \end{aligned} \quad \text{(V.14)}$$

where $\tilde{V}$ is the formal dual of the differential operator V given in (V.2), and X is the local differential polynomial

$$X_i(f_0, \beta_{-1})(z,\bar{z}) = \frac{\delta}{\delta c^i(z,\bar{z})} \sum_{f_0} \langle \beta_{-1}, sf_0 \rangle, \quad \text{(V.15)}$$

together with the complex conjugate expression. With these variations we can define the following nilpotent functional differential operator:

$$\delta = \delta_0 + \sum_\beta \left\langle s\beta, \frac{\delta}{\delta \beta} \right\rangle, \quad \text{(V.16)}$$

which corresponds to the linearized Slavnov operator acting on the space of local functionals in both the fields f and the sources β. Finding a quantum extension $\Gamma[\beta,f]$ of the classical functional Γ^{Cl} such that $\delta\Gamma=0$ amounts to study the δ_0-cohomology in the space of local functionals with respect to the ghost grading (the $\Phi\Pi$ charge). In the Lagrangian field theory language, a quantum extension will exist if the cohomology is trivial at the ghost grading one, i.e., there is no anomaly. It is now customary[20,10] to translate this cohomological problem into the space of local polynomials in the fields and sources and their derivatives spanned by the infinite set of local independent variables of the type

$$\partial_I\partial_{\overline{J}}\chi(z,\overline{z}),\quad \chi\equiv\{\phi,\mu,\overline{\mu},c,\overline{c},\gamma,\eta,\overline{\eta},\zeta,\overline{\zeta}\},\quad |I|\geqslant 0,\ |\overline{J}|\geqslant 0,$$
$$\partial_I\equiv(\partial_1)^{i_1}\ldots(\partial_n)^{i_n},\quad I=(i_1,\ldots,i_n),\quad |I|=i_1+\cdots+i_n, \tag{V.17}$$

$$\partial_{\overline{J}}\equiv(\overline{\partial}_1)^{j_1}\ldots(\overline{\partial}_n)^{j_n},\quad \overline{J}=(j_1,\ldots,j_n),\quad |\overline{J}|=j_1+\cdots+j_n,\delta_I^{M+N}\frac{I!}{M!N!}\equiv\prod_{k=1}^{n}\delta_{i_k}^{m_k+n_k}\frac{i_k!}{m_k!n_k!},$$

$$I+1_l=(i_1,\ldots,i_l+1,\ldots,i_n),\quad \overline{J}+1_{\overline{l}}=(j_1,\ldots,j_l+1,\ldots,j_n),$$

where we have conveniently used a multi-index notation and $|I|$ denotes the length of the multi-index I. The space of local polynomials in the fields and their derivatives can be endowed with the structure of a Fock space. The interchange between the two systems of local complex coordinates $(z,\overline{z})$ and $(Z,\overline{Z})$, can be taken into account. According to a previous work,[11] by considering the coordinates Z and $\overline{Z}$ as independent variables but non local in μ, we enlarge the set $\chi\equiv f\cup\beta$ of fields. The local cohomology will be that of the following differential operator

$$\delta=\left\langle sZ(z,\overline{z}),\frac{\partial}{\partial Z(z,\overline{z})}\right\rangle+\left\langle s\overline{Z}(z,\overline{z}),\frac{\partial}{\partial\overline{Z}(z,\overline{z})}\right\rangle+\sum_{|I|,|\overline{J}|\geqslant 0}\left(\sum_{\chi}\left\langle\partial_I\partial_{\overline{J}}s\chi(z,\overline{z}),\frac{\partial}{\partial\partial_I\partial_{\overline{J}}\chi(z,\overline{z})}\right\rangle\right.$$
$$\left.+\left\langle\partial_I\partial_{\overline{J}}s\lambda(z,\overline{z}),\frac{\partial}{\partial\partial_I\partial_{\overline{J}}\lambda(z,\overline{z})}\right\rangle+\left\langle\partial_I\partial_{\overline{J}}s\overline{\lambda}(z,\overline{z}),\frac{\partial}{\partial\partial_I\partial_{\overline{J}}\overline{\lambda}(z,\overline{z})}\right\rangle\right), \tag{V.18}$$

which turns out to be nilpotent $\delta^2=0$ upon using both the integrability conditions (II.11) and (II.6). Note that the non local part in the μ's has been isolated.

For a given Φ-Π charge p, solutions will be obtained modulo total derivatives, and we get the following descent equations:

$$\begin{cases}\delta\Delta_{2n}^{p}(z,\overline{z})+d\Delta_{2n-1}^{p+1}(z,\overline{z})=0\\ \delta\Delta_{2n-1}^{p+1}(z,\overline{z})+d\Delta_{2n-2}^{p+2}(z,\overline{z})=0\\ \quad\vdots\\ \delta\Delta_{2n-r}^{p+r}(z,\overline{z})+d\Delta_{2n-r-1}^{p+r+1}(z,\overline{z})=0\\ \quad\vdots\\ \delta\Delta_{1}^{p+2n-1}(z,\overline{z})+d\Delta_{0}^{p+2n}(z,\overline{z})=0\\ \delta\Delta_{0}^{p+2n}(z,\overline{z})=0\end{cases} \tag{V.19}$$

where the lower index will label the Poincaré form degree and the upper index is with respect to the ghost grading. The last of these equation has the general solution

$$\Delta_0^{p+2n}(z,\overline{z})=\Delta_0^{p+2n,\natural}(z,\overline{z})+\delta\hat{\Delta}_0^{p+2n-1}(z,\overline{z}), \tag{V.20}$$

where $\Delta_0^{p+2n,\natural}(z,\overline{z})$ is an element of the δ-cohomology space in the space of local functions. It is readily seen[10,11] that

$$\boldsymbol{d}=dz^k\left\{\delta,\frac{\partial}{\partial c^k(z,\overline{z})}\right\}+d\overline{z}^k\left\{\delta,\frac{\partial}{\partial \overline{c}^k(z,\overline{z})}\right\},\tag{V.21}$$

which allows one to define the derivative operator on the local polynomials as a formal derivative

$$\begin{aligned}\partial_i&=\left\{\delta,\frac{\partial}{\partial c^i(z,\overline{z})}\right\}\\&=\left\langle\lambda_i(z,\overline{z}),\frac{\partial}{\partial Z(z,\overline{z})}\right\rangle+\left\langle(\overline{\mu}\cdot\overline{\lambda})_i(z,\overline{z}),\frac{\partial}{\partial\overline{Z}(z,\overline{z})}\right\rangle+\sum_{|I|,|J|\geqslant 0}\left(\left\langle\partial_{I+1_i}\partial_{\overline{J}}\lambda(z,\overline{z}),\frac{\partial}{\partial\partial_I\partial_{\overline{J}}\lambda(z,\overline{z})}\right\rangle\right.\\&\quad\left.+\left\langle\partial_{I+1_i}\partial_{\overline{J}}\overline{\lambda}(z,\overline{z}),\frac{\partial}{\partial\partial_I\partial_{\overline{J}}\overline{\lambda}(z,\overline{z})}\right\rangle+\sum_{\chi}\left\langle\partial_{I+1_i}\partial_{\overline{J}}\chi(z,\overline{z}),\frac{\partial}{\partial\partial_I\partial_{\overline{J}}\chi(z,\overline{z})}\right\rangle\right),\end{aligned}\tag{V.22}$$

and one gets $\overline{\partial}_i$ by complex conjugation.

Substituting the solution Eq. (V.20) from the bottom of the system of descent equations (V.19) we successively get

$$\delta\left[\Delta_1^{p+2n-1}(z,\overline{z})+\frac{\partial\Delta_0^{p+2n,\natural}(z,\overline{z})}{\partial c^i(z,\overline{z})}dz^i+\frac{\partial\Delta_0^{p+2n,\natural}(z,\overline{z})}{\partial\overline{c}^i(z,\overline{z})}d\overline{z}^i+\boldsymbol{d}\hat{\Delta}_0^{p+2n-1}(z,\overline{z})\right]=0,\tag{V.23}$$

which implies that

$$\begin{aligned}&\Delta_1^{p+2n-1}(z,\overline{z})+\frac{\partial\Delta_0^{p+2n,\natural}(z,\overline{z})}{\partial c^i(z,\overline{z})}dz^i+\frac{\partial\Delta_0^{p+2n,\natural}(z,\overline{z})}{\partial\overline{c}^i(z,\overline{z})}d\overline{z}^i+\boldsymbol{d}\hat{\Delta}_0^{p+2n-1}(z,\overline{z})\\&\quad=\Delta_1^{p+2n-1,\natural}(z,\overline{z})+\delta\hat{\Delta}_1^{p+2n-2}(z,\overline{z})\end{aligned}\tag{V.24}$$

and by substituting step by step, we reach the top equation of (V.19) which gives the general solution of the δ-cohomology in the sector of ghost grading p[10,11]

$$\begin{aligned}\Delta_{2n}^{p}(z,\overline{z})&=\sum_{r,s=1}^{n}\frac{\partial^r}{\partial c^{A_r}(z,\overline{z})}\frac{\partial^s}{\partial\overline{c}^{A_s}(z,\overline{z})}\Delta_{2n-r-s}^{p+r+s,\natural}(z,\overline{z})dz^{A_r}\wedge d\overline{z}^{A_s}\\&\quad+\Delta_{2n}^{p,\natural}(z,\overline{z})+\delta\hat{\Delta}_{2n}^{p-1}(z,\overline{z})+\boldsymbol{d}\hat{\Delta}_{2n-1}^{p}(z,\overline{z}),\end{aligned}\tag{V.25}$$

where for the sake of compactness of writing increasing ordered multi-index notation has been used,

$$A_r=(a_1\ldots,,a_r),\quad a_1<\cdots<a_r,\quad dz^{A_r}=dz^{a_1}\wedge\cdots\wedge dz^{a_r},\quad\frac{\partial^r}{\partial c^{A_r}}=\frac{\partial^r}{\partial c^{a_1}\cdots\partial c^{a_r}},\tag{V.26}$$

with of course the complex conjugate expressions. Equation (V.25) links the elements of the diff-mod d cohomology to those of the local functional cohomology, once the $\Delta_{2n-r-s}^{p+r+s,\natural}$, $r,s=0,\ldots,n$ are known as δ-cocycles.

We are interested in finding possible anomalies in the quantum field theoretic sense, that is, $p=1$ in Eq. (V.25). According to our previous analysis in Ref. 11, it turns out that the only relevant tensorial index $2n-r-s$ is of scalar type, namely, for $r=s=n$. The problem reduces into solving the cocycle equation

$$\delta\Delta_0^{2n+1,\natural}(z,\overline{z})=0.\tag{V.27}$$

Following the lines of Refs. 10–12, we decompose the general $\Delta_0^{p,\natural}$, for $p \geqslant 2n$, with respect to its underived ghosts content, namely,

$$\Delta_0^{p,\natural}(z,\bar{z}) = \sum_{r,s=0}^{n} c^{A_r}(z,\bar{z})\bar{c}^{\bar{A}_s}(z,\bar{z})\mathcal{D}^{p-r-s}_{A_r\bar{A}_s}(z,\bar{z}), \tag{V.28}$$

where according to the summation on all possible ordered multi-indices (V.26), the $\mathcal{D}$'s are independent skew-symmetric tensors containing only derivatives of the ghost fields. This canonical decomposition identifies independent sectors according to the ghost grading. Inserting the decomposition (V.28) into the cocycle condition (V.27), introducing the following nilpotent operator:

$$\hat{\delta} = \delta - (c^i(z,\bar{z})\partial_i + \bar{c}^{\bar{\imath}}(z,\bar{z})\partial_{\bar{\imath}}), \quad \hat{\delta}^2 = 0, \tag{V.29}$$

we can canonically decompose with respect to underived ghost fields onto each ghost sector, and find the following chain of 2^{2n} equations:

$$\begin{cases}
\hat{\delta}\mathcal{D}^p(z,\bar{z}) = 0 \\
-\hat{\delta}\mathcal{D}^{p-1}_{\bar{\imath}}(z,\bar{z}) + \partial_{\bar{\imath}}\bar{c}^{\bar{J}}\mathcal{D}^{p-1}_{J}(z,\bar{z}) + \partial_{\bar{\imath}}c^j\mathcal{D}^{p-1}_{j}(z,\bar{z}) + \partial_{\bar{\imath}}\mathcal{D}^p(z,\bar{z}) = 0 \\
-\hat{\delta}\mathcal{D}^{p-1}_{i}(z,\bar{z}) + \partial_i c^j\mathcal{D}^{p-1}_{j}(z,\bar{z}) + \partial_i\bar{c}^{\bar{J}}\mathcal{D}^{p-1}_{J}(z,\bar{z}) + \partial_i\mathcal{D}^p(z,\bar{z}) = 0 \\
\vdots \\
(-)^{k+l}\hat{\delta}\mathcal{D}^{p-\underline{k}-l}_{A_k\bar{A}_l}(z,\bar{z}) + \epsilon^{A_r i}_{A_k}\Bigg(\sum_{t=1}^{k}(-)^{t-1+l}\partial_i c^{a_t}\mathcal{D}^{p-k-\underline{l}}_{A_{r+1_t}\bar{A}_l}(z,\bar{z}) \\
\quad + \sum_{t=1}^{l+1}(-)^{k+l+t}\partial_i\bar{c}^{\bar{a}_t}\delta^{\bar{A}_s}_{\bar{A}_l}\mathcal{D}^{p-\underline{k}-l}_{A_r\bar{A}_{s+1_t}}(z,\bar{z}) + (-)^{k-1}\partial_i\mathcal{D}^{p-\underline{k}-l-1}_{A_r\bar{A}_s}(z,\bar{z})\Bigg) \\
\quad + \epsilon^{\bar{A}_s\bar{\imath}}_{\bar{A}_l}\Bigg(\sum_{t=1}^{k+1}(-)^{t-1}\partial_{\bar{\imath}}c^{a_t}\delta^{A_r}_{A_k}\mathcal{D}^{p-k-\underline{l}}_{A_{r+1_t}\bar{A}_s}(z,\bar{z}) \\
\quad + \sum_{t=1}^{l}(-)^{k+t-1}\partial_{\bar{\imath}}\bar{c}^{\bar{a}_t}\mathcal{D}^{p-\underline{k}-l}_{A_k\bar{A}_{s+1_t}}(z,\bar{z}) + (-)^{k+l-1}\partial_{\bar{\imath}}\mathcal{D}^{p-\underline{k}-l-1}_{A_k\bar{A}_s}(z,\bar{z})\Bigg) = 0 \\
\vdots \\
(\hat{\delta} - \partial_i c^i(z,\bar{z}) - \partial_{\bar{\imath}}\bar{c}^{\bar{\imath}}(z,\bar{z}))\mathcal{D}^{p-2n}_{A_n\bar{A}_n}(z,\bar{z}) + (-1)^{n-1}\epsilon^{A_{n-1}r}_{A_n}\partial_r\mathcal{D}^{p-2n+1}_{A_{n-1}\bar{A}_n}(z,\bar{z}) \\
\quad - \epsilon^{\bar{A}_{n-1}\bar{J}}_{\bar{A}_n}\partial_{\bar{J}}\mathcal{D}^{p-2n+1}_{A_n\bar{A}_{n-1}}(z,\bar{z}) = 0,
\end{cases} \tag{V.30}$$

where $\epsilon^{A_r i}_{A_k}$ is the generalized Kronecker skew-symmetric tensor with respect to the multi-indices, and A_{r+1_t} means $a_1 < \cdots < a_t < \cdots < a_r$ for a given A_r. In the above formulas summation on repeated multi-indices must be performed and $\delta^{\bar{A}_s}_{\bar{A}_l}$ equals 1 if the ordered multi-indices are identical and 0 otherwise.

Since the δ-cohomology is translated in terms of the $\hat{\delta}$-cohomology, the first step is to solve the top equation of the system (V.30). Also, note that the $\hat{\delta}$ operator will act on the space of local polynomials in the following extended set of fields $\chi \equiv f \cup \beta \cup \{\lambda, \bar{\lambda}\}$. Solving the $\hat{\delta}$-cohomology is the technical part of the paper and in Appendix D the following theorem will be established.

Theorem: *Define in matrix notation the following n^2 local expressions of ghost grading one:*

$$\tilde{\Omega}(z,\bar{z}) = (\partial c + \partial\bar{c}\cdot\mu)(z,\bar{z}) = (\hat{\delta}\lambda\cdot\lambda^{-1})(z,\bar{z}), \tag{V.31}$$

and note the $\hat{\delta}$-coboundary

$$\mathrm{tr}\ \tilde{\Omega}(z,\bar{z})=\hat{\delta}\ \ln\det\lambda(z,\bar{z}). \tag{V.32}$$

Then, in the scalar sector of the space of analytic (local) functions in the fields and their derivatives, the ghost sectors with grading p of the $\hat{\delta}$-cohomology are generated by the following nontrivial cocycles

$$\text{for even } p:\quad \mathrm{tr}\ \tilde{\Omega}^{2r+1}(z,\bar{z})\mathrm{tr}\ \tilde{\bar{\Omega}}^{2s+1}(z,\bar{z}),\quad \text{for odd } p,:\quad \mathrm{tr}\ \tilde{\Omega}^{2k+1}(z,\bar{z}), \tag{V.33}$$

while the cocycle $\mathrm{tr}\ \tilde{\Omega}$ *can be reabsorbed by completing the set of generators with* $\ln\det\lambda$ *seen as an independent variable. The same statements hold true for the complex conjugate expressions.*

A nontrivial *local* anomaly modulo $\boldsymbol{d}$ will then be given by [cf. Eq. (V.25)]

$$\Delta^1_{2n}(z,\bar{z})=\frac{\partial^n}{\partial c^{A_n}(z,\bar{z})}\frac{\partial^n}{\partial \bar{c}^{A_n}(z,\bar{z})}\Delta_0^{2n+1,\natural}(z,\bar{z})dz^{A_n}\wedge d\bar{z}^{\bar{A}_n}, \tag{V.34}$$

with the *local* δ-cocycle $\Delta_0^{2n+1,\natural}$ given by the decomposition (V.28). It is also subject to the reality condition $\overline{\Delta^1_{2n}}(z,\bar{z})=\Delta^1_{2n}(z,\bar{z})$.

According to the definition of both $\hat{\delta}$ and (V.31), one considers in matrix notation the n^2 variables of ghost grading one,

$$\Omega(z,\bar{z})=(\delta\lambda\cdot\lambda^{-1})(z,\bar{z})=\tilde{\Omega}(z,\bar{z})+(c\lambda\cdot\lambda^{-1})(z,\bar{z}),\mathrm{tr}\ \Omega(z,\bar{z})=\delta\ \ln\det\lambda(z,\bar{z}).$$

Unfortunately, Ω is not local in the μ fields due to the presence of the λ terms. One has $\delta\Omega(z,\bar{z})=\Omega^2(z,\bar{z})$. Moreover, setting $\Lambda_i\equiv\partial_i\lambda\cdot\lambda^{-1}$, it is easily shown that

$$\begin{aligned}\Omega(z,\bar{z})&=(C^r\Lambda_r)(z,\bar{z})+\partial C(z,\bar{z}),\\ \delta\ \ln\det\lambda(z,\bar{z})&=(C^r\partial_r\ \ln\det\lambda)(z,\bar{z})+\mathrm{tr}(\partial C)(z,\bar{z}),\end{aligned} \tag{V.35}$$

after the use of Eq. (II.11) and the definition (III.6) of the factorized ghosts C. Note that the above variations contain a local part in the μ fields.

In turns out after some rather lengthy analysis based on the above theorem that the possible δ-cocycles $\Delta_0^{2n+1,\natural}$ are not local in the μ external fields due to the presence of the non-local λ terms. The former are listed hereafter

$$\begin{aligned}&\mathrm{tr}\ \Omega^n\ \mathrm{tr}\ \bar{\Omega}^n\ \mathrm{tr}\ \Omega=\delta(\mathrm{tr}\ \Omega^n\ \mathrm{tr}\ \bar{\Omega}^n\ \ln\det\lambda),\quad \text{for odd } n,\\ &\mathrm{tr}\ \Omega^{2r+1}\ \mathrm{tr}\ \bar{\Omega}^{2s+1}\ \mathrm{tr}\ \Omega=\delta(\mathrm{tr}\ \Omega^{2r+1}\ \mathrm{tr}\ \bar{\Omega}^{2s+1}\ \ln\det\lambda),\quad \text{for even } n,\quad n=r+s+1,\\ &\mathrm{tr}\ \Omega^{2n+1}+\mathrm{tr}\ \bar{\Omega}^{2n+1}\neq\delta(\cdots),\quad n\geqslant 3.\end{aligned} \tag{V.36}$$

The first two cocycles are trivial while the last nontrivial δ-cocycle can only produce a local cocycle of ghost grading $2n$ and not $2n+1$ as required. This shows that the local δ-cohomology modulo $\boldsymbol{d}$ is not trivial in that sector.

Therefore, if there were an anomaly, the latter is a nontrivial cocycle of the δ-cohomology modulo $\boldsymbol{d}$. So it is not surprising that the remaining possibility to be considered is that the *local* δ-cocycle $\Delta_0^{2n+1,\natural}$ matching with the principle of locality will appear as the variation of a nonlocal expression in the μ fields according to,

$$\Delta_0^{2n+1,\natural}=\delta\hat{\Delta}_0^{2n}, \tag{V.37}$$

where $\hat{\Delta}_0^{2n}$ does not belong to the nonlocal δ-cohomology modulo $\boldsymbol{d}$ and will provide nonlocal counterterms in the μ fields which are defined up to a total derivative. Since the nonlocal genera-

tors are the λ terms and that the variations (V.35) contain a local part, $\hat{\Delta}_0^{2n}$ can be formally expanded in terms of λ and its (independent) derivatives. By using once more Eq. (II.11), it assumes in the scalar sector the following finite expansion:

$$\hat{\Delta}_0^{2n}=\sum_{|I|=0}^{2n}(T^I\partial_I \ln\det\lambda+\mathrm{tr}(\mathcal{T}^{I+1_i}\cdot\partial_I\Lambda_i)+\text{c.c.}), \tag{V.38}$$

where in multi-index notation (V.17) both the scalar valued, $T^I=T^{\overbrace{1\ldots1}^{i_1}\ldots\overbrace{n\ldots n}^{i_n}}$ and matrix valued, $\mathcal{T}^{I+1_i}$, symmetric tensors are local expressions in the μ external fields with $\dim T^I=\dim \mathcal{T}^{I+1_i}+1=2n-|I|$, and $Q_{\Phi\Pi}(T^I)=Q_{\Phi\Pi}(\mathcal{T}^{I+1_i})=2n$. Recalling that in a Lagrangian formulation counterterms are defined up to a total derivative, so it is for those generated by $\hat{\Delta}_0^{2n}$. Thus, discarding the explicit form of the divergences one can write

$$\begin{aligned}\hat{\Delta}_0^{2n}&=\left(\sum_{|I|=0}^{2n}(-1)^{|I|}\partial_I T^I\right)\ln\det\lambda+\mathrm{tr}\left(\left(\sum_{|I|=0}^{2n}(-1)^{|I|}\partial_I\mathcal{T}^{I+1_i}\right)\cdot\Lambda_i\right)+\partial_i\Gamma^i+\text{c.c.}\\&\equiv R\ln\det\lambda+\mathrm{tr}(\mathcal{R}^{,i}\cdot\Lambda_i)+\partial_i\Gamma^i+\text{c.c.}\end{aligned} \tag{V.39}$$

with $\dim R=\dim\mathcal{R}^{,i}+1=2n=Q_{\Phi\Pi}(R)=Q_{\Phi\Pi}(\mathcal{R}^{,i})$. Substitution of $\hat{\Delta}_0^{2n}$ in Eq. (V.34), together with $[\partial/\partial c^\alpha(z,\bar{z}),\partial_\beta]=0$, provides the anomaly up to a total derivative, one can thus discard the divergences. The δ-variation of $\hat{\Delta}_0^{2n}$ writes

$$\begin{aligned}\delta\hat{\Delta}_0^{2n}=&\underbrace{R\ \mathrm{tr}\partial C+\mathrm{tr}(\mathcal{R}^{,i}\partial_i\cdot\partial C)}_{\text{local part}}+\delta R\ \ln\det\lambda+RC^r\partial_r\ln\det\lambda\\&+\mathrm{tr}(\delta\mathcal{R}^{,i}\cdot\Lambda_i+\mathcal{R}^{,i}\cdot(C^r\partial_r\Lambda_i+\partial_iC^r\Lambda_r+[\partial C,\Lambda_i]))+\text{c.c.},\end{aligned} \tag{V.40}$$

and by requiring the vanishing of the nonlocal part one gets

$$\text{(a)}\ \begin{cases}RC^r=0,\\ \mathcal{R}^{,i}C^r=0,\end{cases}\forall r=1,\ldots,n,\quad\text{(b)}\ \begin{cases}\delta R=0,\\ \delta\mathcal{R}_l^{k,i}=\mathcal{R}_s^{k,i}\partial_lC^s-\mathcal{R}_l^{k,s}\partial_sC^i-\mathcal{R}_l^{s,i}\partial_sC^k.\end{cases} \tag{V.41}$$

Note that $\mathcal{R}_l^{k,i}$ transforms in a rigid manner. Equations (V.41)(a) are solved by

$$\text{(a)}\ \begin{cases}R=\Xi_{A_n}C^{A_n},\\ \mathcal{R}^{,i}=\Sigma^{,i}_{A_n}C^{A_n},\end{cases}\quad\text{(b)}\ \frac{\partial\Xi_{A_n}}{\partial C^r}=\frac{\partial\Sigma^{,i}_{A_n}}{\partial C^r}=0,\quad\forall r=1,\ldots,n, \tag{V.42}$$

with $C^{A_n}\equiv C^1C^2\ldots C^n$, $\delta C^{A_n}=-\mathrm{tr}(\partial C)C^{A_n}$, and $Q_{\Phi\Pi}(\Xi_{A_n})=Q_{\Phi\Pi}(\Sigma^{,i}_{A_n})=n$. The local cocycle (V.37) then reads

$$\Delta_0^{2n+1,\natural}=C^{A_n}(\Xi_{A_n}\partial_rC^r+\Sigma^{k,i}_{l,A_n}\partial_i\partial_kC^l)+\partial_r\Gamma^r_{\mathrm{loc}}+\text{c.c.} \tag{V.43}$$

A direct substitution of (V.42)(a) into Eqs. (V.41)(b) gives, on the other hand

$$(\delta\Xi_{A_n}-\partial_rC^r\Xi_{A_n})C^{A_n}=0\Rightarrow\delta\Xi_{A_n}=\mathrm{tr}(\partial C)\Xi_{A_n}+C^r\xi_{r,A_n}, \tag{V.44}$$

with $Q_{\Phi\Pi}(\xi_{r,A_n})=n$, and on the other hand

$$\delta\Sigma^{k,i}_{l,A_n}=\mathrm{tr}(\partial C)\Sigma^{k,i}_{l,A_n}+\partial_lC^s\Sigma^{k,i}_{s,A_n}-\partial_sC^i\Sigma^{k,s}_{l,A_n}-\partial_sC^k\Sigma^{s,i}_{l,A_n}+C^r\sigma^{k,i}_{r,l,A_n}, \tag{V.45}$$

with $Q_{\Phi\Pi}(\sigma^{k,i}_{r,l,A_n})=n$. Obviously, due to (V.42)(b), the C dependence in both Eqs. (V.44) and (V.45) comes from the underived ghost content of the BRS operator and thus

$$\frac{\partial\xi_{A_n}}{\partial C^r}=\frac{\partial\sigma^{k,i}_{l,A_n}}{\partial C^r}=0,\quad\forall r=1,\ldots,n. \tag{V.46}$$

The terms Ξ_{A_n}, ξ_{r,A_n}, $\Sigma^{k,i}_{l,A_n}$ and $\sigma^{k,i}_{r,l,A_n}$ are local in the fields $\{\phi,\mu,\overline{\mu},c,\overline{c}\}$ and their explicit form has to be separately discussed according to the presence of the ϕ matter fields. The same considerations hold for the complex conjugate expressions.

A. Vacuum anomalies

In the vacuum sector, it is readily seen that $\partial_r=\{\partial/\partial C^r,\delta\}$. This easily implies together with Eqs. (V.42)(b), and (V.46) that $\xi_{r,A_n}=\partial_r\Xi_{A_n}$, and $\sigma^{k,i}_{r,l,A_n}=\partial_r\Sigma^{k,i}_{l,A_n}$. Equations (V.44) and (V.45) rewrite, respectively, as

$$\delta\Xi_{A_n}=\partial_r(C^r\Xi_{A_n}),\quad \delta\Sigma^{k,i}_{l,A_n}=\partial_r(C^r\Sigma^{k,i}_{l,A_n})+\partial_l C^s\Sigma^{k,i}_{s,A_n}-\partial_s C^i\Sigma^{k,s}_{l,A_n}-\partial_s C^k\Sigma^{s,i}_{l,A_n}, \quad \text{(V.47)}$$

showing that Ξ_{A_n} and $\Sigma^{k,i}_{l,A_n}$ are, respectively, a scalar and a tensorial densities. The inhomogeneous term in the δ-variation of μ cuts out the possible μ dependence of both Ξ_{A_n} and $\Sigma^{k,i}_{s,A_n}$; one has to figure out the latter as local expressions in the derivated ghosts C's only. According to both power counting index $2n$ and ghost grading n, it turns out that the most general expressions are labeled by the set of permutations π of the integers $\{1,\ldots,n\}$. Thus there are $n!$ scalar densities of the following type:

$$\Xi_{A_n,(\pi)}=\epsilon^{a_1\cdots a_n}\partial_{a_1}\partial_{i_1}C^{l_1}\cdots\partial_{a_n}\partial_{i_n}C^{l_n}\delta^{i_1}_{l_{\pi(1)}}\cdots\delta^{i_n}_{l_{\pi(n)}}, \quad \text{(V.48)}$$

the π's cover all the possible contractions. Saturation with the product C^{A_n} of the C's provides the solutions (V.42). The latter are numerated as the decompositions of the integer n into integer summands without regard to the order. Let $p(n)$ denote such a decomposition. Independent solutions of (V.42) can be seen as skew symmetrizations of already skew symmetric tensors of maximal rank,

$$R_{(p(n))}=\frac{(-1)^{n(n-1)/2}}{k_1!\cdots k_n!}\mathrm{tr}(V^{k_1})\cdots\mathrm{tr}(V^{k_n}), \quad \text{(V.49)}$$

for a given partition $p(n)$ of the integer n with $k_1+\cdots+k_n=n$, $k_1\leqslant\cdots\leqslant k_n$ and where in matrix notation the n^2 ghost graded 2 quantities $V^l_i\equiv C^r\partial_r\partial_i C^l$ rigidly transforms as

$$\delta V=[\partial C,V],\quad V\equiv C\cdot\partial(\partial C), \quad \text{(V.50)}$$

a transformation law very similar to that of the adjoint of $\mathrm{gl}(n,\boldsymbol{C})$ with matrix parameter ∂C. The first contributions $R_{(p(n))}\partial_r C^r$ to the cocycle (V.43) are developed with respect to the monomial $\partial_r C^r$ while the second are developed with respect to the monomials $\partial_i\partial_k C^l$. It is easy to see that $\Sigma^{k,i}_{s,A_n}\partial_k\partial_i C^s$ is a scalar density of power counting index $2n+1$ and ghost grading $n+1$, so that $\Sigma^{k,i}_{s,A_n}\partial_k\partial_i C^s=\Xi_{A_n}\mathrm{tr}(\partial C)$. One has, as diffeomorphism cocycles labeled by all the partitions of n,

$$R_{p(n)}\mathrm{tr}(\partial C)=\mathcal{R}^{k,i}_{l,p(n)}\partial_k\partial_i C^l. \quad \text{(V.51)}$$

Thus in the vacuum sector, the δ-cocycle modulo $\boldsymbol{d}$ (V.43) reduces to the following linear combination:

$$\Delta_0^{2n+1,\natural}=\sum_{p(n)}A_{p(n)}R_{(p(n))}\mathrm{tr}\ \partial C, \quad \text{(V.52)}$$

where the $A_{p(n)}$'s are complex numbers depending on the field content of the model. The cocycles (V.51) are higher dimensional analogs of the well-known Gel'fand-Fuchs cocycle.[21] For complex dimension $n=1$, one recovers the Gel'fand-Fuchs cocycle $C\partial C\partial^2 C$.[11]

Inserting the cocycle (V.52) into the computational formulas (V.34), one finds the local expression of (U-V part) of the vacuum anomaly modulo $\boldsymbol{d}$

$$\Delta^1_{2n}=(-1)^{n(n-1)/2}\sum_{p(n)} A_{p(n)}\frac{1}{k_1!\cdots k_n!}[\mathrm{tr}(\partial C)\mathrm{tr}((\partial\mathcal{V})^{k_1})\cdots\mathrm{tr}((\partial\mathcal{V})^{k_n})$$

$$+\mathrm{tr}(\partial\mathcal{V})\sum_{l=1}^{n} k_l\mathrm{tr}((\partial\mathcal{V})^{k_1})\cdots\mathrm{tr}((\partial\mathcal{V})^{k_l-1}\partial C)\cdots\mathrm{tr}((\partial\mathcal{V})^{k_n})], \tag{V.53}$$

where the summand is performed over all the partitions $p(n)$ of the integer n, $k_1+\cdots+k_n=n$, with $k_1\leqslant\cdots\leqslant k_n$, and where we have introduced the n^2 vector-valued (1,1)-forms

$$\mathcal{V}\equiv\boldsymbol{\partial}(d\bar{z}\cdot\mu)=\left(dz\cdot\frac{\partial}{\partial c}\right)\left(d\bar{z}\cdot\frac{\partial}{\partial\bar{c}}\right)V, \tag{V.54}$$

fulfilling the following Bianchi-like identities

$$\boldsymbol{\partial}\mathcal{V}=0,\quad \bar{\boldsymbol{\partial}}\mathcal{V}+[\mathcal{V},\boldsymbol{\mu}]=0, \tag{V.55}$$

thanks to the integrability condition (II.6). In the $n=1$ case, the well-known holomorphically split anomaly $\partial C\partial^2\mu$[14,15] is recovered.

Note that there is a very particular linear combination of the anomaly (V.53) given by the component of degree $2n+2$ of the Todd class according to formula (5.19) of Ref. 1. However, formula (1.11) or (8.5) of the quoted reference does not match as a diffeomorphism anomaly in the spirit of our construction in the sense that it is not a diffeomorphism δ-cocycle whereas each term in the summand (V.53) is.

In concluding this section, since the same argument holds for the complex conjugate part and according to the Ward id's (V.8), one can say that similarly to the bidimensional case, at the quantum level, the vacuum functional together with the anomaly (V.53) turns out to be holomorphically factorized in the Beltrami differential parametrizing an integrable complex structure. The anomalous Ward id's correspond to the loss of the vanishing of the divergence (V.10) at the quantum level, a similar phenomenon to the bidimensional case.[17]

A nonlocal functional $\Gamma[\mu]$ analogous to the Wess-Zumino-Polyakov action remains to be found out as functional in the integrating factor λ.

B. Matter field anomalies

Having in the previous subsection extracted all the C ghost dependence of both Ξ_{A_n} and $\Sigma^{k,i}_{l,A_n}$, their matter field dependence under the constraints (V.44) and (V.45), respectively, remain to be studied. Due to the transformation laws of matter fields under diffeomorphisms the ghost grading is this time carried by the $\bar{C}$ ghost fields. One finds according to the power counting, on the other hand for Ξ

$$\Xi_{A_n}=\bar{C}^1\cdots\bar{C}^nK_{A_n,\bar{A}_n}\equiv\bar{C}^{\bar{A}_n}K_{A_n,\bar{A}_n}, \tag{V.56}$$

where $K_{A_n,\bar{A}_n}$ is a differential polynomial in both the μ and matter fields with $Q_{\Phi\Pi}(K_{A_n,\bar{A}_n})=0$ and $\dim(K_{A_n,\bar{A}_n})=2n$. Due to the reality condition the cocycle (V.43) writes in the matter sector as

$$\Delta_0^{2n+1,\natural}=C^{A_n}\bar{C}^{\bar{A}_n}K_{A_n,\bar{A}_n}\mathrm{tr}(\partial C+\overline{\partial C})=c^{A_n}\bar{c}^{\bar{A}_n}\det(I-\mu\cdot\bar{\mu})K_{A_n,\bar{A}_n}\mathrm{tr}(\partial c+\mu\cdot\partial\bar{c}+\overline{\partial c}+\bar{\mu}\cdot\overline{\partial c}). \tag{V.57}$$

where it is more useful to rewrite the variations with respect to the true ghost fields. The cocycle condition (V.41)(b) is equivalent to

$$\delta(c^{A_n}\bar{c}^{\bar{A}_n}\det(I-\mu\cdot\bar{\mu})K_{A_n,\bar{A}_n})=0 \tag{V.58}$$

and yields

$$(\delta-\mathrm{tr}(\partial c+\overline{\partial c}))(\det(I-\mu\cdot\overline{\mu})K_{A_n,\overline{A}_n})=c^r\kappa_{r,A_n,\overline{A}_n}+\overline{c^s}\,\overline{\kappa}_{\overline{s},A_n,\overline{A}_n}. \tag{V.59}$$

Recalling the derivative operator (V.22) combined the equation above, one finds

$$\kappa_{r,A_n,\overline{A}_n}=\partial_r(\det(I-\mu\cdot\overline{\mu})K_{A_n,\overline{A}_n}),\quad \overline{\kappa}_{\overline{s},A_n,\overline{A}_n}=\overline{\partial_s}(\det(I-\mu\overline{\mu})K_{A_n,\overline{A}_n}), \tag{V.60}$$

which implies

$$\delta(\det(I-\mu\cdot\overline{\mu})K_{A_n,\overline{A}_n})=\partial_r(c^r\ \det(I-\mu\cdot\overline{\mu})K_{A_n,\overline{A}_n})+\overline{\partial_s}(\overline{c^s}\ \det(I-\mu\cdot\overline{\mu})K_{A_n,\overline{A}_n}). \tag{V.61}$$

The latter shows that $\det(I-\mu\cdot\overline{\mu})K_{A_n,\overline{A}_n}$ belongs to the uncharged scalar density sector of the diff-mod $\boldsymbol{d}$ cohomology. Given the following variation:

$$\delta\ \ln\det(I-\mu\cdot\overline{\mu})=(c\cdot\partial+\overline{c}\cdot\overline{\partial})\ln\det(I-\mu\cdot\overline{\mu})-\mathrm{tr}(\mu\cdot\partial\overline{c}+\overline{\mu}\cdot\overline{\partial c}) \tag{V.62}$$

together with Eq. (V.61) allows to express (V.57) as

$$\begin{aligned}\Delta_0^{2n+1,\natural}=&c^{A_n}\overline{c^{A_n}}\ \det(I-\mu\cdot\overline{\mu})K_{A_n,\overline{A}_n}\ \mathrm{tr}(\partial c+\overline{\partial c})\\&-\delta(c^{A_n}\overline{c^{A_n}}\ \det(I-\mu\cdot\overline{\mu})K_{A_n,\overline{A}_n}\ \ln\det(I-\mu\cdot\overline{\mu})).\end{aligned} \tag{V.63}$$

On the other hand, the part coming from Σ remains under consideration. Rewriting the term

$$C^{A_n}\Sigma^{k,i}_{l,A_n}\partial_i\partial_k C^l\equiv\mathrm{tr}(VS), \tag{V.64}$$

inside the cocycle (V.43), the δ-cocycle condition yields $\delta S=[\partial C,S]$, which shows that the $2n-1$ ghost graded quantity S depends only on the C ghost fields and cannot depend on matter fields. So no contribution arises from the Σ term in the matter sector.

Summing up, the insertion of the cocycle (V.63) in the constructive equation (V.34) gives rise to the well-known trace anomaly which breaks the holomorphic splitting of the partition function when matter fields are involved.

VI. CONCLUDING REMARKS

Even if the physical motivation in studying higher complex dimensional manifolds is not well stated, the previous consideration must be regarded as an exercise. The link between Beltrami differentials as sources of relevant physical tensors in higher dimension is not yet known. The integrability condition on the μ's is taken into account and ensures the nilpotency of the BRS operator for the diffeomorphims. In fact, the integrability condition and the nilpotency are actually equivalent. In other words, demanding an integrable complex structure gives the nilpotency. Moreover, the integrability condition is preserved under diffeomorphims. The computation of the generalized Gel'fand-Fuchs unintegrated δ-cocycles (V.51) (modulo $\boldsymbol{d}$) is valid upon the use of the integrability condition on the Beltrami differential because of the hidden μ dependence in the C ghost fields and their diffeomorphism variation δC. However, if one wants to directly check that the anomaly (V.53) (which explicitly depends on μ) is a δ-cocycle then the use of the integrability condition is explicitly required.

Once more we emphasize the role of the holomorphic sector and the locality principle which is at the origin of a holomorphically split diffeomorphism anomalies in the vacuum sector with respect to an integrable complex structure. Contrary to the anomaly given in Ref. 1 for the so-called chiral diffeomorphims, the anomaly computed in the present work is more general with respect to the ''true'' diffeomorphisms. However, only the local part of the anomaly is provided, which is the ''universal'' or ultraviolet contribution, independent from the matter fields. The construction was guided by the bidimensional case and relies on the use of an intergrand factor which is non-local in the Beltrami differential. While in the bidimensional situation the conformal (Weyl) anomaly is equivalent to the well-known holomorphically factorized anomaly,[2] higher

dimensions in which diffeomorphic invariant quantities are equivalent to the factorized anomalies remain to be studied. This amounts to finding a globally defined version of the anomalies. Moreover, in the presence of matter fields, one recovers the usual trace anomaly.

Finally, a further careful analysis is needed, based on the local index theorem of Bismut-Gillet and Soulé, as pioneered in Refs. 3 and 4 in the bidimensional case or the attempt made in Ref. 1.

One of us (S.L.) wishes to thank the INFN Section of the University of Genova for its warm hospitality as well as the Theoretical Physics Group of the University of Amsterdam where this work has been partly carried out under European financial support by Contract No. ERBCHBICT930301.

