(Received 28 April 1997; accepted for publication 5 September 1997)

We discuss the algebraic way of solving the descent equations corresponding to the BRST consistency condition for the gauge anomalies and the Chern–Simons terms on a nontrivial bundle. The method of decomposing the exterior space–time derivative as a BRST commutator is extended to the present case. © *1998 American Institute of Physics.* [S0022-2488(98)00607-0]

I. INTRODUCTION

Recently, a new method for solving the descent equations corresponding to the BRST consistency condition for anomalies and generalized Chern–Simons terms has been successfully proposed.[1] This method, originally developed for trivial bundles and flat space–time, relies on the introduction of an algebraic operator which allows us to decompose the exterior derivative as a BRST commutator. This important property has been shown to give a very simple and elegant way of obtaining solutions of the consistency condition. Moreover, these solutions have been proven[2] to be cohomological equivalent to those provided by the so called *Russian formula*.[3–6]

Our aim in the present work is to extend the previous algebraic setup to nontrivial bundles, allowing thus for curved space-time and global properties. Although the method can be applied to several field models, including the gravitational anomalies[7,8] and the topological field theories,[9,10] we shall consider here, as an explicit example, the case of a non-Abelian gauge theory of the Yang–Mills type. We shall focus, in particular, on the algebraic characterization of the gauge anomalies and of the generalized Chern–Simons terms defined on nontrivial bundles.

However, before going any further, let us make some useful remarks on the functional space which shall be used in order to define the BRST differential. In what follows we shall work in the functional space of the local form-polynomials built up essentially with the one-form gauge connection A, the zero form Faddeev–Popov ghost field c and their exterior derivatives. This means that we shall restrict ourselves to the space of the local polynomials constructed by taking suitable exterior products of (A, c, dA, dc), d denoting the space–time differential. As it is well known, this functional space is not the most general space which can be assumed for the BRST differential, as it does not span the set of solutions of the BRST cohomology which explicitly contains the space–time metric, as for instance terms of the Yang–Mills type $F\wedge *F^2$. (The symbol * denotes the usual Hodge operation.) Nevertheless, the space of form-polynomials is known to be sufficiently large in order to include all nontrivial solutions of the descent equations which turn out to be independent of the metric. In fact, as proven by Refs. 11–13, these solutions are exactly given by the gauge anomalies and the Chern–Simons terms which are known to be written in terms of pure differential forms. In addition, being the latters integrated forms of maximum degree, they are left invariant by diffeomorphism transformations. Let us also underline that the present analysis is particularly adapted to the case of the topological theories of the Schwartz type[9] which, being related to a zero curvature condition,[14] can be naturally formulated in terms of form-field polynomials.

The paper is organized as follows. In Sec. II we briefly recall some well-known properties of the nontrivial bundles. Sections III and IV are devoted to the introduction of the BRST differential and of the decomposition of the exterior derivative as a BRST commutator. Finally, in Secs. V and VI we deal with the solutions of the descent equations on nontrivial bundles.

II. GAUGE CONNECTIONS ON NONTRIVIAL BUNDLES

In order to discuss the global structure of the gauge anomalies let us recall some properties of the gauge connections defined on a principal bundle $P(M,G)$, M being an arbitrary space–time base manifold M_{2k-2} of even dimension $(2k-2)$ and G a compact Lie group. (A general introduction to the theory of bundles can be found in Refs. 15 and 16.)

Connections on $P(M,G)$ are locally represented by Lie algebra valued one-forms,

$$A=A_\mu dx^\mu=A^a T^a=A^a_\mu dx^\mu T^a, \tag{1}$$

where T^a are the anti-Hermitian generators of G,

$$[T^a,T^b]=f^{abc}T^c, \quad \mathrm{Tr}(T^aT^b)=\delta^{ab}, \tag{2}$$

f^{abc} being the totally antisymmetric structure constants. The associated two-form field strength is given by

$$F=\tfrac{1}{2}F_{\mu\nu}dx^\mu dx^\nu=dA+A^2=dA+\tfrac{1}{2}\{A,A\}, \tag{3}$$

where a wedge product has to be understood. It obeys the Bianchi identity

$$DF=dF+[A,F]=0, \tag{4}$$

where $D=dx^\mu D_\mu$ is the covariant exterior derivative with respect to the gauge field A and $d=dx^\mu\partial_\mu$ is the exterior space–time derivative.

Gauge transformations of $P(M,G)$ on M are locally represented by means of a G-valued gauge connection A_μ transforming as

$$\delta_G A_\mu=-D_\mu\Omega=-\partial_\mu\Omega-[A_\mu,\Omega], \tag{5}$$

where Ω is a G-valued infinitesimal gauge parameter.

Infinitesimal diffeomorphisms on M are represented by vector fields v^μ. They form an infinite dimensional Lie algebra on M, denoted by $\mathrm{Diff}(M)$. The gauge field transforms under the infinitesimal diffeomorphisms as a vector, i.e.,

$$\delta_D A_\mu=-L_v A_\mu=-v^\nu\partial_\nu A_\mu-(\partial_\mu v^\nu)A_\nu, \tag{6}$$

where L_v denotes the Lie derivative along the infinitesimal vector field v^μ. The inner derivative i_v with respect to the vector field v^μ is defined as usual by

$$i_v dx^\mu=v^\mu. \tag{7}$$

As it is well-known, the inner derivative i_v, the Lie derivative L_v and the exterior derivative d form an infinite dimensional graded Lie subalgebra

$$\begin{aligned}
&\{i_v,i_{v'}\}=0, \quad [L_v,i_{v'}]=i_{[v,v']},\\
&\{i_v,d\}=L_v, \quad [L_v,L_{v'}]=L_{[v,v']},\\
&[L_v, \quad d]=0,\{d,d\}=0,
\end{aligned} \tag{8}$$

with $(v,v')\in\mathrm{Diff}(M)$.

Let us come now to the global properties of a principle bundle. A bundle is called trivial if it has the form $P=M\times G$. Bundles over contractible base manifolds M are trivial.[15,16] In the case of a trivial bundle the set of fields introduced so far is sufficient in order to describe the algebraic

structure of the gauge anomalies. However, as shown in Ref. 3, for the case of a nontrivial bundle one has to introduce a further gauge field, called the reference gauge connection $\mathring{A}$. Such a new connection is chosen to be a fixed background field, due to the fact that the action of v on A is defined only up to a gauge transformation. With the help of the reference connection $\mathring{A}$, all vector fields v on M can be lifted to G. Again, the infinitesimal gauge transformations form an infinite dimensional Lie algebra, now denoted by $\tilde{g}$. Let U be an open trivializing subset of M, $U \subset M$. Then the elements of $\tilde{g}$ are represented on U by pairs of parameters (Ω, v)

$$\Omega \in \Lambda^0(U,g), \quad v \in \mathrm{Diff}(U), \tag{9}$$

where Λ^0 denotes the space of zero-forms with values in the Lie algebra g of G. The reference connection is locally represented by the one-form $\mathring{A}$ on U with values in g,

$$\mathring{A} = \mathring{A}_\mu dx^\mu \in \Lambda^1(U,g). \tag{10}$$

The pairs of parameters obey the commutation relations

$$\begin{aligned}
&[(\Omega',0),(\Omega,0)] = ([\Omega',\Omega],0),\\
&[(0,v'),(0,v)] = (i_{v'} i_v \mathring{F},[v',v]),\\
&[(0,v),(\Omega,0)] = (-L_v\Omega - [i_v \mathcal{A},\Omega],0),
\end{aligned} \tag{11}$$

where $\mathring{F}$ is the two-form field strength associated to $\mathring{A}$,

$$\mathring{F} = \tfrac{1}{2}\mathring{F}_{\mu\nu} dx^\mu dx^\nu = d\mathring{A} + \mathring{A}^2 = d\mathring{A} + \tfrac{1}{2}\{\mathring{A},\mathring{A}\}, \tag{12}$$

which fulfills the Bianchi identity

$$\mathring{D}\mathring{F} = d\mathring{F} + [\mathring{A},\mathring{F}] = 0. \tag{13}$$

The reference connection $\mathring{A}$ ensures that the commutators can be patched together in a consistent way on the overlap $U \cap U'$ of two open subsets U and U' of M. This is achieved by replacing the exterior derivative d in the Lie derivative L_v by the covariant exterior derivative $\mathring{D}$. In fact, one has

$$[(0,v),(\Omega,0)] = (-\mathring{\mathcal{L}}_v\Omega,0), \tag{14}$$

with $\mathring{\mathcal{L}}_v = i_v\mathring{D} + \mathring{D}i_v$. Note that the ordinary Lie derivative L_v in (6) can be rewritten as $L_v = i_v d + d i_v$.

Different reference connections $\mathring{A}$ on P yield isomorphic Lie algebras $\tilde{g}$. Note that the pure gauge transformations $(\Omega,0)$ form an ideal of $\tilde{g}$, while the transformations with respect to the vector fields $(0,v)$ in general do not form a subalgebra of $\tilde{g}$.

Moreover, if the bundle P is trivial, one can choose $U = M$ and $\mathring{A} = 0$. Then $\tilde{g}$ is the semi-direct product of $\Lambda^0(M,g)$ and $\mathrm{Diff}(M)$, meaning that every nontrivial bundle is locally trivial.

The affine space of all connections on P carries an affine representation $\mathcal{R}$ of $\tilde{g}$ given locally by

$$\mathcal{R}(\Omega,v)A = -D(\Omega + i_v(A - \mathring{A})) - i_v F, \tag{15}$$

where $A,\mathring{A}\in\Lambda^1(U,g)$ are the local expressions on U of the connections on P and D is the covariant exterior derivative with respect to A. [$\Lambda^1(U,g)$ denotes the space of the one-forms with values in the Lie algebra g.] Finally, by definition, the fixed reference connection $\mathring{A}$ does not transform under $\tilde{g}$,

$$\mathcal{R}(\Omega,v)\mathring{A}=0. \tag{16}$$

III. THE BRST TRANSFORMATIONS

In order to introduce the BRST differential s, let us replace, as usual, the infinitesimal parameters (Ω,v) introduced in the previous section with Grassmann ghost fields. We will introduce therefore two ghost fields, c and ξ^μ, associated to the gauge and to the diffeomorphism transformations, respectively. Both ghosts have form degree zero and ghost number one.

Concerning the BRST transformations[17] of the various fields and ghosts, we proceed by making use of the so-called Maurer–Cartan horizontality conditions.[5,6] For this purpose we define the nilpotent differential operator of total degree one,

$$\tilde{d}=d-s, \quad \tilde{d}^2=0, \tag{17}$$

where d is the exterior derivative. (The total degree is defined as the sum of the form degree and of the ghost number.) Furthermore, we define the generalized gauge connection[5,6] according to

$$\tilde{A}=A+c+i_\xi(A-\mathring{A}), \tag{18}$$

with i_ξ as the inner derivative with respect to the diffeomorphism ghost ξ^μ,

$$i_\xi dx^\mu=\xi^\mu. \tag{19}$$

The generalized reference connection is simply given by

$$\mathring{\tilde{A}}=\mathring{A}, \tag{20}$$

expressing the fact that $\mathring{A}$ is a fixed background field which does not transform.

The corresponding generalized field strengths of total degree two are given by

$$\tilde{F}=\tilde{d}\tilde{A}+\tilde{A}^2 \quad \text{and} \quad \mathring{\tilde{F}}=\tilde{d}\mathring{\tilde{A}}+\mathring{\tilde{A}}^2, \tag{21}$$

and obey the generalized Bianchi identities

$$\tilde{D}\tilde{F}=\tilde{d}\tilde{F}+[\tilde{A},\tilde{F}]=0 \quad \text{and} \quad \mathring{\tilde{D}}\mathring{\tilde{F}}=\tilde{d}\mathring{\tilde{F}}+[\mathring{\tilde{A}},\mathring{\tilde{F}}]=0, \tag{22}$$

with $\tilde{D}$ and $\mathring{\tilde{D}}$ the generalized covariant exterior derivatives with respect to $\tilde{A}$ and to $\mathring{\tilde{A}}$.

The Maurer–Cartan horizontality conditions can then be expressed by

$$\tilde{F}=\tfrac{1}{2}F_{\mu\nu}\tilde{d}x^\mu\tilde{d}x^\nu, \quad \mathring{\tilde{F}}=\tfrac{1}{2}\mathring{F}_{\mu\nu}\tilde{d}x^\mu\tilde{d}x^\nu, \tag{23}$$

with $\tilde{d}x^\mu$ the generalized differential of degree one,

$$\tilde{d}x^\mu=dx^\mu+\xi^\mu. \tag{24}$$

Expanding these conditions according to the ghost number and the form degree one gets the following set of nilpotent BRST transformations:

$$sc = c^2 - \mathring{\mathcal{L}}_\xi c + \tfrac{1}{2} i_\xi i_\xi \mathring{F},$$

$$sA = D(c + i_\xi (A - \mathring{A})) - i_\xi F, \quad s\mathring{A} = 0, \tag{25}$$

$$sF = [(c + i_\xi (A - \mathring{A})), F] - \mathcal{L}_\xi F, \quad s\mathring{F} = 0,$$

where $\mathcal{L}_\xi = i_\xi D - D i_\xi$ and $\mathring{\mathcal{L}}_\xi = i_\xi \mathring{D} - \mathring{D} i_\xi$ are the covariant Lie derivatives with respect to A and $\mathring{A}$, respectively. [Notice that the relative sign in the definition of the Lie derivatives has now been changed due to the fact that ξ is an odd variable, carrying ghost number one. This implies that i_ξ is even and that $\mathcal{L}_\xi$, $\mathring{\mathcal{L}}_\xi$ have odd degree.] The above BRST transformations are completed by giving the transformation of the diffeomorphism ghost,

$$s\xi^\mu = -\xi^\nu \partial_\nu \xi^\mu. \tag{26}$$

Instead of the ghost c it turns out to be more useful to use the following combination:

$$\hat{c} = c + i_\xi (A - \mathring{A}), \tag{27}$$

as the basic variable. In terms of the new variable $\hat{c}$, the BRST transformations read now as

$$s\xi^\mu = -\xi^\nu \partial_\nu \xi^\mu, \quad s\hat{c} = \hat{c}^2 - \hat{F},$$

$$sA = D\hat{c} - i_\xi F, \quad s\mathring{A} = 0, \tag{28}$$

$$sF = [\hat{c}, F] - \mathcal{L}_\xi F, \quad s\mathring{F} = 0,$$

with $\hat{F}$ defined as

$$\hat{F} = \tfrac{1}{2} i_\xi i_\xi F. \tag{29}$$

Notice, finally, that $\hat{F}$ has form degree zero, ghost number two, and that it transforms covariantly, i.e.,

$$s\hat{F} = [\hat{c}, \hat{F}]. \tag{30}$$

IV. DECOMPOSITION FORMULA AND ALGEBRAIC RELATIONS

As already remarked in the Introduction and as done in previous works,[1,8] we shall assume that the functional space the BRST operator will act upon is identified with the space of form-polynomials constructed out of the variables $(\xi^\mu,\ c,\ A - \mathring{A})$ and the differentials $(d\xi^\mu,\ dc,\ dA,\ d\mathring{A})$. Of course, on the local space of form-polynomials this set of variables can be always replaced by the equivalent basis given by $(\xi^\mu,\ d\xi^\mu,\ \hat{c},\ \mathring{D}\hat{c},\ (A - \mathring{A}),\ F,\ \mathring{F})$. The presence of the covariant derivative $\mathring{D}$ and of the curvatures $(F,\ \mathring{F})$ yields an easy understanding of the latter choice, which turns out to be more convenient in order to solve the BRST consistency condition. We remark also that the use of the combination $(A - \mathring{A})$ relies on the fact that it emerges rather naturally in the BRST transformations (28) and in the formula (27). Let us recall, finally, that the space of form-polynomials is the most suitable choice in order to discuss the anomalies and the Chern–Simons terms, which, as it is well known, can be written in terms of differential forms.[11–13]

Let us now introduce an operator δ of total degree zero defined in the following way:[1,8]

$$\delta\xi^\mu = -dx^\mu, \quad \delta\varphi = 0, \quad \text{for } \varphi = (c, A, \mathring{A}, F, \mathring{F}). \tag{31}$$

From the above expression one sees that δ increases the form degree and decreases the ghost number by one unit, respectively, and that it acts only on the diffeomorphism ghost. The usefulness of the operator δ relies on the fact that it allows us to decompose the covariant exterior space–time derivative $\mathring{D}$ as a BRST commutator. In fact, we have

$$[s,\delta]=-\mathring{D}. \tag{32}$$

Let us remark that the presence of the covariant derivative $\mathring{D}$ in Eq. (32) makes all the difference with respect to the case of a trivial bundle, where only the ordinary exterior space–time derivative d appears. The operators $(s,\ \delta,\ \mathring{D})$ give rise to the following algebraic relations:

$$\begin{gathered}
[s,\delta]=-\mathring{D},\quad [\mathring{D},\delta]=[d,\delta]=2\mathcal{G},\\
\{s,\mathring{D}\}=\{s,d\}=s^2=d^2=0,\quad [\mathcal{G},\delta]=0,\\
\{\mathcal{G},\mathring{D}\}=\{\mathcal{G},d\}=0,\quad \mathcal{G}\mathcal{G}=0,\quad \{\mathcal{G},s\}=\mathcal{K}=\mathring{D}\mathring{D},\quad [\mathcal{K},s]=0,\\
[\mathcal{K},\mathring{D}]=[\mathcal{K},d]=0,\quad [\mathcal{K},\delta]=0,\quad [\mathcal{K},\mathcal{G}]=0,
\end{gathered} \tag{33}$$

where the operator $\mathcal{G}$ is defined as

$$\mathcal{G}\hat{c}=\mathring{F},\quad \mathcal{G}\varphi=0,\quad \text{for}\ \ \varphi=(\xi^\mu,d\xi^\mu,\mathring{D}\hat{c},(A-\mathring{A}),F,\mathring{F}). \tag{34}$$

It decreases the ghost number by one unit and increases the form degree by two units, hence it is an operator of total degree one.

Let us also note that in the case of a trivial bundle $(\mathring{A}=0)$ the operator $\mathcal{G}$ is absent. This is consistent with the results found in Ref. 8. In other words, its presence is related to the global properties of the bundle.

V. COHOMOLOGY AND DESCENT EQUATIONS

It is well-known that the search of the anomalies and of the generalized Chern–Simons actions corresponding to a given set of field transformations can be done in a purely algebraic way by solving the BRST consistency conditions in the space of the integrated local field polynomials.

This leads to the study of the nontrivial solutions of the following cohomology problem:

$$s\Delta=0,\quad \Delta\neq s\overline{\Delta}, \tag{35}$$

where Δ and $\overline{\Delta}$ are integrated local field polynomials. Setting $\Delta=\int \mathcal{Q}_n^g$, the condition (35) translates at the nonintegrated level as

$$s\mathcal{Q}_n^g+d\mathcal{Q}_{n-1}^{g+1}=0, \tag{36}$$

where $\mathcal{Q}_n^g$ is some local polynomial in the fields with ghost number g and form degree n, n denoting the dimension of the space–time. $\mathcal{Q}_n^g$ is said to be nontrivial if

$$\mathcal{Q}_n^g\neq s\overline{\mathcal{Q}}_n^{g-1}+d\overline{\mathcal{Q}}_{n-1}^g. \tag{37}$$

In this case the integral of $\mathcal{Q}_n^g$ on space–time identifies a cohomology class of the BRST operator s and, according to its ghost number, it corresponds to an invariant Chern–Simons action $(g=0)$ or to an anomaly $(g=1)$.

The nonintegrated equation (36), due to the algebraic Poincaré Lemma,[18,12] is easily seen to generate a tower of descent equations,

$$
\begin{aligned}
&s\mathcal{Q}_n^g + d\mathcal{Q}_{n-1}^{g+1} = 0,\\
&s\mathcal{Q}_{n-1}^{g+1} + d\mathcal{Q}_{n-2}^{g+2} = 0,\\
&\cdots\cdots\\
&\cdots\cdots\\
&s\mathcal{Q}_1^{g+n-1} + d\mathcal{Q}_0^{g+n} = 0,\\
&s\mathcal{Q}_0^{g+n} = 0.
\end{aligned}
\tag{38}
$$

As it has been well-known for several years, these equations can be solved by using a transgression procedure based on the so-called *Russian formula*.[3,5,6,19,11,20–22,4,13] More recently an alternative way of finding nontrivial solutions of the ladder (38) has been proposed and successfully applied in the study of the Yang–Mills gauge anomalies.[1] The method makes use of the decomposition formula (32). One easily verifies that once the decomposition has been found, successive applications of the operator δ on the zero-form $\mathcal{Q}_0^{g+n}$ which solves the last equation of the tower (38) give an explicit nontrivial solution for the higher cocycles.

It is a remarkable fact that solving the last equation of the tower of descent equations (38) is only a problem of local BRST cohomology instead of a modulo-d one. One sees then that, due to the operator δ, the study of the cohomology of s modulo d is essentially reduced to the study of the local cohomology of s. The latter can be, e.g., systematically analyzed by using the powerful technique of the spectral sequences.[23]

VI. CHERN–SIMONS TERMS AND GAUGE ANOMALIES

In order to solve the descent equations (38) we use the following strategy. First, we look at the general nontrivial solution of the last descent equation. Then we solve the tower iteratively by using the operators δ and $\mathcal{G}$, as done in Ref. 1.

Let $n=2k$ be the dimension of the base manifold M of a nontrivial bundle $P(M,G)$ with structure group G. Introducing a covariant BRST operator according to

$$
S = s - \hat{c}; \tag{39}
$$

one obtains a remarkable correspondence between the form sector and the gauge sector of the theory,

$$
DF = dF + [A,F] = 0, \quad S\hat{F} = s\hat{F} - [\hat{c},\hat{F}]. \tag{40}
$$

Let us define now the interpolating shifted gauge ghost,

$$
\hat{c}(t) = t\hat{c}, \quad t \in [0,1], \tag{41}
$$

with $\hat{c}(0)=0$ and $\hat{c}(1)=\hat{c}$, and the associated ghost field strength,

$$
\hat{F}(t) = -s\hat{c}(t) + \hat{c}(t)\hat{c}(t), \tag{42}
$$

with $\hat{F}(0)=0$ and $\hat{F}(1)=\hat{F}$. With the help of the interpolating generalized covariant BRST operator,

$$
S_t = s - \hat{c}(t), \tag{43}
$$

with $S_0=s$ and $S_1=S$, one finds the following identities:

$$\frac{d\hat{F}(t)}{dt} = -S_t\hat{c}, \quad S_t\hat{F}(t) = 0. \tag{44}$$

Therefore, in a space–time with dimension $2k$ one has

$$\mathrm{Tr}(\hat{F}^k) = \mathrm{Tr}(\hat{F}^k(1) - \hat{F}^k(0)) = \mathrm{Tr}\int_0^1 dt\ \frac{d}{dt}\ \hat{F}^k(t) = k\ \mathrm{Tr}\int_0^1 dt\ \frac{d\hat{F}(t)}{dt}\ \hat{F}^{k-1}(t)$$

$$= -k\ \mathrm{Tr}\int_0^1 dt\ (S_t\hat{c})\hat{F}^{k-1}(t) = -s\left(k\ \mathrm{Tr}\int_0^1 dt\ \hat{c}\ \hat{F}^{k-1}(t)\right). \tag{45}$$

Using the nilpotency of the BRST operator and the fact that $\mathrm{Tr}(\hat{F}^k) \neq 0$ in a space–time with dimension $2k$, one may conclude that $k\ \mathrm{Tr}\int_0^1 dt\ \hat{c}\ \hat{F}^{k-1}(t)$ is nontrivial. Since $\mathrm{Tr}(\hat{F}^k)$ contains the product of $2k$ fermionic diffeomorphism ghosts ξ^μ, it follows:

> *In a space–time with dimension $2k-1$ a nontrivial solution of the local equation $s\mathcal{Q}_0^{2k-1} = 0$ on a nontrivial bundle can be represented by the integrated parametric formula,*

$$\mathcal{Q}_0^{2k-1} = -k\ \mathrm{Tr}\int_0^1 dt\ \hat{c}\ \hat{F}^{k-1}(t). \tag{46}$$

Acting with the operator $\mathcal{G}$ on the last of the descent equations (38) and using the algebra (33) one finds

$$\mathcal{G}s\mathcal{Q}_0^{2k-1} = 0 = -s\mathcal{G}\mathcal{Q}_0^{2k-1} + \mathring{D}\mathring{D}\mathcal{Q}_0^{2k-1}, \tag{47}$$

which, due to the vanishing of the last term in (47), implies that $\mathcal{G}\mathcal{Q}_0^{2k-1}$ is BRST-closed,

$$s\mathcal{G}\mathcal{Q}_0^{2k-1} = 0. \tag{48}$$

The general solution of (48) has the form

$$\mathcal{G}\mathcal{Q}_0^{2k-1} = s\overline{\mathcal{Q}}_2^{2k-3} + \hat{\mathcal{Q}}_2^{2k-2}, \tag{49}$$

with a possible nontrivial part $\hat{\mathcal{Q}}_2^{2k-2}$,

$$s\hat{\mathcal{Q}}_2^{2k-2} = 0, \hat{\mathcal{Q}}_2^{2k-2} \neq s\hat{\mathcal{Q}}_2^{2k-3}. \tag{50}$$

Recalling now that the operator $\mathcal{G}$ acting on the variable $\hat{c}$ yields $\mathring{F}$, we infer that

$$\hat{\mathcal{Q}}_2^{2k-2} = \mathrm{Tr}(\mathring{F}\mathcal{P}(\hat{c},\hat{F})) = \mathring{F}^a\mathcal{P}^a(\hat{c},\hat{F}), \tag{51}$$

with $\mathcal{P}$ some polynomial in the fields $\hat{c}$ and $\hat{F}$ having form degree zero and ghost number $2k-2$.

In the following we will show that $\mathcal{G}\mathcal{Q}_0^{2k-1}$ is not only BRST-closed but also BRST-exact,

$$\mathcal{G}\mathcal{Q}_0^{2k-1} = s\overline{\mathcal{Q}}_2^{2k-3}. \tag{52}$$

The exactness of $\mathcal{G}\mathcal{Q}_0^{2k-1}$ will be proven by showing that the polynomial $\mathcal{P}^a$ is BRST trivial, due to the fact that the variable $\mathring{F}$ is BRST invariant. Recalling then that $\mathcal{P}^a$ depends only on $(\hat{c},\hat{F})$ due to the fact that it has form degree zero, let us first express the rigid gauge transformations of $(\hat{c},\hat{F})$ as BRST anticommutators, i.e.,

$$\left\{s, \frac{\partial}{\partial\hat{c}^a}\right\} = \delta^a_{rig.} = f^{abc}\hat{c}^b\frac{\partial}{\partial\hat{c}^c} + f^{abc}\hat{F}^b\frac{\partial}{\partial\hat{F}^c}\ . \tag{53}$$

(Here we have taken into account only the part of the BRST operator relative to the fields $\hat{c}$, $\hat{F}$.) It is easily checked by using the Jacobi identity that the operator $\delta^a_{rig.}$ commutes with the BRST operator,

$$[\delta^a_{rig.}, s] = 0. \tag{54}$$

Furthermore, one has

$$\delta^a_{rig.} \mathring{F}^b = 0. \tag{55}$$

Decomposing now Eq. (51) in terms of the eigenvalues of $\delta^a_{rig.}$, we get

$$\delta^a_{rig.}(\mathring{F}^b \mathcal{P}^b)_{(l)} = l(\mathring{F}^b \mathcal{P}^b)_{(l)}, \quad \mathring{F}^b \mathcal{P}^b = \sum_l (\mathring{F}^b \mathcal{P}^b)_{(l)}. \tag{56}$$

For $l \neq 0$ one obtains

$$(\mathring{F}^b \mathcal{P}^b)_{(l)} = \frac{1}{l} \delta^a_{rig.}(\mathring{F}^b \mathcal{P}^b)_{(l)} = \frac{1}{l} \left\{ s, \frac{\partial}{\partial \hat{c}^a} \right\} (\mathring{F}^b \mathcal{P}^b)_{(l)} = s\left(\frac{1}{l} \frac{\partial}{\partial \hat{c}^a} (\mathring{F}^b \mathcal{P}^b)_{(l)} \right), \tag{57}$$

since from Eq. (50) and Eq. (56) it follows that

$$s(\mathring{F}^b \mathcal{P}^b)_{(l)} = 0. \tag{58}$$

However, contributions of the type (57) can be neglected, since they are BRST trivial. What remains is the term corresponding to the eigenvalue $l = 0$,

$$\delta^a_{rig.}(\mathring{F}^b \mathcal{P}^b)_{(0)} = 0. \tag{59}$$

The above equation states that $(\mathring{F}^b \mathcal{P}^b)_{(0)}$ has to be invariant under rigid gauge transformations. However, since $\mathring{F}$ is left invariant by $\delta^a_{rig.}$, Eq. (59) implies that the polynomial $\mathcal{P}(\hat{c}, \hat{F})$ has to be invariant as well. It follows therefore that $(\mathring{F}^b \mathcal{P}^b)_{(0)}$ vanish. This completes our proof.

Repeating and generalizing these arguments to higher $\mathcal{G}$-cocycles one sees that the identity (52) generates a subtower of descent equations between the operators s and $\mathcal{G}$,

$$\begin{aligned}
&\mathcal{G}\mathcal{Q}_0^{2k-1} = s\overline{\mathcal{Q}}_2^{2k-3}, \\
&\mathcal{G}\overline{\mathcal{Q}}_2^{2k-3} = s\overline{\mathcal{Q}}_4^{2k-5}, \\
&\cdots\cdots \\
&\cdots\cdots \\
&\mathcal{G}\overline{\mathcal{Q}}_{2k-4}^{3} = s\overline{\mathcal{Q}}_{2k-2}^{1}, \\
&\mathcal{G}\overline{\mathcal{Q}}_{2k-2}^{1} = \mathcal{P}^0_{2k}(\mathring{F}),
\end{aligned} \tag{60}$$

which end up with a polynomial $\mathcal{P}^0_{2k}(\mathring{F})$ of ghost number zero and form degree $2k$. [In this case one has to incorporate in the rigid gauge transformations of (53), also the contributions of the remaining fields with a nonvanishing form degree.] Moreover, from Eq. (34) it follows that $\mathcal{P}^0_{2k}(\mathring{F})$ is nothing else than the Chern form of $\mathring{F}$ in $2k$ space–time dimensions.

Equipped with this algebraic set up we are now ready to discuss the solutions of the descent equations (38). Before analyzing the general case of a space–time of dimension $n = 2k-1$ let us first solve, as an explicit example, the three dimensional case $(k = 2)$,

$$s\mathcal{Q}_3^0+d\mathcal{Q}_2^1=0,\quad s\mathcal{Q}_2^1+d\mathcal{Q}_1^2=0,\quad s\mathcal{Q}_1^2+d\mathcal{Q}_0^3=0,\quad s\mathcal{Q}_0^3=0. \tag{61}$$

The nontrivial solution of the last descent equation follows from (46) with $(k=2)$,

$$\mathcal{Q}_0^3=-2\,\mathrm{Tr}\int_0^1 dt\ \hat{c}\ \hat{F}(t)=\mathrm{Tr}\left(\frac{1}{3}\hat{c}^3-\hat{F}\hat{c}\right). \tag{62}$$

Acting with the operator δ on the last equation one gets

$$[\delta,s]\mathcal{Q}_0^3+s\,\delta\mathcal{Q}_0^3=0, \tag{63}$$

which, using the decomposition (32), becomes

$$s(\delta\mathcal{Q}_0^3)+d\mathcal{Q}_0^3=0. \tag{64}$$

(Remark that all polynomials $\mathcal{Q}$ are gauge invariant and therefore the covariant exterior derivative $\mathring{D}$ reduces to the ordinary one.) This equation shows that $\delta\mathcal{Q}_0^3$ provides a solution for the cocycle $\mathcal{Q}_1^2$ in Eqs. (61).

In order to find an expression for the next cocycle, we apply the operator δ on Eq. (64). Using then the algebraic relations (33), one has

$$s\left(\frac{\delta^2}{2}\mathcal{Q}_0^3\right)-\mathcal{G}\mathcal{Q}_0^3+d(\delta\mathcal{Q}_0^3)=0. \tag{65}$$

According to (52), the term $\mathcal{G}\mathcal{Q}_0^3$ in (65) can be rewritten as

$$\mathcal{G}\mathcal{Q}_0^3=s\,\mathrm{Tr}(\mathring{\hat{F}}\hat{c})=s\,\overline{\mathcal{Q}}_2^1, \tag{66}$$

so that Eq. (65) becomes

$$s\left(\frac{\delta^2}{2}\mathcal{Q}_0^3-\overline{\mathcal{Q}}_2^1\right)+d(\delta\mathcal{Q}_0^3)=0. \tag{67}$$

Repeating again the previous steps, for the highest level we obtain

$$s\left(\frac{\delta^3}{3!}\mathcal{Q}_0^3-\delta\overline{\mathcal{Q}}_2^1\right)+d\left(\frac{\delta^2}{2}\mathcal{Q}_0^3-\overline{\mathcal{Q}}_2^1\right)=0, \tag{68}$$

from which it follows that $\mathcal{Q}_3^0$ can be identified with $[(\delta^3/3!)\mathcal{Q}_0^3-\delta\overline{\mathcal{Q}}_2^1]$, showing then the usefulness of the operators δ and $\mathcal{G}$ in solving the tower (61).

Summarizing, the algebraic solution of the three dimensional tower of descent equations (61) in the case of a nontrivial bundle is given by

$$\mathcal{Q}_3^0=(\delta^3/3!)\mathcal{Q}_0^3-\delta\overline{\mathcal{Q}}_2^1, \tag{69}$$

$$\mathcal{Q}_2^1=(\delta^2/2)\mathcal{Q}_0^3-\overline{\mathcal{Q}}_2^1, \tag{70}$$

$$\mathcal{Q}_1^2=\delta\mathcal{Q}_0^3, \tag{71}$$

with

$$\mathcal{Q}_0^3=\mathrm{Tr}(\tfrac{1}{3}\hat{c}^3-\hat{F}\hat{c}), \tag{72}$$

$$\mathcal{Q}_1^2=\mathrm{Tr}(-(A-\mathring{A})\hat{c}^2+(A-\mathring{A})\hat{F}+i_\xi F\hat{c}), \tag{73}$$

$$\mathcal{Q}_2^1=\mathrm{Tr}((A-\mathring{A})^2\hat{c}-(A-\mathring{A})i_\xi F-(F+\mathring{\hat{F}})\hat{c}), \tag{74}$$

$$\mathcal{Q}_3^0=\mathrm{Tr}(-\tfrac{1}{3}(A-\mathring{A})^3+(A-\mathring{A})(F+\mathring{F})). \tag{75}$$

In particular, $\mathcal{Q}_3^0$ is recognized to be the three-dimensional Chern–Simons form defined on nontrivial bundles, while $\mathcal{Q}_2^1$ yields the two-dimensional gauge anomaly which, by using the definition of the shifted gauge ghost (27), can be rewritten as

$$\mathcal{Q}_2^1=-\mathrm{Tr}(c\ \mathring{D}A+c\ d\mathring{A}+\mathring{F}i_\xi(A-\mathring{A})). \tag{76}$$

Moreover, in the case of a trivial bundle ($\mathring{A}=0$) the anomaly (76) reduces to the well-known familiar expression

$$\mathcal{Q}_2^1=-\mathrm{Tr}(c\ dA). \tag{77}$$

Finally, acting with the exterior derivative d on $\mathcal{Q}_3^0$ one obtains the related Chern form

$$d\mathcal{Q}_3^0=\mathrm{Tr}(F^2-\mathring{F}^2). \tag{78}$$

Let us come now to the general case of a space–time with dimension $n=2k-1$,

$$\begin{gathered} s\mathcal{Q}_{2k-1}^0+d\mathcal{Q}_{2k-2}^1=0,\\ s\mathcal{Q}_{2k-2}^1+d\mathcal{Q}_{2k-3}^2=0,\\ \cdots\cdots\\ \cdots\cdots\\ s\mathcal{Q}_1^{2k-2}+d\mathcal{Q}_0^{2k-1}=0,\\ s\mathcal{Q}_0^{2k-1}=0. \end{gathered} \tag{79}$$

It is straightforward to iterate the previous construction to obtain the solution of the descent Eqs. (79). The latter is given by

$$\begin{gathered} \mathcal{Q}_0^{2k-1}=-k\ \mathrm{Tr}\int_0^1 dt\ \hat{c}\ \hat{F}^{k-1}(t),\\ \mathcal{Q}_{2p}^{2k-1-2p}=\frac{\delta^{2p}}{(2p)!}\mathcal{Q}_0^{2k-1}-\sum_{q=0}^{p-1}\frac{\delta^{2q}}{(2q)!}\overline{\mathcal{Q}}_{2p-2q}^{2k-1-2p+2q}, \end{gathered} \tag{80}$$

for the even space–time sector and

$$\begin{gathered} \mathcal{Q}_1^{2k-2}=\delta\mathcal{Q}_0^{2k-1},\\ \mathcal{Q}_{2p+1}^{2k-2-2p}=\frac{\delta^{2p+1}}{(2p+1)!}\mathcal{Q}_0^{2k-1}-\sum_{q=0}^{p-1}\frac{\delta^{2q+1}}{(2q+1)!}\overline{\mathcal{Q}}_{2p-2q}^{2k-1-2p+2q}, \end{gathered} \tag{81}$$

for the odd space–time sector and $p=1,2,\ldots,k$. The solutions (80) and (81) generalize the results of Ref. 1 to the case of a nontrivial bundle.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 39, NUMBER 9 SEPTEMBER 1998

Classification of low-dimensional Lie super-bialgebras

C. Juszczak and J. T. Sobczyk
Institute of Theoretical Physics, University of Wrocław, Pl. Maksa Borna 9, 50-204 Wrocław, Poland

(Received 29 December 1997; accepted for publication 19 May 1998)

A thorough analysis of Lie super-bialgebra structures on Lie super-algebras osp(1;2) and super e(2) is presented. A combined technique of computer algebraic computations and subsequent identification of equivalent structures is applied. In all the cases, Poisson–Lie brackets on supergroups are found. The possibility of quantizing them in order to obtain quantum groups is discussed. It turns out to be straightforward for all but one structure for the super-E(2) group. © *1998 American Institute of Physics.* [S0022-2488(98)03409-4]

I. INTRODUCTION

About 10 years of intensive research in quantum groups[1,2] demonstrated the richness of investigated mathematical structures. No wonder that, except for efforts to find their physical applications, many authors tried to classify them from a mathematical point of view. The classifications are based on many different ideas. We do not wish to provide an exhaustive list of them but would like to mention some well-known examples. If the quantum SL(2) group is defined as one that preserves a nondegenerate bilinear form, two inequivalent deformations appear.[3] More complicated analysis of the group GL(3) leads to a conclusion that 26 inequivalent deformations exist in this case.[4] Reference 5 contains a very recent attempt to classify quantum SL(3) groups. A classification of all the 4×4 matrices satisfying the Yang–Baxter (YB) equation was done in Ref. 6. Later this result was used in order to list possible quantum deformations of the supergroup GL(1,1).[7] An interest in deformations of $D=4$ relativistic symmetries led to a classification of deformations of the Lorentz and Poincaré groups.[8]

From the early years of interest in quantum groups it is well known that they are closely related to notions of Lie bialgebras and Lie–Poisson groups. Suppose that a parameter q is introduced such that the value $q=1$ corresponds to an undeformed universal enveloping algebra $U(\mathcal{G})$ or a classical commutative algebra of functions on a Lie group G (with the Lie algebra $\mathcal{G}$). Then the structure of the Hopf algebra of the quantum group gives rise in the classical limit to an extra structure on G or $\mathcal{G}$. Then G becomes a Poisson–Lie group and $\mathcal{G}$ a Lie bialgebra.[9] These structures can be viewed as possible *directions* of quantum deformations. A fundamental fact about them is that all can be quantized, i.e., they arise as the classical limit from a *bona fide* quantum deformation.[10] This suggests that an effective approach to classify quantum groups could be by classifying their classical limits and that seems much easier to pull off. The study of Lie bialgebras becomes, in some cases, even easier, as they might be of the coboundary type, which happens if they can be described by means of a classical r-matrix satisfying the (modified) classical Yang–Baxter equation. Cohomological properties of semisimple Lie groups imply that all related Lie bialgebras are, in fact, coboundaries.[9] More elaborate argument shows that the same is true in the case of inhomogeneous groups of space–time symmetries for any signature of metric for dimensionality of space–time $D>2$.[11] Thus the problem of classification of Lie bialgebra structures contains as a subproblem a classification of solutions of the (modified) classical Yang–Baxter equation which has been studied by many authors. It should be stressed, however, that (in general) Lie algebras admit bialgebra structures that are not coboundaries. Recently, many low-dimensional Lie algebras were investigated for bialgebra structures, revealing a surprising number of possibilities. The two-dimensional Galilei algebra admits nine inequivalent Lie bialgebra structures and only one out of them is a coboundary.[12] The central extension of the Galilei algebra by the mass operator admits 26 inequivalent Lie bialgebra structures out of which eight are coboundaries.[13] Similar analysis aimed mainly at the construction of quantum groups was performed before in the cases of Heisenberg–Weyl and oscillator Lie algebras.[14] The classification of

 © 1998 American Institute of Physics

the possible classical r-matrices (and automatically of Lie bialgebra structures) was done in the case of Lorentz and Poincaré algebras.[15] Classical r-matrices for SL(3) were listed in Ref. 16. Corresponding R-matrices satisfying the Yang–Baxter equation were found in Ref. 17.

In this paper we will study quantum deformations of supergroups and their classical limits—Lie super-bialgebras. Quantum supergroups have been studied by many authors. Knowledge of R-matrices and low-dimensional representations of osp(1,2), su(1,1), gl(2,1), and sl(1,2) has been used to construct integrable models.[18] To our knowledge no systematic investigation of Lie super-bialgebras has yet been undertaken. We decided to study two cases: osp(1,2) and the supersymmetric extension of the e(2) algebra, both treated as complex. The first one is interesting as it plays in the supersymmetric case a role analogous to sl(2). Many papers devoted to quantum supergroups are based on a quantum deformation proposed by Ref. 19. A natural question is: are other deformations possible as is in the case of sl(2)? The supersymmetric extension of e(2) chosen as the e(2) group is one which has a simple structure but admits several inequivalent Lie bialgebras.[20,21] There are four of them, with one being, strictly speaking, a one-parameter family. Two structures are generated by classical r-matrices. All the quantum deformations of the group E(2) are known which could be helpful in finding quantum deformations in the supersymmetric case. Some quantum deformations of super-e(2) algebra have already been discussed in the literature. They can be [in analogy to the e(2) case] obtained by means of a contraction procedure.[22]

The problem of classifying Lie bialgebra structures for a given Lie algebra is mostly a computational one. We found it effective to use a computer at various steps. For a Lie algebra with N generators it is necessary to deal with equations containing the number of parameters which increases as N^3. Some of the equations are linear but the remaining (co-Jacobi identities) are quadratic. The complexity of the problem grows quickly with N. The biggest obstacle in continuing with this program for large N is primarily the fact that not everything can be done by computer. The most delicate part of the problem is to single out orbits under the action of the group of automorphisms of $\mathcal{G}$ in a computer-produced space of solutions.

Our first result is that in the osp(1,2) case all the Lie super-bialgebras are coboundaries. We found three independent classical r-matrices. One solution is quite obvious. As sl(2) is a Lie subalgebra of osp(1,2), any r-matrix for the former algebra satisfying the (not modified!) classical YB equation is automatically the r-matrix for the latter. The third solution corresponds to the quantum deformation of osp(1,2) described in Ref. 19. Relations for quantum OSp(1,2) are given in Ref. 23. The second solution is a new one and requires a detailed study.

In the case of super-e(2) we found six families of independent Lie super-bialgebra structures. In their most general form they are not coboundaries, but four of them contain coboundary members. Some links to the classification of analogous structures on e(2) can be established. Case (i) in our list is clearly analogous with δ_2 of Ref. 21. Case (iv) corresponds to δ_1. It is the infinitesimal form of quantum deformation introduced in Ref. 22. The existence of r-matrix r_2 is again obvious as it consists only of generators of e(2) and satisfies the (not modified!) classical YB equation.

For all the Lie super-bialgebra structures we calculated corresponding Lie–Poisson brackets. Their form is such that in five cases of the super-E(2) group it is easy to go through with the program of constructing quantum supergroups.[24,25] It is sufficient to change Lie–Poisson brackets into (anti) commutators.

The paper is organized as follows. In Sec. II all the basic concepts and notation used in the rest of the paper are introduced. Sections III and IV contain derivations of inequivalent Lie super-bialgebras for osp(1,2) and super-e(2). In Sec. V Poisson–Lie brackets for both cases are presented. In Sec. VI our conclusions and some final remarks are presented.

After completing our study we learned about the paper in which by applying the Drinfeld twisting procedure a new quantum supergroup structure on OSp(1,2) was found.[26] It is clear that it corresponds to the Lie super-bialgebra structure number (1) on our list presented in Sec. IV.

II. BASIC DEFINITIONS AND NOTATION

Super-Lie-algebra $\mathcal{G}$ (Ref. 27) is a graded vector space

$$\mathcal{G}=\mathcal{G}_B\oplus\mathcal{G}_F \tag{1}$$

with the grade function grade($\mathcal{G}_B$)=0, grade($\mathcal{G}_F$)=1. A Lie superalgebra structure is provided by a linear mapping

$$[,]:\mathcal{G}\otimes\mathcal{G}\to\mathcal{G} \tag{2}$$

satisfying the requirements of (graded) antisymmetry and Jacobi identity. In order to express them it is useful to introduce a basis in $\mathcal{G}$ $\{g_i\}\subset\mathcal{G}_B\cup\mathcal{G}_F$ and structure constants

$$[g_i,\ g_j]=c_{ij}{}^k g_k\,. \tag{3}$$

Structure constants have to satisfy

$$c_{ij}{}^k=0 \quad \text{whenever grade}\ (g_i)+\text{grade}\ (g_j)\neq\text{grade}\ (g_k)(\text{mod}\ 2), \tag{4}$$

$$c_{ij}{}^k=-z(i,j)c_{ji}{}^k, \tag{5}$$

and

$$c_{ij}{}^k c_{kl}{}^m z(i,l)+c_{jl}{}^k c_{ki}{}^m z(j,i)+c_{li}{}^k c_{kj}{}^m z(l,j)=0, \tag{6}$$

where

$$z(i,j)=(-1)^{\text{grad}\ (g_i)\text{grad}\ (g_j)}. \tag{7}$$

Lie super-bialgebra structure (see, e.g., Refs. 28 and 29) is a linear mapping

$$\delta:\mathcal{G}\to\mathcal{G}\otimes\mathcal{G}, \tag{8}$$

which in the chosen basis reads

$$\delta(g_i)=f_i{}^{kl}g_k\otimes g_l\,. \tag{9}$$

Here δ has to satisfy several requirements. First of all, it makes the dual linear space $\mathcal{G}^*$ a Lie super-algebra:

$$f_k{}^{ij}=0 \quad \text{whenever grad}\ (g_i)+\text{grad}\ (g_j)\neq\text{grad}\ (g_k)(\text{mod}\ 2), \tag{10}$$

$$f_k{}^{ij}=-z(i,j)f_k{}^{ji}, \tag{11}$$

$$f_i{}^{kj}f_j{}^{lm}z(k,m)+f_i{}^{lj}f_j{}^{mk}z(l,k)+f_i{}^{mj}f_j{}^{kl}z(m,l)=0. \tag{12}$$

Moreover, structure constants c and f have to be related:

$$c_{ij}{}^k f_k{}^{lm}=f_i{}^{lk}c_{kj}{}^m+c_{kj}{}^l f_i{}^{km}z(m,j)+c_{jk}{}^l f_j{}^{km}+f_j{}^{lk}c_{ik}{}^m z(i,l). \tag{13}$$

The coboundary Lie super-bialgebra is a pair $(\mathcal{G},r)$, where $\mathcal{G}$ is a Lie super-bialgebra and $r\in\mathcal{G}_B\wedge\mathcal{G}_B\oplus\mathcal{G}_F\wedge\mathcal{G}_F\subset\mathcal{G}\wedge\mathcal{G}$. such that for every $g_i\in\mathcal{G}$,

$$\delta(g_i)=[r,\ g_i\otimes 1+1\otimes g_i]. \tag{14}$$

The Schouten bracket is defined as

$$[[r,\ r]]\equiv[r_{12},\ r_{13}]+[r_{12},\ r_{23}]+[r_{13},\ r_{23}], \tag{15}$$

where $r_{12}=r\otimes 1$, $r_{23}=1\otimes r$, and $r_{13}=(1\otimes\tau)r_{12}$, where τ is linear and $\tau(g_i\otimes g_j)=z(i,j)g_j\otimes g_i$.

Here r satisfies the classical Yang–Baxter equation (CYBE) if

$$[[r,\ r]]=0 \tag{16}$$

and the modified CYBE if

$$\forall g_i \in \mathcal{G} \quad [[[r,\, r]],\ g_i \otimes 1 \otimes 1 + 1 \otimes g_i \otimes 1 + 1 \otimes 1 \otimes g_i] = 0. \tag{17}$$

The super-e(2) Lie algebra is spanned by the set of generators $\{H, P_+, P_-, D_+, D_-\}$ of grading $\mathrm{grad}\,(H) = \mathrm{grad}\,(P_\pm) = 0$ and $\mathrm{grad}\,(D_\pm) = 1$, which fulfill the following (anti) commutation relations:

$$\begin{gathered}
[H,\, P_\pm] = \pm P_\pm, \quad [H,\, D_\pm] = \pm \tfrac{1}{2} D_\pm, \quad [P_+,\, P_-] = 0, \\
\{D_+,\, D_-\} = 0, \quad \{D_\pm,\, D_\pm\} = P_\pm, \\
[P_\pm,\, D_\pm] = 0, \quad [P_\pm,\, D_\mp] = 0.
\end{gathered} \tag{18}$$

A convenient parametrization of the classical super-E(2) group is obtained by means of exponentiation:

$$g(s,a,b,\xi,\eta) = \exp(sH)\exp(aP_+)\exp(bP_-)\exp(\xi D_+)\exp(\eta D_-). \tag{19}$$

Coproducts are

$$\Delta(s) = s \otimes 1 + 1 \otimes s, \tag{20}$$

$$\Delta(a) = 1 \otimes a + a \otimes \exp(-s) + \frac{1}{2}\, \xi \otimes \xi\, \exp\left(-\frac{s}{2}\right), \tag{21}$$

$$\Delta(b) = 1 \otimes b + b \otimes \exp(s) + \frac{1}{2}\, \eta \otimes \eta\, \exp\left(\frac{s}{2}\right), \tag{22}$$

$$\Delta(\xi) = 1 \otimes \xi + \xi \otimes \exp\left(-\frac{s}{2}\right), \tag{23}$$

$$\Delta(\eta) = 1 \otimes \eta + \eta \otimes \exp\left(\frac{s}{2}\right). \tag{24}$$

The Lie superalgebra osp(1,2) is spanned by the set of generators $\{H, X_+, X_-, V_+, V_-\}$ of grading $\mathrm{grad}(H) = \mathrm{grad}(X_\pm) = 0$ and $\mathrm{grad}(V_\pm) = 1$, which fulfill the following (anti) commutation relations:

$$\begin{gathered}
[H,\, X_\pm] = \pm X_\pm, \quad [H,\, V_\pm] = \pm \tfrac{1}{2} V_\pm, \quad [X_+,\, X_-] = 2H, \\
\{V_+,\, V_-\} = -\tfrac{1}{2} H, \quad \{V_\pm,\, V_\pm\} = \pm \tfrac{1}{2} X_\pm, \\
[X_\pm,\, V_\pm] = 0, \quad [X_\pm,\, V_\mp] = V_\pm.
\end{gathered} \tag{25}$$

In the case of supergroup OSp(1,2) we will use more implicit parametrization by means of 3×3 supermatrices subject to certain constraints:[19]

$$g = \begin{pmatrix} a & \alpha & b \\ \gamma & e & \beta \\ c & \delta & d \end{pmatrix}, \tag{26}$$

where $e = 1 + \alpha\delta$, $\gamma = c\alpha - a\delta$, $\beta = d\alpha - b\delta$, and $ad - bc + \alpha\delta = 1$. Variables denoted by Greek letters are of Grassmanian type. Coproducts follow from matrix multiplication of elements of G.

III. LIE SUPER-BIALGEBRAS FOR osp(1,2)

The problem studied in Secs. III and IV can be formulated in the following way:

Given a set of structure constants $c_{ij}{}^{k}$, find all sets of structure constants $f_{m}{}^{np}$ that give rise to Lie super-bialgebras. Two such sets are considered equivalent if they can be made equal by a change of the basis in $\mathscr{G}$. Verify if obtained structures are of coboundary type.

Initial steps in the analysis can be made using a computer. A most general form of f's is assumed. Constraints imposed by the set of linear equations coming from the cocycle condition (13) are first taken into account. Then the set of quadratic equations coming from the super co-Jacobi conditions (12) is to be solved.

In the case of osp(1,2) we discover that all the possible bialgebra structures are coboundaries and that the classical r-matrix is in one of two possible forms:

$$\begin{aligned} r_a &= x(X_+\wedge X_- + 2V_+\wedge V_-) + y(H\wedge X_+ - V_+\wedge V_+) + z(H\wedge X_- - V_-\wedge V_-), \\ r_b &= \pm\sqrt{uv}X_+\wedge X_- + uH\wedge X_+ + vH\wedge X_-, \end{aligned} \tag{27}$$

where x, y, z, u, v are arbitrary complex numbers.

Identification of automorphisms of superalgebra osp(1,2) is fairly straightforward. They cannot mix fermions with bosons (grading is preserved). As the superalgebra is generated by just the two fermions V_+ and V_-, every automorphism is determined by the following transformation of the fermions:

$$\tilde{V}_+ = aV_+ + bV_-, \quad \tilde{V}_- = cV_+ + dV_-. \tag{28}$$

We easily derive that under the above transformation

$$\begin{aligned} \tilde{H} &= -acX_+ + (ad+bc)H + bdX_-, \\ \tilde{X}_+ &= a^2X_+ - 2abH - b^2X_-, \\ \tilde{X}_- &= -c^2X_+ + 2cdH + d^2X_-. \end{aligned} \tag{29}$$

The operators $\{\tilde{H},\tilde{X}_+,\tilde{X}_-,\tilde{V}_+,\tilde{V}_-\}$ obey the same super-commutation relations as $\{H,X_+,X_-,V_+,V_-\}$ if and only if

$$\det\begin{pmatrix} a & b \\ c & d \end{pmatrix} = 1. \tag{30}$$

Under the transformations (28) and (29) the parameters x, y, z of the r-matrix r_a given in (27) transform as follows:

$$\begin{pmatrix} \tilde{y} & -\tilde{x} \\ -\tilde{x} & \tilde{z} \end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix}\begin{pmatrix} y & -x \\ -x & z \end{pmatrix}\begin{pmatrix} a & c \\ b & d \end{pmatrix}. \tag{31}$$

We notice that this is exactly the way the symmetric form transforms under the change of basis. If we take into account the Sylvester theorem we see that we can make the matrix

$$\begin{pmatrix} y & -x \\ -x & z \end{pmatrix}$$

equal diag (y,y) or diag $(1,0)$ [without the condition (30) it would be possible to make it equal diag $(1,1)$ or diag $(1,0)$].

Thus r_a, if different from zero, is equivalent to one of the following:

$$r_a = \begin{cases} r_2 \equiv H\wedge X_+ - V_+\wedge V_+, & \text{if } x^2 - yz = 0 \\ r_3 \equiv t(H\wedge X_+ - V_+\wedge V_+ + H\wedge X_- - V_-\wedge V_-), & \text{if } x^2 - yz \neq 0. \end{cases} \tag{32}$$

By means of analogous reasoning we arrive at the conclusion that the r-matrix r_b is always equivalent to

$$r_1 \equiv H \wedge X_+ . \tag{33}$$

Here r_3 can also be written in equivalent form as $\tilde{t}(X_+ \wedge X_- + 2V_+ \wedge V_-)$. This is a way to see that it corresponds to the deformation of osp(1,2) presented in Ref. 19. As it stands it satisfies only modified CYBE. One can, however, supplement it by the symmetric ad-invariant expression

$$\tilde{t}(H \otimes H + X_+ \otimes X_- + X_- \otimes X_+ + 2(V_+ \otimes V_- - V_- \otimes V_+)) \tag{34}$$

and obtain an r-matrix satisfying the (not modified) CYBE. This is a way in which a universal R-matrix with the classical limit r_3 can satisfy the Yang–Baxter equation and the quasitriangular deformation of osp(1,2) is obtained.

The parameter t is present in (32) as it cannot be removed by means of the transformation (31). It means that for different values of t we have inequivalent Lie superbialgebras. However, t becomes irrelevant upon quantization since it can be absorbed into a deformation parameter.

IV. LIE SUPER-BIALGEBRAS FOR SUPER-e(2)

The initial steps of the analysis are made using a computer as in the case of osp(1,2). After solving equations quadratic in structure constants it turns out that most of the bialgebra structures are not coboundaries. This makes the investigation more involved since we cannot use the r-matrix formulation and must explicitly state the co-Lie structure for each solution found. The possibilities found by means of the computer are:

Case A:

$$\begin{aligned}
&\delta(H) = H \wedge (aP_+ + bP_-) + cP_+ \wedge P_- , \\
&\delta(P_+) = P_+ \wedge bP_- , \quad \delta(P_-) = -aP_+ \wedge P_- , \\
&\delta(D_+) = \tfrac{1}{2}(aP_+ - bP_-) \wedge D_+ \pm \sqrt{ab} P_+ \wedge D_- , \\
&\delta(D_-) = \tfrac{1}{2}(aP_+ - bP_-) \wedge D_- \pm \sqrt{ab} P_- \wedge D_+ ;
\end{aligned} \tag{35}$$

Case B:

$$\begin{aligned}
&\delta(H) = a(H \wedge P_+ - \tfrac{1}{2} D_+ \wedge D_+) + b(H \wedge P_- + \tfrac{1}{2} D_- \wedge D_-) + cP_+ \wedge P_- , \\
&\delta(P_+) = P_+ \wedge bP_- + d(2H \wedge P_+ - D_+ \wedge D_+), \\
&\delta(P_-) = -aP_+ \wedge P_- + d(2H \wedge P_- + D_- \wedge D_-), \\
&\delta(D_+) = -\tfrac{1}{2}(aP_+ + bP_-) \wedge D_+ + d(H \wedge D_+), \\
&\delta(D_-) = -\tfrac{1}{2}(aP_+ + bP_-) \wedge D_- + d(H \wedge D_-),
\end{aligned} \tag{36}$$

where a, b, c, d are arbitrary complex numbers such that $cd = 0$.

The set of automorphisms of super-e(2) is generated by three transformations:

(1) $\tilde{H} = H + \alpha P_+ + \beta P_- , \quad \tilde{P}_\pm = P_\pm , \quad \tilde{D}_\pm = D_\pm .$
(2) $\tilde{H} = -H, \quad \tilde{P}_\pm = P_\mp , \quad \tilde{D}_\pm = D_\mp .$
(3) $\tilde{H} = H, \quad \tilde{P}_+ = \alpha^2 P_+ , \quad \tilde{D}_+ = \alpha D_+ , \quad \tilde{P}_- = \beta^2 P_- , \quad \tilde{D}_- = \beta D_- .$

When taken into account they lead to a conclusion that a and b can be scaled out to take the value of 1 or 0. It is also possible to show that when $d \neq 0$, then by taking $\tilde{H} = H + (a/2d)P_+ + (b/2d)P_-$, we can make $a = b = c = 0$.

Finally we arrive at six families of bialgebra structures whose representatives can be described by means of the following substitutions:

(i) Case A where $a = b = 0$,

(ii) Case A where $a=1$, $b=0$,
(iii) Case A where $a=b=1$,
(iv) Case B where $a=b=c=0$,
(v) Case B where $a=1$, $b=d=0$,
(vi) Case B where $a=b=1$, $d=0$.

Classical r-matrices exist if both c and d vanish. Their general forms for cases A and B are

$$r_{\mathrm{A}}=aH\wedge P_{+}-bH\wedge P_{-}+\sqrt{ab}D_{+}\wedge D_{-}+fP_{+}\wedge P_{-},$$
$$r_{\mathrm{B}}=a(H\wedge P_{+}-\tfrac{1}{2}D_{+}\wedge D_{+})-b(H\wedge P_{-}+\tfrac{1}{2}D_{-}\wedge D_{-})+fP_{+}\wedge P_{-}. \tag{37}$$

In both cases the term $fP_{+}\wedge P_{-}$ is irrelevant since its commutators (14) with all the generators of super-e(2) vanish.

After substitutions we obtain

$$r_{(\mathrm{ii})}=H\wedge P_{+},$$
$$r_{(\mathrm{iii})}=H\wedge P_{+}-H\wedge P_{-}+D_{+}\wedge D_{-},$$
$$r_{(\mathrm{v})}=H\wedge P_{+}-\tfrac{1}{2}D_{+}\wedge D_{+}, \tag{38}$$
$$r_{(\mathrm{vi})}=H\wedge P_{+}-\tfrac{1}{2}D_{+}\wedge D_{+}-H\wedge P_{-}-\tfrac{1}{2}D_{-}\wedge D_{-}.$$

Only $r_{(\mathrm{ii})}$ and $r_{(\mathrm{v})}$ satisfy the CYBE.

V. POISSON–LIE BRACKETS

Lie super-bialgebras are in 1:1 correspondence with Poisson–Lie structures on supergroups.[28] Poisson–Lie brackets satisfy the following properties:

$$\{f,g\}=-z(f,g)\{g,f\}, \tag{39}$$
$$\{f,gh\}=\{f,g\}h+z(f,g)g\{f,h\}, \tag{40}$$
$$0=z(f,h)\{f,\{g,h\}\}+z(g,f\,)\{g,\{h,f\}\}+z(h,g)\{h,\{f,g\}\}, \tag{41}$$
$$\Delta\{f,g\}=\{\Delta f,\Delta g\}. \tag{42}$$

Poisson–Lie brackets are most easily introduced by means of left- and right-invariant vector fields on a supergroup. In the super case one should distinguish left- and right-hand side derivatives of superfunctions. In the coboundary case with a classical r-matrix r_{kl}, Poisson–Lie brackets are given by[25]

$$\{\phi,\psi\}=(Y_k^{(r)}\phi)r_{kj}(Y_j^{(l)}\psi)-(X_k^{(r)}\phi)r_{kj}(X_j^{(l)}\psi), \tag{43}$$

where $Y_k^{(r,l)}$ denotes left-invariant right (r) or left (l) derivatives and $X_k^{(r,l)}$ right-invariant right (r) or left (l) derivatives. Here Y_k and X_k can be derived from the coproducts.

We present in the following how they act on generators of both supergroups.

(a) Super-E(2)

	a	b	s	ξ	η
$Y_H^{(r,l)}$	$-a$	b	1	$-\xi/2$	$\eta/2$
$Y_{P_+}^{(r,l)}$	1	0	0	0	0
$Y_{P_-}^{(r,l)}$	0	1	0	0	0
$Y_{D_-}^{(r)}$	0	$\eta/2$	0	0	1
$Y_{D_-}^{(l)}$	0	$-\eta/2$	0	0	1
$Y_{D_+}^{(r)}$	$\xi/2$	0	0	1	0
$Y_{D_+}^{(l)}$	$-\xi/2$	0	0	1	0
$X_H^{(r,l)}$	0	0	1	0	0
$X_{P_+}^{(r,l)}$	$\exp(-s)$	0	0	0	0
$X_{P_-}^{(r,l)}$	0	$\exp(s)$	0	0	0
$X_{D_-}^{(r)}$	0	$-\eta\exp(s/2)/2$	0	0	$\exp(s/2)$
$X_{D_-}^{(l)}$	0	$\eta\exp(s/2)/2$	0	0	$\exp(s/2)$
$X_{D_+}^{(r)}$	$-\xi\exp(-s/2)/2$	0	0	$\exp(-s/2)$	0
$X_{D_+}^{(l)}$	$\xi\exp(-s/2)/2$	0	0	$\exp(-s/2)$	0

(44)

(b) OSp(1,2):

	a	α	b	c	δ	d
$Y_H^{(r,l)}$	$a/2$	0	$-b/2$	$c/2$	0	$-d/2$
$Y_{X_+}^{(r,l)}$	0	0	a	0	0	c
$Y_{X_-}^{(r,l)}$	b	0	0	d	0	0
$Y_{V_+}^{(r)}$	0	$a/2$	$\alpha/2$	0	$c/2$	$\delta/2$
$Y_{V_+}^{(l)}$	0	$a/2$	$-\alpha/2$	0	$c/2$	$-\delta/2$
$Y_{V_-}^{(r)}$	$-\alpha/2$	$b/2$	0	$-\delta/2$	$d/2$	0
$Y_{V_-}^{(l)}$	$\alpha/2$	$b/2$	0	$\delta/2$	$d/2$	0
$X_H^{(r,l)}$	$a/2$	$\alpha/2$	$b/2$	$-c/2$	$-\delta/2$	$-d/2$
$X_{X_+}^{(r,l)}$	c	δ	d	0	0	0
$X_{X_-}^{(r,l)}$	0	0	0	a	α	b
$X_{V_+}^{(r)}$	$-\gamma/2$	$e/2$	$-\beta/2$	0	0	0
$X_{V_+}^{(l)}$	$\gamma/2$	$e/2$	$\beta/2$	0	0	0
$X_{V_-}^{(r)}$	0	0	0	$-\gamma/2$	$e/2$	$-\beta/2$
$X_{V_-}^{(l)}$	0	0	0	$\gamma/2$	$e/2$	$\beta/2$

(45)

In the non-coboundary cases Poisson brackets can be calculated by applying the supersymmetric version of the method described in Ref. 21. It is necessary to solve the cocycle equation for an element $\Phi: G \to \mathcal{G} \wedge \mathcal{G}$,

$$\Phi(g_1 g_2) = \Phi(g_1) + g_1 \Phi(g_2) g_1^{-1}, \tag{46}$$

TABLE I. Poisson Lie structures for the group OSp(1,2).

	1	2	3[a]

$\{a,c\}$	$-c^2$	$-c^2$	$1-c^2-a^2$
$\{a,d\}$	$c(a-d)$	$c(a-d)$	$(c-b)(a-d)$
$\{b,c\}$	$-c(a+d)$	$-c(a+d)$	$-(b+c)(a+d)$
$\{b,d\}$	$1-d^2-\alpha\delta$	$1-d^2$	$1-b^2-d^2$
$\{c,d\}$	c^2	c^2	c^2+d^2-1
$\{a,\alpha\}$	$c\alpha-a\delta$		$b\alpha$
$\{b,\alpha\}$	$d\alpha-b\delta$	$-a\alpha$	$-a\alpha$
$\{c,\alpha\}$	$c\delta$	$c\delta$	$c\delta+a\alpha-b\delta$
$\{d,\alpha\}$	$d\delta$	$(d-a)\delta$	$d\delta+b\alpha-a\delta$
$\{a,\delta\}$	$-c\delta$	$-c\delta$	$-c\delta-a\alpha+d\alpha$
$\{b,\delta\}$	$-d\delta$	$-d\delta-c\alpha$	$-(d\delta+b\alpha+c\alpha)$
$\{c,\delta\}$			$d\delta$
$\{d,\delta\}$		$-c\delta$	$-c\delta$
$\{\alpha,\alpha\}$	$2\delta\alpha$	$1-a^2$	$1-a^2-b^2$
$\{\alpha,\delta\}$		$-ac$	$-ac-bd$
$\{\delta,\delta\}$		$-c^2$	$1-c^2-d^2$

[a]All the entries should be multiplied by the parameter t [see (32)].

satisfying ''initial conditions'' determined by the Lie super-bialgebra structure in consideration.

The whole procedure has to be followed in every detail only in the case of Lie super-bialgebra structures (i) and (iv) from the list presented in Sec. III. One finds

$$\Phi_{(\mathrm{i})}(g)=csP_+\wedge P_-, \tag{47}$$

$$\begin{aligned}\Phi_{(\mathrm{iv})}(g)=&-2ae^{s}P_+\wedge H-ae^{s}D_+\wedge D_+-2be^{-s}P_-\wedge H\\&+2abP_-\wedge P_++be^{-s}D_-\wedge D_-+\xi e^{s/2}H\wedge D_+\\&-a\xi e^{3s/2}P_+\wedge D_++\xi be^{-s/2}P_-\wedge D_++\eta e^{-s/2}H\wedge D_-\\&-a\eta e^{s/2}P_+\wedge D_-+\eta be^{-3s/2}P_-\wedge D_--\tfrac{1}{2}\xi\eta D_+\wedge D_-.\end{aligned} \tag{48}$$

For $\Phi(g)=\Phi^{jk}(g)g_j\wedge g_k$ the Poisson–Lie brackets are

$$\{\phi,\psi\}=(X_j^{(r)}\phi)\Phi^{jk}(X_k^{(l)}\psi). \tag{49}$$

In all the remaining cases one can use the fact that they become coboundaries when $c=0$. The parameter c is present in $\delta(H)$ as $cP_+\wedge P_-$. Clearly it appears in Φ as $csP_+\wedge P_-$. It is thus possible to calculate Poisson–Lie brackets using classical r-matrices given in (38) and to add the

$\{\eta,\eta\}$				$2b$		e^s-1

[a]All the entries should be multiplied by the parameter d [see (36)].

extra term to $\{a,b\}$ at the very end of computations. The complete sets of relations making OSp(1,2) and super-E(2) Poisson–Lie supergroups are given in Tables I and II. In the case of OSp(1,2), in order to obtain shorter formulas all the Poisson brackets have been multiplied by the factor 2. The fact that these Poisson–Lie brackets satisfy conditions (39)–(42) was verified explicitly with the use of a computer.

VI. DISCUSSION AND FINAL REMARKS

The relevance of the knowledge of Poisson–Lie brackets lies in the fact that it gives a deep insight into a structure of the corresponding quantum group, in some cases determining it completely.[24]

It is easy to see that in five cases of brackets on the super-E(2) group [an exception is the structure (iv)] it is straightforward to integrate it and obtain a quantum group. In fact, the rhs's of Poisson brackets contain no products of functions which, upon quantization, could lead to ordering ambiguities. It is therefore sufficient to replace $\{,\}\rightarrow(1/h)[,]$ where h is a quantum deformation parameter. By applying duality techniques it must be then possible to obtain quantum deformations of super-e(2) enveloping algebra. Deformation of the super-e(2) enveloping algebra discussed in Ref. 22 corresponds to the structure (iv) of our classification.

In the case of OSp(1,2) a quantization of the first structure appeared very recently in Ref. 26. The third structure is the standard one introduced in Ref. 19. A quantum version of the second structure is missing.

Intertwining operators for a degenerate double affine Hecke algebra and multivariable orthogonal polynomials

Saburo Kakei[a)]
Department of Mathematical Sciences, University of Tokyo, Komaba 3-8-1, Meguro-ku, Tokyo 153-0041, Japan

(Received 18 February 1998; accepted for publication 6 May 1998)

Several properties of the multivariable Hermite and Laguerre polynomials associated with the quantum Calogero models are investigated by using the operators that intertwine representations of a degenerate version of the double affine Hecke algebra. As applications, raising operators and shift operators for the polynomials are constructed in a unified manner. © *1998 American Institute of Physics.* [S0022-2488(98)00909-8]

I. INTRODUCTION

There are intimate relations between quantum mechanics and special functions. Wave functions for some systems can be explicitly written in terms of suitable special functions. Recent studies on integrable quantum many-particle systems reveal that wave functions of some special cases can be written in terms of multivariable analogs of classical orthogonal polynomials.[1–9] In the present paper, we shall consider orthogonal polynomials associated with the quantum Calogero models confined in harmonic potential:[10–13]

$$\mathscr{H}_A=\frac{1}{2}\sum_{j=1}^{N}\left(-\frac{\partial^2}{\partial x_j^2}+x_j^2\right)+\sum_{j<k}\frac{\beta(\beta-1)}{(x_j-x_k)^2}, \tag{1}$$

$$\mathscr{H}_B=\frac{1}{2}\sum_{j=1}^{N}\left\{-\frac{\partial^2}{\partial z_j^2}+z_j^2+\frac{\gamma(\gamma-1)}{z_j^2}\right\}+\sum_{j<k}\left\{\frac{\beta(\beta-1)}{(z_j-z_k)^2}+\frac{\beta(\beta-1)}{(z_j+z_k)^2}\right\}, \tag{2}$$

where we assume that β is a non-negative integer. The subscripts ''A'' and ''B'' signify that the corresponding Hamiltonian is invariant under the action of the Weyl group of A_{N-1} type or B_N type, respectively. (For the latter convenience, we use the letter ''z'' as the coordinates of the B_N-type model.) In these cases, the polynomial part of the wave functions can be regarded as the multivariable generalization of the Hermite (A_{N-1} case) and Laguerre (B_N case) polynomials and has been studied by several authors.[1–9]

Since special functions are related to representation theory, it may be challenging to investigate the algebraic aspect of the multivariable orthogonal polynomials. In the case of the Macdonald polynomials, it has been revealed that the algebraic structure behind the polynomials is the double affine Hecke algebras.[14–17] Since the Jack polynomials can be regarded as a degenerate case of the Macdonald polynomials, their algebraic structure is a degenerate version of the double affine Hecke algebra.[18,19] In previous works,[5,6] we have shown that the Hamiltonians (1) and (2) share the same algebraic structure, that is, a subalgebra of the degenerate double affine Hecke algebra. From this viewpoint, each of the models (1) and (2) corresponds to an individual representation of the algebra.

In this paper, we will investigate several properties of the multivariable Hermite and Laguerre polynomials by using intertwining operators between representation spaces. As applications of the intertwining operators, we will construct raising operators and shift operators for such polynomials. In the case of the Jack polynomials and the multivariable Hermite polynomials, raising operators have already been constructed.[8,20] Our raising operators constructed below have a different

[a)]Electronic mail: kakei@poisson.ms.u-tokyo.ac.jp

form but share the same properties (see Sec. III). We would like to stress that our algebraic method gives a unified viewpoint in order to understand the common structure of the models.

This article is organized as follows. In Sec. II, we recall the relation between Dunkl-type operators and multivariable orthogonal polynomials. The main tools in this article, the intertwining operators, are defined also in Sec. II. Using the intertwining operators, we construct raising operators in Sec. III and shift operators in Sec. IV. The shift operators give an algebraic proof of the norm formula of the multivariable orthogonal polynomials. The last section is devoted to concluding remarks.

II. DUNKL-TYPE OPERATORS AND MULTIVARIABLE ORTHOGONAL POLYNOMIALS

In this section, we define our notation and review the theory of several kinds of multivariable orthogonal polynomials.

In Ref. 21, Dunkl has introduced differential-exchange operators, now called ''Dunkl operators,'' which are associated with root systems. For the A_{N-1}-type root system, the operators are defined as

$$D_j^A=\frac{\partial}{\partial x_j}+\beta\sum_{k(\neq j)}\frac{1-s_{jk}}{x_j-x_k},\quad j=1,\ldots,N,$$

where s_{ij} are elements of the symmetric group $\mathfrak{S}_N$. An element s_{ij} acts on functions of $x_1,\ldots,x_N$ as an operator which permutes arguments x_i and x_j. We remark that the operators D_j preserve the space of the polynomials of variables $x_1,\ldots,x_N$, which we denote $\mathbb{C}[x]$.

Cherednik introduced another version of the Dunkl operators that mutually commute[18] (see also Refs. 22 and 23):

$$\hat{D}_j^A=x_jD_j^A+\beta\sum_{k(<j)}s_{jk}. \tag{3}$$

The algebra generated by the elements $x_j^{\pm 1}$, $\hat{D}_j^A$, and s_{ij} is isomorphic to the degenerate double affine Hecke algebra $\mathfrak{H}'$ associated with the A_{N-1}-type root system.[18,19] We remark that the elements $x_j^{\pm 1}$, D_j^A, and s_{ij} also generate $\mathfrak{H}'$ since D_j^A and $\hat{D}_j^A$ are related through (3). We denote by $\mathfrak{H}_0'$ the subalgebra of $\mathfrak{H}'$ generated by $\hat{D}_j^A$ and s_{ij}, which is isomorphic to the degenerate affine Hecke algebra. We further denote by $\tilde{\mathfrak{H}}'$ the subalgebra of $\mathfrak{H}'$ generated by x_j, $\hat{D}_j^A$, and s_{ij}. In terms of generators, the defining relations are

$$[\hat{D}_i^A,\hat{D}_j^A]=[x_i,x_j]=0,$$

$$s_j^2=1,\quad s_js_{j+1}s_j=s_{j+1}s_js_{j+1},$$

$$[s_i,s_j]=0,\quad |i-j|\neq 1,$$

$$x_is_{ij}=s_{ij}x_j,\quad x_is_{jk}=s_{jk}x_i,\quad i\neq j,k,$$

$$\hat{D}_{j+1}^As_j-s_j\hat{D}_j^A=\beta,\quad s_j\hat{D}_{j+1}^A-\hat{D}_j^As_j=\beta,$$

$$[s_i,\hat{D}_j^A]=0,\quad j\neq i,i+1,$$

$$[\hat{D}_i^A,x_j]=\begin{cases}-\beta x_js_{ij}, & i>i,\\ x_i+\beta\left(\displaystyle\sum_{k(<i)}x_ks_{ik}+\sum_{k(>i)}x_is_{ik}\right), & i=j,\\ -\beta x_is_{ij}, & i<j,\end{cases}$$

where $s_j=s_{j,j+1}$ $(j=1,\ldots,n-1)$ are the simple transpositions.

For a partition $\lambda=(\lambda_1,\ldots,\lambda_N)$ and $w\in\mathfrak{S}_N$, we introduce the notation $x_w^\lambda=x_{w(1)}^{\lambda_j}\cdots x_{w(N)}^{\lambda_N}$. The action of $\hat{D}_j^A$ on monomials x_w^λ is given explicitly by[22–24]

$$\hat{D}_j^A x_w^\lambda = (w(\lambda+\beta\delta))_j x_w^\lambda + \sum_{(\mu,w')<(\lambda,w)} u_{ww'}^{\lambda\mu} x_{w'}^\mu, \tag{4}$$

with $\delta=(N-1,N-2,\ldots,0)$. Here the ordering $<$ is defined as follows: For two pairs (λ,w), (μ,w'), where λ, μ are partitions and $w,w'\in\mathfrak{S}_N$, we define the ordering $<$ as

$$(\mu,w')<(\lambda,w)\Leftrightarrow\begin{cases}\text{(i)} & \mu<_{\mathrm{D}}\lambda,\\ \text{(ii)} & \text{if } \mu=\lambda, \text{ then } w'<_{\mathrm{B}}w,\end{cases}$$

where $<_{\mathrm{D}}$ is the dominance ordering for partitions,[25] and $<_{\mathrm{B}}$ is the Bruhat ordering for the elements of $\mathfrak{S}_N$ (see, for example, Ref. 26). Since the action (4) is triangular, one can diagonalize the operators $\hat{D}_j^A$ simultaneously by a suitable choice of bases of $\mathbb{C}[x]$.[22–24] Such a basis is called a *nonsymmetric Jack polynomial*.

Definition 2.1:[22–24] *A nonsymmetric Jack polynomial $E_w^\lambda(x)$, labeled with the partition $\lambda=(\lambda_1,\ldots,\lambda_N)$ and the element $w\in\mathfrak{S}_N$, is characterized by the following properties:*

(i) $E_w^\lambda(x)=x_w^\lambda+\sum_{(\mu,w')<(\lambda,w)} u_{ww'}^{\lambda\mu}x_{w'}^\mu$,

(ii) $E_w^\lambda(x)$ *is joint eigenfunction for the operators* $\hat{D}_j^A$.

We note that our definition of the nonsymmetric Jack polynomials is slightly different from the one in the references cited above.

The symmetric Jack polynomials are obtained by symmetrizing E_w^λ, i.e.,

$$J_\lambda(x)=\frac{1}{\#\mathfrak{S}_N^\lambda}\prod_{v\in\mathfrak{S}_N} v(E_w^\lambda),$$

where $\mathfrak{S}_N^\lambda$ is a subgroup of $\mathfrak{S}_N$ that preserves λ. The Jack polynomials $J_\lambda(x)$ are pairwise orthogonal with respect to the following scalar product:

$$\langle f(x),g(x)\rangle_J^{(\beta)}=(-1)^{\beta N(N-1)/2}[f\overline{g}(\phi_s^{(\beta)})^2]_0, \tag{5}$$

where $[\cdot]_0$ stands for the constant term and $\overline{g}=g(x^{-1})$. We note that the operators $\hat{D}_j^A$ are self-adjoint with respect to this scalar product.

Next we define an analog of the creation and annihilation operators associated with the Hamiltonian (1):

$$\tilde{a}_j^\dagger=\frac{1}{\sqrt{2}}\,\tilde{\phi}_A^{-1}\circ(-D_j^A+x_j)\circ\tilde{\phi}_A,\quad \tilde{a}_j=\frac{1}{\sqrt{2}}\,\tilde{\phi}_A^{-1}\circ(D_j^A+x_j)\circ\tilde{\phi}_A,$$

with $\tilde{\phi}_A=\Pi_{k=1}^N\exp(-x_k^2/2)$. In Ref. 5, we have introduced a set of commuting operators:

$$\tilde{h}_j^A=\tilde{a}_j^\dagger\tilde{a}_j+\beta\sum_{k(<j)} s_{jk}.$$

These operators give another representation of $\tilde{\mathfrak{H}}'$ on $\mathbb{C}[x]$:

$$\rho^A(x_j)=\tilde{a}_j^\dagger,\quad \rho^A(\hat{D}_j^A)=\tilde{h}_j^A,\quad \rho^A(s_{ij})=s_{ij}.$$

The representation ρ^A is related to the A_{N-1}-type Calogero model. Indeed, the Hamiltonian (1) can be represented by $\tilde{h}_j^A$:

$$\mathscr{H}_A=\phi_A^{(\beta)}\circ\mathrm{Res}\left(\sum_{j=1}^N\tilde{h}_j^A\right)\circ(\phi_A^{(\beta)})^{-1}+\frac{N}{2},$$

with $\phi_A^{(\beta)}=\Pi_{j<k}|x_j-x_k|^\beta \Pi_{j=1}^N \exp(-x_j^2/2)$ a ground state wave function. The notation $\mathrm{Res}(X)$ means that action of X is restricted to symmetric functions of the variables $x_1,\ldots,x_N$. The scalar product corresponds to this case is the following:

$$\langle f,g\rangle_H^{(\beta)}=\int_{-\infty}^{\infty}\cdots\int_{-\infty}^{\infty} f(x)g(x)(\phi_A^{(\beta)})^2\, dx_1\cdots dx_N. \tag{6}$$

By a direct calculation, we see that the operator $\tilde{a}_j^\dagger$ is adjoint of $\tilde{a}_j$ with respect to the scalar product (6) for all $j=1,...,N$. Multivariable Hermite polynomials are defined by using this scalar product.[1,4] In fact, the definition in Ref. 1 and that in Ref. 4 are slightly different. Here we shall follow Ref. 4.

Definition 2.2:[4] *Multivariable Hermite polynomials* $H_\lambda^{(\beta)}(x)$ *are characterized by the following properties:*

(i) $H_\lambda^{(\beta)}=m_\lambda(x)+\sum_{\mu(<_D\lambda)} u_{\lambda\mu}^A m_\mu(x)$,
(ii) $\langle H_\lambda^{(\beta)}(x),m_\mu(x)\rangle_H^{(\beta)}=0$ *for all* $\mu<_D\lambda$.

We now introduce the intertwining operator σ^A, which is a linear operator on $\mathbb{C}[x]$ such that

$$\sigma^A(f(x_1,\ldots,x_N))=f(\tilde{a}_1^\dagger,\ldots,\tilde{a}_N^\dagger)\cdot 1 \quad \text{for all} \quad f(x_1,\ldots,x_N)\in\mathbb{C}[x].$$

The intertwiner σ^A enjoys the following property.

Theorem 2.3: $\sigma^A(Qf(x))=\rho^A(Q)\sigma^A(f(x))$ *for all* $Q\in\mathfrak{H}_0'$, $f(x)\in\mathbb{C}[x]$.

Proof: Since both Q and $f(x)$ are elements of $\tilde{\mathfrak{H}}'$, it suffices to prove $\sigma^A(P\cdot 1)=\rho^A(P)\cdot 1$ for all $P\in\tilde{\mathfrak{H}}'$. We then note that every element P of $\tilde{\mathfrak{H}}'$ can be represented in the following form:

$$P=\sum_{\mathbf{n}}\sum_{w\in\mathfrak{S}_N} p_{\mathbf{n},w}(x)(\hat{D}^A)^{n_1}\cdots(\hat{D}_N^A)^{n_N}w,$$

where $p_{\mathbf{n},w}(x)$ are some polynomials. Since $\hat{D}_j^A\cdot 1=\tilde{h}_j^A\cdot 1=\beta(j-1)$ for all j, we obtain the desired result. □

Using the intertwiner σ^A, we can construct an operator representation of $H_\lambda^{(\beta)}(x)$.

Proposition 2.4:[5,8,9] *Multivariable Hermite polynomials* $H_\lambda^{(\beta)}(x)$ *are related to the Jack polynomials as follows:*

$$H_\lambda^{(\beta)}(x)=2^{-|\lambda|/2}\sigma^A(J_\lambda^{(\beta)}(x))=2^{-|\lambda|/2}J_\lambda^{(\beta)}(\tilde{a}^\dagger)\cdot 1.$$

To prove this relation, it is enough to show $\sigma^A(J_\lambda^{(\beta)}(x))$ satisfies the second property of Definition 2.2. One can find the proofs in Refs. 5 and 9.

Now we turn to the B_N-type model (2). Dunkl operators associated with the B_N-type root system are defined as follows:[13,21]

$$D_j^B=\frac{\partial}{\partial z_j}+\beta\sum_{k(\neq j)}\left(\frac{1-s_{jk}}{z_j-z_k}+\frac{1-t_jt_ks_{jk}}{z_j+z_k}\right)+\gamma\,\frac{1-t_j}{z_j}, \tag{7}$$

where s_{jk} and t_j are elements of the B_N-type Weyl group. An element s_{ij} acts the same as in the A_{N-1}-case and t_j acts as a sign change, i.e., replaces the coordinate z_j by $-z_j$.

We then define Cherednik-type commuting operators associated with (7):

$$\hat{D}_j^B=z_jD_j^B+\beta\sum_{k(<j)}(s_{jk}+t_jt_ks_{ik}).$$

If we make a change of the variables $x_j=z_j^2/2$, $\mathrm{Res}^{(t)}(\hat{D}_j^B)$ is equivalent to $2\hat{D}_j^A$ where the notation $\mathrm{Res}^{(t)}(X)$ means the action of the operator X is restricted to the functions with the symmetry $t_jf(z)=f(z)$.[6] From this fact, we can define the representation of $\tilde{\mathfrak{H}}'$ on $\mathbb{C}[z^2]$:

$$x_j\mapsto\tfrac{1}{2}z_j^2,\quad \hat{D}_j^A\mapsto\tfrac{1}{2}\hat{D}_j^B,\quad s_{ij}\mapsto s_{ij}.$$

We now introduce creation and annihilation operators for the B_N case:

$$\tilde{b}_j^\dagger=\frac{1}{\sqrt{2}}\,\tilde{\phi}_B^{-1}\circ(-D_j^B+z_j)\circ\tilde{\phi}_B,\quad \tilde{b}_j=\frac{1}{\sqrt{2}}\,\tilde{\phi}_B^{-1}\circ(D_j^B+z_j)\circ\tilde{\phi}_B,$$

with $\tilde{\phi}_B=\Pi_{k=1}^N \exp(-z_k^2/2)$. Since the commutation relations of these operators are the same as those of z_j and D_j^B by construction, we can define commuting operators $\tilde{h}_j^B$ as follows:[6]

$$\tilde{h}_j^B=\kappa(\hat{D}_j^B)=\tilde{b}_j^\dagger\tilde{b}_j+\beta\sum_{k(<j)}(s_{jk}+t_jt_ks_{ik}).$$

These operators give another representation of $\tilde{\mathfrak{H}}'$ on $\mathbb{C}[z^2]$:

$$\rho^B(x_j)=\tfrac{1}{2}(\tilde{b}_j^\dagger)^2,\quad \rho^B(\hat{D}_j^A)=\tfrac{1}{2}\tilde{h}_j^B,\quad \rho^B(s_{ij})=s_{ij}.$$

The representation ρ^B is related to the B_N-type Calogero Hamiltonian (2) as follows:

$$\mathscr{H}_B=\phi_B^{(\beta)}\circ\mathrm{Res}\left(\sum_{j=1}^N\tilde{h}_j^B\right)\circ(\phi_B^{(\beta)})^{-1}+\left(\frac{1}{2}+\gamma\right)N,$$

with $\phi_B^{(\beta)}=\Pi_{j<k}|z_j^2-z_k^2|^\beta\Pi_{j=1}^N|z_j|^\gamma\exp(-z_j^2/2)$ the ground state wave function of (2). The scalar product associated with this model is

$$\langle f(z),g(z)\rangle_L^{(\beta)}=\int_{-\infty}^{\infty}\cdots\int_{-\infty}^{\infty}f(z)g(z)(\phi_B^{(\beta)})^2\,dz_1\cdots dz_N. \tag{8}$$

By a direct calculation, we can show that the operator $\tilde{b}_j^\dagger$ is adjoint of $\tilde{b}_j$ with respect to the scalar product (8), and hence the operator $\tilde{h}_j^B$ is self-adjoint for all $j=1,...,N$. Now we define multivariable Laguerre polynomials.[4]

Definition 2.5:[4] *Multivariable Laguerre polynomials $L_\lambda^{(\beta)}(z)$ are characterized by the following properties:*

(i) $L_\lambda^{(\beta)}(z)=m_\lambda(z^2)+\sum_{\mu(<_D\lambda)}u_{\lambda\mu}m_\mu(z^2)$,
(ii) $\langle L_\lambda^{(\beta)}(z),m_\mu(z^2)\rangle_L^{(\beta)}=0$ *for all* $\mu<_D\lambda$.

We define a linear map of $\mathbb{C}[x]$ to $\mathbb{C}[z^2]$ by using ρ^B:

$$\sigma^B(f(x_1,\ldots,x_N))=f((\tilde{b}_1^\dagger)^2/2,\ldots,(\tilde{b}_N^\dagger)^2/2)\cdot 1\quad\text{for all}\quad f(x_1,\ldots,x_N)\in\mathbb{C}[x].$$

As in the A_{N-1} case, the intertwiner σ^B enjoys the following property.

Theorem 2.6: $\sigma^B(Qf(x))=\rho^B(Q)\sigma^B(f(x))\cdot 1$ *for all* $Q\in\mathfrak{H}_0'$, $f(x_1,\ldots,x_N)\in\mathbb{C}[x]$. One can prove this statement in the same fashion as Theorem 2.3, so we omit the details.

We can construct an operator representation of $L_\lambda^{(\beta)}(z)$ by using the intertwiner σ^B.

Proposition 2.7:[6] *Multivariable Laguerre polynomials $L_\lambda^{(\beta)}(z)$ are related to the Jack polynomials as follows:*

$$L_\lambda^{(\beta)}(z)=\sigma^B(J_\lambda^{(\beta)}(x))=J_\lambda^{(\beta)}((\tilde{b}^\dagger)^2/2)\cdot 1.$$

III. CONSTRUCTION OF RAISING OPERATORS

As is shown in the previous section, the multivariable Hermite and Laguerre polynomials are expressed in terms of the Jack polynomials whose arguments are Dunkl-type operators. Some properties of the multivariable Hermite and Laguerre polynomials are obtained directly from those of the Jack polynomials simply by applying ρ^A or ρ^B. As an example, we will construct raising operators for the polynomials.

Lapointe and Vinet constructed raising operators for the Jack polynomials.[20] Using their raising operators, they obtained a Rodorigues-type formula for the Jack polynomials. After the work of Lapointe and Vinet, Ujino and Wadati constructed raising operators for the multivariable Hermite polynomials.[8] The raising operators above are constructed by the use of Dunkl operators of Heckman type which are noncommutative, so their relation to the degenerate double affine Hecke algebra was not clear.

On the other hand, Kirillov and Noumi gave another expression of raising operators by using Cherednik operators.[16] In our notation, their raising operators are expressed in the following form:

$$B_m^{\mathrm{J}}=\sum_{k_1<\cdots<k_m} x_{k_1}x_{k_2}\cdots x_{k_m}(\hat{D}_{k_1}^A+\beta(2-k_1))(\hat{D}_{k_2}^A+\beta(3-k_2))\cdots(\hat{D}_{k_m}^A+\beta(m-k_m+1)).$$

We recall an important property of these operators.

Theorem 3.1:[16] *Actions of the operators $B_m^{\mathrm{J}}\in\tilde{\mathfrak{H}}'$ on the Jack polynomials are given by*

$$B_m^{\mathrm{J}}J_\lambda^{(\beta)}(x)=\prod_{j=1}^{m}(\lambda_j+\beta(m-j+1))J_{\lambda+(1^m)}^{(\beta)}(x),$$

where $\lambda+(1^m)=(\lambda_1+1,\ldots,\lambda_N+1)$.

Applying σ^A or σ^B to B_m^{J}, we obtain raising operators for the Hermite case or the Laguerre case, respectively:

$$B_m^{\mathrm{H}}=\sum_{k_1<\cdots<k_m}\tilde{a}_{k_1}^\dagger\tilde{a}_{k_2}^\dagger\cdots\tilde{a}_{k_m}^\dagger(\tilde{h}_{k_1}^A+\beta(2-k_1))(\tilde{h}_{k_2}^A+\beta(3-k_2))\cdots(\tilde{h}_{k_m}^A+\beta(m-k_m+1)),$$

$$B_m^{\mathrm{L}}=\sum_{k_1<\cdots<k_m}\tilde{b}_{k_1}^\dagger\tilde{b}_{k_2}^\dagger\cdots\tilde{b}_{k_m}^\dagger(\tilde{h}_{k_1}^B+\beta(2-k_1))(\tilde{h}_{k_2}^B+\beta(3-k_2))\cdots(\tilde{h}_{k_m}^B+\beta(m-k_m+1)).$$

From Theorem 3.1 and Propositions 2.4 and 2.7, we immediately have the following:

Proposition 3.2: (i) $B_m^{\mathrm{H}}H_\lambda^{(\beta)}(x)=2^{-m/2}\Pi_{j=1}^m(\lambda_j+\beta(m-j+1))H_{\lambda+(1^m)}^{(\beta)}(x)$,
(ii) $B_m^{\mathrm{L}}L_\lambda^{(\beta)}(z)=\Pi_{j=1}^m(\lambda_j+\beta(m-j+1))L_{\lambda+(1^m)}^{(\beta)}(z)$.

Applying the raising operators repeatedly, one can obtain Rodorigues-type formulas for the multivariable Hermite and Laguerre polynomials:

$$H_\lambda^{(\beta)}(x)=2^{|\lambda|/2}\prod_{(i,j)\in\lambda}(\lambda_i-j+\beta(\lambda_j'-i+1))^{-1}(B_N^{\mathrm{H}})^{\lambda_N}(B_{N-1}^{\mathrm{H}})^{\lambda_{N-1}-\lambda_N}\cdots(B_1^{\mathrm{H}})^{\lambda_1-\lambda_2}\cdot 1,$$

$$L_\lambda^{(\beta)}(z)=\prod_{(i,j)\in\lambda}(\lambda_i-j+\beta(\lambda_j'-i+1))^{-1}(B_N^{\mathrm{L}})^{\lambda_N}(B_{N-1}^{\mathrm{L}})^{\lambda_{N-1}-\lambda_N}\cdots(B_1^{\mathrm{L}})^{\lambda_1-\lambda_2}\cdot 1,$$

where $\lambda'=(\lambda_1',\lambda_2',\ldots)$ is the conjugate partition to λ.

This expression of the raising operators for the multivariable Hermite polynomials is different from those of Ref. 8. The operators for the multivariable Laguerre polynomials have not been presented, as far as we know.

IV. CONSTRUCTION OF SHIFT OPERATORS

In this section, we construct shift operators for the multivariable Hermite and Laguerre polynomials. Each of such shift operators are related to one of the scalar products (5), (6), and (8) (see Theorems 4.2, 4.6, and 4.9 to follow). However, properties related to scalar product cannot be obtained simply by applying ρ^A or ρ^B. It requires a little more effort to construct shift operators.

A. Shift operators for the Jack polynomials

In this subsection, we review the method of constructing shift operators for the Jack polynomials by the use of the Cherednik operators. We note that the shift operators constructed below are different from that of Ref. 27, where Heckman-type operators are used. Our method is based on a

lecture note of Kirillov Jr.[15] All results given in this section can be obtained by taking limiting procedures on those of Ref. 15. However, all proofs given here are algebraic and we avoid using a limiting procedure so that we can apply the results to the Hermite and Laguerre cases.

Consider elements of $\mathfrak{H}_0'$ that have the following forms:

$$\mathscr{X}=\prod_{i<j}(x_i-x_j),\quad \mathscr{Y}_J=\prod_{i<j}(\beta-\hat{D}_i^A+\hat{D}_j^A),\quad \hat{\mathscr{Y}}_J=\prod_{i<j}(-\beta-\hat{D}_i^A+\hat{D}_j^A).$$

We note that these operators preserve $\mathbb{C}[x]$. From the defining relations of $\mathfrak{H}_0'$, we know that

$$\begin{aligned}(s_j+1)(-\beta-\hat{D}_j^A+\hat{D}_{j+1}^A)&=(-\beta-\hat{D}_{j+1}^A+\hat{D}_j^A)(s_j-1),\\ (s_j-1)(\beta-\hat{D}_j^A+\hat{D}_{j+1}^A)&=(\beta-\hat{D}_{j+1}^A+\hat{D}_j^A)(s_j+1),\\ s_j(c-\hat{D}_j^A+\hat{D}_k^A)(c-\hat{D}_{j+1}^A+\hat{D}_k^A)&=(c-\hat{D}_j^A+\hat{D}_k^A)(c-\hat{D}_{j+1}^A+\hat{D}_k^A)s_j,\end{aligned}\tag{9}$$

with c is an arbitrary constant and $k\neq j,\ j+1$. Then, if we define $\mathbb{C}[x]^{\mathfrak{S}_N}$ and $\mathbb{C}[x]^{-\mathfrak{S}_N}$ as

$$\mathbb{C}[x]^{\mathfrak{S}_N}=\{f(x)\in\mathbb{C}[x]\,|\,(s_j-1)f(x)=0\},$$

$$\mathbb{C}[x]^{-\mathfrak{S}_N}=\{f(x)\in\mathbb{C}[x]\,|\,(s_j+1)f(x)=0\},$$

we see that

$$\mathscr{X}\in\mathbb{C}[x]^{-\mathfrak{S}_N},\quad \mathscr{Y}_J(\mathbb{C}[x]^{\mathfrak{S}_N})=\mathbb{C}[x]^{-\mathfrak{S}_N},\quad \hat{\mathscr{Y}}_J(\mathbb{C}[x]^{-\mathfrak{S}_N})=\mathbb{C}[x]^{\mathfrak{S}_N}.\tag{10}$$

We now introduce shift operators for the Jack polynomials:

$$G_J=\mathscr{X}^{-1}\mathscr{Y}_J,\quad \hat{G}_J=\hat{\mathscr{Y}}_J\mathscr{X}.$$

The operators G_J and $\hat{G}_J$ enjoy the following properties:

Lemma 4.1.[15] (i) $G_J J_{\lambda+\delta}^{(\beta)},\ \hat{G}_J J_\lambda^{(\beta+1)}\in\mathbb{C}[x]^{\mathfrak{S}_N}$.

(ii) $G_J J_{\lambda+\delta}^{(\beta)}=c_\lambda^{(\beta+1)}m_\lambda+$ ''lower terms'' with respect to $<_D$, with $c_\lambda^{(\beta+1)}=\Pi_{i<j}\{\lambda_{N-j+1}-\lambda_{N-i+1}+j-i+\beta(j-i-1)\}$.

(iii) $\hat{G}_J J_\lambda^{(\beta+1)}=\tilde{c}_\lambda^{(\beta+1)}m_{\lambda+\delta}+$ ''lower terms'' with respect to $<_D$, with $\tilde{c}_\lambda^{(\beta+1)}=\Pi_{i<j}\{\lambda_{N-j+1}-\lambda_{N-i+1}+j-i+\beta(j-i+1)\}$.

Proof: (i) Follows from (10).

(ii) For the longest element w_0 of $\mathfrak{S}_N$, i.e., $w_0(j)=N-j+1$, Eq. (4) reduces to

$$\hat{D}_j^A x_{w_0}^\lambda=(\lambda_{N-j+1}+\beta(j-1))x_{w_0}^\lambda+\sum_{(\mu,w')<(\lambda,w_0)}u_{w_0w'}^{\lambda\mu}x_{w'}^\mu.$$

Using this relation, we can calculate the action of $\mathscr{Y}_J$:

$$\begin{aligned}\mathscr{Y}_J J_{\lambda+\delta}^{(\beta)}&=\prod_{i<j}(\beta-\hat{D}_i^A+\hat{D}_j^A)(x_{w_0}^{\lambda+\delta}+\text{''lower terms'' with respect to }<)\\ &=c_\lambda^{(\beta+1)}x_{w_0}^{\lambda+\delta}+\text{''lower terms'' with respect to }<.\end{aligned}\tag{11}$$

On the other hand, (10) implies that $\mathscr{Y}_J J_{\lambda+\delta}^{(\beta)}$ is divisible by $\mathscr{X}$. Together with (i), this concludes the proof.

(iii) Can also be proved in a similar way.

The following theorem implies that $\hat{G}_J$ is, in a sense, adjoint of G_J:

Theorem 4.2:[15] *For* $f,g\in\mathbb{C}[x]^{\mathfrak{S}_N}$, $\langle G_J f,g\rangle_J^{(\beta+1)}=\langle f,\hat{G}_J g\rangle_J^{(\beta)}$.

To prove this theorem, we introduce symmetrizer $\mathscr{P}_+$ and antisymmetrizer $\mathscr{P}_-$ as

$$\mathscr{P}_+=\frac{1}{\#\mathfrak{S}_N}\sum_{w\in\mathfrak{S}_N} w,\quad \mathscr{P}_-=\frac{1}{\#\mathfrak{S}_N}\sum_{w\in\mathfrak{S}_N}(-1)^{l(w)}w,$$

where $l(w)$ is the length of the element w. We further prepare a lemma.

Lemma 4.3:[15] $\mathscr{P}_-(\mathscr{Y}_J-\hat{\mathscr{Y}}_J)=\Sigma_j\hat{g}_j(\hat{D}_1^A,\ldots,\hat{D}_N^A)(s_j-1)$ *for some* $\hat{g}_j(x_1,\ldots,x_N)\in\mathbb{C}[x]$.

It should be remarked that this lemma is a degenerate version of a lemma given in Ref. 15. We will give a proof in the Appendix for the reader's convenience.

Now we go back to the proof of Theorem 4.2.

Proof of Theorem 4.2: It is clear that $\mathscr{P}_+$ does not affect the constant term of polynomials. Then, for $f,g\in\mathbb{C}[x]^{\mathfrak{S}_N}$, we know that

$$\begin{aligned}\langle G_J,f,g\rangle_J^{(\beta+1)}&=(-1)^{(\beta+1)N(N-1)/2}[(\mathscr{X}^{-1}\mathscr{Y}_Jf)\overline{g}(\phi_S^{(\beta+1)})^2]_0\\&=(-1)^{(\beta+1)N(N-1)/2}[\mathscr{P}_+((\mathscr{Y}_Jf)\overline{g}\mathscr{X}(\phi_S^{(\beta)})^2)]_0\\&=(-1)^{\beta N(N-1)/2}[\mathscr{P}_-(\mathscr{Y}_Jf)\overline{g}\overline{\mathscr{X}}(\phi_S^{(\beta)})^2]_0.\end{aligned}$$

From Lemma 4.3, we see that $\mathscr{P}_-(\mathscr{Y}_J-\hat{\mathscr{Y}}_J)f=0$ for all $f\in\mathbb{C}[x]^{\mathfrak{S}_N}$. Hence we can replace $\mathscr{Y}_J$ by $\hat{\mathscr{Y}}_J$:

$$\langle G_J,f,g\rangle_J^{(\beta+1)}=(-1)^{\beta N(N-1)/2}[\mathscr{P}_-(\hat{\mathscr{Y}}_Jf)\overline{g}\overline{\mathscr{X}}(\phi_S^{(\beta)})^2]_0=\langle\hat{\mathscr{Y}}_Jf,\mathscr{X}g\rangle_J^{(\beta)}=\langle f,\hat{G}_Jg\rangle_J^{(\beta)}.$$

In the last equality, we have used the self-adjointness of $\hat{D}_j^A$. □

Using Theorem 4.2, we can evaluate the action of G_J and $\hat{G}_J$ on the Jack polynomials.

Proposition 4.4:[15] $G_JJ_{\lambda+\delta}^{(\beta)}=c_\lambda^{(\beta+1)}J_\lambda^{(\beta+1)}$, $\hat{G}_JJ_\lambda^{(\beta+1)}=\tilde{c}_\lambda^{(\beta+1)}J_{\lambda+\delta}^{(\beta)}$, *where the constants* $c_\lambda^{(\beta)}$ *and* $\tilde{c}_\lambda^{(\beta)}$ *are defined in Lemma 4.1.*

Proof: Assume $\mu<_D\lambda$. Then we have

$$\langle G_JJ_{\lambda+\delta}^{(\beta)},m_\mu\rangle_J^{(\beta)}=\langle J_{\lambda+\delta}^{(\beta)},\hat{G}_Jm_\mu\rangle_J^{(\beta)}=\langle J_{\lambda+\delta}^{(\beta)},m_{\mu+\delta}+\text{lower terms}\rangle_J^{(\beta)}=0,$$

where we have used Lemma 4.1 and Theorem 4.2. From this fact, along with Lemma 4.1 (ii), we see that $G_JJ_{\lambda+\delta}^{(\beta)}$ coincides with $c_\lambda^{(\beta+1)}J_\lambda^{(\beta+1)}$. The latter can be proved in a similar way. □

With these preliminaries, it is possible to derive the following result.

Proposition 4.5:[25]

$$\langle J_\lambda^{(\beta)},J_\lambda^{(\beta)}\rangle_J^{(\beta)}=N!\prod_{k=1}^{\beta}\prod_{i<j}\frac{\lambda_i-\lambda_j-k+\beta(j-i+1)}{\lambda_i-\lambda_j+k+\beta(j-i-1)}.\tag{12}$$

Proof: From Proposition 4.4, it follows that

$$\begin{aligned}\langle J_\lambda^{(\beta+1)},J_\lambda^{(\beta+1)}\rangle_J^{(\beta+1)}&=\frac{1}{c_\lambda^{(\beta+1)}}\langle GJ_{\lambda+\delta}^{(\beta)},J_\lambda^{(\beta+1)}\rangle_J^{(\beta+1)}\\&=\frac{1}{c_\lambda^{(\beta+1)}}\langle J_{\lambda+\delta}^{(\beta)},\hat{G}_JJ_\lambda^{(\beta+1)}\rangle_J^{(\beta)}\\&=\frac{\tilde{c}_\lambda^{(\beta+1)}}{c_\lambda^{(\beta+1)}}\langle J_{\lambda+\delta}^{(\beta)},J_{\lambda=\delta}^{(\beta)}\rangle_J^{(\beta)}.\end{aligned}$$

Applying this relation repeatedly, we have

$$\langle J_\lambda^{(\beta)},J_\lambda^{(\beta)}\rangle_J^{(\beta)}=\prod_{k=0}^{\beta-1}\frac{\tilde{c}_{\lambda+k\delta}^{(\beta-k)}}{c_{\lambda+k\delta}^{(\beta-k)}}\langle J_{\lambda+\beta\delta}^{(\beta=0)},J_{\lambda+\beta\delta}^{(\beta=0)}\rangle_S^{(\beta=0)},$$

which gives the desired result.

The norm formula (12) can be rewritten into the following form:

$$\langle J_\lambda^{(\beta)}, J_\lambda^{(\beta)} \rangle_{\mathrm{J}}^{(\beta)} = \frac{(N\beta)!}{(\beta!)^N} \prod_{(i,j)\in\lambda} \frac{j-1+\beta(N-i+1)}{j+\beta(N-i)} \cdot \frac{\lambda_i - j + 1 + \beta(\lambda'_j - i)}{\lambda_i - j + \beta(\lambda'_j - i + 1)}. \tag{13}$$

A proof of the equivalence between (12) and (13) is given by induction on $|\lambda|$.

B. Shift operators for the multivariable Hermite polynomials

In this section, we will construct shift operators for the multivariable Hermite polynomials. It should be noted that Heckman has constructed shift operators for the Hamiltonian H_A without harmonic potential.[28] However, for the application to norm formulas, it is necessary to compute actions of the shift operators on polynomials explicitly. Our method gives a unified and straightforward way to compute such actions.

To construct shift operators, we first introduce $\mathscr{Y}_{\mathrm{H}}$ and $\hat{\mathscr{Y}}_{\mathrm{H}}$ as follows:

$$\mathscr{Y}_{\mathrm{H}} = \rho^A(\mathscr{Y}_{\mathrm{J}}) = \prod_{i<j} (\beta - \tilde{h}_i^A + \tilde{h}_j^A), \quad \hat{\mathscr{Y}}_{\mathrm{H}} = \rho^A(\hat{\mathscr{Y}}_{\mathrm{J}}) = \prod_{i<j} (-\beta - \tilde{h}_i^A + \tilde{h}_j^A).$$

Using these operators, we define shift operators for the multivariable Hermite polynomials:

$$G_{\mathrm{H}} = \mathscr{X}^{-1} \mathscr{Y}_{\mathrm{H}}, \quad \hat{G}_{\mathrm{H}} = \hat{\mathscr{Y}}_{\mathrm{H}} \mathscr{X}.$$

We stress that we have used same $\mathscr{X}$ as (9), and therefore $G_{\mathrm{H}} \neq \rho^A(G_{\mathrm{J}})$ and $\hat{G}_{\mathrm{H}} \neq \rho^A(\hat{G}_{\mathrm{J}})$. This reflects the characteristics of the scalar products (5) and (6).

If we apply ρ^A to (9), we have

$$(s_j + 1)(-\beta - \tilde{h}_j^A + \tilde{h}_{j+1}^A) = (-\beta - \tilde{h}_{j+1}^A + \tilde{h}_j^A)(s_j - 1),$$

$$(s_j - 1)(\beta - \tilde{h}_j^A + \tilde{h}_{j+1}^A) = (\beta - \tilde{h}_{j+1}^A + \tilde{h}_j^A)(s_j + 1),$$

$$s_j (c - \tilde{h}_j^A + \tilde{h}_k^A)(c - \tilde{h}_{j+1}^A + \tilde{h}_k^A) = (c - \tilde{h}_j^A + \tilde{h}_k^A)(c - \tilde{h}_{j+1}^A + \tilde{h}_k^A) s_j,$$

with c an arbitrary constant and $k \neq j,\ j+1$. These relations imply that

$$\mathscr{Y}_{\mathrm{H}}(\mathbb{C}[x]^{\mathfrak{S}_N}) = \mathbb{C}[x]^{-\mathfrak{S}_N}, \quad \hat{\mathscr{Y}}_{\mathrm{H}}(\mathbb{C}[x]^{-\mathfrak{S}_N}) = \mathbb{C}[x]^{\mathfrak{S}_N}. \tag{14}$$

Furthermore, if we apply σ^A to (11), we see that

$$\mathscr{Y}_{\mathrm{H}} H_{\lambda+\delta}^{(\beta)} = c_\lambda^{(\beta+1)} x_{w_0}^{\lambda+\delta} + \text{“lower terms” with respect to } \prec. \tag{15}$$

For the proof of the shift relations for the Jack polynomials (Proposition 4.4), Theorem 4.2 played a crucial role. Here we state an analogous result for the Hermite case:

Theorem 4.6: For $f,\ g \in \mathbb{C}[x]^{\mathfrak{S}_N}$, $\langle G_{\mathrm{H}} f, g \rangle_{\mathrm{H}}^{(\beta+1)} = \langle f, \hat{G}_{\mathrm{H}} g \rangle_{\mathrm{H}}^{(\beta)}$.

Proof: The proof is similar to that of Theorem 4.2. For $f,\ g \in \mathbb{C}[x]^{\mathfrak{S}_N}$, we know that

$$\langle G_{\mathrm{H}} f, g \rangle_{\mathrm{H}}^{(\beta+1)} = \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} \mathscr{P}_-(\mathscr{Y}_{\mathrm{H}} f)\, g\, \mathscr{X}(\phi_A^{(\beta)})^2\, dx_1 \cdots dx_N.$$

On the other hand, applying ρ^A to Lemma 4.3, we obtain

$$\mathscr{P}_-(\mathscr{Y}_{\mathrm{H}} - \hat{\mathscr{Y}}_{\mathrm{H}}) = \sum_j \hat{g}_j(\tilde{a}_1^\dagger, \ldots, \tilde{a}_N^\dagger)(s_j - 1) \quad \text{for some } \hat{g}_j(x_1, \ldots, x_N) \in \mathbb{C}[x].$$

From this relation, we find that $\mathscr{P}_-(\mathscr{Y}_{\mathrm{H}} - \hat{\mathscr{Y}}_{\mathrm{H}}) f = 0$ for all $f \in \mathbb{C}[x]^{\mathfrak{S}_N}$. Hence we can replace $\mathscr{Y}_{\mathrm{H}}$ by $\hat{\mathscr{Y}}_{\mathrm{H}}$:

$$\langle G_{\mathrm{H}} f, g \rangle_{\mathrm{H}}^{(\beta+1)} = \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} \mathscr{P}_-(\hat{\mathscr{Y}}_{\mathrm{H}} f)\, g\, \mathscr{X}(\phi_A^{(\beta)})^2\, dx_1 \cdots dx_N = \langle \hat{\mathscr{Y}}_{\mathrm{H}} f, \mathscr{X} g \rangle_{\mathrm{H}}^{(\beta)} = \langle f, \hat{G}_{\mathrm{H}} g \rangle_{\mathrm{H}}^{(\beta)}.$$

In the last equality, we have used the self-adjointness of the operator $\tilde{h}_j^A$. □

Now we are in position to state the following.

Proposition 4.7: $G_{\mathrm{H}}H_{\lambda+\delta}^{(\beta)}=c_\lambda^{(\beta+1)}H_\lambda^{(\beta+1)}$, $\hat{G}_{\mathrm{H}}H_\lambda^{(\beta+1)}=\tilde{c}_\lambda^{(\beta+1)}H_{\lambda+\delta}^{(\beta)}$, *where the constants* $c_\lambda^{(\beta)}$ *and* $\tilde{c}_\lambda^{(\beta)}$ *are defined in Lemma 4.1.*

Proof: From (14) and (15), we know that $(c_\lambda^{(\beta+1)})^{-1}G_{\mathrm{H}}H_{\lambda+\delta}^{(\beta)}$ satisfies the first condition of Definition 2.2. So it is sufficient to prove the orthogonality which can be shown in the same way as Proposition 4.4. The second equation can be proved in similar way. □

Using Proposition 4.7 and Theorem 4.6, we can prove the norm formula for $H_\lambda^{(\beta)}$.

Proposition 4.8:[1,4]

$$\langle H_\lambda^{(\beta)},H_\lambda^{(\beta)}\rangle_{\mathrm{H}}^{(\beta)}=\frac{\pi^{N/2}N!}{2^{|\lambda|+\beta N(N-1)/2}}\prod_{j=1}^{N}(\lambda_j+\beta(N-j))!\prod_{k=1}^{\beta}\prod_{i<j}\frac{\lambda_i-\lambda_j-k+\beta(j-i+1)}{\lambda_i-\lambda_j+k+\beta(j-i-1)},\tag{16}$$

where $|\lambda|=\Sigma_j\lambda_j$.

Proof: Using Proposition 4.7 and Theorem 4.6, we see that

$$\langle H_\lambda^{(\beta+1)},H_\lambda^{(\beta+1)}\rangle_{\mathrm{H}}^{(\beta+1)}=\frac{\tilde{c}_\lambda^{(\beta+1)}}{c_\lambda^{(\beta+1)}}\langle H_{\lambda+\delta}^{(\beta)},H_{\lambda+\delta}^{(\beta)}\rangle_{\mathrm{H}}^{(\beta)}.$$

On the other hand, since $H_\lambda^{(\beta=0)}(x)$ is direct product of the (one-variable) Hermite polynomials, one can evaluate the norm easily:

$$\langle H_\lambda^{(\beta=0)},H_\lambda^{(\beta=0)}\rangle_{\mathrm{H}}^{(\beta=0)}=\frac{\pi^{N/2}\cdot\#\mathfrak{G}_N^\lambda}{2^{|\lambda|}}\prod_{j=1}^{N}\lambda_j!.$$

Using these relations, one arrives at the formula above. □

The norm formula (16) can be rewritten into the following form:[1]

$$\langle H_\lambda^{(\beta)},H_\lambda^{(\beta)}\rangle_{\mathrm{H}}^{(\beta)}=\frac{\pi^{N/2}}{2^{|\lambda|+\beta N(N-1)/2}}\cdot\frac{\Pi_{j=1}^{N}(j\beta)!}{(\beta!)^N}\times\prod_{(i,j)\in\lambda}\frac{\{j-1+\beta(N-i+1)\}\{\lambda_i-j+1+\beta(\lambda_j'-i)\}}{\lambda_i-j+\beta(\lambda_j'-i+1)}.$$

It should be remarked that other proofs of these formulas have been given via limiting procedure.[1,4]

C. Shift operators for the multivariable Laguerre polynomials

We first define $\mathscr{X}_{\mathrm{L}}$, $\mathscr{Y}_{\mathrm{L}}$, and $\hat{\mathscr{Y}}_{\mathrm{L}}$ as follows:

$$\mathscr{X}_{\mathrm{L}}=\prod_{i<j}(z_i^2-z_j^2),\quad \mathscr{Y}_{\mathrm{L}}=\rho^B(\mathscr{Y}_{\mathrm{J}})=\prod_{i<j}(\beta-\tilde{h}_i^B/2+\tilde{h}_j^B/2),$$

$$\hat{\mathscr{Y}}_{\mathrm{L}}=\rho^B(\hat{\mathscr{Y}}_{\mathrm{J}})=\prod_{i<j}(-\beta-\tilde{h}_i^B/2+\tilde{h}_j^B/2).$$

After same discussion as in the previous subsection, we see that

$$\mathscr{Y}_{\mathrm{L}}(\mathbb{C}[z^2]^{\mathfrak{G}_N})=\mathbb{C}[z^2]^{-\mathfrak{G}_N},\quad \hat{\mathscr{Y}}_{\mathrm{L}}(\mathbb{C}[z^2]^{-\mathfrak{G}_N})=\mathbb{C}[z^2]^{\mathfrak{G}_N},\tag{17}$$

and

$$\mathscr{Y}_{\mathrm{H}}L_{\lambda+\delta}^{(\beta)}=c_\lambda^{(\beta+1)}z_{w_0}^{2(\lambda+\delta)}+\text{“lower terms” with respect to }\prec.\tag{18}$$

Now we define the shift operators for the Laguerre case:

$$G_{\mathrm{L}}=\mathscr{X}_{\mathrm{L}}^{-1}\mathscr{Y}_{\mathrm{L}},\quad \hat{G}_{\mathrm{L}}=\hat{\mathscr{Y}}_{\mathrm{L}}\mathscr{X}_{\mathrm{L}}.$$

These operators enjoy the following properties:

Theorem 4.9: *For* $f,g\in\mathbb{C}[z^2]^{\mathfrak{G}_N}$, $\langle G_{\mathrm{L}}f,g\rangle_{\mathrm{L}}^{(\beta+1)}=\langle f,\hat{G}_{\mathrm{L}}g\rangle_{\mathrm{L}}^{(\beta)}$.

Proof: The proof for this case is also similar to that of Theorem 4.2. For $f,g\in\mathbb{C}[z^2]^{\mathfrak{G}_N}$, we know that

$$\langle G_{\mathrm{L}},f,g\rangle_{\mathrm{L}}^{(\beta+1)}=\int_{-\infty}^{\infty}\cdots\int_{-\infty}^{\infty}\mathscr{P}_{-}(\mathscr{Y}_{\mathrm{L}}f\ )g.\mathscr{X}_{\mathrm{L}}(\phi_B^{(\beta)})^2\ dz_1\cdots dz_N.$$

On the other hand, applying ρ^B to Lemma 4.3, we find that

$$\mathscr{P}_{-}(\mathscr{Y}_{\mathrm{L}}-\hat{\mathscr{Y}}_{\mathrm{L}})=\sum_j\ \hat{g}_j(\tilde{b}_1^{\dagger},\ldots,\tilde{b}_N^{\dagger})(s_j-1)\quad\text{for some}\ \ \hat{g}_j(x_1,\ldots,x_N)\in\mathbb{C}[x].$$

From this relation, we see that $\mathscr{P}_{-}(\mathscr{Y}_{\mathrm{L}}-\hat{\mathscr{Y}}_{\mathrm{L}})f=0$ for all $f\in\mathbb{C}[z^2]^{\mathfrak{G}_N}$. Hence we can replace $\mathscr{Y}_{\mathrm{L}}$ by $\hat{\mathscr{Y}}_{\mathrm{L}}$:

$$\langle G_{\mathrm{H}}f,g\rangle_{\mathrm{L}}^{(\beta+1)}=\int_{-\infty}^{\infty}\cdots\int_{-\infty}^{\infty}\mathscr{P}_{-}(\hat{\mathscr{Y}}_{\mathrm{L}}f\ )g.\mathscr{X}_{\mathrm{L}}(\phi_A^{(\beta)})^2\ dz_1\cdots dz_N=\langle\hat{\mathscr{Y}}_{\mathrm{L}},f,.\mathscr{X}_{\mathrm{L}}g\rangle_{\mathrm{L}}^{(\beta)}=\langle f,\hat{G}_{\mathrm{L}}g\rangle_{\mathrm{L}}^{(\beta)}.$$

In the last equality, we have used the self-adjointness of the operator $\tilde{h}_j^B$. □

We then state the following results:

Proposition 4.10: $G_{\mathrm{L}}L_{\lambda+\delta}^{(\beta)}=c_{\lambda}^{(\beta+1)}L_{\lambda}^{(\beta+1)}$, $\hat{G}_{\mathrm{L}}L_{\lambda}^{(\beta+1)}=\tilde{c}_{\lambda}^{(\beta+1)}L_{\lambda+\delta}^{(\beta)}$, *where the constants* $c_{\lambda}^{(\beta)}$ *and* $\tilde{c}_{\lambda}^{(\beta)}$ *are defined in Lemma 4.1.*

Proof: From (17) and (18), we know that $(c_{\lambda}^{(\beta+1)})^{-1}G_{\mathrm{L}}L_{\lambda+\delta}^{(\beta)}$ satisfies the first condition of Definition 2.5 up to a constant factor. So it is sufficient to prove the orthogonality which can be shown in the same way as Proposition 4.4. The second equation can be proven in a similar way.□

Using Proposition 4.10 and Theorem 4.9, we can prove the norm formula for $L_{\lambda}^{(\beta)}$.

Proposition 4.11:[1,4]

$$\langle L_{\lambda}^{(\beta)},L_{\lambda}^{(\beta)}\rangle_{\mathrm{L}}^{(\beta)}=N!\prod_{j=1}^{N}\ (\lambda_j+\beta(N-j))!\prod_{j=1}^{N}\ \Gamma(\lambda_j+\beta(N-j)+\gamma+1/2)$$
$$\times\prod_{k=1}^{\beta}\prod_{i<j}\ \frac{\lambda_i-\lambda_j-k+\beta(j-i+1)}{\lambda_i-\lambda_j+k+\beta(j-i-1)},\tag{19}$$

where $\Gamma(\cdot)$ *denotes the gamma function.*

Proof: The proof of this proposition is similar to the Hermite case. We only note the following formula for the case $\beta=0$:

$$\langle L_{\lambda}^{(\beta=0)},L_{\lambda}^{(\beta=0)}\rangle_{\mathrm{H}}^{(\beta=0)}=(\#\mathfrak{G}_N^{\lambda})\prod_{j=1}^{N}\ \{\lambda_j!\cdot\Gamma(\lambda_j+\gamma+1/2)\},$$

which follows from the norm formula of the one-variable Laguerre polynomials. □

The norm formula (19) can be rewritten into the following form:[1]

$$\langle L_{\lambda}^{(\beta)},L_{\lambda}^{(\beta)}\rangle_{\mathrm{H}}^{(\beta)}=\frac{\Pi_{j=1}^{N}(j\beta)!}{(\beta!)^N}\prod_{j=1}^{N}\ \Gamma(\lambda_j+\beta(N-j)+\gamma+1/2)$$
$$\times\prod_{(i,j)\in\lambda}\ \frac{\{j-1+\beta(N-i+1)\}\{\lambda_i-j+1+\beta(\lambda_j'-i)\}}{\lambda_i-j+\beta(\lambda_j'-i+1)}.$$

It should be remarked that other proofs of these formulas have been given via limiting procedure.[1,4]

V. CONCLUDING REMARKS

In this paper, we have constructed the raising and shift operators for the multivariable Hermite and Laguerre polynomials by using the intertwining operators σ^A and σ^B.

We restrict ourselves to symmetric polynomials though the operators σ^A and σ^B are applicable to the nonsymmetric case, i.e., we can obtain the nonsymmetric counterparts of the multivariable Hermite and Laguerre polynomials:

$$E_w^{(\mathrm{H})\lambda}(x)=2^{-|\lambda|/2}E_w^{\lambda}(\tilde{a}^{\dagger})\cdot 1, \quad E_w^{(\mathrm{L})\lambda}(z)=E_w^{\lambda}((\tilde{b}^{\dagger})^2/2)\cdot 1.$$

Baker and Forrester named these polynomials nonsymmetric Hermite and Laguerre polynomials, respectively, and studied their properties.[2,3] We note that some of their results may be obtained directly from the corresponding properties of the Jack polynomials by applying the intertwiners.

Our constructs are based on the degenerate double affine Hecke algebra, so it is expected that the results given here extend to the nondegenerate case. As van Diejen[4] already proposed the difference counterpart of the Hamiltonians $\mathscr{H}_A$ and $\mathscr{H}_B$, it would be nice to clarify the algebraic structure of his models. We hope to report on them in the near future.

APPENDIX: PROOF OF LEMMA 4.3

In this Appendix, we will give a proof of Lemma 4.3. We remark again that the proof given in this section is a limiting case of Ref. 15.

We begin by examining some properties of the antisymmetrizer.

Lemma A1:[15] (i) *The antisymmetrizer $\mathscr{P}_-$ is divisible by $1+(-1)^{l(w_0)}w_0$ both on the left and on the right.*

(ii) *For all $j=1,\ldots,N-1$, the antisymmetrizer $\mathscr{P}_-$ is divisible by $1-s_j$ both on the left and on the right.*

Proof: (i) $\mathfrak{G}_N$ can be divided into pairs (w,ww_0). Then, rewriting into the summation over such pairs, we have

$$\mathscr{P}_-=\sum_{(w,ww_0)}\{(-1)^{l(w)}w+(-1)^{l(ww_0)}ww_0\}=\sum_{(w,ww_0)}(-1)^{l(w)}w\{1+(-1)^{l(w_0)}w_0\}.$$

Divisibility on the left is proved similarly.

(ii) Can also be proved by similar discussion. □

From Lemma A1 (ii), we know that $\mathrm{Ker}\,\mathscr{P}_-\supset\Sigma_j\,\mathrm{Ker}(1-s_j)$. To describe the kernel of the antisymmetrizer, we first investigate kernels of $1-s_j$ and their union.

Lemma A2:[15] (i) *Let V be a representation of $\mathfrak{G}_N$, and denote $V_j=\mathrm{Ker}(1-s_j)$, $V'=\Sigma_j V_j$. Then V' is $\mathfrak{G}_N$-invariant.*

(ii) *Assume V is a finite-dimensional irreducible representation of $\mathfrak{G}_N$. Then we have*

$$V'=\begin{cases}0 & \textit{if } V \textit{ is the sign representation,}\\ V & \textit{otherwise.}\end{cases}$$

Proof: (i) From the definition of V_j, it follows that $s_j(s_iv)=s_iv$ for all $v\in s_iV_j$. If we introduce $v_\pm=(v\pm s_iv)/2$, we see that $s_j(v_+-v_-)=v_+-v_-$, which means $v_+-v_-\in V_j$. Since $v_+\in V_i$ by definition, we obtain $v=v_++v_-\in V_i+V_j$. This leads to $s_iV_j\subset V_i+V_j$, which concludes the proof.

(ii) From (i), it follows that V' is a subrepresentation. Due to the irreducibility, V' can be either 0 or V. If $V'=0$, then we have $V_j=0$ for all j. This means that $1-s_j$ is invertible, i.e., for all $v\in V$, there exists u such that $v=(1-s_j)u$. Then we obtain $s_jv=-v$ for all $v\in V$, i.e., V is the sign representation. □

From Lemma A2(ii), it immediately follows that

$$\mathrm{Ker}\,\mathscr{P}_-=\sum_j\ \mathrm{Ker}(1-s_j)$$

for any finite-dimensional representation of $\mathfrak{G}_N$. Note this identity also holds for the representation of $\mathfrak{G}_N$ in the space of polynomials $\mathbb{C}[x]$, since this representation is a direct sum of finite-dimensional representations.

We now introduce operators $\hat{s}_j$ as

$$\hat{s}_j = s_j + \beta \frac{s_j - 1}{x_j - x_{j+1}}.$$

Using these operators, we can define another representation of the degenerate affine Hecke algebra $\mathfrak{h}_0'$ on $\mathbb{C}[x]$:

$$\rho'(\hat{D}_j^A) = x_j, \quad \rho'(s_j) = \hat{s}_j.$$

Using the isomorphism ρ', we introduce the deformed antisymmetrizer $\mathscr{P}_-^{(\beta)}$ as

$$\mathscr{P}_-^{(\beta)} = \rho'(\mathscr{P}_-) = \frac{1}{\#\mathfrak{G}_N} \sum_{w \in \mathfrak{G}_N} (-1)^{l(w)} \hat{w},$$

where $\hat{w} = \rho'(w)$.

Lemma A3:[15] Ker $\mathscr{P}_-^{(\beta)} =$ Ker $\mathscr{P}$ *for the action of* $\mathscr{P}_-^{(\beta)}$ *in* $\mathbb{C}[x]$.

Proof: By discussion similar to Proposition A1, we know that $\mathscr{P}_-^{(\beta)}$ is divisible by $\hat{s}_j - 1$ both on the left and on the right for every $j = 1,...,N-1$. Hence we have

$$\text{Ker } \mathscr{P}_-^{(\beta)} \supset \sum_j \text{Ker}(1 - \hat{s}_j) = \sum_j \text{Ker}(1 - s_j) = \text{Ker } \mathscr{P}, \tag{A1}$$

and thus $\dim(\text{Ker } \mathscr{P}_-^{(\beta)}) \geqslant \dim(\text{Ker } \mathscr{P}_-)$. On the other hand, if we denote $\mathbb{C}[x]_n$ as the space of polynomials of order n, it is clear that $\mathscr{P}_-^{(\beta)}$ preserves $\mathbb{C}[x]_n$. Since $\dim(\text{Ker } \mathscr{P}_-^{(\beta)})$ cannot decrease under specialization, it follows that $\dim(\text{Ker } \mathscr{P}_-^{(\beta)}) \leqslant \dim(\text{Ker } \mathscr{P}_-^{(\beta=0)}) = \dim(\text{Ker } \mathscr{P}_-)$, and hence we have

$$\dim(\text{Ker } \mathscr{P}_-^{(\beta)}) = \dim(\text{Ker } \mathscr{P}_-). \tag{A2}$$

Thus it follows from (A1) and (A2) that Ker $\mathscr{P}_-^{(\beta)} =$ Ker $\mathscr{P} = \Sigma_j$ Ker$(1 - s_j)$. □

We then define $\mathscr{Y}'$ and $\mathscr{Y}'$ as

$$\mathscr{Y}' = \rho'(\mathscr{Y}_J) = \prod_{i<j} (\beta - x_i + x_j), \quad \hat{\mathscr{Y}}' = \rho'(\hat{\mathscr{Y}}_J) = \prod_{i<j} (-\beta - x_i + x_j).$$

Lemma A4:[15]

$$\mathscr{P}_-(\mathscr{Y}' - \hat{\mathscr{Y}}')f = 0 \quad \text{for all } f \in \mathbb{C}[x]^{\mathfrak{G}_N}.$$

Proof: We can show that

$$(1 + (-1)^{N(N-1)/2} w_0)(\mathscr{Y}' - \hat{\mathscr{Y}}') = (\mathscr{Y}' - \hat{\mathscr{Y}}')(1 - w_0)$$

by direct calculation. Considering the action on $\mathbb{C}[x]^{\mathfrak{G}_N}$, we have

$$(1 + (-1)^{N(N-1)/2} w_0)(\mathscr{Y}' - \hat{\mathscr{Y}}')f = 0,$$

for all $f \in \mathbb{C}[x]^{\mathfrak{G}_N}$. Using this formula and Proposition A1 (i), we obtain the desired result. □

From Lemmas A3 and A4, we know that

$$\mathscr{P}_-^{(\beta)}(\mathscr{Y}' - \hat{\mathscr{Y}}')f = 0 \quad \text{for all } f \in \mathbb{C}[x]^{\mathfrak{G}_N}.$$

On the other hand, the following statement can easily be proven:

Lemma A5: Let $\hat{A}$ *be an operator of the form* $\hat{A}=\Sigma_{w\in\mathfrak{G}_N} g_w \hat{w}$ *with* $g_w\in\mathbb{C}[x]$. *If* $\hat{A}f=0$ *for all* $f\in\mathbb{C}[x]^{\mathfrak{G}_N}$, *then* $\hat{A}$ *can be represented in the following form:*

$$\hat{A}=\sum_j \hat{g}_j(\hat{s}_j-1) \quad \text{for some } \hat{g}_j\in\mathbb{C}[x]^{\mathfrak{G}_N}.$$

Proof: The operator $\hat{A}$ can be rewritten as

$$\hat{A}=\sum_{j_1,\ldots,j_k} \hat{g}'_{j_1,\ldots,j_k}(\hat{s}_{j_1}-1)\cdots(\hat{s}_{j_1}-1)+\hat{g}'_0 \quad \text{for some } \hat{g}_{j_1,\ldots,j_k}\in\mathbb{C}[x].$$

Then the assumption of the proposition means $\hat{g}'_0=0$, which gives the desired result. □

Applying Lemma A5 to Lemma A4, we conclude that

$$\mathscr{S}_-^{(\beta)}(\mathscr{Y}'-\hat{\mathscr{Y}}')=\sum_j \hat{g}_j(x_1,\ldots,x_N)(\hat{s}_j-1) \quad \text{for some } \hat{g}_j(x_1,\ldots,x_N)\in\mathbb{C}[x]. \tag{A3}$$

Applying $(\rho')^{-1}$ completes the proof of Lemma 4.3.

Lie-algebraic structure from inhomogeneous Hopf algebras

M. Lagraa[a] and N. Touhami[b]
Laboratoire de Physique Théorique, Université d'Oran Es-Sénia, 31100, Algérie

(Received 18 November 1997; accepted for publication 23 April 1998)

We construct the vector space dual to the space of right-invariant differential forms constructed from a first-order differential calculus on inhomogeneous quantum groups. We show that this vector space is equipped with a structure of a Hopf algebra which closes on a noncommutative Lie algebra satisfying a Jacobi identity.

I. INTRODUCTION

It is well known that the underlying symmetry of the physical systems is governed by the Poincaré group. In fact, the most important observables in field theories such as the energy momentum and the angular momentum are related to the Lie algebra generators of the translations and the rotations. Then, it is especially interesting to study the noncommutative version of the Lie algebras of inhomogeneous Hopf algebras. In addition, due to the presence of the translations, one can hope to obtain new insight on the differential structure of the noncommutative space–time geometry on which it is possible to construct consistently quantum field theories or an Einstein–Cartan gravity.

Different approaches to construct Lie algebras of inhomogeneous quantum groups have been proposed.[1–6] Among them are those which are based on the q-deformed Lie algebra of the Lorentz group augmented consistently by translation generators as q-deformed four-vector derivatives in Minkowski space.[1,2] Other approaches are based on the contraction of q-deformed anti-de Sitter algebra U(O(3,2))[4,5] or on the projective method where a bicovariant differential calculus on inhomogeneous quantum groups such as $\mathrm{IGL}_{q,r}(N)$ or $\mathrm{ISO}_{q,r}(N)$ is obtained as a quotient of those of $\mathrm{GL}_{q,r}(N+1)$ or $\mathrm{SO}_{q,r}(N+1)$ with respect to a suitable Hopf ideal.[6]

In this paper, one presents a quite different approach based on a bicovariant differential calculus on an inhomogeneous Hopf algebra studied in our previous paper.[7] This approach allows us to construct the vector space dual to the right-invariant differential one-forms which is equipped with a Hopf algebra structure which closes on a quantum Lie algebra satisfying a quantum Jacobi identity. Throughout this paper we use the convention of those of Refs. 7 and 8.

II. DIFFERENTIAL CALCULUS ON INHOMOGENEOUS QUANTUM GROUPS

In this section, we start by recalling the definition and some basic properties of the inhomogeneous Hopf algebra $\mathscr{B}$ as well as the bicovariant first-order differential calculus on it.

The quantum groups $\mathscr{G}$ are abstract objects described by corresponding Hopf algebra $\mathscr{B}=\mathrm{poly}(\mathscr{G})$. An inhomogeneous quantum group, $\mathscr{G}$, is generated by a homogeneous quantum group $\mathscr{H}$ whose corresponding unital Hopf algebra is $\mathscr{A}=\mathrm{poly}(\mathscr{H})$ and translations described by elements p^n, $n=1,...,N$ corresponding to an irreducible representation $\Lambda^n{}_m$ of $\mathscr{H}$.[8]

We denote $\Delta:\mathscr{B}\to\mathscr{B}\otimes\mathscr{B}$, the comultiplication (algebra homomorphism), $\epsilon:\mathscr{B}\to C$ the counit (character), and $S:\mathscr{B}\to\mathscr{B}$ the coinverse (algebra antihomomorphism) which satisfy the coassociativity $(\Delta\otimes id)\Delta=(id\otimes\Delta)\Delta$, $(\epsilon\otimes id)\Delta=(id\otimes\epsilon)\Delta=id$, and $m\circ(S\otimes id)\Delta=m\circ(id\otimes S)\Delta=I\epsilon$, where $m:\mathscr{B}\otimes\mathscr{B}\to\mathscr{B}$ is the multiplication map $[m(a\otimes b)=ab]$ and $I_{\mathscr{A}}=I_{\mathscr{B}}=I$ is the unity of $\mathscr{B}$.

These maps act on the generators of $\mathscr{B}$ as:

[a]Electronic mail: lagraa.@elbahia.cerist.dz
[b]Electronic mail: touhami@elbahia.cerist.dz

 © 1998 American Institute of Physics

$$\Delta(\Lambda^n{}_m)=\Lambda^n{}_k\otimes\Lambda^k{}_m,\quad \Delta(p^n)=\Lambda^n{}_k\otimes p^k+p^n\otimes I,$$

$$\epsilon(\Lambda^n{}_m)=\delta^n_m,\quad \epsilon(p^n)=0,$$

$$S(\Lambda^n{}_k)\Lambda^k{}_m=\Lambda^n{}_m S(\Lambda^k{}_m)=\epsilon(\Lambda^k_m),$$

$$S(\Lambda^n{}_k)p^k+S(p^n)=\Lambda^n{}_n S(p^k)+p^n=\epsilon(p^n).$$

To construct a $\mathscr{B}$-bimodule of one-forms Γ, we consider an exterior bicovariant derivative $d:\mathscr{B}\to\Gamma(\Delta_L d=(id\otimes d)\Delta$ and $\Delta_R d=(d\otimes id)\Delta)$ (Ref. 7) from which we construct a right-invariant basis (Maurer–Cartan forms) of the bimodule Γ over $\mathscr{B}$,

$$\Theta^n_m=d\Lambda^n_k S(\Lambda^k_m),\quad \Pi^n=dp^n-\Theta^n_k p^k, \tag{1}$$

which transforms as

$$\Delta_R(\Theta^n_m)=\Theta^n_m\otimes I, \tag{2}$$

$$\Delta_R(\Pi^n)=\Pi^n\otimes I, \tag{3}$$

$$\Delta_L(\Theta^n_m)=\Lambda^n{}_{\ell}S(\Lambda^k{}_m)\otimes\Theta^{\ell}_k, \tag{4}$$

$$\Delta_L(\Pi^n)=\Lambda^n{}_k\otimes\Pi^k+\Lambda^n{}_k S(p^{\ell})\otimes\Theta^k_{\ell}. \tag{5}$$

Following Ref. 7, we can state that there exists linear functionals $f^n{}_m$, $f^{nk}{}_m$, f^n_{km}, and $f^{n\ell}_{mk}\in\mathscr{B}'$ (the dual vector space of $\mathscr{B}$) such that

$$\Pi^n a=(a\star f^n_k)\Pi^k+(a\star f^{n\ell}_k)\Theta^k_{\ell}, \tag{6}$$

$$\Theta^n_m a=(a\star f^n_{mk})\Pi^k+(a\star f^{n\ell}_{mk})\Theta^k_{\ell}, \tag{7}$$

and

$$b\Pi^n=\Pi^k(b\star f^n_k\circ S)+\Theta^k_{\ell}(b\star f^{n\ell}_k\circ S), \tag{8}$$

$$b\Theta^n_m=\Pi^k(b\star f^n_{mk}\circ S)+\Theta^k_{\ell}(b\star f^{n\ell}_{mk}\circ S), \tag{9}$$

where the convolution product of a functional $f\in\mathscr{B}'$ and an element a of $\mathscr{B}$ is defined as $(a\star f)=(f\otimes id)\Delta(a)$ or $(f\star a)=(id\otimes f)\Delta(a)$ and the convolution product of two functionals is defined as $(f_1\star f_2)(a)=(f_1\otimes f_2)\Delta(a)$.

From (6) and (7), we deduce

$$f^n{}_m(I)=\delta^n_m,\quad f^{nm}_{k\ell}(I)=\delta^n_{\ell}\delta^m_k,\quad f^{nm}_k(I)=0,\quad f^n_{km}(I)=0 \tag{10}$$

and

$$f^n{}_m(ab)=f^n{}_k(a)f^k{}_m(b)+f^{nk}_{\ell}(a)f^{\ell}_{km}(b), \tag{11}$$

$$f^{nk}_{m\ell}(ab)=f^{np}_{mq}(a)f^{qk}_{p\ell}(b)+f^n_{mq}(a)f^{qk}_{\ell}(b), \tag{12}$$

$$f^n_{m\ell}(ab)=f^{np}_{mq}(a)f^q_{p\ell}(b)+f^n_{mk}(a)f^k_{\ell}(b), \tag{13}$$

$$f^{nk}_{\ell}(ab)=f^n{}_q(a)f^{qk}_{\ell}(b)+f^{np}_q(a)f^{qk}_{p\ell}(b), \tag{14}$$

for any a and $b\in\mathscr{B}$. From (10) to (14), we can see that the convolution product of different functionals generates an algebra $\mathscr{B}^0\subset\mathscr{B}'$ which can be equipped with a Hopf algebra structure where the comultiplication is given by

$$\Delta'(f^n{}_m)=f^n_k\otimes f^k{}_m+f^{nk}_{\ell}\otimes f^{\ell}_{km},$$

$$\Delta'(f^{nk}_{m\ell})=f^{np}_{mq}\otimes f^{qk}_{p\ell}+f^n_{mq}\otimes f^{qk}_{\ell},$$

$$\Delta'(f^n_{m\ell})=f^{np}_{mq}\otimes f^q_{p\ell}+f^n_{mk}\otimes f^k_{\ell},$$

$$\Delta'(f^{nk}_{\ell})=f^n_q\otimes f^{qk}_{\ell}+f^{np}_q\otimes f^{qk}_{p\ell},$$

the counit is given by $\epsilon'(f^n{}_m)=\delta^n_m\epsilon$, $\epsilon'(f^{nk}_{m\ell})=\delta^n_{\ell}\delta^k_m\epsilon$, and $\epsilon'(f^n_{mk})=\epsilon'(f^{nk}_m)=0$, and the antipode is given by $S'(f)=f\circ S$. One can easily verify that these maps satisfy the Hopf algebra axioms

$$(\Delta'\otimes id)\Delta'=(id\otimes\Delta')\Delta',$$

$$(\epsilon'\otimes id)\Delta'=(id\otimes\epsilon')\Delta'=id,$$

$$m'\circ(S'\otimes id)\Delta'=m'\circ(id\otimes S')\Delta'=I_{\mathscr{B}^0}\epsilon',$$

where m' is the multiplication map defined as $m'\circ(f_1\otimes f_2)=f_1\star f_2$.

In the following one assumes

$$f^{nk}_{m\ell}=\tilde{f}^k{}_m\star f^n_{\ell},\quad f^{nk}_m=\tilde{\eta}^k\star f^n{}_m,\quad f^n_{km}=\tilde{\eta}_k\star f^n{}_m, \tag{15}$$

where $\tilde{\eta}^n$, $\tilde{\eta}_n$, and $\tilde{f}^n{}_m\in\mathscr{B}^0$. One deduces from (10) and (15) that

$$\tilde{\eta}^n(I)=0,\quad \tilde{\eta}_n(I)=0,\quad \tilde{f}^n{}_m(I)=\delta^n_m. \tag{16}$$

The fact that $\mathscr{A}$ is a Hopf subalgebra of $\mathscr{B}$, we have[7]

$$\tilde{\eta}_n(a)=0,\quad a\in\mathscr{A}. \tag{17}$$

From (6) to (7), and (17), one can show[7] that the commutative rules between the elements of $\mathscr{A}$ are given by

$$\Lambda^n{}_k(f^k{}_m\star a)=(a\star f^n{}_k)\Lambda^k{}_m, \tag{18}$$

$$\Lambda^n{}_k(\tilde{f}^n{}_k\circ S\star a)=(a\star\tilde{f}^n{}_k\circ S)\Lambda^k{}_m, \tag{19}$$

where the functionals $f^n{}_m$ and $\tilde{f}^n{}_m$ satisfy

$$f^n{}_m(ab)=f^n{}_k(a)f^k{}_m(b),\quad \tilde{f}^n{}_m(ab)=\tilde{f}^k{}_m(a)\tilde{f}^n{}_k(b) \tag{20}$$

for any a and $b\in\mathscr{A}$. The commutation rules between the elements of $\mathscr{A}$ and the translations are given by

$$p^n a=(a\star\tilde{f}^k{}_n\circ S)p^k+a\star\tilde{\eta}^n\circ S-\Lambda^n{}_k(\tilde{\eta}^k\circ S\star a), \tag{21}$$

and those between the translations are given by

$$p^n p^m=f^n{}_k(\Lambda^m_{\ell})p^{\ell}p^k-(f^n{}_k(\Lambda^m_{\ell})-\delta^n{}_{\ell}\delta^m{}_k)\tilde{\eta}^{\ell}(S(\Lambda^k{}_p))p^p+\tilde{\eta}^n(S(p^m))-\Lambda^n{}_k\Lambda^m_{\ell}\tilde{\eta}^k(S(p^{\ell})). \tag{22}$$

In addition, the generators of $\mathscr{A}$ satisfy the following relations:

$$S(\Lambda^k{}_m)\Lambda^a{}_c\tilde{\eta}_k(p^c)=\tilde{\eta}_m(p^a), \tag{23}$$

$$\Lambda^k{}_m\tilde{\eta}_k(S(p^a))=\tilde{\eta}_m(S(p^b))\Lambda^a{}_b. \tag{24}$$

Finally it is shown in Ref. 7 that this formalism is consistent if the different functionals satisfy the following conditions:

$$\tilde{R}=R+I\otimes Q=R^{-1}+R^{-1}(I\otimes Q), \tag{25}$$

$$Q=\lambda I \quad \lambda\in\mathscr{C}, \quad \lambda\neq -1, \tag{26}$$

$$T=-\tilde{R}T \quad \text{for } \lambda\neq 0 \tag{27}$$

$$\text{or } (\tilde{R}+I\otimes I)T-(\Lambda\perp\Lambda)(\tilde{R}+I\otimes I)T=0 \quad \text{for } \lambda=0, \tag{28}$$

$$(R\otimes I)(I\otimes R)(R\otimes I)=(I\otimes R)(R\otimes I)(I\otimes R), \tag{29}$$

$$(Z\otimes I)R+(\tilde{R}\otimes I)(I\otimes Z)R=(I\otimes R)(Z\otimes I)+(I\otimes R)(\tilde{R}\otimes I)(I\otimes Z), \tag{30}$$

$$(R\otimes I-I\otimes I\otimes I)\ ((I\otimes Z)Z-(Z\otimes I)Z)+T\otimes I-(I\otimes\tilde{R})(\tilde{R}\otimes I)(I\otimes T)=0, \tag{31}$$

and

$$(I\otimes R-I\otimes I\otimes I)((\tilde{Z}\otimes I)T-(I\otimes\tilde{Z})T)-(Z\otimes I)-(\tilde{R}\otimes I)(I\otimes Z)T=0 \tag{32}$$

with

$$\tilde{Z}=-RZ, \tag{33}$$

where $R^{n'}_{km}=f^{n}{}_{m}(\Lambda^{'}{}_{k})$, $\tilde{R}^{n'}_{km}=\tilde{f}^{n}{}_{m}(S(\Lambda^{'}{}_{k}))$, $Q^{n}_{k}=\tilde{\eta}_{k}(S(p^{n}))$, $Z^{nk}_{q}=\tilde{\eta}^{n}(S(\Lambda^{k}{}_{q}))$, $\tilde{Z}^{nk}_{m}=\tilde{f}^{n}{}_{m}(S(p^{k}))$ and $T^{nm}=\tilde{\eta}^{n}(S(p^{m}))$.

Remark (2,1): Equations (25) and (26) imply for $\lambda=0$, $R=\tilde{R}=R^{-1}$, and the R-matrix is subject to a strong constraint $R^{2}=I\otimes I$ used in Ref. 8. In this particular case, (18) and (19) reduce to the same commutation rule of the homogeneous part, which gives for $a=\Lambda^{a}{}_{b}$:

$$\Lambda^{n}{}_{k}\Lambda^{a}{}_{c}R^{kc}_{bm}=R^{na}_{ck}\Lambda^{c}{}_{b}\Lambda^{k}{}_{m},$$

and (21) implies

$$p^{n}\Lambda^{a}{}_{b}=R^{na}_{ck}\Lambda^{c}{}_{b}p^{k}+Z^{na}_{c}\Lambda^{c}{}_{b}-\Lambda^{c}{}_{b}\Lambda^{a}{}_{c}Z^{kc}_{b}.$$

Finally, using (28) and setting $T=-2T'$, (22) implies

$$(R^{nm}_{k'}-\delta^{n}_{k}\delta^{m}_{'})(p^{k}p^{'}-Z^{k'}_{q}p^{q}+T'^{k'}-\Lambda^{k}_{q}\Lambda^{'}_{p}T'^{qp})=0,$$

which are exactly the commutation rules between the elements of the inhomogeneous group $\mathscr{B}$ obtained in Ref. 8.

Remark (2,2): For $\lambda=0$, we also have from (31) the following relation:

$$(R\otimes I-I\otimes I\otimes I)((I\otimes Z)Z-(Z\otimes I)Z)+T\otimes I-(I\otimes R)(R\otimes I)(I\otimes T)=0,$$

which is the condition required by Podles in Ref. 9 for the existence of a four-dimensional covariant differential calculus on a quantum Minkowski space.

III. LIE-ALGEBRAIC STRUCTURE FROM INHOMOGENEOUS HOPF ALGEBRAS

In the following, we shall construct the vector space $\mathscr{T}$ dual to the right-invariant differential one-forms and the quantum commutators of different elements of $\mathscr{T}$. We start by

Proposition (3,1):

The one-form

$$X=\tilde{f}^{a}{}_{m}(\Lambda^{m}{}_{b})\Theta^{b}{}_{a} \tag{34}$$

is left- and right-invariant.

Proof: X is right-invariant. To show the left-invariance, we replace $a \in \mathscr{A}$ by $S^{-1}(\Lambda^a{}_b)$ into (19) then we apply S on both sides to have

$$\Lambda^c{}_b S(\Lambda^n{}_k)\tilde{f}^k{}_m(\Lambda^a{}_c) = \tilde{f}^n{}_k(\Lambda^c{}_b)S(\Lambda^k{}_m)\Lambda^a{}_c .$$

Setting the indices $a = m$, we get

$$\Lambda^c{}_b S(\Lambda^n{}_k)\tilde{f}^k{}_m(\Lambda^m{}_c) = \tilde{f}^n{}_m(\Lambda^m{}_b). \tag{35}$$

Using this relation and (4), we get

$$\Delta_L(X) = \Lambda^c{}_b S(\Lambda^n{}_k)\tilde{f}^k{}_m(\Lambda^m{}_c)\otimes \theta^b{}_n = \tilde{f}^n{}_m(\Lambda^m{}_b)\otimes \Theta^b{}_n = I\otimes X \tag{36}$$

which shows the left-invariance of X. Q.E.D.

Remark (3,1): Instead of (19), we can use (18) to have another left- and right-invariant one-form: $X = f^a{}_m(S^{-1}(\Lambda^m_b))\Theta^b{}_a$.

Remark (3,2): Equations (6)–(9) show that the classical limit of the functionals are, for any $a \in \mathscr{B}$, $f^k{}_m(a) = \delta^k_m \epsilon(a)$ and $f^n{}_k(a) = \delta^n_k \epsilon(a)$ implying $f^n{}_k(S^{-1}(\Lambda^m_b)) = \delta^n_b$ and $\tilde{f}^k{}_m(\Lambda^m{}_c) = \delta^k_c$ and, therefore (34) can be considered as the quantum trace which reduces to the usual trace in the classical limit. In fact (36) shows the invariance of the quantum trace under the left adjoint coaction action.[12] We can now express the action of the derivative d on an element of $a \in \mathscr{B}$ as $da = Xa - aX$ by following the method of differential calculus on the homogeneous quantum groups of Ref. 10. From the left- and the right-invariance of X, it is easy to check the left- and the right-covariance of d. In the following we set $V^a{}_b = \tilde{f}^a{}_k(\Lambda^k{}_b)$. Using the form of X and (9), we get

$$da = Xa - aX = V^a_b(\Theta^b{}_a(a*\epsilon) - \Theta^k_{\not{}}(a*f^{b\not{}}_{ak}\circ S) - \Pi^k(a*f^b_{ak}\circ S)), \tag{37}$$

which can be rewritten under the form

$$da = \Theta^b{}_a(a*L^a{}_b) + \Pi^a(a*L_a), \tag{38}$$

where the linear functionals on $\mathscr{B}$,

$$L^a{}_b = V^a_b\epsilon - V^c{}_d(\tilde{f}^a{}_c * f^d{}_b)\circ S \tag{39}$$

and

$$L_a = -V^c{}_d(\tilde{\eta}_c * f^d{}_a)\circ S, \tag{40}$$

are the generators of the Lie algebra of the inhomogeneous Hopf algebra $\mathscr{B}$. Let us note that by virtue of (17)

$$L_a(a) = 0, \quad a \in \mathscr{A}, \tag{41}$$

and from (37) to (38), we deduce $L^a{}_b(I) = 0$ and $L_a(I) = 0$.

To construct the exterior product of one-forms $\in \Gamma$, we consider, in addition to the right-invariant basis (1), the left-invariant basis $\tilde{\Theta}^a{}_b = S(\Lambda^a{}_c S(\Lambda^d{}_c))\Theta^c{}_d$ and $\tilde{\Pi}^a = S(\Lambda^a{}_b)\Pi^b + S(\Lambda^a{}_b S(p^c))\Theta^b{}_c$ which transforms as

$$\Delta_L(\tilde{\Theta}^a{}_b) = I\otimes\tilde{\Theta}^a{}_b, \quad \Delta_L(\tilde{\Pi}^a) = I\otimes\tilde{\Pi}^a, \tag{42}$$

$$\Delta_R(\tilde{\Theta}^a{}_b) = \tilde{\Theta}^c{}_d\otimes S(\Lambda^a{}_c S(\Lambda^d{}_d)), \tag{43}$$

$$\Delta_R(\tilde{\Pi}^a) = \tilde{\Pi}^b\otimes S(\Lambda^a{}_b) + \tilde{\Theta}^b{}_c\otimes S(\Lambda^a{}_b S(p^c)). \tag{44}$$

Now we consider the bimodule automorphism $\sigma : \Gamma^{\otimes 2} \to \Gamma^{\otimes 2}$ such that $\sigma(\tilde{\omega}\otimes_{\mathscr{B}}\omega) = \omega\otimes_{\mathscr{B}}\tilde{\omega}$ for any left-invariant element $\tilde{\omega}\in\Gamma$ and any right-invariant element $\omega\in\Gamma$, which gives for the one-forms $\Theta^a{}_b$,

$$\sigma(\tilde{\Theta}^e{}_f\otimes_{\mathscr{B}}\Theta^g{}_h)=S(\Lambda^e{}_a S(\Lambda^b{}_f))\sigma(\Theta^a{}_b\otimes_{\mathscr{B}}\Theta^g{}_h)=\Theta^g{}_h\otimes_{\mathscr{B}}S(\Lambda^e{}_d S(\Lambda^a{}_b))\Theta^a{}_b.$$

Using (7) and (17), we get

$$\sigma(\Theta^a{}_b\otimes_{\mathscr{B}}\Theta^c{}_d)=(\tilde{f}^g{}_d * f^c{}_h)(S(\Lambda^a{}_e S(\Lambda^f{}_b)))(\Theta^h{}_g\otimes_{\mathscr{B}}\Theta^e{}_f). \tag{45}$$

Similar considerations give

$$\sigma(\Theta^a{}_b\otimes_{\mathscr{B}}\Pi^c)=f^c{}_f(S(\Lambda^a{}_d S(\Lambda^e_b)))(\Pi^f\otimes_{\mathscr{B}}\Theta^d{}_e)+(\tilde{\eta}^g * f^c{}_f)(S(\Lambda^a{}_d S(\Lambda^e{}_b)))(\Theta^f{}_g\otimes_{\mathscr{B}}\Theta^d{}_e), \tag{46}$$

$$\begin{aligned}\sigma(\Pi^a\otimes_{\mathscr{B}}\theta^b{}_c)=&(\tilde{f}^e{}_c * f^b{}_d)(S(\Lambda^a{}_f))(\Theta^d{}_e\otimes_{\mathscr{B}}\Pi^f)+(\tilde{\eta}_c * f^b{}_d)(S(\Lambda^a{}_f S(p^g)))(\Pi^d\otimes_{\mathscr{B}}\Theta^f{}_g)\\&+(\tilde{f}^e{}_c * f^b{}_d)(S(\Lambda^a{}_f S(p^g)))(\Theta^d{}_e\otimes_{\mathscr{B}}\Theta^f{}_g)\end{aligned} \tag{47}$$

and

$$\begin{aligned}\sigma(\Pi^a\otimes_{\mathscr{B}}\Pi^b)=&f^b{}_c(S(\Lambda^a{}_d))(\Pi^e\otimes_{\mathscr{B}}\Pi^d)+f^b{}_c(S(\Lambda^a{}_d S(p^e)))(\Pi^c\otimes_{\mathscr{B}}\Theta^d{}_e)\\&+(\tilde{\eta}^d * f^b{}_c)(S(\Lambda^a{}_e))(\Theta^c{}_d\otimes_{\mathscr{B}}\Pi^e)+(\tilde{\eta}^d * f^b{}_c)(S(\Lambda^a{}_e S(p^f)))(\Theta^c{}_d\otimes_{\mathscr{B}}\Theta^e{}_f).\end{aligned} \tag{48}$$

In the following we write (38) and (45)–(48) under the compact form

$$da=\Pi^A(a * L_A), \tag{49}$$

$$\sigma(\Pi^A\otimes_{\mathscr{B}}\Pi^B)=\sigma^{AB}_{CD}(\Pi^C\otimes_{\mathscr{B}}\Pi^D), \tag{50}$$

where $\Pi^A=\Theta^a{}_b$ and $L_A=L^a_b$ when the indices A take the values ${}^a{}_b, {}^c{}_d, \ldots$, $\Pi^A=\Pi_a$ and $L_A=L_a$ when the indices A take the values $a,b,\ldots$ and $\sigma^{AB}{}_{CD}$ are given by the coefficients multiplying the tensor products of the one-forms Θ and Π in (45)–(48). Let us note that from (49), we have $d(a_{(1)})S(a_{(2)})=\Pi^A L_A(a)=\Pi(a)$ which tranforms as

$$\begin{aligned}\Delta_L(d(a_{(1)})S(a_{(2)}))=\Delta_L(\Pi(a))&=a_{(1)}S(a_{(4)})\otimes d(a_{(2)})S(a_{(3)})\\&=a_{(1)}S(a_{(3)})\otimes\Pi(a_{(2)})\\&=(id\otimes\Pi)Ad(a),\end{aligned} \tag{51}$$

where the left adjoint coaction action $Ad:\mathscr{B}\to\mathscr{B}\otimes\mathscr{B}$ is defined as $Ad(a)=a_{(1)}S(a_{(3)})\otimes a_{(2)}$, and satisfies

$$(\Delta\otimes id)Ad=(id\otimes Ad)Ad. \tag{52}$$

Here $a_{(1)}$, $a_{(2)}$, and $a_{(3)}$ are elements of $\mathscr{B}$ such that $a_{(1)}\otimes a_{(2)}\otimes a_{(3)}=(id\otimes\Delta)\Delta(a)$.

Theorem (3,1):

1. For any $a,b\in\mathscr{B}$

$$L^a{}_b(ab)=L^a{}_b(a)\epsilon(b)+(\tilde{f}^a{}_c * f^d_b)(S(a))L^c{}_d(b)+(\tilde{\eta}^a * f^c{}_b)(S(a))L_c(b), \tag{53}$$

$$L_a(ab)=L_a(a)\epsilon(b)+f^b{}_a(S(a))L_b(b)+(\tilde{\eta}_c * f^d{}_a)(S(a))L^c{}_d(b). \tag{54}$$

2. For any $a\in\mathscr{B}$, the generators $L^a{}_b$ and L_a close on the following quanium Lie algebra

$$\begin{aligned}[L^b{}_a,L^d{}_c](a)=&(V^b{}_a\delta^g_c\delta^d_h-V^k{}_n(\tilde{f}^b{}_k * f^n{}_a)(S(\Lambda^g{}_c S(\Lambda^d{}_h))))L^h{}_g(a))\\&-V^k_n(\tilde{f}^b{}_k * f^n{}_a)(S(\Lambda^g{}_c S(p^d)))L_g(a)),\end{aligned} \tag{55}$$

$$[L^b{}_a,L_c](a)=(V^b{}_a\delta^g_c-V^k{}_n(\tilde{f}^b{}_k * f^n{}_a)(S(\Lambda^g{}_c))L_g(a)), \tag{56}$$

$$[L_a, L^c{}_d](a) = V^k_n(\tilde{\eta}_k * f^n{}_a)(S(\Lambda^g{}_c S(p^d)))L_g(a)), \tag{57}$$

and

$$[L_a, L_b](a) = 0, \tag{58}$$

satisfying the Jacobi identity

$$[L_A,[L_B,L_C]](a) = [[L_A,L_B],L_C](a) + \sigma^{EF}{}_{AB}[L_E,[L_F,L_C]](a). \tag{59}$$

Proof: Using the Leibniz rule of the derivative d, (38) and (8) to (9), one obtains

$$\begin{aligned} d(ab) &= \Theta^b{}_a(ab * L^a{}_b) + \Pi^a(ab * L_a) \\ &= \Theta^b{}_a(a * L^a{}_b(b + \Pi^a(a * L_a)b + a(\Theta^d{}_c(b * L^c{}_d) + a\Pi^c)(b * L_c)) \\ &= \Theta^b{}_a((a * L^a{}_b)b + (a * (\tilde{f}^a{}_c * f^d{}_b) \circ S)(b * L^c{}_d)) + (a * \tilde{\eta}^a * f^c{}_b) \circ S)(b * L_c) + \Pi^a((a * L_a)b \\ &\quad + (a * f^b{}_a \circ S)(b * L_b) + (a * (\tilde{\eta}_c * f^d{}_a) \circ S)(b * L^c{}_d)) \end{aligned}$$

for any $a, b \in \mathscr{B}$. Identifying the coefficients multiplying $\Theta^b{}_a$ and Π_a, then acting ϵ, one obtains the twisted Leibniz rules for $L^a{}_b$ and L_a as (53) and (54).

Applying the exterior derivative d on both sides of (49), using $d^2 = 0$, and taking into account the grade of d, we get

$$d^2 a = 0 = d(\Pi^A)(a * L_A) - (\Pi^A \wedge \Pi^B)(a * (L_A * L_B), \tag{60}$$

for any $a \in \mathscr{B}$, leading to the Maurer–Cartan formula

$$d\Pi^A L_A(a) = d\Pi(a) = \Pi^A \wedge \Pi^B (L_A * L_B)(a) \tag{61}$$

$$= (\Pi^A \otimes \Pi^B)[L_A, L_B](a), \tag{62}$$

where the exterior product of two one-forms Π^A and Π^B is given by $\Pi^A \wedge \Pi^B = (\Pi^C \otimes \Pi^D) \times (\delta^A_C \delta^B_C - \sigma^{AB}{}_{CD})$ and the commutator $[L_A, L_B](a) = (\delta^C_A \delta^D_B - \sigma^{CD}_{AB})(L_C * L_D)(a)$ for any $a \in \mathscr{B}$.

On the other hand the extension of the derivation (37) to the forms gives

$$d\Pi^A L_A(a) = X \wedge \Pi^A L_A(a) + \Pi^A L_A(a) \wedge X = (I - \sigma)(X \otimes \Pi(a) + \Pi(a) \otimes X).$$

From the left-invariance of X and the property of σ, it follows

$$\begin{aligned} d\Pi(a) &= X \otimes \Pi(a) - \sigma(\Pi(a) \otimes X) \\ &= \Theta^a_b \otimes \Theta^c_d - \sigma(\Theta^c_d \otimes \Theta^a_b)) V^b_a L^d_c(a) + (\Theta^a_b \otimes \Pi^c + \sigma(\Pi^c \otimes \Theta^a_b))) V^b_a L_c(a). \end{aligned}$$

We can now use the different stages of the theorem (5,3) of Ref. 10 to get

$$d\Pi^A L_A(a) = (\Pi^A \otimes \Pi^B)[L_A, L_B](a) = (\Pi^A \otimes \Pi^B)(L_A \otimes L_B) Ad(a). \tag{63}$$

Comparing (61) with (63) we get

$$[L_A, L_B](a) = (L_A * L_B - \sigma^{CD}{}_{AB}(L_C * L_D))(a) = (L_A \otimes L_B) Ad(a)$$

for any $a \in \mathscr{B}$. Using (45)–(48), (63) can be written as

$$\begin{aligned} d\Pi^A L_A(a) &= (\Theta^a{}_b \otimes \Theta^c{}_d)((V^b{}_a \delta^g_c \delta^d_h - V^k{}_n(\tilde{f}^b{}_k * f^n{}_a)(S(\Lambda^g{}_c S(\Lambda^d{}_h)))L^h{}_g(a)) \\ &\quad - V^k{}_n(\tilde{f}^b{}_k * f^n{}_a)(S(\Lambda^g{}_c S(p^d)))L_g(a)) + (\Theta^a{}_b \otimes \Pi^c)(V^b{}_a \delta^g_c \\ &\quad - V^k_n(\tilde{f}^b{}_k * f^n{}_a)(S(\Lambda^g{}_c))L_g(a)) - (\Pi^a \otimes \Theta^c{}_d) V^k_n(\tilde{\eta}_k * f^n{}_a)(S(\Lambda^g{}_c S(p^d)))L_g(a). \end{aligned} \tag{64}$$

Developing now (64) and comparing the coefficients multiplying the different tensor products of Θ_b^a and Π^a with the latter relation, we get (55)–(58).

Finally, we can establish the quantum Jacobi identity (59) by using (52) and (64) as

$$\begin{aligned}[L_A,[L_B,L_C]](a)&=(L_A\otimes L_B\otimes L_C)(id\otimes Ad)Ad(a)\\&=(L_A\otimes L_B\otimes L_C)(\Delta\otimes id)Ad(a)\\&=[(L_A{*}L_B),L_C](a)\\&=[[L_A,L_B],L_C](a)+\sigma^{DE}AB[(L_D{*}L_E),L_C](a)\\&=[[L_A,L_B]](a)+\sigma^{DE}{}_{AB}[L_D,[L_E,L_C]](a).\end{aligned}$$

Q.E.D.

As a consequence of the relations (53) and (54) of this theorem, the universal enveloping algebra $U(\mathscr{T})$ can be equipped with a Hopf algebra structure whose comultiplication is given by

$$\Delta'(L^a{}_b)=L^a{}_b\otimes\epsilon+S'(f^{da}_{cb})\otimes L^c_d+S'(f^{ca}_b\otimes L_c,$$

$$\Delta'(L_a)=L_a\otimes\epsilon+S'(f^b{}_a)\otimes L_b+S'(f^d_{ca})\otimes L^c_d,$$

the antipode S' by

$$S'(L^a{}_b)=-S'^2(f^{da}_{cb}){*}L^c{}_d-S'^2(f^{ca}_b){*}L_c,$$

$$S'(L_a)=-S'^2(f^b{}_a){*}L_b-S'^2(f^d_{ca}){*}L^c{}_d,$$

and the counit by

$$\epsilon'(L^a{}_b)=\epsilon'(L_b)=0.$$

Using the Hopf algebra structure of $\mathscr{B}^0$, one can see that the axioms of the Hopf algebra are satisfied for $U(\mathscr{T})$.

Remark (3,3): By virtue of (41), the relations (55)–(58) reduce to the homogeneous part of (55) which is the Lie bracket verified by the generators of the Lie algebra of the homogeneous quantum groups.[11,12] For any $a\in\mathscr{B}$ of the form $\mathscr{A}p^n+\mathscr{A}$, the convolution product $(L_a{*}L_b)(a)=0$, due to (41), hence (58) is nontrivial only when it is applied on an element of $\mathscr{B}$ which contains products of two translations and more.

Iwasawa decomposition of affine Kac–Moody algebras using Satake diagrams

K. C. Pati and D. Parashar
Department of Physics and Astrophysics, University of Delhi, Delhi-110007, India

(Received 13 February 1997; accepted for publication 26 March 1998)

We carry out the Iwasawa decomposition of the affine Kac–Moody algebras within the general framework of involutive automorphisms which are determined with the help of the Satake diagrams corresponding to these algebras. The parabolic subalgebras essential for the construction of induced representations are computed from the Langlands decomposition. In particular, we consider the untwisted versions, viz., $A_1^{(1)}$ and $A_2^{(1)}$, as representative examples for the purpose of illustration. © *1998 American Institute of Physics.* [S0022-2488(98)01309-7]

I. INTRODUCTION

Recent times have witnessed tremendous activity in developing formal techniques whereby ordinary Lie algebras in general and Kac–Moody algebras in particular could account for a variety of problems with comparative ease and mathematical elegance. It is now well established that the affine Kac–Moody algebras[1,2] play a crucial role in the context of two-dimensional conformal field theories,[3] string theories,[4] and soluble statistical models,[5] among others. Inspired by this strong motivation, we address the study of the affine Kac–Moody algebras but restrict ourselves only to the case of untwisted versions, mainly for reasons of simplicity. The present work makes a preliminary attempt to obtain induced representations of these algebras. In doing so, we are led to devise the Satake diagrams for the affine Kac–Moody algebras in a manner analogous to that of the ordinary Lie algebras.[6] The Satake diagrams so constructed provide the necessary ingredients for the computation of involutive automorphisms of these algebras, a detailed pedagogical description appears elsewhere.[7,8] These involutive automorphisms in turn are used to facilitate the Iwasawa and Langlands decompositions[9] from which the parabolic subalgebras are readily computed and the corresponding representations obtained through Schmidt construction.[10,11]

The paper is organized as follows. In Sec. II, we briefly outline the essential steps for the construction of Satake diagrams from the Dynkin diagrams of the affine Kac–Moody algebras. All possible Satake diagrams for $A_1^{(1)}$ and $A_2^{(1)}$ along with the root transformations have been computed in detail. It is gratifying to observe that our results are in complete accord with those of Cornwell[8] for the untwisted affine Kac–Moody algebras $A_1^{(1)}$ and $A_2^{(1)}$. Section III is devoted to a discussion of the procedure for carrying out the Iwasawa and Langlands decompositions of these algebras within the present framework to enable us to compute parabolic subalgebras. The explicit construction of the Iwasawa and Langlands decompositions are done in Sec. IV for the untwisted affine algebras $A_1^{(1)}$ and $A_2^{(1)}$. It is shown that this leads to parabolic subalgebras which serve as a basis for obtaining the corresponding induced representations for $A_1^{(1)}$ and $A_2^{(1)}$ through the Schmidt construction. Concluding remarks are appended in Sec. V.

II. AFFINE KAC–MOODY ALGEBRAS AND SATAKE DIAGRAMS

An affine Kac–Moody algebra is generated by a set of generators h_{α_i}, $e_{\pm\alpha_i}$, $i=0,1,2,...,l$, where l is the rank of the associated Lie algebra, with the defining relations

$$[h_{\alpha_i},h_{\alpha_j}]=0, \quad [e_{\alpha_i},e_{-\alpha_j}]=\delta_{ij}h_{\alpha_i},$$

$$[e_{\pm\alpha_i},h]=\pm\alpha_i(h)e_{\pm\alpha_i}, \tag{2.1}$$

to complement the Serre's relations. The linear forms α_0, $\alpha_1,\ldots,\alpha_l$ are its simple roots, where $\alpha_0=\delta-\theta$, θ being the highest root and δ the imaginary root. h_{α_0}, $h_{\alpha_1},\ldots,h_{\alpha_l}$ together with the

Affine Untwisted Algebras	Dynkin Diagrams
$A_1^{(1)}$	
$A_l^{(1)}$	$B_l^{(1)}$	$C_l^{(1)}$	$D_l^{(1)}$	$E_6^{(1)}$	$E_7^{(1)}$	$E_8^{(1)}$	$F_4^{(1)}$	$G_2^{(1)}$	
scaling element d, such that $\alpha_1(d)=0$, $i=1,2,...,l$ and $\alpha_0(d)=1$, constitute a basis of the Cartan subalgebra of affine algebra. The Dynkin diagrams of the affine untwisted Kac–Moody algebra are displayed in Table I.

The construction of the Satake diagrams proceeds as follows. Let R be a root systems of affine Kac–Moody algebra. For $\alpha\in R$, let $\overline{\alpha}=\alpha-\sigma(\alpha)$, where σ stands for the involutive automorphism of α. Let us introduce $R_-=\{\overline{\alpha}|\overline{\alpha}\neq 0,\alpha\in R\}$ and $R_0=\{\alpha\in R|\overline{\alpha}=0\}$. If B_- (resp B) denotes the basis of R_- (resp R) and B_0 a basis of R_0 then $B_0=B\cap R_0$. If $B_-=B\backslash B_0=\{\alpha_i\}$ and $B_0=\{\beta_i\}$, then it can be shown that

$$-\sigma(\alpha_i)=\alpha_{\pi(i)}+\sum_l \eta_{il}\beta_l\,. \tag{2.2}$$

where π are the involutive permutations of $(0,1,2,...,l)$ and η_{il} are non-negative integers. We can now associate with B its Satake diagram. Denote the root α_i by $\circ$ as usual (white roots) and the root β_i by $\bullet$ (black roots). If $\pi(i)=k$, it is indicated by

The Satake diagram determines the involution of R uniquely. We note that $\sigma(\beta_i)=\beta_i$ and if $\alpha\in R$ then $\alpha+\sigma(\alpha)\notin R$. As an illustration, consider the following examples.

TABLE II. Satake diagrams of $A_1^{(1)}$ along with their root automorphisms.

Satake Diagrams of $A_1^{(1)}$		Root Automorphisms
(i)		$-\sigma(\alpha_0)=\alpha_0$ $-\sigma(\alpha_1)=\alpha_1$
(ii)		$-\sigma(\alpha_0)=\alpha_1$ $-\sigma(\alpha_1)=\alpha_0$
(iii)		$-\sigma(\alpha_1)=\alpha_1+2\alpha_0$ $\sigma(\alpha_0)=\alpha_0$
(iv)		$-\sigma(\alpha_0)=\alpha_0+2\alpha_1$ $\sigma(\alpha_1)=\alpha_1$

A. Satake diagrams of $A_1^{(1)}$

The Cartan matrix of $A_1^{(1)}$ is

$$C=\begin{pmatrix} 2 & -2 \\ -2 & 2 \end{pmatrix}.$$

The two simple roots of $A_1^{(1)}$ are α_0 and α_1, where $\alpha_0=\delta-\alpha_1$. The possible Satake diagrams of $A_1^{(1)}$ along with their root automorphisms are depicted in Table II.

B. Satake diagrams of $A_2^{(1)}$

The Cartan matrix of $A_2^{(1)}$ is

$$C=\begin{pmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{pmatrix}.$$

The three simple roots of $A_2^{(1)}$ are α_0, α_1, and α_2, where $\alpha_0=\delta-(\alpha_1+\alpha_2)$. The possible Satake diagrams of $A_2^{(1)}$ along with their root automorphisms are given by Table III.

III. IWASAWA AND LANGLANDS DECOMPOSITIONS OF AFFINE KAC–MOODY ALGEBRA

We now extend the notion of direct determination of Iwasawa and Langlands decompositions of Lie algebras. Let $\underset{\sim}{g}$ be a real Kac-Moody algebra generated by its compact real form $\underset{\sim}{g}_K$ by an involutive automorphism defined w.r.t. the Cartan subalgebra $\underset{\sim}{h}$ of $\underset{\sim}{g}_C$, $\underset{\sim}{g}_C$ being the complexification of $\underset{\sim}{g}$. The following commutation relations are satisfied by the elements of $\underset{\sim}{g}_C$.

$$[e_\alpha,h]=\alpha(h)e_\alpha, \quad h\in\underset{\sim}{h}, \quad \alpha\in\Delta,$$

$$[e_\alpha,e_\beta]=\begin{cases} N_{\alpha\beta}e_{\alpha+\beta} & \text{if } \alpha+\beta \text{ is a root} \\ 0 \quad \text{otherwise,} \end{cases} \tag{3.1}$$

$$[e_\alpha,e_{-\alpha}]=h_\alpha, \quad h_\alpha\in\underset{\sim}{h}.$$

Here Δ denotes the set of roots of $\underset{\sim}{g}_C$ w.r.t. $\underset{\sim}{h}$ and the Killing form is defined as $B(e_\alpha,e_{-\alpha})=-1$. Here $\alpha(h)=B(h,h_\alpha)$ is the Killing form of $\underset{\sim}{g}_C$. The compact real form $\underset{\sim}{g}_K$ may be taken

TABLE III. Satake diagrams of $A_2^{(1)}$ along with their root automorphisms.

Satake Diagrams of $A_2^{(1)}$	Root Automorphisms
(i)	$-\sigma(\alpha_0)=\alpha_0$ $-\sigma(\alpha_1)=\alpha_1$ $-\sigma(\alpha_2)=\alpha_2$
(ii) (a) (b) (c) 	(a) $-\sigma(\alpha_1)=\alpha_2$, $-\sigma(\alpha_2)=\alpha_1$, $-\sigma(\alpha_0)=\alpha_0$ (b) $-\sigma(\alpha_1)=\alpha_0$, $-\sigma(\alpha_0)=\alpha_1$, $-\sigma(\alpha_2)=\alpha_2$ (c) $-\sigma(\alpha_0)=\alpha_2$, $-\sigma(\alpha_2)=\alpha_0$, $-\sigma(\alpha_1)=\alpha_1$
(iii) (a) (b) (c) 	(a) $-\sigma(\alpha_1)=\alpha_2+\alpha_0$, $-\sigma(\alpha_2)=\alpha_1+\alpha_0$, $\sigma(\alpha_0)=\alpha_0$ (b) $-\sigma(\alpha_0)=\alpha_2+\alpha_1$, $-\sigma(\alpha_2)=\alpha_0+\alpha_1$, $\sigma(\alpha_1)=\alpha_1$ (c) $\sigma(\alpha_2)=\alpha_2$, $-\sigma(\alpha_1)=\alpha_0+\alpha_2$, $-\sigma(\alpha_0)=\alpha_1+\alpha_2$
(iv) (a) (b) (c) 	(a) $-\sigma(\alpha_0)=\alpha_0+2\alpha_1+2\alpha_2$, $\sigma(\alpha_1)=\alpha_1$, $\sigma(\alpha_2)=\alpha_2$ (b) $-\sigma(\alpha_1)=\alpha_1+2\alpha_0+2\alpha_2$, $\sigma(\alpha_0)=\alpha_0$, $\sigma(\alpha_2)=\alpha_2$ (c) $-\sigma(\alpha_2)=\alpha_2+2\alpha_1+2\alpha_0$, $\sigma(\alpha_0)=\alpha_0$, $\sigma(\alpha_1)=\alpha_1$

to consist of ih_α, $\alpha=\alpha_0,\alpha_1,\ldots,\alpha_l$ and $(e_\alpha+e_{-\alpha})$, $i(e_\alpha-e_{-\alpha})\forall\alpha$. Let $\underset{\sim}{k}$ be the maximal compact subalgebra of $\underset{\sim}{g}$ defined such that $a\in\underset{\sim}{k}$ iff $a\in\underset{\sim}{g}_C$ and $\sigma a=a$. Let $\underset{\sim}{p}$ be the subspace of $\underset{\sim}{g}$ such that $a\in\underset{\sim}{p}$ iff $\tilde{a}\in\underset{\sim}{g}_C$ and $\sigma a=-a$. Thus $\underset{\sim}{k}$ and $\underset{\sim}{p}$ are given by

$$\underset{\sim}{k}=\{ih_\alpha,\alpha=\alpha_0,\alpha_1,\alpha_2,\ldots,\alpha_l \text{ and } (e_\alpha+e_{-\alpha}),\ i(e_\alpha-e_{-\alpha})\forall\alpha|\exp\ \alpha(h)=+1\},\quad (3.2)$$

$$\underset{\sim}{p}=\{i(e_\alpha+e_{-\alpha}),\quad (e_\alpha-e_{-\alpha})\forall\alpha|\exp\ \alpha(h)=-1\}.\quad (3.3)$$

Let $\underset{\sim}{a}$ be the maximal Abelian subalgebra of $\underset{\sim}{p}$ with dimension $|m_1|$ and $\underset{\sim}{m}$ be the centralizer of $\underset{\sim}{a}$ in $\underset{\sim}{k}$. Complexification of $\underset{\sim}{a}\oplus\underset{\sim}{m}$ together with a scaling element d' gives a Cartan subalgebra $\underset{\sim}{h}'$ of $\underset{\sim}{g}_C$ with basis H_0', $H_1',\ldots,H_l'$ and d'. There exists an inner automorphism $V:\underset{\sim}{h}'\to\underset{\sim}{h}$, i.e.,

$$H_j=VH_j',\quad \text{where } V=\prod_\alpha V_\alpha,\quad \alpha\in\Delta.\quad (3.4)$$

Let Δ^+ be the set of positive roots, then

$$h_\alpha=\sum_{j=0}^{l} b_j(\alpha)H_j.\quad (3.5)$$

Thus $\alpha\in\Delta^+$ iff $b_j(\alpha)>0$, where j is the least index such that $b_j(\alpha)\neq 0$. The positive roots can be again divided into the following classes:

$$\text{(i)}\quad \Delta_+^+=\{\alpha|\alpha\in\Delta^+,\quad \alpha(h)\neq\alpha(V\sigma V^{-1}h)\forall h\in\underset{\sim}{h}\},\quad (3.6)$$

$$\text{(ii)}\quad \Delta_-^+=\{\alpha|\alpha\in\Delta^+,\quad \alpha(h)=\alpha(V\sigma V^{-1}h)\forall h\in\underset{\sim}{h}\}.\quad (3.7)$$

Let the subalgebra $\tilde{\underline{\eta}}$ be spanned by the elements $V^{-1}e_\alpha$ for $\alpha \in \Delta_+^+$ and $\underline{n} = \tilde{\underline{\eta}} \cap g$, where $\tilde{\underline{\eta}}$ and $\underline{n}$ are nilpotent subalgebras of $\underline{g}_C$ and $\underline{g}$, respectively. Thus the Iwasawa decomposition of $\underline{g}$ is given by

$$\underline{g} = \underline{k} \oplus \underline{a} \oplus \underline{n}. \tag{3.8}$$

A minimal parabolic subalgebra is defined to be any subalgebra that is conjugate to

$$\underline{p}_1 = \underline{m} \oplus \underline{a} \oplus \underline{n}. \tag{3.9}$$

Any subalgebra of g containing the minimal parabolic subalgebra is a general parabolic subalgebra. There exist $2^{|\tilde{m}_1|}$ classes of parabolic subalgebras of $\underline{g}$ and in each such class there is a standard parabolic subalgebra which can be obtained through the following prescription. Let Σ be the set of roots for $\underline{a}$ and ψ be the set of positive roots in Σ. Let θ denote the subset of ψ and $\langle\theta\rangle$ the set of roots in Σ which arise as a linear combination of roots in θ. Define $\langle\theta\rangle_\pm = \Sigma_\pm \cap \langle\theta\rangle$, where Σ_+ and Σ_- denote the positive and negative roots in Σ. Let $\eta_+(\theta)$, $\eta_-(\theta)$, and $\eta(\theta)$ denote the subspaces of $\underline{a}$ corresponding to $\langle\theta\rangle_+$, $\langle\theta\rangle_-$, and $\Sigma_\pm - \langle\theta\rangle_\pm$, respectively. Now define

$$a_\theta = \{a \in \underline{a} | \lambda(a) = 0 \forall \lambda \in \theta\}, \tag{3.10}$$

and let $a(\theta)$ be the orthogonal component of a_θ in $\underline{a}$ with respect to the Cartan Killing form, then

$$p_\theta = m_\theta \oplus a_\theta \oplus \eta_\theta, \tag{3.11}$$

is a parabolic subalgebra of g, where

$$m_\theta = m \oplus \eta_+(\theta) \oplus \eta_-(\theta) \oplus a(\theta). \tag{3.12}$$

A real Cartan subalgebra $\underline{h}$ is said to be σ invariant if

$$\underline{h} = (\underline{h} \cap \underline{k}) \oplus (\underline{h} \cap \underline{p}). \tag{3.13}$$

A parabolic subalgebra p_θ is said to be cuspidal if there exists a σ-invariant real Cartan subalgebra $\underline{h}$ such that

$$a_\theta = \underline{h} \cap \underline{p}. \tag{3.14}$$

This shows that the minimal parabolic subalgebra is cuspidal.

IV. IWASAWA AND LANGLANDS DECOMPOSITIONS OF $A_1^{(1)}$

Let us consider the involutive automorphism of $A_1^{(1)}$ determined by any one of the Satake diagrams, say (iii), of Table II. The positive roots of $A_1^{(1)}$ are given by

$$\Delta = \{k\alpha_0 + (k-1)\alpha_1, \quad (k-1)\alpha_0 + k\alpha_1, \quad k(\alpha_1 + \alpha_0) \quad \text{where } k \in \mathbb{Z}^+\}. \tag{4.1}$$

These roots are expressed in terms of roots α_1 and imaginary root δ as

$$\Delta = \{\alpha_1, \pm\alpha_1 + n\delta, \text{ where } n \in \mathbb{Z}^+\}. \tag{4.2}$$

From the Satake diagram we see that the basic root automorphisms are given by

$$\sigma(\alpha_0) = \alpha_0, \quad -\sigma(\alpha_1) = \alpha_1 + 2\alpha_0. \tag{4.3}$$

The automorphisms of other roots are determined from the above. For example,

$$\sigma(2\alpha_1 + 3\alpha_0) = -(\alpha_0 + 2\alpha_1), \quad \sigma(3\alpha_1 + 4\alpha_0) = -(2\alpha_0 + 3\alpha_1),$$

and so on. Similarly,

$$\sigma(k(\alpha_1+\alpha_0))=-k(\alpha_1+\alpha_0).$$

From all these relations we see that

$$\exp\ \alpha(h)=+1 \quad \text{for}\ \ \alpha=(k-1)\alpha_1+k\alpha_0 \tag{4.4}$$

and

$$\exp\ \alpha(h)=-1 \quad \text{for}\ \ \alpha=k\alpha_1+(k-1)\alpha_0, \quad k(\alpha_1+\alpha_0). \tag{4.5}$$

So, for $A_1^{(1)}$, k is given by

$$\underset{\sim}{k}=\{ih_\alpha \quad \text{for}\ \ \alpha=\alpha_0,\alpha_1 \quad \text{and}\ \ (e_\alpha+e_{-\alpha}), \quad i(e_\alpha-e_{-\alpha}) \quad \text{for}\ \ \alpha=(k-1)\alpha_1+k\alpha_0\}, \tag{4.6}$$

and similarly $\underset{\sim}{p}$ is given by

$$\underset{\sim}{p}=\{i(e_\alpha+e_{-\alpha}), \quad (e_\alpha-e_{-\alpha}) \quad \text{for}\ \ \alpha=k\alpha_1+(k-1)\alpha_0, \quad k(\alpha_1+\alpha_0)\}. \tag{4.7}$$

We now select a maximal Abelian subalgebra $\underset{\sim}{a}$ in the vector space $\underset{\sim}{p}$. It is clear that $\underset{\sim}{a}$ is one dimensional and may be chosen to have a basis element

$$H_0'=i(e_\alpha+e_{-\alpha}) \quad \text{with}\ \ \alpha=\alpha_1. \tag{4.8}$$

Here $R_A=\{\alpha_1\}$ and R_M is empty. m is one dimensional and its basis element may be taken to be

$$-iH_1'=ih_\beta, \quad \text{where}\ \ \beta=\alpha_1+\alpha_0 \quad \text{as}\ \ \alpha_1(h_\beta)=0, \tag{4.9}$$

so that $H_1'=-h_{\alpha_1+\alpha_0}$.

Note that H_0', H_1' together with a scaling element d' such that $\alpha_0(d')=1$ and $\alpha_1(d')=0$, are the elements of the Cartan subalgebra H'. The inner automorphism of $A_1^{(1)}$ is given by $V_\alpha^{(1)}$ which is obtained from V_{α_1} (inner automorphism of A_1) by the following definition:

$$V_{\alpha_1}^{(1)}(e_{\alpha+n\delta})=t^n\otimes V_{\alpha_1}(e_\alpha) \tag{4.10a}$$

and

$$V_\alpha^{(1)}(d')=d. \tag{4.10b}$$

Applying this to the Cartan subalgebra H' of $A_1^{(1)}$, we obtain

$$H_0=-\left\{\frac{2}{(\alpha_1,\alpha_1)}\right\}^{1/2}h_{\alpha_1}=-2^{1/2}h_{\alpha_1}, \quad H_1=-(h_{\alpha_0}+h_{\alpha_1}), \tag{4.11}$$

along with the scaling element d. With respect to this Cartan subalgebra the set of positive roots is given by

$$\Delta^+=\{-((k-1)\alpha_0+k\alpha_1),(k\alpha_0+(k-1)\alpha_1),-k(\alpha_1+\alpha_0)\}, \tag{4.12}$$

and Δ_+^+ and Δ_-^+ can be written as

$$\Delta_-^+=\{-k(\alpha_1+\alpha_0)\}, \quad \Delta_+^+=\{-((k-1)\alpha_0+k\alpha_1),(k\alpha_0+(k-1)\alpha_1)\}. \tag{4.13}$$

For $A_1^{(1)}$, the basis elements of $\tilde{\underset{\sim}{n}}=\underset{\sim}{n}$ are given by $V_{\alpha_1}^{(1)^{-1}}e_{\alpha'}$ where $\alpha\in\Delta_+^+$ and we see that these are given by the structures

$$
\begin{aligned}
V_{\alpha_1}^{(1)^{-1}} e_{-\alpha_1} &= -\tfrac{1}{2}(e_{\alpha_1} - e_{-\alpha_1}) - \tfrac{1}{2} i 2^{1/2} h_{\alpha_1}, \\
V_{\alpha_1}^{(1)^{-1}} e_{\alpha_0} &= V_{\alpha_1}^{(1)^{-1}} (e_{-\alpha_1+\delta}) = t \otimes \{-\tfrac{1}{2}(e_{\alpha_1} - e_{-\alpha_1}) - \tfrac{1}{2} i 2^{1/2} h_{\alpha_1}\}, \\
V_{\alpha_1}^{(1)^{-1}} e_{-((k-1)\alpha_0 + k\alpha_1)} &= V_{\alpha_1}^{(1)^{-1}} e_{-\alpha_1+(1-k)\delta} = t^{(1-k)} \otimes \{-\tfrac{1}{2}(e_{\alpha_1} - e_{-\alpha_1}) - \tfrac{1}{2} i 2^{1/2} h_{\alpha_1}\}, \\
V_{\alpha_1}^{(1)^{-1}} e_{(k\alpha_0 + (k-1)\alpha_1)} &= V_{\alpha_1}^{(1)^{-1}} e_{-\alpha_1+k\delta} = t^k \otimes \{-\tfrac{1}{2}(e_{\alpha_1} - e_{-\alpha}) - \tfrac{1}{2} i 2^{1/2} h_{\alpha_1}\}.
\end{aligned}
\tag{4.14}
$$

The required Iwasawa decomposition is

$$
A_1^{(1)} = \underset{\sim}{k} \oplus \underset{\sim}{a} \oplus \underset{\sim}{n},
$$

where $\underset{\sim}{k}, \underset{\sim}{a}, \underset{\sim}{n}$ are determined by Eqs. (4.6), (4.8), and (4.14), respectively.

There are $2^{|m_1|}$ classes of parabolic subalgebras of affine Kac–Moody algebra, where $|m_1|$ is the dimension of $\underset{\sim}{a}$. For $A_1^{(1)}$ we see that $|m_1| = 1$ and there will, therefore, be two parabolic subalgebras, one being the minimal parabolic subalgebra and the other the algebra itself. The minimal parabolic subalgebra is given by

$$
\underset{\sim}{p}_1 = \underset{\sim}{m} \oplus \underset{\sim}{a} \oplus \underset{\sim}{n}, \tag{4.15}
$$

where

$$
\underset{\sim}{m} = \{i h_\alpha \quad \text{for} \quad \alpha = \alpha_1 + \alpha_0\}, \quad \underset{\sim}{a} = \{i(e_\alpha + e_{-\alpha}) \quad \text{for} \quad \alpha = \alpha_1\},
$$

and $\underset{\sim}{n}$ is given by Eq. (4.14). The minimal parabolic subalgebra, being the cuspidal parabolic subalgebra, leads to the following definition of a series of representation:

$$
\rho = \mathrm{ind}_{P_1}^{G}(\sigma \otimes \tau), \tag{4.16}
$$

where $\sigma \in \hat{M}$, $\tau \in \hat{N}$, and $P_1 = MAN$, is the cuspidal subgroup. Note that P_1, M, A, N, and G are the groups corresponding to the algebras $\underset{\sim}{p}_1$, $\underset{\sim}{m}$, $\underset{\sim}{a}$, $\underset{\sim}{n}$, and $\underset{\sim}{g}$, respectively. This defines the principal series representation. As P_1 is minimal parabolic and $\tilde{\sigma} = 1_M$, M being Abelian, is the trivial representation, so ρ is irreducible.

A. Iwasawa decomposition of $A_2^{(1)}$

We consider the involutive automorphisms of $A_2^{(1)}$ determined by the Satake diagram iv(b) of Table III. The basic root automorphisms are given by

$$
\sigma(\alpha_0) = \alpha_0, \quad -\sigma(\alpha_1) = \alpha_1 + 2\alpha_0 + 2\alpha_2, \quad \sigma(\alpha_2) = \alpha_2. \tag{4.17}
$$

In terms of roots ''α'' and ''δ'' the basic root automorphisms can be rewritten as

$$
\sigma(\delta - \alpha_1 - \alpha_2) = \delta - \alpha_1 - \alpha_2, \quad -\sigma(\alpha_1) = -\alpha_1 + 2\delta, \quad \sigma(\alpha_2) = \alpha_2. \tag{4.18}
$$

The positive roots of $A_2^{(1)}$ are given by

$$
\Delta = \{\alpha_1, \alpha_2, \quad \pm\alpha_1 + n\delta, \quad \pm\alpha_2 + n\delta, \quad \pm(\alpha_1 + \alpha_2) + n\delta, \quad n\delta, \quad \text{where} \quad n \in \mathbb{Z}^+\}. \tag{4.19}
$$

We can apply the basic root automorphism to find out the automorphisms of other roots and it is easy to see that

$$
\exp\, \alpha(h) = +1 \quad \text{for} \quad \alpha = \alpha_2, \quad -\alpha_1 + n\delta, \quad \alpha_2 + n\delta, \quad -(\alpha_1 + \alpha_2) + n\delta, \tag{4.20}
$$

$$
\exp\, \alpha(h) = -1 \quad \text{for} \quad \alpha = \alpha_1, \quad \alpha_1 + n\delta, \quad -\alpha_2 + n\delta, \quad (\alpha_1 + \alpha_2) + n\delta, \quad n\delta. \tag{4.21}
$$

For $A_2^{(1)}$ the structures for $\underset{\sim}{k}$ and $\underset{\sim}{p}$ are given by

$$\underset{\sim}{k}=\{ih_\alpha \quad \text{for } \alpha=\alpha_0,\alpha_1,\alpha_2, \text{ and } (e_\alpha+e_{-\alpha}), \quad i(e_\alpha-e_{-\alpha})$$

for α given by Eq. (4.20)} and (4.22)

$$\underset{\sim}{p}=\{i(e_\alpha+e_{-\alpha}), \quad (e_\alpha-e_{-\alpha}) \quad \text{for } \alpha \text{ given by Eq. (4.21)}\}. \tag{4.23}$$

Again, in an analogous manner, we select a maximal Abelian subalgebra $\underset{\sim}{a}$; we see that $\underset{\sim}{a}$ is one dimensional and its basis element is given by

$$H_0'=i(e_\alpha+e_{-\alpha}) \quad \text{for } \alpha=\alpha_1. \tag{4.24}$$

Here $R_A=\{\alpha_1\}$, and R_M is empty. m is two dimensional and its basis elements are given by

$$H_1'=-(h_{\alpha_1}+2h_{\alpha_2}), \quad H_2'=-h_\delta. \tag{4.25}$$

The elements H_0', H_1', H_2' together with the scaling element d' form the Cartan subalgebra $\underset{\sim}{h}'$. Defining the inner automorphism of $A_2^{(1)}$ as before, we obtain

$$H_0=-2^{1/2}h_{\alpha_1}, \quad H_1=-(h_{\alpha_1}+2h_{\alpha_2}), \quad H_2=-h_\delta \quad \text{and } d. \tag{4.26}$$

The set of positive roots with respect to this Cartan subalgebra is given by

$$\begin{aligned}\Delta^+=\{&-\alpha_1,\alpha_2,-(\alpha_1+\alpha_2),-(\alpha_1+n\delta),(-\alpha_1+n\delta),\alpha_2+n\delta,\\ &-(-\alpha_2+n\delta),-((\alpha_1+\alpha_2)+n\delta),-(\alpha_1+\alpha_2)+n\delta,-n\delta)\},\end{aligned} \tag{4.27}$$

The Δ_+^+ and Δ_-^+ are then written as

$$\Delta_-^+=\{-n\delta\}, \quad \Delta_+^+=\Delta^+/\Delta_-^+. \tag{4.28}$$

The elements of $\underset{\sim}{\tilde{\eta}}$ are determined by the structure $V_{\alpha_1}^{(1)^{-1}}e_\alpha$, where $\alpha\in\Delta_+^+$. These are given by

$$\begin{aligned}V_{\alpha_1}^{(1)^{-1}}e_{-\alpha_1}&=-\tfrac{1}{2}(e_{\alpha_1}-e_{-\alpha_1})-\tfrac{1}{2}i2^{-1/2}h_{\alpha_1},\\ V_{\alpha_1}^{(1)^{-1}}e_{\alpha_2}&=2^{-1/2}e_{\alpha_2}-i2^{-1/2}(\mathrm{Sgn}\, N_{\alpha_1,\alpha_2})e_{\alpha_1+\alpha_2},\\ V_{\alpha_1}^{(1)^{-1}}e_{-(\alpha_1+\alpha_2)}&=-i2^{-1/2}(\mathrm{Sgn}\, N_{\alpha_1,-(\alpha_1+\alpha_2)})e_{-\alpha_2}+2^{-1/2}e_{-(\alpha_1+\alpha_2)}.\end{aligned} \tag{4.29}$$

The other elements are obtained by using the relations

$$\begin{aligned}&V_{\alpha_1}^{(1)^{-1}}e_{-\alpha_1\pm n\delta}=t^{\pm n}\otimes V_{\alpha_1}^{(1)^{-1}}e_{-\alpha_1}, \quad V_{\alpha_1}^{(1)^{-1}}e_{\alpha_2\pm n\delta}=t^{\pm n}\otimes V_{\alpha_1}^{(1)^{-1}}e_{\alpha_2},\\ &\text{and } V_{\alpha_1}^{(1)^{-1}}e_{-(\alpha_1+\alpha_2)\pm n\delta}=t^{\pm n}\otimes V_{\alpha_1}^{(1)^{-1}}e_{-(\alpha_1+\alpha_2)}.\end{aligned} \tag{4.30}$$

Now $\underset{\sim}{n}$ can be calculated from $\underset{\sim}{\tilde{\eta}}$ and some of its typical elements are given by

$$-\frac{1}{2}(e_{\alpha_1}-e_{-\alpha_1})-\frac{i}{2}2^{-1/2}h_{\alpha_1},$$

$$2^{-1/2}(e_{\alpha_2}-e_{-\alpha_2})-i2^{-1/2}(\mathrm{Sgn}\, N_{\alpha_1,\alpha_2})\{e_{\alpha_1+\alpha_2}-e_{-(\alpha_1+\alpha_2)}\},$$

$$i2^{-1/2}(e_{(\alpha_1+\alpha_2)}-e_{-(\alpha_1+\alpha_2)})+2^{-1/2}(\mathrm{Sgn}\, N_{\alpha_1,-(\alpha_1+\alpha_2)})\{e_{\alpha_2}-e_{-\alpha_2}\}.$$

The remaining elements are similarly obtained by using the above relations (4.30).

For $A_2^{(1)}$ also we see that there will be two parabolic subalgebras, as is the case with $A_1^{(1)}$; one being the minimal parabolic and the other the algebra itself. The minimal parabolic subalgebra is given by

$$\underset{\sim}{p}_1 = \underset{\sim}{m} \oplus \underset{\sim}{a} \oplus \underset{\sim}{n}. \tag{4.31}$$

V. CONCLUSION

Before closing, a few remarks are pertinent. In the present investigation, we have computed the Iwasawa and Langlands decompositions of the affine untwisted Kac–Moody algebras $A_1^{(1)}$ and $A_2^{(1)}$ with the express purpose of determining the parabolic subalgebras which ultimately provide the induced representation. These constructions have been facilitated by the involutive automorphisms derived from the Satake diagrams of these algebras. As mentioned earlier our results are in agreement with those of Cornwell[8] for root automorphisms. We believe that this method is readily amenable to generalization to the case of affine twisted Kac–Moody algebras with suitable redefinition of inner automorphism, supplemented possibly with some extra rule. Such studies are in progress and will be reported in a subsequent communication.

ACKNOWLEDGMENT

We express our deep gratitude to Dr. R. S. Kaushal for fruitful discussions and helpful suggestions.

(Received 24 February 1997; accepted for publication 13 April 1998)

The cohomology groups of Lie superalgebras and, more generally, of ε Lie algebras, are introduced and investigated. The main emphasis is on the case where the module of coefficients is nontrivial. Two general propositions are proved, which help to calculate the cohomology groups. Several examples are included to show the peculiarities of the super case. For $L=sl(1|2)$, the cohomology groups $H^1(L,V)$ and $H^2(L,V)$, with V a finite-dimensional simple graded L-module, are determined, and the result is used to show that $H^2(L,U(L))$ [with $U(L)$ the enveloping algebra of L] is trivial. This implies that the superalgebra $U(L)$ does not admit any nontrivial formal deformations (in the sense of Gerstenhaber). Garland's theory of universal central extensions of Lie algebras is generalized to the case of ε Lie algebras. © *1998 American Institute of Physics.* [S0022-2488(98)01607-7]

I. INTRODUCTION

Cohomology is an important tool in mathematics. Its range of applications contains algebra and topology as well as the theory of smooth manifolds or of holomorphic functions. The cohomology theory of Lie algebras (whose generalization is the main objective of the present paper) has its origins in the work of E. Cartan, but the foundation of the theory, as an independent topic of research, is due to Chevalley and Eilenberg,[1] Koszul,[2] and Hochschild and Serre.[3] A unifying treatment of the cohomology theory of groups, associative algebras, and Lie algebras has been given by Cartan and Eilenberg.[4]

As is well-known, several classical results in Lie algebra theory have a cohomological interpretation. Thus, if L is a Lie algebra, the structure of the extensions of L-modules (and hence the question of semi-simplicity of L-modules) is described by the 1-cohomology of L, and the structure of the Lie algebra extensions (and hence the Levi, Malcev theorem) is related to the 2-cohomology.[1,5]

In view of these remarks, it is hardly surprising that shortly after the birth of supersymmetry, a paper appeared[6] in which the most basic constructions and results of the classical theory are generalized to the case of Lie superalgebras.[7,8] Later on, Leites and Fuks calculated the cohomology groups of the classical Lie superalgebras with trivial coefficients[9] (see also Ref. 10), and Leites and Serganova used cohomological methods to determine systems of generators and relations for these algebras.[11] In addition, we should mention a letter by Retakh and Feigin[12] and the papers by Tripathy and coworkers (see Ref. 13 and the papers cited therein). Apart from this, very little seems to be known about the cohomology of Lie superalgebras, in particular, about the cohomology with nontrivial coefficients.

After the present work was posted on the Internet and submitted for publication, Gruson sent us a copy of the galley proofs of an article,[14] in which she proves the finiteness of the homology of certain modules over a Lie superalgebra. She also drew our attention to a paper by Tanaka,[15] in which the author calculates the dimensions of the homology and cohomology groups of $sl(2|1)$ with coefficients in an arbitrary finite-dimensional simple module. This has a direct bearing on part of our work, and we shall comment on it later on.

Our present interest in this topic has been stimulated by the theory of quantum algebras.[16,17] It is known that, for any semi-simple Lie algebra L, the enveloping algebra $U(L)$ does not admit

a)Electronic mail: scheunert@physik.uni-bonn.de
b)Electronic mail: rzhang@maths.adelaide.edu.au

 © 1998 American Institute of Physics

any nontrivial formal deformations in the sense of Gerstenhaber.[18] We would like to know for which of the simple Lie superalgebras the same holds true. Proceeding as in Ref. 19, this amounts to showing that the second cohomology group $H^2(L,U(L))$ is trivial. Unfortunately, we are far from proving a general result of this type. In fact, all we can say at present is that this is true if L is one of the algebras $osp(1|2n)$ (this is easy to see and, certainly, was already known to Kac[7]), or if L is equal to $sl(1|2)$ (this will be proved in the present work). Moreover, in the meantime we have proved that $H^2(L,U(L))$ is also trivial for the algebras $sl(m|1)$ with $m\geqslant 3$. This will be published elsewhere. Accordingly, our paper is going to be explorative in character.

Let us briefly describe the setup of the present article. In Sec. II we collect the basic definitions and constructions, which will be needed in the subsequent sections. Using the graded multilinear algebra as described in Ref. 20 this is just a simple transcription of the classical situation to the graded case. In doing so, we shall follow the approach of Ref. 3 (see also Ref. 1). In addition, we comment on some peculiarities of the graded case, and we prove two propositions, which will be the main tools in our calculations. The first one shows that it is sufficient to investigate cochains and coboundaries with certain invariance properties; the second proposition gives a general criterion for the cohomology with values in a given module to be trivial.

Section III contains several examples. In the first example we consider the cohomology of semi-simple Lie algebras. This example is included mainly in order to show how far we can get, under the most favorable circumstances, by only using the results of Sec. II. A short look at this example reveals that the same arguments can be applied to the Lie superalgebras $osp(1|2n)$. This will be the content of the second example. The third example contains some special information on the cohomology with trivial coefficients (again well-known in the case of semi-simple Lie algebras). In the fourth example we use the second proposition of Sec. II to determine, for the general linear Lie superalgebras $gl(m|n)$, which of the finite-dimensional simple graded $gl(m|n)$-modules might have a nontrivial cohomology. This discussion also covers the case of the special linear Lie superalgebras $sl(m|n)$, provided that $m\neq n$.

In Sec. IV we generalize Garland's theory of universal central coverings (i.e., extensions) of Lie algebras[21] to the general graded setting. As a simple example, we determine the universal covering of the simple Lie superalgebras $sl(n|n)$/center, with $n\geqslant 2$.

In Sec. V we consider the Lie superalgebra $L=sl(1|2)$ and determine the finite-dimensional simple graded L-modules V for which $H^1(L,V)$ or $H^2(L,V)$ is nontrivial. The result is then used to show that $H^2(L,U(L))$ is trivial. Of course, the modules V in question can be read off from Ref. 15. Nevertheless, we think it is worthwhile to present our own calculations. First of all, this makes our paper self-contained in this respect. Secondly, since we only determine $H^1(L,V)$ and $H^2(L,V)$, our calculations are much simpler and the results much more explicit than those of Ref. 15, where $\dim H^n(L,V)$ is determined for arbitrary n. Finally, this part of our paper is meant to explain how one might investigate $H^2(L,U(L))$ for more general Lie superalgebras L.

Section VI contains a brief discussion of our results. The paper is closed by two appendices. In Appendix A we describe the analog of the exterior (i.e., Grassmann) algebra in the general graded setting. Appendix B contains some special information related to Sec. V. This will be used to show that, for $L=sl(1|2)$, the cohomology group $H^1(L,U(L))$ is nontrivial.

We close this introduction by explaining some of our conventions. The base field will always be a field $\mathbb{K}$ of characteristic zero. We use the standard notation $\mathbb{Z}$ for the ring of integers and $\mathbb{N}$ for the set of natural numbers (according to our convention, $\mathbb{N}$ contains 0). The set of strictly positive integers will be denoted by $\mathbb{N}_*$. As explained above, in Sec. II and Sec. IV as well as in Appendix A we are going to consider the so-called ε Lie algebras[22] (also called color Lie algebras[23]). In these sections, Γ is an arbitrary Abelian group and ε is a commutation factor on Γ with values in $\mathbb{K}$. The reader who is only interested in Lie superalgebras may simply set $\Gamma=\mathbb{Z}_2$ or $\Gamma=\mathbb{Z}$ and choose ε to be the standard commutation factor of supersymmetry, defined by $\varepsilon(\alpha,\beta)=(-1)^{\alpha\beta}$ for all $\alpha,\beta\in\Gamma$. The choice $\Gamma=\mathbb{Z}_2$ leads to general Lie superalgebras, for $\Gamma=\mathbb{Z}$, we obtain the consistently $\mathbb{Z}$-graded Lie superalgebras in the sense of Ref. 7. The multiplication in an ε Lie algebra (and hence in a Lie superalgebra) will be denoted by a pointed bracket $\langle,\rangle$.

II. COHOMOLOGY OF ε LIE ALGEBRAS: DEFINITIONS AND SOME BASIC RESULTS

Let us first introduce the notation which will be used throughout the present section. Quite generally, we adopt the conventions of Ref. 20. In the following, Γ denotes an Abelian group,

$\varepsilon:\Gamma\times\Gamma\to\mathbb{K}$ a commutation factor on Γ with values in $\mathbb{K}$, L an ε Lie algebra,[22] and V a graded L-module. All gradations are understood to be Γ-gradations. If an element of a graded vector space is homogeneous of a certain degree, then this degree will be denoted by the lower case ''Greek analog'' of the letter denoting the element itself. For example, if A,b',g,x are homogeneous elements, their degrees will be denoted by $\alpha,\beta',\gamma,\xi\in\Gamma$, respectively. Only occasionally (but in all cases where there could be any doubts) the degrees will be specified explicitly.

Let $n\geqslant 1$ be a natural number and let

$$\mathrm{Lgr}_n(L,V)=\mathrm{Lgr}_n(\underbrace{L,\ldots,L}_{n};V) \tag{2.1}$$

be the graded vector space of all n-linear mappings of $L^n=L\times\cdots\times L$ into V which can be written as a sum of homogeneous n-linear mappings of L^n into V. Recall that $\mathrm{Lgr}_n(L,V)$ is equal to the space of all n-linear mappings of L^n into V if (for example) Γ is finite or if L is finite-dimensional.

According to Ref. 20 $\mathrm{Lgr}_n(L,V)$ is a graded L-module: If $A\in L$ and $g\in\mathrm{Lgr}_n(L,V)$ are homogeneous, the action of A on g is defined by

$$\begin{aligned}(A_L(g))(A_1,\ldots,A_n)&=A_V(g(A_1,\ldots,A_n))\\&\quad-\sum_{r=1}^{n}\varepsilon(\alpha,\gamma+\alpha_1+\cdots+\alpha_{r-1})g(A_1,\ldots,\langle A,A_r\rangle,\ldots,A_n),\end{aligned} \tag{2.2}$$

for all homogeneous elements $A_1,\ldots,A_n\in L$. [Recall that the ε-commutator of two elements $A,B\in L$ is denoted by $\langle A,B\rangle$. Quite generally, if V is a graded L-module, the representative of an element $A\in L$ in V will be denoted by A_V. If x is an element of V, we shall frequently simplify the notation and write $A\cdot x$ in place of $A_V(x)$.]

On the other hand, again according to Ref. 20, there is a natural representation of the symmetric group $\mathcal{S}_n$ in $\mathrm{Lgr}_n(L,V)$. To describe it, we define a map

$$\varepsilon_n:\mathcal{S}_n\times\Gamma^n\to\mathbb{K}, \tag{2.3}$$

by

$$\varepsilon_n(\pi^{-1};\gamma_1,\ldots,\gamma_n)=\prod_{\substack{i<j\\ \pi(i)>\pi(j)}}\varepsilon(\gamma_i,\gamma_j), \tag{2.4}$$

for all $\pi\in\mathcal{S}_n$ and $\gamma_1,\ldots,\gamma_n\in\Gamma$. The basic property of this map is that

$$\varepsilon_n(\pi\tau;\gamma_1,\ldots,\gamma_n)=\varepsilon_n(\pi;\gamma_1,\ldots,\gamma_n)\varepsilon_n(\tau;\gamma_{\pi(1)},\ldots,\gamma_{\pi(n)}), \tag{2.5}$$

for all $\pi,\tau\in\mathcal{S}_n$ and all $\gamma_1,\ldots,\gamma_n\in\Gamma$. Then the representation $\pi\to\check{S}_\pi$ of $\mathcal{S}_n$ in $\mathrm{Lgr}_n(L,V)$ is given by

$$(\check{S}_\pi(g))(A_1,\ldots,A_n)=\varepsilon_n(\pi;\alpha_1,\ldots,\alpha_n)g(A_{\pi(1)},\ldots,A_{\pi(n)}), \tag{2.6}$$

for all $\pi\in\mathcal{S}_n$, $g\in\mathrm{Lgr}_n(L,V)$, and all homogeneous elements $A_1,\ldots,A_n\in L$. It is known that $\check{S}_\pi$ is an automorphism of the graded L-module $\mathrm{Lgr}_n(L,V)$, for all $\pi\in\mathcal{S}_n$.

Now let $C^n(L,V)$ be the set of all ε-skew-symmetric elements of $\mathrm{Lgr}_n(L,V)$, i.e., the set of all elements $g\in\mathrm{Lgr}_n(L,V)$ such that

$$\check{S}_\pi g=\mathrm{sgn}(\pi)g, \tag{2.7}$$

for all $\pi\in\mathcal{S}_n$, where $\mathrm{sgn}(\pi)$ denotes the signum of the permutation π. We extend this definition to the case of integers $n\leqslant 0$ and set

$$C^n(L,V)=\{0\},\quad \text{if } n\leqslant -1, \tag{2.8}$$

$$C^0(L,V)=V. \tag{2.9}$$

Occasionally, it is useful to identify $C^0(L,V)$ with $\mathrm{Lgr}(\mathbb{K},V)$. Then $C^n(L,V)$ can be identified with $\mathrm{Lgr}(\wedge_\varepsilon^n L,V)$, where $\wedge_\varepsilon^n L$ is the subspace of degree n of the ε-exterior algebra $\wedge_\varepsilon L$ of L. A few comments on the ε-exterior algebra of a Γ-graded vector space are contained in Appendix A. Obviously, $C^n(L,V)$ is a graded L-module, for all n. The elements of $C^n(L,V)$ are called the *n-cochains* of L with values in V.

In the subsequent discussion we follow Ref. 3. First we define, for all integers n, a map

$$C^n(L,V)\times L\to C^{n-1}(L,V), \tag{2.10}$$

denoted by

$$(g,A)\to g_A, \tag{2.11}$$

by

$$g_A=0, \quad \text{if } n\leqslant 0, \tag{2.12}$$

$$g_A=g(A), \quad \text{if } n=1, \tag{2.13}$$

$$g_A(A_2,\ldots,A_n)=g(A,A_2,\ldots,A_n), \quad \text{if } n\geqslant 2, \tag{2.14}$$

where $g\in C^n(L,V)$ and $A,A_2,\ldots,A_n\in L$. It is easy to see that this map is bilinear, homogeneous of degree zero, and L-invariant, i.e.,

$$B\cdot g_A=(B\cdot g)_A+\varepsilon(\beta,\gamma)g_{\langle B,A\rangle}, \tag{2.15}$$

for all homogeneous elements $A,B\in L$ and $g\in C^n(L,V)$.

Next we define, again for all integers n, the linear *coboundary operator*

$$\delta^n: C^n(L,V)\to C^{n+1}(L,V), \tag{2.16}$$

as follows: We set

$$\delta^n=0, \quad \text{if } n\leqslant -1, \tag{2.17}$$

and define δ^n for $n\geqslant 0$ inductively by

$$(\delta^n(g))_A=\varepsilon(\gamma,\alpha)A\cdot g-\delta^{n-1}(g_A), \tag{2.18}$$

where $g\in C^n(L,V)$ and $A\in L$ are homogeneous. [Note that Eq. (2.18) is trivially satisfied if $n\leqslant -1$.] As it stands, Eq. (2.18) defines a linear map of $C^n(L,V)$ into $\mathrm{Lgr}_{n+1}(L,V)$ which is homogeneous of degree zero, but it is easy to see by induction on $n\geqslant 0$ that $\delta^n g$ is ε-skew-symmetric and hence an element of $C^{n+1}(L,V)$. One can now show by induction on n that δ^n is a homomorphism of graded L-modules, i.e., that

$$A\cdot(\delta^n g)=\delta^n(A\cdot g), \tag{2.19}$$

for all n and all $A\in L$, $g\in C^n(L,V)$, and then (very easily) that

$$\delta^{n+1}\circ\delta^n=0, \tag{2.20}$$

for all n. Finally, one can verify inductively that the following explicit formula holds for $n\geqslant 1$:

$$
\begin{aligned}
&(\delta^n g)(A_0,A_1,\ldots,A_n)\\
&=\sum_{r=0}^{n}(-1)^r\varepsilon(\gamma+\alpha_0+\cdots+\alpha_{r-1},\alpha_r)A_r\cdot g(A_0,\ldots,\widehat{A_r},\ldots,A_n)\\
&+\sum_{r<s}(-1)^s\varepsilon(\alpha_{r+1}+\cdots+\alpha_{s-1},\alpha_s)g(A_0,\ldots,A_{r-1},\langle A_r,A_s\rangle,A_{r+1},\ldots,\widehat{A_s},\ldots,A_n),
\end{aligned}
\tag{2.21}
$$

where $g\in C^n(L,V)$ and $A_0,A_1,\ldots,A_n\in L$ are homogeneous, and where the sign $\widehat{\ }$ indicates that the element below it must be omitted. Empty sums (like $\alpha_0+\cdots+\alpha_{r-1}$ for $r=0$ and $\alpha_{r+1}+\cdots+\alpha_{s-1}$ for $s=r+1$) are set equal to zero. In particular, for $n=1$ we have

$$
(\delta^1 g)(A_0,A_1)=\varepsilon(\gamma,\alpha_0)A_0\cdot g(A_1)-\varepsilon(\gamma+\alpha_0,\alpha_1)A_1\cdot g(A_0)-g(\langle A_0,A_1\rangle),
\tag{2.22}
$$

and for $n=2$ we obtain

$$
\begin{aligned}
(\delta^2 g)(A_0,A_1,A_2)=&\varepsilon(\gamma,\alpha_0)A_0\cdot g(A_1,A_2)-\varepsilon(\gamma+\alpha_0,\alpha_1)A_1\cdot g(A_0,A_2)\\
&+\varepsilon(\gamma+\alpha_0+\alpha_1,\alpha_2)A_2\cdot g(A_0,A_1)-g(\langle A_0,A_1\rangle,A_2)\\
&+\varepsilon(\alpha_1,\alpha_2)g(\langle A_0,A_2\rangle,A_1)+g(A_0,\langle A_1,A_2\rangle).
\end{aligned}
\tag{2.23}
$$

Occasionally, it is useful to rewrite Eq. (2.21) in the form

$$
\begin{aligned}
&2(\delta^n g)(A_0,A_1,\ldots,A_n)\\
&\quad=\sum_{r=0}^{n}(-1)^r\varepsilon(\gamma+\alpha_0+\cdots+\alpha_{r-1},\alpha_r)(A_r\cdot g)(A_0,\ldots,\widehat{A_r},\ldots,A_n)\\
&\quad+\sum_{r=0}^{n}(-1)^r\varepsilon(\gamma+\alpha_0+\cdots+\alpha_{r-1},\alpha_r)A_r\cdot g(A_0,\ldots,\widehat{A_r},\ldots,A_n).
\end{aligned}
\tag{2.24}
$$

Remark 2.1: The relations (2.18), (2.19), (2.20) are the basic properties of the coboundary operators δ^n. Of course, they can be checked directly [regarding Eq. (2.21) as the definition of δ^n], but it is much easier to proceed as in Ref. 3, i.e., to follow the steps described above.

Remark 2.2: We could use the ε-skew-symmetry of g to shift the argument $\langle A_r,A_s\rangle$ in the second sum on the right hand side of Eq. (2.21) to the first place. Then this equation would take a form which is similar to the one familiar from the nongraded theory. However, this would lead to additional ε factors which we wanted to avoid.

Next let $Z^n(L,V)$ denote the kernel of δ^n and let $B^n(L,V)$ denote the image of δ^{n-1}. Equation (2.19) implies that $Z^n(L,V)$ and $B^n(L,V)$ are graded submodules of $C^n(L,V)$, and according to Eq. (2.20) we have

$$
B^n(L,V)\subset Z^n(L,V).
\tag{2.25}
$$

The elements of $Z^n(L,V)$ are called *n-cocycles*, the elements of $B^n(L,V)$ are the *n-coboundaries.* Because of (2.25) we can construct the so-called *cohomology groups*,

$$
H^n(L,V)=Z^n(L,V)/B^n(L,V).
\tag{2.26}
$$

Two elements of $Z^n(L,V)$ are said to be *cohomologous* if their residue classes modulo $B^n(L,V)$ coincide, i.e., if their difference lies in $B^n(L,V)$.

Of course, the cohomology groups are graded L-modules, too. Actually, their L-module structure is trivial. To prove this we have to show that for any cocycle $g\in Z^n(L,V)$ and any $A\in L$, the cocycle $A\cdot g$ is a coboundary, and this follows directly from Eq. (2.18).

The following consequence of the foregoing result can be used to facilitate the calculation of the cohomology groups.

Proposition 2.1: We use the notation introduced at the beginning of the present section. Let L' *be a graded subalgebra of* L.

(a) If the L'*-module* $Z^n(L,V)$ *is semi-simple [which is true if the* L'*-module* $C^n(L,V)$ *is semi-simple], then for any cocycle* $g \in Z^n(L,V)$ *there exists an* L'*-invariant cocycle* $g' \in Z^n(L,V)$ *which is cohomologous to* g.

(b) If the L'*-module* $C^{n-1}(L,V)$ *is semi-simple, then any* L'*-invariant coboundary* $b \in B^n(L,V)$ *is equal to* $\delta^{n-1}(g)$ *with an* L'*-invariant cochain* $g \in C^{n-1}(L,V)$.

(Semi-simplicity may be understood in the graded sense.)

Proof: (a) If the graded L'-module $Z^n(L,V)$ is semi-simple, there exists a graded L'-submodule $X^n(L,V)$ of $Z^n(L,V)$ which is complementary to $B^n(L,V)$. By definition, the canonical map,

$$Z^n(L,V) \to H^n(L,V), \tag{2.27}$$

induces an isomorphism,

$$X^n(L,V) \to H^n(L,V), \tag{2.28}$$

of graded L'-modules. Since the L'-module structure of $H^n(L,V)$ is trivial, the same is true for the L'-module structure of $X^n(L,V)$, i.e., all elements of $X^n(L,V)$ are L'-invariant. Thus all we have to do is to choose an element $g' \in X^n(L,V)$ such that the canonical images of g and g' in $H^n(L,V)$ coincide.

(b) If the graded L'-module $C^{n-1}(L,V)$ is semi-simple, there exists a graded L'-submodule $Y^{n-1}(L,V)$ of $C^{n-1}(L,V)$ which is complementary to the kernel of δ^{n-1} [i.e., to $Z^{n-1}(L,V)$]. Then δ^{n-1} induces an isomorphism,

$$Y^{n-1}(L,V) \to B^n(L,V), \tag{2.29}$$

of graded L'-modules. This implies (b) and completes the proof of the proposition.

Next we consider some constructions which can be carried out with the cohomology groups. Let L' be a second ε Lie algebra and let

$$\omega : L' \to L \tag{2.30}$$

be a homomorphism of ε Lie algebras. Then the action of L' on V, defined by

$$A' \cdot x = \omega(A') \cdot x, \tag{2.31}$$

for all $A' \in L'$ and $x \in V$, makes V into a graded L'-module, which we denote by V^ω. If $g \in C^n(L,V)$ with some $n \geqslant 1$, then the map $L'^n \to V$, defined by

$$(A'_1, \ldots, A'_n) \to g(\omega(A'_1), \ldots, \omega(A'_n)), \tag{2.32}$$

for all $A'_1, \ldots, A'_n \in L'$, is an element of $C^n(L', V^\omega)$. This assignment defines a linear map,

$$C^n(L,V) \to C^n(L', V^\omega). \tag{2.33}$$

We extend this definition to the cases $n \leqslant 0$ by defining this map to be equal to id_V if $n = 0$, and to zero if $n \leqslant -1$. Obviously, the map (2.33) is homogeneous of degree zero, and it is easy to see that it is compatible with the coboundary operators, in the obvious sense. In particular, it maps cocycles into cocycles and coboundaries into coboundaries, thus inducing a corresponding map for the cohomology groups:

$$H^n(L,V) \to H^n(L', V^\omega). \tag{2.34}$$

Similarly, let

$$f : V \to W \tag{2.35}$$

be a linear map of V into a second graded L-module W and suppose that f is homogeneous of degree φ and L-invariant. Recall[20] that L-invariance means that

$$f(A\cdot x)=\varepsilon(\varphi,\alpha)A\cdot f(x), \tag{2.36}$$

for all $x\in V$, and for all $A\in L$ which are homogeneous of degree α (stated differently, f is L-linear in the graded sense). For any integer n, we define the map

$$f_c^n: C^n(L,V)\to C^n(L,W), \tag{2.37}$$

by

$$f_c^n=0, \quad \text{if } n\leqslant -1, \tag{2.38}$$

$$f_c^0=f, \quad \text{if } n=0, \tag{2.39}$$

$$f_c^n(g)=f\circ g, \quad \text{if } n\geqslant 1. \tag{2.40}$$

Obviously, f_c^n is homogeneous of degree φ, and it is easy to see that

$$\delta_W^n\circ f_c^n=f_c^{n+1}\circ\delta_V^n, \tag{2.41}$$

where, temporarily, we have marked the coboundary operators for cochains with values in V and W by the subscripts V and W, respectively. Equation (2.41) implies that f_c^n maps cocycles into cocycles and coboundaries into coboundaries, and hence induces a linear map,

$$f^n: H^n(L,V)\to H^n(L,W). \tag{2.42}$$

Of course, f^n is also homogeneous of degree φ. If U is a third graded L-module and if $f': U\to V$ is a linear map which is homogeneous and L-invariant, then, obviously,

$$(f\circ f')_c^n=f_c^n\circ f'^n_c \quad \text{and} \quad (f\circ f')^n=f^n\circ f'^n. \tag{2.43}$$

As a first application of this construction, choose $\sigma\in\Gamma$ and consider the graded L-module V^σ which is obtained from V by a shift of the gradation by σ (see Ref. 20). Recall that, considered as a vector space, V and V^σ coincide, and that the actions of L on V and V^σ are also the same, but that the gradations are related by

$$V^\sigma_\gamma=V_{\gamma+\sigma}, \tag{2.44}$$

for all $\gamma\in\Gamma$. Define the linear map

$$f: V^\sigma\to V, \tag{2.45}$$

by

$$f(x)=\varepsilon(\sigma,\xi)x, \tag{2.46}$$

for all $x\in V^\sigma_\xi$, $\xi\in\Gamma$. Then f is bijective and homogeneous of degree σ, and it is easy to see that f is L-invariant. Consequently,

$$f^n: H^n(L,V^\sigma)\to H^n(L,V) \tag{2.47}$$

is a bijective linear map which is homogeneous of degree σ. Stated differently, f^n is an isomorphism of the graded vector space $H^n(L,V^\sigma)$ onto the graded vector space $H^n(L,V)^\sigma$.

For our second application we suppose that V is the direct sum of a family $(V_i)_{i\in I}$ of graded submodules,

$$V=\bigoplus_{i\in I} V_i. \tag{2.48}$$

Considering the canonical injections $V_i \to V$ and projections $V \to V_i$, it is easy to construct a natural linear map,

$$\bigoplus_{i \in I} H^n(L,V_i) \to H^n(L,V), \tag{2.49}$$

which is injective and homogeneous of degree zero. If I is finite or if L is finite-dimensional, this map is even bijective, i.e., an isomorphism of graded vector spaces. The details are obvious and may be left to the reader.

The third application is less trivial. Consider three graded L-modules U, V, W and a short exact sequence,

$$\{0\} \to U \overset{j}{\to} V \overset{p}{\to} W \to \{0\}, \tag{2.50}$$

where the linear mappings j and p are homogeneous (of degrees ι and π, respectively) and L-invariant. Then there exists a long exact sequence,

$$\ldots \to H^n(L,U) \overset{j^n}{\to} H^n(L,V) \overset{p^n}{\to} H^n(L,W) \overset{\delta^n}{\to} H^{n+1}(L,U) \to \ldots, \tag{2.51}$$

where the maps j^n and p^n have been defined above. The definition of the so-called *connecting homomorphisms* δ^n [not to be confounded with the coboundary operators δ^n of Eq. (2.16)] is standard but a little involved (see Refs. 24,25). Since, in the applications, this definition generally is of little use, we do not give it here, but only mention that δ^n is homogeneous of degree $-\iota - \pi$.

Next we want to construct certain product maps between the spaces of cochains. Let V and W be two graded L-modules and let m and n be two integers. We are going to define a bilinear map,

$$C^m(L,V) \times C^n(L,W) \to C^{m+n}(L, V \otimes W), \tag{2.52}$$

denoted by

$$(g,h) \to g \odot h, \tag{2.53}$$

as follows. If $m<0$ or $n<0$, this map is equal to zero. Now assume that $m,n \geqslant 0$, and let $g \in C^m(L,V)$ and $h \in C^n(L,W)$ be homogeneous of degrees γ and η, respectively. If $m=n=0$, we set

$$g \odot h = g \otimes h; \tag{2.54}$$

if $m=0$, $n>0$, we set

$$(g \odot h)(A_1, \ldots, A_n) = g \otimes h(A_1, \ldots, A_n), \tag{2.55}$$

for all $A_1, \ldots, A_n \in L$; if $m>0$, $n=0$, we set

$$(g \odot h)(A_1, \ldots, A_m) = \varepsilon(\eta, \alpha_1 + \cdots + \alpha_m) g(A_1, \ldots, A_m) \otimes h, \tag{2.56}$$

for all homogeneous elements $A_1, \ldots, A_m \in L$. Finally, suppose that $m,n \geqslant 1$. In that case, we define the $(m+n)$-linear map $g \overline{\otimes} h$ (the graded tensor product of g and h) by

$$\begin{aligned}(g \overline{\otimes} h)&(A_1, \ldots, A_m, A_{m+1}, \ldots, A_{m+n}) \\ &= \varepsilon(\eta, \alpha_1 + \cdots + \alpha_m) g(A_1, \ldots, A_m) \otimes h(A_{m+1}, \ldots, A_{m+n}),\end{aligned} \tag{2.57}$$

for all homogeneous elements $A_1, \ldots, A_{m+n} \in L$ and set

$$g \odot h = \frac{1}{m!n!} \sum_{\pi \in \mathcal{S}_{m+n}} \operatorname{sgn}(\pi) \check{S}_\pi (g \overline{\otimes} h), \tag{2.58}$$

where $\check{S}_\pi$ has been defined in Eq. (2.6).

Remark 2.3: If $m,n\geqslant 1$, let $\mathcal{S}(m,n)$ be the set of all permutations $\pi\in\mathcal{S}_{m+n}$ such that π is increasing on $\{1,2,\ldots,m\}$ and on $\{m+1,m+2,\ldots,m+n\}$ (the appropriate set of shuffle permutations). Then Eq. (2.58) can also be written in the form

$$g\odot h=\sum_{\pi\in\mathcal{S}(m,n)}\operatorname{sgn}(\pi)\check{S}_\pi(g\overline{\otimes}h). \tag{2.59}$$

Obviously, in all cases $g\odot h$ is an element of $C^{m+n}(L,V\otimes W)$. Moreover, it follows from the general theory of graded L-modules[20] that the bilinear map (2.52) is homogeneous of degree zero and L-invariant, i.e., that

$$A\cdot(g\odot h)=(A\cdot g)\odot h+\varepsilon(\alpha,\gamma)g\odot(A\cdot h), \tag{2.60}$$

for all homogeneous elements $A\in L$, $g\in C^m(L,V)$, and $h\in C^n(L,W)$.

The product is also compatible with the other operations introduced above. In fact, using (2.59) it is not difficult to show that for all integers m,n and all elements $A\in L_\alpha$, $g\in C^m(L,V)$, and $h\in C^n(L,W)_\eta$,

$$(g\odot h)_A=\varepsilon(\eta,\alpha)g_A\odot h+(-1)^m g\odot h_A. \tag{2.61}$$

Using this relation and induction on $m+n$ it is easy to rederive Eq. (2.60) and then, again by induction on $m+n$, to obtain the following generalized Leibniz rule:

$$\delta^{m+n}(g\odot h)=(\delta^m g)\odot h+(-1)^m g\odot(\delta^n h), \tag{2.62}$$

which holds for all integers m,n and all $g\in C^m(L,V)$ and $h\in C^n(L,W)$. An immediate consequence of this equation is that the product maps (2.52) induce analogous ones for the cohomology groups:

$$H^m(L,V)\times H^n(L,W)\to H^{m+n}(L,V\otimes W). \tag{2.63}$$

As a final result about the product $\odot$ we notice that it is associative in the obvious sense: If U is a third graded L-module, we have for all integers ℓ,m,n,

$$f\odot(g\odot h)=(f\odot g)\odot h, \tag{2.64}$$

where $f\in C^\ell(L,U)$, $g\in C^m(L,V)$, and $h\in C^n(L,W)$ [of course, it is understood that $U\otimes(V\otimes W)$ and $(U\otimes V)\otimes W$ are canonically identified]. The proof can be carried out by induction on $\ell+m+n$.

In the foregoing discussion, the product of two cocycles $g\in C^m(L,V)$ and $h\in C^n(L,W)$ takes its values in $V\otimes W$. This is the generic case, to which the other possibilities can be reduced. If U is a third graded L-module and if

$$b:V\times W\to U \tag{2.65}$$

is a homogeneous L-invariant bilinear map, we can use the corresponding linear map,

$$\tilde{b}:V\otimes W\to U, \tag{2.66}$$

to construct the maps,

$$\tilde{b}_c^n:C^n(L,V\otimes W)\to C^n(L,U), \tag{2.67}$$

which, when composed with the product maps (2.52), yield the maps

$$C^m(L,V)\times C^n(L,W)\to C^{m+n}(L,U). \tag{2.68}$$

Of course, these have properties analogous to those of $\odot$, in particular, they induce bilinear maps,

$$H^m(L,V)\times H^n(L,W)\to H^{m+n}(L,U), \tag{2.69}$$

which are homogeneous of the same degree as b.

We close this section by showing that for certain coefficient modules V the cohomology groups $H^n(L,V)$ must vanish. Let $U(L)$ be the enveloping algebra of L and let $U_+(L)$ denote the ideal of $U(L)$ which is generated by L. We say that an element X of $U(L)$ (and, by abuse of language, also the representative X_V of X in an L-module V) *does not contain a constant term*, in case $X\in U_+(L)$.

Proposition 2.2: Let L be a finite-dimensional ε Lie algebra, let V be a graded L-module, and let C be a homogeneous element of the ε center of $U(L)$ (i.e., a homogeneous Casimir element of L). Suppose that C does not contain a constant term, and that the operator C_V (the representative of C in V) is invertible. Then we have

$$H^n(L,V)=\{0\}, \quad \text{if } n\neq 0. \tag{2.70}$$

Proof: Let $(E_i)_{i\in I}$ be a basis of L, with E_i homogeneous of degree ϵ_i. We define for all $A\in L$ and $j\in I$,

$$\langle A,E_j\rangle=\sum_{i\in I}\mathrm{ad}_{ij}(A)E_i, \tag{2.71}$$

i.e., $A\to(\mathrm{ad}_{ij}(A))$ is the adjoint representation, written in matrix form.

Let L^* be the coadjoint L-module, i.e., the graded dual of L endowed with the representation contragredient to the adjoint one, and let $(E_i')_{i\in I}$ be the basis of L^* dual to $(E_i)_{i\in I}$, defined by

$$E_i'(E_j)=\delta_{ij}, \quad \text{for all } i,j\in I. \tag{2.72}$$

Then E_i' is homogeneous of degree $-\epsilon_i$.

Now consider an L-invariant r-linear form ϕ on L^* which is homogeneous of degree η. Then

$$C(\phi)=\sum_{i_1,\ldots,i_r\in I}\phi(E_{i_1}',\ldots,E_{i_r}')E_{i_r}\ldots E_{i_1} \tag{2.73}$$

is a Casimir element of L [i.e., an element of the ε center of $U(L)$] which is homogeneous of degree η (see Ref. 26). We define the following elements $C_i(\phi)$; $i\in I$, of $U(L)$:

$$C_i(\phi)=\sum_{i_2,\ldots,i_r\in I}\phi(E_i',E_{i_2}',\ldots,E_{i_r}')E_{i_r}\ldots E_{i_2}. \tag{2.74}$$

Obviously, we have

$$C(\phi)=\sum_{i\in I}C_i(\phi)E_i; \tag{2.75}$$

moreover, $C_i(\phi)$ is homogeneous of degree $\eta-\epsilon_i$, and the L-invariance of ϕ implies that

$$\langle A,C_i(\phi)\rangle=-\sum_{j\in I}\varepsilon(\alpha,\eta-\epsilon_j)\mathrm{ad}_{ij}(A)C_j(\phi), \tag{2.76}$$

for all homogeneous elements $A\in L$ and all $i\in I$.

Now let C be the Casimir element described in the proposition, and suppose that C is homogeneous of degree η. Then it is known[26] that C can be written as a sum of Casimir elements of the form $C(\phi)$ considered above. Consequently, there exist elements $C_i\in U(L)$; $i\in I$, which are homogeneous of degree $\eta-\epsilon_i$ and satisfy

$$C=\sum_{i\in I}C_iE_i, \tag{2.77}$$

as well as

$$\langle A, C_i \rangle = -\sum_{j \in I} \varepsilon(\alpha, \eta - \epsilon_j) \mathrm{ad}_{ij}(A) C_j , \tag{2.78}$$

for all homogeneous elements $A \in L$ and all $i \in I$.

After these preparations the proof of the proposition is easy. For any integer $n \geqslant 1$ we define a linear map,

$$d_n : C^n(L,V) \to C^{n-1}(L,V) \tag{2.79}$$

by

$$(d_n(g))(A_2, \ldots, A_n) = \sum_{i \in I} \varepsilon(\epsilon_i, \gamma) C_i \cdot g(E_i, A_2, \ldots, A_n), \tag{2.80}$$

for all homogeneous elements $g \in C^n(L,V)$ and all $A_2, \ldots, A_n \in L$ (with the obvious interpretation if $n=1$). Then one can check that

$$d_{n+1} \circ \delta^n + \delta^{n-1} \circ d_n = (C_V)^n_c , \tag{2.81}$$

where C_V is the representative of C in V (see the analogous but simpler calculation in the proof of Proposition VII.5.6 in Ref. 27). Of course, C_V is homogeneous of degree η and L-invariant. Thus if $g \in C^n(L,V)$ is a cocycle, the Eqs. (2.81) and (2.41) imply that

$$g = \delta^{n-1}((C_V^{-1})^{n-1}_c d_n(g)); \tag{2.82}$$

hence g is a coboundary and the proposition is proved.

The case $n=0$ (not covered by the proposition) can easily be dealt with: Since $B^0(L,V) = \{0\}$, we have

$$H^0(L,V) = Z^0(L,V) = \{x \in V | A \cdot x = 0, \text{ for all } A \in L\}, \tag{2.83}$$

i.e., $H^0(L,V)$ is the space of all L-invariant elements of V.

Remark 2.4: The definitions and constructions of the present section (but not the two propositions) can be generalized by choosing, for the basic domain of scalars, instead of the field $\mathbb{K}$ an arbitrary associative ε-commutative graded algebra S over $\mathbb{K}$. This follows immediately from the multilinear algebra over S as sketched in the appendix of Ref. 28. A generalization of this type could be useful if one considers the deformations of a superalgebra over a Grassmann algebra, and the deformation parameter is allowed to be odd. (The algebra L may also act on S by ε-derivations; for the super case, see Ref. 6.)

III. EXAMPLES

A. Semi-simple Lie algebras

In our first example we consider a (finite-dimensional) semi-simple Lie algebra L and a finite-dimensional L-module V, and we want to describe the cohomology groups $H^n(L,V)$. Needless to say, this case is well-known; we consider it here in order to show how our propositions can be applied under the most favorable circumstances.

The main input is that all finite-dimensional L-modules are semi-simple (i.e., the corresponding representations are completely reducible). Because of the isomorphism (2.49) we may, therefore, assume that the L-module V is simple (of course, in practice it may be difficult to decompose an L-module into simple submodules). If V is nontrivial, it is well-known that there exists a quadratic Casimir element C of L such that $C_V \neq 0$. Since V is simple, it follows that C_V is invertible. Thus Proposition 2.2 implies that $H^n(L,V) = \{0\}$ if $n \neq 0$, and the same is true for $n = 0$ since 0 is the sole L-invariant element of V.

Thus we may now assume that V is the trivial L-module $\mathbb{K}$ and that $n \geqslant 0$. According to (a) of Proposition 2.1 every cohomology class contains an L-invariant element. Conversely, it follows

from Eq. (2.24) that every L-invariant cochain (with values in $\mathbb{K}$) is a cocycle. Moreover, if g and g' are cohomologous elements of $Z^n(L,\mathbb{K})$ and if g and g' are L-invariant, then (b) of Proposition 2.1 tells us that $g-g'=\delta^{n-1}b$ with an L-invariant cochain $b\in C^{n-1}(L,\mathbb{K})$. As we just have seen, this implies that $\delta^{n-1}b=0$, i.e., that $g=g'$.

Summarizing, we have proved that $H^n(L,\mathbb{K})$ *with* $n\geqslant 1$ *can be identified with the space of all* L*-invariant skew symmetric* n*-linear forms on* L.

The cohomology groups $H^n(L,\mathbb{K})$ with $n\in\{0,1,2\}$ can easily be determined. Obviously, we have

$$H^0(L,\mathbb{K})=\mathbb{K} \tag{3.1}$$

[see Eq. (2.83)]. Let us next recall that the commutator algebra $[L,L]$ of L is equal to L. In view of Eq. (2.22), this implies that $Z^1(L,\mathbb{K})=\{0\}$ and hence

$$H^1(L,\mathbb{K})=\{0\}. \tag{3.2}$$

Moreover, it also follows from $[L,L]=L$ that every L-invariant bilinear form on L is symmetric. This shows that

$$H^2(L,\mathbb{K})=\{0\}. \tag{3.3}$$

On the other hand, it is easy to see that

$$H^3(L,\mathbb{K})\neq\{0\}. \tag{3.4}$$

In fact, if ϕ is the Killing form of L, the assignment

$$(A,B,C)\to\phi([A,B],C) \tag{3.5}$$

(with $A,B,C\in L$) defines a nonzero, L-invariant, skew symmetric, trilinear form on L.

B. The Lie superalgebras $osp(1|2n)$

For (finite-dimensional) simple Lie superalgebras the situation is much more complicated, even for the basic classical ones. However, there is one particular class of algebras (already mentioned by Kac in Sec. 5.5.3 of Ref. 7), namely, the $osp(1|2n)$ algebras, for which the discussion of the preceding example goes through almost verbatim. All we have to do is to interpret it in the super sense and to recall the bijection (2.47). The pertinent information on the $osp(1|2n)$ algebras is contained in Ref. 29. As already mentioned, the cohomology groups $H^n(L,\mathbb{K})$ of the nonexceptional classical simple Lie superalgebras have been described in Ref. 9 (see also Chap. 2, § 6 of Ref. 10 and Ref. 14; in particular, the exceptional algebras are considered in the latter article).

C. Trivial coefficients

Let us return to the general assumptions (where L is an arbitrary ε Lie algebra), and let us consider the case where $V=\mathbb{K}$ is the trivial graded L-module. As noted in Example A, Eq. (2.24) implies that every L-invariant cochain is a cocycle. We would like to mention a classical construction of such cocycles (which, in the case of simple Lie algebras, essentially does the whole job; see Ref. 30 for more details).

Let $m\geqslant 0$ be an integer and let $\phi\in \mathrm{Lgr}_{m+1}(L,\mathbb{K})$ be an L-invariant $(m+1)$-linear form. We want to construct an L-invariant cochain out of ϕ. An obvious ansatz is to consider the ε-skew-symmetrization of the $2(m+1)$-linear form on L defined by

$$(A_0,A_1,\ldots,A_{2m+1})\to\phi(\langle A_0,A_1\rangle,\langle A_2,A_3\rangle,\ldots,\langle A_{2m},A_{2m+1}\rangle), \tag{3.6}$$

for all $A_i\in L$. However, the L-invariance of ϕ and the ε Jacobi identity imply, that the ε-skew-symmetrization of the form (3.6) is equal to zero. The well-known way out is to consider for $m\geqslant 1$ the ε-skew-symmetrization of the $(2m+1)$-linear form $\psi\in \mathrm{Lgr}_{2m+1}(L,\mathbb{K})$ defined by

$$\psi(A_0,A_1,\ldots,A_{2m})=\phi(\langle A_0,A_1\rangle,\langle A_2,A_3\rangle,\ldots,\langle A_{2m-2},A_{2m-1}\rangle,A_{2m}), \tag{3.7}$$

for all $A_i\in L$.

The situation simplifies a little if ϕ is ε-symmetric (and L-invariant). In that case it is sufficient to ε-skew-symmetrize ψ in $A_1,A_2,\ldots,A_{2m-1}$, i.e., already the $(2m+1)$-linear form on L defined by

$$(A_0,A_1,\ldots,A_{2m})\to\sum_{\pi\in\mathcal{S}_{2m-1}}\operatorname{sgn}(\pi)\varepsilon_{2m-1}(\pi;\alpha_1,\ldots,\alpha_{2m-1}) \tag{3.8}$$

$$\phi(\langle A_0,A_{\pi(1)}\rangle,\langle A_{\pi(2)},A_{\pi(3)}\rangle,\ldots,\langle A_{\pi(2m-2)},A_{\pi(2m-1)}\rangle,A_{2m})$$

(for homogeneous elements $A_i\in L$) is ε-skew-symmetric and, of course, L-invariant. Note that the trilinear form (3.5) is the simplest example of the foregoing construction.

The possibility to obtain L-invariant cochains from L-invariant ε-symmetric multilinear forms is welcome and interesting, since the latter forms make their appearance in quite a different context. In fact, if L is finite-dimensional and admits a nondegenerate L-invariant bilinear form which is homogeneous of degree zero, then there is a close relationship between the Casimir elements of L and the ε-symmetric L-invariant multilinear forms on L. For more details, we refer the reader to Ref. 26. However, we note that we do not know of any reason to hope that the situation might be as nice as for semi-simple Lie algebras.

D. Simple $gl(m|n)$-modules for which all Casimir operators are equal to zero

In this example we assume that the field $\mathbb{K}$ is *algebraically closed.* We want to determine all those finite-dimensional simple graded $gl(m|n)$-modules, for which all Casimir operators without a constant term are equal to zero. According to Proposition 2.2, among the finite-dimensional simple graded modules, only these might have a nontrivial cohomology. In view of the detailed knowledge of the Casimir elements of $gl(m|n)$ and of their eigenvalues in a highest weight module[31,26,32,33] (see also Refs. 34–36), it is not difficult to solve this problem.

We are going to use the notation and results of the cited references. To begin with, let us recall some of them. Let m and n be any strictly positive integers. The Lie superalgebra $gl(m|n)$ is defined through its elementary representation in $\mathbb{K}^{m+n}$. If $(e_i)_{1\leqslant i\leqslant m+n}$ is the canonical basis of $\mathbb{K}^{m+n}$, we define the gradation of $\mathbb{K}^{m+n}$ by demanding that the elements $e_1,\ldots,e_m$ are even and the elements $e_{m+1},\ldots,e_{m+n}$ are odd. Correspondingly, we define

$$\sigma_i=\begin{cases}1, & \text{if } 1\leqslant i\leqslant m,\\ -1, & \text{if } m+1\leqslant i\leqslant m+n.\end{cases} \tag{3.9}$$

In Ref. 33 certain generators X_{ij} of the Lie superalgebra under consideration have been introduced. For $gl(m|n)$, these are just the usual basic $(m+n)\times(m+n)$ matrices E_{ij}; $1\leqslant i,j\leqslant m+n$.

Now let $s\geqslant 1$ be an integer and let C_s be the element of the universal enveloping algebra $U(gl(m|n))$ defined by

$$C_s=\sum_{i_1,\ldots,i_s}\sigma_{i_1}\sigma_{i_2}\ldots\sigma_{i_{s-1}}X_{i_s i_1}X_{i_1 i_2}\ldots X_{i_{s-1}i_s}\,. \tag{3.10}$$

Then C_s is a Casimir element of $gl(m|n)$, and (as shown in Ref. 32) the supercenter $Z(gl(m|n))$ of $U(gl(m|n))$ is generated (as an algebra) by the unit element and these elements C_s. Stated differently, every Casimir element can be written as a polynomial in the C_s; $s\geqslant 1$. [By the way, none of the C_s may be dropped. In particular, the algebra $Z(gl(m|n))$ is not finitely generated.]

The elements X_{ii}; $1\leqslant i\leqslant m+n$ span the standard Cartan subalgebra H of $gl(m|n)$. Let ε_i; $1\leqslant i\leqslant m+n$ be the linear form on H which satisfies

$$\varepsilon_i(X_{jj})=\delta_{ij}\,, \tag{3.11}$$

for $1 \leqslant j \leqslant m+n$. We choose the usual system of positive roots of $gl(m|n)$ with respect to H, namely,

$$\Delta^+ = \{\varepsilon_i - \varepsilon_j | 1 \leqslant i < j \leqslant m+n\}. \tag{3.12}$$

Now let $\Lambda \in H^*$ be any linear form on H and let V be a graded highest weight $gl(m|n)$-module with highest weight Λ. If $C \in Z(gl(m|n))$ is any Casimir element, the corresponding Casimir operator C_V is a scalar multiple of id_V,

$$C_V = \chi_\Lambda(C) id_V, \tag{3.13}$$

where χ_Λ is the so-called central character associated to Λ. To solve our problem, we need the eigenvalues $\chi_\Lambda(C)$. According to the foregoing remarks, it is sufficient to know the $\chi_\Lambda(C_s)$; $s \geqslant 1$. These have been investigated in Ref. 33. To describe the pertinent result, we introduce some more notations.

Let 2ρ be the sum of the even positive roots minus the sum of the odd positive roots, i.e.,

$$\rho = \frac{1}{2} \sum_{i<j} \sigma_i \sigma_j (\varepsilon_i - \varepsilon_j). \tag{3.14}$$

We set

$$\lambda = \Lambda + \rho, \tag{3.15}$$

and define the numbers r_i and ℓ_i through

$$r_i = \sigma_i \rho(X_{ii}), \tag{3.16}$$

$$\ell_i = \sigma_i \lambda(X_{ii}). \tag{3.17}$$

If $C \in Z(gl(m|n))$ is fixed, we have

$$\chi_\Lambda(C) = P_C(\ell_1, \ldots, \ell_{m+n}), \tag{3.18}$$

where P_C is a polynomial in $m+n$ indeterminates $Y_1, \ldots, Y_{m+n}$. If C runs through all of $Z(gl(m|n))$, the polynomials P_C form an algebra $T(m|n)$ (the algebra of supersymmetric polynomials in super dimension $(m|n)$;[31] for a recent reference see Ref. 37), and the map of $Z(gl(m|n))$ onto $T(m|n)$ defined by $C \to P_C$ is an algebra isomorphism (the generalized Harish–Chandra isomorphism[26]). Finally, the algebra $T(m|n)$ is generated by the unit element and the polynomials

$$Q_s = \sum_{i=1}^{m+n} \sigma_i (Y_i^s - r_i^s), \tag{3.19}$$

with $s \geqslant 1$ [see the end of Sec. 2 in Ref. 33, in particular, the lines below Eq. (2.36) and Eq. (2.37)]. Note that the constant term of a Casimir element C is equal to $\chi_0(C)$. Consequently, this term is equal to zero if and only if P_C can be written as a polynomial in the Q_s without a constant term.

Next we recall that every finite-dimensional simple graded $gl(m|n)$-module is a highest weight module (this is the sole place where we use that the base field is algebraically closed). Summarizing, we conclude that our problem can be reformulated as follows.

Determine all linear forms $\Lambda \in H^*$ which correspond to finite-dimensional simple graded $gl(m|n)$-modules and satisfy

$$Q_s(\ell_1, \ldots, \ell_{m+n}) = 0, \tag{3.20}$$

for all $s \geqslant 1$.

Let us set

$$L_i=\Lambda(X_{ii}), \tag{3.21}$$

for $1\leqslant i\leqslant m+n$. [Note that in contrast to Eqs. (3.16), (3.17) we have not included a factor of σ_i on the right hand side.] Then the first condition is satisfied if and only if

$$L_i-L_{i+1}\in\mathbb{N}, \tag{3.22}$$

for $1\leqslant i\leqslant m-1$ and for $m+1\leqslant i\leqslant m+n-1$.

The validity of the relations (3.20) is easily seen to be equivalent to the following condition.

Up to the ordering, the numbers,

$$\ell_1,\ell_2,\ldots,\ell_m,r_{m+1},r_{m+2},\ldots,r_{m+n}, \tag{3.23}$$

coincide with the numbers

$$r_1,r_2,\ldots,r_m,\ell_{m+1},\ell_{m+2},\ldots,\ell_{m+n}. \tag{3.24}$$

The subsequent discussion depends on whether $m=n$, $m>n$, or $m<n$. Using Eq. (3.22) and some special properties of the numbers r_i, we first conclude that the conditions (3.20) are satisfied if and only if the following holds true.

If $m=n$, we have

$$\ell_{m+i}=\ell_{m+1-i}, \quad \text{for } 1\leqslant i\leqslant m; \tag{3.25}$$

if $m>n$, there exists a number $k\in\{0,1,\ldots,n\}$ such that

$$\ell_{m+i}=\ell_{m+1-i}, \quad \text{for } 1\leqslant i\leqslant k, \tag{3.26}$$

$$r_{j-n}=\ell_{j-k}, \quad \text{for } n+1\leqslant j\leqslant m, \tag{3.27}$$

$$\ell_{m+i}=\ell_{n+1-i}, \quad \text{for } k+1\leqslant i\leqslant n; \tag{3.28}$$

and if $m<n$, there exists a number $h\in\{0,1,\ldots,m\}$ such that

$$\ell_{m+i}=\ell_{m+1-i}, \quad \text{for } 1\leqslant i\leqslant h, \tag{3.29}$$

$$\ell_{h+j}=r_{m+j}, \quad \text{for } m+1\leqslant j\leqslant n, \tag{3.30}$$

$$\ell_{n+i}=\ell_{m+1-i}, \quad \text{for } h+1\leqslant i\leqslant m. \tag{3.31}$$

Expressed in terms of the coefficients L_i, our final result reads as follows.

Suppose first that $m=n$. Choose the numbers $L_1,L_2,\ldots,L_m$ in accordance with Eq. (3.22) and define

$$L_{m+i}=-L_{m+1-i}, \quad \text{for } 1\leqslant i\leqslant m. \tag{3.32}$$

Suppose next that $m>n$. Let k be any element of $\{0,1,\ldots,n\}$. Choose the numbers $L_1,L_2,\ldots,L_m$ in accordance with Eq. (3.22) and such that

$$L_{n+1-k}=L_{n+2-k}=\cdots=L_{m-k}=n-k. \tag{3.33}$$

Define

$$L_{m+i}=-L_{m+1-i}, \quad \text{for } 1\leqslant i\leqslant k, \tag{3.34}$$

$$L_{m+i}=-L_{n+1-i}-(m-n), \quad \text{for } k+1\leqslant i\leqslant n \tag{3.35}$$

(for $k=0$, resp., $k=n$, the first, resp., second of these equations should be dropped).

Finally, suppose that $m<n$. Let h be any element of $\{0,1,\ldots,m\}$. Choose the numbers $L_{m+1},L_{m+2},\ldots,L_{m+n}$ in accordance with Eq. (3.22) and such that

$$L_{m+1+h}=L_{m+2+h}=\cdots=L_{n+h}=-(m-h). \tag{3.36}$$

Define

$$L_i=-L_{m+n+1-i}+(n-m), \quad \text{for } 1\leqslant i\leqslant m-h, \tag{3.37}$$

$$L_i=-L_{2m+1-i}, \quad \text{for } m-h+1\leqslant i\leqslant m \tag{3.38}$$

(for $h=m$, resp., $h=0$, the first, resp., second of these equations should be dropped).

Then, in all three cases, our conditions are satisfied. Conversely, every solution to our conditions is of this form.

We note that the relation (3.20) with $s=1$ is equivalent to

$$\sum_{i=1}^{m+n} L_i=0, \tag{3.39}$$

and it is easily checked that the numbers L_i specified above satisfy this condition.

Remark 3.1: Needless to say the modules we have found are atypical.[35] Actually, Eqs. (3.25) – (3.31) show that they are maximally atypical in the sense that Λ satisfies the maximal number [equal to min(m,n)] of atypicality conditions.

The foregoing results can immediately be extended to the special linear Lie superalgebras $sl(m|n)$, provided that $m\neq n$. In fact, all we have to do is interpret them appropriately, as explained in Ref. 33. The elements X_{ij} are now given by

$$X_{ij}=E_{ij}-\frac{1}{d}\sigma_i\delta_{ij}I, \tag{3.40}$$

where we have set $d=m-n$, and where I is the unit matrix. Furthermore, the linear forms ε_i are given by

$$\varepsilon_i(X_{jj})=\delta_{ij}-\frac{1}{d}\sigma_j. \tag{3.41}$$

This implies that

$$\sum_{i=1}^{m+n} X_{ii}=0 \tag{3.42}$$

and

$$\sum_{i=1}^{m+n} \sigma_i\varepsilon_i=0. \tag{3.43}$$

Apart from these modifications, everything goes through, and the highest weights of the modules we are looking for are given by the same formulas as above. [We have already noted that the relation (3.39), which should be satisfied because of Eq. (3.42), indeed holds true.]

IV. CENTRAL EXTENSIONS OF ε LIE ALGEBRAS

We start with the basic definitions. Let L be an ε Lie algebra. A *central extension* of L by an ε Lie algebra H is an exact sequence of ε Lie algebras,

$$\{0\}\rightarrow H\overset{\iota}{\rightarrow}E\overset{\pi}{\rightarrow}L\rightarrow\{0\}, \tag{4.1}$$

such that $\iota(H)$ is in the ε center of E. Thus ι and π are homomorphisms of ε Lie algebras (which implies that they are homogeneous of degree zero), ι is injective, π is surjective, and the kernel of π is equal to the image of ι. In particular, H is Abelian. Thus H is nothing but a graded vector space, endowed with the trivial structure of an ε Lie algebra. If

$$\{0\}\to H'\overset{\iota'}{\to}E'\overset{\pi'}{\to}L\to\{0\} \tag{4.2}$$

is a second central extension of L, then by a *morphism* from the central extension (4.1) to the central extension (4.2), we mean a pair (φ,ψ) of ε Lie algebra homomorphisms,

$$\varphi:E\to E',\quad \psi:H\to H', \tag{4.3}$$

such that

$$\pi=\pi'\circ\varphi,\quad \varphi\circ\iota=\iota'\circ\psi, \tag{4.4}$$

i.e., such that the corresponding diagram is commutative. (Obviously, ψ is uniquely determined by φ.) The morphism (φ,ψ) is said to be an *isomorphism* of the central extensions if φ and ψ are bijective. Actually, if one of the maps φ and ψ is bijective, then so is the other.

Consider next the case where the second central extension has the form

$$\{0\}\to H\overset{\iota'}{\to}E'\overset{\pi'}{\to}L\to\{0\}. \tag{4.5}$$

Then the extensions (4.1) and (4.5) are said to be *equivalent* if there exists a morphism (φ,ψ) from the extension (4.1) to the extension (4.5) such that $\psi=id_H$ (which implies that φ is bijective).

As in the Lie algebra case, the central extensions of L by H can be classified by means of the cohomology groups $H^2(L,H)$, where H is regarded as a graded vector space, endowed with the trivial L-module structure. To show this, we choose a homogeneous *section* σ (in the category of vector spaces) of π, i.e., a homogeneous linear map,

$$\sigma:L\to E \tag{4.6}$$

(necessarily of degree zero) such that

$$\pi\circ\sigma=id_L. \tag{4.7}$$

Then we have

$$\pi(\langle\sigma(A),\sigma(B)\rangle-\sigma(\langle A,B\rangle))=0, \tag{4.8}$$

for all $A,B\in L$. Consequently, there exists a unique map,

$$g:L\times L\to H, \tag{4.9}$$

such that

$$\iota(g(A,B))=\langle\sigma(A),\sigma(B)\rangle-\sigma(\langle A,B\rangle), \tag{4.10}$$

for all $A,B\in L$, and it is easy to see that g is a homogeneous 2-cocycle of degree zero, i.e., $g\in Z^2(L,H)_0$.

Consider in addition the central extension (4.5), choose a homogeneous section σ' of π', and construct the corresponding 2-cocycle g'. Then the central extensions (4.1) and (4.5) are equivalent if and only if g and g' are cohomologous.

Conversely, let g be any element of $Z^2(L,H)_0$. Make the graded vector space $L\times H$ into an ε Lie algebra by defining

$$\langle(A,X),(B,Y)\rangle=(\langle A,B\rangle,g(A,B)), \tag{4.11}$$

for all $A,B\in L$ and all $X,Y\in H$. This ε Lie algebra will be denoted by $L(g)$. Let

$$\sigma:L\to L\times H,\quad \iota:H\to L\times H \tag{4.12}$$

be the canonical injections and let

$$\pi:L\times H\to L \tag{4.13}$$

be the canonical projection. Then

$$\{0\}\to H\overset{\iota}{\to}L(g)\overset{\pi}{\to}L\to\{0\} \tag{4.14}$$

is a central extension of L by H, σ is a homogeneous section of π, and the corresponding 2-cocycle of L with values in H is just the 2-cocycle g we started with.

Summarizing, we conclude that there is a bijection between the set of equivalence classes of central extensions of L by H and $H^2(L,H)_0$, the homogeneous component of degree zero of the cohomology group $H^2(L,H)$. [More generally, an analogous result holds for all those extensions (4.1) of L for which H is only assumed to be Abelian; for more details, see Ref. 5.]

In the Lie algebra case, all this is well-known, and it is not at all surprising that this material can be generalized to the present graded setting. We have included these results in order to fix our notation and as a preparation for the investigations to follow. In fact, we now are ready to generalize Garland's theory of universal central extensions of Lie algebras.[21] As we are going to see, most of Garland's statements and proofs can be adopted almost verbatim. In addition, we comment on the *homological* background of these results, and we show how universal central extensions can be constructed.

Let us agree to call an ε Lie algebra L *perfect* if it is equal to its own commutator algebra, i.e., if $\langle L,L\rangle=L$. Using this notion, we call the central extension (4.1) a *covering* of L if E is perfect. In this case, we also call E or π or the pair (E,π) a covering of L, and we shall say that E [or π or (E,π)] covers L. Obviously, if an ε Lie algebra admits a covering, then it is perfect.

Lemma 4.1: If the central extension (4.1) is a covering of L, then there exists at most one morphism from (4.1) to any second central extension of L.

Proof: Let (φ,ψ) and (φ',ψ') be two morphisms from the central extension (4.1) to the central extension (4.2). Obviously, we have

$$(\varphi-\varphi')(\langle A,B\rangle)=\langle\varphi(A)-\varphi'(A),\varphi(B)\rangle+\langle\varphi'(A),\varphi(B)-\varphi'(B)\rangle, \tag{4.15}$$

for all $A,B\in E$. On the other hand, we have

$$\pi'(\varphi(A)-\varphi'(A))=\pi(A)-\pi(A)=0, \tag{4.16}$$

and hence

$$\varphi(A)-\varphi'(A)\in\iota'(H'), \tag{4.17}$$

for all $A\in E$. Consequently, the right hand side of Eq. (4.15) vanishes, which implies that $\varphi=\varphi'$, and hence also $\psi=\psi'$.

Definition 4.1: We say that a covering of an ε Lie algebra L is universal, *if for every central extension of L there is a unique morphism (in the sense of central extensions) from the covering to the central extension.*

We note that the uniqueness requirement in Definition 4.1 automatically follows from Lemma 4.1. Obviously, the definition and Lemma 4.1 imply the following proposition.

Proposition 4.2: Any two universal coverings of an ε Lie algebra L are isomorphic as central extensions, and the two mutually inverse isomorphisms are unique.

We have already noted that if an ε Lie algebra admits a covering, then it is perfect. Conversely, we have the following.

Proposition 4.3: If the ε Lie algebra L is perfect, then L has a universal covering.

Proof: Let $\wedge_\varepsilon L$ be the ε exterior algebra of the graded vector space L (see Appendix A for more information), let $\wedge_\varepsilon$ denote the multiplication in $\wedge_\varepsilon L$, and let $W'=\wedge_\varepsilon^2 L$ be the subspace of $\wedge_\varepsilon L$ of $\mathbb{Z}$-degree 2. Consider the subspace I of W' which is generated by all elements of the form

$$-\langle A,B\rangle\wedge_\varepsilon C+\varepsilon(\beta,\gamma)\langle A,C\rangle\wedge_\varepsilon B+A\wedge_\varepsilon\langle B,C\rangle, \tag{4.18}$$

with homogeneous elements $A,B,C\in L$. Obviously, I is a graded subspace of W'. We set $W=W'/I$ and denote the canonical image of $A\wedge_\varepsilon B$ in W by $f(A,B)$, for all $A,B\in L$. By definition,

$$f:L\times L\to W \tag{4.19}$$

is a 2-cocycle which is homogeneous of degree zero. Thus we have the central extension

$$\{0\}\to W\xrightarrow{\bar{\iota}}L(f)\xrightarrow{\bar{\pi}}L\to\{0\}. \tag{4.20}$$

Consider an arbitrary central extension of L by an Abelian ε Lie algebra H. We know that this extension is equivalent to the extension (4.14) with a suitable 2-cocycle $g\in Z^2(L,H)_0$. Since g is a 2-cocycle, there exists a unique linear map

$$\psi':W\to H, \tag{4.21}$$

such that

$$\psi'(f(A,B))=g(A,B), \tag{4.22}$$

for all $A,B\in L$, and ψ' is homogeneous of degree zero. We define a map

$$\varphi':L(f)=L\times W\to L\times H=L(g) \tag{4.23}$$

by

$$\varphi'(A,X)=(A,\psi'(X)), \tag{4.24}$$

for all $A\in L$ and $X\in W$. Then (φ',ψ') is a morphism from the central extension (4.20) to the central extension (4.14).

Now let $\hat{L}=\langle L(f),L(f)\rangle$ be the commutator algebra of $L(f)$. Since L is perfect, we have $\hat{L}+W=L(f)$ and hence

$$\bar{\pi}(\hat{L})=L, \tag{4.25}$$

$$\hat{L}=\langle\hat{L}+W,\hat{L}+W\rangle=\langle\hat{L},\hat{L}\rangle. \tag{4.26}$$

Thus $\hat{L}$ is perfect. If $\hat{H}$ is the preimage of $\hat{L}$ under $\bar{\iota}$, the central extension (4.20) induces a central extension,

$$\{0\}\to\hat{H}\xrightarrow{\hat{\iota}}\hat{L}\xrightarrow{\hat{\pi}}L\to\{0\}, \tag{4.27}$$

which is a covering of L. Furthermore, if φ is the restriction of φ' to $\hat{L}$ and if ψ is the restriction of ψ' to $\hat{H}$, the pair (φ,ψ) is a morphism from the central extension (4.27) to the central extension (4.14). This shows that (4.27) is a universal covering of L, and thus the proposition is proved.

In the present work we do not consider the homology of ε Lie algebras (it is fairly obvious how this should be introduced). Nevertheless, it would be rather unsatisfactory not to mention the homological interpretation of the preceding proof.

Consider the linear map,

$$\partial_2 : \overset{2}{\wedge}_\varepsilon L \to L, \tag{4.28}$$

given by

$$\partial_2(A \wedge_\varepsilon B) = -\langle A, B\rangle, \tag{4.29}$$

and the linear map,

$$\partial_3 : \overset{3}{\wedge}_\varepsilon L \to \overset{2}{\wedge}_\varepsilon L, \tag{4.30}$$

specified by

$$\partial_3(A \wedge_\varepsilon B \wedge_\varepsilon C) = -\langle A, B\rangle \wedge_\varepsilon C + \varepsilon(\beta, \gamma)\langle A, C\rangle \wedge_\varepsilon B + A \wedge_\varepsilon \langle B, C\rangle, \tag{4.31}$$

for all homogeneous elements $A, B, C \in L$. The ε Jacobi identity is equivalent to

$$\partial_2 \circ \partial_3 = 0. \tag{4.32}$$

Let $Z_2(L)$ be the kernel of ∂_2 and let $B_2(L)$ be the image of ∂_3. Then Eq. (4.32) implies that $B_2(L) \subset Z_2(L)$, and a closer look at the definition of $\hat{H}$ in the proof of Proposition 4.3 shows that

$$\hat{H} = Z_2(L)/B_2(L) = H_2(L) \tag{4.33}$$

(where the last equation is a definition). By definition, $C^n(L, \mathbb{K})$ is the graded dual of $\wedge_\varepsilon^n L$ [see the remark below Eq. (2.9)], and the coboundary map,

$$\delta^n : C^n(L, \mathbb{K}) \to C^{n+1}(L, \mathbb{K}), \tag{4.34}$$

is the graded transpose of the boundary map,

$$\partial_{n+1} : \overset{n+1}{\wedge}_\varepsilon L \to \overset{n}{\wedge}_\varepsilon L \tag{4.35}$$

(we are considering the cases $n = 1,2$ only, but, in fact, this is true for all n). Consequently, the graded dual $\hat{H}^{*\mathrm{gr}}$ of $\hat{H}$ is canonically isomorphic to $H^2(L, \mathbb{K})$.

More explicitly, the canonical isomorphism $\phi : H^2(L, \mathbb{K}) \to \hat{H}^{*\mathrm{gr}}$ can be described as follows. Let $g \in Z^2(L, \mathbb{K})_\gamma$ be a cocycle which is homogeneous of degree γ. We have to give the image of the cohomology class $g + B^2(L, \mathbb{K})$ in $\hat{H}^{*\mathrm{gr}}$. The cocycle g can be regarded as an element $g_0 \in Z^2(L, \mathbb{K}^\gamma)_0$ [recall Eq. (2.44)]. Let

$$\{0\} \to \mathbb{K}^\gamma \to E \to L \to \{0\} \tag{4.36}$$

be a central extension of L which belongs to the equivalence class corresponding to $g_0 + B^2(L, \mathbb{K}^\gamma)$, and let (φ_g, ψ_g) be the morphism from the universal covering (4.27) to (4.36). Then ψ_g can be regarded as a linear form $\hat{H} \to \mathbb{K}$ which is homogeneous of degree γ. This form depends only on the cohomology class $g + B^2(L, \mathbb{K})$ and is the image we are looking for.

The inverse of the isomorphism ϕ can be described even more simply. Let $\hat{g} \in Z^2(L, \hat{H})_0$ be a cocycle such that the cohomology class $\hat{g} + B^2(L, \hat{H})$ corresponds to the equivalence class of the universal covering (4.27). If λ is any element of $\hat{H}^{*\mathrm{gr}}$, then $\lambda \circ \hat{g}$ is an element of $Z^2(L, \mathbb{K})$ and we have

$$\phi^{-1}(\lambda) = \lambda \circ \hat{g} + B^2(L, \mathbb{K}). \tag{4.37}$$

If L is a perfect ε Lie algebra for which $H^2(L,\mathbb{K})$ is finite-dimensional (of dimension s, say), the preceding discussion leads to the following construction of a universal covering of L. Let $(g_r)_{1\leqslant r\leqslant s}$ be a family of homogeneous 2-cochains $g_r\in Z^2(L,\mathbb{K})$, such that the cohomology classes $g_r+B^2(L,\mathbb{K})$ form a basis of $H^2(L,\mathbb{K})$, and let γ_r denote the degree of g_r. Choose a graded vector space H such that H has a homogeneous basis $(e_r)_{1\leqslant r\leqslant s}$, with e_r homogeneous of degree $-\gamma_r$. Define the bilinear map,

$$g:L\times L\to H, \tag{4.38}$$

by

$$g(A,B)=\sum_{r=1}^{s} g_r(A,B)e_r, \tag{4.39}$$

for all $A,B\in L$. Then $g\in Z^2(L,H)_0$, and the corresponding central extension (4.14) is a universal covering of L.

Remark 4.1: Let

$$\{0\}\to\hat{H}\overset{\hat{\iota}}{\to}\hat{L}\overset{\hat{\pi}}{\to}L\to\{0\} \tag{4.40}$$

be a universal covering of the ε Lie algebra L. Then $\hat{L}$ is a universal covering of every ε Lie algebra E which covers L. In fact, if

$$\{0\}\to H\to E\to L\to\{0\} \tag{4.41}$$

is a covering of L and if (φ,ψ) is a morphism from (4.40) to (4.41), then it is easy to see that

$$\{0\}\to\ker(\varphi)\to\hat{L}\overset{\varphi}{\to}E\to\{0\} \tag{4.42}$$

is a covering of E. One can then show directly that this covering is universal, but the simplest way to prove this is to invoke Theorem 4.1.

Remark 4.2: The universal coverings have a property which, apparently, is more general than the one required in their definition. Let

$$\{0\}\to H\overset{\iota}{\to}E\overset{\pi}{\to}L\to\{0\} \tag{4.43}$$

be a universal covering of an ε Lie algebra L and let

$$\{0\}\to H'\overset{\iota'}{\to}E'\overset{\pi'}{\to}L'\to\{0\} \tag{4.44}$$

be a central extension of an ε Lie algebra L'. If $\varrho:L\to L'$ is a homomorphism (of ε Lie algebras), there exists a unique pair (φ,ψ) of homomorphisms,

$$\varphi:E\to E',\quad \psi:H\to H', \tag{4.45}$$

such that

$$\varrho\circ\pi=\pi'\circ\varphi,\quad \varphi\circ\iota=\iota'\circ\psi, \tag{4.46}$$

i.e., such that the corresponding diagram is commutative.

Remark 4.3: One might think to generalize the definition of a universal covering to all (not necessarily perfect) ε Lie algebras, as follows: A central extension (4.1) of an ε Lie algebra L is said to be universal if, for any central extension (4.2) of L, there exists a unique morphism from (4.1) to (4.2). Actually, it can be shown that if (4.1) is universal in this sense, then L and E are perfect, and nothing beyond the universal coverings has been obtained.

Definition 4.2: (a) An ε Lie algebra L is said to be simply connected, *if for every central extension*

$$\{0\}\to H\overset{\iota}{\to}E\overset{\pi}{\to}L\to\{0\} \tag{4.47}$$

of L, there is a unique homomorphism of ε Lie algebras $\sigma:L\to E$, such that $\pi\circ\sigma=id_L$.

(b) A covering,

$$\{0\}\to H\to E\to L\to\{0\}, \tag{4.48}$$

of an ε Lie algebra L is said to be simply connected, in case E is simply connected.

Every simply connected ε Lie algebra L is perfect. In fact, choose $H=L/\langle L,L\rangle$ and consider the trivial central extension,

$$\{0\}\to H\to L\times H\to L\to\{0\} \tag{4.49}$$

of L, where $H\to L\times H$ is the canonical injection and $L\times H\to L$ is the canonical projection. Of course, the canonical injection $L\to L\times H$ is a homomorphism σ of the type described in (a) of Definition 4.2. But if $\varphi:L\to L/\langle L,L\rangle$ is the canonical homomorphism, the map

$$\sigma':L\to L\times H \tag{4.50}$$

defined by

$$\sigma'(A)=(A,\varphi(A)), \tag{4.51}$$

for all $A\in L$ is likewise. Consequently, the uniqueness of σ implies our claim.

Theorem 4.1: *A covering of an ε Lie algebra L is universal if and only if it is simply connected.*

Proof: Let

$$\{0\}\to\hat{H}\overset{\hat{\iota}}{\to}\hat{L}\overset{\hat{\pi}}{\to}L\to\{0\} \tag{4.52}$$

be a simply connected covering of L. We have to show that there exists a (necessarily unique) morphism from this covering to an arbitrary central extension (4.1) of L.

Define

$$E'=\{(A,B)\in E\times\hat{L}\,|\,\pi(A)=\hat{\pi}(B)\}. \tag{4.53}$$

Obviously, E' is a graded subalgebra of the ε Lie algebra $E\times\hat{L}$. Let $\varrho:E'\to\hat{L}$ be the projection onto the second factor of $E\times\hat{L}$. Then ϱ is a surjective homomorphism of ε Lie algebras, and the kernel of ϱ is equal to

$$\ker(\varrho)=\{(\iota(X),0)\,|\,X\in H\}, \tag{4.54}$$

which is contained in the center of E'. Since $\hat{L}$ is simply connected, there exists a unique homomorphism of ε Lie algebras $\sigma:\hat{L}\to E'$, such that $\varrho\circ\sigma=id_{\hat{L}}$. Let $\lambda:\hat{L}\to E$ denote the composition of σ with the projection of E' onto the first factor of $E\times\hat{L}$. The definitions imply that

$$\sigma(B)=(\lambda(B),B)\in E', \tag{4.55}$$

for all $B\in\hat{L}$ and hence (by definition of E') that $\pi\circ\lambda=\hat{\pi}$. In particular, we have $\pi\circ\lambda\circ\hat{\iota}=0$, which shows that

$$(\lambda\circ\hat{\iota})(\hat{H})\subset\iota(H). \tag{4.56}$$

Consequently, there exists a unique homomorphism of ε Lie algebras $\mu:\hat{H}\to H$ such that $\lambda\circ\hat{\iota}=\iota\circ\mu$. Then (λ,μ) is a morphism from the covering (4.52) to the central extension (4.1).

Conversely, let us assume that (4.52) is a universal covering of L. Consider a central extension,

$$\{0\}\to H\overset{\iota}{\to}E\overset{\pi}{\to}\hat{L}\to\{0\}. \tag{4.57}$$

We have to show that there exists a unique homomorphism of ε Lie algebras $\sigma:\hat{L}\to E$ such that $\pi\circ\sigma=id_{\hat{L}}$.

If σ exists, the pair $(\sigma,0)$ is a morphism from the covering

$$\{0\}\to\{0\}\to\hat{L}\overset{id}{\to}\hat{L}\to\{0\} \tag{4.58}$$

to the central extension (4.57). Since $\hat{L}$ is perfect, Lemma 4.1 implies that σ is uniquely determined. Hence it remains to prove that σ exists.

Let $\tilde{E}=\langle E,E\rangle$ be the commutator algebra of E. Since $\hat{L}$ is perfect, we have $\pi(\tilde{E})=\hat{L}$ and hence $E=\tilde{E}+\iota(H)$. This in turn implies that

$$\tilde{E}=\langle\tilde{E}+\iota(H),\tilde{E}+\iota(H)\rangle=\langle\tilde{E},\tilde{E}\rangle, \tag{4.59}$$

i.e., that $\tilde{E}$ is perfect. Let $\tilde{H}$ be the preimage of $\tilde{E}$ under ι. Then the central extension (4.57) induces a central extension,

$$\{0\}\to\tilde{H}\to\tilde{E}\to\hat{L}\to\{0\}, \tag{4.60}$$

and the homomorphism σ exists, if the analogous homomorphism exists for (4.60). Thus we may assume that E is perfect.

Let $\nu:E\to L$ be the (surjective) homomorphism of ε Lie algebras defined by $\nu=\hat{\pi}\circ\pi$. We are going to show that the kernel of ν is contained in the center of E. Thus suppose that A is a homogeneous element of E such that $\hat{\pi}(\pi(A))=0$. Then $\pi(A)$ is central in $\hat{L}$. Consequently, we have

$$\pi(\langle A,B\rangle)=\langle\pi(A),\pi(B)\rangle=0, \tag{4.61}$$

for all $B\in E$, i.e., $\langle A,B\rangle$ belongs to the kernel of π and hence to the center of E. If B and B' are any two homogeneous elements of E, this implies that

$$\langle A,\langle B,B'\rangle\rangle=\langle\langle A,B\rangle,B'\rangle+\varepsilon(\alpha,\beta)\langle B,\langle A,B'\rangle\rangle=0, \tag{4.62}$$

and since E is perfect it follows that A lies in the center of E.

Thus

$$\{0\}\to\ker(\nu)\to E\overset{\nu}{\to}L\to\{0\} \tag{4.63}$$

is a central extension. Since we are assuming that (4.52) is a universal covering, there exists a morphism (φ,ψ) from (4.52) to (4.63). We are going to show that φ is the homomorphism σ we are looking for. To do so we have to show that $\pi\circ\varphi=id_{\hat{L}}$. Let $\omega:\hat{L}\to\hat{L}$ be the linear map defined by $\omega=\pi\circ\varphi-id_{\hat{L}}$. Since (φ,ψ) is a morphism of central extensions, we have

$$\hat{\pi}\circ\omega=\hat{\pi}\circ(\pi\circ\varphi)-\hat{\pi}=\nu\circ\varphi-\hat{\pi}=0, \tag{4.64}$$

and hence ω takes its values in the center of $\hat{L}$. This implies that

$$\omega(\langle A,B\rangle)=\langle\omega(A),(\pi\circ\varphi)(B)\rangle+\langle A,\omega(B)\rangle=0, \tag{4.65}$$

for all $A,B\in\hat{L}$. Since $\hat{L}$ is perfect, it follows that $\omega=0$ and the theorem is proved.

Example: The universal covering of $sl(n|n)/\mathbb{K}\cdot I_{2n}$. For abbreviation, we write L instead of $sl(n|n)/\mathbb{K}\cdot I_{2n}$ (here and in the following, I_{2n} denotes the $2n\times 2n$ unit matrix). It is well-known[8] that L inherits from $gl(n|n)$ a consistent $\mathbb{Z}$-gradation such that

$$L=L_{-1}\oplus L_0\oplus L_1. \tag{4.66}$$

To begin with, we note that

$$\{0\}\to\mathbb{K}\overset{\iota}{\to}sl(n|n)\overset{\pi}{\to}L\to\{0\} \tag{4.67}$$

is a central extension of L, where ι is defined by

$$\iota(c)=\frac{c}{2n}I_{2n}, \tag{4.68}$$

for all $c\in\mathbb{K}$, and where π is the canonical homomorphism. Obviously, there exists a unique linear map,

$$\sigma:L\to sl(n|n), \tag{4.69}$$

such that

$$\sigma(\pi(A))=A-\frac{1}{2n}\,\mathrm{Tr}(A)I_{2n}, \tag{4.70}$$

for all $A\in sl(n|n)$, and we have $\pi\circ\sigma=id_L$. It follows that the 2-cocycle $g\in Z^2(L,\mathbb{K})$ defined by Eq. (4.10) is given by

$$g(\pi(A),\pi(B))=\mathrm{Tr}(\langle A,B\rangle), \tag{4.71}$$

for all $A,B\in sl(n|n)$. Obviously, g is L_0-invariant (but, of course, not L-invariant).

If $n=1$, the Lie superalgebra L is Abelian and hence the theory of universal coverings does not apply (see Remark 4.3). Thus from now on we shall assume that $n\geqslant 2$. Then L is simple and hence perfect. Our main task is to determine $H^2(L,\mathbb{K})$. Since $L_0\simeq sl(n)\times sl(n)$ is semi-simple, Proposition 2.1 implies that every cohomology class contains an L_0-invariant cocycle. On the other hand, there does not exist a nonzero L_0-invariant linear form on L, i.e., $C^1(L,\mathbb{K})$ does not contain a nontrivial L_0-invariant element. Consequently, Proposition 2.1 shows that $H^2(L,\mathbb{K})$ can be identified with the space of all L_0-invariant 2-cochains. Thus we are going to determine this space.

For $n\geqslant 3$, this is easy. Let us first recall that every L_0-invariant bilinear form on L_0 is symmetric. Using this fact, a short look at the representations of L_0 carried by L_0 and $L_{\pm 1}$ shows that there exists, up to the normalization, a unique nonzero super-skew-symmetric L_0-invariant bilinear form on L. As we already know, g has these properties, moreover, g is a 2-cocycle. Thus we conclude, for $n\geqslant 3$, that $H^2(L,\mathbb{K})$ is one-dimensional and that (4.67) is a universal covering of $L=sl(n|n)/\mathbb{K}\cdot I_{2n}$.

Due to the peculiarities of the algebra $sl(2|2)/\mathbb{K}\cdot I_4$, the case $n=2$ is more interesting. In principle, we could proceed in this case as above. However, we prefer to use a different realization of $sl(2|2)/\mathbb{K}\cdot I_4$ which makes the special properties of this algebra manifest (and which has already been used in the description of the super derivations of this algebra[8]).

Let V be a two-dimensional vector space, let ψ be a nondegenerate skew-symmetric bilinear form on V, and let $sp(\psi)$ [equal to $sl(V)$] be the Lie algebra of all linear maps of V into itself leaving the form ψ invariant. Define the bilinear map,

$$P:V\times V\to sp(\psi), \tag{4.72}$$

by

$$P(x,y)z=\psi(x,z)y+\psi(y,z)x, \tag{4.73}$$

for all $x,y,z\in V$. We set

$$L_{\bar{0}}=sp(\psi)\times sp(\psi),\quad L_{\bar{1}}=V\otimes V\otimes V, \tag{4.74}$$

and regard L_1^- as an L_0^--module, where the first (resp., second) factor of L_0^- acts in the natural way on the first (resp., second) tensorial factor of L_1^-. For any $Q \in sp(\psi)$, let Q_1 and Q_2 be the elements of L_0^- defined by

$$Q_1=(Q,0), \quad Q_2=(0,Q). \tag{4.75}$$

Using these data, the $\mathbb{Z}_2$-graded vector space,

$$L=L_0^- \oplus L_1^-, \tag{4.76}$$

becomes a Lie superalgebra, if the bracket of two elements of L_1^- is chosen such that

$$\langle x\otimes y\otimes z, x'\otimes y'\otimes z'\rangle = cP_1(x,x')\psi(y,y')\psi(z,z') - c\psi(x,x')P_2(y,y')\psi(z,z'), \tag{4.77}$$

for all $x,y,\ldots,z' \in V$, where $c \in \mathbb{K}$ is an arbitrary nonzero constant.

This Lie superalgebra is isomorphic to $sl(2|2)/\mathbb{K}\cdot I_4$. More precisely, one can easily show the following.

Let (v_+, v_-) be any basis of V. If we define

$$L_0=L_0^-, \quad L_{\pm 1}=V\otimes V\otimes \mathbb{K}v_\pm, \tag{4.78}$$

then

$$L=L_{-1}\oplus L_0\oplus L_1 \tag{4.79}$$

is a consistent $\mathbb{Z}$-gradation of L, and L and $sl(2|2)/\mathbb{K}\cdot I_4$ are isomorphic as $\mathbb{Z}$-graded Lie superalgebras.

The arbitrariness in the choice of $v_\pm$ reflects the peculiarity of $sl(2|2)/\mathbb{K}\cdot I_4$ we have been alluding to: This algebra admits a large group of outer automorphisms. In fact, let s be an arbitrary element of the group $Sp(\psi)$ [equal to $SL(V)$] and let $\tilde{s}$ be the linear map of L into itself, which induces the identity map on L_0^-, and on L_1^- is given by

$$\tilde{s}(x\otimes y\otimes z)=x\otimes y\otimes s(z), \tag{4.80}$$

for all $x,y,z \in V$. Then $\tilde{s}$ is an automorphism of the Lie superalgebra L.

It is easy to determine the L_0^--invariant super-skew-symmetric bilinear forms on L. Let g be such a form. For the same reasons as above, $g(A,B)$ has to vanish if at least one of the two homogeneous elements $A,B \in L$ is even. On the other hand, the restriction of g to $L_1^- \times L_1^-$ is given by

$$g(x\otimes y\otimes z, x'\otimes y'\otimes z') = \psi(x,x')\psi(y,y')\varphi(z,z'), \tag{4.81}$$

for all $x,y,\ldots,z' \in V$, where φ is an arbitrary symmetric bilinear form on V. Conversely, it is not difficult to check that every bilinear form g with these properties is, in fact, an L_0^--invariant 2-cocycle.

Obviously, the map assigning to any symmetric bilinear form φ on V the L_0^--invariant 2-cocycle specified above is a vector space isomorphism of the spaces under consideration. Consequently, we have

$$\dim H^2(sl(2|2)/\mathbb{K}\cdot I_4, \mathbb{K}) = 3. \tag{4.82}$$

The universal covering of L can now be constructed along the lines specified around Eq. (4.39). Actually, this is not really necessary, since this algebra is known: It is obtained if one sets out to construct the Serre presentation of $sl(2|2)$ and forgets about the so-called supplementary relations. More precisely, the universal covering of $sl(2|2)/\mathbb{K}\cdot I_4$ is the Lie superalgebra $s(2,2)$ considered in Ref. 38. In fact, there is a natural homomorphism of the Lie superalgebra $s(2,2)$ onto the Lie superalgebra $sl(2|2)/\mathbb{K}\cdot I_4$ whose kernel is equal to the three-dimensional center of $s(2,2)$; moreover, it is known that $s(2,2)$ is perfect. Since the universal covering of $sl(2|2)/\mathbb{K}\cdot I_4$ must cover $s(2,2)$ as well (see Remark 4.1), it follows that this universal covering must be

isomorphic to $s(2,2)$. Actually, it is not difficult to construct this isomorphism explicitly. According to Remark 4.1, $s(2,2)$ is also a universal covering of $sl(2|2)$. [Note that this is at variance with Theorem 2.6.1 of Ref. 10, but it is consistent with Ref. 9. On the other hand, in the latter reference, the definition of the two basic 2-cocycles of $sl(2|2)$ is not correct, and it is easy to see that, contrary to what is stated, we have $H^3(L,\mathbb{K})\neq\{0\}$ for both $L=sl(2|2)$ and $L=sl(2|2)/\mathbb{K}\cdot I_4$. We think that these discrepancies and mistakes are due to some trivial slips or misprints.]

V. COHOMOLOGY OF THE LIE SUPERALGEBRA $sl(1|2)$

Throughout the present section we shall assume that the base field $\mathbb{K}$ is *algebraically closed.* Let $U(sl(1|2))$ denote the enveloping algebra of $sl(1|2)$. Our main goal is to show that

$$H^2(sl(1|2),U(sl(1|2)))=\{0\}. \tag{5.1}$$

In order to prove this, we shall first determine $H^1(sl(1|2),V)$ and $H^2(sl(1|2),V)$, for all finite-dimensional simple graded $sl(1|2)$-modules V. Actually, we only need to know those modules V for which these cohomology groups are nontrivial. As explained in the Introduction, this information could be extracted from Ref. 15, but we think it is worthwhile to present our own calculations.

As an abbreviation, we write L instead of $sl(1|2)$. We are going to use the notation and results of Ref. 39. Let us first recall some of the most relevant facts. The basis of L we are going to use consists of four even elements $Q_\pm$, Q_3, B, and four odd elements $V_\pm$ and $W_\pm$. The elements $Q_\pm$, Q_3 span an $sl(2)$ subalgebra of $L_{\bar 0}$; they are normalized such that

$$\langle Q_+,Q_-\rangle=2Q_3. \tag{5.2}$$

The one-dimensional subspace $\mathbb{K}\cdot B$ is the center of $L_{\bar 0}$, and the two-dimensional subspace,

$$H=\mathbb{K}\cdot B+\mathbb{K}\cdot Q_3, \tag{5.3}$$

is a Cartan subalgebra of L. Thus any linear form λ on H (in particular, any weight of an L-module) can and will be identified with the pair (b,q) of values which λ takes on B and Q_3, respectively. For example, $V_\pm$ and $W_\pm$ are root vectors corresponding to the roots $(\frac{1}{2},\pm\frac{1}{2})$ and $(-\frac{1}{2},\pm\frac{1}{2})$, respectively. They are normalized such that $(V_\pm)$ and $(W_\pm)$ are standard $sl(2)$-doublets and satisfy

$$\langle V_\pm,W_\pm\rangle=\pm Q_\pm, \tag{5.4}$$

$$\langle V_\pm,W_\mp\rangle=-Q_3\pm B. \tag{5.5}$$

The reader who prefers a matrix realization may set

$$Q_+=E_{23},\quad Q_-=E_{32},\quad Q_3=\tfrac{1}{2}(E_{22}-E_{33}),\quad B=-\tfrac{1}{2}(2E_{11}+E_{22}+E_{33}), \tag{5.6}$$

$$V_+=E_{21},\quad V_-=E_{31},\quad W_+=E_{13},\quad W_-=-E_{12}, \tag{5.7}$$

where the E_{ij} are the usual basic 3×3 matrices. [The elements are chosen such that the $\mathbb{Z}$-gradation of $sl(1|2)$ as specified in Ref. 8 and the $\mathbb{Z}$-gradation given by Eq. (5.11) coincide.]

For later use we note that the linear map,

$$\omega:L\to L, \tag{5.8}$$

defined by

$$\omega(Q_\pm)=Q_\pm,\quad \omega(Q_3)=Q_3,\quad \omega(B)=-B, \tag{5.9}$$

$$\omega(V_\pm)=W_\pm,\quad \omega(W_\pm)=V_\pm, \tag{5.10}$$

is an automorphism of the Lie superalgebra L.

The simple roots of L with respect to H are chosen such that V_+ and W_+ are the associated root vectors. Thus both of the simple roots are odd, i.e., we do not use a so-called distinguished basis of the root system. For $sl(1|2)$, this choice has certain advantages, for example, it is compatible with the automorphism ω.

