Recall that we seek the first appearance of a nonzero state as the magnetic field is decreased. Hence we view (2.33) as a double eigenvalue problem for h_0 and β in which β is to be determined so as to yield $\underline{h}$, the largest possible value of h_0. Note that β corresponds to a transverse (i.e., parallel to the boundary) wave number, which in the half-plane problem arises naturally through separation of variables. We now tabulate a set of results known for this problem, which will form the basis for our perturbation expansion. With the exception of identities (2.34)–(2.36) below, the proof of the Lemma can be found, for example, in Ref. 15. See also Refs. 6 and 7. The derivation of (2.34)–(2.36) can be found in the appendix.

Lemma: There exists a largest value of $h_0(\beta)$, denoted by $\underline{h}$, for which (2.33) possesses a nontrivial solution. This occurs when β takes the value -1. The corresponding eigenfunction, denoted henceforth by $\underline{\psi}(\xi)$, satisfies

$$\mathcal{L}\underline{\psi}=0 \quad \text{for} \quad 0<\xi<\infty,$$
$$\underline{\psi}_\xi(0)=0, \quad \underline{\psi}_\xi(\infty)=0,$$

with the normalization $\underline{\psi}(0)=1$.

The operator $\mathcal{L}$ is defined by

$$\mathcal{L}(\cdot)\equiv\partial_{\xi\xi}(\cdot)+(1-(\underline{h}\xi-1)^2)(\cdot),$$

and is self-adjoint in the L^2 inner-product.

The solution ψ decays exponentially as $\xi\to\infty$ and, letting $J_0\equiv\int_0^\infty \overline{\psi^2}\,d\xi$, we have that $\overline{\psi}$ satisfies the following identities:

$$J_1\equiv\int_0^\infty \xi\overline{\psi^2}\,d\xi=\frac{1}{\overline{h}}J_0, \tag{2.34}$$

$$J_2\equiv\int_0^\infty \xi^2\overline{\psi^2}\,d\xi=\frac{3}{2\overline{h^2}}\,J_0, \tag{2.35}$$

$$J_3\equiv\int_0^\infty \xi^3\overline{\psi^2}\,d\xi=\frac{1}{6\overline{h^2}}+\frac{5}{2\overline{h^3}}\,J_0. \tag{2.36}$$

Remark: Through numerical approximation one finds $\overline{h}=1.69461+$ and $J_0=1.00784+$.

In light of the absence of any τ dependence in (2.33), we may write

$$\psi_0(\xi,\tau)=W_0(\tau)\overline{\psi}(\xi),$$

where $W_0(\tau)$ is a (perhaps complex) amplitude corresponding to a transverse modulation of $\overline{\psi}(\xi)$ on the τ length scale whose behavior will be determined at higher order. This type of modulation or multiple scale expansion is familiar from many physical systems.[16]

B. Higher order corrections

At orders $\mathcal{O}(1/k^{1/4})$ and $\mathcal{O}(1/k^{1/2})$ we find

$$\mathcal{L}(\psi_i)=2h_i\xi(\overline{h}\xi-1)\overline{\psi}(\xi)W_0(\tau)\quad\text{for}\quad i=1,2,$$

$$(\psi_i)_\xi(0)=0,\quad (\psi_i)_\xi(\infty)=0. \tag{2.37}$$

If we define the L^2 inner-product,

$$\langle\psi,\phi\rangle=\int_0^\infty \psi^*\phi\,d\xi,$$

then the Fredholm Alternative Theorem yields necessary and sufficient solvability conditions for (2.37). That is, orthogonality to $\overline{\psi}$,

$$\langle\overline{\psi},\mathcal{L}(\psi_i)\rangle=0\quad\text{for}\quad i=1,2,$$

implies

$$h_iW_0\,\frac{J_0}{\overline{h}}=0.$$

Thus we conclude $h_1=h_2=0$ so that $\mathcal{L}(\psi_i)=0$ and we have

$$\psi_1=W_1(\tau)\overline{\psi}(\xi)\quad\text{and}\quad\psi_2=W_2(\tau)\overline{\psi}(\xi)$$

with the functions W_1 and W_2 yet to be determined.

Proceeding to $\mathcal{O}(1/k^{3/4})$,

$$\mathcal{L}(\psi_3)=2h_3\xi(\overline{h}\xi-1)\overline{\psi}W_0-2i(\overline{h}\xi-1)\overline{\psi}W_{0\tau}\quad\text{for}\quad 0<\xi<\infty,$$

$$\psi_{3_\xi}(0)=0,\quad \psi_{3_\xi}(\infty)=0. \tag{2.38}$$

Application of the solvability condition at this order yields

$$\langle \overline{\psi}, \mathscr{L}(\psi_3)\rangle = 0 = h_3 W_0 \frac{J_0}{\overline{h}},$$

hence $h_3 = 0$. Now note that since $\partial_\xi(\mathscr{L}(\overline{\psi})) = 0$, one has

$$\mathscr{L}(\overline{\psi}_\xi) = 2\overline{h}(\overline{h}\xi - 1)\overline{\psi}. \tag{2.39}$$

One also readily verifies that $\overline{\psi}_{\xi\xi}(0) = \overline{\psi}_{\xi\xi}(\infty) = 0$ (recall that in fact $\overline{\psi}$ decays exponentially at infinity) so that we find

$$\psi_1 = W_3(\tau)\overline{\psi}(\xi) - \frac{i}{\overline{h}}\overline{\psi}_\xi W_{0_\tau}, \tag{2.40}$$

where W_3 remains to be determined.

We now proceed to order $\mathscr{O}(1/k)$,

$$\mathscr{L}(\psi_4) = h_4[2\xi(\overline{h}\xi - 1)\overline{\psi}]W_0 + \overline{\kappa}[\xi(\overline{h}\xi - 1)(\overline{h}\xi - 2)\overline{\psi} + \overline{\psi}_\xi]W_0 - [2i(\overline{h}\xi - 1)\overline{\psi}]W_{1_\tau},$$

$$\psi_{4_\xi}(0) = 0, \quad \psi_{4_\xi}(\infty) = 0. \tag{2.41}$$

Solvability at this order takes the form,

$$\left(h_4 \frac{J_0}{\overline{h}} - \frac{\overline{\kappa}}{3}\right) W_0 = 0, \tag{2.42}$$

where we have applied the identities (2.34)–(2.35), and integration by parts. Thus

$$h_4 = \frac{\overline{h}}{3J_0}\overline{\kappa} = \frac{\overline{h}}{3J_0}\kappa(s_0). \tag{2.43}$$

Note that we seek the largest value of h (hence of h_4) at which a superconducting solution emerges; clearly we can maximize h_4 by choosing to expand around the point where $\kappa(s_0)$ is a maximum, i.e., by choosing $s_0 = 0$. Consequently, we conclude that *instability first occurs at the point of maximum curvature*, so that

$$\overline{\kappa} = \max_{s_0} \kappa(s_0) = \kappa(0),$$

$$\overline{\kappa}_s = 0,$$

$$\overline{\kappa}_{ss} \leqslant 0.$$

We shall make the (generic) assumption that

$$\overline{\kappa}_{ss} < 0.$$

We have also tacitly assumed that the curvature reaches a unique maximum; in the case of multiple isolated maximums (such as an ellipse), we could construct an exponentially localized solution at each which would interact only exponentially weakly. In the case when the second derivative vanishes at the maximum (such as the disc), our scaling ansatz will prove to be invalid at higher order.

In addition, formula (2.43)—specifically the fact that h_4 is positive—bears the information that onset of superconductivity in a bounded sample occurs at a higher value of applied field than for the case where Ω is a half-space. This correction agrees with that computed by Bauman *et al.*[10] for the disc.

We could proceed to solve for ψ_4 at this point (an explicit solution can be obtained via variation of parameters), however we omit this calculation as it will play no further role in our analysis.

We proceed to the next order and collect terms of $\mathcal{O}(1/k^{5/4})$,

$$\mathcal{L}(\psi_5) = h_5[2\xi(\overline{h}\xi - 1)\overline{\psi}]W_0 + h_4[2\xi(\overline{h}\xi - 1)\overline{\psi}]W_1 + \overline{\kappa}[\xi(\overline{h}\xi - 1)(\overline{h}\xi - 2)\overline{\psi} + \overline{\psi}_\xi]W_1 - [2i(\overline{h}\xi - 1)\overline{\psi}]W_{2_\tau},$$

$$\psi_{5_\xi}(0) = 0, \quad \psi_{5_\xi}(\infty) = 0. \tag{2.44}$$

Once again, integration against $\overline{\psi}$ yields the solvability condition. The terms in W_1 and W_{2_τ} in the solvability condition vanish in an analogous fashion to those in W_0 and W_{1_τ} at the previous order (taking into account the value of h_4 determined by (2.43)). Hence, $h_5 = 0$. Once again, we neglect the calculation of ψ_5 as it plays no further role in our analysis.

Finally, we proceed to the next order and collect terms of $\mathcal{O}(1/k^{3/2})$,

$$\mathcal{L}(\psi_6) = h_6[2\xi(\overline{h}\xi - 1)\overline{\psi}]W_0 + \overline{\kappa}_{ss}\frac{\tau^2}{2}[\xi(\overline{h}\xi - 1)(\overline{h}\xi - 2)\overline{\psi} + \overline{\psi}_\xi]W_0 - \left[\frac{2}{\overline{h}}(\overline{h}\xi - 1)\overline{\psi}_\xi + \overline{\psi}\right]W_{0_{\tau\tau}} + h_4[2\xi(\overline{h}\xi - 1)\overline{\psi}]W_2 + \overline{\kappa}[\xi(\overline{h}\xi - 1)(\overline{h}\xi - 2)\overline{\psi} + \overline{\psi}_\xi]W_2 - [2i(\overline{h}\xi - 1)\overline{\psi}]W_{3_\tau},$$

$$\psi_{6_\xi}(0) = 0, \quad \psi_{6_\xi}(\infty) = 0. \tag{2.45}$$

Once again, we integrate against $\overline{\psi}$. The terms proportional to W_2 and W_{3_τ} in the solvability condition vanish in an analogous fashion to those proportional to W_1 and W_{2_τ} respectively at the previous order. However, we obtain a nontrivial solvability condition for $W_0(\tau)$. Applying the identities (2.34)–(2.36) and integrating by parts yields

$$-\frac{1}{\overline{h}}W_{0_{\tau\tau}} + \left(h_6\frac{J_0}{\overline{h}} - \frac{\overline{\kappa}_{ss}}{6}\tau^2\right)W_0 = 0. \tag{2.46}$$

At this point we see the motivation for the introduction of the τ lengthscale; on this length scale the tranverse variation of the amplitude ($W_{0_{\tau\tau}}$) balances the quadratic variation of the curvature ($\overline{\kappa}_{ss}\tau^2/2$).

Boundary conditions on $W_0(\tau)$ are determined by a need to match to the normal state at large $|\tau|$, for which $\Psi^{(1)}$ and consequently W_0 vanish. Thus, we apply the condition that $W_0(\tau)$ vanishes in the far-field,

$$W_0(\tau) \to 0 \quad \text{as} \quad |\tau| \to \infty \tag{2.47}$$

with the understanding that τ is in the matching region, $1 \ll |\tau| \ll k^{1/4}$. Fortunately, $W_0(\tau)$ decays exponentially and consequently this matching will only introduce exponentially small corrections in the expansion.

Fortuitously, Eq. (2.46) is real, and consequently admits real solutions for W_0 (we expect W_n to be complex in general). We can rescale (2.46) into the standard form for the harmonic oscillator equation; define

$$\zeta = \alpha\tau, \quad w(\zeta) = W_0(\zeta/\alpha), \quad \lambda = -\frac{J_0 h_6}{\alpha^2},$$

where

$$\alpha = \left(\frac{-2\overline{\kappa}_{ss}\overline{h}}{3}\right)^{1/4},$$

remembering that at the maximum of curvature, we have $\overline{\kappa}_{ss}<0$. Equations (2.46) and (2.47) become

$$w_{\zeta\zeta}+\left(\lambda-\frac{1}{4}\,\zeta^2\right)w=0, \quad w(\zeta)\to 0 \quad \text{as} \quad |\zeta|\to\infty.$$

The eigenvalues and eigenfunctions of this problem are given by

$$\lambda_n=n+\tfrac{1}{2}, \quad w_n(\zeta)=\mathrm{He}_n(\zeta)e^{-\zeta^2/4}, \quad n=0,1,2,3,...,$$

where $\mathrm{He}_n(\zeta)$ are the Hermite polynomials (cf. Ref. 17). Note that the smallest eigenvalue is $\lambda_0=1/2$, with corresponding eigenfunction $w_0(\zeta)=e^{-\zeta^2/4}$. Hence, the largest (least negative) eigenvalue for (2.46) is given by

$$h_6=-\frac{1}{2J_0}\left(\frac{-2\overline{\kappa}_{ss}\overline{h}}{3}\right)^{1/2}, \tag{2.48}$$

and the corresponding eigenfunction is

$$W_0(\tau)=e^{-\alpha^2\tau^2/4}. \tag{2.49}$$

The exponential decay of W_0 away from $\tau=0$ reveals that the phenomenon of onset is highly localized near the point of maximum curvature for $\partial\Omega$. We have now completely determined the leading order solution for $\Psi^{(1)}$ to the linearized problem (2.9), (2.10) in the asymptotic regime $\kappa\gg 1$.

III. DISCUSSION

In this paper we have examined the instability of the normal state to superconductivity with decreasing magnetic field for a closed smooth cylindrical region subject to a vertical magnetic field. We have examined the problem asymptotically in the boundary layer limit ($k\gg 1$). Instability first occurs in a region exponentially localized near the point of maximum curvature on the boundary. The transition occurs at a value of the magnetic field,

$$H_{c_3}=\overline{h}k+\frac{\overline{h}}{3J_0}\,\overline{\kappa}-\frac{1}{2J_0}\left(\frac{-2\overline{\kappa}_{ss}\overline{h}}{3}\right)^{1/2}\frac{1}{k^{1/2}}+\mathcal{O}\left(\frac{1}{k}\right), \tag{3.1}$$

where $\overline{h}k$ is the transition value associated with the half-plane (cf. Refs. 2 and 3), the second term is a positive constant times the maximum curvature ($\overline{\kappa}$) that agrees with the correction computed for the disc (cf. Ref. 10), the third term is a negative correction of order $k^{-1/2}$, associated with the quadratic variation of the curvature at the maximum, and the error term follows from continuing the expansion documented in the previous section.

At leading order, the superconducting order-parameter satisfies

$$|\Psi^{(1)}|\sim\overline{\psi}(\xi)e^{-\alpha^2\tau^2/4},$$

where

$$\xi=k\eta, \quad \tau=k^{1/4}s, \quad \text{and} \quad \alpha=\left(\frac{-2\overline{\kappa}_{ss}\overline{h}}{3}\right)^{1/4}.$$

Here $\overline{\psi}$ is the profile associated with transition in the half-plane problem—it is an exponentially decaying function of the normal distance to the boundary (η) scaled by the boundary layer thickness ($1/k$). The amplitude along the boundary is modulated by a Gaussian, $e^{-\alpha^2\tau^2/4}$, where τ

is the arclength measured from the point of maximum curvature (at $s=0$) scaled by a length scale intermediate between the boundary layer thickness and the characteristic length scale of the domain (unity).

Physically, this result is a refinement of the corresponding results for the half-plane and the disc. The half-plane result yields the leading order transition value for the magnetic field and exponentially decaying boundary layer profile, kh and ψ, respectively. The disc calculation shows that transition occurs at a higher value of the magnetic field where the correction is of order unity and proportional to the curvature (i.e., the inverse of the radius). In contrast to the half-plane and disc calculation where onset occurs along the entire boundary simultaneously, in a general domain the profile is exponentially localized near the point of maximum curvature on the boundary on the τ length scale; the transition value is slightly below that of the oscillating disc at the point of maximum curvature.

An additional effect of this exponential localization of the transition profile is that the periodicity of the boundary apparently has an exponentially small effect on the critical magnetic field and the various eigenmodes are never degenerate. This is in sharp contrast to the theoretical calculation for the disc where periodicity ''quantizes'' the transverse wave numbers and at various critical parameter values there is a transition between different modes as the most unstable. We note that this quantization in a disc is captured via formal matched asymptotics in Ref. 18. These characteristics are also observed experimentally.[19,20] We suggest here that this degeneracy occurs only in the presence of symmetry in the sample geometry.

Finally, we note that the approach here is quite general, and should allow for the incorporation of nonlinearity, temporal evolution through relaxational effects, etc. The result we believe will be a Newell–Whitehead–Segal-type equation (cf. Ref. 16),

$$W_T = W_{SS} + [h - \kappa(S)]W - W|W|^2,$$

where W is a transverse modulation amplitude of the boundary layer profile, S is a scaled arc length, T is a slow time scale associated with relaxational effects (cf. Ref. 4), h is a scaled magnetic field, and $\kappa(S)$ measures curvature variation along the boundary. A model of this sort could be used to study hysteresis, symmetry breaking and a host of other phenomena which may lead to better understanding and prediction of the behavior of superconductors.

Note added in proof: After completing our work we learned about Reference 21.

APPENDIX: DERIVATION OF MOMENT IDENTITIES (2.34)–(2.36)

To derive identities (2.34)–(2.36), we observe that the operator $\mathscr{L}$ maps the vector space of functions of the form $a(\xi)\psi + b(\xi)\psi_\xi$, where $a(\xi)$ and $b(\xi)$ are polynomials, into itself. A little algebra shows that for a polynomial $c(\xi)$,

$$\mathscr{L}(2c\bar{\psi}_\xi - c_\xi\bar{\psi}) = -\{c_{\xi\xi\xi} + 4\bar{h}\xi(2-\bar{h}\xi)c_\xi + 4\bar{h}(1-\bar{h}\xi)c\}\bar{\psi}. \tag{A1}$$

Multiplying by $\bar{\psi}$, integrating over the range and applying integration by parts, we reach the identity

$$\int_0^\infty \bar{\psi}\mathscr{L}(2c\bar{\psi}_\xi - c_\xi\bar{\psi})\,d\xi = c_{\xi\xi}(0). \tag{A2}$$

If we now define the moments,

$$J_n \equiv \int_0^\infty \xi^n \overline{\psi^2} d\xi,$$

we can derive a recursion relationship for J_n by choosing $c=\xi^n$, substituting into (A1) and applying the identity (A2)

$$c=1: \quad 0=-4\overline{h}J_0+4\overline{h^2}J_1,$$

$$c=\xi: \quad 0=-12\overline{h}J_1+8\overline{h^2}J_2,$$

$$c=\xi^2: \quad 2=-20\overline{h}J_2+12\overline{h^2}J_3,$$

$$c=\xi^n: \quad 0=-n(n-1)(n-2)J_{n-3}-4\overline{h}(2n+1)J_n+4(n+1)\overline{h^2}J_{n+1} \quad n\geqslant 3.$$

The identities (2.34)–(2.36) and expressions for J_n in terms of J_0 can now be found by solving these relations. ■

(Received 12 June 1997; accepted for publication 29 October 1997)

We propose to parametrize the configuration space of one-dimensional quantum systems of N identical particles by the elementary symmetric polynomials of bosonic and fermionic coordinates. It is shown that in this parametrization the Hamiltonians of the A_N, BC_N, B_N, C_N and D_N Calogero and Sutherland models, as well as their supersymmetric generalizations, can be expressed—for *arbitrary* values of the coupling constants—as quadratic polynomials in the generators of a Borel subalgebra of the Lie algebra $gl(N+1)$ or the Lie superalgebra $gl(N+1|N)$ for the supersymmetric case. These algebras are realized by first order differential operators. This fact establishes the exact solvability of the models according to the general definition given by Turbiner, and implies that the Calogero and Jack–Sutherland polynomials, as well as their supersymmetric generalizations, are related to finite-dimensional irreducible representations of the Lie algebra $gl(N+1)$ and the Lie superalgebra $gl(N+1|N)$. © *1998 American Institute of Physics.* [S0022-2488(98)01003-2]

I. INTRODUCTION

Exact solutions of non-trivial problems are always of great importance. They give a hint about the structure of real problems and also provide a laboratory for testing approximate methods. The non-relativistic many-body Calogero–Sutherland models[1,2] together with their supersymmetric extensions[3–5] provide one of the most valuable sources of exact solutions to one-dimensional many-body quantum mechanical systems. The goal of this article is to try to uncover a hidden reason for the solvability of these models in order to answer the question what is special about them and whether there are other exactly solvable or quasi-exactly solvable many-body problems.

The remarkable discovery of the solvability of the bosonic N-body Calogero[1] and Sutherland[2] models was at the time a state-of-the-art achievement. Of course, this raised the question of whether there existed a regular procedure to generate these models. After a few years, it was found that the models are connected with the root systems of the A_{N-1} Lie algebras,[6] and can be obtained from the Laplace–Beltrami operators defined on the symmetric spaces; this procedure was called ''the method of Hamiltonian reduction.''[6–9] For a contemporary viewpoint on the Hamiltonian reduction method see, for example, Ref. 10 and Ref. 27. The Hamiltonian reduction method provides a regular basis for an explanation of the solvability of the Calogero and Sutherland models, at least for a selected set of values of the coupling constant(s). Considerations of the root systems of the other simple Lie algebras made it possible to find several additional families of exactly solvable multi-dimensional Schrödinger equations and to prove the complete integrability of all these models.

Recently, another explanation of the exact-solvability of bosonic many-body problems was presented, which was based on the finding that the eigenfunctions of the N-body A_{N-1} Calogero–Sutherland models form a flag coinciding with the flag of the finite-dimensional representation spaces of the Lie algebra $gl(N)$.[11,12] It was shown that the Hamiltonians of the Calogero and Sutherland models are nothing but different non-linear elements of the universal enveloping algebra of a Borel subalgebra of the $gl(N)$ algebra. Unlike the ''method of reduction,'' in the second method the coupling constants appear as certain parameters fixing the element of the universal enveloping algebra. The second method can be used to explain the solvability of the above models for *all* allowed values of the coupling constant(s). In the present paper we show that the BC_N, B_N, C_N and D_N Calogero (rational) and Sutherland (trigonometric) Hamiltonians, for *any* values of the coupling constants, are second order polynomials in the generators of the $gl(N+1)$ algebra. These results were made possible by exploiting the fact that the configuration space of the above quantum-mechanical systems can be parametrized by variables in which the permutation symmetry is already encoded. The most suitable variables are given by the elementary symmetric polynomials of the coordinates of the particles. In these variables the eigenfunctions have an especially simple form.

Other approaches have also been used to study the Calogero and Sutherland models. Some of these have been directed toward obtaining closed expressions for the wave functions. The bosonic A_N Calogero model was solved using an operator method in Ref. 13, a similar method was applied to the bosonic A_N Sutherland model in Ref. 14. The eigenfunctions of the BC_N Sutherland model has been studied in Refs. 9,15 (ground-state) and 16. It is worth mentioning the remarkable observation that the wave functions of the bosonic A_N Sutherland models are in correspondence with singular vectors of W-algebras (see, for example, Ref. 17).

Quite recently, supersymmetric extensions of the many-body A_N Calogero[3,4] and Sutherland[5] models were constructed using the standard prescription of supersymmetrization. In the present article we derive the supersymmetric extensions of the BC_N, B_N, C_N and D_N Calogero and Sutherland models and show that their solvability can be explained by the existence of the hidden Lie superalgebra $gl(N+1|N)$. It is worth mentioning that a supersymmetric analogue of the Hamiltonian reduction method has not been constructed for these models so far.

The paper is organized as follows: In the next section we briefly review the bosonic many-body A_N Calogero and Sutherland models with emphasis on the property of exact solvability, and also set up our notation. In Section III we study the supersymmetric extension of the Calogero model and show that it is exactly solvable. In Section IV the same analysis is carried out for the supersymmetric Sutherland model. Section V is devoted to the Calogero models connected with the Lie algebras BC_N, B_N, C_N and D_N as well as their supersymmetric extensions; it is shown that those models are exactly solvable. In Section VI the BC_N, B_N, C_N and D_N Sutherland models and their supersymmetric extensions are explored and their exact solvability is established. The Conclusion contains a summary of the results obtained and a discussion of some possible directions for future investigations. In Appendix A we present a realization of the Lie algebra $gl(N)$ and the Lie superalgebra $gl(N|M)$ in terms of first order differential operators. Appendix B contains the Lie algebraic forms of the Hamiltonians discussed in this paper. Finally, in Appendix C we give some details on the derivation of the Lie algebraic forms of the Hamiltonians for the Calogero and Sutherland models.