APPENDIX A: DIFFEOMORPHISM INVARIANCE OF THE INTEGRABILITY CONDITION

In this Appendix, the diffeomorphism invariance of the integrability condition on μ is proved. With $\boldsymbol{\mu}^{\varphi}$ defined by Eq. (III.2) of the main text, let us compute directly the integrability condition and similarly to the first order differential operator $\boldsymbol{\mathcal{L}}$ defined by Eq. (II.5), one set $\boldsymbol{\mathcal{L}}^{\varphi}=\overline{\boldsymbol{\partial}}-\boldsymbol{\mu}^{\varphi}$. The (0,2)-form with (1,0)-vector values reads

$$\begin{aligned}\overline{\boldsymbol{\partial}}\boldsymbol{\mu}^{\varphi}-(\boldsymbol{\mu}^{\varphi})^2=\boldsymbol{\mathcal{L}}^{\varphi}\boldsymbol{\mu}^{\varphi}&=-(\boldsymbol{\mathcal{L}}^{\varphi}\overline{\varphi})\cdot(\boldsymbol{\mathcal{L}}^{\varphi}(\mu\circ\varphi))\cdot(\partial\varphi+\partial\overline{\varphi}\cdot(\mu\circ\varphi))^{-1}\cdot\partial\\&=-(\boldsymbol{\mathcal{L}}^{\varphi}\overline{\varphi})\cdot((\boldsymbol{\mathcal{L}}^{\varphi}\varphi)\cdot\partial\mu+(\boldsymbol{\mathcal{L}}^{\varphi}\overline{\varphi})\cdot\overline{\partial}\mu)\cdot(\partial\varphi+\partial\overline{\varphi}\cdot(\mu\circ\varphi))^{-1}\cdot\partial\\&=-(\boldsymbol{\mathcal{L}}^{\varphi}\overline{\varphi})\cdot((\boldsymbol{\mathcal{L}}^{\varphi}\overline{\varphi})\cdot\mathcal{L}\mu)\cdot(\partial\varphi+\partial\overline{\varphi}\cdot(\mu\circ\varphi))^{-1}\cdot\partial,\end{aligned}\tag{A1}$$

where the third equality is obtained by using $\partial=\partial\varphi\cdot\partial+\partial\overline{\varphi}\cdot\overline{\partial}$ and $\overline{\boldsymbol{\partial}}=\overline{\boldsymbol{\partial}}\varphi\cdot\partial+\overline{\boldsymbol{\partial}\varphi}\cdot\overline{\partial}$, while the fourth one comes from the identity $\boldsymbol{\mathcal{L}}^{\varphi}\varphi=-(\boldsymbol{\mathcal{L}}^{\varphi}\overline{\varphi})\cdot(\mu\circ\varphi)$. Now, the integrability condition for μ writes

$$\overline{\boldsymbol{\partial}}\boldsymbol{\mu}-\boldsymbol{\mu}^2=0\Leftrightarrow\mathcal{L}_{\bar{\imath}}\mu^{k}_{J}=\mathcal{L}_{\bar{J}}\mu^{k}_{\bar{\imath}},\tag{A2}$$

and shows that $\mathcal{L}\mu$ is a mixed tensor, symmetric in the lower indices. This symmetry implies the vanishing of the last expression (A1),

$$\overline{\boldsymbol{\partial}}\boldsymbol{\mu}-\boldsymbol{\mu}^2=0\Rightarrow\overline{\boldsymbol{\partial}}\boldsymbol{\mu}^{\varphi}-(\boldsymbol{\mu}^{\varphi})^2=0.\tag{A3}$$

APPENDIX B: ON THE EQUIVALENCE BETWEEN COMPLEX STRUCTURES

Any diffeomorphism φ when expressed in terms of its local representative will induce a smooth change of local coordinates. This change of variables can be written in matrix notation (with matrix entries), as well the inverse change of variables, as

$$\begin{pmatrix}\partial\varphi & \partial\overline{\varphi}\\ \overline{\partial\varphi} & \overline{\partial\varphi}\end{pmatrix},\quad\begin{pmatrix}\mathrm{A} & \mathrm{B}\\ \mathrm{C} & \mathrm{D}\end{pmatrix},\tag{B1}$$

with the following relations:

$$\begin{aligned}&\mathrm{A}\cdot\partial\varphi+\mathrm{B}\cdot\overline{\partial\varphi}=I_w,\quad&&\partial\varphi\cdot\mathrm{A}+\partial\overline{\varphi}\cdot\mathrm{C}=I_z,\\&\mathrm{A}\cdot\partial\overline{\varphi}+\mathrm{B}\cdot\overline{\partial\varphi}=0,\quad&&\partial\varphi\cdot\mathrm{B}+\partial\overline{\varphi}\cdot\mathrm{D}=0,\\&\mathrm{C}\cdot\partial\varphi+\mathrm{D}\cdot\overline{\partial\varphi}=0,\quad&&\overline{\partial\varphi}\cdot\mathrm{A}+\overline{\partial\varphi}\cdot\mathrm{C}=0,\\&\mathrm{C}\cdot\partial\overline{\varphi}+\mathrm{D}\cdot\overline{\partial\varphi}=I_{\bar{w}},\quad&&\overline{\partial\varphi}\cdot\mathrm{B}+\overline{\partial\varphi}\cdot\mathrm{D}=I_{\bar{z}}.\end{aligned}\tag{B2}$$

Starting with the equation in the target chart with respect to φ, $(w,\overline{w})=\varphi(z,\overline{z})$,

$$(\partial_{\bar{w}} - (\mu \circ \varphi) \cdot \partial_w) Z = 0, \tag{B3}$$

and by using the two last identities of the right column of the above equations (B2), one gets in the source chart of φ,

$$(\partial_{\bar{z}} - (\bar{\partial}\varphi + \overline{\partial\varphi} \cdot (\mu \circ \varphi)) \cdot (\mathrm{B} \cdot \partial_{\bar{z}} + \mathrm{A} \cdot \partial_Z))(Z \circ \varphi) = 0, \tag{B4}$$

and by Eq. (III.1) of the main text combined with the two first identities of the right column of (B2), one has

$$(\partial_{\bar{z}} - (\mu^\varphi) \cdot \partial_Z + (\mu^\varphi) \cdot \bar{\partial}\overline{\varphi} \cdot [(\mathrm{C} \cdot \partial_Z + \mathrm{D} \cdot \partial_{\bar{z}}) - (\mu \circ \varphi) \cdot (\mathrm{A} \cdot \partial_Z + \mathrm{B} \cdot \partial_{\bar{z}})])(Z \circ \varphi) = 0. \tag{B5}$$

The terms involving $\partial\overline{\varphi}$ is nothing but proportional to Eq. (B3) due to the laws for the change of variables, and thus the last parenthesis vanishes. The remaining

$$(\partial_{\bar{z}} - (\mu^\varphi) \cdot \partial_Z)(Z \circ \varphi) = 0, \tag{B6}$$

shows that $(Z \circ \varphi)$ are also n linear independent solutions of the Beltrami equations on the source of the diffeomorphism φ, see Eq. (III.4) in the main text. Recall the latter

$$(\partial_{\bar{z}} - (\mu^\varphi) \cdot \partial_Z) Z^\varphi = 0. \tag{B7}$$

Thus the mapping $(Z^\varphi, \overline{Z}^\varphi) \to (Z, \overline{Z})$ is indeed biholomorphic; see Theorem 5.3 in Ref. 13. In other words, this result states the equivalence between the complex structures parametrized by $\boldsymbol{\mu}$ and $\boldsymbol{\mu}^\varphi$.

APPENDIX C: TRUE HOLOMORPHIC DIVERGENCE

In the following the computation of the divergence (V.10) is performed. In doing so, several results are required and are listed hereafter.

First, the computation of the inverse matrix

$$\begin{pmatrix} I & \overline{\mu} \\ \mu & I \end{pmatrix}^{-1} = \begin{pmatrix} (I - \overline{\mu} \cdot \mu)^{-1} & -(I - \overline{\mu} \cdot \mu)^{-1} \cdot \overline{\mu} \\ -(I - \mu \cdot \overline{\mu})^{-1} \cdot \mu & (I - \mu \cdot \overline{\mu})^{-1} \end{pmatrix}, \tag{C1}$$

yields in particular the following two identities:

$$(I - \overline{\mu} \cdot \mu)^{-1} - \overline{\mu} \cdot (I - \mu \cdot \overline{\mu})^{-1} \cdot \mu \equiv I, \quad (I - \overline{\mu} \cdot \mu)^{-1} \cdot \overline{\mu} - \overline{\mu} \cdot (I - \mu \cdot \overline{\mu})^{-1} \equiv 0. \tag{C2}$$

Second, one will use the useful identities

$$\partial_{Z^k}\left(\frac{1}{\mathcal{J}} \lambda_i^k\right) + \partial_{\bar{Z}^l}\left(\frac{1}{\mathcal{J}} \overline{\mu_i^r} \overline{\lambda_r^l}\right) \equiv 0, \quad \partial_{Z^k}\left(\frac{1}{\mathcal{J}} \mu_l^r \lambda_r^k\right) + \partial_{\bar{Z}^l}\left(\frac{1}{\mathcal{J}} \overline{\lambda_l^l}\right) \equiv 0, \tag{C3}$$

coming from the Jacobi multipliers device.

We are now in a position to compute the divergences (V.10) of the main text. Taking into account (II.11) and (II.15) one can show, on the one hand,

$$\frac{(I - \mu \cdot \overline{\mu})_l^J \overline{\lambda}_J^r}{\det(\overline{\lambda}(I - \mu \cdot \overline{\mu}))} \partial_{\bar{Z}^r}\left(\frac{1}{\det \lambda} (\lambda^{-1})_k^s \overline{\Theta_s^l}\right) = \frac{1}{\mathcal{J}} (\lambda^{-1})_k^s (\mathcal{L}_l \overline{\Theta_s^l} - \partial_r \mu_l^r \overline{\Theta_s^l} - \partial_s \mu_l^r \overline{\Theta_r^l}) \tag{C4}$$

which relates to the Ward id's (V.8) by virtue of the non-singularity of λ. On the other hand it is straightforward to show that

$$\partial_{Z^r}\left(\frac{1}{\det(\overline{\lambda}(I-\mu\cdot\overline{\mu}))}(I-\mu\cdot\overline{\mu})\cdot\overline{\lambda^r}\right)\equiv 0, \tag{C5}$$

thanks to the identities (C3) and (C2).

APPENDIX D: THE $\hat{\delta}$ COHOMOLOGY

The $\hat{\delta}$ operator, given by formulas (V.29) in the text, is defined on the space of local functions seen, according to the power counting, as differential polynomials in both the matter and the Φ-Π charged fields, and as analytic in the components of the Beltrami differential. The following set of fields:

$$\chi\equiv f_0\cup f_1\cup\beta\cup\{\lambda,\overline{\lambda}\},\quad f_0\equiv\{\phi,\mu,\overline{\mu}\},\quad f_1\equiv\{c,\overline{c}\},\quad \beta\equiv\{\gamma,\eta,\overline{\eta},\zeta,\overline{\zeta}\},$$

will serve as set of generators for our space of local functions. Thanks to the definition of $\hat{\delta}$, these local functions do not contain any underived ghosts c's.

Let us recall that the fields and their derivatives will be considered as independent coordinates, and in practice, will play the role of creation operators, while the annihilators will be the formal derivatives with respect to these coordinates, both acting on the Fock space structure enjoyed by the space of local functions. This Fock space is graded according to the ghost grading. For any operator, its adjoint will be given by the formal replacement of the derivative with respect to some coordinate by the formal multiplication with respect the same coordinate and vice versa.

According to this, let us now introduce the following self-adjoint operator:

$$\nu=\sum_{|I|,|J|\geqslant 0}(|I|+|\overline{J}|)\left(\sum_{f_1}<\partial_I\partial_{\overline{J}}f_1(z,\overline{z})\frac{\partial}{\partial\partial_I\partial_{\overline{J}}f_1(z,\overline{z})}\right) \tag{D1}$$

whose eigenvalues will provide the order of the derivatives of the ghost fields. The operator ν will decompose the space of local functions into a direct sum of subspaces according to its eigenvalues while the operator $\hat{\delta}$ will be filtered according to

$$[\nu,\hat{\delta}]=\sum_{|I|,|J|\geqslant 0}(|I|+|\overline{J}|)\hat{\delta}(|I|+|\overline{J}|),\quad \hat{\delta}=\sum_{|I|,|J|\geqslant 0}\hat{\delta}(|I|+|\overline{J}|). \tag{D2}$$

The general spectral method[20,10] insures that the $\hat{\delta}$-cohomology is isomorphic to the solutions $\tilde{\Delta}$ of the system

$$\begin{cases}\hat{\delta}(|I|+|\overline{J}|)\tilde{\Delta}(z,\overline{z})=0\\ \hat{\delta}^{\dagger}(|I|+|\overline{J}|)\tilde{\Delta}(z,\overline{z})=0\end{cases},\quad |I|+|\overline{J}|\geqslant 0. \tag{D3}$$

In other words, $\tilde{\Delta}$ is in the kernel of the Laplacians $\{\hat{\delta}(|I|+|\overline{J}|),\hat{\delta}^{\dagger}(|I|+|\overline{J}|)\}$.

In the following, we present in full detail the solution of the cohomology by the spectral sequence device. The zero eigenvalue of ν will select the part of $\hat{\delta}$ in which no ghost field is involved, namely,

$$\begin{aligned}\hat{\delta}(0)=\sum_{|I|,|\overline{J}|\geqslant 0}\Bigg(&\sum_{\beta_{-1}}\left\langle\partial_I\partial_{\overline{J}}\frac{\delta\Gamma_0^{\mathrm{Cl}}}{\delta f_0(z,\overline{z})},\frac{\partial}{\partial\partial_I\partial_{\overline{J}}\beta_{-1}(z,\overline{z})}\right\rangle\\&+\sum_{\beta_{-2}}\left\langle\partial_I\partial_{\overline{J}}X(f_0,\beta_1)(z,\overline{z}),\frac{\partial}{\partial\partial_I\partial_{\overline{J}}\beta_{-2}(z,\overline{z})}\right\rangle\Bigg).\end{aligned} \tag{D4}$$

Note that the latter is a nilpotent operator and is an annihilator with respect to the external sources coupled to the BRS variations. One will prove that the $\hat{\delta}$-cohomology does not actually depend on the external sources coupled to the BRS variations by performing a double-filtration. One first filtrates according to the counting operator

$$\mathcal{N}(\beta)=\sum_{|I|,|\overline{J}|\geqslant 0}\left\langle \partial_I\partial_{\overline{J}}\beta(z,\overline{z}),\frac{\partial}{\partial\partial_I\partial_{\overline{J}}\beta(z,\overline{z})}\right\rangle, \tag{D5}$$

with respect to *one* of the external sources $\beta\equiv\{\gamma,\eta^{\overline{l}}_k,\overline{\eta^l_J},\zeta_i,\overline{\zeta_{\overline{i}}}\}$. Next, the second step of filtration is performed with respect to the full counting operator

$$\mathcal{N}=\sum_{\chi}\sum_{|I|,|\overline{J}|\geqslant 0}\left\langle \partial_I\partial_{\overline{J}}\chi(z,\overline{z}),\frac{\partial}{\partial\partial_I\partial_{\overline{J}}\chi(z,\overline{z})}\right\rangle. \tag{D6}$$

By virtue of the isomorphism (D3), the Laplacian corresponding to the given operator in the null subsector of the double filtration $[\mathcal{N},[\mathcal{N}(\beta),\hat{\delta}(0)]]$, shows that the $\hat{\delta}$-cohomology does not depend on any negatively ghost graded external sources β, thus restricts the set of generators into $\chi\equiv f\cup\{\lambda,\overline{\lambda}\}$, $f\equiv f_0\cup f_1$ on which one will now work with.

The second operator $\hat{\delta}(1)$ in the filtration (D2) will necessarily contain the ghost part, $\hat{\delta}_{\mathrm{Gh}}$ of $\hat{\delta}$ since $[\nu,\hat{\delta}_{\mathrm{Gh}}]=\hat{\delta}_{\mathrm{Gh}}$. The latter will play a central role in the computation of the cohomology. For both this reason and for the sake of compactness in the notation let us write it down as

$$\hat{\delta}_{\mathrm{Gh}}=\sum_{|I|\geqslant 0}\delta_I^{M+N}\frac{(I+1_\alpha)!}{(M+1_\alpha)!N!}(\partial_{M+1_\alpha}c^\beta\partial_{N+1_\beta}c^\rho)(z,\overline{z})\frac{\partial}{\partial\partial_{I+1_\alpha}c^\rho(z,\overline{z})}, \tag{D7}$$

$$\alpha,\beta,\rho=1,\ldots,n,\ldots,2n,\quad \alpha\equiv\begin{cases} i, & \text{for } \alpha=1,\ldots,n,\\ \overline{\imath}, & \text{for } \alpha=n+1,\ldots,2n;\end{cases}$$

$$I=(i_1,\ldots,i_{2n}),\quad i_\alpha=\begin{cases} i_k, & \text{for } \alpha=k=1,\ldots,n;\\ \overline{\imath_l}, & \text{for } \alpha=n+1,\ldots,2n,\quad l=\alpha-n\end{cases}$$

$$c^\alpha=\begin{cases} c^i, & \text{for } \alpha=1,\ldots,n;\\ \overline{c^i}, & \text{for } \alpha=n+1,\ldots,2n.\end{cases}$$

The former can be written as

$$\hat{\delta}(1)\equiv\partial_\alpha c^\beta(z,\overline{z})U^\alpha_\beta+R(1), \tag{D8}$$

where, according to the ghost grading, one can make the following decomposition for the operator $U^\alpha_\beta\equiv(U_0)^\alpha_\beta+(U_1)^\alpha_\beta$, where $(U_0)^\alpha_\beta$ is given by the Lie derivatives of the fields described as components of geometrical objects and $(U_1)^\alpha_\beta$ comes from $\hat{\delta}_{\mathrm{Gh}}$. For instance, in the case of matter fields $U^i_j\equiv S^i_j$ yields

$$(S_0)^i_j=\sum_{|M|,|N|\geqslant 0}\Bigg((m_i+1)\sum_{\chi\equiv f_0\cup\{\lambda,\overline{\lambda}\}}\left\langle \partial_{M+1_j}\partial_{\overline{N}}\chi(z,\overline{z}),\frac{\partial}{\partial\partial_{M+1_i}\partial_{\overline{N}}\chi(z,\overline{z})}\right\rangle$$
$$\times\sum_{A_{n-1}}\delta^{A_{r+1_j}}_{A_{n-1}}\left\langle \partial_M\partial_{\overline{N}}\phi_{A_{r+1_j}}(z,\overline{z}),\frac{\partial}{\partial\partial_M\partial_{\overline{N}}\phi_{A_{r+1_i}}(z,\overline{z})}\right\rangle$$
$$+\partial_M\partial_{\overline{N}}\lambda^r_j(z,\overline{z})\frac{\partial}{\partial\partial_M\partial_{\overline{N}}\lambda^r_i(z,\overline{z})}+\partial_M\partial_{\overline{N}}\overline{\mu^s_j}(z,\overline{z})\frac{\partial}{\partial\partial_M\partial_{\overline{N}}\overline{\mu s_i}(z,\overline{z})}$$
$$-\partial_M\partial_{\overline{N}}\mu^i_s(z,\overline{z})\frac{\partial}{\partial\partial_M\partial_{\overline{N}}\overline{\mu^j_s}(z,\overline{z})}\Bigg);\tag{D9}$$

$$(S_1)^i_j=\sum_{|M|\geqslant 0}(m_i+1)\partial_{M+1_j}c^\alpha(z,\overline{z})\frac{\partial}{\partial\partial_{M+1_i}c^\alpha(z,\overline{z})}-\sum_{|M|\geqslant 1}\partial_M c^i(z,\overline{z})\frac{\partial}{\partial\partial_M c^j(z,\overline{z})}.\tag{D10}$$

Note in addition that the trace $S^i_i=\mathrm{tr}\,S$ is nothing else but the ''little z'' indices counting operator

$$\mathrm{tr}\,S=N_\partial+N_\lambda+N_{\overline{\mu}}+N_\phi-N_\mu-N_c\equiv N_z(\downarrow)-N_z(\uparrow).\tag{D11}$$

One has $S^{\dagger j}_i=S^{\sim j}_i\equiv S^i_j$ and $\overline{S}\equiv N_{\overline{z}}(\downarrow)-N_{\overline{z}}(\uparrow)$ with $\overline{S^\dagger}=\overline{S}^\sim$. In full generality, one has for the ghost contribution

$$(U_1)^\alpha_\beta=\sum_{|I|\geqslant 0}\left((i_\alpha+1)\partial_{I+1_\beta}c^\rho(z,\overline{z})\frac{\partial}{\partial\partial_{I+1_\alpha}c^\rho(z,\overline{z})}-\partial_{I+1_\rho+1_\sigma}c^\alpha\frac{\partial}{\partial\partial_{I+1_\rho+1_\sigma}c^\beta(z,\overline{z})}\right),\tag{D12}$$

and the remaining piece $R(1)$ concerns only the ghost derivatives of order greater or equal to three,

$$R(1)=\sum_{|M|\geqslant 0}\partial_{M+1_\alpha+1_\beta}c^\rho(z,\overline{z})R^{M+1_\alpha+1_\beta}_\rho(z,\overline{z}),R^{M+1_\alpha+1_\beta}_\rho(z,\overline{z})$$
$$=\sum_{|N|\geqslant 0}\frac{(M+N+1_\alpha+1_\beta+1_\gamma)!}{(M+1_\alpha+1_\beta)!(N+1_\gamma)!}\partial_{N+1_\rho+1_\gamma}c^\sigma(z,\overline{z})\frac{\partial}{\partial\partial_{M+N+1_\alpha+1_\beta+1_\gamma}c^\sigma(z,\overline{z})}.\tag{D13}$$

Furthermore, the nilpotency, $\hat{\delta}(1)^2=0$, allows one to apply once more the spectral sequence analysis to the operator: $\hat{\delta}(1)$. The filtration will be performed with respect to the following counting operator:

$$\nu'=1+\partial_\alpha c^\beta(z,\overline{z})\frac{\partial}{\partial\partial_\alpha c^\beta(z,\overline{z})}.\tag{D14}$$

Remarkably, the cohomology reduces to the following finite filtration:

$$[\nu',\hat{\delta}(1)]=\sum_{a=1}^{2}a\,\hat{\delta}'(a),\quad \text{where}\begin{cases}\hat{\delta}'(1)=R(1),\\ \hat{\delta}'(2)=\partial_\alpha c^\beta(z,\overline{z})U^\alpha_\beta,\end{cases}\tag{D15}$$

and $\hat{\delta}(1)=\hat{\delta}'(1)+\hat{\delta}'(2)$. According to (D3), one has to solve the system

$$\begin{cases}\hat{\delta}'(a)\tilde{\Delta}(z,\overline{z})=0\\ \hat{\delta}'^\dagger(a)\tilde{\Delta}(z,\overline{z})=0\end{cases},\quad \text{for } a=1,2,\tag{D16}$$

which turns out to be equivalent to

$$\left\langle \tilde{\Delta}(z,\overline{z})|\{\hat{\delta}'^{\dagger}(a),\hat{\delta}'(a)\}|\tilde{\Delta}(z,\overline{z})\right\rangle = ||\hat{\delta}(a)\tilde{\Delta}(z,\overline{z})||^2 + ||\hat{\delta}'^{\dagger}(a)\tilde{\Delta}(z,\overline{z})||^2 \stackrel{!}{=} 0, \tag{D17}$$

where the scalar product is that the local functions induced by the definition of the adjoint operator. For $a=1$, the lowest order of formal derivatives with respect to the ghost derivatives in the Laplacian involved in Eq. (D17) can be seen of order three. So, the cocycle $\tilde{\Delta}$ has to be dependent on the first and second order derivatives of the ghost fields. The second filtration $a=2$, will select the scalar sector, and eliminates the second order ghost derivatives. It is then useful to perform the following change of variables in the first order derivatives of the ghost fields. Define in matrix notation the n^2 variables of ghost grading one,

$$\tilde{\Omega}(z,\overline{z}) = (\partial c + \partial\overline{c}\cdot\mu)(z,\overline{z}) = (\hat{\delta}\lambda\cdot\lambda^{-1})(z,\overline{z}), \tag{D18}$$

with $(\mathrm{tr}\ S)\tilde{\Omega}=0$, and note the $\hat{\delta}$-coboundary

$$\mathrm{tr}\ \tilde{\Omega}(z,\overline{z}) = \hat{\delta}\ \ln\det\lambda(z,\overline{z}). \tag{D19}$$

One has $\hat{\delta}\tilde{\Omega}(z,\overline{z}) = \hat{\delta}'(2)\tilde{\Omega}(z,\overline{z}) = \tilde{\Omega}^2(z,\overline{z})$, and

$$\hat{\delta}\tilde{\Omega}^{2k+1}(z,\overline{z}) = \tilde{\Omega}^{2k+2}(z,\overline{z}), \tag{D20}$$

showing that the $\tilde{\Omega}^{2k+2}$ are $\hat{\delta}$-coboundaries. By taking the trace in order to be in the scalar sector, one readily checks that

$$\hat{\delta}\ \mathrm{tr}\ \tilde{\Omega}^{2k+1}(z,\overline{z}) = \mathrm{tr}\ \tilde{\Omega}^{2k+2}(z,\overline{z}) = -\mathrm{tr}\ \tilde{\Omega}^{2k+2}(z,\overline{z}) = 0. \tag{D21}$$

This yields the following theorem which is the main result of this Appendix.

Theorem: *In the scalar sector of the space of analytic functions in the fields and their derivatives, the ghost sectors with grading p of the $\hat{\delta}$-cohomology are generated by the following nontrivial cocycles*:

$$\text{for even } p: \quad \mathrm{tr}\ \tilde{\Omega}^{2r+1}(z,\overline{z})\mathrm{tr}\ \overline{\tilde{\Omega}}^{2s+1}(z,\overline{z}),$$

$$\text{for odd } p: \quad \mathrm{tr}\ \tilde{\Omega}^{2k+1}(z,\overline{z}),$$

while the cocycle $\mathrm{tr}\ \tilde{\Omega}$ *can be reabsorbed by completing the set of generators with* $\ln\det\lambda$ *seen as an independent variable. The same statements hold true for the complex conjugate expressions.*

Time-dependent plane wave and multipole expansions of the electromagnetic field

Edwin A. Marengo[a] and Anthony J. Devaney
Center for Electromagnetics Research, Northeastern University, Boston, Massachusetts 02115

(Received 24 November 1997; accepted for publication 8 April 1998)

A new and conceptually simple derivation is presented of the time-dependent multipole expansion of the electromagnetic field radiated by a time-varying, localized, volume charge-current distribution. The analysis is based on a new time-dependent plane wave representation of the electromagnetic field (i.e., an ''angular spectrum expansion'' in the time domain), also derived in the paper. Expressions are given for the time-dependent plane wave spectra in terms of a fourfold Radon transform representation of the transverse current distribution. Two alternative expressions for the time-dependent multipole moments are derived; the first gives them in terms of the spectral amplitude vectors of the corresponding time-dependent plane wave representation while the second gives them in terms of a weighted radial-temporal average of the current distribution. Thus the analysis also sheds light on the relationship between the time-dependent plane wave and multipole expansions in their common domains of validity. © *1998 American Institute of Physics.*

I. INTRODUCTION

In describing transient wave phenomena, descriptions directly in space-time domain (where the sources and fields are well-localized) are usually more efficient and insightful than their conventional, frequency domain counterparts. Examples include the pulsed beams (PBs) and the focus wave modes (FWMs), among others.[1,2] This investigation is concerned with the time domain analogs of more traditional (frequency-domain-based) representations, namely, the plane wave and multipole expansions. Thus, the electromagnetic field radiated by a time-varying (e.g., pulsed), localized, volume charge-current distribution is expressed as a sum of time-dependent spherical (multipole) wave functions. We also obtain, via analytic signal representation, a new time-dependent plane wave representation of the electromagnetic field (i.e., an ''angular spectrum expansion'' in the time domain). The relationship between the expansion coefficients (moments) of the time-dependent plane wave and multipole expansions in their common domains of validity is also examined. The work reported here is an extension to the electromagnetic field case of the time domain multipole theory for scalar fields developed in Ref. 3. It is also an extension to the time domain of the frequency domain plane wave representations and multipole expansions of the electromagnetic field developed in Ref. 4.

Time-dependent multipolelike (spherical wave) expansions of electromagnetic radiation fields are not new. Early work in this area is associated with the names of Granzow,[5] Davidon[6] and Campbell *et al.*[7] More recent contributions include those of Heyman and Devaney,[3] where a scalar time-dependent multipole theory for volume source distributions is developed and Hansen,[8] where time-dependent multipole fields are applied to address theoretical aspects of spherical near field scanning. However, even though work in this field is not new, both the procedure we use to derive our results as well as many of the results are new. For instance, the time domain multipole theories in Refs. 6 and 7 originate from the Debye-potential formalism[4] while ours originates from the time-dependent plane wave representation, also derived in the paper. Granzow's[5] and Hansen's[8] focus is on the diffraction problem for prescribed field data over a boundary while ours is on the radiation problem for volume current distributions. Furthermore, our formulation is conceptually

[a]Electronic mail: emarengo@cdsp.neu.edu

 © 1998 American Institute of Physics

simple and insightful in describing the relationship between the time-dependent expansion coefficients (moments) of the time-dependent plane wave and multipole expansions in their common domains of validity. Aspects of our time-dependent plane wave representations of the electromagnetic field have also appeared before in connection with time domain planar near field scanning.[9] Our formulation, however, is given in terms of charge-current distributions (i.e., radiation problem), unlike those in Ref. 9, which are given in terms of fields prescribed over a boundary (i.e., diffraction problem). More importantly, our analysis not only corroborates those of previous contributions but also yields new, alternative expressions for both types of expansions.

Frequency domain plane wave and multipole expansions of scalar and electromagnetic fields have played a key role in classical and quantum-mechanical theories of wave radiation, propagation and diffraction and in defining fundamental limits in antenna theory.[10,11] Thus, in analogy to their frequency domain counterparts, the time-dependent expansion schemes considered here could be useful in treating canonical radiation and scattering problems directly in the time domain. They could also be of interest in diffraction problems formulated in terms of near or far field data (e.g., time domain near field scanning[8] and inverse diffraction from far field data[4]). Furthermore, they could also help in elucidating transient radiation phenomena (e.g., fundamental limitations of antennas driven by short pulses) and—by doing so—also in defining relevant figures of merit for transient radiation.

The remainder of the paper is organized as follows. Section II reviews known results on plane wave and multipole expansions for scalar fields. We examine, in analytic signal representation, the Weyl expansion (or angular spectrum expansion) of the scalar field generated by a localized scalar source distribution that is turned on at some initial time (say $t=0$). We then derive, again in analytic signal representation, a time domain multipole expansion of the scalar field based on the corresponding time-dependent plane wave representation. Methodologically, we Fourier invert to the time domain the corresponding frequency domain multipole expansion. The final form of the time-dependent multipole expansion is given explicitly in terms of real signals using the real spherical harmonics $S^{(1)}_{\ell,m}(\theta,\phi)$ and $S^{(2)}_{\ell,m}(\theta,\phi)$ (also known as tesseral harmonics[12]), defined, respectively, by the real and imaginary parts of the ordinary spherical harmonic of degree ℓ and order m, $Y_{\ell,m}(\theta,\phi)$. An alternative form of the time-dependent multipole expansion in which the time-dependent multipole moments are expressed as a weighted radial-temporal average of the source distribution is also derived.

The main contribution of the paper is contained in Sec. III. There we extend the theory developed in Sec. II for scalar fields to the electromagnetic field case, with the vector spherical harmonics in the latter case playing a role analogous to that of the ordinary spherical harmonics in the scalar case. In Sec. III A we derive, in analytic signal representation, a new time-dependent plane wave representation of the electromagnetic field generated by a time-varying, localized, volume charge-current distribution. The time-dependent plane wave spectra are given in terms of a fourfold Radon transform representation of the transverse current distribution. Later, we derive, following lines analogous to those of the scalar field treatment in Sec. II, a new form of time-dependent multipole expansion of the electromagnetic field; the spherical-wave expansion functions used are the vector analogs of the real spherical harmonics. However, unlike in Sec. II, our electromagnetic field case manipulations in Sec. III are carried out in the time domain. Two alternative expressions for the time-dependent multipole moments (i.e., the expansion coefficients) are derived; the first gives them in terms of the spectral amplitude vectors of the corresponding time-dependent plane wave representation while the second gives them in terms of a weighted radial-temporal average of the current distribution. Emphasis is placed on real spherical harmonics, hence our expansion involves only real time-dependent multipole wave functions and moments.

Notation: We define the temporal and spatial-temporal Fourier transforms, $q(\mathbf{r},\omega)$ and $\tilde{q}(\mathbf{K},\omega)$, respectively, of a scalar source $Q(\mathbf{r},t)$ of finite energy [i.e., square-integrable in $(\mathbf{r},t)$] via

$$q(\mathbf{r},\omega)=\int_{-\infty}^{\infty} dt' e^{i\omega t'} Q(\mathbf{r},t') \tag{1}$$

where

$$Q(\mathbf{r},t)=\frac{1}{2\pi}\int_{-\infty}^{\infty}d\omega' e^{-i\omega' t}q(\mathbf{r},\omega'), \tag{2}$$

and

$$\tilde{q}(\mathbf{K},\omega)=\int_{-\infty}^{\infty}dt' e^{i\omega t'}\int d\mathbf{r}' e^{-i\mathbf{K}\cdot\mathbf{r}'}Q(\mathbf{r}',t') \tag{3}$$

where

$$Q(\mathbf{r},t)=\frac{1}{(2\pi)^4}\int_{-\infty}^{\infty}d\omega' e^{-i\omega' t}\int d\mathbf{K}' e^{i\mathbf{K}'\cdot\mathbf{r}}\tilde{q}(\mathbf{K}',\omega'). \tag{4}$$

Thus the spatial-temporal Fourier transform $\tilde{q}(\mathbf{K},\omega)$ of $Q(\mathbf{r},t)$ is simply the spatial Fourier transform of $q(\mathbf{r},\omega)$. We shall refer to $q(\mathbf{r},\omega)$ as being the source spectrum.

Unless otherwise stated, we shall subsequently use lowercase and uppercase letters to denote frequency and time domain quantities, respectively. Unless otherwise stated, a tilde ($\tilde{}$) over a constituent will denote a spatial-frequency domain constituent. A caret ($\hat{}$) over a vector will denote a unit vector, e.g., $\hat{\mathbf{r}}\equiv\mathbf{r}/|\mathbf{r}|$.

We shall denote the Cartesian coordinates of $\mathbf{r}$ (configuration space) and $\mathbf{K}$ (momentum space) as (x,y,z) and (K_x,K_y,K_z), respectively. The corresponding spherical coordinates will be denoted as (r,θ,ϕ) and (K,α,β), respectively. We also define the $\mathbf{K}$-space unit vector $\mathbf{s}\equiv\mathbf{K}/K$.

In order to simplify the manipulations time-dependent quantities will be manipulated first in analytic signal representation. For example, we define the analytic source distribution $Q^+(\mathbf{r},t)$ corresponding to a real, square-integrable source distribution $Q(\mathbf{r},t)$ by

$$Q^+(\mathbf{r},t)=\frac{1}{2\pi}\int_{0}^{\infty}d\omega' e^{-i\omega' t}q(\mathbf{r},\omega') \tag{5}$$

so that, for real t,

$$Q(\mathbf{r},t)=2\Re\{Q^+(\mathbf{r},t)\}, \tag{6}$$

where $\Re$ denotes the real part. The quantity $Q^+(\mathbf{r},t)$ defined by Eq. (5) is an analytic function in the lower-half plane of the complex t plane.[13] Of particular interest to us is the real-t limit of $Q^+(\mathbf{r},t)$, which defines the real, physical source distribution $Q(\mathbf{r},t)$ via Eq. (6). Subsequently a plus sign $(+)$ in the upper-right of a constituent will denote its analytic extension.

To simplify notation we also define a temporal integration operator ∂_t^{-1} such that

$$\partial_t^{-1}Q(\mathbf{r},t)\equiv\int_{-\infty}^{t}dt' Q(\mathbf{r},t'). \tag{7}$$

The corresponding nth-order temporal integration will be denoted as ∂_t^{-n}.

II. REVIEW OF THE THEORY FOR SCALAR FIELDS

This section reviews time-dependent plane wave and multipole expansions for scalar fields $U(\mathbf{r},t)$ radiated by scalar sources $Q(\mathbf{r},t)$ to the inhomogeneous wave equation

$$\left(\nabla^2-\frac{1}{c^2}\frac{\partial^2}{\partial t^2}\right)U(\mathbf{r},t)=-4\pi Q(\mathbf{r},t). \tag{8}$$

We will assume that the source $Q(\mathbf{r},t)$ is a square-integrable, continuous and continuously differentiable function of $(\mathbf{r},t)$, is confined to within a spherical volume about the origin [such that $Q(\mathbf{r},t)=0$ for $r>a$], and is turned on at some initial time, say $t=0$ [such that $Q(\mathbf{r},t)=0$ for $t<0$]. The radiated field $U(\mathbf{r},t)$ is the causal solution to Eq. (8), given by[14]

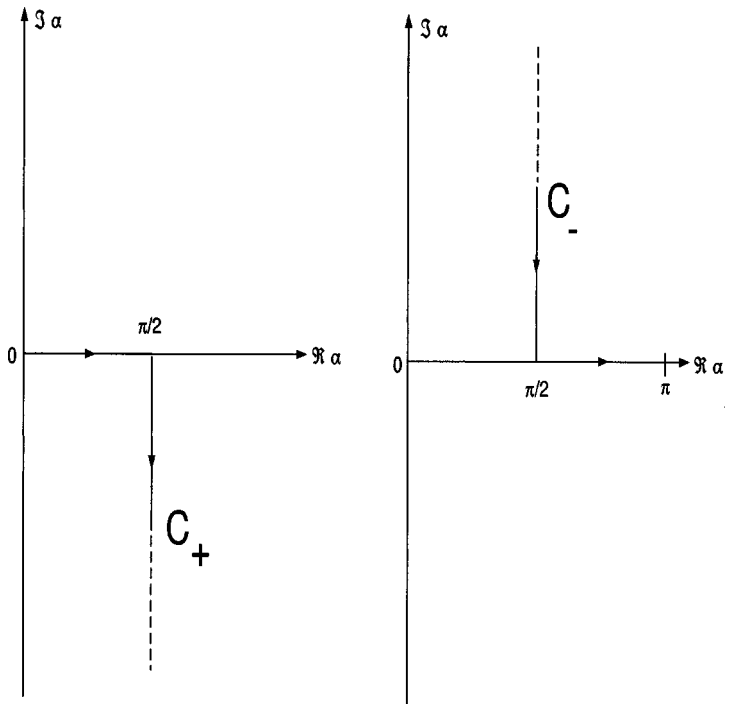

FIG. 1. The α-contours of integration C_+ and C_- in complex α space.

$$U(\mathbf{r},t)=\int_0^\infty dt' \int_{r'\leqslant a} d\mathbf{r}' \frac{Q(\mathbf{r}',t')\,\delta\left(t'-t+\dfrac{|\mathbf{r}-\mathbf{r}'|}{c}\right)}{|\mathbf{r}-\mathbf{r}'|}, \tag{9}$$

where $\delta(\cdot)$ is Dirac's delta function.

A. Plane wave expansion of scalar fields in the time domain

It is well known that the radiated field $U(\mathbf{r},t)$ at points $\mathbf{r}$ within any half-space $|z|\geqslant a$ can be written as a superposition of monochromatic homogeneous and inhomogeneous (evanescent) plane waves; in particular,[15]

$$U(\mathbf{r},t)=2\Re\{U^+(\mathbf{r},t)\}=2\Re\left\{\frac{ic}{(2\pi)^2}\int_0^\infty \frac{\omega}{c}\,d\left(\frac{\omega}{c}\right)\int_{-\pi}^{\pi} d\beta \int_{C_\pm} d\alpha\,\sin\alpha f(\mathbf{s},\omega)e^{[i(\omega/c)(\mathbf{s}\cdot\mathbf{r}-ci)]}\right\} \tag{10}$$

where $\mathbf{s}$ is the unit vector having Cartesian components (in general complex) $(\sin\alpha\cos\beta,\sin\alpha\sin\beta,\cos\alpha)$ while the contours of integration $C_\pm$ in the complex α plane are those shown in Fig. 1, where C_+ is used if $z\geqslant a$ and C_- if $z\leqslant -a$. The real-axis portion of the contours $C_\pm$ contributes to the propagating spectrum, describing homogeneous plane waves propagating into the half-space $z\geqslant a$ or $z\leqslant -a$. The complex portion of the contours $C_\pm$ corresponds, on the other hand, to the evanescent spectrum, describing evanescent plane waves that decay exponentially in amplitude along the z axis (i.e., in $\hat{\mathbf{z}}$ if $z\geqslant a$ and in $-\hat{\mathbf{z}}$ if $z\leqslant -a$). The spectral amplitude function $f(\mathbf{s},\omega)$ in (10) is related to the source spectrum $q(\mathbf{r},\omega)$ by[15]

$$f(\mathbf{s},\omega)=\tilde{q}(\mathbf{K},\omega)|_{\mathbf{K}=(\omega/c)\mathbf{s}}=\int_{r'\leqslant a} d\mathbf{r}'\,e^{-i(\omega/c)\mathbf{s}\cdot\mathbf{r}'}q(\mathbf{r}',\omega). \tag{11}$$

It is noted that since we require $q(\mathbf{r},\omega)$ to be continuous and compactly supported in space, it follows that $\tilde{q}(\mathbf{K},\omega)$ is, for fixed frequency ω, the boundary value, on the real K_x,K_y,K_z axes, of an entire analytic function of three complex variables K_x,K_y,K_z. Thus, for fixed frequency ω,

$f(\mathbf{s},\omega)$ is given by the value of the spatial Fourier transform $\tilde{q}(\mathbf{K},\omega)$, and its analytic continuation into the complex $\mathbf{K}$ plane, of the source spectrum $q(\mathbf{r},\omega)$ evaluated at $\mathbf{K}=(\omega/c)\mathbf{s}$.

By performing the ω integration in (10) and using (5) we obtain

$$U^+(\mathbf{r},t)=-\frac{1}{2\pi c}\frac{\partial}{\partial t}\int_{-\pi}^{\pi}d\beta\int_{C_\pm}d\alpha\,\sin\,\alpha F^+(\mathbf{s},t-\mathbf{s}\cdot\mathbf{r}/c), \tag{12}$$

where from Eq. (11)

$$F^+(\mathbf{s},t)\equiv\frac{1}{2\pi}\int_0^\infty d\omega' e^{-i\omega' t}f(\mathbf{s},\omega')=\int_{r'\leqslant a}d\mathbf{r}' Q^+(\mathbf{r}',t+\mathbf{s}\cdot\mathbf{r}'/c). \tag{13}$$

Equations (12) and (13) define the time-dependent plane wave representation of the analytic signal $U^+(\mathbf{r},t)$ corresponding to the real, physical field $U(\mathbf{r},t)$.

Equation (13) is the time domain analog of (11). The operation defined by the integral on the right-hand side of Eq. (13), sometimes referred to as ''slant-stack transform'' of the analytic source distribution $Q^+(\mathbf{r},t)$, has been studied in recent years by Heyman.[16] It involves spatial Radon projection of $Q^+(\mathbf{r},t)$ evaluated at planes normal to the spectral propagation direction $\mathbf{s}$ and stacking them with a progressive time delay $\mathbf{s}\cdot\mathbf{r}/c$ associated with a wave front propagating at the speed of light along this direction. Mathematically, $F^+(\mathbf{s},t)$ is given by the value of the fourfold Radon transform, and its analytic continuation for complex $\mathbf{s}$,[17] of the analytic source distribution evaluated at the hyperplane $ct-\mathbf{s}\cdot\mathbf{r}=0$ in a four-dimensional space-time domain $(ct,\mathbf{r})$.

The real, physical field $U(\mathbf{r},t)$ is recovered from $U^+(\mathbf{r},t)$ via Eqs. (6) and (5). In the far radiation zone[14]

$$U(r\hat{\mathbf{r}},t)\big|_{r\to\infty}\sim\frac{1}{r}F(\mathbf{s},\tau)\big|_{\mathbf{s}=\hat{\mathbf{r}}} \tag{14}$$

with $\tau=t-r/c$. Thus the time domain radiation pattern is from Eq. (14), the propagating portion of the time-dependent plane-wave spectrum. The evanescent spectrum can be recovered by analytic continuation of the time domain radiation pattern to complex-valued observation directions.[17] The individual contributions of the propagating and evanescent spectra to the total field have been examined in detail by Heyman,[16] who has shown that the contribution from the evanescent spectrum vanishes after a certain time t_E that may be determined *a priori* for a given field point; in regions of space where t_E occurs prior to the causal arrival time of the field, the latter is describable only by its propagating spectrum within the causal time window while noncausal contributions due to both propagating and evanescent spectra cancel out prior to the causal arrival time.