For any weight (b,q); $b,q\in\mathbb{K}$, and any $\gamma\in\mathbb{Z}_2$, there exists (up to isomorphism) a unique simple graded highest weight L-module $V(b,q,\gamma)$ such that the highest weight vectors (which are proportional to each other) have weight (b,q) and $\mathbb{Z}_2$-degree γ. Of course, $V(b,q,\gamma)$ and $V(b,q,\gamma+\overline{1})$ can be transformed into each other by a shift of the $\mathbb{Z}_2$-gradation [see Eq. (2.44)]. The module $V(b,q,\gamma)$ is finite-dimensional if and only if $b=q=0$ or $q\in\frac{1}{2}\mathbb{N}_*$, and any finite-dimensional simple graded L-module is of this type. Moreover, it is atypical[35] if and only if $b=\pm q$, and its dimension is equal to $8q$ (resp., $4q+1$) in the typical (resp., atypical) case.

The Casimir elements of L are known, and the eigenvalues of the Casimir operators in a graded highest weight module have been calculated in terms of a generating function[26,32,33] (see also Example D of Sec. III). In particular, the image of the generalized Harish–Chandra isomorphism is known. It can be regarded as an algebra of polynomials in b,q and, as such, consists of all polynomials of the form $a+(b^2-q^2)P$, where $a\in\mathbb{K}$ is a constant and P is a polynomial in b and (b^2-q^2). This implies that, for a graded highest weight module with highest weight (b,q), all Casimir operators without a constant term are equal to zero, if and only if $b=\pm q$.

Next we recall that L has a consistent $\mathbb{Z}$-gradation, which is fixed by the requirement that the elements $Q_\pm$, Q_3, and B are homogeneous of degree 0, the elements $V_\pm$ are homogeneous of degree 1, and the elements $W_\pm$ are homogeneous of degree -1. Thus we can apply our general theory both in the $\mathbb{Z}_2$-graded and in the $\mathbb{Z}$-graded sense. Actually, this essentially amounts to a matter of formulation (at least in the present article). This is because, for all L-modules V for which a $\mathbb{Z}$-gradation will be of interest, this gradation is simply given by the action of B, as follows:

$$V_r=\{x\in V|2B\cdot x=rx\}, \tag{5.11}$$

for all $r\in\mathbb{Z}$. In particular, this is true for L itself and for the enveloping algebra $U(L)$ (both endowed with the adjoint action of L).

As a final preparatory remark we notice that there is a natural embedding of the Lie superalgebra $osp(1|2)$ into $sl(1|2)$. In fact, if we define

$$U_\pm=\tfrac{1}{2}(V_\pm+W_\pm), \tag{5.12}$$

the elements $Q_\pm$, Q_3, $U_\pm$ satisfy the commutation relations of $osp(1|2)$ as specified in Ref. 39. In particular, we have

$$\langle U_\pm,U_\pm\rangle=\pm\tfrac{1}{2}Q_\pm, \tag{5.13}$$

$$\langle U_\pm,U_\mp\rangle=-\tfrac{1}{2}Q_3. \tag{5.14}$$

The $\mathbb{Z}_2$-graded subalgebra of L spanned by these elements will be denoted by G; by construction, it is isomorphic to $osp(1|2)$.

We recall that the finite-dimensional graded G-modules are semi-simple. The finite-dimensional simple graded G-modules can be labeled by a pair (q,γ), with $q\in\frac{1}{2}\mathbb{N}$ and $\gamma\in\mathbb{Z}_2$: By definition, a highest weight vector v of the corresponding module is homogeneous of degree γ and satisfies $Q_3\cdot v=qv$. We denote this module (which is fixed up to isomorphism) by $U(q,\gamma)$; its dimension is equal to $4q+1$.

Of course, every graded L-module can also be regarded as a graded G-module. For example, choose $b\in\mathbb{K}$, $q\in\frac{1}{2}\mathbb{N}_*$, $\gamma\in\mathbb{Z}_2$, and regard $V(b,q,\gamma)$ as a G-module. If $b\neq\pm q$, this module decomposes into the direct sum of two simple graded G-modules, isomorphic to $U(q,\gamma)$ and $U(q-\frac{1}{2},\gamma+\overline{1})$, respectively. On the other hand, the G-module $V(\pm q,q,\gamma)$ is simple and isomorphic to $U(q,\gamma)$. (Obviously, the latter statement remains true for $q=0$.)

In particular, consider the adjoint L-module L. Regarded as a G-module, it decomposes into two G-submodules: One of them is G itself, the other is spanned by $X_\pm$ and B, with

$$X_{\pm}=\tfrac{1}{2}(V_{\pm}-W_{\pm}). \tag{5.15}$$

The elements $X_{\pm}$ have been chosen such that $X_{\pm}$ and B form a basis of $U(\frac{1}{2},\overline{1})$ as specified in Ref. 39. We remark that $Q_{\pm}$, Q_3, $iX_{\pm}$ also satisfy the commutation relations of $osp(1|2)$.

After these preliminaries we are ready to tackle our main problem: We want to determine the cohomology groups $H^1(L,V)$ and $H^2(L,V)$, with V a finite-dimensional simple graded L-module. In view of the preceding remarks, we deduce from Proposition 2.2 that $H^n(L,V)=\{0\}$ for all n if V is typical. Consequently, we only have to consider the cases where $V=V(\pm q,q,\gamma)$, with $q\in\frac{1}{2}\mathbb{N}$ and $\gamma\in\mathbb{Z}_2$. Actually, if ϱ is the representation afforded by $V(q,q,\gamma)$, then $\varrho\circ\omega$ is (equivalent to) the representation afforded by $V(-q,q,\gamma)$ [where the automorphism ω has been defined by Eqs. (5.8) – (5.10)]. Recalling the isomorphism (2.34) we may assume, therefore, that $V=V(q,q,\gamma)$. On the other hand, the bijection (2.47) shows that it is sufficient to consider only one of the two choices for γ. According to Eq. (5.11), we shall choose $\gamma=\overline{2q}$ (where $\overline{r}=r+2\mathbb{Z}\in\mathbb{Z}_2$ denotes the residue class of the integer r modulo 2), and assume that $V(q,q,\overline{2q})$ is endowed with the consistent $\mathbb{Z}$-gradation defined by Eq. (5.11). To simplify the notation, we write $V(q)$ instead of $V(q,q,\overline{2q})$. Then we have to determine the cohomology groups $H^n(L,V(q))$, with $n\in\{1,2\}$.

The case $n=1$ is simple. We present it in some detail to explain our approach. According to Proposition 2.1, any 1-cocycle of L with values in $V(q)$ is cohomologous to a G-invariant 1-cocycle. Regarded as graded G-modules, L is isomorphic to $U(1,\overline{0})\oplus U(\frac{1}{2},\overline{1})$, and $V(q)$ is isomorphic to $U(q,\overline{2q})$. But a nonzero G-invariant linear map of a G-module $U(p,\overline{2p})$ into a G-module $U(q,\overline{2q})$ (with $p,q\in\frac{1}{2}\mathbb{N}$) exists if and only if $p=q$, and such a map must be even. Consequently, a nonzero G-invariant linear map $g:L\to V(q)$ exists if and only if $q\in\{\frac{1}{2},1\}$. Moreover, if this condition is satisfied, a map of the type in question is even and uniquely determined up to a scalar factor.

On the other hand, let V be any graded L-module, and let $g:L\to V$ be a G-invariant 1-cocycle which is homogeneous of degree $\overline{0}$. Then the G-invariance and the cocycle condition imply that, for all homogeneous elements $X\in G$ and $Y\in L$,

$$X\cdot g(Y)=g(\langle X,Y\rangle)=X\cdot g(Y)-\varepsilon(\xi,\eta)Y\cdot g(X), \tag{5.16}$$

and hence that

$$Y\cdot g(X)=0. \tag{5.17}$$

In particular, we conclude that $g(\langle X,X'\rangle)=0$ for all $X,X'\in G$, which implies that

$$g(X)=0, \tag{5.18}$$

for all $X\in G$.

Thus all we have to do is to determine $H^1(L,V(\frac{1}{2}))$. To construct a nonzero G-module homomorphism of L into $V(\frac{1}{2})$ we introduce a suitable basis in $V(\frac{1}{2})$. According to Ref. 39 there exists a basis (e_+,e_0,e_-) of $V(\frac{1}{2})$ such that $e_{\pm}$ are odd and e_0 is even, such that $e_{\pm}$ and e_0 are weight vectors corresponding to the weights $(\frac{1}{2},\pm\frac{1}{2})$ and $(1,0)$, respectively, and such that

$$V_{\pm}\cdot e_{\pm}=0,\quad V_{\pm}\cdot e_{\mp}=\mp e_0 \tag{5.19}$$

$$W_{\pm}\cdot e_{\pm}=W_{\pm}\cdot e_{\mp}=0, \tag{5.20}$$

$$V_{\pm}\cdot e_0=0,\quad W_{\pm}\cdot e_0=-e_{\pm}. \tag{5.21}$$

(Obviously, this basis is uniquely fixed up to a nonzero overall factor.) The action of $Q_{\pm}$ on the basis vectors can be derived from the commutation relations and the formulas above; it is such that $(e_{\pm})$ is a standard $sl(2)$-doublet and e_0 an $sl(2)$-singlet. It follows that $e_{\pm}$ and e_0 also form a basis of the G-module $V(\frac{1}{2})\simeq U(\frac{1}{2},\overline{1})$ as described in Ref. 39. Consequently, the linear map,

$$g: L \to V(\tfrac{1}{2}), \tag{5.22}$$

defined by

$$g(X) = 0, \quad \text{if } X \in G, \tag{5.23}$$

$$g(B) = e_0, \tag{5.24}$$

$$g(V_\pm - W_\pm) = 2e_\pm, \tag{5.25}$$

is a homomorphism of graded G-modules. Since

$$g(V_\pm + W_\pm) = g(2U_\pm) = 0, \tag{5.26}$$

it follows that

$$g(V_\pm) = -g(W_\pm) = e_\pm. \tag{5.27}$$

It is now easy to check that g is a 1-cocycle. Moreover, since $V(\frac{1}{2})$ does not contain a nonzero G-invariant element, g is not a coboundary. Summarizing, we have shown that

$$H^1(L, V(q)) = \{0\}, \quad \text{if } q \neq \tfrac{1}{2}, \tag{5.28}$$

$$\dim H^1(L, V(\tfrac{1}{2})) = 1. \tag{5.29}$$

The fact that $V(\frac{1}{2})$ is (essentially) the sole finite-dimensional simple graded L-module V for which $H^1(L,V)$ is nontrivial has already been mentioned in the *Additional remarks* at the end of Ref. 7.

The cocycle g can be replaced by a simpler one. Let us regard L as a consistently $\mathbb{Z}$-graded Lie superalgebra and $V(\frac{1}{2})$ as a $\mathbb{Z}$-graded L-module [recall that the $\mathbb{Z}$-gradations are chosen according to Eq. (5.11)]. Then g can be decomposed into its $\mathbb{Z}$-homogeneous components,

$$g = g_0 + g_2, \tag{5.30}$$

where g_r, $r \in \{0,2\}$ is homogeneous of degree r. Explicitly, the nonvanishing values of g_0 and g_2 on the basis vectors $Q_\pm$, Q_3, B, $V_\pm$, $W_\pm$ are given by

$$g_0(V_\pm) = e_\pm, \tag{5.31}$$

$$g_2(B) = e_0, \quad g_2(W_\pm) = -e_\pm. \tag{5.32}$$

Both g_0 and g_2 are 1-cocycles. Hence exactly one of them is not a coboundary. Obviously, g_0 cannot be a coboundary, for $V(\frac{1}{2})$ does not contain a nonzero $\mathbb{Z}$-homogeneous element of degree 0. Consequently, g_2 must be a coboundary. In fact, we have

$$g_2(X) = X \cdot e_0, \tag{5.33}$$

for all $X \in L$.

The 1-cocycle g_0 can be used to construct higher order cocycles, as follows. Choose any integer $n \geqslant 1$. Using the product of cocycles defined in Eq. (2.58) and the associativity of this product [see Eq. (2.64)], we can construct the n-cocycle $g_0^{\odot n} = g_0 \odot \cdots \odot g_0$ (n factors g_0) with values in $V(\frac{1}{2})^{\otimes n}$, which is given by

$$g_0^{\odot n}(X_1, \ldots, X_n) = \sum_{\pi \in \mathcal{S}_n} \operatorname{sgn}(\pi) \varepsilon_n(\pi; \xi_1, \ldots, \xi_n) g_0(X_{\pi(1)}) \otimes \cdots \otimes g_0(X_{\pi(n)}), \tag{5.34}$$

for all homogeneous elements $X_i \in L$. Obviously, $g_0^{\odot n}$ is nonzero and takes its values in the graded L-submodule $W(n)$ of super-skew-symmetric tensors in $V(\frac{1}{2})^{\otimes n}$.

Let $f_n: L^n \to W(n)$ denote the n-cocycle defined by $g_0^{\odot n}$. Of course, f_n is $\mathbb{Z}$-homogeneous of degree zero. Since the degree of a nonzero $\mathbb{Z}$-homogeneous element of $W(n)$ is at least equal to n, there does not exist a nonzero $(n-1)$-linear map of L^{n-1} into $W(n)$, which is $\mathbb{Z}$-homogeneous of degree zero. Consequently, f_n is not a coboundary. On the other hand, it is easy to see that $W(n)$, even when regarded as a $\mathbb{Z}$-graded L-module, is isomorphic to $V(\frac{n}{2})$. Thus we have proved that

$$H^n(L, V(\tfrac{n}{2})) \neq \{0\}, \quad \text{for all } n \geqslant 1. \tag{5.35}$$

Remark 5.1: Our results show that Proposition 2.2 exactly describes the finite-dimensional simple graded L-modules with a nontrivial cohomology, and the same holds for the $osp(1|2n)$ algebras. It would be interesting to know whether this is also true for other simple Lie superalgebras.

Let us next determine the cohomology groups $H^2(L, V(q))$. Since we are going to proceed as for $H^1(L, V(q))$, it should suffice to give the main intermediate steps. For any graded L-module V, the graded L-module $C^2(L, V)$ is canonically isomorphic to $\mathrm{Lgr}(L \wedge_\varepsilon L, V)$ (see Appendix A). Thus we have to determine the structure of $L \wedge_\varepsilon L$. It is known that this module is isomorphic to the graded submodule of super-skew-symmetric tensors in $L \otimes L$. This submodule is semi-simple (whereas $L \otimes L$ is not), and its simple submodules can be determined, with the result that

$$L \wedge_\varepsilon L \simeq V(\tfrac{1}{2}, \tfrac{3}{2}, \overline{1}) \oplus V(-\tfrac{1}{2}, \tfrac{3}{2}, \overline{1}) \oplus V(0,1,\overline{0}). \tag{5.36}$$

This implies that, regarded as a graded G-module, $L \wedge_\varepsilon L$ is isomorphic to

$$2\, U(\tfrac{3}{2}, \overline{1}) \oplus 3\, U(1, \overline{0}) \oplus U(\tfrac{1}{2}, \overline{1}). \tag{5.37}$$

Recalling that the graded G-module $V(q)$ is isomorphic to $U(q, \overline{2q})$, we conclude as before that $H^2(L, V(q))$ is trivial unless $q \in \{\frac{1}{2}, 1, \frac{3}{2}\}$.

Let us consider the case $q = \frac{1}{2}$. Visibly, there exists, up to a scalar factor, a unique nonzero G-invariant linear map $\overline{f}$ of $L \wedge_\varepsilon L$ into $V(\frac{1}{2})$, and this map is even and vanishes on the submodule W isomorphic to

$$W \simeq V(\tfrac{1}{2}, \tfrac{3}{2}, \overline{1}) \oplus V(-\tfrac{1}{2}, \tfrac{3}{2}, \overline{1}). \tag{5.38}$$

Let $f \in C^2(L, V(\frac{1}{2}))$ be the associated bilinear map. We are going to show that f is not a cocycle. According to Proposition 2.1, this will imply that

$$H^2(L, V(\tfrac{1}{2})) = \{0\}. \tag{5.39}$$

In fact, the product map $\langle , \rangle$ of L induces an L-module homomorphism of $L \wedge_\varepsilon L$ onto L, whose kernel is equal to W. Consequently, there exists a unique homomorphism of graded G-modules,

$$g': L \to V(\tfrac{1}{2}), \tag{5.40}$$

such that

$$f(X, Y) = g'(\langle X, Y \rangle), \tag{5.41}$$

for all $X, Y \in L$. But we know that there exists, up to a scalar factor, a unique homomorphism of graded G-modules of L into $V(\frac{1}{2})$, namely, the map g defined by Eqs. (5.22) – (5.25). Thus, by multiplying f by a suitable scalar factor, we may assume that

$$f(X, Y) = g(\langle X, Y \rangle), \tag{5.42}$$

for all $X, Y \in L$. If f would be a 2-cocycle, its $\mathbb{Z}$-homogeneous components f_r, given by

$$f_r(X,Y)=g_r(\langle X,Y\rangle), \quad r\in\{0,2\}, \tag{5.43}$$

would be 2-cocycles as well. However, using Eq. (5.33), it is easy to see that f_2 is not a cocycle.

To proceed, we remark that the condition $q\in\{\frac{1}{2},1,\frac{3}{2}\}$ derived above can be improved by regarding $L\wedge_\varepsilon L$ and $V(q)$ as $L_{\bar 0}$-modules. The same type of argument as before then shows that $H^2(L,V(q))$ is trivial unless $q\in\{0,\frac{1}{2},1\}$; moreover, there exists, up to a scalar factor, a unique $L_{\bar 0}$-invariant linear map of $L\wedge_\varepsilon L$ into $V(1)$. Since (again by Proposition 2.1) any 2-cocycle on L with values in $V(1)$ is cohomologous to an $L_{\bar 0}$-invariant cocycle, we conclude from Eq. (5.35) that $H^2(L,V(1))$ is one-dimensional. Summarizing, we have shown that

$$H^2(L,V(q))=\{0\}, \quad \text{if } q\neq 1, \tag{5.44}$$

$$\dim H^2(L,V(1))=1. \tag{5.45}$$

As an application of the preceding result, let us now prove that $H^2(L,U(L))$ is trivial. The following lemma contains the pertinent information on the L-module $U(L)$.

Lemma 5.1: Any finite-dimensional atypical simple graded subquotient of the adjoint L-module $U(L)$ is isomorphic to one of the three graded L-modules $V(0,0,\overline{0})$ and $V(\pm\frac{1}{2},\frac{1}{2},\overline{1})$.

Proof: Consider two graded submodules $U'\subset U$ of $U(L)$ such that U/U' is a finite-dimensional atypical simple graded L-module. Then U/U' is isomorphic to one of the modules $V(\pm q,q,\gamma)$, with $q\in\mathbb{N}$ and $\gamma\in\mathbb{Z}_2$, and we have to show that $q\in\{0,\frac{1}{2}\}$ and $\gamma=\overline{2q}$.

Let ad denote the adjoint representation of L in $U(L)$. Then ad B is diagonalizable, and the sole eigenvalues of this operator are 0, $\pm\frac{1}{2}$, and ± 1. Since, for $q\geqslant\frac{1}{2}$, the module $V(\pm q,q,\gamma)$ contains nonzero weight vectors with weight $(\pm q\pm\frac{1}{2},q-\frac{1}{2})$, the cases $q\geqslant 1$ are not possible. On the other hand, an eigenvector of ad B is odd if and only if the corresponding eigenvalue is equal to $\pm\frac{1}{2}$, and it is even otherwise. This implies that $\gamma=\overline{2q}$ and proves the lemma.

Remark 5.2: As shown in Appendix B, the adjoint L-module $U(L)$ really has graded subquotients isomorphic to $V(0,0,\overline{0})$ and $V(\pm\frac{1}{2},\frac{1}{2},\overline{1})$.

Remark 5.3: A decomposition of the adjoint L-module $U(L)$ into indecomposable submodules has been constructed in a recent paper by Benamor.[40] (We are grateful to the referee for drawing our attention to this article.) This decomposition is rather complicated, thus we think it would not be adequate to invoke that reference to prove the simple lemma above.

It is now easy to see that $H^2(L,U(L))=\{0\}$. The image of any 2-cochain of L with values in $U(L)$ is contained in a finite-dimensional graded L-submodule of $U(L)$ [use the canonical filtration of $U(L)$]. Thus it is sufficient to show that $H^2(L,V)$ is trivial, for any finite-dimensional graded L-submodule V of $U(L)$. To prove this we choose an increasing sequence of graded L-submodules of $U(L)$,

$$\{0\}=V_0\subset V_1\subset V_2\subset\cdots\subset V_n=V, \tag{5.46}$$

such that V_r/V_{r-1} is a simple graded L-module, for $1\leqslant r\leqslant n$. [Up to the opposite ordering, (5.46) is a Jordan–Hölder sequence of the graded L-module V.] We show by induction on r that

$$H^2(L,V_r)=\{0\}. \tag{5.47}$$

The case $r=0$ is trivial. Now suppose that Eq. (5.47) is true for some $r\in\{0,1,\ldots,n-1\}$. We have a short exact sequence of graded L-modules:

$$\{0\}\to V_r\to V_{r+1}\to V_{r+1}/V_r\to\{0\}. \tag{5.48}$$

Consider the following part of the exact cohomology sequence (2.51) associated to (5.48):

$$\cdots\to H^2(L,V_r)\to H^2(L,V_{r+1})\to H^2(L,V_{r+1}/V_r)\to\cdots\ . \tag{5.49}$$

By assumption, $H^2(L,V_r)$ is trivial, and Lemma 5.1, combined with Eq. (5.44), shows that $H^2(L,V_{r+1}/V_r)$ is trivial as well. Thus, $H^2(L,V_{r+1})$ must be trivial.

Summarizing, we have shown that

$$H^2(L,U(L))=\{0\}, \tag{5.50}$$

i.e., we have proved Eq. (5.1). On the other hand, we shall see in Appendix B that

$$H^1(L,U(L))\neq\{0\}, \tag{5.51}$$

in contrast to what is known for semi-simple Lie algebras.

VI. DISCUSSION

In the present work we have taken some exploratory steps towards a better understanding of the cohomology of Lie superalgebras and their generalizations. It is hardly surprising that the basic definitions and formal techniques known from the cohomology of Lie algebras can immediately be generalized to the general graded setting. In particular, this applies to Garland's theory of universal central extensions of Lie algebras. The picture changes if we try to actually calculate the cohomology groups of Lie superalgebras, especially, when the coefficients are nontrivial. Our main tools in this project were two simple propositions proved in Sec. II.

As for many questions from the theory of Lie superalgebras, the $osp(1|2n)$ algebras behave very much like simple Lie algebras. On the other hand, already for $sl(1|2)$ the situation changes drastically. For any integer $n\geqslant 0$, there exists a finite-dimensional simple graded $sl(1|2)$-module V such that $H^n(sl(1|2),V)$ is nontrivial. Moreover, in Appendix B we are going to show that

$$H^1(sl(1|2),U(sl(1|2)))\neq\{0\}. \tag{6.1}$$

Thus it is remarkable that, nevertheless,

$$H^2(sl(1|2),U(sl(1|2)))=\{0\}. \tag{6.2}$$

Actually, one of the main reasons for our present investigation was to try to prove the analogous result for as many simple Lie superalgebras L as possible, from which it follows that the associative superalgebra $U(L)$ does not admit any nontrivial formal deformations in the sense of Gerstenhaber.[18] To see this, all we have to do is to transcribe the corresponding discussion of Ref. 19 to the present setting. Then Eq. (5.50) implies that the Hochschild 2-cohomology (in the super sense) of the associative superalgebra $U(L)$ with values in $U(L)$ [considered as a graded $U(L)$-bimodule] vanishes. In this connection, we recall that there is an isomorphism relating the cohomology of a Lie algebra L with values in $U(L)$ to the Hochschild cohomology of the associative algebra $U(L)$ (see Theorem 5.1 of chapter XIII in Ref. 4). It would be interesting to know whether an analogous isomorphism exists in the general graded setting.

The methods used in our investigation are completely elementary, and already for the 3-cohomology of $sl(1|2)$ the calculations become quite extensive. On the other hand, in the meantime we have shown that $H^2(L,U(L))=\{0\}$ for $L=sl(m|1)$, $m\geqslant 3$, but up to now we were not able to prove or disprove this for $L=sl(3|2)$. Thus it might turn out that some more profound techniques must be used both in the study of higher order cohomology groups and in the case of more complicated Lie superalgebras.

ACKNOWLEDGMENTS

We should like to thank C. Gruson for sending us a copy of the galley proofs of her article[14] and for drawing our attention to Ref. 15. The present work was initiated during a visit of the first-named author to the Department of Pure Mathematics of the University of Adelaide. The kind invitation by the second-named author and the hospitality extended to the first-named author, both in the Mathematics and in the Physics Department, are gratefully acknowledged.

APPENDIX A: THE ε-EXTERIOR ALGEBRA OF A GRADED L-MODULE

We use the notation introduced at the beginning of Sec. II. Let V be a graded L-module and let

$$T(V)=\bigoplus_{n\in\mathbb{Z}} T_n(V) \tag{A1}$$

be the tensor algebra of V.[20] It is known that $T(V)$ is a $\mathbb{Z}\times\Gamma$-graded associative algebra with a unit element and that

$$T_n(V)=\{0\}, \quad \text{if } n\leqslant -1, \tag{A2}$$

$$T_0(V)=\mathbb{K}, \tag{A3}$$

$$T_n(V)=\underbrace{V\otimes\cdots\otimes V}_{n \text{ factors}}, \quad \text{if } n\geqslant 1. \tag{A4}$$

Moreover, $T(V)$ is a graded L-module, and L acts on $T(V)$ by ε-derivations. Note also that each $T_n(V)$ is a graded L-submodule of $T(V)$.

Now let $J(V,\varepsilon)$ denote the two-sided ideal of $T(V)$, generated by the elements of the form

$$x\otimes y+\varepsilon(\xi,\eta)y\otimes x, \tag{A5}$$

where x and y are homogeneous elements of V. Then the quotient algebra,

$$\wedge_\varepsilon V=T(V)/J(V,\varepsilon), \tag{A6}$$

is called the *ε-exterior (or ε-Grassmann) algebra* of V. The multiplication in $\wedge_\varepsilon V$ will be denoted by $\wedge_\varepsilon$.

Since $J(V,\varepsilon)$ is a $\mathbb{Z}\times\Gamma$-graded ideal, the algebra $\wedge_\varepsilon V$ inherits from $T(V)$ a canonical $\mathbb{Z}\times\Gamma$-gradation. In particular, we have

$$\wedge_\varepsilon V=\bigoplus_{n\in\mathbb{Z}} \overset{n}{\wedge}_\varepsilon V, \tag{A7}$$

where $\wedge_\varepsilon^n V$ is the canonical image of $T_n(V)$ in $\wedge_\varepsilon V$. It follows that

$$\overset{n}{\wedge}_\varepsilon V=\{0\}, \quad \text{if } n\leqslant -1, \tag{A8}$$

$$\overset{0}{\wedge}_\varepsilon V=\mathbb{K}, \tag{A9}$$

$$\overset{1}{\wedge}_\varepsilon V=V. \tag{A10}$$

For $n\geqslant 2$ we also use the notation

$$\overset{n}{\wedge}_\varepsilon V=V\wedge_\varepsilon\cdots\wedge_\varepsilon V \quad (n \text{ factors}). \tag{A11}$$

On the other hand, $J(V,\varepsilon)$ is a Γ-graded L-submodule of $T(V)$, and hence $\wedge_\varepsilon V$ inherits from $T(V)$ the structure of a Γ-graded L-module. Then L acts on $\wedge_\varepsilon V$ by ε-derivations, and each $\wedge_\varepsilon^n V$ is a Γ-graded L-submodule of $\wedge_\varepsilon V$.

The theory of ε-exterior algebras can easily be reduced to the theory of ε'-symmetric algebras,[20] with ε' a commutation factor on a suitable Abelian group Γ'. In fact, set $\Gamma'=\mathbb{Z}\times\Gamma$ and define the commutation factor ε' on Γ' by

$$\varepsilon'((r,\alpha),(s,\beta))=(-1)^{rs}\varepsilon(\alpha,\beta), \tag{A12}$$

for all $r,s\in\mathbb{Z}$ and all $\alpha,\beta\in\Gamma$. Regard V as a Γ'-graded vector space (denoted by V'), such that, for all $(r,\gamma)\in\Gamma'$,

$$V'_{(1,\gamma)}=V_\gamma, \tag{A13}$$

$$V'_{(r,\gamma)}=\{0\}, \quad \text{if } r\neq 1. \tag{A14}$$

On the other hand, regard L as a Γ'-graded ε' Lie algebra (denoted by L'), such that, for all $(r,\gamma)\in\Gamma'$,

$$L'_{(0,\gamma)}=L_\gamma, \tag{A15}$$

$$L'_{(r,\gamma)}=\{0\}, \quad \text{if } r\neq 0, \tag{A16}$$

while leaving the product map unchanged. Obviously, V' and $T(V)$ have a natural structure of a Γ'-graded L'-module.

A priori, $T(V')$ is a $\mathbb{Z}\times\Gamma'=\mathbb{Z}\times\mathbb{Z}\times\Gamma$-graded vector space, where the $\mathbb{Z}$-gradation corresponding to the first factor is the canonical $\mathbb{Z}$-gradation of the tensor algebra $T(V')$, and where the one corresponding to the second factor stems from the $\mathbb{Z}$-gradation of V'. Obviously, these two $\mathbb{Z}$-gradations coincide. Thus we may simply forget about one of them and regard $T(V')$ as a Γ'-graded algebra and a Γ'-graded L'-module. A similar remark applies to the ε'-symmetric algebra $S(V',\varepsilon')$ of V'.

With these conventions, $T(V)$ and $T(V')$ coincide, and $\wedge_\varepsilon V$ is equal to $S(V',\varepsilon')$ (where these statements may be interpreted both in the sense of Γ'-graded algebras and of Γ'-graded L'-modules).

The foregoing observation implies that for any result about ε'-symmetric algebras there is an analogous one for ε-exterior algebras. In particular, from Sec. 12 of Ref. 20 we draw the following conclusions.

Let $n\geqslant 1$ be an integer and let

$$\omega_n: V^n\to\overset{n}{\wedge}_\varepsilon V \tag{A17}$$

be the canonical mapping defined by

$$\omega_n(x_1,\ldots,x_n)=x_1\wedge_\varepsilon\cdots\wedge_\varepsilon x_n, \tag{A18}$$

for all $x_i\in V$. Then ω_n is an ε-skew-symmetric n-linear map, which is homogeneous of degree zero and L-invariant, and the pair $(\wedge^n_\varepsilon V,\omega_n)$ has the following universal property.

For any vector space W and any ε-skew-symmetric n-linear map,

$$g: V^n\to W, \tag{A19}$$

there exists a unique linear map,

$$\hat{g}:\overset{n}{\wedge}_\varepsilon V\to W, \tag{A20}$$

such that

$$g=\hat{g}\circ\omega_n. \tag{A21}$$

Now suppose in addition that W is a graded L-module, and let $\mathrm{Lgr}^a_n(V,W;\varepsilon)$ denote the graded L-submodule of $\mathrm{Lgr}_n(V,\ldots,V;W)$ consisting of all elements which are ε-skew-symmetric. Then the assignment $g\to\hat{g}$ described above induces a graded L-module isomorphism of $\mathrm{Lgr}^a_n(V,W;\varepsilon)$ onto $\mathrm{Lgr}(\wedge^n_\varepsilon V,W)$.

Next, let $T_n^a(V,\varepsilon)$ denote the graded L-submodule of $T_n(V)$ consisting of all ε-skew-symmetric tensors in $T_n(V)$. The ε-skew-symmetrization,

$$t \to \frac{1}{n!} \sum_{\pi \in \mathcal{S}_n} \operatorname{sgn}(\pi) S_\pi(t), \tag{A22}$$

defines a graded L-module homomorphism of $T_n(V)$ onto $T_n^a(V,\varepsilon)$ (recall that the mappings S_π have been defined in Ref. 20). Using the universal property of $(\wedge_\varepsilon^n V, \omega_n)$, it follows that there exists a unique surjective graded L-module homomorphism,

$$\chi_n : \overset{n}{\wedge}_\varepsilon V \to T_n^a(V,\varepsilon), \tag{A23}$$

such that

$$\chi_n(x_1 \wedge_\varepsilon \cdots \wedge_\varepsilon x_n) = \frac{1}{n!} \sum_{\pi \in \mathcal{S}_n} \operatorname{sgn}(\pi) S_\pi(x_1 \otimes \cdots \otimes x_n), \tag{A24}$$

for all $x_i \in V$, and it is easy to see that χ_n is injective, and hence an isomorphism of graded L-modules.

On the other hand, from the Poincaré, Birkhoff, Witt theorem[22] we deduce that to any homogeneous basis of V there corresponds, in the obvious way, a homogeneous basis of $\wedge_\varepsilon V$.

Finally, if V and W are two graded L-modules, then $\wedge_\varepsilon(V \oplus W)$ (regarded as a $\mathbb{Z}\times\Gamma$-graded algebra and as a Γ-graded L-module) is canonically isomorphic to $(\wedge_\varepsilon V) \overline{\otimes}_{\varepsilon'} (\wedge_\varepsilon W)$, where $\overline{\otimes}_{\varepsilon'}$ denotes the graded tensor product of $\mathbb{Z}\times\Gamma$-graded algebras with respect to ε'. This is a special case of an analogous result for ε Lie algebras: If G and L are two ε Lie algebras, the (universal) enveloping algebra $U(G\times L)$ of the direct product $G\times L$ of G and L is canonically isomorphic to the graded tensor product $U(G) \overline{\otimes}_\varepsilon U(L)$ of the Γ-graded algebras $U(G)$ and $U(L)$ (with respect to ε). The proof follows directly from the universal property of enveloping algebras.

In particular, let $U = U_{\bar{0}} \oplus U_{\bar{1}}$ be a $\mathbb{Z}_2$-graded vector space. Applying the preceding result to $V = U_{\bar{0}}$ and $W = U_{\bar{1}}$ (regarded as $\mathbb{Z}_2$-graded vector spaces), we conclude that the super-exterior algebra $\wedge_\varepsilon U$ is canonically isomorphic to $(\wedge U_{\bar{0}}) \overline{\otimes} S(U_{\bar{1}})$, where $\wedge U_{\bar{0}}$ [resp., $S(U_{\bar{1}})$] is the *usual* exterior (resp., symmetric) algebra of the vector space $U_{\bar{0}}$ (resp., $U_{\bar{1}}$), and where $\overline{\otimes}$ denotes the graded tensor product of $\mathbb{Z}$-graded algebras with respect to the commutation factor $(r,s) \to (-1)^{rs}$. In particular, we have the vector space isomorphism

$$\overset{n}{\wedge}_\varepsilon U \simeq \bigoplus_{r=0}^{n} ((\wedge^r U_{\bar{0}}) \otimes S_{n-r}(U_{\bar{1}})). \tag{A25}$$

This enables us to make contact with the definition of the cohomology of Lie superalgebras given in Ref. 10. First, we notice that we have chosen a different overall sign for the coboundary operator (which does not matter). Moreover, there is another discrepancy, which (in our language) amounts to dropping γ in the first sum on the right hand side of Eq. (2.21). This is serious, for it spoils the L-invariance of δ^n [but not the ε-skew-symmetry of $\delta^n g$ and not the validity of the fundamental equation (2.20)]. We suspect that this is a misprint.

APPENDIX B: THE TENSORIAL SQUARE OF THE ADJOINT $sl(1|2)$-MODULE

We keep the notation of Sec. V and write L instead of $sl(1|2)$. Our goal is to investigate the graded L-module $L\otimes L$. Of course, $L\otimes L$ decomposes into the direct sum of the graded L-submodule $T_2^s(L,\varepsilon)$ of super-symmetric tensors with the graded L-submodule $T_2^a(L,\varepsilon)$ of super-skew-symmetric tensors,

$$L \otimes L = T_2^s(L,\varepsilon) \oplus T_2^a(L,\varepsilon). \tag{B1}$$

Moreover, it is known that $T_2^s(L,\varepsilon)$ [resp., $T_2^a(L,\varepsilon)$] is isomorphic to $S_2(L,\varepsilon)$ (resp., to $\wedge_\varepsilon^2 L$) (see Ref. 20 and Appendix A).

The decomposition of $T_2^a(L,\varepsilon)$ into the direct sum of simple graded submodules has already been used in Sec. V, we have

$$T_2^a(L,\varepsilon)\simeq V(\tfrac{1}{2},\tfrac{3}{2},\overline{1})\oplus V(-\tfrac{1}{2},\tfrac{3}{2},\overline{1})\oplus V(0,1,\overline{0}). \tag{B2}$$

Thus all we have to do is to investigate $T_2^s(L,\varepsilon)$. This L-module is not semi-simple. In fact, we find that

$$T_2^s(L,\varepsilon)\simeq V(0,2,\overline{0})\oplus V(0,1,\overline{0})\oplus V_8, \tag{B3}$$

where V_8 is an 8-dimensional indecomposable graded L-module, which can be described as follows. It has a basis consisting of four even weight vectors t,s,v,w and four odd weight vectors $v_\pm, w_\pm$, corresponding to the weights (0,0), (0,0), (1,0), $(-1,0)$ and $(\frac{1}{2},\pm\frac{1}{2})$, $(-\frac{1}{2},\pm\frac{1}{2})$, respectively. The action of L on V_8 is fixed by the equations

$$V_\pm\cdot t=v_\pm,\quad W_\pm\cdot t=w_\pm, \tag{B4}$$

$$V_\pm\cdot v_\mp=\pm v,\quad W_\pm\cdot w_\mp=\pm w\ , \tag{B5}$$

$$W_\pm\cdot v=v_\pm,\quad V_\pm\cdot w=w_\pm, \tag{B6}$$

$$W_\pm\cdot v_\mp=V_\pm\cdot w_\mp=\pm s\ , \tag{B7}$$

$$V_\pm\cdot s=W_\pm\cdot s=0, \tag{B8}$$

while the remaining images of the basis vectors under the action of $V_\pm$ or $W_\pm$ are equal to zero. We note that these equations fix the normalization of the basis vectors up to an overall factor. The even vectors t,s,v,w are $sl(2)$-singlets, while $(v_\pm)$ and $(w_\pm)$ are standard $sl(2)$-doublets. Obviously, t generates the L-module V_8 (but, of course, it is not a highest weight vector). Needless to say, t can be replaced by any vector of the form $t+\lambda s$, with $\lambda\in\mathbb{K}$.

We do not want to specify the eight basis vectors inside $T_2^s(L,\varepsilon)$. Suffice it to note that t can be chosen such that

$$t=Q_+\otimes Q_-+Q_-\otimes Q_++2\,Q_3\otimes Q_3+2\,B\otimes B. \tag{B9}$$

Remark B.1: The decomposition (B3) of $T_2^s(L,\varepsilon)$ has been found independently of Ref. 40. As already noted, in this article a decomposition of $U(L)$ into indecomposable L-submodules has been determined, and (B3) is just the first nontrivial part of it. The module V_8 has been known since the early days of the theory of Lie superalgebras. In fact, it was proved in Sec. 3.B of Ref. 39 that, for both $\gamma\in\mathbb{Z}_2$, we have

$$V(0,\tfrac{1}{2},\gamma)\otimes V(0,\tfrac{1}{2},\gamma)\simeq V(0,1,\overline{0})\oplus V_8, \tag{B10}$$

thus showing that the tensor product of two (typical) simple graded L-modules need not be semi-simple.

The graded L-module V_8 has the following nontrivial graded submodules:

$$V_1=\mathbb{K}s, \tag{B11}$$

$$V_4=\mathbb{K}v_+\oplus\mathbb{K}v_-\oplus\mathbb{K}v\oplus\mathbb{K}s, \tag{B12}$$

$$\overline{V_4}=\mathbb{K}w_+\oplus\mathbb{K}w_-\oplus\mathbb{K}w\oplus\mathbb{K}s, \tag{B13}$$

$$V_7=V_4+\overline{V_4}. \tag{B14}$$

Obviously, V_1 is the submodule consisting of the L-invariant elements of V_8. The modules V_4 and $\overline{V_4}$ are indecomposable, and we have

$$V_7/\overline{V_4} \simeq V_4/V_1 \simeq V(\tfrac{1}{2}, \tfrac{1}{2}, \overline{1}), \tag{B15}$$

$$V_7/V_4 \simeq \overline{V_4}/V_1 \simeq V(-\tfrac{1}{2}, \tfrac{1}{2}, \overline{1}). \tag{B16}$$

Finally, V_8/V_7 is a trivial one-dimensional L-module.

Let us next calculate $\dim H^1(L,V_8)$. Using the information obtained in Sec. V, this is easily done by means of the long cohomology sequence (2.51), applied to various short exact sequences of graded L-modules. In fact, considering the sequence

$$\{0\} \to V_1 \to V_4 \to V_4/V_1 \to \{0\}, \tag{B17}$$

and the analogous one with V_4 replaced by $\overline{V_4}$, we obtain

$$\dim H^1(L,V_4) = \dim H^1(L,\overline{V_4}) = 1, \tag{B18}$$

$$H^2(L,V_4) = H^2(L,\overline{V_4}) = \{0\}. \tag{B19}$$

Considering next the sequence

$$\{0\} \to V_4 \to V_7 \to V_7/V_4 \to \{0\}, \tag{B20}$$

we conclude that

$$\dim H^1(L,V_7) = 2. \tag{B21}$$

Finally, from the cohomology sequence corresponding to

$$\{0\} \to V_7 \to V_8 \to V_8/V_7 \to \{0\} \tag{B22}$$

and from Eq. (2.83) we deduce that

$$\dim H^1(L,V_8) = 1. \tag{B23}$$

The corresponding 1-cocycles can easily be determined. In fact, define two linear maps,

$$g: L \to V_4, \quad \overline{g}: L \to \overline{V_4}, \tag{B24}$$

by

$$g(V_\pm) = v_\pm, \quad \overline{g}(W_\pm) = w_\pm, \tag{B25}$$

$$-g(B) = \overline{g}(B) = s, \tag{B26}$$

with $g(X) = \overline{g}(Y) = 0$ for all other elements X, Y of our standard basis of L. Then g and $\overline{g}$ are 1-cocycles with values in V_4 and $\overline{V_4}$, respectively, and they are not coboundaries. If we regard g and $\overline{g}$ as 1-cocycles with values in V_7, their cohomology classes in $H^1(L,V_7)$ are linearly independent. Finally, if we regard g and $\overline{g}$ as 1-cocycles with values in V_8, they are still not coboundaries, but g and $-\overline{g}$ are cohomologous, with

$$g + \overline{g} = \delta^0 t. \tag{B27}$$

The foregoing results have an immediate bearing on the cohomology of $U(L)$. In fact, it is known[26] that $U(L)$, regarded as a graded L-module (and also as a graded coalgebra) is canonically isomorphic to $S(L,\varepsilon)$. Consequently, there exists a graded L-submodule of $U(L)$, which is a

direct summand of $U(L)$ and which is isomorphic to V_8. (Note that the simple graded subquotients of V_8 are exactly those which according to Lemma 5.1 are allowed.) Using the isomorphism (2.49), we conclude from Eq. (B23) that

$$H^1(L,U(L))\neq\{0\}. \tag{B28}$$

Realizations of su(1,1) and $U_q(\mathrm{su}(1,1))$ and generating functions for orthogonal polynomials

J. Van der Jeugt[a] and R. Jagannathan[b]
Department of Applied Mathematics and Computer Science, University of Ghent, Krijgslaan 281-S9, B-9000 Gent, Belgium

(Received 5 March 1998; accepted for publication 3 April 1998)

Positive discrete series representations of the Lie algebra su(1,1) and the quantum algebra $U_q(\mathrm{su}(1,1))$ are considered. The diagonalization of a self-adjoint operator (the Hamiltonian) in these representations and in tensor products of such representations is determined, and the generalized eigenvectors are constructed in terms of orthogonal polynomials. Using simple realizations of su(1,1), $U_q(\mathrm{su}(1,1))$, and their representations, these generalized eigenvectors are shown to coincide with generating functions for orthogonal polynomials. The relations valid in the tensor product representations then give rise to new generating functions for orthogonal polynomials, or to Poisson kernels. In particular, a group theoretical derivation of the Poisson kernel for Meixner–Pollaczek and Al-Salam–Chihara polynomials is obtained. © *1998 American Institute of Physics.* [S0022-2488(98)01809-X]

I. INTRODUCTION

The Lie algebra su(1,1) [or so(2,1)] has been extensively used as a spectrum generating algebra in many simple quantum systems, such as the nonrelativistic Coulomb problem, the isotropic harmonic oscillator, Schrödinger's relativistic equation, and the Dirac–Coulomb problem (Ref. 1, and references therein). In some interacting boson models the Hamiltonian H can be written as a linear combination of the su(1,1) basis elements $J_0, J_\pm$, such that $H^\dagger = H$, see, e.g., the superfluid bose system.[2,3] In such boson models, the representations that play a role are the positive discrete series representations of su(1,1), often denoted by $\mathscr{D}^+(k)$. For a given Hamiltonian $H = aJ_0 + bJ_+ + cJ_- + d$, with $a^* = a$, $d^* = d$ and $b^* = c$, the important questions are: (1) its spectrum (continuous or discrete); and (2) the expansion of its eigenvectors in terms of the boson states $|k,n\rangle$ [corresponding to eigenstates of J_0 in the representations $\mathscr{D}^+(k)$].

In Ref. 4 a particular element, $H = 2J_0 - J_+ - J_-$, was chosen, and it was shown that the expansion coefficients of the eigenstates of H in the basis $|k,n\rangle$ of the representation $\mathscr{D}^+(k)$ are given as generalized Laguerre polynomials (see also Ref. 5). The main purpose of Ref. 4 was then to consider tensor product representations, and deduce in a Lie algebraic way addition or convolution formulas for orthogonal polynomials [in this case for generalized Laguerre and Jacobi polynomials, cf. Ref. 4, (1.1)]. Following this, the most general Hamiltonian with real coefficients (up to an overall constant and scaling factor) $H = \sigma J_0 - J_+ - J_-$ ($\sigma \in \mathbb{R}$) was considered in Ref. 6 and it was shown that the spectrum of H depends upon whether $|\sigma| = 2$, $|\sigma| < 2$ or $|\sigma| > 2$ (see also Ref. 7 for a particular representation). In each of these cases, the expansion coefficients of the Hamiltonian eigenstates in the $|k,n\rangle$-basis are orthogonal polynomials. In Sec. II, the main results of Refs. 4 and 6 are summarized in the present framework of eigenstates (generalized eigenvectors).

Although the physical applications or interpretations are clear from the above observations, this paper deals primarily with a number of mathematical consequences of choosing particular realizations for the positive discrete series representations.

The general framework for the positive discrete series representations is outlined in Sec. II. The three types of operators are given, together with their spectra and expansion coefficients

(orthogonal polynomials). The tensor product of two positive discrete series representations is considered, and, just as there are ''coupled'' and ''uncoupled'' eigenvectors for J_0 in the tensor product, one can also define coupled and uncoupled eigenstates of the Hamiltonian. The expansion coefficients of uncoupled eigenstates into coupled eigenstates (in an irreducible component of the tensor product), cf. Eq. (2.13), are again orthogonal polynomials (Jacobi, continuous Hahn, or Hahn polynomials).

All the relations given in Sec. II (deduced in Refs. 4 and 6) are obtained by Lie algebraic methods only. The purpose of the present paper is to examine the implications of these relations once a realization for the Lie algebra su(1,1) and its representations $\mathscr{D}^+(k)$ are chosen. For su(1,1), there exists a classical realization such that the J_0-diagonal basis states $|k,n\rangle$ of $\mathscr{D}^+(k)$ are simply the monomials z^n. This realization is considered in Sec. III. As a consequence, the eigenstates of the Hamiltonian H simply become generating functions for the orthogonal polynomials (i.e., the expansion coefficients), and also the J_0-diagonal basis states in an irreducible component of the tensor product become simple functions. Then, it remains to consider the relation connecting coupled and uncoupled eigenstates of the Hamiltonian in the tensor product, and investigate its explicit form in this realization. For the case of Laguerre and Jacobi polynomials, this is done in Sec. IV; the outcome is a generalization of classical generating functions for Laguerre polynomials. For the case of Meixner and Hahn polynomials, this analysis is performed in Sec. V; the outcome is the Poisson kernel formula for Meixner (or Meixner–Pollaczek) polynomials, Eq. (5.5). Although the formula thus obtained is known, the method used to reach it is original and interesting: in this Lie algebraic framework it is a simple consequence of a very general expansion [Eq. (2.13)] in a particular realization.

Then we turn our attention to the q-analog of the results obtained so far. Since the method is purely algebraic, it works not only for the Lie algebra su(1,1) but also for the quantum algebra $U_q(\mathrm{su}(1,1))$.[8] In Sec. VI, the quantum algebra $U_q(\mathrm{su}(1,1))$ is defined, and the positive discrete series representations with a standard basis are given. Next, a self-adjoint operator playing the role of Hamiltonian is considered, and its eigenstates are expanded in the standard basis with expansion coefficients proportional to Al-Salam–Chihara polynomials. Just as for the su(1,1) case, coupled and uncoupled eigenstates of this operator in the tensor product are constructed and the expansion of one into the other is given in terms of Askey–Wilson polynomials. The results presented in Sec. VI are mainly taken from Ref. 6. Just as for su(1,1), the purpose is now to investigate the implication of these formulas once a realization is chosen. For $U_q(\mathrm{su}(1,1))$, this realization is given in Sec. VII, and the standard basis for positive discrete series representations consist again of monomials z^n. Finally, the relation connecting coupled and uncoupled eigenstates is shown to give rise to the (symmetric) Poisson kernel formula for Al-Salam–Chihara polynomials in this realization. Although this formula has recently been found by means of classical methods, the present deduction is simple, purely algebraic, and a natural q-analog of the Poisson kernel for Meixner–Pollaczek polynomials in the su(1,1) framework.

In a final section, two different realizations of su(1,1) and its representations are considered. These realizations have been used in physical models. We show again how our general results of Sec. II have interesting implications for special functions. In particular, integrals over products of Laguerre and Hermite polynomials are expressed in terms of a Meixner polynomial. This section is completed by some general comments and further outlook.

II. THE LIE ALGEBRA su(1,1) AND POSITIVE DISCRETE SERIES REPRESENTATIONS

The Lie algebra su(1,1) is generated by $J_0, J_\pm$ subject to the relations

$$[J_0, J_\pm] = \pm J_\pm, \quad [J_+, J_-] = -2J_0, \tag{2.1}$$

with the conditions $J_0^\dagger = J_0$ and $J_\pm^\dagger = J_\mp$. The positive discrete representations[9] $\mathscr{D}^+(k)$ are labeled by a positive real number k. The representation space is $\ell^2(\mathbb{Z}_+)$, with orthonormal basis vectors denoted by $e_n^{(k)}$, with $n = 0,1,2,\ldots$ (and sometimes denoted by $|k,n\rangle$). The explicit action of the generators in this representation (k) is given by

TABLE I. Orthogonal polynomials appearing in the formal eigenvector $v^{(k)}(x)$.

X	$l_n^{(k)}(x)$	Polynomial	Eigenvalue $\lambda(x)$	Spectrum
X_2	$\sqrt{\frac{n!}{(2k)_n}}\,L_n^{(2k-1)}(x)$	generalized Laguerre	x	$0\leqslant x<\infty$
X_ϕ	$\sqrt{\frac{n!}{\Gamma(2k+n)}}\,P_n^{(k)}(x;\phi)$	Meixner–Pollaczek	$2x\,\sin\phi$	$x\in\mathbb{R}$
X_c	$\sqrt{\frac{(2k)_n}{n!}}\,c^n M_n(x;2k;c^2)$	Meixner	$(c-1/c)(k+x)$	$x\in\mathbb{N}$

$$J_0 e_n^{(k)} = (n+k)e_n^{(k)},$$
$$J_+ e_n^{(k)} = \sqrt{(n+1)(2k+n)}\,e_{n+1}^{(k)}, \tag{2.2}$$
$$J_- e_n^{(k)} = \sqrt{n(2k+n-1)}\,e_{n-1}^{(k)}.$$

In two previous papers,[4,6] a recurrence operator in the Lie algebra su(1,1) was related to a Jacobi matrix. Rather than working with the spectral theory of Jacobi matrices, it will be more appropriate for this paper to use the (equivalent) notion of formal or generalized eigenvectors, to be identified with eigenstates of a Hamiltonian. In Ref. 6, the formal eigenvectors

$$v^{(k)}(x) = \sum_{n=0}^{\infty} l_n^{(k)}(x) e_n^{(k)} \tag{2.3}$$

of the self-adjoint operator $X=\sigma J_0 - J_+ - J_-$ ($\sigma\in\mathbb{R}$) in the representation (k) were studied; in a boson model such as referred to in the Introduction, the Hamiltonian H is essentially equal to this operator X. The formal vector $v^{(k)}(x)$ is a generalized eigenvector of X for the eigenvalue $\lambda(x)$ provided $l_n^{(k)}(x)$ satisfies a three-term recurrence relation.[4,6] This leads to an identification of $l_n^{(k)}(x)$ with orthogonal polynomials in x. These polynomials associated with X are of different type for $|\sigma|=2$, $|\sigma|<2$ or $|\sigma|>2$. Labelling the operator in the three distinct cases as follows:

$$X_2 = 2J_0 - J_+ - J_-, \tag{2.4}$$

$$X_\phi = -2\cos\phi J_0 + J_+ + J_-, \quad 0<\phi<\pi, \tag{2.5}$$

$$X_c = -(c+1/c)J_0 + J_+ + J_-, \quad 0<c<1, \tag{2.6}$$

we can give a summary of some results obtained earlier in Table I. The spectrum of X is determined by the support of the measure of the associated orthogonal polynomials being continuous for $|\sigma|=2$ and $|\sigma|<2$ and discrete for $|\sigma|>2$.

In Table I, $(\alpha)_n=\Gamma(\alpha+n)/\Gamma(\alpha)$ is the common notation for the Pochhammer symbol in terms of the classical Γ function. The definition of the orthogonal polynomials in terms of hypergeometric series is as follows:[10]

$$L_n^{(\alpha)}(x) = \frac{(\alpha+1)_n}{n!}\,{}_1F_1\left[\begin{matrix}-n\\ \alpha+1\end{matrix};x\right], \quad (\alpha>-1); \tag{2.7}$$

$$P_n^{(\lambda)}(x;\phi) = \frac{(2\lambda)_n}{n!}e^{in\phi}\,{}_2F_1\left[\begin{matrix}-n,\lambda+ix\\ 2\lambda\end{matrix};1-e^{-2i\phi}\right], \quad (\lambda>0); \tag{2.8}$$

$$M_n(x;\beta;c) = {}_2F_1\left[\begin{matrix}-n,-x\\ \beta\end{matrix};1-1/c\right], \quad (\beta>0). \tag{2.9}$$

The notation for hypergeometric series is the standard one.[11,12]

TABLE II. Orthogonal polynomial appearing in the expansion (2.13).

X	$S_j^{(k_1,k_2)}(x_1,x_2)$	Polynomial
X_2	$C_1(-1)^j(x_1+x_2)^j P_j^{(2k_1-1,2k_2-1)}\left(\frac{x_2-x_1}{x_2+x_1}\right)$	Jacobi
X_ϕ	$C_2(-2\sin\phi)^j p_j(x_1;k_1,k_2-i(x_1+x_2),k_1,k_2+i(x_1+x_2))$	continuous Hahn
X_c	$C_3(-c+1/c)^j(-x_1-x_2)_j Q_j(x_1;2k_1-1,2k_2-1,x_1+x_2)$	Hahn

By considering the tensor product decomposition for su(1,1) representations, new summation formulas or convolution theorems were obtained for these polynomials. The tensor product decomposes as follows:[9]

$$(k_1)\otimes(k_2)=\bigoplus_{j=0}^{\infty}(k_1+k_2+j). \tag{2.10}$$

The ''coupled basis vectors'' are written in terms of the uncoupled ones by means of the Clebsch–Gordan coefficients:

$$e_n^{(k_1k_2)k}=\sum_{n_1,n_2} C_{n_1,n_2,n}^{k_1,k_2,k}\; e_{n_1}^{(k_1)}\otimes e_{n_2}^{(k_2)}. \tag{2.11}$$

Herein, $k=k_1+k_2+j$ for some integer $j\geqslant 0$, and the sum is such that $n_1+n_2=j+n$. Explicit expressions for the Clebsch–Gordan coefficients are given, e.g., in Ref. 4.

In the tensor product space, the generalized eigenvectors of $\Delta(X)=X\otimes 1+1\otimes X$ can be considered. Again, there are ''uncoupled'' eigenvectors $v^{(k_1)}(x_1)v^{(k_2)}(x_2)$ with eigenvalue $\lambda(x_1+x_2)$, but also ''coupled'' eigenvectors $v^{(k_1k_2)k}(x_1+x_2)$ defined as follows:

$$v^{(k_1k_2)k}(x_1+x_2)=\sum_{n=0}^{\infty} l_n^{(k)}(x_1+x_2)e_n^{(k_1k_2)k}, \tag{2.12}$$

where $k=k_1+k_2+j$ for some integer $j\geqslant 0$. It was shown in Refs. 4 and 6 that

$$v^{(k_1)}(x_1)v^{(k_2)}(x_2)=\sum_{j=0}^{\infty} S_j^{(k_1,k_2)}(x_1,x_2)v^{(k_1k_2)k_1+k_2+j}(x_1+x_2), \tag{2.13}$$

where S is again an orthogonal polynomial given in Table II, according to which of the three cases is considered. The constants in this table are determined by

$$C_1=(j!/((2k_1)_j(2k_2)_j(2k_1+2k_2+j-1)_j))^{1/2}, \tag{2.14}$$

$$C_2=(j!(2k_1+2k_2+2j-1)\Gamma(2k_1+2k_2+j-1)/(\Gamma(2k_1+j)\Gamma(2k_2+j)))^{1/2}, \tag{2.15}$$

$$C_3=C_2(2k_1)_j/j!. \tag{2.16}$$

The polynomials appearing in Table II are defined as follows:[10]

$$P_n^{(\alpha,\beta)}(x)=\frac{(\alpha+1)_n}{n!}\,{}_2F_1\left[\begin{matrix}-n,n+\alpha+\beta+1\\ \alpha-1\end{matrix};\frac{1-x}{2}\right], \tag{2.17}$$

$$p_n(x;a,b,c,d)=i^n\frac{(a+c)_n(a+d)_n}{n!}\,{}_3F_2\left[\begin{matrix}-n,n+a+b+c+d-1,a+ix\\ a+c,a+d\end{matrix};1\right], \tag{2.18}$$

$$Q_n(x;a,b,N)={}_3F_2\left[\begin{matrix}-n,n+a+b+1,-x\\ a+1,-N\end{matrix};1\right]. \tag{2.19}$$

TABLE III. Explicit form of the vectors $v^{(k)}(x,z)$ in the present realization.

X	Series	Generating function
X_2	$\Sigma_{n=0}^{\infty} L_n^{(2k-1)}(x) z^n$	$(1-z)^{-2k} e^{xz/(z-1)}$
X_ϕ	$\Gamma(2k)^{-1} \Sigma_{n=0}^{\infty} P_n^{(k)}(x;\phi) z^n$	$(1-e^{i\phi}z)^{-k+ix}(1-e^{-i\phi}z)^{-k-ix}/\Gamma(2k)$
X_c	$\Sigma_{n=0}^{\infty} \frac{(2k)_n c^n}{n!} M_n(x;2k,c^2) z^n$	$(1-z/c)^x (1-cz)^{-x-2k}$

A number of interesting new convolution identities for orthogonal polynomials were constructed in Ref. 6 from the relation $(k=k_1+k_2+j)$:

$$\sum_{n_1+n_2=n+j} C^{k_1,k_2,k}_{n_1,n_2,n} \; l_{n_1}^{(k_1)}(x_1) l_{n_2}^{(k_2)}(x_2) = l_n^{(k)}(x_1+x_2) S_j^{(k_1,k_2)}(x_1,x_2). \tag{2.20}$$

In the simplest case, where $l_n^{(k)}(x)$ corresponds to a generalized Laguerre polynomial and $S_j^{(k_1,k_2)}(x_1,x_2)$ to a Jacobi polynomial, this relation reduces to Ref. 4, (1.1). Recently, this equation has been applied to find transformation brackets for $U(N)$ boson models.[13]

III. REALIZATION OF su(1,1)

In this section we give a realization of su(1,1) and of the discrete series representation $\mathscr{D}^+(k)$. Assume that $k>1/2$, and consider the Hilbert space of analytic functions $f(z)$ $(z\in\mathbb{C})$ on the unit disc $|z|<1$, with inner product[9]

$$(f_1,f_2)=\frac{2k-1}{\pi}\int\int_{|z|<1} f_1(z)\overline{f_2(z)}(1-|z|^2)^{2k-2}\,dxdy \quad (z=x+iy). \tag{3.1}$$

The following functions form an orthonormal basis:

$$e_n^{(k)} \equiv e_n^{(k)}(z) = \sqrt{\frac{(2k)_n}{n!}}\, z^n, \tag{3.2}$$

since $(e_n^{(k)}, e_m^{(k)}) = \delta_{m,n}$. The realization of the su(1,1) basis elements reads as follows:

$$J_0 = z\frac{d}{dz} + k, \quad J_- = \frac{d}{dz}, \quad J_+ = z^2\frac{d}{dz} + 2kz. \tag{3.3}$$

It is easy to verify that the action of these operators on the basis (3.2) is indeed the same as in (2.2).

Next, consider the formal vectors (2.3), which are now denoted by $v^{(k)}(x,z)$ since in this realization the basis vectors become functions of z. Since the vectors $e_n^{(k)}$ are proportional to z^n, one can see that the $v^{(k)}(x,z)$ are in fact generating functions for the polynomials $l_n^{(k)}(x)$. The explicit forms of the vectors is given in Table III, for each of the three cases considered here.

For each of the cases, the generating function can be found in Ref. 10. One can also find it by explicitly solving the first order differential equation

$$Xv^{(k)}(x,z) = \lambda(x) v^{(k)}(x,z), \tag{3.4}$$

where X is one of (2.4)–(2.6), in the realization (3.3).

Next, consider the tensor product of two representations $(k_1)\otimes(k_2)$ in the present realization, and the coupled vector

$$e_n^{(k_1k_2)k}(z_1,z_2) = \sum_{n_1,n_2} C^{k_1,k_2,k}_{n_1,n_2,n} \; e_{n_1}^{(k_1)}(z_1) e_{n_2}^{(k_2)}(z_2). \tag{3.5}$$

Using properties of the generating function for the Clebsch–Gordan coefficients, this expression can be written as follows:

$$e_n^{(k_1k_2)k}(z_1,z_2)=\left[\frac{(2k_1)_j(2k_2)_j(2k_1+2k_2+2j)_n}{j!n!(2k_1+2k_2+j-1)_j}\right]^{1/2}(-z_1+z_2)^j z_1^n\,{}_2F_1\left[\begin{matrix}-n,2k_2+j\\2k_1+2k_2+2j\end{matrix};1-z_2/z_1\right], \tag{3.6}$$

where, as before, $k=k_1+k_2+j$.

In the following sections we shall consider the explicit forms of (2.12) and (2.13) in this realization, and its consequences.

IV. THE CASE OF JACOBI POLYNOMIALS

Consider Eq. (2.13) in the case $X=X_2$,

$$v^{(k_1)}(x_1,z_1)v^{(k_2)}(x_2,z_2)=\sum_{j=0}^{\infty} S_j^{(k_1,k_2)}(x_1,x_2)v^{(k_1k_2)k_1+k_2+j}(x_1+x_2,z_1,z_2); \tag{4.1}$$

in this situation the polynomials S_j are Jacobi polynomials. Using the formulas of Table II, and the new variables

$$s=x_2+x_1, \quad x_1=s(1-r)/2,$$

$$r=(x_2-x_1)/(x_2+x_1), \quad x_2=s(1+r)/2, \tag{4.2}$$

this equation becomes

$$v^{(k_1)}(s(1-r)/2,z_1)v^{(k_2)}(s(1+r)/2,z_2)$$
$$=\sum_{j=0}^{\infty} C_1(-1)^j s^j P_j^{(2k_1-1,2k_2-1)}(r)v^{(k_1k_2)k_1+k_2+j}(s,z_1,z_2). \tag{4.3}$$

Now we can integrate with respect to the weight function of Jacobi polynomials:

$$\int_{-1}^{1} P_j^{(2k_1-1,2k_2-1)}(r)v^{(k_1)}\left(\frac{s(1-r)}{2},z_1\right)v^{(k_2)}\left(\frac{s(1+r)}{2},z_2\right)(1-r)^{2k_1-1}(1+r)^{2k_2-1}\,dr$$
$$=C_1h_j(-1)^j s^j v^{(k_1k_2)k_1+k_2+j}(s,z_1,z_2), \tag{4.4}$$

where h_j is the norm of the Jacobi polynomials of degree j, i.e.,

$$h_j=\frac{2^{2k_1+2k_2-1}}{2k_1+2k_2+2j-1}\,\frac{\Gamma(2k_1+j)\Gamma(2k_2+j)}{j!\Gamma(2k_1+2k_2+j-1)}. \tag{4.5}$$

Using the expressions for the functions v given in Table III, we obtain

$$C_1h_j(-1)^j s^j v^{(k_1k_2)k_1+k_2+j}(s,z_1,z_2)$$
$$=(1-z_1)^{-2k_1}(1-z_2)^{-2k_2}e^{(s/2)\{[z_1/(z_1-1)]+[z_2/(z_2-1)]\}}$$
$$\times\int_{-1}^{1} P_j^{(2k_1-1,2k_2-1)}(r)e^{j(z_1-z_2)/2(z_1-1)(z_2-1)}(1-r)^{2k_1-1}(1+r)^{2k_2-1}\,dr. \tag{4.6}$$

Lemma 1:

$$I=\int_{-1}^{1}(1-r)^a(1+r)^b P_j^{(a,b)}(r)e^{cr}\,dr$$
$$=2^{a+b+1}\frac{\Gamma(a+j+1)\Gamma(b+j+1)}{j!\Gamma(a+b+2j+2)}e^{-c}(2c)^j\ {}_1F_1\left[\begin{matrix}b+j+1\\ a+b+2j+2\end{matrix};2c\right]. \tag{4.7}$$

Proof: Writing

$$P_j^{(a,b)}(r)=\frac{1}{2^j}\sum_{m=0}^{j}\binom{j+a}{m}\binom{j+b}{j-m}(r-1)^{j-m}(r+1)^m, \tag{4.8}$$

and using

$$\int_{-1}^{1}(1-r)^\alpha(1+r)^\beta e^{\gamma r}\,dr=2^{\alpha+\beta+1}\frac{\Gamma(\alpha+1)\Gamma(\beta+1)}{\Gamma(\alpha+\beta+2)}\,e^{-\gamma}\ {}_1F_1\left[\begin{matrix}\beta+1\\ \alpha+\beta+2\end{matrix};2\gamma\right], \tag{4.9}$$

one obtains, after some simplifications,

$$I=(-1)^j 2^{a+b+1}e^{-c}\frac{\Gamma(a+j+1)\Gamma(b+j+1)}{j!\Gamma(a+b+j+2)}\sum_{j=0}^{m}\frac{(-j)_m}{m!}\ {}_1F_1\left[\begin{matrix}b+m+1\\ a+b+j+2\end{matrix};2c\right]. \tag{4.10}$$

In the sum over m, the ${}_1F_1$ is written explicitly as a series, the two summation variables are changed, and then Vandermonde's summation theorem can be applied; putting $\alpha=a+b+j+2$ and $\beta=b+1$, this gives explicitly

$$\sum_{j=0}^{m}\frac{(-j)_m}{m!}\ {}_1F_1\left[\begin{matrix}\beta+m\\ \alpha\end{matrix};\gamma\right]=\sum_{m=0}^{j}\frac{(-j)_m}{m!}\sum_{k=0}^{\infty}\frac{(\beta+m)_k\gamma^k}{(\alpha)_k k!}$$
$$=\sum_{k=0}^{\infty}\frac{(\beta)_k\gamma^k}{(\alpha)_k k!}\sum_{m=0}^{j}\frac{(b+k)_m(-j)_m}{(b)_m m!}$$
$$=\sum_{k=0}^{\infty}\frac{(\beta)_k\gamma^k}{(\alpha)_k k!}\frac{(-k)_j}{(b)_j}. \tag{4.11}$$

In the last sum k goes from j up to ∞, so let $l=k-j$, and rewrite the series; one finds

$$\frac{(-1)^j\gamma^j}{(\alpha)_j}\sum_{l=0}^{\infty}\frac{(\beta+j)_l\gamma^l}{(\alpha+j)_l l!}=\frac{(-1)^j\gamma^j}{(\alpha)_j}\ {}_1F_1\left[\begin{matrix}\beta+j\\ \alpha+j\end{matrix};\gamma\right]. \tag{4.12}$$

Putting this back in (4.10) finally proves the lemma.

As a consequence, we now have the following explicit form for $v^{(k_1k_2)k_1+k_2+j}(s,z_1,z_2)$:

$$v^{(k_1k_2)k_1+k_2+j}(s,z_1,z_2)=(-1)^j\left[\frac{(2k_1)_j(2k_2)_j}{j!(2k_1+2k_2+j-1)_j}\right]^{1/2}(1-z_1)^{-2k_1-j}(1-z_2)^{-2k_2-j}$$
$$\times(z_1-z_2)^j e^{sz_1/(z_1-1)}\ {}_1F_1\left[\begin{matrix}2k_1+j\\ 2k_1+2k_2+2j\end{matrix};\frac{s(z_1-z_2)}{(z_1-1)(z_2-1)}\right]. \tag{4.13}$$

On the other hand, we know from (2.12) that ($k=k_1+k_2+j$)

$$v^{(k_1k_2)k}(s,z_1,z_2)=\sum_{n=0}^{\infty}l_n^{(k)}(s)e_n^{(k_1k_2)k}(z_1,z_2), \tag{4.14}$$

with $l_n^{(k)}(s)$ given in Table I and $e_n^{(k_1k_2)k}(z_1,z_2)$ given in (3.6). Thus we obtain

$$\sum_{n=0}^{\infty} L_n^{(2k)}(s) z_1^n \, {}_2F_1\left[\begin{matrix} -n, 2k_2+j \\ 2k_1+2k_2+2j \end{matrix}; 1-z_2/z_1\right]$$

$$= (1-z_1)^{-2k_1-j}(1-z_2)^{-2k_2-j} e^{sz_1/(z_1-1)} \, {}_1F_1\left[\begin{matrix} 2k_1+j \\ 2k_1+2k_2+2j \end{matrix}; \frac{s(z_1-z_2)}{(z_1-1)(z_2-1)}\right]. \quad (4.15)$$

This can be rewritten in a more appropriate form:

Proposition 2:

$$\sum_{n=0}^{\infty} L_n^{(b-1)}(s) z_1^n \, {}_2F_1\left[\begin{matrix} -n, a \\ b \end{matrix}; 1-\frac{z_2}{z_1}\right] = (1-z_1)^{a-b}(1-z_2)^{-a} e^{sz_1/(z_1-1)} \, {}_1F_1\left[\begin{matrix} a \\ b \end{matrix}; \frac{s(z_1-z_2)}{(z_1-1)(z_2-1)}\right]. \quad (4.16)$$

This is a generalization of two classical generating functions for the Laguerre polynomials. For $a=0$, or $z_1=z_2$, it reduces to the first classical result

$$\sum_{n=0}^{\infty} L_n^{(b-1)}(s) z_1^n = (1-z_1)^{-b} e^{sz_1/(z_1-1)}; \quad (4.17)$$

for $z_2=0$, it reduces to

$$\sum_{n=0}^{\infty} L_n^{(b-1)}(s) \frac{(b-a)_n}{(b)_n} z_1^n = (1-z_1)^{-b} \, {}_1F_1\left[\begin{matrix} b-a \\ b \end{matrix}; \frac{sz_1}{(z_1-1)}\right]. \quad (4.18)$$

Note that (4.16) can be written in a more general form:

$$\sum_{n=0}^{\infty} {}_1F_1\left[\begin{matrix} -n \\ b \end{matrix}; x\right] \, {}_2F_1\left[\begin{matrix} -n, a \\ b \end{matrix}; y\right] \frac{(b)_n}{n!} z^n$$

$$= (1-z)^{a-b}(1-z+yz)^{-a} e^{xz/(z-1)} \, {}_1F_1\left[\begin{matrix} a \\ b \end{matrix}; \frac{xyz}{(1-z)(1-z+yz)}\right]. \quad (4.19)$$

If one is not interested in the particular form of $v^{(k_1k_2)k_1+k_2+j}(s,z_1,z_2)$, but only in comparing the two expressions of this vector in order to obtain (4.15), many simplifications take place. In particular, note that (4.15) does not explicitly depend upon j but only upon $2k_1+j$ and $2k_2+j$. Thus, one can obtain the same formula (4.16) just by working out only the vector with $j=0$. This will be done for the remaining cases in the following sections.

V. THE CASE OF MEIXNER AND MEIXNER–POLLACZEK POLYNOMIALS

Consider the case $X=X_c$; then (4.1) holds with S_j proportional to a Hahn polynomial. First, assume that $s=x_1+x_2$ is a positive integer (later this condition will disappear by analytic continuation). We can then apply the (discrete) orthogonality relation for Hahn polynomials, and obtain the $j=0$ component

$$v^{(k_1k_2)k_1+k_2}(s,z_1,z_2) \frac{(2k+1+2k_2-1)_{s+1}}{s!(2k_1+2k_2-1)}$$

$$= \sum_{x_1=0}^{s} \frac{(2k_1)_{x_1}(2k_2)_{s-x_1}}{x_1!(s-x_1)!} v^{(k_1)}(x_1,z_1) v^{(k_2)}(s-x_1,z_2). \quad (5.1)$$

With the explicit forms for $v^{(k_1)}$ and $v^{(k_2)}$ from Table III, this gives rise to

$$v^{(k_1k_2)k_1+k_2}(s,z_1,z_2) = (1-cz_1)^{-2k_1}(1-z_2/c)^s(1-cz_2)^{-s-2k_2} \, {}_2F_1\left[\begin{matrix} -s, 2k_1 \\ 2k_1+2k_2 \end{matrix}; 1-\frac{z_2}{z_1}\right]. \quad (5.2)$$

On the other hand, (4.14) now becomes

$$v^{(k_1k_2)k_1+k_2}(s,z_1,z_2)=\sum_{n=0}^{\infty}\frac{(2k_1+2k_2)_n}{n!}M_n(s;2k_1+2k_2,c^2)c^nz_1^n\,{}_2F_1\left[\begin{matrix}-n,2k_2\\2k_1+2k_2\end{matrix};1-\frac{z_2}{z_1}\right]. \tag{5.3}$$

Applying a series transformation on the last ${}_2F_1$ yields

$$\sum_{n=0}^{\infty}\frac{(b)_n}{n!}M_n(s;b,c^2)c^nz_2^n\,{}_2F_1\left[\begin{matrix}-n,a\\b\end{matrix};1-\frac{z_2}{z_1}\right]$$

$$=(1-cz_1)^{-a}(1-cz_2)^{a-b}\left(\frac{1-z_2/c}{1-cz_2}\right)^s\,{}_2F_1\left[\begin{matrix}-s,a\\b\end{matrix};\frac{(c-1/c)(z_2-z_1)}{(1-cz_1)(1-z_2/c)}\right]. \tag{5.4}$$

Given the Meixner polynomials in terms of a ${}_2F_1$, this leads to the following series expression:

Proposition 3:

$$\sum_{n=0}^{\infty}{}_2F_1\left[\begin{matrix}-n,a\\c\end{matrix};x\right]{}_2F_1\left[\begin{matrix}-n,b\\c\end{matrix};y\right]\frac{(c)_nz^n}{n!}$$

$$=(1-z+xz)^{-a}(1-z+yz)^{-b}(1-z)^{a+b-c}\,{}_2F_1\left[\begin{matrix}a,b\\c\end{matrix};\frac{xyz}{(1-z+xz)(1-z+yz)}\right]. \tag{5.5}$$

This formula was already given in Ref. 14, p. 85, eq. (12), and can be interpreted as the Poisson kernel for Meixner or Meixner–Pollaczek polynomials.[15] Observe that (4.19) is a limiting case of (5.5): putting $x=x'/a$ in (5.5) and taking the limit $a\to\infty$ leads to (4.19).

The case of Meixner–Pollaczek polynomials leads essentially to the same formulas.

VI. THE ALGEBRA $U_q(\mathrm{su}(1,1))$

Let $U_q(\mathrm{sl}(2,\mathbb{C}))$ $(0<q<1)$ be the complex unital associative algebra generated by A,B,C,D subject to the relations

$$AD=1=DA,\quad AB=q^{1/2}BA,\quad AC=q^{-1/2}CA,\quad BC-CB=\frac{A^2-D^2}{q^{1/2}-q^{-1/2}}. \tag{6.1}$$

(Compared to Ref. 6, q is replaced by $q^{1/2}$ in order to have q as the basis of the basic hypergeometric series appearing later.) This algebra can be equipped with a comultiplication, counit, and antipode, turning it into a Hopf algebra.[16,8] The Hopf $*$-algebra $U_q(\mathrm{su}(1,1))$ has the following $*$-structure:

$$A^*=A,\quad B^*=-C,\quad C^*=-B,\quad D^*=D. \tag{6.2}$$

The positive discrete representations are labeled by a positive real number k. The representation space is again $\ell^2(\mathbb{Z}_+)$, with orthonormal basis vectors denoted by $e_n^{(k)}$, with $n=0,1,2,\ldots$. The explicit action of the generators in this representation (k) is given by[6]

$$Ae_n^{(k)}=q^{(k+n)/2}e_n^{(k)}, \tag{6.3}$$

$$Ce_n^{(k)}=q^{(1-2k-2n)/4}\frac{\sqrt{(1-q^n)(1-q^{2k+n-1})}}{q^{1/2}-q^{-1/2}}\,e_{n-1}^{(k)}, \tag{6.4}$$

$$Be_n^{(k)}=q^{-(1+2k+2n)/4}\frac{\sqrt{(1-q^{n+1})(1-q^{2k+n})}}{q^{-1/2}-q^{1/2}}\,e_{n+1}^{(k)}. \tag{6.5}$$

Let $s\in\mathbb{R}\backslash\{0\}$, and define

$$Y_s = q^{1/4}B - q^{-1/4}C + \frac{s^{-1}+s}{q^{-1/2}-q^{1/2}}(A-D). \tag{6.6}$$

Under the comultiplication

$$\begin{aligned} &\Delta(A) = A\otimes A, \quad \Delta(B) = A\otimes B + B\otimes D, \\ &\Delta(C) = A\otimes C + C\otimes D, \quad \Delta(D) = D\otimes D, \end{aligned} \tag{6.7}$$

Y_s is twisted primitive, and Y_sA is a self-adjoint element. Here, Y_sA is playing the role of the operator X for su(1,1). In a previous paper,[6] the formal eigenvectors

$$v^{(k)}(x) = \sum_{n=0}^{\infty} l_n^{(k)}(x) e_n^{(k)} \tag{6.8}$$

of Y_sA have been obtained. In order to express the results of Ref. 6, recall the definition of Askey–Wilson[17] and Al-Salam and Chihara polynomials.[18] The Askey–Wilson polynomial is defined by ($x = \cos\theta$)

$$p_m(x;a,b,c,d|q) = a^{-m}(ab,ac,ad;q)_m \, {}_4\varphi_3\left[\begin{matrix} q^{-m}, abcdq^{m-1}, ae^{i\theta}, ae^{-i\theta} \\ ab, ac, ad \end{matrix}; q, q\right], \tag{6.9}$$

and it is symmetric in its parameters a, b, c, and d. In (6.9), the notation for basic hypergeometric series and for the shifted q-factorial is taken from Ref. 12. The Al-Salam and Chihara polynomials are obtained by taking $c = d = 0$ in the Askey–Wilson polynomials:

$$s_m(x;a,b|q) = p_m(x;a,b,0,0|q) = a^{-m}(ab;q)_m \, {}_3\varphi_2\left[\begin{matrix} q^{-m}, ae^{i\theta}, ae^{-i\theta} \\ ab, 0 \end{matrix}; q, q\right]. \tag{6.10}$$

Using the abbreviation $\mu(x) = (x + x^{-1})/2$, it was shown in Ref. 6 that for

$$l_n^{(k)}(x) = \frac{1}{\sqrt{(q,q^{2k};q)_n}} s_n(\mu(x); q^k s, q^k/s|q), \tag{6.11}$$

the vectors (6.8) are formal eigenvectors of Y_sA for the eigenvalue

$$\lambda(x) = 2(\mu(s) - \mu(x))/(q^{1/2} - q^{-1/2}).$$

The tensor product of two $U_q(\mathrm{su}(1,1))$ representations $(k_1)\otimes(k_2)$ is the same as in (2.10), and the Clebsch–Gordan coefficients in

$$e_n^{(k_1k_2)k} = \sum_{n_1,n_2} C_{n_1,n_2,n}^{k_1,k_2,k} \; e_{n_1}^{(k_1)} \otimes e_{n_2}^{(k_2)} \tag{6.12}$$

have been determined, e.g., in Ref. 6. In the tensor product space, the generalized eigenvectors of $\Delta(Y_sA)$ have been considered, both in coupled and uncoupled form. It was shown that

$$v^{k_1;k_2}(x_1,x_2) = \sum_{n_1,n_2} \frac{s_{n_1}(\mu(x_1); q^{k_1}x_2, q^{k_1}/x_2|q)}{\sqrt{(q,q^{2k_1};q)_{n_1}}} \frac{s_{n_2}(\mu(x_2); q^{k_2}s, q^{k_2}/s|q)}{\sqrt{(q,q^{2k_2};q)_{n_2}}} e_{n_1}^{(k_1)} \otimes e_{n_2}^{(k_2)} \tag{6.13}$$

is a generalized eigenvector of $\Delta(Y_sA)$ for the eigenvalue $\lambda(x_1)$. In ''coupled'' form,

$$v^{(k_1k_2)k}(x_1) = \sum_{n=0}^{\infty} \frac{s_n(\mu(x_1); q^k s, q^k/s|q)}{\sqrt{(q,q^{2k};q)_n}} e_n^{(k_1k_2)k} \tag{6.14}$$

is a generalized eigenvector of $\Delta(Y_s A)$ for the same eigenvalue. The relation between the two generalized eigenvectors was given in Ref. 6:

$$v^{k_1;k_2}(x_1,x_2)=\sum_{j=0}^{\infty} C_j p_j(\mu(x_2);q^{k_1}x_1,q^{k_1}/x_1,q^{k_2}s,q^{k_2}/s|q)v^{(k_1k_2)k_1+k_2+j}(x_1), \quad (6.15)$$

where p_j is an Askey–Wilson polynomial and

$$C_j=((q,q^{2k_1},q^{2k_2},q^{2k_1+2k_2+j-1};q)_j)^{-1/2}. \quad (6.16)$$

VII. REALIZATION OF $U_q(\mathrm{su}(1,1))$

A realization of $U_q(\mathrm{su}(1,1))$ and the representation labelled by (k) is closely related to the one given for su(1,1) in Sec. III. The Hilbert space is the same (up to a rescaling of the inner product), and the basis functions are now

$$e_n^{(k)}\equiv e_n^{(k)}(z)=\sqrt{\frac{(q^{2k};q)_n}{(q;q)_n}}\,z^n. \quad (7.1)$$

The realization of the $U_q(\mathrm{su}(1,1))$ generators is given in terms of the operators

$$T_q f(z)=f(qz), \quad D_q=\frac{1-T_q}{(1-q)z}, \quad (7.2)$$

and reads

$$A=q^{k/2}T_{q^{1/2}}, \quad D=q^{-k/2}T_{q^{-1/2}}, \quad (7.3)$$

$$B=q^{(1-2k)/4}\left(z^2 D_q T_{q^{-1/2}}+\frac{1-q^{2k}}{1-q}zT_{q^{1/2}}\right), \quad (7.4)$$

$$C=-q^{(3-2k)/4}D_q T_{q^{-1/2}}. \quad (7.5)$$

For this realization, the formal vectors (6.8) become

$$v^{(k)}(x,z)=\sum_{n=0}^{\infty} s_n(\mu(x);q^k s,q^k/s|q)\,\frac{z^n}{(q;q)_n} \quad (7.6)$$

$$=\frac{(q^k zs,q^k z/s;q)_\infty}{(zx,z/x;q)_\infty}, \quad (7.7)$$

following from a known generating function for the Al-Salam and Chihara polynomials.[10] We also wish to obtain an explicit form for the coupled vectors $e_n^{(k_1k_2)k}(z_1,z_2)$. Using the proof of Lemma 4.4 of Ref. 6, one finds $(k=k_1+k_2+j)$

$$e_n^{(k_1k_2)k}(z_1,z_2)=q^{-nj-nk_1}z_2^{n+j}(q^{k_1}z_1/z_2;q)_j\sqrt{\frac{(q^{2k_1},q^{2k_2};q)_j}{(q,q^{2k_1+2k_2+j-1};q)_j}}$$
$$\times\sqrt{\frac{(q^{2k_1+2k_2+2j};q)_n}{(q;q)_n}}\,{}_3\varphi_2\left[\begin{matrix}q^{-n},q^{2k_1+j},q^{k_1+j}z_1/z_2\\ q^{2k_1+2k_2+2j},0\end{matrix};q,q\right]. \quad (7.8)$$

VIII. POISSON KERNEL FOR AL-SALAM–CHIHARA POLYNOMIALS

In the realization of the previous section, the formal vectors defined in (6.13) can be rewritten using (7.7) and they become

$$v^{k_1;k_2}(x_1,x_2,z_1,z_2)=\frac{(q^{k_1}z_1x_2,q^{k_1}z_1/x_2,q^{k_2}z_2s,q^{k_2}z_2/s;q)_\infty}{(z_1x_1,z_1/x_1,z_2x_2,z_2/x_2;q)_\infty}. \tag{8.1}$$

Note that in all the previous formulas the variables of the Al-Salam and Chihara (or Askey–Wilson) polynomials are $\mu(x_1)$ or $\mu(x_2)$; we can represent $\mu(x_l)=\cos\theta_l$ and thus $x_l=e^{i\theta_l}$ for some real θ_l $(l=1,2)$. The purpose is now to integrate Eq. (6.15) so as to obtain an explicit form for $v^{(k_1k_2)k_1+k_2+j}(x_1,z_1,z_2)$ for $j=0$. Let

$$(a,b,c,d)=(q^{k_1}x_1,q^{k_1}/x_1,q^{k_2}s,q^{k_2}/s). \tag{8.2}$$

If we assume that $q^{k_2}<|s|<q^{-k_2}$, then $\max\{|a|,|b|,|c|,|d|\}<1$, and the Askey–Wilson polynomial in (6.15) has an absolute continuous measure. Using the notation

$$h(x;a)=h(x;a;q)=(ae^{i\theta},ae^{-i\theta};q)_\infty \quad \text{for } x=\cos\theta, \tag{8.3}$$

and

$$h(x;a,b,c,d)=h(x;a)h(x;b)h(x;c)h(x;d), \tag{8.4}$$

the weight function for the Askey–Wilson polynomials reads (Ref. 12, §7.5)

$$w(x)\equiv w(x;a,b,c,d)=\frac{h(x;1,-1,q^{1/2},q^{-1/2})}{\sqrt{1-x^2}h(x;a,b,c,d)}. \tag{8.5}$$

The orthogonality relation for $p_n(x)\equiv p_n(x;a,b,c,d|q)$ is

$$\int_{-1}^{1}p_m(x)p_n(x)w(x)dx=\frac{\delta_{m,n}}{h_n}, \tag{8.6}$$

where

$$h_n=h_0\frac{(abcdq^{-1};q)_n(1-abcdq^{2n-1})}{(1-abcdq^{-1})(q,ab,ac,ad,bc,bd,cd;q)_n}, \tag{8.7}$$

and

$$h_0=\frac{(q,ab,ac,ad,bc,bd,cd;q)_\infty}{2\pi(abcd;q)_\infty}. \tag{8.8}$$

It thus follows from (6.15) that

$$v^{(k_1k_2)k_1+k_2}(x_1,z_1,z_2)=h_0\int_{-1}^{1}w(\mu(x_2);a,b,c,d)v^{k_1;k_2}(x_1,x_2,z_1,z_2)d\mu(x_2). \tag{8.9}$$

Using the explicit form (8.1), the notation

$$f=z_2, \quad g=q^{k_1}z_1, \tag{8.10}$$

and writing $\mu(x_2)=t$, (8.9) becomes

$$v^{(k_1k_2)k_1+k_2}(x_1,z_1,z_2)=h_0\frac{(cf,df;q)_\infty}{(g/a,g/b;q)_\infty}\int_{-1}^{1}\frac{h(t;g)}{h(t;f)}w(t;a,b,c,d)dt. \tag{8.11}$$

The last integral is a known one; in Ref. 12 it is denoted by $J(a,b,c,d,f,g)$, and shown to be equal to a ${}_8W_7$ series, i.e., a very-well-poised ${}_8\varphi_7$ series. Using eq. (6.3.8) of Ref. 12, we obtain

$$v^{(k_1k_2)k_1+k_2}(x_1,z_1,z_2)$$
$$=\frac{(ag,bg,cg,df,abcf;q)_\infty}{(af,bf,g/a,g/b,abcg;q)_\infty}\,{}_8W_7(abcgq^{-1};ab,ac,bc,g/d,g/f;q,df). \quad (8.12)$$

Let us now consider the other form of $v^{(k_1k_2)k_1+k_2}(x_1,z_1,z_2)$, given by (6.14). Using (7.8) and definition (6.10), one finds

$$\begin{aligned} v^{(k_1k_2)k_1+k_2}(x_1,z_1,z_2)&=\sum_{n=0}^{\infty}\frac{s_n(\mu(x_1);q^{k_1+k_2}s,q^{k_1+k_2}/s|q)}{\sqrt{(q,q^{2k_1+2k_2};q)_n}}e_n^{(k_1k_2)k_1+k_2}(z_1,z_2)\\ &=\sum_{n=0}^{\infty}\frac{(q^{2k_1+2k_2};q)_n}{(q;q)_n}(q^{-2k_1-k_2}z_2/s)^n\\ &\quad\times{}_3\varphi_2\left[\begin{matrix}q^{-n},q^{k_1+k_2}sx_1,q^{k_1+k_2}s/x_1\\ q^{2k_1+2k_2},0\end{matrix};q,q\right]\\ &\quad\times{}_3\varphi_2\left[\begin{matrix}q^{-n},q^{2k_1},q^{k_1}z_1/z_2\\ q^{2k_1+2k_2},0\end{matrix};q,q\right], \end{aligned} \quad (8.13)$$

or, putting all this in the notation of (8.2) and (8.10),

$$v^{(k_1k_2)k_1+k_2}(x_1,z_1,z_2)=\sum_{n=0}^{\infty}\frac{(abcd;q)_n}{(q;q)_n}\left(\frac{f}{abc}\right)^n{}_3\varphi_2\left[\begin{matrix}q^{-n},ac,ad\\ abcd,0\end{matrix};q,q\right]{}_3\varphi_2\left[\begin{matrix}q^{-n},ab,g/f\\ abcd,0\end{matrix};q,q\right]. \quad (8.14)$$

Equating (8.14) and (8.12) gives the q-analog of (5.5). Relabelling all the variables, it can be written in the following form:

Proposition 4:

$$\sum_{n=0}^{\infty}{}_3\varphi_2\left[\begin{matrix}q^{-n},a,b\\ f,0\end{matrix};q,q\right]{}_3\varphi_2\left[\begin{matrix}q^{-n},c,d\\ f,0\end{matrix};q,q\right]\frac{(f;q)_n}{(q;q)_n}z^n$$
$$=\frac{(abcz,abdz,acdz,bcdz,fz;q)_\infty}{(acz,bcz,adz,bdz,abcdz;q)_\infty}\,{}_8W_7(abcdzq^{-1};a,b,c,d,abcdz/f;q,fz). \quad (8.15)$$

This formula is the (symmetric) Poisson kernel for Al-Salam–Chihara polynomials, and was derived earlier by classical methods in Ref. 19, (14.8), and Ref. 20. As far as we know, this is the first group theoretical derivation of it.

IX. OTHER su(1,1) REALIZATIONS AND THEIR CONSEQUENCES

In this section two different realizations of su(1,1) and its positive discrete series representations will be considered. For the realization considered so far, the typical feature is that the basis functions $e_n^{(k)}$ are simply monomials z^n. Here, the basis functions will have a more complicated form, and the q-analog will not be treated.

Before turning to the realization, it is useful to observe some realization-independent facts. In Sec. II, the operator X_c $(0<c<1)$ was introduced, and from Table I one can see that its spectrum is identical to that of J_0 apart from the factor $(c-1/c)$. So one can expect that X_c and J_0 are related through a unitary transformation, and this is indeed the case. For $0<c<1$, let $\alpha>0$ be defined through

$$e^{\alpha}=\frac{1+c}{1-c}, \quad (9.1)$$

or, inversely,

$$c=\frac{e^{\alpha}-1}{e^{\alpha}+1}. \tag{9.2}$$

Defining, as usual,

$$J_1=\frac{1}{2}(J_+ + J_-), \quad J_2=\frac{1}{2i}(J_+ - J_-) \tag{9.3}$$

in terms of the su(1,1) basis (2.1), it is well known that the following identity holds [Ref. 1, eq. (97)]:

$$\exp(i\alpha J_2)J_0 \exp(-i\alpha J_2)=(\cosh\ \alpha)J_0-(\sinh\ \alpha)J_1. \tag{9.4}$$

This equation can also be obtained by applying the ''unitary trick'' $J_x\to iJ_1$, $J_y\to iJ_2$, $J_z\to J_0$, $\theta\to i\alpha$ to the su(2) relation $\exp(-i\theta J_y)J_z \exp(i\theta J_y)=(\sin\theta)J_x+(\cos\theta)J_z$ [see Ref. 21, eq. (D.10)]. Then it follows from (2.6) and the above relation between c and α that

$$X_c=(c-1/c)\exp(i\alpha J_2)J_0 \exp(-i\alpha J_2). \tag{9.5}$$

Acting with this equation on the formal eigenvectors $v^{(k)}(m)$ of X_c yields

$$J_0 \exp(-i\alpha J_2)v^{(k)}(m)=(k+m)\exp(-i\alpha J_2)v^{(k)}(m). \tag{9.6}$$

Thus, up to a normalization factor N_m, these elements must coincide with the eigenvectors $e_m^{(k)}$ of J_0, leading to

$$\exp(i\alpha J_2)e_m^{(k)}=N_m v^{(k)}(m). \tag{9.7}$$

In other words, using (2.3), Table I, and the orthogonality for Meixner polynomials, this yields

$$\exp(i\alpha J_2)e_m^{(k)}=\phi_m\sum_{n=0}^{\infty}(1-c^2)^k c^{m+n}\sqrt{\frac{(2k)_m(2k)_n}{m!n!}}\,M_n(m;2k;c^2)e_n^{(k)}, \tag{9.8}$$

where ϕ_m is a phase factor ($|\phi_m|=1$). This relation is realization independent, and for particular realizations it leads to interesting identities. First it should be noted that for the realization of Sec. III, the explicit form of $\exp(i\alpha J_2)e_m^{(k)}$ becomes rather complicated and (9.8) does not reduce to a simple relation. Here, we shall give two different realizations for which (9.8) implies an interesting relation.

First, let $w\geqslant 1$, $r\in(0,\infty)$ and $p_r=-i(d/dr+1/r)$. In Ref. 1 eq. (75), the following realization of su(1,1) is considered:

$$\begin{aligned} J_1&=\tfrac{1}{2}(w^{-2}r^{2-w}p_r^2+\xi r^{-w}-r^w),\\ J_2&=w^{-1}(rp_r-i(w-1)/2),\\ J_0&=\tfrac{1}{2}(w^{-2}r^{2-w}p_r^2+\xi r^{-w}+r^w). \end{aligned} \tag{9.9}$$

These provide a realization of the su(1,1) basis which are Hermitian under the scalar product

$$\langle f,g\rangle=\int_0^{\infty} f^*(r)g(r)r^w\,dr. \tag{9.10}$$

More precisely, $\mathscr{D}^+(k)$ consist of functions of r that are integrable with respect to the above measure, and (9.9) forms a realization of the su(1,1) basis in this representation $\mathscr{D}^+(k)$ provided

$$\xi=k(k-1)-W(W-1), \quad \text{where} \quad W=\frac{w+1}{2w}. \tag{9.11}$$

The normalized eigenfunctions $e_m^{(k)}$ of J_0 are given by

$$e_m^{(k)}=2^W\sqrt{\frac{wm!}{\Gamma(2k+m)}}\exp(-r^w)(2r^w)^{k-W}L_m^{(2k-1)}(2r^w), \tag{9.12}$$

in terms of the Laguerre polynomials (2.7) [see Ref. 1, eq. (89)]. An advantage of this realization is that J_2 is a linear combination of rd/dr, and hence $\exp(i\alpha J_2)$ acting on a function of r takes a simple form, i.e.,

$$\exp(i\alpha J_2)f(r)=e^{\alpha W}f(e^{\alpha/w}r). \tag{9.13}$$

Using all this information, (9.8) becomes

$$\frac{m!}{(2k)_m}\exp(-e^{\alpha}r^w)e^{\alpha k}L_m^{(2k-1)}(2e^{\alpha}r^w)$$

$$=\phi_m\sum_{n=0}^{\infty}(1-c^2)^k c^{n+m}M_n(m;2k;c^2)\exp(-r^w)L_n^{(2k-1)}(2r^w). \tag{9.14}$$

Making the replacements

$$x=2r^w,\quad \rho=e^{\alpha}>1,\quad a=2k-1, \tag{9.15}$$

and keeping in mind the relation (9.2), (9.14) takes a simpler form. In fact, rather than leaving this as an infinite series expression in terms of Laguerre polynomials, it is more convenient to integrate with respect to the orthogonality measure of Laguerre polynomials and then obtain the equivalent expression:

Corollary 5: For $\rho>1$ and $a>-1$,

$$\int_0^{\infty}L_m^{(a)}(\rho x)L_n^{(a)}(x)\exp(-(\rho+1)x/2)x^a dx$$

$$=(-1)^m\frac{\Gamma(a+n+1)}{n!}\frac{(a+1)_m}{m!}\left(\frac{2}{\rho+1}\right)^{a+1}\left(\frac{\rho-1}{\rho+1}\right)^{n+m}M_n\left(m;a+1;\left(\frac{\rho-1}{\rho+1}\right)^2\right). \tag{9.16}$$

The fact that the phase factor ϕ_m is equal to $(-1)^m$ can easily be derived from the case $n=0$. Although we have not found (9.16) in the literature, it is perhaps not new, and it can probably be derived by classical methods as well. Nevertheless, in our treatment it does not require any extra work to derive it, and the appearance of a Meixner polynomial on the rhs of (9.16) has a natural explanation.

As a second example of a different realization, we shall consider the well-known boson realization of su(1,1) (see also Ref. 1). In terms of the annihilation and creation operators

$$a=\frac{1}{\sqrt{2}}\left(x+\frac{d}{dx}\right),\quad a^{\dagger}=\frac{1}{\sqrt{2}}\left(x-\frac{d}{dx}\right), \tag{9.17}$$

we have the realization

$$J_1=\tfrac{1}{4}((a^{\dagger})^2+a^2),\quad J_2=\tfrac{1}{4i}((a^{\dagger})^2-a^2),\quad J_0=\tfrac{1}{4}(aa^{\dagger}+a^{\dagger}a). \tag{9.18}$$

The representation space is $L_2(\mathbb{R})$, with inner product $\langle f,g\rangle=\int f^*(x)g(x)dx$. This corresponds to the positive discrete series representation $\mathscr{D}^+(1/4)$, so $k=1/4$. The normalized eigenvectors $e_n^{(1/4)}$ are given by

$$e_n^{(1/4)} = \frac{1}{\pi^{1/4} 2^n \sqrt{(2n)!}} \exp(-x^2/2) H_{2n}(x), \tag{9.19}$$

with $H_n(x)$ the usual notation for Hermite polynomials (Ref. 22, §22). Since also for this realization J_2 is a linear combination of xd/dx, the simple relation

$$\exp(i\alpha J_2) f(x) = e^{-\alpha/4} f(e^{-\alpha/2} x) \tag{9.20}$$

holds. Plugging all this information in (9.8) gives an expression similar to (9.14), but with Hermite polynomials instead of Laguerre polynomials. Replacing herein $e^{-\alpha/2}$ by λ, and going to the equivalent form in terms of an integral, this result can be expressed as follows:

Corollary 6:

$$\int_{-\infty}^{\infty} H_{2m}(\lambda x) H_{2n}(x) \exp(-(\lambda^2+1)x^2/2) dx$$
$$= (-1)^m \sqrt{\frac{2\pi}{1+\lambda^2}} \left(\frac{1-\lambda^2}{1+\lambda^2}\right)^{n+m} \frac{(2m)!(2n)!}{m!n!} M_n\left(m; 1/2; \left(\frac{1-\lambda^2}{1+\lambda^2}\right)^2\right). \tag{9.21}$$

The phase factor ϕ_m is again easily derived. Again we have not found (9.21) in the literature. Although it can be derived by classical methods, here it has required no extra work.

With the two different realizations considered in this section, the analysis can be continued. For example, another interesting equation is the realization of (2.13) in terms of the above Laguerre polynomials.

In the case of the quantum algebra $U_q(\mathrm{su}(1,1))$, similar developments can be made provided one can find sufficiently simple realizations in terms of q-difference operators and q-special functions.

To conclude, using the explicit knowledge of the expansion coefficients of the eigenstates of a general Hamiltonian in terms of the J_0 eigenstates, we have deduced a number of identities for orthogonal polynomials. By choosing a realization for which the J_0 eigenstates coincide with monomials z^n, generating functions or Poisson kernels were derived. Considering the q-analog of this realization, the Poisson kernel for Al-Salam–Chihara polynomials is found. Finally, we have shown that different realizations for the su(1,1) case give rise to explicit formulas for integrals over orthogonal polynomials expressed as a Meixner polynomial.

ACKNOWLEDGMENTS

Achim Kempf
Department of Applied Mathematics and Theoretical Physics, University of Cambridge, Cambridge CB3 9EW, United Kingdom

(Received 13 February 1998; accepted for publication 18 May 1998)

We study the leading corrections to the emergent canonical commutation relations arising in the statistical mechanics of matrix models, by deriving several related Ward identities, and give conditions for these corrections to be small. We show that emergent canonical commutators are possible only in matrix models in complex Hilbert space for which the numbers of fermionic and bosonic fundamental degrees of freedom are equal, suggesting that supersymmetry will play a crucial role. Our results simplify, and sharpen, those obtained earlier by Adler and Millard. © *1998 American Institute of Physics.* [S0022-2488(98)03310-6]

I. INTRODUCTION

It is widely believed that at distances of order the Planck length $\ell_P \sim 10^{-33}$ cm our conventional notions of the geometry of space–time break down, as a result of quantum gravity effects. One indication of the modifications in physics that might be expected is provided by string theory models of quantum gravity, in which several studies suggest a modification of the uncertainty relation of the form[1]

$$\Delta x \Delta p \geqslant \frac{\hbar}{2}[1+\beta(\Delta p)^2+\cdots], \quad \beta>0, \tag{1a}$$

implying a finite minimum uncertainty $\Delta x_0 = \hbar\beta^{1/2}$ in the vicinity of the Planck length. As discussed by Kempf and collaborators,[2] Eq. (1a) corresponds to a correction to the Heisenberg canonical commutation relations of the form

$$[x,p] = i\hbar(1+\beta p^2+\cdots). \tag{1b}$$

We wish in this paper to discuss modifications of the Heisenberg algebra arising in another context, that of the statistical mechanics of matrix models, and to compare them with Eqs. (1a, 1b). Several years ago, Adler proposed a set of rules for a generalized quantum or trace dynamics, which is a Lagrangian and Hamiltonian mechanics with arbitrary noncommutative phase space variables q, p, and this was developed in a series of papers with various collaborators.[3] For theories in which the action is constructed as the trace of a sum of matrix products of $N\times N$ matrix variables, trace dynamics gives a powerful, basis independent, way of representing the same dynamics that can also be described in terms of the N^2 individual matrix elements. A significant new result emerging from this point of view was obtained by Adler and Millard,[4] who argued that the *statistical mechanics* of trace dynamics takes the form of conventional quantum field theory, with the Heisenberg commutation relations holding for statistical averages over certain effective canonical variables obtained by projection from the original operator canonical variables. Recently, it has become clear[5] that the underlying assumptions of trace dynamics are satisfied by

matrix models, for which the methods of trace dynamics provide a very convenient calculational tool. Hence the results of Adler and Millard can be reinterpreted as providing a statistical mechanics of matrix models, and showing that thermal averages in this statistical mechanics can behave as Wightman functions in an emergent local quantum field theory. These results, together with recent work[6] suggesting that the underlying dynamics for string theory may be a form of a matrix model, raise in turn the question of determining the form of the leading corrections to the Heisenberg algebra implied by the statistics of matrix models, formulating conditions for these corrections to be small, and seeing whether they can be related to the string theory result of Eqs. (1a, 1b).

An investigation of these questions is the focus of this paper, which is organized as follows. In Sec. II we give a brief synopsis of the rules of trace dynamics in the context of matrix models. We show that the conservation of the operator[4,7] $\tilde{C}$ can be understood as a simple consequence of unitary invariance. We also remark that, with Grassmann fermions, $\tilde{C}$ is independent of the classical parts of the matrix phase space variables, and review the statistical mechanics[4,8] of matrix models. In Sec. III we consider the simple case of a bosonic matrix model with Hamiltonian quadratic in the canonical momenta, and, making no approximations, derive a simplified form of the Ward identity used in Ref. 4 to obtain the effective canonical algebra. This analysis shows that there are corrections to the canonical commutator quadratic in the canonical momentum. In Sec. IV we use the symplectic formalism of Ref. 4 to repeat this calculation in the case of a general commutator/anticommutator of canonical variables in a generic matrix model, that can include fermions, and we generalize the treatment of Ref. 4 to allow nonzero sources for the classical parts of the matrix variables. From the analyses of Secs. III and IV, we formulate conditions for the corrections to the emergent canonical algebra to be small. We show that these conditions require $\tilde{C}$ to be an intensive rather than extensive thermodynamic quantity, and that they can be satisfied in complex Hilbert space (if at all) only in matrix models with precisely equal numbers of bosonic and fermionic degrees of freedom. This result strongly suggests that candidate matrix models for prequantum mechanics should be supersymmetric. We conclude by generalizing the conditions to ones that permit the recovery of the full emergent quantum field theory structure derived in Ref. 4. We also compare the prequantum corrections to the canonical algebra derived in Secs. III and IV, in which (as is usual in field theories) the spatial coordinate is simply a label, and the field variables are the dynamical canonical variables, to the string theory inspired expression of Eq. (1b) in which x is a coordinate operator.

II. THE STATISTICAL MECHANICS OF MATRIX MODELS

We begin by reviewing the statistical mechanics of trace dynamics, taking into account the simplifications[5] that become possible when Grassmann algebras are employed to represent the fermion/boson distinction. Let B_1 and B_2 be two $N\times N$ matrices with matrix elements that are even grade elements of a complex Grassmann algebra, and Tr the ordinary matrix trace, which obeys the cyclic property

$$\mathrm{Tr}\ B_1B_2=\sum_{m,n}(B_1)_{mn}(B_2)_{nm}=\sum_{m,n}(B_2)_{nm}(B_1)_{mn}=\mathrm{Tr}\ B_2B_1. \tag{2a}$$

Similarly, let χ_1 and χ_2 be two $N\times N$ matrices with matrix elements that are odd grade elements of a complex Grassmann algebra, which anticommute rather than commute, so that the cyclic property for these takes the form

$$\mathrm{Tr}\ \chi_1\chi_2=\sum_{m,n}(\chi_1)_{mn}(\chi_2)_{nm}=-\sum_{m,n}(\chi_2)_{nm}(\chi_1)_{mn}=-\mathrm{Tr}\ \chi_2\chi_1. \tag{2b}$$

The cyclic/anticyclic properties of Eqs. (2a, 2b) are just those assumed for the trace operation **Tr** of trace dynamics. [In Refs. 3 and 4 the fermionic operators were realized as ordinary matrices with complex matrix elements, all of which anticommute with a grading operator $(-1)^F$ which formed part of the definition of the graded trace **Tr**, for which fermions then obeyed Eq. (2b) while bosons obeyed Eq. (2a). Since the use of Grassmann odd fermions eliminates the need for

the inclusion of the $(-1)^F$ factor, the graded trace obeying Eqs. (2a, 2b) is just the usual matrix trace, for which we use the customary notation Tr.] From Eqs. (2a, 2b), one immediately derives the trilinear cyclic identities

$$\begin{aligned}
&\mathrm{Tr}\ B_1[B_2,B_3]=\mathrm{Tr}\ B_2[B_3,B_1]=\mathrm{Tr}\ B_3[B_1,B_2],\\
&\mathrm{Tr}\ B_1\{B_2,B_3\}=\mathrm{Tr}\ B_2\{B_3,B_1\}=\mathrm{Tr}\ B_3\{B_1,B_2\},\\
&\mathrm{Tr}\ B\{\chi_1,\chi_2\}=\mathrm{Tr}\ \chi_1[\chi_2,B]=\mathrm{Tr}\ \chi_2[\chi_1,B],\\
&\mathrm{Tr}\ \chi_1\{B,\chi_2\}=\mathrm{Tr}\{\chi_1,B\}\chi_2=\mathrm{Tr}[\chi_1,\chi_2]B,
\end{aligned} \tag{2c}$$

which are used repeatedly in trace dynamics calculations.

The basic observation of trace dynamics is that given the trace of a polynomial P constructed from noncommuting matrix or operator variables (we shall use the terms ''matrix'' and ''operator'' interchangeably in the following discussion), one can define a derivative of the c-number Tr P with respect to an operator variable $\mathcal{O}$ by varying and then cyclically permuting so that in each term the factor $\delta\mathcal{O}$ stands on the right, giving the fundamental definition

$$\delta\ \mathrm{Tr}\ P=\mathrm{Tr}\ \frac{\delta\ \mathrm{Tr}\ P}{\delta\mathcal{O}}\ \delta\mathcal{O}, \tag{3a}$$

or in the condensed notation that we shall use throughout this paper, in which $\mathbf{P}\equiv\mathrm{Tr}\ P$,

$$\delta\mathbf{P}=\mathrm{Tr}\ \frac{\delta\mathbf{P}}{\delta\mathcal{O}}\ \delta\mathcal{O}. \tag{3b}$$

Letting $\mathbf{L}[\{q_r\},\{\dot{q}_r\}]$ be a trace Lagrangian that is a function of the bosonic or fermionic operators $\{q_r\}$ and their time derivatives (which are all assumed to obey the cyclic relations of Eqs. (2a-2c) under the trace), and requiring that the trace action $\mathbf{S}=\int dt\mathbf{L}$ be stationary with respect to variations of the q_r's that preserve their bosonic or fermionic type, one finds[3] the operator Euler-Lagrange equations

$$\frac{\delta\mathbf{L}}{\delta q_r}-\frac{d}{dt}\frac{\delta\mathbf{L}}{\delta\dot{q}_r}=0. \tag{3c}$$

Because, by the definition of Eq. (3a), we have

$$\left(\frac{\delta\mathbf{L}}{\delta q_r}\right)_{ij}=\frac{\partial\mathbf{L}}{\partial(q_r)_{ji}}, \tag{3d}$$

for each r the single Euler-Lagrange equation of Eq. (3c) is equivalent to the N^2 Euler-Lagrange equations obtained by regarding $\mathbf{L}$ as a function of the N^2 matrix element variables $(q_r)_{ji}$. Defining the momentum operator p_r conjugate to q_r, which is of the same bosonic or fermionic type as q_r, by

$$p_r\equiv\frac{\delta\mathbf{L}}{\delta\dot{q}_r}, \tag{4a}$$

the trace Hamiltonian $\mathbf{H}$ is defined by

$$\mathbf{H}=\mathrm{Tr}\sum_r\ p_r\dot{q}_r-\mathbf{L}. \tag{4b}$$

In correspondence with Eq. (3d), the matrix elements $(p_r)_{ij}$ of the momentum operator p_r just correspond to the momenta canonical to the matrix element variables $(q_r)_{ji}$. Performing general

same-type operator variations, and using the Euler-Lagrange equations, we find from Eq. (4b) that the trace Hamiltonian **H** is a trace functional of the operators $\{q_r\}$ and $\{p_r\}$,

$$\mathbf{H}=\mathbf{H}[\{q_r\},\{p_r\}], \tag{5a}$$

with the operator derivatives

$$\frac{\delta \mathbf{H}}{\delta q_r}=-\dot{p}_r\,,\quad \frac{\delta \mathbf{H}}{\delta p_r}=\epsilon_r \dot{q}_r\,, \tag{5b}$$

with $\epsilon_r=1(-1)$ according to whether $q_r\,,p_r$ are bosonic (fermionic). Letting **A** and **B** be two trace functions of the operators $\{q_r\}$ and $\{p_r\}$, it is convenient to define the *generalized Poisson bracket*

$$\{\mathbf{A},\mathbf{B}\}=\mathrm{Tr}\sum_r\ \epsilon_r\left(\frac{\delta \mathbf{A}}{\delta q_r}\frac{\delta \mathbf{B}}{\delta p_r}-\frac{\delta \mathbf{B}}{\delta q_r}\frac{\delta \mathbf{A}}{\delta p_r}\right). \tag{6a}$$

Then using the Hamiltonian form of the equations of motion, one readily finds that for a general trace functional $\mathbf{A}[\{q_r\},\{p_r\}]$, the time derivative is given by

$$\frac{d}{dt}\,\mathbf{A}=\{\mathbf{A},\mathbf{H}\}; \tag{6b}$$

in particular, letting **A** be the trace Hamiltonian **H**, and using the fact that the generalized Poisson bracket is antisymmetric in its arguments, it follows that the time derivative of **H** vanishes. An important property of the generalized Poisson bracket is that it satisfies[3] the Jacobi identity,

$$\{\mathbf{A},\{\mathbf{B},\mathbf{C}\}\}+\{\mathbf{C},\{\mathbf{A},\mathbf{B}\}\}+\{\mathbf{B},\{\mathbf{C},\mathbf{A}\}\}=0. \tag{6c}$$

As a consequence, if $\mathbf{Q}_1$ and $\mathbf{Q}_2$ are two conserved charges, that is if

$$0=\frac{d}{dt}\,\mathbf{Q_1}=\{\mathbf{Q_1},\mathbf{H}\},\quad 0=\frac{d}{dt}\,\mathbf{Q_2}=\{\mathbf{Q_2},\mathbf{H}\}, \tag{6d}$$

then their generalized Poisson bracket $\{\mathbf{Q_1},\mathbf{Q_2}\}$ also has a vanishing generalized Poisson bracket with **H**, and is conserved. This has the consequence that Lie algebras of symmetries can be represented as Lie algebras of trace functions under the generalized Poisson bracket operation.

A significant feature of trace dynamics is that, as discovered by Millard,[7] the anti-self-adjoint operator[7,4]

$$\tilde{C}\equiv \sum_{r\ \text{bosons}}[q_r\,,p_r]-\sum_{r\ \text{fermions}}\{q_r\,,p_r\} \tag{7}$$

is conserved by the dynamics. As we shall now show, conservation of $\tilde{C}$ holds whenever the trace dynamics has a global unitary invariance, that is, whenever the trace Hamiltonian obeys

$$\mathbf{H}[\{U^\dagger q_r U\},\{U^\dagger p_r U\}]=\mathbf{H}[\{q_r\},\{p_r\}] \tag{8a}$$

for a constant unitary $N\times N$ matrix U, or equivalently, by Eq. (4b), whenever the trace Lagrangian obeys

$$\mathbf{L}[\{U^\dagger q_r U\},\{U^\dagger \dot{q}_r U\}]=\mathbf{L}[\{q_r\},\{\dot{q}_r\}]. \tag{8b}$$

Letting $U=\exp\Lambda$, with Λ an anti-self-adjoint bosonic generator matrix, and expanding to first order in Λ, Eq. (8a) implies that

$$\mathbf{H}[\{q_r-[\Lambda,q_r]\},\{p_r-[\Lambda,p_r]\}]=\mathbf{H}[\{q_r\},\{p_r\}]. \tag{9a}$$

But applying the definition of the variation of a trace functional given in Eq. (3b), Eq. (9a) becomes

$$\mathrm{Tr}\sum_r \left(-\frac{\delta \mathbf{H}}{\delta q_r}[\Lambda, q_r] - \frac{\delta \mathbf{H}}{\delta p_r}[\Lambda, p_r]\right) = 0, \tag{9b}$$

which by use of the trilinear cyclic identities of Eq. (2c) yields

$$\mathrm{Tr}\ \Lambda \sum_r \left(\frac{\delta \mathbf{H}}{\delta q_r} q_r - \epsilon_r q_r \frac{\delta \mathbf{H}}{\delta q_r} + \frac{\delta \mathbf{H}}{\delta p_r} p_r - \epsilon_r p_r \frac{\delta \mathbf{H}}{\delta p_r}\right) = 0. \tag{9c}$$

Since the generator Λ is an arbitrary anti-self-adjoint $N \times N$ matrix, the anti-self-adjoint matrix that multiplies it in Eq. (9c) must vanish, giving the matrix identity

$$\sum_r \left(\frac{\delta \mathbf{H}}{\delta q_r} q_r - \epsilon_r q_r \frac{\delta \mathbf{H}}{\delta q_r} + \frac{\delta \mathbf{H}}{\delta p_r} p_r - \epsilon_r p_r \frac{\delta \mathbf{H}}{\delta p_r}\right) = 0. \tag{10a}$$

But now substituting the Hamilton equations of Eq. (5b), Eq. (10a) takes the form

$$\begin{aligned} 0 &= \sum_r \ (-\dot{p}_r q_r + \epsilon_r q_r \dot{p}_r + \epsilon_r \dot{q}_r p_r - p_r \dot{q}_r) \\ &= \frac{d}{dt} \sum_r \ (-p_r q_r + \epsilon_r q_r p_r) \\ &= \frac{d}{dt} \left(\sum_{r\ \mathrm{bosons}} [q_r, p_r] - \sum_{r\ \mathrm{fermions}} \{q_r, p_r\} \right), \end{aligned} \tag{10b}$$

completing the demonstration of the conservation of $\tilde{C}$.

Corresponding to the fact that $\tilde{C}$ is conserved in any matrix model with a global unitary invariance, it is easy to see[4,8] that $\tilde{C}$ can be used to construct the generator of global unitary transformations of the Hilbert space basis. Consider the trace functional

$$\mathbf{G}_\Lambda = -\mathrm{Tr}\ \Lambda \tilde{C}, \tag{11a}$$

with Λ a fixed bosonic anti-self-adjoint operator, which can be rewritten, using cyclic invariance of the trace, as

$$\mathbf{G}_\Lambda = \mathrm{Tr}\sum_r \ [\Lambda, p_r] q_r = -\mathrm{Tr}\sum_r \ p_r [\Lambda, q_r]. \tag{11b}$$

Hence for the variations of p_r and q_r induced by $\mathbf{G}_\Lambda$ as canonical generator, which have a structure analogous to the Hamilton equations of Eq. (5b), we get

$$\delta p_r = -\frac{\delta \mathbf{G}_\Lambda}{\delta q_r} = -[\Lambda, p_r], \quad \delta q_r = \epsilon_r \frac{\delta \mathbf{G}_\Lambda}{\delta p_r} = -[\Lambda, q_r]. \tag{11c}$$

Comparing with Eqs. (8a) and (9a), we see that these have just the form of an infinitesimal global unitary transformation.

For each phase space variable q_r, p_r, let us define the *classical part* q_r^c, p_r^c and the noncommutative remainder q_r', p_r', by

$$q_r^c = \frac{1}{N}\mathrm{Tr}\ q_r, \quad p_r^c = \frac{1}{N}\mathrm{Tr}\ p_r, \quad q_r' = q_r - q_r^c, \ \ p_r' = p_r - p_r^c, \tag{12a}$$

so that bosonic q_r^c, p_r^c are *c*-numbers, fermionic q_r^c, p_r^c are Grassmann *c*-numbers (where by a *c*-number we mean a multiple of 1_N, the $N \times N$ unit matrix), and the remainders are traceless,

$$\mathrm{Tr}\ q_r' = \mathrm{Tr}\ p_r' = 0. \tag{12b}$$

Then since q_r^c, p_r^c commute (anticommute) with q_s', p_s' for r, s both bosonic (fermionic), we see that the classical parts of the phase space variables make no contribution to $\tilde{C}$, and Eq. (7) can be rewritten as

$$\tilde{C} = \sum_r \sum_{\text{bosons}} [q_r', p_r'] - \sum_r \sum_{\text{fermions}} \{q_r', p_r'\}. \tag{12c}$$

Thus $\tilde{C}$ is completely independent of the values of the classical parts of the matrix phase space variables.

Making the assumption that trace dynamics is ergodic (which undoubtedly requires an interacting as opposed to a free theory, and may presuppose taking the $N \to \infty$ limit), one can then analyze[4] the statistical mechanics of trace dynamics for the generic case in which the conserved quantities are the trace Hamiltonian **H** and the operator $\tilde{C}$. As discussed in detail in the second paper cited in Ref. 5, the analysis of Ref. 4 carries over to the case in which the fermions are represented by Grassmann matrices; the demonstration of a generalized Liouville theorem still holds, and the requirements for convergence of the partition function are much less stringent, eliminating the complexities addressed in Appendix F of Ref. 4. With Grassmann fermions, for the typical models we are studying the bosonic part of H is a positive operator, from which **H** inherits good positivity properties. The canonical ensemble then takes the simple form given in Eq. (48c) of Ref. 4,

$$\rho = Z^{-1} \exp(-\tau \mathbf{H} - \mathrm{Tr}\ \tilde{\lambda}\tilde{C}), \quad Z = \int d\mu \exp(-\tau \mathbf{H} - \mathrm{Tr}\ \tilde{\lambda}\tilde{C}), \tag{13}$$

with $d\mu$ the invariant matrix (or operator) phase space measure provided by Liouville's theorem, with τ a real number, and with $\tilde{\lambda}$ an anti-self-adjoint matrix that in the generic case (which we assume) has no zero eigenvalues. (Equation (13) can be derived directly[4] by maximizing the entropy subject to the constraints imposed by the conservation of **H** and $\tilde{C}$, or indirectly[8] by first calculating the corresponding microcanonical ensemble corresponding to these conserved quantities, and then using standard statistical physics methods to calculate the canonical ensemble from the microcanonical one.) We wish to make two points about the partition function defined in Eq. (13). First, it is not invariant under the unitary transformation of Eq. (8a) for fixed $\tilde{\lambda}$, but is invariant when $\tilde{\lambda}$ is simultaneously transformed to $U^\dagger \tilde{\lambda} U$; hence the partition function breaks unitary invariance, but has a specific form of unitary covariance. Second, the partition function contains a weighted sum over all possible commutators $[q_r, p_s]$ for bosonic variables and all possible anticommutators $\{q_r, p_s\}$ for fermionic variables; there is no restriction to the classical or quantum mechanical evaluation of these commutators/anticommutators as 0 or $i\delta_{rs}$ respectively. However, statistical integrals like Eq. (13) are typically dominated by specific regions of the integration domain, and we will see, by a study of the Ward identities following from Eq. (13), that this can lead to *effective* quantum mechanical commutators inside statistical averages. The structure of the Ward identities or equipartition theorems following from Eq. (13) will be reanalyzed in the next two sections without making approximations used in Ref. 4, so as to determine the leading corrections to the emergent canonical commutation relations. From this analysis we will infer a set of conditions for obtaining the full emergent quantum field theory structure of Ref. 4.

III. CORRECTIONS TO THE BOSONIC COMMUTATOR $[q_s, p_r]$ IN A SIMPLIFIED UNITARY INVARIANT MATRIX MODEL

We consider in this section the simplified bosonic matrix model with trace Hamiltonian

$$\mathbf{H} = \mathrm{Tr}\left[\sum_r \frac{1}{2} p_r^2 + V(\{q_r\})\right], \tag{14a}$$

with the q_r self-adjoint $N \times N$ complex matrix variables and with V a global unitary invariant potential. This form is general enough to include the matrix model forms of the bosonic field

theories of greatest interest, including the Goldstone model, non-Abelian gauge models, and the Higgs model. As we saw in the previous section, the Hamiltonian dynamics for this model conserves both the real number **H** and the matrix $\tilde{C}$, which in this case is given simply by

$$\tilde{C}=\sum_r [q_r,p_r]. \tag{14b}$$

Letting ρ and Z be respectively the canonical ensemble and partition function given in terms of **H** and $\tilde{C}$ by Eq. (13), we define the ensemble average of an arbitrary function $\mathcal{O}$ of the dynamical variables by

$$\langle \mathcal{O} \rangle_{AV}=\int d\mu \rho \mathcal{O}=Z^{-1}\int d\mu e^{-\tau \mathbf{H}-\mathrm{Tr}(\tilde{\lambda}\tilde{C})}\mathcal{O}. \tag{15}$$

Letting $\mathcal{O}$ be the conserved operator $\tilde{C}$, and noting that the right hand side of Eq. (13) can be a function only of the ensemble parameters $\tilde{\lambda}$ and τ, we have

$$\langle \tilde{C} \rangle_{AV}=f(\tilde{\lambda},\tau), \tag{16a}$$

with f an anti-self-adjoint matrix, which in general can be written as a phase matrix i_{eff} times a commuting magnitude matrix $|f|$,

$$f=i_{\mathrm{eff}}|f|, \quad i_{\mathrm{eff}}^2=-1, \quad i_{\mathrm{eff}}^\dagger=-i_{\mathrm{eff}}, \quad [i_{\mathrm{eff}},|f|]=0. \tag{16b}$$

We shall now specialize to an ensemble for which the magnitude matrix $|f|$ makes no distinction among the different bases in Hilbert space, and so takes the form of a positive real multiple (which we shall call $\hbar$) of the unit matrix. [As discussed in Appendix B of Ref. 4, when **H** can be expressed in terms of the phase space operators $\{q_r,p_r\}$ using only real number coefficients, this assumption implies that we are restricting attention to the special class of ensembles for which $\tilde{\lambda}=i_{\mathrm{eff}}\lambda$, with λ a real multiple of the unit matrix.] Equations (16a, 16b) then become

$$\langle \tilde{C} \rangle_{AV}=i_{\mathrm{eff}}\hbar. \tag{16c}$$

Since for finite N we necessarily have $\mathrm{Tr}\,\tilde{C}=0$, the phase matrix i_{eff} must have vanishing trace,

$$\mathrm{Tr}\, i_{\mathrm{eff}}=0, \tag{16d}$$

which implies that i_{eff} has $N/2$ eigenvalues i and $N/2$ eigenvalues $-i$. Thus, we are making a choice of ensemble for which the $U(N)$ symmetry of **H** is broken, by the term $\mathrm{Tr}\,\tilde{\lambda}\tilde{C}$, to $U(N/2)\times U(N/2)\times R$, with R the discrete reflection symmetry that interchanges the eigenvalues $\pm i$ of i_{eff}. This is clearly the largest symmetry group of the ensemble for which one can have $\langle \tilde{C} \rangle_{AV}\neq 0$; if one were to attempt to preserve the full $U(N)$ symmetry by taking an ensemble with $\tilde{\lambda}=i\lambda$, with λ a c-number, then in the canonical ensemble the term $\mathrm{Tr}\,\tilde{\lambda}\tilde{C}$ would vanish by virtue of the tracelessness of $\tilde{C}$, and the resulting ensemble would have $\langle \tilde{C} \rangle_{AV}=0$. Requiring the largest possible nontrivial symmetry group plays the role in our derivation of giving a single Planck constant for all pairs of canonical variables; if on the other hand, we were to sacrifice all of the $U(N)$ symmetry by allowing generic $\tilde{\lambda}$, then the emergent canonical commutation relations derived below would generically yield $N/2$ different $\hbar$'s for the $N/2$ pairs of canonical variables. It would clearly be desirable to have a deeper justification from first principles of our choice of ensemble, perhaps based on a more detailed understanding of the underlying dynamics, but at present we must simply introduce it as a postulate.

For this choice of ensemble, let us now consider the Ward identity obtained from

$$Z\langle \mathrm{Tr}\,\tilde{C}p_r \rangle_{AV}=\int d\mu e^{-\tau \mathbf{H}-\mathrm{Tr}\,\tilde{\lambda}\tilde{C}}\,\mathrm{Tr}\,\tilde{C}p_r, \tag{17a}$$

by using invariance of the measure $d\mu$ under a constant shift of p_s, which implies

$$0=\int d\mu\,\delta_{p_s}[e^{-\tau\mathbf{H}-\mathrm{Tr}\,\tilde{\lambda}\tilde{C}}\ \mathrm{Tr}\ \tilde{C}p_r]$$

$$=\int d\mu e^{-\tau\mathbf{H}-\mathrm{Tr}\,\tilde{\lambda}\tilde{C}}[(-\tau\delta_{p_s}\mathbf{H}-\mathrm{Tr}\ \tilde{\lambda}\delta_{p_s}\tilde{C})\mathrm{Tr}\ \tilde{C}p_r+\mathrm{Tr}(\delta_{p_s}\tilde{C})p_r+\mathrm{Tr}\ \tilde{C}\delta_{rs}\delta p_s]. \quad (17b)$$

Now from Eqs. (14a, 14b) we have

$$\delta_{p_s}\mathbf{H}=\mathrm{Tr}\ p_s\delta p_s,\ \ \delta_{p_s}\tilde{C}=[q_s,\delta p_s]. \quad (18)$$

Substituting these into Eq. (17b), multiplying by Z^{-1}, and using the trilinear cyclic identities of Eq. (2c), we get

$$0=\langle(-\tau\ \mathrm{Tr}\ p_s\delta p_s-\mathrm{Tr}[\tilde{\lambda},q_s]\delta p_s)\mathrm{Tr}\ \tilde{C}p_r+\mathrm{Tr}[p_r,q_s]\delta p_s+\mathrm{Tr}\ \tilde{C}\delta_{rs}\delta p_s\rangle_{AV}, \quad (19a)$$

which since δp_s is an arbitrary self-adjoint matrix, implies that the operator multiplying δp_s inside the trace must vanish,

$$0=\langle(-\tau p_s-[\tilde{\lambda},q_s])\mathrm{Tr}\ \tilde{C}p_r+[p_r,q_s]+\tilde{C}\delta_{rs}\rangle_{AV}. \quad (19b)$$

Since $\tilde{\lambda}$ is a constant matrix, it can be taken outside the ensemble average, and so the second term in Eq. (19b) takes the form

$$-[\tilde{\lambda},\langle q_s\ \mathrm{Tr}\ \tilde{C}p_r\rangle_{AV}], \quad (19c)$$

which vanishes since the ensemble average inside the commutator in Eq. (19c) is a matrix function only of $\tilde{\lambda}$ and τ, and hence commutes with $\tilde{\lambda}$. Substituting $p_r=p_r^c+p_r'$ into the term multiplied by τ in Eq. (19b), and using $\mathrm{Tr}\ \tilde{C}p_r^c=p_r^c\ \mathrm{Tr}\ \tilde{C}=0$, the traceless part of Eq. (19b) reduces to

$$0=\langle-\tau p_s'\ \mathrm{Tr}\ \tilde{C}p_r'+[p_r,q_s]+\tilde{C}\delta_{rs}\rangle_{AV}. \quad (20a)$$

Since $\langle\tilde{C}\rangle_{AV}=i_{\mathrm{eff}}\hbar$, this equation can be rewritten as the *exact* relation

$$\langle[q_s,p_r]\rangle_{AV}=i_{\mathrm{eff}}\hbar\,\delta_{rs}-\tau\langle p_s'\ \mathrm{Tr}\ \tilde{C}p_r'\rangle_{AV}, \quad (20b)$$

showing that the ensemble averaged commutator of the canonical coordinate and momentum operators has the form of the usual quantum mechanical canonical commutator, with i_{eff} playing the role of the imaginary unit, and with a correction term proportional to τ that is quadratic in the nonclassical parts of the canonical momenta. Using Eqs. (14b) and (16c), Eq. (20b) can also be written in the form

$$\sum_{t,u}\langle[q_t,p_u]\rangle_{AV}(\delta_{\mathrm{tr}}\delta_{us}-\delta_{\mathrm{tu}}\delta_{rs})=-\tau\langle p_s'\ \mathrm{Tr}\ \tilde{C}p_r'\rangle_{AV}. \quad (20c)$$

The derivation given here sharpens that given in Adler and Millard,[4] both in that here no approximations have been made, and that because we are working in complex Hilbert space, we have not had to first project out the parts of q_s and p_r that commute with i_{eff}. (As discussed in the Appendix, this projection is needed in real and quaternionic Hilbert space.)

Equation (20b) sets up a correspondence between two different matrix theories. The first is the underlying classical matrix dynamics following from the trace Hamiltonian equations of Eq. (5b), in which the $2N^2$ matrix elements of $\{q_r\},\{p_r\}$ can be regarded as dynamical variables. In this underlying matrix dynamics, $[q_s,p_r]$ is nonzero for $r\neq s$ and is a rapidly varying function over the matrix phase space. The second is the statistical thermodynamics of this underlying matrix dynamics, in which the fine details of the underlying dynamics have been averaged out. Equation (20b) shows that, when the τ term can be neglected, the *averaged* $[q_s,p_r]$ simplifies to $i_{\mathrm{eff}}\hbar\delta_{rs}$, which vanishes for $r\neq s$ and is a multiple of a constant operator over matrix phase space when $r=s$. Thus, this thermodynamics has a structure that corresponds to that of the Heisenberg matrix

mechanics form of quantum mechanics, with each canonical pair q_r, p_r corresponding to the Heisenberg picture matrices for one quantum mechanical degree of freedom.

The reduction or thinning from the $2N^2$ classical dynamical variables for each r corresponding to unrestricted matrix variables q_r, p_r in the underlying matrix theory, to the two canonical quantum matrix variables q_r, p_r in the statistical thermodynamics derived from the underlying theory, should not be surprising. It is completely analogous to the reduction in the number of degrees of freedom that occurs in the passage from classical molecular dynamics, where the molecular variables are all dynamical variables, to its thermodynamics, where the molecular dynamical variables have been averaged out. The surviving dynamics in classical thermodynamics reflects just the conservation laws of energy and particle number in the underlying molecular dynamics. Similarly, the structure of the matrix thermodynamics following from Eq. (20b) is governed by the conserved quantities $\mathbf{H}, \tilde{C}$ of the underlying matrix dynamics. As discussed at the end of Sec. IV and also on pp. 221–222 of Ref. 4, the correspondence of Eq. (20b) can be further generalized to show that, when the τ terms can be neglected, there is a one to one correspondence between thermodynamic averages over the underlying matrix dynamics with trace Hamiltonian $\mathbf{H} = \mathrm{Tr}\, H$, and the Wightman functions of the quantum field theory with operator Hamiltonian H. In this correspondence, as already noted, i_{eff} plays the role of the imaginary unit i, and the magnitude of $\langle \tilde{C} \rangle_{AV}$ plays the role of Planck's constant.

We conclude this section with several remarks on the principal result of Eq. (20b). First of all, the fluctuations about the ensemble average are fundamental to the possibility of emergent quantum behavior. The average of the commutator on the left hand side of Eq. (20b) is not the same as the commutator of the averages, which in fact vanishes since $\langle q_s \rangle_{AV}$ and $\langle p_r \rangle_{AV}$ are both functions only of τ and $\tilde{\lambda}$,

$$\langle [q_s, p_r] \rangle_{AV} \neq [\langle q_s \rangle_{AV}, \langle p_r \rangle_{AV}] = 0. \tag{21a}$$

Secondly, in order to have emergent quantum behavior, the dynamics must be such that the second term on the right hand side of Eq. (20b) is much smaller than the first term on the right hand side, that is, one must have

$$\hbar^{-1} \tau |\langle p_s' \ \mathrm{Tr}\ \tilde{C} p_r' \rangle_{AV}| \ll 1. \tag{21b}$$

We shall now show that this condition cannot be satisfied if $\tilde{C}$ is an extensive thermodynamic quantity that grows linearly with the size of the system. To see this, we note that a second Ward identity, similar in form to Eq. (20b), can be derived by starting from

$$0 = \int d\mu \, \delta_{p_s} [e^{-\tau \mathbf{H} - \mathrm{Tr}\, \tilde{\lambda} \tilde{C}} \ \mathrm{Tr}\ i_{\mathrm{eff}} \hbar p_r], \tag{22a}$$

in which the factor of $\tilde{C}$ multiplying p_r has been replaced by its ensemble average $i_{\mathrm{eff}} \hbar$, and then proceeding as in Eqs. (17b–20b) above. The resulting Ward identity is

$$0 = i_{\mathrm{eff}} \hbar \, \delta_{rs} - \tau \langle p_s' \ \mathrm{Tr}\ i_{\mathrm{eff}} \hbar p_r' \rangle_{AV}, \tag{22b}$$

and is an analog in our context of the usual equipartition theorem of classical statistical mechanics. Now if $\tilde{C}$ were an extensive quantity, the difference between $\tilde{C}$ and its ensemble average $i_{\mathrm{eff}} \hbar$ would be a fluctuation that vanishes as the system size becomes infinite, which would make it permissible to accurately approximate the right hand side of Eq. (20b) by the right hand side of Eq. (22b). This would lead to the conclusion $\langle [q_s, p_r] \rangle_{AV} = 0$, that is, the thermodynamics would give emergent classical, rather than quantum mechanical, behavior.

Thus, the inequality of Eq. (21b) can hold only if $\tilde{C}$ is not extensive; this conclusion is consistent with the observation that to have the average of $\tilde{C}$ play the role of the intensive quantity $i_{\mathrm{eff}} \hbar$, one would expect that $\tilde{C}$ should behave as a thermodynamically intensive quantity. We shall give further evidence for this conclusion in the next section, where we consider systems containing fermions as well as bosons.

Although we have first discussed the purely bosonic model of this section for expository reasons, it is easy to see from Eqs. (20b, 20c) that the inequality of Eq. (21b) cannot hold in a purely bosonic system. When the right hand side of Eq. (20c) can be neglected, multiplying by δ_{rs} and summing over r,s gives the relation

$$\sum_{t,u} \langle [q_t, p_u] \rangle_{AV} \delta_{tu}(1-N) = 0, \tag{22c}$$

which for $N>1$ implies that $\langle [q_s, p_r] \rangle_{AV} = 0$, again giving classical behavior. Thus, a purely bosonic matrix dynamics system in complex Hilbert space cannot have emergent quantum behavior. However, we shall see in the next section that in the interesting case in which the numbers of bosonic and fermionic degrees of freedom are equal, a condition that holds for supersymmetric theories, the relation of Eq. (22c) is modified, and emergent quantum behavior becomes possible.

IV. CORRECTIONS TO THE FULL CANONICAL ALGEBRA IN A GENERAL UNITARY INVARIANT MATRIX MODEL WITH CLASSICAL SOURCES

Although one can give derivations similar to that of the previous section for other canonical commutators (e.g., the $[p_r, p_s]$ and $[q_r, q_s]$ commutators, or the $[p_s, q_r]$ commutator obtained by interchanging the roles of p and q in the above derivation), and their fermionic anticommutator analogs, it is most efficient in the general case to use the symplectic formalism introduced by Adler and Millard in Ref. 4. In this notation one defines $x_1 = q_1$, $x_2 = p_1$, $x_3 = q_2$, $x_4 = p_2, \ldots$, $x_{2R-1} = q_R$, $x_{2R} = p_R$ for the matrix phase space variables; in terms of these, the Hamilton equations of Eq. (5b), the generalized Poisson bracket of Eq. (6a), and the conserved operator $\tilde{C}$ of Eq. (7) take the form

$$\dot{x}_r = \sum_{s=1}^{2R} \omega_{rs} \frac{\delta \mathbf{H}}{\delta x_s}, \quad \{\mathbf{A}, \mathbf{B}\} = \mathrm{Tr} \sum_{r,s=1}^{2R} \frac{\delta \mathbf{A}}{\delta x_r} \omega_{rs} \frac{\delta \mathbf{B}}{\delta x_s}, \quad \tilde{C} = \sum_{r,s} x_r \omega_{rs} x_s, \tag{23a}$$

with ω a numerical symplectic metric given (in terms of standard Pauli matrices $\tau_{1,2,3}$) by $i\tau_2$ for a bosonic pair of canonical variables, and by $-\tau_1$ for a fermionic canonical pair (see Eqs. (10a–10c) on p. 202, and Eqs. (10a′-10c′) on p. 224, of Ref. 4). This symplectic metric obeys[4] the useful identities

$$\omega_{sr} = -\epsilon_r \omega_{rs} = -\epsilon_s \omega_{rs}, \quad \sum_r \omega_{rs} \omega_{rt} = \sum_r \omega_{sr} \omega_{\mathrm{tr}} = \delta_{st}. \tag{23b}$$

We shall now consider a matrix dynamics generated by a general trace Hamiltonian $\mathbf{H}$, that can contain fermionic as well as bosonic degrees of freedom, and in the statistical partition function shall allow the presence of nonvanishing classical sources J_r^c for the classical parts x_r^c of the phase space variables [cf. Eqs. (12a–12c) above]. Thus we start from the ensemble

$$\rho = Z^{-1} \exp\left(-\tau \mathbf{H} - \mathrm{Tr}\, \tilde{\lambda} \tilde{C} - \sum_r J_r^c x_r^c \right), \quad Z = \int d\mu \exp\left(-\tau \mathbf{H} - \mathrm{Tr}\, \tilde{\lambda} \tilde{C} - \sum_r J_r^c x_r^c \right), \tag{24}$$

which is now used in place of the ensemble of Eq. (13) in the definition of $\langle \mathcal{O} \rangle_{AV}$ given in Eq. (15). For this ensemble, we consider the Ward identity obtained by using shift invariance of the integration measure $d\mu$ starting from

$$Z \langle \mathrm{Tr}\, \tilde{C} \sigma_t x_t' \rangle_{AV} = \int d\mu e^{-\tau \mathbf{H} - \mathrm{Tr}\, \tilde{\lambda} \tilde{C} - \Sigma_r J_r^c x_r^c} \mathrm{Tr}\, \tilde{C} \sigma_t x_t', \tag{25a}$$

where σ_t are a set of c-number auxiliary parameters that are complex for bosonic x_t, and complex Grassmann for fermionic x_t. As in Eqs. (12a, 12b) above, we use the notation x_t' to denote the noncommutative part of x_t that remains when the classical part is subtracted away, that is, $x_t' = x_t - x_t^c$.

The Ward identity derivation now proceeds exactly as in Eqs. (17b–20b). Making a constant shift of the noncommutative part x_s' of the phase space variable x_s, we have

$$0=\int d\mu\,\delta_{x_s'}[e^{-\tau\mathbf{H}-\mathrm{Tr}\,\tilde{\lambda}\tilde{C}-\Sigma_r J_r^c x_r^c}\,\mathrm{Tr}\,\tilde{C}\sigma_t x_t']$$

$$=\int d\mu e^{-\tau\mathbf{H}-\mathrm{Tr}\,\tilde{\lambda}\tilde{C}-\Sigma_r J_r^c x_r^c}$$

$$\times[(-\tau\delta_{x_s'}\mathbf{H}-\mathrm{Tr}\,\tilde{\lambda}\delta_{x_s'}\tilde{C})\mathrm{Tr}\,\tilde{C}\sigma_t x_t'+\mathrm{Tr}(\delta_{x_s'}\tilde{C})\sigma_t x_t'+\mathrm{Tr}\,\tilde{C}\sigma_t\delta_{st}\delta x_s'].\tag{25b}$$

Now from Eqs. (23a, 23b) we have

$$\delta_{x_s'}\mathbf{H}=\mathrm{Tr}\left(\frac{\delta\mathbf{H}}{\delta x_s'}\right)'\delta x_s'=\mathrm{Tr}\sum_r\,\dot{x}_r'\omega_{rs}\delta x_s',$$

$$\mathrm{Tr}\,\tilde{\lambda}\delta_{x_s'}\tilde{C}=\mathrm{Tr}\,\tilde{\lambda}\sum_r\,\omega_{rs}(x_r'\delta x_s'-\epsilon_r\delta x_s' x_r')=\mathrm{Tr}\left[\tilde{\lambda},\sum_r\,\omega_{rs}x_r'\right]\delta x_s',\tag{26}$$

$$\mathrm{Tr}(\delta_{x_s'}\tilde{C})\sigma_t x_t'=\mathrm{Tr}\left[\sigma_t x_t',\sum_r\,\omega_{rs}x_r'\right]\delta x_s'.$$

Substituting these into Eq. (25b) and multiplying by Z^{-1}, we get

$$0=\left\langle\left(-\tau\,\mathrm{Tr}\sum_r\,\dot{x}_r'\omega_{rs}\delta x_s'-\mathrm{Tr}\left[\tilde{\lambda},\sum_r\,\omega_{rs}x_r'\right]\delta x_s'\right)\mathrm{Tr}\,\tilde{C}\sigma_t x_t'\right.$$

$$\left.+\mathrm{Tr}\left[\sigma_t x_t',\sum_r\,\omega_{rs}x_r'\right]\delta x_s'+\mathrm{Tr}\,\tilde{C}\sigma_t\delta_{st}\delta x_s'\right\rangle_{AV},\tag{27a}$$

which since $\delta x_s'$ is an arbitrary traceless matrix (with the adjointness properties of x_s'), implies that the traceless part of the operator multiplying $\delta x_s'$ inside the trace must vanish,

$$0=\left\langle\left(-\tau\sum_r\,\dot{x}_r'\omega_{rs}-\left[\tilde{\lambda},\sum_r\,\omega_{rs}x_r'\right]\right)\mathrm{Tr}\,\tilde{C}\sigma_t x_t'+\left[\sigma_t x_t',\sum_r\,\omega_{rs}x_r'\right]+\tilde{C}\sigma_t\delta_{st}\right\rangle_{AV}.\tag{27b}$$

Since $\tilde{\lambda}$ is a constant matrix, as before it can be taken outside the ensemble average, and so the second term in Eq. (27b) takes the form

$$-\left[\tilde{\lambda},\sum_r\,\omega_{rs}\langle x_r'\,\mathrm{Tr}\,\tilde{C}\sigma_t x_t'\rangle_{AV}\right],\tag{27c}$$

which again vanishes since the ensemble average inside the commutator is a matrix function only of $\tilde{\lambda}$ and τ. Contracting the remainder of Eq. (27b) with $\Sigma_s\omega_{us}$, using Eqs. (16c) and (23b), and noting that $[x_u',\sigma_t x_t']=[x_u,\sigma_t x_t]$ because the classical parts do not contribute to the commutator, we get as our final result

$$\langle[x_u,\sigma_t x_t]\rangle_{AV}=i_{\mathrm{eff}}\hbar\,\omega_{ut}\sigma_t-\tau\langle\dot{x}_u'\,\mathrm{Tr}\,\tilde{C}\sigma_t x_t'\rangle_{AV}.\tag{28a}$$

Equation (28a), like Eq. (20b) of the preceding section that it generalizes, is exact.

In order to have emergent quantum behavior, it is necessary that the second term on the right hand side of Eq. (28a) be much smaller than the first term, that is, we require

$$\hbar^{-1}\tau|\langle\dot{x}_u'\,\mathrm{Tr}\,\tilde{C}\sigma_t x_t'\rangle_{AV}|\ll 1.\tag{28b}$$

Again, by replacing $\tilde{C}$ by its expectation value at the start of the derivation leading to Eq. (28a), we get a second Ward identity

$$0 = i_{\mathrm{eff}}\hbar\,\omega_{ut}\sigma_t - \tau\langle \dot{x}'_u \ \mathrm{Tr}\ i_{\mathrm{eff}}\hbar\,\sigma_t x'_t\rangle_{AV}. \tag{28c}$$

Hence the inequality of Eq. (28b) can be satisfied only if $\tilde{C}$ is not an extensive quantity, since if $\tilde{C}$ were extensive one could, in the large system limit, approximate it in Eq. (28b) by its expectation $i_{\mathrm{eff}}\hbar$, giving an expression that, by Eq. (28c), cannot be small.

Because the derivation of this section is valid for fermions as well as bosons, one can in fact make a stronger statement about the conditions for emergent quantum behavior. Letting the indices t and u in Eq. (28a) be either both bosonic or both fermionic, we get the respective relations

$$\begin{aligned} \langle [q_r, p_r]\rangle_{AV} &= i_{\mathrm{eff}}\hbar - \tau\langle \dot{q}'_r \ \mathrm{Tr}\ \tilde{C}p'_r\rangle_{AV} \quad r \ \text{bosonic}, \\ \langle \{q_r, p_r\}\rangle_{AV} &= i_{\mathrm{eff}}\hbar - \tau\langle \dot{q}'_r \ \mathrm{Tr}\ \tilde{C}p'_r\rangle_{AV} \quad r \ \text{fermionic}. \end{aligned} \tag{29a}$$

Substituting this into Eq. (7) for $\tilde{C}$, taking the ensemble average, and using Eq. (16c), we get

$$\begin{aligned} i_{\mathrm{eff}}\hbar = \langle \tilde{C}\rangle_{AV} &= \left\langle \sum_{r\ \mathrm{bosons}} [q_r, p_r] - \sum_{r\ \mathrm{fermions}} \{q_r, p_r\} \right\rangle_{AV} \\ &= \left(\sum_{r\ \mathrm{bosons}} - \sum_{r\ \mathrm{fermions}} \right) i_{\mathrm{eff}}\hbar - \tau \left(\sum_{r\ \mathrm{bosons}} - \sum_{r\ \mathrm{fermions}} \right) \langle \dot{q}'_r \ \mathrm{Tr}\ \tilde{C}p'_r\rangle_{AV}, \end{aligned} \tag{29b}$$

which on division by $\hbar$ and transposition of terms gives

$$\left(\sum_{r\ \mathrm{bosons}} - \sum_{r\ \mathrm{fermions}} \right) \hbar^{-1}\tau\langle \dot{q}'_r \ \mathrm{Tr}\ \tilde{C}p'_r\rangle_{AV} = i_{\mathrm{eff}} \left(\sum_{r\ \mathrm{bosons}} - \sum_{r\ \mathrm{fermions}} - 1 \right). \tag{29c}$$

When the condition of Eq. (28b) for emergent canonical behavior is satisfied, the left hand side of Eq. (29c) is a sum of very small terms. Assuming that this sum yields at most a finite, bounded total, let us consider the case in which r includes the spatial label of a translation invariant field theory. Then the number of bosonic and fermionic modes per unit volume contributing on the right hand side of Eq. (29c) must be equal, since if not, the right hand side of Eq. (29c) would become infinite as the spatial volume grows to infinity, contradicting the boundedness of the left hand side. Therefore, in a complex Hilbert space (for a discussion of how our arguments must be modified in real and quaternionic Hilbert space, see the Appendix), a candidate pre-quantum mechanics theory must have equal numbers of bosonic and fermionic degrees of freedom, making it plausible that such a candidate theory should be supersymmetric. When the numbers of bosonic and fermionic modes are in balance, Eq. (29c) simplifies to

$$\left(\sum_{r\ \mathrm{bosons}} - \sum_{r\ \mathrm{fermions}} \right) \hbar^{-1}\tau\langle \dot{q}'_r \ \mathrm{Tr}\ \tilde{C}p'_r\rangle_{AV} = -i_{\mathrm{eff}}, \tag{29d}$$

showing that the remainder terms in Eq. (28a), that are neglected when Eq. (28b) is satisfied, sum in Eq. (29c) to give a total of unit magnitude.

Corresponding to the Ward identity of Eq. (28a), we can derive a class of more general Ward identities by replacing $\sigma_t x'_t$ in Eq. (25b) by a general U, constructed as a Weyl ordered (i.e., symmetrized) polynomial in the products $\{\sigma_r x_r\}$, with coefficients that are c-number functions of 1 and of i_{eff}. In place of Eq. (27b), we now get

$$0 = \left\langle \left(-\tau \sum_r \dot{x}'_r \omega_{rs} - \left[\tilde{\lambda}, \sum_r \omega_{rs} x'_r \right] \right) \mathrm{Tr}\ \tilde{C}U + \left[U, \sum_r \omega_{rs} x'_r \right] + \sum_{\text{each } x_s \text{ in } U} U(\text{one } x_s \to \tilde{C})' \right\rangle_{AV}. \tag{30a}$$

As long as U has coefficients that depend only on the matrices (or operators) 1 and i_{eff}, the second term on the right in Eq. (30a), which involves a commutator with $\tilde{\lambda}$, vanishes by the same arguments as before. Contracting the remainder with ω_{us}, but making no approximations, we get as the exact general Ward identity analogous to Eq. (28a),

$$\langle [x_u, U] \rangle_{AV} = \left\langle \sum_s \omega_{us} \sum_{\text{each } x_s \text{ in } U} U(\text{one } x_s \to \tilde{C})' \right\rangle_{AV} - \tau \langle \dot{x}'_u \, \text{Tr} \, \tilde{C} U \rangle_{AV} . \tag{30b}$$

Suppose now that we can make the following two approximations, (i) we replace $\tilde{C}$ in the first term on the right hand side of Eq. (30b) by its ensemble average $i_{\text{eff}}\hbar$, and (ii) we neglect the τ term in Eq. (30b). We then are left with the relation

$$\langle [x_u, U] \rangle_{AV} = \left\langle \sum_s \omega_{us} \sum_{\text{each } x_s \text{ in } U} U(\text{one } x_s \to i_{\text{eff}}\hbar)' \right\rangle_{AV} , \tag{30c}$$

which extends the effective canonical algebra inside ensemble averages to the commutator of x_u with a general Weyl ordered polynomial U.

By the methods of Appendix E of Ref. 4, Eq. (30c) can be extended to include sources for the remainder parts x'_r of the phase space variables. Specializing the relations obtained this way to the case $U = i_{\text{eff}}$ implies that i_{eff} can be freely commuted with phase space variables inside ensemble averages. As argued in Ref. 4, the resulting set of Ward identities then yields the canonical generator structure, including the time evolution relations, of Heisenberg picture quantum field theory. The only assertion in Ref. 4 that cannot be derived this way is the claim that the time evolution equation is more exact than the other generator relations; this claim used the assumption that $\tilde{C}$ can be replaced by its ensemble average inside the τ term, which we have seen is not correct. The remainder of the conclusions of Ref. 4 rest on the two approximations that we made above, which can be rephrased as the assumptions that, (i) in the terms of Eq. (30b) that involve the *unvaried* canonical ensemble ρ of Eq. (13) with a factor of $\tilde{C}$ in the integrand, the fact that the ensemble is sharply peaked around the mean allows us to replace the integrand factor $\tilde{C}$ by its ensemble average $i_{\text{eff}}\hbar$, and (ii) the canonical ensemble displays a certain rigidity, in that terms of the form $\int d\mu \, \delta\rho \, \text{Tr} \, \tilde{C} U$ can be dropped. On the other hand, we have seen that terms of the form $\int d\mu \, \delta\rho \, \text{Tr} \, i_{\text{eff}}\hbar U$ cannot be dropped; this does not contradict our assumptions because $\delta\rho$ can be rapidly varying around the peak of the ensemble.

V. DISCUSSION

We have seen that a statistical mechanics can be formulated for a wide class of matrix models with a global unitary invariance, and that within this statistical mechanics, the ensemble averages of canonical variables obey the exact relations of Eq. (20b), (28a), (29a), and (30b). When these can be approximated by dropping the τ terms [and, in Eq. (30b), replacing the $\tilde{C}$ insertions in U' by their ensemble averages], the result is emergent quantum mechanical behavior for the statistical ensemble averages. The condition for validity of the approximation of neglecting the τ terms is rather delicate: we have argued that it requires that $\tilde{C}$ should be an intensive thermodynamic quantity, and that the numbers of bosonic and fermionic degrees of freedom should balance.

We conclude with some brief remarks:

(1) In the first two references of Ref. 3, it is shown that one can readily formulate trace dynamics models in which global unitary operator invariance is gauged to give a local unitary operator invariance. Since global unitary invariance is a special case of local unitary invariance, the considerations of this paper apply to these models.

(2) In Refs. 5, it is shown that supersymmetric Yang Mills theory, and the related ''matrix model for *M* theory,'' fit naturally into the trace dynamics framework analyzed in this paper. In these models, $\tilde{C}$ vanishes up to a surface term contribution, a behavior consistent with its being an intensive thermodynamic quantity.

(3) Although our final results of Eqs. (20b), (28a), and (29a) superficially resemble the string-inspired formula of Eq. (1b), there is an important difference. In Eq. (1b) the coordinate is a quantum operator, as is usual in nonrelativistic quantum mechanics, whereas in our results of Eqs. (20b), etc., the coordinate is merely a degree of freedom label r, as it always is in quantum field theory, and the coordinates and momenta are canonical field variables with label r. It may be possible to make a connection between the two types of modified commutation relations when the metric structure of the coordinate manifold is taken into account, using the

fact that the proper distance is related to the coordinate interval by $ds^2=g_{\mu\nu}dx^\mu dx^\nu$. In a field theoretic interpretation, dx^μ is just the change in the degree of freedom label, but the metric is a dynamical variable, and hence so is ds. This suggests that there may be an analog of Eq. (1b) involving the relativistic proper distance, and that this is the relation to be compared with our results in this paper.

(4) As is well known, in a complex Hilbert space the canonical algebra $[q,p]=i$, $[q,i]=[p,i]=0$ cannot have finite dimensional representations, since this algebra implies, for example, the relation $q^2p^2+p^2q^2-2qp^2q=-2$, which in a finite dimensional Hilbert space would have a left hand side with trace zero and a right hand side with trace nonzero. However, it is consistent for the canonical algebra to emerge as the limit $N\to\infty$ of an algebra in an N dimensional Hilbert space, which is the behavior argued for in Ref. 4 and here. Because the emergent canonical algebra involves not the imaginary unit i of the underlying complex Hilbert space, but rather the operator $i_{\rm eff}$ with Tr $i_{\rm eff}=0$, a basis for the operator algebra in the emergent theory is provided by a set of operators that commute with $i_{\rm eff}$, together with one additional operator that anticommutes with $i_{\rm eff}$, and that plays the role of the time reversal operator in the emergent complex quantum mechanics. In fact, because the condition Tr $i_{\rm eff}=0$ implies that one can find a representation in which $i_{\rm eff}$ is a real matrix (just as for Pauli matrices $\rho_{1,2,3}$ the matrix $i\rho_3$ can be given the real form $i\rho_2$ by a change of representation), the quantum mechanics emergent from matrix dynamics has the structure of a complexified real quantum mechanics, for which the operator algebra has the form just described (see, e.g., Sec. 2.6 of the second citation in Ref. 3).

(5) We have seen that the emergence of quantum mechanical behavior from matrix model statistical mechanics requires a certain ''rigidity'' of the statistical ensemble. It is easy to see[8,9] that this rigidity is a sufficient condition for the canonical and microcanonical ensembles to give the same Ward identities, and hence the same emergent quantum behavior. The need for a rigid statistical ensemble in our context suggests a possible analogy with the concept of London rigidity in the theory of superconductivity.[10] In the presence of an applied vector potential $\mathbf{A}$, the induced current density in a metal is given by

$$\langle \mathbf{j} \rangle = -\frac{ne}{m}\left\langle \mathbf{p}+\frac{e}{c}\mathbf{A}\right\rangle. \tag{31}$$

In a normal metal the two terms on the right hand side of Eq. (31) nearly cancel, leaving a small residual diamagnetism. However, in a superconductor the rigidity of the wave function leads to the vanishing of $\langle \mathbf{p} \rangle$, giving perfect diamagnetism and the Meissner effect. An analogy with the results of this paper would equate normal metal behavior with the case in which $\tilde{C}$ can be replaced by its ensemble average in the τ term; in this case the right hand side of Eq. (20b) is approximately equal to the right hand side of Eq. (22b), leading to cancellation of the emergent canonical commutator. Similarly, the analogy would equate superconducting behavior with the case in which the τ term containing $\tilde{C}$ can be dropped because of ''rigidity'' of $\delta\rho$, leading through Eqs. (20b), (28a), and (29a) to an emergent canonical commutator as an analog of the superconductive Meissner effect.

APPENDIX: REAL AND QUATERNIONIC HILBERT SPACE

For reasons that we now describe, in real and quaternionic Hilbert space the arguments of this paper must be modified and yield weaker conclusions. The underlying reason for this modification is that only in complex Hilbert space can one have a nonreal trace that nonetheless obeys the cyclic property. In quaternionic Hilbert space, as a consequence of the noncommutativity of the

quaternions, only the real part of the ordinary trace obeys the cyclic property. In real Hilbert space, the trace is necessarily real, and the trace of any anti-self-adjoint operator vanishes. Thus in these two cases, if one follows Refs. 3 and 4 and defines the graded trace **Tr** to be the one that obeys the cyclic property, then the definition must include taking the real part, and to get a nonzero result one must require the operator argument V of **Tr** V to be self-adjoint. As a consequence, in the general case derivation analogous to that starting from Eq. (25b), one must consider $\mathbf{Tr}\{i_{\rm eff},\widetilde{C}\}\sigma_t x_t'$ rather than $\mathrm{Tr}\,\widetilde{C}\sigma_t x_t'$. This gives the following analog of Eq. (28a):

$$\langle[x_u,\sigma_t\{i_{\rm eff},x_t\}]\rangle_{AV}=\{i_{\rm eff},i_{\rm eff}\hbar\}'\omega_{ut}\sigma_t-\tau\langle\dot{x}_u'\ \mathrm{Tr}\{i_{\rm eff},\widetilde{C}\}\sigma_t x_t'\rangle_{AV}, \tag{A1}$$

where the prime on the first term on the right hand side of Eq. (A1) indicates extraction of the traceless part. However, since the traceless part of $\{i_{\rm eff},i_{\rm eff}\hbar\}=-2\hbar$ is zero, Eq. (A1) becomes

$$\langle[x_u,\sigma_t\{i_{\rm eff},x_t\}]\rangle_{AV}=-\tau\langle\dot{x}_u'\ \mathrm{Tr}\{i_{\rm eff},\widetilde{C}\}\sigma_t x_t'\rangle_{AV}, \tag{A2}$$

which has a structure more like the equation obtained by subtracting Eq. (28c) from Eq. (28a) than like Eq. (28a) itself. In complex Hilbert space, Eqs. (A2) *and* Eqs. (28a, 28c) all hold, and conditions for emergent quantum behavior can be formulated from the latter as in the text; in the real and quaternionic Hilbert space cases, only Eq. (A2) holds, and we cannot proceed with the analysis of the text.

The remarks made here correct a subtle error made in Sec. 6 of Adler and Millard.[4] There, the classical sources introduced in this paper were set to zero, and Ward identities were derived by varying x_s, not just the noncommutative part x_s' as we have done here. This gives as the Ward identity analogous to Eq. (A1)

$$\langle[x_u,\sigma_t\{i_{\rm eff},x_t\}]\rangle_{AV}=\{i_{\rm eff},i_{\rm eff}\hbar\}\omega_{ut}\sigma_t-\tau\langle\dot{x}_u\ \mathrm{Tr}\{i_{\rm eff},\widetilde{C}\}\sigma_t x_t\rangle_{AV}. \tag{A3}$$

Equation (A3) is a valid relation, but it actually implies *two* relations, quite different in structure, for its classical or c-number part and its primed or traceless part. Separating Eq. (A3) into these parts, and ignoring interference terms between x^c and x' in the τ term, one finds that the primed part of Eq. (A3) gives Eq. (A2), while the c-number part of Eq. (A3) becomes an equipartition identity for x^c and gives no direct information about the expectation of the commutator. Hence the arguments of Ref. 4 do not, in their present form, provide evidence for emergent quantum behavior in the real and quaternionic Hilbert space cases.

Closure of field operators, asymptotic Abelianness, and vacuum structure in hyperfunction quantum field theory

(Received 2 September 1997; accepted for publication 18 May 1998)

Though, in contrast to standard quantum field theory (QFT), the tensor-algebra over the test-function space of hyperfunction quantum field theory has no local structure, the localization properties of states on this algebra can be used to derive asymptotic Abelianness in spacelike directions. Again, in contrast to standard QFT, the closure of (Hermitian) field operators can destroy localization properties. This problem is addressed in a natural modification of the definition of the closure, called the local closure. This allows one, in conjunction with asymptotic Abelianness, to define a proper reduction of the field algebra to the subspace of the translation invariant states, and to investigate the dimension of this subspace. © *1998 American Institute of Physics.* [S0022-2488(98)00810-X]

I. INTRODUCTION

In general relativistic quantum field theory one usually expects that an irreducible quantum field has a one-dimensional vacuum subspace. However, in standard quantum field theory (QFT), i.e., in the general theory of quantized fields in the sense of Gårding and Wightman,[1] Borchers[2] indicated that an irreducible quantum field can have a vacuum subspace of dimension larger than one. Usually one refers to the fact that the vacuum subspace has a dimension larger than one as *Borchers's anomaly*. Its appearance is considered as an unwanted pathology of standard QFT.

The mathematical analysis of the dimension of the vacuum subspace of an irreducible relativistic quantum field in standard QFT has to deal with a number of difficult and to a large extent technical problems. Thus a complete analysis is still missing. For a more detailed discussion of Borchers's anomaly and its (technical) difficulties we refer to Ref. 3. Therefore a discussion of this anomaly in a more general framework might offer a new perspective. Accordingly we have asked ourselves whether Borchers's anomaly can occur in hyperfunction quantum field theory (HFQFT), i.e., general relativistic quantum field theory in terms of Fourier hyperfunctions as introduced in Ref. 4 and systematically investigated and extended in Ref. 5.

Besides being more general than standard QFT, HFQFT allows ''more'' explicit models to be analyzed in a rigorous way.[6] As it is well known, the question of which type of generalized functions one should use in the formulation of relativistic quantum field theory has not yet found a final answer. Thus we like to consider our present discussion as a contribution to an answer to this question in favor of Fourier hyperfunctions. Other reasons why it might be desirable to consider quantum field theory in terms of hyperfunctions are given in Ref. 7.

Though various technical aspects are simpler in HFQFT than in standard QFT (mainly related to the fact that the sheaf of Fourier hyperfunctions is flabby while the sheaf of distributions is not flabby), HFQFT has to live with the following two difficulties: First, the tensor-algebra over the test function space of HFQFT has no local structure (this means for instance that there are no nontrivial test functions with compact support, and there are no pairs of test functions with spacelike separated supports). Nevertheless, states on this algebra can have local properties and are localizable in the strict sense just as tempered distributions (most clearly expressed by the fact that hyperfunctions form a sheaf of complex vector spaces). This is used to derive asymptotic

 © 1998 American Institute of Physics

Abelianness in spacelike directions in hyperfunction quantum field theory. Second, the closure of (Hermitian) field operators in HFQFT can destroy localization properties. This problem is solved by proposing a suitable definition of the closure, called the local closure, and this definition is applied successfully, in conjunction with asymptotic Abelianness, to define a reduction of the field algebra to the subspace of translation invariant states. This allows one to investigate the vacuum structure of the theory and to show that Borchers's anomaly[2] can indeed occur in HFQFT.

Now we indicate briefly the contents of the following subsections.

In Sec. II, we recall a few basic facts about Fourier hyperfunctions. In Sec. III, we formulate hyperfunction quantum field theory in terms of the sequence of vacuum expectation values of the field as a state $\mathscr{W}$ on the tensor algebra $\mathscr{B}$ over the test function space $Q(\mathbf{D}^4)$ of HFQFT. In Ref. 1 it is shown how this approach is related to the standard one. Since the test function space of Fourier hyperfunctions contains no nontrivial function with compact support, axioms have to be modified from those for tempered fields. In order to define the local closure a *-algebra $\mathscr{C}$ is introduced which is an extension of $\mathscr{B}$ and which contains enough information about locality. It is shown in Sec. V that the state $\mathscr{W}$ can be extended to a state on $\mathscr{C}$. In Sec. VI, we study a representation Π of $\mathscr{C}$ obtained by GNS construction of this extended state, and we prove the asymptotic Abelianness of $\Pi(\mathscr{B})$ and $\Pi(\mathscr{C})$. In Sec. VII, we define the local closure $\hat{\Pi}$ of Π and prove asymptotic Abelianness of $\hat{\Pi}(\mathscr{C})$. The domain $\hat{\mathscr{D}}$ of the local closure $\hat{\Pi}$ is such that it allows one to define a reduction of the field algebra to the space of translation invariant states, and to prove that the reduced algebra is Abelian. Thus, in Sec. VIII, we can discuss Borchers's anomaly in HFQFT.

II. FOURIER HYPERFUNCTIONS

In distribution theory, one introduces the space of tempered distributions in order to have a natural domain for the Fourier transformation. In hyperfunction theory too, we introduce the space of Fourier hyperfunctions, i.e., hyperfunctions with some growth restrictions at infinity which are needed for defining the Fourier transformation as an automorphism. A way to achieve this is to compactify the underlying space $\mathbf{R}^n$. The radial compactification $\mathbf{D}^n$ of $\mathbf{R}^n$ has proved to be very useful. It is defined in a natural way as follows: Let S_∞^{n-1} be the $(n-1)$-dimensional sphere at infinity, which is homeomorphic to the unit sphere $S^{n-1}=\{x\in\mathbf{R}^n;|x|=1\}$ by the mapping $x\to x_\infty$, where the point $x_\infty\in S_\infty^{n-1}$ lies on the ray connecting the origin with the point $x\in S^{n-1}$. The set $\mathbf{R}^n\cup S_\infty^{n-1}$ equipped with its natural topology is denoted by $\mathbf{D}^n$ (a fundamental system of neighborhoods of x_∞ is given by all open cones of arbitrary vertex generated by arbitrary open neighborhoods of x_∞ in S_∞^{n-1}, see Ref. 5).

The spaces of test functions we are going to use later are inductive limit spaces

$$\underset{\sim}{\mathscr{O}}(\mathbf{D}^n)$$

of functions on $\mathbf{D}^n$ for $n=4k$ $(k=1,2,...)$ which we describe now. For reasons which become obvious soon we introduce and study the spaces

$$\underset{\sim}{\mathscr{O}}(K)$$

for a closed subset K of $\mathbf{D}^n$.

Let $\{U_m;m\in\mathbf{N}\}$ be a fundamental sequence of neighborhoods of K in $Q^n=\mathbf{D}^n+i\mathbf{R}^n$, with $U_m\supset\supset U_{m+1}$. Then let $\mathscr{O}_c^m(U_m)$ be the Banach space of functions f analytic on $U_m\cap\mathbf{C}^n$ and continuous on $U_m\cap\mathbf{C}^n$ such that

$$\|f\|_m=\sup_{z\in U_m\cap\mathbf{C}^n}|f(z)|e^{|z|/m} \tag{2.1}$$

is finite. The space $\mathscr{O}(K)$ is now defined as the inductive limit of the Banach spaces $\mathscr{O}_c^m(U_m)$:

$$\underset{\sim}{\mathscr{O}}(K)=\operatorname{ind}\lim_{m\to\infty}\mathscr{O}_c^m(U_m). \tag{2.2}$$

$\mathcal{Q}(K)$ consists of rapidly decreasing analytic function on K. Its basic properties are collected in Proposition 2.1 (see Ref. 4).

Proposition 2.1:

(a) $\mathcal{Q}(K)$ is a DFS-space (a dual Fréchet–Schwartz space), i.e., the all embedding maps $\mathcal{O}_c^m(U_m)\to\mathcal{O}_c^{m+1}(U_{m+1})$. $m=1,2,...$, are compact.

(b) $\mathcal{Q}(\mathbf{D}^n)$ is nuclear and barreled.

(c) $\otimes^k\mathcal{Q}(\mathbf{D}^4)$ is dense in $\mathcal{Q}(\mathbf{D}^{4k})$ and the completion $\hat{\otimes}^k\mathcal{Q}(\mathbf{D}^4)$ of $\hat{\otimes}^k\mathcal{Q}(\mathbf{D}^4)$ is equal to $\mathcal{Q}(\mathbf{D}^{4k})$.

Let $\mathcal{Q}(Q^n)$ be the linear space of rapidly decreasing entire functions $f(z)$ in $\mathbf{C}^n$, i.e., for every $r>0$

$$\sup\{|f(z)|e^{\eta|z|};z\in\mathbf{C}^n,\quad |\mathrm{Im}\ z|<r\}<\infty$$

for some $\eta=\eta(r)>0$. Let V be an open set in Q^n. Define a Banach space $\mathcal{Q}_c(V;\eta)$ of functions f analytic in $V\cap\mathbf{C}^n$, continuous on $V\cap\mathbf{C}^n$ such that

$$\|f\|_{V,\eta}=\sup_{z\in V\cap\mathbf{C}^m}|f(z)|e^{\eta|z|}$$

is finite. Then we have the following proposition (see Proposition 2.6 of Ref. 8).

Proposition 2.2: Let K be a compact set in $\mathbf{D}^n$, V an open neighborhood of K in Q^n. Then there exists an open neighborhood W with $K\subset W\subset V$ such that every $f\in\mathcal{Q}_c(V;\eta)$ is approximated by a sequence $\{f_j\}\subset\mathcal{Q}(Q^n)$ in the norm $\|\cdot\|_{W,\eta/4}$. In particular, $f\in\mathcal{Q}(K)$ is approximated by a sequence $\{f_j\}\subset\mathcal{Q}(\mathbf{D}^n)$ in some norm $\|\cdot\|_m$ of $\mathcal{O}_c^m(U_m)$.

The following proposition gives the definition and the basic properties of the Fourier transformation $\mathcal{F}$ on $\mathcal{Q}(\mathbf{D}^n)$.

Proposition 2.3: The Fourier transformation $\mathcal{F}$ is well defined on $\mathcal{Q}(\mathbf{D}^n)$ by

$$(\mathcal{F}f)(p)=(2\pi)^{-n/2}\int e^{ip\cdot x}f(x)dx. \tag{2.3}$$

$\mathcal{F}$ is an isomorphism of the topological vector space $\mathcal{Q}(\mathbf{D}^n)$ with inverse

$$(\overline{\mathcal{F}}\tilde{f})(x)=(2\pi)^{-n/2}\int e^{-ip\cdot x}\tilde{f}(p)dp. \tag{2.4}$$

A Fourier hyperfunction on $\mathbf{D}^n$ is by definition an element of the topological dual $\mathcal{Q}(\mathbf{D}^n)'$ of the space $\mathcal{Q}(\mathbf{D}^n)$. Therefore we can extend the above definition of the Fourier transformation to Fourier hyperfunctions by duality, i.e., for all $f\in\mathcal{Q}(\mathbf{D}^n)$ and $\mu\in\mathcal{Q}(\mathbf{D}^n)'$ one defines

$$(\mathcal{F}\mu)(f)=\mu(\mathcal{F}f). \tag{2.5}$$

Then $\mathcal{F}$ is an isomorphism on $\mathcal{Q}(\mathbf{D}^n)'$.

If $K\subset\mathbf{D}^n$ is any closed subset then $\mathcal{Q}(\mathbf{D}^n)$ is contained in $\mathcal{Q}(K)$. For a Fourier hyperfunction μ on $\mathbf{D}^n$, denote by $C(\mu)$ the class of all those closed subsets $K\subset\mathbf{D}^n$ such that there is a continuous extension μ_K of μ to $\mathcal{Q}(K)$. Any such subset $K\in C(\mu)$ is called a carrier of the Fourier hyperfunction μ. μ has a smallest carrier, called the support of μ (see Ref. 8):

$$\mathrm{supp}\ \mu=\cap_{K\in C(\mu)}K.$$

Here we want to stress the following facts. For an open set Ω in $\mathbf{D}^n$, the set $\mathcal{R}(\Omega)$ of Fourier hyperfunction on Ω is defined by

$$\mathcal{R}(\Omega)=\mathcal{Q}(\mathbf{D}^n)'/\mathcal{Q}(\mathbf{D}^n\setminus\Omega)'. \tag{2.6}$$

The notion of support of a Fourier hyperfunction expresses their localization properties on $\mathbf{D}^n$. But a more complete description of these localization properties of Fourier hyperfunctions is contained in the fact that the correspondence $\Omega\to\mathcal{R}(\Omega)$ forms a (flabby) sheaf[9] on $\mathbf{D}^n$, and is thus well

suited to express the localization properties as needed in quantum field theory (see Ref. 5). However, in contrast to the space $\mathscr{S}'(\Omega)$ of tempered distribution on Ω, we cannot endow the space $\mathscr{R}(\Omega)$ with any reasonable topology since $\mathscr{D}(\mathbf{D}^n\backslash\Omega)'$ is dense in $\mathscr{D}(\mathbf{D}^n)'$ (see Lemma 8.6.4 of Ref. 9).

III. HYPERFUNCTION QUANTUM FIELDS

Before we can formulate concisely our basic assumptions some notation has to be introduced. Let us begin with the tensor algebra $\mathscr{B}$ over the test function space of hyperfunction quantum field theory defined as the locally convex direct sum of the spaces $\mathscr{B}_n=\mathscr{D}(\mathbf{D}^{4n})$:

$$\mathscr{B}=\oplus_{n=0}^{\infty}\mathscr{B}_n, \quad \mathscr{B}_0=\mathbf{C}, \quad \mathscr{B}_n=\mathscr{D}(\mathbf{D}^{4n}), \quad n=1.2,\ldots . \tag{3.1}$$

A continuous involution * is defined on $\mathscr{B}$ by

$$f^*=(\overline{f}^{[0]},\overline{f}^{[1]}(x_1),\ldots,\overline{f}^{[n]}(x_n,\ldots,x_1),\ldots,0,0,\ldots)\in\mathscr{B} \tag{3.2}$$

for all $f=(f^{[0]},f^{[1]}(x_1),\ldots,f^{[n]}(x_1,\ldots,x_n),\ldots,0,0,\ldots)\in\mathscr{B}$.
Furthermore, a noncommutative multiplication $\otimes$ is defined on $\mathscr{B}$ by

$$(f\otimes g)^{[n]}(x_1,\ldots,x_n)=\sum_{k=0}^{n} f^{[k]}(x_1,\ldots,x_k)g^{[n-k]}(x_{k+1},\ldots,x_n). \tag{3.3}$$

for all $f, g\in\mathscr{B}$. With these operations $\mathscr{B}$ is a graded topological *-algebra called the (completed) *tensor algebra of test functions* for hyperfunction quantum field theory. $\mathscr{B}$ is the completed tensor algebra over the test function space $\mathscr{D}(\mathbf{D}^4)$. A state $\mathscr{W}$ on $\mathscr{B}$ is a continuous linear functional on $\mathscr{B}$ which is non-negative in the sense that $\mathscr{W}(f^*\otimes f)\geqslant 0$ for all $f\in\mathscr{B}$ and which is normalized to one on the unit element $\mathbf{1}=(1,0,\ldots)$ of $\mathscr{B}$, i.e., $\mathscr{W}(\mathbf{1})=1$.

The proper Poincaré group $G=\mathscr{P}_+^{\uparrow}$ acts naturally on $\mathbf{D}^4$. This induces an action α of G as automorphisms of $\mathscr{B}$ according to the following formula:

$$\alpha_{(a,\Lambda)}(f)=f_{(a,\Lambda)} \tag{3.4}$$

for all $f\in\mathscr{B}$ and all $(a,\Lambda)\in G$ where for $n=1,2,\ldots$,

$$f^{[n]}_{(a,\Lambda)}(x_1,\ldots,x_n)=f^{[n]}(\Lambda^{-1}(x_1-a),\ldots,\Lambda^{-1}(x_n-a)). \tag{3.5}$$

Denote by $\overline{V}_+=\{p=(p^0,\mathbf{p})\in\mathbf{R}^4;\ p^2=(p^0)^2-\mathbf{p}^2\geqslant 0,\ p^0\geqslant 0\}$ the closed forward light cone and introduce the sets

$$\mathscr{S}_n=\{(p_1,\ldots,p_n)\in\mathbf{R}^{4n};p_1\in\overline{V}_+,p_1+p_2\in\overline{V}_+,\ldots,p_1+\cdots+p_n\in\overline{V}_+\}.$$

The Fourier transformation $\mathscr{F}$ on $\mathscr{D}(\mathbf{D}^n)$ extends naturally to $\mathscr{B}$. The Fourier transform $\mathscr{F}f$ of $f\in\mathscr{B}$ is denoted by $\tilde{f}$. Now we can introduce the space

$$E_{\mathrm{sp}}=\{f=(f^{[0]},\ldots,f^{[n]},\ldots,0,0,\ldots); \quad \tilde{f}^{[n]}(p_1,\ldots,p_n)\in\mathscr{D}(\overline{S}_n)\}\supset\mathscr{B} \tag{3.6}$$

where $\overline{S}_n$ is the closure of S_n in $\mathbf{D}^{4n}$. The space E_{sp} is equipped with the topology induced by the spaces $\mathscr{D}(\overline{S}_n)$ for $n=1,2,\ldots$. Next, let $\overline{K}_i^n$ denote the closure of the set $K_i^n=\{(x_1,\ldots,x_n)\in\mathbf{R}^{4n}:(x_i-x_{i+1})^2\geqslant 0\}$ in $\mathbf{D}^{4n}$. To each $g\in\mathscr{D}(\overline{K}_i^n)$ assign the function $f=c_i^n(g)$ defined by

$$f(x_1,\ldots,x_n)=g(x_1,\ldots,x_i,x_{i+1},\ldots,x_n)-g(x_1,\ldots,x_{i+1},x_i,\ldots,x_n). \tag{3.7}$$

For $n=2,3,\ldots$ introduce the vector spaces

$$E_{\diagup,n}=\mathrm{span}\{c_i^n(g_i):g_i\in\mathscr{D}(\overline{K}_i^n), \quad i=1,\ldots,n-1\} \tag{3.8}$$

and the locally convex sum of these spaces

$$E_{\mathscr{O}}=\oplus_{n=0}^{\infty}E_{\mathscr{O},n},\quad E_{\mathscr{O},0}=E_{\mathscr{O},1}=\{0\}. \tag{3.9}$$

The following properties of the space $E_{\mathscr{O}}$ are of interest to us.

Proposition 3.1:

(a) $E_{\mathscr{O}}$ is invariant under the involution *, i.e., $E_{\mathscr{O}}^{*}\subset E_{\mathscr{O}}$.

(b) $E_{\mathscr{O}}$ is a $\mathscr{B}$ module, i.e., for all $f\in E_{\mathscr{O}}$ and all $g\in\mathscr{B}$ we have $f\otimes h\in E_{\mathscr{O}}$ and $h\otimes f\in E_{\mathscr{O}}$.

Proof: For $g\in\tilde{\mathscr{O}}(\overline{K}_i^n)$ we know $g^*\in\tilde{\mathscr{O}}(K_{n-i}^n)$. Now from

$$f^{*[n]}(x_1,\ldots,x_n)=g^*(x_1,\ldots,x_i,x_{i+1},\ldots,x_n)-g^*(x_i,\ldots,x_{i+1},x_i,\ldots,x_n)$$

it follows that $f^*\in E_{\mathscr{O}}$ whenever $f\in E_{\mathscr{O}}$. Thus part (a) follows. In order to prove (b) assume that $f\in E_{\mathscr{O}}$ and $h\in\mathscr{B}$ are given. Since

$$(f\otimes h)^{[n]}(x_1,\ldots,x_n)=\sum_{k=1}^{n}f^{[k]}(x_1,\ldots,x_k)h^{[n-k]}(x_{k+1},\ldots,x_n)$$

and $f^{[k]}(x_1,\ldots,x_k)$ is a sum of elements of the form

$$g(x_1,\ldots,x_i,x_{i+1},\ldots,x_k)-g(x_1,\ldots,x_{i+1},x_i,\ldots,x_k)$$

it follows $f\otimes h\in E_{\mathscr{O}}$. In the same way we have $h\otimes f\in E_{\mathscr{O}}$. □

Hyperfunction quantum field theory, i.e., relativistic quantum field theory in terms of Fourier hyperfunctions, is now defined by the following list of conditions. We consider here only the simplest version, i.e., one neutral scalar field.

H_0 *Quantum fields as operator valued Fourier hyperfunctions:* The sequence of vacuum expectation values $\mathscr{W}$ is a state on the test function algebra $\mathscr{B}$.

H_1 *Relativistic covariance:* The state $\mathscr{W}$ is invariant under the Poincaré group $G=\mathscr{P}_+^{\uparrow}$, i.e., for all $f\in\mathscr{B}$ and all $(a,\Lambda)\in G$ we have

$$\mathscr{W}(f_{(a,\Lambda)})=\mathscr{W}(f).$$

H_2 *Spectral condition:* The energy momentum spectrum of the theory is contained in the closed forward light cone $\overline{V}_+=\{p=(p^0,\mathbf{p})\in\mathbf{R}^4;\ p^2=(p^0)^2-\mathbf{p}^2\geqslant 0,\ p^0\geqslant 0\}$. i.e., the state $\mathscr{W}\in\mathscr{B}'$ has a continuous linear extension to the space E_{sp}.

H_3 *Causality or local commutativity:* For spacelike separations field operators ''commute,'' i.e., for all $n=2,3,\ldots$ and all $i=1,\ldots,\underline{n}-1$ the functionals $\mathscr{W}\circ c_i^n:\mathscr{B}_n=\tilde{\mathscr{O}}(\mathbf{D}^{4n})\to\mathbf{C}$ have continuous linear extensions to $\tilde{\mathscr{O}}(K_i^n)$. (We say for brevity $\mathscr{W}\in\mathscr{B}'$ has a continuous linear extension to $E_{\mathscr{O}}$.)

Remark 3.2: (a) In our investigations we will actually only rely on the invariance of the state $\mathscr{W}$ under the subgroup of translations T_4.

(b) The restriction $\mathscr{W}_n=\mathscr{W}_{|\mathscr{B}_n}$ is a Fourier hyperfunction of $4n$ variables. The spectral condition $(\underline{H}_2)$ means that the support of the Fourier transform $\tilde{\mathscr{W}}_n(p_1,\ldots,p_n)$ of $\mathscr{W}_n$ is contained in S_n. Similarly, the condition of local commutativity (H_3) means that the support of

$$\mathscr{W}_n(x_1,\ldots,x_i,x_{i+1},\ldots,x_n)-\mathscr{W}_n(x_1,\ldots,x_{i+1},x_i,\ldots,x_n)$$

is contained in $\overline{K}_i^n$.

There are some immediate consequences of the above assumptions.

Proposition 3.3:

(a) Condition (H_0) implies the existence of a strongly cyclic *-representation Π of the *-algebra $\mathscr{B}$ in a complex Hilbert space $\mathscr{H}$ with strongly cyclic unit vector Ω and domain $\mathscr{D}(\Pi)=\Pi(\mathscr{B})\Omega$ such that for all $f\in\mathscr{B}$,

$$\mathscr{W}(f)=(\Omega,\Pi(f)\Omega)$$

where $(\cdot,\cdot)$ denotes the inner product of $\mathscr{H}$.

(b) If in addition condition (H_1) is taken into account there is a strongly continuous unitary

representation U of the Poincaré group G on $\mathscr{H}$ such that for all $f \in \mathscr{B}$ and all $(a,\Lambda) \in G$ one has

$$U(a,\Lambda)\Pi(f)U(a,\Lambda)^{-1} = \Pi(f_{(a,\Lambda)}).$$

(c) Conditions $(H_0)-(H_2)$ imply that the spectrum $\sigma(P)$ of the generator $P=(P^0,P^1,P^2,P^3)$ of the translations in the representation U, i.e., the energy momentum operator, is contained in the closed forward light cone $\overline{V}_+$.

(d) Assume $(H_0)-(H_3)$ and denote $A(f)=\Pi(j_1(f))$ for all $f \in \mathscr{B}_1$ where j_1 is the natural embedding of $\mathscr{B}_1$ into $\mathscr{B}$. Then, in addition to the above, we have for all $\Psi \in \mathscr{D}=\mathscr{D}(\Pi)$, as an identity for vector-valued Fourier hyperfunctions,

$$A(x)A(y)\Psi = A(y)A(x)\Psi$$

for all spacelike separated points x, y, i.e., $(x-y)^2<0$.

Proof: Since this is basically the generalized GNS construction we refer to the literature (Proposition 3.1.4 of Ref. 3). □

Compared to general quantum field theory in the sense of Wightman[1] the above list of hypotheses does not contain the condition of uniqueness of the (cyclic) vacuum state and the condition of completeness of the theory (irreducibility of the field A). In the framework given by the above hypotheses $(H_0)-(H_3)$ we intend to investigate the relation between these two conditions.

The subspace of translation invariant states in the Hilbert space $\mathscr{H}$ is

$$\mathscr{H}_0 = \{\Psi \in \mathscr{H} : U(a)\Psi = \Psi \quad \text{for all} \quad a \in T_4\}, \tag{3.10}$$

where $U(a)=U(a,1)$ denotes the representation of the translation group in $\mathscr{H}$ as given in part (b) of Proposition 3.2. By the above the cyclic unit vector Ω is contained in $\mathscr{H}_0$. Based on experiences from local quantum field theory it was believed that an irreducible quantum field theory has to have a unique cyclic vacuum state, i.e., $\dim \mathscr{H}_0 = 1$, until in 1965 Borchers[2] indicated that $d_0 = \dim \mathscr{H}_0 = \infty$ could occur since there are infinite dimensional irreducible representations of Abelian *-algebras. Since then various authors have investigated ''Borchers's anomaly'' but a comprehensive analysis is still missing.[3]

IV. ASYMPTOTIC ABELIANNESS I

Given a state $\mathscr{W}$ on the algebra $\mathscr{B}$ satisfying hypotheses H_0-H_3 we have the representations Π of $\mathscr{B}$ and $U(\cdot)$ of the translation group T_4 on the Hilbert space $\mathscr{H}$ according to Proposition 3.3. Here we intend to show that the system $\{(\Pi(\mathscr{B}),\ U(\lambda a));\ \lambda \in \mathbf{R}\}$ is asymptotically Abelian for spacelike $a \in T_4$. This proof is done in several steps.

Lemma 4.1: Let π be a permutation of $\{1,...,n\}$ such that $\pi(i) \leqslant j$ and $\pi(i+1) \geqslant j+1$. Let $a=(0,\mathbf{a})$ be a unit vector in $\mathbf{R}^4$ and $\phi^{\pi}_{\lambda a}(x_1,\ldots,x_n)=\phi(y_{\pi(1)},\ldots,y_{\pi(n)})$, where $y_k=x_k$ for $k=1,...,j$, $y_{\underline{k}}=x_k-\lambda a$ for $k=j+1,...,n$ and, $\phi \in \mathscr{O}_{\sim}(\mathbf{D}^{4n})$. Then for any $F^i \in \mathscr{O}_{\sim}(\mathbf{D}^{4n})'$ with $\operatorname{supp} F^i \subset K_i$, we have, as $\lambda \to \infty$,

$$F^i(\phi^{\pi}_{\lambda a}) \to 0. \tag{4.1}$$

Proof: For simplicity we consider $\pi=1$ (identity) and $i=j$. Let $\|\phi\|_r \leqslant N$. Then $|\phi(z)| \leqslant N e^{-|z|/r}$ for $|\operatorname{Im} z| \leqslant 1/r$. Since

$$|F^j(\phi^1_{\lambda a})| \leqslant M_{m,U} \sup_{U \cap \mathbf{C}^{4n}} |\phi^1_{\lambda a}(z)| e^{|z|/m}$$

holds for any $m \in \mathbf{N}$ and neighborhood U of $\overline{K_j}$ in Q^{4n} such that $m \geqslant r$ and $U \cap \mathbf{C}^{4n} \subset \{z; |\operatorname{Im} z| \leqslant 1/r\}$, it suffices to prove

$$\sup_{U \cap \mathbf{C}^{4n}} e^{-\Sigma_{k=1}^{j}|z_k|/r} e^{-\Sigma_{k=j+1}^{n}|z_k-\lambda a|/r} e^{|z|/m} \to 0 \tag{4.2}$$

as $\lambda\to\infty$ for some $m\in\mathbf{N}$ and neighborhood U of $\overline{K_j}$ in Q^{4n}. Let $V=\{\xi\in\mathbf{R}^4:\xi^2\geqslant 0\}$ and W be a neighborhood of V in Q^4 such that $W\cap\mathbf{C}^4\subset\{\xi\in\mathbf{R}^4;\xi_0^2>(1-\epsilon)\boldsymbol{\xi}^2-\epsilon\}\times i\{\eta\in\mathbf{R}^4;|\eta|<1/m\}$ for some $\epsilon>0$. Then $U=\{(z_1,\ldots,z_{j-1},z,z-\xi,z_{j+2},\ldots,z_n);|\mathrm{Im}\, z|,|\mathrm{Im}\, z_k|\leqslant 1/m,\xi\in W\}$ is a neighborhood of $\overline{K_j}$. Let $B_\lambda=\{z\in\mathbf{C}^4;|\mathrm{Re}\, z|\leqslant\lambda/4,|\mathrm{Im}\, z|\leqslant 1/m\}$ and $U_\lambda=\{(z_1,\ldots,z_{j-1},z,z-\xi,z_{j+2},\ldots,z_n)\in U;z\in B_\lambda\}$. Since $\mathrm{dist}(B_\lambda,W+\lambda a)\geqslant\lambda/4$, it follows

$$\begin{aligned}
&\sup_{U_\lambda\cap\mathbf{C}^{4n}} e^{-\Sigma_{k=1}^{j}|z_k|/r}e^{-\Sigma_{k=j+1}^{n}|z_k-\lambda a|/r}e^{|z|/m}\\
&\leqslant \sup_{U_\lambda\cap\mathbf{C}^{4n}} e^{-\Sigma_{k=1}^{j-1}|z_k|(1/r-1/m)}e^{-|z_j|/r}e^{-|z_{j+1}-\lambda a|/r}\\
&\quad\times e^{|z_j|/m}e^{|z_{j+1}|/m}e^{-\Sigma_{k=j+2}^{n}|z_k|(1/r-1/m)}e^{\Sigma_{k=j+2}^{n}|\lambda a|/m}\\
&\leqslant M \sup_{z\in B_\lambda\cap\mathbf{C}^4,\,\xi\in W\cap\mathbf{C}^4} e^{-|z|(1/r-1/m)}e^{-|z-\xi-\lambda a|(1/r-1/m)}e^{|\lambda a|/m}e^{\Sigma_{k=j+2}^{n}|\lambda a|/m}\\
&\leqslant Me^{-\lambda/4(1/r-1/m)}e^{(n-j)\lambda/m}=Me^{-\lambda(1/4r-(n-j-1/4)/m)}.
\end{aligned}$$

With $B_\lambda^c=\{z\in\mathbf{C}^4;|\mathrm{Re}\, z|\geqslant\lambda/4,|\mathrm{Im}\, z|\leqslant 1/m\}$ we estimate as follows:

$$\begin{aligned}
&\sup_{(U\setminus U_\lambda)\cap\mathbf{C}^{4n}} e^{-\Sigma_{k=1}^{j}|z_k|/r}e^{-\Sigma_{k=j+1}^{n}|z_k-\lambda a|/r}e^{|z|/m}\\
&\leqslant M \sup_{z\in B_\lambda^c\cap\mathbf{C}^4,\,\xi\in W\cap\mathbf{C}^4} e^{-|z|(1/r-1/m)}e^{-|z-\xi-\lambda a|(1/r-1/m)}e^{|\lambda a|/m}e^{\Sigma_{k=j+2}^{n}|\lambda a|/m}\\
&\leqslant Me^{-\lambda/4(1/r-1/m)}e^{(n-j)\lambda/m}=Me^{-\lambda(1/4r-(n-j-1/4)/m)}.
\end{aligned}$$

This yields Eq. (4.2) if we choose m sufficiently large. □

Lemma 4.2: Let $\mathscr{W}\in\mathscr{B}'$ be a state satisfying hypotheses H_0–H_3. Then one has for any spacelike vector a, any $h\in\mathscr{B}_p$, $f\in\mathscr{B}_j$, $g\in\mathscr{B}_k$, $u\in\mathscr{B}_q$, as $\lambda\to\infty$,

$$\mathscr{W}(h\otimes f\otimes g_{\lambda a}\otimes u)-\mathscr{W}(h\otimes g_{\lambda a}\otimes f\otimes u)\to 0.$$

Proof: Let $\phi=h\otimes u\otimes f\otimes g_{\lambda a}\in\mathscr{B}_{p+q+j+k}$. Then $\mathscr{W}(h\otimes f\otimes g_{\lambda a}\otimes u)-\mathscr{W}(h\otimes g_{\lambda a}\otimes f\otimes u)$ is a finite sum of terms of the form $W^i(\phi_{\lambda a}^{\pi})$ for some i and permutations π, where

$$W^i(x_1,\ldots,x_n)=\mathscr{W}_n(x_1,\ldots,x_i,x_{i+1},\ldots,x_n)-\mathscr{W}_n(x_1,\ldots,x_{i+1},x_i,\ldots,x_n),$$

which satisfies the condition for $F^i(\phi_{\lambda a}^{\pi})$ in Lemma 4.1. Now the lemma follows from Lemma 4.1. □

Finally we can conclude that the system $\{(\Pi(\mathscr{B}),U(\lambda a));\lambda\in\mathbf{R}\}$ is asymptotically Abelian.

Proposition 4.3: Suppose $\mathscr{W}\in\mathscr{B}'$ satisfies hypotheses H_0–H_3 and let Π be the representation of $\mathscr{B}$ and U the representation of the Poincaré group G as determined by Proposition 3.3. Then we have, for any $\Phi,\Psi\in\mathscr{D}=\mathscr{D}(\Pi)$, $f,g\in\mathscr{B}$ and any spacelike vector a, as $\lambda\to\infty$,

$$(\Psi,\Pi(f\,)\Pi(g_{\lambda a})\Phi)-(\Psi,\Pi(g_{\lambda a})\Pi(f\,)\Phi)\to 0.$$

Proof: Since f and g are finite sum of elements from $\mathscr{B}_n$'s, the proposition follows from Lemma 4.2. □

V. A PROBLEM OF MONOTONE CONTINUOUS EXTENSION

Consider the representation Π as given by Proposition 4.3. Following Borchers[2] we intend to investigate the subspace $\mathscr{H}_0$ of ''vacuum states'' as introduced in (3.10) by finding an Abelian reduction of the field algebra $\Pi(\mathscr{B})$ to this subspace. However, as it is well known,[3] there is a serious difficulty with this reduction since one cannot expect that the domain $\mathscr{D}$ of the represen-

tation Π is invariant under the projection Q_0 onto the subspace $\mathscr{H}_0$. Accordingly one would like to construct an extension $\hat{\Pi}$ of Π in the Hilbert space $\mathscr{H}$ with a domain $\hat{\mathscr{D}}$ such that $Q_0\hat{\Pi}(\mathscr{B})\times(\hat{\mathscr{D}}\cap\mathscr{H}_0)\subset\hat{\mathscr{D}}$. In standard QFT one takes for $\hat{\Pi}$ the closure $\overline{\Pi}$ of Π. In HFQFT however, there is an additional problem related to the remark at the end of Sec. II.

Let $K\subset L$ be a pair of compact sets in $\mathbf{D}^n$, and suppose each connected component of L intersects K. Then the natural inclusion: $\mathscr{Q}(K)'\to\mathscr{Q}(L)'$ has a dense image (see Lemma 8.6.4 of Ref. 9). Thus the ''standard closure'' (see Sec. VII) may destroy the localization properties and therefore also locality in hyperfunction quantum field theory. But locality is essential in deriving asymptotic Abelianness which in turn has been recognized to be instrumental for the reduction mentioned above. Accordingly, in the definition of the extension $\hat{\Pi}$, we propose to modify the definition of the closure in a way which takes this potential ''loss of locality'' into account. This is done by taking for $\hat{\Pi}$ the ''local closure'' of the representation Π. The definition of the local closure is naturally based on the locality module (see Definition 7.1). Our suggestion for the definition of the local closure relies on the extension of a given state $\mathscr{W}$ on $\mathscr{B}$ to a state on an enlarged *-algebra $\mathscr{C}$ which is defined as the *-algebra generated by the tensor algebra $\mathscr{B}$ and the ''locality module'' E_ℓ. The existence of this monotone continuous extension is shown in this section.

Let $F_{\ell,n}$ be the linear space generated by the elements f of the form

$$f=c^n_{i_1}\circ c^n_{i_2}\circ\cdots\circ c^n_{i_k}(g), \tag{5.1}$$

where $g\in\mathscr{Q}(\cap_{j=1}^k\overline{K^n_{i_j}})$ and $i_j-i_{j-1}\geqslant 2$.

Proposition 5.1: Let $\mathscr{W}\in\mathscr{B}'$ have a continuous linear extension to E_ℓ. Then the mapping

$$\mathscr{W}\circ c^n_{i_1}\circ c^n_{i_2}\circ\cdots\circ c^n_{i_k}:\mathscr{B}_n=\mathscr{Q}(\mathbf{D}^{4n})\to\mathbf{C}$$

is continuously extended to $\mathscr{Q}(\cap_{j=1}^k\overline{K^n_{i_j}})$. (We say for brevity $\mathscr{W}\in\mathscr{B}'$ has a continuous linear extension to $F_\ell=\oplus_{n=0}^\infty F_{n,\ell}$.)

Proof: Let $\mathscr{F}_n=\mathscr{F}_n(x_1,\ldots,x_n)$ be the Fourier hyperfunction defined by

$$\mathscr{Q}(\mathbf{D}^{4n})\ni g\to\mathscr{W}(c^n_{i_1}\circ c^n_{i_2}\circ\cdots\circ c^n_{i_k}(g)).$$

Let $g\in\mathscr{Q}(\mathbf{D}^{4n})$. Then $f=c^n_{i_1}\circ c^n_{i_2}\circ\cdots\circ\check{c}^n_{i_j}\circ\cdots\circ c^n_{i_k}(g)\in\mathscr{Q}(\mathbf{D}^{4n})$. Note that $c^n_l\circ c^n_j=c^n_l\circ c^n_j$ if $|i-j|\geqslant 2$.

$$\mathscr{F}_n(g)=\mathscr{W}(c^n_{i_j}\circ c^n_{i_1}\circ c^n_{i_2}\circ\cdots\circ c^n_{i_j}\circ\cdots\circ c^n_{i_k}(g))=\mathscr{W}(c^n_{i_j}(f\ ))$$

can be extended to $g\in\mathscr{Q}(\overline{K^n_{i_j}})$, and supp $\mathscr{F}_n\subset\overline{K^n_{i_j}}$. Therefore supp $\mathscr{F}_n\subset\cap_{j=1}^k\overline{K^n_{i_j}}$ and $\mathscr{F}_n$ can be extended to $\mathscr{Q}(\cap_{j=1}^k\overline{K^n_{i_j}})$. □

Corollary 5.2: Let $\mathscr{C}$ be the *-algebra generated by $\mathscr{B}$ and E_ℓ and let $\mathscr{W}\in\mathscr{B}'$ have a continuous linear extension to E_ℓ. Then $\mathscr{W}$ extends continuously to $\mathscr{C}$.

Proof: Let $\mathscr{C}=\oplus_{n=0}^\infty\mathscr{C}_n$. Then it follows from Proposition 3.1 that $\mathscr{C}_n\subset\mathscr{B}_n+F_{\ell,n}=\{f+g;f\in\mathscr{B}_n,g\in F_{\ell,n}\}$. Thus $\mathscr{W}$ extends continuously to $\mathscr{C}$ by Proposition 5.1. □

Lemma 5.3: (a) Let K be a compact set in $\mathbf{D}^n$, and $f\in\mathscr{Q}(K)$. Then there exist $m\in\mathbf{N}$ and a sequence $\{f_j\}\subset\mathscr{Q}(\mathbf{D}^n)$ such that $\|f_j-f\|_m\to 0$ as $j\to\infty$, where $\|\cdot\|_m$ is a norm of $\mathscr{O}^m_c(U_m)$ defined by (2.1).

(b) Let $\|g_j-g\|_m\to 0$ as $j\to\infty$ for $g\in\mathscr{Q}(L)$ with $L\subset\mathbf{D}^k$ and $g_j\in\mathscr{Q}(\mathbf{D}^k)$. Then $f_j\otimes g_j\to f\otimes g$ in $\mathscr{Q}(K\times L)$ as $j\to\infty$.

Proof: (a) follows from Proposition 2.2. For (b), we define a Banach space $\mathscr{O}^m_c(U_m\times V_m)$ with a norm

$$\|f\|_m=\sup_{z\in(U_m\times V_m)\cap\mathbf{C}^{n+k}}|f(z)|e^{|z|/m}.$$

Now we conclude by

$$\|f_j\otimes g_j - f\otimes g\|_m \leqslant \|f_j - f\|_m \|g_j\|_m + \|f\|_m \|g_j - g\|_m \to 0$$

as $j\to\infty$. □

Proposition 5.4: Let $\mathscr{W}$ be a state on $\mathscr{B}$ which satisfies condition H_3. Then $\mathscr{W}$ extends continuously to a state on $\mathscr{C}$.

Proof: Since $\mathscr{W}$ satisfies H_3 it has a continuous linear extension to E_ℓ. Proposition 5.1 implies that $\mathscr{W}$ can be extended continuously to F_ℓ. Now let $h+f\in\mathscr{C}$ with $h\in F_\ell$ and $f\in\mathscr{B}$ be given. Then it follows from Lemma 5.3 that there exists a sequence $\{h_m\}\subset\mathscr{B}$ such that $\mathscr{W}(h_m)\to\mathscr{W}(h)$ as $m\to\infty$. Since $\mathscr{W}((h_m+f)^*\otimes(h_m+f))\geqslant 0$, it suffices to prove $\mathscr{W}((h_m+f)^*\otimes(h_m+f))\to\mathscr{W}((h+f)^*\otimes(h+f))$ as $m\to\infty$. Since an element of $F_{\ell,k}$ is a sum of the elements of the form

$$h^{[k]} = c^k_{i_2}\circ c^k_{i_2}\circ\cdots\circ c^k_{i_s}(g^{[k]})$$

with $g^{[k]}\in\mathscr{C}^m_c(U_m)\subset\mathscr{Q}(\cap_{j=1}^s\overline{K^k_{i_j}})$ and $h^{[k]}$ is approximated by

$$h^{[k]}_m = c^n_{i_1}\circ c^n_{i_2}\circ\cdots\circ c^n_{i_n}(g^{[k]}_m)$$

with $g^{[k]}_m\in\mathscr{Q}(\mathbf{D}^{4k})$, it suffices to show that for $m\to\infty$

$$\mathscr{W}((h^{[k]}_m)^*\otimes h^{[n-k]}_m)\to\mathscr{W}((h^{[k]})^*\otimes h^{[n-k]}), \tag{5.2}$$

$$\mathscr{W}((h^{[k]}_m)^*\otimes f^{[n-k]})\to\mathscr{W}((h^{[k]})^*\otimes f^{[n-k]}). \tag{5.3}$$

$$\mathscr{W}((f^{[k]})^*\otimes h^{[n-k]}_m)\to\mathscr{W}((f^{[k]})^*\otimes h^{[n-k]}). \tag{5.4}$$

Note that

$$\begin{aligned}(h^{[k]})^*\otimes h^{[n-k]} &= c^k_{i_1}\circ c^k_{i_2}\circ\cdots\circ c^k_{i_s}(g^{[k]*})\otimes c^{n-k}_{j_1}\circ c^{n-k}_{j_2}\circ\cdots\circ c^{n-k}_{j_t}(g^{[n-k]})\\ &= c^n_{i_1}\circ c^n_{i_2}\circ\cdots\circ c^n_{i_s}\circ c^n_{i_{s+1}}\circ c^n_{i_{s+2}}\circ\cdots\circ c^n_{i_{s+t}}(g^{[k]*}\otimes g^{[n-k]}).\end{aligned}$$

where $i_{s+l}=k+j_l$, $g^{[k]}\in\mathscr{Q}(\cap_{j=1}^s\overline{K^k_{i_j}})$ and $g^{[n-k]}\in\mathscr{Q}(\cap_{i=1}^t\overline{K^{n-k}_{j_i}})$. Since

$$\mathscr{W}\circ c^n_{i_1}\circ c^n_{i_2}\circ\cdots\circ c^n_{i_s}\circ c^n_{i_{s+1}}\circ c^n_{i_{s+2}}\circ\cdots\circ c^n_{i_{s+t}}:\ \mathscr{Q}(\mathbf{D}^{4n})\to\mathbf{C}$$

is extended continuously to $\mathscr{Q}(\cap_{j=1}^{s+t}\overline{K^n_{i_j}})\supset\mathscr{Q}(\cap_{j=1}^s\overline{K^k_{i_j}})\otimes\mathscr{Q}(\cap_{i=1}^t\overline{K^{n-k}_{j_i}})$ by Proposition 5.1, Equation (5.2) follows from

$$g^{[k]}_m\otimes g^{[n-k]}_m\to g^{[k]}\otimes g^{[n-k]},$$

which in turn follows from Lemma 5.3. The relations (5.3) and (5.4) are easy to prove. □

VI. ASYMPTOTIC ABELIANNESS II

Let $\mathscr{W}$ be a state on $\mathscr{B}$ which satisfies hypothesis H_3. By Proposition 5.4 it has a monotone continuous linear extension to a state on the *-algebra $\mathscr{C}$ introduced in Corollary 5.2. After the corresponding preparations we are going to show that the GNS-representation of this state on $\mathscr{C}$ also is asymptotically Abelian.

Lemma 6.1: Let π be a permutation of $\{1,\ldots,n\}$ such that $\pi(i)\leqslant j$ and $\pi(i+1)\geqslant j+1$. Let $a=(0,\mathbf{a})$ be a unit vector in $\mathbf{R}^4$ and $\phi^\pi_{\lambda a}(x_1,\ldots,x_n)=\phi(y_{\pi(1)},\ldots,y_{\pi(n)})$, where $y_k=x_k$ for $k=1,\ldots,j$, $y_k=x_k-\lambda a$ for $k=j+1,\ldots,n$. Let $L_k=\underline{K_k}$ or $L_k=\mathbf{D}^{4n}$, and $L=\cap_{1\leqslant k\leqslant n-1}L_k$. Let $\phi\in\mathscr{Q}(L)$ and $F^i\in\mathscr{Q}(\mathbf{D}^{4n})'$ such that supp $F^i\subset L\cap K_i$. Then in the limit $\lambda\to\infty$ one has

$$F^i(\phi^\pi_{\lambda a})\to 0. \tag{6.1}$$

Proof: For simplicity assume $\pi=1$ (identity) and $i=j$. Since $\phi\in\mathscr{O}(L)$, there are positive numbers r, N and a neighborhood O of L in Q^{4n} such that $|\phi(z)|\leqslant Ne^{-|z|/r}$ for $z\in O\cap\mathbf{C}^{4n}$. Since

$$|F^j(\phi^1_{\lambda a})|\leqslant M_{m,V}\sup_{V\cap\mathbf{C}^{4n}}|\phi^1_{\lambda a}(z)|e^{|z|/m}$$

holds for any $m\in\mathbf{N}$ and neighborhood V of $L\cap\overline{K_j}$ in Q^{4n} such that $m\geqslant r$ and $V\subset O$, it suffices to prove

$$\sup_{V\cap\mathbf{C}^{4n}}\exp(-\Sigma_{k=1}^{j}|z_k|/r)\exp(-\Sigma_{k=j+1}^{n}|z_k-\lambda a|/r)\exp(|z|/m)\to 0 \tag{6.2}$$

as $\lambda\to\infty$ for some $m\in\mathbf{N}$ and neighborhood V of $L\cap\overline{K_j}$ in Q^{4n}. The difference between formulas (4.2) and (6.2) is that of U and V. U is a neighborhood of K_j and V is a neighborhood of $L\cap K_j$. Since we can choose V so that $V\subset U$, the proof of Lemma 4.1 applies. □

Now, as an extension of Proposition 4.3 asymptotic Abelianness follows for the GNS-representation Π of $\mathscr{C}$.

Proposition 6.2: As in Proposition 4.7 let Π be the *-representation of $\mathscr{C}$ associated with the state $\mathscr{W}$ which on $\mathscr{B}$ satisfies the hypotheses H_0–H_3. For any Φ, $\Psi\in\mathscr{D}=\mathscr{D}(\Pi)$, $f,g\in\mathscr{C}$ and any spacelike vector a, we have

$$(\Psi,\Pi(f)\Pi(g_{\lambda a})\Phi)-(\Psi,\Pi(g_{\lambda a})\Pi(f)\Phi)\to 0$$

as $\lambda\to\infty$ (asymptotically abelian).

Proof: The proposition follows from Lemma 6.1 by using the same argument as in Lemma 4.2. □

VII. THE LOCAL CLOSURE AND ASYMPTOTIC ABELIANNESS III

We prepare the definition of the local closure by reminding the reader of the (standard) closure of a representation of a *-algebra.

Let $\mathscr{D}$ be a dense subspace of a Hilbert space $\mathscr{H}$. Denote by $\mathscr{L}^\dagger(\mathscr{D},\mathscr{H})$ the set of all linear operators A such that $\mathscr{D}(A)=\mathscr{D}$ and $\mathscr{D}(A^*)\supset\mathscr{D}$, and put $\mathscr{L}^\dagger(\mathscr{D})=\{A\in\mathscr{L}^\dagger(\mathscr{D},\mathscr{H});A\mathscr{D}\subset\mathscr{D}$ and $A^*\mathscr{D}\subset\mathscr{D}\}$. $\mathscr{L}^\dagger(\mathscr{D})$ is a *-algebra with the involution $A\to A^\dagger=A^*_{|\mathscr{D}}$. A *-subalgebra $\mathscr{P}$ of $\mathscr{L}^\dagger(\mathscr{D})$ with identity operator is called an *O*-algebra*.

A *-representation $\pi:\mathscr{A}\to\mathscr{L}^\dagger(\mathscr{D})$ of a *-algebra $\mathscr{A}$ is called *closed* iff its domain is closed in the graph topology (see Definition 3.1.4 of Ref. 3 and Definition 2.4 of Ref. 10). We begin with the following lemma (Lemma 2.6 in Ref. 10).

Lemma: Suppose π is a *-representation of the a *-algebra $\mathscr{A}$ on a Hilbert space $\mathscr{H}$. Then, there is a unique minimal closed extension $\boldsymbol{\pi}$ of π. Furthermore, the domain of $\boldsymbol{\pi}$ is given by

$$\mathscr{D}(\boldsymbol{\pi})=\cap_{A\in\mathscr{A}}\operatorname{dom}\overline{\pi(A)}.$$

Corollary: Under the assumptions of the above lemma the following holds:

(a) $\boldsymbol{\pi}(B)\mathscr{D}(\boldsymbol{\pi})\subset\mathscr{D}(\boldsymbol{\pi})$ for all $B\in\mathscr{A}$ and $\boldsymbol{\pi}(AB)f=\boldsymbol{\pi}(A)\boldsymbol{\pi}(B)f$ for all A, $B\in\mathscr{A}$ and all $f\in\mathscr{D}(\pi)$.

(b) If $U(a,\Lambda)$ is a unitary representation of the Poincaré group such that

$$U(a,\Lambda)\mathscr{D}(\pi)\subset\mathscr{D}(\pi)\quad\text{and}\quad U(a,\Lambda)\pi(A)U(a,\Lambda)^{-1}=\pi(\alpha_{(a,\Lambda)}(A)),$$

then

$$U(a,\Lambda)\mathscr{D}(\boldsymbol{\pi})\subset\mathscr{D}(\boldsymbol{\pi})\quad\text{and}\quad U(a,\Lambda)\boldsymbol{\pi}(A)U(a,\Lambda)^{-1}=\boldsymbol{\pi}(\alpha_{(a,\Lambda)}(A)).$$

Proof: In fact, let $f\in\mathscr{D}(\boldsymbol{\pi})$. Then there exists a sequence $\{f_n\in\mathscr{D}(\pi);\ n=1,2,...\}$ such that $f_n\to f$ and $\pi(C)f_n\to\boldsymbol{\pi}(C)f$ for all $C\in\mathscr{A}$. Let $g=U(a,\Lambda)f$ and $g_n=U(a,\Lambda)^{-1}f_n$. Then $g_n\to g$ and $\pi(A)g_n=\pi(A)U(a,\Lambda)^{-1}f_n=U(a,\Lambda)^{-1}\pi(\alpha_{(a,\Lambda)}(A))f_n\to U(a,\Lambda)^{-1}\boldsymbol{\pi}(\alpha_{(a,\Lambda)}(A))f$. This shows that $g\in\mathscr{D}(\pi(A))$. Since $A\in\mathscr{A}$ is arbitrary we have

$$U(a,\Lambda)\mathscr{D}(\boldsymbol{\pi})\subset\mathscr{D}(\boldsymbol{\pi}) \quad \text{and} \quad U(a,\Lambda)\boldsymbol{\pi}(A)U(a,\Lambda)^{-1}=\boldsymbol{\pi}(\alpha_{(a,\Lambda)}(A)).$$

□

Definition 7.1: Given a state $\mathscr{W}\in\mathscr{B}'$ which satisfies hypothesis H_3 denote by Π the GNS-representation of its monotone extension to the *-algebra $\mathscr{C}$. Introduce the subspace of the representation space

$$\hat{\mathscr{D}}=\cap_{f\in\mathscr{C}}\,\mathrm{dom}\,\overline{\Pi(f)},\quad \hat{\Pi}(f)=\overline{\Pi(f)}_{|\hat{\mathscr{D}}}.$$

Then the *local closure* $\hat{\Pi}$ (of the field induced by the state $\mathscr{W}$) is defined as the mapping

$$\hat{\Pi}: f\in\mathscr{B}\to\hat{\Pi}(f)\in\mathscr{L}^{\dagger}(\hat{\mathscr{D}}).$$

As a counterpart of Proposition 6.2 we get that the local closure preserves asymptotic Abelianness.

Proposition 7.2: Let $\mathscr{W}$ be a state on $\mathscr{B}$ satisfying hypothesis H_3 and let Π be the associated GNS-representation of its extension to a state on $\mathscr{C}$. Then the local closure $\hat{\Pi}$ satisfies the following: For any $\Phi,\ \Psi\in\hat{\mathscr{D}},\ f,g\in\mathscr{C}$, and any spacelike vector a, one has, as $\lambda\to\infty$,

$$(\Psi,\hat{\Pi}(f)\hat{\Pi}(g_{\lambda a})\Phi)-(\Psi,\hat{\Pi}(g_{\lambda a})\hat{\Pi}(f)\Phi)\to 0.$$

Proof: Given $f\in\mathscr{B}_i$, $g\in\mathscr{B}_j$ and $\Phi,\ \Psi\in\hat{\mathscr{D}}$ there are sequences Φ_n, Ψ_n in $\mathscr{D}(\Pi)$ such that $\Phi_n\to\Phi$, $\Psi_n\to\Psi$, $\Pi(f^*)\Psi_n\to\hat{\Pi}(f^*)\Psi$, and $\Pi(g)\Phi_n\to\hat{\Pi}(g)\Phi$ as $n\to\infty$. The functionals

$$\tilde{\mathscr{O}}(\mathbf{D}^{4i})\times\tilde{\mathscr{O}}(\mathbf{D}^{4j})\ni(f,g)\to(\Psi_n,\Pi(f)\Pi(g)\Phi_n)\in\mathbf{C}$$

define Fourier hyperfunctions $F_n\in\tilde{\mathscr{O}}(\mathbf{D}^{4(i+j)})'$, and it follows that $F_n(f\otimes g)\to(\Psi,\hat{\Pi}(f)\hat{\Pi}(g)\Phi)$ as $n\to\infty$. Since $\tilde{\mathscr{O}}(\mathbf{D}^{4(i+j)})$ is a barreled space, the sequence $\{F_n\}$ is equicontinuous and converges to a Fourier hyperfunction F, uniformly on every compact subset of $\tilde{\mathscr{O}}(\mathbf{D}^{4(i+j)})$ (See the Corollary of Theorem 33.1 of Ref. 11). Thus the functional

$$\tilde{\mathscr{O}}(\mathbf{D}^{4i})\times\tilde{\mathscr{O}}(\mathbf{D}^{4j})\ni(f,g)\to(\Psi,\hat{\Pi}(f)\hat{\Pi}(g)\Phi)\in\mathbf{C}$$

defines a Fourier hyperfunction $F\in\tilde{\mathscr{O}}(\mathbf{D}^{4(i+j)})'$ such that

$$F(f\otimes g)=(\Psi,\hat{\Pi}(f)\hat{\Pi}(g)\Phi).$$

From the definition of the local closure ($\hat{\mathscr{D}}=\cap_{f\in\mathscr{C}}\,\mathrm{dom}\,\overline{\Pi(f)}$) it also follows

$$F_n(h)=(\Psi_n,\Pi(h)\Phi_n)\to(\Psi,\hat{\Pi}(h)\Phi)=F(h),$$

for all $h\in E_{\swarrow,i+j}$. This shows that not only F_n but also F satisfies the condition of local commutativity, i.e., the support of

$$F(x_1,\ldots,x_k,x_{k+1},\ldots,x_{i+j})-F(x_1,\ldots,x_{k+1},x_k,\ldots,x_{i+j})$$

is contained in $\overline{K_k^{i+j}}$. Since the asymptotic Abelianness follows from locality we conclude as in Propositions 4.3 respectively 6.2. □

Remark 7.3: Let $F_n\in\tilde{\mathscr{O}}(K_k^{i+j})'$, $n=1,2,\ldots$ be given. The limit $\lim_{n\to\infty}F_n(f)$ for all $f\in\tilde{\mathscr{O}}(\mathbf{D}^{4(i+j)})$, if it exists, defines an element $F\in\tilde{\mathscr{O}}(\mathbf{D}^{4(i+j)})'$. However, the limit $\lim_{n\to\infty}F_n(f)$ for all $f\in\tilde{\mathscr{O}}(K_k^{i+j})$, if it exists, defines an element $F\in\tilde{\mathscr{O}}(K_k^{i+j})'$. This is the technical reason why we have defined $\hat{\mathscr{D}}$ by $\cap_{f\in\mathscr{C}}\,\mathrm{dom}\,\overline{\Pi(f)}$, not by $\cap_{f\in\mathscr{B}}\,\mathrm{dom}\,\overline{\Pi(f)}$.

Proposition 7.4: Suppose $\mathscr{W}\in\mathscr{B}'$ satisfies hypotheses H_0-H_3 and let Π be the representation of $\mathscr{B}$ and U the representation of the Poincaré group G as determined by Proposition 3.3. Denote by Q_0 the orthogonal projection operator onto the subspace $\mathscr{H}_0$ of vacuum states [Eq. (3.10)] and let $\hat{\Pi}$ be the local closure as given in Definition 5.2. Then the following holds:

(a) $Q_0\hat{\Pi}(\mathscr{C})\hat{\mathscr{D}}_0\subset\hat{\mathscr{D}}_0$ where $\hat{\mathscr{D}}_0=\hat{\mathscr{D}}\cap\mathscr{H}_0$;

(b) $\hat{\mathscr{D}}_0$ is dense in $\mathscr{H}_0$.

Proof: Given any $\Psi \in \hat{\mathscr{D}}_0$, any $f,g \in \mathscr{C}$ and any spacelike $a \in \mathbf{R}^4$, Proposition 7.2 implies

$$\|\hat{\Pi}(g)U(\lambda a)\hat{\Pi}(f\ )\Psi\|^2-(\Psi,\hat{\Pi}(g^*_{-\lambda a}g_{-\lambda a})\hat{\Pi}(f^*f\ )\Psi)$$
$$=(\Psi,\hat{\Pi}(f^*)\hat{\Pi}(g^*_{-\lambda a}g_{-\lambda a})\hat{\Pi}(f\ )\Psi)-(\Psi,\hat{\Pi}(g^*_{-\lambda a}g_{-\lambda a})\hat{\Pi}(f^*f\ )\Psi)\to 0$$

as $\lambda\to\infty$ and therefore, since for all λ,

$$|(\Psi,\hat{\Pi}(g^*_{-\lambda a}g_{-\lambda a})\hat{\Pi}(f^*f\ )\Psi)|\leq\|\hat{\Pi}(g^*g)\Psi\|\|\hat{\Pi}(f^*f\ )\Psi\|,$$

we deduce that $\{\|\hat{\Pi}(g)U(\lambda a)\hat{\Pi}(f\ )\Psi\|;\ \lambda\in\mathbf{R}\}$ is bounded. Let $\Phi\in\mathscr{D}(\hat{\Pi}(g)^*)$. Then we have

$$(\Phi,\hat{\Pi}(g)U(\lambda a)\hat{\Pi}(f\ )\Psi)=(\hat{\Pi}(g)^*\Phi,U(\lambda a)\hat{\Pi}(f\ )\Psi)\to(\hat{\Pi}(g)^*\Phi,Q_0\hat{\Pi}(f\ )\Psi)$$

as $\lambda\to\infty$ (Theorem 8 of Ref. 12). Since $\mathscr{D}(\hat{\Pi}(g)^*)$ is dense and $\{\|\hat{\Pi}(g)U(\lambda a)\hat{\Pi}(f\ )\Psi\|;\ \lambda\in\mathbf{R}\}$ is bounded, $\hat{\Pi}(g)U(\lambda a)\hat{\Pi}(f\ )\Psi$ converges weakly for $\lambda\to\infty$. Since $U(\lambda a)\hat{\Pi}(f\ )\Psi\to Q_0\hat{\Pi}(f\ )\Psi$ weakly as $\lambda\to\infty$, we conclude that $Q_0\hat{\Pi}(f\ )\Psi\in\operatorname{dom}\overline{\hat{\Pi}(g)}=\operatorname{dom}\overline{\Pi(g)}$. Since g is arbitrary this implies $Q_0\hat{\Pi}(f\ )\Psi\in\hat{\mathscr{D}}$ and thus $Q_0\hat{\Pi}(\mathscr{C})\hat{\mathscr{D}}_0\subset\hat{\mathscr{D}}_0$. Since $\hat{\Pi}(\mathscr{C})\Omega\subset\hat{\mathscr{D}}$ is dense in $\mathscr{H}$, $Q_0\hat{\Pi}(\mathscr{C})\Omega\subset Q_0\hat{\Pi}(\mathscr{C})\hat{\mathscr{D}}_0$ is dense in $\mathscr{H}_0$. Thus $\hat{\mathscr{D}}_0$ is dense in $\mathscr{H}_0$. □

Remark 7.5: Since $\mathscr{C}_{\sim}(\mathbf{D}^{4n})$ is dense in $\mathscr{C}_{\sim}(K_i^n)$ we actually know that $\hat{\Pi}(\mathscr{B})\Omega=\Pi(\mathscr{B})\Omega$ is dense in $\mathscr{H}$.

The above proposition enables us to define a reduction of the field algebra $\Pi(\mathscr{B})$ (notation of Proposition 7.4) to the subspace of vacuum states $\mathscr{H}_0$. By part (a) we know that the domain $\hat{\mathscr{D}}_0$ is left invariant under all operators $Q_0\hat{\Pi}(f\ )Q_0$, $f\in\mathscr{C}$. Hence products of these operators are well defined, and it follows easily that

$$\mathscr{P}_0=\vee\{Q_0\hat{\Pi}(f\ )Q_{0|\hat{\mathscr{D}}_0};f\in\mathscr{C}\} \tag{7.1}$$

is an algebra in $\mathscr{H}_0$ with the domain $\hat{\mathscr{D}}_0$ which is dense in the vacuum subspace $\mathscr{H}_0$. The following proposition asserts that this algebra is actually Abelian and admits a natural involution.

Proposition 7.6: Under the assumptions of Proposition 7.4 the set of operators $\mathscr{P}_0$ is an Abelian O^*-algebra in $\mathscr{H}_0$ with dense domain $\hat{\mathscr{D}}_0$.

Proof: It is also an O^*-algebra since $\operatorname{dom}(Q_0\hat{\Pi}(f\ )Q_0)^*=\operatorname{dom}Q_0\hat{\Pi}(f\ )^*Q_0\supset\operatorname{dom}Q_0\hat{\Pi}(f^*)Q_0\supset\hat{\mathscr{D}}_0$, hence $(Q_0\hat{\Pi}Q_0)^*_{|\hat{\mathscr{D}}_0}\in\mathscr{P}_0$. For the Abelianness of this algebra it suffices to show

$$(\Psi,\hat{\Pi}(f\ )Q_0\hat{\Pi}(g)\Phi)=(\Psi,\hat{\Pi}(g)Q_0\hat{\Pi}(f\ )\Phi)$$

for all Φ, $\Psi\in\mathscr{D}_0$ and $f,g\in\mathscr{C}$. And this follows easily from the relations

$$(\Psi,\hat{\Pi}(f\ )U(\lambda a)\hat{\Pi}(g)\Phi)\to(\Psi,\hat{\Pi}(f\ )Q_0\hat{\Pi}(g)\Phi).$$

$$(\Psi,\hat{\Pi}(g)U(-\lambda a)\hat{\Pi}(f\ )\Phi)\to(\Psi,\hat{\Pi}(g)Q_0\hat{\Pi}(f\ )\Phi),$$

$$(\Psi,\hat{\Pi}(f\ )U(\lambda a)\hat{\Pi}(g)\Phi)-(\Psi,\hat{\Pi}(g)U(-\lambda a)\hat{\Pi}(f\ )\Phi)\to 0$$

as $\lambda\to\infty$. □

VIII. VACUUM STRUCTURE

Suppose a HFQFT is given in terms of a state $\mathscr{W}$ on the test function algebra $\mathscr{B}$ which satisfies hypotheses H_0–H_3. According to Proposition 3.3 we have a field O^*-algebra $\Pi(\mathscr{B})$ with dense domain $\mathscr{D}=\Pi(\mathscr{B})\Omega$ in a complex Hilbert space $\mathscr{H}$, a unitary representation U of the translation group in $\mathscr{H}$ and a strongly cyclic unit vector $\Omega\in\mathscr{D}$ which is invariant under all translations. In Sec. VII, by taking the local closure, we obtained an extension $\mathscr{P}=\hat{\Pi}(\mathscr{B})$ of the field O^*-algebra $\Pi(\mathscr{B})$ with dense domain $\hat{\mathscr{D}}$ in the Hilbert space $\mathscr{H}$ which allows a reduction $\mathscr{P}_0$

[Eq. (7.1)] to the subspace $\mathscr{H}_0$ of translation invariant states since Proposition 7.4 shows $Q_0\hat{\Pi}(\mathscr{B})\hat{\mathscr{D}}_0\subset\hat{\mathscr{D}}_0=\hat{\mathscr{D}}\cap\mathscr{H}_0$ where Q_0 is the orthogonal projector onto $\mathscr{H}_0$. From here on the discussion of ''Borchers's anomaly'' is basically the same as in standard QFT. We indicate the basic steps. First one has to decide on how to express the irreducibility of the field, either in terms of the weak or the strong commutant of the field algebra to be trivial. A natural choice is the weak commutant (see Ref. 3)

$$\mathscr{P}'_w=\{X\in\mathscr{B}(\mathscr{H});\forall u,v\in\hat{\mathscr{D}},\forall A\in\mathscr{P},(X^*u,Av)=(A^*u,Xv)\}. \tag{8.1}$$

The commutant of the weak commutant of the field algebra is the von Neumann algebra $\mathscr{R}$ associated with $\mathscr{P}$:

$$\mathscr{R}=(\mathscr{P}'_w)'.$$

This algebra contains the projector Q_0 as the following lemma shows.

Lemma 8.1: Under the assumptions of Proposition 7.4 we have

(a) $Q_0\in\mathscr{R}$.

(b) $Q_0\mathscr{P}'_wQ_{0|\mathscr{H}_0}=\mathscr{P}'_{w|\mathscr{H}_0}\subset(\mathscr{P}_0)'_w$.

(c) The mapping

$$\mathscr{P}'_w\ni S\to\phi(S)=Q_0SQ_0\in\mathscr{P}'_{w|\mathscr{H}_0} \tag{8.2}$$

is an isomorphism.

Proof: For $S\in\mathscr{P}'_w$ denote $S(x)=U(x)SU(-x)$. Then we have

$$(\hat{\Pi}(f)^*\Omega,U(-x)S\Omega)=(\hat{\Pi}(f_x)^*\Omega,S\Omega)=(\Omega,S\hat{\Pi}(f_x)\Omega)=(\Omega,SU(x)\hat{\Pi}(f)\Omega).$$

The Fourier transform of this equation is

$$(\hat{\Pi}(f)^*\Omega,E(-d^4p)S\Omega)=(\Omega,SE(d^4p)\hat{\Pi}(f)\Omega).$$

Hence, by the spectral condition, its support must be contained in $\{0\}$. Thus, $(\hat{\Pi}(f)^*\Omega,U(-x)S\Omega)$ is constant and equal to $(\hat{\Pi}(f)^*\Omega,S\Omega)$ $(x=0)$. Since $\hat{\Pi}(\mathscr{B})\Omega$ is dense in $\mathscr{H}$, this implies $S(-x)\Omega=S\Omega$. Since

$$\begin{aligned}(\hat{\Pi}(f)\Omega,S(-x)\hat{\Pi}(g)\Omega)&=(\hat{\Pi}(f_x)\Omega,S\hat{\Pi}(g_x)\Omega)=(\hat{\Pi}(g_x)^*\hat{\Pi}(f_x)\Omega,S\Omega)\\&=(\hat{\Pi}(g_x)^*\hat{\Pi}(f_x)\Omega,S(x)\Omega)=(\hat{\Pi}(g)^*\hat{\Pi}(f)\Omega,S\Omega)\\&=(\hat{\Pi}(f)\Omega,S\hat{\Pi}(g)\Omega)\end{aligned}$$

and $\hat{\Pi}(\mathscr{B})\Omega$ is dense in $\mathscr{H}$, it follows $S(-x)=S$, i.e., $[U(x),S]=0$. Consequently $U(x)\in\mathscr{R}$ and therefore $Q_0\in\mathscr{R}$.

For the proof of part (b) observe that for any $T\in\mathscr{P}'_w$, $\Phi,\Psi\in\hat{\mathscr{D}}_0$, and $B\in\Pi(\mathscr{C})$ one has, denoting the local closure of B by $\overline{B}$ and observing $Q_0\in(\mathscr{P}'_w)'$,

$$(\Psi,T\overline{B}\Phi)=(\Psi,T_{|\mathscr{H}_0}Q_0\overline{B}Q_0\Phi)$$

$$(\Psi,T\overline{B}\Phi)=(\overline{B}^*\Psi,T\Phi)=((Q_0\overline{B}Q_0)^*\Psi,T_{|\mathscr{H}_0}\Phi).$$

This implies (b).

Finally consider $S\in\mathscr{P}'_w$ such that $Q_0S=0$ on $\mathscr{H}_0$, then $S\Omega=SQ_0\Omega=Q_0S\Omega=0$ and therefore, for all $f,g\in\mathscr{B}$,

$$(\hat{\Pi}(f)\Omega,S\hat{\Pi}(g)\Omega)=(\hat{\Pi}(g)^*\hat{\Pi}(f)\Omega,S\Omega)=0.$$

Since $\hat{\Pi}(\mathscr{B})\Omega$ is dense in the Hilbert space $\mathscr{H}$ this proves $S=0$. Thus we conclude. □

Let $\mathscr{P}'_s=\{X\in\mathscr{B}(\mathscr{H});\forall A\in\mathscr{P},AX\supset XA\}$ be the strong commutant of $\mathscr{P}$ and let d_0 be the dimension of $\mathscr{H}_0$. Then the following proposition is well known (see Proposition 3.1.12 of Ref. 3) in standard quantum field theory.

Proposition 8.2: Let a Wightman theory be given by a O^*-algebra $\mathscr{P}$ with strongly cyclic vector Ω such that $\mathscr{P}'_s=\mathscr{P}'_w$. Then the condition

$$(1)\quad \mathscr{P}'_w=\mathbf{C}(\mathscr{H})$$

implies the condition

$$(2)\quad d_0=1 \quad \text{or} \quad d_0=\infty.$$

The above proposition asserts that an irreducible standard quantum field theory may have not only a one-dimensional but also an infinite-dimensional vacuum subspace. This phenomenon is called sometimes Borchers's anomaly.

According to Proposition 7.6 the reduction of the field algebra $\mathscr{P}$ of HFQFT to the vacuum subspace $\mathscr{H}_0$, i.e., the set $\mathscr{P}_0$ introduced in (7.1), is an Abelian O^*-algebra. If this reduced algebra $\mathscr{P}_0$ is irreducible we know $(\mathscr{P}_0)'_w=\mathbf{C}(\mathscr{H}_0)$. Now Lemma 7.1 implies first $\mathscr{P}'_{w|\mathscr{H}_0}=\mathbf{C}(\mathscr{H}_0)$ and then $\mathscr{P}'_w=\mathbf{C}(\mathscr{H}_0)$, i.e., the field algebra $\mathscr{P}$ itself is irreducible. Recall that an Abelian O^*-algebra can be irreducible not only in a one-dimensional but also in an infinite-dimensional space, whereas an Abelian von Neumann algebra can be irreducible only in a one-dimensional space (see Ref. 10). Thus we deduce that Borchers's anomaly can occur in HFQFT.

ACKNOWLEDGMENTS

Most of the work for this paper was done during S.N.'s visit to the Department of Mathematics and Applied Mathematics, University of Durban-Westville. We are very grateful to the Foundation for Research Development (International Liaison and Open Research Programmes Departments) which promoted this collaboration through their generous funding. Finally we thank the referee of this paper for a number of very helpful suggestions and hints.

(Received 30 March 1998; accepted for publication 4 May 1998)

The convergence of large-order expansions in $\delta=1/D$, where D is the dimensionality of coordinate space, for energies $E(\delta)$ of Coulomb systems is strongly affected by singularities at $\delta=1$ and $\delta=0$. Padé–Borel approximants with modifications that completely remove the singularities at $\delta=1$ and remove the dominant singularity at $\delta=0$ are demonstrated. A renormalization of the interelectron repulsion is found to move the dominant singularity of the Borel function $F(\delta)=\Sigma_j E'_j/j!$, where E'_j are the the expansion coefficients of the energy with singularity structure removed at $\delta=1$, farther from the origin and thereby accelerate summation convergence. The ground-state energies of He and H_2^+ are used as test cases. The new methods give significant improvement over previous summation methods. *Shifted* Borel summation using $F_m(\delta)=\Sigma_j E'_j/\Gamma(j+1-m)$ is considered. The standard deviation of results calculated with different values of the shift parameter m is proposed as a measure of summation accuracy. © *1998 American Institute of Physics.* [S0022-2488(98)04210-8]

I. INTRODUCTION

Large-order perturbation theory in $1/D$, where D is the dimensionality of coordinate space, was proposed by Mlodinow[1,2] as an alternative to variational methods and coupling-constant perturbation theories for solving the Schrödinger equation. This ''dimensional perturbation theory'' has some appealing features. The first-order theory gives a semiquantitative description of electron correlation[3–11] and other subtle many-body effects[12] and it is relatively easy to calculate the perturbation expansion to very high order, using recursion relations.[13,14] $1/D$ expansions have now been calculated through 30th order for two-electron atoms[15] and tenth order for three-electron atoms.[16] Large-order expansions have also been calculated for the H atom in an external field[17–21] and for the H_2^+ molecule.[19,22,23]

The expansions for energies of Coulombic systems are, in general, divergent, due to singularities in the energy function $E(\delta)$, with $\delta=1/D$ treated as a continuous complex variable. One type of singularity is a pole in $E(\delta)$ that results from the fact that for certain integer values of D the expectation value of the Coulomb potential can diverge at particle coalescences.[24] This singularity can be accurately characterized and removed either by subtraction[25] or by rescaling,[5,26] making partial sums of the expansion appear rapidly convergent at low orders. A second characteristic type of singularity is a complicated branch point or essential singularity at $\delta=0$, which leads to divergence at higher orders.[15] This singularity can in principle be explained by an instanton analysis.[27–29] The zeroth-order limit of the perturbation theory corresponds to localization at an extremum of an effective potential that is the sum of the three-dimensional Coulomb potential and a centrifugal potential that comes from the dimensional continuation of the kinetic energy operator. For applications to bound systems, one generally chooses an extremum that corresponds

to a stable minimum. However, there typically exist sub-barrier trajectories in imaginary time that allow for tunneling out of the minimum. This causes the zeroth-order limit to be singular, with the energy expansion coefficients diverging as a factorial.

Summation methods in which the Coulombic poles are removed from $E(\delta)$ and then the remainder expansion is summed with Padé approximants or Padé–Borel approximants yield apparently convergent results at all orders.[15,30,31] Our purpose here is to refine those methods to improve the rate of convergence. Our strategy is to renormalize the Hamiltonian, by redefining the dimensional continuation in such a way that the effect of the singularity at the origin is mitigated, and to improve the techniques for modeling the singularities. In addition, we develop a method for estimating the accuracy of a given summation approximant. He and H_2^+ are used as test cases.

II. SUMMATION APPROXIMANTS

The asymptotic expansion in $1/D$ for the electronic energy of an atom or molecule has the form

$$E(\delta)\sim\delta^2\sum_{j=0}^{k}E_j\delta^j, \tag{1}$$

where $\delta=1/D$. There are various algorithms for computing the expansion coefficients E_j, but the most efficient, especially for problems with more than one degree of freedom, seems to be the matrix method of Dunn *et al.*[14] The direct evaluation of Eq. (1) at $\delta=1/3$ using partial sums, from truncation at given k, typically gives slow convergence at low orders and rapid divergence at high order.

For ground states of Coulombic systems, E has an expansion about $D=1$ in the form[24]

$$E(\delta)\sim a_{-2}(D-1)^{-2}+a_{-1}(D-1)^{-1}+\cdots. \tag{2}$$

For a one-electron atom with nuclear charge Z, the first term in Eq. (2) constitutes the exact solution, with $a_{-2}=2Z^2$. For two-electron atoms a_{-2} is equal to the ground-state energy of a two-electron Schrödinger equation in which the Coulomb potentials have been replaced with delta functions.[24,32] The exact solution for this equation was obtained by Rosenthal[33] for arbitrary Z.

To remove the effects of the poles one can either rescale the expansion,[5,26] by multiplying it by $(1-\delta)^2$, or explicitly subtract out the δ expansions of the poles.[25,30] If the residues are known exactly then subtraction works best. We consider two approaches for the case where a_{-2} is known but a_{-1} is not known: subtracting the second-order pole and rescaling to remove the first-order pole,

$$E(\delta)\sim\delta^2[a_{-2}(1-\delta)^{-2}+(1-\delta)^{-1}E'(\delta)], \tag{3a}$$

$$E'(\delta)=\sum_{j=0}^{k}\delta^jE'_j,\quad E'_j=E_j-E_{j-1}-a_{-2},\quad E_{-1}=0, \tag{3b}$$

or subtraction of both poles,

$$E(\delta)\sim\delta^2[a_{-2}(1-\delta)^{-2}+a_{-1}(1-\delta)^{-1}+E'(\delta)], \tag{4a}$$

$$E'(\delta)=\sum_{j=0}^{k}\delta^jE'_j,\quad E'_j=E_j-(j+1)a_{-2}-a_{-1}, \tag{4b}$$

with

$$a_{-1}=\lim_{\delta\to1}\sum_{j=0}^{k}\delta^j(E_j-E_{j-1}-a_{-2}). \tag{5}$$

Equation (5) can be evaluated using Padé summation.[30] The use of approximants based on Eqs. (4) has been called *hybrid* summation,[25] since it is the combination of an expansion about $\delta=1$ and an expansion about $\delta=0$. We will refer to the approach in Eqs. (3) as *rescaled hybrid* summation.

It is possible to obtain convergent results by summing the expansions for E' with Padé approximants or with Padé-Borel approximants. The latter give a somewhat better convergence rate. Here we employ a more general technique[28] that will be useful not just for summing the energy expansion but also for analyzing the singularity structure at $\delta=0$ and for estimating summation accuracy. Consider a function $F_m(\delta)$ with asymptotic expansion

$$F_m(\delta)\sim\sum_{j=j_0}^{k}\delta^j F_{m,j}, \quad F_{m,j}=E'_j/\Gamma(j+1-m), \tag{6}$$

where j_0 is the smallest integer greater than or equal to m. This function is related to $E'(\delta)$ by the transform

$$E'(\delta)=\sum_{j=0}^{j_0-1}E'_j\delta^j+e^{-(m-1)i\xi}\lim_{y\to\infty}\int_0^{ye^{i\xi}}x^{-m}F_m(\delta x e^{i\xi})\exp(-xe^{i\xi})dx, \tag{7}$$

with the angle ξ chosen so that $F(\delta x e^{i\xi})$ is nonsingular along the path of integration and $-\pi/2<\xi<\pi/2$. If $m=0$ then Eq. (7) is the usual Borel sum. For the function F_m in Eq. (7) we will substitute Padé approximants of the expansion in Eq. (6). For $m\neq 0$ we will refer to the summation method as *shifted* Padé–Borel summation.

III. RENORMALIZATION

A. Charge renormalization

The standard approach to analytic continuation of the Hamiltonian to arbitrary D is to continue the kinetic energy operator to D dimensions while keeping the physical, three-dimensional, definition for the potential energy operator.[32,34] If the energy is expressed in atomic units multiplied by Z^2/D^2, then the effective potential for an S state of the two-electron atom at large D is

$$V_{\rm eff}(r_1,r_2,\theta)=V_{\rm centr}+V_{\rm Coul}, \tag{8}$$

$$V_{\rm centr}=\left(\frac{1-6\delta+8\delta^2}{8\sin^2\theta}-\frac{1}{8}\right)\left(\frac{1}{r_1^2}+\frac{1}{r_2^2}\right), \tag{9}$$

$$V_{\rm Coul}=-r_1^{-1}-r_2^{-1}+\lambda\,(r_1^2+r_2^2-2r_1r_2\cos\theta)^{-1/2}. \tag{10}$$

$V_{\rm centr}$ is the centrifugal potential from the D-dimensional kinetic energy operator while $V_{\rm Coul}$ is the three-dimensional Coulomb potential, with $\lambda=1/Z$. This effective potential has a stable global minimum, with $r_1=r_2$, as long as λ is less than a critical value $\lambda_c\approx 0.8144$. For H^-, with $\lambda=1$, this symmetric extremum is a saddle point,[35,36] and if this point is used for the zeroth order of the perturbation theory, then the coefficients of the energy expansion will be complex numbers. Similarly, the symmetric large-D extrema for the H_2^+ and H_2 molecules also correspond to saddle points.[35,37,38]

A strategy for calculating $1/D$ expansions for systems that are unstable in the large-D limit was proposed in Ref. 39, using the fact that the definition of the dimensional continuation of the Hamiltonian is arbitrary as long as it gives the correct operator at $D=3$. If we renormalize the repulsive part of the Coulomb potential, by replacing it with a continuous function of δ such that the repulsion becomes weaker as δ approaches zero, it is possible to ensure that the symmetric extremum will be a minimum. This approach is closely related to the renormalized perturbation theory developed by Killingbeck for anharmonic oscillators.[40]

Charge renormalization was applied to large-order perturbation theory for H^- in Ref. 41. The parameter λ in Eq. (10) was replaced with the linear polynomial

$$\lambda(\delta)=\lambda_0+\lambda_1\delta, \quad \lambda_1=3(Z^{-1}-\lambda_0) \tag{11}$$

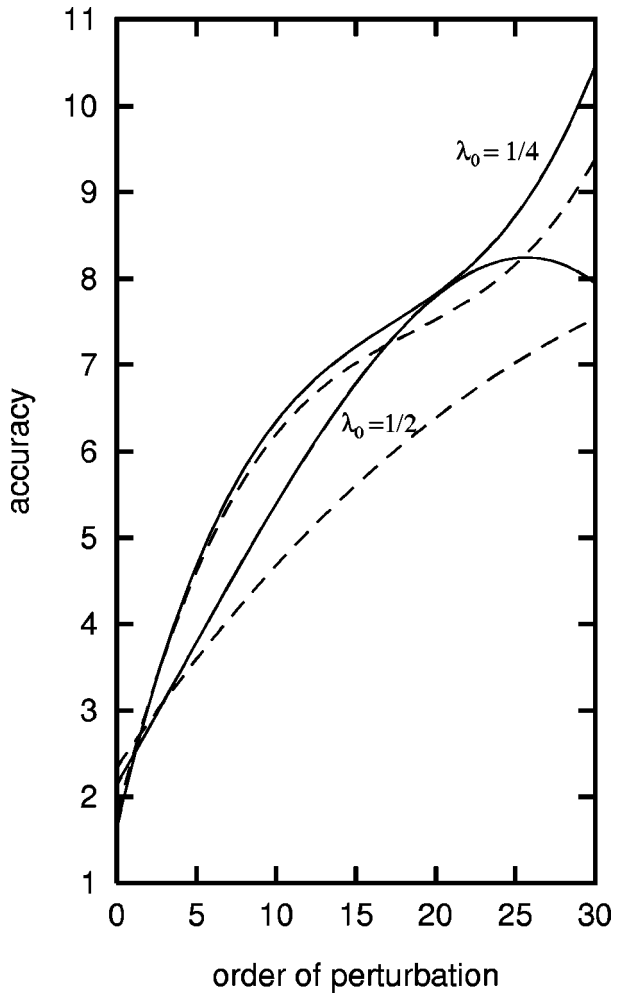

FIG. 1. Cubic polynomial fits of the number of accurate digits from summation approximants for the ground state energy of He, as a function of order, with ''accuracy'' defined as $-\log|\Delta E/E_{\text{exact}}|$, where $\Delta E = E_{\text{approx}} - E_{\text{exact}}$, with E_{exact} from Ref. 42. The dashed curves are from unshifted hybrid Padé–Borel approximants while the solid curves are from unshifted rescaled hybrid Padé–Borel approximants. Results are shown for $\lambda_0 = 1/2$ (unrenormalized) and for $\lambda_0 = 1/4$, as labeled, with $\lambda(\delta) = \lambda_0 + \lambda_1 \delta$.

with λ_0 treated as a free parameter. λ_1 is defined so that $\lambda(1/3) = 1/Z$. (This modification of λ does not affect the scale factor in the energy units. We continue to use atomic units multiplied by Z^2/D^2, where Z is independent of D.) The hybrid expansion, Eq. (4a), with Padé–Borel summation of E' gave convergent results for H^- for any value of λ_0 less than λ_c. The fastest convergence was for $\lambda_0 \approx (2Z)^{-1}$, which gave a more accurate result at given order for the ground-state energy of H^- than had been obtained[15] for the ground-state energy of He with unrenormalized λ. This rapid convergence for H^- suggests that the use of a δ-dependent potential energy operator could be used to improve the convergence even for systems that are stable at large D.

Figure 1 shows the effect on the convergence for He of setting $\lambda_0 = (2Z)^{-1}$. Since there is a fair amount of scatter in the convergence from order to order, we have plotted cubic polynomial fits to more clearly show the convergence patterns. The dashed curves correspond to hybrid approximants, based on Eq. (4a), while the solid curves correspond to rescaled hybrid approximants, based on Eq. (3a). The expansion of E' was summed with unshifted Padé–Borel approximants. We define the ''accuracy'' of a summation approximant S_k at given order k as

$$\alpha(k) = -\log_{10}|(S_k - E_{\text{exact}})/E_{\text{exact}}|, \tag{12}$$

which is a continuous measure of the number of accurate digits.

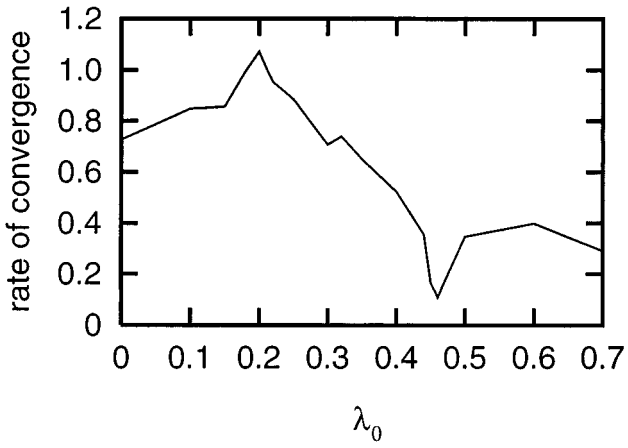

FIG. 2. The rate of convergence at low order for unshifted rescaled hybrid Padé–Borel approximants for the ground state energy of He, as a function of the renormalization parameter λ_0, using $\lambda(\delta)=\lambda_0+\lambda_1\delta$. The rate of convergence is defined here as the parameter α_1 from the three-parameter least-squares fit of the accuracy $\alpha(k)=\alpha_0+\alpha_1 k+\alpha_2 k^2+\alpha_3 k^3$ with α_0 constrained to equal the accuracy of S_0.

Several characteristic trends are evident. First, it is clear that the rescaled hybrid summation is the better of the two summation methods. It is possible to somewhat improve the accuracy of the unscaled hybrid approximants by applying Shanks extrapolation, with some subjective judgement, to the Padé-approximant sequences for a_{-1}, but the results remain less dependable than those from the rescaled hybrid method. The general shapes of the rescaled hybrid curves are representative of those over a wide range of λ_0. They begin with an almost linear increase in the number of accurate digits. Then, upon reaching an accuracy plateau of between approximately 6 and 8 digits the rate of convergence slows significantly. For $\lambda_0<0.8/Z$ there is a return to a more rapid convergence rate, beginning at around 25th order. Figure 2 shows the initial slope of $\alpha(k)$ as a function of λ_0. The increasing rate of convergence is balanced at very low order by the fact that the zeroth-order accuracy decreases for λ_0 far from the physical value. (The zeroth-order result is equal to the exact energy for $\lambda_0\approx 0.46$, which corresponds to a dip in Fig. 2.) Nevertheless, there is for the He atom a clear advantage to choosing λ_0 in the general neighborhood of $0.5/Z$.

The functional form chosen for $\lambda(\delta)$ is essentially arbitrary. In addition to the linear polynomial, Eq. (11), we have considered a quadratic polynomial,

$$\lambda(\delta)=\lambda_0+\lambda_1\delta+\lambda_2\delta^2, \tag{13}$$

$$\lambda_1=\frac{9}{2Z}-4\lambda_0-\frac{1}{2}\lambda(1), \quad \lambda_2=3\lambda_0+\frac{3}{2}\lambda(1)-\frac{9}{2Z}, \tag{14}$$

with $\lambda(1)$ and $\lambda_0=\lambda(0)$ treated as free parameters. This makes it possible to control the behavior at both of the solvable limits, $\delta=0$ and $\delta=1$. The position of the dominant singularities in the Borel function depend only on the value of λ_0. Therefore the rate of convergence of the summation approximants depends less strongly on $\lambda(1)$ than on $\lambda(0)$. We find in practice that certain choices of $\lambda(1)$ do improve the convergence at low and intermediate orders, especially for H^-, for which the linear $\lambda(\delta)$ can imply a very large value for $\lambda(1)$.

B. Effect on singularity structure

Analysis of the expansion coefficients for the ground-state energy of two-electron atoms has shown[15] that the dominant singularities of $F_0(\delta)$ (i.e., the singularities nearest to the origin of the complex δ plane) are a complex-conjugate pair of square-root branch points in the negative half-plane. Let $-\beta e^{\pm ib}$ be their locations. Then the coefficients of the asymptotic expansion in δ

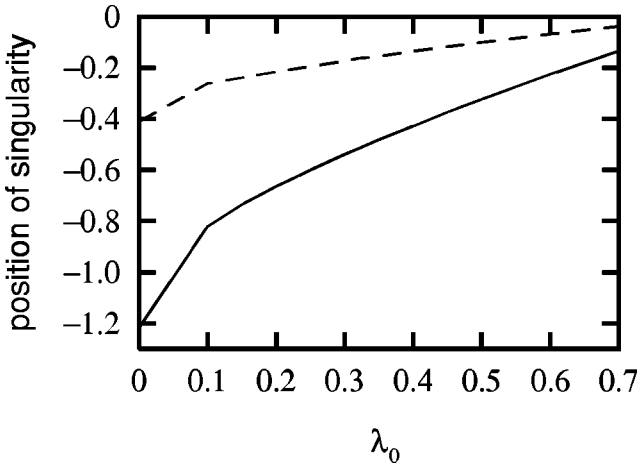

FIG. 3. Real part (solid curve) and imaginary part (dashed curve) of one of the dominant singularities in the Borel functions of the two-electron isoelectronic series, as a function of λ_0. The other dominant singularity is at the complex conjugate of this location.

of the expression $G(\delta+\beta e^{ib})^{1/2}+G^*(\delta+\beta e^{-ib})^{1/2}$, where G is a constant, will in the limit of large order be equal to the coefficients $F_{0,j}$ of the asymptotic expansion of F_0, Eq. (6). Thus, in the limit of large j we have

$$F_{0,j}\sim 2|G|\beta^{1/2}(-1)^j\,\frac{\Gamma(j-1/2)}{\Gamma(-1/2)\Gamma(j+1)}\,\beta^{-j}\,\cos\left[\left(j-\frac{1}{2}\right)b-\arg\,G\right]. \tag{15}$$

Now compare this to the function

$$f(\delta)=\gamma(\delta+\beta e^{ib})^{-1}+\gamma^*(\delta+\beta e^{-ib})^{-1}, \tag{16}$$

which has the expansion coefficients

$$f_j=2|\gamma|\beta^{-1}(-1)^j\beta^{-j}\,\cos[(j+1)b-\arg\,\gamma]. \tag{17}$$

If we set $\gamma=2^{-1}\pi^{-1/2}\beta^{3/2}|G|e^{i(\arg G+3b/2)}$, then $f_j\sim F_{3/2,j}$, which implies that the dominant singularities of $F_{3/2}(\delta)$ will be first-order poles at the same locations as the dominant branch points in $F_0(\delta)$.

The effect on convergence of the renormalization can be understood in terms of the effect on the locations of the dominant singularities of $F_m(\delta)$. A convenient method for determining these locations is to examine the singularities of the Padé approximants of F_m. Previously[15] we used the quadratic Padé approximants of F_0 for this purpose, noting the positions of the branch points nearest the origin. Once the branch points are approximately identified in this manner, the result can be refined by noting the positions of the corresponding poles in the linear Padé approximants of $F_{3/2}$, which stabilize somewhat faster.

We find that the positions of these singularities depend only on the value of λ_0. In general, there appear to be three distinct complex-conjugate pairs of singularities in the Borel functions. For λ_0 close to λ_c the dominant singularities are in the positive half plane, but as λ_0 decreases this pair rapidly moves away from the origin. For $\lambda_0<0.8$ the dominant singularities are the pair in the negative half plane. Figure 3 shows the real and imaginary parts of this pair. The steady movement away from the origin as λ_0 decreases is presumably related to the improvement in convergence. In the limit $\lambda_0\to 0$ the singularities in the Borel function must disappear, since $E'(\delta)$ is then nonsingular. It is interesting to note that the mechanism for this disappearance is for the prefactor multiplying the dominant singularities to go to zero, rather than for the positions of the singularities to move out to infinity. The third pair of singularities has an imaginary part of $\pm\pi$ with a small real part that depends weakly on λ_0. This is far enough from the origin that these can be expected to have no significant effect on the rate of convergence.

C. Effect on roundoff error

The recursive computation of the energy expansion coefficients E_k is somewhat unstable to roundoff error,[14,15] on account of their factorial divergence. However, in the hydrogenic limit $Z \to \infty$ (i.e., $\lambda \to 0$) the energy expansion is convergent, with only a linear increase in E_k with k. At small but nonzero λ the perturbation theory is still divergent but the growth of the expansion coefficients is nearly linear until very high order. This apparently comes about through massive cancellations of intermediate quantities that grow factorially. The result is extreme loss of precision near the hydrogenic limit.

The number of significant figures in the E_k decreases approximately linearly with k. It was stated previously[15,31] that roundoff error in the E_k becomes manifest in the S_k at about the value of k for which the precision of the E_k intersects the accuracy of the S_k. More careful analysis reveals that this rule is generally valid but somewhat conservative. The actual propagation of error in the summation approximants is complicated, with some approximants much less sensitive than others and thereby retaining their accuracy beyond the intersection. Such approximants can be identified empirically by adding to the E_k random error of a given magnitude.

For the renormalized calculations we find that the rate of precision loss depends mainly on the value of the parameter λ_0, increasing as λ_0 decreases. We have used quadruple-precision arithmetic (32 decimal digits) for computing the E_k in the calculations reported here, so that the roundoff error is always less than the convergence accuracy.

D. Renormalization for diatomic molecules

Within the Born–Oppenheimer approximation the Hamiltonian is not homogeneous, since the internuclear distance R is treated as a parameter rather than as a dynamical variable. Therefore, transformation to atomic units multiplied by D^{-2} replaces R with the D-dependent parameter $\tilde{R} = R/D^2$. In a recent study of H_2^+ it was shown that renormalization of this D dependence is a simple and effective way to improve the convergence of the $1/D$ expansion.[23] One replaces $\tilde{R}$ with

$$\tilde{R} = \frac{2(3+\beta)}{(D-1)(D+\beta)} R, \tag{18}$$

with β treated as a free parameter. (The factor of $D-1$ is included to give a reasonable $D \to 1$ limit.) An important effect of this renormalization is to ensure that the $D \to \infty$ limit corresponds to an effective potential with a single global minimum. Otherwise the molecule undergoes a symmetry breaking transition to a double-well problem as R increases, which significantly degrades the convergence of the large-order expansion. For many-electron diatomic molecules a renormalization of the interelectron repulsion, completely analogous to the procedure for atoms in Sec. III A, could be used to attenuate the effect on convergence of the interelectron repulsion in addition to the R renormalization that prevents the symmetry breaking.

IV. ESTIMATING THE ACCURACY OF THE SUMMATION APPROXIMANTS

We have calculated the summation approximants S_k using a range of integer and half-integer values for the shift parameter m in the Borel function F_m. The best results tend to correspond to $m = 0$, 1/2, 1, and 3/2, but which of these four is best at given order appears to be random. Therefore, to obtain an estimate of the accuracy of the summation at given order k we compute the standard deviation σ_k from the mean $\overline{S_k}$ of the four different S_k.

Figure 4 shows results for the He ground state energy with $\lambda_0 = 0.5/Z$. The dotted curve shows the actual accuracy of the mean. The solid curve shows $-\log_{10}|\sigma_k/\overline{S_k}|$. The largest disagreements between the actual accuracy and this estimate occurs at very high orders, where the mean tends to be significantly more accurate than the individual approximants and the estimate is too conservative.

V. DARBOUX–BOREL APPROXIMANTS

The singularity structure of the Borel function $F(\delta)$ for H_2^+ is similar to that for the two-electron atom except that the dominant singularity is typically a square-root branch point that lies

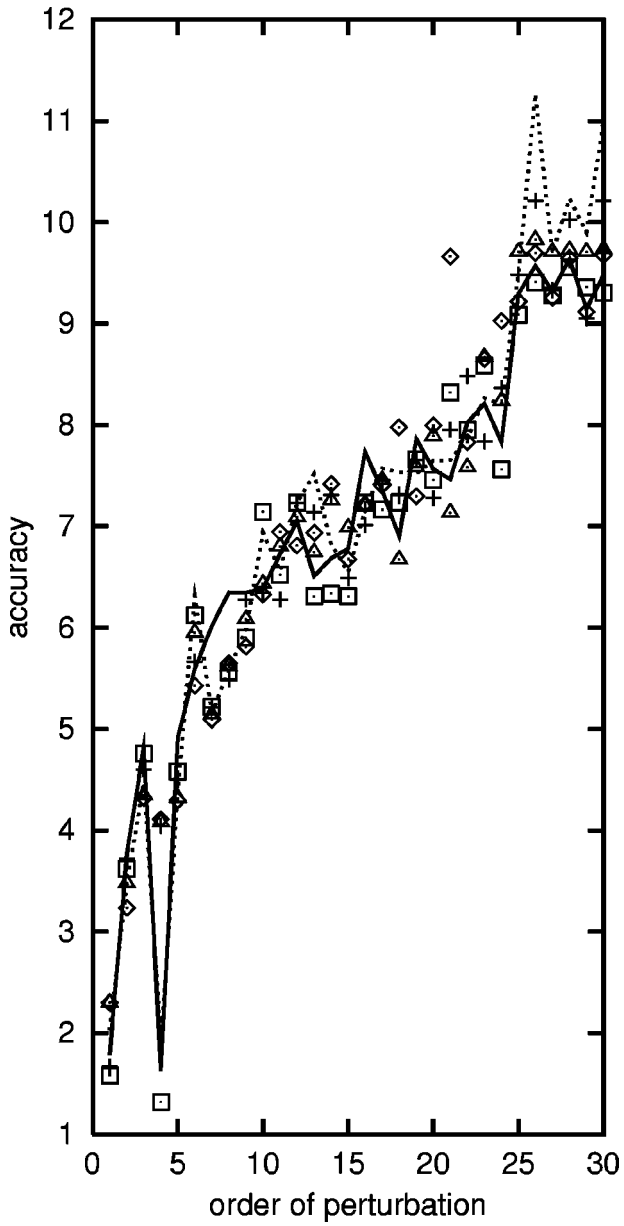

FIG. 4. Accuracy of rescaled hybrid Padé–Borel approximants for the ground state energy of He, as a function of order in the perturbation expansion. The points are determined using Borel functions F_m with the values of the shift parameter indicated as follows: $+$, $m=0$; $\square$, $m=-1/2$; $\triangle$, $m=-1$; $\diamond$, $m=-3/2$. The dotted curve shows $-\log_{10}|(\overline{S_k}-E_{\text{exact}})/E_{\text{exact}}|$, where $\overline{S_k}$ is the mean of the four summation approximants at order k. The solid curve shows $-\log_{10}|\sigma_k/\overline{S_k}|$, where σ_k is the standard deviation from the mean of the four approximants at order k.

on the negative real axis.[22,29] Because this problem is separable, in ellipsoidal coordinates, it is straightforward to derive an exact solution for the location δ_0 of the branch point.[29] Since this singularity is the nearest to the origin in the complex plane, it follows from Darboux's theorem[43] that the expression $g(\delta)(1-\delta/\delta_0)^{1/2}+h(\delta)$, where g and h are nonsingular for $|\delta|\leqslant|\delta_0|$, has the same expansion coefficients in the limit of large order as the actual expansion of F. This suggests the use of Darboux approximants,[44]

$$F_{[L,N/M]}(\delta)=\frac{R_N(\delta)}{Q_M(\delta)}(1-\delta/\delta_0)^{1/2}+\frac{P_L(\delta)}{Q_M(\delta)}, \tag{19}$$

where P_L, Q_M, and R_N are polynomials of degrees L, M, and N, respectively. These polyno-

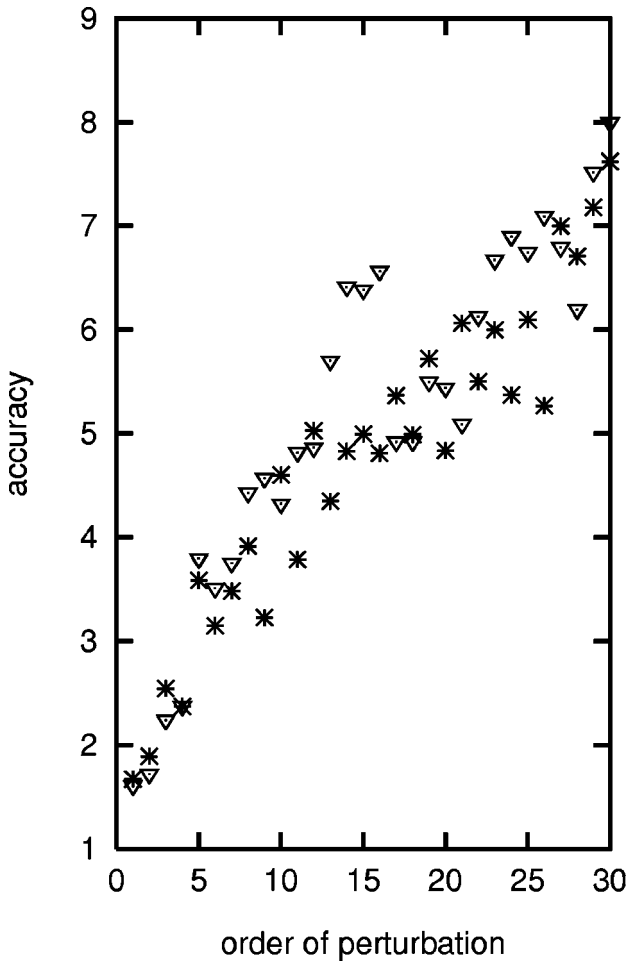

FIG. 5. Accuracy of rescaled hybrid Darboux–Borel approximants (∇) and rescaled hybrid Padé–Borel approximants (∗) for the ground state energy of H_2^+ with internuclear distance $R=2$, as a function of order in the perturbation expansion. The Borel summation is unshifted.

mials can be determined by setting $F_{[L,M/N]}$ equal to the expansion of F, expanding the square root, multiplying through by Q_M, and then solving the resulting set of linear equations.

Figure 5 compares accuracies of Darboux–Borel and Padé–Borel approximants for the ground-state energy of H_2^+. These results correspond to internuclear distance $R=2$, which is very close to the equilibrium bond length. (The renormalized D-dimensional Hamiltonian for this problem is described in Ref. 23.) There is noticeable improvement in accuracy from the Darboux approximants. This is seen as well for other values of R.

VI. DISCUSSION

Our central results are the following: (1) Summation accuracy depends significantly on removing the Coulombic poles at the $D\rightarrow 1$ limit, and rescaling removes the first-order pole more effectively than subtraction using an approximate residue. (2) Renormalization of the D-dimensional Hamiltonian, by multiplying the interelectron potential with a polynomial in δ can significantly improve the rate of convergence. (3) Comparison of results from shifted Borel transforms, given by Eqs. (6) and (7), yields a standard deviation σ_k that provides a reliable estimate of the summation accuracy at given order k. A reasonable summation procedure is to carry out a series of inexpensive moderate-order calculations using a quadratic $\lambda(\delta)$ over the full range of λ_0 values, with some arbitrary value of $\lambda(1)$, in order to determine an approximate range of λ_0 that can be expected to yield the fastest convergence. In the case of He, for example, a plot such as in Fig. 2 would suggest $0.15\leqslant\lambda_0\leqslant 0.25$. Then additional moderate-order calculations could be used to determine an optimal pair of λ_0 and $\lambda(1)$ to be used in the expensive large-order calculation.

One could smooth the convergence of the approximant sequence by using the mean $\overline{S_k}$ of various shifted approximants, eliminating $\overline{S_k}$ that have large σ_k. For example, if σ_{27} is greater than σ_{26}, as in Fig. 4, then $\overline{S_{26}}$ would be retained as the 27th-order result.

We find that the best two-parameter fit of summation accuracy versus order, for two-electron atoms and for H_2^+, is $\alpha(k)=\alpha_0+\alpha_1 k^{1/2}$. However, there appears to be a systematic deviation from this behavior, with a leveling off of accuracy at intermediate orders followed by an increase at higher orders, which led us to use cubic polynomials for the fits in Fig. 1. For He the plateau is at approximately eight significant figures. This effect was noted in Ref. 15, for unrenormalized expansions, and was attributed to the need to model more than just the dominant singularity in the Borel function. For He one obtains approximately three significant figures by explicitly including the poles at $\delta=1$, and apparently, seven figures from modeling also the dominant branch point in the Borel function. This explanation is supported by the behavior of the Darboux–Borel summation for H_2^+ in Fig. 5, which explicitly includes the square-root branch point. In that case there is rapid convergence to almost seven figures at 14th order but then it is not until 29th order that the convergence resumes. The plateau for the Padé–Borel results is less distinct, presumably because at intermediate orders the Padé approximants are still refining the description of the branch point while also attempting to decipher other singularity structure. By order 27 the Padé–Borel accuracy is about equal to the Darboux–Borel accuracy.

We have shown results only for ground states, but in general we expect similar singularity structure, and hence similar convergence behavior, for the lowest eigenstate of any given symmetry. With other excited states there are branch points in the *energy* function $E(\delta)$.[31] Although not the dominant singularities, in practice they dominate the convergence behavior until very high order. For example, it has been estimated[31] that the asymptotic behavior due to the singularity at the origin for the $1s2s\ ^1S$ state of He will not assert itself until 88th order. In that case Borel summation is not very effective, and it is more appropriate to use a summation method designed to model the apparent dominating singularities.

Recent tenth-order calculations for the three-electron atom[16] show convergence behavior almost identical to that for two-electron atoms. It remains to be seen if this will hold as well for four-electron atoms. Loeser[6] has formulated the $1/D$ expansion for S states of all atoms in the periodic table. However, with four electrons there are ten independent internal coordinates at large D but only 9 at $D=3$. Therefore it is not clear that Loeser's theory will converge to the physical solution when taken to large order. Such coordinate redundancies proliferate quadratically as the number of electrons increases. An alternative formulation that avoids this situation is ''partial'' dimensional continuation, applied recently in a study of triatomic molecular rotation spectra.[45] In that case one body-fixed axis was allowed to rotate in D dimensions while the other axis was treated as rotating about the first in only three dimensions. Some sort of related procedure could, in principle, give a D-dependent Hamiltonian with the physical number of coordinates.

Probably a more serious obstacle to applying the $1/D$ expansion to many-electron systems is the rapid increase in computational cost with increasing numbers of internal coordinates.[14] With larger systems it will be necessary to introduce approximations, such as separability assumptions[46] or basis-set truncations. The tradeoff will be between a small systematic error, from a large-order inexact theory, and a random, but possibly larger, error from truncating the exact theory at lower order.

Fermion realization of the nuclear Sp(6,*R*) model

Jutta Escher[a] and J. P. Draayer
Department of Physics and Astronomy, Louisiana State University, Baton Rouge, Louisiana 70803-4001

(Received 6 April 1998; accepted for publication 29 May 1998)

A fermion realization of the nuclear Sp(6,*R*) model, which complements the traditional bosonic representation, is developed. A recursive process is presented in which symplectic matrix elements of arbitrary one-body fermion operators between states of excitation $N\hbar\omega$ and $N'\hbar\omega$ in the same or in different symplectic bands are related back to valence shell matrix elements, which can be evaluated by standard shell model techniques. Matrix elements so determined may be used to calculate observables such as electron scattering form factors which carry detailed structural information on nuclear wave functions. © *1998 American Institute of Physics.* [S0022-2488(98)02110-0]

I. INTRODUCTION

Extensive effort has been devoted to developing the relevant mathematical and computational tools for a fully microscopic treatment of collective nuclear phenomena. In particular, ever since the noncompact symplectic group in three dimensions, Sp(6,*R*), was recognized as the appropriate dynamical group for a many-body theory of nuclear collective motion,[1–3] it has received careful and detailed attention. This group is of special interest because it is also the dynamical group of the three-dimensional harmonic oscillator and thus it establishes an important link between the nuclear shell model and the collective model. Generalized vector coherent state theory and boson realizations of the symplectic algebra have been employed to construct the discrete infinite-dimensional unitary irreducible representations of Sp(6,*R*).[4–13] Methods have been introduced for calculating the necessary orthonormalization factors for symplectic basis states and the requisite matrix elements of the symplectic generators.[7,14–16] In addition, a procedure has been developed for evaluating matrix elements of general two-body interactions of the type used in standard microscopic treatments of nuclear many-body systems.[17–19]

Despite practical limitations due to the large sizes of the Hilbert spaces involved, various applications have proven the symplectic approach to be successful in reproducing collective nuclear properties, such as excitation energies, quadrupole moments, and electromagnetic transition probabilities.[20–24] Unfortunately, until now it has not been possible to evaluate matrix elements of arbitrary one-body operators between symplectic basis states. These matrix elements are of particular interest since they are required for the calculation of observables, such as nuclear form factors, which carry very detailed structural information on nuclear wave functions. It is our purpose in this article to provide a new, fermionic, realization of the sp(6,*R*) algebra, which complements the traditional bosonic representation and leads to a method for determining matrix elements of a general one-body operator in a $\mathrm{Sp}(6,R)\supset\mathrm{U}(3)$ basis. Specifically, a recursive process is presented in which symplectic matrix elements of arbitrary one-body fermion operators between states of excitation $N\hbar\omega$ and $N'\hbar\omega$ in the same or in different symplectic bands are related back to valence shell matrix elements, which can be evaluated by standard shell model techniques. The fermionic realization of the symplectic algebra is particularly well suited for this approach, since the requisite valence shell matrix elements are readily available.[25]

The article is organized as follows: To establish the notation, in Sec. II we give a brief summary of the generators of the symplectic algebra, their bosonic representation, commutation relations, and matrix elements. In Sec. III the symplectic generators are recast in terms of fermi-

onic creation and annihilation operators. The symplectic model space is reviewed in Sec. IV. In Sec. V we present the derivation of the matrix element formula for a general one-body operator acting in the symplectic space. Concluding remarks are given in Sec. VI. The derivations in Secs. III and V make use of both oscillator boson operators and fermion creation and annihilation operators. Phase conventions, conjugation properties, commutation relations, and matrix elements of the former are given in Appendix A, and conjugation properties and commutation relations of various SU(3)-coupled products of the latter are derived in Appendix B. In addition, Appendix C provides a compilation of various important SU(3) recoupling rules.

II. GENERATORS OF THE SYMPLECTIC ALGEBRA

The generators of the symplectic algebra $sp(6,R)$ can be realized in terms of bilinear products of harmonic oscillator bosons in a Cartesian scheme:[26]

$$C_{ij}=\sum_s \left(b_i^\dagger(s)b_j(s)+\frac{1}{2}\delta_{ij}\right)-\frac{1}{A}\sum_s b_i^\dagger(s)\sum_t b_j(t)-\frac{1}{2}\delta_{ij},$$

$$B_{ij}^\dagger=\frac{1}{2}\sum_s b_i^\dagger(s)b_j^\dagger(s)-\frac{1}{2A}\sum_s b_i^\dagger(s)\sum_t b_j^\dagger(t), \tag{1}$$

$$B_{ij}=\frac{1}{2}\sum_s b_i(s)b_j(s)-\frac{1}{2A}\sum_s b_i(s)\sum_t b_j(t),$$

where the sums run over all A particles in the system and the two-body $1/A$ terms effect the removal of spurious center-of-mass excitations from the A-particle system. (Refer to Appendix A for details on the boson creation and annihilation operators.) The commutation relations for the symplectic algebra in this basis are easily inferred from the commutation relations of its building blocks and are listed by Hecht.[13]

Making use of the spherical components $b_{1q}^{\dagger(10)}(s)$ and $\tilde{b}_{1q}^{(01)}(s)$ of the boson creation and annihilation operators, the symplectic generators can be written as SU(3) irreducible tensor operators:

$$C_{lm}^{(11)}=\sqrt{2}\sum_s \{b^\dagger(s)\times\tilde{b}(s)\}_{lm}^{(11)}-\frac{\sqrt{2}}{A}\sum_{st}\{b^\dagger(s)\times\tilde{b}(t)\}_{lm}^{(11)},$$

$$A_{lm}^{(20)}=\frac{1}{\sqrt{2}}\sum_s \{b^\dagger(s)\times b^\dagger(s)\}_{lm}^{(20)}-\frac{1}{\sqrt{2}A}\sum_{st}\{b^\dagger(s)\times b^\dagger(t)\}_{lm}^{(20)}, \tag{2}$$

$$B_{lm}^{(02)}=\frac{1}{\sqrt{2}}\sum_s \{\tilde{b}(s)\times\tilde{b}(s)\}_{lm}^{(02)}-\frac{1}{\sqrt{2}A}\sum_{st}\{\tilde{b}(s)\times\tilde{b}(t)\}_{lm}^{(02)},$$

transforming according to the SU(3) irreps $(\lambda\mu)=(11)$, (20), and (02), respectively. The overall normalization factor is chosen in agreement with the convention used by Rosensteel.[27] The symplectic $2\hbar\omega$ raising and lowering operators, $A_{lm}^{(20)}$ and $B_{lm}^{(02)}$, respectively, are related to each other via Hermitian conjugation: $B_{lm}^{(02)}=(-1)^{l-m}(A_{l-m}^{(20)})^\dagger$. Both $A_{lm}^{(20)}$ and $B_{lm}^{(02)}$ have $l=0$ and 2 components, whereas $C_{lm}^{(11)}$ has $l=1$ and 2 components. The relevant commutation relations between the spherical components of the symplectic raising and lowering operators are given by Rosensteel:[27]

$$[A^{(20)}_{l_1m_1},A^{(20)}_{l_2m_2}]=[B^{(02)}_{l_1m_1},B^{(02)}_{l_2m_2}]=0,$$

$$[B^{(02)}_{l_1m_1},A^{(20)}_{l_2m_2}]=\frac{1}{2}\sqrt{10}\sum_{lm}\langle(02)l_1m_1;(20)l_2m_2|(11)lm\rangle C^{(11)}_{lm}$$
$$+2\sqrt{\frac{2}{3}}(-1)^{l_2+m_2}\delta_{l_1l_2}\delta_{m_1(-m_2)}H_0. \tag{3}$$

Here $\langle -;-|-\rangle$ denotes a Wigner SU(3) coupling coefficient (see Appendix C) and $H_0=\hat{N}_b+\frac{3}{2}$, where $\hat{N}_b=\Sigma_{i=1}^{3}C_{ii}$ counts the number of harmonic oscillator bosons in the system.

The eight operators $C^{(11)}_{lm}$ generate the $su(3)$ subalgebra of $sp(3,R)$ and are related to the angular momentum operator L_q and the Elliott (algebraic) quadrupole operator $Q^a_{2m}=\sqrt{4\pi/5}\Sigma_s(r_s^2Y_{2m}(\hat{r}_s)+p_s^2Y_{2m}(\hat{p}_s))$, here given in units of $\hbar=\omega=m=1$, as follows:

$$C^{(11)}_{1q}=L_q,\quad q=0,\pm1$$
$$C^{(11)}_{2m}=\frac{1}{\sqrt{3}}Q^a_{2m},\quad m=0,\pm1,\pm2. \tag{4}$$

We can also express the collective quadrupole operator $Q^c_{2m}=\sqrt{16\pi/5}\Sigma_s r_s^2Y_{2m}(\hat{r}_s)$ as a linear combination of SU(3) irreducible tensor operators:

$$Q^c_{2m}=Q^a_{2m}+\sqrt{3}(A^{(20)}_{2m}+B^{(02)}_{2m}). \tag{5}$$

Matrix elements for $C^{(11)}$ in the standard SU(3) basis are given by[28,29]

$$\langle(\lambda'\mu')|||C^{(11)}|||(\lambda\mu)\rangle=(-1)^{\phi}\sqrt{2C_2(\lambda\mu)}\,\delta_{(\lambda'\mu')(\lambda\mu)},$$
$$\phi=\begin{cases}1, & \text{for } \mu\neq0\\ 0, & \text{for } \mu=0,\end{cases} \tag{6}$$
$$C_2(\lambda\mu)=\frac{2}{3}(\lambda^2+\lambda\mu+\mu^2+3\lambda+3\mu).$$

The reduced matrix element $\langle(\lambda'\mu')|||C^{(11)}|||(\lambda\mu)\rangle$ is related to the full SU(3) matrix element via the Wigner–Eckart theorem for SU(3) (see Appendix C). The symbol $C_2(\lambda\mu)$ denotes the second-order Casimir invariant of SU(3), and the choice of the phase is consistent with that of reference 29.

Several strategies for calculating matrix elements of the symplectic generators $A^{(20)}$ and $B^{(02)}$ have been explored. A direct way is to use the Sp(6,R) commutation relations to derive recursion formulas, as shown by Rosensteel.[27] Another approach is to start from approximate matrix elements and proceed by successive approximations, adjusting the matrix elements until the commutation relations are precisely satisfied.[3] Deenen and Quesne[16] have employed a boson mapping to obtain the generator matrix elements, and Castaños *et al.*[15] have derived simple analytical functions for some special irreps. The most elegant method, outlined by Rowe in reference 7, involves vector-valued coherent state representation theory and evaluates matrix elements of the symplectic raising and lowering operators by relating them to the matrix elements of a much simpler $u(3)\otimes$*Weyl* algebra.

III. FERMION REALIZATION OF THE SYMPLECTIC GENERATORS

In a fermion second quantization formulation, the one-body part of $C^{(11)}$ takes the form

$$\mathscr{F}(C^{(11)s=0}_{LM\sigma=0}) = \left(1-\frac{1}{A}\right)\sqrt{2}\sum_{\rho\rho'}\left\langle \underbrace{(\nu 0) lm \frac{1}{2}\sigma''}_{\rho}\middle| \{b^\dagger \times \tilde{b}\}^{(11)s=0}_{LM\sigma=0}\middle| \underbrace{(\nu' 0) l' m' \frac{1}{2}\sigma'}_{\rho'}\right\rangle \times a^\dagger_{(\nu 0) lm (1/2)\sigma''} a_{(\nu' 0) l' m' (1/2)\sigma'}, \tag{7}$$

where $a^\dagger_\rho$ and a_ρ are fermion creation and annihilation operators (see Appendix B). Note that $b^\dagger$, $\tilde{b}$, and $C^{(11)}_{LM}$ do not act on the spin part of the wave functions; thus one needs to treat these operators as $s=\sigma=0$ objects, as has been explicitly expressed in the above equation.

Utilizing the symmetry properties of the Clebsch–Gordan and SU(3) Wigner coefficients and the definition of the proper SU(3) irreducible tensor operator $\tilde{a}_{(0\nu') l' (-m') (1/2) (-\sigma')} \equiv (-1)^{\nu'+l'-m'+1/2-\sigma'} a_{(\nu' 0) l' m' (1/2)\sigma'}$, we obtain

$$\begin{aligned}\mathscr{F}(C^{(11)s=0}_{LM\sigma=0}) &= \left(1-\frac{1}{A}\right)\sqrt{2}\sum_{\nu\nu'}\left\langle (\nu 0)\frac{1}{2}\middle\|\middle\| \{b^\dagger\times\tilde{b}\}^{(11)s=0}\middle\|\middle\| (\nu' 0)\frac{1}{2}\right\rangle \sqrt{d(\nu 0)}\,\frac{1}{2} \\ &\quad \times \{a^\dagger_{(\nu 0)(1/2)} \times \tilde{a}_{(0\nu')(1/2)}\}^{(11)s=0}_{LM\sigma=0} \\ &= \left(1-\frac{1}{A}\right)\sum_{\nu} \sqrt{\frac{1}{6}\nu(\nu+1)(\nu+2)(\nu+3)} \\ &\quad \times \{a^\dagger_{(\nu 0)(1/2)} \times \tilde{a}_{(0\nu)(1/2)}\}^{(11)s=0}_{LM\sigma=0},\end{aligned} \tag{8}$$

where $d(\lambda\mu)=\frac{1}{2}(\lambda+1)(\mu+1)(\lambda+\mu+2)$ denotes the dimension of the su(3) irrep $(\lambda\mu)$ and use has been made of Eq. (A6), which expresses the triple-reduced matrix element in terms of ν and ν' only (see Appendix A). Analogously one derives the fermion realization for the one-body part of the symplectic raising and lowering operators.

The two-body parts of the symplectic generators can be obtained in the same manner. A general symmetric two-body operator for A identical particles, $\mathscr{G}=\sum_{s<t=1}^{A} g(\mathbf{x}_s,\boldsymbol{\sigma}_s,\mathbf{x}_t,\boldsymbol{\sigma}_t)$, where s and t refer to the s-th and t-th particles, respectively, takes the following form in a fermion second quantized formulation:

$$\mathscr{G} = \frac{1}{4}\sum_{\substack{\rho_1,\rho_1' \\ \rho_2,\rho_2'}} \langle \rho_1\rho_2 | g(\mathbf{x}_1,\boldsymbol{\sigma}_1,\mathbf{x}_2,\boldsymbol{\sigma}_2) | \rho_1'\rho_2'\rangle a^\dagger_{\rho_1} a^\dagger_{\rho_2} a_{\rho_2'} a_{\rho_1'}. \tag{9}$$

Here $|\rho_1\rho_2\rangle$ denotes the direct product of the single-particle wave functions $|\rho_1\rangle$ and $|\rho_2\rangle$. For the cases that are of interest here, the function $g(\mathbf{x}_1,\boldsymbol{\sigma}_1,\mathbf{x}_2,\boldsymbol{\sigma}_2)$ can be written as a product $g(1)g(2)\equiv g(\mathbf{x}_1,\boldsymbol{\sigma}_1)g(\mathbf{x}_2,\boldsymbol{\sigma}_2)$, where $g(t)$, with $t=1$ or 2, acts solely on the single-particle wave function with subscript t. Thus the two-body part of the symplectic generator $C^{(11)}$ is written as

$$\mathcal{G}(C^{(11)s=0}_{LM\sigma=0}) = -\frac{1}{\sqrt{8}A}\sum_{\substack{\rho_1,\rho_1'\\ \rho_2,\rho_2'}}\Bigg\langle \underbrace{(\nu_1 0) l_1 m_1 \frac{1}{2}\sigma_1}_{\rho_1};\underbrace{(\nu_2 0) l_2 m_2 \frac{1}{2}\sigma_2}_{\rho_2}\Bigg|$$
$$\times\{b^\dagger(1)\times\tilde{b}(2)\}^{(11)s=0}_{LM\sigma=0}\Bigg|\underbrace{(\nu_1' 0) l_1' m_1' \frac{1}{2}\sigma_1'}_{\rho_1'};\underbrace{(\nu_2' 0) l_2' m_2' \frac{1}{2}\sigma_2'}_{\rho_2'}\Bigg\rangle$$
$$\times a^\dagger_{(\nu_1 0) l_1 m_1 (1/2)\sigma_1} a^\dagger_{(\nu_2 0) l_2 m_2 (1/2)\sigma_2} a_{(\nu_2' 0) l_2' m_2' (1/2)\sigma_2'} a_{(\nu_1' 0) l_1' m_1' (1/2)\sigma_1'}$$
$$= -\frac{1}{\sqrt{8}A}\sum_{\substack{(\lambda\mu)S\\ (\lambda'\mu')S'}}\sqrt{\frac{1}{8}d(\lambda\mu)(2S+1)}\Big\langle\{(\nu_1 0)\times(\nu_2 0)\}(\lambda\mu);\Big\{\frac{1}{2}\times\frac{1}{2}\Big\}S\Big|\Big|\Big|$$
$$\times\{b^\dagger(1)\times\tilde{b}(2)\}^{(11)s=0}\Big|\Big|\Big|\{(\nu_1' 0)\times(\nu_2' 0)\}(\lambda'\mu');\Big\{\frac{1}{2}\times\frac{1}{2}\Big\}S'\Big\rangle$$
$$\times\sum_{\substack{\nu_1\nu_2\\ \nu_1'\nu_2'}}\{\{a^\dagger_{(\nu_1 0)(1/2)}\times a^\dagger_{(\nu_2 0)(1/2)}\}^{(\lambda\mu)S}\times\{\tilde{a}_{(0\nu_1')(1/2)}\times\tilde{a}_{(0\nu_2')(1/2)}\}^{(\mu'\lambda')S'}\}^{(11)s=0}_{LM\sigma=0}, \tag{10}$$

and analogously for $\mathcal{G}(A^{(20)s=0}_{LM\sigma=0})$ and $\mathcal{G}(B^{(02)s=0}_{LM\sigma=0})$. Here use has been made of the symmetry properties of the Clebsch–Gordan and Wigner coefficients and of the Wigner–Eckart theorem for both SU(2) and SU(3). Upon evaluation of the triple-reduced matrix elements of $\{b^\dagger(1)\times\tilde{b}(2)\}^{(11)}$, $\{b^\dagger(1)\times b^\dagger(2)\}^{(20)}$, and $\{\tilde{b}(1)\times\tilde{b}(2)\}^{(02)}$ (see Appendix A), we find the following fermionic expressions for the symplectic generators $C^{(11)}$, $A^{(20)}$, and $B^{(02)}$, respectively:

$$C^{(11)}_{LM} = \Big(1-\frac{1}{A}\Big)\sum_\nu\sqrt{\frac{1}{6}\nu(\nu+1)(\nu+2)(\nu+3)}\{a^\dagger_{(\nu 0)(1/2)}\times\tilde{a}_{(0\nu)(1/2)}\}^{(11)s=0}_{LM\sigma=0}$$
$$-\frac{1}{4A}\sum_{\substack{\nu\nu' S\\ (\lambda\mu)(\lambda'\mu')}}\sqrt{\frac{1}{4}d(\lambda\mu)\nu(\nu'+3)(2S+1)}\begin{Bmatrix}(\nu-1,0) & (10) & (\nu 0) & -\\ (\nu'+1,0) & (01) & (\nu' 0) & -\\ (\lambda'\mu') & (11) & (\lambda\mu) & -\\ - & - & - & \end{Bmatrix}$$
$$\times\{\{a^\dagger_{(\nu 0)(1/2)}\times a^\dagger_{(\nu' 0)(1/2)}\}^{(\lambda\mu)S}\times\{\tilde{a}_{(0,\nu-1)(1/2)}\times\tilde{a}_{(0,\nu'+1)(1/2)}\}^{(\mu'\lambda')S}\}^{(11)s=0}_{LM\sigma=0}, \tag{11}$$

$$A^{(20)}_{LM} = \Big(1-\frac{1}{A}\Big)\sum_\nu\sqrt{\frac{1}{12}(\nu+1)(\nu+2)(\nu+3)(\nu+4)}\{a^\dagger_{(\nu+2,0)(1/2)}\times\tilde{a}_{(0\nu)(1/2)}\}^{(20)s=0}_{LM\sigma=0}$$
$$-\frac{1}{4A}\sum_{\substack{\nu\nu' S\\ (\lambda\mu)(\lambda'\mu')}}\sqrt{\frac{1}{12}d(\lambda\mu)\nu\nu'(2S+1)}\begin{Bmatrix}(\nu-1,0) & (10) & (\nu 0) & -\\ (\nu'-1,0) & (10) & (\nu' 0) & -\\ (\lambda'\mu') & (20) & (\lambda\mu) & -\\ - & - & - & \end{Bmatrix}$$
$$\times\{\{a^\dagger_{(\nu 0)(1/2)}\times a^\dagger_{(\nu' 0)(1/2)}\}^{(\lambda\mu)S}\times\{\tilde{a}_{(0,\nu-1)(1/2)}\times\tilde{a}_{(0,\nu'-1)(1/2)}\}^{(\mu'\lambda')S}\}^{(20)s=0}_{LM\sigma=0}, \tag{12}$$

and

$$B^{(02)}_{LM}=\left(1-\frac{1}{A}\right)\sum_{\nu}\ \sqrt{\frac{1}{12}(\nu+1)(\nu+2)(\nu+3)(\nu+4)}\{a^{\dagger}_{(\nu 0)(1/2)}\times\tilde{a}_{(0,\nu+2)(1/2)}\}^{(02)s=0}_{LM\sigma=0}$$

$$-\frac{1}{4A}\sum_{\substack{\nu\nu' S\\(\lambda\mu)(\lambda'\mu')}}\sqrt{\frac{1}{12}d(\lambda\mu)(\nu+3)(\nu'+3)(2S+1)}\begin{Bmatrix}(\nu+1,0) & (01) & (\nu 0) & -\\ (\nu'+1,0) & (01) & (\nu' 0) & -\\ (\lambda'\mu') & (02) & (\lambda\mu) & -\\ - & - & - & \end{Bmatrix}$$

$$\times\{\{a^{\dagger}_{(\nu 0)(1/2)}\times a^{\dagger}_{(\nu' 0)(1/2)}\}^{(\lambda\mu)S}\times\{\tilde{a}_{(0,\nu+1)(1/2)}\times\tilde{a}_{(0,\nu'+1)(1/2)}\}^{(\mu'\lambda')S}\}^{(02)s=0}_{LM\sigma=0}. \tag{13}$$

Making use of the properties of the coupling coefficients and of the Hermitian conjugation properties of the generators, one can verify that $B^{(02)}_{LM}=(-1)^{L-M}(A^{(20)}_{L-M})^{\dagger}$ holds, as expected. This relation serves as a stringent test for the fermionic expressions of $A^{(20)}$ and $B^{(02)}$.

IV. SYMPLECTIC MODEL SPACE

A basis for the Hilbert space is generated by applying symmetrically coupled products of the $2\hbar\omega$ raising operator $A^{(20)}$ with itself to the usual $0\hbar\omega$ shell-model states. The $0\hbar\omega$ starting configurations are labeled by the Elliott SU(3) quantum numbers $(\lambda_\sigma\mu_\sigma)$[30,31] and by N_σ, the eigenvalue of the oscillator boson number operator which takes the minimum value consistent with the Pauli Exclusion Principle. The product of $N_n/2$ raising tensors $A^{(20)}$, each of which promotes a particle from a given shell into a higher-lying shell $2\hbar\omega$ above, generates $N_n\hbar\omega$ excitations for each starting irrep $N_\sigma(\lambda_\sigma\mu_\sigma)$. Each such product operator $\mathscr{P}^{N_n(\lambda_n\mu_n)}_{\alpha_n}$, labeled according to its SU(3) content, $(\lambda_n\mu_n)$, is then coupled with $|N_\sigma(\lambda_\sigma\mu_\sigma)\rangle$ to good SU(3) symmetry $\rho(\lambda_\omega\mu_\omega)$, with ρ denoting the multiplicity of the coupling $(\lambda_n\mu_n)\times(\lambda_\sigma\mu_\sigma)$.