II. BOSONIC (MANY-BODY) A_{N-1} CALOGERO AND SUTHERLAND MODELS (REVIEW)

In this section we briefly review, following Ref. 12, the *exact-solvability* of the bosonic many-body Calogero and Sutherland models or, more precisely, the A_{N-1} Calogero and Sutherland models. For the sake of simplicity, in Sections II–IV we refer to these models as the Calogero and Sutherland models.

The Calogero and Sutherland models describe systems of N identical particles situated on the line and the circle, respectively. The degrees of freedom of these models are parametrized by N real coordinates x_i. The Hamiltonian of the Calogero model is defined by

$$\mathscr{H}_{\mathrm{Cal}}=\frac{1}{2}\sum_{i=1}^{N}\left[-\frac{\partial^2}{\partial x_i^2}+\omega^2 x_i^2\right]+g\sum_{i<j}\frac{1}{(x_i-x_j)^2}, \tag{2.1}$$

where $g=\nu(\nu-1)>-\frac{1}{4}$ is the coupling constant and ω is the harmonic oscillator frequency. For convenience only, we place the center-of-mass under the influence of the harmonic oscillator force. The ground state eigenfunction is given by

$$\Psi_0^{(c)}(x)=\Delta^{\nu}(x)e^{-\omega(X^2/2)}, \tag{2.2}$$

where $\Delta(x)=\Pi_{i<j}|x_i-x_j|$ is the Vandermonde determinant and $X^2=\Sigma_i x_i^2$. One should stress the point that to a fixed value of the coupling constant g there correspond two different values of the parameter ν, namely, $\nu=\alpha$ and $\nu=(1-\alpha)$, giving rise to two families of eigenfunctions. Of course, α should be chosen in such a way as to minimize the eigenvalue; then (2.2) corresponds to the ground state. The value $\nu=(1-\alpha)$ inserted in (2.2) describes the ground state (if normalizable) but of *another* family. If $g=0$, this family comprises the states of negative parity with respect to permutations. As has been shown by F. Calogero, any eigenstate of the system can be written in the form

$$\Psi(x)=\Psi_0^{(c)}(x)P_c(x), \tag{2.3}$$

where $P_c(x)$ is a certain polynomial in the x_i's, symmetric under the permutation of any two particles. We refer to these polynomials as *Calogero polynomials*. The operator having the Calogero polynomials as eigenfunctions is obtained from the Hamiltonian (2.1) by a ''gauge'' rotation, by which we mean the similarity transformation

$$h_{\mathrm{Cal}}=(\Psi_0^{(c)})^{-1}\mathscr{H}_{\mathrm{Cal}}\Psi_0^{(c)}. \tag{2.4}$$

The Hamiltonian of the Sutherland model is defined by

$$\mathscr{H}_{\mathrm{Suth}}=-\frac{1}{2}\sum_{k=1}^{N}\frac{\partial^2}{\partial x_k^2}+\frac{g}{4}\sum_{k<l}\frac{1}{\sin^2(\frac{1}{2}(x_k-x_l))}, \tag{2.5}$$

where $g=\nu(\nu-1)>-\frac{1}{4}$ is the coupling constant. There are two families of eigenfunctions, cf. the discussion above. The ground state eigenfunction is given by

$$\Psi_0^{(s)}(x)=(\Delta^{(trig)}(x))^{\nu}, \tag{2.6}$$

where $\Delta^{(trig)}(x)=\Pi_{i<j}|\sin(\frac{1}{2}(x_i-x_j)|$ is a trigonometric analogue of the Vandermonde determinant. It was shown by B. Sutherland that similarly to the Calogero model any eigenfunction of the Hamiltonian (2.5) can be written in the form

$$\Psi(x)=\Psi_0^{(s)}(x)P_s(e^{ix}), \tag{2.7}$$

where $P_s(e^{ix})$ is a certain polynomial in e^{ix_j}, symmetric under the permutation of any two particles. These polynomials are the so-called Jack–Sutherland polynomials[18,2] (for a general description, see, for example, Refs. 19 and 20). Performing a gauge rotation of $\mathscr{H}_{\mathrm{Suth}}$ with the gauge factor $\Psi_0^{(s)}$ we arrive at the operator

$$h_{\mathrm{Suth}}=(\Psi_0^{(s)})^{-1}\mathscr{H}_{\mathrm{Suth}}\Psi_0^{(s)}, \tag{2.8}$$

which has the Jack–Sutherland polynomials as eigenfunctions.

In order to study the internal dynamics we introduce the center-of-mass coordinate $Y=\Sigma_{j=1}^{N}x_j$ and the translation-invariant relative Perelomov coordinates:[21]

$$y_i=x_i-\frac{1}{N}Y, i=1,2,\ldots,N, \tag{2.9}$$

which obey the constraint $\Sigma_{i=1}^{N}y_i=0$. In order to incorporate the permutation symmetry and the translation invariance we consider two sets of coordinates:[12]

$$(x_1,x_2,\ldots,x_N)\to(Y,\tau_n(x)=\sigma_n(y(x))|n=2,3,\ldots,N), \tag{2.10}$$

and

$$(x_1,x_2,\ldots,x_N)\to(e^{iY},\eta_n(x)=\sigma_n(e^{iy(x)})|n=1,2,\ldots,(N-1)), \tag{2.11}$$

where

$$\sigma_k(x)=\sum_{i_1<i_2<\cdots<i_k} x_{i_1}x_{i_2}\cdots x_{i_k} \tag{2.12}$$

are the elementary symmetric polynomials (see, for example, Ref. 20). $\sigma_k(y(x))$ are thus the elementary symmetric polynomials with translation-invariant arguments (due to the constraint $\Sigma_{i=1}^N y_i=0$, the symmetric polynomials can be considered as defined in $\mathbf{R}^N$ and then restricted to the hyperplane $\Sigma_{i=1}^N y_i=0$). Then the following statement holds:[12]

After separation of the center-of-mass, the operators h_{Cal} and h_{Suth}, when written in the coordinates τ (2.10) and η (2.11), respectively, are quadratic polynomials in the generators of the Borel subalgebra of $gl(N)$ spanned by the operators J_{ij}^0 and J_i^- realized as first order differential operators (see Appendix A, Eq. (A1)):

$$h=\sum_{i,j,k,l=2}^{N} A_{ijkl}J_{ij}^0J_{kl}^0+\sum_{i,j,k=2}^{N} B_{ijk}J_{ij}^0J_k^-+\sum_{i,j=2}^{N} C_{ij}J_{ij}^0+\sum_{i=2}^{N} D_iJ_i^-$$

(see Appendix B). The operators J_{ij}^0 and J_i^- can be represented by triangular matrices and preserve the flag of spaces of inhomogeneous polynomials

$$\mathscr{P}_n=\ \mathrm{span}\left\{v_2^{n_2}v_3^{n_3}v_4^{n_4}\ldots v_N^{n_N}\middle|0\leqslant\sum\ n_i\leqslant n\right\},$$

where $v_k=\tau_k$ and $v_k=\eta_{k+1}$, respectively, and $k=2,\ldots,N$. The coupling constants g (see (2.1) and (2.5)) appear only in the coefficients C_{ij} and D_i and are not related to the dimension of the representation of $gl(N)$. Consequently, each Hamiltonian (2.1), (2.5) has one or several infinite families of polynomial eigenfunctions.

This statement leads to the important conclusion that the Calogero and Jack–Sutherland polynomials are intimately connected with the finite-dimensional irreducible representations of the Lie algebra $gl(N)$. It also provides a simple computational tool for deriving the explicit form of the Calogero and Jack–Sutherland polynomials.

III. THE SUPERSYMMETRIC MANY-BODY CALOGERO MODEL

In order to proceed to the problem of the supersymmetric generalizations of (2.1) and (2.5), let us first recall[3] that in a supersymmetric system of particles each bosonic degree of freedom x_i is accompanied by the fermionic variables ϑ_i and $\vartheta_i^\dagger$, which obey the standard anti-commutation rules $\{\vartheta_i,\vartheta_j\}=\{\vartheta_i^\dagger,\vartheta_j^\dagger\}=0$ and $\{\vartheta_i,\vartheta_j^\dagger\}=\delta_{ij}$. Throughout the paper we use a concrete realization of this algebra:

$$\vartheta_i=\theta_i,\ \vartheta_i^\dagger=\frac{\partial}{\partial\theta^i}.$$

It is convenient to introduce the ''cmino'' Ψ—the fermionic analogue of the center-of-mass coordinate as

$$\Psi=\sum_{i=1}^{N}\ \theta_i, \tag{3.1}$$

which is the super-partner of Y. We can also define the fermionic analogue of the Perelomov coordinates (2.9)

$$\lambda_i = \theta_i - \frac{1}{N}\Psi. \tag{3.2}$$

In order to construct the supersymmetric many-body Calogero model let us introduce the supercharges Q and $Q^\dagger$ as defined in Ref. 3:

$$Q = \sum_k \frac{\partial}{\partial\theta_k}\left(p_k - i\frac{\partial W}{\partial x^k}\right), \quad Q^\dagger = \sum_k \theta_k\left(p_k + i\frac{\partial W}{\partial x^k}\right), \tag{3.3}$$

where $Q^2 = Q^{\dagger 2} = 0$, $p_k = -i(\partial/\partial x_k)$, and the superpotential is

$$W(x_1, x_2, \ldots, x_N) = -\frac{\omega}{2}\sum_{i=1}^N x_i^2 + \nu\sum_{i<j}\log|x_i - x_j|. \tag{3.4}$$

Then the supersymmetric Hamiltonian $\mathscr{H}_{\mathrm{sCal}} = \frac{1}{2}\{Q, Q^\dagger\}$ has the form[3]

$$\mathscr{H}_{\mathrm{sCal}} = \frac{1}{2}\sum_{i=1}^N\left[-\frac{\partial^2}{\partial x_i^2} + \omega^2 x_i^2\right] + \omega\sum_{i=1}^N \theta_i\frac{\partial}{\partial\theta^i} + \sum_{i<j}\frac{\nu}{(x_i - x_j)^2}\left[(\nu - 1) + \theta_i - \theta_j\left(\frac{\partial}{\partial\theta_i} - \frac{\partial}{\partial\theta_j}\right)\right] + C, \tag{3.5}$$

where $C = -\frac{1}{2}\nu\omega N(N-1) - \frac{1}{2}N\omega$. The ground state eigenfunction remains the same (cf. (2.2)) as for the bosonic many-body Calogero model (2.1). It is easy to see that a gauge rotation of $\mathscr{H}_{\mathrm{sCal}}$ with the ground state wave function $\Psi_0^{(c)}$ as a gauge factor affects only the bosonic part of the Hamiltonian. Defining

$$h_{\mathrm{sCal}} = -2(\Psi_0^{(c)})^{-1}\mathscr{H}_{\mathrm{sCal}}\Psi_0^{(c)} \tag{3.6}$$

[cf. (2.4)], we obtain

$$h_{\mathrm{sCal}} = \sum_{i=1}^N \frac{\partial^2}{\partial x_i^2} - 2\omega\sum_{i=1}^N\left[x_i\frac{\partial}{\partial x_i} + \theta_i\frac{\partial}{\partial\theta^i}\right] + 2\nu\sum_{i<j}\left[\frac{1}{x_i - x_j}\left(\frac{\partial}{\partial x_i} - \frac{\partial}{\partial x_j}\right) - \frac{\theta_i - \theta_j}{(x_i - x_j)^2}\left(\frac{\partial}{\partial\theta_i} - \frac{\partial}{\partial\theta_j}\right)\right]. \tag{3.7}$$

This expression can be called the *rational* form of the supersymmetric many-body Calogero model. Similar to the bosonic case the eigenfunctions of the operator (3.7) after separation of the center-of-mass remain polynomials but now in (y^i, λ^i). These polynomials are symmetric under the permutation of any pair of particles $(x^i, \theta^i) \leftrightarrow (x^j, \theta^j)$, and can be considered as the supersymmetric analogue of the Calogero polynomials.

Now let us introduce permutation-symmetric variables. One can construct two sets of such variables: (i) a set analogous to the Newton polynomials

$$s_n = \sum_{i=1}^N x_i^n, \rho_n = \sum_{i=1}^N \theta_i x_i^{n-1} \tag{3.8}$$

and (ii) a set analogous to the elementary symmetric polynomials

$$\sigma_k = \sum_{i_1 < i_2 < \cdots < i_k} x_{i_1}x_{i_2}\cdots x_{i_k}, \zeta_k = \frac{1}{(k-1)!}\sum_{i_1 \neq i_2 \neq \cdots \neq i_k} \theta_{i_1}x_{i_2}\cdots x_{i_k}. \tag{3.9}$$

The variables s_n and ρ_n as well as σ_k and ζ_k are symmetric under the permutation, $(x^i, \theta^i) \leftrightarrow (x^j, \theta^j)$. However, the property $\sigma_{N+k} = 0, \zeta_{N+k} = 0, k = 1, 2, \ldots$ implies that the variables σ_k and ζ_k, has the advantage that they avoid the difficulties associated with the overcompleteness of the basis, which plague the variables s_n and ρ_n. Therefore, in the sequel we make use of the variables σ_k and ζ_k.

It is worth mentioning the following relations between the two sets of variables:

$$\sum_{k=0}^{N}\sigma_k(x)t^k=\exp\left[\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n}s_n(x)t^n\right],$$
$$\sum_{k=0}^{N}\zeta_k(x)t^k=\left(\sum_{m=1}^{\infty}(-1)^{m+1}\rho_m(x,\theta)t^m\right)\exp\left[\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n}s_n(x)t^n\right]. \tag{3.10}$$

A convenient way of succinctly writing these relations is obtained if one introduces the ''superspace'' coordinates

$$\chi_i=\sigma_i+\alpha\zeta_i,\ \phi_i=x_i+\alpha\theta_i, \tag{3.11}$$

where α is a Grassmann number, $\alpha^2=0$; then

$$\sum_{k=0}^{N}\chi_k(\phi_i)t^k=\exp\left[\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n}s_n(\phi_i)t^n\right], \tag{3.12}$$

encodes both the relations (3.10).

The ''superspace'' formulation makes it possible to write formulas in a more compact way. The ''supercoordinate'' ϕ_i is clearly an $N=1$ superfield. However, one should stress that the models we study possess $N=2$ supersymmetry, while the ''superspace'' formulation is not manifestly $N=2$ supersymmetric. Nevertheless, later on we will see explicitly that the superspace (we drop the quotation marks hereafter) formulation turns out to be a useful computational aid. For example, one can rewrite the Hamiltonian h_{sCal} in the superspace coordinates as follows:

$$h_{\mathrm{sCal}}=\int d\alpha d\bar{\alpha}\sum_{i=1}^{N}\frac{\delta}{\delta\bar{\phi}_i}\frac{\delta}{\delta\phi_i}-\int d\alpha\mathscr{W}-\int d\bar{\alpha}\bar{\mathscr{W}}. \tag{3.13}$$

Here $\bar{\alpha}$ is a Grassmann variable independent of α and

$$\frac{\delta}{\delta\phi_i}=\frac{\partial}{\partial\theta_i}+\alpha\frac{\partial}{\partial x_i},\ \frac{\delta}{\delta\bar{\phi}_i}=\frac{\partial}{\partial\theta_i}+\bar{\alpha}\frac{\partial}{\partial x_i}, \tag{3.14}$$

while

$$\mathscr{W}=\omega\sum_{i=1}^{N}\phi_i\frac{\delta}{\delta\phi_i}-\nu\sum_{i<j}\frac{1}{\phi_i-\phi_j}\left(\frac{\delta}{\delta\phi_i}-\frac{\delta}{\delta\phi_j}\right),\ \bar{\mathscr{W}}=\mathscr{W}(\bar{\phi}), \tag{3.15}$$

where $\bar{\phi}_i=x_i+\bar{\alpha}\theta_i$. Notice that we have not introduced any superderivatives; $\delta/\delta\phi_i$ and $\delta/\delta\bar{\phi}_i$ should be considered as ''superfields'' (since they do not contain derivatives with respect to t, α and/or $\bar{\alpha}$).

Like we did in Section II we would like to separate the dynamics of the center-of-mass and the relative motion, and encode in relative coordinates the translation invariance and permutation symmetry of the system. In order to implement these requirements we introduce the translation-invariant and permutation-symmetric coordinates of the relative motion

$$\tau_k(y)=\sigma_k(y(x)),\kappa_k(y,\lambda)=\zeta_k(y(x),\lambda(\theta)), \tag{3.16}$$

for example, in the symmetric polynomials (3.9) the arguments (x's) are replaced by the translation-invariant y's (2.9) and the θ's are replaced by the translation-invariant λ's (3.2). Here $\tau_0=1,\tau_1=0$ and $\kappa_0=\kappa_1=0$. The next step is to make the change of variables

$$(x_i,\theta_i|i=1,2,\ldots,N)\to(Y,\tau_k;\Psi,\kappa_k|k=2,3,\ldots,N) \tag{3.17}$$

in the Hamiltonian h_{sCal}. In general, this is a tedious and cumbersome calculation. Fortunately, the superspace formulation allows us to avoid most of the tiresome algebraic calculations. Let us define

$$\tilde{\phi}_i = \phi_i - \frac{1}{N}\sum_{j=1}^{N} \phi_j . \tag{3.18}$$

Then the expression for $\psi_i = \tau_i + \alpha\kappa_i$ can be obtained from the relation

$$\sum_{k=0}^{N} \psi_k(\tilde{\phi}_i) t^k = \exp\left[\sum_{n=1}^{\infty} \frac{(-1)^n}{n} s_n(\tilde{\phi}_i) t^n\right]. \tag{3.19}$$

The derivative

$$\frac{\delta}{\delta\phi_i(\alpha)} = \frac{\partial}{\partial\theta_i} + \alpha\frac{\partial}{\partial x_i}$$

satisfies

$$\frac{\delta\phi_j(\beta)}{\delta\phi_i(\alpha)} = \delta_{ij}(\alpha-\beta) = \delta_{ij}\delta(\alpha-\beta), \tag{3.20}$$

where we have used that $\int d\alpha\,\delta(\alpha-\beta) f(\alpha) = f(\beta)$. We now make the change of variables

$$(\phi_i | i = 1, \ldots, N) \to \left(\chi_1 = \sum_{k=1}^{N} \phi_k ; \psi_j \,\middle|\, j = 2, \ldots, N\right).$$

Under such a change of variables the derivatives transform as (from now on we suppress the center-of-mass coordinate χ_1)

$$\frac{\delta}{\delta\phi_i(\alpha)} = -\int d\beta \frac{\delta\psi_j(\beta)}{\delta\phi_i(\alpha)} \frac{\delta}{\delta\psi_j(\beta)}, \tag{3.21}$$

where

$$\frac{\delta}{\delta\psi_i(\alpha)} = \frac{\partial}{\partial\kappa_i} + \alpha\frac{\partial}{\partial\tau_i},$$

and summation over j is assumed. To prove the relation (3.21) one simply writes both sides of the equality in components. It is convenient to perform the change of variables in two steps: to write,

$$\frac{\delta}{\delta\phi_i(\alpha)} = \int d\beta d\gamma \frac{\delta\tilde{\phi}_j(\gamma)}{\delta\phi_i(\alpha)} \frac{\delta\psi_k(\beta)}{\delta\tilde{\phi}_j(\gamma)} \frac{\delta}{\delta\psi_k(\beta)}, \tag{3.22}$$

and then use the definition of $\tilde{\phi}_i$ together with (3.21) which leads to $\delta\tilde{\phi}_j(\gamma)/\delta\phi_i(\alpha) = (\delta_{ij} - 1/N)\delta(\alpha-\gamma)$. Let us give as an example the expression for the Laplace operator in the new coordinates

$$\sum_{i=1}^{N}\int d\alpha d\beta \frac{\delta}{\delta\phi_i(\beta)}\frac{\delta}{\delta\phi_i(\alpha)} \to \sum_{i=1}^{N}\sum_{j,k=2}^{N}\sum_{l,m=1}^{N}\int d\alpha d\beta \int d\gamma\left(\delta_{il}-\frac{1}{N}\right) \times \frac{\delta\psi_j(\gamma)}{\delta\tilde{\phi}_l(\beta)}\frac{\delta}{\delta\psi_j(\gamma)}\int d\epsilon\left(\delta_{im}-\frac{1}{N}\right)\frac{\delta\psi_k(\epsilon)}{\delta\tilde{\phi}_m(\alpha)}\frac{\delta}{\delta\psi_k(\epsilon)}. \tag{3.23}$$

The above considerations imply that within the framework of the superspace formalism the calculations for the supersymmetric models follow closely the calculations carried out in the bosonic case.[12] In fact, for most of the terms the supersymmetric results can be obtained from the bosonic ones by judiciously replacing the bosonic coordinates by superspace coordinates. More details can be found in Appendix C. The derivation makes extensive use of the generating function (3.12).

In the superspace coordinates the Laplace operator becomes (after reinserting the center-of-mass coordinate)

$$\sum_{k=1}^{N}\int d\alpha d\bar{\alpha}\frac{\delta}{\delta\bar{\phi}_k}\frac{\delta}{\delta\phi_k} = \int d\alpha d\bar{\alpha}\left[N\frac{\delta}{\delta\bar{\chi}_1}\frac{\delta}{\delta\chi_1}+\sum_{i,j=2}^{N}\mathscr{A}_{ij}\frac{\delta}{\delta\bar{\psi}_j}\frac{\delta}{\delta\psi_i}\right] + \int d\alpha\sum_{i=2}^{N}\mathscr{B}_i\frac{\delta}{\delta\psi_i}+\int d\bar{\alpha}\sum_{i=2}^{N}\bar{\mathscr{B}}_i\frac{\delta}{\delta\bar{\psi}_i}, \tag{3.24}$$

where

$$\psi_i=\tau_i+\alpha\kappa_i,\ \frac{\delta}{\delta\psi_i}=\frac{\partial}{\partial\kappa_i}+\alpha\frac{\partial}{\partial\tau_i}, \tag{3.25}$$

and

$$\mathscr{A}_{ij}=\frac{(N-i+1)(j-1)}{N}\psi_{i-1}\bar{\psi}_{j-1}+\sum_{l\geqslant\max(1,j-i)}(j-i-2l)\psi_{i+l-1}\bar{\psi}_{j-l-1} -\sum_{l\geqslant1} l[\bar{\psi}_{i+l}\psi_{j-2-l}-\psi_{i+l}\bar{\psi}_{j-2-l}], \tag{3.26}$$

$$\mathscr{B}_i(\psi)=-\frac{1}{2N}\sum_{i=2}^{N}(N-i+2)(N-i+1)\psi_{i-2},\ \bar{\mathscr{B}}_i=\mathscr{B}_i(\bar{\psi}). \tag{3.27}$$

The final expression for the Laplace operator in components is given by

$$\sum_{i=1}^{N}\frac{\partial^2}{\partial x_i^2}=N\frac{\partial^2}{\partial Y^2}+\sum_{i,j=2}^{N}\left[A_{ij}^{\tau\tau}\frac{\partial^2}{\partial\tau_i\partial\tau_j}+A_{ij}^{\tau\kappa}\frac{\partial^2}{\partial\tau_i\partial\kappa_j}+A_{ij}^{\kappa\tau}\frac{\partial^2}{\partial\tau_j\partial\kappa_i}+A_{ij}^{\kappa\kappa}\frac{\partial^2}{\partial\kappa_j\partial\kappa_i}\right] +\sum_{i=2}^{N}\left[B_i^{\tau}\frac{\partial}{\partial\tau_i}+B_i^{\kappa}\frac{\partial}{\partial\kappa_i}\right], \tag{3.28}$$

where

$$A_{ij}^{\tau\tau}=\frac{(N-i+1)(j-1)}{N}\tau_{i-1}\tau_{j-1}+\sum_{l\geqslant\max(1,j-i)}(j-i-2l)\tau_{i+l-1}\tau_{j-l-1},$$

$$A_{ij}^{\tau\kappa}=\frac{(N-i+1)(j-1)}{N}\tau_{i-1}\kappa_{j-1}+\sum_{l\geqslant\max(1,j-i)}(j-i-2l)\tau_{i+l-1}\kappa_{j-l-1} -\sum_{l\geqslant1} l[\kappa_{i+l}\tau_{j-2-l}-\tau_{i+l}\kappa_{j-2-l}],$$

$$A_{ij}^{\kappa\tau}=\frac{(N-i+1)(j-1)}{N}\kappa_{i-1}\tau_{j-1}+\sum_{l\geqslant\max(1,j-i)}(j-i-2l)\kappa_{i+l-1}\tau_{j-l-1}$$
$$+\sum_{l\geqslant 1} l[\kappa_{i+l}\tau_{j-2-l}-\tau_{i+l}\kappa_{j-2-l}], \tag{3.29}$$

$$A_{ij}^{\kappa\kappa}=\frac{(N-i+1)(j-1)}{N}\kappa_{i-1}\kappa_{j-1}+\sum_{l\geqslant\max(1,j-i)}(j-i-2l)\kappa_{i+l-1}\kappa_{j-l-1}+2\sum_{l\geqslant 1} l\kappa_{i+l}\kappa_{j-2-l},$$

$$B_i^{\tau}=-\frac{(N-i+2)(N-i+1)}{N}\tau_{i-2},$$

$$B_i^{\kappa}=-\frac{(N-i+2)(N-i+1)}{N}\kappa_{i-2}.$$

As expected, $A_{ij}^{\tau\tau}$ and B_i^{τ} coincide with the expressions found in Ref. 12 for the bosonic Calogero model. Let us note that the coefficient functions A_{ij} and B_i are second and first order polynomials in τ_i and κ_i, respectively.