B. Multipole theory in the frequency domain

The multipole expansion of the radiated field spectrum $u(\mathbf{r},\omega)$ is readily obtained by expanding the spectral amplitudes $f(\mathbf{s},\omega)$ of the (frequency domain) angular spectrum expansion

$$u(\mathbf{r},\omega)=\frac{i\omega/c}{2\pi}\int_{-\pi}^{\pi}d\beta\int_{C_\pm}d\alpha\,\sin\,\alpha f(\mathbf{s},\omega)e^{i(\omega/c)\mathbf{s}\cdot\mathbf{r}} \tag{15}$$

into a series of spherical harmonics $Y_{\ell,m}(\alpha,\beta)$ (see Appendix A for a review) so that

$$f(\mathbf{s},\omega)=\sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell}(-i)^\ell\tilde{a}_{\ell,m}(\omega)Y_{\ell,m}(\alpha,\beta) \tag{16}$$

where

$$\tilde{a}_{\ell,m}(\omega)=i^\ell\int_{-\pi}^{\pi}d\beta\int_0^\pi d\alpha\,\sin\,\alpha f(\mathbf{s},\omega)Y^*_{\ell,m}(\alpha,\beta). \tag{17}$$

By substituting from Eqs. (16) and (17) into Eq. (15) while interchanging orders of integration and summation one readily finds

$$u(\mathbf{r},\omega)=\frac{i\omega}{c}\sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell}\tilde{a}_{\ell,m}(\omega)\Pi_{\ell,m}(\mathbf{r},\omega), \tag{18}$$

where

$$\Pi_{\ell,m}(\mathbf{r},\omega)=(-i)^{\ell}\frac{1}{2\pi}\int_{-\pi}^{\pi}d\beta\int_{C_{\pm}}d\alpha Y_{\ell,m}(\alpha,\beta)e^{i(\omega/c)\mathbf{s}\cdot\mathbf{r}} \tag{19}$$

is precisely the angular spectrum representation of the scalar multipole field of degree ℓ and order m, i.e.,[4]

$$\Pi_{\ell,m}(\mathbf{r},\omega)=h_{\ell}^{(1)}\left(\frac{\omega}{c}r\right)Y_{\ell,m}(\theta,\phi). \tag{20}$$

In Eq. (20), $h_{\ell}^{(1)}(\cdot)$ is the spherical Hankel function of the first kind of order ℓ (as defined in Ref. 14). Even though Eqs. (18) and (20) were derived for $\omega>0$, they apply to all real ω. This fact is implicit in our time-dependent multipole treatment (Sec. II C). For example, the operator $\mathscr{L}_{\ell}^{(r,t)}$ in Eq. (24) applies to both analytic and real signals.

The multipole expansion Eq. (18) is valid for $r\geqslant a$ while the plane wave expansion Eq. (15) is valid for $|z|\geqslant a$. However, it is obvious that as long as $\mathbf{r}$ is outside the source, one can always decompose the radiated field spectrum $u(\mathbf{r},\omega)$ in the form Eq. (15) by a suitable choice of coordinates.[16]

An alternative expression for the multipole moments $\tilde{a}_{\ell,m}(\omega)$ is obtained by substituting (11) on (17) and interchanging orders of integration so as to yield[4]

$$\tilde{a}_{\ell,m}(\omega)=4\pi\int_{r'\leqslant a}d\mathbf{r}'q(\mathbf{r}',\omega)\Lambda_{\ell,m}^{*}(\mathbf{r}',\omega) \tag{21}$$

with

$$\Lambda_{\ell,m}(\mathbf{r},\omega)\equiv j_{\ell}\left(\frac{\omega}{c}r\right)Y_{\ell,m}(\theta,\phi)=(-i)^{\ell}\frac{1}{4\pi}\int_{-\pi}^{\pi}d\beta\int_{0}^{\pi}d\alpha\,\sin\alpha Y_{\ell,m}(\alpha,\beta)e^{i(\omega/c)\mathbf{s}\cdot\mathbf{r}}, \tag{22}$$

where $j_{\ell}(\cdot)$ is the spherical Bessel function of the first kind and order ℓ (as defined in Ref. 4).

The multipole expansion enjoys several advantages over the angular spectrum expansion. First of all, we see from Eq. (17) that the multipole moments $\tilde{a}_{\ell,m}(\omega)$ are defined only by the real $\mathbf{s}$ (propagating) spectral amplitudes $f(\mathbf{s},\omega)$. Thus, in contrast to the angular spectrum expansion—which requires analytic continuation—the multipole expansion requires no analytic continuation of $f(\mathbf{s},\omega)$ for complex values of the polar angle α. In addition, unlike the plane waves $e^{i(\omega/c)\mathbf{s}\cdot\mathbf{r}}$, the multipole fields $\Pi_{\ell,m}(\mathbf{r},\omega)$ obey Sommerfeld's radiation condition. Hence, the multipole expansion is, unlike the angular spectrum expansion, a true mode expansion of the radiation field spectrum. This can be of interest if one wishes to approximate the radiated field either by truncating the series (18) or by limiting the (α,β) region of integration in (15). In the former case the approximation will obey Sommerfeld's radiation condition while in the latter it will not. These advantages are obtained, however, at the expense of the increased complexity of the spherical wave fields $\Pi_{\ell,m}(\mathbf{r},\omega)$ as compared to the plane waves $e^{i(\omega/c)\mathbf{s}\cdot\mathbf{r}}$.

C. Time-dependent multipole expansion of the scalar field

Next we obtain a time domain multipole expansion for the scalar field $U(\mathbf{r},t)$ following the lines of Ref. 3. Our starting point is the result [see Ref. 18, Eq. (10.1.16)]

$$\frac{1}{2\pi}\int_0^\infty d\omega e^{-i\omega t}h_\ell^{(1)}\left(\frac{\omega}{c}r\right)\tilde{a}_{\ell,m}(\omega)=-(-i)^\ell\frac{c}{r}\partial_t^{-1}\mathscr{L}_\ell^{(r,t)}a_{\ell,m}^+(t), \tag{23}$$

where

$$a_{\ell,m}^+(t)=\frac{1}{2\pi}\int_0^\infty d\omega e^{-i\omega t}\tilde{a}_{\ell,m}(\omega)$$

and

$$\mathscr{L}_\ell^{(r,t)}a_{\ell,m}^+(t)=\sum_{n=0}^{\ell}\frac{(\ell+n)!}{n!(\ell-n)!}\left(\frac{2r}{c}\right)^{-n}\partial_t^{-n}a_{\ell,m}^+(\tau). \tag{24}$$

In Eqs. (23) and (24) $\tau=t-r/c$ (as before) and ∂_t^{-n} denotes nth-order temporal integration [recall (7)].

By Fourier inverting Eq. (18) over positive frequencies while using Eqs. (20) and (23) we obtain

$$U^+(\mathbf{r},t)=\frac{1}{r}\sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell}(-i)^\ell Y_{\ell,m}(\theta,\phi)\mathscr{L}_\ell^{(r,t)}a_{\ell,m}^+(t). \tag{25}$$

The analytic time-dependent multipole moments $a_{\ell,m}^+(t)$ are obtained by Fourier inverting over positive frequencies both sides of Eq. (17), thus giving

$$a_{\ell,m}^+(t)=i^\ell\int_{-\pi}^{\pi}d\beta\int_0^\pi d\alpha\,\sin\alpha F^+(\mathbf{s},t)Y_{\ell,m}^*(\alpha,\beta). \tag{26}$$

Thus, for fixed t, the analytic time-dependent multipole moments $a_{\ell,m}^+(t)$ are, apart from the factor i^ℓ, given by projections of the analytic time-dependent plane wave spectrum $F^+(\mathbf{s},t)$ [see Eq. (13)] onto the set of spherical harmonics $Y_{\ell,m}(\alpha,\beta)$. Note, however, that—as expected from our discussion in Eq. (17)—only the real-$\mathbf{s}$, propagating plane wave spectral components enter into play in Eq. (26).

An alternative form of Eq. (25) due to Hansen and Norris[19] is obtained using (see Ref. 19 and references therein)

$$h_\ell^{(1)}\left(\frac{\omega}{c}r\right)Y_{\ell,m}(\theta,\phi)=i^{-\ell}\tilde{P}_{\ell m}^{\omega}\frac{e^{i(\omega/c)r}}{i(\omega/c)r}, \tag{27}$$

where

$$\tilde{P}_{\ell m}^{\omega}=(-1)^m\sqrt{\frac{(2\ell+1)(\ell-m)!}{4\pi(\ell+m)!}}\left(\frac{1}{i(\omega/c)}\frac{\partial}{\partial x}+i\frac{1}{i\dfrac{\omega}{c}}\frac{\partial}{\partial y}\right)^m P_\ell^{(m)}\left(\frac{1}{i\dfrac{\omega}{c}}\frac{\partial}{\partial z}\right),\quad m\geqslant 0, \tag{28}$$

where $P_\ell^{(m)}(\cdot)$ is the mth derivative of the Legendre polynomial and for $m<0$, $\tilde{P}_{\ell,-m}^{\omega}=(-1)^m\tilde{P}_{\ell m}^{\omega *}$. On substituting from Eqs. (27) and (28) into Eqs. (18) and (20) while using the complex-point source field expansion of the real-point source field [see Eq. (16) in Ref. 19]

$$\frac{e^{i(\omega/c)r}}{4\pi r}=\frac{1}{4\pi j_0(i(\omega/c)\rho)}\int_{-\pi}^{\pi}d\phi'\int_0^\pi d\theta'\,\sin\theta'\frac{e^{i(\omega/c)\xi(\theta',\phi')}}{4\pi\xi(\theta',\phi')}, \tag{29}$$

where $\xi=|\mathbf{r}-i\rho\hat{\mathbf{r}}'|=\xi_r+i\xi_i$ is the complex length having real and imaginary parts ξ_r and ξ_i, respectively, where $\rho\leqslant a$ is a positive constant (such that $\xi_r\geqslant 0$ and $-\rho\leqslant\xi_i\leqslant\rho$), and transforming to the time domain one obtains

$$U^{+}(\mathbf{r},t)=\sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell}(-i)^{\ell}\int_{-\pi}^{\pi}d\phi'\int_{0}^{\pi}d\theta'\ \sin\ \theta'\widetilde{L_0}\widetilde{P}^{t}_{\ell m}\ \frac{a^{+}_{\ell,m}(t-\xi(\theta',\phi')/c)}{4\pi\xi(\theta',\phi')},\qquad(30)$$

where $\widetilde{L_0}$ is a time domain operator whose frequency domain representation is $1/j_0((i\omega/c)\rho)$ [see Eq. (37) in Ref. 19] while $\widetilde{P}^{t}_{\ell m}$ is the time domain analog of $\widetilde{P}^{\omega}_{\ell m}$. Equation (30) is the result Eq. (59) in Ref. 19; it is an analytic field expansion in terms of time-dependent multipoles with complex-source locations. Unlike in Eq. (25), in Eq. (30) the basis functions are directionally localized; hence they are of interest in well-collimated wave radiation and propagation (see, e.g., Heyman and Felsen[1]). However, the real-signal counterpart of the analytic complex-source multipole expansion Eq. (30) is complicated and involves convolutions; in contrast, the real-signal version of Eq. (25) is straightforward and can be written in terms of the operator $\mathscr{L}^{(r,t)}_{\ell}$. This is done below.

We use (25) to recover the real, physical field $U(\mathbf{r},t)=2\Re\{U^{+}(\mathbf{r},t)\}$. In order to evaluate the real part of expression (25) we consider the real spherical harmonics $S^{(j)}_{\ell,m}$, with $\ell=0,1,...,$ $m=0,1,...,\ell$ (see Appendix A). They obey the following orthogonality and completeness properties:[3]

$$\int_{-\pi}^{\pi}d\beta\int_{0}^{\pi}d\alpha\ \sin\ \alpha S^{(j)}_{\ell,m}(\alpha,\beta)S^{(j')}_{\ell',m'}(\alpha,\beta)=\delta_{\ell,\ell'}\delta_{m,m'}\delta_{j,j'}\ \frac{1}{c_m},\qquad(31)$$

where $c_m=1$ or 2 for $m=0$ or $m\geqslant 1$, respectively, and

$$\sum_{\ell=1}^{\infty}\sum_{m=0}^{\ell}\sum_{j=1,2}c_m S^{(j)}_{\ell,m}(\alpha,\beta)S^{(j)}_{\ell,m}(\alpha',\beta')=\frac{1}{\sin\ \alpha}\ \delta(\beta-\beta')\delta(\alpha-\alpha')\equiv\delta(\mathbf{s}-\mathbf{s}').\qquad(32)$$

[In Eq. (32), α' and β' are, respectively, the polar and azimuthal coordinates of the unit vector $\mathbf{s}'$.]

By taking the real part to both sides of Eq. (25) while using Eqs. (26), (32), and (31) one obtains (see derivation in Appendix B)

$$U(\mathbf{r},t)=\frac{1}{r}\sum_{\ell=0}^{\infty}\sum_{m=0}^{\ell}\sum_{j=1,2}c_m S^{(j)}_{\ell,m}(\theta,\phi)\mathscr{L}^{(r,t)}_{\ell}q^{(j)}_{\ell,m}(t),\qquad(33)$$

where we have introduced the new (real) multipole moments $q^{(j)}_{\ell,m}(t)$, defined via

$$q^{(j)}_{\ell,m}(t)=\int_{-\pi}^{\pi}d\beta\int_{0}^{\pi}d\alpha\ \sin\ \alpha F(\mathbf{s},t)S^{(j)}_{\ell,m}(\alpha,\beta).\qquad(34)$$

On comparing Eqs. (14) and (33) with $\mathscr{L}^{(r,t)}_{\ell}$ given by Eq. (24), the far field is seen to correspond to the lowest order term (i.e., $n=0$) in the series expansion Eq. (24) corresponding to $\mathscr{L}^{(r,t)}_{\ell}$. Thus from Eq. (24) $\mathscr{L}^{(r,t)}_{\ell}q^{(j)}_{\ell,m}(t)|_{r\to\infty}\sim q^{(j)}_{\ell,m}(\tau)$. Using this result in Eq. (33) yields

$$U(\mathbf{r},t)|_{r\to\infty}\sim\frac{1}{r}\sum_{\ell=0}^{\infty}\sum_{m=0}^{\ell}\sum_{j=1,2}c_m S^{(j)}_{\ell,m}(\theta,\phi)q^{(j)}_{\ell,m}(\tau).\qquad(35)$$

Also, from (14) and (35), the time domain radiation pattern reduces to

$$F(\hat{\mathbf{r}},t)=\sum_{\ell=0}^{\infty}\sum_{m=0}^{\ell}\sum_{j=1,2}c_m S^{(j)}_{\ell,m}(\theta,\phi)q^{(j)}_{\ell,m}(t).\qquad(36)$$

Since the multipole moments $q^{(j)}_{\ell,m}(t)$ define via Eq. (33) the field everywhere outside the source, it follows from Eq. (34) that the time domain radiation pattern $F(\hat{\mathbf{r}},t)$ also determines the field everywhere outside the source (problem of inverse diffraction from far field data[3,4]).

Equation (34) defines the real time-dependent multipole moments $q^{(j)}_{\ell,m}(t)$ as projections of the time-dependent plane wave spectrum onto the set of real spherical harmonics. An alternative

formula for $q^{(j)}_{\ell,m}(t)$ based on a radially dependent weighted time average of $Q(\mathbf{r},t)$ follows readily from the time domain analog of Eq. (21). The remainder of this section is based on Eq. (21) and the following result:[3]

$$j_\ell(z)=\frac{(z/2)^\ell}{2\ell!}\int_{-1}^{1}d\eta(1-\eta^2)^\ell e^{iz\eta}. \tag{37}$$

We begin by substituting from Eq. (37) into Eq. (21), thus obtaining

$$\tilde{a}_{\ell,m}(\omega)=\frac{4\pi c^{-\ell}\omega^\ell}{\ell!2^{\ell+1}}\int_{r\leqslant a}d\mathbf{r}q(\mathbf{r},\omega)Y^*_{\ell,m}(\theta,\phi)r^\ell\int_{-1}^{1}d\eta(1-\eta^2)^\ell e^{-i\omega r\eta/c}. \tag{38}$$

The analytic time-dependent multipole moments $a^+_{\ell,m}(t)$ are obtained by Fourier inverting $\tilde{a}_{\ell,m}(\omega)$ as given by Eq. (38) over positive frequencies. This procedure yields

$$a^+_{\ell,m}(t)=\frac{1}{2\pi}\int_0^\infty d\omega e^{-i\omega t}\tilde{a}_{\ell,m}(\omega)=i^\ell\int_{-\pi}^{\pi}d\phi\int_0^\pi d\theta\,\sin\,\theta Y^*_{\ell,m}(\theta,\phi)F^+_\ell(\hat{\mathbf{r}},t), \tag{39}$$

where

$$F^+_\ell(\hat{\mathbf{r}},t)=\frac{4\pi c^{-\ell}}{\ell!2^{\ell+1}}\int_{r\leqslant a}drr^\ell\int_{-1}^{1}d\eta(1-\eta^2)^\ell\frac{\partial^\ell}{\partial t^\ell}Q^+(\mathbf{r},t+r\eta/c). \tag{40}$$

The real time-dependent multipole moments $q^{(j)}_{\ell,m}(t)$ follow from Eqs. (39) and (40) with $q^+_{\ell,m}(t)=(-i)^\ell a^+_{\ell,m}(t)$:

$$q^{(j)}_{\ell,m}(t)=\int_{-\pi}^{\pi}d\phi\int_0^\pi d\theta\,\sin\,\theta S^{(j)}_{\ell,m}(\theta,\phi)F_\ell(\hat{\mathbf{r}},t), \tag{41}$$

where

$$F_\ell(\hat{\mathbf{r}},t)=\frac{4\pi c^{-\ell}}{\ell!2^{\ell+1}}\int_{r\leqslant a}drr^\ell\int_{-1}^{1}d\eta(1-\eta^2)^\ell\frac{\partial^\ell}{\partial t^\ell}Q(\mathbf{r},t+r\eta/c). \tag{42}$$

The time-dependent real multipole moments $q^{(j)}_{\ell,m}(t)$ are now given from Eqs. (41) and (42) by the projection of an ℓ-dependent (effective) time domain radiation pattern $F_\ell(\hat{\mathbf{r}},t)$ onto the set of real spherical harmonics. This latter quantity is computed using a two-step procedure described below.

The first step is that of η integration in (42). It involves radially dependent weighted time averaging of the ℓth time derivative of the source distribution, $(\partial^\ell/\partial t^\ell)Q(\mathbf{r},t)$ (η integration plays the role of temporal integration). The term $(1-\eta^2)^\ell$ in Eq. (42) acts as weighting kernel. The η-integration limits in Eq. (42) define the time window $t\pm r/c$ within which weighted time averaging of $(\partial^\ell/\partial t^\ell)Q(\mathbf{r},t)$ is carried out. This first step acts on both the temporal and radial dependence of the source. The temporal nature of the source enters into play here through both time derivation and time averaging. On the other hand, both ℓ and r (and, therefore, also the source's radius a) control the effective time averaging window.

The second step is that of radial integration. It acts only on the radial dependence of the source. Thus it plays a role in controlling the relative relevance of the outer versus the inner source's structure in defining $q^{(j)}_{\ell,m}(t)$.

III. TIME-DEPENDENT PLANE WAVE AND MULTIPOLE EXPANSIONS OF ELECTROMAGNETIC FIELDS

In Gaussian systems of units, the time-dependent electric and magnetic field vectors $\mathscr{E}(\mathbf{r},t)$ and $\mathscr{H}(\mathbf{r},t)$, respectively, generated in free space by a time-dependent current distribution $\mathscr{J}(\mathbf{r},t)$, are the causal solutions to the vector wave equations[14]

$$\left(\nabla^2-\frac{1}{c^2}\frac{\partial^2}{\partial t^2}\right)\mathscr{E}(\mathbf{r},t)=-4\pi\left[-\frac{1}{c^2}\frac{\partial}{\partial t}+\partial_t^{-1}\nabla\nabla\cdot\right]\mathscr{T}(\mathbf{r},t),$$
$$\left(\nabla^2-\frac{1}{c^2}\frac{\partial^2}{\partial t^2}\right)\mathscr{H}(\mathbf{r},t)=-4\pi\,\frac{1}{c}\,\nabla\times\mathscr{T}(\mathbf{r},t), \tag{43}$$

where, again, ∂_t^{-1} denotes integration over time [see Eq. (7)]. Here and henceforth it is assumed that $\mathscr{T}(\mathbf{r},t)$ is a square-integrable, continuous and continuously differentiable function of $(\mathbf{r},t)$, is confined to a finite region of radius a around the origin, and is turned on at some initial time $t=0$. In Secs. III A and III B we derive new time-dependent plane wave and multipole expansions for $\mathscr{E}(\mathbf{r},t)$ and $\mathscr{H}(\mathbf{r},t)$ in terms of $\mathscr{T}(\mathbf{r},t)$.

A. Plane wave expansion of electromagnetic fields in the time domain

It follows from (43) that each Cartesian component of the electromagnetic field vectors $\mathscr{E}(\mathbf{r},t)$, $\mathscr{H}(\mathbf{r},t)$ satisfies an inhomogeneous scalar wave equation of the form Eq. (8). Therefore, the results of Sec. II are applicable to each Cartesian component of $\mathscr{E}(\mathbf{r},t)$ and $\mathscr{H}(\mathbf{r},t)$. Thus, we introduce the analytic field vectors $\mathscr{E}^+(\mathbf{r},t)=(1/2\pi)\int_0^\infty d\omega e^{-i\omega t}\mathbf{E}(\mathbf{r},\omega)$, $\mathscr{H}^+(\mathbf{r},t)=(1/2\pi)\int_0^\infty d\omega e^{-i\omega t}\mathbf{H}(\mathbf{r},\omega)$, where $\mathbf{E}(\mathbf{r},\omega)$ and $\mathbf{H}(\mathbf{r},\omega)$ are, respectively, the electric and magnetic field spectrum. They are related to the analytic current distribution $\mathscr{T}^+(\mathbf{r},t)=(1/2\pi)\int_0^\infty d\omega e^{-i\omega t}\mathbf{J}(\mathbf{r},\omega)$ by Eq. (43) with $\mathscr{E}$, $\mathscr{H}$ and $\mathscr{T}$ substituted by $\mathscr{E}^+$, $\mathscr{H}^+$ and $\mathscr{T}^+$, respectively.

By applying to Eq. (43) the scalar case result Eq. (12) one obtains

$$\mathscr{E}^+(\mathbf{r},t)=-\frac{1}{2\pi c}\frac{\partial}{\partial t}\int_{-\pi}^{\pi}d\beta\int_{C_\pm}d\alpha\,\sin\alpha\,\mathbf{F}_E^+(\mathbf{s},t-\mathbf{s}\cdot\mathbf{r}/c),$$
$$\mathscr{H}^+(\mathbf{r},t)=-\frac{1}{2\pi c}\frac{\partial}{\partial t}\int_{-\pi}^{\pi}d\beta\int_{C_\pm}d\alpha\,\sin\alpha\,\mathbf{F}_H^+(\mathbf{s},t-\mathbf{s}\cdot\mathbf{r}/c), \tag{44}$$

where from Eq. (13)

$$\mathbf{F}_E^+(\mathbf{s},t)=\int_{r'\leqslant a}d\mathbf{r}'\left[-\frac{1}{c^2}\frac{\partial}{\partial t}+\partial_t^{-1}\nabla'\nabla'\cdot\right]\mathscr{T}^+(\mathbf{r}',t+\mathbf{s}\cdot\mathbf{r}'/c),$$
$$\mathbf{F}_H^+(\mathbf{s},t)=\frac{1}{c}\int_{r'\leqslant a}d\mathbf{r}'\nabla'\times\mathscr{T}^+(\mathbf{r}',t+\mathbf{s}\cdot\mathbf{r}'/c), \tag{45}$$

with ∇' operating on $\mathbf{r}'$ (∇' does not act on $t+\mathbf{s}\cdot\mathbf{r}'/c$). The results Eqs. (44) and (45) above define a new time-dependent plane wave representation for electromagnetic fields whose interpretation is analogous to that of its scalar counterpart Eqs. (12) and (13).

Next we would like to express Eq. (45) more compactly in terms of the slant-stack transform

$$\hat{\mathscr{T}}^+(\mathbf{s},t)=\int_{r'\leqslant a}d\mathbf{r}'\mathscr{T}^+(\mathbf{r}',t+\mathbf{s}\cdot\mathbf{r}'/c) \tag{46}$$

of the analytic time-dependent current distribution $\mathscr{T}^+$. By manipulating the integrals of Eq. (45) while using (46) we obtain (see derivation in Appendix C)

$$\mathbf{F}_E^+(\mathbf{s},t)=\frac{1}{c^2}\frac{\partial}{\partial t}\{\mathbf{s}\times[\mathbf{s}\times\hat{\mathscr{T}}^+(\mathbf{s},t)]\},$$
$$\mathbf{F}_H^+(\mathbf{s},t)=-\frac{1}{c^2}\frac{\partial}{\partial t}[\mathbf{s}\times\hat{\mathscr{T}}^+(\mathbf{s},t)]. \tag{47}$$

We see from Eq. (47) that $\mathbf{F}_E^+(\mathbf{s},t)$ and $\mathbf{F}_H^+(\mathbf{s},t)$ are defined by the transverse part (relative to $\mathbf{s}$)—and its analytic continuation to complex $\mathbf{s}$—of $\hat{\mathscr{T}}^+(\mathbf{s},t)$. We see also from Eq. (47) that

$$\mathbf{s}\cdot\mathbf{F}_E^+(\mathbf{s},t)=\mathbf{s}\cdot\mathbf{F}_H^+(\mathbf{s},t)=0,$$
$$\mathbf{F}_E^+(\mathbf{s},t)=-\mathbf{s}\times\mathbf{F}_H^+(\mathbf{s},t). \tag{48}$$

Hence, the terms in the integrands of (44) represent—for each $\mathbf{s}$—electromagnetic plane waves, as expected.

We conclude this section by applying the scalar case result Eq. (14) to each Cartesian component of the field vectors, thus obtaining from (47) the far zone approximations

$$\mathscr{E}(r\hat{\mathbf{r}},t)|_{r\to\infty}\sim\frac{1}{r}\mathbf{F}_E(\hat{\mathbf{r}},\tau)|_{r\to\infty}=\frac{1}{c^2 r}\frac{\partial}{\partial t}\{\hat{\mathbf{r}}\times[\hat{\mathbf{r}}\times\hat{\mathscr{T}}(\hat{\mathbf{r}},\tau)]\},$$
$$\mathscr{H}(r\hat{\mathbf{r}},t)|_{r\to\infty}\sim\frac{1}{r}\mathbf{F}_H(\hat{\mathbf{r}},\tau)|_{r\to\infty}=-\frac{1}{c^2 r}\frac{\partial}{\partial t}[\hat{\mathbf{r}}\times\hat{\mathscr{T}}(\hat{\mathbf{r}},\tau)] \tag{49}$$

where, as before, $\tau=t-r/c$. Expressions (49) have been derived before in connection with questions of realizability of time domain radiation patterns[17] and in time domain antenna characterization.[20]

B. Time-dependent multipole expansion of the electromagnetic field

Next we will obtain an expansion of the analytic time-dependent electric and magnetic field vectors $\mathscr{E}^+(\mathbf{r},t)$ and $\mathscr{H}^+(\mathbf{r},t)$ in terms of vector spherical wave functions. Methodologically, first we will expand the analytic time-dependent plane wave spectra [$\mathbf{F}_E^+(\mathbf{s},t)$ and $\mathbf{F}_H^+(\mathbf{s},t)$] into a series of the two sets of vector functions $\mathbf{Y}_{\ell,m}(\alpha,\beta)$ and $\mathbf{s}\times\mathbf{Y}_{\ell,m}(\alpha,\beta)$; later we will substitute the vector spherical harmonics expansions for $\mathbf{F}_E^+(\mathbf{s},t)$ and $\mathbf{F}_H^+(\mathbf{s},t)$ into the time-dependent plane wave expansions—Eq. (44). The first step above yields

$$\mathbf{F}_E^+(\mathbf{s},t)=\sum_{\ell=1}^{\infty}\sum_{m=-\ell}^{\ell}(-i)^{\ell}[a_{\ell,m}^+(t)\mathbf{s}\times\mathbf{Y}_{\ell,m}(\alpha,\beta)+b_{\ell,m}^+(t)\mathbf{Y}_{\ell,m}(\alpha,\beta)],$$
$$\mathbf{F}_{\mathbf{H}}^+(\mathbf{s},t)=\sum_{\ell=1}^{\infty}\sum_{m=-\ell}^{\ell}(-i)^{\ell}[-a_{\ell,m}^+(t)\mathbf{Y}_{\ell,m}(\alpha,\beta)+b_{\ell,m}^+(t)\mathbf{s}\times\mathbf{Y}_{\ell,m}(\alpha,\beta)]. \tag{50}$$

It is noted that the forms of the expansions above are consistent with Eq. (48).

By making use of the orthogonality condition of the vector spherical harmonics, Eq. (A8), we obtain from Eq. (50)

$$a_{\ell,m}^+(t)=-\frac{i^{\ell}}{\ell(\ell+1)}\int_{-\pi}^{\pi}d\beta\int_0^{\pi}d\alpha\,\sin\alpha\mathbf{F}_H^+(\mathbf{s},t)\cdot\mathbf{Y}_{\ell,m}^*(\alpha,\beta),$$
$$b_{\ell,m}^+(t)=\frac{i^{\ell}}{\ell(\ell+1)}\int_{-\pi}^{\pi}d\beta\int_0^{\pi}d\alpha\,\sin\alpha\mathbf{F}_{\mathbf{E}}^+(\mathbf{s},t)\cdot\mathbf{Y}_{\ell,m}^*(\alpha,\beta). \tag{51}$$

Thus the analytic time-dependent multipole moments $a_{\ell,m}^+(t)$ and $b_{\ell,m}^+(t)$ are defined by the projections of $\mathbf{F}_H^+(\mathbf{s},t)$ and $\mathbf{F}_E^+(\mathbf{s},t)$, respectively, onto the set of vector spherical harmonics.

The time-dependent multipoles can also be expressed directly in terms of the slant-stack transform of the current distribution by substituting from Eq. (47) into Eq. (51), thus giving

$$a^{+}_{\ell,m}(t)=\frac{i^{\ell}c^{-2}}{\ell(\ell+1)}\frac{\partial}{\partial t}\int_{-\pi}^{\pi}d\beta\int_{0}^{\pi}d\alpha\ \sin\alpha[\mathbf{s}\times\hat{\mathscr{T}}^{+}(\mathbf{s},t)]\cdot\mathbf{Y}^{*}_{\ell,m}(\alpha,\beta),$$
$$b^{+}_{\ell,m}(t)=\frac{i^{\ell}c^{-2}}{\ell(\ell+1)}\frac{\partial}{\partial t}\int_{-\pi}^{\pi}d\beta\int_{0}^{\pi}d\alpha\ \sin\alpha\{\mathbf{s}\times[\mathbf{s}\times\hat{\mathscr{T}}^{+}(\mathbf{s},t)]\}\cdot\mathbf{Y}^{*}_{\ell,m}(\alpha,\beta). \tag{52}$$

Next we insert the series expansions Eq. (50) into the time-dependent plane wave expansions of the field vectors $\mathscr{E}(\mathbf{r},t)$ and $\mathscr{H}(\mathbf{r},t)$ [refer to Eq. (44)] and interchange orders of summation and integration, thus finding

$$\mathscr{E}^{+}(\mathbf{r},t)=-\frac{1}{2\pi c}\frac{\partial}{\partial t}\sum_{\ell=1}^{\infty}\sum_{m=-\ell}^{\ell}\int_{-\pi}^{\pi}d\beta\int_{C_{\pm}}d\alpha\ \sin\alpha(-i)^{\ell}[a^{+}_{\ell,m}(t-\mathbf{s}\cdot\mathbf{r}/c)\mathbf{s}\times\mathbf{Y}_{\ell,m}(\alpha,\beta)$$
$$+b^{+}_{\ell,m}(t-\mathbf{s}\cdot\mathbf{r}/c)\mathbf{Y}_{\ell,m}(\alpha,\beta)],$$
$$\mathscr{H}^{+}(\mathbf{r},t)=-\frac{1}{2\pi c}\frac{\partial}{\partial t}\sum_{\ell=1}^{\infty}\sum_{m=-\ell}^{\ell}\int_{-\pi}^{\pi}d\beta\int_{C_{\pm}}d\alpha\ \sin\alpha(-i)^{\ell}[-a^{+}_{\ell,m}(t-\mathbf{s}\cdot\mathbf{r}/c)\mathbf{Y}_{\ell,m}(\alpha,\beta)$$
$$+b^{+}_{\ell,m}(t-\mathbf{s}\cdot\mathbf{r}/c)\mathbf{s}\times\mathbf{Y}_{\ell,m}(\alpha,\beta)]. \tag{53}$$

Next we shall solve the integrals over $\mathbf{s}$ above so as to obtain the sought-after time-dependent multipole expansion of the electromagnetic field. For this purpose we will use the vector counterpart of Eqs. (19) and (20), given by[4]

$$\frac{(-i)^{\ell}}{2\pi}\int_{-\pi}^{\pi}d\beta\int_{C_{\pm}}d\alpha\ \sin\alpha\mathbf{Y}_{\ell,m}(\alpha,\beta)e^{i(\omega/c)\mathbf{s}\cdot\mathbf{r}}=h^{(1)}_{\ell}\left(\frac{\omega}{c}r\right)\mathbf{Y}_{\ell,m}(\theta,\phi). \tag{54}$$

Furthermore, by applying the curl operator $\nabla\times$ to both sides of (54) while using $\nabla e^{i(\omega/c)\mathbf{s}\cdot\mathbf{r}}=i(\omega/c)\mathbf{s}e^{i(\omega/c)\mathbf{s}\cdot\mathbf{r}}$ and $\nabla\times\mathbf{Y}_{\ell,m}(\alpha,\beta)=0$, one readily obtains[4]

$$\frac{(-i)^{\ell}}{2\pi}\int_{-\pi}^{\pi}d\beta\int_{C_{\pm}}d\alpha\ \sin\alpha\mathbf{s}\times\mathbf{Y}_{\ell,m}(\alpha,\beta)e^{i(\omega/c)\mathbf{s}\cdot\mathbf{r}}=\frac{-ic}{\omega}\nabla\times\left[h^{(1)}_{\ell}\left(\frac{\omega}{c}r\right)\mathbf{Y}_{\ell,m}(\theta,\phi)\right]. \tag{55}$$

The following results follow readily from Eqs. (54) and (55) and Eqs. (23) and (24):

$$\frac{(-i)^{\ell}}{2\pi}\int_{-\pi}^{\pi}d\beta\int_{C_{\pm}}d\alpha\ \sin\alpha a^{+}_{\ell,m}(t-\mathbf{s}\cdot\mathbf{r}/c)\mathbf{Y}_{\ell,m}(\alpha,\beta)$$
$$=\frac{1}{2\pi}\int_{0}^{\infty}d\omega e^{-i\omega t}\tilde{a}_{\ell,m}(\omega)h^{(1)}_{\ell}\left(\frac{\omega}{c}r\right)\mathbf{Y}_{\ell,m}(\theta,\phi)$$
$$=-(-i)^{\ell}\frac{c}{r}\mathbf{Y}_{\ell,m}(\theta,\phi)\partial_t^{-1}\mathscr{L}^{(r,t)}_{\ell}a^{+}_{\ell,m}(t) \tag{56}$$

and, similarly,

$$\frac{(-i)^{\ell}}{2\pi}\int_{-\pi}^{\pi}d\beta\int_{C_{\pm}}d\alpha\ \sin\alpha a^{+}_{\ell,m}(t-\mathbf{s}\cdot\mathbf{r}/c)\mathbf{s}\times\mathbf{Y}_{\ell,m}(\alpha,\beta)=\frac{1}{2\pi}\int_{0}^{\infty}d\omega e^{-i\omega t}\tilde{a}_{\ell,m}(\omega)\left\{\frac{-ic}{\omega}\right.$$
$$\left.\times\nabla\left[h^{(1)}_{\ell}\left(\frac{\omega}{c}r\right)\mathbf{Y}_{\ell,m}(\theta,\phi)\right]\right\}=(-i)^{\ell}\frac{c^2}{r}\partial_t^{-2}\nabla\times[\mathbf{Y}_{\ell,m}(\theta,\phi)\mathscr{L}^{(r,t)}_{\ell}a^{+}_{\ell,m}(t)]. \tag{57}$$

By substituting from Eqs. (56) and (57) into Eq. (53) we obtain

$$\mathscr{E}^{+}(\mathbf{r},t)=\sum_{\ell=1}^{\infty}\sum_{m=-\ell}^{\ell}\frac{1}{r}(-i)^{\ell}\{-c\partial_t^{-1}\nabla\times[\mathbf{Y}_{\ell,m}(\theta,\phi)\mathscr{L}_{\ell}^{(r,t)}a_{\ell,m}^{+}(t)]+\mathbf{Y}_{\ell,m}(\theta,\phi)\mathscr{L}_{\ell}^{(r,t)}b_{\ell,m}^{+}(t)\}$$
$$\mathscr{H}^{+}(\mathbf{r},t)=\sum_{\ell=1}^{\infty}\sum_{m=-\ell}^{\ell}\frac{1}{r}(-i)^{\ell}\{-\mathbf{Y}_{\ell,m}(\theta,\phi)\mathscr{L}_{\ell}^{(r,t)}a_{\ell,m}^{+}(t)-c\partial_t^{-1}\nabla[\mathbf{Y}_{\ell,m}(\theta,\phi)\mathscr{L}_{\ell}^{(r,t)}b_{\ell,m}^{+}(t)]\}. \tag{58}$$

Furthermore, we can now express the real electric and magnetic fields using the real vector spherical harmonics (refer to Appendix A for a review) following lines analogous to those used for scalar fields in Sec. II C. By analogy with our treatment of the scalar field we begin by introducing the new (real) multipole moments

$$c_{\ell,m}^{(j)}(t)=-\frac{1}{\ell(\ell+1)}\int_{-\pi}^{\pi}d\beta\int_{0}^{\pi}d\alpha\ \sin\alpha\mathbf{F}_H(\mathbf{s},t)\cdot\mathbf{S}_{\ell,m}^{(j)}(\alpha,\beta),$$
$$d_{\ell,m}^{(j)}(t)=\frac{1}{\ell(\ell+1)}\int_{-\pi}^{\pi}d\beta\int_{0}^{\pi}d\alpha\ \sin\alpha\mathbf{F}_E(\mathbf{s},t)\cdot\mathbf{S}_{\ell,m}^{(j)}(\alpha,\beta). \tag{59}$$

We can also express $c_{\ell,m}^{(j)}(t)$ and $d_{\ell,m}^{(j)}(t)$ in terms of the slant-stack transform of the current distribution by substituting from Eq. (47) into Eq. (59). This procedure yields

$$c_{\ell,m}^{(j)}(t)=\frac{c^{-2}}{\ell(\ell+1)}\frac{\partial}{\partial t}\int_{-\pi}^{\pi}d\beta\int_{0}^{\pi}d\alpha\ \sin\alpha[\mathbf{s}\times\hat{\mathscr{T}}(\mathbf{s},t)]\cdot\mathbf{S}_{\ell,m}^{(j)}(\alpha,\beta),$$
$$d_{\ell,m}^{(j)}(t)=\frac{c^{-2}}{\ell(\ell+1)}\frac{\partial}{\partial t}\int_{-\pi}^{\pi}d\beta\int_{0}^{\pi}d\alpha\ \sin\alpha\{\mathbf{s}\times[\mathbf{s}\times\hat{\mathscr{T}}(\mathbf{s},t)]\}\cdot\mathbf{S}_{\ell,m}^{(j)}(\alpha,\beta), \tag{60}$$

in analogy to its analytic signal counterpart Eq. (52). Both forms of time-dependent multipole moments defined above [i.e., Eqs. (59) and (60)] appear to be new.

By employing the vector counterpart of the procedure used to derive Eq. (33) from Eq. (25) (see Appendix B), we obtain from Eq. (58) the sought-after time-dependent multipole representation for the real, physical fields:

$$\mathscr{E}(\mathbf{r},t)=\sum_{\ell=1}^{\infty}\sum_{m=0}^{\ell}\sum_{j=1,2}c_m\frac{1}{r}\{-c\partial_t^{-1}\nabla\times[\mathbf{S}_{\ell,m}^{(j)}(\theta,\phi)\mathscr{L}_{\ell}^{(r,t)}c_{\ell,m}^{(j)}(t)]+\mathbf{S}_{\ell,m}^{(j)}(\theta,\phi)\mathscr{L}_{\ell}^{(r,t)}d_{\ell,m}^{(j)}(t)\},$$
$$\mathscr{H}(\mathbf{r},t)=\sum_{\ell=1}^{\infty}\sum_{m=0}^{\ell}\sum_{j=1,2}c_m\frac{1}{r}\{-\mathbf{S}_{\ell,m}^{(j)}(\theta,\phi)\mathscr{L}_{\ell}^{(r,t)}c_{\ell,m}^{(j)}-c\partial_t^{-1}\nabla\times[\mathbf{S}_{\ell,m}^{(j)}(\theta,\phi)\mathscr{L}_{\ell}^{(r,t)}d_{\ell,m}^{(j)}(t)]\}, \tag{61}$$

where, as before, $c_m=1$ or 2 if $m=0$ or $m\geqslant 1$, respectively. Equation (61) is, to the authors' knowledge, also new. Note also that Eq. (59) gives the real electric and magnetic multipole moments in terms of the far electric and magnetic fields while Eq. (60) gives them in terms of the transverse part of the slant-stack transform of the current distribution. Thus, Eq. (61) yields solutions to the radiation problem as well as to the inverse diffraction problem from time domain far field data. The theory above also corroborates, in the time domain, the well-known result that the radiation pattern uniquely determines the radiated field everywhere outside the source, as is evident from Eqs. (61) and (59).

In analogy to our treatment of the scalar field in Sec. II, we conclude this section with alternative expressions for the real time-dependent multipole moments $c_{\ell,m}^{(j)}(t)$ and $d_{\ell,m}^{(j)}(t)$. The corresponding derivation follows by analogy with the procedure used in Sec. II.

We conveniently rewrite $a_{\ell,m}^{+}(t)$ as defined in Eq. (52) as

$$a^{+}_{\ell,m}(t)=-\frac{i^{\ell}c^{-1}}{\ell(\ell+1)}\int_{r\leqslant a}d\mathbf{r}\int_{-\pi}^{\pi}d\beta\int_{0}^{\pi}d\alpha\ \sin\alpha[\nabla\times\mathscr{T}^{+}(\mathbf{r},t+\mathbf{s}\cdot\mathbf{r}/c)]\cdot\mathbf{Y}^{*}_{\ell,m}(\alpha,\beta). \quad (62)$$

The result above was obtained by using (see Appendix C)

$$\mathbf{s}\times\hat{\mathscr{T}}^{+}(\mathbf{s},t)=-c\,\partial_t^{-1}\int d\mathbf{r}\nabla\times\mathscr{T}^{+}(\mathbf{r},t+\mathbf{s}\cdot\mathbf{r}/c). \quad (63)$$

A convenient expression for $b^{+}_{\ell,m}(t)$ is obtained, on the other hand, by substituting from Eq. (46) into Eq. (52) and interchanging orders of **r** and **s** integration, thus giving

$$b^{+}_{\ell,m}(t)=-\frac{i^{\ell}c^{-2}}{\ell(\ell+1)}\frac{\partial}{\partial t}\int_{r\leqslant a}d\mathbf{r}\int_{-\pi}^{\pi}d\beta\int_{0}^{\pi}d\alpha\ \sin\alpha\,\mathscr{T}^{+}(\mathbf{r},t+\mathbf{s}\cdot\mathbf{r}/c)\cdot\mathbf{Y}_{\ell,m}(\alpha,\beta), \quad (64)$$

where we have made use of $\mathbf{s}\times\mathbf{s}\times\mathbf{S}^{(j)}_{\ell,m}(\alpha,\beta)=-\mathbf{S}^{(j)}_{\ell,m}(\alpha,\beta)$ and the well-known vector identity $\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c})=\mathbf{b}\cdot(\mathbf{c}\times\mathbf{a})=\mathbf{c}\cdot(\mathbf{a}\times\mathbf{b})$.