It will be convenient to use the general shorthand notation, Γ, for a U(3) or SU(3) representation label, and α for an appropriate set of U(3) subgroup labels. We thus introduce, following the notation of Hecht,[32]

$$\begin{aligned}\Gamma_\sigma&\equiv[\sigma_1\sigma_2\sigma_3]\equiv N_\sigma(\lambda_\sigma\mu_\sigma)=N_\sigma(\sigma_1-\sigma_2,\sigma_2-\sigma_3),\\ \Gamma_n&\equiv[n_1n_2n_3]\equiv N_n(\lambda_n\mu_n)=N_n(n_1-n_2,n_2-n_3),\\ \Gamma_\omega&\equiv[\omega_1\omega_2\omega_3]\equiv N_\omega(\lambda_\omega\mu_\omega)=N_\omega(\omega_1-\omega_2,\omega_2-\omega_3),\end{aligned} \tag{14}$$

where $(\lambda\mu)$ are SU(3) labels and the $N_\sigma=\sigma_1+\sigma_2+\sigma_3$, $N_n=n_1+n_2+n_3$, and $N_\omega=\omega_1+\omega_2+\omega_3$ give the number of squares in the U(3) Young tableaux. With this convention, the product operators, which are defined recursively, can be written as

$$\mathscr{P}^{\Gamma_n}_{\alpha_n}(A^{(20)})=\sum_{\Gamma_{n'}\beta\alpha_{n'}}\langle(20)\beta;\Gamma_{n'}\alpha_{n'}|\Gamma_n\alpha_n\rangle X^{\Gamma_n}(\Gamma_{n'})A^{(20)}_{\beta}\mathscr{P}^{\Gamma_{n'}}_{\alpha_{n'}}(A^{(20)}), \tag{15}$$

with $A^{(20)}$ adding a $2\hbar\omega$ excitation to the $N_{n'}$ excitation ($N_{n'}=n'_1+n'_2+n'_3$) that is created by the action of the operator $\mathscr{P}^{\Gamma_{n'}}_{\alpha_{n'}}(A^{(20)})$; and the factor

$$X^{\Gamma_n}(\Gamma_{n'})=\frac{1}{n_1+n_2+n_3}(n_1n_2n_3|||\mathscr{A}^{(20)}|||n'_1n'_2n'_3) \tag{16}$$

is required to properly normalize the raising polynomials (for details see reference 32). The n_i in the above equation denote the number of oscillator bosons in the i-th direction, and we have $N_n=N_{n'}+2$. The operator $\mathscr{A}^{(20)}$ is a generator of the $u(3)\otimes Weyl$ algebra; the evaluation of its matrix elements and its relation to the symplectic generator $A^{(20)}$ are discussed in references 33, 7.

We thus obtain a basis of Sp(3,R) states that are reduced according to the subgroup chain

$$\begin{array}{ccccccccc}\mathrm{Sp}(3,R) & \supset & \mathrm{U}(3) & \supset & \mathrm{SO}(3) & \supset & \mathrm{SO}(2)\\ \Gamma_\sigma & & \Gamma_n\rho\ \ \Gamma_\omega & & \kappa\ \ L & & M.\end{array} \tag{17}$$

For each $0\hbar\omega$ SU(3) starting irrep $\Gamma_\sigma = N_\sigma(\lambda_\sigma\mu_\sigma)$ a basis for a symplectic representation is given by states of the form

$$|\Phi[\Gamma_\sigma\Gamma_n\rho\Gamma_\omega\alpha_\omega]\rangle \equiv \sum_{\alpha_n\alpha_\sigma} \langle \Gamma_n\alpha_n;\Gamma_\sigma\alpha_\sigma|\Gamma_\omega\alpha_\omega\rangle_\rho \mathscr{P}^{\Gamma_n}_{\alpha_n}(A^{(20)})|\Gamma_\sigma\alpha_\sigma\rangle, \tag{18}$$

where $N_n/2 = 0,1,2,\ldots$, counts the number of boson excitations, $N_\omega = N_\sigma + N_n$, $(\lambda_n\mu_n)$ ranges over the set $\Omega = \{(n_1-n_2, n_2-n_3) | n_1 \geqslant n_2 \geqslant n_3 \geqslant 0; N_n = n_1+n_2+n_3; n_1,n_2,n_3$ even integers$\}$, $\rho\Gamma_\omega$ includes all SU(3) irreps resulting from the coupling $\Gamma_n \times \Gamma_\sigma$, and $\alpha_\omega = \kappa LM$ denotes quantum numbers associated with the group chain SU(3)$\supset$SO(3)$\supset$SO(2). Alternatively, one can also choose subgroup labels $\alpha_\omega = \varepsilon\Lambda M_\Lambda$, which are associated with the chain SU(3)$\supset$SU(2)$\times$U(1)$\supset$SO(2). The states of the Sp(3,R)$\supset$SU(3) basis are thus labeled by three types of U(3) quantum numbers: $\Gamma_\sigma = N_\sigma(\lambda_\sigma\mu_\sigma)$, the symplectic bandhead or Sp(3,R) lowest weight U(3) symmetry, which specifies the Sp(3,R) irreducible representation; $\Gamma_n = N_n(\lambda_n\mu_n)$, the U(3) symmetry of the raising polynomial; and $\Gamma_\omega = N_\omega(\lambda_\omega\mu_\omega)$, the U(3) symmetry of the final state. Any given symplectic representation space $N_\sigma(\lambda_\sigma\mu_\sigma)$ is infinite dimensional, since $N_n/2$, the number of boson excitations, can take any positive integer value. In practical applications, one must therefore either truncate the symplectic Hilbert space, or restrict oneself to interactions and observables for which the matrix elements depend solely on the symplectic irrep and can be calculated analytically.

The states of Equation (18) are eigenstates of the harmonic oscillator Hamiltonian, $H_0|\Phi\rangle = E_0|\Phi\rangle$, with eigenvalues $E_0 = (N_\omega + \frac{3}{2})\hbar\omega$. Two such states with different U(3) content $\Gamma_\omega = N_\omega(\lambda_\omega\mu_\omega)$ are orthogonal, whereas two states with identical U(3) symmetry Γ_ω, but different $\rho\Gamma_n = \rho N_n(\lambda_n\mu_n)$ quantum numbers, are generally not orthogonal. The states $|\Phi(\Gamma_\sigma\Gamma_n\rho\Gamma_\omega\alpha_\omega)\rangle$ of Equation (18) can be related to the orthonormal basis states $|\Gamma_\sigma\Gamma_n\rho\Gamma_\omega\alpha_\omega\rangle$ of the unitary irreducible representation of Sp(3,R), by

$$|\Phi[\Gamma_\sigma\Gamma_{n_i}\rho_i\Gamma_\omega\alpha_\omega]\rangle = \sum_j [\mathscr{K}(\Gamma_\sigma,\Gamma_\omega)]_{\Gamma_{n_i}\rho_i,\Gamma_{n_j}\rho_j}|\Gamma_\sigma\Gamma_{n_j}\rho_j\Gamma_\omega\alpha_\omega\rangle. \tag{19}$$

Here $|\Gamma_\sigma\Gamma_n\rho\Gamma_\omega\alpha_\omega\rangle$, without the letter Φ stands for the orthonormal basis states, and the symbol $[\mathscr{K}(\Gamma_\sigma,\Gamma_\omega)]_{n_i\rho_i,n_j\rho_j}$ denotes the matrix elements of $\mathscr{K}$, the positive Hermitian square root of the overlap matrix $\mathscr{K}^2$, which has matrix elements

$$[\mathscr{K}^2(\Gamma_\sigma,\Gamma_\omega)]_{\Gamma_{n'}\rho',\Gamma_n\rho} \equiv \langle\Phi[\Gamma_\sigma\Gamma_{n'}\rho'\Gamma_\omega\alpha_\omega]|\Phi[\Gamma_\sigma\Gamma_n\rho\Gamma_\omega\alpha_\omega]\rangle. \tag{20}$$

The matrix $\mathscr{K}^2$ is diagonal in Γ_σ and Γ_ω and independent of U(3) subgroup labels α_ω, and its rows and columns are labeled by Γ_n and ρ. Due to the smallness of the off-diagonal matrix elements of $\mathscr{K}^2$ the orthonormal basis states in Equation (19) can also be tagged by those labels $\Gamma_{n_i}\rho_i$ which correspond to the dominant values of $\Gamma_n\rho$ in these states. The method for calculating the matrix elements of $\mathscr{K}^2$, and therefore of $\mathscr{K}$, is given in reference 7. An approximation formula for the matrix elements of $\mathscr{K}$ has been worked out by Hecht.[32]

V. MATRIX ELEMENTS OF ARBITRARY ONE-BODY OPERATORS

In this section we derive a recursion formula in which symplectic matrix elements of arbitrary one-body operators between states of excitation $N_{n_1}\hbar\omega$ and $N_{n_2}\hbar\omega$ in the same or in different symplectic bands are related back to valence shell matrix elements, which can be evaluated by standard shell model techniques. The derivation of the desired recursion formula makes use of the fact that the symplectic basis states are constructed by applying polynomials $\mathscr{P}^{\Gamma_n}_{\alpha_n}(A^{(20)})$ of symmetrically coupled products of the symplectic raising operator $A^{(20)}$ with itself to $0\hbar\omega$ shell model configurations $|\Gamma_\sigma\alpha_\sigma\rangle$. (As before, we will denote the orthonormal basis states by $|\Gamma_\sigma\Gamma_n\rho\Gamma_\omega\alpha_\omega\rangle$, without the letter Φ.) Using Equations (18) and (15) and the definition of the SU(3) Racah coefficients U (see Appendix C), we can now express a symplectic basis state $|\Phi[\Gamma_\sigma\Gamma_n\rho\Gamma_\omega\alpha_\omega]\rangle$ of excitation $N_n\hbar\omega$ in terms of basis states $|\Phi[\Gamma_\sigma\Gamma_{n'}\rho'\Gamma_{\omega'}\alpha_{\omega'}]\rangle$ of excitation $N_{n'}\hbar\omega$ with $N_{n'} = N_n - 2$:

$$|\Phi[\Gamma_\sigma \Gamma_n \rho \Gamma_\omega \alpha_\omega]\rangle = \sum_{\Gamma_{n'} \rho' \Gamma_{\omega'} \beta \alpha_{\omega'}} U[(20)\Gamma_{n'}\Gamma_\omega \Gamma_\sigma; \Gamma_{n-} \rho \Gamma_{\omega'} \rho'_-] \times \langle (20)\beta; \Gamma_{\omega'} \alpha_{\omega'} | \Gamma_\omega \alpha_\omega \rangle X^{\Gamma_n}(\Gamma_{n'}) A^{(20)}_\beta |\Phi[\Gamma_\sigma \Gamma_{n'} \rho' \Gamma_{\omega'} \alpha_{\omega'}]\rangle. \quad (21)$$

[This can be proved by decoupling the raising polynomial $\mathscr{P}^{\Gamma_n}_{\alpha_n}(A^{(20)})$ from the lowest weight state $|\Gamma_\sigma \alpha_\sigma\rangle$, inserting the definition of $\mathscr{P}^{\Gamma_n}_{\alpha_n}(A^{(20)})$ given in Equation (15), coupling the raising polynomial $\mathscr{P}^{\Gamma'_n}_{\alpha'_n}(A^{(20)})$ to $|\Gamma_\sigma \alpha_\sigma\rangle$, and making use of the property (C22) of the SU(3) Racah coefficient U.] An analogous expression can be obtained for the bra state $\langle \Phi[\Gamma_\sigma \Gamma_n \rho \Gamma_\omega \alpha_\omega]|$.

The task at hand is to evaluate matrix elements of arbitrary one-body operators. Since any one-body operator can be expanded in terms of the fermion unit operators $\{a^\dagger_{(\eta 0)(1/2)} \times \tilde{a}_{(0\eta')(1/2)}\}^{\Gamma S}_{\alpha\Sigma}$ by employing the formalism of second quantization and SU(3) recoupling techniques, it suffices to evaluate the following matrix element:

$$\langle \Gamma_{\sigma_2} \Gamma_{n_2} \rho_2 \Gamma_{\omega_2} \alpha_{\omega_2}; S_2 \Sigma_2 | \{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma} | \Gamma_{\sigma_1} \Gamma_{n_1} \rho_1 \Gamma_{\omega_1} \alpha_{\omega_1}; S_1 \Sigma_1 \rangle. \quad (22)$$

Here we have introduced a simplified, but unambiguous, notation for the fermion creation and annihilation operators: $a^\dagger_{(\eta 0)(1/2)} \to a^\dagger_\eta$, $\tilde{a}_{(0\eta)(1/2)} \to \tilde{a}_\eta$, and $S_1\Sigma_1$ and $S_2\Sigma_2$ denote the spin and spin projection of the ket and bra states, respectively. We need only consider the case of $\eta \geqslant \eta'$, since the matrix element of $\{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma}$ for $\eta < \eta'$ can be obtained through complex conjugation from the matrix element of $\{a^\dagger_{\eta'} \times \tilde{a}_\eta\}^{\tilde{\Gamma} S}_{\bar{\alpha} - \Sigma}$, where $\tilde{\Gamma} = (\mu\lambda)$ is the irrep conjugate to $\Gamma = (\lambda\mu)$ and $\bar{\alpha} = \kappa l(-m)$ for $\alpha = \kappa l m$.

Using the $\mathscr{K}$-matrix and applying the step-down procedure outlined above to the ket state $|\Phi[\Gamma_\sigma \Gamma_n \rho \Gamma_\omega \alpha_\omega]\rangle$, the matrix element can be written as

$$\begin{aligned}
&\langle \Gamma_{\sigma_2} \Gamma_{n_2} \rho_2 \Gamma_{\omega_2} \alpha_{\omega_2}; S_2 \Sigma_2 | \{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma} | \Gamma_{\sigma_1} \Gamma_{\hat{n}_1} \hat{\rho}_1 \Gamma_{\omega_1} \alpha_{\omega_1}; S_1 \Sigma_1 \rangle \\
&= \sum_{\Gamma_{n_1} \rho_1} [\mathscr{K}^{-1}(\Gamma_{\sigma_1}, \Gamma_{\omega_1})]_{\Gamma_{\hat{n}_1} \hat{\rho}_1, \Gamma_{n_1} \rho_1} \\
&\quad \times \langle \Gamma_{\sigma_2} \Gamma_{n_2} \rho_2 \Gamma_{\omega_2} \alpha_{\omega_2}; S_2 \Sigma_2 | \{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma} | \Phi[\Gamma_{\sigma_1} \Gamma_{n_1} \rho_1 \Gamma_{\omega_1} \alpha_{\omega_1}]; S_1 \Sigma_1 \rangle \\
&= \sum_{\Gamma_{n_1} \rho_1} [\mathscr{K}^{-1}(\Gamma_{\sigma_1}, \Gamma_{\omega_1})]_{\Gamma_{\hat{n}_1} \hat{\rho}_1, \Gamma_{n_1} \rho_1} \\
&\quad \times \sum_{\Gamma_{\omega'_1} \Gamma_{\hat{n}'_1} \hat{\rho}'_1} U[(20)\Gamma_{\hat{n}'_1} \Gamma_{\omega_1} \Gamma_{\sigma_1}; \Gamma_{n_1 -} \rho_1 \Gamma_{\omega'_1} \hat{\rho}'_{1-}] X^{\Gamma_{n_1}}(\Gamma_{\hat{n}'_1}) \\
&\quad \times \sum_{\Gamma_{n'_1} \rho'_1} [\mathscr{K}(\Gamma_{\sigma_1}, \Gamma_{\omega'_1})]_{\Gamma_{\hat{n}'_1} \hat{\rho}'_1, \Gamma_{n'_1} \rho'_1} \Bigg\{ \sum_{\alpha_{\omega'_1} \beta_1} \langle (20)\beta_1; \Gamma_{\omega'_1} \alpha_{\omega'_1} | \Gamma_{\omega_1} \alpha_{\omega_2} \rangle \\
&\quad \times \langle \Gamma_{\sigma_2} \Gamma_{n_2} \rho_2 \Gamma_{\omega_2} \alpha_{\omega_2}; S_2 \Sigma_2 | \{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma} A^{(20)}_{\beta_1} | \Gamma_{\sigma_1} \Gamma_{n'_1} \rho'_1 \Gamma_{\omega'_1} \alpha_{\omega'_1}; S_1 \Sigma_1 \rangle \Bigg\}. \quad (23)
\end{aligned}$$

Note that the symplectic raising and lowering operators do not act on the spin part of the wave functions.

We now consider the term in parentheses and express the operator $\{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma} A^{(20)}_{\beta_1}$ as

$$\{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma} A^{(20)}_{\beta_1} = A^{(20)}_{\beta_1} \{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma} + [\{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma}, A^{(20)}_{\beta_1}]. \quad (24)$$

Recalling that the fermion realization of $A^{(20)}$ is given by Equation (12), we obtain

$$\{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma} A^{(20)}_{\beta_1} = A^{(20)}_{\beta_1}\{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma}$$
$$+\left(1-\frac{1}{A}\right)\sum_{\nu}\sqrt{\frac{1}{12}(\nu+1)(\nu+2)(\nu+3)(\nu+4)}[\{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma}, \{a^\dagger_{\nu+2} \times \tilde{a}_{\nu}\}^{(20)s=0}_{\beta_1\sigma=0}]$$
$$-\frac{1}{4A}\sum_{\substack{\nu\nu' S' \\ \Gamma_a\Gamma_b}}\sqrt{\frac{d(\Gamma_a)}{12}\nu\nu'(2S'+1)}\begin{Bmatrix} (\nu-1,0) & (10) & (\nu 0) & - \\ (\nu'-1,0) & (10) & (\nu' 0) & - \\ \Gamma_b & (20) & \Gamma_a & - \\ - & - & - & \end{Bmatrix}$$
$$\times[\{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma}, \{\{a^\dagger_\nu \times a^\dagger_{\nu'}\}^{\Gamma_a S'} \times \{\tilde{a}_{\nu-1} \times \tilde{a}_{\nu'-1}\}^{\tilde{\Gamma}_b S'}\}^{(20)s=0}_{\beta_1\sigma=0}]. \tag{25}$$

Therefore, the expression in the parentheses of Equation (23) is comprised of three terms: $\{\cdots\} = C_1 + (1-1/A)C_2 + (1/4A)C_3$, where A denotes the number of nucleons in the system. The first of these is given by

$$C_1 \equiv \sum_{\alpha'_{\omega_1}\beta_1} \langle (20)\beta_1; \Gamma_{\omega'_1}\alpha'_{\omega_1} | \Gamma_{\omega_1}\alpha_{\omega_1}\rangle$$
$$\times \langle \Gamma_{\sigma_2}\Gamma_{n_2}\rho_2\Gamma_{\omega_2}\alpha_{\omega_2}; S_2\Sigma_2 | A^{(20)}_{\beta_1}\{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma} | \Gamma_{\sigma_1}\Gamma_{n'_1}\rho'_1\Gamma_{\omega'_1}\alpha_{\omega'_1}; S_1\Sigma_1\rangle. \tag{26}$$

To evaluate C_1, we insert a complete set of states:

$$1 = \sum_{\substack{\Gamma_{\sigma''}\Gamma_{n''}\rho'' \\ \Gamma_{\omega''}\alpha_{\omega''}S''\Sigma''}} |\Gamma_{\sigma''}\Gamma_{n''}\rho''\Gamma_{\omega''}\alpha_{\omega''}; S''\Sigma''\rangle\langle\Gamma_{\sigma''}\Gamma_{n''}\rho''\Gamma_{\omega''}\alpha_{\omega''}; S''\Sigma''|, \tag{27}$$

between $A^{(20)}_{\beta_1}$ and $\{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma}$ and make use of the following relation:

$$\langle \Gamma_{\sigma_2}\Gamma_{n_2}\rho_2\Gamma_{\omega_2}\alpha_{\omega_2}; S_2\Sigma_2 | A^{(20)}_{\beta_1} | \Gamma_{\sigma''}\Gamma_{n''}\rho''\Gamma_{\omega''}\alpha_{\omega''}; S''\Sigma''\rangle$$
$$= \delta_{\Gamma_{\sigma''}\Gamma_{\sigma_2}}\delta_{N_{n''}N_2-2}\delta_{S''S_2}\delta_{\Sigma''\Sigma_2}\langle \Gamma_{\sigma_2}\Gamma_{n_2}\rho_2\Gamma_{\omega_2}\alpha_{\omega_2}; S_2\Sigma_2 | A^{(20)}_{\beta_1} | \Gamma_{\sigma_2}\Gamma_{n''}\rho''\Gamma_{\omega''}\alpha_{\omega''}; S_2\Sigma_2\rangle. \tag{28}$$

The delta functions in this expression reflect the fact that the symplectic generator $A^{(20)}$ only connects states within a symplectic irrep which have the same spin and differ by $2\hbar\omega$ in their excitation. Note that these delta functions significantly restrict the sum over $\Gamma_{\sigma''}\Gamma_{n''}\rho''\Gamma_{\omega''}\alpha_{\omega''}S''\Sigma''$ of the complete set of states. Only states which are constructed from the lowest weight irrep $\Gamma_{\sigma''} = \Gamma_{\sigma_2}$ by applying a raising polynomial $\mathscr{P}^{\Gamma_{n''}}_{\alpha_{n''}}(A^{(20)})$ which is characterized by $\Gamma_{n''} = (n''_1, n''_2, n''_3)$ with $N_{n''} = n''_1 + n''_2 + n''_3 = n^{(2)}_1 + n^{(2)}_2 + n^{(2)}_3 - 2$ [where $\Gamma_{n_2} = (n^{(2)}_1, n^{(2)}_2, n^{(2)}_3)$] can yield nonvanishing contributions. Employing the (generalized) Wigner–Eckart theorem, and making use of the symmetry properties of the SU(3) coupling and recoupling coefficients, we obtain the following expression for C_1:

$$
\begin{aligned}
C_1 = (-1)^{\Gamma+\Gamma_{\omega_1}+\Gamma_{\omega_2}} & \sqrt{\frac{d(\Gamma_{\omega_1})}{d(20)d(\Gamma)}} \\
& \times \sum_{\Gamma_{n''}\rho''\Gamma_{\omega''}} \sqrt{d(\Gamma_{\omega''})} \langle \Gamma_{\sigma_2}\Gamma_{n_2}\rho_2\Gamma_{\omega_2}; S_2 | | | A^{(20)} | | | \Gamma_{\sigma_2}\Gamma_{n''}\rho''\Gamma_{\omega''}; S_2 \rangle \\
& \times \sum_{\rho_3} \langle \Gamma_{\sigma_2}\Gamma_{n''}\rho''\Gamma_{\omega''}; S_2 | | | \{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma S} | | | \Gamma_{\sigma_1}\Gamma_{n_1'}\rho_1'\Gamma_{\omega_1'}; S_1 \rangle_{\rho_3} \\
& \times \sum_{\rho_4\rho_5} \Phi_{\rho_3\rho_4}[\Gamma_{\omega''}\tilde{\Gamma}; \Gamma_{\omega_1'}] \Phi_{\rho_4\rho_5}[\Gamma_{\omega_1'}\tilde{\Gamma}_{\omega''}; \tilde{\Gamma}] \\
& \times \sum_{\rho_6} U[\Gamma_{\omega_2}\tilde{\Gamma}_{\omega''}\Gamma_{\omega_1}\Gamma_{\omega_1'}; (20)_{--}\tilde{\Gamma}\rho_5\rho_6] \langle \Gamma_{\omega_1}\alpha_{\omega_1}; \Gamma\alpha | \Gamma_{\omega_2}\alpha_{\omega_2} \rangle_{\rho_6} \langle S_1\Sigma_1 S\Sigma | S_2\Sigma_2 \rangle,
\end{aligned}
\tag{29}
$$

where we have introduced the abbreviation $(-1)^{\Gamma_i} \equiv (-1)^{(\lambda_i+\mu_i)}$ for $\Gamma_i = (\lambda_i \mu_i)$.

The matrix element of the second term in Equation (25) takes the form

$$
\begin{aligned}
C_2 \equiv \sum_\nu & \sqrt{\frac{1}{12}(\nu+1)(\nu+2)(\nu+3)(\nu+4)} \sum_{\alpha_{\omega_1'}\beta_1} \langle (20)\beta_1; \Gamma_{\omega_1'}\alpha_{\omega_1'} | \Gamma_{\omega_1}\alpha_{\omega_1} \rangle \\
& \times \langle \Gamma_{\sigma_2}\Gamma_{n_2}\rho_2\Gamma_{\omega_2}\alpha_{\omega_2}; S_2\Sigma_2 | [\{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma}, \{a^\dagger_{\nu+2} \times \tilde{a}_\nu\}^{(20)s=0}_{\beta_1\sigma=0}] | \Gamma_{\sigma_1}\Gamma_{n_1'}\rho_1'\Gamma_{\omega_1'}\alpha_{\omega_1'}; S_1\Sigma_1 \rangle,
\end{aligned}
\tag{30}
$$

and can be evaluated by using the commutator of Equation (B8) (see Appendix B). The delta functions in Equation (B8) restrict the sum over ν to two terms only: one term with $\nu = \eta$ and one with $\nu = \eta' - 2$. Again making use of the Wigner–Eckart theorem and the symmetry properties of the coupling coefficients, we obtain

$$
\begin{aligned}
C_2 = & -(-1)^\Gamma \sqrt{\frac{1}{2}(\eta+1)(\eta+2)} \sqrt{\frac{d(\Gamma_{\omega_1})}{d(\Gamma)d(\Gamma_{\omega_1'})}} \\
& \times \sum_{\Gamma''} (-1)^{\Gamma''} \sqrt{d(\Gamma'')} U[(20)(\eta 0)\Gamma''(0\,\eta'); (\eta+2,0)\Gamma] \\
& \times \sum_{\rho_3} \langle \Gamma_{\sigma_2}\Gamma_{n_2}\rho_2\Gamma_{\omega_2}; S_2 | | | \{a^\dagger_{\eta+2} \times \tilde{a}_{\eta'}\}^{\Gamma'' S} | | | \Gamma_{\sigma_1}\Gamma_{n_1'}\rho_1'\Gamma_{\omega_1'}; S_1 \rangle_{\rho_3} \\
& \times \sum_{\rho_4} U[\Gamma_{\omega_2}\tilde{\Gamma}''\Gamma_{\omega_1}(20); \Gamma_{\omega_1'}\rho_{3-}\tilde{\Gamma}_-\rho_4] \langle \Gamma_{\omega_1}\alpha_{\omega_1}; \Gamma\alpha | \Gamma_{\omega_2}\alpha_{\omega_2} \rangle_{\rho_4} \\
& \times \langle S_1\Sigma_1 S\Sigma | S_2\Sigma_2 \rangle \\
& + (-1)^{\eta+\eta'-\Gamma} \sqrt{\frac{1}{24}(\eta'-1)\eta'(\eta'+1)(\eta'+2)} \sqrt{\frac{d(\Gamma_{\omega_1})}{d(\eta 0)d(\Gamma_{\omega_1'})}} \\
& \times \sum_{\Gamma''} \sqrt{d(\Gamma'')} U[\Gamma(\eta' 0)\Gamma''(0, \eta'-2); (\eta 0)(20)] \\
& \times \sum_{\rho_3} \langle \Gamma_{\sigma_2}\Gamma_{n_2}\rho_2\Gamma_{\omega_2}; S_2 | | | \{a^\dagger_\eta \times \tilde{a}_{\eta'-2}\}^{\Gamma'' S} | | | \Gamma_{\sigma_1}\Gamma_{n_1'}\rho_1'\Gamma_{\omega_1'}; S_1 \rangle_{\rho_3} \\
& \times \sum_{\rho_4} U[\Gamma_{\omega_2}\tilde{\Gamma}''\Gamma_{\omega_1}(20); \Gamma_{\omega_1'}\rho_{3-}\tilde{\Gamma}_-\rho_4] \langle \Gamma_{\omega_1}\alpha_{\omega_1}; \Gamma\alpha | \Gamma_{\omega_2}\alpha_{\omega_2} \rangle_{\rho_4} \langle S_1\Sigma_1 S\Sigma | S_2\Sigma_2 \rangle.
\end{aligned}
\tag{31}
$$

Note that the sum over Γ'' is restricted by coupling requirements $(\eta+2,0)\times(0\,\eta') \to \Gamma''$, $(20)\times\Gamma \to \Gamma''$, and $\Gamma_{\omega_1'}\times\Gamma'' \to \Gamma_{\omega_2}$ in the first term and $(\eta 0)\times(0,\eta'-2) \to \Gamma''$, $\Gamma\times(20) \to \Gamma''$, and $\Gamma_{\omega_1'}\times\Gamma'' \to \Gamma_{\omega_2}$ in the second term.

The matrix element of the third term in Equation (25) originates from the two-body center-of-mass correction in the fermion realization of $A^{(20)}$ [Equation (13)] and can be evaluated once the commutator,

$$[\{a^{\dagger}_{\eta}\times\tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma},\{\{a^{\dagger}_{\nu}\times a^{\dagger}_{\nu'}\}^{\Gamma_a S'}\times\{\tilde{a}_{\nu-1}\times\tilde{a}_{\nu'-1}\}^{\tilde{\Gamma}_b S'}\}^{(20)s=0}_{\beta_1\sigma=0}], \tag{32}$$

is worked out. Upon doing so and employing the Wigner–Eckart theorem, recoupling coefficients, their symmetry and orthogonalization properties, it turns out that (while the commutator is non-zero) the contribution to the matrix element of Equation (22) vanishes identically: $C_3=0$.

We can now combine Equations (23), (29), (31), apply the Wigner–Eckart theorem to the matrix element under consideration, and utilize the orthonormality of the Clebsch–Gordan and Wigner coupling coefficients to obtain the final expression, a recursion formula for triple-reduced matrix elements of the one-body unit operator $\{a^{\dagger}_{\eta}\times\tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma}$:

$$\begin{aligned}
&\langle\Gamma_{\sigma_2}\Gamma_{n_2}\rho_2\Gamma_{\omega_2};S_2|||\{a^{\dagger}_{(\eta 0)(1/2)}\times\tilde{a}_{(0\eta')(1/2)}\}^{\Gamma S}|||\Gamma_{\sigma_1}\Gamma_{\hat{n}_1}\hat{\rho}_1\Gamma_{\omega_1};S_1\rangle_{\rho}\\
&=\sum_{\Gamma_{n_1}\rho_1}[\mathscr{K}^{-1}(\Gamma_{\sigma_1}\Gamma_{\omega_1})]_{\Gamma_{\hat{n}_1}\hat{\rho}_1,\Gamma_{n_1}\rho_1}\\
&\times\sum_{\Gamma_{\hat{n}_1'}\hat{\rho}_1'\Gamma_{\omega_1'}}U[(20)\Gamma_{\hat{n}_1'}\Gamma_{\omega_1}\Gamma_{\sigma_1};\Gamma_{n_1-}\rho_1\Gamma_{\omega_1'}\hat{\rho}_{1-}']X^{\Gamma_{n_1}}(\Gamma_{\hat{n}_1'})\\
&\times\sum_{\Gamma_{n_1'}\rho_1'}[\mathscr{K}(\Gamma_{\sigma_1}\Gamma_{\omega_1'})]_{\Gamma_{\hat{n}_1'}\hat{\rho}_1',\Gamma_{n_1'}\rho_1'}\\
&\times\Bigg\{(-1)^{\Gamma+\Gamma_{\omega_1}+\Gamma_{\omega_2}}\sqrt{\frac{d(\Gamma_{\omega_1})}{6d(\Gamma)}}\\
&\times\sum_{\Gamma_{n''}\rho''\Gamma_{\omega''}}\sqrt{d(\Gamma_{\omega''})}\langle\Gamma_{\sigma_2}\Gamma_{n_2}\rho_2\Gamma_{\omega_2};S_2|||A^{(20)}|||\Gamma_{\sigma_2}\Gamma_{n''}\rho''\Gamma_{\omega''};S_2\rangle\\
&\times\sum_{\rho_3}\langle\Gamma_{\sigma_2}\Gamma_{n''}\rho''\Gamma_{\omega''};S_2|||\{a^{\dagger}_{\eta}\times\tilde{a}_{\eta'}\}^{\Gamma S}|||\Gamma_{\sigma_1}\Gamma_{n_1'}\rho_1'\Gamma_{\omega_1'};S_1\rangle_{\rho_3}\\
&\times\sum_{\rho_4\rho_5}\Phi_{\rho_3\rho_4}[\Gamma_{\omega''}\tilde{\Gamma};\Gamma_{\omega_1'}]\Phi_{\rho_4\rho_5}[\Gamma_{\omega_1'}\tilde{\Gamma}_{\omega''};\tilde{\Gamma}]U[\Gamma_{\omega_2}\tilde{\Gamma}_{\omega''}\Gamma_{\omega_1}\Gamma_{\omega_1'};(20)_{--}\tilde{\Gamma}\rho_5\rho]\\
&-\left(1-\frac{1}{A}\right)(-1)^{\Gamma}\sqrt{\frac{(\eta+1)(\eta+2)}{2d(\Gamma)}}\sqrt{\frac{d(\Gamma_{\omega_1})}{d(\Gamma_{\omega_1'})}}\\
&\times\sum_{\Gamma''}(-1)^{\Gamma''}\sqrt{d(\Gamma'')}U[(20)(\eta 0)\Gamma''(0\eta');(\eta+2,0)\Gamma]\\
&\times\sum_{\rho_3}\langle\Gamma_{\sigma_2}\Gamma_{n_2}\rho_2\Gamma_{\omega_2};S_2|||\{a^{\dagger}_{\eta+2}\times\tilde{a}_{\eta'}\}^{\Gamma''S}|||\Gamma_{\sigma_1}\Gamma_{n_1'}\rho_1'\Gamma_{\omega_1'};S_1\rangle_{\rho_3}\\
&\times U[\Gamma_{\omega_2}\tilde{\Gamma}''\Gamma_{\omega_1}(20);\Gamma_{\omega_1'}\rho_{3-}\tilde{\Gamma}_{-}\rho]\\
&+\left(1-\frac{1}{A}\right)(-1)^{\eta+\eta'-\Gamma}\sqrt{\frac{(\eta'-1)\eta'(\eta'+1)(\eta'+2)}{24d(\eta 0)}}\sqrt{\frac{d(\Gamma_{\omega_1})}{d(\Gamma_{\omega_1'})}}\\
&\times\sum_{\Gamma''}\sqrt{d(\Gamma'')}U[\Gamma(\eta' 0)\Gamma''(0,\eta'-2);(\eta 0)(20)]\\
&\times\sum_{\rho_3}\langle\Gamma_{\sigma_2}\Gamma_{n_2}\rho_2\Gamma_{\omega_2};S_2|||\{a^{\dagger}_{\eta}\times\tilde{a}_{\eta'-2}\}^{\Gamma''S}|||\Gamma_{\sigma_1}\Gamma_{n_1'}\rho_1'\Gamma_{\omega_1'};S_1\rangle_{\rho_3}\\
&\times U[\Gamma_{\omega_2}\tilde{\Gamma}''\Gamma_{\omega_1}(20);\Gamma_{\omega_1'}\rho_{3-}\tilde{\Gamma}_{-}\rho]\Bigg\}.
\end{aligned} \tag{33}$$

To evaluate this expression, a series of ingredients are necessary: First, numeric values for the SU(3) Racah coefficients $U[\Gamma_1\Gamma_2\Gamma\Gamma_3;\Gamma_{12}\rho_{12}\rho_{12,3}\Gamma_{23}\rho_{23}\rho_{1,23}]$ and $\Phi_{\rho\rho'}[\Gamma_1\Gamma_2;\Gamma_3] = Z[\Gamma_1(00)\Gamma_3\Gamma_2;\Gamma_{1-}\rho\Gamma_{2-}\rho']$ are required. These may be calculated with a computer code published by Akiyama and Draayer.[34] Second, matrix elements of the symplectic raising operator $A^{(20)}$ and of the $\mathscr{K}$-matrix, which effects the orthonormalization of the symplectic basis states, are needed. Both types can be obtained from the matrix elements of $\mathscr{A}^{(20)}$, a generator of the $u(3)\otimes Weyl$ algebra, as is outlined in Reference 7. Third, matrix elements of the form $\langle\Gamma_{\sigma_2}\Gamma_{n''}\rho''\Gamma_{\omega''};S_2|||\{a^\dagger_\eta\times\tilde{a}_{\eta'}\}^{\Gamma S}|||\Gamma_{\sigma_1}\Gamma_{n_1'}\rho_1'\Gamma_{\omega_1'};S_1\rangle_{\rho_3}$ between states of excitation $N_{n''}$ and $N_{n_1'}$ are requisite ingredients. Here $N_{n''}=N_{n_2}-2$ as a result of the delta function $\delta_{N_{n''},N_{n_2}-2}$, introduced through the symplectic generator $A^{(20)}$ [see also Equation (28)], and $N_{n_1'}=N_{n''}-(\eta-\eta') = N_{\hat{n}_1}-2$. Furthermore, one needs values for the matrix elements of the operators $\{a^\dagger_{\eta+2}\times\tilde{a}_{\eta'}\}^{\Gamma''S}_{\alpha''\Sigma}$ and $\{a^\dagger_\eta\times\tilde{a}_{\eta'-2}\}^{\Gamma''S}_{\alpha''\Sigma}$ between the original bra state of excitation N_{n_2} and ket states with $N_{n_1'}=N_{n_2}-(\eta-\eta'+2)=N_{\hat{n}_1}-2$. Thus the desired matrix element is expressed in terms of known quantities and unit matrix elements involving states of lower excitation. Hence, through repeated application of this recursive process matrix elements of arbitrary one-body operators between symplectic basis states may be related back to valence shell matrix elements, which in turn can be evaluated by means of standard shell model techniques. A user-friendly computer code, which calculates the latter, has been published by Bahri and Draayer.[25]

The above formula has been derived for fermionic unit operators of the form $\{a^\dagger_\eta\times\tilde{a}_{\eta'}\}^{\Gamma S}_{\alpha\Sigma}$ with $\eta\geqslant\eta'$. The recursive process also covers the case $\eta>\eta'$, since the following relation holds:

$$\begin{aligned}\langle\Gamma_{\sigma_2}\Gamma_{n_2}\rho_2\Gamma_{\omega_2};S_2|||\{a^\dagger_\eta\times\tilde{a}_{\eta'}\}^{\Gamma S}|||\Gamma_{\sigma_1}\Gamma_{n_1}\rho_1\Gamma_{\omega_1};S_1\rangle_\rho&\\ =(-1)^{\eta+\eta'-\Gamma_{\omega_1}+\Gamma_{\omega_2}+S_1+S_2}\sqrt{\frac{d(\Gamma_{\omega_1})}{d(\Gamma_{\omega_2})}}\ \sqrt{\frac{2S_1+1}{2S_2+1}}&\\ \times\langle\Gamma_{\sigma_1}\Gamma_{n_1}\rho_1\Gamma_{\omega_1};S_1|||\{a^\dagger_{\eta'}\times\tilde{a}_\eta\}^{\tilde{\Gamma}S}|||\Gamma_{\sigma_2}\Gamma_{n_2}\rho_2\Gamma_{\omega_2};S_2\rangle^*_\rho\,.&\end{aligned}\tag{34}$$

A stringent test of Equation (33) is given by the following: One can evaluate the matrix element

$$\langle\Gamma_{\sigma_2}\Gamma_{n_2}\rho_2\Gamma_{\omega_2};S_2|||\{a^\dagger_\eta\times\tilde{a}_{\eta'}\}^{\Gamma S}|||\Gamma_{\sigma_1}\Gamma_{n_1}\rho_1\Gamma_{\omega_1};S_1\rangle_\rho\tag{35}$$

by stepping down on the bra-side, and proceeding analogously to the derivation given above. The result is a recursion formula analogous to Equation (33). Alternatively, using relation (34) in conjunction with Equation (33) yields an expression for the matrix element of Equation (35) which exactly equals the formula that is obtained by stepping down on the ket-side. Another test was carried out by encoding the recursion formula and using the one-body matrix elements so obtained to calculate expectation values of the particle number operator $\hat{N}$ and the symplectic raising and lowering operators $A^{(20)}$ and $B^{(02)}$, as well as the expectation values of $C^{(11)}$ for the valence shell. For $A\to\infty$, perfect agreement with the matrix elements of $A^{(20)}$ and $B^{(02)}$ as evaluated by means of a code that is based on the vector coherent state method outlined in reference 7 was obtained, as well as agreement with the matrix elements of $\hat{N}$ and $C^{(11)}$, which can be evaluated analytically.

VI. CONCLUDING REMARKS

We have introduced a fermion realization of the Sp(6,R) algebra. Specifically, we expressed the symplectic generators in terms of fermion creation and annihilation operators in a $\mathrm{Sp}(6,R)\supset\mathrm{U}(3)\supset\mathrm{SO}(3)$ basis. The new formalism was employed to derive a recursive process for calculating matrix elements of arbitrary one-body operators. The resulting formula requires as input SU(3) coupling coefficients, matrix elements of symplectic generators, and valence shell matrix elements of one-body unit operators. These ingredients may be calculated using published computer codes; references for those were given. The new formalism allows for the evaluation of

physical observables in the nuclear Sp(6,R) model which until now were only available, if at all, as an approximation to the exact result. First applications include symplectic calculations of longitudinal and transverse nuclear form factors,[35] which can be compared to those extracted from experiments.

One can also employ the recursion formula of Equation (33) to derive a recursion relation for $A^{(20)}$ for the special case of a large number of nucleons in the system ($A\rightarrow\infty$). Upon doing so, and comparing the result to the formula that was derived by Rosensteel using a step-down procedure analogous to the one outlined above,[27] we find that exact agreement requires the following relations to hold:

$$\begin{aligned}&(\eta+3)(\eta+4)U[(02)(\eta+2,0)(22)(0\eta);(\eta0)(20)]\\&\quad=(\eta-1)\eta U[(20)(\eta-2,0)(22)(0\eta);(\eta0)(02)],\end{aligned}\tag{36}$$

$$\begin{aligned}&(\eta+3)(\eta+4)U[(02)(\eta+2,0)(11)(0\eta);(\eta0)(20)]\\&\quad-(\eta-1)\eta U[(20)(\eta-2,0)(11)(0\eta);(\eta0)(02)]=\sqrt{10\eta(\eta+3)},\end{aligned}\tag{37}$$

$$U[(02)(\eta+2,0)(00)(0\eta);(\eta0)(20)]=U[(20)(\eta-2,0)(00)(0\eta);(\eta0)(02)]=1.\tag{38}$$

While Equation (38) was known previously,[36] the other two relations, Equation (36) and Equation (37), are new and may prove valuable for analytic work that involves SU(3) Racah coefficients.

ACKNOWLEDGMENTS

The authors wish to thank George Rosensteel for valuable input and for providing them with a code which evaluates matrix elements of symplectic raising and lowering operators. They furthermore acknowledge inspiring discussions on the subject with Jorge Hirsch and Octavio Castaños. One of the authors (J.E.) would also like to thank Amiram Leviatan and the Racah Institute of Physics, Jerusalem, for support during the final write-up of this paper.

APPENDIX A: BOSON CREATION AND ANNIHILATION OPERATORS

Given position $x_i(s)$ and momentum $p_i(s)$ coordinates of the s-th particle ($i=1,2,3$ and $s=1,\ldots,A$), one-body operators $b_i^\dagger(s)$ and $b_i(s)$, which create and annihilate, respectively, one oscillator quantum in the i-th direction of the s-th particle, can be defined as follows:

$$\begin{aligned}b_i^\dagger(s)&\equiv\frac{1}{\sqrt{2}}(x_i(s)-ip_i(s)),\\b_i(s)&\equiv\frac{1}{\sqrt{2}}(x_i(s)+ip_i(s)).\end{aligned}\tag{A1}$$

These operators are related to each other by Hermitian conjugation $b_i(s)=(b_i^\dagger(s))^\dagger$ and satisfy the standard boson commutation relations:

$$\begin{aligned}[b_i(s),b_j^\dagger(t)]&=\delta_{st}\delta_{ij},\\[b_i^\dagger(s),b_j^\dagger(t)]&=[b_i(s),b_j(t)]=0.\end{aligned}\tag{A2}$$

They may also be viewed as the components of SU(3) irreducible tensor operators, $b_{1q}^{\dagger(10)}$ and $\tilde{b}_{1q}^{(01)}$ ($q=0,\pm1$), transforming according to the $(\lambda\mu)=(10)$ and $(\lambda\mu)=(01)$ SU(3) irreps, respectively:

$$b_{1,\pm1}^{\dagger(10)}\equiv\mp\frac{1}{\sqrt{2}}(b_1^\dagger\pm ib_2^\dagger),\quad b_{1,0}^{\dagger(10)}\equiv b_3^\dagger,\tag{A3}$$

and

$$\tilde{b}^{(01)}_{1,\pm 1} \equiv \mp \frac{1}{\sqrt{2}}(b_1 \pm i b_2), \quad \tilde{b}^{(01)}_{1,0} \equiv b_3, \tag{A4}$$

where the subscript $(1,q)$ denotes the angular momentum character $(l=1;\ q=0,\pm 1)$ of the spherical components of the boson creation and annihilation operators. For the sake of simplicity the angular momentum label $l=1$ and the particle index s will be suppressed from here on, except where needed to avoid ambiguities. The operators $b^{\dagger(10)}_q$ and $\tilde{b}^{(01)}_q$ satisfy the conjugation relation $\tilde{b}^{(01)}_q = (-1)^q (b^{\dagger(10)}_{-q})^\dagger$, and their commutator is given by $[\tilde{b}^{(01)}_q, b^{\dagger(10)}_{q'}] = (-1)^q \delta_{q(-q')}$. Matrix elements of the boson creation and annihilation operators take a very simple form in the standard SU(3) basis:

$$\begin{aligned} \langle (\eta 0) S \| b^{\dagger(10)s=0} \| (\lambda \mu) S' \rangle &= \langle (\lambda+1, \mu) S \| b^{\dagger(10)s=0} \| (\eta - 1, 0) S' \rangle = \sqrt{\eta}\, \delta_{(\lambda\mu)(\eta-1,0)} \delta_{SS'}, \\ \langle (\lambda \mu) S \| \tilde{b}^{(01)s=0} \| (\eta 0) S' \rangle &= \langle (\eta - 1, 0) S \| \tilde{b}^{(01)s=0}_s \| (\lambda+1, \mu) S' \rangle = \sqrt{\eta+2}\, \delta_{(\lambda\mu)(\eta-1,0)} \delta_{SS'}. \end{aligned} \tag{A5}$$

The $b^{\dagger(10)}_q$ and $\tilde{b}^{(01)}_q$ are scalars in spin space, as has been noted explicitly in Equation (A5). [For the definition of the triple-reduced matrix element and the relevant phase conventions refer to Appendix C.]

Since the creation and annihilation operators $b^{\dagger(10)}_q$ and $\tilde{b}^{(01)}_q$ are SU(3) irreducible tensor operators, two or more of them may be coupled to form new SU(3) tensors. Matrix elements of such tensor products can be evaluated with the help of SU(3) reduction rules as given in Appendix C. A relevant example is the matrix element of the one-body operator $\{b^{\dagger(10)s=0} \times \tilde{b}^{(01)s=0}\}^{(11)S=0}$, evaluated between two single-particle states,

$$\begin{aligned} &\langle (\nu 0)\, \tfrac{1}{2} \| \{ b^{\dagger(10)s=0} \times \tilde{b}^{(01)s=0} \}^{(11)S=0} \| (\nu' 0)\, \tfrac{1}{2} \rangle \\ &\quad = \sum_{(\lambda''\mu'')S''} \Phi_{11}[(10)(01);(11)]\, U[(\nu' 0)(01)(\nu 0)(10);(\lambda''\mu'')(11)]\, U\left(\frac{1}{2}\, 0\, \frac{1}{2}\, 0; S'' 0\right) \\ &\qquad \times \langle (\nu 0)\, \tfrac{1}{2} \| b^{\dagger(10)s=0} \| (\lambda''\mu'') S'' \rangle \langle (\lambda''\mu'') S'' \| \tilde{b}^{(01)s=0} \| (\nu' 0)\, \tfrac{1}{2} \rangle \\ &\quad = \sqrt{\frac{2}{3}\nu(\nu+3)}\, \delta_{\nu\nu'}, \end{aligned} \tag{A6}$$

where $U[\cdots]$ and $\Phi[\cdots]$ are Racah recoupling coefficients (see Appendix C). For the tensor product of two raising (lowering) operators, acting on a single-particle state, one may proceed analogously to obtain

$$\begin{aligned} \langle (\nu 0)\, \tfrac{1}{2} \| \{ b^{\dagger(10)s=0} \times b^{\dagger(10)s=0} \}^{(20)S=0} \| (\nu' 0)\, \tfrac{1}{2} \rangle &= \sqrt{\nu(\nu-1)}\, \delta_{\nu,\nu'+2}, \\ \langle (\nu 0)\, \tfrac{1}{2} \| \{ \tilde{b}^{(01)s=0} \times \tilde{b}^{(01)s=0} \}^{(02)S=0} \| (\nu' 0)\, \tfrac{1}{2} \rangle &= \sqrt{(\nu+3)(\nu+4)}\, \delta_{\nu',\nu+2}. \end{aligned} \tag{A7}$$

Matrix elements of a SU(3)-coupled tensor product of two boson operators, acting on a two-particle state, can be evaluated using Millener's reduction rule[37] (see also Appendix C). For the product of a creation and an annihilation operator, coupled to $(\lambda\mu)=(11)$, this method yields

$$\begin{aligned} &\langle \{ (\nu_1 0) \times (\nu_2 0) \} (\lambda\mu); \{ \tfrac{1}{2} \times \tfrac{1}{2} \} S \| \{ b^{\dagger(10)0}(1) \times \tilde{b}^{(01)0}(2) \}^{(11)0} \| \\ &\quad \times \{ (\nu_1' 0) \times (\nu_2' 0) \} (\lambda'\mu'); \{ \tfrac{1}{2} \times \tfrac{1}{2} \} S' \rangle \\ &\quad = \sqrt{\nu_1(\nu_2+3)}\, \delta_{SS'} \delta_{\nu_1', \nu_1 - 1} \delta_{\nu_2', \nu_2 + 1} \begin{Bmatrix} (\nu_1 - 1, 0) & (10) & (\nu_1 0) & - \\ (\nu_2 + 1, 0) & (01) & (\nu_2 0) & - \\ (\lambda'\mu') & (11) & (\lambda\mu) & - \\ - & - & - & \end{Bmatrix}, \end{aligned} \tag{A8}$$

whereas for two creation operators, coupled to $(\lambda\mu)=(20)$, we obtain

$$\begin{aligned}&\langle\{(\nu_1 0)\times(\nu_2 0)\}(\lambda\mu);\{\tfrac{1}{2}\times\tfrac{1}{2}\}S|||\{b^{\dagger(10)0}(1)\times b^{\dagger(10)0}(2)\}^{(20)0}|||\\&\quad\times\{(\nu_1' 0)\times(\nu_2' 0)\}(\lambda'\mu');\{\tfrac{1}{2}\times\tfrac{1}{2}\}S'\rangle\\&\quad=\sqrt{\nu_1\nu_2}\,\delta_{SS'}\delta_{\nu_1',\nu_1-1}\delta_{\nu_2',\nu_2-1}\begin{Bmatrix}(\nu_1-1,0) & (10) & (\nu_1 0) & -\\(\nu_2-1,0) & (10) & (\nu_2 0) & -\\(\lambda'\mu') & (20) & (\lambda\mu) & -\\- & - & - & \end{Bmatrix},\end{aligned}\tag{A9}$$

and for two annihilation operators we find

$$\begin{aligned}&\langle\{(\nu_1 0)\times(\nu_2 0)\}(\lambda\mu);\{\tfrac{1}{2}\times\tfrac{1}{2}\}S|||\{\tilde{b}^{(01)0}(1)\times\tilde{b}^{(01)0}(2)\}^{(02)0}|||\{(\nu_1' 0)\times(\nu_2' 0)\}(\lambda'\mu');\{\tfrac{1}{2}\times\tfrac{1}{2}\}S'\rangle\\&=\sqrt{(\nu_1+3)(\nu_2+3)}\,\delta_{SS'}\delta_{\nu_1',\nu_1+1}\delta_{\nu_2',\nu_2+1}\begin{Bmatrix}(\nu_1+1,0) & (01) & (\nu_1 0) & -\\(\nu_2+1,0) & (01) & (\nu_2 0) & -\\(\lambda'\mu') & (02) & (\lambda\mu) & -\\- & - & - & \end{Bmatrix},\end{aligned}\tag{A10}$$

where $b^{\dagger}(t)$ and $\tilde{b}(t)$ ($t=1,2$ here) act only on that part of the wave function which refers to particle t.

APPENDIX B: FERMION SECOND QUANTIZATION

A general one-body operator that acts symmetrically on a system of A identical particles is given by

$$\mathscr{F}=\sum_s f(\mathbf{r}_s,\boldsymbol{\sigma}_s),\tag{B1}$$

where $\mathbf{r}_s$ and $\boldsymbol{\sigma}_s$ represent the position and spin (or spin–isospin) coordinates, respectively, of the s-th particle. In a fermion second quantization formulation this one-body operator takes the form

$$\mathscr{F}=\sum_{\rho,\rho'}\langle\rho'|f(\mathbf{r},\boldsymbol{\sigma})|\rho\rangle a^{\dagger}_{\rho'}a_{\rho},\tag{B2}$$

where ρ labels the available single-particle states and $a^{\dagger}_{\rho}$ and a_{ρ} are single-particle creation and annihilation operators that satisfy the usual fermion anti-commutation relations:

$$\begin{aligned}\{a_{\rho},a^{\dagger}_{\rho'}\}&=\delta_{\rho,\rho'},\\\{a_{\rho},a_{\rho'}\}&=\{a^{\dagger}_{\rho},a^{\dagger}_{\rho'}\}=0.\end{aligned}\tag{B3}$$

For fermions in a harmonic oscillator potential, ρ stands for a set of quantum numbers $\rho=\eta l m\tfrac{1}{2}\sigma$ or $\rho=\eta l\tfrac{1}{2}j m_j$, depending on whether the states are characterized by an LS- or jj-coupling scheme, respectively. Here η is the principal quantum number (major oscillator shell) of the single-particle level; l, $\tfrac{1}{2}$, and j label the orbital, spin, and total angular momenta with projections m, σ, and m_j, respectively. (In a spin–isospin formalism, one has $\rho=\eta l m\tfrac{1}{2}\sigma\tfrac{1}{2}\tau$ or $\rho=\eta l\tfrac{1}{2}j m_j\tfrac{1}{2}\tau$, respectively, where the additional $\tfrac{1}{2}$ denotes the isospin quantum number with projection τ.) For the present purposes it is most convenient to use the LS-coupling scheme.

Since the single-particle harmonic oscillator wave functions, $|\eta l m\tfrac{1}{2}\sigma\rangle=a^{\dagger}_{\eta l m(1/2)\sigma}|_-\rangle$, where $|_-\rangle$ denotes the particle vacuum, transform irreducibly under a set of physically relevant SU(3) and SU(2) symmetry group operations, the fermion creation operator $a^{\dagger}_{\eta l m(1/2)\sigma}$ is a double irreducible tensor operator of rank $(\lambda\mu)=(\eta 0)$ in SU(3), which labels its orbital character (with subgroup labels l and m), and of rank $s=\tfrac{1}{2}$ in SU(2) for the spin part (with subgroup label σ) and

should be written as $a^{\dagger}_{(\eta 0)lm(1/2)\sigma}$. Since $a_{\rho}=(a^{\dagger}_{\rho})^{\dagger}$ is not a proper irreducible tensor operator with respect to the above group transformations, it is advantageous to define $\tilde{a}_{(0\eta)lm(1/2)\sigma} \equiv(-1)^{\eta+l+m+(1/2)+\sigma} a_{(\eta 0)l(-m)(1/2)(-\sigma)}$ which is a proper irreducible tensor operator of rank $(\lambda\mu)=(0\eta)$ in SU(3) and rank $s=\frac{1}{2}$ in (spin-)SU(2).

It thus becomes possible to construct tensor products from the fermion creation and annihilation operators, such as

$$\{a^{\dagger}_{(\eta_1 0)(1/2)}\times\tilde{a}_{(0\eta_2)(1/2)}\}^{(\lambda\mu)S}_{\kappa LM\Sigma}=\sum_{\alpha_1\alpha_2\sigma_1\sigma_2}\langle(\eta_1 0)\alpha_1;(0\eta_2)\alpha_2|(\lambda\mu)\kappa LM\rangle \times\langle\tfrac{1}{2}\sigma_1\,\tfrac{1}{2}\sigma_2|S\Sigma\rangle a^{\dagger}_{(\eta_1 0)\alpha_1(1/2)\sigma_1}\tilde{a}_{(0\eta_2)\alpha_2(1/2)\sigma_2}, \tag{B4}$$

which moves a particle from the η_2-th major oscillator shell to the η_1-th shell. The possible $(\lambda\mu)$ values are given by the coupling rule $(\eta_1 0)\times(0\eta_2)=\oplus_{k=0}^{\min(\eta_1,\eta_2)}(\eta_1-k,\eta_2-k)$ (see reference 38) and α_i is an abbreviation for the set of possible subgroup labels $\alpha_i=\kappa_i l_i m_i$, where $\kappa_i=1$ must hold here. The total intrinsic spin S can take the values 0 or 1 with projection $\Sigma=0$ or $\Sigma=0$, ±1, respectively. The product $\{a^{\dagger}_{(\eta_1 0)(1/2)}\times a^{\dagger}_{(\eta_2 0)(1/2)}\}^{(\lambda\mu)S}_{\kappa LM\Sigma}$, on the other hand, creates a pair of fermions with one particle in the η_1-th shell and one in the η_2-th shell, and the pair is coupled to $(\lambda\mu)\in\{(\eta_1 0)\times(\eta_2 0)\}=\{\oplus_{k=0}^{\min(\eta_1,\eta_2)}(\eta_1+\eta_2-2k,k)\}$ and $S=0$ or 1. Similarly, the product $\{\tilde{a}_{(0\eta_1)(1/2)}\times\tilde{a}_{(0\eta_2)(1/2)}\}^{(\lambda\mu)S}_{\kappa LM\Sigma}$ annihilates a SU(3)-coupled pair of fermions with one particle in the η_1-th shell, one in the η_2-th shell, $(\lambda\mu)\in\{(0\eta_1)\times(0\eta_2)\}=\{\oplus_{k=0}^{\min(\eta_1,\eta_2)}(k,\eta_1+\eta_2-2k)\}$, and $S=0$ or 1. One can furthermore construct a SU(3) irreducible tensor which destroys a pair of fermions in a particular SU(3)-coupled configuration, and creates a new pair configuration:

$$\begin{aligned}&\{\{a^{\dagger}_{(\eta_1 0)(1/2)}\times a^{\dagger}_{(\eta_2 0)(1/2)}\}^{(\lambda_1\mu_1)S_1}\times\{\tilde{a}_{(0\nu_1)(1/2)}\times\tilde{a}_{(0\nu_2)(1/2)}\}^{(\lambda_2\mu_2)S_2}\}^{\rho(\lambda\mu)S}_{\kappa LM\Sigma}\\ &\quad=\sum_{\alpha_1\alpha_2\Sigma_1\Sigma_2}\langle(\lambda_1\mu_1)\alpha_1;(\lambda_2\mu_2)\alpha_2|(\lambda\mu)\alpha\rangle_{\rho}\langle S_1\Sigma_1 S_2\Sigma_2|S\Sigma\rangle\\ &\qquad\times\{a^{\dagger}_{(\eta_1 0)(1/2)}\times a^{\dagger}_{(\eta_2 0)(1/2)}\}^{(\lambda_1\mu_1)S_1}_{\alpha_1\Sigma_1}\{\tilde{a}_{(0\nu_1)(1/2)}\times\tilde{a}_{(0\nu_2)(1/2)}\}^{(\lambda_2\mu_2)S_2}_{\alpha_2\Sigma_2},\end{aligned} \tag{B5}$$

where ρ denotes the multiplicity of $(\lambda\mu)$ in the coupling $(\lambda_1\mu_1)\times(\lambda_2\mu_2)\to(\lambda\mu)$.

The Hermitian adjoint of the above products are given by

$$\begin{aligned}(\{a^{\dagger}_{(\eta_1 0)(1/2)}\times\tilde{a}_{(0\eta_2)(1/2)}\}^{(\lambda\mu)S}_{\kappa LM\Sigma})^{\dagger}&=(-1)^{\eta_2-\eta_1+L+M+\Sigma}\{a^{\dagger}_{(\eta_2 0)(1/2)}\times\tilde{a}_{(0\eta_1)(1/2)}\}^{(\mu\lambda)S}_{\kappa L-M-\Sigma},\\ (\{a^{\dagger}_{(\eta_1 0)(1/2)}\times a^{\dagger}_{(\eta_2 0)(1/2)}\}^{(\lambda\mu)S}_{\kappa LM\Sigma})^{\dagger}&=(-1)^{-\eta_1-\eta_2-L+M-1+\Sigma}\{\tilde{a}_{(0\eta_2)(1/2)}\times\tilde{a}_{(0\eta_1)(1/2)}\}^{(\mu\lambda)S}_{\kappa L-M-\Sigma},\end{aligned} \tag{B6}$$

and

$$\begin{aligned}&(\{\{a^{\dagger}_{(\eta_1 0)(1/2)}\times a^{\dagger}_{(\eta_2 0)(1/2)}\}^{(\lambda_1\mu_1)S_1}\times\{\tilde{a}_{(0\nu_1)(1/2)}\times\tilde{a}_{(0\nu_2)(1/2)}\}^{(\lambda_2\mu_2)S_2}\}^{\rho(\lambda\mu)S}_{\kappa LM\Sigma})^{\dagger}\\ &\quad=(-1)^{\nu_1+\nu_2-\eta_1-\eta_2+(\lambda_1+\mu_1)+(\lambda_2+\mu_2)+(\lambda+\mu)-L+M+\Sigma}\\ &\qquad\times\sum_{\rho'}(-1)^{\rho'_{\max}-\rho'}\Phi_{\rho'\rho}[(\lambda_2\mu_2)(\lambda_1\mu_1);(\lambda\mu)]\\ &\qquad\times\{\{a^{\dagger}_{(\nu_2 0)(1/2)}\times a^{\dagger}_{(\nu_1 0)(1/2)}\}^{(\mu_2\lambda_2)S_2}\times\{\tilde{a}_{(0\eta_2)(1/2)}\times\tilde{a}_{(0\eta_1)(1/2)}\}^{(\mu_1\lambda_1)S_1}\}^{\rho'(\mu\lambda)S}_{\kappa L-M-\Sigma},\end{aligned} \tag{B7}$$

where the phase matrix Φ is a special case of the recoupling coefficient Z, $\Phi_{\rho\rho'}[(\lambda_1\mu_1)\times(\lambda_2\mu_2);(\lambda\mu)]=Z[(\lambda_1\mu_1)(00)(\lambda\mu)(\lambda_2\mu_2);(\lambda_1\mu_1)_-\rho(\lambda_2\mu_2)_-\rho']$, and can be evaluated with available computer codes (see also Appendix C). The symbol $\rho'_{\max}$ denotes the maximum multiplicity in the coupling $(\mu_2\lambda_2)\times(\mu_1\lambda_1)\to(\mu\lambda)$, and ρ' takes on values $1,2,\ldots,\rho'_{\max}$.

The following commutation relations, which are required for the derivation of the fermionic expressions for the symplectic generators, can be derived by making use of the commutation rules of the uncoupled components [see Equation (B3)] and SU(3) coupling and recoupling techniques. For clarity we abbreviate $(\lambda_i \mu_i)$ with the symbol Γ_i, $(-1)^{\Gamma_i} \equiv (-1)^{\lambda_i+\mu_i}$, and $\hat{S} \equiv \sqrt{2S+1}$:

$$
\begin{aligned}
&[\{a^\dagger_\eta \times \tilde{a}_{\eta'}\}^{\Gamma_1 S_1}_{\alpha_1 \Sigma_1}, \{a^\dagger_\nu \times \tilde{a}_{\nu'}\}^{\Gamma_2 S_2}_{\alpha_2 \Sigma_2}] \\
&\quad = (-1)^{\eta+\nu} \sum_{s\sigma} \hat{S}_1 \hat{S}_2 \langle S_1 \Sigma_1 S_2 \Sigma_2 | s\sigma \rangle \begin{Bmatrix} \frac{1}{2} & \frac{1}{2} & S_1 \\ s & S_2 & \frac{1}{2} \end{Bmatrix} \\
&\qquad \times \Bigg\{ -\delta_{\eta'\nu} (-1)^{-s-\Gamma_1} \sqrt{\frac{d(\Gamma_1)}{d(\eta 0)}} \sum_{\Gamma\alpha} \{a^\dagger_\eta \times \tilde{a}_{\nu'}\}^{\Gamma s}_{\alpha\sigma} \\
&\qquad \times \sum_\rho \langle \Gamma_1 \alpha_1; \Gamma_2 \alpha_2 | \Gamma \alpha \rangle_\rho U[\Gamma_1(\nu 0)\Gamma(0\nu'); (\eta 0)_{--}\Gamma_{2-}\rho] \\
&\qquad + \delta_{\eta\nu'} (-1)^{S_1+S_2-\Gamma_2} \sqrt{\frac{d(\Gamma_2)}{d(\nu 0)}} \sum_{\Gamma\alpha} \{a^\dagger_\nu \times \tilde{a}_{\eta'}\}^{\Gamma s}_{\alpha\sigma} \\
&\qquad \times \sum_\rho \langle \Gamma_2 \alpha_2; \Gamma_1 \alpha_1 | \Gamma \alpha \rangle_\rho U[\Gamma_2(\eta 0)\Gamma(0\eta'); (\nu 0)_{--}\Gamma_{1-}\rho] \Bigg\},
\end{aligned} \tag{B8}
$$

and

$$
\begin{aligned}
&[\{a^\dagger_\eta \times a^\dagger_{\eta'}\}^{\Gamma_1 S_1}_{\alpha_1 \Sigma_1}, \{a^\dagger_\nu \times \tilde{a}_{\nu'}\}^{\Gamma_2 S_2}_{\alpha_2 \Sigma_2}] \\
&\quad = (-1)^{\eta+\nu-\Gamma_2} \sqrt{\frac{d(\Gamma_2)}{d(\nu 0)}} \sum_{s\sigma} \hat{S}_1 \hat{S}_2 \langle S_2 \Sigma_2 S_1 \Sigma_1 | s\sigma \rangle \begin{Bmatrix} \frac{1}{2} & \frac{1}{2} & S_2 \\ s & S_1 & \frac{1}{2} \end{Bmatrix} \\
&\qquad \times \Bigg\{ \delta_{\nu'\eta'} (-1)^{s+S_1-\Gamma_1} \sum_{\Gamma\alpha} \{a^\dagger_\nu \times a^\dagger_\eta\}^{\Gamma s}_{\alpha\sigma} \\
&\qquad \times \sum_\rho \langle \Gamma_2 \alpha_2; \Gamma_1 \alpha_1 | \Gamma \alpha \rangle_\rho U[\Gamma_2(\eta' 0)\Gamma(\eta 0); (\nu 0)_{--}\Gamma_{1-}\rho] \\
&\qquad + \delta_{\nu'\eta} (-1)^s \sum_{\Gamma\alpha} \{a^\dagger_\nu \times a^\dagger_{\eta'}\}^{\Gamma s}_{\alpha\sigma} \sum_\rho \langle \Gamma_2 \alpha_2; \Gamma_1 \alpha_1 | \Gamma \alpha \rangle_\rho U[\Gamma_2(\eta 0)\Gamma(\eta' 0); (\nu 0)_{--}\Gamma_{1-}\rho] \Bigg\},
\end{aligned} \tag{B9}
$$

and

$$
\begin{aligned}
&[\{\tilde{a}_\eta \times \tilde{a}_{\eta'}\}^{\Gamma_1 S_1}_{\alpha_1 \Sigma_1}, \{a^\dagger_\nu \times \tilde{a}_{\nu'}\}^{\Gamma_2 S_2}_{\alpha_2 \Sigma_2}] \\
&\quad = -\sum_{s\sigma} \hat{S}_1 \hat{S}_2 \langle S_1 \Sigma_1 S_2 \Sigma_2 | s\sigma \rangle \begin{Bmatrix} \frac{1}{2} & \frac{1}{2} & S_1 \\ s & S_2 & \frac{1}{2} \end{Bmatrix} \\
&\qquad \times \Bigg\{ \delta_{\eta'\nu} (-1)^{\eta'+\eta-\Gamma_1+s} \sqrt{\frac{d(\Gamma_1)}{d(0\eta)}} \sum_{\Gamma\alpha} \{\tilde{a}_\eta \times \tilde{a}_{\nu'}\}^{\Gamma s}_{\alpha\sigma} \\
&\qquad \times \sum_\rho \langle \Gamma_1 \alpha_1; \Gamma_2 \alpha_2 | \Gamma \alpha \rangle_\rho U[\Gamma_1(\eta' 0)\Gamma(0\nu'); (0\eta)_{--}\Gamma_{2-}\rho] \\
&\qquad + \delta_{\eta\nu} (-1)^{S_1-s} \sqrt{\frac{d(\Gamma_1)}{d(0\eta')}} \sum_{\Gamma\alpha} \{\tilde{a}_{\eta'} \times \tilde{a}_{\nu'}\}^{\Gamma s}_{\alpha\sigma} \\
&\qquad \times \sum_\rho \langle \Gamma_1 \alpha_1; \Gamma_2 \alpha_2 | \Gamma \alpha \rangle_\rho U[\Gamma_1(\eta 0)\Gamma(0\nu'); (0\eta')_{--}\Gamma_{2-}\rho] \Bigg\},
\end{aligned} \tag{B10}
$$

where $d(\Gamma)=d(\lambda\mu)=\frac{1}{2}(\lambda+1)(\mu+1)(\lambda+\mu+2)$ is the dimension of the SU(3) irrep $\Gamma=(\lambda\mu)$.

In order to derive the recursion relation (33), it is furthermore necessary to evaluate the commutator of the two-body operator $\{\{a^\dagger_\eta\times a^\dagger_{\eta'}\}^{\Gamma_1 S_1}\times\{\tilde{a}_\tau\times\tilde{a}_{\tau'}\}^{\Gamma_2 S_2}\}^{\rho_3\Gamma_3 S_3}_{\alpha_3\Sigma_3}$ with $\{a^\dagger_\nu\times\tilde{a}_{\nu'}\}^{\Gamma_4 S_4}_{\alpha_4\Sigma_4}$, where ρ_3 denotes the multiplicity of Γ_3 in the coupling $\Gamma_1\times\Gamma_2\to\Gamma_3$. We obtain the following expression:

$$
\begin{aligned}
&[\{\{a^\dagger_\eta\times a^\dagger_{\eta'}\}^{\Gamma_1 S_1}\times\{\tilde{a}_\tau\times\tilde{a}_{\tau'}\}^{\Gamma_2 S_2}\}^{\rho_3\Gamma_3 S_3}_{\alpha_3\Sigma_3},\{a^\dagger_\nu\times\tilde{a}_{\nu'}\}^{\Gamma_4 S_4}_{\alpha_4\Sigma_4}]\\
&\quad=-\sum_{\Gamma\rho}\sum_{\rho_5\Gamma_5\alpha_5}(-1)^{\Gamma_1-\Gamma_3+\Gamma_4-\Gamma}\sqrt{\frac{d(\Gamma)d(\Gamma_3)}{d(\Gamma_1)d(\Gamma_4)}}\sum_{\rho'\rho''}\Phi_{\rho\rho'}[\Gamma_2\Gamma_4;\Gamma]\Phi_{\rho'\rho''}[\Gamma\tilde{\Gamma}_2;\Gamma_4]\\
&\qquad\times\sum_{\tilde{\rho}}\langle\Gamma_3\alpha_3;\Gamma_4\alpha_4|\Gamma_5\alpha_5\rangle_{\tilde{\rho}}U[\Gamma_3\tilde{\Gamma}_2\Gamma_5\Gamma;\Gamma_1\rho_3\rho_5\Gamma_4\rho''\tilde{\rho}]\\
&\qquad\times\sum_{sS_5\Sigma_5}(-1)^{S_1+S_4-S_5+s}\hat{S}_2\hat{S}_3\hat{S}_4\hat{s}\langle S_3\Sigma_3 S_4\Sigma_4|S_5\Sigma_5\rangle\begin{Bmatrix}\frac{1}{2}&\frac{1}{2}&S_2\\ s&S_4&\frac{1}{2}\end{Bmatrix}\begin{Bmatrix}S_2&S_1&S_3\\ S_5&S_4&s\end{Bmatrix}\\

\end{aligned}
\tag{B11}
$$

APPENDIX C: SU(3) COUPLING AND RECOUPLING RULES

The work presented here makes extensive use of SU(2) and SU(3) coupling techniques and the (generalized) Wigner–Eckart theorem. The relevant definitions of the SU(2) coupling coefficients, along with their phase and normalization conventions, can be found in most textbooks on quantum mechanics. Analytic expressions and numerical values for special cases of these coefficients, as well as useful relations between different coupling coefficients, are compiled in various monographs on angular momentum theory, as for instance in reference 39. In contrast, analogous results for the SU(3) case required here are distributed over about a dozen different articles. For the convenience of the reader and as a practical reference for future analytical and numeric work in this field, we list the basic definitions and relations in this appendix. We also point the reader to sources of additional information and to publicly available computer codes. Specifically, we consider the coupling of two, three, and four irreducible SU(3) representations and give the Wigner–Eckart theorem for SU(3). The results presented here are primarily taken from publications by

Hecht *et al.*,[28,36,40–42] Draayer *et al.*,[34,43–45] O'Reilly,[38] Millener,[37] and Vergados.[46] Several new relations are included as well. The phase conventions used here are those employed in reference 44.

1. SU(3) Wigner coefficients: Coupling of two SU(3) irreps

If α represents a set of labels used to distinguish orthonormal basis states within a given irreducible SU(3) representation $\Gamma=(\lambda\mu)$, the Wigner coefficients $\langle\Gamma_1\alpha_1;\Gamma_2\alpha_2|\Gamma\alpha\rangle_\rho$ are defined as the elements of a unitary transformation between coupled and uncoupled orthonormal irreps of SU(3) in the α-scheme:[44]

$$|\Gamma\alpha\rangle_\rho=\sum_{\alpha_1\alpha_2}\langle\Gamma_1\alpha_1;\Gamma_2\alpha_2|\Gamma\alpha\rangle_\rho|\Gamma_1\alpha_1\rangle|\Gamma_2\alpha_2\rangle, \tag{C1}$$

and the inverse transformation is given by

$$|\Gamma_1\alpha_1\rangle|\Gamma_2\alpha_2\rangle=\sum_{\rho\Gamma\alpha}\langle\Gamma_1\alpha_1;\Gamma_2\alpha_2|\Gamma\alpha\rangle_\rho|\Gamma\alpha\rangle_\rho\,. \tag{C2}$$

Here $\alpha=\epsilon\Lambda M_\Lambda$ for the SU(3)$\supset$SU(2)$\otimes$U(1) (canonical) group chain and $\alpha=\kappa lm$ for the SU(3)$\supset$SO(3) reduction. The subgroup chains impose certain restrictions on the above couplings, for example, $\epsilon=\epsilon_1+\epsilon_2$, $M_\Lambda=M_{\Lambda_1}+M_{\Lambda_2}$, and $\Lambda=\Lambda_1+\Lambda_2,\ldots,|\Lambda_1-\Lambda_2|$ must hold for the canonical group chain, and the usual angular momentum coupling rules, $l=l_1+l_2,\ldots,|l_1-l_2|$, and $m=m_1+m_2$ apply for the chain containing SO(3). The conjugates of the relevant SU(3) basis states are given by[44]

$$|\Gamma\alpha\rangle^*=(-1)^{\chi_\alpha}|\tilde{\Gamma}\,\overline{\alpha}\rangle, \tag{C3}$$

where $\tilde{\Gamma}=(\mu\lambda)$ is the conjugate irrep to $\Gamma=(\lambda\mu)$, and $\overline{\alpha}$ and χ_i depend on the selected subgroup chain:[47]

$$\begin{gathered}\text{for } \alpha=\epsilon\Lambda M_\Lambda, \text{ one has } \overline{\alpha}=(-\epsilon)\Lambda(-M_\Lambda) \text{ and } \chi_i=\frac{1}{3}(\lambda_i-\mu_i)-\frac{1}{6}\epsilon_i-M_{\Lambda_i};\\ \text{for } \alpha=\kappa lm \text{ one has } \overline{\alpha}=\kappa l(-m) \text{ and } \chi_i=(\lambda_i-\mu_i)+l_i-m_i\,.\end{gathered} \tag{C4}$$

The outer multiplicity label $\rho=1,2,\ldots,\rho_{\max}$ is used to distinguish multiple occurrences of a given Γ in the direct product $\Gamma_1\times\Gamma_2$: $\rho=1,2,\ldots,\rho_{\max}$, where $\rho_{\max}$ denotes the number of possible couplings $\Gamma_1\times\Gamma_2$, and the possible Γ irreps in the product can be obtained by coupling the appropriate Young diagrams.[48] O'Reilly[38] determines a closed formula for the decomposition of the outer product $(p,q)\times(r,s)$ of finite-dimensional irreps of SU(3) for arbitrary positive integers p, q, r, and s:

$$(r,s)\times(p,q)=\bigoplus_{k=0}^{\min(q,r+s)}\bigoplus_{j=0}^{\min(s,p,r+s-k)}\bigoplus_{i=\max(0,j-s+k)}^{\min(p-j+k,r)}(r+p-j-2i+k,s+q+i-j-2k), \tag{C5}$$

and furthermore derives necessary and sufficient conditions for a SU(3) irrep (m,n) to appear as summand in the product $(r,s)\times(p,q)$.

Draayer and Akiyama[44] give a prescription for the unique determination, including the phases, of all SU(3)$\supset$SU(2)$\otimes$U(1) Wigner coefficients and derive their relevant conjugation and symmetry properties. Since the SU(3)$\supset$SO(3) reduction is related to the SU(3)$\supset$SU(2)$\otimes$U(1) reduction via the coefficients of the transformation between the $\alpha=\kappa lm$ and the $\alpha=\epsilon\Lambda M_\Lambda$ schemes,[44,45] it suffices to determine the conjugation relationship and symmetry properties for the SU(3)$\supset$SU(2)$\otimes$U(1) chain only. The corresponding SU(3)$\supset$SO(3) results follow then from the known relationships among the transformation brackets between the two schemes. These relations

are given in reference 44 and a computer code which allows for a numerical determination of SU(3)⊃SU(2)⊗U(1) and SU(3)⊃SO(3) Wigner coefficients, as well as SU(3) Racah coefficients, is published in reference 34. Analytic expressions for Wigner coefficients which are of particular interest in p-shell and ds-shell nuclear shell-model calculations are tabulated in reference 28 for the canonical subgroup chain and in references 46, 41 for the SU(3)⊃SO(3) chain.

The most important of the symmetry relations of the SU(3) Wigner coefficients is the one that involves a $1\leftrightarrow 3$ interchange of the quantum labels:

$$\langle \Gamma_1\alpha_1;\Gamma_2\alpha_2|\Gamma_3\alpha_3\rangle_\rho=(-1)^{\varphi+\chi_2}\sqrt{\frac{\dim(\Gamma_3)}{\dim(\Gamma_1)}}\,\langle \Gamma_3\alpha_3;\tilde{\Gamma}_2\overline{\alpha_2}|\Gamma_1\alpha_1\rangle_\rho, \tag{C6}$$

where $\varphi=(\lambda_1+\mu_1)+(\lambda_2+\mu_2)-(\lambda_3+\mu_3)$. The dimension of the SU(3) irrep Γ is given by $\dim(\Gamma)=\dim(\lambda\mu)=\frac{1}{2}(\lambda+1)(\mu+1)(\lambda+\mu+2)$, and $\overline{\alpha_i}$ and χ_i are as defined in Equation (C4).

The $1\leftrightarrow 2$ interchange is more complicated:

$$\langle \Gamma_1\alpha_1;\Gamma_2\alpha_2|\Gamma_3\alpha_3\rangle_\rho=\sum_{\rho'}\Phi_{\rho\rho'}[\Gamma_1,\Gamma_2;\Gamma_3]\langle \Gamma_2\alpha_2;\Gamma_1\alpha_1|\Gamma_3\alpha_3\rangle_{\rho'}, \tag{C7}$$

since it requires a phase matrix Φ, which is a special case of the recoupling coefficient Z that occurs in the coupling of three SU(3) irreps:

$$\Phi_{\rho\rho'}[\Gamma_1,\Gamma_2;\Gamma_3]=Z[\Gamma_1(00)\Gamma_3\Gamma_2;\Gamma_{1-}\rho\Gamma_{2-}\rho']. \tag{C8}$$

If the SU(3) coupling $\Gamma_1\times\Gamma_2\to\Gamma_3$ is unique, that is, when $\rho_{\max}=1$, the matrix reduces to a simple phase factor: $\Phi_{11}[\Gamma_1,\Gamma_2;\Gamma_3]=(-1)^{\varphi}=(-1)^{\Gamma_1+\Gamma_2-\Gamma_3}$, where $(-1)^{\Gamma_i}\equiv(-1)^{\lambda_i+\mu_i}$ for $\Gamma_i=(\lambda_i\mu_i)$.

Another set of useful relations involves the conjugate irrep $\tilde{\Gamma}=(\mu\lambda)$ of $\Gamma=(\lambda\mu)$; for the canonical group chain,[44]

$$\langle \Gamma_1\alpha_1;\Gamma_2\alpha_2|\Gamma_3\alpha_3\rangle_\rho=(-1)^{\varphi+\rho_{\max}-\rho}\langle \tilde{\Gamma}_1\overline{\alpha_1};\tilde{\Gamma}_2\overline{\alpha_2}|\tilde{\Gamma}_3\overline{\alpha_3}\rangle_\rho \tag{C9}$$

holds and for $\alpha=\kappa lm$ one has[44]

$$\langle \Gamma_1\alpha_1;\Gamma_2\alpha_2|\Gamma_3\alpha_3\rangle_\rho=(-1)^{\varphi+\rho_{\max}-\rho+l_1+l_2-l_3}\langle \tilde{\Gamma}_1\overline{\alpha_1};\tilde{\Gamma}_2\overline{\alpha_2}|\tilde{\Gamma}_3\overline{\alpha_3}\rangle_\rho. \tag{C10}$$

With the phase and normalization conventions of reference 44, one obtains the following orthonormality relations for the Wigner SU(3) coupling coefficients:

$$\sum_{\alpha_1\alpha_2}\langle \Gamma_1\alpha_1;\Gamma_2\alpha_2|\Gamma\alpha\rangle_\rho\langle \Gamma_1\alpha_1;\Gamma_2\alpha_2|\Gamma'\alpha\rangle_{\rho'}=\delta_{\Gamma'\Gamma}\delta_{\rho'\rho} \tag{C11}$$

and

$$\sum_{\rho\Gamma\alpha}\langle \Gamma_1\alpha_1;\Gamma_2\alpha_2|\Gamma\alpha\rangle_\rho\langle \Gamma_1\alpha_1';\Gamma_2\alpha_2'|\Gamma\alpha\rangle_\rho=\delta_{\alpha_1\alpha_1'}\delta_{\alpha_2\alpha_2'}. \tag{C12}$$

It is possible to factor out the dependence of the above SU(3)⊃SO(3) and SU(3)⊃SU(2)⊗U(1) Wigner coupling coefficients on the M or M_Λ subgroup labels, respectively, by defining so-called double-barred or ''reduced'' SU(3) coupling coefficients:

$$\langle \Gamma_1\kappa_1l_1m_1;\Gamma_2\kappa_2l_2m_2|\Gamma\kappa lm\rangle_\rho=\underbrace{\langle \Gamma_1\kappa_1l_1;\Gamma_2\kappa_2l_2||\Gamma\kappa l\rangle_\rho}_{\text{reduced Wigner coefficient}}\underbrace{\langle l_1m_1,l_2m_2|lm\rangle}_{\text{geometric part}}, \tag{C13}$$

for $\alpha=\kappa lm$, and

$$\langle \Gamma_1 \epsilon_1 \Lambda_1 M_{\Lambda_1}; \Gamma_2 \epsilon_2 \Lambda_2 M_{\Lambda_2} | \Gamma \epsilon \Lambda M_\Lambda \rangle_\rho = \underbrace{\langle \Gamma_1 \epsilon_1 \Lambda_1; \Gamma_2 \epsilon_2 \Lambda_2 || \Gamma_3 \epsilon \Lambda \rangle_\rho}_{\text{reduced Wigner coefficient}} \underbrace{\langle \Lambda_1 M_{\Lambda_1}, \Lambda_2 M_{\Lambda_2} | \Lambda M_\Lambda \rangle}_{\text{geometric part}}, \tag{C14}$$

for $\alpha = \epsilon \Lambda M_\Lambda$. The ''geometric'' part $\langle \text{--}|\text{-}\rangle$ is simply a SU(2) Clebsch–Gordan coefficient. From the unitarity of the full SU(3) Wigner and the ordinary SU(2) Clebsch–Gordan coefficients it follows that the double-bar coefficients are also unitary. With the phase convention introduced by Draayer and Akiyama[44] they become real, and therefore orthogonal.

2. SU(3) Racah coefficients: Coupling of three SU(3) irreps

Coupling of three SU(3) irreps Γ_1, Γ_2, and Γ_3 to a given resulting SU(3) irrep Γ can be accomplished in three different ways, depending on the order of the coupling: (i) $\{\Gamma_1 \otimes \Gamma_2\} \otimes \Gamma_3 \to \Gamma$, or (ii) $\Gamma_1 \otimes \{\Gamma_2 \otimes \Gamma_3\} \to \Gamma$, or (iii) $\{\Gamma_1 \otimes \Gamma_3\} \otimes \Gamma_2 \to \Gamma$. The transformation from one coupling order to another requires the introduction of a so-called SU(3)-Racah or 6-($\lambda\mu$) coefficient. More specifically, recoupling from scheme (i) to (ii) involves a unitary transformation with coefficients $U[\Gamma_1 \Gamma_2 \Gamma \Gamma_3; \Gamma_{12} \rho_{12} \rho_{12,3} \Gamma_{23} \rho_{23} \rho_{1,23}]$ (see reference 28):

$$\begin{aligned} &|\{\{\Gamma_1 \times \Gamma_2\}^{\rho_{12} \Gamma_{12}} \times \Gamma_3\}_\alpha^{\rho_{12,3} \Gamma}\rangle \\ &\quad = \sum_{\Gamma_{23} \rho_{1,23} \rho_{23}} U[\Gamma_1 \Gamma_2 \Gamma \Gamma_3; \Gamma_{12} \rho_{12} \rho_{12,3} \Gamma_{23} \rho_{23} \rho_{1,23}] |\{\Gamma_1 \times \{\Gamma_2 \times \Gamma_3\}^{\rho_{23} \Gamma_{23}}\}_\alpha^{\rho_{1,23} \Gamma}\rangle, \end{aligned} \tag{C15}$$

and the inverse transformation is given by[36]

$$\begin{aligned} &|\{\Gamma_1 \times \{\Gamma_2 \times \Gamma_3\}^{\rho_{23} \Gamma_{23}}\}_\alpha^{\rho_{1,23} \Gamma}\rangle \\ &\quad = \sum_{\Gamma_{12} \rho_{12} \rho_{12,3}} U[\Gamma_1 \Gamma_2 \Gamma \Gamma_3; \Gamma_{12} \rho_{12} \rho_{12,3} \Gamma_{23} \rho_{23} \rho_{1,23}] |\{\{\Gamma_1 \times \Gamma_2\}^{\rho_{12} \Gamma_{12}} \times \Gamma_3\}_\alpha^{\rho_{12,3} \Gamma}\rangle. \end{aligned} \tag{C16}$$

The notation is a straightforward generalization of that introduced by Racah[39] for the 6-j symbols of SU(2). Whenever a coupling is multiplicity-free, the associated ρ-label may be omitted, provided the notation remains unambiguous.

Similarly, the transformation from scheme (i) to scheme (iii) requires a transformation coefficient $Z[\Gamma_2 \Gamma_1 \Gamma \Gamma_3; \Gamma_{12} \rho_{12} \rho_{12,3} \Gamma_{13} \rho_{13} \rho_{13,2}]$ which is defined through[37]

$$\begin{aligned} &|\{\{\Gamma_1 \times \Gamma_2\}^{\rho_{12} \Gamma_{12}} \times \Gamma_3\}_\alpha^{\rho_{12,3} \Gamma}\rangle \\ &\quad = \sum_{\Gamma_{13} \rho_{13} \rho_{13,2}} Z[\Gamma_2 \Gamma_1 \Gamma \Gamma_3; \Gamma_{12} \rho_{12} \rho_{12,3} \Gamma_{13} \rho_{13} \rho_{13,2}] |\{\{\Gamma_1 \times \Gamma_3\}^{\rho_{13} \Gamma_{13}} \times \Gamma_2\}_\alpha^{\rho_{13,2} \Gamma}\rangle. \end{aligned} \tag{C17}$$

The U- and Z-functions depend only on the SU(3) representations involved in the coupling and not on the specific subgroup chain chosen to specify the states. Most of the SU(3) recoupling coefficients needed for ds-shell nuclear shell model calculations have been tabulated by Hecht,[28] and a computer code that evaluates SU(3) Racah coefficients for arbitrary couplings and multiplicity was developed by Akiyama and Draayer.[34] Special cases and symmetry properties of the SU(3) coefficients can be found in reference 36. Most notably, one has $U[\cdots] = 1$ whenever Γ_1 or Γ_2 or Γ_3 or $\Gamma = (00)$, and

$$U[\Gamma_1 \Gamma_2 \Gamma_1 \tilde{\Gamma}_2; \Gamma_{12} \rho \rho' (00)_{--}] = (-1)^{\Gamma_1 + \Gamma_2 + \Gamma_{12}} \delta_{\rho \rho'} \sqrt{\frac{d(\Gamma_{12})}{d(\Gamma_1) d(\Gamma_2)}}. \tag{C18}$$

Under conjugation the SU(3) Racah coefficients exhibit the following symmetry:

$$U[\Gamma_1\Gamma_2\Gamma\Gamma_3;\Gamma_{12}\rho_{12}\rho_{12,3}\Gamma_{23}\rho_{23}\rho_{1,23}] = (-1)^{\rho_{12}^{\max}-\rho_{12}+\rho_{12,3}^{\max}-\rho_{12,3}+\rho_{23}^{\max}-\rho_{23}+\rho_{1,23}^{\max}-\rho_{1,23}} U[\tilde{\Gamma}_1\tilde{\Gamma}_2\tilde{\Gamma}\tilde{\Gamma}_3;\tilde{\Gamma}_{12}\rho_{12}\rho_{12,3}\tilde{\Gamma}_{23}\rho_{23}\rho_{1,23}], \tag{C19}$$

$$Z[\Gamma_2\Gamma_1\Gamma\Gamma_3;\Gamma_{12}\rho_{12}\rho_{12,3}\Gamma_{13}\rho_{13}\rho_{13,2}] = (-1)^{\rho_{12}^{\max}-\rho_{12}+\rho_{12,3}^{\max}-\rho_{12,3}+\rho_{13}^{\max}-\rho_{13}+\rho_{13,2}^{\max}-\rho_{13,2}} Z[\tilde{\Gamma}_2\tilde{\Gamma}_1\tilde{\Gamma}\tilde{\Gamma}_3;\tilde{\Gamma}_{12}\rho_{12}\rho_{12,3}\tilde{\Gamma}_{13}\rho_{13}\rho_{13,2}].$$

A straightforward generalization of the relations between SU(2) unitary recoupling coefficients and SU(2) Wigner coefficients leads to the corresponding relationships between SU(3) unitary (Racah) recoupling and SU(3) Wigner coefficients.

$$\begin{aligned} U[\Gamma_1\Gamma_2\Gamma\Gamma_3;\Gamma_{12}\rho_{12}\rho_{12,3}\Gamma_{23}\rho_{23}\rho_{1,23}] &= \sum_{\alpha_1\alpha_2\alpha_3\alpha_{12}\alpha_{23}} \langle\Gamma_1\alpha_1;\Gamma_2\alpha_2|\Gamma_{12}\alpha_{12}\rangle_{\rho_{12}}\langle\Gamma_{12}\alpha_{12};\Gamma_3\alpha_3|\Gamma\alpha\rangle_{\rho_{12,3}} \\ &\quad\times\langle\Gamma_2\alpha_2;\Gamma_3\alpha_3|\Gamma_{23}\alpha_{23}\rangle_{\rho_{23}}\langle\Gamma_1\alpha_1;\Gamma_{23}\alpha_{23}|\Gamma\alpha\rangle_{\rho_{1,23}}, \end{aligned} \tag{C20}$$

for $\alpha_i=\epsilon_i\Lambda_iM_i$ or $\alpha_i=\kappa_il_im_i$.

The Z- and U-coefficients are related to each other as follows:

$$\begin{aligned} Z[\Gamma_2\Gamma_1\Gamma\Gamma_3;\Gamma_{12}\rho_{12}\rho_{12,3}\Gamma_{13}\rho_{13}\rho_{13,2}] &= \sum_{\Gamma_{23}\rho_{23}\rho_{1,23}} U[\Gamma_1\Gamma_2\Gamma\Gamma_3;\Gamma_{12}\rho_{12}\rho_{12,3}\Gamma_{23}\rho_{23}\rho_{1,23}]\sum_{\rho'_{23}}\Phi_{\rho_{23}\rho'_{23}}[\Gamma_2,\Gamma_3;\Gamma_{23}] \\ &\quad\times U[\Gamma_1\Gamma_3\Gamma\Gamma_2;\Gamma_{13}\rho_{13}\rho_{13,2}\Gamma_{23}\rho'_{23}\rho_{1,23}], \end{aligned} \tag{C21}$$

with the geometrical phase $\Phi_{\rho\rho'}$ as defined in Equation (C8). Further useful relations for the U- and Z-recoupling coefficients are given in reference 28, for the SU(3)$\supset$SU(2)$\otimes$U(1) chain, and in references 46, 37, for the SU(3)$\supset$SO(3) chain. The following one, which holds for both cases, is especially important:

$$\sum_{\rho_{1,23}}\langle\Gamma_1\alpha_1;\Gamma_{23}\alpha_{23}|\Gamma\alpha\rangle_{\rho_{1,23}}U[\Gamma_1\Gamma_2\Gamma\Gamma_3;\Gamma_{12}\rho_{12}\rho_{12,3}\Gamma_{23}\rho_{23}\rho_{1,23}] = \sum_{\alpha_2\alpha_3\alpha_{12}}\langle\Gamma_2\alpha_2;\Gamma_3\alpha_3|\Gamma_{23}\alpha_{23}\rangle_{\rho_{23}}\langle\Gamma_1\alpha_1;\Gamma_2\alpha_2|\Gamma_{12}\alpha_{12}\rangle_{\rho_{12}}\langle\Gamma_{12}\alpha_{12};\Gamma_3\alpha_3|\Gamma\alpha\rangle_{\rho_{12,3}}. \tag{C22}$$

A similar relation is given by Millener for the Z-coefficient.[37]

3. SU(3) 9-($\lambda\mu$) coefficients: Coupling of four SU(3) irreps

If the coupling of four SU(3) irreps Γ_1, Γ_2, Γ_3 and Γ_4 is required, the resulting irrep Γ may be constructed in three different ways: (i) $\{\Gamma_1\otimes\Gamma_2\}\otimes\{\Gamma_3\otimes\Gamma_4\}\rightarrow\Gamma$, or (ii) $\{\Gamma_1\otimes\Gamma_3\}\otimes\{\Gamma_2\otimes\Gamma_4\}\rightarrow\Gamma$, or (iii) $\{\Gamma_1\otimes\Gamma_4\}\otimes\{\Gamma_2\otimes\Gamma_3\}\rightarrow\Gamma$. In analogy to the SU(2) Jahn–Hope symbol it is possible to define a unitary SU(3) or 9-($\lambda\mu$) symbol, which effects the transformation from one coupling order to another. In particular, for the transition from scheme (i) to (ii) one defines[36]

$$|\{\{\Gamma_1\times\Gamma_2\}^{\rho_{12}\Gamma_{12}}\times\{\Gamma_3\times\Gamma_4\}^{\rho_{34}\Gamma_{34}}\}_{\alpha}^{\rho_{12,34}\Gamma}\rangle=\sum_{\rho_{13}\Gamma_{13}\rho_{24}\Gamma_{24}\rho_{13,24}}\begin{Bmatrix}\Gamma_1&\Gamma_2&\Gamma_{12}&\rho_{12}\\ \Gamma_3&\Gamma_4&\Gamma_{34}&\rho_{34}\\ \Gamma_{13}&\Gamma_{24}&\Gamma&\rho_{13,24}\\ \rho_{13}&\rho_{24}&\rho_{12,34}&\end{Bmatrix}\times|\{\{\Gamma_1\times\Gamma_3\}^{\rho_{13}\Gamma_{13}}\times\{\Gamma_2\times\Gamma_4\}^{\rho_{24}\Gamma_{24}}\}_{\alpha}^{\rho_{13,24}\Gamma}\rangle. \tag{C23}$$

Similarly, one obtains for the transformation from scheme (i) to (iii),

$$\begin{aligned}&|\{\{\Gamma_1\times\Gamma_2\}^{\rho_{12}\Gamma_{12}}\times\{\Gamma_3\times\Gamma_4\}^{\rho_{34}\Gamma_{34}}\}_{\alpha}^{\rho_{12,34}\Gamma}\rangle\\&\quad=\sum_{\rho_{14}\Gamma_{14}\rho_{23}\Gamma_{23}\rho_{14,23}}\begin{Bmatrix}\Gamma_1&\Gamma_2&\Gamma_{12}&\rho_{12}\\ \Gamma_4&\Gamma_3&\Gamma_{34}&\rho_{34}\\ \Gamma_{14}&\Gamma_{23}&\Gamma&\rho_{14,23}\\ \rho_{14}&\rho_{23}&\rho_{12,34}&\end{Bmatrix}\\&\qquad\times\sum_{\rho'_{34}}\Phi_{\rho_{34}\rho'_{34}}(\Gamma_3,\Gamma_4;\Gamma_{34})|\{\{\Gamma_1\times\Gamma_4\}^{\rho_{14}\Gamma_{14}}\times\{\Gamma_2\times\Gamma_3\}^{\rho_{23}\Gamma_{23}}\}_{\alpha}^{\rho_{14,23}\Gamma}\rangle.\end{aligned} \tag{C24}$$

The unitary 9-($\lambda\mu$) symbols can be expressed as a sum over SU(3) Wigner coupling coefficients:

$$\begin{aligned}&\begin{Bmatrix}\Gamma_1&\Gamma_2&\Gamma_{12}&\rho_{12}\\ \Gamma_3&\Gamma_4&\Gamma_{34}&\rho_{34}\\ \Gamma_{13}&\Gamma_{24}&\Gamma&\rho_{13,24}\\ \rho_{13}&\rho_{24}&\rho_{12,34}&\end{Bmatrix}\\&\quad=\sum_{\alpha_i\alpha_{ik}}\langle\Gamma_1\alpha_1;\Gamma_2\alpha_2|\Gamma_{12}\alpha_{12}\rangle_{\rho_{12}}\langle\Gamma_3\alpha_3;\Gamma_4\alpha_4|\Gamma_{34}\alpha_{34}\rangle_{\rho_{34}}\langle\Gamma_{13}\alpha_{13};\Gamma_{24}\alpha_{24}|\Gamma\alpha\rangle_{\rho_{13,24}}\\&\qquad\times\langle\Gamma_1\alpha_1;\Gamma_3\alpha_3|\Gamma_{13}\alpha_{13}\rangle_{\rho_{13}}\langle\Gamma_2\alpha_2;\Gamma_4\alpha_4|\Gamma_{24}\alpha_{24}\rangle_{\rho_{24}}\langle\Gamma_{12}\alpha_{12};\Gamma_{34}\alpha_{34}|\Gamma\alpha\rangle_{\rho_{12,34}},\end{aligned} \tag{C25}$$

or in terms of the Racah Z and U coefficients defined above,[37]

$$\begin{aligned}&\begin{Bmatrix}\Gamma_1&\Gamma_2&\Gamma_{12}&\rho_{12}\\ \Gamma_3&\Gamma_4&\Gamma_{34}&\rho_{34}\\ \Gamma_{13}&\Gamma_{24}&\Gamma&\rho_{13,24}\\ \rho_{13}&\rho_{24}&\rho_{12,34}&\end{Bmatrix}\\&\quad=\sum_{\Gamma_0\rho_{13,2}\rho_{04}\rho_{12,3}}U[\Gamma_{13}\Gamma_2\Gamma\Gamma_4;\Gamma_0\rho_{13,2}\rho_{04}\Gamma_{24}\rho_{24}\rho_{13,24}]Z[\Gamma_2\Gamma_1\Gamma_0\Gamma_3;\Gamma_{12}\rho_{12}\rho_{12,3}\Gamma_{13}\rho_{13}\rho_{13,2}]\\&\qquad\times U[\Gamma_{12}\Gamma_3\Gamma\Gamma_4;\Gamma_0\rho_{12,3}\rho_{04}\Gamma_{34}\rho_{34}\rho_{12,34}].\end{aligned} \tag{C26}$$

Various symmetry relations and special cases of the 9-($\lambda\mu$) coefficients can be found in references 40, 36, and a computer code which provides numerical values for these recoupling coefficients is publicly available.[34]

4. Matrix elements and the Wigner–Eckart theorem for SU(3)

The Wigner–Eckart theorem for the group SU(2) yields SU(2)-reduced (double-bar) matrix elements of an SO(3) irreducible tensor operator. Analogously, the generalized Wigner–Eckart

theorem allows one to express matrix elements of SU(3) irreducible tensor operators as a sum over ρ of the product of a ρ-dependent generalized reduced matrix element multiplied by the corresponding Wigner coefficient:[44]

$$\langle \Gamma_3 \alpha_3 | T^{\Gamma_2 \alpha_2} | \Gamma_1 \alpha_1 \rangle = \sum_{\rho} \langle \Gamma_1 \alpha_1 ; \Gamma_2 \alpha_2 | \Gamma_3 \alpha_3 \rangle_{\rho} \langle \Gamma_3 ||| T^{\Gamma_2} ||| \Gamma_1 \rangle_{\rho}. \tag{C27}$$

Note that the triple-bar matrix element is independent of the chosen subgroup chain.

In analogy to the well-known reduction rules for SU(2),[39] one can derive expressions for the triple-bar matrix elements of a SU(3)-coupled tensor product acting on a one-component system:

$$\langle \Gamma ||| \{ T^{\Gamma_1} \times T^{\Gamma_2} \}^{\rho_3 \Gamma_3} ||| \Gamma' \rangle_{\rho} = \sum_{\rho_1 \rho_2 \Gamma''} \langle \Gamma ||| T^{\Gamma_1} ||| \Gamma'' \rangle_{\rho_1} \langle \Gamma'' ||| T^{\Gamma_2} ||| \Gamma' \rangle_{\rho_2} \times \sum_{\rho_3'} \Phi_{\rho_3 \rho_3'} [\Gamma_1 \Gamma_2 ; \Gamma_3] U [\Gamma' \Gamma_2 \Gamma \Gamma_1 ; \Gamma'' \rho_2 \rho_1 \Gamma_3 \rho_3' \rho]. \tag{C28}$$

Often one has to consider a quantum-mechanical system which consists of two subsystems, 1 and 2 (for example, protons and neutrons). Reduced matrix elements for the irreducible tensor product of two operators, $R^{\Gamma_r}(1)$ and $S^{\Gamma_s}(2)$, which depend only on variables of the first and second subsystem, respectively, may be evaluated with the help of the following expression:

$$\langle \{ \Gamma_1 \times \Gamma_2 \} \rho \Gamma ||| \{ R^{\Gamma_r}(1) \times S^{\Gamma_s}(2) \}^{\rho_t \Gamma_t} ||| \{ \Gamma_1' \times \Gamma_2' \} \rho' \Gamma' \rangle_{\tilde{\rho}} = \sum_{\rho_1 \rho_2} \begin{Bmatrix} \Gamma_1' & \Gamma_r & \Gamma_1 & \rho_1 \\ \Gamma_2' & \Gamma_s & \Gamma_2 & \rho_2 \\ \Gamma' & \Gamma_t & \Gamma & \tilde{\rho} \\ \rho' & \rho_t & \rho & \end{Bmatrix} \langle \Gamma_1 ||| R^{\Gamma_r}(1) ||| \Gamma_1' \rangle_{\rho_1} \langle \Gamma_2 ||| S^{\Gamma_s}(2) ||| \Gamma_2' \rangle_{\rho_2}. \tag{C29}$$

(Received 13 November 1997; accepted for publication 7 May 1998)

An operator formalism for bosonic $\beta-\gamma$ system on arbitrary algebraic curves is introduced. The classical degrees of freedom are identified and their commutation relations are postulated. The explicit realization of the algebra formed by the fields is given in the Hilbert space equipped with a bilinear form. The construction is based on the ''Gaussian'' representation for $\beta-\gamma$ system on the complex sphere [Alvarez-Gaumé *et al.*, Nucl. Phys. B **311**, 333 (1988)]. Detailed computations are provided for two- and four-point correlation functions. © *1998 American Institute of Physics.* [S0022-2488(98)03510-5]

I. INTRODUCTION

Since the middle of the 1980s tremendous progress has been achieved in understanding the structure of $D=2$ conformal field theories (CFTs).[1] Most of that work was motivated by string theory, but CFTs have also been actively investigated because of their role in describing phase transition phenomena. In string theory it is necessary to consider CFTs defined on topologically nontrivial $D=2$ manifolds, in particular on closed higher genus Riemann surfaces (RS) of genus g.[2] The properties of CFTs on the torus are now relatively well known and, at least in the context of string theory, it turns out that the class of acceptable models are those which are modular invariant.[3]

There have been many efforts to give a satisfactory description of CFTs also on higher genus RS, for instance by means of an operator formalism.[4] Usually, an operator formalism of such kind makes it possible to introduce the notions of vacuum, creation, and annihilation operators, normal ordering, etc. In this way, theories defined on curved space–times resemble ordinary quantum field theories in flat space. A valid operator formalism for string theory application should be able to reproduce the relevant correlation functions and their analytical properties. Usually these properties (the structure of zeros and poles) are strong enough to determine these correlators up to an overall constant.[5,6]

One version of operator formalism has been developed for the $b-c$ systems in Refs. 7 and 8. In this paper we would like to extend it in such a way that also the bosonic $\beta-\gamma$ systems can effectively be treated.

These systems are in fact interesting examples of CFTs. They were extensively studied in the second half of the 1980s after they turned out to be a necessary ingredient (as Faddeev–Popov superghosts) in the perturbative approach to strings.[9–12] A treatment on hyperelliptic curves, mainly in connection with the computation of amplitudes in superstring theory at two loops, can for instance be found in Ref. 13. $\beta-\gamma$ systems have also been studied in the context of the Wess–Zumino–Witten model.[14]

The analysis of the $\beta-\gamma$ systems is in many respects analogous to that of the $b-c$ systems. In fact, the only difference lies in the statistics, since the $\beta-\gamma$ fields commute while the $b-c$ fields

a)Electronic mail: fferrari@lpthe.jussieu.fr

anticommute. Following Ref. 9, many formulas characterizing both systems can be written in common. If by **b** (and **c**) one denotes either the b or β (c or γ) fields with conformal dimension λ (and $1-\lambda$), then both theories are defined by the action:

$$S=\frac{1}{\pi}\int d^2\, z(\mathbf{b}\bar{\partial}\mathbf{c}), \tag{1}$$

where $\bar{\partial}\equiv\partial/\partial\bar{z}$. It follows from (1) that the one-pion exchanges (OPEs) for the fields are

$$\mathbf{c}(z)\mathbf{b}(w)\sim\frac{1}{z-w},\quad \mathbf{b}(z)\mathbf{c}(w)\sim\frac{\epsilon}{z-w}, \tag{2}$$

where $\epsilon=1$ for $b-c$ systems and $\epsilon=-1$ for $\beta-\gamma$ systems. The energy–momentum tensor, determined by the dependence of (1) on the metric (in order to derive it one has to write the action in the covariant form) carries no dependence on ϵ:

$$T=-\lambda\mathbf{b}\partial\mathbf{c}+(1-\lambda)(\partial\mathbf{b})\mathbf{c}. \tag{3}$$

The OPEs of the elementary fields with T can be described with the same formula both in the fermionic and bosonic cases, as they are determined only by conformal dimensions:

$$T(z)\mathbf{b}(w)\sim\frac{\lambda}{(z-w)^2}\,\mathbf{b}(w)+\frac{1}{z-w}\,\partial\mathbf{b}(w)+\cdots, \tag{4}$$

$$T(z)\mathbf{c}(w)\sim\frac{1-\lambda}{(z-w)^2}\,\mathbf{c}(w)+\frac{1}{z-w}\,\partial\mathbf{c}(w)+\cdots. \tag{5}$$

The OPE with two energy–momentum tensors depends on ϵ since in calculating it one has to (anti)commute elementary fields:

$$T(z)T(w)\sim\frac{-\epsilon(6\lambda^2-6\lambda+1)}{(z-w)^4}+\frac{2T(w)}{(z-w)^2}+\frac{\partial T(w)}{z-w}+\cdots. \tag{6}$$

The correlation functions of the $\beta-\gamma$ systems were intensively studied at the end of the last decade.[11,12]

In string theory computations, one would like to compute the correlators also within the bosonized version of the theory. It turns out that in addition to the scalar fields with quadratic action one has to introduce also auxiliary fermionic fields $\eta-\xi$ of conformal dimensions one and zero. One gets an infinite number of inequivalent representations (q vacua in Ref. 9) of the basic algebra in a Hilbert space.

For $\lambda\geqslant 1$ and $g\geqslant 2$ only the zero modes in the **b** fields are present. In both bosonic and fermionic cases one has to insert delta functions for any zero mode in order to obtain a reasonable correlator. Without these insertions one gets vanishing or diverging amplitudes in the case of fermionic or bosonic systems, respectively. In the path integral approach this follows from the properties of the integrals

$$\int_{\mathbf{R}} dx\to\infty,\quad \int d\zeta=0, \tag{7}$$

where ζ is an element of a Grassmann algebra satisfying $\zeta^2=0$. In the fermionic case $\delta(\zeta)=\zeta$, so that any insertion in the amplitudes of a delta function $\delta(b)$ is equivalent to an insertion of a b field. In the bosonic case one has instead to make sense of true delta functions (or step functions) containing field operators in their argument.

The manipulations with delta function operators become straightforward in the ''Gaussian'' representation for β and γ fields.[15] In that representation one sees that inequivalent vacua can be chosen and that they cannot be interchanged under the action of a finite number of elementary excitations. Each vacuum state is determined by a choice of signs in an infinite product of

Gaussian (or, strictly speaking ''Fresnelian'') functions $\exp(\pm(i/2)x^2)$. The general property of deltalike operators is that they can map one vacuum state into another.[15] Some operations in the Gaussian representation may seem formal, e.g., formally infinite normalization factors have to be included. However, there is always a unique procedure to handle with these factors in order to obtain finite results.

The Gaussian representation makes it possible to define an operator formalism for the β–γ systems following the ideas of Ref. 8, where the case of the b–c systems has been discussed. In Ref. 8, the classical degrees of freedom are identified and the simplest possible anticommutation relations are postulated. Some of the elementary oscillators are defined as annihilation or creation operators. The remaining excitations correspond to the zero modes of the model. It has been demonstrated that these definitions enable the calculation of the correlation functions of the theory. The construction is not restricted to any particular class of RS—it can be done on arbitrary algebraic curve.

The aim of this paper is to present in detail the construction of an analogous operator formalism on RS for β–γ systems. The outcome of our computations are correlation functions with all the necessary analytic properties.

The operator formalism for the β–γ systems exhibits some similarities and also some interesting differences with respect to the operator formalism found in the case of the b–c fields in Ref. 8. The starting point is the same, one chooses the same classical degrees of freedom, and postulates the simplest possible commutation (instead of anticommutation) relations. One decomposes the elementary excitations into annihilation, creation, and zero mode sectors. A fundamental property of the normal ordering is that the difference between an ordered and an unordered product of two fields is equal to the Weierstrass kernel $K_\lambda(z,w)$, which is one of the basic building blocks in the construction of the correlation functions. $K_\lambda(z,w)$ is a λ differential in z, a $1-\lambda$ differential in w, and its only finite singularity in z is a single pole at $z=w$ (provided z and w parametrize points on the same branch of the RS). In our investigations we need to introduce multivalued fields on the complex sphere. In this sense one can think that new classes of CFTs containing multivalued models are defined on the sphere.[7] The computation of the correlation functions for β–γ systems is quite different from the case of the b–c systems. In the bosonic case many nontrivial manipulations with Fresnel integrals are required before reaching the final result. This will be shown in detail in Secs. II–IV.

The experience from the β–γ systems can hopefully be used in dealing with more complicated and important systems, such as for instance the bosonic theories with quadratic action. These theories provide the basis of the Coulomb gas formulation of minimal models. Therefore, the construction of an operator formalism for the β–γ systems can shed some light on the treatment of the minimal models on arbitrary RS represented as algebraic curve. Until now, only the case of hyperelliptic and Z_N symmetric curves have been studied in this context.[16,17]

II. $\lambda=-1$ COMPUTATIONS ON THE SPHERE

To better explain the ideas of the calculations, it is useful to start with the simpler situation of the complex sphere. We choose in this section $g=0$ and $\lambda=-1$ in order to have β rather than γ field zero modes.

The classical degrees of freedom are identified as

$$\beta(z)=\sum_{j=-\infty}^{+\infty}\beta_j z^{-j+1}dz^{\lambda}, \tag{8}$$

$$\gamma(z)=\sum_{k=-\infty}^{+\infty}\gamma_k z^{-k-2}dz^{1-\lambda}. \tag{9}$$

In quantum theory one postulates the following commutation relations:

$$[\gamma_k,\beta_j]=\delta_{j+k,0}. \tag{10}$$

The normal ordering is defined by assigning to the elementary excitations β_j and γ_k the property that they are creation or annihilation operators. Annihilation operators correspond to $j \geqslant 2$ and $k \geqslant -1$. Creation operators are those with $j \leqslant -2$ and $k \leqslant -2$. The remaining β_j operators $(j=0,\pm 1)$ correspond to the three zero modes (holomorphic vectors fields).

The above assignment implies

$$\gamma(z)\beta(w) = :\gamma(z)\beta(w): + \frac{1}{z-w}, \tag{11}$$

which should be understood as an identity in the radial ordered correlation functions.

Another important identity is [in $\exp(ip\beta(z))$] the introduction of normal ordering (makes no modification):

$$\gamma(z)\mathrm{e}^{ip\beta(w)} = :\gamma(z)\mathrm{e}^{ip\beta(w)}: + \frac{ip}{z-w}\,\mathrm{e}^{ip\beta(w)}. \tag{12}$$

Let us start calculating the propagator of the theory. It is known from the general discussion and it will also be very clearly seen in the course of the computations that the propagator requires three (the number of β field zero modes) insertions of delta functions of β fields.

Using the Wick theorem one calculates:

$$\begin{aligned}\langle 0|\gamma(z)\beta(w)\exp\left(i\sum_{r=1}^{3} p_r\beta(w_r)\right)|0\rangle = \frac{1}{z-w}\langle 0|\exp\left(i\sum_{r=1}^{3}\sum_{j=-\infty}^{+\infty} p_r\beta_j w_r^{-j+1}\right)|0\rangle \\ + \sum_{r=1}^{3}\frac{ip_r}{z-w_r}\langle 0|\beta(w)\exp\left(i\sum_{t=1}^{3}\sum_{j=-\infty}^{+\infty} p_t\beta_j w_t^{-j+1}\right)|0\rangle.\end{aligned} \tag{13}$$

Finally, the integration over $\Pi_{r=1}^{3}(dp_r/2\pi)$ has to be performed.

The computations will be done in the ''Gaussian'' representation for the β–γ systems.[15] The basic definitions of that construction are summarized in Appendix A.

In order to evaluate (13) one calculates

$$\exp\left(i\sum_{n=-\infty}^{+\infty} A_n\beta_n\right)|0\rangle \tag{14}$$

with the state $|0\rangle$ taken to be the state $\Phi^{(-1)}$ defined in (A8)

$$|0\rangle = \Phi^{(-1)} = \exp\frac{i}{2}\left(\sum_{n\geqslant -1} x_n^2 - \sum_{n<-1} x_n^2\right). \tag{15}$$

A concrete realization of the operators β_n is given by [see (A2)]

$$\beta_n = -\frac{i}{\sqrt{2}}\left(x_{-n} - i\frac{\partial}{\partial x_{-n}}\right). \tag{16}$$

The operators β_n involve only x_{-n} and acting on $\exp(-(i/2)x_{-n}^2)$ give 0. It follows that

$$\exp\left(i\sum_{n=-\infty}^{+\infty} A_n\beta_n\right)|0\rangle = \exp\left(-\frac{i}{2}\sum_{m<-1} x_m^2\right)\exp\left(i\sum_{n\leqslant 1} A_n\beta_n\right)\exp\left(\frac{i}{2}\sum_{m\geqslant -1} x_m^2\right). \tag{17}$$

Repeating steps similar to those presented in the end of Appendix A one finds

$$\exp\left(-\frac{i}{2}\sum_{m<-1}x_m^2\right)\exp\left(i\sum_{n\leqslant 1}A_n\beta_n\right)\exp\left(\frac{i}{2}\sum_{m\leqslant 1}x_{-m}^2\right)$$
$$=\exp\left(-\frac{i}{2}\sum_{m<-1}x_m^2\right)\exp\left(-\frac{i}{2}\sum_{n\leqslant 1}((A_n+i\sqrt{2}x_{-n})^2+x_{-n}^2)\right). \tag{18}$$

To define a bilinear form we introduce the right vacuum:

$$\langle 0|=\exp\frac{i}{2}\left(\sum_{m>1}x_m^2-\sum_{m\leqslant 1}x_m^2\right). \tag{19}$$

A proper normalization of scalar product is included in a (formally infinite) factor V:

$$\langle 0|\prod_{s=1}^{3}\delta(\beta(z_s)|0\rangle=\frac{1}{V}\int\prod_{s=1}^{3}dp_s\int\prod_{k=-\infty}^{+\infty}dx_k\,\exp\left(-i\sum_{m<1}x_m^2\right)$$
$$\times\exp\left(-\frac{i}{2}\sum_{m>1}(A_{-m}+i\sqrt{2}x_m)^2\right)$$
$$\times\exp\left(-\frac{i}{2}\sum_{m=0,\pm 1}((A_m+i\sqrt{2}x_{-m})^2+2x_{-m}^2))\right) \tag{20}$$

for $A_m=\Sigma_{s=1}^{3}\,p_s z_s^{1-m}$. It will soon become clear that V should be defined as

$$V=\left(\prod_{m<1}\int\exp(-ix_m^2)dx_m\right)\left(\prod_{n>1}\int\exp(ix_n^2)dx_n\right)$$
$$\times\left(\prod_{k=0,\pm 1}\int\exp\left(-\frac{i}{2}p_k^2\right)dp_k\right)\left(\prod_{l=0,\pm 1}\int\exp(-ix_l^2)dx_l\right). \tag{21}$$

It is most convenient to integrate first over $\Pi_m\,dx_m$ for $m<1$ and then for $m>1$. Both integrations are trivial and contribute only to overall normalization. Next one should integrate over $\Pi_{s=1}^{3}\,dp_s$ after a convenient change of variables that will produce an appropriate Jacobian. The trivial integration over $\Pi_{m=0,\pm 1}\,dx_m$ will be performed later.

The above-mentioned change of variables is

$$p_j\to A_m,\quad j=1,2,3,\quad m=0,\pm 1, \tag{22}$$

$$\int\prod_{j=1}^{3}dp_j=\int\prod_{m=-1}^{1}dA_m\,\det\left(\frac{\partial A_n}{\partial p_k}\right)^{-1}, \tag{23}$$

where

$$\det\left(\frac{\partial A_n}{\partial p_k}\right)=(w_1-w_2)(w_1-w_3)(w_2-w_3). \tag{24}$$

The integration over dp_s and dx_n cancel precisely the factor V and the final result is

$$\langle 0|\prod_{s=1}^{3}\delta(\beta(w_s)|0\rangle=\frac{1}{(w_1-w_2)(w_1-w_3)(w_2-w_3)}. \tag{25}$$

In the computation of the second term in (13) it is sufficient to concentrate on the most important point without repeating many of the above arguments,

$$\beta(w)\exp\left(i\sum_{n=-\infty}^{+\infty}A_n\beta_n\right)|0\rangle=-\frac{i}{\sqrt{2}}\sum_{j=-\infty}^{+\infty}w^{-j+1}\left(x_{-j}-i\frac{\partial}{\partial x_{-j}}\right)\exp\left(-\frac{i}{2}\sum_{m<-1}x_m^2\right)$$
$$\times\exp\left(-\frac{i}{2}\sum_{n\leqslant 1}((A_n+i\sqrt{2}x_{-n})^2+x_{-n}^2)\right)$$
$$=-\exp\left(-\frac{i}{2}\sum_{m<-1}x_m^2\right)\sum_{j\leqslant 1}w^{-j+1}(A_j+i\sqrt{2}x_{-j})$$
$$\times\exp\left(-\frac{i}{2}\sum_{n\leqslant 1}((A_n+i\sqrt{2}x_{-n})^2+x_{-n}^2)\right). \tag{26}$$

With the above definition of the right vacuum $\langle 0|$ one gets

$$\langle 0|\beta(w)\exp\left(i\sum_{n-\infty}^{+\infty}A_n\beta_n\right)|0\rangle=-\frac{1}{V}\int\prod_{s=1}^{3}dp_s\int\prod_{k=-\infty}^{+\infty}dx_k\sum_{j\leqslant 1}w^{-j+1}(A_j+i\sqrt{2}x_{-j})$$
$$\times\exp\left(-i\sum_{m<1}x_m^2\right)\exp\left(-\frac{i}{2}\sum_{m>1}(A_{-m}+i\sqrt{2}x_m)^2\right)$$
$$\times\exp\left(-\frac{i}{2}\sum_{m=0,\pm 1}((A_m+i\sqrt{2}x_{-m})^2+2x_{-m}^2)\right). \tag{27}$$

As before, it is most convenient to perform first the integration over $\Pi_{m<-1}\,dx_m$ and then over $\Pi_{m>1}\,dx_m$. The sum over $j\leqslant 1$ reduces to three terms with $j=0,\pm 1$. All the other terms vanish due to integration over antisymmetric function in $x_n(n>1)$.

Having in mind future generalizations, the following notation is useful:

$$A_j=\sum_{k=1}^{3}R_{jk}p_k. \tag{28}$$

Thus, in computating the second term in (13) one is left with the evaluation of

$$-i\frac{1}{V'}\int\prod_{j=0,\pm 1}dA_j\int\prod_{n=0,\pm 1}dx_n\,\det\left(\frac{\partial A_m}{\partial p_r}\right)^{-1}\sum_{s=1}^{3}\sum_{j,k=-1}^{1}\frac{R_{sk}^{-1}A_k}{z-w_s}w^{1-j}(A_j+i\sqrt{2}x_{-j})$$
$$\times\exp\left(-\frac{i}{2}\sum_{l=-1}^{1}((A_l+i\sqrt{2}x_{-l})^2+2x_l^2)\right) \tag{29}$$

with

$$V'=\left(\prod_{k=0,\pm 1}\int\exp\left(-\frac{i}{2}p_k^2\right)dp_k\right)\left(\prod_{l=0,\pm 1}\int\exp(-ix_l^2)dx_l\right). \tag{30}$$

It is useful to perform still another change of variables:

$$\tilde{A}_j=A_j+i\sqrt{2}x_{-j}. \tag{31}$$

Thus one can rewrite (29) as

$$-i\,\frac{1}{V'}\int\prod_{j=0,\pm1}d\tilde{A}_j\int\prod_{n=0,\pm1}dx_n\left(\det\left(\frac{\partial\tilde{A}_m}{\partial p_r}\right)\right)^{-1}$$

$$\times\sum_{s=1}^{3}\sum_{j,k=-1}^{1}\frac{R_{sk}^{-1}(\tilde{A}_k-i\sqrt{2}x_{-k})}{z-w_s}\,w^{1-j}\tilde{A}_j\,\exp\left(-\frac{i}{2}\sum_{l=-1}^{1}(\tilde{A}_l^2+2x_l^2)\right). \tag{32}$$

The integration over $\Pi_{j=-1}^{1}\,d\tilde{A}_j$ gives nonzero result only for $k=j$. Terms with $i\sqrt{2}x_{-k}$ drop out (they give rise to integral linear in $\tilde{A}_j$). The integration over $\Pi_{l=-1}^{1}\,dx_l$ is then trivial and one obtains

$$-\sum_{s=1}^{3}\sum_{j=-1}^{1}\frac{R_{sj}^{-1}}{z-w_s}\,w^{1-j}. \tag{33}$$

In order to get the numerical factor in (33) one has to use

$$\int_{\mathbf{R}}A^2\mathrm{e}^{-(i/2)A^2}dA=-i\int_{\mathbf{R}}\mathrm{e}^{-(i/2)A^2}dA. \tag{34}$$

The matrix R^{-1} is of the form:

$$R^{-1}=\frac{1}{(w_1-w_2)(w_1-w_3)(w_2-w_3)}\begin{pmatrix} w_2-w_3 & w_3^2-w_2^2 & w_2w_3(w_2-w_3)\\ w_3-w_1 & w_2^2-w_3^2 & w_1w_3(w_3-w_1)\\ w_1-w_2 & w_w^2-w_1^2 & w_1w_2(w_1-w_2)\end{pmatrix} \tag{35}$$

and the final result is (one has to include det $\partial\tilde{A}/\partial p$):

$$\begin{aligned}\langle 0|\gamma(z)\beta(w)\prod_{s=1}^{3}\delta(\beta(w_s))|0\rangle&=\frac{1}{(w_1-w_2)(w_1-w_3)(w_2-w_3)}\\ &\times\left(\frac{1}{z-w}-\frac{(w-w_2)(w-w_3)}{(z-w_1)(w_1-w_2)(w_1-w_3)}\right.\\ &\left.+\frac{(w-w_1)(w-w_3)}{(z-w_2)(w_1-w_2)(w_2-w_3)}-\frac{(w-w_1)(w-w_2)}{(z-w_3)(w_1-w_3)(w_2-w_3)}\right)\\ &=\frac{1}{z-w}\prod_{s=1}^{3}\frac{w-w_s}{z-w_s}\prod_{m<n}(w_m-w_n)^1.\end{aligned} \tag{36}$$

It is clear that the above expression has all the analytical properties that the propagator of the bosonic β–γ systems should possess.

III. THE PROPAGATOR ON ARBITRARY ALGEBRAIC CURVES

In this section the β–γ system with $\lambda\geqslant 1$ given by (1) is defined on arbitrary RS represented by means of the algebraic equation

$$F(z,y)=y^NP_N(z)+y^{N-1}P_{N-1}(z)+\cdots+P_0(z)=0, \tag{37}$$

where $P_j(z)$ are polynomials in z. y can be viewed either as single-valued functions on the RS or as multivalued function on the complex sphere. The monodromy properties of $y(z)$ then define the RS.

The classical degrees of freedom are identified as

$$\beta(z)=\sum_{s=0}^{N-1}\sum_{j=-\infty}^{+\infty}\beta_{s,j}z^{-j-\lambda}f_s(z), \tag{38}$$

$$\gamma(z)=\sum_{p=0}^{N-1}\sum_{k=-\infty}^{+\infty}\gamma_{p,k}z^{-k+\lambda-1}\phi_p(z), \tag{39}$$

where

$$f_k(z)=\frac{y^{N-1-k}(z)dz^{\lambda}}{(F_y(z,y(z)))^{\lambda}} \tag{40}$$

and

$$\phi_k(z)=\frac{dz^{1-\lambda}}{(F_y(z,y(z)))^{1-\lambda}}\,(y^k(z)+y^{k-1}(z)P_{N-1}(z)+\cdots+P_{N-k}(z)). \tag{41}$$

The basic commutation relations are

$$[\gamma_{p,k},\beta_{s,j}]=\delta_{s,p}\delta_{j+k,0}. \tag{42}$$

The price paid for the simple commutation relations (42) is the complicated definition of basis (41).

The normal ordering is introduced by assigning to the elementary excitations $\beta_{s,j}$ and $\gamma_{s,k}$ the property that they are creation or annihilation operators. Annihilation operators are those with $j\geqslant 1-\lambda$ and $k\geqslant\lambda$ and creation operators with $j\leqslant-\lambda-M_s$ and $k\leqslant\lambda-1$ (M_s is a number of zero modes in the s sector of the theory). The remaining operators $\beta_{s,j}$ with $-\lambda-M_s<j<1-\lambda$ correspond to zero modes.

From the above assignment it follows that

$$\gamma(z)\beta(w)=:\gamma(z)\beta(\psi):+\frac{1}{z-w}\sum_{n=0}^{N-1}f_n(z)\phi_n(w)=:\gamma(z)\beta(w):+K_{\lambda}(z,w). \tag{43}$$

It is an identity in radial ordered correlation functions. $K_{\lambda}(z,w)$ is the Weierstrass kernel (see Sec. I).

A simple implication of (43) is

$$\gamma(z)e^{ip\beta(w)}=:\gamma(z)e^{ip\beta(w)}:+ipK_{\lambda}(z,w)e^{ip\beta(w)}. \tag{44}$$

We wish to calculate the propagator for the β–γ system. In order to have finite correlators one has to insert a number M_{tot} of delta functions in the β fields, where M_{tot} is the total number of β zero modes:

$$M_{\mathrm{tot}}=\sum_{s=0}^{N-1}M_s=(g-1)(2\lambda-1). \tag{45}$$

The Wick theorem implies

$$\begin{aligned}&\langle 0|\gamma(z)\beta(w)\exp\left(i\sum_{r=1}^{M_{\mathrm{tot}}}p_r\beta(w_r)\right)|0\rangle\\&=K_{\lambda}(z,w)\langle 0|\exp\left(i\sum_{r=1}^{M_{\mathrm{tot}}}\sum_{s=0}^{N-1}\sum_{j=-\infty}^{+\infty}p_r\beta_{s,j}w_r^{-j-\lambda}f_s(w_r)\right)|0\rangle\\&\quad+\sum_{r=1}^{M_{\mathrm{tot}}}ip_rK_{\lambda}(z,w_r)\langle 0|\beta(w)\exp\left(i\sum_{r=1}^{M_{\mathrm{tot}}}\sum_{s=0}^{N-1}\sum_{j=-\infty}^{+\infty}p_t\beta_{s,j}w_t^{-j-\lambda}f_s(w_t)\right)|0\rangle.\end{aligned} \tag{46}$$

The propagator is obtained after integration over $\Pi_{r=1}^{M_{\mathrm{tot}}}(dp_r/2\pi)$.

As in Sec. II, the computations will be performed in the ''Gaussian'' representation for the β–γ system.[15] However, complications can be expected on a Riemann surface due to the appearance of M_s zero modes in the sector s of the theory.

A first attempt to accommodate these zero modes is to modify the way in which the $\beta_{s,j}$ and $\gamma_{p,k}$ excitations are realized:

$$\beta_{s,j}=-\frac{i}{\sqrt{2}}\left(x_{s,-j-\nu_s}-i\,\frac{\partial}{\partial x_{s,-j-\nu_s}}\right), \tag{47}$$

$$\gamma_{p,n}=\frac{1}{\sqrt{2}}\left(x_{p,n+\nu_p}+i\,\frac{\partial}{\partial x_{p,n+\nu_p}}\right), \tag{48}$$

where ν_s is to be related to the number M_s of zero modes in the s sector.

Let us suppose that the vacuum state is taken as

$$\Phi^{\bar{\kappa}}(x)=\exp\left(\frac{i}{2}\sum_{s=0}^{N-1}\left(\sum_{n\geqslant\kappa_s}x_{s,n}^2-\sum_{n<\kappa_s}x_{s,n}^2\right)\right), \tag{49}$$

where κ_s is again chosen in an appropriate way. Unfortunately, it turns out that nothing can be achieved in this way. The conditions that $\beta_{s,j}$ and $\gamma_{s,k}$ are annihilation operators only for $j\geqslant 1-\lambda$, $k\geqslant\lambda$ imply in fact that

$$\kappa_s=\lambda, \quad \nu_s=0. \tag{50}$$

We conclude that the only way to accommodate the generic structure of zero modes is to redefine the scalar product in an appropriate way. We shall come back to this point shortly.

In calculating (46) one follows most of steps described in Sec. II. The vacuum state is that introduced in (49) with $\kappa_s=\lambda$. One finds

$$\begin{aligned}\exp\left(i\sum_{s=0}^{N-1}\sum_{j=-\infty}^{+\infty}A_{s,j}\beta_{s,j}\right)|0\rangle&=\exp\left(i\sum_{s=0}^{N-1}\sum_{j\leqslant\lambda}A_{s,j}\beta_{s,j}\right)|0\rangle\\&=\exp\left(-\frac{i}{2}\sum_{s=0}^{N-1}\left(\sum_{n<\lambda}x_{s,n}^2+\sum_{j\leqslant-\lambda}((A_{s,j}+i\sqrt{2}x_{s,-j})^2+x_{s,-j}^2)\right)\right)\end{aligned} \tag{51}$$

with

$$A_{s,j}=\sum_{r=1}^{M_{\rm tot}}p_r w_r^{-j-\lambda}f_s(w_r). \tag{52}$$

The correct definition of $\langle 0|$ is

$$\langle 0|=\exp\left(\frac{i}{2}\sum_{s=0}^{N-1}\left(\sum_{n\geqslant\lambda+M_s}x_{s,n}^2-\sum_{n<\lambda+M_s}x_{s,n}^2\right)\right). \tag{53}$$

A possible way of thinking about $\langle 0|$ is that under the conjugation

$$x_{s,n}^{\dagger}=x_{s,-n+2\lambda+M_s-1}. \tag{54}$$

The conjugation on elementary excitations can be deduced from (47) and (48) to be

$$\beta_{s,n}^{\dagger}=-\beta_{s,-n-2\lambda-M_s+1}, \quad \gamma_{s,n}^{\dagger}=\gamma_{s,-n+2\lambda+M_s-1}. \tag{55}$$

This definition of conjugation is analogous to that obtained for the $b-c$ system on arbitrary RS.[18] For $g=0$ and $\lambda=-1$ (the situation discussed in Sec. II) $M_{\rm tot}=3$ and $\beta_n^\dagger=-\beta_{-n}$, $\gamma_n^\dagger=\gamma_{-n}$.

The first term in (46) is

$$\frac{1}{\mathbf{V}_\lambda}\int\prod_{s=0}^{N-1}\prod_{j=-\infty}^{+\infty}dx_{s,j}\int\prod_{r=1}^{M_{\rm tot}}dp_r\,\exp\left(\frac{i}{2}\sum_{s=0}^{N-1}\left(\sum_{n\geqslant\lambda+M_s}x_{s,n}^2-\sum_{n<\lambda+M_s}x_{s,n}^2\right)\right)$$
$$\times\exp\left(-\frac{i}{2}\sum_{s=0}^{N-1}\left(\sum_{n<\lambda}x_{s,n}^2+\sum_{j\geqslant\lambda}((A_{s,-j}+i\sqrt{2}x_{s,j})^2+x_{s,j}^2)\right)\right). \tag{56}$$

The normalization factor (formally infinite) $\mathbf{V}_\lambda$ is

$$\mathbf{V}_\lambda=\left(\int\prod_{s=0}^{N-1}\prod_{n<\lambda}\exp(-ix_{s,n}^2)dx_{s,n}\right)\left(\int\prod_{s=0}^{N-1}\prod_{n\geqslant\lambda+M_s}\exp(ix_{s,n}^2)dx_{s,n}\right)\left(\int\prod_{r=1}^{M_{\rm tot}}\right.$$
$$\left.\times\exp\left(-\frac{i}{2}p_r^2\right)dp_j\right)\left(\int\prod_{s=0}^{N-1}\prod_{n=\lambda}^{\lambda+M_s-1}\exp(-ix_{s,n}^2)dx_{s,n}\right). \tag{57}$$

One integrates first over $\Pi_{s=0}^{N-1}\,\Pi_{n<\lambda}\,dx_{s,n}$ and then over $\Pi_{s=0}^{N-1}\,\Pi_{n\geqslant\lambda+M_s}\,dx_{s,n}$. What remains is

$$\frac{1}{\mathbf{V}'_\lambda}\int\prod_{s=0}^{N-1}\prod_{n=\lambda}^{\lambda+M_s-1}dx_{s,n}\int\prod_{r=1}^{M_{\rm tot}}\exp\left(-\frac{i}{2}p_r^2\right)dp_j$$
$$\times\exp\left(-\frac{i}{2}\sum_{s=0}^{N-1}\sum_{n=\lambda}^{\lambda+M_s-1}((A_{s,-n}+i\sqrt{2}x_{s,n})^2+2x_{s,n}^2)\right) \tag{58}$$

with

$$\mathbf{V}'_\lambda=\left(\int\prod_{r=1}^{M_{\rm tot}}\exp\left(-\frac{i}{2}p_r^2\right)dp_j\right)\left(\int\prod_{s=0}^{N-1}\prod_{n=\lambda}^{\lambda+M_s-1}\exp(-ix_{s,n}^2)dx_{s,n}\right). \tag{59}$$

The number of integrations to be done over $dx_{s,n}$ is equal $M_{\rm tot}$. It is very convenient to introduce an index L which runs over all the allowed pairs $(s,n)L=1,...,M_{\rm tot}$. There is still minor technical complications due to the fact that in (58) expressions with $x_{s,n}$ are combined with $A_{s,-n}$. The following definition will be adopted: If the index J denotes a pair (s,n) then

$$x_J\equiv x_{s,n},\quad A_J\equiv A_{s,-n}. \tag{60}$$

A change of variables is to be done

$$p_j\to A_{r,-k}=\sum_{n=1}^{M_{\rm tot}}p_n w_n^{k-\lambda}f_r(w_n)=\sum_{n=1}^{M_{\rm tot}}p_n\Omega_L(w_n). \tag{61}$$

$\Omega_L(w)$ are β field zero modes, i.e., holomorphic λ differentials. Introducing a similar notation as in Sec. II one can write

$$A_L=\sum_{j=1}^{M_{\rm tot}}R_{Lj}p_j, \tag{62}$$

where

$$R_{Lj}=\begin{pmatrix} \Omega_1(w_1) & \Omega_1(w_2) & \cdots & \Omega_1(w_{M_{\rm tot}}) \\ \cdots & \cdots & \cdots & \cdots \\ \Omega_{M_{\rm tot}}(w_1) & \Omega_{M_{\rm tot}}(w_2) & \cdots & \Omega_{M_{\rm tot}}(w_{M_{\rm tot}}) \end{pmatrix} \tag{63}$$

is a matrix of zero modes. The result is that only the Jacobian arising due to the change of variables (61) gives nontrivial contribution. The remaining integrations cancel the normalization factor $\mathbf{V}'_\lambda$ and the first term in (46) is

$$\frac{K_\lambda(z,w)}{\det\,\Omega_L(w_j)}. \tag{64}$$

In order to calculate the next term in (46) one should follow the procedure presented in Sec. II with the above-explained modifications due to the presence of N sectors and M_s zero modes in each of them. The result is

$$-\det(\Omega_L(w_j))\sum_{s,N=1}^{M_{\rm tot}} K_\lambda(z,w_s)R^{-1}_{sN}\Omega_N(w). \tag{65}$$

The final result can be written in compact form

$$\langle 0|\,\gamma(z)\beta(w)\prod_{r=1}^{M_{\rm tot}}\delta(\beta(w_r))|0\rangle=\det\begin{pmatrix} K_\lambda(z,w) & K_\lambda(z,w_1) & \cdots & K_\lambda(z,w_{M_{\rm tot}}) \\ \Omega_1(w) & \Omega_1(w_1) & \cdots & \Omega_1(w_{M_{\rm tot}}) \\ \cdots & \cdots & \cdots & \cdots \\ \Omega_{M_{\rm tot}}(w) & \Omega_{M_{\rm tot}}(w_1) & \cdots & \Omega_{M_{\rm tot}}(w_{M_{\rm tot}}) \end{pmatrix} \times(\det\,\Omega_L(w_j))^{-2}. \tag{66}$$

It has all the necessary analytical properties of the propagator: poles as $z\to w$, $z\to w_r$, $w_{r_1}\to w_{r_2}$ $(r_1\neq r_2)$ and zeroes as $w\to w_j$.

One can also define

$$\frac{\langle 0|\,\gamma(z)\beta(w)\Pi_{r=1}^{M_{\rm tot}}\delta(\beta(w_r))|0\rangle}{\langle 0|\Pi_{r=1}^{M_{\rm tot}}\delta(\beta(w_r))|0\rangle}=\det\begin{pmatrix} K_\lambda(z,w) & K_\lambda(z,w_1) & \cdots & K_\lambda(z,w_{M_{\rm tot}}) \\ \Omega_1(w) & \Omega_1(w_1) & \cdots & \Omega_1(w_{M_{\rm tot}}) \\ \cdots & \cdots & \cdots & \cdots \\ \Omega_{M_{\rm tot}}(w) & \Omega_{M_{\rm tot}}(w_1) & \cdots & \Omega_{M_{\rm tot}}(w_{M_{\rm tot}}) \end{pmatrix} \times(\det\,\Omega_L(w_j))^{-1}. \tag{67}$$

IV. THE FOUR-POINT CORRELATOR

The operator formalism also allows the calculation of higher order correlation functions. In this section the computation of the four-point correlator

$$\langle 0|\,\gamma(z_1)\gamma(z_2)\beta(w_1)\beta(w_2)\prod_{s=1}^{M_{\rm tot}}\delta(\beta(u_s))|0\rangle \tag{68}$$

is presented. The Wick theorem implies

$$\langle 0|\,\gamma(z_1)\gamma(z_2)\beta(w_1)\beta(w_2)\prod_{s=1}^{M_{\rm tot}}\exp(ip_s\beta(u_s))|0\rangle$$

$$=(K_\lambda(z_1,w_1)K_\lambda(z_2,w_2)+K_\lambda(z_1,w_2)K_\lambda(z_2,w_1))\langle 0|\prod_{s=1}^{M_{\rm tot}}\exp(ip_s\beta(u_s))|0\rangle$$

$$+K_\lambda(z_1,w_1)\sum_{t=1}^{M_{\rm tot}} ip_tK_\lambda(z_2,u_t)\langle 0|\beta(w_2)\prod_{s=1}^{M_{\rm tot}} \exp(ip_s\beta(u_s))|0\rangle$$

$$+K_\lambda(z_1,w_2)\sum_{t=1}^{M_{\rm tot}} ip_tK_\lambda(z_2,u_t)\langle 0|\beta(w_1)\prod_{s=1}^{M_{\rm tot}} \exp(ip_s\beta(u_s))|0\rangle$$

$$+K_\lambda(z_2,w_1)\sum_{t=1}^{M_{\rm tot}} ip_tK_\lambda(z_1,u_t)\langle 0|\beta(w_2)\prod_{s=1}^{M_{\rm tot}} \exp(ip_s\beta(u_s))|0\rangle$$

$$+K_\lambda(z_2,w_2)\sum_{t=1}^{M_{\rm tot}} ip_tK_\lambda(z_1,u_t)\langle 0|\beta(w_1)\prod_{s=1}^{M_{\rm tot}} \exp(ip_s\beta(u_s))|0\rangle$$

$$-\sum_{t_1,t_2=1}^{M_{\rm tot}} p_{t_1}p_{t_2}K_\lambda(z_1,u_{t_1})K_\lambda(z_2,u_{t_2})\langle 0|\beta(w_1)\beta(w_2)\prod_{s=1}^{M_{\rm tot}} \exp(ip_s\beta(u_s))|0\rangle. \quad (69)$$

Only the last term in (69) requires a new analysis.
It is necessary to compute

$$\beta(w_1)\beta(w_2)\exp\left(i\sum_{s=0}^{N-1}\sum_{j=-\infty}^{+\infty} A_{s,j}\beta_{s,j}\right)|0\rangle$$

$$=-\frac{1}{2}\sum_{r,s=0}^{N-1}\sum_{j,k=-\infty}^{+\infty}\Psi_{r,-j}\Psi_{s,-k}\left(x_{r,j}-i\,\frac{\partial}{\partial x_{r,j}}\right)\left(x_{s,k}-i\,\frac{\partial}{\partial x_{s,k}}\right)\exp\left(-\frac{i}{2}\sum_{s'=0}^{N-1}\sum_{n'<\lambda}x^2_{s',n'}\right)$$

$$\times\exp\left(-\frac{i}{2}\sum_{q=0}^{N-1}\sum_{m\geqslant\lambda}((A_{q,-m}+i\sqrt{2}x_{q,m})^2+x^2_{q,m})\right)$$

$$=\sum_{r,s=0}^{N-1}\sum_{j,k\geqslant\lambda}\Psi_{r,-j}\Psi_{s,-k}((A_{r,-j}+i\sqrt{2}x_{r,j})(A_{s,-k}+i\sqrt{2}x_{s,k})+i\,\delta_{jk})$$

$$\times\exp\left(-\frac{i}{2}\sum_{s'=0}^{N-1}\sum_{n'<\lambda}x^2_{s',n'}\right)\exp\left(-\frac{i}{2}\sum_{q=0}^{N-1}\sum_{m\geqslant\lambda}((A_{q,m}+i\sqrt{2}x_{q,-m})^2+x^2_{q,-m})\right), \quad (70)$$

where

$$\beta(w)=\sum_{s=0}^{N-1}\sum_{j=-\infty}^{+\infty}\Psi_{s,j}\beta_{s,j}, \quad \Psi_{s,j}(w)=f_s(w)w^{-j-\lambda} \quad (71)$$

so that

$$A_{r,j}=\sum_{s=1}^{M_{\rm tot}} p_s\Psi_{r,j}(u_s). \quad (72)$$

In the correlator

$$\langle 0|\beta(w_1)\beta(w_2)\exp\left(i\sum_{r=1}^{M_{\rm tot}} p_r\beta(u_r)\right)|0\rangle$$

$$=\frac{1}{\mathbf{V}_\lambda}\int\prod_{s=0}^{N-1}\prod_{j=-\infty}^{+\infty}dx_{s,j}\int\prod_{r=1}^{M_{\rm tot}}dp_r\,\exp\left(\frac{i}{2}\sum_{t=0}^{N-1}\left(\sum_{n\geqslant\lambda+M_s}x_{s,n}^2-\sum_{n<\lambda+M_s}x_{s,n}^2\right)\right)$$
$$\times\sum_{r,s=1}^{N-1}\sum_{j,k\geqslant\lambda}\Psi_{r,-j}\Psi_{s,-k}((A_{r,-j}+i\sqrt{2}x_{r,j})(A_{s,-k}+i\sqrt{2}x_{s,k})+i\,\delta_{j,k}\delta_{r,s})$$
$$\times\exp\left(-\frac{i}{2}\sum_{s=0}^{N-1}\left(\sum_{n<\lambda}x_{s,n}^2+\sum_{j\geqslant\lambda}((A_{s,-j}+i\sqrt{2}x_{s,j})^2+x_{s,j}^2)\right)\right) \tag{73}$$

the integrations over $dx_{s,n}$ for $n<\lambda$ are trivial. In the integrations over $dx_{s,n}$ for $n\geqslant\lambda+M_s$ a crucial observation is that in the sum over $j,\,k>\lambda$ the only terms that survive are those for which $j,\,k\leqslant\lambda+M_s-1$. The reason is that (34) holds. One obtains therefore

$$\langle 0|\beta(w_1)\beta(w_2)\exp\left(i\sum_{r=1}^{M_{\rm tot}} p_r\beta(u_r)\right)$$

$$=\frac{1}{\mathbf{V}'_\lambda}\int\prod_{s=0}^{N-1}\prod_{n=\lambda}^{\lambda+M_s-1}dx_{s,n}\int\prod_{r=1}^{M_{\rm tot}}dp_r\sum_{r,s=1}^{N-1}\sum_{j,k=\lambda}^{\lambda+M_s-1}\Psi_{r,-j}\Psi_{s,-k}((A_{r,-j}+i\sqrt{2}x_{r,j})$$
$$\times(A_{s,-k}+i\sqrt{2}x_{s,k})+i\,\delta_{j,k}\delta_{r,s})$$
$$\times\exp\left(-\frac{i}{2}\sum_{s=0}^{N-1}\sum_{n=\lambda}^{\lambda+M_s-1}((A_{s,-n}+i\sqrt{2}x_{s,n})^2+2x_{s,n}^2)\right). \tag{74}$$

At this point it is very convenient to rewrite the above expression using the indices L introduced in Sec. III.

$$\langle 0|\beta(w_1)\beta(w_2)\exp\left(i\sum_{r=1}^{M_{\rm tot}} p_r\beta(u_r)\right)|0\rangle$$

$$=\frac{1}{\mathbf{V}'_\lambda}\int\prod_{J=1}^{M_{\rm tot}}\int\prod_{r=1}^{M_{\rm tot}}dp_r\sum_{K,L=1}^{M_{\rm tot}}\Psi_K\Psi_L((A_K+i\sqrt{2}x_K)$$
$$\times(A_L+i\sqrt{2}x_L)+i\,\delta_{K,L})\exp\left(-\frac{i}{2}\sum_{J=1}^{M_{\rm tot}}((A_J+i\sqrt{2}x_J^2+2x_J^2)\right). \tag{75}$$

One should not forget that in (69) this expression is multiplied by $(-)p_{t_1}p_{t_2}$. Performing the standard changes of variables $p_r\to A_L$ and $A_J\to\tilde{A}_J=A_J+i\sqrt{2}x_J$, the remaining integrals are

$$\frac{1}{\mathbf{V}'_\lambda}\int\prod_{K=1}^{M_{\rm tot}}dx_K\int\prod_{J=1}^{M_{\rm tot}}d\tilde{A}_J\,\exp\left(-\frac{i}{2}\sum_{J=1}^{M_{\rm tot}}(\tilde{A}_J^2+2x_J^2)\right)R^{-1}_{t_1M}R^{-1}_{t_2N}(\tilde{A}_M-i\sqrt{2}x_M)$$
$$\times(\tilde{A}_N-i\sqrt{2}x_N)\sum_{K,L=1}^{M_{\rm tot}}\Psi_K\Psi_L(\tilde{A}_K\tilde{A}_L+i\,\delta_{K,L}). \tag{76}$$

One can replace $\Psi_J(z)$ with $\Omega_J(z)$ as for the allowed values of J only the zero modes appear in the above expression, which we denote with the symbol Ω_J.

The integrals to be evaluated are

$$\int \prod_{Q=1}^{M_{\rm tot}} d\tilde{A}_Q(\tilde{A}_M - i\sqrt{2}x_M)(\tilde{A}_N - i\sqrt{2}x_N)(\tilde{A}_K\tilde{A}_L + i\,\delta_{K,L})\exp\left(-\frac{i}{2}\sum_{S=1}^{M_{\rm tot}}\tilde{A}_S^2\right). \tag{77}$$

It is clear that terms with x_M drop out. Terms linear in x_M give rise to terms linear or of the third order in $\tilde{A}_P$ which yield no contribution after integration. Also the quadratic term containing $x_M x_N$ gives rise to integral with $\tilde{A}_K\tilde{A}_L + i\,\delta_{K,L}$ which integrated gives 0 because of (34).

The tensor structure of (77) implies that it must be of the form

$$\text{const}(\,\delta_{N,K}\delta_{M,L} + \delta_{N,L}\delta_{M,K}) \int \prod_{S=1}^{M_{\rm tot}} d\tilde{A}_S \exp\left(-\frac{i}{2}\sum_{S=1}^{M_{\rm tot}}\tilde{A}_S^2\right).$$

Using

$$\int dp p^4 \exp\left(-\frac{i}{2}p^2\right) = -3\int dp \exp\left(-\frac{i}{2}p^2\right) \tag{78}$$

and

$$\int dp p^2 \exp\left(-\frac{i}{2}p^2\right) = -i\int dp \exp\left(-\frac{i}{2}p^2\right) \tag{79}$$

it is easy to verify that const$=-1$.

After performing the remaining trivial integrations the final expression for the last term in (69) is (apart from the Jacobian $\det(\partial A_J/p_r)$)

$$\sum_{t_1,t_2=1}^{M_{\rm tot}} K_\lambda(z_1,u_{t_1})K_\lambda(z_2,u_{t_2})(R^{-1}_{t_1L}\Omega_L(w_2)R^{-1}_{t_2K}\Omega_K(w_1) + R^{-1}_{t_1K}\Omega_K(w_1)R^{-1}_{t_2L}\Omega_L(w_2)). \tag{80}$$

Altogether (69) is equal to

$$\begin{aligned}
&\frac{1}{\det\,\Omega_I(u_J)}\,(K_\lambda(z_1,w_1)K_\lambda(z_2,w_2) + K_\lambda(z_1,w_2)K_\lambda(z_2,w_1)\\
&\quad + -\sum_{t=1}^{M_{\rm tot}}\sum_{K=1}^{M_{\rm tot}}(K_\lambda(z_1,w_1)K_\lambda(z_2,u_t)R^{-1}_{tK}\Omega_K(z_2) + K_\lambda(z_1,w_2)K_\lambda(u_t,w_1)R^{-1}_{tK}\Omega_K(z_2)\\
&\quad + K_\lambda(z_2,w_1)K_\lambda(u_t,w_2)R^{-1}_{tK}\Omega_K(z_1) + K_\lambda(z_1,w_1)K_\lambda(u_t,w_2)R^{-1}_{tK}\Omega_K(z_1))\\
&\quad + \sum_{t_1,t_2=1}^{M_{\rm tot}}\sum_{L,K=1}^{M_{\rm tot}}(K_\lambda(u_{t_1},w_1)K_\lambda(u_{t_2},w_2)R^{-1}_{t_1L}\Omega_L(z_2)R^{-1}_{t_2K}\Omega_K(z_1))\\
&\quad + K_\lambda(u_{t_1},w_1)K_\lambda(u_{t_2},w_2)R^{-1}_{t_1K}\Omega_K(z_1)R^{-1}_{t_2}\Omega_L(z_2)).
\end{aligned} \tag{81}$$

With manipulations analogous to those used in the derivation of (65) it is possible to write down (81) in a compact form. The details are given in Appendix B. The four-point correlator is

$$\begin{aligned}
&\frac{\langle 0|\beta(z_1)\beta(z_2)\gamma(w_1)\gamma(w_2)\Pi_{s=1}^{M_{\rm tot}}\delta(\beta(u_s))|0\rangle}{\langle 0|\Pi_{s=1}^{M_{\rm tot}}\delta(\beta(u_s))|0\rangle}\\
&\quad = \frac{\langle 0|\beta(z_1)\gamma(w_1)\Pi_{s=1}^{M_{\rm tot}}\delta(\beta(u_s))|0\rangle}{\langle 0|\Pi_{s=1}^{M_{\rm tot}}\delta(\beta(u_s))|0\rangle}\,\frac{\langle 0|\beta(z_2)\gamma(w_2)\Pi_{s=1}^{M_{\rm tot}}\delta(\beta(u_s))|0\rangle}{\langle 0|\Pi_{s=1}^{M_{\rm tot}}\delta(\beta(u_s))|0\rangle}\\
&\qquad + \frac{\langle 0|\beta(z_1)\gamma(w_2)\Pi_{s=1}^{M_{\rm tot}}\delta(\beta(u_s))|0\rangle}{\langle 0|\Pi_{s=1}^{M_{\rm tot}}\delta(\beta(u_s))|0\rangle}\,\frac{\langle 0|\beta(z_2)\gamma(w_1)\Pi_{s=1}^{M_{\rm tot}}\delta(\beta(u_s))|0\rangle}{\langle 0|\Pi_{s=1}^{M_{\rm tot}}\delta(\beta(u_s))|0\rangle}.
\end{aligned} \tag{82}$$

APPENDIX A: GAUSSIAN REPRESENTATION

The aim of this Appendix is to provide a short but self-consistent presentation of the construction of ''Gaussian'' representation for the β–γ system proposed in Ref. 15. The notation corresponds to that used in Sec. II where the RS is a complex sphere.

The elementary excitations for β and γ satisfy the commutation relations:

$$[\gamma_n, \beta_m] = \delta_{n+m,0}. \tag{A1}$$

They are represented as

$$\beta_n = -\frac{i}{\sqrt{2}}\left(x_{-n} - i\,\frac{\partial}{\partial x_{-n}}\right), \tag{A2}$$

$$\gamma_n = \frac{1}{\sqrt{2}}\left(x_n + i\,\frac{\partial}{\partial x_n}\right). \tag{A3}$$

The operators β_n and γ_m act on functions of x_n. The vector space they act on is a product of ''Gaussian'' factors $\exp(\pm(i/2)x_n^2)$ multiplied by polynomials in x_m. In this vector ''Fock space'' the scalar product is defined in the following way:

$$\langle \Phi_1 | \Phi_2 \rangle \equiv \frac{1}{V_\lambda} \int \prod_n dx_n (\Phi_1(x))^* \Phi_2(x). \tag{A4}$$

It is assumed that $x_n^* = x_{-n}$ (but in the case of general RS this rule will have to be modified). V_λ is a formally infinite normalization factor equal to

$$V_\lambda = \left(\frac{\int dp\, \exp\left(-\frac{i}{2}p^2\right)}{2\pi}\right)^{2\lambda-1} \left(\prod_{m<-\lambda} \int \exp(-ix_m^2)dx_m\right)\left(\prod_{n\geqslant 1-\lambda} \int \exp(ix_n^2)dx_n\right). \tag{A5}$$

It is understood that (A4) is defined in such a way that the two formally infinite terms in numerator and denominator cancel each other.

A choice of the vaccum state is a choice of ''Bose sea level.'' A vacuum state $\Phi^{(\lambda)}$ can be constructed such that

$$\langle \Phi^{(\lambda)} | \Phi^{(\lambda)} \rangle = \infty \tag{A6}$$

(the explanation for that infinity can be found in Sec. I) but (assume that $\lambda \geqslant 2$)

$$\langle \Phi^{(\lambda)} | \prod_{j=1-\lambda}^{\lambda-1} \delta(\gamma_j) | \Phi^{(\lambda)} \rangle = 1. \tag{A7}$$

The correct definition is

$$\Phi^\lambda(x) = \exp\frac{i}{2}\left(\sum_{n\geqslant\lambda} x_n^2 - \sum_{n<\lambda} x_n^2\right). \tag{A8}$$

It satisfies

$$(\Phi^{(\lambda)}(x))^* = \Phi^{1-\lambda}(x) \tag{A9}$$

so that

$$\Phi_0^{(\lambda)}(\Phi_0^{(\lambda)})^* = \exp i\left(\sum_{n\geqslant\lambda} x_n^2 - \sum_{n<-\lambda} x_n^2\right). \tag{A10}$$

The integration over $dx_{\lambda-1}\cdots dx_{1-\lambda}$ in (A4) lead to (A6).
On the other hand,

$$\begin{aligned}\delta(\gamma_n)\exp\left(-\frac{i}{2}x_n^2\right)&=\frac{1}{2\pi}\int dp\ \exp(ip\gamma_n)\exp\left(-\frac{i}{2}x_n^2\right)\\&=\frac{1}{2\pi}\int dp\ \exp\left(\frac{i}{\sqrt{2}}p\left(x_n+i\frac{\partial}{\partial x_n}\right)\right)\exp\left(-\frac{i}{2}x_n^2\right)\\&=\frac{1}{2\pi}\int dp\ \exp\left(\frac{i}{2}x_n^2-\frac{i}{2}(p-i\sqrt{2}x_n)^2\right)\\&=\frac{1}{2\pi}\int dp\ \exp\left(-\frac{1}{2}p^2\right)\exp\left(\frac{i}{2}x_n^2\right).\end{aligned}\tag{A11}$$

Therefore, thanks to the appropriate definition of the normalization factor V_λ, (A7) holds.
An important identity used above is

$$\exp\left(a\frac{\partial}{\partial x_{-n}}\right)\exp\left(\frac{i}{2}x_{-n}^2\right)=\exp\left(iax_{-n}+\frac{i}{2}a^2\right)\exp\left(\frac{i}{2}x_{-n}^2\right).\tag{A12}$$

APPENDIX B: DERIVATION OF (82)

The aim of this Appendix is to provide a proof that the four-point correlation function can be represented by (82). The starting point is (81) and the basic trick is that used in the derivation of (65):

$$\sum_{s,N=1}^{M_{\rm tot}}K_\lambda(z,w_s)R_{sN}^{-1}\Omega_N(w)=K_\lambda(z,w)-\det\begin{pmatrix}K_\lambda(z,w)&K_\lambda(z,w_1)&\cdots&K_\lambda(z,w_{M_{\rm tot}})\\\Omega_1(w)&\Omega_1(w_1)&\cdots&\Omega_1(w_{M_{\rm tot}})\\\cdots&\cdots&\cdots&\cdots\\\Omega_{M_{\rm tot}}(w)&\Omega_{M_{\rm tot}}(w_1)&\cdots&\Omega_{M_{\rm tot}}(w_{M_{\rm tot}})\end{pmatrix}\times(\det\Omega_L(w_j))^{-1}.\tag{B1}$$

Thanks to (B1) all the summations in (81) can be eliminated. One obtains (everything has to be multiplied by $(1/\det\Omega_I(u_J))$

$$\begin{aligned}&K_\lambda(z_1,w_1)K_\lambda(z_2,w_2)+K_\lambda(z_1,w_2)K_\lambda(z_2,w_1)+-K_\lambda(z_1,w_1)K_\lambda(z_2,w_2)\\&+\frac{1}{(\det\Omega_I(u_J))}K_\lambda(z_1,w_1)\det\begin{pmatrix}K_\lambda(z_2,w_2)&K_\lambda(z_2,u_1)&\cdots&K_\lambda(z_2,u_{M_{\rm tot}})\\\Omega_1(w_2)&\Omega_1(u_1)&\cdots&\Omega_1(u_{M_{\rm tot}})\\\cdots&\cdots&\cdots&\cdots\\\Omega_{M_{\rm tot}}(w_2)&\Omega_{M_{\rm tot}}(u_1)&\cdots&\Omega_{M_{\rm tot}}(u_{M_{\rm tot}})\end{pmatrix}\\&-K_\lambda(z_1,w_2)K_\lambda(z_2,w_1)\\&+\frac{1}{(\det\Omega_I(u_J))}K_\lambda(z_1,w_2)\det\begin{pmatrix}K_\lambda(z_2,w_1)&K_\lambda(z_2,u_1)&\cdots&K_\lambda(z_2,u_{M_{\rm tot}})\\\Omega_1(w_1)&\Omega_1(u_1)&\cdots&\Omega_1(u_{M_{\rm tot}})\\\cdots&\cdots&\cdots&\cdots\\\Omega_{M_{\rm tot}}(w_1)&\Omega_{M_{\rm tot}}(u_1)&\cdots&\Omega_{M_{\rm tot}}(u_{M_{\rm tot}})\end{pmatrix}\\&-K_\lambda(z_2,w_1)K_\lambda(z_1,w_2)\end{aligned}$$

$$+\frac{1}{(\det\,\Omega_I(u_J))}\,K_\lambda(z_2,w_1)\det\begin{pmatrix} K_\lambda(z_1,w_2) & K_\lambda(z_1,u_1) & \cdots & K_\lambda(z_1,u_{M_{\rm tot}}) \\ \Omega_1(w_2) & \Omega_1(u_1) & \cdots & \Omega_1(u_{M_{\rm tot}}) \\ \cdots & \cdots & \cdots & \cdots \\ \Omega_{M_{\rm tot}}(w_2) & \Omega_{M_{\rm tot}}(u_1) & \cdots & \Omega_{M_{\rm tot}}(u_{M_{\rm tot}}) \end{pmatrix}$$

$$-K_\lambda(z_2,w_2)K_\lambda(z_1,w_1)$$

$$+\frac{1}{(\det\,\Omega_I(u_J))}\,K_\lambda(z_2,w_2)\det\begin{pmatrix} K_\lambda(z_1,w_1) & K_\lambda(z_1,u_1) & \cdots & K_\lambda(z_1,u_{M_{\rm tot}}) \\ \Omega_1(w_1) & \Omega_1(u_1) & \cdots & \Omega_1(u_{M_{\rm tot}}) \\ \cdots & \cdots & \cdots & \cdots \\ \Omega_{M_{\rm tot}}(w_1) & \Omega_{M_{\rm tot}}(u_1) & \cdots & \Omega_{M_{\rm tot}}(u_{M_{\rm tot}}) \end{pmatrix}$$

$$+\left(K_\lambda(z_1,w_2)-\frac{1}{(\det\,\Omega_I(u_J))}\det\begin{pmatrix} K_\lambda(z_1,w_2) & K_\lambda(z_1,u_1) & \cdots & K_\lambda(z_1,u_{M_{\rm tot}}) \\ \Omega_1(w_2) & \Omega_1(u_1) & \cdots & \Omega_1(u_{M_{\rm tot}}) \\ \cdots & \cdots & \cdots & \cdots \\ \Omega_{M_{\rm tot}}(w_2) & \Omega_{M_{\rm tot}}(u_1) & \cdots & \Omega_{M_{\rm tot}}(u_{M_{\rm tot}}) \end{pmatrix}\right)$$

$$\times\left(K_\lambda(z_2,w_1)-\frac{1}{(\det\,\Omega_I(u_J))}\det\begin{pmatrix} K_\lambda(z_2,w_1) & K_\lambda(z_2,u_1) & \cdots & K_\lambda(z_2,u_{M_{\rm tot}}) \\ \Omega_1(w_1) & \Omega_1(u_1) & \cdots & \Omega_1(u_{M_{\rm tot}}) \\ \cdots & \cdots & \cdots & \cdots \\ \Omega_{M_{\rm tot}}(w_1) & \Omega_{M_{\rm tot}}(u_1) & \cdots & \Omega_{M_{\rm tot}}(u_{M_{\rm tot}}) \end{pmatrix}\right)$$

$$+\left(K_\lambda(z_1,w_1)-\frac{1}{(\det\,\Omega_I(u_J))}\det\begin{pmatrix} K_\lambda(z_1,w_1) & K_\lambda(z_1,u_1) & \cdots & K_\lambda(z_1,u_{M_{\rm tot}}) \\ \Omega_1(w_1) & \Omega_1(u_1) & \cdots & \Omega_1(u_{M_{\rm tot}}) \\ \cdots & \cdots & \cdots & \cdots \\ \Omega_{M_{\rm tot}}(w_2) & \Omega_{M_{\rm tot}}(u_1) & \cdots & \Omega_{M_{\rm tot}}(u_{M_{\rm tot}}) \end{pmatrix}\right)$$

$$\times\left(K_\lambda(z_2,w_2)-\frac{1}{(\det\,\Omega_I(u_J))}\det\begin{pmatrix} K_\lambda(z_2,w_2) & K_\lambda(z_2,u_1) & \cdots & K_\lambda(z_2,u_{M_{\rm tot}}) \\ \Omega_1(w_2) & \Omega_1(u_1) & \cdots & \Omega_1(u_{M_{\rm tot}}) \\ \cdots & \cdots & \cdots & \cdots \\ \Omega_{M_{\rm tot}}(w_2) & \Omega_{M_{\rm tot}}(u_1) & \cdots & \Omega_{M_{\rm tot}}(u_{M_{\rm tot}}) \end{pmatrix}\right). \tag{B2}$$

All except two terms cancel each other and (81) turns out to be equal

$$\frac{1}{(\det\,\Omega_I(u_J))^3}\left(\det\begin{pmatrix} K_\lambda(z_1,w_2) & K_\lambda(z_1,u_1) & \cdots & K_\lambda(z_1,u_{M_{\rm tot}}) \\ \Omega_1(w_2) & \Omega_1(u_1) & \cdots & \Omega_1(u_{M_{\rm tot}}) \\ \cdots & \cdots & \cdots & \cdots \\ \Omega_{M_{\rm tot}}(w_2) & \Omega_{M_{\rm tot}}(u_1) & \cdots & \Omega_{M_{\rm tot}}(u_{M_{\rm tot}}) \end{pmatrix}\right)$$

$$\times\left(\det\begin{pmatrix} K_\lambda(z_2,w_1) & K_\lambda(z_2,u_1) & \cdots & K_\lambda(z_2,u_{M_{\rm tot}}) \\ \Omega_1(w_1) & \Omega_1(u_1) & \cdots & \Omega_1(u_{M_{\rm tot}}) \\ \cdots & \cdots & \cdots & \cdots \\ \Omega_{M_{\rm tot}}(w_1) & \Omega_{M_{\rm tot}}(u_1) & \cdots & \Omega_{M_{\rm tot}}(u_{M_{\rm tot}}) \end{pmatrix}\right)$$

$$+\left\langle \det\begin{pmatrix} K_\lambda(z_1,w_1) & K_\lambda(z_1,u_1) & \cdots & K_\lambda(z_1,u_{M_{\rm tot}}) \\ \Omega_1(w_1) & \Omega_1(u_1) & \cdots & \Omega_1(u_{M_{\rm tot}}) \\ \cdots & \cdots & \cdots & \cdots \\ \Omega_{M_{\rm tot}}(w_2) & \Omega_{M_{\rm tot}}(u_1) & \cdots & \Omega_{M_{\rm tot}}(u_{M_{\rm tot}}) \end{pmatrix} \right\rangle$$

$$\times\left\langle \det\begin{pmatrix} K_\lambda(z_2,w_2) & K_\lambda(z_2,u_1) & \cdots & K_\lambda(z_2,u_{M_{\rm tot}}) \\ \Omega_1(w_2) & \Omega_1(u_1) & \cdots & \Omega_1(u_{M_{\rm tot}}) \\ \cdots & \cdots & \cdots & \cdots \\ \Omega_{M_{\rm tot}}(w_2) & \Omega_{M_{\rm tot}}(u_1) & \cdots & \Omega_{M_{\rm tot}}(u_{M_{\rm tot}}) \end{pmatrix} \right\rangle . \tag{B3}$$

By looking at (67) one immediately gets (82).

Application of the discrete Wentzel–Kramers–Brillouin method to spin tunneling

Anupam Garg[a)]
Department of Physics and Astronomy, Northwestern University, Evanston, Illinois 60208

(Received 9 December 1997; accepted for publication 17 June 1998)

A discrete version of the Wentzel–Kramers–Brillouin (WKB) method is developed and applied to calculate the tunnel splittings between classically degenerate states of spin Hamiltonians. The results for particular model problems are in complete accord with those previously found using instanton methods. The discrete WKB method is more elementary and also yields wave functions. © *1998 American Institute of Physics.* [S0022-2488(98)03710-4]

I. INTRODUCTION

A large variety of problems in physics can be modeled in terms of a spin of large magnitude that is then described by a Hamiltonian which is a polynomial in the spin components. It is natural in many of these cases to seek a semiclassical description. This is especially so when the system possesses a number of degenerate states in the classical limit, and one wishes to see how this degeneracy is lifted by quantum tunneling. Examples include the Lipkin–Meshov–Glick model in nuclear physics,[1–3] the rotational spectrum of polyatomic molecules,[4] and the Hamamoto–Mottleson model[5] for the $\Delta I=4$ staggering of the rotational spectra of certain superdeformed nuclei.

Perhaps the simplest example of such a problem is provided by the Hamiltonian

$$\mathscr{H}=-k_1S_z^2+k_2S_x^2, \tag{1.1}$$

where $k_1>0$, $k_2>0$, and S_α $(\alpha=x,y,z)$ are components of the spin operator $\mathbf{S}$ obeying the usual commutation rules

$$[S_\alpha,S_\beta]=i\epsilon_{\alpha\beta\gamma}S_\gamma. \tag{1.2}$$

Further, the spin has a magnitude S, i.e., the operator $\mathbf{S}\cdot\mathbf{S}$ has eigenvalue $S(S+1)$. As $S\to\infty$, the system is more and more classical, and in the limit it has two degenerate ground states corresponding to $S_z/S=\pm1$. For large but finite S, the quantal analogs of these states will be admixed by a tunneling matrix element $\Delta_0/2$. The two lowest energy eigenstates will then be split by an amount Δ_0. The goal of a tunneling calculation is to find an expression for Δ_0 that is asymptotically valid as $S\to\infty$. In analogy with the result for particles with a position like coordinate in a potential well, we expect this expression to take the form

$$\Delta_0=e^{-(B_0+B_1+B_2+\cdots)}, \tag{1.3}$$

where

$$B_0\gg B_1\gg B_2\gg\cdots \tag{1.4}$$

in the sense that B_1/B_0, $B_2/B_1,\ldots\to0$ as $S\to\infty$. By looking at the commutation relations for the scaled operators S_α/S, we can see that $1/S$ plays the same role as $\hbar$ in conventional Wentzel–Kramers–Brillouin (WKB) theory, and we thus expect $B_0=O(S)$. As is often done for a particle in a well, it is convenient to call e^{-B_0} the Gamow factor, or the WKB exponent, and the remaining terms $e^{-(B_1+B_2+\cdots)}$ the prefactor.

In many physical problems, it is only sensible or possible to calculate Δ_0 to ''exponential accuracy,'' i.e., to find only the leading term B_0 in Eq. (1.3). As a general point of formalism, however, it is clearly desirable to have a proper asymptotic approximation Δ_0' to Δ_0 itself and not just to $\ln \Delta_0$. In other words, we demand that $\Delta_0'/\Delta_0 \to 1$ as $S \to \infty$. For this one must know all B_n that are of $O(S^0)$ or greater. The first correct calculation to such accuracy that we know of was done by Enz and Schilling,[6,7] who mapped the spin onto a canonically conjugate variable pair via a Villain transformation, and then applied an instanton method[8] to the resulting problem. Great care must be taken in this approach with operator ordering problems, leading to a rather complex calculation. A more natural approach is one based on Klauder's spin-coherent-state path integral.[9] A naive application of instanton methods for the tunnel splitting to this path integral,[10] however, only gives the leading S dependence correctly. In particular, terms of $O(S^0)$ in $\ln \Delta_0$ are incorrectly obtained.[11,12] A correct calculation within this formalism has only recently been done by Belinicher, Providencia, and Providencia,[13] who show that it is necessary to consider nondifferentiable paths by a careful examination of the discrete time version of the path integral. Once again, the simplicity of the instanton approach is lost.

It is therefore desirable to have a means of calculating the tunnel splitting using only elementary methods of analysis. Such an approach is provided by the discrete WKB method. (An alternative approach, used in Ref. 14, also meets the criterion of being elementary.) In the present context, the method consists of writing the Schrödinger equation as a recursion relation for the expansion coefficients of an energy eigenstate in the S_z basis, and solving this recursion relation under the assumption that the coefficients in the recursion relation vary slowly with m, the S_z eigenvalue. By and large, the method is a straightforward generalization of the continuous WKB method,[15] and it may also be viewed as equivalent to the use of semiclassical dynamics for Bloch electrons.

The earliest appearance of this method in a physics context of which we are aware is by Schulten and Gordon,[16] who use it to find semiclassical approximations for the $3j$ (Wigner) and $6j$ (Racah) symbols. A cogent review of the method in the context of atomic physics has been given by Braun,[17] who also cites its application in a variety of other physics settings, as well as earlier discussions in Russian mathematics texts. It has also been previously applied to spin tunneling problems by van Hemmen and Sütő.[18,19] These authors have not, however, utilized the method to its full potential. Specifically, they calculate Δ_0 for a class of Hamiltonians including

$$\mathscr{H} = -\gamma S_z^2 - \alpha S_x, \tag{1.5}$$

but only the leading S dependence is correctly found. One of the goals of this paper is to show that the prefactor can also be found correctly to order S^0 with little extra labor. (See Sec. V.)

We will illustrate the discrete WKB method by applying it to Eqs. (1.1) and (1.5). We will find the splittings Δ_k, $k=0,1,2,\ldots$ for all low lying pairs of energy levels for Eq. (1.1), and the lowest splitting Δ_0 for Eq. (1.5). Our answers for Δ_0 agree completely with those of Enz and Schilling,[7] or Belinicher, Providencia, and Providencia,[13] and we believe they are obtained with much less effort. While the discrete WKB method does not have the nice geometrical structure of the spin-coherent-state path integral approach, it provides compensation in that it yields wave functions in the course of the calculation, which may be of further use; for evaluating matrix elements of perturbations, see, e.g., Refs. 20 and 21. Other problems commonly solved by the continuous WKB method, such as escape from a metastable well, are also amenable to the method, but we do not discuss these here.

The plan of the paper is as follows. In Sec. II we briefly review the discrete WKB method. Our discussion is heuristic and physically motivated. See Braun[17] for one that is more formal. In Sec. III we derive a formula [see Eq. (3.11)] for the tunnel splitting for a symmetric double well problem analogous to that for the continuous case.[22,23] We apply the method to the Hamiltonian (1.1) in Sec. IV, and to (1.5) in Sec. V. We compare our answers for the splittings with numerical results, and in the case of Eq. (1.5) to answers given by van Hemmen and Sütő,[19] and Scharf, Wreszinski, and van Hemmen.[14]

II. THE DISCRETE WKB METHOD

To introduce the discrete WKB method, let us consider the Hamiltonian (1.1), and focus on an energy eigenfunction $|\psi\rangle$. Denoting S_z eigenfunctions $|m\rangle$ with $S_z|m\rangle = m|m\rangle$ as usual, and writing $C_m = \langle m|\psi\rangle$, it is easy to see that Schrödinger's equation takes the form of a three-term recursion relation connecting C_{m-2}, C_m, and C_{m+2}. The step $\Delta m = 2$ in the index is inconvenient, so it is preferable to change the notation somewhat, and relabel the states which are connected to each other by an index j, with $j = 1,2,\ldots,N$, where N equals S or $S+1$. The Schrödinger equation then takes the form

$$w_j C_j + t_{j,j+1} C_{j+1} + t_{j,j-1} C_{j-1} = E C_j, \tag{2.1}$$

where $w_j = \mathscr{H}_{jj}$ and $t_{j,j\pm1} = \mathscr{H}_{j,j\pm1}$, with $t_{N,N+1}$ and $t_{N+1,N}$ being understood as zero. We may also assume that $t_{j,j+1} \neq 0$ for any j, since otherwise the matrix for $\mathscr{H}$ is block diagonal, and Eq. (2.1) may be regarded as applying to one block. We can also choose the phases of the basis states so that all $t_{j,j\pm1}$ are real. Hermiticity then yields $t_{j+1,j} = t^*_{j,j+1} = t_{j,j+1}$.

The above problem is equivalent to a tight-binding model for an electron on a one-dimensional lattice with on-site energies w_j, and hopping matrix elements $t_{j,j\pm1}$, and indeed our notation is chosen to reflect this analogy. If w_j and $t_{j,j+1}$ vary slowly enough with j (how slowly will be seen below) we may use the approximation of semiclassical electron dynamics. To do this we first note that for the uniform case where $w_j = w$ and $t_{j,j+1} = t$ for all j, the eigenstates are Bloch states with wavefunction e^{iqj} and energy $E(q) = w + 2t\cos q$. For the nonuniform case, we first extend j to be a continuous variable, and define $w(j)$ and $t(j)$ to be extensions of w_j and $t_{j,j\pm1}$ via the relations

$$w(j) = w_j, \tag{2.2}$$

$$t(j) = (t_{j,j+1} + t_{j,j-1})/2, \tag{2.3}$$

which are required to hold whenever j is an integer. We further demand that $w(j)$ and $t(j)$ be smooth enough that if j/N is regarded as a quantity of order N^0, then

$$\frac{dw}{dj} = O\left(\frac{w(j)}{N}\right), \tag{2.4}$$

and likewise for $t(j)$. This equation is the formal statement of ''slowly varying'' coefficients. Whether or not it can be satisfied depends, of course, on the problem under consideration, and it is this condition which determines whether or not the problem is amenable to solution by the discrete WKB method. It is easy to see that it holds for Eq. (1.1) whenever $S \gg 1$.

We next define a local wave vector $q(j)$ by the relation

$$\cos q(j) = (E - w(j))/2t(j). \tag{2.5}$$

Further, since the electron velocity is given by $\partial E/\partial q$ in semiclassical dynamics, we define

$$v(j) = -2t(j)\sin q(j). \tag{2.6}$$

Then by a straightforward repeat of the arguments employed in the continuous WKB method (see e.g., Ref. 15), it is a simple matter to show that two linearly independent solutions to Eq. (1.1) are given by

$$C_j \sim \frac{1}{\sqrt{v(j)}} \exp\left(\pm i \int^j q(j')\,dj'\right). \tag{2.7}$$

A general solution is obtained by taking linear combinations of these two solutions.

A formal proof of Eq. (2.7) is given by Braun,[17] along with connection formulas, Bohr–Sommerfeld quantization rules, etc. We will therefore limit ourselves to a few key comments and comparisons with the continuous WKB method.

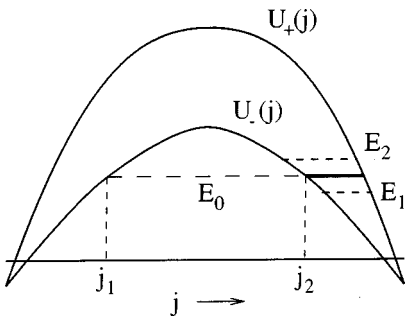

FIG. 1. Discrete WKB potential energy diagram for tunnel splitting problem. For a particle with energy E_0, the region between j_1 and j_2 is classically forbidden.

The first point is that Eq. (2.7) represents a development of $\log C_j$ in powers of N^{-1}, in which only the leading two terms are kept. To this accuracy, we need only keep the first two terms of $w(j)$ and $t(j)$ in an expansion in powers of $1/N$. Alternatively, we can use any expression for these functions which will reproduce the first two terms correctly. In particular, Eqs. (2.2) and (2.3) need only hold to this order. In considering this point, it should be remembered that j/N is regarded as being of $O(1)$.

The second point is that the factor $1/\sqrt{v}$ in Eq. (2.7) has the effect of normalizing each of the two solutions so that the probability flux is conserved and has a value of unity. This follows from noting that $|C_j|^2 \sim 1/v$, so that the particle spends a time inversely proportional to its velocity in any given coordinate segment dj. Since this is exactly what we expect for a classical particle, the quantum mechanical wave function is correctly adjusted to give a conserved probability flux.

The third point is that for a given energy E, the classically accessible region of motion is defined by the inequalities

$$U^-(j) \leqslant E \leqslant U^+(j), \tag{2.8}$$

where

$$U^{\pm} = w(j) \pm 2|t(j)|. \tag{2.9}$$

This follows from Eqs. (2.5) and (2.6) because whenever the condition (2.8) is violated, $q(j)$ and $v(j)$ acquire imaginary parts. The expression (2.7) (with $\sqrt{v(j)}$ replaced by $\sqrt{|v(j)|}$ as usual) then describes an exponentially decaying or growing wave function as opposed to an oscillatory one. It may also be noted that for uniform w_j and $t_{j,j\pm1}$, the quantities $U^{\pm}$ would be the limits of the allowable range of Bloch state energies. More generally they may be regarded as local, j-dependent band edges.

Finally, let us note the conditions for the validity of Eq. (2.7). The physical requirement is that the wavelength of the particle should not change by very much over dimensions of the wavelength itself, which is equivalent to demanding that

$$|dq(j)/dj| \ll 1. \tag{2.10}$$

In addition to failing if $w(j)$ and $t(j)$ do not vary slowly (as defined above), it is easy to see that Eq. (2.10) is violated whenever $q \approx 0$ or $\pm\pi$. In light of Eqs. (2.8) and (2.9), this is hardly surprising, since these are turning points of the classical motion. Solutions of the form (2.7) on opposite sides of these points must be related to each other by the above-mentioned connection formulas, as in the usual WKB method.

III. GENERAL FORMULA FOR TUNNEL SPLITTING

In this section we consider the problem where the functions w_j and $t_{j,j+1}$ possess reflection symmetry about some point, and the central region is classically forbidden for some energies. The band-edge functions $U^{\pm}(j)$ then have the form shown in Fig. 1. We will derive a formula [see Eq. (3.11)] for the tunnel splitting between states formed from symmetrical states localized in the two

potential wells. Our approach is completely analogous to that for a continuous coordinate.[22] A formula very close to Eq. (3.11) also appears in van Hemmen and Wreszinski,[23] but our method and notation are sufficiently different, and the argument sufficiently brief, that it is worth giving it in toto.

It is convenient to shift the index j so that it runs over the values

$$-\frac{N-1}{2},-\frac{N-3}{2},\ldots,\frac{N-1}{2}. \tag{3.1}$$

Note that j takes on integer values when N is odd, and half-integer values when N is even. With this labeling, we have

$$t_{j,k}=t_{-k,-j}=t_{k,j}. \tag{3.2}$$

It is also convenient, for future use, to define $j_0=1$ or 1/2, depending on whether N is odd or even, respectively. In either case, j_0 labels the first site to the right of the midpoint. We also define $J=(N-1)/2$, and $t_{\rm mid}=t_{10}$ or $t_{1/2,-1/2}$ for odd or even N.

Let C_j be the normalized wave function localized in the right well, and which satisfies the Schrödinger equation (2.1), neglecting the possibility of tunneling, with some energy E_0. Further, let a_j and s_j be the exact associated antisymmetric and symmetric wave functions, respectively, and let them have energies E_1 and E_2, where $(E_1+E_2)/2=E_0$. These functions are given to very good accuracy by

$$a_j=\frac{1}{\sqrt{2}}(C_j-C_{-j}),\qquad s_j=\frac{1}{\sqrt{2}}(C_j+C_{-j}). \tag{3.3}$$

Since the product C_jC_{-j} is everywhere exponentially small, these functions are properly normalized to unity.

The Schrödinger equations obeyed by C_j and a_j are

$$(w_j-E_0)C_j+t_{j,j-1}C_{j-1}+t_{j,j+1}C_{j+1}=0, \tag{3.4}$$

$$(w_j-E_1)a_j+t_{j,j-1}a_{j-1}+t_{j,j+1}a_{j+1}=0. \tag{3.5}$$

We multiply Eq. (3.4) by a_j, Eq. (3.5) by C_j, subtract the latter from the former, and sum the result from $j=j_0$ to $J\equiv(N-1)/2$. This yields

$$(E_1-E_0)\sum_{j\geqslant j_0}C_ja_j+\Sigma_1-\Sigma_2=0, \tag{3.6}$$

where

$$\Sigma_1=\sum_{j\geqslant j_0}a_j(t_{j,j-1}C_{j-1}+t_{j,j+1}C_{j+1}), \tag{3.7}$$

$$\Sigma_2=\sum_{j\geqslant j_0}C_j(t_{j,j-1}a_{j-1}+t_{j,j+1}a_{j+1}). \tag{3.8}$$

By shifting the index of summation in Eq. (3.8) we can see that most of the terms in the sums Σ_1 and Σ_2 are identical. Recalling that $t_{J,J+1}=0$, and that $a_0=0$ for odd N, we obtain

$$\Sigma_1-\Sigma_2=\begin{cases}a_1t_{\rm mid}C_0 & (\text{odd } N)\\ a_{1/2}t_{\rm mid}(C_{1/2}+C_{-1/2}) & (\text{even } N).\end{cases} \tag{3.9}$$

To evaluate the sum $\Sigma_j a_jC_j$ in Eq. (3.6), we use Eq. (3.3). Since C_{-j} is exponentially small everywhere in the right-hand well, and since C_j is normalized,

$$\sum_{j\geqslant j_0} C_j a_j \approx \frac{1}{\sqrt{2}} \sum_{j\geqslant j_0} C_j^2 = \frac{1}{\sqrt{2}}. \tag{3.10}$$

Substituting Eqs. (3.3), (3.9), and (3.10) in Eq. (3.6), and recalling that $E_1 - E_2 = 2(E_1 - E_0)$, we obtain[22]

$$E_1 - E_2 = \begin{cases} -2t_{\text{mid}} C_0 (C_1 - C_{-1}) & (\text{odd } N) \\ -2t_{\text{mid}} (C_{1/2}^2 - C_{-1/2}^2) & (\text{even } N). \end{cases} \tag{3.11}$$

Equation (3.11) is the sought after formula for the splitting. Note that unlike the case of a particle with a continuous coordinate degree of freedom, it is not now necessary for the antisymmetric state to have the higher energy. In fact, it is not hard to show that

$$\text{sgn}(E_1 - E_2) = \begin{cases} 1 & (\text{odd } N) \\ -\text{sgn } t & (\text{even } N). \end{cases} \tag{3.12}$$

IV. TUNNEL SPLITTINGS FOR MODEL HAMILTONIAN (1.1)

We now apply our general formalism to the Hamiltonian (1.1). Writing a general eigenstate of $\mathscr{H}$ as

$$|\psi\rangle = \sum_m C_m |m\rangle, \tag{4.1}$$

where $S_z|m\rangle = m|m\rangle$, Schrödinger's equation becomes

$$(w_m - E) C_m + t_{m,m+2} C_{m+2} + t_{m,m-2} C_{m-2} = 0, \tag{4.2}$$

with

$$w_m = (k_1 + \tfrac{1}{2} k_2)(S(S+1) - m^2), \tag{4.3}$$

$$t_{m,m+2} = \tfrac{1}{4} k_2 [(S(S+1) - m(m+1))(S(S+1) - (m+1)(m+2))]^{1/2}. \tag{4.4}$$

For convenience, we have added a constant $k_1 S(S+1)$ to the Hamiltonian, and thus to w_m.

As noted earlier, Eq. (4.2) is of the same form as Eq. (2.1) with the minor difference that the index m jumps in steps of 2 rather than 1. We can take care of this point by changing the integral in the exponential in Eq. (2.7) to $\int q(m')dm'/2$, leaving the other formulas unaffected.

One elementary point should be noted at this stage. For half-integer S, Kramers's theorem ensures an exact double degeneracy of all energy eigenstates of the Hamiltonian (1.1). This means that Δ_k vanishes. In the spin-coherent-state path integral approach, this result comes about because the kinetic term in the action is a Berry phase, and different symmetry related paths acquire phases which give rise to destructive interference for half-integer S.[24–26] In the discrete WKB method, this result comes about from an almost trivial separation of the eigenvalue problem into two isomorphic disjoint subspaces.

There are two steps in the calculation of Δ_k via Eq. (3.11). First, one must find the wave function C_m in the classically allowed and disallowed regions separately. In the present case, an expression for the former can be found exactly and in such a way that it actually holds in part of the disallowed region. This allows one to match on to the quasiclassical wave function given by Eq. (2.7) without using connection formulas. The second step consists of substituting the quasiclassical wave function into Eq. (3.11).

To execute the first step, let us consider a wave function $C_m^{(k)}$ with energy $E_0^{(k)}$ which corresponds to the kth state localized in the well near $m = -S$, and begin by finding it near this well. The coefficients w_m and $t_{m,m+2}$ are evaluated by writing $m = -S + n$, and expanding Eqs. (4.3) and (4.4) in powers of $1/S$, with n regarded as a quantity of order S^0. This yields

$$w_{-S+n}=(k_1+\tfrac{1}{2}k_2)(2n+1)S, \tag{4.5}$$

$$t_{-S+n,-S+n+2}=\tfrac{1}{2}k_2S((n+1)(n+2))^{1/2}. \tag{4.6}$$

Rewriting $C_{-S+n}=b_n$, the recursion relation (4.2) reads

$$(2k_1+k_2)S(n+\tfrac{1}{2})b_n+\tfrac{1}{2}k_2S\sqrt{n(n+1)}b_{n-2}+\tfrac{1}{2}k_2S\sqrt{(n+1)(n+2)}b_{n+2}=Eb_n, \tag{4.7}$$

which is immediately recognizable as arising from the harmonic oscillator Hamiltonian

$$\mathscr{H}_{\rm osc}=(2k_1+k_2)S(a^\dagger a+\tfrac{1}{2})+\tfrac{1}{2}k_2S(a^2+(a^\dagger)^2), \tag{4.8}$$

where a and $a^\dagger$ are the usual annihilation and creation operators obeying $[a,a^\dagger]=1$. To see this let us denote the kth energy state of $\mathscr{H}_{\rm osc}$ by $|\psi_k\rangle$, and the number eigenstates by $|n\rangle$ with $a^\dagger a|n\rangle=n|n\rangle$. It is then apparent that $b_n^{(k)}=\langle n|\psi_k\rangle$ obeys the eigenvalue equation (4.7).

To find $b_n^{(k)}$, we transform to position and momentum operators x and p obeying $[x,p]=i$ via $a=(x+ip)/\sqrt{2}$, $a^\dagger=(x-ip)/\sqrt{2}$. In terms of these,

$$\mathscr{H}_{\rm osc}=(k_1+\tfrac{1}{2}k_2)S(x^2+p^2)+\tfrac{1}{2}k_2S(x^2-p^2). \tag{4.9}$$

It follows that the kth state $|\psi_k\rangle$ has an energy

$$E_0^{(k)}=(k+\tfrac{1}{2})\omega_0, \tag{4.10}$$

$$\omega_0=2S(k_1(k_1+k_2))^{1/2}. \tag{4.11}$$

The wave function of this state is given by a textbook formula:

$$\langle x|\psi_k\rangle=(2^{2k}(k!)^2\pi\xi^2)^{-1/4}e^{-x^2/2\xi^2}H_k(x/\xi), \tag{4.12}$$

where H_k is the kth Hermite polynomial, and

$$\xi^2=\left(\frac{k_1}{k_1+k_2}\right)^{1/2}\equiv\tanh(\kappa/2). \tag{4.13}$$

It is also useful to write $\xi=e^{-\theta}$, in terms of which we have the symmetrical relations

$$e^{-2\theta}=\tanh(\kappa/2), \qquad e^{-\kappa}=\tanh\,\theta. \tag{4.14}$$

The number states $|n\rangle$ on the other hand, have wave functions

$$\langle x|n\rangle=(2^{2n}(n!)^2\pi)^{-1/4}e^{-x^2/2}H_n(x). \tag{4.15}$$

We can thus evaluate the overlap $\langle n|\psi_k\rangle=b_n^{(k)}$ in the x representation. The requisite integrals are most simply found by using the generating function for the Hermite polynomials,

$$e^{2xz-z^2}=\sum_{n=0}^{\infty}\frac{z^n}{n!}H_n(x). \tag{4.16}$$

The final result for $b_n^{(k)}$ is

$$b_n^{(k)}=\cos(\pi D)\left(\frac{n!k!}{2^{n+k}\cosh\,\theta}\right)^{1/2}\sum_{j=0}^{[k/2]}\frac{(-1)^j(\tanh\,\theta)^{D+2j}(2\,\mathrm{sech}\,\theta)^{k-2j}}{(D+j)!(k-2j)!j!}. \tag{4.17}$$

Here $D\equiv(n-k)/2$, and $[x]$ denotes the largest integer less than or equal to x. Note that the $\cos(\pi D)$ factor accounts for the vanishing of $b_n^{(k)}$ if $n-k$ is odd. The latter fact is a simple

consequence of the parity relation $H_n(-x)=(-1)^n H_n(x)$. It can be seen as a restatement of the separation of $\mathscr{H}$ into two subspaces, or of the $\Delta m=2$ step in Eq. (4.2), and rigorously implies $C_m^{(k)}=0$ for odd $m+S-k$ for the entire range of m.

Next, let us find $C_m^{(k)}$ in the central or classically forbidden region where $S-m$ and $S+m$ are both $O(S)$. In this region, we have to sufficient accuracy

$$w(m)=(k_1+\tfrac{1}{2}k_2)((S+\tfrac{1}{2})^2-m^2)+O(S^0), \tag{4.18}$$

$$t(m)=\tfrac{1}{4}k_2((S+\tfrac{1}{2})^2-m^2)+O(S^0). \tag{4.19}$$

It is easy to see that $d(w/t)/dm=O(S^{-1})$, so the quasiclassicality condition (2.10) holds if $S\gg 1$. Equation (2.5) then yields for the local wave vector

$$\begin{aligned}\cos\, q(m) &= \frac{2E_0^{(k)}-(2k_1+k_2)((S+\frac{1}{2})^2-m^2)}{k_2((S+\frac{1}{2})^2-m^2)} \\ &= -\left(\frac{2k_1+k_2}{k_2}\right)+\frac{2E_0^{(k)}}{k_2(2S+1)}\left(\frac{1}{S+\frac{1}{2}-m}+\frac{1}{S+\frac{1}{2}+m}\right).\end{aligned} \tag{4.20}$$

For the discrete WKB method to work, the energy levels which are split must lie well below the barrier, i.e., $E_0^{(k)}\ll(k_1+k_2/2)S^2$. The second term in Eq. (4.20) is then of order S^{-1} relative to the first, and we can solve for $q(m)$ as an expansion in powers of $1/S$. Equation (4.13) implies that

$$1+2k_1/k_2=\cosh\,\kappa, \tag{4.21}$$

so that

$$q(m)=\pi+i\left[\kappa-\frac{E_0^{(k)}}{\omega_0}\left(\frac{1}{S+\frac{1}{2}-m}+\frac{1}{S+\frac{1}{2}+m}\right)+O\left(\frac{E_0^{(k)}}{\omega_0 S^2}\right)\right]. \tag{4.22}$$

The exponent in Eq. (2.7) therefore equals (recalling the extra factor of 1/2 due to the step $\Delta m=2$)

$$\phi(m)=i\int^m q(m')\frac{dm'}{2}=\frac{i\pi m}{2}-\frac{\kappa m}{2}+\frac{E_0^{(k)}}{2\omega_0}\ln\left(\frac{S+\frac{1}{2}+m}{S+\frac{1}{2}-m}\right)+\cdots. \tag{4.23}$$

Similarly, correct to leading order in S, we have

$$|v(m)|=\frac{\omega_0}{2S}\left(\left(S+\frac{1}{2}\right)^2-m^2\right). \tag{4.24}$$

We now substitute Eqs. (4.23) and (4.24) into Eq. (2.7), changing the normalization from unit flux to total unit probability in accord with the discussion in Sec. III. Writing the result only for the nonzero $C_m^{(k)}$, i.e., for $m+S-k$ even, we have

$$C_m^{(k)}\approx A_k\frac{(S+\frac{1}{2}+m)^{(2k-1)/4}}{(S+\frac{1}{2}-m)^{(2k+3)/4}}e^{i\pi(m-k)/2}e^{-\kappa m/2}, \tag{4.25}$$

where A_k is the normalization constant, and we have used $E_0^{(k)}/\omega_0=k+\frac{1}{2}$.

It is now possible to match Eqs. (4.25) and (4.17) directly, since both results are valid in the region $S\gg n\gg 1$. We first find $b_n^{(k)}$ for $S\gg n\gg k$, with $k=O(1)$:

$$b_n^{(k)}=\frac{\cos(\pi(n-k)/2)}{\sqrt{k!}}\left(\frac{2}{\pi}\right)^{1/4}(\mathrm{sech}\,\theta)^{(2k+1)/2}(\tanh\,\theta)^{(n-k)/2}n^{(2k-1)/4}. \tag{4.26}$$

To find $C_m^{(k)}$ in the overlap region, we put $m=-S+n$ in Eq. (4.25), recall that $e^{-\kappa}=\tanh\theta$, and in this way obtain for $n\gg 1$,

$$C_{-S+n}^{(k)}=\frac{A_k}{(2S)^{(2k+3)/4}}\cos(\pi(n-k)/2)e^{-i\pi S/2}(\tanh\theta)^{(n-S)/2}n^{(2k-1)/4}. \tag{4.27}$$

Comparing with Eq. (4.26) we obtain

$$A_k=e^{i\pi S/2}\left(\frac{2}{\pi}\right)^{1/4}\frac{1}{\sqrt{k!}}(\operatorname{sech}\theta)^{(2k+1)/2}(\tanh\theta)^{(S-k)/2}(2S)^{(2k+3)/4}. \tag{4.28}$$

The last step is to apply Eq. (3.11) for the splitting. The only issue requiring caution is that of even versus odd N, the number of points on which the wave function $C_m^{(k)}$ is nonzero. We have $N=S+1$ for even k and $N=S$ for odd k. Thus the parity of N is that of $S+k-1$. Both cases can be easily handled at the same time, however. From Eq. (4.25), we see that for $|m|\ll S$, the nonvanishing $C_m^{(k)}$'s are given by $(A_k/S)e^{-\kappa m/2}$ up to an overall phase. Thus, the factor multiplying $2t_{\mathrm{mid}}$ in Eq. (3.11) equals $2\sinh\kappa|A_k/S|^2$ in magnitude in both cases. Similarly, we see from Eq. (4.4) that t_{mid} equals $k_2S^2/4$ in both cases. Thus,

$$\Delta_k=k_2\sinh\kappa|A_k|^2 \tag{4.29}$$

for all k and S.

It remains to substitute Eq. (4.28) into Eq. (4.29). We quote the answer in terms of the parameters ω_0 and θ:

$$\Delta_k=\frac{1}{k!}\left(\frac{4S}{\sinh 2\theta}\right)^k\Delta_0, \tag{4.30}$$

$$\Delta_0=4\omega_0\left(\frac{S}{\pi}\right)^{1/2}\operatorname{sech}\theta(\tanh\theta)^S. \tag{4.31}$$

For some purposes, it may be desirable to write these results in terms of the ratio ξ defined in Eq. (4.13). The conversion is easily done using the formulas

$$\tanh\theta=(1-\xi^2)/(1+\xi^2), \tag{4.32}$$

$$\operatorname{sech}\theta=2\xi/(1+\xi^2), \tag{4.33}$$

$$(1/\sinh 2\theta)=2\xi/(1-\xi^4). \tag{4.34}$$

As mentioned before, the result (4.31) for the ground state splitting agrees with that of Enz and Schilling,[7] and Belinicher, Providencia, and Providencia.[13] A comparison with numerically obtained exact answers is given in Table I. As is evident, the agreement is quite good, and improves with increasing S.

The formula (4.30) for the higher splittings is, to our knowledge, new.

V. TUNNEL SPLITTING FOR MODEL HAMILTONIAN (1.5)

In this section we apply our method to the Hamiltonian (1.5), limiting ourselves to finding the ground state tunnel splitting Δ_0. This time the recursion relation connects contiguous coefficients C_{m-1}, C_m, and C_{m+1}, and

$$w(m)=-\gamma m^2, \tag{5.1}$$

$$t(m)=(-\alpha/2)(S'^2-m^2)^{1/2}, \tag{5.2}$$

where we have introduced the convenient abbreviation

TABLE I. Comparison between numerical and analytical [Eq. (4.31)] results for the ground state tunnel splitting for the Hamiltonian (1.1). Numbers in parentheses give the power of 10 multiplying the answer. We have chosen $k_1=5.0/S$, $k_2=20.0/S$. This scaling keeps ω_0 fixed as $S\to\infty$.

S	Δ_0 (numerical)	Δ_0 (analytic)	Error(%)
10	9.282(−3)	9.749(−3)	5.0
11	3.738(−3)	3.906(−3)	4.5
12	1.497(−3)	1.558(−3)	4.1

20	8.910(−7)	9.115(−7)	2.3

$$S'=S+1/2. \tag{5.3}$$

Let us begin, as in Sec. IV, by finding the wave function for the state localized in the right-hand well, C_m, in the classically accessible region. This time the answer depends on how the parameters α and γ are taken to vary as $S\to\infty$. To see this note that the lower band-edge function $U^-(m)$ now has a quadratic as opposed to linear form near its minima (see Fig. 2). If we define

$$m=S'\cos\theta, \tag{5.4}$$

then

$$U^-(m)=-\gamma S'^2\cos^2\theta-\alpha S'\sin\theta. \tag{5.5}$$

The mimima are located at $\theta=\theta_1$, $\pi-\theta_1$, where

$$\sin\theta_1=\alpha/2\gamma S'. \tag{5.6}$$

It follows that if α and γ remain fixed as $S\to\infty$, the minima approach the points $m=\pm S$, which gives us a problem similar to that of Sec. IV. For novelty's sake, let us therefore take α and γ to scale so that θ_1 remains fixed and not close to 0 as $S\to\infty$. We shall see that our final answer for Δ_0 will hold even when this condition is not satisfied.

For future use, let us define θ_0 as the angle at which the classical expression for the energy (not $U^-(m)$) has a minimum. We have

$$\sin\theta_0=\alpha/2\gamma S. \tag{5.7}$$

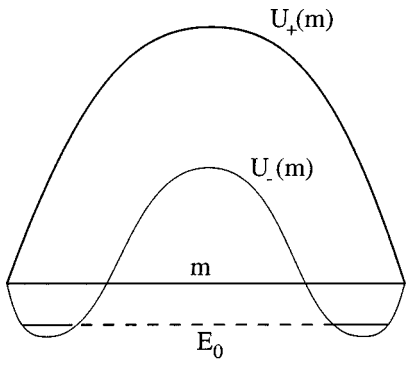

FIG. 2. Sketch of the band-edge functions for the Hamiltonian (1.5). The key point is that $U^-(m)$ now has a quadratic minimum.

Further,

$$\sin\ \theta_1=(1-(1/2S)+\cdots)\sin\ \theta_0,\quad \cos\ \theta_1=\cos\ \theta_0-\sin^2\ \theta_0/2S\ \cos\ \theta_0+\cdots. \tag{5.8}$$

With the above conditions on θ_1, it is easy to find C_m near the potential minima. Let us define

$$m_1=S'\ \cos\ \theta_1. \tag{5.9}$$

The conditions on α and γ imply that $S-m_1=O(S)$. Since the wave function we seek is essentially that for the ground state of a harmonic oscillator, its spatial extent, Δm, on the other hand, is of order $S^{1/2}$. This can be seen by expanding the semiclassical Hamiltonian in powers of q and $m-m_1$. We have

$$\begin{aligned}\mathscr{H}_{\rm sc}(q,m)&=w(m)+2t(m)\cos\ q\\ &\approx-\gamma S'^2(1+\sin^2\ \theta_1)+\gamma S'^2\ \sin^2\ \theta_1 q^2+\gamma\ \cot^2\ \theta_1(m-m_1)^2+\cdots.\end{aligned} \tag{5.10}$$

The leading neglected terms are, ignoring S' independent constants, of order $S'(m-m_1)q^2 \equiv h_1$, $S'^2q^4\equiv h_2$, and $(m-m_1)^3/S'\equiv h_3$. It follows that the small oscillation frequency ω_0 and the ground state energy E_0 (in the absence of tunneling, needless to say) are given by

$$\omega_0=2\gamma S'\ \cos\ \theta_1, \tag{5.11}$$

$$E_0=-\gamma S'^2(1+\sin^2\ \theta_1)+\gamma S'\ \cos\ \theta_1. \tag{5.12}$$

The wave function can be written down directly as for a harmonic oscillator with a continuous spatial coordinate,

$$C_m=\left(\frac{\cos\ \theta_1}{\pi S'\ \sin^2\ \theta_1}\right)^{1/4}\exp\left(-\frac{\cos\ \theta_1}{2S'\ \sin^2\ \theta_1}(m-m_1)^2\right), \tag{5.13}$$

which is already normalized to unity inside the well.

What is the range of validity of Eq. (5.13)? This can be found by demanding that the terms ignored, h_1, h_2, and h_3, be much smaller than $\omega_0/2$, the value of the q^2 and $(m-m_1)^2$ terms in Eq. (5.10). Since the kinetic and potential energies are equal for a harmonic oscillator, we have $q^2\propto(m-m_1)^2/S'^2$ in the region of validity. Thus, $h_1=O(m-m_1)^3/S'=O(h_3)$, and $h_2=O(m-m_1)^4/S'^2\ll h_1,h_3$. Demanding that $\omega_0/2\gg h_1$, we find that Eq. (5.13) is valid provided

$$|m-m_1|\ll(S')^{2/3}. \tag{5.14}$$

Note that this range keeps us clear of the end point $m=S$.

The second step is to find C_m in the classically forbidden region, especially near the point $m=0$ (if S is integral) or $m=1/2$ (if S is half-integral). Since $q(m)$ is imaginary, we define

$$q(m)=i\kappa(m), \tag{5.15}$$

with $\kappa(m)>0$. Using the basic definition (2.5) with the energy (5.12), we obtain

$$\cosh\ \kappa(m)=\frac{\sin^2\ \theta+\sin^2\ \theta_1}{2\sin\ \theta\ \sin\ \theta_1}-\frac{\cos\ \theta_1}{2S'\ \sin\ \theta\ \sin\ \theta_1}+O(S')^{-2}. \tag{5.16}$$

Writing

$$\kappa(m)=\kappa_0(m)+\kappa_1(m)+\cdots, \tag{5.17}$$

where κ_j is of order $1/S'^j$, we obtain

$$\kappa_0(m)=\frac{1}{2}\log\left(\frac{S'^2-m^2}{S'^2\ \sin^2\ \theta_1}\right), \tag{5.18}$$

$$\kappa_1(m)=\frac{1}{2}\left[\frac{1}{m-m_1}-\frac{1}{m+m_1}\right]. \tag{5.19}$$

The exponent in Eq. (2.7) therefore equals

$$\begin{aligned}\phi(m)&=\phi_0(m)+\phi_1(m)\\ &=\tfrac{1}{2}[(S'+m)\log(S'+m)-(S'-m)\log(S'-m)\\ &\quad -2m\ \log(eS'\ \sin\ \theta_1)]\\ &\quad +\tfrac{1}{2}[\log(m_1-m)-\log(m_1+m)].\end{aligned} \tag{5.20}$$

Here, ϕ_0 and ϕ_1 are the quantities in the first and second square brackets above, and correspond, respectively, to κ_0 and κ_1.

The velocity is now easy to find. To leading order in S, we get

$$|v(m)|=2\gamma S'^2\ \sin\ \theta_1\ \sin\ \theta\times\sinh\ \kappa_0=\gamma(m_1^2-m^2). \tag{5.21}$$

The wave function in the central region therefore equals

$$C_m=\frac{A}{m+m_1}\exp\ \phi_0(m), \tag{5.22}$$

where A is a constant that must be found by matching the solution with Eq. (5.13). This in turn is done by expanding $\phi_0(m)$ in powers of $m-m_1$, which is permissible as $|m-m_1|\ll S^{2/3}$ in the matching region. We find

$$\phi_0(m)=\phi_{00}-\frac{\cos\ \theta_1}{2S'\ \sin^2\ \theta_1}(m-m_1)^2; \tag{5.23}$$

$$\phi_{00}=S'[\log\ \cot(\theta_1/2)-\cos\ \theta_1]. \tag{5.24}$$

Putting $m=m_1$ in the pre-exponential factor in Eq. (5.22), we see that the forbidden region C_m has exactly the structure required to match on to Eq. (5.13). Comparing the two expressions, we obtain

$$A=2m_1\left(\frac{\cos\ \theta_1}{\pi S'\ \sin^2\ \theta_1}\right)^{1/4}e^{-\phi_{00}}. \tag{5.25}$$

The final step is to apply the formula (3.11) for the splitting. In doing this, the following simplifications are useful. First,

$$\phi_0(m)=-m\ \log\ \sin\ \theta_1\quad \text{for}\ \ m=O(1). \tag{5.26}$$

Second, to leading order in S,

$$\omega_0=2\gamma S\ \cos\ \theta_0. \tag{5.27}$$

Collecting together all these facts, we obtain, for both integral and half-integral S,

$$\Delta_0=4\omega_0\left(\frac{S}{\pi}\right)^{1/2}\frac{\cos^{3/2}\ \theta_0}{\sin\ \theta_0}\left(\frac{1-\cos\ \theta_0}{1+\cos\ \theta_0}\right)^{S+1/2}e^{2S\ \cos\ \theta_0}. \tag{5.28}$$

This is the main result of this section. It can be seen to be identical to Eq. (16) of Enz and Schilling,[7] via the substitutions $A=\gamma$, $a=\sin\ \theta_0$ and $b=0+$. It is almost, but not quite identical to Eq. (4.11) of Garg and Kim,[12] which errs by a factor of $O(S^0)$.

Several comments about Eq. (5.28) are in order. First, although we have only derived it assuming that $\sin\ \theta_0\gg 1/S$, it holds in fact for all $\sin\ \theta_0$, provided of course that the WKB approximation itself is valid. This can be seen from the numerical comparison we give below, and also analytically, by assuming that $\sin\ \theta_0=O(1/S)$ from the very start. This suggests that Eq. (5.28) holds uniformly for all $\sin\ \theta_0$ not too close to 1, but we have not investigated this point carefully. As a subcomment, note that in the limit $\theta_0\to 0$, i.e., vanishing α, $\Delta_0\sim\alpha^{2S}$. This is of course,

TABLE II. Comparison between numerical and various analytical and semianalytical results for the ground state tunnel splitting of the Hamiltonian (1.5). The parameters are $\alpha=\gamma=1$. As in Table I, $x(n)$ denotes the number $x\times 10^n$. The quantities Δ_n, Δ_{asymp}, and Δ_{int} are taken from Table I of van Hemmen and Sütő (Ref. 19), and are, respectively, the numerically computed splitting, the result (5.31), and the numerically evaluated integral expression (5.32). The quantity Δ_0 is given by Eq. (5.28) of this work.

[a]The numbers have been given to greater accuracy and corrected in a few places.

exactly what is expected from perturbation theory—it takes $2S$ applications of the perturbation $-\alpha S_x$ to connect the states with $S_z=\pm S$.[27] Second, the WKB validity restriction means that the field α in Eq. (1.5) cannot be too large. Quantitatively, we require that the energy barrier be much greater than ω_0, the level spacing in the well. This condition can be shown to be equivalent to

$$1-\sin\,\theta_0 \gg S^{-2/3}. \tag{5.29}$$

Third, as long as Eq. (5.29) holds, in the limit where the field is large and the barrier is small, Eq. (5.28) reduces to

$$\Delta_0=4\sqrt{3}\,\omega_0(B_0/2\pi)^{1/2}e^{-B_0}, \tag{5.30}$$

where $B_0=(2/3)S\,\cos^3\theta_0=(16/3)\Delta U/\omega_0$, ΔU being the energy barrier. This form is the well-known answer for the tunnel splitting of a massive particle moving in a quartic potential double well. The spin problem can be transformed into such a problem by noting that (i) in this limit $S_x\approx S$, so that the commutator $[S_y,S_z]=iS_x$ can be approximately reproduced by writing $S_z=x$, $S_y=-Sp$, where p and x are momentum and position operators with the commutator $[p,x]=-i$, and (ii) expanding the square root in the relation $S_x=[S^2-(S_y^2+S_z^2)]^{1/2}$, and rewriting S_y and S_z in terms of p and x as indicated above. We leave it to the reader to check that the frequency ω_0 and energy barrier ΔU of this particle problem are given by $2\gamma S\,\cos\theta_0$ and $\gamma S^2\,\cos^3\theta_0/4$, so that the answer for Δ_0 is indeed given by Eq. (5.30).

Fourth, let us compare our result for Δ_0 with the numerical and analytic answers obtained by van Hemmen and Sütő,[19] which apply when $\sin\theta_0=O(1/S)$. This comparison is shown in Table II. The parameters are $\gamma=\alpha=1$, and the two approximate forms for the splitting are given by

$$\Delta_{\text{asymp}}=2\gamma S\,\exp[-2S\,\log(\gamma S)], \tag{5.31}$$

$$\Delta_{\text{int}}=\frac{\omega_0}{2}\,\exp\left[-\int_{-m_t}^{m_t}\cosh^{-1}\left(\frac{-E_0-\gamma m^2}{\alpha[S(S+1)-m^2]^{1/2}}\right)\right]. \tag{5.32}$$

In Eq. (5.32), $\pm m_t$ are the classical turning points, where $E_0=w(m)$, and E_0 is the numerically obtained ground state energy. van Hemmen and Sütő describe Δ_{asymp} as an ''asymptotic'' result, and Δ_{int} as the ''exact WKB'' answer. As can be seen from the columns containing the ratios of the splittings given by these formulas to the numerically found splittings, neither result asymptotes to the correct answer. [Recall that two functions $f(x)$ and $g(x)$ are said to be asymptotically equal as $x\to x_0$, i.e., $f(x)\sim g(x)$, if $f(x)/g(x)\to 1$ as $x\to x_0$.] Δ_{asymp} actually gets worse with increasing S, which indicates that a multiplicative term such as e^{-cS} has been omitted (c is some constant), while Δ_{int} is off by a term of S^0.[28] Neither result therefore meets the goal set in Sec. I

of our paper: to find all terms B_n in Eq. (1.3) that are of order S^0 or greater. Equation (5.28), on the other hand, does just that. It is also obvious that the recipe given by van Hemmen and Sütő [see Eq. (5.19) of Ref. 19] cannot really be exact in general as regards the prefactor.

Last, Eq. (5.28) can be compared with the answer obtained by Scharf, Wreszinski, and van Hemmen,[14] which is valid when $\sin\theta_0 = O(1/S)$. Their result—see their Eqs. (1.7) and (1.8), and Table I—is also off by $O(S^0)$. In fact the discrepancy is again $(e/\pi)^{1/2}$, which is to be expected in light of their method.[28]

[28] Readers may wonder if all that is wrong with van Hemmen and Sütő's formula is the typographical omission of a factor of $2^{-1/2}$. This is not so. An inspection of the arguments accompanying their Eqs. (5.19) and (C.10-12) reveals that there is no scope for such a factor and it is purely accidental that the error seems to be $2^{1/2}$ in this case. Indeed, use of a similar formula for potential problems with massive particles in one dimension also yields incorrect prefactors; for the quartic double well, e.g., the error is known to be $(e/\pi)^{1/2}$. The same error is present in Scharf, Wreszinski, and van Hemmen's result (Ref. 14).

Quantum coordinates of an event in local quantum physics

R. Giannitrapani
Dipartimento di Fisica, Università di Trento, Povo (TN) I-38050, Italy

(Received 8 April 1998; accepted for publication 19 May 1998)

Recently Toller [quant-ph/9702060 (1997)] has proposed, using the formalism of positive-operator-valued measures, a possible definition of quantum coordinates for events in the context of quantum mechanics. In this short note we analyze this definition from the point of view of local algebras in the framework of local quantum theories. © *1998 American Institute of Physics.* [S0022-2488(98)00710-5]

I. INTRODUCTION

Local quantum theory is now a well established framework for physical concepts and theories.[1,2] An interesting problem is to see whether a given local quantum theory admits a sharp localization of a space–time event; this problem is intrinsically related to the definition of space-time at small scale and so to the quantum gravity problem.

In a recent work[3] Toller has proposed defining the localizability of an event using quantum coordinates via positive operator valued (POV) measures;[4] such a useful formalism has been used[5–8] to investigate the long-standing problem[9–14] of time in quantum mechanics and the quantum coordinates of Toller are a generalization of these works. In this short note we want to stress the fact that such quantum observable for the coordinates of an event cannot be built with quasilocal operators.

II. POV MEASURES IN THE LOCAL FRAMEWORK

Let $\mathcal{M}$ be the Minkowsky space–time and $\mathcal{F}(\mathcal{M})$ be the σ-algebra of borel subsets of $\mathcal{M}$; to the physical quantum object that defines the event is associated an Hilbert space $\mathcal{H}$ and we call $\mathcal{B}(\mathcal{H})$ the algebra of bounded linear operators on $\mathcal{H}$ and with $\mathcal{B}(\mathcal{H})^+$ the positive ones. A POV measure on $\mathcal{M}$ with value in $\mathcal{B}(\mathcal{H})^+$ is a map

$$\tau:\mathcal{F}(\mathcal{M})\rightarrow\mathcal{B}(\mathcal{H})^+$$

such that τ is σ-additive in the weak topology, $\tau(\emptyset)=0$ and $\tau(\mathcal{M})\leqslant 1$. If τ has to fix a quantum event we require that it is covariant with respect to a unitary representation of the Poincaré group. We remark on the fact that we cannot, in general, require the normalization $\tau(\mathcal{M})=1$ for the POV measure, as discussed in Ref. 1.

Let us now consider the formulation of a local quantum theory[3] in terms of local operators algebras; it is defined by a net of C^*-algebras, i.e., by an inclusion preserving assignment to every open, bounded region $\mathcal{O}$ of $\mathcal{M}$ of a unital C^*-algebra $\mathcal{A}(\mathcal{O})$; the closure in the norm topology of their union is the algebra of quasilocal observables

$$\mathcal{A}=\overline{\bigcup_{\mathcal{O}\subset\mathcal{M}}\mathcal{A}(\mathcal{O})}.$$

It is apparent that $\tau(\mathcal{T})$, with $\mathcal{T}\in\mathcal{F}(\mathcal{M})$ and $\mathcal{T}\neq\emptyset$, is not a local operator, i.e., it does not belong to one of the local algebras $\mathcal{A}(\mathcal{O})$. To see this, note that the vacuum state Ω is invariant under the translations on $\mathcal{M}$ and so

$$(\Omega,\tau(\mathcal{T})\Omega)=(\Omega,U(x)\tau(\mathcal{T})U^{-1}(x)\Omega)=(\Omega,\tau(\mathcal{T}_x)\Omega),$$

where $U(x)$ is an unitary representation on $\mathcal{H}$ of the group of spacetime translations and $\mathcal{T}_x$ is the region $\mathcal{T}$ transformed with the translation by x. If for $\mathcal{T}$ we have

 © 1998 American Institute of Physics

$$(\Omega, \tau(\mathscr{T})\Omega) = \epsilon$$

with $\epsilon > 0$, there does exist an integer n such that $n\epsilon > 1$. Now we can choose $n-1$ vectors $\{x_1, \ldots, x_{n-1}\}$ such that $\mathscr{T} \cap \mathscr{T}_{x_i} = \varnothing$ and $\mathscr{T}_{x_i} \cap \mathscr{T}_{x_j} = \varnothing \ \forall i, j;\ i \neq j$; for the additivity of τ and the invariance of the vacuum we have

$$(\Psi, \tau(\mathscr{T} \cup \mathscr{T}_{x1} \cup \ldots \cup \mathscr{T}_{x_{n-1}})\Omega) = n\epsilon > 1$$

that is impossible. So $(\Omega, \tau(\mathscr{T})\Omega) = 0$ and, since $\tau(\mathscr{T})$ is bounded and positive, for the Reeh–Schlieder[15] theorem it cannot be a local operator.

With a more complicated demonstration we can see that it is not a quasilocal operator. To see this we need the following trivial lemma.

Lemma 1: Given a POV measure τ on $\mathscr{M}$ covariant with respect to a unitary representation of the translations group, if $\tau(\mathscr{T})$ is a quasilocal operator for some region $\mathscr{T}$ then it is a quasilocal operator for every translated regions $\mathscr{T}_x$.

A second necessary lemma is a standard result of local quantum physics (see Refs. 3, 16, and 17); let us consider n quasilocal operators

$$A_1 \ldots A_n \in \mathscr{A}$$

and the automorphism of $\mathscr{A}$ associated to a translation of x given by $\alpha_x A \equiv U(x) A U^{-1}(x)$. Let us divide the set of the indices $\{1 \ldots n\}$ in two disjoint subsets I and J and define n new quasi-local operator $A'_1 \ldots A'_n$ by

$$A'_i = A_i, \quad i \in I,$$

$$A'_i = A_i(x), \quad i \in J,$$

where $A_i(x) = \alpha_x A_i$. If we indicate $x = (t, \mathbf{x})$ then we have

Lemma 2 (Cluster property): For $|\mathbf{x}| \to \infty$

$$(\Omega, A'_1 \cdots A'_n \Omega) \to \left(\Omega, \prod_{i \in I} A'_i \Omega \right) \cdot \left(\Omega, \prod_{j \in J} A'_j \Omega \right).$$

With these lemmas we can now demonstrate the following

Proposition 1: If τ is a POV measure on $\mathscr{M}$ covariant with respect to the space–time translations group, then $\tau(\mathscr{T}) \notin \mathscr{A}$ for all $\mathscr{T} \in \mathscr{F}(\mathscr{M})$ with $\tau(\mathscr{T}) \neq 0$.

Proof:

Let us suppose that $\tau(\mathscr{T})$ is a quasilocal operator and let ψ be a normalized vector such that

$$(\psi, \tau(\mathscr{T})\psi) = p$$

with $0 < p \leqslant 1$; since the subset of vectors obtained by applying quasilocal operators to Ω is dense in $\mathscr{H}$ one can assume that

$$\psi = A\Omega,$$

where A is a quasilocal operator. Defining the vector $\psi_x = A(x)\Omega$, where $x = (t, \mathbf{x})$, for the covariance property of τ we have

$$(\psi_x, \tau(\mathscr{T}_x)\psi_x) = p.$$

We can now show that a vector sequence $\{\tilde{\psi}_x\}$ exists such that, for $|\mathbf{x}| \to \infty$,

$$(\tilde{\psi}_x, \tau(\mathscr{T} \cup \mathscr{T}_x)\tilde{\psi}_x) \to 2p$$

and this is obviously impossible since $\tau(\mathscr{M}) \leqslant 1$.

In fact, let us define the normalized vector

$$\tilde{\psi}_x = \frac{A(x)A\Omega}{\|A(x)A\Omega\|};$$

using the clustering lemma one can see that

$$\|A(x)A\Omega\|^2 \to \|A(x)\Omega\|^2 \cdot \|A\Omega\|^2 = 1$$

and that

$$(\tilde{\psi}_x, \tau(\mathscr{T})\tilde{\psi}_x) \to (\Omega, A^*(x)A(x)\Omega) \cdot (\Omega, A^*\tau(\mathscr{T})A\Omega) = (\psi, \tau(\mathscr{T})\psi) = p$$

for $|\mathbf{x}| \to \infty$. Similarly, in the same limit,

$$(\tilde{\psi}_x, \tau(\mathscr{T}_x)\tilde{\psi}_x) \to (\Omega, A^*A\Omega) \cdot (\Omega, A^*(x)\tau(\mathscr{T}_x)A(x)\Omega) = (\psi_x, \tau(\mathscr{T}_x)\psi_x) = p.$$

So

$$(\tilde{\psi}_x, \tau(\mathscr{T} \cup \mathscr{T}_x)\tilde{\psi}_x) = (\tilde{\psi}_x, \tau(\mathscr{T})\tilde{\psi}_x) + (\tilde{\psi}_x, \tau(\mathscr{T}_x)\tilde{\psi}_x) \to 2p.$$

If $2p > 1$ the demonstration is over; otherwise we can repeat the same argument finding normalized states such that the preceding probability tends toward $4p$ and so on. □

So we see that the existence of a normalized POV measure covariant with respect to a unitary representation of the group of translations on $\mathscr{M}$ is incompatible with the local principle if we require that $\rho(\mathscr{T})$ is quasilocal.

III. CONCLUSIONS

The use of POV measures as observables is motivated by some deep considerations for the foundations of quantum mechanics.[18,19] In particular, the use of positive bounded operators is very interesting, not necessarily projectors, as generalized propositions; it is an open problem to see what kind of observables it is possible to build with them. In this note we have shown that a localizability for events in space–time cannot be described by one of these observables if the generalized propositions have to belong to the algebra of quasilocal operators; further investigations are necessary in this direction.

(Received 21 January 1998; accepted for publication 27 February 1998)

We analyze the structure of the perturbative series expansion of Chern–Simons gauge theory in the light-cone gauge. After introducing a regularization prescription that entails the consideration of framed knots, we present the general form of the vacuum expectation value of a Wilson loop. The resulting expression turns out to give the same framing dependence as the one obtained using nonperturbative methods and perturbative methods in covariant gauges. It also contains the Kontsevich integral for Vassiliev invariants of framed knots. © *1998 American Institute of Physics.* [S0022-2488(98)02909-0]

I. INTRODUCTION

Chern–Simons gauge theory has provided a very useful tool to study different aspects of the theory of knot and link invariants. Since its formulation by Witten in 1988[1] it has been studied from both perturbative and nonperturbative points of view. While nonperturbative methods[1–6] have led to its connection to polynomial invariants as the Jones polynomial[7] and its generalizations,[8–10] perturbative ones[11–14] have provided representations of Vassiliev invariants.

One of the advantages of the Chern–Simons approach to Vassiliev invariants is that it provides different representations of them because the perturbative analysis of the theory can be carried out in different gauges. Most of the perturbative analysis has been performed in covariant gauges, mostly in the Landau gauge. The loop structure in this gauge has been extensively analyzed in Refs. 11 and 15–17. Vacuum expectation values of Wilson loops have also been studied in a variety of papers.[11–14,18,19] These analyses lead to a representation of Vassiliev invariants for knots and links, which is equivalent to the one proposed by Bott and Taubes in Ref. 20.

The perturbative Chern–Simons series expansion in noncovariant gauges has not been studied so extensively. The loop structure has been analyzed in the light-cone gauge in Refs. 21 and 22. A first step into the study of vacuum expectation values of Wilson loops was presented in Ref. 23, where a second-order analysis was carried out in the axial gauge. No systematic study of the perturbative series expansion corresponding to Wilson loops has been carried out in the light-cone gauge. The main goal of this paper is to begin with this study. In the process we find that the light-cone gauge leads to the Kontsevich integral[24,25] for Vassiliev invariants of framed knots.

Chern–Simons gauge theory was first studied in the light-cone gauge in Ref. 4. That paper points out a close relation between the vacuum expectation value of a Wilson line and the Knizhnik–Zamolodchikov equations.[26] This fact is used to prove that, for SU(N) as gauge group, vacuum expectation values of Wilson loops are related to the HOMFLY polynomial[8] for links. From a perturbative point of view, vacuum expectation values of Wilson loops have been considered only in Ref. 27, where it is conjectured that the corresponding perturbative series expansion

a)Electronic mail: labasti@nxth04.cern.ch

 © 1998 American Institute of Physics

is related to the Kontsevich integral[24] for Vassiliev invariants. In the present paper we prove this conjecture.

Vacuum expectation values of Wilson loops are ill-defined in the light-cone gauge because of the presence of singularities. To have a well-defined perturbative expansion we introduce framed Wilson loops. The fact that the right object to be studied in Chern–Simons gauge theory is a framed Wilson loop has been known since the theory was first formulated in Ref. 1. The reason to introduce a framing might result differently in each approach, but in general it is related to the presence of singularities in the n-point correlation functions at coincident points. This will indeed be the case in the light-cone gauge. A version of the Kontsevich integral for Vassiliev invariants adapted to the case of framed knots and links was presented in Ref. 25. In this paper we will consider the case of framed knots but a similar construction holds for framed links. We show that the vacuum expectation value of a Wilson loop contains the Kontsevich integrals introduced in Ref. 25.

The paper is organized as follows. In Sec. II we discuss the quantization of Chern–Simons gauge theory in the light-cone gauge. In Sec. III we analyze the general features of the perturbative series expansion of Wilson loops. In Sec. IV, after introducing a regularization that involves framed knots, we prove the finiteness of the perturbative series expansion. In addition, we extract the framing dependence and show that the perturbative series contains the Kontsevich integral for Vassiliev invariants of framed knots. Finally, in Sec. V we state our conclusions and we discuss some open problems and future work.

II. CHERN–SIMONS GAUGE THEORY IN THE LIGHT-CONE GAUGE

In this section we introduce Chern–Simons gauge theory in the light-cone gauge from a perturbation theory point of view. Let us consider a semisimple compact Lie group G and a connection A. The action of the Chern–Simons theory over a three-dimensional Minkowski space $\mathbf{M}^3$ is defined by the integral:

$$S_{\mathrm{CS}}(A)=\frac{k}{4\pi}\int_{\mathbf{M}^3}\mathrm{Tr}\left(A\wedge dA+\frac{2}{3}A\wedge A\wedge A\right), \tag{2.1}$$

where Tr denotes the trace over the fundamental representation of G, and k is a real parameter. This action is invariant under gauge transformation

$$A_\mu\rightarrow h^{-1}A_\mu h+h^{-1}\partial_\mu h, \tag{2.2}$$

where h is a map from $\mathbf{M}^3$ to G, which is connected to the identity map. For maps that are not connected to the identity, (2.1) transforms into itself plus a term of the form $2\pi kn$, n being the winding number of the map. If k is an integer, the exponential of the action, $\exp(iS_{\mathrm{CS}})$, which is what enters the functional integral, is invariant under both types of gauge transformations.

Relative to the action (2.1) and to the gauge transformation (2.2), we choose the following conventions. The gauge group generators, T^a, $a=1\cdots\dim(G)$, will be taken anti-Hermitian, satisfying

$$[T^a,T^b]=-f_{abc}T^c, \tag{2.3}$$

f_{abc} being the structure constants of the group G. They are normalized so that

$$\mathrm{Tr}(T^aT^b)=-\tfrac{1}{2}\delta^{ab} \tag{2.4}$$

in the fundamental representation. A point in $\mathbf{M}^3$ will be denoted by coordinates x^μ, with μ running from zero to two, $\mu=2$ being the time coordinate.

In order to define the perturbative series expansion associated to the action (2.1) we must make a gauge choice. This choice is defined by a gauge-fixing condition, which in our case will be corresponding to the light-cone gauge:

$$n^\mu A_\mu=0, \tag{2.5}$$

where n^μ is a constant vector satisfying $n^2=0$. The corresponding gauge-fixing term to be added to the action (2.1) is

$$S_{\rm gf}=\int_{\mathbf{M}^3} d^3x\ \mathrm{Tr}(dn^\mu A_\mu+bn^\mu D_\mu c), \tag{2.6}$$

where d is an auxiliary field, and c and b are ghost fields; D_μ stands for the covariant derivative, $D_\mu c=\partial_\mu c+[A_\mu,c]$. In order to define the perturbative series expansion it is convenient to rescale the fields by $A\to gA$, where $g=\sqrt{4\pi/k}$. The quantum action, $S=S_{\rm CS}+S_{\rm gf}$, becomes

$$S=-\frac{1}{2}\int_{\mathbf{M}^3} d^3x\,\epsilon^{\mu\nu\rho}\left(A^a_\mu\partial_\nu A^a_\rho-\frac{g}{3}f_{abc}A^a_\mu A^b_\nu A^c_\rho\right)-\frac{1}{2}\int_{\mathbf{M}^3} d^3x(d^aA^a_\mu n^\mu+b^an^\mu D^{ab}_\mu c^b), \tag{2.7}$$

where

$$D^{ab}_\mu=\partial_\mu\delta^{ab}-gf_{abc}A^c_\mu. \tag{2.8}$$

Following Ref. 4 we introduce light-cone coordinates:

$$x^+=x^1+x^2,\quad x^-=x^1-x^2, \tag{2.9}$$

and light-cone components for the gauge connection:

$$A_+=A_1+A_2,\quad A_-=A_1-A_2. \tag{2.10}$$

Choosing the vector n^μ as $(0,1,-1)$ the gauge-fixing condition (2.5) implies $A_-=0$. Notice that the gauge condition (2.5) does not fix the gauge completely. For example, in our particular choice of n^μ we still have gauge invariance under gauge transformations (2.2), in which the gauge parameter h depends only on x^0 and x^+. The quantum action (2.7) takes the following form:

$$S=\int_{\mathbf{M}^3} d^3x(A^a_+\partial_-A^a_0-A^a_0\partial_-A^a_+-b^a\partial_-c^a). \tag{2.11}$$

Actually, to consider this action as the quantum action of the theory constitutes a rather simplified version of the full story. The perturbative higher-loop analysis in axial-type gauges is a very delicate issue, which requires us to take into consideration some specific prescription to regulate unphysical poles. Fortunately, this analysis has been done for the case of Chern–Simons gauge theory in Ref. 21. In these works it is shown that the effect of higher-loop contributions is a shift of the parameter k entering the Chern–Simons action (2.1) by the quantity c_v, which denotes the value of the quadratic Casimir in the adjoint representation of the gauge group. Though strictly speaking this has been proved at one loop, it is believed that, as in the case of covariant gauges, it holds at any order in higher loops. In this paper we will assume that higher-loop effects just account for the shift of the parameter k in (2.1), and we will work with (2.11) as the quantum action of the theory.

The quantum action (2.11) has three important properties. First, it does not have derivatives in the transverse direction, second, it is quadratic in the fields, and third, the ghost fields are not coupled to the gauge fields. This last property implies that the ghost fields can be integrated out trivially. The second property implies that there are no interaction vertices and therefore that all the correlation functions are determined by the two-point correlation functions. Certainly, this property notably simplifies the structure of the perturbative series expansion.

The two-point correlation functions corresponding to the gauge fields entering (2.11) have been computed in Ref. 4. Their result is more conveniently expressed after performing a Wick rotation to Euclidean space $\mathbf{R}\times\mathbf{C}$. A point in Euclidean space will be denoted as (t,z), where $z=x^1+ix^2$. After introducing $A_z=A_1+iA_2$ and $A_{\bar z}=A_1-iA_2$ one finds:[4]

$$\langle A^a_z(x)A^b_m(x')\rangle=0,\quad \langle A^a_m(x)A^b_n(x')\rangle=\delta^{ab}\epsilon_{mn}\frac{1}{2\pi i}\frac{\delta(t-t')}{z-z'}, \tag{2.12}$$

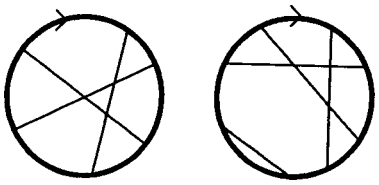

FIG. 1. Examples of Feynman diagrams.

with m, $n=\{0,z\}$, and ϵ_{mn} is antisymmetric with $\epsilon_{0z}=1$.

III. PERTURBATIVE EXPANSION OF THE WILSON LOOP

Wilson loops are gauge-invariant operators of Chern–Simons gauge theory labeled by a loop C embedded in $\mathbf{M}^3$ and a representation R of the gauge group G. They are defined by the holonomy along the loop C of the gauge connection A:

$$\mathscr{W}_R(C,G)=\mathrm{Tr}\left[P_R\ \exp\ g\ \oint A\right], \tag{3.1}$$

where P_R denotes that the integral is path-ordered and that A must be considered in the representation R of G. In Chern–Simons gauge theory one considers vacuum expectation values of products of Wilson-line operators:

$$\begin{aligned}&\langle \mathscr{W}_{R_1}(C_1,G)\mathscr{W}_{R_2}(C_2,G)\cdots\mathscr{W}_{R_n}(C_n,G)\rangle\\ &\quad=\frac{1}{Z_k}\int [DA]\mathscr{W}_{R_1}(C_1,G)\mathscr{W}_{R_2}(C_2,G)\cdots\mathscr{W}_{R_n}(C_n,G)e^{iS_k(A)},\end{aligned} \tag{3.2}$$

where Z_k is the partition function of the theory:

$$Z_k=\int [DA]e^{iS_{\mathrm{CS}}(A)}. \tag{3.3}$$

As shown in Ref. 1 the quantity (3.2) is a link invariant associated to a colored n-component link whose j-component C_j carries the representation R_j of the gauge group G. In this paper we will consider only the vacuum expectation value of a single loop $\langle W_R(C,G)\rangle$. This quantity can be expressed as a perturbative series expansion in the coupling constant g, which is the result of evaluating all the corresponding Feynman diagrams. The structure of these diagrams is obtained using standard field theory methods. A typical diagram of order i consists of a solid thick circle representing the oriented path C, with i propagators attached to it in a certain order (see some examples in Fig. 1). A term in the sum of the perturbative series may be regarded as constructed out of two Feynman rules: the one corresponding to the propagator (2.12):

$$D^{ab}_{mn}(x-x')=\delta^{ab}\epsilon_{mn}\frac{1}{2\pi i}\frac{\delta(t-t')}{z-z'}, \tag{3.4}$$

while all other components of $D_{\mu\nu}$ vanish; and the one corresponding to the vertex between the end point of a propagator and the oriented path C:

$$V^{j\mu a}_i(x)=g(T^a_{(R)})^j_i\int dx^\mu. \tag{3.5}$$

Notice that, as discussed in the previous section, there are not three-vertices in the light-cone gauge. The Feynman rules are depicted in Fig. 2.

The power series expansion corresponding to $\langle \mathscr{W}_R(C,G)\rangle$ can be written as:[13]

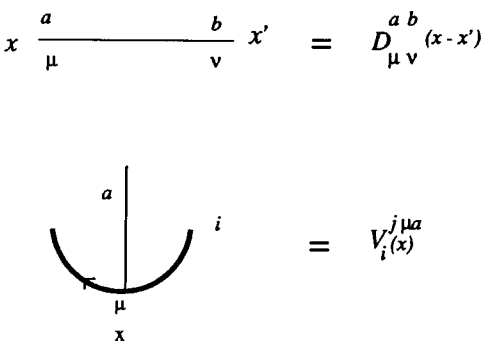

FIG. 2. Feynman rules.

$$\langle \mathscr{W}_R(C,G)\rangle = \dim R \sum_{i=0}^{\infty} \sum_{j=1}^{d_i} \alpha_{ij}(C) r_{ij}(R) x^i, \tag{3.6}$$

where $x = ig^2/2$ is the expansion parameter. The quantities $\alpha_{ij}(C)$, or geometrical factors, are combinations of path integrals of some kernels along the loop C, and the r_{ij} are traces of products of generators of the Lie algebra associated to the gauge group G. The index i corresponds to the order in perturbation theory, and j labels independent contributions at a given order, d_i being the number of these at order i. In (3.6) dim R denotes the dimension of the representation R. Notice the convention $\alpha_{01}(C) = 1$. For a given order in perturbation theory, $\{r_{ij}\}_{\{j=1\cdots d_i\}}$ represents a basis of independent group factors.

The choice of basis in (3.6) is not unique. As shown in Ref. 19, there is a special type of basis, called canonical, for which the series (3.6) satisfies a factorization theorem. Let us introduce some notation to recall the definition of a canonical basis. A group factor is an element in the center of the universal enveloping algebra of G, its general form being a trace over products of generators and structure constants with all indices contracted. It may also be represented in terms of diagrams that look like Feynman diagrams in which propagators and three-vertices are attached to a circle in a certain order, which represents the trace. In this way one considers three group-theoretical Feynman rules as the ones depicted in Fig. 3. A canonical basis consists of an independent set of group factors made out of connected diagrams or products of nonoverlapping connected subdiagrams (see Ref. 19 for more details).

The factorization theorem[19] states that (3.6) may be written as an exponentiation over the elements of a canonical basis, which are not the product of connected subdiagrams. These elements are called primitive and (3.6) takes the form:

$$\langle \mathscr{W}_R(C,G)\rangle = \dim R \, \exp\left\{ \sum_{i=0}^{\infty} \sum_{j=1}^{\hat{d}_i} \alpha^c_{ij}(C) r^c_{ij}(R) x^i \right\}. \tag{3.7}$$

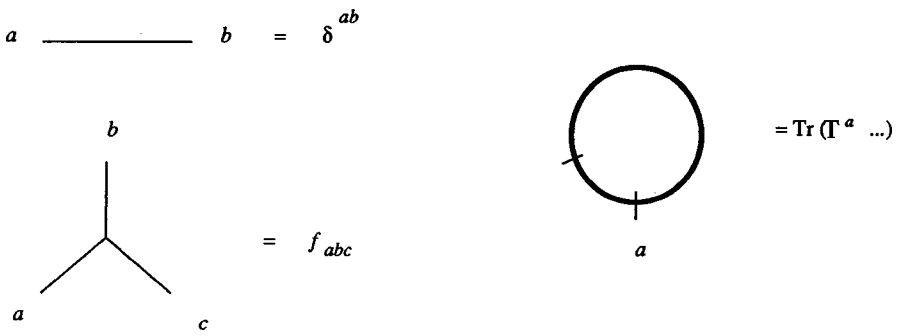

FIG. 3. Group-theoretical rules.

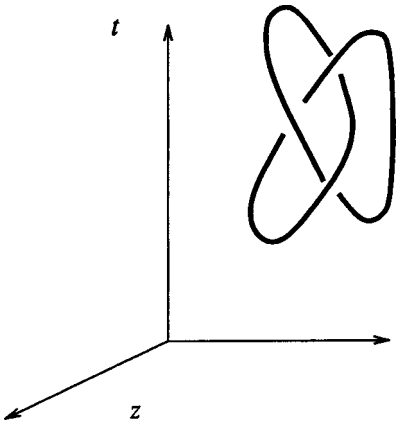

FIG. 4. Example of a Morse knot.

In this expression the superindex c denotes the primitive connected diagrams. The quantities $\alpha_{ij}^{c}(C)$ are their corresponding geometrical factors, which in general are linear combinations of the $\alpha_{ij}(C)$ entering (3.6). In (3.7), $\hat{d}_i$ denotes the number of independent primitive group factors at order i. For a more detailed discussion about the properties of (3.7) we refer the reader to Ref. 19. Here we will recall only a few facts. In the series expansion (3.6) of $\langle \mathscr{W}_R(C,G) \rangle$ there is a class of diagrams that contain at least one collapsible propagator. A propagator is called collapsible whenever its two legs are attached to two points in the oriented path C, which can be considered as the end points of a part of C in which no other propagator is attached. Notice that in the right-hand side of (3.7) all these diagrams have factorized out as the exponentiation of the diagram of order 1, its geometrical factor being $\alpha_{11}^{c}(C)$. The perturbative analysis carried out in the Landau gauge in Ref. 13 demonstrated that if one chooses a canonical basis all the dependence on the framing is contained in $\alpha_{11}^{c}(C)$. In this paper we will show that, as expected, this also holds when the theory is analyzed in the light-cone gauge.

As shown in Refs. 28 and 29, each term of the perturbative series expansion (3.6) is a Vassiliev invariant. The quantities $\alpha_{ij}^{c}(C)$, $i>1$, in the exponential of (3.7) represent a particular choice of a basis of primitive ones. The analysis of the perturbative series expansion of the theory in the light-cone gauge will provide integral expressions for these invariants. Actually, in order to make contact with the Kontsevich integral we are not going to construct the integral expression for the primitive elements $\alpha_{ij}^{c}(C)$, $i>1$. We will not make the choice of a canonical basis except in our discussion on the framing dependence. Instead, we will analyze the perturbative series expansion as it results from the application of the Feynman rules without selecting a particular basis of group factors. As will be shown in the next section, this will lead us to the Kontsevich integral for Vassiliev invariants.

Before entering into the analysis of the perturbative series expansion corresponding to a Wilson loop, we must discuss the potential problems that might be encountered because of the particular form of the gauge-field propagator (3.4). This propagator is singular when its two end points coincide. Actually, it is particularly singular in this situation, because both the numerator and the denominator lead to divergences. This fact tells us that, as in other gauges, one must consider Wilson loops with oriented paths C with no self-intersections. In other words, one must consider knots. However, contrary to covariant gauges, in the light-cone gauge we have two special kinds of singularities, there may be situations in which only one, the numerator or the denominator, leads to a divergence. In order to avoid singularities from the numerators one is forced to avoid paths with sections in which t, the first component of a generic point (t,z) in $\mathbf{R}\times\mathbf{C}$, is constant. This constraint, together with the fact that one is only allowed to consider the non-self-intersecting paths, implies that one must consider paths C, which correspond to Morse knots. A Morse knot in $\mathbf{R}\times\mathbf{C}$ is a knot in which t is a Morse function on it. A Morse knot is characterized by $2n$ extrema, half of them maxima, and the other half minima. An example of a Morse knot is depicted in Fig. 4.

The third potential problem due to the structure of (3.4) comes from situations in which the

two end points of the propagator are close to one of the extrema of a Morse knot since the denominator then vanishes. To solve this problem we will introduce a regularization procedure based on the introduction of a framing for the knot. The resulting invariants will correspond to invariants of framed knots.

IV. THE KONTSEVICH INTEGRAL FOR FRAMED KNOTS

In this section we will apply the Feynman rules derived in the previous section to construct the perturbative series expansion corresponding to a Wilson loop for a Morse knot. As argued before, this requires the introduction of a regularization procedure; this will be achieved by considering framed knots. In the first part of this section we will describe this procedure in detail. In three subsequent subsections we will first prove the finiteness of the resulting perturbative series expansion, then we will extract the framing dependence, and, finally, we will obtain the Kontsevich integral for framed knots.

Let us consider a framed oriented Morse knot K on $\mathbf{R}\times\mathbf{C}$. The framing of K is defined by a vector $m^{\mu}(K)$ normal to K such that along the coordinates $(t(a),z(a))$, $a\in S^1$, which define K, we have another set of coordinates $(t(a),z(a))+\varepsilon(m^0(t,z),m^z(t,z))$, which define a companion knot K_{ε}. For small ε, K_{ε} is also a Morse knot, which does not intersect K and becomes K in the limit $\varepsilon\to 0$. We assign to K_{ε} the orientation that is naturally inherited from K. The framing is characterized by the vector $m^{\mu}(K)$ or, equivalently, by the companion knot K_{ε}. It is natural to associate to each choice of framing the integer number that corresponds to the linking number, l, between K and K_{ε}.

Our regularization of the vacuum expectation value of a Wilson loop is based on the replacement of the propagator (3.4), which is attached to two points on K, by a propagator attached to a point in K and another in K_{ε}. As it is described below, there exists a precise way to carry out this replacement. Certainly, the resulting regularized integrals entering the power series expansion are finite for Morse knots. We have to show that they remain also finite in the limit $\varepsilon\to 0$. Before doing this, let us give full details of how the propagator replacement is carried out.

Let us assume that the Morse knot K possesses $2n$ extrema. There are $2n$ curves k^i, $i=1,\ldots,2n$, joining the different maxima and minima of K. For each curve k^i there is a one-to-one correspondence between points on k^i and the values that the variable t takes. The Morse knot can therefore be regarded as a complex multivalued function of the variable t with $2n$ components, each one corresponding to a curve k^i, which is completely labeled by the values that the complex variable z takes in k^i as a function of t. One can think of two different parametrizations of K, the previous one: $(t(a),z(a))$, $a\in S^1$, and a new one: $z^i(t)$, $t\in I^i$, $i=1,\ldots,2n$, where $I^i=[t_i^-,t_i^+]$ is the segment of $\mathbf{R}$ whose end points are the values that the coordinate t takes at the two extrema joined by the curve k^i. A similar analysis can be done for the companion knot K_{ε}. It also possesses $2n$ extrema and $2n$ curves k_{ε}^i, parametrized by $z_i'(t)$, $t\in I_{\varepsilon}^i$, $i=1,\ldots,2n$.

It is convenient to trade the integrations along the S^1 parameter a of K by integrations over the height parameter t. Let us consider a propagator attached to the curves k^i and k^j. Using (3.4), it is easy to show that for such a propagator:

$$dx^{\mu}dx^{\nu}\langle A_{\mu}^{a}(x)A_{\nu}^{b}(x')\rangle\to\frac{1}{2\pi i}\,dt_i dt_j\delta(t_i-t_j)p_{ij}\,\frac{\dot{z}_i(t_i)-\dot{z}_j(t_j)}{z_i(t_i)-z_j(t_j)},\tag{4.1}$$

where

$$p_{ij}=\begin{cases}1 & \text{if } k_i \text{ and } k_j \text{ have the same orientation}\\ -1 & \text{if } k_i \text{ and } k_j \text{ have opposite orientations.}\end{cases}\tag{4.2}$$

The propagators (4.1) may appear attached to two points lying on different curves k^i and k^j, $i\neq j$, or to two points lying on the same curve k^i. In the second case the regularization consists of just replacing one of the points on k^i of the propagator by a point on k_{ε}^i. Since the delta function in the propagator (4.1) implies that its two end points must be at the same height, there is no ambiguity in doing this. Notice, however, that in this case, since we have a path-ordered integration, when evaluating the delta function in (4.1) we must take into account the appearance of a factor 1/2. In the first case, $i\neq j$, one uses the same procedure, namely one of the end points is

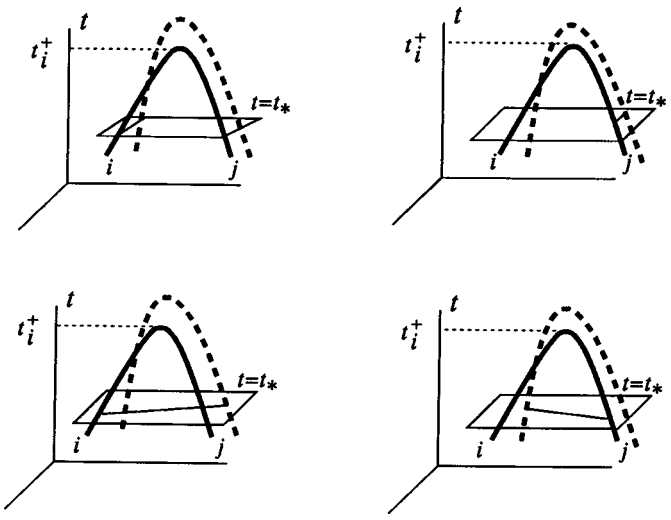

FIG. 5. Generic divergent contributions.

attached to the curve corresponding to the companion knot. However, there are now two possible ways of doing this. We will use the following prescription: we will add both possibilities and multiply the result by a factor 1/2. For the same reasons as in the second case, this last step is well defined. Notice that in this case there is no additional factor 1/2 after the evaluation of the delta functions, since the variables of integration in each curve are now free.

The regularization prescription leads to the following formulas for the propagator (4.1). For $i=j$:

$$\frac{1}{2\pi i}\frac{1}{2}\,ds\,\frac{\dot{z}_i(s)-\dot{z}_i'(s)}{z_i(s)-z_i'(s)}, \tag{4.3}$$

while for $i\neq j$:

$$\frac{1}{2\pi i}\frac{1}{2}\,ds\left(\frac{\dot{z}_i(s)-\dot{z}_j'(s)}{z_i(s)-z_j'(s)}+\frac{\dot{z}_i'(s)-\dot{z}_j(s)}{z_i'(s)-z_j(s)}\right)p_{ij}\,. \tag{4.4}$$

A. Finiteness

We will now prove that our prescription is finite in the limit $\varepsilon\to 0$. There are four sources of singularities. All originate when the two end points of a propagator are near an extremum. We will describe the situation for the case in which this extremum is a maximum, but it will become clear that a similar analysis can be carried out in the case in which it corresponds to a minimum. The four configurations that lead to divergences are depicted in Fig. 5. We have drawn only the part of K around the maximum. We will assume that the rest of the diagram is the same in the four cases. Let us compute the four contributions after integrating from t_* to t_i^+. Using (4.3) and (4.4) one finds, after adding them up:

$$\frac{1}{2\pi i}\frac{1}{2}\log\frac{(z_i(s)-z_i'(s))(z_j(s)-z_j'(s))}{(z_i(s)-z_j'(s))(z_i'(s)-z_j(s))}\bigg|_{s=t}^{s=t_i^+}. \tag{4.5}$$

The most dangerous contribution is the one coming from the upper limit. However, since $|z_i(t_i^+)-z_i'(t_i^+)|=|z_j(t_i^+)-z_i'(t_i^+)|=\varepsilon$, and $|z_i(t_i^+)-z_j'(t_i^+)|=|z_j(t_i^+)-z_j'(t_i^+)|=\varepsilon$, one finds a cancellation of divergences in the limit $\varepsilon\to 0$ and therefore the contribution is finite. One also encounters divergences from the lower limit of (4.5) in the $\varepsilon\to 0$ limit. However, these divergences cancel against the ones originated after integration under the height t_*. One is therefore left with a term of the form:

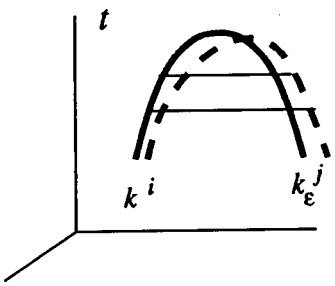

FIG. 6. Higher-order divergent contributions.

$$-\frac{1}{2\pi i}\frac{1}{2}\log((z_i(t_*)-z_j'))(z_i'(t_*)-z_j(t_*))), \tag{4.6}$$

which has to be taken into account when integrating over t_*. Notice that (4.6) is finite in the limit $\varepsilon\to 0$ for values of t_* away from t_i^+, but it diverges when t_* approaches t_i^+. However, this divergence is too soft and it does not generate singularities in the integration, except in situations of the kind depicted in Fig. 6. All the contributions of this type will be treated below when analyzing the factorization of the framing dependence, and it will be shown that all possible divergences cancel out. We can therefore affirm that the perturbative series expansion corresponding to a Morse knot is finite in the limit $\varepsilon\to 0$.

B. The framing contribution

In this section we are going to compute the lowest-order contribution to the perturbative series expansion of the vacuum expectation value of a Wilson loop. Using the factorization theorem discussed in Sec. III, we will obtain the full dependence on the framing. Our result can be stated very simply: if K is a framed Morse knot:

$$\langle \mathscr{W}_R(K,G)\rangle = e^{2\pi i l h}\langle \mathscr{W}_R(K,G)\rangle', \tag{4.7}$$

where $h=\mathrm{Tr}(T^a_{(R)}T^a_{(R)})/k$, l is the linking number between K and its companion knot K_e, and $\langle \mathscr{W}_R(K,G)\rangle'$ is a framing-independent quantity. This result agrees with the one found nonperturbatively,[1] and in covariant gauges.[13]

The lowest-order contribution to the perturbative series expansion has the form:

$$ig^2\frac{1}{2\pi i}\frac{1}{2}\mathrm{Tr}(T^a_{(R)}T^a_{(R)})\sum_{i,j=1}^{2n}\int_{\max\{t_i^-,t_j^-\}}^{\min\{t_i^+,t_j^+\}} ds\,\frac{\dot z_i(s)-\dot z_j'(s)}{z_i(s)-z_j'(s)}\,p_{ij}. \tag{4.8}$$

Notice that, owing to the prescription (4.4), the sum is over all possible values of i and j and not only for $i\leqslant j$. The factor i in front of this expression is due to the fact that one is considering the functional integral of i times the action (2.7). In general, in the perturbative series expansion, one must include a factor i for each power of g^2. According to our previous arguments, the integral (4.8) is certainly finite in the limit $\varepsilon\to 0$. Actually it can be computed very easily. The key observation is that an integral of the form

$$\int_{t_*}^{t'_*} ds\,\frac{\dot z_i(s)-\dot z_j'(s)}{z_i(s)-z_j'(s)} \tag{4.9}$$

develops an imaginary part, which counts the number of times that the curve k_e^j winds around the curve k^i, times 2π. The real parts just cancel with each other, following a mechanism similar to the one described in our proof of finiteness. After summing over all the values of i, the contribution from the integral in (4.8) for $i=j$ is just $2\pi i$ times the twist tw of the band made by the two knots K and K_e, i.e., the number of times that the band twists around itself. The basic contributions to tw are shown in Fig. 7. The analysis of the contributions from $i\neq j$ is very similar. The real parts cancel among themselves and some of the real contributions from the case $i=j$, as

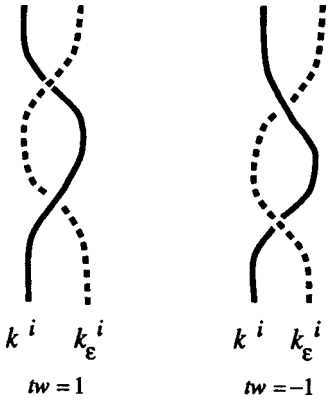

FIG. 7. Basic contributions to the twist of a framed knot.

described in the proof of finiteness. The imaginary parts now count the number of times that the curve k^i twists around the curve k^j, times 2π. Certainly, for this counting one can take the limit $\varepsilon \to 0$. If the Morse knot K is viewed in such a way that its projection in the plane corresponding to Im $z=0$ contains only single crossings, one can compute the contribution just assigning values $\pm 1/2$ to the two types of crossings shown in Fig. 8. The result of performing the integral in (4.8) is precisely $2\pi i$ times the writhe w of the knot K for that given view. Notice that although we get factors of modulus 1/2 from each crossing, they are counted twice in (4.8). Thus the full contribution from (4.8) is

$$ig^2 \tfrac{1}{2} \operatorname{Tr}(T^a_{(R)} T^a_{(R)})(w+tw) = 2\pi i h l \tag{4.10}$$

since $l = w + tw$. In obtaining (4.10) we have used $g^2 = 4\pi/k$. Recall that $h = \operatorname{Tr}(T^a_{(R)} T^a_{(R)})/k$. Notice that, although w and tw depend on the view of the knot K, their combination l, the linking number between K and K_ε, is independent of it.

As shown in previous works,[13,19] the contribution found at first order exponentiates if one considers a canonical basis. Let us describe the reasons for this exponentiation by analyzing what occurs at next order in perturbation theory. At second order one encounters the two group factors corresponding to the Feynman diagrams shown in Fig. 9. Diagrams *a* and *b* share the same group factor:

$$\operatorname{Tr}(T^a_{(R)} T^a_{(R)} T^b_{(R)} T^b_{(R)}), \tag{4.11}$$

while diagram *c* possesses a different one:

$$\operatorname{Tr}(T^a_{(R)} T^b_{(R)} T^a_{(R)} T^b_{(R)}). \tag{4.12}$$

If one decomposes this group factor in terms of the first one and a new group factor using the commutation relations (2.3):

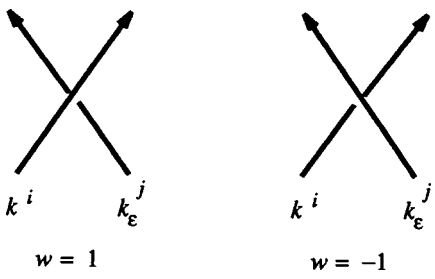

FIG. 8. Basic contributions to the writhe.

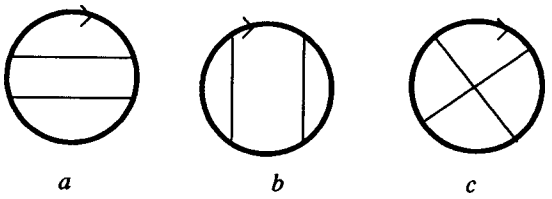

FIG. 9. Feynman diagrams contributing at second order.

$$\mathrm{Tr}(T^a_{(R)}T^b_{(R)}T^a_{(R)}T^b_{(R)}) = \mathrm{Tr}(T^a_{(R)}T^b_{(R)}T^b_{(R)}T^a_{(R)}) - f_{abc}\ \mathrm{Tr}(T^a_{(R)}T^b_{(R)}T^c_{(R)}), \tag{4.13}$$

the full sum of the geometrical terms multiplying the first group factor can be written as 1/2 times a product of integrations over contributions coming from a single propagator. It precisely gives the second-order term of the exponential of (4.10). A similar rearrangement can be done at any order. Notice that in order to extract the terms building the exponential of (4.10) one modifies the group factors that remain in the rest. This mechanism is encoded in the factorization theorem.[19] Recall that in our analysis of finiteness we postponed the discussion on the cancellation of divergences from diagrams as the one in Fig. 6. Now is the moment to discuss that issue. These diagrams are indeed the ones having group factors as (4.11). Together with the ones coming after rearranging group factors as done in (4.13), after adding them up, one obtains an expression that can be written as a product of the contribution from the first order. Since that first-order contribution is finite, the contribution at any arbitrary higher order is also finite. Notice also that this argument shows that all the dependence on the framing is contained in the exponential factor and therefore we can affirm that (4.7) holds. Indeed all the potential dependence on the framing must come from diagrams that lead to divergences. As we have seen, these diagrams only contribute to the exponential factor in (4.7). This behavior is entirely similar to that occurring in the Landau gauge.[13]

C. The Kontsevich integral

In this section we will prove that the perturbative series expansion for the vacuum expectation value of the Wilson loop contains the Kontsevich integral for framed knots as presented in Ref. 25.

Let us begin by writing all the contributions to a given order m. To carry this out we must consider all possible ways of connecting $2m$ points on the Morse knot by m propagators, following the regularization prescription described in the previous section, i.e., with one point of the propagator attached to K and the other to its companion knot K_ε, and then path-order integrating. The path-order integration can be split into a sum such that enters in each term a path-ordered integration along $2m$ curves among the set k^i, k^i_ε, $i=1,...,2n$. This set of curves builds the Morse knot under consideration. A given term in this sum might contain propagators joining k^i and k^i_ε. In this case one must introduce a factor 1/2 as explained in our discussion leading to (4.3). The contributions coming from propagators joining k^i and k^j_ε, with $i\neq j$, have also a factor 1/2 due to the double counting, as explained in the discussion of Eq. (4.4). Accordingly, propagators joining different curves must be replaced by 1/2 the sum of their two possible choices of attaching their end points.

To each rearrangement of the m propagators corresponds a group factor. These are easily obtained using the group-theoretical Feynman rules shown in Fig. 3. To fix ideas we will present in detail the second-order contribution, $m=2$, for a particular group factor. For $m=2$ one must take into consideration the two group factors (4.11) and (4.12). As discussed above, the group factor (4.11) is associated to the framing dependence. We will analyze the contribution corresponding to the group factor (4.12). This contribution is of the form

$$(ig)^2\int_0^1 ds_1\int_{s_1}^1 ds_2\int_{s_2}^1 ds_3\int_{s_3}^1 ds_4\dot{x}^{\mu_1}(s_1)\dot{x}^{\mu_2}(s_2)\dot{x}^{\mu_3}(s_3)\dot{x}^{\mu_4}(s_4\times\langle A^{a_1}_{\mu_1}(x(s_1))A^{a_3}_{\mu_3}(x(s_3))\rangle$$
$$\times\langle A^{a_2}_{\mu_2}(x(s_2))A^{a_4}_{\mu_4}(x(s_4))\rangle\mathrm{Tr}(T^{a_1}T^{a_2}T^{a_3}T^{a_4}). \tag{4.14}$$

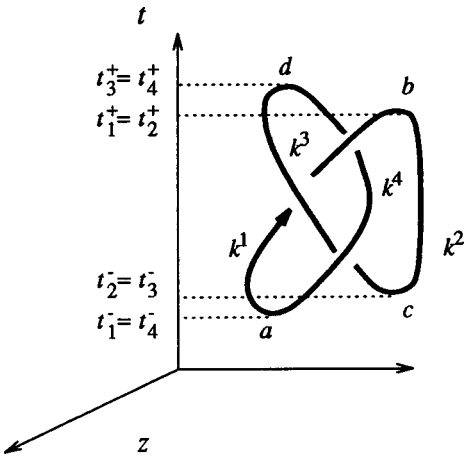

FIG. 10. Labeled trefoil knot.

We will now write more explicitly this multiple integral taking into account the form of the propagator (3.4). The delta function in this propagator imposes very strong restrictions on the possible contributions. Its presence implies that the only nonvanishing configurations are those in which the two end points of each propagator are at the same height. To be more concrete let us consider the computation of (4.14) for the trefoil knot shown in Fig. 10. This knot is made out of four curves, k^1, k^2, k^3, and k^4, whose end points are the four critical points a, b, c, and d. The heights of these critical points are

$$a \to t_1^- = t_4^- , \quad b \to t_1^+ = t_2^+ , \quad c \to t_2^- = t_3^- , \quad d \to t_3^+ = t_4^+ . \tag{41.5}$$

They are depicted in Fig. 10.

To obtain all the contributions we will divide in four parts the circle that represents the knot in Fig. 10. Then we will join these parts by lines representing the propagators, taking into account the ordering of the four points to which they are attached. This ordering and the delta function in the height imply that no line can have its two end points attached to the same part. They also imply that there are no contributions in which two end points of different lines are attached to one part and the other two to another part. The only possibilities are shown in Fig. 11. There is a total of eight contributions. Notice that this result is general for any Morse knot made out of four curves. The contributions are easily depicted on the knot itself as shown in Fig. 12. For each contribution,

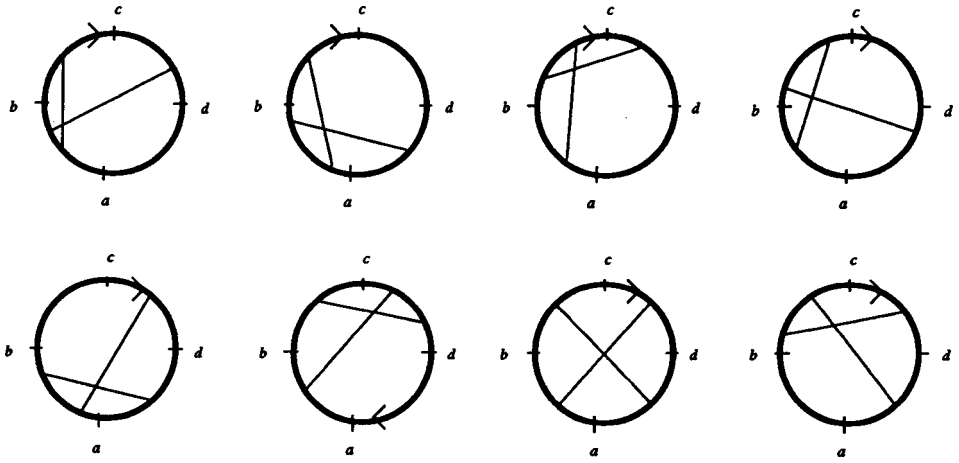

FIG. 11. Contributions to a Morse knot made out of four curves.

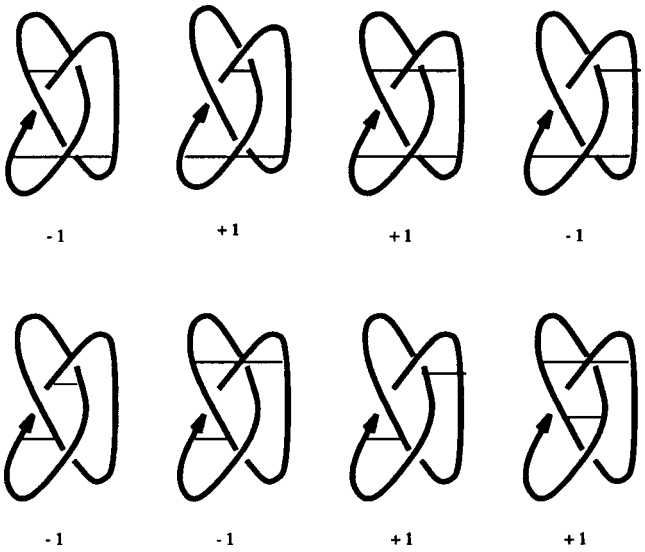

FIG. 12. Contributions corresponding to the trefoil knot.

one must compute a sign, which is the product of the p_{ij} in (4.2). The resulting signs are displayed in Fig. 12. To be more explicit, let us write, for example, the integral associated to the first contribution. It takes the form

$$(ig)^2 \frac{1}{(2\pi i)^2} \frac{1}{2^2} \int_{t_2^- < s_1 < s_2 < t_1^+} ds_1 ds_2 \times \left(\frac{\dot{z}_1(s_1) - \dot{z}_2'(s_1)}{z_1(s_1) - z_2'(s_1)} + \frac{\dot{z}_1'(s_1) - \dot{z}_2(s_1)}{z_1'(s_1) - z_2(s_1)} \right) \left(\frac{\dot{z}_3(s_2) - \dot{z}_1'(s_2)}{z_3(s_2) - z_1'(s_2)} + \frac{\dot{z}_3'(s_2) - \dot{z}_1(s_2)}{z_3'(s_2) - z_1(s_2)} \right). \quad (4.16)$$

Similar expressions can be easily written for the rest of the contributions depicted in Fig. 12. The data entering in the double integral (4.16) are shown in Fig. 13. Notice that this integral is not divergent if we take the limit $\varepsilon \to 0$ before performing the integration. This feature is common to all the contributions corresponding to the group factor under consideration. As shown in our discussion on finiteness, only the contributions related to framing are potentially divergent. One could therefore remove in (4.16) the terms with primes and the factor $1/2^2$. The integral to be computed takes the form:

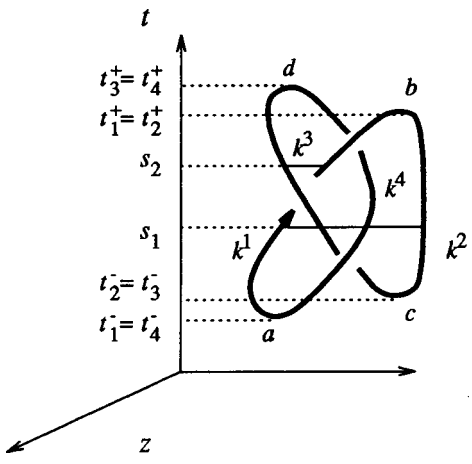

FIG. 13. Details on the labeling of one of the contributions.

$$(ig)^2 \frac{1}{(2\pi i)^2} \int_{t_2^- < s_1 < s_2 < t_1^+} ds_1 ds_2 \frac{\dot{z}_1(s_1) - \dot{z}_2(s_1)}{z_1(s_1) - \dot{z}_2(s_1)} \frac{\dot{z}_3(s_2) - \dot{z}_1(s_2)}{z_3(s_2) - z_1(s_2)}. \tag{4.17}$$

One of the two integrations can easily be performed, leading to

$$(ig)^2 \frac{1}{(2\pi i)^2} \int_{t_2^- < s_2 < t_1^+} ds_2 \log\left(\frac{z_1(s_2) - z_2(s_2)}{z_1(t_2^-) - z_2(t_2^-)} \right) \frac{\dot{z}_3(s_2) - \dot{z}_1(s_2)}{z_3(s_2) - z_1(s_2)}. \tag{4.18}$$

Notice that, as argued before, this integral is finite. Although z_1 and z_2 get close to each other when $s_2 \to t_1^+$, the singularity in the integrand, being logarithmic, is too mild to lead to a divergent result. Expressions similar to (4.18) can easily be obtained for the rest of the contributions depicted in Fig. 12.

We are now in a position to write the form of the general contribution originated from the Feynman rules of the theory. Notice that the most significant fact of our previous discussion is the presence of the delta function in the height of the propagator (3.4). It implies that the only nonvanishing configurations of the propagators are those in which their two end points have the same height; in other words, only contributions in which the line representing the propagator is horizontal do not vanish. This observation allows us to rearrange the contributions to the perturbative series expansion in the following way. Consider all possible pairings $\{z_i(s), z_j'(s)\}$ of curves k^i and k_ε^j, $i,j = 1,...,2n$, where $2n$ is the number of extrema of the Morse knot under consideration. A contribution at order m in perturbation theory will involve a path-ordered integral in the heights $s_1 < \cdots < s_r < \cdots < s_m$ of a product of m propagators of the form (4.3) and (4.4):

$$\prod_{r=1}^{m} \frac{dz_{i_r}(s_r) - dz'_{j_r}(s_r)}{z_{i_r}(s_r) - z'_{j_r}(s_r)}. \tag{4.19}$$

This product is characterized by a set of m ordered pairings, each one labeled by a pair of numbers (i_r, j_r) with $r = 1,...,m$. We will denote an ordered pairing of m propagators generically by P_m. One must take into account all possible ordered pairings, i.e., one must sum over all the possible P_m. The group factor that corresponds to each ordered pairing P_m is simply obtained by placing the group generators at the end points of the propagators and taking the trace of the product, which results after traveling along the knot. The resulting group factor will be denoted by $R(P_m)$.

Another ingredient in (4.4) that must be taken into account is the factor p_{ij}. For each pairing $P_m = \{(i_r, j_r), r = 1,...,m\}$ there will be a contribution from their product. Certainly, the result will be a sign that will depend on the ordered pairing P_m. We will denote such a product by

$$s(P_m) = \prod_{r=1}^{m} p_{i_r j_r}. \tag{4.20}$$

We are now in a position to write the full expression for the contribution to the perturbative series expansion at order m. It takes the form

$$(ig^2)^m \left(\frac{1}{2\pi i} \right)^m \frac{1}{2^m} \sum_{P_m} \int_{t_{P_m}^- < t_1 < \cdots < t_r < \cdots < t_m < t_{P_m}^+} s(P_m) \prod_{r=1}^{m} \frac{dz_{i_r}(t_r) - dz'_{j_r}(t_r)}{z_{i_r}(t_r) - z'_{j_r}(t_r)} R(P_m), \tag{4.21}$$

where $t_{P_m}^+$ and $t_{P_m}^-$ are highest and lowest heights, which can be reached by the last and first propagators of a given ordered pairing P_m. This expression corresponds to the Kontsevich integral for framed knots as presented in Ref. 25.

V. CONCLUSIONS AND OPEN PROBLEMS

In this paper we have presented an analysis of Chern–Simons gauge theory in the light-cone gauge from a perturbative point of view. As it became clear in our discussion in Sec. III, only vacuum expectation values associated to Morse knots are suitable for calculation in the light-cone

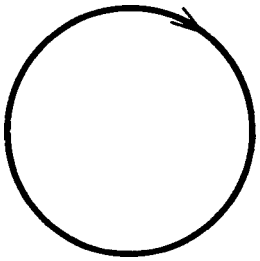

FIG. 14. Unknot with two critical points.

gauge, at least if no additional regularization to the one considered in the paper is introduced. We have shown that the regularization prescription leads to the consideration of framed knots, and that the vacuum expectation value possesses a dependence on the framing that agrees with the ones appearing in other gauges and in the nonperturbative analysis of the theory. We have also shown that the perturbative series expansion contains the Kontsevich integral for framed knots.

Our results, however, demonstrate that something has been missed in the perturbative series expansion. Indeed, contrary to what is obtained in other gauges or in nonperturbative approaches, according to our result (4.21), the vacuum expectation value corresponding to the unknot shown in Fig. 14 carrying a representation R of the gauge group is just dim R (in the trivial framing). In other words, all the contributions in (4.21) vanish and one is left with the zeroth-order contribution, which is just dim R. Actually, the expression (4.21) does not lead to knot invariants. It is well known[24] that the Kontsevich integral is only invariant under deformations of the knot which preserve the number of critical points. To obtain a truly invariant quantity one must take into account a correction to the sum of the contributions (4.21). If we denote by $Z_m(K,K_\varepsilon)$ the contribution shown in (4.21) (order m), the quantity that leads to a knot invariant is[24]

$$\frac{\dim R+\Sigma_{m=1}^{\infty} Z_m(K,K_\varepsilon)}{(1+(1/\dim R)\Sigma_{m=1}^{\infty} Z_m(U,U_\varepsilon))^{n/2}}, \tag{5.1}$$

where U and U_ε are the unknots shown in Fig. 15, and n is the number of critical points of the knot K. The coefficients of the powers of g in this expression are Vassiliev invariants.

The fact that the perturbative series expansion corresponding to the terms (4.21) is not invariant under all kinds of deformations of the knot is something that one could have expected. As discussed in Sec. III, the perturbative construction fails for knots that are not of the Morse type. In a deformation of the knot in which the number of critical points is changed, one has to consider at some intermediate step a knot that is not of the Morse type. The analysis presented here is not applicable to that situation and it is therefore consistent to find that the final expression for the perturbative expansion is not invariant under those types of deformations. A very interesting problem is to understand, from the point of view of Chern–Simons gauge theory, why the de-

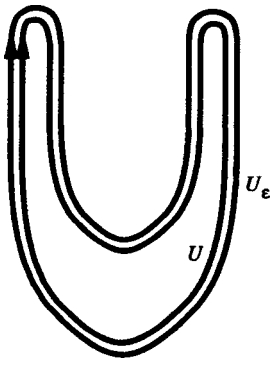

FIG. 15. Unknots U and U_ϵ with four critical points.

nominator of (5.1) has to be included there. Presumably, this would reconcile the results obtained here with the ones from covariant gauges and from nonperturbative approaches. This and other related issues are at present under investigation.

A Lie algebra for closed strings, spin chains, and gauge theories

C.-W. H. Lee[a] and S. G. Rajeev[b]
Department of Physics and Astronomy, University of Rochester, Rochester, New York 14627

(Received 23 January 1998; accepted for publication 21 May 1998)

We consider quantum dynamical systems whose degrees of freedom are described by $N\times N$ matrices, in the planar limit $N\to\infty$. Examples are gauge theories and the M(atrix)-theory of strings. States invariant under U(N) are ''closed strings,'' modeled by traces of products of matrices. We have discovered that the U(N)-invariant operators acting on both open and closed string states form a remarkable new Lie algebra which we will call the heterix algebra. (The simplest special case, with one degree of freedom, is an extension of the Virasoro algebra by the infinite-dimensional general linear algebra.) Furthermore, these operators acting on closed string states only form a quotient algebra of the heterix algebra. We will call this quotient algebra the cyclix algebra. We express the Hamiltonian of some gauge field theories (like those with adjoint matter fields and dimensionally reduced pure QCD models) as elements of this Lie algebra. Finally, we apply this cyclix algebra to establish an isomorphism between certain planar matrix models and quantum spin chain systems. Thus we obtain some matrix models solvable in the planar limit; e.g., matrix models associated with the Ising model, the XYZ model, models satisfying the Dolan–Grady condition and the chiral Potts model. Thus our cyclix Lie algebra describes the dynamical symmetries of quantum spin chain systems, large-N gauge field theories, and the M(atrix)-theory of strings. © *1998 American Institute of Physics.* [S0022-2488(98)01810-6]

I. NTRODUCTION

The string is emerging as a verstile concept in physics, second only to the notion of a particle in its usefulness. The instantaneous configuration of a string can be thought of roughly as a curve in space, with an energy proportional to its length. The curve may be closed, or open with some extra degrees of freedom stuck at its endpoints. The string is being intensely studied as the fundamental object in the quantum theory of gravity and perhaps even the unified theory of all forces of nature.

The modern notion of a relativistic string theory originated in attempts to understand hadron dynamics, in the 1960s and early 1970s. However, it is now established that quantum chromodynamics (QCD) is the fundamental theory of strong interactions: the hadrons are not elementary particles but instead are bound states of quarks and gluons. In spite of this, attempts to understand hadron dynamics in terms of strings have not altogether ceased. Many features of hadron dynamics which originally prompted people to construct the string theory still do not have a satisfactory explanation. For example, the squares of the masses of hadrons increase linearly with their angular momenta, a characteristic property of strings. Indeed, it seems very plausible that there is a version of string theory which is equivalent to QCD but that directly describes hadrons. (Such a theory has been constructed in two dimensions.[1]) Since the gluon degrees of freedom are represented by matrices, this suggests that at least this type of string can be thought of as made of more elementary entities described by products of matrices. Connections to noncommutative geometry are also natural, as suggested in Ref. 2.

Meanwhile, in recent years the strings that appear in theories of quantum gravity have also

[a]Electronic mail: cwhlee@pas.rochester.edu
[b]Electronic mail: rajeev@pas.rochester.edu

 © 1998 American Institute of Physics

come to be seen as made of more elemental objects (''string bits''[3,4]), again described by matrices.[5,6] Indeed the underlying mathematical structures have much in common with earlier work on QCD with some extra symmetries (such as supersymmetry) added. These M(atrix)-theories are thought to describe not only stringlike excitations but also M(embranes) and are collectively known as the M-theory. The underlying symmetries and geometrical significance of this theory still remain M(ysterious).

Both of the above applications of string theory involve fundamental degrees of freedom represented by $N\times N$ matrices. In both cases the limit $N\to\infty$ is important, as it simplifies many issues. There are, in fact, many inequivalent ways of letting N go to infinity, the simplest one is the so-called planar large-N limit. It is called as such because it was originally[7] constructed by summing Feynman diagrams which have planar topology. (Other limits such as the double scaling limit which gives the continuum string theory are of interest as well.) We view this planar limit as a linear approximation to the general large-N limit discussed in Ref. 8.

Thus, the understanding of the quantum matrix models is of fundamental importance to modern theoretical physics. The two great challenges of theoretical physics — that of understanding hadron dynamics and that of developing a quantum theory of gravity — are both intertwined with the dynamics of quantum matrix models.

We have discovered the fundamental dynamical symmetry of matrix models in the large-N limit: it is a remarkable new Lie algebra which we will call the heterix algebra. It is thus the algebra of symmetries that will help us solve both of the two great problems of theoretical physics. In addition, we will find a connection to a third branch of theoretical physics: we can understand the solvability of quantum spin chain models within the formalism of the heterix algebra.

The outline of this paper is as follows. In Sec. II, we will introduce heterix algebra axiomatically. We will also discuss aspects of its structure such as its Cartan subalgebra and root vectors. In particular, we will show that this Lie algebra is an extension of another Lie algebra by $gl_{+\infty}$.[9] In Sec. III, we will study the simplest heterix algebra in which there is only one degree of freedom. It will turn out that the noncommutative algebra is simplified to the Virasoro algebra. Thus our algebra can be viewed as a generalization of the Virasoro algebra. In Sec. IV, we will show that gauge-invariant observables in the planar large-N limit can be formulated in terms of the elements of this algebra. Moreover, closed string bit states in this large-N limit provide a representation for this Lie algebra. However, this representation is not faithful and thus there are many relations among some elements of this algebra. We will quotient out these relations and get another Lie algebra — the cyclix algebra.[10]

In Sec. V, we will discuss the applications of the cyclix algebra to various gauge field theories, which, in the planar large-N limit, are multi-matrix models. In Sec. VI, we will construct more tractable multi-matrix models with the aid of quantum spin chain models. In addition, we will find that we can understand the solvability of quantum spin chain models within the formalism of the cyclix algebra.

II. THE HETERIX LIE ALGEBRA

In this section we will give a self-contained definition of a certain Lie algebra, which we will call the heterix algebra. In a latter section we will see that closed string operators provide a representation for this algebra, albeit an unfaithful one. The defining representation in this section is on the combined state space of open and closed strings and is, of course, faithful.

Define a complex vector space $\mathcal{T}_{op}$ of *finite* linear combinations of orthogonal states of an open string: $s^L=s^{l_1l_2\cdots l_d}$. (See Appendix A for a more detailed explanation of the notation.) This is just the space of all tensors (with no particular symmetry properties) on the complex vector space C^Λ:

$$\mathcal{T}_{op}=\oplus_{r=1}^{\infty}\otimes^r C^\Lambda. \tag{1}$$

This vector space should be thought of as the space of states of an open string propagating in a discrete model of space–time with Λ points. In addition define $\mathcal{T}_c$ of finite linear combinations of orthogonal states $\Psi^{(K)}=\Psi^{(k_1\cdots k_c)}$ labelled by cyclically symmetric indices. Thus $\mathcal{T}_c$ is the space of *cyclically symmetric tensors* on C^Λ and should be viewed as the space of states of a closed string propagating in discretized space. Our Lie algebra will be defined by the commutators of some

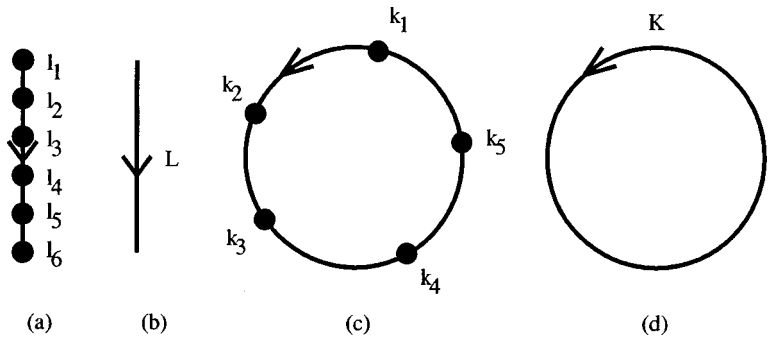

FIG. 1. (a) A typical open string state s^L in detail. There is a series of 6 indices l_1, l_2, ..., and l_6. Each index is represented by a solid bead. These solid beads are connected by thick lines (in contrast with the thin lines in latter figures). The arrow indicates the direction of the integer sequence L. (b) An open string state in brief. The beads are omitted. They will be consistently omitted in all ensuing brief figures. The integer sequence is represented by the letter L. The length of the line does not indicate the number of indices the line carries. (c) A typical closed string state $\Psi^{(K)}$ with five indices in detail. There is a series of indices k_1, k_2, ..., and k_5. Notice the cyclic symmetry of this state. (d) A closed string state in brief. The state is represented by the equivalence class (K), but in the figure we simply label the state as K. The size of the circle does not indicate the number of indices the circle carries.

operators on the total space of closed and open strings $\mathcal{T}=\mathcal{T}_c\oplus\mathcal{T}_{op}$. Thus $\mathcal{T}$ has an orthogonal basis $\{\Psi^{(K)},s^L\}$ as (K) ranges over (nonempty) equivalence classes of cyclically symmetric sequences and L over all nonempty sequences. Typical open and closed string states are illustrated in Fig. 1. [The reader can compare Figs. 1(a) and 1(b) with Figs. 1(a) and 1(b) in Ref. 11.]

Now let us introduce some operators that act on these states. Define the operator $\tilde{f}^{(I)}_{(J)}$ by its action on $\mathcal{T}$ as follows:

$$\tilde{f}^{(I)}_{(J)}\Psi^{(K)}=\delta^K_{(J)}\Psi^{(I)} \quad \text{and} \quad \tilde{f}^{(I)}_{(J)}s^L=0. \tag{2}$$

This operator just converts the closed string state $\Psi^{(K)}$ to $\Psi^{(I)}$, with a multiplicative factor which is the number of cyclic permutations of K that is equal to J. It gives zero if there are no such permutations or if it acts on an open string state. Clearly $\tilde{f}^{(I)}_{(J)}$ is a finite rank operator. The operator $\tilde{f}^{(I)}_{(J)}$ is shown pictorially in Fig. 2. Also shown in the same figure is the action of $\tilde{f}^{(I)}_{(J)}$ on $\Psi^{(K)}$.

In addition let us define the operator γ^I_J by its actions on closed strings,

$$\gamma^I_J\Psi^{(K)}=\delta^K_{(J)}\Psi^{(I)}+\sum_{K_1K_2=(K)}\delta^{K_1}_J\Psi^{(IK_2)}, \tag{3}$$

and on open strings as shown:

$$\gamma^I_Js^L=\delta^L_Js^I+\sum_{L_1L_2=L}\delta^{L_1}_Js^{IL_2}+\sum_{L_1L_2=L}\delta^{L_2}_Js^{L_1I}+\sum_{L_1L_2L_3=L}\delta^{L_2}_Js^{L_1IL_3}. \tag{4}$$

Clearly, it is the direct sum of an operator g^I_J acting on closed strings and σ^I_J acting on open strings: $\gamma^I_J=g^I_J\oplus\sigma^I_J$. Here σ^I_J has been defined in a previous paper.[11] These operators are not finite rank, unlike the $\tilde{f}^{(I)}_{(J)}$; indeed they are not even bounded.

Let us describe Eq. (3) in words. Regard (K) as a circle of points labelled by positive integers. If J has more indices than K, then the action of γ^I_J on $\Psi^{(K)}$ gives zero. When J is shorter than K, each segment of K that is identical to J is replaced with I and then a sum over all the resultant terms is taken. This is done even if some of the segments agreeing with J overlap partially with each other. If J does not overlap with any segment of K, then we get zero.

Next, consider the case when the length of J is the same as that of K, i.e., $\#(J)=\#(K)=c$. Then we get zero if no cyclic permutation of J agrees with K; otherwise, we replace K with I and multiply $\Phi^{(I)}$ by the number of cyclic permutatations of K that agree with J.

Equation (3) is illustrated in Fig. 3. Using the identities in Appendix A, Eq. (3) can be rewritten as

$$\gamma_J^I \Psi^{(K)} = \delta_{(J)}^K \Psi^{(I)} + \sum_A \delta_{(JA)}^K \Psi^{(IA)}. \tag{5}$$

This form is more convenient for some calculations.

We can understand Eq. (4) analogously. Again, if J is longer than K, we get zero. Otherwise, each segment of K that agrees with J is replaced with I and a sum over all such resultants is taken. The first term represents the case when J is identical to K; the second when J agrees with the beginning of K; the third when J agrees with the end of K; and the last term, which is the ''generic'' one, describes the case when J agrees with some segment in the middle of K. Of course we get zero if there is no segment of K that agrees with J. Equation (4) is depicted in Fig. 4.

The reader can notice from the figures an analogy between the action of our operators on states and the action of some viruses on DNA molecules.

Altogether, $\{\tilde{f}_{(J)}^{(I)}, \gamma_J^I\}$ is a linearly independent set of operators. This fact, the proof of which can be found in Appendix B, is of some importance, as we will define a Lie algebra with this set as a basis soon. The operators g_J^I acting on closed string states alone do not form a linearly independent set, however. We will derive some relations among them in a later section.

The product of two operators $\tilde{f}_{(J)}^{(I)}, \tilde{f}_{(L)}^{(K)}$ is a finite linear combination of such operators. Moreover, the $\tilde{f}_{(J)}^{(I)}$'s are linearly independent so that they span an associative algebra. Their commuta-

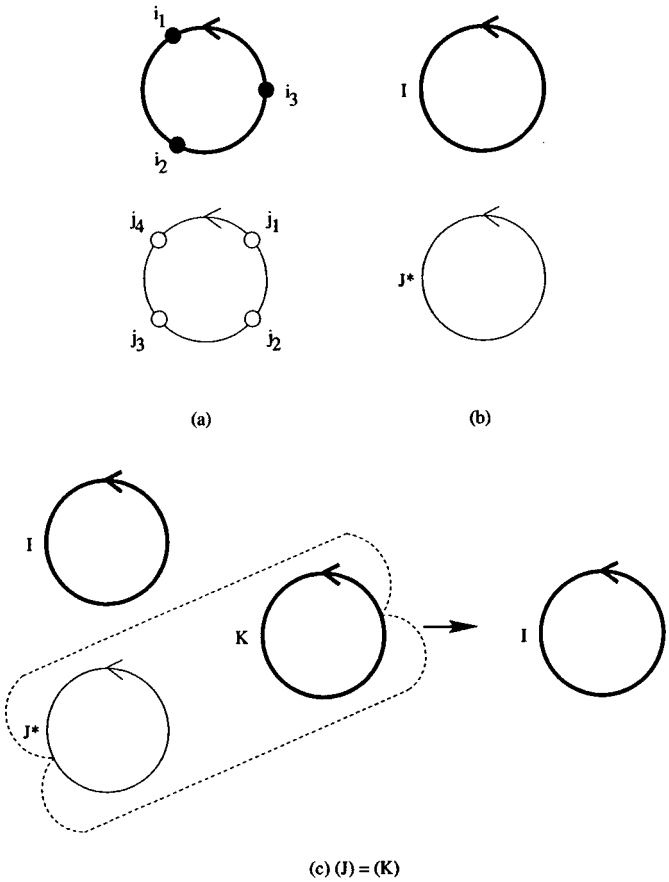

FIG. 2. (a) A detailed diagrammatic representation of a typical $\tilde{f}_{(J)}^{(I)}$. The upper circle represents (I), whereas the lower circle represents (J). In this example, there are three indices in I and four indices in J. An index in I is represented by a solid bead, whereas an index in J is represented by a hollow bead. Moreover, the solid beads are joined by thick lines, while the hollow ones are joined by thin lines. Note the sequence J is put in the clockwise instead of the counter-clockwise direction. (b) $\tilde{f}_{(J)}^{(I)}$ in brief. An asterisk is added to J to signify the fact that J is in the counter-clockwise direction. (c) The action of $\tilde{f}_{(J)}^{(I)}$ on $\Psi^{(K)}$. The dotted lines connect the line segments to be ''annihilated'' together. The figure on the right of the arrow is the resultant closed string state.