Dropping the decoupled center-of-mass terms one can show that in superspace coordinates the remaining part of the Hamiltonian $h_{\mathrm{sCal}}^{(\mathrm{rel})}$, which describes the relative motion, becomes

$$h_{\mathrm{sCal}}^{(\mathrm{rel})}=\int d\alpha d\bar{\alpha}\sum_{i,j=2}^{N}\mathscr{A}_{ij}\frac{\delta}{\delta\bar{\psi}_j}\frac{\delta}{\delta\psi_i}-\int d\alpha\mathscr{W}-\int d\bar{\alpha}\bar{\mathscr{W}}, \tag{3.30}$$

where $\mathscr{A}_{ij}$ is given in (3.26) and

$$\mathscr{W}=\omega\sum_{i=2}^{N} i\psi_i\frac{\delta}{\delta\psi_i}+\frac{1}{2}\left(\frac{1}{N}+\nu\right)\sum_{i=2}^{N}(N-i+2)(N-i+1)\psi_{i-2}\frac{\delta}{\delta\psi_i},\ \bar{\mathscr{W}}=\mathscr{W}(\bar{\psi}). \tag{3.31}$$

Finally, in component form $h_{\mathrm{sCal}}^{(\mathrm{rel})}$ looks like

$$h_{\mathrm{sCal}}^{(\mathrm{rel})}=\sum_{i,j=2}^{N}\left[A_{ij}^{\tau\tau}\frac{\partial^2}{\partial\tau_i\partial\tau_j}+A_{ij}^{\tau\kappa}\frac{\partial^2}{\partial\tau_i\partial\kappa_j}+A_{ij}^{\kappa\tau}\frac{\partial^2}{\partial\kappa_i\partial\tau_j}+A_{ij}^{\kappa\kappa}\frac{\partial^2}{\partial\kappa_j\partial\kappa_i}\right]$$
$$-\left(\frac{1}{N}+\nu\right)\sum_{i=2}^{N}(N-i+2)(N-i+1)\left[\tau_{i-2}\frac{\partial}{\partial\tau_i}+\kappa_{i-2}\frac{\partial}{\partial\kappa_i}\right]-2\omega\sum_{i=2}^{N} i\left[\tau_i\frac{\partial}{\partial\tau_i}+\kappa_i\frac{\partial}{\partial\kappa_i}\right], \tag{3.32}$$

where $A_{ij}^{\tau\tau}, A_{ij}^{\tau\kappa}, A_{ij}^{\kappa\tau}, A_{ij}^{\kappa\kappa}, B_i^{\tau}, B_i^{\kappa}$ are given in (3.29). This form can be called the *algebraic* form of the supersymmetric many-body Calogero Hamiltonian.

It turns out that we are able to rewrite the supersymmetric Calogero Hamiltonian $h_{\mathrm{sCal}}^{(\mathrm{rel})}$ in terms of generators of the Borel subalgebra of the algebra $gl(N|N-1)$ spanned by first order differential operators in the variables $(\tau_k,\kappa_k), k=2,\ldots,N$ (see Appendix A2). The result is given in Appendix B, Eq. (B2). Since the expression (B2) contains no positive-root generators J_i^+, Q_γ^+, then in accordance with the general definition given in Ref. 11 we conclude that the supersymmetric many-body Calogero model (3.5) is exactly solvable. The existence of the representation (B2) proves that there are infinitely many eigenfunctions of the operator (3.7) having the form of polynomials in the variables (τ_k,κ_k). It also implies that eigenfunctions of the supersymmetric many-body Calogero model (3.5) have a factorizable form being the product of the ground-state eigenfunction multiplied by a polynomial in the variables (τ_k,κ_k). These polynomials are related to finite-dimensional irreducible representations of the algebra $gl(N|N-1)$ in the realization (A3).

IV. THE SUPERSYMMETRIC MANY-BODY SUTHERLAND MODEL

In this section we analyze the exact-solvability of the supersymmetric Sutherland model.

In order to define the supersymmetric extension of the bosonic many-body Sutherland model (2.5) we use the standard prescription of supersymmetrization already used in the previous section. Let us take the supercharges $Q, Q^\dagger$ (see (3.3)) with a superpotential

$$W(x_1, x_2, \ldots, x_N) = \nu \sum_{i<j} \log \left| \sin\left(\frac{1}{2}(x_i - x_j) \right) \right| = \nu \log \Delta^{(trig)}, \tag{4.1}$$

[cf. (3.4)] and then construct the supersymmetric Hamiltonian $\mathscr{H}_{\mathrm{sCal}} = \frac{1}{2}\{Q, Q^\dagger\}$. After carrying out the calculation the Hamiltonian of the supersymmetric many-body Sutherland model emerges:[5]

$$\mathscr{H}_{\mathrm{sSuth}} = -\frac{1}{2}\sum_{k=1}^{N} \frac{\partial^2}{\partial x_k^2} + \frac{1}{4}\sum_{k<l} \frac{\nu}{\sin^2(\frac{1}{2}(x_k - x_l))} \left[\nu - 1 + (\theta_k - \theta_l)\left(\frac{\partial}{\partial \theta_k} - \frac{\partial}{\partial \theta_l} \right) \right] + C, \tag{4.2}$$

where $C = -N(N^2-1)\nu^2/3$. The ground state wave function remains the same as in the bosonic case, $\Psi_0^{(s)} = (\Delta^{(trig)}(x))^\nu$, where $\Delta^{(trig)}(x) = \Pi_{k<l} |\sin(\frac{1}{2}(x_k - x_l))|$. Introducing the gauge-rotated Hamiltonian $h_{\mathrm{sSuth}} = -2(\Psi_0^{(s)})^{-1} \mathscr{H} \Psi_0^{(s)}$, we get

$$h_{\mathrm{sSuth}} = \sum_{k=1}^{N} \frac{\partial^2}{\partial x_k^2} + \nu \sum_{k<l} \left[\cot\left(\frac{1}{2}(x_k - x_l) \right) \left(\frac{\partial}{\partial x_k} - \frac{\partial}{\partial x_l} \right) - \frac{1}{2} \frac{(\theta_k - \theta_l)}{\sin^2(\frac{1}{2}(x_k - x_l))} \left(\frac{\partial}{\partial \theta_k} - \frac{\partial}{\partial \theta_l} \right) \right]. \tag{4.3}$$

It is worth mentioning that if the operator (4.3) is written in the coordinates e^{ix_j}, it appears in its *rational* form, which is a supersymmetric generalization of the rational form of the Sutherland Hamiltonian (see Ref. 2).

One can show that like in the bosonic case [cf. (2.8)] after separation of the center-of-mass motion the eigenfunctions of the operator (4.3) remain polynomials but now in the coordinates (e^{iy_k}, λ_k). These polynomials are symmetric under the permutation of any pair of particles $(x_i, \theta_i) \leftrightarrow (x_j, \theta_j)$ and can be considered as a supersymmetric analogue of the Jack–Sutherland polynomials.

In the superspace coordinates (3.11), (3.14) the Hamiltonian h_{sSuth} can be written

$$h_{\mathrm{sSuth}} = \int d\alpha d\bar{\alpha} \sum_{k=1}^{N} \frac{\delta}{\delta \bar{\phi}_i} \frac{\delta}{\delta \phi_i} + \nu \int d\alpha \mathscr{W} + \nu \int d\bar{\alpha} \bar{\mathscr{W}}, \tag{4.4}$$

where

$$\mathscr{W}(\phi) = \frac{1}{2}\sum_{k<l} \cot\left(\frac{1}{2}(\phi_k - \phi_l) \right) \left(\frac{\delta}{\delta \phi_k} - \frac{\delta}{\delta \phi_l} \right), \bar{\mathscr{W}} = \mathscr{W}(\bar{\phi}). \tag{4.5}$$

Next, we introduce the new variables [cf. (3.16)]

$$\eta_n + \alpha \mu_n = \sigma_n(\exp[i(y_k + \alpha \lambda_k)]), n = 1, \ldots, N-1, \tag{4.6}$$

and

$$\sigma_N + \alpha \zeta_N = \sigma_N(\exp[i(x_k + \alpha \theta_k)]), n = N, \tag{4.7}$$

where $\alpha^2 = 0$, σ_n is defined in (3.9) and y_i, λ_i are given in (2.9), (3.2), respectively. Furthermore,

$$\begin{aligned} \sum_{k=0}^{N} \eta_k t^k &= \exp\left[\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} s_n(e^{iy_k}) t^n \right], \\ \sum_{k=0}^{N} \mu_k t^k &= \left(\sum_{m=1}^{\infty} (-1)^{m+1} \rho_m(e^{iy_k}, \lambda_i e^{iy_k}) t^m \right) \exp\left[\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} s_n(e^{iy_k}) t^n \right], \end{aligned} \tag{4.8}$$

[cf. (3.10)], where we have set $\eta_N=1$ and $\mu_N=0$.

Following the same procedure as in Section III one can rewrite the Laplace operator in the new coordinates (4.6), (4.7):

$$-\sum_{i=1}^{N}\frac{\partial^2}{\partial x_i^2}=N\left(\sigma_N\frac{\partial}{\partial\sigma_N}\right)^2+\sum_{i,j=1}^{N-1}\left[A_{ij}^{\eta\eta}\frac{\partial^2}{\partial\eta_i\partial\eta_j}+A_{ij}^{\eta\mu}\frac{\partial^2}{\partial\eta_i\partial\mu_j}+A_{ij}^{\mu\eta}\frac{\partial^2}{\partial\eta_j\partial\mu_i}+A_{ij}^{\mu\mu}\frac{\partial^2}{\partial\mu_j\partial\mu_i}\right]$$
$$+\sum_{i=1}^{N-1}\left[B_i^{\eta}\frac{\partial}{\partial\eta_i}+B_i^{\mu}\frac{\partial}{\partial\mu_i}\right], \tag{4.9}$$

where

$$A_{ij}^{\eta\eta}=\frac{j(N-i)}{N}\eta_i\eta_j+\sum_{l\geqslant\max(1,j-i)}(j-i-2l)\,\eta_{i+l}\eta_{j-l},$$

$$A_{ij}^{\eta\mu}=\frac{j(N-i)}{N}\eta_i\mu_j+\sum_{l\geqslant\max(1,j-i)}(j-i-2l)\,\eta_{i+l}\mu_{j-l}-\sum_{l\geqslant1}l[\mu_{i+l-1}\eta_{j-l-1}-\eta_{i+l-1}\mu_{j-l-1}],$$

$$A_{ij}^{\mu\eta}=\frac{j(N-i)}{N}\mu_i\eta_j+\sum_{l\geqslant\max(1,j-i)}(j-i-2l)\mu_{i+l}\eta_{j-l}+\sum_{l\geqslant1}l[\mu_{i+l-1}\eta_{j-l-1}-\eta_{i+l-1}\mu_{j-l-1}], \tag{4.10}$$

$$A_{ij}^{\mu\mu}=\frac{j(N-i)}{N}\mu_i\mu_j+\sum_{l\geqslant\max(1,j-i)}(j-i-2l)\mu_{i+l}\mu_{j-l}+2\sum_{l\geqslant1}l\mu_{i+l-1}\mu_{j-l+1},$$

$$B_i^{\eta}=\frac{i(N-i)}{N}\eta_i,$$

$$B_i^{\mu}=\frac{i(N-i)}{N}\mu_i.$$

As expected, the coefficients $A_{ij}^{\eta\eta}$ and B_i^{η} coincide with the expressions found in Ref. 12 for the bosonic Sutherland model. Furthermore, the coefficient functions A_{ij} and B_i are second and first order polynomials in η_i and μ_i, respectively. Similar to what happens in the bosonic case the Laplace operator (4.9) possesses infinitely many polynomial eigenfunctions.[12] These have the form of supersymmetric analogies of the Bethe-ansatz wave functions.

After omitting the center-of-mass motion associated with σ_N and ζ_N, the final expression for the supersymmetric many-body Sutherland Hamiltonian h_{sSuth} takes the form [cf. Section III, Eq. (3.32)]

$$h_{\mathrm{sSuth}}^{(\mathrm{rel})}=\sum_{i,j=1}^{N-1}\left[A_{ij}^{\eta\eta}\frac{\partial^2}{\partial\eta_i\partial\eta_j}+A_{ij}^{\eta\mu}\frac{\partial^2}{\partial\eta_i\partial\mu_j}+A_{ij}^{\mu\eta}\frac{\partial^2}{\partial\eta_j\partial\mu_i}+A_{ij}^{\mu\mu}\frac{\partial^2}{\partial\mu_j\partial\mu_i}\right]$$
$$+\left(\frac{1}{N}+\nu\right)\sum_{i=1}^{N-1}i(N-i)\left[\eta_i\frac{\partial}{\partial\eta_i}+\mu_i\frac{\partial}{\partial\mu_i}\right], \tag{4.11}$$

where $A_{ij}^{\eta\eta},A_{ij}^{\eta\mu},A_{ij}^{\mu\eta},A_{ij}^{\mu\mu},B_i^{\eta},B_i^{\mu}$ are given in (4.10). This expression can be called the *algebraic* form of the supersymmetric many-body Sutherland Hamiltonian.

In superspace coordinates the Hamiltonian $h_{\mathrm{sSuth}}^{(\mathrm{rel})}$ describing the relative motion can be written

$$-h_{\mathrm{sSuth}}^{(\mathrm{rel})}=\int d\alpha d\bar{\alpha}\sum_{i,j=1}^{N-1}\mathscr{A}_{ij}\frac{\delta}{\delta\bar{\psi}_j}\frac{\delta}{\delta\psi_i}+\int d\alpha\mathscr{W}+\int d\bar{\alpha}\bar{\mathscr{W}}, \tag{4.12}$$

where

$$\mathscr{W}=\frac{1}{2}\left(\frac{1}{N}+\nu\right)\sum_{i=1}^{N-1} i(N-i)\psi_i\frac{\delta}{\delta\psi_i},\ \overline{\mathscr{W}}=\mathscr{W}(\overline{\psi}), \tag{4.13}$$

$$\psi_i=\eta_i+\alpha\mu_i,\ \frac{\delta}{\delta\psi_i}=\frac{\partial}{\partial\mu_i}+\alpha\frac{\partial}{\partial\eta_i}, \tag{4.14}$$

[cf. (3.25)], while

$$\mathscr{A}_{ij}=\frac{j(N-i)}{N}\psi_i\overline{\psi}_j-\sum_{l\geqslant\max(1,j-i)}(j-i-2l)\psi_{i+l}\overline{\psi}_{j-l}+\sum_{l\geqslant 1} l[\overline{\psi}_{i+l-1}\psi_{j-l+1}-\psi_{i+l-1}\overline{\psi}_{j-l+1}], \tag{4.15}$$

[cf. (3.26)]. The method of the calculation of the coefficients $\mathscr{A}_{ij}$ is similar to that presented in Appendix C.

It turns out that the Hamiltonian governing the relative motion can be rewritten in terms of the generators of a Borel subalgebra of the Lie superalgebra $gl(N|N-1)$ (see Appendix A 2) after substituting $\kappa_i\to\mu_{i-1}$ and $\tau_i\to\eta_{i-1}$. The final result is given in Appendix B, Eq. (B4). Since the expression (B4) contains no positive-root generators T_i^+, Q_γ^+, then in accordance with the general definition[11] we conclude that the supersymmetric many-body Sutherland model (4.2) is exactly solvable. The existence of the representation (B4) proves that there are infinitely many eigenfunctions of the operator (4.3) having the form of polynomials in the variables (η_k,μ_k). It also leads to the conclusion that eigenfunctions of the supersymmetric many-body Sutherland model (4.2) have a factorizable form being the product of the ground-state eigenfunction multiplied by a polynomial in the variables (η_k,μ_k). These polynomials are related to finite-dimensional irreducible representations of the algebra $gl(N|N-1)$ in the realization (A3).

To conclude, the supersymmetric many-body Sutherland models possess the algebraic form (4.11) and also the Lie-algebraic form (B4) represented by second-order polynomials in the generators of the of the algebra $gl(N|N-1)$ with certain coefficients.

V. THE BC_N, B_N, C_N AND D_N CALOGERO MODELS AND THEIR SUPERSYMMETRIC EXTENSIONS

It is well-known that there is a deep connection between the integrable Calogero–Sutherland systems and Lie algebras (see the discussion in the Introduction). This connection is explicitly realized in the Hamiltonian reduction method[6,7] (see also Refs. 8–10). In particular, the celebrated many-body Calogero and Sutherland models discussed in Section II are related to the Lie algebras A_{N-1} and are therefore known as the Calogero and Sutherland systems of A_{N-1}-type. A natural question emerges: What are the integrable systems corresponding to the other simple Lie algebras like B_N, C_N, D_N, etc., appearing in the Hamiltonian reduction method? The answer and a complete classification of these systems is given in Ref. 6 (for a review, see Refs. 8 and 9). In the present paper we focus on the quantum Calogero (rational) and Sutherland (trigonometric) systems of the BC_N, B_N, C_N and D_N types leaving for a future publication the case of the exceptional algebras.

A. The bosonic case

Unlike the A_{N-1} many-body Calogero model, the BC_N, B_N, C_N and D_N Calogero models are not translation invariant, and describe systems with boundaries. However, they are still permutation invariant with respect to the interchange of any pair of coordinates. The configuration space of these models is $\{x_i | x_i>0; j<k: x_j<x_k\}$. In this section we will show that like the A_{N-1} many-body Calogero system, all the BC_N, B_N, C_N, D_N quantum Calogero systems are not only completely integrable, but also exactly-solvable possessing a hidden algebra $gl(N+1)$.

It is well known that the Hamiltonians of the BC_N, B_N, C_N Calogero models are all given by (see Ref. 6)

$$\mathscr{H}^{(c)}_{BCD}=\frac{1}{2}\sum_{i=1}^{N}[-\partial_i^2+\omega^2 x_i^2]+g\sum_{i<j}\left[\frac{1}{(x_i-x_j)^2}+\frac{1}{(x_i+x_j)^2}\right]+\frac{g_2}{2}\sum_{i=1}^{N}\frac{1}{x_i^2}, \tag{5.1}$$

where $g=\nu(\nu-1)$ and $g_2=\nu_2(\nu_2-1)$. When the coupling constant g_2 tends to zero, the Hamiltonian $\mathscr{H}^{(c)}_{BCD}$ degenerates to the Hamiltonian of the D_N Calogero model. The ground state eigenfunction of the Hamiltonian (5.1) is given by

$$\Psi_0=\left[\prod_{i<j}|x_i-x_j|^{\nu}|x_i+x_j|^{\nu}\prod_{i=1}^{N}|x_i|^{\nu_2}\right]e^{-\omega/2\sum_{i=1}^{N}x_i^2}, \tag{5.2}$$

[cf. (2.2)].

One should stress the point (see also the discussion in Section II) that to fixed values of the coupling constants g,g_2 there corresponds two different values of the parameter $\nu(\nu_2)$: $\nu(\nu_2)=\alpha(\alpha_2)$ and $(1-\alpha(\alpha_2))$ giving rise to four families of eigenfunctions. Of course, $\alpha(\alpha_2)$ should be chosen in such a way as to minimize the eigenvalue and then (5.2) corresponds to the ground state. The ground state can be denoted as (α,α_2). The other values $\nu(\nu_2)$ inserted in (5.2) describe the ground states (if normalizable) of three *other* families: $(1-\alpha,\alpha_2),(\alpha,1-\alpha_2)$, $(1-\alpha,1-\alpha_2)$. If $g_2=0$, the sectors $(\alpha,1-\alpha_2),(1-\alpha,1-\alpha_2)$ correspond to totally antisymmetric states with respect to the reflections $x_i\leftarrow -x_i$. In what follows, for the sake of simplicity, we call (5.2) the ground state, of course keeping in mind the above discussion.

Following the same approach as in Sections II–IV, we make a gauge rotation of (5.1) with the ground-state eigenfunction as the gauge factor; $h^{(c)}_{BCD}=-2\Psi_0^{-1}\mathscr{H}\Psi_0$. A straightforward calculation gives (we omit an additive constant)

$$h^{(c)}_{BCD}=\sum_{i=1}^{N}\partial_i^2+2\nu\sum_{i<j}\left[\frac{1}{x_i-x_j}(\partial_i-\partial_j)+\frac{1}{x_i+x_j}(\partial_i+\partial_j)\right]+\nu_2\sum_{i=1}^{N}\frac{1}{x_i}\partial_i-2\omega\sum_{i=1}^{N}x_i\partial_i. \tag{5.3}$$

We call this operator the *rational* form of the BC_N,B_N,C_N and D_N Calogero systems.

The Hamiltonian (5.1) as well as the operator (5.3) is invariant under the permutation of any pair of the coordinates $x_i\leftrightarrow x_j$ and also under the action of the reflection group $\mathbf{Z}_2^{\oplus N}$: $x_i\rightarrow -x_i, i=1,2,\ldots,N$. An infinite set of eigenfunctions of (5.3) are given as polynomials in the x's and are classified by the representations of the reflection group $\mathbf{Z}_2^{\oplus N}$. For the sake of simplicity, we consider in what follows only the eigenfunctions of the Hamiltonian (5.3), which are *totally symmetric* under the reflection and permutation group actions. The *totally (anti)symmetric-(anti)symmetric* eigenfunctions under the reflection and/or permutation group actions are reproduced by a change of parameters ν,ν_2 in (5.1). This fact implies that it is sufficient to look for eigenfunctions to the operator (5.3) of the form

$$\Psi^{\nu,\nu_2}=F(x_1^2,x_2^2,\ldots,x_N^2), \tag{5.4}$$

Now let us construct variables which encode the permutation invariance of the system. Analogous to what was done for the A_{N-1} Calogero model[12] we use as new variables the elementary symmetric polynomials σ_k [see (2.12)] but with x_i^2 as arguments:

$$\sum_{k=0}^{N}\widetilde{\sigma}_k(x_i^2)t^k=\exp\left[\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n}s_{2n}(x_i)t^n\right], \tag{5.5}$$

[cf. (2.10), (3.10)]. Finally, in the new variables the Hamiltonian $h^{(c)}_{BCD}$ becomes

$$h^{(c)}_{BCD}=\sum_{i,j=1}^{N}A_{ij}\frac{\partial}{\partial\widetilde{\sigma}_i}\frac{\partial}{\partial\widetilde{\sigma}_j}+\sum_{j=1}^{N}B_j\frac{\partial}{\partial\widetilde{\sigma}_j} \tag{5.6}$$

where [cf. (3.28)]

$$\begin{aligned}A_{ij}&=4\sum_{l\geqslant 0}(2l+1+j-i)\widetilde{\sigma}_{i-l-1}\widetilde{\sigma}_{j+l},\\ B_j&=2[1+\nu_2+2\nu(N-j)](N-j+1)\widetilde{\sigma}_{j-1}-4\omega j\widetilde{\sigma}_j,\end{aligned} \tag{5.7}$$

and $\widetilde{\sigma}_k=0$, when $k>N$ or $k<0$. The method of the calculation of the coefficients A_{ij}, B_j is similar to that presented in Appendix C. This expression can be called the *algebraic* form of the BC_N, B_N, C_N and D_N Calogero Hamiltonians.

Similar to what happened in all previously discussed cases the coefficients A_{ij}, B_j are polynomials of second and first degree in $\widetilde{\sigma}_k$, respectively. Hence, there exists a Lie algebraic form of the Hamiltonian and $h^{(c)}_{BCD}$ can be written in terms of generators of a Borel subalgebra of $gl(N+1)$ (see Appendix A 1) as in Section II. The result is presented in Appendix B, Eq. (B5). Then in accordance with the general definition given in Ref. 11 we can conclude that all BC_N, B_N, C_N, D_N Calogero models (5.1) are exactly solvable. The existence of the representation (5.6) proves that there are infinitely many eigenfunctions of the operator (5.3) having the form of polynomials in the variables $\widetilde{\sigma}_k$. It also implies that totally (anti)symmetric-(anti)symmetric eigenfunctions with respect to permutations and reflections of the BC_N, B_N, C_N and D_N Calogero models (5.1) have a factorizable form being the product of the ground-state eigenfunction (5.2) multiplied by a polynomial in the variables $\widetilde{\sigma}_k$. These polynomials are related to finite-dimensional irreducible representations of the Lie algebra $gl(N+1)$ in the realization (A1) and can be called the BC_N *Calogero* polynomials.