Next we make use of the vector counterpart of Eq. (22):[4]

$$\frac{(-i)^{\ell}}{4\pi}\int_{-\pi}^{\pi}d\beta\int_{0}^{\pi}d\alpha\ \sin\alpha\,\mathbf{Y}_{\ell,m}(\alpha,\beta)e^{i(\omega/c)\mathbf{s}\cdot\mathbf{r}}=j_{\ell}\left(\frac{\omega}{c}r\right)\mathbf{Y}_{\ell,m}(\theta,\phi). \quad (65)$$

By substituting from (65) into Eqs. (63) and (64) we obtain after some manipulations

$$a^{+}_{\ell,m}(t)=-\frac{i^{\ell}c^{-1}}{\ell(\ell+1)}\frac{4\pi c^{-\ell}}{\ell!2^{\ell+1}}\int_{-\pi}^{\pi}d\phi\int_{0}^{\pi}d\theta\ \sin\theta\mathbf{Y}^{*}_{\ell,m}(\theta,\phi)\cdot\left\{\int_{r\leqslant a}drr^{\ell}[\nabla\times\mathbf{I}^{+}(\mathbf{r},t)]\right\}, \quad (66)$$

$$b^{+}_{\ell,m}(t)=-\frac{i^{\ell}c^{-2}}{\ell(\ell+1)}\frac{4\pi c^{-\ell}}{\ell!2^{\ell+1}}\frac{\partial}{\partial t}\int_{-\pi}^{\pi}d\phi\int_{0}^{\pi}d\theta\ \sin\theta\mathbf{Y}^{*}_{\ell,m}(\theta,\phi)\cdot\left[\int_{r\leqslant a}drr^{\ell}\mathbf{I}^{+}(\mathbf{r},t)\right],$$

with

$$\mathbf{I}^{+}(\mathbf{r},t)=\int_{-1}^{1}d\eta(1-\eta^2)^{\ell}\frac{\partial^{\ell}}{\partial t^{\ell}}\mathscr{T}^{+}(\mathbf{r},t+r\eta/c). \quad (67)$$

Equation (66) has been derived before from the Debye representation;[6,7] here it has been obtained from the time-dependent plane wave representation.

Finally, the real time-dependent electric and magnetic multipole moments $c^{(j)}_{\ell,m}(t)$ and $d^{(j)}_{\ell,m}(t)$ are readily obtained from Eqs. (66) and (67) by recalling that $c^{+}_{\ell,m}(t)=(-i)^{\ell}a^{+}_{\ell,m}(t)$ and $d^{+}_{\ell,m}(t)=(-i)^{\ell}b^{+}_{\ell,m}(t)$. We obtain

$$c^{(j)}_{\ell,m}(t)=-\frac{c^{-1}}{\ell(\ell+1)}\frac{4\pi c^{-\ell}}{\ell!2^{\ell+1}}\int_{-\pi}^{\pi}d\phi\int_{0}^{\pi}d\theta\ \sin\theta\mathbf{S}^{(j)}_{\ell,m}(\theta,\phi)\cdot\left\{\int_{r\leqslant a}drr^{\ell}[\nabla\times\mathbf{I}(\mathbf{r},t)]\right\}, \quad (68)$$

$$d^{(j)}_{\ell,m}(t)=-\frac{c^{-2}}{\ell(\ell+1)}\frac{4\pi c^{-\ell}}{\ell!2^{\ell+1}}\frac{\partial}{\partial t}\int_{-\pi}^{\pi}d\phi\int_{0}^{\pi}d\theta\ \sin\theta\mathbf{S}^{(j)}_{\ell,m}(\theta,\phi)\cdot\left[\int_{r\leqslant a}drr^{\ell}\mathbf{I}(\mathbf{r},t)\right],$$

with

$$\mathbf{I}(\mathbf{r},t)=\int_{-1}^{1}d\eta(1-\eta^2)^{\ell}\frac{\partial^{\ell}}{\partial t^{\ell}}\mathscr{T}(\mathbf{r},t+r\eta/c). \quad (69)$$

Equations (68) and (69) are the electromagnetic case counterparts of Eqs. (41) and (42) and their interpretation is analogous to that of Eqs. (41) and (42).

APPENDIX A: ORDINARY AND VECTOR SPHERICAL HARMONICS

We use the standard definition of the spherical harmonics:[14]

$$Y_{\ell,m}(\theta,\phi)=y_{\ell,m}P_{\ell}^{m}(\cos\ \theta)e^{im\phi} \tag{A1}$$

with

$$y_{\ell,m}=\sqrt{\frac{(2\ell+1)(\ell-m)!}{4\pi(\ell+m)!}}, \tag{A2}$$

where $\ell=0,1,2,...$, $m=0,\pm1,...,\pm\ell$, and $P_{\ell}^{m}(x)$ are the associated Legendre polynomials, defined by means of the Rodrigues formula

$$P_{\ell}^{m}(x)=\frac{(-1)^m}{2^{\ell}\ell!}\,(1-x^2)^{m/2}\left(\frac{d}{dx}\right)^{\ell+m}(x^2-1)^{\ell}. \tag{A3}$$

The spherical harmonics obey the orthogonality and closure properties[14]

$$\int_{-\pi}^{\pi}d\phi\int_{0}^{\pi}d\theta\ \sin\ \theta Y_{\ell,m}^{*}(\theta,\phi)Y_{\ell',m'}(\theta,\phi)=\delta_{\ell,\ell'}\delta_{m,m'}, \tag{A4}$$

$$\sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell}Y_{\ell,m}(\theta,\phi)Y_{\ell,m}^{*}(\theta',\phi')=\frac{1}{\sin\ \theta}\,\delta(\theta-\theta')\,\delta(\phi-\phi')\equiv\delta(\hat{\mathbf{r}}-\hat{\mathbf{r}}'). \tag{A5}$$

The real spherical harmonics $S_{\ell,m}^{(1)}(\theta,\phi)\equiv\Re\{Y_{\ell,m}(\theta,\phi)\}$ and $S_{\ell,m}^{(2)}(\theta,\phi)\equiv\Im\{Y_{\ell,m}(\theta,\phi)\}$, where $\ell=0,1,2,...$, and $m=0.1,...,\ell$, obey, on the other hand, the orthogonality and closure properties of Eqs. (31) and (32).[3]

The vector spherical harmonic $\mathbf{Y}_{\ell,m}(\theta,\phi)$ is defined by[14,21]

$$\mathbf{Y}_{\ell,m}(\theta,\phi)=\mathbf{L}Y_{\ell,m}(\theta,\phi), \tag{A6}$$

where

$$\mathbf{L}=-i\mathbf{r}\times\nabla=-i\left(\mathbf{u}_{\phi}\frac{\partial}{\partial\theta}-\frac{1}{\sin\ \theta}\,\mathbf{u}_{\theta}\frac{\partial}{\partial\phi}\right). \tag{A7}$$

In Eq. (A7), $\mathbf{u}_{\theta}$ and $\mathbf{u}_{\phi}$ are, respectively, the unit vectors in the positive θ and ϕ directions. The $\mathbf{Y}_{\ell,m}(\theta,\phi)$'s are defined for $\ell=1,2,...$, and $m=0,\pm1,...,\pm\ell$. The value $\ell=0$ is excluded since $Y_{0,0}=1/\sqrt{4\pi}$, hence from Eqs. (A6) and (A7) $\mathbf{Y}_{0,0}=0$.

The vector spherical harmonics $\mathbf{Y}_{\ell,m}(\theta,\phi)$ are everywhere tangential to the unit sphere [such that $\hat{\mathbf{r}}\cdot\mathbf{Y}_{\ell,m}(\theta,\phi)=0$]. They satisfy the orthogonality condition[14,21]

$$\int_{-\pi}^{\pi}d\phi\int_{0}^{\pi}d\theta\ \sin\ \theta\mathbf{Y}_{\ell,m}^{*}(\theta,\phi)\cdot\mathbf{Y}_{\ell',m'}(\theta,\phi)=\ell(\ell+1)\,\delta_{\ell,\ell'}\delta_{m,m'}. \tag{A8}$$

They also form, together with the associated vector functions $\hat{\mathbf{r}}\times\mathbf{Y}_{\ell,m}(\theta,\phi)$, a complete orthogonal set in terms of which all well-behaved vector functions $\mathbf{F}(\hat{\mathbf{r}})$ with $\hat{\mathbf{r}}\cdot\mathbf{F}(\hat{\mathbf{r}})=0$ can be expanded.[14,21]

We define the real vector spherical harmonics $\mathbf{S}_{\ell,m}^{(j)}$ via

$$\mathbf{S}^{(1)}_{\ell,m}(\theta,\phi)=\mathcal{F}\{\mathbf{Y}_{\ell,m}(\theta,\phi)\}=-i\mathbf{L}S^{(1)}_{\ell,m},$$
$$\mathbf{S}^{(2)}_{\ell,m}(\theta,\phi)=\Re\{\mathbf{Y}_{\ell,m}(\theta,\phi)\}=i\mathbf{L}S^{(2)}_{\ell,m}, \tag{A9}$$

so that, from (31) and $L^2Y_{\ell,m}=\ell(\ell+1)Y_{\ell,m}$ (see Refs. 14 and 21),

$$\int_{-\pi}^{\pi}d\phi\int_{0}^{\pi}d\theta\,\sin\theta\mathbf{S}^{(j)}_{\ell,m}(\theta,\phi)\cdot\mathbf{S}^{(j')}_{\ell',m'}(\theta,\phi)=\ell(\ell+1)\delta_{\ell,\ell'}\delta_{m,m'}\delta_{j,j'}\frac{1}{c_m}. \tag{A10}$$

They also form, together with the vector functions $\hat{\mathbf{r}}\times\mathbf{S}^{(j)}_{\ell,m}(\theta,\phi)$ a complete orthogonal set in terms of which all well-behaved vector functions $\mathbf{F}(\hat{\mathbf{r}})$ with $\hat{\mathbf{r}}\cdot\mathbf{F}(\hat{\mathbf{r}})=0$ can be expanded.

APPENDIX B: DERIVATION OF EQ. (33)

A key step in deriving (33) will consist in showing that

$$2\Re\left\{\sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell}(-i)^{\ell}Y^{m}_{\ell}(\theta,\phi)\mathscr{L}^{(r,t)}_{\ell}a^{+}_{\ell,m}(t)\right\}=\sum_{\ell=0}^{\infty}\sum_{m=0}^{\ell}\sum_{j=1,2}c_mS^{(j)}_{\ell,m}(\theta,\phi)\mathscr{L}^{(r,t)}_{\ell}q^{(j)}_{\ell,m}(t) \tag{B1}$$

with $a^{+}_{\ell,m}(t)$ and $q^{(j)}_{\ell,m}(t)$ given by (26) and (34), respectively, and where $c_m=1$ or 2 for $m=0$ or $m\geqslant 1$, respectively. To simplify the manipulations we will use Dirac bra-ket notation.[21] Thus we represent the spherical and real spherical harmonics $Y_{\ell,m}$ and $S^{(j)}_{\ell,m}$, respectively, by the vectors (kets) $|\ell,m\rangle$ and $|\ell,m,j\rangle$, where[21]

$$Y_{\ell,m}(\theta,\phi)\equiv\langle\mathbf{r}|\ell,m\rangle, \tag{B2}$$

$$S^{(j)}_{\ell,m}(\theta,\phi)\equiv\langle\mathbf{r}|\ell,m,j\rangle. \tag{B3}$$

In Dirac bra-ket notation, the orthogonality and closure properties defined in Eqs. (A4) and (A5) and Eqs. (31) and (32) translate into

$$\langle\ell,m|\ell',m'\rangle=\delta_{\ell,\ell'}\delta_{m,m'}, \tag{B4}$$

$$\sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell}|\ell,m\rangle\langle\ell,m|=I, \tag{B5}$$

$$\langle\ell,m,j|\ell',m',j'\rangle=\frac{1}{c_m}\delta_{\ell,\ell'}\delta_{m,m'}\delta_{j,j'}, \tag{B6}$$

$$\sum_{\ell=0}^{\infty}\sum_{m=0}^{\ell}\sum_{j=1,2}c_m|\ell,m,j\rangle\langle\ell,m,j|=I, \tag{B7}$$

where I is the identity operator. We introduce, conveniently, the new analytic multipole moments

$$q^{+}_{\ell,m}(t)\equiv(-i)^{\ell}a^{+}_{\ell,m}(t), \tag{B8}$$

which are the ordinary spherical harmonic counterpart of $q^{(j)}_{\ell,m}(t)$. By substituting from (B8) into (25) and (26) while using Dirac bra-ket notation we obtain

$$U(\mathbf{r},t)=\frac{1}{r}2\Re\left\{\sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell}\langle\mathbf{r}|\ell,m\rangle\mathscr{L}^{(r,t)}_{\ell}\langle\ell,m|F^{+}(t)\rangle\right\}. \tag{B9}$$

By inserting the identity operator right after the term $\langle\ell,m|$ in Eq. (B9) while making use of Eqs. (B5) and (B7) and interchanging orders of summation one readily finds

$$U(\mathbf{r},t)=\frac{1}{r}\sum_{\ell'=0}^{\infty}\sum_{m'=0}^{\ell'}\sum_{j'=1,2}c_{m'}\langle\mathbf{r}|\ell',m',j'\rangle\mathscr{L}_{\ell'}^{(r,t)}\langle\ell',m',j'|F(t)\rangle. \tag{B10}$$

Finally, we complete our derivation of Eq. (33) by substituting expression (B3) and $q_{\ell',m'}^{(j')}(t)=\langle\ell',m',j'|F(t)\rangle$ [this follows from Eq. (34)] in Eq. (B10).

APPENDIX C: DERIVATION OF EQS. (47)

Consider a four-dimensional (4D) space-time with Cartesian coordinates ($x_0=ct$, $x_1=x$, $x_2=y$, $x_3=z$) and denote the coordinate vector in space-time as $\mathbf{x}$. The Radon transform $R\mathbf{f}(\mathbf{v},\xi)$ of a rather arbitrary vector function $\mathbf{f}(\mathbf{x})$ is defined as

$$R\mathbf{f}(\mathbf{v},\xi)=\int d\mathbf{x}\mathbf{f}(\mathbf{x})\,\delta(\xi-\mathbf{v}\cdot\mathbf{x}), \tag{C1}$$

where $\mathbf{v}$ is a unit vector in 4D Radon domain and ξ is a scalar. We will use the property [see Ref. 22, Eq. (6.7)]

$$R(\mathscr{H}\mathbf{f})=\mathscr{H}\left(v_1\frac{\partial}{\partial\xi},\ldots,v_n\frac{\partial}{\partial\xi}\right)R\mathbf{f}, \tag{C2}$$

where x_k is the kth Cartesian component of $\mathbf{x}$, v_k is the kth Cartesian component of the unit vector $\mathbf{v}$ and $\mathscr{H}(\partial/\partial x_1,\ldots,\partial/\partial x_n)$ is a linear operator with constant coefficients.

By putting $\mathbf{f}^+(\mathbf{x})\equiv\mathscr{T}^+(\mathbf{r},t=x_0/c)$, Eq. (46) and the various definitions above yield

$$\hat{\mathscr{T}}^+(\mathbf{s},t)=\frac{1}{\sqrt{2}}R\mathbf{f}^+(\mathbf{v}_\mathbf{s},ct/\sqrt{2}), \tag{C3}$$

where $\mathbf{v}_\mathbf{s}=(1/\sqrt{2})(1,-\mathbf{s})$ is the unit vector whose Cartesian components are ($x_0=(1/\sqrt{2})$, $x_1=-(1/\sqrt{2})$, $x_2=-(1/\sqrt{2})$, $x_3=-(1/\sqrt{2})$).

By substituting into Eq. (45) from Eqs. (C1)–(C3) we obtain

$$\mathbf{F}_E^+(\mathbf{s},t)=\frac{1}{\sqrt{2}}R\left\{\left[-\frac{1}{c^2}\frac{\partial}{\partial t}+\partial_t^{-1}\nabla\nabla\cdot\right]\mathbf{f}^+\right\}(\mathbf{v}_\mathbf{s},ct/\sqrt{2}) \tag{C4}$$

and

$$\mathbf{F}_H^+(\mathbf{s},t)=\frac{1}{c\sqrt{2}}R\{\nabla\times\mathbf{f}^+\}(\mathbf{v}_\mathbf{s},ct/\sqrt{2}). \tag{C5}$$

Using Eqs. (C2) and (C3) one can easily show that

$$\begin{aligned}R\{\nabla\nabla\cdot\mathbf{f}\}(\mathbf{v}_\mathbf{s},ct/\sqrt{2})&=\frac{1}{c^2}\frac{\partial^2}{\partial t^2}[\mathbf{ss}\cdot R\mathbf{f}(\mathbf{v}_\mathbf{s},ct/\sqrt{2})],\\ R\{\nabla\times\mathbf{f}\}(\mathbf{v}_\mathbf{s},ct/\sqrt{2})&=-\frac{1}{c}\frac{\partial}{\partial t}[\mathbf{s}\times R\mathbf{f}(\mathbf{v}_\mathbf{s},ct/\sqrt{2})].\end{aligned} \tag{C6}$$

The final step consists of applying the results (C6)–(C3) to Eqs. (C4)–(C5) and substituting into the result thus obtained from Eq. (C3).

(Received 23 December 1997; accepted for publication 26 March 1998)

The duality transformation described by Arnol'd, which relates the orbits for different central potentials through a change of variables, is shown to be an example of a generalized canonical transformation, in an extended phase space that includes time as a dynamical variable. © *1998 American Institute of Physics.* [S0022-2488(98)00307-7]

I. INTRODUCTION

Classical mechanics is an old subject, but new discoveries are still being made about the mathematical structure of the theory. Arnol'd has described a remarkable and beautiful class of duality transformations[1–3] in classical mechanics, that relate the orbits of two different central potentials, which he calls dual potentials. In the most striking example, the elliptical orbits of an isotropic Hooke's law potential $[V_2(r)=1/2kr^2]$ transform into the Keplerian elliptical orbits of an inverse-square force $[V_{-1}(r)=-\gamma/r]$. The interesting fact that these two, most basic examples in mechanics—the harmonic oscillator and the inverse-square force—are connected by a change of variables, deserves to be more widely known.[4]

The purpose of this paper is to show that Arnol'd's transformation may be expressed as a new kind of canonical transformation. The duality transformation is no ordinary canonical transformation in phase space, but rather a generalized canonical transformation in an extended phase space that includes time as one of the generalized coordinates. Thus, this duality transformation, in addition to providing an interesting insight into the Kepler problem, also serves as a novel example of a canonical transformation.

In Secs. II and V, Arnol'd's transformation is described. In Sec. III we define the generalized canonical transformation. In Sec. IV we show that Arnol'd's transformation is an example of a generalized canonical transformation.

II. ARNOL'D'S DUALITY TRANSFORMATION

We begin by considering motion of a mass m in a two-dimensional orbit plane with Cartesian coordinates ξ and η, under the influence of a central potential $V_{\mathrm{H}}(\rho)$, where $\rho=\sqrt{\xi^2+\eta^2}$ is the radial coordinate. The time coordinate for the $\xi\eta$ orbit is denoted by τ. To define the duality transformation it is useful to combine ξ and η in a complex variable ζ, as $\zeta=\xi+i\eta$.

The duality transformation is a transformation of space and time variables $(\xi,\eta,\tau)\rightarrow(x,y,t)$ that transforms orbits of $V_{\mathrm{H}}(\rho)$ into dual orbits in the space–time with coordinates (x,y,t); the dual orbits correspond to some other central force. Let $z=x+iy$. The transformation equations are[1]

$$z=\zeta^{\alpha}, \tag{1}$$

$$\frac{dt}{d\tau}=|\zeta|^{2(\alpha-1)}, \tag{2}$$

where α is a free parameter. We may choose α as appropriate to make the transformation interesting. For example, the transformation appropriate for the duality of Hooke and Kepler elliptical orbits has $\alpha=2$.

 © 1998 American Institute of Physics

The reason for the transformation of time (2) is that then the law of equal areas holds in the dual (xy) space. The equal-area law holds in the $\xi\eta$ plane, because $V_{\rm H}(\rho)$ is central: $|\zeta|^2 d\phi/dt$ is constant, where $\phi=\arg\zeta$ is the angular coordinate and $|\zeta|\equiv\rho$ is the radial coordinate, in the $\xi\eta$ plane. For (1)–(2) the equal-area law also holds in the xy plane; i.e., $|z|^2 dF/dt$ is constant where $F=\arg z=\alpha\phi$ is the angular coordinate in the xy plane, because

$$|z|^2\,\frac{dF}{dt}=\alpha|\zeta|^2\,\frac{d\phi}{d\tau}.$$

Before constructing the generalized canonical transformation, it is useful to see how the equation of motion changes under the transformation (1)–(2). First, the equation of motion in the $\xi\eta$ plane is

$$\frac{d^2\zeta}{d\tau^2}=-\frac{1}{m}\left(\frac{\zeta}{\rho}\right)\frac{dV_{\rm H}}{d\rho},$$

and the energy of the $\xi\eta$ orbit is

$$E_{\rm H}=\frac{m}{2}\left|\frac{d\zeta}{d\tau}\right|^2+V_{\rm H}(\rho).$$

The equation of motion of the dual orbit that results from transforming the $\xi\eta$ orbit by the change of variables (1)–(2) is

$$\frac{d^2z}{dt^2}=-\frac{\alpha^2}{m}\left(\frac{z}{r}\right)\frac{d}{dr}\left[V_{\rm K}(r)-\frac{E_{\rm H}}{r^{2(\alpha-1)/\alpha}}\right];\tag{3}$$

in this equation $r\equiv|z|$ is the radial coordinate in the xy plane, and $V_{\rm K}(r)$ is the function

$$V_{\rm K}(r)=\frac{V_{\rm H}(r^{1/\alpha})}{r^{2(\alpha-1)/\alpha}}.\tag{4}$$

A general proof that $z(t)$ satisfies (3) is a straightforward exercise in calculus with complex numbers.[1–3] As a specific example, suppose $V_{\rm H}(\rho)$ is an isotropic Hooke's law potential, $V_{\rm H}(\rho)=1/2k\rho^2$, and let $\alpha=2$ in the transformation; then $V_{\rm K}(r)$ is a constant $(k/2)$, and the equation of motion for the dual orbit is

$$\frac{d^2z}{dt^2}=-\frac{4E_{\rm H}}{m}\frac{z}{r^3},$$

which is the equation for a Keplerian orbit. We shall derive (3) from the generalized canonical transformation in Sec. IV.

The duality transformation described so far is a transformation between *orbits*: We have only considered the transformation in space, not in phase space. In Sec. IV we shall construct the transformation between *systems*, and show that it is a generalized canonical transformation.

III. THE GENERALIZED CANONICAL TRANSFORMATION

Canonical transformations—transformations in phase space (q,p)—are a standard, but advanced, topic in classical mechanics.[5,6] It will be useful to review briefly the canonical transformation in general terms.

The canonical equations of motion are

$$\dot q=\frac{\partial H}{\partial p}\quad\text{and}\quad\dot p=-\frac{\partial H}{\partial q},\tag{5}$$

where H is the Hamiltonian. The variables q and p have n components. An overdot ($\dot{}$) denotes the derivative with respect to time τ, the independent evolution variable. These equations of motion may be derived from a variational principle in phase space: $\delta I=0$, where I is the integral

$$I=\int_{\tau_1}^{\tau_2}(p\dot{q}-H(q,p))d\tau.$$

The variation δ is over trajectories in phase space with given, fixed end points. A transformation in phase space $(q,p,H)\rightarrow(Q,P,K)$ is canonical if

$$pdq-Hd\tau=PdQ-Kd\tau+dF, \tag{6}$$

where dF is an arbitrary complete differential, and K is the transformed Hamiltonian. If (6) holds, then the variational principle $\delta I=0$ in the transformed representation gives the canonical equations of motion with Hamiltonian $K(Q,P)$,

$$\dot{Q}=\frac{\partial K}{\partial P} \quad \text{and} \quad \dot{P}=-\frac{\partial K}{\partial Q}. \tag{7}$$

The contribution to I from the complete differential, $\int dF=F(\tau_2)-F(\tau_1)$, has variation 0 because the end points are fixed. To be even more flexible, we could also allow the right side of (6) to be multiplied by a constant, but that would only be a scale transformation.

The Arnol'd transformation (1)–(2) is not an ordinary canonical transformation, because (2) is a position-dependent transformation of time. But we shall see that the Arnol'd transformation is a generalized canonical transformation is an extended phase space that includes time as a coordinate.

To define the *generalized* canonical transformations, we extend the $2n$-dimensional phase space $(q;p)$ to $2n+2$ dimensions $(q,\tau;p,\mathscr{E})$ where the time τ is now treated as another coordinate and $\mathscr{E}$ is the momentum conjugate to τ; and we take the Hamiltonian for this extended system to be $\tilde{H}$, given by

$$\tilde{H}(q,\tau;p,\mathscr{E})=H(q;p)+\mathscr{E}. \tag{8}$$

Then the canonical equations, with an evolution parameter s that parametrizes the position on the trajectory in the extended phase space, are

$$\frac{dq}{ds}=\frac{\partial\tilde{H}}{\partial p}=\frac{\partial H}{\partial p} \quad \text{and} \quad \frac{d\tau}{ds}=\frac{\partial\tilde{H}}{\partial\mathscr{E}}=1, \tag{9}$$

$$\frac{dp}{ds}=-\frac{\partial\tilde{H}}{\partial q}=-\frac{\partial H}{\partial q} \quad \text{and} \quad \frac{d\mathscr{E}}{ds}=\frac{\partial\tilde{H}}{\partial\tau}=0. \tag{10}$$

Thus, for (8) we have $\tau(s)=s$, and $\mathscr{E}$ is a constant because τ is an ignorable coordinate. Also, q and p satisfy the original equations of motion because $\tau=s$. The extension of the phase space has had no real effect on dynamics. But in this extended phase space we can make more general canonical transformations, including transformation of time, i.e., more general than an ordinary canonical transformation. The capability to make more general transformations may reveal new aspects of the theory, as in Arnol'd's duality relations.

A generalized canonical transformation is a canonical transformation in the extended phase space,

$$(q,\tau;p,\mathscr{E};\tilde{H})\rightarrow(Q,t;P,E;\tilde{K}),$$

such that the equations of motion in the new representation, *for the same evolution parameter* s, are the canonical equations with transformed Hamiltonian $\tilde{K}$. The condition for the transformation to be canonical is, analogous to (6), that

$$p\,dq+\mathscr{E}\,d\tau-\tilde{H}\,ds=P\,dQ+E\,dt-\tilde{K}\,ds. \tag{11}$$

[We could also add a complete differential to the right side of (11), but that is not necessary in this paper.] It is important to realize that the evolution parameter (s) must be the same for the $(q,\tau;p,\mathscr{E})$ and $(Q,t;P,E)$ systems, so that the same variational principle $\delta I=0$ applies to both systems.

In Sec. IV we apply this formalism, i.e., the condition (11), to the Arnol'd transformation.

IV. THE DUALITY TRANSFORMATION AS A GENERALIZED CANONICAL TRANSFORMATION

In Sec. I we defined a system with coordinates (ξ,η), or $\zeta=\xi+i\,\eta$, and time τ. The extended phase space for that system is the six-dimensional space with coordinates (ξ,η,τ) and conjugate momenta $(p_\xi,p_\eta,\mathscr{E})$. The Hamiltonian for this extended system is, by (8),

$$\tilde{H}=\frac{1}{2m}\,(p_\xi^2+p_\eta^2)+V_{\mathrm{H}}(\sqrt{\xi^2+\eta^2})+\mathscr{E}. \tag{12}$$

Again, we denote by s the independent evolution variable for trajectories in the six-dimensional (6D) phase space, and let an overdot $(\dot{})$ denote d/ds. The canonical equations are

$$(\dot{\xi},\dot{\eta},\dot{\tau})=\left(\frac{p_\xi}{m},\ \frac{p_\eta}{m},\ 1\right),$$

$$(\dot{p}_\xi,\dot{p}_\eta,\dot{\mathscr{E}})=\left(-\frac{\partial V_{\mathrm{H}}}{\partial\xi},-\frac{\partial V_{\mathrm{H}}}{\partial\eta},\ 0\right).$$

The projection of the trajectory to the $(\xi,\eta;p_\xi,p_\eta)$ subspace of the 6-D extended space is the trajectory of the original problem.

Now we apply the duality transformation (1)–(2) to this system. To construct a generalized canonical transformation we must supplement the rules (1)–(2) by transformation rules for the conjugate momenta. That is, we seek a generalized canonical transformation,

$$(\zeta,\tau;p_\zeta,\mathscr{E};\tilde{H})\rightarrow(z,t;P_z,E;\tilde{K}),$$

such that the coordinate part of the transformation is the Arnol'd duality transformation (1)–(2),

$$(z,t)=\left(\zeta^\alpha,\int|\zeta|^{2(\alpha-1)}d\tau\right), \tag{13}$$

where $z=x+iy$. The momentum $p_\zeta\equiv p_\xi+ip_\eta$ and the transformed momentum $P_z\equiv P_x+iP_y$ are required to be $p_\zeta=m\,d\zeta/d\tau$ and $P_z=M\,dz/dt$, where M is a parameter to be determined. M is the mass of the particle in the dual problem. The desired transformed momentum P_z conjugate to z is[3]

$$P_z=\frac{\alpha M}{m}\,\frac{z\zeta^*}{|z|^2}\,p_\zeta. \tag{14}$$

The transformed momentum E conjugate to t can be any function of $\mathscr{E}$, because both of these quantities turn out to be constants of the motion; we will leave E unspecified.

For this transformation to be canonical, the transformation rules must satisfy the condition (11). For (13) and (14) we have

$$P_x\,dx+P_y\,dy=\mathrm{Re}\ P_z^*\,dz=\frac{\alpha^2M}{m}\,(p_\xi\,d\xi+p_\eta\,d\eta).$$

At this point we choose to fix the value of M by

$$M=\frac{m}{\alpha^2}.$$

[We could instead leave M unspecified, and multiply the right side of (11) by the constant $m/(\alpha^2 M)$, a rescaling.] Then the condition (11) determines that the transformed Hamiltonian must be

$$\tilde{K}=\tilde{H}-\mathscr{E}\frac{d\tau}{ds}+E\frac{dt}{ds}.$$

We are free to set the evolution parameter s equal to τ, the time in the original problem, which is, after all, required by the equation of motion in the original 6-D phase space; then the transformed Hamiltonian becomes

$$\tilde{K}=\frac{1}{2m}(p_\xi^2+p_\eta^2)+V_{\mathrm{H}}(\sqrt{\xi^2+\eta^2})+E(\xi^2+\eta^2)^{(\alpha-1)}. \tag{15}$$

Finally, we rewrite $\tilde{K}$ in terms of the new coordinates and momenta, from the relations

$$\xi^2+\eta^2=(x^2+y^2)^{1/\alpha},$$

$$p_\xi^2+p_\eta^2=\alpha^2(P_x^2+P_y^2)(x^2+y^2)^{(\alpha-1)/\alpha}.$$

The result is that the transformed Hamiltonian is

$$\tilde{K}=\left(\frac{1}{2M}(P_x^2+P_y^2)+V_{\mathrm{K}}(\sqrt{x^2+y^2})+E\right)(x^2+y^2)^{(\alpha-1)/\alpha}, \tag{16}$$

where $V_{\mathrm{K}}(r)$ is determined from the original potential by Eq. (4).

Because the transformation is canonical in the 6-D phase space, the equations of motion in the (x,y,t) representation are canonical, with Hamiltonian $\tilde{K}$. The independent evolution parameter is τ (or s), and the equations of motion are

$$\frac{dx}{d\tau}=\frac{\partial\tilde{K}}{\partial P_x}=\frac{P_x}{M}r^{2(\alpha-1)/\alpha}, \tag{17}$$

$$\frac{dy}{d\tau}=\frac{\partial\tilde{K}}{\partial P_y}=\frac{P_y}{M}r^{2(\alpha-1)/\alpha}, \tag{18}$$

$$\frac{dt}{d\tau}=\frac{\partial\tilde{K}}{\partial E}=r^{2(\alpha-1)/\alpha}, \tag{19}$$

where $r=\sqrt{x^2+y^2}$; and similarly,

$$\frac{dP_x}{d\tau}=-\frac{\partial\tilde{K}}{\partial x}=-\frac{x}{r}\left(\frac{2(\alpha-1)\tilde{K}}{\alpha r^{3-2/\alpha}}+\frac{dV_{\mathrm{K}}}{dr}\right)r^{2(\alpha-1)/\alpha}, \tag{20}$$

$$\frac{dP_y}{d\tau}=-\frac{\partial\tilde{K}}{\partial y}=-\frac{y}{r}\left(\frac{2(\alpha-1)\tilde{K}}{\alpha r^{3-2/\alpha}}+\frac{dV_{\mathrm{K}}}{dr}\right)r^{2(\alpha-1)/\alpha}, \tag{21}$$

$$\frac{dE}{d\tau}=-\frac{\partial\tilde{K}}{\partial t}=0. \tag{22}$$

It should be emphasized that τ is not the time coordinate of the transformed system. The time coordinate is t and τ (or s) is the independent variable that parametrizes the position on the trajectory in the 6-D phase space $(x,y,t;P_x,P_y,E)$. The equations of motion for $(x,y;P_x,P_y)$ as functions of the time t of the transformed system are

$$\frac{dx}{dt}=\frac{dx/d\tau}{dt/d\tau}=\frac{P_x}{M}, \tag{23}$$

$$\frac{dy}{dt}=\frac{dy/d\tau}{dt/d\tau}=\frac{P_y}{M}; \tag{24}$$

and similarly,

$$\frac{dP_x}{dt}=-\frac{x}{r}\left(\frac{2(\alpha-1)\tilde{K}}{\alpha r^{3-2/\alpha}}+\frac{dV_{\mathrm{K}}}{dr}\right), \tag{25}$$

$$\frac{dP_y}{dt}=-\frac{y}{r}\left(\frac{2(\alpha-1)\tilde{K}}{\alpha r^{3-2/\alpha}}+\frac{dV_{\mathrm{K}}}{dr}\right). \tag{26}$$

These t-dependent equations are equivalent to (3). It is possible to derive the equation of motion (3) directly, without the formalism of the generalized canonical transformation; but then the full structure of the transformation is not revealed.

The canonical equations (17)–(22) have an unfamiliar form, because x and y appear in the velocities, and P_x and P_y appear in the forces. But the equations of motion (23)–(26) do reduce to a familiar form. First, $\tilde{K}$ is a constant of motion, as may be proven directly, or, more simply, from the fact that $\tilde{K}$ is the Hamiltonian for a system with translation invariance in the evolution parameter (τ). Therefore, for any particular trajectory we may write

$$\tilde{K}=\gamma,$$

where γ is a constant. Then the equations (23)–(26) are isomorphic to the motion of mass M in the central potential,

$$V_{\mathrm{eff}}(r;\gamma)=\frac{-\gamma}{r^{2(\alpha-1)/\alpha}}+V_{\mathrm{K}}(r).$$

Equations (23)–(26) and (16) are not simply the equations for motion in a fixed potential. Any particular trajectory is the same as motion in a potential, but the potential depends on the trajectory. For example, different initial values $(x_0,y_0,P_{0x},P_{0y},E_0)$ will have different values of γ.

The constant of the motion E, which is the momentum conjugate to the time t, may be determined from (16). For a trajectory with $\tilde{K}=\gamma$ we have

$$-E=\frac{1}{2M}(P_x^2+P_y^2)-\frac{\gamma}{r^{2(\alpha-1)/\alpha}}+V_{\mathrm{K}}(r);$$

that is, $-E$ equals the total energy of the effective potential problem in the xy plane.

Finally, we return to the duality of orbits: What is the transform of an orbit of the original (ξ,η,τ) system? We may answer this question from the generalized canonical transformation. Let E_{H} be the energy (value of H) of the $\xi\eta$ orbit. Then by (15) the value of $\tilde{K}$ is $E_{\mathrm{H}}+E(\xi^2+\eta^2)^{(\alpha-1)}$. Because $\tilde{K}$ is a constant of the motion, the value of E is 0. Thus the dual orbit is a trajectory of $V_{\mathrm{eff}}(r;\gamma)$ with $\gamma=E_{\mathrm{H}}$, and total energy $-E=0$.

Solutions of the (x,y,t) *system with* $E\neq 0$. The transform of any orbit of the original (ξ,η,τ) dynamical system is an orbit of the (x,y,t) dynamical system, and that (x,y,t) orbit has $E=0$. But the (x,y,t) system (17)–(22) also has orbits with $E\neq 0$. A trajectory with $E\neq 0$ is not the transform of any solution of the original (ξ,η,τ) system. So, what is the connection between the (x,y,t) trajectories with $E\neq 0$, and the original (ξ,η,τ) system?

The answer to this question emerges from the observation that t is not a local function of (ξ,η,τ). The relation (2) that defines t is a differential relation, so $t=\int(\xi^2+\eta^2)^{\alpha-1}d\tau$ is a *path-dependent* function of the (ξ,η,τ) variables. Thus the transformation $(\xi,\eta,\tau)\rightarrow(x,y,t)$ is a one-to-one correspondence between *paths* in (ξ,η,τ) and (x,y,t), rather than a one-to-one correspondence between *points* in these spaces.

The variational principle $\delta I=0$ is different for the (ξ,η,τ) and (x,y,t) systems. The integrand of the action integral I is the same in both cases, by (11). But the conditions at the end points are different. For the (ξ,η,τ) system, I is stationary with respect to variations (δ) that leave the end points fixed in (ξ,η,τ); then $\delta I=0$ implies the canonical equations with Hamiltonian $\tilde{H}$. For the (x,y,t) system, I is stationary with respect to variations (δ') that leave the end points fixed in (x,y,t), and we denote this variation by δ'; then $\delta' I=0$ implies the canonical equations (17)–(22) with Hamiltonian $\tilde{K}$. The variation δ' also leaves the end points fixed in (ξ,η,τ): The end points of (ξ,η) are fixed because the transformation $(\xi,\eta)\rightarrow(x,y)$ is just a point transformation (1), and the end points of τ are fixed because $\tau=s$ and the integral I is over a fixed interval of s.

The variations δ and δ' are different, because t is a path-dependent function of (ξ,η,τ). The set of paths with fixed end points in (ξ,η,τ) do not all have fixed end points in (x,y,t), because the end points of t depend on the path in (ξ,η,τ).

The orbits of $\tilde{H}$ satisfy $\delta I=0$, and therefore also $\delta' I=0$: The meaning of $\delta I=0$ is that I is stationary for any variation that leaves the end points of the path fixed in (ξ,η,τ); then, *a fortiori*, I is stationary for variations that leave the end points fixed in both (ξ,η,τ) and (x,y,t), i.e., $\delta' I=0$. Thus any orbit of $\tilde{H}$ transforms to an orbit of $\tilde{K}$. But the converse is not true, because $\delta' I=0$ does not imply $\delta I=0$; so there exist orbits of $\tilde{K}$ that are not the transforms of orbits of $\tilde{H}$.

The dynamical solutions of the (x,y,t) system that have $E=0$, have corresponding trajectories in (ξ,η,τ) for which $\tilde{H}$ is a constant of the motion, by (15). These are the orbits of $\tilde{K}$ that are transforms of orbits of $\tilde{H}$.

A dynamical solution of the (x,y,t) system that has $E\neq 0$, has a corresponding trajectory in (ξ,η,τ) for which $\tilde{H}$ is not a constant of the motion; thus, the trajectory in (ξ,η,τ) is not a solution of the original problem. The equations of motion satisfied by this (ξ,η,τ) trajectory derive not from $\delta I=0$, but rather from $\delta' I=0$. That is, I is stationary with respect to constrained variations, subject to the constraint that the end points t_1 and t_2 are fixed.

We may implement this constrained variation by the method of the undetermined Lagrange multiplier. The constrained variational principle $\delta' I=0$ is equivalent to the unconstrained variational principle,

$$\delta\left[I-\lambda\int_{s_1}^{s_2}(\xi^2+\eta^2)^{\alpha-1}\left(\frac{d\tau}{ds}\right)ds+\lambda(t_2-t_1)\right]=0, \tag{27}$$

where λ is the Lagrange multiplier; λ would be determined by the given value of t_2-t_1. It can be shown that the trajectory in (ξ,η,τ), that corresponds to an (x,y,t) trajectory for which the momentum conjugate to t has the value E, is a solution of the constrained equations with Lagrange multiplier $\lambda=E$. That is, E is the Lagrange multiplier for the constrained equations in the (ξ,η,τ) space. For the case $\lambda=0$, the constrained variational principle (27) is equivalent to $\delta I=0$, which is the original problem whose solutions are orbits of $\tilde{H}$.

The final conclusion is thus that the transform of an orbit of $\tilde{H}$, i.e., of an orbit that obeys $\delta I=0$, is an orbit of $\tilde{K}$ with $E=0$; and the transform of a trajectory that obeys (27), the variational principle for constrained variations, is an orbit of $\tilde{K}$ with $E=\lambda$.

V. DUAL POWER-LAW POTENTIALS

We have seen that the duality transformation (1)–(2) transforms an orbit of $V_{\rm H}(\rho)$ in the $\xi\eta$ plane into a dual orbit of the potential $V_{\rm eff}(r;\gamma)$ in the xy plane. If the energy of the $\xi\eta$ orbit is $E_{\rm H}$, then the parameter in $V_{\rm eff}(r;\gamma)$ is $\gamma=E_{\rm H}$. As a class of examples of this transformation, we now consider power-law potentials.

The result to be proven is that if $V_{\rm H}(\rho)$ is a power-law potential,

$$V_{\rm H}(\rho)=\tfrac{1}{2}k\rho^{\nu},$$

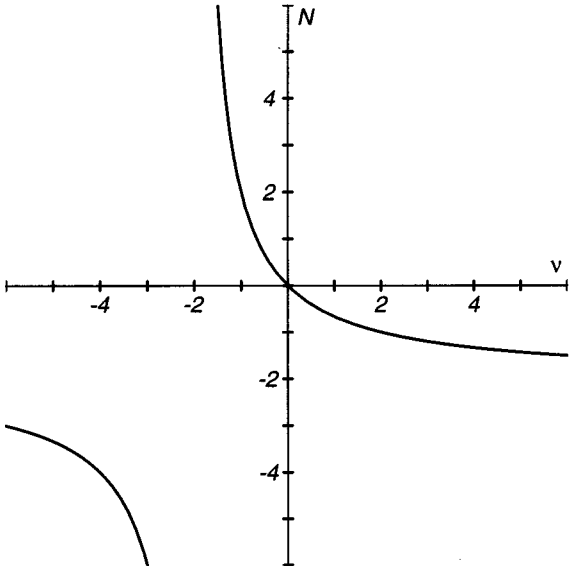

FIG. 1. The exponents ν and N of the dual power-law potentials.

then there exists a value of α such that the dual potential $V_{\text{eff}}(r;\gamma)$ is also a power law, for any orbit energy E_{H}. We construct this dual power-law potential by making $V_{\text{K}}(r)$ a constant. By (4),

$$V_{\text{K}}(r)=\frac{k}{2}\,r^{(\nu+2-2\alpha)/\alpha},$$

so the appropriate choice of α is

$$\alpha=\frac{\nu+2}{2};$$

with this choice the dual potential is

$$V_{\text{eff}}(r;\gamma)=-\gamma r^{N}+\frac{k}{2},$$

where

$$N=\frac{-2\nu}{\nu+2}.$$

In a more symmetric form, the relation between the dual exponents is

$$(\nu+2)(N+2)=4.$$

The constant term $k/2$ in $V_{\text{eff}}(r;\gamma)$ does not affect the dynamics in the dual problem, although it does contribute to the total energy $-E$. Thus, the dual orbit is an orbit for the power-law potential $-\gamma r^{N}$. For example, the dual potential of the isotropic Hooke's law potential ($\nu=2$) is the potential of an inverse-square force ($N=-1$); and *vice versa*. As another example, if $\nu=-4$ then $N=-4$; the potential $\propto\rho^{-4}$ is self-dual. Figure 1 shows the relation between the dual powers N and ν.