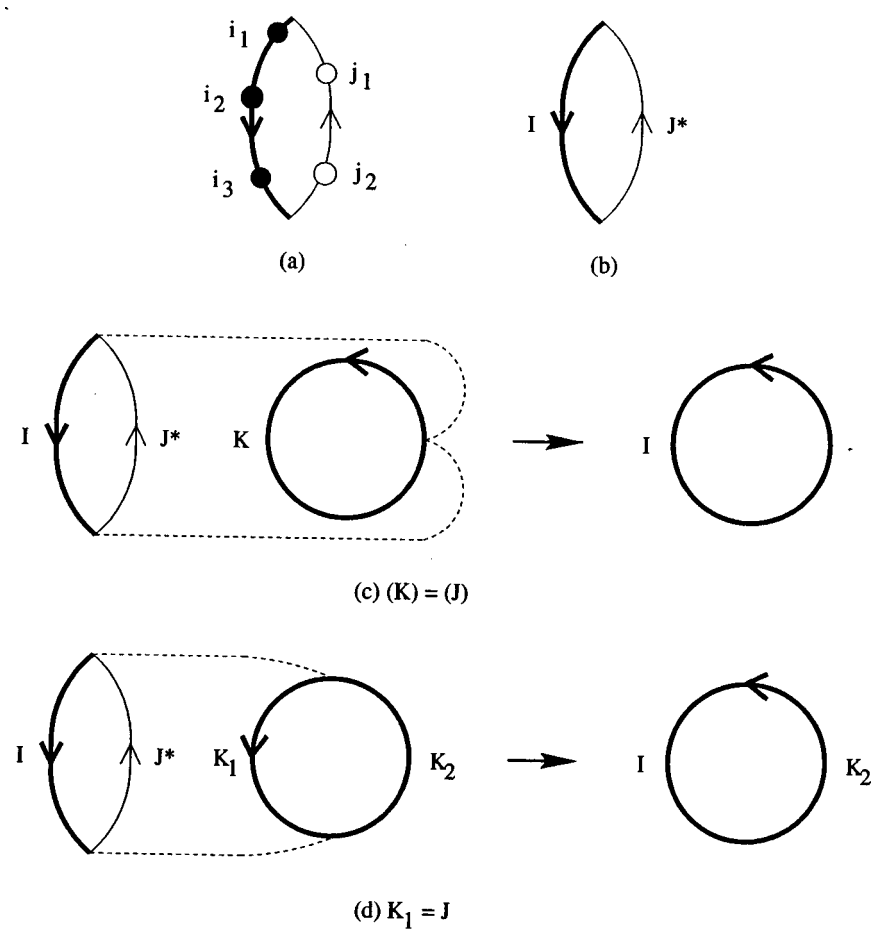

FIG. 3. (a) A typical γ_J^I. There are three indices in I and two indices in J. Note that J is in reverse. (b) A concise representation of γ_J^I. Again an asterisk is added to J to signify the fact that J is put in reverse. (c),(d) The action of γ_J^I on $\Psi^{(K)}$. Only the first two terms of Eq. (3) are shown.

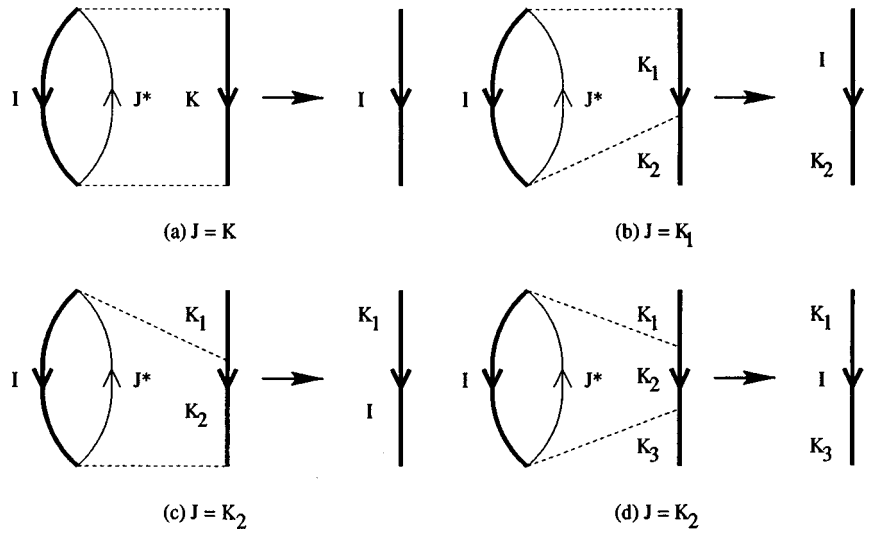

FIG. 4. (a)–(d) The action of γ_J^I on s^L (c.f. Fig 8 in Ref. 11). Only the first four terms are shown.

tors span a Lie algebra which we will also call $\tilde{F}'_\Lambda$. However, the product $\gamma^I_J \gamma^K_L$ cannot be written, in general, as a finite linear combination of the γ's and $\tilde{f}$'s. A proof of this statement can be found in Appendix C.

Nevertheless, it is a remarkable fact that the commutators of any two stringlike operators defined above can, in fact, be written as finite linear combinations of themselves. In fact we see, by a straightforward (but tedious) computation, that the commutator between two γ's reads

$$
\begin{aligned}
[\gamma^I_J, \gamma^K_L] = {} & \delta^K_J \gamma^I_L + \sum_{J_1 J_2 = J} \delta^K_{J_2} \gamma^I_{J_1 L} + \sum_{K_1 K_2 = K} \delta^{K_1}_J \gamma^{IK_2}_L + \sum_{\substack{J_1 J_2 = J \\ K_1 K_2 = K}} \delta^{K_1}_{J_2} \gamma^{IK_2}_{J_1 L} + \sum_{J_1 J_2 = J} \delta^K_{J_1} \gamma^I_{L J_2} \\
& + \sum_{K_1 K_2 = J} \delta^{K_2}_J \gamma^{K_1 I}_L + \sum_{\substack{J_1 J_2 = J \\ K_1 K_2 = K}} \delta^{K_2}_{J_1} \gamma^{K_1 I}_{L J_2} + \sum_{J_1 J_2 J_3 = J} \delta^K_{J_2} \gamma^I_{J_1 L J_3} + \sum_{K_1 K_2 K_3 = K} \delta^{K_2}_J \gamma^{K_1 I K_3}_L \\
& + \sum_{\substack{J_1 J_2 = J \\ K_1 K_2 = K}} \delta^{K_1}_{J_2} \delta^{K_2}_{J_1} \tilde{f}^{(I)}_{(L)} + \sum_{\substack{J_1 J_2 J_3 = J \\ K_1 K_2 = K}} \delta^{K_1}_{J_3} \delta^{K_2}_{J_1} \tilde{f}^{(I)}_{(J_2 L)} + \sum_{\substack{J_1 J_2 = J \\ K_1 K_2 K_3 = K}} \delta^{K_1}_{J_2} \delta^{K_3}_{J_1} \tilde{f}^{(I K_2)}_{(L)} \\
& + \sum_{\substack{J_1 J_2 J_3 = J \\ K_1 K_2 K_3 = K}} \delta^{K_1}_{J_3} \delta^{K_3}_{J_1} \tilde{f}^{(I K_2)}_{(J_2 L)} - (I \leftrightarrow K, J \leftrightarrow L). \qquad (6)
\end{aligned}
$$

Moreover, the commutators between a γ and an $\tilde{f}$, and between two $\tilde{f}$'s, are

$$
[\gamma^I_J, \tilde{f}^{(K)}_{(L)}] = \delta^K_{(J)} \tilde{f}^{(I)}_{(L)} + \sum_{K_1 K_2 = (K)} \delta^{K_1}_J \tilde{f}^{(I K_2)}_{(L)} - \delta^I_{(L)} \tilde{f}^{(K)}_{(J)} - \sum_{L_1 L_2 = (L)} \delta^I_{L_2} \tilde{f}^{(K)}_{(L_1 J)} \qquad (7)
$$

and

$$
[\tilde{f}^{(I)}_{(J)}, \tilde{f}^{(K)}_{(L)}] = \delta^K_{(J)} \tilde{f}^{(I)}_{(L)} - \delta^I_{(L)} \tilde{f}^{(K)}_{(J)}, \qquad (8)
$$

respectively. The proof of the above three equations will be relegated to Appendix D. Some terms in Eq. (6) are depicted in Figs. 5–7. Illustrated in Fig. 8 are the two Lie algebraic relations Eqs. (7) and (8). Let us call the Lie algebra with the basis $\{\tilde{f}^{(I)}_{(J)}, \gamma^I_J\}$ and the above commutation relations the *heterix algebra*, $\hat{\Gamma}_\Lambda$.

Let us explore the structure of the heterix algebra. First of all, we see from Eq. (7) that $\tilde{F}'_\Lambda$ is a proper ideal of the cyclix algebra. Next, consider the subspace $\mathcal{H}$ spanned by all vectors of the forms γ^I_I and $\tilde{f}^{(I)}_{(I)}$, where I is an arbitrary finite integer sequence of integers between 1 and Λ inclusive. It turns out that $\mathcal{H}$ is a Cartan subalgebra of the heterix algebra. (We define, following Ref. 12, a Cartan subalgebra to be a nilpotent subalgebra which is its own normalizer.) (The proof can be found in Appendix E.) In addition, we have the following special cases of Eq. (7) and (8):

$$
[\gamma^I_I, \tilde{f}^{(K)}_{(L)}] = \left(\delta^K_{(I)} + \sum_{K_1 K_2 = (K)} \delta^{K_1}_I - \delta^I_{(L)} - \sum_{L_1 L_2 = (L)} \delta^I_{L_1} \right) \tilde{f}^{(K)}_{(L)} \qquad (9)
$$

and

$$
[\tilde{f}^{(I)}_{(I)}, \tilde{f}^{(K)}_{(L)}] = (\delta^K_{(I)} - \delta^I_{(L)}) \tilde{f}^{(K)}_{(L)}. \qquad (10)
$$

Therefore, every $\tilde{f}^{(K)}_{(L)}$ is a root vector of the cyclix algebra with respect to the subalgebra $\mathcal{H}$.

Suppose we define some operators as follows:

$$
l^I_J \equiv \gamma^I_J - \sum_{i=1}^{\Lambda} \gamma^{iI}_{iJ} - \tilde{f}^{(I)}_{(J)} \quad \text{and} \quad r^I_J \equiv \gamma^I_J - \sum_{j=1}^{\Lambda} \gamma^{Ij}_{Jj} - \tilde{f}^{(I)}_{(J)}. \qquad (11)
$$

The actions of these operators on $\mathcal{T}$ are

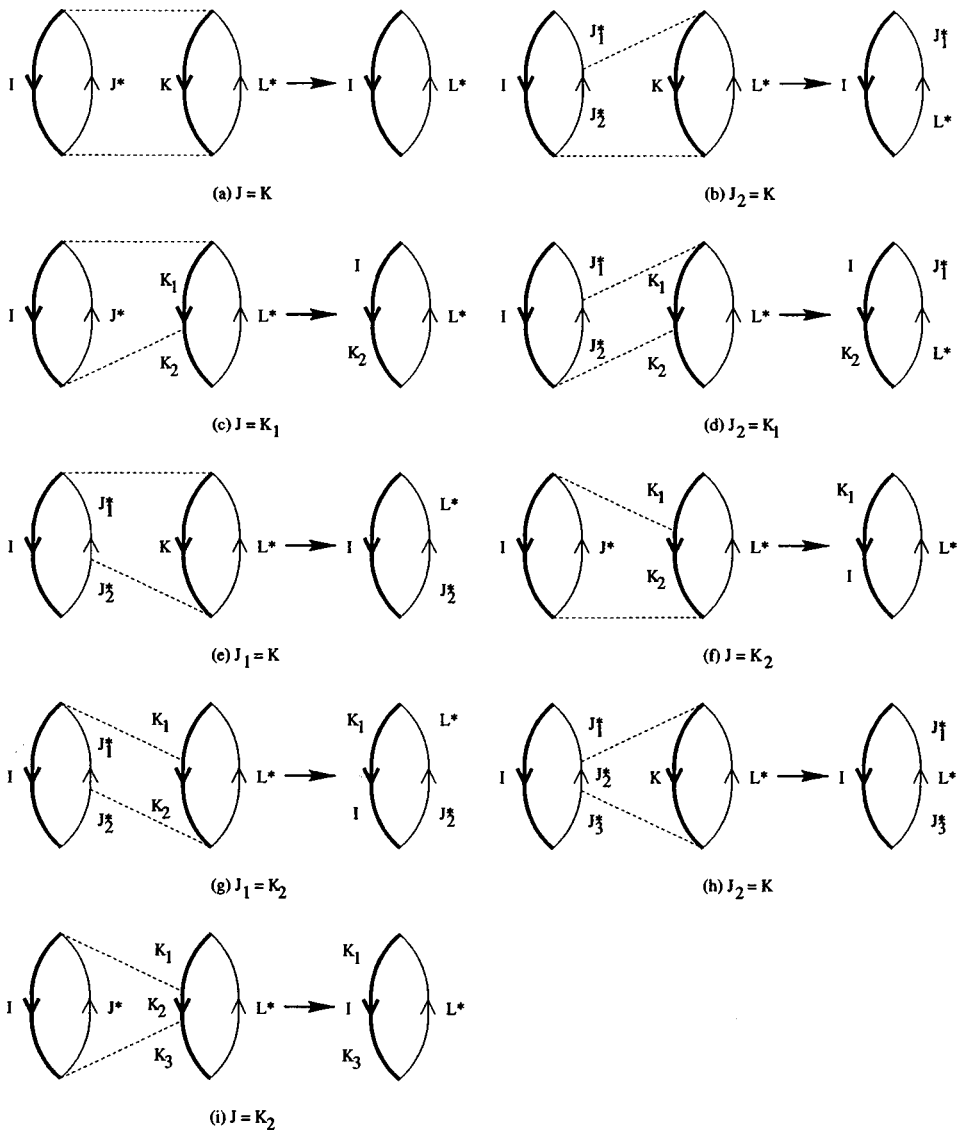

FIG. 5. Diagrammatic representations of the first nine terms on the rhs of Eq. (6).

$$l_J^I s^K = \delta_J^K s^I + \sum_{K_1 K_2 = K} \delta_J^{K_1} s^{I K_2}, \quad l_J^I \Psi^{(K)} = 0, \tag{12}$$

$$r_J^I s^K = \delta_J^K s^I + \sum_{K_1 K_2 = K} \delta_J^{K_2} s^{K_1 I}, \quad r_J^I \Psi^{(K)} = 0.$$

Hence they act only on the open string states: l_J^I and r_J^I are precisely the operators defined in a previous paper[11] on open strings. From the results of that paper, we deduce that the algebra consisting of finite linear combinations of l_J^I's, $\hat{L}'_\Lambda$, is a subalgebra of the heterix algebra. Similarly, the algebra consisting of finite linear combinations of r_J^I's, $\hat{R}'_\Lambda$, is also a subalgebra of the cyclix algebra.

Now define

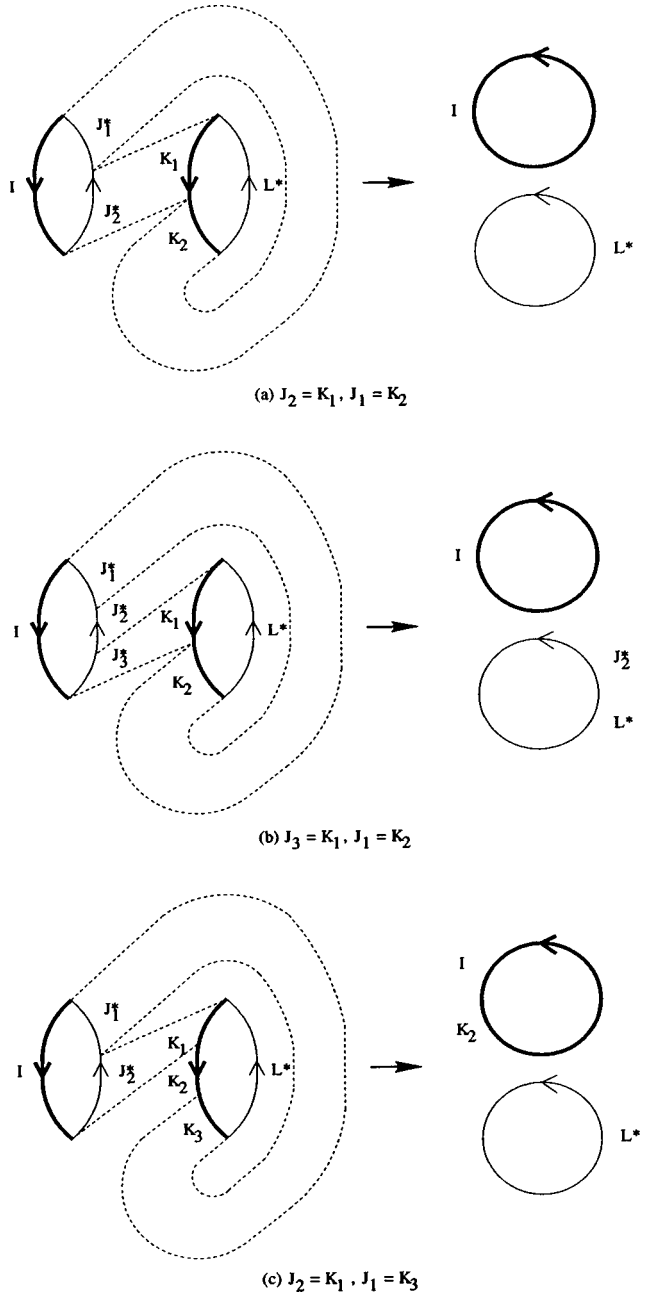

FIG. 6. Diagrammatic representations of the tenth to twelfth terms on the rhs of Eq. (6).

$$f^I_J \equiv \gamma^I_J - \sum_{i=1}^{\Lambda} \gamma^{iI}_{iJ} - \sum_{j=1}^{\Lambda} \gamma^{Ij}_{Jj} + \sum_{i,j=1}^{\Lambda} \gamma^{iIj}_{iJj} - \tilde{f}^{(I)}_{(J)} + \sum_{i=1}^{\Lambda} \tilde{f}^{(iI)}_{(iJ)}$$
$$= l^I_J - \sum_{j=1}^{\Lambda} l^{Ij}_{Jj} = r^I_J - \sum_{i=1}^{\Lambda} r^{iI}_{iJ}. \tag{13}$$

Its action on $\mathcal{T}$ reads

$$f^I_J s^K = \delta^K_J s^I \quad \text{and} \quad f^I_J \Psi^{(K)} = 0. \tag{14}$$

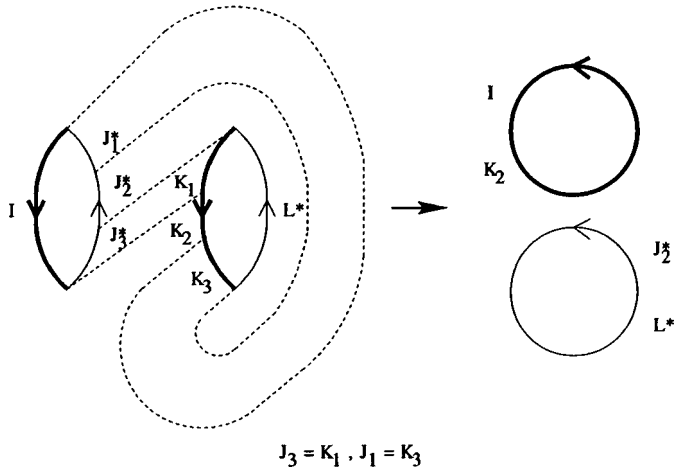

FIG. 7. Diagrammatic representations of the thirteenth term on the rhs of Eq. (6).

Hence this f^I_J also acts only on open strings; it too was introduced in Ref. 11. The algebra consisting of finite linear combinations of f^I_J's, F'_Λ, is a subalgebra of $\hat{L}'_\Lambda$, $\hat{R}'_\Lambda$ and the heterix algebra. We deduce from Eqs. (2), (3), (4) and (14) that

$$\begin{aligned}[\gamma^I_J, f^K_L] &= \delta^K_J f^I_L + \sum_{K_1K_2=K} \delta^{K_1}_J f^{IK_2}_L + \sum_{K_1K_2=K} \delta^{K_2}_J f^{K_1I}_L + \sum_{K_1K_2K_3=K} \delta^{K_2}_J f^{K_1IK_3}_L - \delta^I_L f^K_J \\ &\quad - \sum_{L_1L_2=L} \delta^I_{L_1} f^K_{JL_2} - \sum_{L_1L_2=L} \delta^I_{L_2} f^K_{L_1J} - \sum_{L_1L_2L_3=L} \delta^I_{L_2} f^K_{L_1JL_3}, \\ [\tilde{f}^{(I)}_{(J)}, f^K_L] &= 0. \end{aligned} \tag{15}$$

In particular,

$$\begin{aligned}[\gamma^I_I, f^K_L] &= \Bigg(\delta^K_I + \sum_{K_1K_2=K} \delta^{K_1}_I + \sum_{K_1K_2=K} \delta^{K_2}_I + \sum_{K_1K_2K_3=K} \delta^{K_2}_I \\ &\quad - \delta^I_L - \sum_{L_1L_2=L} \delta^I_{L_1} - \sum_{L_1L_2=L} \delta^I_{L_2} - \sum_{L_1L_2L_3=L} \delta^I_{L_2} \Bigg) f^K_L, \\ [\tilde{f}^{(I)}_{(I)}, f^K_L] &= 0. \end{aligned} \tag{16}$$

Thus every f^K_L is also a root vector with respect to the Cartan subalgebra $\mathcal{H}$. In fact, a root vector with respect to $\mathcal{H}$ is either of the form $\tilde{f}^{(K)}_{(L)}$ or f^K_L. The proof of this assertion can be found in Appendix F. Hence every root space is one-dimensional.

The reader can refer to Ref. 11 for a more detailed discussion of the Lie algebraic relations among the f's, l's, r's and γ's. Also shown in detail in the same article are various diagrammatic representations of f's, l's, r's, and the Lie algebraic relations pertaining to them.

Now let us consider various quotient algebras from the heterix algebra. Since $\tilde{F}'_\Lambda$ is a proper ideal, we can make the set of all cosets $\gamma^I_J + \tilde{F}'_\Lambda$ into a quotient algebra. This quotient algebra is nothing but the centrix algebra $\hat{\Sigma}_\Lambda$ (Ref. 11) defined previously. The union of $\hat{L}'_\Lambda$ and $\hat{R}'_\Lambda$, the multix algebra $\hat{M}'_\Lambda$,[11] is another proper ideal, thus we can make the set of all cosets $\gamma^I_J + \hat{M}'_\Lambda$ and $\tilde{f}^{(I)}_{(J)} + \hat{M}'_\Lambda$ a quotient algebra as well. Note that every operator in $\hat{M}'_\Lambda$ acts on $\mathcal{T}_c$ to produce 0. We conjecture that $\mathcal{T}_c$ provides a faithful representation for the quotient algebra of all cosets $\gamma^I_J + \hat{M}'_\Lambda$ and $\tilde{f}^{(I)}_{(J)} + \hat{M}'_\Lambda$. As we will see in the next section, the corresponding $\Lambda = 1$ quotient algebra is precisely the Virasoro algebra without any central extension. Therefore the quotient algebra with $\Lambda > 1$ can be regarded as a generalization of the Virasoro algebra.

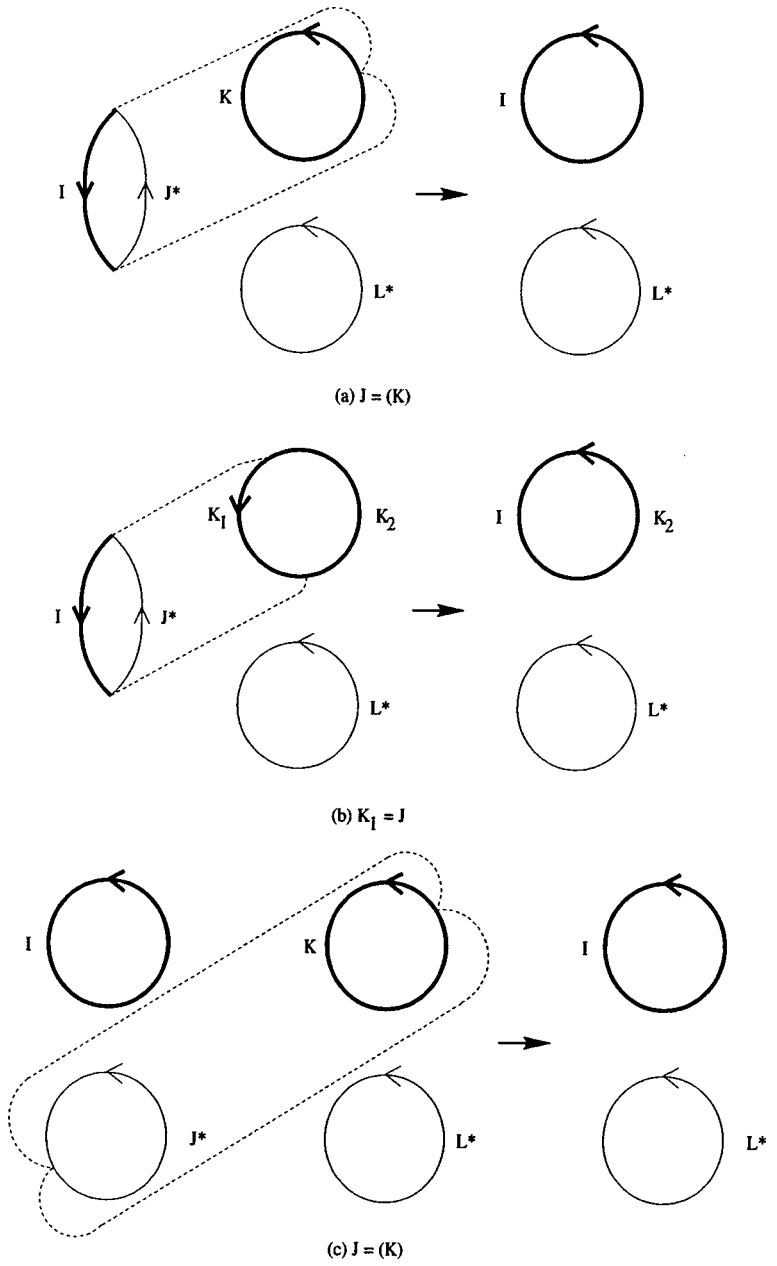

FIG. 8. Diagrammatic representations of the rhs of Eqs. (7) and (8). Only the first two terms and the first term are depicted in these two equations, respectively.

The Lie bracket of the subalgebra $\tilde{F}_\Lambda$ is given by Eq. (8). If we rescale each vector by defining

$$f^{(I)}_{(J)} \equiv \frac{\tilde{f}^{(I)}_{(J)}}{\sqrt{\delta^I_{(I)}\delta^J_{(J)}}}, \tag{17}$$

then the Lie bracket between two $f^{(I)}_{(J)}$'s is similar to that in Eq. (8), except that the delta function there with the generic form $\delta^I_{(J)}$ should be replaced with another delta function such that this new delta function yields simply 1 if $(I)=(J)$, and remains 0 otherwise. Then there is a one-to-one correspondence between each $f^{(I)}_{(J)}$ and each complex matrix $(a_{ij})_{i,j}\in Z_+$ such that all but one a_{ij} is nonzero, and that nonzero entry is 1. Thus the Lie algebras $\tilde{F}'_\Lambda$, for any Λ, are all isomorphic to $gl_{+\infty}$, the inductive limit of the general linear algebras. $gl_{+\infty}$ and the Kac–Moody algebra associated with it were thoroughly studied, and their properties can be found in, e.g., Kac's work.[9]

III. THE SPECIAL CASE $\Lambda=1$

Let us consider the cyclix algebra for the simplest special case $\Lambda=1$: this is useful as it will connect our Lie algebra with more familiar algebras such as the Virasoro algebra. Then all the sequences are repetitions of the number 1 some numbers of times. We can simplify the notations and write $\Psi^{(K)}$ as $\Psi^{(\#(K))}$, s^K as $s^{\#(K)}$, γ_J^I as $\gamma_{\#(J)}^{\#(I)}$, and $\tilde{f}_{(J)}^{(I)}$ as $\tilde{f}_{(\#(J))}^{(\#(I))}$. We can deduce from Eqs. (2), (3) and (4) that the actions of $\tilde{f}_{(b)}^{(a)}$ and γ_b^a, where a and b are the number of integers in the various sequences, on $\Psi^{(c)}$ and s^c, where c is also a positive integer, are given by

$$\tilde{f}_{(b)}^{(a)}\Psi^{(c)}=c\,\delta_b^c\Psi^{(a)}, \tag{18}$$

$$\tilde{f}_{(b)}^{(a)}s^c=0, \tag{19}$$

$$\gamma_b^a\Psi^{(c)}=c\,\theta(b\leqslant c)\Psi^{(a+c-b)}, \tag{20}$$

and

$$\gamma_b^a s^c=(c-b+1)\,\theta(b\leqslant c)s^{a+c-b}. \tag{21}$$

where θ(condition) is 1 if the condition holds, and 0 otherwise. The Lie brackets for the $\Lambda=1$ cyclix algebra are

$$\begin{aligned}[\gamma_b^a,\gamma_d^c]=&\,\theta(c\leqslant b)[2\gamma_{b+d-1}^{a+c-1}+2\gamma_{b+d-2}^{a+c-2}+\cdots+2\gamma_{b+d-c+1}^{a+1}\\&+(b-c+1)\gamma_{b+d-c}^a]+\theta(2\leqslant c\leqslant b)[\tilde{f}_{(b+d-2)}^{(a+c-2)}+2\tilde{f}_{(b+d-3)}^{(a+c-3)}\\&+\cdots+(c-1)\tilde{f}_{(b+d-c)}^{(a)}]+\theta(b<c)[2\gamma_{b+d-1}^{a+c-1}+2\gamma_{b+d-2}^{a+c-2}\\&+\cdots+2\gamma_{d+1}^{a+c-b+1}+(c-b+1)\gamma_d^{a+c-b}]+\theta(2\leqslant b<c)[\tilde{f}_{(b+d-2)}^{(a+c-2)}\\&+\tilde{f}_{(b+d-3)}^{(a+c-3)}+\cdots+(b-1)\tilde{f}_{(b)}^{(a+c-d)}]-(a\leftrightarrow c,b\leftrightarrow d),\end{aligned} \tag{22}$$

$$[\gamma_b^a,\tilde{f}_{(d)}^{(c)}]=c\,\theta(b\leqslant c)\tilde{f}_{(d)}^{(a+c-b)}-d\,\theta(a\leqslant d)\tilde{f}_{(b+d-a)}^{(c)} \tag{23}$$

and

$$[\tilde{f}_{(b)}^{(a)},\tilde{f}_{(d)}^{(c)}]=b\,\delta_b^c\tilde{f}_{(d)}^{(a)}-a\,\delta_d^a\tilde{f}_{(b)}^{(c)}. \tag{24}$$

These three equations can be deduced from Eqs. (6), (7) and (8), respectively.

The Cartan subalgebra $\mathcal{H}$ is now spanned by vectors of the forms γ_a^a and $\tilde{f}_{(a)}^{(a)}$. A root vector reads $\tilde{f}_{(d)}^{(c)}$ or $f_d^c=\gamma_d^c-2\gamma_{d+1}^{c+1}+\gamma_{d+2}^{c+2}-\tilde{f}_{(d)}^{(c)}+\tilde{f}_{(d+1)}^{(c+1)}$. The expression for f_d^c can be deduced from Eq. (13). The eigenequations are

$$[\gamma_a^a,\tilde{f}_{(d)}^{(c)}]=(c\,\theta(a\leqslant c)-d\,\theta(a\leqslant d))\tilde{f}_{(d)}^{(c)},\quad [\tilde{f}_{(a)}^{(a)},\tilde{f}_{(d)}^{(c)}]=a(\delta_a^c-\delta_d^a)\tilde{f}_{(d)}^{(c)}, \tag{25}$$

$$[\gamma_a^a,f_d^c]=(\theta(a\leqslant c)(c-a+1)-\theta(a\leqslant d)(d-a+1))f_d^c,$$

and

$$[\tilde{f}_{(a)}^{(a)},f_d^c]=0. \tag{26}$$

Let us consider the quotient algebra of all cosets $\gamma_b^a+\hat{M}_1'$ and $\tilde{f}_{(b)}^{(a)}+\hat{M}_1'$. *In the rest of this section and in the accompanying appendices, we will write* $\gamma_b^a+\hat{M}_1'$ *and* $\tilde{f}_{(b)}^{(a)}+\hat{M}_1'$ *simply as* g_b^a

and $\tilde{f}^{(a)}_{(b)}$, *respectively*. $\mathcal{T}_c$ still provides a representation for this quotient algebra — the actions of g^a_b and $\tilde{f}^{(a)}_{(b)}$ on $\mathcal{T}_c$ are still described by Eqs. (18) and (20). However, there is now a relation among $\tilde{f}$'s and g's:

$$\tilde{f}^{(a)}_{(b)} = g^a_b - g^{a+1}_{b+1}. \tag{27}$$

Hence,

$$g^a_b = \begin{cases} -\tilde{f}^{(a)}_{(b)} - \tilde{f}^{(a-1)}_{(b-1)} - \cdots - \tilde{f}^{(a-b+1)}_{(1)} + g^{a-b+1}_1 & \text{if } a \geqslant b, \\ -\tilde{f}^{(a)}_{(b)} - \tilde{f}^{(a-1)}_{(b-1)} - \cdots - \tilde{f}^{(1)}_{(b-a+1)} + g^1_{b-a+1}, & \text{if } a < b. \end{cases} \tag{28}$$

A simplification brought about by setting Λ to 1 is that we can write a basis for the quotient algebra easily. Indeed, the set of all $\tilde{f}^{(a)}_{(b)}$'s, g^1_b's and g^a_1's where a and b are arbitrary positive integers form a basis for the $\Lambda = 1$ quotient algebra. The proof of this statement will be given in Appendix G. The same proof also shows that $\mathcal{T}_c$ provides not only a representation, but also a *faithful* representation for this quotient algebra. From Eq. (23), we deduce that the subspace $\tilde{F}'_1$ spanned by all the vectors of the form $\tilde{f}^{(c)}_{(d)}$ forms a proper ideal of this quotient algebra.

The set of all $\tilde{f}^{(a)}_{(a)}$'s, where a is arbitrary, and g^1_1 form a basis for a Cartan subalgebra. The proof of this statement will be seen in Appendix H. In addition, since $\tilde{F}'_1$ is a proper ideal of the quotient algebra, the same proof reveals that any root vector with respect to this Cartan subalgebra must be a linear combination of a number of $\tilde{f}^{(a)}_{(b)}$'s. Therefore, all root vectors are of the form $\tilde{f}^{(c)}_{(d)}$'s with $c \neq d$. The corresponding eigenequations, which can be deduced from Eqs. (9) and (10), are

$$[g^1_1, \tilde{f}^{(c)}_{(d)}] = (c-d)\tilde{f}^{(c)}_{(d)} \tag{29}$$

and

$$[\tilde{f}^{(a)}_{(a)}, \tilde{f}^{(c)}_{(d)}] = a(\delta^c_a - \delta^a_d)\tilde{f}^{(c)}_{(d)}. \tag{30}$$

As $\tilde{F}'_1$ is a proper ideal of this $\Lambda = 1$ quotient algebra, we can form yet another quotient algebra of cosets of the form $v + \tilde{F}'_1$ where v is an arbitrary vector of the previous quotient algebra. This new quotient algebra is spanned by the cosets $g^a_1 + \tilde{F}_\Lambda$ and $g^1_b + \tilde{F}'_1$, where a and b run over all positive integers. It is a straightforward matter to show that the following Lie brackets are true:

$$[g^a_1 + \tilde{F}'_1, g^c_1 + \tilde{F}'_1] = (c-a)(g^{a+c-1}_1 + \tilde{F}'_1),$$

$$[g^a_1 + \tilde{F}'_1, g^1_d + \tilde{F}'_1] = \begin{cases} (2-a-d)(g^{a-d+1}_1 + \tilde{F}'_1), & \text{if } d \leqslant a, \\ (2-a-d)(g^1_{d-a+1} + \tilde{F}'_1), & \text{if } a \leqslant d, \end{cases} \tag{31}$$

$$[g^1_b + \tilde{F}'_1, g^1_d + \tilde{F}'_1] = (b-d)(g^1_{b+d-1} + \tilde{F}'_1).$$

Let us define

$$L_a = \begin{cases} -g^{a+1}_1 + \tilde{F}'_1, & \text{if } a \geqslant 0, \\ -g^1_{1-a} + \tilde{F}'_1, & \text{if } a \leqslant 0. \end{cases} \tag{32}$$

Note that the L here is *not* an integer sequence. Then Eq. (31) becomes

$$[L_a, L_b] = (a-b)L_{a+b}. \tag{33}$$

The reader can notice at once that this is the Lie algebraic relation of the Virasoro algebra without any central element.[13] Consequently, the $\Lambda=1$ quotient algebra of all cosets γ_b^a and $\tilde{f}_{(b)}^{(a)}$ can be regarded as an extension of the Virasoro algebra by an algebra isomorphic to $gl_{+\infty}$. The quotient algebras $\gamma_J^I+\hat{M}'_\Lambda+\tilde{F}_\Lambda$ for $\Lambda>1$ can then be regarded as generalizations of the Virasoro algebra, as stated in the previous section.

IV. CANONICAL REALIZATION

We have presented the operators acting on strings somewhat abstractly in the last section. Although the diagrammatic descriptions give the definitions of the operators a natural motivation, it would be better to have a more direct derivation of these relations in terms of more familiar operators such as those satisfying canonical commutation relations.

Let us define some bosonic operators which satisfy the canonical commutation relations:

$$[a_{\mu_2}^{\mu_1}(k_1),a^{\dagger\mu_3}_{\mu_4}(k_2)]=\delta_{k_1k_2}\delta^{\mu_1}_{\mu_4}\delta^{\mu_3}_{\mu_2},$$
$$[a_{\mu_2}^{\mu_1}(k_1),a_{\mu_4}^{\mu_3}(k_2)]=0,\quad [a^{\dagger\mu_1}_{\mu_2}(k_1),a^{\dagger\mu_3}_{\mu_4}(k_2)]=0. \tag{34}$$

These operators create and annihilate ''gluons,'' the most fundamental entities in our theory. The name ''gluons'' comes from the application of our theory to regularized QCD, in which case these operators act on gluons. The indices μ,ν and $\upsilon=1,2,\ldots,N$ label a quantum number we will call ''color.'' In this context, Λ is the possible number of distinct quantum states of a gluon excluding color. These quantum states are denoted by the numbers 1, 2, ..., Λ.

We identify the closed string states with a ring of gluons:

$$\Psi^{(K)}|0\rangle\equiv N^{-c/2}a^{\dagger\upsilon_2}_{\upsilon_1}(k_1)a^{\dagger\upsilon_3}_{\upsilon_2}(k_2)\cdots a^{\dagger\upsilon_1}_{\upsilon_c}(k_c)|0\rangle, \tag{35}$$

where $c=\#(K)$. (The summation convention for color indices is implicit in the above and following expressions.) A factor of $N^{-c/2}$ is inserted so that the state has a finite norm in the large-N limit. [Now the beads and connecting lines in Fig. 1(c) acquire some extra meanings — a solid bead represents a creation operator. Two beads connected by a line represents that the two corresponding creation operators share a common color index. This index is being summed over.]

We will now look at the operators which can map the above single glueball states to linear combinations of such states. In general they could also create states with several glueballs, but their amplitudes are suppressed by terms of order at least $1/N$: this fact is rather well known[3] and is a reflection in the Hamiltonian formalism of the planarity of Feynman diagrams in perturbation theory.[7] As an alternative to reading the relevant papers cited above, the reader can also consult and adapt an argument in a paper by one of us,[14] where an operator in the large-N limit is shown to propagate a single meson state to a linear combination of single meson states only.

There are two classes of such operators:

$$\tilde{f}^{(I)}_{(J)}\equiv N^{-(a+b)/2}a^{\dagger\mu_2}_{\mu_1}(i_1)a^{\dagger\mu_3}_{\mu_2}(i_2)\cdots a^{\dagger\mu_1}_{\mu_a}(i_a)a^{\nu_b}_{\nu_1}(j_b)a^{\nu_{b-1}}_{\nu_b}(j_{b-1})\cdots a^{\nu_1}_{\nu_2}(j_1) \tag{36}$$

and

$$\gamma_J^I\equiv N^{-(a+b-2)/2}a^{\dagger\mu_2}_{\mu_1}(i_1)a^{\dagger\mu_3}_{\mu_2}(i_2)\cdots a^{\dagger\nu_b}_{\mu_a}(i_a)a^{\nu_{b-1}}_{\nu_b}(j_b)a^{\nu_{b-2}}_{\nu_{b-1}}(j_{b-1})\cdots a^{\mu_1}_{\nu_1}(j_1). \tag{37}$$

These operators can act on a gluon segment of a glueball. (Now Figs. 2 and 3 can be regarded as illustrations of these operators. The solid beads represent creation operators, whereas the hollow beads represent annihilation operators. A connecting line, regardless of thickness, symbolizes the fact that the two corresponding operators share a common color index, and this index is being summed over.)

In the large-N limit, such operators propagate single glueball states to linear combinations of single glueball states:

$$\tilde{f}^{(I)}_{(J)}\Psi^{(K)}=\delta^{K}_{(J)}\Psi^{(I)}$$

and

$$\gamma^{I}_{J}\Psi^{(K)}=\delta^{K}_{(J)}\Psi^{(I)}+\sum_{K_1K_2=(K)}\delta^{K_1}_{J}\Psi^{(IK_2)}.$$

These are just the formulas [Eqs. (2) and (3)] we had in the previous section. Thus we have a representation of the Lie algebra of the last section on glueball states.

The representation we have obtained, however, is not faithful: we are only considering closed string states here. To emphasize this fact we will denote the operator acting on closed string states alone by g^{I}_{J}. (We would have a faithful representation if we included the open string states as well, but in this paper we will not consider them.) Indeed, using Eqs. (3) and (2), the reader can show that the following relations hold:

$$\begin{gathered}
\tilde{f}^{(I)}_{(J)}=g^{I}_{J}-\sum_{k=1}^{\Lambda}g^{Ik}_{Jk},\quad \tilde{f}^{(I)}_{(J)}=g^{I}_{J}-\sum_{k=1}^{\Lambda}g^{kI}_{kJ},\quad \tilde{f}^{(I)}_{(J)}=g^{I_2I_1}_{J}-\sum_{k=1}^{\Lambda}g^{I_2I_1k}_{Jk}\quad \text{if } I_1I_2=I,\\
\tilde{f}^{(I)}_{(J)}=g^{I_2I_1}_{J}-\sum_{k=1}^{\Lambda}g^{kI_2I_1}_{kJ}\quad \text{if } I_1I_2=I,\quad \tilde{f}^{(I)}_{(J)}=g^{I}_{J_2J_1}-\sum_{k=1}^{\Lambda}g^{Ik}_{J_2J_1k}\quad \text{if } J_1J_2=J,\\
\tilde{f}^{(I)}_{(J)}=g^{I}_{J_2J_1}-\sum_{k=1}^{\Lambda}g^{kI}_{kJ_2J_1}\quad \text{if } J_1J_2=J,\\
\tilde{f}^{(I)}_{(J)}=g^{I_2I_1}_{J_2J_1}-\sum_{k=1}^{\Lambda}g^{I_2I_1k}_{J_2J_1k}\quad \text{if } I_1I_2=I\quad \text{and } J_1J_2=J,\\
\tilde{f}^{(I)}_{(J)}=g^{I_2I_1}_{J_2J_1}-\sum_{k=1}^{\Lambda}g^{kI_2I_1}_{kJ_2J_1}\quad \text{if } I_1I_2=I\quad \text{and } J_1J_2=J.
\end{gathered}\tag{38}$$

These relations are generalizations of Eq. (27).

The quotient of the heterix algebra by the kernel of this representation was called the cyclix algebra[10] $\hat{C}_{\Lambda}$. As has been stated in a previous section, we conjecture that $\hat{C}_{\Lambda}=\hat{\Gamma}_{\Lambda}/\hat{M}'_{\Lambda}$. The results in Sec. III show that this conjecture is true for $\Lambda=1$.

V. APPLICATION TO GAUGE FIELD THEORY

We are going to apply the cyclix algebra to physical models which can be formulated as matrix models in the large-N limit. In this section, we will concentrate on gauge field theories in the large-N limit. We will find that we can express the physical observables of these theories in terms of the elements of the cyclix algebra. (Indeed, we will see in a future paper[15] that closed superstring models and M-theory can be formulated in terms of the supersymmetric generalization of the cyclix algebra in a similar manner.) However, they will look complicated. In the next section, we will construct multi-matrix models *integrable* in the large-N limit associated with integrable quantum spin chain models satisfying the periodic boundary condition. Studying the ways these multi-matrix models are solved can shed light on how the more complicated gauge field theories are solved.

In this section we will let the regulator $\Lambda\to\infty$, so that the momentum indices will take an infinite number of values. In order that the previous discussions of our algebra apply directly here, we will need to regularize the field theory such that the momentum variables can take only a finite number Λ of distinct values. But this is mostly a technicality, since we will only talk of field theories without divergences for which the limit $\Lambda\to\infty$ should exist: dimensional reductions of gauge theory to $1+1$ dimesnions. The deeper problem of describing renormalizable field theories this way is being studied.

The first gauge field model is a $(1+1)$-dimensional SU(N) gauge theory coupled to bosonic matter in the adjoint representation. This model has been studied by Dalley and Klebanov[16] in detail, and so we will only give a brief account here. Let g be the strong coupling constant, α and β be ordinary space-time indices, A_α be a gauge potential and ϕ be a scalar field in the adjoint representation of the gauge group U(N). Both ϕ and A_α are $N\times N$ Hermitian matrix fields. (We can regard both A_α and ϕ as describing the gluons of a Yang–Mills theory in three dimensions, dimensionally reduced to $1+1$ dimensions.) Let the covariant derivative $D_\alpha\phi=\partial_\alpha\phi+\mathrm{i}[A_\alpha,\phi]$ and the Yang–Mills field $F_{\alpha\beta}=\partial_\alpha A_\beta-\partial_\beta A_\alpha+\mathrm{i}[A_\alpha,A_\beta]$. Lastly, let m be the mass of a boson and g be the gauge field coupling strength. Then the Minkowski space action is

$$S=\int d^2x\ \mathrm{Tr}\left[\frac{1}{2}D_\alpha\phi D^\alpha\phi-\frac{1}{2}m^2\phi^2-\frac{1}{4g^2}F_{\alpha\beta}F^{\alpha\beta}\right]. \tag{39}$$

We then transform the Minkowski coordinates to light-cone coordinates, and choose the light-cone gauge $A_-=(A_0-A_3)/\sqrt{2}=0$. Then A_+ is not dynamical and can be eliminated by the constrained equations. We canonically quantize the adjoint matter field:

$$\phi^\mu_\nu(x^+=0)=\frac{1}{\sqrt{2\pi}}\int_0^\infty\frac{dk^+}{\sqrt{2k^+}}[a^\mu_\nu(k^+)\mathrm{e}^{-\mathrm{i}k^+x^-}+a^{\dagger\mu}_\nu(k^+)\mathrm{e}^{\mathrm{i}k^+x^-}], \tag{40}$$

where μ and ν are color indices. The creation and annihilation operators satisfy the canonical commutation relation equation (34). One of the constraints dictates that the Hilbert space on which the creation and annihilation operators act be spanned by color singlet states:

$$N^{-c/2}\mathrm{Tr}[a^\dagger(k_1^+)\cdots a^\dagger(k_c^+)]|0\rangle. \tag{41}$$

Equation (41) is exactly in the form of a single glueball state $\Psi^{(K)}|0\rangle$ defined in Eq. (35). Thus the creation operator can be interpreted as a creation operator for a gluon. Furthermore, we can obtain the light-cone momentum and energy in terms of the elements of the cyclix algebra:

$$P^+=\int_0^\infty dk\ kg^k_k, \tag{42}$$

and

$$P^-=\frac{1}{2}m^2\int_0^\infty\frac{dk}{k}g^k_k+\frac{g^2N}{4\pi}\int_0^\infty\frac{dk}{k}Cg^k_k+\frac{g^2N}{8\pi}\int_0^\infty\frac{dk_1dk_2dk_3dk_4}{\sqrt{k_1k_2k_3k_4}}\{A\,\delta(k_1+k_2-k_3-k_4)g^{k_1k_2}_{k_3k_4}$$
$$+B\,\delta(k_1-k_2-k_3-k_4)g^{k_1}_{k_2k_3k_4}+B\,\delta(k_1+k_2+k_3-k_4)g^{k_1k_2k_3}_{k_4}\}, \tag{43}$$

where

$$A=\frac{(k_2-k_1)(k_4-k_3)}{(k_1+k_2)^2}-\frac{(k_3+k_1)(k_4+k_2)}{(k_4-k_2)^2},$$

$$B=\frac{(k_1+k_4)(k_3-k_2)}{(k_3+k_2)^2}+\frac{(k_3+k_4)(k_1-k_2)}{(k_1+k_2)^2},$$

and

$$C=\int_0^k dp\,\frac{(k+p)^2}{p(k-p)^2}.$$

This adjoint matter model can be used to study glueball spectrum.[17] Consider next a $(3+1)$-dimensional QCD model with only gluons and no quarks. If we apply the dimensional reduction

to it, we will obtain an effective Yang–Mills model in $1+1$ dimensions with two adjoint matter fields ϕ_1 and ϕ_2, which are constant multiples of transverse gluon fields. Rewrite the adjoint matter fields in the helicity basis

$$\phi_{\pm}=\frac{\phi_1 \pm i\phi_2}{\sqrt{2}}, \tag{44}$$

and canonically quantize $\phi_{\pm}$:

$$\phi^{\mu}_{\pm\,\nu}(x^+=0)=\frac{1}{\sqrt{2\pi}}\int_0^{\infty}\frac{dk^+}{\sqrt{2k^+}}[a^{\mu}_{\nu}(k^+,\pm)e^{-ik^+x^-}+a^{\dagger\mu}_{\nu}(k^+,\pm)e^{ik^+x^-}]. \tag{45}$$

Then the light-front momentum and energy are

$$P^+=\int_0^{\infty}dk\;\; k\sum_{j=+,-} g^{k,j}_{k,j},$$

and

$$\begin{aligned}
P^-=&\frac{m^2_{\rm ind}}{2}\int_0^{\infty}\frac{dk}{k}g^{k,+}_{k,+}+\frac{g^2}{8\pi}\int_0^{\infty}\frac{dk_1dk_2dk_3dk_4}{\sqrt{k_1k_2k_3k_4}}\delta(k_1+k_2-k_3-k_4)\\
&\cdot\{(D[k_1,k_2,k_3]-1)g^{k_3,+;k_4,-}_{k_1,-;k_2,+}+(-E[k_1,k_2,k_3]-1)g^{k_3,+;k_4,+}_{k_1,+;k_2,+}\\
&+(D[k_1,k_2,k_3]-E[k_1,k_2,k_3]+2)g^{k_3,+;k_4,-}_{k_1,+;k_2,-}\}\\
&+\frac{g^2}{8\pi}\int_0^{\infty}\frac{dk_1dk_2dk_3dk_4}{\sqrt{k_1k_2k_3k_4}}\delta(k_1+k_2+k_3-k_4)\\
&\cdot\{(F[k_1,k_2,k_3]+1)\\
&\times(g^{k_1,+;k_2,-;k_3,+}_{k_4,+}+g^{k_3,+;k_2,-;k_1,+}_{k_4,+}+g^{k_4,+}_{k_1,+;k_2,-;k_3,+}+g^{k_4,+}_{k_3,+;k_2,-;k_1,+})\\
&+(F[k_1,k_2,k_3]-1)(g^{k_3,-;k_2,-;k_1,+}_{k_4,-}+g^{k_1,+;k_2,-;k_3,-}_{k_4,-}+g^{k_4,+}_{k_3,+;k_2,+;k_1,-}\\
&+g^{k_4,+}_{k_1,-;k_2,+;k_3,+})\}+(\text{positive helicity}\leftrightarrow\text{negative helicity}),
\end{aligned} \tag{46}$$

where

$$E[x_1,x_2,x_3]=\frac{(x_1+x_3)(x_1+2x_2-x_3)}{(x_1-x_3)^2},\quad D[x_1,x_2,x_3]=E[x_2,-x_3,-x_1],$$

and

$$F[x_3,x_2,x_1]=E[x_3,x_1,-x_2],$$

and $m_{\rm ind}$ is the induced mass due to normal ordering the creation and annihilation operators.

The various algebras described in this paper can also be modified to study supersymmetric models with fermionic adjoint matter fields. Not long ago there were studies on $d>2$ noncritical superstrings using a matrix model.[18] The superfields were presented as matrices. Canonical quantization yielded a number of operators satisfying various canonical commutation and anticommutation relations. The Hilbert space on which these operators acted were composed of closed strings of bosonic and fermionic creation operators. The terms in the supercharge operators could be written in a way analogous to the gluonic operators, except that there were fermionic operators in addition to bosonic operators, which are the only operators present in the gluonic operators defined in Eq. (37). The various algebras described in this paper can be generalized to superalgebras[15] to

study this noncritical superstring model. A closely related model is a supersymmetric Yang–Mills theory with a fermionic matter field.[16,19] Moreover, these superalgebras can also be employed to study M-theory, which is being conjectured as a matrix model.[5]

VI. SOLVABLE MATRIX AND SPIN CHAIN MODELS

Now that we have learned how to formulate gauge field theories in the large-N limit in the language of the cyclix algebra, let us turn to integrable periodic quantum spin chain models and the associated, more tractable multi-matrix models. Understanding the properties of these solvable matrix models may shed new light on the mathematics of the more difficult gauge field theories.

Consider the Hamiltonian of a matrix model in the form of the linear combination $H=\Sigma_{IJ}h_I^J g_J^I$, where $h_I^J\neq 0$ only if I and J have the same number of indices. (This means that the ''parton number'' is conserved. Note that the gauge field theories described in the previous section are not of this type.) Such linear combinations form a subalgebra of the cyclix algebra. Let us call this $\hat{C}_\Lambda^0$.

There is an isomorphism between multi-matrix models whose Hamiltonians are in $\hat{C}_\Lambda^0$ and periodic quantum spin chains. Consider a spin chain with c sites. At any site $p=1,2,\ldots$ or c there is a variable i_p called *spin* that describes the quantum state of that site, and that can take the value 1, 2, . . . , or Λ. We impose the periodic boundary condition. We will show that a subspace of these states, namely, the states with zero total momentum, provides a (nonfaithful) representation of the algebra $\hat{C}_\Lambda^0$.

A basis of states is given by the set of states of the form $|k_1k_2\ldots k_c\rangle$. Define the operator $X_j^i(p)$ by its action on these collective spin chain states by the formula

$$X_j^i(p)|k_1k_2\ldots k_c\rangle\equiv\delta_j^{k_p}|k_1k_2\ldots k_{p-1}ik_{p+1}\ldots k_c\rangle. \tag{47}$$

[Those who are familiar with the theory of the Hubbard model can notice at once that $X_j^i(p)$ is the Hubbard operator at the site p, which is conventionally written as X_p^{ij}.[20]] Furthermore, we impose the periodic boundary condition $X_j^i(p+c)=X_j^i(p)$. It can be verified that if I and J have the same length $a\leqslant c$, then

$$r_c(g_J^I)\equiv\sum_{p=1}^{c}X_{j_1}^{i_1}(p)X_{j_2}^{i_2}(p+1)\cdots X_{j_a}^{i_a}(p+a-1) \tag{48}$$

satisfies the commutation relations of the algebra $\hat{C}_\Lambda^0$. If we further define $r_c(g_J^I)=0$ for $a>c$, we will have a representation r_c of $\hat{C}_\Lambda^0$. The cyclically symmetric states of the matrix model correspond to the states of the periodic spin chain with zero total momentum. The representation is not faithful as it is sets all generators of length a greater than the number of spins c to zero; if we take spin chains of all possible lengths, we will get a faithful representation.

We are now ready to associate the matrix model where the Hamiltonian $H=\Sigma_{IJ}h_I^J g_J^I$ is in $\hat{C}_\Lambda^0$, with the quantum spin chain with the Hamiltonian

$$H^{\text{spin}}=\sum_{IJ}h_I^J\sum_{p=1}^{c}X_{j_1}^{i_1}(p)X_{j_2}^{i_2}(p+1)\cdots X_{j_a}^{i_a}(p+a-1). \tag{49}$$

Therefore, matrix models conserving the parton number correspond to quantum spin systems with interactions involving neighborhoods of spins at the sites p, $p+1,\ldots,$ and $p+a-1$.

Recall that a convenient way of solving spin chain systems[21] is via the Bethe ansatz. This ansatz is applicable whenever the spin wave S-matrix satisfies the Yang–Baxter equation, in which case we say that the spin chain system is integrable. Then this integrable spin chain system yields an integrable multi-matrix model.

Let us look at the simplest example, the quantum Ising spin chain.[22,23] The Hamiltonian $H_{\text{Ising}}^{\text{spin}}$ of this model is

$$H^{\text{spin}}_{\text{Ising}}(\tau,\lambda)=\sum_{p=1}^{c}\tau^z(p)+\lambda\sum_{p=1}^{c}\tau^x(p)\tau^x(p+1). \tag{50}$$

Here λ is a constant, and $\tau_p^{x,y,z}$ are Pauli matrices at site p. Moreover, $\tau_{c+1}^{x,y,z}=\tau^{x,y,z}$. Two Pauli matrices at different sites (i.e., with different subscripts) commute with each other. Let us rewrite the Ising spin chain as a two-matrix model. We set the quantum state 1 for a boson in the matrix model to correspond to the spin-up state in the Ising spin chain, and the quantum state 2 to correspond to the spin-down state. Since

$$\tau_p^z=X_1^1(p)-X_2^2(p),\quad \tau_p^x+\mathrm{i}\tau_p^y=2X_2^1(p)\quad\text{and}\quad \tau_p^x-\mathrm{i}\tau_p^y=2X_1^2(p), \tag{51}$$

we obtain the corresponding element in $\hat{C}_2^0$:

$$H^{\text{matrix}}_{\text{Ising}}=H_0+\lambda V, \tag{52}$$

where

$$H_0=g_1^1-g_2^2\quad\text{and}\quad V=\lambda[g_{11}^{22}+g_{12}^{21}+g_{21}^{12}+g_{22}^{11}]. \tag{53}$$

This is a two-matrix model with the Hamiltonian

$$\begin{aligned}H^{\text{matrix}}_{\text{Ising}}=&\,\mathrm{tr}[a^\dagger(1)a(1)-a^\dagger(2)a(2)]+(\lambda/N)\mathrm{tr}[a^\dagger(2)a^\dagger(2)a(1)a(1)\\&+a^\dagger(2)a^\dagger(1)a(2)a(1)+a^\dagger(1)a^\dagger(2)a(1)a(2)\\&+a^\dagger(1)a^\dagger(1)a(2)a(2)].\end{aligned} \tag{54}$$

Our results, along with known results of the Ising spin chain,[23] give the spectrum of this matrix model in the large N limit:

$$E(n_p,c,\lambda)=-2\sum_{p=-c}^{c}\left(1+2\lambda\,\cos\left[\frac{2\pi p}{2c+1}\right]+\lambda^2\right)^{1/2}n_p, \tag{55}$$

where c is any positive integer and $n_p=0$ or 1. Also, we must impose the condition $\Sigma_{p=-c}{}^{c}n_p p=0$ to get cyclically symmetric states. Let us underscore that *the matrix model defined by the Hamiltonian* $H^{\text{matrix}}_{\text{Ising}}$ *in Eqs. (53) or (54) is an integrable matrix model in the large-N limit.*

Equation (55) manifests the self-duality of the Ising model:

$$E(n_p,c,\lambda)=\lambda E(n_p,c,1/\lambda). \tag{56}$$

Indeed, under the operator dual transformation

$$\tilde{\tau}^x(p)\equiv\tau^z(p)\tau^z(p+1)\quad\text{and}\quad\tilde{\tau}^z(p)\equiv\tau^x(1)\tau^x(2)\cdots\tau^x(p), \tag{57}$$

the Hamiltonian is changed to

$$H^{\text{spin}}_{\text{Ising}}(\tilde{\tau},\lambda)=\sum_{p=1}^{c}\tilde{\tau}^x(p)\tilde{\tau}^x(p+1)+\lambda\sum_{p=1}^{c}\tilde{\tau}^z(p). \tag{58}$$

Since $\tilde{\tau}^x(p)$'s and $\tilde{\tau}^z(p)$'s satisfy the same algebra as $\tau^x(p)$'s and $\tau^z(p)$'s,

$$H^{\text{spin}}_{\text{Ising}}(\tilde{\tau},\lambda)=\lambda H^{\text{spin}}_{\text{Ising}}(\tau,1/\lambda), \tag{59}$$

i.e., the Ising model is self-dual.

It is possible to understand the solvability of the Ising model in terms of the Dolan–Grady conditions[24,25] and the Onsager algebra. Let us digress to summarize this method. Suppose we have a system whose Hamiltonian can be written as

$$H = H_0 + V \tag{60}$$

with the two terms in the Hamiltonian satisfying the Dolan–Grady conditions:

$$[H_0,[H_0,[H_0,V]]] = 16[H_0,V] \tag{61}$$

and

$$[V,[V,[V,H_0]]] = 16[V,H_0]. \tag{62}$$

Then we can construct operators satisfying an infinite-dimensional Lie algebra

$$[A_m,A_n] = 4G_{m-n}, \quad [G_m,A_n] = 2A_{n+m} - 2A_{n-m}, \quad \text{and } [G_m,G_n] = 0 \tag{63}$$

by the following recursion relations:

$$\begin{gathered} A_0 = H_0, \quad A_1 = V, \quad A_{n+1} - A_{n-1} = \tfrac{1}{2}[G_1,A_n], \\ G_1 = \tfrac{1}{4}[A_1,A_0], \quad \text{and } G_n = \tfrac{1}{4}[A_n,A_0]. \end{gathered} \tag{64}$$

This Lie algebra is called the Onsager Lie algebra. It is known to be isomorphic to an infinite direct sum of su(2) algebras. In particular, the system will admit an infinite number of conserved quantities:[26]

$$Q_m = -\tfrac{1}{2}(A_m + A_{-m} + \lambda A_{m+1} + \lambda A_{-m+1}). \tag{65}$$

Thus any such system should be integrable.

In the case of the Ising model we choose H_0 and V as above. The Lie brackets of the g_J^I then allow us to verify easily that the first of the Dolan–Grady conditions is satisfied. This, together with the self-duality of the Ising model, guarantee that the other Dolan–Grady condition is satisfied also. [Equation (62) could also be verified directly. The only caveat is that as the operators act on closed string states only, we have to treat all $\tilde{f}$'s as linear combinations of g's in order for Eq. (62) to hold true.] Moreover, we see that the Onsager algebra is a subalgebra of our algebra $\hat{C}_\Lambda^0$: all the conserved quantities are just linear combinations of our g_J^I and $\tilde{f}_J^I$. This suggests that there may be other models that are integrable by this method: we need to identify pairs of elements in our algebra that satisfy the Dolan–Grady conditions.

We can transcribe other integrable quantum spin chain models with the periodic boundary condition to integrable matrix models in the large-N limit. Some examples are listed below:

(i) *A generalization of the Ising model*.[26] The Hamiltonian is

$$H_{\mathrm{GI}}^{\mathrm{spin}} = \sum_{p=1}^{c} \tau_p^z + \lambda \sum_{p=1}^{c} [\tau_p^x \tau_{p+1}^x + v\{\tau_p^x \tau_{p+1}^y - \tau_p^y \tau_{p+1}^x\}], \tag{66}$$

where λ and v are constants. The corresponding Hamiltonian in the matrix model is

$$H_{\mathrm{GI}}^{\mathrm{matrix}} = g_1^1 - g_2^2 + \lambda[g_{11}^{22} + (1-2iv)g_{12}^{21} + (1+2iv)g_{21}^{12} + g_{22}^{11}]. \tag{67}$$

This model satisfies the Dolan–Grady conditions and hence is integrable using the Onsager subalgebra.

(ii) *The XYZ model*.[27] This is a generalization of the Ising model in another direction. It does not satisfy the Dolan–Grady condition, but is integrable by methods using the Yang–Baxter equation. The Hamiltonian is

$$H_{\mathrm{XYZ}}^{\mathrm{spin}} = \sum_{p=1}^{c} \tau_p^z \tau_{p+1}^z - \lambda \sum_{p=1}^{c} [\tau_p^x \tau_{p+1}^x + v\,\tau_p^y \tau_{p+1}^y]. \tag{68}$$

The corresponding Hamiltonian in the matrix model is

$$H_{\mathrm{XYZ}}^{\mathrm{matrix}}=g_{11}^{11}-g_{12}^{12}-g_{21}^{21}+g_{22}^{22}-\lambda[(1-v)(g_{11}^{22}+g_{22}^{11})+(1+v)(g_{12}^{21}+g_{21}^{12})]. \tag{69}$$

(iii) *The chiral Potts model.*[28] This is a model in which the number of quantum states available for a site is not restricted to 2 but is any finite positive integer. The Hamiltonian is

$$H_{\mathrm{CP}}^{\mathrm{spin}}=\sum_{p=1}^{c}\sum_{k=1}^{\Lambda-1}[\tilde{\alpha}_k Q_p^k+\lambda\alpha_k P_p^k P_{p+1}^{\Lambda-k}], \tag{70}$$

where

$$\alpha_k=\frac{e^{i\phi(2k/n-1)}}{\sin\,\pi k/n},\quad \tilde{\alpha}_k=\frac{e^{i\varphi(2k/n-1)}}{\sin\,\pi k/n},\quad \cos\,\varphi=\lambda\,\cos\,\phi,\quad \omega=e^{2\pi i/n},$$

$$\sigma_j=\begin{pmatrix}1&0&0&\dots&0\\0&\omega&0&\dots&0\\0&0&\omega^2&\dots&0\\&&\dots&&\\0&0&0&\dots&\omega^{n-1}\end{pmatrix},$$

and

$$\Gamma_j=\begin{pmatrix}0&0&0&\dots&0&1\\1&0&0&\dots&0&0\\0&1&0&\dots&0&0\\&&&\dots&&\\0&0&0&\dots&1&0\end{pmatrix}. \tag{71}$$

This model is exactly solvable by the Yang–Baxter method. The Hamiltonian of the associated solvable multi-matrix model is

$$H_{\mathrm{CP}}^{\mathrm{matrix}}=\sum_{k=1}^{\Lambda-1}\left[\tilde{\alpha}_k\sum_{j=1}^{\Lambda}\omega^{k(j-1)}g_j^j+\lambda\alpha_k\sum_{j_1,j_2=1}^{\Lambda}g_{j_1,j_2}^{j_1+k,j_2-k}\right], \tag{72}$$

where j_1+k should be replaced with $j_1+k-\Lambda$ if $j_1+k>\Lambda$ and j_2-k should be replaced with $j_2+\Lambda-k$ if $j_2-k\leqslant 0$ in $g_{j_1,j_2}^{j_1+k,j_2-k}$ in the above equation.

APPENDIX A: NOTATION FOR MULTI-INDICES

Much of our work involves manipulating tensors carrying multiple indices. For the convenience of the reader, we give here a summary of the notations used in this paper for multi-indices. We have attempted to match the notations with our other papers[10,11] and to make this Appendix self-contained. More details can be found in Ref. 11.

We will use lower case Latin letters such as i, j, i_1, and j_2 to denote indices which are positive integers 1, 2, . . . , and Λ. Here Λ itself is a fixed positive integer, denoting the number of degrees of freedom of gluons. A *nonempty* sequence of indices $i_1 i_2 i_3 \cdots i_a$ will be denoted by the corresponding uppercase letter I. The length of the sequence I will be denoted by $\#(I)$.

A capital letter I denotes a *nonempty* sequence of indices $i_1 i_2 \cdots i_a$, each taking values from the set $\{1,2,\ldots,\Lambda\}$. The length $\#(I)$ of I is just the number of elements in the sequence. Two sequences are equal if they have the same entries. Concatenation of two sequences will be denoted by

$$IJ = i_1 i_2 \cdots i_a j_1 j_2 \cdots j_b .$$

In particular,

$$Ij = i_1 i_2 \cdots i_a j, \tag{A1}$$

when only a single index is added at the end.

The Kronecker symbol has the obvious definition:

$$\delta^I_J \equiv \begin{cases} 1 & \text{if } I = J, \\ 0 & \text{if } I \neq J. \end{cases}$$

Thus,

$$\sum_{I_1 I_2 = I} X^{I_1} Y^{I_2}_K \equiv \sum_{I_1 I_2} \delta^{I_1 I_2}_I X^{I_1} Y^{I_2}_K , \tag{A2}$$

where X^{I_1} is a function dependent on I_1 and $Y^{I_2}_K$ is another function dependent on I_2 and K, denotes the sum over all the ways in which a given index I can be split into two *nonempty* subsequences I_1 and I_2. If there is no way to split I as required, then the sum simply yields 0.

We define (I) to be the equivalence class of all cyclic permutations of I. In fact (I) can be viewed as a discrete model for a closed loop, or closed string. The corresponding Kronecker delta function is defined by the following relation:

$$\delta^I_{(J)} \equiv \delta^I_J + \sum_{J_1 J_2 = J} \delta^I_{J_2 J_1} . \tag{A3}$$

Equation (A3) means that the delta function returns the number of different cyclic permutations of J such that each permuted sequence is identical with I. *Thus $\delta^I_{(J)}$ can take any non-negative integer as its value, not just 0 or 1.* The reader can verify from this definition that

$$\delta^I_{(J)} = \delta^J_{(I)} . \tag{A4}$$

Next, the expression

$$\sum_{(I)} X^I ,$$

where X^I is dependent on the equivalence class (I), i.e., $X^I = X^J$ if $(I) = (J)$, means that *all possible distinct equivalence classes* (I) are summed. Note that each equivalence class appears only *once* in the sum. In all cases of interest to us, it turns out that there are only a finite number of (I)'s such that $X^I \neq 0$.

Now we can introduce the formula that defines the following summation:

$$\sum_{I_1 I_2 \cdots I_n = (I)} X^{I_1, I_2, \ldots, I_n} \equiv \sum_{I_1, I_2, \ldots, I_n} \delta^{I_1 I_2 \cdots I_n}_{(I)} X^{I_1, I_2, \ \ldots \ , I_n}. \tag{A5}$$

In words, in Eq. (A5) we sum over all distinct ways of cyclically permuting I, and then all *distinct sets* of n nonempty sequences $I_1, I_2, \ldots, I_n$ (but note that within a particular set of $I_1, I_2, \ldots, I_n$, some of the sequences can be identical) such that $I_1 I_2 \cdots I_n$ is the same as this permuted sequence. This equation, together with Eq. (A4), then leads to

$$\delta_{(I)}^{I_1 I_2 \cdots I_n} = \sum_{I_1' I_2' \cdots I_n' = (I)} \delta_{I_1'}^{I_1} \delta_{I_2'}^{I_2} \cdots \delta_{I_n'}^{I_n}. \tag{A6}$$

A direct consequence of Eq. (A6) is

$$\delta_{(I)}^{I_1 I_2 \cdots I_n} = \delta_{(I)}^{I_2 I_3 \cdots I_n I_1}.$$

In addition, the reader can verify from Eq. (A5) together with Eqs. (A2), (A3) and (A4) that

$$\begin{aligned} \sum_{I_1 I_2 \cdots I_n = (I)} = \sum_{I_1, I_2, \ldots, I_n} \Bigg(& \delta_I^{I_1 I_2 \cdots I_n} + \sum_{I_{11} I_{12} = I_1} \delta_I^{I_{12} I_2 I_3 \cdots I_n I_{11}} + \delta_I^{I_2 I_3 \cdots I_n I_1} \\ & + \sum_{I_{21} I_{22} = I_2} \delta_I^{I_{22} I_3 \cdots I_n I_1 I_{21}} + \cdots + \delta_I^{I_n I_1 I_2 \cdots I_{n-1}} \\ & + \sum_{I_{n1} I_{n2} = I_n} \delta_I^{I_{n2} I_1 I_2 \cdots I_{n-1} I_{n1}} \Bigg). \end{aligned} \tag{A7}$$

APPENDIX B: LINEAR INDEPENDENCE OF STRINGLIKE OPERATORS

In this Appendix, we are going to show that the set of all $\tilde{f}_{(J)}^{(I)}$'s defined by Eq. (2) and all γ_J^I's defined by Eqs. (3) and (4) is linearly independent. This can be proved by *ad absurdum* as follows. Assume on the contrary that the set is linearly dependent. Then there exists an equation

$$\sum_{p=1}^{r} \alpha_p \tilde{f}_{(J_p)}^{(I_p)} + \sum_{p=r+1}^{s} \alpha_p \gamma_{J_p}^{I_p} = 0 \tag{B1}$$

such that r and s are positive integers with $r \leqslant s$ ($r = s$ means that the second sum vanishes), and all α_p's for $p = 1, 2, \ldots,$ and s are nonzero complex constants. In addition, in the above equation either $(I_p) \neq (I_q)$ or $(J_p) \neq (J_q)$ if $1 \leqslant p \leqslant r$, $1 \leqslant q \leqslant r$ and $p \neq q$, and either $I_p \neq I_q$ or $J_p \neq J_q$ if $r+1 \leqslant p \leqslant s$, $r+1 \leqslant q \leqslant s$ and $p \neq q$.

Assume that $s > r$. We can assume without loss of generality that

(1) $J_{r+1} = J_{r+2} = \cdots = J_{r+x}$;
(2) $J_{r+1} \neq J_{r+x+1}$, $J_{r+1} \neq J_{r+x+2}$, ..., and $J_{r+1} \neq J_s$; and
(3) $\#(J_{r+1}) \leqslant \#(J_p)$ for all $p = r+1, r+2, \ldots,$ and s for some integer x such that $r < x \leqslant s$.

Consider the action of the lhs of Eq. (B1) on $s^{J_{r+1}}$. We get

$$\left(\sum_{p=1}^{r} \alpha_p \tilde{f}_{(J_p)}^{(I_p)} + \sum_{p=r+1}^{s} \alpha_p \gamma_{J_p}^{I_p} \right) s^{J_{r+1}} = \sum_{p=r+1}^{r+x} \alpha_p s^{I_p}. \tag{B2}$$

Combining Eqs. (B1) and (B2) yields

$$\sum_{p=r+1}^{r+x} \alpha_p s^{I_p} = 0,$$

which is impossible because s^{I_r}, $s^{I_{r+1}}$, ..., $s^{I_{r+x}}$ are linearly independent. Therefore, $s = r$ and Eq. (B1) can be simplified to

$$\sum_{p=1}^{r} \alpha_p \tilde{f}_{(J_p)}^{(I_p)} = 0. \tag{B3}$$

Again we can assume without loss of generality that

(1) $(J_1) = (J_2) = \cdots = (J_y)$; and

(2) $(J_1)\neq(J_{y+1})$, $(J_1)\neq(J_{y+2})$, ..., and $(J_1)\neq(J_r)$ for some integer y such that $1\leqslant y\leqslant r$.

Consider the action of the lhs of Eq. (B3) on $\tilde{f}^{(I_1)}_{(J_1)}$:

$$\left(\sum_{p=1}^{r}\alpha_p\tilde{f}^{(I_p)}_{(J_p)}\right)\Psi^{(I_1)}_{(J_1)}=\sum_{p=1}^{y}\delta^{J_1}_{(J_1)}\alpha_p\Psi^{(I_p)}.$$

However, the rhs of this equation is impossible to vanish because $\Psi^{(I_1)}$, $\Psi^{(I_2)}$, ..., $\Psi^{(I_y)}$ are linearly independent. Thus the set of all $\tilde{f}^{(I)}_{(J)}$'s together with all γ^I_J's is linearly independent. Q.E.D.

APPENDIX C: MULTIPLICATION OF TWO STRINGLIKE OPERATORS

The assertion that the product $\gamma^I_J\gamma^K_L$ cannot be written in general as a finite linear combination of γ's and $\tilde{f}$'s can be proved by contradiction as follows. Consider the case when $\Lambda=1$. Let $\gamma^a_b=\gamma^{11\cdots1}_{11\cdots1}$, where the number 1 shows up a times in the superscript and b times in the subscript of γ. Moreover, let $\Psi^{(c)}=\Psi^{(11\cdots1)}$, where the number 1 shows up c times, and $s^d=s^{11\cdots1}$, where the number 1 shows up d times.

Assume that $\gamma^1_1\gamma^1_1=\Sigma_{p=1}{}^r\alpha_p\gamma^p_p+\Sigma_{q=1}{}^s\beta_q\tilde{f}^{(q)}_{(q)}$, where α_1, α_2, ..., α_r, β_1, β_2, ..., and β_s are nonzero complex numbers for some positive integers r and s. Then from the equations $\gamma^1_1\gamma^1_1(s^1)=\gamma^1_1(\gamma^1_1s^1)=1^2s^1$, $\gamma^1_1\gamma^1_1(s^2)=\gamma^1_1(\gamma^1_1s^1)=2^2s^1$, ..., and $\gamma^1_1\gamma^1_1(s^r)=\gamma^1_1(\gamma^1_1s^1)=r^2s^1$, we deduce that $\alpha_1=1$ and $\alpha_2=\alpha_3=\cdots=\alpha_r=2$. Hence $\gamma^1_1\gamma^1_1=\gamma^1_1+2\Sigma_{p=2}{}^r\gamma^p_p+\Sigma_{q=1}{}^s\beta_q\tilde{f}^{(q)}_{(q)}$. However, $\gamma^1_1\gamma^1_1(s^{r+1})=(r+1)^2s^{r+1}$ and $\gamma^1_1+2\Sigma_{p=2}{}^r\gamma^p_p+\Sigma_{q=1}{}^s\beta_q\tilde{f}^{(q)}_{(q)}(s^{r+1})=(r^2+2r-1)s^{r+1}$, leading to a contradiction.

Thus we assume instead $\gamma^1_1\gamma^1_1=\Sigma_{q=1}{}^s\beta_q\tilde{f}^{(q)}_{(q)}$, where the β_q's are nonzero complex numbers. However, $\gamma^1_1\gamma^1_1(\Psi^{(s+1)})=(s+1)^2\Psi^{(s+1)}$ whereas $\Sigma_{q=1}{}^s\beta_q\tilde{f}^{(q)}_{(q)}\Psi^{(s+1)}=0$, leading to a contradiction, too. Consequently, it is impossible to write $\gamma^1_1\gamma^1_1$ as a finite linear combination of γ's and $\tilde{f}$'s.

This proof can be easily generalized to the case $\Lambda>1$. Q.E.D.

APPENDIX D: THE COMMUTATION RELATIONS OF THE STRING-LIKE OPERATORS

What we need to do is to show that the three equations satisfy

$$[\gamma^I_J,\gamma^K_L]\Psi^{(P)}=\gamma^I_J(\gamma^K_L\Psi^{(P)})-\gamma^K_L(\gamma^I_J\Psi^{(P)}),\tag{D1}$$

$$[\gamma^I_J,\tilde{f}^{(K)}_{(L)}]\Psi^{(P)}=\gamma^I_J(\tilde{f}^{(K)}_{(L)}\Psi^{(P)})-\tilde{f}^{(K)}_{(L)}(\gamma^I_J\Psi^{(P)}),\tag{D2}$$

$$[\tilde{f}^{(I)}_{(J)},\tilde{f}^{(K)}_{(L)}]\Psi^{(P)}=\tilde{f}^{(I)}_{(J)}(\tilde{f}^{(K)}_{(L)}\Psi^{(P)})-\tilde{f}^{(K)}_{(L)}(\tilde{f}^{(I)}_{(J)}\Psi^{(P)}),\tag{D3}$$

$$[\gamma^I_J,\gamma^K_L]s^M=\gamma^I_J(\gamma^K_Ls^M)-\gamma^K_L(\gamma^I_Js^M),\tag{D4}$$

$$[\gamma^I_J,\tilde{f}^{(K)}_{(L)}]s^M=\gamma^I_J(\tilde{f}^{(K)}_{(L)}s^M)-\tilde{f}^{(K)}_{(L)}(\gamma^I_Js^M),\tag{D5}$$

and

$$[\tilde{f}^{(I)}_{(J)},\tilde{f}^{(K)}_{(L)}]s^M=\tilde{f}^{(I)}_{(J)}(\tilde{f}^{(K)}_{(L)}s^M)-\tilde{f}^{(K)}_{(L)}(\tilde{f}^{(I)}_{(J)}s^M).\tag{D6}$$

for any integer sequences I, J, K, L, M, and P. Equations (D5) and (D6) are trivially true. That Eq. (8) satisfies Eq. (D3) is also straightforward. What is remaining is whether Eq. (7) satisfies Eq. (D2), and whether Eq. (6) satisfies Eqs. (D4) and (D1).

Consider Eq. (7). The action of the Lie bracket operator on the lhs of this equation on $\Psi^{(P)}$, where P is arbitrary, can be evaluated using Eqs. (5) and (2), and we get

$$[\gamma^I_J,\tilde{f}^{(K)}_{(L)}]\Psi^{(P)}=\sum_{(Q)}\left(\delta^I_{(Q)}\delta^K_{(J)}\delta^P_{(L)}+\sum_A\delta^{IA}_{(Q)}\delta^K_{(JA)}\delta^P_{(L)}\right.$$

$$- \delta^K_{(Q)} \delta^I_{(L)} \delta^P_{(J)} - \sum_{A'} \delta^K_{(Q)} \delta^{IA'}_{(L)} \delta^P_{(JA')} \Bigg) \Psi^{(Q)}. \tag{D7}$$

On the other hand, the action of the operators on the rhs of Eq. (7) (let us call this linear combination of operators $g\tilde{f}^{I,K}_{J,L}$) on $\Psi^{(P)}$ is

$$g\tilde{f}^{I,K}_{J,L}\Psi^{(P)} = \sum_{(Q)} \Bigg(\delta^K_{(J)} \delta^I_{(Q)} \delta^P_{(L)} + \sum_{K_1 K_2 = (K)} \delta^{K_1}_J \delta^{IK_2}_{(Q)} \delta^P_{(L)} - \delta^I_{(L)} \delta^K_{(Q)} \delta^P_{(J)} - \sum_{L_1 L_2 = (L)} \delta^I_{L_2} \delta^K_{(Q)} \delta^P_{(L_1 J)} \Bigg) \Psi^{(Q)}. \tag{D8}$$

The rhs of Eqs. (D7) and (D8) can be seen to be the same by using the delta function defined in Eq. (A3).

Let us determine the correctness of Eq. (6). The properties of the delta functions discussed in Appendix A will be extensively used. To verify Eq. (D4), consider the action of the Lie bracket operator on the lhs of Eq. (6) on s^P, where P is arbitrary:

$$\begin{aligned}
[\gamma^I_J, \gamma^K_L] s^P = \sum_Q \Bigg(& \delta^I_Q \delta^K_J \delta^P_L + \sum_C \delta^I_Q \delta^{CK}_J \delta^P_{CL} + \sum_D \delta^I_Q \delta^{KD}_J \delta^P_{LD} \\
& + \sum_{C,D} \delta^I_Q \delta^{CKD}_J \delta^P_{CLD} + \sum_A \delta^{AI}_Q \delta^K_{AJ} \delta^P_L + \sum_{A,C} \delta^{AI}_Q \delta^{CK}_{AJ} \delta^P_{CL} \\
& + \sum_{A,D} \delta^{AI}_Q \delta^{KD}_{AJ} \delta^P_{LD} + \sum_{A,C,D} \delta^{AI}_Q \delta^{CKD}_{AJ} \delta^P_{CLD} + \sum_B \delta^{IB}_Q \delta^K_{JB} \delta^P_L \\
& + \sum_{B,C} \delta^{IB}_Q \delta^{CK}_{JB} \delta^P_{CL} + \sum_{B,D} \delta^{IB}_Q \delta^{KD}_{JB} \delta^P_{LD} + \sum_{B,C,D} \delta^{IB}_Q \delta^{CKD}_{JB} \delta^P_{CLD} \\
& + \sum_{A,B} \delta^{AIB}_Q \delta^K_{AJB} \delta^P_L + \sum_{A,B,C} \delta^{AIB}_Q \delta^{CK}_{AJB} \delta^P_{CL} + \sum_{A,B,D} \delta^{AIB}_Q \delta^{KD}_{AJB} \delta^P_{LD} \\
& + \sum_{A,B,C,D} \delta^{AIB}_Q \delta^{CKD}_{AJB} \delta^P_{CLD} \Bigg) s^Q - (I \leftrightarrow K, J \leftrightarrow L).
\end{aligned} \tag{D9}$$

After a tedious calculation (for more details on the intermediate steps, please see Ref. 14), Eq. (D9) leads to

$$\begin{aligned}
[\gamma^I_J, \gamma^K_L] s^P = \sum_Q \Bigg\{ & \delta^K_J \Bigg(\delta^I_Q \delta^P_L + \sum_E \delta^{EI}_Q \delta^P_{EL} + \sum_F \delta^{IF}_Q \delta^P_{LF} + \sum_{E,F} \delta^{EIF}_Q \delta^P_{ELF} \Bigg) \\
& + \sum_{J_1 J_2 = J} \delta^K_{J_2} \Bigg(\delta^I_Q \delta^P_{J_1 L} + \sum_E \delta^{EI}_Q \delta^P_{EJ_1 L} + \sum_F \delta^{IF}_Q \delta^P_{J_1 LF} + \sum_{E,F} \delta^{EIF}_Q \delta^P_{EJ_1 LF} \Bigg) \\
& + \sum_{K_1 K_2 = K} \delta^{K_1}_J \Bigg(\delta^{IK_2}_Q \delta^P_L + \sum_E \delta^{EIK_2}_Q \delta^P_{EL} + \sum_F \delta^{IK_2 F}_Q \delta^P_{LF} + \sum_{E,F} \delta^{EIK_2 F}_Q \delta^P_{ELF} \Bigg) \\
& + \sum_{J_1 J_2 = J} \delta^K_{J_1} \Bigg(\delta^I_Q \delta^P_{LJ_2} + \sum_E \delta^{EI}_Q \delta^P_{ELJ_2} + \sum_F \delta^{IF}_Q \delta^P_{LJ_2 F} + \sum_{E,F} \delta^{EIF}_Q \delta^P_{ELJ_2 F} \Bigg) \\
& + \sum_{K_1 K_2 = K} \delta^{K_2}_J \Bigg(\delta^{K_1 I}_Q \delta^P_L + \sum_E \delta^{EK_1 I}_Q \delta^P_{EL} + \sum_F \delta^{K_1 IF}_Q \delta^P_{LF} + \sum_{E,F} \delta^{EK_1 IF}_Q \delta^P_{ELF} \Bigg)
\end{aligned}$$

$$+\sum_{\substack{J_1J_2=J\\K_1K_2=K}}\delta^{K_1}_{J_2}\Big(\delta^{IK_2}_{Q}\delta^{P}_{J_1L}+\sum_{E}\delta^{EIK_2}_{Q}\delta^{P}_{EJ_1L}+\sum_{F}\delta^{IK_2F}_{Q}\delta^{P}_{J_1LF}+\sum_{E,F}\delta^{EIK_2F}_{Q}\delta^{P}_{EJ_1LF}\Big)$$

$$+\sum_{\substack{J_1J_2=J\\K_1K_2=K}}\delta^{K_2}_{J_1}\Big(\delta^{K_1I}_{Q}\delta^{P}_{LJ_2}+\sum_{E}\delta^{EK_1I}_{Q}\delta^{P}_{ELJ_2}+\sum_{F}\delta^{K_1IF}_{Q}\delta^{P}_{LJ_2F}+\sum_{E,F}\delta^{EK_1IF}_{Q}\delta^{P}_{ELJ_2F}\Big)$$

$$+\sum_{J_1J_2J_3=J}\delta^{K}_{J_2}\Big(\delta^{I}_{Q}\delta^{P}_{J_1LJ_3}+\sum_{E}\delta^{EI}_{Q}\delta^{P}_{EJ_1LJ_3}+\sum_{F}\delta^{IF}_{Q}\delta^{P}_{J_1LJ_3F}+\sum_{E,F}\delta^{EIF}\delta^{P}_{EJ_1LJ_3F}\Big)$$

$$+\sum_{K_1K_2K_3=K}\delta^{K_2}_{J}\Big(\delta^{K_1IK_3}_{Q}\delta^{P}_{L}+\sum_{E}\delta^{EK_1IK_3}_{Q}\delta^{P}_{EL}$$

$$+\sum_{F}\delta^{K_1IK_3F}_{Q}\delta^{P}_{LF}+\sum_{E,F}\delta^{EK_1IK_3F}_{Q}\delta^{P}_{ELF}\Big)+\Gamma_1\Bigg\}s^{Q}-(I\leftrightarrow K,J\leftrightarrow L),\tag{D10}$$

where

$$\Gamma_1=\delta^{IK}_{Q}\delta^{P}_{JL}+\sum_{E}\delta^{EIK}_{Q}\delta^{P}_{EJL}+\sum_{F}\delta^{IFK}_{Q}\delta^{P}_{JFL}+\sum_{G}\delta^{IKG}_{Q}\delta^{P}_{JLG}$$

$$+\sum_{E,F}\delta^{EIFK}_{Q}\delta^{P}_{EJFL}+\sum_{F,G}\delta^{IFKG}_{Q}\delta^{P}_{JFLG}+\sum_{E,G}\delta^{EIKG}_{Q}\delta^{P}_{EJLG}$$

$$+\sum_{E,F,G}\delta^{EIFKG}_{Q}\delta^{P}_{EJFLG}+(I\leftrightarrow K,J\leftrightarrow L).\tag{D11}$$

If we substitute Eq. (D10) without Γ_1 into Eq. (D9), we will obtain exactly the action of operators on the rhs of Eq. (7) on s^P. Γ_1 is reproduced when I and K are interchanged with J and L respectively in Eq. (D11) and so it is cancelled. Consequently, Eq. (D4) is indeed satisfied.

Now let us verify Eq.(D1). Consider the Lie bracket operator on the lhs of Eq. (6) on $\Psi^{(P)}$, where P is again arbitrary. We then obtain

$$[\gamma^{I}_{J},\gamma^{K}_{L}]\Psi^{(P)}=\sum_{(Q)}\Big(\delta^{I}_{(Q)}\delta^{K}_{(J)}\delta^{P}_{(L)}+\sum_{A}\delta^{IA}_{(Q)}\delta^{K}_{(JA)}\delta^{P}_{(L)}+\sum_{B}\delta^{I}_{(Q)}\delta^{KB}_{(J)}\delta^{P}_{(LB)}$$

$$+\sum_{A,B}\delta^{IA}_{(Q)}\delta^{KB}_{(JA)}\delta^{P}_{(LB)}\Big)\Psi^{(Q)}-(I\leftrightarrow K,J\leftrightarrow L).\tag{D12}$$

The first three summations on the rhs of this equation can be turned into the following expressions:

$$\delta^{I}_{(Q)}\delta^{K}_{(J)}\delta^{P}_{(L)}=\delta^{K}_{J}\delta^{I}_{(Q)}\delta^{P}_{(L)}+\sum_{\substack{J_1J_2=J\\K_1K_2=K}}\delta^{K_1}_{J_2}\delta^{K_2}_{J_1}\delta^{I}_{(Q)}\delta^{P}_{(L)},\tag{D13}$$

$$\sum_{A}\delta^{IA}_{(Q)}\delta^{K}_{(JA)}\delta^{P}_{(L)}=\sum_{K_1K_2=K}\delta^{K_1}_{J}\delta^{IK_2}_{(Q)}\delta^{P}_{(L)}+\sum_{K_1K_2=K}\delta^{K_2}_{J}\delta^{IK_1}_{(Q)}\delta^{P}_{(L)}$$

$$+\sum_{K_1K_2K_3=K}\delta^{K_2}_{J}\delta^{K_1IK_3}_{(Q)}\delta^{P}_{(L)}+\sum_{\substack{J_1J_2=J\\K_1K_2K_3=K}}\delta^{K_1}_{J_2}\delta^{K_3}_{J_1}\delta^{IK_2}_{(Q)}\delta^{L}_{(L)},\tag{D14}$$

and

$$\sum_{B}\delta^{I}_{(Q)}\delta^{KB}_{(J)}\delta^{P}_{(LB)}=\sum_{J_1J_2=J}\delta^{K}_{J_2}\delta^{I}_{(Q)}\delta^{P}_{(J_1L)}+\sum_{J_1J_2=J}\delta^{K}_{J_1}\delta^{I}_{(Q)}\delta^{P}_{(J_2L)}$$

$$+\sum_{J_1J_2J_3=J}\delta^K_{J_2}\delta^I_{(Q)}\delta^P_{(J_1LJ_3)}+\sum_{\substack{J_1J_2J_3=J\\K_1K_2=K}}\delta^{K_1}_{J_3}\delta^{K_2}_{J_1}\delta^I_{(Q)}\delta^P_{(J_2L)}. \tag{D15}$$

The fourth summation is more complicated. This can be manipulated to be

$$\begin{aligned}\sum_{A,B}\delta^{IA}_{(Q)}\delta^{KB}_{(JA)}\delta^P_{(LB)}=\delta^K_J\sum_C\delta^{IC}_{(Q)}\delta^P_{(LC)}&+\sum_{J_1J_2=J}\sum_C\delta^K_{J_1}\delta^{IC}_{(Q)}\delta^P_{(LJ_2C)}\\&+\sum_{K_1K_2=K}\sum_C\delta^{K_1}_J\delta^{IK_2C}_{(Q)}\delta^P_{(LC)}+\sum_{J_1J_2=J}\sum_C\delta^K_{J_2}\delta^{IC}_{(Q)}\delta^P_{(J_1LC)}\\&+\sum_{K_1K_2=K}\sum_C\delta^{K_2}_J\delta^{K_1IC}_{(Q)}\delta^P_{(LC)}+\sum_{\substack{J_1J_2=J\\K_1K_2=K}}\delta^{K_2}_{J_1}\delta^{IK_1}_{(Q)}\delta^P_{(J_2L)}\\&+\sum_{\substack{J_1J_2=J\\K_1K_2=K}}\delta^{K_1}_{J_2}\delta^{IK_2}_{(Q)}\delta^P_{(J_1L)}+\sum_{\substack{J_1J_2=J\\K_1K_2=K}}\sum_C\delta^{K_1}_{J_2}\delta^{IK_2C}_{(Q)}\delta^P_{(J_1LC)}\\&+\sum_{\substack{J_1J_2=J\\K_1K_2=K}}\sum_C\delta^{K_2}_{J_1}\delta^{K_1IC}_{(Q)}\delta^P_{(LJ_2C)}+\sum_{J_1J_2J_3=J}\sum_C\delta^K_{J_2}\delta^{IC}_{(Q)}\delta^P_{(J_1LJ_3C)}\\&+\sum_{K_1K_2K_3=K}\sum_C\delta^{K_2}_J\delta^{K_1IK_3C}_{(Q)}\delta^P_{(LC)}+\sum_{\substack{J_1J_2J_3=J\\K_1K_2K_3=K}}\delta^{K_1}_{J_3}\delta^{K_3}_{J_1}\delta^{IK_2}_{(Q)}\delta^P_{(J_2L)}+\Gamma_2,\end{aligned} \tag{D16}$$

where

$$\begin{aligned}\Gamma_2=&\sum_{\substack{P_1P_2=(P)\\Q_1Q_2=(Q)}}\delta^I_{Q_1}\delta^K_{Q_2}\delta^{P_1}_L\delta^{P_2}_J+\sum_{\substack{P_1P_2P_3=(P)\\Q_1Q_2Q_3=(Q)}}\delta^K_{Q_1}\delta^I_{Q_2}\delta^{P_1}_{Q_3}\delta^{P_2}_L\delta^{P_3}_J\\&+\sum_{\substack{P_1P_2P_3=(P)\\Q_1Q_2Q_3=(Q)}}\delta^I_{Q_1}\delta^K_{Q_2}\delta^{P_1}_{Q_3}\delta^{P_2}_J\delta^{P_3}_L+\sum_{\substack{P_1P_2P_3P_4=(P)\\Q_1Q_2Q_3Q_4=(Q)}}\delta^I_{Q_1}\delta^K_{Q_3}\delta^{P_1}_J\delta^{P_3}_L\delta^{P_2}_{Q_2}\delta^{P_4}_{Q_4}.\end{aligned} \tag{D17}$$

If we substitute Eqs. (D13), (D14), (D15) and (D16) without Γ_2 into Eq. (D12), we will obtain exactly the action of the operators on the rhs of Eq. (6) on $\Psi^{(P)}$. Γ_2 is reproduced when I and K are interchanged with J and L, respectively, in Eq. (D17) and so it is cancelled. Hence Eq. (D1) is also satisfied. Consequently, Eq. (6) is true. Q.E.D.

APPENDIX E: CARTAN SUBALGEBRA OF THE HETERIX ALGEBRA

First of all, it is obvious that $\mathcal{H}$ is Abelian. *A fortiori*, $\mathcal{H}$ is nilpotent. To proceed on, let us digress and state the following two lemmas:

Lemma 1: Let

$$[\gamma^I_I,\gamma^K_L]=\sum_{k=1}^{p}\alpha^{N_k}_{M_k}\gamma^{M_k}_{N_k}+\sum_{k=p+1}^{q}\alpha^{N_k}_{M_k}\tilde{f}^{(M_k)}_{(N_k)},$$

$$[\gamma^I_I,\tilde{f}^{(K)}_{(L)}]=\sum_{k=1}^{q}\alpha^{N_k}_{M_k}\tilde{f}^{(M_k)}_{(N_k)},\quad [\tilde{f}^{(I)}_{(I)},\gamma^K_L]=\sum_{k=1}^{q}\alpha^{N_k}_{M_k}\tilde{f}^{(M_k)}_{(N_k)},$$

and

$$[\tilde{f}^{(I)}_{(I)},\tilde{f}^{(K)}_{(L)}]=(\delta^{K}_{(I)}-\delta^{I}_{(L)})\tilde{f}^{(K)}_{(L)},$$

where p and q are finite non-negative integers such that $q\geqslant p$, M_k's *and* N_k's *are positive integer sequences such that* $\gamma^{M_k}_{N_k}\neq\gamma^{M'_k}_{N'_k}$ *and* $\tilde{f}^{(M_k)}_{(N_k)}\neq\tilde{f}^{(M'_k)}_{(N'_k)}$ *for* $k\neq k'$, *and* $\alpha^{N_k}_{M_k}$'s *are nonzero numerical coefficients. Then*

$$\#(M_k)-\#(N_k)=\#(K)-\#(L)$$

for every $k=1,2,\ldots,p$ or q.

This lemma can be proved by using Eqs. (6), (7) and (8) with $J=I$.

Lemma 2: With the same assumptions as in the previous lemma, we have

$$\#(M_k)+\#(N_k)\geqslant\#(K)+\#(L)$$

for every $k=1,2,\ldots,p$ *or* q.

This lemma can also be proved by using the same equations with $J=I$.

Let r and s be *positive* integers such that $s\geqslant r$. We are now ready to show for arbitrary nonzero complex numbers $\xi^{L_i}_{K_i}$'s where $i=1,2,\ldots,s$ and arbitrary integer sequences L_i's and K_i's such that $\gamma^{K_i}_{L_i}\neq\gamma^{K'_i}_{L'_i}$ and $\tilde{f}^{(K_i)}_{(L_i)}\neq\tilde{f}^{(K'_i)}_{(L'_i)}$ for $i\neq i'$, and $K_i\neq L_i$ for at least one i in $\{1,2,\ldots,r\}$ that there exisits a sequence I such that

$$\left[\gamma^{I},\sum_{i=1}^{r}\xi^{L_i}_{K_i}\gamma^{K_i}_{L_i}+\sum_{i=r+1}^{s}\xi^{L_i}_{K_i}\tilde{f}^{(K_i)}_{(L_i)}\right]$$

does not belong to $\mathcal{H}$. Indeed, let j be an integer such that

(1) $K_j\neq L_j$;
(2) $\#(K_j)-\#(L_j)\geqslant\#(K_i)-\#(L_i)$ for all $i=1,2,\ldots$ and r; and
(3) $\#(K_j)+\#(L_j)\leqslant\#(K_i)+\#(L_i)$ for any $i=1,2,\ldots$ or r such that $\#(K_j)-\#(L_j)=\#(K_i)-\#(L_i)$.

If $\#(K_j)\geqslant\#(L_j)$, then consider

$$\begin{aligned}\left[\gamma^{K_j}_{K_j},\sum_{i=1}^{r}\xi^{L_i}_{K_i}\gamma^{K_i}_{L_i}+\sum_{i=r+1}^{s}\xi^{L_i}_{K_i}\tilde{f}^{(K_i)}_{(L_i)}\right]&=\xi^{L_j}_{K_j}\gamma^{K_j}_{L_j}+\xi^{L_j}_{K_j}\left(\sum_{k=2}^{p_j}\alpha^{N_{jk}}_{M_{jk}}\gamma^{M_{jk}}_{N_{jk}}+\sum_{k=p_j+1}^{q_j}\alpha^{N_{jk}}_{M_{jk}}\tilde{f}^{(M_{jk})}_{(N_{jk})}\right)\\&\quad+\sum_{\substack{i=1\\ i\neq j}}^{r}\xi^{L_i}_{K_i}\left(\sum_{k=1}^{p_i}\alpha^{N_{ik}}_{M_{ik}}\gamma^{M_{ik}}_{N_{ik}}+\sum_{k=p_i+1}^{q_i}\alpha^{N_{ik}}_{M_{ik}}\tilde{f}^{(M_{ik})}_{(N_{ik})}\right)\\&\quad+\sum_{i=r+1}^{s}\xi^{L_i}_{K_i}\sum_{k=1}^{q'_i}\alpha^{N_{ik}}_{M_{ik}}\tilde{f}^{(M_{ik})}_{(N_{ik})},\end{aligned}\tag{E1}$$

where we have set $\alpha^{N_{j1}}_{M_{j1}}=1$, and each p_i, q_i for $i=1,2,\ldots,r$ and q'_i for $i=r+1,2,\ldots,s$ are dependent on i. Let us assume that

$$\gamma^{M_{ik}}_{N_{ik}}=\gamma^{K_i}_{L_i}\tag{E2}$$

for some $i\in\{1,2,\ldots,r\}$ but $i\neq j$ and $k\in\{1,2,\ldots,p_i\}$. Then $\#(M_{ik})=\#(K_j)$ and $\#(N_{ik})=\#(L_j)$. By Lemmas 1 and 2, we get $\#(K_i)=\#(K_j)$ and $\#(L_i)=\#(L_j)$. However, we also know that $K_i\neq K_j$ or $L_i\neq L_j$ and so there is no $k\in\{1,2,\ldots,p_i\}$ such that Eq. (E2) holds. This is a contradiction and so we conclude that

$$\gamma^{M_{ik}}_{N_{ik}}\neq\gamma^{K_i}_{L_i}$$

for *all* $i \in \{1,2,\ldots,r\}$ but $i \neq j$ and $k \in \{1,2,\ldots,p_i\}$. From Eq. (E1), we deduce that

$$\left[\gamma_{K_j}^{K_j}, \sum_{i=1}^{r} \xi_{K_i}^{L_i} \gamma_{L_i}^{K_i} + \sum_{i=r+1}^{s} \xi_{K_i}^{L_i} \tilde{f}_{(L_i)}^{(K_i)}\right]$$

does not belong to $\mathcal{H}$. Similarly, if $\#(K_j) \leqslant \#(L_j)$, then

$$\left[\gamma_{L_j}^{L_j}, \sum_{i=1}^{r} \xi_{K_i}^{L_i} \gamma_{L_i}^{K_i} + \sum_{i=1}^{s} \xi_{K_i}^{L_i} \tilde{f}_{(L_i)}^{(K_i)}\right]$$

does not belong to $\mathcal{H}$. Consequently,

$$\sum_{i=1}^{r} \xi_{K_i}^{L_i} \gamma_{L_i}^{K_i} + \sum_{i=r+1}^{s} \xi_{K_i}^{L_i} \tilde{f}_{(L_i)}^{(K_i)}$$

does not belong to the normalizer (see Ref. 12 for the definition of a normalizer) of $\mathcal{H}$ if $r \neq 0$ and $K_i \neq L_i$ for at least one $i = 1,2,\leqslant r$.

Now, consider

$$\sum_{i=1}^{r} \xi_{K_i}^{L_i} \gamma_{K_i}^{K_i} + \sum_{i=r+1}^{s} \xi_{K_i}^{L_i} \tilde{f}_{(L_i)}^{(K_i)},$$

where r is a non-negative integer and s a positive integer, $\xi_{K_i}^{L_i}$'s are complex constants and $\tilde{f}_{(L_i)}^{(K_i)} \neq \tilde{f}_{(L_i')}^{(K_i')}$ for $i \neq i'$, and $(K_i) \neq (L_i)$ for at least one $i \in \{r+1, r+2, \ldots, s\}$. We may well assume without loss of generality that $(K_{r+1}) \neq (L_{r+1})$. Then

$$\left[\tilde{f}_{(K_{r+1})}^{(K_{r+1})}, \sum_{i=1}^{r} \xi_{K_i}^{L_i} \gamma_{K_i}^{K_i} + \sum_{i=r+1}^{s} \xi_{K_i}^{L_i} \tilde{f}_{(L_i)}^{(K_i)}\right]$$

does not belong to $\mathcal{H}$, too. As a result, the normalizer of $\mathcal{H}$ is $\mathcal{H}$ itself. It is therefore that $\mathcal{H}$ is a Cartan subalgebra of the heterix algebra. Q.E.D.

APPENDIX F: ROOT VECTORS OF THE HETERIX ALGEBRA

Since the set of all $\tilde{f}_{(L)}^{(K)}$'s is linearly independent and the root for which $\tilde{f}_{(L)}^{(K)}$ is a root vector is distinct from the root for which $\tilde{f}_{(L')}^{(K')}$, where $(K) \neq (K')$ or $(L) \neq (L')$, is a root vector, every root vector which is a finite linear combination of $\tilde{f}_{(L)}^{(K)}$'s only must be a constant multiple of one $\tilde{f}_{(L)}^{(K)}$ only. Hence we only need to show that if a root vector is of the form

$$f = \sum_{P,Q} a_P^Q \gamma_Q^P + \sum_{(P),(Q)} b_{(P)}^{(Q)} \tilde{f}_{(Q)}^{(P)},$$

where a finite but *nonzero* number of a_P^Q's are nonzero, and a finite number of $b_{(P)}^{(Q)}$'s are nonzero as well, then f must be a constant multiple of a f_L^K.

Indeed, let

$$[\gamma_M^M, f] = \lambda_M f \quad \text{and} \quad [\tilde{f}_{(M)}^{(M)}, f] = \lambda_{(M)} f,$$

where each λ_M and each $\lambda_{(M)}$ are complex constants for any integer sequence M. Since

$$[\tilde{f}_{(M)}^{(M)}, f] \in \tilde{F}_\Lambda$$

but $f \notin \tilde{F}_\Lambda$, $\lambda_{(M)} = 0$ for any (M). Now obtain an expression for λ_M starting with the equation

$$[\gamma_M^M, f]s^K = \lambda_M f s^K \tag{F1}$$

as follows. From Eq. (4), we deduce that

$$\sigma_Q^P s^J = \sum_I \left(\delta_Q^J \delta_I^P + \sum_{J_1 J_2 = J} \delta_Q^{J_2} \delta_I^{J_1 P} + \sum_{J_1 J_2 = J} \delta_Q^{J_1} \delta_I^{P J_2} \sum_{J_1 J_2 J_3 = J} \delta_Q^{J_2} \delta_I^{J_1 P J_3} \right) s^I.$$

Therefore,

$$\begin{aligned}
[\sigma_M^M, f]s^K = \sum_{I,P,Q} \Bigg(& \delta_I^M \delta_Q^K \delta_M^P + \sum_{K_1 K_2 = K} \delta_I^M \delta_Q^{K_2} \delta_M^{K_1 P} + \sum_{K_1 K_2 = K} \delta_I^M \delta_Q^{K_1} \delta_M^{P K_2} \\
& + \sum_{K_1 K_2 K_3 = K} \delta_I^M \delta_Q^{K_2} \delta_M^{K_1 P K_3} + \sum_{I_1 I_2 = I} \delta_{I_2}^M \delta_Q^K \delta_I^P + \sum_{\substack{I_1 I_2 = I \\ K_1 K_2 = K}} \delta_{I_2}^M \delta_Q^{K_2} \delta_I^{K_1 P} \\
& + \sum_{\substack{I_1 I_2 = I \\ K_1 K_2 = K}} \delta_{I_2}^M \delta_Q^{K_1} \delta_I^{P K_2} + \sum_{\substack{I_1 I_2 = I \\ K_1 K_2 K_3 = K}} \delta_{I_2}^M \delta_Q^{K_2} \delta_I^{K_1 P K_3} + \sum_{I_1 I_2 = I} \delta_{I_1}^M \delta_Q^K \delta_I^P \\
& + \sum_{\substack{I_1 I_2 = I \\ K_1 K_2 = K}} \delta_{I_1}^M \delta_Q^{K_2} \delta_I^{K_1 P} + \sum_{\substack{I_1 I_2 = I \\ K_1 K_2 = K}} \delta_{I_1}^M \delta_Q^{K_1} \delta_I^{P K_2} + \sum_{\substack{I_1 I_2 = I \\ K_1 K_2 K_3 = K}} \delta_{I_1}^M \delta_Q^{K_2} \delta_I^{K_1 P K_3} \\
& + \sum_{I_1 I_2 I_3 = I} \delta_{I_2}^M \delta_Q^K \delta_I^P + \sum_{\substack{I_1 I_2 I_3 = I \\ K_1 K_2 = K}} \delta_{I_2}^M \delta_Q^{K_2} \delta_I^{K_1 P} + \sum_{\substack{I_1 I_2 I_3 = I \\ K_1 K_2 = K}} \delta_{I_2}^M \delta_Q^{K_1} \delta_I^{P K_2} \\
& + \sum_{\substack{I_1 I_2 I_3 = I \\ K_1 K_2 K_3 = K}} \delta_{I_2}^M \delta_Q^{K_2} \delta_I^{K_1 P K_3} \Bigg) a_P^Q s^I - \sum_{I,P,Q} \Bigg(\delta_I^P \delta_M^K \delta_Q^M + \sum_{K_1 K_2 = K} \delta_I^P \delta_M^{K_2} \delta_Q^K \\
& + \sum_{K_1 K_2 = K} \delta_I^P \delta_M^{K_1} \delta_Q^K + \sum_{K_1 K_2 K_3 = K} \delta_I^P \delta_M^{K_2} \delta_Q^K + \sum_{I_1 I_2 = I} \delta_{I_2}^P \delta_M^K \delta_{I_1 Q} + \sum_{\substack{I_1 I_2 = I \\ K_1 K_2 = K}} \delta_{I_2}^P \delta_M^{K_2} \delta_{I_1 Q}^K \\
& + \sum_{\substack{I_1 I_2 = I \\ K_1 K_2 = K}} \delta_{I_2}^P \delta_M^{K_1} \delta_{I_1 Q}^K + \sum_{\substack{I_1 I_2 = I \\ K_1 K_2 K_3 = K}} \delta_{I_2}^P \delta_M^{K_2} \delta_{I_1 Q}^K + \sum_{I_1 I_2 = I} \delta_{I_1}^P \delta_M^K \delta_{Q I_2} + \sum_{\substack{I_1 I_2 = I \\ K_1 K_2 = K}} \delta_{I_1}^P \delta_M^{K_2} \delta_{Q I_2}^K \\
& + \sum_{\substack{I_1 I_2 = I \\ K_1 K_2 = K}} \delta_{I_1}^P \delta_M^{K_1} \delta_{Q I_2}^K + \sum_{\substack{I_1 I_2 = I \\ K_1 K_2 K_3 = K}} \delta_{I_1}^P \delta_M^{K_2} \delta_{Q I_2}^K + \sum_{I_1 I_2 I_3 = I} \delta_{I_2}^P \delta_M^K \delta_{I_1 Q I_3} \\
& + \sum_{\substack{I_1 I_2 I_3 = I \\ K_1 K_2 = K}} \delta_{I_2}^P \delta_M^{K_2} \delta_{I_1 Q I_3}^K + \sum_{\substack{I_1 I_2 I_3 = I \\ K_1 K_2 = K}} \delta_{I_2}^P \delta_M^{K_1} \delta_{I_1 Q I_3}^K + \sum_{\substack{I_1 I_2 I_3 = I \\ K_1 K_2 K_3 = K}} \delta_{I_2}^P \delta_M^{K_2} \delta_{I_1 Q I_3}^K \Bigg) a_P^Q s^I.
\end{aligned} \tag{F2}$$

As a result, we can combine Eqs. (F1) and (F2) together to obtain an equation which is too long to be written down here for *any* integer sequences I, K, and M.

Let us find an a_R^S in f such that $R \neq S$, $a_R^S \neq 0$, $a_{R_1}^{S_1} = a_{R_2}^{S_2} = 0$ for all R_1's, S_1's, R_2's and S_2's such that $R_1 R_2 = R$ and $S_1 S_2 = S$, and $a_{R_2}^{S_2} = 0$ for all R_2's and S_2's such that $R_1 R_2 R_3 = R$ and $S_1 S_2 S_3 = S$ for some R_1, R_3, S_1 and S_3. The reader can easily convince himself or herself that such an a_R^S always exists. Let us choose $I = R$ and $K = S$ in Eq. (F2). Then when we combine Eqs. (F1) and (F2), we get

$$\lambda_M=\delta_M^R+\sum_{R_1R_2=R}\delta_M^{R_1}+\sum_{R_1R_2=R}\delta_M^{R_2}+\sum_{R_1R_2R_3=R}\delta_M^{R_2}-\delta_S^M-\sum_{S_1S_2=S}\delta_{S_1}^M-\sum_{S_1S_2=S}\delta_{S_2}^M-\sum_{S_1S_2S_3=S}\delta_{S_2}^M. \tag{F3}$$

Therefore, we obtain after some manipulation that

$$\lambda_M-\sum_{j=1}^{\Lambda}\lambda_{Mj}-\sum_{i=1}^{\Lambda}\lambda_{iM}+\sum_{i,j=1}^{\Lambda}\lambda_{iMj}=\delta_M^R-\delta_S^M.$$

This means

$$[f_R^R,f]\neq 0 \quad \text{and} \quad [f_S^S,f]\neq 0.$$

Thus $f\in F'_\Lambda$. Since we know that every f_L^K is a root vector, and the set of all f_L^K's is linearly independent, $f=f_L^K$ for some K and L. Q.E.D.

APPENDIX G: A BASIS FOR A $\Lambda=1$ QUOTIENT LIE ALGEBRA

We are going to prove that the set of all $\tilde{f}_{(b)}^{(a)}$, g_b^1 and g_1^a where a and b are arbitrary positive integers form a basis for the quotient algebra of all *cosets* γ_b^a and $\tilde{f}_{(b)}^{(a)}$. Indeed, consider the equation

$$\sum_{a,b=1}^{\infty}\alpha_{(a)}^{(b)}\tilde{f}_{(b)}^{(a)}+\sum_{d=1}^{\infty}\alpha^d g_d^1+\sum_{c=2}^{\infty}\alpha_c g_1^c=0, \tag{G1}$$

where only a finite number of the α's are nonzero. Let n be an integer such that for all a's and b's such that $\alpha_{(a)}^{(b)}\neq 0$, we have $n>b$ and for all d's such that $\alpha^d\neq 0$, we have $n>d$ also. Then

$$\left(\sum_{a,b=1}^{\infty}\alpha_{(a)}^{(b)}\tilde{f}_{(b)}^{(a)}+\sum_{d=1}^{\infty}\alpha^d g_d^1+\sum_{c=2}^{\infty}\alpha_c g_1^c\right)\Psi^{(n)}=\sum_{d=1}^{\infty}n\alpha^d\Psi^{(n-d+1)}+\sum_{c=2}^{\infty}n\alpha_c\Psi^{(n+c-1)}.$$

For the rhs of this equation to vanish, we need $\alpha^d=0$ and $\alpha_c=0$ for all c's and d's. Hence Eq. (G1) becomes

$$\sum_{a,b=1}^{\infty}\alpha_{(a)}^{(b)}\tilde{f}_{(b)}^{(a)}=0.$$

Then

$$\sum_{a,b=1}^{\infty}\alpha_{(a)}^{(b)}\tilde{f}_{(b)}^{(a)}\Psi^{(e)}=\sum_{a=1}^{\infty}e\,\alpha_{(a)}^{(e)}\Psi^{(a)}$$

for any positive integer e. Thus $\alpha_{(a)}^{(e)}=0$ also for any positive a and e. Consequently, the set of all $\tilde{f}_{(b)}^{(a)}$'s, g_b^1's and g_1^a's where a and b are arbitrary integers is linearly independent. Q.E.D.

APPENDIX H: CARTAN SUBALGEBRA OF A $\Lambda=1$ QUOTIENT LIE ALGEBRA

This can be seen as follows. From the results of Sec. II, we know that the subspace spanned by all $\tilde{f}_{(a)}^{(a)}$'s and g_1^1 forms an Abelian subalgebra. Moreover, consider a vector v of the form

$$v=\sum_{a,b=1}^{\infty}\alpha_{(a)}^{(b)}\tilde{f}_{(b)}^{(a)}+\sum_{d=2}^{\infty}\alpha^d g_d^1+\sum_{c=2}^{\infty}\alpha_c g_1^c$$

where only a finite number of the α's are not equal to 0, and where $\alpha_{(a)}^{(a)}=0$ for all $a=1,2,\ldots,\infty$. If all the α^d's and α_c's vanish, then choose a particular a_0 such that there exists a b with $\alpha_{(a_0)}^{(b)}\neq 0$. Then

$$[\tilde{f}^{(a_0)}_{(a_0)},v]=\sum_{b=1}^{\infty} a_0\alpha^{(b)}_{(a_0)}\tilde{f}^{(a_0)}_{(b)}-\sum_{a=1}^{\infty} a_0\alpha^{(a_0)}_{(a)}\tilde{f}^{(a)}_{(a_0)}\neq 0.$$

Hence v does not commute with the subspace spanned by all $\tilde{f}^{(a)}_{(a)}$'s and g^1_1. If there exists at least one nonzero α^d or α_c, set m to be the maximum of all a's and b's such that $\alpha^{(b)}_{(a)}\neq 0$. Then $\alpha^{(b')}_{(a')}=0$ if either b' or $a'>m$. Use Eq. (27) to rewrite each g^1_d and g^c_1 such that $\alpha^d\neq 0$ and $\alpha_c\neq 0$ as

$$g^1_d=\tilde{f}^{(1)}_{(d)}+\tilde{f}^{(2)}_{(d+1)}+\cdots+\tilde{f}^{(m)}_{(m+d-1)}+g^{m+1}_{d+m}$$

and

$$g^c_1=\tilde{f}^{(c)}_{(1)}+\tilde{f}^{(c+1)}_{(2)}+\cdots+\tilde{f}^{(m+c-1)}_{(m)}+g^{c+m}_{m+1}.$$

Then

$$v=\sum_{a,b=1}^{\infty}\alpha'^{(b)}_{(a)}\tilde{f}^{(a)}_{(b)}+\sum_{d=2}^{\infty}\alpha^d g^{m+1}_{d+m}+\sum_{c=2}^{\infty}\alpha_c g^{c+m}_{m+1},$$

where

$$\alpha'^{(b)}_{(a)}=\begin{cases}\alpha^{(b)}_{(a)}+\alpha_{a-b+1} & \text{if } a>b,\\ \alpha^{(b)}_{(a)}+\alpha^{b-a+1} & \text{if } b>a.\end{cases}$$

It is possible for $\alpha'^{(b)}_{(a)}\neq 0$ only if $b\leqslant m$ or $a\leqslant m$. If $\alpha'^{(b_0)}_{(a_0)}\neq 0$ for a particular pair of numbers b_0 and a_0, then

$$[\tilde{f}^{(b_0)}_{(b_0)},v]\neq 0 \quad \text{if } b_0\leqslant m \quad \text{or} \quad [\tilde{f}^{(a_0)}_{(a_0)},v]\neq 0 \quad \text{if } a_0\leqslant m$$

because

$$\left[\tilde{f}^{(b_0)}_{(b_0)},\sum_{d=2}^{\infty}\alpha^d g^{m+1}_{d+m}\right]=0 \quad \text{and} \quad \left[\tilde{f}^{(b_0)}_{(b_0)},\sum_{c=2}^{\infty}\alpha_c g^{c+m}_{m+1}\right]=0$$

if $b_0\leqslant m$, and

$$\left[\tilde{f}^{(a_0)}_{(a_0)},\sum_{d=2}^{\infty}\alpha^d g^{m+1}_{d+m}\right]=0 \quad \text{and} \quad \left[\tilde{f}^{(a_0)}_{(a_0)},\sum_{c=2}^{\infty}\alpha_c g^{c+m}_{m+1}\right]=0$$

if $a_0\leqslant m$. If all $\alpha'^{(b)}_{(a)}$'s vanish, then

$$v=\sum_{d=2}^{\infty}\alpha^d g^{m+1}_{d+m}+\sum_{c=2}^{\infty}\alpha_c g^{c+m}_{m+1}$$

and so

$$[\tilde{f}^{(m+1)}_{(m+1)},v]=\sum_{d=2}^{\infty}(m+1)\alpha^d\tilde{f}^{(m+1)}_{(d+m)}-\sum_{c=2}^{\infty}(m+1)\alpha_c\tilde{f}^{(c+m)}_{(m+1)}\neq 0.$$

Operator formulation of Wigner's *R*-matrix theories for the Schrödinger and Dirac equations

Radosław Szmytkowski
Faculty of Applied Physics and Mathematics, Technical University of Gdańsk, ul. Narutowicza 11/12, PL 80-952 Gdańsk, Poland

(Received 21 January 1998; accepted for publication 1 May 1998)

The *R*-matrix theories for the Schrödinger and Dirac equations are formulated in the language of integral operators. In the nonrelativistic theory the central role is played by an integral operator $\hat{\mathscr{R}}_{\mathsf{b}}(E)$ relating function values to normal derivatives on a surface $\mathscr{S}$ of a closed volume $\mathscr{V}$, inside which the function satisfies the Schrödinger equation at energy E. In the relativistic theory, the same role is played by two integral operators, $\hat{\mathscr{R}}_{\mathsf{b}}^{(+)}(E)$ and $\hat{\mathscr{R}}_{\mathsf{b}}^{(-)}(E)$, linking on the surface $\mathscr{S}$ values of upper and lower components of spinor wave functions satisfying in the volume $\mathscr{V}$ the Dirac equation at energy E. Systematic procedures for constructing the operators $\hat{\mathscr{R}}_{\mathsf{b}}(E)$ and $\hat{\mathscr{R}}_{\mathsf{b}}^{(\pm)}(E)$, generalizing the methods due to Kapur and Peierls and to Wigner, are presented. © *1998 American Institute of Physics.* [S0022-2488(98)00210-2]

I. INTRODUCTION

The *R*-matrix theory originated in the late 1930s[1] within the framework of the nuclear reactions theory. At the early stages of the evolvement of the method, the most significant contributions were made by Wigner[2–6] and since then the method has been invariably associated with his name. In the field of nuclear physics the theory achieved the most spectacular successes in the 1950s and the early 1960s.[7,8] Later, the interest of the nuclear physics community in the *R*-matrix theory diminished but at nearly the same time it was recognized that the method was ideally suited for applications in atomic and molecular physics. Over the last 30 years the *R*-matrix theory has evolved into one of the most popular and accurate methods used in theoretical studies of such atomic and molecular phenomena as electron collisions with atoms, molecules and ions, atomic and molecular photoionization and spectra of Rydberg systems.[9–11]

To summarize the most important features of the *R*-matrix theory, let us consider scattering of a particle of energy E in a field of a real local potential $V(\mathbf{r})$. In the *R*-matrix approach one divides the physical space into two regions separated by an imagined closed surface $\mathscr{S}$. It is assumed that in the external region the potential $V(\mathbf{r})$ is so simple that a general solution of a time-independent wave equation governing the dynamics of the particle in that region is known either analytically or at least in a numerical form. To the contrary, in the internal region $\mathscr{V}$ the potential $V(\mathbf{r})$ may be much more complicated. It was pointed out by Kapur and Peierls[1] and by Wigner and co-workers[2–6] that from the point of view of the external region, the domain $\mathscr{V}$ may be treated as a ''black box'' and the collision matrix $\mathsf{U}(E)$ may still be found provided one knows a natural boundary condition obeyed on the surface $\mathscr{S}$ by all solutions of the wave equation considered. It was shown by Teichmann and Wigner[6] that if an orthonormal set of basis functions $\{\Phi_i\}$ spanning the surface $\mathscr{S}$ is given, a general matrix form of such a natural boundary condition for the Schrödinger equation is

$$\mathsf{P}(E)=\mathsf{R}_{\mathsf{b}}(E)[\mathsf{D}(E)-\mathsf{b}\mathsf{P}(E)]. \tag{1}$$

In Eq. (1) $\mathsf{P}(E)$ and $\mathsf{D}(E)$ are column matrices containing, respectively, projections of the wave function Ψ and its normal derivative $\nabla_n\Psi$ at the surface $\mathscr{S}$ onto the surface basis functions $\{\Phi_i\}$, b is an arbitrary Hermitian matrix which may be chosen at one's will. The goal of the theory is to find the energy-dependent matrix $\mathsf{R}_{\mathsf{b}}(E)$. Once this goal is achieved, the collision matrix $\mathsf{U}(E)$ may be expressed in terms of the *R*-matrix $\mathsf{R}_{\mathsf{b}}(E)$.[6–8]

 © 1998 American Institute of Physics

Some years ago Nesbet[12,13] pointed out that since the Schrödinger equation is not a matrix equation but a partial differential equation, it is more fundamental to formulate the theory in terms of integral operators rather than in terms of matrices. According to Nesbet, in the nonrelativistic theory the central role is played not by the matrix $\mathsf{R}_{\mathfrak{b}}(E)$ itself but by an integral operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$ such that

$$\Psi(E,\boldsymbol{\rho})=\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)[\nabla_n\Psi(E,\boldsymbol{\rho})-\hat{\mathfrak{b}}\Psi(E,\boldsymbol{\rho})]. \tag{2}$$

Here $\boldsymbol{\rho}$ is an arbitrary point on the surface $\mathscr{S}$ and $\hat{\mathfrak{b}}$ is a Hermitian integral operator acting on functions defined on the surface $\mathscr{S}$ which may be chosen at our will. The operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$ is independent of the choice of a particular basis set spanning the surface $\mathscr{S}$. However, once such a basis set is chosen, matrix elements of the operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$ between basis functions form the matrix $\mathsf{R}_{\mathfrak{b}}(E)$ in that particular representation.

In this work we present the thorough discussion of the operator formulation of the version of the *R*-matrix theory due to Kapur and Peierls[1,14] and to Wigner.[2,3,4,6] We consider both the nonrelativistic case when the wave equation of the particle is the Schrödinger equation as well as the relativistic case of a particle whose dynamics are governed by the Dirac equation. There are two main motivations for undertaking this work. First, the operator formulation of the *R*-matrix theory is more general and elegant than the matrix approach. It is more transparent and therefore better suited for examining mathematical aspects of the method. Such a formulation is also in accord with the permanent trend in theoretical physics to make a mathematical formalism underlying any theoretical method as general and (to a reasonable extent) as rigorous as possible. Even if providing a general mathematical formulation of a particular method does not result in an immediate breakthrough in practical applications, usually it leads to better understanding of the essence of the method and may stimulate its further development. The second motivation is of a more practical nature. It appears that the operator formulation of the *R*-matrix theory relatively simply yields results which are valid for an arbitrarily shaped volume $\mathscr{V}$. This is of particular significance in the case of the *R*-matrix theory for the Dirac equation since previous attempts to develop such a theory based on a matrix approach[15–18] led to difficulties: the resulting theories either contained an error (this was shown by Szmytkowski and Hinze[17,18]) or were restricted solely to a spherically symmetric volume $\mathscr{V}$.[17,18]

The plan of the paper is as follows. In Sec. II the notation used subsequently is introduced. Section III deals with the nonrelativistic *R*-matrix theory. In Sec. III A it is shown how the operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$ arises in the theory. A method of constructing the integral kernel of the operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$ is discussed in Sec. III B. The operator formulation of the *R*-matrix theory for the Dirac equation is the subject of Sec. IV. In Sec. IV A two operators $\hat{\mathscr{R}}^{(+)}_{\hat{\mathfrak{b}}}(E)$ and $\hat{\mathscr{R}}^{(-)}_{\hat{\mathfrak{b}}}(E)$ are introduced. The operator $\hat{\mathscr{R}}^{(+)}_{\hat{\mathfrak{b}}}(E)$ is, to some extent, an analog of the nonrelativistic operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$. The nonrelativistic limit of the operator $\hat{\mathscr{R}}^{(+)}_{\hat{\mathfrak{b}}}(E)$ is discussed in Sec. IV B. In Sec. IV C the explicit forms of the operators $\hat{\mathscr{R}}^{(\pm)}_{\hat{\mathfrak{b}}}(E)$ are found. Finally, conclusions are presented in Sec. V.

II. PRELIMINARIES

Before we proceed to the matter, we acquaint the reader with the notation used throughout the paper. In the following, we shall restrict our considerations to a finite volume $\mathscr{V}$ bounded by a surface $\mathscr{S}$. Everywhere in the paper $\mathbf{r}$ stands for a position vector of a point in the volume $\mathscr{V}$. If the point $\mathbf{r}$ lies on the boundary $\mathscr{S}$, we use the symbol $\boldsymbol{\rho}$ instead of $\mathbf{r}$. Moreover, $\mathbf{n}(\boldsymbol{\rho})$ means an outward unit vector normal to the surface $\mathscr{S}$ at the point $\boldsymbol{\rho}$. Since this should not cause any misunderstanding, we shall use the same symbols to denote inner products of scalar or spinor functions. Thus, if $\Phi(\mathbf{r})$ and $\Phi'(\mathbf{r})$ are two scalar functions (such functions appear in the nonrelativistic theory), their volume and surface scalar products are

$$\langle\Phi|\Phi'\rangle\equiv\int_{\mathscr{V}}d^3\mathbf{r}\;\Phi^*(\mathbf{r})\Phi'(\mathbf{r}),\quad(\Phi|\Phi')\equiv\int_{\mathscr{S}}d^2\boldsymbol{\rho}\;\Phi^*(\boldsymbol{\rho})\Phi'(\boldsymbol{\rho}), \tag{3}$$

respectively, where the asterisk denotes the complex conjugation. If, in turn, $\Phi(\mathbf{r})$ and $\Phi'(\mathbf{r})$ are two spinor functions (encountered in the Dirac theory), their volume and surface scalar products are

$$\langle\Phi|\Phi'\rangle\equiv\int_{\mathscr{V}} d^3\mathbf{r}\ \Phi^\dagger(\mathbf{r})\Phi'(\mathbf{r}),\quad (\Phi|\Phi')\equiv\int_{\mathscr{S}} d^2\boldsymbol{\rho}\ \Phi^\dagger(\boldsymbol{\rho})\Phi'(\boldsymbol{\rho}),\tag{4}$$

respectively, where the dagger denotes the matrix Hermitian conjugation. In Eqs. (3) and (4) $d^3\mathbf{r}$ is an infinitesimal volume element around the point $\mathbf{r}$ and $d^2\boldsymbol{\rho}$ is an infinitesimal scalar surface element around the point $\boldsymbol{\rho}$.

The following notation concerning the operators will be used: if $\hat{\mathscr{O}}$ is an integral operator on the surface $\mathscr{S}$ and if $\mathscr{O}(\boldsymbol{\rho},\boldsymbol{\rho}')$ is its integral kernel, then for any well behaving scalar or spinor function $\Phi(\boldsymbol{\rho})$ we have

$$\hat{\mathscr{O}}\Phi(\boldsymbol{\rho})=\int_{\mathscr{S}} d^2\boldsymbol{\rho}'\ \mathscr{O}(\boldsymbol{\rho},\boldsymbol{\rho}')\Phi(\boldsymbol{\rho}'),\tag{5}$$

$$\Phi^\dagger(\boldsymbol{\rho})\hat{\mathscr{O}}=\int_{\mathscr{S}} d^2\boldsymbol{\rho}'\ \Phi^\dagger(\boldsymbol{\rho}')\mathscr{O}(\boldsymbol{\rho}',\boldsymbol{\rho})\tag{6}$$

[here the dagger denotes either the complex or the matrix Hermitian conjugation according to the type of the function $\Phi(\boldsymbol{\rho})$ used].

We also define a family of delta functions, $\delta^{(1)}_{\mathscr{S}}(\mathbf{r})$, $\delta^{(2)}(\boldsymbol{\rho}-\boldsymbol{\rho}')$ and $\delta^{(3)}(\mathbf{r}-\mathbf{r}')$, such that for any reasonable function $\Phi(\mathbf{r})$, either scalar or spinor, one has

$$\int_{\mathscr{V}} d^3\mathbf{r}\ \delta^{(1)}_{\mathscr{S}}(\mathbf{r})\Phi(\mathbf{r})=\int_{\mathscr{S}} d^2\boldsymbol{\rho}\ \Phi(\boldsymbol{\rho}),\tag{7}$$

$$\int_{\mathscr{S}} d^2\boldsymbol{\rho}'\ \delta^{(2)}(\boldsymbol{\rho}'-\boldsymbol{\rho})\Phi(\boldsymbol{\rho}')=\Phi(\boldsymbol{\rho}),\tag{8}$$

$$\int_{\mathscr{V}} d^3\mathbf{r}'\ \delta^{(3)}(\mathbf{r}'-\mathbf{r})\Phi(\mathbf{r}')=\Phi(\mathbf{r}),\quad \int_{\mathscr{V}} d^3\mathbf{r}'\ \delta^{(3)}(\mathbf{r}'-\boldsymbol{\rho})\Phi(\mathbf{r}')=\Phi(\boldsymbol{\rho}).\tag{9}$$

It may be inferred from Eqs. (7), (8) and the second of Eqs. (9) that, formally,

$$\delta^{(3)}(\mathbf{r}'-\boldsymbol{\rho})=\delta^{(2)}(\boldsymbol{\rho}'-\boldsymbol{\rho})\,\delta^{(1)}_{\mathscr{S}}(\mathbf{r}'),\quad \delta^{(1)}_{\mathscr{S}}(\mathbf{r})=\int_{\mathscr{S}} d^2\boldsymbol{\rho}'\ \delta^{(3)}(\boldsymbol{\rho}'-\mathbf{r}).\tag{10}$$

III. *R*-MATRIX THEORY FOR THE SCHRÖDINGER EQUATION

A. The operator $\hat{\mathscr{R}}_{\mathfrak{b}}(E)$

In this section we shall be concerned with a nonrelativistic pointlike and spinless particle of mass m moving with energy E in the field of force described by a real, local, in general noncentral potential $V(\mathbf{r})$. We restrict our considerations to the volume $\mathscr{V}$ bounded by the surface $\mathscr{S}$. [It is to be emphasized that the particle's movement is not constrained to the volume $\mathscr{V}$. The particle may leave and enter this volume across the surface $\mathscr{S}$ freely but we focus our attention on its movement when it penetrates the domain $\mathscr{V}$.] The Schrödinger equation describing the dynamics of the particle is

$$[\hat{H}-E]\Psi(E,\mathbf{r})=0,\tag{11}$$

where the Hamiltonian $\hat{H}$ is

$$\hat{H}=-\frac{\hbar^2}{2m}\,\boldsymbol{\nabla}^2+V(\mathbf{r}). \tag{12}$$

It will be assumed hereafter that energy E is real.

Consider now two wave functions $\Psi(E,\mathbf{r})$ and $\Psi'(E,\mathbf{r})$ which are solutions to the wave equation (11) corresponding to the same energy E. Premultiplying the equation for $\Psi(E,\mathbf{r})$ by $\Psi'^*(E,\mathbf{r})$ and the complex conjugate of the equation for $\Psi'(E,\mathbf{r})$ by $\Psi(E,\mathbf{r})$, subtracting, integrating the result over the volume $\mathscr{V}$, and making use of the Green integration theorem, we obtain

$$\langle\hat{H}\Psi'|\Psi\rangle-\langle\Psi'|\hat{H}\Psi\rangle=\frac{\hbar^2}{2m}\,(\Psi'|\nabla_n\Psi)-\frac{\hbar^2}{2m}\,(\nabla_n\Psi'|\Psi), \tag{13}$$

where $\nabla_n\Psi(E,\boldsymbol{\rho})$ denotes the outward normal derivative of the function $\Psi(E,\mathbf{r})$ at the surface point $\boldsymbol{\rho}$. By virtue of Eq. (11) and the reality of E, the left-hand side of Eq. (13) is zero. Consequently, we have

$$(\Psi'|\nabla_n\Psi)=(\nabla_n\Psi'|\Psi). \tag{14}$$

Equation (14) may be formally interpreted that the normal derivative operator ∇_n, when acting on functions satisfying in the interior of the volume $\mathscr{V}$ the Schrödinger equation (11) at the fixed energy E, is Hermitian with respect to the surface scalar product $(|)$.

We shall introduce now an auxiliary energy-dependent linear Hermitian integral operator $\hat{\mathscr{B}}(E)$ defined on $L^2_{(|)}(\mathscr{S})$ such that

$$\nabla_n\Psi(E,\boldsymbol{\rho})=\hat{\mathscr{B}}(E)\Psi(E,\boldsymbol{\rho}) \tag{15}$$

for any solution to Eq. (11) at energy E. The operator $\hat{\mathscr{B}}(E)$ is represented by an integral kernel $\mathscr{B}(E,\boldsymbol{\rho},\boldsymbol{\rho}')$ in terms of which Eq. (15) may be rewritten in the form

$$\nabla_n\Psi(E,\boldsymbol{\rho})=\int_{\mathscr{S}}d^2\boldsymbol{\rho}'\;\mathscr{B}(E,\boldsymbol{\rho},\boldsymbol{\rho}')\Psi(E,\boldsymbol{\rho}'). \tag{16}$$

The existence of the operator $\hat{\mathscr{B}}(E)$ has been proved by Szmytkowski[19] who has demonstrated that the kernel $\mathscr{B}(E,\boldsymbol{\rho},\boldsymbol{\rho}')$ has the representation

$$\mathscr{B}(E,\boldsymbol{\rho},\boldsymbol{\rho}')=\sum_i\;\Psi_i(E,\boldsymbol{\rho})b_i(E)\Psi_i^*(E,\boldsymbol{\rho}'), \tag{17}$$

where $\{\Psi_i(E,\mathbf{r})\}$ are those solutions to the Schrödinger equation (11) at energy E which have constant normal derivatives on $\mathscr{S}$,

$$\nabla_n\Psi_i(E,\boldsymbol{\rho})=b_i(E)\Psi_i(E,\boldsymbol{\rho}) \tag{18}$$

and are normalized according to $(\Psi_i|\Psi_i)=1$ (notice that the surface, *not* volume, scalar product has been used for the normalization purposes). It has been shown[19] that the numbers $\{b_i(E)\}$ are real and that the surface functions $\{\Psi_i(E,\boldsymbol{\rho})\}$ are such that $(\Psi_i|\Psi_j)=\delta_{ij}$.

It should be emphasized that the operators ∇_n and $\hat{\mathscr{B}}(E)$ are not identical. If $\Phi(\mathbf{r})$ is any sufficiently regular function defined in the volume $\mathscr{V}$, in general one has

$$\nabla_n\Phi(\boldsymbol{\rho})\neq\hat{\mathscr{B}}(E)\Phi(\boldsymbol{\rho}) \tag{19}$$

unless $\Phi(\mathbf{r})$ obeys in $\mathscr{V}$ the Schrödinger equation (11) at energy E.

We are now prepared to introduce an integral operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$ defined on $L^2_{(|)}(\mathscr{S})$, with the integral kernel $\mathscr{R}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')$, a matrix representation of which plays the central role in the R-matrix theory. Let $\hat{\mathfrak{b}}$ be some linear Hermitian integral operator defined on $L^2_{(|)}(\mathscr{S})$, with the integral kernel $\mathfrak{b}(\boldsymbol{\rho},\boldsymbol{\rho}')$. The operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$ is then defined as an operator reciprocal to the operator $\hat{\mathscr{B}}(E)-\hat{\mathfrak{b}}$ in the sense of

$$\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)[\hat{\mathscr{B}}(E)-\hat{\mathfrak{b}}]\hat{\mathscr{P}}(E)=\hat{\mathscr{P}}(E), \tag{20}$$

where $\hat{\mathscr{P}}(E)$ is the projector on the manifold of surface parts of solutions to the Schrödinger equation (11) at energy E with the kernel

$$\mathscr{P}(E,\boldsymbol{\rho},\boldsymbol{\rho}')=\sum_i \Psi_i(E,\boldsymbol{\rho})\Psi_i^*(E,\boldsymbol{\rho}'). \tag{21}$$

The functions $\{\Psi_i(E,\mathbf{r})\}$ have been defined below Eq. (17). In principle, the operator $\hat{\mathfrak{b}}$ used in the definition (20) may be arbitrary and the only restriction we impose on $\hat{\mathfrak{b}}$ is that the operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$ should exist. In terms of the operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$ the surface relation (15) may be rewritten in the form

$$\Psi(E,\boldsymbol{\rho})=\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)[\nabla_n-\hat{\mathfrak{b}}]\Psi(E,\boldsymbol{\rho}) \tag{22}$$

or, equivalently, in terms of the kernel $\mathscr{R}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')$, in the form

$$\Psi(E,\boldsymbol{\rho})=\int_{\mathscr{S}} d^2\boldsymbol{\rho}'\ \mathscr{R}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')[\nabla_n'-\hat{\mathfrak{b}}]\Psi(E,\boldsymbol{\rho}'). \tag{23}$$

To relate the operator and matrix formulations of the theory, we assume that some set of surface functions $\{\Phi_i(\boldsymbol{\rho})\}\in L^2_{(|)}(\mathscr{S})$ orthonormal under the surface scalar product $(|)$ and spanning the surface $\mathscr{S}$ is given. In this basis the kernel $\mathscr{R}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')$ has a bilinear expansion

$$\mathscr{R}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')=\sum_{i,j} \Phi_i(\boldsymbol{\rho})(\Phi_i|\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}\Phi_j)\Phi_j^*(\boldsymbol{\rho}'), \tag{24}$$

where the energy-dependent expansion coefficients

$$(\Phi_i|\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}\Phi_j)\equiv\int_{\mathscr{S}} d^2\boldsymbol{\rho}\int_{\mathscr{S}} d^2\boldsymbol{\rho}'\ \Phi_i^*(\boldsymbol{\rho})\mathscr{R}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')\Phi_j(\boldsymbol{\rho}'), \tag{25}$$

matrix elements of the operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$ between the basis functions $\{\Phi_i(\boldsymbol{\rho})\}$, form an R-matrix $\mathsf{R}_{\mathsf{b}}(E)$ in that particular representation. The matrix representation of Eq. (22), obtained by projecting the latter from the left on the basis functions $\{\Phi_i(\boldsymbol{\rho})\}$ is

$$\mathsf{P}(E)=\mathsf{R}_{\mathsf{b}}(E)[\mathsf{D}(E)-\mathsf{b}\mathsf{P}(E)], \tag{26}$$

where $\mathsf{P}(E)$ and $\mathsf{D}(E)$ are column matrices with elements $\{P_i(E)=(\Phi_i|\Psi)\}$ and $\{D_i(E)=(\Phi_i|\nabla_n\Psi)\}$, respectively, and b is a square matrix with elements $\{b_{ij}=(\Phi_i|\hat{\mathfrak{b}}\Phi_j)\}$. The relation (26) is identical with the relation (1) found by Teichmann and Wigner.[6] We have thus succeeded to formulate the R-matrix theory for the Schrödinger equation in terms of integral operators and to relate this formulation to the standard matrix approach to the theory. It remains to find the explicit form of the operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$. In Sec. III B we shall construct its kernel following the method due to Kapur and Peierls and to Wigner.

B. Construction of the operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$

In this section it will be our goal to find the operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$ defined by Eq. (20) by constructing its integral kernel $\mathscr{R}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')$. We shall follow, with improvements whenever they are necessary, an approach due to Kapur and Peierls[1] and to Wigner and co-workers.[2–6] For further purposes we shall need a set of functions $\{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\}$ defined as solutions of the boundary-value problem consisting of the Schrödinger differential equation

$$[\hat{H}-E_{\hat{\mathfrak{b}}k}]\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})=0 \tag{27}$$

and the boundary condition

$$\nabla_n \Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}) = \hat{\mathfrak{b}} \Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}) \tag{28}$$

with $\{E_{\hat{\mathfrak{b}}k}\}$ being eigenvalues. Because of the Hermicity of the operator $\hat{\mathfrak{b}}$ under the surface scalar product $(|)$, the boundary-value problem (27) and (28) is self-adjoint with respect to the volume scalar product $\langle|\rangle$ and therefore the eigenvalues $\{E_{\hat{\mathfrak{b}}k}\}$ are real and eigenfunctions belonging to different eigenvalues are orthogonal in the sense of

$$\langle \Psi_{\hat{\mathfrak{b}}k} | \Psi_{\hat{\mathfrak{b}}k'} \rangle = 0 \quad (E_{\hat{\mathfrak{b}}k} \neq E_{\hat{\mathfrak{b}}k'}). \tag{29}$$

In what follows, we shall assume that the functions belonging to degenerate eigenvalues (if there are any) have been also orthogonalized and that the normalization factors of the eigenfunctions have been chosen so that

$$\langle \Psi_{\hat{\mathfrak{b}}k} | \Psi_{\hat{\mathfrak{b}}k'} \rangle = \delta_{kk'}\,. \tag{30}$$

We assume also that the boundary condition operator $\hat{\mathfrak{b}}$ is such that the set of eigenfunctions $\{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\}$ is complete in the volume $\mathscr{V}$. The corresponding closure relation is then

$$\sum_k \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r}) \Psi^*_{\hat{\mathfrak{b}}k}(\mathbf{r}') = \delta^{(3)}(\mathbf{r}-\mathbf{r}') \quad (\mathbf{r},\mathbf{r}' \in \mathscr{V} \setminus \mathscr{S}). \tag{31}$$

[Notice that, because the functions $\{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\}$ are constrained to obey the boundary condition (28), it is not known *a priori* whether the relation (31) holds also for the points $\mathbf{r}$ and $\mathbf{r}'$ lying on the surface $\mathscr{S}$ or not. We shall study this problem later in this section.]

By virtue of the assumed completeness of the set $\{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\}$, one may use these functions for expanding the wave function $\Psi(E,\mathbf{r})$ satisfying the Schrödinger equation (11). Denoting the expansion by $\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\mathbf{r})$, one has

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\mathbf{r}) \equiv \sum_k \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r}) \langle \Psi_{\hat{\mathfrak{b}}k} | \Psi \rangle \tag{32}$$

or, explicitly,

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\mathbf{r}) \equiv \int_{\mathscr{V}} d^3\mathbf{r}' \left\{ \sum_k \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r}) \Psi^*_{\hat{\mathfrak{b}}k}(\mathbf{r}') \right\} \Psi(E,\mathbf{r}'). \tag{33}$$

The expansion coefficients $\langle \Psi_{\hat{\mathfrak{b}}k} | \Psi \rangle$ in Eq. (32) may be found in the standard way: One premultiplies Eq. (11) by $\Psi^*_{\hat{\mathfrak{b}}k}(\mathbf{r})$, postmultiplies the complex conjugate of Eq. (27) by $\Psi(E,\mathbf{r})$, subtracts and integrates the result over the volume $\mathscr{V}$ obtaining

$$\langle \hat{H} \Psi_{\hat{\mathfrak{b}}k} | \Psi \rangle - \langle \Psi_{\hat{\mathfrak{b}}k} | \hat{H} \Psi \rangle = [E_{\hat{\mathfrak{b}}k} - E] \langle \Psi_{\hat{\mathfrak{b}}k} | \Psi \rangle \tag{34}$$

which, after utilizing the explicit form (12) of the Hamiltonian $\hat{H}$ and the assumed Hermicity of the potential $V(\mathbf{r})$, becomes

$$\frac{\hbar^2}{2m} \langle \Psi_{\hat{\mathfrak{b}}k} | \boldsymbol{\nabla}^2 \Psi \rangle - \frac{\hbar^2}{2m} \langle \boldsymbol{\nabla}^2 \Psi_{\hat{\mathfrak{b}}k} | \Psi \rangle = [E_{\hat{\mathfrak{b}}k} - E] \langle \Psi_{\hat{\mathfrak{b}}k} | \Psi \rangle. \tag{35}$$

The left-hand side of Eq. (35) may be simplified by using the Green integration theorem which states that

$$\langle \Psi_{\hat{\mathfrak{b}}k} | \boldsymbol{\nabla}^2 \Psi \rangle - \langle \boldsymbol{\nabla}^2 \Psi_{\hat{\mathfrak{b}}k} | \Psi \rangle = (\Psi_{\hat{\mathfrak{b}}k} | \nabla_n \Psi) - (\nabla_n \Psi_{\hat{\mathfrak{b}}k} | \Psi). \tag{36}$$

Transforming the second surface integral on the right-hand side of Eq. (36) with the aid of the boundary condition (28) and substituting the resulting equation to Eq. (35) one arrives at

$$\langle \Psi_{\hat{\mathfrak{b}}k} | \Psi \rangle = \frac{\hbar^2}{2m} \frac{(\Psi_{\hat{\mathfrak{b}}k} | [\nabla_n - \hat{\mathfrak{b}}] \Psi)}{E_{\hat{\mathfrak{b}}k} - E}, \tag{37}$$

hence, it follows that

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E, \mathbf{r}) = \frac{\hbar^2}{2m} \sum_k \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r}) \frac{(\Psi_{\hat{\mathfrak{b}}k} | [\nabla_n - \hat{\mathfrak{b}}] \Psi)}{E_{\hat{\mathfrak{b}}k} - E}. \tag{38}$$

For the sake of convenience, we shall rewrite the latter equation in the explicit form

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E, \mathbf{r}) = \int_{\mathscr{S}} d^2\boldsymbol{\rho}' \frac{\hbar^2}{2m} \sum_k \frac{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r}) \Psi^*_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')}{E_{\hat{\mathfrak{b}}k} - E} [\nabla'_n - \hat{\mathfrak{b}}] \Psi(E, \boldsymbol{\rho}'). \tag{39}$$

Equation (39) holds for an arbitrary point $\mathbf{r}$ in the volume $\mathscr{V}$ and in particular it is valid also for points on the surface $\mathscr{S}$, i.e., one has

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E, \boldsymbol{\rho}) = \int_{\mathscr{S}} d^2\boldsymbol{\rho}' \frac{\hbar^2}{2m} \sum_k \frac{\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}) \Psi^*_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')}{E_{\hat{\mathfrak{b}}k} - E} [\nabla'_n - \hat{\mathfrak{b}}] \Psi(E, \boldsymbol{\rho}'). \tag{40}$$

To proceed further, we shall define an integral operator $\hat{\overline{\mathscr{R}}}_{\hat{\mathfrak{b}}}(E)$ relating the surface functions $\Psi(E, \boldsymbol{\rho})$ and $\overline{\Psi}_{\hat{\mathfrak{b}}}(E, \boldsymbol{\rho})$ in the following way:

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E, \boldsymbol{\rho}) = \hat{\overline{\mathscr{R}}}_{\hat{\mathfrak{b}}}(E) [\nabla_n - \hat{\mathfrak{b}}] \Psi(E, \boldsymbol{\rho}). \tag{41}$$

The operator $\hat{\overline{\mathscr{R}}}_{\hat{\mathfrak{b}}}(E)$ is represented by its integral kernel $\overline{\mathscr{R}}_{\hat{\mathfrak{b}}}(E, \boldsymbol{\rho}, \boldsymbol{\rho}')$ which, from Eqs. (40) and (41), is found to be

$$\overline{\mathscr{R}}_{\hat{\mathfrak{b}}}(E, \boldsymbol{\rho}, \boldsymbol{\rho}') = \frac{\hbar^2}{2m} \sum_k \frac{\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}) \Psi^*_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')}{E_{\hat{\mathfrak{b}}k} - E}. \tag{42}$$

Consider now the problem of convergence of the expansion $\overline{\Psi}_{\hat{\mathfrak{b}}}(E, \mathbf{r})$. If the point $\mathbf{r}$ lies in the interior of the volume $\mathscr{V}$, by virtue of the closure relation (31) and Eq. (33) we have

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E, \mathbf{r}) \equiv \int_{\mathscr{V}} d^3\mathbf{r}' \left\{ \sum_k \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r}) \Psi^*_{\hat{\mathfrak{b}}k}(\mathbf{r}') \right\} \Psi(E, \mathbf{r}') = \Psi(E, \mathbf{r}) \quad (\mathbf{r} \in \mathscr{V} \setminus \mathscr{S}). \tag{43}$$

On utilizing this result in Eq. (39) we obtain

$$\Psi(E, \mathbf{r}) = \int_{\mathscr{S}} d^2\boldsymbol{\rho}' \frac{\hbar^2}{2m} \sum_k \frac{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r}) \Psi^*_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')}{E_{\hat{\mathfrak{b}}k} - E} [\nabla'_n - \hat{\mathfrak{b}}] \Psi(E, \boldsymbol{\rho}') \quad (\mathbf{r} \in \mathscr{V} \setminus \mathscr{S}). \tag{44}$$

The relation (44) is valid for points $\mathbf{r}$ lying arbitrarily close to the surface $\mathscr{S}$. The function $\Psi(E, \mathbf{r})$ obeys the second-order differential equation (11) and therefore it is continuous across the surface $\mathscr{S}$. Hence, we must have

$$\Psi(E, \boldsymbol{\rho}) = \lim_{\mathbf{r} \to \boldsymbol{\rho}} \int_{\mathscr{S}} d^2\boldsymbol{\rho}' \frac{\hbar^2}{2m} \sum_k \frac{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r}) \Psi^*_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')}{E_{\hat{\mathfrak{b}}k} - E} [\nabla'_n - \hat{\mathfrak{b}}] \Psi(E, \boldsymbol{\rho}') \quad (\mathbf{r} \in \mathscr{V} \setminus \mathscr{S}) \tag{45}$$

and comparison of Eqs. (22) and (45) yields the following representation of the kernel $\mathscr{R}_{\hat{\mathfrak{b}}}(E, \boldsymbol{\rho}, \boldsymbol{\rho}')$:

$$\mathscr{R}_{\hat{\mathfrak{b}}}(E, \boldsymbol{\rho}, \boldsymbol{\rho}') = \lim_{\mathbf{r} \to \boldsymbol{\rho}} \left\{ \frac{\hbar^2}{2m} \sum_k \frac{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r}) \Psi^*_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')}{E_{\hat{\mathfrak{b}}k} - E} \right\}. \tag{46}$$

The question which arises now is: Can the operations $\underline{\lim}_{\mathbf{r}\to\boldsymbol{\rho}}$ and Σ_k be interchanged in Eq. (46)? Or, in other words, are the kernels $\mathscr{R}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')$ and $\overline{\mathscr{R}}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')$ identical? We shall show now that in the nonrelativistic case discussed in the present section the answer is positive. To this end, we observe that the question posed is closely related to the following problem: How does the closure relation for the functions $\{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\}$ look whenever any of the points $\mathbf{r},\mathbf{r}'$ lies on the surface $\mathscr{S}$? On the ground of the analysis of the form of Eq. (31) and the first of Eqs. (10) we assume that the following relations hold:

$$\sum_k \Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho})\Psi^*_{\hat{\mathfrak{b}}k}(\mathbf{r}') = \mathscr{A}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}')\,\delta^{(1)}_{\mathscr{S}}(\mathbf{r}') \quad (\mathbf{r}'\in\mathscr{V}), \tag{47}$$

$$\sum_k \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\Psi^*_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}') = \mathscr{A}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}')\,\delta^{(1)}_{\mathscr{S}}(\mathbf{r}) \quad (\mathbf{r}\in\mathscr{V}), \tag{48}$$

where the kernel $\mathscr{A}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}')$ defining the surface integral operator $\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}$ is to be found. It stems from the definitions (33) and (47) that the kernel $\mathscr{A}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}')$ relates the surface functions $\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho})$ and $\Psi(E,\boldsymbol{\rho})$ according to

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho}) = \int_{\mathscr{S}} d^2\boldsymbol{\rho}'\ \mathscr{A}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}')\Psi(E,\boldsymbol{\rho}'). \tag{49}$$

Equivalently, in an abstract form Eq. (49) reads

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho}) = \hat{\mathscr{A}}_{\hat{\mathfrak{b}}}\Psi(E,\boldsymbol{\rho}). \tag{50}$$

To determine $\mathscr{A}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}')$ we postmultiply the kernel

$$\sum_{k'} \Psi_{\hat{\mathfrak{b}}k'}(\boldsymbol{\rho})\Psi^*_{\hat{\mathfrak{b}}k'}(\mathbf{r}')$$

with an arbitrary eigenfunction from the basis set $\{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r}')\}$ and integrate the result over the volume $\mathscr{V}$. On one hand, from the orthogonality relation (30) one obtains

$$\int_{\mathscr{V}} d^3\mathbf{r}' \left\{ \sum_{k'} \Psi_{\hat{\mathfrak{b}}k'}(\boldsymbol{\rho})\Psi^*_{\hat{\mathfrak{b}}k'}(\mathbf{r}') \right\} \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r}') = \Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}). \tag{51}$$

On the other hand, from Eq. (47) one finds

$$\int_{\mathscr{V}} d^3\mathbf{r}' \left\{ \sum_{k'} \Psi_{\hat{\mathfrak{b}}k'}(\boldsymbol{\rho})\Psi^*_{\hat{\mathfrak{b}}k'}(\mathbf{r}') \right\} \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r}') = \hat{\mathscr{A}}_{\hat{\mathfrak{b}}}\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}). \tag{52}$$

From Eqs. (51) and (52) one infers that

$$\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}) = \Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}). \tag{53}$$

This relation holds for an arbitrary scalar eigenfunction $\Psi_{\hat{\mathfrak{b}}k}$ and therefore we conclude that

$$\hat{\mathscr{A}}_{\hat{\mathfrak{b}}} = \hat{\mathscr{T}} \Leftrightarrow \mathscr{A}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}') = \delta^{(2)}(\boldsymbol{\rho}-\boldsymbol{\rho}') \tag{54}$$

(here $\hat{\mathscr{T}}$ denotes the unit operator) which, in conjunction with Eq. (50), implies that

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho}) = \Psi(E,\boldsymbol{\rho}), \tag{55}$$

i.e., the eigenfunction expansion $\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\mathbf{r})$ converges to the function $\Psi(E,\mathbf{r})$ also at the surface $\mathscr{S}$. From Eqs. (41) and (56) we infer that

$$\Psi(E,\boldsymbol{\rho}) = \hat{\bar{\mathscr{R}}}_{\hat{\mathfrak{b}}}(E)[\nabla_n - \hat{\mathfrak{b}}]\Psi(E,\boldsymbol{\rho}), \tag{56}$$

hence it follows that the operators $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$ and $\hat{\tilde{\mathscr{R}}}_{\hat{\mathfrak{b}}}(E)$ are identical,

$$\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)=\hat{\tilde{\mathscr{R}}}_{\hat{\mathfrak{b}}}(E) \tag{57}$$

and therefore [cf. Eq. (42)] one has

$$\mathscr{R}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')=\frac{\hbar^2}{2m}\sum_k \frac{\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho})\Psi^*_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')}{E_{\hat{\mathfrak{b}}k}-E}, \tag{58}$$

which means that the operations Σ_k and $\lim_{\mathbf{r}\to\boldsymbol{\rho}}$ in Eq. (46) do commute. We have thus completed the task of finding the kernel of the operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$. It is to be noticed that, in virtue of the reality of the eigenvalues $\{E_{\hat{\mathfrak{b}}k}\}$, it follows from Eq. (58) that the kernel $\mathscr{R}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')$ possesses the property

$$\mathscr{R}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')=\mathscr{R}^*_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho}',\boldsymbol{\rho}), \tag{59}$$

which means that the operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$ is Hermitian.

Once the kernel $\mathscr{R}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')$ has been determined, the R-matrix $\mathsf{R}_{\mathfrak{b}}(E)$ may be found. Projecting Eq. (58) from the left and from the right on the surface basis functions $\{\Phi_i(\boldsymbol{\rho})\}$ we get the well known result for $\mathsf{R}_{\mathfrak{b}}(E)$ (cf., for instance, Ref. 9)

$$\mathsf{R}_{\mathfrak{b}}(E)=\frac{\hbar^2}{2m}\sum_k \frac{\mathsf{P}_{\mathfrak{b}k}\mathsf{P}^{\dagger}_{\mathfrak{b}k}}{E_{\mathfrak{b}k}-E}, \tag{60}$$

where $\{\mathsf{P}_{\mathfrak{b}k}\}$ are column vectors with elements $\{P_{i,\mathfrak{b}k}=(\Phi_i|\Psi_{\hat{\mathfrak{b}}k})\}$ and $\{\mathsf{P}^{\dagger}_{\mathfrak{b}k}\}$ are row vectors with elements $\{P^*_{i,\mathfrak{b}k}=(\Psi_{\hat{\mathfrak{b}}k}|\Phi_i)\}$. Equation (60) is to be used in Eq. (25). Thus, we have completed the task of finding the matrix $\mathsf{R}_{\mathfrak{b}}(E)$ using the integral operators formalism.

In addition, it is to be noticed that as a by-product of the determination of the operator $\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}$, from Eqs. (47), (48) and the second of Eqs. (54) we obtain the following extensions of the closure relation (31) for the cases when the point $\mathbf{r}'$ lies on the surface $\mathscr{S}$,

$$\sum_k \Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')\Psi^*_{\hat{\mathfrak{b}}k}(\mathbf{r})=\sum_k \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\Psi^*_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')=\delta^{(3)}(\mathbf{r}-\boldsymbol{\rho}') \quad (\mathbf{r}\in\mathscr{V}). \tag{61}$$

IV. *R*-MATRIX THEORY FOR THE DIRAC EQUATION

A. The operators $\hat{\mathscr{R}}^{(\pm)}_{\hat{\mathfrak{b}}}(E)$

In this section we shall present an operator formulation of the R-matrix theory for a Dirac particle moving in a real, local, in general noncentral potential $V(\mathbf{r})$. As in the nonrelativistic case discussed above, we restrict our considerations to the closed volume $\mathscr{V}$ surrounded by the surface $\mathscr{S}$ [in this connection, see a remark preceding Eq. (11)]. The time-independent Dirac equation describing the particle is

$$[\hat{H}-E]\Psi(E,\mathbf{r})=0, \tag{62}$$

where E is the total energy of the particle (including its rest energy mc^2) and the Hamiltonian $\hat{H}$ is

$$\hat{H}=-ic\hbar\,\boldsymbol{\alpha}\cdot\boldsymbol{\nabla}+\beta mc^2+V(\mathbf{r}), \tag{63}$$

where the Hermitian 4×4 Dirac matrices $\boldsymbol{\alpha}$ and β are defined as usual.[20]

Before proceeding further, we have to define a matrix function

$$\alpha_n(\boldsymbol{\rho})=\mathbf{n}(\boldsymbol{\rho})\cdot\boldsymbol{\alpha} \tag{64}$$

and a set of matrices

$$\beta^{(\pm)}=\frac{I\pm\beta}{2},\quad \alpha_n^{(\pm)}(\boldsymbol{\rho})=\beta^{(\pm)}\alpha_n(\boldsymbol{\rho}), \tag{65}$$

where I is the unit 4×4 matrix. The matrices $\alpha_n^{(\pm)}(\boldsymbol{\rho})$ and $\beta^{(\pm)}$ satisfy the following relations:

$$\alpha_n^{(+)}(\boldsymbol{\rho})+\alpha_n^{(-)}(\boldsymbol{\rho})=\alpha_n(\boldsymbol{\rho}),\quad \beta^{(+)}+\beta^{(-)}=I, \tag{66}$$

$$\alpha_n^{(\pm)\dagger}(\boldsymbol{\rho})=\alpha_n^{(\mp)}(\boldsymbol{\rho}),\quad \beta^{(\pm)\dagger}=\beta^{(\pm)}. \tag{67}$$

For the sake of later applications, we list also the following properties of the matrices $\beta^{(\pm)}$ and $\alpha_n^{(\pm)}(\boldsymbol{\rho})$:

$$\beta^{(\pm)}\beta^{(\pm)}=\beta^{(\pm)},\quad \beta^{(\pm)}\beta^{(\mp)}=0,\quad \alpha_n^{(\pm)}(\boldsymbol{\rho})\alpha_n^{(\pm)}(\boldsymbol{\rho})=0,\quad \alpha_n^{(\pm)}(\boldsymbol{\rho})\alpha_n^{(\mp)}(\boldsymbol{\rho})=\beta^{(\pm)}, \tag{68}$$

$$\alpha_n^{(\pm)}(\boldsymbol{\rho})\beta^{(\pm)}=0,\quad \beta^{(\pm)}\alpha_n^{(\pm)}(\boldsymbol{\rho})=\alpha_n^{(\pm)}(\boldsymbol{\rho}),\quad \beta^{(\pm)}\alpha_n^{(\mp)}(\boldsymbol{\rho})=0,\quad \alpha_n^{(\pm)}(\boldsymbol{\rho})\beta^{(\mp)}=\alpha_n^{(\pm)}(\boldsymbol{\rho}), \tag{69}$$

which may be easily derived from the definitions (64) and (65) and the anticommutation relations satisfied by the matrices $\boldsymbol{\alpha}$ and β.[20] Henceforth, whenever the matrices $\alpha_n^{(\pm)}(\boldsymbol{\rho})$ multiply an integral operator, we shall omit their argument $\boldsymbol{\rho}$ and assume that the following notational convention holds: If $\hat{\mathscr{O}}$ is an operator with a kernel $\mathscr{O}(\boldsymbol{\rho},\boldsymbol{\rho}')$, then $\alpha_n^{(\pm)}\hat{\mathscr{O}}$ and $\hat{\mathscr{O}}\alpha_n^{(\pm)}$ are operators with kernels $\alpha_n^{(\pm)}(\boldsymbol{\rho})\mathscr{O}(\boldsymbol{\rho},\boldsymbol{\rho}')$ and $\mathscr{O}(\boldsymbol{\rho},\boldsymbol{\rho}')\alpha_n^{(\pm)}(\boldsymbol{\rho}')$, respectively.

After that preparation we are now ready to attack the problem posed. Let $\Psi(E,\mathbf{r})$ and $\Psi'(E,\mathbf{r})$ be two solutions to Eq. (62) at the same energy E. On applying the Gauss divergence theorem we find

$$\langle\hat{H}\Psi'|\Psi\rangle-\langle\Psi'|\hat{H}\Psi\rangle=(\Psi'|ic\hbar\alpha_n\Psi). \tag{70}$$

By virtue of the reality of E, the left-hand side of this equation vanishes and we obtain

$$(\Psi'|i\alpha_n\Psi)=0. \tag{71}$$

On utilizing Eqs. (66) and (67) we may rewrite this relation in two equivalent forms,

$$(i\alpha_n^{(+)}\Psi'|\Psi)=(\Psi'|i\alpha_n^{(+)}\Psi),\quad (i\alpha_n^{(-)}\Psi'|\Psi)=(\Psi'|i\alpha_n^{(-)}\Psi). \tag{72}$$

Relations (72) may be formally interpreted that $i\alpha_n^{(\pm)}$, when acting on solutions of the Dirac equation (62) at fixed energy E, are Hermitian with respect to the surface scalar product $(|)$.

In the next step, we introduce two auxiliary energy-dependent linear Hermitian integral operators $\hat{\mathscr{B}}^{(\pm)}(E)$ defined on $L^2_{(|)}(\mathscr{S})$ such that

$$i\alpha_n^{(\pm)}(\boldsymbol{\rho})\Psi(E,\boldsymbol{\rho})=\gamma^{(\pm)}\hat{\mathscr{B}}^{(\pm)}(E)\Psi(E,\boldsymbol{\rho}) \tag{73}$$

for any solution of Eq. (62) at energy E. In Eq. (73) and hereafter

$$\gamma^{(\pm)}=\pm\left(\frac{\hbar}{2mc}\right)^{\pm1} \tag{74}$$

are numerical constants introduced for later convenience, primarily to facilitate a later discussion of the nonrelativistic limit [notice that $\gamma^{(\mp)}=-(\gamma^{(\pm)})^{-1}$]. The operators $\hat{\mathscr{B}}^{(\pm)}(E)$ are represented by their integral kernels $\mathscr{B}^{(\pm)}(E,\boldsymbol{\rho},\boldsymbol{\rho}')$ and Eq. (73) may be equivalently rewritten in the form

$$i\alpha_n^{(\pm)}(\boldsymbol{\rho})\Psi(E,\boldsymbol{\rho})=\gamma^{(\pm)}\int_{\mathscr{S}}d^2\boldsymbol{\rho}'\ \mathscr{B}^{(\pm)}(E,\boldsymbol{\rho},\boldsymbol{\rho}')\Psi(E,\boldsymbol{\rho}'). \tag{75}$$

The existence of the operators $\hat{\mathscr{B}}^{(\pm)}(E)$ has been proved by Szmytkowski[21] who has shown that the kernels $\mathscr{B}^{(\pm)}(E,\boldsymbol{\rho},\boldsymbol{\rho}')$ may be written in the forms

$$\mathscr{B}^{(+)}(E,\boldsymbol{\rho},\boldsymbol{\rho}')=\sum_i \beta^{(+)}\Psi_i(E,\boldsymbol{\rho})b_i(E)\Psi_i^\dagger(E,\boldsymbol{\rho}')\beta^{(+)}, \tag{76}$$

$$\mathscr{B}^{(-)}(E,\boldsymbol{\rho},\boldsymbol{\rho}')=(\gamma^{(-)})^2\sum_i \beta^{(-)}\Psi_i(E,\boldsymbol{\rho})b_i^{-3}(E)\Psi_i^\dagger(E,\boldsymbol{\rho}')\beta^{(-)}, \tag{77}$$

where $\{\Psi_i(E,\mathbf{r})\}$ are those solutions to the Dirac equation (62) at energy E which on the surface $\mathscr{S}$ satisfy the relations

$$i\alpha_n^{(+)}(\boldsymbol{\rho})\Psi_i(E,\boldsymbol{\rho})=\gamma^{(+)}b_i(E)\beta^{(+)}\Psi_i(E,\boldsymbol{\rho}) \tag{78}$$

and are normalized according to $(\Psi_i|\beta^{(+)}\Psi_i)=1$. It may be shown[21] that, as in the nonrelativistic case, the numbers $\{b_i(E)\}$ are real and that the surface spinor functions $\{\Psi_i(E,\boldsymbol{\rho})\}$ are orthogonal in the sense of $(\Psi_i|\beta^{(+)}\Psi_j)=\delta_{ij}$.

It is to be noticed that Eqs. (76) and (77) imply the following property of the operators $\hat{\mathscr{B}}^{(\pm)}(E)$:

$$\beta^{(\pm)}\hat{\mathscr{B}}^{(\pm)}(E)\beta^{(\pm)}=\hat{\mathscr{B}}^{(\pm)}(E). \tag{79}$$

Moreover, the operators $\hat{\mathscr{B}}^{(+)}(E)$ and $\hat{\mathscr{B}}^{(-)}(E)$ are not independent. Indeed, operating on Eq. (73) from the left with $-i\alpha_n^{(\mp)}(\boldsymbol{\rho})$ yields

$$\beta^{(\mp)}\Psi(E,\boldsymbol{\rho})=-\gamma^{(\pm)}i\alpha_n^{(\mp)}\hat{\mathscr{B}}^{(\pm)}(E)\Psi(E,\boldsymbol{\rho}). \tag{80}$$

Operating then on this equation from the left with $\alpha_n^{(\pm)}\hat{\mathscr{B}}^{(\mp)}(E)$ and transforming the resulting equation with the aid of Eq. (80) gives

$$\beta^{(\pm)}\Psi(E,\boldsymbol{\rho})=\alpha_n^{(\pm)}\hat{\mathscr{B}}^{(\mp)}(E)\alpha_n^{(\mp)}\hat{\mathscr{B}}^{(\pm)}(E)\Psi(E,\boldsymbol{\rho}), \tag{81}$$

which implies that the operators $\hat{\mathscr{B}}^{(\pm)}(E)$ and $\alpha_n^{(\pm)}\hat{\mathscr{B}}^{(\mp)}(E)\alpha_n^{(\mp)}$ are reciprocal in the sense of

$$[\alpha_n^{(\pm)}\hat{\mathscr{B}}^{(\mp)}(E)\alpha_n^{(\mp)}]\hat{\mathscr{B}}^{(\pm)}(E)\hat{\mathscr{P}}^{(\pm)}(E)=\hat{\mathscr{P}}^{(\pm)}(E), \tag{82}$$

where the projectors $\hat{\mathscr{P}}^{(\pm)}(E)$ are related to the operator $\hat{\mathscr{P}}(E)$ projecting on the surface parts of solutions to the Dirac equation (62) at energy E in the following way:

$$\hat{\mathscr{P}}^{(\pm)}(E)=\beta^{(\pm)}\hat{\mathscr{P}}(E)\beta^{(\pm)}. \tag{83}$$

Integral kernels of the projectors $\hat{\mathscr{P}}^{(\pm)}(E)$ are

$$\mathscr{P}^{(+)}(E,\boldsymbol{\rho},\boldsymbol{\rho}')=\sum_i \beta^{(+)}\Psi_i(E,\boldsymbol{\rho})\Psi_i^\dagger(E,\boldsymbol{\rho}')\beta^{(+)}, \tag{84}$$

$$\mathscr{P}^{(-)}(E,\boldsymbol{\rho},\boldsymbol{\rho}')=(\gamma^{(-)})^2\sum_i \beta^{(-)}\Psi_i(E,\boldsymbol{\rho})b_i^{-2}(E)\Psi_i^\dagger(E,\boldsymbol{\rho}')\beta^{(-)}, \tag{85}$$

where the numbers $\{b_i(E)\}$ and the functions $\{\Psi_i(E,\mathbf{r})\}$ have been defined below Eqs. (76) and (77).

A note analogous to that remarked in the paragraph following Eq. (18) is in order here. Namely, we emphasize that the operators $i\alpha_n^{(\pm)}$ and $\gamma^{(\pm)}\hat{\mathscr{B}}^{(\pm)}(E)$ are not identical and for an arbitrary four-component spinor function $\Phi(\boldsymbol{\rho})$ defined on $\mathscr{S}$ in general one has

$$i\alpha_n^{(\pm)}(\boldsymbol{\rho})\Phi(\boldsymbol{\rho})\neq\gamma^{(\pm)}\hat{\mathscr{B}}^{(\pm)}(E)\Phi(\boldsymbol{\rho}) \tag{86}$$

unless $\Phi(\boldsymbol{\rho})$ coincides with a surface part of some solution to the Dirac equation (62) at energy E.

Let $\hat{\mathfrak{b}}^{(+)}$ and $\hat{\mathfrak{b}}^{(-)}$ be two linear Hermitian integral operators defined on $L^2_{(|)}(\mathscr{S})$, with the integral kernels $\mathfrak{b}^{(+)}(\boldsymbol{\rho},\boldsymbol{\rho}')$ and $\mathfrak{b}^{(-)}(\boldsymbol{\rho},\boldsymbol{\rho}')$, respectively. It will be assumed that the operators $\hat{\mathfrak{b}}^{(\pm)}$ are such that

$$\beta^{(\pm)}\hat{\mathfrak{b}}^{(\pm)}\beta^{(\pm)}=\hat{\mathfrak{b}}^{(\pm)} \tag{87}$$

[cf. Eq. (79)] and such that

$$\hat{\mathfrak{b}}^{(\pm)}\alpha_n^{(\pm)}\hat{\mathfrak{b}}^{(\mp)}\alpha_n^{(\mp)}=\alpha_n^{(\pm)}\hat{\mathfrak{b}}^{(\mp)}\alpha_n^{(\mp)}\hat{\mathfrak{b}}^{(\pm)}=\beta^{(\pm)} \tag{88}$$

[cf. Eq. (82)]. We define the operators $\hat{\mathscr{R}}^{(+)}_{\hat{\mathfrak{b}}}(E)$ and $\hat{\mathscr{R}}^{(-)}_{\hat{\mathfrak{b}}}(E)$, possessing the property

$$\beta^{(\pm)}\hat{\mathscr{R}}^{(\pm)}_{\hat{\mathfrak{b}}}(E)\beta^{(\pm)}=\hat{\mathscr{R}}^{(\pm)}_{\hat{\mathfrak{b}}}(E), \tag{89}$$

as the operators reciprocal to the operators $\hat{\mathscr{B}}^{(+)}(E)-\hat{\mathfrak{b}}^{(+)}$ and $\hat{\mathscr{B}}^{(-)}(E)-\hat{\mathfrak{b}}^{(-)}$, respectively, in the sense of

$$\hat{\mathscr{R}}^{(\pm)}_{\hat{\mathfrak{b}}}(E)[\hat{\mathscr{B}}^{(\pm)}(E)-\hat{\mathfrak{b}}^{(\pm)}]\hat{\mathscr{P}}^{(\pm)}(E)=\hat{\mathscr{P}}^{(\pm)}(E). \tag{90}$$

In Sec. IV B we shall show how the operator $\hat{\mathscr{R}}^{(+)}_{\hat{\mathfrak{b}}}(E)$ is related to the operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$ encountered in the nonrelativistic theory.

In terms of the operators $\hat{\mathscr{R}}^{(\pm)}_{\hat{\mathfrak{b}}}(E)$ the surface relation (73) may be rewritten as

$$\beta^{(\pm)}\Psi(E,\boldsymbol{\rho})=-\gamma^{(\mp)}\hat{\mathscr{R}}^{(\pm)}_{\hat{\mathfrak{b}}}(E)[i\alpha_n^{(\pm)}-\gamma^{(\pm)}\hat{\mathfrak{b}}^{(\pm)}]\Psi(E,\boldsymbol{\rho}) \tag{91}$$

or, explicitly,

$$\beta^{(\pm)}\Psi(E,\boldsymbol{\rho})=-\gamma^{(\mp)}\int_{\mathscr{S}}d^2\boldsymbol{\rho}'\ \mathscr{R}^{(\pm)}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')[i\alpha_n^{(\pm)}(\boldsymbol{\rho}')-\gamma^{(\pm)}\hat{\mathfrak{b}}^{(\pm)}]\Psi(E,\boldsymbol{\rho}'). \tag{92}$$

Assume now that a complete set of spinor functions $\{\Phi_i(\boldsymbol{\rho})\}\in L^2_{(|)}(\mathscr{S})$ orthonormal with respect to the surface scalar product $(|)$, spanning the surface $\mathscr{S}$, is given. In the basis $\{\Phi_i(\boldsymbol{\rho})\}$ the kernels $\mathscr{R}^{(\pm)}_{\mathfrak{b}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')$ have bilinear expansions

$$\mathscr{R}^{(\pm)}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')=\sum_{i,j}\ \beta^{(\pm)}\Phi_i(\boldsymbol{\rho})(\Phi_i|\hat{\mathscr{R}}^{(\pm)}_{\hat{\mathfrak{b}}}\Phi_j)\Phi_j^\dagger(\boldsymbol{\rho}')\beta^{(\pm)}, \tag{93}$$

where the coefficients

$$(\Phi_i|\hat{\mathscr{R}}^{(+)}_{\hat{\mathfrak{b}}}\Phi_j)\equiv\int_{\mathscr{S}}d^2\boldsymbol{\rho}\int_{\mathscr{S}}d^2\boldsymbol{\rho}'\ \Phi_i^\dagger(\boldsymbol{\rho})\mathscr{R}^{(+)}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')\Phi_j(\boldsymbol{\rho}') \tag{94}$$

and

$$(\Phi_i|\hat{\mathscr{R}}^{(-)}_{\hat{\mathfrak{b}}}\Phi_j)\equiv\int_{\mathscr{S}}d^2\boldsymbol{\rho}\int_{\mathscr{S}}d^2\boldsymbol{\rho}'\ \Phi_i^\dagger(\boldsymbol{\rho})\mathscr{R}^{(-)}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')\Phi_j(\boldsymbol{\rho}') \tag{95}$$

form R-matrices $\mathsf{R}^{(+)}_{\mathfrak{b}}(E)$ and $\mathsf{R}^{(-)}_{\mathfrak{b}}(E)$, respectively. To relate the matrix and operator formulations of the theory, we need a matrix representation of Eq. (91). Projecting the latter equation from the left on the basis spinor functions $\{\Phi_i(\boldsymbol{\rho})\}$ gives

$$\mathsf{P}^{(\pm)}(E)=\mathsf{R}^{(\pm)}_{\mathfrak{b}}(E)\left[\pm\left(\frac{2mc}{\hbar}\right)^{\pm1}\mathsf{Q}^{(\pm)}(E)-\mathsf{b}^{(\pm)}\mathsf{P}^{(\pm)}(E)\right], \tag{96}$$

where $\mathsf{P}^{(\pm)}(E)$ and $\mathsf{Q}^{(\pm)}(E)$ are column matrices with elements $\{P_i^{(\pm)}(E)=(\Phi_i|\beta^{(\pm)}\Psi)\}$ and $\{Q_i^{(\pm)}(E)=(\Phi_i|i\alpha_n^{(\pm)}\Psi)\}$, respectively, and $\mathsf{b}^{(\pm)}$ are square matrices with elements

$\{b_{ij}^{(\pm)}=(\Phi_i|\hat{\mathfrak{b}}^{(\pm)}\Phi_j)\}$. Equations (96) are the counterparts of the nonrelativistic formula (1). The relation which corresponds to the choice of the upper sign in Eq. (96) was found before by Chang.[16]

In Sec. IV C we shall show how the integral kernels of the operators $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}^{(\pm)}(E)$ may be constructed.

B. The nonrelativistic limit

It is of interest to investigate the nonrelativistic limit of Eq. (91) in order to relate the relativistic and nonrelativistic formulations of the operator versions of the *R*-matrix theory. To accomplish this goal, we proceed in the standard manner and express the relativistic four-component wave function $\Psi(E,\mathbf{r})$ in terms of two-component spinors $\psi_U(E,\mathbf{r})$ and $\psi_L(E,\mathbf{r})$ in the following way:

$$\Psi(E,\mathbf{r})=\begin{pmatrix}\psi_U(E,\mathbf{r})\\ \psi_L(E,\mathbf{r})\end{pmatrix}. \tag{97}$$

It is a standard problem in introductory quantum mechanics to show that in the nonrelativistic limit the function $\psi_U(E,\mathbf{r})$ obeys the Schrödinger equation

$$\left[-\frac{\hbar^2}{2m}\boldsymbol{\nabla}^2+V(\mathbf{r})-E\right]\psi_U(E,\mathbf{r})=0 \quad (c\to\infty) \tag{98}$$

[cf. Eqs. (11) and (12)] while

$$\psi_L(E,\mathbf{r})\xrightarrow{c\to\infty}-\left(\frac{\hbar}{2mc}\right)i\boldsymbol{\sigma}\cdot\boldsymbol{\nabla}\psi_U(E,\mathbf{r}), \tag{99}$$

where $\boldsymbol{\sigma}$ is a vector composed of the Pauli matrices. The relation (99) holds for arbitrary $\mathbf{r}$, in particular it is also valid on the surface $\mathscr{S}$, i.e., for $\mathbf{r}=\boldsymbol{\rho}$. Next, we notice that, as a consequence of Eqs. (87) and (89), the operators $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}^{(+)}(E)$ and $\hat{\mathfrak{b}}^{(+)}$ act on an arbitrary function

$$\Phi(\boldsymbol{\rho})=\begin{pmatrix}\phi_U(\boldsymbol{\rho})\\ \phi_L(\boldsymbol{\rho})\end{pmatrix} \tag{100}$$

from $L^2_{(|)}(\mathscr{S})$ in the following way:

$$\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}^{(+)}(E)\Phi(\boldsymbol{\rho})\equiv\begin{pmatrix}\hat{\mathscr{R}}'_{\hat{\mathfrak{b}}}(E)\,\phi_U(\boldsymbol{\rho})\\ 0\end{pmatrix}, \quad \hat{\mathfrak{b}}^{(+)}\Phi(\boldsymbol{\rho})\equiv\begin{pmatrix}\hat{\mathfrak{b}}'\,\phi_U(\boldsymbol{\rho})\\ 0\end{pmatrix}, \tag{101}$$

where $\hat{\mathscr{R}}'_{\hat{\mathfrak{b}}}(E)$ and $\hat{\mathfrak{b}}'$ are operators acting on two-component functions. Making use of Eq. (101), the surface relation (91) may be rewritten in terms of the upper component of $\Psi(E,\boldsymbol{\rho})$ and of the operators $\hat{\mathscr{R}}'_{\hat{\mathfrak{b}}}(E)$ and $\hat{\mathfrak{b}}'$ in the following way:

$$\psi_U(E,\boldsymbol{\rho})=\hat{\mathscr{R}}'_{\hat{\mathfrak{b}}}(E)\left[\left(\frac{2mc}{\hbar}\right)i\boldsymbol{\sigma}\cdot\mathbf{n}(\boldsymbol{\rho})\,\psi_L(E,\boldsymbol{\rho})-\hat{\mathfrak{b}}'\,\psi_U(E,\boldsymbol{\rho})\right]. \tag{102}$$

The relation (102) is exact. Passing in this relation to the nonrelativistic limit, making use of Eq. (99) and utilizing well-known properties of the Pauli matrices, which give

$$[\boldsymbol{\sigma}\cdot\mathbf{n}(\boldsymbol{\rho})][\boldsymbol{\sigma}\cdot\boldsymbol{\nabla}]=\nabla_n+i\boldsymbol{\sigma}\cdot[\mathbf{n}(\boldsymbol{\rho})\times\boldsymbol{\nabla}], \tag{103}$$

we obtain

$$\psi_U(E,\boldsymbol{\rho})=\hat{\mathscr{R}}'_{\hat{\mathfrak{b}}}(E)[\nabla_n+i\boldsymbol{\sigma}\cdot[\mathbf{n}(\boldsymbol{\rho})\times\boldsymbol{\nabla}]-\hat{\mathfrak{b}}']\psi_U(E,\boldsymbol{\rho}) \quad (c\to\infty). \tag{104}$$

It is understood that in Eq. (104) $\psi_U(E,\boldsymbol{\rho})$, $\hat{\mathscr{R}}'_{\hat{\mathfrak{b}}}(E)$ and $\hat{\mathfrak{b}}'$ stand for nonrelativistic limits of the quantities which have been denoted with the same symbols before the passage to the limit has been done. Comparison between Eqs. (22) and (104) shows that in the nonrelativistic limit

$$\hat{\mathscr{R}}'_{\hat{\mathfrak{b}}}(E) \xrightarrow{c\to\infty} \hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E).\hat{\mathscr{T}} \tag{105}$$

(here $\hat{\mathscr{T}}$ is the unit 2×2 operator) provided that the operator $\hat{\mathfrak{b}}^{(+)}$ is chosen so that

$$\hat{\mathfrak{b}}' \xrightarrow{c\to\infty} \hat{\mathfrak{b}}.\hat{\mathscr{T}} + i\boldsymbol{\sigma}\cdot[\mathbf{n}(\boldsymbol{\rho})\times\boldsymbol{\nabla}], \tag{106}$$

where $\hat{\mathfrak{b}}$ is the operator used in the formulation of the theory for the Schrödinger equation (cf. Sec. III A). It is interesting and somewhat surprising that the operators $\hat{\mathfrak{b}}'$ and $\hat{\mathfrak{b}}.\hat{\mathscr{T}}$ do not coincide. This observation is, however, consistent with earlier findings of Norrington and Grant[22,23] and of Thumm and Norcross[24] who investigated the nonrelativistic limit of the matrix formulation of the theory in the specific case of the spherically symmetric volume $\mathscr{V}$.

C. Construction of the operators $\hat{\mathscr{R}}^{(\pm)}_{\hat{\mathfrak{b}}}(E)$

Thus far we have discussed some properties of the operators $\hat{\mathscr{R}}^{(\pm)}_{\hat{\mathfrak{b}}}(E)$ but have not touched the problem of construction of integral kernels of these operators. This will be the subject of the present section.

To achieve the goal, we need a set of auxiliary spinor functions $\{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\}$ defined as eigenfunctions of the boundary value problem consisting of the differential equation [cf. Eq. (62)]

$$[\hat{H}-E_{\hat{\mathfrak{b}}k}]\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})=0 \tag{107}$$

and of the homogeneous boundary condition

$$i\alpha_n^{(\pm)}(\boldsymbol{\rho})\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}) = \gamma^{(\pm)}\int_{\mathscr{S}} d^2\boldsymbol{\rho}'\ \mathfrak{b}^{(\pm)}(\boldsymbol{\rho},\boldsymbol{\rho}')\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}'). \tag{108}$$

In Eq. (107) $\hat{H}$ is the Dirac Hamiltonian defined by Eq. (63) and $E_{\hat{\mathfrak{b}}k}$ is an eigenvalue for the problem belonging to an eigenfunction $\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})$. In the more compact operator notation the boundary condition (108) reads

$$i\alpha_n^{(\pm)}(\boldsymbol{\rho})\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}) = \gamma^{(\pm)}\hat{\mathfrak{b}}^{(\pm)}\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}). \tag{109}$$

At first sight it might seem that Eqs. (107) and (109) constitute two eigenvalue problems depending on which of the two possible signs is chosen in Eq. (109). Yet this is not the case: It is easy to verify that, because of relation (88), both boundary conditions (109) are essentially equivalent and consequently we have only one eigenvalue problem. For the sake of later applications, we notice also here that the boundary condition (109) may be equivalently rewritten, after operating on it from the left with $-i\alpha_n^{(\mp)}(\boldsymbol{\rho})$, in the form

$$\beta^{(\mp)}\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}) = -\gamma^{(\pm)}i\alpha_n^{(\mp)}\hat{\mathfrak{b}}^{(\pm)}\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}) \tag{110}$$

hence, it follows that

$$\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}) \equiv \beta^{(\pm)}\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}) + \beta^{(\mp)}\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}) = [\beta^{(\pm)} - \gamma^{(\pm)}i\alpha_n^{(\mp)}\hat{\mathfrak{b}}^{(\pm)}]\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}). \tag{111}$$

Henceforth we shall assume that the integral operators $\hat{\mathfrak{b}}^{(\pm)}$ are such that the eigenfunctions $\{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\}$ form a complete set in the interior of the volume $\mathscr{V}$. It may be inferred from Eqs. (107) and (109) and from properties of the operators $\hat{\mathfrak{b}}^{(\pm)}$ that eigenvalues $\{E_{\hat{\mathfrak{b}}k}\}$ are real and eigenfunctions $\{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\}$ belonging to different eigenvalues are orthogonal. Indeed, after premultiplying Eq. (107) (with k replaced by k') by $\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\mathbf{r})$, postmultiplying the matrix Hermitian conjugate of Eq.

(107) by $\Psi_{\hat{\mathfrak{b}}k'}(\mathbf{r})$, subtracting, integrating the result over the volume $\mathscr{V}$, employing the Gauss divergence theorem, making use of the boundary condition (107) and of the Hermicity of $\hat{\mathfrak{b}}^{(\pm)}$, one arrives at

$$[E^{*}_{\hat{\mathfrak{b}}k}-E_{\hat{\mathfrak{b}}k'}]\langle\Psi_{\hat{\mathfrak{b}}k}|\Psi_{\hat{\mathfrak{b}}k'}\rangle=0, \tag{112}$$

hence the validity of the assertion follows immediately. Hereafter we shall assume that functions belonging to degenerate eigenvalues (if there are any) have also been orthogonalized and that the functions $\{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\}$ have been normalized so that

$$\langle\Psi_{\hat{\mathfrak{b}}k}|\Psi_{\hat{\mathfrak{b}}k'}\rangle=\delta_{kk'}\,. \tag{113}$$

On the ground of the assumed completeness, the eigenfunctions $\{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\}$ obey the closure relation

$$\sum_{k}\ \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\mathbf{r}')=\delta^{(3)}(\mathbf{r}-\mathbf{r}')I\quad(\mathbf{r},\mathbf{r}'\in\mathscr{V}\setminus\mathscr{S}) \tag{114}$$

[cf. the remark following Eq. (31)].

Consider now a problem of expanding the function $\Psi(E,\mathbf{r})$ satisfying the Dirac equation (62) in the series of eigenfunctions $\{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\}$. Denoting the expansion by $\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\mathbf{r})$, we have

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\mathbf{r})\equiv\sum_{k}\ \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\langle\Psi_{\hat{\mathfrak{b}}k}|\Psi\rangle \tag{115}$$

or equivalently

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\mathbf{r})\equiv\int_{\mathscr{V}}d^3\mathbf{r}'\left\{\sum_{k}\ \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\mathbf{r}')\right\}\Psi(E,\mathbf{r}'). \tag{116}$$

The expansion coefficients $\langle\Psi_{\hat{\mathfrak{b}}k}|\Psi\rangle$ may be found in the routine way. We premultiply Eq. (62) by $\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\mathbf{r})$, postmultiply the matrix Hermitian conjugate of Eq. (107) by $\Psi(E,\mathbf{r})$, subtract and integrate over the volume $\mathscr{V}$ obtaining

$$ic\hbar\int_{\mathscr{V}}d^3\mathbf{r}\ \ \boldsymbol{\nabla}\cdot[\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\mathbf{r})\boldsymbol{\alpha}\Psi(E,\mathbf{r})]=[E_{\hat{\mathfrak{b}}k}-E]\langle\Psi_{\hat{\mathfrak{b}}k}|\Psi\rangle. \tag{117}$$

Employing the Gauss divergence theorem, the volume integral on the left-hand side may be converted into a surface integral

$$\int_{\mathscr{V}}d^3\mathbf{r}\ \boldsymbol{\nabla}\cdot[\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\mathbf{r})\boldsymbol{\alpha}\Psi(E,\mathbf{r})]=\int_{\mathscr{S}}d^2\boldsymbol{\rho}\ \Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho})\alpha_n(\boldsymbol{\rho})\Psi(E,\boldsymbol{\rho}). \tag{118}$$

This yields

$$\langle\Psi_{\hat{\mathfrak{b}}k}|\Psi\rangle=\frac{(\Psi_{\hat{\mathfrak{b}}k}|ic\hbar\alpha_n\Psi)}{E_{\hat{\mathfrak{b}}k}-E}. \tag{119}$$

Making use of the properties of the matrices $\alpha_n(\boldsymbol{\rho})$ and $\alpha^{(\pm)}_n(\boldsymbol{\rho})$, of the boundary condition (109) and of the Hermicity property of the operators $\hat{\mathfrak{b}}^{(\pm)}$ we transform this expression to the form

$$\langle\Psi_{\hat{\mathfrak{b}}k}|\Psi\rangle=\frac{c\hbar(\Psi_{\hat{\mathfrak{b}}k}|[i\alpha^{(\pm)}_n-\gamma^{(\pm)}\hat{\mathfrak{b}}^{(\pm)}]\Psi)}{E_{\hat{\mathfrak{b}}k}-E} \tag{120}$$

and consequently we arrive at

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\mathbf{r})=\sum_k\ \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\ \frac{c\hbar(\Psi_{\hat{\mathfrak{b}}k}|[i\alpha_n^{(\pm)}-\gamma^{(\pm)}\hat{\mathfrak{b}}^{(\pm)}]\Psi)}{E_{\hat{\mathfrak{b}}k}-E} \tag{121}$$

or equivalently

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\mathbf{r})=\int_{\mathscr{S}}d^2\boldsymbol{\rho}'\ c\hbar\sum_k\ \frac{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')}{E_{\hat{\mathfrak{b}}k}-E}[i\alpha_n^{(\pm)}(\boldsymbol{\rho}')-\gamma^{(\pm)}\hat{\mathfrak{b}}^{(\pm)}]\Psi(E,\boldsymbol{\rho}'). \tag{122}$$

In particular, if the point $\mathbf{r}$ lies on the surface $\mathscr{S}$, then we have

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho})=\int_{\mathscr{S}}d^2\boldsymbol{\rho}'\ c\hbar\sum_k\ \frac{\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')}{E_{\hat{\mathfrak{b}}k}-E}[i\alpha_n^{(\pm)}(\boldsymbol{\rho}')-\gamma^{(\pm)}\hat{\mathfrak{b}}^{(\pm)}]\Psi(E,\boldsymbol{\rho}'). \tag{123}$$

At that moment, it is convenient to define two integral operators $\hat{\bar{\mathscr{R}}}^{(\pm)}_{\hat{\mathfrak{b}}}(E)$ (notice the bar) such that [cf. Eq. (91)]

$$\beta^{(\pm)}\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho})=-\gamma^{(\mp)}\hat{\bar{\mathscr{R}}}^{(\pm)}_{\hat{\mathfrak{b}}}(E)[i\alpha_n^{(\pm)}-\gamma^{(\pm)}\hat{\mathfrak{b}}^{(\pm)}]\Psi(E,\boldsymbol{\rho}). \tag{124}$$

Comparison of Eqs. (123) and (124) shows that the operators $\hat{\bar{\mathscr{R}}}^{(\pm)}_{\hat{\mathfrak{b}}}(E)$ have the integral kernels

$$\bar{\mathscr{R}}^{(\pm)}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')=c\hbar\,\gamma^{(\pm)}\sum_k\ \frac{\beta^{(\pm)}\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')\beta^{(\pm)}}{E_{\hat{\mathfrak{b}}k}-E}. \tag{125}$$

By virtue of the closure relation (114), in the interior of the volume $\mathscr{V}$ one has

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\mathbf{r})\equiv\int_{\mathscr{V}}d^3\mathbf{r}'\left\{\sum_k\ \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\mathbf{r}')\right\}\Psi(E,\mathbf{r}')=\Psi(E,\mathbf{r})\quad(\mathbf{r}\in\mathscr{V}\backslash\mathscr{S}), \tag{126}$$

i.e., the expansion $\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\mathbf{r})$ does converge to the function $\Psi(E,\mathbf{r})$ and consequently

$$\Psi(E,\mathbf{r})=\int_{\mathscr{S}}d^2\boldsymbol{\rho}'\ c\hbar\sum_k\ \frac{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')}{E_{\hat{\mathfrak{b}}k}-E}[i\alpha_n^{(\pm)}(\boldsymbol{\rho}')-\gamma^{(\pm)}\hat{\mathfrak{b}}^{(\pm)}]\Psi(E,\boldsymbol{\rho}')\quad(\mathbf{r}\in\mathscr{V}\backslash\mathscr{S}). \tag{127}$$

This relation is valid for the point $\mathbf{r}$ laying as close to the boundary $\mathscr{S}$ as we please and therefore, in view of the continuity of the function $\Psi(E,\mathbf{r})$ across $\mathscr{S}$, one has

$$\Psi(E,\boldsymbol{\rho})=\lim_{\mathbf{r}\to\boldsymbol{\rho}}\int_{\mathscr{S}}d^2\boldsymbol{\rho}'\ c\hbar\sum_k\ \frac{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')}{E_{\hat{\mathfrak{b}}k}-E}[i\alpha_n^{(\pm)}(\boldsymbol{\rho}')-\gamma^{(\pm)}\hat{\mathfrak{b}}^{(\pm)}]\Psi(E,\boldsymbol{\rho}')\quad(\mathbf{r}\in\mathscr{V}\backslash\mathscr{S}) \tag{128}$$

and consequently

$$\begin{aligned}\beta^{(\pm)}\Psi(E,\boldsymbol{\rho})=\lim_{\mathbf{r}\to\boldsymbol{\rho}}\int_{\mathscr{S}}d^2\boldsymbol{\rho}'\ c\hbar\sum_k\ &\frac{\beta^{(\pm)}\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')\beta^{(\pm)}}{E_{\hat{\mathfrak{b}}k}-E}[i\alpha_n^{(\pm)}(\boldsymbol{\rho}')\\&-\gamma^{(\pm)}\hat{\mathfrak{b}}^{(\pm)}]\Psi(E,\boldsymbol{\rho}')\quad(\mathbf{r}\in\mathscr{V}\backslash\mathscr{S}),\end{aligned} \tag{129}$$

which, in conjunction with Eq. (92), implies

$$\mathscr{R}^{(\pm)}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')=\lim_{\mathbf{r}\to\boldsymbol{\rho}}\left\{c\hbar\,\gamma^{(\pm)}\sum_k\ \frac{\beta^{(\pm)}\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')\beta^{(\pm)}}{E_{\hat{\mathfrak{b}}k}-E}\right\}. \tag{130}$$

This is to be compared with Eq. (125).

We now ask the question: Are the operations $\lim_{\mathbf{r}\to\boldsymbol{\rho}}$ and Σ_k in Eq. (130) interchangeable freely? Relying on the apparent similarity of the relativistic theory discussed here to the nonrelativistic theory exposed in Sec. III B one might expect that the answer to this question is positive. However, this is *not* the case. In the relativistic theory the operations $\lim_{\mathbf{r}\to\boldsymbol{\rho}}$ and Σ_k do *not* commute and accordingly one finds $\hat{\mathscr{R}}^{(\pm)}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')\neq\overline{\mathscr{R}}^{(\pm)}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho},\boldsymbol{\rho}')$ and $\hat{\mathscr{R}}^{(\pm)}_{\hat{\mathfrak{b}}}(E)\neq\hat{\bar{\mathscr{R}}}^{(\pm)}_{\hat{\mathfrak{b}}}(E)$. To show this (and find the consequences of interchanging the two operations) we need to find a direct relation between the surface functions $\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho})$ and $\Psi(E,\boldsymbol{\rho})$. We begin with an observation that the closure relation (114) cannot hold whenever any of the points $\mathbf{r}$ or $\mathbf{r}'$ lies on the surface $\mathscr{S}$ since the upper and the lower components of the surface spinor functions $\{\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho})\}$ are related by the boundary condition (109). Therefore, we assume that

$$\sum_k \Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\mathbf{r}')=\mathscr{A}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}')\,\delta^{(1)}_{\mathscr{S}}(\mathbf{r}') \quad (\mathbf{r}'\in\mathscr{S}), \tag{131}$$

$$\sum_k \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')=\mathscr{A}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}')\,\delta^{(1)}_{\mathscr{S}}(\mathbf{r}) \quad (\mathbf{r}\in\mathscr{S}) \tag{132}$$

[cf. Eq. (114) and the first of Eqs. (9)] and hope that, in the course of the following considerations, we shall be able to find the surface kernel $\mathscr{A}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}')$. Substituting the relation (131) into the definition (116) we get

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho})=\int_{\mathscr{S}} d^2\boldsymbol{\rho}'\ \mathscr{A}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}')\Psi(E,\boldsymbol{\rho}'), \tag{133}$$

which implies that the kernel $\mathscr{A}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}')$ defines the integral operator $\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}$ transforming the surface function $\Psi(E,\boldsymbol{\rho})$ into $\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho})$,

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho})=\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}\Psi(E,\boldsymbol{\rho}). \tag{134}$$

An important property of the operator $\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}$ may be deduced from the definitions (131) and (132) and the relation (111). On one hand, it follows from Eq. (111) that

$$\sum_k \Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\mathbf{r}')=[\hat{\mathscr{I}}-\gamma^{(\pm)}i\alpha_n^{(\mp)}\hat{\mathfrak{b}}^{(\pm)}]\beta^{(\pm)}\left\{\sum_k \Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')\right\}, \tag{135}$$

where $\hat{\mathscr{I}}$ is the unit operator. On the other hand, if $\Phi(\boldsymbol{\rho})$ is any reasonable spinor function defined on the surface $\mathscr{S}$, from Eq. (132) and the Hermicity of the operators $\hat{\mathfrak{b}}^{(\pm)}$ under the surface scalar product $(|)$ we readily obtain

$$\begin{aligned}
&\int_{\mathscr{S}} d^2\boldsymbol{\rho}'\left\{\sum_k \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')\right\}\Phi(\boldsymbol{\rho}')\\
&\quad=\sum_k \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\int_{\mathscr{S}} d^2\boldsymbol{\rho}'\{[\beta^{(\pm)}-\gamma^{(\pm)}i\alpha_n^{(\mp)}\hat{\mathfrak{b}}^{(\pm)}]\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')\}^{\dagger}\Phi(\boldsymbol{\rho}')\\
&\quad=\int_{\mathscr{S}} d^2\boldsymbol{\rho}'\left\{\sum_k \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')\right\}\beta^{(\pm)}[\hat{\mathscr{I}}+\gamma^{(\pm)}\hat{\mathfrak{b}}^{(\pm)}i\alpha_n^{(\pm)}]\Phi(\boldsymbol{\rho}').
\end{aligned} \tag{136}$$

Equations (131), (132), (135) and (136) imply that the operator $\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}$ may be sought in any of the two equivalent forms

$$\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}=[\hat{\mathscr{I}}-\gamma^{(+)}i\alpha_n^{(-)}\hat{\mathfrak{b}}^{(+)}].\hat{\mathscr{A}}^{(+)}_{\hat{\mathfrak{b}}}[\hat{\mathscr{I}}+\gamma^{(+)}\hat{\mathfrak{b}}^{(+)}i\alpha_n^{(+)}], \tag{137}$$

$$\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}=[\hat{\mathscr{I}}-\gamma^{(-)}i\alpha_n^{(+)}\hat{\mathfrak{b}}^{(-)}].\hat{\mathscr{A}}^{(-)}_{\hat{\mathfrak{b}}}[\hat{\mathscr{I}}+\gamma^{(-)}\hat{\mathfrak{b}}^{(-)}i\alpha_n^{(-)}], \tag{138}$$

where the operators

$$\hat{\mathscr{A}}^{(\pm)}_{\hat{\mathfrak{b}}}=\beta^{(\pm)}\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}\beta^{(\pm)} \tag{139}$$

have the integral kernels $\mathscr{A}^{(\pm)}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}')=\beta^{(\pm)}\mathscr{A}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}')\beta^{(\pm)}$ defined formally by

$$\sum_k \beta^{(\pm)}\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\mathbf{r}')\beta^{(\pm)}=\mathscr{A}^{(\pm)}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}')\,\delta^{(1)}_{\mathscr{T}}(\mathbf{r}') \quad (\mathbf{r}'\in\mathscr{T}). \tag{140}$$

The operators $\hat{\mathscr{A}}^{(+)}_{\hat{\mathfrak{b}}}$ and $\hat{\mathscr{A}}^{(-)}_{\hat{\mathfrak{b}}}$ are related; it is readily derivable from Eqs. (137) to (139) that

$$\hat{\mathscr{A}}^{(\pm)}_{\hat{\mathfrak{b}}}=(\gamma^{(\pm)})^2\alpha_n^{(\pm)}\hat{\mathfrak{b}}^{(\mp)}\hat{\mathscr{A}}^{(\mp)}_{\hat{\mathfrak{b}}}\hat{\mathfrak{b}}^{(\mp)}\alpha_n^{(\mp)}. \tag{141}$$

To find the explicit form of the operator $\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}$, we postmultiply the kernel

$$\sum_{k'} \Psi_{\hat{\mathfrak{b}}k'}(\boldsymbol{\rho})\Psi^{\dagger}_{\hat{\mathfrak{b}}k'}(\mathbf{r}')$$

by any function $\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r}')$ from the complete set $\{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r}')\}$ and integrate over the volume $\mathscr{T}$. From the orthogonality relation (113) we infer that

$$\int_{\mathscr{T}} d^3\mathbf{r}'\left\{\sum_{k'} \Psi_{\hat{\mathfrak{b}}k'}(\boldsymbol{\rho})\Psi^{\dagger}_{\hat{\mathfrak{b}}k'}(\mathbf{r}')\right\}\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r}')=\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}). \tag{142}$$

On the other hand, from Eq. (131) we have

$$\int_{\mathscr{T}} d^3\mathbf{r}'\left\{\sum_{k'} \Psi_{\hat{\mathfrak{b}}k'}(\boldsymbol{\rho})\Psi^{\dagger}_{\hat{\mathfrak{b}}k'}(\mathbf{r}')\right\}\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r}')=\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}). \tag{143}$$

Equating the right-hand sides of Eqs. (142) and (143) we find

$$\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho})=\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}). \tag{144}$$

At first sight Eq. (144) might seem to imply that, as in the nonrelativistic theory, the operator $\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}$ is the unit operator. Yet this is *not* the case. The reason is that in the relativistic theory the functions $\{\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho})\}$ are multicomponent and their upper and lower components are related by the algebraic condition (109). Rewriting Eq. (144) with the aid of Eqs. (137) and (138) we obtain

$$[\hat{\mathscr{T}}-\gamma^{(\pm)}i\alpha_n^{(\mp)}\hat{\mathfrak{b}}^{(\pm)}]\hat{\mathscr{A}}^{(\pm)}_{\hat{\mathfrak{b}}}[\hat{\mathscr{T}}+\gamma^{(\pm)}\hat{\mathfrak{b}}^{(\pm)}i\alpha_n^{(\pm)}]\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho})=\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}). \tag{145}$$

Upon operating on both sides of this equation with $\beta^{(\pm)}$ and utilizing the boundary condition (109) we get

$$\hat{\mathscr{A}}^{(\pm)}_{\hat{\mathfrak{b}}}[\hat{\mathscr{T}}+(\gamma^{(\pm)})^2(\hat{\mathfrak{b}}^{(\pm)})^2]\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho})=\beta^{(\pm)}\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}) \tag{146}$$

and accordingly

$$\hat{\mathscr{A}}^{(\pm)}_{\hat{\mathfrak{b}}}=\beta^{(\pm)}[\hat{\mathscr{T}}+(\gamma^{(\pm)})^2(\hat{\mathfrak{b}}^{(\pm)})^2]^{-1}\beta^{(\pm)} \tag{147}$$

since the relation (136) holds for an arbitrary eigenfunction $\Psi_{\hat{\mathfrak{b}}k}$. Hence, it follows that

$$\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}=[\beta^{(\pm)}-\gamma^{(\pm)}i\alpha_n^{(\mp)}\hat{\mathfrak{b}}^{(\pm)}][\hat{\mathscr{T}}+(\gamma^{(\pm)})^2(\hat{\mathfrak{b}}^{(\pm)})^2]^{-1}[\beta^{(\pm)}+\gamma^{(\pm)}\hat{\mathfrak{b}}^{(\pm)}i\alpha_n^{(\pm)}] \tag{148}$$

and consequently Eq. (134) may be written in the form

$$\overline{\Psi}_{\hat{\mathfrak{b}}}(E,\boldsymbol{\rho})=[\beta^{(\pm)}-\gamma^{(\pm)}i\alpha_n^{(\mp)}\hat{\mathfrak{b}}^{(\pm)}][\hat{\mathscr{T}}+(\gamma^{(\pm)})^2(\hat{\mathfrak{b}}^{(\pm)})^2]^{-1}[\beta^{(\pm)}+\gamma^{(\pm)}\hat{\mathfrak{b}}^{(\pm)}i\alpha_n^{(\pm)}]\Psi(E,\boldsymbol{\rho}). \tag{149}$$

Substituting this relation to Eq. (124), after straightforward manipulations we arrive at

$$\beta^{(\pm)}\Psi(E,\boldsymbol{\rho})=-\gamma^{(\mp)}[\hat{\mathscr{R}}_{\mathfrak{b}}^{(\pm)}(E)-\hat{\mathfrak{b}}^{(\pm)}[(\gamma^{(\mp)})^2\hat{\mathscr{T}}+(\hat{\mathfrak{b}}^{(\pm)})^2]^{-1}][i\alpha_n^{(\pm)}-\gamma^{(\pm)}\hat{\mathfrak{b}}^{(\pm)}]\Psi(E,\boldsymbol{\rho}) \tag{150}$$

hence, on comparing Eqs. (91) and (150), we find the relationship between the operators $\hat{\mathscr{R}}_{\mathfrak{b}}^{(\pm)}(E)$ and $\hat{\bar{\mathscr{R}}}_{\mathfrak{b}}^{(\pm)}(E)$,

$$\hat{\mathscr{R}}_{\mathfrak{b}}^{(\pm)}(E)=\hat{\bar{\mathscr{R}}}_{\mathfrak{b}}^{(\pm)}(E)-\hat{\mathfrak{b}}^{(\pm)}[(\gamma^{(\mp)})^2\hat{\mathscr{T}}+(\hat{\mathfrak{b}}^{(\pm)})^2]^{-1}. \tag{151}$$

Equation (150) may be perceived as a set of two homogeneous coupled equations for the functions $\beta^{(+)}\Psi(E,\boldsymbol{\rho})$ and $\beta^{(-)}\Psi(E,\boldsymbol{\rho})$. Indeed, upon utilizing the properties of the matrices $\alpha_n^{(\pm)}(\boldsymbol{\rho})$ and $\beta^{(\pm)}$ the two relations constituting Eq. (150) may be explicitly rewritten in the form

$$\beta^{(+)}\Psi(E,\boldsymbol{\rho})=-\gamma^{(-)}\hat{\mathscr{R}}_{\mathfrak{b}}^{(+)}(E)i\alpha_n^{(+)}\beta^{(-)}\Psi(E,\boldsymbol{\rho})-\hat{\mathscr{R}}_{\mathfrak{b}}^{(+)}(E)\hat{\mathfrak{b}}^{(+)}\beta^{(+)}\Psi(E,\boldsymbol{\rho}), \tag{152}$$

$$\beta^{(-)}\Psi(E,\boldsymbol{\rho})=-\gamma^{(+)}\hat{\mathscr{R}}_{\mathfrak{b}}^{(-)}(E)i\alpha_n^{(-)}\beta^{(+)}\Psi(E,\boldsymbol{\rho})-\hat{\mathscr{R}}_{\mathfrak{b}}^{(-)}(E)\hat{\mathfrak{b}}^{(-)}\beta^{(-)}\Psi(E,\boldsymbol{\rho}), \tag{153}$$

where the operators $\hat{\mathscr{R}}_{\mathfrak{b}}^{(\pm)}(E)$ have been given by Eq. (151). The following problem arises now: Since Eqs. (152) and (153) are homogeneous and coupled, are they consistent? This should be the case if the relations (151) are correct; therefore seeking an answer to the question posed provides a test for correctness of the method of construction of the operators $\hat{\mathscr{R}}_{\mathfrak{b}}^{(\pm)}(E)$ presented above. [It is to be emphasized that testing the theory in that manner is by no means insipid. This is just the way in which Szmytkowski and Hinze[17,18] recognized an error in earlier attempts[15,16] to formulate the *R*-matrix theory for the Dirac equation within the framework of the matrix language.] To clear up the problem we solve Eq. (153) for $\beta^{(-)}\Psi(E,\boldsymbol{\rho})$ obtaining

$$\beta^{(-)}\Psi(E,\boldsymbol{\rho})=-\gamma^{(+)}\beta^{(-)}[\hat{\mathscr{T}}+\hat{\mathscr{R}}_{\mathfrak{b}}^{(-)}(E)\hat{\mathfrak{b}}^{(-)}]^{-1}\hat{\mathscr{R}}_{\mathfrak{b}}^{(-)}(E)i\alpha_n^{(-)}\beta^{(+)}\Psi(E,\boldsymbol{\rho}). \tag{154}$$

Substituting this relation into the right-hand side of Eq. (152), making use of Eq. (151) and of the relations

$$\hat{\bar{\mathscr{R}}}_{\mathfrak{b}}^{(\pm)}(E)=-\alpha_n^{(\pm)}\hat{\mathfrak{b}}^{(\mp)}\hat{\bar{\mathscr{R}}}_{\mathfrak{b}}^{(\mp)}(E)\hat{\mathfrak{b}}^{(\mp)}\alpha_n^{(\mp)} \tag{155}$$

which stem from the explicit form (125) of the kernels $\bar{\mathscr{R}}_{\mathfrak{b}}^{(\pm)}(E,\boldsymbol{\rho},\boldsymbol{\rho}')$, the conditions (110) and the Hermicity of the operators $\hat{\mathfrak{b}}^{(\pm)}$ [please notice that the relations analogous to Eq. (155) but with $\hat{\bar{\mathscr{R}}}_{\mathfrak{b}}^{(\pm)}(E)$ replaced by $\hat{\mathscr{R}}_{\mathfrak{b}}^{(\pm)}(E)$ do not hold], utilizing the properties of the matrices $\alpha_n^{(\pm)}(\boldsymbol{\rho})$ and $\beta^{(\pm)}$ and employing Eq. (88) transforms the right-hand side of Eq. (152) to $\beta^{(+)}\Psi(E,\boldsymbol{\rho})$. Similarly, determining $\beta^{(+)}\Psi(E,\boldsymbol{\rho})$ from Eq. (152)

$$\beta^{(+)}\Psi(E,\boldsymbol{\rho})=-\gamma^{(-)}\beta^{(+)}[\hat{\mathscr{T}}+\hat{\mathscr{R}}_{\mathfrak{b}}^{(+)}(E)\hat{\mathfrak{b}}^{(+)}]^{-1}\hat{\mathscr{R}}_{\mathfrak{b}}^{(+)}(E)i\alpha_n^{(+)}\beta^{(-)}\Psi(E,\boldsymbol{\rho}) \tag{156}$$

and substituting the result to the right-hand side of Eq. (153) transforms the latter, after some manipulations, to $\beta^{(-)}\Psi(E,\boldsymbol{\rho})$. Since in both cases the final results obtained are identical with the left-hand sides of the respective equations, one is led to the conclusion that Eqs. (152) and (153) are indeed consistent.

Given the relation (151) between the operators $\hat{\mathscr{R}}_{\mathfrak{b}}^{(\pm)}(E)$ and $\hat{\bar{\mathscr{R}}}_{\mathfrak{b}}^{(+)}(E)$, one may find the matrix representation of the operators $\hat{\mathscr{R}}_{\mathfrak{b}}^{(\pm)}(E)$ in the surface basis $\{\Phi_i(\boldsymbol{\rho})\}$. Projecting Eq. (151) from the left and from the right onto the spinor functions from the set $\{\Phi_i(\boldsymbol{\rho})\}$ one obtains

$$\mathsf{R}_{\mathfrak{b}}^{(\pm)}(E)=\frac{\hbar^2}{2m}\sum_k\frac{\mathsf{P}_{\mathfrak{b}k}^{(\pm)}\mathsf{P}_{\mathfrak{b}k}^{(\pm)\dagger}}{E_{\mathfrak{b}k}-E}-\frac{\mathfrak{b}^{(\pm)}}{(\gamma^{(\mp)})^2\mathsf{I}+(\mathfrak{b}^{(\pm)})^2}, \tag{157}$$

where $\{\mathsf{P}_{\mathfrak{b}k}^{(\pm)}\}$ are column vectors with elements $\{P_{i,\mathfrak{b}k}^{(\pm)}=(\Phi_i|\beta^{(\pm)}\Psi_{\hat{\mathfrak{b}}k})\}$, $\{\mathsf{P}_{\mathfrak{b}k}^{(\pm)\dagger}\}$ are row vectors with elements $\{P_{i,\mathfrak{b}k}^{(\pm)*}=(\beta^{(\pm)}\Psi_{\hat{\mathfrak{b}}k}|\Phi_i)\}$, $\mathsf{b}^{(\pm)}$ are square matrices with elements $\{b_{ij}^{(\pm)}=(\Phi_i|\hat{\mathfrak{b}}^{(\pm)}\Phi_j)\}$ and I is the matrix of the unit operator with elements $\{I_{ij}=\delta_{ij}\}$. The result (157) is to be used in Eq. (96).

Let us examine somewhat closer the right-hand side of Eq. (157). Its first constituent is the matrix representation of the operators $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}^{(\pm)}(E)$ in the basis $\{\Phi_i(\boldsymbol{\rho})\}$; its form is formally identical with that of the nonrelativistic matrix $\mathsf{R}_{\mathfrak{b}}(E)$ given by Eq. (61) (cf., however, Sec. IV B). To the contrary, the second term on the right-hand side of Eq. (157) does not have its counterpart in the nonrelativistic theory. The origin of the occurrence of this term is the structure of the Dirac equation which is the set of coupled first-order equations while the Schrödinger equation is the second-order equation. The additional term in the formula for the matrix $\mathsf{R}_{\mathfrak{b}}^{(+)}(E)$ vanishes in the event when $\gamma^{(+)}=0$ (i.e., $\gamma^{(-)}=\infty$, which corresponds to the nonrelativistic limit $c\to\infty$) and in the exceptional case $\mathsf{b}^{(+)}=0$. With regard to the matrix $\mathsf{R}_{\mathfrak{b}}^{(-)}(E)$, the second term in Eq. (157) vanishes in the case $\mathsf{b}^{(-)}=0$. It is to be mentioned that the particular case of Eq. (157) was obtained, in a different way, by Szmytkowski and Hinze[18] who considered a spherically symmetric volume $\mathscr{V}$ and used a very particular surface basis $\{\Phi_i(\boldsymbol{\rho})\}$.

Finally, it is to be noticed that once the operator $\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}$ has been determined [cf. Eq. (148)], the explicit forms of the relations (131) and (132) may be given. We shall not discuss the general case when the operators $\hat{\mathfrak{b}}^{(\pm)}$ are arbitrary [but still related by Eq. (88)] and consider instead what happens if $\gamma^{(+)}=0$, $\hat{\mathfrak{b}}^{(+)}=\hat{0}$ or $\hat{\mathfrak{b}}^{(-)}=\hat{0}$ (here $\hat{0}$ denotes the null operator).

The first case, $\gamma^{(+)}=0$, corresponds to the nonrelativistic limit $c\to\infty$. From Eq. (148) one finds

$$\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}=\beta^{(+)}\Rightarrow\mathscr{A}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}')=\delta^{(2)}(\boldsymbol{\rho}-\boldsymbol{\rho}')\beta^{(+)}\quad(c\to\infty)\tag{158}$$

and, after substitution to Eqs. (131) and (132),

$$\sum_k\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')\Psi_{\hat{\mathfrak{b}}k}^{\dagger}(\mathbf{r})=\sum_k\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\Psi_{\hat{\mathfrak{b}}k}^{\dagger}(\boldsymbol{\rho}')=\delta^{(3)}(\mathbf{r}-\boldsymbol{\rho}')\beta^{(+)}\quad(\mathbf{r}\in\mathscr{V},c\to\infty).\tag{159}$$

This result is in accord with the relation (61) found in the nonrelativistic case.

In the event when $\hat{\mathfrak{b}}^{(+)}=\hat{0}$, from the boundary condition (109) and the properties of the matrices $\alpha_n^{(\pm)}(\boldsymbol{\rho})$ one infers that the basis functions $\{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\}$ possess the property

$$\beta^{(-)}\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho})=0\quad(\hat{\mathfrak{b}}^{(+)}=\hat{0}),\tag{160}$$

i.e., their lower components vanish identically on $\mathscr{S}$. From Eq. (148) one finds

$$\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}=\beta^{(+)}\Rightarrow\mathscr{A}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}')=\delta^{(2)}(\boldsymbol{\rho}-\boldsymbol{\rho}')\beta^{(+)}\quad(\hat{\mathfrak{b}}^{(+)}=\hat{0})\tag{161}$$

and consequently

$$\sum_k\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')\Psi_{\hat{\mathfrak{b}}k}^{\dagger}(\mathbf{r})=\sum_k\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\Psi_{\hat{\mathfrak{b}}k}^{\dagger}(\boldsymbol{\rho}')=\delta^{(3)}(\mathbf{r}-\boldsymbol{\rho}')\beta^{(+)}\quad(\mathbf{r}\in\mathscr{V},\hat{\mathfrak{b}}^{(+)}=\hat{0}).\tag{162}$$

It is to be emphasized that although the relations (159) and (162) are seemingly identical, they refer to completely different situations. In the case of Eq. (159) the operator $\hat{\mathfrak{b}}^{(+)}$ is arbitrary and $c=\infty$ while in the case of Eq. (162) the operator $\hat{\mathfrak{b}}^{(+)}$ is the null operator and the speed of light c is finite.

It remains to consider the third special case, namely that when $\hat{\mathfrak{b}}^{(-)}=\hat{0}$. Now one finds that the upper components of the functions $\{\Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\}$ vanish identically on $\mathscr{S}$,

$$\beta^{(+)}\Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho})=0\quad(\hat{\mathfrak{b}}^{(-)}=\hat{0}),\tag{163}$$

and that

$$\hat{\mathscr{A}}_{\hat{\mathfrak{b}}}=\beta^{(-)}\Rightarrow\mathscr{A}_{\hat{\mathfrak{b}}}(\boldsymbol{\rho},\boldsymbol{\rho}')=\delta^{(2)}(\boldsymbol{\rho}-\boldsymbol{\rho}')\beta^{(-)}\quad(\hat{\mathfrak{b}}^{(-)}=\hat{0}) \tag{164}$$

and consequently

$$\sum_k \Psi_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\mathbf{r})=\sum_k \Psi_{\hat{\mathfrak{b}}k}(\mathbf{r})\Psi^{\dagger}_{\hat{\mathfrak{b}}k}(\boldsymbol{\rho}')=\delta^{(3)}(\mathbf{r}-\boldsymbol{\rho}')\beta^{(-)}\quad(\mathbf{r}\in\mathscr{V},\hat{\mathfrak{b}}^{(-)}=\hat{0}). \tag{165}$$

The reader should compare the relations (159), (162) and (165) with the closure relation (114).

V. CONCLUDING REMARKS

In this paper we have formulated Wigner's *R*-matrix theory in the language of integral operators rather than matrices. In the first part of the work, following the ideas of Nesbet,[12,13] we have shown that in the nonrelativistic theory for particles described by the Schrödinger equation the central role is played by the integral operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$ which relates function values to normal derivatives on a surface $\mathscr{S}$ of a closed volume $\mathscr{V}$ inside which the function satisfies the Schrödinger equation at energy E. Matrix elements of the operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$ between functions from an orthonormal scalar basis set spanning the surface $\mathscr{S}$ form an *R*-matrix $\mathsf{R}_{\mathfrak{b}}(E)$. The method due to Kapur and Peierls[1] and to Wigner,[2–4,6] has been used, with necessary modifications and improvements, to construct an integral kernel of the operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$.

In the second part of the work we have developed the operator formulation of Wigner's *R*-matrix theory for the Dirac equation. It has been found that in the relativistic theory a counterpart of the nonrelativistic operator $\hat{\mathscr{R}}_{\hat{\mathfrak{b}}}(E)$ is an integral operator $\hat{\mathscr{R}}^{(+)}_{\hat{\mathfrak{b}}}(E)$ relating on the enclosing surface $\mathscr{S}$ values of upper and lower components of spinor wave functions satisfying in the volume $\mathscr{V}$ the Dirac equation at energy E. Besides the operator $\hat{\mathscr{R}}^{(+)}_{\hat{\mathfrak{b}}}(E)$, another operator $\hat{\mathscr{R}}^{(-)}_{\hat{\mathfrak{b}}}(E)$ arises in the relativistic theory in the natural way. By generalizing Wigner's method,[2–4,6] we have constructed explicit forms of the operators $\hat{\mathscr{R}}^{(\pm)}_{\hat{\mathfrak{b}}}(E)$. It has been shown that although there are apparent similarities between the nonrelativistic and relativistic theories, the explicit form of the operator $\hat{\mathscr{R}}^{(+)}_{\hat{\mathfrak{b}}}(E)$ contains a component which does not have its counterpart in the nonrelativistic theory. This component vanishes in the nonrelativistic limit. This agrees with a result obtained earlier by Szmytkowski and Hinze[17,18] who found such a correction in the matrix representation of the operator $\hat{\mathscr{R}}^{(+)}_{\hat{\mathfrak{b}}}(E)$ in a particular case of the spherically symmetric volume $\mathscr{V}$ and for a very special choice of a spinor basis spanning the surface $\mathscr{S}$.

ACKNOWLEDGMENTS

I am grateful to Professor Cz. Szmytkowski for commenting on the manuscript. The work was supported in part by the Polish State Committee for Scientific Research under Grant No. 950/P03/97/12. Financial support rendered by the Alexander von Humboldt Foundation is also gratefully acknowledged.

Extension of Bertrand's theorem and factorization of the radial Schrödinger equation

Zuo-Bing Wu and Jin-Yan Zeng
Department of Physics, Peking University, Beijing 100871, People's Republic of China

(Received 2 April 1998; accepted for publication 25 May 1998)

The Bertrand's theorem is extended, i.e., closed orbits still may exist for central potentials other than the power law Coulomb potential and isotropic harmonic oscillator. It is shown that for the combined potential $V(r)=W(r)+b/r^2(W(r)=ar^\nu)$, when (and only when) $W(r)$ is the Coulomb potential or isotropic harmonic oscillator, closed orbits still exist for suitable angular momentum. The correspondence between the closeness of classical orbits and the existence of raising and lowering operators derived from the factorization of the radial Schrödinger equation is investigated. © *1998 American Institute of Physics.*
[S0022-2488(98)00110-8]

I. INTRODUCTION

The orbit of a classical particle in a central field, due to the angular momentum conservation, must lie in a plane perpendicular to the angular momentum. However, the orbit is, in general, not closed. In classical mechanics there is a famous Bertrand's theorem,[1,2] which says that the only central forces that result in closed orbits for all bound particles are the inverse square law and Hooke's law. For the two central potentials, apart from the energy and angular momentum, there exist an additional conserved quantity, which implies a higher dynamical symmetry than the geometrical symmetry (space isotropy).

Over fifty years ago, Schrödinger introduced the factorization method[3] to treat the eigenvalue problem of a one-dimensional harmonic oscillator and the quantized energy eigenvalues of a harmonic oscillator are connected by energy raising and lowering operators. The factorization method was generalized in the supersymmetry quantum mechanics (SSQM)[4] with the help of the concept of supersymmetry and shape invariance. SSQM mainly focuses on the factorization of one-dimensional Schrödinger equation (including the radial Schrödinger equation of a particle in a central field)[5] and the relation of eigenstates between two quantum systems (supersymmetric partner).

It was shown[6,7] that only for the Coulomb potential and isotropic harmonic oscillator the radial Schrödinger equation can be factorized and both the angular momentum and energy raising and lowering operators can be constructed. This reminds us that there may exist a certain connection between the factorization of radial Schrödinger equation and the closeness of classical orbits. Careful examination shows that in the derivation of Bertrand's theorem and in Ref. 6, a power law central potential ($V(r)=ar^\nu$) was assumed. For such a power law central potential, the Bertrand's theorem does hold. However, more careful analysis shows that if the restriction of power law form central potential is relaxed, the Bertrand's theorem needs reexamination. In Sec. II, it is shown that for the combined type of central potential $V(r)=W(r)+b/r^2(W(r)=ar^\nu)$, when $W(r)$ is the Coulomb potential or isotropic harmonic potential, there still exists closed orbits for suitable angular momenta. The factorization of the corresponding radial Schrödinger equation and the connection between the closeness of classical orbits and the existence of raising and lowering operators are investigated in Sec. III. A brief summary is given in Sec. IV.

II. EXTENSION OF BERTRAND'S THEOREM

It will be shown that if the restriction of a pure power law central potential is relaxed, the Bertrand's theorem may be extended. In particular, when an additional central potential b/r^2 is added to $W(r)=ar^\nu$,

 © 1998 American Institute of Physics

$$V(r)=W(r)+b/r^2, \tag{1}$$

we will show that when and only when $W(r)$ is the Coulomb potential or isotropic harmonic potential, there still exists closed orbits for some suitable angular momenta.

The equations of motion of a particle in the central potential (1) is expressed as ($\mu=1$)

$$\begin{aligned} &\dot{r}=p_r, \quad \dot{\theta}=L/r^2, \\ &\dot{p}_r=L^2/r^3+f(r), \quad \dot{L}=0, \end{aligned} \tag{2}$$

where L is the angular momentum and $f(r)=-dV/dr=g(r)+2b/r^3$, $g(r)=-dW/dr=-a\nu r^{\nu-1}$. It was shown[2] that for a circular orbit at radius r_0 to be possible, the force must be attractive and

$$E=L^2/2r_0^2+V(r_0), \quad f(r_0)=-L^2/r_0^3. \tag{3}$$

To guarantee the stability of a circular orbit $r=r_0$, it is required[2] that the second derivative of the effective potential $U(r)=V(r)+L^2/2r^2$ must be positive, i.e.,

$$-f'(r_0)-3f(r_0)/r_0>0. \tag{4}$$

It is noted that the inclusion of the additional force $2b/r^3$ does not alter the stability condition (4), so we have

$$-g'(r_0)-3g(r_0)/r_0>0, \quad \text{i.e.,} \quad a\nu(\nu+2)>0. \tag{5}$$

Thus $\nu<-2$ or $\nu>0$ for $a>0$, and $-2<\nu<0$ for $a<0$. Since we are interested in the bounded motion, the case $\nu<-2$ for $a>0$ is excluded. Thus, we obtain the stability condition for circular orbits: $a\nu>0$, i.e., $g(r)<0$.

To seek the condition for closeness of an orbit, let us consider the orbit equation[2] for potential (1)

$$\frac{d^2u}{d\theta^2}+\left(1+\frac{2b}{L^2}\right)u=-\frac{1}{L^2}\frac{d}{du}W\left(\frac{1}{u}\right), \quad u=\frac{1}{r}. \tag{6}$$

Introducing $\kappa=\sqrt{1+2b/L^2}$, $\xi=\kappa u$ and $\phi=\kappa\theta$, we get

$$\frac{d^2\xi}{d\phi^2}+\xi=J(\xi), \quad J(\xi)\equiv-\frac{1}{L^2}\frac{d}{d\xi}W\left(\frac{\kappa}{\xi}\right). \tag{7}$$

Using (3), it can be shown that at $\xi=\xi_0=\kappa/r_0$, $J(\xi_0)=\xi_0$. In addition, using (5) and $g(r)<0$, one gets

$$\beta^2\equiv 1-J'(\xi_0)=3+\frac{r}{g}\frac{dg}{dr}\bigg|_{r=r_0}>0,$$

then $\beta^2=\nu+2$. Thus, the stability condition for circular orbits also may be expressed as: $\beta^2>2$ for $a>0$, and $2>\beta^2>0$ for $a<0$.

Using the Taylor expansion of $J(\xi)$ at ξ_0, a deviation of an orbit from a circle ξ_0, $\delta\xi=\xi-\xi_0$, is governed by

$$\frac{d^2\delta\xi}{d\phi^2}+\delta\xi=J'(\xi_0)\delta\xi+\frac{1}{2}J''(\xi_0)(\delta\xi)^2+\frac{1}{6}J'''(\xi_0)(\delta\xi)^3+O((\delta\xi)^4). \tag{8}$$

For a small deviation of an orbit from circularity, to the first order of $\delta\xi$, Eq. (8) is reduced to

$$\frac{d^2\delta\xi}{d\phi^2}+\beta^2\delta\xi=0. \tag{9}$$

The solution to (9) can be expressed as

$$\delta\xi = a_1 \cos(\beta\phi), \quad \text{i.e.,} \quad \delta u = \frac{a_1}{\kappa}\cos(\beta\kappa\theta). \tag{10}$$

It can be seen that for $\beta\kappa = q/p$ (a rational number, q and p are integers), when $\theta = \theta_0 + 2\pi p$, $\delta u = \delta u_0$, i.e., the orbit remains closed. Thus, we get the condition for closeness of orbits against a small deviation from circularity: $\beta\kappa$ must be a rational number.

To seek the condition for a closed orbit when the deviation from circularity is considerable, $\delta\xi$ can be expressed as the Fourier expansion, i.e., in addition to the fundamental term in (10), more terms in the Fourier expansion should be included in $\delta\xi$. Substituting $\delta\xi$ in (8) and using the arguments similar to those in Ref. 2, one gets $\beta^2 = 0$, 1 and 4 for closed orbits. Thus, we obtain the conclusion: when (and only when) $\beta^2 = 1(\nu = -1)$ for $a < 0$, and $\beta^2 = 4(\nu = 2)$ for $a > 0$, the orbit is closed. Then, κ must be a rational number. Therefore, for the potential (1), when (and only when) $W(r)$ is the Coulomb potential or isotropic harmonic oscillator, closed orbits still exist for suitable angular momentum $L = \sqrt{2b/(\kappa^2 - 1)}$, where κ is a rational number.

Example: For the valence electron in an alkalis atom $V(r)$ may be approximately expressed as $(e = \mu = \hbar = 1)$[8]

$$V(r) = -\frac{1}{r} - \frac{\lambda}{r^2} \quad (0 < \lambda \ll 1). \tag{11}$$

In this case, the orbit equation (6) is reduced to

$$d\theta = -du/\sqrt{2E/L^2 + 2u/L^2 - \kappa^2 u^2}, \tag{12}$$

where $\kappa = \sqrt{1 - 2\lambda/L^2}$. Integrating (12), we get

$$u = \frac{1}{r} = \frac{1}{L^2\kappa^2}\left[1 + \sqrt{1 + 2EL^2\kappa^2}\cos\kappa(\theta - \theta_0)\right], \tag{13}$$

where $\sqrt{1 + 2EL^2\kappa^2} = \sqrt{1 + 2E(L^2 - 2\lambda)} \geqslant 0$ to make the solution (13) having sense. For $1 + 2EL^2\kappa^2 = 0$, the orbits are circular. Because $\kappa < 1$ for $\lambda > 0$, no elliptic orbits exist. However, when κ is a rational number, closed orbits (other than ellipses) still exist. Some illustrative examples are displayed in Fig. 1. In Fig. 1(a), $\kappa = 1/2(L = 2/3\sqrt{6\lambda})$, Fig. 1(b), $\kappa = 2/3(L = 3/5\sqrt{10\lambda})$ and Fig. 1(c), $\kappa = 3/4(L = 4/7\sqrt{14\lambda})$, there exists closed orbits around the center with period 2, 3 and 4, respectively. The geometry of closed orbits is dependent on $\kappa(L)$, but irrelevant to the energy E.

III. FACTORIZATION OF THE RADIAL SCHRÖDINGER EQUATION

For a particle in the central field $V(r)$, the energy eigenfunction may be chosen as the simultaneous eigenstate of the complete set of conserved observables $(H, \mathbf{l}^2, l_z)$, and the radial wave function $R_{n,l}(r) = \chi_{n,l}(r)/r$, ($l$ are nonnegative integers) satisfies the radial Schrödinger equation $(\hbar = \mu = 1)$

$$\begin{aligned} H\chi_{n,l}(r) &= E_n\chi_{n,l}(r), \\ H &= -\tfrac{1}{2}\, d^2/dr^2 + l(l+1)/2r^2 + V(r). \end{aligned} \tag{14}$$

For the potential (1), (14) is reduced to

$$\left[\frac{d^2}{dr^2} - \frac{l(l+1)}{r^2} - 2W(r) - \frac{2b}{r^2}\right]\chi_{n,l}(r) = -2E_n\chi_{n,l}(r). \tag{15}$$

Let $l'(l'+1) = l(l+1) + 2b$, i.e., $l' = -1/2 + (l + 1/2)\sqrt{1 + 2b/(l+1/2)^2}$, (15) can be rewritten as

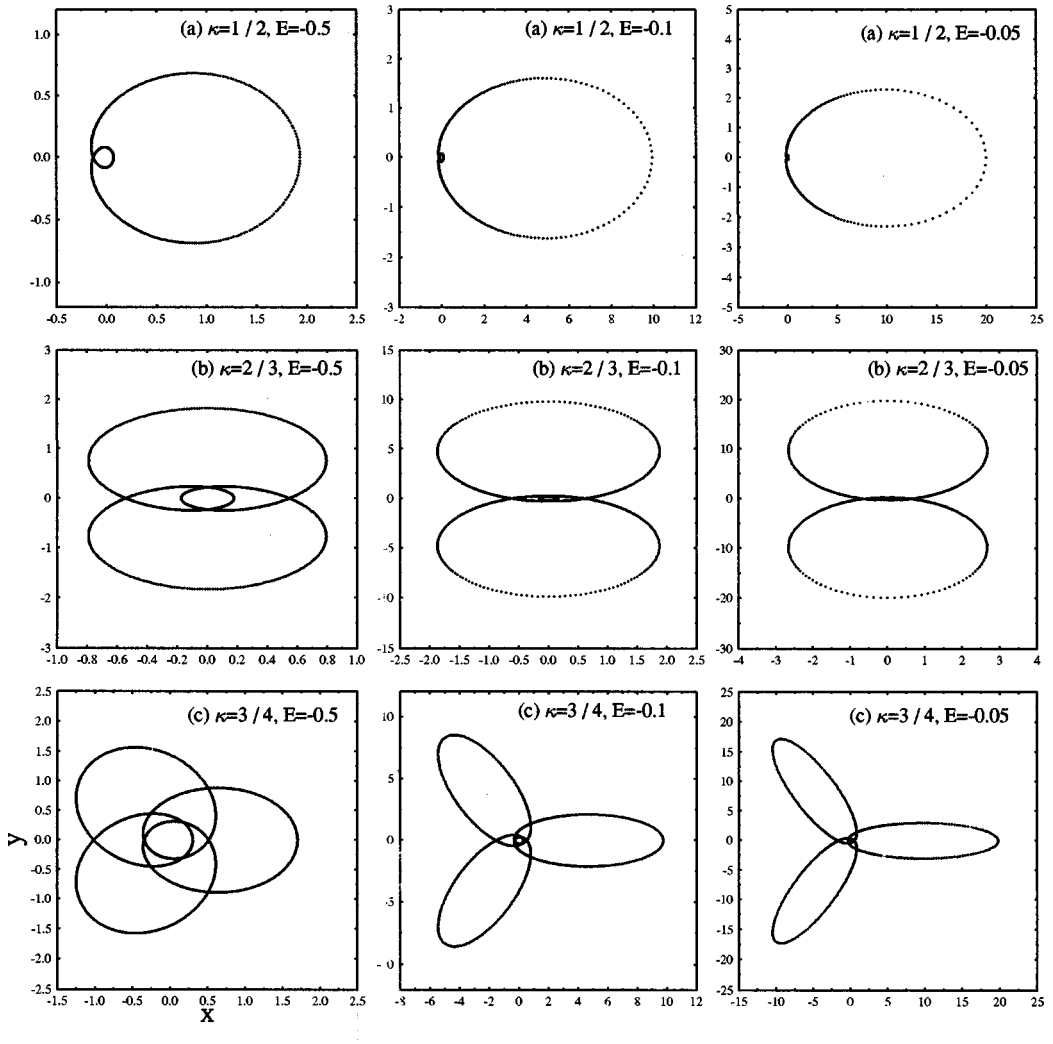

FIG. 1. The closed orbits of the valence electron in an alkalis atom ($\lambda = 0.2$).

$$\mathscr{D}_{l'}(r)\chi_{n,l'}(r) = -2E_n\chi_{n,l'}(r),$$
$$\mathscr{D}_{l'}(r) = d^2/dr^2 - l'(l'+1)/r^2 - 2W(r), \tag{16}$$

which has the same form as the usual radial Schrödinger equation with the central potential $W(r)$, but the nonnegative integer quantum number l is replaced by a noninteger l'. It has been shown[6,7] that if the power law central potential $W(r)$ is assumed, only for the Coulomb potential or isotropic harmonic oscillator the radial Schrödinger equation can be factorized to derive the raising and lowering operators of $l'(\Delta l' = \pm 1)$. However, for $\Delta l' = \pm 1$, the shift in l is by no means ± 1. Therefore, though the radial Schrödinger equation can be factorized for the central potential (1), no angular momentum raising and lowering operators ($\Delta l = \pm 1$) can be constructed, which is intimately connected with the breaking of the dynamical symmetry of Coulomb potential and isotropic harmonic oscillator due to the added term b/r^2 in (1).

For the Coulomb potential and isotropic harmonic oscillator, whose exact eigenvalues are well known, the energy raising and lowering operators have been derived by using different approaches in Refs. 6 and 9. For a particle in a more general central potential, the exact energy eigenvalues are usually unknown. To derive the energy raising and lowering operators, we may use the WKB approximation. According to the WKB approximation, the eigenvalues of bounded states of (16) take the form[10] (note: here the usual angular momentum l has been replaced by l')

$$E_n=\alpha_\nu n^{2\nu/(\nu+2)}, \tag{17}$$

where

$$\alpha_\nu=a^{2/(\nu+2)}2^{\nu/(\nu+2)}\left[\nu\sqrt{\pi}\,\frac{\Gamma\left(\frac{1}{\nu}+\frac{3}{2}\right)}{\Gamma\left(\frac{1}{\nu}\right)}\right]^{2\nu/(\nu+2)}>0, n=n_r+\frac{l'}{2}+\frac{3}{4}\ \text{for}\ a>0,$$

and

$$\alpha_\nu=-(-a)^{2/(\nu+2)}2^{\nu/(\nu+2)}\left[(-\nu)a\sqrt{\pi}\,\frac{\Gamma\left(1-\frac{1}{\nu}\right)}{\Gamma\left(-\frac{1}{2}-\frac{1}{\nu}\right)}\right]^{2\nu/(\nu+2)}<0,$$

$$n=n_r+\frac{2l'+\nu+3}{2(\nu+2)}\ \text{for}\ a<0.$$

Thus, (16) may be recast into

$$\begin{aligned}&\mathscr{D}_n(r)\chi_{n,l'}(r)=l'(l'+1)\chi_{n,l'}(r),\\ &\mathscr{D}_n(r)=r^2d^2/dr^2-2ar^{\nu+2}+2\alpha_\nu n^{2\nu/(\nu+2)}r^2.\end{aligned} \tag{18}$$

(1) For $a>0$, the factorizability of (18) requires

$$(rd/dr-\sqrt{2a}r^{\nu/2+1}+A)(rd/dr+\sqrt{2a}r^{\nu/2+1}+B)\chi_{n,l'}(r)=\mathscr{D}_n(r)\chi_{n,l'}(r)+AB\chi_{n,l'}(r), \tag{19}$$

then we have

$$\begin{aligned}&A+B+1=0,\\ &\sqrt{2a}r^{\nu/2+1}(A-B+\nu/2+1)=2\alpha_\nu n^{2\nu/(\nu+2)}r^2.\end{aligned} \tag{20}$$

The solution to (20) is $\nu=2$, $\alpha_2=2\sqrt{2a}$, $A=2n-3/2$, and $B=-(2n-1/2)$. Thus, (19) is reduced to

$$\begin{aligned}&[rd/dr-\sqrt{2a}r^2+2n-3/2][rd/dr+\sqrt{2a}r^2-(2n-1/2)]\chi_{n,l'}(r)\\ &\quad=\mathscr{D}_n(r)\chi_{n,l'}(r)-(2n-3/2)(2n-1/2)\chi_{n,l'}(r).\end{aligned} \tag{21}$$

Similarly, (18) also can be factorized as

$$\begin{aligned}&[rd/dr+\sqrt{2a}r^2-(2n+3/2)][rd/dr-\sqrt{2a}r^2+(2n+1/2)]\chi_{n,l'}(r)\\ &\quad=\mathscr{D}_n(r)\chi_{n,l'}(r)-(2n+1/2)(2n+3/2)\chi_{n,l'}(r).\end{aligned} \tag{22}$$

Using (21) and (22), one may obtain the energy raising and lowering operators

$$\begin{aligned}&\chi_{n+2,l'}(r)\sim[rd/dr-\sqrt{2a}r^2+(2n+1/2)]\chi_{n,l'}(r),\\ &\chi_{n-2,l'}(r)\sim[rd/dr+\sqrt{2a}r^2-(2n-1/2)]\chi_{n,l'}(r).\end{aligned} \tag{23}$$

(2) For $a<0$, the factorizability of (18) requires

$$(rd/dr-\sqrt{-2\alpha_\nu}n^{\nu/(\nu+2)}r+A)(rd/dr+\sqrt{-2\alpha_\nu}n^{\nu/(\nu+2)}r+B)\chi_{n,l'}(r)$$
$$=\mathscr{D}_n(r)\chi_{n,l'}(r)+AB\chi_{n,l'}(r), \tag{24}$$

then we have

$$\begin{aligned} A+B+1&=0,\\ \sqrt{-2\alpha_\nu}n^{\nu/(\nu+2)}r(A-B+1)&=-2ar^{\nu+2}. \end{aligned} \tag{25}$$

The solution to (25) is $\nu=-1$, $\alpha_{-1}=-a^2/2$, $A=n-1$, and $B=-n$. Thus, (24) is reduced to

$$[rd/dr+ar/n+n-1][rd/dr-ar/n-n]\chi_{n,l'}(r)=\mathscr{D}_n(r)\chi_{n,l'}(r)-(n-1)n\chi_{n,l'}(r). \tag{26}$$

Similarly, (18) also can be factorized as

$$[rd/dr-ar/n-(n+1)][rd/dr+ar/n+n]\chi_{n,l'}(r)=\mathscr{D}_n(r)\chi_{n,l'}(r)-n(n+1)\chi_{n,l'}(r). \tag{27}$$

Using (26) and (27) and introducing the scaling operator $\mathscr{M}(k)$ defined by $\mathscr{M}(k)f(r)=f(kr)$, one obtains the energy raising and lowering operators

$$\begin{aligned} \chi_{n+1,l'}(r)&\sim\mathscr{M}\left(\frac{n}{n+1}\right)(rd/dr+ar/n+n)\chi_{n,l'}(r)=[rd/dr+ar/(n+1)+n]\mathscr{M}\left(\frac{n}{n+1}\right)\chi_{n,l'}(r),\\ \chi_{n-1,l'}(r)&\sim\mathscr{M}\left(\frac{n}{n-1}\right)(rd/dr-ar/n-n)\chi_{n,l'}(r)=[rd/dr-ar/(n-1)-n]\mathscr{M}\left(\frac{n}{n-1}\right)\chi_{n,l'}(r). \end{aligned} \tag{28}$$

Thus, we arrive at the conclusion that, for the potential (1), only when $W(r)$ is the Coulomb potential or isotropic harmonic oscillator, the radial Schrödinger equation can be factorized to derive the energy raising and lowering operators.

For a classical particle in the Coulomb potential $W(r)=-1/r$, the orbit is always closed for any negative energy ($E<0$) and positive angular momentum L, i.e., an ellipse, of which the length of semimajor axis is $a=1/2|E|$ and the eccentricity $e=\sqrt{1-2|E|L^2}$. This is guaranteed by the existence of an additional conserved quantity—the Runge–Lenz vector $\mathbf{R}=\mathbf{p}\times\mathbf{L}-\mathbf{r}/r$, which determines the direction of semimajor axis and the eccentricity $e=|R|$. In quantum mechanics, the angular momentum and bound energy are quantized. Therefore, it is not surprising that for the Coulomb potential the radial Schrödinger equation can be factorized and there exist four kinds of raising and lowering operators connecting various eigenstates of energy and angular momentum.[6]

However, for the combined central potential (11), the dynamical symmetry O_4 is broken and $\mathbf{R}$ no longer remains constant, and the orbit, in general, is not closed. It has been shown in Sec. II that for suitable angular momenta $L=\sqrt{2\lambda/(1-\kappa^2)}$ (κ is a rational number), the orbits are still closed (but not ellipses). Therefore, it is understandable why no angular momentum raising and lowering operators ($\Delta l=\pm 1$) exist, but energy raising and lowering operators for a fixed l' [see (28)] still can be constructed. In fact, for $\lambda=0$, (28) is just the raising and lowering operators $B(l,n\uparrow)$ and $B(l,n\downarrow)$ given in Eq. (33) of Ref. 6. It is noted that the angular momentum raising and lowering operators A, C and D in Ref. 6 no longer exist for the combined potential (11). For the isotropic harmonic oscillator, the situation is similar.

IV. SUMMARY

The Bertrand's theorem is extended in this paper. For a classical particle in a power law central potential $W(r)$, the Bertrand's theorem does hold, i.e., only for the Coulomb potential or isotropic harmonic oscillator, closed orbits always exist for continuous energy and angular momentum. Accordingly, in quantum mechanics there exist both energy and angular momentum raising and lowering operators connecting neighboring discrete energy and angular momentum eigenstates. For the combined potential (1), it is shown that when $W(r)$ is the Coulomb potential or isotropic harmonic oscillator, classical closed orbits (other than ellipse) still exist for continuous

energy, but only for suitable angular momenta. From this one can understand why in this case there exist only energy raising and lowering operators in quantum mechanics, but no angular momentum raising and lowering operators.

(Received 17 November 1997; accepted for publication 23 January 1998)

A constructive reversed index theorem concerning the polar decomposition of an operator into a product of a unitary exponential phase operator and a Hermitian amplitude operator is investigated. Its applications to the construction of Hermitian phase operators of fermions and phase-difference operators between bosons or fermions are presented. Specifically, a Hermitian operator is constructed for the phase difference between a single-mode fermion and boson, which is justified by the fact that it is exactly the interaction part of the Hamiltonian of the Jaynes-Cummings Model. Furthermore, a Hermitian phase operator of a single-mode boson can also be defined referring to a single-mode fermion. All those quantized phases and phase-differences are found to obey a quantum addition rule instead of the ordinary commutative addition rule. © *1998 American Institute of Physics.* [S0022-2488(98)00107-8]

I. INTRODUCTION

Phase is one of the most important and perplexing aspects in quantum physics. The concept of phase is most important because, experimentally, it plays an essential role in the interference phenomena, through which many quantum properties can be revealed and, theoretically, it leads to the gauge theory. It is also a most perplexing aspect because it enters the experiments merely as a parameter without a quantum description. The nonexistence of a proper operator for a simple quantum system such as a single harmonic oscillator or single-mode bosonic field was known by Dirac seventy years ago.[1]

The difficulty of quantizing the phase variable of a quantum harmonic oscillator can most elegantly be illustrated by an index theorem. The index[2] of an operator O in a Hilbert space is defined as

$$\mathrm{index}(O)\equiv \dim \ker(O)-\dim \ker(O^\dagger), \tag{1}$$

in which $\dim \ker(O)$ denotes the dimension of the kernel space $\ker(O)=\{|\psi\rangle|O|\psi\rangle=0\}$ of the operator O. Because of the relation $\ker(O)=\ker(O^\dagger O)$, the index can equivalently be defined by

$$\mathrm{index}(O)\equiv \dim \ker(O^\dagger O)-\dim \ker(OO^\dagger). \tag{2}$$

This index of an operator is invariant under a very general deformation of the Hilbert space. For two arbitrary reversible coordinate transformations P and Q in the Hilbert space of the system, the index value cannot be changed due to the relation

$$\dim \ker(POQ)=\dim \ker(O). \tag{3}$$

[a)]Current address: Institute of Theoretical Physics, Academia Sinica, Beijing 100080, P.R. China.

 © 1998 American Institute of Physics

If an operator O has a polar decomposition, i.e., it can be decomposed into a product $O=\mathscr{E}A$ (or $O=A\mathscr{E}$) of a unitary exponential phase operator $\mathscr{E}$ and a Hermitian amplitude operator A, then its index according to the second definition, Eq. (2),

$$\text{index}(O)=\dim\ker(A^2)-\dim\ker(\mathscr{E}A^2\mathscr{E}^\dagger), \tag{4}$$

vanishes because of Eq. (3). In other words, if an operator does not have a zero index, it cannot have a polar decomposition as long as it is restricted to the original Hilbert space. This may be referred to as a no-go index theorem.[3]

As is well known, in the Hilbert space $\mathscr{H}_b$ of a single harmonic oscillator or a single-mode bosonic field described by ladder operators $b^\dagger$ and b satisfying canonical commutation relation $[b,b^\dagger]=1$, there is a state, vacuum state that is annihilated by the destruction operator while there is no state that can be destructed by the creation operator. As a result, according to the first definition, Eq. (1), we have an index condition[2–4]

$$\text{index}(b)\equiv\dim\ker(b)-\dim\ker(b^\dagger)=1. \tag{5}$$

Therefore a Hermitian phase operator defined by the polar decomposition is unattainable in the original Hilbert space $\mathscr{H}_b$. However, when the Hilbert space is modified so that the operator carrying the information of phase has a vanishing index, a Hermitian operator can exist for the description of phase properties because of a reversed index theorem discussed in the next section.

As the first application, the phase difference operators for bosons are constructed and a quantum addition rule of quantized phase differences is introduced in Sec. III. In Sec. IV its applications to the constructions of phase and phase difference operators for fermions are discussed. Finally, in Sec. V a phase difference operator is constructed to describe the phase difference between a single-mode boson and fermion.

II. REVERSED INDEX THEOREM

Generally, for an operator O in a certain Hilbert space, if the following commutation relation holds (which is satisfied by all the operators concerned later on)

$$[O^\dagger O,OO^\dagger]=0, \tag{6}$$

then it can always be decomposed into a product $O=EA$ of a Hermitian amplitude operator $A=\sqrt{O^\dagger O}$ as a function of the operator $O^\dagger O$ and a *nonunitary* exponential phase operator E satisfying

$$E^\dagger E=1-P_O,\quad EE^\dagger=1-P_{O^\dagger}, \tag{7}$$

with P_O and $P_{O^\dagger}$ being the projectors on the kernel space $\ker(O)$ and $\ker(O^\dagger)$, respectively. Outside the kernel space $\ker(O)$ the nonunitary exponential phase operator can be written as $E=OA^{-1}$, which is supposed to be identically zero inside the kernel space $\ker(O)$. For example, the annihilation operator b of a quantum harmonic oscillator can be decomposed into a product of nonunitary exponential phase operator $E=b(\sqrt{N})^{-1}$ (Ref. 5) and a Hermitian amplitude operator $A=\sqrt{N}$. If the operator O possesses a zero index, however, it can have unitary polar decompositions.

The vanishing index means that the kernel space $\ker(O)$ has the same dimension as the kernel space of its Hermitian conjugate $\ker(O^\dagger)$ according to the definition, Eq. (1). Since we are mainly dealing with separable Hilbert space with a countable number of bases, these two kernel spaces are also separable Hilbert spaces. As a result they can be in a one-to-one correspondence with each other. In this sense the kernel spaces are not necessarily restricted to finite-dimensional spaces. The orthonormal bases of these two kernel space are denoted as $\{|\phi_i\rangle|i\in S\}$ for $\ker(O)$ and $\{|\psi_i\rangle|i\in S\}$ for $\ker(O^\dagger)$, respectively, with S being a subset of the natural number set, finite or infinite. An isomorphism $Y:\ker(O)\mapsto\ker(O^\dagger)$ can be established as

$$Y=\sum_{i\in S}|\psi_i\rangle\langle\phi_i|, \tag{8}$$

which is reversible and its reverse is exactly its Hermitian conjugate because we have $YY^\dagger = P_{O^\dagger}$ and $Y^\dagger Y = P_O$ where the projectors, i.e., the identity operators, on those two kernel spaces are

$$P_O = \sum_{i \in S} |\phi_i\rangle\langle\phi_i|, \quad P_{O^\dagger} = \sum_{i \in S} |\psi_i\rangle\langle\psi_i|. \tag{9}$$

Now we are ready for the reversed index theorem: It is possible to decompose an operator O with vanishing index satisfying a commutation relation, Eq. (6), into a product of a unitary operator and a Hermitian operator.

This is because relation Eq. (6) ensures a nonunitary exponential phase operator E and the vanishing index ensures an isomorphism Y between kernel spaces $\ker(O)$ and $\ker(O^\dagger)$ and operator

$$\mathscr{E} = E + Y, \tag{10}$$

defined in the whole Hilbert space, is unitary and satisfies the polar decomposition $O = \mathscr{E}A$. Therefore there exists a Hermitian phase operator defined by the exponential function.

This polar decomposition depends obviously on the choice of the isomorphism Y or the orthonormal bases of kernel spaces $\ker(O)$ and $\ker(O^\dagger)$. Therefore the Hermitian phase operator is not unique which depends on the experimental setup of measuring the Hermitian phase operator.[6] This degree of freedom is somewhat similar to the gauge freedom and the isomorphism plays a role of connection to make the comparison of phases possible.

In the following sections, as the applications of the above reversed index theorem, the Hermitian phase difference operators between boson and boson, fermion and fermion, boson and fermion are constructed, which enable a complete quantum description of the phase variable.

III. PHASE-DIFFERENCE OPERATORS OF BOSONS

As shown in the introductory section, the no-go index theorem excludes a Hermitian phase operator for a single-mode boson or a single harmonic oscillator in its original Hilbert space. Many efforts have been tried to solve this problem by introducing another degree of freedom[7,8] or truncating the original Hilbert space to a finite-dimensional one.[9] However, these additional structures are rather artificial so they are not a satisfactory quantum description of phase.[10]

Taking account of the fact that what is physical and measurable is only the difference of an observable, a natural way to circumvent the no-go index theorem, however, is to consider the phase *difference* between two bosons,[11,12] which are supposed to be described by ladder operators $\{b_i, b_i^\dagger | i = 1,2\}$ satisfying canonical commutation rules $(i,j = 1,2)$,

$$[b_i, b_j^\dagger] = \delta_{ij}, \quad [b_i, b_j] = [b_i^\dagger, b_j^\dagger] = 0.$$

The Hilbert space $\mathscr{H}_{2b}$ is spanned by the common eigenstates $|n_1, n_2\rangle$ $(n_1, n_2 = 0,1,2,\ldots)$ of the number operators $N_i = b_i^\dagger b_i$ $(i = 1,2)$. From the correspondence between classical and quantum physics, the information of the phase difference between these two modes of boson is carried by operator $J_+ = b_1^\dagger b_2$. In the Hilbert space $\mathscr{H}_{2b}$ both the kernel space $\ker(J_+)$ spanned by bases $|n,0\rangle$ $(n = 0,1,2,\ldots)$ and the kernel space $\ker(J_+^\dagger)$ spanned by bases $|0,n\rangle$ $(n = 0,1,2,\ldots)$ are countably infinite-dimensional Hilbert spaces and they can be in a one-to-one correspondence with each other. Therefore we have a vanishing index,

$$\mathrm{index}(J_+) = 0. \tag{11}$$

Thus a polar decomposition of operator J_+ is possible according to the reversed index theorem discussed above and a Hermitian phase difference operator is attainable. The most general isomorphism $Y_{12}: \ker(J_+) \mapsto \ker(J_+^\dagger)$ is given by

$$Y_{12} = U_{12}\, P_{10}\, X_{12}, \tag{12}$$

where U_{12}, called the bosonic connection operator, is an arbitrary unitary operator commuting with number operator N_1, $P_{10}=|0\rangle_1\langle 0|_1$ is the vacuum projector of the first mode, and X_{12} is a linear quantum transformation,[13]

$$X_{12}=e^{i(\pi/2)(b_1^\dagger b_2+b_2^\dagger b_1)}, \tag{13}$$

which exchanges the Hilbert spaces of two modes of the boson, $X_{12}b_1=b_2X_{12}$, for example. Unlike the case of a single harmonic oscillator, where the Hermitian phase operator defined by polar decomposition does not exist, there is an infinite number of Hermitian phase-difference operators for two-mode boson.

The most important choice of the isomorphism Y_{12} is to require that it commutes with the total number operator N_1+N_2, which reduces the bosonic connection operator U_{12} in Eq. (12) to a diagonal matrix. Therefore the exponential phase difference operator is

$$\mathscr{E}_{12}=E_1^\dagger E_2+e^{i\phi_{12}(N_2)}\,P_{10}\,X_{12}, \tag{14}$$

where $E_i=b_i(\sqrt{N_i})^{-1}$ is the nonunitary phase operator for the ith mode ($i=1,2$) and the phase-difference function $\phi_{12}(x)$ is an arbitrary real function. The Hermitian phase-difference operator defined by the exponential function $\mathscr{E}_{12}=\exp\{i\mathscr{P}_{12}\}$, which is called the direct phase-difference operator, possesses a new type of eigenvalue, namely a countable and dense type.[12] There is a countably infinite number of eigenvalues, which shows its conjugation relationship with the number operator, and it is dense in a 2π window, which shows its periodic nature. The phase-difference states, eigenstates of the phase-difference operator $\mathscr{P}_{12}$ form an orthonormal and complete basis of the Hilbert space $\mathscr{H}_{2b}$.

Another important choice of the the isomorphism Y'_{12} leads to the indirect phase-difference operator. Classically, for three harmonic oscillators there are three direct phase differences Φ_{ij}. Trivially, we can have an indirect phase difference between first two oscillators by comparing them with the third oscillator, $\Phi'_{12}=\Phi_{13}+\Phi_{32}$, which is obviously equal to the direct phase difference Φ_{12} because of the identity

$$\Phi_{12}+\Phi_{23}+\Phi_{31}=0. \tag{15}$$

When three quantum oscillators are concerned, there are three different direct phase-difference operators $\mathscr{P}_{ij}$ $(i,j=1,2,3,i\neq j)$ which are not commuting with one another describing the quantum phase differences. The ordinary addition of two of them, $\mathscr{P}_{12}+\mathscr{P}_{23}$, for example, does not satisfy the polar decomposition and is therefore not a quantum phase difference at all. However, one can introduce a quantum addition rule[12] of two phase operators $\mathscr{P}_1$ and $\mathscr{P}_2$ according to

$$\mathscr{P}_1\dot{+}\mathscr{P}_2\equiv -i\,\ln\{e^{i\mathscr{P}_1}e^{i\mathscr{P}_2}\}\quad(\mathrm{mod}\,2\pi), \tag{16}$$

which reduces to the ordinary addition rule when these two operators are commuting and may not be commutative when they are not commuting with each other. The indirect phase-difference operator is defined as

$$\mathscr{P}'_{12}=\mathscr{P}_{13}\dot{+}\mathscr{P}_{32}. \tag{17}$$

Its exponential function, the indirect exponential phase-difference operator satisfies the polar decomposition, which corresponds to a choice of the bosonic connection operator,

$$U'_{12}=e^{i\{\phi_{12}(N_2)+\phi_{23}(N_3)\}}\,X_{23}. \tag{18}$$

Similar to the classical identity, Eq. (15), fulfilled by those three classical phase differences according to the normal addition rule, the quantum combinations of three quantized phase differences according to the quantum addition rule have the following properties $(i,j,k=1,2,3)$:

$$\mathrm{spec}(\mathscr{P}_{ij}\dot{+}\mathscr{P}_{jk}\dot{+}\mathscr{P}_{ki})=\{0,\pi\}, \tag{19a}$$

$$\mathrm{spec}(\mathscr{P}_{ij}\dot{+}\mathscr{P}_{ki}\dot{+}\mathscr{P}_{jk})=\left\{0,\frac{\pi}{2},\pi,\frac{3\pi}{2}\right\}, \tag{19b}$$

where $\mathrm{spec}(O)$ denotes the spectrum of the operator O and all those phase-difference functions ϕ_{ij} are taken as zero for simplicity. This is because for the exponential phase difference operators we have

$$(\mathscr{E}_{ij}\mathscr{E}_{jk}\mathscr{E}_{ki})^2=1, \quad (\mathscr{E}_{ij}\mathscr{E}_{ki}\mathscr{E}_{jk})^4=1,$$

considering the fact that the permutators X_{ij} $(i,j=1,2,3)$ defined as in Eq. (13) which are the generators of the permutation group P_3. The existence of additional nonzero eigenvalues in spectra, Eq. (19), is a purely quantum feature.

Generally for a K-mode boson let us consider K quantized phase difference $\mathscr{P}_{ij}$ in which the subscript of each mode appears exactly twice. When they are added up in such a way that their subscripts are arranged in a chainlike order as in Eq. (19a) we have the following spectrum:

$$\mathrm{spec}(\mathscr{P}_{\delta,K}\equiv\mathscr{P}_{12}\dot{+}\mathscr{P}_{23}\dot{+}\cdots\dot{+}\mathscr{P}_{K-1,K}\dot{+}\mathscr{P}_{K1})=\left\{\frac{2m\pi}{K-1}\middle| m=0,1,\ldots,K-2\right\}. \tag{20}$$

We may change the orders of those noncommuting phase-difference operators in the above spectrum to obtain another spectrum. Let us denote the resulting operator as $\mathscr{P}'_{\delta,K}$ after the rearrangement of the subscripts. In order to obtain a chainlike ordering of the subscripts again, let use suppose we need to exchange at *least* L times the phase-difference operators. Then the exponential phase-difference operator is found to satisfy the relation

$$\{e^{i\mathscr{P}'_{\delta,K}}\}^{(L+1)(K-1)}=1,$$

from which the spectrum of $\mathscr{P}'_{\delta,K}$ is obtained as

$$\frac{2m\pi}{(L+1)(K-1)}, \tag{21}$$

with $m=0,1,2,\ldots,(L+1)(K-1)-1$.

IV. PHASE AND PHASE-DIFFERENCE OPERATORS OF FERMIONS

The second application of the above reversed index theorem is to construct a Hermitian phase operator for a single-mode fermion and phase-difference operator between two modes of a fermion.

A single-mode fermion or a single fermionic oscillator can be described by fermionic creation and annihilation operators $f^\dagger$ and f satisfying anticommutator $\{f,f^\dagger\}=1$. Its Hilbert space $\mathscr{H}_f$ is spanned by the eigenstates $|\sigma\rangle$ $(\sigma=0,1)$ of the fermionic number operator $N_f=f^\dagger f$. The index of the fermionic annihilation operator has a vanishing index $(f)=0$ in Hilbert space $\mathscr{H}_f$. Therefore a polar decomposition of the annihilation operator f is possible and a Hermitian phase operator can be therefore well defined.

The most general isomorphism from a one-dimensional kernel space $\ker(f)$ spanned by the ground state $|0\rangle$ to another one-dimensional kernel space $\ker(f^\dagger)$ spanned by the exited state $|1\rangle$ is

$$Y_f=\exp(-i2\alpha)f^\dagger, \tag{22}$$

with α being an arbitrary real number that determines the limits of a 2π window of phase variable. Therefore the unitary exponential phase operator $\mathscr{E}_f$ and the Hermitian phase operator defined by the exponential function are, respectively,

$$\mathscr{E}_f=f+f^\dagger e^{-i2\alpha}=e^{-i\mathscr{P}_f}, \tag{23a}$$

$$\mathscr{P}_f=\alpha+\frac{\pi}{2}(1-e^{i\alpha}\mathscr{E}). \tag{23b}$$

This Hermitian phase operator can be and is always being measured in the interferometer. In fact the essential element of the interferometer is a single-mode fermion by identifying its two paths with two fermionic number states. The number operator carries the which-way information while the phase operator shows the interference pattern. The complementariness of the which-way information showing the particle property and interference pattern showing the wave property is just a manifestation of the noncommuting property of the phase operator and the number operator.[6]

Let us consider a two-mode fermion, which is described by ladder operators $\{f_i, f_i^\dagger | i=1,2\}$ satisfying anticommutation rules $(i,j=1,2)$,

$$\{f_i, f_j^\dagger\}=\delta_{ij}, \quad \{f_i, f_j\}=\{f_i^\dagger, f_j^\dagger\}=0.$$

Its Hilbert space $\mathscr{H}_{2f}$ is spanned by the common eigenstates of two fermionic number operators $N_{fi}=f_i^\dagger f_i$ $(i=1,2)$. Similar to the case of a two-mode boson, the phase difference is contained in the operator $f_1^\dagger f_2$, whose index is obviously zero in the Hilbert space $\mathscr{H}_{2f}$. Therefore we have polar decomposition,

$$f_1^\dagger f_2=\mathscr{E}_{12}^f N_2(1-N_1), \tag{24}$$

in which the unitary exponential phase-difference operator is $\mathscr{E}_{12}^f=f_1^\dagger f_2+Y_{12}^f$ with the isomorphism $Y_{12}^f:\ker(f_1^\dagger f_2)\mapsto\ker(f_2^\dagger f_1)$ given by

$$Y_{12}^f=U_{12}^f(f_1 f_2+f_2^\dagger), \tag{25}$$

where the fermionic connection operator U_{12}^f is an arbitrary 3×3 matrix belonging to a representation of group $U(3)$ in the kernel space $\ker(f_2^\dagger f_1)$.

There are two well defined phase operators $\mathscr{P}_1^f$ and $\mathscr{P}_2^f$ for two modes. As it turns out, the exponential function of their normal subtraction $\mathscr{P}_1^f-\mathscr{P}_2^f$ does not satisfy the polar decomposition, Eq. (24), as a phase difference factor should be. However, when they are summed up,

$$\mathscr{P}_{12}^f=\mathscr{P}_1^f \dot{-} \mathscr{P}_2^f \equiv \mathscr{P}_1^f \dot{+} (-\mathscr{P}_2^f), \tag{26}$$

according to the quantum addition rule, Eq. (16), its exponential function satisfies polar decomposition, Eq. (25), which corresponds to the following fermionic connection operator:

$$U_{12}^{f\prime}=e^{-2i\alpha_2}\mathscr{E}_{f1}N_{f2}+e^{2i\alpha_1}(1-N_{f1})(1-N_{f2}). \tag{27}$$

The eigenvalues of this fermionic phase-difference operator $\mathscr{P}_{12}^f$ are found to be $\alpha_1-\alpha_2 \pm \pi/2$ which are both two-fold degenerated. Those four fermionic phase-difference states form an orthonormal and complete basis of Hilbert space $\mathscr{H}_{2f}$. In the fermionic number state basis $\{|\sigma_1,\sigma_2\rangle | \sigma_1,\sigma_2=0,1\}$, by assuming that $\alpha_1=\pi$ and $\alpha_2=\pi/2$, one of the eigenstates corresponding to the eigenvalue π is

$$\frac{1}{\sqrt{2}}\{|0,1\rangle-|1,0\rangle\}, \tag{28}$$

which is exactly an EPR state of two fermions. This provides a different view point of an EPR entangled state: It is just one of the eigenstates of the phase difference operator of these two fermions or two-level systems.

When a three-mode fermion is concerned, there are three different quantum phase differences $\mathscr{P}_{12}^f$, $\mathscr{P}_{23}^f$, and $\mathscr{P}_{31}^f$ between each of two modes. When they are added up by using the quantum addition rule, we have identities

$$\mathscr{P}_{ij}^f \dot{+} \mathscr{P}_{jk}^f \dot{+} \mathscr{P}_{ki}^f = 0, \tag{29a}$$

$$\mathscr{P}_{ij}^f \dot{+} \mathscr{P}_{ki}^f \dot{+} \mathscr{P}_{jk}^f = \pi, \tag{29b}$$

with $i,j,k=1,2,3$. However, when they are added up by using the ordinary addition rule we cannot have similar identities. Similarly, for a finite-mode of a fermion, when the subscripts of the fermionic phase-difference operators are arranged in an even permutation of the chainlike order like in Eq. (29a), their quantum addition yields zero and when they are arranged in an odd permutation of the chainlike order, their quantum addition yields the additional phase π, which has no classical correspondence.

V. PHASE-DIFFERENCE OPERATOR BETWEEN BOSON AND FERMION

There are two distinct kinds of systems, namely bosons and fermions. The phase difference between two modes of a boson can be described by the direct and indirect phase difference operators as seen in Sec. III and the phase of a single-mode fermion and the phase difference between two modes of fermions can also be described by Hermitian operators as shown in Sec. IV. To complete the quantization of phase, we shall construct a Hermitian operator describing the phase difference between a single-mode fermion and a single-mode boson.

Because there is no phase operator for a single-mode boson, the phase difference between a single-mode fermion and boson cannot be defined by the difference of phases of different systems either. Similar to the two-mode boson case, the phase difference information must be contained in operator $b^\dagger f$ whose kernel space is spanned by the basis

$$\{|n,0\rangle \equiv |n\rangle_b|0\rangle_f | n=0,1,2,\ldots\}. \tag{30}$$

The kernel space $\ker(bf^\dagger)$ of its Hermitian conjugate is spanned by the basis

$$\{|n,1\rangle | n=0,1,2,\ldots\} \cup \{|0,\sigma\rangle | \sigma=0,1\}, \tag{31}$$

which is seemingly a little larger than the kernel space $\ker(b^\dagger f\ )$. But when the property of countable infinity is taken into account, these two kernel spaces have exactly the same dimension and the index of operator $b^\dagger f$ vanishes,

$$\mathrm{index}(b^\dagger f\ ) = 0. \tag{32}$$

The isomorphism Y_{bf} from kernel space $\ker(b^\dagger f\ )$ to kernel space $\ker(bf^\dagger)$ is most generally found to be

$$Y_{bf} = U_0 P_0 (1-N_f) + U_{bf} E f^\dagger, \tag{33}$$

with U_{bf} and U_0 being two unitary operators commuting with the fermionic operators. By requiring the phase-difference factor $\mathscr{E}_{bf}$ to commute with the total number operator $\Delta = N + N_f$, an exponential phase-difference operator and the Hermitian phase-difference operator defined by exponential function for bosonic and fermionic systems are, respectively,

$$\mathscr{E}_{bf} = E^\dagger f + e^{2i\phi(\Delta)}(P_0 f + E) f^\dagger = e^{i\mathscr{P}_{bf}}, \tag{34a}$$

$$\mathscr{P}_{bf} = \phi(\Delta) + \frac{\pi}{2}(1 - e^{-i\phi(\Delta)}\mathscr{E}_{bf}), \tag{34b}$$

where the phase-difference function $\phi(x)$ is an arbitrary real function. The eigenvalues of the phase-difference operator $\mathscr{P}_{bf}$ is found to be $\phi(n)+\sigma\pi$ with $n=0,1,2,\ldots$, and $\sigma=0,1$. In the following discussions the phase-difference function is supposed to be zero for simplicity.

As a physical justification of considering the phase difference between a boson and fermion, let us consider the Jaynes-Cummings model (JCM),[14] through which many quantum features can be revealed. It is also the simplest model describing the interaction between light and matter and attracts much attention. The most generally generalized JCM was investigated from an algebraic point of view and an su(2) structure was revealed.[15] Under the rotating wave approximation, the interaction part of the Hamiltonian can be rewritten in terms of the phase-difference operator between the light and matter as

$$H_I = g\frac{2}{\pi}\sqrt{\Delta}\mathscr{P}_{bf}. \tag{35}$$

Therefore the phase-difference operator of a boson and fermion gives a rather intuitive physical meaning to this model: It just compares the phase difference between a fermion, the matter, and a boson, the light. Therefore a two-level atom in a cavity field can be regarded as an interferometer between a fermion and a boson.

At this point one is able to define a Hermitian phase operator for single-mode boson as follows despite the no-go index theorem. At first we compare this single-mode boson with a single-mode fermion and we have a Hermitian phase-difference operator $\mathscr{P}_{bf}$. Since there exists a Hermitian phase operator $\mathscr{P}_f$ for a single-mode fermion one can subtract the contribution of the phase of the fermion to obtain a Hermitian phase operator for the single-mode boson. But again these two quantized phases are not commuting with each other and therefore they must be combined by using the quantum addition rule, Eq. (16). The resulting phase operator,

$$\mathscr{P}_N \equiv \mathscr{P}_{bf} \dot{-} \mathscr{P}_f, \tag{36}$$

turns out to be exactly the Hermitian phase operator introduced by Newton[7] by adding an additional fermionic degree of freedom to the original single-mode boson, which is unitarily equivalent to the infinite number states approach[16] and the relative number state approach.[8,17] We see that this kind of approach to the phase operator can be interpreted as a phase operator of single-mode boson referring to a single-mode fermion.

Integrable and solvable many-body problems in the plane via complexification

F. Calogero[a),b)]

(Received 21 January 1998; accepted for publication 8 June 1998)

A simple prescription allows us to transform, by appropriate complexification, any *one-dimensional* many-body problem (describing ''motions on a line'') with Newtonian (''acceleration equals forces'') equations of motion featuring forces which depend *analytically* on the positions, and possibly on the velocities, of the particles, and which are moreover *scaling-* or *translation-invariant*, into a *two-dimensional* many-body problem (describing ''motions in the plane'') with *rotation-invariant* equations of motion. If the original (one-dimensional) model is Hamiltonian, the two-dimensional model is also Hamiltonian (in fact, bi-Hamiltonian). In this manner, starting from known integrable or solvable one-dimensional many-body problems, integrable or solvable many-body problems *in the plane*, generally featuring much richer dynamics, are obtained. Several examples are exhibited. Finally another, more direct, prescription is outlined, to transform by complexification almost *any* one-dimensional many-body problem into a *rotation-invariant* many-body problem *in the plane*. © *1998 American Institute of Physics.*

I. INTRODUCTION

Consider a one-dimensional many-body problem characterized by Newtonian equations of motion,

$$\ddot{z}_j = f_j^{(1)}(\dot{z}_j; z_j) + \sum_{k=1, k\neq j}^{n} f_{jk}^{(2)}(\dot{z}_j, \dot{z}_k; z_j, z_k). \tag{1.1}$$

Here $z_j \equiv z_j(t)$ is the coordinate of the j-th particle, and, for simplicity, we only consider models with autonomous one- and two-body forces, although what follows holds as well in, or is easily extendable to, more general cases. As usual, superimposed dots denote time-derivatives.

If, as we hereafter assume, the functions $f^{(1)}$ and $f^{(2)}$ depend *analytically* on their arguments, the equations of motion (1.1) can be assumed to hold for complex values of the coordinates z_j; thereby one-dimensional motions occurring on the real line are extended to two-dimensional motions extending throughout the complex plane. Trivial as this extension is, it generally entails a substantial enrichment of the qualitative features of the motion. It is, moreover, clear that, if the original model is integrable or solvable (see below), the motions in the complex domain are also integrable or solvable.

By identifying the complex plane with the real physical plane (see below), one can identify in this manner integrable or solvable two-dimensional models, which, in our opinion, do qualify as genuine *many-body problems in the plane* iff the corresponding equations of motion are *rotation-invariant*.

Recently several such integrable or solvable many-body problems have been exhibited;[1–3] several others are displayed below. Indeed, as we point out below, any model characterized by Newtonian equations of motion, see (1.1), which are either *scaling-* or *translation-invariant*, yields

by appropriate transformations a *many-body problem in the plane* characterized by *rotation-invariant* equations of motion.

In the following, Sec. II, we collect several useful formulas, and thereby also establish our notation. The result outlined above is given in Sec. III, and examples of integrable or solvable many-body problems in the plane are displayed in Sec. IV, which constitutes the core of this paper. Future developments are outlined in Sec. V.

II. NOTATION AND PRELIMINARIES

Two-vectors in the plane are denoted by a superimposed arrow. We use for them a formally three-dimensional notation, by writing $\vec{r}\equiv(x,y,0)$ and $\hat{z}\wedge\vec{r}\equiv(-y,x,0)$. The symbol $\wedge$ is defined by this formula, which corresponds, see below, to the usual (''three-dimensional'') vector product. Indeed here and always below $\hat{z}$ denotes the unit vector orthogonal to the plane: $\hat{z}\equiv(0,0,1)$. Of course these formulas entail $\hat{z}\wedge(\hat{z}\wedge\vec{r})=-\vec{r}$.

Circular coordinates in the plane are defined as usual by setting $x=r\cos\theta, y=r\sin\theta$, $r^2=x^2+y^2, \tan\theta=x/y$, so that $\vec{r}=r(\cos\theta,\sin\theta,0)$, $\hat{z}\wedge\vec{r}=r(\cos(\theta+\pi/2),\sin(\theta+\pi/2),0)=r(-\sin\theta,\cos\theta,0)$.

The scalar and pseudoscalar products of 2 two-vectors are defined in the standard manner:

$$\vec{r}_j\cdot\vec{r}_k\equiv c_{jk}=x_jx_k+y_jy_k=r_jr_k\cos(\theta_j-\theta_k), \tag{2.1}$$

$$\hat{z}\cdot\vec{r}_j\wedge\vec{r}_k\equiv s_{jk}=x_jy_k-y_jx_k=r_jr_k\sin(\theta_j-\theta_k). \tag{2.2}$$

These definitions entail the following identities (and many others!):

$$c_{12}=c_{21}, c_{11}=r_1^2, \quad s_{12}=-s_{21}, s_{11}=0, \quad \theta_1-\theta_2=\arctan(s_{12}/c_{12}), \tag{2.3}$$

$$\vec{r}_1=(c_{12}\vec{r}_2-s_{12}\hat{z}\wedge\vec{r}_2)/r_2^2, \quad r_1^2r_2^2\equiv c_{11}c_{22}=c_{12}^2+s_{12}^2, \tag{2.4}$$

$$(c_{11}c_{22}-c_{12}^2)\vec{r}_3=(c_{13}c_{22}-c_{23}c_{12})\vec{r}_1+(c_{11}c_{23}-c_{12}c_{13})\vec{r}_2, \quad s_{12}\vec{r}_3=c_{23}\hat{z}\wedge\vec{r}_1-c_{13}\hat{z}\wedge\vec{r}_2, \tag{2.5}$$

$$c_{11}c_{22}c_{33}-c_{11}c_{23}^2-c_{22}c_{31}^2-c_{33}c_{12}^2+2c_{12}c_{23}c_{31}=0, \tag{2.6}$$

$$s_{12}s_{34}=c_{13}c_{24}-c_{14}c_{23}=r_1r_2r_3r_4\sin(\theta_1-\theta_2)\sin(\theta_3-\theta_4), \tag{2.7}$$

$$c_{12}s_{34}-c_{34}s_{12}=c_{13}s_{24}-c_{24}s_{13}=r_1r_2r_3r_4\sin(\theta_1-\theta_2-\theta_3+\theta_4). \tag{2.8}$$

In the following we occasionally use the convenient short-hand notation $\vec{r}_{jk}\equiv\vec{r}_j-\vec{r}_k$, entailing $r_{jk}^2=r_j^2+r_k^2-2\vec{r}_j\cdot\vec{r}_k=c_{jj}+c_{kk}-2c_{jk}$.

The one-to-one correspondence (hereafter denoted by the convenient symbol $\doteq$) among the *physical plane* spanned by the *real* two-vector $\vec{r}$, and the *complex plane* spanned by the *complex* number $z=x+iy$, is given by the following self-evident formulas: $z\doteq\vec{r}, iz\doteq\hat{z}\wedge\vec{r}, |z|^2=r^2$, $\theta=\arg(z)$. They entail the following relations:

$$z_1/z_2=r_2^{-2}(c_{12}-is_{12}), \tag{2.9}$$

$$z_1z_2/z_3\doteq r_3^{-2}(\vec{r}_1c_{23}+\vec{r}_2c_{13}-\vec{r}_3c_{12}), \tag{2.10}$$

$$z_1z_2/(z_3z_4)=r_3^{-2}r_4^{-2}[c_{13}c_{24}+c_{14}c_{23}-c_{12}c_{34}-i(c_{14}s_{23}+c_{23}s_{14})]. \tag{2.11}$$

The left-hand side of this formula is evidently invariant under the interchange of the indices 1 and 2, or 3 and 4; this holds as well for the right-hand side [this is evident for the real part; it is less evident, but of course also true, for the imaginary part, see (2.8)].

$$z_1z_2z_3/z_4z_5=(1/3)r_4^{-2}r_5^{-2}\cdot\{\vec{r}_1[-c_{23}c_{45}+2(c_{24}c_{35}+c_{25}c_{34})]$$
$$+\vec{r}_2[-c_{13}c_{45}+2(c_{14}c_{35}+c_{15}c_{34})]+\vec{r}_3[-c_{12}c_{45}+2(c_{14}c_{25}+c_{15}c_{24})]$$
$$-\vec{r}_4[c_{12}c_{35}+c_{13}c_{25}+c_{23}c_{15}]-\vec{r}_5[c_{12}c_{34}+c_{13}c_{24}+c_{23}c_{14}]\}. \tag{2.12}$$

Let $f(z)$ be an *analytic* function of the complex variable $z=x+isy$ with $s=1$ or $s=-1$, so that $\partial f/\partial z=\partial f/\partial x=-is\partial f/\partial y$. Then set

$$f(z)\equiv f(x+isy)=F(\vec{r})+i\hat{F}(\vec{r}), \tag{2.13a}$$

with $F(\vec{r})$ and $\hat{F}(\vec{r})$ *real* functions of the real two-vector $\vec{r}\equiv(x,sy,0)$ (note that $\vec{r}\doteq z$ if $s=+1$,$\vec{r}\doteq z^\star$ if $s=-1$). Then

$$(\partial/\partial\vec{r})F(\vec{r})=s(\hat{z}\wedge\partial/\partial\vec{r})\hat{F}(\vec{r}),(\partial/\partial\vec{r})\hat{F}(\vec{r})=-s(\hat{z}\wedge\partial/\partial\vec{r})F(\vec{r}). \tag{2.13b}$$

Consider now a system characterized by the Hamiltonian equations of motion

$$\dot{z}_j=\partial h(\mathbf{z},\mathbf{Z})/\partial Z_j,\dot{Z}_j=-\partial h(\mathbf{z},\mathbf{Z})/\partial z_j, \tag{2.14}$$

with $h(\mathbf{z},\mathbf{Z})$ an *analytic* function of the n complex ''canonical coordinates'' z_j and of the corresponding ''canonical momenta'' Z_j. (Throughout this paper we use for convenience lower and upper cases for the canonical coordinates and the corresponding momenta.) Now set

$$z_j=x_j+iy_j,Z_j=X_j-iY_j, \tag{2.15a}$$

namely,

$$z_j\doteq\vec{r}_j,Z_j^\star\doteq\vec{R}_j, \tag{2.15b}$$

and

$$h(\mathbf{z},\mathbf{Z})=H(\vec{\mathbf{r}},\vec{\mathbf{R}})+i\tilde{H}(\vec{\mathbf{r}},\vec{\mathbf{R}}). \tag{2.16}$$

Here of course $H(\mathbf{r},\mathbf{R})$ and $\tilde{H}(\mathbf{r},\mathbf{R})$ are two real functions of the (real) two-vectors $\vec{r}_j\equiv(x_j,y_j,0)$ and $\vec{R}_j\equiv(X_j,Y_j,0)$. Then (2.14) yield

$$\dot{\vec{r}}_j=+(\partial/\partial\vec{R}_j)H(\vec{\mathbf{r}},\vec{\mathbf{R}}),\quad \dot{\vec{R}}_j=-(\partial/\partial\vec{r}_j)H(\vec{\mathbf{r}},\vec{\mathbf{R}}), \tag{2.17}$$

$$\dot{\vec{r}}_j=+[\hat{z}\wedge(\partial/\partial\vec{R}_j)]\tilde{H}(\vec{\mathbf{r}},\vec{\mathbf{R}}),\quad \dot{\vec{R}}_j=+[\hat{z}\wedge(\partial/\partial\vec{r}_j)]\tilde{H}(\vec{\mathbf{r}},\vec{\mathbf{R}}). \tag{2.18}$$

The equations (2.17) are *real* Hamiltonian equations for the (real) two-vector canonical coordinates $\vec{r}_j$ and the corresponding (real) two-vector canonical momenta $\vec{R}_j$. The equations (2.18), instead, are not Hamiltonian (for these choices of canonical coordinates and momenta): note the positive sign in the right-hand-sides of both these equations. They are instead Hamiltonian for the canonical coordinates $\vec{\hat{r}}_j$ and the (new) canonical momenta $\vec{\hat{R}}_j$ defined as follows:

$$\vec{\hat{r}}_j=\vec{r}_j,\quad \vec{\hat{R}}_j=\hat{z}\wedge\vec{R}_j;\quad \hat{H}(\vec{\mathbf{r}},\vec{\mathbf{R}})=\tilde{H}(\vec{\mathbf{r}},\vec{\mathbf{R}}), \tag{2.19}$$

which indeed transform (2.18) into

$$\dot{\vec{\hat{r}}}_j=+(\partial/\partial\vec{\hat{R}}_j)\hat{H}(\vec{\mathbf{r}},\vec{\mathbf{R}}),\quad \dot{\vec{\hat{R}}}_j=-(\partial/\partial\vec{\hat{r}}_j)\hat{H}(\vec{\mathbf{r}},\vec{\mathbf{R}}). \tag{2.20}$$

It is thereby seen that the complex Hamiltonian system (2.14), with analytic Hamiltonian function $h(\mathbf{z},\mathbf{Z})$, yields two distinct *real* Hamiltonian structures, see (2.17) and (2.20); and let us emphasize that the three Hamiltonian evolutions (2.14), (2.17) and (2.20) are completely equivalent.

Likewise, consider a system characterized by the (complex) Lagrangian evolution,

$$(d/dt)[\partial l(\mathbf{z},\dot{\mathbf{z}})/\partial \dot{z}_j] = \partial l(\mathbf{z},\dot{\mathbf{z}})/\partial z_j, \tag{2.21}$$

with $l(\mathbf{z},\dot{\mathbf{z}})$ an *analytic* function of all its arguments z_j and $\dot{z}_j$, $j=1,\ldots,n$, and set

$$l(\mathbf{z},\dot{\mathbf{z}}) = \mathcal{L}(\vec{\mathbf{r}},\dot{\vec{\mathbf{r}}}) + i\tilde{\mathcal{L}}(\vec{\mathbf{r}},\dot{\vec{\mathbf{r}}}), \tag{2.22}$$

with $\mathcal{L}(\vec{\mathbf{r}},\dot{\mathbf{r}})$ and $\tilde{\mathcal{L}}(\vec{\mathbf{r}},\dot{\vec{\mathbf{r}}})$ *real* functions of the *real* two-vectors $\vec{r}_j \doteq z_j, \dot{\vec{r}}_j \doteq \dot{z}_j$. It is then easily seen that two equivalent (real) Lagrangian evolutions correspond to (2.21):

$$(d/dt)[(\partial/\partial \dot{\vec{r}}_j)\mathcal{L}(\vec{\mathbf{r}},\dot{\vec{\mathbf{r}}})] = (\partial/\partial \vec{r}_j)\mathcal{L}(\vec{\mathbf{r}},\dot{\vec{\mathbf{r}}}), \tag{2.23a}$$

$$(d/dt)[(\partial/\partial \dot{\vec{r}}_j)\tilde{\mathcal{L}}(\vec{\mathbf{r}},\dot{\vec{\mathbf{r}}})] = (\partial/\partial \vec{r}_j)\tilde{\mathcal{L}}(\vec{\mathbf{r}},\dot{\vec{\mathbf{r}}}). \tag{2.23b}$$

The ''complex plane'' versions of the connection between the Lagrangian and Hamiltonian avatars of the equations of motion (2.14) and (2.21) read as follows:

$$h(\mathbf{z},\mathbf{Z}) = \sum_{j=1}^{n} Z_j \dot{z}_j - l(\mathbf{z}_j,\dot{\mathbf{z}}_j), \tag{2.24a}$$

$$Z_j = \partial l(\mathbf{z},\dot{\mathbf{z}})/\partial \dot{z}_j. \tag{2.24b}$$

The corresponding ''real plane'' relations read as

$$H(\vec{\mathbf{r}},\vec{\mathbf{R}}) = \sum_{j=1}^{n} (\vec{R}_j \cdot \dot{\vec{r}}_j) - \mathcal{L}(\vec{\mathbf{r}},\dot{\vec{\mathbf{r}}}), \tag{2.25a}$$

$$\vec{R}_j = (\partial/\partial \dot{\vec{r}}_J)\mathcal{L}(\vec{\mathbf{r}},\dot{\vec{\mathbf{r}}}); \tag{2.25b}$$

$$\tilde{H}(\vec{\mathbf{r}},\vec{\mathbf{R}}) = \sum_{j=1}^{n} (\hat{z} \cdot \vec{R}_j \wedge \dot{\vec{r}}_j) - \tilde{\mathcal{L}}(\vec{\mathbf{r}},\dot{\vec{\mathbf{r}}}), \tag{2.26a}$$

$$\vec{R}_j = [\hat{z} \wedge (\partial/\partial \dot{\vec{r}}_j)]\tilde{\mathcal{L}}(\vec{\mathbf{r}},\dot{\vec{\mathbf{r}}}). \tag{2.26b}$$

Finally, for future reference below, we report here a Proposition and its Corollary.[3] Consider the dynamical system characterized by equations of motion of Newtonian type having the following structure:

$$\zeta_j'' = \sum_{k,m=1}^{n} \zeta_k' \zeta_m' \varphi_{jkm}(\boldsymbol{\zeta}), \tag{2.27}$$

where $\zeta_j \equiv \zeta_j(\tau)$ and the primes denote differentation with respect to τ.

Then set

$$z_j(t) = \zeta_j(\tau), \quad \tau = [\exp(at) - 1]/a, \tag{2.28}$$

assuming of course these equations make sense, and in particular $\zeta_j(\tau)$ is well defined for complex values of τ if a is complex, see below.

Proposition: The $z_j(t)$'s evolve according to the equations of motion,

$$\ddot{z}_j = a\dot{z}_j + \sum_{k,m=1}^{n} \dot{z}_k \dot{z}_m \varphi_{jkm}(\mathbf{z}). \tag{2.29}$$

Note that, for the validity of this Proposition, no restriction is *a priori* required on the arbitrary functions $\varphi_{jkm}(\mathbf{z})$ [except the nontrivial requirement that (2.28) be well defined, see above and below].

Corollary: If the system (2.27) is *integrable* [a property which of course only holds for special choices of the functions $\varphi_{jkm}(\mathbf{z})$] so that the solutions $\zeta_j(\tau)$ are globally defined for all (complex) values of τ, and $a = \pm i\Omega$, with $\Omega > 0$ a real nonvanishing constant, *all* solutions of (2.29) are *completely periodic* (note that these motions extend then necessarily into the *complex* plane), the generic solution having period $T = 2\pi/\Omega$.