B. The supersymmetric extensions

The BC_N, B_N, C_N and D_N Calogero models discussed above have also natural supersymmetric extensions. These can be constructed in a straightforward way. Let us consider the supercharges (3.3) with the superpotential W given by

$$W=\nu\sum_{i<j}\left(\log|x_i-x_j|+\log|x_i+x_j|\right)+\nu_2\sum_{i=1}^{N}\log|x_i|-\frac{\omega}{2}\sum_{i=1}^{N}x_i^2 \tag{5.8}$$

[cf. (3.4)]. After some calculations the supersymmetric Hamiltonian $\mathscr{H}^{(c)}_{\mathrm{sBCD}}=\frac{1}{2}\{Q,Q^\dagger\}$ of the supersymmetric BC_N, B_N, C_N, D_N Calogero models emerges:

$$\begin{aligned}\mathscr{H}^{(c)}_{\mathrm{sBCD}}=&\frac{1}{2}\sum_{i=1}^{N}\left[-\frac{\partial^2}{\partial x_i^2}+\omega^2x_i^2\right]+\frac{\nu_2}{2}\sum_{i=1}^{N}\frac{1}{x_i^2}\left[\nu_2-1+\theta_i\frac{\partial}{\partial\theta_i}\right]\\&+\omega\sum_{i=1}^{N}\theta_i\frac{\partial}{\partial\theta_i}+\nu\sum_{i<j}\frac{1}{(x_i-x_j)^2}\left[\nu-1+(\theta_i-\theta_j)\left(\frac{\partial}{\partial\theta_i}-\frac{\partial}{\partial\theta_i}\right)\right]\\&+\nu\sum_{i<j}\frac{1}{(x_i+x_j)^2}\left[(\nu-1)+(\theta_i+\theta_j)\left(\frac{\partial}{\partial\theta_i}+\frac{\partial}{\partial\theta_i}\right)\right]+C,\end{aligned} \tag{5.9}$$

where the constant $C=-2N[\nu(N-1)-\nu_2-1]$. Again, like for the other supersymmetric extensions the ground-state eigenfunction remains the same as in the bosonic case and is given by (5.4). Making the gauge rotation of the Hamiltonian (5.9):
$h^{(c)}_{sBCD}=-2\Psi_0^{-1}\mathscr{H}^{(c)}_{\mathrm{sBCD}}\Psi_0$, we get

$$\begin{aligned}h^{(c)}_{\mathrm{sBCD}}=&\sum_{i=1}^{N}\frac{\partial^2}{\partial x_i^2}+2\nu\sum_{i<j}\left[\frac{1}{x_i-x_j}\left(\frac{\partial}{\partial x_i}-\frac{\partial}{\partial x_j}\right)-\frac{(\theta_i-\theta_j)}{(x_i-x_j)^2}\left(\frac{\partial}{\partial\theta_i}-\frac{\partial}{\partial\theta_j}\right)\right]\\&+2\nu\sum_{i<j}\left[\frac{1}{x_i+x_j}\left(\frac{\partial}{\partial x_i}+\frac{\partial}{\partial x_j}\right)-\frac{(\theta_i+\theta_j)}{(x_i+x_j)^2}\left(\frac{\partial}{\partial\theta_i}+\frac{\partial}{\partial\theta_j}\right)\right]\\&-2\omega\sum_{i=1}^{N}\left[x_i\frac{\partial}{\partial x_i}+\theta_i\frac{\partial}{\partial\theta_i}\right]+\nu_2\sum_{i=1}^{N}\left[\frac{1}{x_i}\frac{\partial}{\partial x_i}-\frac{\theta_i}{x_i^2}\frac{\partial}{\partial\theta_i}\right].\end{aligned} \tag{5.10}$$

We call this operator the *rational* form of the supersymmetric BC_N, B_N, C_N Calogero systems.

The superspace coordinates χ_i which are invariant under the permutation and parity transformations are defined through the relation

$$\sum_{k=0}^{N} \chi_k(\phi_i^2)t^k = \exp\left[\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} s_{2n}(\phi_i)t^n\right], \tag{5.11}$$

[cf. (5.5) and (3.19)], where $\phi_i = x_i + \alpha\theta_i$ as in Sections III and IV, and $\chi_k(\phi_i^2) = \tilde{\sigma}_k(x_i^2) + \alpha\tilde{\zeta}_k(x_i^2, 2x_i\theta_i)$. Here $\tilde{\sigma}$ and $\tilde{\zeta}$ are the elementary symmetric polynomials defined in (3.9) but of the new arguments: $x \to x^2, \theta \to 2x\theta$. Using the same technique as in Sections III and IV, one can find the representation of the supersymmetric models directly from the analogous representation for the bosonic cases (for details see Appendix C). Finally, in the superspace coordinates (5.11) the Hamiltonian $h^{(c)}_{\mathrm{sBCD}}$ has the form

$$h^{(c)}_{\mathrm{sBCD}} = \int d\alpha d\bar{\alpha} \sum_{i,j=1}^{N} \mathscr{A}_{ij} \frac{\partial}{\partial\bar{\chi}_i} \frac{\partial}{\partial\chi_j} + \int d\alpha \sum_{j=1}^{N} \mathscr{B}_j \frac{\partial}{\partial\chi_j}, \tag{5.12}$$

where

$$\begin{aligned} \mathscr{A}_{ij} &= 2\sum_{l\geqslant 0} \{2(2l+1+j-i)\chi_{i-l-1}\bar{\chi}_{j+l} - l \\ &\quad \times [\chi_{j+l}\bar{\chi}_{i-l-1} - \bar{\chi}_{j+l}\chi_{i-l-1} + \chi_{i+l-1}\bar{\chi}_{j-l} - \bar{\chi}_{i+l-1}\chi_{j-l}]\}, \\ \mathscr{B}_j &= 2[1+\nu_2+2\nu(N-j)](N-j+1)\chi_{j-1} - 4\omega j\chi_j . \end{aligned} \tag{5.13}$$

For completeness we give the form of $h^{(c)}_{\mathrm{sBCD}}$ in components

$$\begin{aligned} h^{(c)}_{\mathrm{sBCD}} &= \sum_{i,j=1}^{N} \left[A_{ij}^{\tilde{\sigma}\tilde{\sigma}} \frac{\partial^2}{\partial\tilde{\sigma}_i\partial\tilde{\sigma}_j} + A_{ij}^{\tilde{\sigma}\tilde{\zeta}} \frac{\partial^2}{\partial\tilde{\sigma}_i\partial\tilde{\zeta}_j} + A_{ij}^{\tilde{\zeta}\tilde{\sigma}} \frac{\partial^2}{\partial\tilde{\zeta}_i\partial\tilde{\sigma}_j} + A_{ij}^{\tilde{\zeta}\tilde{\zeta}} \frac{\partial^2}{\partial\tilde{\zeta}_j\partial\tilde{\zeta}_i} \right] \\ &\quad + \sum_{j=1}^{N} \left\{ 2[1+\nu_2+2\nu(N-j)](j-N+1) \left[\tilde{\sigma}_{j-1}\frac{\partial}{\partial\tilde{\sigma}_j} + \tilde{\zeta}_{j-1}\frac{\partial}{\partial\tilde{\zeta}_j} \right] \right. \\ &\quad \left. - 4\omega j \left[\tilde{\sigma}_j\frac{\partial}{\partial\tilde{\sigma}_j} + \tilde{\zeta}_j\frac{\partial}{\partial\tilde{\zeta}_j} \right] \right\}, \end{aligned} \tag{5.14}$$

where

$$A_{ij}^{\tilde{\sigma}\tilde{\sigma}} = 4\sum_{l\geqslant 0} (2l+1+j-i)\tilde{\sigma}_{i-l-1}\tilde{\sigma}_{j+l},$$

$$\begin{aligned} A_{ij}^{\tilde{\sigma}\tilde{\zeta}} &= 2\sum_{l\geqslant 0} [2(2l+1+j-i)\tilde{\sigma}_{i-l-1}\tilde{\zeta}_{j+l} \\ &\quad - l[\tilde{\sigma}_{j-l-1}\tilde{\zeta}_{i+l} - \tilde{\sigma}_{i+l}\tilde{\zeta}_{j-l-1} + \tilde{\sigma}_{j-l}\tilde{\zeta}_{i+l-1} - \tilde{\sigma}_{i+l-1}\tilde{\zeta}_{j-l}]] \\ A_{ij}^{\tilde{\zeta}\tilde{\sigma}} &= 2\sum_{l\geqslant 0} [2(2l+1+j-i)\tilde{\zeta}_{i-l-1}\tilde{\sigma}_{j+l} \\ &\quad + l[\tilde{\sigma}_{j-l-1}\tilde{\zeta}_{i+l} - \tilde{\sigma}_{i+l}\tilde{\zeta}_{j-l-1} + \tilde{\sigma}_{j-l}\tilde{\zeta}_{i+l-1} - \tilde{\sigma}_{i+l-1}\tilde{\zeta}_{j-l}]] \\ A_{ij}^{\tilde{\zeta}\tilde{\zeta}} &= 4\sum_{l\geqslant 0} [(2l+1+j-i)\tilde{\zeta}_{i-l-1}\tilde{\zeta}_{j+l} - l\tilde{\zeta}_{i+l}\tilde{\zeta}_{j-l-1} - l\tilde{\zeta}_{i+l-1}\tilde{\zeta}_{j-l}]. \end{aligned} \tag{5.15}$$

From the expression (5.14) with the coefficients (5.15) it follows that $h^{(c)}_{sBCD}$ can be written as a quadratic polynomial in the generators of a Borel subalgebra of $gl(N+1|N)$ and, hence, the BC_N Calogero model is exactly solvable.

The existence of the representation of (5.14) in terms of the generators of a Borel subalgebra of $gl(N+1|N)$ (see (B6)), proves that the operator $h^{(c)}_{sBCD}$ has infinitely many eigenfunctions having the form of polynomials. These polynomials are related to finite-dimensional irreducible representations of the algebra $gl(N+1|N)$ in the realization (A3) and can be called the supersymmetric BC_N Calogero polynomials.

So the supersymmetric BC_N, B_N, C_N and D_N Calogero models possess the algebraic form and also the Lie-algebraic form (B6) being represented by second-order polynomials in the generators of the of the algebra $gl(N+1|N)$ with certain coefficients.

VI. THE BC_N, B_N, C_N AND D_N SUTHERLAND MODELS AND THEIR SUPERSYMMETRIC EXTENSIONS

Similar to what was done in Section V for the BC_N, B_N, C_N and D_N Calogero models the present section is devoted to a consideration of the BC_N, B_N, C_N and D_N Sutherland models.

A. The bosonic case

The Hamiltonians for BC_N, B_N, C_N, D_N Sutherland models are special cases of the general BC_N Hamiltonian[6]

$$\mathscr{H}^{(s)}_{BCD} = -\frac{1}{2}\sum_{i=1}^{N}\frac{\partial^2}{\partial x_i^2} + \frac{g}{4}\sum_{i<j}\left[\frac{1}{\sin^2(\frac{1}{2}(x_i-x_j))} + \frac{1}{\sin^2(\frac{1}{2}(x_i+x_j))}\right] + \frac{g_2}{4}\sum_{i=1}^{N}\frac{1}{\sin^2(x_i)} + \frac{g_3}{8}\sum_{i=1}^{N}\frac{1}{\sin^2\left(\frac{x_i}{2}\right)}, \tag{6.1}$$

where $g=\nu(\nu-1)$, $g_2=\nu_2(\nu_2-1)$ and $g_3=\nu_3(\nu_3+2\nu_2-1)$. From the general Hamiltonian the B_N, C_N and D_N cases are obtained as follows:

(i) B_N case: $\nu_2=0$,
(ii) C_N case: $\nu_3=0$, and
(iii) D_N case: $\nu_2=\nu_3=0$.

The ground state wave function is[9,15]

$$\Psi_0 = \left[\prod_{i<j}\left|\sin\left(\frac{1}{2}(x_i-x_j)\right)\right|^{\nu}\left|\sin\left(\frac{1}{2}(x_i+x_j)\right)\right|^{\nu}\prod_{i=1}^{N}|\sin(x_i)|^{\nu_2}\left|\sin\left(\frac{x_i}{2}\right)\right|^{\nu_3}\right]. \tag{6.2}$$

Again, one should emphasize (see also the discussion in Sections II and V A) that to a fixed value of the coupling constant $g(g_2)[g_3]$ there corresponds two different values of the parameter $\nu(\nu_2)[\nu_3]$: $\nu(\nu_2)[\nu_3]=\alpha(\alpha_2)[\alpha_3]$ and $1-\alpha(1-\alpha_2)[1-\alpha_3]$ giving rise to eight families of eigenfunctions. In order to get the ground state the parameters α,α_2,α_3 should be chosen in such a way as to minimize the eigenvalue and then (6.2) corresponds to the ground state. It can be denoted $(\alpha,\alpha_2,\alpha_3)$. The other values of ν,ν_2,ν_3, if inserted in (6.2), describe (provided that the corresponding wave functions are normalizable) the ground states of the remaining seven *other* families of eigenstates:

$$(\alpha,\alpha_2,1-\alpha_3),(\alpha,1-\alpha_2,\alpha_3),(\alpha,1-\alpha_2,1-\alpha_3),$$

$$(1-\alpha,\alpha_2,\alpha_3),(1-\alpha,1-\alpha_2,\alpha_3),(1-\alpha,\alpha_2,1-\alpha_3),$$

$$(1-\alpha,1-\alpha_2,1-\alpha_3).$$

So taking different values of ν,ν_2,ν_3 in (6.2) one can exhaust all the types of ground states corresponding to the different families mentioned above. In what follows, for the sake of simplicity, we continue to call (6.2) the ground state, of course, keeping in mind the above discussion.

Using the same approach as in Sections II–IV, we make a gauge rotation of (6.1) with the ground-state eigenfunction as gauge factor, $h^{(s)}_{BCD}=-2\Psi_0^{-1}\mathscr{H}^{(s)}_{BCD}\Psi_0$. A straightforward calculation leads to the operator (we omit an additive constant)

$$h^{(s)}_{BCD}=\sum_{i=1}^{N}\partial_i^2+\nu\sum_{i<j}\left[\cot\left(\frac{1}{2}(x_i-x_j)\right)(\partial_i-\partial_j)+\cot\left(\frac{1}{2}(x_i+x_j)\right)(\partial_i+\partial_j)\right]$$
$$+\nu_2\sum_{i=1}^{N}\cot(x_i)\partial_i+\frac{\nu_3}{2}\sum_{i=1}^{N}\cot\left(\frac{x_i}{2}\right)\partial_i. \tag{6.3}$$

It is worth mentioning that if the operator (6.3) is written in the coordinates e^{ix}, it appears in its *rational* form[15] (cf. the rational form of the A_{N-1} Sutherland Hamiltonian in Ref. 2).

According to the above discussion about eight different families of eigenfunctions, it is sufficient to study the operator (6.3) for generic ν,ν_2,ν_3 and consider only eigenfunctions which are symmetric under reflections. In particular, this implies that eigenfunctions of (6.3) have the form

$$P^{\nu,\nu_2,\nu_3}=F(\cos x_1,\cos x_2,\ldots,\cos x_N), \tag{6.4}$$

where F is permutationally symmetric.

Next we encode the symmetry properties of the problem studied by introducing the permutation and reflection-invariant periodic variables $\hat\sigma_k(\cos x)$, which satisfy

$$\sum_{k=0}^{N}\hat\sigma_k(\cos(x_i))t^k=\exp\left[\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n}s_n(\cos(x_i))t^n\right], \tag{6.5}$$

[cf. (4.8), (5.11)]. Let us emphasize that these variables (6.5) are characterized by the same period as the original Hamiltonian (6.1). In these variables the Hamiltonian $h^{(s)}_{BCD}$ becomes

$$h^{(s)}_{BCD}=\sum_{i,j=1}^{N}A_{ij}\frac{\partial}{\partial\hat\sigma_i}\frac{\partial}{\partial\hat\sigma_j}+\sum_{j=1}^{N}B_j\frac{\partial}{\partial\hat\sigma_j}, \tag{6.6}$$

where

$$A_{ij}=N\hat\sigma_{i-1}\hat\sigma_{j-1}-\sum_{l\geqslant 0}[(i-l)\hat\sigma_{i-l}\hat\sigma_{j+l}+(l+j-1)\hat\sigma_{i-l-1}\hat\sigma_{j+l-1}$$
$$-(i-2-l)\hat\sigma_{i-2-l}\hat\sigma_{j+l}-(l+j+1)\hat\sigma_{i-l-1}\hat\sigma_{j+l+1}]$$
$$B_j=\frac{\nu_3}{2}(j-N-1)\hat\sigma_{j-1}-\left[\nu_2+\frac{\nu_3}{2}+1+\nu(2N-j-1)\right]j\hat\sigma_j-\nu(N-j+1)(N-j+2)\hat\sigma_{j-2}, \tag{6.7}$$

and $\hat\sigma_k=0$, when $k<0$ or $k>N$. The method of the calculation of the coefficients A_{ij},B_j is similar to that presented in Appendix C. This expression can be called the *algebraic* form of the BC_N,B_N,C_N and D_N Sutherland Hamiltonians. Similar to what happened in all previously discussed bosonic cases the coefficients A_{ij},B_j are polynomials of second and first degree in $\hat\sigma_k$, respectively. Hence, the Hamiltonian $h^{(s)}_{BCD}$ can be written in terms of generators of the Borel subalgebra of $gl(N+1)$ realized as first order differential operators (see Appendix A1) as in Sections II and V A. The result is given in Eq. (B7) (see Appendix B).

Then in accordance with the general definition given in Ref. 11 we conclude that all BC_N,B_N,C_N,D_N Sutherland models (6.1) are exactly solvable. The existence of the representation (6.6) proves that there are infinitely many eigenfunctions of the operator (5.3) having the form of polynomials in the variables $\hat\sigma_k$. It also implies that totally (anti)symmetric-(anti)symmetric

eigenfunctions with respect to permutations and reflections of the BC_N, B_N, C_N and D_N Sutherland models (6.1) have a factorizable form being the product of the ground-state eigenfunction (6.2) multiplied by a polynomial in the variables $\hat{\sigma}_k$. These polynomials are related to finite-dimensional irreducible representations of the Lie algebra $gl(N+1)$ in the realization (A1). They can be called the BC_N Jack–Sutherland polynomials.

B. The supersymmetric extensions

The bosonic BC_N, B_N, C_N and D_N Sutherland models (6.1) have natural supersymmetric extensions. In this subsection we will construct these models and show that, as was the case for the other supersymmetric extensions discussed in Sections III, IV and V B, these models are also exactly solvable. Let us introduce the supercharges (3.3) with the superpotential W given by

$$W=\nu\sum_{i<j}\left[\log\left|\sin\left(\frac{1}{2}(x_i-x_j)\right)\right|+\log\left|\sin\left(\frac{1}{2}(x_i+x_j)\right)\right|\right]+\nu_2\sum_{i=1}^{N}\log|\sin(x_i)|+\nu_3\sum_{i=1}^{N}\log\left|\sin\left(\frac{x_i}{2}\right)\right| \tag{6.8}$$

[cf. (3.4), (5.8)]. From the general formula $\mathscr{H}^{(s)}_{sBCD}=\frac{1}{2}\{Q,Q^\dagger\}$, we derive the supersymmetric Hamiltonians of the BC_N, B_N, C_N and D_N Sutherland models:

$$\begin{aligned}\mathscr{H}^{(s)}_{sBCD}=&-\frac{1}{2}\sum_{i=1}^{N}\frac{\partial^2}{\partial x_i^2}+\frac{\nu}{4}\sum_{i<j}\left[\frac{1}{\sin^2(\frac{1}{2}(x_i-x_j))}\left[\nu-1+(\theta_k-\theta_l)\left(\frac{\partial}{\partial\theta_k}-\frac{\partial}{\partial\theta_l}\right)\right]\right.\\&\left.+\frac{1}{\sin^2(\frac{1}{2}(x_i+x_j))}\left[\nu-1+(\theta_k+\theta_l)\left(\frac{\partial}{\partial\theta_k}+\frac{\partial}{\partial\theta_l}\right)\right]\right]+\sum_{i=1}^{N}\left\{\frac{\nu_3}{8}\left[\frac{1}{\sin^2\left(\frac{x_i}{2}\right)}\right.\right.\\&\left.\left.\times\left[\nu_3-1\,\theta_i\frac{\partial}{\partial\theta_i}\right]\right]+\frac{\nu_2}{2}\left[\frac{1}{\sin^2(x_i)}\left[\nu_2+2\nu_3-1+\theta_i\frac{\partial}{\partial\theta_i}\right]\right]\right\}+C,\end{aligned} \tag{6.9}$$

where $C=-\frac{1}{2}\sum_{i=1}^{N}[\nu(N-i)+\nu_2+\nu_3/2]^2$. As should be familiar by now, the next step is to introduce the gauge-rotated Hamiltonian $h^{(s)}_{sBCD}=-2\Psi_0^{-1}\mathscr{H}^{(s)}_{sBCD}\Psi_0$. After some calculations we get

$$\begin{aligned}h^{(s)}_{BCD}=&\sum_{i=1}^{N}\partial_i^2+\nu\sum_{i<j}\left[\cot\left(\frac{1}{2}(x_i-x_j)\right)\left(\frac{\partial}{\partial x_i}-\frac{\partial}{\partial x_j}\right)-\frac{1}{2}\frac{(\theta_i-\theta_j)}{\sin^2(\frac{1}{2}(x_i-x_j))}\left(\frac{\partial}{\partial\theta_i}-\frac{\partial}{\partial\theta_j}\right)\right]\\&+\nu\sum_{i<j}\left[\cot\left(\frac{1}{2}(x_i+x_j)\right)\left(\frac{\partial}{\partial x_i}+\frac{\partial}{\partial x_j}\right)-\frac{1}{2}\frac{(\theta_i+\theta_j)}{\sin^2(\frac{1}{2}(x_i+x_j))}\left(\frac{\partial}{\partial\theta_i}+\frac{\partial}{\partial\theta_j}\right)\right]\\&+\nu_2\sum_{i=1}^{N}\left[\cot(x_i)\frac{\partial}{\partial x_i}-\frac{\theta_i}{\sin^2(x_i)}\frac{\partial}{\partial\theta_i}\right]+\frac{\nu_3}{2}\sum_{i=1}^{N}\left[\cot\left(\frac{x_i}{2}\right)\frac{\partial}{\partial x_i}-\frac{1}{2}\frac{\theta_i}{\sin^2\left(\frac{x_i}{2}\right)}\frac{\partial}{\partial\theta_i}\right].\end{aligned} \tag{6.10}$$

It is worth mentioning that if the operator (6.10) is written in the coordinates e^{ix} it appears in its *rational* form. This expression should be compared to the rational form of the supersymmetric A_N Sutherland model (4.3) and the BC_N Sutherland model (6.3).