For the special case $\nu=2$ and $N=-1$ it is interesting to consider a specific orbit.[3] A particular elliptical orbit of $V_2(\rho)=\frac{1}{2}k\rho^2$ may be written as

$$(\xi(\tau),\eta(\tau))=(A\,\cos\,\omega\tau,B\,\sin\,\omega\tau),$$

where $\omega=\sqrt{k/m}$. This Hooke orbit is an ellipse centered at the origin. The dual orbit is[3] in parametric form with independent parameter τ,

$$x(\tau)=a(\cos 2\omega\tau-e) \tag{28}$$

$$y(\tau)=a\sqrt{1-e^2}\,\sin 2\omega\tau, \tag{29}$$

$$t(\tau)=\frac{T}{2\pi}\,(2\omega\tau-e\,\sin 2\omega\tau). \tag{30}$$

This Kepler orbit is an ellipse with a focal point at the origin, with semimajor axis $a=(B^2-A^2)/2$ and eccentricity $e=(B^2-A^2)/(B^2+A^2)$. The period of revolution is T, given by $T=\sqrt{4\pi^2a^3M/\gamma}$, where the strength of the Newtonian potential is $\gamma=1/2k(A^2+B^2)$.

Equations (28)–(30) are a standard parametrization of a Keplerian orbit. The variable $2\omega\tau$, which parametrizes the position and time on the orbit, is called the *eccentric anomaly* in celestial mechanics.[5,7] A nice aspect of the Arnol'd transformation is that it gives a new meaning to the eccentric anomaly: The eccentric anomaly is twice the phase angle of the dual Hooke ellipse.

Arnol'd's duality transformation reveals this interesting connection between two basic examples in mechanics—the harmonic oscillator and the inverse-square force. The duality is extended to other power laws by Fig. 1. The duality is even more generally between $V_{\rm H}(\rho)$ and $V_{\rm eff}(r;\gamma)$. The transformation is an example of a generalized canonical transformation, in an extended space that includes both space and time variables. We are left with the question of whether there are other interesting applications of this generalized kind of canonical transformation.

Lattice approximation of quantum statistical traces at a complex temperature

J. Lukkarinen[a)]
Helsinki Institute of Physics, P.O. Box 9, 00014 University of Helsinki, Finland

(Received 23 October 1997; accepted for publication 26 March 1998)

We show that the addition of an imaginary part to the temperature in the Gibbs ensemble will not destroy the convergence of the standard lattice approximation scheme for quantum mechanical systems with Hamiltonians of the type $\hat{H} = \hat{p}^2/2m + V(\hat{x})$, provided the potential function V is real and bounded from below and it satisfies the condition $\int d^n\mathbf{x}\, \exp(-tV(\mathbf{x})) < \infty$ for all $t > 0$. As a by-product we obtain an explicit bound for the real-temperature lattice kernels and a simple condition for the convergence of the real-temperature lattice expectation values of observables given by polynomially bounded functions. © *1998 American Institute of Physics.* [S0022-2488(98)00407-1]

I. INTRODUCTION

Ever since the introduction of the path-integrals by Feynman, the path-integral formulas with a complex ''temperature'' have presented an elusive mathematical problem—for instance, the Wiener measure, which is so useful for positive temperature statistics, cannot be extended to the complex case.[1] In fact, since real time processes and real temperature statistics can be identified with each other via analytic continuation, the present numerical nonperturbative methods in quantum field theories rely mostly on computations with lattice approximations to the *imaginary time*, i.e., real temperature, path-space measures.

There have already been proposals for numerical evaluation of the complex path-integrals,[2,3] but only now can we establish rigorously the assumed relations between the complex lattice integrals and the continuum traces. Also, the result of Theorem III.5 has been used[4] as an assumption in the derivation of a lattice approximation to the quantum microcanonical ensemble and the theorem now yields a wide range of potentials for which this approximation is valid.

For an introduction to the mathematics of operators on a Hilbert space, see, e.g., the second part of the comprehensive series[5] by Reed and Simon. The path-space measures and their applications are discussed in detail in another book[6] by Simon and the proofs of the statements made in the following section can be found from Sec. 6 of that book.

II. NOTATIONS AND DEFINITIONS

We will now consider quantum mechanics on the separable Hilbert space $L^2(\mathbb{R}^n)$; in the following, n will always denote the number of dimensions of the parameter space and we will use boldface letters for vectors in $\mathbb{R}^n$. In the same spirit, the n-dimensional Lebesque measure with respect to variable $\mathbf{x}$ is denoted by $d^n\mathbf{x}$. Operators will be distinguished by a ''hat''—especially the multiplication operator defined by a measurable function F will be denoted by $\hat{F}$.

The free Hamiltonian is defined in the standard way,

$$\hat{H}_0 := \frac{\hat{p}^2}{2m} = -\frac{\hbar^2}{2m}\nabla^2,$$

with the usual domain for this operator. To simplify the following discussion we will from now on

a)Electronic mail: jani.lukkarinen@helsinki.fi

use the natural units $\hbar=1$ and, in addition, consider only the case $m=1$. The results for the situation $m\neq 1$ are easily reproduced from the following formulas by simply replacing t by t/m and the potential V by mV.

It is well-known that $\hat{H}_0$ generates an analytic semigroup on the right half-plane, where $e^{-\beta\hat{H}_0}$ are bounded integral operators for Re $\beta>0$ and they are given by the integral kernels

$$P(\mathbf{a},\mathbf{b};\beta):=\frac{1}{(2\pi\beta)^{n/2}}\exp\left(-\frac{1}{2\beta}|\mathbf{a}-\mathbf{b}|^2\right).$$

It is also evident that these integral kernels satisfy the semigroup property exactly, i.e., that for all $\mathbf{a}$, $\mathbf{b}\in\mathbb{R}^n$ and Re β_1, Re $\beta_2>0$,

$$\int d^n\mathbf{c}P(\mathbf{a},\mathbf{c};\beta_1)P(\mathbf{c},\mathbf{b};\beta_2)=P(\mathbf{a},\mathbf{b};\beta_1+\beta_2).$$

The potential V is assumed to be locally in $L^1(\mathbb{R}^n)$ and positive, but the results easily generalize for all real L^1_{loc} potentials bounded from below [just replace V by $V+\operatorname{ess\,sup}(-V)$]. The Hamiltonian $\hat{H}=\hat{H}_0+\hat{V}$ can now be defined as a sum of quadratic forms, when it is self-adjoint and bounded from below and, therefore, $e^{-\beta\hat{H}}$ (as well as $e^{-\beta\hat{V}}$) is an analytic semigroup on the right half-plane. In addition, we shall also require that

$$\int d^n\mathbf{a}e^{-tV(\mathbf{a})}<\infty,\quad \text{for all}\quad t>0, \tag{1}$$

so that $e^{-t\hat{H}}$ is trace-class for $t>0$ by the Golden, Thompson, Symanzik-inequality.[7]

Under these assumptions $e^{-t\hat{H}}$ is an integral operator for $t>0$ and it has an integral kernel K_∞, which can be obtained with aid of the conditional Wiener measure μ: for all $\mathbf{a}$, $\mathbf{b}\in\mathbb{R}^n$ and for all $t>0$ define

$$K_\infty(\mathbf{a},\mathbf{b};t)=\int d\mu_{\mathbf{a},\mathbf{b};t}(\boldsymbol{\omega})e^{-\int_0^t ds V(\boldsymbol{\omega}(s))}.$$

In addition to (1) we shall now require the potential V to be such that the Wiener integrals can be almost everywhere obtained from the lattice kernels

$$K_N(\mathbf{a},\mathbf{b};t):=\int\prod_{k=1}^{N-1}d^n\mathbf{x}_k\left(\frac{N}{2\pi t}\right)^{Nn/2}\exp\left[-\frac{N}{2t}\sum_{k=1}^{N}|\mathbf{x}_{k-1}-\mathbf{x}_k|^2-\frac{t}{N}\sum_{k=1}^{N}V(\mathbf{x}_k)\right]_{\mathbf{x}_N=\mathbf{b}}^{\mathbf{x}_0=\mathbf{a}},$$

i.e., that

$$K_\infty(\mathbf{a},\mathbf{b};t)=\lim_{N\to\infty}K_N(\mathbf{a},\mathbf{b};t),\quad \text{for all}\quad t>0\quad \text{and for almost all}\quad \mathbf{a},\mathbf{b}\in\mathbb{R}^n. \tag{2}$$

This requirement is clearly satisfied for *all* $\mathbf{a}$ and $\mathbf{b}$ if V is continuous, since then $\int ds V(\boldsymbol{\omega}(s))$ can be approximated by suitable Riemann sums leading to (2) by using the definition of the Wiener measure.

We shall also need the operator

$$\hat{T}(\beta):=e^{-\beta\hat{H}_0}e^{-\beta\hat{V}},$$

which is clearly a bounded integral operator for Re $\beta>0$, since then $\|\hat{T}(\beta)\|\leqslant\|e^{-\beta\hat{H}_0}\|\|e^{-\beta\hat{V}}\|\leqslant 1$. Notice that $K_N(\cdot,\cdot;\beta)$ is nothing but the integral kernel of the operator $\hat{T}(\beta/N)^N$.

III. TWO LATTICE THEOREMS

In this section we will prove two theorems concerning the convergence of traces of lattice operators. The first theorem will show that also certain unbounded multiplication operators are

measurable using the (real-temperature) Gibbs statistics if the potential increases sufficiently fast at infinity. This will be proven by using the explicit bounds given by the following lemma and its two corollaries. The rather technical proofs of the lemma and the corollaries are included in Sec. IV—the lemma itself is an extension of a result derived by Symanzik[8] for the continuum kernels.

Lemma III.1: For all $\mathbf{a}$, $\mathbf{b}$ *in* $\mathbb{R}^n$, *for all* $t>0$ *and for all positive integers* N,

$$K_N(\mathbf{a},\mathbf{b};t)\leqslant C_n t^{(n-1)/2}\int d^n\mathbf{c}P(\mathbf{a},\mathbf{c};t)e^{-tV(\mathbf{c})}P(\mathbf{c},\mathbf{b};t)\left(\frac{1}{|\mathbf{a}-\mathbf{c}|^{n-1}}+\frac{1}{|\mathbf{c}-\mathbf{b}|^{n-1}}\right)+\frac{1}{N}e^{-tV(\mathbf{b})}P(\mathbf{a},\mathbf{b};t), \tag{3}$$

where C_n *depends only on the dimension* n.

Taking the limit $N\to\infty$ in the previous lemma shows that *(3) is valid for almost all* $\mathbf{a}$, $\mathbf{b}$ *and for all* $t>0$ *also when* $N=\infty$.

Corollary III.2: Assume that in addition to (1) the potential satisfies

$$\int d^n\mathbf{a}|\mathbf{a}|^r e^{-tV(\mathbf{a})}<\infty,$$

for some $r\geqslant 0$ *and for all* $t>0$. *Then there exists functions* F_r *and* G_r, *continuous on* $(0,\infty)$, *such that for all* $t>0$ *and for all* $N<\infty$,

$$\int d^n\mathbf{a}|\mathbf{a}|^r K_N(\mathbf{a},\mathbf{a};t)\leqslant F_r(t)$$

and for all N, *including* ∞,

$$\int d^n\mathbf{a}d^n\mathbf{b}|\mathbf{a}|^r K_N(\mathbf{a},\mathbf{b};t)\leqslant G_r(t).$$

If the above assumption on the potential is true for 0 and r then it is clearly true for all values s in $(0,r)$ by the inequality $|\mathbf{a}|^s\leqslant 1+|\mathbf{a}|^r$. If the potential has no singularity in a neighborhood of the origin, it is enough to find one $r\geqslant 0$ for the statement to be true for all s with $0\leqslant s\leqslant r$.

Corollary III.3: For all N, *including* ∞, *and for all* $t>0$, $\operatorname{ess\,sup}_{\mathbf{a},\mathbf{b}\in\mathbb{R}^n}K_N(\mathbf{a},\mathbf{b};t)\leqslant C_n' t^{-n/2}$.

The convergence properties of the lattice traces are easily derived from these results; we only have to be careful that the limit of the traces of the integral kernels does give the trace of the continuum integral operator. This leads to the appearance of the factor of 2 in Eq. (4), which will be discussed more after the proof of the theorem.

Theorem III.4: Let A *be a measurable function bounded by a degree* $r\geqslant 0$ *polynomial and assume that the potential additionally satisfies*

$$\int d^n\mathbf{a}|\mathbf{a}|^{2r}e^{-tV(\mathbf{a})}<\infty,\ \text{for all}\ t>0.$$

Then for all $t>0$ *and* $N\geqslant 2$ *the operators* $\hat{A}e^{-t\hat{H}}$ *and* $\hat{A}\hat{T}(t/N)^N$ *are both Hilbert-Schmidt and trace-class and*

$$\operatorname{Tr}(\hat{A}e^{-t\hat{H}})=\lim_{k\to\infty}\operatorname{Tr}\left(\hat{A}\hat{T}\left(\frac{t}{2k}\right)^{2k}\right), \tag{4}$$

$$\operatorname{Tr}(\hat{A}\hat{T}(t/N)^N)=\int d^n\mathbf{a}\,A(\mathbf{a})K_N(\mathbf{a},\mathbf{a};t). \tag{5}$$

Proof: The requirement for A is equivalent to finding a $C\geqslant 0$ such that $|A(\mathbf{a})|\leqslant C(1+|\mathbf{a}|^r)$ for all $\mathbf{a}$. It follows now from Corollaries III.2 and III.3 that for $1\leqslant N\leqslant\infty$,

$$\int d^n\mathbf{a}d^n\mathbf{b}|A(\mathbf{a})K_N(\mathbf{a},\mathbf{b};t)|^2<\infty.$$

The operators $\hat{A}e^{-t\hat{H}}$ and $\hat{A}\hat{T}(t/N)^N$ are given by the integral kernels $A(\mathbf{a})K_N(\mathbf{a},\mathbf{b};t)$ and, therefore, they are Hilbert-Schmidt.

Since $\hat{A}e^{-t\hat{H}}$ is a product of the two Hilbert-Schmidt operators $\hat{A}e^{-(t/2)\hat{H}}$ and $e^{-(t/2)\hat{H}}$, it is trace-class. Moreover, the trace can be expressed in terms of the integral kernels of these Hilbert-Schmidt operators:

$$\mathrm{Tr}(\hat{A}e^{-t\hat{H}})=\int d^n\mathbf{a}d^n\mathbf{b}A(\mathbf{a})K_\infty\left(\mathbf{a},\mathbf{b};\frac{t}{2}\right)K_\infty\left(\mathbf{b},\mathbf{a};\frac{t}{2}\right).$$

Using Lemma III.1 and Corollary III.3 to give an upper bound for the Lebesque dominated convergence theorem shows now that

$$\begin{aligned}\int d^n\mathbf{a}d^n\mathbf{b}A(\mathbf{a})K_\infty\left(\mathbf{a},\mathbf{b};\frac{t}{2}\right)K_\infty\left(\mathbf{b},\mathbf{a};\frac{t}{2}\right)&=\lim_{N\to\infty}\int d^n\mathbf{a}d^n\mathbf{b}A(\mathbf{a})K_N\left(\mathbf{a},\mathbf{b};\frac{t}{2}\right)K_N\left(\mathbf{b},\mathbf{a};\frac{t}{2}\right)\\&=\lim_{N\to\infty}\int d^n\mathbf{a}\,A(\mathbf{a})K_{2N}(\mathbf{a},\mathbf{a};t),\end{aligned}$$

where the second equality follows from Fubini's theorem and a careful inspection of the definition of K_{2N}. Therefore,

$$\mathrm{Tr}(\hat{A}e^{-t\hat{H}})=\lim_{N\to\infty}\int d^n\mathbf{a}\,A(\mathbf{a})K_{2N}(\mathbf{a},\mathbf{a};t). \tag{6}$$

It has already been proven that both $\hat{A}\hat{T}(t)$ and $\hat{T}(t)^{N-1}$ are Hilbert-Schmidt for all $t>0$ and thus $\hat{A}\hat{T}(t/N)^N$ is trace-class and its trace can be expressed in terms of the kernels of these operators. It is then a matter of inspection to conclude

$$\mathrm{Tr}(\hat{A}\hat{T}(t/N)^N)=\int d^n\mathbf{a}\,A(\mathbf{a})K_N(\mathbf{a},\mathbf{a};t) \tag{7}$$

and the theorem follows from Eqs. (6) and (7). □

If $\lim_N K_N(\mathbf{a},\mathbf{a};t)$ exists for almost all $\mathbf{a}$, then an application of the dominated convergence theorem in (6) shows that $\mathrm{Tr}(\hat{A}e^{-t\hat{H}})=\lim_N\int d^n\mathbf{a}A(\mathbf{a})K_N(\mathbf{a},\mathbf{a};t)$. Therefore, also odd lattice sizes can be included in the limit, for instance, if V is continuous (then K_∞ is continuous and thus finite on the diagonal).

In the second theorem we will work with temperatures having an imaginary part. The following proof relies on a simple property of the Hilbert-Schmidt operators given as Lemma IV.1 in Sec. IV. To make the theorem easier to use, we will now state all the assumptions made on the potential explicitly.

Theorem III.5: Assume that A is an essentially bounded measurable function and $V\in L^1_{\mathrm{loc}}$ is a potential bounded from below for which (2) holds and

$$\int d^n\mathbf{a}e^{-tV(\mathbf{a})}<\infty,\quad\text{for all}\quad t>0.$$

Then for all complex β with $\mathrm{Re}\,\beta>0$, $\hat{A}e^{-\beta\hat{H}}$ *is trace-class and*

$$\mathrm{Tr}(\hat{A}e^{-\beta\hat{H}})=\lim_{N\to\infty}\int d^n\mathbf{a}\,A(\mathbf{a})K_{2N}(\mathbf{a},\mathbf{a};\beta).$$

Proof: Let $f_N(\beta)=\int d^n\mathbf{a}\, A(\mathbf{a})K_{2N}(\mathbf{a},\mathbf{a};\beta)$ and $g(\beta)=\mathrm{Tr}(\hat{A}e^{-\beta\hat{H}})$. Both are then well-defined on the right half-plane: f_N is an $2N$-fold integral over an absolutely integrable function and, by the Schwarz inequality, self-adjointness of $\hat{H}$ and Theorem III.4,

$$|g(\beta)|^2\leqslant \mathrm{Tr}(|\hat{A}|^2e^{-\mathrm{Re}\,\beta\hat{H}})\mathrm{Tr}(e^{-\mathrm{Re}\,\beta\hat{H}})<\infty.$$

In addition, g and all f_N are analytic on the right half-plane, as can be seen, e.g., by a standard application of Morera's theorem—note that

$$g(\beta)=\sum_n \langle\psi_n|\hat{A}\psi_n\rangle e^{-\beta E_n},$$

where $\{E_n\}$ are the eigenvalues of $\hat{H}$ and $\{\psi_n\}$ is a corresponding orthonormal basis.

Since Theorem III.4 states that $\lim_{N\to\infty} f_N(\beta)=g(\beta)$ for positive β, the theorem will follow from the Vitali convergence theorem[9] if we can only prove that the sequence (f_N) is uniformly bounded on every compact subset of the half-plane.

An argument similar to one in the proof of Theorem III.4 shows that $f_N(\beta)=\mathrm{Tr}(\hat{A}\hat{T}(\beta/2N)^{2N})$. Therefore, Lemma IV.1 establishes the bound $|f_N(\beta)|\leqslant\|\hat{A}\|\mathrm{Tr}(\hat{T}^*\hat{T})^N$, where $\hat{T}=\hat{T}(\beta/2N)$. However, as $\hat{T}^*\hat{T}=e^{-(\beta^*/2N)\hat{V}}e^{-(\mathrm{Re}\,\beta/N)\hat{H}_0}e^{-(\beta/2N)\hat{V}}$,

$$\mathrm{Tr}(\hat{T}^*\hat{T})^N=\mathrm{Tr}(\hat{T}(\mathrm{Re}\ \beta/N)^N)\leqslant F_0(\mathrm{Re}\ \beta)<\infty$$

by Corollary III.2 and Theorem III.4 If S is a compact set in the right half-plane, it follows that $F_0(\mathrm{Re}\,S)$ is bounded since F_0 was continuous. This proves that (f_N) is uniformly bounded on every compact subset of the right half-plane and hence completes the proof. □

If V is continuous, then the limit can be taken by using all values of N: Define $h_N(\beta)=\int d^n\mathbf{a}\, A(\mathbf{a})K_N(\mathbf{a},\mathbf{a};\beta)$. By the remark after Theorem III.4, $\lim_N h_N=g$ on the positive real axis. Also,

$$|h_{2N+1}(\beta)|=\left|\mathrm{Tr}\left(\hat{A}\hat{T}\left(\frac{\beta}{2N+1}\right)^{2N+1}\right)\right|\leqslant\|\hat{A}\|\|\hat{T}\|\mathrm{Tr}(\hat{T}^*\hat{T})^N\leqslant\|\hat{A}\|F_0\left(\mathrm{Re}\ \beta\frac{2N}{2N+1}\right),$$

and thus the sequence (h_N) is uniformly bounded on the right half-plane.

IV. PROOFS OF THE LEMMAS

Proof of Lemma III.1: By the relation between geometric and arithmetic means, $\exp(-(t/N)\sum_{k=1}^N V(\mathbf{x}_k))\leqslant(1/N)\sum_{k=1}^N\exp(-tV(\mathbf{x}_k))$. Using this and the semigroup property of the integral kernels P, we arrive at the inequality

$$K_N(\mathbf{a},\mathbf{b};t)\leqslant\frac{1}{N}e^{-tV(\mathbf{b})}P(\mathbf{a},\mathbf{b};t)+\int d^n\mathbf{c}e^{-tV(\mathbf{c})}\frac{1}{N}\sum_{k=1}^{N-1}P\left(\mathbf{a},\mathbf{c};k\frac{t}{N}\right)P\left(\mathbf{c},\mathbf{b};(N-k)\frac{t}{N}\right).$$

The terms in the last sum are explicitly

$$\begin{aligned}&\left(\frac{1}{2\pi t}\frac{N}{\sqrt{k(N-k)}}\right)^n\exp\left[-\frac{1}{2t}\left(\frac{N}{k}|\mathbf{a}-\mathbf{c}|^2+\frac{N}{N-k}|\mathbf{c}-\mathbf{b}|^2\right)\right]\\&\quad=P(\mathbf{a},\mathbf{c};t)P(\mathbf{c},\mathbf{b};t)\frac{N}{\sqrt{k(N-k)}}\left(\frac{N-k}{k}\right)^{(n-1)/2}\exp\left[-\frac{N-k}{k}\frac{|\mathbf{a}-\mathbf{c}|^2}{2t}\right]\\&\qquad\times\left(\frac{N}{N-k}\right)^{n-1}\exp\left[-\frac{k}{N-k}\frac{|\mathbf{c}-\mathbf{b}|^2}{2t}\right]\end{aligned}\tag{8}$$

$$= P(\mathbf{a},\mathbf{c};t)P(\mathbf{c},\mathbf{b};t)\frac{N}{\sqrt{k(N-k)}}\left(\frac{k}{N-k}\right)^{(n-1)/2}\exp\left[-\frac{k}{N-k}\frac{|\mathbf{c}-\mathbf{b}|^2}{2t}\right]$$
$$\times\left(\frac{N}{k}\right)^{n-1}\exp\left[-\frac{N-k}{k}\frac{|\mathbf{a}-\mathbf{c}|^2}{2t}\right]. \tag{9}$$

Assume now that $n>1$ and consider first the case $1\leqslant k\leqslant N/2$. Since, $t^s e^{-tr}\leqslant(s/re)^s$ for all positive r, s and t, the expression (8) has an upper bound

$$P(\mathbf{a},\mathbf{c};t)P(\mathbf{c},\mathbf{b};t)\frac{N}{\sqrt{k(N-k)}}2^{n-1}\left(\frac{(n-1)t}{e|\mathbf{a}-\mathbf{c}|^2}\right)^{(n-1)/2}.$$

On the other hand, if $N/2\leqslant k\leqslant N-1$, then the same reasoning can be applied to (9) leading to the same bound apart from the change of $|\mathbf{a}-\mathbf{c}|$ to $|\mathbf{c}-\mathbf{b}|$. Since in both cases these upper bounds are positive, the terms under inspection are for all $1\leqslant k\leqslant N-1$ bounded by

$$P(\mathbf{a},\mathbf{c};t)P(\mathbf{c},\mathbf{b};t)\left(\frac{4(n-1)}{e}\right)^{(n-1)/2}t^{(n-1)/2}\left(\frac{1}{|\mathbf{a}-\mathbf{c}|^{n-1}}+\frac{1}{|\mathbf{c}-\mathbf{b}|^{n-1}}\right)\frac{N}{\sqrt{k(N-k)}}.$$

Now $(1/N)\sum_{k=1}^{N-1}[k/N(1-(k/N))]^{-1/2}$ is a lower Riemann sum for the integral $\int_0^1 ds\,[1/\sqrt{s(1-s)}]=\pi$ and, therefore for all N,

$$\frac{1}{N}\sum_{k=1}^{N-1}\frac{N}{\sqrt{k(N-k)}}\leqslant\pi \tag{10}$$

and the Lemma follows if we choose $C_n=\pi 2^{n-1}(n-1)^{(n-1)/2}e^{-(n-1)/2}$.

The case $n=1$ is even simpler to prove, as then both of the exponentials in (8) can be majorized by one and the Lemma, with the choice $C_1=\pi$, follows from (10). □

Proofs of Corollaries III.2 and III.3: Define the following two functions on $(0,\infty)$

$$I_s(t)\coloneqq\int d^n\mathbf{a}|\mathbf{a}|^s e^{-tV(\mathbf{a})},\quad J_s(t)\coloneqq\int d^n\mathbf{a}|\mathbf{a}|^s P(\mathbf{0},\mathbf{a};t),$$

where s is a real parameter. J_s is finite for $s>-n$ and, in fact, it is then continuous, since a change of variables and relying on n-dimensional spherical coordinates shows that

$$J_s(t)=(2t)^{s/2}\frac{\Gamma((n+s)/2)}{\Gamma(n/2)}. \tag{11}$$

Under the assumptions of the theorem, also I_0 and I_r are everywhere finite. They are then also continuous, since for every converging sequence (t_k) in $(0,\infty)$ dominated convergence can be used to prove $\lim_{k\to\infty}I_s(t_k)=I_s(\lim t_k)$.

The rest is just a matter of bookkeeping when integrating both sides of the inequality (3). Using Jensen's inequality for $r\geqslant 1$ and the obvious relation $(1+|\mathbf{a}|)^r-|\mathbf{a}|^r\leqslant 1$ for $0\leqslant r<1$ it is easy to prove that for $r\geqslant 0$ and $\mathbf{a}$, $\mathbf{b}\in\mathbb{R}^n$

$$|\mathbf{a}|^r\leqslant 2^r(|\mathbf{a}-\mathbf{b}|^r+|\mathbf{b}|^r).$$

Applying this result, Eq. (11) and a little algebra shows that

$$\int d^n\mathbf{a}|\mathbf{a}|^r K_N(\mathbf{a},\mathbf{a};t)\leqslant C^{(1)}t^{-n/2}I_r(t)+C^{(2)}t^{(r-n)/2}I_0(t),$$

$$\int d^n\mathbf{a}d^n\mathbf{b}|\mathbf{a}|^r K_N(\mathbf{a},\mathbf{b};t)\leqslant C^{(3)}I_r(t)+C^{(4)}t^{r/2}I_0(t),$$

where the constants $C^{(k)}$ depend only on n and r. The functions on the right hand sides are continuous and can therefore be chosen as F_r and G_r.

Since $e^{-tV(\mathbf{c})}P(\mathbf{c},\mathbf{b};t)\leqslant(2\pi t)^{-n/2}$, Corollary III.3 is an immediate consequence of (11) and Lemma III.1. □

Lemma IV.1: If $\hat{A}$ is bounded, $\hat{T}$ is Hilbert-Schmidt and $N\geqslant 1$, then

$$|\mathrm{Tr}(\hat{A}\hat{T}^{2N})|\leqslant\|\hat{A}\|\mathrm{Tr}(\hat{T}^*\hat{T})^N.$$

Proof: By the Schwarz inequality,

$$|\mathrm{Tr}(\hat{A}\hat{T}^{2N})|^2\leqslant\mathrm{Tr}[(\hat{A}\hat{T}^N)^*(\hat{A}\hat{T}^N)]\mathrm{Tr}[(\hat{T}^N)^*\hat{T}^N]$$

and since $\mathrm{Tr}[(\hat{A}\hat{T}^N)^*(\hat{A}\hat{T}^N)]=\mathrm{Tr}[|\hat{A}|^2\hat{T}^N(\hat{T}^N)^*]\leqslant\|\hat{A}\|^2\mathrm{Tr}[(\hat{T}^N)^*\hat{T}^N]$, we get

$$|\mathrm{Tr}(\hat{A}\hat{T}^{2N})|\leqslant\|\hat{A}\|\mathrm{Tr}[(\hat{T}^N)^*\hat{T}^N].$$

Using a method similar to the so called min-max principle, Fan has shown[10] that for any finite-dimensional operator (i.e., matrix) $\hat{B}$, $\mathrm{Tr}[(\hat{B}^N)^*\hat{B}^N]\leqslant\mathrm{Tr}(\hat{B}^*\hat{B})^N$. The finite-dimensional operators are dense in $\mathscr{T}_2=$the Hilbert space of Hilbert–Schmidt operators with the inner product $(\cdot,\cdot)_{\mathrm{HS}}$. Since the product, the inner product and the norm are continuous on $\mathscr{T}_2$ and $\mathrm{Tr}[(\hat{B}^N)^*\hat{B}^N]=\|\hat{B}^N\|_{\mathrm{HS}}^2$, $\mathrm{Tr}(\hat{B}^*\hat{B})^N=(\hat{B}^*\hat{B},(\hat{B}^*\hat{B})^{N-1})_{\mathrm{HS}}$, it is obvious that the result of Fan is valid for every Hilbert−Schmidt operator. □

V. DISCUSSION

The main results of this paper are the two theorems, III.4 and III.5. The first one justifies the faith of the lattice community that also expectation values of polynomials are measurable with the lattice Monte Carlo methods if the potential increases sufficiently fast at infinity. The second one establishes the possibility of using the lattice integrals for computations of the expectation values even when the temperature has an imaginary part.

There are a few shortcomings of the present results. First, the exact class of potentials for which the integral kernels K_N can be used was not determined. This is not a serious problem since, by accepting the necessity for a double limit, statistics given by any potential in L^1_{loc} can be approached with the lattice integrals by replacing V by a sequence $V_k\in C^\infty$ which converges to it pointwise almost everywhere. The second shortcoming is the class of observables in Theorem III.5: the present proof cannot be easily extended to include also polynomial observables for polynomial potentials, although it is very natural to expect the integrals to converge to the right limit by Theorem III.4. Finally, the necessity of using only an even number of lattice points has no natural explanation and as such it is expected to be an artifact of the present approach. Indeed, as has been noted earlier, the requirement of even lattice sizes can be dropped for continuous potentials.

Generalized plasma dispersion functions

D. J. Percival[a] and P. A. Robinson[b]
School of Physics, The University of Sydney, New South Wales 2006, Australia

(Received 29 August 1997; accepted for publication 12 December 1997)

Generalized plasma dispersion functions have recently arisen in the derivation of an exact expression for the quadratic response tensor for a plasma with constituent species having Maxwellian velocity distributions. A range of mathematical properties satisfied by the generalized plasma dispersion functions are derived here, including recursion relations, series expansions, and approximate analytic forms, including Padé approximants. These properties are of central importance to the application of the exact quadratic response tensor to descriptions of second-order processes in weak and strong turbulence theory, such as three-wave interactions in warm plasmas. © *1998 American Institute of Physics.* [S0022-2488(98)02807-2]

I. INTRODUCTION

The plasma dispersion function[1] is widely used in descriptions of linear wave processes in collisionless warm plasmas, where constituent species satisfy a Maxwellian velocity distribution. The plasma dispersion function $Z(u)$ is usually defined for complex u by the integral expression

$$Z(u)=\frac{1}{\sqrt{\pi}}\int_{-\infty}^{\infty}\frac{dt\ e^{-t^2}}{t-u}, \tag{1}$$

for $\mathrm{Im}(u)=0$ and by the analytic continuation of (1) for $\mathrm{Im}(u)<0$. $Z(u)$ is closely related to the error function erf, with

$$Z(u)=i\sqrt{\pi}e^{-u^2}[1+\mathrm{erf}(iu)], \tag{2}$$

for all complex u. The linear response tensor, describing the linear plasma response to an electromagnetic disturbance, can be expressed in terms of $Z(u)$. The properties of the plasma dispersion function have been widely studied in the literature,[1–3] and are often applied in analytic treatments of wave processes in both space and laboratory plasmas (e.g., Refs. 4, 5 and the references cited therein).

Recently, an exact expression for the quadratic response tensor for a collisionless Maxwellian plasma was derived.[6] The quadratic response tensor describes all second-order wave processes (i.e., interactions between triads of waves, including coalescence and decay), and its exact representation permits a complete analytic description of processes previously only treated with relatively simple approximations.[7–10] An important point is that the validity of widely used approximate forms can now be assessed by comparison with the exact expression.

An important second-order wave process is the coalescence of two waves to give a third (product) wave; the reverse interaction describes a three-wave decay process. If two waves with frequencies ω_1, ω_2 and wave vectors $\mathbf{k}_1$, $\mathbf{k}_2$ coalesce, then the product wave has a frequency ω and wave vector $\mathbf{k}$ which satisfies the wave matching conditions

$$\omega_1+\omega_2=\omega, \quad \mathbf{k}_1+\mathbf{k}_2=\mathbf{k}, \tag{3}$$

imposed by the conservation of wave energy and momentum, respectively. The strength of wave coupling is described by the quadratic response tensor, which is a function of the frequencies and wave vectors of the interacting waves.

A key step in deriving the exact quadratic response tensor for a Maxwellian plasma was the introduction of the *generalized* plasma dispersion function $Y_{m,n}$, $m,n \geqslant 0$, defined by[6]

$$Y_{m,n}(a,b,c) = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} dx\ e^{-x^2} \frac{x^m}{(x-c)^n} Z(a+bx), \quad m,n \geqslant 0, \tag{4}$$

for complex arguments a, b, c. This function is a generalization of the familiar plasma dispersion function $Z(u)$ of Ref. 1, in the sense that it also involves resonant integrals over velocity distributions; moreover, the lowest-order function $Y_{0,0}(a,b,c) = Y_{0,0}(a,b)$ reduces to $Z(a)$ in the limit $b \to 0$. The exact quadratic response tensor is given by a linear combination of $Z(u)$ and generalized plasma dispersion functions $Y_{m,n}$ of orders $0 \leqslant m,n \leqslant 3$. The derivation of mathematical properties satisfied by the $Y_{m,n}$ is the subject of this paper; these properties are of central importance in the application of the exact quadratic response tensor to particular physical processes.

In the treatment of a three-wave process satisfying (3) using the exact quadratic response tensor, the arguments a, b, and c of the generalized plasma dispersion functions $Y_{m,n}(a,b,c)$ have physical meanings. In particular, the magnitudes of the parameters a and c are determined by the ratio of the wave phase speed to plasma thermal speed for a coalescing wave and a product wave, respectively, while $b = -\cot\theta$ where θ is the angle between the coalescing wave vectors $\mathbf{k}_1$ and $\mathbf{k}_2$. Approximate forms of the $Y_{m,n}(a,b,c)$ suitable for application to particular interacting waves and geometries can be derived from the exact quadratic response tensor.

In this paper we derive a range of properties of the generalized plasma dispersion functions, as well as discussing approximations and the stability of numerical evaluations. Useful recursive properties of the generalized plasma dispersion functions are derived in Sec. II, and some partial differential equations satisfied by the $Y_{m,n}$ are written down. In Sec. III, the $Y_{m,n}$ are evaluated as the sum of terms involving Hermite polynomials and derivatives of the plasma dispersion function $Z(u)$. The real and imaginary parts of the generalized plasma dispersion functions for real arguments are identified; the latter are useful in discussions of plasma instabilities, for example. Some new results involving the nth derivative of the plasma dispersion function $Z^{(n)}$ are derived in Sec. IV. The results of a numerical investigation of the $Y_{0,n}$ for $n \leqslant 3$ and real arguments are also presented. In Sec. V, several useful analytical approximations, including Padé approximants for the lower-order $Y_{m,n}(a,b,c)$ are developed.

II. SYMMETRIES AND DERIVATIVE IDENTITIES

In this section, we derive recursive properties of the $Y_{m,n}$, as well as some differential equations which they obey. The generalized plasma dispersion functions (4) satisfy several symmetry properties and derivative identities, analogous with those satisfied by the plasma dispersion function of Ref. 1. To begin, since

$$\frac{x^m}{(x-c)^n} = \frac{x^{m-1}}{(x-c)^{n-1}} + \frac{cx^{m-1}}{(x-c)^n}, \quad m,n \geqslant 1, \tag{5}$$

it follows from the definition (4) that the recursion relation

$$Y_{m,n}(a,b,c) = Y_{m-1,n-1}(a,b,c) + cY_{m-1,n}(a,b,c), \quad m,n \geqslant 1, \tag{6}$$

is satisfied by $Y_{m,n}$. Therefore, only functions of the form $Y_{0,n}$, with $n \geqslant 0$, require explicit evaluation. The quadratic response tensor derived in Ref. 6 can then be expressed using $Z(u)$ and the generalized plasma dispersion functions $Y_{0,n}$, with $0 \leqslant n \leqslant 3$.

Using the symmetry[2,3]

$$Z^{(n)}(u^*) = (-1)^{n+1}[Z^{(n)}(-u)]^*, \quad n \geqslant 0, \tag{7}$$

for the nth derivative of $Z(u)$, denoted $Z^{(n)}(u)$, where it is understood that $Z^{(0)}(u)=Z(u)$, it can be shown by substitution into the definition (4) that

$$Y_{0,n}(a^*,b^*,c^*)=(-1)^{n+1}[Y_{0,n}(-a,b,-c)]^*, \quad n\geqslant 0. \tag{8}$$

The general result,

$$Y_{m,n}(a^*,b^*,c^*)=(-1)^{m+n+1}[Y_{m,n}(-a,b,-c)]^*, \quad m,n\geqslant 0, \tag{9}$$

can be proved by induction using (8) and the recursion relation (6). Other symmetry properties which can be proved using (7) in the definition (4) are

$$Y_{m,n}(a,b,c)=(-1)^{m+n}Y_{m,n}(a,-b,-c), \quad m,n\geqslant 0, \tag{10}$$

and

$$Y_{m,n}(a^*,b^*,c^*)=-[Y_{m,n}(-a,-b,c)]^*, \quad m,n\geqslant 0. \tag{11}$$

It is straightforward to show by direct partial differentiation of the definition (4) that the generalized plasma dispersion function satisfies the first-order partial differential equations

$$\frac{\partial Y_{m,n}}{\partial a}=\frac{\partial Y_{m-1,n}}{\partial b}, \quad m\geqslant 1, \quad n\geqslant 0, \tag{12}$$

and

$$\frac{\partial Y_{m,n}}{\partial c}=nY_{m,n+1}, \quad m,n\geqslant 0, \tag{13}$$

where the arguments of $Y_{m,n}(a,b,c)$ have been omitted for brevity. Using (12) and (13), together with the recursion relation (6) and the ordinary differential equation

$$\frac{d^2Z(u)}{du^2}+2u\,\frac{dZ(u)}{du}+2Z(u)=0, \tag{14}$$

satisfied by the plasma dispersion function,[1] it can be shown that $Y_{m,n}(a,b,c)$ is a solution of the partial differential equations

$$\frac{\partial^2 Y_{m,n}}{\partial a^2}+2a\,\frac{\partial Y_{m,n}}{\partial a}+2b\,\frac{\partial Y_{m,n}}{\partial b}+2Y_{m,n}=0, \tag{15}$$

and

$$\frac{\partial^2 Y_{m,n}}{\partial b\,\partial c}=n\,\frac{\partial Y_{m,n}}{\partial a}+c\,\frac{\partial^2 Y_{m,n}}{\partial a\,\partial c}. \tag{16}$$

Partial derivatives of the generalized plasma dispersion functions appear in the exact quadratic response tensor derived in Ref. 6, and are easily evaluated using (12).

III. EVALUATION OF $Y_{0,n}(a,b,c)$

In this section, we express the $Y_{0,n}$, $n\geqslant 0$ in terms of series involving the Hermite polynomials and derivatives of the standard plasma dispersion function Z. From the recursion relation (6), it is straightforward to show that the generalized plasma dispersion functions of arbitrary order can be expressed as linear combinations of the lowest-order functions of the form $Y_{0,n}$, $n\geqslant 0$. Thus only the functions $Y_{0,n}$ require explicit evaluation.

A. Evaluation of $Y_{0,0}(a,b)$

The function $Y_{0,0}(a,b,c)=Y_{0,0}(a,b)$ is independent of c and may be evaluated by substituting the plasma dispersion function in the form (1) into the definition (4) with $m=n=0$ to give

$$Y_{0,0}(a,b)=\frac{1}{\pi}\int_{-\infty}^{\infty}dx\int_{-\infty}^{\infty}dt\ e^{-x^2-t^2}\ \frac{1}{t-a-bx}. \tag{17}$$

Transforming to polar coordinates with $x=r\cos\theta$, $t=r\sin\theta$, and $dx\,dt=r\,dr\,d\theta$, the θ integration is of an elementary type and can be performed immediately. The remaining integral over radius r can be rewritten in terms of the plasma dispersion function to give

$$Y_{0,0}(a,b)=\frac{1}{\sqrt{1+b^2}}\,Z\left(\frac{a}{\sqrt{1+b^2}}\right),\quad \mathrm{Im}(a)\geqslant 0, \tag{18}$$

and the analytic continuation of (18) when $\mathrm{Im}(a)<0$.

B. Series expressions for $Y_{0,n}$, $n\geqslant 1$

The function $Y_{0,1}(a,b,c)$ can be evaluated by expanding the plasma dispersion function in the definition (4) in a power series about $x=c$ to give

$$Y_{0,1}(a,b,c)=\frac{1}{\sqrt{\pi}}\int_{-\infty}^{\infty}dx\ e^{-x^2}\sum_{n=0}^{\infty}\ \frac{b^n}{n!}\,(x-c)^{n-1}Z^{(n)}(a+bc), \tag{19}$$

where $Z^{(n)}$ denotes the nth derivative of the plasma dispersion function. Taking the integral inside the summation and using a standard integral [Ref. 11, Eq. (3.462.4)] gives

$$\int_{-\infty}^{\infty}dx(x-c)^n e^{-x^2}=\sqrt{\pi}(2i)^{-n}H_n(-ic),\quad n\geqslant 0, \tag{20}$$

where H_n is a Hermite polynomial of integer order n; then

$$Y_{0,1}(a,b,c)=Z(c)Z(a+bc)+\sum_{n=1}^{\infty}\ \frac{b^n}{n!(2i)^{n-1}}\,H_{n-1}(-ic)Z^{(n)}(a+bc). \tag{21}$$

In writing (21), the leading term $n=0$ has been written explicitly, identifying $Z(c)$ using (1). The evaluation of $Y_{0,2}(a,b,c)$ proceeds by analogy to give

$$Y_{0,2}(a,b,c)=bZ(c)Z^{(1)}(a+bc)+Z^{(1)}(c)Z(a+bc)+\sum_{n=2}^{\infty}\ \frac{b^n}{n!(2i)^{n-2}}\,H_{n-2}(-ic)Z^{(n)}(a+bc). \tag{22}$$

In general, if $b\neq 0$, then

$$Y_{0,n}(a,b,c)=\sum_{k=0}^{n-1}\ \frac{b^k}{k!(n-k-1)!}\,Z^{(n-k-1)}(c)Z^{(k)}(a+bc)+\sum_{k=n}^{\infty}\ \frac{b^k}{k!(2i)^{k-n}}$$
$$\times H_{k-n}(-ic)Z^{(k)}(a+bc),\quad n\geqslant 1. \tag{23}$$

Otherwise,

$$Y_{0,n}(a,0,c)=\frac{1}{(n-1)!}\,Z^{(n-1)}(c)Z(a),\quad n\geqslant 1. \tag{24}$$

In writing (23) and (24), the definition

$$Z^{(n)}(u)=\frac{n!}{\sqrt{\pi}}\int_{-\infty}^{\infty}\frac{dx\ e^{-x^2}}{(x-u)^{n+1}},\quad \mathrm{Im}(u)>0, \tag{25}$$

and its analytic continuation for $\mathrm{Im}(u)\leqslant 0$, is required. To our knowledge, (25) has not appeared explicitly in the literature, although it is easily established by repeated differentiation of (1).