III. ROTATION-INVARIANT TWO-DIMENSIONALIZATIONS VIA COMPLEXIFICATION

It is obvious that, if the (complex) Newtonian equations of motion (1.1) are *invariant under the rescaling transformation* $z_j \to c z_j$, with c an arbitrary (complex) constant, the real equations in the plane, obtained from (1.1) via the correspondence introduced above among real two-vectors $\vec{r}$ and complex numbers z, are *invariant under rotations*, since for $c = \exp(i\theta)$, with θ a real arbitrary ''angle,'' the *rescaling transformation*,

$$z_j \to z_j \exp(i\theta), \tag{3.1}$$

corresponds to a *rotation in the plane*, namely, in real Cartesian coordinates,

$$x_j \to x_j \cos\theta - y_j \sin\theta, \quad y_j \to x_j \sin\theta + y_j \cos\theta, \tag{3.2}$$

or equivalently, in real circular coordinates,

$$r_j \to r_j, \quad \theta_j \to \theta_j + \theta. \tag{3.3}$$

Various integrable and solvable many-body problems in the plane were obtained in this manner.[1–3]

Suppose now that the (complex) Newtonian equations of motion (1.1) are *translation-invariant*, namely that, after having being rewritten (for convenience, see below) with z_j replaced by u_j, they are invariant under the translation $u_j \to u_j + u_0$, with u_0 an arbitrary complex constant, so that they read as

$$\ddot{u}_j = \sum_{k=1}^{n} f_{jk}(\dot{u}_j, \dot{u}_k; u_j - u_k). \tag{3.4}$$

It is then clear that, by setting

$$u_j = \log(z_j), \tag{3.5a}$$

which of course entails

$$\dot{u}_j = \dot{z}_j/z_j, \quad \ddot{u}_j = [\ddot{z}_j - \dot{z}_j^2/z_j]/z_j, \tag{3.5b}$$

one obtains new equations of motion for the new coordinates z_j which are *scaling-invariant*:

$$\ddot{z}_j = \dot{z}_j^2/z_j + z_j \sum_{k=1}^{n} f[\dot{z}_j/z_j, \dot{z}_k/z_k; \log(z_j/z_k)]. \tag{3.6}$$

Hence, by complexification, one obtains from these equations real many-body problems in the plane which do possess the essential property of being *rotation-invariant*. This opens the possibility to generate new integrable or solvable many-body problems in the plane; several examples

are displayed below, and of course several others can be produced by the diligent reader. Note, however, that these new models need not be *translation-invariant*, and that they generally contain velocity-dependent forces.

If there exists a Lagrangian $l(\mathbf{u},\dot{\mathbf{u}})$ which yields the equations of motion (3.4), via (3.5) one immediately gets the corresponding Lagrangian that yields (3.6). Likewise, if $h(\mathbf{u},\mathbf{U})$ is a Hamiltonian that yields (3.4), the corresponding Hamiltonian that yields (3.6) is obtained via (3.5a) and the position

$$U_j = Z_j z_j\,, \tag{3.7}$$

which introduces the canonical momenta Z_j conjugated to the canonical coordinates z_j. After complexification, one then obtains, via (2.16), (2.19) and (2.22), new *real* Hamiltonians and Lagrangians that yield, via (2.17), (2.20) and (2.23), new *real rotation-invariant* equations of motion which are interpretable as the equations of motions of *many-body problems in the plane*.

Let us end this Section by emphasizing that our requirement of *rotation-invariance* applies here to the (second-order) equations of motion of Newtonian type, not to the (first-order) Hamiltonian equations. At the end of this paper (see Sec. V), we outline another (more general, but rather trivially so) version of the complexification prescription — not employed in the examples presented in the following, Sec. IV — which allows us to transform *any* one-dimensional problem for which complexification makes sense, into a corresponding *rotation-invariant* real two-dimensional problem. Again, if the original one-dimensional problem is Hamiltonian, the two-dimensional problem obtained via this trick is also Hamiltonian, and, in fact, even its Hamiltonian equations are then *rotation-invariant*. And of course solvability or integrability is again preserved by such an extension from one- to two-dimensional space.

IV. INTEGRABLE AND SOLVABLE MANY-BODY PROBLEMS IN THE PLANE

In this Section we present an overview of integrable and solvable many-body problems in the plane.

By overview we mean a terse presentation, consisting mainly of an identification of each system, including the display of its Newtonian equations of motion, as well as their Hamiltonian and Lagrangian versions. We do not analyze the corresponding motions in the plane, except for some occasional remarks, such as the identification of special solutions, or special models which feature only completely periodic motions. For systems with ''nearest-neighbor'' interactions — that is, systems in which the j-th particle interacts only with the $(j-1)$-th and $(j+1)$-th ones; of course these particles need not be close to each other as they move in the plane — we always ignore the ''end-point'' issue, namely the additional prescription needed to specify the interaction experienced by the first and last particles (if their number is finite). Hence, each of the models described below requires further study, to analyze in detail its motions: a worthwhile task, in view of the much greater richness of available motions in the plane, as compared to those on the line (see, for instance, Ref. 1).

In each case we reveal the reason that underpins the ''integrability'' or ''solvability'' of the model under display. Let us emphasize in this connection that the definition and distinction among *integrable* and *solvable* models is heuristic: useful but not quite precise. We call here ''integrable'' those models which possess at least as many (globally defined) integrals of motion as degrees of freedom, generally as a consequence of the possibility to recast their equations of motion (nontrivially!)[4] in ''Lax-pair form.'' We identify instead as ''solvable'' those models for which a technique of solution is known — a technique which may be implemented quite explicitly or only partly so, and which is generally based on an appropriate change of variables. According to this terminology, ''solvability'' is generally more stringent than (namely, it entails) ''integrability;'' although in fact, for finite-dimensional systems, these two notions tend to overlap altogether.

All the integrable or solvable many-body problems in the plane presented below feature velocity-dependent one- and two-body (''pair'' or ''nearest-neighbor'') forces. As we already emphasized, all of them are invariant under rotations in the plane. Most of them are, instead, not

invariant under translations. All the new systems are Hamiltonian; we generally also display, as mentioned above, their Hamiltonian and Lagrangian structures (in more or less explicit detail, as the case may be).

Each of the Subsections below is devoted to a different system. All of these systems but one are new, at least in their two-dimensional avatars, and most of them have been obtained using the results reported in the preceding Section. We also report one case which is not quite new,[1] to exhibit a similarity solution not previously given (''model three,'' see Sec. IV C). The criteria for selecting the models displayed, among all those which can be obtained from known integrable and solvable systems using the results of the preceding Sec. III, as well as for deciding the amount of explicit detail in each case and the format of the results being exhibited, are based on ''aesthetic'' considerations and the related effort to maximize the ''user-friendly'' character of our presentation.

Finally, let us mention the somewhat special status of the last of the many-body systems reported (''model eleven''), as presented in Sec. IV L below: in this case the equations of motion can be exhibited only in Hamiltonian form (not in Newtonian form), and the *general solution* is given.

A. Model one

The Newtonian equations of motion for this system read as follows:

$$\ddot{\vec{r}}_j = r_j^{-2}[2\dot{\vec{r}}_j(\dot{\vec{r}}_j\cdot\vec{r}_j) - \vec{r}_j|\dot{\vec{r}}_j|^2] - (\alpha + \hat{\alpha}\hat{z}\wedge)\sum_{k=1,k\neq j}^{n} r_{jk}^{-6}$$
$$\cdot\{\vec{r}_j r_k^2[r_{jk}^4 - r_{jk}^2(r_j^2 - 3r_k^2) + 2(r_j^2 - r_k^2)^2] + \vec{r}_k r_j^2[r_{jk}^2(r_j^2 + r_k^2) - 2(r_j^2 - r_k^2)^2]\}. \tag{4.1}$$

Here α and $\hat{\alpha}$ are two (real) arbitrary ''coupling constants.''

This model features one-body velocity-dependent forces (quadratic in the velocities), and two-body velocity-independent forces. It is obviously rotation-invariant; it is not translation invariant. It is clearly invariant under the scale transformation $\vec{r}_j \to c\vec{r}_j$ with c an arbitrary constant.

The equations of motion (4.1) can be cast into the Lagrangian form (2.23). There are indeed two (families of) Lagrangians that yield (4.1):

$$\mathcal{L}(\vec{\mathbf{r}},\dot{\vec{\mathbf{r}}}) = (A^2+\hat{A}^2)^{-1}\sum_{j=1}^{n} r_j^{-4}(A\lambda_j + \hat{A}\hat{\lambda}_j) + \sum_{j,k=1;j\neq k}^{n} r_{jk}^{-4}[(GA - \hat{G}\hat{A})\mu_{jk} - (G\hat{A} + \hat{G}A)\hat{\mu}_{jk}], \tag{4.2}$$

$$\mathcal{L}(\vec{\mathbf{r}},\dot{\vec{\mathbf{r}}}) = (A^2+\hat{A}^2)^{-1}\sum_{j=1}^{n} r_j^{-4}(A\hat{\lambda}_j - \hat{A}\lambda_j) + \sum_{j,k=1;j\neq k}^{n} r_{jk}^{-4}[(GA - \hat{G}\hat{A})\hat{\mu}_{jk} + (G\hat{A} + \hat{G}A)\mu_{jk}], \tag{4.3}$$

$$\lambda_j \equiv (1/8)[2(\dot{\vec{r}}_j\cdot\vec{r}_j)^2 - |\dot{\vec{r}}_j|^2 r_j^2], \quad \hat{\lambda}_j \equiv (1/4)[2(\dot{\vec{r}}_j\cdot\vec{r}_j)(\hat{z}\cdot\dot{\vec{r}}_j\wedge\vec{r}_j), \tag{4.4}$$

$$\mu_{jk} \equiv 2r_j^2 r_k^2 - (r_j^2 + r_k^2)(\vec{r}_j\cdot\vec{r}_k), \quad \hat{\mu}_{jk} \equiv -(r_j^2 - r_k^2)(\hat{z}\cdot\vec{r}_j\wedge\vec{r}_k). \tag{4.5}$$

Each of these two Lagrangians depends on the 4 *real* constants $A,\hat{A},G,\hat{G}$, which are related to the 2 *real* constants α and $\hat{\alpha}$ [see (4.1)] as follows:

$$\alpha = 8[(A^2 - \hat{A}^2)G - 2A\hat{A}\hat{G}], \quad \hat{\alpha} = 8[(A^2 - \hat{A}^2)\hat{G} + 2A\hat{A}G]. \tag{4.6}$$

Likewise, there are (families of) Hamiltonians that yield, via (2.17) and (2.18) with (2.19) and (2.20), the Newtonian equations of motion (4.1):

$$H(\vec{\mathbf{r}},\vec{\mathbf{R}}) = \sum_{j=1}^{n}(A\Lambda_j + \hat{A}\hat{\Lambda}_j) - \sum_{j,k=1;j\neq k}^{n} r_{jk}^{-4}[(GA - \hat{G}\hat{A})\mu_{jk} - (G\hat{A} + \vec{G}A)\hat{\mu}_{jk}], \tag{4.7}$$

$$\tilde{H}(\vec{\mathbf{r}},\vec{\mathbf{R}})=\sum_{j=1}^{n}(-A\hat{\Lambda}_j+\hat{A}\Lambda_j)-\sum_{j,k=1;j\neq k}^{n} r_{jk}^{-4}[(GA-\hat{G}\hat{A})\hat{\mu}_{jk}+(G\hat{A}+\hat{G}A)\mu_{jk}], \tag{4.8}$$

$$\Lambda_j\equiv 2[2(\vec{r}_j\cdot\vec{R}_j)^2-r_j^2R_j^2], \quad \hat{\Lambda}_j\equiv 4(\vec{r}_j\cdot\vec{R}_j)(\hat{z}\cdot\vec{R}_j\wedge\vec{r}_j), \tag{4.9}$$

of course again with (4.5) and (4.6).

The Hamiltonian (4.7) is related to the Lagrangian (4.2) via (2.25); likewise $\tilde{H}$ (4.8) is related to $\tilde{\mathcal{L}}$ (4.3) via (2.26).

Both (4.2) and (4.3) yield, via (2.25b) and (2.26b),

$$\vec{R}_j=\frac{1}{4}(A^2+\hat{A}^2)^{-1}r_j^{-4}\cdot\{A[2\vec{r}_j(\dot{\vec{r}}_j\cdot\vec{r}_j)-\dot{\vec{r}}_jr_j^2]+\hat{A}[\vec{r}_j(\hat{z}\cdot\dot{\vec{r}}_j\wedge\vec{r}_j)-\hat{z}\wedge\vec{r}_j(\dot{\vec{r}}_j\cdot\vec{r}_j)]\}, \tag{4.10a}$$

and both (4.7), respectively (4.8) yield, via (2.20a), respectively (2.21a),

$$\dot{\vec{r}}_j=4\{A[2\vec{r}_j\cdot(\vec{r}_j\cdot\vec{R}_j)-\vec{R}_jr_j^2]+\hat{A}[-2\hat{z}\wedge\vec{r}_j(\vec{r}_j\cdot\vec{R}_j)+\vec{z}\wedge\vec{R}_jr_j^2]\}, \tag{4.10b}$$

which is in fact equivalent to (4.10a).

The equations of motion (4.1) possess the two constants of motion,

$$C=\sum_{j=1}^{n}(\dot{\vec{r}}_j\cdot\vec{r}_j)/r_j^2, \quad \hat{C}=\sum_{j=1}^{n}(\hat{z}\cdot\dot{\vec{r}}_j\wedge\vec{r}_j)/r_j^2. \tag{4.11}$$

A simple proof of this fact, as well as of the existence of $2n-2$ additional (real) constants of motion entailing the *integrability* of the system (4.1), are implied by the results given below.

The system (4.1) possesses the ''similarity solution'' (written using polar coordinates)

$$r_j(t)=r_0\,\exp(ut), \quad \theta_j(t)=\theta_0+2\pi j/n+vt, \tag{4.12}$$

which features the 4 arbitrary (real) constants r_0,θ_0,u and v. The corresponding picture sees n particles sitting equispaced on a circular ring centered at the origin, which rotates with the constant (arbitrary) angular velocity v and whose radius evolves exponentially in time: for $u>0$ it diverges as $t\to\infty$, for $u<0$ it tends to zero, while for $u=0$ it remains constant and the motion is periodic with period $T=2\pi r/|v|$ (if $v\neq 0$; if v also vanishes, the system is at equilibrium). There are in fact $n!$ such solutions, obtained by replacing the index j in the right-hand side of the second equation (4.12) with k, and by then assigning to these indices as their values an arbitrary permutation of the n numbers $1,2,\ldots,n$.

Note moreover that, if $r_j(t),\theta_j(t)$ is, in circular coordinates, a solution of (4.1), then $r_j'(t)=c\,\exp(ut)r_j(t)$, $\theta_j'(t)=\theta_j(t)+\theta_0+vt$ is also a solution (with c,u,θ_0 and v four arbitrary constants); while $\tilde{r}_j(t)=r_j(t)\exp[ut+\beta(t)]$, $\tilde{\theta}_j(t)=\theta_j(t)+\theta_0+vt+\hat{\beta}(t)$ provides a solution of the new many-body system characterized by equations of motion which differ from (4.1) only due to the additional presence, in the left-hand-side, of the term $[\ddot{\beta}(t)+\dddot{\hat{\beta}}(t)\hat{z}\wedge]\vec{r}_j$.

The complete integrability of the equations of motion (4.1), as well as the other results mentioned above, are due to the equivalence of (4.1) to the complex equations of motion,

$$\ddot{z}_j=\dot{z}_j^2/z_j+8a^4g^2\sum_{k=1,k\neq j}^{n} z_j^2z_k(z_j+z_k)/(z_j-z_k)^3, \tag{4.13}$$

with

$$a^2=A+i\hat{A}, g^2=G+i\hat{G}, \tag{4.14}$$

entailing, via (4.6),

$$8a^4g^2=\alpha+i\hat{\alpha}. \tag{4.15}$$

Dividing (4.12) by z_j and summing over j from 1 to n yields

$$(d/dt)\sum_{j=1}^{n}(\dot{z}_j/z_j)=0, \tag{4.16}$$

because the double sum in the right-hand side vanishes due to the antisymmetry of the summand. This yields (4.11).

The complex Lagrangian that yields, via (2.21), the equations of motion (4.13) reads as

$$l(\mathbf{z},\dot{\mathbf{z}})=(8a^2)^{-1}\sum_{j=1}^{n}(\dot{z}_j/z_j)^2-a^2g^2\sum_{j,k=1;j\neq k}^{n}z_jz_k/(z_j-z_k)^2, \tag{4.17}$$

and the corresponding [see (2.24)] complex Hamiltonian reads as

$$h(\mathbf{z},\mathbf{Z})=a^2\left\{2\sum_{j=1}^{n}z_j^2Z_j^2+g^2\sum_{j,k=1;j\neq k}^{n}z_jz_k/(z_j-z_k)^2\right\}. \tag{4.18}$$

They yield, via (2.22) as well as (2.16), the real Lagrangians (4.2)–(4.5) as well as two real Hamiltonians [see (4.7)–(4.9) and (2.19), (2.20)].

The similarity solution (4.12) reads, in complex coordinates, as

$$z_j(t)=\exp[\varphi(t)+2\pi ij/n],\quad \varphi(t)=\log(r_0)+i\theta_0+(u+iv)t, \tag{4.19}$$

and it satisfies (4.13) since the quantities

$$\epsilon_j\equiv\sum_{k=1,k\neq j}^{n}\exp[2\pi i(j+k)/n][\exp(2\pi ij/n)+\exp(2\pi ik/n)]/[\exp(2\pi ij/n)-\exp(2\pi ik/n)]^3 \tag{4.20}$$

vanish.

[*Proof*: by dividing the numerator and denominator in the right-hand side of (4.20) by $\exp(6\pi ij/n)$, and then setting $k=j+l \bmod (n)$, it is easily seen that $\epsilon_j=\epsilon$ is independent of j. But by summing (4.20) over j from 1 to n one then gets $n\epsilon=0$, since the right-hand side vanishes due to the antisymmetry of the summand under the exchange of the dummy indices j and k in the double sum.]

Finally, the complete integrability of the complex equations of motion (4.13) is demonstrated by setting

$$z_j=\exp(2aq_j), \tag{4.21}$$

transforming thereby (4.13) into

$$\ddot{q}_j=g^2a^3\sum_{k=1,k\neq j}^{n}\cosh[a(q_j-q_k)]/\{\sinh[a(q_j-q_k)]\}^3, \tag{4.22}$$

which are the equations of motion corresponding to the well-known *integrable* Hamiltonian,[5,6]

$$\mathcal{H}(\mathbf{q},\mathbf{Q})=\frac{1}{2}\sum_{j=1}^{n}Q_j^2+(g^2a^2/4)\sum_{j,k=1;j\neq k}^{n}\{\sinh[a(q_j-q_k)]\}^{-2}. \tag{4.23}$$

Hence the system reported in this Subsection corresponds, up to an appropriate (complex) rescaling, to the application of the technique of Sec. III to the integrable translation-invariant system associated with this Hamiltonian.

B. Model two

In this case, which features one- and two-body forces, we write the equations of motion, and the corresponding Hamiltonian and Lagrangian, only in the complex version. They read as

$$\ddot{z}_j = a\dot{z}_j + \dot{z}_j^2/z_j + 4\sum_{k=1,k\neq j}^{n} \dot{z}_j\dot{z}_k z_j(z_j+z_k)\cdot\{(z_j-z_k)[4z_jz_k+b(z_j-z_k)^2]\}^{-1}, \tag{4.24}$$

$$h(\mathbf{z},\mathbf{Z}) = \sum_{j=1}^{n}\left\{\exp(sz_jZ_j)\prod_{k=1,k\neq j}^{n}\{[b(z_j^2+z_k^2)-2(2+b)z_jz_k]^{1/2}/(z_j-z_k)\}-(a/s)\log z_j\right\}, \tag{4.25}$$

$$l(\mathbf{z},\mathbf{Z}) = -\sum_{j=1}^{n}\left\{[\dot{z}_j/(sz_j)]\left(1+\log[\dot{z}_j/(sz_j)]-\sum_{k=1,k\neq j}^{n}\log\{[b(z_j^2+z_k^2)-2(2+b)z_jz_k]^{1/2}/(z_j-z_k)\}\right)-(a/s)\log z_j\right\}, \tag{4.26}$$

$$Z_j = (sz_j)^{-1}\left(\log[\dot{z}_j/(sz_j)]-\sum_{k=1,k\neq j}^{n}\log\{[b(z_j^2+z_k^2)-2(2+b)z_jz_k]^{1/2}/(z_j-z_k)\}\right). \tag{4.27}$$

In these formulas the (complex) constants a, b and s are arbitrary ($s\neq 0$). Note that s does not appear in the Newtonian equations of motion (4.24), which are invariant under the rescaling $z_j \to cz_j$, hence yield, via the transition from the complex to the real plane (see Secs. II and III), Newtonian equations of motion for the real 2-vectors $\vec{r}_j(t)$ which are rotation-invariant, contain 4 arbitrary real constants and can be written in Hamiltonian and Lagrangian form. The derivation of the relevant formulas is an easy task using the formulas of Sec. II; we forsake here their explicit display.

If the constant a is imaginary, $a=\pm i\Omega, \Omega>0$, the generic solution of (4.24) is completely periodic with period $T=2\pi/\Omega$.

By dividing (4.24) by z_j and summing over j from 1 to n it is easily seen that

$$w(t) = \sum_{j=1}^{n}[\dot{z}_j(t)/z_j(t)] \tag{4.28}$$

satisfies the linear equation

$$\dot{w} = aw, \tag{4.29a}$$

implying

$$w(t) = w(0)\exp(at). \tag{4.29b}$$

Likewise, it is easily seen that the system (4.24) possesses $n!$ ''similarity solutions'' of the form

$$z_j(t) = \varphi(t)\exp(2\pi ik/n), \tag{4.30}$$

with the values of the index j on the left-hand side matched to the values of k on the right-hand side by an arbitrary permutation of the n positive integers $1,2,\ldots,n$. This corresponds to a configuration of the n particles equally spaced on a circle centered at the origin, with radius $r(t)=|\varphi(t)|$ and angular phase $\theta(t)=\arg[\varphi(t)]$. The (complex) function $\varphi(t)$ satisfies the equation

$$n\dot{\varphi} = w, \tag{4.31a}$$

implying, via (4.29b),

$$\varphi(t)=r_0\ \exp(i\theta_0)\exp\{c[\exp(at)-1]\}, \tag{4.31b}$$

with

$$\varphi(0)=r_0\ \exp(i\theta_0), \quad \dot{\varphi}(0)=ac\varphi(0). \tag{4.31c}$$

Hence, with $a=\alpha+i\hat{\alpha}, c=\gamma\ \exp(i\eta)$,

$$r(t)=r_0\ \exp\{\gamma[\exp(\alpha t)\cos(\hat{\alpha}t+\eta)-\cos\ \eta]\}, \tag{4.32a}$$

$$\theta(t)=\theta_0+\gamma[\exp(\alpha t)\sin(\hat{\alpha}t+\eta)-\sin\ \eta], \tag{4.32b}$$

with the 4 real constants r_0, γ, η and θ_0 *a priori* arbitrary. Clearly if $\alpha>0$ the behavior as $t\to+\infty$ is rather unwieldy, while if $\alpha<0$ it is more reasonable. Of course if $\alpha=0$ this solution is periodic with period $T=2\pi/|\hat{\alpha}|$.

The system (4.24) is *integrable* because, via the position $z_j=\exp(2u_j)$, it gets transformed into the ''Ruijsenaars-type'' system,

$$\ddot{u}_j=a\dot{u}_j+2\sum_{k=1,k\neq j}^{n}\dot{u}_j\dot{u}_k\mathrm{cotanh}(u_j-u_k)/[1+b\sinh^2(u_j-u_k)] \tag{4.33}$$

[see, for instance, Eq. (2.5a) with (2.5f) of Ref. 3, or Ref. 7 from which we obtained (4.25)].

C. Model three

The Newtonian equations of motion for this system read as follows:

$$\begin{aligned}\ddot{\vec{r}}_j=&(\alpha+\hat{\alpha}\hat{z}\wedge)\dot{\vec{r}}_j+(\beta+\hat{\beta}\hat{z}\wedge)\vec{r}_j+\sum_{k=1,k\neq j}^{n}r_{jk}^{-2}\cdot(2[\dot{\vec{r}}_j(\dot{\vec{r}}_k\cdot\vec{r}_{jk})+\dot{\vec{r}}_k(\dot{\vec{r}}_j\cdot\vec{r}_{jk})-\vec{r}_j(\dot{\vec{r}}_j\cdot\dot{\vec{r}}_k)]\\&+(\lambda+\hat{\lambda}\hat{z}\wedge)\{(\dot{\vec{r}}_j+\dot{\vec{r}}_k)[r_j^2-(\vec{r}_j\cdot\vec{r}_k)]-\vec{r}_j[\vec{r}_k\cdot(\dot{\vec{r}}_j+\dot{\vec{r}}_k)]+\vec{r}_k[\vec{r}_j\cdot(\dot{\vec{r}}_j+\dot{\vec{r}}_k)]\}\\&+(\mu+\hat{\mu}\hat{z}\wedge)\{\vec{r}_j[r_j^2-2(\vec{r}_j\cdot\vec{r}_k)]+\vec{r}_kr_j^2\}),\end{aligned} \tag{4.34a}$$

or equivalently, in complex notation,

$$\ddot{z}_j=A\dot{z}_j+Bz_j+\sum_{k=1,k\neq j}^{n}(z_j-z_k)^{-1}[2\dot{z}_j\dot{z}_k+L(\dot{z}_j+\dot{z}_k)z_j+Mz_j^2], \tag{4.34b}$$

with $A=\alpha+i\hat{\alpha},\ B=\beta+i\hat{\beta},\ L=\lambda+i\hat{\lambda},\ M=\mu+i\hat{\mu}$.

This model is not new;[1] it contains 8 real (arbitrary) coupling constants, hence it features a rich gamut of behaviors.[1] Here we exhibit (in complex notation) a simple ''similarity solution'' (in fact, $n!$ of them), namely

$$z_j(t)=\varphi(t)\exp(2\pi ik/n), \tag{4.35}$$

with the usual [see above, after (4.30)] match by permutation among the values of the indexes j and k. Here the (complex) function $\varphi(t)$ satisfies the equation

$$\ddot{\varphi}=A\dot{\varphi}+\left[B+\frac{1}{2}(n-1)M\right]\varphi+(1-n)\dot{\varphi}^2/\varphi, \tag{4.36a}$$

entailing, via $\varphi=\psi^{1/n}$,

$$\ddot{\psi}=A\dot{\psi}-n\left[B+\frac{1}{2}(n-1)M\right]\psi. \tag{4.36b}$$

Hence

$$\varphi(t)=[c_+\ \exp(\eta_+ t)+c_-\ \exp(\eta_- t)]^{1/n}, \tag{4.37a}$$

with $\eta_\pm$ the two roots of the equation

$$\eta^2-A\eta-n\left[B+\frac{1}{2}(n-1)M\right]=0. \tag{4.37b}$$

In writing (4.37a) we have, for simplicity, assumed these two (generally complex) roots η_+ and η_- to be different. It is clear from (4.36b) how (4.37a) must be modified when this is not the case.

To obtain (4.36a) we used the following identities:

$$\sum_{k=1}^{n-1}[1-\exp(2\pi ik/n)]^{-1}=(n-1)/2, \tag{4.38a}$$

$$\sum_{k=1}^{n-1}[1+\exp(2\pi ik/n)]/[1-\exp(2\pi ik/n)]=0, \tag{4.38b}$$

$$\sum_{k=1}^{n-1}\exp(2\pi ik/n)/[1-\exp(2\pi ik/n)]=(1-n)/2. \tag{4.38c}$$

D. Model four

The Newtonian equations of motion for this *integrable many-body problem in the plane* read as follows:

$$\ddot{\vec{r}}_j=[2\dot{\vec{r}}_j(\dot{\vec{r}}_j\cdot\vec{r}_j)-\vec{r}_j|\dot{\vec{r}}_j|^2]/r_j^2+[g_j(\vec{\mathbf{r}})+\hat{g}_j(\vec{\mathbf{r}})\hat{z}\wedge]\vec{r}_j\,, \tag{4.39}$$

or equivalently,

$$\ddot{r}_j=\dot{r}_j^2/r_j+r_j g_j(\vec{\mathbf{r}}), \tag{4.40a}$$

$$\ddot{\theta}_j=\hat{g}_j(\vec{\mathbf{r}}), \tag{4.40b}$$

with

$$g_j(\vec{\mathbf{r}})=\sum_{k=1,k\neq j}^{n}[\alpha\ \log(r_j/r_k)-\hat{\alpha}(\theta_j-\theta_k)+[\beta\ \log(r_j/r_k)\{[\log(r_j/r_k)]^2-3(\theta_j-\theta_k)^2\}$$
$$-\hat{\beta}(\theta_j-\theta_k)\{-3[\log(r_j/r_k)]^2+(\theta_j-\theta_k)^2\}]/\{[\log(r_j/r_k)]^2+(\theta_j-\theta_k)^2\}^3], \tag{4.41a}$$

$$\hat{g}_j(\vec{\mathbf{r}})=\sum_{k=1,k\neq j}^{n}[\hat{\alpha}\ \log(r_j/r_k)+\alpha(\theta_j-\theta_k)+[\hat{\beta}\ \log(r_j/r_k)\{[\log(r_j/r_k)]^2-3(\theta_j-\theta_k)^2\}$$
$$+\beta(\theta_j-\theta_k)\{-3[\log(r_j/r_k)]^2+(\theta_j-\theta_k)^2\}]/\{[\log(r_j/r_k)]^2+(\theta_j-\theta_k)^2\}^3]. \tag{4.41b}$$

This Hamiltonian (see below) model features one-body velocity-dependent forces, and two-body velocity-independent forces: see (4.39), and note that to write the two-body contribution, see (4.41), as well as the equivalent version (4.40) of the equations of motion, we employed circular coordinates; see Sec. II.

These equations of motion are clearly rotation-invariant; they are not translation-invariant. They are invariant under the rescaling transformation $\vec{r}_j \to c\vec{r}_j$, with c an arbitrary constant. In fact, it is clear (see also below) that, if $r_j(t)$, $\theta_j(t)$, $j=1,\ldots,n$, is, in circular coordinates, a solution of (4.40),

$$\tilde{r}_j(t) = r_0 \exp(ut) r_j(t), \tag{4.42a}$$

$$\tilde{\theta}_j(t) = \theta_0 + vt + \theta_j(t), \tag{4.42b}$$

is also a solution; here r_0, u, θ_0 and v are 4 arbitrary (real) constants ($r_0 > 0$).

These equations of motion feature the 4 arbitrary real ''coupling constants'' $\alpha, \hat{\alpha}, \beta, \hat{\beta}$. If $\alpha < 0$ and $\hat{\alpha} = 0$, the generic solution is, up to a transformation of type (4.42), completely periodic with period $T = 2\pi(-\alpha)^{-1/2}$ (see below for a justification of this statement).

If the quantity b/a is *real* and *negative*, with a and b defined as follows:

$$a = \alpha + i\hat{\alpha}, \quad b = \beta + i\hat{\beta}, \tag{4.43}$$

this model possesses the following similarity solutions (written in circular coordinates):

$$r_j(t) = r_0 \exp(ut), \tag{4.44a}$$

$$\theta_j = \theta_0 + vt + [-b/(2an)]^{1/4} \xi_k . \tag{4.44b}$$

Here r_0, θ_0 and v are 4 arbitrary real constants ($r_0 > 0$), the real root should of course be taken in the right-hand side of (4.44b), the indices k there are related to the indices j by any permutation of the n positive integers from 1 to n, and the n real numbers ξ_k are the n roots of the Hermite polynomial of order n,

$$H_n(\xi_k) = 0, \tag{4.45a}$$

so that[8]

$$\sum_{j=1}^{n} \xi_j = 0, \tag{4.45b}$$

$$\xi_j = 2 \sum_{k=1, k\neq j}^{n} (\xi_j - \xi_k)^{-3}. \tag{4.45c}$$

These similarity solutions feature the n particles sitting, appropriately spaced, on a circle centered at the origin which rotates uniformly and whose radius evolves exponentially in time. The verification that (4.44) with (4.45) satisfies (4.40) is an easy task (see also below).

The ''complex-plane'' avatar of these equations of motion reads as

$$\ddot{z}_j = \dot{z}_j^2/z_j + z_j \sum_{k=1, k\neq j}^{n} \{a \log(z_j/z_k) + b[\log(z_j/z_k)]^{-3}\}, \tag{4.46}$$

with the complex ''coupling constants'' a and b related to $\alpha, \hat{\alpha}, \beta$ and $\hat{\beta}$ by (4.43). The Hamiltonian $h(\mathbf{z}, \mathbf{Z})$ and the Lagrangian $l(\mathbf{z}, \dot{\mathbf{z}})$ that yield these equations read as

$$h(\mathbf{z}, \mathbf{Z}) = \frac{1}{2} \sum_{j=1}^{n} z_j^2 Z_j^2 + V(\mathbf{z}), \tag{4.47a}$$

$$l(\mathbf{z}, \dot{\mathbf{z}}) = \frac{1}{2} \sum_{j=1}^{n} \dot{z}_j^2/z_j^2 - V(\mathbf{z}), \tag{4.47b}$$

with

$$V(\mathbf{z})=\frac{1}{4}\sum_{k,j=1;k\neq j}^{n}\{-a[\log(z_j/z_k)]^2+b[\log(z_j/z_k)]^{-2}\}. \tag{4.47c}$$

From these formulas, using the results of Sec. II, one can easily obtain the real Hamiltonians and Lagrangians that yield the equations (4.39) or (4.40) with (4.41).

The integrability of these equations of motion, as well as more straightforward proofs of some of the results reported above, follow from well-known properties of the integrable system[6] defined by the Hamiltonian:

$$H(\mathbf{u},\mathbf{U})=\frac{1}{2}\sum_{j=1}^{n}U_j^2+\frac{1}{4}\sum_{j,k=1;j\neq k}^{n}\{-a(u_j-u_k)^2+b(u_j-u_k)^{-2}\}, \tag{4.48}$$

whose equations of motion,

$$\ddot{u}_j=\sum_{k=1,j\neq j}^{n}[a(u_j-u_k)+b(u_j-u_k)^{-3}], \tag{4.49}$$

yield (4.46) via (3.5).

E. Model five

The Newtonian equations of motion for this system read as follows:

$$\ddot{\vec{r}}_j=[2\dot{\vec{r}}_j(\dot{\vec{r}}_j\cdot\vec{r}_j)-\vec{r}_j|\dot{\vec{r}}_j|^2]/r_j^2+(\alpha+\hat{\alpha}\hat{z}\wedge)\dot{\vec{r}}_j+2\sum_{k=1,k\neq j}^{n}(\rho_{jk}-\hat{\rho}_{jk}\hat{z}\wedge)$$
$$\times[\dot{\vec{r}}_j(\dot{\vec{r}}_k\cdot\vec{r}_j)+\dot{\vec{r}}_k(\dot{\vec{r}}_j\cdot\vec{r}_j)-\vec{r}_j(\dot{\vec{r}}_j\cdot\dot{\vec{r}}_k)], \tag{4.50}$$

with

$$\rho_{jk}=\log(r_j/r_k)\{[\log(r_j/r_k)]^2+(\theta_j-\theta_k)^2\}^{-1}, \tag{4.51a}$$

$$\hat{\rho}_{jk}=(\theta_j-\theta_k)\{[\log(r_j/r_k)]^2+(\theta_j-\theta_k)^2\}^{-1}. \tag{4.51b}$$

Hence they contain velocity-dependent one- and two-body forces [to write the latter we also employed circular coordinates; see (4.51) and Sec. II].

These equations of motion are clearly invariant under rotations in the plane ($\theta_j\to\theta_j+\theta_0$, with θ_0 an arbitrary real constant), as well as under rescaling ($\vec{r}_j\to c\vec{r}_j$, with c an arbitrary real constant). They contain 2 arbitrary (real) ''coupling constants,'' α and $\hat{\alpha}$; for $\alpha=0$ and $\hat{\alpha}\neq 0$, the generic motion is *completely periodic*, with period $T=2\pi/|\hat{\alpha}|$ (this is implied by the Corollary reported at the end of Sec. II; see below).

The ''complex plane'' version of the equations of motion (4.50) reads as

$$\ddot{z}_j=\dot{z}_j^2/z_j+a\dot{z}_j+2\sum_{k=1,k\neq j}^{n}\dot{z}_j\dot{z}_k/[z_j\log(z_j/z_k)], \tag{4.52}$$

with

$$a=\alpha+i\hat{\alpha}. \tag{4.53}$$

It admits the (complex) similarity solution $z_j(t)=z_0\exp\{c[b+\exp(at)]^{1/n}\exp(2\pi ik/n)\}$, with z_0, c and b arbitrary complex constants ($z_0\neq 0$), and the index k related to the index j via an arbitrary permutation of the n positive integers from 1 to n.

The many-body system (4.50) is Hamiltonian. Indeed the (complex) Hamiltonian,

$$h(\mathbf{z},\mathbf{Z})=\sum_{j=1}^{n}\left\{\exp(sz_jZ_j)/\left[\prod_{k=1,k\neq j}^{n}\log(z_j/z_k)\right]-(a/s)\log(z_j)\right\}, \tag{4.54}$$

yields, via (2.14), the (complex) equations of motion (4.52). The corresponding expressions for the Lagrangian $l(\mathbf{z},\dot{\mathbf{z}})$ and for the canonical momenta Z_j read as

$$l(\mathbf{z},\dot{\mathbf{z}})=\sum_{j=1}^{n}\left\{[\dot{z}_j/(sz_j)]\left[-1+\log[\dot{z}_j/(sz_j)]+\sum_{k=1,k\neq j}^{n}\log\log(z_j/z_k)\right]+(a/s)\log(z_j)\right\}, \tag{4.55}$$

$$Z_j=(sz_j)^{-1}\left\{\log[\dot{z}_j/(sz_j)]+\sum_{k=1,k\neq j}^{n}\log\log(z_j/z_k)\right\}. \tag{4.56}$$

Note the presence in these expressions of the arbitrary (complex) constant s, which does not appear in the equations of motion (4.52).

The solvability of this model is demonstrated via (3.5), which transforms (4.52) into the solvable[8,1,4,7] equations of motion,

$$\ddot{u}_j=a\dot{u}_j+2\sum_{k=1,k\neq j}^{n}\dot{u}_j\dot{u}_k/(u_j-u_k). \tag{4.57}$$

Note that, except for notational changes, these equations of motion correspond to (the special case of) (4.34b) with $B=L=M=0$.

F. Model six

The Newtonian equations of motion for this system read as follows:

$$\ddot{\vec{r}}_j=[2\dot{\vec{r}}_j(\dot{\vec{r}}_j\cdot\vec{r}_j)-\vec{r}_j|\dot{\vec{r}}_j|^2]/r_j^2+(\alpha+\hat{\alpha}\hat{z}\wedge)\{\vec{r}_{j+1}-[2\vec{r}_j(\vec{r}_j\cdot\vec{r}_{j-1})-\vec{r}_{j-1}r_j^2]/r_{j-1}^2\}. \tag{4.58}$$

Hence they feature velocity-dependent one-body forces and velocity-independent ''nearest-neighbor'' forces.

These equations of motion are clearly invariant under rotation and rescaling; they are not invariant under translations. They contain (rather trivially, see below) the 2 arbitrary (real) ''coupling constants'' α and $\hat{\alpha}$.

They possess the following ''similarity solution'' (written in circular coordinates; see Sec. II):

$$r_j(t)=r_0\,\exp[(u+ju')t],\quad \theta_j(t)=\theta_0+(v+jv')t. \tag{4.59}$$

Here r_0,θ_0,u,u',v and v' are 6 arbitrary (real) constants ($r_0>0$).

The equations of motion (4.58) are Hamiltonian and Lagrangian; see (2.17), (2.20) and (2.23), with

$$H(\vec{\mathbf{r}},\vec{\mathbf{R}})=(1/2)\sum_j[(\vec{R}_j\cdot\vec{r}_j)^2-(\hat{z}\cdot\vec{R}_j\wedge\vec{r}_j)^2]+V(\vec{\mathbf{r}}), \tag{4.60a}$$

$$\tilde{H}(\vec{\mathbf{r}},\vec{\mathbf{R}})=\sum_j(\vec{R}_j\cdot\vec{r}_j)(\hat{z}\cdot\vec{R}_j\wedge\vec{r}_j)+\hat{V}(\vec{\mathbf{r}}), \tag{4.60b}$$

$$\mathcal{L}(\vec{\mathbf{r}},\dot{\vec{\mathbf{r}}})=(1/2)\sum_j[(\dot{\vec{r}}_j\cdot\vec{r}_j)^2-(\hat{z}\cdot\dot{\vec{r}}_j\wedge\vec{r}_j)^2]/r_j^4-V(\vec{\mathbf{r}}), \tag{4.61a}$$

$$\tilde{\mathcal{L}}(\vec{\mathbf{r}},\dot{\vec{\mathbf{r}}})=-\sum_j(\dot{\vec{r}}_j\cdot\vec{r}_j)(\hat{z}\cdot\dot{\vec{r}}_j\wedge\vec{r}_j)/r_j^4-\hat{V}(\vec{\mathbf{r}}), \tag{4.61b}$$

$$V(\vec{\mathbf{r}})=(\alpha^2+\hat{\alpha}^2)^{-1}\sum_j\ [-\alpha(\vec{r}_j\cdot\vec{r}_{j-1})+\hat{\alpha}(\hat{z}\cdot\vec{r}_j\wedge\vec{r}_{j-1})]/r_{j-1}^2, \tag{4.62a}$$

$$\hat{V}(\vec{\mathbf{r}})=(\alpha^2+\hat{\alpha}^2)^{-1}\sum_j\ [\hat{\alpha}(\vec{r}_j\cdot\vec{r}_{j-1})+\alpha(\hat{z}\cdot\vec{r}_j\wedge\vec{r}_{j-1})]/r_{j-1}^2, \tag{4.62b}$$

$$\vec{R}_j=[(\dot{\vec{r}}_j\cdot\vec{r}_j)+(\hat{z}\cdot\dot{\vec{r}}_j\wedge\vec{r}_j)\hat{z}\wedge]\vec{r}_j/r_j^4. \tag{4.63}$$

The ''complex-plane'' avatar of (4.58) reads as follows:

$$\ddot{z}_j=\dot{z}_j^2/z_j+a(z_{j+1}-z_j^2/z_{j-1}), \tag{4.64}$$

with $a=\alpha+i\hat{\alpha}$. It yields, via the position

$$z_j=a^j\ \exp(u_j), \tag{4.65}$$

the *integrable* ''Toda'' equations,[6]

$$\ddot{u}_j=\exp(u_{j+1}-u_j)-\exp(u_j-u_{j-1}). \tag{4.66}$$

G. Model seven

The Newtonian equations of motion for this system read as follows:

$$\begin{aligned}
\ddot{\vec{r}}_j=&(\alpha+\hat{\alpha}\hat{z}\wedge)\dot{\vec{r}}_j+[2\dot{\vec{r}}_j(\dot{\vec{r}}_j\cdot\vec{r}_j)-\vec{r}_j|\dot{\vec{r}}_j|^2]/r_j^2\\
&-\{\dot{\vec{r}}_j[\dot{\vec{r}}_{j+1}\cdot(\vec{r}_j-\vec{r}_{j+1})]+\dot{\vec{r}}_{j+1}[\dot{\vec{r}}_j\cdot(\vec{r}_j-\vec{r}_{j+1})]-(\vec{r}_j-\vec{r}_{j+1})(\dot{\vec{r}}_j\cdot\dot{\vec{r}}_{j+1})\}/|\vec{r}_j-\vec{r}_{j+1}|^2\\
&-(\dot{\vec{r}}_j\{(\dot{\vec{r}}_{j-1}\cdot\vec{r}_j)[(\vec{r}_j\cdot\vec{r}_{j-1})+r_{j-1}^2]+2(\dot{\vec{r}}_{j-1}\cdot\vec{r}_{j-1})[r_j^2-2(\vec{r}_j\cdot\vec{r}_{j-1})]\}\\
&+\dot{\vec{r}}_{j-1}\{(\dot{\vec{r}}_j\cdot\vec{r}_j)[(\vec{r}_j\cdot\vec{r}_{j-1})+r_{j-1}^2]+2(\dot{\vec{r}}_j\cdot\vec{r}_{j-1})[r_j^2-2(\vec{r}_j\cdot\vec{r}_{j-1})]\}\\
&+\vec{r}_j\{(\dot{\vec{r}}_j\cdot\dot{\vec{r}}_{j-1})[r_{j-1}^2-2(\vec{r}_j\cdot\vec{r}_{j-1})+(\dot{\vec{r}}_j\cdot\vec{r}_j)(\dot{\vec{r}}_{j-1}\cdot\vec{r}_{j-1})+(\dot{\vec{r}}_j\cdot\vec{r}_{j-1})[(\dot{\vec{r}}_{j-1}\cdot\vec{r}_j)\\
&-4(\dot{\vec{r}}_{j-1}\cdot\vec{r}_{j-1})]\}+\vec{r}_{j-1}\{(\dot{\vec{r}}_j\cdot\dot{\vec{r}}_{j-1})[-r_j^2+2(\vec{r}_j\cdot\vec{r}_{j-1})]+(\dot{\vec{r}}_j\cdot\vec{r}_j)[(\dot{\vec{r}}_{j-1}\cdot\vec{r}_{j-1})-(\dot{\vec{r}}_{j-1}\cdot\vec{r}_j)]\\
&+(\dot{\vec{r}}_j\cdot\vec{r}_{j-1})[(\dot{\vec{r}}_j\cdot\vec{r}_{j-1})+(\dot{\vec{r}}_{j-1}\cdot\vec{r}_{j-1})]\})/(3r_{j-1}^2|\vec{r}_j-\vec{r}_{j-1}|^2).
\end{aligned} \tag{4.67}$$

Hence they feature velocity-dependent one-body and ''nearest-neighbor'' forces.

These equations of motion are clearly invariant under rotation and rescaling; they are not invariant under translation. They contain the 2 arbitrary (real) ''coupling constants'' α and $\hat{\alpha}$; if $\alpha=0$ and $\hat{\alpha}\neq 0$, the generic solution of (4.67) is *completely periodic*, with period $T=2\pi/|\hat{\alpha}|$ (this remarkable fact is implied by the results written below, together with the Corollary reported at the end of Sec. II).

The ''complex-plane'' version of (4.67) reads as follows:

$$\ddot{z}_j=a\dot{z}_j+\dot{z}_j^2/z_j-\dot{z}_j\dot{z}_{j+1}/(z_j-z_{j+1})-\dot{z}_j\dot{z}_{j-1}z_j/[z_{j-1}(z_j-z_{j-1})], \tag{4.68}$$

with $a=\alpha+i\hat{\alpha}$, and it admits the ''similarity solution''

$$z_j(t)=z_0[\varphi(t)]^{\lambda+j}, \tag{4.69a}$$

with $\varphi(t)$ any (complex) solution of the (complex) transcendental equation,

$$\varphi(t)[1-\varphi(t)]^{-1}\ \exp\{[1-\varphi(t)]^{-1}\}=c\ \exp[b\ \exp(at)]. \tag{4.69b}$$

Here z_0, λ, c and b are 4 arbitrary complex constants.

There are two Hamiltonians, and correspondingly two Lagrangians, that yield the equations of motion (4.68) via (2.14) and (2.21):

$$h^{(+)}(\mathbf{z},\mathbf{Z}) = \sum_j \{\exp(sz_jZ_j)[1-(z_{j+1}/z_j)] - (a/s)\log(z_j)\}, \tag{4.70a}$$

$$h^{(-)}(\mathbf{z},\mathbf{Z}) = \sum_j \{\exp(sz_jZ_j)[1-(z_j/z_{j+1})] - (a/s)\log(z_j)\}, \tag{4.71a}$$

$$l^{(+)}(\mathbf{z},\dot{\mathbf{z}}) = \sum_j [\dot{z}_j/(sz_j)][-1+\log\{\dot{z}_j/[s(z_j-z_{j+1})\} + (a/s)\log(z_j)], \tag{4.70b}$$

$$l^{(-)}(\mathbf{z},\dot{\mathbf{z}}) = \sum_j [\dot{z}_j/(sz_j)][-1+\log\{\dot{z}_j z_{j-1}/[s(z_j(z_{j+1}-z_j)]\} + (a/s)\log(z_j)]. \tag{4.71b}$$

Note that these expressions contain the arbitrary (complex) constant s, that does not appear in the equations of motion (4.68). The main hint to find them came from Refs. 4, 7 and especially 9.

It is a simple exercise to obtain from these formulas, using the results reported in Sec. II, explicit expressions for real Hamiltonians and Lagrangians that yield, via (2.17), (2.20) and (2.23), the real equations of motion in the plane (4.67).

The *integrability* of the equations of motion (4.67) and (4.68) is entailed by the fact that, via (3.5), the latter read as follows:

$$\ddot{u}_j = a\dot{u}_j - \dot{u}_j\dot{u}_{j+1}/[1-\exp(u_j-u_{j+1})] + \dot{u}_j\dot{u}_{j-1}/[1-\exp(u_{j-1}-u_j)], \tag{4.72}$$

namely they coincide with (a special case of) the equations of motion of the integrable ''Ruijsenaars–Toda model'' [see e.g., Eq. (3.5.4a) of Ref. 3, or Eq. (1.3) of Ref. 9 and the Proposition of Sec. II].

Note that ''more general'' versions of (4.72) or (4.68) are easily obtained via simple transformations such as $u_j \to u_j + bt + j\log(c)$, $z_j \to cj\exp(bt)z_j$, with b and c arbitrary complex constants. The diligent reader may easily write down the generalized versions of (4.72) and (4.68) entailed by such simple transformations, and with somewhat more effort the corresponding versions of (4.67), as well as the Hamiltonians and Lagrangians that yield these generalized equations.

H. Model eight

The Newtonian equations of motion for this system read as follows:

$$\ddot{\vec{r}}_j = (1+\gamma+\hat{\gamma}\hat{z}\wedge)[2\dot{\vec{r}}_j(\dot{\vec{r}}_j\cdot\vec{r}_j) - \vec{r}_j|\dot{\vec{r}}_j|^2]/r_j^2 + (\alpha+\hat{\alpha}\hat{z}\wedge)\dot{\vec{r}}_j + (\beta+\hat{\beta}\hat{z}\wedge)\vec{r}_j - \sum_{k=j\pm1} r_{jk}^{-2}[(\gamma+\hat{\gamma}\hat{z}\wedge)$$
$$\times[2\dot{\vec{r}}_j(\dot{\vec{r}}_j\cdot\vec{r}_{jk}) - \vec{r}_{jk}\dot{r}_j^2] + (\alpha+\hat{\alpha}\hat{z}\wedge)\{\dot{\vec{r}}_j[r_j^2-(\vec{r}_j\cdot\vec{r}_k)] - \vec{r}_j(\dot{\vec{r}}_j\cdot\vec{r}_k) + \vec{r}_k(\dot{\vec{r}}_j\cdot\vec{r}_j)\} + (\beta+\hat{\beta}\hat{z}\wedge)$$
$$\times\{\vec{r}_j[r_j^2-2(\vec{r}_j\cdot\vec{r}_k)] + \vec{r}_k r_j^2\}]. \tag{4.73}$$

Hence they feature velocity-dependent one-body and ''nearest-neighbor'' forces. The 6 (real) coupling constants $\alpha, \hat{\alpha}, \beta, \hat{\beta}, \gamma, \hat{\gamma}$ are arbitrary.

This system is rotation-invariant. It is not translation-invariant. It is invariant under the rescaling $\vec{r}_j \to c\vec{r}_j$.

The special case with $\gamma=-1$, $\hat{\gamma}=\alpha=\hat{\alpha}=0$ was already known [see Eq. (3.7.12) of Ref. 3)].

The system (4.73) possesses the similarity solution (written in circular coordinates, Sec. II)

$$r_j(t) = r_0\rho^j\exp(ut), \quad \theta_j(t) = \theta_0 + j\eta + vt. \tag{4.74}$$

Here $r_0, \rho, u, \theta_0, \eta$ and v are 6 arbitrary real constants ($r_0>0,\ \rho>0$).

The system

$$\ddot{\vec{r}}_j=(1+\gamma+\hat{\gamma}\hat{z}\wedge)[2\dot{\vec{r}}_j(\dot{\vec{r}}_j\cdot\vec{r}_j)-\vec{r}_j|\dot{\vec{r}}_j|^2]/r_j^2+(\alpha+\hat{\alpha}\hat{z}\wedge)\dot{\vec{r}}_j$$
$$-\sum_{k=j\pm1}\sum r_{jk}^{-2}(\gamma+\hat{\gamma}\hat{z}\wedge)[2\dot{\vec{r}}_j(\dot{\vec{r}}_j\cdot\vec{r}_{jk})-\vec{r}_{jk}|\dot{\vec{r}}_j|^2] \tag{4.75}$$

can be obtained from (4.73) by first setting $\alpha=\hat{\alpha}=\beta=\hat{\beta}=0$, and by then applying the Proposition reported at the end of Sec. II (see below). Hence this integrable system, in the special case $\alpha=0,\hat{\alpha}\neq0$, features only completely periodic solutions (the generic solution has period $T=2\pi/|\hat{\alpha}|$). In the special (translation-invariant) case $\gamma=-1,\hat{\gamma}=0$, this system was already known [see Eq. (3.7.11) of Ref. 3]. The equations of motion (4.75) possess the similarity solution

$$r_j(t)=r_0\rho^j\ \exp\{\exp(\alpha t)[\lambda\ \cos(\hat{\alpha}t)-\mu\ \sin(\hat{\alpha}t)]\}, \tag{4.76a}$$

$$\theta_j(t)=\theta_0+j\,\eta+\exp(\alpha t)[\mu\ \cos(\hat{\alpha}t)+\lambda\ \sin(\hat{\alpha}t)], \tag{4.76b}$$

featuring the 6 arbitrary real constants $r_0,\rho,\lambda,\mu,\theta_0$ and η ($r_0>0,\rho>0$). The corresponding motion is, as $t\to+\infty$, rather unwieldy if $\alpha>0$ and $\hat{\alpha}\neq0$; it is more reasonable if $\alpha<0$, and it is of course completely periodic with period $T=2\pi/|\hat{\alpha}|$ if $\alpha=0,\ \hat{\alpha}\neq0$.

The ''complex-plane'' version of (4.73) reads as follows:

$$\ddot{z}_j=(1+c)\dot{z}_j^2/z_j+a\dot{z}_j+bz_j-(c\dot{z}_j^2+a\dot{z}_jz_j+bz_j^2)[(z_j-z_{j+1})^{-1}+(z_j-z_{j-1})^{-1}], \tag{4.77a}$$

$$a=\alpha+i\hat{\alpha},\quad b=\beta+i\hat{\beta},\quad c=\gamma+i\hat{\gamma}. \tag{4.77b}$$

These equations of motion correspond, via (2.14) and (2.21), to the following Hamiltonian $h(\mathbf{z},\mathbf{Z})$ and Lagrangian $l(\mathbf{z},\dot{\mathbf{z}})$:

$$h(\mathbf{z},\mathbf{Z})=\sum_j\ \{\lambda z_jZ_j+\nu[\mu\ \log\sinh(z_jZ_j/\nu)+\rho\ \log(1-z_{j+1}/z_j)]\}, \tag{4.78a}$$

$$l(\mathbf{z},\dot{\mathbf{z}})=\nu\sum_j\ \left\{\frac{1}{2}\mu[(w_j+1)\log(w_j+1)-(w_j-1)\log(w_j-1)]-\rho\ \log(1-z_{j+1}/z_j)\right\}, \tag{4.78b}$$

$$w_j=[(\dot{z}_j/z_j)-\lambda]/\mu, \tag{4.78c}$$

entailing [see (2.24b)]

$$Z_j=(\nu/z_j)\,\mathrm{arc\ cotanh}(w_j)=\frac{1}{2}(\nu/z_j)\log[(w_j+1)/(w_j-1)]. \tag{4.78d}$$

The 4 (complex) constants λ,μ,ν,ρ are related to the 3 (complex) constants a,b,c [see (4.77b)] as follows:

$$c=-\rho/\mu,\quad a=2\rho\lambda,\quad b=\rho\mu(1-\lambda^2). \tag{4.79}$$

The integrability of the system (4.77) is demonstrated via the position

$$z_j=\exp(-cu_j). \tag{4.80}$$

Thereby the equations of motion (4.77) take the form

$$\ddot{u}_j=R(\dot{u}_j)[g(u_{j+1}-u_j)-g(u_j-u_{j-1})], \tag{4.81a}$$

with

$$R(v)=Ev^2+Av+B, \tag{4.81b}$$

$$g(u)=[g_1-g_2\ \exp(-cu)]/[1-\exp(-cu)], \tag{4.81c}$$

entailing

$$g'(u)=E[g(u)-g_1][g(u)-g_2], \tag{4.81d}$$

and

$$c=E(g_2-g_1), \quad a=A(g_2-g_1), \quad b=B(g_2-g_1). \tag{4.81e}$$

These equations have been identified as integrable ones by Yamilov (on the basis of previous work with Shabat).[10] The Hamiltonian (4.78) has also been obtained from Ref. 10.

I. Models nine and ten

The Newtonian equations of motion of ''model nine'' read as follows:

$$\begin{aligned}\ddot{\vec{r}}_j=&[2\dot{\vec{r}}_j(\dot{\vec{r}}_j\cdot\vec{r}_j)-\vec{r}_j|\dot{\vec{r}}_j|^2]/r_j^2+(\beta+\hat{\beta}\hat{z}\wedge)\cdot\{-[2\dot{\vec{r}}_j(-a_j^{(+)}r_j^2+4b_jc_j^{(+)})+\dot{\vec{r}}_{j+1}(-|\dot{\vec{r}}_j|^2r_j^2\\&+4b_j^{(+)2})-2\vec{r}_j(|\dot{\vec{r}}_j|^2c^{(+)}+2a^{(+)}b^{(+)})]/(3r_j^4)+[2\dot{\vec{r}}_j(-a_j^{(-)}r_{j-1}^2+4b_j^{(-)}c_j^{(-)})\\&+\dot{\vec{r}}_{j-1}(-|\dot{\vec{r}}_j|^2r_{j-1}^2+4b_j^{(-)2})-2\vec{r}_{j-1}(|\dot{\vec{r}}_{j-1}|^2c^{(-)}+2a^{(-)}b^{(-)})]/(3r_{j-1}^4)\},\end{aligned} \tag{4.82a}$$

with the short-hand notation

$$\begin{gathered}a_j^{(\pm)}\equiv(\dot{\vec{r}}_j\cdot\dot{\vec{r}}_{j\pm1}); \quad b_j^{(+)}\equiv(\dot{\vec{r}}_j\cdot\vec{r}_j), \quad b_j^{(-)}\equiv(\dot{\vec{r}}_j\cdot\vec{r}_{j-1});\\ c_j^{(+)}\equiv(\dot{\vec{r}}_{j+1}\cdot\vec{r}_j), \quad c_j^{(-)}\equiv(\dot{\vec{r}}_{j-1}\cdot\vec{r}_{j-1}).\end{gathered} \tag{4.82b}$$

Hence they feature one-body forces quadratic in the velocities and ''nearest-neighbor'' forces cubic in the velocities, and they contain the 2 arbitrary (real) coupling constants β and $\hat{\beta}$.

These equations of motion are rotation- and scaling-invariant. They are not translation-invariant.

They possess the ''similarity solution'' (4.74). The ''complex plane'' version of (4.82) reads as

$$\ddot{z}_j=\dot{z}_j^2/z_j-b\dot{z}_j^2[(\dot{z}_{j+1}/z_j^2)-(\dot{z}_{j-1}/z_{j-1}^2)], \tag{4.83a}$$

with

$$b=\beta+i\hat{\beta}. \tag{4.83b}$$

These equations are Hamiltonian and Lagrangian [see (2.14) and (2.21)], with

$$h(\mathbf{z},\mathbf{Z})=-\sum_j \log\{z_j[Z_j-b(z_j/z_{j-1})]\}, \tag{4.84a}$$

$$l(\mathbf{z},\dot{\mathbf{z}})=\sum_j [b(\dot{z}_j/z_{j-1})-\log(\dot{z}_j/z_j)], \tag{4.84b}$$

$$Z_j=-(\dot{z}_j)^{-1}+b/z_{j-1}. \tag{4.84c}$$

The integrability of this model is demonstrated via the position

$$z_j = b^{-j} \exp(u_j), \tag{4.85}$$

which transforms (4.83a) into

$$\ddot{u}_j = -\dot{u}_j^2[\dot{u}_{j+1} \exp(u_{j+1}-u_j) - \dot{u}_{j-1} \exp(u_j - u_{j-1})]. \tag{4.86}$$

The integrability of these evolution equations has been recently demonstrated by Suris.[9] The Hamiltonian and Lagrangian (4.84) have also been obtained from Ref. 9.

The Newtonian equations of motion of ''model ten'' read as follows:

$$\begin{aligned}\ddot{\vec{r}}_j =& [2\dot{\vec{r}}_j(\dot{\vec{r}}_r \cdot \vec{r}_j) - \vec{r}_j|\dot{\vec{r}}_j|^2]/r_j^2 + (\beta + \hat{\beta}\hat{z}\wedge)\{\dot{\vec{r}}_{j+1} + \{\dot{\vec{r}}_{j-1}[r_j^2 r_{j-1}^2 - 4(\vec{r}_j \cdot \vec{r}_{j-1})^2] \\ &+ 2\vec{r}_j[(\dot{\vec{r}}_{j-1} \cdot \vec{r}_j) r_{j-1}^2 - 4(\dot{\vec{r}}_{j-1}\vec{r}_{j-1})(\vec{r}_j \cdot \vec{r}_{j-1})] + 2\vec{r}_{j-1}[2(\dot{\vec{r}}_{j-1} \cdot \vec{r}_j)(\vec{r}_j \cdot \vec{r}_{j-1}) \\ &+ (\dot{\vec{r}}_{j-1} \cdot \vec{r}_{j-1}) r_j^2]\}/(3r_{j-1}^4)\} + (\beta^2 - \hat{\beta}^2 + 2\beta\hat{\beta}\hat{z}\wedge)\{[\vec{r}_j r_{j+1}^2 - 2\vec{r}_{j+1}(\vec{r}_{j+1} \cdot \vec{r}_j)]/r_j^2 \\ &+ \{\vec{r}_j[4(\vec{r}_j \cdot \vec{r}_{j-1})^2 - r_j^2 r_{j-1}^2] - 2\vec{r}_{j-1}(\vec{r}_j \cdot \vec{r}_{j-1}) r_j^2\}/(3r_{j-1}^4)\},\end{aligned} \tag{4.87}$$

or equivalently, in complex notation,

$$\ddot{z}_j = \dot{z}_j^2/z_j + b[\dot{z}_{j+1} - \dot{z}_{j-1}(z_j/z_{j-1})^2] + b^2[-z_{j+1}^2/z_j + z_j^3/z_{j-1}^2], \tag{4.88}$$

with $b = \beta + i\hat{\beta}$.

The forces appearing in the right-hand side of the equations of motion (4.87) feature a one-body term quadratic in the velocities, a ''nearest-neighbor'' term linear in the velocities and another ''nearest-neighbor'' velocity-independent term. These equations contain (linearly and quadratically) the 2 arbitrary real constants β and $\hat{\beta}$.

These equations of motion possess the similarity solution (4.74).

They are Hamiltonian. As for the preceding ''model nine,'' we write the corresponding Hamiltonian and Lagrangian only in complex notation, see (2.14) and (2.21), leaving to the diligent reader the task to derive, via (2.15), (2.16) (2.19) and (2.22), the explicit expressions of the real Hamiltonians and Lagrangians that yield directly (4.87):

$$h(\mathbf{z}, \mathbf{Z}) = \sum_j (s z_j^2 Z_j^2 + a z_{j+1} Z_j), \tag{4.89a}$$

$$l(\mathbf{z}, \dot{\mathbf{z}}) = (4s)^{-1} \sum_j [(\dot{z}_j/z_j)^2 - 2a\dot{z}_j z_{j+1}/z_j^2 + a^2(z_{j+1}/z_j)^2], \tag{4.89b}$$

$$Z_j = (\dot{z}_j - a z_{j+1})/(2s z_j^2). \tag{4.89c}$$

Here s is an arbitrary complex constant.

The *integrability* of this model is demonstrated via the position (4.85), which transforms (4.88) into

$$\ddot{u}_j = \dot{u}_{j+1} \exp(u_{j+1}-u_j) - \dot{u}_{j-1} \exp(u_j - u_{j-1}) - \exp[2(u_{j+1}-u_j)] + \exp[2(u_j - u_{j-1})], \tag{4.90}$$

a dynamical system whose integrability has been recently demonstrated by Suris.[9] The Hamiltonian and the Lagrangians (4.89) have also been obtained from Ref. 9.

J. Model eleven

This model is Hamiltonian and completely solvable; we exhibit below its *general solution*. It is, however, a somewhat degenerate system, as indeed demonstrated by its complete solvability, although its motions are far from trivial, see below; and there is no simple way, in the general n-body case, to write explicitly its Newtonian equations of motion.

Its Hamiltonians in the plane, and the corresponding equations of motion, read, in the notation of Sec. II, as follows:

$$H(\vec{\mathbf{r}},\vec{\mathbf{R}})=(1/2)\sum_{j,k=1}^{n}\{\alpha[(\vec{R}_j\cdot\vec{r}_{jk})(\vec{R}_k\cdot\vec{r}_{jk})-(\hat{z}\cdot\vec{R}_j\cdot\wedge\vec{r}_{jk})(\hat{z}\cdot\vec{R}_k\wedge\vec{r}_{jk})]-\hat{\alpha}[(\vec{R}_j\cdot\vec{r}_{jk})(\hat{z}\cdot\vec{R}_k\wedge\vec{r}_{jk})$$
$$+(\vec{R}_k\cdot\vec{r}_{jk})(\hat{z}\cdot\vec{R}_j\wedge\vec{r}_{jk})]\}+\sum_{j=1}^{n}[\beta(\vec{r}_j\cdot\vec{R}_j)-\hat{\beta}(\hat{z}\cdot\vec{R}_j\wedge\vec{r}_j)], \tag{4.91}$$

$$\tilde{H}(\vec{\mathbf{r}},\vec{\mathbf{R}})=(1/2)\sum_{j,k=1}^{n}\{\hat{\alpha}[(\vec{R}_j\cdot\vec{r}_{jk})(\vec{R}_k\cdot\vec{r}_{jk})-(\hat{z}\cdot\vec{R}_j\cdot\wedge\vec{r}_{jk})(\hat{z}\cdot\vec{R}_k\wedge\vec{r}_{jk})]+\alpha[(\vec{R}_j\cdot\vec{r}_{jk})(\hat{z}\cdot\vec{R}_k\wedge\vec{r}_{jk})$$
$$+(\vec{R}_k\cdot\vec{r}_{jk})(\hat{z}\cdot\vec{R}_j\wedge\vec{r}_{jk})]\}+\sum_{j=1}^{n}[\hat{\beta}(\vec{r}_j\cdot\vec{R}_j)+\beta(\hat{z}\cdot\vec{R}_j\wedge\vec{r}_j)], \tag{4.92}$$

$$\dot{\vec{r}}_j=(\beta+\hat{\beta}\hat{z}\wedge)\vec{r}_j+(\alpha+\hat{\alpha}\hat{z}\wedge)\sum_{k=1}^{n}[\vec{r}_{jk}(\vec{R}_k\cdot\vec{r}_{jk})+\hat{z}\wedge\vec{r}_{jk}(\hat{z}\cdot\vec{R}_k\wedge\vec{r}_{jk})], \tag{4.93a}$$

$$\dot{\vec{R}}_j=-(\beta+\hat{\beta}\hat{z}\wedge)\vec{R}_j-2(\alpha+\hat{\alpha}\hat{z}\wedge)\sum_{k=1}^{n}[\vec{R}_j(\vec{R}_k\cdot\vec{r}_{jk})+\hat{z}\wedge\vec{R}_j(\hat{z}\cdot\vec{R}_k\wedge\vec{r}_{jk})]. \tag{4.93b}$$

These equations contain the 4 arbitrary coupling constants $\alpha,\hat{\alpha},\beta,\hat{\beta}$; the solvability of the model would not be marred by an (arbitrary) time-dependence of these quantities (see below), but we hereafter assume, for simplicity, that they are all time-independent.

Note that these Hamiltonians, and (of course) the corresponding equations of motion, are rotation-invariant. They are moreover translation-invariant, namely invariant under the transformation $\vec{r}_j=\vec{r}_j+\vec{r}_0$ with $\vec{r}_0$ an arbitrary constant two-vector, iff $\beta=\hat{\beta}=0$.

A somewhat more general, but still solvable, version of this model exists, which features appropriate combinations of the vectors $\vec{r}_j$ and $\vec{r}_k$ in place of $\vec{r}_{jk}\equiv\vec{r}_j-\vec{r}_k$, and therefore lacks translation-invariance even when $\beta=\hat{\beta}=0$. We forsake to display and treat this case, which the diligent reader might easily retrieve from the results reported below.

The complex-plane versions of (4.91)–(4.93) read as follows (with $a=\alpha+i\hat{\alpha},b=\beta+i\hat{\beta}$):

$$h(\mathbf{z},\mathbf{Z})=(1/2)a\sum_{j,k=1}^{n}Z_jZ_k(z_j-z_k)^2+b\sum_{j=1}^{n}z_jZ_j, \tag{4.94}$$

$$\dot{z}_j=bz_j+a\sum_{k=1}^{n}Z_k(z_j-z_k)^2, \tag{4.95a}$$

$$\dot{Z}_j=-bZ_j-2aZ_j\sum_{k=1}^{n}Z_k(z_j-z_k). \tag{4.95b}$$

Hereafter we focus on these equations; the transformation of the results, presented below in complex-plane notation, into the corresponding results in real-plane language, is a trivial task; see Sec. II.

The equations of motion (4.95) can be generalized or simplified via the following transformations:

$$z_j(t)=\varphi(t)\tilde{z}_j(\tau),\quad Z_j(t)=\Phi(t)\tilde{Z}_j(\tau),\quad \tau\equiv\tau(t), \tag{4.96}$$

which yield

$$\tilde{z}_j' = \tilde{b}\tilde{z}_j + \tilde{a}\sum_{k=1}^{n} \tilde{Z}_k(\tilde{z}_j - \tilde{z}_k)^2, \tag{4.97a}$$

$$\tilde{Z}_j' = \tilde{c}\tilde{Z}_j - 2\tilde{a}\tilde{Z}_j\sum_{k=1}^{n} \tilde{Z}_k(\tilde{z}_j - \tilde{z}_k), \tag{4.97b}$$

with

$$\tilde{b} = (b - \dot{\varphi}/\varphi)/\dot{\tau}, \quad \tilde{c} = (b + \dot{\Phi}/\Phi)/\dot{\tau}, \quad \tilde{a} = a\varphi\Phi/\dot{\tau}. \tag{4.98}$$

Here of course the prime denotes differentiation with respect to the variable τ.

It is thus seen that, by appropriate choice of the 3 *a priority* arbitrary functions φ, Φ and τ, one can control the more general version (4.97) of the equations of motion, where $\tilde{a}(\tau)$, $\tilde{b}(\tau)$ and $\tilde{c}(\tau)$ are 3 essentially arbitrary functions of the independent variable τ, by reducing them to the simpler version

$$\dot{z}_j = \sum_{k=1}^{n} Z_k(z_j - z_k)^2, \tag{4.99a}$$

$$\dot{Z}_j = -2Z_j\sum_{k=1}^{n} Z_k(z_j - z_k). \tag{4.99b}$$

In particular, (4.95) can be reduced (up to a trivial notational change) to (4.99), by setting $\varphi(t) = \exp(bt)$, $\Phi(t) = \exp(-bt)$, $\tau = at$. Hence hereafter our attention will be confined to solving (4.99).

It is now convenient to note that these equations of motion (4.99) can be rewritten in the form

$$\dot{z}_j = c_0 z_j^2 - 2c_1 z_j + c_2, \tag{4.100a}$$

$$\dot{Z}_j = -2Z_j(c_0 z_j - c_1), \tag{4.100b}$$

by setting

$$c_m = \sum_{k=1}^{n} Z_k z_k^m, \quad m = 0,1,2. \tag{4.101}$$

Note the degeneracy of the equations of motion (4.100a), which imply that, for $n > 3$, the quantities $z_j(0)$ and $\dot{z}_j(0)$ cannot be all assigned independently.

It is moreover easy to verify that (4.101) and (4.100) entail that the 3 quantities c_m are constants of motion:

$$\dot{c}_m = 0, \quad m = 0,1,2. \tag{4.102}$$

It is then a trivial matter to solve (4.100):

$$z_j(t) = (c_1/c_0)\{1 - \gamma\,\mathrm{cotanh}[2\gamma c_1 t + \alpha_j]\}, \tag{4.103a}$$

$$Z_j(t) = Z_j(0)\sinh(\alpha_j)/\sinh(2\gamma c_1 t + \alpha_j), \tag{4.103b}$$

$$\alpha_j = \mathrm{arctanh}\{[1 - (c_0/c_1)z_j(0)]/\gamma\}, \tag{4.103c}$$

$$\gamma = (1 - c_0 c_2/c_1^2)^{1/2}. \tag{4.103d}$$

Here of course all the constants $c_0, c_1, c_2, \gamma, \alpha_j, z_j(0)$ and $Z_j(0)$ are complex; this accounts for the richness of the motions entailed by (103), whose detailed analysis is left as an easy task for the diligent reader.

Let us end by emphasizing that the findings reported in this Subsection are closely connected, for instance via the results of Sec. III, with the results of Ref. 11.

V. OUTLOOK

In this paper we have exhibited several *integrable* or *solvable* dynamical systems, whose equations of motion are naturally interpretable as the *Newtonian equations of motion for a many-body problem in the plane*. It is clear from the techniques we have introduced and employed how other models sharing these properties could be obtained. As mentioned above, to select those we have displayed, we have been guided mainly by ''aesthetic'' considerations, trying to strike a fair balance between the contradictory requirements to avoid overwhelming the reader with too many examples yet to exhibit a representative sample of the systems that are treatable. Analogous ''aesthetic'' criteria have also been employed to balance the contradictory requirements, in presenting each model, to seek maximal generality or *vice versa* maximal simplicity. We have tried in this respect to make our presentation user-friendly, having also in mind potential users interested rather in applications than in the underlying theory. It is clear that many of the models presented above could be further generalized by appropriate changes of variables, such as $z_j \to \tilde{z}_j = (z_j)^\lambda$ or $z_j \to \tilde{z}_j = f(t)\zeta_j(\tau) + g(t), \tau \equiv \tau(t)$.

Our main purpose in this paper has been to present a simple technique suitable to manufacture integrable or solvable many-body problems in the plane, and to exhibit several such models, rather than to study their solutions. We have, however, in most cases exhibited special (''similarity'') solutions, to give at least an idea of the motions entailed by these models. But these results give only a glimpse of the behaviors of these systems, and are certainly inadequate to display all the reachness of the motions exhibited by their solutions (see, for instance, Ref. 1). Hence much work remains to be done, in the guise of a detailed study of the solutions of each model, possibly including their display by appropriate computer graphics.

Let us end by mentioning three additional directions for further research, and two final remarks, which also open vistas of additional research.

Three directions for further research. (i) The study of quantized versions of these models, in particular of those which only feature *completely periodic motions*, for which it is natural to conjecture the existence of quantized versions featuring *equispaced energy spectra*. (ii) The investigation of the limit in which the number n of particles becomes infinite, including in particular the cases in which the particles give rise to continuous distributions (strings in the plane, and perhaps also blobs; for seminal progress in that direction see Ref. 12). (iii) The introduction of related *discretized* models, in which the *real* space and/or time variables are replaced by lattice entries (much work has already been done in this direction for ''one-dimensional'' integrable and solvable models, see e.g., Refs. 9 and 13).

First remark. There is of course a simple trick to transform by complexification *any* analytical problem for the n complex variables $z_j, j = 1, \ldots, n,$ into a *rotation-invariant* problem in the plane for $n+1$ real two-vectors $\vec{r}_j, j = 0,1, \ldots, n$. The trick is to set, instead of $z_j = x_j + iy_j$ (see Sec. II),

$$z_j = \hat{r}_0 \cdot \vec{r}_j + i\hat{z} \cdot \hat{r}_0 \wedge \vec{r}_j, j = 1, \ldots, n, \tag{5.1}$$

with $\hat{r}_0 \equiv \vec{r}_0 / r_0$ the unit two-vector in the direction of $\vec{r}_0$, and to supplement the equations of motion for $\vec{r}_j(t), j = 1, \ldots, n$, obtained via this position from those for $z_j(t)$, with the additional *rotation-invariant* (and trivial!) equation,

$$\dot{\vec{r}}_0 = 0. \tag{5.2}$$

Note that this equation is automatically yielded by any Hamiltonian problem, where the original (complex) Hamiltonian $h(z_j, Z_j; j = 1, \ldots, n)$ generates new (real) Hamiltonians $H(\vec{r}_0, \vec{r}_j, \vec{R}_j; j = 1, \ldots, n)$ and $\hat{H}(\vec{r}_0, \vec{\hat{r}}_j, \vec{\hat{R}}_j; j = 1, \ldots, n)$ via the technique of Sec. II, using (5.1) and correspondingly [instead of (2.15)]

$$z_j=\hat{r}_0\cdot\vec{r}_j+i\hat{z}\cdot\hat{r}_0\wedge\vec{r}_j\,,\quad Z_j=\hat{r}_0\cdot\vec{R}_j-i\hat{z}\cdot\hat{r}_0\wedge\vec{R}_j\,,\quad j=1,\ldots,n. \tag{5.3}$$

Second remark. Let us reemphasize that the main message of this paper is to advocate that the study of integrable systems be extended to the complex plane (''go complex, man!''), especially by appropriately interpreting such an extension, which generally entails a substantial enrichment of the dynamical behaviors displayed by the systems under consideration, in terms of ''physical'' (*real* and *rotation-invariant*) models *in the plane*.

ACKNOWLEDGMENTS

Much of the work reported in this paper was done while visiting the UFR 920 at the Université Paris 6. It is a pleasure to thank professor Jean-Pierre Françoise for the pleasant hospitality there and for many useful discussions, as well as the institutions that have facilitated such visits, including the CNRS in France and the CNR in Italy.

Two families of nonstandard Poisson structures for Newton equations

Krzysztof Marciniak[a] and Stefan Rauch-Wojciechowski[b]
Department of Mathematics, Linköping University, S 581-83 Linköping, Sweden

(Received 10 March 1998; accepted for publication 30 April 1998)

Two families of nonstandard two-dimensional Poisson structures for systems of Newton equations are studied. They are closely related either with separable systems or with the so-called quasi-Lagrangian systems. A theorem characterizing the general form of bi-Hamiltonian formulation for separable systems in two and in n dimensions is formulated and proved. © *1998 American Institute of Physics.* [S0022-2488(98)03810-9]

I. INTRODUCTION

In this paper we study two different types of nonstandard Poisson operators related to systems of Newton equations, i.e., second-order ordinary differential equations (ODEs) of the form $q_{,xx}=F(q)$, where $q=(q_1,\ldots,q_n)$, q_i, $x\in\mathbf{R}$, and with a function F not depending explicitly on the velocity $q_{,x}$ (throughout the whole article *comma* followed by a subscript denotes derivation with respect to the subscript variable, so for example $q_{,xx}=d^2q/dx^2$ and $x_{,t}=dx/dt$). Such systems originate in physics as equations of motion of type acceleration=external force. The study and efforts to solve these equations were over centuries major driving factors for development of classical mechanics and resulted in introducing the Lagrangian and Hamiltonian formalisms.

The majority of Newton equations are not solvable in any explicit sense, but those which are are of considerable interest in applications (Kepler problem, integrable rigid body motions) as well as in theoretical understanding of the formalism of classical mechanics.

If the force F is potential, i.e., if $F=-\partial V/\partial q$, then the Newton equations $q_{,xx}=F(q)$ naturally admit the energy integral of motion and possibly some extra integrals of motion so that they can be solved by quadratures. The most complete characterization of classes of Newton equations solvable by quadratures is given in the framework of their Hamiltonian formulation by the Liouville theorem about completely integrable systems.[1]

Completely integrable systems are very rare and several different tools were developed for their characterization; for instance, the classical separability theory for the Hamilton–Jacobi equation,[1] Kac–Moody algebraic constructions of complete sets of commuting integrals of motion,[2,3] the classical r-matrix approach,[4] or the bi-Hamiltonian approach.[5] All these are quite general and powerful construction schemes which lead to large classes of completely integrable Hamiltonian systems, but very few of these systems correspond to some physically interpretable sets of equations like Newton equations or equations of rigid body motion. It is a highly nontrivial task to construct completely integrable sets of Newton equations.

In the present paper we study the relationship between systems of Newton equations and Poisson operators. More precisely, we present two families of Poisson operators of relatively general form, inspired by two illustrative examples of completely integrable Newton equations. We show how their Poisson property inevitably leads to two classes of Newton equations.

The first family of Poisson operators is related to the classically (pointwise) separable natural Hamiltonian systems $H=\frac{1}{2}p^2+V(q)$ which also admit a second (nonstandard) Hamiltonian formulation. We need to mention that the bi-Hamiltonian formulation for the most important cases of separable systems (elliptic and parabolic separable) has been determined before,[6,7] where for given classes of potentials a bi-Hamiltonian formulation has been found. Here we proceed in the oppo-

site direction: we show that a certain type of assumption about the Poisson operator inevitably leads to the class of separable systems.

The second family of Poisson operators describes a completely new class of Newton equations. This new family consists of systems with nonpotential forces and so they have no Lagrangian formulation and thus they have no standard Hamiltonian formulation. Instead, they have what we call a *quasi-Lagrangian* formulation and a certain nonstandard Hamiltonian formulation.

This paper is organized as follows. We start with the mentioned assumptions about the structure of a Poisson operator in a five-dimensional phase space. These assumptions are inspired by two examples (Examples 2.1 and 2.2 below) and by the previous results[6,7] about the bi-Hamiltonian structure of separable natural Hamiltonian systems. In Sec. III we formulate a theorem about bi-Hamiltonian formulation for all two-dimensional separable natural Hamiltonians. This theorem admits a generalization to arbitrary dimension, which is done in Sec. IV, where we give a complete characterization of bi-Hamiltonian formulation for all natural Hamiltonians separable in generalized elliptic coordinates or any of its degenerations[8] which correspond to indecomposable metrics. What happens in the decomposable case is illustrated by Example 4.3. In the last section we introduce and discuss new class of systems—the already mentioned quasi-Lagrangian systems; we explain how they lead to sets of nonpotential Newton equations and how they generalize Example 2.2 coming from the Harry–Dym hierarchy. We also find for them a completely new Hamiltonian formulation.

II. STARTING POINT: A POISSON OPERATOR

Let us consider a five-dimensional phase space $\mathscr{M}$ with variables denoted by (x,y,π,ρ,c) or by (r,w,s,z,d). We remind the reader that an operator Π mapping covector fields (gradients) on $\mathscr{M}$ into vector fields on $\mathscr{M}$ is called a *Poisson operator*, if the corresponding bilinear mapping, defined for any pair of functions $f,g\colon \mathscr{M}\to\mathbf{R}$ by

$$\{f,g\}_\Pi=(\nabla f,\Pi\nabla g)$$

[where $(\cdot,\cdot)$ is the dual map between the cotangent and tangent spaces and ∇ is the gradient operator in M] yields a Poisson bracket, that is, if

(1) it is antisymmetric: $\{f,g\}_\Pi=-\{g,f\}_\Pi$;
(2) it satisfies the Leibniz rule: $\{fg,h\}_\Pi=f\{g,h\}_\Pi+\{f,h\}_\Pi g$; and
(3) it satisfies the Jacobi identity: if h is a third function on $\mathscr{M}$, then

$$\{\{f,g\}_\Pi,h\}_\Pi+\{\{g,h\}_\Pi,f\}_\Pi+\{\{h,f\}_\Pi,g\}_\Pi=0.$$

Thus, an operator Π is Poisson if its matrix is antisymmetric and if the Jacobi identities $\{\{x,y\}_\Pi,\pi\}_\Pi+\text{cycl}=0$, etc. hold for all triples of coordinates (cycl means the cyclic permutation of variables).

In what follows we will not distinguish between Poisson operators and their matrices.

Now let $\mathscr{M}$ be endowed with a standard (degenerate) Poisson operator

$$\Pi_0=\left[\begin{array}{cc|c} 0 & I & 0\\ -I & 0 & 0\\ \hline 0 & 0 & 0\end{array}\right], \tag{2.1}$$

where

$$I=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}$$

is a 2×2 identity matrix. Thus, if $\{\cdot,\cdot\}_{\Pi_0}$ denotes the Poisson bracket induced by (2.1), then $\{x,\pi\}_{\Pi_0}=\{y,\rho\}_{\Pi_0}=\{r,s\}_{\Pi_0}=\{w,z\}_{\Pi_0}=1$ and the remaining elementary Poisson brackets are equal to zero. We introduce two different labelings of the phase space variables since they will correspond to two different families of Poisson structures which we present below.

Let us now consider an *antisymmetric* operator of a quite general form:

$$\left[\begin{array}{cc|cc|c} 0 & 0 & \mu+f_{11} & f_{12} & \\ 0 & 0 & f_{21} & \mu+f_{22} & \\ \hline -\mu-f_{11} & -f_{21} & 0 & F & \mathscr{A} \\ -f_{12} & -\mu-f_{22} & -F & 0 & \\ \hline \multicolumn{4}{c|}{*} & \end{array}\right] \tag{2.2}$$

where $f_{ij}=f_{ij}(x,y)$ [or $f_{ij}=f_{ij}(r,w)$], $i,j=1,2$, are arbitrary functions of the position coordinates, F is an arbitrary function on the phase space not depending on the last coordinate (c or d, respectively), and $\mathscr{A}$ is a column vector of functions on the phase space with the last entry equal to zero due to the antisymmetry of (2.2). The parameter $\mu\in\mathbf{R}$ is introduced in order to study the compatibility of (2.2) with the canonical Poisson operator (2.1). Here and in what follows $*$ denotes those matrix elements, which are determined by the requirement of antisymmetry of a given matrix.

In this paper we investigate the following question: what conditions must be satisfied in order to turn (2.2) into a Poisson operator? It will be shown that the study of this problem leads to new facts about systems of Newton equations, in particular about separable systems.

To motivate further development, let us present two examples:

Example 2.1: The well-known Garnier system,[9]

$$\begin{aligned} 0&=x_{,tt}+(x^2+y^2+c-\lambda_1)x,\\ 0&=y_{,tt}+(x^2+y^2+c-\lambda_2)y, \end{aligned} \tag{2.3}$$

with $x=x(t)$, $y=y(t)$, $\lambda_1,\lambda_2,c=\text{const}$, has the bi-Hamiltonian form[6]

$$\frac{d}{dt}\begin{bmatrix} x\\ y\\ \pi\\ \rho\\ c\end{bmatrix}=\Pi_0\nabla\left(\tfrac{1}{2}\pi^2+\tfrac{1}{2}\rho^2+V(x,y,c)\right)=\Pi_1\nabla c \tag{2.4}$$

(where $\pi=x_{,t}$, $\rho=y_{,t}$) with the second Poisson operator

$$\Pi_1=\left[\begin{array}{cc|cc|c} 0 & 0 & -\frac{1}{2}x^2+\lambda_1 & -\frac{1}{2}xy & \pi\\ 0 & 0 & -\frac{1}{2}xy & -\frac{1}{2}y^2+\lambda_2 & \rho\\ \hline \frac{1}{2}x^2-\lambda_1 & \frac{1}{2}xy & 0 & \frac{1}{2}y\pi-\frac{1}{2}x\rho & -V_{,x}\\ \frac{1}{2}xy & \frac{1}{2}y^2-\lambda_2 & \frac{1}{2}x\rho-\frac{1}{2}y\pi & 0 & -V_{,y}\\ \hline \multicolumn{4}{c|}{*} & 0 \end{array}\right],$$

where $V(x,y,c)=V(x,y)+\frac{1}{2}c(x^2+y^2)$ and $V(x,y)=\frac{1}{4}(x^2+y^2)^2-\frac{1}{2}(\lambda_1x^2+\lambda_2y^2)$. It can be easily shown that the above potential $V(x,y)$ is separable, since it satisfies the appropriate criterion of separability (see, for instance, Refs. 10 and 11). In the present paper we will show that it is not a coincidence: there is a close relationship between Poisson operators of the type (2.2) and separable systems.

Example 2.2: The stationary Harry Dym equation

$$\tfrac{1}{4}(u^{-1/2})_{,xxx}-\kappa(u^{-1/2})_{,x}=0$$

for $u=u(x)$, $\kappa\in\mathbf{R}$, after integrating it once, takes the following Newton form:

$$0=r_{,xx}-\kappa r+wr^{-5}, \tag{2.5}$$

$$0 = w_{,xx} - 4\kappa w + d, \tag{2.6}$$

in terms of the new variables $u = r^{-4}$, $w = \kappa r^6 - r^5 r_{,xx}$, with an integration constant d. Observe that it is a *driven* system, which means that the equation (2.6) is independent of (2.5), while the x evolution of r is driven by the solution of (2.6). The above system is not Lagrangian, but it can be shown that it has a nonstandard Hamiltonian formulation, which is important if one wants to consider complete integrability of the equations (2.5)–(2.6):

$$\frac{d}{dx}\begin{bmatrix} r \\ w \\ s \\ z \\ d \end{bmatrix} = \Pi_1 \nabla d, \quad \text{with } \Pi_1 = \left[\begin{array}{cccc|c} 0 & 0 & -\frac{1}{2}r^2 & 0 & \mathscr{E}_{,s} \\ 0 & 0 & 0 & -\frac{1}{2}r^2 & \mathscr{E}_{,z} \\ \frac{1}{2}r^2 & 0 & 0 & rz & \mathscr{E}_{,r} \\ 0 & \frac{1}{2}r^2 & -rz & 0 & \mathscr{E}_{,w} \\ \hline -\mathscr{E}_{,s} & -\mathscr{E}_{,z} & -\mathscr{E}_{,r} & -\mathscr{E}_{,w} & 0 \end{array}\right],$$

where

$$s = r w_{,x} - 2 w r_{,x}, \quad z = r r_{,x} \tag{2.7}$$

are the momenta conjugate to r, w through the generating function

$$E(r,w,d) = r r_{,x} w_{,x} - w r_{,x}^2 - \kappa w r^2 + \tfrac{1}{2} d r^2 + \frac{w^2}{2r^4}. \tag{2.8}$$

The function $\mathscr{E}$ is the Legendre transform of E,

$$\mathscr{E} = s r_{,x}(r,w,s,z) + z w_{,x}(r,w,s,z) - E = \frac{zs}{r} + \frac{w z^2}{r^2} + \kappa w r^2 - \tfrac{1}{2} d r^2 - \frac{w^2}{2r^4}, \tag{2.9}$$

where the functions $r_{,x}(r,w,s,z)$, $w_{,x}(r,w,s,z)$ are obtained by inverting the formulas in (2.7). The origin and meaning of the function E will be explained later.

Let us thus require the operator (2.2) to be a Poisson operator. Motivated by the above examples we can see that it makes sense to investigate (at least) two possible choices of the last column $\mathscr{A}$ (the superscript ^{T} denotes transposition of matrices):

Case A: $\mathscr{A} = \Pi_0 \nabla H \equiv (H_{,\pi}, H_{,\rho}, H_{,x}, H_{,y}, 0)^T$, $H = \frac{1}{2}(\pi^2 + \rho^2) + V(x,y,c)$ (cf. Example 2.1).

Case B: $\mathscr{A} = \Theta_0 \nabla \mathscr{E} \equiv (\mathscr{E}_{,s}, \mathscr{E}_{,z}, \mathscr{E}_{,r}, \mathscr{E}_{,w}, 0)^T$, with $\mathscr{E} = 1/\Delta(-az^2 + bsz - cs^2) - k(r,w,d)$, where Θ_0 is a symmetric operator of the form

$$\Theta_0 = \left[\begin{array}{cc|c} 0 & I & 0 \\ I & 0 & 0 \\ \hline 0 & 0 & 0 \end{array}\right], \tag{2.10}$$

$\Delta = b^2 - 4ac$, and where the coefficients a, b, c are given as

$$a = Aw^2 + Bw + \alpha_1,$$

$$b = -2Arw - Br - Cw + \alpha_2,$$

$$c = Ar^2 + Cr + \alpha_3$$

(A, B, C, α_i, $i = 1,2,3$ are constants). This choice of $\mathscr{A}$ may seem peculiar, but the system in Example 2.2 is a particular realization of the above system. Moreover, this assumption, being sufficiently general, leads to new interesting types of Newton equations—the already mentioned quasi-Lagrangian systems.

It is also possible to consider multi-dimensional variants of the above cases. An n-dimensional generalization of case A is investigated in Sec. III.

III. CASE A—TOWARDS SEPARABLE SYSTEMS

Let us thus consider an antisymmetric operator of the form

$$\left[\begin{array}{cccc|c} 0 & 0 & \mu+f_{11} & f_{12} & \pi \\ 0 & 0 & f_{21} & \mu+f_{22} & \rho \\ -\mu-f_{11} & -f_{21} & 0 & F & -V_{,x} \\ -f_{12} & -\mu-f_{22} & -F & 0 & -V_{,y} \\ \hline -\pi & -\rho & V_{,x} & V_{,y} & 0 \end{array}\right] \tag{3.1}$$

acting in the phase space of variables x,y,π,ρ,c, with $f_{ij}=f_{ij}(x,y)$, $i,j=1,2$, $V=V(x,y,c)$, $F=F(x,y,\pi,\rho)$, and with some real parameter μ. Let us require the above operator to be a Poisson operator. The Jacobi identity applied to all triples of x,y,π,ρ yields then

$$\begin{bmatrix} f_{11}+\mu & f_{12} \\ f_{21} & f_{22}+\mu \end{bmatrix}\begin{bmatrix} F_{,\pi} \\ F_{,\rho} \end{bmatrix}=\begin{bmatrix} \{f_{11},\rho\}-\{f_{12},\pi\} \\ \{f_{21},\rho\}-\{f_{22},\pi\} \end{bmatrix}, \tag{3.2}$$

where $\{\cdot,\cdot\}$ denotes the Poisson bracket associated with (3.1). If the determinant of the 2×2 matrix on the left-hand side of (3.2) is different from zero, the above equation shows that F is linear in momenta, that is

$$F=g_1(x,y)\pi+g_2(x,y)\rho+\Lambda(x,y), \tag{3.3}$$

and that the functions $g_1=F_{,\pi}$ and $g_2=F_{,\rho}$ are determined by the functions f_{ij}. Further, $\{\{x,y\},c\}+\text{cycl}=0$ implies the symmetry of f_{ij}: $f_{12}=f_{21}$. The conditions $\{\{x,\pi\},c\}+\text{cycl}=0$ and $\{\{y,\rho\},c\}+\text{cycl}=0$ yield

$$f_{11,y}=f_{22,x}=0 \tag{3.4}$$

and

$$f_{11,x}+V_{,xc}=0, \quad f_{22,y}+V_{,yc}=0. \tag{3.5}$$

Using (3.3), we get from $\{\{x,\rho\},c\}+\text{cycl}=0$ and from $\{\{y,\pi\},c\}+\text{cycl}=0$

$$f_{21,x}+g_1=0, \quad f_{12,y}-g_2=0 \tag{3.6}$$

and

$$f_{12,x}+V_{,yc}-g_1=0, \quad f_{21,y}+V_{,c}+g_2=0. \tag{3.7}$$

Moreover, we can conclude that $\Lambda(x,y)\equiv0$. The last Jacobi identity $\{\{\pi,\rho\},c\}+\text{cycl}=0$ yields

$$g_{1,x}=g_{1,y}+g_{2,x}=g_{2,y}=0, \tag{3.8}$$

and the following second-order partial differential equation for V:

$$f_{12}V_{,xx}-f_{21}V_{,yy}+(f_{22}-f_{11})V_{,xy}+V_{,xc}V_{,y}-V_{,yc}V_{,x}-g_1V_{,x}-g_2V_{,y}=0. \tag{3.9}$$

Notice that μ does not appear explicitly in any of the above equations.

Let us now solve the equations (3.4)–(3.9). First, (3.8) implies that $g_1=g_1(y)$, $g_2=g_2(x)$ and thus $\partial g_1(y)/\partial y+\partial g_2(x)/\partial x=0$ integrates to

$$g_1=-Ay-D, \quad g_2=Ax+B$$

for some constants A,B,D. This, combined with (3.6) and with $f_{12}=f_{21}$ gives in turn

$$f_{12}=f_{21}=Axy+Dx+By-C$$

with a new constant C. The equations (3.7) now determine the dependence of V on c

$$V_{,c}=-A(x^2+y^2)-2(Bx+Dy)-K, \tag{3.10}$$

where K is also a constant. This makes it possible to solve (3.5) and we obtain

$$f_{11}=Ax^2+2Bx+\alpha, \quad f_{22}=Ay^2+2Dy+\beta$$

(α,β=const). By inserting the above solutions into (3.2) we obtain an identity which shows that the equations (3.2), though used only partly, do not impose any restrictions on these solutions.

At this stage the equation (3.9) reads

$$\begin{aligned}&(V_{,yy}-V_{,xx})(Axy+By+Dx-C)-V_{,xy}(Ay^2-Ax^2+2Dy-2Bx+\beta-\alpha)\\&\quad+3(Ax+B)V_{,y}-3(Ay+D)V_{,x}=0.\end{aligned} \tag{3.11}$$

The equation (3.10) gives

$$V(x,y,c)=W(x,y)-c(A(x^2+y^2)+2(Bx+Dy)+K). \tag{3.12}$$

After inserting (3.12) in (3.11), we easily check that the function $W(x,y)$ also satisfies the equation (3.11) with the same coefficients. The remarkable fact is that this is the well-known criterion of separability of a natural Hamiltonian system (Bertrand–Darboux equation[10,11]) generated in the canonical way by the Hamiltonian $H=(\pi^2+\rho^2)/2+W(x,y)$. Thus, we have proved the following theorem.

Theorem 3.1: *Let the operator of the form*

$$\Pi_1=\left[\begin{array}{cccc|c} 0 & 0 & f_{11} & f_{12} & \pi \\ 0 & 0 & f_{21} & f_{22} & \rho \\ -f_{11} & -f_{21} & 0 & F & -V_{,x} \\ -f_{12} & -f_{22} & -F & 0 & -V_{,y} \\ \hline -\pi & -\rho & V_{,x} & V_{,y} & 0 \end{array}\right],$$

acting in the five-dimensional phase space with variables x,y,π,ρ,c, with $f_{ij}=f_{ij}(x,y)$, $i,j=1,2$, $\det(f_{ij})\neq 0$, $V=V(x,y,c)$ and with $F=F(x,y,\pi,\rho)$, be a Poisson operator. Then

(1) Π_1 *must have the form*

$$\left[\begin{array}{cc|cc|c} 0 & 0 & Ax^2+2Bx+\alpha & Axy+By+Dx-C & \pi \\ 0 & 0 & Axy+By+Dx-C & Ay^2+2Dy+\beta & \rho \\ \hline & & 0 & (Ax+B)\rho-(Ay+D)\pi & -V_{,x} \\ \multicolumn{2}{c|}{*} & (Ay+D)\pi-(Ax+B)\rho & 0 & -V_{,y} \\ \hline -\pi & -\rho & V_{,x} & V_{,y} & 0 \end{array}\right]$$

with $A,B,C,D,\alpha,\beta=$const;

(2) *V must have the form*

$$V(x,y,c)=W(x,y)-c(A(x^2+y^2)+2(Bx+Dy)+h) \tag{3.13}$$

($h=$const) *where the function $W=W(x,y)$ satisfies the separability criterion for two-dimensional natural Hamiltonian systems (Bertrand–Darboux equation[10])*

$$\begin{aligned}&(W_{,yy}-W_{,xx})(Axy+By+Dx-C)-W_{,xy}(Ay^2-Ax^2+2Dy-2Bx+\beta-\alpha)\\&\quad+3(Ax+B)W_{,y}-3(Ay+D)W_{,x}=0;\end{aligned} \tag{3.14}$$

and

(3) Π_1 *is compatible with* Π_0.

The last part of the above theorem is true since its proof is valid for any value of μ.
Conclusion (2) of the above theorem yields the following corollary.
Corollary 3.2: The natural two-dimensional Hamiltonian system

$$\frac{d}{dt}\begin{bmatrix} x \\ y \\ \pi \\ \rho \end{bmatrix} = \begin{bmatrix} 0 & I \\ -I & 0 \end{bmatrix} \nabla\left(\tfrac{1}{2}\pi^2 + \tfrac{1}{2}\rho^2 + W(x,y)\right),$$

with W(x,y) satisfying the criterion of separability (3.14), has in the extended (five-dimensional) phase space of variables x,y,π,ρ,c a bi-Hamiltonian formulation of the form

$$\frac{d}{dt}\begin{bmatrix} x \\ y \\ \pi \\ \rho \\ c \end{bmatrix} = \Pi_0 \nabla\left(\tfrac{1}{2}\pi^2 + \tfrac{1}{2}\rho^2 + V(x,y,c)\right) = \Pi_1 \nabla c \tag{3.15}$$

with V determined by (3.13), and with Π_1 *as in Conclusion (1) of Theorem 3.1.* Since $\Pi_0 \nabla c = 0$ the natural question arises: is it possible to extend the system (3.15) to a bi-Hamiltonian chain? In other words, we have to check if there exists a function $K = K(x,y,\pi,\rho)$ on our phase space such that $\Pi_0 \nabla K = \Pi_1 \nabla H$ with $H = (\frac{1}{2}\pi^2 + \frac{1}{2}\rho^2 + V(x,y,c))$ and such that K is a Casimir function for Π_1. A direct integration of $\Pi_0 \nabla K = \Pi_1 \nabla H$ leads to

$$K = \tfrac{1}{2}\pi^2 f_{22} + \tfrac{1}{2}\rho^2 f_{11} - \rho\pi f_{12} + \Psi(x,y,c), \tag{3.16}$$

where Ψ has to satisfy the equations

$$\begin{bmatrix} \Psi_{,x} \\ \Psi_{,y} \end{bmatrix} = \begin{bmatrix} f_{22} - (\alpha + \beta - h) & -f_{12} \\ -f_{21} & f_{11} - (\alpha + \beta - h) \end{bmatrix} \begin{bmatrix} V_{,x} \\ V_{,y} \end{bmatrix} \tag{3.17}$$

with f_{ij}, α, β as in Theorem 3.1. The demand $\Pi_1 \nabla K = 0$ leads further to the relation $h = \alpha + \beta$ (thus showing that the sought chain exists only for a special choice of integration constants) and, moreover, to $\Psi_{,c} = f_{12} f_{21} - f_{11} f_{22} = -\det(f)$. Combining all this with (3.17) we finally get

$$K = \tfrac{1}{2}\pi^2 f_{22} + \tfrac{1}{2}\rho^2 f_{11} - \rho\pi f_{12} - c \det(f) + \overline{\Psi}(x,y), \tag{3.18}$$

where the function $\overline{\Psi}$ can be established from the relation

$$\begin{bmatrix} \overline{\Psi}_{,x} \\ \overline{\Psi}_{,y} \end{bmatrix} = \begin{bmatrix} f_{22} & -f_{12} \\ -f_{21} & f_{11} \end{bmatrix} \begin{bmatrix} W_{,x} \\ W_{,y} \end{bmatrix}, \tag{3.19}$$

which is solvable since the compatibility condition $\overline{\Psi}_{xy} = \overline{\Psi}_{yx}$ for (3.19) has exactly the form of the separability criterion (3.14), which is satisfied by the function W. Thus the bi-Hamiltonian vector field (3.15) extends to the following bi-Hamiltonian chain:

$$\Pi_0 \nabla c = 0,$$

$$\Pi_0 \nabla H = \Pi_1 \nabla c,$$

$$\Pi_0 \nabla K = \Pi_1 \nabla H,$$

$$\Pi_1 \nabla K = 0,$$

with K given by (3.18) and by (3.19).

IV. GENERALIZATION TO *N* DIMENSIONS

The results of Sec. III can be generalized from two to n dimensions so that a simple assumption about the form of a $(2n+1)$-dimensional Poisson operator completely determines its structure. Moreover, it appears again to be the structure of a Poisson pencil for separable systems.[12]

Consider a $2n+1$-dimensional phase space $\mathscr{M}$ endowed with coordinates (q,p,c) where $q=(q_1,\ldots,q_n)$, $p=(p_1,\ldots,p_n)$, $c\in\mathbf{R}$. For the purposes of this section we temporarily modify our notation: for a function $F\colon \mathscr{M}\to\mathbf{R}$ we denote its derivative with respect to q_j by $F_{,j}$ so that $F_{,j}\equiv F_{,q_j}=\partial F/\partial q_j$. Similarly, $F_{,c}:=\partial F/\partial c$. The derivative of F with respect to p_j will be denoted by the standard expression $\partial F/\partial p_j$.

Consider also an antisymmetric operator of the form

$$\left[\begin{array}{c|c|c} 0 & f(q)+\mu I_n & p^T \\ \hline * & B(q,p) & -V_{,q}^T \\ \hline -p & V_{,q} & 0 \end{array}\right], \tag{4.1}$$

where f,B are $n\times n$ matrices with entries $f_{ij}(q)$ and $B_{ij}(q,p)$, respectively, $i,j=1,\ldots,n$, $B_{ij}=-B_{ji}$, I_n is $n\times n$ identity matrix, $\mu\in\mathbf{R}$, $V=V(q,c)$, $V_q=(V_{,1},\ldots,V_{,n})$, and where the superscript ^{T} denotes the transpose of matrix. As in Sec. III let us require the above operator to be a Poisson operator. Let us denote also the Poisson bracket induced by (4.1) again by $\{\cdot,\cdot\}$. The equations $\{\{q_i,q_j\},q_k\}+\text{cycl}=0$ and $\{\{q_i,q_j\},p_k\}+\text{cycl}=0$ are satisfied identically, while the equations $\{\{q_i,q_j\},c\}+\text{cycl}=0$ yield symmetry of f: $f_{ij}=f_{ji}$. The equations $\{\{q_i,p_j\},p_k\}+\text{cycl}=0$ give

$$\sum_{s=1}^{n}(f_{is}+\mu\delta_{is})\frac{\partial B_{jk}}{\partial p_s}=\{f_{ij},p_k\}-\{f_{ik},p_j\},\quad i,j,k=1,\ldots,n, \tag{4.2}$$

with $\delta_{ii}=1$, $\delta_{ij}=0$, $i\neq j$. If $\det(f+\mu\delta)\neq 0$, then (4.2) implies that B_{jk} are linear in momenta, that is

$$B_{jk}=\sum_{s=1}^{n}g_{jk}^s p_s+\Lambda_{jk} \tag{4.3}$$

with some functions $g_{jk}^s=g_{jk}^s(q)$, $\Lambda_{jk}=\Lambda_{jk}(q)$. Due to the skew-symmetry of B_{jk}, we have also $g_{jk}^s=-g_{kj}^s$, $\Lambda_{jk}=-\Lambda_{kj}$.

The next set of Jacobi identities $\{\{q_i,p_j\},c\}+\text{cycl}=0$ gives $\Lambda_{ij}\equiv 0$ and

$$f_{ij,s}-g_{ij}^s+V_{,jc}\delta_{si} \tag{4.4}$$

with $V_{,jc}=\partial^2 V/\partial q_i\partial c$. We will treat the equation $\{\{p_i,p_j\},p_k\}+\text{cycl}=0$ later. The last set $\{\{p_i,p_j\},c\}+\text{cycl}=0$ leads to

$$\sum_{r,s=1}^{n}g_{ij,s}^r p_s p_r-\sum_{r=1}^{n}g_{ij}^r V_{,r}+\sum_{r=1}^{n}V_{,ir}f_{rj}+V_{,ic}V_{,j}-\sum_{r=1}^{n}V_{,jr}f_{ri}-V_{,jc}V_{,i}=0. \tag{4.5}$$

By taking the coefficients at linearly independent powers of momenta we get the following conditions:

$$g_{ij,s}^s=0, \tag{4.6}$$

$$g_{ij,s}^r+g_{ij,r}^s=0, \tag{4.7}$$

and

$$\sum_{r=1}^{n}g_{ij}^r V_{,r}-\sum_{r=1}^{n}V_{,ir}f_{rj}-V_{,ic}V_{,j}+\sum_{r=1}^{n}V_{,jr}f_{ri}+V_{,jc}V_{,i}=0. \tag{4.8}$$

The system of equations (4.4)–(4.8) is analogous to the system (3.4)–(3.9), but the procedure of its integration is more complicated. We outline it shortly below.

First, assume $i\neq j$. For $s\neq i$ (4.4) reads $f_{ij,s}-g^s_{ij}=0$. If, moreover, $s\neq j$, we also have $f_{ji,s}-g^s_{ji}=0$. Due to the symmetry of f, $f_{ij}=f_{ji}$, we obtain $g^s_{ij}=g^s_{ji}$, and because g^s_{ij} are antisymmetric in the lower indices we get $g^s_{ij}=0$ for $s\neq i,j$. The equation (4.7) for $r=i$ reads thus $g^i_{ij,s}=0$, $s\neq i,j$, and, by virtue of (4.6), we see that g^i_{ij} is a function of q_j only: $g^i_{ij}=g^i_{ij}(q_j)$. Similarly, $g^j_{ij}=g^j_{ij}(q_i)$. The equation (4.7) for $r=i$, $s=j$ then yields $g^i_{ij,j}=-g^j_{ij,i}=-A_{ij}$ with some constants A_{ij}. By separating variables in this system we integrate it to

$$g^j_{ij}=A_{ij}q_i+b_{ij},\quad g^i_{ij}=-A_{ij}q_j-d_{ij} \tag{4.9}$$

with the integration constants b_{ij} and d_{ij}, and therefore

$$B_{ij}=g^i_{ij}p_i+g^i_{ij}p_j=-(A_{ij}q_j+d_{ij})p_i+(A_{ij}q_i+b_{ij})p_j.$$

Due to the skew-symmetry $g^j_{ij}=-g^j_{ji}$, the equation (4.9) implies $A_{ij}=A_{ji}$ and $b_{ij}=d_{ji}$.

Finally we can calculate f_{ij} (still for $i\neq j$). By (4.4) $f_{ij,s}=g^s_{ij}=0$ and therefore $f_{ij}=f_{ij}(q_i,q_j)$. By using (4.4) and the symmetry of f, we conclude that

$$f_{ij}=A_{ij}q_iq_j+b_{ij}q_j+d_{ij}q_i+c_{ij}$$

with some integration constants $c_{ij}=c_{ji}$.

Let us now turn to the case $i=j$. The equation (4.4) implies that $f_{ii}=f_{ii}(q_i)$ and that $f_{ii,i}+V_{,ic}=0$. By using (4.4) again one can show that $f_{ii}=A_{ij}q_i^2+2b_{ij}q_i+\alpha_i$, which proves that $A_{ij}=A_i$ and that $b_{ij}=b_i$. However, $A_{ij}=A_{ji}$ and so $A_{ij}=A$ for all $i,j=1,...,n$. Moreover, $d_{ij}=b_{ji}$ and so $d_{ij}=d_j=b_j$. To summarize our calculations let us collect the above results:

$$g^s_{ij}=0,\quad s\neq i,j, \tag{4.10}$$

$$g^j_{ij}=Aq_i+b_i,\quad g^i_{ij}=-Aq_j-b_j, \tag{4.11}$$

$$B_{ij}=-(Aq_j+b_j)p_i+(Aq_i+b_i)p_j, \tag{4.12}$$

$$f_{ij}=Aq_iq_j+b_iq_j+b_jq_i+c_{ij}, \tag{4.13}$$

with the constants $A,b_i,c_{ij}=c_{ji}$, $i,j=1,...,n$. Observe also that (4.13) is valid even for $i=j$ with $\alpha_i=c_{ii}$.

Due to (4.13) the equation (4.4) yields now $V_{,ci}=V_{,ic}=-f_{ii,i}=-2(Aq_i+b_i)$ and so

$$V(q,c)=W(q)-c\left(\sum_{i=1}^{n}(Aq_i^2+2b_iq_i)+h\right) \tag{4.14}$$

with $h=\text{const}$.

Up to now we did not use the equations $\{\{p_i,p_j\},p_k\}+\text{cycl}=0$. One can, however, show that by virtue of (4.12) it becomes an identity. As in the case $n=2$ considered in Sec. III one can also check, again by using (4.12) and (4.13), that (4.2) are also satisfied identically and so they do not impose any other restrictions on our solutions (4.10)–(4.13).

Let us now turn to the equation (4.8). Due to (4.10)–(4.13) it reads as

$$\begin{aligned}&(V_{,jj}-V_{,ii})(Aq_iq_j+b_iq_j+b_jq_i+c_{ij})\\&\quad+\sum_{r\neq i,j}(V_{,jr}(Aq_rq_i+b_rq_i+b_iq_r+c_{ri})-V_{,ir}(Aq_rq_j+b_rq_j+b_jq_r+c_{rj}))\\&\quad-V_{,ij}(Aq_j^2-Aq_i^2+2b_jq_j-2b_iq_i+c_{jj}-c_{ii})+3(Aq_i+b_i)V_{,j}-3(Aq_j+b_j)V_{,i}=0.\end{aligned} \tag{4.15}$$

Inserting (4.14) into (4.15) we easily check that the function $W(q)$ satisfies exactly the same equation (4.15) with the same coefficients. This equation has been found previously[13] and serves

as a criterion of separability (in generalized elliptic coordinates or any of its degenerations) of natural Hamiltonian systems generated in the canonical way by $H=\frac{1}{2}\Sigma_{i=1}^{n}p_i^2+W(q)$.

The results of the above derivation shall be formulated as the following theorem.

Theorem 4.1: *Let the antisymmetric operator of the form*

$$\Pi_1=\left[\begin{array}{c|c|c} 0 & f(q) & p^T \\ \hline -f^T(q) & B(q,p) & -V_{,q}^T \\ \hline -p & V_{,q} & 0 \end{array}\right]$$

acting in the $2n+1$*-dimensional phase space with variables* (q,p,c)*, where* $q=(q_1,\ldots,q_n)$*,* $p=(p_1,\ldots,p_n)$*,* $c\in\mathbf{R}$*, with* $n\times n$ *matrices* f *and* B *with entries* $f_{ij}(q)$ *and* $B_{ij}(q,p)$ *respectively, with* $B_{ij}=-B_{ji}$*,* $\det(f)\neq 0$ *and with* $V=V(q,c)$*,* $V_{,q}=(V_{,1},\ldots,V_{,n})$*,* $V_{,i}=\partial V/\partial q_i$*, be a Poisson operator. Then*

(1) Π_1 *must have the form*

$$\left[\begin{array}{c|c|c} 0 & Aq_iq_j+b_iq_j+b_jq_i+c_{ij} & p^T \\ \hline * & (Aq_i+b_i)p_j-(Aq_j+b_j)p_i & -V_{,q}^T \\ \hline -p & V_{,q} & 0 \end{array}\right], \tag{4.16}$$

with constants $A,b_i,c_{ij}=c_{ji}$*,* $i,j=1,\ldots,n$;

(2) $V(q,c)$ *must have the form*

$$V(q,c)=W(q)-c\left(\sum_{i=1}^{n}(Aq_i^2+2b_iq_i)+h\right) \tag{4.17}$$

with $h=$*const where the function* $\mathrm{W}(q)$ *satisfies the separability criterion (4.15) for n-dimensional natural Hamiltonian systems*; and

(3) Π_1 *is compatible with the standard Poisson operator*

$$\left[\begin{array}{cc|c} 0 & I_n & 0 \\ -I_n & 0 & 0 \\ \hline 0 & 0 & 0 \end{array}\right]$$

in the extended phase space of variables (q,p,c).

As in Sec. III, this theorem also yields the following corollary:

Corollary 4.2: The natural n-dimensional Hamiltonian system

$$\frac{d}{dt}\begin{bmatrix} q^T \\ p^T \end{bmatrix}=\begin{bmatrix} 0 & I_n \\ -I_n & 0 \end{bmatrix}\nabla\left(\frac{1}{2}\sum_{i=1}^{n}p_i^2+W(q)\right)$$

with $q=(q_1,\ldots,q_n)$*,* $p=(p_1,\ldots,p_n)$ *and with W(q) satisfying the criterion of separability (4.15) has in the extended* ($2n+1$-dimensional) phase space of variables (q,p,c), $\mathrm{c}\in\mathbf{R}$ *a bi-Hamiltonian formulation of the form*

$$\frac{d}{dt}\begin{bmatrix} q^T \\ p^T \\ c \end{bmatrix}=\left[\begin{array}{cc|c} 0 & I_n & 0 \\ -I_n & 0 & 0 \\ \hline 0 & 0 & 0 \end{array}\right]\nabla\left(\frac{1}{2}\sum_{i=1}^{n}p_i^2+V(q,c)\right)=\Pi_1\nabla c$$

with V(q,c) determined by (4.17) and with Π_1 *as in (4.16).*

It has to be mentioned that the equations (4.15) can also be satisfied by decomposable potentials, that is, potentials of the type $V(\overline{q},\hat{q})=V_1(\overline{q})+V_2(\hat{q})$, where $\overline{q}$ and $\hat{q}$ denote coordinates on subspaces $\mathbf{R}_r^n$ and $\mathbf{R}_s^n$ of $\mathbf{R}^n$, respectively (with $\mathbf{R}^n=\mathbf{R}_r^n\oplus\mathbf{R}_s^n$ being their direct sum), whereas neither of V_i has to be separable on the appropriate subspace. Moreover, the above theorem does not encompass all separable potentials, only those which are indecomposable, for if $V=V(\overline{q},\hat{q})=V_1(\overline{q})+V_2(\hat{q})$ with $\overline{q}=(q_1,\ldots,q_r)$, $\hat{q}=(q_{r+1},\ldots,q_n)$ and if V_1 is separable on the subspace

spanned by the coordinates $\overline{q}$ and V_2 is separable on the subspace spanned by $\hat{q}$, then V has a Hamiltonian structure which does not have the form (4.16), as the example below shows.

Example 4.3: Consider a $(2n+2)$-dimensional phase space of variables $(\overline{q},\hat{q},\overline{p},\hat{p},c,d)$, $\overline{q}=(q_1,\ldots,q_r)$, $\hat{q}=(q_{r+1},\ldots,q_n)$, $\overline{p}=(p_1,\ldots,p_r)$, $\hat{p}=(p_{r+1},\ldots,p_n)$, $c,d\in\mathbf{R}$, with the antisymmetric Poisson operator

$$\left[\begin{array}{cccc|c|c} 0 & 0 & \overline{f}(\overline{q}) & 0 & \overline{p}^T & 0 \\ 0 & 0 & 0 & \hat{f}(\hat{q}) & 0 & \hat{p}^T \\ -\overline{f}(\overline{q}) & 0 & \overline{B}(\overline{q},\overline{p}) & 0 & -V_{,\overline{q}}^T & 0 \\ 0 & -\hat{f}(\hat{q}) & 0 & \hat{B}(\hat{q},\hat{p}) & 0 & -V_{,\hat{q}}^T \\ \hline -\overline{p} & 0 & V_{,\overline{q}} & 0 & 0 & 0 \\ \hline 0 & -\hat{p} & 0 & V_{,\hat{q}} & 0 & 0 \end{array}\right], \tag{4.18}$$

where $\overline{f}=\overline{f}(\overline{q})$ and $\overline{B}=\overline{B}(\overline{q},\overline{p})$ are $r\times r$ matrices with entries $\overline{f}_{ij}(\overline{q})$ and $\overline{B}_{ij}(\overline{q},\overline{p})$, respectively; $\overline{B}_{ij}=-\overline{B}_{ji}$, where $\hat{f}=\hat{f}(\hat{q})$ and $\hat{B}=\hat{B}(\hat{q},\hat{p})$ are $(n-r)\times(n-r)$ matrices with entries $\hat{f}_{ij}(\hat{q})$ and $\hat{B}_{ij}(\hat{q},\hat{p})$, respectively; $\hat{B}_{ij}=-\hat{B}_{ji}$; and where $V=V(\overline{q},\hat{q},c,d)=\overline{V}(\overline{q},c)+\hat{V}(\hat{q},d)$, $V_{,\overline{q}}=(V_{,1},\ldots,V_{,r})$, and $V_{,\hat{q}}=(V_{,r+1},\ldots,V_{,n})$. One can check that the Poisson identities for (4.18) split into two separate classes, one involving only bar variables $\overline{q},\overline{p}$ and the other one involving only hat variables $\hat{q},\hat{p}$, each class leading to the equations of exactly the same form as (4.2)–(4.8). It means that $\overline{f}_{ij}$, $\hat{f}_{ij}$ are both of the form (4.13) (with two different sets of constants) and that both $\overline{B}_{ij}$ and $\hat{B}_{ij}$ are given by (4.12) (again, with two different sets of constants). It also means that both $\overline{V}(\overline{q})$ and $\hat{V}(\hat{q})$ satisfy the separability criterion analogous to (4.15). It is, however, impossible to transform this operator to the form (4.16).

One can also consider decomposable potentials which decompose into more than two independent parts. Such potentials correspond (in the sense described above) to Poisson operators which generalize (4.18) by having more blocks and more than two last columns depending ov V.

V. CASE B—TOWARDS QUASI-LAGRANGIAN SYSTEMS

Let us now consider an antisymmetric operator of the form

$$\left[\begin{array}{cccc|c} 0 & 0 & f_{11} & f_{12} & \mathscr{E}_{,s} \\ 0 & 0 & f_{21} & f_{22} & \mathscr{E}_{,z} \\ -f_{11} & -f_{21} & 0 & F & \mathscr{E}_{,r} \\ -f_{12} & -f_{22} & -F & 0 & \mathscr{E}_{,w} \\ \hline -\mathscr{E}_{,s} & -\mathscr{E}_{,z} & -\mathscr{E}_{,r} & -\mathscr{E}_{,w} & 0 \end{array}\right] \tag{5.1}$$

in the five-dimensional phase space of variables r,w,s,z,d, where $f_{ij}=f_{ij}(r,w)$, $i,j=1,2$, $F=F(r,w,s,z)$, and where

$$\mathscr{E}=\frac{1}{\Delta}(-az^2+bsz-cs^2)-k(r,w,d), \tag{5.2}$$

with $\Delta=b^2-4ac$ and with the polynomials a,b,c given by

$$\begin{aligned} a&=Aw^2+Bw+\alpha_1, \\ b&=-2Arw-Br-Cw+\alpha_2, \\ c&=Ar^2+Cr+\alpha_3 \end{aligned} \tag{5.3}$$

$(A,B,C,\alpha_i=\text{const},\ i=1,2,3)$.

The structures of the above type originate in the framework of the theory of a special type of Newton systems, the so-called quasi-Lagrangian systems. Here we shall present only those fea-

tures of quasi-Lagrangian systems which are relevant for understanding the origins of Poisson operators of type B. A more complete theory of quasi-Lagrangian structures is being developed in a separate paper.[14]

Consider the configuration space of variables r,w and a function on its tangent bundle given by

$$E=ar_{,x}^2+br_{,x}w_{,x}+cw_{,x}^2+k(r,w,d) \tag{5.4}$$

with a,b,c given by (5.3). The *quasi-Lagrangian* equations for E are *defined* as

$$\frac{\partial E}{\partial r}+\frac{d}{dx}\frac{\partial E}{\partial r_{,x}}=0, \quad \frac{\partial E}{\partial w}+\frac{d}{dx}\frac{\partial E}{\partial w_{,x}}=0. \tag{5.5}$$

They differ from the classical Lagrange equations by having a plus sign instead of a minus sign between derivatives. This simple modification leads to equations which do not follow from any variational principle but nonetheless possess many interesting properties which make them worth studying (see Ref. 14). They explicitly read

$$2ar_{,xx}+bw_{,xx}+k_{,r}=0, \quad br_{,xx}+2cw_{,xx}+k_{,w}=0,$$

so they do not have any first-order x derivatives. This is a nontrivial fact, which is a consequence of our special choice of the coefficients a,b,c, in (5.3). If the determinant $\Delta=b^2-4ac$ of the above system is different from zero, then they can be written as a system of Newton equations

$$r_{,xx}=\frac{1}{\Delta}(2ck_{,r}-bk_{,w}), \quad w_{,xx}=\frac{1}{\Delta}(2ak_{,w}-bk_{,r}). \tag{5.6}$$

They usually do not have any Lagrangian formulation, and thus any standard Hamiltonian formulation. However, if we introduce momentum type variables

$$s=\frac{\partial E}{\partial r_{,x}}=2ar_{,x}+bw_{,x}, \quad z=\frac{\partial E}{\partial w_{,x}}=br_{,x}+2cw_{,x}, \tag{5.7}$$

then it can be shown that Eqs. (5.6) in the variables r,w,s,z,d attain the form

$$\frac{d}{dx}\begin{bmatrix} r \\ w \\ s \\ z \\ d \end{bmatrix}=\Theta_0\nabla\mathscr{E}, \tag{5.8}$$

with the symmetric operator Θ_0 given by (2.10) and with $\mathscr{E}$ given exactly by (5.2). The function $\mathscr{E}$ is the Legendre transform of E with the momenta defined by (5.7):

$$\mathscr{E}=sr_{,x}(r,w,s,z)+zw_{,x}(r,w,s,z)-E(r,w,r_{,x}(r,w,s,z),w_{,x}(r,w,s,z),d),$$

where $r_{,x}(r,w,s,z)$ and $w_{,x}(r,w,s,z)$ are obtained by inverting the formulas (5.7), while E itself in terms of variables r,w,s,z,d attains the form

$$E=E(r,w,r_{,x}(r,w,s,z),w_{,x}(r,w,s,z),d)=\frac{1}{\Delta}(-az^2+bsz-cs^2)+k(r,w,d).$$

The function E appears to be an integral of motion for (5.6) and will thus be referred to as *energy* of the system (5.6). The systems of type (5.8) may be called *quasi-gradient* systems, since $\Theta_0\nabla\mathscr{E}=(\mathscr{E}_{,s},\mathscr{E}_{,z},\mathscr{E}_{,r},\mathscr{E}_{,w},0)$ is obtained by permutation of the entries of the four-dimensional gradient $(\mathscr{E}_{,r},\mathscr{E}_{,w},\mathscr{E}_{,s},\mathscr{E}_{,z})$ of $\mathscr{E}$. It is also important to observe that in Example 2.2 the energy E is a Casimir of Π_1, that is, $\Pi_1\nabla E=0$.

Similar to case A, let us require the operator (5.1) to be Poisson. We can now completely determine the structure of this operator if we assume that the energy E, corresponding to $\mathscr{E}$ as described above, is a Casimir function of (5.1) (like in Example 2.2).

Let us start with the Casimir property of E. The requirement $\Pi_1 \nabla E = 0$ immediately leads to two sets of linear homogeneous equations for the functions f_{ij},

$$\begin{aligned} &0=(f_{11}+k_{,d})(-2\gamma)+f_{12}\beta, \quad 0=f_{21}(-2\gamma)+(f_{22}+k_{,d})\beta, \\ &0=(f_{11}+k_{,d})\beta+f_{12}(-2\alpha), \quad 0=f_{21}\beta+(f_{22}+k_{,d})(-2\alpha), \end{aligned} \tag{5.9}$$

where $\alpha=a/\Delta$, $\beta=b/\delta$, $\gamma=c/\Delta$, and, moreover, to

$$F=-2\frac{T_{,r}}{T_{,z}}k_{,d}, \quad F=-2\frac{T_{,w}}{T_{,s}}k_{,d}, \tag{5.10}$$

$$T_{,w}T_{,z}+T_{,s}T_{,r}=0, \tag{5.11}$$

where T is the kinetic energy part of $\mathscr{E}$,

$$T=\frac{1}{\Delta}(-az^2+bsz-cs^2).$$

Since we assume that $\Delta\neq 0$, Eqs. (5.9) have only zero solutions and we immediately get

$$f_{11}=f_{22}=-k_{,d}, \quad f_{12}=f_{21}=0. \tag{5.12}$$

One can also easily see that (5.11) is the condition of compatibility for (5.10) and that it is also satisfied identically due to our choice of a,b,c in (5.3).

Let us now use our main assumption that the operator (5.1) is Poisson. The formula (3.2) (with $\mu=0$ and with new labeling of variables) is still valid and, due to (5.12), it reads

$$\begin{bmatrix} F_{,s} \\ F_{,z} \end{bmatrix} = \frac{1}{k_{,d}} \begin{bmatrix} \{k_{,d},z\} \\ -\{k_{,d},s\} \end{bmatrix}. \tag{5.13}$$

Let us denote $k_{,d}$ by $G=G(r,w)$ [so that $G=-f_{11}=-f_{22}$ by virtue of (5.12)]. Then, due to (5.13), we get

$$F=G_{,r}z-G_{,w}s. \tag{5.14}$$

Furthermore, all Jacobi identities involving the variable d imply the following, heavily overdetermined set of equations,

$$\begin{gathered} 0=G_{,w}\beta+2G\gamma_{,r}, \\ 0=2\alpha G_{,w}+\beta G_{,r}+2\beta_{,r}G, \\ 0=\alpha G_{,r}+\alpha_{,r}G, \\ 0=2\beta_{,w}G+2\gamma G_{,r}+\beta G_{,w}, \\ 0=\gamma_{,w}G+\gamma G_{,w}, \\ 0=2\alpha_{,w}G+\beta G_{,r}, \\ 0=2\gamma G_{,wr}-\beta G_{,ww}-2\gamma_{,r}G_{,w}+\beta_{,w}G_{,w}, \\ 0=\beta G_{,rr}-2\alpha G_{,rw}-G_{,r}\beta_{,r}+2\alpha_{,w}G_{,r}, \\ 0=2\alpha G_{,ww}-2\gamma G_{,rr}+\beta_{,r}G_{,w}+2\gamma_{,r}G_{,r}-2\alpha_{,w}G_{,w}-\beta_{,w}G_{,r}, \end{gathered} \tag{5.15}$$

which is certainly solvable since we have already seen one of its solutions in Example 2.2. Let us solve this system. Observe that the third and the fifth of the above equations are total derivatives

$$(\alpha G)_{,r}=0, \quad (\gamma G)_{,w}=0.$$

So, for $\alpha\neq 0$ and $\gamma\neq 0$, $G(r,w)=\xi(w)/\alpha=\eta(r)/\gamma$ for some functions ξ and η depending only on w and r, respectively. Since $\alpha=a/\Delta$ and $\gamma=c/\Delta$, it means that $\xi(w)=\chi a(w)$ and $\eta(r)=\chi c(r)$ for some constant χ. This yields immediately

$$G(r,w)=\chi\Delta(r,w). \tag{5.16}$$

For $\alpha=0$ or for $\gamma=0$ the above solution remains valid. One can check, through a lengthy calculation, that G given by (5.16) satisfies also all the remaining equations (5.15). Thus, it is in fact their general solution. We conclude that

$$k(r,w,d)=\chi\Delta d+\mathscr{F}(r,w) \tag{5.17}$$

with some arbitrary function $\mathscr{F}$.

One can also check that comparison of the first of the equations in (5.10) with (5.14),

$$F=-2\frac{T_{,r}}{T_{,z}}\,G=G_{,r}z-G_{,w}s,$$

leads exactly to the first three equations of (5.15), while comparison of the second equation in (5.10) with (5.14),

$$F=-2\frac{T_{,w}}{T_{,s}}\,G=G_{,r}z-G_{,w}s,$$

leads to the next three equations of (5.15). This shows that the conditions (5.10) are satisfied automatically whenever k is given by (5.17). Thus we have proved the following theorem.

Theorem 5.1: *Let Π_1 be an antisymmetric operator of the form*

$$\Pi_1=\left[\begin{array}{cccc|c} 0 & 0 & f_{11} & f_{12} & \mathscr{E}_{,s} \\ 0 & 0 & f_{21} & f_{22} & \mathscr{E}_{,z} \\ -f_{11} & -f_{21} & 0 & F & \mathscr{E}_{,r} \\ -f_{12} & -f_{22} & -F & 0 & \mathscr{E}_{,w} \\ \hline -\mathscr{E}_{,s} & -\mathscr{E}_{,z} & -\mathscr{E}_{,r} & -\mathscr{E}_{,w} & 0 \end{array}\right]$$

acting in the five-dimensional phase space of variables r,w,s,z,d, and let

$$\mathscr{E}=\frac{1}{\Delta}\,(-az^2+bsz-cs^2)-k(r,w,d)$$

with $\Delta=b^2-4ac$ and with the polynomials a,b,c given by

$$a=Aw^2+Bw+\alpha_1,$$

$$b=-2Arw-Br-Cw+\alpha_2,$$

$$c=Ar^2+Cr+\alpha_3$$

with some constants A,B,C,α_i, $i=1,2,3$. Further, let $f_{ij}=f_{ij}(r,w)$, $i,j=1,2$ and let $F=F(r,w,s,z)$. If Π_1 is a Poisson operator, and if the energy E associated with $\mathscr{E}$ through $E=(1/\Delta)(-az^2+bsz-cs^2)+k(r,w,d)$ is a Casimir function of Π_1 (i.e., $\Pi_1\nabla E=0$), then we have the following:

(1) *The function k must be of the form* $k(r,w,d)=\chi\Delta d+\mathscr{F}(r,w)$ *with some constant* χ *and with* $\mathscr{F}$ *arbitrary function of r and w.*

(2) *The operator* Π_1 *must have the form*

$$\Pi_1=\left[\begin{array}{cccc|c} 0 & 0 & -\chi\Delta & 0 & \mathscr{E}_{,s} \\ 0 & 0 & 0 & -\chi\Delta & \mathscr{E}_{,z} \\ \chi\Delta & 0 & 0 & F & \mathscr{E}_{,r} \\ 0 & \chi\Delta & -F & 0 & \mathscr{E}_{,w} \\ \hline -\mathscr{E}_{,s} & -\mathscr{E}_{,z} & -\mathscr{E}_{,r} & -\mathscr{E}_{,w} & 0 \end{array}\right]$$

with $F=\chi(\Delta_{,r}z-\Delta_{,w}s)$.

(3) *The system (5.8) also has a Hamiltonian formulation, so that*

$$\frac{d}{dx}\begin{bmatrix} r \\ w \\ s \\ z \\ d \end{bmatrix}=\Theta_0\nabla\mathscr{E}=\Pi_1\nabla d.$$

VI. CONCLUSIONS

In this paper we have shown how relatively general assumptions about a Poisson operator lead either to the class of separable potential Newton equations or to a new class of systems—quasi-Lagrangian systems. In this way we have found a bi-Hamiltonian characterization for all separable potentials in two dimensions and for indecomposable potentials in *n* dimensions. In order to characterize bi-Hamiltonian formulations for decomposable potentials one has to describe all possible ways of splitting $\mathbf{R}^n$ into its subspaces as in the classification scheme of Kalnins and Miller.[8] Since it is technically complex we have chosen to illustrate it with a simple example.

The quasi-Lagrangian family of Newton equations and their Hamiltonian (but not bi-Hamiltonian) formulation is completely new, discovered only very recently, and is currently under investigation. The results will be published in a separate paper,[14] where the question of their complete integrability will be thoroughly discussed.

Stochastic construction of a Feynman path integral representation for Green's functions in radiative transfer

Steven D. Miller[a)]
Johnson Foundation, University of Pennsylvania and University City Science Center, Philadelphia, Pennsylvania 19104

(Received 23 September 1997; accepted for publication 16 June 1998)

A construction of a stochastic, Lagrangian path integral representation is presented for classical Green's functions or propagators for radiative transfer in random scattering medias. As Fermat rays comprising the initial collimated pulse (e.g., from a laser) enter the medium, they evolve into a bundle of random paths or trajectories due to scattering. Stochastically, this can be interpreted as a bundle of randomly evolving Markov trajectories traced out by a gas or ensemble of ''Brownian-type'' classical point photons undergoing multiple scatterings. The path integral is structurally of the same form as a Wick rotated Euclidean quantum Feynman integral with direct optical analogs of the Hamiltonian and Lagrangian emerging. However, the optical stochastic integral is real and is defined in real time becoming exponentially damped rather than oscillatory. The calculation also constitutes an alternative mathematical derivation of the time dependent diffusion equation from the radiative transfer theory. The limits of the path integral representation give a maximally diffused Gaussian distribution of the heat kernal form (the large scatter limit) and a Beer's law exponential decay corresponding to the extremal Fermat rays obeying Euler–Lagrange equations (the zero scatter limit). The approach also highlights the direct structural analogs between classical radiative transfer and optical diffusion in real time (t) and ordinary quantum mechanics in Euclidean time ($\sqrt{(-1)}t=it$).

I. INTRODUCTION

Multiple scattering of light in random medias can be described by the following levels of theoretical description. The macroscopic approach resides in solving an effective hyperbolic diffusion equation, which gives spatiotemporal variations in the scalar diffuse intensity or fluence $\phi(\mathbf{x},t)$ at points $\{\mathbf{x}\}$ at time t, or $\phi(\mathbf{x})$ in the steady state.[1,2] This approach is excellent in the bulk of the medium on length scales much larger than the mean free path l, and when the particles comprising the medium scatter strongly and isotropically with little or no absorption.[1]

The mesoscopic approach[1,3,4] commonly utilized in astrophysics and nuclear engineering, is based on the heuristic radiative transfer theory (RTT). Spatiotemporal variations in optical radiance or intensity $R(\mathbf{x},\mathbf{\Omega},t)$ at points $\mathbf{x}$, from propagation direction $\mathbf{\Omega}$, are described by an integrodifferential balance equation, structurally similar to the Boltzmann equation of kinetic theory. Although the formalism is flexible, the general analytical solutions are unknown even in one dimension; most approaches to the equation are therefore a compromise between computational tractability and accuracy. The macroscopic diffusion approach is recovered in the limit of length scales larger than 1 and when the particles are highly scattered.[1] In both descriptions, we quantify scattering and absorption properties of the medium by the bulk parameters μ_s and μ_a, respectively, which are the scattering probability per unit length and the absorption probability per unit length (in cm^{-1}). The macroscopic approach is recovered from the mesoscopic approach in the diffusion approximation when $\mu_s \gg \mu_a$.

The microscopic or analytical approach begins with Maxwell's equations or the wave equations and the scattering–absorbing properties of individual particles. Differential and integral equations are developed for statistical quantities such as correlation functions and field variances.

This approach has a mathematically rigorous structure and can (in principle) include all possible wave related phenomenology.[1] However, the various theories which can provide solutions are all approximate, being viable only within specific ranges of parameters. The Dyson and Bethe–Salpeter equations and Twersky's theory are examples of this type.[1,5]

Each of these viewpoints essentially represents a qualitative improvement on the previous one. In this paper, we will concentrate on the more pragmatic transport and diffusion approaches where wave properties are ignored, and interpret the classical probabilistic multiple scattering of light as a fundamental stochastic process with Markovian structure. A collimated light pulse (from a laser, for example) is incident at a point on a turbid media. As Fermat rays comprising the pulse enter the medium, they evolve irreversibly into a bundle of random paths or trajectories due to scattering. This can be interpreted as a bundle of Markov chains traced out by a statistical ensemble of Brownian-type classical point photons being randomly scattered and absorbed.

A simple stochastic analysis for the Brownian-type motions of the ensemble of classical Markov photons is then used to construct a stochastic path integral representation for the propagator of the scattered light pulse. Structurally, the path integral representation is of the same form as the Wick rotated Feynman path integral for the quantum amplitude. Recently, interest has also been renewed in stochastic analysis as a means of interpreting quantization and Feynman path sums.[6] However, the stochastic integral representation for the scattered light pulse is exponentially damped and real (describing a probability or Green's function in real time) rather than complex and oscillatory. Optical analogs for the Hamiltonian and Lagrangian are also identified. The path integral itself can be interpreted as a partition function analog for the statistical ensemble of Brownian optical paths. The limit $\mu_s \gg \mu_a$, give a Gaussian (heat) kernal for maximally diffused light. The zero-scattering ($\mu_s \to 0$) limit reduces the integral to a time dependent Beer's law for a collimated pulse. This last point is analogous to the classical limit of quantum mechanics where the classical Euler–Lagrangian path is recovered in the limit as Planck's constant goes to zero. Solutions and interpretations of radiative transfer as a sum over paths have been considered in Refs. 7–11 in connection with some technological applications. However, the path integral representations here were not derived and were presented heuristically. In this paper we derive and justify a path integral representation using a more rigorous stochastic based approach not previously considered. The approach also highlights some direct analogs between classical radiative transfer in real time and ordinary quantum mechanics in Euclidean time.

II. CONSTRUCTION OF A STOCHASTIC FEYNMAN PATH INTEGRAL REPRESENTATION

We begin with the fundamental equation of radiative transfer.[1,3,4] Let $\mathscr{M}$ be a semi-infinite scattering medium and let F be a region of free space with smooth boundary $\partial\mathscr{M} \equiv (\mathscr{M} \cap F)$ at $z=0$, since $\mathbf{x}=(x,y,z)=(x,y,0)$ on the boundary. For a slab, the boundaries are $\partial\mathscr{M}_1 = (\mathscr{M} \cap F)_1$ at $z=0$ and $\partial\mathscr{M}_2 = (\mathscr{M} \cap F)_2$ at $z=d$. At each $\mathbf{x}=(x,y,z) \in \mathscr{M}$, we have homogeneous coefficients $\mu_s(\mathbf{x})=\mu_s$ and $\mu_a(\mathbf{x})=\mu_a$. If a light pulse (e.g., from a laser or fiber) comprised of collimated or Fermat rays $\{\mathscr{R}\}$, is incident normal to $(\mathscr{M} \cap F)$ or $z=0$ at $t_0=0$, the evolving scattered light distribution within $\mathscr{M}$ for $t > t_0 = 0$ is given by the radiative transfer equation,

$$\frac{1}{c}\frac{\partial R(\mathbf{x},\mathbf{\Omega},t)}{\partial t} + [\mathbf{\Omega}.\nabla + (\mu_s+\mu_a)]R(\mathbf{x},\mathbf{\Omega},t) = \left(\frac{\mu_s+\mu_a}{4\pi}\right)\int \mathscr{P}(\mathbf{\Omega}|\mathbf{\Omega}')R(\mathbf{x},\mathbf{\Omega}',t)\,d\mathbf{\Omega}', \quad (1)$$

where $R(\mathbf{x},\mathbf{\Omega},t)$ is the radiance at $\mathbf{x}$ from direction $\mathbf{\Omega}$ at time t, and $\mathbf{x} \in \mathscr{M}$ and $t \in \mathbb{R}$. The differential $d\mathbf{\Omega}'$ is a solid angle with $d\mathbf{\Omega}' \equiv \sin\theta' d\theta' d\phi'$. The function $\mathscr{P}(\mathbf{\Omega}|\mathbf{\Omega}')$ is the phase function or scattering probability for all scatterings $\mathbf{\Omega}' \to \mathbf{\Omega}$,[1] which equals unity for isotropic scatter. In this paper, we will initially consider isotropic scattering. A solution $R(\mathbf{x},\mathbf{\Omega},t)$ can be considered on the basis of initial data. The initial data can be the incident radiance $R(\mathbf{x}_0,\mathbf{\Omega}_0,t_0)=R(z=z_0;\theta_0,\phi_0,t_0)$ at boundary $\mathbf{x}_0=(x_0,y_0,z_0)=(0,0,z_0)=(0,0,0) \in (\mathscr{M} \cap F)_1$ at time t_0, where the unit vector $\mathbf{\Omega}_0$ is normal to the plane $z=z_0$ for the incident pulse and points into the medium along ($\theta_0=\pi/2$). The radiance $R(\mathbf{x},\mathbf{\Omega},t)$ at any point below the initial data point at time $t > t_0$, arises from all possible scattered optical paths that pass through $\mathbf{x}$ at time t in the direction $\mathbf{\Omega}$. We will present an independent derivation of a stochastic path integral representation

for these Brownian-type paths. Given initial data at some point $\mathbf{x}_0=(x_0,y_0,z_0)$, the radiance $R(\mathbf{x},\mathbf{\Omega},t)$ is given by Huygen's principle in terms of the Green's function $G(\mathbf{x},\mathbf{\Omega},t;\mathbf{x}_0,\mathbf{\Omega}_0,t_0)$,

$$R(\mathbf{x},\mathbf{\Omega},t)=\int d^3x\int dt\int d\mathbf{\Omega}G(\mathbf{x},\mathbf{\Omega},t;\mathbf{x}_0,\mathbf{\Omega}_0,t_0)R(\mathbf{x}_0,\mathbf{\Omega}_0,t_0). \tag{2}$$

If we integrate over all scatterings of order n over all paths, then

$$R(\mathbf{x},\mathbf{\Omega},t)=\int\int\int\prod_{n>0} d^3x_n d\mathbf{\Omega}_n dt_n G(\mathbf{x_{n+1}},\mathbf{\Omega}_{n+1},t_{n+1};\mathbf{x_n},\mathbf{\Omega}_n,t_n)R(\mathbf{x_0},\mathbf{\Omega}_0,t_0). \tag{3}$$

This highlights the fundamental Markovian structure of radiative transport within the macroscopic and mesoscopic approaches. The classical Green's function or propagator $G(\mathbf{x}_{n+1},t_{n+1};\mathbf{x}_n,t_n)$ therefore must satisfy a Markov–Kolmogorov evolution equation,[12,13]

$$G(\mathbf{x_{n+1}},t_{n+1};\mathbf{x_{n-1}},t_{n-1})=\int\int d^3x_n dt_n G(\mathbf{x_{n+1}},t_{n+1};\mathbf{x_n},t_n)G(\mathbf{x_n},t_n;\mathbf{x_{n-1}},t_{n-1}), \tag{4}$$

where the angular integral is now absorbed into $\int d^3x$ (we are only concerned with the probability of light arriving at $\mathbf{x}_{n+1}$ at $t=t_{n+1}$, regardless of the direction of its approach). The probability of reaching $\mathbf{x}_{n+1}$ from the nth scattering at $\mathbf{x}_n$, does not depend on the previous history or orientations of the path which brought it to $\mathbf{x}_n$. There is therefore no memory of the past for a given present which defines a Markov process.[12]

The first step of the derivation requires that we consider the Green's function or transition probability $G(\mathbf{x}_{n+1},t_{n+1};\mathbf{x}_n,t_n)$ over an infinitesimally small time interval δt. For convenience we will set $\mathbf{x}'=\mathbf{x}_n$, $t=t_n$, $\mathbf{x}=\mathbf{x}_{n+1}$, and $t_n=t+\delta t$, giving a propagator $G(\mathbf{x},t+\delta t;\mathbf{x}',t)$. The Kolmogorov integral in this infinitesimal limit can be written as

$$G(\mathbf{x},t+\delta t)=\int d^3x' G(\mathbf{x},t+\delta t;\mathbf{x}',t)G(\mathbf{x}',t), \tag{5}$$

where any $G(\mathbf{x},t)$ reduces to $G(\mathbf{x},t;\mathbf{x}_0,t_0)$ when $G(\mathbf{x},t_0)=\delta(\mathbf{x}-\mathbf{x}_0)$. For small δt, the moments of the Markovian Green's function are expandable in powers $(\delta t)^\beta$ for all integer $\beta>0$. We can define a set $\{\mathscr{U}_\beta(x,y,x,t)\}$ or $\{\mathscr{U}_\beta(\mathbf{x},t)\}$ for all $\beta\in Z$ by

$$\mathscr{U}_\beta(\mathbf{x}',t)=\frac{1}{\delta t}\left(\frac{\beta}{\beta!}\right)\int G(\mathbf{x},t+\delta t;\mathbf{x}',t)(\mathbf{x}-\mathbf{x}')^\beta d^3x. \tag{6}$$

For a homogeneous, linear Markov process $G(\mathbf{x},t+\delta t;\mathbf{x}',t)$, the integral on the right over the Green's function or kernel, should be constant for all $\mathbf{x}\in\mathbb{R}^3$ and $t\in\mathbb{R}$. For example, at order $\beta=2$, then $\mathscr{U}_2(\mathbf{x},t)=\mathscr{U}_2=\text{const}$. We will return to this point (and verify it) later. Note also, this definition is strictly valid only in the limit as $\delta t\to 0$ which is true for $\mu_s\gg\mu_a$, the diffusion approximation. The propagator or kernel $G(\mathbf{x},t+\delta t;\mathbf{x}',t)$ is also normalized as

$$\int d^3x G(\mathbf{x},t+\delta t;\mathbf{x}',t)=1. \tag{7}$$

Given any arbitrary smooth real function $\psi(\mathbf{x})$ one can form a Taylor expansion of $\psi(\mathbf{x})$ with respect to $\psi(\mathbf{x}')$,

$$\psi(\mathbf{x})=\psi(\mathbf{x}')+\sum_{\beta=0}^{\infty}\frac{(\mathbf{x}-\mathbf{x}')^\beta}{\beta!}\frac{\partial^{(\beta)}\psi(\mathbf{x}')}{\partial\mathbf{x}^\beta}=\left((\mathbf{x}-\mathbf{x}')\frac{\partial\psi(\mathbf{x}')}{\partial\mathbf{x}}\right)+\left(\frac{(\mathbf{x}-\mathbf{x}')^2}{2}\frac{\partial^2\psi(\mathbf{x}')}{\partial\mathbf{x}^2}\right)+\cdots. \tag{8}$$

An integrodifferential equation for the evolution of the statistical average $\langle\psi(\mathbf{x})\rangle$ can then be derived. Equation (5) is multiplied by $\psi(\mathbf{x}')$ with $\psi(\mathbf{x})$ placed under $\int d^3x'$ and then integrated over d^3x using the right-hand side of Eq. (8). A straightforward calculation using the definition for $\mathscr{U}_\beta(\mathbf{x},t)$ and the propagator normalization (7) gives

$$\langle \psi(\mathbf{x})\rangle_{t+\delta t} = \int d^3x'\, \psi(\mathbf{x}')G(\mathbf{x}',t+\delta t)$$

$$= \int\int \sum_{\beta=1}^{\infty} \frac{(\mathbf{x}-\mathbf{x}')^\beta}{\beta!}\left[\left(\frac{\partial}{\partial \mathbf{x}}\right)^\beta \psi(\mathbf{x}')\right] G(\mathbf{x},t+\delta t;\mathbf{x}',t)G(\mathbf{x}',t)d^3x$$

$$= \langle \psi(\mathbf{x}')\rangle_t + \delta t \sum_{\beta=1}^{\infty} \int d^3x' G(\mathbf{x}',t)\left[\left(\frac{\partial}{\partial \mathbf{x}}\right)^\beta \psi(\mathbf{x}')\right]\left[\frac{1}{\beta}\,\mathscr{U}_\beta(\mathbf{x}',t)\right], \tag{9}$$

where the expectation value or average of $\psi(\mathbf{x})$ at time $t\in\mathbb{R}$ associated with $G(\mathbf{x},t)$ is given by the usual statistical mechanical definition,

$$\langle \psi(\mathbf{x})\rangle_t = \int d^3x\, \psi(\mathbf{x})G(\mathbf{x},t). \tag{10}$$

Given a function $\psi(\mathbf{x})$, the differential equation for the statistical average $\langle \psi(\mathbf{x})\rangle$, in the limit as $\delta t\to 0$ is

$$\lim_{\delta t-\to 0}|\langle \psi(\mathbf{x})\rangle_{t+\delta t} - \langle \psi(\mathbf{x})\rangle_t|/\delta t = \frac{\partial}{\partial t}\langle \psi(\mathbf{x})\rangle = \sum_{\beta=1}^{\infty}\left\langle \frac{1}{\beta}\,\mathscr{U}_\beta(\mathbf{x},t)\left(\frac{\partial}{\partial \mathbf{x}}\right)^\beta \psi(\mathbf{x})\right\rangle$$

$$= \sum_{\beta=1}^{\infty}\left[\int d^3x\left(\frac{1}{\beta}\,\mathscr{U}_\beta(\mathbf{x},t)\left(\frac{\partial}{\partial \mathbf{x}}\right)^\beta \psi(\mathbf{x})\right)G(\mathbf{x},t)\right]$$

$$\equiv -\langle \xi\psi(\mathbf{x})\rangle, \tag{11}$$

where the operator ξ is defined as

$$\xi \equiv -\sum_{\beta=1}^{\infty}\frac{1}{\beta}\,\mathscr{U}_\beta(\mathbf{x},t)(\partial/\partial \mathbf{x})^\beta = \left(\mathscr{U}_1(\mathbf{x},t)\,\frac{\partial}{\partial \mathbf{x}}\right) + \left(\frac{1}{2}\,\mathscr{U}_2(\mathbf{x},t)\,\frac{\partial^2}{\partial \mathbf{x}^2}\right) + \cdots. \tag{12}$$

If we now set $\psi(\mathbf{x})=\mathbf{x}$, $\mathbf{x}^2$, $\mathbf{x}^3$ in (11), where $\mathbf{x}\in\mathscr{R}$, lies on a collimated or Fermat ray $\mathscr{R}$ within medium $\mathscr{M}$, we obtain time dependent fluctuation, dispersion or moments relations. These describe to each order β, the time dependent deviation or dispersion of the incident collimated beam due to scattering, away from the Fermat or straight ray propagation,

$$\partial\langle \mathbf{x}\rangle/\partial t = \langle \mathscr{U}_1\rangle,$$

$$\partial\langle \mathbf{x}^2\rangle/\partial t = \langle \mathbf{x}\mathscr{U}_1\rangle + \langle \mathscr{U}_2\rangle, \tag{13}$$

$$\partial\langle \mathbf{x}^3\rangle/\partial t = \langle \mathbf{x}^2\mathscr{U}_1\rangle + 2\langle \mathbf{x}\mathscr{U}_2\rangle + 2\langle \mathscr{U}_3\rangle,$$

and so on for all integers $\beta\in Z$. Zero dispersion (with time) around $\mathbf{x}\in\mathscr{R}$ at order 2 for example, requires $\langle \mathbf{x}^2\rangle = t\langle \mathbf{x}\mathscr{U}_1\rangle + \langle \mathscr{U}_2\rangle = 0$ or $\mathscr{U}_1=0$ and $\mathscr{U}_2=0$. The $\mathscr{U}_2$ will later be identified as a diffusion coefficient.

If the choice $\psi(\mathbf{x})=\delta(\mathbf{x}-\mathbf{x}')$ is made then $G(\mathbf{x},t)=\langle \delta(\mathbf{x}-\mathbf{x}')\rangle$. If this is now inserted back into Eq. (11), then integrating by parts gives a generic differential equation for $G(\mathbf{x}',t)$ to all orders in β,

$$\frac{\partial G(\mathbf{x}',t)}{\partial t} = \sum_{\beta=1}^{\infty}\frac{(-1)^\beta}{\beta}\left[\frac{\partial}{\partial \mathbf{x}'}\right]^\beta \mathscr{U}_\beta(\mathbf{x}',t)G(\mathbf{x}',t) = -\mathscr{H}G(\mathbf{x}',t), \tag{14}$$

where $\mathscr{H}$ is given by

$$-\mathscr{H} = \sum_{\beta=1}^{\infty}\frac{(-1)^\beta}{\beta}\left[\frac{\partial}{\partial \mathbf{x}'}\right]^\beta \mathscr{U}_\beta(\mathbf{x}',t) \equiv \sum_{\beta=1}^{\infty}\mathscr{H}_\beta. \tag{15}$$

Note that $\mathbf{x}$ and $\mathbf{x}'$ are just equivalent stochastic spatial vector labels. Linear, scalar optical diffusions will emerge from truncation at some β. For now, we keep the calculation defined to all orders in β until we have the final result.

Given any $G(\mathbf{x},t)$ we can define the Fourier transform $\mathscr{F}(\mathbf{x},t)$ at fixed $t\in\mathbb{R}$ and its inverse as

$$\mathscr{F}(\mathbf{c},t)=\langle\exp(i\mathbf{c}\cdot\mathbf{x})\rangle=\int d^3x\ \exp(i\mathbf{c}\cdot\mathbf{x})G(\mathbf{x},t) \tag{16a}$$

$$G(\mathbf{x},t)=\int d^3c\ \exp(-i\mathbf{c}\cdot\mathbf{x})\mathscr{F}(\mathbf{c},t). \tag{16b}$$

The Fourier transform $\mathscr{F}$ then essentially takes all spatial vectors $\{\mathbf{x}(t)\}$ at fixed $t\in\mathbb{R}$ to a conjugate set of variables $\{\mathbf{c}(t)\}$ at the same $t\in\mathbb{R}$. The βth order fluctuations or moments $[\langle\mathbf{x}\rangle]^\beta$ can then be expressed as the βth derivatives of $\mathscr{F}$ since

$$\mathscr{F}(\mathbf{c},t)=\sum_{\beta=1}^{\infty}(i\mathbf{c})^\beta\frac{\langle\mathbf{x}\rangle^\beta}{\beta!}=\left((i\mathbf{c})\langle\mathbf{x}\rangle+(i\mathbf{c})^2\frac{\langle\mathbf{x}\rangle^2}{2}\right)+\cdots. \tag{17}$$

If we expand $\mathscr{F}$ as

$$\langle\exp(i\mathbf{c}\cdot\mathbf{x})\rangle=\exp\left[\sum_{\beta=1}^{\infty}(1/\beta!)(i\mathbf{c})^\beta\mathscr{S}_\beta\right]=\exp\left[i\mathbf{c}\mathscr{S}_1-\frac{1}{2}\mathbf{c}^2\mathscr{S}_2\right], \tag{18}$$

then the $\mathscr{S}(\mathbf{x})$ can be identified within this context as statistical Thiele semi-invariants or ''linked moments.'' [14] For independent stochastic variables $\{\mathbf{e}\}$ and $\{\mathbf{f}\}$ we have the linearity $\mathscr{S}_\beta(\mathbf{e}+\mathbf{f})=\mathscr{S}_\beta(\mathbf{e})+\mathscr{S}_\beta(\mathbf{f})$. We can apply the notation,

$$\mathscr{S}_\beta(\mathbf{x})\equiv\langle\mathbf{x}^\beta{:}\,\text{link}\rangle. \tag{19}$$

To express linked moments (at fixed t) in terms of ordinary moments we expand both sides of (18) so that we obtain intrinsic correlators,

$$\langle\mathbf{x}{:}\,\text{link}\rangle=\langle\mathbf{x}\rangle, \tag{20a}$$

$$\langle\mathbf{x}^2{:}\,\text{link}\rangle=\langle\mathbf{x}^2\rangle-\langle\mathbf{x}\rangle\langle\mathbf{x}\rangle, \tag{20b}$$

$$\langle\mathbf{x}^3{:}\,\text{link}\rangle=\langle[\mathbf{x}-\langle\mathbf{x}\rangle]^3\rangle, \tag{20c}$$

$$\langle\mathbf{x}^4{:}\,\text{link}\rangle=\langle(\mathbf{x}-\langle\mathbf{x}\rangle)^4\rangle-3[\langle(\mathbf{x}-\langle\mathbf{x}\rangle)^2\rangle]^2, \tag{20d}$$

and so on. This already suggests that $\beta=2$ is the maximum order for diffuse light with second order correlations $\mathscr{S}_2(\mathbf{x})=\langle\mathbf{x}^2{:}\,\text{link}\rangle$. We will return to this point. The Fourier transform $\mathscr{F}(\mathbf{c},t)$ can now be written in the compact symbolic form

$$\langle\exp(i\mathbf{c}\cdot\mathbf{x})\rangle=\exp[\langle\exp(i\mathbf{c}\cdot\mathbf{x})-1]\rangle{:}\,\text{link}]. \tag{21}$$

One can then derive a Feynman-type stochastic path integral from these results. The operator $\mathscr{H}$ can be written as

$$-\mathscr{H}=\sum_{\beta=1}^{\infty}\frac{(-1)^\beta}{\beta}\left[\frac{\partial}{\partial\mathbf{x}}\right]^\beta\mathscr{U}_\beta(\mathbf{x},t)=\sum_{\beta=1}^{\infty}\mathscr{H}_\beta. \tag{22}$$

Associated with this operator, we define $\mathscr{H}(\mathbf{c},\mathbf{x},t)$ at fixed t,

$$-\mathscr{H}(\mathbf{c},\mathbf{x},t)=\sum_{\beta=1}^{\infty}[i\mathbf{c}]^\beta\frac{1}{\beta}\mathscr{U}_\beta(\mathbf{x},t), \tag{23}$$

where we have used $\mathbf{c}=i\partial/\partial\mathbf{x}$. This follows from differentiation of the inverse of Fourier transform $\mathscr{F}$ so that $\partial G/\partial\mathbf{x}=-i\mathbf{c}G$. The diffusion coefficients $\mathscr{U}_\beta$ can be expressed as moments strictly in the limit as $\delta t\to 0$,[12]

$$\mathscr{U}_\beta(\mathbf{x},t)=\lim_{\delta t-\to 0}\frac{1}{\delta t}\langle[\mathbf{x}(t+\delta t)-\mathbf{x}(t))]^\beta\rangle \tag{24}$$

or as the linked moments previously defined,

$$\mathscr{U}_\beta(\mathbf{x},t)=\lim_{\delta t-\to 0}\frac{1}{\delta t}\langle[\mathbf{x}(t+\delta t)-\mathbf{x}(t)]^\beta:\text{link}\rangle. \tag{25}$$

If we set $\delta\mathbf{x}\equiv\mathbf{x}(t+\delta t)-\mathbf{x}(t)$, then using (23) we can write the operator $\mathscr{H}$ as

$$-\mathscr{H}(\mathbf{x},\mathbf{c},t)=\frac{1}{\delta t}\langle[\exp(i\mathbf{c}\cdot\delta\mathbf{x})-1]:\text{link}\rangle. \tag{26}$$

The Fourier transform can then be written as

$$\mathscr{F}=\langle\exp(i\mathbf{c}\cdot\delta\mathbf{x})\rangle=\int d[\delta\mathbf{x}]\exp(i\mathbf{c}\cdot\delta\mathbf{x})G(\mathbf{x}+\delta\mathbf{x},t+\delta t;\mathbf{x},t)=\exp[-\mathscr{H}(\mathbf{c},\mathbf{x},t)]. \tag{27}$$

This is correct to order δt. The inverse Fourier transform gives an expression for the transition probability or Green's function,

$$\begin{aligned}G(\mathbf{x}+\delta\mathbf{x},t+\delta t;\mathbf{x},t)&=\int d^3c\ \exp[-i\mathbf{c}\cdot\delta\mathbf{x}-\mathscr{H}(\mathbf{c},\mathbf{x})\,\delta t]\\&=\int d^3c\ \exp\left[-i\,\delta t\left(\mathbf{c}\,\frac{\delta\mathbf{x}}{\delta t}-\mathscr{H}(\mathbf{c},\mathbf{x})\right)\right].\end{aligned} \tag{28}$$

We can see at once that this structure is essentially a ''piece'' of a Feynman path sum[15,16] if we identify $\mathbf{c}$ as a conjugate momentum analog and $\mathscr{H}$ as a Hamiltonian analog. However, let us first consider the truncation order β required to describe noninteracting classical Brownian-type diffusing photon paths. Since light is massless and chargeless there are no interactions or forces between the individual photon paths in any ensemble of paths. The equations describing classical light diffusion away from the Fermat propagation, must then be linear. It is also not possible to apply an exterior field or perturbation that would induce vectorial drift of the paths. We therefore set $\mathscr{U}_1=0$ and $\mathscr{U}_2(\mathbf{x},t)=\mathscr{U}_2=2\mathscr{U}=\text{constant}$, which is Eq. (6) to the second order for a homogeneous, linear Markov process, with all $\mathscr{U}_\beta=0$ for $\beta>2$. Equation (14) is then linear and hyperbolic and describes a free homogeneous, diffusing light distribution due to a Dirac function point source profile,

$$\frac{\partial}{\partial t}G(\mathbf{x},t)=\frac{1}{2}\mathscr{U}_2\left[\frac{\partial}{\partial\mathbf{x}}\right]^2G(\mathbf{x},t)\equiv\frac{1}{2}\mathscr{U}_2\nabla^2G(\mathbf{x},t)=0, \tag{29a}$$

$$\frac{\partial}{\partial t}G(\mathbf{x},t)-\mathscr{U}\nabla^2G(\mathbf{x},t)=0. \tag{29b}$$

This is the free, linear optical diffusion equation. We will briefly return to the kernel solution of this equation and its relation to (6) in Sec. III B. The correlations are second order as defined in (20b). Note that δt is infinitesimal only when $\mu_s\gg\mu_a$ (the diffusion approximation condition) so that this method constitutes an alternative derivation of the time dependent optical diffusion equation from the transfer equation of (1). The ''Hamiltonian'' $\mathscr{H}$ is then quadratic in $\mathbf{c}$ when $\beta=2$. Equation (28) can be substituted into the Markov–Kolmogorov equations in (4) to give

$$\int \prod_{n>0} d^3\mathbf{x_n} \int \prod_{n>0} d^3\mathbf{c_n} \exp\left[-i\int_0^t \delta t\left(\mathbf{c_n}\frac{\delta \mathbf{x_n}}{\delta t}-\mathscr{H}_2\right)\right]$$
$$=\int \mathscr{D}x \int \mathscr{D}c \exp\left[-i\int_0^t \delta t\left(\mathbf{c}\frac{\delta \mathbf{x}}{\delta t}-\mathscr{H}_2\right)\right]. \tag{30}$$

This is a Hamiltonian path integral structure in a ''phase space'' $(\mathbf{x}(t),\mathbf{c}(t))=(x(t),y(t),c_1(t),c_2(t),c_3(t))$ at fixed t. Note that $\delta t=\int \delta t$ with limits t and 0. The result is essentially the same as the Feynman path measure in quantum mechanics for the evolution kernal of a wave function for a particle of mass m (Ref. 15) in phase space $(\mathbf{x}(t),\mathbf{p}(t))$, where the Hamiltonian is $H=p^2/2m$ and the Lagrangian is $L=\frac{1}{2}m(d\mathbf{x}(t)/dt)^3$. From Eq. (22) or (23) to order $\beta=2$ (which is now the lowest order in the absence of drift) and $\frac{1}{2}\mathscr{U}_2=\mathscr{U}=$constant, the quadratic Hamiltonian analog is

$$\mathscr{H}(\mathbf{c},t)\equiv\mathscr{H}=\tfrac{1}{2}|\mathbf{c}(t)|^2(\mathscr{U}_2)^2\equiv c^2\mathscr{U}_2. \tag{31}$$

The ''conjugate momentum'' $\mathbf{c}(t)$ is identified in the optical diffusion description with the speed of light in the medium and is a constant so that $d\mathbf{c}(t)/dt=0$ for elastic scattering. However we do not fix $|\mathbf{c}(t)|=c=$const. or perform a functional analytical continuation until the functional integrals over all d^3c_n are performed. We first perform a functional analytic continuation $(i\to 1)$ to get a viable classical (real) integral in Lagrangian form in real time, since the effect of the Fourier transform was to introduce Euclidean time $(i\,\delta t)$. The stochastic evolution of the bundle of random optical (Markov) paths due to scattering, has a real Feynman path measure representation in $(1+3)$ Minkowski space,

$$G(\mathbf{x},t;\mathbf{x}',0)=\int \prod_{n=0} d^3x_n \exp\left(-\int_0^t \mathscr{L}dt'\right)\equiv\int \prod_{n>0} d^3x_n \exp[-S(\mathbf{x}(t))]=\int \mathscr{D}x \exp[-S], \tag{32}$$

where the ''momentum'' integral $\int d^3c$ is performed to yield the Lagrangian form with the action $S(\mathbf{x}(t))=\int \mathscr{L}dt$. The analytically continued integral is exponentially damped rather than oscillatory which ensures the correct attenuative optical decay into the random medium. We can therefore identify the following direct analogies or dualities between classical scalar optical diffusion or radiative transfer and ordinary quantum mechanics,

i	1
it	t
$\mathbf{p}$	$\mathbf{c}$
$1/2m$	$\mathscr{U}$
$H=p^2/2m$	$\mathscr{H}_2=c^2\mathscr{U}=\mathscr{H}$
$L=\frac{1}{2}m[d\mathbf{x}(t)/dt]^2$	$\mathscr{L}=(1/4\mathscr{U})[d\mathbf{x}(t)/dt]^2$.

Given the standard Feynman path integral for quantum mechanics, these substitutions will recover the classical physics of radiative transfer and optical diffusion theory.

III. LIMITS OF THE OPTICAL PATH INTEGRAL

In this section we consider the limits of the integral as (1) $\mu_s\to 0$ or $n=0$ and (2) $n\to\infty$ (or $\mu_s\gg\mu_a$).

A. Zero scattering limit: $\mu_s\to 0$ or $n=0$

We consider the limit as scattering vanishes. Consider the action $S[\mathbf{x}'(t)]$ at t, where $\mathbf{x}'\in\mathscr{R}$ and where $\mathscr{R}$ is an interior Fermat ray such that $\mathbf{x}$ does not lie on the Fermat ray. The Taylor expansion of $S[\mathbf{x}]$ with respect to $S[\mathbf{x}']$ as in (8) is

$$S[\mathbf{x}]=S[\mathbf{x}']+\delta\mathbf{x}\partial_{\mathbf{x}}S[\mathbf{x}']+\tfrac{1}{2}\delta\mathbf{x}\delta\mathbf{x}\partial_{\mathbf{x}}\partial_{\mathbf{x}}S[\mathbf{x}']+\tfrac{1}{6}\delta\mathbf{x}\delta\mathbf{x}\delta\mathbf{x}\partial_{\mathbf{x}}\partial_{\mathbf{x}}\partial_{\mathbf{x}}S[\mathbf{x}']+\cdots. \tag{33}$$

Cubic and higher order terms ($\beta>2$) would correspond to classical photon–photon interactions or forces which do not exist. However we require $\partial S[\mathbf{x}']/\partial\mathbf{x}=0$ since points $\{\mathbf{x}'\}$ on the Fermat rays $\mathscr{R}$ are critical points for the action. Again, this is consistent with setting $\mathscr{U}_1=0$ and $\mathscr{U}_\beta=0$ for all $\beta>2$. There is a ''classical limit'' analog as $\mu_s\to 0$, and the diffuse light pulse reduces to a collimated pulse as the Brownian paths collapse to the minimum (extremal) path of Fermat propagation between two points.

The Euler–Lagrange equations here simply state that Fermat ray propagation within the medium in the absense of scattering is an extrema (that is, the speed of light is a constant). The Euler Lagrange equations with $\mathscr{L}=(1/4\mathscr{U})(d\mathbf{x}/dt)^2$ are

$$\frac{d}{dt}\left(\frac{\partial\mathscr{L}}{\partial\mathbf{x}}\right)=\frac{1}{4\mathscr{U}}\left(\frac{d^2\mathbf{x}(t)}{dt^2}\right)=\frac{\partial\mathscr{L}}{\partial\mathbf{x}}=0 \tag{34}$$

so that const.$=2\mathscr{U}\mathbf{c}(t)$ and $|\mathbf{c}(t)|=c$ is the speed of light in a medium requiring $d\mathbf{c}(t)/dt=0$. The distribution of paths must collapse to the single Fermat path $\mathscr{R}$. In the limit as $\mu_s\to 0$ with no Brownian scatter paths (paths with $n>0$) connecting any fixed points $\mathbf{x}'$ and $\mathbf{x}$ for $n=0$,

$$G(\mathbf{x},t;\mathbf{x}',0)=\exp\left[-\int_0^t dt(2\mathscr{U})^{-1}\left(\frac{d\mathbf{x}(t)}{dt}\right)^2\right]=\exp\left[-\int_0^t dt(2\mathscr{U})^{-1}c\left(\frac{d\mathbf{x}(t)}{dt}\right)\right], \tag{35}$$

where $\mathbf{x}$ now lies on a straight line from $\mathbf{x}'$. Since $(d\mathbf{x}(t)/dt)=\mathbf{c}$ and the arc length $(d\mathbf{x}(t)/dt)^2dt^2$ is now a line segment of a straight Fermat geodesic, the integral is trivial and gives

$$G(\mathbf{x},t;\mathbf{x}',0)=\exp[-(2\mathscr{U})^{-1}c|\mathbf{x}-\mathbf{x}'|) \tag{36}$$

since $t=|\mathbf{x}-\mathbf{x}'|/c$ or $dt=dx/c$. The homogeneous diffusion constant $\mathscr{U}$ in this formalism is related to the usual diffusion constant definition $\mathscr{D}$ by a factor of $\frac{2}{3}$ so that $\mathscr{U}=3\mathscr{D}/2$, where $\mathscr{D}=c[3(\mu_a+\mu_s)]^{-1}$ is the form given in the literature as Refs. 2, 17, 18. Since $\mathscr{D}$ and $\mathscr{U}$ are constants, they are simply rescaled by a factor of $\frac{3}{2}$ to make both formalisms match, hence $(3/2\mathscr{U})c=(\mu_s+\mu_a)$. With hindsight, one can always redefine (6) to within this factor.

It is important to note the time dependence is now removed from the coherent Green's function in (36). Since the two points $\mathbf{x}'$ and $\mathbf{x}$ are fixed, all Fermat rays $\mathscr{R}$ propagate from $\mathbf{x}'$ to $\mathbf{x}$ at the *same* time. The probability is then simply $G(\mathbf{x};\mathbf{x}')$ for all Fermat rays $\mathscr{R}$ in a coherent or collimated pulse. It is only when the Fermat rays scatter and evolve into random Brownian-type trajectories that there exist probabilities $\{G(\mathbf{x},t)\}$ for the random paths to arrive at $\mathbf{x}$ in different times t, having started from the same $\mathbf{x}'$. However, the coherent intensity at $\mathbf{x}$ varies in time with the source. For example, if the source intensity at $\mathbf{x}'$ has the profile $I_0(t)$ then the intensity of unscattered light at $\mathbf{x}$ is simply

$$I(\mathbf{x},t+|\mathbf{x}-\mathbf{x}'|/c)=G(\mathbf{x},\mathbf{x}')I_0(t)=I_0(t)\exp[-\mu_a|\mathbf{x}-\mathbf{x}'|], \tag{37}$$

which is Beer's law with time dependence. The effect of the phase function $\mathscr{P}(\mathbf{\Omega}|\mathbf{\Omega}')$ is built into the (unknown) kernel $G(\mathbf{x},t;\mathbf{x}',t')$. The anisotropy is $g=\langle\cos\theta\rangle=\int\int\cos\theta\mathscr{P}(\theta|\theta')d\theta d\varphi$, the average of the azimuthal scatter angle θ (the polar angle is φ). In the standard diffusion approximation,[1] $g=0$ or g is small (i.e., $g>0$ but $g\ll 1$) and $\mathscr{P}=1$. Via the similarity relation,[1,4,17] an anisotropic scattering medium with nonzero anisotropy factor $g\in[0,1]$ and scatter coefficient μ_s', is equivalent to an isotropic scattering medium with $g=0$ and the scatter coefficient μ_s such that $\mu_s=\mu_s'(1-g)$. The diffusion coefficient becomes $(3/2\mathscr{U})c=[\mu_a+\mu_s(1-g)]$. Therefore, increasing $g\to 1$ for an anisotropic medium, has the same effect as reducing μ_s to zero for an isotropic medium. The distribution of scattered light paths between two points $(\mathbf{x},\mathbf{x}')$ becomes more ellipsoidal and collapses back to the Fermat straight line connecting the points, as $g\to 1$. This is again described by Eq. (36).

B. Large scatter limit: $n\gg 0$ or $\mu_s\gg\mu_a$

When $n\to\infty$ (or becomes large) one can perform the path integral using Gaussian integrals as is done in ordinary quantum mechanics.[16] We have $\int\Pi_n d^3x\to\int\mathscr{D}x$ for large n, where $\mathscr{D}x$ is the path measure. Very few functional path integrals can be performed, but free linear systems gen-

erally have a Gaussian representation. The solution is the well known homogeneous, heat kernal form which describes free linear diffusion of light out from a point source or impulse,

$$G(\mathbf{x},t;\mathbf{x}',0)=(4\pi\mathscr{U}t)^{-1/2}\exp[-(\mathbf{x}-\mathbf{x}')^2(4\mathscr{U}t)^{-1}], \tag{38}$$

which automatically satisfies the linear, optical diffusion equation (29) with $\langle(\mathbf{x}-\mathbf{x}')(\mathbf{x}-\mathbf{x}')\rangle = \mathscr{U}_2 t \equiv 2\mathscr{U}t$. The transformations $it\leftrightarrow t$ and $\mathscr{U}\leftrightarrow 1/2m$ give the free particle wave function of quantum theory which has the same Gaussian form. As a final check on the consistency of the description, we substitute the Markovian kernel (38) into Eq. (6) at second order ($\beta=2$), and integrate over the semi-infinite region $[0,\infty)$. We should then find that $\mathscr{U}_2(\mathbf{x},t)=\mathscr{U}_2=\mathscr{U}$ for all $\mathbf{x}\in\mathscr{M}$ and $t\in\mathbb{R}$,

$$\begin{aligned}\mathscr{U}_2(\mathbf{x}',t)&=\frac{1}{2t}\int G(\mathbf{x},t+\delta t;\mathbf{x}',t)(\mathbf{x}-\mathbf{x}')^2 d\mathbf{x}\\ &=\frac{1}{t}\frac{1}{(4\pi\mathscr{U}t)^{1/2}}\int_0^\infty(\mathbf{x}-\mathbf{x}')^2\exp[-(4\mathscr{U}t)^{-1}(\mathbf{x}-\mathbf{x}')^2]d\mathbf{x},\end{aligned} \tag{39}$$

where we have set $t=0$. The right-hand side is simply a standard Gaussian integral,

$$\int_0^\infty v^2\exp[-av^2]dv=\frac{1}{4}\left(\frac{\pi}{a^3}\right)^{1/2} \tag{40}$$

with $a=(4\mathscr{U}t)^{-1}$ and $v=(\mathbf{x}-\mathbf{x}')$ and $dv=d\mathbf{x}$. Hence,

$$\mathscr{U}_2(\mathbf{x}',t)=\left(\frac{1}{(t^{3/2})(4)^{1/2}(\pi)^{1/2}(\mathscr{U})^{1/2}}\right)\left(\frac{(\pi)^{1/2}(4)^{3/2}(\mathscr{U})^{3/2}t^{3/2}}{4}\right)=\mathscr{U} \tag{41}$$

as required.

IV. CONCLUDING REMARKS

Beginning with the transfer equation, we have presented a simple stochastic derivation and interpretation of the scalar optical diffusion equation and a path integral representation of the Green's function or propagator of radiative transfer. Although optical path integral representations for radiative transfer have been presented heuristically in the literature, this approach and interpretation has not previously been considered, and justifies their use from a more rigorous and fundamental viewpoint. A direct duality can also be made with classical radiative transfer in real time and ordinary quantum theory in Euclidean time.

(Received 25 February 1998; accepted for publication 25 May 1998)

We propose a new criterion to analyze the order of phase transitions within a finite size scaling analysis. It refers to response functions like order parameter susceptibilities and the specific heat and states different monotony behavior in volume for first- and second-order transitions close to the transition point. The criterion applies to analytical and numerical studies of phase diagrams including tricritical behavior.

I. INTRODUCTION

Finite size scaling analysis is particularly useful in numerical simulations to distinguish first- from second-order phase transitions by their different onset in a large but finite volume. Usually it is the specific scaling behavior of the peak in a susceptibility, the shift in the critical coupling/temperature, and the width of the critical region that anticipates the nature of the transition in the thermodynamic limit.[1–4] In this letter we formulate a new criterion in a finite volume to distinguish first- from second-order phase transitions. For a certain interval of the scaling region response functions with a nonanalytic behavior in the infinite volume limit show different monotony behavior for first- and second-order transitions. Examples for such functions are the specific heat and order parameter susceptibilities. They are increasing in volume in a certain neighborhood of T_c for second-order transitions, and decreasing for first-order transitions for some range in the scaling region, which will be specified below.

For definiteness we fix the notation in terms of an order parameter susceptibility $\chi(T,L)$, considered as a function of the temperature T and the spatial size parameter L, so that a symmetric D-dimensional volume is of size L^D. By $T_c(L)$ we denote the location of the maximum of $\chi(\cdot,L)$ in volume L^D associated with the phase transition at $T_c \equiv T_c(\infty)$. In the infinite volume

$$\chi(t+T_c(\infty),L=\infty)<\infty \quad \text{as} \quad t\to 0 \tag{1}$$

for a first-order transition at T_c, with a possible discontinuity at $t=0$ in the associated order parameter, with t denoting the scaling field $t=(T-T_c(L))/T_c(L)$, whereas

$$\chi(t+T_c(\infty),L=\infty)\simeq \mathscr{A}|t|^{-\gamma} \quad \text{as} \quad t\to 0 \tag{2}$$

for a second-order transition with critical exponent $\gamma>0$. On the other hand, in the opposite order of limits, $\chi(T_c(L),L)$ diverges in both cases as L approaches infinity. Stated differently, at $T_c(L)$, in the limit $L\to\infty$ χ has a δ-function singularity or a power law type of singularity for a first- or second-order transition, respectively. It is this difference that is responsible for the different monotony properties for $t\neq 0$ in the finite volume.

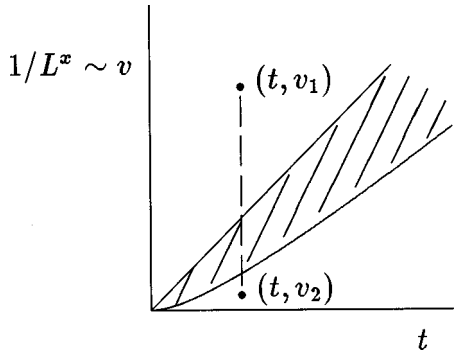

FIG. 1. (t,v) plane in the vicinity of a phase transition at $t=v=0$. t denotes the scaling field $t=(T-T_c(L))/T_c(L)$, v is inverse to some power of the volume L^x with $x>0$. Let us consider the susceptibility as a function of t and v. Then, for a first-order transition, $\chi(t,v_1)>\chi(t,v_2)$, whereas for a second-order transition $\chi(t,v_1)<\chi(t,v_2)$. The shaded part is the crossover region between different asymptotic behavior as $(t,v)\to 0$.

The essential statement of the monotony criterion is the following (details will be given below): For a sufficiently large size $L_s<\infty$, there is always a size L_l with $L_l>L_s$ and such that (cf. Fig. 1)

$$\chi(\delta+T_c(L),L\geqslant L_l)<\chi(\delta+T_c(L_s),L_s) \quad \text{for first order,} \tag{3}$$

$$\chi(\delta+T_c(L),L\geqslant L_l)>\chi(\delta+T_c(L_s),L_s) \quad \text{for second order,} \tag{4}$$

that is, $\chi(\delta+T_c(L),L)$ is decreasing or increasing in volume for a first- or second-order phase transition, respectively. The susceptibility is measured at fixed distance δ to the volume dependent maximum, constrained by

$$c_1\sigma(L)^{1/(1+\epsilon)}<|\delta|<c_2\sigma(L_s). \tag{5}$$

Here $\sigma(L)=L^{-D}$ or $\sigma(L)=L^{-1/\nu}$ for first- or second-order transition, respectively, with ν being the critical exponent of the correlation length, $\xi\sim|T-T_c|^{-\nu}$ as $T\to T_c$. Hence $\sigma(L)$ is the width of the critical region in the volume L^D, c_1, c_2, and ϵ are positive constants, typically $\epsilon=1$. Beyond the general constraint that both linear sizes L_s and L_l have to be sufficiently large, in addition L_l has to be sufficiently larger than L_s, so that $\sigma(L_l)$ is considerably smaller than $\sigma(L_s)$. The monotony behavior of χ does *not* refer to values of L_l close to L_s. In terms of Fig. 1, L_s and L_l are separated by the shaded area, for which we do not make any predictions on the behavior of χ.

In Sec. II we make these statements more precise. We specify the conditions under which the criterion holds and give the proof. As it turns out, the criterion applies whenever the standard conjectures on finite size scaling behavior hold. Rigorous proofs of these standard conjectures are missing in general, and we do not attempt to give such proofs in the treatment below. In Sec. III we conclude with some remarks on testing the criterion in analytical and numerical calculations.

II. STATEMENTS OF THE CRITERION

Let t denote the scaling field, i.e., $t=(T-T_c(L))/T_c(L)$. $T_c(L)$ locates the maximum of the susceptibility in the volume L^D. Furthermore we set $v=L^{-m}$ with some $m>0$. The infinite volume limit is obtained as $v\to 0$ from above.

The transition region is given by small t and v. Let

$$H^2:=\{(t,v)\in\mathbf{R}^2|v\geqslant 0\} \tag{6}$$

denote a half plane, $\mathcal{U}\subseteq H^2$ the intersection of an open neighborhood of $0\in\mathbf{R}^2$ with H^2 and $\mathcal{U}^*=\mathcal{U}\setminus\{0\}$.

A. First-order transitions

The typical behavior of a susceptibility close to a first-order transition is summarized by the following definition (with $v=L^{-D}$). As usual, $C(\mathscr{U}^*)$ denotes the set of real valued continuous functions in $\mathscr{U}^*$.

Definition 1: Let $\omega>0$. $\Psi_1^\omega(\mathscr{U})$ *is the set of functions* $\chi\in C(\mathscr{U}^*)$ *with the following properties.*

(1) $\chi\in C^1(\mathscr{U}^*\setminus\{(\mathbf{R},0)\})$, *that is,* χ *is continuously differentiable for* $v\neq 0$.

(2) There exists $\nu(t)>0$ *such that for all* $v<|t|/\nu(t)$

$$|\chi(t,v)|\leqslant\omega.$$

(3) With appropriate positive constants c, K_1, K_2 *and* ϵ *we have in* $\mathscr{U}^*$ *for* $v\neq 0$

$$\left|\chi(0,v)-\frac{c}{v}\right|<\frac{K_1}{v^{1-\epsilon}},$$

$$\left|\frac{\partial}{\partial t}\,\chi(t,v)\right|<\frac{K_2}{v^2}.$$

It follows already from this definition that $\nu(t)$ is bounded from below by some positive constant. This is part of the following proposition. The main statement is the monotony behavior of a function that obeys Definition 1.

Proposition 1: Let $\omega>0$, $\chi\in\Psi_1^\omega(\mathscr{U})$. *There exist positive* δ, ϵ *such that the following statements hold.*

(1) For all t *with* $|t|<\epsilon\delta$,

$$\nu(t)>\epsilon. \tag{7}$$

(2) For all (t,v), $(t,w)\in\mathscr{U}^*$ *with* $\nu(t)w<|t|<\epsilon v$ *and* $v<\delta$, *we have* $w<v$ *and*

$$\chi(t,v)>|\chi(t,w)|. \tag{8}$$

The proposition includes the case $w=0$ of infinite volume. In this case, in the critical region $|t|/v<\epsilon$, the susceptibility χ is always larger in the finite volume than in the infinite one.

Proof: Let $\chi\in\Psi_1^\omega(\mathscr{U})$, $\omega>0$.

(α) There are ϵ, $\delta>0$ such that for all t, v with $v<\delta$, $|t|<\epsilon v$

$$\chi(t,v)\geqslant 2\omega. \tag{9}$$

For

$$\chi(t,v)=\chi(0,v)+t\int_0^1 ds\,\frac{\partial}{\partial\eta}\,\chi(\eta,v)\bigg|_{\eta=st},$$

and there are c_0, $K>0$ so that

$$\chi(0,v)>\frac{c_0}{v},$$

$$\left|\frac{\partial}{\partial\eta}\,\chi(\eta,v)\right|<\frac{K}{v^2}$$

in $\mathscr{U}^*$. Hence, with $\epsilon=c_0/(2K)$,

$$\chi(t,v) \geqslant \frac{c_0}{v} - \frac{|t|K}{v^2} > \frac{c_0 - \epsilon K}{v} = \frac{c_0}{2v}.$$

Choosing $\delta = c_0/(4\omega)$, we get for $v < \delta$ the lower bound (9) on $\chi(t,v)$.

(β) By definition of $\nu(t)$, we have whenever $\nu(t)w < |t|$ the upper bound

$$|\chi(t,w)| \leqslant \omega. \tag{10}$$

(γ) Summarizing α and β, it follows that for all w, v with $\nu(t)w < |t| < \epsilon v$, $v < \delta$, the strict bound

$$|\chi(t,w)| < \chi(t,v)$$

holds. Furthermore, (10) implies that $|\chi(t,w')| \leqslant \omega$ for all $0 \leqslant w' \leqslant w$. Hence it must hold that $w < v$. It follows that

$$\frac{|t|}{\nu(t)} \leqslant \frac{|t|}{\epsilon}$$

and hence $\nu(t) > \epsilon$ for $|t| < \epsilon\delta$. □

The remainder of this section is devoted to the function class $\Psi_1^{\omega}(\mathscr{U})$. As an example of such a function we consider the following typical representation of the magnetic susceptibility in the volume L^D close to a first-order phase transition:

$$\chi_2(T,L) = c_2 L^D \exp(-f_2 L^{2D}(T - T_c(L))^2) + \eta_2(T,L). \tag{11}$$

Here c_2, f_2 are positive real constants and $\eta_2(\cdot,L)$ is analytic for $L < \infty$, locally uniformly convergent as $L \nearrow \infty$ [so that $\eta_2(\cdot,\infty)$ is analytic]. Furthermore, $T_c(L) = T_c - d_2 L^{-m} + o(L^{-m})$, with $m \geqslant 0$.

We can view χ_2 as a function of some Ψ_1^{ω} in essentially two ways. The first one corresponds to the point of view given in Sec. I, in which the scaling field t measures the distance of the temperature T to the volume dependent location of the peak $T_c(L)$. It does not refer to a particular volume dependence of $T_c(L)$ itself. That is, m does not need further specification except that $m \geqslant 0$.

We set $v = L^{-D}$, $t = (T - T_c(L))/T_c(L)$, and

$$\chi(t,v) = \chi_2(T,L) = c v^{-1} \exp(-f(v) v^{-2} t^2) + \eta(t,v), \tag{12}$$

where $\eta(t,v) \equiv \eta_2(T,L)$ and $f(v) = f_2 T_c(L)^2$, $c = c_2$.

Lemma 1: $\chi \in \Psi_1^{\omega}(\mathscr{U})$ *for some* $\omega > 0$ *and sufficiently small* $\mathscr{U}$. $\nu(t)$ of *Definition 1 satisfies* $\nu(t)^{-1} \to 0$ *as* $|t| \to 0$.

Proof: For α, $\beta > 0$ and $x \in \mathbf{R}$ the function

$$f_{\alpha,\beta}(x) = x^{\alpha} \exp(-\beta x^2)$$

attains its maximum at $x^2 = \alpha/(2\beta)$, is positive and monotone decreasing for $x > (\alpha/(2\beta))^{1/2}$, and satisfies on $\mathbf{R}$ the bound

$$|f_{\alpha,\beta}(x)| \leqslant \left(\frac{\alpha}{2\beta e}\right)^{\alpha/2}.$$

We prove that $\chi(t,v)$ match the criteria of Definition 1 to belong to some $\Psi_1^{\omega}(\mathscr{U})$. There is $\delta > 0$ such that for all $v < \delta$ we have $\hat{f} \leqslant f(v) \leqslant \bar{f}$ for some $\hat{f}, \bar{f} > 0$. We choose $\mathscr{U}$ such that $(t,v) \in \mathscr{U}$ implies that $v < \delta$ and $|t| < \hat{f}^{1/2}$ and put

$$K_{\eta} = \max_{(t,v) \in \mathscr{U}} (|\eta(t,v)|, |\partial_t \eta(t,v)|).$$

Condition (1) is obviously satisfied. To show condition (2) we notice that for

$$\frac{|t|}{v} > \nu(t) > \left(\frac{1}{2\hat{f}}\right)^{1/2}$$

one obtains

$$|\chi(t,v)| < \left|\frac{c}{|t|}\frac{|t|}{v}\exp\left(-f(v)\left(\frac{|t|}{v}\right)^2\right)+\eta\right| \leqslant c\,\frac{\nu(t)}{|t|}\exp(-f(v)\nu(t)^2)+|\eta|.$$

We choose $\nu(t)=|t|^{-1}$ and obtain with $\omega = c/(\hat{f}e)+K_\eta$,

$$|\chi(t,v)| \leqslant \omega.$$

To verify the third condition, we compute

$$|\chi(0,v)-cv^{-1}| = |\eta(t,v)| \leqslant K_\eta,$$

and notice that there is $K>0$ such that

$$\left|\frac{\partial}{\partial t}\chi(t,v)\right| \leqslant \frac{2|t|}{v^2}f|\chi| + |\partial_t\eta(t,v)| \leqslant \frac{2\overline{f}}{v^2}\left[c\left(\frac{1}{2\hat{f}e}\right)^{1/2}+\hat{f}^{1/2}K_\eta\right]+K_\eta \leqslant \frac{K}{v^2}.$$

Hence, $\chi \in \Psi_1^\omega(\mathscr{U})$. □

The next lemma states that the susceptibility χ_2 matches the criteria of Definition 1 also if the scaling field t measures the distance of T from the phase transition point, i.e., to $T_c(L=\infty)$. The only additional constraint then is that the peak $T_c(L)$ of χ_2 converges sufficiently fast to $T_c(\infty)$, namely that

$$|T_c(L)-T_c(\infty)| \leqslant \frac{c}{L^m} \quad \text{with} \quad m \geqslant D. \tag{13}$$

We set $v=L^{-D}$, $t=(T-T_c(\infty))/T_c(\infty)$, and

$$\chi(t,v)=\chi_2(T,L)=cv^{-1}\exp(-fv^{-2}(t+dv^n)^2)+\eta(t,v), \tag{14}$$

where now $\eta(t,v)\equiv\eta_2(T,L)$ and $f=f_2T_c(\infty)^2$, $d=d_2/T_c(\infty)$, and $n=m/D$. Similar to the above, we get

Lemma 2: Let $n \geqslant 1$. *Then* $\chi \in \Psi_1^\omega(\mathscr{U})$ *for some* $\omega>0$ *and sufficiently small* $\mathscr{U}$. $\nu(t)$ *of Definition 1 satisfies* $\nu(t)^{-1}\to 0$ *as* $|t|\to 0$.

Proof: For a, b, $\epsilon \in \mathbf{R}$, $\epsilon \neq 0$,

$$(a+b)^2 \geqslant a^2\left(1-\frac{1}{\epsilon^2}\right)+b^2(1-\epsilon^2).$$

We choose δ, $\eta>0$ sufficiently small such that the following estimates on χ are true for all t, v with $|t|<\eta$, $0<v<\delta$, identifying $\mathscr{U}$.

χ obviously satisfies condition (1) of Definition 1. To show condition (2) we estimate

$$|\chi(t,v)| \leqslant cv^{-1}\exp(-fv^{-2}(\tfrac{1}{2}t^2-(dv^n)^2))+|\eta| \leqslant 2cv^{-1}\exp\left(-\frac{f}{2}v^{-2}t^2\right)+|\eta|. \tag{15}$$

Proceeding as in the proof of the previous lemma we obtain condition (2), with appropriate ω. To realize the third condition, we first notice that

$$|\chi(0,v)-cv^{-1}| \leqslant cv^{-1}|e^{-fd^2v^{2(n-1)}}-1|+|\eta| \leqslant \frac{K}{v^{1-\epsilon}}$$

for some positive constant K, with $\epsilon=\min(1,2(n-1)) \geqslant 0$. Finally there is $K'>0$ such that

$$\left|\frac{\partial}{\partial t}\chi(t,v)\right| = 2fv^{-2}|t+dv^n||\chi| + |\partial_t\eta(t,v)| \leqslant 2fcv^{-2}\left(\frac{1}{2fe}\right)^{1/2}\cdot 2 = \frac{K'}{v^2}. \tag{16}$$

Hence $\chi \in \Psi_1^{\omega}(\mathscr{U})$. □

Finally, we state without proof that every function $\chi: \mathscr{U}^* \to \mathbf{R}$ of the form

$$\chi(t,v) = \frac{1}{v} f\left(\frac{t}{v}\right) + \tilde{\chi}(t,v) \tag{17}$$

belongs to $\Psi_1^{\omega}(\mathscr{U})$ for some $\mathscr{U}$ and with appropriate $\omega > 0$, if the following conditions are satisfied.

(1a) $\tilde{\chi}(t,v) \in C^1(\mathscr{U}^*)$.

(1b) $\tilde{\chi}(t,v)$ together with its (first) partial derivatives are uniformly bounded in $\mathscr{U}^*$.

(2a) $f \in C^1(\mathbf{R})$ is a non-negative function with $f(0) > 0$.

(2b) $\lim_{x \to \pm\infty} |x|^{1+\epsilon} f(x) = 0$ for some $\epsilon > 0$.

(2c) $(d/dx)f(x)$ is uniformly bounded on $\mathbf{R}$.

Any such function has the property that it ''approaches δ'' locally, i.e., there is $c > 0$ so that for any test function $g(t)$ supported in a small neighborhood of $t = 0$,

$$\lim_{v \to 0+} [\chi(t,v)]g = \lim_{v \to 0+} \int dt\ \chi(t,v)g(t) = cg(0).$$

The example discussed above corresponds to

$$g(x) = \left(\frac{c}{\pi}\right)^{1/2} \exp(-cx^2), \quad c > 0.$$

B. Second-order transitions

In contrast to the first-order case, at a second-order transition the susceptibility χ can be divergent in the infinite volume limit as the critical temperature is approached. (It need not be divergent, since another second derivative of a suitable thermodynamic potential may be divergent instead.) If χ is divergent with a critical exponent, it is described by the following definition (with $v = L^{-1/\nu}$, $\nu > 0$ being the critical exponent of the correlation length ξ).

Definition 2: Let $\gamma > 0$. $\Psi_2^{\gamma}(\mathscr{U})$ is the set of functions $\chi \in C(\mathscr{U}^*)$ that satisfy the following conditions.

(1) There are constants $\mathscr{A}$, K, $\epsilon > 0$ such that in $\mathscr{U}^*$,

$$|\chi(t,0) - \mathscr{A}|t|^{-\gamma}| \leqslant K|t|^{-\gamma+\epsilon}.$$

Furthermore, there exist ν, $\mathscr{C} > 0$ so that for $|t| > \nu v$,

$$\chi(t,v) \geqslant \mathscr{C}\chi(t,0).$$

(2) The are constants η, $\mathscr{B} > 0$ such that for $|t| < \eta v$,

$$|\chi(t,v)| < \mathscr{B}v^{-\gamma}.$$

Functions that obey Definition 2 are always increasing in volume close to the transition.

Proposition 2: Let $\gamma > 0$ and $\chi \in \Psi_2^{\gamma}(\mathscr{U})$. There are constants ν, $\epsilon > 0$ such that for all t, v, w with $\nu w < |t| < \epsilon v$ we have $w < v$ and

$$|\chi(t,v)| < \chi(t,w).$$

The inequality includes the case $w = 0$, corresponding to infinite volume. That is, the susceptibility is always smaller in finite volume than in the infinite volume as long as we are in the critical region $|t|/v < \epsilon$.

Proof: Let $\chi \in \Psi_2^{\gamma}(\mathscr{U})$, $\gamma > 0$. There are numbers $\mathscr{C}$, $\mathscr{D}$, $\nu > 0$ such that in $\mathscr{U}^*$ for $|t| > \nu w$,

$$\chi(t,w) > \mathscr{C}\chi(t,0) > \mathscr{D}|t|^{-\gamma}.$$

Furthermore, there are $\eta, \mathscr{B} > 0$ such that for $|t| < \eta v$,

$$|\chi(t,v)| < \mathscr{B}v^{-\gamma}.$$

We choose $\epsilon = \min(\eta, (\mathscr{D}/\mathscr{B})^{1/\gamma})$ and get for $\nu w < |t| < \epsilon v$,

$$|\chi(t,v)| < \mathscr{B}v^{-\gamma} < \mathscr{B}\left(\frac{\epsilon}{|t|}\right)^{\gamma} < \frac{\mathscr{B}\epsilon^{\gamma}}{\mathscr{D}}\,\chi(t,w) < \chi(t,w).$$

This proves the lemma. □

The specific property for a second-order transition that the singular part of the free energy density behaves as a generalized homogeneous function implies for the susceptibility in a volume L^D a typical form like

$$\chi_2(T,L) = |T-T_c|^{-\gamma} Q((T-T_c)L^{1/\nu}) + \eta(T,L), \tag{18}$$

with some $\gamma > 0$. Here $\eta(\cdot, L)$ has similar analyticity properties as in (11) above, $\nu > 0$ is the critical exponent of the correlation length $\xi \sim |T-T_c|^{-\nu}$. Q is continuous and behaves as

$$\lim_{x\to 0} |x|^{-\gamma} Q(x) = K > 0,$$

$$\lim_{x\to \pm\infty} Q(x) = C > 0.$$

The first equation expresses the absence of a divergence of χ_2 for finite L, the second one its presence in the infinite volume case. With $t = (T-T_c)/T_c$, $v = L^{-1/\nu}$, and

$$\chi(t,v) := \chi_2(T,L)$$

it is straightforward to verify that χ belongs to $\Psi_2^{\gamma}(\mathscr{C})$.

More generally, every function χ: $\mathscr{C}^* \to \mathbf{R}$ of the form

$$\chi(t,v) = \frac{1}{v^{\gamma}} f\left(\frac{t}{v}\right) + \tilde{\chi}(t,v) \tag{19}$$

with $\gamma > 0$ belongs to some $\Psi_2^{\gamma}(\mathscr{C})$, if the following conditions are satisfied:
(1) $\tilde{\chi}(t,v) \in C^1(\mathscr{C}^*)$.
(2a) $f \in C^1(\mathbf{R})$, and $f(0) > 0$,
(2b) $\lim_{x\to\pm\infty} |x|^{\gamma} f(x) = C$ for some finite $C > 0$.

Compared to the first-order case (17) the essential difference comes from property (2b).

As an example,

$$\chi(t,v) = (t^2+v^2)^{-(m/2)}, \quad m > 0,$$

belongs to the class Ψ_2^m.

III. APPLICATIONS

The monotony criterion has been applied in the framework of convergent series expansions of $O(N)$ symmetric scalar models on the lattice, with ϕ^4 and ϕ^6 interactions, performed to the twentieth order in the hopping parameter (corresponding to the inverse temperature) both in the infinite and finite volume.[5] This class of models admits both first- and second-order transition regions. By means of the series representation it is hard to compute the scaling behavior of a susceptibility $\chi(T,L)$ at the maximum $T_c(L)$, since $T_c(L)$ as well as the transition at $T_c(\infty)$ are extrapolated as the convergence radius of the series. In contrast to other criteria that have been proposed so far (cf. Refs. 1–3), the monotony criterion circumvents this difficulty in that it allows

us to determine the order of the transition by the different L-dependence of $\chi(T,L)$ already close to, but not at $T_c(L)$, that is by an increase in volume for a second-order transition, and a decrease for a first-order transition. This feature is always needed in cases where it is not possible to work directly at the pseudocritical temperature $T_c(L)$.

In series representations the larger volume L_l^D is conveniently chosen to be infinite so that (3)–(5), with $L=\infty$ and $\sigma(L)=0$, give strong criteria in the whole scaling region. In Monte Carlo simulations both volumes L_s^D and L_l^D must be finite. The monotony criterion works equally well in this case. Both volumes have to be sufficiently large in order to match the conditions of the criterion (which reflect the standard assumptions of finite size scaling). Some care is needed to ensure that the susceptibility is actually measured at a temperature that satisfies (5), i.e., out of a region where the difference in the volume dependence between first- and second-order transitions appears. In particular this concerns the lower bound on δ in (5) because for $L_l<\infty$, also in case of a first-order transition, a small neighborhood around the peak at $T_c(L)$ exists, where $\chi(T,L)$ is increasing in volume because of the rounding of the δ-singularity.

To summarize, let λ denote a generic coupling constant. Application of the monotony criterion amounts to a choice of two sizes L_s and L_l with L_s, L_l, and L_l/L_s sufficiently large. Let us define the ratio r,

$$r(L_s,L_l;\lambda) := 1-\frac{\chi(T_c(L_s)+\delta,L_s;\lambda)}{\chi(T_c(L_l)+\delta,L_l;\lambda)}, \tag{20}$$

with δ satisfying the constraint (5). The monotony criterion then says that

$$r(L_s,L_l;\lambda)\begin{cases} >0, & \text{second order} \\ <0, & \text{first order} \\ =0, & \text{tricritical point for } r \text{ changing sign at } \lambda. \end{cases}$$

In (20) the susceptibility is measured at fixed distance to the volume-dependent location of its maximum. A reasonable alternative is to measure $\chi(T,L)$ for both volumes at the same temperature T regardless of L, but T chosen as $T=T_c(\infty)+\delta$. This requires that $T_c(L)$ approaches $T_c=T_c(\infty)$ according to

$$|T_c(L)-T_c(\infty)| \leqslant c\,\sigma(L), \tag{21}$$

cf. (5) and (13). The behavior (21) meets the standard finite size scaling behavior.

Other applications of the monotony criterion so far have been the three-dimensional Gross-Neveu model[6] and the electroweak phase transition of the early universe.[7]

Continuous iteration of dynamical maps

R. Aldrovandi[a] and L. P. Freitas[b]

Rua Pamplona, 145, 01405-900 São Paulo SP, Brazil

(Received 10 November 1997; accepted for publication 16 June 1998)

A precise meaning is given to the notion of continuous iteration of a mapping. Usual discrete iterations are extended into a dynamical flow which is a homotopy of them all. The continuous iterate reveals that a dynamic map is formed by independent component modes evolving without interference with each other. An application to turbulent flow suggests that the velocity field assumes nonseparable values. © *1998 American Institute of Physics.* [S0022-2488(98)03410-0]

I. INTRODUCTION

There are two main approaches to describe the evolution of a dynamical system.[1] The first has its roots in classical mechanics—the solutions of the dynamical differential equations provide the continuous motion of the representative point in phase space.[2] The second takes a quite different point of view: it models evolution by the successive iterations of a well-chosen map, so that the state is known after each step, as if the ''time'' parameter of the system were only defined at discrete values.[3] It is possible to go from the first kind of description to the second through the snapshots leading to a Poincaré map. Our aim here is to present the first steps into a converse procedure, going from a discrete to a continuous description *while preserving the idea of iteration.* This is possible if we are able to ''interpolate'' between the discrete values in such a way that the notion of iteration keeps its meaning in the intervals.

Iteration is a particular case of function composition: given a basic map $f(x)=f^{\langle 1\rangle}(x)$, its first iterate is $f^{\langle 2\rangle}(x)=[f\circ f](x)=f[f(x)]$, its nth iterate is $f^{\langle n\rangle}(x)=f[f^{\langle n-1\rangle}(x)]=f^{\langle n-1\rangle}[f(x)]$, etc. The question is whether or not, given the set of functions $f^{\langle n\rangle}(x)$, an interpolation $f^{\langle t\rangle}(x)$ with real values of t can be found which represents the one-parameter continuous group (or semigroup) describing the dynamical flow of the system. In order to do it, $f^{\langle t\rangle}$ should satisfy the conditions

$$f^{\langle t\rangle}[f^{\langle t'\rangle}(x)]=f^{\langle t'\rangle}[f^{\langle t\rangle}(x)]=f^{\langle t+t'\rangle}(x), \tag{I.1}$$

$$f^{\langle 0\rangle}(x)=\mathrm{Id}(x)=x. \tag{I.2}$$

We shall find in what follows a map interpolation $f^{\langle t\rangle}(x)$ with these properties. It is a well-known fact that Taylor series $f(x)$, $g(x)$ satisfying the conditions $f(0)=0$, $g(0)=0$, and with nonvanishing coefficients of x are invertible and constitute a group by composition.[4] The neutral element is the identity function $e(x)=\mathrm{Id}(x)=x$ and two functions f, g are inverse to each other if it is true that $f[g(x)]=g[f(x)]=\mathrm{Id}(x)=x$. In this case, $g=f^{\langle -1\rangle}$ and $f=g^{\langle -1\rangle}$ (we are taking the liberty of using the word ''function'' even for purely formal series and multivalued maps). The clue to the question lies in the formalism of Bell polynomials, which attributes to every such function f a matrix $B[f]$, whose inverse represents the inverse function and such that the matrix product represents the composition operation. In other words, these matrices provide a linear representation of the group formed by the functions with the operation of composition. Composition is thus represented by matrix product and, consequently, iterations are represented by matrix powers. Furthermore, the representation is faithful, and the function f is completely determined by $B[f]$. Now, in the matrix group there does exist a clear interpolation of discrete powers by real powers and the inverse way, going from matrices to functions, yields a map interpolation with the desired properties.

Section II is a short presentation of Bell polynomials, with only the minimum information necessary for our present objective. It is shown how a matrix $B[f]$ can be found which represents each formal series f, and that the composition $f\circ g$ of two functions is represented by the (right-) product of the respective matrices: $B[f\circ g]=B[g]B[f]$. The identity matrix corresponds to the identity function, $B[\mathrm{Id}]=I$, the matrix $B[f^{\langle n\rangle}]$ corresponding to the nth iterate, $f^{\langle n\rangle}$ is the nth power $B^n[f]$, and the Lagrange inverse $f^{\langle -1\rangle}$ to a series f is represented by the respective inverse matrix, $B[f^{\langle -1\rangle}]=B^{-1}[f]$. The necessity of finding $B^t[f]$ for noninteger ''t'' leads to the problem of defining functions of matrices, succinctly discussed in Sec. III. Given a matrix B, there exists a very convenient basis of projectors in terms of which any function of B is defined in a simple way. A method is given to obtain the members of this basis in a closed form, in terms of powers of B. The procedure is applied to Bell matrices in Sec. IV to obtain $B^t[f]=B[f^{\langle t\rangle}]$ for any value of t, from which the function $f^{\langle t\rangle}(x)$ can be extracted and shown to satisfy conditions (I.1) and (I.2). It turns out that, though it is quite natural to call ''time'' the continuous label t, this ''time'' is related to a certain class of flows, among all those leading to a specific Poincaré map. There is an extra bonus: The matrix decomposition in terms of projectors is reflected in a decomposition of the original map, and of its iterate, into a sum in terms of certain ''elementary functions,'' each one with an independent and well-defined time evolution. An application, relating a simplified turbulence model to nonseparable solutions of the double harmonic oscillator, is given in Sec. V.

II. BELL MATRICES

Given a formal series with vanishing constant term,

$$g(x)=\sum_{j=1}^{\infty}\frac{g_j}{j!}\,x^j, \tag{II.1}$$

its Bell polynomials $B_{nk}[g]$ are certain polynomials[5] in the Taylor coefficients g_i, defined by

$$B_{nk}(g_1,g_2,\ldots,g_{n-k+1})=\frac{1}{k!}\left\{\frac{d^n}{dt^n}\,[g(t)]^k\right\}_{t=0}. \tag{II.2}$$

Their properties are in general obtained from their appearance in the multinomial theorem, which reads

$$\frac{1}{k!}\left(\sum_{j=1}^{\infty}\frac{g_j}{j!}\,t^j\right)^k=\sum_{n=k}^{\infty}\frac{t^n}{n!}\,B_{nk}(g_1,g_2,\ldots,g_{n-k+1}). \tag{II.3}$$

Depending on the situation, one or another of the notations

$$B_{nk}[g]=B_{nk}(g_1,g_2,\ldots,g_{n-k+1})=B_{nk}\{g_j\}, \tag{II.4}$$

is more convenient. The symbol $\{g_j\}$ represents the Taylor coefficient list of g, with g_j a typical member. Some properties coming immediately from the multinomial theorem are the following:

$$B_{n1}[g]=g_n, \tag{II.5}$$

$$B_{nn}[g]=(g_1)^n, \tag{II.6}$$

$$B_{nk}[cg(t)]=c^kB_{nk}[g(t)], \tag{II.7}$$

$$B_{nk}[g(ct)]=c^nB_{nk}[g(t)], \tag{II.8}$$

where c is a constant. Given two formal Taylor series,

$$f(u)=\sum_{j=1}^{\infty}\frac{f_j}{j!}\,u^j,\quad g(t)=\sum_{j=1}^{\infty}\frac{g_j}{j!}\,t^j, \tag{II.9}$$

their composition

$$F(t)=[f\circ g](t)=f[g(t)]=\sum_{j=1}^{\infty}\frac{t^n}{n!}F_n[f;g] \tag{II.10}$$

will have the Taylor coefficients F_n given by the Faà di Bruno formula,

$$F_n[f;g]=\sum_{k=1}^{n} f_k B_{nk}\{g_j\}. \tag{II.11}$$

Other properties can be obtained from the double generating function

$$e^{ug(t)}-1=\sum_{n=1}^{\infty}\frac{t^n}{n!}\sum_{j=1}^{n}u^j B_{nj}[g]. \tag{II.12}$$

Series like (II.1) constitute a group under the composition operation $(f\circ g)(x)=f[g(x)]$. The identity series ''e'' such that $e(x)=\mathrm{Id}(x)=x$ plays the role of the neutral element and each series g possesses an inverse $g^{\langle -1\rangle}$, satisfying $g^{\langle -1\rangle}\circ g=g\circ g^{\langle -1\rangle}=e$ and given by the Lagrange inversion formula. The simplest example of a Bell matrix and its inverse is given by the well-known case of the Stirling numbers: matrices formed by the first and second kind of Stirling numbers are inverse to each other, because they correspond to functions inverse to each other. In effect, consider the series

$$g(x)=\ln(1+x)=\sum_{j=1}^{\infty}\frac{(-)^{j-1}}{j}x^j, \tag{II.13}$$

whose inverse is

$$f(u)=e^u-1=\sum_{j=1}^{\infty}\frac{1}{j!}u^j. \tag{II.14}$$

A generating function for the Stirling numbers of the first kind $s_k{}^{(j)}$ is

$$\frac{1}{k!}(\ln(1+x))^k=\sum_{n=k}^{\infty}\frac{x^n}{n!}s_n{}^{(k)}. \tag{II.15}$$

It follows from (II.3) that

$$B_{nk}[\ln(1+x)]=B_{nk}(0!,-1!,2!,-3!,\ldots)=B_{nk}\{(-)^{j-1}(j-1)!\}=s_n{}^{(k)}. \tag{II.16}$$

For the Stirling numbers of the second kind $S_k{}^{(j)}$, the generating function is

$$\frac{1}{k!}(e^u-1)^k=\sum_{n=k}^{\infty}\frac{u^n}{n!}S_n{}^{(k)}, \tag{II.17}$$

from which

$$B_{nk}[e^u-1]=B_{nk}(1,1,1,\ldots,1)=B_{nk}\{1\}=S_n{}^{(k)}. \tag{II.18}$$

The inverse property of Stirling numbers is $\Sigma_{k=j}^{n}\, s_n{}^{(k)}\, S_k{}^{(j)}=\delta_n{}^j$, the same as

$$\sum_{k=j}^{n} B_{nk}[\ln(1+x)]B_{kj}[e^u-1]=\delta_{nj}. \tag{II.19}$$

The polynomials $B_{nk}[g]$ are the entries of a (lower-)triangular matrix $B[g]$, with n as row index and k as the column index. From (II.5), the function coefficients constitute the first column,

so that actually $B[g]$ is an overcomplete representative of g. From (II.6), the eigenvalues of $B[g]$ are $(g_1)^j$. Triangular matrices form a group, of which the set of matrices (B_{nk}) constitutes a subgroup. Hereby comes the most fascinating property of Bell polynomials: The matrices $B[g]=(B_{nk}[g])$, with the operation of matrix product, provide a representation of the series composition group:

$$B[g]B[f]=B[f\circ g]. \tag{II.20}$$

It is in reality an antirepresentation because of the inverse order, but this does not represent any problem. This property comes easily by using twice (II.3), as

$$\begin{aligned}\frac{1}{k!}\,(f[g(t)])^k&=\frac{1}{k!}\left(\sum_{j=1}^{\infty}\frac{f_j}{j!}\,g^j\right)^k\\&=\sum_{n=k}^{\infty}\frac{g(t)^n}{n!}\,B_{nk}[f]\\&=\sum_{n=k}^{\infty}\sum_{j=n}^{\infty}\frac{t^j}{j!}\,B_{jn}[g]B_{nk}[f]\\&=\sum_{j=k}^{\infty}\frac{t^j}{j!}\sum_{n=k}^{j}B_{jn}[g]B_{nk}[f],\end{aligned}$$

from which

$$B_{jk}[f(g(t))]=\sum_{n=k}^{j}B_{jn}[g]B_{nk}[f], \tag{II.21}$$

which is just (II.20). Associativity can be easily checked, and it is trivial to see that the ''identity'' series $e(x)=x$ has the representative $B_{nk}[e]=\delta_{nk}$, so that $B[e]=I$. The series $g(t)$ with $g_1=0$ can be attributed to a matrix, but a singular one and, consequently, outside the group. Summing up, infinite Bell matrices constitute a linear representation of the group of invertible formal series. If we consider only the first N rows and columns, what we have is an approximation, but it is important to notice that the group properties hold at each order N. The general aspect of a Bell matrix can be illustrated by the case $N=5$:

$$B[g]=\begin{pmatrix} g_1 & 0 & 0 & 0 & 0\\ g_2 & {g_1}^2 & 0 & 0 & 0\\ g_3 & 3g_1g_2 & {g_1}^3 & 0 & 0\\ g_4 & 4g_1g_3+3{g_2}^2 & 6{g_1}^2g_2 & {g_1}^4 & 0\\ g_5 & 10g_2g_3+5g_1g_4 & 15g_1{g_2}^2+10{g_1}^2g_3 & 10{g_1}^3g_2 & {g_1}^5\end{pmatrix}. \tag{II.22}$$

The result (II.19) is the best example of the general property

$$B[f]B[f^{\langle -1\rangle}]=I. \tag{II.23}$$

It is evident that, given the series f, its inverse series can be obtained from

$$B[f^{\langle -1\rangle}]=B^{-1}[f] \tag{II.24}$$

by simple matrix inversion. The inversion properties of Bell matrices have been used in the study of cluster expansions for real gases.[6] Because $B[g^{\langle n\rangle}]=B^n[g]$, Bell matrices convert function iteration into matrix power and provide a linearization of the process of iteration.

Suppose now that we are able to obtain the matrix B^t, with t an arbitrary real number. The continuous iteration of $g(x)$ will then be that function $g^{\langle t\rangle}$ such that $B[g^{\langle t\rangle}]=B^t[g]$. By (II.5), its Taylor coefficients are fixed by $g^{\langle t\rangle}{}_n=B[g^{\langle t\rangle}]_{n1}=B^t[g]_{n1}$. To arrive at B^t, let us make a short preliminary incursion into the subject of matrix functions.

III. MATRIX FUNCTIONS

Suppose a function $F(\lambda)$ is given which can be expanded as a power series $F(\lambda)=\Sigma_{k=0}^{\infty}\, c_k(\lambda-\lambda_0)^k$ inside the convergence circle $|\lambda-\lambda_0|<r$. Then the function $F(B)$, whose argument is now a given $N\times N$ matrix B, is defined by $F(B)=\Sigma_{k=0}^{\infty}\, c_k(B-\lambda_0)^k$ and has a sense whenever the eigenvalues of B lie within the convergence circle. Given the eigenvalues $x_1,x_2,\ldots,x_N$, the set of eigenprojectors $\{Z_j[B]=|x_j\rangle\langle x_j|\}$ constitutes a basis in which B is written

$$B=\sum_{j=1}^{N} x_j Z_j[B], \tag{III.1}$$

and the function $F(B)$, defined as above, can also be written[7] as the matrix

$$F(B)=\sum_{j=1}^{N} F(x_j) Z_j[B]. \tag{III.2}$$

Thus, for example, $e^B=\Sigma_{j=1}^{N}\, e^{x_j} Z_j$ and $B^\alpha=\Sigma_{j=1}^{N}\, x_j{}^\alpha\, Z_j[B]$. The basis $\{Z_j[B]\}$ depends on B, but is the same for every function F. The Z_j's, besides being projectors (that is, idempotents, $Z_j^2=Z_j$), can be normalized so that $\mathrm{tr}(Z_j)=1$ for each j and are then orthonormal by the trace, $\mathrm{tr}(Z_iZ_j)=\delta_{ij}$. Other properties follow easily, for example, $\mathrm{tr}[F(B)]=\Sigma_{j=1}^{N}\, F(x_j)Z_j$ and $\mathrm{tr}[B^kZ_j]=(x_j)^k$. If B is a normal matrix diagonalized by a matrix U, $UBU^{-1}=B_{\mathrm{diagonal}}$, then the entries of Z_k are given by $(Z_k)_{rs}=U_{rk}^{-1}U_{ks}$ (no summation, of course).

A set of N powers of B is enough to fix the projector basis. Using for $F(B)$ in (III.2) the power functions $B^0=I$, $B^1,B^2,\ldots,B^{N-1}$, we have $I=\Sigma_{j=1}^{N}\, Z_j$; $B=\Sigma_{j=1}^{N}\, x_j\, Z_j$; $B^2=\Sigma_{j=1}^{N}\, x_j{}^2Z_j;\ldots;$ $B^k=\Sigma_{j=1}^{N}\, x_j{}^kZ_j;\ldots;B^{N-1}=\Sigma_{j=1}^{N}\, x_j{}^{N-1}Z_j$. For $k\geqslant N$, the B^k's are no more independent. This comes from the Cayley–Hamilton theorem,[8] by which B satisfies its own secular equation

$$\Delta(x)=\det[xI-B]=(x-x_1)(x-x_2)(x-x_3)\cdots(x-x_N)=0.$$

$\Delta(B)=0$ will give B^N in terms of lower powers of B, so that the higher powers of B can be computed from the lower powers.

Inversion of the above expressions for the powers of B in terms of the Z_j's leads to a closed form for each Z_j,

$$Z_j[B]=\frac{(B-x_1)(B-x_2)\cdots(B-x_{j-1})(B-x_{j+1})\cdots(B-x_{N-1})(B-x_N)}{(x_j-x_1)(x_j-x_2)\cdots(x_j-x_{j-1})(x_j-x_{j+1})\cdots(x_j-x_{N-1})(x_j-x_N)}. \tag{III.3}$$

The function $F(B)$ is consequently given by

$$F(B)=\sum_j \left\{\prod_{k\neq j}\frac{B-x_k}{x_j-x_k}\right\}F(x_j). \tag{III.4}$$

Thus, in order to obtain $F(B)$, it is necessary to find the eigenvalues of B and the detailed form of its first $(N-1)$ powers. Though for N not too large the $Z_j[B]$'s can be directly computed, we shall give closed expressions for them. These expressions involve some symmetric functions of the eigenvalues.

Let us examine the spectrum $\{x_k\}$ of B in some more detail. The eigenvalues x_k will be called ''letters'' and indicated collectively by the ''alphabet'' $\mathbf{x}=\{x_1,x_2,x_3,\ldots,x_N\}$. A monomial is a ''word.'' It will be convenient to consider both the alphabet $\mathbf{x}$ and its ''reciprocal,'' the alphabet $\mathbf{x}^*=\{x^*{}_1,x^*{}_2,x^*{}_3,\ldots,x^*{}_N\}$ where each $x^*{}_j=-1/x_j$. Notice that taking the reciprocal is an involution, $\mathbf{x}^{**}=\mathbf{x}$. A symmetric function in the variables $x_1,x_2,x_3,\ldots,x_N$ is any polynomial

$P(x_1,x_2,x_3,\ldots,x_N)$ which is invariant under all the permutations of the x_k's. Only one kind of them will be needed here, the ''jth elementary symmetric functions,'' σ_j = sum of all words with j distinct letters:

$$\sigma_0[\mathbf{x}]=1(\text{by convention}),$$

$$\sigma_1[\mathbf{x}]=x_1+x_2+x_3+\cdots+x_N,$$

$$\sigma_2[\mathbf{x}]=x_1x_2+x_1x_3+\cdots+x_1x_N+\cdots+x_2x_3+x_2x_4+\cdots+\cdots+x_{N-1}x_N,$$

$$\vdots$$

$$\sigma_N[\mathbf{x}]=x_1x_2x_3\cdots x_{N-1}x_N.$$

The symmetric functions of $\mathbf{x}$ and $\mathbf{x}^*$ are related by

$$(-)^j\sigma_{N-j}[\mathbf{x}]=\sigma_N[\mathbf{x}]\sigma_j[\mathbf{x}^*]. \tag{III.5}$$

Their generating function is

$$\sum_{j=0}^{N}\sigma_j[\mathbf{x}]t^j=\sum_{j=1}^{N}(1+x_jt)=\prod_{j=1}^{N}(1-t/x^*{}_j)=\frac{1}{\sigma_N[\mathbf{x}^*]}\prod_{j=1}^{N}(x^*{}_j-t),$$

so that

$$\prod_{j=1}^{N}(x^*{}_j-t)=\sigma_N[\mathbf{x}^*]\sum_{j=0}^{N}\sigma_j[\mathbf{x}]t^j.$$

We use the involution property and (III.5) to write the general expression

$$\prod_{j=1}^{N}(x_j-t)=\sigma_N[\mathbf{x}]\sum_{j=0}^{N}\sigma_j[\mathbf{x}^*]t^j=\sum_{j=0}^{N}(-)^j\sigma_{N-j}[\mathbf{x}]t^j. \tag{III.6}$$

The jth eigenvalue is absent in the numerator of expression (III.3) for Z_j. We shall need some results involving an alphabet with one missing letter. Let $\sigma_{ji}[\mathbf{x}]$ be the sum of all j-products of the alphabet $\mathbf{x}$, but excluding x_i. For example, $\sigma_{Ni}[\mathbf{x}]=\Pi_{k\neq i}^{N}x_k$. We put by convention $\sigma_{0i}=1$ and find that

$$\sigma_{ki}[\mathbf{x}]=\sum_{p=0}^{k}(-)^px_i{}^p\sigma_{k-p}[\mathbf{x}]=\sum_{j=0}^{k}(-x_i)^{k-j}\sigma_j[\mathbf{x}]. \tag{III.7}$$

In the absence of the ith letter, (III.6) becomes

$$\prod_{j=1;j\neq i}^{N}(x_j-t)=\sigma_{Ni}[\mathbf{x}]\sum_{j=0}^{N}\sigma_{ji}[\mathbf{x}^*]t^j. \tag{III.8}$$

The projectors (III.3) are then

$$Z_j[B]=\prod_{k=1;k\neq j}^{N}\frac{x_k-B}{x_k-x_j}=\frac{\Sigma_{k=0}^{N}\sigma_{kj}[\mathbf{x}^*]B^k}{\Sigma_{k=0}^{N}\sigma_{kj}[\mathbf{x}^*]x_j{}^k}, \tag{III.9}$$

clearly written in the basis $\{I,B,B^2,\ldots,B^{N-1}\}$. In our application to Bell matrices, it will be convenient to use instead the basis $\{B,B^2,\ldots,B^N\}$. This is due to the fact that we shall prefer to start from the matrix $B[g]$, corresponding to g, and not from the matrix I, corresponding to the identity function. The mappings of interest, like the logistic map for example, have a general ''$\cap$'' aspect and the identity map does not have the same end points: the identity map has Brouwer[9]

degree 1, while the dynamical maps of interest can be characterized by their degree 0. The Cayley–Hamilton theorem implies $\Sigma_{j=0}^{N}\ \sigma_j[\mathbf{x}^*]B^j=0$, from which we obtain the identity B^0 as

$$I=-\sum_{j=1}^{N}\ \sigma_j[\mathbf{x}^*]B^j. \tag{III.10}$$

Replacing this identity in (III.9), the projectors are recast into another form,

$$Z_i[B]=\frac{I+\Sigma_{k=1}^{N}\sigma_{ki}[\mathbf{x}^*]B^k}{1+\Sigma_{k=1}^{N}\sigma_{ki}[\mathbf{x}^*]x_i{}^k}=\frac{\Sigma_{k=1}^{N}\{\sigma_{ki}[\mathbf{x}^*]-\sigma_k[\mathbf{x}^*]\}B^k}{\Sigma_{k=1}^{N}\{\sigma_{ki}[\mathbf{x}^*]-\sigma_k[\mathbf{x}^*]\}x_i{}^k}. \tag{III.11}$$

Using (III.7) and (III.5) we get

$$Z_i[B]=\frac{\Sigma_{k=1}^{N}\{\Sigma_{j=0}^{k-1}(x_i)^{j-k}\sigma_j[\mathbf{x}^*]\}B^k}{\Sigma_{j=0}^{N-1}(N-j)(x_i)^j\sigma_j[\mathbf{x}^*]}=\frac{\Sigma_{k=1}^{N}\{\Sigma_{j=0}^{k-1}(x_i)^{j-k}(-)^j\sigma_{N-j}[\mathbf{x}]\}B^k}{\Sigma_{j=0}^{N-1}(N-j)(x_i)^j(-)^j\sigma_{N-j}[\mathbf{x}]}, \tag{III.12}$$

where we have also used $\Sigma_{r=1}^{N}\{\Sigma_{j=0}^{r-1}(x_i)^j\sigma_j[\mathbf{x}^*]\}=\Sigma_{j=0}^{N-1}(N-j)(x_i)^j\sigma_j[\mathbf{x}^*]$. There is a good immediate check: Replacing B by the eigenvalues we find, as expected,

$$Z_i[x_k]=\delta_{ik}I. \tag{III.13}$$

The projectors are now clearly in the basis $\{B,B^2,\ldots,B^N\}$. Actually, each Z_i is now just that given in the basis $\{I,B,B^2,\ldots,B^{N-1}\}$ multiplied by (B/x_i): instead of (III.3),

$$Z_j[B]=\frac{(B-x_1)(B-x_2)\cdots(B-x_{j-1})B(B-x_{j+1})\cdots(B-x_{N-1})(B-x_N)}{(x_j-x_1)(x_j-x_2)\cdots(x_j-x_{j-1})x_j(x_j-x_{j+1})\cdots(x_j-x_{N-1})(x_j-x_N)}. \tag{III.14}$$

The Z_i's and the powers B^k can be seen as components of two formal column ''vectors.'' The linear conditions $B^n=\Sigma_{j=1}^{N}\ x_j{}^nZ_j$ are then represented by a matrix $\Lambda=[x_j{}^n]$,

$$\begin{pmatrix} B^1\\ B^2\\ .\\ .\\ .\\ B^N\end{pmatrix}=\begin{pmatrix} x_1 & x_2 & x_3 & . & . & x_N\\ x_1{}^2 & x_2{}^2 & x_3{}^2 & . & . & x_N{}^2\\ . & . & . & . & . & .\\ . & . & . & . & . & .\\ . & . & . & . & . & .\\ x_1{}^N & x_2{}^N & x_3{}^N & . & . & x_N{}^N\end{pmatrix}\begin{pmatrix} Z_1\\ Z_2\\ .\\ .\\ .\\ Z_N\end{pmatrix}, \tag{III.15}$$

and what we have done has been to obtain its inverse:

$$Z_i[B]=\sum_{k=1}^{N}\ [\Lambda^{-1}]_{ik}B^k, \tag{III.16}$$

$$[\Lambda^{-1}]_{ik}=\frac{\Sigma_{j=0}^{k-1}(x_i)^{j-k}(-)^j\sigma_{N-j}[\mathbf{x}]}{\Sigma_{j=0}^{N-1}(N-j)(x_i)^j(-)^j\sigma_{N-j}[\mathbf{x}]}. \tag{III.17}$$

It seems a difficult task to improve the above expressions, as it would mean knowing a closed analytical expression for the recurrent summation of the form $\Sigma_{j=0}^{k-1}\ u^j\sigma_j[\mathbf{x}^*]$. A closed expression for $\sigma_j[\mathbf{x}^*]$ would be necessary and, even for the simple alphabet consisting of powers of a fixed letter a, which we shall find in the application to Bell matrices, this would be equivalent to solving an as yet unsolved problem in Combinatorics. In effect, in terms of such an alphabet $\{a^j\}$ with N letters, the symmetric function is given by $\sigma_k=\Sigma_{j=1}^{N(N+1)/2}\ q_{j,k,N}a^j$, where $q_{j,k,N}$ = number of partitions of j into k unequal summands, each one $\leqslant N$. These conditional partition numbers have the generating function $\Pi_{r=1}^{N}[1+ua^r]=1+\Sigma_{j\text{ and }k\geqslant 1}q_{j,k,N}a^ju^k$, but have no known closed expression. They are calculated, one by one, just in this way.[10]

Bell matrices are not normal, that is, they do not commute with their transposes. Normality is the condition for diagonalizability. This means that Bell matrices cannot be put into diagonal form by a similarity transformation. As it happens, this will not be a difficulty because we know their eigenvalues. That functions of matrices are completely determined by their spectra is justified on much more general grounds. Matrix algebras are very particular kinds of von Neumann algebras and it is a very strong result of the still more general theory of Banach algebras[11] that functions on such spaces, as long as they can be defined, are fixed by the spectra. Another point worth mentioning is that the infinite Bell matrices which constitute the true, complete representation of the group of invertible series will belong, as limits for $N\to\infty$ of $N\times N$ matrices, to a hyperfinite von Neumann algebra. Our considerations here are purely formal from the mathematical point of view, as we are only discussing formal series. We are not concerned with the topological intricacies involved in the convergence problems, though they surely deserve a detailed study. By the way, the infinite algebra generated by Bell matrices would provide a good guide in the study of function algebras with the composition operation.

IV. THE CONTINUOUS ITERATE

We are now in a position to find, given a function g, the matrix $B^t[g]$ and its corresponding function, the continuous iterate $g^{\langle t\rangle}(x)$. Since many things—the $B[g]$ spectrum, for example—will depend only on the first-order Taylor coefficient, we shall put $g_1=a$. By (II.6), the letters in the eigenvalue-alphabet of $B[g]$ will be simple powers of a and the alphabet $\mathbf{a}=(a^1,a^2,\ldots,a^N)$ will have the reciprocal $\mathbf{a}^*=(-a^{-1},-a^{-2},\ldots,-a^{-N})$. The matrix Λ has entries $(\Lambda_{ik})=(a^{ik})$ and the projectors

$$Z_i[B]=\sum_{k=1}^{N}\Lambda^{-1}{}_{ik}B^k[g] \tag{IV.1}$$

now have the coefficients

$$[\Lambda^{-1}]_{ik}=\frac{\Sigma_{j=0}^{k-1}a^{i(j-k)}(-)^j\sigma_{N-j}[\mathbf{a}]}{\Sigma_{r=1}^{N}\Sigma_{j=0}^{r-1}a^{ij}(-)^j\sigma_{N-j}[\mathbf{a}]}.$$

We can verify easily that $\mathrm{tr}\, Z_i[B]=1$ and $BZ_i=a^iZ_i$. A consequence of the latter is

$$f(B)Z_i=f(a^i)Z_i, \tag{IV.2}$$

whose particular case

$$B^tZ_i=a^{it}Z_i \tag{IV.3}$$

will be helpful later on. To give an idea of their aspect, we show the projector matrices $Z_i^{(N)}[B[g]]$ for $N=3$:

$$Z_1{}^{(3)}=\begin{pmatrix}1 & 0 & 0\\ \dfrac{g_2}{g_1(1-g_1)} & 0 & 0\\ \dfrac{3g_2{}^2+g_3(1-g_1)}{g_1(1-g_1)^2(1+g_1)} & 0 & 0\end{pmatrix},\quad Z_2{}^{(3)}=\begin{pmatrix}0 & 0 & 0\\ \dfrac{-g_2}{g_1(1-g_1)} & 1 & 0\\ \dfrac{-3g_2{}^2}{g_1{}^2(1-g_1)^2} & \dfrac{3g_2}{g_1(1-g_1)} & 0\end{pmatrix},$$

$$Z_3{}^{(3)}=\begin{pmatrix}0 & 0 & 0\\ 0 & 0 & 0\\ \dfrac{3g_2{}^2-g_1g_3(1-g_1)}{g_1{}^2(1-g_1)^2(1+g_1)} & \dfrac{-3g_2}{g_1(1-g_1)} & 1\end{pmatrix}.$$

Because they do not have the form (II.22), they cannot be the Bell matrices of any function. They inherit, however, a good property of the Bell matrices: for each N, the projectors $Z_j{}^{(N)}$ contain, in their higher rows, the projectors $Z_j{}^{(k)}$ for all $k<N$. The upper-left 2×2 submatrices of the $Z_k{}^{(3)}$'s above are just $Z_k{}^{(2)}$.

We can take the first-column entries of the matrix (IV.1) as Taylor coefficients defining the functions

$$R_i{}^{(N)}(x)=\sum_{r=1}^{\infty}\frac{x^r}{r!}\,[Z_i[B]]_{r1} \tag{IV.4}$$

$$=\sum_{k=1}^{N}\,[\Lambda^{-1}{}_{ik}g^{\langle k\rangle}(x)]. \tag{IV.5}$$

To each projector Z_i corresponds such an ''elementary function'' $R_i{}^{(N)}(x)$, a relationship reflecting in part that between the series and their Bell matrices. Taking the summation of all $R_i{}^{(N)}$'s in (IV.4) and using $I=\Sigma_{i=1}^{N}\,Z_i$, we find

$$\sum_{i=1}^{N}\,R_i{}^{(N)}(x)=\sum_{r=1}^{\infty}\,\frac{x^r}{r!}\left[\sum_{i=1}^{N}\,Z_i[B]\right]_{r1}=\sum_{r=1}^{\infty}\,\frac{x^r}{r!}\,\delta_{r1}=x. \tag{IV.6}$$

Thus, just as the projectors give a decomposition of the identity matrix, the elementary functions provide a decomposition of the identity function,

$$\mathrm{Id}=\sum_{i=1}^{N}\,R_i{}^{(N)}. \tag{IV.7}$$

Applying to $B[g]$ the general form (III.2) for the function of a matrix, we have

$$B^t=\sum_{i=1}^{N}\,a^{it}Z_i[B]=\sum_{k=1}^{N}\,C^{(N)}{}_k(t)B^k, \tag{IV.8}$$

where

$$C^{(N)}{}_k(t)=\sum_{i=1}^{N}\,a^{it}\Lambda^{-1}{}_{ik}\,. \tag{IV.9}$$

The coefficients of the continuum iterate function

$$g^{\langle t\rangle}(x)=\sum_{r=1}^{\infty}\,g_r{}^{\langle t\rangle}\,\frac{x^r}{r!} \tag{IV.10}$$

will be

$$g_r{}^{\langle t\rangle}=[B^t[g]]_{r1}=\sum_{i=1}^{N}\,a^{it}[Z_i[B]]_{r1}=\sum_{k=1}^{N}\,C^{(N)}{}_k(t)B^k[g]_{r1}=\sum_{k=1}^{N}\,C^{(N)}{}_k(t)g_r{}^{\langle k\rangle}. \tag{IV.11}$$

Therefore,

$$g^{\langle t\rangle}(x)=\sum_{k=1}^{N}\,C^{(N)}{}_k(t)g^{\langle k\rangle}(x)=\sum_{k=1}^{N}\,\left[\sum_{i=1}^{N}\,a^{it}\Lambda^{-1}{}_{ik}\right]g^{\langle k\rangle}(x). \tag{IV.12}$$

Time dependence is factorized in the alternative form

$$g^{\langle t\rangle}(x)=\sum_{k=1}^{N}\,a^{kt}R_k{}^{(N)}(x). \tag{IV.13}$$

One of the announced properties, (I.2), follows immediately: $g^{\langle 0\rangle}(x)=\mathrm{Id}(x)$. For $t=1$, a suggestive decomposition of the function comes up:

$$g(x)=\sum_{k=1}^{N} a^k R_k{}^{(N)}(x). \tag{IV.14}$$

It remains to show that (IV.13) does satisfy property (I.1). Notice first that, from the definition (IV.4) of $R_i{}^{(N)}$ and the multinomial theorem (II.3),

$$\begin{aligned} R_i{}^{(N)}[g^{\langle t\rangle}(x)] &= \sum_{r=1}^{\infty} [Z_i[B]]_{r1} \frac{[g^{\langle t\rangle}(x)]^r}{r!} \\ &= \sum_{r=1}^{\infty} \sum_{j\geqslant r} \frac{x^j}{j!} B_{jr}[g^{\langle t\rangle}][Z_i[B]]_{r1} \\ &= \sum_{j=1}^{\infty} \frac{x^j}{j!} \sum_{r=1}^{j} B^t_{jr}[g][Z_i[B]]_{r1} \\ &= \sum_{j=1}^{\infty} \frac{x^j}{j!} [B^t Z_i]_{j1}. \end{aligned} \tag{IV.15}$$

Therefore,

$$\begin{aligned} g^{\langle t'\rangle}(g^{\langle t\rangle}(x)) &= \sum_{i=1}^{N} a^{it'} R_i{}^{(N)}[g^{\langle t\rangle}(x)] \\ &= \sum_{r=1}^{\infty} \frac{x^r}{r!} \sum_{i=1}^{N} a^{it'} [B^t Z_i]_{r1} \\ &= \sum_{r=1}^{\infty} \frac{x^r}{r!} \left[B^t \sum_{i=1}^{N} a^{it'} Z_i \right]_{r1} \\ &= \sum_{r=1}^{\infty} \frac{x^r}{r!} [B^t B^{t'}]_{r1} = \sum_{r=1}^{\infty} \frac{x^r}{r!} g^{\langle t+t'\rangle}{}_{r1} = g^{\langle t+t'\rangle}(x), \end{aligned}$$

just the result looked for. Notice also that, using (IV.3) and (IV.4) in (IV.15), we obtain

$$R_k{}^{(N)}[g^{\langle t\rangle}(x)] = a^{kt} R_k{}^{(N)}(x) \tag{IV.16}$$

and, consequently,

$$R_k{}^{(N)}[g^{\langle t+t'\rangle}(x)] = a^{k(t+t')} R_k{}^{(N)}(x) = a^{kt'} R_k{}^{(N)}[g^{\langle t\rangle}(x)]. \tag{IV.17}$$

The function decomposition is preserved in time, as we can write

$$g(x)=\sum_{k=1}^{N} R_k{}^{(N)}[g(x)], \quad g^{\langle t\rangle}(x)=\sum_{k=1}^{N} R_k{}^{(N)}[g^{\langle t\rangle}(x)]. \tag{IV.18}$$

All the above expressions hold for each value of N and give approximations to that order. Of course, exact results would only really come out when $N\to\infty$. The exact expressions would, as long as they are defined, take forms like

$$R_j(x)=\sum_{k\geqslant 1} [\Lambda^{-1}{}_{jk} g^{\langle k\rangle}(x)], \tag{IV.19}$$

$$g(x)=\sum_{k\geqslant 1} a^k R_k(x), \tag{IV.20}$$

$$g^{\langle t\rangle}(x)=\sum_{k\geqslant 1} a^{kt} R_k(x). \tag{IV.21}$$

It is tempting to conjecture that the elementary functions R_i play, in function space and with the operation of composition, the role of projectors. In fact, this is not so. Their properties mirror only partially those of the projectors Z_i. If we calculate $R_i[R_j(x)]$ using (IV.4) and the multinomial theorem, we find $R_i[R_j(x)]=R_i(x^j/j!)$. The composition gives rise to a change in the variable. Thus, the functions R_i fail even to satisfy the defining idempotent property: in general, $R_i\circ R_i\neq R_i$. An explicit example of $R_j(x)$, for which all these properties can be tried out, is given below [see (V.6)].

We can introduce $\epsilon=\ln a$ and rewrite (IV.13) as

$$x(t)=g^{\langle t\rangle}(x_0)=\sum_{k\geqslant 1} e^{k\epsilon t} R_k(x_0), \tag{IV.22}$$

a decomposition of $g^{\langle t\rangle}(x)$ into a sum of modes, each one evolving independently according to

$$x_k(t)=e^{k\epsilon t}x_k(0)=e^{k\epsilon t}R_k(x_0). \tag{IV.23}$$

The imaginary ''frequency'' $k\epsilon$ plays the role of a ''modular Lyapunov exponent'' of the kth mode. We have thus a ''multi-Hamiltonian'' flow $x(t)$ with one Hamiltonian for each projector component: Equations (IV.16) and (IV.17) show $R_k{}^{(N)}$ as a representation of the one-dimensional group engendered by the kth dynamical flow

$$R_k[g^{\langle t\rangle}(x)]=e^{k\epsilon t}R_k[g^{\langle 0\rangle}(x)]. \tag{IV.24}$$

The function $g^{\langle t\rangle}(x)$ is actually a Lagrange interpolation in the convenient variable $(g_1)^t=a^t$, which coincides with the discrete iterates at each integer value of t and *keeps the meaning of a continuum iterate in between*. It is a homotopy of all the usual discrete iterations. As announced in Sec. III, we have used the basis $\{B,B^2,B^3,\ldots,B^N\}$, instead of $\{I,B,B^2,\ldots,B^{N-1}\}$, because in the latter the matrix ''I'' would correspond to the identity function $\mathrm{Id}(x)=x$, which does not have the same end points of the maps of interest.

The variable t has been given the sense of a ''time.'' If it is really time, $g^{\langle n\rangle}(x)$ will give the nth point of a Poincaré map. Now, there are in principle (infinitely) many dynamical flows corresponding to a given Poincaré map. The function $g^{\langle t\rangle}(x)$ as given above would correspond to a class of them, that of the flows with equal intervals of time between successive points on the Poincaré section. To consider other cases, we recall that any strictly monotonous function of a first-given ''time'' is another ''time.''

Finally, we cannot resist exhibiting a ''thing of beauty.'' By the very manner in which it has been obtained, the expression (IV.12) for the continuum iterate is equivalent to the highly mnemonic determinantal equation

$$\begin{vmatrix} g^{\langle 1\rangle}(x) & a & a^2 & \ldots & \ldots & a^N \\ g^{\langle 2\rangle}(x) & a^2 & a^4 & \ldots & \ldots & a^{2N} \\ g^{\langle 3\rangle}(x) & a^3 & a^6 & \ldots & \ldots & a^{3N} \\ \ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\ g^{\langle N\rangle}(x) & a^N & a^{2N} & \ldots & \ldots & a^{N^2} \\ g^{\langle t\rangle}(x) & a^t & a^{2t} & \ldots & \ldots & a^{Nt} \end{vmatrix} = 0. \tag{IV.25}$$

Expansion along the first column or the last row and comparison with (IV.11) and (IV.13) will give determinant expressions for $C^{(N)}{}_k(t)$ and $R_k{}^{(N)}(x)$.

V. AN APPLICATION TO TURBULENCE

Let us describe an application of our basic result (IV.21), which shows that a relationship may exist between harmonic oscillators and turbulence. Consider the special case of the logistic map

$$g(x)=4x(1-x), \tag{V.1}$$

which is helpful in modeling the velocity field in fully developed turbulence (the ''poor man's Navier–Stokes equation'').[12] It takes the interval $[0, 1]$ into itself. The coordinate transformation $x'=2x-1$, $y'=2y-1$, takes it into a map $[-1,1]\to[-1,1]$. We shall write $v(x)=2x-1$, in terms of which the logistic map takes the form

$$g(x)=\tfrac{1}{2}[1-T_2(2x-1)], \tag{V.2}$$

where $T_2(z)=2z^2-1=\cos[2\arccos z]$ is the second-order Chebyshev polynomial of the first kind. Using $v^{\langle -1\rangle}(u)=\frac{1}{2}(u+1)$, we notice that

$$T_2(z)=-v\circ g\circ v^{\langle -1\rangle}(z).$$

Iterating once this expression, we have $[T_2\circ T_2](z)=-v\circ g\circ v^{\langle -1\rangle}[-v]\circ g\circ v^{\langle -1\rangle}(z)$. As $v^{\langle -1\rangle}[-v(u)]=1-u$, but $g(1-u)=g(u)$, we arrive at $T_2{}^{\langle 2\rangle}(z)=-v\circ g^{\langle 2\rangle}\circ v^{\langle -1\rangle}(z)$. In the same way we obtain the nth iterate

$$T_2{}^{\langle n\rangle}(z)=-v\circ g^{\langle n\rangle}\circ v^{\langle -1\rangle}(z)=1-2g^{\langle n\rangle}[\tfrac{1}{2}(1+z)]. \tag{V.3}$$

Now, these Chebyshev polynomials[13] have a very interesting property, easily proved from the definition: they transform composition into index product:

$$T_n[T_m(z)]=[T_n\circ T_m](z)=T_{nm}(z).$$

Therefore, $T_2{}^{\langle n\rangle}(z)=T_{2^n}(z)=\cos[2^n\arccos z]$, and we obtain a closed expression for the n-iterate of g: $g^{\langle n\rangle}=v^{\langle -1\rangle}\circ[-T_{2^n}(z)]\circ v$, or

$$g^{\langle n\rangle}(x)=\tfrac{1}{2}\{1-T_{2^n}(z)(2x-1)\}=\tfrac{1}{2}\{1-\cos[2^n\ \arccos(2x-1)]\}=\sin^2[2^{n-1}\ \arccos(2x-1)]. \tag{V.4}$$

We proceed to find a continuum version of this iterate. The result,

$$g^{\langle \alpha\rangle}(x)=\tfrac{1}{2}\{1-\cos[2^\alpha\ \arccos(2x-1)\}, \tag{V.5}$$

can be naively anticipated, but we shall prove it. In the present case $a=4$, the eigenvalue alphabet is $(4^1,4^2,4^3,\ldots)$ and matrix $\Lambda^{-1}{}_{jn}$ in (III.17) is such that $\Sigma_{n\geqslant 1}\ \Lambda^{-1}{}_{kn}4^{np}=\delta_k^p$. We use the second expression in (V.4) in the form $g^{\langle n\rangle}(x)=-(1/2)\Sigma_{p\geqslant 1}[(-)^p/(2p)!]\ 4^{np}[\arccos(2x-1)]^{2p}$ and calculate (IV.19):

$$R_k(x)=\sum_{n\geqslant 1}\ \Lambda^{-1}{}_{kn}g^{\langle n\rangle}(x)=-\frac{1}{2}\,\frac{(-)^k}{(2k)!}\,[\arccos(2x-1)]^{2k} \tag{V.6}$$

[notice that (IV.6) is trivially satisfied]. Equation (IV.21) gives then

$$g^{\langle \alpha\rangle}(x)=\sum_{k\geqslant 1}\ 4^{k\alpha}R_k(x)=-\frac{1}{2}\sum_{k\geqslant 1}\ \frac{(-)^k}{(2k)!}\,[2^\alpha\ \arccos(2x-1)]^{2k},$$

which is the same as (V.5).

Let us now recall some facts about the double oscillator. Given $x=\cos\omega t$ and $y=\cos(n\omega t)$, we have of course $y=T_n[x]$, which solves the differential equation $(1-x^2)y''-xy'-n^2y=0$. This leads to the usual, ''isolated,'' finite Lissajous curves. When the two frequencies are not commensurate, $y=\cos(\nu\omega t)$, the differential equation becomes

$$(1-x^2)y''-xy'-\nu^2y=0, \tag{V.7}$$

whose solution $y=\cos[\nu \arccos x]$ is not a polynomial in the general case. It is a well-known fact that, when ν is not a rational number, each one of these transcendental, infinite Lissajous curves is dense in the (x,y) square,[14] and that the topology of the space of such trajectories is not even first separable.[15]

Now, the related functions

$$T_{2^\alpha}(z)=\cos[2^\alpha \arccos(2x-1)]=1-2g^{\langle\alpha\rangle}[\tfrac{1}{2}(1+z)]$$

are just the continuum versions of the Chebyshev polynomials obtained from (V.5). For each value of α, $T_{2^\alpha}(z)$ solves (V.7) with $\nu=2^\alpha$, and constitutes one of the Lissajous curves. The continuum parameter α, which can be interpreted as ''time'' for the logistic map, is a label for Lissajous curves from the point of view of the double oscillator. It is just the set of its values which constitutes a nonseparable space: all trajectories with α irrational are ultimately indistinguishable. However rough the ''poor man's'' model may be, the result suggests that the velocity field in turbulent flow can assume a large amount of nonseparable values.

VI. CONCLUDING REMARKS

In the passage from functions to Bell matrices, composition is translated into matrix product and iteration into matrix powers. Continuous powers of matrices have a sound meaning, which is translated back into continuous iteration and makes of it also a sound concept, respecting properties (I.1)–(I.2). The usual discrete iterations are thus extended into a continuous flow. The term-by-term factorization of the x and t dependencies of $g^{\langle t\rangle}(x)$ reveals itself as a decomposition into independently evolving modes, one for each projector of the corresponding Bell matrix.

Once it is established that iteration can have a continuous meaning and is, furthermore, a homotopy, new possibilities are made open to study, such as the use of the conservation of degrees like Brouwer's and Morse's. It is our contention that, with the continuum version of iterations, it will be possible to get a better understanding of the detailed unfolding of bifurcations and of the general relationship between the differential and the mapping approaches to chaotic dynamics.

Vertex operator representation of the soliton tau functions in the $A_n^{(1)}$ Toda models by dressing transformations

H. Belich,[a] G. Cuba,[b] and R. Paunov[c]

(Received 16 January 1998; accepted for publication 5 May 1998)

We study the relation between the group-algebraic approach and the dressing symmetry one to the soliton solutions of the $A_n^{(1)}$ Toda field theory in $1+1$ dimensions. Originally, solitons in the affine Toda models were found by Olive, Turok, and Underwood. Single solitons are created by exponentials of elements which addiagonalize the principal Heisenberg subalgebra. Alternatively, Babelon and Bernard exploited the dressing symmetry to reproduce the known expressions for the fundamental tau functions in the sine-Gordon model. In this paper we show the equivalence between these two methods to construct solitons in the $A_n^{(1)}$ Toda models. © *1998 American Institute of Physics.* [S0022-2488(98)01010-X]

I. INTRODUCTION

Exact localizable solutions of a relativistic field theory with finite energy are known in the literature as (depending on the dimension of the space–time) solitons (kinks) or monopoles.[1] Such solutions play an important role, since they are interpreted as new particles, which appear in the spectrum of the theory. As argued in Refs. 1 and 2, the particles corresponding to solitons (or monopoles) are of nonperturbative nature. Usually, the solitons (monopoles) are also characterized by nontrivial topological charges. This provides a connection between the field theory and the geometry.[3] There exists[4] a remarkable duality which exchanges the sine-Gordon model with the massive Thirring model. Under this duality transformation perturbative particles are mapped into solitons and vice versa. The duality also exchanges Noether currents with topological ones. Recently,[5] Seiberg and Witten have shown that there exist supersymmetric field theories in four dimensions which exhibit exact duality.

Within the inverse scattering method (ISM),[6] soliton equations are required to admit Lax or zero curvature representation. This representation guarantees that the spectrum of the Lax operator is constant in time. The leading idea of the ISM is to consider the time evolution as an evolution of the scattering data of the corresponding Lax operator. In view of the zero curvature condition, the equations of motion for the associated scattering data can be found explicitly. In the framework of the ISM, solitons correspond to vanishing reflection coefficients. Imposing this condition, the inverse spectral transformation reduces to a linear algebraic system. The integrability (in the sense of Liouville) also ensures that the interaction between the single solitons is elastic. This intriguing property survives the quantization and was used to get exact quantum S matrices in various integrable models.[7]

The propagation of waves in one-dimensional lattices with exponential nearest-neighbor interaction was studied by Toda.[8] In this pioneering paper, exact soliton solutions were also studied. The Toda lattice equations admit a field theoretical analog in $1+1$ dimensions[9] which exhibit both the integrability and the relation to the Lie algebras. Due to the last sequence of papers, it became clear that (generalized) Cartan matrices can be used to construct integrable exponential interactions in two dimensions. It was also shown that the field equations admit zero curvature representation of a Lax connection whose components belong to a certain Lie algebra. A deep relation between integrable hierarchies and the Kac–Moody (or affine) Lie algebras[10] has been clarified by

Drinfeld and Sokolov.[11] In the last paper the crucial role of Heisenberg subalgebras was also explained and the gradations related to them in constructing integrable evolution equations.[12,13]

Soliton solutions of the sine-Gordon model have been known since the early days of the ISM.[6] N-soliton solutions in the $A_n^{(1)}$ Toda models are found by the use of the Hirota method in Ref. 14. It also became clear that physical observables, when evaluated on solitons, take finite real quantities for imaginary values of the coupling constant. These results have been extended by using group-algebraic methods,[15,16] which also provide a bridge between the integrable models and the Kac–Moody algebras. In particular, the soliton tau functions corresponding to a fundamental highest weight state $|\Lambda\rangle$ of the affine Lie algebra admit the representation

$$\frac{\tau_\Lambda(\Phi)}{\tau_\Lambda(\Phi_0)}=\langle\Lambda|\prod_{i=1}^{N}(1+X_iF^{r_i}(\mu_i))|\Lambda\rangle, \tag{I.1}$$

where Φ_0 is the vacuum solution, X_i are numerical factors depending exponentially on the light cone coordinates, and F^{r_i} are elements of the affine Lie algebra which diagonalize the adjoint action of the principal Heisenberg subalgebra (for details see Refs. 10 and 15) and N is the number of the solitons. The above expression is analogous to the representation obtained by the Kyoto group[17] for the tau function of the KP hierarchy.

Integrable models possess a dressing symmetry.[18] The dressing group acts by gauge transformations on the Lax connection and preserves its form. An important property of the dressing symmetry is that it is a Lie–Poisson group. Applications of this symmetry to the Toda field theories has been done in Ref. 19. Using the dressing symmetry, an alternative expression for the soliton tau functions arises,

$$\frac{\tau_\Lambda(\Phi)}{\tau_\Lambda(\Phi_0)}=\langle\Lambda|g_-^{-1}(x^+,x^-).g_+(x^+,x^-)|\Lambda\rangle, \tag{I.2}$$

where g_-^{-1} and g_+ are triangular elements of the affine group which generate solitons from the vacuum. Babelon and Bernard demonstrated that the expressions (I.1) and (I.2) are equivalent, at least for affine sine-Gordon solitons.[20] In our previous paper[21] we obtained explicit expressions for the elements $g_\pm$ (I.2). In the present work, by using the results of Ref. 21, we show that the vertex operator representation of the tau functions (I.1) corresponding to fundamental representations of the affine Lie algebra is a consequence of the dressing group expression (I.2) for arbitrary $A_n^{(1)}$ Toda solitons.

The paper is organized as follows: In Sec. II we introduce the $A_n^{(1)}$ Toda models, their soliton solutions and briefly comment on the results of Ref. 21. Section III is also complementary: the vertex operator representation of the $A_n^{(1)}$ algebras in the principal gradation is derived. In Sec. IV we obtain the vertex operator representation of the monosoliton tau functions starting from the dressing symmetry. Section V generalizes this result to generic soliton solutions. The Appendix contains a brief summary of the Lie algebraic background used in the paper.

II. $A_n^{(1)}$ TODA SOLITONS AND THE RELATED DRESSING TRANSFORMATIONS

Solitons in the $A_n^{(1)}$ Toda models have been found by Hollowood,[14] who used the Hirota equations. Physically relevant solutions appear for imaginary values of the coupling constant, nevertheless the components of the Toda field are complex. Affine Toda field theories and their soliton solutions are also studied from the point of view of the ISM.[22] The underlying Jost solutions[6] as well as the elements of the transition matrix lose, in general, their nice analyticity properties. A similar phenomenon occurs when one considers the scattering data related to a linear differential operator of an arbitrary order.[23] In Ref. 21 we developed an elegant method to get $A_n^{(1)}$ Toda solitons. It strongly exploits the fact that the Lax connection belongs to the $A_n^{(1)}$ Lie algebra in the *principal* gradation (for a summary of the Lie algebraic background, see the Appendix). The dynamical variables which we use to describe the soliton dynamics, appeared previously in the study of the periodic solutions of the Korteweg–de Vries (KdV) equation and of the periodic Toda chain.[24] The same approach, applied to the sine-Gordon solitons, was recently exploited to compute form factors in the quantum theory.[25]

To get the $A_n^{(1)}$ Toda equations, we impose the zero curvature condition

$$\partial_+ A_- - \partial_- A_+ + [A_+, A_-] = 0 \tag{II.1a}$$

on the Lax connection

$$A_\pm = \pm \partial_\pm \Phi + m e^{\pm ad\Phi} \mathscr{E}_\pm, \quad \partial_\pm = \frac{\partial}{\partial x^\pm}, \tag{II.1b}$$

which belongs to the loop Lie algebra $\tilde{\mathscr{G}} = \widetilde{\mathrm{SL}(n+1)}$; $x^\pm = x \pm t$ are the light cone coordinates in the two-dimensional Minkowski space. The elements $\mathscr{E}_\pm = \mathscr{E}_{\pm 1}$ are generators of grade ± 1 of the principal Heisenberg subalgebra (A7), (A23),

$$\mathscr{E}_k = \lambda^k \sum_{p \in \mathbb{Z}_{n+1}} |p\rangle\langle p+k| \tag{II.1c}$$

and Φ is a diagonal matrix

$$\Phi = \frac{1}{2} \sum_{i \in \mathbb{Z}_{n+1}} \varphi_i E^{ii}. \tag{II.1d}$$

The $A_n^{(1)}$ Toda models have a conformally invariant extension[26] known as the A_n conformal affine Toda (CAT) model. It also admits a zero curvature representation (II.1a) for a connection of the form (II.1b) in the *affine* Lie algebra $\hat{\mathscr{G}} = \hat{\mathrm{sl}}(n+1) = A_n^{(1)}$.[10] The affine algebra analog of (II.1d) is

$$\Phi \to \Phi + \eta \hat{d} + \frac{\hat{c}}{2(n+1)} \zeta, \tag{II.2}$$

where (see the Appendix) $\hat{d}$ and $\hat{c}$ are the derivation and the central element, respectively. The A_n CAT field equations are

$$\begin{aligned} \partial_+ \partial_- \varphi_i &= m^2 e^{2\eta} (e^{\varphi_i - \varphi_{i+1}} - e^{\varphi_{i-1} - \varphi_i}), \\ \partial_+ \partial_- \eta &= 0, \\ \partial_+ \partial_- \zeta &= m^2 e^{2\eta} \sum_{i \in \mathbb{Z}_{n+1}} e^{\varphi_i - \varphi_{i+1}}. \end{aligned} \tag{II.3}$$

The first of the above equations coincides with the $A_n^{(1)}$ Toda equations provided that $\eta = 0$. As noted in Ref. 20, affine Toda solitons arise after imposing the last restriction. In such a case (II.3) admit a Hirota bilinear representation[14]

$$\partial_+ \tau_k \partial_- \tau_k - \tau_k \partial_+ \partial_- \tau_k = m^2 (\tau_{k+1} \tau_{k-1} - \tau_k^2), \tag{II.4a}$$

$$e^{-\varphi_k} = \frac{\tau_k}{\tau_{k-1}}, \quad k \in \mathbb{Z}_{n+1}, \tag{II.4b}$$

$$e^{\zeta_0 - \zeta} = \prod_{k \in \mathbb{Z}_{n+1}} \tau_k, \tag{II.4c}$$

where

$$\zeta_0 = (n+1) m^2 x^+ x^-. \tag{II.4d}$$

The above value of the field ζ together with $\varphi_k = 0$, $k \in \mathbb{Z}_{n+1}$ corresponds to the vacuum solution of the CAT model. The $A_n^{(1)}$ Toda vacuum is obtained by ignoring the additional field ζ.

In Ref. 21 we used an alternative procedure to get $A_n^{(1)}$ Toda solitons. The approach we used strongly relies on the work[27] where several soliton equations, including the sine-Gordon equation, have been studied. The dynamics of the $A_n^{(1)}$ Toda solitons is governed by the following *algebraic* equations:

$$\prod_{l=1}^{N} \frac{\epsilon_{kl}+\omega^{r_j}\mu_j}{\epsilon_{kl}+\mu_j}=c_j\omega^{r_j(1-k)}\frac{e(\omega^{r_j}\mu_j)}{e(\mu_j)},$$
$$e(\lambda)=\exp\left\{m\left(\lambda x^{+}+\frac{x^{-}}{\lambda}\right)\right\}, \tag{II.5a}$$

$$\epsilon^{-\varphi_k}=(-)^N\prod_{j=1}^{N}\frac{\epsilon_{kj}}{\mu_j}, \quad k\in\mathbb{Z}_{n+1}, \tag{II.5b}$$

where the integer N stands for the number of solitons; μ_j, $j=1,...,N$ are (complex) parameters related to the soliton rapidities, and r_j are discrete parameters which take nonvanishing values in the cyclic group $\mathbb{Z}_{n+1}$. The latter are known in the literature[14–16] as *soliton species*. The relation between solitons and N-body integrable relativistic systems was studied in detail.[28,29] In order to simplify our analysis, only solitons with $|\mu_i|\neq|\mu_j|$ $(i\neq j)$ will be considered. Certain particular solutions which violate this restriction are also known.[30] Let us note that in contrast to Refs. 14–16, we are working with a real value of the coupling constant. This implies that the solutions (II.5a), (II.5b) are solitons in the *algebraic* sense.

Transformation groups for soliton equations were introduced in Ref. 17. They have also been studied in relation to the underlying Riemann problem[31] and are known as groups of dressing transformations. In the present paper we will not comment on the Poisson–Lie properties[18,19] of the dressing group. For dressing group elements which create monosoliton solutions from the vacuum in the sine-Gordon model this problem has been discussed in Ref. 32. One believes that[20] in the limit $N\to\infty$, the N-soliton solutions are dense in the dressing group orbit of the vacuum, and therefore, the soliton parameters are expected to provide a convenient coordinate system on the dressing group.

To introduce the group of dressing transformations we first recall that the zero curvature condition (II.1a) can be equivalently written as the compatibility condition of the linear system

$$(\partial_{\pm}+A_{\pm})T=0. \tag{II.6}$$

We shall also impose the normalization condition $T|_{x^+=x^-=0}=1$. An element of the dressing group is represented by a pair of triangular elements $(g_+(x),g_-(x))$ of the corresponding loop (or affine) Lie group. This is to say that $g_{\pm}(x)=e^{\mathscr{H}}e^{\mathscr{N}_{\pm}}$ where $\mathscr{H}$ is the Cartan subalgebra and $\mathscr{N}_{\pm}$ contain all the elements of positive (negative) grade. The gradation is introduced by the derivation $\hat{d}$ of the loop (affine) Lie algebra (A18) and (A19). The dressing group acts on the components of the Lax connection by gauge transformations

$$A_\mu\to A_\mu^g=-\partial_\mu g_{\pm}g_{\pm}^{-1}+g_{\pm}A_\mu g_{\pm}^{-1}, \tag{II.7a}$$

or equivalently

$$T(x)\to T(x)^g=g_{\pm}(x)T(x)g_{\pm}^{-1}(0). \tag{II.7b}$$

The space–time independent factors $g_{\pm}^{-1}(0)$ are added to ensure the normalization condition $T|_{x^+=x^-=0}=1$. The gauge transformations are also required to preserve the form of the Lax connection (II.1b). Therefore, the dressing transformations form a symmetry group of the corresponding field equations (II.3). Since the group elements g_+ and g_- produce the same result (II.7a), it turns out that they are a solution of the factorization problem

$$g_-^{-1}(x)g_+(x)=T(x)g_-^{-1}(0)g_+(0)T^{-1}(x). \tag{II.8}$$

Comparing (II.1b) with (II.7a), one observes that g_+ and g_- have opposite components on the Cartan torus $e^{\mathscr{H}}$. Therefore, the solution of (II.8) is unique. The multiplication in the dressing group is the same as in the dual of the loop group.[18,19] In particular, the map $(g_+,g_-) \to g_-^{-1}g_+$ is not an isomorphism of Lie groups.

In the CAT models based on arbitrary simple Lie algebras, one associates a group-algebraic tau function to each highest weight vector $|\Lambda\rangle$,

$$\tau_\Lambda(\Phi)=\langle\Lambda|e^{-2\Phi}|\Lambda\rangle. \tag{II.9}$$

Suppose that a solution Φ (II.2), (II.3) with $\eta=0$ is related to the vacuum solution $\phi_0=(m^2/2)x^+x^-\hat{c}$ by dressing transformation (g_+,g_-). The following relation[19,20]

$$\frac{\tau_\Lambda(\Phi)}{\tau_\Lambda(\phi_0)}=\langle\Lambda|g_-^{-1}(x)g_+(x)|\Lambda\rangle \tag{II.10}$$

between the tau functions of the two solutions is valid. In Ref. 20 it was observed that, after factorizing out the contribution which belongs to the center of the affine group, one can perform the calculation of the element $g_\pm$ in the corresponding loop group:

$$g_\pm(x)=\exp\left(\pm\frac{\zeta_0-\zeta}{2(n+1)}\hat{c}\right)\tilde{g}_\pm(x), \tag{II.11}$$

where $\tilde{g}_\pm$, considered as elements of the loop group, generate the $A_n^{(1)}$ Toda solution $\Phi=\frac{1}{2}\Sigma_{i\in\mathbb{Z}_{n+1}}\varphi_i|i\rangle\langle i|$ from the vacuum $\Phi_0=0$. We recall that the above identity has been established in Ref. 20 for the affine Lie algebra $A_1^{(1)}=\hat{\mathrm{sl}}(2)$. However, it is easy to check that the proof can be easily generalized for an arbitrary affine Lie algebra.

The representation (II.5a), (II.5b) of the N-soliton solutions was used[21] to calculate the elements $\tilde{g}_\pm$ which by (II.7a) generate these solutions from the vacuum. It turns out that the dressing group elements $\tilde{g}_\pm$ can be factorized into a product of monosoliton factors

$$\tilde{g}_\pm=\tilde{g}_\pm(N)\tilde{g}_\pm(N-1)\cdots\tilde{g}_\pm(1), \tag{II.12}$$

where

$$\tilde{g}_\pm(i)=e^{K(F_i)+P_i}e^{W_\pm(i)}. \tag{II.13a}$$

In the above expression, F_i, $K(F_i)$, and P_i are diagonal traceless matrices

$$F_i=\frac{1}{2}\sum_{k\in\mathbb{Z}_{n+1}}f_{ki}|k\rangle\langle k|, \quad P_i=\frac{1}{2}\sum_{k\in\mathbb{Z}_{n+1}}p_{ki}|k\rangle\langle k|,$$

$$K(F_i)=\sum_{k\in\mathbb{Z}_{n+1}}K_k(F_i)|k\rangle\langle k|, \tag{II.13b}$$

$$\sum_{k\in\mathbb{Z}_{n+1}}f_{ki}=\sum_{k\in\mathbb{Z}_{n+1}}p_{ki}=\sum_{k\in\mathbb{Z}_{n+1}}K_k(F_i)=0.$$

The quantities $K_k(F_i)$ obey the relations

$$k_k(F_i)-K_{k+1}(F_i)=\frac{f_{ki}+f_{ki+1}}{2}, \tag{II.13c}$$

which agree with the periodicity property $K_k(F_i)=K_{k+n+1}(F_i)$ since F_i is traceless. The loop algebra elements $W_\pm(i)$ are given by

$$W_{\pm}(i) = -K(F_i) + \sum_{k=1}^{n} f_{ki} \mathscr{S}_{\pm}^{k}(\mu_i),$$

$$\mathscr{S}_{\pm}^{k}(\mu_i) = \mathscr{B}_{\pm}^{k}(\mu_i) - \mathscr{B}_{\pm}^{n+1}(\mu_i), \tag{II.13d}$$

$$\mathscr{B}_{\pm}^{k}(\mu_i) = \mp \left(\frac{1}{2} + \frac{\left(\frac{\lambda}{\mu_i}\right)^{\pm(n+1)}}{1-\left(\frac{\lambda}{\mu_i}\right)^{\pm(n+1)}} \right) E^{kk} \mp \sum_{l \gtrless k} \frac{\left(\frac{\lambda}{\mu_i}\right)^{l-k\pm(n+1)}}{1-\left(\frac{\lambda}{\mu_i}\right)^{\pm(n+1)}} E^{kl} \mp \sum_{l \gtrless k} \frac{\left(\frac{\lambda}{\mu_i}\right)^{l-k}}{1-\left(\frac{\lambda}{\mu_i}\right)^{\pm(n+1)}} E^{kl}.$$

In the above expressions λ stands for the loop (or spectral) parameter (see the Appendix). Note that the elements $\mathscr{B}_{\pm}^{k}(\mu_i)$, in contrast to $\mathscr{S}_{\pm}^{k}(\mu_i)$, are not in the loop algebra $\mathrm{sl}(n+1)$. Due to the diagonal (λ-depending) contributions with nonvanishing trace, $\mathscr{B}_{\pm}^{k}(\mu_i)$ are in the loop algebra $\widetilde{\mathrm{gl}}(n+1)$. Taking into account the loop algebra analog of (A13) together with (A23) one gets

$$\mathscr{S}_{\pm}^{k}(\mu_i) = \mp \sum_{r \in \mathbb{Z}_{n+1}} \omega^{r}(\omega^{-rk}-1)\left(\frac{F_0^r}{2} + \sum_{p \gtrless 0} \frac{F_p^r}{\mu_i^p} \right). \tag{II.14}$$

The elements of the Cartan subalgebra $K(F_i)$ (II.13b), (II.13c) can also be expanded in the alternative basis (A13). Therefore, from (II.13d) and the above expansions, we obtain

$$W_{\pm}(i) = \sum_{k \in \mathbb{Z}_{n+1}} f_{ki} W_{\pm}^{k}(\mu_i), \tag{II.15a}$$

where

$$W_{+}^{k}(\mu_i) = -\sum_{r=1}^{n} \left(\frac{1-\omega^{-rk}}{1-\omega^{-r}} F_0^r + \omega^{r(1-k)} \sum_{p \geqslant 1} \frac{F_p^r}{\mu_i^p} \right), \tag{II.15b}$$

$$W_{-}^{k}(\mu_i) = \sum_{r=1}^{n} \left(-\frac{1-\omega^{r(1-k)}}{1-\omega^{-r}} F_0^r + \omega^{r(1-k)} \sum_{p \leqslant -1} \frac{F_p^r}{\mu_i^p} \right). \tag{II.15c}$$

Note that neither $W_{+}^{k}(\mu_i)$ nor $W_{-}^{k}(\mu_i)$ contain contributions belonging to the principal Heisenberg subalgebra. Moreover, the identities

$$W_{+}^{k}(\mu_i) - W_{-}^{k}(\mu_i) = -\sum_{r=1}^{n} \omega^{r(1-k)} \sum_{p \in \mathbb{Z}} \frac{F_p^r}{\mu_i^p} \tag{II.16}$$

are valid. The above expression together with (II.15a)–(II.15c) provides a hint of how to relate the dressing group approach to the group-algebraic methods, developed in Refs. 15 and 16. This relation has been conjectured for general integrable hierarchies which admit a vacuum solution.[13]

Up to now we discussed the properties of the factors $\tilde{g}_{\pm}(k)$ (II.12) which produce single solitons without specifying their relation to the N-soliton solution (II.5a), (II.5b). This relation has been discussed in detail in Ref. 21. Here we only list the results. First of all, it has been shown that the diagonal matrices F_l, $l=1,\ldots,N$ (II.13b) satisfy the identities

$$\begin{aligned} &\sum_{k \in \mathbb{Z}_{n+1}} \omega^{r(1-k)} \left(\frac{\rho_{kl}(\omega^r \mu_{l+1})}{\rho_{kl}(\mu_{l+1})} - \omega^{-r} \frac{\rho_{k+1l}(\omega^r \mu_{l+1})}{\rho_{k+1l}(\mu_{l+1})} \right) \beta_k(F_{l+1}) \\ &\quad = \delta_{r,r_{l+1}}(1-\omega^r) \prod_{a \neq l+1} \frac{\omega^r \mu_{l+1} - \mu_a}{\mu_{l+1} - \mu_a} \prod_{a=1}^{N} \frac{\mu_{+1} + \epsilon_{1a}}{\omega^r \mu_{l+1} + \epsilon_{1a}} \\ &\quad \times \sum_{k \in \mathbb{Z}_{n+1}} \left(1 + \mu_{l+1} \frac{d}{d\lambda} \ln \frac{\rho_{kl}}{\rho_{k+1l}}(\mu_{l+1}) \right) \beta_k(F_{l+1}). \end{aligned} \tag{II.17a}$$

In the above system r is a discrete parameter which belongs to $\mathbb{Z}_{n+1}$; $r_i = 1,\ldots,n$ stand for the

soliton species (II.5a), (II.5b) related to the soliton with the rapiditylike parameter μ_i for $i=1,...,N$. It was noted in Ref. 21 that (II.17a) is a system of algebraic equations which determines the variables

$$\beta_k(F_l)=\exp\left(K_k(F_l)-\frac{f_{kl}}{2}\right). \tag{II.17b}$$

The quantities $K_k(F_l)$ and f_{kl} which appear in the above definition are introduced by (II.13a) and (II.13c). The functions ρ_{al} (II.17a) on λ, $a\in\mathbb{Z}_{n+1}$, $l=1,...,N$ can be considered as components of $n+1$-dimensional column vectors $\rho_l(\lambda)$. The following relations are valid:

$$\begin{aligned}\rho_l(\lambda)&=\mathscr{D}^{(ll-1)}(\lambda)\rho_{l-1}(\lambda),\\ \rho_{l-1}(\lambda)&=\mathscr{D}^{(l-1l)}(\lambda)\rho_l(\lambda),\end{aligned} \tag{II.17c}$$

where $\mathscr{D}^{(ll-1)}(\lambda)$ and $\mathscr{D}^{(l-1l)}(\lambda)$ are $(n+1)\times(n+1)$ matrices $(\mathscr{D}^{(ll-1)}(\lambda)\mathscr{D}^{(l-1l)}(\lambda)=1)$. Their matrix elements are given by

$$\begin{aligned}\mathscr{D}^{(ll-1)}_{ab}(\lambda)&=\frac{\gamma_l\beta_b(F_l)}{(n+1)\rho_{bl-1}(\mu_l)}\sum_{q\in\mathbb{Z}_{n+1}}\omega^{q(a-b)}\frac{\lambda-\omega^q e^{f_{bl}}\mu_l}{\lambda-\omega^q\mu_l}\\ \mathscr{D}^{(l-1l)}_{ab}(\lambda)&=\frac{\rho_{al-1}(\mu_l)}{(n+1)\gamma_l\beta_b(F_l)}\sum_{q\in\mathbb{Z}_{n+1}}\omega^{q(a-b)}\frac{\lambda-\omega^q e^{-f_{bl}}\mu_l}{\lambda-\omega^q\mu_l}\\ \gamma_l&=\left(\prod_{p\in\mathbb{Z}_{n+1}}\rho_{pl-1}(\mu_l)\right)^{1/n+1}.\end{aligned} \tag{II.17d}$$

The first relation (II.17c) together with

$$\rho_{j0}(\lambda)=\frac{1}{n+1} \tag{II.17e}$$

determines uniquely the vectors $\rho_l(\lambda)$. The entries of the diagonal matrices P_l are fixed by the relations[21]

$$\exp\left[K_a(F_{l-1})+\frac{p_{al-1}}{2}\right]=\frac{\rho_{al-1}(\mu_l)}{\gamma_l}. \tag{II.17f}$$

Therefore, Eqs. (II.17a)–(II.17f) provide a recursive method to obtain the factorized expression (II.12) for a dressing group element in the loop group which generate the N-soliton solution (II.5a), (II.5b) from the vacuum. In view of the close relation (II.11) between the dressing group elements in the affine group and in the loop group, the decomposition (II.12) together with the recurrence relations (II.17a)–(II.17f), will play a crucial role in obtaining the vertex operator representation for the soliton tau function. Note also that due to (II.13c), the quantities $\beta_k(F_i)$ (II.17b) satisfy the relation

$$e^{-f_{kl}}=\frac{\beta_k(F_l)}{\beta_{k-1}(F_l)}, \tag{II.18}$$

which resembles (II.4b). However β_k, as it can be seen from (II.17a), (II.17c), and (II.17d), do not satisfy the Hirota bilinear equations (II.4a) in general. This is to say that the fields F_l (II.13b) *do not* satisfy the $A^{(1)}_n$ Toda equations for arbitrary values of l.

The components $\rho_{al}(\lambda)$ of the vectors $\rho_l(\lambda)$ (II.17a), (II.17c), (II.17d) satisfy algebraic and differential equations which will be important in what follows. First of all, combining (II.17c) with (II.17d), we get

$$\sum_{a,r\in\mathbb{Z}_{n+1}} \frac{\omega^{r(a'-a)}}{\lambda-\omega^r\mu_l}\left(\frac{\lambda-\omega^r e^{-f_{al}}\mu_l}{\lambda-\omega^r\mu_l}\frac{\rho_{al}(\lambda)}{\gamma_l\beta_a(F_l)}-\frac{\rho_{al-1}(\lambda)}{\rho_{al-1}(\mu_l)}\right)=0 \tag{II.19}$$

for any $a'\in\mathbb{Z}_{n+1}$. From the above identity and the second equation (II.17d) we deduce the relations

$$\sum_{a\in\mathbb{Z}_{n+1}} \frac{d\mathscr{D}^{(l-1l)}_{a'a}}{d\lambda}(\lambda)\rho_{al}(\lambda)=\frac{\rho_{a'l-1}(\mu_l)}{n+1}\sum_{a,r\in\mathbb{Z}_{n+1}} \frac{\omega^{r(a'-a)}}{\lambda-\omega^r\mu_l}\left(\frac{\rho_{al}(\lambda)}{\gamma_l\beta_a(F_l)}-\frac{\rho_{al-1}(\lambda)}{\rho_{al-1}(\mu_l)}\right). \tag{II.20}$$

In view of (II.17c), the following representation,

$$\rho_j(\lambda)=\mathscr{D}^{(jj-1)}\cdots\mathscr{D}^{(10)}\rho_0(\lambda), \tag{II.21a}$$

takes place. Differentiating the above identity with respect to λ and taking into account that $\rho_0(\lambda)$ (II.17e) does not depend on the spectral parameter, one obtains

$$\frac{d\rho_j}{d\lambda}(\lambda)=\sum_{l=1}^{j}\mathscr{D}^{(jl)}(\lambda)\frac{d\mathscr{D}^{(ll-1)}}{d\lambda}(\lambda)\rho_{l-1}(\lambda), \tag{II.21b}$$

where the matrices $\mathscr{D}^{(jl)}(\lambda)$ for $j\geqslant l$ are given by

$$\begin{aligned}\mathscr{D}^{(jl)}(\lambda)&=\mathscr{D}^{(jj-1)}(\lambda)\cdots\mathscr{D}^{(l+1l)}(\lambda),\\ \rho_j(\lambda)&=\mathscr{D}^{(jl)}(\lambda)\rho_l(\lambda),\\ \mathscr{D}^{(jj)}(\lambda)&=1.\end{aligned} \tag{II.21c}$$

Since $\mathscr{D}^{(l-1l)}$ is the inverse of $\mathscr{D}^{(ll-1)}$, we can rewrite (II.21b) as follows:

$$\frac{d\rho_j}{d\lambda}(\lambda)=-\sum_{l=1}^{j}\mathscr{D}^{(jl-1)}(\lambda)\frac{d\mathscr{D}^{(l-1l)}}{d\lambda}(\lambda)\rho_l(\lambda). \tag{II.21d}$$

Inserting (II.20) into the above identity we obtain

$$\frac{d\rho_{kj}}{d\lambda}(\lambda)=-\frac{1}{n+1}\sum_{l=1}^{j}\sum_{a,a',r\in\mathbb{Z}_{n+1}}\frac{\omega^{r(a'-a)}}{\lambda-\omega^r\mu_l}\mathscr{D}^{(jl-1)}_{ka'}(\lambda)\rho_{a'l-1}(\lambda)\left(\frac{\rho_{al}(\lambda)}{\gamma_l\beta_a(F_l)}-\frac{\rho_{al-1}(\lambda)}{\rho_{al-1}(\mu_l)}\right). \tag{II.22}$$

This result will be used in Sec. V to demonstrate the equivalence between expressions (I.1) and (I.2) for the N-soliton tau functions.

III. FREE FIELD REALIZATION OF THE $A_n^{(1)}$ LIE ALGEBRAS IN THE PRINCIPAL GRADATION

Realizations of infinite dimensional Lie algebras in terms of harmonic oscillators play a crucial role in the representation theory. They are also important in the applications to the string theory and the two-dimensional conformal models (for a review, see Ref. 33). In the simplest case of the affine Lie algebra $A_1^{(1)}=\hat{\mathrm{sl}}(2)$, the free field (or vertex operator) construction was obtained in Ref. 34. This result has been generalized for affine Lie algebras $\hat{\mathscr{G}}$ in the principal gradation[35] when the underlying classical Lie algebras $\mathscr{G}$ are simply laced and the level of the corresponding representation is one. The vertex operator realization of $\hat{\mathscr{G}}$ with $\mathscr{G}$ being nonsimply laced as well as for twisted affine Lie algebras, is also known.[15,16] In the present section we limit our attention on the $A_n^{(1)}$ Lie algebras in the principal gradation only. A detailed discussion of the general case is given in Ref. 10.

As is seen from (II.10), general solutions of the CAT models (II.1a), (II.2), and (II.3) can be written by using the highest weight representations of the affine Lie algebras $\hat{\mathscr{G}}$. The representa-

tion spaces are generated by the action of arbitrary products of negative grade elements (A19) on the highest-weight state $|\Lambda\rangle$. The latter is annihilated by the elements of positive grade of the affine Lie algebra

$$F_k^r|\Lambda\rangle=0, \quad k\geqslant 1, \quad r\in\mathbb{Z}_{n+1}, \tag{III.1a}$$

where we have used the notation (A22). We also recall that $F^0_{p(n+1)}\equiv 0$, $p\in\mathbb{Z}$ since these elements are not in the affine algebra. The highest-weight state is an eigenvector of the subalgebra $\hat{\mathscr{G}}_0$ of the elements of $\mathbb{Z}$ grade zero (A18) and (A19),

$$F_0^r|\Lambda\rangle=\Lambda(F_0^r)|\Lambda\rangle, \quad \hat{d}|\Lambda\rangle=\Lambda(\hat{d})|\Lambda\rangle, \quad \hat{c}|\Lambda\rangle=\Lambda(\hat{c})|\Lambda\rangle. \tag{III.1b}$$

In view of (A23), the generators $\mathscr{E}_k=(n+1)F_k^0$ $(k\neq 0 \bmod(n+1))$ form a Heisenberg subalgebra. It is known as the *principal* Heisenberg subalgebra. Since $\mathscr{E}_k$ are bosonic oscillators, they admit a Fock space representation, built up on the Fock vacuum $|0\rangle$,

$$\begin{aligned} \mathscr{E}_k|0\rangle&=0, \quad k\geqslant 1,\\ \langle 0|\mathscr{E}_k&=0, \quad k\leqslant -1. \end{aligned} \tag{III.2}$$

It is known that when the value of the central charge $\hat{c}$ is 1, all the irreducible highest representations of the Lie algebras $A_n^{(1)}$ are expressed in terms of the elements of the (principal) Heisenberg subalgebra only.[10,34,35] In this section we give an elementary demonstration of this statement.

We start by introducing the notations

$$\mathscr{E}(\mu)=\sum_{\substack{k\in\mathbb{Z}\\ k\neq 0 \bmod(n+1)}} \frac{\mathscr{E}_k}{\mu^k}, \tag{III.3a}$$

$$\begin{aligned} \theta_r(\mu)&=i\sum_{\substack{k\in\mathbb{Z}\\ k\neq 0 \bmod(n+1)}} \frac{\omega^{-rk}-1}{k}\frac{\mathscr{E}_k}{\mu^k},\\ \theta_r(\mu)&=\theta_{r+n+1}(\mu), \quad \theta_0(\mu)=0, \end{aligned} \tag{III.3b}$$

where i is the imaginary unit $i^2=-1$. The above expressions are related by the identity

$$\mathscr{E}(\mu)=-\frac{i}{n+1}\,\mu\,\frac{d}{d\mu}\sum_{r\in\mathbb{Z}_{n+1}}\theta_r(\mu). \tag{III.3c}$$

We also define the bosonic normal product $::$ in the standard way: $\mathscr{E}_k$ with $k\geqslant 1$ are moved to the right, while $\mathscr{E}_k$ with $k\leqslant -1$ are moved to the left in each normal ordered monomial containing generators of the Heisenberg subalgebra only. Since the Heisenberg subalgebra does not contain elements of grade zero, it turns out that each normal ordered monomial of positive (negative) grade annihilates the Fock vacuum $|0\rangle$ ($\langle 0|$) (III.2). Taking into account (III.2) and the Heisenberg commutation relations (A23) we get the contraction identities

$$\begin{aligned} \theta_r(\mu_1)\theta_s(\mu_2)&=\langle\theta_r(\mu_1)\theta_s(\mu_2)\rangle+:\theta_r(\mu_1)\theta_s(\mu_2):,\\ \mathscr{E}(\mu_1)\theta_s(\mu_2)&=\langle\mathscr{E}(\mu_1)\theta_s(\mu_2)\rangle+:\mathscr{E}(\mu_1)\theta_s(\mu_2):,\\ |\mu_1|&>|\mu_2|. \end{aligned} \tag{III.4a}$$

The corresponding vacuum expectation values are given by

$$\langle\theta_r(\mu_1)\theta_s(\mu_2)\rangle=\ln\frac{(\mu_1-\omega^{-r}\mu_2)(\mu_1-\omega^s\mu_2)}{(\mu_1-\mu_2)(\mu_1-\omega^{s-r}\mu_2)}, \tag{III.4b}$$

$$\langle \mathscr{E}(\mu_1)\theta_r(\mu_2)\rangle = i\,\frac{(1-\omega^r)\mu_1\mu_2}{(\mu_1-\mu_2)(\mu_1-\omega^r\mu_2)}.$$

To obtain a realization of the basic representations of the affine Lie algebras $A_n^{(1)}$ we introduce the *vertex* operators

$$V^r(\mu) = :e^{i\theta_r(\mu)}: = \exp\left(\sum_{k\leqslant -1}\ \frac{1-\omega^{-kr}}{k}\,\frac{\mathscr{E}_k}{\mu^k}\right)\exp\left(\sum_{k\geqslant 1}\ \frac{1-\omega^{-kr}}{k}\,\frac{\mathscr{E}_k}{\mu^k}\right)\ . \qquad r=1,\ldots,n. \tag{III.5}$$

Using the Wick theorem one deduces the following operator products:

$$\mathscr{E}(\mu_1)V^r(\mu_2) = \frac{(\omega^r-1)\mu_1\mu_2}{(\mu_1-\mu_2)(\mu_1-\omega^r\mu_2)}\,V^r(\mu_2) + :\mathscr{E}(\mu_1)V^r(\mu_2):$$

$$V^r(\mu_1)V^s(\mu_2) = \frac{(\mu_1-\mu_2)(\mu_1-\omega^{s-r}\mu_2)}{(\mu_1-\omega^{-r}\mu_2)(\mu_1-\omega^s\mu_2)}:e^{i(\theta_r(\mu_1)+\theta_s(\mu_2))}: \qquad |\mu_1|>|\mu_2|. \tag{III.6}$$

In view of (A23) and (III.2) we also get

$$\mathscr{E}(\mu_1)\mathscr{E}(\mu_2) = \frac{\mu_1\mu_2}{(\mu_1-\mu_2)^2} - (n+1)\,\frac{\mu_1^{n+1}\mu_2^{n+1}}{(\mu_1^{n+1}-\mu_2^{n+1})^2} + :\mathscr{E}(\mu_1)\mathscr{E}(\mu_2):, \qquad |\mu_1|>|\mu_2|. \tag{III.7}$$

By using the notion of radial ordering[33] which is an analog of the standard time ordering in the field theory, one can extend the operator products (III.6) and (III.7) to the region $|\mu_1|<|\mu_2|$ in accordance with the ''local'' commutativity relations

$$A(\mu_1)B(\mu_2) = B(\mu_2)A(\mu_1), \quad |\mu_1|\neq|\mu_2|,$$

for $A(\mu)$, $B(\mu)$ being $\mathscr{E}(\mu)$ (III.3a) or $V^r(\mu)$ (III.5). This enables us to use the Laurent expansions

$$V^r(\mu) = \sum_{l\in\mathbb{Z}}\ \frac{V_l^r}{\mu^l}, \quad V_l^r = \oint_{\mathscr{S}^1}\frac{d\mu}{2\pi i\mu}\,\mu^l V^r(\mu). \tag{III.8}$$

Note also that the normal ordered terms which appear on the right-hand side of (III.6) and (III.7) have finite matrix elements when evaluated between normalizable states in the bosonic Fock space.

To compute the commutators of the Laurent coefficients $\mathscr{E}_k$, $k\in\mathbb{Z}\backslash(n+1)\mathbb{Z}$ and V_k^r we shall use the *contour* deformation technique.[33] Let us briefly recall it: Suppose that $A(\mu)$ and $B(\mu)$ are meromorphic operator valued functions on μ which *locally* commute $A(\mu_1)B(\mu_2) = A(\mu_2)B(\mu_1)$ for $|\mu_1|\neq|\mu_2|$. Then the commutator between the Laurent coefficients

$$A_k = \oint_{\mathscr{S}^1}\frac{\mu^k d\mu}{2\pi i\mu}\,A(\mu), \quad B_l = \oint_{S^1}\frac{\mu^l d\mu}{2\pi i\mu}\,B(\mu) \tag{III.9a}$$

is given by

$$[A_k,B_l] = \left(\oint_{|\mu_1|>|\mu_2|} - \oint_{|\mu_1|<|\mu_2|}\right)\mu_1^k\,\frac{d\mu_1}{2\pi i\mu_1}\,\mu_2^l\,\frac{d\mu_2}{2\pi i\mu_2}\,A(\mu_1)B(\mu_2). \tag{III.9b}$$

Using the above identity, the Cauchy theorem, and taking into account (III.6) one gets

$$[\mathscr{E}_k, V_l^r] = \left(\oint_{|\mu_1|>|\mu_2|} - \oint_{|\mu_1|<|\mu_2|} \right) \mu_1^k \frac{d\mu_1}{2\pi i \mu_1} \mu_2^l \frac{d\mu_2}{2\pi i \mu_2} \mathscr{E}(\mu_1) V^r(\mu_2)$$

$$= \oint \mu_2^{l+1} \frac{d\mu_2}{2\pi i \mu_2} \left(\oint_{C_{\mu_2}} - \oint_{C_{\omega^r \mu_2}} \right) \mu_1^{k+1} \frac{d\mu_1}{2\pi i \mu_1} (\omega^r - 1) \frac{V^r(\mu_2)}{(\mu_1 - \mu_2)(\mu_1 - \omega^r \mu_2)}$$

$$= (\omega^{kr} - 1) V_{k+l}^r, \tag{III.10a}$$

where C_μ stands for a small counterclockwise oriented contour which surrounds the point μ. Similarly from the second equation (III.6) we obtain the commutators

$$[V_k^r, V_l^s] = \frac{(\omega^r - 1)(\omega^s - 1)}{(\omega^{r+s} - 1)} (\omega^{sk} - \omega^{rl}) V_{k+l}^{r+s}, \qquad r + s \neq 0 \bmod(n+1), \tag{III.10b}$$

$$[V_k^r, V_l^{-r}] = -\omega^r (1 - \omega^{-r})^2 ((\omega^{-rk} - \omega^{rl}) \mathscr{E}_{k+l} + k \omega^{-rk} \delta_{k+l,0}). \tag{III.10c}$$

In deriving the above equations we have also used the identity

$$\theta_r(\omega^p \mu) = \theta_{p+r}(\mu) - \theta_p(\mu),$$

which is a straightforward consequence from (III.3b). Using the contour deformation technique one also concludes that (III.7) is equivalent to the Heisenberg commutators (A23). Therefore we conclude that $\mathscr{E}_k$, $k \in \mathbb{Z}(n+1)\mathbb{Z}$ together with V_k^r, $r = 1,...,n$, $k \in \mathbb{Z}$ form a Lie algebra. The last is *isomorphic* to the Lie algebra $A_n^{(1)}$ in the principal gradation. To see this it is sufficient to set

$$F_k^r = \frac{\omega^{rl} V_k^r}{(n+1)(\omega^r - 1)}, \quad l \in \mathbb{Z}_{n+1}, r = 1,..., n, \tag{III.11}$$

and to verify that (III.10a)–(III.10c) together with (A15) coincide with (A21). In the above equation, $l \in \mathbb{Z}_{n+1}$ is an additional parameter. Note that the map

$$\mathscr{E}_k \to \mathscr{E}_k, \quad V_k^r \to \omega^r V_k^r, \quad r = 1,..., n \tag{III.12}$$

is an automorphism of order $(n+1)$ of the Lie algebra (III.10a)–(III.10c), (A23). It is clear that this automorphism is *outer*, and therefore the representations of $A_n^{(1)}$ corresponding to different values of the additional parameter l (III.11) are *inequivalent*. Due to (III.2), (III.5), and (III.11) we obtain highest weight representations characterized by

$$F_0^r |\Lambda_l\rangle = \frac{\omega^{rl}}{(n+1)(\omega^r - 1)} |\Lambda_l\rangle, \quad \hat{c} = |\Lambda_l\rangle = |\Lambda_l\rangle, \quad \hat{d} |\Lambda_l\rangle = 0, \tag{III.13}$$

where the highest-weight state coincides with the Fock vacuum (III.2). Since $\hat{c} = 1$, we conclude that representations constructed by us are the $n+1$ *inequivalent fundamental* representations[10] of the Lie algebra $A_n^{(1)}$ in the principal gradation.