As in Sections III, IV and V B it is convenient to use the superspace formalism and to introduce the superspace coordinates χ_i, which satisfies:

$$\sum_{k=0}^{N}\chi_k(\cos(\phi_i))t^k=\exp\left[\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n}s_n(\cos(\phi_i))t^n\right]. \tag{6.11}$$

Here $\chi_k(\cos(\phi_i))=\hat{\sigma}_k(\cos x_i)+\alpha\hat{\zeta}_k(\cos x_i,-\theta_i \sin x_i)$, where $\hat{\sigma}_k$ and $\hat{\zeta}_k$ are the elementary symmetric polynomials defined in (3.9) but of new arguments: $x\to\cos x$, $\theta\to-\theta \sin x$. In terms of these variables the Hamiltonian (6.10) becomes

$$h^{(s)}_{sBCD}=\int d\alpha d\overline{\alpha}\sum_{i,j=1}^{N}\mathscr{A}_{ij}\frac{\partial}{\partial\overline{\chi}_i}\frac{\partial}{\partial\chi_j}+\int d\alpha\sum_{j=1}^{N}\mathscr{B}_j\frac{\partial}{\partial\chi_j}, \tag{6.12}$$

where

$$\begin{aligned}\mathscr{A}_{ij}=&N\chi_{i-1}\overline{\chi}_{j-1}-\sum_{l\geqslant 0}[(i-l)\chi_{i-l}\overline{\chi}_{j+l}+(l+j-1)\chi_{i-l-1}\overline{\chi}_{j+l-1}\\&-(i-2-l)\chi_{i-2-l}\overline{\chi}_{j+l}-(l+j+1)\chi_{i-l-1}\overline{\chi}_{j+l+1}+l[\chi_{i+l-1}\overline{\chi}_{j-l-1}-\overline{\chi}_{i+l-1}\overline{\chi}_{j-l-1}\\&+\chi_{i+l+1}\chi_{j-l-3}-\chi_{i+l+1}\overline{\chi}_{j-l-3}+\chi_{i+l+1}\overline{\chi}_{j-l-1}-\overline{\chi}_{i+l+1}\chi_{j-l-1}]],\\ \mathscr{B}_j=&\frac{\nu_3}{2}(j-N-1)\chi_{j-1}-\left(\nu_2+\frac{\nu_3}{2}+1+\nu(2N-j-1)\right)j\chi_j-\nu(N-j+1)(N-j+2)\chi_{j-2}.\end{aligned} \tag{6.13}$$

The method of the calculation of the coefficients $\mathscr{A}_{ij}$, $\mathscr{B}_j$ is similar to that presented in Appendix C. In components $h^{(s)}_{sBCD}$ becomes

$$\begin{aligned}h^{(s)}_{sBCD}=&\sum_{i,j=1}^{N}\left[A^{\hat{\sigma}\hat{\sigma}}_{ij}\frac{\partial^2}{\partial\hat{\sigma}_i\partial\hat{\sigma}_j}+A^{\hat{\sigma}\hat{\zeta}}_{ij}\frac{\partial^2}{\partial\hat{\sigma}_i\partial\hat{\zeta}_j}+A^{\hat{\zeta}\hat{\sigma}}_{ij}\frac{\partial^2}{\partial\hat{\zeta}_i\partial\hat{\sigma}_j}+A^{\hat{\zeta}\hat{\zeta}}_{ij}\frac{\partial^2}{\partial\hat{\zeta}_j\partial\hat{\zeta}_i}\right]\\&+\sum_{j=1}^{N}\left\{\frac{\nu_3}{2}(j-N-1)\left[\hat{\sigma}_{j-1}\frac{\partial}{\partial\hat{\sigma}_j}+\hat{\zeta}_{j-1}\frac{\partial}{\partial\hat{\zeta}_j}\right]-\left(\nu_2+\frac{\nu_3}{2}+1+\nu(2N-j-1)\right)j\right.\\&\left.\times\left[\hat{\sigma}_j\frac{\partial}{\partial\hat{\sigma}_j}+\hat{\zeta}_j\frac{\partial}{\partial\hat{\zeta}_j}\right]-\nu(N-j+1)(N-j+2)\left[\hat{\sigma}_{j-2}\frac{\partial}{\partial\hat{\sigma}_j}+\hat{\zeta}_{j-2}\frac{\partial}{\partial\hat{\zeta}_j}\right]\right\},\end{aligned} \tag{6.14}$$

where

$$\begin{aligned}A^{\hat{\sigma}\hat{\sigma}}_{ij}=&N\hat{\sigma}_{i-1}\hat{\sigma}_{j-1}-\sum_{l\geqslant 0}[(i-l)\hat{\sigma}_{i-l}\hat{\sigma}_{j+l}+(l+j-1)\hat{\sigma}_{i-l-1}\hat{\sigma}_{j+l-1}\\&-(i-2-l)\hat{\sigma}_{i-2-l}\hat{\sigma}_{j+l}-(l+j+1)\hat{\sigma}_{i-l-1}\hat{\sigma}_{j+l+1}],\\ A^{\hat{\sigma}\hat{\zeta}}_{ij}=&N\hat{\sigma}_{i-1}\hat{\zeta}_{j-1}-\sum_{l\geqslant 0}[(i-l)\hat{\sigma}_{i-l}\hat{\zeta}_{j+l}+(l+j-1)\hat{\sigma}_{i-l-1}\hat{\zeta}_{j+l-1}\\&-(i-2-l)\hat{\sigma}_{i-2-l}\hat{\zeta}_{j+l}-(l+j+1)\hat{\sigma}_{i-l-1}\hat{\zeta}_{j+l+1}\\&-l[\hat{\sigma}_{j-l-1}(\hat{\zeta}_{i+l-1}+\hat{\zeta}_{i+l+1})+\hat{\sigma}_{i+l+1}(\hat{\zeta}_{j-l-3}-\hat{\zeta}_{j-l-1})]]\\ A^{\hat{\zeta}\hat{\sigma}}_{ij}=&N\hat{\zeta}_{i-1}\hat{\sigma}_{j-1}-\sum_{l\geqslant 0}[(i-l)\hat{\zeta}_{i-l}\hat{\sigma}_{j+l}+(l+j-1)\hat{\zeta}_{i-l-1}\hat{\sigma}_{j+l-1}\\&-(i-2-l)\hat{\zeta}_{i-2-l}\hat{\sigma}_{j+l}-(l+j+1)\hat{\zeta}_{i-l-1}\hat{\sigma}_{j+l+1}\\&+l[\hat{\sigma}_{j-l-1}(\hat{\zeta}_{i+l-1}+\hat{\zeta}_{i+l+1})+\hat{\sigma}_{i+l+1}(\hat{\zeta}_{j-l-3}-\hat{\zeta}_{j-l-1})]],\end{aligned} \tag{6.15}$$

$$A_{ij}^{\hat{\xi}\hat{\xi}}=N\hat{\xi}_{i-1}\hat{\xi}_{j-1}-\sum_{l\geqslant 0}\,[(i-l)\hat{\xi}_{i-l}\hat{\xi}_{j+l}+(l+j-1)\hat{\xi}_{i-l-1}\hat{\xi}_{j+l-1}$$

$$-(i-2-l)\hat{\xi}_{i-2-l}\hat{\xi}_{j+l}-(l+j+1)\hat{\xi}_{i-l-1}\hat{\xi}_{j+l+1}$$

$$+l[\hat{\xi}_{i+l-1}\hat{\xi}_{j-l-1}-\hat{\xi}_{i+l+1}\hat{\xi}_{j-l-3}+2\hat{\xi}_{i+l+1}\hat{\xi}_{j-l-1}]].$$

From the expression (6.14) with the coefficients (6.15) it follows, that $h^{(s)}_{sBCD}$ can be written as a quadratic polynomial in the generators of a Borel subalgebra of $gl(N+1|N)$ and, hence, the BC_N Sutherland model is exactly solvable.

The existence of the representation of (6.14) in terms of the generators of a Borel subalgebra of $gl(N+1|N)$ (see (B8)) proves that there are infinitely many eigenfunctions of (6.14) having the form of polynomials. These polynomials are related to finite−dimensional irreducible representations of the algebra $gl(N+1|N)$ in the realization (A3). These polynomials can be called the supersymmetric BC_N Sutherland polynomials.

So the supersymmetric BC_N, B_N, C_N and D_N Sutherland models possess an algebraic form and also the Lie-algebraic form (B8) being represented by second-order polynomials in the generators of the of the algebra $gl(N+1|N)$ with certain coefficients.

VII. CONCLUSION

In this paper we have described the rational, algebraic and Lie−algebraic forms of the integrable $A_N-B_N-C_N-D_N$ rational (Calogero) and trigonometric (Sutherland) Hamiltonians in addition to the superspace expressions for the supersymmetric generalizations of the these models. We have shown that

All Hamiltonians of the integrable $A_N-B_N-C_N-D_N$ rational (Calogero) and trigonometric (Sutherland) models possess the **same** *hidden algebra $gl(N+1)$ and can be represented by second-degree polynomials in the generators of a Borel subalgebra of the $gl(N+1)$−algebra. If the configuration space is parametrized by permutationally symmetric coordinates v, the Hamiltonians have a triangular form and preserve the flag of spaces of inhomogeneous polynomials*

$$\mathscr{P}_n=\ \mathrm{span}\left\{ v_1^{n_1}v_2^{n_2}v_3^{n_3}\ldots v_N^{n_N}\,\middle|\, 0\leqslant\sum\ n_i\leqslant n\right\}.$$

Consequently, each Hamiltonian possesses one or several infinite families of polynomial eigenfunctions.

All Hamiltonians of the supersymmetric generalizations of the $A_N-B_N-C_N-D_N$ rational (Calogero) and trigonometric (Sutherland) models possess the **same** *hidden algebra $gl(N+1|N)$ and can be represented by second-degree polynomials in the generators of a Borel subalgebra of the $gl(N+1|N)$-algebra. If the configuration space is parametrized by permutationally symmetric coordinates v,κ (where $\kappa^2=0$), the Hamiltonians have a triangular form and preserve the flag of spaces of inhomogeneous polynomials*

$$\mathscr{P}_n=\ \mathrm{span}\left\{ v_1^{n_1}v_2^{n_2}\ldots v_N^{n_N}\kappa_1^{m_1}\kappa_2^{m_2}\ldots\kappa_N^{m_N}\,\middle|\, 0\leqslant\sum\ n_i+\sum\ m_i\leqslant n, m_i=0,1\right\}.$$

Consequently, each Hamiltonian has one or several infinite families of polynomial eigenfunctions. The integrability of the A_N supersymmetric system was proven in Ref. 5; *as for the $B_N-C_N-D_N$ systems, it is an open question.*

As an interesting issue for future study we would like to mention the question about whether there exists a Lie algebraic description of the higher $A_N-B_N-C_N-D_N$ rational (Calogero) and trigonometric (Sutherland) Hamiltonians. It is very probable that this will be the case and, perhaps, even the Lax operator can be represented in terms of $gl(N)$-generators. There are almost no doubts that it will be possible to extend the analysis of Sections II–VI to the case of the exceptional simple Lie algebras. In particular, a special case of the one-parametric $G(2)$ rational and trigonometric Hamiltonians corresponding to three-body interactions only[22,23] possesses a hidden

$gl(3)$-algebra and, hence, is expressible in terms of the $gl(3)$ generators.[23] Recently, a Lie algebraic form for the general $G(2)$ rational and trigonometric models was found.[24]

The question about the integrability of the above supersymmetric models leads naturally to the question about the possibility to develop the Hamiltonian reduction method for the supersymmetric cases and attempt to connect these models to $2d$ supersymmetric gauge theories along the lines of Ref. 10.

An alternative description of the supersymmetric models discussed in this paper can be obtained by using the matrix representation of the θ^α's in terms of the Pauli matrices, $\sigma^{\pm,3}$:

$$\theta^1=\sigma^-\otimes 1\otimes 1\otimes\cdots,\quad \frac{\partial}{\partial\theta^1}=\sigma^+\otimes 1\otimes 1\otimes\cdots,$$

$$\theta^2=\sigma^3\otimes\sigma^-\otimes 1\otimes\cdots,\quad \frac{\partial}{\partial\theta^2}=\sigma^3\otimes\sigma^+\otimes 1\otimes\cdots \tag{7.1}$$

$$\vdots$$

In this formalism our supersymmetric models become matrix generalizations of the ''scalar'' $A_N-B_N-C_N-D_N$ Calogero and Sutherland models. For the A_N case our matrix models are particular cases of the general construction with internal degrees of freedom proposed in Ref. 25.

The existence of the Lie algebraic form for the exactly solvable $A_N-B_N-C_N-D_N$ Calogero and Sutherland models can be considered as a good starting point to investigate whether there exist other exactly solvable problems and/or quasi-exactly solvable generalizations (for definitions see, for instance, Refs. 26 and 27). The first step in applying the Lie algebraic formalism to the search for quasi-exactly-solvable problems was taken in Ref. 28.

As a final comment we would like to mention that a great challenge in the subject is the search for solutions of the N-body elliptic model (for a description see, for example, Ref. 9). For the two-body case, the rational and algebraic forms have been known since Hermite's days. Recently, it was found that the 2-body case (the Lame operator) admits a Lie algebraic form with the hidden algebra $gl(2)$ and is a *quasi-exactly-solvable* problem[29] (see also Ref. 11). It gives a hint that the three-body (and more generally the N-body) elliptic problem has to be quasi-exactly solvable if any analytic solution exists whatsoever. However, all attempts to find a rational, algebraic or Lie algebraic form even for the three-body elliptic model have failed so far.

APPENDIX A: REPRESENTATIONS OF THE LIE ALGEBRA $gl(N)$ AND THE LIE SUPERALGEBRA $gl(N|M)$

1. $gl(N)$

The generators of the Lie algebra $gl(N)$ can be realized by first order differential operators. For our purposes we need one of the simplest realizations of $gl(N)$ acting on the real (complex) space of dimension $(N-1)$. This is the space of minimal dimension where this algebra can act. The generators can be represented in the following form:

$$
\begin{aligned}
E_{0i} &= J_i^- = \frac{\partial}{\partial \tau_i}, i = 2,3,\ldots,N, \\
E_{ij} &= J_{i,j}^0 = \tau_i J_j^- = \tau_i \frac{\partial}{\partial \tau_j}, i,j = 2,3,\ldots,N, \\
E_{00} &= J^0 = n - \sum_{k=2}^{N} \tau_k \frac{\partial}{\partial \tau_k}, \\
E_{i0} &= J_i^+ = \tau_i J^0, i = 2,3,\ldots,N,
\end{aligned}
\tag{A1}
$$

where the parameter $n \in \mathbf{R}$ ($\mathbf{C}$). One of the generators, namely $J^0 + \Sigma_{p=2}^{N} J_{p,p}^0$, is proportional to a constant and, if it is removed, we end up with the algebra $sl(N)$. The generators $J_{i,j}^0$ form the algebra of the vector fields of $sl(N-1)$, which is a subalgebra of $gl(N)$. If n is a non-negative integer, the representation (A1) becomes the finite-dimensional representation acting on the space of polynomials in $(N-1)$ variables of the following type:

$$
V_n(t) = \text{span}\left\{ \tau_2^{n_2} \tau_3^{n_3} \tau_4^{n_4} \ldots \tau_N^{n_N} \middle| 0 \leqslant \sum n_i \leqslant n \right\}. \tag{A2}
$$

This representation corresponds to a Young tableau with one row and n blocks and is irreducible. The positive-root generators J_i^+ define the highest-weight vector. If the J_i^+'s are removed, the remaining generators form a Borel subalgebra.

2. $gl(N|M)$

Similar to what was done for the algebra $gl(N)$ one can construct a representation of the Lie superalgebra $gl(N|M)$ in terms of first order differential operators over the direct sum of a even space and an odd space. Again the simplest realization of $gl(N|M)$ act on the space $C^{(N-1|M)}$ spanned by the even variables $(\tau^i | i = 1,2,\ldots,N-1))$ and the odd variables $(\kappa^\gamma | \gamma = 1,2,\ldots,M)$ and is given by

$$
\begin{aligned}
E_{ij} &= J_{ij}^0 = \tau^i \frac{\partial}{\partial \tau^j}, \quad E_{00} = J^0 = -n + \sum_i \tau^j \frac{\partial}{\partial \tau^j} + \sum_\gamma \kappa^\gamma \frac{\partial}{\partial \kappa^\gamma}, \\
E_{i0} &= J_i^+ = \tau^i J^0, \quad E_{0i} = J_i^- = \frac{\partial}{\partial \tau^i}, \\
E_{\gamma i} &= Q_{\gamma i} = \kappa^\gamma \frac{\partial}{\partial \tau^i}, \quad E_{i\gamma} = \overline{Q}_{i\gamma} = \tau^i \frac{\partial}{\partial \kappa^\gamma}, \\
E_{0\gamma} &= Q_\gamma^- = \frac{\partial}{\partial \kappa^\gamma}, \quad E_{\gamma 0} = Q_\gamma^+ = \kappa^\gamma T^0, \\
E_{\gamma\beta} &= T_{\gamma\beta}^0 = \kappa^\gamma \frac{\partial}{\partial \kappa^\beta},
\end{aligned}
\tag{A3}
$$

where the parameter $n \in \mathbf{R}$ ($\mathbf{C}$). Here the indices run over the following values, $i = 1 \ldots N-1$ and $\gamma = 1 \ldots M$. The subset $\{E_{ij}, E_{\gamma i}, E_{i\gamma}, E_{\gamma\beta}\}$ form the ''vector field'' representation of $gl(N-1|M)$. The algebra has a $\mathbf{Z}_2$ gradation and it is clear that the elements with an odd number of Greek indices are odd and the elements with an even number are even. Using the composite index notation $I = (0,i,\gamma)$, the commutation relations of the superalgebra can be written [cf. the commutation relations in the defining $(N+M)\times(N+M)$ supermatrix representation, with $(E_{IJ})_{MN} = \delta_{IN}\delta_{JM}$]

$$[E_{IJ},E_{KL}]=\delta_{JK}E_{IL}-\delta_{IL}E_{KJ} \quad \text{(both even)},$$

$$[E_{IJ},E_{KL}]=\delta_{JK}E_{IL}-\delta_{IL}E_{KJ} \quad (E_{IJ}\text{even},E_{KL}\text{odd}),$$

$$\{E_{IJ},E_{KL}\}=\delta_{JK}E_{IL}+\delta_{IL}E_{KJ} \quad \text{(both odd)}. \tag{A4}$$

The Lie superalgebra $gl(N|M)$ is not simple. There are two different cases: (i) $N\neq M$ and (ii) $N=M$. Let us consider the first case, when $N\neq M$. Removing the unit element $\Sigma_{I=0}^{N+M}E_{II}$ we are left with the superalgebra $sl(N|M)$, which is simple. The ''diagonal'' generators for this case are given by

$$H_{II}=\begin{cases} E_{00}-E_{11}, & I=0 \\ E_{II}-E_{I+1,I+1}, & 1\leqslant I\leqslant N-1 \\ E_{II}+E_{I+1,I+1}, & I=N \\ E_{II}-E_{I+1,I+1}, & N+1\leqslant I\leqslant N+M-1. \end{cases} \tag{A5}$$

When $N=M$ the situation is slightly more complicated. There are two one-dimensional Abelian ideals, which must be removed in order to make the algebra simple.

The generators of $gl(N|M)$ defined in (A3) act in the space spanned by the monomials $\{\tau_1^{i_1}\cdots\tau_{N-1}^{i_{N-1}}\kappa_1^{\delta_1}\cdots\kappa_M^{\delta_M}\}$. Here δ_k equals either 0 or 1. When n (in the expression for T^0 above) is an integer we have finite-dimensional highest weight representations whose highest weight vectors satisfy $\Sigma_{k=1}^{N-1}i_k+\Sigma_{k=1}^{M}\delta_k=n$. These representations form a flag of spaces.

APPENDIX B: THE LIE ALGEBRAIC FORMS OF THE A_{N-1}, BC_N, B_N, C_N AND D_N HAMILTONIANS

In this Appendix we collect all Lie algebraic forms of the Hamiltonians for the (supersymmetric) A_{N-1}, BC_N, B_N, C_N and D_N Calogero and Sutherland models found in Ref. 12 and in the present paper.

(i) A_{N-1} *Calogero model*

The Lie algebraic form of the many-body Calogero model is the following:[12]

$$\begin{aligned} h_{\text{Cal}}=&\sum_{j=2}^{N}\left\{\frac{(N-j+1)(j-1)}{N}(J_{j-1,j})^2-2\sum_{\ell=1}^{j-1}\ell J_{j+\ell-1,j}J_{j-\ell-1,j}\right\} \\ &+2\sum_{2\leqslant k<j\leqslant N}\left\{\frac{(N-j+1)(k-1)}{N}J_{j-1,j}J_{k-1,k}-\sum_{\ell=1}^{k-1}(j-k+2\ell)J_{j+\ell-1,j}J_{k-\ell-1,k}\right\} \\ &-2\omega\sum_{k=2}^{N}kJ_{k,k}-\left(\frac{1}{N}+\nu\right)\sum_{k=2}^{N}(N-k+2)(N-k+1)J_{k-2,k}, \end{aligned} \tag{B1}$$

where the following notations are introduced for the $gl(N)$ generators (A1): $J_{ij}\equiv J_{ij}^0$, $J_{0,k}^0\equiv J_k^-$, $J_{1,k}^0\equiv 0$.

The supersymmetric Calogero model has the Lie algebraic form:

$$h^{(\mathrm{rel})}_{\mathrm{sCal}}=\sum_{i,j=2}^{N}\left\{\frac{(N-i+1)(j-1)}{N}[J_{i-1,j}J_{j-1,i}+J_{i-1,i}T_{j-1,j}+J_{j-1,j}T_{i-1,i}-T_{i-1,j}T_{j-1,i}]\right.$$
$$+\sum_{l>\max(1,j-i)}(j-i-2l)[J_{i+l-1,j}J_{j-l-1,i}+J_{i+l-1,i}T_{j-l-1,j}+J_{j-l-1,j}T_{i+l-1,i}$$
$$\left.-T_{i+l-1,j}T_{j-l-1,i}]\right\}+\sum_{l\geqslant 1}l[T_{j-2-l,j}J_{i+l,i}-T_{i+l,j}J_{j-2-l,i}+T_{i+l,i}J_{j-2-l,j}-T_{j-2-l,i}J_{i+l,j}$$
$$-2T_{i+l,j}T_{j-2-l,i}]-2\omega\sum_{j=2}^{N}j[J_{jj}+T_{jj}]-\left(\frac{1}{N}+\nu\right)\sum_{j=2}^{N}(N-j+2)(N-j+1)$$
$$\times[J_{j-2,j}+T_{j-2,j}], \tag{B2}$$

where the following conventions are used for the $gl(N|N-1)$ generators (A3): $J_{ij}\equiv J^0_{ij}=0$ and $T_{ij}\equiv T^0_{ij}0$, if i and/or j is less than 2 or greater than N.

(ii) A_{N-1} *Sutherland model*

The Lie algebraic form of the many-body Sutherland model in terms of the $gl(N)$ generators is the following:[12]

$$-h_{\mathrm{Suth}}=\sum_{j=1}^{N-1}\left\{\frac{j(N-j)}{N}(J_{j,j})^2-2\sum_{l=1}^{j}lJ_{j+l,j}J_{j-l,j}\right\}+\nu\sum_{l=1}^{N-1}l(N-l)J_{l,l}$$
$$+2\sum_{1\leqslant k<j\leqslant N-1}\left\{\frac{k(N-j)}{N}J_{j,j}J_{k,k}-\sum_{l=1}^{k}(j-k+2l)J_{j+l,j}J_{k-l,k}\right\}. \tag{B3}$$

Here we have used the identifications $J_{ij}\equiv J^0_{ij}$, $J_{0,i}\equiv J^-_i\equiv J_{N,i}$, $J_{1,i}=0$. The supersymmetric many-body Sutherland model written in terms of the $gl(N|N-1)$ generators has the form

$$-h^{(\mathrm{rel})}_{\mathrm{sSuth}}=\sum_{i,j=1}^{N-1}\left\{\frac{j(N-i)}{N}[J_{i,j}J_{j,i}+J_{i,i}T_{j,j}+J_{j,j}T_{i,i}-T_{i,j}T_{j,i}]\right.$$
$$\left.+\sum_{l>\max(1,j-i)}(j-i-2l)[J_{i+l,j}J_{j-l,i}+J_{i+l,i}T_{j-l,j}+J_{j-l,j}T_{i+l,i}-T_{i+l,j}T_{j-l,i}]\right\}$$
$$+\sum_{l\geqslant 1}l[T_{j-l-1,j}J_{i+l-1,i}-T_{i+l-1,j}J_{j-l-1,i}+T_{i+l-1,i}J_{j-l-1,j}-T_{j-l-1,i}J_{i+l-1,j}$$
$$-2T_{i+l-1,j}T_{j-l+1,i}]+\sum_{i=1}^{N-1}i(N-i)\left[\nu J_{i,i}+\left(\frac{2}{N}+\nu\right)T_{i,i}\right]. \tag{B4}$$

In (B4) $J_{ij}\equiv j^0_{ij}=0$ and $T_{i,j}\equiv T^0_{ij}=0$ are by definition zero when i and/or j is greater than $N-1$ or less than 1.