The infinite series in (23) is convergent for all a and c provided $|b|<1$. This result can be established by expressing the $Z^{(n)}$ in the series using the alternative integral expression[2]

$$Z^{(n)}(u)=\frac{1}{\sqrt{\pi}}\int_{-\infty}^{\infty}dx\ \frac{(-1)^n H_n(x)e^{-x^2}}{x-u}, \tag{26}$$

so that the infinite series in (23) becomes

$$\sum_{k=n}^{\infty}\frac{b^k}{k!(2i)^{k-n}}H_{k-n}(-ic)Z^{(k)}(a+bc)=\frac{(-b)^n}{\sqrt{\pi}}\int_{-\infty}^{\infty}\frac{dx\ e^{-x^2}}{x-a-bc}\sum_{k=0}^{\infty}\frac{1}{(k+n)!}\left(\frac{-b}{2i}\right)^k \times H_k(-ic)H_{k+n}(x),\quad n\geqslant 1. \tag{27}$$

In writing (27), the integral and summation on the right side have been interchanged, and the sum index redefined to begin at $k=0$. From Ref. 12 [Eq. (5.12.2.1)], the sum

$$\sum_{k=0}^{\infty}\frac{t^k}{k!}H_k(u)H_{k+n}(v)=(1-4t^2)^{-(n+1)/2} \times\exp\left[\frac{4tuv-4t^2(u^2+v^2)}{1-4t^2}\right]H_n\left(\frac{v-2tu}{\sqrt{1-4t^2}}\right),\quad |t|<1/2, \tag{28}$$

can be derived. The absolute value of the nth term in the convergent series (28) with $t=-b/2i$, $u=-ic$, $v=x$ is an upper bound for the corresponding term in (27). Therefore the series in (23) converges absolutely whenever $|b|<1$.

When $|b|>1$, an alternative convergent series expression for the $Y_{0,n}$ is required. Substituting the plasma dispersion function definition (1) into (4) for the case $m=0$, $n=1$ gives

$$Y_{0,1}(a,b,c)=\frac{1}{\pi}\int_{-\infty}^{\infty}\frac{dx\ e^{-x^2}}{x-c}\int_{-\infty}^{\infty}\frac{dy\ e^{-y^2}}{y-(a+bx)}, \tag{29}$$

which may be written as

$$Y_{0,1}(a,b,c)=\frac{1}{\pi}\int dy\ \frac{e^{-y^2}}{y-(a+bc)}\int dx\ e^{-x^2}\left[\frac{1}{x-c}-\frac{1}{x-(y-a)/b}\right]. \tag{30}$$

The x integration may be performed in terms of plasma dispersion functions; the y integration follows from the definition (4) to give the identity

$$Y_{0,1}(a,b,c)=Z(c)Z(a+bc)-Y_{0,1}(-a/b,1/b,a+bc). \tag{31}$$

Comparing (31) with the series expression (21), and making the transformations $-a/b\rightarrow a$, $1/b\rightarrow b$, and $a+bc\rightarrow c$, leads to the alternative series expression

$$Y_{0,1}(a,b,c)=-\sum_{n=1}^{\infty}\frac{b^{-n}}{n!(2i)^{n-1}}H_{n-1}(-i(a+bc))Z^{(n)}(c). \tag{32}$$

Again using a term-by-term comparison test with the convergent series (28), it can be shown that (32) is convergent whenever $|b|>1$. By analogy, one can derive for the general case

$$Y_{0,n}(a,b,c) = -b^{n-1}\sum_{k=n}^{\infty} \frac{b^{-k}}{k!(2i)^{k-n}} H_{k-n}(-i(a+bc))Z^{(k)}(c), \quad n \geqslant 1. \tag{33}$$

C. Real and imaginary parts of $Y_{0,n}(a,b,c)$

It is possible to separate the generalized plasma dispersion function $Y_{0,n}(a,b,c)$ explicitly into real and imaginary parts when its arguments are real. This is analogous to the well-known separation into real and imaginary parts of the plasma dispersion function $Z(u)$ for real u, given by[1]

$$Z(u) = \text{Re } Z(u) + i\sqrt{\pi}e^{-u^2}, \tag{34}$$

with

$$\text{Re } Z(u) = -2e^{-u^2}\int_0^u dt\ e^{t^2}. \tag{35}$$

From the definition (4) of the generalized plasma dispersion function with $m=0$, $n=1$, $Y_{0,1}(a,b,c)$ can be written as

$$Y_{0,1}(a,b,c) = \frac{1}{\sqrt{\pi}} \int dx\ e^{-x^2}[\mathscr{P}[1/(x-c)] + i\pi\delta(x-c)][\text{Re } Z(a+bx) + i\sqrt{\pi}e^{-(a+bx)^2}], \tag{36}$$

where $\mathscr{P}[1/(x\text{-}c)]$ denotes the Cauchy principal value of the integral at the pole $x=c$, and where the real and imaginary parts of the plasma dispersion function have been written explicitly using (34). Multiplying out the integrand in (36) and performing the two integrals over the delta function leaves two integrals to be evaluated. The integral $\mathscr{P}\int dx\ e^{-x^2}[1/(x-c)]e^{-(a+bx)^2}$ can be evaluated in terms of Re $Z(a+bx)$ using the substitution $y = \sqrt{1+b^2}[x + ab/(1+b^2)]$. The resulting separation gives

$$\text{Re } Y_{0,1}(a,b,c) = \frac{1}{\sqrt{\pi}}\mathscr{P}\int dx\ e^{-x^2}\frac{\text{Re } Z(a+bx)}{x-c} - \text{Im } Z(c)\text{Im } Z(a+bc), \tag{37}$$

and

$$\text{Im } Y_{0,1}(a,b,c) = \text{Im } Z\left(\frac{a}{\sqrt{1+b^2}}\right)\text{Re } Z\left(\frac{b(a+bc)+c}{\sqrt{1+b^2}}\right) + \text{Im } Z(c)\text{Re } Z(a+bc). \tag{38}$$

The above result can be generalized to $Y_{0,n}(a,b,c)$ with $n \geqslant 2$ by reexpressing the $Z^{(n)}$ via repeated differentiation of (34), to give

$$\text{Re } Y_{0,n}(a,b,c) = \frac{1}{\sqrt{\pi}}\mathscr{P}\int dx\ e^{-x^2}\frac{\text{Re } Z(a+bx)}{(x-c)^n} - \frac{1}{(n-1)!}[\text{Im } Z(a+bc)\text{Im } Z^{(n-1)}(c) + b^{n-1}\ \text{Im } Z(c)\text{Im } Z^{(n-1)}(a+bc)], \tag{39}$$

and

$$\text{Im } Y_{0,n}(a,b,c) = \frac{1}{(n-1)!}\left[\text{Im } Z^{(n-1)}(c)\text{Re } Z(a+bc) + b^{n-1}\ \text{Im } Z(c)\text{Re } Z^{(n-1)}(a+bc) + (\sqrt{1+b^2})^{n-1}\ \text{Im } Z\left(\frac{a}{\sqrt{1+b^2}}\right)\text{Re } Z^{(n-1)}\left(\frac{b(a+bc)+c}{\sqrt{1+b^2}}\right)\right], \tag{40}$$

for $n \geqslant 2$.

It is instructive to compare Im $Y_{0,n}(a,b,c)$ given by (38) and (40) with the series expressions (23) and (33) for $Y_{0,n}(a,b,c)$ calculated in the previous section. It is clear that for real arguments a, b, c, the imaginary part of the series solution in (23) and (33) has been explicitly summed. Therefore only the real part of the generalized plasma dispersion function needs to be approximated analytically or numerically to be useful in applications to nonlinear wave interactions involving weakly damped wave modes.

IV. DERIVATIVES OF THE PLASMA DISPERSION FUNCTION

Some analytic properties of the nth derivative of the plasma dispersion function $Z^{(n)}(u)$ have been considered in Refs. 2 and 3. The motivation for that work was the development of a systematic computational tool for the calculation of plasma dispersion by expanding linear dispersion integrals in terms of a set of orthogonal polynomials. The expansion of the dispersion integrals for a Maxwellian plasma in terms of Hermite polynomials led to a consideration of $Z^{(n)}$. The derivation given in Ref. 6 of the exact quadratic response tensor in terms of generalized plasma dispersion functions $Y_{m,n,}$ which may themselves be expressed as series in $Z^{(n)}$, motivates us to reexamine the derivatives of the plasma dispersion function. In this section, some new useful analytic results are presented. The numerical computation of $Z^{(n)}(u)$ for complex u is considered in Appendix A.

Repeated differentiation of $Z(u)$ expressed in the form (2) gives

$$Z^{(n)}(u)=(-1)^n H_n(u)Z(u)+2(-1)^n\sum_{k=1}^{n}\left\langle \begin{matrix} n \\ k \end{matrix}\right\rangle i^{k+1}H_{n-k}(u)H_{k+1}(iu). \tag{41}$$

To our knowledge, (41) has not appeared in the literature before, and is obtained by using Rodrigues's formula,

$$H_n(u)=(-1)^n e^{u^2}\frac{d^n}{du^n}\,e^{-u^2}, \tag{42}$$

and the identity [Ref. 13, Eq. (7.1.19)]

$$\frac{d^{n+1}}{du^{n+1}}\,\mathrm{erf}(u)=(-1)^n\,\frac{2}{\sqrt{\pi}}\,H_n(u)e^{-u^2}. \tag{43}$$

The identity (41) makes explicit the close relationship between the $Z^{(n)}$ and the Hermite polynomials; their respective three-term recursion relations differ only by a sign in one term. For real argument u, all terms in the finite sum in (41) are real, since $H_k(u)$ when k is an even or odd integer, is a linear combination of only even or odd powers of u, respectively, so that $i^k H_k(iu)$ is always real for real u. It follows that

$$\mathrm{Im}\ Z^{(n)}(u)=(-1)^n H_n(u)\mathrm{Im}\ Z(u)=i\sqrt{\pi}e^{-u^2}(-1)^n H_n(u), \tag{44}$$

and that only the real part of $Z^{(n)}(u)$ presents computational difficulties for real u.

An alternative expression for $Z^{(n)}$ in terms of the repeated integral of the complementary error function $\mathrm{erfc}(u)=[1-\mathrm{erf}(u)]$, defined by

$$I^n\ \mathrm{erfc}(x)=\int_x^\infty I^{n-1}\ \mathrm{erfc}(x')dx';\quad I^0\ \mathrm{erfc}(x)=\mathrm{erfc}(x), \tag{45}$$

is given by[2]

$$Z^{(n)}(u)=i\sqrt{\pi}(2i)^n n!e^{-u^2}I^n\ \mathrm{erfc}(-iu), \tag{46}$$

which can be obtained using Ref. 13 [Eq. (7.2.9)] to rewrite the nth derivative of (2). Note that $I^n \operatorname{erfc}(x)$ may be rewritten in terms of confluent hypergeometric functions or parabolic cylinder functions,[13] so the nth derivative of the plasma dispersion function is also related to these special functions.

The power series and asymptotic expansions of $Z^{(n)}$ can be derived by taking the nth derivative of the corresponding expansions of the plasma dispersion function.[1] This yields

$$Z^{(n)}(u)=(-1)^n H_n(u) i\sqrt{\pi} e^{-u^2} - u^{1-n} \sum_{j=j_{\min}}^{\infty} \frac{(-1)^j \sqrt{\pi}\Gamma(2j+2)u^{2j}}{\Gamma(j+3/2)\Gamma(2j+2-n)}, \quad |u| \ll 1, \tag{47}$$

with

$$j_{\min}=\begin{cases} (n-1)/2, & n \text{ odd}, \\ n/2, & n \text{ even}, \end{cases} \tag{48}$$

and

$$Z^{(n)}(u)=(-1)^n H_n(u) \sigma i\sqrt{\pi} e^{-u^2} - \frac{(-1)^n}{u^{n+1}} \sum_{j=0}^{\infty} \frac{\Gamma(j+\frac{1}{2})\Gamma(2j+n+1)}{\sqrt{\pi}\Gamma(2j+1)u^{2j}}, \quad |u| \gg 1, \tag{49}$$

with

$$\sigma=\begin{cases} 0, & \operatorname{Im}(u)>0, \\ 1, & \operatorname{Im}(u)=0, \\ 2, & \operatorname{Im}(u)<0. \end{cases} \tag{50}$$

In deriving the imaginary parts of (47) and (49), Rodrigues's formula (42) is used. The asymptotic and power series expansions are useful in practice to obtain approximate forms for the generalized plasma dispersion functions $Y_{m,n}$.

Simple expressions for $Z^{(n)}(0)$ may be written down using (41) and the zero-argument properties of the Hermite polynomials. These give

$$Z^{(n)}(0)=\begin{cases} i\sqrt{\pi}(-1)^{2k+1}\dfrac{(2k)!}{k!}, & n=2k, \\ (-1)^{k+1}2^{2k+1}k!, & n=2k+1. \end{cases} \tag{51}$$

From (51) it follows that there are $(k+1)$ zero crossings of $Z^{(n)}(u)$ with $u \geqslant 0$ when $n=2k$ or $n=2k+1$.

A. Numerical results

The real and imaginary parts of the lowest-order generalized plasma dispersion function $Y_{0,0}(a,b)$ are graphed in Fig. 1 for real a with $0 \leqslant a \leqslant 10$ for $b=0.1,1,10$. The minimum in $\operatorname{Re} Y_{0,0}(a,b)$ becomes shallow and shifts to higher a with increasing b. The magnitude of the maximum in $\operatorname{Im} Y_{0,0}(a,b)$ diminishes with increasing b such that the area under the curve is constant and independent of b. This may be proved by evaluating the integral $\int_{-\infty}^{\infty} \operatorname{Im} Y_{0,0}(a,b)da$ using (18) with (34) and showing that the result is independent of b. For $b \leqslant 0.1$, $Y_{0,0}(a,b)$ is indistinguishable from $Z(a)$ on the scale of the graphs in Fig. 1.

The real parts of $Y_{0,1}(a,b,c)$, $Y_{0,2}(a,b,c)$, and $Y_{0,3}(a,b,c)$ are graphed in Figs. 2, 3, and 4, respectively, for a number of parameter values. In graphing the generalized dispersion functions using the series expressions (23) and (33), numerical evaluation of the derivatives of the plasma dispersion function is required; this task is addressed in the Appendix. Padé approximants for the generalized plasma dispersion functions are also illustrated in Figs. 1 and 2; Padé approximants are discussed in Sec. V B.

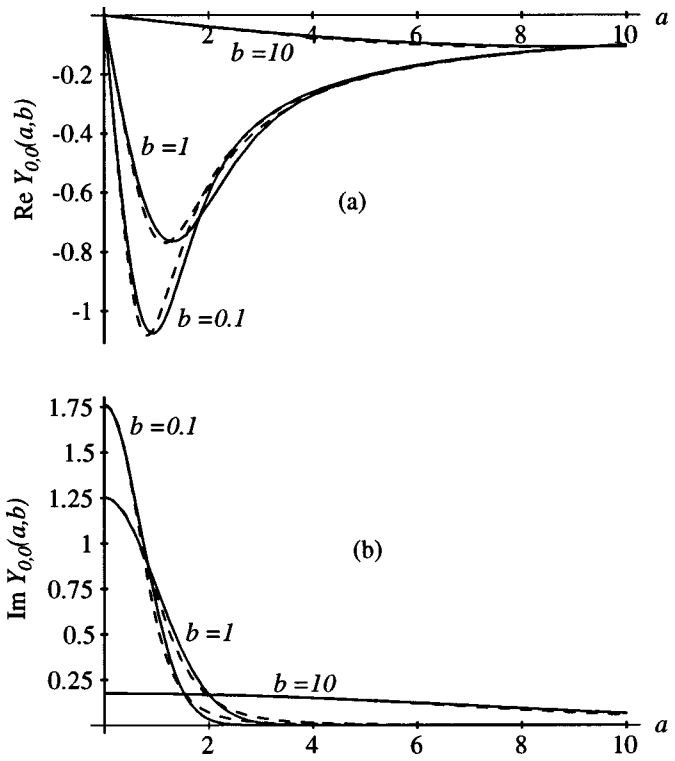

FIG. 1. Graphs of the (a) real and (b) imaginary parts of $Y_{0,0}(a,b)$ (solid curves) and their respective Padé approximants (dashed curves), for $0 \leqslant a \leqslant 10$ and $|b| = 0.1,1,10$, as labeled. When $|b| = 0.1$, the real and imaginary parts of $Y_{0,0}(a,b)$ are indistinguishable from those of $Z(a)$ on the scale of the given graphs.

V. APPROXIMATIONS FOR $Y_{0,n}(a,b,c)$

In the application of the quadratic response tensor to the treatment of specific nonlinear wave processes, such as the three-wave process satisfying the matching conditions (3), approximate analytic forms for the generalized plasma dispersion functions are required. As noted in the Introduction, the arguments of $Y_{m,n}(a,b,c)$ then have physical meaning, with the magnitudes of a and c given by the ratio of the wave phase speed to the plasma thermal speed for two of the interacting waves, and with $b = -\cot\theta$, where θ is the angle between the coalescing wave vectors. From these identifications, two classes of approximation are possible. *Geometric approximations* may be made for some interaction geometries; for example, the limit $|b| \ll 1$ holds for the coalescence of near perpendicularly propagating waves, while $|b| \gg 1$ for near parallel propagating or counterpropagating interacting waves. *Phase speed approximations* depend on the ratio of the phase speed of the interacting waves to the thermal speed of the plasma. The limiting cases $|a| \ll 1$, $|c| \ll 1$ and $|a| \gg 1$, $|c| \gg 1$ should then give useful approximate forms. In this section, analytic approximations and Padé approximants for the generalized plasma dispersion function are derived and discussed.

A. Analytic approximations

The approximation of the lowest-order generalized plasma dispersion function $Y_{0,0}(a,b)$ in various limits is straightforward. From (18), we have immediately

$$Y_{0,0}(a,b) \approx \begin{cases} Z(a), & |b|^2 \ll 1, \\ \dfrac{1}{b} Z\left(\dfrac{a}{b}\right), & |b|^2 \gg 1. \end{cases} \tag{52}$$

Approximate forms for the higher-order generalized plasma dispersion functions may be derived from the series expansions (23) and (33) for parameter ranges where the series rapidly converge, so that only leading terms need be retained. The power series and asymptotic expan-

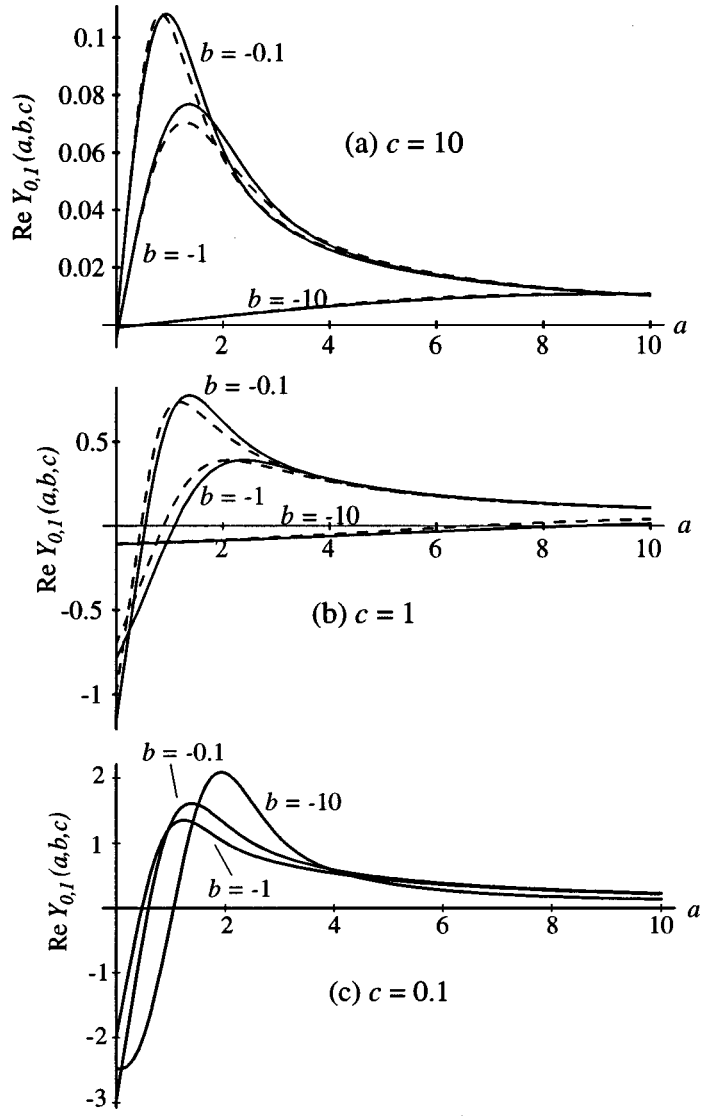

FIG. 2. The graph of Re $Y_{0,1}(a,b,c)$ (solid lines) with $0 \leqslant a \leqslant 10$ and (a) $c=10$, (b) $c=1$, and (c) $c=0.1$ for the physically relevant cases, with b taking the values -0.1, -1, and -10, as labeled. The Padé approximants for Re $Y_{0,1}$ are also shown (dashed line) for comparison, except for the case $c=0.1$, for which the simple approximant fails. Note the changes of scale on the vertical axes.

sions for the derivatives of the plasma dispersion function given by (47) and (49), respectively, can then be used to approximate the remaining terms in the series. This procedure can also be adopted to give geometric approximations of the quadratic response tensor for specific interaction geometries whenever $|b| \ll 1$ or $|b| \gg 1$ applies.

Simple phase-speed approximations for $Y_{0,1}(a,b,c)$ can be derived directly from the definition (4). If $|a| \gg 1$, then $Z(a+bx)$ may be approximated by the first term in its asymptotic expansion $-1/(a+bx)$ for small $|x|$, where the contribution of the integrand to the integral is significant (in view of the e^{-x^2} factor appearing in the integral). Then

$$Y_{0,1}(a,b,c) \approx \frac{1}{\sqrt{\pi}} \int \frac{dx\ e^{-x^2}}{(c-x)(a+bx)} \tag{53}$$

can be evaluated in terms of the plasma dispersion function, via partial fractions, to give

$$Y_{0,1}(a,b,c) \approx Z(a+bc)[Z(c)-Z(-a/b)], \tag{54}$$

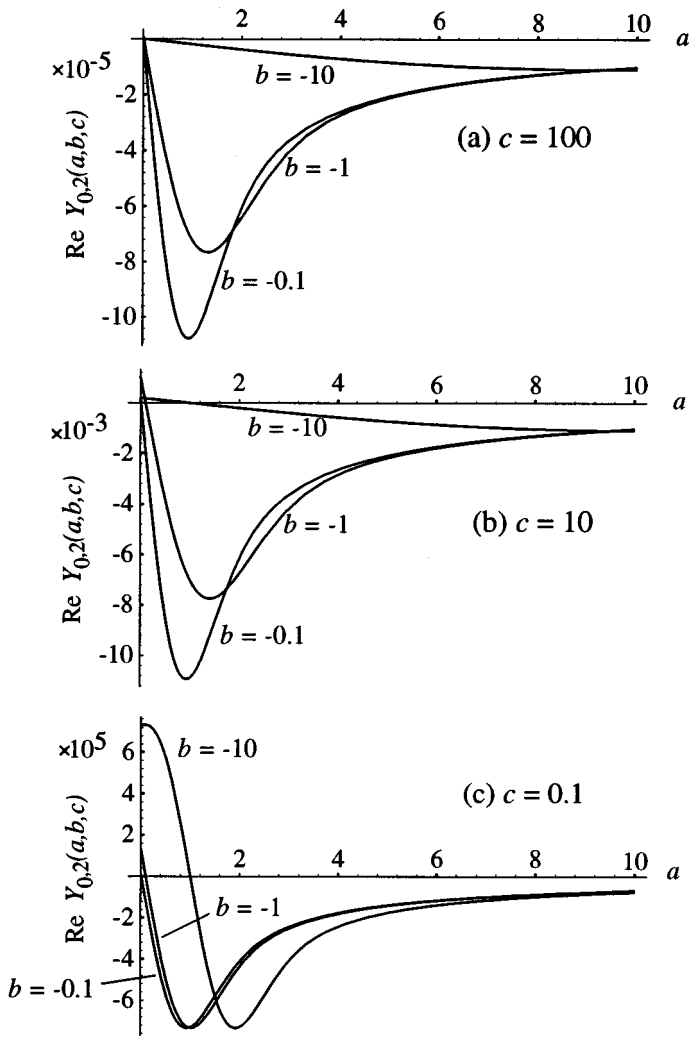

FIG. 3. The graph of Re $Y_{0,2}(a,b,c)$ with $0 \leqslant a \leqslant 10$ and (a) $c=100$, (b) $c=10$, and (c) $c=0.1$ for the physically relevant cases, with b taking the values -0.1, -1, and -10 as labeled.

where $|a+bc| \gg 1$ also holds. Comparisons with numerical evaluations suggest this approximation is valid for a wider range of parameters, failing only when $|a| \leqslant 1$, $|c| \leqslant 1$ or when $a+bc \approx 0$. An analogous approximation can be derived for the higher-order generalized plasma dispersion functions. In particular,

$$Y_{0,2}(a,b,c) \approx bZ^{(1)}(a+bc)[Z(c)-Z(-a/b)]+Z^{(1)}(c)Z(a+bc), \tag{55}$$

and

$$Y_{0,3}(a,b,c) \approx \frac{b^2}{2} Z^{(2)}(a+bc)[Z(c)-Z(-a/b)]+\tfrac{1}{2}Z(a+bc)Z^{(2)}(c)+bZ^{(1)}(a+bc)Z^{(1)}(c). \tag{56}$$

Repeated use of the recursion relation (6) generates approximate forms for $Y_{1,1}$, $Y_{1,2}$, and $Y_{2,2}$ which also appear in the quadratic response tensor for a thermal plasma. The power series and asymptotic expansions for the $Z^{(n)}$ may then be used to obtain simple analytic forms for the $Y_{m,n}$.

A more useful phase speed approximation for the generalized plasma dispersion function $Y_{0,n}(a,b,c)$ holds when $|c| \gg 1$ such that the resonant denominator $(x-c)^n$ in the definition (4) can be approximated by $(-c)^n$. It follows that

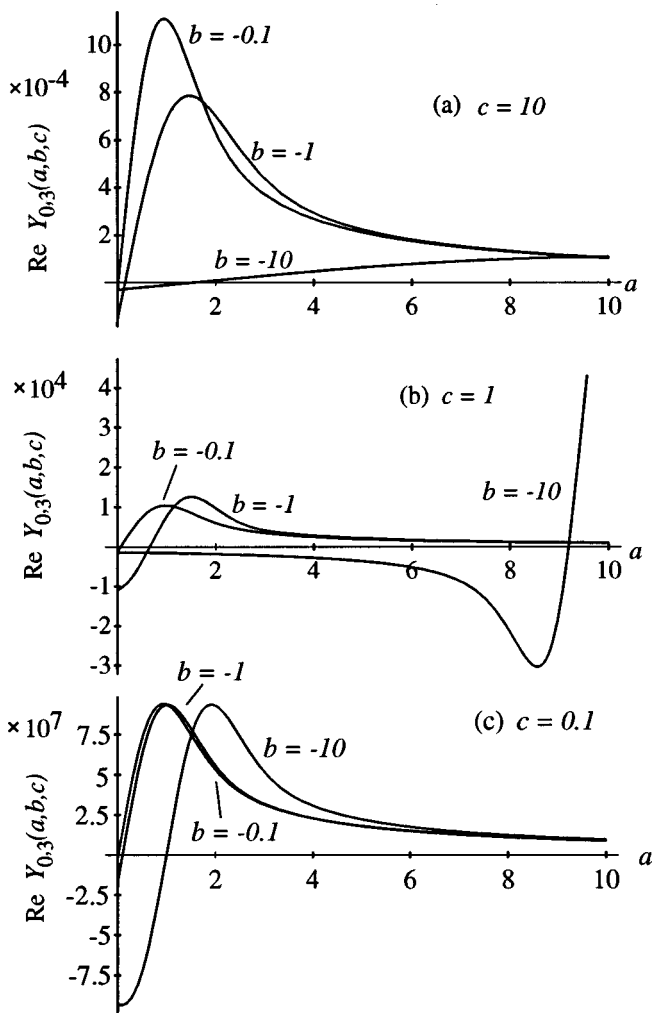

FIG. 4. The graph of Re $Y_{0,3}(a,b,c)$ with $0 \leqslant a \leqslant 10$ and (a) $c=10$, (b) $c=1$, and (c) $c=0.1$ for the physically relevant cases with b taking the values -0.1, -1 and -10, as labeled. Note the changes of scale on the vertical axes.

$$Y_{0,n}(a,b,c) \approx Y_{0,0}(a,b)/(-c)^n, \quad |c| \gg 1. \tag{57}$$

Substitution of (57) into the recursion relation (6) gives $Y_{m,n} \approx 0$ whenever $m \neq 0$. Taken together with (57), we find

$$Y_{m,n}(a,b,c) \approx \begin{cases} \dfrac{1}{(-c)^n \sqrt{1+b^2}}\, Z\left(\dfrac{a}{\sqrt{1+b^2}}\right), & m=0, \\ 0, & m \neq 0. \end{cases} \tag{58}$$

The validity of (58) is demonstrated in a particular case by comparing Re $Y_{0,1}$ with $c=10$ graphed in Fig. 2(a), respectively, with Re $Y_{0,0}$ shown in Fig. 1(a). Physically, the limit $|c| \gg 1$ corresponds to a product wave phase speed much greater than the plasma thermal speed in a three-wave coalescence process.

B. Padé approximants

The use of (modified) Padé approximants for the plasma dispersion function $Z(u)$ is a widely used technique in the analytic treatment of the dispersive properties of a Maxwellian plasma.[14–19]

This approach can be extended to the description of second-order (three-wave) wave processes in a Maxwellian plasma by deriving Padé approximants for the generalized plasma dispersion functions $Y_{0,n}$.

The Padé approximant $\tilde{Z}(u)$ for the plasma dispersion function $Z(u)$ may be written in the multipole form

$$\tilde{Z}(u)=\sum_{j=1}^{N}\left(\frac{\alpha_j}{u-\beta_j}+\frac{\alpha_j^*}{u+\beta_j^*}\right), \tag{59}$$

where the coefficients α_j, β_j are chosen so that the approximant fits a total of $2N$ leading terms selected jointly from the power series and the asymptotic expansion of $Z(u)$ given by (47) and (49) with $n=0$. The general form (59) satisfies the symmetry (7) with $n=0$. The $N=2$ Padé approximant which fits the first two terms of both the power series and asymptotic expansions of the plasma dispersion function is[16]

$$\tilde{Z}(u)=\frac{i\sqrt{\pi}+(\pi-2)u}{1-i\sqrt{\pi}u-(\pi-2)u^2}, \tag{60}$$

which may be numerically expressed in the two-pole form

$$\tilde{Z}(u)=\frac{\alpha}{u-\beta}+\frac{\alpha^*}{u+\beta^*}, \tag{61}$$

with

$$\alpha=-\frac{1}{2}-\frac{i\sqrt{\pi}}{2\sqrt{3\pi-8}}, \quad \beta=\frac{\sqrt{3\pi-8}-i\sqrt{\pi}}{2(\pi-2)}. \tag{62}$$

In Ref. 19, it is argued on physical grounds that the two-pole approximant (61) is the most useful form since it satisfies the correct symmetries, the requirement of non-negative wave damping in a Maxwellian plasma, has a monotonically decreasing imaginary part, and does not lead to spurious wave growth.

Substitution of the approximant (61) into the definition (4) of the generalized plasma dispersion function with $m=0$ and $n=0,1$ and performing the integrations using partial fractions gives the two lowest-order Padé approximants,

$$\tilde{Y}_{0,0}(a,b)=\frac{\alpha}{a-\sqrt{1+b^2}\beta}+\frac{\alpha^*}{a+\sqrt{1+b^2}\beta^*}, \tag{63}$$

and

$$\tilde{Y}_{0,1}(a,b,c)=\tilde{Z}(c)\tilde{Z}(a+bc)-\left[\frac{\alpha}{a+bc-\beta}\,\tilde{Z}\left(\frac{\beta-a}{b}\right)+\frac{\alpha^*}{a+bc+\beta^*}\,\tilde{Z}\left(\frac{-\beta^*-a}{b}\right)\right], \tag{64}$$

where the tilde again denotes a Padé approximated quantity. Padé approximants for higher-order generalized plasma dispersion functions may be derived from (63) and (64) using the recursion relation (6), together with the derivative identities (12). A graphical comparison of the real and imaginary parts of the Padé approximant $\tilde{Y}_{0,0}$ with those of $Y_{0,0}$ for particular real arguments is shown in Fig. 1. In Fig. 2, the Padé approximant for Re $Y_{0,1}(a,b,c)$ is compared with the exact expression when $c\geqslant 1$. For $c<1$, the Padé approximant for the generalized dispersion functions is poor because the effect of the resonant denominator $(x-c)^n$ in the defining integral (4) of $Y_{m,n}$ is inadequately approximated.

Padé approximants for the remaining generalized dispersion functions $Y_{1,1}$, $Y_{1,2}$, and $Y_{2,2}$ appearing in the exact quadratic response tensor may be written down using the recursion relation (6). Taking these results together, a simple rational approximation for the quadratic response tensor can then be written down. However, care must be taken with such a procedure. In general,

the two-pole Padé approximant is inadequate when the pole at $x=c$ in (4) is close to the origin, i.e., when $|c|<1$. The physical significance of this case is in the treatment of three-wave interactions when the product wave phase speed is slow in comparison with the plasma thermal speed.

VI. SUMMARY

A wide variety of mathematical properties of the generalized plasma dispersion functions $Y_{m,n}$, $m,n\geqslant 0$ have been examined here, including recursion relations, partial differential equations, and series expansions in terms of products of Hermite polynomials and derivatives of the standard plasma dispersion function $Z^{(n)}$, $n\geqslant 0$. Analytic and Padé approximate forms for the generalized plasma dispersion functions have also been discussed, and the ranges of validity for these approximations have been identified. Since the evaluation of the $Y_{m,n}$ requires the evaluation of the $Z^{(n)}$, these derivatives have been examined here, with some new analytic results obtained for them. The numerical stability of the recursive computation of the $Z^{(n)}$ has also been treated. Collectively, these results find a wide physical application in the treatment of second-order wave processes in warm collisionless plasmas with constituent species having Maxwellian velocity distributions, since it was shown in Ref. 6 that the exact quadratic response tensor which describes such processes can be written in terms of the $Y_{m,n}$ with $0\leqslant m,n\leqslant 3$. Such processes include many of those relevant to the theory and application of weak turbulence and parametric three-wave interactions.

The summability of the series expressions (23) and (33) for the generalized plasma dispersion functions remains an open question. Although numerous summable series involving Hermite polynomials are reported in the literature,[12] we have not been able to manipulate the series (23) or (33) into any known summable form. Further attention to this issue in the future would be desirable, motivated by the utility of a finite series expression for the exact quadratic response tensor for application to specific second-order plasma processes.

APPENDIX: NUMERICAL COMPUTATION OF $Z^{(n)}$

The numerical evaluation of the generalized plasma dispersion functions using the series expansions derived in Sec. III requires the computation of a sequence of $Z^{(n)}$. It is straightforward to derive the recursion relation[2,3]

$$Z^{(n+1)}(u)=-2uZ^{(n)}(u)-2nZ^{(n-1)}(u), \quad n\geqslant 1, \tag{A1}$$

by repeated application of the differential equation $Z^{(1)}(u)=-2-2uZ(u)$ satisfied by the plasma dispersion function. However, analysis of the stability of this recursion relation shows it to be unstable to upward iteration for large $|u|$. The argument is as follows: Assuming that $Z^{(n+1)}(u)\approx 0$ in (A1), the approximate recursion relation may be solved to give

$$Z^{(n)}(u)\approx\left(\frac{-1}{u}\right)^n n!\,Z(u). \tag{A2}$$

The initial assumption may be justified *a posteriori* only for fixed n and for $|u|\to\infty$ such that the right side of (A1) tends to zero. A comparison of (A2) with the first term in the asymptotic expansion (49) with $Z(u)\approx -1/u$ demonstrates that (A2) is the required form of solution for large $|u|$. However, a second growing solution of the recursion relation (51) may be identified by assuming $Z^{(n-1)}(u)\approx 0$ and then solving (A2) to give

$$Z^{(n)}(u)=(-2u)^n Z(u), \tag{A3}$$

which grows indefinitely for fixed n and $|u|\to\infty$, or for fixed $|u|>\frac{1}{2}$ and $n\to\infty$, again justifying the initial assumption *a posteriori* in these regimes. In any upward iteration scheme using (A1), inevitable numerical roundoff error will cause this unwanted second solution to grow to dominate the required solution in the regime of large $|u|$. The remedy is to perform *downward* iteration for large $|u|$, starting with $Z^{(\nu)}(u)=0$, $Z^{(\nu-1)}(u)=1$ for some large integer ν, and then normalizing

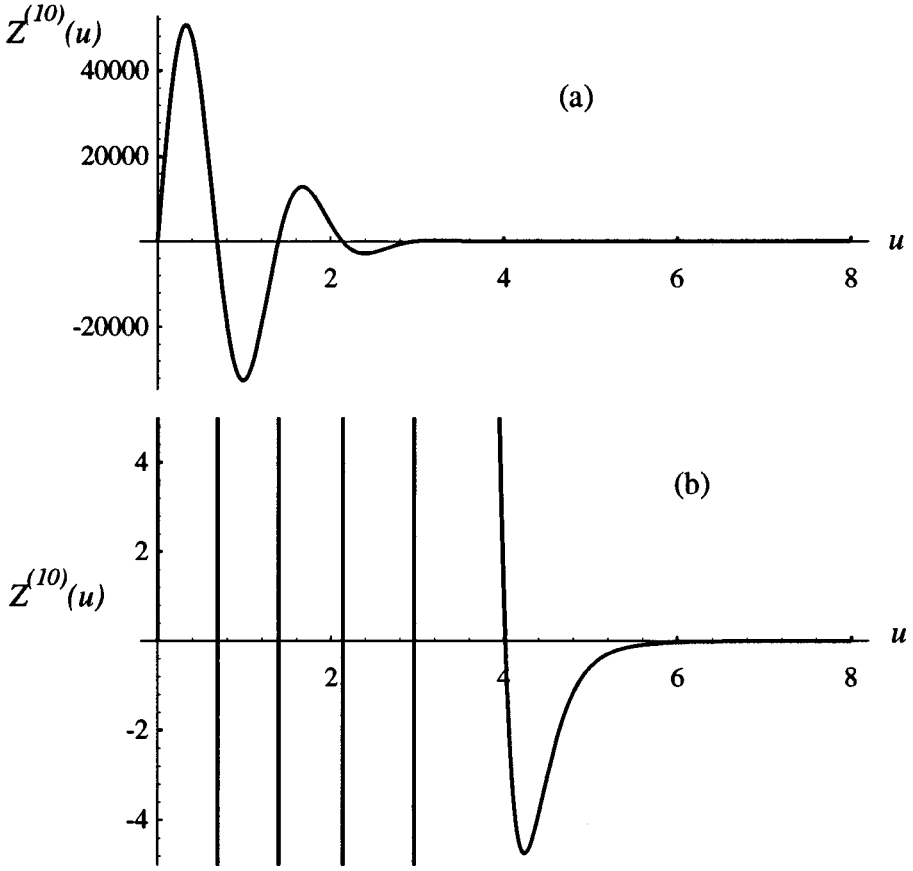

FIG. 5. Numerical evaluation of the real part of $Z^{(10)}(u)$ for real u in the domain $0 \leqslant u \leqslant 8$. For clarity, the vertical axis of (a) near the origin is magnified and illustrated in (b). Upward iteration using (A1) is stable in the oscillating regime; downward iteration is stable in the decaying regime for large u. The boundary between the two regimes is at $u \approx 3.2$.

the sequence of $Z^{(n)}(u)$, $n \leqslant \nu$ so obtained using the known form of $Z^{(0)}(u)$. The numerical solution of second-order difference equations and the stability of downward iteration techniques were reviewed in Ref. 20.

It is instructive to consider the form of $\mathrm{Re}\, Z^{(n)}(u)$ for large n, sketched in Fig. 5 for real argument u. There are two distinct regimes: a rapidly oscillating regime with $0 \leqslant u \leqslant \sqrt{n}$ and a decaying regime $u \geqslant \sqrt{n}$, where $Z^{(n)}(u)$ tends to zero. Upward iteration using the recursion relation (A1) is stable in the oscillating regime; downward recursion is required in the decaying regime. The expression (41) for the $Z^{(n)}(u)$ involving a finite sum of Hermite polynomials is useful for numerical computation only in the oscillating regime; catastrophic cancellation in the summation is a problem in the decaying regime for large n. The boundary $u = \sqrt{n}$ between the two regimes has been obtained empirically. We postulate that there are k zeros of $\mathrm{Re}\, Z^{(2k)}(u)$ and $\mathrm{Re}\, Z^{(2k+1)}(u)$ with $u < \sqrt{n}$ and only one zero crossing for $u > \sqrt{n}$. This result has been directly demonstrated numerically for $n \leqslant 100$ but not yet proved for all n.

A possible alternative scheme[2,3] for the computation of a sequence of $Z^{(n)}$ is to compute repeated integrals of the complementary error function and relate them to $Z^{(n)}$ using (46). An analysis of the recursive computation of $I^n \operatorname{erfc}(x)$ for real x using downward iteration has been given in Ref. 21. A generalization of this analysis to a complex argument is required here. For complex u in the upper half-plane with $\mathrm{Im}\, u > 0$, a sequence $Z(u)$, $Z^{(1)}(u), \ldots, Z^{(N)}(u)$ can be calculated using downward recursion to a relative error not exceeding 10^{-p} if the starting ν satisfies

$$\nu \geqslant \left(\sqrt{N} + \frac{p \ln 10 + \ln 2}{2\sqrt{2}\ \mathrm{Im}(u)} \right)^2 . \tag{A4}$$

From (A4), it is clear that as u approaches the real axis, the lower bound of ν grows indefinitely. Therefore on or near the real axis, the evaluation of the $Z^{(n)}(u)$ via the recursive computation of repeated integrals of the error function is inappropriate, and direct computation using (41) is required.

(Received 9 February 1998; accepted for publication 5 March 1998)

Advection and diffusion of a substance around a curved obstacle is analyzed when the advection velocity is large compared to the diffusion velocity, i.e., when the Peclet number is large. Asymptotic expressions for the concentration are obtained by the use of boundary layer theory, matched asymptotic expansions, etc. The results supplement and extend previous ones for straight obstacles. They apply to electrophoresis, the flow of ground water, chromatography, sedimentation, etc. © *1998 American Institute of Physics.* [S0022-2488(98)00707-5]

I. INTRODUCTION

Advection–diffusion processes occur in many different physical contexts, such as electrophoresis, ground water flow, chromatography, sedimentation, etc. Their quantitative description leads to the advection–diffusion equation for a concentration, together with appropriate boundary conditions. Our objective is to present a method for solving the resulting boundary value problems for the steady state in the difficult case in which the advection velocity is large compared to the relevant diffusion velocity, i.e., in the case of a large Peclet number. Previously, we treated the cases in which the flow is blocked by an impermeable infinite strip of finite width, either normal to the advection velocity[1] or oblique to it.[2] Now we consider blocking by curved cylindrical sheets, such as those shown in Figs. 1 and 2, and by axially symmetric bodies.