We proceed by calculating the tau functions (II.9) in terms of the components of the field (II.1d), (II.2) with $\eta = 0$. Also taking into account the last identity (A13), one obtains

$$\Phi = \frac{1}{2} \sum_{\substack{1 \leqslant r \leqslant n \\ k \in \mathbb{Z}_{n+1}}} \omega^{r(1-k)} \varphi_k F_0^r + \frac{\zeta}{2(n+1)} \hat{c}. \tag{III.14}$$

Combining the above expression with (III.13) we derive

$$\langle \Lambda_l | \Phi | \Lambda_l \rangle = \frac{\zeta}{2(n+1)} + \frac{1}{2(n+1)} \sum_{\substack{1 \leqslant r \leqslant n \\ k \in \mathbb{Z}_{n+1}}} \frac{\omega^{r(l+1-k)}}{\omega^r - 1} \varphi_k. \tag{III.15}$$

Therefore the group-algebraic tau functions (II.9) satisfy the identities

$$\frac{\tau_{\Lambda_k}(\Phi)}{\tau_{\Lambda_{k-1}}(\Phi)} = e^{-\varphi_k}, \quad k \in \mathbb{Z}_{n+1}, \tag{III.16a}$$

$$\prod_{k \in \mathbb{Z}_{n+1}} \tau_{\Lambda_k}(\Phi) = e^{-\zeta}. \tag{III.16b}$$

Comparing the above identities with the definition (II.4a)–(II.4c) of the Hirota tau functions we get the relations

$$\tau_{\Lambda_k}(\Phi) = \exp\left(-\frac{\zeta_0}{n+1}\right)\tau_k(\Phi), \tag{III.17}$$

where ζ_0 is the vacuum value (II.4d) of the field ζ (II.2).

IV. DERIVATION OF THE VERTEX OPERATOR REPRESENTATION FOR ONE-SOLITON TAU FUNCTIONS

In the present section we focus our attention on the equivalence between the representations (I.1) and (I.2) for one-soliton solutions of the A_n CAT equations. The existence of one-solitons, i.e., solitary waves which propagate without changing their shape, is not a distinguishing property of the integrable evolution equations. As a counterexample, one can quote the existence of kink solution of the φ^4 model in $1+1$ dimensions.[1] Monosoliton solutions of the affine Toda equations based on arbitrary simple Lie algebra are also known.[36]

In accordance with (II.5a), (II.5b) the evolution of a single soliton is dictated by

$$e^{-\varphi_k} = \frac{1+X_k}{1+X_{k-1}}, \quad X_k = -\frac{\omega^{rk}}{c}\frac{e(\mu)}{e(\omega^r\mu)}, \tag{IV.1}$$

where μ is the unique rapidity like parameter, $r=1,...,n$ is the soliton species, and c stands for the constant which appear on the right-hand side of (II.5a). From the above identities it follows that the corresponding tau functions (II.4a), (II.4b) are given by

$$\tau_k = 1 + X_k. \tag{IV.2}$$

In this section we shall demonstrate that the representations (I.1) and (I.2) for the one-soliton tau functions associated with the fundamental representations of the Lie algebra $A_n^{(1)}$ are equivalent. Denote by $\tilde{g}_{\pm}(\mu)$ the dressing group elements which generate the one-soliton solution (IV.1) of the $A_n^{(1)}$ Toda model from the vacuum. Taking into account (II.12) and (II.13a) we get

$$\begin{gathered}\tilde{g}(\mu) = \tilde{g}_-^{-1}(\mu)\tilde{g}_+(\mu) = e^{-W_-(\Phi)}.e^{W_+(\Phi)}, \\ \Phi = \frac{1}{2}\sum_{k \in \mathbb{Z}_{n+1}} \varphi_k E^{kk},\end{gathered} \tag{IV.3}$$

where φ_k are the components of the $A_n^{(1)}$ Toda field and $W_{\pm}(\Phi) = \Sigma_{k \in \mathbb{Z}_{n+1}}\, \varphi_k W_{\pm}^k(\mu)$ according to (II.15a). The elements $W_{\pm}(\mu)$ has been introduced by (II.15b), (II.15c). In what follows we shall use the representations

$$W_{\pm}(\Phi) = \sum_{k=1}^{n} \varphi_k \tilde{W}_{\pm}^k(\mu), \quad \tilde{W}_{\pm}^k(\mu) = W_{\pm}^k(\mu) - W_{\pm}^{n+1}(\mu), \tag{IV.4a}$$

$$\tilde{W}^k_{\pm}(\mu)=-\sum_{k=1}^{n}\ \frac{1-\omega^{-rk}}{1-\omega^{-r}}\ \oint_{\lambda\gtrless|\mu|}\frac{d\lambda}{2\pi i\lambda}\,\frac{\omega^r\lambda-\mu}{\lambda-\mu}\,F^r(\lambda), \tag{IV.4b}$$

where

$$F^r(\lambda)=\sum_p\ \frac{F^r_p}{\lambda^p},\quad F^r_p=\oint\frac{\lambda^p d\lambda}{2\pi i\lambda}\,F^r(\lambda). \tag{IV.4c}$$

To calculate the element (IV.3) in the fundamental representation (III.11), (III.13) of the affine Lie algebra $A^{(1)}_n$ we first introduce the notation

$$h(\alpha)=e^{-\alpha W_-(\Phi)}.e^{\alpha W_+(\Phi)},\quad h(\alpha)=\sum_{l=0}^{\infty}\ \frac{\alpha^l}{l!}\,\frac{d^l}{d\alpha^l}\,h(0), \tag{IV.5a}$$

$$\frac{d^l}{d\alpha^l}\,h(0)=-W_-(\Phi)\,\frac{d^{l-1}}{d\alpha^{l-1}}\,h(0)+\frac{d^{l-1}}{d\alpha^{l-1}}\,h(0).W_+(0)=\sum_{k=0}^{l}\,(-)^k\binom{l}{k}W^k(\Phi)W^{l-k}_+(\Phi). \tag{IV.5b}$$

Using (IV.4a), (IV.4b) and since the matrix (II.1d) is traceless, one can also write

$$W_{\pm}(\Phi)=\sum_{r=1}^{n}\ \frac{\hat{\varphi}_r}{1-\omega^{-r}}\ \oint_{|\lambda|\gtrless|\mu|}\frac{d\lambda}{2\pi i\lambda}\,\frac{\omega^r\lambda-\mu}{\lambda-\mu}\,F^r(\lambda), \tag{IV.6}$$

where we have introduced the discrete Fourier transform of φ_k ($\varphi_k=\varphi_{k+n+1}$) according to

$$\hat{\varphi}_r=\sum_{k\in\mathbb{Z}_{n+1}}\omega^{-kr}\varphi_k,\quad \varphi_k=\frac{1}{n+1}\sum_{r\in\mathbb{Z}_{n+1}}\omega^{kr}\hat{\varphi}_r. \tag{IV.7a}$$

Let us also recall the identity

$$\sum_{k\in\mathbb{Z}_{n+1}}\omega^{k(i-j)}=(n+1)\,\delta^{(n+1)}_{i,j}, \tag{IV.7b}$$

where the $\delta^{(n+1)}_{i,j}$ is the Kronecker symbol on the cyclic group: It vanishes for $i-j\neq 0 \bmod (n+1)$ and $\delta^{(n+1)}_{i,j}=1$ if $i-j=0 \bmod (n+1)$.

We proceed by calculating explicitly the Taylor expansion (IV.5a). First of all, we note that

$$\begin{aligned}\frac{dh}{d\alpha}(0)&=W_+(\Phi)-W_-(\Phi)\\&=-\sum_{r=1}^{n}\ \frac{\hat{\varphi}_r}{1-\omega^{-r}}\ \oint_{C_\mu}\frac{d\lambda}{2\pi i\lambda}\,\frac{\omega^r\lambda-\mu}{\lambda-\mu}\,F^r(\lambda)\\&=-\sum_{r=1}^{n}\ \hat{\varphi}_r\omega^r F^r(\mu).\end{aligned} \tag{IV.8}$$

The above identities agree with (II.15a), (II.16). To calculate the higher derivatives of $h(\alpha)$ (IV.5a) we first observe that due to (III.6) one gets

$$
\begin{aligned}
&W_-(\Phi)V^r(\mu)-V^r(\mu)W_+(\Phi)\\
&\quad=\frac{1}{n+1}\sum_{s=1}^{n}\frac{\omega^{s(k+1)}\hat{\varphi}_s}{(\omega^s-1)^2}\left(\oint_{|\lambda|>|\mu|}-\oint_{|\lambda|<|\mu|}\right)\frac{d\lambda}{2\pi i\lambda}\,\frac{\omega^s\lambda-\mu}{\lambda-\mu}\,V^s(\lambda)V^r(\mu)\\
&\quad=\frac{1}{n+1}\sum_{s=1}^{n}\frac{\omega^{s(k+2)}\hat{\varphi}_s}{(\omega^s-1)^2}\left(\oint_{|\lambda|>|\mu|}-\oint_{|\lambda|<|\mu|}\right)\frac{d\lambda}{2\pi i\lambda}\,\frac{\lambda-\omega^{r-s}\mu}{\lambda-\omega^r\mu}:e^{i(\theta_s(\lambda)+\theta_r(\mu))}\\
&\quad=\frac{1}{n+1}\sum_{s=1}^{n}\frac{\omega^{s(k+1)}}{\omega^s-1}\,\hat{\varphi}_sV^{r+s}(\mu),\quad k\in\mathbb{Z}_{n+1},
\end{aligned}
\tag{IV.9}
$$

in the irreducible representation of $A_n^{(1)}$ with a highest-weight $|\Lambda_k\rangle$ (III.11)–(III.13). Using the above identity together with (IV.5b), it is easy to prove inductively that

$$
\frac{d^lh}{d\alpha^l}(0)=(-)^l\sum_{s_1,\ldots,s_l=1}^{n}\prod_{j=1}^{l}\Psi_{s_j}(\Phi)\cdot V^{s_1+\cdots+s_l}(\mu),
\tag{IV.10a}
$$

$$
\Psi_s(\Phi)=\frac{1}{n+1}\,\frac{\omega^{s(k+1)}}{\omega^s-1}\,\hat{\varphi}_s,
\tag{IV.10b}
$$

where we have omitted the dependence on the parameter $k\in\mathbb{Z}_{n+1}$ which label the different fundamental representations of the affine Lie algebra. Substituting the last result into the Taylor expansion (IV.5a), it turns out that (IV.3) is given by the following intermediate expression:

$$
\tilde{g}(\mu)=h(1)=\sum_{l=0}^{\infty}\frac{(-1)^l}{l!}\sum_{s_1,\ldots,s_l=1}^{n}\prod_{j=1}^{l}\Psi_{s_j}(\Phi)\cdot V^{s_1+\cdots+s_l}(\mu).
\tag{IV.11}
$$

In order to write the right-hand side of the above identity in a more convenient form, we recall that in view of (III.3b) and (III.5), the vertex operators are periodic functions on the upper case index $V^s(\mu)=V^{s+n+1}(\mu)$ with $V^0(\mu)=1$. This observation suggests that we introduce the commutative associative algebra $\mathscr{F}$ of (complex) dimension $n+1$. It is generated by the elements V^s, $s\in\mathbb{Z}_{n+1}$. The multiplication $\star$ in $\mathscr{F}$ is defined by

$$
V^r\star V^s=V^{r+s}.
\tag{IV.12}
$$

Due to the periodicity condition, the element $V^0=V^{n+1}$ is the unity of $\mathscr{F}$. It is worthwhile to note that (IV.12) describes the ''*fusion rules*'' of a class of rational conformal field theories.[37] They correspond to a theory of a free massless scalar field in two dimensions which is compactified on circle with a rational value of the square of the radius. The algebra $\mathscr{F}$ can be endowed with a symmetric bilinear invariant form

$$
\begin{aligned}
&\langle a,b\rangle_{\mathscr{F}}=\langle b,a\rangle_{\mathscr{F}},\\
&\langle a,b\star c\rangle_{\mathscr{F}}=\langle a\star b,c\rangle_{\mathscr{F}},\quad a,b,c\in\mathscr{F},
\end{aligned}
\tag{IV.13a}
$$

which is uniquely fixed by

$$
\langle V^r,V^s\rangle_{\mathscr{F}}=\delta_{r+s,0}^{(n+1)}.
\tag{IV.13b}
$$

The algebra $\mathscr{F}$ together with the above bilinear form is an example of a Fröbenius algebra. Fröbenius algebras and their deformations appear in the study of the topological field theory.[38] We go back to the problem of simplifying expression (IV.11). Using the multiplication rules (IV.12) we can rewrite (IV.11) in the following form:

$$
\tilde{g}=\mathscr{F}\exp\left\{-\sum_{s=1}^{n}\Psi_s(\Phi)V^s\right\},
\tag{IV.14}
$$

where the symbol $\mathscr{F}$ means that the exponential is taken in the Fröbenius algebra (IV.12)–(IV.13b). In the above expression the dependence on μ of the elements V^s, $s=1,...,n$ was skipped. Note that the Fourier transformation (IV.7a) diagonalizes the ''fusion rules'' (IV.12),

$$V^r \star \hat{V}^s = \omega^{rs}\hat{V}^s, \quad \hat{V}^p \star \hat{V}^q = (n+1)\,\delta_{p,q}^{(n+1)}\hat{V}^p. \tag{IV.15}$$

Substituting the above expression into (IV.14) we obtain

$$\tilde{g} = \frac{1}{n+1}\sum_{p\in\mathbb{Z}_{n+1}} e^{-\Sigma_{s=1}^{n}\omega^{ps}\Psi_s(\Phi)}\hat{V}^p = \frac{1}{n+1}\sum_{p,r\in\mathbb{Z}_{n+1}} \omega^{-pr}\cdot e^{\chi_p(\Phi)}V^r, \tag{IV.16a}$$

$$\chi_p(\Phi) = -\sum_{s=1}^{n}\omega^{ps}\Psi_s(\Phi), \quad p\in\mathbb{Z}_{n+1}. \tag{IV.16b}$$

Due to the identity (IV.7b), the above quantities satisfy the restriction

$$\sum_{p\in\mathbb{Z}_{n+1}}\chi_p(\Phi) = 0. \tag{IV.17a}$$

Moreover, taking into account (IV.10b), we get the recurrence relations

$$\chi_p(\Phi) - \chi_{p+1}(\Phi) = \varphi_{p+k+1}, \tag{IV.17b}$$

where $k\in\mathbb{Z}_{n+1}$ is the parameter which labels the $n+1$ unequivalent fundamental representations of $A_n^{(1)}$ (III.11), (III.13). Comparing (IV.17a) and (IV.17b) with the definition (II.4a)–(II.4c) of the Hirota tau functions, we get

$$e^{\chi_p(\Phi)} = \frac{\tau_{p+k}(\Phi)}{(\Pi_{l\in\mathbb{Z}_{n+1}}\tau_l(\Phi))1/n+1}, \quad p\in\mathbb{Z}_{n+1}. \tag{IV.18}$$

Substituting back the above expression into (IV.16a) and taking into account (IV.1) as well as the vertex operator realization of the affine Lie algebra $A_n^{(1)}$ (III.5), (III.11), and (III.8), we conclude that

$$\begin{aligned}\tilde{g}(\mu) &= \frac{1}{n+1}\sum_{p,q\in\mathbb{Z}_{n+1}}\omega^{-pq}e^{\chi_p(\Phi)}V^q(\mu)\\ &= \frac{1}{(n+1)\Pi_{l\in\mathbb{Z}_{n+1}}\tau_l^{1/(n+1)}(\Phi)}\sum_{p,q\in\mathbb{Z}_{n+1}}(\omega^{-pq}+\omega^{p(r-q)+rk}X_0)V^q(\mu)\\ &= \frac{1}{\Pi_{l\in\mathbb{Z}_{n+1}}\tau_l^{1/(n+1)}(\Phi)}\,(1+(n+1)(\omega^r-1)X_0F^r(\mu)).\end{aligned} \tag{IV.19a}$$

From the above identity, (II.10), (II.11), and (II.4c) one derives

$$\begin{aligned}\frac{\tau_{\Lambda_k}(\Phi)}{\tau_{\Lambda_k}(\Phi_0)} &= \exp\left(\frac{\zeta_0-\zeta}{n+1}\right)\langle\Lambda_k|\tilde{g}_-(\mu)\tilde{g}_+(\mu)|\Lambda_k\rangle\\ &= \frac{\exp\left(\dfrac{\zeta_0-\zeta}{n+1}\right)}{\Pi_{l\in\mathbb{Z}_{(n+1)}}\tau_l^{1/(n+1)}(\Phi)}\,\langle\Lambda_k|(1+(n+1)(\omega^r-1)X_0F^r(\mu))|\Lambda_k\rangle\\ &= \langle\Lambda_k|(1+(n+1)(\omega^r-1)X_0F^r(\mu))|\Lambda_k\rangle.\end{aligned} \tag{IV.19b}$$

Therefore, the representations (I.1) and (I.2) are equivalent in the one-soliton case.

V. *N*-SOLITON TAU FUNCTIONS AND VERTEX OPERATORS

The existence of *N*-soliton solutions is a peculiar property of the integrable field theories. From another point of view,[29] soliton solutions provide a relation of classes of solutions of integrable nonlinear partial differential equations with certain dynamical systems with a finite number of degrees of freedom. The latter are known as *N*-body integrable systems (for a review, see Ref. 28). The *N*-soliton solutions, in the in- and out-limit, become asymptotically a superposition of monosolitons separated in the space. Moreover, the transformation from the in-variables to the out-variables is canonical. The underlying generating function of this transformation is known as the classical *S*-matrix.[6] An intriguing property of the classical *S*-matrix is that it is represented as a sum of terms, each of them representing a two-particle scattering. It is well known that the last property admits a generalization valid within the quantum theory: The quantum *S*-matrix which describes collision of solitons in a given quantum integrable model is a product of factors describing two particle interactions.[7] *N*-soliton solutions of the Toda field theories have been obtained both within the ISM[22] and by using the Hirota method.[39]

We recall that the algebraic *N*-soliton solutions (II.5a), (II.5b) in the $A_n^{(1)}$ Toda models are generated from the vacuum by the dressing group elements (II.12)–(II.15c). Due to the factorized expression (II.12), we can also write

$$\begin{aligned}\tilde{g}=\tilde{g}_-^{-1}\tilde{g}_+&=\tilde{g}_-^{-1}(1)\ldots\tilde{g}_-^{-1}(N)\cdot\tilde{g}_+(N)\cdots\tilde{g}_+(1)\\ &=\tilde{g}(1)\cdot \mathrm{Ad}\,\tilde{g}_+^{-1}(1)(\tilde{g}(2))\cdots\mathrm{Ad}(\tilde{g}_+^{-1}(1))\cdots\tilde{g}_+^{-1}(N-1))\cdot(\tilde{g}(N)),\\ \tilde{g}(i)&=\tilde{g}_-^{-1}(i)\tilde{g}_+(i).\end{aligned} \tag{V.1}$$

In the above expression and in what follows we shall assume that the rapiditylike parameters μ_i, $i=1,\ldots,N$ corresponding to the factors (II.13a)–(II.13d) are radially ordered $|\mu_1|>|\mu_2|>\cdots>|\mu_N|$. In view of (IV.16a), (IV.16b), and the vertex operator construction of the affine Lie algebra $A_n^{(1)}$ (III.5), (III.8), (III.11), to calculate (V.1) in the fundamental representations, one first has to obtain an expression for the adjoint action of $\tilde{g}_+(i)$ on the elements of the alternative basis (A22). To do that we first note that diagonal traceless $(n+1)\times(n+1)$ matrices $D=\Sigma_{k\in\mathbb{Z}_{n+1}}\,d_k|k\rangle\langle k|$ are written in the alternative basis (A13), (A15) as follows:

$$D=\sum_{s\in\mathbb{Z}_{n+1}}\omega^s\tilde{d}_sF_0^s, \tag{V.2}$$

where $\hat{d}_s$, $s\in\mathbb{Z}_{n+1}$ is the discrete Fourier transformation (IV.7a) of the (diagonal) entries of D. Note that F_0^0 is *not* an element of the Lie algebra A_n. However, since D is traceless, it is clear that the coefficient $\hat{d}_0$ which multiplies F_0^0 vanishes. The above expression can be considered as an element either of the classical Lie algebra A_n or of the affine algebra $A_n^{(1)}$. Taking into account the commutation relations (A21) together with (A23), it is easy to get

$$[F^r(\mu),D]=\frac{1}{n+1}\sum_{\substack{k\in\mathbb{Z}\\ s\in\mathbb{Z}_{n+1}}}\frac{\omega^s(\omega^{sk}-1)\hat{d}_s}{\mu^k}F_k^{r+s} \tag{V.3a}$$

from where it is easy to get

$$\begin{aligned}e^{-D}F^r(\mu)e^D&=\sum_{l=0}^{\infty}\frac{(-1)^l}{l!}\,\mathrm{ad}^lD\cdot F^r(\mu)\\ &=\sum_{k\in\mathbb{Z}}\frac{1}{\mu^k}\sum_{l=0}^{\infty}\frac{1}{l!}\sum_{s_1,\ldots,s_l\in\mathbb{Z}_{n+1}}\prod_{j=1}^{l}\omega^{s_j}\frac{\omega^{s_jk}-1}{n+1}\,\hat{d}_{s_j}F_k^{r+s_1+\cdots+s_l}.\end{aligned} \tag{V.3b}$$

The right-hand side of Eq. (V.3b) is of the same form as (IV.11). This suggests using the approach developed in Sec. IV to write (V.3b) explicitly as a linear combination of the affine algebra elements. In order to do that we first introduce the following (reducible) representation of the algebra $\mathscr{F}$ (IV.12):

$$V^s(F_k^r)=F_k^{r+s}, \quad r,s\in\mathbb{Z}_{n+1}, \quad k\in\mathbb{Z}. \tag{V.4}$$

In complete analogy with the derivation of the expression (IV.14), we conclude that

$$e^{-D}F^r(\mu)e^D=\sum_{k\in\mathbb{Z}_{n+1}}\frac{1}{\mu^k}\mathscr{F}\exp\left(\sum_{s\in\mathbb{Z}_{n+1}}\frac{\omega^s(\omega^{sk}-1)}{n+1}\hat{d}_sV^s\right)(F_k^r). \tag{V.5}$$

As in Sec. IV, we diagonalize the operators V^s (V.4),

$$V^s(\hat{F}_k^p)=\omega^{ps}\hat{F}_k^p, \quad \hat{F}_k^p=\sum_r\omega^{-pr}F_k^r, \quad F_k^r=\frac{1}{n+1}\sum_p\omega^{pr}\hat{F}_k^p. \tag{V.6}$$

Combining (V.5) with (V.6) we obtain

$$\begin{aligned}
e^{-D}F^r(\mu)e^D&=\frac{1}{n+1}\sum_{\substack{k\in\mathbb{Z}\\ p\in\mathbb{Z}_{n+1}}}\frac{\omega^{pr}}{\mu^k}e^{d_{k+p+1}-d_{p+1}}\hat{F}_k^p\\
&=\frac{1}{n+1}\sum_{\substack{k\in\mathbb{Z}\\ p,s\in\mathbb{Z}_{n+1}}}\frac{\omega^{p(r-s)}}{\mu^k}e^{d_{k+p+1}-d_{p+1}}F_k^s\\
&=\frac{1}{n+1}\sum_{l,p,s\in\mathbb{Z}_{n+1}}\omega^{p(r-s)}\frac{e^{d_{l+p+1}}}{e^{d_{p+1}}}\sum_{k\in\mathbb{Z}}\frac{F^s_{k(n+1)+l}}{\mu^{k(n+1)+l}}\\
&=\frac{1}{(n+1)^2}\sum_{l,p,q,s\in\mathbb{Z}_{n+1}}\omega^{p(r-s)+lq}\frac{e^{d_{l+p+1}}}{e^{d_{p+1}}}F^s(\omega^q\mu).
\end{aligned} \tag{V.7}$$

As a consequence of the above identity and (II.17f), one obtains

$$e^{-\mathrm{ad}(K(F_i)+P_i)}F^r(\omega^a\lambda)=\sum_{s,q\in\mathbb{Z}_{n+1}}U^{ra}_{sq}(i)F^s(\omega^q\lambda), \tag{V.8a}$$

where $K(F_i)$ and P_i are diagonal traceless matrices (II.13b) and

$$\begin{aligned}
U^{ra}_{sq}(i)&=M^{r+a}_{s+q}(i)N^a_q(i),\\
M^r_s(i)&=\frac{\omega^{s-r}}{n+1}\sum_{p\in\mathbb{Z}_{n+1}}\frac{\omega^{p(r-s)}}{\rho_{pi}(\mu_i+1)},\\
N^a_q(i)&=\frac{\omega^{a-q}}{n+1}\sum_{p\in\mathbb{Z}_{n+1}}\omega^{p(q-a)}\rho_{pi}(\mu_{i+1}).
\end{aligned} \tag{V.8b}$$

In what follows we shall also need the commutators $[W^k_+(\mu_i),F^s(\lambda)]$ where the affine algebra elements $W^k_+(\mu_i)$ and $F^s(\lambda)$ are given by (II.15b) and (IV.4c), respectively. Using (A21) with $\hat{c}=1$ we get

$$[W_+^k(\mu_i),F^s(\lambda)]=-\frac{1}{n+1}\sum_{r=1}^{n}\frac{(1-\omega^{-rk})\mu_i-\omega^s(1-\omega^{r(1-k)})\lambda}{(1-\omega^{-r})(\mu_i-\omega^s\lambda)}F^{r+s}(\lambda)$$
$$+\frac{1}{n+1}\sum_{r=1}^{n}\frac{(1-\omega^{-rk})\mu_i-\omega^{-r}(1-\omega^{r(1-k)})\lambda}{(1-\omega^{-r})(\mu_i-\omega^{-r}\lambda)}F^{r+s}(\omega^{-r}\lambda)$$
$$-\frac{1}{(n+1)^2}\sum_{r=1}^{n}\frac{\omega^{-rk}\lambda\mu_i}{(\mu_i-\omega^{-r}\lambda)^2}\delta_{r+s,0}^{(n+1)},\quad |\mu_i|>|\lambda|. \tag{V.9a}$$

From the above expression, (II.13b), and (II.15a) we also derive the commutator

$$[W_+(i),F^s(\lambda)]=\sum_{k\in\mathbb{Z}_{n+1}}f_{ki}[W_+^k(\mu_i),F^s(\lambda)]$$
$$=\frac{1}{n+1}\sum_{r=1}^{n}\frac{\hat{f}_{ri}}{1-\omega^{-r}}\left(\frac{\mu_i-\omega^{r+s}\lambda}{\mu_i-\omega^s\lambda}F^{r+s}(\lambda)-\frac{\mu_i-\lambda}{\mu_i-\omega^{-r}\lambda}F^{r+s}(\omega^{-r}\lambda)\right)$$
$$-\frac{\hat{f}_{-si}}{(n+1)^2}\frac{\lambda\mu_i}{(\mu_i-\omega^{-s})^2},\quad |\mu_i|>|\lambda|,\quad s\in\mathbb{Z}_{n+1}, \tag{V.9b}$$

where $\hat{f}_{ri}$ stands for the discrete Fourier transformation (IV.7a) of f_{ki}, $k\in\mathbb{Z}_{n+1}$. Using (V.9b) one proves inductively

$$\mathrm{ad}^l\ W_+(i)F^s(\lambda)=\frac{\mu_i-\lambda}{\mu_i-\omega^s\lambda}\sum_{k=0}^{l}(-)^{l-k}\binom{l}{k}$$
$$\times\sum_{r_1,\ldots,r_l=1}^{n}\frac{\mu_i-\omega^{r_1+\cdots+r_k+s}\lambda}{\mu_i-\omega^{-r_{k+1}-\cdots-r_l}\lambda}\prod_{p=1}^{l}\psi_{r_p i}F^{r_1+\cdots+r_l+s}(\omega^{-r_{k+1}-\cdots-r_l}\lambda)$$
$$+\frac{\mu_i(\mu_i-\lambda)}{(n+1)^2(\mu_i-\omega^s\lambda)}\sum_{k=0}^{l-1}(-)^{l-k}\binom{l-1}{k}$$
$$\times\sum_{r_1,\ldots,r_{l-1}=1}^{n}\frac{\lambda\omega^{-r_{k+1}-\cdots-r_{l-1}}}{(\mu_i-\omega^{-r_{k+1}-\cdots-r_{l-1}}\lambda)(\mu_i-\omega^{r_l+\cdots+r_k+s}\lambda)}$$
$$\cdot\hat{f}_{-r_1\cdots-r_{l-1}-si}\prod_{p=1}^{l-1}\psi_{r_p i},\quad l\geqslant 1,$$

$$\psi_{ri}=\frac{\hat{f}_{ri}}{(n+1)(1-\omega^{-r})},\quad r=1,\ldots,n. \tag{V.10}$$

Note that after the change $\hat{f}_{ri}\to\hat{\varphi}_i$, the quantities ψ_{ri} coincide up to phase with (IV.10b). To write the right-hand side of the above identity in a compact form, we consider the commutative associative algebra $\mathscr{A}=\mathscr{F}\times\mathscr{T}$. We recall that $\mathscr{F}$ is the Fröbenius algebra (IV.12)–(IV.13b) while $\mathscr{T}$ is spanned on the elements $\mathbb{T}^r$, $r\in\mathbb{Z}_{n+1}$. The multiplication in $\mathscr{A}$ is introduced by

$$V^r*V^s=V^{r+s},\quad \mathbb{T}^r*\mathbb{S}^s=\mathbb{T}^{r+s},\quad V^r*\mathbb{T}^s=\mathbb{T}^s*V^r. \tag{V.11a}$$

We shall also need specific representations of $\mathscr{A}$. They are defined by the relations

$$V^r(g(\lambda)F^s(\lambda))=g(\lambda)V^r(F^s(\lambda))=g(\lambda)F^{r+s}(\lambda),$$
$$\mathbb{T}^r(g(\lambda)F^s(\lambda))=g(\omega^{-r}\lambda)\mathbb{T}^r(F^s(\lambda))=g(\omega^{-r}\lambda)F^s(\omega^{-r}\lambda), \tag{V.11b}$$

where g is a function on the complex parameter λ. It is also assumed that the algebra $\mathscr{A}$ acts trivially on μ_i (V.10). Using (V.11a) and (V.11b), it is easy to check that (V.10) can be written as follows:

$$
\begin{aligned}
(-)^l \mathrm{ad}^l\ W_+(i)F^s(\lambda) = \frac{\mu_i-\lambda}{\mu_i-\omega^s\lambda}\Bigg(\Bigg(\sum_{r-1}^{n}\psi_{ri}V^r(\mathbb{T}^r-1)\Bigg)_*^l \frac{\mu_i F^s(\lambda)}{\mu_i-\lambda} \\
-\omega^s\Bigg(\sum_{r=1}^{n}\omega^r\psi_{ri}V^r(\mathbb{T}^r-1)\Bigg)_*^l \frac{\lambda F^s(\lambda)}{\mu_i-\lambda}\Bigg) + \frac{\mu_i(\mu_i-\lambda)}{(n+1)^2(\mu_i-\omega^s\lambda)} \\
\times\Bigg\langle \sum_{p\in\mathbb{Z}_{n+1}}\hat{f}_{pi}V^p, \Bigg(\sum_{r=1}^{n}\psi_{ri}V^r(1\otimes_{\mathscr{F}}\mathbb{T}^r-\mathbb{T}^{-r}\otimes_{\mathscr{F}}1)\Bigg)_*^{l-1} V^s\Bigg\rangle_{\mathscr{F}} \\
\times\frac{1}{\mu_i-\omega^s\lambda}\otimes\frac{\lambda}{\mu_i-\lambda},
\end{aligned}
\tag{V.12}
$$

where $\langle\ ,\ \rangle_{\mathscr{F}}$ is the invariant bilinear form in the Fröbenius algebra $\mathscr{F}$ (IV.12)–(IV.13b). We have also used the notation

$$
(\mathscr{P})_*^l = \underbrace{\mathscr{P}*\ldots*\mathscr{P}}_{l}
\tag{V.13a}
$$

to indicate that the lth power of $\mathscr{P}\in\mathscr{A}$ is taken with respect to the multiplication (V.11a). In what follows we shall use the operators

$$
\mathscr{A}\ \exp(\mathscr{P}) = \sum_{l=0}^{\infty}\frac{(\mathscr{P})_*^l}{l!}, \quad \mathscr{A}\ \frac{\exp(\mathscr{P})-1}{\mathscr{P}} = \sum_{l=1}^{\infty}\frac{(\mathscr{P})_*^{l-1}}{l!}.
\tag{V.13b}
$$

Note that the second of the above operators has eigenvalue one when applied on the zero modes of $\mathscr{P}$. Taking into account (V.12) together with (V.13a), (V.13b) we obtain

$$
\begin{aligned}
e^{-\mathrm{ad}\ W_+(i)\cdot}F^s(\lambda) = \frac{\mu_i-\lambda}{\mu_i-\omega^s\lambda}\Bigg(\mathscr{A}\ \exp\Bigg(\sum_{r=1}^{n}\psi_{ri}V^r(\mathbb{T}^r-1)\Bigg)\frac{\mu_i F^s(\lambda)}{\mu_i-\lambda} - \omega^s.\mathscr{A} \\
\times\exp\Bigg(\sum_{r=1}^{n}\omega^r\psi_{ri}V^r(\mathbb{T}^r-1)\Bigg)\frac{\lambda F^s(\lambda)}{\mu_i-\lambda}\Bigg) + \frac{\mu_i(\mu_i-\lambda)}{(n+1)^2(\mu_i-\omega^s\lambda)} \\
\times\Bigg\langle \sum_{p\in\mathbb{Z}_{n+1}}\hat{f}_{p_i}V^p, \mathscr{A}\ \frac{\exp(\Sigma_{r=1}^{n}\psi_{ri}V^r(1\otimes_{\mathscr{F}}\mathbb{T}^r-\mathbb{T}^{-r}\otimes_{\mathscr{F}}1))-1}{\Sigma_{r=1}^{n}\psi_{ri}V^r(1\otimes_{\mathscr{F}}\mathbb{T}^r-\mathbb{T}^{-r}\otimes_{\mathscr{F}}1)}\ V^s\Bigg\rangle_{\mathscr{F}} \\
\times\frac{1}{\mu_i-\omega^s\lambda}\otimes\frac{\lambda}{\mu_i-\lambda}.
\end{aligned}
\tag{V.14}
$$

In view of the above equation, we shall need the (reducible) representations (V.11b) of $\mathscr{A}$ (V.11a) spanned on the vectors $g(\omega^r\lambda)F^s(\omega^r\lambda)$, $r,s\in\mathbb{Z}_{n+1}$ for g being an arbitrary meromorphic function on λ. It is easy to check that

$$
G^{pq}(\lambda) = \sum_{r,s\in\mathbb{Z}_{n+1}}\omega^{-ps+rq}g(\omega^r\lambda)F^s(\omega^r\lambda)
\tag{V.15a}
$$

are eigenvectors of $\mathscr{T}$,

$$
V^kG^{pq}(\lambda) = \omega^{pk}G^{pq}(\lambda), \quad \mathbb{T}^kG^{pq}(\lambda) = \omega^{kq}G^{pq}(\lambda).
\tag{V.15b}
$$

Due to the identity (IV.7b), the inverse of (V.15a) is given by

$$g(\omega^r\lambda)F^s(\omega^r\lambda)=\frac{1}{(n+1)^2}\sum_{p,q\in\mathbb{Z}_{n+1}}\omega^{ps-rq}G^{pq}(\lambda). \tag{V.15c}$$

Note also that

$$\sum_{r=1}^{n}\omega^{rp}\psi_{ri}=\frac{f_{pi}}{2}-K_p(F_i), \tag{V.16a}$$

where the diagonal traceless matrices F_i and $K(F_i)$ have been defined by (II.13b). To obtain the above identity we have also used the relations (II.13c). Taking into account (II.17b) we can write

$$\exp\left(-\sum_{r=1}^{n}\omega^{rp}\psi_{ri}\right)=\beta_p(F_i) \tag{V.16b}$$

substituting back (V.15a)–(V.16b) into (V.14) one gets

$$\begin{aligned}e^{-\mathrm{ad}\,W_+(i)}\cdot F^s(\lambda)=&\frac{\mu_i-\lambda}{(n+1)^2(\mu_i-\omega^s\lambda)}\\&\times\sum_{p,q,r',s'\in\mathbb{Z}_{n+1}}\omega^{p(s-s')+r'q}\,\frac{\mu_i-\omega^{r'+s'}\lambda}{\mu_i-\omega^{r'}\lambda}\,\frac{\beta_p(F_i)}{\beta_{p+q}(F_i)}\,F^{s'}(\omega^{r'}\lambda)\\&+\frac{\lambda\mu_i(\mu_i-\lambda)}{(n+1)^4(\mu_i-\omega^s\lambda)}\sum_{a,q,q'p,p'\in\mathbb{Z}_{n+1}}f_{ai}\,\frac{\omega^{as+pq+p'(q'+1)}}{(\mu_i-\omega^{p+s}\lambda)(\mu_i-\omega^{p'}\lambda)}\\&\times\frac{\beta_{a-q}(F_i)-\beta_{a+q'}(F_i)}{\beta_{a+q'}(F_i)(\ln\,\beta_{a-q}(F_i)-\ln\,\beta_{a+q'}(F_i))}.\end{aligned} \tag{V.17}$$

Therefore, the adjoint action of the affine group element $e^{-W_+(i)}$ on the affine algebra, can be written as follows:

$$\begin{aligned}e^{-\mathrm{ad}\,W_+(i)}F^s(\omega^c\lambda)=&\sum_{q,v\in\mathbb{Z}_{n+1}}W^{sc}_{qv}[F_i](i;\lambda)F^q(\omega^v\lambda)+Z^{sc}[F_i](i,\lambda)\\&\text{for}\quad|\mu_i|>|\lambda|.\end{aligned} \tag{V.18a}$$

Due to (II.15a), $W_+(i)$ are linear in the entries f_{ki} of the diagonal matrices F_i (II.13b). This is to say that the relations

$$\begin{aligned}&\sum_{q,v\in\mathbb{Z}_{n+1}}W^{sc}_{qv}[F_i](i;\lambda)W^{qv}_{kl}[-F_i](i;\lambda)=\delta^{(n+1)}_{s,k}\delta^{(n+1)}_{c,l},\\&\sum_{q,v\in\mathbb{Z}_{n+1}}W^{sc}_{qv}[F_i](i;\lambda)Z^{qv}[-F_i](i;\lambda)+Z^{sc}[F_i](i;\lambda)=0\end{aligned} \tag{V.18b}$$

are valid. Comparing (V.17) with (V.18a) we obtain

$$\begin{aligned}&W^{sc}_{qv}[F_i](i;\lambda)=K^{s+c}_{q+v}[F_i](i;\lambda)L^c_v[F_i](i;\lambda),\\&K^s_q[F_i](i;\lambda)=\frac{1}{n+1}\,\frac{\mu_i-\omega^q\lambda}{\mu_i-\omega^s\lambda}\sum_{p\in\mathbb{Z}_{n+1}}\omega^{p(s-q)}\beta_p(F_i),\\&L^c_v[F_i](i;\lambda)=\frac{1}{n+1}\,\frac{\mu_i-\omega^c\lambda}{\mu_i-\omega^v\lambda}\sum_{p\in\mathbb{Z}_{n+1}}\omega^{p(v-c)}\beta_p(-F_i),\end{aligned} \tag{V.18c}$$

and

$$Z^{sc}[F_i](i,\lambda)=\frac{\omega^c\lambda\mu_i(\mu_i-\omega^c\lambda)}{(n+1)^4(\mu_i-\omega^{s+c}\lambda)}\sum_{\substack{a,b,p\\ v,v'}} f_{pi}\,\frac{\omega^{sa+(p-a)v+(b+1-p)v'+c(a-b-1)}}{(\mu_i-\omega^v\lambda)(\mu_i-\omega^{v'}\lambda)}$$
$$\times\frac{\beta_a(F_i)-\beta_b(F_i)}{\beta_b(F_i)(\ln\,\beta_a(F_i)-\ln\,\beta_b(F_i))}. \tag{V.18d}$$

Taking into account that the matrices F_i (II.13b) are traceless and the identity

$$\sum_{\substack{p\in\mathbb{Z}_{n+1}\\ 1\leqslant r\leqslant n}}\frac{\omega^{(p-a)r}}{1-\omega^r}\,f_{pi}=-(n+1)\ln\,\beta_a(F_i),$$

we conclude that (V.18d) can be alternatively written in the form

$$Z^{sc}[F_i](i,\lambda)=\frac{\lambda(\mu_i-\omega^c\lambda)}{(n+1)^3(\mu_i-\omega^{s+c}\lambda)}\sum_{a,b,v\in\mathbb{Z}_{n+1}}\frac{\omega^{a(s+c+v)-b(v+c)}}{\lambda-\omega^v\mu_i}\,\frac{\beta_a(F_i)}{\beta_b(F_i)}$$
$$+\frac{\lambda\omega^c\delta^{(n+1)}_{s,0}}{(n+1)(\mu_i-\omega^{s+c}\lambda)}. \tag{V.19a}$$

After certain trivial algebraic manipulations involving the first term of the above expression and using (II.18), (II.17d) we arrive at the result

$$Z^{sc}[-F_i](i,\lambda)=\frac{\lambda\omega^c}{\gamma_i(n+1)^2(\omega^{s+c}\lambda-\mu_i)}\sum_{a,b\in\mathbb{Z}_{n+1}}\omega^{(s+c)a-bc}\mathscr{D}^{(ii-1)}_{ab}(\lambda)\,\frac{\rho_{bi-1}(\mu_i)}{\beta_a(F_i)}$$
$$+\frac{\lambda\omega^c\delta^{(n+1)}_{s,0}}{(n+1)(\mu_i-\omega^{s+c}\lambda)}, \tag{V.19b}$$

where γ_i are the constants defined by (II.17d).

Equations (V.8a), (V.8b), and (V.18a) provide an expression for the adjoint action of the element (II.13a) on the affine Lie algebra

$$\tilde{g}_+^{-1}(i)F^s(\omega^c\lambda)\tilde{g}_+(i)=\sum_{r,v\in\mathbb{Z}_{n+1}}(R^{sc}_{rv}(i;\lambda)F^r(\omega^v\lambda)+U^{sc}_{rv}(i)Z^{rv}[F_i](i;\lambda))$$
$$=\sum_{r,v\in\mathbb{Z}_{n+1}}R^{sc}_{rv}(i;\lambda)(F^r(\omega^v\lambda)-Z^{rv}[-F_i](i;\lambda)),\quad |\mu_i|>|\lambda|, \tag{V.20a}$$

where $R^{sc}_{rv}(i;\lambda)$ are the elements of the matrix $R(j;\mu_i)=U(j)W(j;\mu_i)$ which acts on tensor product $\mathbb{C}^{n+1}\otimes\mathbb{C}^{n+1}$,

$$R^{sc}_{rv}(i;\lambda)=\sum_{p,q\in\mathbb{Z}_{n+1}}U^{sc}_{pq}(i)W^{pq}_{rv}(i;\lambda)=P^c_v(i;\lambda)Q^{s+c}_{r+v}(i;\lambda),$$

$$P^c_v(i;\lambda)=\frac{1}{n+1}\sum_{p\in\mathbb{Z}_{n+1}}\omega^{(p-1)(v-c)}\,\frac{\lambda-\omega^{-v}e^{-f_{pi}}\mu_i}{\lambda-\omega^{-v}\mu_i}\,\frac{\rho_{pi}(\mu_{i+1})}{\beta_p(F_i)}, \tag{V.20b}$$

$$Q^s_r(i;\lambda)=\frac{\mu_i-\omega^r\lambda}{(n+1)^2}\sum_{a,b\in\mathbb{Z}_{n+1}}\omega^{(a-1)s-br}\,\frac{\beta_b(F_i)}{\rho_{ai}(\mu_{i+1})}\sum_{p\in\mathbb{Z}_{n+1}}\frac{\omega^{(b+1-a)p}}{\mu_i-\omega^p\lambda}.$$

Note that the second identity (V.20a) is a consequence of (V.18b). Comparing the above equations with (II.17d) and taking into account (II.18) we obtain the following alternative expressions:

$$P_v^c(i;\lambda)=\frac{\gamma_i}{n+1}\sum_{a,b\in\mathbb{Z}_{n+1}}\omega^{(a-1)v-(b-1)c}\,\frac{1}{\rho_{ai-1}(\mu_i)}\,\mathscr{D}_{ab}^{(i-1i)}(\lambda)\rho_{bi}(\mu_{i+1})$$

$$Q_r^s(i;\lambda)=\frac{1}{(n+1)\gamma_i}\sum_{a,b\in\mathbb{Z}_{n+1}}\omega^{(a-1)s-(b-1)r}\,\frac{1}{\rho_{ai}(\mu_{i+1})}\,\mathscr{D}_{ab}^{(ii-1)}(\lambda)\rho_{bi-1}(\mu_i), \tag{V.21}$$

which together with (IV.7b), (II.21c) yield

$$(P(j;\lambda)\cdots P(k;\lambda))_v^c=\frac{\gamma_j\cdots\gamma_k}{n+1}\sum_{a,b\in\mathbb{Z}_{n+1}}\omega^{(a-1)v-(b-1)c}\,\frac{1}{\rho_{ak-1}(\mu_k)}\,\mathscr{D}_{ab}^{(k-1j)}(\lambda)\rho_{bj}(\mu_{j+1})$$

$$(Q(j;\lambda)\cdots Q(k;\lambda))_r^s=\frac{1}{(n+1)\gamma_j\cdots\gamma_k}\sum_{a,b\in\mathbb{Z}_{n+1}}\omega^{(a-1)s-(b-1)r}\,\frac{1}{\rho_{aj}(\mu_{j+1})}\,\mathscr{D}_{ab}^{(jk-1)}(\lambda)\rho_{bk-1}(\mu_k).$$

$$\text{for}\quad k\leqslant j. \tag{V.22a}$$

Therefore, as a consequence of (V.20b), (II.21c) and the above identities we get

$$(R(j;\mu_{j+1})\cdots R(k;\mu_{j+1}))_{rv}^{p0}=\frac{1}{(n+1)^2}\sum_{a,a',b'\in\mathbb{Z}_{n+1}}\omega^{(a-1)v+(a'-1)p-(b'-1)(r+v)}$$
$$\times\frac{\rho_{ak-1}(\mu_{j+1})}{\rho_{ak-1}(\mu_k)}\,\mathscr{D}_{a'b'}^{(jk-1)}(\mu_{j+1})\,\frac{\rho_{b'k-1}(\mu_k)}{\rho_{a'j}(\mu_{j+1})}. \tag{V.22b}$$

On the other hand, using (II.17d) and (II.21c), it is not difficult to show that

$$\mathscr{D}_{ab}^{(jk)}(\omega^r\lambda)=\omega^{r(a-b)}\mathscr{D}_{ab}^{(jk)}(\lambda).$$

Inserting this identity into (V.22b) and taking into account (II.17e) one obtains

$$(R(j;\mu_{j+1})\cdots R(1;\mu_{j+1}))_{rv}^{p0}=\frac{\delta_{v,0}^{(n+1)}}{n+1}\sum_{a\in\mathbb{Z}_{n+1}}\omega^{(a-1)(p-r)}\,\frac{\rho_{aj}(\omega^r\mu_{j+1})}{\rho_{aj}(\mu_{j+1})}$$

and therefore

$$\sum_{p\in\mathbb{Z}_{n+1}}\omega^{p(1-k)}(R(j;\mu_{j+1})\cdots R(1;\mu_{j+1}))_{rv}^{p0}=\omega^{r(1-k)}\delta_{v,0}^{(n+1)}\,\frac{\rho_{kj}(\omega^r\mu_{j+1})}{\rho_{kj}(\mu_{j+1})}. \tag{V.23a}$$

Using similar arguments and (II.17b)–(II.22) we also prove the identity

$$\sum_{\substack{l<l<j\\ p\in\mathbb{Z}_{n+1}}}\omega^{p(1-k)}(R(j;\mu_{j+1})\cdots R(l;\mu_{j+1})Z[-F_l](l;\mu_{j+1}))^{p0}=-\frac{\mu_{j+1}}{n+1}\cdot\frac{d\,\ln\rho_{kj}}{d\lambda}(\mu_{j+1}), \tag{V.23b}$$

where the functions $Z^{sc}[\pm F_i]$ have been defined by (V.18a), (V.18b).

Now we are ready to calculate the product (V.1). Inserting back (V.18a) and (V.18b) into (V.1) we get

$$\mathrm{Ad}(\tilde{g}_+^{-1}(1)\cdots\tilde{g}_+^{-1}(i-1))F^p(\mu_i)=\sum_{r,v\in\mathbb{Z}_{n+1}}(R(i-1;\mu_i)\cdots R(1;\mu_i))_{rv}^{p0}F^r(\omega^v\mu_i)$$
$$-\sum_{j=1}^{i-1}(R(i-1;\mu_i)\cdots R(j;\mu_i)Z[-F_j](j;\mu_i))^{p0}. \tag{V.24}$$

On the other hand one can repeat the procedure developed in Sec. IV to obtain a result analogous to (IV.16a), (IV.16b),

$$\tilde{g}(i)=\tilde{g}_{-}^{-1}(i)\tilde{g}_{+}(i)=\frac{\hat{\beta}_0(F_i)}{n+1}+\sum_{p\in\mathbb{Z}_{n+1}}(\omega^p-1)\hat{\beta}_p(F_i)F^p(\mu_i) \tag{V.25}$$

where $\hat{\beta}_k(F_i)$, $k\in\mathbb{Z}_{n+1}$ is the discrete Fourier transformation (IV.7a) of $\beta_k(F_i)$ (II.17b). Inserting back the above expression into (V.24) and taking into account (V.23a), (V.23b), and (II.17a) we conclude that

$$\mathrm{Ad}(\tilde{g}_{+}^{-1}(1)\cdots\tilde{g}_{+}^{-1}(i-1))\tilde{g}(i)=Y_i(1+X_iF^{r_i}(\mu_i)),$$

$$X_i=(n+1)(1-\omega^{r_i})\prod_{a\neq i}\frac{\omega^{r_i}\mu_i-\mu_a}{\mu_i-\mu_a}\prod_{a=1}^{N}\frac{\mu_i+\epsilon_{1a}}{\omega^{r_i}\mu_i+\epsilon_{1a}}, \tag{V.26a}$$

$$Y_i=\frac{1}{n+1}\sum_{k\in\mathbb{Z}_{n+1}}\left(1+\mu_i\frac{d}{d\lambda}\ln\frac{\rho_{ki-1}}{\rho_{k+1i-1}}(\mu_i)\right)\beta_k(F_i).$$

Note that due to (II.5a), the quantities X_i depend exponentially on the light cone variables x^+ and x^-. Combining (V.26a), (II.10), and (II.11) we deduce the relation

$$\frac{\tau_\Lambda(\Phi)}{\tau_\Lambda(\Phi_0)}=\exp\left(\frac{\zeta_0-\zeta}{a+1}\right)\prod_{i=1}^{N}Y_i\langle\Lambda|(1+X_1F^{r_1}(\mu_1))\cdots(1+X_NF^{r_N}(\mu_N))|\Lambda\rangle \tag{V.26b}$$

for any fundamental representation with highest weight vector $|\Lambda\rangle$ of the affine Lie algebra $A_n^{(1)}$. Therefore, the representations (I.1) and (I.2) coincide provided that

$$\exp\left(\frac{\zeta-\zeta_0}{n+1}\right)=\prod_{i=1}^{N}Y_i. \tag{V.27}$$

We hope to go back to the proof of the above equation elsewhere.

APPENDIX: THE AFFINE LIE ALGEBRA $A_n^{(1)}$ IN THE PRINCIPAL GRADATION

The purpose of this Appendix is to resume some basic facts from the theory of the Lie algebras. We will focus our attention on the simple Lie algebras A_n and on the untwisted affine Lie algebras $A_n^{(1)}$. More detailed exposition can be found in Refs. 10, 15, and 16.

We recall that the Lie algebra sl$(n+1)$, $n\geqslant 1$ is the set of the traceless $(n+1)\times(n+1)$ matrices. Within the Cartan classification they are known as A_n Lie algebras. The Cartan subalgebra consists of all traceless linear combinations of the diagonal elementary matrices $E^{ii}=|i\rangle\langle i|$ $(i=1\cdots n+1)$. The root system can be embedded into the $(n+1)$-dimensional Euclidean space. Fixing an orthonormalized basis e_i, the roots are $\alpha_{ij}=e_i-e_j$, $i\neq j$ $(i,j=1,...,n+1)$. To each root one associates a step operator $E^{\alpha_{ij}}=E^{ij}=|i\rangle\langle j|$ $(i\neq j)$ which is an eigenvector of the adjoint action of the Cartan subalgebra $\mathscr{H}$. As simple roots one chooses the vectors $\alpha_i=e_i-e_{i+1}$, $i=1,...,n$. The related step operators satisfy the commutation relations

$$[H_\xi,E^{\pm\alpha_i}]=\pm\alpha_i\cdot\xi E^{\pm\alpha_i}=\pm(\xi_i-\xi_{i+1})E^{\pm\alpha_i},$$

$$[E^{\alpha_i}E^{-\alpha_j}]=\delta_{ij}H_{\alpha_i}, \tag{A.1}$$

$$H_\xi=\sum_i\xi_i|i\rangle\langle i|.$$

The generic step operators are obtained by successive commutators of E^{α_i} and their transposed $E^{-\alpha_i}$.

In the theory of the Lie algebras it is important to study their finite order inner automorphisms. The general theory has been developed by Kac[10] and reviewed in Ref. 12. In this paper we shall only use a special inner automorphism σ of the simple Lie algebra A_n of order $n+1$ ($\sigma^{n+1}=1$). Before introducing it, we recall that the fundamental weights are

$$\lambda_i=\sum_{k=1}^{i} e_k-\frac{i}{n+1}\sum_{k=1}^{n+1} e_k,$$
$$2\frac{\alpha_i\cdot\lambda_j}{\alpha_i\cdot\alpha_i}=\delta_{ij},\quad i,j=1,...,n. \tag{A2}$$

We also set $\rho=\Sigma_{i=1}^{n}\lambda_i$ and define[10,11]

$$\sigma(X)=SXS^{-1},$$
$$S=\exp\left(2\pi i\,\frac{H_\rho}{n+1}\right), \tag{A3}$$

for an arbitrary element X of the Lie algebra A_n. Note that in the defining representation, the element S which implements the automorphism σ takes the following form:

$$S=\omega^{n/2}\sum_{k=1}^{n+1}\omega^{1-k}E^{kk},$$
$$\omega=\exp\left(\frac{2\pi i}{n+1}\right). \tag{A4}$$

From the commutation relations (A1) and the above identity, one concludes that σ acts trivially on the elements of $\mathscr{H}$ and as a multiplication by phase on the step operators:

$$\sigma(H_\xi)=H_\xi,$$
$$\sigma(E^{\alpha_{kl}})=\omega^{\alpha_{kl}\cdot\rho}E^{\alpha_{kl}}=\omega^{l-k}E^{\alpha_{kl}}. \tag{A5}$$

The Lie algebra $\mathscr{G}=A_n$ together with the automorphism σ is a $\mathbb{Z}_{n+1}$ graded algebra

$$\mathscr{G}=\oplus_{k\in Z_{n+1}}\mathscr{G}_k,$$
$$\sigma(\mathscr{G}_k)=\omega^k\mathscr{G}_k, \tag{A6}$$
$$[\mathscr{G}_k,\mathscr{G}_l]\subseteq\mathscr{G}_{k+l}.$$

It is well known that for a given simple Lie algebra $\mathscr{G}$, its Cartan subalgebra is fixed up to a conjugation by elements belonging to the corresponding Lie group. In particular, instead of $\mathscr{H}$, one can introduce an *alternative* Cartan subalgebra $\mathscr{H}'$, spanned on the mutually commuting generators:

$$\mathscr{E}_i=\sum_{k=1}^{n+1-i}E^{kk+i}+\sum_{k=1}^{i}E^{n+1+k-ik}=\sum_{k\in Z_{n+1}}|k\rangle\langle k+i|. \tag{A7}$$

To show that the above elements actually generate certain Cartan subalgebra, it suffices to note that the matrix with entries

$$\Omega_{ij}=\omega^{(i-1)(j-1)},$$
$$\Omega_{ij}^{-1}=\frac{\omega^{-(i-1)(j-1)}}{n+1} \tag{A8}$$

diagonalizes $\mathscr{E}_i$ (A7),

$$\Omega^{i-1}\mathscr{E}_i\Omega=\sum_{k=1}^{n+1}\omega^{i(k-1)}E^{kk}. \tag{A9}$$

It is worthwhile to note that the alternative Cartan subalgebra generators are eigenvectors of the inner automorphism σ,

$$\sigma(\mathscr{E}_i)=\omega^i\mathscr{E}_i. \tag{A10}$$

For general simple Lie algebras, it is known[10,15] that the eigenvalues of the corresponding automorphism σ, when restricted to the alternative Cartan algebra, are in correspondence to the Betti numbers. To complete the alternative basis of the Lie algebra A_n, we introduce the generators

$$\begin{aligned} F^i&=\Omega E^{i+1\,i}\Omega^{-1}, \quad i=1,...,n,\\ [\mathscr{E}_i,F^j]&=(\omega^{ij}-1)F^j. \end{aligned} \tag{A11}$$

Due to the grade decomposition (A6) and the above commutation relations one gets

$$\begin{aligned} F^i&=\sum_{k\in Z_{n+1}}F^i_k,\\ \sigma(F^i_k)&=\omega^kF^i_k,\\ [\mathscr{E}_i,F^j_k]&=(\omega^{ij}-1)F^j_{k+i}. \end{aligned} \tag{A12}$$

We thus end up with a basis which is formed by the alternative Cartan generators $\mathscr{E}_i$ (A7) and F^i_k, $i=1,...,n$, $k\in\mathbb{Z}_{n+1}$. Due to (A8) and (A11) the transformation which gives back the Cartan–Weyl basis is

$$\begin{aligned} E^{il}&=\frac{\mathscr{E}_{l-i}}{n+1}+\sum_{r=1}^{n}\omega^{r(1-i)}F^r_{l-i}, \quad i<l,\\ E^{il}&=\frac{\mathscr{E}_{n+1+l-i}}{n+1}+\sum_{r=1}^{n}\omega^{r(1-i)}F^r_{n+1+l-i}, \quad i>l,\\ E^{ii}-E^{n+1\,n+1}&=\sum_{r=1}^{n}\omega^r(\omega^{-ri}-1)F^r_0. \end{aligned} \tag{A13}$$

The commutation relations in the alternative basis are completed by

$$[F^r_i,F^s_l]=\frac{\omega^{sk}-\omega^{rl}}{n+1}F^{r+s}_{k+l}. \tag{A14}$$

Introducing notation

$$F^r_k=\begin{cases} F^r_k, & r=1,...,n, \quad k\in\mathbb{Z}_{n+1}\\ \dfrac{1}{n+1}\mathscr{E}_k & r=0, \quad k=1,...,n, \end{cases} \tag{A15}$$

we see that the commutation relations in the alternative basis assume the uniform expression (A14).

The A_n Lie algebras are equipped with a nondegenerated invariant scalar product $(X,Y)=\mathrm{tr}(X\cdot Y)$. The trace is taken in the defining representation. In the alternative basis (A15) this scalar product is given by

$$(F_k^r, F_l^s) = \frac{\omega^{sk}}{n+1}\,\delta_{k+l,0}^{(n+1)}, \tag{A16}$$

where $\delta_{k,l}^{(n+1)}$ is the delta function in the cyclic group $\mathbb{Z}_{n+1}$. To treat integrable evolution equations, one has to extend the classical Lie algebras by introducing the spectral (or loop) parameter.[11] This implies that the Lax connection belongs to the loop Lie algebra $\tilde{\mathcal{G}} = \mathbb{C}[\lambda, \lambda^{-1}] \otimes \mathcal{G}$. In other words, the loop algebra is the set of the Laurent series with coefficients in the corresponding (classical) Lie algebra $\mathcal{G}$. Therefore $\tilde{\mathcal{G}}$ is spanned on the elements $X_k = \lambda^k X$, $k \in \mathbb{Z}$, $X \in \mathcal{G}$. The Lie bracket is

$$[X_k, Y_l] = [X, Y]_{k+l}. \tag{A17}$$

Loop algebras $\tilde{\mathcal{G}}$ possess central extension,[10] known as affine (or Kac–Moody) algebras $\hat{\mathcal{G}} = \tilde{\mathcal{G}} \oplus \mathbb{C}\hat{c} \oplus \mathbb{C}\hat{d}$,

$$\begin{gathered}
[X_k, Y_l] = [X, Y]_{k+l} + \frac{k}{(n+1)}\,\hat{c}\,\delta_{k+l,0}(X, Y), \\
[\hat{d}, X_k] = kX_k, \\
[\hat{c}, \hat{\mathcal{G}}] = 0.
\end{gathered} \tag{A18}$$

The normalization factor which multiplies the central element $\hat{c}$ is chosen for convenience. The derivation $\hat{d}$ can be used to define a $\mathbb{Z}$ gradation in $\hat{\mathcal{G}}$:

$$\begin{gathered}
\hat{\mathcal{G}} = \oplus_{k \in \mathbb{Z}} \hat{\mathcal{G}}_k, \\
[\hat{d}, \hat{\mathcal{G}}_k] = k\hat{\mathcal{G}}_k.
\end{gathered} \tag{A19}$$

Since σ is an automorphism of the underlying classical Lie algebra $\mathcal{G} = A_n = \mathrm{sl}(n+1)$, it is clear that the commutators (A18) together with the restriction

$$\begin{gathered}
X(\omega\lambda) = \sigma X(\lambda), \\
X(\lambda) = \sum_{l \in \mathbb{Z}} \lambda^l X_l, \\
\sigma X(\lambda) = \sum_l \lambda^l \sigma(X_l),
\end{gathered} \tag{A20}$$

still define a Lie algebra. In the literature[10,12,15] it is known as the affine Lie algebra $A_n^{(1)}$ in the principle gradation. Taking into account (A14), (A16), (A18), together with the above restrictions, we obtain the commutation relations

$$\begin{gathered}
[F_k^r, F_l^s] = \frac{\omega^{sk} - \omega^{rl}}{n+1}\,F_{k+l}^{r+s} + \frac{k\omega^{rl}}{(n+1)^2}\,\hat{c}\,\delta_{r+s,0}^{(n+1)}\,\delta_{k+l,0}, \\
r, s \in \mathbb{Z}_{n+1}, \quad k, l \in \mathbb{Z}.
\end{gathered} \tag{A21}$$

Note that the generators F_k^0 with $k = 0 \bmod(n+1)$ are not in the affine Lie algebra $A_n^{(1)}$. We thus end up with the following alternative basis:

$$\begin{gathered}
F_k^r, \quad r = 1, \ldots, n, \quad k \in \mathbb{Z}, \\
F_k^0, \quad k \in \mathbb{Z}, \quad k \neq 0 \mod(n+1)
\end{gathered} \tag{A22}$$

of the $A_n^{(1)}$ Lie algebra in the principal gradation. The generators F_k^0, $k \neq 0 (\mathrm{mod})$ form a basis of Heisenberg subalgebra in the *principal* gradation.[10–15] In analogy with (A15), we will also use the following generators:

$$\mathscr{E}_k = (n+1) F_k^0,$$
$$[\mathscr{E}_k, \mathscr{E}_l] = k \hat{c} \, \delta_{k+l,0}, \quad k \neq 0 (\mathrm{mod}\ \ n+1). \tag{A23}$$

From the above commutation relations we conclude that $\mathscr{E}_{\pm k}$, $k \geqslant 1$ form an infinite set of noninteracting bosonic oscillators.

ACKNOWLEDGMENTS

It is a pleasure to thank L. A. Ferreira and M. A. C. Kneipp for discussions on the subject. R.P. is also grateful to J. P. Zubelli for bringing to his attention the monograph.[23] Two of us, H.B. and G.C., are supported by CNPq-Brazil while R.P. is supported by FAPERJ-Rio de Janeiro. We deeply acknowledge both foundations for invaluable financial support.

After embedding the Kadomtsev–Petviashvili equation in higher dimensions and extending the Painlevé analysis approach to a new form such that the coefficients of the expansion around the singular manifold possess conformal invariance and contain explicit new space variables, we can get infinitely many Painlevé integrable models in $(3+1)$-dimensions and higher dimensions. Some concrete higher dimensional modified Korteweg–de Vries type of extensions are given. Whether the models are Lax integrable or integrable under other meanings remain still open. © *1998 American Institute of Physics.* [S0022-2488(98)00510-6]

I. INTRODUCTION

Integrable models in $(1+1)$- and $(2+1)$-dimensions have been deeply studied by many mathematicians and physicists and widely applied in many physical fields like the classical and quantum field theory,[1] condense matter physics,[2] fluid mechanics,[3] plasma physics,[4] optics,[5] particle and nuclear physics,[6] universe,[7] geophysics,[8] planetary and space science.[9] Actually, the existence of the localized excitations (solitons or solitary waves) is one of the basic nonlinear phenomena in many other natural sciences, for instance, communications,[10] chemistry,[11] and biology.[12]

However, there is no one known real significant $(n+1)$-dimensional $(n\geqslant 3)$ nontrivial nonlinear integrable model except the ''$2+2$'' dimensional self-dual Yang–Mills field equation[13] though the real physical space is $(3+1)$-dimensional. Because the real physical space is $(3+1)$-dimensional, various physicists and mathematicians have tried to find some nontrivial $(3+1)$-dimensional integrable models[13,14] for a long time. But there is little progress in this direction.

Recently, we have proposed some possible directions to find some nontrivial integrable models in higher dimensions.

Based on the fact that all the known $(2+1)$-dimensional integrable models possess a common generalized Virasoro type symmetry algebra,[15]

$$[\sigma(f_1),\sigma(f_2)]=\sigma(\dot{f}_2 f_1-\dot{f}_1 f_2), \tag{1}$$

where $\sigma(f)$ with f being an arbitrary function of a single independent variable is a symmetry of the integrable model, we proposed a general method to get some integrable models under the meaning that they possess the generalized Virasoro symmetry algebra (1) in Refs. 16 and 17.

$(2+1)$-dimensional breaking soliton equations[18] are a special type of integrable extension of the $(1+1)$-dimensional integrable models. A $(2+1)$-dimensional breaking soliton equation and

[a)]Electronic mail: sylou@public.nbptt.zj.cn

 © 1998 American Institute of Physics

its corresponding $(1+1)$-dimensional integrable model possess a common recursion operator.[19,20] Using the same common recursion operator, the breaking soliton equation can be extended to any dimensions.[20,17]

Usually, using the symmetry constraint[21–23] (or reduction[24–26]) approaches, one can always get some lower dimensional integrable models from higher dimensional ones. In Refs. 27 and 28, we pointed out that using the inner parameter dependent symmetry constraints, one can also get some types of integrable models in the same or even higher dimensions.

It is also known that for every known $(1+1)$-dimensional and $(2+1)$-dimensional integrable model, there is an invariant form with conformal invariance (invariance under the Möbious transformation). And the conformal invariance also plays a very important role in the study of other integrable properties like infinitely many symmetries and the Darboux transformation.[29,28] These facts hint to us that if we want to find a higher dimensional integrable model, starting from a conformal invariant form may be one of the best convenient ways. In Refs. 17, 30, and 31, we can see that some quite general higher dimensional conformal invariant models are integrable under the meaning that they possess the Painlevé property.

Getting some lower dimensional integrable models from a higher dimensional one is quite easy, say, one can use some limit procedures or symmetry reduction approaches.[21–26] In Ref. 32, we have also pointed out that the inverse procedure of the above (i.e., to obtain higher dimensional integrable models from the lower dimensional ones) is possible. On the other hand, from the symmetry reductions of $(1+1)$-dimensional and $(2+1)$-dimensional integrable models, we know that the ordinary differential equation (ODE) reductions can usually be casted to several forms, say, the Riccati equation and the Painlevé I–VI equations.[33] This fact shows us that all the higher dimensional integrable models can be considered as the deformations of a small set of integrable ODEs. For instance, some types of $(1+1)$-dimensional and $(2+1)$-dimensional sinh-Gordon equations and the Mikhailov–Dodd–Bullough (MDB) equations have been obtained by deforming a simple Riccati equation[32]

$$\phi_t = \phi^2. \tag{2}$$

In this paper, we would like to propose another approach to get higher dimensional integrable models from lower dimensional ones. The singularity analysis is one of the most powerful methods to study the integrabilities of integrable models. For instance, using the singularity analysis of an integrable model proposed by Weiss, Tabor, and Carnevale (WTC),[34] one can obtain the Painlevé property, Bäcklund transformation, Lax pair, symmetries, bilinear form and some types of exact solutions[33–37] for some kinds of integrable models. However, to our knowledge, no one uses the Painlevé analysis approach to get some new integrable models under any meanings.

In Sec. II, after extending the Painlevé approach to a general form, we propose a possible general approach to get some higher dimensional Painlevé integrable (*P*-integrable) models from lower dimensional ones by means of the extended Painlevé analysis approach. In Sec. III, taking the Kadomtsev–Petviashvili (KP) equation as a seed integrable model and using the method outlined in Sec. II, we obtain various higher dimensional *P*-integrable models especially in $(3+1)$-dimensions. Section IV is a summary and discussion.

II. GENERAL THEORY

For a given *n*-dimensional *N* order PDE,

$$F(x_0 \equiv t, x_1, x_2, \ldots, x_n, u, u_{x_i}, u_{x_i x_j}, \ldots, u_{x_{i_1} x_{i_2}, \ldots, x_{i_N}}) = 0, \tag{3}$$

where the function F is a polynomial function of the field u and its derivatives, the model is said to possess the Painlevé property if all the movable singularities of its solution with respect to an arbitrary singular manifold $\phi \equiv \phi(x_0, x_1, x_2, \ldots, x_n) = 0$ are poles. That is to say, if expanding the solution of (3) near the singular manifold ϕ, we should have the form[34]

$$u = \sum_{j=0}^{\infty} u_j \phi^{j+\alpha} \tag{4}$$

with $N-1$ further arbitrary functions $u_{j1},u_{j2},\ldots,u_{j_{N-1}}$ and negative integer α. Substituting (4) into (3), we can get a recursion relation to determine the expansion coefficients u_j,

$$(j+1)(j-j_1)(j-j_2)\cdots(j-j_{N-1})u_j=f_j(x_i,\phi_{x_i},\phi_{x_{i_1}x_{i_2}},\ldots,u_1,u_2,\ldots,u_{j-1})\equiv f_j, \tag{5}$$

where $j_1,j_2,\ldots,j_{N-1}$ should be positive integers and the resonance conditions

$$f_{j_i}=0 \quad (i=1,2,...,N-1), \tag{6}$$

should be satisfied identically.

If we take

$$u_j=0 \quad (j>-\alpha), \tag{7}$$

then we get a Bäcklund transformation of (3), i.e., if $u_{-\alpha}$ is a solution of (3), then the truncated expansion u given by (4) with (6) is also a solution of (3). Furthermore, if $u=0$ is a solution of (3), the single soliton solution of (3) can be obtained from the Bäcklund transformation and the trivial solution $u_{-\alpha}=0$. Usually, when one uses the truncated expansions to discuss the Bäcklund transformation or exact solutions, no one discusses any properties of the equations $u_j=0$, $(j\geqslant-\alpha)$ i.e.,

$$f_j=0 \quad (j\geqslant-\alpha, j\neq j_1,j_2,\ldots,j_{N-1}). \tag{8}$$

Because equations (7) for different j must be consistent when we use the truncation expansion to study the integrable property of (3), we believe that many equations of (7) or some combinations of u_j $(j\geqslant-\alpha)$ may be integrable.

The models obtained from (7) possess the same dimensions as the original model (3). In order to get some higher-dimensional integrable models from (3), we may take the following two steps. First, we should embed the lower dimensional integrable model (3) in higher dimensions. In other words, we should consider u as not only dependent on the explicit independent variables $\{x_1,\ldots,x_n,t\}$ but also some implicit ones, say, $\{x_{n+1},\ldots,x_{n+m}\}$. Second, the Painlevé expansion (4) should be extended to a different resummation form such that the implicit independent variables $\{x_{n+1},\ldots,x_{n+m}\}$ appear explicitly in the new expansion coefficients and the same number of arbitrary functions are still included in the new expansion form. The second step can be realized because of the singular manifold ϕ being arbitrary. For instance, we can take

$$\xi\equiv\left(\frac{\phi_{x_{n+1}}}{\phi}-\frac{\phi_{x_{n+1}x_{n+1}}}{2\phi_{x_{n+1}}}\right)^{-1} \tag{9}$$

as a new expansion variable, i.e., we change the expansion (4) as

$$u=\sum_{j=0}^{\infty}u'_j\xi^{j+\alpha} \tag{10}$$

with arbitrary $\xi, u'_{j_1},u'_{j_2},\ldots,u'_{j_{N-1}}$ and the same integers $j_1,j_2,\ldots,j_{N-1}$, and α as in (4). From Eq. (9) one can easily prove the following identities:

$$\xi_{x_i}=P_i-P_{ix_{n+1}}\xi+\tfrac{1}{2}(P_iS+P_{ix_{n+1}x_{n+1}})\xi^2, \quad i=0,1,2,...,n, \tag{11}$$

where the functions

$$P_i\equiv\frac{\phi_{x_i}}{\phi_{x_{n+1}}}, \quad S\equiv\frac{\phi_{x_{n+1}x_{n+1}x_{n+1}}}{\phi_{x_{n+1}}}-\frac{3}{2}\left(\frac{\phi_{x_{n+1}x_{n+1}}}{\phi_{x_{n+1}}}\right)^2\equiv\{\phi,x_{n+1}\} \tag{12}$$

are all conformal invariant. In other words, P_i and S are invariant under the Möbious transformation

$$\phi \to \frac{a+b\phi}{c+d\phi}, \quad ad \neq bc. \tag{13}$$

It is straightforward to see that all the expansion coefficients u_j' in (10) are all conformal invariant because they are functions of P_i, S and $\{u_{j_1}', u_{j_2}', \ldots, u_{j_{N-1}}'\}$. Now a further independent variable x_{n+1} has been included explicitly to the expansion coefficients u_j' though the original equation (3) is not x_{n+1} dependent explicitly.

If taking $n=1$, $x_1=x$, and $x_2=x_1=x$, the expansion function (9) and the extended approach proposed above reduced to Conte's simplification for the usual Painlevé analysis approach.[36]

On the other hand, the conformal invariance plays very important roles in integrable theory. For instance, starting from the conformal invariance of the Korteweg–de Vries (KdV) and KP equations, one can obtain the infinitely many symmetries, Darboux transformations, sine-Gordon extensions, etc.[29] Starting from a quite general conformal form one can get infinitely many *P*-integrable models.[31] Now it is reasonable to assume that:

Assumption. If Eq. (3) is integrable, then the equations obtained from vanishing the coefficients of the extended Painlevé expansion (10), for $u_j'=0$, $j \geqslant -\alpha$, are integrable.

Though we have not yet proved this assumption and/or even the assumption may not be completely true, we can still obtain various higher-dimensional integrable models under some special meanings, say, under the Painlevé meaning (the model possesses a variant form with Painlevé property), from lower ones by checking the assumption for some given lower dimensional integrable models and small j. It is interesting that if the seed equation (3) is $(2+1)$-dimensional, then the integrable models obtained from the assumption are $(3+1)$-dimensional. Furthermore, the assumption can be used in many times to get some integrable models in arbitrary dimensions no matter how many dimensions the seed model has. For instance, if the seed model is $(1+1)$-dimensional, then using the assumption once, one may get some $(2+1)$-dimensional models (after some necessary integrability verification of the obtained models because the assumption has not yet been proved). Using the obtained $(2+1)$-dimensional integrable models as seeds, one may obtain some $(3+1)$-dimensional integrable models and so on.

Now a natural and important question is whether the new independent variables introduced in this way are genuinely new independent variables? In our experience, the new independent variables are genuinely entered into every coefficient of the series expansion (10). The new variables can be absorbed only when we considered all the terms of the expansion (10).

III. HIGHER-DIMENSIONAL *P*-INTEGRABLE MODELS FROM THE KP EQUATION

A. *P*-integrable models from the KP equation directly

The $(2+1)$-dimensional KP equation ($x_0=t$, $x_1=x$, $x_2=y$, $x_3=z$)

$$(u_t - 6uu_x + u_{xxx})_x + 3\sigma^2 u_{yy} = 0 \tag{14}$$

is one of the most important integrable physical models which is widely used in many physical fields such as fluid mechanics, plasma physics, optics, condense matter physics, geophysics, planetary and space science, etc. And the model is widely studied by various mathematicians and physicists. The Painlevé property of the KP equation was first proved by WTC.[34] In order to obtain some nontrivial $(3+1)$-dimensional model from the KP equation, we restudy the Painlevé property of the model by using the new expansion (10) and considering u of (14) is not only a function of $\{x,y,t\}$ but also a function of z. As in the usual case,[34] by means of the leading order analysis, we have

$$\alpha = -2, \quad u_0' = 2P_1^2 \tag{15}$$

in (10) for the KP equation (14). Substituting (10) with (11) and (15) into (14) we get the recursion relation of the coefficients u_j'

$$(j+1)(j-4)(j-5)(j-6)u_j' = f_j'(S, P_i, P_{ix_i}, \ldots, u_0', \ldots, u_{j-1}') \equiv f_j', \tag{16}$$

where f_j' is a complicated function of $u_0',\ldots,u_{j-1}'$ and the conformal invariants P_i, S and their derivatives. After solving (16) out one by one, f_j' becomes only a function of the conformal invariants. The first three of u_j' read

$$u_1' = -2P_{1x} - 2P_1P_{1z}, \tag{17}$$

$$u_2' = \frac{1}{6P_1^2}(4P_1P_{1xx} + 4P_1^2P_{1xz} + 2P_1P_{1x}P_{1z} - 3P_{1x}^2 + 4P_1^4S + P_1P_0 + P_1^2P_{1z}^2 + 4P_1^3P_{1zz} + 3\sigma^2P_2^2), \tag{18}$$

$$\begin{aligned} u_3' = \frac{1}{6P_1^4}(&P_1^2P_{0x} - 2P_1^2P_{1t} - P_1^4P_{1xzz} - P_1^3P_{1xxz} - P_1^5S_x - 2P_1^3P_{0z} - 15\sigma^2P_1^2P_2P_{2z} \\ &+ P_1P_{1x}P_0 + 2P_1^2P_{1z}P_0 + P_1^3P_{1xz}P_{1z} + 4P_1P_{1x}P_{1xx} - 2P_1^4P_{1x}S - 3P_{1x}^3 \\ &+ 3\sigma^2P_{1x}P_2^2 + P_1^2P_{1x}P_{1xz} - P_1^3P_{1x}P_{1zz} - P_1^2P_{1xxx} + 15\sigma^2P_1P_2^2P_{1z} - P_1P_{1z}P_{1x}^2 \\ &+ 12\sigma^2P_1P_2P_{2x} - 3\sigma^2P_1^2P_{2y} + P_1^2P_{1z}P_{1xx} - 12\sigma^2P_1P_2P_{1y}). \end{aligned} \tag{19}$$

Using the relations (12), (15), (17)–(19), and the computer algebra, say, MAPLE or MATHEMATICA, it is easy to prove that the following three resonant conditions (16) for $j=4,5,6$ are satisfied identically. The Painlevé property of the KP equation is reobtained under the new configuration.

Now using the assumption, we may obtain a set of Painlevé integrable models

$$f_j' = 0, \quad j = 2,3,7,8,..., \tag{20}$$

where $j=4$, 5, 6 disappear due to the resonance conditions as these values are satisfied identically. It is difficult to prove the Painlevé property for whole set. We can only check the integrabilities for small j of (20).

After substituting (12) into (20) for $j=3$ [i.e., (19) with $u_3'=0$], we have

$$\phi_{xxxx}\phi_x^2 + \phi_x^2\phi_{xt} + \phi_{xx}^3 - \phi_t\phi_x\phi_{xx} - 4\phi_x\phi_{xx}\phi_{xxx} + 3\sigma^2\phi_{yy}\phi_x^2 - 3\sigma^2\phi_y^2\phi_{xx} = 0, \tag{21}$$

i.e.,

$$\left(\frac{\phi_t}{\phi_x} + \{\phi,x\} + \frac{3}{2}\sigma^2\frac{\phi_y^2}{\phi_x^2}\right)_x + 3\sigma^2\left(\frac{\phi_y}{\phi_x}\right)_y = 0. \tag{22}$$

From (21) we see that it is not explicitly z dependent. The integrability of (21) is trivial because it is really the original $(2+1)$-dimensional KP equation in its Schwarz form[34] and Eqs. (14) and (22) are related by[32,35]

$$u = \frac{1}{2}\{\phi,x\} + \frac{\phi_{xx}^2}{2\phi_x^2} + \sigma^2\frac{\phi_y^2}{4\phi_x^2} - \frac{\sigma^2}{2}\int^x\left(\frac{\phi_y}{\phi_x}\right)_y dx. \tag{23}$$

The usual Schwarz KP equation appears as a special case of our assumption, $u_3'=0$, which is natural because we obtain (20) from the KP equation.

Though we can prove the Painlevé property of (20) for $j=7$, we do not write it down because (20) with $j=7$ is too complicated after substituting (12) in (about two or more printed pages). So we discuss only for $j=2$ here. Substituting $j=2$ and (12) into (20) [i.e., (18) with $u_2'=0$] yields a nontrivial $(3+1)$-dimensional model

$$4\phi_x\phi_z^4\phi_{xxx} - 3\phi_z^4\phi_{xx}^2 + 3\phi_x^4\phi_{zz}^2 + \phi_x\phi_t\phi_z^4 + 3\sigma^2\phi_y^2\phi_z^4 - 6\phi_x^2\phi_z^2\phi_{xx}\phi_{zz} = 0. \tag{24}$$

Making the following transformation

$$\phi = e^f, \tag{25}$$

Eq. (24) can be rewritten as

$$f_t+4f_{xxx}-2f_x^3-3f_{xx}^2f_x^{-1}+3\sigma^2f_y^2f_x^{-1}+3f_x^3f_{zz}^2f_z^{-4}-6f_xf_{xx}f_{zz}f_z^{-2}=0. \tag{26}$$

Equation (26) is a $(3+1)$-dimensional extension of the potential modified KdV (PMKdV) equation. The first four $\{y,z\}$ independent terms are equivalent to the PMKdV equation. The fifth term and the sixth and seventh terms of (26) are the y and z part modification of the PMKdV equation.

In order to prove the integrability of (26) [then (24)], we change (26) to an equivalent equation system

$$4UW^4U_{xx}-3W^4U_x^2-2W^4U^4+3U^4W_z^2+UGW^4-6U^2W^2U_xW_z+3\sigma^2V^2W^4=0, \tag{27}$$

$$U_t=G_x, \tag{28}$$

$$V_t=G_y, \tag{29}$$

$$W_t=G_z, \tag{30}$$

by using further transformations

$$f_x=U,\ \ f_y=V,\ \ f_z=W,\ \ f_t=G. \tag{31}$$

Equations (28)–(30) are the consistent conditions of the transformation (31). To prove the Painlevé property of the equation system (27)–(30), we may use both the traditional WTC approach[34] or its extended form proposed in Sec. II. Using the extended WTC approach we can not only prove the Painlevé property of the system (27)–(30) but also get some more integrable models both in $(4+1)$-dimensions and in $(3+1)$-dimensions (combining with some suitable reduction approaches). So we would like take the extended approach to prove the Painlevé property of (27)–(30) again in Sec. III B.

B. *P*-integrable models from the system (27)–(30)

Expanding U,V,W,G as

$$U=\sum_{j=0}^{\infty}U_j\xi^{j+\alpha_1},\quad V=\sum_{j=0}^{\infty}V_j\xi^{j+\alpha_2},\quad W=\sum_{j=0}^{\infty}W_j\xi^{j+\alpha_3},\quad G=\sum_{j=0}^{\infty}G_j\xi^{j+\alpha_4}, \tag{32}$$

where ξ is given by (9) with $n=3$, $x_0=t$, $x_1=x$, $x_2=y$, $x_3=z$, and $\alpha_1=\alpha_2=\alpha_3=\alpha_4=-1$,

$$U_0=\pm P_1,\quad V_0=\pm P_2,\quad W_0=\pm P_3,\quad G_0=\pm P_0 \tag{33}$$

are determined by the leading order analysis and the relation (11) for $n=3$.

Substituting (32) with $\alpha_i=-1$, (33) and (11) into (27)–(30), one can see that all the needed five resonances are located at

$$j=-1,1,1,1,1. \tag{34}$$

The resonance at $j=-1$ is related to ϕ (and then ξ) being arbitrary. The resonance conditions at $j=1$ read

$$\begin{aligned}&3U_0(P_1W_0-U_0P_3)(W_0^2P_{1x_4}-U_0(W_0P_{3x_4}+W_{0z}))+2W_0^3U_0P_{1x}\\&+W_0^2(W_0P_1-3U_0P_3)U_{0x}-2W_0[(2U_0^2W_0^2-3U_0^2P_3^2\\&+3U_0W_0P_1P_3-2W_0^2P_1^2)U_1-U_0(5P_1^2W_0-2W_0U_0^2-3P_1P_3U_0)W_1]=0,\end{aligned} \tag{35}$$

$$U_{0t}-G_{0x}+U_0P_{0x_4}-G_0P_{1x_4}=0, \tag{36}$$

$$V_{0t}-G_{0y}+V_0P_{0x_4}-G_0P_{2x_4}=0, \tag{37}$$

$$W_{0t}-G_{0z}+W_0P_{0x_4}-G_0P_{3x_4}=0. \tag{38}$$

It is straightforward to see that all the resonance conditions (35)–(38) are satisfied identically because of the relations (33) and (12) with $n=3$. So the equation system (27)–(30) possesses the Painlevé property and then Eq. (26) [and (24)] is a $(3+1)$-dimensional *P*-integrable model under the meaning that it possesses the conformal invariance and the Painlevé property.

Using the further assumption to the system (27)–(30), some $(4+1)$-dimensional models with the Painlevé property can be obtained. For instance, from $U_2=V_2=W_2=G_2=0$, we get

$$\begin{aligned}&(3\sigma^2P_2^2+P_0P_1-2P_1^4S+P_1^2P_{1x_4}^2+2P_1P_{1x}P_{1x_4}-3P_{1x}^2)P_3^4+3(P_3^2P_{3x_4}^2+2P_3P_{3z}P_{1x_4}+P_{3z}^2)P_1^4\\&\quad-6P_1^2P_3^2P_{1x}P_{3z}-6P_1^3P_3^3P_{1x_4}P_{3x_4}-6P_1^2P_3^3P_{1x}P_{3x_4}-6P_3^2P_1^3P_{3x}P_{1x_4}=0,\end{aligned} \tag{39}$$

i.e.,

$$\begin{aligned}&8\phi_z^4\phi_x\phi_{x_4}^3\phi_{xx}\phi_{xx_4}+4\phi_z^4\phi_x^2\phi_{x_4}^2\phi_{xx}\phi_{x_4x_4}-3\phi_z^4\phi_{x_4}^4\phi_{xx}^2+3\phi_x^4\phi_{x_4}^4\phi_{zz}^2-6\phi_z^2\phi_x^2\phi_{x_4}^4\phi_{xx}\phi_{zz}\\&\quad+\phi_t\phi_x\phi_z^4\phi_{x_4}^4-2\phi_x^4\phi_z^4\phi_{x_4x_4x_4}\phi_{x_4}-4\phi_z^4\phi_x^2\phi_{xx_4}\phi_{x_4}^2+3\sigma^2\phi_y^2\phi_z^4\phi_{x_4}^4+\phi_x^4\phi_z^4\phi_{x_4x_4}^2=0.\end{aligned} \tag{40}$$

The Painlevé property of (40) can be proved in the same way. Using the classical and nonclassical Lie approach, some kinds of $(3+1)$-dimensional Painlevé integrable reductions can be obtained from (40). The simplest three $(3+1)$-dimensional reductions are

$$6\phi_z^4\phi_{xx}^2+3\phi_x^4\phi_{zz}^2-6\phi_z^2\phi_x^2\phi_{xx}\phi_{zz}+\phi_t\phi_x\phi_z^4-2\phi_x\phi_z^4\phi_{xxx}+3\sigma^2\phi_y^2\phi_z^4=0, \tag{41}$$

$$\begin{aligned}&8\phi_z^4\phi_x\phi_{x_4}^3\phi_{xx}\phi_{xx_4}+4\phi_z^4\phi_x^2\phi_{x_4}^2\phi_{xx}\phi_{x_4x_4}-3\phi_z^4\phi_{x_4}^4\phi_{xx}^2+3\phi_x^4\phi_{x_4}^4\phi_{zz}^2-6\phi_z^2\phi_x^2\phi_{x_4}^4\phi_{xx}\phi_{zz}\\&\quad+\phi_t\phi_x\phi_z^4\phi_{x_4}^4-2\phi_x^4\phi_z^4\phi_{x_4x_4x_4}\phi_{x_4}-4\phi_z^4\phi_x^2\phi_{xx_4}\phi_{x_4}^2+\phi_x^4\phi_z^4\phi_{x_4x_4}^2=0,\end{aligned} \tag{42}$$

and

$$\begin{aligned}&8\phi_z^4\phi_x\phi_{x_4}^3\phi_{xx}\phi_{xx_4}+4\phi_z^4\phi_x^2\phi_{x_4}^2\phi_{xx}\phi_{x_4x_4}-3\phi_z^4\phi_{x_4}^4\phi_{xx}^2+3\phi_x^4\phi_{x_4}^4\phi_{zz}^2-6\phi_z^2\phi_x^2\phi_{x_4}^4\phi_{xx}\phi_{zz}\\&\quad-2\phi_x^4\phi_z^4\phi_{x_4x_4x_4}\phi_{x_4}-4\phi_z^4\phi_x^2\phi_{xx_4}\phi_{x_4}^2+3\sigma^2\phi_y^2\phi_z^4\phi_{x_4}^4+\phi_x^4\phi_z^4\phi_{x_4x_4}^2=0.\end{aligned} \tag{43}$$

Equations (41)–(43) can be obtained by using the symmetry constraints

$$\phi_x-\phi_{x_4}=0, \tag{44}$$

$$\phi_y=0, \tag{45}$$

and

$$\phi_t=0, \tag{46}$$

respectively. One can easily see that the difference between the reduction (41) and the original equation (24) is only the ratio of the coefficients of the terms $\phi_z^4\phi_x\phi_{xxx}$ and $\phi_z^4\phi_{xx}^2$. Equations (42) and (43) can also be obtained directly from the KdV equation and the Boussinesq equation by using the method proposed here.

C. The Painlevé property of (40) and further Painlevé integrable models

Now we use the extended Painlevé analysis and the assumption further on (40) to prove its Painlevé property and get some more higher dimensional *P*-integrable models.

Using the transformation (25), Eq. (40) becomes

$$f_t f_x f_z^4 f_{x_4}^4 + 3\sigma^2 f_y^2 f_z^4 f_{x_4}^4 + 8 f_z^4 f_x f_{x_4}^3 f_{xx} f_{xx_4} + f_z^4 f_x^4 f_{x_4}^4 + 4 f_z^4 f_x^2 f_{x_4}^2 f_{xx} f_{x_4x_4} - 3 f_z^4 f_{x_4}^4 f_{xx}^2 + 3 f_x^4 f_{x_4}^4 f_{zz}^2$$
$$- 6 f_z^2 f_x^2 f_{x_4}^4 f_{xx} f_{zz} - 2 f_x^4 f_z^4 f_{x_4} f_{x_4x_4x_4} - 4 f_z^4 f_x^2 f_{x_4}^2 f_{xx_4}^2 + f_x^4 f_z^4 f_{x_4x_4}^2 = 0. \quad (47)$$

Substituting the further transformations

$$f_x = U, \quad f_y = V, \quad f_z = W, \quad f_t = G, \quad f_{x_4} = H \quad (48)$$

into (47) yields an equivalent system

$$GUW^4H^4 + 3\sigma^2 V^2 W^4 H^4 + 8 W^4 U H^3 H_x U_{x_4} + 4 W^4 U^2 H^2 U_x H_{x_4} - 3 W^4 H^4 U_x^2 + U^4 W^4 H^4$$
$$+ U^4 W^4 H_{x_4}^2 + 3 U^4 H^4 W_z^2 - 6 W^2 U^2 H^4 U_x W_z - 2 U^4 W^4 H H_{x_4x_4} - 4 W^4 U^2 H^2 U_{x_4}^2 = 0, \quad (49)$$

$$U_t = G_x, \quad (50)$$

$$V_t = G_y, \quad (51)$$

$$W_t = G_z, \quad (52)$$

$$H_t = G_{x_4}. \quad (53)$$

Equations (50)–(53) are the consistent conditions of the transformation (48).

To prove the Painlevé property of the equation system (49)–(53), we expand U, V, W, G, H as

$$U = \sum_{j=0}^{\infty} U_j \xi^{j+\alpha_1}, \quad V = \sum_{j=0}^{\infty} V_j \xi^{j+\alpha_2}, \quad W = \sum_{j=0}^{\infty} W_j \xi^{j+\alpha_3},$$

$$G = \sum_{j=0}^{\infty} G_j \xi^{j+\alpha_4}, \quad H = \sum_{j=0}^{\infty} H_j \xi^{j+\alpha_4}, \quad (54)$$

where ξ is given by (9) with $n=4$, $x_0=t$, $x_1=x$, $x_2=y$, $x_3=z$ and $\alpha_1=\alpha_2=\alpha_3=\alpha_4=-1$,

$$U_0 = \pm P_1, \quad V_0 = \pm P_2, \quad W_0 = \pm P_3, \quad G_0 = \pm P_0, \quad H_0 = \pm P_4 \quad (55)$$

are fixed by the leading order analysis and the relation (11) for $n=4$.

Substituting (54) with $\alpha_i = -1$, (55) and (11) into (49)–(53), we see that all the required six resonances are located at

$$j = -1, 1, 1, 1, 1, 1. \quad (56)$$

The resonance at $j=-1$ is related to ϕ (and then ξ) being arbitrary. The resonance conditions at $j=1$ require that the expansion coefficients $\{U_1, V_1, W_1, G_1, H_1\}$ should be arbitrary. The related resonance conditions are

$$(P_0^2 - G_0^2)(2P_4P_3U_1 + 2P_1P_4W_1 + 2P_1P_3H_1) + P_1P_3(G_{0x_4}P_0 - G_0P_{0x_4}) = 0, \quad (57)$$

$$U_{0t} - G_{0x} + U_0 P_{0x_4} - G_0 P_{1x_4} = 0, \quad (58)$$

$$V_{0t} - G_{0y} + V_0 P_{0x_4} - G_0 P_{2x_4} = 0, \quad (59)$$

$$H_{0t} - G_{0x_4} + H_0 P_{0x_4} - G_0 P_{4x_4} = 0, \quad (60)$$

$$W_{0t} - G_{0z} + W_0 P_{0x_4} - G_0 P_{3x_4} = 0. \quad (61)$$

It is straightforward to see that all the resonance conditions (57)–(61) are satisfied identically because of the relations (55) and (12) with $n=4$. So the equation system (49)–(53) possesses the Painlevé property.

Using the assumption further to the system (49)–(53), some $(5+1)$-dimensional models with the Painlevé property can be obtained. The simplest five of them read

$$\begin{aligned}
&P_3^4P_1^4P_{4x_4}^2-3P_3^4P_4^4P_{1x}^2+3P_1^4P_4^4P_{3z}^2+P_1^4P_4^4P_3^4S+4P_3^4P_1^4P_4^3P_{4x_5x_5}-2P_3^4P_1^4P_4P_{4x_4x_4}\\

where P_0, P_1, P_2, P_3, P_4, and S are given by (12) with $n=4$. Equations (62)–(66) (which come from $U_2=0$, $V_2=0$, $W_2=0$, $G_2=0$, and $H_2=0$) are all conformal invariant because S, P_i, $i=0,1,...,4$ and their derivatives are all conformal invariant.

Using the classical and nonclassical Lie approach, some kinds of $(3+1)$-dimensional P-integrable reductions can be obtained from (62)–(66). Here we list some simple ones. Substituting

$$x_4=x_5=x$$

which is equivalent to take the symmetry constraints

$$\phi_{x_4}=\phi_x, \quad \phi_{x_5}=\phi_\eta, (\eta=x+x_4)$$

into (62)–(66), we get four independent $(3+1)$-dimensional Painlevé integrable models:

$$6\phi_x^4\phi_{zz}^2+2\phi_t\phi_x\phi_z^4+2\phi_z^4\phi_{xxx}\phi_x+3\phi_z^4\phi_{xx}^2+6\sigma^2\phi_y^2\phi_z^4-12\phi_x^2\phi_z^2\phi_{xx}\phi_{zz}=0, \quad (67)$$

$$6\phi_y\phi_x^4\phi_{zz}^2-6\phi_z^4\phi_{xxy}\phi_x^2+8\phi_z^4\phi_x\phi_y\phi_{xxx}+12\phi_z^4\phi_{xx}\phi_{xy}\phi_x-9\phi_z^4\phi_y\phi_{xx}^2$$
$$-12\phi_y\phi_z^2\phi_x^2\phi_{zz}\phi_{xx}+2\phi_y\phi_t\phi_z^4\phi_x+6\sigma^2\phi_y^3\phi_z^4=0, \quad (68)$$

$$6\phi_x^4\phi_{zz}^2+2\phi_t\phi_x\phi_z^4+8\phi_z^4\phi_{xxx}\phi_x-9\phi_z^4\phi_{xx}^2+6\sigma^2\phi_y^2\phi_z^4$$
$$+12\phi_z^3\phi_{xx}\phi_x\phi_{xz}-12\phi_x^2\phi_z^2\phi_{xx}\phi_{zz}-6\phi_z^3\phi_x^2\phi_{xxz}=0, \quad (69)$$

$$-6\phi_x^4\phi_t\phi_{zz}^2-2\phi_t^2\phi_x\phi_z^4-6\sigma^2\phi_y^2\phi_t\phi_z^4-8\phi_z^4\phi_t\phi_{xxx}\phi_x+9\phi_t\phi_z^4\phi_{xx}^2$$
$$+12\phi_x^2\phi_t\phi_z^2\phi_{xx}\phi_{zz}+6\phi_z^4\phi_{txx}\phi_x^2-12\phi_z^4\phi_{xx}\phi_{tx}\phi_z=0. \quad (70)$$

Substituting $x_5=x_4=z$ into (62)–(66), we get only three independent $(3+1)$-dimensional reductions:

$$-6\phi_z^4\phi_{xx}^2+16\phi_z^3\phi_{xx}\phi_x\phi_{xz}-8\phi_z^2\phi_x^2\phi_{xz}^2+6\sigma^2\phi_y^2\phi_z^4+2\phi_x^4\phi_{zzz}\phi_z$$
$$-\phi_x^4\phi_{zz}^2+2\phi_t\phi_x\phi_z^4-4\phi_x^2\phi_z^2\phi_{xx}\phi_{zz}=0, \quad (71)$$

$$6\sigma^2\phi_y^2\phi_z^4+16\phi_x\phi_z^3\phi_{xx}\phi_{xz}-4\phi_x^2\phi_z^2\phi_{xx}\phi_{zz}-8\phi_x^2\phi_z^2\phi_{xz}^2+12\phi_x^3\phi_z\phi_{xz}\phi_{zz}$$
$$+8\phi_x^4\phi_{zzz}\phi_z-13\phi_x^4\phi_{zz}^2+2\phi_t\phi_x\phi_z^4-6\phi_x^3\phi_{xzz}\phi_z^2-6\phi_z^4\phi_{xx}^2=0, \quad (72)$$

and

$$2\phi_t^2\phi_x\phi_z^4-6\phi_t\phi_z^4\phi_{xx}^2+16\phi_t\phi_z^3\phi_{xx}\phi_x\phi_{xz}-8\phi_t\phi_x^2\phi_x^2\phi_{xz}^2-4\phi_x^2\phi_t\phi_z^2\phi_{xx}\phi_{zz}-6\phi_x^4\phi_{tzz}\phi_z^2$$
$$+8\phi_x^4\phi_z\phi_t\phi_{zzz}+12\phi_x^4\phi_{zz}\phi_{tz}\phi_z-13\phi_x^4\phi_t\phi_{zz}^2+6\sigma^2\phi_y^2\phi_t\phi_z^4=0. \quad (73)$$

In the same way, substituting $x_5=x_4=y$ into (62)–(66) leads to four further $(3+1)$-dimensional reductions:

$$-12\phi_x^2\phi_z^2\phi_y^4\phi_{xx}\phi_{zz}+8\phi_x^2\phi_z^4\phi_y^2\phi_{xx}\phi_{yy}+2\phi_t\phi_x\phi_z^4\phi_y^4+6\sigma^2\phi_z^4\phi_y^6-6\phi_x^3\phi_z^4\phi_{xyy}\phi_y^2$$
$$+8\phi_x^4\phi_z^4\phi_y\phi_{yyy}+12\phi_x^3\phi_z^4\phi_{yy}\phi_{xy}\phi_y+16\phi_z^4\phi_y^3\phi_{xx}\phi_x\phi_{xy}-8\phi_z^4\phi_y^2\phi_x^2\phi_{xy}^2$$
$$-19\phi_x^4\phi_z^4\phi_{yy}^2-6\phi_z^4\phi_y^4\phi_{xx}^2+6\phi_x^4\phi_y^4\phi_{zz}^2=0, \tag{74}$$

$$-6\phi_x^4\phi_z^3\phi_{yyz}\phi_y^2+6\sigma^2\phi_z^4\phi_y^6+8\phi_x^2\phi_z^4\phi_y^2\phi_{xx}\phi_{yy}-19\phi_x^4\phi_z^4\phi_{yy}^2+2\phi_t\phi_x\phi_z^4\phi_y^4$$
$$+6\phi_x^4\phi_y^4\sigma_{zz}^2-8\phi_z^4\phi_y^2\phi_x^2\phi_{xy}^2+16\phi_z^4\phi_y^3\phi_{xx}\phi_x\phi_{xy}-6\phi_z^4\phi_y^4\phi_{xx}^2$$
$$+12\phi_x^4\phi_z^3\phi_y\phi_{yz}\phi_{yy}-12\phi_x^2\phi_z^2\phi_y^4\phi_{xx}\phi_{zz}+8\phi_x^4\phi_z^4\phi_y\phi_{yyy}=0, \tag{75}$$

$$6\sigma^2\phi_z^4\phi_y^6+8\phi_x^2\phi_z^4\phi_y^2\phi_{xx}\phi_{yy}-7\phi_x^4\phi_z^4\phi_{yy}^2+2\phi_t\phi_x\phi_z^4\phi_y^4+6\phi_x^4\phi_y^4\phi_{zz}^2-8\phi_z^4\phi_y^2\phi_x^2\phi_{xy}^2$$
$$+16\phi_z^4\phi_y^3\phi_{xx}\phi_x\phi_{xy}-6\phi_z^4\phi_y^4\phi_{xx}^2-12\phi_x^2\phi_z^2\phi_y^4\phi_{xx}\phi_{zz}+2\phi_x^4\phi_z^4\phi_y\phi_{yyy}=0, \tag{76}$$

$$2\phi_t^2\phi_x\phi_z^4\phi_y^4+6\sigma^2\phi_z^4\phi_t\phi_y^6+8\phi_x^4\phi_z^4\phi_t\phi_{yyy}\phi_y-19\phi_x^4\phi_z^4\phi_t\phi_{yy}^2-8\phi_z^4\phi_t\phi_y^2\phi_x^2\phi_{xy}^2$$
$$-12\phi_x^2\phi_z^2\phi_t\phi_y^4\phi_{xx}\phi_{zz}+6\phi_x^4\phi_t\phi_y^4\phi_{zz}^2-6\phi_z^4\phi_t\phi_y^4\phi_{xx}^2+16\phi_z^4\phi_t\phi_y^3\phi_{xx}\phi_x\phi_{xy}$$
$$-6\phi_x^4\phi_z^4\phi_{tyy}\phi_y^2+12\phi_x^4\phi_z^4\phi_{yy}\phi_{ty}\phi_y+8\phi_z^4\phi_x^2\phi_t\phi_y^2\phi_{xx}\phi_{yy}=0. \tag{77}$$

The contributions of the z, y and t part among Eqs. (24), (41), and (67) are same. The only difference in these three equations is the coefficients of the terms which possess the factors $\phi_x\phi_{xxx}$ and ϕ_{xx}^2. This difference cannot be ruled out by rescaling the independent and dependent variables x and ϕ. Using some different symmetry constraints on (62)–(66), we can also get various other types of $(3+1)$-dimensional Painlevé integrable models. For instance, using the constraints $\{\phi_{x_5}=\phi_x,\ \phi_y=0\}$ on (62)–(66) leads to four further different $(3+1)$-dimensional P-integrable models.

All the models (62)–(77) can now be considered as new seed models. If we use the extended Painlevé analysis approach and the assumption on these seeds, we can get various P-integrable models in $(6+1)$-dimensions, $(5+1)$-dimensions, $(4+1)$-dimensions, and $(3+1)$-dimensions with help of the symmetry reduction approach. But we do not discuss this problem further.

IV. SUMMARY AND DISCUSSION

Though the $(1+1)$-dimensional and $(2+1)$-dimensional integrable models have been widely applied in many scientific fields and deeply studied in mathematics, there is little progress in the study of the higher dimensional space especially in $(3+1)$ dimensions. One has not yet even found any $(3+1)$-dimensional completely integrable model while the real physics space-time is $(3+1)$-dimensional.

In this paper, after embedding the lower dimensional integrable models in higher dimensions and extending the standard WTC Painlevé analysis approach to a more general form such that the new expansion coefficients are conformal invariant, we have proposed an assumption to get some more P-integrable models in higher dimensions from a known lower dimensional one. Starting from the $(2+1)$-dimensional KP equation, some $(4+1)$-dimensional, $(5+1)$-dimensional and $(3+1)$-dimensional P-integrable models are given explicitly. All the equations are conformal invariant at the same time. Possessing the conformal invariance is also an important property of an integrable model. For example, infinitely many symmetries and the Darboux transformation of the KdV equation can be obtained from the conformal invariance of its Schwarz form.[29,17] Some quite general conformal invariant forms can be changed to the corresponding forms with the Painlevé property.[17,31] The $(3+1)$-dimensional Painlevé integrable models (24), (41), (42), (67)–(69), (71), (72), and (74)–(76) are all the generalizations of the PMKdV equation while Eqs. (42), (70), and (77) are not.

Though the assumption is based on that the original model is integrable and the result equations come from vanishing the consistent Painlevé expansion coefficients with the conformal

invariance, we still have to check the Painlevé property of the result models one by one because we have not yet proved the assumption strictly. Even if the assumption is not completely true, it is still possible to get some *P*-integrable models from the approach after checking the Painlevé property of the result equations.

To reduce a higher dimensional model to some lower ones, one can use some possible limiting procedure, the classical and nonclassical Lie approaches or the direct method.[21–23] Now we know that it is also possible to get some higher dimensional models from lower ones. For instance, one can get some suitable deformation relations,[32] inner parameter dependent symmetry constraints[32] and from the extended Painlevé analysis proposed in this paper.

Though we have obtained some $(3+1)$-dimensional *P*-integrable models from the well known KP equation, more about these equations should be studied further because the real physical space is $(3+1)$-dimensional and there is no knowledge on the $(3+1)$-dimensional soliton solutions. Especially, whether the obtained $(3+1)$-dimensional *P*-integrable models obtained here are really integrable under other meaning (say, whether the models possess Lax pairs, infinitely many symmetries or conservation laws) is still open. We hope that some mathematicians and physists will join in with us to solve this important problem in future studies.

Rational solutions of the KP hierarchy and the dynamics of their poles. II. Construction of the degenerate polynomial solutions

(Received 15 September 1997; accepted for publication 3 June 1998)

A general approach to constructing the polynomial solutions satisfying various reductions of the Kadomtsev–Petviashvili (KP) hierarchy is described. Within this approach, the reductions of the KP hierarchy are equivalent to certain differential equations imposed on the τ-function of the hierarchy. In particular, the *l*-reduction and the *k*-constraint as well as their generalized counterparts are considered. A general construction of the rational solutions to these reductions is found and the particular solutions are explicitly derived for some typical examples including the KdV and Gardner equations, the Boussinesq and classical Boussinesq systems, the NLS and Yajima–Oikawa equations. It is shown that the degenerate rational solutions of the KP hierarchy are related to stationary manifolds of the Calogero–Moser (CM) hierarchy of dynamical systems. The scattering dynamics of interacting particles in the CM systems may become complicated due to an anomalously slow fractional-power rate of the particle motion along the stationary manifolds.

I. INTRODUCTION

It is generally believed that all known hierarchies of $(1+1)$-dimensional equations integrable by means of the inverse scattering method can be represented as certain reductions of a universal Kadomtsev–Petviashvili (KP) hierarchy of $(2+1)$-dimensional equations and/or of its extentions to modified and multicomponent cases. This hypothesis originates from a unifying Sato theory[1–3] that describes the KP hierarchy in terms of the pseudodifferential operator $\mathscr{L}=\partial_x+u_2\partial_x^{-1}+u_3\partial_x^{-2}+\cdots$. The infinite set of functions u_n for $n\geqslant 3$ can be expressed through the scalar function $u_2=u(t_1,t_2,\ldots)$ that depends on $t_1=x$ and on an infinite sequence of the time variables t_k, $k\geqslant 2$. Then, equations of the KP hierarchy arise from the generalized Lax equation,

$$\frac{\partial \mathscr{L}}{\partial t_k}=[B_k,\mathscr{L}], \quad k\geqslant 1, \tag{1.1}$$

where B_k is a differential part of $\mathscr{L}^k$. A typical example is the KP equation (see Ref. 3),

$$-4\frac{\partial^2 u}{\partial t_1 \partial t_3}+6\frac{\partial^2 u^2}{\partial t_1^2}+\frac{\partial^4 u}{\partial t_1^4}+3\frac{\partial^2 u}{\partial t_2^2}=0. \tag{1.2}$$

Equations of the KP hierarchy are associated with the isospectral deformation of the eigenvalue problems $\mathscr{L}\psi=\lambda\psi$ and $\mathscr{L}^*\bar{\psi}=\lambda\bar{\psi}$, where λ is a spectral parameter, $\mathscr{L}^*$ is a formal operator adjoint, and ψ and $\bar{\psi}$ are eigenfunctions satisfying the time evolution problems,

$$\frac{\partial \psi}{\partial t_k}=B_k\psi, \quad \frac{\partial \bar{\psi}}{\partial t_k}=-B_k^*\bar{\psi}, \quad k\geqslant 1. \tag{1.3}$$

The KP hierarchy is closely related to the modified KP hierarchy which starts with the modified KP equation,

$$-4\frac{\partial^2 v}{\partial t_1 \partial t_3}-2\frac{\partial^2 v^3}{\partial t_1^2}+\frac{\partial^4 v}{\partial t_1^4}+3\frac{\partial^2 v}{\partial t_2^2}+6\frac{\partial}{\partial t_1}\left(\frac{\partial v}{\partial t_1}\,\partial_{t_1}^{-1}\,\frac{\partial v}{\partial t_2}\right)=0. \tag{1.4}$$

Within the Sato approach, the modified KP hierarchy can be constructed by means of the gauge transformation of the KP hierarchy which results in modification of the pseudodifferential operator $\mathscr{L}$.[4] On the other hand, solutions of the modified KP hierarchy are formally expressed through the eigenfunction ψ satisfying Eqs. (1.3) according to the relation, $v=\psi^{-1}\partial\psi/\partial t_1$.

Besides its own meaning, the KP hierarchy is useful for generating numerous integrable hierarchies of $(1+1)$-dimensional equations by means of a certain reductive procedure. The conventional l-reduction arises under the condition imposed to the operator $\mathscr{L}$,

$$\mathscr{L}^l=B_l, \quad l\geqslant 2, \tag{1.5}$$

so that the whole set of functions u_n become independent on t_l as well as on t_{nl} (see, e.g., Ref. 3). For $l=2$ this reduction leads to the KdV hierarchy, for $l=3$ it produces the Boussinesq hierarchy, and so on.

Another reductive procedure was recently proposed through a symmetry constraint[5] which was also formulated as the k-constraint imposed on the operator $\mathscr{L}$.[6] The k-constraint occurs under the condition,

$$\mathscr{L}^k=B_k+\psi\partial_x^{-1}\bar{\psi}, \quad k\geqslant 1, \tag{1.6}$$

and leads to coupled nonlinear equations between the functions $u_2,u_3,\ldots,u_{k-1}$ of the KP hierarchy and the eigenfunctions ψ and $\bar{\psi}$. Typical examples of the k-constrained KP hierarchy include the NLS equation for $k=1$, the Yajima–Oikawa equations for $k=2$, and so on (see Refs. 5, 6).

The reductive procedure applied to the KP hierarchy typically gives an idea as to which exact solutions, such as soliton and rational solutions, remain invariant under the reduction and hence represent the exact solutions of the $(1+1)$-dimensional equations.[7–11] This search for the explicit solutions is especially straightforward if one deals with the functions u_n of the KP hierarchy and the eigenfunctions ψ and $\bar{\psi}$ under the zero boundary conditions at infinity. In contrast, a structure of explicit solutions with nonzero boundary conditions is not so obvious and is not usually under consideration. Some results concerned with multisoliton solutions of the k-constrained KP hierarchy under the nonzero boundary conditions for the fields ψ and $\bar{\psi}$ were obtained quite recently by Loris and Willox[12,13] while the existence of rational solutions for this reduction remains an open question. Therefore, a natural problem is how to detect those rational solutions of the KP hierarchy that satisfy a generalized reduction or constraint imposed to the operator $\mathscr{L}$.

The generalized l-reduction of the KP hierarchy can be formulated by means of a modification of the condition (1.5) given by

$$\mathscr{L}^l-\alpha\mathscr{L}=B_l-\alpha B_1, \quad l\geqslant 2, \tag{1.7}$$

where the parameter α is arbitrary. This reduction describes solutions of the KP hierarchy which depend on t_l according to the form, $u_m=u_m(t_1+\alpha t_l,t_2,\ldots,t_{l-1},t_{l+1},\ldots)$. A typical example is the Boussinesq equation for acoustic waves[14] which arises from the condition (1.7) for $l=3$.

The generalized k-constraint was formulated by Loris and Willox[13] as the condition,

$$\mathscr{L}^k+\beta\mathscr{L}^{-1}=B_k+\psi\partial^{-1}\bar{\psi}, \quad k\geqslant 1, \tag{1.8}$$

where the constant β is related to the asymptotic values of the eigenfunctions ψ and $\bar{\psi}$ at infinity, i.e., $\psi\bar{\psi}\to\beta$ as $t_1\to\infty$. In particular, the NLS equation at the continuous-wave background[15] arises from the condition (1.8) for $k=1$.

This paper is devoted to studies of the rational solutions satisfying the generalized reductions (1.7) and (1.8). The main ideas and methods of this paper follow those of the previous paper[16] referred to henceforth as paper I. The aims of both papers are twofold; (i) to analyze and classify

various sets of rational solutions of the single-component KP hierarchy through the construction of the equivalent polynomial τ-function and (ii) to relate the different structure of the polynomials to different dynamics of particles in a many-body Calogero–Moser (CM) system and its higher commuting flows.[17,18]

The τ-function representation of solutions of the KP hierarchy appears naturally within the framework of the Hirota bilinear transformation (see, e.g., Ref. 3),

$$u=\frac{\partial^2}{\partial t_1^2}\log\,\tau,\quad \psi=c\,\frac{\tau^+}{\tau},\quad \bar{\psi}=\bar{c}\,\frac{\tau^-}{\tau},\quad v=\frac{\partial}{\partial t_1}\log\frac{\tau^+}{\tau}, \tag{1.9}$$

where c and $\bar{c}$ are arbitrary constants, the function $\tau=\tau(t_1,t_2,\ldots)$ is referred to as the τ-function of the KP hierarchy while the associated functions $\tau^{\pm}$ are expressed through τ as follows:

$$\tau^{\pm}=\tau\left(t_1\mp\frac{1}{\lambda},t_2\mp\frac{1}{2\lambda^2},\ldots\right)\exp\left(\pm\sum_{n=1}^{\infty}\lambda^n t_n\right). \tag{1.10}$$

It was recently proved by Shiota[19] (following the pioneer paper by Krichever[20]) that zeros of the polynomial τ-function of the KP hierarchy describe motion of particles in the whole hierarchy of the CM dynamical systems.

In paper I it was shown that a general polynomial τ-function of the KP hierarchy can be factorized through a set of partial polynomial solutions generated by derivatives of certain exponential functions with only one value of the spectral parameter λ. These partial solutions were referred to as the degenerate polynomials of the KP hierarchy. Different types of scattering of particles in the CM hierarchy were analyzed in paper I with the help of the factorizing identities and the degenerate polynomials were shown to be related to anomalous scattering of particles accompanying slow rates of the particle motion. The first example of such an anomalous scattering was presented by Gorshkov *et al.*[21] for the KP1 equation and later by Ward[22] and Ioannidou[23] for an integrable chiral model. Recently, it was shown by Ablowitz and Villarroel[24] that the degenerate rational solutions of the KP1 equation naturally appear in the inverse scattering formalism through a multiple pole expansion of the associated eigenfunction ψ (which is equivalent to the pole expansion of the Baker–Akhiezer function used in a geometric method).[20] However, in previous works a complete classification of the degenerate rational solutions of the KP hierarchy has not been proposed.

In this paper we develop a unifying approach to constructing the degenerate polynomial solutions of the KP hierarchy by using the theory of generalized Schur polynomials and vertex operators. This approach enables us to characterize all degenerate polynomials in terms of stationary manifolds of the CM hierarchy[25] and to find a simple representation of the rational solutions satisfying the generalized l-reduction and k-constraint of the KP hierarchy. A general scheme for constructing the degenerate polynomials is described and particular applications of the scheme to some physically meaningful nonlinear evolution equations are also given.

The paper is organized as follows. The basic notation and properties of the generalized Schur polynomials and the vertex operators acting on these polynomials are described in Sec. II. A connection of these polynomials with the stationary manifolds of the CM system is discussed in Sec. III. A general classification of the stationary manifolds and of the related rational solutions to the l-reduced KP hierarchy is given in Sec. IV. The rational solutions to the generalized l-reduction and k-constraint of the KP hierarchy are constructed in Sec. V and VI, respectively. A classification of different dynamics of the anomalous scattering of particles in the CM hierarchy is considered in Sec. VII. Finally, Sec. VIII concludes the paper.

II. THE GENERALIZED SCHUR POLYNOMIALS

Exact solutions of the KP hierarchy can be expressed through one of the conventional representations of the τ-function. Following paper I, only the Wronskian representation[26] is considered here but it enables us to generate all classes of rational solutions without loss of generality. Within the Wronskian representation, the τ-function is

$$\tau = W_N[\phi_1, \phi_2, \ldots, \phi_N] = \det \left| \frac{\partial^{k-1} \phi_n}{\partial t_1^{k-1}} \right|_{1 \leqslant n,k \leqslant N}, \tag{2.1}$$

where the entries of the Wronskian determinant $\phi_n = \phi_n(t_1, t_2, \ldots)$, $n = \overline{1,N}$ satisfy the differential equations

$$\frac{\partial \phi_n}{\partial t_k} = \frac{\partial^k \phi_n}{\partial t_1^k}, \quad k \geqslant 1. \tag{2.2}$$

A degenerate polynomial τ-function is generated by a partial solution of Eq. (2.2),

$$\phi_n = \left(\sum_{j=1}^{n} \alpha_j P_{m_j}(p) \right) e^{\Phi(p)}, \tag{2.3}$$

where α_j are arbitrary coefficients, p is a spectral parameter, the phase factor is given by

$$\Phi(p) = \sum_{k=1}^{\infty} p^k t_k, \tag{2.4}$$

and the functions $P_n(p)$ are defined by a generating exponential function,

$$P_n(p) = e^{-\Phi(p)} \frac{\partial^n}{\partial p^n} e^{\Phi(p)}. \tag{2.5}$$

These functions are quasipolynomials of the time variables t_k because they contain infinite series of t_k. However, the time variables t_k enter the quasipolynomials $P_n(p)$ only in the form of a finite number of the generalized time variables $\theta_k(p)$ given by

$$\theta_k(p) = \frac{1}{k!} \frac{\partial^k \Phi(p)}{\partial p^k} = \sum_{m=k}^{\infty} \binom{m}{k} p^{m-k} t_m. \tag{2.6}$$

Hence we refer to $P_n(p)$ as the generalized Schur polynomials. In the limit $p \to 0$ the polynomial $P_n(p)$ reduces to a conventional Schur polynomial $p_n(t_1, t_2, \ldots) = P_n(0)$ arising from the expansion $e^{\Phi(p)} = \sum_{n=1}^{\infty} (1/n!) p_n(t_1, t_2, \ldots) p^n$. The first few generalized polynomials have the form,

$$P_1 = \theta_1, \quad P_2 = \theta_1^2 + 2\theta_2, \quad P_3 = \theta_1^3 + 6\theta_1\theta_2 + 6\theta_3,$$

$$P_4 = \theta_1^4 + 12\theta_1^2\theta_2 + 12\theta_2^2 + 24\theta_1\theta_3 + 24\theta_4,$$

$$P_5 = \theta_1^5 + 20\theta_1^3\theta_2 + 60\theta_1\theta_2^2 + 60\theta_1^2\theta_3 + 120\theta_2\theta_3 + 120\theta_1\theta_4 + 120\theta_5.$$

The key property of the Schur polynomials $P_n(p)$ is that they satisfy the original system (2.2) rewritten in terms of the generalized variables θ_k and also the following relation:

$$\frac{\partial P_n}{\partial \theta_k} = \frac{\partial^k P_n}{\partial \theta_1^k} = \frac{n!}{(n-k)!} P_{n-k}. \tag{2.7}$$

Using this key property, Matveev[27] proved the following lemma.

Lemma 2.1: Suppose that $m_1 < m_2 < \cdots < m_n$ and $\alpha_n = 1$ in Eq. (2.3). Then, there exists constants θ_{k0}, $k = \overline{1,m_n}$ so that the superposition of the Schur polynomials in Eq. (2.3) is reducible to a polynomial of the highest degree, i.e.,

$$\sum_{j=1}^{n} \alpha_j P_{m_j}(p) = \widetilde{P}_{m_n}(p) \equiv P_{m_n}(p; \theta_1 - \theta_{10}, \theta_2 - \theta_{20}, \ldots, \theta_{m_n} - \theta_{m_n 0}). \tag{2.8}$$

According to Lemma 2.1, the degenerate rational solutions of the KP hierarchy can be expressed through the leading-order polynomials $\tilde{P}_{m_n}(p)$ with different values of the phase constants θ_{k0}. Then, the rational solution of this type has the form,

$$\tau = \tau_p(\theta_1, \theta_2, \ldots) e^{N\Phi(p)}, \tag{2.9}$$

where $\tau_p(\theta_1, \theta_2, \ldots)$ is a polynomial (or, equivalently, quasipolynomial) with respect to the time variables $\theta_n \equiv \theta_n(p)$ or t_n, respectively. This polynomial τ-function is given by the Wronskian determinant,

$$\tau_p(\theta_1, \theta_2, \ldots) = W_N[\tilde{P}_{m_1}(p), \tilde{P}_{m_2}(p), \ldots, \tilde{P}_{m_N}(p)]. \tag{2.10}$$

Using Eqs. (1.10) and (2.10), we find the associated functions $\tau^{\pm}$ for the polynomial representation,

$$\tau^{\pm} = \left(\frac{\lambda - p}{\lambda}\right)^{\pm N} \tau_p\left(\theta_1 \mp \frac{1}{\lambda - p}, \theta_2 \mp \frac{1}{2(\lambda - p)^2}, \ldots\right) \exp(N\Phi(p) \pm \Phi(\lambda)), \tag{2.11}$$

where the spectral parameter λ may be arbitrary. However, the rational representations for the eigenfunctions ψ and $\bar{\psi}$ arise only in the limit $\lambda \to 0$ provided that the constants c and $\bar{c}$ are chosen appropriately. Then, the rational solutions to the KP hierarchy can be expressed through a scalar polynomial function $\tau_p = \tau_p(\theta_1, \theta_2, \ldots)$ as follows:

$$u = \frac{\partial^2}{\partial \theta_1^2} \log \tau_p, \quad \psi = \rho \frac{S(\mu)\tau_p}{\tau_p}, \quad \bar{\psi} = \bar{\rho} \frac{S^{-1}(\mu)\tau_p}{\tau_p}, \quad v = \frac{\partial}{\partial \theta_1} \log \frac{S(\mu)\tau_p}{\tau_p}. \tag{2.12}$$

Here the parameters ρ and $\bar{\rho}$ define the boundary conditions of the eigenfunctions ψ and $\bar{\psi}$ as $t_1 \to \infty$, the parameter μ is $\mu = -p^{-1}$, and the generalized vertex operator $S(\mu)$ is introduced to characterize shifts of the phase variables $\theta_k \equiv \theta_k(p)$,

$$S(\mu) = \exp\left[-\sum_{k=1}^{\infty} \frac{1}{k} \mu^k \frac{\partial}{\partial \theta_k}\right]. \tag{2.13}$$

The action of the vertex operator on the generalized Schur polynomials $P_n(p)$ is described by the following lemma.

Lemma 2.2: If $P_n(p)$ satisfies Eq. (2.7) for any k and $S(\mu)$ is defined by Eq. (2.13), then the following identities are valid:

$$S^k(\mu) P_n(p) = \sum_{j=0}^{k} (-\mu)^j \binom{k}{j} \frac{\partial P_n(p)}{\partial \theta_j}, \tag{2.14}$$

$$S^{-k}(\mu) P_n(p) = \sum_{j=0}^{\infty} \mu^j \binom{j+k-1}{k-1} \frac{\partial P_n(p)}{\partial \theta_j}. \tag{2.15}$$

Lemma 2.2 has a classic analog in the theory of group characters (see, e.g., Ref. 28). Within the given context, the formulas (2.14) and (2.15) have already been used for the construction of integrable hierarchies[11] and that of the rational solutions.[14] Importantly, these formulas are not applicable to the action of vertex operators on the polynomial function $\tau_p(\theta_1, \theta_2, \ldots)$ because the polynomial function τ_p does not generally satisfy the key relations (2.7).

The multicomponent generalization of the vertex operator can be defined through the product of the vertex operators (2.13),

$$S(\nu_1, \ldots, \nu_k) = \prod_{i=1}^{k} S(\mu_i), \tag{2.16}$$

where the parameters ν_i are related to μ_j by the partial sums,

$$\nu_i=(-1)^{i-1}\sum_{z_1+\ldots+z_k=i}\mu_1^{z_1}\ldots\mu_k^{z_k}, \tag{2.17}$$

and the indices z_l are either zeros or unities. Using the formulas (2.14) and (2.16) one can prove the following lemma.

Lemma 2.3: If $P_n(p)$ satisfies Eq. (2.7) for any k and $S(\nu_1,\ldots,\nu_k)$ is defined by Eqs. (2.16) and (2.17), then the following identity is satisfied:

$$S(\nu_1,\ldots,\nu_k)P_n(p)=1-\sum_{i=1}^{k}\nu_i\frac{\partial P_n(p)}{\partial\theta_i}. \tag{2.18}$$

III. CONNECTION WITH THE CM HIERARCHY

Properties of the degenerate rational solutions of the KP hierarchy are described by the construction of the polynomial function $\tau_p(\theta_1,\theta_2,\ldots)$ within the form (2.10). The following theorem proved by Shiota[19] clarifies a relationship between this polynomial function and the dynamics of particles in the CM hierarchy of dynamical systems.

Theorem 3.1: Let the function $\tau_p(t_1,t_2,\ldots)$ be a monic polynomial in t_1 having R zeros $x_j(t_2,\ldots)$, $j=\overline{1,R}$ according to the representation,

$$\tau_p(t_1,t_2,\ldots)=\prod_{j=1}^{R}(t_1-x_j(t_2,\ldots)). \tag{3.1}$$

This function is the τ-function of the KP hierarchy if and only if the motion of zeros of τ_p is governed by the hierarchy of the CM dynamical systems,

$$\frac{\partial x_j}{\partial t_n}=\frac{\partial H_n}{\partial p_j},\quad \frac{\partial p_j}{\partial t_n}=-\frac{\partial H_n}{\partial x_j},\quad n\geqslant 2, \tag{3.2}$$

where $H_n=(-1)^n\mathrm{Sp}(L)^n$ and the elements of the matrix L are $L_{ij}=p_j\delta_{ij}+(1-\delta_{ij})(x_i-x_j)^{-1}$. In the particular case $n=2$, this system is just the Calogero–Moser system of particles,[17,18]

$$\frac{\partial^2 x_j}{\partial t_2^2}=8\sum_{i\neq j}\frac{1}{(x_i-x_j)^3}, \tag{3.3}$$

where x_j are coordinates of particles, while the velocities of particles are $v_j=\partial x_j/\partial t_2=2p_j$.

Collorary 3.2: The degree of the polynomial τ-function with respect to t_1 denoted by R coincides with the number of particles of the corresponding CM system.

Collorary 3.3: The number of linearly independent time variables $\theta_n(p)$ of the polynomial τ-function denoted by G coincides with the dimension of a dynamical manifold of the corresponding CM system.

A general solution describing normal scattering of R particles along a manifold of the dimension $G=2R$ is well known for the CM systems (3.2) and (3.3) (see, e.g., Ref. 19, and references therein). In paper I it was shown that besides a general solution there exists a wide set of degenerate solutions which describe anomalous scattering of particles with asymptotically equal velocities, i.e. when $v_j\to 2p$ as $t_2\to\pm\infty$. A complete picture of dynamical processes occurring in the CM systems can be explained as a superposition of elementary processes of either normal or anomalous scattering.[16] Here we study only the anomalous scattering in the CM hierarchy which is described by zeros of the degenerate polynomials $\tau_p(\theta_1,\theta_2,\ldots)$ according to Theorem 3.1.

Proposition 3.4: The degenerate polynomial $\tau_p(\theta_1,\theta_2,\ldots)$ given by Eq. (2.10) corresponds to the CM system of R particles, where

$$R=\sum_{j=1}^{N}m_j-\frac{N(N-1)}{2}. \tag{3.4}$$

Proof: Suppose that $0<m_1<m_2<\ldots<m_N$ in Eq. (2.10). The polynomials $P_n(p)$ at the leading order approximation with respect to θ_1 (or, equivalently, to t_1) are $P_n(p)\sim\theta_1^n+O(\theta_1^{n-2})$. Expanding the Wronskian $W_N[\tilde{P}_{m_1}(p),\ldots,\tilde{P}_{m_N}(p)]$ within this approximation, we find the result (3.4) for the degree of the polynomial $\tau_p(\theta_1,\theta_2,\ldots)$ which is equivalent to the number of particles R according to Collorary 3.2. □

The degenerate polynomials of the KP hierarchy and the corresponding dynamics of the CM systems can be classified into two different groups. The first group consists of the polynomials which can be reduced to the generalized Schur polynomials $P_R(p;\theta_1,\ldots,\theta_R)$. It is clear from the parametrization of these polynomials that a dynamical manifold of the CM system described by $P_R(p)$ has the dimension $G=R$ with the ''additional'' parameter p determining the asymptotic velocity of the particles as $t_2\to\infty$. The other group of the polynomial τ-functions which includes the rest of the polynomials τ_p describes the anomalous scattering occurring near one of the stationary manifolds of the CM hierarchy.[25]

Definition 3.5: A manifold of the CM hierarchy is stationary with respect to the time t_l if

$$\frac{\partial x_j}{\partial t_l}=0, \text{ for all } j \text{ and } l\geqslant 2. \tag{3.5}$$

Stationary manifolds of the CM hierarchy form certain embeddings into dynamical manifolds describing the anomalous dynamics of the CM particles. To be specific, the stationary manifolds have the dimension G which is less than the number of particles R, i.e., although all asymptotic velocities of particles are specified by a single parameter p, the asymptotic phases of the coordinates $x_j(t_2,\ldots)$ in the limit $t_2\to\infty$ are functionally dependent. The following result proves that all polynomial functions of the form (2.10) excepting those reducible to the polynomials $P_n(p)$ describe, within a particular limit, a certain stationary manifold of the CM hierarchy.

Proposition 3.6: Suppose that the polynomial τ-function of the KP hierarchy is given by

$$\tau_p(t_1,t_2,\ldots)=W_N[p_{m_1},p_{m_2},\ldots,p_{m_N}], \tag{3.6}$$

where $p_n\equiv p_n(t_1,t_2,\ldots)=P_n(0)$. Zeros of this polynomial function describe one of the stationary manifolds of the CM hierarchy if $N>1$ and the set $\{m_j\}_{j=1}^N$ is different from the ordered set $\{j\}_{j=1}^N$.

Proof: In the case $m_N<R$ it is clearly seen from Eq. (3.6) that the function $\tau_p(t_1,t_2,\ldots)$ is independent of at least the variables $t_{m_N+1},\ldots,t_R$ and hence, zeros of the polynomial function τ_p do not depend on these times.

In the case $m_N\geqslant R$ it follows from Eq. (3.4) that the only possible solution is $\tau_p(t_1,t_2,\ldots)=W_N[p_1,p_2,\ldots,p_{N-1},p_R]$ which is realized for $m_N=R$ and $R>N$. Then, it can be shown that the polynomial function τ_p does not depend on time t_R, i.e., corresponds to the stationary manifold with respect to t_R. In the exceptional case $R=N$ the condition of the proposition is not satisfied, and, indeed, the function τ_p is now reducible to the Schur polynomial $p_N(t_1,t_2,\ldots)$ (see paper I). □

In the next section we classify degenerate polynomial τ-functions of the KP hierarchy into different subgroups corresponding to different stationary manifolds of the CM hierarchy. This classification is directly related to the construction of rational solutions of the l-reduced KP hierarchy.

IV. THE *l*-REDUCED KP HIERARCHY

The following lemma can be readily proved by using the definition of the l-reduction (1.5) (see Ref. 3 for details).

Lemma 4.1: The polynomial τ-function of the l-reduced KP hierarchy satisfies the differential equation,

$$\frac{\partial\tau_p}{\partial t_l}=0, \qquad l\geqslant 2. \tag{4.1}$$

Collorary 4.2: Zeros of the function $\tau_p(t_1,t_2,\ldots)$ satisfying the l-reduced KP hierarchy define the stationary manifold of the CM hierarchy with respect to the time t_l.

Collorary 4.3: The τ-function of the l-reduced KP hierarchy does not depend on variables $t_l,t_{2l},\ldots,t_{nl}$.

Collorary 4.3 follows from the identity $L^{nl}=(B_l)^n=B_{nl}$ and leads to the fact that the τ-function of the l-reduced KP hierarchy also gives a subset of solutions of the nl-reduced hierarchies. In order to present a closed classification scheme for the rational solutions of the l-reduced KP hierarchy we assume that the function $\tau_p(t_1,t_2,\ldots)$ satisfies the complimentary constraints,

$$\frac{\partial\tau_p}{\partial t_j}\neq 0, \qquad j=\overline{1,l-1}. \tag{4.2}$$

Then, the following result defines a structural element of the polynomial τ-function of the l-reduced KP hierarchy.

Proposition 4.4: The differential equation (4.1) is satisfied by the $(l-1)$ families of the polynomial τ-functions,

$$\tau_p(t_1,t_2,\ldots)=W_{n_j}[p_jp_{j+l},\ldots,p_{j+(n_j-1)l}], \qquad j=\overline{1,l-1}, \tag{4.3}$$

where $p_n\equiv p_n(t_1,t_2,\ldots)=P_n(0)$ and n_j are positive integers enumerating the families of the polynomials.

A proof can be given by means of a direct differentiation of $\tau_p(t_1,t_2,\ldots)$ with respect to t_l, use the formula (2.7) for $p=0$, and elimination of two identical columns in the Wronskian determinants. This result has been widely used in previous literature (see, e.g., Ref. 11). A less known fact is that the $(l-1)$ families of the polynomials given by Eq. (4.3) do not cover all possible rational solutions of the l-reduced KP hierarchy except for the simple case $l=2$. Indeed, a more general solution can still be constructed through a combination of the particular solutions (4.3) in the following form:

$$\tau_p(t_1,t_2,\ldots)=\tau_l^{n_1n_2\ldots n_{l-1}}=W_N[p_1,p_{1+l},\ldots,p_{1+(n_1-1)l};\ldots;p_{l-1},p_{2l-1},\ldots,p_{n_{l-1}l-1}], \tag{4.4}$$

where $N=\Sigma_{j=1}^{l-1}n_j$. As follows from Collorary 4.2, zeros of this polynomial solution define a general construction of the stationary manifold of the CM hierarchy with respect to the time t_l. By using Eq. (3.4) we find that the number of particles forming a stationary configuration is not arbitrary but given by the expression,

$$R=\sum_{j=1}^{l-1}n_j\left(j+\frac{1}{2}(n_j-l+1)-\frac{1}{2}\sum_{i=1}^{l-1}(n_i-n_j)\right). \tag{4.5}$$

The dimension of the stationary manifold G is less than the number of particles R because the time variables t_l, t_{2l}, and so on, do not parametrize the function $\tau_l^{n_1n_2\ldots n_{l-1}}$. It seems to be difficult to find G for a general solution (4.4) (see, e.g., Ref. 14). Still for the particular solutions (4.3) we find the result,

$$R=\tfrac{1}{2}n_j(2j+(l-1)(n_j-1)), \quad G=j+(l-1)(n_j-1). \tag{4.6}$$

Example 4.5: The KdV hierarchy $(l=2)$.

The KdV hierarchy starts with the KdV equation,

$$-4\frac{\partial u}{\partial t_3}+12u\frac{\partial u}{\partial t_1}+\frac{\partial^3u}{\partial t_1^3}=0. \tag{4.7}$$

A complete set of the polynomial τ-functions for the KdV hierarchy[29,30] is given by Eq. (4.4) for $l=2$ and $n_1=n$, i.e.,

$$\tau_p(t_1,t_3,\ldots)=\tau_2^n=W_n[p_1,p_3,\ldots,p_{2n-1}]. \tag{4.8}$$

Zeros of these polynomials define the stationary manifolds for the CM dynamical system (3.3) with respect to t_2.[25] It follows from Eq. (4.6) that these stationary manifolds exist only for $R=n(n+1)/2$ particles and have $G=n$ parameter subspace.[29] For reference, we reproduce here the first polynomials of this family, omitting a constant factor in front of τ_2^n,

$$\tau_2^1 \cong t_1,$$

$$\tau_2^2 \cong t_1^3 - 3t_3,$$

$$\tau_2^3 \cong t_1^6 - 15t_1^3 t_3 - 45t_3^2 + 45t_1 t_5,$$

$$\tau_2^4 \cong t_1^{10} - 45t_1^7 t_3 - 4725t_1 t_3^3 + 315t_1^5 t_5 + 4725t_1^2 t_3 t_5 - 4725t_5^2 - 1575t_1^3 t_7 + 4725t_3 t_7.$$

Example 4.6: The Boussinesq hierarchy ($l=3$).

The Boussinesq hierarchy starts with the Boussinesq equation,

$$3\frac{\partial^2 u}{\partial t_2^2} + 6\frac{\partial^2 u^2}{\partial t_1^2} + \frac{\partial^4 u}{\partial t_1^4} = 0. \tag{4.9}$$

A general rational solution of the Boussinesq equation[14] is expressed through the polynomial τ-function (4.4) for $l=3$, $n_1=n$, and $n_2=m$, i.e.,

$$\tau_p(t_1,t_2,\ldots) = \tau_3^{nm} = W_{n+m}[p_1,p_4,\ldots,p_{3n-2};p_2,p_5,\ldots,p_{3m-1}]. \tag{4.10}$$

Zeros of these polynomials define the stationary manifold of the first higher-order commuting flow of the CM hierarchy (3.2), i.e., that with respect to t_3. It was found by Galkin *et al.*[14] that the number of particles R forming the stationary configuration and the dimension of the manifolds G are specified as follows:

$$R = n^2 + m(m+1) - nm, \tag{4.11}$$

$$G = \begin{cases} 2m-n & m \geqslant 2n \\ m+n & 2n > m \geqslant n/2. \\ 2n-m-1 & n/2 > m \end{cases} \tag{4.12}$$

The first polynomials are

$$\tau_3^{1,0} \cong t_1, \quad \tau_3^{0,1} \cong t_1^2 + 2t_2,$$

$$\tau_3^{2,0} \cong t_1^4 + 4t_1^2 t_2 - 4t_2^2 - 8t_4, \quad \tau_3^{1,1} \cong t_1^2 - 2t_2,$$

$$\tau_3^{0,2} \cong t_1^6 + 10t_1^4 t_2 + 20t_1^2 t_2^2 + 40t_2^3 - 40t_1^2 t_4 + 80t_2 t_4 - 80t_1 t_5,$$

$$\begin{aligned}\tau_3^{3,0} \cong\ & t_1^9 + 16t_1^7 t_2 + 56t_1^5 t_2^2 - 560t_1 t_2^4 - 112t_1^5 t_4 - 2240t_1 t_2^2 t_4 - 2240t_1 t_4^2 - 280t_1^4 t_5 + 1120t_1^2 t_2 t_5 \\ & + 1120t_2^2 t_5 - 2240t_4 t_5 + 1120t_1^2 t_7 + 2240t_2 t_7,\end{aligned}$$

$$\tau_3^{2,1} \cong t_1^4 - 4t_1^2 t_2 - 4t_2^2 + 8t_4, \quad \tau_3^{1,2} \cong t_1^5 - 20t_1 t_2^2 + 20t_5,$$

$$\begin{aligned}\tau_3^{0,3} \cong\ & t_1^{12} + 28t_1^{10} t_2 + 260t_1^8 t_2^2 + 1120t_1^6 t_2^3 + 2800t_1^4 t_2^4 + 11200t_1^2 t_2^5 + 11200t_2^6 - 280t_1^8 t_4 - 2240t_1^6 t_2 t_4 \\ & - 11200t_1^4 t_2^2 t_4 + 44800t_1^2 t_2^3 t_4 + 67200t_2^4 t_4 - 11200t_1^4 t_4^2 + 134400t_1^2 t_2 t_4^2 + 44800t_2^2 t_4^2 - 89600t_4^3 \\ & - 960t_1^7 t_5 - 4480t_1^5 t_2 t_5 - 44800t_1^3 t_2^2 t_5 - 89600t_1 t_2^3 t_5 - 89600t_1^3 t_4 t_5 + 179200t_1 t_2 t_4 t_5 \\ & - 89600t_1^2 t_5^2 + 179200t_2 t_5^2 + 8960t_1^5 t_7 - 179200t_1 t_2^2 t_7 + 179200t_5 t_7 + 22400t_1^4 t_8 + 89600t_1^2 t_2 t_8 \\ & - 89600t_2^2 t_8 - 179200t_4 t_8.\end{aligned}$$

We notice from these explicit formulas that the polynomial solutions related to the symmetry of the KP hierarchy with respect to the transformation $t_k \to (-1)^{k-1} t_k$ appear naturally from the general formula (4.10) for $m, n \neq 0$. □

A straightforward generalization of the polynomial solutions (4.3) which satisfies the k-constraint (1.6) of the KP hierarchy was recently presented by Loris and Willox.[11] Unfortunately, the rational solutions of the l-reduced and k-constrained KP hierarchies usually turn out to be physically meaningless since they are either singular or complex. However, the results on the existence and dimension of stationary manifolds of the CM hierarchy serve as an useful tool for constructing and analyzing the degenerate rational solutions which satisfy the generalized reductions of the KP hierarchy. The latter solutions often describe physically interesting phenomena within the underlying nonlinear evolution equations. In the next two sections we construct the rational solutions satisfying the generalized l-reduction and k-constraint of the KP hierarchy and present a few examples where the rational solutions are physically meaningful.

V. THE GENERALIZED l-REDUCED KP HIERARCHY

Here we consider the generalized l-reduction of the KP hierarchy defined by the condition (1.7). Using a simple modification of the methods of Ref. 3 one can prove the following lemma.

Lemma 5.1: The polynomial τ-function of the generalized l-reduced KP hierarchy satisfies the differential equation,

$$\frac{\partial \tau_p}{\partial t_l} = \alpha \frac{\partial \tau_p}{\partial t_1}, \quad l \geqslant 2. \tag{5.1}$$

As in Lemma 4.1, we assume here that there are no differential relations similar to Eq. (5.1) for the evolution of $\tau_p(t_1, t_2, \ldots)$ with respect to the time variables t_j for $j = \overline{1, l-1}$. The differential equation (5.1) implies that functions of the KP hierarchy depend on t_l in the form of a stationary phase, i.e., $u_k = u_k(t_1 + \alpha t_l, t_2, \ldots, t_{l-1}, t_{l+1}, \ldots)$. It is important that no rational solutions to the generalized l-reduction could be constructed by means of the Schur polynomials $p_n(t_1, t_2, \ldots)$ and, therefore, we have to consider the generalized Schur polynomials $P_n(p)$ given by Eq. (2.5) at $p \neq 0$. Thus, a set of the rational solutions of the generalized l-reduced KP hierarchy is prescribed by the following result.

Proposition 5.2: The differential equation (5.1) is satisfied by the $(l-1)$ families of the polynomial τ-functions,

$$\tau_p(\theta_1, \theta_2, \ldots) = W_n[P_1(p), S^{-1}(\nu_1, \ldots, \nu_{l-2}) P_3(p), \ldots, S^{-(n-1)}(\nu_1, \ldots, \nu_{l-2}) P_{2n-1}(p)]. \tag{5.2}$$

Here n is a positive integer, $P_n(p)$ is the generalized Schur polynomial (2.5), and the generalized vertex operator $S(\nu_1, \ldots, \nu_{l-2})$ is defined by Eqs. (2.16) and (2.17). The parameters ν_i for $i = \overline{1, l-2}$ are given by

$$\nu_i = -\binom{l}{2}^{-1} \binom{l}{i+2} p^{-i} \tag{5.3}$$

and the parameter p is one of the $(l-1)$ roots of the algebraic equation,

$$l p^{l-1} = \alpha. \tag{5.4}$$

Proof: First, we find that the polynomial function $\tau_p(\theta_1, \theta_2, \ldots)$ defined by Eq. (5.2) satisfies a certain differential equation with respect to the generalized time variables $\theta_k \equiv \theta_k(p)$. This can be done by differentiating each column of the Wronskian (5.2) with respect to θ_2, by subsequent subtracting of the nearbouring column multiplied by a certain factor and by using the formulas (2.7) and (2.18). As a result, we find the following differential equation for $\tau_p(\theta_1, \theta_2, \ldots)$,

$$\frac{\partial \tau_p}{\partial \theta_2} = \sum_{i=3}^{l} \nu_{i-2} \frac{\partial \tau_p}{\partial \theta_i}. \tag{5.5}$$

This relation should be compared with the differential equation (5.1) To do this, we rewrite Eq. (5.1) in terms of the variables θ_k as follows:

$$(lp^{l-1}-\alpha)\frac{\partial\tau_p}{\partial\theta_1}+\sum_{i=2}^{l}\binom{l}{i}p^{l-i}\frac{\partial\tau_p}{\partial\theta_i}=0. \tag{5.6}$$

The leading-order term $\partial\tau_p/\partial\theta_1$ is always dominant in Eq. (5.6) because the time variable θ_1 always has a different weight in the polynomial function $\tau_p(\theta_1,\theta_2,\ldots)$ compared to the other time variables. Therefore, we have to remove this term and specify p as a root of the algebraic equation (5.4). Then, by comparing the coefficients in Eqs. (5.5) and (5.6) we find the parameters ν_i in the form (5.3). □

It is obvious that the expression (5.2) generalizes the polynomial solutions (4.8) for the 2-reduced KP hierarchy (the KdV hierarchy) (see Example 4.5). The polynomial function $\tau_p(\theta_1,\theta_2,\ldots)$ given by Eq. (5.2) has the degree $R=n(n+1)/2$ and is parametrized by $G=n$ linear superpositions of the time variables θ_k (see examples below). This polynomial function generates a rational solution of the generalized l-reduced KP hierarchy according to the representation (2.12). A more general rational solution can still be constructed within the framework of the original Wronskian representation (2.1) where the functions ϕ_n are specified according to the particular $(l-1)$ solutions (5.2) [recall that the parameter p may have $(l-1)$ values]. This general rational solution can always be analyzed by applying the superposition formula found in paper I.

Example 5.4: The Gardner equation $(l=2)$.

The reduction $v=v(t_1+\alpha t_2,t_3,\ldots)$ transforms the modified KP hierarchy to a hierarchy of the Gardner equation. The Gardner equation follows from (1.4) in the form,

$$-4\frac{\partial v}{\partial t_3}+3(\alpha^2+2\alpha v-2v^2)\frac{\partial v}{\partial t_1}+\frac{\partial^3 v}{\partial t_1^3}=0. \tag{5.7}$$

Equivalently, the Gardner equation can be thought as the modified KdV equation under the nonzero boundary conditions at infinity. Indeed, the modified KdV equation,

$$-4\frac{\partial w}{\partial t_3}+\frac{9}{2}\alpha^2\frac{\partial w}{\partial t_1}-6w^2\frac{\partial w}{\partial t_1}+\frac{\partial^3 w}{\partial t_1^3}=0, \tag{5.8}$$

reduces to the Gardner equation (5.7) by means of the transformation, $w=v-\alpha/2$. A single family of the rational solutions of the Gardner equation is expressed through the representation (2.12) with the polynomial τ-function given by Eq. (5.2) for $l=2$, i.e.,

$$\tau_p(\theta_1,\theta_2,\ldots)=W_n[P_1(p),P_3(p),\ldots,P_{2n-1}(p)], \tag{5.9}$$

where $p=\alpha/2$. The first polynomials are just the polynomials of the KdV hierarchy (see Example 4.5) with t_k replaced by θ_k, i.e., $\tau_p=\tau_2^n(\theta_1,\theta_3,\ldots)$. These polynomials can further be used to construct the real nonsingular solutions of the (focusing) Gardner equation which follows from Eq. (5.7) under the transformation $\alpha\to i\tilde{\alpha}$ and $v\to i\tilde{v}$. To do this, we just shift phases of the variables θ_k in the function $\tau_p(\theta_1,\theta_2,\ldots)$ and rewrite Eq. (2.12) for v in the equivalent form,

$$v=\frac{\partial}{\partial\theta_1}\log\frac{S^{1/2}(\mu)\tau_p}{S^{-1/2}(\mu)\tau_p}, \tag{5.10}$$

where $\mu=-p^{-1}=-2\alpha^{-1}$. Then, the transformation given above ensures the function $\tilde{v}$ be real and nonsingular. Within this context, the rational solutions (5.9) and (5.10) describe an algebraic soliton of the Gardner equation for $n=1$,[31] a structural instability of the algebraic soliton due to a resonance with a long wave shelf for $n=2$,[32] and the scattering dynamics of two and more algebraic solitons complicated by excitations of the wave shelfs for $n\geqslant 3$.

Example 5.5: The Boussinesq equation for acoustic waves $(l=3)$.

The reduction $u=u(t_1+\alpha t_3,t_2,t_4,\ldots)$ transforms the KP hierarchy to a hierarchy of the Boussinesq equation for acoustic waves. The latter equation follows from Eq. (1.2) in the form,

$$3\frac{\partial^2 u}{\partial t_2^2}-4\alpha\frac{\partial^2 u}{\partial t_1^2}+6\frac{\partial^2 u^2}{\partial t_1^2}+\frac{\partial^4 u}{\partial t_1^4}=0. \tag{5.11}$$

Equivalently, the Boussinesq equation for acoustic waves can be thought of as the Boussinesq equation (4.9) under the nonzero boundary conditions at infinity. Indeed, the transformation, $u \to u-\alpha/3$ reduces Eq. (4.9) to the form (5.11). Two particular families of the rational solutions of the Boussinesq equation (5.11) are expressed through the polynomial τ-function (5.2) for $l=3$, i.e.,

$$\tau_p(\theta_1,\theta_2,\ldots)=W_n[P_1(p),S^{-1}(\nu)P_3(p),\ldots,S^{-(n-1)}(\nu)P_{2n-1}(p)], \tag{5.12}$$

where $p=\pm\sqrt{\alpha/3}$, and $S(\nu)$ is given by Eq. (2.13) with the parameter $\nu=-(3p)^{-1}$.[14] The first polynomials (5.12) can be transformed by means of the phase translations to the polynomials of the KdV hierarchy (see Example 4.5) with the residue terms, i.e., $\tau_p=\tau_2^n(z_1,z_3,\ldots)+\Delta\tau_2^n(z_1,z_3,\ldots)$, where z_k are new variables, i.e.,

$$z_1=\theta_1, \quad z_3=\theta_3+\nu\theta_2+\tfrac{1}{4}\nu^2\theta_1,$$

$$z_5=\theta_5+2\nu\theta_4+\tfrac{3}{2}\nu^2\theta_3+\tfrac{3}{2}\nu^3\theta_2+\tfrac{9}{16}\nu^4\theta_1,$$

$$z_7=\theta_7+3\nu\theta_6+\tfrac{15}{4}\nu^2\theta_5+\tfrac{9}{2}\nu^3\theta_4+\tfrac{63}{16}\nu^4\theta_3+\tfrac{63}{16}\nu^5\theta_2+\tfrac{105}{64}\nu^6\theta_1,$$

and $\Delta\tau_2^n$ are the residue terms, i.e.,

$$\Delta\tau_2^1=0, \quad \Delta\tau_2^2=0, \quad \Delta\tau_2^3=\tfrac{45}{4}\nu^6,$$

$$\Delta\tau_2^4=-\frac{42525}{8}\nu^8 z_1^2+\frac{14175}{4}\nu^6 z_1 z_3+\frac{382725}{64}\nu^{10}.$$

These polynomials can further be used to construct the real nonsingular rational solutions to the (elliptic) Boussinesq equation which follows from Eq. (5.11) under the transformation $t_2 \to iy$. This equation describes stationary wave processes in a medium with positive dispersion. The rational solutions to this equation correspond to multilump wave structures propagating with a constant velocity.[14,21]

VI. THE GENERALIZED *k*-CONSTRAINED KP HIERARCHY

Here we consider the generalized k-constraint of the KP hierarchy defined by the condition (1.8). Loris and Willox[13] proved the following result by using the technique based on a bilinear formulation and identities (see also Ref. 11).

Lemma 6.1: The τ-function of the generalized k-constrained KP hierarchy defined by Eq. (1.8) admits the Wronskian solutions in the form (2.1) with the functions $\phi_n(t_1,t_2,\ldots)$, $n=\overline{1,N}$ satisfying Eqs. (2.2) and the complimentary equation,

$$\frac{\partial\phi_n}{\partial t_k}+\beta\partial_{t_1}^{-1}\phi_n=c_n\phi_n, \tag{6.1}$$

where c_n is arbitrary and $\partial_{t_1}^{-1}$ is a formal operator of integration with respect to t_1.

This lemma is a modification of Theorem 3 by Loris and Willox.[13] Although they formulate the theorem for a particular exponential representation of the functions ϕ_n which is suitable for soliton solutions, the proof is based on the pseudodifferential equation (6.1) rather than on the explicit representation of the functions ϕ_n. In order to proceed with the rational solutions of the generalized k-constraint we apply a simple trick which essentially simplifies the analysis. Let us introduce an auxillary ''time'' variable t_{-1} according to the pseudo-differential equation,

$$\frac{\partial\phi_n}{\partial t_{-1}}=\partial_{t_1}^{-1}\phi_n. \tag{6.2}$$

Then, we can construct the polynomial function $\tau_p(t_1,t_2,\ldots;t_{-1})$ of the generalized k-constrained KP hierarchy according to the formulas (2.1)–(2.10) taking into account the auxillary equation (6.2). The only modification of this analysis is an extension of the generalized variables $\theta_k(p)$ to the form,

$$\theta_k(p)\to\tilde{\theta}_k(p)=\theta_k(p)+\frac{(-1)^k}{p(1+k)}\,t_{-1}. \tag{6.3}$$

As a result, the generalized k-constraint (1.8) can be reformulated for the polynomial solutions of the KP hierarchy as follows.

Lemma 6.2: The polynomial τ-function of the generalized k-constrained KP hierarchy satisfies the differential equation,

$$\frac{\partial\tau_p}{\partial t_k}+\beta\,\frac{\partial\tau_p}{\partial t_{-1}}=0,\quad k\geqslant 1. \tag{6.4}$$

For the particular case $k=1$ the differential equation (6.4) follows from the analysis of the nonlocal Boussinesq equation (see formulas (19) and (20) in Ref. 12) and also from the analysis of the Davey–Stewartson system at the continuous-wave background as a generalized reduction of the KP hierarchy (see formulas (19) and (31) in Ref. 15). The result of Lemma 6.2 enables us to construct a set of the rational solutions of the generalized k-constrained KP hierarchy.

Proposition 6.3: The differential equation (6.4) is satisfied by the $(k-1)$ families of the polynomial τ-functions,

$$\tau_p=W_n[P_1(p),S^{-1}(\nu_1,\ldots,\nu_{k-1})S(\mu)P_3(p),\ldots,S^{-(n-1)}(\nu_1,\ldots,\nu_{k-1})S^{n-1}(\mu)P_{2n-1}(p)], \tag{6.5}$$

where $S(\mu)$ and $S(\nu_1,\ldots,\nu_{k-1})$ are defined by Eqs. (2.13) and (2.16), respectively. The parameter μ is $\mu=-p^{-1}$, while the parameters ν_i for $i=\overline{1,k-1}$ are given by

$$\nu_i=-\binom{k+1}{2}^{-1}\binom{k+1}{i+2}p^{-i}. \tag{6.6}$$

Last, the parameter p is one of the $(k+1)$ roots of the algebraic equation,

$$kp^{k+1}=\beta. \tag{6.7}$$

Proof: First, we express Eq. (6.4) through the derivatives of $\tau_p(\tilde{\theta}_1,\tilde{\theta}_2,\ldots)$ with respect to the variables $\tilde{\theta}_k$ given by Eqs. (2.6) and (6.3). This leads to the differential equation for τ_p,

$$\left(kp^{k-1}-\frac{\beta}{p^2}\right)\frac{\partial\tau_p}{\partial\theta_1}+\sum_{i=2}^{k}\left[\binom{k}{i}p^{k-i}+\frac{(-1)^i\beta}{p^{i+1}}\right]\frac{\partial\tau_p}{\partial\theta_i}=\beta\sum_{i=k+1}^{\infty}\frac{(-1)^{i+1}}{p^{i+1}}\frac{\partial\tau_p}{\partial\theta_i}, \tag{6.8}$$

where we have omited the sign ''tilde'' for convenience. Moreover, after the transformation of the differential equation (6.4) to the form (6.8) we can treat the extra variable t_{-1} as a phase constant since the equations of the KP hierarchy are only expressed through the time variables t_k for $k\geqslant 1$.

The first term in Eq. (6.8) is removed if the parameter p is a root of the algebraic equation (6.7). The rest of terms in Eq. (6.8) disappear due to a special structure of the polynomial function $\tau(\theta_1,\theta_2,\ldots)$ given by (6.5). To show this, we apply a standard analysis described in the proof of Proposition 5.2 and find from Eq. (6.5) the differential relation for $\tau_p(\theta_1,\theta_2\ldots)$,

$$\frac{\partial\tau_p}{\partial\theta_2}=-\sum_{i=3}^{k}\mu^{i-2}\frac{\partial\tau_p}{\partial\theta_i}\left(1-\sum_{j=1}^{i-2}\frac{\nu_j}{\mu^j}\right)-\sum_{i=k+1}^{\infty}\mu^{i-2}\frac{\partial\tau_p}{\partial\theta_i}\left(1-\sum_{j=1}^{k-1}\frac{\nu_j}{\mu_j}\right). \tag{6.9}$$

Substituting Eq. (6.9) into Eq. (6.8) and taking into account Eq. (6.7) we find that the parameter p can be eliminated if μ is given $\mu=-p^{-1}$, while the left-hand side and right-hand-side of Eq. (6.8) reduce the system of linear equations for the coefficients $\nu_1,\ldots,\ \nu_{k-1}$,

$$1-\sum_{m=1}^{i-2}\frac{\nu_m}{\mu^m}=\frac{2}{k+1}\left[1+\frac{(k-1)!(-1)^i}{i!(k-i)!}\right] \tag{6.10}$$

for $3\leqslant i\leqslant k$ and

$$1-\sum_{m=1}^{k-1}\frac{\nu_m}{\mu^m}=\frac{2}{k+1}. \tag{6.11}$$

This linear algebraic system is not degenerate and the only solution is given by Eq. (6.6). Indeed, a direct substitution of Eq. (6.6) into Eqs. (6.10) and (6.11) produces the system of combinatorial identities,

$$\sum_{m=0}^{i}(-1)^m\binom{k+1}{m+2}=k+(-1)^i\binom{k}{i+2} \tag{6.12}$$

for $1\leqslant i\leqslant k-2$ and

$$\sum_{m=0}^{k-1}(-1)^m\binom{k+1}{m+2}=k. \tag{6.13}$$

For $i=1$ the equality (6.12) is obviously satisfied. Furthermore, the equality (6.12) is satisfied for any $(i+1)$ provided it is valid for i. This statement is a consequence of the Pascal' triangle identity,

$$\binom{k+1}{i+3}=\binom{k}{i+2}+\binom{k}{i+3}. \tag{6.14}$$

Finally, Eq. (6.13) is satisfied due to the combinatorial identity,

$$\sum_{m=-2}^{k-1}(-1)^m\binom{k+1}{m+2}=0. \qquad \square \tag{6.15}$$

By comparing the results of Propositions 5.2 and 6.3, we conclude that the only difference in the rational solutions of the generalized l-reduced and k-constrained KP hierarchies is the appearance of the vertex operator $S(\mu)$ in the columns of the Wronskian determinant (6.5). This additional operator provides an annihilation of the infinite sum in the right-hand side of Eq. (6.8) due to the remarkable property (2.15).

Example 6.4: The NLS hierarchy at the CW background $(k=1)$.

The NLS hierarchy at the continuous-wave (CW) background starts with the NLS equation written in the form,

$$-\frac{\partial\psi}{\partial t_2}+\frac{\partial^2\psi}{\partial t_1^2}+2(\psi\overline{\psi}-\beta)\psi=0,\quad \frac{\partial\overline{\psi}}{\partial t_2}+\frac{\partial^2\overline{\psi}}{\partial t_1^2}+2(\psi\overline{\psi}-\beta)\overline{\psi}=0, \tag{6.16}$$

where the functions ψ and $\overline{\psi}$ are supposed to have the nonzero boundary conditions at infinity, i.e., $\psi\overline{\psi}\to\beta$ as $t_1\to\infty$. Two particular families of rational solutions of the NLS hierarchy at the CW background are expressed by means of the formula (2.12) through the function τ_p given by Eq. (6.5) for $k=1$, i.e.,

$$\tau_p(\theta_1,\theta_2,\ldots)=W_n[P_1(p),S(\mu)P_3(p),\ldots,S^{n-1}(\mu)P_{2n-1}(p)], \tag{6.17}$$

where $p=\pm\sqrt{\beta}$ and $\mu=-p^{-1}$.[15] The first polynomials (6.17) can be transformed by means of the phase translations exactly to the polynomials of the KdV hierarchy (see Example 4.5), i.e., $\tau_p=\tau_2^n(z_1,z_3,\ldots)$, where z_k are new variables, i.e.,

$$z_1=\theta_1, \quad z_3=\theta_3-\mu\theta_2+\tfrac{1}{4}\mu^2\theta_1,$$

$$z_5=\theta_5-2\mu\theta_4+\tfrac{3}{2}\mu^2\theta_3-\tfrac{1}{2}\mu^3\theta_2+\tfrac{1}{16}\mu^4\theta_1,$$

$$z_7=\theta_7-3\mu\theta_6+\tfrac{15}{4}\mu^2\theta_5-\tfrac{5}{2}\mu^3\theta_4+\tfrac{15}{16}\mu^4\theta_3-\tfrac{3}{16}\mu^5\theta_2+\tfrac{1}{64}\mu^6\theta_1.$$

These polynomials can further be used to construct the real nonsingular rational solutions to the (focusing) NLS equation which arises under the transformation $t_2\to it$ and the reduction $\overline{\psi}=\psi^*$, where ψ^* is complex conjugate to ψ. These rational solutions describe the modulational instability of a CW background under a localized perturbation of the algebraic profile.[33,34]

In addition, the same set of the polynomial τ-function also gives the rational solutions of another physically important equation which is the Kaup equation (or, equivalently, the classical Boussinesq system).[35] The polynomials $\tau_p(\theta_1,\theta_2,\ldots)$ given by Eq. (6.17) generate the rational solutions of the Kaup equation written in the form,

$$\frac{\partial^2 v}{\partial t_2^2}-4\beta\frac{\partial^2 v}{\partial t_1^2}-\frac{\partial^4 v}{\partial t_1^4}-2\frac{\partial v}{\partial t_1}\frac{\partial^2 v}{\partial t_1\partial t_2}+2\frac{\partial}{\partial t_1}\left[\left(\frac{\partial v}{\partial t_1}\right)^3-\frac{\partial v}{\partial t_1}\frac{\partial v}{\partial t_2}\right]=0, \tag{6.18}$$

within an equivalent bilinear representation (5.10).[36]

Example 6.5: The Yajima–Oikawa hierarchy ($k=2$).

The Yajima–Oikawa hierarchy starts with the system,

$$\frac{\partial u}{\partial t_2}=\frac{\partial\psi\overline{\psi}}{\partial t_1}, \quad \frac{\partial\psi}{\partial t_2}=\frac{\partial^2\psi}{\partial t_1^2}+2u\psi, \quad -\frac{\partial\overline{\psi}}{\partial t_2}=\frac{\partial^2\overline{\psi}}{\partial t_1^2}+2u\overline{\psi}, \tag{6.19}$$

where we impose the boundary conditions, $u\to 0$ and $\psi\overline{\psi}\to\beta$ as $t_1\to\infty$. Three particular families of the rational solutions of the Yajima–Oikawa hierarchy are expressed by means of the formula (2.12) through the function τ_p given by Eq. (6.5) for $k=2$, i.e.,

$$\tau_p(\theta_1,\theta_2,\ldots)=W_n[P_1(p),S^{-1}(\nu)S(\mu)P_3(p),\ldots,S^{-(n-1)}(\nu)S^{n-1}(\mu)P_{2n-1}(p)], \tag{6.20}$$

where p may have three values, $p=(\beta/2)^{1/3}$ and $p=(\beta/2)^{1/3}(-1\pm\sqrt{3}i)/2$, $S(\mu)$ and $S(\nu)$ are both given by Eq. (2.13) with the parameters $\mu=-p^{-1}$ and $\nu=-(3p)^{-1}$. The first polynomials (6.20) can be transformed by means of the phase translations to the polynomials of the KdV hierarchy (see Example 4.5) with the residue terms, i.e., $\tau_p=\tau_2^n(z_1,z_3,\ldots)+\Delta\tau_2^n(z_1,z_3,\ldots)$, where z_k are new variables, i.e.,

$$z_1=\theta_1, \quad z_3=\theta_3+(\nu-\mu)\theta_2+\tfrac{1}{4}(\nu-\mu)^2\theta_1,$$

$$\begin{aligned}z_5=\theta_5&+2(\nu-\mu)\theta_4+\tfrac{3}{2}(\nu-\mu)^2\theta_3+\tfrac{1}{2}(3\nu^3-5\nu^2\mu+3\nu\mu^2-\mu^3)\theta_2\\&+\tfrac{1}{16}(9\nu^4-20\nu^3\mu+14\nu^2\mu^2-4\nu\mu^3+\mu^4)\theta_1,\end{aligned}$$

$$\begin{aligned}z_7=\theta_7&+3(\nu-\mu)\theta_6+\tfrac{15}{4}(\nu-\mu)^2\theta_5+\tfrac{1}{2}(9\nu^3-19\nu^2\mu+15\nu\mu^2-5\mu^3)\theta_4+\tfrac{1}{16}(63\nu^4-156\nu^3\mu\\&+138\nu^2\mu^2-60\nu\mu^3+15\mu^4)\theta_3+\tfrac{1}{16}(63\nu^5-147\nu^4\mu+130\nu^3\mu^2-58\nu^2\mu^3+15\nu\mu^4-3\mu^5)\theta_2\\&+\tfrac{1}{64}(105\nu^6-294\nu^5\mu+303\nu^4\mu^2+359\nu^3\mu^3+39\nu^2\mu^4-6\nu\mu^5+\mu^6)\theta_1,\end{aligned}$$

and $\Delta\tau_2^n$ are the residue terms, i.e.,

$$\Delta\tau_2^1=0, \quad \Delta\tau_2^2=0, \quad \Delta\tau_2^3=\tfrac{45}{4}\nu^4(\nu-\mu)^2,$$

$$\Delta\tau_2^4=\frac{798525}{64}\,\nu^3\mu^3 z_1^4-\frac{4725}{8}\,\nu^4(9\nu^4-24\nu^3\mu+22\nu^2\mu^2-8\nu\mu^3+\mu^4)z_1^2$$
$$+\frac{14175}{64}\,\nu^3(16\nu^3-32\nu^2\mu+16\nu\mu^2-169\mu^3)z_1z_3$$
$$+\frac{4725}{64}\,\nu^4(81\nu^6-270\nu^5\mu+351\nu^4\mu^2-228\nu^3\mu^3+79\nu^2\mu^4-14\nu\mu^5+\mu^6).$$

Within a physical context, the Yajima–Oikawa system (6.19) transformed according to the reduction $t_2\to it$ and $\psi=i\psi^*$ describes a resonance of a mean flow and short dispersive waves. The rational solutions to this system have not yet been analyzed. However, by an analogy with the NLS hierarchy at the CW background (see Example 6.4), these solutions seem to be relevant for description of the modulational instability of a CW background under a localized perturbation of the algebraic profile.

VII. ANOMALOUS SCATTERING IN THE CM HIERARCHY

We have shown that all degenerate rational solutions of the KP hierarchy excepting those reducible to the generalized Schur polynomials $P_n(p)$ describe, within a particular limit, the stationary manifolds of the CM hierarchy (see Proposition 3.6). Hence, in a general case, these solutions describe the scattering dynamics of interacting particles in a neighborhood of the stationary manifolds. The stationary manifolds of the CM system (3.3), i.e., those with respect to the time t_2, are especially important because they are relevant for the rational solutions satisfying the generalized reductions of the KP hierarchy. Here we study the dynamical processes of scattering of the CM particles associated with this family of the rational solutions.

Proposition 7.1: Suppose that the τ-function of the KP hierarchy is given by

$$\tau_p(\theta_1,\theta_2,\ldots)=W_N[\widetilde{P}_1(p),\widetilde{P}_3(p),\ldots,\widetilde{P}_{2N-1}(p)], \tag{7.1}$$

where the tilde means that the translations of the time variables $\theta_k=\theta_k(p)$ may be arbitrary. Define the index s for the scattering rate of R particles according to the asymptotic representation $x_j-2pt_2\sim t_2^s$ as $t_2\to\infty$ for $j=\overline{1,R}$, where $x_j(t_2,\ldots)$ are zeros of the τ-function given by Eq. (3.1). Then, the scattering dynamics described by the polynomials (7.1) occur near a stationary manifold of the CM system (3.3) of $R=N(N+1)/2$ particles, and the scattering rate s may only have the particular values,

$$s=s_{k,m}=\frac{k}{2k+m}, \tag{7.2}$$

where for each integer $k=\overline{1,N-1}$ there exists a set of integers $m=\{2l-1\}_{l=1}^{N-k}$.

Proof: Noting that the τ-function given by Eq. (7.1) can be reduced, within a particular limit, to the form $\tau(t_1,t_3,\ldots)=W_N[p_1,p_3,\ldots,p_{2N-1}]$ which describes a stationary manifold of the CM system (3.3) of $R=N(N+1)/2$ particles according to Collorary (4.2) and Proposition 4.4. Therefore, a more general form (7.1) of the τ-function describes the scattering dynamics of R particles occurring near this stationary manifold. In order to find the scattering rate of the particle dynamics, we need to show that zeros of the polynomial function $\tau_p(\theta_1,\theta_2,\ldots)$ have the asymptotic representation $\theta_1\sim\theta_2^s$ as $\theta_1,\ \theta_2\to\infty$, where the index s is given by Eq. (7.2).

The polynomial solution (7.1) has generally $G=R=N(N+1)/2$ parameters. Among these parameters, $G_1=N$ parameters correspond to the phases $\theta_1,\ \theta_3,\ldots,\theta_{2N-1}$ which define the configuration of the stationary manifold of the CM system while $G_2=N(N-1)/2$ parameters can be regarded as amplitudes of elementary excitations of particles near the stationary manifold. We show that an individual elementary excitation can be described by the particular polynomial function τ_p following from Eq. (7.1),

$$\tau_p(\theta_1,\theta_2,\ldots)=\tau_N^{m,k}=W_N[P_1(p),\ldots,S_m^{-1}(a)P_{1+2k}(p),\ldots,S_m^{-2}(a)P_{1+4k}(p),\ldots], \tag{7.3}$$

where k and m are the same integers as below Eq. (7.2), while the operator $S_m(a)$ is given by a modification of Eq. (2.13) in the form,

$$S_m(a)=\exp\left[-\sum_{i=1}^{\infty}\frac{1}{i}\,a^i\,\frac{\partial}{\partial\theta_{mi}}\right]. \tag{7.4}$$

Using the standard analysis, one can readily show that the polynomial function $\tau_p(\theta_1,\theta_2,\ldots)$ given by Eq. (7.3) depends on the phases θ_{2k+m} and θ_{2k} only in the form of a linear superposition $(\theta_{2k+m}+a\,\theta_{2k})$. Next, because the time variables θ_{2k+m} define the stationary manifold of the CM system, zeros of the polynomial $\tau_N^{m,k}$ have the asymptotic representation $\theta_1\sim\theta_{2k+m}^{1/(2k+m)}$ as θ_1, $\theta_{2k+m}\to\infty$. Substituting the linear superposition in this asymptotic representation and recalling that $\theta_{2k}\sim\theta_2^k$ as θ_2, $\theta_{2k}\to\infty$, we conclude that the (m,k) elementary excitation of the stationary manifold of the CM system prescribed by Eq. (7.4) displays the fractional scattering rate s defined by Eq. (7.2). Finally, it is clear that there exists exactly $G_2=N(N-1)/2$ particular representations (7.4) for each polynomial function (7.1). Therefore, all possible asymptotical scattering rates are listed in the formula (7.2). □

Example 7.2: The stationary manifold of 6 particles $(N=3)$.

The following polynomial τ-function of the KP hierarchy follows from Eq. (7.1) at $N=3$ and describes the scattering dynamics of $R=6$ particles occurring near the corresponding stationary manifold of the CM system (3.3),

$$\tau_p=z_1^6-15z_1^3z_3-45z_3^2+45z_1z_5+\Delta, \tag{7.5}$$

where

$$z_1=\theta_1,\quad z_3=\theta_3+b\,\theta_2+\tfrac{1}{64}(16b^2+9a^2)\,\theta_1,$$

$$z_5=\theta_5+2b\,\theta_4+\frac{3}{32}\,(16b^2-a^2)\,\theta_3+a\,\theta_2^2+c\,\theta_2-\frac{3}{512}\,a(16b^2+9a^2)\,\theta_1^2-\frac{3}{8}\,\alpha\theta_1\theta_3$$
$$+\frac{5}{8}\,ab\,\theta_1\theta_2-\frac{1}{2048}\,(81a^4+1360a^2b^2+384b^4-1024bc)\,\theta_1,$$

and

$$\Delta=-\frac{225}{8}\,az_5-\frac{135}{512}\,a(19a^2+256b^2)z_3+45a^2\theta_2^2-\frac{45}{32}\,a(9a^2b+16b^3-32c)\,\theta_2$$
$$-\frac{45}{262144}\,(2781a^6+32704a^4b^2+129024a^2b^4-16384b^6$$
$$+36864a^2bc+65536b^3c-65536c^2).$$

Here the variables z_1, z_3, and z_5 define the $G_1=3$ parameters of the stationary manifold, while the constants a, b, and c correspond to the $G_2=3$ elementary excitations of the particles near the manifold. It follows from zeros of the polynomial function (7.5) that if $a\neq0$ the scattering rate s is $s_{2,1}=2/5$ according to Eq. (7.2). If $a=0$ but $b\neq0$, then the scattering rate is slower, i.e., $s_{1,1}=1/3$. At last, if $a=b=0$ but $c\neq0$ then the rate is still slower, i.e., $s_{1,2}=1/5$. For a, b, and c all equal to zero, the particles are not excited and lie on the stationary manifold of the CM system.□

Thus, we conclude that the existence of the stationary manifolds of the CM system leads to a slowing down of the anomalous scattering of interacting particles according to a hierarchy of characteristic scattering rates (7.2). It is worthwhile to notice that the rates of anomalous scattering occurring far from the stationary manifolds of the CM systems are higher than those given by Eq. (7.2). Indeed, zeros of the degenerate polynomials of the KP hierarchy including the generalized Schur polynomials $P_n(p)$ have generally an asymptotic representation $\theta_1\sim\theta_2^{1/2}$ as θ_1, $\theta_2\to\infty$, i.e., the scattering rate is generally $s=1/2$. Only if the degenerate polynomials reduce to the form (7.1) the scattering rate becomes slower with respect to the time t_2, i.e., $s_{k,m}<1/2$. A first example

of the anomalous scattering occurring near the stationary manifolds of the CM system was presented by Gorshkov *et al.*[21] and recently reproduced by Ablowitz and Villarroel for the lump solutions in the KP1 equation.[24] Although we do not consider here the rational solutions of the KP1 equation, the results presented can further be generalized to describe the same scattering dynamics of the lump solitons as the particles in the CM system (see also Ref. 21).

VIII. CONCLUSION

In this paper we have developed a general approach to construct and analyze the degenerate rational solutions of equations of the KP hierarchy and its reductions. In particular, we have presented the rational solutions to the generalized l-reduction and k-constraint of the KP hierarchy which correspond to the reductions of the KP hierarchy under the nonzero boundary conditions at infinity. We have also shown that these solutions describe anomalously slow dynamical processes of scattering occurring near the stationary manifolds of the CM dynamical system.

Since the paper does not cover all possible generalized reductions of the KP hierarchy (see, e.g., Refs. 5, 6 for other reductions) it is worthwhile to summarize our approach and present a general scheme of a search for the polynomial τ-function satisfying a generalized reduction of the KP hierarchy. Suppose that the reduction is formulated in terms of a differential equation imposed on the τ-function of the KP hierarchy. Then, in order to find the particular form of the polynomial function $\tau_p(\theta_1,\theta_2,\ldots)$ (2.10) satisfying this reduction, one needs

(i) to rewrite the differential equation in terms of the generalized time variables $\theta_k(p)$;
(ii) to choose p such that the leading-order term $\partial\tau_p/\partial\theta_1$ is removed;
(iii) to find the first nonzero coefficient in front of the derivative $\partial\tau_p/\partial\theta_m$, then the polynomials τ_p generalize the polynomials of the m-reduced KP hierarchy given by (4.4);
(iv) to introduce the generalized vertex operators (2.13) and (2.16) which displace phases of the polynomials $P_n(p)$ in each subsequent column of the Wronskian determinant (2.10);
(v) to find the parameters of the vertex operators by comparing the differential equation derived for the polynomial function (2.10) with that of the given reduction.

This scheme and the approaches used in both papers I and II can be developed for analysis of the rational solutions of multicomponent KP hierarchies which include such an important example as the Davey–Stewartson system (see, e.g., Ref. 15). The τ-function of the multicomponent KP hierarchies can be expressed through a multicomponent Wronskian[26] which can be treated in the same manner as that in a single-component case. The classification and construction of rational solutions of the multicomponent KP hierarchies remain open for further studies.

ACKNOWLEDGMENTS

This work was inspired by discussions with Professor M. J. Ablowitz and Dr. I. Loris and was completed during the author's visit to the Vrije Universiteit Brussel in February, 1997. The author is very grateful to Professor F. Lambert for his warm hospitality and encouragement. The direct linearization of a nonlinear partial differential equation, when it is possible, is a purely algebraic process, which should not imply strong conditions on the solutions at infinity. Thus, it should be possible to manage it in such a way that the relevant inversion equation is not of the Marchenko form, but others, e.g., the true Gelfand–Levitan form, which preserves the local character of the approach. This is demonstrated on the Korteweg–de Vries case. © *1998 American Institute of Physics.* [S0022-2488(98)02610-3]

I. INTRODUCTION

Processing the direct linearization of a nonlinear partial differential equation (E) is giving a linear integral equation, called ''Spectral'' because ''spectral variables'' only are involved, the space variables being fixed, and whose solutions are those of a ''spectral'' problem depending on solutions of (E) as parameters.[1,2] This process is possible when special algebraic conditions are fulfilled, and so, it is a purely algebraic and ''local'' process,[2] that should not need or imply boundary conditions on the solutions of E. Yet, common experience shows that the so-called ''inverse scattering transform'' works only for a special class of solutions of E, usually with a vanishing condition at ∞. This is satisfactory for people of scattering theory but, in light of a direct linearization, it is very surprising. We study here the most simple process of direct linearization, that of Korteweg–de Vries equation. In classical and very well-known results,[3] this process is handled in such a way that it reduces the research of solutions to what we call[4] a Faddeev–Marchenko inversion equation, and the necessary vanishing of the solutions of (E) at infinity is related to the structure of this equation. In the present paper, we show that the process can be handled in other ways, which rather correspond to a Gelfand–Levitan equation, or other inversion equations with the same ''local'' significance. The reader understands that we use the words ''Gelfand–Levitan equations'' for inversion equations whose kernel is sitting on a finite support, ''Marchenko equations'' if the support is semi-infinite, as they are called in books on inverse problems[4,5] and not in some papers on inverse methods!

In Sec. II, a very general spectral integral equation is given, and shown to yield solutions, in the general case, of a matricial 2×2 Korteweg–de Vries equation. This equation has been obtained, and its properties are derived, as simple applications of the linearization method we previously described[6] for matricial cases. However, in this scalar case it is easier to handle it with $(k+\lambda)$ in the kernel denominator, the kernel numerator again being constructed from the Korteweg–de Vries dispersion relations. The way we handle ''parasite'' and ''free'' terms follows the lines of our previous method, so that, here, we do not give details on why we do so: we only state and prove the results.

In Sec. III, we first study the most general matricial case when the spectral measure is supported by one point only on the imaginary axis, and we show that a geometric transformation reduces here the matricial case to the scalar Korteweg–de Vries equation. The solutions we obtain generalize, in some way, solitons. We study then the case where the ''spectral measure'' has its support on the real axis, where it is even, and we show that again the matricial Korteweg–de Vries equation diagonalizes and that the inversion equation in this case is nothing but the familiar Gelfand–Levitan equation of the radial Schrodinger problem!

The main interest of this paper in our opinion is the following.

(1) A local approach may be a key to solutions fulfilling prescribed conditions at a finite distance and more generally to new classes of solutions, both for Korteweg–de Vries and for related nonlinear equations (e.g., Painlevé ones).
(2) The method seems open to many generalizations, both by using algebraic direct linearizations for other nonlinear partial differential equations and by looking for other inversion equations.

II. THE SPECTRAL INTEGRAL EQUATION AND KORTEWEG–DE VRIES LINEARIZATION

We start from the spectral integral equation,

$$f_1(k,x,t)=\sin[kx+k^3t]+\lim_{\epsilon\to 0+}\int \frac{d\mu(\lambda)}{k+\lambda+i\epsilon}\sin[(k+\lambda)x+(k^3+\lambda^3)t+\nu(\lambda)]f_1(\lambda,x,t), \tag{2.1}$$

which will be written for short as

$$f_1(k,x,t)=\sin[kx+k^3t]+\oint T(k,\lambda,x,t)f_1(\lambda,x,t), \tag{2.2}$$

and gathered with its ''sister'' equation,

$$f_2(k,x,t)=\cos[kx+k^3t]+\oint T(k,\lambda,x,t)f_2(\lambda,x,t). \tag{2.3}$$

We assume throughout that the support of $d\mu(\lambda)$ is contained in $\mathrm{Im}\,\lambda\geqslant 0$. ϵ and the limit process are used if part of the support is on the real axis. We assume also that the properties of this measure are such that (2.2) and (2.3) are Fredholm equations, for which the Fredholm alternative holds. In the generic cases, and/or at generic values of x and t, we use the working assumption that the homogeneous equation,

$$f(k,x,t)=\oint T(k,\lambda,x,t)f(\lambda,x,t), \tag{2.4}$$

has no solution but $f=0$. Let us now introduce the following functions, which we call ''the prepotentials:''

$$u_{11}(x,t)=\int d\mu(\lambda)\sin[\lambda x+\lambda^3t+\nu(\lambda)]f_1(\lambda,x,t), \tag{2.5}$$

$$u_{12}(x,t)=\int d\mu(\lambda)\cos[\lambda x+\lambda^3t+\nu(\lambda)]f_1(\lambda,x,t), \tag{2.6}$$

$$u_{21}(x,t)=\int d\mu(\lambda)\sin[\lambda x+\lambda^3t+\nu(\lambda)]f_2(\lambda,x,t), \tag{2.7}$$

$$u_{22}(x,t)=\int d\mu(\lambda)\cos[\lambda x+\lambda^3t+\nu(\lambda)]f_2(\lambda,x,t). \tag{2.8}$$

It is a matter of straightforward calculations, by applying the differential operator to both sides of (2.2) or (2.3), and reducing parasite terms, to show the following equations:

$$\frac{\partial}{\partial x}f_1(k,x,t)=\cos(kx+k^3t)[k+u_{12}(x,t)]-\sin(kx+k^3t)u_{11}(x,t)$$
$$+\oint T(k,\lambda,x,t)\frac{\partial f_1}{\partial x}(\lambda,x,t), \tag{2.9}$$

$$\frac{\partial}{\partial x} f_2(k,x,t) = -\sin(kx+k^3t)[k+u_{21}(x,t)] + \cos(kx+k^3t)u_{22}(x,t) + \oint T(k,\lambda,x,t) \frac{\partial}{\partial x} f_2(\lambda,x,t), \tag{2.10}$$

$$\left(\frac{\partial^2}{\partial x^2}+k^2\right) f_1(k,x,t) = 2\cos(kx+k^3t) \frac{\partial}{\partial x} u_{12}(x,t) - 2\sin(kx+k^3t) \frac{\partial}{\partial x} u_{11}(x,t) + \oint T(k,\lambda,x,t)\left(\frac{\partial^2}{\partial x^2}+\lambda^2\right) f_1(\lambda,x,t), \tag{2.11}$$

$$\left(\frac{\partial^2}{\partial x^2}+k^2\right) f_2(k,x,t) = 2\cos(kx+k^3t) \frac{\partial}{\partial x} u_{22}(x,t) - 2\sin(kx+k^3t) \frac{\partial}{\partial x} u_{21}(x,t) + \oint T(k,\lambda,x,t)\left(\frac{\partial^2}{\partial x^2}+\lambda^2\right) f_2(\lambda,x,t). \tag{2.12}$$

A word of explanation for a reader not familiar with the author's words;[2] ''*parasite*'' terms are terms which appear when the operator applies inside the integral *and* which are not *similar* to the left-hand side of the equation [contrary to the one in (2.12), for instance]. Parasite terms can be reduced if algebraic calculations can kill for them the denominator $k+\lambda$, so that, thanks to the separability of $\sin[(k+\lambda)x+(k^3+\lambda^3)t+\nu(\lambda)]$, the former parasite term becomes a combination of ''free'' terms. In the four equations above [and in (2.2) and (2.3)], you can see only the left-hand side, free terms, and an integral term similar to the left-hand side of the equation—as a matter of fact, you see in the six equations the same equation with different free terms. Again, you can obtain the same equation by using a function of x and t only to multiply both sides (a ''*compatible*'' operation). Thus, it is easy to combine (2.11) or (2.12) and convenient linear combinations of f_1 and f_2, as given by (2.2) and (2.3), to obtain an expression that satisfies the homogeneous equation (2.4) and therefore vanishes, the key trick in direct linearization.

The result is the Schrodinger matricial problem:

$$\left(\frac{\partial^2}{\partial x^2}+k^2-\mathbf{V}(x,t)\right)\mathbf{f}(k,x,t)=0, \tag{2.13}$$

where

$$\mathbf{f}(k,x,t)=\begin{pmatrix} f_1(k,x,t) \\ f_2(k,x,t) \end{pmatrix} \tag{2.14}$$

$$\mathbf{V}(x,t)=\begin{pmatrix} -2\dfrac{\partial}{\partial x}u_{11} & 2\dfrac{\partial}{\partial x}u_{12} \\ -2\dfrac{\partial}{\partial x}u_{21} & 2\dfrac{\partial}{\partial x}u_{22} \end{pmatrix}. \tag{2.15}$$

Now, we wish to obtain the time operator of the Lax pair.

Again, it is a matter of lengthy but straightforward calculations to show first, from (2.5)–(2.8) and (2.13), and using ''primes'' to denote x derivatives:

$$\frac{\partial^2 u_{11}}{\partial x^2} = 2\frac{\partial}{\partial x}\int d\mu(\lambda)\cos[\lambda x+\lambda^3 t+\nu(\lambda)]\lambda f_1(\lambda,x,t) - 2u'_{11}u_{11}+2u'_{12}u_{21}, \tag{2.16}$$

$$\frac{\partial^2 u_{12}}{\partial x^2} = -2\frac{\partial}{\partial x}\int d\mu(\lambda)\sin[\lambda x+\lambda^3 t+\nu(\lambda)]\lambda f_1(\lambda,x,t) - 2u'_{11}u'_{12}+2u'_{12}u_{22}, \tag{2.17}$$

$$\frac{\partial^2 u_{21}}{\partial x^2}=2\frac{\partial}{\partial x}\int d\mu(\lambda)\cos[\lambda x+\lambda^3 t+\nu(\lambda)]\lambda f_2(\lambda,x,t)-2u'_{21}u_{11}+2u'_{22}u_{21}, \tag{2.18}$$

$$\frac{\partial^2 u_{22}}{\partial x^2}=-2\frac{\partial}{\partial x}\int d\mu(\lambda)\sin[\lambda x+\lambda^3 t+\nu(\lambda)]\lambda f_2(\lambda,x,t)-2u'_{21}u_{12}+2u'_{22}u_{22}. \tag{2.19}$$

Then we apply $(\partial/\partial t-k^2(\partial/\partial x))$ to both sides of (2.2), and do the standard work on parasite and free terms, using (2.16) and (2.17), to obtain

$$\begin{aligned}\left(\frac{\partial}{\partial t}-k^2\frac{\partial}{\partial x}\right)f_1(k,x,t)&=\cos(kx+k^3t)\left[-ku'_{11}+\left(u'_{12}u_{22}-u'_{11}u_{12}-\frac{1}{2}u''_{12}\right)\right]\\&+\sin(kx+k^3t)\left[-ku'_{12}+\left(u'_{11}u_{11}-u'_{12}u_{21}+\frac{1}{2}u''_1\right)\right]\\&+\oint T(k,\lambda,x,t)\left(\frac{\partial}{\partial t}-\lambda^2\frac{\partial}{\partial x}\right)f_1(\lambda,x,t),\end{aligned} \tag{2.20}$$

and, with similar derivations,

$$\begin{aligned}\left(\frac{\partial}{\partial t}-k^2\frac{\partial}{\partial x}\right)f_2(k,x,t)&=\cos(kx+k^3t)\left[-ku'_{21}+\left(u'_{22}u_{22}-u'_{21}u_{12}-\frac{1}{2}u''_{22}\right)\right]\\&+\sin(kx+k^3t)\left[-ku'_{22}+\left(u'_{21}u_{11}-u'_{22}u_{21}+\frac{1}{2}u''_{21}\right)\right]\\&+\oint T(k,x,t)\left(\frac{\partial}{\partial t}-\lambda^2\frac{\partial}{\partial x}\right)f_2(\lambda,x,t),\end{aligned} \tag{2.21}$$

whereas it follows from (2.9) (2.10), (2.2), and (2.3), that

$$\frac{\partial f_1}{\partial x}+u_{11}f_1-u_{12}f_2=k\cos+\oint T(k,\lambda,x,t)\left[\frac{\partial f_1}{\partial x}+u_{11}f_1-u_{12}f_2\right], \tag{2.22}$$

$$\frac{\partial f_2}{\partial x}+u_{21}f_1-u_{22}f_2=-k\sin+\oint T(k,\lambda,x,t)\left[\frac{\partial f_1}{\partial x}+u_{21}f_1-u_{22}f_2\right], \tag{2.23}$$

where we used condensed notations to make it easier to grasp. With the same care, we write down the result obtained after combining (2.20)–(2.23) into the homogeneous vectorial equation:

$$\frac{\partial \mathbf{f}}{\partial t}-k^2\frac{\partial \mathbf{f}}{\partial x}-\frac{1}{2}\mathbf{V}\frac{\partial \mathbf{f}}{\partial x}+\frac{1}{4}\mathbf{V}'\mathbf{f}=0. \tag{2.24}$$

The asymptotic behavior of f as $k\to\pm\infty$ on the real axis can be derived from (2.2), (2.3), and the values of prepotentials and their derivatives. Setting

$$\mathbf{f}^0=\begin{pmatrix}\sin(kx+k^3t)\\ \cos(kx+k^3t)\end{pmatrix}, \tag{2.25}$$

we obtain

$$\mathbf{f}=\mathbf{f}^{(0)}+k^{-1}\mathbf{f}^{(1)}+k^{-2}\mathbf{f}^{(2)}+0(k^{-3})\quad(k\to\pm\infty), \tag{2.26}$$

where

$$\mathbf{f}^{(1)}=\mathbf{P}\mathbf{f}^{(0)}, \tag{2.27}$$

$$\mathbf{P}=\begin{bmatrix} u_{12}(x,t) & u_{11}(x,t) \\ u_{22}(x,t) & u_{21}(x,t) \end{bmatrix}, \tag{2.28}$$

$$\mathbf{f}^{(2)}=-\mathbf{Q}\mathbf{f}^{(0)}. \tag{2.29}$$

$$\mathbf{Q}=\begin{bmatrix} v_{12}(x,t) & v_{11}(x,t) \\ v_{22}(x,t) & v_{21}(x,t) \end{bmatrix} \tag{2.30}$$

$$v_{11}(x,t)=\int d\mu(\lambda)\sin[\lambda x+\lambda^3 t+\nu(\lambda)]\lambda f_1(\lambda,x,t), \tag{2.31}$$

$$v_{12}(x,t)=\int d\mu(\lambda)\cos[\lambda x+\lambda^3 t+\nu(\lambda)]\lambda f_1(\lambda,x,t), \tag{2.32}$$

$$v_{21}(x,t)=\int d\mu(\lambda)\sin[\lambda x+\lambda^3 t+\nu(\lambda)]\lambda f_2(\lambda,x,t), \tag{2.33}$$

$$v_{22}(x,t)=\int d\mu(\lambda)\cos[\lambda x+\lambda^3 t+\nu(\lambda)]\lambda f_2(\lambda,x,t). \tag{2.34}$$

It follows from (2.16)–(2.19) that

$$v'_{11}=u'_{12}u_{22}-u'_{11}u_{12}-\tfrac{1}{2}u''_{12}, \tag{2.35}$$

$$v'_{12}=u'_{11}u_{11}-u'_{12}u_{21}+\tfrac{1}{2}u''_{11}, \tag{2.36}$$

$$v'_{21}=u'_{22}u_{22}-u'_{21}u_{12}-\tfrac{1}{2}u''_{22}, \tag{2.37}$$

$$v'_{22}=u'_{21}u_{11}-u'_{22}u_{21}+\tfrac{1}{2}u''_{21}. \tag{2.38}$$

Now, let us write down the commutator of the linear operators acting on **f** in the spectral problem (2.13) and in the auxiliary problem (2.24), and seek the asymptotic behavior of the result. After two terms identically vanishing at positive orders of k, we get at order 0 in k the Korteweg–de Vries matricial equation for **V**:

$$\frac{\partial \mathbf{V}}{\partial t}+\frac{1}{4}\mathbf{V}'''-\frac{3}{4}(\mathbf{V}\mathbf{V}'+\mathbf{V}'\mathbf{V})=0. \tag{2.39}$$

III. THE SCALAR KORTEWEG–DE VRIES EQUATION

There are several cases where **V** can be diagonalized, so that (2.39) yields two families of solutions for the familiar Korteweg–de Vries equation:

$$\frac{\partial V}{\partial t}+\frac{1}{4}\frac{\partial^3 V}{\partial x^3}-\frac{3}{2}V\frac{\partial V}{\partial x}=0, \tag{3.1}$$

where V is a (scalar) function of x and t. We pinpoint two examples, both showing a degree of generality such that we cannot call them special cases.

A. First example—solitons

We choose the spectral measure $d\mu(\lambda)$ in the starting equations as

$$d\mu(\lambda)=\mu_0\delta(\lambda-i\kappa), \quad \kappa>0. \tag{3.2}$$

Setting

$$\cos\ \nu(i\kappa)=\alpha(\kappa); \quad \sin\ \nu(i\kappa)=i\beta(\kappa), \tag{3.3}$$

We obtain

$$f_1(i\kappa,x,t)=\frac{i\ \sinh(\kappa x-\kappa^3 t)}{1+S}, \tag{3.4}$$

$$f_2(i\kappa,x,t)=\frac{\cosh(\kappa x-\kappa^3 t)}{1+S}, \tag{3.5}$$

where

$$S=-\frac{\mu_0}{2\kappa}\left[\alpha(\kappa)\sinh X+\beta(\kappa)\cosh X\right], \tag{3.6}$$

$$X=2(\kappa x-\kappa^3 t). \tag{3.7}$$

Notice that if μ_0 is real and $\nu(\lambda)$ is an odd function, f_2 and if_1 are real. From (2.15) we derive the matrix elements of $\mathbf{V}$:

$$V_{11}=\mu_0(1+S)^{-2}[\mu_0(\alpha^2-\beta^2)+(2\kappa\alpha-\beta\alpha\mu_0)\sinh X+(2\kappa\beta-\mu_0\alpha^2)\cosh X], \tag{3.8}$$

$$V_{12}=i\mu_0(1+S)^{-2}(2\kappa-\beta\mu_0)(\alpha\ \cosh X+\beta\ \sinh X), \tag{3.9}$$

$$V_{12}=-i\mu_0(1+S)^{-2}(2\kappa+\beta\mu_0)(\alpha\ \cosh X+\beta\ \sinh X), \tag{3.10}$$

$$V_{22}=\mu_0(1+S)^{-2}[\mu_0(\alpha^2-\beta^2)+(2\kappa\alpha+\beta\alpha\mu_0)\sinh X+(2\kappa\beta+\mu_0\alpha^2)\cosh X]. \tag{3.11}$$

It is easy to see that

$$V_{22}-V_{11}=2\mu_0^2\alpha(1+S)^{-2}(\alpha\ \cosh X+\beta\ \sinh X), \tag{3.12}$$

and setting

$$\gamma=\kappa/\mu_0\alpha;\quad \delta=\beta/2\alpha, \tag{3.13}$$

we get

$$V_{12}=i(\gamma-\delta)(V_{22}-V_{11});\quad V_{21}=-i(\gamma+\delta)(V_{22}-V_{11}). \tag{3.14}$$

It follows that V can be diagonalized on a basis of eigenvectors that do not depend on x and t. If U is the matrix made of them, inserting $\mathbf{U}^*\mathbf{\Lambda}\mathbf{U}$ for $\mathbf{V}$ in the matricial Korteweg–de Vries equation readily yields the equation (3.1) for either of the two diagonal components of $\mathbf{\Lambda}$:

$$\lambda^{\pm}=\tfrac{1}{2}[(V_{22}+V_{11})\pm(V_{22}-V_{11})\Gamma], \tag{3.15}$$

where

$$\Gamma=[1+4(\gamma^2-\delta^2)]^{1/2}. \tag{3.16}$$

For a proof, calculate $\lambda^{\pm}$ as zeros of $\det(\mathbf{V}-\lambda\mathbf{I})$, then check that $\mathbf{V}-\lambda^{\pm}\mathbf{I}$ is proportional to $V_{22}-V_{11}$, so that, in the equation for eigenvectors, this factor, which is the only term depending on x and t, can be dropped.

From (3.8), (3.11), (3.12), and (3.13), we obtain the more attractive form

$$\lambda^{\pm}=4\kappa^2\ \frac{1-4\delta^2+2\gamma(\sinh X+2\delta\ \cosh X)\pm\Gamma(\cosh X+2\delta\sinh X)}{(\sinh X+2\delta\ \cosh X-2\gamma)^2}. \tag{3.17}$$

These families of solutions are, of course, solitary waves depending only on X. They are generally singular at one value of X.

They are real for μ_0 real and $\nu(\lambda)$ odd. Since they are functions of X only, they should be solutions, as a function of X, of

$$\frac{d}{dX}[4\kappa^2(\Lambda''-\Lambda)-3\Lambda^2]=0. \tag{3.18}$$

As a matter of fact, it is not difficult to check that they are solutions of

$$2\kappa^2(\Lambda'^2-\Lambda^2)-\Lambda^3=0, \tag{3.19}$$

which is more restrictive than (3.18).

B. Second example: Gelfand–Levitan inversion

We choose the spectral measure on the real axis [this is why $i\epsilon$ was necessary in (2.1)], and ''symmetric,'' meaning that if $d\mu(\lambda)$ is a Stieltjes measure $m(\lambda)d\lambda$, $m(\lambda)$ is even.

We also assume that $\nu(\lambda)$ is an odd function of λ. Now suppose a solution f of the homogeneous equation (2.4) be written as a sum of its even part and its odd part as a function of k:

$$f(k,\cdot)=f^+(k,\cdot)+f^-(k,\cdot). \tag{3.20}$$

Substituting (3.20) into (3.4) yields for f^+ and f^- the equations

$$f^+(k,x,t)=\int d\mu(\lambda)T^+(k,\lambda,x,t)f^+(\lambda,x,t), \tag{3.21}$$

$$f^-(k,x,t)=\int d\mu(\lambda)T^-(k,\lambda,x,t)f^-(\lambda,x,t), \tag{3.22}$$

where

$$2T^+(k,\lambda,x,t)=\frac{\sin[(k+\lambda)x+(k^3+\lambda^3)t+\nu(\lambda)]}{k+\lambda}+\frac{\sin[(k-\lambda)x+(k^3-\lambda^3)t-\nu(\lambda)]}{k-\lambda}, \tag{3.23}$$

$$2T^-(k,\lambda,x,t)=\frac{\sin[(k+\lambda)x+(k^3+\lambda^3)t+\nu(\lambda)]}{k+\lambda}-\frac{\sin[(k-\lambda)x+(k^3-\lambda^3)t-\nu(\lambda)]}{k-\lambda}. \tag{3.24}$$

It follows that our assumption on (2.4) (no solution but 0) implies the same for (3.21) and (3.22). Now, let us study the problem at $t=0$. Our remarks imply that $f_1(k,x)$ is an odd function of k, and the unique solution of

$$f_1(k,x)=\sin kx+\int d\mu(\lambda)T^-(k,\lambda,x,0)f_1(\lambda,x). \tag{3.25}$$

From now on we assume to be simple that $\nu(\lambda)=0$. Hence T^- is equal to a simple integral, which for $x>0$ reads

$$T^-(k,\lambda,x,0)=-\int_0^x \sin ky\ \sin \lambda y\ dy. \tag{3.26}$$

Inserting it in (3.25), we get, after defining the kernels,

$$L_1(x,y)=-\int d\mu(\lambda)f_1(\lambda,x)\sin \lambda y, \tag{3.27}$$

$$G_1(x,y)=\int d\mu(\lambda)\sin \lambda x\ \sin \lambda y, \tag{3.28}$$

the equations

$$f_1(k,x)=\sin\, kx+\int_0^x L_1(x,y)\sin\, ky\; dy, \tag{3.29}$$

$$L_1(x,z)+G_1(x,z)+\int_0^z L_1(x,y)G_1(y,z)dy=0. \tag{3.30}$$

On the other hand, a glance at Eqs. (2.5)–(2.8) shows that because of the parity properties, only u_{11} and u_{22} do not vanish, so that the potential $\mathbf{V}$, given by (2.15), is diagonal for any x and t. Comparing (2.15) and (3.27) shows that

$$V_{11}=2\frac{d}{dx}L_1(x,x). \tag{3.31}$$

By the same token, we successively obtain

$$f_2(k,x)=\cos\, kx+\int d\mu(\lambda)\left[\int_0^z \cos\, ky\, \cos\, \lambda y\; dy\right] f_2(\lambda,x), \tag{3.32}$$

$$L_2(x,y)=\int d\mu(\lambda) f_2(\lambda,x)\cos\, \lambda y, \tag{3.33}$$

and, setting

$$G_2(x,z)=-\int d\mu(\lambda)\cos\, \lambda x\, \cos\, \lambda z, \tag{3.34}$$

$$f_2(k,x)=\cos\, kx+\int_0^z \cos\, kyL_2(x,y)dy, \tag{3.35}$$

$$L_2(x,z)+G_2(x,z)+\int_0^z L_2(x,y)G_2(y,z)dy=0, \tag{3.36}$$

$$V_{22}=2\frac{d}{dx}L_2(x,x). \tag{3.37}$$

Hence, in this case, the Gelfand–Levitan equations are reproduced with their usual relations to potentials. If t is different from zero, the parity properties remain, and f_1 is still an odd function of k, the unique solution of

$$f_1(k,x,t)=\sin(kx+k^3t)+\int d\mu(\lambda)T^-(k,\lambda,x,t)f_1(\lambda,x,t), \tag{3.38}$$

and f_2 still an even function of k, and the unique solution of

$$f_2(k,x,t)=\cos(kx+k^3t)+\int d\mu(\lambda)T^+(k,\lambda,x,t)f_2(\lambda,x,t). \tag{3.39}$$

Because of parity properties, $\mathbf{V}$ remains diagonal. Hence V_{11} and V_{22} define two families of solutions of the Korteweg–de Vries equation (3.1). So as to describe them, we can solve (3.38) and (3.39). It is also possible to construct a system of equations of the Gelfand–Levitan form with kernels which are integrated from 0 to x or 0 to t. This is done in the Appendix. However, we think that for solving the Korteweg–de Vries equation the best management is done by directly solving (2.2) and (2.3).

Remarks:

(1) Following the lines above, it is not difficult to add Dirac measures on the imaginary axis to the Gelfand–Levitan case.

(2) Setting in (2.2) and (2.3),

$$\nu(\lambda)=-ip;\quad d\mu(\lambda)=2e^{-p}\,d\rho(\lambda), \tag{3.40}$$

then letting $p\to+\infty$, and gathering the two equations, we obtain for $f=f_2+if_1$ the equation

$$f(k,x,t)=e^{i(kx+k^3t)}-i\lim_{\epsilon\to 0^+}\int\frac{d\rho(\lambda)}{k+\lambda+i\epsilon}\,e^{i[(k+\lambda)x+(k^3+\lambda^3)t]}f(\lambda,x,t), \tag{3.41}$$

which is commonly used[3] to linearize the Korteweg–de Vries equation, and can easily be used to derive the Faddeev–Marchenko equations as we used (3.25) to derive the Gelfand–Levitan equation. Setting (3.40), and

$$d\rho(\lambda)=\mu\,\delta(\lambda-i\kappa),\quad e^{-X_0}=2\kappa/\mu, \tag{3.42}$$

can also be done directly in (3.17). The limit of $\lambda^{\pm}$ as p goes to $+\infty$ is then 0 for λ^+ and

$$\lambda^-=-2\kappa^2/\cosh^2[\tfrac{1}{2}(X-X_0)], \tag{3.43}$$

which is the usual soliton.

(3) When spectral equations like (2.1) are used, a problem sometimes arises: is it possible to construct $d\mu(\lambda)$ from the potential values at a given t? This problem is solved if a Gelfand–Levitan or a Marchenko equation exists, since $d\mu(\lambda)$ can be identified with the corresponding ''measures'' (respectively, spectral measure or reflection coefficient). In other cases, one should study separately this previously ''direct'' problem, now an inverse one.

APPENDIX: INVERSION EQUATIONS (GELFAND–LEVITAN EXAMPLE) FOR $t\neq 0$

With the symmetry assumptions of the Gelfand–Levitan example, and $t\neq 0$, Eq. (3.25) is replaced by (3.38) [with $\nu(\lambda)$ set to zero in $T^-(k,\lambda,x,t)$].

We easily derive, from Eq. (3.24),

$$T^-(k,\lambda,x,t)=\int_0^x\sin(ky+k^3t)\sin(\lambda y+\lambda^3t)dy$$
$$-(k^2+\lambda^2)\int_0^t\sin k^3s\,\sin\lambda^3s\,ds-k\lambda\int_0^t\cos k^3s\,\cos\lambda^3s\,ds. \tag{A1}$$

Now, setting

$$L(x,y,t,u)=-\int d\mu(\lambda)f_1(\lambda,x,t)\sin(\lambda y+\lambda^3u), \tag{A2}$$

we can derive from (A1) the representation:

$$f_1(k,x,t)=\sin(kx+k^3t)+\int_0^x\sin(kz+k^3t)L(x,z,t,t)dz$$
$$+k^2\int_0^t\sin k^3sL(x,0,t,s)ds-\int_0^t\sin k^3s\left[\frac{\partial^2}{\partial y^2}L(x,y,t,s)\right]_{y=0}ds$$
$$+k\int_0^t\cos k^3s\left[\frac{\partial}{\partial y}L(x,y,t,s)\right]_{y=0}ds. \tag{A3}$$

Setting then

$$G(x,y,t,u)=\int d\mu(\lambda)\sin(\lambda x+\lambda^3 t)\sin(\lambda y+\lambda^3 u), \tag{A4}$$

we multiply both sides of (A3) by $\sin(ky+k^3u)d\mu(k)$ and integrate, obtaining

$$\begin{aligned} &L(x,y,t,u)+G(x,y,t,u)+\int_0^x L(x,z,t,t)G(y,z,t,u)dz \\ &-\int_0^t\left[\frac{\partial^2}{\partial x^2}G(x,y,s,u)\right]_{x=0}L(x,0,t,s)ds \\ &-\int_0^t G(0,y,s,u)\left[\frac{\partial^2}{\partial y^2}L(x,y,t,u)\right]_{y=0}ds \\ &+\int_0^t\left[\frac{\partial}{\partial x}G(x,y,s,u)\right]_{x=0}\left[\frac{\partial}{\partial y}L(x,y,t,s)\right]_{y=0}ds=0 \end{aligned} \tag{A5}$$

whereas Eq. (2.15) yields the expected relation between $V(x,t)$ and $L(x,x,t,t)$. The equation (A5) is readily transformed into a linear integral Fredholm equation for the vectorial function,

$$\mathbf{L}(\mathbf{x},\mathbf{y},\mathbf{t},\mathbf{u})=\begin{pmatrix} L(x,y,t,u) \\ L(x,0,t,u) \\ \left[\frac{\partial}{\partial y}L(x,y,t,u)\right]_{y=0} \\ \left[\frac{\partial^2}{\partial y^2}L(x,y,t,u)\right]_{y=0} \end{pmatrix}, \tag{A6}$$

G being known from $d\mu(\lambda)$, as well as its derivatives.

Thus, the generalization at $t\neq 0$ of the Gelfand–Levitan formulas is more complicated than a direct use of (3.38). Similar results, with similar remarks, apply in the even case.

ACKNOWLEDGMENTS

It is a pleasure for me to acknowledge the information that I received on previous studies of Korteweg–de Vries from Marco Boiti and Boris Konopelcenko, and the very helpful suggestions from the referee.

The Lanczos potential for vacuum space–times with an Ernst potential

P. Dolan[a] and B. D. Muratori[b]
Department of Mathematics, Huxley Building, Imperial College, 180 Queen's Gate, London SW7 2BZ, England

(Received 24 March 1998; accepted for publication 27 May 1998)

By a particular choice of tetrad and coordinate systems, we find the Lanczos potential for general vacuum stationary axisymmetric space–times and for general vacuum cylindrically symmetric solutions. This result is particularly elegant and unifies the treatment of the Lanczos potential and the Ernst potential for vacuum stationary axially symmetric and cylindrically symmetric space–times. The Lanczos potential for such large classes of vacuum space–times is expressed very simply in terms of spin-coefficients for a null tetrad. © *1998 American Institute of Physics.* [S0022-2488(98)00910-4]

I. INTRODUCTION

Let a space–time M endowed with a metric of signature $(+,-,-,-)$ with the usual Levi-Civita connection for covariant differentiation have the Riemann tensor defined as

$$v_{c;ab}-v_{c;ba}=R_{abc}{}^{h}v_{h}, \tag{1}$$

where $a,b,c,h=0,1,2,3$ and we can decompose the Riemann tensor into its irreducible parts as follows:

$$R_{abcd}=G_{abcd}+E_{abcd}+C_{abcd}, \tag{2}$$

where

$$G_{abcd}=\tfrac{1}{12}R(g_{ac}g_{bd}-g_{ad}g_{bc}), \tag{3}$$

$$E_{abcd}=\tfrac{1}{2}(g_{ac}S_{bd}+g_{bd}S_{ac}-g_{ad}S_{bc}-g_{bc}S_{ad}), \tag{4}$$

$$S_{ab}=R_{ab}-\tfrac{1}{4}Rg_{ab}, \tag{5}$$

$$R_{ab}=R_{ahb}{}^{h}, \quad R=R^{e}{}_{e}. \tag{6}$$

The tensor C_{abcd} is the Weyl conformal curvature tensor: It satisfies the same algebraic symmetries as the Riemann tensor and is traceless in all pairs of indices. Because G_{abcd} and E_{abcd} can both be shown to be derivable from simpler irreducible tensors with fewer indices, namely S_{ab} and R, Lanczos[1] thought he could make the Weyl tensor also derivable from a simpler tensor field. This tensor field is now known as the *Lanczos potential* and it satisfies the following index symmetries:

$$L_{abc}=-L_{bac}, \tag{7}$$

together with the algebraic conditions

$$L_{a}{}^{e}{}_{e}=0, \quad L_{abc}+L_{bca}+L_{cab}=0, \tag{8}$$

[a]Electronic mail: pdolan@ma.ic.ac.uk
[b]Electronic mail: b.muratori@ma.ic.ac.uk

 © 1998 American Institute of Physics

where the last two conditions (8) can be seen to be duals of each other on the first two indices ($L_a{}^e{}_e = {}^*L_a{}^e{}_e = 0$). We have thus reduced L_{abc} to at most 16 independent components but to have a perfect match with the Weyl tensor, Lanczos further suggested the imposition of the six equations

$$L_{ab}{}^e{}_{;e} = 0 \tag{9}$$

known as the *Lanczos differential gauge conditions* so as to have only ten effective degrees of freedom. For simplicity we follow the conventions and methods of Dolan and Kim[2,3] rather than Lanczos.[1]

The potential-field relations of the Lanczos potential to the Weyl tensor are

$$\begin{aligned} C_{abcd} = {} & L_{abc;d} - L_{abd;c} + L_{cda;b} - L_{cdb;a} \\ & + L_{(ad)}g_{bc} + L_{(bc)}g_{ad} - L_{(ac)}g_{bd} - L_{(bd)}g_{ac} + \tfrac{2}{3}L^{ef}{}_{e;f}(g_{ac}g_{bd} - g_{ad}g_{bc}), \end{aligned} \tag{10}$$

where $L_{bd} = L_b{}^c{}_{d;c} - L_b{}^c{}_{c;d}$, (10) are known as the *Weyl–Lanczos relations*.

With the introduction of such a potential tensor for the conformal curvature tensor Lanczos achieved in Eq. (10) the gravitational analogue of the potential 4-vector A_a for the electromagnetic field $F_{ab} = A_{a;b} - A_{b;a}$.

Starting with the 20 Bianchi identities

$$R_{abcd;e} + R_{abde;c} + R_{abec;d} = 0, \tag{11}$$

which decompose into the 4 irreducible equations

$$G^{ae}{}_{;e} = 0, \tag{12}$$

where

$$G_{ab} = R_{ab} - \tfrac{1}{2}Rg_{ab} \tag{13}$$

is the Einstein tensor, and the 16 irreducible equations

$$C_{abc}{}^e{}_{;e} = J_{abc}, \tag{14}$$

where

$$J_{abc} = R_{c[a;b]} - \tfrac{1}{6}g_{c[a}R_{;b]} \tag{15}$$

is known as the Schouten tensor. We see that, like the potential field L_{abc}, the tensor field J_{abc} is irreducible with at most 16 independent components because of its symmetries and only 10 effective degrees of freedom because of the six identities

$$J_{ab}{}^s{}_{;s} = 0. \tag{16}$$

We note that the right-hand side of (15) can be rewritten entirely in terms of covariant derivatives of the *irreducible* tensor field S_{ab}, i.e., the traceless part of Ricci and Einstein tensors.

If we substitute (10) into (14), we obtain the following tensor wave equation:[2]

$$\begin{aligned} & \Box L_{abc} + R^n{}_{asc}L_b{}^s{}_n - R^n{}_{bsc}L_a{}^s{}_n - R^n{}_{abs}L_n{}^s{}_c + R_{nc}L_{ab}{}^n \\ & \quad - R_{nb}L_c{}^n{}_a + R_{na}L_c{}^n{}_b + R^l{}_{bns}L_l{}^{ns}g_{ac} - R^l{}_{ans}L_l{}^{ns}g_{bc} = J_{abc}. \end{aligned} \tag{17}$$

Dolan and Kim[2] further simplified this wave equation and made it *linear* with the use of the following identity (valid only in four dimensions):

$$C^n{}_{asc}L_b{}^s{}_n - C^n{}_{bsc}L_a{}^s{}_n - C^n{}_{abs}L_n{}^b{}_c + C^m{}_{bns}L_m{}^{sn}g_{ac} - C^m{}_{ans}L_m{}^{sn}g_{bc} = 0, \tag{18}$$

resulting in

$$\Box L_{abc}+2R_c{}^s L_{abs}-R_a{}^s L_{bcs}+R_b{}^s L_{acs}-g_{ac}R^{ls}L_{lbs}+g_{bc}R^{ls}L_{las}-\tfrac{1}{2}RL_{abc}=J_{abc}. \tag{19}$$

In empty space, this wave equation reduces to the remarkably simple equation

$$\Box L_{abc}=0. \tag{20}$$

There are several ways of solving the Weyl–Lanczos relations, though none are ever as straightforward as one would like them to be. The three most familiar ways are by a method of general observers,[4] a method of Killing vectors[3] (not necessarily timelike), or the most obvious of all is a simple comparison of the Weyl–Lanczos relations (WL) with the Newman–Penrose (NP) field equations in order to try to identify some sort of equivalence between the spin coefficients and the Lanczos coefficients. This approach may be inappropriate and is not at all intuitive unless one has made an appropriate choice of tetrad, canonical or otherwise, where there are special relations between the spin coefficients and many of them are made to vanish. This is exactly what we aim to do in this paper. We want to show that, given the appropriate choice of tetrad, we can reduce the Lanczos coefficients (in the cases of stationary axial symmetry and cylindrical symmetry) to being simple combinations of the spin coefficients. We begin with a very quick review of some of the known ways of determining the Lanczos tensor for some space–times. It is hoped that, in finding the Lanczos potential for vacuum space–times with an Ernst potential, we can relate the two and thereby have a tensor form of the Ernst potential. The full physical significance of the Lanczos tensor is thought to lie in its suitability for the quantization of the gravitational field[5–7] in the same way as quantum electrodynamics relies on the electromagnetic four vector A_a. Just as the wave equation for the electromagnetic field is derivable from the wave equation for the electromagnetic four vector, so is the Penrose curved space wave equation for the Weyl tensor derivable from the wave equation for the Lanczos tensor (19). So both classical theories are formally consistent in the same way.

General observers. Solutions of the Lanczos potential can be found in tensor form through the method of general observers described by a unit timelike vector u_a (Ref. 4) as follows:

$$u^e u_e=1.$$

We define the electric and the magnetic parts of the Weyl tensor as

$$E_{ac}=C_{abcd}u^b u^d, \tag{21}$$

$$H_{ac}={}^*C_{abcd}u^b u^d=\tfrac{1}{2}\eta_{ab}{}^{ef}C_{efcd}u^b u^d, \tag{22}$$

where η_{abcd} is the completely antisymmetric Levi-Civita tensor, thus, both E_{ac} and H_{ac} are spacelike, symmetric and traceless, i.e.,

$$\begin{aligned} &E_{ac}=E_{ca}, \quad E_{ae}u^e=0, \quad E^e{}_e=0,\\ &H_{ac}=H_{ca}, \quad H_{ae}u^e=0, \quad H^e{}_e=0, \end{aligned} \tag{23}$$

and the relation which enables us to go back from these to the original Weyl tensor is

$$\begin{aligned} C_{abcd}=&2u_a u_c E_{bd}+2u_b u_d E_{ac}-2u_a u_d E_{bc}-2u_b u_c E_{ad}\\ &+g_{ad}E_{bc}+g_{bc}E_{ad}-g_{ac}E_{bd}-g_{bd}E_{ac}\\ &+\eta_{ab}{}^{pq}u_p u_d H_{qc}-\eta_{ab}{}^{pq}u_p u_c H_{qd}\\ &+\eta_{cd}{}^{pq}u_b u_p H_{aq}-\eta_{cd}{}^{pq}u_a u_p H_{bq}. \end{aligned} \tag{24}$$

The projection tensor h_{ab} is defined as

$$h_{ab}=g_{ab}-u_a u_b, \tag{25}$$

and has the following properties:

$$h_a{}^e h_{eb} = h_{ab}, \quad h_{ab} = h_{ba}, \quad h^e{}_e = 3, \quad h_{ae} u^e = 0.$$

The covariant derivative of u_a may now be separated into its irreducible parts

$$u_{a;b} = \sigma_{ab} + \tfrac{1}{3}\theta h_{ab} + \omega_{ab} + a_a u_b, \tag{26}$$

where the shear tensor is symmetric and traceless and is given by

$$\sigma_{ab} = h_a{}^e h_b{}^f u_{(e;f)} - \tfrac{1}{3}\theta h_{ab}, \tag{27}$$

the vorticity tensor is antisymmetric and is given by

$$\omega_{ab} = h_a{}^e h_b{}^f u_{[e;f]}, \tag{28}$$

the expansion is

$$\theta = u^e{}_{;e}, \tag{29}$$

the acceleration vector is

$$a_a = u_{a;e} u^e, \tag{30}$$

and all the subtensors $\sigma_{ab}, \omega_{ab}, a_a$ are spacelike, i.e.,

$$\sigma_{ae} u^e = 0, \quad \sigma^e{}_e = 0, \quad \omega_{ae} u^e = 0, \quad a_e u^e = 0. \tag{31}$$

The vorticity tensor is equivalent to a vorticity vector

$$\omega^a = \tfrac{1}{2}\eta^{aefg}\omega_{ef} u_g, \quad \Rightarrow \omega_{ab} = \eta_{abef}\omega^e u^f. \tag{32}$$

Using the three dynamical equations (33), (34), (35) and the three equations of constraint (36), (37), (38) obeyed by these four irreducible quantities, namely

$$\dot{\theta} + \frac{\theta^2}{3} + \sigma^2 - \omega^2 - a^e{}_{;e} = R_{gh} u^g u^h, \tag{33}$$

where $\dot{\theta} = \theta_{;e} u^e$, $\sigma^2 = \sigma_{ef}\sigma^{ef}$, $\omega^2 = \omega_{ef}\omega^{ef}$, known as Raychaudhuri's equation, together with

$$\begin{aligned} &h_a{}^e h_b{}^f \dot{\sigma}_{ef} - \tfrac{1}{3} h_{ab}(\sigma^2 - \omega^2 - a^h{}_{;h}) + a_a a_b - h_a{}^e h_b{}^f a_{(e;f)} + \tfrac{2}{3}\theta\sigma_{ab} + \sigma_{ae}\sigma^e{}_b + \omega_{ae}\omega^e{}_b \\ &\quad = R_{aebf} u^e u^f - \tfrac{1}{3} R_{ef} u^e u^f h_{ab}, \end{aligned} \tag{34}$$

where $\dot{\sigma}_{ab} = \sigma_{ab;e} u^e$, and

$$h_a{}^e h_b{}^f \dot{\omega}_{ef} - h_a{}^e h_b{}^f a_{[e;f]} + \tfrac{2}{3}\theta\omega_{ab} + \sigma_{ae}\omega^e{}_b - \sigma_{be}\omega^e{}_a = 0, \tag{35}$$

where $\dot{\omega}_{ab} = \omega_{ab;e} u^e$, governing the behavior of the shear and the vorticity, and

$$\tfrac{2}{3}\theta_{,e} h^e{}_a - (\sigma^f{}_e + \omega^f{}_e)_{;f} h^e{}_a - a^e(\sigma_{ae} + \omega_{ae}) = R_{ef} u^e h^f{}_a, \tag{36}$$

$$\omega^e{}_{;e} + 2\omega^e a_e = 0, \tag{37}$$

$$h_{(a}{}^e h_{b)}{}^f \eta_e{}^{ghi} u_i (\sigma_{fg} + \omega_{fg})_{;h} + a_{(a}\omega_{b)} = H_{ab}, \tag{38}$$

Novello and Velloso have shown that the Lanczos tensors of several space–times are also expressible in terms of these quantities, the only restriction being that the space–time has to be a perfect fluid[8] with

$$T_{ab} = \rho u_a u_b - p h_{ab}. \tag{39}$$

Their results correspond to the following three lemmas which we quote below.

Lemma 1: If in a given space–time, there is a field of observers u^a that is shear-free irrotational and expansion-free ($\sigma_{ab}=\omega_{ab}=\theta=0$), *then the Lanczos potential is given by*

$$L_{abc}=a_a u_b u_c-a_b u_a u_c-\tfrac{1}{3}(a_a g_{bc}-a_b g_{ac}). \tag{40}$$

Lemma 2: If in a given space–time there is a field of observers u^a which is geodetic and irrotational ($a_a=\omega_{ab}=0$), *and such that either*
$H_{ab}\neq 0$ *and*

$$(i)\quad \sigma_a{}^e\sigma_{eb}-\sigma^2 h_{ab}-\tfrac{1}{3}\theta\sigma_{ab}=0, \tag{41}$$

or $H_{ab}=0$ *and*

$$(ii)\quad \dot{\sigma}_{ab}+\theta\sigma_{ab}=0, \tag{42}$$

then the Lanczos potential is given by

$$(i)\quad L_{abc}=\sigma_{ac}u_b-\sigma_{bc}u_a\,, \tag{43}$$

and

$$(ii)\quad L_{abc}=\tfrac{1}{3}(\sigma_{ac}u_b-\sigma_{bc}u_a), \tag{44}$$

respectively.

Lemma 3: If in a given space–time there is a field of observers u^a which is geodetic, shear-free and expansion-free such that the vorticity vector ω_a is covariantly constant

$$\omega_{a;b}=0, \tag{45}$$

then the Lanczos potential is given by

$$L_{abc}=\tfrac{1}{9}[2\omega_{ab}u_c+\omega_{ac}u_b-\omega_{bc}u_a]. \tag{46}$$

A fourth lemma was introduced by Dolan and Kim[3] and consists of a generalization of the first lemma above to any vacuum space–time with a hypersurface-orthogonal Killing vector.

Lemma 4: If a given space–time has a non-null hypersurface-orthogonal Killing vector K_a, $K_{[a;b}K_{c]}=0$, *and,*

$$u_a=\frac{K_a}{K},\quad K=\sqrt{K^eK_e},\quad u^eu_e=\epsilon,\quad \epsilon=\pm 1,$$

then the Lanczos tensor is given by

$$L_{abc}=a_a u_b u_c-a_b u_a u_c-\tfrac{1}{3}\epsilon(a_a g_{bc}-a_b g_{ac}). \tag{47}$$

Using *Lemmas 1* and *4* Dolan and Kim[3] were able to produce two Lanczos tensors for the Schwarzschild space–time, the difference between the two being attributable to a gauge transformation. Also, using *Lemma 4*, they found a Lanczos tensor for the Bondi axially symmetric space–time[9] which is exact and not approximate or given asymptotically.

Now Ernst[10,11] together with Plebañski[12] in examining the work of Papapetrou[13] on stationary axisymmetric space–times have introduced a complex potential $\mathscr{E}$ related to the norm K^2 and the vorticity vector associated with the timelike Killing vector K_a,[14]

$$\mathscr{E}_{,a}=2K^s(K_{s;a}+\tfrac{1}{2}i\,\eta_{astu}K^{t;u}). \tag{48}$$

This should give a very wide class of vacuum space–times for which to generate Lanczos potentials in a straightforward manner.

II. STATIONARY AXIALLY SYMMETRIC VACUUM SPACE–TIMES

The line element for stationary axisymmetric space–times can be expressed as follows in Weyl canonical coordinates (t,φ,ρ,z), and signature $(+,-,-,-)$:

$$ds^2=f(dt-wd\varphi)^2-f^{-1}[P^{-2}(d\rho^2+dz^2)+R^2d\varphi^2], \tag{49}$$

where f, P, R and w are functions of ρ and z only.

For a comprehensive review of the definitions of axisymmetric space–times together with the vacuum field equations we refer the reader to Ref. 15. We can introduce four orthogonal 1-forms in order to describe the line element (49) as follows:[16]

$$\begin{aligned}\sigma^1&=f^{1/2}(dt-wd\varphi),\quad \sigma^2=f^{-1/2}Rd\varphi,\\ \sigma^3&=f^{-1/2}P^{-1}d\rho,\quad \sigma^4=f^{-1/2}P^{-1}dz,\end{aligned} \tag{50}$$

$$g_{ab}dx^adx^b=(\sigma^1)^2-(\sigma^2)^2-(\sigma^3)^2-(\sigma^4)^2. \tag{51}$$

From (50), we can define a conventional null tetrad system

$$\begin{aligned}l_a&=(1/\sqrt{2})(f^{1/2},-(f^{-1/2}R+f^{1/2}w),0,0)=(1/\sqrt{2})(\sigma^1-\sigma^2),\\ n_a&=(1/\sqrt{2})(f^{1/2},f^{-1/2}R-f^{1/2}w,0,0)=(1/\sqrt{2})(\sigma^1+\sigma^2),\\ m_a&=(1/\sqrt{2})f^{-1/2}P^{-1}(0,0,1,i)=(1/\sqrt{2})(\sigma^3+i\sigma^4),\\ \overline{m}_a&=(1/\sqrt{2})f^{-1/2}P^{-1}(0,0,1,-i)=(1/\sqrt{2})(\sigma^3-i\sigma^4).\end{aligned} \tag{52}$$

Stationary axially symmetric space–times are best described in terms of their Ernst potential $\mathscr{E}$ explained below. If we consider a coordinate transformation on (49) to prolate spheroidal coordinates of the form

$$\rho=k(x^2-1)^{1/2}(1-y^2)^{1/2}, \tag{53}$$

$$z=kxy, \tag{54}$$

where k is an arbitrary constant, then the line element becomes

$$ds^2=f(dt-wd\varphi)^2-\frac{1}{f}\left[P^{-2}\left(\frac{dx^2}{x^2-1}+\frac{dy^2}{1-y^2}\right)+R^2d\varphi^2\right]. \tag{55}$$

Ernst[10,11] showed that the field equations governing the gravitational field of a uniformly rotating axially symmetric source may be derived from a single potential $\mathscr{E}$, now known as the Ernst potential. The expression of the metric functions in terms of the Ernst potential can be described as follows.

We rewrite f in terms of two complex functions $\hat{\alpha}$ and $\hat{\beta}$,

$$f=\frac{\hat{\alpha}\overline{\hat{\alpha}}-\hat{\beta}\overline{\hat{\beta}}}{(\hat{\alpha}+\hat{\beta})(\overline{\hat{\alpha}}+\overline{\hat{\beta}})}, \tag{56}$$

$$P^2=\frac{\hat{P}^2}{\hat{\alpha}\overline{\hat{\alpha}}-\hat{\beta}\overline{\hat{\beta}}}, \tag{57}$$

where $\hat{P}=\hat{P}(x,y)$, $\hat{\alpha}=\hat{\alpha}(x,y)$, $\hat{\beta}=\hat{\beta}(x,y)$, and neither $\hat{\alpha}$ nor $\hat{\beta}$ bear any relation to the NP spin coefficients. If we now consider the function $\mathscr{E}$, defined below

$$\mathscr{E}=\frac{\hat{\alpha}-\hat{\beta}}{\hat{\alpha}+\hat{\beta}}, \tag{58}$$

we see that this can be rewritten as

$$\mathscr{E}=\frac{(\hat{\alpha}-\hat{\beta})(\overline{\hat{\alpha}}+\overline{\hat{\beta}})}{(\hat{\alpha}+\hat{\beta})(\overline{\hat{\alpha}}+\overline{\hat{\beta}})}=\frac{\hat{\alpha}\overline{\hat{\alpha}}-\hat{\beta}\overline{\hat{\beta}}}{(\hat{\alpha}+\hat{\beta})(\overline{\hat{\alpha}}+\overline{\hat{\beta}})}+\frac{\hat{\alpha}\overline{\hat{\beta}}-\hat{\beta}\overline{\hat{\alpha}}}{(\hat{\alpha}+\hat{\beta})(\overline{\hat{\alpha}}+\overline{\hat{\beta}})}, \tag{59}$$

and so we can write the defining equation of f in terms of $\mathscr{E}$ as

$$f=\mathrm{Re}[\mathscr{E}]=\mathrm{Re}\left[\frac{\hat{\alpha}-\hat{\beta}}{\hat{\alpha}+\hat{\beta}}\right]=\mathrm{Re}\left[\frac{\xi-1}{\xi+1}\right], \tag{60}$$

where $\mathscr{E}$ is the Ernst potential and the function $\xi=\hat{\alpha}/\hat{\beta}$ is a related potential which is often simpler to use.

The remaining functions w, R, and P in the metric can be best looked at if we go back to cylindrical coordinates and redefine P as being an exponential by

$$P=e^{\hat{\gamma}},$$

where $\hat{\gamma}=\hat{\gamma}(x,y)$, and the metric now is

$$ds^2=f(dt-wd\varphi)^2-f^{-1}[e^{-2\hat{\gamma}}(d\rho^2+dz^2)+R^2d\varphi^2]. \tag{61}$$

In this notation, Ernst[10,11] showed that the remaining functions satisfy the following differential equations:

$$\frac{\partial w}{\partial \rho}=-\frac{2\rho}{(\xi\overline{\xi}-1)^2}\,\mathrm{Im}\left[(\overline{\xi}+1)^2\,\frac{\partial \xi}{\partial z}\right], \tag{62}$$

$$\frac{\partial w}{\partial z}=-\frac{2\rho}{(\xi\overline{\xi}-1)^2}\,\mathrm{Im}\left[(\overline{\xi}+1)^2\,\frac{\partial \xi}{\partial \rho}\right], \tag{63}$$

$$\frac{\partial \gamma}{\partial \rho}=\frac{\rho}{(\xi\overline{\xi}-1)^2}\left[\frac{\partial \xi}{\partial \rho}\frac{\partial \overline{\xi}}{\partial \rho}-\frac{\partial \xi}{\partial z}\frac{\partial \overline{\xi}}{\partial z}\right], \tag{64}$$

$$\frac{\partial \gamma}{\partial z}=\frac{2\rho}{(\xi\overline{\xi}-1)^2}\,\mathrm{Re}\left[\frac{\partial \xi}{\partial \rho}\frac{\partial \overline{\xi}}{\partial z}\right]. \tag{65}$$

Thus any stationary axially symmetric line element can be fully described (up to constants of integration) by (60)–(65), and from now on we can consider the Ernst potential as defining the whole space–time in question.

Ernst[16] and Höenselaers[17] further showed that the Weyl scalars for all vacuum stationary axially symmetric space–times are given by

$$\Psi_0=\frac{1}{8}\left[2\eth\eth\mathscr{E}+\frac{1}{f}\,(\eth\mathscr{E})^2\right], \tag{66}$$

$$\Psi_2=-\frac{1}{8}\left[-2\eth^*\eth\mathscr{E}+\frac{1}{f}\,(\eth\mathscr{E})(\eth^*\mathscr{E})\right], \tag{67}$$

$$\Psi_4=\frac{1}{8}\left[2\eth^*\eth^*\mathscr{E}+\frac{1}{f}\,(\eth^*\mathscr{E})^2\right], \tag{68}$$

$$\Psi_1=\Psi_3=0, \tag{69}$$

where the differential operator $\eth$ is defined as follows:

Given a field η of spin weight s we have

$$\eth\eta=P^{1-s}\nabla(P^s\eta), \quad \eth^*\eta=P^{1+s}\nabla^*(P^{-s}\eta), \tag{70}$$

and in the ρ, z coordinate system we had earlier $\nabla=\partial/\partial\rho+i\,\partial/\partial z$ and ∇^* is its complex conjugate.

Thus the operators $\eth$ and $\eth^*$ raise and lower the spin-weight by one, respectively. In our case *the Ernst potential $\mathscr{E}$ is of spin-weight* 0. It should be noted that, though related to the operator $\eth$ as defined by Penrose,[18] this operator is to be considered as completely distinct.

Using the formalism developed above, it is also possible to give the Newman–Penrose spin coefficients *almost entirely* in terms of derivatives of the Ernst potential,[16]

$$\alpha=-\frac{1}{2\sqrt{2}}f^{1/2}\eth(\ln P)-\frac{1}{4\sqrt{2}}f^{-1/2}\eth\mathscr{E}, \tag{71}$$

$$\beta=\frac{1}{\sqrt{2}}f^{1/2}\eth^*(\ln P)+\frac{1}{4\sqrt{2}}f^{-1/2}\eth^*\mathscr{E}, \tag{72}$$

$$\kappa=-\frac{1}{2\sqrt{2}}f^{1/2}R^{-1}\eth R+\frac{1}{2\sqrt{2}}f^{-1/2}\eth\mathscr{E}, \tag{73}$$

$$\nu=\frac{1}{2\sqrt{2}}f^{1/2}R^{-1}\eth^*R-\frac{1}{2\sqrt{2}}f^{-1/2}\eth^*\mathscr{E}, \tag{74}$$

$$\tau=\frac{1}{2\sqrt{2}}f^{1/2}R^{-1}\eth R, \tag{75}$$

$$\pi=-\frac{1}{2\sqrt{2}}f^{1/2}R^{-1}\eth^*R. \tag{76}$$

It should be noted that because only Ψ_0, Ψ_2 and Ψ_4 can be nonzero, stationary axially symmetric space–times can only be Petrov types I, II, D or N.

A. Construction of the Lanczos tensor

Because of our choice of tetrad, and the fact that the metric components depend only on two variables (ρ and z), we were able to discard any terms involving the D or the Δ operators in the Newman–Penrose[19] field equations as well as being helped by the vanishing of six of the spin coefficients. Following the method introduced by Sibgatulin,[20] of expressing the Weyl scalars solely in terms of spin coefficients and their derivatives, we were able to express the field equations in the following form:

$$\epsilon=\gamma=\sigma=\lambda=\rho=\mu=0, \quad \tau=-\overline{\pi}, \tag{77}$$

$$\begin{aligned} D\zeta&=\frac{1}{\sqrt{2}}\left[(f^{-1/2}+f^{1/2}\omega R^{-1})\frac{\partial}{\partial t}+f^{1/2}R^{-1}\frac{\partial}{\partial\varphi}\right]\zeta=0, \quad \forall\zeta=\zeta(\rho,z),\\ \Delta\zeta&=\frac{1}{\sqrt{2}}\left[(f^{-1/2}-f^{1/2}\omega R^{-1})\frac{\partial}{\partial t}-f^{1/2}R^{-1}\frac{\partial}{\partial\varphi}\right]\zeta=0, \quad \forall\zeta=\zeta(\rho,z), \end{aligned} \tag{78}$$

$$\Psi_0=-(\delta-3\beta-\tau-\overline{\alpha}+\overline{\pi})\kappa, \tag{79}$$

$$\Psi_2=(\overline{\delta}+\overline{\beta}-\overline{\tau}-\alpha)\tau+\kappa\nu, \tag{80}$$

$$\Psi_2=(-\delta+\overline{\alpha}-\overline{\pi}-\beta)\pi+\kappa\nu, \tag{81}$$

$$\Psi_4=(\overline{\delta}+\pi-\overline{\tau}+3\alpha+\overline{\beta})\nu, \tag{82}$$

$$\Psi_2=\nu\kappa-\tau\pi, \tag{83}$$

$$\Psi_1=\Psi_3=0. \tag{84}$$

We now examine the Weyl–Lanczos relations in scalar form as given by Dolan and Kim[3] including a factor of (-1) on the left-hand side which had been erroneously omitted, giving the gauge conditions $L_{ab}{}^{e}{}_{;e}=0$ separately,

$$-\tfrac{1}{2}\Psi_0=DL_4-(\delta-3\beta-\overline{\alpha}+\overline{\pi})L_0+3\kappa L_5, \tag{85}$$

$$-2\Psi_1=3DL_5-3(\delta-\beta-\overline{\alpha}+\overline{\pi})L_1-3\pi L_4+6\kappa L_6+(\overline{\delta}-3\alpha+\overline{\beta}-\overline{\tau})L_4-\Delta L_0-3\tau L_1, \tag{86}$$

$$-\Psi_2=DL_6-(\delta+\beta-\overline{\alpha}+\overline{\pi})L_2-2\pi L_5+\kappa L_7+(\overline{\delta}-\alpha+\overline{\beta}-\overline{\tau})L_5-\Delta L_1+\nu L_0-2\tau L_2, \tag{87}$$

$$-2\Psi_3=3(\overline{\delta}+\alpha+\overline{\beta}-\overline{\tau})L_6-3\Delta L_2+6\nu L_1-3\tau L_3+DL_7-(\delta+3\beta-\overline{\alpha}+\overline{\pi})L_3-3\pi L_6, \tag{88}$$

$$-\tfrac{1}{2}\Psi_4=(\overline{\delta}+3\alpha+\overline{\beta}-\overline{\tau})L_7-\Delta L_3+3\nu L_2, \tag{89}$$

where

$$\begin{gathered}\Psi_0=C_{abcd}l^a m^b l^c m^d,\quad \Psi_1=C_{abcd}l^a m^b l^c n^d,\quad \Psi_2=C_{abcd}l^a m^b \overline{m}^c n^d,\\ \Psi_3=C_{abcd}l^a n^b \overline{m}^c n^d,\quad \Psi_4=C_{abcd}\overline{m}^a n^b \overline{m}^c n^d,\end{gathered} \tag{90}$$

$$\begin{gathered}L_0=L_{abc}l^a m^b l^c,\quad L_1=L_{abc}l^a m^b \overline{m}^c,\quad L_2=L_{abc}\overline{m}^a n^b l^c,\\ L_3=L_{abc}\overline{m}^a n^b \overline{m}^c,\quad L_4=L_{abc}l^a m^b m^c,\quad L_5=L_{abc}l^a m^b n^c,\\ L_6=L_{abc}\overline{m}^a n^b m^c,\quad L_7=L_{abc}\overline{m}^a n^b n^c.\end{gathered} \tag{91}$$

The gauge conditions are

$$DL_5-(\delta-\beta-\overline{\alpha}+\overline{\pi}-3\tau)L_1+2\kappa L_6-(\overline{\delta}-3\alpha+\overline{\beta}-\overline{\tau}+\pi)L_4+\Delta L_0=0, \tag{92}$$

$$DL_6-(\delta+\beta-\overline{\alpha}+\overline{\pi}-2\tau)L_2+\kappa L_7-(\overline{\delta}-\alpha+\overline{\beta}-\overline{\tau}+2\pi)L_5+\Delta L_1-\nu L_0=0, \tag{93}$$

$$(\overline{\delta}+\alpha+\overline{\beta}-\overline{\tau}+3\pi)L_6-\Delta L_2+2\nu L_1-DL_7+(\delta+3\beta-\overline{\alpha}+\overline{\pi}-\tau)L_3=0. \tag{94}$$

Because all the tensors involved depend only on the two coordinates ρ and z, we can reasonably assume the same for the Lanczos scalars $L_0,\ldots,L_7$, hence, $DL_n=\Delta L_n=0$ for $n=0-7$. Four equations [(86), (88), (92), (94)] may be solved by setting $L_1=L_4=L_6=L_3=0$, thus leaving us with four equations [(85), (87), (89), (93)] still to be satisfied. There are only five relevant NP equations required to do this, namely (79), (80), (81), (82) and the purely algebraic relation (83). Again, Eqs. (85) and (89) can be solved by comparison with the NP equations and we can then verify that this solution is also in agreement with (87) and (93) thus giving us the simple answer

$$\begin{gathered}L_0=-\tfrac{1}{2}\kappa,\quad L_5=-\tfrac{1}{6}\tau,\\ L_7=-\tfrac{1}{2}\nu,\quad L_2=-\tfrac{1}{6}\pi.\end{gathered} \tag{95}$$

To illustrate (95), we give some well-known examples of stationary axially symmetric vacuum space–times, but it should be stressed that all line elements which can be written in the form (55) and satisfy the vacuum Einstein equations will have (95) as a solution for their Lanczos tensor to within a gauge transformation.

B. Tomimatsu–Sato, Kerr and Schwarzschild solutions

If we now return to the equation for axially symmetric stationary line elements (55), we can obtain various well-known space–times via specification of the Ernst potential $\mathscr{E}$. We can write the associated function ξ in a general way as

$$\xi=\frac{\hat{\alpha}(x,y;p,q,\delta)}{\hat{\beta}(x,y;p,q,\delta)}, \tag{96}$$

where δ is a constant (not necessarily an integer) and both the functions $\hat{\alpha}$ and $\hat{\beta}$ can be given in terms of polynomials of order δ^2 and δ^2-1, respectively, and p and q are scalar polynomials in δ satisfying the following algebraic relation:

$$p^2+q^2=1.$$

Thus both the functions $\hat{\alpha}$ and $\hat{\beta}$ can be expressed in terms of polynomials in x, y, p and q for various values of δ as follows:

1. $\delta=1$

$$\hat{\alpha}=px-iqy, \quad \hat{\beta}=1, \tag{97}$$

$$\xi=px-iqy, \tag{98}$$

so f is determined by (56) or (60) and $e^{\hat{\gamma}}$ is given by

$$e^{\hat{\gamma}}=\frac{A[x^2p^2+q^2y^2-1]}{x^2-y^2}, \tag{99}$$

where A is an arbitrary constant of integration of (65) and (64). w is given by

$$w=\frac{2qp^{-1}(1-y^2)(px+1)}{x^2p^2+q^2y^2-1}+w_0, \tag{100}$$

where w_0 is again a constant of integration of (62) and (63).

This choice of ξ gives us the Kerr metric[21] in prolate spheroidal coordinates and the Lanczos tensor is then given by

$$L_5=-\tfrac{1}{6}\tau, \quad L_2=-\tfrac{1}{6}\pi. \tag{101}$$

The reasons for this simple solution lie entirely in the choice of coordinates and of tetrad. Had we decided, for example, to use more well known coordinates such as the Boyer–Lindquist coordinates[22] for the Kerr metric, together with the Kinnersley tetrad,[23] things would not have simplified themselves in the desired manner and Eq. (78) would not have been satisfied. We also note that, due to (77), the solution of the Lanczos tensor for the Kerr metric only depends on one of the spin coefficients π or τ.

The Schwarzschild solution is contained as the nonrotating subset of the above solution; this is most easily seen if we transform (98) to the better known Boyer–Lindquist coordinates mentioned above via the following local coordinate transformation:[15]

$$px+1=\frac{r}{m}, \quad qy=\frac{a}{m}\cos\,\theta, \quad \varphi'=\varphi, \quad t'=t. \tag{102}$$

And the Schwarzschild solution is given by the $a=0$ case of (102), or, equivalently $q=0$.

2. $\delta=2$

$$\hat{\alpha}=p^2x^4+q^2y^4-1-2ipqxy(x^2-y^2), \quad \hat{\beta}=2px(x^2-1)-2iqy(1-y^2), \tag{103}$$

$$\xi=\frac{p^2x^4+q^2y^4-1-2ipqxy(x^2-y^2)}{2px(x^2-1)-2iqy(1-y^2)}. \tag{104}$$

Because of the increasing complexity of the Ernst function, ξ, and all the surrounding equations, it is profitable to introduce three new functions A, B, and C which enable us to write f, w, and $e^{\hat{\gamma}}$ as

$$f=\frac{A}{B}, \quad w=\frac{2p^{-1}q(1-y^2)C}{A}, \quad e^{\hat{\gamma}}=\frac{A}{p^4(x^2-y^2)^4}, \tag{105}$$

where

$$A=[p^2(x^2-1)^2+q^2(1-y^2)^2]^2-4p^2q^2(x^2-1)(1-y^2)(x^2-y^2)^2, \tag{106}$$

$$B=(p^2x^4+q^2y^4-1+2px^3-2px)^2+4q^2y^2(px^3-pxy^2+1-y^2)^2, \tag{107}$$

$$\begin{aligned}C=&p^2(x^2-1)[(x^2-1)(1-y^2)-4x^2(x^2-y^2)]\\&-p^3x(x^2-1)[2(x^4-1)+(x^2+3)(1-y^2)+q^2(1+px)(1-y^2)^2].\end{aligned} \tag{108}$$

This choice of Ernst potential leads to the well known $\delta=2$ Tomimatsu–Sato[24,25] solution which is algebraically general and is thought to describe the field of a spinning mass with a ring singularity on the equatorial plane outside the event horizon as well as inside it (as is the case for the Kerr metric). The Lanczos potential may be computed from (95) and has all four Lanczos scalars nonvanishing.

3. General integer δ

Tomimatsu and Sato[25] gave an approximate expression for the function ξ for any integer value of δ in the limit $q\ll 1$,

$$\xi\simeq\frac{(x+1)^\delta+(x-1)^\delta}{(x+1)^\delta-(x-1)^\delta}+iq\xi_1(x,y)+\cdots, \tag{109}$$

and

$$\xi_1(x,y)=\frac{1}{[(x+1)^\delta-(x-1)^\delta]^2}\sum_{l=1}^{\delta}a_{2l-1}(x)P_{2l-1}(y), \tag{110}$$

where $P_l(y)$ is a Legendre polynomial and $a_l(x)$ is a polynomial of at most order $2\delta-l-1$ and satisfying the following differential equation:

$$(x^2-1)\frac{d^2a_l}{dx^2}-(4\delta-2)x\frac{da_l}{dx}+(4\delta^2-l(l+1))a_l=0, \tag{111}$$

and $e^{\hat{\gamma}}$ is given by

$$e^{\hat{\gamma}}=\frac{A}{p^{2\delta}(x^2-y^2)^{\delta^2}}. \tag{112}$$

Again the Lanczos scalars may be computed in terms of (95). It is interesting to notice that for the case $q=0$, all the Tomimatsu solutions with the Ernst potential given above reduce to the Weyl–Papapetrou solutions, where we only have the first term in the expansion of ξ in Eq. (109) above, namely

$$\xi=\frac{(x+1)^{\delta}+(x-1)^{\delta}}{(x+1)^{\delta}-(x-1)^{\delta}}. \tag{113}$$

Recently, Hori[26–29] further generalized the Tomimatsu–Sato solutions to include the cases of *noninteger* δ as well as the cases where δ is *complex*. Hori found that *only* the cases where the deformation parameter δ is an integer lead to asymptotic flatness. The Weyl–Lanczos relations in these cases are also solved by the Lanczos scalars (95). We note that the solution (95) is also valid in nonempty space–times provided $\Phi_{11}=\Lambda=0$.

C. *C*-metric

To see that the *C*-metric is also a stationary axially symmetric metric and that therefore the appropriate nonvanishing Lanczos scalars may be given by (95), we first have to consider a coordinate transformation. We start with the line element as[30]

$$ds^2=A^{-2}(x+y)^{-2}\left[Fdt^2-\frac{1}{F}\,dy^2-\frac{1}{G}\,dx^2-Gdp^2\right], \tag{114}$$

in coordinates (t,x,y,p), signature $(+,-,-,-)$, and where

$$F=-1+y^2-2mAy^3, \quad G=1-x^2-2mAx^3, \tag{115}$$

and m and A are constants, then consider a transformation of the form

$$z=A^{-2}(x+y)^{-2}[1+mAxy(x-y)+xy], \tag{116}$$

$$r=A^{-2}(x+y)^{-2}F^{1/2}G^{1/2}, \tag{117}$$

and $\varphi=p$, $t=t$. This gives us the line element

$$ds^2=e^{\mu}dt^2-r^2e^{-\mu}d\varphi^2-e^{\omega}(dz^2+dr^2), \tag{118}$$

where ω and μ are functions of z and r.

We recognize this line element as being of the form (49) and thus stationary axially symmetric. And so the Lanczos scalars will be given by (95).

III. VACUUM CYLINDRICALLY SYMMETRIC SPACE–TIMES

We can find the solution for the Lanczos tensor-potential in a cylindrically symmetric space–time in a way analogous to the one we followed in finding the solution for stationary axially symmetric space–times in Sec. II. The line element for these space–times is[14]

$$ds^2=f^{-1}[e^{2\hat{\gamma}}(dt^2-dr^2)-r^2d\varphi^2]-f(dz-wd\varphi)^2, \tag{119}$$

in coordinates (t,r,φ,z) and signature $(+,-,-,-)$ and where f, $\hat{\gamma}$, w are all functions of r only.

We choose our tetrad to be

$$\begin{aligned} l_a&=(1/\sqrt{2})f^{-1/2}e^{\hat{\gamma}}(1,1,0,0),\\ n_a&=(1/\sqrt{2})f^{-1/2}e^{\hat{\gamma}}(1,-1,0,0),\\ m_a&=(1/\sqrt{2})(0,0,f^{-1/2}r+if^{1/2}w,-if^{1/2}),\\ \overline{m}_a&=(1/\sqrt{2})(0,0,f^{-1/2}r-if^{1/2}w,if^{1/2}). \end{aligned} \tag{120}$$

In this frame, the spin coefficients and the Weyl scalars satisfy

$$\alpha=\beta=\kappa=\nu=\tau=\pi=0, \quad \rho=\overline{\rho}, \quad \mu=\overline{\mu}, \tag{121}$$

and

$$\Psi_1=\Psi_3=0. \tag{122}$$

Construction of the Lanczos tensor. Following (120), it is also possible to show

$$\delta\zeta=\overline{\delta}\zeta=0, \quad \forall\,\zeta=\zeta(t,r). \tag{123}$$

Therefore the Newman–Penrose field equations[19] reduce, *in vacuo*, to

$$\Psi_0=D\sigma+(\rho+\overline{\rho}+\overline{\epsilon}-3\epsilon)\sigma, \tag{124}$$

$$\Psi_2=D\mu+(\epsilon+\overline{\epsilon}-\overline{\rho})\mu)-\sigma\lambda, \tag{125}$$

$$\Psi_2=-\Delta\rho+(\gamma+\overline{\gamma}-\overline{\mu})-\sigma\lambda, \tag{126}$$

$$\Psi_4=-\Delta\lambda-(\mu+\overline{\mu}-\overline{\gamma}+3\gamma)\lambda, \tag{127}$$

$$\Psi_2=\mu\rho-\sigma\lambda, \tag{128}$$

$$\Psi_1=\Psi_3=0. \tag{129}$$

The Weyl–Lanczos relations, when all the vanishing quantities have been removed, become

$$-\tfrac{1}{2}\Psi_0=(D-3\epsilon+\overline{\epsilon}-\overline{\rho})L_4-3\sigma L_1, \tag{130}$$

$$-\tfrac{1}{2}\Psi_2=(D+\epsilon+\overline{\epsilon}-\overline{\rho})L_6+2\mu L_1-\sigma L_3, \tag{131}$$

$$-\tfrac{1}{2}\Psi_2=-(\Delta-\gamma-\overline{\gamma}+\overline{\mu})L_1-\lambda L_4+2\rho L_6, \tag{132}$$

$$-\tfrac{1}{2}\Psi_4=-(\Delta+3\gamma-\overline{\gamma}+\overline{\mu})L_3-3\lambda L_6, \tag{133}$$

where we have already assumed that we can apply condition (123) to the Lanczos scalars and we have set L_0, L_2, L_4, and L_7 to zero in order to satisfy all equations involving Ψ_1 and Ψ_3 trivially. We are thus left with a strictly analogous system of equations to (79)–(84) and (85)–(89) whose solution is

$$\begin{aligned} &L_4=-1/2\sigma, \quad L_1=-1/6\rho, \\ &L_3=-1/2\lambda, \quad L_6=-1/6\mu. \end{aligned} \tag{134}$$

IV. CONCLUSION

We have given a closed form for the Lanczos tensor for some space–times with an Ernst potential. Through the completeness relation

$$L_{abc}=T_{abc}+\overline{T}_{abc}, \tag{135}$$

between the Lanczos tensor and the Lanczos scalars where

$$\begin{aligned} T_{abc}=&L_0U_{ab}n_c+L_1(M_{ab}n_c-U_{ab}m_c) \\ &+L_2(V_{ab}n_c-M_{ab}m_c)-L_3V_{ab}m_c \\ &-L_4U_{ab}\overline{m}_c+L_5(U_{ab}l_c-M_{ab}\overline{m}_c)+L_6(M_{ab}l_c-V_{ab}\overline{m}_c)+L_7V_{ab}l_c, \end{aligned} \tag{136}$$

and

$$\begin{aligned} &V_{ab}=l_am_b-l_bm_a, \quad U_{ab}=-n_a\overline{m}_b+n_b\overline{m}_a, \\ &M_{ab}=l_an_b-l_bn_a+m_a\overline{m}_b-m_b\overline{m}_a, \end{aligned} \tag{137}$$

we can express the Weyl tensor as coming from a three index tensor L_{abc}.

We note that our solution (95) is not entirely expressible in terms of the Ernst potential. This is due to the presence of the R^2 factor (respectively, r^2 for cylindrical symmetry) in g_{33}, without which we would have had $\tau=\pi=0$ (respectively, $\rho=\mu=0$) and so the Lanczos scalars would have been entirely expressible in terms of derivatives of the Ernst potential as follows:

$$L_0=\frac{1}{4\sqrt{2}}\,f^{-1/2}\eth\mathscr{E},\quad L_7=\frac{1}{4\sqrt{2}}\,f^{-1/2}\eth^*\mathscr{E}, \tag{138}$$

with corresponding expressions for the cylindrically symmetric case. In many articles in the literature (see, e.g., Refs. 31 and 32) the factor of R^2 (respectively, r^2) is set to one for simplicity since it has to satisfy Laplace's equation.

Future work includes examining whether the Ernst potential is still related to the Lanczos potential, in a similar way to the above description, in more general cases, namely those with metric,

$$g_{ab}=\begin{pmatrix} f & -f\omega_1 & -f\omega_2 & -f\omega_3 \\ -f\omega_1 & f\omega_1^2-f^{-1} & f\omega_1\omega_2 & f\omega_1\omega_3 \\ -f\omega_2 & f\omega_1\omega_2 & f\omega_2^2-f^{-1} & f\omega_2\omega_3 \\ -f\omega_3 & f\omega_1\omega_3 & f\omega_2\omega_3 & f\omega_3^2-f^{-1} \end{pmatrix}, \tag{139}$$

where the functions f and ω_α, $\alpha=1,2,3$ depend on all three space variables only and not the time. These spacetimes are no longer axially symmetric, but only stationary, though, as indicated earlier, an Ernst potential may still be defined for them.[32]

Static stringlike solutions in five-dimensional relativity

Pierre Gravel[a)]

(Received 5 November 1997; accepted for publication 3 June 1998)

We exhibit a family of static cylindrically symmetric solutions to $(4+1)$ Kaluza–Klein gravity which are separable functions of the spatial radial coordinate $x^2=r$ and the extra coordinate $x^5=\psi$. These contain solutions other than radiative and, when interpreted as string solutions, display behaviors which differ from the standard $(3+1)$-dimensional static strings. All of those solutions with nonvanishing mass density obey the relativistic matter equation of state. © *1998 American Institute of Physics.* [S0022-2488(98)02010-6]

I. INTRODUCTION

In this paper, the conventions about the metric, curvature tensor, and indices will be those of the book by Adler *et al.*[1] and the work of Wesson *et al.* (see Ref. 2 and references therein). In particular, the metric is of signature $(+,-,-,-,\pm)$, greek indices run from 1 to 5 and latin indices from 1 to 4, and the eigenvalues of the four-dimensional stress tensor will be $(\rho,-p_2,-p_3,-p_4)$.

The essence of the induced-matter approach to the Kaluza–Klein formalism is that ''matter'' should come from the behavior of the $x^5=\psi$ dependent part of the five-dimensional vacuum field equations without the fifth dimension being necessarily compactified. This, of course, is at variance with the original Kaluza–Klein idea, where the extra dimension is either actually absent or compactified on a small circle. In this nonprojective, noncylindrical reinterpretation of higher-dimensional pure gravity, the five-dimensional vacuum Einstein equations are each rewritten as a strictly four-dimensional part on the one side (the four-dimensional curvature) with the other, ''matter,'' side containing all terms depending on the $g_{\alpha 5}$'s and their derivatives, and the ψ derivatives of the $g_{\alpha\beta}$'s. Thus in this formalism, four-dimensional matter is a manifestation of five-dimensional pure gravity.

The standard tests of general relativity do not falsify the theory[3–5] and the formalism has been extended in a number of directions, including cosmology,[6,7] wave propagation,[8,9] inflation,[10] solitons/black holes,[11–13] and other special solutions.[14,15] The formalism has also been extended to the process of obtaining D-dimensional matter-gravity equations from $(D+1)$-dimensional empty space–time Einstein equations.[16] Here we shall restrict ourselves to the original $D=4$ case. For a recent review of the field, one should consult Ref. 17.

Our goal here is to find new solutions with cylindrical symmetry. Such solutions where the metric coefficients depend only on the radius and time coordinates already exist.[18] However, it is known that metrics which are independent of the fifth coordinate can lead to radiation only.[19] By allowing the metric to depend on the fifth coordinate, new, nonradiative solutions with cylindrical symmetry can be found. In this paper, new solutions of this type are found using the separability assumption and some of their properties are discussed.

II. FINDING SEPARABLE CYLINDRICAL METRICS

We are interested in studying diagonal metrics which extend Vilenkin's cylindrical form[20] in two ways: they have to describe five-dimensional spaces and their coefficients are to be allowed to vary with the radius r and the extra coordinate ψ. The axis of cylindrical symmetry is chosen to

[a)]Electronic mail: gravelp@sv2.rmc.ca

 © 1998 American Institute of Physics

be that of the z variable and the metrics are assumed to be invariant under boosts in that direction. If we also assume separability of the coefficients with respect to the radial and the extra variable, then the form of such metrics will be

$$ds^2=A(r)^2a(\psi)^2(dt^2-dz^2)-B(r)^2b(\psi)^2dr^2-C(r)^2c(\psi)^2d\theta^2+\epsilon F(r)^2f(\psi)^2d\psi^2$$

with $\epsilon=\pm 1$. However, we shall assume that $\epsilon=-1$ in the interpretation part of this paper. The usual $\cos^2\theta$ factor in front of $d\theta^2$ has been absorbed into the differentials. It is also possible to absorb $B(r)$ and $f(\psi)$ into their associated differentials. This will make the computations come easier. We will keep $b(\psi)$ and $c(\psi)$ distinct to study conical defects in Sec. IV.

So for our metric we will use

$$ds^2=A(r)^2a(\psi)^2(dt^2-dz^2)-b(\psi)^2dr^2-C(r)^2c(\psi)^2d\theta^2+\epsilon F(r)^2d\psi^2. \tag{1}$$

Then the five-dimensional Einstein equations which are not identically satisfied separate to give

$$\begin{aligned}
R^1{}_1=R^4{}_4=0:\quad & F^2\left(\frac{A''}{A}+\frac{A'^2}{A^2}+\frac{A'C'}{AC}+\frac{A'F'}{AF}\right)=\frac{m}{2}=\epsilon b^2\left(\frac{a''}{a}+\frac{a'2}{a^2}+\frac{a'b'}{ab}+\frac{a'c'}{ac}\right),\\
R^2{}_2=0:\quad & F^2\left(2\frac{A''}{A}+\frac{C''}{C}+\frac{F''}{F}\right)=n=\epsilon b^2\left(\frac{b''}{b}+2\frac{b'a'}{ba}+\frac{b'c'}{bc}\right),\\
R^3{}_3=0:\quad & F^2\left(\frac{C''}{C}+2\frac{C'A'}{CA}+\frac{C'F'}{CF}\right)=p=\epsilon b^2\left(\frac{c''}{c}+2\frac{c'a'}{ca}+\frac{c'b'}{cb}\right),\\
R^5{}_5=0:\quad & F^2\left(\frac{F''}{F}+2\frac{F'A'}{FA}+\frac{F'C'}{FC}\right)=q=\epsilon b^2\left(2\frac{a''}{a}+\frac{b''}{b}+\frac{c''}{c}\right),\\
R^2{}_5=0:\quad & -2\frac{A'b'}{Ab}-2\frac{F'a'}{Fa}+2\frac{A'a'}{Aa}+\frac{C'c'}{Cc}-\frac{F'c'}{Fc}-\frac{C'b'}{Cb}=0,
\end{aligned} \tag{2}$$

where m, n, p, and q are separation constants. The prime denotes the derivative taken with respect to the variable on which a function depends and to carry out full separation of the equations we have assumed that none of the functions A, C, F, a, b, or c vanishes. At any rate, these would give degenerate metrics in five dimensions. We restrict ourselves in this work to the case: $m=n=p=q=0$. We look first at the left-hand sides (the r set of equations).

Multiplying the $R^1{}_1=0$ equation by A/A' (assuming A is not a constant), leads to the relation $(A^2)'BF=c_1$ (all the c_i's will be constants). Similarly, $R^3{}_3=0$ will give $A^2B'F=c_3$, while $R^5{}_5=0$ gives $A^2BF'=c_5$. Thus $(A^2BF)'=c_1+c_3+c_5=c$ [a constant, not to be confused with $c(\psi)$] and we have

$$A^2BF=cr+c_6.$$

Using this combination in the relation defining c_1 we get $(A^2)'/A^2=c_1/(cr+c_6)$ so that after integration we have

$$A^2=c_7(cr+c_6)^{c_1/c}.$$

Similar work on the equations defining c_3 and c_5 leads to

$$C=c_8(cr+c_6)^{c_3/c},$$

$$F=c_9(cr+c_6)^{c_5/c}.$$

From this point on we will use the symbols c_i to represent what was understood up until now to be c_i/c, so that in particular we now have $c_1+c_3+c_5=1$.

Substituting these solutions in $R^2{}_2=0$ we obtain the following relation linking the constants of the r set:

$$c_1{}^2+4(c_1c_3+c_1c_5+c_3c_5)=0. \tag{3}$$

This implies in particular that c_1, c_3, and c_5 cannot all be of the same sign if $c_1\neq 0$ (which, as we shall see later on, has to be satisfied if the density is not to vanish).

Solving the ψ equations is accomplished through a similar process, the equations being similar in form. We get the functions

$$a^2=d_5(d\psi+d_4)^{d_1/d},$$

$$b=d_6(d\psi+d_4)^{d_2/d},$$

$$c=d_7(d\psi+d_4)^{d_3/d},$$

where $d=d_1+d_2+d_3$, together with the relation

$$d_1{}^2+4(d_1d_2+d_1d_3+d_2d_3)=0 \tag{4}$$

and we rename from now on the (d_i/d)'s, as we did the (c_i/c)'s above.

Finally, the equation $R^2{}_5=0$ leads to the following compatibility equation between the c_i's and the d_i's:

$$c_1d_1+2c_3d_3-2c_1d_2-2c_3d_2-2c_5d_1-2c_5d_3=0. \tag{5}$$

To sum up, when c_6 and d_4 are absorbed in the differentials, when the separation constants all vanish, and provided we take Eqs. (3)–(5) into account, the possible static separable metrics in five dimensions which are cylindrically symmetric about the z coordinate axis are

$$\begin{aligned} ds^2=&(ar\pm 1)^{c_1}(b\psi\pm 1)^{d_1}(dt^2-dz^2)-(b\psi\pm 1)^{2d_2}dr^2\\ &-(ar\pm 1)^{2c_3}(b\psi\pm 1)^{2d_3}d\theta^2+\epsilon(ar\pm 1)^{2c_5}d\psi^2, \end{aligned} \tag{6}$$

where the constants a and b are positive. We shall keep only solutions with the negative sign in the following, as they exhibit interesting singularities in four dimensions which are particular to the ''five to four formalism.''

III. THE STRESS TENSOR

In the Ponce de Leon–Wesson formalism, the stress-energy-momentum tensor induced in four dimensions is given by those terms in $G^{\alpha}{}_{\beta}$ which contain the coefficient g_{55} or derivatives with respect to ψ of the metric coefficients. In the case of a general cylindrical metric of the form

$$ds^2=B_1{}^2(dt^2-dz^2)-B_2{}^2dr^2-B_3{}^2d\theta^2-B_5{}^2d\psi^2,$$

with

$$B_i=B_i(r,\psi),$$

this separation leads to the nonvanishing stress tensor components

$$\begin{aligned} T_1{}^1=T_4{}^4=&-\frac{B_{5,rr}}{B_2{}^2B_5}+\frac{B_{2,r}B_{5,r}}{B_2{}^3B_5}-\frac{B_{3,r}B_{5,r}}{B_3B_2{}^2B_5}-\frac{B_{1,r}B_{5,r}}{B_1B_2{}^2B_5}\\ &+\epsilon\left(\frac{B_{1,\psi\psi}}{B_1B_5{}^2}+\frac{B_{2,\psi\psi}}{B_2B_5{}^2}+\frac{B_{3,\psi\psi}}{B_3B_5{}^2}-\frac{B_{3,\psi}B_{5,\psi}}{B_3B_5{}^3}-\frac{B_{1,\psi}B_{5,\psi}}{B_1B_5{}^3}-\frac{B_{2,\psi}B_{5,\psi}}{B_2B_5{}^3}\right.\\ &\left.+\frac{B_{1,\psi}B_{3,\psi}}{B_1B_3B_5{}^2}+\frac{B_{1,\psi}B_{2,\psi}}{B_1B_2B_5{}^2}+\frac{B_{2,\psi}B_{3,\psi}}{B_2B_3B_5{}^2}\right), \end{aligned}$$

$$T_2{}^2=-2\frac{B_{1,r}B_{5,r}}{B_1B_2{}^2B_5}-\frac{B_{3,r}B_{5,r}}{B_3B_2{}^2B_5}$$
$$+\epsilon\left(2\frac{B_{1,\psi\psi}}{B_1B_5{}^2}+2\frac{B_{3,\psi\psi}}{B_3B_5{}^2}+\frac{B_{1,\psi}{}^2}{B_1{}^2B_5{}^2}-2\frac{B_{1,\psi}B_{5,\psi}}{B_1B_5{}^3}-\frac{B_{3,\psi}B_{5,\psi}}{B_3B_5{}^3}+2\frac{B_{1,\psi}B_{3,\psi}}{B_1B_3B_5{}^2}\right),$$

$$T_3{}^3=-\frac{B_{5,rr}}{B_2{}^2B_5}-2\frac{B_{1,r}B_{5,r}}{B_1B_2{}^2B_5}+\frac{B_{2,r}B_{5,r}}{B_2{}^3B_5}$$
$$+\epsilon\left(2\frac{B_{1,\psi\psi}}{B_1B_5{}^2}+\frac{B_{2,\psi\psi}}{B_2B_5{}^2}+\frac{B_{1,\psi}{}^2}{B_1{}^2B_5{}^2}-2\frac{B_{1,\psi}B_{5,\psi}}{B_1B_5{}^3}-\frac{B_{2,\psi}B_{5,\psi}}{B_2B_5{}^3}+2\frac{B_{1,\psi}B_{2,\psi}}{B_1B_2B_5{}^2}\right), \quad (7)$$

$$T_5{}^5=\frac{\epsilon}{B_5{}^2}\left(\frac{B_{1,\psi}{}^2}{B_1{}^2}+\frac{B_{2,\psi}B_{3,\psi}}{B_2B_3}+2\frac{B_{1,\psi}B_{3,\psi}}{B_1B_3}-2\frac{B_{1,\psi}B_{2,\psi}}{B_1B_2}\right),$$

$$T_5{}^2=2\frac{B_{1,r\psi}}{B_1B_2{}^2}+\frac{B_{3,r\psi}}{B_2{}^2B_3}-2\frac{B_{1,r}B_{2,\psi}}{B_1B_2{}^3}-\frac{B_{3,r}B_{2,\psi}}{B_3B_2{}^3}-2\frac{B_{5,r}B_{1,\psi}}{B_1B_2{}^2B_5}-\frac{B_{5,r}B_{3,\psi}}{B_2{}^2B_3B_5}.$$

In the separable case with vanishing separation constants, this means that the stress tensor becomes, after some computation

$$T^1{}_1=\frac{c_1}{2}\,q(r,\psi),$$

$$T^2{}_2=-(c_1+c_3)q(r,\psi),$$

$$T^3{}_3=c_3q(r,\psi),$$

$$T^1{}_1=T^4{}_4,$$

where

$$q(r,\psi)=\frac{ac_5}{(ar-1)^2(b\psi-1)^{2d_2/d}}. \quad (8)$$

We see that this stress tensor vanishes at r-infinity, which is desirable. The density and pressure of whatever fluid surrounds the z-axis are given by the values of the diagonal components of $T^\alpha{}_\beta$ in a comoving system where the unit velocity of a fluid element reads (1,0,0,0).[21] Since the stress tensor is already in diagonal form, the change to such a system is readily made, and we get

$$\rho=c_1q/2,$$

$$p_r=(c_1+c_3)q,$$

$$p_\theta=-c_3q, \quad (9)$$

$$p_z=-c_1q/2.$$

Thus this stress tensor cannot be matched with the usual perfect fluid stress tensor since its spatial eigenvalues are not equal (unless they all vanish).

About the best we can do to extract an equation of state from the stress tensor is to interpret the average of its spatial components as a perfect fluid isotropic pressure. Then the tracelessness of the stress tensor gives us the equation of state of radiation or ultrarelativistic matter since

$$p_{\text{avg}}=\frac{1}{3}\,(-T^2{}_2-T^3{}_3-T^4{}_4)=\frac{c_1}{6}\,q(r,\psi)=\frac{1}{3}\,\rho, \quad (10)$$

and thus $\rho=3p_{\text{avg}}$.

Let us assume that $(b\psi-1)$ is positive and that two of the pressures are equal (they cannot all be of the same sign, as the form of the stress tensor shows). Then in order for the density ρ to be positive at large r values (the most natural choice), the combination ac_1c_5 must be positive. We first consider the case where ac_5 is positive. Then c_1 must be positive, there is tension along the z-axis in all possible cases and these are as follows:

$p_r=p_\theta$: pressure along dr and $d\theta$:

$$ds^2=(ar-1)(b\psi-1)^{(10\pm2\sqrt{3})/11}(dt^2-dz^2)-(b\psi-1)^{-4(-1\pm2\sqrt{3})/11}dr^2$$
$$-(ar-1)^{-1}(b\psi-1)^{2(-1\pm2\sqrt{3})/11}d\theta^2+\epsilon(ar-1)d\psi^2. \tag{11}$$

$p_z=p_\theta$: pressure along dr and tension along $d\theta$:

$$ds^2=(ar-1)(b\psi-1)^{2(1\mp\sqrt{3})/5}(dt^2-dz^2)-(b\psi-1)^{4/5}dr^2$$
$$-(ar-1)(b\psi-1)^{(2\pm4\sqrt{3})/5}d\theta^2+\epsilon(ar-1)^{-1}d\psi^2.$$

The solution with $p_r=p_z$ would contradict the assumption of positivity of the mass density as $c_1=-1/3$ in this case. Finally, the solution with vanishing pressures and density, namely

$$ds^2=(dt^2-dz^2)-(b\psi-1)^2dr^2-d\theta^2+\epsilon(ar-1)d\psi^2, \tag{12}$$

is common to all three cases. This can be considered to be a class of Minkowski spaces in four dimensions, its members being parametrized by ψ. In these, the c_i's and d_i's have been solved for using the pressure conditions and relations (3)–(5). We shall not cover the case where ac_5 is negative except to say that the spatial coordinates exchange their tension and pressures roles (that is, if we insist on keeping the density positive). We are mainly interested in the case where there is tension along the z coordinate and the density is positive.

Given the form of the metric, there exists a hypersurface at which the four-dimensional space becomes singular since the stress tensor is singular at $r=1/a$. Note that although this is a true singularity in four dimensions, it is not in five, since the full five-dimensional empty space–time Einstein equations are everywhere satisfied. This indicates that the validity of the space–time split between the set $(x_1,\ldots,x_4)$ and x_5 must be questioned in the neighborhood of $r=1/a$, and that whatever symmetry breaking process allows us to restrict our considerations to a $GL(4,\mathbf{R})\times G$ does not work close to this hypersurface.

IV. METRICS WITH IDENTIFIABLE CONICAL DEFECTS

We may look in another direction. The general solution can be specialized so as to put into explicit form the angular dependence on θ. This happens if the c_i's are given the values $c_1=c_5=0$ and $c_3=1$. In that case we have $d_1=1(-1/3)$, $d_2=-1/2(5/6)$, and $d_3=1/2(1/2)$ and we have either of two radiation solutions

$$ds^2=(b\psi-1)(dt^2-dz^2)-(b\psi-1)^{-1}dr^2-(ar-1)^2(b\psi-1)d\theta^2+\epsilon d\psi^2$$

or

$$ds^2=(b\psi-1)^{-1/3}(dt^2-dz^2)-(b\psi-1)^{5/3}dr^2-(ar-1)^2(b\psi-1)d\theta^2+\epsilon d\psi^2$$

and the pressure is along the r direction while the tension is along the θ direction; there is no z pressure or tension. On hypersurfaces of constant ψ such metrics can be interpreted, after proper rescaling of r, t, and z, as those of infinite strings

$$ds^2=(d\bar{t}^2-d\bar{z}^2)-d\bar{r}^2-(a\sqrt{b\psi-1}\bar{r}-1)^2(b\psi-1)d\theta^2$$

and

$$ds^2=(d\bar{t}^2-d\bar{z}^2)-d\bar{r}^2-(a(b\psi-1)^{-5/6}\bar{r}-1)^2(b\psi-1)d\theta^2$$

with conical angular defects[22,23] at large $\bar{r}$ values of $2\pi[1-(a(b\psi-1))^{-1}]$ and $2\pi[1-(b\psi-1)^{2/3}/a]$, respectively. Hence the lensing effect would be ''mass-dependent.''

The fact that we have obtained radiation only is due to our insisting that the $d\theta^2$ factor be exactly quadratic in $\bar{r}$. If we want $\rho\neq 0$ solutions, then $c_1\neq 0$ and since the equation of state is of no help in solving for the c_i's (since it is identically given by the tracelessness of the stress tensor) we can only find the relation between c_1 and c_3 [assuming c_5 has been eliminated from (3) using $c_1+c_2+c_5=1$]; what we get is that the solution pair (c_1,c_3) lies on an ellipse, in the plane of these variables, which is tangent to the $c_3=1$ line at the point (0,1), which shows that solutions with non-negligible matter density are possible with the spatial part remaining nearly flat.

V. DISCUSSION

A few final remarks are in order. First, as in other solutions based on the Wesson–Ponce de Leon ansatz which were obtained under the separability condition, no study of the stability of these solutions under perturbation has been carried out here. Nor have we tried to find other solutions from these using the generating techniques of Geroch[24] to see whether this would yield solutions which could be physically interesting.

Then, because four-dimensional solutions internal and external to the singular hypersurface are completely specified as a matching pair by the nonsingular five-dimensional solution, the matter outside the hypersurface is as exotic as the one inside. Hence in order to match such solutions to external ordinary matter, the asymptotic flatness of the four-dimensional solution has to be used in an essential way. It also shows that it would be interesting to analyze the behavior of the four- and five-dimensional geodesics close to the $r=1/a$ hypersurface to classify the 5-D ones according to their behavior in 4-D. This could possibly lead to an interpretation of the extra coordinate different from all those which have been suggested before.

Finally, we still have to show what the solutions with nonvanishing separation constants look like. At a similar level, the introduction of either the t variable (nonstatic cylindrical solutions) or the z variable (static radial solutions) in the metric coefficients could possibly remove some of the exotism from these string solutions. We intend to take a closer look at these avenues in coming publications.

Universality of the future chronological boundary

Steven G. Harris[a)]
Department of Mathematics, Saint Louis University, St. Louis, Missouri 63103

(Received 20 October 1997; accepted for publication 3 June 1998)

The purpose of this note is to establish, in a categorical manner, the universality of the Geroch-Kronheimer-Penrose (GKP) causal boundary when considering the types of causal structures that may profitably be put on any sort of boundary for a space–time. Actually, this can only be done for the future causal boundary (or the past causal boundary) separately; furthermore, only the chronology relation, not the causality relation, is considered, and the GKP topology is eschewed. The final result is that there is a unique map, with the proper causal properties, from the future causal boundary of a space–time onto any ''reasonable'' boundary which supports some sort of chronological structure and which purports to consist of a future completion of the space–time. Furthermore, the future causal boundary construction is categorically unique in this regard. © *1998 American Institute of Physics.* [S0022-2488(98)01910-0]

I. INTRODUCTION AND DISCUSSION

The causal boundary of Geroch, Kronheimer, and Penrose[1] (also explicated in Ref. 2, Sec. 6.8) has played a role in helping to make clear the purely causal aspects of space–times, especially at timelike or null infinity. Being defined in terms of the pasts and futures of points, it seems to be a ''natural'' object for focusing on such matters. However, it has generally been considered somewhat opaque in application and difficult to calculate. Is it still worth pursuing in spite of its somewhat formidable reputation? An affirmative answer may be forthcoming if the intuitive sense of naturalness accruing to the causal boundary can be justified in a precise and general manner. It is the purpose of this note to do exactly that: to show that the causal boundary is a ''universal object'' in the strict categorical sense, that is to say, that in an appropriate mathematical category, the causal boundary construction is the essentially unique way of completing a space–time in such a way as to yield a model to which any other causal completion process can naturally be compared (by means of a map from the causal boundary to the other boundary).

However, some caveats are in order: First of all, the categorical constructions performed here operate only on the future causal boundary (or, alternatively, only the past causal boundary), not on the melding together of the future and past boundaries that constitutes one of the more complicated issues in the full Geroch-Kronheimer-Penrose (GKP) construction. Effectively, this is the portion of the GKP construction which places an endpoint on each future-endless causal curve in a space–time, leaving past endpoints unaccounted for. Correspondingly, the categorical comparison will be made only with any ''reasonable'' future completion of a space–time—a completion of all future causal curves only. One way to understand why this is necessary is by noting that although the future causal boundary completes all future causal curves, and the past causal boundary completes all past causal curves, the combination of the two creates additional causal relations which can result in an object which is no longer complete in either future or past. (An example is given in the Appendix.)

Second, in this presentation, only the chronology relation will be addressed, not the causality relation; this is more a matter of simplification than anything else: Categorical results can be obtained by working with only the one relation, so that is the path followed here, though there is no barrier to including both relations. Accordingly, the boundary construction here is called the future chronological boundary, allowing a distinction from the GKP (future) causal boundary.

Finally, all topology is eschewed from the approach here, with notions of convergence being

[a)]Electronic mail: harrissg@slu.edu

treated by purely chronological means. This allows an enormous savings of complexity, as well as the avoidance of one of the more difficult elements of the GKP causal boundary. (A topology can be inferred from the chronological notion of convergence developed herein, but this will not play an explicit role.)

As a model for the construction followed here, consider the problem of completing a Riemannian manifold. There is more than one way to do this: One could take the one-point compactification, the Cauchy completion, or some arbitrary isometric embedding into a complete metric space. Part of the issue is that one is liable to end up with a nonmanifold as one's complete object: The category of Riemannian manifolds and differentiable functions is not big enough to contain all the completions we may wish to consider. So the first thing to do is to expand to a larger category, the category **Met** of metric spaces and continuous functions. We will use Cauchy completion as our method of completing not just any Riemannian manifold, but any metric space at all. This is actually a functor $\mathbf{C}:\mathbf{Met}\to\mathbf{Met}_0$ from **Met** to the subcategory of complete metric spaces, $\mathbf{Met}_0$; this means that not only does each metric space X have a Cauchy completion $\mathbf{C}(X)$, but also that for every map $f:X\to Y$ in **Met**, there is an extension of f to the completions, $\mathbf{C}(f):\mathbf{C}(X)\to\mathbf{C}(Y)$, which works with compositions and with identity maps, i.e., $\mathbf{C}(f\circ g)=\mathbf{C}(f)\circ\mathbf{C}(g)$ and $\mathbf{C}(\mathrm{id}_X)=\mathrm{id}_{\mathbf{C}(X)}$. We need to take note not only of the completion of each metric space X but also of its embedding into its completion, $i_X:X\to\mathbf{C}(X)$. This is a natural transformation $\mathbf{i}:\mathbf{I}_{\mathbf{Met}}\dot{\to}\mathbf{U}\circ\mathbf{C}$, where $\mathbf{I}_{\mathbf{Met}}$ is the identity functor on **Met** and $\mathbf{U}:\mathbf{Met}_0\to\mathbf{Met}$ is the ''forgetful'' (i.e., inclusion) functor; this means that for any map $f:X\to Y$, the embeddings on X and Y work with the extension to f, i.e., $i_Y\circ f=\mathbf{C}(f)\circ i_X$ [also, as a natural transformation, i_X is considered as technically mapping X to $\mathbf{U}(\mathbf{C}(X))$]. The importance of the Cauchy construction for completion is that it is universal in the sense of being a left adjoint to the forgetful functor; this means that for any map from a metric space into a complete metric space, there is a unique extension of that map to the Cauchy completion: For any X in **Met**, any Y in $\mathbf{Met}_0$, and any map $f:X\to\mathbf{U}(Y)$, there is a unique map $f_0:\mathbf{C}(X)\to Y$ such that $\mathbf{U}(f_0)\circ i_X=f$ (more simply, ignoring the forgetful functor: for any $f:X\to Y$ with Y complete, there is a unique $f_0:\mathbf{C}(X)\to Y$ such that $f_0\circ i_X=f$). Since left adjoints are unique up to natural isomorphism (a natural transformation consisting of isomorphisms) (Ref. 3, Corollary IV.1), this tells us that Cauchy completion is *the* correct construction for the ''free'' completion of a metric space, in exact analogy with the free vector space on a set: It is functorial, natural, and universal. (But note that we had to expand from Riemannian manifolds to the larger setting of metric spaces in order to obtain a category in which the functoriality of the construction comes into play.)

The general idea here is to define a category of objects which includes both space–times and space–times that have boundaries attached to them, and to show that the future chronological boundary is a functorial, natural, and universal construction. The category, called chronological sets, consists, roughly speaking, of objects that are space–time-like in that they possess a relation that works like the chronology relation in a space–time. There is a great deal of freedom in choosing which properties of the space–time relation to abstract and axiomatize for our new category. The ones chosen here seem to be the minimum ones needed to carry enough structure to be able to replace topology as the means for defining convergence for appropriate sequences of points. The approach here is somewhat reminiscent of the causal spaces axiomatized in Ref. 4, and some of the language (such as ''full'' and ''chain'') from that paper is borrowed for this one; but there is a great deal of simplification achieved by concentrating solely on the chronology relation.

What is the practical impact of establishing the universality of the future chronological boundary? How does this help in understanding space–times? The answer lies in being able to relate any proposed future boundary for a space–time to what is essentially the GKP future (pre-)boundary points, in a manner respecting the chronological relations—so long as the proposed boundary includes an extension of the chronology relation of the space–time and does so in a ''reasonable'' manner (such as being past-distinguishing). Some examples at this point may help:

First an artificial example: Consider a space–time M obtained from Minkowski two-space ($\mathbb{L}^2$) by excising a timelike line segment L (such as $\{(0,t)|0\leqslant t\leqslant 1\}$). (A closely related example is considered in detail at the end of Sec. IV.) The most obvious way to put a helpful boundary on M is to embed it back into $\mathbb{L}^2$ in the obvious way, yielding L as the boundary points for M. However, this is not the only useful possibility. Let us expand our conception of M to include anything conformal to $\mathbb{L}^2-L$. Then, considering that the metric may become inherently singular

as the points of L are approached, we may wish to choose a boundary construction that respects L as a physical blockage between its left and right sides; typically, we may choose as boundary two copies of L, one for the left side and one for the right side of the slit in M, joined at the top and the bottom, i.e., a boundary of the form $\{(0^-,t)|0\leqslant t\leqslant 1\}\cup\{(0^+,t)|0\leqslant t\leqslant 1\}$, with $(0^-,0)$ and $(0^+,0)$ identified, as well as $(0^-,1)$ and $(0^+,1)$. (By ''physical blockage'' here I refer to the chronology relation in the space–time-*cum*-boundary: We have, for instance, $(-0.1,0.3)\ll(0^-,0.5)$, and $(0.1,0.3)\ll(0^+,0.5)$, but no chronology relation between $(-0.1,0.3)$ and $(0^+,0.5)$. This reflects an impossibility of passage from one side of the slit to the other.) The GKP causal boundary produces precisely this latter boundary, in addition to the standard points at future and past null- and timelike-infinity associated with Minkowski space. The future (pre-)boundary points of the GKP construction are similar, with the only difference being that there is a ''double-point'' at the top of the boundary: $(0^-,1)$ and $(0^+,1)$ are not identified but kept distinct. This last is the future chronological boundary.

What, then, does the universality of the future chronological boundary have to say in this example? It says that the future chronological boundary covers any other (past-distinguishing) boundary. For instance, the full GKP causal boundary identifies the double-point of the future chronological boundary into a single point. The first boundary mentioned, consisting of L itself, identifies all the pairs of points $(0^-,t)$ and $(0^+,t)$. Other boundaries can be imagined, such as identifying $(0^-,t)$ and $(0^+,t)$ for some but not all t. [Note that past-distinguishment in the boundary necessitates retaining the identification of $(0^-,0)$ and $(0^+,0)$.] The point is that *any* appropriate boundary construction for M, intending to add future end points for all timelike curves, can be mapped onto by the future chronological boundary, in a manner that appropriately preserves the chronological relation; that this mapping is unique; and that the entire construction is categorical in nature.

For a more realistic example, let our space–time be Schwarzschild space. The standard picture of the (future) singularity is of $\mathbb{S}^2\times\mathbb{R}^1$: a two-sphere (parametrized by ϕ and θ) at each point of $r=0$ and any $t\in\mathbb{R}$, using Schwarzschild coordinates. We also have future null-infinity ($\mathscr{I}^+=\mathbb{S}^2\times\mathbb{R}^1{:}r=\infty$, other coordinates arbitrary) and future timelike-infinity (i^+, a single point). What other reasonable options are there for future boundary points in Schwarzschild? The boundary just described is the future chronological boundary (external Schwarzschild is conformal to a standard static space–time, which makes it easy to find its causal boundary). It follows that any past-distinguishing way of putting a future boundary on Schwarzschild must be a quotient of this: We can collapse the singularity to, for instance, a projective space or lens space at each value of t, and we can make identifications in $\mathscr{I}^+$, but we cannot blow up i^+ into a sphere or anything other than a single point.

It may be helpful to outline some of the complexities encountered in this presentation.

The first step is to define a category which contains both reasonable (strongly causal) space–times and any such space–time combined with a boundary of any sort (including an extension of the chronology relation to the boundary). The next step is to define a ''future-completion'' construction which will apply to any object in this category; it should replicate the GKP future (pre-)boundary construction when applied to space–times, and should yield nothing new when applied to an object which is already ''future-complete.'' It is also intended that this future-completion construction not change anything in the original object, but just add additional points.

A problem arises in this, however: The condition used to define the chronology relation for the new (future boundary) points—the same criterion as in the GKP construction—is not necessarily compatible with the preexisting chronology relation in the original object. (Among space–times, global hyperbolicity prevents this from happening, but the idea is to provide a construction for all strongly causal space–times.) The problem is that if the same criterion is applied to the original object, then more pairs of points ought to be considered as chronologically related than was originally the case. For instance, if the object is the space–time M from the example above, then the criterion applied to M would have $(-1,-1)\ll(0.5,1)$; but there is no timelike curve between those points in M. Among other things, this incompatibility interferes with the functoriality of the future-completion construction.

The solution is to define an additional construction (''past-determination'') on these objects whose sole purpose is to add in precisely those additional chronology relations so that when the future-completion construction is applied, the result is compatible with the chronology relation in

the past-determined object. This defeats the intent of preserving the original chronology relation for the object, but there is no getting around this point. Indeed, this is precisely the tack chosen by GKP: The chronology relation in the GKP construction results in additional relations within the space–time, exactly the same ones as the past-determination construction here. The exposition here essentially separates out this portion of the GKP construction for its own categorical and universal explication.

One still has to contend with the question of whether it makes a difference if one first past-determines and then future-completes, or does it the other way around. As it turns out, these operations are categorically commutative; but that takes some doing to establish.

Finally, one needs to make a comparison between the future chronological boundary construction here—the GKP future (pre-)boundary—and the full GKP causal boundary. A difficulty arises in that the simple definition of future-complete used here is not generally satisfied by the GKP causal boundary; a slight generalization is needed, allowing, for instance, for the identification of points such as in the causal boundary of the example M above. But all goes through, as exemplified in that example.

In summation: Section II introduces the basic category and the future-completion operation; this applies, without further modification, to globally hyperbolic space–times. Section III defines the past-determination operation, extending the results of Sec. II to, for instance, all strongly causal space–times. Section IV addresses the generalization that is necessary in order to include such completions as those deriving from the full GKP construction.

A word on what this paper addresses and what it does not:

The intent here is to provide a justification for the use of the causal boundary construction. This is accomplished largely though showing how at least the future portion of that construction provides a universal standard of comparison for any other future-completing boundary, in terms of the chronology relation.

One obvious failing of this enterprise is to evince a similar standard of comparison for the full causal boundary. This, however, I believe to be innately impossible: As evidenced in the Appendix, the full causal boundary simply does not result in a complete object. This does not necessarily mean that the full causal boundary is an inappropriate tool, but it does detract from hopes of its having a universal role in boundary considerations.

Another element missing here is the causality relation. I believe it possible to do much of the same work here with the causality relation included, but it seems an unnecessary complication at this point. The chronology relation suffices to cover much of the necessary structures, and it yields a satisfactory universality result.

Topology is probably the most complex element missing from this development. It would be desireable to have a universality result which included full topological information, not just chronological. This is a matter under investigation and the subject for another paper.

II. CHRONOLOGICAL SETS AND FUTURE COMPLETION

The intent here is to abstract and axiomatize the chronology relation in a space–time: A point x chronologically precedes a point y, written $x \ll y$, if and only if there is a future-directed timelike curve from x to y. This is the relation that must be emulated for the new category.

We start with a subset of the needed properties:

A *prechronological set* is a set X together with a relation $\ll$ satisfying the following conditions:

(1) $\ll$ is transitive: $x \ll y \ll z$ implies $x \ll z$;
(2) $\ll$ is nonreflexive: for all x, *not* $(x \ll x)$;
(3) X has no isolates: for all x, $I^-(x) = \{y | y \ll x\}$, the *past* of x, or $I^+(x) = \{y | x \ll y\}$, the *future* of x, is nonempty; and
(4) $\ll$ is full: for any $x \ll y$, there is some z with $x \ll z \ll y$.

For any nonempty subset A of a prechronological set X, the *past* of A, $I^-[A]$, is $\cup_{a \in A} I^-(a)$ (the *future* of A, and all subsequent dualizations, are defined analogously). A nonempty subset P

is a *past set* if $I^-[P]=P$. [In general, ( ) will be used to indicate application of an operator to an entity to be regarded as a single-element argument, [ ] will be used to indicate application to each of the various elements making up the argument.]

1. Proposition: In a prechronological set, any nonempty set of the form $I^-[A]$ is a past set.

Proof: By transitivity, $I^-[I^-[A]]\subset I^-[A]$. Now suppose $x\ll a$ for $a\in A$; then, by fullness, there is some y with $x\ll y\ll a$. Thus $I^-[I^-[A]]=I^-[A]$. □

A past set is *decomposable* if it is the union of two proper subsets that are past sets. An indecomposable past set is often called an IP.

2. Theorem: *In a prechronological set, a past set P is indecomposable if and only if for every x and y in P, there is some $z\in P$ with $x\ll z$ and $y\ll z$.*

Proof: (This theorem is due to Geroch, Kronheimer, and Penrose; the proof here is adapted from Ref. 2, in the proof of Proposition 6.8.1.)

Suppose P is decomposable as $P_1\cup P_2$ (proper past subsets). Then neither $P_1\subset P_2$ nor $P_2\subset P_1$, so we can find $x_1\in P_1-P_2$ and $x_2\in P_2-P_1$. Then there can be no $y\in P$ with $x_1\ll y$ and $x_2\ll y$: If y is in, say, P_1, then since $x_2\ll y$, $x_2\in P_1$ also, which is false.