(iii) BC_N, B_N, C_N *and* D_N *Calogero models*

The bosonic BC_N, B_N, C_N and D_N Calogero models have the following Lie algebraic form in terms of the $gl(N+1)$ generators:

$$h^{(c)}_{BCD}=4\sum_{i,j=1}^{N}\sum_{l\geqslant 0}(2l+1+j-i)J_{i-l-1,j}J_{j+l,i}-4\omega\sum_{i=1}^{N}iJ_{i,i}$$
$$+2\sum_{i=1}^{N}\left\{[1+\nu_2+2\nu(N-j)](N-j+1)-\frac{N}{2}(N+3-2i)\right\}J_{i-1,i}, \tag{B5}$$

and the supersymmetric extensions have the form

$$h^{(c)}_{sBCD}=2\sum_{i,j=1}^{N}\sum_{l\geqslant 0}[2(2l+1+j-i)[J_{i-l-1,j}J_{j+l,i}+J_{i-l-1,j}T_{j+l,i}+T_{i-l-1,j}J_{j+l,i}$$
$$-T_{i-l-1,j}T_{j+l,i}]+l[T_{j-l-1,j}J_{i+l,i}-T_{i+l,j}J_{j-l-1,i}-T_{i+l-1,j}J_{j-l,i}+T_{j-l,j}J_{i+l-1,i}$$
$$-T_{j-l-1,i}J_{i+l,j}+T_{i+l,i}J_{j-l-1,j}+T_{i+l-1,i}J_{j-l,j}-T_{j-l,i}J_{i+l-1,j}+T_{i+l,j}T_{j-l-1,i}$$
$$+T_{i+l-1,j}T_{j-l,i}]]+\sum_{i=1}^{N}2[1+\nu_2+2\nu(N-j)](N-j+1)\cdot\left\{\frac{N}{2}(N+3-2i)T_{i-1,i}\right.$$
$$\left.-\frac{N}{2}(N+3-2i)J_{i-1,i}\right\}-4\omega\sum_{i=1}^{N}i[J_{i,i}+T_{i,i}] \tag{B6}$$

in terms of the $gl(N+1|N)$ generators. In the above two formulas, as well as in the two formulas below, we have used that $J_{ij}\equiv J^0_{ij}=0$ and $T_{ij}\equiv T^0_{ij}=0$ when i and/or j is greater than N or less than 1.

(iv) *BC_N, B_N, C_N and D_N Sutherland models*

Finally, the Lie algebraic form of the bosonic BC_N, B_N, C_N and D_N Sutherland models is

$$h^{(s)}_{BCD}=\sum_{i,j=1}^{N}\left[NJ_{i-1,j}J_{j-1,i}-\sum_{l\geqslant 0}[(i-l)J_{i-l,j}J_{j+l,i}+(l+j-1)J_{i-l-1,j}J_{j+l-1,i}-(i-2-l)\right.$$
$$\times J_{i-2-l,j}J_{j+l,i}-(l+j+1)J_{i-l-1,j}J_{j+l+1,i}]$$
$$+\sum_{j=1}^{N}\left[\frac{\nu_3}{2}(j-N-1)J_{j-1,j}-\left(\nu_2+\frac{\nu_3}{2}+1+N+\nu(2N-j-1)\right)jJ_{j,j}\right.$$
$$\left.\left.-[\nu(N-j+1)(N-j+2)+2N]J_{j-2,j}\right]\right] \tag{B7}$$

in terms of the $gl(N+1)$ generators, and the Lie algebraic form of their supersymmetric extensions is

$$h^{(s)}_{sBCD}=\sum_{i,j=1}^{N}\left\{N(J_{i-1,j}J_{j-1,i}-T_{i-1,j}T_{j-1,i})-\sum_{l\geqslant 0}[(i-l)[J_{i-l,j}J_{j+l,i}+T_{i-l,j}J_{j+l,i}+J_{i-l,j}T_{j+l,i}\right.$$
$$-T_{i-l,j}T_{j+l,i}]+(l+j-1)[J_{i-l-1,j}J_{j+l-1,i}+J_{i-l-1,j}T_{j+l-1,i}+T_{i-l-1,j}J_{j+l-1,i}$$
$$-T_{i-l-1,j}T_{j+l-1,i}]-(i-2-l)[J_{i-2-l,j}J_{j+l,i}+T_{i-2-l,j}J_{j+l,i}+J_{i-2-l,j}T_{j+l,i}$$
$$-T_{i-2-l,j}T_{j+l,i}]-(l+j+1)[J_{i-l-1,j}J_{j+l+1,i}+T_{i-l-1,j}J_{j+l+1,i}+J_{i-l-1,j}T_{j+l+1,i}$$
$$-T_{i-l-1,j}T_{j+l+1,i}]+l[J_{j-l-1,j}(T_{i+l-1,i}+T_{i+l+1,i})+J_{i+l+1,j}(T_{j-l-3,i}-T_{j-l-1,i})$$
$$-J_{j-l-1,i}(T_{i+l-1,j}+T_{i+l+1,j})-J_{i+l+1,i}(T_{j-l-3,j}-T_{j-l-1,j})-T_{I+l+1,j}(T_{j-l-1,i}$$
$$\left.-T_{j-l-3,i})-(T_{i+l-1,j}+T_{i+l-1,j})T_{j-l-1,i}]]\right\}+\sum_{j=1}^{N}\left[\frac{\nu_3}{2}(j-N-1)[J_{j-1,j}+T_{j-1,j}]\right.$$
$$-\left(\nu_2+\frac{\nu_3}{2}+1+\nu(2N-j-1)\right)j[J_{j,j}+T_{j,j}]-Nj[J_{j,j}-T_{j,j}]$$
$$\left.-[\nu(N-j+1)(N-j+2)](J_{j-2,j}+T_{j-2,j})-2N(J_{j-2,j}-T_{j-2,j})\right] \tag{B8}$$

in terms of the $gl(N+1|N)$ generators.

In conclusion, let us emphasize the fact that all Lie algebraic forms of the supersymmetric models (B2), (B4), (B6), (B8) contain no fermionic (odd) generators.

APPENDIX C: DERIVING THE LIE ALGEBRAIC FORMS: TECHNICAL DETAILS

In this Appendix we will give some details of the derivation of the Lie algebraic forms of the Hamiltonians discussed in this paper. We will exemplify the method for the BC_N Calogero models. The other cases are tackled in a similar way.

1. Bosonic BC_N Calogero model

Our final goal is to derive (5.6)–(5.7). Let us recall that the gauge-rotated BC_N Hamiltonian is given by

$$h^{(c)}_{BCD}=\sum_{i=1}^{N}\partial_i^2+2\nu\sum_{i<j}\left[\frac{1}{x_i-x_j}(\partial_i-\partial_j)+\frac{1}{x_i+x_j}(\partial_i+\partial_j)\right]+\nu_2\sum_{i=1}^{N}\frac{1}{x_i}\partial_i-2\omega\sum_{i=1}^{N}x_i\partial_i. \quad \text{(C1)}$$

After the change of variables $x_i\to\widetilde{\sigma}_i$ the Hamiltonian becomes

$$h^{(c)}_{BCD}=\sum_{\ell,k=1}^{N}\sum_{i=1}^{N}\frac{\partial\widetilde{\sigma}_\ell}{\partial x_i}\frac{\partial\widetilde{\sigma}_k}{\partial x_i}\frac{\partial}{\partial\widetilde{\sigma}_k}\frac{\partial}{\partial\widetilde{\sigma}_l}+\sum_{k=1}^{N}\sum_{i=1}^{N}\frac{\partial^2\widetilde{\sigma}_k}{\partial x_i^2}\frac{\partial}{\partial\widetilde{\sigma}_k}-2\omega\sum_{k=1}^{N}\sum_{i=1}^{N}x_i\frac{\partial\widetilde{\sigma}_k}{\partial x_i}\frac{\partial}{\partial\widetilde{\sigma}_k}$$
$$+\nu\sum_{k=1}^{N}\sum_{i\neq j}\left[\frac{1}{x_i+x_j}\left(\frac{\partial\widetilde{\sigma}_k}{\partial x_i}+\frac{\partial\widetilde{\sigma}_k}{\partial x_j}\right)+\frac{1}{x_i-x_j}\left(\frac{\partial\widetilde{\sigma}_k}{\partial x_i}-\frac{\partial\widetilde{\sigma}_k}{\partial x_j}\right)\right]\frac{\partial}{\partial\widetilde{\sigma}_k}+\nu_2\sum_{k=1}^{N}\sum_{i=1}^{N}\frac{1}{x_i}\frac{\partial\widetilde{\sigma}_k}{\partial x_i}\frac{\partial}{\partial\widetilde{\sigma}_k}. \quad \text{(C2)}$$

As an example, let us express

$$\widetilde{B}_k=\sum_{i\neq j}^{N}\left[\frac{1}{x_i+x_j}\left(\frac{\partial\widetilde{\sigma}_k}{\partial x_i}+\frac{\partial\widetilde{\sigma}_k}{\partial x_j}\right)+\frac{1}{x_i-x_j}\left(\frac{\partial\widetilde{\sigma}_k}{\partial x_i}-\frac{\partial\widetilde{\sigma}_k}{\partial x_j}\right)\right] \quad \text{(C3)}$$

and

$$\widetilde{A}_{\ell,k}=\sum_{i=1}^{N}\frac{\partial\widetilde{\sigma}_\ell}{\partial x_i}\frac{\partial\widetilde{\sigma}_k}{\partial x_i} \quad \text{(C4)}$$

in terms of the $\widetilde{\sigma}$ variables. The approach we will follow is to represent the generating functions of (C3) and (C4)

$$\widetilde{A}(t,p)=\sum_{k=0}^{N}\widetilde{A}_{\ell,k}t^\ell p^k,\quad \widetilde{B}(t)=\sum_{k=0}^{N}\widetilde{B}_k t^k,$$

in terms of the generating function of the $\widetilde{\sigma}$ variables

$$G(t)=\sum_{k=0}^{N}\widetilde{\sigma}_k(x)t^k=\exp\left[\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n}s_{2n}(x)t^n\right]. \quad \text{(C5)}$$

Let us begin by calculating the generating function $\widetilde{B}(t)$ for (C3)

$$\widetilde{B}(t)=\sum_{i\neq j}\left[\frac{1}{x_i-x_j}\left(\frac{\partial}{\partial x_i}-\frac{\partial}{\partial x_j}\right)+\frac{1}{x_i+x_j}\left(\frac{\partial}{\partial x_i}+\frac{\partial}{\partial x_j}\right)\right]G(t)$$
$$=2\sum_{i\neq j}\left\{\sum_{m=1}^{\infty}(-1)^{m+1}\left[\frac{x_i^{2m-1}+x_j^{2m-1}}{x_i+x_j}+\frac{x_i^{2m-1}-x_j^{2m-1}}{x_i-x_j}\right]t^m\right\}G(t). \quad \text{(C6)}$$

Using the relation

$$\frac{x_i^{2n-1}+x_j^{2n-1}}{x_i+x_j}+\frac{x_i^{2n-1}-x_j^{2n-1}}{x_i-x_j}=2\sum_{l=0}^{n-1}x_i^{2l}x_j^{2(n-1)-2l}, \quad \text{(C7)}$$

and making rather obvious mathematical transformations, one can show that

$$\widetilde{B}(t)=\left[4t^3\frac{\partial^2}{\partial t^2}-4(2N-2)t^2\frac{\partial}{\partial t}+4tN(N-1)\right]G(t). \tag{C8}$$

Substituting (C5) in (C8) we find that $\widetilde{B}_k$ in (C3) is

$$\widetilde{B}_k=4(N-k+1)(N-k)\widetilde{\sigma}_{k-1}. \tag{C9}$$

Next we proceed to the calculation of (C4). The corresponding generating function can be written as

$$\widetilde{A}(t,p)=\sum_{i=1}^{N}\frac{\partial G(p)}{\partial x_i}\frac{\partial G(t)}{\partial x_i}=4\sum_{i=1}^{N}\sum_{k,\ell=1}^{\infty}(-1)^{k+\ell}x_i^{2(k+\ell)-2}t^k p^\ell G(t)G(p). \tag{C10}$$

Changing the summation variables to $r=k+\ell$ and $u=k-\ell$ one obtains that

$$\widetilde{A}(t,p)=4\sum_{i=1}^{N}\sum_{r=2}^{\infty}(-1)^r s_{2(r-1)}(tp)^{\frac{r}{2}}\sum_{u}\left(\frac{t}{p}\right)^{u/2}G(t)G(p). \tag{C11}$$

The sum over u is easily determined

$$\sum_{u}\left(\frac{t}{p}\right)^{u/2}=\left(\frac{t}{p}\right)^{-r-2/2}\left(\frac{1-\left(\frac{t}{p}\right)^{r-1}}{1-\frac{t}{p}}\right). \tag{C12}$$

Using this formula it is easy to transform (C11) to the following expression for the generating function:

$$\widetilde{A}(t,p)=\frac{4t}{1-\frac{t}{p}}\left[t\frac{\partial}{\partial t}-p\frac{\partial}{\partial p}\right]G(t)G(p). \tag{C13}$$

Expanding the rhs of (C13) we arrive at the final expression for (C4),

$$\widetilde{A}_{\ell,k}=4\sum_{q\geqslant 0}(2q+1+l-k)\widetilde{\sigma}_{k-q-1}\widetilde{\sigma}_{\ell+q}. \tag{C14}$$

The other terms in (C2) can be calculated using the same method which finally leads to the results presented in (5.6) and (5.7).

2. Supersymmetric BC_N Calogero model

For the supersymmetric models the calculations are similar to those carried out for the bosonic models. In terms of the superspace ϕ-coordinates (3.11) the gauge rotated Hamiltonian (5.10) is written as

$$\begin{aligned}h^{(c)}_{sBCD}=&\int d\alpha d\bar{\alpha}\sum_{i=1}^{N}\frac{\delta}{\delta\phi_i(\bar{\alpha})}\frac{\delta}{\delta\phi_i(\alpha)}+2\nu\int d\alpha\sum_{i<j}\left[\frac{1}{\phi_i(\alpha)-\phi_j(\alpha)}\left(\frac{\delta}{\delta\phi_i(\alpha)}-\frac{\delta}{\delta\phi_j(\alpha)}\right)\right.\\&\left.+\frac{1}{\phi_i(\alpha)+\phi_j(\alpha)}\left(\frac{\delta}{\delta\phi_i(\alpha)}+\frac{\delta}{\delta\phi_j(\alpha)}\right)\right]+\nu_2\int d\alpha\sum_{i=1}^{N}\frac{1}{\phi_i(\alpha)}\frac{\delta}{\delta\phi_i(\alpha)}\\&-2\omega\int d\alpha\sum_{i=1}^{N}\phi_i(\alpha)\frac{\delta}{\delta\phi_i(\alpha)}.\end{aligned} \tag{C15}$$

Now we make the change of variables $\phi_i \to \chi_i$ (see (5.11)) using the relation (3.21). Finally, an expression similar to (C2) emerges except for the fact that the bosonic coordinates are replaced by supercoordinates with integration over the Grassmann variables:

$$h^{(c)}_{sBCD} = \sum_{i=1}^{N} \int d\alpha d\overline{\alpha} d\beta d\overline{\beta} \frac{\delta\chi_k(\overline{\beta})}{\delta\phi_i(\overline{\alpha})} \frac{\delta\chi_l(\beta)}{\delta\phi_i(\alpha)} \frac{\delta}{\delta\chi_l(\overline{\beta})} \frac{\delta}{\delta\chi_l(\beta)}$$
$$- 2\nu \int d\alpha d\beta \sum_{i<j} \sum_{k=1}^{N} \left[\frac{1}{\phi_i(\alpha) - \phi_j(\alpha)} \left(\frac{\delta\chi_k(\beta)}{\delta\phi_i(\alpha)} + \frac{\delta\chi_k(\beta)}{\delta\phi_j(\alpha)} \right) + \frac{1}{\phi_i(\alpha) + \phi_j(\alpha)} \right.$$
$$\left. \times \left(\frac{\delta\chi_k(\beta)}{\delta\phi_i(\alpha)} + \frac{\delta\chi_k(\beta)}{\delta\phi_j(\alpha)} \right) \right] \frac{\delta}{\delta\chi_k(\beta)} - \nu_2 \int d\alpha d\beta \sum_{i=1}^{N} \sum_{k=1}^{N} \frac{1}{\phi_i(\alpha)} \frac{\delta\chi_k(\beta)}{\delta\phi_i(\alpha)} \frac{\delta}{\delta\chi_k(\beta)}$$
$$+ 2\omega \int d\alpha \sum_{i=1}^{N} \sum_{k=1}^{N} \phi_i(\alpha) \frac{\delta\chi_k(\beta)}{\delta\phi_i(\alpha)} \frac{\delta}{\delta\chi_k(\beta)}. \tag{C16}$$

For terms linear in derivatives the process of calculation is exactly the same as for the bosonic case. The final result can be obtained from the bosonic calculation simply by replacing the σ-coordinates by χ-supercoordinates. However, for the term quadratic in derivatives:

$$\sum_{i=1}^{N} \int d\alpha d\overline{\alpha} d\beta d\overline{\beta} \frac{\delta\chi_k(\overline{\beta})}{\delta\phi_i(\overline{\alpha})} \frac{\delta\chi_l(\beta)}{\delta\phi_i(\alpha)} \frac{\delta}{\delta\chi_l(\overline{\beta})} \frac{\delta}{\delta\chi_l(\beta)} \equiv \int d\beta d\overline{\beta} \widetilde{\mathscr{H}}^{(s)}_{k,\ell} \frac{\delta}{\delta\chi_l(\overline{\beta})} \frac{\delta}{\delta\chi_l(\beta)}, \tag{C17}$$

a slight complication arises. Again our strategy is to make use of a generating function of the χ coordinates

$$\mathscr{G}(\beta,p) = \sum_{k=0}^{N} \chi_k(\phi_i(\beta)) p^k = \exp\left[\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} s_{2n}(\phi_i(\beta)) p^n \right] \tag{C18}$$

and try to represent the generating function for

$$\widetilde{\mathscr{H}}^{(s)}_{k,\ell} = \sum_{i=1}^{N} \int d\alpha d\overline{\alpha} \frac{\delta\chi_k(\overline{\beta})}{\delta\phi_i(\overline{\alpha})} \frac{\delta\chi_\ell(\beta)}{\delta\phi_i(\alpha)},$$

i.e.,

$$\widetilde{\mathscr{H}}^{(s)}(t,p) = \sum_{k,\ell=1}^{N} \widetilde{\mathscr{H}}^{(s)}_{k,\ell} t^k p^\ell, \tag{C19}$$

in terms of $\mathscr{G}(\beta,p)$. In what follows we use the notation $\phi_i := \phi_i(\beta)$ and $\overline{\phi_i} := \phi_i(\overline{\beta})$.

Let us first note that

$$\widetilde{\mathscr{H}}^{(s)}(t,p) = 4 \sum_{i=1}^{N} \sum_{m,n=1}^{\infty} (-1)^{n+m} \overline{\phi}_i^{2n-1} \phi_i^{2m-1} t^n p^m \mathscr{G}(\beta,p) \mathscr{G}(\overline{\beta},t), \tag{C20}$$

[cf. (C10)]. After some simple mathematical transformations similar to those leading to (C11) $\widetilde{\mathscr{H}}^{(s)}(t,p)$ can be rewritten as

$$2 \sum_{r=2}^{\infty} (-1)^r (tp)^{r/2} \sum_{u} [s_{2r-2}(\overline{\phi}) + s_{2r-2}(\phi)] \left(\frac{t}{p} \right)^{u/2} \mathscr{G}(\beta,p) \mathscr{G}(\overline{\beta},t)$$
$$+ 4 \sum_{r=2}^{\infty} (-1)^r (tp)^{r/2} \sum_{u} u \left[\frac{s_{2r-2}(\overline{\phi}) - s_{2r-2}(\phi)}{2(r-1)} \right] \left(\frac{t}{p} \right)^{u/2} \mathscr{G}(\beta,p) \mathscr{G}(\overline{\beta},t). \tag{C21}$$

Using (C12) together with the relation

$$\sum_u u\left(\frac{t}{p}\right)^{u/2}=\left(\frac{t}{p}\right)^{-(r-2/2)}\frac{1}{\left(1-\frac{t}{p}\right)^2}\left[-(r-2)+r\frac{t}{p}-r\left(\frac{t}{p}\right)^{r-1}+(r-2)\left(\frac{t}{p}\right)^r\right], \tag{C22}$$

(C21) takes the form

$$4\frac{t}{1-\frac{t}{p}}\sum_{r=1}^{\infty}(-1)^{r+1}[s_{2r}(\phi)p^r-s_{2r}(\bar{\phi})t^r]\mathcal{G}(\beta,p)\mathcal{G}(\bar{\beta},t)$$

$$-2\frac{t}{p}\frac{t+p}{\left(1-\frac{t}{p}\right)^2}\sum_{r=1}^{\infty}\frac{(-1)^{r+1}}{r}[s_{2r}(\bar{\phi})-s_{2r}(\phi)](t^r-p^r)\mathcal{G}(\beta,p)\mathcal{G}(\bar{\beta},t). \tag{C23}$$

Evidently, the first term in (C23) is equal to

$$\frac{4t}{1-\frac{t}{p}}\left[t\frac{\partial}{\partial t}-p\frac{\partial}{\partial p}\right]\mathcal{G}(\beta,p)\mathcal{G}(\bar{\beta},t) \tag{C24}$$

[cf. (C13)]. In order to calculate the second term in (C23) we need to use two relations:

$$-\sum_{r=1}^{\infty}\frac{(-1)^{r+1}}{r}[s_{2r}(\bar{\phi})-s_{2r}(\phi)](t^r-p^r)=\left[\exp\left[-\sum_{r=1}^{\infty}\frac{(-1)^{r+1}}{r}[s_{2r}(\bar{\phi})-s_{2r}(\phi)](t^r-p^r)\right]-1\right], \tag{C25}$$

and

$$\mathcal{G}(\beta,t)\mathcal{G}(\bar{\beta},p)=\exp\left[\frac{1}{2}\sum_{r=1}^{\infty}\frac{(-1)^{r+1}}{r}[s_{2r}(\bar{\phi})+s_{2r}(\phi)](t^r+p^r)\right]$$

$$\times\exp\left[\frac{1}{2}\sum_{r=1}^{\infty}\frac{(-1)^{r+1}}{r}[s_{2r}(\bar{\phi})-s_{2r}(\phi)](t^r-p^r)\right]. \tag{C26}$$

Finally, the second term in (C23) becomes

$$2\frac{t}{p}\frac{t+p}{\left(1-\frac{t}{p}\right)^2}[\mathcal{G}(\beta,t)\mathcal{G}(\bar{\beta},p)-\mathcal{G}(\beta,p)\mathcal{G}(\bar{\beta},p)]. \tag{C27}$$

We should emphasize that the bosonic part of this expression vanishes. Combining (C23) and (C26) we obtain the final expression for the generating function $\tilde{\mathcal{H}}^{(s)}(t,p)$ in terms of the generating function $\mathcal{G}(\beta,p)$:

$$\tilde{\mathcal{H}}^{(s)}(t,p)=\frac{4t}{1-\frac{t}{p}}\left[t\frac{\partial}{\partial t}-p\frac{\partial}{\partial p}\right]\mathcal{G}(\beta,p)\mathcal{G}(\bar{\beta},t)-2\frac{t}{p}\frac{t+p}{\left(1-\frac{t}{p}\right)^2}[\mathcal{G}(\beta,t)\mathcal{G}(\bar{\beta},p)$$

$$-\mathcal{G}(\beta,p)\mathcal{G}(\bar{\beta},p)] \tag{C28}$$

[cf. (C13)]. Expanding $\tilde{\mathcal{H}}^{(s)}(t,p)$ in powers of t,p we arrive at the explicit expression for the coefficients in front of the second derivative terms

$$\tilde{\mathscr{H}}^{(s)}_{\ell,k}=2\sum_{q\geqslant 0}\{2(2q+1+k-\ell)\chi_{\ell-q-1}\overline{\chi}_{k+q}-l[\chi_{k+q}\overline{\chi}_{\ell-q-1}-\overline{\chi}_{k+q}\chi_{\ell-q-1}$$
$$+\chi_{\ell+q-1}\overline{\chi}_{k-q}-\overline{\chi}_{\ell+q-1}\chi_{k-q}]\} \tag{C29}$$

[cf. (C14)] given in (5.12). Making similar calculations for the coefficients in front of the terms linear in derivatives we come to the conclusion that these coefficients are equal to those given by (5.7) with replacement of σ's by χ's [see (5.7) and (5.13)].

(Received 26 June 1997; accepted for publication 27 August 1997)

For any principal bundle P, one can consider the subspace of the space of connections on its tangent bundle TP given by the tangent bundle T.$\mathscr{A}$ of the space of connections $\mathscr{A}$ on P. The tangent gauge group acts freely on T.$\mathscr{A}$. Appropriate BRST operators are introduced for quantum field theories that include as fields elements of T.$\mathscr{A}$, as well as tangent vectors to the space of curvatures. As the simplest application, the BRST symmetry of the so-called BF-Yang–Mills theory is described and the relevant gauge fixing conditions are analyzed. A brief account on the topological BF theories is also included and the relevant Batalin–Vilkovisky operator is described. © *1998 American Institute of Physics.*

I. INTRODUCTION

In this paper we study the BRST complexes arising from the action of the (iterated) tangent bundle of the group of gauge transformations $\mathscr{G}$ on the (iterated) tangent bundle of the space of connections $\mathscr{A}$.