The flux $\mathbf{j}$ of a substance with concentration p is $\mathbf{j}=-D\boldsymbol{\nabla}p+v\mathbf{i}p$, where D is the diffusion coefficient and v is the advection velocity in the direction of the unit vector $\mathbf{i}$. In the steady state, conservation of mass implies that $\boldsymbol{\nabla}\cdot\mathbf{j}=0$, which we write as

$$\Delta p-2cp_x=0. \tag{1.1}$$

The Peclet number is $c=vL/2D$, where L is the width of an obstacle or some other reference length. On the surface B of an impermeable obstacle, the normal flux must vanish, i.e., $\mathbf{j}\cdot\mathbf{n}=0$. This condition can be written as

$$\partial_n p-(2c\ \cos\ \beta)p=0, \quad \mathbf{x}\ \text{ on }\ B. \tag{1.2}$$

Here $\mathbf{n}$ is the unit normal to B and $\cos\beta=\mathbf{n}\cdot\mathbf{i}$, so that β is the angle between the x axis and $\mathbf{n}$. In the exterior of a bounded obstacle, we suppose that $p=1$ at infinity:

$$p\to 1, \quad \text{as}\ \ |\mathbf{x}|\to\infty. \tag{1.3}$$

An exact solution of (1.1) that satisfies (1.2) on any surface B is, with H a constant,

$$p(\mathbf{x})=He^{2cx}. \tag{1.4}$$

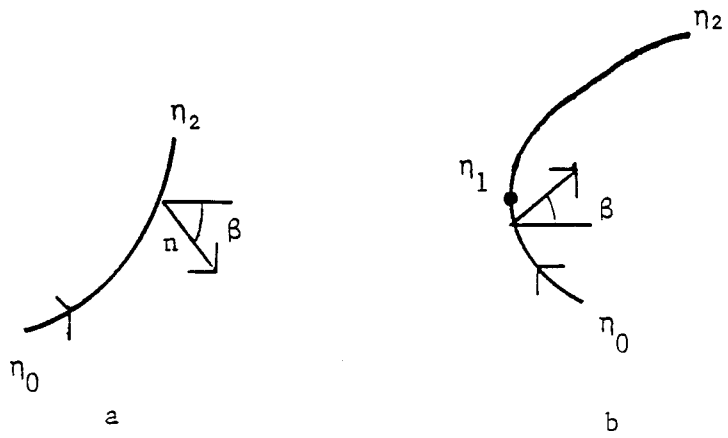

FIG. 1. Two examples of the normal cross section, in the x,y plane, of a nontrapping cylindrical obstacle B with generators parallel to the z axis. In each case the arclength η increases upward from the value η_0 at the lower end point, in the direction of the arrow. The unit tangent vector **t** points in this direction and the unit vector **n** points to the right. The angle β between the positive x axis and **n** is shown. In (a), $\beta<0$ and the curvature $\kappa(\eta)>0$. In (b), $\beta>0$ for $\eta_0<\eta<\eta_1$, $\beta<0$ for $\eta>\eta_1$, and $\beta(\eta_1)=0$ while $\kappa(\eta)<0$ for all η.

When B is a closed surface, (1.4) holds in the bounded domain inside B and H determines the total quantity of the substance in the domain. Since this solution does not satisfy (1.3), it does not hold in an exterior domain.

The flow upstream of a nontrapping boundary B, such as one of those in Fig. 1, is nearly parallel to the x axis except close to B. For c large, the flowing particles are concentrated in a thin diffusive boundary layer on the upstream or front side of B. They flow along B in this layer under the combined influence of advection and diffusion. At the downstream edge or edges of B, they leave the surface and flow away parallel to the x axis, creating a shadow behind B. This shadow is gradually filled as a result of diffraction and diffusion, so it ultimately disappears.

Many features of this flow are similar to those that occur when short waves hit a body, and we have analyzed those features before.[1,2] However, the concentration of particles in the diffusive boundary layer on the front side of B is a special feature of advection–diffusion, which does not occur in wave problems. This effect is enhanced when the front surface of B is concave to the left, as in Fig. 2, so that it can trap particles. Then the concentration becomes exponentially large there, and we shall show that it is given asymptotically by (1.4), with a particular value of H.

To analyze the concentration phenomenon, we shall find the first terms in the expansion of p within the diffusive boundary layer on the front side of B. In Sec. II, we treat nontrapping cylindrical boundaries, excluding the edges. In Sec. III, we complete that treatment by considering the special expansions that are needed near the edges. In Sec. IV, we analyze trapping cylindrical boundaries by finding the diffusive boundary layer expansion, the special expansion near the

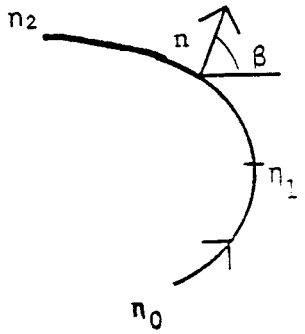

FIG. 2. The normal cross section of a trapping cylindrical obstacle with $\beta<0$ for $\eta_0<\eta<\eta_1$, $\beta>0$ for $\eta>\eta_1$, and $\beta(\eta_1)=0$, while $\kappa(\eta)>0$ for all η.

upstream edge, and the special expansion near a point where the boundary is normal to the advection velocity. We match the latter expansion to the diffusive boundary layer expansion in Sec. V. Then we complete this analysis by finding the special expansion valid near the downstream edge. In Sec. VII, we treat a special case. Finally, in Sec. VIII, we consider axially symmetric nontrapping boundaries.

II. DIFFUSIVE BOUNDARY LAYER ON A NONTRAPPING BOUNDARY

We consider the two-dimensional case in which B is a nontrapping cylindrical obstacle with generators parallel to the z axis. Then the cross section of B in the plane $z=0$ is a curve $x_0(\eta)$, $y_0(\eta)$, where η is arclength along it. When the obstacle is a thin sheet, the curve B is an open arc, with end points at η_0 and η_2, as is shown in Fig. 1. To determine p on the front or upstream side of B, we introduce the distance σ from B along the unit normal $\mathbf{n}$ to B, and write $(x,y)=[x_0(\eta),y_0(\eta)]+\sigma\mathbf{n}$. Then η, σ are curvilinear coordinates in the neighborhood of B. In terms of them,

$$\nabla p = p_\sigma\, \mathbf{n}(\eta) + [1+\sigma\kappa(\eta)]^{-1} p_\eta\, \mathbf{t}(\eta). \tag{2.1}$$

Here $\mathbf{n}(\eta)$ and $\mathbf{t}(\eta)$ are, respectively, the unit normal vector and the unit tangent vector to B while $\kappa(\eta)$ is the curvature of B. When η increases in the direction of increasing y, the y component of $\mathbf{t}$ is positive, and we choose the direction of $\mathbf{n}$ so that its x component is positive. Then we define the angle $\beta(\eta)$ between n and the positive x axis such that

$$\mathbf{n}\cdot\mathbf{i}=\cos\beta, \quad \mathbf{t}\cdot\mathbf{i}=-\sin\beta, \quad -\pi/2\leqslant\beta\leqslant\pi/2. \tag{2.2}$$

With these definitions, $\sigma<0$ on the upstream side of B. The curvature $\kappa(\eta)=\beta'(\eta)$ is positive when B is concave to the left, as in Fig. 1(a), and κ is negative when B is concave to the right, as in Fig. 1(b).

In anticipation of the boundary layer nature of p on the front side of B, we introduce the stretched coordinate $\xi=c\sigma$ and consider $p(\xi,\eta)$. Then we rewrite (1.1)–(1.3) as

$$p_{\xi\xi}-2\cos\beta\, p_\xi + c^{-1}\kappa(1+c^{-1}\kappa\xi)^{-1}p_\xi + 2c^{-1}(1+c^{-1}\kappa\xi)^{-1}\sin\beta\, p_\eta + c^{-2}(1+c^{-1}\kappa\xi)^{-2}p_{\eta\eta} - c^{-3}\kappa'(1+c^{-1}\kappa\xi)^{-3}\xi p_\eta = 0, \tag{2.3}$$

$$p_\xi - 2\cos\beta\, p = 0, \quad \text{at } \xi=0, \tag{2.4}$$

$$p\to 1, \quad \text{as } \xi\to-\infty. \tag{2.5}$$

To solve (2.3)–(2.5) near B for c large and $\xi\leqslant 0$, we seek an asymptotic expansion for p of the form

$$p = 1 + cQ^{(1)} + Q^{(0)} + c^{-1}Q^{(-1)} + O(c^{-2}), \quad \xi\leqslant 0. \tag{2.6}$$

We substitute (2.6) into (2.3)–(2.5) and equate coefficients of c^j, $j=1,0,-1$ in each equation, to obtain

$$Q^{(1)}_{\xi\xi} - 2\cos\beta\, Q^{(1)}_\xi = 0, \tag{2.7}$$

$$Q^{(0)}_{\xi\xi} - 2\cos\beta\, Q^{(0)}_\xi = -\kappa Q^{(1)}_\xi - 2\sin\beta\, Q^{(1)}_\eta, \tag{2.8}$$

$$Q^{(-1)}_{\xi\xi} - 2\cos\beta\, Q^{(-1)}_\xi = \kappa Q^{(0)}_\xi - 2\sin\beta\, Q^{(0)}_\eta + \xi\kappa^2 Q^{(1)}_\xi + 2\sin\beta\, \xi\kappa Q^{(1)}_\eta - Q^{(1)}_{\eta\eta}, \tag{2.9}$$

$$Q^{(j)}_\xi - 2\cos\beta\, Q^{(j)} = 2\delta_{j0}\cos\beta \quad \text{at } \xi=0, \quad j=1,0,-1, \tag{2.10}$$

$$Q^{(j)}\to 0, \quad \text{as } \xi\to-\infty. \tag{2.11}$$

The solution of (2.7) that satisfies (2.10) and (2.11) is

$$Q^{(1)}(\xi,\eta)=e^{2\xi\cos\beta}A_1(\eta). \tag{2.12}$$

To determine A_1 we use (2.12) for $Q^{(1)}$ in (2.8), integrate the resulting equation with respect to ξ from $-\infty$ to ξ, and use (2.11). In this way we get

$$Q^{(0)}_{\xi}-2\cos\beta\,Q^{(0)}=-\left[\kappa A_1+\sin\beta\left(\frac{A_1}{\cos\beta}\right)'-\frac{2\sin^2\beta\,\beta'}{\cos\beta}\,\xi A_1\right]e^{2\xi\cos\beta}. \tag{2.13}$$

Now we set $\xi=0$ in (2.13) and note that the left side equals $2\cos\beta$ in view of (2.10). Then since $\kappa=\beta'$, we can write (2.13) at $\xi=0$ as

$$\sin\beta\left(\frac{A_1}{\cos\beta}\right)'+\beta' A_1=-2\cos\beta. \tag{2.14}$$

The solution of (2.14) is

$$A_1(\eta)=-2\cot\beta(\eta)\left(\int_{\eta_0}^{\eta}\cos\beta(\eta')\,d\eta'+a_1\right)=-2\cot\beta(\eta)[y_0(\eta)-y_0(\eta_0)+a_1]. \tag{2.15}$$

Except for the undetermined constant a_1, (2.15) determines $A_1(\eta)$ and then (2.12) gives $Q^{(1)}$.

Now we use (2.14) in (2.13), solve for $Q^{(0)}$ and impose the condition (2.11) to get

$$Q^{(0)}(\xi,\eta)=\left[2\xi\cos\beta+\xi^2\frac{\sin^2\beta}{\cos\beta}\,\kappa A_1+A_0(\eta)\right]e^{2\xi\cos\beta}. \tag{2.16}$$

The function $A_0(\eta)$ is undetermined. To find it we use (2.12) for $Q^{(1)}$ and (2.16) for $Q^{(0)}$ in (2.9), integrate (2.9) with respect to ξ from $-\infty$ to 0, and use (2.10) and (2.11). In this way, we obtain

$$\begin{aligned}\sin\beta\left(\frac{A_0(\eta)}{\cos\beta}\right)'+\beta' A_0(\eta)=\sin\beta\left(\frac{1}{\cos\beta}-\frac{\sin^2\beta}{2\cos^4\beta}\,\beta' A_1\right)'-\frac{1}{2}\left(\frac{A_1}{\cos\beta}\right)''\\ -\frac{1}{2}\beta'\sin\beta\left(\frac{A_1}{\cos^2\beta}\right)'-\frac{\beta'^2 A_1}{2\cos\beta}.\end{aligned} \tag{2.17}$$

The solution of (2.17) for $A_0(\eta)$ can be written as follows, with a_0' an arbitrary constant:

$$\begin{aligned}A_0(\eta)=\cot\beta\Bigg[a_0'-\beta+\frac{1}{\sin\beta\cos\beta}+\frac{\cos^4\beta-\sin^2\beta}{2\cos^4\beta\sin\beta}\,\kappa A_1\\ +\int_{\eta_0}^{\eta}\frac{\beta'^2\sin^2\beta+\beta''\sin\beta\cos\beta}{2\cos^3\beta}A_1(\eta')\,d\eta'\Bigg].\end{aligned} \tag{2.18}$$

We can simplify this formula by using in the integral the first expression for $A_1(\eta)$ in (2.15). Then, by integrating by parts once we can evaluate the integral. Upon combining terms, simplifying, and setting $a_0=a_0'-\beta(\eta_0)+\beta'(\eta_0)a_1/\cos\beta(\eta_0)$, we get

$$A_0(\eta)=\cot\beta\left[a_0+\frac{1}{\sin\beta\cos\beta}+\beta'(\eta)A_1(\eta)\frac{\cot 2\beta}{\cos^3\beta}\right]. \tag{2.19}$$

Finally, we write the diffusive boundary layer expansion (2.6) as follows, by using (2.12) for $Q^{(1)}$ and (2.16) for $Q^{(0)}$:

$$p(\xi,\eta)=1+e^{2\xi\cos\beta}\left[cA_1(\eta)+2\xi\cos\beta+\xi^2\beta'\frac{\sin^2\beta}{\cos\beta}A_1(\eta)+A_0(\eta)\right]+O(c^{-1}). \tag{2.20}$$

The functions $A_1(\eta)$ and $A_0(\eta)$ are given by (2.15) and (2.19), respectively, which contain the arbitrary constants a_1 and a_0.

The expansion (2.20) is valid at interior points of nontrapping boundaries B, such as those shown in Figs. 1(a) and 1(b). At the end points η_0 and η_2, it must be replaced by the edge boundary layers that have been determined in Ref. 2. In the next section, we shall show how matching the upstream edge boundary layer expansion to (2.20) determines a_1 and a_0 for B of the form in Fig. 1(a). We shall also show how to determine a_1 and a_0 for B of the form in Fig. 1(b) in order to make $A_1(\eta)$ and $A_0(\eta)$ finite at the point η_1 where $\beta(\eta_1)=0$. In a later section, we shall consider trapping boundaries, like that in Fig. 2.

III. DETERMINING THE CONSTANTS IN THE EXPANSION FOR A NONTRAPPING BOUNDARY

First, we shall complete the determination of the diffusive boundary layer expansion (2.20) for a nontrapping boundary B, such as that shown in Fig. 1(a). Since $-\pi/2<\beta(\eta)<0$, the expansion (2.20) is not singular for any point in the interval $\eta_0<\eta<\eta_2$. To find the constants a_1 and a_0, we consider $p(\xi,\eta)$ near the leading or upstream edge $(0,\eta_0)$. We can represent p near that edge by another expansion, the edge boundary layer expansion. This involves the stretched variable $u=c(\eta-\eta_0)$ and the consideration of p as a function of ξ and u in the form

$$p=1+F_0(\xi,u)+O(c^{-1}). \tag{3.1}$$

Previously we determined this expansion when the boundary B was a strip of width $2L$ with its normal making an angle $\beta_0<0$ with the x axis, Ref. 2, Result 3 (iii). Then we expanded it for large values of u and matched it to the diffusive boundary layer expansion, which was a special case of (2.20). In that way, we determined the constants a_1 and a_0 and found for $p(\xi,\eta)$ the expansion

$$p\sim 1-e^{2\xi\cos\beta_0}\left[\frac{2c\cos^2\beta_0}{\sin\beta_0}(\eta-\eta_0)-2\xi\cos\beta_0+\frac{1}{\sin\beta_0}\right]. \tag{3.2}$$

We get exactly this same result even when B is curved—the curvature enters at a higher order.

The result (3.2) is valid when $\eta\to\eta_0$, $c\to\infty$, and $u=c(\eta-\eta_0)\to\infty$. Therefore, for η near η_0, it must agree with (2.20). When (2.20) is expanded for η near η_0, it becomes

$$\begin{aligned}p\sim 1-e^{2\xi\cos\beta_0}&\left[\frac{2c\cos\beta_0}{\sin\beta_0}([\eta-\eta_0]\cos\beta_0+a_1)-2\xi\cos\beta_0-\cot\beta_0\left(a_0+\frac{1}{\sin\beta_0\cos\beta_0}\right)\right]\\&+O\left[\frac{1}{c},\eta-\eta_0(\eta-\eta_0)^2\right]+a_1 f(\xi,\eta-\eta_0,c).\end{aligned} \tag{3.3}$$

Here $\beta_0=\beta(\eta_0)$ and the function f is $O(1)$ as $c\to\infty$. Equations (3.2) and (3.3) do indeed match, provided that a_1 and a_0 have the values

$$a_1=0,\quad a_0=-\frac{1+\sin\beta_0}{\sin\beta_0\cos\beta_0}. \tag{3.4}$$

With the values (3.4), which apply to B of the form in Fig. 1(a), the expansion (2.20) for p is completely determined, and it can be written as follows in the open interval $\eta_0<\eta<\eta_2$:

$$\begin{aligned}p(\xi,\eta)\sim 1+e^{2\xi}\cos\beta&\left[\left(-2c\cot\beta-2\xi^2\beta'\sin\beta-\frac{2\beta'\cot 2\beta}{\sin^2\beta\cos\beta}\right)[y_0(\eta)-y_0(\eta_0)]\right.\\&\left.+2\xi\cos\beta+\frac{1}{\sin^2\beta}-\cot\beta\frac{1+\sin\beta_0}{\sin\beta_0\cos\beta_0}\right],\quad \eta_0<\eta<\eta_2.\end{aligned} \tag{3.5}$$

Near η_0 the leading edge boundary layer expansion (3.1) applies, and it is given in Ref. 2. Near η_2 the trailing edge boundary layer applies, and it is also given in Ref. 2. The expansion (3.5) and these two edge expansions determine p all along the illuminated or front side of a boundary such as that in Fig. 1(a).

Next we shall consider a nontrapping boundary of the form shown in Fig. 1(b), which has a single point η_1 at which $\beta(\eta_1)=0$, and two downstream edges at η_0 and η_2. The leading term $cA_1(\eta)$ in (2.20) can be made regular at η_1 by choosing $a_1=y_0(\eta_0)-y_0(\eta_1)$. Then (2.15) becomes

$$A_1(\eta)=-2\cot\beta(\eta)\int_{\eta_1}^{\eta}\cos\beta(\eta')d\eta'=-2\cot\beta(\eta)[y_0(\eta)-y_0(\eta_1)]. \tag{3.6}$$

By considering the limit of the integral as η tends to η_1, we find that

$$A_1(\eta_1)=-\frac{2}{\kappa(\eta_1)}. \tag{3.7}$$

Here $\kappa(\eta_1)=\beta'(\eta_1)$ is the curvature of B at η_1, which is assumed to be negative. Then $A_1(\eta_1)$ is finite and positive, so the leading term in (2.20) is finite and positive at η_1.

At the next order, c^0, (2.20) contains three terms. The first two are obviously finite at $\eta=\eta_1$. The third term, $A_0(\eta)$, given by (2.19), is proportional to $\cot\beta(\eta)$, which is singular at η_1. We expand its coefficient as follows for η near η_1:

$$\begin{aligned}a_0+\frac{1}{\sin\beta\cos\beta}+\beta'A_1\frac{\cot 2\beta}{\cos^3\beta}&=a_0+\left(\frac{1}{\beta}+O(\eta-\eta_1)\right)-\left(\frac{1}{\beta}+\frac{\beta''(\eta_1)}{2[\beta'(\eta_1)]^2}+O(\eta-\eta_1)\right)\\&=a_0-\frac{\beta''(\eta_1)}{2[\beta'(\eta_1)]^2}+O(\eta-\eta_1).\end{aligned} \tag{3.8}$$

This coefficient will vanish at $\eta=\eta_1$ if a_0 has the value

$$a_0=\frac{\beta''(\eta_1)}{2[\beta'(\eta_1)]^2}=\frac{\kappa'(\eta_1)}{2\kappa^2(\eta_1)}. \tag{3.9}$$

Then $A_0(\eta)$ has a finite limit at η_1.

By using (2.19) for A_0 with a_0 given by (3.9), and (3.6) for A_1, we can write (2.20) as follows:

$$\begin{aligned}p(\xi,\eta)\sim 1+e^{2\xi\cos\beta}\Bigg[&\left(-2c\cot\beta-2\xi^2\beta'\sin\beta-\frac{2\beta'\cot 2\beta}{\sin^2\beta\cos\beta}\right)[y_0(\eta)-y_0(\eta_1)]\\&+2\xi\cos\beta+\frac{1}{\sin^2\beta}+\frac{\kappa'(\eta_1)}{2\kappa^2(\eta_1)}\cot\beta\Bigg],\quad \eta_0<\eta<\eta_2.\end{aligned} \tag{3.10}$$

This expression is finite at η_1. Near the downstream end points η_0 and η_2, p is given by trailing edge boundary layer expansions like that given in Ref. 2. These expansions and (3.10) determine p all along the front side of a boundary such as that in Fig. 1(b), for which $\beta(\eta)$ vanishes at just one point η_1, where $\kappa(\eta_1)<0$. From (3.7) and (3.10) we find that at this point

$$p(0,\eta_1)-1\sim-\frac{2c}{\kappa(\eta_1)}. \tag{3.11}$$

IV. TRAPPING BOUNDARIES

When the boundary B is concave to the left, as in Fig. 2, it can trap particles in the region to the left of B and to the right of $x_0(\eta_0)$. We assume that $x_0(\eta_0)>x_2(\eta_0)$. Therefore, we expect p to be exponentially large in this region, just as it is within a closed boundary. Thus, we assume

that p contains a term of the form (1.4). In addition, we expect there to be a diffusive boundary layer along the upstream side of B. Thus we seek an asymptotic expansion for p to the left of B of the form

$$p\sim e^{2c[x-x_0(\eta_0)]}(ch_1+h_0)+1+e^{2\xi\cos\beta}\left\{cA_1(\eta)+2\xi\cos\beta+\xi^2\beta'\frac{\sin^2\beta}{\cos\beta}A_1(\eta)+A_0(\eta)\right\},$$

$$\eta_2>\eta>\eta_0,\quad \eta\neq\eta_1. \tag{4.1}$$

In (4.1), h_1 and h_0 are constants, so the first term satisfies the differential equation (1.1), satisfies the boundary condition (1.2), and is exponentially small for $x<x_0(\eta_0)$. Consequently, the other terms in (4.1) must satisfy (1.1), (1.2) and tend to 1 at $x=-\infty$. These are just the conditions used to determine the diffusive boundary layer expansion (2.20). Therefore the functions $A_1(\eta)$ and $A_0(\eta)$ are again given by (2.15) and (2.19), respectively.

We shall write (2.15) for A_1 with η_2 instead of η_0 as the end point of integration and we shall keep (2.19) for A_0 unchanged:

$$A_1(\eta)=2\cot\beta(\eta)\left(\int_\eta^{\eta_2}\cos\beta(\eta')d\eta'+a_1\right),\quad \eta\neq\eta_1, \tag{4.2}$$

$$A_0(\eta)=\cot\beta(\eta)\left[a_0+\frac{1}{\sin\beta\cos\beta}+\frac{\beta' A_1\cot 2\beta}{\cos^3\beta}\right],\quad \eta\neq\eta_1. \tag{4.3}$$

At η_1, where $\beta(\eta_1)=0$, these expressions are not valid, and we shall see below that they are singular there. As a consequence, the constants a_1 and a_0 may have different values for $\eta>\eta_1$ and $\eta<\eta_1$. We shall allow this possibility, but at the end of Sec. V we shall see that, in fact, they have the same values in both regions.

Now, as in Sec. III, we represent p near the farthest upstream edge at η_2 by an edge boundary layer expansion, and we match it to (4.1) for η near η_2. The first term in (4.1) is exponentially small at $x_0(\eta_2)$, so it plays no role in the matching. Therefore the analysis is exactly the same as that in Sec. III when the difference in the signs of $\beta(\eta_2)$ and $\beta(\eta_0)$ are taken into account. The result of the matching is

$$a_1=0,\quad a_0=-\frac{1-\sin\beta_2}{\sin\beta_2\cos\beta_2},\quad \beta_2=\beta(\eta_2). \tag{4.4}$$

Thus, A_1 and A_0 are completely determined in the interval $\eta_2>\eta>\eta_1$, and they are both singular at η_1. Therefore we next introduce a new boundary layer expansion in the neighborhood of η_1.

We define the boundary layer variable τ by

$$\tau=c^{1/2}(\eta-\eta_1). \tag{4.5}$$

Then we write the boundary layer expansion of p as

$$p\sim e^{2c[x-x_0(\eta_0)]}(ch_1+h_0)+1+\sum_{j=-1}^{3}c^{j/2}q^{(j)}(\xi,\tau). \tag{4.6}$$

The first term is regular at η_1, so it has been left unchanged. Only the diffusive boundary layer expansion has been modified. The differential equation satisfied by this expansion, which we call q, is (2.3), with ∂_η replaced by $c^{1/2}\partial_\tau$, while the boundary conditions (2.4) and (2.5) are unchanged. In (2.3), we write $\beta(\eta)=\beta(\eta_1+c^{-1/2}\tau)$, and then we expand $\cos\beta(\eta)$, $\sin\beta(\eta)$, $\kappa(\eta)$, and $\kappa'(\eta)$ in powers of $c^{-1/2}$, retaining terms up to c^{-2}.

The resulting equation for q is

$$q_{\xi\xi}-2q_{\xi}+c^{-1}[(\kappa_1^2\tau^2+\kappa_1)q_{\xi}+2\kappa_1\tau q_{\tau}+q_{\tau\tau}]+c^{-3/2}[(\kappa_1\kappa_1'\tau^3+\kappa_1'\tau)q_{\xi}+\kappa_1'\tau^2 q_{\tau}]$$
$$+c^{-2}\left[\tau^4\left(\frac{\kappa_1\kappa_1''}{3}+\frac{(\kappa_1')^2}{4}-\frac{\kappa_1^4}{12}\right)q_{\xi}+\left(\frac{\kappa_1''\tau^2}{2}-\xi\kappa_1^2\right)q_{\xi}+(\kappa_1''-\kappa_1^3)\,\frac{\tau^3}{3}\,q_{\tau}-2\xi\kappa_1^2\tau q_{\tau}\right.$$
$$\left.-2\xi\kappa_1 q_{\tau\tau}\right]+O(c^{-5/2})=0. \tag{4.7}$$

Here $\kappa_1=\kappa(\eta_1)$, $\kappa_1'=\kappa'(\eta_1)$, and $\kappa_1''=\kappa''(\eta_1)$. Similarly we expand $\cos\beta(\eta)$ in the boundary condition (2.4), and we get

$$q_{\xi}-2q+\left[c^{-1}\kappa_1^2\tau^2+c^{-3/2}\kappa_1\kappa_1'\tau^3+c^{-2}\tau^4\left(-\frac{\kappa_1^4}{12}+\frac{\kappa_1\kappa_1''}{3}+\frac{(\kappa_1')^2}{4}\right)+O(c^{-5/2})\right]q$$
$$=2+O(c^{-1}),\quad \text{at}\quad \xi=0. \tag{4.8}$$

Now we substitute the expansion for q, given by the final sum in (4.6), into (4.7) and (4.8). Then in each equation we equate coefficients of the first five powers of $c^{-1/2}$. From (4.7) we obtain, with $L=\partial_{\xi}^2-2\partial_{\xi}$,

$$Lq^{(3)}=0, \tag{4.9}$$

$$Lq^{(2)}=0, \tag{4.10}$$

$$Lq^{(1)}=-(\kappa_1^2\tau^2+\kappa_1)q_{\xi}^{(3)}-2\kappa_1\tau q_{\tau}^{(3)}-q_{\tau\tau}^{(3)}, \tag{4.11}$$

$$Lq^{(0)}=-[\kappa_1\kappa_1'\tau^3q_{\xi}^{(3)}+\kappa_1'\tau q_{\xi}^{(3)}+\kappa_1'\tau^2q_{\tau}^{(3)}]-[\kappa_1^2\tau^2q_{\xi}^{(2)}+\kappa_1q_{\xi}^{(2)}+2\kappa_1\tau q_{\tau}^{(2)}+q_{\tau\tau}^{(2)}] \tag{4.12}$$

$$Lq^{(-1)}=-\left[\tau^4\left(\frac{\kappa_1'\kappa_1''}{3}+\frac{(\kappa_1')^2}{4}-\frac{\kappa_1^4}{12}\right)q_{\xi}^{(3)}+\left(\frac{1}{2}\,\kappa_1''\tau^2-\xi\kappa_1^2\right)q_{\xi}^{(3)}+\left(\frac{\kappa_1''}{3}-\frac{\kappa_1^3}{3}\right)\tau^3q_{\tau}^{(3)}-2\xi(\kappa_1^2\tau q_{\tau}^{(3)}\right.$$
$$\left.+\kappa_1q_{\tau\tau}^{(3)})\right]-[\kappa_1\kappa_1'\tau^3q_{\xi}^{(2)}+\kappa_1'\tau q_{\xi}^{(2)}+\kappa_1'\tau^2q_{\tau}^{(2)}]-[\kappa_1^2\tau^2q_{\xi}^{(1)}+\kappa_1q_{\xi}^{(1)}+2\kappa_1\tau q_{\tau}^{(1)}+q_{\tau\tau}^{(1)}]. \tag{4.13}$$

From (4.8) we get at $\xi=0$, with $L_1=\partial_{\xi}-2$,

$$L_1q^{(3)}=0, \tag{4.14}$$

$$L_1q^{(2)}=0, \tag{4.15}$$

$$L_1q^{(1)}+\kappa_1^2\tau^2q^{(3)}=0, \tag{4.16}$$

$$L_1q^{(0)}+\kappa_1^2\tau^2q^{(2)}+\kappa_1\kappa_1'\tau^3q^{(3)}=2, \tag{4.17}$$

$$L_1q^{(-1)}+\kappa_1^2\tau^2q^{(1)}+\kappa_1\kappa_1'\tau^3q^{(2)}+\tau^4\left[\frac{1}{4}\,(\kappa_1')^2+\frac{\kappa_1\kappa_1''}{3}-\frac{\kappa_1^2}{12}\right]q^{(3)}=0. \tag{4.18}$$

In addition, (2.5) yields

$$q^{(j)}\to 0,\quad \text{as}\quad \xi\to-\infty. \tag{4.19}$$

The solution $q^{(3)}$ of (4.9) satisfying (4.14) and (4.19) is, with $B_3(\tau)$ arbitrary,

$$q^{(3)}(\xi,\tau)=B_3(\tau)e^{2\xi}. \tag{4.20}$$

We use (4.20) in (4.11), integrate from $\xi=-\infty$ to $\xi=0$, and use (4.16) to obtain the solvability condition

$$\tfrac{1}{2}B_3''+\kappa_1\tau B_3'+\kappa_1 B_3=0. \tag{4.21}$$

The solution of (4.21) is, with b_3 and d_3 arbitrary,

$$B_3(\tau)=b_3e^{-\kappa_1\tau^2}\int_0^\tau e^{\kappa_1u^2}du+d_3e^{-\kappa_1\tau^2}. \tag{4.22}$$

Since $d_3e^{-\kappa_1\tau^2}$ is exponentially small as $\tau\to\pm\infty$, it will play no role in the matching. This term may be viewed as an exponentially small correction to the first term in (4.6), and can thus be neglected.

Now that the solvability condition (4.21) is satisfied, (4.11) has a solution satisfying (4.16) and (4.19). To find it we use (4.20)–(4.22) to write (4.11) in the form

$$q^{(1)}_{\xi\xi}-2q^{(1)}_{\xi}=-2\kappa_1^2\tau^2\beta_3(\tau)e^{2\xi}. \tag{4.23}$$

The solution of (4.23) and the boundary conditions is, with $B_1(\tau)$ arbitrary,

$$q^{(1)}(\xi,\tau)=[-\kappa_1^2\tau^2B_3(\tau)\xi+B_1(\tau)]e^{2\xi}. \tag{4.24}$$

Similarly, the solution of (4.10), (4.15), and (4.19) is

$$q^{(2)}(\xi,\tau)=B_2(\tau)e^{2\xi}. \tag{4.25}$$

By using (4.20) and (4.25) in (4.12), integrating from $\xi=-\infty$ to $\xi=0$, and using (4.17), we get the solvability condition

$$\frac{1}{2}B_2''+\kappa_1\tau B_2'+\kappa_1B_2=-2-\kappa_1'\left(\frac{\tau^2}{2}B_3\right)'. \tag{4.26}$$

The solution $B_2(\tau)$ of (4.26) is, when we neglect the term $d_3e^{-\kappa_1\tau^2}$ in (4.22) for B_3,

$$B_2(\tau)=-\frac{2}{\kappa_1}+b_2e^{-\kappa_1\tau^2}\int_0^\tau e^{\kappa_1u^2}du-b_3\frac{\kappa_1'}{3}e^{-\kappa_1\tau^2}\int_0^\tau(\tau^3-u^3)e^{\kappa_1u^2}du+d_2e^{-\kappa_1\tau^2}. \tag{4.27}$$

Matching the boundary layer expansion with (4.1) requires that $b_2=0$, as we will verify in Sec. V. Thus, we set $b_2=0$, and we also take $d_2=0$ because it represents an exponentially small correction to the first term in (4.6), just like the d_3 term in (4.22),

$$B_2(\tau)=-\frac{2}{\kappa_1}-b_3\frac{\kappa_1'}{3}e^{-\kappa_1\tau^2}\int_0^\tau(\tau^3-u^3)e^{\kappa_1u^2}du. \tag{4.28}$$

Finally to determine $B_1(\tau)$ in (4.24), we use (4.28), (4.24), and (4.25) in (4.13), integrate from $\xi=-\infty$ to $\xi=0$, and use (4.18). After some calculation, we get the solvability condition

$$B_1'+2\kappa_1\tau B_1=-\frac{b_3}{2}\kappa_1^2\tau^2-\kappa_1'\tau^2B_2+(\kappa_1^3-\kappa_1'')\frac{\tau^3}{3}B_3. \tag{4.29}$$

The solution of (4.29) is

$$B_1(\tau)=b_1\int_0^\tau e^{\kappa_1(u^2-\tau^2)}du+\left(\frac{2\kappa_1'}{\kappa_1}-\frac{b_3}{2}\kappa_1^2\right)\int_0^\tau u^2e^{\kappa_1(u^2-\tau^2)}du+\frac{b_3}{12}(\kappa_1^3-\kappa_1'')$$
$$\times\int_0^\tau(\tau^4-u^4)e^{\kappa_1(u^2-\tau^2)}du+\frac{b_3}{18}(\kappa_1')^2\int_0^\tau(\tau^3-u^3)^2e^{\kappa_1(u^2-\tau^2)}du. \tag{4.30}$$

Now we have found the first three terms $q^{(3)}$, $q^{(2)}$, and $q^{(1)}$ in the boundary layer expansion (4.6) about the point η_1. They are given by (4.20), (4.24), and (4.25). In these results, B_3 is given by (4.22) with $d_3=0$ and b_3 undetermined, B_2 is given by (4.28), and B_1 by (4.30) with b_1 undetermined. In Sec. V, we will match (4.6) with (4.1) and thereby determine b_3 and b_1, as well as the values of a_1 and a_0 for $\eta<\eta_1$.

V. MATCHING THE EXPANSION ABOUT η_1 TO THE DIFFUSIVE BOUNDARY LAYER EXPANSION

The two expansions (4.1) and (4.6) both represent p on and near the front side of the boundary B. Therefore they must be asymptotically equal near η_1, where both of them are valid. Since the exponential function and the constant 1 are the same in both expansions, we need consider only the final terms, which describe the diffusive boundary layer. We begin by expanding the boundary layer terms in (4.1) for η near η_1. We set $\eta=\eta_1+c^{-1/2}\tau$, use this in (4.1), and expand in powers of $c^{-1/2}$. From (4.2), with $a_1=0$, we obtain

$$A_1(\eta)=A_1(\eta_1+c^{-1/2}\tau)\sim\frac{2sc^{1/2}}{\kappa_1\tau}-\left(\frac{2}{\kappa_1}+\frac{s\kappa_1'}{\kappa_1^2}\right)$$
$$+c^{-1/2}\tau\left(\frac{\kappa_1'}{\kappa_1^2}-\frac{s\kappa_1''}{3\kappa_1^2}-\frac{2s\kappa_1}{3}+\frac{s}{2}\frac{(\kappa_1')^2}{\kappa_1^3}\right)+O(c^{-1}). \tag{5.1}$$

Here

$$s=\int_{\eta_1}^{\eta_2}\cos\beta(u)du=y_0(\eta_2)-y_0(\eta_1). \tag{5.2}$$

Next, from (4.3) we get

$$A_0(\eta)=\frac{c^{3/2}}{\tau^3}\cdot\frac{s}{\kappa_1^2}-\frac{c}{\tau^2}\cdot\frac{s\kappa_1'}{2\kappa_1^3}+\frac{c^{1/2}}{\tau}\left(-\frac{s}{2}-\frac{\kappa_1'}{2\kappa_1^3}+\frac{a_0}{\kappa_1}\right)+O(1). \tag{5.3}$$

We also find that

$$e^{2\xi\cos\beta(\eta)}=e^{2\xi}(1-c^{-1}\xi\kappa_1^2\tau^2+O(c^{-2})), \tag{5.4}$$

$$2\xi\cos\beta=O(1), \tag{5.5}$$

$$\xi^2\beta'\sin^2\beta\,A_1(\eta)/\cos\beta=O(c^{-1/2}). \tag{5.6}$$

Now we combine (5.1), (5.3) and (5.4)–(5.6) to evaluate the boundary layer terms in (4.1):

$$e^{2\xi\cos\beta}\{cA_1+2\xi\cos\beta+\xi^2\beta'\sin^2\beta\,A_1/\cos\beta+A_0\}$$
$$\sim c^{3/2}e^{2\xi}s\left(\frac{2}{\kappa_1\tau}+\frac{1}{\kappa_1^2\tau^3}\right)$$
$$+ce^{2\xi}\left(-\frac{2}{\kappa_1}-\frac{s\kappa_1'}{\kappa_1^2}-\frac{s\kappa_1'}{2\kappa_1^3\tau^2}\right)+c^{1/2}e^{2\xi}\left[-s\xi\left(2\kappa_1\tau+\frac{1}{\tau}\right)+\frac{\kappa_1'\tau}{\kappa_1^2}\right.$$
$$\left.-s\tau\left(\frac{\kappa_1''}{3\kappa_1^2}+\frac{2\kappa_1}{3}-\frac{(\kappa_1')^2}{2\kappa_1^3}\right)+\frac{a_0}{\kappa_1\tau}-\frac{1}{2\tau}\left(s+\frac{\kappa_1'}{\kappa_1^3}\right)\right]. \tag{5.7}$$

This must match the sum $c^{3/2}q^{(3)}(\xi,\tau)+cq^{(2)}(\xi,\tau)+c^{1/2}q^{(1)}(\xi,\tau)$ in (4.6) when this sum is expanded for τ large and positive. Upon comparing powers of c we see that $q^{(3)}$, $q^{(2)}$, and $q^{(1)}$ must match the coefficients of $c^{3/2}$, c, and $c^{1/2}$ in (5.7), respectively. Since each $q^{(j)}$ is proportional to $e^{2\xi}$, this factor cancels out. Then, by using (4.20), (4.25), and (4.24), we can write the matching conditions for $\tau>0$ as follows:

$$B_3(\tau)\sim s\left(\frac{2}{\kappa_1\tau}+\frac{1}{\kappa_1^2\tau^3}\right),\quad \tau\to+\infty, \tag{5.8}$$

$$B_2(\tau)\sim-\frac{2}{\kappa_1}-\frac{s\kappa_1'}{\kappa_1^2}-\frac{s\kappa_1'}{2\kappa_1^3\tau^2}, \tag{5.9}$$

$$-\kappa_1^2\tau^2B_3(\tau)\xi+B_1(\tau)\sim\left[-s\xi\left(2\kappa_1\tau+\frac{1}{\tau}\right)+\frac{\kappa_1'\tau}{\kappa_1^2}-s\tau\left(\frac{\kappa_1''}{3\kappa_1^2}+\frac{2\kappa_1}{3}-\frac{(\kappa_1')^2}{2\kappa_1^3}\right)\right.$$
$$\left.+\frac{a_0}{\kappa_1\tau}-\frac{1}{2\tau}\left(s+\frac{\kappa_1'}{\kappa_1^3}\right)\right]. \tag{5.10}$$

To use (5.8), we expand the integral for B_3 in (4.22) for large τ to obtain

$$B_3(\tau)\sim b_3\left(\frac{1}{2\kappa_1\tau}+\frac{1}{4\kappa_1^2\tau^3}\right). \tag{5.11}$$

Upon using (5.11) in (5.8) we see that the two sides become identical when b_3 has the value

$$b_3=4s\equiv4\int_{\eta_1}^{\eta_2}\cos\,\beta(u)du. \tag{5.12}$$

Next we expand the integral in (4.28) for large τ to get

$$B_2(\tau)\sim-\frac{2}{\kappa_1}-b_3\kappa_1'\left(\frac{1}{4\kappa_1^2}+\frac{1}{8\tau^2\kappa_1^3}\right). \tag{5.13}$$

When b_3 has the value $4s$ given by (5.12), the expression (5.13) for B_2 matches exactly the right side of (5.9). This agreement also confirms that setting $b_2=0$ was correct.

Next we consider (5.10), and use (5.11) for B_3 on the left side with $b_3=4s$. Then the terms linear in ξ on the left side agree exactly with those linear in ξ on the right side. Now we expand $B_1(\tau)$, given by (4.30), for $\tau\to+\infty$. After a long calculation we get

$$B_1(\tau)\sim\tau\left[\frac{\kappa_1'}{\kappa_1^2}+b_3\left(-\frac{\kappa_1}{6}-\frac{\kappa_1''}{12\kappa_1^2}+\frac{(\kappa_1')^2}{8\kappa_1^3}\right)\right]+\frac{1}{\tau}\left[\frac{2b_1}{\kappa_1}+\frac{b_3}{8}-\frac{\kappa_1'}{2\kappa_1^3}\right]. \tag{5.14}$$

We now use (5.14) in (5.10) and set $b_3=4s$. The coefficients of τ match exactly, and those of τ^{-1} match when b_1 has the value

$$b_1=\frac{a_0-\kappa_1 s}{2}. \tag{5.15}$$

Here a_0 is given by (4.4), and s by (5.2). Thus b_1 is known, and the boundary layer about η_1 is completely determined through the terms in (4.6) with positive powers of $c^{1/2}$, i.e., $q^{(3)}$, $q^{(2)}$, and $q^{(1)}$ are determined.

Now for $\tau<0$, we must match this boundary layer to the boundary layer expansion in (4.1). The expansions of B_3, B_2, and B_1 that we have obtained for $\tau>0$ are also valid for $\tau<0$ because B_3 and B_1 are odd functions of τ and B_2 is an even function. The expansion (5.7) is also valid for both positive and negative τ, provided that $a_1=0$. Since the boundary layer expansion matched

(5.7) for $\tau>0$, it also matches for $\tau<0$, provided that a_1 and a_0 have the same values for $\tau<0$ as they do for $\tau>0$. Thus, these constants must also have the values given in (4.4) for $\tau<0$, i.e., for $\eta<\eta_1$.