Suppose P is indecomposable. For any x_1 and x_2 in P, let $Q_i=\{q\in P|\,not(x_i\ll q)\}$, and let $P_i=I^-[Q_i]$ (for each i). Note that $P_i\subset Q_i$: For $x\in P_i$, there is some $q\in P$ with $x\ll q$ and $not(x_i\ll q)$; thus, $x\in P$ and $not(x_i\ll x)$ (lest $x_i\ll q$), so $x\in Q_i$. Therefore P_i cannot be all of P, since Q_i is not (since x_i is in P and $P=I^-[P]$, there must be some $p_i\in P$ with $x_i\ll p_i$). Since P_1 and P_2 are both past sets, it follows from P being an IP that $P\neq P_1\cup P_2$, i.e., there is some $p\in P$ with $p\notin I^-[Q_1]$ and $p\notin I^-[Q_2]$. Now, since $P=I^-[P]$, there is some $z\in P$ with $p\ll z$; it then follows that z must be in neither Q_i, i.e., that $x_1\ll z$ and $x_2\ll z$. □

A *future chain* in a prechronological set X is a sequence $\{x_n|n\geqslant 1\}$ of points in X such that for all n, $x_n\ll x_{n+1}$.

A subset S of a prechronological set X is called *dense* in X if for all x and y in X with $x\ll y$, there is some s in S with $x\ll s\ll y$. X is *separable* (in a chronological sense) if there is a countable dense set.

The following theorem shows how future chains in a chronological set replace future timelike curves in a space–time; this is adapted from Proposition 6.8.1 in Ref. 2, due to Geroch, Kronheimer, and Penrose, which makes essentially the same statement with ''timelike curve'' in the place of ''chain.''

3. Theorem: *A past set in a separable prechronological set is indecomposable if and only if it is the past of a future chain.*

Proof: Let P be $I^-[\{x_n|n\geqslant 1\}]$ for $\{x_n\}$ a future chain; then for any p_1 and p_2 in P, there are numbers n_1 and n_2 with $p_1\ll x_{n_1}$ and $p_2\ll x_{n_2}$. Let $k=1+\max\{n_1,n_2\}$; then x_k is in P and has each p_i in its past.

Let P be an IP. If S is the countable dense set for the prechronological set, then $P\cap S=\{p_n|n\geqslant 1\}$ is a dense set in P. Since $p_1\epsilon P$ and P is a past set, there is some $x_1\epsilon P$ with $p_1\ll x_1$. Suppose we have defined $\{x_1,\ldots,x_k\}$ with $x_i\in P$ and $x_{i-1}\ll x_i$ and $p_i\ll x_i$ for each $i\leqslant k$. Then by Theorem 2 there is some $x_{k+1}\in P$ with $x_k\ll x_{k+1}$ and $p_{k+1}\ll x_{k+1}$. This defines for us the future chain $\{x_n\}$ in P with $p_n\ll x_n$ for each n. Clearly, $I^-[\{x_n\}]\subset P$. For any $x\in P$, since P is a past set, there is some $y\in P$ with $x\ll y$; then there is some k with $x\ll p_k\ll y$, so $p_k\ll x_k$ shows us $x\ll x_k$. Thus $I^-[\{x_n\}]=P$. □

We will say that an IP P is *generated* by any future chain c for which $P=I^-[c]$.

A prechronological set is called *past-distinguishing* if for points x and y, $I^-(x)=I^-(y)$ implies $x=y$. (Unlike nearly all the other terms defined here, this one is traditional, following the usage in Ref. 2.)

For a future chain $c=\{x_n|n\geqslant 1\}$, a point x is called a *future limit* of c if $I^-(x)=I^-[c]$. Note that if x is a future limit of c, then for all n, $x_n\ll x$, since $I^-(x)$ includes $I^-(x_{n+1})$. Also, if x is a future limit of c, then it is also a future limit of every subchain of c; and, conversely, if x is a future limit of some subchain of c, then it is also a future limit of c. Clearly, in a past-distinguishing prechronological set, a future chain can have at most one future limit. [We could define a topology from this notion of convergence—a set is (future-) closed if it contains all future limits of future chains within it—but this will not be pursued here.]

A prechronological set that is separable is called a *chronological set*. A chronological set for which every future chain has a future limit is called *future-complete*.

It will prove useful to have the $\ll$ relation determined, in a certain sense, by I^-: Specifically, call a prechronological set X *past-determined* if for any x and y in X, if $I^-(x)$ is nonempty and for some $w \ll y$, $I^-(x) \subset I^-(w)$, then $x \ll y$. [We can also say that x is past-determined if $I^-(x)$ is nonempty and whenever $I^-(x) \subset I^-(w)$, $x \ll y$ for all $y \gg w$.]

4. Theorem: *A strongly causal space–time is a past-distinguishing chronological set; if it has the property that the past of x is contained in the past of y implies that x causally precedes y (for instance, any globally hyperbolic space–time), then it is past-determined. A future limit of a future chain in a space–time is the same as a topological limit.*

Proof: A space–time is clearly a prechronological set; it is separable in the chronological sense because it is separable in the topological sense. A strongly causal space–time is past-distinguishing.[2]

If $I^-(x) \subset I^-(w)$ implies $x \in J^-(w)$ (points causally preceding w), then with $w \ll y$ also, we have $x \ll y$. Globally hyperbolic space–times are examples of this: For $I^-(x) \subset I^-(w)$, consider any $z \ll x$; then since $z \in I^-(x)$, z is also in $I^-(w)$, so $z \ll w$. It follows that the space $C(z,w)$ of causal curves from z to w is compact in the C^0 topology. Let σ be a future timelike curve with $\sigma(0)=z$ and $\sigma(1)=x$; for all $t<1$, there is also a future timelike curve τ_t from $\sigma(t)$ to w. Let c_t be the concatenation of $\sigma|_{[0,t]}$ with τ_t; then the family of causal curves $\{c_t\}$ has a causal limit curve c_1 in $C(z,w)$; since c_1 must pass through x, this shows $x \in J^-(w)$.

In a strongly causal space–time, each point has a fundamental neighborhood system $\{U_n\}$ such that for each n, U_n is geodesically convex and for any point $x \in U_n$, any other point $y \in U_n$ is timelike-related to x iff it is joined to x by a timelike geodesic in U_n ($x \ll y$ but not joined by a timelike geodesic in U_n implies that the timelike geodesic connecting them must exit and re-enter U_n, which can be prevented with correct choice of U_n). Let $c=\{x_n\}$ be a future chain. First suppose that c has a topological limit x; then c eventually enters all such neighborhoods U_n of x as just described. For any $y \ll x$, we have $x \in I^+(y)$, a neighborhood of x; thus, eventually, $x_n \in I^+(y)$, i.e., $y \ll x_n$: $I^-(x) \subset I^-[c]$. If any x_m fails to be in the past of x, the same is true for all x_k with $k>m$. Consider such an x_k in a neighborhood U_n of x as above; due to the chronological relation in U_n being given by the geodesic structure, this is essentially the same causal relations as exist in Minkowski space: In particular, x_{k+1} is not in *closure*$(I^-(x))$, and all x_j for $j>k+1$ are in $I^+(x_{k+1})$, whose closure does not include x. This violates x being the limit of c; thus we must have $I^-(x)=I^-[c]$. Conversely, suppose that $I^-(x)=I^-[c]$; then we have $x_n \ll x$ for each n (since $x_n \in I^-[c]$). Using the neighborhoods U_n of x from above, we can find a past chain $\{y_i\}$ in $I^+(x)$ and a future chain $\{z_i\}$ in $I^-(x)$ with x the topological limit of both chains and the sets $\{V_i=I^-(y_i) \cap I^+(z_i)\}$ a fundamental neighborhood system for x. Then for each i, since $z_i \in I^-(x)=I^-[c]$, $x_n \gg z_i$ for sufficiently large n. Since $x_n \ll x \ll y_i$, this gives $x_n \in V_i$ for sufficiently large n, i.e., x is the topological limit of c. □

For a chronological set X, let $\hat{\partial}(X)=\{P \mid P$ is an IP in X such that P is not $I^-(x)$ for any point $x \in X\}$, the *future chronological boundary* of X. Let $\hat{X}=X \cup \hat{\partial}(X)$, the *future chronological completion* of X. Define an extension of $\ll$ on X to $\hat{X}$ by the following:

(1) among points in X, there is no change in $\ll$;
(2) for $x \in X$ and $P \in \hat{\partial}(X)$, $x \ll P$ iff $x \in P$;
(3) for $x \in X$ and $P \in \hat{\partial}(X)$, $P \ll x$ iff for some $y \in X$ with $y \ll x$, $P \subset I^-(y)$; and
(4) for $P \in \hat{\partial}(X)$ and $Q \in \hat{\partial}(X)$, $P \ll Q$ iff for some $y \in Q$, $P \subset I^-(y)$.

Where it is necessary to distinguish between the relation on X and that on $\hat{X}$, $\hat{I}^-$ will be used for the latter. [Thus $x \in \hat{I}^-(y)$ iff $x \in I^-(y)$, and so on.] Note that $\hat{I}^-(P)=P \cup \{Q \in \hat{\partial}(X) \mid Q \subset I^-(w)$ for some $w \in P\} = \hat{I}^-[P]$ (the first being the past of a single point in $\hat{X}$, the last being the past of a subset of $\hat{X}$); in particular, $\hat{I}^-(P) \cap X = P$. Also note that P is a future limit of a future chain c (in $\hat{X}$) if and only if P is generated by c ($I^-[c]=P$ iff $I^-[c]=I^-[P]$ iff $\hat{I}^-[c]=\hat{I}^-[P]$ iff $\hat{I}^-[c]=\hat{I}^-(P)$).

5. Theorem: *Let X be a chronological set. Then*

(1) *$\hat{X}$ is a chronological set;*
(2) *if X is past-distinguishing, then so is $\hat{X}$;*

(3) *if X is past-determined, then so is $\hat{X}$; and*
(4) *$\hat{X}$ is future-complete.*

Proof: (1) $\hat{X}$ is a chronological set:

This is a matter of routine checking of various cases. For instance, to show transitivity, one of the cases to be established is that for x in X and P and Q in $\hat{\partial}(X)$, if $x \ll P \ll Q$, then $x \ll Q$: We have $x \in P$ and $P \subset I^-(w)$ for some $w \in Q$; then $x \ll w$, and, since Q is a past set, $x \in Q$, i.e., $x \ll Q$.

A set which is dense in X is dense in $\hat{X}$ as well (routine to establish).

Note that $\hat{X}$ has no isolates, since for any $P \in \hat{\partial}(X)$, $\hat{I}^-(P)$ includes the elements of P, which is nonempty.

(2) If X is past-distinguishing, then $\hat{X}$ is also (x, P, and Q as above, with $y \in X$):

Suppose $\hat{I}^-(x) = \hat{I}^-(y)$. Then, in particular, $I^-(x) = I^-(y)$, so $x = y$.

Suppose $\hat{I}^-(x) = \hat{I}^-(P)$. Then, in particular, $\hat{I}^-(P) \cap X = I^-(x)$; but this means $P = I^-(x)$, which is forbidden by the definition of $\hat{\partial}(X)$.

Suppose $\hat{I}^-(P) = \hat{I}^-(Q)$. Then, in particular, $\hat{I}^-(P) \cap X = \hat{I}^-(Q) \cap X$, which just means precisely that $P = Q$.

(3) If X is past-determined, then $\hat{X}$ is also (notation as above):

First note that if $\hat{I}^-(x)$ is nonempty, then so is $I^-(x)$ ($P \ll x$ requires some $w \ll x$), and $\hat{I}^-(P)$ is always nonempty.

Suppose $\hat{I}^-(x) \subset \hat{I}^-(w)$ with $w \ll y$; then $I^-(x) \subset I^-(w)$, so $x \ll y$. Suppose $\hat{I}^-(x) \subset \hat{I}^-(Q)$ with $Q \ll y$, i.e., $Q \subset I^-(w)$ and $w \ll y$; then $I^-(x) \subset Q$, so $I^-(x) \subset I^-(w)$, so $x \ll y$.

Suppose $\hat{I}^-(x) \subset \hat{I}^-(w)$ with $w \in R$ and $\hat{I}^-(x)$ nonempty; then we can find $z \in R$ with $w \ll z$, so the previous result gives us $x \ll z$, so $x \in R$, so $x \ll R$. Suppose $\hat{I}^-(x) \subset \hat{I}^-(Q)$ with $Q \subset I^-(w)$ and $w \in R$; then pick z the same, and the previous result gives $x \ll z$, so $x \in R$, i.e., $x \ll R$.

Suppose $\hat{I}^-(P) \subset \hat{I}^-(w)$ with $w \ll y$; then $P \subset I^-(w)$, so $P \ll y$. Suppose $\hat{I}^-(P) \subset \hat{I}^-(Q)$ with $Q \subset I^-(w)$ and $w \ll y$; then $P \subset Q$, so $P \subset I^-(w)$, so $P \ll y$.

Suppose $\hat{I}^-(P) \subset \hat{I}^-(w)$ with $w \in R$; then pick $z \in R$ (i.e., $z \ll R$) with $w \ll z$, and the previous result yields $P \ll z$, so $P \ll R$. Suppose $\hat{I}^-(P) \subset \hat{I}^-(Q)$ with $Q \subset I^-(w)$ and $w \in R$ (i.e., $w \ll R$); then the previous result yields $P \ll w$, so $P \ll R$.

(4) $\hat{X}$ is future-complete:

First consider a future chain $c = \{x_n\}$ made up of points of X. Let $P = I^-[c]$; then P is an IP in X. If there is a point $x \in X$ with $I^-(x) = P$, then x is a future limit of c: Since each $x_n \ll x$, for any $\alpha \in \hat{I}^-(x_n)$, $\alpha \ll x$ also; for $y \in I^-(x)$, we have $y \in I^-[c]$; and for $Q \ll x$ with $Q \in \hat{\partial}(X)$, we have $Q \subset I^-(w)$ for some $w \ll x$, hence $w \ll x_n$ for some n, so $Q \ll x_n$. Now suppose, on the other hand, that $P \in \hat{\partial}(X)$; then P is a future limit of c, as noted previously.

Now consider a future chain c in which there is some subchain c' consisting of points in X. By the paragraph above, c' has a future limit, which is then also a future limit for c.

For a future chain consisting solely of elements of $\hat{\partial}X$, just interpolate elements of S (the countable dense subset of X) into the chain, resulting in a new future chain to which the previous paragraph applies; this has the same future limits as the original one. □

Let $f: X \to Y$ be a set map between prechronological sets. We will call f *chronological* if $x \ll y$ in X implies $f(x) \ll f(y)$ in Y; f will be called *future-continuous* if, in addition, whenever x is a future limit of a future chain c in X, $f(x)$ is a future limit of $f[c]$ (necessarily a future chain in Y). For any chronological set X, we have the future-continuous map $\hat{\iota}_X: X \to \hat{X}$ given by $\hat{\iota}_X(x) = x$; this is the *standard future injection* of X (that it is future-continuous follows directly from the definitions).

For M and N strongly causal space–times, a function $f: M \to N$ is both past- and future-continuous if and only if it is (topologically) continuous and carries timelike curves to timelike curves, preserving time-orientation. This can be seen by examining, for a point $x \in M$ with sequence $\{x_n\}$ topologically converging to x, a fundamental neighborhood system of the form described in the proof of Theorem 4, $\{V_i = I^-(y_i) \cap I^+(z_i)\}$ for $\{y_i\}$ a past chain and $\{z_i\}$ a future chain, both with x as topological limit. With f both past- and future-continuous, we have $f(x)$ is

the topological limit of the chains $\{f(y_i)\}$ and $\{f(z_i)\}$, so $\{W_i = I^-(f(y_i)) \cap I^+ f(z_i))\}$ is a fundamental neighborhood system for $f(x)$. Eventually, $x_n \in V_i$, whence $f(x_n) \in W_i$; thus f is topologically continuous. However, a merely future-continuous function need not be continuous: Consider $f:\mathbb{L}^2 \to \mathbb{L}^2$ defined by $f(x,t) = (x,t)$ for $t > 0$ and $f(x,t) = (x,t-1)$ for $t \leqslant 0$ ($\mathbb{L}^n$ denotes Minkowski n-space).

Let $f:X \to Y$ be a chronological map between chronological sets with Y past-distinguishing; we will define a map $\hat{f}:\hat{X} \to \hat{Y}$, the *future completion* of f. First we define $f:\mathscr{P}(X) \to \mathscr{P}(Y)$ (the power sets) by $f(S) = \underline{I^-}[f[S]]$. For any point $x \in X$, we just let $\hat{f}(x) = f(x)$. For an IP $P \in \hat{\partial}(X)$, first note that $f(P)$ is an IP in Y: This is because for any future chain c generating P, $f(P) = \underline{I^-}[f[c]]$. If there is some $y \in Y$ with $I^-(y) = f(P)$, then we let $\hat{f}(P) = y$; otherwise, we let $\hat{f}(P) = f(P)$. [Note that $\hat{f}$ can be defined even if Y is not past-distinguishing, so long as there is never more than a single point $y \in Y$ for which $I^-(y)$ is the same as a given $f(P)$.]

6. Proposition: Let $f:X \to Y$ be a chronological map between chronological sets with Y past-determined and past-distinguishing (or, more generally: for any future chain in X with no future limit in X, its image under f does not have more than one future limit in $\hat{Y}$); then $\hat{f}$ is also chronological. If f is future-continuous, then $\hat{f}$ is the unique future-continuous map such that $\hat{f} \circ \hat{\imath}_X = \hat{\imath}_Y \circ f$.

Proof: That $\hat{f} \circ \hat{\imath}_X = \hat{\imath}_Y \circ f$ is clear. From this and f being chronological it follows that $x \ll y$ in X implies $\hat{f}(x) \ll \hat{f}(y)$. Suppose $x \ll P$ for $x \in X$ and $P \in \hat{\partial}(X)$. Let P be generated by a future chain $c = \{x_n\}$, so that $\underline{f}[c]$ generates $f(P)$. We have $x \in P$, so $x \ll x_n$ for some n; thus $f(x) \ll f(x_n)$, so $\underline{f}(x) \in f(P)$. If $f(P) \in \hat{\partial}(Y)$, this is all we need for $\hat{f}(x) \ll \hat{f}(P)$; otherwise, for some $y \in Y$, $f(P) = I^-(y)$, so $f(x) \in I^-(y)$, or $f(x) \ll y$, so $\hat{f}(x) \ll \hat{f}(P)$. If $P \ll x$ (same notation), then $P \subset I^-(w)$ for some $w \ll x$. With the future chain c as before, we have for all n, $x_n \ll w \ll x$, so $f(x_n) \ll f(w) \ll \underline{f}(x)$. This gives us $f(P) \subset I^-(f(w))$. If $f(P) \in \hat{\partial}(Y)$, then $\hat{f}(P) \ll \hat{f}(x)$; otherwise, for some $y \in Y$, $f(P) = I^-(y)$, so $y \ll f(x)$ by Y being past-determined. Finally, suppose $P \ll Q$ for P and Q in $\hat{\partial}(X)$; then there is some $x \in X$ with $P \ll x \ll Q$, so the previous results apply.

Suppose f is future-continuous. Clearly, for a point $x \in X$ being a future limit of a future chain of points $c = \{x_n\}$ in X, the same is true for $\hat{f}(x)$ and $\{\hat{f}(x_n)\}$. For $P \in \hat{\partial}(X)$ being a future limit of the chain, since P is generated by c, $f(P)$ is generated by $\underline{f}[c]$. Thus if $f(P) \in \hat{\partial}(Y)$, then it is the future limit of $f[c]$, and we are done, since $\hat{f}(P) = f(P)$. Otherwise, for some $y \in Y$, $f(P) = I^-(y)$ and again we are done, since $\hat{f}(P) = y$ and y is a future limit of $f[c] = \hat{f}[c]$. We need concern ourselves solely with chains of points in X, for any other sort can have points of X interpolated into it with no change in future limits.

The restriction of $\hat{f}$ to X is uniquely determined by $\hat{f} \circ \hat{\imath}_X = \hat{\imath}_Y \circ f$. For $\hat{f}$ to be future-continuous, for any $P \in \hat{\partial}(X)$, since P is a future limit of any chain c generating it, we must have $\hat{f}(P)$ a future limit of $f[c]$. With Y past-distinguishing (or, more generally, with the definition of $\hat{f}$ above yielding a well-defined function), this is unique. □

Another way to express the previous result is more closely related to adjunctions:

7. Corollary: Let $f:X \to Y$ be a future-continuous function between chronological sets with Y past-determined, past-distinguishing, and future-complete (or, more generally: for any future chain in X, its image under f has exactly one future limit in Y, which is past-determined); then there is a unique future-continuous function $\hat{f}:\hat{X} \to Y$ such that $\hat{f} \circ \hat{\imath}_X = f$.

Proof: We need but note that with Y being future complete, $\hat{Y} = Y$ and $\hat{\imath}_Y$ is the identity map on Y; then Proposition 6 applies. □

Conversely, we could have started with Corollary 7 and deduced Proposition 6: Given future-continuous $f:X \to Y$ with Y past-determined and past-distinguishing, we have $\hat{\imath}_Y \circ f:X \to \hat{Y}$ fulfilling the hypotheses of Corollary 7, yielding $\hat{f}:\hat{X} \to \hat{Y}$ as the unique future-continuous map such that $\hat{f} \circ \hat{\imath}_X = \hat{\imath}_Y \circ f$.

These results allow us to define some categories, some functors, a natural transformation, and an adjunction: Let **Chron** be the category of chronological sets with morphisms all chronological functions; since the composition of chronological functions is clearly chronological, this is a category. Let **PdetPdisChron** be the subcategory of past-determined, past-distinguishing chronological sets, with morphisms all future-continuous functions; again, a composition of future-

continuous functions is future-continuous, so this is a category. Let **FcplPdetPdisChron** be the full subcategory of **PdetPdisChron** of objects which are also future-complete. Then future completion is a functor $\hat{}$**:PdetPdisChron**$\to$**FcplPdetPdisChron** (we need only check that $\widehat{g\circ f}=\hat{g}\circ\hat{f}$; this follows from the uniqueness part of Proposition 6, since $\hat{g}\circ\hat{f}$ has the requisite properties); while Theorem 5 gives us the right properties for the future completion of any chronological set, Proposition 6 gives us functoriality only for this subcategory. We also have the forgetful functor $\hat{\mathbf{U}}$:**FcplPdetPdisChron**$\to$**PdetPdisChron**. The maps $\hat{\iota}_X$ define a natural transformation $\hat{\boldsymbol{\iota}}$:**I**$\dot{\to}\hat{\mathbf{U}}\circ\hat{}$ (where **I** is the identity functor on **PdetPdisChron**). Finally, Proposition 7 gives us the universality condition on $\hat{\boldsymbol{\iota}}$ making $\hat{}$ left adjoint to $\hat{\mathbf{U}}$. From category theory we obtain

8. Theorem: *The future completion functor and the standard future injection are, up to natural isomorphism, the unique construction yielding a future-continuous map from any past-determined, past-distinguishing chronological set to a future-complete, past-determined, past-distinguishing chronological set, consistent with all future-continuous maps and yielding a unique extension for any future-continuous map into a future-complete, past-determined, past-distinguishing chronological set.* □

To restate the previous three theorems in summary form:

(1) For X in **Chron**, Y in **PdetPdisChron**, and $f:X\to Y$ future-continuous, $\hat{f}:\hat{X}\to\hat{Y}$ is the unique future-continuous map with $\hat{f}\circ\hat{\iota}_X=\hat{\iota}_Y\circ f$.
(2) For X in **Chron**, Y in **FcplPdetPdisChron**, and $f:X\to Y$ future-continuous, $\hat{f}:\hat{X}\to Y$ is the unique future-continuous map with $\hat{f}\circ\hat{\iota}_X=f$.
(3) Restricted to **PdetPdisChron**, the construction of $\hat{X}$, $\hat{f}$, and $\hat{\iota}_X$ is functorial, natural, and universal, hence unique as a way to fulfill (1) and (2) in such a manner.

III. PAST-DETERMINATION FUNCTOR

It is quite common for a space–time not to be past-determined, so there is a limited application of the functor $\hat{}$ to space–times. However, this can be remedied if we are willing to create new $\ll$ relations in the space–time, in order to make it past-determined. We will do this generally:

Consider a prechronological set X; using the same set X, let us define a new relation, $\ll^p$: For any x and y in X, set $x\ll^p y$ if $x\ll y$ or if $I^-(x)$ is nonempty and for some $w\ll y$, $I^-(x)\subset I^-(w)$; we will use I^{-p} to denote the past of a point (or set) using the $\ll^p$ relation. Clearly, $\ll^p$ is an extension of $\ll$. Note that if X is past-determined, then $\ll^p$ is identical to $\ll$.

Two properties of $\ll^p$ should be noted: First, for any x, $I^-[I^{-p}(x)]=I^-(x)$: If $y\ll z\ll^p x$, then $z\ll x$ (and so $y\ll x$) or $I^-(z)\subset I^-(w)$ for some $w\ll x$; we have $y\in I^-(z)$, so we get $y\in I^-(w)$, i.e., $y\ll w$, so $y\ll x$. On the other hand, if $y\ll x$, then by fullness there is some z with $y\ll z\ll x$; this gives us $z\ll^p x$, so $y\in I^-[I^{-p}(x)]$. [Also, $I^{-p}[I^-(x)]=I^{-p}(x)$; this is done similarly.] Second, $I^-(x)\subset I^-(y)$ if and only if $I^{-p}(x)\subset I^{-p}(y)$: Given $I^-(x)\subset I^-(y)$, if $z\ll^p x$, then we have $z\ll x$ [so $z\in I^-(x)\subset I^-(y)\subset I^{-p}(y)$] or we have $I^-(z)\neq\varnothing$ and $I^-(z)\subset I^-(w)$ for some $w\ll x$; in the latter case, we have $w\ll y$ also, so $z\ll^p y$. On the other hand, given $I^{-p}(x)\subset I^{-p}(y)$, we obtain, from the first property noted, $I^-(x)=I^-[I^{-p}(x)]\subset I^-[I^{-p}(y)]=I^-(y)$. In particular, we have $I^-(x)=I^-(y)$ if and only if $I^{-p}(x)=I^{-p}(y)$.

For a space–time, the physical significance of the $\ll^p$ relation can be viewed this way: Consider any observer as compiling an encyclopedia of all events witnessed; the space–time is to be thought of also as the set of encyclopedias, with the event p corresponding to the history of all events in $I^-(p)$. Then $p\ll^p q$ means that not only has q transcribed all the events that are written at p, but, moreover, has had a chance to think about them (i.e., an observer has traveled from some event w, which has recorded all events that are written at p, and then continued on to event q).

We will use X^p to denote X with the relation $\ll^p$; call it the *past-determination* of X.

If $c=\{x_n\}$ is a future chain in X^p, then we have for all n, $I^-(x_n)\subset I^-(w_n)$ for some sequence $\{w_n\}$ with $w_n\ll x_{n+1}$. This gives us $w_n\in I^-(x_{n+1})\subset I^-(w_{n+1})$, so $w_n\ll w_{n+1}$:$c'=\{w_n\}$ is a future chain in X. Note that $I^-[c']=I^-[c]$, due to the interweavings $I^-(x_n)\subset I^-(w_n)$ and $I^-(w_n)\subset I^-(x_{n+1})$; in general, when this interweaving obtains, we will say that c' (in X) is an *associated* chain to c (in X^p). This works well for looking at future limits:

9. Lemma: Let c' be a future chain in X associated to a future chain c in X^p. Then a point x is a future limit of c in X^p if and only if it is a future limit of c' in X.

Proof: Suppose $I^{-p}(x)=I^{-p}[c]$; then $I^-(x)=I^-[c]=I^-[c']$. Now suppose $I^-(x)=I^-[c']$; then $I^-(x)=I^-[c]$. Let $c=\{x_n\}$. For $z\ll^p x$, we have $I^-(z)$ is nonempty and $I^-(z)\subset I^-(w)$ for some $w\ll x$; since $I^-(x)=I^-[c]$, we have $w\ll x_n$ for some n, so $z\in I^{-p}[c]$. On the other hand, if $z\in I^{-p}[c]$, then $I^-(z)$ is nonempty and $I^-(z)\subset I^-(w)$ for some $w\ll x_n$ for some n; then [since $I^-[c]=I^-(x)$] $w\ll x$ also, so $z\ll^p x$. □

10. Proposition: For any prechronological set X, X^p is a past-determined prechronological set. If X is a chronological set, so is X^p; if X is past-distinguishing, so is X^p; and if X is future-complete, so is X^p.

Proof: This is largely routine. For example, to show X^p is past-determined, consider $I^{-p}(x)\subset I^{-p}(w)$ with $I^{-p}(x)$ nonempty and $w\ll^p y$; we want to show $x\ll^p y$. From $w\ll^p y$ we know that for some $v\ll y$, $I^-(w)\subset I^-(v)$ (this is true even if $w\ll y$). We have $I^-(x)\subset I^-(w)$, so $I^-(x)\subset I^-(v)$. Since $I^{-p}(x)$ is nonempty, so is $I^-(x)$. Thus $x\ll^p y$.

Suppose X is future-complete. Let $c=\{x_n\}$ be a future chain in X^p. Let x be a future limit of an associated future chain c' in X; then by Lemma 9, x is also a future limit of c in X^p. □

Past-determination works well with future-continuous functions, so long as the domain has the property that every point is a future limit of some future chain; let us call this property being *past-connected*. Clearly, any space–time is past-connected, and future completion preserves being past-connected (since an element of the future chronological boundary is always a future limit of any of its generating chains). Also, forming the past-determination of a prechronological set preserves being past-connected, in virtue of Lemma 9.

11. Proposition: If $f:X\to Y$ is a future-continuous map between prechronological sets, and X is past-connected, then the same function $f^p=f:X^p\to Y^p$ between the past-determinations is also future-continuous.

Proof: First we will show that f^p is chronological; we must show that if $x\ll^p y$, then $f(x)\ll^p f(y)$: We have $I^-(x)$ is nonempty and $I^-(x)\subset I^-(w)$ for some $w\ll y$. We have some $z\ll x$, so $f(z)\ll f(x)$: $I^-(f(x))$ is nonempty. With x a future limit of a future chain c, $f(x)$ is a future limit of $f[c]$, so $I^-(f(x))=I^-[f[c]]$. We have $c\subset I^-(w)$, so $f[c]\subset I^-(f(w))$, so $I^-[f[c]]\subset I^-(f(w))$. Therefore $I^-(f(x))\subset I^-(f(w))$ and $f(w)\ll f(y)$: $f(x)\ll^p f(y)$.

Now suppose that $c=\{x_n\}$ is a future chain in X^p with future limit x. For c' an associated chain in X, we know by Lemma 9 that x is also a future limit in X of c'; then $f(x)$ is a future limit in Y of $f[c']$. Furthermore, $f[c']$ is an associated chain of $f[c]$ (the relations defining association are preserved by a chronological function), so Lemma 9 also gives us that $f(x)$ is a future limit in Y^p of $f[c]$. □

For any prechronological set X, let us denote by $\iota^p_X:X\to X^p$ the map which, on the set level, is the identity map. This is clearly chronological, and it is also future-continuous: If, for a future chain c and point x in X, $I^-(x)=I^-[c]$, then $I^{-p}(x)=I^{-p}[c]$ also (using the second property of $\ll^p$ mentioned at the beginning of this section).

12. Corollary: Let $f:X\to Y$ be a future-continuous map between prechronological sets, with X past-connected and Y past-determined; then there is a unique future-continuous map $f^p:X^p\to Y$ such that $f^p\circ\iota^p_X=f$.

Proof: By Proposition 10, $Y^p=Y$. Then the map $f^p:X^p\to Y^p$ given by Proposition 11 fills the required condition, and uniquely does so because of what ι^p_X is on the set level. □

Proposition 11 and Corollary 12 have the same categorical properties as Proposition 6 and Corollary 7, and we derive similar categorical constructions: We have a functor **p**: **PconChron** $\to$**PdetPconChron**, where **-Pcon-** denotes the subcategory of past-connected objects. We also have a natural transformation $\boldsymbol{\iota}^{\mathbf{p}}:\mathbf{I}\dot{\to}\mathbf{U}^{\mathbf{p}}\circ\mathbf{p}$, where $\mathbf{U}^{\mathbf{p}}$: **PdetPconChron**$\to$**PconChron** is the forgetful functor and **I** is the identity functor on **PconChron**. Then Corollary 12 is precisely the statement that **p** (via $\boldsymbol{\iota}^{\mathbf{p}}$) is a left adjoint to $\mathbf{U}^{\mathbf{p}}$. (The same applies to the restriction, in all cases, to the respective subcategories of past-distinguishing objects, **-Pdis-**, which will be used for composition with the future completion functor.) Thus, similar to Theorem 8, we can conclude that the past-determination functor is the unique way to create a past-determined chronological set (at least, if one starts with all points being future limits), in a categorical, natural, and universal manner. Summarizing as before, we have

(4) For X in **PconPrechron**, Y in **Prechron**, and $f:X\to Y$ future-continuous, $f^p:X^p\to Y^p$ is the unique future-continuous map with $f^p\circ\iota^p_X=\iota^p_Y\circ f$.

(5) For X in **PconPrechron**, Y in **PdetPrechron**, and $f:X\to Y$ future-continuous, $f^p:X^p\to Y$ is the unique future-continuous map with $f^p\circ\iota_X^p=f$.
(6) Restricted to **PconChron** (or, more generally, **PconPrechron**), the construction of X^p, f^p, and ι_X^p is functorial, natural, and universal, hence the unique way to fulfill (4) and (5) in such a manner. The same is true for the further restriction to **PconPdisChron**.

We can combine these results with those of the previous section, composing the categorical items: Restricting the functor $\hat{}$ to **PdetPconPdisChron**, we have the composition $\hat{}\circ\mathbf{p}$:**PconPdisChron**$\to$**FcplPdetPconPdisChron** and the forgetful functor $\mathbf{U}^+=\hat{\mathbf{U}}\circ\mathbf{U}^{\mathbf{p}}$ in the opposite direction. For any X in **PconChron**, let $\iota_X^\uparrow=\hat{\iota}_{X^p}\circ\iota_X^p:X\to\widehat{X^p}$; then the collection of maps $\{\iota_X^\uparrow\}$ forms a natural transformation $\boldsymbol{\iota}^\uparrow:\mathbf{I}\dot{\to}\mathbf{U}^+\circ\hat{}\circ\mathbf{p}$ ($\mathbf{I}$ as above), and this yields $\hat{}\circ\mathbf{p}$ as left adjoint to $\mathbf{U}^+$. Summarizing as before, we have

(7) For X in **PconChron**, Y in **PdisChron**, and $f:X\to Y$ future-continuous, $\widehat{f^p}:\widehat{X^p}\to\widehat{Y^p}$ is the unique future-continuous map with $\widehat{f^p}\circ\iota_X^\uparrow=\iota_Y^\uparrow\circ f$.
(8) For X in **PconChron**, Y in **FcplPdetPdisChron**, and $f:X\to Y$ future-continuous, $\widehat{f^p}:\widehat{X^p}\to Y$ is the unique future-continuous map with $\widehat{f^p}\circ\iota_X^\uparrow=f$.
(9) Restricted to **PconPdisChron**, the construction of $\widehat{X^p}$, $\widehat{f^p}$, and $\iota_X^\uparrow$ is the functorial, natural, and universal, hence the unique way to fulfill (7) and (8) in such a manner.

We need to consider how past-determination interacts with future completion. First, let us compare the past of a point x of X in $\hat{X}^p$ with its past in $\widehat{X^p}$: For $y\in X$, we have $y\in\hat{I}^{-p}(x)$ if $y\ll x$ or if $\hat{I}^-(y)$ is nonempty and $\hat{I}^-(y)\subset\hat{I}^-(w)$ for some $w\ll x$; while we have $y\in\widehat{I^{-p}}(x)$ if $y\ll x$ or if $I^-(y)$ is nonempty and $I^-(y)\subset I^-(w)$ for some $w\ll x$. These are equivalent conditions: For instance, suppose $I^-(y)\subset I^-(w)$; then $P\ll y$ means $P\subset I^-(z)$ for some $z\ll y$, which then yields $z\ll w$, so $P\ll w$, also. For $Q\in\hat{\partial}(X)$, we have $Q\in\hat{I}^{-p}(x)$ if $Q\ll x$—i.e., if $Q\subset I^-(w)$ for some $w\ll x$—or if $\hat{I}^-(Q)$ is nonempty and $\hat{I}^-(Q)\subset\hat{I}^-(w)$ for some $w\ll x$; while for $Q\in\hat{\partial}(X^p)$, we have $Q\in\widehat{I^{-p}}(x)$ if $Q\subset I^{-p}(w)$ for some $w\ll^p x$. But to compare these two conditions directly is awkward, and we will instead use a pair of maps to aid in the analysis.

For a chronological set X, let us define the maps $i:\hat{X}^p\to\widehat{X^p}$ and $j:\widehat{X^p}\to\hat{X}^p$ as follows: Both maps are to be the identity on X. For $P\in\hat{\partial}(X)$, let c be any future chain in X generating P; then $i(P)=I^{-p}[c]$. For $Q\in\hat{\partial}(X^p)$, let c be a future chain in X^p generating Q; let c' be an associated chain in X, and let $j(Q)=I^-[c']$.

13. Proposition: For any chronological set X, the maps i and j above are future-continuous and give an isomorphism between $\hat{X}^p$ *and* $\widehat{X^p}$.

Proof: We will use $\hat{\ll}$ to denote the relation in $\hat{X}$, $\hat{\ll}^p$ to denote the relation in $\hat{X}^p$ and $\widehat{\ll^p}$ to denote that in $\widehat{X^p}$.

First we will treat $i:\hat{X}^p\to\widehat{X^p}$. We have that for $x\in X(=X^p)$, $i(x)=x$, and for $P\in\hat{\partial}(X)$, $i(P)=I^{-p}[c]$ for a future chain c in X generating P; we need to see that this is well-defined. Clearly, $I^{-p}[c]$ is an IP in X^p; it is in $\hat{\partial}(X^p)$ because if $I^{-p}[c]=I^{-p}(x)$, then $I^-[c]=I^-(x)$, which is impossible with $P\in\hat{\partial}(X)$. We can also write it as $I^{-p}[P]$, which shows that it is independent of the chain taken as the generator for P.

To show i is chronological, consider x and y in X, P and Q in $\hat{\partial}(X)$, and future chains $c=\{x_n\}$ and $d=\{y_n\}$ generating P and Q, respectively:

It is largely routine to show that if $x\hat{\ll}^p y$, then $x\widehat{\ll^p}y$. Since $i(x)=x$ and $i(y)=y$, we are done.

If $x\hat{\ll}^p Q$, then we have $x\hat{\ll}Q$ or we have $\hat{I}^-(x)\neq\varnothing$ and $\hat{I}^-(x)\subset\hat{I}^-(w)$ for some $w\hat{\ll}Q$ (as above, we can take $w\in X$). In the first case, we have $x\in Q=I^-[d]\subset I^{-p}[d]$. In the second case, we have $I^-(x)\neq\varnothing$ and $I^-(x)\subset I^-(w)$ and $w\ll y_n$ for some n (since $w\in Q$), so $x\ll^p y_n$, so again $x\in I^{-p}[d]$. In either case, this gives us $x\in i(Q)$, so $i(x)\widehat{\ll^p}i(Q)$, and we are done.

If $P\hat{\ll}^p y$ (or Q), then we have that $P\hat{\ll}y$ (or Q)—in which case we have $P\subset I^-(w)$ for some $w\ll y$ (or $w\in Q$)—or we have that $\hat{I}^-(P)\neq\varnothing$ and $\hat{I}^-(P)\subset\hat{I}^-(w)$ for some $w\hat{\ll}y$ (or Q)—in which case we again have $P\subset I^-(w)$ and $w\ll y$ (or $w\in Q$). Then in either case we have

$I^-[c]\subset I^-(w)$, so $i(P)=I^{-p}[c]\subset I^{-p}(w)$, with $w\ll^p i(y)$ [or $w\in i(Q)$], so $i(P)\widehat{\ll^p} i(y)$ [or $i(Q)$], and we are done.

Now we consider $j:\widehat{X^p}\to\hat{X}^p$. For $x\in X^p$, $j(x)=x$, and for $Q\in\hat{\partial}(X^p)$, $j(Q)=I^-[c']$ for c' a future chain in X associated to a chain c in X^p generating Q. Clearly $I^-[c']$ is an IP in X; it is in $\hat{\partial}(X)$ because if x is a future limit in X for c', then it is also a future limit in X^p for c, which is impossible for $Q\in\hat{\partial}(X^p)$. We can also write it as $I^-[Q]$, which shows it is independent of the chain taken as the generator for Q and of the chain in X associated to that one.

To show j is chronological, consider x and y in X, P and Q in $\hat{\partial}(X^p)$, and $c=\{x_n\}$ and $d=\{y_n\}$ future chains in X^p generating, respectively, P and Q:

It is routine to show that if $x\widehat{\ll^p}y$, then $x\hat{\ll}^p y$. Thus $j(x)\hat{\ll}^p j(y)$.

If $x\widehat{\ll^p}Q$, then $x\in Q$. To show $j(x)\hat{\ll}^p j(Q)$, we must show either that $x\hat{\ll}I^-[Q]$ or that $\hat{I}^-(x)\neq\varnothing$ and $\hat{I}^-(x)\subset\hat{I}^-(w)$ for some $w\hat{\ll}I^-[Q]$, i.e., $w\in\hat{I}^-[Q]$. If $x\in I^-[Q]$, then we have $x\hat{\ll}\hat{I}^-[Q]$. Otherwise, the only way for x to be in Q is for there to be some $q\in Q$ with $x\ll^p q$, i.e., $I^-(x)\neq\varnothing$ and $I^-(x)\subset I^-(w)$ for some $w\ll q$; then $\hat{I}^-(x)\subset\hat{I}^-(w)$, also. Since w is in $I^-[Q]$, this shows $j(x)\hat{\ll}^p j(Q)$.

If $P\widehat{\ll^p}y$ (or Q), then $P\subset I^{-p}(w)$ for some $w\ll^p y$ (or in Q). We then have $j(P)=I^-[P]\subset I^-[I^{-p}(w)]=I^-(w)$. Taking the case of y, we need only [since $I^-(w)\neq\varnothing$] look at $I^-(w)\subset I^-(z)$ for some $z\ll y$. We have $j(P)\subset I^-(z)$ [and $I^-(j(P))=I^-[P]$ contains points in P, so is nonempty], so $j(P)\hat{\ll}^p y$. For the case of Q, we have $w\in Q$, so for some $q\in Q$, $w\ll^p q$; again, we consider only $I^-(w)\subset I^-(z)$ for some $z\ll q$. We have $j(P)\subset I^-(z)$ with $z\in I^-[Q]$, i.e., $z\hat{\ll}j(Q)$; thus, $j(P)\hat{\ll}^p j(Q)$.

Now we consider the compositions: For $P\in\hat{\partial}(X)$, $j(i(P))=I^-[I^{-p}[P]]=I^-[P]=P$. Thus we have $j\circ i=1_{\hat{X}^p}$. For $Q\in\hat{\partial}(X^p)$, $i(j(Q))=I^{-p}[I^-[Q]]=I^{-p}[Q]=Q$ [using $I^{-p}[I^-(x)]=I^{-p}(x)$]. This gives us $i\circ j=1_{\widehat{X^p}}$.

Now we know that i and j provide an isomorphism of sets-with-a-relation between $\hat{X}^p$ and $\widehat{X^p}$. Since future limits are defined purely in terms of the relations, we automatically get that both maps are future-continuous. □

It is tempting to think of the maps i_X and j_X, as collections for all X in **PconPdisChron**, as forming a pair of natural transformations $\mathbf{i}:\mathbf{p}\circ\hat{}\dot{\to}\hat{}\circ\mathbf{p}$ and $\mathbf{j}:\hat{}\circ\mathbf{p}\dot{\to}\mathbf{p}\circ\hat{}$; since they are inverses of one another, we would then have a natural isomorphism between the two constructions. This would then establish that all that was done with the construction of $\widehat{X^p}$ can also be done with the construction of $\hat{X}^p$. Since this latter is the construction that precisely reproduces the GKP future causal boundary, this is a desirable outcome. However, there is a problem: One cannot compose the functors in the order $\mathbf{p}\circ\hat{}$, since Proposition 6 allows us to conclude that $\hat{f}:\hat{X}\to\hat{Y}$ is future-continuous (starting with $f:X\to Y$ future-continuous) only if Y is already past-determined. But there is a way around this difficulty, thereby establishing the categorical nature of the GKP construction:

We will use X^+ to denote $\hat{X}^p$, for X any chronological set. For a future-continuous function $f:X\to Y$ between chronological sets, we cannot in general consider $\hat{f}^p$, since $\hat{f}$ is not in general future-continuous unless Y is past-determined. But so long as Y is past-distinguishing and X is past-connected, we can use $\widehat{f^p}:\widehat{X^p}\to\widehat{Y^p}$, which is future-continuous; then we can define $f^+=j_Y\circ\widehat{f^p}\circ i_X:X^+\to Y^+$. Finally, we define $\iota_X^+=j_X\circ\iota_X^\uparrow:X\to X^+$.

14. Theorem: *For any chronological set X, X^+ is past-determined and future-complete, and $\iota_X^+:X\to X^+$ is future-continuous; if X is past-connected (or, respectively, past-distinguishing), then so is X^+. If X is past-connected and Y is a past-distinguishing chronological set, then for any future-continuous map $f:X\to Y$, $f^+:X^+\to Y^+$ is the unique future-continuous map such that $f^+\circ\iota_X^+=\iota_Y^+\circ f$. If Y is also past-determined and future-complete, than $f^+:X^+\to Y$ is the unique future-continuous map such that $f^+\circ\iota_X^+=f$.*

Proof: These claims (especially in the first sentence) are largely automatic consequences of previous results. However, it is worth some effort to explore in finer detail how the maps are related, such as how to express $\iota_X^\uparrow$ and ι_X^+ (defined by compositions through X^p) as compositions through $\hat{X}$. To do this we need to establish that several diagrams involving the injections ι commute. Some of these follow from categorical principles when in the category **PconChron**, but

others involve the particularities of these maps (especially when past-connectedness is not assumed).

One noncategorical result is the application of future-completion using the full strength of Proposition 6: The purely categorical use of future completion applies only to the category of past-determined, past-distinguishing chronological sets [as per summary statement (3)], but we need to apply it to the map $\iota^p_X : X \to X^p$, where it would be pointless to assume X past-determined. But Proposition 6 gives us the result anyway, as displayed in Diagram 1:

$$\begin{array}{ccc} X & \xrightarrow{\iota^p_X} & X^p \\ \downarrow{\scriptstyle \hat{\iota}_X} & & \downarrow{\scriptstyle \hat{\iota}_{X^p}} \\ \hat{X} & \xrightarrow{\widehat{\iota^p_X}} & \widehat{X^p} \end{array}$$

Diagram 1. Composition is $\iota^{\uparrow}_X$.

The map ι^p_X is always future-continuous, as is the standard future injection $\hat{\iota}$, whether for X or for X^p. By Proposition 6, we can define future completion of ι^p_X, and have it be future-continuous, even without X^p being past-distinguishing, so long as for any future chain c in X generating an element of $\hat{\partial}(X)$, $\iota^p_X[c]$ has no more than one future-limit in $\widehat{X^p}$; but this is manifestly the case, since $\hat{\partial}(X^p)$ (or $\hat{\partial}$ in general) is defined in such a way that no two elements can have identical pasts. Proposition 6 also yields that Diagram 1 commutes, and, as indicated, the composition is $\iota^{\uparrow}_X$.

For X past-connected, an entirely categorical result comes from starting with $\hat{\iota}_X : X \to \hat{X}$ and applying the past-determination functor and the natural transformation ι^P, yielding the commutative diagram of future-continuous maps shown in Diagram 2.

$$\begin{array}{ccc} X & \xrightarrow{\iota^p_X} & X^p \\ \downarrow{\scriptstyle \hat{\iota}_X} & & \downarrow{\scriptstyle (\hat{\iota}_X)^p} \\ \hat{X} & \xrightarrow{\iota^p_{\hat{X}}} & \hat{X}^p \end{array}$$

Diagram 2. Composition is ι^+_X (see Diagram 4).

Even if X is not past-connected, Diagram 2 still commutes (since each composition is just inclusion), and $(\hat{\iota}_X)^p$ is still future-continuous: For chronologicality, we need to show that if $x \ll^p y$ (in X), then $x \hat{\ll}^p y$ (in $\hat{X}$): If $I^-(x) \subset I^-(w)$ for $w \ll y$, then $\hat{I}^-(x) \subset \hat{I}^-(w)$ and $w \hat{\ll} y$. For future-continuity, we need to show that if x is a future limit of a future chain c in X^p, then x is also a future limit of c in $\hat{X}^p$: If x is a future limit of c in X^p, then by Lemma 9 x is a future limit of an associated future chain c' in X; application of the future-continuous $\hat{\iota}_X$ shows that x is a future limit of c' also in $\hat{X}$; then, applying Lemma 9 once more (with c' being associated to c in $\hat{X}$ as well as in X), we have x a future limit of c in $\hat{X}^p$.

The identification of the composition in Diagram 2 as ι^+_X will follow from Diagram 4. But before that we must consider Diagram 3: This commutes because both $i_X \circ (\hat{\iota}_X)^p$ and $\hat{\iota}_{X^p}$ are just inclusion on the set-level. Commuting in the other direction, with j_X, then follows automatically.

$$\begin{array}{ccc} X^p & = & X^p \\ \downarrow{\scriptstyle (\hat{\iota}_X)^p} & & \downarrow{\scriptstyle \hat{\iota}_{X^p}} \\ \hat{X}^p & \underset{j_X}{\overset{i_X}{\rightleftarrows}} & \widehat{X^p} \end{array}$$

Diagram 3.

The final result involving commuting injections is shown in Diagram 4. To establish the commutativity, we first combine Diagrams 2 and 3 into Diagram 5 and compare with Diagram 1; we use the uniqueness property of future completion from Proposition 6 [summary statement (1)] to see that that the bottom lines of Diagrams 1 and 5 must be the same, and that is the content of Diagram 4. (As before, establishing the result with i_X automatically yields the result for j_X.) Combining this with Diagram 1 and the definition of ι_X^+ yields the identification alluded to in Diagram 2.

$$\begin{array}{ccc} \hat{X} & = & \hat{X} \\ \downarrow \iota^p_{\hat{X}} & & \downarrow \widehat{\iota^p_X} \\ \hat{X}^p & \underset{j_X}{\overset{i_X}{\rightleftarrows}} & \widehat{X^p} \end{array}$$

Diagram 4.

$$\begin{array}{ccccc} X & \xrightarrow{\iota^p_X} & X^p & = & X^p \\ \downarrow \hat{\iota}_X & & \downarrow (\hat{\iota}_X)^p & & \downarrow \hat{\iota}_{X^p} \\ \hat{X} & \xrightarrow{\iota^p_{\hat{X}}} & \hat{X}^p & \xrightarrow{i_X} & \widehat{X^p} \end{array}$$

Diagram 5. Diagrams 2 and 3 combined.

Finally, in Diagram 6 we consider the diagram derived from future-continuous $f:X\to Y$ for X past-connected and Y past-distinguishing. The top two portions of Diagram 6 commute due to previously established results [summary statements (1) and (4)]. The bottom portion commutes, as that is the definition of f^+. The overall structure of Diagram 6 can be expressed as Diagram 7.

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ \downarrow \iota^p_X & & \downarrow \iota^p_Y \\ X^p & \xrightarrow{f^p} & Y^p \\ \downarrow \hat{\iota}_{X^p} & & \downarrow \hat{\iota}_{Y^p} \\ \widehat{X^p} & \xrightarrow{\widehat{f^p}} & \widehat{Y^p} \\ \cong \uparrow i_X & & \cong \downarrow j_Y \\ \hat{X}^p = X^+ & \xrightarrow{f^+} & Y^+ = \hat{Y}^p \end{array}$$

Diagram 6.

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ \downarrow \iota^+_X & & \downarrow \iota^+_Y \\ X^+ & \xrightarrow{f^+} & Y^+ \end{array}$$

Diagram 7. Overall structure of Diagram 6.

The map f^+ is unique for fulfilling its role in Diagram 7, since for any other future-continuous map $g:X^+\to Y^+$ making Diagram 7 commute, $i_Y\circ g\circ j_X$ would fill the role of $\widehat{f^p}$ in Diagram 6, and the uniqueness portion of summary statement (4) would show $i_Y\circ g\circ j_X=\widehat{f^p}$, so $g=f^+$.

If Y is also past-determined and future-complete, then $Y^+=Y$ and $\iota_Y^+=1_Y$, yielding the last statement in the theorem. □

Theorem 14 enables us to define the functor $+$: **PconPdisChron**$\to$ **FcplPdetPconPdisChron**, with $X^+=\hat{X}^p$ and $f^+:X^+\to Y^+$, even though we cannot define f^+ as $\hat{f}^p$. We also have the natural transformation $\boldsymbol{\iota}^+:\mathbf{I}\dot{\to}\mathbf{U}^+\circ+$ (where **I** denotes the identity on **PconPdisChron**) yielding $+$ as left adjoint to $\mathbf{U}^+$. Since a functor can have only one left adjoint, up to natural isomorphism, there must be a natural isomorphism, then, between $+$ and $\hat{}\circ\mathbf{p}$. This is provided, in fact, by $\mathbf{i}:+\dot{\to}\hat{}\circ\mathbf{p}$ and $\mathbf{j}:\hat{}\circ\mathbf{p}\dot{\to}+$, whose naturality is a triviality.

Expressing this in summary form as before, we have

(10) For X in **PconChron**, Y in **PdisChron**, and $f:X\to Y$ future-continuous, $f^+:X^+\to Y^+$ is the unique future-continuous map with $f^+\circ\iota_X^+=\iota_Y^+\circ f$.

(11) For X in **PconChron**, Y in **FcplPdetPdisChron**, and $f:X\to Y$ future-continuous, $f^+:X^+\to Y$ is the unique future-continuous map with $f^+\circ\iota_X^+=f$.

(12) Restricted to **PconPdisChron**, the construction of X^+, f^+, and ι_X^+ is functorial, natural, and universal, hence the unique way to fulfill (10) and (11).

For a space–time M, $\hat{M}^p$ is precisely the addition to M of the GKP future causal boundary: $\hat{M}$ is identified with the IPs of M [the TIPs—IPs not of the form $I^-(x)$ for any point x—being $\hat{\partial}(M)$], and the $\ll^p$ relation is exactly that as specified by GKP. Since any strongly causal space–time M is in **PconPdisChron**, any ''reasonable'' way of future-completing M—an embedding of M into a past-determined, past-distinguishing, future-complete object—must contain the GKP future boundary in the sense of Theorem 14: there is a unique future-continuous extension of the embedding to the GKP future completion of M.

Typically, one applies these ideas by starting with a strongly causal space–time M and a purported future completion of it, such as a topological embedding of M into another space–time N, $j:M\to N$, which preserves the chronological relations of M and which includes future end points for all the endless timelike curves in M. The actual object which is the purported future completion of M is the closure of $j(M)$ in N; call this object Y, with a chronology relation inherited from N. Then, since M is past-connected and Y (typically) is past-distinguishing, we have, from Theorem 14, $j^+:M^+\to Y^+$; assuming Y is itself future-complete, we have $Y^+=Y^p$. Then, in particular, j^+ maps $\hat{\partial}(M)$ to the boundary of $j[M]$ in N. If we had the good sense to choose the enveloping space–time N in such a way that every point in the closure of $j[M]$ was actually a future end point of a timelike curve in M (mediated by j)—or if we restrict Y to be just such points—then Y is mapped onto by j^+, with the boundary-points of Y being covered by $j^+[\hat{\partial}(M)]$. This places strong restrictions on just what Y can be.

As an example, consider a space–time M which is conformal to $K\times\mathbb{L}^1$, where K is any compact Riemannian manifold (recall $\mathbb{L}^n$ denotes Minkowski n-space). M is globally hyperbolic (any $K\times\{t\}$ is a Cauchy surface), hence past-determined. The future chronological boundary of M consists of a single point i^+ which is the future limit of every endless timelike curve. (This can be seen by observing that for any point $p\in M$ and any future-endless timelike curve c, c eventually enters the future of p; this is best noted by looking at projections into the factors K and $\mathbb{L}^1$.) Thus for any past-distinguishing, past-determined, future-complete chronological set Y and any future-continuous map $f:M\to Y$, f has a unique future-continuous extension to $M\cup\{i^+\}$; this means precisely that there is some point $y^+\in Y$ such that for every endless timelike curve c in M, y^+ is the future limit of $f\circ c$. In other words, any ''reasonable'' way of putting a future boundary on M essentially replicates the GKP procedure, producing i^+ and nothing more (any other points in Y which are neither in $f[M]$ nor y^+ are not the future limit of anything in $f[M]$ and are in that sense disconnected from M).

More generally, for M any strongly causal space–time, let $f:M\to Y$ be any future-continuous map into a past-distinguishing, future-complete, chronological set. Applying the past-determination functor we have $f^p:M^p\to Y^p$, a future continuous map into a past-determined, past-distinguishing, future-complete chronological set. Thus we have the future extension of f^p to $f^+:M^+\to Y^p$. Since $\hat{\partial}(M)$ (the GKP future causal boundary of M) contains the future limit of

every future-endless timelike curve in M, the same is true of its image in Y^p under f^+; assuming that f is an embedding of M into Y, this means that the portion of Y which is directly connected to $f[M]$—i.e., the points of Y which are future limits of chains coming from M—consists, aside from $f[M]$ itself, of a set future-continuously mapped onto by the GKP future causal boundary of M.

IV. GENERALIZED CONDITIONS AND RESULTS

In a space–time, for every point x, $I^-(x)$ is an IP; this is not necessarily so in a chronological set X. A future chain c may not have a future limit because the point x which one might nominate for the future limit of c, has a decomposable past. However, this can still play the role of a future limit in a more generalized sense. Let us order by inclusion the IPs contained within $I^-(x)$ (for any $x \in X$); if P is maximal in this ordering, call it a *past component of* x [so if $I^-(x)$ is an IP, there is only that one past component]. Let us call x a *generalized future limit* of a future chain c if $I^-[c]$ is a past component of x. As before, if x is a generalized future limit of c, then it is a generalized future limit of any subchain of c; conversely, if it is a generalized future limit of some subchain of c, then it is a generalized future limit of c. Call X *generalized past-distinguishing* if whenever x and y in X share a past component, $x=y$ (this is a stronger condition than being past-distinguishing). If X is generalized past-distinguishing, a future chain can have no more than one generalized future limit. Call X *generalized future-complete* if every future chain has a generalized future limit (a weaker condition than being future-complete). Call a chronological function $f:X\to Y$ *generalized future-continuous* if for every generalized future limit x of a future chain c in X, $f(x)$ is a generalized future limit of $f[c]$ (this is neither a stronger nor a weaker property than being future-continuous); a composition of generalized future-continuous functions is generalized future-continuous. Finally, call a point $x \in X$ *generalized past-determined* if $I^-(x)$ is nonempty and for any w with $I^-(w)$ containing some past component of x, $x \ll y$ for all $y \gg w$ (a stronger property than being past-determined); and X is generalized past-determined if all of its points are.

These generalized notions are what are needed to provide the mappings into chronological sets with decomposable pasts for some of the points; a typical example would be starting with a space–time and embedding it into another manifold to create a boundary for the space–time, with some of the boundary points possibly having decomposable pasts. We still get useful information, such as analogs of Proposition 7, Corollary 12, and Theorem 14—allowing a comparison with the GKP future causal boundary—so long as the envelopment obeys these generalized notions:

15. Theorem: *For any generalized future-continuous map $f:X\to Y$ with X a past-connected chronological set and Y a generalized past-determined, generalized past-distinguishing, generalized future-complete chronological set, there are unique generalized future-continuous maps $\hat{f}:\hat{X}\to Y$, $f^p:X^p\to Y$, and $f^+:X^+\to Y$ such that $\hat{f}\circ\hat{\iota}_X = f^p\circ\iota_X^p = f^+\circ\iota_X^+ = f$.*

Proof: First consider $\hat{f}$: For any $P \in \hat{\partial}(X)$, with c a future chain generating P, $\hat{f}[c]=f[c]$ must have a unique generalized future limit $y \in Y$, so $\hat{f}(P)=y$ is forced. For $x \ll P$, with P generated by c, we have $x \in P$, so $\hat{f}(x)=f(x)\in f[P]=f[I^-[c]]\subset I^-[f[c]]$, which is a past component of $\hat{f}(P)$; that implies $I^-[f[c]]\subset I^-(\hat{f}(P))$, so $\hat{f}(x)\ll\hat{f}(P)$. For $P\ll x$, with P generated by c, we have $I^-[c]\subset I^-(w)$ for some $w\ll x$, which implies $c\subset I^-(w)$ (as in the proof of Proposition 6); therefore, $I^-[f[c]]\subset I^-(f(w))$ and $f(w)\ll f(x)$. With $\hat{f}(P)$ the generalized future limit of $f[c]$, we know that $I^-[f[c]]$ is a past component of $\hat{f}(P)$; thus, since $\hat{f}(P)$ is generalized past-determined, we have $\hat{f}(P)\ll f(x)=\hat{f}(x)$. For $P\ll Q$, we interpolate $P\ll x\ll Q$. Thus $\hat{f}$ is chronological. Generalized future-continuity follows from that of f, since the only new future limits are those in $\hat{\partial}(X)$.

Next consider f^p: For $x\ll^p y$ in X, we have $I^-(x)\subset I^-(w)$ for some $w\ll y$. We also have, since X is past-connected, that x is a future limit of some future chain c, so $I^-[c]\subset I^-(w)$. Thus $I^-[f[c]]\subset I^-(f(w))$ and $f(w)\ll f(y)$. Since f is generalized future-continuous, $f(x)$ is the generalized future limit of $f[c]$, i.e., $I^-[f[c]]$ is a past component of $f(x)$. Since $f(x)$ is generalized past-determined, this gives us $f(x)\ll f(y)$. Therefore f^p is chronological. For generalized future-continuity, the proof in Proposition 11 suffices, once we obtain an extension of Lemma 9, that x is a generalized future limit of a future chain c in X^p if and only if x is a generalized future limit of any associated chain c' in X:

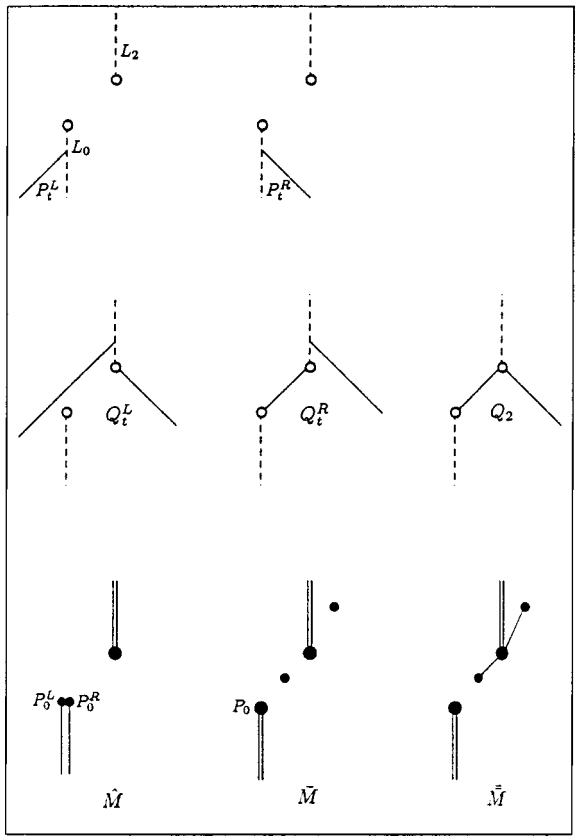

FIG. 1. IPs in M and three embeddings for it.

With $I^-[c']$ a past component of x in X, we need to have $I^{-p}[c]$ a past component of x in X^p (the other way being easy). The proof of Lemma 9 shows that $I^{-p}[c]\subset I^{-p}(x)$, we just need to show it a maximal IP with that property. Suppose d is a chain in X^p with $I^{-p}[c]\subset I^{-p}[d]\subset I^{-p}(x)$; then $I^-[c']\subset I^-[d']\subset I^-(x)$, where d' is a chain in X associated to d. Since $I^-[c']$ is maximal with the property of being an IP contained in the past of x, we have $I^-[c']=I^-[d']$, and it follows that $I^{-p}[c]=I^{-p}[d]$.

Finally, f^+ comes from the previous two constructions, just as in Theorem 14. □

As an example, let us consider the space–time M formed from $\mathbb{L}^2$ by deleting two timelike half-lines: $L_0=\{(0,t)|t\leqslant 0\}$ and $L_2=\{(2,t)|t\geqslant 2\}$. Then $\hat{\partial}(M)$ consists of these IPs (illustrated in Fig. 1): for each $t\leqslant 0$, P_t^L, bounded by L_0 and the null line from $(0,t)$ going to the left in the past, and P_t^R, bounded by L_0 and the null line from $(0,t)$ going to the right in the past; for each $t>2$, Q_t^L, bounded by L_2, the null line from $(2,t)$ going to the left in the past, and the null line from (2,2) going to the right in the past, and Q_t^R, bounded by L_2, the null line from $(2,t)$ going to the right in the past, the null line going from (2,2) to (0,0), and L_0; Q_2, bounded by the null line from (2,2) going to the right in the past, the null line going from (2,2) to (0,0), and L_0; and the usual future causal boundary for $\mathbb{L}^2$, consisting of the pasts of null lines going out to future infinity, as well as the entire space–time. In $\hat{M}$, we have $P_0^R\ll(3,4)$ [because $\hat{I}^-(P_0^R)\subset I^-(3,3)$], but there is no relation between P_0^L and (3,4). Also, since there is no relation between (1,1) and (3,4), the space is not past-determined (same for M). The past-determination of $\hat{M}$ adds some relations: $(s,s)\ll^p(3,4)$ for $0<s<2$; however, even in $\hat{M}^p$, there is no relation between P_0^L [or (x,t) for $x<0$ and $t<x$] and (3,4).

A typical embedding of M to create a boundary for it would be to use $\hat{M}$, except to coalesce P_0^R and P_0^L into a point P_0, with P_0 not related to (3,4); call this $\bar{M}$. This is not past-determined, since (1,1) is not related to (3,4). We can add relations to $\bar{M}$ by saying that two points are related if there is a curve between them, causal in $\mathbb{L}^2$, somewhere timelike, allowed to include ''one side'' of L_0 or L_2 but not to cross either of them (the points P and Q being identified with one side or

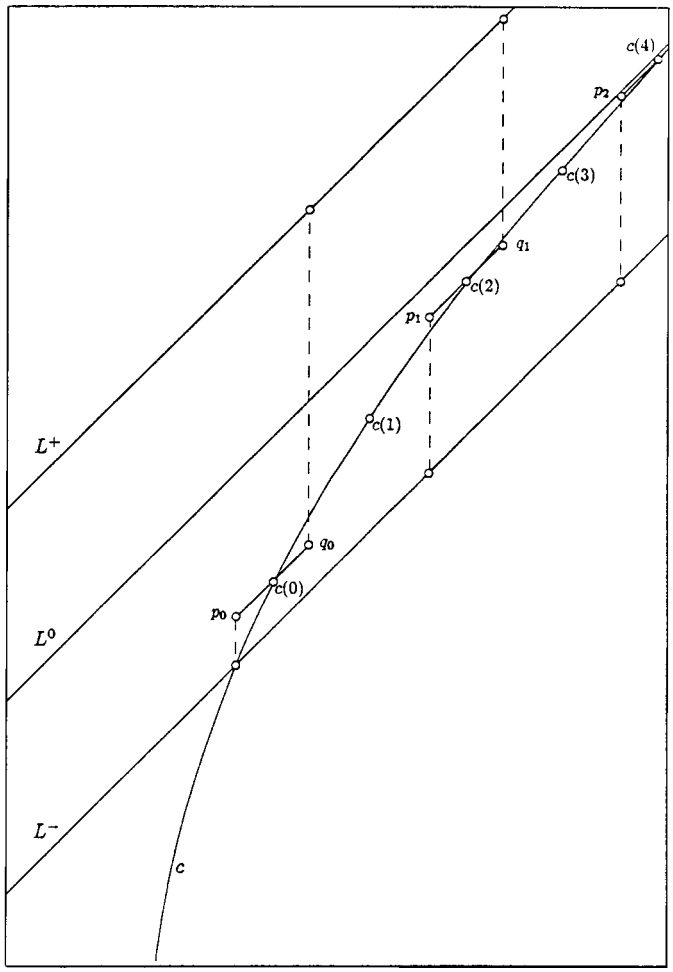

FIG. 2. Space–time with incomplete full causal boundary.

the other of those two lines). This space, $\bar{\bar{M}}$, is past-determined, past-distinguishing, and generalized future-complete (since P_0 has two past components, it is not future-complete); hence we get a generalized future-continuous map from M^+ to $\bar{\bar{M}}$; this is just the map coalescing P_0^R and P_0^L into P_0. Similarly, any means of adding complete boundaries to the slits in M will end up being a quotient of the boundaries from $\hat{M}$.

APPENDIX: AN EXAMPLE WITH THE FULL CAUSAL BOUNDARY

Why has the foregoing structure been involved solely with the future chronological boundary and not with some combination of future and past, such as the complete causal boundary of the GKP construction? In a nutshell, the reason is that the combined causal boundary, future with past, is, in general, neither future- nor past-complete: It is as if one were to attempt a completion of a Riemannian manifold by adding end points to all finite-length endless curves, and then one found, for instance, that the added end points themselves constituted a finite-length endless curve. Here is an example of how that can happen with the GKP causal boundary and a rather ordinary space–time (illustrated in Fig. 2):

Our space–time M will be a subset of Minkowski two-space, $\mathbb{L}^2$, in which we will cut an infinite number of slits and poke an infinite collection of holes. First we select three parallel null lines as reference objects, say $L^+=\{t=x+1\}$, $L^0=\{t=x\}$, and $L^-=\{t=x-1\}$; we also select a future-timelike curve c asymptotic (in the future) to the middle null line, say $c(s)=(\sinh s,\cosh s)$. For each positive integer k, consider a short null segment centered at $c(2k)$, parallel to the reference lines, say from $(\sinh(2k)-0.5,\cosh(2k)-0.5)$ to $(\sinh(2k)+0.5,\cosh(2k)+0.5)$, and denote the past and future end points of these null segments by, respectively, p_k and q_k. To form M, delete from $\mathbb{L}^2$ each vertical segment from p_k down to L^-, each vertical segment from q_k up to L^+, and each point $c(n)$, all k and all n.

The future causal boundary for M includes an IP P_n corresponding to each of the deleted points $c(n)$, while the past causal boundary includes an IF F_n for the same. (The future causal boundary also has, for each of the slits, IPs for each point of the left and right sides of the slit, except a single IP for the bottom point; an IP for future timelike infinity, i^+; and IPs for future null infinity, $\mathscr{I}^+$—but with points corresponding to the null lines between L^- and L^+ missing from the usual $\mathscr{I}^+$ for $\mathbb{L}^2$, due to the slits. The past causal boundary also has, for each slit, IFs for each point of the left and right sides, except a single IF for the top; and past timelike and null infinity, i^- and $\mathscr{I}^-$. However, we shall be largely unconcerned with these other points in the causal boundary.) We have each $P_{2k}\subset P_{2k+1}$, so that within $\hat{M}$, $P_{2k}\ll P_{2k+1}$, but no other relations obtain among these boundary points, due to the slits; and the future chronological completion of M is precisely the same as adding the GKP future causal boundary to M. Similarly, within $\check{M}$, the past chronological completion of M (the same as adding the GKP past causal boundary), we have $F_{2k-1}\ll F_{2k}$ (since $F_{2k-1}\supset F_{2k}$) but no other relations among those particular boundary points.

There is more than one scheme for combining future and past causal boundaries into a single causal boundary (see, for instance, Refs. 5 and 6 for a good alternative to the GKP prescription), but they all agree in a space–time as simple as this one: Each P_n is identified with F_n, which we will call z_n (and the two copies of the left side of each slit—the one from the future causal boundary and the one from the past causal boundary—are identified, and the same with the right sides, with a single boundary point for the top and one for the bottom of each slit); this is called M^* in Ref. 2. Thus in any choice of chronology relation on M^* which makes the obvious mappings from $\hat{M}$ and $\check{M}$ to M^* chronological, we must have $z_{2k-1}\ll z_{2k}$ (from $\check{M}$) and $z_{2k}\ll z_{2k+1}$ (from $\hat{M}$), so that $\{z_n\}$ is a future chain in M^*. However, this chain has no future limit in M^*—for instance, the past of L^0 is not an IP, since the slits decompose that past into an infinite number of past sets: In essence, the chain $\{z_n\}$ ''escapes'' our intended completion of M by aiming for the ''hole'' in $\mathscr{I}^+$ left by the missing points corresponding to the null lines between L^- and L^+.

Szabados, in Sec. 6 of Ref. 5, proposes a chronology relation on M^* that, in this case, would leave no relations at all among the $\{z_n\}$; this construction has the advantage of not adding any additional relations among the points of M—unlike the GKP construction in the future or past causal boundaries, or the future and past completions defined here—but the disadvantage of not preserving relations already defined in $\hat{M}$ or $\check{M}$.

Symplectic gravity models in four, three and two dimensions

Oleg Kechkin[a] and Maria Yurova[b]
Institute of Nuclear Physics, Moscow State University, Moscow 119899, Russia

(Received 1 May 1997; accepted for publication 4 February 1998)

A class of the $D=4$ gravity models describing a coupled system of n Abelian vector fields and the symmetric $n\times n$ matrix generalizations of the dilaton and Kalb–Ramond fields is considered. It is shown that the Peccei–Quinn axion matrix can be entered and the resulting equations of motion possess the $\mathrm{Sp}(2n,R)$ symmetry in four dimensions. The stationary case is studied. It is established that the theory allows a σ-model representation with a target space which is invariant under the $\mathrm{Sp}[2(n+1),R]$ group of isometry transformations. The chiral matrix of the coset $\mathrm{Sp}[2(n+1),R]/\mathrm{U}(n+1)$ is constructed. A Kähler formalism based on the use of the Ernst $(n+1)\times(n+1)$ complex symmetric matrix is developed. The stationary axisymmetric case is considered. The Belinsky–Zakharov chiral matrix depending on the original field variables is obtained. The Kramer–Neugebauer transformation, which algebraically maps the original variables into the target space ones, is presented. © *1998 American Institute of Physics.*

I. INTRODUCTION

In recent years much attention has been paid to the study of symmetries for gravity models arising as the low energy limit of superstring theory.[1–7] This activity was motivated by the problems of supersting theory, as well as by the remarkable results obtained for the Einstein and Einstein–Maxwell theories in three and two dimensions. Namely, it established the chiral matrix formulations for the latter theories in the stationary case, and their complete integrability in the stationary axisymmetric case.[8–21]

Recently it was shown that the simplest string gravity model, the Einstein–Maxwell–Dilaton–Axion (EMDA) system, can be represented as the 2×2 matrix generalization of the pure Einstein theory.[22,23] It means that one can exchange the complex symmetric 2×2 matrix, describing the EMDA theory in three dimensions, by the Ernst potential of the Einstein theory to obtain this last one from the former system.[22] Thus the mentioned matrix (the Ernst matrix potential) generalizes the Ernst potential to the EMDA case, and both the Einstein and EMDA theories belong to the same class of gravity models. In Ref. 23 it was shown that the established analogy is the more complete one, and can be naturally prolonged to the stationary axisymmetric case. It had been shown that the EMDA system, as the Einstein theory, allows both the target space representation and the formulation based on the use of the original field components. These two formulations are differentially related in three dimensions and can be algebraically mapped one into another in two dimensions.[23] This map is known as the Kramer–Neugebauer transformation for the stationary axisymmetric Einstein equations;[24] its existence is an important property of the theory.[25]

The formal properties of the EMDA theory do not actually depend on the Ernst matrix potential dimension and it is possible to consider a series of similar gravity models in three and two dimensions. All these models exist as the chiral ones and possess the remarkable features of the Einstein theory. But first of all one must answer the question: what kind of four-dimensional theories when reduced to three and two dimensions lead to such models?

In this paper we present such a class of four-dimensional theories. Any theory generalizes the EMDA system by the following way: here the dilaton and Kalb–Ramond fields become the n

$\times n$ symmetric matrices, and instead of the Maxwell field one has the column of n Maxwell fields (thus, the EMDA theory corresponds to the case of $n=1$).

It is shown that one can introduce the Peccei–Quinn axion matrix for an arbitrary $n \geqslant 1$ and that the resulting equations of motion possess the $\mathrm{Sp}(2n,R)$ hidden symmetry. This fact generalizes the one for the EMDA theory which $\mathrm{Sp}(2,R) \sim \mathrm{SL}(2,R)$ symmetry is known as the S-duality.[26,27] Also it is shown that the model admits the discrete symmetry transformation which had been named as the ''strong-weak coupling duality'' for the low energy heterotic string theory with moduli fields in four dimensions.[3]

In the next section we consider the stationary case and reduce the four-dimensional model with an arbitrary n to three dimensions. We use an approach which was first formulated by Israel and Wilson for the Einstein–Maxwell theory in Ref. 28, and recently had been generalized to the EMDA theory in Ref. 29. It is shown that the system under consideration allows the σ-model representation with a symmetric target space, which is a natural matrix generalization of the EMDA one.

Then, the Kähler formalism based on the use of the $(n+1)\times(n+1)$ Ernst matrix potential is developed. It is shown that the motion equations become the matrix-valued Ernst equation. The chiral $2(n+1)\times 2(n+1)$ matrix constructed on the real and imaginary parts of the Ernst matrix potential is presented. This matrix belongs to the coset $\mathrm{Sp}[2(n+1),R]/\mathrm{U}(n+1)$, and the established chiral formulation possesses the $\mathrm{Sp}[2(n+1),R]$ group of symmetry transformations. The corresponding transformations for the Ernst matrix potential have the ''matrix-valued $\mathrm{SL}(2,R)$ form'' and directly generalize the transformations for the Einstein theory. Also it is shown that the $\mathrm{Sp}(2n,R)$ symmetry, corresponding to one of the four-dimensional motion equations, exists as the subgroup of the complete $\mathrm{Sp}[2(n+1),R]$ symmetry group. At the end of the section the discrete transformation, which is the analogy of the strong-weak coupling duality for the low energy heterotic string theory in three dimensions,[4] is presented.

In the following section we demonstrate some new features of the model, which arise in the stationary axisymmetric case. It is established that the theory allows the alternative Ernst-like formulation using two real $(n+1)\times(n+1)$ matrices, which are the nondualized (i.e., depended on the original nontarget space field components) analogies of the Ernst matrix and its complex conjugation. These two real matrices are used for the construction of the new $2(n+1)\times 2(n+1)$ chiral matrix which coincides with the Belinsky–Zakharov one for the case of the Einstein theory (see also Ref. 23 for the EMDA theory case). This new matrix undergoes the same $\mathrm{Sp}[2(n+1),R]$ transformations as the coset chiral matrix under the action of the isometry group. The above mentioned real Ernst-like matrix potentials transform as their complex Ernst analogies.

At the end of the paper we present the Kramer–Neugebauer map for an arbitrary n. It turned out that this transformation has an especially simple form in terms of the real and complex pairs of the Ernst matrix potentials.

II. FOUR-DIMENSIONAL EQUATIONS

In this paper we consider a class of gravity models with the action

$$ {}^4S = \int d^4x |g|^{1/2} \{ -R + \mathrm{Tr}[\tfrac{1}{2}(\partial p p^{-1})^2 - pFF^T + \tfrac{1}{3}(pH)^2] \}, \tag{1} $$

where R is the Ricci scalar for the metric $g_{\mu\nu}$, $(\mu = 0,\ldots,3)$; $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$ and

$$ H_{\mu\nu\lambda} = \partial_\mu B_{\nu\lambda} - \tfrac{1}{2}(A_\mu F^T_{\nu\lambda} + F_{\nu\lambda} A^T_\mu) + \text{cyclic}. \tag{2} $$

Here the symmetric $n\times n$ matrix p is constructed on the scalar field components ($p = e^{-2\phi}$ for the EMDA case, where ϕ is the dilaton field), $B_{\mu\nu}$ is the symmetric $n\times n$ matrix which contains the antisymmetric tensor Kalb–Ramond fields (i.e., $B^T_{\mu\nu} = B_{\mu\nu}$ and $B_{\mu\nu} = -B_{\nu\mu}$), and A_μ is the $n \times 1$ column of the Abelian vector fields. This action describes the Einstein and EMDA theories in the cases of $n=0$ and $n=1$, respectively, and provides their natural generalization for an arbitrary n. The models of such type arise in the low energy limit of the heterotic string theory after the compactification of extra dimensions on a torus.[1–7]

As it has been done for the EMDA theory and for the string gravity with moduli fields, one can establish an alternative formulation of the problem which is connected with the dualization of the axion field $H_{\mu\nu\lambda}$ in four dimensions. Namely, using the first equation of the Euler–Lagrange ones,

$$\nabla^{\mu}(pH^{\mu\nu\lambda}p)=0, \tag{3}$$

$$\nabla_{\mu}(pF^{\mu\nu})+\tfrac{1}{2}pH^{\mu\nu\lambda}F_{\mu\nu}=0, \tag{4}$$

$$\nabla J^{p}+pFF^{T}-\tfrac{2}{3}(pH)^{2}=0, \tag{5}$$

$$R_{\mu\nu}=\mathrm{Tr}[\tfrac{1}{2}J^{p}_{\mu}J^{p}_{\nu}-2p(F_{\mu\lambda}F^{T^{\nu\lambda}}-\tfrac{1}{4}g_{\mu\nu}FF^{T})+pH_{\mu\lambda\sigma}pH^{\lambda\sigma}_{\nu}-\tfrac{1}{3}g_{\mu\nu}(pH)^{2}], \tag{6}$$

where $J^{p}=(\nabla p)p^{-1}$, it is possible to introduce the symmetric pseudoscalar matrix q,

$$H^{\mu\nu\lambda}=\tfrac{1}{2}E^{\mu\nu\lambda\sigma}p^{-1}q_{,\sigma}p^{-1} \tag{7}$$

generalizing the Peccei-Quinn axion field. It satisfies the relation

$$\nabla J^{q}-J^{p}J^{q}+p\tilde{F}F^{T}=0, \tag{8}$$

where $J^{q}=(\nabla q)p^{-1}$ and $\tilde{F}^{\mu\nu}=\tfrac{1}{2}E^{\mu\nu\lambda\sigma}F_{\lambda\sigma}$, which together with Eqs. (4)–(6), rewritten using Eq. (7) as

$$\nabla_{\mu}(pF^{\mu\nu}+q\tilde{F}^{\mu\nu})=0, \tag{9}$$

$$\nabla J^{p}+(J^{q})^{2}+pFF^{T}=0, \tag{10}$$

$$R_{\mu\nu}=\mathrm{Tr}[\tfrac{1}{2}(J^{p}_{\mu}J^{p}_{\nu}+J^{q}_{\mu}J^{q}_{\nu})-2p(F_{\mu\lambda}F^{T\lambda}_{\ \ \nu}-\tfrac{1}{4}g_{\mu\nu}FF^{T})] \tag{11}$$

form the complete system for the action

$${}^{4}S=\int d^{4}x|g|^{1/2}\{-R+\mathrm{Tr}[\tfrac{1}{2}((J^{p})^{2}+(J^{q})^{2})-pFF^{T}-q\tilde{F}F^{T}]\}. \tag{12}$$

The action of this type was considered for the first time by Breitenlohner *et al.* in Ref. 30, where some remarkable properties of the model had been established.

The main purpose of this paper is to show a complete formal analogy between the series of models described by the action (1), and the Einstein theory in three and two dimensions. However, the simplest representative of the series, which possesses all the typical properties in four dimensions, is the EMDA theory. Namely, let us establish the symmetries of the theory for an arbitrary $n\geqslant 1$. To do it one can introduce the complex variables

$$z=q+ip, \tag{13}$$

$$\mathscr{F}=\tfrac{1}{2}(F+i\tilde{F}). \tag{14}$$

Then the set of motion equations obtains the form:

$$\nabla_{\mu}(z.\mathscr{F}^{\mu\nu}-\overline{z.\mathscr{F}}^{\mu\nu})=0, \tag{15}$$

$$\nabla J^{z}-J^{z}(J^{z}-\overline{J^{z}})-\frac{i}{2}(z-\overline{z}).\overline{\mathscr{F}}\mathscr{F}^{+}=0, \tag{16}$$

$$R_{\mu\nu}=\mathrm{Tr}\{2J^{z}_{(\mu}\overline{J^{z}_{\nu)}}+i(z-\overline{z})(.\mathscr{F}_{\mu\lambda}\mathscr{F}^{+\lambda}_{\ \ \nu.}+\overline{\mathscr{F}}_{\mu\lambda}\mathscr{F}^{T\lambda}_{\ \ \nu.})\}, \tag{17}$$

where $J^{z}=\nabla z(z-\overline{z})^{-1}$ (see also Ref. 26 for the EMDA case).

It is not difficult to prove using a straightforward calculation that these equations are invariant under the transformation

$$z \to s^T (z^{-1} + l)^{-1} s + r, \quad \mathcal{F} \to s^{-1}(I + lz)\mathcal{F}, \tag{18}$$

where the constant matrices $r^T = r$, $l^T = l$ and s are real. The former formula from (18) also can be rewritten using the following $2n \times 2n$ matrices

$$m = \begin{pmatrix} p^{-1} & p^{-1}q \\ qp^{-1} & p + qp^{-1}q \end{pmatrix} \tag{19}$$

(see the similar matrix for the Einstein–Dilaton–Axion theory in Ref. 31),

$$g = \begin{pmatrix} (s^T)^{-1} & (s^T)^{-1} r \\ l(s^T)^{-1} & s + l(s^T)^{-1} r \end{pmatrix}, \tag{20}$$

as

$$m \to g^T m g. \tag{21}$$

The above introduced matrix g satisfies the relation $g^T j g = j$, where

$$j = \begin{pmatrix} 0 & -I \\ I & 0 \end{pmatrix}, \tag{22}$$

and I is the unit matrix, so that $g \in \mathrm{Sp}(2n,R)$ (also from the relations $m^T j m = j$ and $m^T = m$ it follows that $m \in \mathrm{Sp}(2n,R)/\mathrm{U}(n)$, see the third chapter for details). Thus the motion equations possess the $\mathrm{Sp}(2n,R)$ symmetry for an arbitrary $n \geqslant 1$.

Not all the symplectic transformations (21) can be represented in the Gauss decomposition form (20). For example, one can prove that $j \in \mathrm{Sp}(2n,R)$, but only the limit procedure defined by the matrices $l = -r = s \to \infty$ allows one to obtain the matrix j from Eq. (20). The corresponding map is $m \to m^{-1}$; and using complex variables one has:

$$z \to -z^{-1}, \quad \mathcal{F} \to z\mathcal{F}. \tag{23}$$

It is not difficult to prove that this transformation is actually the symmetry transformation for the equations (15)–(17). The map (23) generalizes the strong-weak coupling duality of the EMDA theory to the case of an arbitrary n. It has the same form as the transformation established for the low energy heterotic string theory with moduli in four dimensions.[3]

It is easy to see that only the $\mathrm{GL}(n,R)$ subgroup of the complete $\mathrm{Sp}[2(n+1),R]$ group, defined by a matrix s, preserves the action (12) which can be rewritten as

$${}^4S = \int d^4x |g|^{1/2} \{ -R + \mathrm{Tr}[2 J^z \overline{J^z} + i(z\mathcal{F}\mathcal{F}^T - \overline{z\mathcal{F}}\mathcal{F}^+)] \}. \tag{24}$$

The situation is the same for the EMDA theory which possesses the $\mathrm{Sp}(2,R) \sim \mathrm{SL}(2,R)$ symmetry only for the motion equations.[26,27] This symmetry is connected with the notable S-duality for the low energy heterotic string theory. The subgroup $\mathrm{SL}(2,Z)$ of the group $\mathrm{SL}(2,R)$ is an exact symmetry for the heterotic string in four dimensions.[3]

Also one can see that the discussed models do not possess any analogy with the T-duality transformations,[3] thus the established $\mathrm{Sp}(2n,R)$ symmetry is the single nontrivial one.

III. REDUCTION TO THREE DIMENSIONS

In this section we study the stationary case using the classical approach of Israel and Wilson.[28] This method also had been explored for the EMDA theory analysis;[29] one can find its application to the string gravity with moduli fields in Ref. 4.

First of all, it is convenient to parametrize the four-dimensional line element as

$$ds_4^2 = g_{\mu\nu}dx^\mu dx^\nu = f(dt - \omega_m dx^m)^2 - f^{-1}h_{mn}dx^m dx^n, \tag{25}$$

where $m = 1,2,3$. (In this section all vector variables, as well as the operator ∇, will be related with the three-metric h_{mn}.)

Then, the $\mu = m$ component of Eq. (9) allows one to introduce the magnetic potential u according to

$$pF^{mn} + q\tilde{F}^{mn} = \frac{1}{\sqrt{2}} fE^{mnk}u_{,k}, \tag{26}$$

while for the electric potential v we put

$$F_{m0} = \frac{1}{\sqrt{2}} v_{,m}. \tag{27}$$

Using the relations[28] $F^{0m} = \omega_n F^{mn} + h^{mn}F_{n0}$ and $F_{mn} = f^{-2}h_{mk}h_{nl}F^{kl} + 2F_{0[m}\omega_{n]}$, it is possible to rewrite the $\mu = 0$ component of Eq. (9) as

$$\nabla[f^{-1}(p\nabla v - qp^{-1}(\nabla u - q\nabla v))] = -f^{-2}\boldsymbol{\tau}\nabla u, \tag{28}$$

where $\boldsymbol{\tau} = -f^2\nabla\times\boldsymbol{\omega}$. The second electromagnetic equation can be obtained from the Bianchi identity $F_{[mn,k]} = 0$; the result is

$$\nabla[f^{-1}p^{-1}(\nabla u - q\nabla v)] = f^{-2}\boldsymbol{\tau}\nabla v. \tag{29}$$

The equations (8) and (10) transform to

$$\nabla J^q - J^p J^q - f^{-1}[(\nabla u - q\nabla v)\nabla v^T + p\nabla v(\nabla u - q\nabla v)^T p^{-1}) = 0, \tag{30}$$

$$\nabla J^p + (J^p)^2 + f^{-1}[p\nabla v\nabla v^T - (\nabla u - q\nabla v)(\nabla u - q\nabla v)^T p^{-1}] = 0. \tag{31}$$

Then, the $\binom{m}{0}$-component of the Einstein equations (11) means the existence of the rotational potential χ

$$\nabla\chi + v^T\nabla u - u^T\nabla v = \boldsymbol{\tau}, \tag{32}$$

which accordingly with the definition of $\boldsymbol{\tau}$ satisfies

$$\nabla[f^{-2}(\nabla\chi + v^T\nabla u - u^T\nabla v)] = 0; \tag{33}$$

while the $(_{00})$-component of Eq. (11) leads to the following equation for the function f:

$$f\nabla^2 f - (\nabla f)^2 + (\nabla\chi + v^T\nabla u - u^T\nabla v)^2 - f[\nabla v^T p\nabla v + (\nabla u - q\nabla v)^T p^{-1}(\nabla u - q\nabla v)] = 0. \tag{34}$$

Finally, the $(^{mn})$-component of Eq. (11) after the lowering of the three-dimensional indexes takes the form:

$${}^3R_{mn} = \tfrac{1}{2}\mathrm{Tr}[J_m^p J_n^p + J_m^q J_n^q] + \tfrac{1}{2}f^{-2}[f_{,m}f_{,n} + \boldsymbol{\tau}_m\boldsymbol{\tau}_n] - f^{-1}[v_{,m}^T p v_{,n} + (u_{,m} - qv_{,m})^T p^{-1}(u_{,n} - qv_{,n})], \tag{35}$$

where ${}^3R$ is constructed using the metric h_{mn} and $\boldsymbol{\tau}_m$ is given by Eq. (32).

One can prove that Eqs. (28)–(31) and (33)–(35) are the Euler–Lagrange ones for the action

$$\begin{aligned} {}^3S = \int d^3x h^{1/2}\{ &-{}^3R + \tfrac{1}{2}\,\mathrm{Tr}[(J^p)^2 + (J^q)^2] + \tfrac{1}{2}f^{-2}[(\nabla f)^2 + (\nabla\chi + v^T\nabla u - u^T\nabla v)^2] \\ &- f^{-1}[\nabla v^T p\nabla v + (\nabla u - q\nabla v)^T p^{-1}(\nabla u - q\nabla v)]\}. \end{aligned} \tag{36}$$

Hence this system allows the sigma-model representation in the stationary case.

This result contains the one for the EMDA theory (see Refs. 29 and 32), which admits some compact matrix formulations. To establish them for an arbitrary n, it is convenient to introduce the complex potentials

$$\Phi = u - zv, \qquad \mathscr{E} = if - \chi + v^T \Phi, \tag{37}$$

which together with the matrix z, entered before (13), form the set of Ernst-like potentials[33,34] for this problem (see also Ref. 22 for the EMDA case). These potentials can be combined into the following $(n+1)\times(n+1)$ symmetric matrix

$$E = \begin{pmatrix} \mathscr{E} & \Phi^T \\ \Phi & -z \end{pmatrix}, \tag{38}$$

which provides the Kähler representation of the model. Namely, it is easy to check that

$$^3S = \int d^3x h^{1/2} \{ -{}^3R + 2\ \mathrm{Tr}(J^E \overline{J^E}) \}, \tag{39}$$

where $J^E = \nabla E (E - \overline{E})^{-1}$ and the two-form $\mathscr{K} = 2i\ \mathrm{Tr}(\mathscr{J}^E \wedge \overline{\mathscr{J}^E})$, corresponding to the target space metric $dl^2 = 2\ \mathrm{Tr}(\mathscr{J}^E \overline{\mathscr{J}^E})$ with $\mathscr{J}^E = dE(E - \overline{E})^{-1}$, is exact. The Kähler formulations of the Einstein and Einstein-Maxwell theories are well known in the literature.[16] Another example of the Kähler systems can be found in Ref. 35.

The equations following from the action (39)

$$\nabla J^E = J^E (J^E - \overline{J^E}), \tag{40}$$

$$^3R_{mn} = 2\ \mathrm{Tr}(J^E_{(m} \overline{J^E}_{n)}) \tag{41}$$

coincide with the Ernst ones[33] in the case of $n = 0$. Thus it is natural to name the matrix function E as the ''matrix Ernst potential'' for an arbitrary n. This Ernst-like representation for the model provides the above mentioned complete formal analogy between it and the Einstein theory in the stationary case.

Then, using the real and imaginary parts of $E = Q + iP$,

$$P = \begin{pmatrix} f - v^T p v & -v^T p \\ -pv & -p \end{pmatrix}, \quad Q = \begin{pmatrix} v^T w - \chi & w^T \\ w & -q \end{pmatrix}, \tag{42}$$

where $w = u - qv$, one can rewrite the action (39) as

$$^3S = \int d^3x h^{1/2} \{ -{}^3R + \tfrac{1}{2}\ \mathrm{Tr}[(J^P)^2 + (J^Q)^2] \}, \tag{43}$$

with $J^P = (\nabla P) P^{-1}$ and $J^Q = (\nabla Q) P^{-1}$.

Now let us establish an alternative matrix formulation of the problem based on the use of the original nontarget space variables. One can see that the first equation of motion corresponding to the action (43),

$$\nabla J^Q - J^P J^Q = 0, \tag{44}$$

$$\nabla J^P + (J^Q)^2 = 0, \tag{45}$$

$$^3R_{mn} = \tfrac{1}{2} \mathrm{Tr}[J^P_m J^P_n + J^Q_m J^Q_n], \tag{46}$$

being written as $\nabla[P^{-1}(\nabla Q) P^{-1}] = 0$, ensures the compatibility condition for the relation

$$\nabla\times\mathbf{\Omega}=P^{-1}(\nabla Q)P^{-1} \tag{47}$$

which defines the vector matrix $\mathbf{\Omega}$. Then, using the relations (7), (26), (32) and the definition of $\boldsymbol{\tau}$ one obtains the explicit form of this matrix:

$$\mathbf{\Omega}=\begin{pmatrix} \boldsymbol{\omega} & -\sqrt{2}(\mathbf{A}+A_0\boldsymbol{\omega})^T \\ -\sqrt{2}(\mathbf{A}+A_0\boldsymbol{\omega}) & 2\mathbf{B}+(\vec{A}+A_0\boldsymbol{\omega})A_0^T+A_0(\mathbf{A}+A_0\boldsymbol{\omega})^T \end{pmatrix}, \tag{48}$$

where $B_m=2B_{0m}$. It is easy to see that the matrix $\mathbf{\Omega}$ consists of the original field variables from Eqs. (1) and (2) which had been named as ''nondualized'' in Ref. 23 for the case of the EMDA theory.

The remaining components of the Kalb–Ramond field $B_{mn}\equiv\frac{1}{2}E_{mnk}C^k$ satisfy the nondynamical equation

$$\nabla\mathbf{C}=\{\nabla[\mathbf{B}\times\boldsymbol{\omega}]+[\mathbf{B}-(\mathbf{A}+A_0\boldsymbol{\omega})A_0^T-A_0(\mathbf{A}+A_0\boldsymbol{\omega})^T]\nabla\times\boldsymbol{\omega}+(\mathbf{A}+A_0\boldsymbol{\omega})\nabla\times(\mathbf{A}+A_0\boldsymbol{\omega})^T\}$$
$$+\nabla\times(\mathbf{A}+A_0\boldsymbol{\omega})(\mathbf{A}+A_0\boldsymbol{\omega})^T, \tag{49}$$

as it follows from Eqs. (7) and the t-independance of the q.

Then, it is easy to see from Eqs. (47) that the matrices P and $\mathbf{\Omega}$ satisfy the relation $\nabla\times[P\nabla\times(\mathbf{\Omega})P]=0$ which also can be rewritten using the matrix current $J^{\mathbf{\Omega}}=P\nabla\times\mathbf{\Omega}$ as

$$\nabla\times J^{\mathbf{\Omega}}-J^{\mathbf{\Omega}}\times J^P=0. \tag{50}$$

This relation together with Eqs. (45) and (46), expressed in terms of the matrices P and $\mathbf{\Omega}$,

$$\nabla J^P+(J^{\mathbf{\Omega}})^2=0, \tag{51}$$

$${}^3R_{mn}=\tfrac{1}{2}\mathrm{Tr}[J^P_mJ^P_n+J^{\mathbf{\Omega}}_mJ^{\mathbf{\Omega}}_n], \tag{52}$$

form the set of motion equations for the action

$${}^3S=\int d^3xh^{1/2}(-{}^3R+\tfrac{1}{2}\,\mathrm{Tr}[(J^P)^2-(J^{\mathbf{\Omega}})^2]), \tag{53}$$

thus these matrices provide an alternative Lagrange formulation of the theory under consideration.

To establish the symmetry group of the system, it is convenient to introduce the $2(n+1)\times2(n+1)$ symmetric matrix

$$M=\begin{pmatrix} P^{-1} & P^{-1}Q \\ QP^{-1} & P+QP^{-1}Q \end{pmatrix}, \tag{54}$$

which possesses the symplectic property

$$M^TJM=J,\quad \text{where}\quad J=\begin{pmatrix} 0 & -I \\ I & 0 \end{pmatrix}. \tag{55}$$

Then the action (43) obtains the form

$${}^3S=\int d^3xh^{1/2}\{-{}^3R+\tfrac{1}{4}\,\mathrm{Tr}[(J^M)^2]\}, \tag{56}$$

where $J^M=\nabla MM^{-1}$, and the corresponding equations of motion are

$$\nabla J^M=0, \tag{57}$$

$${}^3R_{mn}=\tfrac{1}{4}\mathrm{Tr}[J^M_mJ^M_n]. \tag{58}$$

It is known that in the case of $n=0$ (for the Einstein theory) a matrix M belongs to the coset $\mathrm{Sp}(2,R)/\mathrm{U}(1)$ [or, equivalently, to the $\mathrm{SL}(2,R)/\mathrm{O}(2)$].[12] Also, it has been established that for the EMDA theory one has $M\in\mathrm{Sp}(4,R)/\mathrm{U}(2)$.[22,36] Hence it is natural to suppose that $M\in\mathrm{Sp}[2(n+1),R]/\mathrm{U}(n+1)$ for an arbitrary n.

This supposition really takes place and the local isomorphism can be established as follows. One can see that a matrix M remains symplectic and symmetric under the transformation

$$M\to G^T M G \tag{59}$$

with an arbitrary symplectic matrix G. It means that the group of the isometry transformations for the action (56) is isomorphic to $\mathrm{Sp}[2(n+1),R]$. The set of the corresponding generators $\Gamma=G-I$ can be obtained from (59); the result is

$$\Gamma=\begin{pmatrix} -\Gamma_S^T & \Gamma_R \\ \Gamma_L & \Gamma_S \end{pmatrix}, \tag{60}$$

where $(n+1)\times(n+1)$ infinitesimal matrices Γ_R and Γ_L are symmetric, and Γ_S is an arbitrary matrix of the same dimension. Then, to obtain the coset, one must remove all the antisymmetric generators from Eq. (60), i.e., to exclude the set of generators which is defined by the matrix

$$\tilde{\Gamma}=\begin{pmatrix} \tilde{\Gamma}_S & \tilde{\Gamma}_R \\ -\tilde{\Gamma}_R & \tilde{\Gamma}_S \end{pmatrix}, \tag{61}$$

where $\tilde{\Gamma}_S^T=-\tilde{\Gamma}_S$ and $\tilde{\Gamma}_R^T=\tilde{\Gamma}_R$.

From the other hand, the generators u of the group $\mathrm{U}(n+1)$ can be found from the relation $\mathrm{U}^+\mathrm{U}=I$ in the infinitesimal case of $\mathrm{U}=I+u$. The result is

$$u=u_1+iu_2, \tag{62}$$

where $u_1^T=-u_1$ and $u_2^T=u_2$ are the real $(n+1)\times(n+1)$ matrices. Now one can prove using a straightforward calculation of the commutators for the corresponding generators that the waiting isomorphism can be defined as

$$\tilde{\Gamma}_S\equiv u_1, \quad \tilde{\Gamma}_R\equiv u_2. \tag{63}$$

Now let us establish the action of the $\mathrm{Sp}[2(n+1),R]$ group of the isometry transformations on the Ernst matrix potential E. One can see that the matrix

$$G=\begin{pmatrix} (S^T)^{-1} & (S^T)^{-1}R \\ L(S^T)^{-1} & S+L(S^T)^{-1}R \end{pmatrix}, \tag{64}$$

with $R^T=R$ and $L^T=L$ possesses the symplectic property and describes all the belonging to $\mathrm{Sp}[2(n+1),R]$ transformations which can be continuously connected with the identical one. It is easy to show that the corresponding transformation for the matrix E is

$$E\to S^T(E^{-1}+L)^{-1}S+R. \tag{65}$$

Thus the matrix E undergoes the ''matrix-valued $\mathrm{SL}(2,R)$'' transformations which are the matrix generalizations of the $\mathrm{SL}(2,R)$ ones for the Einstein theory. Namely, the transformation defined by the matrix L is the matrix generalization of the Ehlers one,[37] while the matrices S and R define the transformations which generalize the rescaling and gauge shift correspondingly for the stationary Einstein system.[12]

The transformation (65) has the same form as the transformation for the matrix z in Eq. (18). It is not difficult to prove that one can identify the $\mathrm{Sp}(2n,R)$ subgroup of the complete group $\mathrm{Sp}[2(n+1),R]$, defined by the matrices

$$L=\begin{pmatrix} 0 & 0 \\ 0 & l \end{pmatrix}, \quad S=\begin{pmatrix} 1 & 0 \\ 0 & s \end{pmatrix}, \quad R=\begin{pmatrix} 0 & 0 \\ 0 & r \end{pmatrix}, \tag{66}$$

where $l^T=l$ and $r^T=r$, with the $\mathrm{Sp}(2n,R)$ symmetry transformations (18) of the motion equations (15)–(17) in the stationary case.

As an example of a symplectic transformation which cannot be represented in the form of (64), one can take the matrix J. It is easy to see that the corresponding map is $M\to M^{-1}$ and its complex representation has the form $E\to -E^{-1}$. This transformation can be obtained from the decomposition formula (64) using the limit procedure as it has been done in the four-dimensional case. It also provides an analogy with the strong-weak coupling duality transformation of the low energy heterotic string theory with moduli in three dimensions.[4]

At the end of this section we want to note that all the transformations discussed here preserve both the actions and the corresponding sets of motion equations.

IV. TWO-DIMENSIONAL CASE

In this section we consider some additional properties of the theory which arise in the stationary and axisymmetric case.

Here one can parametrize the three-dimensional line element in the Lewis–Papapetrou form:

$$ds_3^2=e^{2\gamma}(d\rho^2+dz^2)+\rho^2 d\varphi^2. \tag{67}$$

Then Eq. (57) transforms to

$$\nabla(\rho J^M)=0 \tag{68}$$

which is the Euler–Lagrange equation for the action

$$^2S=\frac{1}{4}\int d\rho\ dz\ \rho\ \mathrm{Tr}[(J^M)^2], \tag{69}$$

while the Einstein equations (58) become the relations defining the function γ:

$$\begin{aligned} \gamma_{,z}&=\frac{\rho}{4}\mathrm{Tr}[J^M_\rho J^M_z], \\ \gamma_{,\rho}&=\frac{\rho}{8}\mathrm{Tr}[(J^M_\rho)^2-(J^M_z)^2] \end{aligned} \tag{70}$$

(the operator ∇ is connected with the flat metric δ_{ab} in this section).

The remarkable fact is that one can obtain another chiral matrix for the stationary axisymmetric equations of the problem. To make it, we first consider the formalism based on the use of the matrices P and Q. It is easy to see that the φ-independent equations of motion (44)–(45) take the form

$$\nabla(\rho J^Q)-\rho J^P J^Q=0, \tag{71}$$

$$\nabla(\rho J^P)+\rho(J^Q)^2=0, \tag{72}$$

and can be derived from the action

$$^2S=\frac{1}{2}\int d\rho\ dz\ \rho\ \mathrm{Tr}[(J^P)^2+(J^Q)^2]. \tag{73}$$

Also, from Eq. (46) one obtains:

$$\gamma_{,z}=\frac{\rho}{2}\mathrm{Tr}[J_\rho^P J_z^P+J_\rho^Q J_z^Q],$$
$$\gamma_{,\rho}=\frac{\rho}{4}\mathrm{Tr}[(J_\rho^P)^2-(J_z^P)^2+(J_\rho^Q)^2-(J_z^Q)^2]. \tag{74}$$

The equation (71), being written as $\nabla[\rho P^{-1}(\nabla Q)P^{-1}]=0$, provides the compatibility condition for the relation

$$\nabla\Omega=\rho P^{-1}(\tilde{\nabla}Q)P^{-1} \tag{75}$$

which defines the symmetric matrix Ω (here, accordingly with Ref. 12, $\tilde{\nabla}_\rho=\nabla_z$ and $\tilde{\nabla}_z=-\nabla_\rho$). Then, using a straightforward calculation one obtains that

$$\Omega=\mathbf{\Omega}_\varphi. \tag{76}$$

It is easy to see that the compatibility condition for the relation (75), rewritten as $\nabla Q=-\rho^{-1}P(\tilde{\nabla}\Omega)P$, and Eq. (72), expressed in terms of the matrices P and Ω,

$$\nabla(\rho^{-1}J^\Omega)+\rho^{-1}J^\Omega J^P=0, \tag{77}$$

$$\nabla(\rho^{-1}J^P)+\rho^{-1}(J^\Omega)^2=0, \tag{78}$$

form the Euler–Lagrange set of equations for the action

$${}^2S=\frac{1}{2}\int d\rho\ dz\ \mathrm{Tr}[\rho(J^P)^2-\rho^{-1}(J^\Omega)^2], \tag{79}$$

where $J^\Omega=P\nabla\Omega$. Also one can see from Eq. (49), that $\nabla\mathbf{C}=0$ and, fixing a gauge, it is possible to put $\mathbf{C}=0$ without lose of generality. Then, for the function γ one has

$$\gamma_{,z}=\tfrac{1}{2}\mathrm{Tr}[\rho J_\rho^P J_z^P-\rho^{-1}J_\rho^\Omega J_z^\Omega],$$
$$\gamma_{,\rho}=\tfrac{1}{4}\mathrm{Tr}[\rho((J_\rho^P)^2-(J_z^P)^2)+\rho^{-1}((J_\rho^\Omega)^2-(J_z^\Omega)^2)]. \tag{80}$$

The new chiral matrix N can be defined as follows

$$N=\begin{pmatrix} P & -P\Omega \\ -\Omega P & \Omega P\Omega-\rho^2P^{-1}\end{pmatrix}. \tag{81}$$

It satisfies the equation

$$\nabla[\rho J^N]=0, \tag{82}$$

where $J^N=\nabla NN^{-1}$, while the relations for the function γ are

$$\Gamma_{,z}=\frac{\rho}{4}\mathrm{Tr}[J_\rho^N J_z^N],$$
$$\Gamma_{,\rho}=\frac{\rho}{8}\mathrm{Tr}[(J_\rho^N)^2-(J_z^N)^2], \tag{83}$$

with

$$\Gamma=\gamma-\frac{1}{2}\ln|\det P|+\frac{n+1}{2}\ln\rho. \tag{84}$$

It is easy to check that the introduced symmetric matrix N satisfies the nongroup relation

$$NJN=-\rho^2 J \tag{85}$$

which is equivalent to the normalization condition $\det N=-\rho^2$ in the case of the Einstein theory (see also Ref. 23 for the EMDA case).

An analogy between the model under consideration and the Einstein theory allows us to establish one additional property of the system. Namely, the relation (75) provides the differential correspondence between the formulations of the problem based on the use of the dualized matrix Q and the original one Ω. The remarkable fact is that also there is a pure algebraical map

$$P\to\rho P^{-1}, \quad Q\to i\Omega, \tag{86}$$

which directly transforms Eqs. (71) and (72) into (77) and (78). The corresponding transformation for the function γ is

$$e^{2\gamma^{\Omega}}=\frac{\rho^{(n+1)/2}}{|\det P|}e^{2\gamma^{Q}}, \tag{87}$$

where γ^{Ω} is connected with matrices P and Ω, and γ^{Q} is related with the formulation using P and Q. The map (86) coincides with the Kramer–Neugebauer transformation in the cases of $n=0$ (Ref. 24) and $n=1$ (Ref. 23) and can naturally preserve this name for an arbitrary n.

Now let us establish the action of the $\mathrm{Sp}[2(n+1),R]$ group on the matrices P and Ω. To make it one can introduce the matrices

$$E_{\pm}=\Omega\pm\rho P^{-1}. \tag{88}$$

It is easy to check that the matrix N remains symmetric and preserves the property (85) under the transformation $N\to G^{T}NG$ with an arbitrary symplectic matrix G. Then, in the case of the matrix G, possessing the decomposition property (64), one has

$$E_{\pm}\to S^{T}(E_{\pm}^{-1}+L)^{-1}S+R. \tag{89}$$

Thus the real nondualized matrix variables $E_{\pm}$ transform under the $\mathrm{Sp}[2(n+1),R]$ group of transformations as the matrix Ernst potentials E and $\overline{E}$.

The entered matrices $E_{\pm}$, being the analogy for the Ernst ones E and $\overline{E}$, provide also the compact Lagrange formulation of the problem. Namely, one can check that the action (79) can be rewritten as

$${}^{2}S=-2\int d\rho\, dz\, \rho\, \mathrm{Tr}[J^{E_+}J^{E_-}], \tag{90}$$

where $J^{E_{\pm}}=(E_{\pm}-E_{\mp})^{-1}\nabla E_{\pm}-\frac{1}{2}\nabla\rho$.

Also one can see that the above established Kramer–Neugebauer map has an especially simple form in terms of the Ernst matrices $E,\overline{E}$ and their real analogies E_{+},E_{-}:

$$E\to iE_{+}, \quad \overline{E}\to iE_{-}. \tag{91}$$

V. CONCLUSION

In this paper we have considered a class of gravity models with the Einstein theory as the first representative, the EMDA theory as the second one, etc. It is shown that all the models have the same formal properties which are the natural matrix generalizations of the ones for the Einstein theory in three and two dimensions. Namely, the substitution $P\to f$, $Q\to\chi$ and $\mathbf{\Omega}\to\boldsymbol{\omega}$ (or $\Omega\to\omega$ in the stationary axisymmetric case) directly transforms all the relations for $n\geqslant 1$ to the Einstein theory relations. An analogy established here is even a more complete one, and it is possible to develop the Hauser–Ernst formalism[17,19] and to construct the Geroch group[8,9] in the stationary axisymmetric case for the model with an arbitrary n.

New exact solutions of the gravitational field equations for a homogeneous flat Friedmann–Robertson–Walker Universe filled with a causal bulk-viscous fluid with a bulk viscosity coefficient proportional to the Hubble function are obtained in the framework of the full causal Israel–Stewart–Hiscock (ISH) theory. The evolution equation of the Universe is reduced to a first kind Abel-type first-order differential equation and new classes of exact solutions of the field equations are generated from some particular solutions of this equation leading to two classes of general solutions of the Einstein field equations corresponding to particular values of the parameters entering in the physical model. The obtained solutions are represented mathematically in an exact parametric form and are interpreted physically as describing cosmological particle production. The evolution of the temperature, entropy, deceleration parameter, and bulk viscosity coefficient is also considered for each model. © *1998 American Institute of Physics.* [S0022-2488(98)01710-1]

I. INTRODUCTION

Dissipative processes are supposed to play a fundamental role in the evolution and dynamics of the early Universe. Thirty years ago Misner[1] suggested that the observed large scale isotropy of the Universe is due to the action of the neutrino viscosity which was effective when the Universe was about 1 s old. Bulk viscosity may arise in a different context during the evolution of the early Universe like in the evolution of cosmic strings due to their interaction with each other and the surrounding matter, in classical description of the (quantum) particle production phase, interaction between matter and radiation, quark and gluon plasma viscosity, different components of dark matter, and in many other physical phenomena.[2] The first attempts at creating a theory of relativistic dissipative fluids were those of Eckart[3] and Landau and Lifshitz.[4] These theories are now known to be pathological in several respects. Regardless of the choice of equation of state, all equilibrium states in these theories are unstable and in addition signals may be propagated through the fluid at velocities exceeding the speed of light.[5] These problems arise due to the first-order nature of the theory, i.e., it considers only first-order deviations from the equilibrium leading to parabolic differential equations, hence to infinite speeds of propagation for heat flow and viscosity in contradiction with the principle of causality. While such paradoxes appear particularly glaring in relativistic theory, infinite propagation speeds already constitute a difficulty at the classical level, since one does not expect thermal disturbances to be carried faster than some (suitably defined) mean molecular speed. Conventional theory is thus applicable only to phenomena which are ''quasistationary,'' i.e., slowly varying on space and time scales characterized by mean free path and mean collision time.[5] This is inadequate for many phenomena in high-energy astrophysics and relativistic cosmology involving steep gradients or rapid variations. These deficiencies can be traced to the fact that the conventional theories (both classical and relativistic) make overly restrictive hypothesis concerning the relation between the fluxes and densities of entropy, energy, and particle number. In the case of a simple fluid, for instance, the conventional theory postulates that entropy flux is simply proportional to heat flux and that entropy density is independent of heat flow and viscosity.[5] This postulate is indeed correct to first order in deviations from equilibrium;

however, in order to infer the correct linear phenomenological laws from the expression for the entropy production, the latter is required to second order. The neglected second-order terms are necessary to prevent noncausal and unstable behavior.[5]

A relativistic second-order theory was found by Israel[5] and developed by Israel and Stewart[6] into what is called ''transient'' or ''extended'' irreversible thermodynamics in which the deviations from equilibrium (bulk stress, heat flow, and shear stress) are treated as independent dynamical variables, leading to a total of 14 dynamical fluid variables to be determined. However, Hiscock and Lindblom[7] and Hiscock and Salmonson[8] have shown that most versions of the causal second-order theories omit certain divergence terms. The truncated causal thermodynamics of bulk viscosity leads to pathological behavior in the late Universe while the solutions of the full causal theory are well behaved for all times. Therefore the best currently available theory for analyzing dissipative processes in the Universe is the full Israel–Stewart–Hiscock (ISH) causal thermodynamics.

Very recently, Chimento and Jakubi[9,10] have found the exact general solution to the Einstein gravitational field equations in a homogeneous Universe filled with a full causal viscous fluid source obeying the relation $\xi\sim\rho^{1/2}$, corresponding to two different choices of the state equations for pressure, bulk viscosity coefficient, temperature, and bulk relaxation time. The equation describing the dynamics of the Universe takes in this case the form of a particular Painleve–Ince equation which can be linearized by means of an appropriate transformation. The exact solution of the gravitational field equations is expressed in an exact parametrical form as a two-parameter family. Depending on the values of the parameters Chimento and Jakubi classified their solutions according to their number of singularities and obtained several scenarios for the dynamics of the Universe. So, in the case[9] $p=(\gamma-1)\rho$, $\xi\sim\rho^s$, $T\sim\rho^r$ and $\tau\sim\xi/\rho\sim\rho^{s-1}$, the evolution of the Universe begins at a singularity asymptotically approaching a Minkowskian space–time or is asymptotically Friedmann or de Sitter. Chimento[11] considered in detail the properties of the corresponding Painleve–Ince equation whose invariant form was reduced to a linear inhomogeneous ordinary second-order differential equation with constant coefficients by means of a nonlocal transformation. Exact singular and late time inflationary solutions of the gravitational field equations with bulk viscosity coefficient proportional to the Hubble factor have been obtained by Chimento *et al.*[12] in the framework of a nonlinear generalization of the causal linear thermodynamics of bulk viscosity proposed by Maartens and Mendez[13] in order to obtain a thermodynamically consistent viscous fluid inflation.

Our intention in the present paper is to obtain some new classes of exact solutions of the gravitational field equations for a flat Friedmann–Robertson–Walker (FRW) Universe filled with a bulk-viscous imperfect fluid under the framework of the full Israel–Stewart–Hiscock causal theory. By supposing that the bulk viscosity coefficient is proportional to the square root of the density, $\xi\sim\rho^{1/2}$ or equivalently proportional with the Hubble factor H, $\xi\sim H$, with the use of a mathematical formalism different from that of Chimento and Jakubi,[9–11] we reduce the equation describing the evolution of the dissipative processes dominated Universe to a first kind Abel-type first-order differential equation. Particular solutions of the Abel-type equation are used to generate new general solutions of the evolution equation (and, consequently, of the Einstein field equations), corresponding to some particular values of the parameters involved in our physical model. The obtained solutions of the gravitational field equations are expressed in a parametric form and they describe inflationary evolution of a FRW Universe filled with a bulk-viscous fluid. The linear theory is supposed to be applicable at least locally and for short intervals of time and from a physical point of view, we interpret these inflationary solutions as describing particle production in the early Universe with creation pressure modeled by means of bulk-viscous pressure. The behavior of the energy density, temperature, bulk viscosity coefficient, deceleration parameter, and entropy is analyzed for each case.

The present paper is organized as follows. In Sec. II we present the field equations for a bulk-viscous fluid-filled FRW Universe in the framework of the full Israel–Stewart–Hiscock theory and the first-order first kind Abel-type evolution equation that has to be integrated is also obtained. The first class of solutions, corresponding to fixed values of parameters is presented in Sec. III. In Sec. IV we generate the second class of solutions. Certain physical properties of the obtained solutions are considered in Sec. V and the equivalence between causal bulk-viscous and

particle production models is explicitly considered. Finally, in Sec. VI we summarize and conclude our results.

II. GEOMETRY, THERMODYNAMICS, FIELD EQUATIONS, AND CONSEQUENCES

For a spatially flat Friedmann–Robertson–Walker (FRW) Universe with line element

$$ds^2=dt^2-a^2(t)(dx_1^2+dx_2^2+dx_3^2) \tag{1}$$

filled with a bulk-viscous cosmological fluid the energy momentum tensor is given by

$$T_i^k=(\rho+p+\Pi)u_iu^k-(p+\Pi)\delta_i^k, \tag{2}$$

where ρ is the energy density, p the thermodynamic pressure, Π the bulk-viscous pressure, and u_i the four velocity satisfying the condition $u_iu^i=1$.

Using (1) and (2) the gravitational field equations take the form:

$$3H^2=\rho, \tag{3}$$

$$2\dot{H}+3H^2=-p-\Pi. \tag{4}$$

From the continuity equation $T^k_{i;k}=0$ or from Eqs. (3) and (4), we obtain

$$\dot{\rho}+3(\rho+p)H=-3\Pi H. \tag{5}$$

The causal evolution equation for the bulk viscous pressure in the most general case including nonlinear terms is given by:[13]

$$\tau\dot{\Pi}=-3\xi H-\frac{1}{2}\,\tau\Pi\left(3H+\frac{\dot{\tau}}{\tau}-\frac{\dot{\xi}}{\xi}-\frac{\dot{T}}{T}\right)+\xi\chi(\Pi), \tag{6}$$

where T is the temperature, ξ the bulk viscosity coefficient, τ the relaxation time, $\chi(\Pi)$ the thermodynamic ''force'' associated to the thermodynamic ''flux'' Π and we have denoted $H=\dot{a}/a$ (Hubble factor). Equation (6) arises as the simplest way to satisfy the H theorem (i.e., for the entropy production to be non-negative), $S^i_{;i}=-(\Pi/T)\chi(\Pi)\geqslant 0$, where $S^i=sN^i-(\tau\Pi^2/2\xi T)u^i$ is the entropy flow vector and $N^i=nu^i$ is the particle flow vector[5,6] and to maintain quadratic dissipative contributions to the effective nonequilibrium specific entropy[13] $S_{\rm eff}=S-(\tau/2nT\xi)\Pi^2$. For $\chi=-\Pi/\xi$ we obtain the linear Israel–Stewart theory[5,6] describing small deviations from equilibrium.

Maartens and Mendez[13] have considered a nonlinear generalization of the linear causal thermodynamics leading to a thermodynamically consistent inflation with $\chi=-\Pi/(\xi+\tau_*\Pi)$, where $\tau_*=k^2\tau$, $k=$const, is a characteristic nonlinear time scale. For $\tau_*\ll 1/\Pi$ the usual Israel–Stewart theory is recovered.

In order to describe the general evolution of a bulk-viscous dissipative cosmological fluid with arbitrary nonlinear viscosity we shall consider that it is characterized by an iterative structure whose single steps are based on the possibility of neglecting in the field equations the effects due to nonlinearity. Thus the time evolution of a nonlinear viscous Universe consists of an infinite number of linear epochs each of which being related to the previous one by well-defined transformations laws for some physical quantities necessary to individualize a given dissipative linear regime.

From a mathematical point of view this means that we consider for the thermodynamic ''force'' $\chi(\Pi)$ a ''piecewise linear approximation'' of the form

$$\chi(\Pi)\approx\chi^i(\Pi)\approx-\frac{\Pi^{(i)}}{\xi^{(i)}_{\rm eff}},\quad t_i\leqslant t\leqslant t_{i+1},\quad i=1,...,n \tag{7}$$

and we suppose that at least locally and for a short interval of time, $t_i\leqslant t\leqslant t_{i+1}, |t_{i+1}-t_i|\ll 1$, $i=1,...,n$, the relations $\xi^{(i)}_{\rm eff}\approx\xi(t^{(i)}_m)$, and $\Pi^{(i)}\approx\Pi(t^{(i)}_m), \forall t^{(i)}_m\in[t_i,t_{i+1}], i=1,...,n$ hold.

In order to close the system of equations (3)–(6) we have to give the equation of state for p and specify T, τ, and ξ. We shall assume the following laws:[14]

$$p=(\gamma-1)\rho, \tag{8}$$

$$\xi=\alpha\rho^{s}, \tag{9}$$

$$T=\beta\rho^{r}, \tag{10}$$

$$\tau=\frac{\xi}{\rho}=\alpha\rho^{s-1}, \tag{11}$$

where $1\leqslant\gamma\leqslant 2$, $\alpha\geqslant 0$, $\beta\geqslant 0$, $r\geqslant 0$, and $s\geqslant 0$ are constants. Equations (8)–(10) are standard in cosmological models whereas (11) is a simple procedure to ensure that the speed of viscous pulses does not exceed the speed of light.[14]

In the context of irreversible thermodynamics p, ρ, T, and the number density n are equilibrium magnitudes which are related by equations of state of the form $\rho=\rho(T,n)$ and $p=p(T,n)$. From the general requirement that the entropy is a state function we obtain the equation $(\partial\rho/\partial n)_T=(\rho+p)/n-(T/n)(\partial p/\partial T)_n$. In the present model this relation would impose the constraint $r=(\gamma-1)/\gamma$ so that $0\leqslant r\leqslant 1/2$ for $1\leqslant\gamma\leqslant 2$, a range of values which is usually considered in the physical literature.[9–11] With this choice for $\gamma=4/3$ we obtain the usual relationship for thermal radiation relating the energy density ρ to temperature T, $\rho\sim T^4$. But this equation is valid only for equilibrium and leads to a vanishing bulk-viscosity coefficient.[15] On the other hand the evolution law for the temperature[16]

$$\frac{\dot{T}}{T}=-3H\left(\frac{\dfrac{\partial p}{\partial T}}{\dfrac{\partial\rho}{\partial T}}+\frac{\Pi}{\left[T\dfrac{\partial\rho}{\partial T}\right]}\right)$$

leads, in the case of a FRW Universe and in the framework of the full causal theory to a nonbarotropic equation for temperature of the form $T\sim\rho^{a_1}a^{3(\gamma a_1-b_1)}$, where $a_1\equiv\rho/nTc_\nu$, $b_1=(1/nc_\nu)(\partial p/\partial T)$, where we have denoted $c_\nu=(1/n)(\partial\rho/\partial T)$, and n is the particle number.[16] In fact any reliable expression linking ρ to T should depend very much on the different kinds of particle species making up the early cosmological fluid and their proportions in it, something that no one knows. In the first moments of the Universe's expansion the material content is completely unknown and in that nonequilibrium environment even the concept of an equation of state is inadequate, the energy density and pressure being independent functions of the expansion scale factors and time. So, we shall analyze in the present paper a generalized physical model by considering that r, α, and γ are independent parameters and we shall not impose *a priori* any limitations on the range of values of r.

The growth of the total comoving entropy over a proper time interval (t_0,t_1) is given by:[14]

$$\Sigma_1-\Sigma_0=-\frac{3}{k_B}\int_{t_0}^{t_1}\frac{H\Pi a^3}{T}\,dt, \tag{12}$$

where k_B is the Boltzmann's constant.

The Israel–Stewart theory is derived under the assumption that the thermodynamical state of the fluid is close to equilibrium which means that the nonequilibrium bulk-viscous pressure should be small when compared to the local equilibrium pressure, that is[14] $|\Pi|\ll p=(\gamma-1)\rho$. If this condition is violated then one is effectively assuming that the linear theory holds also in the nonlinear regime far from equilibrium. For a fluid description of the matter, the condition of the smallness of the bulk-viscous pressure ought to be satisfied[14] but in the nonlinear theory this constraint is not necessary[13] and it is not maintained without affecting the thermodynamical consistency of the theory.

To see if a cosmological model inflates or not it is convenient to introduce the deceleration parameter q,

$$q=-H^{-2}(\dot{H}+H^2)=\frac{d}{dt}\left(\frac{1}{H}\right)-1. \tag{13}$$

The positive sign of the deceleration parameter corresponds to standard decelerating models whereas the negative sign indicates inflation.

By using the gravitational field equations (3) and (4) it is easy to check that the deceleration parameter can be expressed in the form

$$q=\frac{\rho+3p+3\Pi}{2\rho}. \tag{14}$$

With these assumptions and supposing that locally and for a short interval of time t so that $t_i\leqslant t\leqslant t_{i+1}$ and $|t_{i+1}-t_i|\ll 1$, $i=1,...,n$ the dynamics of the bulk-viscous fluid is linear, $\chi(\Pi)\approx-\Pi/\xi$, the field equations, and the causal evolution equation for the bulk viscosity lead to the following evolution equation[14] for the Hubble factor H:

$$\ddot{H}+\tfrac{3}{2}[1+(1-r)\gamma]H\dot{H}+3^{1-s}\alpha^{-1}H^{2-2s}\dot{H}-(1+r)H^{-1}\dot{H}^2$$
$$+\tfrac{9}{4}(\gamma-2)H^3+\tfrac{1}{2}3^{2-s}\alpha^{-1}\gamma H^{4-2s}=0. \tag{15}$$

We shall consider exact solutions of Eq. (15) corresponding to a bulk-viscous fluid with a bulk viscosity coefficient proportional to the square root of the density or to the Hubble factor, that is we choose $s=1/2$. In this case Eq. (15) takes the form:

$$\ddot{H}+\left\{\frac{3}{2}[1+(1-r)\gamma]+\frac{\sqrt{3}}{\alpha}\right\}H\dot{H}-(1+r)H^{-1}\dot{H}^2+\frac{9}{4}\left[\left(1+\frac{2}{\sqrt{3}\alpha}\right)\gamma-2\right]H^3=0. \tag{16}$$

By means of the transformations[17]

$$H^2=y,\quad \eta=\frac{3}{2}\left[1+(1-r)\gamma+\frac{2}{\sqrt{3}\alpha}\right]\int H dt \tag{17}$$

we obtain the equation

$$\frac{d^2y}{d\eta^2}+\frac{dy}{d\eta}-\frac{1+r}{2}\frac{1}{y}\left(\frac{dy}{d\eta}\right)^2+\frac{2b}{1-r}y=0, \tag{18}$$

where we have denoted

$$b=\frac{(1-r)\left[\left(1+\frac{2}{\sqrt{3}\alpha}\right)\gamma-2\right]}{\left[1+(1-r)\gamma+\frac{2}{\sqrt{3}\alpha}\right]^2}.$$

We shall consider in the following that r and α are arbitrary independent (positive) parameters (independent of γ), so we will not impose any special conditions on the range of values of the parameter b, but we shall consider both cases $b=1/4$ and $b=2/9$ in the present paper.

With the use of the mathematical substitution $dy/d\eta=y^{(1+r)/2}/w$, Eq. (18) is transformed into the following (first kind) Abel-type first-order differential equation for the unknown function w:

$$\frac{dw}{dy}-y^{-(1+r)/2}w^2-\frac{2b}{1-r}y^{-r}w^3=0. \tag{19}$$

By introducing a new independent variable $z=2/(1-r)y^{(1-r)/2}$, $r\neq 1$, Eq. (19) becomes

$$\frac{dw}{dz}-w^2-bzw^3=0. \tag{20}$$

By means of the substitution $w=-(1/\psi)\ (d\psi/dz)$ Eq. (20) takes the form of an Euler-type linear second-order differential equation:

$$\psi^2\ \frac{d^2z}{d\psi^2}+bz=0 \tag{21}$$

and has the general solutions

$$z=C_1\psi^{m_1}+C_2\psi^{m_2},\quad b<\tfrac{1}{4}, \tag{22}$$

$$z=(C_3+C_4\ \ln|\psi|)\psi^{1/2},\quad b=\tfrac{1}{4}, \tag{23}$$

where C_i, $i=1,2,3,4$ are constants of integration and we have denoted $m_1=(1+\sqrt{1-4b})/2$ and $m_2=(1-\sqrt{1-4b})/2$. So, by an appropriate choice of values of integration constants we obtain the following two classes of particular solutions to Eq. (20):

$$w_i^{(p)}=-\frac{1-r}{2m_i}\,y^{-(1-r)/2},\quad i=1,2\ \text{ and }\ b<\frac{1}{4}, \tag{24}$$

$$w_3^{(p)}=-(1-r)y^{-(1-r)/2},\quad b=\tfrac{1}{4}. \tag{25}$$

We shall consider now that Eq. (19) has two general solutions $w_i(y)$, $i=1,2$ which can be generated from the particular solutions obtained above by means of the transformation

$$w_i(y)=\frac{E_i(y)}{u_i(y)}+w_i^{(p)},\quad i=1,2,3 \tag{26}$$

(usual in the theory of the Abel-type differential equations), with

$$E_i(y)=y^{[(1-r)/m_i](3b/2m_i-1)},\quad i=1,2\ \text{ and }\ b<\tfrac{1}{4}, \tag{27}$$

$$E_3(y)=y^{(r-1)/2},\quad b=\tfrac{1}{4} \tag{28}$$

with $u_i(y)$, $i=1,2,3$ some arbitrary functions to be determined and satisfying the following first-order differential equations:

$$\frac{du_i}{dy}+\frac{By^{M_i}}{u_i}+\omega_i y^{(1/2)(M_i-1)}=0,\quad i=1,2\ \text{ and }\ b<\frac{1}{4}, \tag{29}$$

$$\frac{du_3}{dy}+\left(\frac{1}{(1-r)u_3}-1\right)\frac{1}{2y}=0,\quad b=\frac{1}{4}, \tag{30}$$

where we have denoted $B=2b/(1-r)$, $\omega_i=1-(3b/m_i)$, and $M_i=-r+[2(1-r)/m_i](3b/2m_i-1)$, $i=1,2$.

Equations (29) and (30) represent the basic equations describing the dynamics of our bulk-viscous fluid-filled FRW Universe in the framework of the full ISH theory.

III. THE FIRST CLASS OF SOLUTIONS

We shall start our study of bulk-viscous Universes in the causal ISH theory by considering that the parameter b entering in the evolution equations satisfies the condition $b<1/4$. In this case the equations (29) describing the evolution and dynamics of a bulk viscous fluid-filled FRW Universe contain two constants denoted M_i and ω_i, $i=1,2$. In the present section we shall

consider some classes of exact general solutions of the field equations obtained by imposing some mathematical conditions on these parameters. A possible and simple choice leading to an exact analytical solution of equations (29) can be obtained if we choose the value of parameter b so that the condition

$$\omega_i = 1 - \frac{3b}{m_i} = 0, \quad i = 1,2 \tag{31}$$

holds. Equation (31) is satisfied for $b=0$ and $b=2/9$. The case $b=0$ will not be considered here. The unique value of m_i, $i=1,2$ corresponding to $b=2/9$ and satisfying Eq. (31) is $m=m_1=(1+\sqrt{1-4b})/2=2/3$. In view of the definition of b, taking into account that $b=2/9$ and denoting $f=1+(1-r)\gamma$, we obtain the following algebraic parametric compatibility relation between the positive constants α, γ, and r:

$$\left(\frac{2f^2}{9} - f + 3 - 2r\right)\alpha^2 + \frac{2}{9\sqrt{3}}(9-5f)\alpha + \frac{8}{27} = 0. \tag{32}$$

The condition of α being real leads to the following condition for r:

$$r > 1. \tag{33}$$

For these values of parameters it follows from (29) that the function $u=u_1$ satisfies the equation:

$$\frac{du}{dy} + \frac{4}{9(1-r)}\frac{y^{(r-3)/2}}{u} = 0. \tag{34}$$

The general solution of equation (34) can be easily expressed as

$$y = \left[\frac{9(r-1)^2}{16}u^2 - K\right]^{2/(r-1)}, \tag{35}$$

where K is an arbitrary constant of integration. Using (35), (27), and (26) we obtain the following class of exact solutions of Eq. (19), corresponding to our particular choice of parameter b:

$$w(u) = \left(\frac{9(r-1)^2}{16}u^2 - K\right)\left[\frac{\left(\frac{9(r-1)^2}{16}u^2 - K\right)^{1/2}}{u} + \frac{3}{4}(r-1)\right]. \tag{36}$$

By introducing a new parameter $\nu > 0$ by means of the transformation

$$\nu = \left[\frac{9(r-1)^2}{16}u^2 - K\right]^{-1/(r-1)} \tag{37}$$

we can express the first classes of solutions of the gravitational field equations for a bulk-viscous fluid-filled FRW Universe with bulk viscosity coefficient proportional to the Hubble factor and with the parameter $b=2/9$ in the following exact parametrical form [here we have written σ in (38) for the variable of integration to distinguish it from the independent variable ν].

$$t - t_0 = \frac{1-r}{\beta_1}\int_{\nu_0}^{\nu}[(1+K\sigma^{r-1})^{-1/2} + 1]\,d\sigma; \tag{38}$$

$$H = \frac{1}{\nu}, \tag{39}$$

$$a = a_0 \nu^{2(1-r)/\beta_1}[1 + (1+K\nu^{r-1})^{1/2}]^{2/\beta_1}, \tag{40}$$

$$\rho=\frac{3}{\nu^2}, \tag{41}$$

$$p=\frac{3(\gamma-1)}{\nu^2}, \tag{42}$$

$$\xi=\frac{\sqrt{3}\alpha}{\nu}, \tag{43}$$

$$T=\frac{3^r\beta}{\nu^{2r}}, \tag{44}$$

$$\tau=\frac{\alpha}{\sqrt{3}}\,\nu, \tag{45}$$

$$q=\frac{\beta_1}{1-r}\,\frac{1}{(1+K\nu^{r-1})^{-1/2}+1}-1, \tag{46}$$

$$\Delta\Sigma=-S_0\int_{\nu_0}^{\nu}\sigma^{2r-3+[6(1-r)/\beta_1]}[1+(1+K\sigma^{r-1})^{1/2}]^{6/\beta_1}\times\left[\frac{3\gamma(r-1)[(1+K\sigma^{r-1})^{-1/2}+1]}{2\beta_1}+1\right]d\sigma, \tag{47}$$

where a_0, t_0, and $\Sigma(\nu_0)$ are constants of integration and we have denoted $S_0=2*3^{1-r}a_0^3/\beta k_B$, $\Delta\Sigma=\Sigma(\nu)-\Sigma(\nu_0)$, and $\beta_1=f+2/\alpha\sqrt{3}$.

IV. THE SECOND CLASS OF SOLUTIONS

We shall consider now a second class of general solutions of the gravitational field equations describing a FRW Universe filled with a bulk-viscous cosmological fluid in the framework of the full causal ISH theory, generated by the general solution of Eq. (30) corresponding to the value 1/4 of the parameter b. In view of the definition of b and taking into account that $b=1/4$, we obtain the following algebraic parametric compatibility relation between the positive constants α, γ, and r:

$$\left(\frac{f^2}{4}-f+3-2r\right)\alpha^2+\left(\frac{2-f}{\sqrt{3}}\right)\alpha+\frac{1}{3}=0 \tag{48}$$

and we have also denoted $f=1+(1-r)\gamma$ in this case. The condition of α being real leads to the condition

$$r>1. \tag{49}$$

For the sake of simplicity we denote u_3 by u, $u_3=u$. The solution generating function $u(y)$ to be determined satisfies the following first-order differential equation:

$$\frac{du}{dy}+\left(\frac{1}{(1-r)u}-1\right)\frac{1}{2y}=0 \tag{50}$$

having the general solution

$$y=K^2e^{2u}[(r-1)u+1]^{2/(1-r)} \tag{51}$$

with K an arbitrary integration constant.

By using the mathematical substitution $F(u)=(r-1)u+1$, denoting $\Delta\Sigma=(\Sigma-\Sigma_0)/S_0$, $\beta_0=K(3f/2+\sqrt{3}/\alpha)$, $S_0=3^{1-r}a_0^3K^{2(1-r)}/(r-1)\beta k_B$, $F_0=(r-1)u_0+1$, and taking $u>0$ as pa-

rameter we can express the general solution of the gravitational field equations for a FRW space–time filled with a causal bulk-viscous cosmological fluid with bulk viscosity coefficient proportional to the Hubble factor in the following exact parametrical form:

$$t-t_0=\frac{2(r-1)}{\beta_0}\int_{u_0}^{u}e^{-\sigma}F^{1/(r-1)}(\sigma)d\sigma, \tag{52}$$

$$H=Ke^{u}F^{1/(1-r)}(u), \tag{53}$$

$$a=a_0e^{2(r-1)Ku/\beta_0}, \tag{54}$$

$$\rho=3K^2e^{2u}F^{2/(1-r)}(u), \tag{55}$$

$$p=3(\gamma-1)K^2e^{2u}F^{2/(1-r)}(u), \tag{56}$$

$$\xi=\alpha\sqrt{3}Ke^{u}F^{1/(1-r)}(u), \tag{57}$$

$$T=\beta 3^rK^{2r}e^{2ur}F^{2r/(1-r)}(u), \tag{58}$$

$$\tau=\frac{\alpha}{\sqrt{3}K}e^{-u}F^{-1/(1-r)}(u), \tag{59}$$

$$q=\frac{\beta_0}{2(1-r)K}(F^{-1}(u)-1)-1, \tag{60}$$

$$\begin{aligned}\Delta\Sigma=\beta_2^{-3}&[e^{\beta_2(F-1)}[\beta_3\beta_2^2F^2+2(\beta_2+\beta_3)(1-\beta_2F)]\\&-e^{\beta_1(F_0-1)}[\beta_3\beta_2^2F_0^2+2(\beta_2+\beta_3)(1-\beta_2F_0)]],\end{aligned} \tag{61}$$

where t_0, a_0, and u_0 are constants of integration and we have denoted $\beta_2=2[(3K/\beta_0)-1]$ and $\beta_3=2\{1+[3\gamma(r-1)K]/\beta_0\}$.

V. SOME PHYSICAL ASPECTS

The behavior of the dissipative causal bulk-viscous cosmological solutions described by Eqs. (38)–(47) and (52)–(61) essentially depends on the considered range of values of the parameters ν and u. For the first class of solutions (38)–(47) it is obvious that the parameter ν cannot be negative because $\nu<0$ would lead to $H(\nu)<0$ and consequently to $\xi(\nu)<0,\forall\nu<0$. To obtain a thermodynamically consistent cosmological evolution it is necessary that $\nu\geqslant 0$. For the first solution the direction (arrow) of time is inverse to the sense of variation of the parameter ν: to increasing time corresponds a decreasing parameter. In the limit of small values of the time $t\to 0$, corresponding to $\nu\to\infty$, we have from Eq. (37) that $\nu\to\infty$ for $u\to 4\sqrt{K}/3(r-1)$ leading to $y\to 0$ and consequently to $H\to 0$ and from Eq. (40) to $a\to 0$ for $t\to 0$. The Universe described by the first solution starts its evolution from a state of zero energy and a singularity in the space–time geometry. This model implies the appearance of the Universe from the large quantum fluctuation of a quantum vacuum (from ''nothing'') which must be present prior to the existence of the particles and matter in the space–time. But for $a\to 0$ due to the presence of large quantum effects only the quantum cosmology can provide a coherent description of the dynamics of the Universe. So we shall consider that the description of the evolution of the Universe according to the classical Einstein gravitational equations begins only at a large enough scale factor a when due to a specific particle content of the early cosmological fluid, bulk-viscous type dissipative processes begin to play an important role and consequently, we shall restrict the range of variation of the parameter ν by introducing an upper finite limit $\nu=\nu_m<\infty$ leading to a history of the Universe starting at a time $t=t_0>0$ (corresponding to the value $\nu=\nu_m$ of the parameter) from a nonsingular state, characterized by constant and finite values of the scale factor $a(t=t_0)=a_0\neq 0$, the energy density $\rho(t=t_0)=\rho_0\neq 0$, and consequently with constant nonzero pressure, temperature, and bulk viscosity coefficient. The solution is free of singularity in the entire range $t\geqslant t_0$.

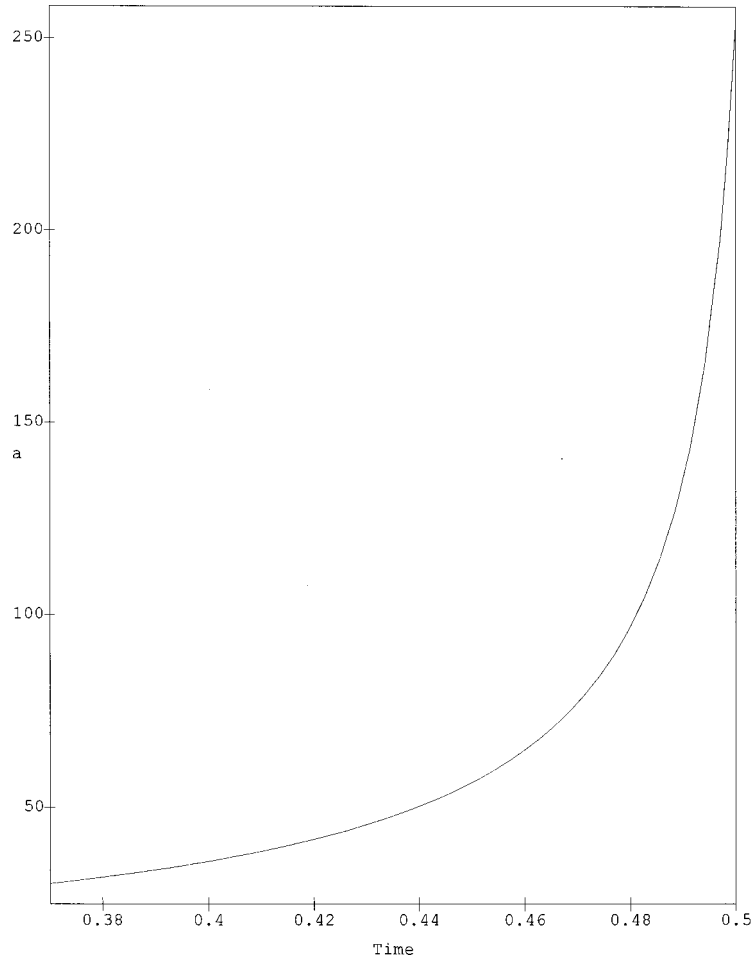

FIG. 1. Variation of the scale factor against the time for $b=2/9$, $r=1.3$, and $\gamma=4/3$.

The Universe shows an inflationary behavior with $q<0$ for all $t>t_0$ so this type of causal bulk-viscous Universe will experience an inflationary era from the beginning of its classical period of existence and its dynamics is reduced to a very rapidly expanding phase. During this period of evolution of the Universe the Hubble factor, energy density, temperature, and bulk viscosity coefficient are rapidly increasing. The Universe enters into a period of accelerated heating and is dominated by thermal processes. A large amount of comoving entropy is produced as a result of dissipative processes. As this thermal Universe expands, the intensity of the bulk-viscous type processes is explosively increasing. The time dependence of the scalar factor a, the energy density ρ, and the deceleration parameter q for the first class of solutions are represented in Figs. 1–3.

In order to obtain the behavior of the Universe in the large time limit $t\to\infty$ ($\nu\to 0$) we observe from Eq. (37) that $\nu\to 0$ in the limit $u\to\infty$ and consequently we obtain from Eq. (26) and for $b=2/9$ that $\lim_{u\to\infty} w=w^{(p)}=[3(r-1)/4]y^{(r-1)/2}$. So the particular solution (24) generating the first general solution (38)–(47) of the gravitational field equations represents the solution of the causal bulk-viscous cosmological fluid in the limit of small parameter ν, corresponding to large times t, and describing the large time dynamics of the model. In this limit we immediately obtain from the field equations

$$H=-\frac{(r-1)}{[1+(1-r)\gamma+2/\sqrt{3}\alpha]}\frac{1}{t}<0$$

and $\xi(t)<0$, $t\to\infty$ leading to a negative bulk viscosity coefficient and consequently a thermodynamically consistent cosmological model can be obtained from the first solution only for positive

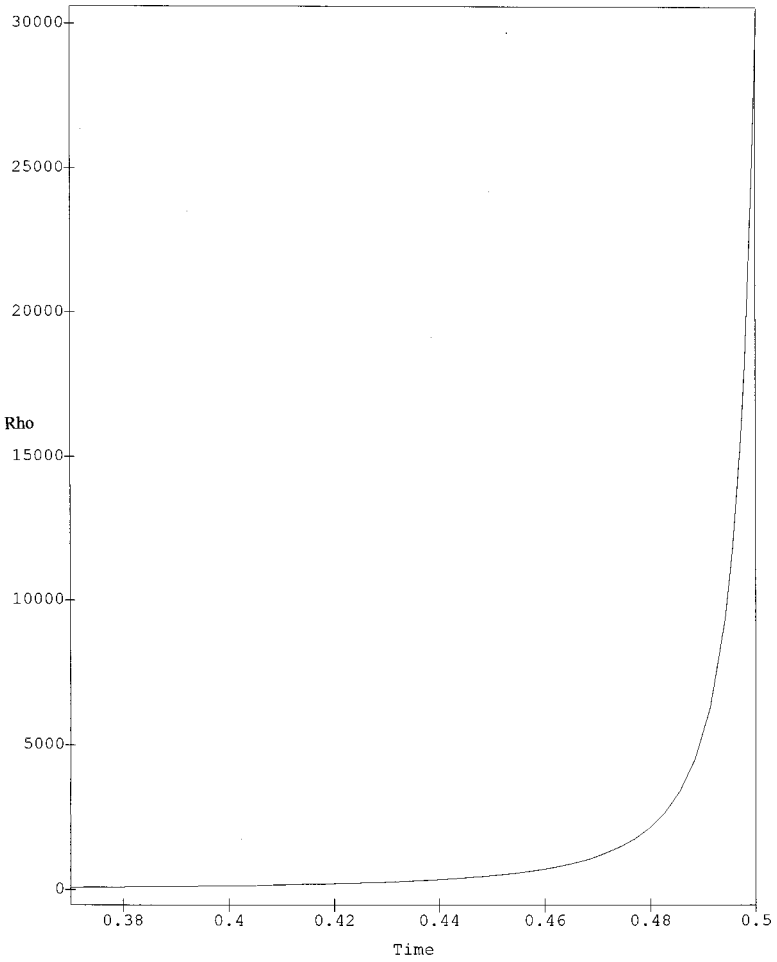

FIG. 2. Variation of the energy density against the time for $b=2/9$, $r=1.3$, and $\gamma=4/3$.

nonzero values of the parameter ν, $\nu>\nu_0>0$. So, a physically consistent evolution of the Universe described by the first solution is obtained only for a finite period of time $t_0\leqslant t\leqslant t_c$, corresponding to a finite range of variation of the parameter $\nu\in[\nu_0,\nu_m]$.

The second class of solutions (52)–(61) leads to physically consistent behavior of the corresponding cosmological model and is defined for all values of r satisfying the condition (49), $r>1$, only for positive values of the parameter u, $u\geqslant 0$. For negative values of the parameter u and for some values of r ($r=1.4$, for example) the time function (52) has imaginary values and for negative u and some classes of r values the Hubble factor $H(u)$ becomes negative leading to a negative bulk viscosity coefficient and consequently, we shall consider the behavior of this class of solutions only in the range of the positive values of the parameter $u\in[0,\infty)$. The Universe starts its evolution at the moment $t=t_0$ (corresponding to the value $u=0$ of the parameter) from a nonsingular state characterized by constant and finite values of the scale factor $a(t=t_0)=a_0\neq 0$, the energy density $\rho(t=t_0)=\rho_0\neq 0$, and consequently with constant nonzero pressure, temperature, and bulk viscosity coefficient. The solutions are free of singularity in the entire range $t_0\leqslant t<\infty$. From the beginning the evolution of the Universe is inflationary and is associated with a rapid increase of the energy density, temperature, and bulk viscosity coefficient. The Universe is heated due to the action of the dissipative processes and a large amount of comoving entropy is produced. In the large time limit the Universe will end in a state characterized by constant values of the scale factor, energy density, temperature, and comoving entropy and its inflationary evolution is stopped. So, this solution can describe the evolution of the Universe only for a finite interval of time $t_0\leqslant t\leqslant t_c$ thus showing a very similar evolution with the Universe described by the first class of solutions. The time dependence of the scalar factor a, the energy density ρ, the

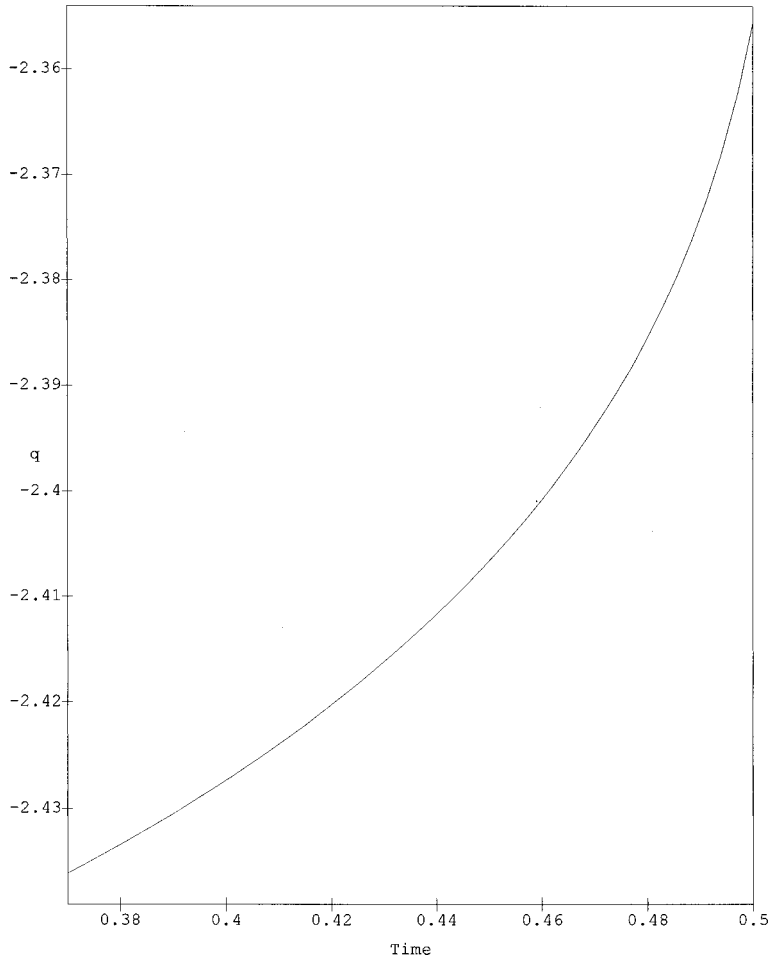

FIG. 3. Variation of the decelerating parameter against the time for $b=2/9$, $r=1.3$, and $\gamma=4/3$.

deceleration parameter q, the entropy Σ, and the Kretschmann scalar $R_{ijkl}R^{ijkl}$ for the second class of solutions are represented in Figs. 4–8.

The nonsingular character of the solutions in the range $t_0 \leqslant t \leqslant t_c$ is consistent with the finite character of the invariants $R_{ij}R^{ij}$ and $R_{ijkl}R^{ijkl}$ for the case of $b=1/4$.

$$R_{ij}R^{ij}=12\left[\left(\frac{\ddot{a}}{a}\right)^2+\left(\frac{\ddot{a}}{a}\right)\left(\frac{\dot{a}}{a}\right)^2+\left(\frac{\dot{a}}{a}\right)^4\right] \tag{62}$$

$$=12(Ke^uF^{1/(1-r)})^4\left[\left[\frac{\beta_0}{2(1-r)K}\,(F^{-1}-1)\right]^2+\frac{3\beta_0}{2(1-r)K}\,(F^{-1}-1)+3\right], \tag{63}$$

$$R_{ijkl}R^{ijkl}=12\left[\left(\frac{\ddot{a}}{a}\right)^2+\left(\frac{\dot{a}}{a}\right)^4\right] \tag{64}$$

$$=12(Ke^uF^{1/(1-r)})^4\left[\left[1+\frac{\beta_0}{2(1-r)K}\,(F^{-1}-1)\right]^2+1\right]. \tag{65}$$

We have also obtained the invariants for the first solution ($b=2/9$) after a tedious but straightforward calculation. We shall not present them here in order to avoid lengthy and cumbersome expressions. These invariants are all finite for all values of the time $t \geqslant t_0$. The presence of a heating period in the framework of the causal viscous theory has been already mentioned in the literature[13,16] and it is always associated with the presence of an inflationary era. The association

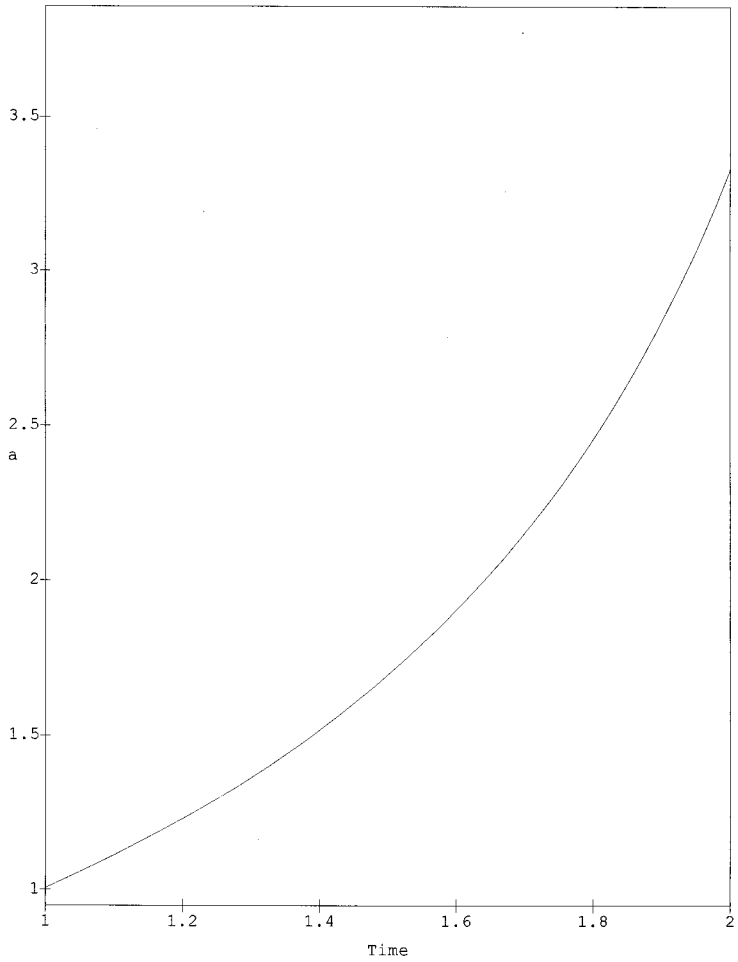

FIG. 4. Variation of the scale factor against the time for $b=1/4$, $r=1.3$, and $\gamma=4/3$.

between heating period, entropy production, and inflation is a specific characteristic of the general solution of the gravitational field equations for a bulk-viscous cosmological fluid with a bulk viscosity coefficient proportional to H and $0\leqslant r\leqslant 1/2$.

From Eq. (14) it follows that, because $q<0$ for all $t\geqslant t_0$,

$$\rho+3p_{\text{eff}}<0 \quad \text{for all} \quad t\geqslant t_0=0 \tag{66}$$

(where $p_{\text{eff}}=p+\Pi$) and

$$\rho+3p<3H^2[3\gamma-2(q+1)]. \tag{67}$$

For periods of time for which the condition

$$q>\frac{3\gamma}{2}-1>0 \quad \text{for all} \quad \gamma\in[1,2] \tag{68}$$

holds, the strong energy condition $\rho+3p>0$ is violated by causal bulk-viscous (noninflationary) cosmological models. On the other hand, from (14) it follows that during a causal bulk-viscous inflationary period $p\ll|\Pi|$ which clearly contradicts the condition of smallness of bulk-viscous pressure. In the nonlinear generalization of the full causal theory describing far from equilibrium evolution of a viscous cosmological fluid this condition no longer holds.

The solutions obtained in the present paper describe bulk-viscosity-driven inflationary Universes and are thermodynamically consistent only in the framework of the nonlinear generalization

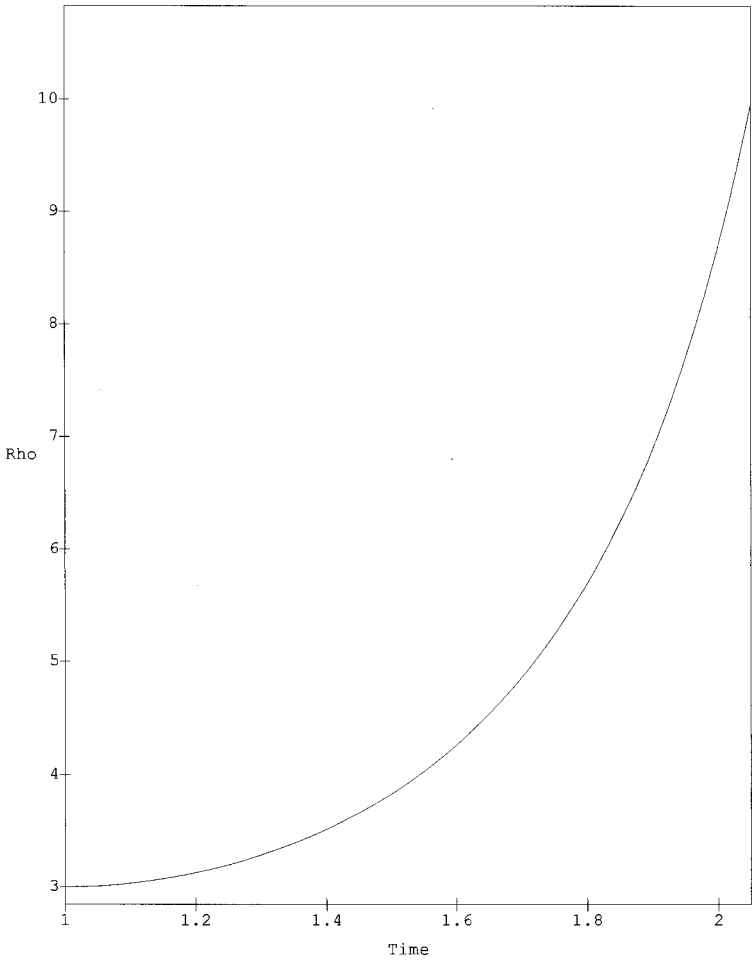

FIG. 5. Variation of the energy density against the time for $b=1/4$, $r=1.3$, and $\gamma=4/3$.

of the linear causal thermodynamics or in our approximation only for periods of time for which $\xi_{\rm eff}^{(i)}\approx\xi$, $i=1,...,n$. In the case of the nonlinear theory of Maartens and Mendez[13] this relation can be expressed as $\xi_{\rm eff}^{(i)}(t)\approx(1+k_i^2(\Pi^{(i)}/\rho))\xi(t),\forall t\in[t_i,t_{i+1}]$, $i=1,...,n$. Consequently, the obtained solutions can describe far from equilibrium inflationary evolution only for periods of time for which the condition

$$k_i^2\,\frac{\Pi^{(i)}}{\rho}\ll 1,\quad i=1,...,n \tag{69}$$

is satisfied. So in this model by an appropriate choice of the constants k_i, $i=1,...,n$ entering in the expression of the nonlinear relaxation time $\tau_*^{(i)}=k_i^2\tau$ it is always possible to obtain (69) for successive short time intervals and the evolution of a nonlinear far from equilibrium causal bulk-viscous Universe can be reduced to a sequence of a large number of linear epochs, $n\to\infty$, so that in each era the nonlinear relaxation time τ_* is related to the linear one by means of different constants k_i, $i=1,...,n$, so that the equation (69) is satisfied during the corresponding bulk-viscous regime.

The causal bulk viscous inflationary solutions we have obtained in the present paper lead to a rapid increase of the energy density, temperature, and entropy of the cosmological fluid filling the early Universe due to the presence of intense dissipative processes. But these results can be interpreted also from the alternative point of view of another physical theory. In fact the cosmological behavior of our solutions is exactly what is expected from a theory describing particle production in the early Universe.

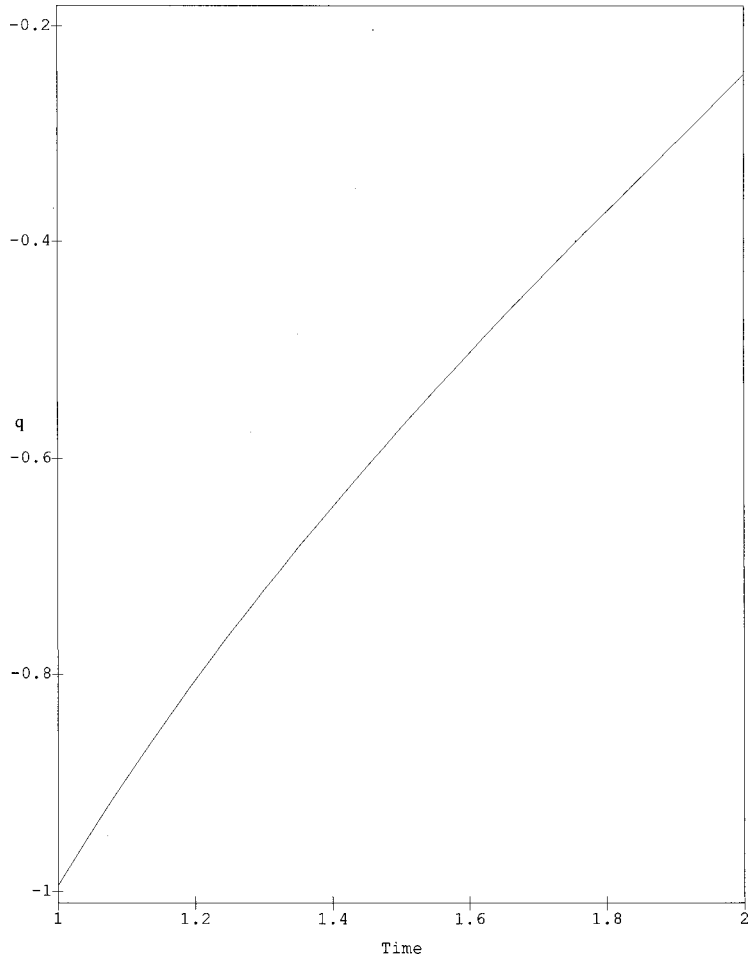

FIG. 6. Variation of the decelerating parameter against the time for $b=1/4$, $r=1.3$, and $\gamma=4/3$.

As was observed first by Zeldovich[18] and later on confirmed by Murphy[19] and Hu[20] a nonvanishing particle production rate is equivalent to a bulk-viscous pressure in the cosmological fluid or from a quantum point of view with a viscosity of the vacuum. This is due to the simple circumstance that any source term in the energy balance of a relativistic fluid may be formally rewritten in terms of an effective bulk viscosity. Barrow[21] has considered creation processes in string-driven inflation within a fluid model and concluded that this process may be described phenomenologically in terms of an effective bulk viscosity. From the point of view of the kinetic theory based on a Boltzmann type equation it follows that this simple phenomenological approach is compatible with the kinetic theory in homogeneous space–times but not in inhomogeneous ones.[22] Consequently if it is possible to describe particle production processes consistently by means of an effective viscous pressure one is able to study, at least on a simple classical phenomenological level, the impact of these processes on the early dynamics of the Universe.

The possibility that the bulk-viscous pressure of the full ISH theory may also be interpreted as an effective description for particle production processes has been considered in detail by Zimdahl.[16] The creation process leads to considerable changes in the thermodynamical behavior of the Universe and if the chemical potential of the newly created particles is zero, $\mu=0$, then the nonvanishing bulk pressure Π associated with an increase in the number of fluid particles satisfies formally the same equation (6) as in the case of presence of a real dissipative bulk viscosity.[16]

In order to analyze the equivalence between the full ISH theory and particle production we shall make the fundamental assumption that immediately after creation all newly created particles are (approximately) amenable to an adiabatic perfect fluid description; that is we suppose that the energy density of the created cosmological fluid obeys an equation of state of the form

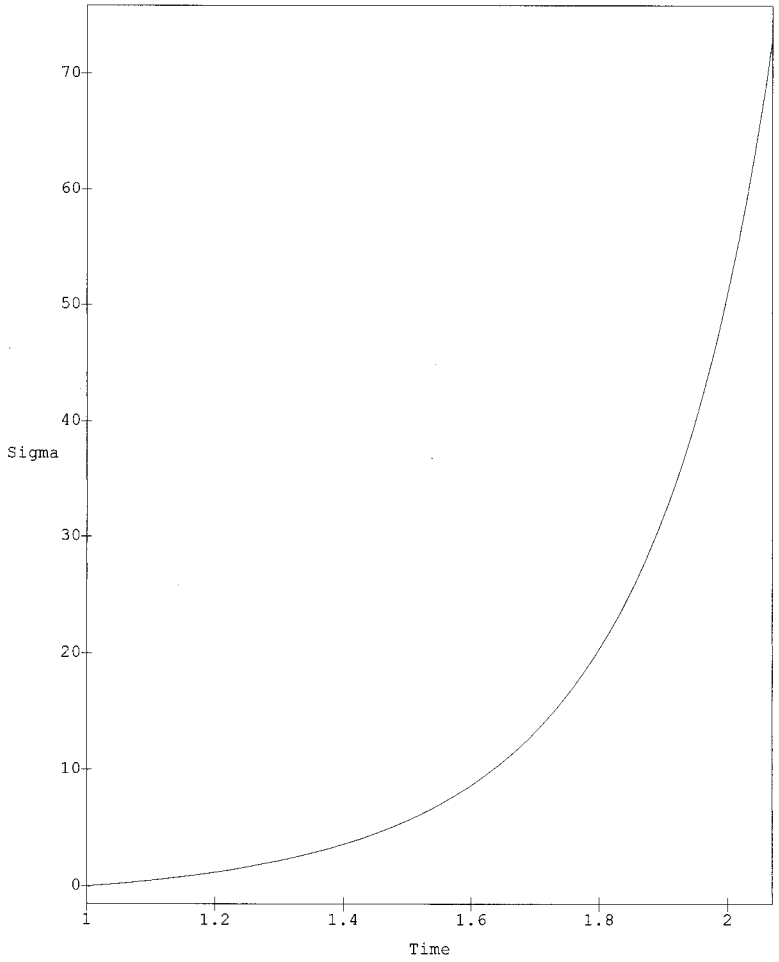

FIG. 7. Variation of the entropy $\Delta\Sigma=(\Sigma-\Sigma_0)/S_0$ against the time for $b=1/4$, $r=1.3$, and $\gamma=4/3$.

$$\rho=\rho_0\left(\frac{n}{n_0}\right)^{\gamma}=kn^{\gamma}, \tag{70}$$

where n is the particle number density and $k=\rho_0/n_0^{\gamma}>0$ is a constant. We suppose that the pressure is given by $p=(\gamma-1)\rho$. By using (70) Eq. (5) takes the form of a particle number balance equation

$$\dot{n}+3Hn=\Gamma n, \tag{71}$$

where

$$\Gamma=-\frac{\Pi}{\gamma H}=\frac{H}{\gamma}[3\gamma-2(q+1)]\geqslant 0 \tag{72}$$

is the particle production rate.

The condition of non-negativity of Γ implies $H>0$ (particle creation takes place only in an expanding Universe) and

$$q<\frac{3\gamma}{2}-1. \tag{73}$$

Condition (73) is automatically satisfied by all inflationary Universes (with $q<0$).

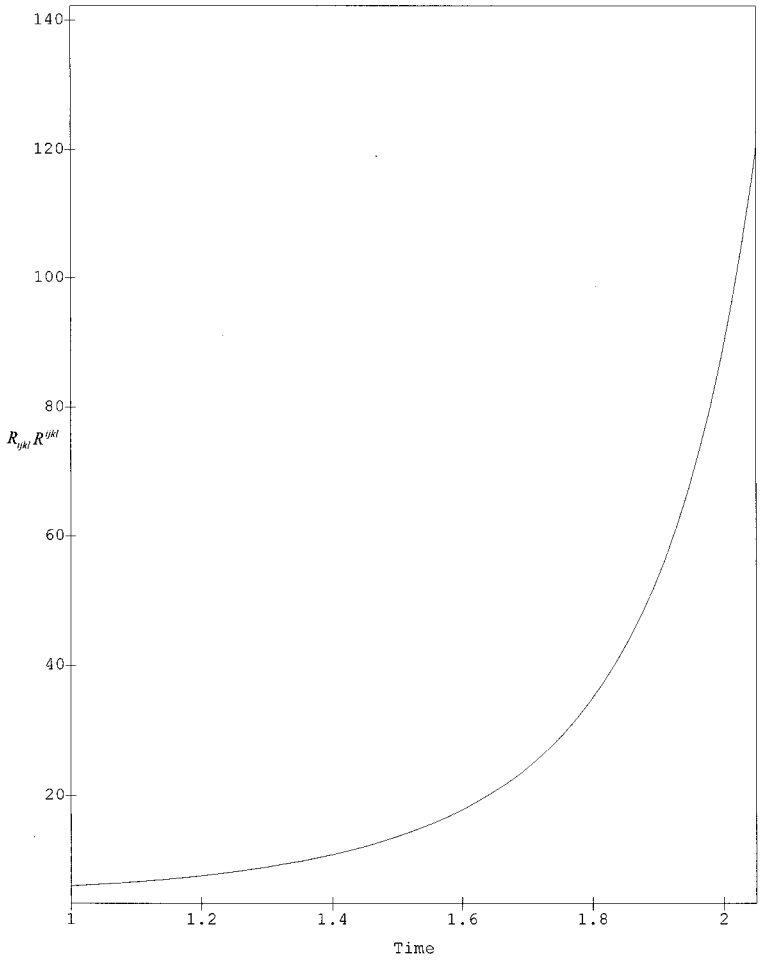

FIG. 8. Variation of the Kretschmann scalar $R_{ijkl}R^{ijkl}$ against the time for $b=1/4$, $r=1.3$, and $\gamma=4/3$.

From the causal evolution equation of the bulk-viscous pressure (6) it follows that the dynamics of the particle production rate is described in the general nonlinear case by the following linear first-order differential equation:

$$\tau\dot{\Gamma}+\left[\left(\frac{\dot{H}}{H}+\frac{1}{2}\left(3H+\frac{\dot{\tau}}{\tau}-\frac{\dot{\xi}}{\xi}-\frac{\dot{T}}{T}\right)\right)\tau\right]\Gamma=-\frac{1}{\gamma}\frac{\chi(-\gamma H\Gamma)}{H}+\frac{s_0}{\gamma^2}\left(\frac{3}{k}\right)^{1/\gamma}\xi TH^{2(1/\gamma-1)}, \quad (74)$$

where s_0 is the (constant) entropy of the newly produced particles. The entropy production, entirely due to particle creation, is given by $S^i_{;j}=-(\Pi/T)\chi(\Pi)>0$. In the case of a linear bulk-viscous regime (which we consider that can model inflationary viscous far from equilibrium dynamics for small time intervals) we obtain for the particle creation rate the evolution equation

$$\tau\dot{\Gamma}+\left[1+\left(\frac{\dot{H}}{H}+\frac{1}{2}\left(3H+\frac{\dot{\tau}}{\tau}-\frac{\dot{\xi}}{\xi}-\frac{\dot{T}}{T}\right)\right)\tau\right]\Gamma=\frac{s_0}{\gamma^2}\left(\frac{3}{k}\right)^{1/\gamma}\xi TH^{2(1/\gamma-1)}. \quad (75)$$

So a causal bulk viscous inflationary cosmological model is mathematically equivalent with a particle creation model with particle production rate satisfying Eqs. (72) or (75). The particle creation rate is a complicated function of the Hubble factor, temperature, relaxation time, and of a generalized bulk-viscosity coefficient related to the bulk-viscous pressure (that plays the role of a ''creation pressure''). During the particle creation era the temperature of the newly created particle is described by a law of the form $T\sim n^{\gamma r}$ which taking into account that r has arbitrary values leads in the present model to a different thermal behavior of a gas of particles during creation comparatively to an ideal gas.[16]

VI. CONCLUSIONS AND FINAL REMARKS

In the present paper we have presented two new classes of solutions of the Einstein gravitational field equations for a causal bulk-viscous fluid-filled FRW space–time corresponding to a relaxation of the constraints imposed to the parameters entering in the physical mode. We have supposed that the linear model of Israel and Stewart[5,6] can accurately describe bulk viscous far from equilibrium inflation only for very short intervals of time and that for small periods it is a reasonable approximation to the more general nonlinear bulk-viscous type inflationary theories.[13] Both obtained solutions are inflationary, show a similar behavior, and lead to a rapid increase of the energy density, temperature, and comoving entropy of the Universe. This physical behavior naturally fits into the framework of the models describing particle creation in the early Universe and that is why we interpret them as describing on a phenomenological classical level, particle production in a homogeneous FRW space–time (which in fact is essentially a quantum process). Due to the presence of a negative bulk-viscous type particle creation pressure the strong energy condition is violated in the present models. We suppose that in our solutions the entire inflation driving bulk-viscous pressure is due to particle production on a classical level, the effect of the ''real'' viscosity being neglected. With this physical interpretation the inflationary classes of solutions which frequently appear in near- or far- from-equilibrium bulk-viscous cosmologies can be used to study the essential influence of particle creation on the dynamics of the Universe which is always modified compared with the standard FRW behavior as long as there is a substantial change in the number of relevant particle species. On the other hand, inflation and particle creation have been analyzed mainly in space–times with de Sitter or power-law type scale factors. The solutions presented in this paper show that inflation, a general and very attractive feature of many cosmological models, can be described mainly by complicated mathematical models.

One of the most attractive features of the inflationary scenarios is that they might account for the remarkable large scale homogeneity of the Universe as evidenced by the isotropy of the cosmic microwave background. The observed structures consisting of galaxies, clusters of galaxies, etc., are assumed to have developed from initial small fluctuations and one of the key problems in the theory of the galaxy formation is the explanation of a sufficient growth of density inhomogeneities about a homogeneous and isotropic background. Cosmological perturbations in viscous cosmological fluids, having both bulk and shear viscosity have been considered by Zimdahl[23] using the fluctuation dissipation theorems of Landau–Lifshitz type while Zimdahl *et al.*[24] analyzed perturbations in a viscous Universe with particle production. In these papers noncausal thermodynamics has been used to describe dissipative processes. In the presence of particle creation it has been shown[24] that the gauge invariantly defined fractional adiabatic energy-density perturbations are unstable on large cosmic scales and they grow quadratically with the cosmic time. The gravitational stability against small perturbations of the cosmological models obtained in the present paper will be the subject of future research.

Whether one of these models actually describes a well-determined period in the very early dynamics and evolution of our Universe can only be decided once reliable knowledge about the quantum mechanisms that characterize particle or strings creation out of the quantum vacuum close to the Planck time becomes available from the underlying quantum physics.

On a certain formulation of the Einstein equations

Paweł Nurowski[a)]

(Received 13 April 1998; accepted for publication 8 June 1998)

We define a certain differential system on an open set of $\mathbf{R}^6$. The system locally defines a Lorentzian four-manifold satisfying the Einstein equations. The converse statement is indicated and its details are postponed to the forthcoming paper.
© *1998 American Institute of Physics.* [S0022-2488(98)01310-3]

Let $\mathscr{U}$ be an open subset of $\mathbf{R}^6$. Suppose that on $\mathscr{U}$ we have six one-forms $(F,\bar{F},T,\Lambda,E,\bar{E})$ which satisfy the following conditions:

(i) T, Λ are real- and F, E are complex-valued one-forms;

(ii) $F\wedge F\wedge T\wedge\Lambda\wedge E\wedge E\neq 0$ at each point p of $\mathscr{U}$;

(iii) there exist complex-valued one-forms Ω and Γ on $\mathscr{U}$, and a certain complex function α on $\mathscr{U}$ such that

$$\begin{aligned} dF&=(\Omega-\bar{\Omega})\wedge F+E\wedge T+\bar{\Gamma}\wedge\Lambda,\\ dT&=\Gamma\wedge F+\bar{\Gamma}\wedge\bar{F}-(\Omega+\bar{\Omega})\wedge T,\\ d\Lambda&=\bar{E}\wedge F+E\wedge\bar{F}+(\Omega+\bar{\Omega})\wedge\Lambda,\\ dE&=2\Omega\wedge E+\bar{F}\wedge T+\alpha\Lambda\wedge F. \end{aligned} \tag{1}$$

The aim of this paper is to prove that we can associate to such $\mathscr{U}$ a Lorentzian four-manifold that satisfies the Einstein equations. The proof will be a direct consequence of the following sequence of Lemmas.

Lemma 1: If $(F,\bar{F},T,\Lambda,E,\bar{E})$ *satisfy* (1) *then there exist complex functions a, h on* $\mathscr{U}$ *and a real constant* λ *such that*

$$\begin{aligned} d\Gamma&=2\Gamma\wedge\Omega+\alpha T\wedge\bar{F}+a(T\wedge\Lambda+F\wedge\bar{F})+h\Lambda\wedge F,\\ d\Omega&=E\wedge\Gamma-\left(\alpha+\frac{\lambda}{2}\right)(T\wedge\Lambda+F\wedge\bar{F})+a\Lambda\wedge F. \end{aligned} \tag{2}$$

Sketch of the proof: Condition (iii) can be understood as follows. We consider the forms $(F,\bar{F},T,\Lambda,E,\bar{E})$ as the basic objects. We assume that their differentials have a special form (iii) with certain auxiliary forms $(\Omega,\bar{\Omega},\Gamma,\bar{\Gamma})$. Suppose that we have the system of ten forms $(F,\bar{F},T,\Lambda,E,\bar{E},\Omega,\bar{\Omega},\Gamma,\bar{\Gamma})$ satisfying (1). Then

$$d^2\Lambda=d^2T=d^2F=d^2E=0 \tag{3}$$

imply that the differentials $d\Gamma$ and $d\Omega$ have a special form. The proof that $d\Gamma$ and $d\Omega$ have the form (2) is a direct (but lengthy) calculation which uses (3) and the independence condition (ii). To obtain information about the differentials of the functions appearing in (2) one has to use

$$d^2\Gamma=d^2\Omega=0. \tag{4}$$

These equations show, in particular, that λ must be a real constant. □

[a)]Permanent address: Instytut Fizyki Teoretycznej, Wydzial Fizyki, Uniwersytet Warszawski, ul. Hoża 69, Warszawa, Poland. Electronic mail: nurowski@fuw.edu.pl

 © 1998 American Institute of Physics

There are also other equations that are implied by (3) and (4). They carry information about the differentials of α, a, h and about the decompositions of Γ and Ω onto the basis one-forms $(F,\overline{F},T,\Lambda,E,\overline{E})$. Explicitly we have

$$\begin{aligned} d\alpha &= \alpha_1 F + \gamma_4 \overline{F} + \gamma_1 T + \alpha_4 \Lambda - 2aE, \\ da &= a_1 F + \alpha_4 \overline{F} + \alpha_1 T + a_4 \Lambda + hE - (3\alpha + \lambda)\Gamma - 2a\Omega, \\ dh &= h_1 F - a_4 \overline{F} - a_1 T + h_4 \Lambda + 4a\Gamma - 4h\Omega, \end{aligned} \tag{5}$$

where the possible forms of Ω and Γ are

$$\begin{aligned} \Omega &= \omega_1 F + \omega_2 \overline{F} + \omega_3 T + \omega_4 \Lambda, \\ \Gamma &= \gamma_1 F - 4\omega_4 \overline{F} - 4\omega_1 T + \gamma_4 \Lambda - (3\alpha + \lambda)E \end{aligned} \tag{6}$$

and $\gamma_1, \gamma_4, \alpha_1, \alpha_4, a_1, a_4, h_1, h_4, \omega_1, \omega_2, \omega_3, \omega_4$ are complex functions on $\mathscr{U}$. The differentials of these functions can be further analyzed by looking at equations such as $d^2\alpha = 0$, etc.

Reformulating the above statements in the language of the theory of differential systems we say that the differential system (1), (2), (5), (6) is still not closed. For example, the equations of the sort $d^2\alpha = 0$ should still be added.

Lemma 2: $\mathscr{U}$ is locally foliated by two-dimensional manifolds $\mathscr{S}_x$, which are tangent to the real distribution $\mathscr{V}$ defined by

$$\Lambda(\mathscr{V}) = F(\mathscr{V}) = T(\mathscr{V}) = 0.$$

Here the proof is an immediate application of the Froebenius theorem, since the forms $(F,\overline{F},T,\Lambda)$ form a closed differential ideal due to the relations (1). □

Let us define

$$G = F\overline{F} - T\Lambda \tag{7}$$

on $\mathscr{U}$. G constitutes a degenerate metric on $\mathscr{U}$. It has the signature $(+,+,+,-,0,0)$.

Lemma 3: G is constant along any leaf $\mathscr{S}_x$ of the foliation $\{\mathscr{S}_x\}$.

To prove this we define a basis of vector fields $(f,\overline{f},X,Y,e,\overline{e})$, which is the respective dual of $(F,\overline{F},T,\Lambda,E,\overline{E})$. Then we notice that the distribution $\mathscr{V}$ is spanned by vector fields of the form

$$V = Ue + \overline{U}\overline{e},$$

where U is any complex function on $\mathscr{U}$. Using an arbitrary V and the explicit form of G one easily finds that $\mathscr{L}_V G = 0$ due to Eq. (1) and the properties of the Lie derivative $\mathscr{L}_V$. □

Now we introduce an equivalence relation $\sim$ on $\mathscr{U}$ which identifies points lying on the same leave of $\{\mathscr{S}_x\}$. We assume that the quotient space $\mathscr{M} = \mathscr{U}/\sim$ is a four-manifold. According to Lemma 3, G projects down to a well-defined nondegenerate Lorentzian metric g on $\mathscr{M}$.

Theorem 1: *The Lorentzian metric g on $\mathscr{M} = \mathscr{U}/\sim$ satisfies the Einstein equations $R_{ij} = \lambda g_{ij}$ and is not conformally flat.*

Proof: To prove the theorem, we first consider a four-dimensional submanifold $\mathscr{M}'$ of $\mathscr{U}$ that is transversal to the leaves of $\{\mathscr{S}_x\}$. We have a natural inclusion $\iota: \mathscr{M}' \hookrightarrow \mathscr{U}$. $\mathscr{M}'$ may be equipped with a Lorentzian metric $g' = \iota^* G$. It is clear that $(\mathscr{M},g)$ and $(\mathscr{M}',g')$ are locally isometrically equivalent. This statement does not depend on the choice of $\mathscr{M}'$. Thus, we may represent $(\mathscr{M},g)$ by $(\mathscr{M}',g')$. In this way, it is enough to show that g' satisfies the Einstein equations. To do this, we first observe that $g' = \iota^*(F)\iota^*(\overline{F}) - \iota^*(T)\iota^*(\Lambda)$. Thus, a set of forms $\theta^i = (\iota^*(F), \iota^*(\overline{F}), \iota^*(T), \iota^*(\Lambda))$, $(i = 1,2,3,4)$ constitutes a null cotetrad for g'. To calculate the curvature we need to know $d\theta^i$. But these, due to the fact that $\iota^* d = d\iota^*$, are given by the relations (1). To simplify the notation, we will omit the signs of the pullback ι^* in all of the formulas. On doing that we find that the connection one-forms for g' determined by

$$dF=-\Gamma^1{}_1\wedge F-\Gamma^1{}_3\wedge T-\Gamma^1{}_4\wedge\Lambda,$$

$$d\overline{F}=-\Gamma^2{}_2\wedge\overline{F}-\Gamma^2{}_3\wedge T-\Gamma^2{}_4\wedge\Lambda,$$

$$dT=-\Gamma^3{}_1\wedge F-\Gamma^3{}_2\wedge\overline{F}-\Gamma^3{}_3\wedge T,$$

$$d\Lambda=-\Gamma^4{}_1\wedge F-\Gamma^4{}_2\wedge\overline{F}-\Gamma^4{}_4\wedge\Lambda,$$

$$g_{ik}\Gamma^k{}_j+g_{jk}\Gamma^k{}_i=0,\quad g_{ij}=\begin{pmatrix}0&1&0&0\\1&0&0&0\\0&0&0&-1\\0&0&-1&0\end{pmatrix}$$

read

$$\Gamma^i{}_j=\begin{pmatrix}\overline{\Omega}-\Omega&0&-E&-\overline{\Gamma}\\0&\Omega-\overline{\Omega}&-\overline{E}&-\Gamma\\-\Gamma&-\overline{\Gamma}&\Omega+\overline{\Omega}&0\\-\overline{E}&-E&0&-\Omega-\overline{\Omega}\end{pmatrix}.$$

The curvature $\mathscr{R}^i{}_j=d\Gamma^i{}_j+\Gamma^i{}_k\wedge\Gamma^k{}_j$ of this connection can be calculated using the relations (1) and their consequences (2). Modulo the obvious reality conditions its components read as follows (we lower indices by means of the metric g_{ij}).

$$\mathscr{R}_{23}=-\overline{F}\wedge T-\alpha\Lambda\wedge F,$$

$$\mathscr{R}_{14}=\overline{\alpha}\overline{F}\wedge T+a(\Lambda\wedge T-F\wedge\overline{F})-h\Lambda\wedge F,$$

$$\tfrac{1}{2}(\mathscr{R}_{43}-\mathscr{R}_{12})=-(\alpha+\tfrac{1}{2}\lambda)(\Lambda\wedge T-F\wedge\overline{F})-a\Lambda\wedge F.$$

These should be compared with the definitions of the spinorial coefficients of the Weyl tensor Ψ_μ, $\mu=0,1,2,3,4$, the traceless Ricci tensor S_{ij}, and the Ricci scalar R given by

$$\begin{aligned}\mathscr{R}_{23}=&\Psi_4\overline{F}\wedge T+\Psi_3(\Lambda\wedge T-F\wedge\overline{F})+(\Psi_2+\tfrac{1}{12}R)\Lambda\wedge F\\&+\tfrac{1}{2}S_{33}F\wedge T+\tfrac{1}{2}S_{32}(\Lambda\wedge T+F\wedge\overline{F})+\tfrac{1}{2}S_{22}\Lambda\wedge\overline{F},\end{aligned}$$

$$\begin{aligned}\mathscr{R}_{14}=&(-\Psi_2-\tfrac{1}{12}R)\overline{F}\wedge T-\Psi_1(\Lambda\wedge T-F\wedge\overline{F})-\Psi_0\Lambda\wedge F\\&-\tfrac{1}{2}S_{11}F\wedge T-\tfrac{1}{2}S_{41}(\Lambda\wedge T+F\wedge\overline{F})-\tfrac{1}{2}S_{44}\Lambda\wedge\overline{F},\end{aligned}$$

$$\begin{aligned}\tfrac{1}{2}(\mathscr{R}_{43}-\mathscr{R}_{12})=&\Psi_3\overline{F}\wedge T+(\Psi_2-\tfrac{1}{24}R)(\Lambda\wedge T-F\wedge\overline{F})+\Psi_1\Lambda\wedge F\\&+\tfrac{1}{2}S_{31}F\wedge T+\tfrac{1}{4}(S_{12}+S_{34})(\Lambda\wedge T+F\wedge\overline{F})+\tfrac{1}{2}S_{42}\Lambda\wedge\overline{F}.\end{aligned}$$

Looking at these equations we easily get $S_{ij}=R_{ij}-\frac{1}{4}Rg_{ij}\equiv 0$. This proves the Einstein property of the metric.

The spinorial coefficients for the Weyl tensor are also easy to obtain. They read

$$\Psi_0=h,\quad \Psi_1=-a,\quad \Psi_2=-\alpha-\frac{\lambda}{3},\quad \Psi_3=0,\quad \Psi_4=-1.$$

Due to the nonvanishing of Ψ_4 the metric is never conformally flat.

We can also interpret the constant λ which for the first time appeared in Eq. (2). One easily reads from the above that it is proportional to the Ricci scalar $R=4\lambda$. This concludes the proof of the Theorem. □

We, additionally, note that the metric is of the Cartan–Petrov–Penrose type D iff

$$a=0; \quad h=-(3\alpha+\lambda)^2 \tag{8}$$

and of the type N iff

$$h=a=0, \quad \lambda=-3\alpha. \tag{9}$$

The metric is algebraically special iff $I^3=27J^2$, where

$$I=-h+\tfrac{1}{3}(3\alpha+\lambda)^2, \quad J=a^2+\tfrac{1}{27}(3\alpha+\lambda)^3+\tfrac{1}{3}h(3\alpha+\lambda).$$

The converse of the present paper can be stated in the following theorem (see Ref. 1 for details).

Theorem 2: *Let $\mathscr{M}$ be a four-dimensional manifold with a Lorentzian conformally nonflat metric g satisfying the Einstein equations $R_{ij}=\lambda g_{ij}$. Then, there exists a double branched cover $\widetilde{\mathscr{P}}$ of the bundle of null directions $\mathscr{P}$ over $\mathscr{M}$*[2,3]

(i) which is a fibration over $\mathscr{M}$ with fibers being two-dimensional tori (or, in algebraically special cases, their degenerate counterparts[1]*)*

and

(ii) on which there exists a unique system of one-forms $(F,\overline{F},T,\Lambda,E,\overline{E})$ which satisfies the following three conditions:

(i) T, Λ are real- and F, E are complex-valued one-forms,
(ii) $F\wedge\overline{F}\wedge T\wedge\Lambda\wedge E\wedge\overline{E}\neq 0$ at each point p of $\widetilde{\mathscr{P}}$;
(iii)

$$\begin{aligned} dF&=(\Omega-\overline{\Omega})\wedge F+E\wedge T+\overline{\Gamma}\wedge\Lambda,\\ dT&=\Gamma\wedge F+\overline{\Gamma}\wedge\overline{F}-(\Omega+\overline{\Omega})\wedge T,\\ d\Lambda&=\overline{E}\wedge F+E\wedge\overline{F}+(\Omega+\overline{\Omega})\wedge\Lambda,\\ dE&=2\Omega\wedge E+\overline{F}\wedge T+\alpha\Lambda\wedge F \end{aligned}$$

with certain complex-valued one-forms Ω and Γ, and a certain complex function α on $\widetilde{\mathscr{P}}$.

I warmly thank Andrzej Trautman for stimulating my interest in Refs. 4–6. I am also very grateful to Mike Crampin, Simonetta Fritelli, Jerzy Lewandowski, Lionel Mason, Ted Newman, David Robinson, and Helmuth Urbantke for helpful discussions. (Received 13 April 1998; accepted for publication 20 April 1998)

Given a conformally nonflat Einstein space–time we define a fibration $\tilde{\mathscr{P}}$ over it. The fibers of this fibration are elliptic curves (two-dimensional tori) or their degenerate counterparts. Their topology depends on the algebraic type of the Weyl tensor of the Einstein metric. The fibration $\tilde{\mathscr{P}}$ is a double branched cover of the bundle $\mathscr{P}$ of null direction over the space–time and is equipped with six linearly independent one-forms which satisfy a certain relatively simple system of equations. © *1998 American Institute of Physics.* [S0022-2488(98)01210-9]

I. DEFINITIONS

In Ref. 1 we defined a certain differential system $\mathscr{T}$ on an open set U of $\mathbf{R}$.[6] We showed that a pair $(U,\mathscr{T})$ naturally defines a four-dimensional conformally nonflat Lorentzian space–time $(\mathscr{M},g)$ which satisfies the Einstein equations $R_{ij}=\lambda g_{ij}$. In this paper we prove the converse statement. In particular, we give a construction which associates a certain six-dimensional elliptic fibration $\tilde{\mathscr{P}}$ with any conformally nonflat Lorentzian Einstein space–time. Moreover, we show how $\tilde{\mathscr{P}}$ may be equipped with a unique differential system which has all the properties of the system $\mathscr{T}$ on U.

We briefly recall the definitions of the geometrical objects we need in the following. Let $\mathscr{M}$ be a four-dimensional-oriented and time-oriented manifold equipped with a Lorentzian metric g of signature $(+,+,+,-)$. It is convenient to introduce a null frame $(m,\bar{m},k,l)$ on $\mathscr{M}$ with a coframe $\theta^i=(\theta^1,\theta^2,\theta^3,\theta^4)=(M,\bar{M},K,L)$ so that

$$g=g_{ij}\theta^i\theta^j=M\bar{M}-KL. \tag{1}$$

[Such expressions as $\theta^i\theta^j$ mean the symmetrized tensor product, e.g., $\theta^i\theta^j=\frac{1}{2}(\theta^i\otimes\theta^j+\theta^j\otimes\theta^i)$. Also, we will denote by round (respectively, square) brackets the symmetrization (respectively, antisymmetrization) of indices, e.g., $a_{(ik)}=\frac{1}{2}(a_{ik}+a_{ki})$, $a_{[ik]}=\frac{1}{2}(a_{ik}-a_{ki})$, etc.]

The Lorentz group $\mathbf{L}$ consists of matrices $\lambda^i_j\in\mathbf{GL}(4,\mathbf{C})$ such that

$$g_{jl}=g_{ik}\lambda^i{}_j\lambda^k{}_l,$$

$$\lambda^2{}_2=\overline{\lambda^1{}_1},\quad \lambda^2{}_1=\overline{\lambda^1{}_2},\quad \lambda^2{}_3=\overline{\lambda^1{}_3},\quad \lambda^2{}_4=\overline{\lambda^1{}_4}, \tag{2}$$

$$\lambda^3{}_2=\overline{\lambda^3{}_1},\quad \lambda^3{}_3=\overline{\lambda^3{}_3},\quad \lambda^3{}_4=\overline{\lambda^3{}_4},\quad \lambda^4{}_2=\overline{\lambda^4{}_1},\quad \lambda^4{}_3=\overline{\lambda^4{}_3},\quad \lambda^4{}_4=\overline{\lambda^4{}_4}.$$

We will denote the inverse of the Lorentz matrix $\lambda^i{}_j$ by $\tilde{\lambda}^i{}_j$.

The connected component of the identity element of $\mathbf{L}$ is the proper ortochroneous Lorentz group, which we denote by $\mathbf{L}^{\uparrow}_{+}$.

Given g and θ^i the connection one-forms $\Gamma_{ij}=g_{ik}\Gamma^k{}_j$ are uniquely defined by

$$d\theta^i=-\Gamma^i{}_j\wedge\theta^j,\quad \Gamma_{ij}+\Gamma_{ji}=0. \tag{3}$$

The connection coefficients Γ_{ijk} are determined by $\Gamma_{ij}=\Gamma_{ijk}\theta^k$ (we lower and raise indices by means of the metric and its inverse). Using them we define the curvature two-forms $\mathscr{R}^k{}_i$, the Riemann tensor $R^i{}_{jkl}$, the Ricci tensor R_{ij}, and its scalar R by

$$\mathscr{R}^k{}_i=\tfrac{1}{2}R^k{}_{imj}\theta^m\wedge\theta^j=d\Gamma^k{}_i+\Gamma^k{}_j\wedge\Gamma^j{}_i, \quad R_{ij}=R^k{}_{ikj}, \quad R=g^{ij}R_{ij}.$$

We also introduce the traceless Ricci tensor by

$$S_{ij}=R_{ij}-\tfrac{1}{4}g_{ij}R.$$

Note that the vanishing of S_{ij} is equivalent to the Einstein equations $R_{ij}=\lambda g_{ij}$ for the metric g. We define the Weyl tensor $C^i{}_{jkl}$ by

$$C_{ijkl}=R_{ijkl}+\tfrac{1}{3}Rg_{i[k}g_{l]j}+R_{j[k}g_{l]i}+R_{i[l}g_{k]j},$$

and its spinorial coefficients Ψ_μ by

$$\begin{aligned}\mathscr{R}_{23}&=\Psi_4\overline{M}\wedge K+\Psi_3(L\wedge K-M\wedge\overline{M})+(\Psi_2+\tfrac{1}{12}R)L\wedge M\\&\quad+\tfrac{1}{2}S_{33}M\wedge K+\tfrac{1}{2}S_{32}(L\wedge K+M\wedge\overline{M})+\tfrac{1}{2}S_{22}L\wedge\overline{M},\\ \mathscr{R}_{14}&=(-\Psi_2-\tfrac{1}{12}R)\overline{M}\wedge K-\Psi_1(L\wedge K-M\wedge\overline{M})-\Psi_0L\wedge M\\&\quad-\tfrac{1}{2}S_{11}M\wedge K-\tfrac{1}{2}S_{41}(L\wedge K+M\wedge\overline{M})-\tfrac{1}{2}S_{44}L\wedge\overline{M},\\ \tfrac{1}{2}(\mathscr{R}_{43}-\mathscr{R}_{12})&=\Psi_3\overline{M}\wedge K+(\Psi_2-\tfrac{1}{24}R)(L\wedge K-M\wedge\overline{M})+\Psi_1L\wedge M\\&\quad+\tfrac{1}{2}S_{31}M\wedge K+\tfrac{1}{4}(S_{12}+S_{34})(L\wedge K+M\wedge\overline{M})+\tfrac{1}{2}S_{42}L\wedge\overline{M}.\end{aligned}$$

II. THE BUNDLE OF NULL COFRAMES

Let $\mathscr{F}(\mathscr{M})$ denote the bundle of oriented and time oriented null coframes over $\mathscr{M}$. This means that $\mathscr{F}(\mathscr{M})$ is the set of all equally oriented null coframes θ^i at all points of $\mathscr{M}$. The mapping $\pi:\mathscr{F}(\mathscr{M})\to\mathscr{M}$, which maps a coframe θ^i at $x\in\mathscr{M}$ onto x, gives the canonical projection. A fiber $\pi^{-1}(x)$ in $\mathscr{F}(\mathscr{M})$ consists of all the null coframes at point x which have the same orientation and time orientation. If θ^j is a null coframe at $x\in\mathscr{M}$, then any other equivalently oriented null coframe at x is given by $\theta'^i=\lambda^i{}_j\theta^j$, where $\lambda^i{}_j$ is a certain element of $\mathbf{L}^\uparrow_+$. This defines an action of $\mathbf{L}^\uparrow_+$ on $\mathscr{F}(\mathscr{M})$. Thus, $\mathscr{F}(\mathscr{M})$ is a ten-dimensional principal fiber bundle with $\mathbf{L}^\uparrow_+$ as its structural group.

It is well known that the bundle $\mathscr{F}(\mathscr{M})$ is equipped with a natural four-covector-valued one-form e^i, $i=1,2,3,4$, the Cartan soldering form, which is defined as follows. Take any vector v_c tangent to $\mathscr{F}(\mathscr{M})$ at a point c. Let c be in the fiber $\pi^{-1}(x)$ over a point $x\in\mathscr{M}$. This means that c may be identified with a certain null coframe θ^i_c at x.

Then, the formal definition of e^i reads: $e^i(v_c)=\theta^i_c(\pi_*v_c)$. The first two components of e^i are complex and mutually conjugated. The remaining two are real. Altogether, they constitute a system of four well-defined linearly independent one-forms on $\mathscr{F}(\mathscr{M})$. In the following we will denote them by

$$F=e^1=\overline{e^2}, \quad T=\overline{T}=e^3, \quad \Lambda=\overline{\Lambda}=e^4. \tag{4}$$

A theorem which we present below is a null coframe reformulation of the Elie Cartan theorem on affine connections.

Theorem 1: *Let $e^i=(F,\overline{F},T,\Lambda)$ be the soldering form on $\mathscr{F}(\mathscr{M})$. Then*

(i) the system of equations

$$de^i+\omega^i{}_j\wedge e^j=0, \quad g_{ki}\omega^i{}_j+g_{ji}\omega^i{}_k=0 \tag{5}$$

for a matrix of complex-valued one-forms $\omega^i{}_j$ $(i,j=1,2,3,4)$ on $\mathscr{F}(\mathscr{M})$ has a unique solution,

(ii) $\omega^i{}_j$ *uniquely defines six complex-valued one-forms* $(E,\overline{E},\Gamma,\overline{\Gamma},\Omega,\overline{\Omega})$ *by*

$$\omega^i{}_j=\begin{pmatrix} \overline{\Omega}-\Omega & 0 & -E & -\overline{\Gamma} \\ 0 & \Omega-\overline{\Omega} & -\overline{E} & -\Gamma \\ -\Gamma & -\overline{\Gamma} & \Omega+\overline{\Omega} & 0 \\ -\overline{E} & -E & 0 & -\Omega-\overline{\Omega} \end{pmatrix}, \tag{6}$$

(iii) the forms $(F,\overline{F},T,\Lambda,E,\overline{E},\Gamma,\overline{\Gamma},\Omega,\overline{\Omega})$ *are linearly independent at each point of* $\mathscr{F}(\mathscr{M})$.

For completeness we sketch the proof.

First, we show that if there is a solution to (5) then it is unique. To do this we assume the existence of two solutions—$\omega^i{}_j$ and $\hat{\omega}^i{}_j$.

Subtracting $de^i+\hat{\omega}^i{}_j\wedge e^j=0$ from $de^i+\omega^i{}_j\wedge e^j=0$ we get

$$(\omega^i{}_j-\hat{\omega}^i{}_j)\wedge e^j=0. \tag{7}$$

Now, let e^μ, $\mu=1, 2, 3, 4, 5, 6$, be a system of one-forms such that the ten one-forms (e^i,e^μ) constitute a basis of one-forms on $\mathscr{F}(\mathscr{M})$. Let $\omega^i{}_j=\omega^i{}_{jk}e^k+\omega^i{}_{j\mu}e^\mu$ and $\hat{\omega}^i{}_j=\hat{\omega}^i{}_{jk}e^k+\hat{\omega}^i{}_{j\mu}e^\mu$ be the corresponding decompositions of the solutions. Then (7) easily yields $\omega^i{}_{j\mu}=\hat{\omega}^i{}_{j\mu}$ and $\omega_{i[jk]}=\hat{\omega}_{i[jk]}$. The defining properties of the solutions give also $\omega_{(ij)k}=0=\hat{\omega}_{(ij)k}$. Now, due to the identity $A_{ijk}=A_{i[jk]}-A_{j[ik]}-A_{k[ij]}$, which is true for any A_{ijk} such that $A_{(ij)k}=0$, we get $\omega_{ijk}=\hat{\omega}_{ijk}$. This shows that $\omega^i{}_j=\hat{\omega}^i{}_j$, hence the uniqueness.

We proceed to the construction of a solution.

Given a sufficiently small neighborhood $\mathscr{O}$ in $\mathscr{M}$ we identify $\pi^{-1}(\mathscr{O})$ with $\mathscr{O}\times\mathbf{L}^\uparrow_+$. Then, the soldering form may be written as

$$e^i=\lambda^i{}_j\theta^j. \tag{8}$$

Taking de^i and using Eq. (3) one easily finds that

$$\omega^i{}_j=\lambda^i{}_k\Gamma^k{}_m\tilde{\lambda}^m_j-d\lambda^i{}_k\tilde{\lambda}^k{}_j \tag{9}$$

is a solution to (5). Given this solution one defines the forms (E,Γ,Ω) by

$$E=-\omega^1{}_3,\quad \Gamma=-\omega^2{}_4,\quad \Omega=\tfrac{1}{2}(\omega^2{}_2+\omega^3{}_3). \tag{10}$$

This is in accordance with (6) due to $\omega_{(ij)}=0$ and the reality properties of e^i.

To prove the linear independence of the system $(F,\overline{F},T,\Lambda,E,\overline{E},\Gamma,\overline{\Gamma},\Omega,\overline{\Omega})$ it is enough to observe that the six one-forms $d\lambda^1{}_k\tilde{\lambda}^k{}_3$, $d\lambda^2{}_k\tilde{\lambda}^k{}_3$, $d\lambda^1{}_k\tilde{\lambda}^k{}_4$, $d\lambda^2{}_k\tilde{\lambda}^k{}_4$, $d\lambda^1{}_k\tilde{\lambda}^k{}_1$, and $d\lambda^3{}_k\tilde{\lambda}^k{}_3$ constitute a basis of right invariant forms on $\mathbf{L}^\uparrow_+$.

The theorem is proven.

III. THE STRUCTURE EQUATIONS

Consider the ten well-defined forms $(F,\overline{F},T,\Lambda,E,\overline{E},\Omega,\overline{\Omega},\Gamma,\overline{\Gamma})$ on $\mathscr{F}(\mathscr{M})$ given by (4) and (10). The differentials of the first four forms are given by (5) and (6). In the basis $(F,\overline{F},T,\Lambda,E,\overline{E},\Omega,\overline{\Omega},\Gamma,\overline{\Gamma})$ they assume the form

$$dF=(\Omega-\overline{\Omega})\wedge F+E\wedge T+\overline{\Gamma}\wedge\Lambda, \tag{11}$$

$$dT=\Gamma\wedge F+\overline{\Gamma}\wedge\overline{F}-(\Omega+\overline{\Omega})\wedge T, \tag{12}$$

$$d\Lambda=\overline{E}\wedge F+E\wedge\overline{F}+(\Omega+\overline{\Omega})\wedge\Lambda. \tag{13}$$

The differentials of the other forms may be easily calculated using the local representation (9) and the well-known structure equations

$$d\omega^i{}_j = -\omega^i{}_k \wedge \omega^k{}_j + \tfrac{1}{2} R^k{}_{smn} \lambda^i{}_k \tilde{\lambda}^s{}_j \tilde{\lambda}^m{}_l \tilde{\lambda}^n{}_p e^l \wedge e^p. \tag{14}$$

These differentials are by far much more complicated than the differentials of dF, dT, and $d\Lambda$. In particular, the decompositions of dF, dT, and $d\Lambda$ onto the basis of two-forms associated with $(F,\bar{F},T,\Lambda,E,\bar{E},\Omega,\bar{\Omega},\Gamma,\bar{\Gamma})$ have only constant coefficients. It turns out that in the differentials dE, $d\Omega$, and $d\Gamma$ coefficients which are functions appear. The zero sets of these functions have a well-defined geometrical meaning and define certain subsets of $\mathscr{F}(\mathscr{M})$. Now, the hope is that when we restrict ourselves to such subsets then the differentials of E, Ω, and Γ will have a much simpler form than their differentials on the whole $\mathscr{F}(\mathscr{M})$. Our aim now is to study this possibility.

IV. EXPLICIT EXPRESSIONS FOR THE BASIC FORMS ON $\mathscr{F}(\mathscr{M})$

We concentrate on the analysis of $dE = -d\omega^1{}_3$.

Let us introduce the matrices $\lambda^i{}_j(w,z,y)$ and $\lambda^i{}_j(w',z',y')$ such that

$$\lambda^i{}_j(w,z,y) = \begin{pmatrix} |w|w^{-1}(1+\overline{yz}) & |w|w^{-1}\overline{yz} & |w|w^{-1}(1+\overline{yz})z & |w|w^{-1}\overline{y} \\ w|w|^{-1}\overline{yz} & w|w|^{-1}(1+yz) & w|w|^{-1}(1+yz)\overline{z} & w|w|^{-1}y \\ |w|(1+\overline{yz})y & |w|(1+yz)\overline{y} & |w||1+\overline{yz}|^2 & |w||y|^2 \\ \overline{z}|w|^{-1} & z|w|^{-1} & |z|^2|w|^{-1} & |w|^{-1} \end{pmatrix},$$

$$\lambda^i{}_j(w',z',y') = \begin{pmatrix} |w'|w'^{-1}\overline{y'}z' & |w'|w'^{-1}(1+\overline{y'}\overline{z'}) & |w'|w'^{-1}\overline{y'} & |w'|w'^{-1}(1+\overline{y'}\overline{z'})z' \\ w'|w'|^{-1}(1+y'z') & w'|w'|^{-1}y'\overline{z'} & w'|w'|^{-1}y' & w'|w'|^{-1}(1+y'z')\overline{z'} \\ |w'|(1+y'z')\overline{y'} & |w'|(1+\overline{y'}\overline{z'}) & |w'||y'|^2 & y'|w'||1+\overline{y'}\overline{z'}|^2 \\ z'|w'|^{-1} & \overline{z'}|w'|^{-1} & |w'|^{-1} & |z'|^2|w'|^{-1} \end{pmatrix}.$$

Then, it is well known that $\mathbf{L}^{\uparrow}_{+}$ can be represented by

$$\mathbf{L}^{\uparrow}_{+} = \mathscr{U} \cup \mathscr{U}', \tag{15}$$

where

$$\mathscr{U} = \{\lambda^i{}_j(w,z,y) \text{ such that } (w,z,y) \in \mathbf{C}^3, w \neq 0\}, \tag{16}$$

$$\mathscr{U}' = \{\lambda^i{}_j(w',z',y') \text{ such that } (w',z',y') \in \mathbf{C}^3, w' \neq 0\}. \tag{17}$$

On the intersection $\mathscr{U} \cap \mathscr{U}'$, the coordinates (w,z,y) and (w',z',y') shall be related by

$$w = -\frac{w'}{z'^2}, \quad z = \frac{1}{z'}, \quad y = -z'(1+y'z'), \tag{18}$$

$$w' = -\frac{w}{z^2}, \quad z' = \frac{1}{z}, \quad y' = -z(1+yz). \tag{19}$$

Thus, we can cover any $\pi^{-1}(\mathscr{O}) \cong (\mathscr{O} \times \mathbf{L}^{\uparrow}_{+})$ by the two charts $\mathscr{O} \times \mathscr{U}$ and $\mathscr{O} \times \mathscr{U}'$. Now, on $\mathscr{O}$ consider the coframe θ^i of (1). Inserting $\lambda^i{}_j = \lambda^i{}_j(w,z,y)$ or $\lambda^i{}_j(w',z',y')$ to the formulas (8), (9), (14) and using the definitions (1), (4), (10) we easily obtain the following two lemmas.

Lemma 1: On $\mathscr{O} \times \mathscr{U}$ the forms F, T, Λ, E, Ω and Γ read

$$F = \frac{|w|}{w}[(1+\overline{yz})(M+zK) + \overline{yz}\overline{M} + \overline{y}\overline{L}], \tag{20}$$

$$T = |w|[|1+\overline{yz}|^2 K + y(1+\overline{yz})M + \overline{y}(1+yz)\overline{M} + y\overline{y}\overline{L}], \tag{21}$$

$$\Lambda=\frac{1}{|w|}\,[L+z\overline{z}K+z\overline{M}+\overline{z}M], \tag{22}$$

$$E=\frac{1}{w}\,[dz+\Gamma_{32}+z(\Gamma_{21}+\Gamma_{43})+z^2\Gamma_{14}], \tag{23}$$

$$\Omega=-\frac{1}{2}\,\frac{dw}{w}-ydz-y\Gamma_{32}-\frac{1}{2}\,(1+2yz)(\Gamma_{21}+\Gamma_{43})-z(1+yz)\Gamma_{14}, \tag{24}$$

$$\Gamma=w[dy-y^2dz-y^2\Gamma_{32}-y(1+yz)(\Gamma_{43}-\Gamma_{12})-(1+yz)^2\Gamma_{14}]. \tag{25}$$

Lemma 2: On $\mathscr{O}\times\mathscr{U}'$ the forms F, T, Λ, E, Ω and Γ read

$$F=\frac{|w'|}{w'}\,[(1+\overline{y'}\overline{z'})(\overline{M}+z'L)+\overline{y'}z'M+\overline{y'}K], \tag{26}$$

$$T=|w'|[|1+\overline{y'}\overline{z'}|^2L+y'(1+\overline{y'}\overline{z'})\overline{M}+\overline{y'}(1+y'z')M+y'\overline{y'}K], \tag{27}$$

$$\Lambda=\frac{1}{|w'|}\,[K+z'\overline{z'}L+z'M+\overline{z'}\overline{M}], \tag{28}$$

$$E=\frac{1}{w'}\,[dz'+\Gamma_{41}+z'(\Gamma_{12}+\Gamma_{34})+z'^2\Gamma_{23}], \tag{29}$$

$$\Omega=-\frac{1}{2}\,\frac{dw'}{w'}-y'dz'-y'\Gamma_{41}-\frac{1}{2}\,(1+2y'z')(\Gamma_{12}+\Gamma_{34})-z'(1+y'z')\Gamma_{23}, \tag{30}$$

$$\Gamma=w'[dy'-y'^2dz'-y'^2\Gamma_{41}-y'(1+y'z')(\Gamma_{34}-\Gamma_{21})-(1+y'z')^2\Gamma_{23}]. \tag{31}$$

Note that this Lemma follows from the previous one by applying transformations $M\leftrightarrow\overline{M}$, $K\leftrightarrow L$, $1\leftrightarrow2$, and $3\leftrightarrow4$, where the last two transformations refer to the tetrad indices.

Now one can easily find the differential of *dE*.

Lemma 3: The decomposition of dE onto the basis $(F,\overline{F},T,\Lambda,E,\overline{E},\Omega,\overline{\Omega},\Gamma,\overline{\Gamma})$ of one-forms on $\pi^{-1}(\mathscr{O})$ reads

$$dE=2\Omega\wedge E+\phi T\wedge F+b(\Lambda\wedge T+F\wedge\overline{F})+\beta F\wedge\Lambda+\psi T\wedge\overline{F}+a(\Lambda\wedge T-F\wedge\overline{F})+\alpha\Lambda\wedge F,$$

where $\phi,b,\beta,\psi,a,\alpha$ are well-defined functions on $\pi^{-1}(\mathscr{O})$.

The functions $\phi,b,\beta,\psi,a,\alpha$ are given by

$$\phi=\frac{1}{|w|^2}\,\Phi,\quad b=\overline{w}(\tfrac{1}{2}\phi_{\overline{z}}+\overline{y}\phi),\quad \beta=\overline{w}^2(\tfrac{1}{2}\phi_{\overline{z}\overline{z}}+\overline{y}\phi_{\overline{z}}+\overline{y}^2\phi),$$

$$\psi=\frac{1}{w^2}\,\Psi,\quad a=w(\tfrac{1}{4}\psi_z+y\psi),\quad \alpha=-w^2(\tfrac{1}{12}\psi_{zz}+y^2\psi+\tfrac{1}{2}y\psi_z)-\tfrac{1}{12}R,$$

$$\Phi=\tfrac{1}{2}S_{33}-\overline{z}S_{23}-zS_{13}+z\overline{z}(S_{12}+S_{34})+\tfrac{1}{2}\overline{z}^2S_{22}+\tfrac{1}{2}z^2S_{11}-\overline{z}^2zS_{24}-z^2\overline{z}S_{14}+\tfrac{1}{2}z^2\overline{z}^2S_{44},$$

and

$$\Psi=\Psi_4-4\Psi_3z+6\Psi_2z^2-4\Psi_1z^3+\Psi_0z^4$$

on $\mathscr{O}\times\mathscr{U}$ and by

$$\phi=\frac{1}{|w'|^2}\,\Phi',\quad b=\overline{w}'(\tfrac{1}{2}\phi_{\overline{z}'}+\overline{y}'\phi),\quad \beta=\overline{w}'^2(\tfrac{1}{2}\phi_{\overline{z}'\overline{z}'}+\overline{y}'\phi_{\overline{z}'}+\overline{y}'^2\phi),$$

$$\psi=\frac{1}{w'^2}\,\Psi',\quad a=w'(\tfrac{1}{4}\psi_{z'}+y'\psi),\quad \alpha=-w'^2(\tfrac{1}{12}\psi_{z'z'}+y'^2\psi+\tfrac{1}{2}y'\psi_{z'})-\tfrac{1}{12}R,$$

$$\Phi'=\tfrac{1}{2}S_{44}-\overline{z}'S_{14}-z'S_{24}+z'\overline{z}'(S_{12}+S_{34})+\tfrac{1}{2}\overline{z}'^2S_{11}$$
$$+\tfrac{1}{2}z'^2S_{22}-\overline{z}'^2z'S_{13}-z'^2\overline{z}'S_{23}-\tfrac{1}{2}\overline{z}'^2\overline{z}'^2S_{33}$$

and

$$\Psi'=\Psi_0-4\Psi_1z'+6\Psi_2z'^2-4\Psi_3z'^3+\Psi_4z'^4$$

on $\mathscr{O}\times\mathscr{U}'$.

The following three cases are of particular interest.

(a) The metric g of the four-manifold $\mathscr{M}$ satisfies the Einstein equations $R_{ij}=\lambda g_{ij}$ and is not conformally flat. This case is characterized by $\Phi\equiv 0$ and $\Psi\not\equiv 0$.
(b) The metric g is conformally flat but not Einstein. This case corresponds to $\Psi\equiv 0$, $\Phi\not\equiv 0$.
(c) The metric g is of constant curvature. This means that $\Psi\equiv\Phi\equiv 0$.

In the first two cases there is a canonical choice of certain six-dimensional subsets in $\mathscr{F}(\mathscr{M})$. This is defined by the demand that on such sets certain components of dE should identically vanish. This approach is impossible in case (c) since this implies an immediate reduction of dE to the form

$$dE=2\Omega\wedge E+\tfrac{1}{12}R\Lambda\wedge F. \tag{32}$$

V. DISTINGUISHED SUBSET OF $\mathscr{F}(\mathscr{M})$

From now on we consider case (a). This is the most interesting generic Einstein case.

Imposing the restrictions (a) on dE we immediately see that

$$dE=2\Omega\wedge E+\psi T\wedge\overline{F}+a(\Lambda\wedge T-F\wedge\overline{F})+\alpha\Lambda\wedge F,$$

where ψ,a,α are the same as in the Lemma 1. Since we are in the not conformally flat case (a) we have $\psi\neq 0$. This makes possible the restriction to such a set $\mathscr{W}\subset\pi^{-1}(\mathscr{O})$ in which a identically vanish. Thus we consider

$$\mathscr{W}=\mathscr{W}_1\cup\mathscr{W}_2, \tag{33}$$

where

$$\mathscr{W}_1=\{(x;w,z,y)\in(\mathscr{O}\times\mathscr{U})\ \text{ such that }\ \psi y+\tfrac{1}{4}\psi_z=0\},$$

$$\mathscr{W}_2=\{(x;w',z',y')\in(\mathscr{O}\times\mathscr{U}')\ \text{ such that }\ \psi y'+\tfrac{1}{4}\psi_{z'}=0\},$$

or (what is the same due to the nonvanishing of w and w')

$$\mathscr{W}_1=\{(x;w,z,y)\in(\mathscr{O}\times\mathscr{U})\ \text{ such that }\ \Psi y+\tfrac{1}{4}\Psi_z=0\}, \tag{34}$$

$$\mathscr{W}_2=\{(x;w',z',y')\in(\mathscr{O}\times\mathscr{U}')\ \text{ such that }\ \Psi' y'+\tfrac{1}{4}\Psi'_{z'},=0\}. \tag{35}$$

On $\mathscr{W}$ we have

$$dE=2\Omega\wedge E+\psi T\wedge\overline{F}+\alpha\Lambda\wedge F.$$

One can still simplify this relation by restricting oneself to a subset $\tilde{\mathscr{P}}_0$ of $\mathscr{W}$ in which $\psi=-1$. Then, $\tilde{\mathscr{P}}_0$ is a subset of $\pi^{-1}(\mathscr{O})$, which is given by

$$\tilde{\mathscr{P}}_0=\tilde{\mathscr{P}}_{01}\cup\tilde{\mathscr{P}}_{02}, \tag{36}$$

where

$$\tilde{\mathscr{P}}_{01}=\{(x;w,z,y)\in(\mathscr{O}\times\mathscr{U}) \text{ such that } \Psi y+\tfrac{1}{4}\Psi_z=0,\ \Psi+w^2=0\} \tag{37}$$

and

$$\tilde{\mathscr{P}}_{02}=\{(x;w',z',y')\in(\mathscr{O}\times\mathscr{U}') \text{ such that } \Psi' y'+\tfrac{1}{4}\Psi'_{z'}=0,\ \Psi'+w'^2=0\}. \tag{38}$$

It follows from the construction that on $\tilde{\mathscr{P}}_0$ we have

$$dE=2\Omega\wedge E+\overline{F}\wedge T+\alpha F\wedge\Lambda.$$

VI. ELLIPTIC FIBRATION

We study the geometry and topology of the set $\tilde{\mathscr{P}}_0$.

The equations defining $\tilde{\mathscr{P}}_0$ may be written as

$$y=-\frac{1}{4}\frac{\Psi_z}{\Psi},\quad y'=-\frac{1}{4}\frac{\Psi'_{z'}}{\Psi'}, \tag{39}$$

$$\Psi+w^2=0,\quad \Psi'+w'^2=0. \tag{40}$$

We see that the first pair of equations uniquely subordinates y to z and y' to z'. The second pair gives a relation between w and z and w' and z'. Thus, locally among the parameters $(x;w,z,y)$ in $\mathscr{O}\times\mathscr{U}$ [respectively, $(x;w',z',y')$ in $\mathscr{O}\times\mathscr{U}'$], only x and z (respectively, x and z') are free. This shows that $\tilde{\mathscr{P}}_0$ is six dimensional. Moreover, $\tilde{\mathscr{P}}_0$ is fibered over $\mathscr{O}$ with two-dimensional fibers. These are locally parametrized by z or z'. To discuss the topology of fibers one observes that the relation between w and z (respectively, w' and z') is purely polynomial. Over every point of $\mathscr{O}$ it has the form

$$w^2=-\Psi_4+4\Psi_3 z-6\Psi_2 z^2+4\Psi_1 z^3-\Psi_0 z^4 \tag{41}$$

or

$$w'^2=-\Psi_0+4\Psi_1 z'-6\Psi_2 z'^2+4\Psi_3 z'^3-\Psi_4 z'^4. \tag{42}$$

Assume for a moment (a) that $w=0$ and $w'=0$ are the allowed values of the parameters and (b) that equations

$$-\Psi_4+4\Psi_3 z-6\Psi_2 z^2+4\Psi_1 z^3-\Psi_0 z^4=0, \tag{43}$$

$$-\Psi_0+4\Psi_1 z'-6\Psi_2 z'^2+4\Psi_3 z'^3-\Psi_4 z'^4=0 \tag{44}$$

for z and z' have only distinct roots. Then, the relations (41)–(42), as being fourth order in the parameters z and z', describe a two-dimensional torus. (This is a well-known fact of classical algebraic geometry, see, e.g., Ref. 2. I am very grateful to Roger Penrose for clarifying this for me).[3]

Let us comment on (a) and (b).

(a) We know that w and w' cannot be zero by their definitions. So to have a torus fibration over the Einstein space–time we need to accept that w and w' may vanish. A price paid for this is that some of the forms $(F,\overline{F},T,\Lambda,E,\overline{E},\Omega,\overline{\Omega},\Gamma,\overline{\Gamma})$ will be singular on the resulting fibration at

these values of w and w'. With these remarks, from now on, we accept that w and w' may vanish. This enables us to introduce the fibration $\tilde{\mathscr{P}}$ over $\mathscr{M}$ which, over the neighborhood $\mathscr{O}\subset\mathscr{M}$ is given by

$$\tilde{\mathscr{P}}=\tilde{\mathscr{P}}_1\cup\tilde{\mathscr{P}}_2, \tag{45}$$

where

$$\tilde{\mathscr{P}}_1=\{(x;w,z,y)\in(\mathscr{O}\times\mathbf{C}^3)\ \text{ such that }\ \Psi y+\tfrac{1}{4}\Psi_z=0,\ \Psi+w^2=0\}, \tag{46}$$

$$\tilde{\mathscr{P}}_2=\left\{(x;w',z',y')\in(\mathscr{O}\times\mathbf{C}^3)\ \text{ such that }\ \Psi' y'+\frac{1}{4}\Psi'_{z'}=0,\ \Psi'+w'^2=0\right\} \tag{47}$$

and the transition functions between (w,z,y) and (w',z',y') coordinates are given by (18).

(b) The discussion in (a) means that $\tilde{\mathscr{P}}$ is a torus fibration over $\mathscr{O}$ provided that Eqs. (43) and (44) have distinct roots. It is well known that the number of distinct roots in (43) and (44) is directly related to the algebraic (Cartan–Petrov–Penrose[4–6]) classification of space–times. Thus, if the space–time $\mathscr{M}$ is algebraically general in $\mathscr{O}$, then $\tilde{\mathscr{P}}$ is a torus fibration over $\mathscr{O}$. In the algebraically special cases the fibers of $\tilde{\mathscr{P}}$ are degenerate tori. These topologically are:

(II) a torus with one vanishing cycle in the Cartan–Petrov–Penrose type II,

(D) two spheres touching each other in two different points in the Cartan–Petrov–Penrose type D,

(III) a sphere with one singular point in the Cartan–Petrov–Penrose type III,

(N) two spheres touching each other in one point in the Cartan–Petrov–Penrose type N.

The pure situations considered so far may be a bit more complicated when the Cartan–Petrov–Penrose type of the Einstein space–time varies from point to point. Imagine, for example, that along a continuous path from x to x' in $\mathscr{O}$ the Cartan–Petrov–Penrose type of the Einstein space–time changes from I to II. Then the fiber of $\tilde{\mathscr{P}}$ over x' is only a torus with one vanishing cycle although the fiber over the starting point x was a torus. It is clear that more complicated situations may occur, and that the fibers of $\tilde{\mathscr{P}}$ over different points of $\mathscr{M}$ can have topologies II, D, III, and N. Fibrations of this type are widely used in algebraic geometry. They are called elliptic, since their fibers can be any kind (even degenerate) of an elliptic curve.

VII. THE MAIN THEOREM

In Secs. IV–VI, for the clarity of presentation, we restricted ourselves to the neighborhood $\mathscr{O}$ of $\mathscr{M}$. We ended up with an elliptic fibration $\tilde{\mathscr{P}}$ over $\mathscr{O}$. This, however, can be easily prolonged to an elliptic fibration over the whole $\mathscr{M}$. To see this it is enough to observe that a fiber over any point in $\mathscr{O}$ is essentially defined by the Weyl tensor. Since the Weyl tensor is uniquely defined on the whole $\mathscr{M}$ then we can use equations like (41) to uniquely define the elliptic fibers over all $\mathscr{M}$.

Summing up the information from Secs. IV–VI we have the following theorem.

Theorem 2: *Given a four-dimensional conformally nonflat space–time $\mathscr{M}$ satisfying the Einstein equations $R_{ij}=\lambda g_{ij}$ one naturally defines a fibration $\Pi:\tilde{\mathscr{P}}\to\mathscr{M}$ with the following properties.*

(1) A fiber $\Pi^{-1}(x)$ over a point $x\in\mathscr{M}$ is a (possibly degenerate) elliptic curve $\mathscr{C}$ given by

$$\mathscr{C}=\mathscr{C}_1\cup\mathscr{C}_2,$$

$$\mathscr{C}_1=\{(w,z)\in\mathbf{C}^2\ \text{ such that }\ w^2=-\Psi_4+4\Psi_3 z-6\Psi_2 z^2+4\Psi_1 z^3-\Psi_0 z^4\},$$

$$\mathscr{C}_2=\{(w',z')\in\mathbf{C}^2\ \text{ such that }\ w'^2=-\Psi_0+4\Psi_1 z'-6\Psi_2 z'^2+4\Psi_3 z'^3-\Psi_4 z'^4\},$$

where the transition functions between (w,z) and (w',z') coordinates are given by

$$w=-\frac{w'}{z'^2},\quad z=\frac{1}{z'}.$$

(2) The degeneracy of a fiber depends on the algebraic type of the space–time metric and may change from point to point.

(3) There is a unique construction of a certain surface $\tilde{\mathscr{P}}_0$ of dimension six immersed in the bundle of null coframes $\mathscr{F}(\mathscr{M})$. $\tilde{\mathscr{P}}_0$ is fibered over $\mathscr{M}$ and $\tilde{\mathscr{P}}$ may be viewed as an extension of $\tilde{\mathscr{P}}_0$ achieved by adding to each fiber of $\tilde{\mathscr{P}}_0$ at most four points.

(4) There are ten one-forms $(F,\overline{F},T,\Lambda,E,\overline{E},\Omega,\overline{\Omega},\Gamma,\overline{\Gamma})$ on $\tilde{\mathscr{P}}$ with the following properties:

(a) Forms T,Λ are real, all the other are complex valued.

(b) The forms are defined in two steps. First, by restricting the soldering form components e^i and the Levi–Civita connection components ω^i_j from $\mathscr{F}(\mathscr{M})$ to $\tilde{\mathscr{P}}_0$ and second, by extending the restrictions to $\tilde{\mathscr{P}}$.

(c) $(F,\overline{F},T,\Lambda,E,\overline{E})$ constitute the basis of one-forms on $\tilde{\mathscr{P}}$.

(d) The forms satisfy the following equations on $\tilde{\mathscr{P}}$:

$$\begin{aligned} dF&=(\Omega-\overline{\Omega})\wedge F+E\wedge T+\overline{\Gamma}\wedge\Lambda,\\ dT&=\Gamma\wedge F+\overline{\Gamma}\wedge\overline{F}-(\Omega+\overline{\Omega})\wedge T,\\ d\Lambda&=\overline{E}\wedge F+E\Lambda\overline{F}+(\Omega+\overline{\Omega})\wedge\Lambda,\\ dE&=2\Omega\wedge E+\overline{F}\wedge T+\alpha\Lambda\wedge F, \end{aligned} \tag{48}$$

with a certain function α on $\tilde{\mathscr{P}}$.

The explicit formulas for the forms on $\tilde{\mathscr{P}}_1$ (respectively, on $\tilde{\mathscr{P}}_2$) may be obtained from the expressions of Lemma 1 (respectively, Lemma 2) by inserting the relations $y=-\Psi_z/(4\Psi)$ and $w^2+\Psi=0$ [respectively, $y'=-\Psi'_{z'}/(4\Psi')$ and $w'^2+\Psi'=0$].

VIII. RELATION BETWEEN THE ELLIPTIC FIBRATION AND THE BUNDLE OF NULL DIRECTIONS

Finally we note that the bundle $\tilde{\mathscr{P}}$ constitutes a double branched cover of the Penrose bundle $\mathscr{P}$ of null directions over the space–time.
To see this consider the map f given by

$$\tilde{\mathscr{P}}_1\ni(x;w,z,y)\overset{f}{\to}(x,z)\in\mathscr{O}\times\mathbf{C},$$

$$\tilde{\mathscr{P}}_2\ni(x;w',z',y')\overset{f}{\to}(x,z')\in\mathscr{O}\times\mathbf{C}.$$

Since on the intersection $\tilde{\mathscr{P}}_1\cap\tilde{\mathscr{P}}_2$ the coordinates z and z' are related by $z'=1/z$, then the two copies of $\mathbf{C}$, which appear in the above relations may be considered as two coordinate charts (say around the North and the South pole, respectively) on the two-dimensional sphere. This sphere is the sphere of null directions at a given point of $\mathscr{O}$ which can be seen as follows.

Consider directions of all the one-forms $L(z)=L+z\overline{z}K+z\overline{M}+\overline{z}M$ at $x\in\mathscr{O}$ for all the values of the complex parameter z. These directions are in one to one correspondence with null directions $k(z)=k+z\overline{z}\overline{l}-zm-\overline{zm}$ via $L(z)=-g(k(z))$. These null directions do not form a sphere yet, since the direction corresponding to the vector l is missing. But the missing direction is included in the family of null directions corresponding to the directions of one-forms $K(z')=K+z'\overline{z'}L+z'\overline{M}+\overline{z'}M$ at x. Thus the space parametrized by z and z' subject to the relation $z'=1/z$ is in one to one correspondence with the sphere of null directions at x. This proves the assertion that f is a cover of $\mathscr{P}$.

The map f is a double cover since if z (or z') is not a root of (43) [respectively, (44)] then $f^{-1}(z)$ is a two-point set. In at most four cases when z is a root $f^{-1}(z)$ is a one-point set. This proves that f is a singular cover.

As we know the singular points are branch points, which proves the statement from the beginning of this section.

ACKNOWLEDGMENTS

I am deeply indebted to Andrzej Trautman who focused my attention on the problem of encoding Einstein equations on natural bundles associated with a space–time. Without his influence this work would never have been completed. I would also like to express my gratitude to Paolo Budinich, Mike Crampin, Ludwik Dąbrowski, Jerzy Lewandowski, Roger Penrose, David Robinson, and Jacek Tafel for helping me at various stages of the present work. Perturbations in inflationary cosmologies with smooth exit

Daniel Tilley and Roy Maartens
School of Computer Science and Mathematics, University of Portsmouth, Portsmouth PO1 2EG, Britain

(Received 24 March 1998; accepted for publication 4 June 1998)

We give a comprehensive analysis of how scalar and tensor perturbations evolve in cosmologies with a smooth transition from power-law-like and de Sitter-like inflation to a radiation era. Analytic forms for the superhorizon and subhorizon perturbations in the inflationary and radiation dominated eras are found. © *1998 American Institute of Physics.* [S0022-2488(98)01110-4]

I. INTRODUCTION

In Ref. 1, the evolution of perturbations for a decaying vacuum cosmology given in Ref. 2, with smooth exit from inflation to radiation domination, was found exactly on superhorizon scales. The solution confirmed the standard result,[3–7] within gauge invariant perturbation theory that superhorizon density perturbations are strongly amplified through the transition from inflation to radiation. This transition is often approximated as an instantaneous jump,[3,4,7] since superhorizon modes change on a time scale that is much greater than the transition time. To avoid problems in the matching conditions for a jump transition, we consider only smooth transitions.

Given the variety of methods and models that have been used, we believe it is useful to do a comparative study using the same method on two broad classes of transition models, i.e., those based on power-law-like and de Sitter-like inflation. We use the class of power-law-like models first given in Ref. 8. The second class of models is a generalization of the models of Refs. 5 and 8 with a de Sitter-like inflationary era. The models, together with the necessary equations in perturbation theory, are discussed in Sec. II. In Sec. III we present our results for scalar and tensor perturbations on superhorizon scales, and show how they confirm the standard predictions. In Sec. IV we present solutions for scalar and tensor perturbations on subhorizon scales. However, toy models that evolve smoothly from inflation to radiation dominated eras are only applicable for superhorizon modes around the time of transition, since on subhorizon scales, the dynamics of the reheating era have a significant effect. The solutions for subhorizon scales therefore do not apply during the transition era. Section V gives some concluding remarks.

Throughout this paper we use units in which $8\pi G=1=c$.

II. THE MODELS AND PERTURBATION EQUATIONS

A flat Friedmann–Lemaitre–Robertson–Walker (FLRW) background has metric

$$ds^2=-dt^2+a^2(t)[dx^2+dy^2+dz^2], \tag{1}$$

where t is the physical time and $a(t)$ is the expansion scale factor. The background pressure p, energy density ρ, and Hubble parameter $H=\dot{a}/a$ (where a dot denotes a derivative with respect to cosmic time t) satisfy the field equations

$$p=-2\dot{H}-3H^2, \tag{2}$$

$$\rho=3H^2. \tag{3}$$

The pressure index and effective adiabatic sound speed are defined by

$$w=\frac{p}{\rho}, \tag{4}$$

 © 1998 American Institute of Physics

$$c_s^2=\frac{dp}{d\rho}=\frac{\dot{p}}{\dot{\rho}} \tag{5}$$

Inflation is characterized by $\ddot{a}>0$, so that the epoch t_e of exit is given by $\ddot{a}(t_e)=0$. The radiation dominated era is characterized by $p\approx\frac{1}{3}\rho$, $H\approx 1/2t$.

Scalar and tensor perturbations lead to a metric of the form

$$ds^2=a^2(\eta)\{-(1+2\Phi)d\eta^2+[(1-2\Psi)\gamma_{ij}+h_{ij}]dx^i dx^j\}, \tag{6}$$

in the longitudinal gauge, where η is conformal time $(d\eta=dt/a)$.[4] Here Φ and Ψ are gauge-invariant amplitudes of the scalar metric perturbations. The field equations require $\Phi=\Psi$ when the spatial part of the energy–momentum tensor is diagonal. The tensor perturbations are gauge invariantly described by $h_{ij}=hQ_{ij}$, where Q_{ij} is a symmetric traceless three tensor and h represents the amplitude of a gravitational wave.

The evolution of adiabatic scalar perturbations Φ is given by[4]

$$\frac{d^2\Phi}{d\eta^2}+3aH(1+c_s^2)\frac{d\Phi}{d\eta}-\nabla^2\Phi+3a^2H^2(c_s^2-w)\Phi=0. \tag{7}$$

Decomposing $\Phi(\eta,\vec{x})$ into eigenmodes $\tilde{\Phi}(\eta,\vec{k})$ of the comoving Laplacian, and then using the cosmic time t and scale factor a as the dynamical variables, respectively, gives

$$\frac{d^2\tilde{\Phi}}{dt^2}+3H\left(\frac{4}{3}+c_s^2\right)\frac{d\tilde{\Phi}}{dt}+\left[3H^2(c_s^2-w)+\left(\frac{k}{a}\right)^2\right]\tilde{\Phi}=0, \tag{8}$$

$$\frac{d^2\tilde{\Phi}}{da^2}+\frac{1}{a}\left(\frac{7}{2}+3c_s^2-\frac{3}{2}w\right)\frac{d\tilde{\Phi}}{da}+\left[\frac{3}{a^2}(c_s^2-w)+\frac{k^2}{a^4H^2}\right]\tilde{\Phi}=0, \tag{9}$$

where k is the comoving wave number. The decomposition allows us to follow the evolution of a single mode through the inflationary and radiation dominated eras. The physical length scale λ corresponding to the comoving wave number k is $\lambda=2\pi a/k$. This will equal the Hubble radius H^{-1} when

$$k=2\pi aH. \tag{10}$$

Superhorizon modes are characterized by $k\ll aH$. For these modes one can neglect the k^2 term in Eqs. (8) and (9) (and subsequent equations). The solutions of the truncated equations will be a good approximation to the limit of the solutions of the full equations, provided[9]

$$k^2\Phi\to 0 \quad \text{as} \quad k\to 0. \tag{11}$$

For adiabatic superhorizon scalar perturbations, the growing modes have a conserved quantity[10] which can be used to determine $\tilde{\Phi}$:

$$\zeta\equiv\tilde{\Phi}+\frac{2}{3(1+w)}\left(\tilde{\Phi}+\frac{1}{H}\frac{d\tilde{\Phi}}{dt}\right)\Rightarrow\tilde{\Phi}=-\zeta\frac{H}{a}\int\frac{a\dot{H}}{H^2}dt. \tag{12}$$

Equation (12) can be used to express the growing perturbations at late times in terms of their early time forms.[4] In Refs. 5–7, ζ is used to estimate the amplification of perturbations through a smooth transition. This amplification has been disputed in Ref. 11 (see also Refs. 12 and 13).

The density perturbations in the longitudinal gauge are given by[4]

$$\frac{\delta\rho}{\rho}=-2\left(\frac{k^2}{3a^2H^2}+1\right)\tilde{\Phi}-\frac{2}{H}\frac{d\tilde{\Phi}}{dt}. \tag{13}$$

The Fourier mode $\tilde{h}$ of the amplitude h of the tensor perturbations satisfies[4]

$$\frac{d^2\tilde{h}}{dt^2}+3H\frac{d\tilde{h}}{dt}+\left(\frac{k}{a}\right)^2\tilde{h}=0, \tag{14}$$

which may also be rewritten with a as the dynamical variable:

$$a^2\frac{d^2\tilde{h}}{da^2}+\left(4a+\frac{a^2}{H}\frac{dH}{da}\right)\frac{d\tilde{h}}{da}+\frac{k^2}{a^4H^2}\tilde{h}=0. \tag{15}$$

For superhorizon modes one can reduce to quadrature:

$$\tilde{h}=C+D\int\frac{dt}{a^3}=C+D\int\frac{da}{a^4H}, \tag{16}$$

where C and D are constant. It follows that D corresponds to the decaying mode and therefore there is no amplification in long-wavelength tensor perturbations.[3,4]

A. Power-law-like models

In Ref. 8 a simple class of power-law-like inflation models, which exit smoothly to a radiation era, is given by

$$a(t)=\frac{a_e}{\sqrt{t_e}}(1+m)^{(2n-1)/2}t^n(t+mt_e)^{(1-2n)/2}, \tag{17}$$

where the parameter n satisfies $n>1$ to achieve inflationary expansion, and

$$m=\frac{n+\sqrt{n(2n-1)}}{2n(n-1)}.$$

For $t\ll mt_e$,

$$a\approx a_e\left(1+\frac{1}{m}\right)^{(2n-1)/2}\left(\frac{t}{t_e}\right)^n,$$

showing the early power-law-like inflation era. For $t\gg mt_e$,

$$a\approx a_e(1+m)^{(2n-1)/2}\left(\frac{t}{t_e}\right)^{1/2},$$

as in a radiation dominated era. Thus we have a cosmology which evolves smoothly from power-law-like inflation to a radiation dominated era. The Hubble rate follows on differentiating Eq. (17):

$$H(t)=\frac{t+2nmt_e}{2t(t+mt_e)}. \tag{18}$$

Using Eqs. (2) and (3), Eq. (18) gives

$$p=\frac{t^2+4nmt_et-4n(3n-2)m^2t_e^2}{4t^2(t+mt_e)^2}, \tag{19}$$

$$\rho=\frac{3(t+2nmt_e)^2}{4t^2(t+mt_e)^2}. \tag{20}$$

It follows that the pressure index and effective adiabatic sound speed given by Eqs. (4) and (5) are

$$w=\frac{t^2+4nmt_et-4n(3n-2)m^2t_e^2}{3t^2+12nmt_et+12n^2m^2t_e^2}, \tag{21}$$

$$c_s^2=\frac{t(t+mt_e)(t+2nmt_e)-[t^2+4nmt_et-4n(3n-2)m^2t_e^2](2t+mt_e)}{3t(t+mt_e)(t+2nmt_e)-3(t+2nmt_e)^2(2t+mt_e)}. \tag{22}$$

The evolution of scalar and tensor perturbations for this model is given by Eqs. (8), (13), and (14). Using Eqs. (17), (18), (21), and (22), we get

$$t^2\frac{d^2\tilde{\Phi}}{dt^2}+t\left[\frac{t+2nmt_e}{2(t+mt_e)}\right]U(t)\frac{d\tilde{\Phi}}{dt}+\left[\frac{t+2nmt_e}{2(t+mt_e)}\right]^2V(t)\tilde{\Phi}=0, \tag{23}$$

where

$$U(t)=\frac{5t(t+mt_e)(t+2nmt_e)-(5t^2+20nmt_et+4n(n+2)m^2t_e^2)(2t+mt_e)}{t(t+mt_e)(t+2nmt_e)-(t+2nmt_e)^2(2t+mt_e)},$$

$$V(t)=\frac{t(t+mt_e)(t+2nmt_e)-[t^2+4nmt_et-4n(3n-2)m^2t_e^2](2t+mt_e)}{t(t+mt_e)(t+2nmt_e)-(t+2nmt_e)^2(2t+mt_e)}$$
$$-\frac{t^2+4nmt_et-4n(3n-2)m^2t_e^2}{(t+2nmt_e)^2}+k^2\frac{t_e(1+m)^{1-2n}t^{2-2n}(t+mt_e)^{2n+1}}{a_e^2(t+2nmt_e)^2},$$

and

$$\frac{\delta\rho}{\rho}=-2\left[\frac{4k^2t_e(1+m)^{1-2n}t^{2-2n}(t+mt_e)^{2n+1}}{3a_e^2(t+2nmt_e)^2}+1\right]\tilde{\Phi}-\left[\frac{4t(t+mt_e)}{t+2nmt_e}\right]\frac{d\tilde{\Phi}}{dt}, \tag{24}$$

and

$$t^2\frac{d^2\tilde{h}}{dt^2}+3t\left[\frac{t+2nmt_e}{2(t+mt_e)}\right]\frac{d\tilde{h}}{dt}+\left[\frac{k^2t_e(1+m)^{1-2n}(t+mt_e)^{2n-1}t^{2-2n}}{a_e^2}\right]\tilde{h}=0. \tag{25}$$

B. de Sitter-like models

In Ref. 8 a new exact inflationary solution is given, using a as the effective dynamical variable. The Hubble rate is given by

$$H(a)=\frac{2H_ea_e^2}{a^2+a_e^2}, \tag{26}$$

where H_e is the Hubble rate at exit. A similar model [but one which does not produce an exact solution for superhorizon scalar perturbations, unlike (26)[1]] is proposed in Ref. 5:

$$H(a)=\frac{2^{1/2}H_ea_e^2}{(a^4+a_e^4)^{1/2}}. \tag{27}$$

For both Hubble rates, when $a\ll a_e$, H is approximately constant as in a de Sitter inflation era, and for $a\gg a_e$, the Hubble rate decays like a^{-2}, as in a radiation dominated era. Thus for both models we have a cosmology which evolves smoothly from inflation to a radiation dominated era.

Here we generalize these models by considering the class of Hubble rates

$$H(a)=\frac{2^{1/\ell}a_e^2H_e}{(a^{2\ell}+a_e^{2\ell})^{1/\ell}}, \tag{28}$$

parametrized by ℓ ($\ell>0$). For Eq. (26), $\ell=1$, and for (27), $\ell=2$. Using Eq. (28), $H\approx$constant for $a\ll a_e$ (inflation), and $H\propto a^{-2}$ for $a\gg a_e$ (radiation domination), confirming that the model has the desired properties for all positive ℓ.

Using Eqs. (2) and (3), Eq. (28) gives

$$p=\frac{2^{2/\ell}H_e^2a_e^4(a^{2\ell}-3a_e^{2\ell})}{(a^{2\ell}+a_e^{2\ell})^{1+2/\ell}}, \tag{29}$$

$$\rho=\frac{2^{2/\ell}3H_e^2a_e^4}{(a^{2\ell}+a_e^{2\ell})^{2/\ell}}. \tag{30}$$

The pressure index and effective adiabatic sound speed given by Eqs. (4) and (5) are

$$w=\frac{1}{3}\left(\frac{a^{2\ell}-3a_e^{2\ell}}{a^{2\ell}+a_e^{2\ell}}\right), \tag{31}$$

$$c_s^2=\frac{1}{3}\left[\frac{a^{2\ell}-(2\ell+3)a_e^{2\ell}}{a^{2\ell}+a_e^{2\ell}}\right]. \tag{32}$$

Applying Eq. (10) to Eq. (28) and taking $k_e=2\pi a_eH_e$ (the comoving wave number of the Hubble radius at exit), the epoch a_- of leaving and a_+ of re-entering the Hubble radius are given exactly in this class of models by

$$\frac{a_\pm}{a_e}=\frac{k_e}{k}\left[1\pm\sqrt{1-\left(\frac{k}{k_e}\right)^{2\ell}}\right]^{1/\ell}. \tag{33}$$

Scales with $k\geqslant k_e$ never cross the Hubble radius and remain subhorizon. For superhorizon scales with $k\ll k_e$, Eq. (33) reduces to

$$\frac{a_\pm}{a_e}\approx\left(\frac{2^{1/\ell}k_e}{k}\right)^{\pm1}.$$

The scalar and tensor perturbations for this model are governed by Eqs. (9), (13), and (15). Using Eqs. (28), (31), and (32) we get

$$a^2\frac{d^2\tilde{\Phi}}{da^2}+a\left[\frac{4a^{2\ell}-(2\ell-2)a_e^{2\ell}}{a^{2\ell}+a_e^{2\ell}}\right]\frac{d\tilde{\Phi}}{da}+\left[\pi^2\left(\frac{k}{k_e}\right)^2\frac{(a^{2\ell}+a_e^{2\ell})^{2/\ell}}{2^{2/\ell-2}a_e^2a^2}-\frac{2\ell a_e^{2\ell}}{(a^{2\ell}+a_e^{2\ell})}\right]\tilde{\Phi}=0, \tag{34}$$

$$\frac{\delta\rho}{\rho}=-2\left[\frac{1}{3}\left(\frac{k}{k_e}\right)^2\frac{(a^{2\ell}+a_e^{2\ell})^{2/\ell}}{2^{2/\ell}a_e^2a^2}+1\right]\tilde{\Phi}-2a\frac{d\tilde{\Phi}}{da}, \tag{35}$$

and

$$a^2\frac{d^2\tilde{h}}{da^2}+2a\left[\frac{a^{2\ell}+2a_e^{2\ell}}{a^{2\ell}+a_e^{2\ell}}\right]\frac{d\tilde{h}}{da}+\left[\pi^2\left(\frac{k}{k_e}\right)^2\frac{(a^{2\ell}+a_e^{2\ell})^{2/\ell}}{2^{2/\ell-2}a_e^2a^2}\right]\tilde{h}=0. \tag{36}$$

III. SUPERHORIZON PERTURBATIONS

For the modes which leave the Hubble radius (during inflation), while they remain outside the Hubble radius, we can neglect the k-term in Eqs. (23)–(25), (34), (35) and (36). Only Eqs. (25) and (36), using (16), give exact solutions for the truncated equations. However, using Refs. 14 and 15 we can give analytic forms for the solutions in the inflationary and radiation dominated eras for Eqs. (23), (24), (34), and (35), since they reduce to Bessel forms. For all solutions, A_j, B_j, $j=1,2,...$ are used to denote arbitrary constants. For Eq. (11) to be satisfied it is required that for scalar perturbations A_j, $B_j \sim k^q$ as $k \to 0$, where $q > -2$. For all scalar perturbation solutions this is assumed to be the case.

A. Power-law-like model

For $t \ll mt_e$ Eq. (23) has solution

$$\tilde{\Phi} \approx A_1 + B_1 \left(\frac{t_e}{t} \right)^{n+1}, \tag{37}$$

describing modes that leave well before exit, while for $t \gg mt_e$

$$\tilde{\Phi} \approx A_2 + B_2 \left(\frac{t_e}{t} \right)^{3/2}, \tag{38}$$

describing modes that remain superhorizon in the radiation era. In Eqs. (37) and (38), A_j correspond to the constant modes, and B_j to the decaying modes.

The conserved quantity given by Eq. (12), applied to the case of the model given by (17), leads to

$$\tilde{\Phi} = \zeta \, \frac{(t+mt_e)^{(2n-3)/2}(t+2nmt_e)}{t^{n+1}} \int \frac{t^n(t^2+4nmt_e t+2nm^2 t_e^2)}{(t+2nmt_e)^2(t+mt_e)^{(2n-1)/2}} \, dt, \tag{39}$$

where we neglect the decaying contributions (and therefore no constant of integration arises from the integral). Amplification of the scalar growing modes according to Eqs. (37) and (38) is given by the factor $\alpha = A_2/A_1$. Using Eq. (39), we find that

$$A_1 = \frac{\zeta}{(n+1)},$$

and

$$A_2 = \frac{2}{3} \, \zeta.$$

Therefore

$$\alpha = \tfrac{2}{3}(n+1) > \tfrac{4}{3}, \tag{40}$$

so that amplification is only significant for large n. This is in agreement with results based on instantaneous transition models.[3,4,7]

The density perturbations in the inflationary and radiation dominated eras are found analytically using Eqs. (24), (37), and (38). For modes that leave the Hubble radius well before exit ($t \ll mt_e$)

$$\frac{\delta\rho}{\rho} \approx -2A_1 + \frac{2}{n} \, B_1 \left(\frac{t_e}{t} \right)^{n+1}, \tag{41}$$

while for modes that are still superhorizon during radiation domination ($t \gg mt_e$)

$$\frac{\delta\rho}{\rho}\approx -2A_2+4B_2\left(\frac{t_e}{t}\right)^{3/2}. \tag{42}$$

The density perturbations undergo the same amplification (40) as the potential perturbations.

The tensor perturbations are given by Eq. (16):

$$\tilde{h}=A_3+B_3\int t^{-3n}(t+mt_e)^{3(2n-1)/2}dt. \tag{43}$$

During power-law inflation ($t\ll mt_e$)

$$\tilde{h}\approx A_3+B_3\,\frac{m^{(6n-3)/2}t_e^{-1/2}}{1-3n}\left(\frac{t_e}{t}\right)^{3n-1}, \tag{44}$$

while for those modes that remain superhorizon during radiation domination ($t\gg mt_e$)

$$\tilde{h}\approx A_3-2B_3t^{-1/2}. \tag{45}$$

The results (43)–(45) imply that tensor perturbations do not grow.

B. de Sitter-like model

For modes that leave the Hubble radius when $a\ll a_e$, Eq. (34) has superhorizon solutions

$$\tilde{\Phi}\approx A_4\left(\frac{a}{a_e}\right)^{2\ell}+B_4\,\frac{a_e}{a}. \tag{46}$$

For superhorizon modes during radiation domination ($a\gg a_e$)

$$\tilde{\Phi}\approx\left(\frac{a_e}{a}\right)^{3/2}Z_{-3/2\ell}\left[-i\sqrt{\frac{2}{\ell}}\left(\frac{a_e}{a}\right)^{\ell}\right], \tag{47}$$

where Z_ν denotes a linear combination of the Bessel functions J_ν and Y_ν. Using the asymptotic forms of the Bessel functions,[14,15] Eq. (47) reduces to

$$\tilde{\Phi}\approx A_5+B_5\left(\frac{a_e}{a}\right)^3. \tag{48}$$

It follows that in the inflationary era, $|\tilde{\Phi}|$ grows as $a^{2\ell}$, while in the radiation dominated era, $|\tilde{\Phi}|$ is approximately constant (while the scales are still superhorizon). Thus growing superhorizon scalar perturbations are strongly amplified during inflation and then remain approximately constant after inflation. The amplification factor is clearly much greater than that for the power-law-like model.

We can calculate the amplification using Eq. (12), which gives

$$\tilde{\Phi}=\frac{2\zeta}{a(a^{2\ell}+a_e^{2\ell})^{1/\ell}}\int\frac{a^{2\ell}(a^{2\ell}+a_e^{2\ell})^{1/\ell}}{(a^{2\ell}+a_e^{2\ell})}\,da. \tag{49}$$

Evaluating the integral in the inflation and radiation eras and using Eqs. (46) and (48), we find

$$A_4=\frac{2\zeta}{2\ell+1},$$

and

$$A_5=\frac{2\zeta}{3}.$$

The amplification from the epoch a_i ($a_i \ll a_e$) to the radiation era is thus

$$\alpha = \frac{1}{3}(2\ell+1)\left(\frac{a_e}{a_i}\right)^{2\ell}. \tag{50}$$

The explicit dependence in (50) of the amplification on the initial epoch a_i shows that amplification, and thus the spectrum, is not scale invariant.

The density perturbations are given using Eqs. (35), (46), and (47). For modes beyond the Hubble radius during inflation

$$\frac{\delta\rho}{\rho} \approx -2(2\ell+1)A_4\left(\frac{a}{a_e}\right)^{2\ell}, \tag{51}$$

while for superhorizon modes during the radiation dominated era ($a \gg a_e$)

$$\frac{\delta\rho}{\rho} \approx 2i\sqrt{2\ell}\left(\frac{a_e}{a}\right)^{\ell+3/2} Z_{(2\ell-3)/2\ell}\left[-i\sqrt{\frac{2}{\ell}}\left(\frac{a_e}{a}\right)^{\ell}\right] - 2\left(\frac{a_e}{a}\right)^{3/2} Z_{-3/2\ell}\left[-i\sqrt{\frac{2}{\ell}}\left(\frac{a_e}{a}\right)^{\ell}\right], \tag{52}$$

which leads to

$$\frac{\delta\rho}{\rho} \approx -2A_5 + 4B_5\left(\frac{a_e}{a}\right)^3. \tag{53}$$

During inflation ($a \ll a_e$), $\delta\rho/\rho$ grows as $a^{2\ell}$, while in the radiation dominated era ($a \gg a_e$), $\delta\rho/\rho$ is approximately constant. The amplification is the same as (50).

The evolution of the tensor perturbations for superhorizon modes is given by Eq. (16):

$$\tilde{h} = A_6 + B_6 \int \frac{(a^{2\ell} + a_e^{2\ell})^{1/\ell} a_e}{a^4}\, da. \tag{54}$$

For the inflationary era ($a \ll a_e$) Eq. (54) gives

$$\tilde{h} \approx A_6 - \frac{1}{3} B_6\left(\frac{a_e}{a}\right)^3, \tag{55}$$

while for the radiation dominated era ($a \gg a_e$)

$$\tilde{h} \approx A_6 - B_6\left(\frac{a_e}{a}\right). \tag{56}$$

Unlike the scalar the tensor perturbations do not grow during inflation.

IV. SUBHORIZON PERTURBATIONS

For perturbations on scales inside the Hubble radius [where $k/(aH)$ is not negligible], Eqs. (23)–(25) and (34)–(36) cannot be solved exactly. We can, however, give analytic forms for the solutions in inflation and radiation domination using Refs. 14 and 15, since the equations reduce to Bessel forms.

A. Power-law-like model

Defining the comoving wave numbers

$$k_1 \equiv \frac{a_e(1-n)}{t_e(1+1/m)^{(1-2n)/2}}, \quad k_2 \equiv \frac{a_e}{2t_e(1+m)^{(1-2n)/2}},$$

we find the following. During power-law-like inflation ($t \ll m t_e$), the scalar and tensor perturbations evolve as

$$\tilde{\Phi}\approx\left(\frac{t_e}{t}\right)^{(n+1)/2} Z_{(n+1)/2(1-n)}\left[\frac{k}{k_1}\left(\frac{t}{t_e}\right)^{1-n}\right], \tag{57}$$

$$\frac{\delta\rho}{\rho}\approx\left[\frac{-2}{3}\left(\frac{k}{k_1}\right)^2(1-n)^2\left(\frac{t}{t_e}\right)^{(2-2n)}-2\right]\left(\frac{t_e}{t}\right)^{(n+1)/2} Z_{(n+1)/2(1-n)}\left[\frac{k}{k_1}\left(\frac{t}{t_e}\right)^{(1-n)}\right]$$
$$+\frac{2(1-n)}{n}\frac{k}{k_1}\left(\frac{t}{t_e}\right)^{(1-3n)/2} Z_{(3-n)/2(1-n)}\left[\frac{k}{k_1}\left(\frac{t}{t_e}\right)^{(1-n)}\right], \tag{58}$$

$$\tilde{h}\approx\left(\frac{t}{t_e}\right)^{(1-3n)/2} Z_{(3n-1)/2(1-n)}\left[\frac{k}{k_1}\left(\frac{t}{t_e}\right)^{1-n}\right]. \tag{59}$$

During radiation domination ($t\gg mt_e$), we find the following:

$$\tilde{\Phi}\approx\left(\frac{t_e}{t}\right)^{3/4} Z_{3/2}\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]$$
$$=\left(\frac{t_e}{t}\right)^{3/2}\left\{A_7\sin\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]-B_7\cos\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]\right\}$$
$$-\frac{k}{k_2}\left(\frac{t_e}{t}\right)\left\{A_7\cos\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]+B_7\sin\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]\right\}, \tag{60}$$

$$\frac{\delta\rho}{\rho}\approx\left[\frac{-8}{3}\left(\frac{k}{k_2}\right)^2\frac{t}{t_e}-2\right]\left(\frac{t_e}{t}\right)^{3/4} Z_{3/2}\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]+2\frac{k}{k_2}\left(\frac{t_e}{t}\right)^{3/4} Z_{5/2}\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]$$
$$=\left[\frac{-8}{3}\left(\frac{k}{k_2}\right)^2\frac{t}{t_e}-2\right]\left(\frac{t_e}{t}\right)^{3/2}\left\{A_7\sin\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]-B_7\cos\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]\right\}$$
$$+\left[\frac{8}{3}\left(\frac{k}{k_2}\right)^2\frac{t}{t_e}+2\right]\frac{t_e}{t}\frac{k}{k_2}\left\{A_7\cos\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]+B_7\sin\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]\right\}$$
$$-\frac{k}{k_2}A_8\left(\frac{t_e}{t}\right)^2\left\{3\sin\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]-3\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\cos\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]\right.$$
$$\left.-\left(\frac{k}{k_2}\right)^2\frac{t}{t_e}\sin\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]\right\}-\frac{k}{k_2}B_8\left(\frac{t_e}{t}\right)^2\left\{3\cos\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]+3\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\sin\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]\right.$$
$$\left.-\left(\frac{k}{k_2}\right)^2\frac{t}{t_e}\cos\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]\right\}, \tag{61}$$

$$\tilde{h}\approx\left(\frac{t_e}{t}\right)^{1/4} Z_{1/2}\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]=\left(\frac{t_e}{t}\right)^{1/2}\left\{A_9\sin\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]-B_9\cos\left[\frac{k}{k_2}\left(\frac{t}{t_e}\right)^{1/2}\right]\right\}. \tag{62}$$

As expected, density perturbations oscillate after re-entry, since radiation pressure balances gravitational infall. Note that while there are nondecaying oscillations in the density perturbations, the tensor perturbation oscillations are purely decaying. At late times, the density perturbation (61) has the form

$$\frac{\delta\rho}{\rho}\approx A\cos\left(\frac{k}{k_2}\frac{a}{a_e}\right)+B\sin\left(\frac{k}{k_2}\frac{a}{a_e}\right),$$

in agreement with the standard results for the radiation era (Ref. 16, p. 152).

B. de Sitter-like model

Subhorizon perturbations during inflation ($a \ll a_e$) have the form

$$\tilde{\Phi} \approx \left(\frac{a}{a_e}\right)^{(2\ell-1)/2} Z_{-(2\ell+1)/2}\left(-\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a_e}{a}\right), \tag{63}$$

$$\frac{\delta\rho}{\rho} \approx -\frac{2}{3}\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\right)^2\left(\frac{a}{a_e}\right)^{(2\ell-5)/2} Z_{-(2\ell+1)/2}\left(-\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a_e}{a}\right)$$
$$-\frac{2\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\left(\frac{a}{a_e}\right)^{(2\ell-3)/2} Z_{-(2\ell+3)/2}\left(-\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a_e}{a}\right), \tag{64}$$

$$\tilde{h} \approx \left(\frac{a_e}{a}\right)^{3/2} Z_{-3/2}\left(-\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a_e}{a}\right)$$
$$= A_{10}\left[\cos\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a_e}{a}\right) + \frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a_e}{a}\sin\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a_e}{a}\right)\right]$$
$$-B_{10}\left[\sin\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a_e}{a}\right) + \frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a_e}{a}\sin\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a_e}{a}\right)\right]. \tag{65}$$

Subhorizon perturbations during radiation domination ($a \gg a_e$) are given by

$$\tilde{\Phi} \approx \left(\frac{a_e}{a}\right)^{3/2} Z_{3/2}\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)$$
$$= A_{11}\left(\frac{a_e}{a}\right)^3\left[\sin\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right) - \frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\cos\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k}\frac{a}{a_e}\right)\right]$$
$$-B_{11}\left(\frac{a_e}{a}\right)^3\left[\cos\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right) + \frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right.$$
$$\left.\times\sin\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)\right], \tag{66}$$

$$\frac{\delta\rho}{\rho} \approx \left[-\frac{2}{3}\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\right)^2\left(\frac{a}{a_e}\right)^2 - 2\right]\left(\frac{a_e}{a}\right)^{3/2} Z_{3/2}\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)$$
$$+\frac{2\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\left(\frac{a_e}{a}\right)^{1/2} Z_{5/2}\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)$$
$$= \left[\frac{-2}{3}\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\right)^2\left(\frac{a}{a_e}\right)^2 - 2\right]\left(\frac{a_e}{a}\right)^3 A_{11}\left[\sin\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)\right.$$
$$\left.-\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\cos\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)\right] + \left[\frac{2}{3}\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\right)^2\left(\frac{a}{a_e}\right)^2 + 2\right]$$
$$\times\left(\frac{a_e}{a}\right)^3 B_{11}\left[\cos\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right) + \frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\sin\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)\right]$$
$$-A_{12}\left(\frac{a_e}{a}\right)^3\left[\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)^2\sin\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)\right.$$

$$-3\sin\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)$$

$$+3\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\cos\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)\Bigg]+B_{12}\left(\frac{a_e}{a}\right)^3\Bigg[\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)^2$$

$$\times\cos\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)-3\cos\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)-\frac{3\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}$$

$$\times\sin\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)\Bigg], \tag{67}$$

$$\tilde{h}\approx\left(\frac{a_e}{a}\right)^{1/2}Z_{1/2}\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)=\frac{a_e}{a}\left[A_{13}\sin\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)\right.$$

$$\left.-B_{13}\cos\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)\right]. \tag{68}$$

Once again, we see that the density perturbations contain nondecaying oscillations while the tensor perturbation oscillations are purely decaying. At late times, the density perturbation (67) has the form

$$\frac{\delta\rho}{\rho}\approx A\cos\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right)+B\sin\left(\frac{\pi}{2^{(1-\ell)/\ell}}\frac{k}{k_e}\frac{a}{a_e}\right),$$

as in the power-law-like case.

V. CONCLUSIONS

Our main result is a comprehensive presentation of analytic solutions for the scalar and tensor perturbations on super- and subhorizon scales for two classes of cosmology, where the scale factor evolves smoothly from an inflationary era to a radiation dominated era. These classes encompass parametrized power-law-like and de Sitter-like inflationary behavior. Our results confirm the amplification of superhorizon scalar perturbations for all values of the parameters which define the classes of models. Explicit forms, given in Eq. (40) and (50), of the amplification for scalar perturbations show how the de Sitter-like inflation is much more effective in amplification than the power-law-like inflation. On subhorizon scales, the detailed form of oscillating modes after reentry was found, showing that there are nondecaying modes for density perturbations, but not for tensor perturbations. Taken together, these results provide a unified catalog of perturbation solutions in what can be taken as the two main types of inflationary models with smooth exit.

Algebraic solutions for point groups: The tetrahedral group for the group chain $T \supset D_2 \supset C_2$

Jin-Quan Chen[a] and Peng-Dong Fan
Department of Physics, Nanjing University,

(Received 24 December 1997; accepted for publication 13 May 1998)

A factorization lemma is discovered for the irreducible symmetry operators (ISO's) of a semidirect product group of two abelian groups. By means of it, simple algebraic expressions of the $T \supset D_2$ single-valued irreducible matrices, ISO's and symmetry adapted functions are derived. Using the double-induced technique, the algebraic solutions for the double-valued representations of group T in the group chain $T \supset C_2$ are also obtained. The simplicity and elegance of the algebraic solution of the point group can be compared with that of the analytic solution of the rotation group. © *1998 American Institute of Physics.* [S0022-2488(98)02510-9]

I. INTRODUCTION

The importance of working with symmetry-adapted functions (SAF's) was realized by many early researchers of solid-state physics (e.g., von der Laga and Bethe[1] in the 1930's and 1940's). In later work, Altmann, and Cracknell[2–4] extended some of these early ideas to generally practical and computational levels. By using the projection operator method, Bradley and Cracknell[4] calculated the SAF's for both single-valued (s.v.) and double-valued (d.v.) reps of all crystal point groups. However, the d.v. SAF's are given in the uncoupled form (i.e., a linear combination of the products of Y_{lm} and the spin wave functions), which is not convenient. By using the building up method, Butler[5] calculated both the s.v. and d.v. SAF's for the dihedral group D_6, as well as the octahedral and icosahedral groups. The interest in the symmetry adapted functions has persisted to the present. Recently, by using a Gaussian integration technique Fernando *et al.*[6] obtained the symmetry adapted functions for identity reps of all crystal point groups.

Until recently the solutions to the SAF's problem were restricted to the numerical, and the results were tabulated for each irrep of each group chain for angular momentum up to a certain value (12 in Ref. 4 and 8 in Ref. 5). It is highly desirable to seek algebraic expressions for the SAF's of all point groups so that they have closed and simple formulas, and the SAF's for any high angular momentum can be readily obtained.

The lack of algebraic solutions to the SAF's problem is due to the lack of algebraic solutions to the irreducible symmetry operators (ISO's) (or the generalized projection operators), with which the SAF's are obtained by the projection operator method. One of the obstacles for obtaining algebraic expressions of the ISO's is associated with the conventional labeling schemes for irreps of point groups, such as the Mulliken, Koster,[7] or Butler[5] notations. Obviously a precondition for obtaining algebraic solutions is the use of quantum numbers to label irreps, just as the use of j for the irreps of SO(3) is. In 1977 a new approach to group representation theory was proposed,[8,9] in which an analogy with the three operators $(J^2, J_z, \overline{J_z})$ for the rotation group, three sets of the operators, $(C, C(s), \overline{C}(s))$ are introduced, whose eigenvalues $(\lambda, \rho, \overline{\rho})$, the counterpart of the quantum numbers $(j, m, \overline{m})$, are used for labeling or distinguishing the irreps, the components of irreducible basis vectors, and the multiple occurrence of the irrep λ in a given reducible representation space. The following three sets of operators, $C, (C, C(s)), (C, C(s), \overline{C}(s))$, are called the CSCO-I, CSCO-II, and CSCO-III, which are the complete set of commuting operators (CSCO) in the class space, any representation space which is multiplicity free, and the group space, respectively. The new approach not only put the representation theory of finite groups

(including the space groups) and compact Lie groups on the same footing, but also provides a powerful method, the *eigenfunction method*, for finding irreps and various coupling coefficients for finite and Lie groups.[9,10]

Very recently, a so-called double-induced technique was proposed and used, in conjunction with the *eigenfunction method*, for obtaining algebraic solutions of the tetrahedral group in the group chain $T \supset C_3$.[11] Simple algebraic expressions of the $T \supset C_3$ irreducible matrices, ISO's and SAF's are derived for both single-valued and double-valued reps in a unified way without using any knowledge of the irreducible matrices.

The purpose of this paper is to derive the algebraic solutions of the group T in the group chain $T \supset D_2$ for the s.v. reps and $T \supset C_2$ for the d.v. reps. For the former, the double-induced technique is not suitable, and a factorization lemma is first introduced for the ISO's of a semidirect product group of two abelian groups, and applied to the group chain $T \supset D_2$. For the $T \supset C_2$ d.v. reps, the double-induced technique can be used with slight extension. Extremely simple expressions are derived for the ISO's and SAF's, which are functions of only the quantum numbers characterizing the group chain instead of all the matrix elements. The high symmetry of the SAF's are disclosed for the first time and the time reversal property of the SAF's are also discussed.

II. A FACTORIZATION LEMMA FOR ISO'S OF A SEMIDIRECT PRODUCT GROUP

For the s.v. reps, the group chain $T \supset D_2$ is canonical and the subgroup C_2 is redundant in the group chain $T \supset D_2 \supset C_2$. Since the group T is a semidirect product of D_2 and C_3

$$T = D_2 \wedge C_3, \tag{1}$$

and both D_2 and C_3 are abelian, instead of using the more sophisticated double-induced representation technique, we can use a factorization lemma to be introduced below for obtaining its ISO in a straightforward way. For this purpose we need to first introduce a generalized ISO by

$$\mathcal{P}^{(\lambda)}_{\rho,\nu} = \frac{h_\lambda}{|G|} \sum_{a=1}^{|G|} \mathcal{D}^{(\lambda)}_{\rho\nu}(R_a)^* R_a, \tag{2a}$$

where h_λ is the dimension of the irrep λ, $|G|$ is the order of G, and $\mathcal{D}^{(\lambda)}_{\rho\nu}(R_a)$ is a generalized irreducible matrix element of R_a defined in Eqs. (3-212) of Ref. 9 between two irreducible basis vectors in two different classification schemes, the $G \supset G(s)$ basis ψ^λ_ρ and $G \supset G(s')$ basis φ^λ_ν, with $\rho(\nu)$ specifying the irreps of $G(s)(G(s'))$

$$\mathcal{D}^{(\lambda)}_{\rho\nu}(R_a) = \langle \psi^\lambda_\rho | R_a | \varphi^\lambda_\nu \rangle. \tag{2b}$$

The group chains $G \supset G(s)$ and $G \supset G(s')$ are assumed to be canonical so that the labeling (λ,ρ) or (λ,ν) for irreducible basis vectors is unique.

The generalized ISO obeys the eigenvalue equations[9]

$$\begin{pmatrix} C \\ C(s) \\ \overline{C}(s') \end{pmatrix} \mathcal{P}^{(\lambda)}_{\rho,\nu} = \begin{pmatrix} \lambda \\ \rho \\ \nu \end{pmatrix} \mathcal{P}^{(\lambda)}_{\rho,\nu}, \tag{2c}$$

where $(C, C(s))$ is the CSCO of the group chain $G \supset G(s)$, the analogy of (J^2, J_z) of the group chain $\mathrm{SO}(3) \supset \mathrm{SO}(2)$, while $\overline{C}(s')$ is obtained by replacing the elements R_a in the CSCO $C(s')$ of $G(s')$ by their intrinsic operators $\overline{R}_a$, which are defined in the group space by the following equation:

$$\overline{R}_a R_b = R_b R_a, \quad a,b = 1,2,\ldots,|G|, \tag{3}$$

which implies that

$$\overline{R}_a R_b R_c \cdots R_d = R_b R_c \cdots R_d R_a. \tag{4}$$

Notice that $\overline{C}(s')$ is the analogy of the third component of the angular momentum in the intrinsic (or body-fixed) coordinate system.[9]

The generalized ISO satisfies

$$\mathcal{P}^{(\lambda)}_{\rho,\nu}\mathcal{P}^{(\lambda')}_{\nu',\rho'}=\delta_{\lambda\lambda'}\delta_{\nu\nu'}\mathcal{P}^{(\lambda)}_{\rho,\rho'}, \tag{5a}$$

$$(\mathcal{P}^{(\lambda)}_{\rho,\nu})^{\dagger}=\mathcal{P}^{(\lambda)}_{\nu,\rho}. \tag{5b}$$

When $G(s')\to G(s), \overline{C}(s')\to\overline{C}(s), \varphi^{\lambda}_{\nu}\to\psi^{\lambda}_{\rho}, \mathcal{D}^{(\lambda)}_{\rho\nu}(R_a)\to D^{(\lambda)}_{\rho\rho}(R_a)$, the generalized ISO goes over to the conventional ISO $\mathcal{P}^{(\lambda)}_{\rho,\rho}$ and Eqs. (2) and (5) remain valid.

The generalized and conventional ISO's differ only in the intrinsic quantum numbers ν and $\overline{\rho}$, which serve as the multiplicity label. Since the multiplicity separation can be chosen freely, it gives us a flexibility in choosing the intrinsic quantum number. For example, it can be chosen in such a way so as to make the factorization of the ISO's as simple as possible.

Since the numerical factor $h_\lambda/|G|$ in the ISO $\mathcal{P}^{(\lambda)}_{\rho,\nu}$ or $\mathcal{P}^{(\lambda)}_{\rho,\overline{\rho}}$ is unimportant in applications except in the case of reading out the irreducible matrices from the ISO's, for the sake of clarity we are sloppy about the numerical factor of the ISO, but careful about its phase. For reading out the irreducible matrix elements from the ISO's it is convenient to write the ISO's in the normalized form

$$\mathcal{P}^{(\lambda)\overline{\rho}}_{\rho}=\sqrt{\frac{h_\lambda}{|G|}}\sum_{a=1}^{|G|}D^{(\lambda)}_{\rho\overline{\rho}}(R_a)^{*}R_a, \tag{6}$$

The normalization is easily found according to the assumption that the scalar product of two elements is $(R_a,R_b)=\delta_{ab}$ and will be inserted into the final expression of the ISO's.

Lemma: If H and K are two abelian groups with the ISO's P^ρ and $\wp^\nu$, respectively, then the ISO's of the semidirect product group $G=H\wedge K$ for four possible classifications are factored in the following way:

$$G\supset H, \overline{G}\supset\overline{K}: \quad \mathcal{P}^{(\lambda)}_{\rho,\nu}=P^\rho\wp^\nu, \tag{7a}$$

$$G\supset K, \overline{G}\supset\overline{H}: \quad \mathcal{P}^{(\lambda)}_{\nu,\rho}=\wp^\nu P^\rho, \tag{7b}$$

$$G\supset H, \overline{G}\supset\overline{H}: \quad \mathcal{P}^{(\lambda)}_{\rho,\rho'}=P^\rho\wp^\nu P^{\rho'}, \tag{7c}$$

$$G\supset K, \overline{G}\supset\overline{K}: \quad \mathcal{P}^{(\lambda)}_{\nu,\nu'}=\wp^\nu P^\rho\wp^{\nu'}. \tag{7d}$$

Proof: Since P^ρ and $\wp^\nu$ are the ISO of H and K, respectively, they are eigenvectors of the CSCO's of H and K, denoted by $C(s)$ and $C(s')$

$$C(s)P^\rho=\rho P^\rho, \quad C(s')\wp^\nu=\nu\wp^\nu. \tag{8}$$

Since $C(s)$ and $C(s')$ are the CSCO of H and K, they have $|H|$ and $|K|$ distinct eigenvalues of ρ and ν, respectively. The operators $C(s)$ and $C(s')$ can be easily found, for example, the generators of the abelian groups H and K can be chosen as $C(s)$ and $C(s')$, respectively. Now let us derive the eigenvalue equations satisfied by $P^\rho\wp^\nu$. Using (4), (8) and the fact that $\wp^\nu$ commutes with $C(s')$ we can show that $P^\rho\wp^\nu$ is a common eigenvector of $C(s)$ and $\overline{C}(s')$

$$\begin{pmatrix} C(s) \\ \overline{C}(s') \end{pmatrix}P^\rho\wp^\nu=\begin{pmatrix} C(s)P^\rho\wp^\nu \\ P^\rho\wp^\nu C(s') \end{pmatrix}=\begin{pmatrix} \rho \\ \nu \end{pmatrix}P^\rho\wp^\nu. \tag{9a}$$

It is to be noted that the set of operators $(C(s),\overline{C}(s'))$ has $|G|=|H|\times|K|$ sets of eigenvalues (ρ,ν) and for a given (ρ,ν) we have a unique eigenvector $P^\rho\wp^\nu$. In other words,$(C(s),\overline{C}(s'))$ is already a CSCO-III of G, and C is redundant. This can also be shown in the following way. Since

C commutes with $C(s)$ and $\overline{C}(s')$, $CP^{\rho}\wp^{\nu}$ remains an eigenvector of $(C(s),\overline{C}(s'))$ with the same eigenvalue set (ρ,ν). Due to the uniqueness of the solution in the eigenvalue Eq. (9a), $CP^{\rho}\wp^{\nu}$ is necessarily proportional to $P^{\rho}\wp^{\nu}$, i.e.,

$$CP^{\rho}\wp^{\nu}=\lambda P^{\rho}\wp^{\nu}. \tag{9b}$$

Thus $P^{\rho}\wp^{\nu}$ is a simultaneous eigenvector of $(C,C(s),\overline{C}(s'))$. Comparing (9) with (2c) we know that $P^{\rho}\wp^{\nu}$ is necessarily the ISO $\mathcal{P}^{(\lambda)}_{\rho,\nu}$ of G. It confirms the statement that for a semidirect product of two abelian groups, the operator C is redundant for determining the ISO of G. Actually, according to a theorem due to Dirac (see Theorem 3 in p. 78 of Ref. 12: A linear operator that commutes with each of a complete set of commuting observables is a function of those observables), C is necessarily a function of $C(s)$ and $\overline{C}(s')$, and thus λ is a function of ρ and ν.

Equation (7b) can be proved in the same way, while Eqs. (7c) and (7d) can be derived from Eq.(5a).

Remark 1: By comparing (7a) and (7b) with (7c) and (7d) it is seen that the factorization of the generalized ISO's is simpler than the conventional ones.

Remark 2: The ISO's $\mathcal{P}^{(\lambda)}_{\rho,\rho'}=P^{\rho}\wp^{\nu}P^{\rho'}$ with different values of ν differ at most by a ν-dependent factor so long as the irrep λ of G can be induced from ν. Therefore, to obtain $\mathcal{P}^{(\lambda)}_{\rho,\rho'}$ through using $P^{\rho}\wp^{\nu}P^{\rho'}$ we can choose any value ν which is compatible with λ. Similar remarks apply to $\mathcal{P}^{(\lambda)}_{\nu,\nu'}=\wp^{\nu}P^{\rho}\wp^{\nu'}$.

Remark 3: We have a unified expression $P^{\rho}\wp^{\nu}$ for the $G\supset H$ generalized ISO's for both one-dimensional and multidimensional irreps, but with the essential difference that the factors P^{ρ} and $\wp^{\nu}$ are interchangeable for one-dimensional irreps but not for multidimensional irreps. In other words, for one-dimensional irreps the generators of both the subgroups H and K have definite values ρ and ν, respectively, while for multi-dimensional irreps only the generator of H (not K) has the definite value ρ. Therefore, we can use (ρ,ν) or $A_{\rho\nu}$ as labels for the one-dimensional irreps, and write

$$\mathcal{P}^{A_{\rho\nu}}=P^{\rho}\wp^{\nu}=\wp^{\nu}P^{\rho}. \tag{10}$$

Remark 4: The factorization Eq. (10) for one dimensional irreps apply to any semidirect product group $G=H\wedge K$ without the restriction that the groups H and K be abelian.

To show this we need to introduce the concept of the so-called *representation group*. A *representation group* $\mathcal{G}$ is defined[9] as the matrix group formed by all representation matrices of an abstract group G in a given representation space (reducible or irreducible). Suppose $G=H\wedge K$, where H and K are nonabelian groups. Obviously in any one-dimensional irrep of G, the *representation group* $\mathcal{G}$ is abelian and is a *direct* product of the *representation groups* $\mathcal{H}$ and $\mathcal{K}$

$$\mathcal{G}=\mathcal{H}\times\mathcal{K}, \tag{11}$$

and thus any one-dimensional ISO of G can be expressed as a product of the one-dimensional ISO P^{ρ} of H and the one-dimensional ISO $\wp^{\nu}$ of K. Therefore (10) is valid in general cases and can be used, for example, to write down immediately the ISO's of the one-dimensional irreps of the octahedral group $O=T\wedge C_2$.

Notice that the reverse is not true. In other words, the product of the one-dimensional ISO's of nonabelian groups H and K is in general not an ISO of G.

III. THE $T\supset D_2$ s.v. REPRESENTATIONS

The starting point for finding algebraic solutions to the double point group $G^{\dagger}$ is the construction of its group table. Inconsistencies of the group table for the double point group $O^{\dagger}$ given in Ref. 4 have been pointed out in Refs. 13 and 11. A self consistent group table for the group $T^{\dagger}$ is constructed in Ref. 11 and given in Table I with the Bradley–Cracknell notation[4] for the group elements, which is identical to the group table given in Ref. 14, constructed using Altermann's quaternion realization of rotations.[13]

A. Irreducible symmetry operators

According to (7a), the generalized ISO, or the $T\supset D_2$ and $\overline{T}\supset\overline{C}_3$ ISO of the group $T=D_2\wedge C_3$, $\mathcal{P}^{(\lambda)}_{\nu\nu',\rho}\propto\mathcal{P}^{(\lambda)\rho}_{\nu\nu'}$, is a product of the projection operators $\wp^{\nu\nu'}$ and P^{ρ} for the groups D_2 and C_3

$$\mathcal{P}^{(\lambda)\rho}_{\nu\nu'}=\wp^{\nu\nu'}P^{\rho} \tag{12}$$

where

$$\wp^{\nu\nu'}=(e+\nu C_{2x})(e+\nu' C_{2y}),\nu,\nu'=\pm 1, \tag{13a}$$

$$P^{\rho}\equiv P^{\rho_\mu}=\sum_{k=0}^{2}(\rho_\mu^{*})^k(C_{31}^{+})^k,\quad \rho\equiv\rho_\mu=\exp\left(-\frac{2\pi\mu i}{3}\right),\quad \mu=0,\pm 1, \tag{13b}$$

The irrep λ in (12) is decided from the quantum numbers ν,ν', and ρ of C_{2x},C_{2y}, and C_{31}^{+}. As mentioned in Sec. II, the one-dimensional irreps are those in which all the operators, and hence the generators of T can have definite values. In order to find the values of ν,ν' and ρ in the one-dimensional reps of T, we examine the commutation relations between D_2 and C_3. Using Table I, it is easy to get the following results:

$$C_{31}^{+}C_{2i}=C_{2i+1}C_{31}^{+},\quad i=1,2,3(\text{mod } 3), \tag{14a}$$

where

$$C_{21}\equiv C_{2x},\quad C_{22}\equiv C_{2y},\quad C_{23}\equiv C_{2z}.$$

By taking the Hermitian conjugate of (14a), we get

$$C_{31}^{-}C_{2i}=C_{2i-1}C_{31}^{-},\quad i=1,2,3(\text{mod } 3). \tag{14b}$$

From the above we know that when $C_{2x}=C_{2y}=C_{2z}=1$, C_{31}^{+} and C_{31}^{-} commute with C_{2x},C_{2y},C_{2z}, and thus all elements of T can be diagonalized simultaneously. Therefore, we know that in the one-dimensional irreps of T, $\nu=\nu'=1$, and $C_{31}^{+}=\rho_\mu,\mu=0,\pm 1$, which correspond to three one-dimensional irreps of T, designated as A_μ in the modified Mulliken notation introduced in Ref. 11, with the ISO's

$$\mathcal{P}^{(A_\mu)}=\frac{1}{\sqrt{12}}\wp^{++}P^{\rho_\mu},\quad \mu=0,\pm 1, \tag{15a}$$

where $\wp^{++}=1+C_{2x}+C_{2y}+C_{2z}$ is the projection operator for the identity representation of the group D_2. The irreps A_0,A_1,A_{-1} correspond to the irrep $(A,{}^1E,{}^2E)$ in Mulliken notation, or $(\Gamma_1,\Gamma_2,\Gamma_3)$ in Koster notation.

Excluding the value $(+,+)$, the set of operators (C_{2x},C_{2y}) takes three possible values, $(+-,-+,--)$. Since for the group T there is only a single three-dimensional irrep, the irrep F,we must have

$$\mathcal{P}^{(F)\rho}_{\nu\nu'}=\wp^{\nu\nu'}P^{\rho}, \tag{15b}$$

where $\nu\nu'$ is the component index, while ρ is the index which distinguishes the equivalent irreps. Usually only one set of the ISO's are needed, which can be conveniently chosen as $\rho=1$, thus the $T\supset D_2$ generalized ISO's are

$$\mathcal{P}^{(F)1}_{\nu\nu'}=\wp^{\nu\nu'}(1+C^{+}_{31}+C^{-}_{31}),\quad (\nu,\nu')=(+-,-+,--). \tag{15c}$$

The $T\supset D_2$ conventional ISO can be obtained from the generalized one as

$$\mathcal{P}^{(F)\overline{\nu\nu'}}_{\nu\nu'}=\mathcal{P}^{(F)1}_{\nu\nu'}(\mathcal{P}^{(F)1}_{\nu\nu'})^{\dagger}=\wp^{\nu\nu'}(1+C^{+}_{31}+C^{-}_{31})\wp^{\overline{\nu\nu'}}. \tag{15d}$$

Equation (15) gives the algebraic expressions of the s.v. $T\supset D_2$ ISO's. In order to compare our results with those derived by Folland,[15] we will transform Eq. (15d) into another form. Using (14) we have

$$C^{+}_{31}\wp^{\nu,\nu'}=\wp^{\nu\nu',\nu}C^{+}_{31},\quad C^{-}_{31}\wp^{\nu,\nu'}=\wp^{\nu',\nu\nu'}C^{-}_{31}. \tag{16a}$$

Using (15d) and (16a)

$$\mathcal{P}^{(F)\overline{\nu\nu'}}_{\nu\nu'}=\wp^{\nu\nu'}(\wp^{\overline{\nu\nu'}}+\wp^{\overline{\nu\nu'},\overline{\nu}}C^{+}_{31}+\wp^{\overline{\nu'},\overline{\nu\nu'}}C^{-}_{31}). \tag{16b}$$

If the ISO's $\mathcal{P}^{(F)\overline{\nu\nu'}}_{\nu\nu'}$ with proper normalization are regarded as the elements of a matrix $\mathbf{P}^{(F)}$ with rows $\nu\nu'$ and columns $\overline{\nu\nu'}$ in the order of $+-,-+,--$, then from (16b) we have

$$\mathbf{P}^{(F)}=\frac{1}{2}\begin{pmatrix} \wp_{+-}, & \wp_{+-}C^{-}_{31}, & \wp_{+-}C^{+}_{31} \\ \wp_{-+}C^{+}_{31}, & \wp_{-+}, & \wp_{-+}C^{-}_{31} \\ \wp_{--}C^{-}_{31}, & \wp_{--}C^{+}_{31}, & \wp_{--} \end{pmatrix}. \tag{16c}$$

Equation (16c) has been obtained by using the induction method[15] in a less transparent way.

B. The irreducible matrices

Since (ν,ν') or $(C_{2x},C_{2y})=(1,-1),(-1,1),(-1,-1)$, the matrix for $C_{2z}=C_{2x}C_{2y}$ is diagonal with elements $(-1,-1,1)$. From (15c) and (16a) we can obtain the irreducible matrix of C^{+}_{31}. Putting them together we have

$$\mathcal{D}^{F}(C_{2z})=\begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix},\quad \mathcal{D}^{F}(C^{+}_{31})=\begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}. \tag{17}$$

C. The $T\supset D_2$ s.v. SAF's

We choose the coordinate system for the group chain $T\supset D_2$ as shown in Fig. 1. The Euler angles (α,β,γ) for $C_{2x},C_{2y},C_{2z},C^{+}_{31}$, and C^{-}_{31} are given in Table II of Ref. 11 and listed below:

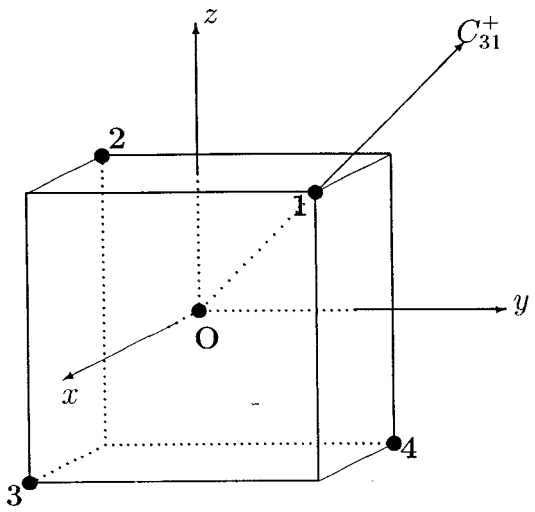

FIG. 1. The coordinate system xyz for $T\supset D_2$, with **1, 2, 3**, and **4** indicating the four vertices of the terahedral. The axes of C_{31}^{+}–C_{34}^{+} are from the origin to the vertices **1**–**4**.

$$\begin{array}{ccccc} C_{2x} & C_{2y} & C_{2z}^{-} & C_{31}^{+} & C_{31}^{-} \\ (0,\pi,\pi) & (0,\pi,0) & (0,0,\pi) & \left(0,\frac{\pi}{2},\frac{\pi}{2}\right) & \left(\frac{\pi}{2},\frac{\pi}{2},3\pi\right) \end{array}.$$

Applying $\mathcal{P}^{(A_\mu)}$ in (15a) and $\mathcal{P}^{(F)--}_{\nu\nu'}$ (noting that the choice of $\overline{\nu\nu'}$ is arbitrary), which are given by the third column of (16c), to Y_{lm} and using the following results[16]

$$C_{2x}|jm\rangle=(-1)^{-j}|j-m\rangle,\quad C_{31}^{+}|j\bar{m}\rangle=\sum_m d^j_{mm}\left(\frac{\pi}{2}\right)i^{-\bar{m}}|jm\rangle,$$

$$C_{2y}|jm\rangle=(-1)^{j-m}|j-m\rangle,\ C_{31}^{-}|j\bar{m}\rangle=(-1)^{-\bar{m}}\sum_m i^{-m}d^j_{mm}\left(\frac{\pi}{2}\right)|jm\rangle,$$

as well as the fact that $i^{-m}=i^m, i^{-\bar{m}}=i^{\bar{m}}$ for even m and $\bar{m}$, we obtain the $T\supset D_2$ s.v. unnormalized SAF's:

One-dimensional irrep

$$\varphi^{(A_\mu)\bar{m}}=Y_{l\bar{m}}+(-1)^lY_{l-\bar{m}}+(1+(-1)^l)[\rho_\mu^* i^{\bar{m}}+\rho_\mu]d^l_{0\bar{m}}\left(\frac{\pi}{2}\right)Y_{l0}$$

$$+2\sum_{m=2,4,6,\ldots}[\rho_\mu^* i^{\bar{m}}+\rho_\mu i^m]d^l_{m\bar{m}}\left(\frac{\pi}{2}\right)[Y_{lm}+(-1)^lY_{l-m}],\ \ \bar{m}=\text{even}. \tag{18a}$$

Three-dimensional irrep

With the conventional labeling (x,y,z) in place of $(+-,-+,--)$ for the components of the irrep F, we have

$$\varphi_x^{(F)\bar{m}}=i^{\bar{m}}\sum_{m=1,3,5,\ldots}d^l_{m\bar{m}}\left(\frac{\pi}{2}\right)[Y_{lm}+(-1)^lY_{l-m}],$$

$$\varphi_y^{(F)\bar{m}}=-\sum_{m=1,3,5,\ldots}i^m d^l_{m\bar{m}}\left(\frac{\pi}{2}\right)[Y_{lm}-(-1)^lY_{l-m}],\quad \bar{m}=\text{even} \tag{18b}$$

$$\varphi_z^{(F)\bar{m}}=Y_{l\bar{m}}-(-1)^lY_{l-\bar{m}}.$$

Notice that the quantum number $\bar{m}$ in (18) serves as the multiplicity label (for more detail, see Sec. IV E in Ref. 11). Equation (18) is the sought-for algebraic expression for the s.v. $T\supset D_2$ SAF's.