Our main original motivation for such a study was the understanding of the BRST and the Batalin–Vilkovisky (BV) structure of four-dimensional BF theories. These topological theories have been shown[1] to be strictly related to the four-dimensional Yang–Mills theory.

Let us first recall what BF action functionals are in both three and four dimensions. We consider ''space–time'' to be given by a closed, oriented Riemannian manifold M with a gauge structure given by a G-principal bundle P with base M. The group G is a simple compact connected Lie group [typically SU(N)] with Lie algebra denoted by $\mathfrak{g}$. Unless otherwise stated, the forms we are considering on M will take values in the adjoint bundle and hence their local expression will take values in $\mathfrak{g}$.

When $M \equiv M^3$ is a *three-dimensional* space, then the most known topological theory is that defined in terms of the Chern–Simons action functional,

$$\mathrm{CS}(A) \equiv \int_{M^3} \mathrm{Tr}(A \wedge dA + \tfrac{1}{3} A \wedge [A,A]),$$

where A is (the local expression of) a connection on $P(M,G)$.

We can also introduce a field $\hat{B}$ given by a 1-form. The 1-form $A + t\hat{B}$ is again a connection.

The three-dimensional topological BF action functional is then defined in terms of the Chern–Simons action functional by

$$S_{BF,t}(A,\hat{B}) \equiv \frac{1}{2t}\,(\mathrm{CS}(A+t\hat{B}) - \mathrm{CS}(A-t\hat{B})) = \int_{M^3} \mathrm{Tr}\left(2(\hat{B} \wedge F_A) + \frac{t^2}{3}\,\hat{B} \wedge [\hat{B},\hat{B}]\right), \quad \text{(I.1)}$$

where F_A denotes the curvature of A and t is a real parameter. The action functional (I.1) is called the *BF action functional with cosmological constant*.[2]

In the limit $t\to 0$ we obtain, up to a factor 2, the so-called *pure BF action functional*,

$$S_{BF}=\int_{M^3}\mathrm{Tr}(\hat{B}\wedge F_A).$$

One can define observables related to links in M^3 for both $S_{BF,t}$ and S_{BF}; it has been shown in Ref. 2 that the corresponding expectation values give the coefficients of the Homfly–Jones polynomials in the first case and are related to the Alexander–Conway polynomials in the second case.

In *four dimensions* we first consider the topological Chern action functional

$$\int_M \mathrm{Tr}(F_A\wedge F_A).$$

Then we consider a field B given by a 2-form. The four-dimensional topological *BF action functional (with cosmological constant)* is then defined as

$$S_{BF,t}\equiv\frac{1}{2t}\int_M \mathrm{Tr}((F_A+tB)\wedge(F_A+tB)-F_A\wedge F_A)=\int_M \mathrm{Tr}\left(B\wedge F_A+\frac{t}{2}B\wedge B\right), \tag{I.2}$$

and again the *pure BF action functional* S_{BF} is defined as the limit of the above one when t goes to 0.

In four dimensions one may also start with the Yang–Mills action functional

$$S_{\mathrm{YM}}=\int_M \mathrm{Tr}(F_A\wedge *F_A),$$

where $*$ is the Hodge operator. (We omit the coupling constant here.)

The corresponding BF-Yang–Mills (BFYM) action functional reads

$$S_{BF\mathrm{YM},t}\equiv\int_M \mathrm{Tr}\left(B\wedge F_A+\frac{t}{2}B\wedge *B\right), \tag{I.3}$$

whose limit $t\to 0$ gives again the pure BF action functional.

When $t=1$, (I.3) *is equivalent, by Gaussian integration, to the Yang–Mills action functional*.

When $t=0$, (I.3) has an extra-symmetry, namely, the translation $B\to B+d_A\tau$ where τ is a 1-form. In order to extend this symmetry for a generic t and carry on the perturbative expansion around the critical solutions for the BF-Yang–Mills theory, it is necessary to deform the action functional (I.3) into the following action functional:

$$S_{BF\mathrm{YM},\eta,t}\equiv\int_M \mathrm{Tr}\left(B\wedge F_A+\frac{t}{2}(B-d_A\eta)\wedge *(B-d_A\eta)\right). \tag{I.4}$$

Here η is a 1-form and the new symmetry reads, for a generic 1-form τ,

$$B\to B+d_A\tau,\quad \eta\to\eta+\tau. \tag{I.5}$$

It is now possible to show that in perturbation theory, the action functional (I.4) is equivalent to the Yang–Mills action functional and we refer to Ref. 1 for such a discussion.

By now it is clear, just by inspecting all the action functionals written above, that in both the three- and the four-dimensional BF theories, the field $\hat{B}$ and, respectively, B belong to some tangent space to the space of fields; the connections in three dimensions and the curvatures in four.

Some care is to be applied in four dimensions, for the space of ''curvatures'' is not the space of fields where one performs the functional integration.

Specifically, in the BFYM theories with action functional (I.4), one works with triples (A,η,B) where the pair (A,η) belongs to the tangent bundle of the space of connections and B is a tangent vector at F_A to the vector space of 2-forms.

The relevant BRST cohomology should accommodate both the gauge invariance and the invariance under translations (I.5); the latter condition implies that eventually no physical quantity should depend on the field η; that is, the theory should behave like a topological field theory as far as the field η is concerned.

The existence of such a BRST cohomology is *a priori* not obvious; the purpose of this paper is to describe in details such a BRST cohomology, which is nothing but a straightforward extension of the BRST cohomology arising from the action of the tangent gauge group on the tangent bundle of connections.

The plan of the paper is as follows:

In Sec. II we recall some aspects of the topological field theories of cohomological type as discussed in Ref. 3.

In Secs. III and IV we study the space of connections of the tangent bundle of a principal bundle (tangent connections) and the relevant gauge group.

In Secs. V and VI we discuss the BRST cohomology arising from the action of the tangent gauge group on the tangent bundle of connections.

In Sec. VII we show that it is possible to extend the above BRST operator to the 2-form B.

In Sec. VIII we show that the construction can be indefinitely iterated by including 2^n 2-forms B_i, 2^n 1-forms η_i and the relevant ghosts.

In Sec. IX we consider the BV construction corresponding to the action functional (I.2).

In Sec. X we discuss the orbit space and the moduli space relevant to the action functional (I.4).

Some of the results of Secs. VI, VII, X have been anticipated in Ref. 1.

As a final remark, we notice that the 2-form B in four-dimensional BF theories can be interpreted geometrically as a tangent vector to the space of connections over the following bundle.

Take the space $\mathscr{P}_A(P)$ of (free) horizontal paths on P with respect to a connection A. This is a principal G-bundle, whose base space is the space of the free paths on M. The initial-point map $ev_0:\mathscr{P}_A(P)\to P$ is a bundle morphism, so ev_0^*A is a connection on $\mathscr{P}_A(P)$. Any form $B \in \Omega^2(M,\mathrm{ad}\, P)$, once integrated over the paths, represents a tangent vector to the space of connections on $\mathscr{P}_A(P)$. The computation of the relevant holonomies allows us to define observables corresponding to imbedded tori in a (simply connected) 4-manifold M, for which expectation values with respect to the different BF action functionals can be computed. We refer to a separate paper[4] for such a discussion.

II. SYMMETRIES IN GAUGE AND TOPOLOGICAL FIELD THEORIES

In this section we review some well known facts concerning gauge invariance in topological (cohomological) theories and in Yang–Mills theories and the BRST structure of such theories.

The main symmetry group we are considering is the gauge group $\mathscr{G}$ that acts on the space $\mathscr{A}$ of (irreducible) smooth connections on P. We assume that we have divided $\mathscr{G}$ by its center, so that $\mathscr{G}$ acts freely on $\mathscr{A}$ yielding the principal bundle of gauge-orbits.

As usual, we denote by ad P the associated bundle $P\times_{Ad}\mathfrak{g}$ and by $\Omega^*(M,\mathrm{ad}\, P)$ the graded Lie algebra of tensorial form on P of the adjoint type, or equivalently, of forms on M with values in ad P. For any $A\in\mathscr{A}$ the covariant exterior derivative will be a linear map,

$$d_A:\Omega^*(M,\mathrm{ad}\, P)\to\Omega^{*+1}(M,\mathrm{ad}\, P).$$

The space $\mathscr{A}$ is an affine space and its tangent space $\mathrm{T}_A\mathscr{A}$ is the vector space $\Omega^1(M,\mathrm{ad}\, P)$.

A quantity (observable, action functional) is gauge invariant if it is invariant under the action of the group $\mathscr{G}$. It is moreover independent of the connection if it is invariant under the translation group $\Omega^1(M,\mathrm{ad}\, P)$. In quantum field theories one may wish to consider simultaneously both kinds of invariance.

In this case one is naturally led to consider the semidirect product

$$\mathcal{G}_T \triangleq \mathcal{G} \ltimes \Omega^1(M, \text{ad } P). \tag{II.1}$$

In this group the product of two elements (g_1, ρ_1) and (g_2, ρ_2) is defined by

$$(g_1, \rho_1)(g_2, \rho_2) = (g_1 g_2, \text{Ad}_{g_2^{-1}} \rho_1 + \rho_2).$$

Here $g_i \in \mathcal{G}$ and $\rho_i \in \Omega^1(M, \text{ad } P)$.

The group $\mathcal{G}_T$ acts on the space of connections as follows:

$$A \cdot (g, \rho) = A^g + \rho, \tag{II.2}$$

where A^g denotes the gauge-transformed connection.

This action is not free since $(g, A - A^g) \in \mathcal{G}_T$ leaves the connection A fixed. At the infinitesimal level, we see that the freedom of the action is missing since we have nontrivial solutions of the equation

$$\rho + d_A \chi = 0, \quad \rho \in \Omega M^1(M, \text{ad } P), \quad \chi \in \Omega^0(M, \text{ad } P),$$

where d_A is the covariant exterior derivative.

From a field-theoretical point of view, dealing with a symmetry that does not correspond to a free action is troublesome since a gauge fixing mechanism and a consistent definition of ghost fields may not be available.

The cure for this problem is to require ρ to belong to a complementary space of the image of $d_A : \Omega^0(M, \text{ad } P) \to \Omega^1(M, \text{ad } P)$. In other words we have to choose a *connection on the bundle of gauge orbits*,

$$\mathcal{A} \mapsto \frac{\mathcal{A}}{\mathcal{G}}. \tag{II.3}$$

Choosing such a connection is also called *fixing the gauge*. We denote the above connection on the bundle of gauge orbits by the symbol c.

In turn any connection c on $\mathcal{A}$, determines a connection on the bundle

$$\frac{P \times \mathcal{A}}{\mathcal{G}} \mapsto M \times \frac{\mathcal{A}}{\mathcal{G}}. \tag{II.4}$$

In fact the 1-form on $P \times \mathcal{A}$ given by

$$(A + c)_{(p,A)}(X, \eta) \triangleq A(X)_p + c(\eta)_{(A,p)}, \quad X \in \text{T}_p P, \eta \in \text{T}_A \mathcal{A} \tag{II.5}$$

defines a $\mathcal{G}$-invariant connection on $P \times \mathcal{A}$,[5] i.e., a connection on the principal G-bundle (II.4).

The exterior derivative on forms on $P \times \mathcal{A}$ which are of order (k, s) (i.e., of order k as forms on P and order s as forms on $\mathcal{A}$) can be written as $d_{\text{tot}} = d + (-1)^k \delta$, where d and δ are the exterior derivatives on P and $\mathcal{A}$, respectively. Analogously we set the following convention for the commutator:

$$[\omega_1, \omega_2] = (-1)^{k_1 k_2 + s_1 s_2 + 1} [\omega_2, \omega_1],$$

where (k_i, s_i) denotes the order of the form ω_i. As a consequence we have the following expression for the total exterior covariant derivative,

$$d_{A+c} = d_A + (-1)^k \delta_c, \tag{II.6}$$

where k denotes again the order of the form on P. In particular we have to remember Eq. (II.6) when computing curvatures and their Bianchi identity.

The order of a form with respect to the space $\mathcal{A}$ is called the *ghost number*.

The operator δ (or some of its restrictions or extensions) is as an example of what in quantum field theory is called a BRST (or a BRS) operator; it describes the symmetry of the fields that one considers in the theory.

We have in mind essentially two cases.

The first case is that of the *topological field theory* à la Baulieau–Singer[3] or, according to Witten's terminology,[6] of a *cohomological field theory*. In this case the theory has no degrees of freedom and the action functional is invariant under (infinitesimal) translations of the space of fields. The corresponding BRST operator is then the exterior derivative on the space of fields ($\mathscr{A}$ in the previous case).

The second case is that of a field theory (generally not topological) in which there is a symmetry group acting on the space of fields and the theory is only required to be invariant under such a symmetry group. In this last case the BRST operator is just the restriction of the exterior derivative on the space of fields to the orbits of that symmetry group.

In the Yang–Mills theory, the BRST operator is the exterior derivative along the gauge orbits.

Mixed cases will also (and especially) be considered in this paper, namely, theories for which the BRST operator is the exterior derivative for some of the fields and the derivative along the fibers (orbits) for other fields.

We may say that these theories are ''semitopological'' or topological in some fields and nontopological in others. We use this terminology, even though topological field theories are not only those of cohomological type.

In a topological theory (of the cohomological type) defined for an even-dimensional space, the typical action functional is defined in terms of characteristic classes, so is independent of the choice of the connection.

Let us come back to the Baulieu–Singer theory. Such a theory is invariant under translations in the space of connections, the action functional is represented by characteristic classes, and the field equations are obtained by considering the structure equation for the connection (II.5) and the relevant Bianchi identities.

The structure equations read

$$F_A+\psi+\phi=d_A A+d_A c+\tfrac{1}{2}[c,\ c]-\delta A+\delta c, \tag{II.7}$$

where the left-hand side gives the various components of the curvature of the connection (II.5); F_A,ψ,ϕ are respectively forms of degree (2,0), (1,1), and (0,2) on the product space,

$$P\times\mathscr{A}.$$

The previous equation can be rewritten as

$$\delta A=d_A c-\psi,\quad \delta c=-\tfrac{1}{2}[c,\ c]+\phi. \tag{II.8}$$

Notice that the form ψ is minus the projection of $\Omega^1(M,\mathrm{ad}\ P)$ onto the horizontal subspace at A.

The Bianchi identity defines the transformation properties of ψ and ϕ (and F_A),

$$\delta\psi=d_A\phi-[\psi,\ c],\quad \delta\phi=[\phi,\ c], \tag{II.9}$$

$$d_A F_A=0,\quad \delta F_A=[F_A,\ c]-d_A\psi. \tag{II.10}$$

By comparing the first equation in (II.8) with the action (II.2), we see that we have successfully turned around the problem of the nonfreedom of the action (II.2).

As was recalled before, the *Yang–Mills* theory, as opposed to the previous topological theory, involves the restriction of the transformation (II.8) to the orbit passing through $A\in\mathscr{A}$. The relevant equations are then

$$\delta A=d_A c,\quad \delta c=-\tfrac{1}{2}[c,\ c], \tag{II.11}$$

where c in (II.11) is now the *Maurer–Cartan form* on $\mathscr{G}$, and δ is the exterior derivative on $\mathscr{G}$ or, more precisely, on the $\mathscr{G}$-orbit passing through A.

The equations (II.11) are the classical BRST equations.[7]

A final remark is in order. Whenever we have a nonfree action of a group over a manifold, one is naturally led to consider the corresponding equivariant cohomology. In our case the group is $\mathscr{G}_T$

with its nonfree action on $\mathscr{A}$. But $\mathscr{G}_T$ is the semidirect product of an Abelian (contractible) subgroup $\Omega^1(M,\mathrm{ad}\,P)$ times $\mathscr{G}$, which behaves in many ways like a ''compact group'' and acts freely on (the contractible space) $\mathscr{A}$.

So one has just to consider this last action, or the cohomology of the principal bundle (II.4) (which in turn is just the equivariant cohomology corresponding to the nonfree action of $\mathscr{G}$ on P).

In the following sections we will extend this procedure by considering the action of the tangent bundle of the gauge group (which also is a Lie group) on the tangent space to the space of connections. This may look irrelevant from a purely topological point of view since, as will be recalled below, the tangent gauge group is again the semidirect product of $\mathscr{G}$ times an Abelian contractible group. This implies that the classifying spaces for the gauge group and for its tangent bundle are homotopically equivalent.

But the BRST structure of the tangent gauge group will show an interesting degree of flexibility, due exactly to the fact that there is a large Abelian normal subgroup of the tangent gauge group. This will allow us to include into the BRST algebra the 2-form fields B of the four-dimensional BF theories.

However, before doing so, we need to discuss some basic facts of the differential geometry of the tangent bundle of a principal bundle.

III. TANGENT PRINCIPAL BUNDLES AND THEIR GAUGE GROUPS

Let G be a Lie group and let $\mathfrak{g}$ its Lie algebra. The tangent bundle $\mathrm{T}G$ is a Lie group with respect to the multiplication given by the tangent map of the multiplication $m:G\times G\mapsto G$

$$\mathrm{T}m:\mathrm{T}G\times\mathrm{T}G\mapsto\mathrm{T}G.$$

Explicitly this multiplication is given by

$$(k,u_k)(h,v_h)\equiv(kh,kv_h+u_kh)\quad k,h\in G;u_k\in\mathrm{T}_kG;v_h\in\mathrm{T}_hG.$$

Here the right and left multiplications of a vector by an element of G denote the push-forward of the corresponding multiplications in G.

Since we can represent any vector u_k as $u_k=kx$ for a unique $x\in\mathfrak{g}=\mathrm{T}_eG$, there is an isomorphism

$$\mathrm{T}G\tilde{\to}G\ltimes\mathfrak{g},\quad(k,uk)\rightsquigarrow(k,k^{-1}u_k)\tag{III.1}$$

and on the semidirect product $G\ltimes\mathfrak{g}$ the product of two elements is defined as

$$(k,x)(h,y)\equiv(kh,\mathrm{Ad}_{h^{-1}}(x)+y)\quad k,h\in G;x,y\in\mathfrak{g}.$$

The inverse of the element $(k,x)\in(G\ltimes\mathfrak{g})$ is given by

$$(k,x)^{-1}=(k^{-1},-\mathrm{Ad}_k(x)),\tag{III.2}$$

and the conjugation on $G\ltimes\mathfrak{g}$ is given by

$$(k,x)(h,y)(k,x)^{-1}=(khk^{-1},\mathrm{Ad}_k\mathrm{Ad}_{h^{-1}}(x)+\mathrm{Ad}_k(y)-\mathrm{Ad}_k(x)).\tag{III.3}$$

The adjoint action of $G\ltimes\mathfrak{g}$ on $T_{(e,0)}(G\ltimes\mathfrak{g})=\mathfrak{g}\times\mathfrak{g}$ is given by

$$\mathrm{Ad}_{(k,z)}(x,y)=(\mathrm{Ad}_k(x),\mathrm{Ad}_k([z,x]+y)),\tag{III.4}$$

whereas the commutator is given by

$$[(x_1,y_1),\ (x_2,y_2)]=([x_1,\ y_2],[x_1,\ y_2]+[y_1,\ x_2]).\tag{III.5}$$

So $\mathrm{Lie}(\mathrm{T}G)$ is isomorphic as a Lie algebra to the semidirect sum $\mathfrak{g}\oplus_s\mathfrak{g}$. We now consider a G-principal bundle $P\mapsto M$, with base space M. Its tangent bundle is a $\mathrm{T}G$-principal bundle with right action of $\mathrm{T}G$ on $\mathrm{T}P$ given by the tangent map to the right action $R:P\times G\mapsto P$,

$$\begin{aligned} &\mathrm{T}R:\mathrm{T}P\times\mathrm{T}G\mapsto\mathrm{T}P,\\ &((p,X),(k,u_k))\rightsquigarrow(pk,Xk+pu_k). \end{aligned} \tag{III.6}$$

Here and in what follows, Xk and pu_k (with $p\in P$, $X\in \mathrm{T}_pP$, $k\in G$, $u_k\in \mathrm{T}_kG$) are simplified notations for the partial tangent maps $\mathrm{T}_1R:\mathrm{T}P\times G\to\mathrm{T}P$ and $\mathrm{T}_2R:P\times\mathrm{T}G\to\mathrm{T}P$. We now rewrite the previous action, by considering the isomorphism (III.1). If $(k,x)\in G\ltimes\mathfrak{g}$, and $i(x)$ denotes the fundamental vector field in P generated by $x\in\mathfrak{g}$, then the action (III.6) becomes

$$(p,X)(k,x)=(pk,Xk+i(x)|_{pk}). \tag{III.7}$$

It is easy to check directly that (III.7) defines a good action

$$\begin{aligned} [(p,X)(k,x)](h,y)&=(pkh,(Xk)h+(i(x)|_{pk})h+i(y)|_{pkh})\\ &=(pkh,X(kh)+i(\mathrm{Ad}_{h^{-1}}x)|_{pkh}+i(y)|_{pkh})\\ &=(p,X)[(k,x)(h,y)]. \end{aligned}$$

The action (III.7) is free and moreover $\pi:\mathrm{T}P\mapsto\mathrm{T}M$ is a $(G\ltimes\mathfrak{g})$-principal fiber bundle.

We now shift to the infinite-dimensional case. We consider the tangent bundle $\mathrm{T}\mathscr{G}$ of the group of gauge transformations.

This can be identified with the semidirect product of $\mathscr{G}\ltimes\Omega^0(M,\mathrm{ad}\,P)$, where the product of two elements is defined by

$$(g_1,\zeta_1)(g_2,\zeta_2)=(g_1g_2,\mathrm{Ad}_{g_2^{-1}}\zeta_1+\zeta_2). \tag{III.8}$$

Its Lie algebra is given by the semidirect sum $\Omega^0(M,\mathrm{ad}\,P)\oplus_s\Omega^0(M,\mathrm{ad}\,P)$ whose commutator is defined as follows:

$$[(\chi_1,\zeta_1),\,(\chi_2,\zeta_2)]=([\chi_1,\,\chi_2],[\chi_1,\,\zeta_2]+[\zeta_1,\,\zeta_2]).$$

The tangent map to the action of $\mathscr{G}$ on $\mathscr{A}$ defines the action of $\mathrm{T}\mathscr{G}$ on $\mathrm{T}\mathscr{A}\sim\mathscr{A}\times\Omega^1(M,\mathrm{ad}\,P)$ as follows:

$$(A,\eta)\cdot(g,\zeta)=(A^g,\mathrm{Ad}_{g^{-1}}(\eta)+d_{A^g}\zeta). \tag{III.9}$$

The fundamental vector field at $(A,\eta)\in\mathrm{T}\mathscr{A}$ corresponding to $(\chi,\zeta)\in\mathrm{Lie}(\mathrm{T}\mathscr{G})$ is given by

$$(d_{A\chi},[\eta,\,\chi]+d_A\zeta). \tag{III.10}$$

The action (III.9) is free when we understand that only irreducible connections on P are taken into account and that the group $\mathscr{G}$ has been divided by its center.

A *gauge transformation* for $\mathrm{T}P$ is, by definition, a map

$$f:\mathrm{TP}\to G\ltimes\mathfrak{g}\ \text{such that}\ f[(p,X)(k,x)]=(k,x)^{-1}f(p,X)(k,x).$$

We have the following:

Theorem III.1: *The tangent bundle* $\mathrm{T}\mathscr{G}$ *of the gauge Lie group* $\mathscr{G}$ *is a proper subgroup of the group* $\mathscr{G}_{\mathrm{TP}}$ *of gauge transformations for* $\mathrm{T}P$.

Proof of Theorem III.1: We consider the tangent map to the evaluation map $ev:P\times\mathscr{G}\to G$ at $(g,\chi)\in\mathscr{G}\ltimes\Omega^0(M,\mathrm{ad}\,P)\sim\mathrm{T}\mathscr{G}$.

It is a map,

$$\mathrm{T}P\to G\ltimes\mathfrak{g},$$

given by

$$(g(p),g^{-1}\,dg(p,X)+\chi(p))\in G\ltimes\mathfrak{g},$$

where we have to remember that the logarithmic derivative $g^{-1}\,dg$ is a map defined on TP with values in $\mathfrak{g}$.