Now we have completed the determination of the diffusive boundary layer expansion in (4.1). The functions A_1 and A_0 in it are given by (4.2) and (4.3), with a_1 and a_0 given by (4.4). Thus,

$$A_1(\eta)=2\cot\beta(\eta)\cdot\int_{\eta}^{\eta_2}\cos\beta(u)du=2\cot\beta(\eta)\cdot[y_0(\eta_2)-y_0(\eta)],\quad \eta\neq\eta_1, \tag{5.16}$$

$$A_0(\eta)=\cot\beta(\eta)\left[\frac{\sin\beta_2-1}{\sin\beta_2\cos\beta_2}+\frac{1}{\sin\beta\cos\beta}+\frac{\beta' A_1\cot 2\beta}{\cos^3\beta}\right],\quad \eta\neq\eta_1. \tag{5.17}$$

The expansion of p around η_1 is given by (4.6). We can rewrite it more fully through terms of order $c^{1/2}$, by using (4.20)–(4.28) and (5.12):

$$p\sim e^{2c[x-x_0(\eta_0)]}(ch_1+h_0)+1+e^{2\xi}\Bigg[(c^{3/2}-c^{1/2}\kappa_1^2\tau^2\xi)4se^{-\kappa_1\tau^2}$$
$$\times\int_0^{\tau}e^{\kappa_1 u^2}du-c\left(\frac{2}{\kappa_1}+\frac{4s\kappa_1'}{3}e^{-\kappa_1\tau^2}\int_0^{\tau}(\tau^3-u^3)e^{\kappa_1 u^2}du\right)+c^{1/2}B_1(\tau)\Bigg]. \tag{5.18}$$

The constant s is defined in (5.2) and B_1 is given by (4.30), with b_1 determined by (5.15).

The constants h_1 and h_0 are still undetermined.

VI. LOWER EDGE BOUNDARY LAYER AND DETERMINATION OF h_1

We now determine a boundary layer expansion near the lower edge at η_0, where the previous expansions are not valid. By matching it to (4.11), we shall determine the constant h_1 in (4.1). The constant h_0 can be found in the same way by continuing the procedure to the next order. As in Sec. III, we introduce $u=c(\eta-\eta_0)$, but instead of (3.1) we write

$$p(\xi,u)=1+cF_1(\xi,u)+F_0(\xi,u)+O(c^{-1}). \tag{6.1}$$

The term proportional to c is needed to match the term $ch_1e^{2c[x-x_0(\eta_0)]}$ in (4.1). Next, we change variables from η to u in (2.3) and (2.4), replacing ∂_η by $c\partial_u$ and writing $\beta(\eta)=\beta(\eta_0+c^{-1}u)$ $=\beta(\eta_0)+\beta'(\eta_0)c^{-1}u+O(c^{-2})$. Then we can write (2.3) and (2.4) as follows:

$$[\partial_\xi^2+\partial_u^2-2\cos\beta_0\partial_\xi+2\sin\beta_0\partial_u]p+c^{-1}[2u\kappa_0\sin\beta_0\partial_\xi-2\xi\kappa_0\sin\beta_0\partial_u+2\kappa_0 u\cos\beta_0\partial_u$$
$$+\kappa_0\partial_\xi-2\xi\kappa_0\partial_u^2]p+O(c^{-2})p=0, \tag{6.2}$$

$$[\partial_\xi-2\cos\beta_0+c^{-1}2\kappa_0 u\sin\beta_0+O(c^{-2})]p=0,\quad \text{at } \xi=0,\quad u>0. \tag{6.3}$$

Substituting (6.1) for p into (6.2) and (6.3), and equating coefficients of c in each equation, yields

$$[\partial_\xi^2+\partial_u^2-2\cos\beta_0\partial_\xi+2\sin\beta_0\partial_u]F_1(\xi,u)=0, \tag{6.4}$$

$$[\partial_\xi-2\cos\beta_0]F_1=0,\quad \text{at } \xi=0,\quad u>0. \tag{6.5}$$

The coefficients of c^0 give

$$[\partial_\xi^2+\partial_u^2-2\cos\beta_0\partial_\xi+2\sin\beta_0\partial_u]F_0(\xi,u)$$
$$=[2\xi\kappa_0\partial_u^2+2\xi\kappa_0\sin\beta_0\partial_u-2\kappa_0 u\cos\beta_0\partial_u-\kappa_0\partial_\xi-2\kappa_0 u\sin\beta_0\partial_\xi]F_1(\xi,u), \tag{6.6}$$

$$[\partial_\xi - 2\cos\beta_0]F_0 = 2\cos\beta_0 - 2\kappa_0 u \sin\beta_0 \cdot F_1, \quad \text{at } \xi=0, \quad u>0. \tag{6.7}$$

Now we expand p given by (4.1) for η near η_0 by writing $\eta=\eta_0+c^{-1}u$ and expanding in power of c^{-1}:

$$p-1\sim e^{2\xi\cos\beta_0}\left(1-\frac{2u\xi\kappa_0\sin\beta_0}{c}\right)\left\{e^{-2u\sin\beta_0}(ch_1+h_0)\left(1-\frac{u^2}{c}\kappa_0\cos\beta_0\right)+cA_1(\eta_0)\right.$$
$$\left.+uA_1'(\eta_0)+2\xi\cos\beta_0+\frac{\xi^2\kappa_0}{\cos\beta_0}\sin^2\beta_0 A_1(\eta_0)+A_0(\eta_0)\right\}. \tag{6.8}$$

We require that p given by (6.1) be asymptotically equal to p given by (6.8). Then, from the coefficients of c and c^0 we obtain

$$F_1(\xi,u)\sim e^{2\xi\cos\beta_0}\{h_1e^{-2u\sin\beta_0}+A_1(\eta_0)\}, \quad \text{as } u\to+\infty, \tag{6.9}$$

$$F_0(\xi,u)\sim e^{2\xi\cos\beta_0}\left\{-2u\xi\kappa_0\sin\beta_0(h_1e^{-2u\sin\beta_0}+A_1(\eta_0))+e^{-2u\sin\beta_0}(h_0-h_1u^2\kappa_0\cos\beta_0)\right.$$
$$\left.+A_1'(\eta_0)u+2\xi\cos\beta_0+\frac{\xi^2\kappa_0\sin^2\beta_0}{\cos\beta_0}A_1(\eta_0)+A_0(\eta_0)\right\}, \quad \text{as } u\to+\infty. \tag{6.10}$$

To find F_1 we write

$$F_1(\xi,u)=e^{\xi\cos\beta_0-u\sin\beta_0}G_1(\xi,u). \tag{6.11}$$

Then from (6.4) and (6.5) we get the following conditions on G_1:

$$(\partial_\xi^2+\partial_u^2-1)G_1=0, \tag{6.12}$$

$$(\partial_\xi-\cos\beta_0)G_1=0, \quad \text{at } \xi=0, \quad u>0. \tag{6.13}$$

A solution of (6.12) can be expressed in terms of K_0, the modified Bessel function, in the form

$$G_1(\xi,u)=(\partial_\xi+\cos\beta_0)\int_0^\infty \mathscr{G}_1(\omega)K_0([(u-\omega)^2+\xi^2]^{1/2})d\omega. \tag{6.14}$$

The function $\mathscr{G}_1(\omega)$ is arbitrary so far.

Substitution of (6.14) into the boundary condition (6.13) and the use of (6.12) yields

$$\left(-\frac{d^2}{du^2}+\sin^2\beta_0\right)\int_0^\infty \mathscr{G}_1(\omega)K_0(|\omega-u|)d\omega=0, \quad u>0,$$
$$\equiv\phi(u), \quad u<0. \tag{6.15}$$

The boundary condition holds for $u>0$, and we define $\phi(u)$ to be the value of the left side of (6.15) for $u<0$. The problem (6.15) for $\mathscr{G}_1(\omega)$ is of the Wiener–Hopf type, so to solve it we introduce the Fourier transforms,

$$\tilde{\mathscr{G}}_1(\alpha)=\int_0^\infty e^{i\alpha\omega}\mathscr{G}_1(\omega)d\omega, \quad \phi(\alpha)=\int_{-\infty}^0 e^{i\alpha\omega}\phi(\omega)d\omega. \tag{6.16}$$

Then we Fourier transform (6.15) to obtain

$$(\alpha^2+\sin^2\beta_0)\tilde{\mathscr{G}}_1(\alpha)\frac{\pi}{\sqrt{\alpha^2+1}}=\tilde{\phi}(\alpha). \tag{6.17}$$

From (6.16) we assume that $\tilde{\mathscr{G}}_1(\alpha)$ is analytic for Im $\alpha \geqslant \varepsilon_1$ and that $\tilde{\phi}(\alpha)$ is analytic for Im $\alpha \leqslant \varepsilon_2$, for some positive ε_1 and ε_2. Now we factor the denominator of (6.17) and rewrite (6.17) as

$$\frac{\pi(\alpha^2+\sin^2\beta_0)}{\sqrt{\alpha+i}}\,\tilde{\mathscr{G}}_1(\alpha)=\sqrt{\alpha-i}\,\tilde{\phi}(\alpha). \tag{6.18}$$

The right side of (6.18) is analytic for Im $\alpha \leqslant 1$ and the left side is analytic for Im $\alpha \geqslant |\sin\beta_0|$, so both sides are analytic for all α and are therefore equal to a constant D_1. Thus

$$\tilde{\mathscr{G}}_1(\alpha)=\frac{D_1\sqrt{\alpha+i}}{\pi(\alpha^2+\sin^2\beta_0)}. \tag{6.19}$$

Inverting the Fourier transform (6.16) then yields

$$\mathscr{G}_1(u)=\frac{D_1}{2\pi^2}\int_{\mathscr{C}}\frac{\sqrt{\alpha+i}}{(\alpha^2+\sin^2\beta_0)}\,e^{-i\alpha u}d\alpha. \tag{6.20}$$

We choose the contour $\mathscr{C}$ to be a horizontal line above the branch point at $\alpha=-i$ and above the two poles of the integrand, so on $\mathscr{C}$, Im $\alpha>|\sin\beta_0|$.

Now we use the solution (6.20) in (6.14) to get

$$G_1(\xi,u)=(\partial_\xi+\cos\beta_0)\,\frac{D_1}{2\pi^2}\int_{\mathscr{C}}\frac{\sqrt{\alpha+i}}{(\alpha^2+\sin^2\beta_0)}\int_0^\infty K_0([\xi^2+(u-\omega)^2]^{1/2})e^{-i\alpha\omega}d\omega d\alpha. \tag{6.21}$$

For $\omega<0$ we can evaluate the integral with respect to α by closing the contour $\mathscr{C}$ in the upper half-plane. Because of the regularity of the integrand above $\mathscr{C}$, we obtain

$$\int_{\mathscr{C}}e^{-i\alpha\omega}\,\frac{\sqrt{\alpha+i}}{\alpha^2+\sin^2\beta_0}\,d\alpha=0. \tag{6.22}$$

Therefore we can extend the ω integration to $-\infty$ in (6.21) without changing the value of the right side. Then we can evaluate the ω integral by setting $\omega=u-\zeta$. First we find that for $|\text{Im }\alpha|<1$,

$$\begin{aligned}\int_{-\infty}^{\infty}K_0([\xi^2+(u-\omega)^2]^{1/2})e^{-i\alpha\omega}d\omega&=\int_{-\infty}^{\infty}K_0([\xi^2+\zeta^2]^{1/2})e^{i\alpha\zeta}d\zeta\cdot e^{-i\alpha u}\\&=\frac{\pi e^{-|\xi|\sqrt{1+\alpha^2}}}{\sqrt{1+\alpha^2}}\cdot e^{-i\alpha u},\quad |\text{Im }\alpha|<1.\end{aligned} \tag{6.23}$$

By using (6.23) in (6.21), and choosing $\mathscr{C}$ so that Im $\alpha<1$ and also Im $\alpha>|\sin\beta_0|$, we get

$$G_1(\xi,u)=(\partial_\xi+\cos\beta_0)\,\frac{D_1}{2\pi}\int_{\mathscr{C}}\frac{e^{-i\alpha u-|\xi|\sqrt{1+\alpha^2}}}{(\alpha^2+\sin^2\beta_0)\sqrt{\alpha-i}}\,d\alpha,\quad |\sin\beta_0|<\text{Im }\alpha<1. \tag{6.24}$$

Finally, (6.11) and (6.24) yield the solution $F_1(\xi,u)$ explicitly, except for the undetermined constant D_1.

In order to use the matching condition (6.9) we must evaluate the integral in (6.24) for $u\to+\infty$. To do so we consider a parallel contour $\mathscr{C}'$ on which $-1<\text{Im }\alpha<-|\sin\beta_0|$. This contour lies below the two poles of the integrand, but above the branch point at $-i$. On it the factor $e^{-i\alpha u}$ has the absolute value $e^{-u|\text{Im }\alpha|}$, so the integral along $\mathscr{C}'$ tends to zero exponentially as $u\to+\infty$. Therefore to evaluate the integral along $\mathscr{C}$ in (6.24) we shift the contour to $\mathscr{C}'$ and evaluate the residues at the poles:

$$\int_{\mathscr{C}} \cdots d\alpha = \int_{\mathscr{C}'} \cdots d\alpha - 2\pi i[\mathrm{res}(i \sin \beta_0) + \mathrm{res}(-i \sin \beta_0)]$$

$$= \int_{\mathscr{C}'} \cdots d\alpha - \pi e^{i\pi/4} \frac{e^{\xi \cos \beta_0}}{\sin \beta_0} \left[\frac{e^{u \sin \beta_0}}{\sqrt{1-\sin \beta_0}} - \frac{e^{-u \sin \beta_0}}{\sqrt{1+\sin \beta_0}} \right]. \tag{6.25}$$

We substitute (6.25) for the integral in (6.24) and we use the result in (6.11) for F_1. For $u \to +\infty$ we can neglect the integral over $\mathscr{C}'$, and thus we obtain

$$F_1(\xi,u) \sim \cot \beta_0 (-D_1 e^{i\pi/4}) e^{2\xi \cos \beta_0} \left[\frac{1}{\sqrt{1-\sin \beta_0}} - \frac{e^{-2u \sin \beta_0}}{\sqrt{1+\sin \beta_0}} \right], \quad u \to +\infty. \tag{6.26}$$

Now we use (6.26) in the matching condition (6.9). The factor $e^{2\xi \cos \beta_0}$ cancels, and the remaining factors yield the equation

$$\cot \beta_0 (D_1 e^{i\pi/4}) \left[\frac{e^{-2u \sin \beta_0}}{\sqrt{1+\sin \beta_0}} - \frac{1}{\sqrt{1-\sin \beta_0}} \right] = h_1 e^{-2u \sin \beta_0} + A_1(\eta_0). \tag{6.27}$$

Equating the terms independent of u determines D_1 in terms of A_1, which is given by (5.16):

$$D_1 = -A_1(\eta_0) e^{-i\pi/4} \tan \beta_0 \sqrt{1-\sin \beta_0} = -2e^{-i\pi/4} \sqrt{1-\sin \beta_0} \int_{\eta_0}^{\eta_2} \cos \beta(\eta) d\eta. \tag{6.28}$$

Then equating the terms involving $e^{-2u \sin \beta_0}$ determines h_1:

$$h_1 = -2 \cot \beta_0 \sqrt{\frac{1-\sin \beta_0}{1+\sin \beta_0}} \int_{\eta_0}^{\eta_2} \cos \beta(\eta) d\eta = -2 \cot \beta_0 \sqrt{\frac{1-\sin \beta_0}{1+\sin \beta_0}} [y_0(\eta_2) - y_0(\eta_0)]. \tag{6.29}$$

Since $\beta_0 < 0$ we see that $h_1 > 0$.

This completes the determination of the leading terms in the edge boundary layer expansion, and in the coefficient of the exponential term in (4.1). It shows that h_1 is proportional to the width of the boundary B. The next term F_0 in the edge boundary layer expansion can be found by solving (6.6) and (6.7). Then the matching condition (6.10) will determine an arbitrary constant D_0 in the expression for F_0, and the constant h_0 in (4.1).

VII. THE SPECIAL CASE $x_0(\eta_0) = x_0(\eta_2)$

In the special case in which $x_0(\eta_0) = x_0(\eta_2)$, the preceding analysis does not apply. This is because we assumed that $x_0(\eta_0) > x_0(\eta_2)$ in treating the boundary layer at the upper edge. Then the first term in (4.1) was exponentially small at η_2, and played no role in the matching. When $x_0(\eta_0) = x_0(\eta_2)$ this term must be included in the matching, just as it was included at the lower edge η_0 in (6.8), which led to the matching condition (6.9) and ultimately to (6.27). When this term is included in the matching condition at the upper edge η_2, the following equation, analogous to (6.27), is obtained:

$$-\cot \beta_2 (D_1^* e^{-i\pi/4}) \left[\frac{e^{2w \sin \beta_2}}{\sqrt{1-\sin \beta_2}} - \frac{1}{\sqrt{1+\sin \beta_2}} \right] = h_1 e^{2w \sin \beta_2} + A_1(\eta_2). \tag{7.1}$$

Here D_1^* is the arbitrary constant multiplier in F_1 in the upper edge boundary layer expansion, analogous to D_1 in (6.26), and $w = c(\eta_2 - \eta)$.

We now equate terms independent of w in (7.1) and use (4.2) for A_1 to get

$$D_1^* = A_1(\eta_2) e^{i\pi/4} \tan \beta_2 \sqrt{1+\sin \beta_2} = 2e^{i\pi/4} a_1 \sqrt{1+\sin \beta_2}. \tag{7.2}$$

Then the terms proportional to $e^{2w \sin \beta_2}$ yield

$$h_1 = -D_1^* e^{-i\pi/4} \cot \beta_2 / \sqrt{1-\sin \beta_2} = -2a_1 \cot \beta_2 \sqrt{\frac{1+\sin \beta_2}{1-\sin \beta_2}}. \tag{7.3}$$

The constant a_1 in these equations is not yet determined. To determine it, and the constant D_1, we use (6.27).

Equating the terms independent of u in (6.27) yields the first equality in (6.28). Now $A_1(\eta_2)$ is given by (4.2) with $a_1 \neq 0$, so

$$D_1 = -2e^{-i\pi/4} \sqrt{1-\sin \beta_0} \left(\int_{\eta_0}^{\eta_2} \cos \beta(\eta) d\eta + a_1 \right). \tag{7.4}$$

Then the terms in (6.27) independent of u yield h_1 in terms of D_1. The use of (7.4) gives

$$h_1 = -2 \cot \beta_0 \sqrt{\frac{1-\sin \beta_0}{1+\sin \beta_0}} \left(\int_{\eta_0}^{\eta_2} \cos \beta(\eta) d\eta + a_1 \right). \tag{7.5}$$

Equating the two expressions (7.5) and (7.3) for h_1 gives an equation for a_1 that has the solution

$$a_1 = -\int_{\eta_0}^{\eta_2} \cos \beta(\eta) d\eta \left[1 - \frac{\tan \beta_0}{\tan \beta_2} \left(\frac{1+\sin \beta_2}{1-\sin \beta_2} \right)^{1/2} \left(\frac{1+\sin \beta_0}{1-\sin \beta_0} \right)^{1/2} \right]^{-1}. \tag{7.6}$$

By using (7.6) in (7.7) we get

$$h_1 = 2 \cot \beta_2 \left(\frac{1+\sin \beta_2}{1-\sin \beta_2} \right)^{1/2} \left[1 - \frac{\tan \beta_0}{\tan \beta_2} \left(\frac{1+\sin \beta_2}{1-\sin \beta_2} \right)^{1/2} \left(\frac{1+\sin \beta_0}{1-\sin \beta_0} \right)^{1/2} \right]^{-1} [y_0(\eta_2) - y_0(\eta_0)]. \tag{7.7}$$

With D_1^* given by (7.2) and D_1 by (7.4), the leading terms in the asymptotic expansion for p in the edge boundary layers are determined. The constant h_1 given by (7.7) completes the determination of the diffusive boundary layer in (4.1). The boundary layer around η_1, constructed in Sec. IV, was matched to the diffusive boundary layer in Sec. V with $a_1 = 0$. Since $a_1 \neq 0$ in the present case, it must be taken into account in the matching. Its effect is to change the value of s from that given in (5.2) to

$$s = \int_{\eta_1}^{\eta_2} \cos \beta(\eta) d\eta + a_1 = y_0(\eta_2) - y_0(\eta_0) + a_1. \tag{7.8}$$

Then p in that boundary layer is given by (5.18) with s determined by (7.8).

VIII. AXIALLY SYMMETRIC OBSTACLES

We consider an obstacle axially symmetric about the x axis, which is the direction of the advection velocity. We introduce cylindrical coordinates (y, φ, x), where y is radial distance from the x axis, which is the polar axis, and φ is the angle about the x axis. Because $p = 1$ at infinity and the obstacle B is symmetric about the x axis, the concentration p is independent of φ. Then (1.1) and (1.2) simplify to

$$p_{yy} + y^{-1} p_y + p_{xx} - 2c p_x = 0, \tag{8.1}$$

$$\partial_n p - 2c \cos \beta p = 0, \quad \text{on } B. \tag{8.2}$$

As before, β is the angle between the normal to the obstacle and the positive x axis.

Now we consider the curve of intersection of the obstacle with a plane containing the x axis, and we call it B. We write the equation of B as $[x_0(\eta), y_0(\eta)]$, where η is the arclength along B, measured from the x axis. We define σ and $\xi = c\sigma$ as in Sec. II, and we define $\beta(\eta)$ by (2.2). In these variables, (8.1) and (8.2) become

$$p_{\xi\xi}+[y_0(\eta)+c^{-1}\xi\sin\beta(\eta)]^{-1}[c^{-1}\sin\beta\, p_\xi+c^{-2}(1+c^{-1}\xi\kappa)^{-1}\cos\beta\, p_\eta]$$
$$+c^{-1}\kappa(1+c^{-1}\xi\kappa)^{-1}p_\xi+c^{-2}(1+c^{-1}\xi\kappa)^{-2}p_{\eta\eta}-c^{-3}\xi\kappa'(1+c^{-1}\xi\kappa)^{-3}p_\eta$$
$$-2[\cos\beta p_\xi-c^{-1}(1+c^{-1}\xi\kappa)^{-1}\sin\beta\, p_\eta]=0, \tag{8.3}$$

$$p_\xi-2\cos\beta\, p=0, \quad \text{at } \xi=0. \tag{8.4}$$

We seek a solution $p(\xi,\eta,c)$ of (8.3), (8.4), and (2.5). For c large and $\xi\leqslant 0$, we assume that p has an asymptotic expansion of the form (2.6). We substitute it into (8.3), (8.4), and (2.5) and equate coefficients of c and of c^0. The coefficients of c yield (2.7), (2.10), and (2.11) with $j=1$, so their solution for $Q^{(1)}(\xi,\eta)$ is (2.12). The coefficient of c^0 in (8.3) is

$$Q^{(0)}_{\xi\xi}-2\cos\beta\, Q^{(0)}_\xi=-\left(\kappa+\frac{\sin\beta}{y_0}\right)Q^{(1)}_\xi-2\sin\beta\, Q^{(1)}_\eta. \tag{8.5}$$

We use (2.12) for $Q^{(1)}$ in (8.5) and integrate the resulting equation from $\xi=-\infty$ to $\xi=0$. After making use of (2.10) and (2.11) with $j=0$, we obtain

$$A_1'+\left(\frac{\kappa}{\sin\beta\cos\beta}+\frac{1}{y_0\cos\beta}\right)A_1=-\frac{2\cos^2\beta}{\sin\beta}. \tag{8.6}$$

The solution of (8.6) is

$$A_1(\eta)=-2\cot\beta\left[\int_0^\eta\cos\beta(\eta')e^{\int_\eta^{\eta'}y_0^{-1}(\eta'')\sec\beta(\eta'')d\eta''}d\eta'+a_1e^{-\int^\eta y_0^{-1}(\eta')\sec\beta(\eta')d\eta'}\right]. \tag{8.7}$$

Substitution of (8.7) for $A_1(\eta)$ into (2.12) for $Q^{(1)}(\xi,\eta)$, and the use of (2.12) in (2.6) yields

$$p-1=ce^{2\xi\cos\beta}A_1(\eta)+O(1), \quad \xi\leqslant 0. \tag{8.8}$$

This is the leading-order term in the expansion of $p-1$, with $A_1(\eta)$ given by (8.7), in which the constant a_1 is undetermined. In general, the result (8.8) is not valid at $\eta=0$ or any other point η_1 where $\beta(\eta_1)=0$, since the factor $\cot\beta(\eta)$ in (8.7) becomes infinite there. However, if $\kappa(0)<0$, we can make (8.7) finite and positive there by setting $a_1=0$, and then (8.8) becomes

$$p(\xi,\eta)-1=-2ce^{2\xi\cos\beta(\eta)}\cot\beta(\eta)\int_0^\eta\cos\beta(\eta')e^{-\int_{\eta'}^\eta y_0^{-1}(\eta'')\sec\beta(\eta'')d\eta''}d\eta'+O(1), \quad \xi\leqslant 0. \tag{8.9}$$

At $\eta=0$ we find that $A_1(0)=-1/\kappa(0)$, so that

$$p(0,0)-1=-c/\kappa(0)+O(1). \tag{8.10}$$

The right side is positive when $\kappa(0)<0$, so (8.9) and (8.10) hold only in that case. The three-dimensional result (8.10), which gives $p-1$ on the axis, is smaller by a factor of $\frac{1}{2}$ than the two-dimensional result (3.11). It can be shown that in the axially symmetric case in N dimensions, $p-1$ on the axis is smaller by a factor of $1/(N-1)$ than the two-dimensional result (3.11).

When $\kappa(0)>0$, we must include exponential terms in the expansion and proceed as in Secs. IV–VI. We shall not carry out this calculation here.

A linearizing transformation for the Korteweg–de Vries equation; generalizations to higher-dimensional nonlinear partial differential equations

H. J. S. Dorren[a)]
Department of Electrical Engineering, Eindhoven University of Technology, P.O. Box 513, 5600 MB Eindhoven, The Netherlands

(Received 12 September 1997; accepted for publication 10 April 1998)

It is shown that the Korteweg–de Vries (KdV) equation can be transformed into an ordinary linear partial differential equation in the wave number domain. Explicit solutions of the KdV equation can be obtained by subsequently solving this linear differential equation and by applying a cascade of (nonlinear) transformations to the solution of the linear differential equation. It is also shown that similar concepts apply to the nonlinear Schrödinger equation. The role of symmetry is discussed. Finally, the procedure which is followed in the one-dimensional cases is successfully applied to find special solutions of higher-dimensional nonlinear partial differential equations. © *1998 American Institute of Physics.*

I. INTRODUCTION

Inverse scattering transformations (IST) form a powerful tool to solve certain classes of nonlinear partial differential equations (NPDEs). However, the success of the applicability of the IST is, modulo a few exceptions, limited to one-dimensional NPDEs only. This important limitation is caused by the fact that the IST uses the inverse problem of the Schrödinger equation to generate the solutions of the differential equations which have to be solved. The inverse problem of the Schrödinger equation is a well-studied problem in one dimension. Higher-dimensional NPDEs are rarely solved using inverse scattering techniques. There are a few reasons for the restricted applicability of inverse scattering methods in dimensions higher than one. The first reason is that higher-dimensional inverse scattering algorithms, like, for example, the Newton–Marchenko method (the inverse scattering problem of the Schrödinger equation in three-dimensions), are so complicated that is nearly impossible to apply these methods to real data. An alternative to the three-dimensional inverse scattering problem is given by the so-called $\bar{\partial}$ approach, which is successfully generalized to N dimensions (for an overview of the applications we refer to the book by Ablowitz and Clarkson[1]). But in applying the $\bar{\partial}$ approach, we readily face a second important restriction to the application of higher-dimensional inverse scattering methods. This restriction deals with the fact that for higher-dimensional inverse scattering methods the existence of the obtained solutions is difficult to prove. In one-dimensional cases this problem does not occur, since both the scattering data and the potential function depend on one single coordinate. In the three-dimensional case, where the scattering data depend on a three-component wave vector measured at a unit sphere, the five-dimensional data are mapped onto a three-dimensional potential function. As a result of this, in the three-dimensional inverse scattering problem two variables are redundant. The redundancy problem puts strong constraints on the classes of potential functions to be reconstructed and introduces additional complications in the application of inverse scattering methods for solving higher-dimensional NPDEs.

Another interesting and powerful approach which was successfully applied to other classes of NPDEs was developed by Calogero and Eckhaus.[2,3] It was shown by these authors that large classes of NPDEs can be transformed into linear partial differential equations by applying a cascade of limiting procedures involving rescaling techniques and asymptotic expansions. From now on we take over the Calogero terminology by denoting NPDEs which can be linearized using

a)Electronic mail: H.J.S.Dorren@ele.tue.nl

limiting procedures ''*C*-integrable NPDEs,'' whereas those NPDEs which can be solved using inverse scattering techniques are called ''*S* integrable.'' Calogero[2] suggested that because the limiting procedures mentioned above all preserve the integrability, perhaps one universal equation follows by limiting procedures form large classes (all?) NPDEs. Keeping this idea in mind, we can conclude that it is not clear how *S*-integrable NPDEs fit in this concept, since these equations can be transformed into a linear integral equation. There is another important point with respect to *C* integrability which should be mentioned. The concept of *C*-integrability is easily generalized to higher dimensions.[4] An implication of this generalization is that if it is possible to fit in the concept of *S* integrability into the concept of *C*-integrability, an effective method is obtained to find solutions of higher-dimensional NPDEs.

Without aiming to be general, it is shown in this paper that in one dimension *S*-integrable NPDEs are indeed *C*-integrable. We show how to find a cascade of transformations that transform *S*-integrable NPDEs into an ordinary linear differential equation. Moreover, it is shown that in one dimension, there exists a clear relationship between solutions of the linearized equation and the inverse scattering transformation. From the results obtained in this paper, it must be concluded that in one dimension *S* integrability is a special case of *C*-integrability. Moreover, it is shown that by generalizing the ordinary linear differential equation, large classes of other integrable NPDEs can be obtained. All the obtained NPDEs contain an amount of symmetry. This symmetry is also present in its linearization. The most simple example, the linearization of the KdV equation, is only invariant under Galileian transformations. The linearization of the nonlinear Schrödinger equation is also invariant under the SU(2) generators.

This paper has the following structure. In Sec. II we derive a linearization scheme for the KdV equation. We give explicitly the linearized partial differential equation and the cascade of transformation that leads to the KdV-equation. In Sec. III, we solve the linearized equations and derive explicit solutions of the KdV equation using the transformations discovered in Sec. II. As an explicit example, the soliton solutions are constructed. In Sec. IV, the relation of the linearization method and the IST is highlighted. It is shown that the IST can be regarded as a special case of the linearizing procedure described in Sec. II. In Sec. V, the relation between more general one-dimensional differential equations and a generalization of the linearization procedure of Sec. II is discussed. As an explicit example, the nonlinear Schrödinger equation is investigated. In Sec. VI the concepts of Sec. II are generalized to more dimensions. As an example the three-dimensional equivalent of the KdV equation is investigated. We conclude this paper with a discussion.

II. A LINEARIZING TRANSFORMATION FOR THE KORTEWEG-DE VRIES EQUATION

As a starting point we consider the KdV equation:

$$u_{xxx}+u_t=6u_xu, \qquad u(x,t=0)=u_0(x). \tag{1}$$

It is well known that the KdV equation can be transformed into a linear integral equation.[5,6] We can ask ourselves the question whether it is also possible to transform the KdV equation directly into a linear differential equation. Without loss of generality, we can decompose a solution $u(x,t)$ of Eq. (1) in an infinite series of functions:

$$u(x,t)=\sum_{n=1}^{\infty} f^{(n)}(x,t). \tag{2}$$

If it is possible to solve all the functions $f^{(n)}(x,t)$ which determine the solution $u(x,t)$ in Eq. (1), we have solved the KdV equation. In this section it is shown that all the functions $f^{(n)}(x,t)$ can be obtained by applying nonlinear transformations to the solution of a linear differential equation. In order to find this differential equation, we substitute Eq. (2) into Eq. (1). We then obtain the following result:

$$\sum_{n=1}^{\infty} f_{xxx}^{(n)}(x,t)+f_t^{(n)}(x,t)=6\sum_{n=1}^{\infty}\sum_{m=1}^{\infty} f_x^{(m)}(x,t)f^{(n)}(x,t),$$
$$\sum_{n=1}^{\infty} f^{(n)}(x,t=0)=\sum_{n=1}^{\infty} f_0^{(n)}(x). \tag{3}$$

Before we continue, we first have to explain the main concept used throughout this paper. The left-hand side of Eq. (3) describes a linear partial differential operator. The difficulties in solving the KdV equation, however, are related to the nonlinear nature of the right-hand side of Eq. (1). The presence of the nonlinear term makes that the standard techniques of substitution of special (exponential) solutions breaks down. We can overcome this problem by performing a perturbation theory. Instead of substituting a regular perturbation series $u(x,t)=\Sigma_{n=1}^{\infty}\epsilon^{(n)}f^{(n)}(x,t)$ into Eq. (1), and equalizing the different orders of ϵ, we treat in this paper the order n in Eq. (2) as the perturbation parameter. We can then find solutions of the differential equation by equalizing the sum of the perturbation parameter on both sides of Eq. (3). To illustrate this idea we take as an example the following solution:

$$u(x,t)=\sum_{n=1}^{\infty} A_n e^{in(kx-\omega t)}. \tag{4}$$

If we substitute, for example, the $n=2$ term of Eq. (4) onto the left-hand side of Eq. (3), we find that this contribution can be compared to the $n=1$ contribution on the right-hand side. If we substitute the full perturbation series, Eq. (4) into Eq. (1), is clear that there are always two equal orders on the right-hand side and the left-hand side which can be compared.

To implement this simple idea in a more general fashion (which is not valid for exponential solutions only) we proceed by equalizing the different orders of $f^{(n)}(x,t)$ in Eq. (3). If we collect the terms $f^{(n)}(x,t)$ of equal order (the sum of the upper indices of the nonlinear terms equals the upper index on the left-hand side), we obtain the following equations:

$$f_{xxx}^{(1)}(x,t)+f_t^{(1)}(x,t)=0,$$
$$f_{xxx}^{(2)}(x,t)+f_t^{(2)}(x,t)=6f_x^{(1)}(x,t)f^{(1)}(x,t),$$
$$f_{xxx}^{(3)}(x,t)+f_t^{(3)}(x,t)=6f_x^{(1)}(x,t)f^{(2)}(x,t)+6f_x^{(2)}(x,t)f^{(1)}(x,t), \tag{5}$$
$$f_{xxx}^{(4)}(x,t)+f_t^{(4)}(x,t)=6f_x^{(1)}(x,t)f^{(3)}(x,t)+6f_x^{(2)}(x,t)f^{(2)}(x,t)+6f_x^{(3)}(x,t)f^{(1)}(x,t),$$
$$\vdots$$

It is clear that if all the orders on the left-hand side of Eq. (5) and the right-hand side of Eq. (5) are summed up, Eq. (3) is retained. To deal with the nonlinearity in Eq. (5), it is convenient to introduce the following ansatz:

$$6f_x^{(n)}(x,t)f^{(m)}(x,t)=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} G(x,t|x',t')f^{(n+m)}(x',t')dx'dt'. \tag{6}$$

The ansatz given in Eq. (6) introduces a constraint on the space of all the possible functions $f^{(n)}(x,t)$. In the following section it will be shown that the solutions we obtain using the linearization method are more general than the solutions obtained using the IST. If we can construct a satisfactory kernel $G(x,t|x',t')$, we can solve all the equations in Eq. (6) simultaneously. If we substitute Eq. (6) into Eq. (5), we find that Eq. (5) transforms into

$$f^{(1)}_{xxx}(x,t)+f^{(1)}_{t}(x,t)=0;$$

$$f^{(2)}_{xxx}(x,t)+f^{(2)}_{t}(x,t)=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}G(x,t|x',t')f^{(2)}(x',t')dx'dt';$$

$$f^{(3)}_{xxx}(x,t)+f^{(3)}_{t}(x,t)=2\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}G(x,t|x',t')f^{(3)}(x',t')dx'dt';$$

$$\vdots \tag{7}$$

$$f^{(n)}_{xxx}(x,t)+f^{(n)}_{t}(x,t)=(n-1)\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}G(x,t|x',t')f^{(n)}(x',t')dx'dt';$$

$$\vdots$$

From this result we can conclude that we have transformed the KdV equation (1), by using the ansatz (6) and doing some bookkeeping, into an infinite series of equations which all have a similar structure. In order to solve the integration kernel $G(x,t|x',t')$, it is convenient to perform the remaining part of the analysis in the Fourier domain. The Fourier transform of $f^{(n)}(x,t)$ is given by

$$f^{(n)}(x,t)=\frac{1}{2\pi}\int_{-\infty}^{\infty}\tilde{f}^{(n)}(k)e^{ikz}dk, \quad z=x-\frac{\omega(k)}{k}t. \tag{8}$$

We first solve $f^{(1)}(x,t)$ because this is the solution of a linear partial differential equation. If Eq. (8) is applied on both sides of $f^{(1)}(x,t)$ in Eq. (7), we obtain the following relationship:

$$f^{(1)}_{xxx}(x,t)+f^{(1)}_{t}(x,t)=\frac{1}{2\pi}\int_{-\infty}^{\infty}i[\omega(k)-k^3]\tilde{f}^{(1)}(k)e^{ikz}dk=0. \tag{9}$$

It follows from Eq. (9) that nontrivial solutions $f^{(1)}(x,t)$ exist if the following dispersion relation is satisfied:

$$\omega(k)=-k^3. \tag{10}$$

It is remarkable to conclude that the function $f^{(1)}(x,t)$ constraints the dispersion relation of all the remaining equations given in Eq. (7). As a result of this, the Fourier transform of the left-hand side of all the equations is given in Eq. (7) can be computed simultaneously. We continue by computing the Fourier transform of the right-hand side of Eq. (7). To carry out this calculation, it is useful to assume that the integration kernel $G(x,t|x',t')$ is invariant under translations in time and space:

$$G(x,t|x',t')=G(x-x'|t-t'). \tag{11}$$

Our aim is to compute the Fourier transform $\mathcal{F}(\cdot)$ of the right-hand side of all the equations appearing in Eq. (7):

$$\mathcal{F}\left(\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}G(x-x'|t-t')f^{(n)}(x',t')dx'dt'\right). \tag{12}$$

To perform this computation, we first define the Fourier transform $\tilde{G}(k)$ of the integration kernel $G(x-x'|t-t')$:

$$G(x-x'|t-t')=\frac{1}{2\pi}\int_{-\infty}^{\infty}\tilde{G}(k)e^{ik[z-z']}dk. \tag{13}$$

The variable z in Eq. (13) is specified by Eq. (8). If Eq. (8) and Eq. (13) are substituted into Eq. (12) and if the integrations over z' and k' are carried out, we obtain the following result:

$$\mathcal{F}\left(\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} G(x-x'|t-t')f^{(n)}(x',t')dx'dt' \right) = \frac{1}{2\pi}\int_{-\infty}^{\infty} \tilde{G}(k)\tilde{f}^{(n)}(k)e^{ikz}dk. \tag{14}$$

Once the Fourier transform of both the left-hand side and the right-hand side of Eq. (7) are computed, we find by combining Eq. (7), Eq. (9), and Eq. (14) that

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} i[\omega(k)-k^3]\tilde{f}^{(n)}(k)e^{ikz}dk = (n-1)\frac{1}{2\pi}\int_{-\infty}^{\infty}\tilde{G}(k)\tilde{f}^{(n)}(k)e^{ikz}dk. \tag{15}$$

If we define

$$g^{(n)}(z,k) = \tilde{f}^{(n)}(k)e^{ikz}, \tag{16}$$

we find that a solution of $g^{(n)}(z,k)$ is given by the following differential equation:

$$\frac{d}{dz}g^{(n)}(z,k) + ikq^{(n)}(z,k) = (n-1)S(k)g^{(n)}(z,k), \quad S(k) = -\frac{\tilde{G}(k)}{k^2}. \tag{17}$$

From this final result, it follows that the cascade of equations given by Eq. (7) in the Fourier domain is equivalent with

$$\begin{aligned}
&\frac{d}{dz}g^{(1)}(z,k) + ikg^{(1)}(z,k) = 0;\\
&\frac{d}{dz}g^{(2)}(z,k) + ikg^{(2)}(z,k) = S(k)g^{(2)}(z,k);\\
&\frac{d}{dz}g^{(3)}(z,k) + ikg^{(3)}(z,k) = 2S(k)g^{(3)}(z,k);\\
&\vdots\\
&\frac{d}{dz}g^{(n)}(z,k) + ikg^{(n)}(z,k) = (n-1)S(k)g^{(n)}(z,k);\\
&\vdots
\end{aligned} \tag{18}$$

From this simple derivation we can conclude that in the Fourier domain the KdV equation can be linearized into an ordinary linear differential equation. If this differential equation is solved we can retain a solution of the KdV equation by using Eq. (6). Explicit solutions of the KdV equation can be computed by solving the following problem:

$$\begin{aligned}
&\frac{d}{dz}g^{(n)}(z,k) + ikg^{(n)}(z,k) = (n-1)S(k)g^{(n)}(z,k),\\
&6f_x^{(n)}(x,t)f^{(m)}(x,t) = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} G(x-x'|t-t')f^{(n+m)}(x',t')dx'dt'.
\end{aligned} \tag{19}$$

With this result we have shown that the KdV equation can be transformed into an ordinary linear differential equation. The second equation in Eq. (19) defines a constraint on the solutions $f^{(n)}(x,t)$.

In the following section the equations given above will be solved and solutions of the KdV equation will be computed. The solutions which are obtained by using the linearization method

described above are more general than the solutions obtained using an inverse scattering approach, because the method also applies to nonexponential functions $f^{(n)}(x,t)$. It follows from Eq. (3) that the method introduced in this paper can also be applied if the functions $f^{(n)}(x,t)$ are polynomials. In the following sections it will be shown explicitly that solutions obtained by the IST form a special subclass of the solutions which can be obtained by the linearization method. An important conclusion that already can be drawn from the results of this section is that the linearization method can easily be generalized to higher dimensions. This will be demonstrated later in this paper. It can be concluded from the approach followed in this section that there are two important factors which determine the transformations from the linear ordinary differential equation to the nonlinear partial differential equation. The first factor is the dispersion relation. The dispersion relation defines the linear part of the nonlinear partial differential equation. The second factor is the ansatz given in Eq. (6) which deals with the nonlinearity. By modifying the dispersion relation and the ansatz (6), it is possible to construct other NPDEs which can be linearized into a similar form as presented in Eq. (19). It is an interesting puzzle to find out whether there are other equations (not in the KdV hierarchy) which can be linearized using a similar approach as presented in this paper. In general, one can expect that the method presented in this paper can be used to find solutions of NPDEs for which the nonlinear part consists of a power series. For investigating the integrability of these equations, it is not necessary to find a suitable Lax pair. Explicit examples are given in following sections in which it is shown that generalizations of Eq. (19) can be transformed into other S-integrable NPDEs. For example, it is shown that the nonlinear Schrödinger equation can be linearized into a similar form as given in Eq. (19). Apparently symmetry plays an important role in the linearization process of NPDEs. The linearization of the KdV equation is invariant under Galileian transformations. This invariance is already known for a long time[7] but can be used here to consider the concept of integrability from a different point of view. The Galileian invariance can be regarded as the most simple symmetry in the hierarchy of equations which will follow. This Galileian invariance also explains the presence of solitons. If we introduce more symmetry in the linearized differential equation, we obtain that the linear differential equation can be transformed into more complicated NPDEs.

III. SOLUTIONS OF THE KDV EQUATION