The s.v. $T\supset D_2$ SAF's have been calculated by Bradley and Cracknell with the projection operator method and tabulated in pp. 66–70 of Ref. 4 with accuracy to 12 digits for l up to 12. To facilitate a comparison with these tables, we use the real functions Y^c_{lm} and Y^s_{lm} defined in Ref. 4

$$Y^{(+)}_{lm}\equiv Y^c_{lm}=\frac{1}{\sqrt{2}}(Y_{lm}+Y_{l,-m})_{B-C},\quad Y^{(-)}_{lm}\equiv Y^s_{lm}=\frac{-i}{\sqrt{2}}(Y_{lm}-Y_{l,-m})_{B-C},\ \ m>0. \tag{19}$$

The $(Y_{lm})_{B-C}$ defined in Ref. 4 is related to the Y_{lm}[16] in Condon–Shortley phase convention as

$$(Y_{lm})_{B-C}=(-1)^{(m+|m|)/2}Y_{lm}. \tag{20}$$

Equation (18) can be rewritten as

$$\varphi^{(A_\mu)\bar{m}}=\sqrt{1+\delta_{\bar{m}0}}\,Y^{(\pi_l)}_{l\bar{m}}+\frac{1}{\sqrt{2}}(1+\pi_l)(i^{\bar{m}}\rho^*_\mu+\rho_\mu)d^l_{0\bar{m}}\left(\frac{\pi}{2}\right)Y^{(\pi_l)}_{l0}$$

$$+2\sum_{m=2,4,6,\ldots}(i^{\bar{m}}\rho^*_\mu+i^m\rho_\mu)d^l_{m\bar{m}}\left(\frac{\pi}{2}\right)Y^{(\pi_l)}_{lm},\quad \mu=0,\pm1, \tag{21a}$$

$$\varphi^{(F)\bar{m}}_x=-i^{\bar{m}}\sum_{m=1,3,5,\ldots}d^l_{m\bar{m}}\left(\frac{\pi}{2}\right)Y^{(\pi_{l+1})}_{lm},$$

$$\varphi^{(F)\bar{m}}_y=(-1)^l\sum_{m=1,3,5,\ldots}i^{m-1}d^l_{m\bar{m}}\left(\frac{\pi}{2}\right)Y^{(\pi_l)}_{lm},\quad \varphi^{(F)\bar{m}}_z=Y^{(\pi_{l+1})}_{l\bar{m}}, \tag{21b}$$

with $\pi_l=+(-)$ for $l=$ even (odd) and

$$\bar{m}=\begin{cases}0,2,4,\ldots\\ 2,4,6,\ldots\end{cases}\quad\text{for}\quad\begin{cases}A_\mu,\ l=\text{even};\quad F,\ l=\text{odd},\\ A_\mu,\ l=\text{odd};\quad F,\ l=\text{even}.\end{cases} \tag{21c}$$

It is noted that the SAF's $\varphi^{(A_0)}$ and$\varphi^{(F)}$ are real, while $\varphi^{(A_1)}=(\varphi^{(A_{-1})})^*$, i.e., under the time reversal $\hat{T}$ we have

$$\hat{T}\varphi^{(F)}_k=\varphi^{(F)}_k,\ \ k=x,y,z,$$
$$\hat{T}\varphi^{(A_0)}=\varphi^{(A_0)},\quad \hat{T}\varphi^{(A_1)}=(\varphi^{(A_1)})^*=\varphi^{(A_{-1})}. \tag{22}$$

With these algebraic expressions, it is easy to find the exact numerical expression of the SAF's $\psi^{(\Gamma)\bar{m}}_\mu$ for any l with the help of some software, say the Maple software. The $T\supset D_2$ SAF's for $j=1$–3, and a part for $j=6,8,13$ are listed in Table II, which is produced automatically. Notice that the SAF's $\psi^{(\Gamma)\bar{m}}_\mu$ with different multiplicity quantum numbers $\bar{m}$ may be neither orthogonal nor linearly independent. However, the SAF's in (21) happen to be orthogonal in the quantum number $\bar{m}$, and their numerical values are identical to the results in Ref. 4.

D. The relation between the $T\supset C_3$ and $T\supset D_2$ bases

Now we are going to find the transformation matrix between the bases of $T\supset C_3$ and $T\supset D_2$. From the $T\supset C_3$ irreducible matrices of C^+_{31} and C_{2z} given in (37) of Ref. 11 and the corresponding matrices for the group chain $T\supset D_2$ given in (17) we can easily find the similarity transformation matrix between the two bases

TABLE II. The $T\supset D_2$ s.v. SAF's. The superscript is the multiplicity label. For $l=6$, 8, and 13 only the SAF's of one-dimensional irreps with multiplicity are listed, and the SAF's $|A_{-1}\rangle(=|A_1\rangle^*)$ are not listed.

$$\bar{m}=0 \quad |F,x\rangle = |11,c\rangle$$
$$|F,y\rangle = |11,s\rangle$$
$$|F,z\rangle = |10,c\rangle$$

$$\bar{m}=0 \quad |A_1\rangle = \frac{\sqrt{2}}{2}|20,c\rangle + i\frac{\sqrt{2}}{2}|22,c\rangle$$

$$\bar{m}=2 \quad |F,x\rangle = |21,s\rangle$$
$$|F,y\rangle = |21,c\rangle$$
$$|F,z\rangle = |22,s\rangle$$

$$\bar{m}=2 \quad |A_0\rangle = |32,s\rangle$$
$$\bar{m}=0 \quad |F,x\rangle^1 = -\frac{\sqrt{2\cdot 3}}{4}|31,c\rangle + \frac{\sqrt{2\cdot 5}}{4}|33,c\rangle$$
$$|F,y\rangle^1 = -\frac{\sqrt{2\cdot 3}}{4}|31,s\rangle - \frac{\sqrt{2\cdot 5}}{4}|33,s\rangle$$
$$|F,z\rangle^1 = |30,c\rangle$$

$$\bar{m}=2 \quad |F,x\rangle^2 = -\frac{\sqrt{2\cdot 5}}{4}|31,c\rangle - \frac{\sqrt{2\cdot 3}}{4}|33,c\rangle$$
$$|F,y\rangle^2 = \frac{\sqrt{2\cdot 5}}{4}|31,s\rangle - \frac{\sqrt{2\cdot 3}}{4}|33,s\rangle$$
$$|F,z\rangle^2 = |32,c\rangle$$

$$\bar{m}=0 \quad |A_0\rangle^1 = \frac{\sqrt{2}}{4}|60,c\rangle - \frac{\sqrt{2\cdot 7}}{4}|64,c\rangle$$

$$\bar{m}=2 \quad |A_0\rangle^2 = \frac{\sqrt{11}}{4}|62,c\rangle - \frac{\sqrt{5}}{4}|66,c\rangle$$

$$\bar{m}=0$$
$$|A_1\rangle^1 = \frac{\sqrt{2\cdot 31}}{16}|80,c\rangle - i\frac{\sqrt{3\cdot 5\cdot 7\cdot 31}}{124}|82,c\rangle - \frac{\sqrt{2\cdot 7\cdot 11\cdot 31}}{248}|84,c\rangle - i\frac{\sqrt{11\cdot 13\cdot 31}}{124}|86,c\rangle - \frac{\sqrt{2\cdot 5\cdot 11\cdot 13\cdot 31}}{496}|88,c\rangle$$
$$\bar{m}=2$$
$$|A_1\rangle^2 = i\frac{\sqrt{3\cdot 5\cdot 7}}{32}|80,c\rangle + \frac{\sqrt{2}}{2}|82,c\rangle + i\frac{\sqrt{3\cdot 5\cdot 11}}{48}|84,c\rangle - i\frac{\sqrt{3\cdot 7\cdot 11\cdot 13}}{96}|88,c\rangle$$

$$\bar{m}=2$$
$$|A_0\rangle^1 = \frac{\sqrt{2\cdot 3\cdot 5\cdot 19}}{48}|13\ 2,s\rangle - \frac{\sqrt{3\cdot 11\cdot 17}}{48}|13\ 6,s\rangle - \frac{\sqrt{3\cdot 17\cdot 23}}{48}|13\ 10,s\rangle$$
$$\bar{m}=4$$
$$|A_0\rangle^2 = \frac{5\sqrt{3\cdot 19}}{48}|13\ 4,s\rangle + \frac{\sqrt{2\cdot 3\cdot 5}}{24}|13\ 8,s\rangle - \frac{\sqrt{3\cdot 11\cdot 23}}{48}|13\ 12,s\rangle$$
$$\bar{m}=2$$
$$|A_1\rangle^1 = \frac{17\sqrt{3}}{48}|13\ 2,s\rangle + i\frac{3\sqrt{2\cdot 5\cdot 11\cdot 17}}{544}|13\ 4,s\rangle + \frac{\sqrt{2\cdot 3\cdot 5\cdot 11\cdot 17\cdot 19}}{1632}|13\ 6,s\rangle + i\frac{\sqrt{11\cdot 17\cdot 19}}{136}|13\ 8,s\rangle$$
$$+\frac{\sqrt{2\cdot 3\cdot 5\cdot 17\cdot 19\cdot 23}}{1632}|13\ 10,s\rangle + i\frac{\sqrt{2\cdot 5\cdot 17\cdot 19\cdot 23}}{544}|13\ 12,s\rangle$$
$$\bar{m}=4$$
$$|A_1\rangle^2 = -i\frac{3\sqrt{5\cdot 11\cdot 17}}{16\sqrt{293}}|13\ 2,s\rangle + \frac{293\sqrt{2\cdot 3}}{96\sqrt{293}}|13\ 4,s\rangle - i\frac{53\sqrt{2\cdot 19}}{32\sqrt{293}}|13\ 6,s\rangle - \frac{5\sqrt{3\cdot 5\cdot 19}}{24\sqrt{293}}|13\ 8,s\rangle$$
$$+i\frac{\sqrt{2\cdot 11\cdot 19\cdot 23}}{32\sqrt{293}}|13\ 10,s\rangle + \frac{5\sqrt{2\cdot 3\cdot 11\cdot 19\cdot 23}}{96\sqrt{293}}|13\ 12,s\rangle$$

$$\begin{pmatrix} \varphi_x^F \\ \varphi_y^F \\ \varphi_z^F \end{pmatrix} = \frac{1}{\sqrt{3}} \begin{pmatrix} \epsilon & 1 & \epsilon^* \\ \epsilon^* & 1 & \epsilon \\ 1 & 1 & 1 \end{pmatrix} \begin{pmatrix} \psi_1^F \\ \psi_0^F \\ \psi_{-1}^F \end{pmatrix}. \tag{23}$$

IV. THE $T\supset C_2$ d.v. REPRESENTATIONS

For the d.v. reps, the group chain $T\supset C_2$ is canonical and D_2 is redundant in the group chain $T\supset D_2\supset C_2$. To find the algebraic solutions for the group chain $T\supset C_2$ we need to use the

double-induced technique. We follow the six steps in Sec. II of Ref. 11 to find the algebraic solution of $T \supset C_2$. We first note that the CSCO of T is

$$C = C_{31}^{+} + C_{32}^{+} + C_{33}^{+} + C_{34}^{+} = \mathbf{5+6+7+8}, \tag{24}$$

where (and in the following) we use boldface integers to denote the group element listed in Table I, e.g., **5** represents the element $R_5 = C_{31}^{+}$. In the d.v. reps, C has three distinct eigenvalues $(2, 2\epsilon, 2\epsilon^*)$, $\epsilon = e^{-2\pi i/3}$, corresponding to the three irreps $(E_{1/2}, E_{3/2}, E_{-3/2})$ in the modified Mulliken notation,[11] or $(\Gamma_5, \Gamma_6, \Gamma_7)$ in Koster notation, respectively.

A. The C_2 double-induced representation

We choose the subgroup $C_2 = (e, C_{2z})$, and the CSCO of C_2 is

$$C_{2z} = \exp(-\pi J_z i). \tag{25}$$

Its eigenvalue is denoted by ϱ,

$$\varrho \equiv \varrho_\mu = \exp(-\pi\mu i) = \begin{cases} -i \\ i \end{cases}, \quad \text{for} \quad \mu = \begin{cases} \frac{1}{2} \\ -\frac{1}{2} \end{cases}. \tag{26}$$

Notice the subtle difference between the notations for the quantum number $\rho_\mu = \exp[-2\pi\mu i/3]$ of C_{31}^{+} and the quantum number $\varrho_\mu = \exp(-\mu\pi i)$ of C_{2z}.

The projection operators of C_2 is defined as

$$P^{\varrho} \equiv P^{\varrho_\mu} \equiv P^{\mu} = e + \varrho^* C_{2z}. \tag{27}$$

The group T can be expanded in double cosets of C_2

$$T = C_2(e + C_{2x} + C_{31}^{-} + C_{31}^{+})C_2. \tag{28}$$

According to (9c) in Ref. 11, sandwiching the four coset generators between P^{ϱ} and $P^{\bar{\varrho}}$, and inserting the normalization coefficients we get four common eigenvectors of C_{2z} and $\overline{C}_{2z}$

$$\begin{aligned} \varphi^1_{\varrho,\bar{\varrho}} &= \frac{1}{2\sqrt{2}} P^{\varrho} e P^{\bar{\varrho}}, \quad \varphi^2_{\varrho,\bar{\varrho}} = \frac{1}{2\sqrt{2}} P^{\varrho} C_{2x} P^{\bar{\varrho}}, \\ \varphi^3_{\varrho,\bar{\varrho}} &= \tfrac{1}{2} P^{\varrho} C_{31}^{-} P^{\bar{\varrho}}, \quad \varphi^4_{\varrho,\bar{\varrho}} = \tfrac{1}{2} P^{\varrho} C_{31}^{+} P^{\bar{\varrho}}. \end{aligned} \tag{29a}$$

Using

$$P^{\varrho} P^{\varrho'} = 3\delta_{\varrho,\varrho'} P^{\varrho}, \quad C_{2x} P^{\varrho} = P^{\varrho^*} C_{2x}$$

we have

$$\varphi^1_{\varrho\bar{\varrho}} = \delta_{\varrho\bar{\varrho}} \varphi^1_{\varrho}, \quad \varphi^2_{\varrho\bar{\varrho}} = \delta_{\varrho\bar{\varrho}^*} \varphi^2_{\varrho}, \tag{29b}$$

with

$$\varphi^1_{\varrho} = \frac{1}{\sqrt{2}} P^{\varrho}, \quad \varphi^2_{\varrho} = \frac{1}{\sqrt{2}} P^{\varrho} C_{2x}. \tag{29c}$$

Using Table I, the four basis vectors can be written explicitly

$$\varphi^1_{\varrho} = \frac{1}{\sqrt{2}}[\mathbf{1} - \varrho\mathbf{4}], \quad \varphi^2_{\varrho} = \frac{1}{\sqrt{2}}[\mathbf{2} - \varrho\mathbf{3}],$$

$$\varphi^3_{\varrho\bar{\varrho}}=\tfrac{1}{2}[\mathbf{9}-\varrho\mathbf{12}-\bar{\varrho}\mathbf{11}-\varrho\bar{\varrho}\mathbf{10}],\quad \varphi^4_{\varrho\bar{\varrho}}=\tfrac{1}{2}[\mathbf{5}+\varrho\mathbf{7}+\bar{\varrho}\mathbf{8}-\varrho\bar{\varrho}\mathbf{6}], \tag{30}$$

where we used the fact that for d.v. reps, $\varrho^*=-\varrho$ and $\varrho\bar{\varrho}$ is real.

We choose the elements **1, 2, 9**, and **5** as the representatives of $\varphi^1_{\varrho\bar{\varrho}}-\varphi^4_{\varrho\bar{\varrho}}$, respectively. The four basis vectors $\varphi^1_{\varrho\bar{\varrho}}-\varphi^4_{\varrho\bar{\varrho}}$ form the double-induced rep. The task of finding the eigenvectors of the CSCO-III in the 12-dimensional group space of T is reduced to finding the eigenvector of the CSCO-I in the four-dimensional double-induced rep space.

Following the same steps as in Sec. IV A of Ref. 11 we can find the rep matrix M of the operator C, the CSCO of T, in the basis (30), which is defined as $C\varphi^i_{\rho\bar{\rho}}=\Sigma_j M_{ji}\varphi^j_{\rho\bar{\rho}}$.

(1) Highlighting the elements **1**, **2**, **9**, and **5** in rows 5–8 of Table I which correspond to the elements $C^+_{31}-C^+_{34}$. (2) Collecting the highlighted numbers in each column, we obtain the following table:

R_i	1	2	3	4	5	6	7	8	9	10	11	12
CR_i	5	5	5	5	−9	9	9	9	1−2	1+2	1−2	1+2

The table shows e.g., $CR_5=-R_9+\cdots$. The terms involving elements other than R_1, R_2, R_5, and R_9 are ignored. Using the above table and (30) we have

$$C\varphi^1_{\varrho}=\frac{1}{\sqrt{2}}[\mathbf{5}-\varrho\mathbf{5}]=\sqrt{2}(1-\varrho)\varphi^4_{\varrho\bar{\varrho}},$$

$$C\varphi^2_{\varrho}=\frac{1}{\sqrt{2}}[\mathbf{5}-\varrho\mathbf{5}]=\sqrt{2}(1-\varrho)\varphi^4_{\varrho\varrho^*}, \tag{31}$$

$$C\varphi^3_{\varrho\bar{\varrho}}=\tfrac{1}{2}[\mathbf{1}-\mathbf{2}-\varrho(\mathbf{1}+\mathbf{2})-\bar{\varrho}(\mathbf{1}-\mathbf{2})-(\varrho\bar{\varrho})(\mathbf{1}+\mathbf{2})]=f_{\varrho\bar{\varrho}}\varphi^1_{\varrho}+g_{\varrho\bar{\varrho}}\varphi^2_{\varrho},$$

$$C\varphi^4_{\varrho\bar{\varrho}}=\tfrac{1}{2}[-\mathbf{9}+\varrho\mathbf{9}+\bar{\varrho}\mathbf{9}-\varrho\bar{\varrho}\mathbf{9}]=-(1-\varrho-\bar{\varrho}+\varrho\bar{\varrho})\varphi^3_{\varrho\bar{\varrho}},$$

where

$$f_{\varrho\bar{\varrho}}=\frac{1}{\sqrt{2}}(1-\varrho-\bar{\varrho}-\varrho\bar{\varrho}), \tag{32a}$$

$$g_{\varrho\bar{\varrho}}=-\frac{1}{\sqrt{2}}(1+\varrho-\bar{\varrho}+\varrho\bar{\varrho}).$$

It is easy to show that

$$f_{\varrho\bar{\varrho}}=\sqrt{2}(1-\varrho)\delta_{\varrho\bar{\varrho}},\quad g_{\varrho\bar{\varrho}}=-\sqrt{2}(1+\varrho)\delta_{\varrho\bar{\varrho}^*}. \tag{32b}$$

From (31) and (32) we obtain the matrix M.

$$M=\sqrt{2}\begin{pmatrix} 0 & 0 & (1-\varrho)\delta_{\varrho\bar{\varrho}} & 0 \\ 0 & 0 & -(1+\varrho)\delta_{\varrho\bar{\varrho}^*} & 0 \\ 0 & 0 & 0 & -\frac{1}{\sqrt{2}}(1-\varrho-\bar{\varrho}+\varrho\bar{\varrho}) \\ (1-\varrho)\delta_{\varrho\bar{\varrho}} & (1-\varrho)\delta_{\varrho\bar{\varrho}^*} & 0 & 0 \end{pmatrix}. \tag{33}$$

(There are three misprints in the eigenvalue equations in Ref. 11: the $\tilde{M}$ in Eqs. (9g), (24), and (27) should be replaced by M.) The eigenvectors of the matrix in (33) are divided into two cases:

Case (i): $\bar{\varrho}=\varrho$.

In this case the matrix M becomes three-dimensional. In the basis $\{\varphi^1_\varrho,\varphi^3_{\varrho\varrho},\varphi^4_{\varrho\varrho}\}$, the rep matrix of C is

$$M=\begin{pmatrix} 0 & \sqrt{2}(1-\varrho) & 0 \\ 0 & 0 & 2\varrho \\ \sqrt{2}(1-\varrho) & 0 & 0 \end{pmatrix}. \tag{34}$$

Its eigenvalue is found as $\lambda=2,2\epsilon,2\epsilon^*\{\epsilon=\exp(-[2\pi i/3])\}$, and its eigenvectors are

$$\mathcal{P}^{(\lambda)\varrho}_\varrho=\frac{1}{\sqrt{3}}\left[\varphi^1_\varrho+\frac{1+\varrho}{\sqrt{2}}\left(\frac{\lambda}{2}\right)\varphi^3_{\varrho\varrho}+\frac{1-\varrho}{\sqrt{2}}\left(\frac{\lambda}{2}\right)^*\varphi^4_{\varrho\varrho}\right],\quad \varrho=\pm i, \tag{35a}$$

where we used the fact that $(\lambda/2)^2=\lambda^*/2$.

Case (ii): $\bar{\varrho}=\varrho^*$.

In the basis $\{\varphi^2_\varrho,\varphi^3_{\varrho,\varrho^*},\varphi^4_{\varrho\varrho^*}\}$ the rep matrix of C is

$$M=\begin{pmatrix} 0 & -\sqrt{2}(1+\varrho) & 0 \\ 0 & 0 & -2 \\ \sqrt{2}(1-\varrho) & 0 & 0 \end{pmatrix}. \tag{35b}$$

Its eigenvalue $\lambda=2,2\epsilon,2\epsilon^*$ with the eigenvectors

$$\mathcal{P}^{(\lambda)-\varrho}_\varrho=i^{1+\mu}\frac{1}{\sqrt{3}}\left[\varphi^2_\varrho-\frac{1-\varrho}{\sqrt{2}}\left(\frac{\lambda}{2}\right)\varphi^3_{\varrho\varrho^*}+\frac{1-\varrho}{\sqrt{2}}\left(\frac{\lambda}{2}\right)^*\varphi^4_{\varrho\varrho^*}\right],\quad \varrho=\pm i, \tag{35c}$$

where $\varrho=e^{-\pi\mu i},\mu=\pm\frac{1}{2}$. The phase factor $\sqrt{i}$ for $\mu=-\frac{1}{2}$ is chosen so that the SAF's will be real, while the phase factor $(\sqrt{i})^3$ for $\mu=\frac{1}{2}$ is determined from $\mathcal{P}^{(\lambda)\varrho'}_\varrho=(\mathcal{P}^{(\lambda)\varrho}_{\varrho'})^\dagger$.

B. The $T\supset C_2$ d.v. ISO's

In the following it is convenient to change the notation from $\mathcal{P}^{(\lambda)\bar{\varrho}}_\varrho$ to $\mathcal{P}^{(\lambda)\bar{\mu}}_\mu$ with $\varrho=e^{-\pi\mu i},\bar{\varrho}=e^{-\pi\bar{\mu}i}$. Using (35) and (29) we have the $T\supset C_2$ ISO's

$$\begin{aligned}
\mathcal{P}^{(\lambda)\mu}_\mu&=\frac{1}{\sqrt{6}}\left[P^\mu+\frac{1}{2\sqrt{2}}P^\mu(i^{-\mu}\lambda C^-_{31}+i^\mu\lambda^* C^+_{31})P^\mu\right],\\
\mathcal{P}^{(\lambda)\mu}_{-\mu}&=\frac{1}{\sqrt{6}}\left[i^{1-\mu}P^{-\mu}C_{2x}+\frac{(-1)^{1/2+\mu}}{2\sqrt{2}}P^{-\mu}(\lambda C^-_{31}-\lambda^* C^+_{31})P^\mu\right],
\end{aligned}\qquad \mu=\pm\tfrac{1}{2} \tag{36}$$

Choosing $\mu=\frac{1}{2}$, and ignoring the normalization, we obtain the $T\supset C_2$ d.v. generalized projection operators

$$\begin{aligned}
\mathbf{P}^{(\lambda)}_{1/2}&=P^{1/2}+\frac{\sqrt{2}}{4}P^{1/2}(\sqrt{i^*}\lambda C^-_{31}+\sqrt{i}\lambda^* C^+_{31})P^{1/2},\\
\mathbf{P}^{(\lambda)}_{-1/2}&=\sqrt{i}P^{-1/2}C_{2x}-\frac{\sqrt{2}}{4}P^{-1/2}(\lambda C^-_{31}-\lambda^* C^+_{31})P^{1/2}.
\end{aligned} \tag{37}$$

Recall that $\lambda=2,2\epsilon,2\epsilon^*$ for the irreps $E_{1/2},E_{3/2},E_{-3/2}$, respectively.

The simplicity of the algebraic expression for the $T\supset C_2$ ISO's $\mathcal{P}_{\mu}^{(\lambda)\bar{\mu}}$ is to be noted. It is a function of only three quantum numbers $\lambda,\mu,\bar{\mu}$, and contains only three terms, while in the original form (6), the ISO's of T for the three d.v. two-dimensional irreps involve altogether $3\times 2^2\times 12=144$ irreducible matrix elements, and each ISO has 12 terms.

C. $T\supset C_2$ irreducible matrices

The matrices of C_{2z} are diagonal, while the representation matrices of the coset generators $\hat{k}_i=C_{2x},C_{31}^{+},C_{31}^{-}$ are obtained in the following way. According to Sec. IV C in Ref. 11, we know that the coefficients of $P^{\varrho}\hat{k}_iP^{\bar{\varrho}}$ in (36) are equal to

$$\sqrt{h_\lambda/12}D^{\Gamma}_{\varrho\bar{\varrho}}(\hat{k}_i)^*.$$

Consequently from (36) we immediately get the algebraic expression for the $T\supset C_2$ irreducible matrices in the order of $\mu=\frac{1}{2},-\frac{1}{2}$:

$$\begin{aligned} D^{(\lambda)}(C_{2z})&=\begin{pmatrix} -i & 0\\ 0 & i\end{pmatrix},\quad D^{(\lambda)}(C_{31}^{+})=\frac{\lambda}{2\sqrt{2}}\begin{pmatrix}\sqrt{i^*}, & -1\\ 1, & \sqrt{i}\end{pmatrix}.\\ D^{(\lambda)}(C_{2x})&=\begin{pmatrix} 0 & i\sqrt{i}\\ \sqrt{i} & 0\end{pmatrix}^*,\quad D^{(\lambda)}(C_{31}^{-})=\frac{\lambda^*}{2\sqrt{2}}\begin{pmatrix}\sqrt{i}, & 1\\ -1, & \sqrt{i^*}\end{pmatrix}.\end{aligned}\tag{38}$$

The matrices for other elements are obtained through

$$D^{(\lambda)}_{\varrho,\bar{\varrho}}(C_{2z}^{j}C_{2x})=\varrho^{j}D^{\lambda}_{\varrho,\bar{\varrho}}(C_{2x}),D^{(\lambda)}_{\varrho\bar{\varrho}}(C_{2z}^{j}C_{31}^{\pm}C_{2z}^{k})=\varrho^{j}D^{(\lambda)}_{\varrho\bar{\varrho}}(C_{31}^{\pm})\bar{\varrho}^{k}.$$

The elements of $C_{2z}^{j}C_{2x}$ and $C_{2z}^{j}C_{31}^{\pm}C_{2z}^{k}$ are listed below:

j	0	1		
$C_{2z}^{j}C_{2x}$	C_{2x}	C_{2y}		
(j,k)	(00)	(01)	(10)	(11)
$C_{2z}^{j}C_{31}^{+}C_{2z}^{k}$	C_{31}^{+}	$\tilde{C}_{34}^{+}$	$\tilde{C}_{33}^{+}$	$\tilde{C}_{32}^{+}$
$C_{2z}^{j}C_{31}^{-}C_{2z}^{k}$	C_{31}^{-}	C_{33}^{-}	C_{34}^{-}	$\tilde{C}_{32}^{-}$

D. The $T\supset C_2$ d.v. SAF's

In order to obtain real SAF's, we choose the coordinate system $x''y''z$ as shown in Fig. 2, which is obtained from rotating the coordinate system xyz in Fig. 1 through angle $-\pi/4$ about the z axis. Using (11) of Ref. 11 and the Euler angles in the system xyz shown in Sec. III C, we obtain the Euler angles for C_{2x} and $C_{31}^{\pm}$ in the $x''y''z$ system

$$C_{2x}=R\left(0,\pi,\frac{\pi}{2}\right),\quad C_{31}^{+}=R\left(\frac{\pi}{4},\frac{\pi}{2},\frac{\pi}{4}\right),\quad C_{31}^{-}=R\left(\frac{3\pi}{4},\frac{\pi}{2},\frac{11\pi}{4}\right).$$

It should be mentioned that if for the group chain $T\supset D_2$ we also choose the coordinate system $x''y''z$, then the $T\supset D_2$ SAF's $\varphi^{(A_\mu)}$ will become real, however, the SAF's $\varphi^{(F)}$ will become complex.

Applying (37) to $|j\bar{m}\rangle$ and using $P^{\mu}|j\bar{m}\rangle=2\delta_{\mu,\bar{m}(\mathrm{mod}\,2)}|j\bar{m}\rangle$, we obtain the $T\supset C_2$ d.v. SAF

$$\varphi_{1/2}^{(E_\mu)\bar{m}}=|j\bar{m}\rangle+\sqrt{2}\sum_{m=1/2}^{(2)}\mathrm{Re}(\lambda\sqrt{i}^{m+\bar{m}-1})d^{j}_{m\bar{m}}\left(\frac{\pi}{2}\right)|jm\rangle,\tag{39}$$

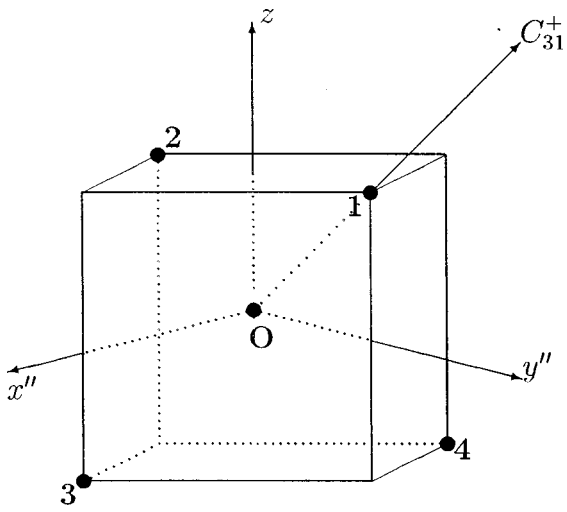

FIG. 2. The coordinate system $x''y''z$ for $0 \supset T \supset C_2$, $xyz \xrightarrow{R(\omega)} x''y''z$, $R(\omega) \equiv R(0,0,-\pi/4)$.

$$\varphi_{-1/2}^{(E_\mu)\bar{m}} = (-1)^{j-1/2+\kappa_{\bar{m}}} |j-\bar{m}\rangle + \sqrt{2} \sum_{m=-1/2}^{(2)} \mathrm{Re}(\lambda \sqrt{i}^{m+\bar{m}}) d^j_{m\bar{m}}\left(\frac{\pi}{2}\right) |jm\rangle,$$

where $\bar{m} = \frac{1}{2} (\mathrm{mod}\, 2)$, and $\lambda = 2, 2\epsilon, 2\epsilon^*$ ($\epsilon = e^{-(2\pi/3)i}$), for $\mu = \frac{1}{2}, \frac{3}{2}, -\frac{3}{2}$, respectively, $\kappa_{\bar{m}}$ is an integer

$$\kappa_{\bar{m}} = \tfrac{1}{2}(\bar{m} - \tfrac{1}{2}).$$

The summation symbol in (39) stands for

$$\sum_{m=\mu}^{(2)} = \sum_{m=\mu,\mu+2,\mu-2,\cdots}.$$

Since for $E_{1/2}$ the eigenvalue $\lambda = 2$, and the condition that $\lambda \sqrt{i}^{m+\bar{m}-1}$ be real imposes an extra condition for the summation index m in (39): $m = \bar{m} \pmod 4$ for $\varphi_{1/2}^{(E_{1/2})\bar{m}}$ and similarly $m = -\bar{m} \pmod 4$ for $\varphi_{-1/2}^{(E_{1/2})\bar{m}}$.

Notice that all the coefficients in (39) are real and they have the following symmetries:

$$\begin{aligned} \langle \varphi_{1/2}^{(E_\nu)\bar{m}} | jm \rangle &= (-1)^{j-1/2+\kappa_m} \langle \varphi_{-1/2}^{(E_\nu)\bar{m}} | j-m \rangle, \quad \nu = \tfrac{1}{2}, \pm\tfrac{3}{2}, \\ \langle \varphi_{\mu}^{(E_{3/2})\bar{m}} | jm \rangle &= (-1)^{\kappa_m + \kappa_{\bar{m}}} \langle \varphi_{\mu}^{(E_{-3/2})\bar{m}} | jm \rangle, \quad \mu = \pm\tfrac{1}{2}. \end{aligned} \tag{40}$$

Under the time reversal $\hat{T} = -i\sigma_y K$ the SAF's transform as

$$\begin{aligned} \hat{T} \varphi_{\mu}^{(E_{1/2})\bar{m}} &= (-1)^{1/2-\mu} (-1)^{\kappa_{\bar{m}}} \varphi_{-\mu}^{(E_{1/2})\bar{m}}, \quad \mu = \pm\tfrac{1}{2} \\ \hat{T} \varphi_{\mu}^{(E_\nu)\bar{m}} &= (-1)^{1/2-\mu} (-1)^{\kappa_{\bar{m}}} \varphi_{-\mu}^{(E_{-\nu})-\bar{m}}, \quad \nu = \pm\tfrac{3}{2}, \quad \mu = \pm\tfrac{1}{2}. \end{aligned} \tag{41}$$

Again the quantum number $\bar{m}$ in (39) serves as the multiplicity label. The exact numerical expression of the SAF's for $j = \frac{1}{2}$-$\frac{9}{2}$ are shown in Table III. Notice that the listed SAF's with different $\bar{m}$ are linearly independent but in general not orthogonal. The high symmetries (40) of the coefficients in Table III are to be noted. The $T \supset C_2$ d.v. SAF's for the lowest two angular momenta $j = \frac{1}{2}, \frac{3}{2}$ have been given by Damhus.[17] No other systematic tables for the $T \supset C_2$ SAF's are available. Even if such tables do exist, the symmetries of the SAF's would be buried in the vast numerical data and cannot be easily discovered.

TABLE III. The $T\supset C_2$ d.v. SAF's for $j=\frac{1}{2}$-$\frac{9}{2}$. For $j=\frac{9}{2}$ only the SAF's with multiplicity are listed.

$\bar{m}=\frac{1}{2}$

$$|E_{1/2}\tfrac{1}{2}\rangle = |\tfrac{1}{2}\tfrac{1}{2}\rangle$$

V. SUMMARY

A factorization lemma for the direct-product group of two abelian groups is discovered, with which the ISO's for the group T can be written down without any derivation.

The algebraic expressions of the ISO's and SAF's of the group T are given in (15) and (18) for the group chain $T\supset D_2$, and in (36) and (39) for the group chain $T\supset C_2$.

The simplicity of the expressions (36) for the $T\supset C_2$ ISO's $\mathcal{P}_{\mu}^{(\lambda)\bar{\mu}}$ is remarkable that they are functions of the quantum numbers λ,μ, and $\bar{\mu}$ only without involving any irreducible matrix elements, and they are simpler than the algebraic expressions for the $T\supset C_3$ ISO's given in (35) of Ref. 11. The simplicity can be appreciated more clearly if they are compared with the usual ''numerical'' expressions of the ISO's involving all the $36(=3\times12)$ two by two matrices.

The SAF's $\psi_{\underline{\mu}}^{(\lambda)\bar{m}}$ are functions of the quantum numbers j,λ,μ, and $\bar{m}$ only. The intrinsic quantum number $m$plays an important role as the multiplicity label for the SAF's, and as an index for specifying the transformation property of the SAF's under the time reversal, despite the fact

TABLE III. (*Continued*).

$$|E_{3/2\,\frac{1}{2}}\rangle^1 = \frac{\sqrt{3\cdot5\cdot7}}{60}\left|\frac{9}{2}-\frac{7}{2}\right\rangle+\frac{\sqrt{3\cdot5}}{10}\left|\frac{9}{2}-\frac{3}{2}\right\rangle-\frac{\sqrt{5\cdot7}}{10}\left|\frac{9}{2}\frac{5}{2}\right\rangle+\frac{\sqrt{2\cdot3\cdot5}}{12}\left|\frac{9}{2}\frac{1}{2}\right\rangle+\frac{\sqrt{3\cdot5\cdot7}}{20}\left|\frac{9}{2}\frac{9}{2}\right\rangle$$

$$|E_{3/2-\frac{1}{2}}\rangle^1 = \frac{\sqrt{3\cdot5\cdot7}}{20}\left|\frac{9}{2}-\frac{9}{2}\right\rangle+\frac{\sqrt{5\cdot7}}{10}\left|\frac{9}{2}-\frac{5}{2}\right\rangle+\frac{\sqrt{2\cdot3\cdot5}}{12}\left|\frac{9}{2}-\frac{1}{2}\right\rangle-\frac{\sqrt{3\cdot5}}{10}\left|\frac{9}{2}\frac{3}{2}\right\rangle+\frac{\sqrt{3\cdot5\cdot7}}{60}\left|\frac{9}{2}\frac{7}{2}\right\rangle$$

$\tilde{m}=\frac{5}{2}$

$$|E_{3/2\,\frac{1}{2}}\rangle^2 = -\frac{5\sqrt{2\cdot3}}{24}\left|\frac{9}{2}-\frac{7}{2}\right\rangle-\frac{\sqrt{3\cdot7}}{12}\left|\frac{9}{2}\frac{1}{2}\right\rangle+\frac{\sqrt{2}}{2}\left|\frac{9}{2}\frac{5}{2}\right\rangle-\frac{\sqrt{2\cdot3}}{8}\left|\frac{9}{2}\frac{9}{2}\right\rangle$$

$$|E_{3/2-\frac{1}{2}}\rangle^2 = -\frac{\sqrt{2\cdot3}}{8}\left|\frac{9}{2}-\frac{9}{2}\right\rangle-\frac{\sqrt{2}}{2}\left|\frac{9}{2}-\frac{5}{2}\right\rangle-\frac{\sqrt{3\cdot7}}{12}\left|\frac{9}{2}-\frac{1}{2}\right\rangle-\frac{5\sqrt{2\cdot3}}{24}\left|\frac{9}{2}\frac{7}{2}\right\rangle$$

$\tilde{m}=\frac{1}{2}$

$$|E_{-3/2\,\frac{1}{2}}\rangle^1 = \frac{\sqrt{3\cdot5\cdot7}}{60}\left|\frac{9}{2}-\frac{7}{2}\right\rangle-\frac{\sqrt{3\cdot5}}{10}\left|\frac{9}{2}-\frac{3}{2}\right\rangle+\frac{\sqrt{2\cdot3\cdot5}}{12}\left|\frac{9}{2}\frac{1}{2}\right\rangle+\frac{\sqrt{5\cdot7}}{10}\left|\frac{9}{2}\frac{5}{2}\right\rangle+\frac{\sqrt{3\cdot5\cdot7}}{20}\left|\frac{9}{2}\frac{9}{2}\right\rangle$$

$$|E_{-3/2-\frac{1}{2}}\rangle^1 = \frac{\sqrt{3\cdot5\cdot7}}{20}\left|\frac{9}{2}-\frac{9}{2}\right\rangle-\frac{\sqrt{5\cdot7}}{10}\left|\frac{9}{2}-\frac{5}{2}\right\rangle+\frac{\sqrt{2\cdot3\cdot5}}{12}\left|\frac{9}{2}-\frac{1}{2}\right\rangle+\frac{\sqrt{3\cdot5}}{10}\left|\frac{9}{2}\frac{3}{2}\right\rangle+\frac{\sqrt{3\cdot5\cdot7}}{60}\left|\frac{9}{2}\frac{7}{2}\right\rangle$$

$\tilde{m}=\frac{5}{2}$

$$|E_{-3/2\,\frac{1}{2}}\rangle^1 = \frac{5\sqrt{2\cdot3}}{24}\left|\frac{9}{2}-\frac{7}{2}\right\rangle+\frac{\sqrt{3\cdot7}}{12}\left|\frac{9}{2}\frac{1}{2}\right\rangle+\frac{\sqrt{2}}{2}\left|\frac{9}{2}\frac{5}{2}\right\rangle+\frac{\sqrt{2\cdot3}}{8}\left|\frac{9}{2}\frac{9}{2}\right\rangle$$

$$|E_{-3/2-\frac{1}{2}}\rangle^2 = \frac{\sqrt{2\cdot3}}{8}\left|\frac{9}{2}-\frac{9}{2}\right\rangle-\frac{\sqrt{2}}{2}\left|\frac{9}{2}-\frac{5}{2}\right\rangle+\frac{\sqrt{3\cdot7}}{12}\left|\frac{9}{2}-\frac{1}{2}\right\rangle+\frac{5\sqrt{2\cdot3}}{24}\left|\frac{9}{2}\frac{7}{2}\right\rangle$$

that the SAF's are in general not orthogonal in $\bar{m}$. A similar situation occurs for the rotation group, the irreducible basis vectors of which are in general not orthogonal in the intrinsic quantum number K, the third component of the total angular momentum in the intrinsic (body-fixed) coordinate system.[18]

From the results of our previous paper[11] and this paper it is seen that the elegance of the algebraic solutions of the point group T in both the group chains $T\supset C_3$ and $T\supset D_2\supset C_2$ can be compared with that of the analytic solutions of the rotation group. An application of the double-induced technique to all other point groups is straightforward and will be reported elsewhere.

Finally it should be mentioned that an extremely simple relation between the SAF's of the octahedral group O and tetrahedral group T has been found,[19] namely the $T\supset G(s)$ SAF's are just the $O\supset T\supset G(s)$ SAF's, where $G(s)$ can be any subgroup of T, e.g., $G(s)=C_3,C_2,D_2$. In other words, the SAF's found in Ref. 11 and this paper are also the SAF's of the group O. The SAF's of the groups O and T listed in pp. 66–70 of Ref. 4 offered a verification of the above conclusion.

Algebraic expressions of the Clebsch-Gordon coefficients of the point group $T^\dagger$

Jin-Quan Chen[a] and Peng-Dong Fan
Department of Physics, Nanjing University, Nanjing, 210008, People's Republic of China

(Received 24 March 1998; accepted for publication 5 May 1998)

A method for finding algebraic expressions of the Clebsch-Gordan (CG) coefficients of point groups is proposed and applied to the tetrahedral group. It is shown that in constructing the CG coefficients the irreducible symmetry operator (ISO) of a double group $G^\dagger$ can be replaced by an effective ISO which is much simpler than the usual ISO. The effective ISO for the group chain $T^\dagger \supset C_3^\dagger$ is $\mathscr{P}^{(\lambda)}_{\mu,\mu} = \delta_{\mu\mu} + 3d^{(\lambda)}_{\mu\mu}(C_{2z})^* C_{2z}$, where $d^{(\lambda)}(C_{2z})$ is the matrix of C_{2z} in the irrep λ of $T^\dagger$. With this effective ISO and the algebraic expression of $d^{(\lambda)}(C_{2z})$, the algebraic expressions are derived for the real CG coefficients of $T^\dagger$ in the group chain $T^\dagger \supset C_3^\dagger$. The algebraic expressions for the complex (real) CG coefficients of the group chain $T^\dagger \supset D_2^\dagger \supset C_2^\dagger$ ($T^\dagger \supset C_2^\dagger$) have also been obtained. © *1998 American Institute of Physics.* [S0022-2488(98)04110-3]

I. INTRODUCTION

The irreducible representations of point groups are well known, along with their Clebsch-Gordan (CG) coefficients, subduction coefficients, etc. However, all the solutions to the point groups are numerical.[1–11] Recently, by using the double-induced technique, the algebraic expressions of the irreducible symmetry operators (ISO's), irreducible matrices, and symmetry adapted functions (SAF's) are found for the double group $T^\dagger$ in the group chain $T \supset C_3$ and $T \supset D_2 \supset C_2$.[12,13] What makes the algebraic solution appealing is the fact that the irreducible matrices, the ISO's and SAF's are merely functions of the quantum numbers (λ,μ) characterizing the group chain [the analogy of (j,m) for $SO_3 \supset SO_2$], and these expressions are valid for both single-valued and double-valued reps. The remaining task in seeking the algebraic solutions of the point group T is to get the algebraic expressions of its Clebsch-Gordan (CG) coefficients, which is the main purpose of the present paper. In Refs. 12 and 13 it has been shown that with the available algebraic expression of the ISO's, the projection operator method for constructing the SAF's becomes extremely simple. In this paper we will show that the same applies to the construction of the CG coefficients.

Since in this paper we always deal with both the single-valued (s.v.) and double-valued (d.v.) reps simultaneously, the symbol for the double group $G^\dagger$ will be replaced simply by G.

The numerical tables of the $T \supset D_2 \supset C_2$ CG coefficients have been first calculated in Ref. 3, the 3-Γ (or $3jm$) symbols for the group chain $T \supset C_3$ have been tabulated in Refs. 14–16 and for the group chain $T \supset C_2$ in Ref. 16. The CG coefficients for the group chains $T \supset D_2 \supset C_2$ and $T \supset C_3$ can also be easily obtained from the code PGIR.[17]

Various methods were used for computing the CG coefficients numerically, which include:

(1) The projection operator method[18] and its variations (see Sec. VII.E in Ref. 19).

(2) The Griffith method[2] based on the transformation properties of the direct product under the generators of the group.

(3) The Golding method.[15] First calculate the subduction coefficients $\langle jm|\Gamma\mu\rangle$ for a set of minimum j values, and then obtain the CG coefficients of G from those of $SO_3 \supset SO_2$. If there is a multiplicity in $\Gamma_1 \times \Gamma_2 \to \Gamma$, then use the calculated CG coefficients to find the subduction coefficients $\langle j'm'|\Gamma\mu\rangle$ for a higher j' value, and repeat the above process for obtaining another set of CG coefficients.

(4) The Butler-Wybourne method,[7] or the building up method which uses only character theory results.

(5) The eigenfunction method[8,19] by which the CG coefficients are obtained by diagonalizing a set of commuting operators, the analogy of (J^2,J_z), in the Kronecker product representation of G.

Though straightforward in principle, the projection operator method in its original form is quite tedious and is avoided by many people for constructing the CG coefficients of the high-order point groups O and I.[20,21] It will be shown in this paper that the projection operator for constructing the $G\supset C_n$ CG coefficients, where C_n is the maximal cyclic group of G, can be replaced by an effective projection operator, which can be written, up to a multiplicative factor, as

$$\mathscr{P}_{\mu}^{(\Gamma)\bar{\mu}}=\sum_{i=1}^{q} M_i^{-1} d_{\mu\mu}^{(\Gamma)}(\beta_i)^{*}\beta_i, \tag{1}$$

where M_i is the number of times an element of G appears in the double coset $C_n\beta_i C_n$, q is the number of double cosets, β_i is the double coset generator, and $d_{\mu\mu}^{(\Gamma)}(\beta_i)$ is the irreducible matrix elements. Therefore the effective projection operator of a point group of any order is almost as simple as the projection operator of a group of order q, which is very small, $q=2$, 2, 3, 4 for the groups D_n,T,O,I, respectively. With the effective projection operator, the algebraic expressions for the CG coefficients of point groups can be derived. As examples, the method is used for obtaining the algebraic expressions of the $T\supset C_3$ CG coefficients. With slight modifications, the method is also used for finding the algebraic expressions of the $T\supset D_2\supset C_2$ and $T\supset C_2$ CG coefficients. Using these algebraic expressions numerical tables of the CG coefficients are easily generated and tabulated.

II. THE EFFECTIVE ISO'S OF $G\supset C_n$

Before discussing the group chain $T\supset C_3$, let us consider a more general group chain $G\supset C_n$. The maximal cyclic groups C_n of G are

$$\begin{aligned}&\text{Dihedral groups} && D_n\supset C_n,\\ &\text{Tetrahedral group} && T\supset C_3,\\ &\text{Octahedral group} && O\supset C_4,\\ &\text{Icosahedral group} && I\supset C_5.\end{aligned} \tag{2}$$

Since the number of double cosets, q, is the smallest for the maximal cyclic group, the group chains (2) are the simplest ones, and will be referred to as the natural group chains. The axis of C_n is chosen as the z axis, and the generator of C_n is

$$C_{nz}=\exp\left(-i\frac{2\pi}{n}J_z\right), \tag{3a}$$

and its eigenvalue is denoted by

$$\rho\equiv\rho_{\mu}=\exp\left(-i\frac{2\mu\pi}{n}\right), \tag{3b}$$

with the values of μ given below:

n	2	3	4	5
μ	$0,1;\pm\frac{1}{2}$	$0,\pm1;\pm\frac{1}{2},\frac{3}{2}$	$0,\pm1,2;\pm\frac{1}{2},\pm\frac{3}{2}$	$0,\pm1,\pm2;\pm\frac{1}{2},\pm\frac{3}{2},\frac{5}{2}$

(3c)

where $\mu=$ integers (half integers) are for the s.v. (d.v.) reps.

The un-normalized projection operator of C_n is

$$P^{\rho}\equiv P^{\mu}=\sum_{s=0}^{n-1}\rho^{*s}(C_{nz})^{s}. \tag{3d}$$

The normalized $G\supset C_n$ ISO is defined as

$$\mathscr{P}_{\rho}^{(\lambda)\bar{\rho}}=\sqrt{\frac{h_\lambda}{|\mathbf{g}|}}\sum_{a=1}^{|\mathbf{g}|}D_{\rho\rho}^{(\lambda)}(R_a)^{*}R_a, \tag{4}$$

where h_λ is the dimension of the irrep λ, $|\mathbf{g}|$ the order of G, R_a the ath group element, and $D_{\rho\rho}^{(\lambda)}(R_a)$ is the irreducible matrix element of R_a,

$$D_{\rho\rho}^{(\lambda)}(R_a)=\langle\psi_{\rho}^{\lambda}|R_a|\psi_{\rho}^{\lambda}\rangle.$$

In the double-induced method,[12,13] the group G is decomposed into double cosets,

$$G=\sum_{i=1}^{q}\oplus C_n\beta_i C_n, \tag{5a}$$

where β_i are coset generators. Let $M(\beta_i)\equiv M_i$ be the number of times an element appears in the double coset $C_n\beta_i C_n$. For the natural group chains (2) M_i is either n or 1 and is decided as following. In general, the frequency M_i for an element in the double coset $C_n\beta_i C_n$ is equal to the intersection of the right coset $C_n\beta_i$ and the left coset $\beta_i C_n$, see, for example, Ref. 22. In the decomposition (5a) some double cosets, say the first p double cosets, are coincidental with the right or left cosets,

$$C_n\beta_i C_n=\beta_i C_n=C_n\beta_i, \quad i=1,2,\ldots,p, \tag{5b}$$

then obviously

$$M_i=\begin{cases} n, & i=1,\ldots,p \\ 1, & i=p+1,\ldots,q. \end{cases}$$

Any element of G can be expressed as

$$R_a=C_{nz}^{s}\beta_i C_{nz}^{t}, \quad s,t=0,1,\ldots,n-1. \tag{5c}$$

In the $G\supset C_n$ basis $\psi_{\rho}^{(\lambda)}$, the irreducible matrix elements can be expressed as

$$D_{\rho\rho}^{(\lambda)}(C_{nz}^{s}\beta_k C_{nz}^{t})=\rho^{s}d_{\rho\rho}^{(\lambda)}(\beta_k)\bar{\rho}^{t}. \tag{6}$$

Due to (3b) there is a one to one correspondence between ρ and μ, and since the quantum number μ is additive, it is more convenient to use μ instead of ρ as the component index for the irreps. Therefore in the following we switch to the μ notation.

From (5c) and (6) we know that the $G\supset C_n$ ISO in (4) can be factored as

$$\mathscr{P}_{\mu}^{(\lambda)\bar{\mu}}=\sqrt{\frac{h_\lambda}{|\mathbf{g}|}}\,\dot{\mathscr{P}}_{\mu}^{(\lambda)\bar{\mu}}, \tag{7a}$$

$$\dot{\mathscr{P}}_{\mu}^{(\lambda)\bar{\mu}}=\sum_{i=1}^{q}M_i^{-1}P^{\mu}d_{\mu\mu}^{(\lambda)}(\beta_i)^{*}\beta_i P^{\bar{\mu}}. \tag{7b}$$

The normalized ISO satisfies the relation

$$(\mathscr{P}_{\mu}^{(\lambda)\bar{\mu}})^{\dagger}=\mathscr{P}_{\mu}^{(\lambda)\mu}, \tag{8a}$$

$$\mathscr{P}_{\mu}^{(\lambda)\bar{\mu}}\mathscr{P}_{\mu'}^{(\lambda')\bar{\mu}'}=\delta_{\lambda\lambda'}\delta_{\bar{\mu}\bar{\mu}'}\mathscr{P}_{\mu}^{(\lambda)\bar{\mu}'}. \tag{8b}$$

Let us consider the Kronecker product $D^{(\lambda_1)}\times D^{(\lambda_2)}$. Applying the ISO's to a basis vector $|\bar{\mu}_1\bar{\mu}_2\rangle\equiv|\lambda_1\bar{\mu}_1\lambda_2\bar{\mu}_2\rangle$, referred to as the initial or trial state, in the Kronecker product space, and using (8) we get a normalized symmetry adapted state, referred to as the final state,

$$\Psi_{\mu}^{(\lambda)\bar{\mu}_1\bar{\mu}_2}=\dot{\mathscr{N}}\mathscr{P}_{\mu}^{(\lambda)\bar{\mu}}|\bar{\mu}_1\bar{\mu}_2\rangle,\quad \dot{\mathscr{N}}^{-1}=\langle\bar{\mu}_1\bar{\mu}_2|\dot{\mathscr{P}}_{\mu}^{(\lambda)\bar{\mu}}|\bar{\mu}_1\bar{\mu}_2\rangle^{1/2}. \tag{9a}$$

From it we obtain an expression for the CG coefficients first derived in Ref. 23,

$$C_{\lambda_1\mu_1,\lambda_2\mu_2}^{(\lambda)\bar{\mu},\mu}=\frac{\langle\mu_1\mu_2|\mathscr{P}_{\mu}^{(\lambda)\bar{\mu}}|\bar{\mu}_1\bar{\mu}_2\rangle}{\langle\bar{\mu}_1\bar{\mu}_2|\dot{\mathscr{P}}_{\mu}^{(\lambda)\bar{\mu}}|\bar{\mu}_1\bar{\mu}_2\rangle^{1/2}}=\sqrt{\frac{h_\lambda}{|\mathbf{g}|}}\,\dot{\mathscr{N}}\sum_{a=1}^{|\mathbf{g}|}D_{\mu_1\mu_1}^{(\lambda_1)}(R_a)D_{\mu_2\mu_2}^{(\lambda_2)}(R_a)D_{\mu\mu}^{(\lambda)}(R_a)^*. \tag{9b}$$

Using

$$\frac{1}{n}\sum_{k=0}^{n-1}(\rho_\mu^*\rho_m)^k=\dot{\delta}_{\mu,m},$$

where

$$\dot{\delta}_{\mu,m}=\begin{cases}1, & \mu=m(\mathrm{mod}\ n)\\ 0, & \text{otherwise}\end{cases} \tag{9c}$$

we have

$$P^{\mu}|\mu_1\mu_2\rangle=\dot{\delta}_{\mu,\mu_1+\mu_2}n|\mu_1\mu_2\rangle. \tag{9d}$$

Using (9a) and (9d) we get

$$\Psi_{\mu}^{(\lambda)\bar{\mu}_1\bar{\mu}_2}=\mathscr{N}\sum_{\mu_1\mu_2}{}'\sum_{i=1}^{q}M_i^{-1}d_{\mu\mu}^{(\lambda)}(\beta_i)^*d_{\bar{\mu}_1\bar{\mu}_1}^{(\lambda_1)}(\beta_i)d_{\bar{\mu}_2\bar{\mu}_2}^{(\lambda_2)}(\beta_i)|\mu_1\mu_2\rangle, \tag{10a}$$

where Σ' means that the summation is subjected to the condition $\mu\doteq\mu_1+\mu_2$, and the quantum numbers with bars have to obey $\bar{\mu}\doteq\bar{\mu}_1+\bar{\mu}_2$. The $\mathscr{N}$ is the normalization factor given by

$$\mathscr{N}=n^2\dot{\mathscr{N}}\sqrt{\frac{h_\lambda}{|\mathbf{g}|}}, \tag{10b}$$

$$\dot{\mathscr{N}}^{-1}=\left[\sum_{i=1}^{q}M_i^{-1}d_{\mu\mu}^{(\lambda)}(\beta_i)^*d_{\bar{\mu}_1\bar{\mu}_1}^{(\lambda_1)}(\beta_i)d_{\bar{\mu}_2\bar{\mu}_2}^{(\lambda_2)}(\beta_i)\right]^{1/2}. \tag{10c}$$

From (10a) we get a simple expression for the CG coefficients

$$C_{\lambda_1\mu_1,\lambda_2\mu_2}^{(\lambda)\bar{\mu},\mu}=\mathscr{N}\sum_{i=1}^{q}M_i^{-1}d_{\bar{\mu}_1\bar{\mu}_1}^{(\lambda_1)}(\beta_i)d_{\bar{\mu}_2\bar{\mu}_2}^{(\lambda_2)}(\beta_i)d_{\mu\mu}^{(\lambda)}(\beta_i)^*, \tag{11a}$$

$$\mu\doteq\mu_1+\mu_2,\quad \bar{\mu}\doteq\bar{\mu}_1+\bar{\mu}_2. \tag{11b}$$

Equation (11b) will be referred to as the magnetic quantum number conservation rule.

The quantum number $\bar{\mu}$ in (11) serves as the multiplicity label. The CG coefficients are in general not orthogonal with respect to $\bar{\mu}$. Obviously the expression (11a) is a great simplification over (9b), which involves only a summation of q terms instead of $|\mathbf{g}|$ terms.

Equation (10a) suggests that acting on $|\bar{\mu}_1\bar{\mu}_2\rangle$ the ISO's $\mathscr{P}_{\mu}^{(\lambda)\bar{\mu}}$ in (7) can be replaced by the following effective ISO's

$$\mathscr{P}_{\mu}^{(\lambda)\bar{\mu}}=n^2\sqrt{\frac{h_\lambda}{|\mathbf{g}|}}\sum_{i=1}^{q} M_i^{-1}d_{\mu\mu}^{(\lambda)}(\beta_i)^*\beta_i, \tag{12}$$

so long as we imposed the conservation rules of the magnetic quantum numbers $\bar{\mu}_1+\bar{\mu}_2\doteq\bar{\mu}$ for the initial state and $\mu_1+\mu_2\doteq\mu$ for the final state.

Remark 1: Applying the ISO (7) to the $SO_3\supset SO_2$ basis $|jm\rangle$, we get what is usually called the symmetry adapted function (SAF), or the $SO_3\supset G\supset C_n$ irreducible basis,

$$\psi_{\mu}^{\lambda}=\mathscr{N}\sum_{m}{}'\sum_{i=1}^{q} M_i^{-1}d_{\mu\mu}^{(\lambda)}(\beta_i)^*D_{mm}^{(j)}(\beta_i)|jm\rangle, \quad \bar{m}\doteq\bar{\mu}. \tag{13}$$

where Σ' means the summation is subjected to the condition $m=\mu\ (\mathrm{mod}\ n)$.

Equation (13) shows that acting on $|jm\rangle$ the ISO's $\mathscr{P}_{\mu}^{(\lambda)\bar{\mu}}$ in (7) can also be replaced by the effective ISO's (12), but with the magnetic quantum number conservation rule replaced by $m\doteq\mu$, $\bar{m}\doteq\bar{\mu}$.

Remark 2. The ISO's in the form (12) are a drastic simplification over the usual form (4). It contains only q instead of $|\mathbf{g}|$ terms. Obviously, for a given group, the larger the n, the smaller the number q of the double cosets, and the simpler the effective ISO. For the group chains $T\supset C_3$, $O\supset C_4$, and $I\supset C_5$, $q=2$, 3, and 4, respectively. Therefore the effective ISO's of the group I_h of order 120 contains only four terms.

Remark 3. An important discovery is that only the irreducible matrices of the coset generators are needed for constructing the SAF's and CG coefficients. Therefore the usual way of listing the matrices for all elements is a waste of time. For all point groups we only need to list the irreducible matrices of at most three operators (since $q_{\max}=4$, and one of the generators is the identity operator). For example, for the group I, we do not need the matrices of all 60 elements, but only three. In case one needs the matrices of the elements other than the coset generators, one can construct them easily with the help of the group table and (6).

Remark 4. Among the $|\mathbf{g}|$ elements of a group G, only the q double-coset generators play a key role, while the role played by all the remaining $|\mathbf{g}|-q$ elements, the vast majority, is merely to ensure the magnetic-quantum-number-conservation rules for the initial (trial) state and for the final (projected) state.

III. THE CG COEFFICIENTS OF $T\supset C_3$

The conventional irrep labels, the Mulliken notation or Koster notation are inadequate for writing algebraic expressions of point groups. In deriving algebraic expressions it is vital to use quantum numbers as irrep labels. The quantum number of the group T is the eigenvalue λ of the CSCO (complete set of commuting operators), $C=C_{31}^{+}+C_{32}^{+}+C_{33}^{+}+C_{34}^{+}$, of T.[12] However, in listing the CG coefficients it is better to use some kind of labeling scheme that is more familiar to readers. It is what is called the modified Mulliken notation introduced in Refs. 12 and 24 according to the following recipe:

An irrep of G is labeled by $\Gamma=A,E,F,G,H,I$ for the irreps of dimension 1,2,3,4,5,6, respectively, as in the Mulliken notation. If more than one irrep has the same dimension, we use a subscript μ_m to distinguish them, where $\mu_m=\mu_{\max}$, the largest possible quantum number of C_n, in all cases with the exception that for the irrep $E_{-3/2}$ of T, for which $\mu_m=\mu_{\min}=-\frac{3}{2}$. In analogy with the Lie group, μ_m can be regarded as the ''highest weight'' of the irrep, and the possible values of μ of an irrep are called the ''weights'' of the irrep.

For example, for the group T there are three one-dimensional irreps A_μ, $\mu=0,\pm1$, three two-dimensional irreps E_ν, $\nu=\frac{1}{2},\frac{3}{2},-\frac{3}{2}$, and one three-dimensional irrep F. The correspondence between the modified Mulliken notation, Koster notation, the eigenvalues λ, as well as the ''weights'' for each irrep of T are shown in Table I.

TABLE I. The eigenvalues λ,ρ_μ of the CSCO-II, (C,C_{3z}), of T.

	A_0	A_1	A_{-1}	F	$E_{1/2}$	$E_{3/2}$	$E_{-3/2}$
	Γ_1	Γ_2	Γ_3	Γ_4	Γ_5	Γ_6	Γ_7
λ	4	4ϵ	$4\epsilon^*$	0	2	2ϵ	$2\epsilon^*$
μ (''the weights'')	0	1	-1	$(1,0,-1)$	$(\frac{1}{2},-\frac{1}{2})$	$(\frac{3}{2},\frac{1}{2})$	$(-\frac{3}{2},-\frac{1}{2})$
$\rho_\mu=\exp\left(-\frac{2\pi\mu i}{3}\right)$	1	ϵ	ϵ^*	$(\epsilon,1,\epsilon^*)$			

[a] $\epsilon=\exp(-2\pi i/3)$ and $\frac{3}{2}\doteq-\frac{3}{2}$.

We now apply the method introduced in Sec. II to the tetrahedral group. The s. v. and d. v. ISO's of $T\supset C_3$ have been obtained in (31) and (35) of Ref. 12, which can be written as (ignoring the normalizations),

$$\mathscr{P}_\mu^{(\lambda)\bar{\mu}}=P^\mu\delta_{\mu\bar{\mu}}+d_{\mu\bar{\mu}}^{(\lambda)*}(C_{2z})P^\mu C_{2z}P^{\bar{\mu}}, \tag{14}$$

where P^μ is the projection operator of C_3, λ stands for the irrep A_μ ($\mu=0,\pm1$), F, E_ν ($\nu=\frac{1}{2},\pm\frac{3}{2}$), and $d_{\mu\bar{\mu}}^{(\lambda)}(C_{2z})$ is the matrix element of irrep λ of C_{2z}. The subgroup C_3 is generated from C_{31}^+,

$$C_{31}^+=\exp\left(-\frac{2\pi J_z i}{3}\right). \tag{15}$$

Its eigenvalue is denoted by $\rho\equiv\rho_\mu$, $\rho=\rho_\mu=\exp(-2\pi\mu i/3)$, with the range of μ given in (3c). Notice that the irrep $\frac{3}{2}$ of C_3 is equivalent to $-\frac{3}{2}$, i.e., $\frac{3}{2}\doteq-\frac{3}{2}$.

The effective ISO's for $T\supset C_3$ are

$$\mathscr{P}_\mu^{(\lambda)\bar{\mu}}=\delta_{\mu\bar{\mu}}+3d_{\mu\bar{\mu}}^{(\lambda)*}(C_{2z})C_{2z}. \tag{16}$$

The algebraic expressions for the irreducible matrix of the generator C_{2z} has been found in (37) and (38) of Ref. 12,

$$d^{(A_\mu)}(C_{2z})=1,\quad d_{\mu\bar{\mu}}^{(F)}(C_{2z})=\frac{2}{3}-\delta_{\mu\bar{\mu}},$$

$$d_{\mu\bar{\mu}}^{(E_\nu)}(C_{2z})=\frac{\nu}{|\nu|}i(-1)^{\delta_{\mu\nu}\delta_{\mu\bar{\mu}}}\sqrt{\frac{2-\delta_{\mu\bar{\mu}}}{3}}, \tag{17}$$

where $\nu=\frac{1}{2}$, $\mu,\bar{\mu}=\pm\frac{1}{2}$; $\nu=\frac{3}{2}$, $\mu,\bar{\mu}=\frac{1}{2},\frac{3}{2}$; and $\nu=-\frac{3}{2}$, $\mu,\bar{\mu}=-\frac{1}{2},-\frac{3}{2}$.

In Ref. 12 an ISO with a chosen intrinsic quantum number $\bar{\mu}$ is called the generalized projection operator, which is to be used as projection operator for constructing the CG coefficients. Corresponding to the $T\supset C_3$ generalized projection operators in (40) of Ref. 12, we have the effective generalized projection operators

$$\begin{aligned}
&\mathbf{P}^{A_\mu}=1+3C_{2z}, && \bar{\mu}_1+\bar{\mu}_2\doteq\mu,\\
&\mathbf{P}_\mu^{F}=\delta_{\mu0}-(-1)^\mu C_{2z}, && \bar{\mu}_1+\bar{\mu}_2\doteq0,\\
&\mathbf{P}_\mu^{E_\nu}=\delta_{\mu\nu}+(-1)^{\mu-1/2+|\nu|}\sqrt{3}C_{2z}, && \bar{\mu}_1+\bar{\mu}_2\doteq\nu,
\end{aligned} \tag{18}$$

where the condition $\mu_1+\mu_2\doteq\mu$ has been omitted for simplicity.

A. The CG series

Instead of using the character theory, we can use a method similar to the one used in Lie groups[8,25] to determine the CG series of T. As mentioned before, in the modified Mulliken

notation Γ_{μ_m},μ_m can be regarded as the ''highest weight'' of the irrep. However the ''highest weight'' is not unique for some irreps. For example, the irreps A_1 and F have the same ''highest weight'' 1. However, the nonuniqueness of the ''highest weight'' causes so much trouble for us.

First we construct the weight system of the product representation $\lambda_1\times\lambda_2$, which is an algebraic sum of the weights of the irreps λ_1 and λ_2 modulo 3, and then use the subtraction method to determine the CG series.

Example: Let us consider $F\times F$. The weights of F are $(1,0,-1)$ and the weight system of $F\times F$ is $(2,1,0,-1,-2;1,0,-1;0)\doteq(1^3,0^3,-1^3)$. Since the irrep F is self-time-reversal, the identity irrep A_0 occurs once and only once in the product $F\times F$. Consulting Table I we get the CG series $F\times F=A_0+A_1+A_{-1}+2F$.

In this way we can easily obtain the following results.

$$\begin{gathered}A_{\mu_1}\times A_{\mu_2}=A_{\mu_1+\mu_2},\qquad A_\mu\times F=F,\quad \mu=0,\pm1,\\ F\times F=A_0+A_1+A_{-1}+2F,\\ F\times E_\nu=E_{1/2}+E_{3/2}+E_{-3/2},\quad \nu=\frac{1}{2},\pm\frac{3}{2},\\ A_{\pm1}\times(E_{1/2},E_{\pm3/2},E_{\mp3/2})=(E_{\pm3/2},E_{\mp3/2},E_{1/2}),\\ E_{\nu_1}\times E_{\nu_2}=A_\mu+F,\end{gathered}\tag{19a}$$

with μ given by

(ν_1,ν_2)	$(\frac{1}{2},\frac{1}{2})$	$(\frac{3}{2},-\frac{3}{2})$	$(\frac{1}{2},\frac{3}{2})$	$(-\frac{3}{2},-\frac{3}{2})$	$(\frac{1}{2},-\frac{3}{2})$	$(\frac{3}{2},\frac{3}{2})$
μ	0	0	1	1	-1	-1

(19b)

Using the eigenvalue λ as the irrep label, the last CG series can be written in a concise form:

$$(\lambda_1)\times(\lambda_2)=A_\mu+F,\quad \rho_\mu=\frac{1}{4}\lambda_1\lambda_2,\tag{20}$$

where $\lambda=2,\ 2\exp(-\frac{2}{3}\pi i),\ 2\exp(\frac{2}{3}\pi i)$ for the irrep $E_{1/2},E_{3/2},E_{-3/2}$.

B. The $T\supset C_3$ CG coefficients

Applying (18) to an appropriate initial state $|\lambda_1\overline{\mu_1}\lambda_2\overline{\mu_2}\rangle$ and using the CG series (19) we can obtain the CG coefficients easily. For the group T there is no multiplicity except that the irrep F occurs twice in the product $F\times F$. Therefore we will omit the multiplicity label $\overline{\mu_1}\overline{\mu_2}$ except for the irrep F in $F\times F$.

(1) $A_{\mu_1}\times A_{\mu_2}=A_{\mu_1+\mu_2}$,

$$\Psi^{A_{\mu_1+\mu_2}}=|A_{\mu_1},A_{\mu_2}\rangle,\tag{21a}$$

(2) $A_{\mu_1}\times F=F$,

$$\Psi^{F}_{\mu_1+\mu_2}=|A_{\mu_1},F\mu_2\rangle,\tag{21b}$$

(3) $A_{\mu_1}\times E_\nu=E_{\nu'}$,

$$\Psi^{E_{\nu'}}_{\mu_1+\mu_2}=|A_{\mu_1},E_\nu\mu_2\rangle,\tag{21c}$$

(4) $F\times F=A_1+A_0+A_{-1}+2F$,

TABLE II. The trial states $|\bar{\mu}_1\bar{\mu}_2\rangle$ used in (22b) and (22c).

$F\times E_{1/2}$:	$E_{1/2}$	$\|0,\frac{1}{2}\rangle$,	$E_{3/2}$	$\|1,\frac{1}{2}\rangle$, $E_{-3/2}\|1,\frac{1}{2}\rangle$
$F\times E_{3/2}$:	$E_{1/2}$	$\|0,\frac{1}{2}\rangle$,	$E_{3/2}$	$\|0,\frac{3}{2}\rangle$, $E_{-3/2}\|0,\frac{3}{2}\rangle$
$F\times E_{-3/2}$:	$E_{1/2}$	$\|1,-\frac{1}{2}\rangle$,	$E_{3/2}$	$\|0,\frac{3}{2}\rangle$, $E_{-3/2}\|0,\frac{3}{2}\rangle$
$E_{1/2}\times E_{1/2}$:	A_0	$\|\frac{1}{2},-\frac{1}{2}\rangle$,	F	$\|\frac{1}{2},-\frac{1}{2}\rangle$
$E_{1/2}\times E_{3/2}$:	A_1	$\|\frac{1}{2},\frac{1}{2}\rangle$,	F	$\|-\frac{1}{2},\frac{1}{2}\rangle$
$E_{1/2}\times E_{-3/2}$:	A_{-1}	$\|-\frac{1}{2},-\frac{1}{2}\rangle$,	F	$\|\frac{1}{2},-\frac{1}{2}\rangle$
$E_{3/2}\times E_{3/2}$:	A_{-1}	$\|\frac{1}{2},\frac{3}{2}\rangle$,	F	$\|\frac{3}{2},\frac{3}{2}\rangle$
$E_{3/2}\times E_{-3/2}$:	A_0	$\|\frac{1}{2},-\frac{1}{2}\rangle$,	F	$\|\frac{1}{2},-\frac{1}{2}\rangle$
$E_{-3/2}\times E_{-3/2}$:	A_1	$\|-\frac{1}{2},\frac{3}{2}\rangle$,	F	$\|\frac{3}{2},\frac{3}{2}\rangle$

$$\Psi^{A_\mu}=|F0,F\mu\rangle+3\sum_{\mu_1,\mu_2}{}'d^{(F)}_{\mu_1 0}d^{(F)}_{\mu_2\mu}|F\mu_1,F\mu_2\rangle,$$

$$\Psi^{(F)\bar{\mu}_1\bar{\mu}_2}_{\mu}=|F\bar{\mu}_1,F\bar{\mu}_2\rangle\delta_{\mu 0}-(-1)^{\mu}\sum_{\mu_1\mu_2}{}'d^{(F)}_{\mu_1\bar{\mu}_1}d^{(F)}_{\mu_2\bar{\mu}_2}|F\mu_1,F\mu_2\rangle, \tag{22a}$$

where for simplicity we ignore the normalization factor and $d^{(F)}_{\mu\bar{\mu}}=d^{(F)}_{\mu\bar{\mu}}(C_{2z})$. Since the irrep F occurs twice, we need take two initial states, which are chosen as $|F0,F0\rangle$ and $|F1,F-1\rangle$. The two sets of the CG coefficients are not orthogonal. The orthogonalized CG coefficients are listed in Table III.

(5) $F\times E_\nu=\Sigma_{\nu'}E_{\nu'}$

$$\Psi^{E_{\nu'}}_{\mu}=|F\bar{\mu}_1,E_\nu\bar{\mu}_2\rangle\delta_{\mu\nu'}+(-1)^{\mu-1/2+|\nu'|}\sqrt{3}\sum_{\mu_1\mu_2}{}'d^{(F)}_{\mu_1\bar{\mu}_1}d^{(E_\nu)}_{\mu_2\bar{\mu}_2}|F\mu_1,E_\nu\mu_2\rangle,$$

$$\bar{\mu}_1+\bar{\mu}_2\doteq\nu'. \tag{22b}$$

(6) $E_{\nu_1}\times E_{\nu_2}=A_\mu+F$, or $(\lambda_1)\times(\lambda_2)=A_\mu+F$.

$$\Psi^{A_\mu}=|\lambda_1\bar{\mu}_1,\lambda_2\bar{\mu}_2\rangle+3\sum_{\mu_1\mu_2}{}'d^{(\lambda_1)}_{\mu_1\bar{\mu}_1}d^{(\lambda_2)}_{\mu_2\bar{\mu}_2}|\lambda_1\mu_1,\lambda_2\mu_2\rangle,$$

$$\mu\doteq\bar{\mu}_1+\bar{\mu}_2,$$

$$\Psi^{F}_{\mu}=|\lambda_1\bar{\mu}_1,\lambda_2\bar{\mu}_2\rangle\delta_{\mu 0}-(-1)^{\mu}\sum_{\mu_1\mu_2}{}'d^{(\lambda_1)}_{\mu_1\bar{\mu}_1}d^{(\lambda_2)}_{\mu_2\bar{\mu}_2}|\lambda_1\mu_1,\lambda_2\mu_2\rangle,$$

$$\bar{\mu}_1+\bar{\mu}_2\doteq 0. \tag{22c}$$

The initial states $|F\bar{\mu}_1,E_\nu\bar{\mu}_2\rangle$ and $|\lambda_1\bar{\mu}_1,\lambda_2\bar{\mu}_2\rangle$ in cases 5 and 6 are listed in Table II.

From the algebraic expression (22) we easily constructed the numerical table shown in Table III, where only the CG coefficients with $\Gamma_1\leqslant\Gamma_2$ are listed. The CG coefficients have the property that

$$C^{(\Gamma)r,\mu}_{\Gamma_2\mu_2,\Gamma_1\mu_1}=(-1)^{\Gamma_1+\Gamma_2+\Gamma+r}C^{(\Gamma)r,\mu}_{\Gamma_1\mu_1,\Gamma_2\mu_2}, \tag{23}$$

where r is the multiplicity label, $r=0$ for multiplicity free cases, or $r=0,1$ for $F\times F\to F$, and the phase $(-1)^{\Gamma}=1,-1,i$ for the irreps A_μ,F,E_ν, respectively.[14]

It is to be noted that all the $T\supset C_3$ CG coefficients are real.

TABLE III. The CG coefficients of the group chain $T \supset C_3$.

$F \times F$

$$\Psi^{A_0} = \frac{1}{\sqrt{3}}[|00\rangle + |1\,-1\rangle + |-\,11\rangle], \qquad \Psi^{A_1} = \frac{1}{\sqrt{3}}[|01\rangle + |10\rangle + |-\,-1\,1\rangle]$$

$$\Psi^{A_{-1}} = \frac{1}{\sqrt{3}}[|0\,-1\rangle + |-\,10\rangle + |11\rangle],$$

$$\Psi_0^{(F)0} = \sqrt{\tfrac{2}{3}}|00\rangle - \frac{1}{\sqrt{6}}|1\,-1\rangle - \frac{1}{\sqrt{6}}|-\,11\rangle, \qquad \Psi_0^{(F)1} = \frac{1}{\sqrt{2}}[|1\,-1\rangle - |-\,11\rangle]$$

$$\Psi_1^{(F)0} = \sqrt{\tfrac{2}{3}}\,|-1\,-1\rangle - \frac{1}{\sqrt{6}}|10\rangle - \frac{1}{\sqrt{6}}|01\rangle, \qquad \Psi_1^{(F)1} = \frac{1}{\sqrt{2}}[|01\rangle - |10\rangle]$$

$$\Psi_{-1}^{(F)0} = \sqrt{\tfrac{2}{3}}\,|-10\rangle - \frac{1}{\sqrt{6}}|11\rangle - \frac{1}{\sqrt{6}}|0\,-1\rangle, \qquad \Psi_{-1}^{(F)1} = \frac{1}{\sqrt{2}}[|-10\rangle - |0\,-1\rangle]$$

$F \times E_{1/2}$

$$\Psi_{1/2}^{E_{1/2}} = \sqrt{\tfrac{1}{3}}|0\,\tfrac{1}{2}\rangle - \sqrt{\tfrac{2}{3}}|1\,-\tfrac{1}{2}\rangle, \qquad \Psi_{-1/2}^{E_{1/2}} = -\sqrt{\tfrac{2}{3}}|-1\,\tfrac{1}{2}\rangle - \sqrt{\tfrac{1}{3}}|0\,-\tfrac{1}{2}\rangle$$

$$\Psi_{1/2}^{E_{3/2}} = \sqrt{\tfrac{2}{3}}|0\,\tfrac{1}{2}\rangle + \sqrt{\tfrac{1}{3}}|1\,-\tfrac{1}{2}\rangle, \qquad \Psi_{3/2}^{E_{3/2}} = -\sqrt{\tfrac{1}{3}}|1\,\tfrac{1}{2}\rangle + \sqrt{\tfrac{2}{3}}|-1\,-\tfrac{1}{2}\rangle$$

$$\Psi_{-1/2}^{E_{-3/2}} = \sqrt{\tfrac{2}{3}}|0\,-\tfrac{1}{2}\rangle - \sqrt{\tfrac{1}{3}}|-1\,\tfrac{1}{2}\rangle, \qquad \Psi_{3/2}^{E_{-3/2}} = -\sqrt{\tfrac{2}{3}}|1\,\tfrac{1}{2}\rangle - \sqrt{\tfrac{1}{3}}|-1\,-\tfrac{1}{2}\rangle$$

$F \times E_{3/2}$

$$\Psi_{1/2}^{E_{1/2}} = \sqrt{\tfrac{2}{3}}|0\,\tfrac{1}{2}\rangle - \sqrt{\tfrac{1}{3}}|-1\,\tfrac{3}{2}\rangle, \qquad \Psi_{-1/2}^{E_{1/2}} = \sqrt{\tfrac{1}{3}}|-1\,\tfrac{1}{2}\rangle + \sqrt{\tfrac{2}{3}}|1\,\tfrac{3}{2}\rangle$$

$$\Psi_{1/2}^{E_{3/2}} = \sqrt{\tfrac{1}{3}}|0\,\tfrac{1}{2}\rangle + \sqrt{\tfrac{2}{3}}|-1\,\tfrac{3}{2}\rangle, \qquad \Psi_{3/2}^{E_{3/2}} = \sqrt{\tfrac{2}{3}}|1\,\tfrac{1}{2}\rangle - \sqrt{\tfrac{1}{3}}|0\,\tfrac{3}{2}\rangle$$

$$\Psi_{-1/2}^{E_{-3/2}} = -\sqrt{\tfrac{2}{3}}|-1\,\tfrac{1}{2}\rangle + \sqrt{\tfrac{1}{3}}|1\,\tfrac{3}{2}\rangle, \qquad \Psi_{3/2}^{E_{-3/2}} = \sqrt{\tfrac{2}{3}}|0\,\tfrac{3}{2}\rangle + \sqrt{\tfrac{1}{3}}|1\,\tfrac{1}{2}\rangle$$

$F \times E_{-3/2}$

$$\Psi_{1/2}^{E_{1/2}} = -\sqrt{\tfrac{1}{3}}|1\,-\tfrac{1}{2}\rangle - \sqrt{\tfrac{2}{3}}|-1\,\tfrac{3}{2}\rangle, \qquad \Psi_{-1/2}^{E_{1/2}} = \sqrt{\tfrac{2}{3}}|0\,-\tfrac{1}{2}\rangle - \sqrt{\tfrac{1}{3}}|1\,\tfrac{3}{2}\rangle$$

$$\Psi_{1/2}^{E_{3/2}} = \sqrt{\tfrac{1}{3}}|-1\,\tfrac{3}{2}\rangle - \sqrt{\tfrac{2}{3}}|1\,-\tfrac{1}{2}\rangle, \qquad \Psi_{3/2}^{E_{3/2}} = \sqrt{\tfrac{2}{3}}|0\,\tfrac{3}{2}\rangle + \sqrt{\tfrac{1}{3}}|-1\,-\tfrac{1}{2}\rangle$$

$$\Psi_{-1/2}^{E_{-3/2}} = -\sqrt{\tfrac{2}{3}}|1\,\tfrac{3}{2}\rangle - \sqrt{\tfrac{1}{3}}|0\,-\tfrac{1}{2}\rangle, \qquad \Psi_{3/2}^{E_{-3/2}} = \sqrt{\tfrac{1}{3}}|0\,\tfrac{3}{2}\rangle - \sqrt{\tfrac{2}{3}}|-1\,-\tfrac{1}{2}\rangle$$

$E_{1/2} \times E_{1/2}$

$$\Psi^{A_0} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}\,-\tfrac{1}{2}\rangle - |-\tfrac{1}{2}\,\tfrac{1}{2}\rangle],$$

$$\Psi_0^{(F)} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}\,-\tfrac{1}{2}\rangle + |-\tfrac{1}{2}\,\tfrac{1}{2}\rangle], \qquad \Psi_1^{(F)} = |\tfrac{1}{2}\,\tfrac{1}{2}\rangle, \qquad \Psi_{-1}^{(F)} = -|-\tfrac{1}{2}\,-\tfrac{1}{2}\rangle$$

$E_{1/2} \times E_{3/2}$

$$\Psi^{A_1} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}\,\tfrac{1}{2}\rangle - |-\tfrac{1}{2}\,\tfrac{3}{2}\rangle],$$

$$\Psi_0^{(F)} = -|-\tfrac{1}{2}\,\tfrac{1}{2}\rangle, \qquad \Psi_1^{(F)} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}\,\tfrac{1}{2}\rangle + |-\tfrac{1}{2}\,\tfrac{3}{2}\rangle], \qquad \Psi_{-1}^{(F)} = |\tfrac{1}{2}\,\tfrac{3}{2}\rangle$$

$E_{1/2} \times E_{-3/2}$

$$\Psi^{A_{-1}} = \frac{1}{\sqrt{2}}[|-\tfrac{1}{2}\,-\tfrac{1}{2}\rangle + |\tfrac{1}{2}\,\tfrac{3}{2}\rangle],$$

$$\Psi_0^{(F)} = -|\tfrac{3}{2}\,\tfrac{3}{2}\rangle, \qquad \Psi_1^{(F)} = |\tfrac{1}{2}\,\tfrac{1}{2}\rangle, \qquad \Psi_{-1}^{(F)} = -\frac{1}{\sqrt{2}}[|\tfrac{1}{2}\,\tfrac{3}{2}\rangle + |\tfrac{3}{2}\,\tfrac{1}{2}\rangle]$$

$E_{3/2} \times E_{-3/2}$

$$\Psi^{A_0} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}\,-\tfrac{1}{2}\rangle + |\tfrac{3}{2}\,\tfrac{3}{2}\rangle],$$

$$\Psi_0^{(F)} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}\,-\tfrac{1}{2}\rangle - |\tfrac{3}{2}\,\tfrac{3}{2}\rangle], \qquad \Psi_1^{(F)} = |\tfrac{3}{2}\,-\tfrac{1}{2}\rangle, \qquad \Psi_{-1}^{(F)} = |\tfrac{1}{2}\,\tfrac{3}{2}\rangle$$

$E_{-3/2} \times E_{-3/2}$

$$\Psi^{A_1} = \frac{1}{\sqrt{2}}[|-\tfrac{1}{2}\,\tfrac{3}{2}\rangle - |\tfrac{3}{2}\,-\tfrac{1}{2}\rangle],$$

$$\Psi_0^{(F)} = -|\tfrac{3}{2}\,\tfrac{3}{2}\rangle, \qquad \Psi_1^{(F)} = -\frac{1}{\sqrt{2}}[|\tfrac{3}{2}\,-\tfrac{1}{2}\rangle + |-\tfrac{1}{2}\,\tfrac{3}{2}\rangle], \qquad \Psi_{-1}^{(F)} = |-\tfrac{1}{2}\,-\tfrac{1}{2}\rangle$$

IV. THE $T\supset D_2\supset C_2$ CG COEFFICIENTS

The group chain $T\supset D_2\supset C_2$ is a little bit more complicated than $T\supset C_3$ in that for the s. v. reps, the subgroup C_2 is redundant, while for the d. v. reps, the subgroup D_2 is redundant. In other words, we actually use two different group chains, $T\supset D_2$ and $T\supset C_2$, for the s. v. and d. v. reps of T, respectively. In this section we need to use the ISO's, instead of the effective ISO's. Now the axis of C_{2z} is chosen as the z axis. The $T\supset D_2$ generalized projection operators have been found in (14a) and (15c) of Ref. 13 and are cited in the following,

1. One-dimensional s. v. irreps:

$$\mathbf{P}^{(A_\mu)}=P^{\rho_\mu}\wp^{++},\quad \mu=0,\pm 1, \tag{24a}$$

where P^{ρ_μ} and $\wp^{\nu\nu'}$ are the projection operators of C_3 and D_2, respectively,

$$\wp^{\nu\nu'}=(e+\nu C_{2x})(e+\nu' C_{2y}),\quad \nu,\nu'=\pm 1. \tag{24b}$$

The set of eigenvalues $(\nu\nu')=(++),(+-),(-+),(--)$ can be used to label the four s. v. irreps of D_2.

2. Three-dimensional s. v. irrep:

From the third column in the matrix given in (15c) of Ref. 13 and using (15a) in Ref. 13 we have

$$\begin{cases}\mathbf{P}_x^{(F)}=C_{31}^{+}\wp^{--},\\ \mathbf{P}_y^{(F)}=C_{31}^{-}\wp^{--},\\ \mathbf{P}_z^{(F)}=\wp^{--},\end{cases} \tag{24c}$$

where the components x,y,z have the quantum numbers $(\nu\nu')=(+-,-+,--)$, respectively.

The irreducible matrix of C_{31}^{+} is given in (16) of Ref. 13,

$$\mathscr{D}^F(C_{31}^{+})=\tilde{\mathscr{D}}^F(C_{31}^{-})=\begin{pmatrix}0&0&1\\1&0&0\\0&1&0\end{pmatrix}. \tag{24d}$$

3. Two-dimensional d. v. irreps:

From (36) in Ref. 13 we have the $T\supset C_2$ generalized projection operators,

$$\begin{cases}\mathbf{P}_{1/2}^{(\lambda)}=P^{1/2}+\dfrac{1}{2\sqrt{2}}P^{1/2}(i^{-1/2}\lambda C_{31}^{-}+i^{1/2}\lambda^{*}C_{31}^{+})P^{1/2},\\ \mathbf{P}_{-1/2}^{(\lambda)}=\sqrt{i}C_{2x}P^{1/2}-\dfrac{1}{2\sqrt{2}}P^{-1/2}(\lambda C_{31}^{-}-\lambda^{*}C_{31}^{+})P^{1/2},\end{cases} \tag{25}$$

where $P^{\pm 1/2}$ are the projection operators of C_2, $P^{\sigma}=1+\varrho_\sigma^{*}C_{2z}$, with $\varrho_\sigma=\exp(-\pi\sigma i)$, and $\lambda=2$, $2\epsilon\equiv 2\exp(-\frac{2}{3}\pi i)$, $2\epsilon^{*}$ for the irreps $E_{1/2}$, $E_{3/2}$ and $E_{-3/2}$, respectively. Recall that μ, ν, ν', and σ are the quantum numbers of C_{31}^{+}, C_{2x}, C_{2y}, and C_{2z}, respectively.

The irreducible matrices of $C_{31}^{\pm}$, C_{2x}, C_{2y} are listed in Eq. (37) of Ref. 13

$$D^{(\lambda)}(C_{31}^{+})=\tilde{D}^{(\lambda)}(C_{31}^{-})^{*}=\frac{\lambda}{2\sqrt{2}}\begin{pmatrix}\sqrt{i^{*}}, & -1\\ 1, & \sqrt{i}\end{pmatrix}, \tag{26a}$$

$$D^{(\lambda)}(C_{2x})=-\tilde{D}^{(\lambda)}(C_{2y})=\begin{pmatrix}0 & i\sqrt{i}\\ \sqrt{i} & 0\end{pmatrix}^{*}. \tag{26b}$$

The CG coefficients for the three cases are found in the following way.

A. s. v.×s. v.→s. v. reps

The projection operators for the s. v. irreps of T in (24a) and (24c) can be written as $\mathbf{P}^{(\Gamma)}=O^{\Gamma}\wp^{\nu\nu'}$, where O^{Γ} is an operator depending on Γ, and $(\nu\nu')=(++)$ and $(--)$ for $\Gamma=A_{\mu}$ and $\Gamma=F$, respectively. The quantum numbers of the initial state $|\Gamma_1\nu_1\nu_1',\Gamma_2\nu_2\nu_2'\rangle$ have to obey the following conditions:

$$\nu_1\nu_2=\nu, \quad \nu_1'\nu_2'=\nu'. \tag{27}$$

Equation (27) is crucial for choosing the initial state. Notice that the quantum numbers $(\nu\nu')=(++)$ for the states $|A_{\mu}\rangle$ and $\nu\nu'=+-,-+,--$ for the states $|Fx\rangle,|Fy\rangle,|Fz\rangle$, respectively.

(1) $A_{\mu_1}\times A_{\mu_2}=A_{\mu_1+\mu_2}$. Equation (21a) still holds.

(2) $A_{\mu}\times F=F,\ \mu=0,\pm1$.

Applying (24c) to the state $|A_{\mu},Fz\rangle$ which has $(\nu\nu')=(--)$ and using (24d), we obtain

$$\Psi_k^F=\rho_{\mu}^{\kappa}|A_{\mu},Fk\rangle, \quad k=x,y,z, \tag{28a}$$

where $\kappa=1,2,3$ for $k=x,y,z$, respectively.

(3) $F\times F=A_0+A_1+A_{-1}+2F$.

Applying (24a) to the state $|Fx,Fx\rangle$ with $(\nu\nu')=(++)$, and (24c) to the states $|Fx,Fy\rangle \pm|Fy,Fx\rangle$ which has $(\nu\nu')=(--)$, we obtain the CG coefficients of irrep A_{μ} and F, respectively,

$$\Psi^{A_{\mu}}=\frac{1}{\sqrt{3}}[|Fx,Fx\rangle+\rho_{\mu}^{*}|Fy,Fy\rangle+\rho_{\mu}|Fz,Fz\rangle],$$

$$\Psi_z^{(F)r}=\sqrt{\frac{1}{2}}\,[|Fx,Fy\rangle+(-1)^r|Fy,Fx\rangle], \quad r=0,1; \quad x,y,z \text{ in cyclic.} \tag{28b}$$

B. s. v.×d. v.→d. v. reps

The projection operators in (25) have the intrinsic quantum number[13] $\bar{\sigma}=\frac{1}{2}$, therefore the quantum numbers of the initial state $|\Gamma_1\bar{\sigma}_1,\Gamma_2\bar{\sigma}_2\rangle$ have to obey

$$\bar{\sigma}_1+\bar{\sigma}_2=\frac{1}{2}.$$

The quantum number σ of C_{2z} is not explicitly given for the s. v. irreducible basis vectors and needs to be found out in the following way: Since in the states $|A_{\mu}\rangle$ $(\mu=0,\pm1)$ and $|Fz\rangle$, the operator C_{2z} has the eigenvalue $\varrho_{\sigma}=\exp(-\pi\sigma i)=1$, these states have $\sigma=0$.

(1) $A_{\mu}\times E_{\nu}=E_{\nu'}$.

We choose the state $|A_{\mu},E_{\nu\frac{1}{2}}\rangle$ which has $\sigma=\frac{1}{2}$ as the initial state for projection. Using (25) we have

$$\Psi_{\sigma}^{(E_{\nu'})}=|A_{\mu},E_{\nu}\sigma\rangle. \tag{29a}$$

(2) $F\times E_{\nu}=\Sigma_{\nu'}E_{\nu'}$, or $F\times(\lambda)=\Sigma_{\lambda'}(\lambda')$

Similarly, choosing $|Fz,\lambda\frac{1}{2}\rangle$ as the initial state for projection we obtain,

$$\Psi_{1/2}^{(\lambda')}=\frac{1}{\sqrt{3}}\left[\left|Fz,\lambda\,\frac{1}{2}\right\rangle-\frac{1}{4}\left(i^{-1/2}\lambda'\lambda^{*}\left|Fy,\lambda-\frac{1}{2}\right\rangle-i^{1/2}\lambda'^{*}\lambda\left|Fx,\lambda-\frac{1}{2}\right\rangle\right)\right],$$

$$\Psi_{-1/2}^{(\lambda')}=\frac{1}{\sqrt{3}}\left[-\left|Fz,\lambda-\frac{1}{2}\right\rangle-\frac{1}{4}\left(i^{1/2}\lambda'\lambda^{*}\left|Fy,\lambda\,\frac{1}{2}\right\rangle-i^{-1/2}\lambda'^{*}\lambda\left|Fx,\lambda\,\frac{1}{2}\right\rangle\right)\right]. \tag{29b}$$

C. d. v.×d. v.→s. v. reps

We now consider $(\lambda_1)\times(\lambda_2)=A_\mu+F$. From (26) we have

$$C_{2x}\left|\lambda_1\,\frac{1}{2},\lambda_2-\frac{1}{2}\right\rangle=-\left|\lambda_1-\frac{1}{2},\lambda_2\,\frac{1}{2}\right\rangle,\quad C_{2y}\left|\lambda_1\,\frac{1}{2},\lambda_2-\frac{1}{2}\right\rangle=-\left|\lambda_1-\frac{1}{2},\lambda_2\,\frac{1}{2}\right\rangle. \tag{29c}$$

Applying (24a) to the state $|\lambda_1\,\frac{1}{2},\lambda_2-\frac{1}{2}\rangle$ and using (24b) and (29c) we obtain compact expressions for the CG coefficients of the irrep A_μ and F,

$$\begin{cases}\Psi^{A_\mu}=\dfrac{1}{\sqrt{2}}\left(\left|\lambda_1\,\dfrac{1}{2},\lambda_2-\dfrac{1}{2}\right\rangle-\left|\lambda_1-\dfrac{1}{2},\lambda_2\,\dfrac{1}{2}\right\rangle\right)\delta_{\rho_\mu,\lambda_1\lambda_2/4},\\ \Psi_x^F=-\dfrac{\lambda_1\lambda_2}{4\sqrt{2}}i^{-1/2}\left(\left|\lambda_1\dfrac{1}{2},\lambda_2\dfrac{1}{2}\right\rangle-i\left|\lambda_1-\dfrac{1}{2},\lambda_2-\dfrac{1}{2}\right\rangle\right),\\ \Psi_y^F=\dfrac{\lambda_1^*\lambda_2^*}{4\sqrt{2}}i^{1/2}\left(\left|\lambda_1\,\dfrac{1}{2},\lambda_2\,\dfrac{1}{2}\right\rangle+i\left|\lambda_1-\dfrac{1}{2},\lambda_2-\dfrac{1}{2}\right\rangle\right),\\ \Psi_z^F=\dfrac{1}{\sqrt{2}}\left(\left|\lambda_1\,\dfrac{1}{2},\lambda_2-\dfrac{1}{2}\right\rangle+\left|\lambda_1-\dfrac{1}{2},\lambda_2\,\dfrac{1}{2}\right\rangle\right).\end{cases} \tag{29d}$$

Equations (28) and (29) are the algebraic expressions for the $T\supset D_2\supset C_2$ CG coefficients. From (29) we can easily obtain the numerical results as listed in Table IV. It is seen that some of the CG coefficients are imaginary, in agreement with the assertion of Butler[26] that some $3jm$ factors of $T\supset D_2$ must be complex. However, the $T\supset C_2$ CG coefficients can be chosen to be all real, as shown in Ref. 16. In the next section, we are going to derive the algebraic expressions for the $T\supset C_2$ real CG coefficients.

V. THE $T\supset C_2$ CG COEFFICIENTS

The group chain $T\supset C_2$ is not canonical for the s. v. reps, as is seen from the fact that both the projection operators $\mathbf{P}_x^{(F)}$ and $\mathbf{P}_y^{(F)}$ in (24c) have $C_{2z}=-1$. They can be linearly combined into the two new operators $\mathbf{P}_1^{(F)}$ and $\mathbf{P}_2^{(F)}$ so that $\mathbf{P}_1^{(F)},\mathbf{P}_2^{(F)},\mathbf{P}_3^{(F)}(=\mathbf{P}_z^{(F)})$ carry the irrep F which is identical to that of Ref. 16.

$$\mathbf{P}_1^{(F)}=\frac{1}{\sqrt{2}}[i^{3/2}C_{31}^{+}+i^{-3/2}C_{31}^{-}]\wp^{--},$$

$$\mathbf{P}_2^{(F)}=-\frac{i}{\sqrt{2}}[i^{3/2}C_{31}^{+}-i^{-3/2}C_{31}^{-}]\wp^{--},\qquad \mathbf{P}_3^{(F)}=\wp^{--}, \tag{30}$$

where the projection operators of components 1,2,3 have the quantum numbers $C_{2z}=-1,-1,1$ or $\sigma=1,1,0$, respectively [recall $\varrho_\sigma=\exp(-\pi\sigma i)$].

The corresponding irreducible matrices of C_{2z}, C_{2x}, C_{31}^{+} and C_{31}^{-} are

$$D^{(F)}(C_{2z})=\begin{pmatrix}-1&0&0\\0&-1&0\\0&0&1\end{pmatrix},\quad D^{(F)}(C_{2x})=\begin{pmatrix}0&-i&0\\i&0&0\\0&0&-1\end{pmatrix},$$
$$D^{(F)}(C_{31}^{+})=\tilde{D}^{(F)*}(C_{31}^{-})=\frac{1}{2}\begin{pmatrix}-i&-1&-\sqrt{2i}\\-1&i&\sqrt{2i^*}\\-\sqrt{2i}&\sqrt{2i^*}&0\end{pmatrix}. \tag{31}$$

We also change the phase factor of the d. v. projection operator $\mathbf{P}_{-1/2}^{(\lambda)}$ in (25) by multiplying it with i, i.e., the new d. v. projection operators are

TABLE IV. The CG coefficients of $T \supset D_2 \supset C_2$.

$F \times E_{1/2}$

$$\Psi_{1/2}^{(E_{1/2})} = \frac{1}{\sqrt{3}}[|z\tfrac{1}{2}\rangle - i^{-1/2}|y-\tfrac{1}{2}\rangle + i^{1/2}|x-\tfrac{1}{2}\rangle], \qquad \Psi_{-1/2}^{(E_{1/2})} = \frac{1}{\sqrt{3}}[-|z-\tfrac{1}{2}\rangle - i^{1/2}|y\tfrac{1}{2}\rangle + i^{-1/2}|x\tfrac{1}{2}\rangle]$$

$$\Psi_{1/2}^{(E_{3/2})} = \frac{1}{\sqrt{3}}[|z\tfrac{1}{2}\rangle - i^{-1/2}\epsilon|y-\tfrac{1}{2}\rangle + i^{1/2}\epsilon^*|x-\tfrac{1}{2}\rangle], \qquad \Psi_{-1/2}^{(E_{3/2})} = \frac{1}{\sqrt{3}}[-|z-\tfrac{1}{2}\rangle - i^{1/2}\epsilon|y\tfrac{1}{2}\rangle + i^{-1/2}\epsilon^*|x\tfrac{1}{2}\rangle]$$

$$\Psi_{1/2}^{(E_{-3/2})} = \frac{1}{\sqrt{3}}[|z\tfrac{1}{2}\rangle - i^{-1/2}\epsilon^*|y-\tfrac{1}{2}\rangle + i^{1/2}\epsilon|x-\tfrac{1}{2}\rangle], \qquad \Psi_{-1/2}^{(E_{-3/2})} = \frac{1}{\sqrt{3}}[-|z-\tfrac{1}{2}\rangle - i^{1/2}\epsilon^*|y\tfrac{1}{2}\rangle + i^{-1/2}\epsilon|x\tfrac{1}{2}\rangle]$$

$F \times E_{3/2}$

$$\Psi_{1/2}^{(E_{1/2})} = \frac{1}{\sqrt{3}}[|z\tfrac{1}{2}\rangle - i^{-1/2}\epsilon^*|y-\tfrac{1}{2}\rangle + i^{1/2}\epsilon|x-\tfrac{1}{2}\rangle], \qquad \Psi_{-1/2}^{(E_{1/2})} = \frac{1}{\sqrt{3}}[-|z-\tfrac{1}{2}\rangle - i^{1/2}\epsilon^*|y\tfrac{1}{2}\rangle + i^{-1/2}\epsilon|x\tfrac{1}{2}\rangle]$$

$$\Psi_{1/2}^{(E_{3/2})} = \frac{1}{\sqrt{3}}[|z\tfrac{1}{2}\rangle - i^{-1/2}|y-\tfrac{1}{2}\rangle + i^{1/2}|x-\tfrac{1}{2}\rangle], \qquad \Psi_{-1/2}^{(E_{3/2})} = \frac{1}{\sqrt{3}}[-|z-\tfrac{1}{2}\rangle - i^{1/2}|y\tfrac{1}{2}\rangle + i^{-1/2}|x\tfrac{1}{2}\rangle]$$

$$\Psi_{1/2}^{(E_{-3/2})} = \frac{1}{\sqrt{3}}[|z\tfrac{1}{2}\rangle - i^{-1/2}\epsilon|y-\tfrac{1}{2}\rangle + i^{1/2}\epsilon^*|x-\tfrac{1}{2}\rangle], \qquad \Psi_{-1/2}^{(E_{-3/2})} = \frac{1}{\sqrt{3}}[-|z-\tfrac{1}{2}\rangle - i^{1/2}\epsilon|y\tfrac{1}{2}\rangle + i^{-1/2}\epsilon^*|x\tfrac{1}{2}\rangle]$$

$F \times E_{-3/2}$

$$\Psi_{1/2}^{(E_{1/2})} = \frac{1}{\sqrt{3}}[|z\tfrac{1}{2}\rangle - i^{-1/2}\epsilon|y-\tfrac{1}{2}\rangle + i^{1/2}\epsilon^*|x-\tfrac{1}{2}\rangle], \qquad \Psi_{-1/2}^{(E_{1/2})} = \frac{1}{\sqrt{3}}[-|z-\tfrac{1}{2}\rangle - i^{1/2}\epsilon|y\tfrac{1}{2}\rangle + i^{-1/2}\epsilon^*|x\tfrac{1}{2}\rangle]$$

$$\Psi_{1/2}^{(E_{3/2})} = \frac{1}{\sqrt{3}}[|z\tfrac{1}{2}\rangle - i^{-1/2}\epsilon^*|y-\tfrac{1}{2}\rangle + i^{1/2}\epsilon|x-\tfrac{1}{2}\rangle], \qquad \Psi_{-1/2}^{(E_{3/2})} = \frac{1}{\sqrt{3}}[-|z-\tfrac{1}{2}\rangle - i^{1/2}\epsilon^*|y\tfrac{1}{2}\rangle + i^{-1/2}\epsilon|x\tfrac{1}{2}\rangle]$$

$$\Psi_{1/2}^{(E_{-3/2})} = \frac{1}{\sqrt{3}}[|z\tfrac{1}{2}\rangle - i^{-1/2}|y-\tfrac{1}{2}\rangle + i^{1/2}|x-\tfrac{1}{2}\rangle], \qquad \Psi_{-1/2}^{(E_{-3/2})} = \frac{1}{\sqrt{3}}[-|z-\tfrac{1}{2}\rangle - i^{1/2}|y\tfrac{1}{2}\rangle + i^{-1/2}|x\tfrac{1}{2}\rangle]$$

$E_{1/2} \times E_{1/2}$

$$\Psi^{A_0} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle - |-\tfrac{1}{2}\tfrac{1}{2}\rangle], \qquad \Psi_x^{(F)} = -i^{-1/2}\frac{1}{\sqrt{2}}[|\tfrac{1}{2}\tfrac{1}{2}\rangle - i|-\tfrac{1}{2}-\tfrac{1}{2}\rangle]$$

$$\Psi_y^{(F)} = i^{1/2}\frac{1}{\sqrt{2}}[|\tfrac{1}{2}\tfrac{1}{2}\rangle + i|-\tfrac{1}{2}-\tfrac{1}{2}\rangle], \qquad \Psi_z^{(F)} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle + |-\tfrac{1}{2}\tfrac{1}{2}\rangle]$$

$E_{1/2} \times E_{3/2}$

$$\Psi^{A_1} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle - |-\tfrac{1}{2}\tfrac{1}{2}\rangle], \qquad \Psi_x^{(F)} = -i^{-1/2}\epsilon\frac{1}{\sqrt{2}}[|\tfrac{1}{2}\tfrac{1}{2}\rangle - i|-\tfrac{1}{2}-\tfrac{1}{2}\rangle]$$

$$\Psi_y^{(F)} = i^{1/2}\epsilon^*\frac{1}{\sqrt{2}}[|\tfrac{1}{2}\tfrac{1}{2}\rangle + i|-\tfrac{1}{2}-\tfrac{1}{2}\rangle], \qquad \Psi_z^{(F)} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle + |-\tfrac{1}{2}\tfrac{1}{2}\rangle]$$

$E_{1/2} \times E_{-3/2}$

$$\Psi^{A_{-1}} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle - |-\tfrac{1}{2}\tfrac{1}{2}\rangle], \qquad \Psi_x^{(F)} = -i^{-1/2}\epsilon^*\frac{1}{\sqrt{2}}[|\tfrac{1}{2}\tfrac{1}{2}\rangle - i|-\tfrac{1}{2}-\tfrac{1}{2}\rangle]$$

$$\Psi_y^{(F)} = i^{1/2}\epsilon\frac{1}{\sqrt{2}}[|\tfrac{1}{2}\tfrac{1}{2}\rangle + i|-\tfrac{1}{2}-\tfrac{1}{2}\rangle], \qquad \Psi_z^{(F)} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle + |-\tfrac{1}{2}\tfrac{1}{2}\rangle]$$

$E_{3/2} \times E_{3/2}$

$$\Psi^{A_{-1}} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle - |-\tfrac{1}{2}\tfrac{1}{2}\rangle], \qquad \Psi_x^{(F)} = -i^{-1/2}\epsilon^*\frac{1}{\sqrt{2}}[|\tfrac{1}{2}\tfrac{1}{2}\rangle - i|-\tfrac{1}{2}-\tfrac{1}{2}\rangle]$$

$$\Psi_y^{(F)} = i^{1/2}\epsilon\frac{1}{\sqrt{2}}[|\tfrac{1}{2}\tfrac{1}{2}\rangle + i|-\tfrac{1}{2}-\tfrac{1}{2}\rangle], \qquad \Psi_z^{(F)} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle + |-\tfrac{1}{2}\tfrac{1}{2}\rangle]$$

$E_{3/2} \times E_{-3/2}$

$$\Psi^{A_0} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle - |-\tfrac{1}{2}\tfrac{1}{2}\rangle], \qquad \Psi_x^{(F)} = -i^{-1/2}\frac{1}{\sqrt{2}}[|\tfrac{1}{2}\tfrac{1}{2}\rangle - i|-\tfrac{1}{2}-\tfrac{1}{2}\rangle]$$

$$\Psi_y^{(F)} = i^{1/2}\frac{1}{\sqrt{2}}[|\tfrac{1}{2}\tfrac{1}{2}\rangle + i|-\tfrac{1}{2}-\tfrac{1}{2}\rangle], \qquad \Psi_z^{(F)} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle + |-\tfrac{1}{2}\tfrac{1}{2}\rangle]$$

$E_{-3/2} \times E_{-3/2}$

$$\Psi^{A_1} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle - |-\tfrac{1}{2}\tfrac{1}{2}\rangle], \qquad \Psi_x^{(F)} = -i^{-1/2}\epsilon\frac{1}{\sqrt{2}}[|\tfrac{1}{2}\tfrac{1}{2}\rangle - i|-\tfrac{1}{2}-\tfrac{1}{2}\rangle]$$

$$\Psi_y^{(F)} = i^{1/2}\epsilon^*\frac{1}{\sqrt{2}}[|\tfrac{1}{2}\tfrac{1}{2}\rangle + i|-\tfrac{1}{2}-\tfrac{1}{2}\rangle], \qquad \Psi_z^{(F)} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle + |-\tfrac{1}{2}\tfrac{1}{2}\rangle]$$

$\epsilon = \exp(-2\pi i/3)$.

$$\mathbf{P}^{(\lambda)}_{1/2}=P^{1/2}+\frac{1}{2\sqrt{2}}P^{1/2}(i^{-1/2}\lambda C^{-}_{31}+i^{1/2}\lambda^{*}C^{+}_{31})P^{1/2},$$
$$\mathbf{P}^{(\lambda)}_{-1/2}=i^{3/2}C_{2x}P^{1/2}-\frac{i}{2\sqrt{2}}P^{-1/2}(\lambda C^{-}_{31}-\lambda^{*}C^{+}_{31})P^{1/2}. \tag{32}$$

The irreducible matrices of C_{2x}, C^{+}_{31} and C^{-}_{31} in (26) are changed into

$$D^{(\lambda)}(C^{+}_{31})=\tilde{D}^{(\lambda)*}(C^{-}_{31})=\frac{\lambda}{2\sqrt{2}}\begin{pmatrix}\sqrt{i^{*}} & -i\\ -i & \sqrt{i}\end{pmatrix} \tag{33a}$$

$$D^{(\lambda)}(C_{2x})=-\tilde{D}^{(\lambda)}(C_{2y})=\begin{pmatrix}0, & \sqrt{i}\\ i\sqrt{i}, & 0\end{pmatrix}^{*}. \tag{33b}$$

From (31) and (33a) it is seen that the irreducible matrices of C^{+}_{31} and C^{-}_{31} are symmetric now.

Applying the generalized ISO's to appropriate trial states, we can obtain the CG coefficients easily.

A. s. v.×s. v.→s. v. reps

(1) $A_{\mu_1}\times A_{\mu_2}$ remains the same as (21a).

(2) $A_{\mu}\times F=F$.

Applying (30) to the trial state $|A_{\mu},F3\rangle$ with $\nu\nu'=--$ and using (31), we obtain

$$\Psi^{(F)}_{1}=\cos\left(\frac{2\mu\pi}{3}\right)|A_{\mu},F1\rangle+\sin\left(\frac{2\mu\pi}{3}\right)|A_{\mu},F2\rangle,$$
$$\Psi^{(F)}_{2}=-\sin\left(\frac{2\mu\pi}{3}\right)|A_{\mu},F1\rangle+\cos\left(\frac{2\mu\pi}{3}\right)|A_{\mu},F2\rangle,\qquad \Psi^{(F)}_{3}=|A_{\mu},F3\rangle. \tag{34a}$$

(3) $F\times F=A_0+A_1+A_{-1}+2F$.

Applying $\mathbf{P}^{(A_\mu)}$ in (24a) to the trial states $|33\rangle\equiv|F3,F3\rangle$ with $\nu\nu'=++$, we obtain

$$\Psi^{(A_\mu)}=\frac{1}{\sqrt{3}}[|33\rangle-\Re e(i\rho_\mu)(|11\rangle-|22\rangle)-\Re e(\rho_\mu)(|12\rangle+|21\rangle)]. \tag{34b}$$

From (31) we have

$$C_{2x}|F1\rangle=i|F2\rangle,\quad C_{2x}|F2\rangle=-i|F1\rangle,$$
$$C_{2y}|F1\rangle=-i|F2\rangle,\quad C_{2y}|F2\rangle=i|F1\rangle. \tag{34c}$$

From (34c) we know that both the states $|12\rangle-|21\rangle$ and $|11\rangle+|22\rangle$ have $\nu\nu'=--$. Applying (30) to $|11\rangle+|22\rangle$ and $|12\rangle-|21\rangle$, we obtain

$$\Psi^{(F)0}_{1}=-\frac{1}{\sqrt{2}}[|23\rangle+|32\rangle],\quad \Psi^{(F)1}_{1}=\frac{1}{\sqrt{2}}[|13\rangle-|31\rangle],$$
$$\Psi^{(F)0}_{2}=-\frac{1}{\sqrt{2}}[|13\rangle+|31\rangle],\quad \Psi^{(F)1}_{2}=\frac{1}{\sqrt{2}}[|32\rangle-|23\rangle], \tag{34d}$$
$$\Psi^{(F)0}_{3}=\frac{1}{\sqrt{2}}[|11\rangle+|22\rangle],\quad \Psi^{(F)1}_{3}=\frac{1}{\sqrt{2}}[|12\rangle-|21\rangle].$$

TABLE V. The CG coefficients of $T \supset C_2$.

$F \times F$

$$\Psi^{A_1} = \frac{1}{\sqrt{3}}[|33\rangle - \frac{\sqrt{3}}{2}(|11\rangle - |22\rangle) + \tfrac{1}{2}(|12\rangle + |21\rangle)],$$

$$\Psi^{A_0} = \frac{1}{\sqrt{3}}[|33\rangle - |12\rangle - |21\rangle],$$

$$\Psi^{A_{-1}} = \frac{1}{\sqrt{3}}[|33\rangle + \frac{\sqrt{3}}{2}(|11\rangle - |22\rangle) + \tfrac{1}{2}(|12\rangle + |21\rangle)],$$

$F \times E_{1/2}$

$$\Psi^{(E_{1/2})}_{1/2} = \frac{1}{\sqrt{3}}[|3\,\tfrac{1}{2}\rangle - \sqrt{2}|1-\tfrac{1}{2}\rangle],$$

$$\Psi^{(E_{1/2})}_{-1/2} = \frac{1}{\sqrt{3}}[-|3-\tfrac{1}{2}\rangle + \sqrt{2}|2\,\tfrac{1}{2}\rangle]$$

$$\Psi^{(E_{3/2})}_{1/2} = \frac{1}{\sqrt{3}}[|3\,\tfrac{1}{2}\rangle + \frac{\sqrt{2}}{2}|1-\tfrac{1}{2}\rangle + \frac{\sqrt{6}}{2}|2-\tfrac{1}{2}\rangle],$$

$E_{1/2} \times E_{3/2}$

$$\Psi^{A_1} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle - |-\tfrac{1}{2}\,\tfrac{1}{2}\rangle],$$

$$\Psi^{(F)}_1 = -\tfrac{1}{2}|\tfrac{1}{2}\,\tfrac{1}{2}\rangle + \frac{\sqrt{3}}{2}|-\tfrac{1}{2}-\tfrac{1}{2}\rangle$$

$$\Psi^{(F)}_2 = -\frac{\sqrt{3}}{2}|\tfrac{1}{2}\,\tfrac{1}{2}\rangle - \tfrac{1}{2}|-\tfrac{1}{2}-\tfrac{1}{2}\rangle,$$

$$\Psi^{(F)}_3 = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle + |-\tfrac{1}{2}\,\tfrac{1}{2}\rangle]$$

$E_{1/2} \times E_{-3/2}$

$$\Psi^{A_{-1}} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle - |-\tfrac{1}{2}\,\tfrac{1}{2}\rangle],$$

$$\Psi^{(F)}_1 = -\tfrac{1}{2}|\tfrac{1}{2}\,\tfrac{1}{2}\rangle - \frac{\sqrt{3}}{2}|-\tfrac{1}{2}-\tfrac{1}{2}\rangle$$

$$\Psi^{(F)}_2 = \frac{\sqrt{3}}{2}|\tfrac{1}{2}\,\tfrac{1}{2}\rangle - \tfrac{1}{2}|-\tfrac{1}{2}-\tfrac{1}{2}\rangle,$$

$$\Psi^{(F)}_3 = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle + |-\tfrac{1}{2}\,\tfrac{1}{2}\rangle]$$

$E_{3/2} \times E_{3/2}$

$$\Psi^{A_{-1}} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle - |-\tfrac{1}{2}\,\tfrac{1}{2}\rangle],$$

$$\Psi^{(F)}_1 = -\tfrac{1}{2}|\tfrac{1}{2}\,\tfrac{1}{2}\rangle - \frac{\sqrt{3}}{2}|-\tfrac{1}{2}-\tfrac{1}{2}\rangle$$

$$\Psi^{(F)}_2 = \frac{\sqrt{3}}{2}|\tfrac{1}{2}\,\tfrac{1}{2}\rangle - \tfrac{1}{2}|-\tfrac{1}{2}-\tfrac{1}{2}\rangle,$$

$$\Psi^{(F)}_3 = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle + |-\tfrac{1}{2}\,\tfrac{1}{2}\rangle]$$

$E_{3/2} \times E_{-3/2}$

$$\Psi^{A_0} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle - |-\tfrac{1}{2}\,\tfrac{1}{2}\rangle],$$

$$\Psi^{(F)}_1 = |\tfrac{1}{2}\,\tfrac{1}{2}\rangle$$

$$\Psi^{(F)}_2 = |-\tfrac{1}{2}-\tfrac{1}{2}\rangle,$$

$$\Psi^{(F)}_3 = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle + |-\tfrac{1}{2}\,\tfrac{1}{2}\rangle]$$

$E_{-3/2} \times E_{-3/2}$

$$\Psi^{A_1} = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle - |-\tfrac{1}{2}\,\tfrac{1}{2}\rangle],$$

$$\Psi^{(F)}_1 = -\tfrac{1}{2}|\tfrac{1}{2}\,\tfrac{1}{2}\rangle + \frac{\sqrt{3}}{2}|-\tfrac{1}{2}-\tfrac{1}{2}\rangle$$

$$\Psi^{(F)}_2 = -\frac{\sqrt{3}}{2}|\tfrac{1}{2}\,\tfrac{1}{2}\rangle - \tfrac{1}{2}|-\tfrac{1}{2}-\tfrac{1}{2}\rangle,$$

$$\Psi^{(F)}_3 = \frac{1}{\sqrt{2}}[|\tfrac{1}{2}-\tfrac{1}{2}\rangle + |-\tfrac{1}{2}\,\tfrac{1}{2}\rangle]$$

B. s. v.×d. v.→d. v. reps

(1) $A_\mu \times E_\nu$ is the same as Eq. (29a).
(2) $F \times E_\nu = \Sigma_{\nu'} E_{\nu'}$, or $F \times (\lambda) = \Sigma_{\lambda'}(\lambda')$.
Applying (32) to the initial state $|F3,\lambda\,\frac{1}{2}\rangle$ we obtain,

$$\Psi^{(\lambda')}_{1/2} = \sqrt{\frac{1}{3}}\left|F3,\lambda\ \frac{1}{2}\right\rangle + \sqrt{\frac{2}{3}}\left[\Re e(-\lambda'\lambda^*/4)\left|F1,\lambda-\frac{1}{2}\right\rangle + \Re e(i\lambda'\lambda^*/4)\left|F2,\lambda-\frac{1}{2}\right\rangle\right],$$

$$\Psi^{(\lambda')}_{-1/2} = -\sqrt{\frac{1}{3}}\left|F3,\lambda-\frac{1}{2}\right\rangle + \sqrt{\frac{2}{3}}\left[\Re e(i\lambda'\lambda^*/4)\left|F1,\lambda\ \frac{1}{2}\right\rangle + \Re e(\lambda'\lambda^*/4)\left|F2,\lambda\ \frac{1}{2}\right\rangle\right]. \tag{35a}$$

C. d. v.×d. v.→s. v. reps

From (33a) we again have (29c). Similar to the case of $T \supset D_2 \supset C_2$ we have

$$\Psi^{(F)}_1 = \Re e(\lambda_1\lambda_2/4)\left|\lambda_1\ \frac{1}{2},\lambda_2\ \frac{1}{2}\right\rangle + \Re e(i\lambda_1\lambda_2/4)\left|\lambda_1-\frac{1}{2},\lambda_2-\frac{1}{2}\right\rangle,$$

$$\Psi^{(F)}_2 = \Im m(\lambda_1\lambda_2/4)\left|\lambda_1\ \frac{1}{2},\lambda_2\ \frac{1}{2}\right\rangle + \Im m(i\lambda_1\lambda_2/4)\left|\lambda_1-\frac{1}{2},\lambda_2-\frac{1}{2}\right\rangle, \tag{35b}$$

$$\Psi^{(F)}_3 = \frac{1}{\sqrt{2}}\left[\left|\lambda_1\ \frac{1}{2},\lambda_2-\frac{1}{2}\right\rangle + \left|\lambda_1-\frac{1}{2},\lambda_2\ \frac{1}{2}\right\rangle\right],$$

and $\Psi^{(A_\mu)}$ is identical to the one in Eq. (29d). From (34) and (35) we see that all the CG coefficients are real, and the numerical results for (34b) and (35) are listed in the Table V.

VI. SUMMARY

Using the effective ISO's or the factored ISO's the algebraic expressions of the CG coefficients, (21) and (22), (28) and (29), (34) and (35), for the group chain $T \supset C_3$, $T \supset D_2 \supset C_2$, $T \supset C_2$ are derived for the first time. Although they are not as elegant as the analytic expression for the $SO_3 \supset SO_2$ CG coefficients, their compactness, especially for the d. v. × d. v. CG coefficients, is remarkable. The projection operator method is often quoted as extremely difficult for large-order groups. From the sequent papers[12,13] and the present one, it is seen that this ''accusation'' is not totally fair. With the effective ISO's the projection operator method becomes extremely simple and powerful, which enable us to find algebraic expressions for the SAF's and CG coefficients. *Therefore it is the time for a rehabilitation of the projection operator method.*

Addendum: Overcoming dissipative distortions by a waveform restorer and designer [J. Math. Phys. 36, 2324 (1995)]

S. K. Foong[a)]
Department of Natural Sciences, Faculty of Education, University of the Ryukyus, Okinawa 903-0213, Japan

(Received 27 May 1998; accepted for publication 5 June 1998)

If observation is restricted to just a single point in space, then Kac's path integral solution of the telegrapher equation, a wave equation with a damping term, gives the same solution for an infinite number of inputs consisting of the solutions of the wave equation without damping. While this was implicit in a previous publication by the author [J. Math. Phys. **36**, 2324 (1995)], it is made explicit here along with examples. © *1998 American Institute of Physics.* [S0022-2488(98)04610-6]

In Ref. 1, I gave an algorithm for a waveform restorer and a designer motivated by Kac's path integral solution of the telegrapher equation, a wave equation with a damping term. This addendum is motivated by comments and questions I received after the paper was published. To facilitate the discussion, recall that the (generalized) Kac's solution to the following telegrapher type equation with completely general initial conditions:

$$\frac{1}{v^2}\frac{\partial^2 F}{\partial t^2}+\frac{2a}{v^2}\frac{\partial F}{\partial t}-O_{\mathbf{x}}F=0, \quad t\geqslant 0,$$
$$F(\mathbf{x},0)=\kappa(\mathbf{x}), \quad \frac{\partial F}{\partial t}(\mathbf{x},0)=\xi(\mathbf{x}), \tag{1}$$

is given by an average over the history of an undamped wave ϕ at the point

$$F(\mathbf{x},t)=\int_{-t}^{t}\phi(\mathbf{x},r)g(t,r)dr, \quad t\geqslant 0. \tag{2}$$

In Eq. (1), a is assumed to be a positive constant, and $O_{\mathbf{x}}$ is *any* linear and spatial operator such as the Laplacian ∇^2. The undamped wave $\phi(\mathbf{x},t)$ in Eq. (2) satisfies, for all time,

$$\frac{1}{v^2}\frac{\partial^2 \phi}{\partial t^2}-O_{\mathbf{x}}\phi=0,$$
$$\phi(\mathbf{x},0)=\kappa(\mathbf{x}), \quad \frac{\partial \phi}{\partial t}(\mathbf{x},0)=\xi(\mathbf{x}). \tag{3}$$

$\phi(\mathbf{x},t)$ was called the would-have-been wave since if a vanishes, then $F(\mathbf{x},t)=\phi(\mathbf{x},t)$ for $t\geqslant 0$. $g(t,r)$, parametrized by t, denotes the distribution of Kac's randomized time $S(t)$, defined by

$$S(t)=\int_0^t(-1)^{N(\tau)}\,d\tau, \tag{4}$$

where $N(t)$, with $N(0)=0$, is a random variable Poisson distributed with intensity a:

[a)]Electronic-mail: foong@edu.u-ryukyu.ac.jp

 © 1998 American Institute of Physics

$$P(N(t)-N(t')=k)=\begin{cases} e^{-a(t-t')}(a(t-t'))^k/k!, & k\geqslant 0; \\ 0, & k<0. \end{cases} \tag{5}$$

The value of $S(t)$ is denoted by r. In Eq. (2), there is no averaging of ϕ over space, and while F and ϕ are the waveforms at the same arbitrary point $\mathbf{x}$ in space, the argument t in F is assumed positive but in ϕ t may assume both positive and negative values.

The density distribution $g(t,r)$ is given by, with $u\equiv\sqrt{t^2-r^2}$,

$$g(t,r)=e^{-at}\delta(t-r)+\frac{ae^{-at}}{2}\theta(t-|r|)\left[I_0(au)+\frac{t+r}{u}I_1(au)\right]. \tag{6}$$

Since g is known, Eq. (2) may be paraphrased as the following: Knowing ϕ yields F. It is natural to ask if the converse, knowing F yields ϕ, is also true. Equation (2) may be viewed as a matrix multiplication, and so the question amounts to asking whether a left inverse g^{-1} of g exists, such that

$$\int_0^t d\tau g^{-1}(t,\tau)g(\tau,r)=\delta(t-r), \tag{7}$$

which would evidently enable the following restoration of ϕ from F:

$$\int_0^t d\tau g^{-1}(t,\tau)F(\mathbf{x},\tau)=\int_\infty^\infty dr\,\phi(\mathbf{x},r)\int_0^t d\tau g^{-1}(t,\tau)g(\tau,r)=\phi(\mathbf{x},t). \tag{8}$$

Strong evidence that the answer to the above question is negative is provided by the fact that when the time t is discretized, the discretized version of $g(t,r)$ is a rectangular matrix (g_{ij}). This can be seen from Eq. (4): with $t=m\Delta t$, r takes a value from $-(m-1)\Delta t$ to $m\Delta t$, i.e., $0\leqslant i\leqslant m$ and $-(m-1)\leqslant j\leqslant m$, and so (g_{ij}) is an $m\times(2m-1)$ matrix. Since a $p\times q$ matrix has a left inverse if and only if the rank of the matrix is q, it is necessary that $p\geqslant q$, and hence (g_{ij}) does not have a left inverse, a fact that remains to be true as we let $\Delta t\to 0$, and it appears that the same would remain true for the limit $g(t,r)$.

An ansatz consisting of a power series for the inverse also fails. Let

$$g^{-1}(t,\tau)=e^{a\tau}\left\{\delta(t-\tau)+\theta(\tau)\,\theta(t-\tau)\sum_{k=1}^{\infty}c_k^i(t,\tau)a^k\right\}. \tag{9}$$

By expanding the modified Bessel function in powers of a, g takes the form

$$g(\tau,r)=e^{-a\tau}\left[\delta(\tau-r)+\theta(\tau-|r|)\frac{a}{2}+\cdots\right]. \tag{10}$$

Hence, up to order a, we have

$$\int_0^t g^{-1}(t,\tau)g(\tau,r)d\tau=\delta(t-r)+\theta(r)\,\theta(t-r)c_1(t,r)a+\theta(t-|r|)\frac{a}{2}+O(a^2). \tag{11}$$

On the right-hand side of Eq. (11), we require the coefficients of all orders of a to vanish. Hence, for the term first order in a, we have

$$\theta(r)\,\theta(t-r)c_1(t,r)+\theta(t-|r|)\tfrac{1}{2}=0, \tag{12}$$

which has no solution for $-t<r<0$. The generality of the ansatz, Eq. (9), is another strong hint pointing to the nonexistence of the inverse of g.

The nonuniqueness of $\phi(\mathbf{x},t)$ for $|t|\leqslant T$, given $F(\mathbf{x},t)$ for $0\leqslant t\leqslant T$ (T is some arbitrary time interval) at an arbitrary *fixed* point $\mathbf{x}=\mathbf{x}_f$, say, was implicit in Ref. 1. There are actually an infinite

number of possible undamped waves $\phi(\mathbf{x}_f,t)$, which, when substituted into Eq. (2), give the same observed $F(\mathbf{x}_f,t)$. This can be easily seen as follows. It was shown in Ref. 1 that $F(\mathbf{x},t)$ may be written as a sum of two components:

$$F(\mathbf{x},t)=F_1(\mathbf{x},t)+F_2(\mathbf{x},t), \tag{13}$$

where the F_i are given by

$$F_i(\mathbf{x},t)\equiv\int_0^t dr\,h_i(t,r)\,\phi_i(\mathbf{x},r), \quad i=1,2, \tag{14}$$

where $\phi_1(\mathbf{x},t)=[\phi(\mathbf{x},t)+\phi(\mathbf{x},-t)]/2$ and $\phi_2(\mathbf{x},t)=[\phi(\mathbf{x},t)-\phi(\mathbf{x},-t)]/2$, namely the symmetric part and the antisymmetric part, with respect to t, of ϕ, respectively, and $h_1(t,r)\equiv g(t,r)+g(t,-r)$ and $h_2(t,r)\equiv g(t,r)-g(t,-r)$, the symmetric and antisymmetric parts (up to a factor of 2), with respect to r, of $g(t,r)$. These h_i have left inverses h_i^{-1} expressible in closed form:

$$h_1^{-1}(t,\tau)=e^{a\tau}\left\{\delta(t-\tau)-\theta(t-\tau)\left[ae^{a\tau}-\frac{2}{\pi}\int_0^a dy\,\frac{\sin ty}{y}[w(y)\cosh(\tau w(y))+a\,\sinh(\tau w(y))]\right]\right\}, \tag{15}$$

where $w(y)\equiv\sqrt{a^2-y^2}$, and

$$h_2^{-1}(t,\tau)=e^{a\tau}\left[\delta(t-\tau)-\theta(t-\tau)\,\frac{a\tau}{\sqrt{t^2-\tau^2}}J_1(a\sqrt{t^2-\tau^2})\right], \tag{16}$$

satisfying, for each value of i,

$$\int_r^t d\tau\,h_i^{-1}(t,\tau)h_i(\tau,r)=\delta(t,r), \quad r>0. \tag{17}$$

Hence, the ϕ can be restored from the F_i as follows: From Eq. (14), we obtain the ϕ_i by multiplying the observed F_i by h_i^{-1} and performing an integration—

$$\phi_i(\mathbf{x},t)=\int_0^t d\tau\,h_i^{-1}(t,\tau)F_i(\mathbf{x},\tau), \tag{18}$$

and then taking the linear combination of ϕ_i—

$$\begin{aligned}\phi(\mathbf{x},t)&=\phi_1(\mathbf{x},t)+\phi_2(\mathbf{x},t),\\ \phi(\mathbf{x},-t)&=\phi_1(\mathbf{x},t)-\phi_2(\mathbf{x},t),\end{aligned} \tag{19}$$

for $t>0$.

However, there are infinite choices for the pairs $F_i(\mathbf{x},t)$ for $0\leqslant t\leqslant T$, and each pair F_i gives rise to a unique pair of ϕ_i via Eq. (18), yielding a different $\phi(\mathbf{x},t)$ for $|t|\leqslant T$. All these different ϕ at $\mathbf{x}_f$ would yield the same F at $\mathbf{x}_f$. Hence, knowing F yields ϕ is false, and the left inverse of g does not exist.

We now consider an explicit example:

$$F(t)=\begin{cases}1, & \text{for } 0\leqslant t\leqslant 1,\\ 0, & \text{for } t\geqslant 1,\end{cases} \tag{20}$$

an observed pulse of unit height lasting for a unit time. Since the validity of the following discussion is independent of $\mathbf{x}_f$, it will be suppressed. Let us consider the following two choices out of an infinite possible choices for F_i: (1) $F_1(t)=F(t)$ and $F_2(t)=0$, and (2) $F_1(t)=0$ and $F_2(t)=F(t)$.

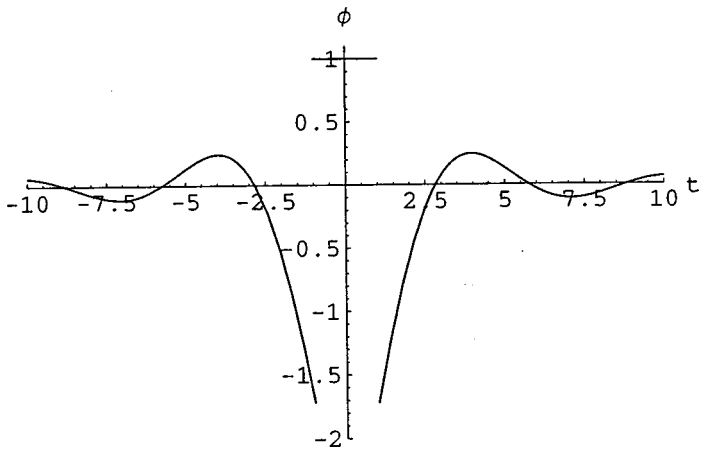

FIG. 1. A $\phi(t)$ that would give the observed pulse F of unit height lasting for a unit time of Eq. (20).

Choice (1). It follows from Eq. (18) that

$$\phi_2(t)=0, \tag{21}$$

and

$$\phi_1(t)=\begin{cases} \int_0^t d\tau h_1^{-1}(t,\tau), & \text{for } 0\leqslant t\leqslant 1, \\ \int_0^1 d\tau h_1^{-1}(t,\tau), & \text{for } t\geqslant 1. \end{cases} \tag{22}$$

The integral in Eq. (22) corresponding to $0\leqslant t\leqslant 1$ can be done explicitly with the help of Ref. 2 (item 2.481) to yield

$$\phi_1(t)=\frac{1}{2}+e^{at}-\frac{1}{2}e^{2at}+\frac{2}{\pi}e^{at}\int_0^a dy\,\frac{\sin ty}{y}\sinh(t\sqrt{a^2-y^2}). \tag{23}$$

The integral in Eq. (23) is of the form $I(\alpha)=\int_0^\alpha d\beta\,\sin\beta\sinh(\sqrt{\alpha^2-\beta^2})/\beta$. Letting $\beta=\alpha\sin\theta$, the integral becomes

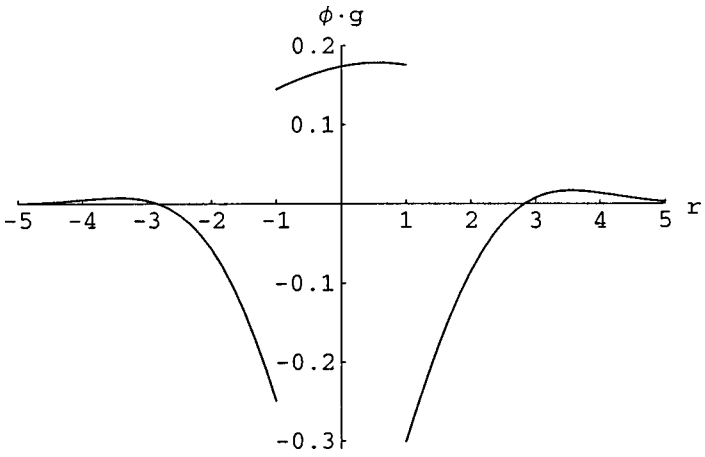

FIG. 2. This graph shows the contribution to F of the $\phi(t)$, $|t|<5$, given in Fig. 1.

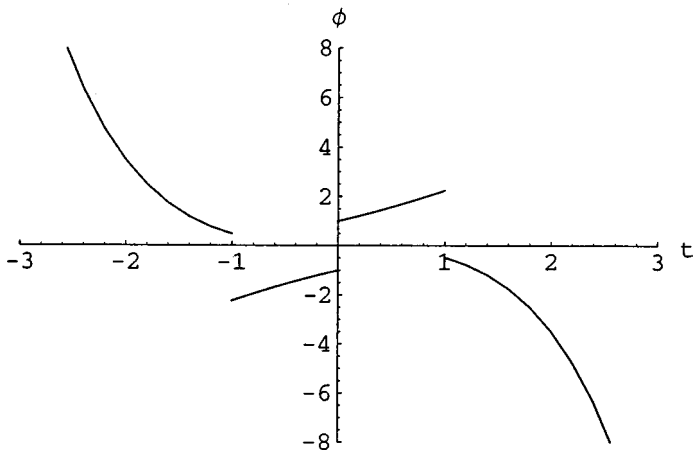

FIG. 3. Another $\phi(t)$ that would give the observed pulse F of unit height lasting for a unit time of Eq. (20).

$$I(\alpha)=\int_0^{\pi/2}\cot\,\theta\,\sin(\alpha\,\sin\,\theta)\sinh(\alpha\,\cos\,\theta)d\theta=\frac{\pi}{2}(\cosh\,\alpha-1), \tag{24}$$

which may be evaluated with the help of Ref. 2 (items 3.933 and 3.934). Hence, we have

$$\phi_1(\mathbf{x},t)=1, \quad \text{for } 0\leqslant t\leqslant 1, \tag{25}$$

and it follows from Eqs. (19) and (21) that

$$\phi(\mathbf{x},t)=1, \quad \text{for } -1\leqslant t\leqslant 1. \tag{26}$$

This ϕ clearly yields $F(t)=1$ for $0\leqslant t\leqslant 1$ upon application of Eq. (2).

For $|t|>1$, Eq. (22) yields

$$\phi(t)=-\frac{1}{2}(e^{2a}-1)+\frac{2}{\pi}e^{a}\int_0^{a}dy\,\frac{\sin|t|y}{y}\,\sinh(\sqrt{a^2-y^2}). \tag{27}$$

By using the software MATHEMATICA, $\phi(t)$ with $a=1$ is plotted in Fig. 1, and $\phi(r)g(t,r)$, without considering the contribution from the delta function in g, is plotted for $t=5$ in Fig. 2. The graph shows the contribution to F of ϕ at times $|t|<5$. The contribution to $F(t)$ coming from $e^{-at}\int\phi(r)\,\delta(t-r)dr=e^{-at}\phi(t)$ at $t=5$ amounts to 8.863×10^{-4}, which when added to the area under the graph in Fig. 2 gives $F(t=5)=0$, as required by Eq. (20).

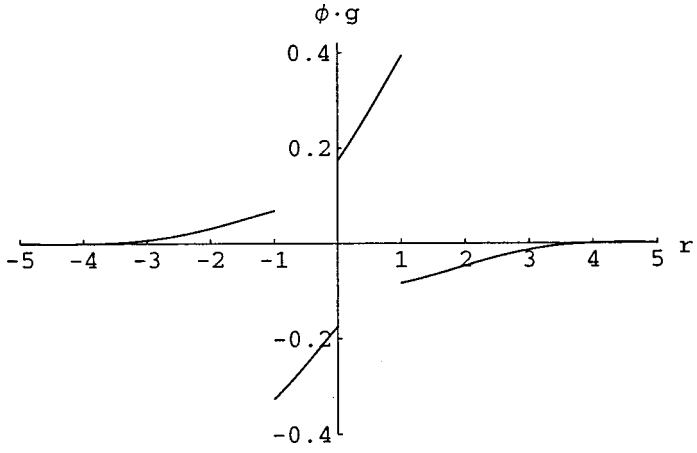

FIG. 4. This graph shows the contribution to F of the $\phi(t)$, $|t|<5$, given in Fig. 3.

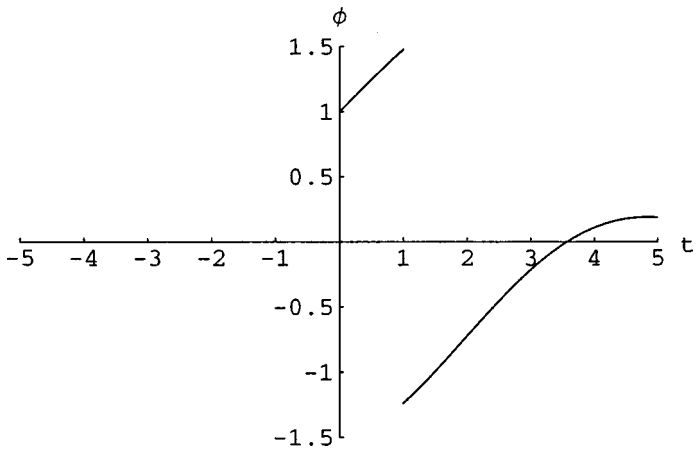

FIG. 5. A $\phi(t)$, where $\phi(t)=0$ for $t<0$, that would give the observed pulse F of Eq. (20).

Choice (2). It follows from Eq. (18) that

$$\phi_1(t)=0, \tag{28}$$

and hence

$$\phi(t)=\begin{cases} \int_0^t d\tau h_2^{-1}(t,\tau), & \text{for } 0\leqslant t\leqslant 1, \\ \int_0^1 d\tau h_2^{-1}(t,\tau), & \text{for } t\geqslant 1. \end{cases} \tag{29}$$

Substituting h_2^{-1} given by Eq. (16) into the above gives, with $\alpha\equiv at$,

$$\begin{aligned}\phi(t)&=e^{at}-a\int_0^t d\tau \frac{\tau e^{a\tau}}{\sqrt{t^2-\tau^2}} J_1(a\sqrt{t^2-\tau^2}) \\ &=e^{\alpha}-\alpha\int_0^{\pi/2} d\theta \sin\theta e^{\alpha\sin\theta} J_1(\alpha\cos\theta), \quad \text{for } 0\leqslant t\leqslant 1\end{aligned} \tag{30}$$

and

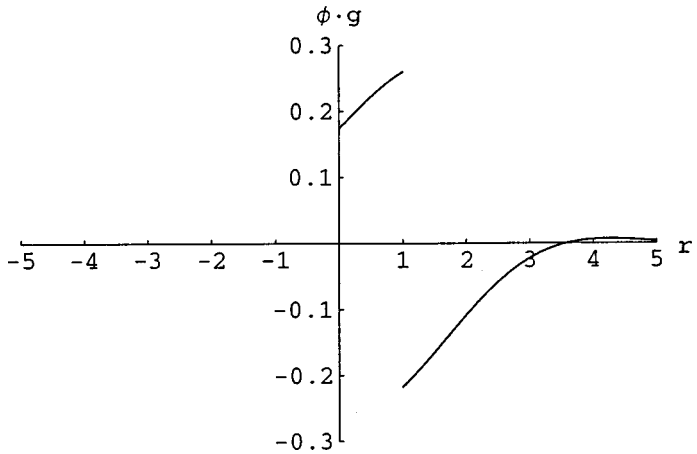

FIG. 6. This graph shows the contribution to F of the $\phi(t)$, $|t|<5$, given in Fig. 5.

$$\phi(t) = -a\int_0^1 d\tau \frac{\tau e^{a\tau}}{\sqrt{t^2-\tau^2}} J_1(a\sqrt{t^2-\tau^2}), \quad \text{for } t \geqslant 1. \tag{31}$$

Since $\phi_1 = 0$, $\phi(t)$ is antisymmetric with respect to t, $\phi(-t) = -\phi(t)$. Figure 3 is a plot of $\phi(t)$ with $a=1$. Figure 4 is a plot of $\phi(r)g(t,r)$, excluding the contribution from the delta function in g, for $t=5$.

Both ϕ, as plotted in Fig. 1 and Fig. 3, would give rise to the same observed pulse F of unit height lasting for a unit time of Eq. (20). Hence, we conclude that, if he knows only F at the point, he would not be able to obtain a unique would-have-been wave ϕ at the same point. This result is independent of the Kac's formalism which we used to derive it. We wish to emphasize that for a given Cauchy data, both the $F(x,t)$ and $\phi(x,t)$ are unique. However, it is assumed here that the observer (restorer) has available to him only the distorted waves F or F_i at one point in space only, and has absolutely no knowledge of their values elsewhere.

We summarize the discussion up to this point: Given only that two waves $F(\mathbf{x}_f,t)$, $0 \leqslant t \leqslant T$ and $\phi(\mathbf{x}_f,t)$, $-T \leqslant t \leqslant T$ at an arbitrary chosen point $\mathbf{x}_f$ share the *same* Cauchy data at $t=0$ (but the data are not given), propagate under Eq. (1) and Eq. (3), respectively, then $F(\mathbf{x}_f,t)$, $0 \leqslant t \leqslant T$ can be obtained from $\phi(\mathbf{x}_f,t)$, $-T \leqslant t \leqslant T$ via Eq. (2). However, it is impossible, without further information, to obtain $\phi(\mathbf{x}_f,t)$ for any value of t (except the trivial case of $t=0$) from $F(\mathbf{x}_f,t)$, $0 \leqslant t \leqslant T$. An example of the ''further information'' is the knowledge of the two components $F_1(x_f,t)$ and $F_2(x_f,t)$ of $F(x_f,t)$, which would allow the restoration of $\phi(\mathbf{x}_f,t)$, $-T \leqslant t \leqslant T$.

In closing, another example of the ''further information'' should be mentioned, namely, $\phi(\mathbf{x}_f,t)=0$ for $t<0$. In this case, g^{-1}, which satisfies

$$\int_0^t g^{-1}(t,\tau)g(\tau,r)\,d\tau = \delta(t-r), \quad r>0, \tag{32}$$

is conjectured to be[3,4]

$$g^{-1}(t,\tau) = e^{a\tau}\left\{\delta(t-\tau) - \theta(t-\tau)\left[\left(\frac{t-\tau}{t+\tau} + a\tau\right)\frac{J_1(aw)}{w} + \frac{a\tau}{t+\tau}J_o(aw)\right]\right\}, \quad t,\tau>0, \tag{33}$$

where $w=\sqrt{t^2-\tau^2}$. Hence, $\phi(\mathbf{x},t)$ can be restored as follows:

$$\phi(\mathbf{x},t) = \int_0^t g^{-1}(t,\tau)F(\mathbf{x},\tau)\,d\tau. \tag{34}$$

Given only $F(\mathbf{x}_f,t)$ and $\phi(\mathbf{x}_f,t)=0$ for $t<0$, without the knowledge of F_i, the restoration can be carried out.

For F of Eq. (20), $\phi(t)$ resulting from Eq. (34) with $a=1$ is plotted in Fig. 5, and $\phi(r)g(t,r)$, without considering the contribution from the delta function in g, is plotted for $t=5$ in Fig. 6.

ACKNOWLEDGMENT

I wish to thank Professor S. Matsumoto for a discussion which has improved the presentation of this paper.

Decomposition of time-ordered products and path-ordered exponentials

C. S. Lam[a)]
Department of Physics, McGill University,
3600 University Street, Montreal, QC H3A 2T8, Canada

(Received 29 April 1998; accepted for publication 21 May 1998)

We present a decomposition formula for U_n, an integral of time-ordered products of operators, in terms of sums of products of the more primitive quantities C_m, which are the integrals of time-ordered commutators of the same operators. The resulting factorization enables a summation over n to be carried out to yield an explicit expression for the time-ordered exponential, an expression which turns out to be an exponential function of C_m. The Campbell–Baker–Hausdorff formula and the non-Abelian eikonal formula obtained previously are both special cases of this result. © *1998 American Institute of Physics.* [S0022-2488(98)00610-0]

I. INTRODUCTION

The path-ordered exponential $U(T,T')=\mathscr{P}\exp(\int_{T'}^{T}H(t)dt)$ is the solution of the first order differential equation $dU(T,T')/dT=H(T)U(T,T')$ with the initial condition $U(T',T')=\mathbf{1}$. The function $H(T)$ can be a finite-dimensional matrix or an infinite-dimensional operator. In the latter case all concerns of domain and convergence will be ignored. The parameter t labeling the path shall be referred to as ''time,'' so path-ordering and time-ordering are synonymous in the present context. The path-ordered exponential is usually computed from its power series expansion, $U(T,T')=\Sigma_{n=0}^{\infty}U_n$, in terms of the time-ordered products $U_n=\mathscr{P}(\int_{T'}^{T}H(t)dt)^n/n!$.

Path-ordered exponential can be found in many areas of theoretical physics. It is the time-evolution operator in quantum mechanics if iH is the Hamiltonian. It is the nonintegrable phase factor (Wilson line) of the Yang–Mills theory if $-iH=A$ is the non-Abelian vector potential. It defines an element of a Lie group connected to the identity via a path whose tangent vector at time t is given by the Lie-algebra element $-iH(t)$. It can be used to discuss canonical transformation and classical particle trajectories.[1] It also gives rise to useful formulas in many other areas of mathematical physics by suitable choices of $H(t)$, some of which will be mentioned later. Likewise, time-ordered products are ubiquitous. For example, free-field matrix elements of time-ordered products of an interaction Hamiltonian give rise to perturbation diagrams.

The main result of this paper is a *decomposition theorem* for the time-ordered products U_n. It provides a formula equating them to sums of products of the more primitive quantities C_m. The factorization thus achieved enables U_n to be summed up and $U(T,T')$ expressed as an exponential function of the C_m's.

This result grew out of a non-Abelian eikonal formula. The Abelian version of the eikonal formula[2] is well known. It gives rise to a geometrical interpretation for elastic scattering at high energies,[3] besides being a useful tool in dealing with infrared divergence[4] in QED. The non-Abelian version was originally developed to deal with the consistency problem of baryonic amplitudes in large-N_c QCD,[5,6] but it proves to be useful also in understanding gluon reggeization and reggeon factorization.[7,8] It is expected to be valuable also in the discussion of geometrical pictures and infrared problems in QCD.

The generalization in this paper can be used to take the non-Abelian eikonal formula a step further to include small transverse motions of the high-energy trajectory. Such corrections to the usual eikonal formula are known to be crucial in obtaining the Landau–Pomeranchuk–Migdal effect[9] in QED and so are expected to be important as well in the case of QCD. However, we shall postpone all such physical applications and concentrate in this paper on the development of mathematical formulas.

On the mathematical side, one can derive the Campbell–Baker–Hausdorff formula[10] as a corollary of the formulas developed in these pages.

Statements, explanations, and simple illustrations of the results will be found in the main text, while proofs and other details will be relegated to the Appendices.

The formulas are combinatorial in character. They cannot be adequately explained without a suitable set of notations, which we develop in Sec. II. The main result of the paper, the decomposition theorem, will be discussed in Secs. III and IV. This theorem can be stated for a more general time-ordered product U_n, in which all the $H_i(t)$ are different. This will be dealt with in Sec. III. The special case when these $H_i(t)=H(t)$ are identical will be taken up in Sec. IV. This in turn leads to the exponential formula for $U(T,T')$ in Sec. V. The final section, Sec. VI, is put in mainly to illustrate the versatility of our results in deriving other formulas useful in mathematics and physics, by suitable choices of $H_i(t)$. Among them are the Campbell–Baker–Hausdorff formula for the multiplication of group elements, and the non-Abelian generalization of the eikonal formula in physics.

II. DEFINITIONS

We start by generalizing the definition of U_n to cases when the operators $H(t)$ are all different.

Let $[s]=[s_1s_2\cdots s_n]$ be a permutation of the n numbers $[12\cdots n]$, and S_n the corresponding permutation group. We define the *time-ordered product* $U[s]$ to be the integral

$$U[s]=U[s_1s_2\cdots s_n]=\int_{R[s]}dt_1dt_2\cdots dt_nH_{s_1}(t_{s_1})H_{s_2}(t_{s_2})\cdots H_{s_n}(t_{s_n}), \tag{2.1}$$

taken over the hyper-triangular region $R[s]=\{T\geqslant t_{s_1}\geqslant t_{s_2}\geqslant\cdots\geqslant t_{s_n}\geqslant T'\}$, with the operator $H_{s_i}(t_{s_i})$ standing to the left of $H_{s_j}(t_{s_j})$ if $t_{s_i}>t_{s_j}$. The operator $U_n=U_n[T,T']$ is then defined to be the average of $U[s]$ over all permutations $s\in S_n$:

$$U_n=\frac{1}{n!}\sum_{s\in S_n}U[s]. \tag{2.2}$$

In the special case when all $H_i(t)=H(t)$ are identical, this U_n coincides with the one in Sec. I.

The *decomposition theorem* expresses U_n as sums of products of the *time-ordered commutators* $C[s]=C[s_1s_2\cdots s_n]$. These are defined analogous to $U[s_1s_2\cdots s_n]$, but with the products of H_i's changed to nested multiple commutators:

$$C[s]=\int_{R[s]}dt_1dt_2\cdots dt_n[H_{s_1}(t_{s_1}),[H_{s_2}(t_{s_2}),[\cdots,[H_{s_{n-1}}(t_{s_{n-1}}),H_{s_n}(t_{s_n})]\cdots]]]. \tag{2.3}$$

For $n=1$, we let $C[s_i]=U[s_i]$ by definition. Similarly, the operator $C_n=C_n[T,T']$ is defined to be the average of $C[s]$ over all permutations $s\in S_n$:

$$C_n=\frac{1}{n!}\sum_{s\in S_n}C[s]. \tag{2.4}$$

It is convenient to use a ''*cut*'' (a vertical bar) to denote products of $C[\cdots]$'s. For example, $C[31|2]\equiv C[31]C[2]$, and $C[71|564|2|3]\equiv C[71]C[564]C[2]C[3]$.

We are now in a position to state the main theorem.

III. GENERAL DECOMPOSITION THEOREM

$$n!U_n=\sum_{s\in S_n}C[s_1\cdots|\cdots|\cdots\qquad\cdots s_n]\equiv\sum_{s\in S_n}C[s]_c. \tag{3.1}$$

A cut (vertical bar) is placed after s_i if and only if $s_j>s_i$ for all $j>i$. An element $s\in S_n$ with cuts placed this way will be denoted by $[s]_c$.

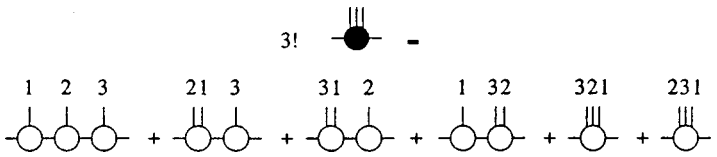

FIG. 1. The decomposition of $3!U_3$ (filled circle) in terms of $C[s]$'s.

In view of the fundamental nature of this theorem, two separate proofs shall be provided for it in Appendix A.

A. Examples

For illustrative purposes here are explicit formulas for $n=1,2,3,$ and 4:

$$1!U_1=C[1], \qquad 2!U_2=C[1|2]+C[21],$$
$$3!U_3=C[1|2|3]+C[21|3]+C[31|2]+C[1|32]+C[321]+C[231], \tag{3.2}$$

$$\begin{aligned}4!U_4=&C[1|2|3|4]+C[321|4]+C[231|4]+C[421|3]+C[241|3]+C[431|2]+C[341|2]\\&+C[1|432]+C[1|342]+C[21|43]+C[31|42]+C[41|32]+C[21|3|4]+C[31|2|4]\\&+C[41|2|3]+C[1|32|4]+C[1|42|3]+C[1|2|43]+C[4321]+C[3421]+C[4231]\\&+C[3241]+C[2341]+C[2431].\end{aligned}$$

The formula (3.1) can be displayed graphically, with a filled circle with n lines on top indicating U_n, and an open circle with n tops on top indicating $C[s]$. This is shown in Fig. 1 for $n=3$.

B. Factorization

In the special case when all the $H_i(t)$'s mutually commute, the only surviving $C[\cdots]$'s are those with one argument, so Eq. (3.1) reduces to a *factorization theorem*:

$$U_n=\frac{1}{n!}\prod_{i=1}^{n} C[i]. \tag{3.3}$$

Thus the general decomposition theorem in (3.1) may be thought of as a *non-Abelian generalization of this factorization theorem.*

IV. SPECIAL DECOMPOSITION THEOREM

Great simplification occurs when all $H_i(t)=H(t)$ are identical, for then $U[s]$ and $C[s]$ depend only on n but not on the particular $s\in S_n$. Hence all $U[s]=U_n$ and all $C[s]=C_n$. In this case the decomposition theorem becomes

$$U_n=\sum \xi(m_1m_2\cdots m_k)C_{m_1}C_{m_2}\cdots C_{m_k},$$
$$\xi(m)\equiv\xi(m_1m_2\cdots m_k)=\prod_{i=1}^{k}\left[\sum_{j=i}^{k} m_j\right]^{-1}. \tag{4.1}$$

The sum in the first equation is taken over all k, and all $m_i>0$ such that $\Sigma_{i=1}^{k} m_i=n$. Note that $\xi(m)=\xi(m_1m_2\cdots m_k)$ is *not* symmetric under the interchange of the m_i's. It is this asymmetry that produces the commutator terms in the formulas for K_n in Eq. (5.4).

See Appendix B for a proof of this special decomposition theorem.
We list below this special decomposition up to $n=5$:

$$1!U_1=C_1, \qquad 2!U_2=C_1^2+C_2,$$

$$3!U_3=C_1^3+2C_2C_1+C_1C_2+2C_3, \tag{4.2}$$

$$4!U_4=C_1^4+6C_3C_1+2C_1C_3+3C_2^2+3C_2C_1^2+2C_1C_2C_1+C_1^2C_2+6C_4,$$

$$5!U_5=C_1^5+24C_4C_1+6C_1C_4+12C_3C_2+8C_2C_3+12C_3C_1^2+6C_1C_3C_1+2C_1^2C_3+8C_2^2C_1$$
$$+4C_2C_1C_2+3C_1C_2^2+4C_2C_1^3+3C_1C_2C_1^2+2C_1^2C_2C_1+C_1^3C_2.$$

The case for $n=3$ is explicitly shown in Fig. 2.

V. EXPONENTIAL FORMULA FOR $U(T,T')$

The factorization character in (4.1) and (4.2) suggests that it may be possible to sum up the power series U_n to yield an explicit exponential function of the C_n's. This is indeed the case.

A. Commutative C_i's

First assume all the C_{m_i} in (4.1) commute with one another. Then, as will be shown in Appendix C,

$$U[T,T']=1+\sum_{n=1}^{\infty} U_n=\prod_{j=1}^{\infty}\sum_{m=0}^{\infty}\frac{1}{j^m m!}C_j^m=\exp\left[\sum_{j=1}^{\infty}\frac{C_j}{j}\right]. \tag{5.1}$$

Explicit calculation of low-order terms can also be obtained from (4.2) for further verification. This yields

$$U_0=1, \qquad U_1=C_1, \qquad U_2=\tfrac{1}{2}(C_1^2+C_2), \qquad U_3=\frac{1}{3!}C_1^3+\frac{1}{2}C_1C_2+\frac{1}{3}C_3,$$

$$U_4=\frac{1}{4!}C_1^4+\frac{1}{3}C_1C_3+\frac{1}{8}C_2^2+\frac{1}{4}C_1^2C_2+\frac{1}{4}C_4, \tag{5.2}$$

$$U_5=\frac{1}{5!}C_1^5+\frac{1}{4}C_1C_4+\frac{1}{6}C_2C_3+\frac{1}{6}C_1^2C_3+\frac{1}{8}C_1C_2^2+\frac{1}{12}C_1^3C_2+\frac{1}{5}C_5,$$

$$\sum_{i=0}^{5} U_n=\exp\left[C_1+\frac{1}{2}C_2+\frac{1}{3}C_3+\frac{1}{4}C_4+\frac{1}{5}C_5\right]+R,$$

where R contains products of C's whose subscript indices add up to 6 or more.

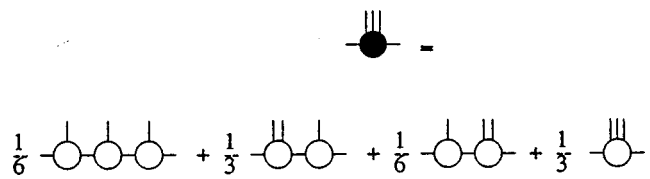

FIG. 2. Graphical form for the decomposition of U_3 (filled circle) in Eq. (4.2).

B. General exponential formula

In general the C_j's do not commute with one another so the exponent in (5.1) must be corrected by terms involving commutators of the C_j's. The exponent K can be computed by taking the logarithm of $U(T,T')$:

$$U(T,T')=1+\sum_{n=1}^{\infty} U_n=\exp[K]\equiv\exp\left[\sum_{i=1}^{\infty} K_i\right],$$
$$K=\ln\left[1+\sum_{n=1}^{\infty} U_n\right]=\sum_{\ell=1}^{\infty}\frac{(-)^{\ell-1}}{\ell}\left[\sum_{n=1}^{\infty} U_n\right]^{\ell}\equiv\sum_{n=1}^{\infty}\frac{C_n}{n}+\sum_{m}\eta(m)C_m, \tag{5.3}$$

in which the last sum is taken over *all* $m=(m_1m_2\cdots m_k)$ for $k\geqslant 2$, and $C_m\equiv C_{m_1}C_{m_2}\cdots C_{m_k}$. The resulting expression must be expressible as (multiple-)commutators of the C's. Only commutators of $H(t)$, in the form of C_m and their commutators, enter into K. This is so because in the special case when $H(t)$ is a member of a Lie algebra, $U(T,T')$ is a member of the corresponding Lie group and so K must also be a member of a Lie algebra.

By definition, K_i contains i factors of $H(t)$. Calculation for the first five is carried out in Appendix D. The result is

$$K_1=C_1,\qquad K_2=\tfrac{1}{2}C_2,\qquad K_3=\tfrac{1}{3}C_3+\tfrac{1}{12}[C_2,C_1],\qquad K_4=\tfrac{1}{4}C_4+\tfrac{1}{12}[C_3,C_1],$$
$$K_5=\tfrac{1}{5}C_5+\tfrac{3}{40}[C_4,C_1]+\tfrac{1}{60}[C_3,C_2]+\tfrac{1}{360}[C_1,[C_1,C_3]]+\tfrac{1}{240}[C_2,[C_2,C_1]]$$
$$+\tfrac{1}{720}[C_1,[C_1,[C_1,C_2]]]. \tag{5.4}$$

K_n consists of C_n/n, plus the compensating terms in the form of commutators of the C's. By counting powers of $H(t)$ it is clear that the subscripts of these C's must add up to n, but beyond that all independent commutators and multiple commutators may appear. For that reason it is rather difficult to obtain an explicit formula valid for all K_n, if for no other reason than the fact that new commutator structures appear in every new n. It is however very easy to compute K_n using (5.3) in a computer. This is actually how K_5 was obtained.

Nevertheless, when we stick to commutators of a definite structure, their coefficients in K can be computed as follows.

C. Coefficient $\eta(m_1m_2\cdots m_k)$

It is not difficult to compute $\eta(m_1\cdots m_k)$ for small k (but arbitrary m_i). The computation for $k\leqslant 4$ will be given below. In order to avoid excessive subscripts we shall use variables like w,x,y,z to denote the positive integers m_i.

1. $\eta(xy)$

According to (5.3), C_xC_y can come from U_{x+y}, or U_xU_y. The former corresponds to $\ell=1$, and the latter $\ell=2$. Using (4.2), we obtain

$$\eta(xy)=\frac{1}{(x+y)y}-\frac{1}{2xy}=\frac{y-x}{2xy(x+y)}. \tag{5.5}$$

The antisymmetry under x,y exchange shows explicitly that it is the commutator $\eta(xy)\times[C_x,C_y]$ that enters into K.

Using this formula, we can verify the coefficients of the single commutator terms appearing in (5.4): $\eta(2,1)=1/12$, $\eta(3,1)=1/12$, $\eta(4,1)=3/40$, $\eta(3,2)=1/60$.

2. $\eta(xyz)$

According to (5.3), $C_xC_yC_z$ can come from $U_{x+y+z}(\ell=1)$, U_xU_{y+z} and $U_{x+y}U_z(\ell=2)$, and $U_xU_yU_z(\ell=3)$. Using (4.2), we get

$$\eta(xyz)=\frac{1}{(x+y+z)(y+z)z}-\frac{1}{2}\left[\frac{1}{x(y+z)z}+\frac{1}{(x+y)yz}\right]+\frac{1}{3}\frac{1}{xyz}$$

$$=\frac{y^2(x+z)+y(2x^2+2z^2-3xz)-xz(x+z)}{6xyz(x+y)(y+z)(x+y+z)}. \tag{5.6}$$

Because of the Jacobi identity there are only two independent double commutators in K. They can be taken to be $\alpha[C_x,[C_y,C_z]]+\beta[C_y,[C_x,C_z]]$, if $y\neq z$. We may take $\beta=0$ if $x=y$. In any case, we have $\alpha=\eta(xyz)$.

We can use this formula to verify the double commutator terms in (5.4): $\eta(1,1,2)=1/360$, $\eta(2,2,1)=1/240$.

3. $\eta(wxyz)$

$C_wC_xC_yC_z$ may come from $U_{w+x+y+z}$, $U_{w+x+y}U_z$, $U_{w+x}U_{y+z}$, U_wU_{x+y+z}, $U_{w+x}U_yU_z$, $U_wU_{x+y}U_z$, $U_wU_xU_{y+z}$, and $U_wU_xU_yU_z$. Thus

$$\eta(wxyz)=[(w+x+y+z)(x+y+z)(y+z)z]^{-1}-[2(w+x+y)(x+y)yz]^{-1}$$
$$-[2(w+x)x(y+z)z]^{-1}-[2w(x+y+z)(y+z)z]^{-1}+[3(w+x)yz]^{-1}$$
$$+[3w(x+y)yz]^{-1}+[3wx(y+z)z]^{-1}-[4wxyz]^{-1}. \tag{5.7}$$

It can be shown (Appendix E) that this is also the coefficient of the triple commutator $[C_w,[C_x,[C_y,C_z]]]$.

This formula leads to $\eta(1,1,1,2)=1/720$, agreeing with the coefficient of the last term in (5.4).

D. Gauge invariance

Under the ''gauge transformation,''

$$\delta H(t)=\frac{d\Lambda(t)}{dt}+[\Lambda(t),H(t)]\equiv\delta_{-1}H(t)+\delta_0H(t), \tag{5.8}$$

where $\Lambda(t)$ is an arbitrary operator vanishing at $t=T$ and $t=T'$, $U(T,T')$ is gauge invariant. This means that $K=K(T,T')$ must also be gauge invariant. Since δ_{-1} decreases the power of H by one, and δ_0 leaves it unchanged, the gauge invariance must be implemented order-by-order as

$$\delta_{-1}U_{n+1}+\delta_0U_n=0, \tag{5.9}$$

$$\delta_{-1}K_{n+1}+\delta_0K_n=0. \tag{5.10}$$

Equation (5.9) is easy to verify but Eq. (5.10) is not. See Appendix F. The reason is that U_n transforms simply under a gauge change, as in (5.9), but C_n does not. It is this complexity of gauge behavior of C_n that makes the verification of (5.10) complicated, but we will do it explicitly for the first few orders in Appendix F. From this point of view, the reason why the dependence of K_n on C_m is so complicated is simply because the complexity is necessary to offset the complexity of the gauge behavior of C_m, so that the gauge change of K_n becomes simple again, as in (5.10).

VI. FORMULAS RESULTING FROM SPECIFIC CHOICES OF $H_I(T)$

It is well known that the path-ordered exponential $U[T,T']$ obeys the composition law

$$U[T,T']=U[T,T'']U[T'',T'] \tag{6.1}$$

if $T\geqslant T''\geqslant T'$. We can combine this with a judicious choice of $H(t)$ to obtain many mathematical formulas. Three of them are presented below for illustrative purposes. The first two are purely mathematical results; the third is a non-Abelian eikonal formula useful for high-energy scattering amplitudes.

A. Campbell–Baker–Hausdorff formula

Let $T=2$, $T''=1$, and $T'=0$. Let $H(t)=P$ for $2\geqslant t\geqslant 1$ and $H(t)=Q$ for $1>t\geqslant 0$, where P and Q are arbitrary matrices or operators. Using (6.1) and (5.4), we obtain in this case (see Appendix G for details)

$$C_m=\frac{1}{(m-1)!}(\text{ad } P)^{m-1}Q, \tag{6.2}$$

where as usual $(\text{ad } P)V\equiv[P,V]$ for any operator V. Substituting this into (5.4) we get

$$\begin{gathered}\exp(P)\cdot\exp(Q)=\exp[K_1+K_2+K_3+K_4+K_5+\cdots],\\ K_1=P+Q,\qquad K_2=\tfrac{1}{2}[P,Q],\\ K_3=\tfrac{1}{12}[P,[P,Q]]+\tfrac{1}{12}[Q,[Q,P]],\qquad K_4=-\tfrac{1}{24}[P,[Q,[P,Q]]],\\ K_5=-\tfrac{1}{720}[P,[P,[P,[P,Q]]]]-\tfrac{1}{720}[Q,[Q,[Q,[Q,P]]]]+\tfrac{1}{360}[P,[Q,[Q,[Q,P]]]]\\ +\tfrac{1}{360}[Q,[P,[P,[P,Q]]]]+\tfrac{1}{120}[P,[Q,[P,[Q,P]]]]+\tfrac{1}{120}[Q,[P,[Q,[P,Q]]]],\end{gathered} \tag{6.3}$$

which is the Campbell–Baker–Hausdorff formula. The case when $[P,Q]$ commutes with P and Q is well known. In that case all K_n for $n\geqslant 3$ are zero. Otherwise, up to and including K_4 this formula can be found in Eq. (15), Sec. 6.4, Chap. II of Ref. 10.

If necessary, we may also use the general knowledge for the coefficient $\eta(m)$ obtained in Sec. V C to deduce information on higher-order terms.

B. Translational operator

A simple and trivial example to illustrate the commutative formula (5.1) is obtained by choosing $T=3$, $T'=0$, $H(t)=a(d/dx)$ for $t\in[2,3]$, $H(t)=f(x)$ for $t\in[1,2]$, and $H(t)=-a(d/dx)$ for $t\in[0,1]$. $f(x)$ is an arbitrary function of x and a is a constant. In this case $C_n/n=(a^n/n!)(d^nf(x)/dx^n)$ (see Appendix H), so all commutators of C_i vanish and (5.1) is valid. We get

$$\begin{aligned}U[T,T']&=\exp(\text{ad}/dx)\cdot\exp(f(x))\cdot\exp(-\text{ad}/dx)\\ &=\exp[K]=\exp\left[\sum_{n=0}^{\infty}a^nf^{(n)}(x)/n!\right]=\exp[f(x+a)].\end{aligned} \tag{6.4}$$

This formula, expressing the fact that $\exp(\text{ad}/dx)$ is a translational operator, is of course well-known. There is absolutely no need to derive it with this heavy apparatus. We include it here just to illustrate how different choices of $H(t)$ can lead to different formulas.

C. Non-Abelian eikonal formula

A useful formula in high-energy scattering is obtained from (3.1) by choosing $H_i(t)=\exp(ik_i\cdot pt)V_i\equiv\exp(i\omega_it)$, where V_i are time-independent operators, and p,k_i are arbitrary four-momenta. We should also choose $[T,T']$ to be $[\infty,-\infty]$ to correspond to ''on-shell amplitudes'' and $[T,T']=[\infty,0]$ to correspond to ''off-shell amplitudes.''

In that case, (3.1) reads

$$\begin{gathered}U[123\cdots n]=a[123\cdots n]V_1V_2V_3\cdots V_n,\\ C[123\cdots n]=a[123\cdots n]\cdot\\ [V_1,[V_2,[V_3,[\cdots,[V_{n-1},V_n]\cdots]]]],\end{gathered} \tag{6.5}$$

$$a[123\cdots n]=i^{n-1}\left(\prod_{j=1}^{n-1}\frac{1}{\Sigma_{i=1}^{j}\omega_i+i\epsilon}\right)L_{[T,T']},$$

$$L_{[\infty,-\infty]}=2\pi\delta\left(\sum_{i=1}^{n}\omega_i\right),\qquad L_{[\infty,0]}=\frac{1}{\Sigma_{i=1}^{n}\omega_i+i\epsilon}.$$

Similar formulas can be obtained for $U[s]$ and $C[s]$ for any $s\in S_n$ by permutation. They are the tree amplitudes with vertex V_i governing the emission of n bosons with momenta k_i from a common source particle with momentum p. The bosons are arranged along the tree in the order dictated by the permutation s. This formula is valid in the high-energy approximation where $p^0\gg k_i^\mu$, whence spins can be ignored and the product of propagators along the source line can be approximated by $a[s]$. $n!U_n$ is then the complete tree amplitude obtained by summing the $n!$ tree diagrams. The decomposition theorem for U_n in this case has been derived directly.[5] Its on-shell version exhibits spacetime and color interference, and can be used to prove the self-consistency of the baryonic scattering amplitudes in large-N_c QCD[6]. It also explains the emergence of reggeized gluons and the factorization of high-energy near-forward scattering amplitudes into multiple-reggeon exchanges.[7,8]

APPENDIX A: TWO PROOFS OF THE GENERAL DECOMPOSITION THEOREM

On account of the importance of the decomposition theorem (3.1) to the rest of this paper, we shall provide two separate proofs for it. Actually a third proof exists, along the lines given in Ref. 5 for the ''multiple commutator formula'' [which is simply the ''non-Abelian eikonal formula'' (6.5)]. However, this requires the expansion of every operator $H_i(t)$ into a sum over a complete set of time-independent operators, thus introducing lots of indices and even more complicated notations. So we shall skip that third proof here.

The combinatorics needed for a general proof are unfortunately rather involved, though the basic idea in either case is really quite simple. In order not to be bogged down with complicated notations, we will start with the simplest case, $n=2$, which already contains most of the basic ideas.

1. $n=2$

a. The decomposition theorem

In that case, the decomposition theorem (3.1) reads

$$2!U_2=U[12]+U[21]=C[1|2]+C[21]=C[1]C[2]+C[21], \tag{A1}$$

$$U[12]=\int_{R[12]}dt_1\,dt_2H_1(t_1)H_2(t_2)=\int_{T'}^{T}dt_1dt_2\theta(t_1-t_2)H_1(t_1)H_2(t_2), \tag{A2}$$

$$U[21]=\int_{R[21]}dt_1\,dt_2H_2(t_2)H_1(t_1)=\int_{T'}^{T}dt_1dt_2\theta(t_2-t_1)H_2(t_2)H_1(t_1) \tag{A3}$$

$$C[1|2]=C[1]C[2]=\int_{T'}^{T}dt_1dt_2H_1(t_1)H_2(t_2), \tag{A4}$$

$$C[21]=\int_{R[21]}dt_1dt_2[H_2(t_2),H_1(t_1)]. \tag{A5}$$

b. First proof for n=2

The first proof makes use of the simple observation that the union of the two triangular integration regions, $R[12]=\{T\geqslant t_1\geqslant t_2\geqslant T'\}$, and $R[21]=\{T\geqslant t_2\geqslant t_1\geqslant T'\}$, is the square region $\{T\geqslant t_1,t_2\geqslant T'\}$. Thus

$$U[12]+U[21]=\int_{R[12]\cup R[21]} H_1(t_1)H_2(t_2)+\int_{R[21]}[H_2(t_2),H_1(t_1)]$$
$$=C[1]C[2]+C[21]\equiv C[1|2]+C[21]. \tag{A6}$$

c. Second proof for n=2

Equation (3.1) is clearly true when $T=T'$, for both sides then vanish. To prove its general validity for any T', it is sufficient to show the T'-derivatives of both sides to be equal. For $n=2$, we have to show that

$$\frac{d}{dT'}\{U[12]+U[21]\}=\frac{d}{dT'}\{C[1|2]+C[21]\}. \tag{A7}$$

This identity is true because

$$\frac{d}{dT'}U[12]=-\int_{T'}^{T}H_1(t)dt\ H_2(T'),\qquad \frac{d}{dT'}U[21]=-\int_{T'}^{T}H_2(t)dt\ H_1(T'),$$
$$\frac{d}{dT}C[1|2]=-H_1(T')\int_{T'}^{T}H_2(t)dt-\int_{T'}^{T}H_1(t)dt\ H_2(T'), \tag{A8}$$
$$\frac{d}{dT'}C[21]=-\left[\int_{T'}^{T}H_2(t)dt,H_1(T')\right].$$

We shall now proceed to the general proofs.

2. First proof for arbitrary *n*

In the case of $n=2$, the ''first proof'' involves two crucial steps. Step one is to recognize that the union of the two triangular regions, $R[12]$ and $R[21]$, is a square, thus allowing the first term on the right-hand side of (A6) to be factorized. The generalization of this to an arbitrary n is the subject of discussions that immediately follow. The second crucial step is to introduce commutators to rewrite $H_2(t_2)H_1(t_1)$ as a sum of two terms: $H_1(t_1)H_2(t_2)+[H_2(t_2),H_1(t_1)]$. The generalization of this step to arbitrary n will then be discussed. In a final subsection, these two steps will be assembled to complete the proof of the general decomposition theorem.

a. Sums and Cartesian products of hyper-triangular regions

Let $[s]$ be a sequence of n natural numbers, not necessarily consecutive, and $[s]=[\tilde{s}_1\tilde{s}_2\cdots\tilde{s}_p]$ be a partition of this sequence into p subsequences. For example, $[s]=[3254167]$ could be partitioned into three subsequences $[\tilde{s}_1]=[32]$,$[\tilde{s}_2]=[5416]$, and $[\tilde{s}_3]=[7]$. We define the *set* $\{\tilde{s}_1;\tilde{s}_2;\cdots;\tilde{s}_p\}$ to consist of all sequences of these n natural numbers, obtained by merging and interleaving the numbers in $\tilde{s}_1,\tilde{s}_2,\cdots,\tilde{s}_p$ in all possible ways, subject to the condition that the original orderings of numbers within each $\tilde{s}_i$ be kept fixed. This set then contains $n!/(k_1!k_2!\cdots k_p!)$ sequences, where k_i is the number of numbers in the subsequence $\tilde{s}_i$, and $\Sigma_{i=1}^{p}k_i=n$. In the explicit examples above, the set $\{32;5416;7\}$ will consist of $7!/(2!4!1!)=105$ sequences, which among others include $[3254167]$,$[3524176]$, and $[7534162]$, but *not* $[2354167]$ and $[6541732]$ because the original orderings are not kept in these last two cases: the numbers 2 and 3 are reversed in the first instance and the number 6 appears before the numbers 5,4,1 in the second.

Given a permutation $s \in S_n$, recall that the hyper-triangular integration region $R[s]$ is defined to be $\{T \geqslant t_{s_1} \geqslant t_{s_2} \geqslant \cdots \geqslant t_{s_n} \geqslant T'\}$. We shall now define the integration region $R\{\tilde{s}_1;\tilde{s}_2;\cdots;\tilde{s}_p\}$ to be the union of all the regions $R[t]$ with $[t] \in \{\tilde{s}_1;\tilde{s}_2;\cdots;\tilde{s}_p\}$. A moment's thought reveals that this is nothing but the Cartesian product of the individual hyper-triangular regions $R[\tilde{s}_1], R[\tilde{s}_2], \cdots, R[\tilde{s}_p]$. This leads to a *factorization theorem* for the following sums of $U[t]$:

$$\sum_{[t] \in \{\tilde{s}_1;\tilde{s}_2;\cdots;\tilde{s}_p\}} U[t] = \int_{R\{\tilde{s}_1;\tilde{s}_2;\cdots;\tilde{s}_p\}} dt_1\, dt_2 \cdots dt_n H_{s_1}(t_{s_1}) H_{s_2}(t_{s_2}) \cdots H_{s_n}(t_{s_n})$$
$$= U[\tilde{s}_1] U[\tilde{s}_2] \cdots U[\tilde{s}_p]. \tag{A9}$$

A factorization theorem similar to this will be used for the proof of the decomposition theorem.

b. Canonical ordering

From now on we shall denote $H_{s_i}(t_{s_i})$ simply as H_{s_i}, and $H_{s_1} H_{s_2} \cdots H_{s_n}$ as $H[s_1|s_2|\cdots|s_n] \equiv H_c[s]$. The subscript "$c$" of H serves to indicate that a vertical bar is to be put after each number in the sequence $[s]$ to indicate that products of operators should be taken.

A similar symbol without the vertical bar will denote *nested multiple commutators*. Thus $H[1|2|3|4] = H_1 H_2 H_3 H_4 = H_c[1234]$, but $H[12|34] = [H_1, H_2] \cdot [H_3, H_4]$ and $H[1234] = [H_1, [H_2, [H_3, H_4]]]$, etc.

Suppose $[s] = [s_1 s_2 \cdots s_n]$ is a sequence of n numbers, not necessarily consecutive. Then $[s]_c$ will be used to denote the same sequence, but with *vertical bars inserted after* s_i *if* $s_i < s_j$ *for all* $i < j$. For example, if $[s] = [7125]$, then $[s]_c = [71|2|5]$, and if $[s] = [21345]$, then $[s]_c = [21|3|4|5]$. An operator of the form $H[s]_c$ will be called a *canonical operator*. Please note the difference between $H_c[s]$ and $H[s]_c$. The former is generally not a canonical operator, but the latter is, by definition.

Let $s \in S_n$. From (2.1), the integrand in $U[s]$ is given by $H_c[s]$, which as mentioned above is generally *not* a canonical operator. By introducing commutators, it is possible to *canonically order* this operator, meaning that it can be written as a linear combination of canonical operators. I shall illustrate how this is done by looking at a simple example, $H[3|2|1] = H_3 H_2 H_1 = H_c[321]$:

$$\begin{aligned} H[3|2|1] &= H_3 H_2 H_1 \\ &= H_3 [H_2, H_1] + [H_3, H_1] H_2 + H_1 H_3 H_2 = [H_2, H_1] H_3 + [H_3, [H_2, H_1]] \\ &\quad + [H_3, H_1] H_2 + H_1 H_3 H_2 \\ &= H[21|3] + H[321] + H[31|2] + H[1|3|2] \qquad \text{(A10)} \\ &= H[21|3] + H[321] + H[31|2] + H[1|2|3] + H[1|32]. \qquad \text{(A11)} \end{aligned}$$

Note that the first three terms of (A10) are canonical operators but not the fourth. This is then fixed in (A11) so that all its five operators are now canonical.

With this example in mind, we can now discuss how to canonically order an arbitrary operator of the form $H_c[s]$, where $[s]$ is a sequence of numbers, not necessarily consecutive.

Locate the smallest number s_0 in the sequence. By introducing commutators and commutators of commutators, we shall try to move H_{s_0}, and commutators involving it, to the extreme left. This results in a sum of a number of terms which can be described as follows.

Suppose s_0 is situated somewhere in the middle of $[s]$ so that $[s] = [\tilde{s}_1 s_0 \tilde{s}_2]$, with a subsequence $[\tilde{s}_1]$ before s_0 and a subsequence $[\tilde{s}_2]$ after. Let $[\tilde{s}_1']$ and $[\tilde{s}_1'']$ be two complementary subsequences of numbers in $[\tilde{s}_1]$ in the sense that all numbers in $[\tilde{s}_1]$ appear either in $[\tilde{s}_1']$ or $[\tilde{s}_1'']$. For example, if $[\tilde{s}_1] = [7352]$, then $[\tilde{s}_1'], [\tilde{s}_1'']$ may be $[3], [752]$, or $[75], [32]$, etc., but not $[7], [52]$ (3 is left out), nor $[37], [52]$ (order of 7,3 are reversed). If $[\tilde{s}_1]$ has q numbers, then there are altogether 2^q pairs of complementary subsequences like that.

Now we are ready to describe the terms obtained by the move of H_{s_0} and its commutators to the extreme left in order to achieve canonical ordering. They involve all terms of the form $H[\tilde{s}_1' s_0]H_c[t]$, where $[t]=[\tilde{s}_1''\tilde{s}_2]$ is the sequence obtained by prepending the subsequence $[\tilde{s}_1'']$ to the subsequence $[\tilde{s}_2]$. Since s_0 is the smallest number in $[s]$, the operator $H[\tilde{s}_1' s_0]$ is canonical, though the remaining factor $H_c[t]$ may not be. If not, we will then repeat the same procedure, find the smallest number t_0 of $[t]$, and move H_{t_0} and its commutators to the extreme left of $H_c[t]$ to render sections of $H_c[t]$ canonical. Continuing thus, eventually $H_c[s]$ can be rendered into sums of canonical operators.

We can describe this result in another way, more useful for our subsequent proof. Given a canonical operator $H[u]_c$, with $[u]\in S_n$, this result states that it will appear in the canonical ordering of $H_c[s]$ iff $[s]\in\{u\}$, where $\{u\}$ is the *set* of permutations obtained by changing the vertical bars in $[u]_c$ into semicolons '';'', and the square brackets $[\cdots]_c$ into curly brackets $\{\cdots\}$. For example, if $[u]_c=[21|3]$, then $\{u\}=\{21;3\}=\{[321],[231],[213]\}$, and the operators $H_c[s]$ containing the canonical operator $H[21|3]$ are $H_c[321]=H[3|2|1]$, $H_c[231]=H[2|3|1]$, and $H_c[213]=H[2|1|3]$.

c. Proof

We can now assemble these two ingredients into a proof of the general decomposition theorem (3.1). According to the rule for canonical ordering, the integrand $H[u]_c$ will be contained in $U[s]$ iff $[s]\in\{u\}\equiv\{\tilde{u}_1;\tilde{u}_2;\cdots;\tilde{u}_q\}$. The integration region for the integrand $H[u]_c$ is therefore $\cup_{[s]\in\{u\}}R[s]=R\{u\}$. The resulting integral is therefore

$$\int_{R\{u\}} dt_1\cdots dt_n\ H[\tilde{u}_1|\tilde{u}_2|\cdots|\tilde{u}_q]=C[\tilde{u}_1]C[\tilde{u}_2]\cdots C[\tilde{u}_q]=C[\tilde{u}_1|\tilde{u}_2|\cdots|\tilde{u}_q]. \tag{A12}$$

The last step is similar to the one used to obtain the factorization theorem (A9). Summing over all possible $[u]\in S_n$ is equivalent to summing over all possible $s\in S_n$; by doing so we will get from (A12) the general decomposition theorem (3.1).

3. Second proof for arbitrary *n*

The decomposition theorem is trivially true when $T=T'$, thus its general validity would follow if the T'-derivatives of (3.1) are obeyed:

$$\frac{d}{dT'}\sum_{[u]\in S_n} U[u]=\frac{d}{dT'}\sum_{[u]\in S_n} C[u]_c. \tag{A13}$$

Our second proof consists of proving this equation, with the help of the identities

$$\frac{d}{dT'}U[u]=-U[u']H_r(T'), \tag{A14}$$

$$\frac{d}{dT'}C[\tilde{u}_j]=-[C[\tilde{u}_j'],H_s(T')], \tag{A15}$$

where r is the last element in $[u]\in S_n$ and s is the last element of $[\tilde{u}_j]$. In other words, $[u]=[u'r]$ and $[\tilde{u}_j]=[\tilde{u}_j's]$. $[\tilde{u}_j]$ is one of the sequences between vertical bars in $[u]_c$, and by definition $C[u]_c$ is given by a product of $C[\tilde{u}_j]$ over different j.

We have to be careful with (A14) and (A15) when $[u]$ or $[\tilde{u}_j]$ contains only one number. In that case $[u']$ and $[\tilde{u}_j']$ are void and $U[u']=1$. Moreover,

$$\frac{d}{dT'}C[s]=-H_s(T'). \tag{A16}$$

Let $S_{n-1}[m]$ be the permutation group of the first n natural numbers with the number m removed. Using (A14), the left-hand side of (A13) becomes

$$\frac{d}{dT'}\sum_{[u]\in S_n} U[u] = -\sum_{m=1}^{n}\sum_{[u']\in S_{n-1}[m]} U[u']H_m(T'). \tag{A17}$$

In order for (A13) to be true, the right-hand side must also be given by (A17).

Now in (A17) the operators $H_m(T')$ always appear at the extreme right. On the other hand, if we apply (A15), (A16) to compute the right-hand side of (A13), the operators $H_m(T')$ may also appear at other positions. In fact, when $H_m(T')$ appears m is always the last element of $[\tilde{u}_j] = [\tilde{u}_j' m]$ for some j. To determine for what $[u]_c$ this occurs we consider an arbitrary element $[u'] \in S_{n-1}[m]$. Suppose $[u']_c = [\tilde{u}_1'|\tilde{u}_2'|\cdots|\tilde{u}_k']$. We will now discuss where in $[u']_c$ we may insert the number m to obtain a legitimate $[u]_c$ for some $[u]\in S_n$ in which m appears just before a vertical bar, or the right-hand square bracket]. If m is to be inserted at the end of a subsequence $\tilde{u}_j'$, then m must be smaller than all the numbers in $\tilde{u}_j'$. Since the last element of $\tilde{u}_j'$ increases with j, if m may appear at the end of $\tilde{u}_j'$ it may also appear at the end of $\tilde{u}_\ell'$ for all $\ell > j$. On the other hand, there may be a smallest $j=j_0$. In that case, it is not allowed to insert m at the end of $[\tilde{u}_j']$ for $j<j_0$, but the insertion $[\tilde{u}_1'|\cdots|m|\tilde{u}_{j_0}'|\cdots|\tilde{u}_k]$ is allowed.

So consider a fixed $[u'] \in S_{n-1}[m]$ and all the resulting $[u]\in S_n$ with these insertions of the number m. Using (A15) and (A16), it is now easy to see that $dC[u]_c/dT'$, summed over all such $[u]$'s, will give $-C[u']_c H_m(T']$. Summing over all $[u']$ and all m, we therefore regain the right-hand side of (A17), and hence proving (A13), provided

$$\sum_{[u']\in S_{n-1}[m]} U[u'] = \sum_{[u']\in S_{n-1}[m]} C[u']_c. \tag{A18}$$

This last identity follows from the induction hypothesis (on n), which we may invoke, because (3.1) is true for $n=2$. This completes the second proof of the decomposition theorem.

APPENDIX B: SPECIAL DECOMPOSITION THEOREM

When the operator functions $H_i(t)$ are all identical, the decomposition theorem reduces to Eq. (4.1), as we shall show by deriving the expression for $\xi(m)$. This is equal to the number of $[s]_c = [\tilde{s}_1|\tilde{s}_2|\cdots|\tilde{s}_k]$ with $[\tilde{s}_j]$ containing m_j numbers ($\Sigma_j\, m_j = n$), divided by $n!$.

We remind the readers how to construct $[s]_c$ for every $s\in S_n$. A vertical bar is placed behind a number s_i iff $s_i < s_j$ for all $i<j$.

Thus the last element of $[\tilde{s}_1]$ is always the smallest of the n numbers, i.e., the number ''1.'' There are therefore $[(n-1)!/(m_1-1)!(n-m_1)!](m_1-1)! = n!/(n-m_1)!$ ways of constructing $[\tilde{s}_1]$.

Similarly, the last element of $[\tilde{s}_2]$ is the smallest number in the residue sequence $[s]/[\tilde{s}_1] = [\tilde{s}_2\tilde{s}_3\cdots\tilde{s}_k]$. The remaining m_2-1 numbers in $\tilde{s}_2$ can be chosen arbitrarily from the $n-1-m_1$ elements in the residue sequence, so there are $(n-1-m_1)!/(n-m_1-m_2)!$ ways of doing so. Continuing thus, the total number of ways is simply the product of these numbers. After dividing by $n!$, we get

$$\xi(m_1 m_2\cdots m_k) = \left[(n-m_1)(n-m_1-m_2)\cdots\left(n-\sum_{i=1}^{k-1} m_i\right)\right]^{-1}, \tag{B1}$$

which is the same as the formula given in (4.1).

APPENDIX C: EXPONENTIAL FORMULA FOR COMMUTING C_i'S

To obtain (5.1) when all the C_i's commute, we need to know the number of $[s]_c$ whose vertical bars separate the sequence into m_j subsequences of length j ($j=1,2,3,\cdots$).

The number of ways that n numbers can be divided into m_j groups of j numbers is $n!/\Pi_j(m_j!j!^{m_j})$. From any one of these groupings we can produce $\Pi_j(m_j-1)!$ viable $[s]_c$'s in the following way. Recall that the vertical bars of $[s]_c$ are put behind a number s_i iff $s_i<s_k$ for all $i<k$. Stated differently, this means that (i) the last number in each group of numbers separated by the vertical bars is always the smallest number of that group, and that (ii) the groups must be arranged in such a way that their smallest numbers increase from left to right. For a given grouping of numbers, there are $\Pi_j(j-1)!^{m_j}$ ways of arranging the orderings within each group to satisfy (i). Once this is done, we can order the different groups in a unique way so that (ii) is satisfied. Hence the number of $[s]_c$ is given by $[n!/\Pi_j(m_j!j!^{m_j})][\Pi_j(j-1)!^{m_j}]=n!/(\Pi_j m_j!j^{m_j})$. From this the rest of (5.1) follows easily.

APPENDIX D: GENERAL EXPONENTIAL FORMULA

(5.4) can be computed from (5.3) and (4.1) as follows. If $P(U_n)$ is a polynomial of U_n, then $[P(U_n)]_m$ is obtained from $P(U_n)$ by discarding all products of U_i's whose ''degree'' (sum of indices i) is not equal to m. With this convention we have $K_n=\Sigma_{\ell=1}^{n}(-)^{\ell-1}[U^{\ell}]_n$, so

$$K_1=U_1=C_1, \qquad K_2=U_2-\tfrac{1}{2}U_1^2=\tfrac{1}{2}C_2,$$

$$K_3=U_3-\tfrac{1}{2}(U_1U_2+U_2U_1)+\tfrac{1}{3}U_1^3=\tfrac{1}{3}C_3+\tfrac{1}{12}[C_2,C_1], \tag{D1}$$

$$K_4=U_4-\tfrac{1}{2}[U_1U_3+U_3U_1+U_2^2]+\tfrac{1}{3}[U_1^2U_2+U_1U_2U_1+U_2U_1^2]-\tfrac{1}{4}U_1^4,$$

$$K_5=U_5-\tfrac{1}{2}[U_1U_4+U_4U_1+U_2U_3+U_3U_2]+\tfrac{1}{3}[U_1^2U_3+U_1U_3U_1+U_3U_1^2+U_2^2U_1$$
$$+U_2U_1U_2+U_1U_2^2]-\tfrac{1}{4}[U_1^3U_2+U_1^2U_2U_1+U_1U_2U_1^2+U_2U_1^3]+\tfrac{1}{5}U_1^5.$$

Substituting in the expressions given in (4.2) for U_i into the last two equations, we obtain the expression for K_4 and K_5 given in (5.4).

APPENDIX E: NESTED MULTIPLE COMMUTATORS

Given n operators $C_{m_i}\equiv B_i$, we denoted their nested multiple commutators by

$$B[s]\equiv B[s_1s_2\cdots s_n]\equiv[B_{s_1},[B_{s_2},[\cdots,[B_{s_{n-1}},B_{s_n}]\cdots]]], \tag{E1}$$

where $s\in S_n$. We want to show that the $(n-1)!$ nested operators $B[s'1]$, with $s'\in S_{n-1}[1]$ [this is defined just below eq. (A16)] forms a linear basis for all the n-tuple multiple commutators. In other words, if V_n is the vector space spanned by these $(n-1)!$ nested commutators, then V_n contains all n-tuple multiple commutators.

This means that (i) multiple commutators not of the nested form can be written as linear combinations of the multiple commutators of the nested form, and (ii) nested multiple commutators with B_1 not at the last place can be written as linear combinations of those with B_1 at the last place.

We shall use M_n to denote the vector space generated by all n-tuple multiple commutators. We shall now proceed to show that $M_n=V_n$.

To denote a multiple commutator not of the nested type, we use parentheses to single out those factors within it that are nested. For example,

$$B[((123)4(567))8]=[B[(123)4(567)],B_8],$$

$$B[(123)4(567)]=B[(123)4567]=[B[(123)],[B_4,[B_5,[B_6,B_7]]]], \tag{E2}$$

$$B[(123)]=B[123]=[B_1,[B_2,B_3]].$$

Note that if $[s]$ is any sequence of numbers, then $B[\cdots(s)]=B[\cdots s]$. In other words, the pair of parentheses located at the end can be dropped.

To prove (i), we must show that all the parentheses can be removed. This can be accomplished via the Jacobi identity

$$[A_1,[A_2,A_3]]=[A_3,[A_2,A_1]]-[A_2,[A_3,A_1]], \tag{E3}$$

with A_1 being the operator contained in the leftmost pair of parentheses. The identity will be used to move A_1 to the right. If it reaches the end then the parentheses can be dropped. Repeating this procedure eventually we can gradually move all the parentheses to the end and have them all dropped. This shows that $M_n=V_n$.

We shall now prove (ii) by induction.

For $n=2$ this is obvious because

$$[B_2,B_1]=-[B_2,B_1]. \tag{E4}$$

For $n=3$ this follows from (E4) and the Jacobi identity (E3). We merely have to take $B_i=A_i$.

Assuming this can be done for n up to $n=m-1$, we must now show it to be true for $n=m$.

Unless B_1 is at the beginning position there is nothing to prove, for otherwise B_1 and operators to its right are located in an $M_n=V_n$ for $n\leqslant m-1$, so B_1 can be moved to the end.

If B_1 is located at the first position, so that the nested multiple commutator is of the form $B[1s]$ for some sequence $[s]$ with $n-1$ numbers, then using (E3) with $B_1=A_1$ we can move B_1 to the right. Again it and the operators to its right now belongs to M_n with $n\leqslant m-1$, so by the induction hypothesis B_1 can be moved to the end. This completes the proof of (ii).

In particular, V_4 is spanned by the 6 nested commutators $B[4321],B[4231],B[3421]$, $B[3241],B[2431]$, and $B[2341]$. Only the first nested commutator contains the term $B_4B_3B_2B_1$, so the coefficient of this nested commutator in K is identical to the coefficient of this term in K, a fact that has been used in Sec. V C 3 to compute the coefficient of a nested commutator.

This result can also be used to understand why only the particular nested commutators of H_i defined in C_m occur in K.

APPENDIX F: GAUGE INVARIANCE

We want to study in this Appendix the behavior of U_n, C_n, and K_n under the ''gauge transformation''

$$\delta H(t)=\frac{d\Lambda(t)}{dt}+[\Lambda(t),H(t)]\equiv\delta_{-1}H(t)+\delta_0H(t), \tag{F1}$$

where $\Lambda(t)$ is an arbitrary function of t vanishing at the boundaries: $\Lambda(T)=\Lambda(T')=0$.

Recall that $U_n=U[123\cdots n]$ and $C_n=C[123\cdots n]$, that time is ordered according to the sequence of indices in the square bracket, and that an operator $H(t_i)$ is present inside the integral at the position of the index i. The only difference between $U[\cdots]$ and $C[\cdots]$ is that this operator appears as a factor in a straight product in the former, and it appears inside a nested multiple commutator in the latter.

We shall now introduce an index with a prime to denote the operator Λ. At the position where i' appears in the sequence will be the operator $\Lambda(t_i)$. If the primed index is inside $U[\cdots]$, then Λ is a member of a straight product as before. If it appears inside $C[\cdots]$, then it is a part of the nested commutators.

We will also introduce parentheses $(i'i)$ to denote commutators. Thus at the position this appears should stand the operator $[\Lambda(t_i),H(t_i)]$.

With these notations we are now ready to discuss the gauge properties of the various quantities.

For $U_n=U[123\cdots n]$ it is simple:

$$\delta_0U_{n+1}=\sum_{j=1}^{n}\{-U[12\cdots j'j\cdots n]+U[12\cdots jj'\cdots n]\}=-\sum_{j=1}^{n}U[12\cdots(j'j)\cdots n], \tag{F2}$$

$$\delta_{-1}U_n=\sum_{j=1}^{n} U[12\cdots(j'j)\cdots n]. \tag{F3}$$

Clearly (5.9) is satisfied and U is gauge invariant.

Now for C_n:

$$\delta_0 C_{n+1}=\sum_{j=1}^{n}\{-C[12\cdots j'j\cdots n]+C[12\cdots jj'\cdots n]\}, \tag{F4}$$

$$\delta_{-1}C_n=\sum_{j=1}^{n} C[12\cdots(j'j)\cdots n], \tag{F5}$$

so they look deceptively similar to the equations for U_n. However, since the operators in $C[\cdots]$ appear in *nested* commutators, the two terms in (F4) can be combined into $-C[12\cdots(j'j)\cdots n]$ only with the help of the Jacobi identity, and this we can do only for $j\leqslant n-1$. Jacobi identity involves double commutators and those are absent at $j=n$. Instead, we can use the antisymmetry of a single commutator to add up these two terms. Hence

$$\delta_0 C_{n+1}=-\sum_{j=1}^{n-1} C[12\cdots(j'j)\cdots n]-2C[12\cdots(n'n)]. \tag{F6}$$

The parentheses in the last term may be dropped; we kept it there just for the uniformity of notation with the other terms. The main difference between this and (F2) is that this last term now has a factor of 2, which makes $\delta_{-1}C_{n+1}+\delta_0 C_n\neq 0$. It is this ''slight'' difference that eventually makes K very complicated just in order to keep its gauge invariance according to (5.10)!

We shall now use (D1) and (F6) to verify (5.10) for the first few orders. Since K_n contains the term C_n/n, it is useful to compute

$$\frac{1}{n+1}\delta_{-1}C_{n+1}+\frac{1}{n}\delta_0 C_n=\frac{1}{n(n+1)}\left\{\sum_{j=1}^{n-1} C[12\cdots(j'j)\cdots n]-(n-1)C[12\cdots(n'n)]\right\}. \tag{F7}$$

Referring back to (5.4), commutator terms are not present at K_n for $n=1,2$, which means that gauge invariance of K demands (F7) to be zero for $n=1$, which it is. For $n=2$,

$$\begin{aligned}\delta_{-1}K_3+\delta_0 K_2&=\tfrac{1}{3}\delta_{-1}C_3+\tfrac{1}{2}\delta_0 C_2+\tfrac{1}{12}\delta_{-1}([C_2,C_1])\\&=\tfrac{1}{6}(C[(1'1)2]-C[1(2'2)]-[C[(1'1)],C_1]).\end{aligned} \tag{F8}$$

The last expression is arrived at by using (F7), $\delta_{-1}C_1=0$, and $\delta_{-1}C_2=-2C[(1'1)]$. Now use the observation just before Eq. (A6) to obtain the identity

$$[C_1,C[(1'1)]]=C[1(2'2)]-C[(1'1)2]. \tag{F9}$$

Substituting this back into (F8) we conclude that $\delta_{-1}K_3+\delta_0 K_2=0$.

I have verified (5.10) to one higher order. The verification becomes increasingly more difficult at larger n.

APPENDIX G: CAMPBELL–BAKER–HAUSDORFF FORMULA

Consider a special case in which $T=2$, $T'=0$, $H(t)=P$ for $2\geqslant t\geqslant 1$, and $H(t)=Q$ for $1\geqslant t\geqslant 0$. The operators P and Q are completely arbitrary.

We consider the ramification of (5.4) in this special case. Using (6.1) with $T''=1$, the left-hand-side of (5.4) is just $\exp(P)\exp(Q)$. To compute the right-hand side we must first compute the C_m's in this special situation using (2.3).

Clearly $C_1=P+Q$. For C_m with $m\geqslant 2$, in order for the commutators inside (2.3) not to vanish we must have t_m between 0 and 1, and all the other $t_i(1\leqslant i\leqslant m-1)$ between 1 and 2. Thus

$C_m=(\text{ad } P)^{m-1}Q/(m-1)!$, where as usual $(\text{ad } P)V=[P,V]$ for any operator V. Substituting this back into (5.4) we get the Campbell–Baker–Hausdorff formula shown in (6.3).

APPENDIX H: TRANSLATIONAL OPERATOR

Consider now the special case when $T=3$, $T'=0$, $H(t)=\text{ad}/dx$ for t between 3 and 2, $H(t)=f(x)$ for t between 2 and 1, and $H(t)=-\text{ad}/dx$ for t between 1 and 0. Here $f(x)$ is an arbitrary function and a is a constant.

By using (6.1) the left-hand side of (5.4) becomes $\exp(\text{ad}/dx)\cdot\exp(f(x))\cdot\exp(-\text{ad}/dx)$. To compute the right-hand side we need to compute C_m using (2.3). It is clear that $C_1=f(x)$. To compute C_{m+1} for $m\geqslant 1$, note the following. In order for the commutators in (2.3) not to vanish, t_{m+1} must either be between 0 and 1, or between 1 and 2. We shall denote the former contribution by C'_{m+1}, and the latter by C''_{m+1}.

To compute C'_{m+1}, we must have t_m to be between 1 and 2, and t_i for $i<m$ to be between 2 and 3. Hence $C'_{m+1}=a^m(d^mf(x)/dx^m)/(m-1)!$. For C''_{m+1}, we must have all t_i for $i\leqslant m$ to be between 2 and 3, hence $C''_{m+1}=a^m(d^mf(x)/dx^m)/m!$. Adding up the two, we get $C_{m+1}=C'_{m+1}+C''_{m+1}=(m+1)a^m(d^mf(x)/dx^m)/m!$. Hence all the C_i's commute with one another, so (5.1) can be used instead. (6.4) then follows immediately.

Finite-dimensional irreducible representations of twisted Yangians

A. I. Molev[a)]
School of Mathematics and Statistics, Carslaw Building (F07), University of Sydney, Sydney, New South Wales 2006, Australia

(Received 1 December 1997; accepted for publication 29 April 1998)

We study quantized enveloping algebras called twisted Yangians. They are analogs of the Yangian $Y(gl(N))$ for the classical Lie algebras of *B*, *C*, and *D* series. The twisted Yangians are subalgebras in $Y(gl(N))$ and coideals with respect to the coproduct in $Y(gl(N))$. We give a complete description of their finite-dimensional irreducible representations. Every such representation is highest weight and we give necessary and sufficient conditions for an irreducible highest weight representation to be finite dimensional. The result is analogous to Drinfeld's theorem for the ordinary Yangians. Its detailed proof for the *A* series is also reproduced. For the simplest twisted Yangians we construct an explicit realization for each finite-dimensional irreducible representation in tensor products of representations of the corresponding Lie algebras. © *1998 American Institute of Physics.*

I. INTRODUCTION

The Yangian Y(a) associated with a simple complex Lie algebra a is a deformation of the universal enveloping algebra $U(a[t])$ in the class of Hopf algebras.[1,2] In the case of the *A* series one can also define the Yangian $Y(N)=Y(gl(N))$ for the reductive complex Lie algebra $a=gl(N)$ (see, e.g., Ref. 3). The Yangian $Y(sl(N))$ can be identified with a (Hopf) subalgebra in $Y(gl(N))$. The Yangians are closely related to rational solutions of the Yang–Baxter equation[1] and play the role of quantum symmetry groups of certain integrable systems; see, e.g., Refs. 4–7. Finite-dimensional irreducible representations of the Yangians were classified by Drinfeld.[2] In the case of $a=gl(2)$ this had been done by Tarasov;[8,9] see also Ref. 10. [In these papers the language of the quantum inverse scattering theory and integrable models was used. Representations of the Yangian Y(2) appear there in the form of the *monodromy matrix* for the XXX-model]. This result plays the main role in the proof in the general case. Representations of the Yangians were further studied in Refs. 11–18.

For any a the Yangian Y(a) contains the universal enveloping algebra U(a). However, the *A* series case seems to be exceptional since only in this case does there exists an algebra homomorphism $Y(a)\to U(a)$ identical on U(a). This homomorphism is important for applications of the ''quantum theory'' to the representation theory of the Lie algebra $gl(N)$. In particular, it can be used to construct Laplace operators for $gl(N)$, to derive characteristic identities and Capelli identities.[15,19–23]

It was shown by Olshanski[24] that the Yangian $Y(N)$ is isomorphic to a certain projective limit algebra. Namely, there exist natural algebra homomorphisms $A_N(M+1)\to A_N(M)$, where $A_N(M)$ denotes the $gl(M)$-centralizer in $U(gl(N+M))$, and the projective limit A_N of the chain $\{A_N(M)\}$ as $M\to\infty$ contains $Y(N)$ as a subalgebra. This construction can be applied to other series of classical Lie algebras.[25] However, as a result one obtains not the corresponding Yangian Y(a), but different algebras which were called twisted Yangians;[25] see also Ref. 26. Defining relations for the twisted Yangian can be written in the form of a reflection-type equation [see (2.16) below] which allows one to use a special *R*-matrix technique for their study. Some other algebras associated with the reflection equation were studied in Refs. 27–29.

Let $g(N)$ denote the orthogonal Lie algebra $o(N)$ or symplectic Lie algebra $sp(N)$. We regard $g(N)$ as a fixed point subalgebra in $gl(N)$ with respect to an involutive automorphism σ. The twisted Yangian is a deformation of the universal enveloping algebra $U(gl(N)[t]^\sigma)$, where

$$\mathrm{gl}(N)[t]^{\sigma}=\{A(t)\in \mathrm{gl}(N)[t]\,|\,\sigma(A(t))=A(-t)\}.$$

We denote by $\mathrm{Y}^{+}(N)$ and $\mathrm{Y}^{-}(N)$ the twisted Yangians corresponding to the orthogonal and symplectic Lie algebras, respectively. Similar to the A series case the algebra $\mathrm{Y}^{\pm}(N)$ contains the corresponding universal enveloping algebra $\mathrm{U}(\mathrm{g}(N))$ and one has a natural algebra homomorphism $\mathrm{Y}^{\pm}(N)\to\mathrm{U}(\mathrm{g}(N))$ identical on $\mathrm{U}(\mathrm{g}(N))$.

A detailed description of the algebraic structure of the Yangian $\mathrm{Y}(N)$ and the twisted Yangians $\mathrm{Y}^{\pm}(N)$ is contained in Ref. 30. An explicit formula for the formal series (the Sklyanin determinant) whose coefficients generate the center of $\mathrm{Y}^{\pm}(N)$ was given in Ref. 31. Bethe-type commutative subalgebras in $\mathrm{Y}^{\pm}(N)$ were constructed in Ref. 32. These results were applied in Refs. 19, 31, and 33 to construct Laplace operators for the orthogonal and symplectic Lie algebras and to get characteristic identities and Capelli identities.

In this paper we give a complete description of the finite-dimensional irreducible representations for all twisted Yangians. Our approach is very close to the $\mathrm{gl}(N)$-case and we use some ideas and results of that case in our constructions.

Section II contains definitions and preliminary results on the Yangian $\mathrm{Y}(N)$ and the twisted Yangians $\mathrm{Y}^{\pm}(N)$.

In Sec. III we give detailed proofs of Drinfeld's and Tarasov's theorems describing the finite-dimensional irreducible representations of $\mathrm{Y}(N)$. These representations can be constructed as follows. First, using the homomorphism $\mathrm{Y}(N)\to\mathrm{U}(\mathrm{gl}(N))$ one extends any finite-dimensional irreducible representation $L(\lambda)$ of the Lie algebra $\mathrm{gl}(N)$ to the Yangian $\mathrm{Y}(N)$. Using the Hopf algebra structure on $\mathrm{Y}(N)$ one can consider representations of the form

$$L(\lambda^{(1)})\otimes\cdots\otimes L(\lambda^{(k)}). \tag{1.1}$$

Then any finite-dimensional irreducible representation of $\mathrm{Y}(\mathrm{sl}(N))$ [or $\mathrm{Y}(N)$, up to tensoring with one-dimensional representations of the center of $\mathrm{Y}(N)$] can be realized as the irreducible quotient of the cyclic span in (1.1) of the tensor product of the highest weight vectors of the $L(\lambda^{(i)})$. In the case $N=2$ there is no need to use quotients as any finite-dimensional irreducible representation of $\mathrm{Y}(\mathrm{sl}(2))$ is isomorphic to a tensor product (1.1). A criterion of irreducibility of the representation (1.1) of $\mathrm{Y}(\mathrm{sl}(2))$ in terms of ''strings'' (subsets in $\mathbb{C}$ of the form $\{a,a+1,...,b\}$) was given by Chari and Pressley.[11,13] We give a proof of this result below (Corollary 3.11).

Alternatively, every finite-dimensional irreducible representation of $\mathrm{Y}(N)$ is highest weight (see Definition 3.1). It is isomorphic to a representation of the form $L(\lambda(u))$, where $\lambda(u)=(\lambda_1(u),...,\lambda_N(u))$ is a collection of formal series in u^{-1}. Moreover, given a set $\lambda(u)$ there exists a unique (up to an isomorphism) irreducible highest weight module $L(\lambda(u))$. Drinfeld's theorem[2] (see Theorem 3.12 below) provides necessary and sufficient conditions for $L(\lambda(u))$ to be finite-dimensional.

In Secs. IV–VII we give analogs of these descriptions for the twisted Yangians. Namely, using the homomorphism $\mathrm{Y}^{\pm}(N)\to\mathrm{U}(\mathrm{g}(N))$ we extend any finite-dimensional irreducible representation $V(\mu)$ of the Lie algebra $\mathrm{g}(N)$ to the twisted Yangian $\mathrm{Y}^{\pm}(N)$. The subalgebra $\mathrm{Y}^{\pm}(N)\subset\mathrm{Y}(N)$ is a left coideal,

$$\Delta(\mathrm{Y}^{\pm}(N))\subset\mathrm{Y}(N)\otimes\mathrm{Y}^{\pm}(N), \tag{1.2}$$

and so, we may construct representations of $\mathrm{Y}^{\pm}(N)$ of the form

$$L(\lambda^{(1)})\otimes\cdots\otimes L(\lambda^{(k)})\otimes V(\mu). \tag{1.3}$$

As in the $\mathrm{gl}(N)$-case, any finite-dimensional irreducible representation of $\mathrm{Y}^{\pm}(N)$ (up to tensoring with one-dimensional representations of the center) can be realized as the irreducible quotient of the cyclic span in (1.3) of the tensor product of the highest weight vectors of the $L(\lambda^{(i)})$ and $V(\mu)$.

On the other hand, we prove that any finite-dimensional irreducible representations of $\mathrm{Y}^{\pm}(N)$ is highest weight, that is, isomorphic to a representation of the form $V(\mu(u))$ (see Definition 4.1), and we find necessary and sufficient conditions for $V(\mu(u))$ to be finite-dimensional; see Theorems 5.8, 6.9, 7.7 for the cases of C, D, B series, respectively.

The key part of the proof is a detailed study of the simplest cases $\mathrm{Y}^{\pm}(2)$ and $\mathrm{Y}^{+}(3)$. We use a modified Tarasov's argument[8,9] and also use some ideas from Refs. 11 and 13, as well as Refs. 34 and 35 where representations of the super-Yangians were studied. We give explicit realizations for all finite-dimensional irreducible representations of the simplest twisted Yangians $\mathrm{Y}^{-}(2)$ and $\mathrm{Y}^{+}(2)$ and prove analogs of Chari–Pressley's theorem for these algebras; see Corollaries 5.5, 5.7 and Corollaries 6.5, 6.6, respectively. The *B* series case requires an extra care. We construct raising and lowering operators in a $\mathrm{Y}^{+}(3)$-module $V(\mu(u))$ which preserve the subspace of $\mathrm{Y}^{+}(2)$-singular vectors. To get the necessary conditions for $V(\mu(u))$ to be finite-dimensional we examine the weights of the $\mathrm{Y}^{+}(2)$-singular vectors and use the results for the case of $\mathrm{Y}^{+}(2)$.

Some of the results of this paper [mainly for the case of $\mathrm{Y}^{-}(2n)$] were announced without complete proofs in Ref. 36.

II. DEFINITIONS AND PRELIMINARY RESULTS

Our main reference for the algebraic structure of the Yangian $\mathrm{Y}(N)$ and the twisted Yangians $\mathrm{Y}^{\pm}(N)$ is the expository paper—Ref. 30. In this section we give necessary definitions and formulate some results to be used in the subsequent sections.

We shall assume that given positive integer N, indices i,j run through the set $\{-n,\dots,-1,0,1,\dots,n\}$ if $N=2n+1$ and run through the set $\{-n,\dots,-1,1,\dots,n\}$ if $N=2n$.

The *Yangian* $\mathrm{Y}(N)=\mathrm{Y}(\mathrm{gl}(N))$ is the complex associative algebra with the generators $t_{ij}^{(1)},t_{ij}^{(2)},\dots$ where $-n\leqslant i,j\leqslant n$, and the defining relations

$$[t_{ij}^{(r+1)},t_{kl}^{(s)}]-[t_{ij}^{(r)},t_{kl}^{(s+1)}]=t_{kj}^{(r)}t_{il}^{(s)}-t_{kj}^{(s)}t_{il}^{(r)},$$

where $r,s=0,1,2,\dots$ and $t_{ij}^{(0)}:=\delta_{ij}$. For any i,j define the formal power series

$$t_{ij}(u)=\delta_{ij}+t_{ij}^{(1)}u^{-1}+t_{ij}^{(2)}u^{-2}+\cdots\in\mathrm{Y}(N)[[u^{-1}]].$$

Then the defining relations can be also written as follows:

$$[t_{ij}(u),t_{kl}(v)]=\frac{1}{u-v}\,(t_{kj}(u)t_{il}(v)-t_{kj}(v)t_{il}(u)). \tag{2.1}$$

They can also be written as a single *ternary relation* (see, e.g., Ref. 30, Sec. 1) for the *T-matrix*,

$$T(u):=\sum_{i,j}t_{ij}(u)\otimes E_{ij}\in\mathrm{Y}(N)[[u^{-1}]]\otimes\mathrm{End}\mathbb{C}^N,$$

where the E_{ij} are the standard matrix units. It has the form

$$R(u-v)T_1(u)T_2(v)=T_2(v)T_1(u)R(u-v). \tag{2.2}$$

Here $T_1(u)$ and $T_2(u)$ are regarded as elements of $\mathrm{Y}(N)[[u^{-1}]]\otimes\mathrm{End}\mathbb{C}^N\otimes\mathrm{End}\mathbb{C}^N$, the subindex of $T(u)$ indicates to which copy of $\mathrm{End}\mathbb{C}^N$ this matrix corresponds; $R(u)=1-u^{-1}P$, where P is the permutation operator in $\mathbb{C}^N\otimes\mathbb{C}^N$.

The following analog of the Poincaré–Birkhoff–Witt theorem holds for the algebra $\mathrm{Y}(N)$ (Ref. 30, Corollary 1.23):

Given an arbitrary linear order on the set of generators $\{t_{ij}^{(r)}\}$, *any element of the algebra* $\mathrm{Y}(N)$ *is uniquely written as a linear combination of ordered monomials in the generators.*

In what follows we shall always assume that a linear order $\prec$ is chosen in such a way that

$$t_{i_1j_1}^{(r_1)}\prec t_{i_2j_2}^{(r_2)}\prec t_{i_3j_3}^{(r_3)} \tag{2.3}$$

as soon as $i_1>j_1$, $i_2=j_2$, and $i_3<j_3$.

We shall regard the set of the matrix units $\{E_{ij}\}$ as a basis of the Lie algebra $\mathrm{gl}(N)$. The mapping

$$E_{ij}\mapsto t_{ij}^{(1)} \tag{2.4}$$

defines an inclusion $\mathrm{U}(\mathrm{gl}(N))\hookrightarrow \mathrm{Y}(N)$. The mapping

$$t_{ij}(u)\mapsto \delta_{ij}+E_{ij}u^{-1} \tag{2.5}$$

defines an algebra homomorphism $\mathrm{Y}(N)\to \mathrm{U}(\mathrm{gl}(N))$.

The *quantum determinant* $\mathrm{qdet}\, T(u)$ of the matrix $T(u)$ is a formal series in u^{-1} with coefficients from $\mathrm{Y}(N)$ defined as follows:

$$\mathrm{qdet}\, T(u)=\sum_{p\in \mathfrak{S}_N} \mathrm{sgn}(p)t_{p(-n),-n}(u)\cdots t_{p(n),n}(u-N+1),$$

where $\mathfrak{S}_N$ is the group of permutations of the indices $\{-n,\ldots,n\}$. The coefficients of the quantum determinant $\mathrm{qdet}\, T(u)$ are algebraically independent generators of the center of the algebra $\mathrm{Y}(N)$.

The *quantum comatrix* $\hat{T}(u)=(\hat{t}_{ij}(u))$ is defined by the following formula:

$$\mathrm{qdet}\, T(u)=\hat{T}(u)T(u-N+1). \tag{2.6}$$

The matrix element $\hat{t}_{ij}(u)$ equals $(-1)^{i+j}$ times the quantum determinant of the submatrix of $T(u)$ obtained by removing the ith column and jth row.

Each of the following mappings defines an antiautomorphism of the algebra $\mathrm{Y}(N)$: the change of sign in u,

$$\sigma: T(u)\mapsto T(-u); \tag{2.7}$$

a matrix transposition,

$$T(u)\mapsto T^{t}(u); \tag{2.8}$$

the comatrix transformation,

$$T(u)\mapsto \hat{T}(u). \tag{2.9}$$

The shift in u,

$$T(u)\mapsto T(u+a),\quad a\in\mathbb{C} \tag{2.10}$$

and the multiplication by a formal series

$$T(u)\mapsto \varphi(u)T(u),\quad \varphi(u)\in 1+u^{-1}\mathbb{C}[[u^{-1}]] \tag{2.11}$$

define automorphisms of $\mathrm{Y}(N)$.

The *Yangian* $\mathrm{Y}(\mathrm{sl}(N))$ for the Lie algebra $\mathrm{sl}(N)$ can be defined as the subalgebra of $\mathrm{Y}(N)$ consisting of the elements fixed by all automorphisms of the form (2.11). One has a tensor product decomposition

$$\mathrm{Y}(N)\simeq \mathrm{Z}(N)\otimes \mathrm{Y}(\mathrm{sl}(N)), \tag{2.12}$$

where $\mathrm{Z}(N)$ denotes the center of $\mathrm{Y}(N)$.

Using the automorphism of $\mathrm{Y}(N)$ of the form $T(u)\mapsto T^{t}(-u)$, one can show that the following identity holds:[5]

$$\mathrm{qdet}\, T(u)=\hat{T}^{t}(u-1)T^{t}(u). \tag{2.13}$$

The coproduct $\Delta:\mathrm{Y}(N)\to \mathrm{Y}(N)\otimes \mathrm{Y}(N)$ is defined by

$$\Delta(t_{ij}(u))=\sum_{a} t_{ia}(u)\otimes t_{aj}(u). \tag{2.14}$$

Let us now define the *twisted Yangians* $\mathrm{Y}^+(N)$ and $\mathrm{Y}^-(N)$ corresponding to the orthogonal Lie algebra $\mathrm{o}(N)$ and symplectic Lie algebra $\mathrm{sp}(N)$, respectively. To consider both cases simultaneously, it will be convenient to use the symbol θ_{ij} which is defined as follows:

$$\theta_{ij} := \begin{cases} 1, & \text{in the orthogonal case} \\ \mathrm{sgn}(i)\mathrm{sgn}(j), & \text{in the symplectic case.} \end{cases}$$

Whenever the double sign $\pm$ or $\mp$ occurs, the upper sign corresponds to the orthogonal case and the lower sign to the symplectic case. By $X \mapsto X^t$ we will denote the matrix transposition such that $(E_{ij})^t = \theta_{ij} E_{-j,-i}$. Let us introduce the *S-matrix* $S(u) = (s_{ij}(u))$ by setting $S(u) := T(u)T^t(-u)$, or, in terms of matrix elements,

$$s_{ij}(u) = \sum_a \theta_{aj} t_{ia}(u) t_{-j,-a}(-u). \tag{2.15}$$

Write $s_{ij}(u) = \delta_{ij} + s_{ij}^{(1)} u^{-1} + s_{ij}^{(2)} u^{-2} + \cdots$. The twisted Yangian $\mathrm{Y}^{\pm}(N)$ is the subalgebra of $\mathrm{Y}(N)$ generated by the elements $s_{ij}^{(1)}, s_{ij}^{(2)}, \ldots$, where $-n \leqslant i,j \leqslant n$. One can show that the *S*-matrix satisfies the following *quaternary relation* and *symmetry relation* (see Ref. 30, Sec. 3):

$$\begin{gathered} R(u-v)S_1(u)R^t(-u-v)S_2(v) = S_2(v)R^t(-u-v)S_1(u)R(u-v), \\ S^t(-u) = S(u) \pm \frac{S(u) - S(-u)}{2u}. \end{gathered} \tag{2.16}$$

Here we use the same notation as for the ternary relation (2.2), where $R^t(u)$ is obtained from $R(u)$ by applying the transposition t in either of the two copies of $\mathrm{End}\mathbb{C}^N$. The relations (2.16) are defining relations for the algebra $\mathrm{Y}^{\pm}(N)$ and they can be rewritten in terms of the generating series $s_{ij}(u)$ as follows:

$$\begin{aligned} [s_{ij}(u), s_{kl}(v)] = {} & \frac{1}{u-v} \left(s_{kj}(u)s_{il}(v) - s_{kj}(v)s_{il}(u) \right) \\ & - \frac{1}{u+v} \left(\theta_{k,-j} s_{i,-k}(u) s_{-j,l}(v) - \theta_{i,-l} s_{k,-i}(v) s_{-l,j}(u) \right) \\ & + \frac{1}{u^2 - v^2} \left(\theta_{i,-j} s_{k,-i}(u) s_{-j,l}(v) - \theta_{i,-j} s_{k,-i}(v) s_{-j,l}(u) \right), \end{aligned} \tag{2.17}$$

and

$$\theta_{ij} s_{-j,-i}(-u) = s_{ij}(u) \pm \frac{s_{ij}(u) - s_{ij}(-u)}{2u}. \tag{2.18}$$

The elements

$$s_{ij}^{(2k)}, \quad i+j \geqslant 0, \qquad s_{ij}^{(2k-1)}, \quad i+j > 0, \qquad k = 1,2,..., \tag{2.19}$$

in the case of $\mathrm{Y}^+(N)$, and the elements

$$s_{ij}^{(2k)}, \quad i+j > 0, \qquad s_{ij}^{(2k-1)}, \quad i+j \geqslant 0, \qquad k = 1,2,..., \tag{2.20}$$

in the case of $\mathrm{Y}^-(N)$, form a system of linearly independent generators. An analog of the Poincaré–Birkhoff–Witt theorem for the algebra $\mathrm{Y}^{\pm}(N)$ can be formulated as follows (Ref. 30, Remark 3.14):

Given an arbitrary linear order on the set of the above generators, any element of the algebra $\mathrm{Y}^{\pm}(N)$ *is uniquely written as a linear combination of ordered monomials in the generators.*

Similar to the case of $\mathrm{Y}(N)$ we shall always assume that a linear order $\prec$ is chosen in such a way that

$$s_{i_1 j_1}^{(r_1)} \prec s_{i_2 j_2}^{(r_2)} \prec s_{i_3 j_3}^{(r_3)} \tag{2.21}$$

as soon as $i_1 > j_1$, $i_2 = j_2$, and $i_3 < j_3$.

Introduce the following elements of the Lie algebra $\mathrm{gl}(N)$:

$$F_{ij} = E_{ij} - \theta_{ij} E_{-j,-i}, \quad -n \leqslant i,j \leqslant n.$$

Denote by $\mathrm{g}(N)$ the Lie subalgebra of $\mathrm{gl}(N)$ spanned by the elements F_{ij}. Then $\mathrm{g}(N)$ is isomorphic to $\mathrm{o}(2n)$ or $\mathrm{sp}(2n)$ if $N = 2n$, and to $\mathrm{o}(2n+1)$ if $N = 2n+1$.

The mapping

$$F_{ij} \mapsto s_{ij}^{(1)} \tag{2.22}$$

defines an inclusion $\mathrm{U}(\mathrm{g}(N)) \hookrightarrow \mathrm{Y}^{\pm}(N)$. The mapping

$$s_{ij}(u) \mapsto \delta_{ij} + F_{ij}(u \pm \tfrac{1}{2})^{-1} \tag{2.23}$$

defines an algebra homomorphism $\mathrm{Y}^{\pm}(N) \to \mathrm{U}(\mathrm{g}(N))$.

There is an analog of the quantum determinant for the twisted Yangians. It is denoted by $\mathrm{sdet}\, S(u)$ and is called the *Sklyanin determinant*. This is a formal series in u^{-1} and its coefficients generate the center of the algebra $\mathrm{Y}^{\pm}(N)$. The Sklyanin determinant is related to the quantum determinant by

$$\mathrm{sdet}\, S(u) = \gamma_N(u)\ \ \mathrm{qdet}\, T(u)\ \ \mathrm{qdet}\, T(-u+N-1), \tag{2.24}$$

where $\gamma_N(u) \equiv 1$ for $\mathrm{Y}^{+}(N)$ and $\gamma_N(u) = (2u+1)/(2u-N+1)$ for $\mathrm{Y}^{-}(N)$. An explicit determinant-type expression for $\mathrm{sdet}\, S(u)$ in terms of the generators $s_{ij}(u)$ is given in Ref. 31.

Define the *Sklyanin comatrix* $\hat{S}(u) = (\hat{s}_{ij}(u))$ by

$$\mathrm{sdet}\, S(u) = \hat{S}(u) S(u-N+1). \tag{2.25}$$

An explicit expression for $\hat{s}_{ij}(u)$ can also be found from Ref. 31, Sec. 6.

The restriction of the antiautomorphism (2.7) to the subalgebra $\mathrm{Y}^{\pm}(N)$ yields an antiautomorphism

$$\sigma : S(u) \mapsto S^t(u). \tag{2.26}$$

We shall need the following result.

Proposition 2.1: The mapping

$$S(u) \mapsto \gamma_N(u) \hat{S}\left(-u + \frac{N}{2} - 1\right), \tag{2.27}$$

defines an automorphism of the algebra $\mathrm{Y}^{\pm}(N)$.

Proof: Note that the mapping $T(u) \mapsto \widetilde{T}(u)$ with

$$\widetilde{T}(u) = \hat{T}^t\left(u + \frac{N}{2} - 1\right) = \mathrm{qdet}\, T\left(u + \frac{N}{2}\right)\left(T^t\left(u + \frac{N}{2}\right)\right)^{-1}$$

defines an automorphism of the algebra $\mathrm{Y}(N)$. To see this, it suffices to present this map as a composition of antiautomorphisms of the form (2.8), (2.9) and an automorphism of the form (2.10). Denote by $\widetilde{S}(u)$ the image of the matrix $S(u) = T(u)T^t(-u)$ under this automorphism. That is,

$$\widetilde{S}(u)=\widetilde{T}(u)\widetilde{T}^{t}(-u)=\hat{T}^{t}\Big(u+\frac{N}{2}-1\Big)\hat{T}\Big(-u+\frac{N}{2}-1\Big).$$

By (2.6) and (2.13) we have

$$\widetilde{S}\Big(-u+\frac{N}{2}-1\Big)S(u-N+1)=\hat{T}^{t}(-u+N-2)\hat{T}(u)T(u-N+1)T^{t}(-u+N-1)$$

$$=\mathrm{qdet}\ T(u)\hat{T}^{t}(-u+N-2)T^{t}(-u+N-1)=\mathrm{qdet}\ T(u)\ \ \mathrm{qdet}\ T(-u+N-1),$$

which equals $\gamma_N^{-1}(u)$ sdet $S(u)$ by (2.24). Note that

$$\gamma_N(u)\,\gamma_N\Big(-u+\frac{N}{2}-1\Big)=1,$$

and so, using (2.25) we obtain that

$$\widetilde{S}(u)=\gamma_N(u)\hat{S}\Big(-u+\frac{N}{2}-1\Big).$$

Thus, the subalgebra $\mathrm{Y}^{\pm}(N)\subset\mathrm{Y}(N)$ is stable under the automorphism $T(u)\mapsto\widetilde{T}(u)$ and its restriction to $\mathrm{Y}^{\pm}(N)$ yields the automorphism (2.27) which completes the proof. □

We shall use the following commutation relations between matrix elements of the matrices $\hat{S}(u)$ and $S(u)$:

$$[\hat{s}_{ij}(u),s_{kl}(v)]=-\frac{1}{u-v-N+1}\sum_a\ (\delta_{kj}\hat{s}_{ia}(u)s_{al}(v)-\delta_{il}s_{ka}(v)\hat{s}_{aj}(u))$$

$$+\frac{1}{u+v+1}\sum_a\ (\delta_{i,-k}\theta_{ak}\hat{s}_{-a,j}(u)s_{al}(v)-\delta_{j,-l}\theta_{al}s_{ka}(v)\hat{s}_{i,-a}(u))$$

$$+\frac{1}{(u-v-N+1)(u+v+1)}\sum_a\ (\delta_{i,-k}\theta_{jk}\hat{s}_{-j,a}(u)s_{al}(v)$$

$$-\delta_{j,-l}\theta_{il}s_{ka}(v)\hat{s}_{a,-i}(u)). \tag{2.28}$$

They easily follow from the quaternary relation; see (2.16). Indeed, inverting its both sides and multiplying from the left and right by $S_2(v)$ we obtain

$$R^{t}(u+v+N)S_1^{-1}(u)R(v-u)S_2(v)=S_2(v)R(v-u)S_1^{-1}(u)R^{t}(u+v+N).$$

To get (2.28) rewrite this first in terms of the matrix elements of $S^{-1}(u)$ and $S(u)$, then use (2.25) and the centrality of the Sklyanin determinant in $\mathrm{Y}^{\pm}(N)$. (In a slightly different form this calculation was performed in Ref. 30, Sec. 7).

Multiplication by an even formal series

$$S(u)\mapsto\psi(u)S(u),\quad \psi(u)\in 1+u^{-2}\mathbb{C}[[u^{-2}]] \tag{2.29}$$

defines an automorphism of $\mathrm{Y}^{\pm}(N)$.

The *special twisted Yangian* $\mathrm{SY}^{\pm}(N)$ is defined by the equality $\mathrm{SY}^{\pm}(N)=\mathrm{Y}(\mathrm{sl}(N))\cap\mathrm{Y}^{\pm}(N)$. In other words, $\mathrm{SY}^{\pm}(N)$ is the subalgebra of $\mathrm{Y}^{\pm}(N)$ consisting of elements which are stable under all automorphisms of the form (2.29). One has the following tensor product decomposition analogous to (2.12):

$$\mathrm{Y}^{\pm}(N)\simeq\mathrm{Z}^{\pm}(N)\otimes\mathrm{SY}^{\pm}(N), \tag{2.30}$$

where $\mathrm{Z}^{\pm}(N)$ denotes the center of $\mathrm{Y}^{\pm}(N)$.

The images of the generators $s_{ij}(u)$ under coproduct Δ are given by

$$\Delta(s_{ij}(u))=\sum_{a,b}\ \theta_{bj}t_{ia}(u)t_{-j,-b}(-u)\otimes s_{ab}(u). \tag{2.31}$$

This implies that the subalgebra $\mathrm{Y}^{\pm}(N)\subset\mathrm{Y}(N)$ is a left coideal; see (1.2).

III. FINITE-DIMENSIONAL IRREDUCIBLE REPRESENTATIONS OF Y(N) and Y(sl(N))

For this section only we adopt a more standard enumeration of the generators $t_{ij}(u)$ of the Yangian $\mathrm{Y}(N)$: We let the indices i,j run through the set $\{1,...,N\}$. All formulas from the previous section should be understood accordingly. In the following definitions we follow Ref. 2 and Refs. 11–13.

Definition 3.1: A representation L of the Yangian $\mathrm{Y}(N)$ is called *highest weight* if there exists a nonzero vector $\xi\in L$ such that L is generated by ξ,

$$t_{ij}(u)\xi=0 \quad \text{for } 1\leqslant i<j\leqslant N, \tag{3.1}$$

and

$$t_{ii}(u)\xi=\lambda_i(u)\xi \quad \text{for } 1\leqslant i\leqslant N \tag{3.2}$$

for some formal series $\lambda_i(u)\in 1+u^{-1}\mathbb{C}[[u^{-1}]]$. The vector ξ is called the *highest weight vector* of L and the set $\lambda(u):=(\lambda_1(u),\ldots,\lambda_N(u))$ is the *highest weight* of L. □

Sometimes we shall also refer to L as a representation *with the highest weight* $\lambda(u)$. The definition of a *lowest weight representation* is obtained by replacing (3.1) with the relations

$$t_{ji}(u)\xi=0 \quad \text{for } 1\leqslant i<j\leqslant N.$$

Definition 3.2: Let $\lambda(u)=(\lambda_1(u),\ldots,\lambda_N(u))$ be any set of formal series where $\lambda_i(u)\in 1+u^{-1}\mathbb{C}[[u^{-1}]]$. The *Verma module* $M(\lambda(u))$ is the quotient of $\mathrm{Y}(N)$ by the left ideal generated by all the coefficients of the series $t_{ij}(u)$ for $1\leqslant i<j\leqslant N$ and $t_{ii}(u)$-$\lambda_i(u)$ for $1\leqslant i\leqslant N$. □

The following properties of $M(\lambda(u))$ are immediate from the Poincaré–Birkhoff–Witt theorem for $\mathrm{Y}(N)$. First, ordered monomials in the coefficients of the series $t_{ij}(u)$ with $i>j$ [assuming that (2.3) is satisfied] form a basis of $M(\lambda(u))$. The Verma module $M(\lambda(u))$ is obviously a representation of $\mathrm{Y}(N)$ with the highest weight $\lambda(u)$ and any representation with the highest weight $\lambda(u)$ is isomorphic to a quotient of $M(\lambda(u))$. Further, $M(\lambda(u))$ has a unique irreducible quotient which we denote by $L(\lambda(u))$. Indeed, the sum of all submodules of $M(\lambda(u))$ which do not contain the highest weight vector 1 is a unique maximal proper submodule K, and $L(\lambda(u))$ is the quotient $M(\lambda(u))/K$. Moreover, if an irreducible $\mathrm{Y}(N)$-module L contains a nonzero vector ξ satisfying (3.1) and (3.2) then L is isomorphic to $L(\lambda(u))$.

Using the inclusion (2.4) we may regard any $\mathrm{Y}(N)$-module as a $\mathrm{gl}(N)$-module. Relations (2.1) imply that

$$[E_{ij},t_{kl}(u)]=\delta_{kj}t_{il}(u)-\delta_{il}t_{kj}(u), \tag{3.3}$$

where we identify the elements $E_{ij}\in\mathrm{gl}(N)$ with their images in $\mathrm{Y}(N)$. Let h be the diagonal subalgebra in $\mathrm{gl}(N)$ with the basis $E_{11},\ldots,E_{NN}$ and let $\epsilon_1,\ldots,\epsilon_N$ be the dual basis in h*. Choose the standard system of positive roots R_+ for $\mathrm{gl}(N)$ corresponding to the upper triangular Borel subalgebra. Then the elements $\alpha_1=\epsilon_1-\epsilon_2,\ldots,\alpha_{N-1}=\epsilon_{N-1}-\epsilon_N$ form a basis in R_+. If L is a representation of $\mathrm{Y}(N)$ with the highest weight $\lambda(u)$, and ξ is its highest weight vector, then ξ is also a $\mathrm{gl}(N)$-highest weight vector of the $\mathrm{gl}(N)$-weight $\lambda=(\lambda_1,\ldots,\lambda_N)$ where λ_i is the coefficient at u^{-1} in the series $\lambda_i(u)$. By (3.3) all $\mathrm{gl}(N)$-weights of L have the form $\lambda-\omega$, where ω is a linear combination of the α_i with coefficients from $\mathbb{Z}_+$. Moreover, the subspace in L of vectors of $\mathrm{gl}(N)$-weight λ if one-dimensional and spanned by ξ.

The following result is contained in Ref. 2.

Theorem 3.3: *Every finite-dimensional irreducible representation L of $\mathrm{Y}(N)$ is highest weight. Moreover, L contains a unique (up to scalar multiples) highest weight vector.*

Proof: The $\mathrm{gl}(N)$-module L admits a weight space decomposition

$$L=\bigoplus_{\lambda\in \mathrm{h}^*} L_\lambda, \quad L_\lambda=\{\eta\in L\,|\,E_{ii}\eta=\lambda_i\eta,\ \ i=1,\ldots,N\}. \tag{3.4}$$

To see this, we note that by (3.3) the direct sum L' of all weight subspaces in L is a $\mathrm{Y}(N)$-submodule. This submodule is nontrivial because L is finite-dimensional and so it contains an eigenvector for the commutative subalgebra h. Since L is irreducible as a $\mathrm{Y}(N)$-module we conclude that $L'=L$.

Introduce the subspace in L

$$L^0:=\{\eta\in L\,|\,t_{ij}(u)\,\eta=0 \quad \text{for } 1\leqslant i<j\leqslant N\}. \tag{3.5}$$

By (3.3) the weight space decomposition (3.4) induces that of L^0:

$$L^0=\bigoplus_{\lambda\in \mathrm{h}^*} L^0_\lambda, \quad L^0_\lambda=L^0\cap L_\lambda. \tag{3.6}$$

Since the $\mathrm{gl}(N)$-module L is finite-dimensional there exists a nonzero vector $\eta_0\in L$ of a $\mathrm{gl}(N)$-weight λ' such that $\lambda'+\alpha$ is not a weight of L for any $\alpha\in R_+$. We see from (3.3) that the vectors $t_{ij}^{(r)}\eta_0$ with $i<j$ and $r\geqslant 1$ have the $\mathrm{gl}(N)$-weight $\lambda'+\epsilon_i-\epsilon_j$ and therefore are equal to zero. This proves that the subspace L^0 is nontrivial.

Relations (2.1) and (3.3) imply that $\mathrm{Y}(N)$ can be equipped with a $\mathbb{Z}^N$-grading

$$\mathrm{Y}(N)=\bigoplus_{\nu\in\mathbb{Z}^N} \mathrm{Y}(N)_\nu,$$

where

$$\mathrm{Y}(N)_\nu=\{y\in \mathrm{Y}(N)\,|\,[E_{ii},y]=\nu_i y,\ \ i=1,\ldots,N\}.$$

In particular, $\mathrm{Y}(N)_0$ is a subalgebra in $\mathrm{Y}(N)$. Denote by I and I' the left and right ideals in $\mathrm{Y}(N)$, respectively, generated by the coefficients of the series $t_{ij}(u)$ and $t_{ji}(u)$, where $1\leqslant i<j\leqslant N$. Set $I_0=\mathrm{Y}(N)_0\cap I$. Exactly as in the case of semisimple Lie algebras (see, e.g., Ref. 37, Sec. 7.4) one derives from the Poincaré–Birkhoff–Witt theorem for $\mathrm{Y}(N)$ that $I_0=I'\cap Y(N)_0$ and that I_0 is a two-sided ideal in $\mathrm{Y}(N)_0$. Moreover, $\mathrm{Y}(N)_0=\mathrm{Y}\oplus I_0$, where Y is the subspace in $\mathrm{Y}(N)_0$ with the basis formed by ordered monomials in the generators $t_{ii}^{(r)}$. Consider the algebra $\mathscr{Y}=Y(N)_0/I_0$. We see from (2.1) that $[t_{ii}(u),t_{ii}(v)]=0$ and

$$[t_{ii}(u),t_{jj}(v)]=\frac{1}{u-v}\,(t_{ji}(u)t_{ij}(v)-t_{ji}(v)t_{ij}(u)).$$

So, if $i<j$ each commutator $[t_{ii}^{(r)},t_{jj}^{(s)}]$ belongs to I_0. This implies that the algebra $\mathscr{Y}$ is commutative and freely generated by the elements $t_{ii}^{(r)}$ mod I_0.

Further, we note that the subspace L^0 has a natural structure of a $\mathrm{Y}(N)_0$-module and hence also of a $\mathscr{Y}$-module because L^0 is annihilated by I_0. Therefore, L^0 contains a nonzero vector ξ which is a common eigenvector for all operators $t_{ii}^{(r)}$. So, ξ generates a highest weight $\mathrm{Y}(N)$-submodule in L. Since L is irreducible this submodule coincides with L which proves that L is highest weight.

Finally, if ξ has a $\mathrm{gl}(N)$-weight λ_0 then nonzero weight subspaces in (3.6) can only correspond to the $\mathrm{gl}(N)$-weights λ of the form $\lambda_0-\omega$, where ω is a $\mathbb{Z}_+$-linear combination of the α_i. Moreover, the subspace $L^0_{\lambda_0}$ is one-dimensional. However, each subspace L^0_λ is $\mathscr{Y}$-invariant. If it is nonzero for a certain $\lambda\neq\lambda_0$ then a common eigenvector in L^0_λ for all $t_{ii}^{(r)}$ generates a proper submodule is L, which makes a contradiction. □

Remark 3.4: It follows from the proof that if L is an irreducible highest weight representation of $\mathrm{Y}(N)$ (not necessary finite-dimensional) then the subspace (3.5) is one-dimensional and spanned by the highest weight vector ξ of L. □

Due to Theorem 3.3, to describe the finite-dimensional irreducible representations of $\mathrm{Y}(N)$ it suffices to find necessary and sufficient conditions for an irreducible highest weight representation

$L(\lambda(u))$ to be finite-dimensional. The case of the simplest Yangian Y(2) plays a key role in the proof. We shall be assuming now that $N=2$. The following result is due to Tarasov.[8,9]

Proposition 3.5: If $\dim L(\lambda(u))<\infty$ *then there exists a formal series* $\varphi(u)\in 1+u^{-1}\mathbb{C}[[u^{-1}]]$ *such that* $\varphi(u)\lambda_1(u)$ *and* $\varphi(u)\lambda_2(u)$ *are polynomials in* u^{-1}.

Proof: Let ξ denote the highest weight vector of $L(\lambda(u))$. Since $L(\lambda(u))$ is finite-dimensional there exists a non-negative integer k such that the vector $t_{21}^{(k+1)}\xi$ is a linear combination of $t_{21}^{(1)}\xi,\dots,t_{21}^{(k)}\xi$. Take the minimum k with this property. Let us show that then for any vector $t_{21}^{(r)}\xi$ with $r\geqslant k+1$ we have

$$t_{21}^{(r)}\xi=a_1^{(r)}\xi_1+\cdots+a_k^{(r)}\xi_k \tag{3.7}$$

for some complex coefficients $a_i^{(r)}$, where $\xi_i:=t_{21}^{(i)}\xi$, $i=1,\dots,k$. Indeed, this is true for $r=k+1$ by our choice of k. Relations (2.1) imply that

$$t_{11}^{(2)}t_{21}(u)=t_{21}(u)(t_{11}^{(2)}-t_{11}^{(1)}-u)+t_{21}^{(1)}t_{11}(u), \tag{3.8}$$

and taking the coefficient at u^{-p} we obtain

$$t_{11}^{(2)}t_{21}^{(p)}=-t_{21}^{(p+1)}+t_{21}^{(1)}t_{11}^{(p)}+t_{21}^{(p)}(t_{11}^{(2)}-t_{11}^{(1)}). \tag{3.9}$$

Write $\lambda_1(u)=1+\lambda_1^{(1)}u^{-1}+\lambda_1^{(2)}u^{-2}+\cdots$. Then by (3.9), for any $p\geqslant 1$,

$$t_{21}^{(p+1)}\xi=-t_{11}^{(2)}t_{21}^{(p)}\xi+(\lambda_1^{(2)}-\lambda_1^{(1)})t_{21}^{(p)}\xi+\lambda_1^{(p)}t_{21}^{(1)}\xi. \tag{3.10}$$

Hence, for $p=1,\dots,k-1$ we have

$$t_{11}^{(2)}\xi_p=\lambda_1^{(p)}\xi_1+(\lambda_1^{(2)}-\lambda_1^{(1)})\xi_p-\xi_{p+1} \tag{3.11}$$

and applying (3.7) with $r=k+1$, we get

$$t_{11}^{(2)}\xi_k=\lambda_1^{(k)}\xi_1+(\lambda_1^{(2)}-\lambda_1^{(1)})\xi_k-(a_1^{(k+1)}\xi_1+\cdots+a_k^{(k+1)}\xi_k). \tag{3.12}$$

Now (3.7) follows from (3.10) to (3.12) by an obvious induction on r.

Rewriting (3.7) in terms of generating series we obtain

$$t_{21}(u)\xi=a_1(u)\xi_1+\cdots+a_k(u)\xi_k, \tag{3.13}$$

where $a_i(u)=u^{-i}+a_i^{(k+1)}u^{-k-1}+\cdots$. Applying both sides of (3.8) to ξ and using (3.13) we obtain

$$(t_{11}^{(2)}-\lambda_1^{(2)}+\lambda_1^{(1)}+u)(a_1(u)\xi_1+\cdots+a_k(u)\xi_k)=\lambda_1(u)\xi_1. \tag{3.14}$$

Using (3.11) and (3.12) and taking the coefficient at ξ_p, $p=2,\dots,k$ in this relation we get

$$-a_{p-1}(u)+ua_p(u)-a_p^{(k+1)}a_k(u)=0.$$

This implies that for any $p=1,\dots,k$ one has $a_p(u)=A_p(u)a_k(u)$ for a monic polynomial $A_p(u)$ of degree $k-p$ in u. Further, taking the coefficient at ξ_1 in (3.14) we obtain $\lambda_1(u)=B(u)a_k(u)$ for a monic polynomial $B(u)$ of degree k in u.

Similarly, repeating this argument with the use of

$$t_{22}^{(2)}t_{21}(u)=t_{21}(u)(t_{22}^{(2)}+t_{22}^{(1)}+u)-t_{21}^{(1)}t_{22}(u)$$

instead of (3.8) we obtain that $\lambda_2(u)=C(u)a_k(u)$ for a monic polynomial $C(u)$ of degree k in u. Thus, the desired series is $\varphi(u)=(a_k(u)u^k)^{-1}$. □

Given $\lambda=(\lambda_1,\dots,\lambda_N)\in\mathfrak{h}^*\simeq\mathbb{C}^N$ we shall denote by $L(\lambda)$ the irreducible $\mathrm{gl}(N)$-module with the highest weight λ with respect to the basis $\{E_{11},\dots,E_{NN}\}$ in $\mathfrak{h}$. The representation $L(\lambda)$ is finite-dimensional if and only if $\lambda_i-\lambda_{i+1}\in\mathbb{Z}_+$ for all $i=1,\dots,N-1$. The homomorphism (2.5) allows us to consider any representation $L(\lambda)$ as a $\mathrm{Y}(N)$-module. It is obviously highest weight

with $\lambda_i(u)=1+\lambda_i u^{-1}$, $i=1,...,N$. The Hopf algebra structure on $\mathrm{Y}(N)$ [see (2.14)] allows one to naturally equip any tensor product $L_1\otimes L_2$ of $\mathrm{Y}(N)$-modules with a $\mathrm{Y}(N)$-action by the rule

$$y\cdot(\xi_1\otimes\xi_2):=\Delta(y)(\xi_1\otimes\xi_2),\quad y\in Y(N),\quad \xi_i\in L_i. \tag{3.15}$$

Let us now return to the case $N=2$. A basis in the irreducible gl(2)-module $L(\alpha,\beta)$ with the highest weight (α,β) is formed by the elements $(E_{21})^r\xi$, where ξ is the highest weight vector and $r=0,...,\alpha-\beta$ if $\alpha-\beta\in\mathbb{Z}_+$; or $r\in\mathbb{Z}_+$ otherwise. Using (3.15) we can construct representations of $\mathrm{Y}(2)$ of the form

$$L=L(\alpha_1,\beta_1)\otimes\cdots\otimes L(\alpha_k,\beta_k). \tag{3.16}$$

In accordance with (2.14) the generators of $\mathrm{Y}(2)$ act by the rule

$$t_{ij}(u)(\eta_1\otimes\cdots\otimes\eta_k)=\sum_{a_1,\ldots,a_{k-1}} t_{ia_1}(u)\eta_1\otimes t_{a_1a_2}(u)\eta_2\otimes\cdots\otimes t_{a_{k-1}j}(u)\eta_k, \tag{3.17}$$

where $\eta_i\in L(\alpha_i,\beta_i)$. By (2.5) all generators $t_{ab}^{(r)}$ with $r\geqslant 2$ act as zero operators in each $L(\alpha_i,\beta_i)$ and so, by (3.17) we have for any $\eta\in L$,

$$t_{ij}^{(r)}\eta=0\quad\text{for } r\geqslant k+1. \tag{3.18}$$

For a multiset of complex numbers $\{\alpha_1,\ldots,\alpha_k,\beta_1,\ldots,\beta_k\}$ (repetitions of elements are allowed) we can find a re-enumeration of the α_i and a re-enumeration of the β_i such that the following condition is satisfied:

$$\begin{gathered}\text{for every } i=1,...,k \text{ we have: if the multiset}\\ \{\alpha_p-\beta_q\,|\,i\leqslant p,q\leqslant k\} \text{ contains non-negative integers}\\ \text{then } \alpha_i-\beta_i \text{ is minimal among them.}\end{gathered} \tag{3.19}$$

Indeed, choose first a minimal non-negative integer difference among all differences $\alpha_p-\beta_q$ if it exists. Re-enumerating the indices if necessary, we may assume that this difference is $\alpha_1-\beta_1$. Then we proceed by induction, considering the differences $\alpha_p-\beta_q$ with $p,q\geqslant 2$ and so on. The following proposition was proved in Ref. 9.

Proposition 3.6: Let $L(\lambda_1(u),\lambda_2(u))$ be an irreducible highest weight representation of $\mathrm{Y}(2)$ *and $\lambda_1(u)$ and $\lambda_2(u)$ be polynomials of degree $\leqslant$k in u^{-1}. Fix decompositions*

$$\lambda_1(u)=(1+\alpha_1u^{-1})\cdots(1+\alpha_ku^{-1}), \tag{3.20}$$

$$\lambda_2(u)=(1+\beta_1u^{-1})\cdots(1+\beta_ku^{-1}), \tag{3.21}$$

and assume that condition (3.19) is satisfied. Then $L(\lambda_1(u),\lambda_2(u))$ is isomorphic to the tensor product (3.16).

Proof: Let ξ_i be the highest weight vector of $L(\alpha_i,\beta_i)$. We have

$$t_{11}(u)\xi_i=(1+\alpha_iu^{-1})\xi_i,\quad t_{22}(u)\xi_i=(1+\beta_iu^{-1})\xi_i,\quad t_{12}(u)\xi_i=0. \tag{3.22}$$

Therefore, for the vector $\xi:=\xi_1\otimes\cdots\otimes\xi_k$ there holds

$$t_{11}(u)\xi=\lambda_1(u)\xi,\quad t_{22}(u)\xi=\lambda_2(u)\xi,\quad t_{12}(u)\xi=0, \tag{3.23}$$

which follows immediately from (3.17). Thus, the cyclic $\mathrm{Y}(2)$-span of the vector ξ in L is a highest weight module with the highest weight $(\lambda_1(u),\lambda_2(u))$. Therefore, to prove Proposition 3.6 we only need to show that the representation L is irreducible.

We use induction on k. For $k=1$ this is obvious, because $L(\alpha,\beta)$ is an irreducible gl(2)-module and hence it is also irreducible as a $\mathrm{Y}(2)$-module. Suppose now that $k>1$. Let us prove first that any nonzero submodule $\widetilde{L}$ of L contains the vector ξ. Note that $\widetilde{L}$ contains a nonzero

vector η such that $t_{12}(u)\,\eta=0$. Indeed, gl(2)-weights of L have the form $(\Sigma_i\ \alpha_i-r,\ \Sigma_i\ \beta_i+r)$ with $r\in\mathbb{Z}_+$. Therefore, there exists a gl(2)-weight (μ_1,μ_2) of $\widetilde{L}$ such that (μ_1+1,μ_2-1) is not a weight. Then a vector η of the gl(2)-weight (μ_1,μ_2) is annihilated by $t_{12}(u)$. Write η in the form

$$\eta=\sum_{r=0}^{p}(E_{21})^r\xi_1\otimes\eta_r,$$

with $p\geqslant 0$, where $\eta_r\in L(\alpha_2,\beta_2)\otimes\cdots\otimes L(\alpha_k,\beta_k)$; and if $\alpha_1-\beta_1\in\mathbb{Z}_+$ then $p\leqslant\alpha_1-\beta_1$. We may assume that $\eta_p\neq 0$. Applying $t_{12}(u)$ to η with the use of (2.14) and (3.15) we get

$$\sum_{r=0}^{p}\left(t_{11}(u)(E_{21})^r\xi_1\otimes t_{12}(u)\,\eta_r+t_{12}(u)(E_{21})^r\xi_1\otimes t_{22}(u)\,\eta_r\right)=0. \tag{3.24}$$

Using (2.5) and the commutation relations in gl(2) we can write

$$t_{11}(u)(E_{21})^r\xi_1=(1+(\alpha_1-r)u^{-1})(E_{21})^r\xi_1 \tag{3.25}$$

and

$$t_{12}(u)(E_{21})^r\xi_1=u^{-1}r(\alpha_1-\beta_1-r+1)(E_{21})^{r-1}\xi_1. \tag{3.26}$$

Taking the coefficient at $(E_{21})^p\xi_1$ in (3.24) we get

$$(1+(\alpha_1-p)u^{-1})t_{12}(u)\,\eta_p=0.$$

This implies that $t_{12}(u)\,\eta_p=0$. On the other hand, by the induction hypotheses, the representation $L(\alpha_2,\beta_2)\otimes\cdots\otimes L(\alpha_k,\beta_k)$ is irreducible, and so

$$\eta_p=\text{const}\cdot\xi_2\otimes\cdots\otimes\xi_k, \tag{3.27}$$

where ''const'' is a nonzero constant; see Remark 3.4. Suppose now that $p\geqslant 1$ and take the coefficient at $(E_{21})^{p-1}\xi_1$ in (3.24). By (3.25) and (3.26) we have

$$(1+(\alpha_1-p+1)u^{-1})t_{12}(u)\,\eta_{p-1}+u^{-1}p(\alpha_1-\beta_1-p+1)t_{22}(u)\,\eta_p=0. \tag{3.28}$$

Relations (3.27) and (3.17) imply that

$$t_{22}(u)\,\eta_p=(1+\beta_2u^{-1})\cdots(1+\beta_ku^{-1})\,\eta_p. \tag{3.29}$$

Multiply both sides of (3.28) by u^k:

$$(u+\alpha_1-p+1)u^{k-1}t_{12}(u)\,\eta_{p-1}+p(\alpha_1-\beta_1-p+1)u^{k-1}t_{22}(u)\,\eta_p=0. \tag{3.30}$$

The operators $u^{k-1}t_{ij}(u)$ in $L(\alpha_2,\beta_2)\otimes\cdots\otimes L(\alpha_k,\beta_k)$ are polynomials in u by (3.18) and we may put $u=-\alpha_1+p-1$ in (3.30). Taking into account (3.29) we get

$$p(\alpha_1-\beta_1-p+1)(\alpha_1-\beta_2-p+1)\cdots(\alpha_1-\beta_k-p+1)=0.$$

However, this is impossible because of condition (3.19). Therefore, p has to be equal to 0 and so, η is a multiple of ξ.

To complete the proof we have to show that the submodule of L generated by ξ coincides with L. Using the antiautomorphism (2.7) we equip the vector space V^* dual to a Y(2)-module V with a structure of Y(2)-module. Namely, set

$$(y\cdot f)(v)=f(\sigma(y)v),\quad y\in Y(2),\quad f\in V^*,\quad v\in V.$$

Then one can easily see that $L(\alpha_i,\beta_i)^* \simeq L'(-\alpha_i,-\beta_i)$, where $L'(-\alpha_i,-\beta_i)$ is the lowest weight representation of gl(2) whose lowest weight vector is the vector ξ_i' dual to ξ_i. This implies that

$$L^* \simeq L'(-\alpha_1,-\beta_1)\otimes\cdots\otimes L'(-\alpha_k,-\beta_k). \tag{3.31}$$

Similar to the case of representation L, any nonzero submodule of L^* contains a nonzero vector η' such that $t_{21}(u)\,\eta' = 0$. Modifying the previous argument for lowest weight representations we prove that η' coincides (up to a nonzero factor) with the vector $\xi' := \xi_1' \otimes \cdots \otimes \xi_k'$. Now, if the submodule in L generated by ξ is proper, then its annihilator in L^* is a nonzero submodule which does not contain ξ'. Contradiction. □

Proposition 3.6 allows one to get necessary and sufficient conditions for $L(\lambda(u))$ to be finite-dimensional.

Proposition 3.7: Let $L(\lambda(u))$ be an irreducible representation of Y(2) *with the highest weight $\lambda(u)=(\lambda_1(u),\lambda_2(u))$. Then $L(\lambda(u))$ is finite-dimensional if and only if there exists a formal series $\varphi(u) \in 1+u^{-1}\mathbb{C}[[u^{-1}]]$ such that $\varphi(u)\lambda_1(u)$ and $\varphi(u)\lambda_2(u)$ are polynomials in u^{-1} with decompositions*

$$\varphi(u)\lambda_1(u) = (1+\alpha_1 u^{-1})\cdots(1+\alpha_k u^{-1}), \tag{3.32}$$

$$\varphi(u)\lambda_2(u) = (1+\beta_1 u^{-1})\cdots(1+\beta_k u^{-1}), \tag{3.33}$$

and $\alpha_i-\beta_i \in \mathbb{Z}_+$, $i=1,...,k$ for certain re-enumerations of the α_i and β_i.

Proof: Let $\dim L(\lambda(u))<\infty$. By Proposition 3.5, taking the composition of our representation with an automorphism of the form (2.11) we may assume that (3.32) and (3.33) are satisfied for a certain series $\varphi(u)$. Re-enumerate the α_i and β_i in such a way that condition (3.19) is satisfied. Now use Proposition 3.6. Since the representation (3.16) is finite-dimensional this gives the relations $\alpha_i-\beta_i \in \mathbb{Z}_+$ for all $i=1,...,k$.

Conversely, let (3.32) and (3.33) hold with $\alpha_i-\beta_i \in \mathbb{Z}_+$, $i=1,...,k$. Then the representation (3.16) is finite-dimensional and the composition of $L(\lambda(u))$ with the automorphism (2.11) corresponding to the series $\varphi(u)$ is isomorphic to the irreducible quotient of the Y(2)-cyclic span in L of the vector ξ; see (3.23). Therefore, $\dim L(\lambda(u))<\infty$. □

The following reformulation of this result is due to Drinfeld.[2]

Theorem 3.8: *The irreducible highest weight representation $L(\lambda_1(u),\lambda_2(u))$ of* Y(2) *is finite-dimensional if and only if there exists a monic polynomial $P(u) \in \mathbb{C}[u]$ such that*

$$\frac{\lambda_1(u)}{\lambda_2(u)} = \frac{P(u+1)}{P(u)}. \tag{3.34}$$

In this case $P(u)$ is unique.

Proof: If $\dim L(\lambda_1(u),\lambda_2(u))<\infty$ then by Proposition 3.7 relations (3.32) and (3.33) hold for a certain series $\varphi(u)$. If $\alpha_i-\beta_i \in \mathbb{Z}_+$ for all i we put

$$P(u) = \prod_{i=1}^{k} (u+\beta_i)\cdots(u+\alpha_i-1).$$

Conversely, suppose (3.34) is satisfied for $P(u)=(u+\gamma_1)\cdots(u+\gamma_s)$. Introduce the polynomials

$$\lambda_1'(u) = (1+(\gamma_1+1)u^{-1})\cdots(1+(\gamma_s+1)u^{-1})$$

and

$$\lambda_2'(u) = (1+\gamma_1 u^{-1})\cdots(1+\gamma_s u^{-1}).$$

By Proposition 3.7, the irreducible highest weight representation $L(\lambda_1'(u),\lambda_2'(u))$ is finite-dimensional. However, $\lambda_1'(u)$ and $\lambda_2'(u)$ satisfy (3.34) and so, there exists an automorphism of

$\mathrm{Y}(2)$ of the form (2.11) such that its composition with the representation $L(\lambda_1'(u),\lambda_2'(u))$ is isomorphic to $L(\lambda_1(u),\lambda_2(u))$. Thus, the latter is also finite-dimensional.

To complete the proof of the theorem, suppose that $Q(u)$ is another monic polynomial in u and

$$\frac{P(u+1)}{P(u)}=\frac{Q(u+1)}{Q(u)}.$$

This means that $P(u)/Q(u)$ is periodic in u which is only possible for $P(u)=Q(u)$. □

The polynomial $P(u)$ defined by (3.34) is called the *Drinfeld polynomial*; see also Corollary 3.13 below.

Relation (3.34) motivates the following notation which will be used in the sequel. For two formal series $\lambda_1(u)$ and $\lambda_1(u)$ in u^{-1} we shall write

$$\lambda_1(u)\to\lambda_2(u), \tag{3.35}$$

if there exists a monic polynomial $P(u)$ in u such that (3.34) holds.

Due to the decomposition (2.12) we can establish a correspondence between representations of $\mathrm{Y}(N)$ and $\mathrm{Y}(\mathrm{sl}(N))$ analogous to the correspondence between the representations of the Lie algebras $\mathrm{gl}(N)$ and $\mathrm{sl}(N)$. Consider the following *similarity classes* of finite-dimensional irreducible representations of $\mathrm{Y}(N)$: Two representations belong to the same class if one can be obtained from the other by the composition with an automorphism (2.11). Since the subalgebra $\mathrm{Y}(\mathrm{sl}(N))$ is stable with respect to all automorphisms of the form (2.11), any representation from such a class, restricted to the subalgebra $\mathrm{Y}(\mathrm{sl}(N))$ gives the same representation of $\mathrm{Y}(\mathrm{sl}(N))$. Moreover, all finite-dimensional irreducible representations of $\mathrm{Y}(\mathrm{sl}(N))$ can be obtained in this way. In particular, using Theorem 3.8 we obtain a complete description of finite-dimensional irreducible representations of the Yangian $\mathrm{Y}(\mathrm{sl}(2))$.

Corollary 3.9: There is a one-to-one correspondence between finite-dimensional irreducible representations of the Yangian $\mathrm{Y}(\mathrm{sl}(2))$ *and monic polynomials in u. Every such representation is isomorphic to a representation of the form (3.16).*

Proof: The first claim follows from the fact that the ratios $\lambda_1(u)/\lambda_2(u)$ take the same value for all representations $L(\lambda_1(u),\lambda_2(u))$ of $\mathrm{Y}(2)$ of a given similarity class and hence by Theorem 3.8 the similarity classes are parametrized by monic polynomials in u.

Further, given a monic polynomial $P(u)$ we may find polynomials $\lambda_1(u)$ and $\lambda_2(u)$ in u^{-1} such that relation (3.34) holds; see the proof of Theorem 3.8. Then by Proposition 3.6, the representation $L(\lambda_1(u),\lambda_2(u))$ of $\mathrm{Y}(2)$ is isomorphic to a tensor product (3.16) and its restriction to $\mathrm{Y}(\mathrm{sl}(2))$ gives the finite-dimensional irreducible representation corresponding to $P(u)$. □

Remark 3.10: Tensoring $L(\lambda_1(u),\lambda_2(u))$ by factors of the form $L(\gamma,\gamma)$ is equivalent to multiplying both $\lambda_1(u)$, and $\lambda_2(u)$ simultaneously by $\gamma(u)=1+\gamma u^{-1}$. However, the representations $L(\lambda_1(u),\lambda_2(u))$ and $L(\gamma(u)\lambda_1(u),\gamma(u)\lambda_2(u))$ of $\mathrm{Y}(2)$ belong to the same similarity class. Therefore, we might add to Corollary 3.9 the condition that in (3.16) all differences $\alpha_i-\beta_i$ are positive integers. □

Since all finite-dimensional irreducible representation of $\mathrm{Y}(\mathrm{sl}(2))$ have the form of (3.16) it is useful to have a criterion of irreducibility of such representations.

Following Ref. 11 we define the *string* corresponding to a pair of complex numbers (α,β) with $\alpha-\beta\in\mathbb{Z}_+$ as the set

$$S(\alpha,\beta)=\{\beta,\beta+1,\ldots,\alpha-1\}\subset\mathbb{C}.$$

If $\alpha=\beta$ the set $S(\alpha,\beta)$ is considered to be empty. We say that two strings S_1 and S_2 are *in general position* if either

(i) $S_1\cup S_2$ is not a string, or

(ii) $S_1\subseteq S_2$, or $S_2\subseteq S_1$.

The following result is contained in Refs. 11 and 13.

Corollary 3.11: Consider the representation L of $\mathrm{Y}(2)$ *or* $\mathrm{Y}(\mathrm{sl}(2))$ *given by (3.16) where all differences $\alpha_i-\beta_i$ are non-negative integers. Then L is irreducible if and only if the strings $S(\alpha_1,\beta_1),\dots,S(\alpha_1,\beta_k)$ are pairwise in general position.*

Proof: Suppose that the strings are pairwise in general position and assume first that $\alpha_1-\beta_1\leqslant\cdots\leqslant\alpha_k-\beta_k$. Then one easily checks that (3.19) holds and so, by Proposition 3.6 representation (3.16) is irreducible. To complete the proof of the ''if'' part note that if representation (3.16) is irreducible, then any permutation of the tensor factors yields an isomorphic representation L'. Indeed, the submodule in L' generated by the tensor product of the highest weight vectors of the $L(\alpha_i,\beta_i)$ is highest weight with the same $\lambda_1(u)$ and $\lambda_2(u)$ given by (3.20) and (3.21). Therefore, L is isomorphic to a subquotient of L'. As L and L' have the same dimension, they have to be isomorphic.

Conversely, let $k=2$ and let $L(\alpha_1,\beta_1)\otimes L(\alpha_2,\beta_2)$ be irreducible. Suppose that the strings $S(\alpha_1,\beta_1)$ and $S(\alpha_2,\beta_2)$ are not in general position. Then $\alpha_2-\beta_1$, $\alpha_1-\beta_2\in\mathbb{Z}_+$ and either both of $\beta_1-\beta_2$ and $\alpha_1-\alpha_2$, or both of $\beta_2-\beta_1$ and $\alpha_2-\alpha_1$ are positive integers. The strings $S(\alpha_1,\beta_2)$ and $S(\alpha_2,\beta_1)$ are in general position and so, the representation $L(\alpha_1,\beta_2)\otimes L(\alpha_2,\beta_1)$ is irreducible. Since it has the same highest weight as the irreducible representation $L(\alpha_1,\beta_1)\otimes L(\alpha_2,\beta_2)$ these two representations have to be isomorphic and, in particular, have the same dimension:

$$(\alpha_1-\beta_1+1)(\alpha_2-\beta_2+1)=(\alpha_1-\beta_2+1)(\alpha_2-\beta_1+1).$$

This implies that $(\alpha_1-\alpha_2)(\beta_1-\beta_2)=0$, which is impossible.

Now consider the general case. Suppose that L is irreducible but two strings $S(\alpha_i,\beta_i)$ and $S(\alpha_j,\beta_j)$ are not in general position. Permuting the factors in (3.16) if necessary, we may assume that i and j are adjacent. However, the representation $L(\alpha_i,\beta_i)\otimes L(\alpha_j,\beta_j)$ is reducible. Contradiction. □

We are now able to prove Drinfeld's classification theorem for representations of the Yangian $\mathrm{Y}(N)$, N is an arbitrary positive integer; see Ref. 2. Theorem 3.3 and the following theorem provide a complete description of finite-dimensional irreducible representations of $\mathrm{Y}(N)$. We use notation (3.35).

Theorem 3.12: *The irreducible highest weight representation $L(\lambda(u))$, $\lambda(u)=(\lambda_1(u),\dots,\lambda_N(u))$ of* $\mathrm{Y}(N)$ *is finite-dimensional if and only if the following relation holds:*

$$\lambda_1(u)\to\lambda_2(u)\to\cdots\to\lambda_N(u). \tag{3.36}$$

Proof: Suppose that $\dim L(\lambda(u))<\infty$. By the Poincaré–Birkhoff–Witt theorem for $\mathrm{Y}(N)$, for any $i\in\{1,\dots,N-1\}$ the subalgebra in $\mathrm{Y}(N)$ generated by the coefficients of the series $t_{ii}(u)$, $t_{i,i+1}(u)$, $t_{i+1,i}(u)$, $t_{i+1,i+1}(u)$ is isomorphic to $\mathrm{Y}(2)$. The cyclic span of the highest weight vector of $L(\lambda(u))$ with respect to this subalgebra is a representation with the highest weight $(\lambda_i(u),\lambda_{i+1}(u))$. Its irreducible quotient is finite-dimensional and so, applying Theorem 3.8 we get (3.36).

Conversely, let

$$\frac{\lambda_i(u)}{\lambda_{i+1}(u)}=\frac{P_i(u+1)}{P_i(u)} \tag{3.37}$$

for certain polynomials $P_i(u)$, $i=1,\dots,N-1$ given by

$$P_i(u)=(u+\gamma_1^{(i)})\cdots(u+\gamma_{s_i}^{(i)}).$$

Consider first the irreducible highest weight representation $L(\lambda'(u))$ of $\mathrm{Y}(N)$ with the highest weight $\lambda'(u)=(\lambda_1'(u),\dots,\lambda_N'(u))$, where

$$\lambda_i'(u)=\prod_{a=1}^{i-1}(1+\gamma_1^{(a)}u^{-1})\cdots(1+\gamma_{s_a}^{(a)}u^{-1})\prod_{a=i}^{N-1}(1+(\gamma_1^{(a)}+1)u^{-1})\cdots(1+(\gamma_{s_a}^{(a)}+1)u^{-1}).$$

These polynomials have the form

$$\lambda_i'(u)=(1+\alpha_1^{(i)}u^{-1})\cdots(1+\alpha_k^{(i)}u^{-1})$$

with $k=\Sigma\, s_i$ and the condition $\alpha_r^{(i)}-\alpha_r^{(i+1)}\in\mathbb{Z}_+$ is satisfied for each $r=1,...,k$ and $i=1,...,N-1$. Consider the tensor product

$$L(\alpha_1)\otimes\cdots\otimes L(\alpha_k), \tag{3.38}$$

where $L(\alpha_r)$ is the irreducible representation of $\mathrm{gl}(N)$ with the highest weight $\alpha_r=(\alpha_r^{(1)},\ldots,\alpha_r^{(N)})$. The generators $t_{ij}(u)$ act in the representation (3.38) by the rule (3.17). So, the tensor product of the highest weight vectors of the $L(\alpha_r)$ generates a representation of $\mathrm{Y}(N)$ with the highest weight $\lambda'(u)$. Hence, its irreducible quotient is isomorphic to $L(\lambda'(u))$. Representation (3.38) is finite-dimensional, and therefore $L(\lambda'(u))$ is. Finally, note that the $\lambda_i'(u)$ satisfy (3.37) and so, there exists an automorphism of $\mathrm{Y}(N)$ of the form (2.11) such that its composition with the representation $L(\lambda'(u))$ is isomorphic to $L(\lambda(u))$ which completes the proof. □

We conclude this section with a description of finite-dimensional irreducible representations of the Yangian $\mathrm{Y}(\mathrm{sl}(N))$ implied by Theorem 3.12; see Ref. 2.

Corollary 3.13: There is a one-to-one correspondence between finite-dimensional irreducible representations of the Yangian $\mathrm{Y}(\mathrm{sl}(N))$ *and the families of monic polynomials* $\{P_1(u),\ldots,P_{N-1}(u)\}$ *in* u. *Every such representation is isomorphic to a subquotient of a representation of the form (3.38).* □

The $P_i(u)$ are called the *Drinfeld polynomials* associated with the representation $L(\lambda(u))$ of $\mathrm{Y}(\mathrm{sl}(N))$. Note that our definition of $P_i(u)$ given by (3.37) differs from that of Ref. 2 by a shift in u.

Remark 3.14: Contrary to the case $N=2$, it is not true for $N\geqslant 3$ that every finite-dimensional irreducible representation of $\mathrm{Y}(\mathrm{sl}(N))$ is isomorphic to a tensor product (3.38). For example, the $\mathrm{Y}(\mathrm{sl}(3))$-module $L(\lambda(u))$ with

$$\lambda_1(u)=(1+3u^{-1})(1+u^{-1}),\quad \lambda_2(u)=1+3u^{-1},\quad \lambda_3(u)=1+2u^{-1}$$

can be shown to have dimension 8 (see, e.g., Ref. 18) and it is not isomorphic to a tensor product of type (3.38). However, this is still true for ''generic'' representations of $\mathrm{Y}(\mathrm{sl}(N))$; see, e.g., Refs. 16–18.

IV. HIGHEST WEIGHT REPRESENTATIONS OF THE TWISTED YANGIANS

Here we define highest weight representations of the algebras $\mathrm{Y}^{\pm}(N)$ and prove an analog of Theorem 3.3 for $\mathrm{Y}^{\pm}(N)$. We also find some necessary conditions for an irreducible highest weight representation to be finite-dimensional and construct a family of representations of $\mathrm{Y}^{\pm}(N)$.

From now until the end of the paper we shall be assuming that the generators $t_{ij}(u)$ of $\mathrm{Y}(N)$ as well as the basis elements E_{ij} of the Lie algebra $\mathrm{gl}(N)$ are parameterized by the indices $i,j\in\{-n,-n+1,\ldots,n\}$, where $n=[N/2]$ and the index 0 is skipped in $N=2n$ (see Sec. II).

Definition 4.1: A representation V of the twisted Yangian $\mathrm{Y}^{\pm}(N)$ is called *highest weight* if there exists a nonzero vector $\xi\in V$ such that V is generated by ξ,

$$s_{ij}(u)\xi=0\quad\text{for}\quad -n\leqslant i<j\leqslant n, \tag{4.1}$$

and

$$s_{ii}(u)\xi=\mu_i(u)\xi \tag{4.2}$$

for some formal series $\mu_i(u)\in 1+u^{-1}\mathbb{C}[[u^{-1}]]$, where $i=1,\ldots,n$ if $N=2n$ and $i=0,\ldots,n$ if $N=2n+1$. The vector ξ is called the *highest weight vector* of V and the set $\mu(u):=(\mu_1(u),\ldots,\mu_n(u))$ or $\mu(u):=(\mu_0(u),\ldots,\mu_n(u))$ is the *highest weight* of V. □

Due to the symmetry relation (2.18), the vector ξ is also an eigenvector for the generators $s_{-i,-i}(u)$, $i=1,\ldots,n$. Moreover, if $N=2n+1$ the component $\mu_0(u)$ of the highest weight has to be even: $\mu_0(u)=\mu_0(-u)$.

If we replace (4.1) by the relations

$$s_{ji}(u)\xi=0 \quad \text{for } -n\leqslant i<j\leqslant n.$$

we get the definition of a *lowest weight representation.*

Definition 4.2: Let $\mu(u)=(\mu_1(u),\dots,\mu_n(u))$ or $\mu(u)=(\mu_0(u),\dots,\mu_n(u))$ be any set of formal series where $\mu_i(u)\in 1+u^{-1}\mathbb{C}[[u^{-1}]]$ for $i=1,\dots,n$ and $\mu_0(u)\in 1+u^{-2}\mathbb{C}[[u^{-2}]]$. The *Verma module* $M(\mu(u))$ is the quotient of $\mathrm{Y}^{\pm}(N)$ by the left ideal generated by all the coefficients of the series $s_{ij}(u)$ for $-n\leqslant i<j\leqslant n$ and $s_{ii}(u)-\mu_i(u)$ for $i=1,\dots,n$ or $i=0,\dots,n$, respectively. □

The following properties of $M(\mu(u))$ are immediate from the Poincaré–Birkhoff–Witt theorem for $\mathrm{Y}^{\pm}(N)$ (see Sec. II). First, ordered monomials in the generators (2.19) or (2.20) with the additional condition $i>j$ [assuming that (2.21) is satisfied] form a basis of $M(\mu(u))$. Further, $M(\mu(u))$ is a representation of $\mathrm{Y}^{\pm}(N)$ with the highest weight $\mu(u)$ and any representation of the highest weight $\mu(u)$ is isomorphic to a quotient of $M(\mu(u))$. The module $M(\mu(u))$ has a unique irreducible quotient which we denote by $V(\mu(u))$. Moreover, if an irreducible $\mathrm{Y}^{\pm}(N)$-module V contains a nonzero vector ξ satisfying (4.1) and (4.2) then V is isomorphic to $V(\mu(u))$.

Using the inclusion (2.22) we may regard any $\mathrm{Y}^{\pm}(N)$-module as a $\mathrm{g}(N)$-module. Relations (2.17) imply that

$$[F_{ij},s_{kl}(u)]=\delta_{kj}s_{il}(u)-\delta_{il}s_{kj}(u)-\theta_{k,-j}\delta_{i,-k}s_{-j,l}(u)+\theta_{i,-l}\delta_{-l,j}s_{k,-i}(u), \tag{4.3}$$

where we identify the elements $F_{ij}\in\mathrm{g}(N)$ with their images in $\mathrm{Y}^{\pm}(N)$. Set $\mathrm{h}=$span of $\{F_{11},\dots,F_{nn}\}$. Then h is a Cartan subalgebra in $\mathrm{g}(N)$. Choose the standard system of positive roots R_+ for $\mathrm{g}(N)$ with respect to h corresponding to the upper triangular Borel subalgebra and let $\alpha_1,\dots,\alpha_n$ be a basis in R_+. If V is a representation of $\mathrm{Y}^{\pm}(N)$ with the highest weight $\mu(u)$ then its highest weight vector ξ is also a $\mathrm{g}(N)$-highest weight vector of the $\mathrm{g}(N)$-weight $\mu=(\mu_1,\dots,\mu_n)$ where μ_i is the coefficient at u^{-1} in the series $\mu_i(u)$. By (4.3) all $\mathrm{g}(N)$-weights of V have the form $\mu-\omega$, where ω is a $\mathbb{Z}_+$-linear combination of the α_i. Moreover, the subspace in V of vectors of $\mathrm{g}(N)$-weight μ if one-dimensional and spanned by ξ.

Theorem 4.3: *Every finite-dimensional irreducible representation V of $\mathrm{Y}^{\pm}(N)$ is highest weight. Moreover, V contains a unique (up to scalar multiples) highest weight vector.*

Proof: The proof follows the same steps as that of Theorem 3.3. We set

$$V^0:=\{\eta\in V\,|\,s_{ij}(u)\,\eta=0 \quad \text{for } -n\leqslant i<j\leqslant n\}. \tag{4.4}$$

By (4.3) we have the weight space decomposition

$$V^0=\bigoplus_{\mu\in\mathrm{h}^*} V^0_\mu, \tag{4.5}$$

where

$$V^0_\mu=\{\eta\in V^0\,|\,F_{ii}\,\eta=\mu_i\,\eta\},\quad \mu_i=\mu(F_{ii}).$$

Introduce the h-centralizer in $\mathrm{Y}^{\pm}(N)$:

$$\mathrm{Y}^{\pm}(N)_0=\{y\in Y^{\pm}(N)\,|\,[F_{ii},y]=0 \ \text{ for all } \ i\}.$$

Denote by I the left ideal in $\mathrm{Y}^{\pm}(N)$ generated by the coefficients of the series $s_{ij}(u)$, where $-n\leqslant i<j\leqslant n$ and set $I_0=\mathrm{Y}^{\pm}(N)_0\cap I$. We derive from the Poincaré–Birkhoff–Witt theorem for $\mathrm{Y}^{\pm}(N)$ that I_0 is a two-sided ideal in $\mathrm{Y}^{\pm}(N)_0$. Next, using (2.17) we verify that the algebra $\mathscr{Y}:=\mathrm{Y}^{\pm}(N)_0/I_0$ is commutative and generated by the elements $s_{ii}^{(r)}$ mod I_0.

Further, V^0 is a nonzero $\mathscr{Y}$-module (cf. the proof of Theorem 3.3) and the weight spaces V^0_μ are $\mathscr{Y}$-invariant. If $V^0_{\mu_0}\neq 0$ for a certain μ_0 then there exists a nonzero element $\xi\in V^0_{\mu_0}$ which is a common eigenvector for the generators $s_{ii}^{(r)}$. So, ξ generates a highest weight $\mathrm{Y}^{\pm}(N)$-submodule in V. Since V is irreducible this submodule coincides with V which proves that V is highest weight.

Finally, the subspace $V^0_{\mu_0}$ is one-dimensional and nonzero weight subspaces in (4.5) can only correspond to the g(N)-weights μ of the form $\mu_0-\omega$, where ω is a $\mathbb{Z}_+$-linear combination of the α_i. If V^0_μ is nonzero for a certain $\mu\neq\mu_0$ then a common eigenvector in V^0_μ for all $s^{(r)}_{ii}$ generates a proper submodule in V, which makes a contradiction. □

Remark 4.4: The above proof implies that if V is an irreducible highest weight representation of $\mathrm{Y}^{\pm}(N)$ then the subspace (4.4) is one-dimensional and spanned by the highest weight vector ξ of V. □

Due to Theorem 4.3, to describe the finite-dimensional irreducible representations of $\mathrm{Y}^{\pm}(N)$ it suffices to find necessary and sufficient conditions for an irreducible highest weight representation $V(\mu(u))$ to be finite-dimensional. Some necessary conditions are provided by the following proposition. We use notation (3.35).

Proposition 4.5: If the irreducible highest weight representation $V(\mu(u))$ of the algebra $\mathrm{Y}^{\pm}(N)$ is finite-dimensional then the following relation holds:

$$\mu_1(u)\to\mu_2(u)\to\cdots\to\mu_n(u).$$

Proof: Let J be the left ideal of $\mathrm{Y}^{\pm}(N)$ generated by the coefficients of the series $s_{-i,j}(u)$, where $i,j=1,\ldots,n$. Denote by Norm J the normalizer of J:

$$\mathrm{Norm}\ J=\{y\in\mathrm{Y}^{\pm}(N)\,|\,Jy\subseteq J\}.$$

The subspace

$$V(\mu(u))^J=\{v\in V(\mu(u))\,|\,Jv=0\}$$

has a natural structure of a Norm J/J-module. Note that the highest weight vector ξ of $V(\mu(u))$ is contained in $V(\mu(u))^J$. Defining relations (2.17) show that the mapping

$$t^{(r)}_{ij}\mapsto s^{(r)}_{ij}\ \mathrm{mod}\ J,\quad 1\leqslant i,j\leqslant n$$

defines an algebra homomorphism $\mathrm{Y}(n)\to\mathrm{Norm}\ J/J$. By making use of this homomorphism we may regard $V(\mu(u))^J$ as a $\mathrm{Y}(n)$-module. The cyclic span of the vector ξ is a finite-dimensional representation of $\mathrm{Y}(n)$ with the highest weight $(\mu_1(u),\ldots,\mu_n(u))$. Applying Theorem 3.12 we complete the proof. □

Given $\mu=(\mu_1,\ldots,\mu_n)\in\mathrm{h}^*$ consider the irreducible g(N)-module $V(\mu)$ with the highest weight μ with respect to the basis $\{F_{11},\ldots,F_{nn}\}$ in h. It is finite-dimensional if and only if the following conditions are satisfied (see, e.g., Ref. 37, Sec. 7.2):

$$\mu_i-\mu_{i+1}\in\mathbb{Z}_+\qquad\text{for } i=1,\ldots,n-1 \tag{4.6}$$

and

$$-\mu_1-\mu_2\in\mathbb{Z}_+\quad\text{for o}(2n), \tag{4.7}$$

$$-\mu_1\in\mathbb{Z}_+\quad\text{for sp}(2n), \tag{4.8}$$

$$-2\mu_1\in\mathbb{Z}_+\quad\text{for o}(2n+1). \tag{4.9}$$

The homomorphism (2.23) allows us to extend $V(\mu)$ to a $\mathrm{Y}^{\pm}(N)$-module. This module is obviously highest weight with

$$\mu_i(u)=\frac{1+(\mu_i\pm 1/2)u^{-1}}{1\pm 1/2u^{-1}},\quad i=1,\ldots,n, \tag{4.10}$$

and $\mu_0(u)=1$ if $N=2n+1$.

Using (2.31) we can equip any tensor product $L\otimes V$ of a $\mathrm{Y}(N)$-module L and a $\mathrm{Y}^{\pm}(N)$-module V with a $\mathrm{Y}^{\pm}(N)$-action by the rule

$$y\cdot(\xi\otimes\eta):=\Delta(y)(\xi\otimes\eta),\quad y\in \mathrm{Y}^{\pm}(N),\quad \xi\in L,\quad \eta\in V. \tag{4.11}$$

In particular, we can construct representations of $\mathrm{Y}^{\pm}(N)$ of the form (1.3).

Decomposition (2.30) enables one to establish a correspondence between representations of the twisted Yangian $\mathrm{Y}^{\pm}(N)$ and the special twisted Yangian $\mathrm{SY}^{\pm}(N)$ analogous to the *A* series case (see Sec. III). Consider the *similarity classes* of finite-dimensional irreducible representations of $\mathrm{Y}^{\pm}(N)$: Two representations belong to the same class if one can be obtained from the other by the composition with an automorphism (2.29). Since the subalgebra $\mathrm{SY}^{\pm}(N)$ is stable with respect to all automorphisms of the form (2.29), any representation from such a class, restricted to the subalgebra $\mathrm{SY}^{\pm}(N)$ gives the same representation of the latter. Moreover, all finite-dimensional irreducible representations of $\mathrm{SY}^{\pm}(N)$ can be obtained in this way.

In the next three sections we consider separately the twisted Yangians corresponding to the series *C*, *D*, and *B*, respectively. We obtain a description of finite-dimensional irreducible representations for the algebras $\mathrm{Y}^{\pm}(N)$ and $\mathrm{SY}^{\pm}(N)$.

V. REPRESENTATIONS OF $\mathrm{Y}^{-}(2n)$

As for the Yangian $\mathrm{Y}(N)$ the representations of the simplest twisted Yangian $\mathrm{Y}^{-}(2)$ play an important role in the general case.

Irreducible highest weight representations $V(\mu(u))$ of $\mathrm{Y}^{-}(2)$ are parametrized by formal series $\mu(u)\in 1+u^{-1}\mathbb{C}[[u^{-1}]]$. The following is an analog of Proposition 3.5 for the algebra $\mathrm{Y}^{-}(2)$.

Proposition 5.1: If $\dim V(\mu(u))<\infty$ *then there exists an even formal series* $\psi(u)\in 1+u^{-2}\mathbb{C}[[u^{-2}]]$ *such that* $\psi(u)\mu(u)$ *is a polynomial in* u^{-1}.

Proof: The symmetry relation (2.18) implies that

$$(2u-1)s_{1,-1}(u)=(-2u-1)s_{1,-1}(-u),$$

and so, for any $r\geqslant 1$,

$$s_{1,-1}^{(2r-1)}=2s_{1,-1}^{(2r)}. \tag{5.1}$$

Denote by ξ the highest weight vector of $V(\mu(u))$. Take the minimum non-negative integer k such that $s_{1,-1}^{(2k+2)}\xi$ is a linear combination of the vectors $s_{1,-1}^{(2)}\xi,\ldots,s_{1,-1}^{(2k)}\xi$; such k exists because $V(\mu(u))$ is finite-dimensional. Let us prove that for any $r\geqslant k+1$ we have

$$s_{1,-1}^{(2r)}\xi=a_1^{(2r)}\xi_1+\cdots+a_k^{(2r)}\xi_k \tag{5.2}$$

for some complex coefficients $a_i^{(2r)}$, where $\xi_i:=s_{1,-1}^{(2i)}\xi$, $i=1,\ldots,k$. This is true for $r=k+1$ by our choice of *k*. Taking in (2.17) $i=k=l=1$, $j=-1$, and exchanging u and v we get

$$[s_{11}(u),s_{1,-1}(v)]=\frac{2u+1}{u^2-v^2}\,s_{1,-1}(v)s_{11}(u)-\frac{u+v+1}{u^2-v^2}\,s_{1,-1}(u)s_{11}(v)$$
$$+\frac{1}{u+v}\,s_{1,-1}(u)s_{-1,-1}(v). \tag{5.3}$$

Take the coefficient at $u^{-3}v^{-2p}$ in this relation. Using (5.1) and the fact that the series $s_{11}(u)+s_{-1,-1}(u)$ is even in u [see (2.18)], we obtain

$$[s_{11}^{(3)},s_{1,-1}^{(2p)}]=2s_{1,-1}^{(2p+2)}+s_{1,-1}^{(2p)}(2s_{11}^{(2)}+s_{11}^{(1)})-s_{1,-1}^{(2)}(3s_{11}^{(2p)}+s_{-1,-1}^{(2p)}). \tag{5.4}$$

Write $\mu(u)=1+\mu^{(1)}u^{-1}+\mu^{(2)}u^{-2}+\cdots$. Then applying both sides of (5.4) to ξ we get

$$2s_{1,-1}^{(2p+2)}\xi=s_{11}^{(3)}s_{1,-1}^{(2p)}\xi-(\mu^{(3)}+2\mu^{(2)}+\mu^{(1)})s_{1,-1}^{(2p)}\xi+(3\mu^{(2p)}+\mu_{-}^{(2p)})s_{1,-1}^{(2)}\xi, \tag{5.5}$$

where $\mu_{-}^{(r)}$ is the eigenvalue of $s_{-1,-1}^{(r)}$ at ξ. In particular, for $p=1,\ldots,k-1$ we have

$$s_{11}^{(3)}\xi_p=2\xi_{p+1}+(\mu^{(3)}+2\mu^{(2)}+\mu^{(1)})\xi_p-(3\mu^{(2p)}+\mu_-^{(2p)})\xi_1. \tag{5.6}$$

The use of (5.2) with $r=k+1$ gives

$$s_{11}^{(3)}\xi_k=2(a_1^{(2k+2)}\xi_1+\cdots+a_k^{(2k+2)}\xi_k)+(\mu^{(3)}+2\mu^{(2)}+\mu^{(1)})\xi_k-(3\mu^{(2k)}+\mu_-^{(2k)})\xi_1. \tag{5.7}$$

Now (5.2) follows from (5.5) to (5.7) by an induction on r. Rewriting (5.2) in terms of generating series and using (5.1) we obtain

$$s_{1,-1}(u)\xi=(2u+1)(a_1(u)\xi_1+\cdots+a_k(u)\xi_k), \tag{5.8}$$

where the $a_i(u)$ are even series in u^{-1}: $a_i(u)=u^{-2i}+a_i^{(2k+2)}u^{-2k-2}+\cdots$. Taking the coefficient at u^{-3} in (5.3) and replacing v with u we get

$$\begin{aligned}s_{11}^{(3)}s_{1,-1}(u)=&\,s_{1,-1}(u)(s_{11}^{(3)}+2s_{11}^{(2)}+s_{11}^{(1)}+2u^2)\\&-(s_{1,-1}^{(2)}+(u+1)s_{1,-1}^{(1)})s_{11}(u)+(s_{1,-1}^{(2)}-us_{1,-1}^{(1)})s_{-1,-1}(u).\end{aligned}$$

Apply both sides to the vector ξ. Then using (5.8) and the symmetry relation (2.18) we find that

$$\begin{aligned}&(s_{11}^{(3)}-\mu^{(3)}-2\mu^{(2)}-\mu^{(1)}-2u^2)(a_1(u)\xi_1+\cdots+a_k(u)\xi_k)\\&\quad=-\left(\frac{2u+1}{2u}\,\mu(u)+\frac{2u-1}{2u}\,\mu(-u)\right)\xi_1.\end{aligned} \tag{5.9}$$

Using (5.6) and (5.7) and taking the coefficient at ξ_p, $p=2,\ldots,k$ in this relation we get

$$a_{p-1}(u)-u^2a_p(u)+\text{const}\cdot a_k(u)=0.$$

Therefore, for any $p=1,\ldots,k$ one has $a_p(u)=A_p(u)a_k(u)$ for a monic polynomial $A_p(u)$ of degree $k-p$ in u^2. Hence, taking the coefficient at ξ_1 in (5.9) we obtain that