In order to show that it is a gauge transformation for TP, it is enough to see that for any $(p,X)\in \mathrm{T}P$ and $(k,x)\in G\ltimes\mathfrak{g}$ we have the equation,

$$\begin{aligned} g^{-1}\,dg\{(p,X)(k,x)\} &= g^{-1}\,dg\{(pk, Xk + i(x)|_{pk})\} \\ &= \mathrm{Ad}_{k^{-1}}[g^{-1}\,dg(p,X)] + x - \mathrm{Ad}_{k^{-1}}\mathrm{Ad}_{g^{-1}(p)}\mathrm{Ad}_k x \\ &= p_2(\mathrm{Ad}_{(k,x)^{-1}}\{g^{-1}\,dg(p,X)\}), \end{aligned}$$

where $p_2:\mathfrak{g}\oplus_s\mathfrak{g}\to\mathfrak{g}$ is the projection onto the second component. For any $\eta\in\Omega^1(M,\mathrm{ad}\,P)$ and for any $(g,\chi)\in\mathscr{G}\ltimes\mathrm{Lie}(\mathscr{G})$ the map

$$(p,X)\rightsquigarrow(g(p), g^{-1}\,dg(p,X)+\chi(p)+\eta(p,X))$$

is also a gauge transformation on TP and this shows that the inclusion $\mathrm{T}\mathscr{G}\hookrightarrow\mathscr{G}_{\mathrm{T}P}$ is proper. □

We have also shown that the group $\mathscr{G}_{\mathrm{T}P}$ includes the group $\mathscr{G}_{\mathrm{aff}}$ of *affine gauge transformations*, defined as the semidirect product $\mathrm{T}\mathscr{G}\ltimes\Omega^1(M,\mathrm{ad}\,P)$, whose elements are triples $(g,\chi,\eta)\in\mathscr{G}\ltimes\Omega^0(M,\mathrm{ad}\,P)\ltimes\Omega^1(M,\mathrm{ad}\,P)$. The product of two such triples is given by

$$(g_1,\chi_1,\tau_1)(g_2,\chi_2,\tau_2)=(g_1g_2,\mathrm{Ad}_{g_2^{-1}}\chi_1+\chi_2,\mathrm{Ad}_{g_2^{-1}}\tau_1+\tau_2,). \tag{III.11}$$

The Lie algebra of $\mathscr{G}_{\mathrm{aff}}$ is

$$(\Omega^0(M,\mathrm{ad}\,P)\oplus_s\Omega_0(M,\mathrm{ad}\,P))\oplus_s\Omega^1(M,\mathrm{ad}\,P)$$

and the relevant commutator is given by

$$[(\zeta_1,\chi_1,\tau_1),(\zeta_2,\chi_2,\tau_2)]=([\zeta_1,\,\zeta_2],[\zeta_1,\,\chi_2]+[\chi_1,\,\zeta_2],[\zeta_1,\,\tau_2]+[\tau_1,\,\zeta_2]).$$

IV. TANGENT CONNECTIONS

Now we discuss the structure of the space of connections of the principal TG-bundle TP.

For any manifold M we can consider its double tangent bundle TTM,

$$\begin{array}{ccc} \mathrm{TT}M & \xrightarrow{\mathrm{T}\pi_M} & \mathrm{T}M \\ \downarrow{\scriptstyle \pi_{\mathrm{T}M}} & & \downarrow{\scriptstyle \pi_M} \\ \mathrm{T}M & \xrightarrow{\pi_M} & M. \end{array}$$

Let us consider a rectangle in M centered at x, i.e., a C^2-map $\underline{x}:[a,b]\times[a',b']\mapsto M$, with $(0,0)\in(a,b)\times(a',b')$, $\underline{x}(0,0)=x$. We will denote by s and t the two variables and by a prime the derivative with respect to s, by a dot the derivative with respect to t. A tangent vector in TTM at $(\underline{x}(0,0),\underline{x}'(0,0))$ can be represented as $(\dot{\underline{x}}(0,0),(d\underline{x}'/dt)(0,0))$. When it is not otherwise specified, the derivatives are understood to be computed at (0,0). Notice that two rectangles are meant to be equivalent if they have the same first order derivatives as well as the mixed derivatives of order 2. Everything that follows is defined on the equivalence classes. Identifying double tangents with equivalence classes of rectangles provides us also with a (noncanonical) extension of the double tangent vector to the image of the rectangle.

In our notation we have, for a given $[\underline{x}]\in\mathrm{TT}M$, $\mathrm{T}\pi_M[\underline{x}]=\dot{\underline{x}}$ and $\pi_{\mathrm{T}M}[\underline{x}]=\underline{x}'$.

There is a canonical involution $\alpha_M:\mathrm{TT}M\mapsto\mathrm{TT}M$ given by

$$\alpha_M\left(x,\underline{x}',\dot{\underline{x}},\frac{d\underline{x}'}{dt}\right)=\left(x,\dot{\underline{x}},\underline{x}',\frac{d\dot{\underline{x}}}{ds}\right). \tag{IV.1}$$

It is well known[8] that for any connection A on P, one can induce a connection $\mathring{A}$ on TP. If $\underline{p}$ is any rectangle in P centered at p, then $\mathring{A}$ is, by definition, the 1-form on TP with values in $\mathfrak{g} \oplus_s \mathfrak{g}$, given by

$$\mathring{A}_{p,p'}\left(\dot{\underline{p}}, \frac{d\underline{p}'}{dt}\right) = \left(A_p(\dot{\underline{p}}), \left.\frac{d}{ds}\right|_{s=0} [A_{\underline{p}(s,0)}(\dot{\underline{p}}(s,0))]\right). \tag{IV.2}$$

Notice that the canonical involution has been used in the definition of the above connection.

A more general connection on TP can be obtained by considering the evaluation map,

$$ev: \mathscr{A} \times TP \to \mathfrak{g},$$

$$(A; p, X) \rightsquigarrow A_p(X). \tag{IV.3}$$

The tangent map of (IV.3)

$$Tev: T\mathscr{A} \times TTP \to \mathfrak{g} \oplus_s \mathfrak{g}, \tag{IV.4}$$

evaluated at $(A, \eta) \in T\mathscr{A}$ and composed with the canonical involution α_P gives a connection on TP. In fact we have the following:

Theorem IV.1: *For any* $(A, \eta) \in T\mathscr{A}$*, the 1-form* $\omega(A, \eta)$ *on* TP *given by*

$$\omega(A, \eta)([\underline{p}]) \equiv Tev(A, \eta; \alpha_P[\underline{p}]) = \left(A_p(\dot{\underline{p}}), \left.\frac{d}{ds}\right|_{s=0} A_{\underline{p}(s,0)}(\dot{\underline{p}}(s,0)) + \eta(\dot{\underline{p}})\right) \tag{IV.5}$$

defines a connection on TP.

Proof of Theorem IV.1: The adjoint action of the group on its Lie algebra, extends, in an obvious way, to Lie-algebra valued forms. So we have a natural map $\mathrm{ad}: G \times \Omega^*(P, \mathfrak{g}) \mapsto \Omega^*(P, \mathfrak{g})$ and its derivative $T\,\mathrm{ad}_G = \mathrm{ad}_{TG}$ [see (III.4)]. If we consider again the derivative in the first variable of the right multiplication on P, i.e., the map $T_1R: TP \times G \to TP$ and we denote by $\Delta_G: G \to G \times G$ the diagonal map in G and by $p_V: V \times U \to V$ the projection on V for any pair of spaces (V, U), then the ad-equivariance of the connections is given by the following equation:

$$ev \circ p_{\mathscr{A} \times TP} = ev \circ (\mathrm{ad} \times T_1R) \circ (\mathbb{I} \times \Delta_G): \mathscr{A} \times TP \times G \to \mathfrak{g}, \tag{IV.6}$$

where the evaluation map is given by (IV.3). The derivative of both sides of (IV.6) gives

$$Tev \circ p_{T\mathscr{A} \times TTP} = Tev \circ (\mathrm{ad}_{TG} \times T_1R) \circ (\mathbb{I} \times \Delta_{TG}). \tag{IV.7}$$

The equivariance of (IV.5) follows when we notice that

$$T\,T_1R = \alpha_P \circ T_1TR \circ \alpha_P: TTP \times TG \to TTP,$$

where α_P is the canonical involution. Finally we notice that the difference $\omega(A, \eta) - \mathring{A}$ evaluated at $[\underline{p}]$ gives $\eta(\dot{\underline{p}})$. But the projection $T\pi_P$ applied to the fundamental vector field in $(p, X) \in TP$ determined by $(a, b) \in \mathfrak{g} \oplus_s \mathfrak{g}$ yields $i(a)_p$, i.e., the fundamental vector field in P corresponding to a evaluated at p. The theorem follows from the fact that $\mathring{A}$ is a connection and η is a tensorial 1-form. □

When we consider the inclusion

$$\iota: P \hookrightarrow TP, \quad \iota(p) = (p, 0), \tag{IV.8}$$

then the pullback of the connection $\omega(A, \eta)$ via (IV.8) is simply given by

$$[\iota^* \omega(A, \eta)]_p(X) = (A(X)_p, \eta(X)_p) \in \mathfrak{g} \oplus_s \mathfrak{g}, \quad X \in T_pP. \tag{IV.9}$$

Also we have the following:

Theorem IV.2: *The inclusion of* $T\mathscr{A}$ *into the space of connections of* TP *is proper.*

Proof of Theorem IV.2: The bundle $\mathrm{T}.\mathscr{A}$ can be identified with an affine space modeled on

$$\Omega^1(M,\mathrm{ad}\ P)\oplus\Omega^1(M,\mathrm{ad}\ P)\sim\Omega^1(M,\mathrm{ad}\ P\oplus\mathrm{ad}\ P),$$

while the space of connections on $\mathrm{T}P$ can be identified with an affine space modeled on $\Omega^1(\mathrm{T}M,\mathrm{ad}\,\mathrm{T}P)$. The theorem is proved when we notice that the projection $M\to\mathrm{T}M$ determines a proper inclusion of $\Omega^*(M)$ into $\Omega^*(\mathrm{T}M)$ and that the pair of projections $\mathrm{T}P\to P$, $\mathrm{T}G\to G$ determines

(1) a homomorphism of the $\mathrm{T}G$-principal bundle $\mathrm{T}P\times\mathfrak{g}\times\mathfrak{g}\to\mathrm{ad}\,\mathrm{T}P$ (where the left $\mathrm{T}G$-adjoint action on $\mathfrak{g}\times\mathfrak{g}$ is considered) onto the G-principal bundle $P\times\mathfrak{g}\times\mathfrak{g}\to\mathrm{ad}\ P\oplus\mathrm{ad}\ P$ (where the left G-adjoint action on $\mathfrak{g}\times\mathfrak{g}$ is considered), and hence
(2) a proper inclusion of the space of sections $\Gamma(\mathrm{ad}\ P\oplus\mathrm{ad}\ P)$ into the space of sections $\Gamma(\mathrm{ad}\,\mathrm{T}P)$. □

Two final remarks are in order.

(A) By iterating the procedure, we obtain an inclusion

$$\mathrm{T}^n.\mathscr{A}(P)\hookrightarrow.\mathscr{A}(\mathrm{T}^nP),$$

where T^n denotes the n-iterated tangent bundle and $.\mathscr{A}(\bullet)$ denotes the space of connections of a given principal bundle.

(B) When we consider only irreducible connections, then $\mathscr{A}\mapsto\mathscr{A}/\mathscr{G}$ is a principal bundle and so is $\mathrm{T}^n.\mathscr{A}\mapsto\mathrm{T}^n.\mathscr{A}/\mathrm{T}^n\mathscr{G}$.

V. TOPOLOGICAL FIELD THEORIES FOR TANGENT PRINCIPAL BUNDLES

Here we want to extend the topological field theory discussed in Sec. II to the case when the principal bundle is the *tangent bundle* $\mathrm{T}P$. The purpose of this section is to write the BRST equations for this case.

Here we will consider only those special connections for $\mathrm{T}P$ that are determined by elements of $\mathrm{T}.\mathscr{A}$, i.e., by pairs (A,η) where A is a connection on P and η is any element of $\Omega^1(M,\mathrm{ad}\ P)$.

In analogy with the discussion of Sec. II we will begin by including, among the admissible symmetries, besides the tangent gauge group $\mathrm{T}.\mathscr{G}$, the full translation group on the affine space $\mathrm{T}.\mathscr{A}$.

Namely, we want to consider the action of the group $\mathrm{T}\mathscr{G}_{\mathrm{T}}$ [tangent bundle of the group $\mathscr{G}_{\mathrm{T}}$ defined in (II.1)] on $\mathrm{T}.\mathscr{A}$. This action is given by the derivative of (II.2)

$$\begin{aligned}&\mathrm{T}.\mathscr{A}\times\mathrm{T}.\mathscr{G}_T\to\mathrm{T}.\mathscr{A},\\&(A,\eta)(g,\rho,\xi,\tau)\rightsquigarrow(A^g+\rho,\mathrm{Ad}_{g^{-1}}\eta+d_{A^g}\xi+\tau).\end{aligned}\tag{V.1}$$

Since (II.2) is not free, neither is (V.1).

We have an obvious infinite-dimensional analog of Theorem IV.1,

Theorem V.1: *Any pair $(c,\hat{c})$ where c is a connection on (II.3) and $\hat{c}$ is a tangent vector to the space of connections on (II.3), defines a connection $\omega(c,\hat{c})$ on*

$$\mathrm{T}.\mathscr{A}\mapsto\frac{\mathrm{T}.\mathscr{A}}{\mathrm{T}.\mathscr{G}}.\tag{V.2}$$

Explicitly $\hat{c}$ is an assignment to each connection $A\in\mathscr{A}$ of a map $\hat{c}_A:\Omega^1(M,\mathrm{ad}\ P)\mapsto\Omega^0(M,\mathrm{ad}\ P)$ with the property of $\mathscr{G}$-equivariance,

$$\hat{c}_{A^g}(\mathrm{Ad}_{g^{-1}}\tau)=\mathrm{Ad}_{g^{-1}}(\hat{c}_A(\tau)),$$

and of tensoriality

$$\mathrm{Im}(d_A|_{\Omega^0(M,\mathrm{ad\,P})})\subset\ker(\hat{c}_A).$$

In physics $\hat{c}$ is an *infinitesimal variation of the gauge fixing*.

By using the same notation of the previous theorem, we have also the following:

Theorem V.2: *The pair* $(c,\hat{c})$ *determines a connection on the* TG *principal bundle* T$P\times$T.$\mathscr{A}\to$T$M\times$T.$\mathscr{A}$ *that is* T.$\mathscr{G}$*-invariant, i.e., determines a connection on the principal* TG*-bundle,*

$$\frac{\mathrm{T}P\times\mathrm{T}.\mathscr{A}}{\mathrm{T}.\mathscr{G}}\mapsto\mathrm{T}M\times\frac{\mathrm{T}.\mathscr{A}}{\mathrm{T}.\mathscr{G}}. \tag{V.3}$$

If we consider a rectangle $([\underline{p}],[\underline{A}])$ on T$P\times$T.$\mathscr{A}$ centered at $(p,A)\in P\times\mathscr{A}$, with $X=\dot{\underline{p}}$, and $\eta=\dot{\underline{A}}$, then the explicit expression of such a connection at $(p,X,A,\eta)\in\mathrm{T}P\times\mathrm{T}.\mathscr{A}$ is given by

$$\omega(A,\eta)([\underline{p}])+\omega(c,\hat{c})([\underline{A}]), \tag{V.4}$$

where the notation here is completely analogous to the one of Theorem IV.1.

A simple calculation shows

Theorem V.3: *When we identify the double tangent bundle* TT.$\mathscr{A}$ *with* $\mathscr{A}\times\Omega^1(M,\mathrm{ad}\,P)^{\times 3}$, *then the connection determined by* $(c,\hat{c})$ *is a map*

$$(A,\eta,\gamma,\sigma)\rightsquigarrow\left(c_A(\gamma),\left.\frac{d}{ds}\right|_{s=0}c_{A+s\eta}(\gamma)+\hat{c}_A(\gamma)+c_A(\sigma)\right).$$

From now on we set

$$\xi_{A,\eta}(\gamma)\equiv\left.\frac{d}{ds}\right|_{s=0}c_{A+s\eta}(\gamma)+\hat{c}_A(\gamma). \tag{V.5}$$

Since space–time for us is M and not TM, we want to avoid dealing with forms on TP, as opposed to forms on P.

We consider then again the inclusion map (IV.8) $P\to\mathrm{T}P$ and establish the following:

Convention i: All the forms on T$P\times$T.$\mathscr{A}$ *are pulled back to forms on* $P\times$T.$\mathscr{A}$.

In the use of Convention i we should be aware that, even though (IV.8) is a morphism of principal bundles, the pullback of a connection on T$P\times$T.$\mathscr{A}$ is *not* (strictly speaking) a connection on $P\times$T.$\mathscr{A}$. It is a $(\mathfrak{g}\oplus_s\mathfrak{g})$-valued 1-form that would become a connection only if we decided to disregard the second copy of $\mathfrak{g}$.

Moreover, when considering the decomposition T.$\mathscr{A}\sim\mathscr{A}\times\Omega^1(M,\mathrm{ad}\,P)$ we also assume the following:

Convention ii: We will omit the components of the forms on $P\times$T.$\mathscr{A}$ *which have degree higher than 0 as forms on* $\Omega^1(M,\mathrm{ad}\,P)$.

When we assume both the previous conventions, then the connection (V.4) becomes the following $(\mathfrak{g}\oplus_s\mathfrak{g})$-valued 1-form on $P\times\mathscr{A}$, depending on $\eta\in\Omega^1(M,\mathrm{ad}\,P)$,

$$(A+c;\eta+\xi)_{p,A,\eta}(X,\gamma)\equiv(A_p(X)+c_A(\gamma);\eta_p(X)+\xi_{A,\eta}(\gamma)),\quad X\in\mathrm{T}_pP,\gamma\in\mathrm{T}_A\mathscr{A}, \tag{V.6}$$

where (V.5) has been used.

We will, in the future, refer to (V.6) as a ''connection'' with an associate ''covariant exterior derivative,'' ''curvature'' and ''Bianchi identities;'' but, as has been explained above, this will clearly be an abuse of language.

The covariant exterior derivative for $(\mathfrak{g}\oplus_s\mathfrak{g})$-valued forms on $P\times\mathscr{A}$ is given by

$$d_{(A,\eta)}+\pm\delta_{(c,\xi)}. \tag{V.7}$$

More precisely the covariant exterior derivative applied to the pair of $\mathfrak{g}$-valued forms (ω,ω'), with degree (k,k') as forms on P, is given by

$$(d_A\omega+(-1)^k\delta\omega+(-1)^k[c,\ \omega],d_A\omega'+(-1)^{k'}\delta\omega'+[\,\eta+(-1)^k\xi\ ,\omega]+[(-1)^{k'}c,\ \omega']), \tag{V.8}$$

where we used (III.5). The curvature of (V.6) is a $(\mathfrak{g}\oplus_s\mathfrak{g})$-valued 2-form on $P\times\mathscr{A}$ which we can compute in a similar way as

$$(F_A+\psi+\phi;\ \ d_A\eta+\tilde{\psi}+\tilde{\phi}), \tag{V.9}$$

where $(F_A, d_A\eta)$, $(\psi,\tilde{\psi})$ and $(\phi,\tilde{\phi})$ are, respectively, the (2,0), the (1,1) and the (0,2) components.

We now compute explicitly the structure equation and the Bianchi identities.

First we obtain once again the Eqs. (II.8), (II.9), and (II.10).

The structure equations give moreover

$$\tilde{\psi}=-\delta\eta+d_A\xi+[\eta,\ c], \tag{V.10}$$

$$\tilde{\phi}=\delta\xi+[c,\ \xi]. \tag{V.11}$$

Finally the Bianchi identities for the second component of the curvature give

$$\delta\tilde{\psi}=-[\tilde{\psi},\ c]+d_A\tilde{\phi}+[\eta,\ \phi]-[\xi,\ \phi],\quad \delta\tilde{\phi}=[\tilde{\phi},\ c]+[\phi,\ \xi]. \tag{V.12}$$

So we have:

Theorem V.4: *The transformations for the set of fields* $A,\eta,c,\xi,\psi,\phi,\tilde{\psi},\tilde{\phi}$ *given by the components of the connection (V.6) and the curvature (V.9) are as follows*:

$$\delta A=d_Ac-\psi, \tag{V.13}$$

$$\delta\eta=-\tilde{\psi}+d_A\xi+[\eta,\ c], \tag{V.14}$$

$$\delta F_A=-d_A\psi+[F_A,\ c], \tag{V.15}$$

$$\delta(d_A\eta)=-d_A\tilde{\psi}+[F_A,\ \xi]+[d_A\eta,\ c]-[\psi,\ \eta], \tag{V.16}$$

$$\delta c=-\tfrac{1}{2}[c,\ c]+\phi, \tag{V.17}$$

$$\delta\xi=\tilde{\phi}-[c,\ \xi], \tag{V.18}$$

$$\delta\psi=d_A\phi-[\psi,\ c], \tag{V.19}$$

$$\delta\tilde{\psi}=-[\tilde{\psi},\ c]+d_A\tilde{\phi}+[\eta,\ \phi]-[\xi,\ \psi], \tag{V.20}$$

$$\delta\phi=[\phi,\ c], \tag{V.21}$$

$$\delta\tilde{\phi}=[\tilde{\phi},\ c]+[\phi,\ \xi]. \tag{V.22}$$

The transformation laws in Theorem V.4 show how to overcome the problem of the lack of freedom of (V.1). As before the key element has been the introduction of a (equivariant) coboundary operator relevant to a principal bundle (in this case (V.3)).

VI. RESTRICTIONS TO THE ORBITS

Two possible fiber imbeddings can be considered,

$$j_A:\mathscr{G}\hookrightarrow\mathscr{A},\ \ j_A(g)=A^g, \tag{VI.1}$$

$$j_{(A,\eta)}:\mathrm{T}\mathscr{G}\hookrightarrow\mathrm{T}\mathscr{A},\ \ j_{(A,\eta)}(g,\chi)=(A^g,\mathrm{Ad}_{g^{-1}}(\eta)+d_{A^g}\chi). \tag{VI.2}$$

First we can pull back the bundle

$$P\times\mathrm{T}\mathscr{A}\mapsto M\times\mathrm{T}\mathscr{A} \tag{VI.3}$$

to

$$P\times \mathrm{T}\mathscr{G}\mapsto M\times \mathrm{T}\mathscr{G}$$

via (VI.2).

Then we pull back the 1-form (c,ξ) (without changing notation). This form then becomes the Maurer–Cartan form on $\mathrm{T}\mathscr{G}$, and the structure equations and Bianchi identities become simply

$$\delta A = d_A c,\quad \delta c = -\tfrac{1}{2}[c,\,c],\quad \delta\xi = -[c,\xi],\quad \delta\eta = d_A\xi + [\,\eta,\,c\,]. \tag{VI.4}$$

This is the generalization to the tangent bundle of the ordinary BRST equations.[7]

Starting from (VI.1) we obtain another restriction that will allow us to have a BRST symmetry that includes the 2-form field B considered in four-dimensional BF theories.

We begin by noticing that the group $\mathscr{G}_{\mathrm{aff}}$ considered in Sec. III is the right symmetry group for the action functional (I.4). Here the action of $\mathscr{G}_{\mathrm{aff}}$ on triples (A,η,B) with $(A,\eta)\in \mathrm{T}\mathscr{A}$ and $B\in\Omega^2(M,adP)$ is defined as follows [Notice that this action of $\mathscr{G}_{\mathrm{aff}}$ on $\mathrm{T}\mathscr{A}$ does *not* coincide with the restriction of the action of $\mathscr{G}_{TP}$ on $\mathscr{A}(\mathrm{T}P)$.]

$$(A,\eta)\cdot(g,\zeta,\tau) = (A^g,\tau + Ad_{g^{-1}}\eta + d_{A^g}\zeta), \tag{VI.5}$$

$$B\cdot(g,\zeta,\tau) = Ad_{g^{-1}}B + d_{A^g}\tau + d^2_{A^g}\zeta. \tag{VI.6}$$

The group $\mathscr{G}_{\mathrm{aff}}$ is just a subgroup of $\mathrm{T}\mathscr{G}_{\mathrm{T}}$ since we have

$$\mathscr{G}_{\mathrm{aff}} \equiv j^*(\mathrm{T}\mathscr{G}_T),$$

where j is the inclusion $j:\mathscr{G}\hookrightarrow\mathscr{G}_{\mathrm{T}}$. The action (VI.5) is the corresponding restriction of (V.1).

Requiring the invariance under the group of affine gauge transformations is tantamount to considering a ''*semitopological*'' *field theory where both the invariance under* $\mathrm{T}\mathscr{G}$ *and the independency of the choice of the tangent vector* $\eta\in \mathrm{T}_A\mathscr{A}$ *is considered*.

To turn around the problem of the nonfreedom of (VI.5) we proceed along the same lines of the previous section.

First, we consider the pulled-back bundle $j_A^*\mathrm{T}\mathscr{A}$ and pull back to it the 1-form (c,ξ) (again without changing notation).

Now, as in (VI.4), c becomes the Maurer–Cartan form on $\mathscr{G}$, but ξ, differently from (VI.4), does not become any more the second component of the Maurer–Cartan form on $\mathrm{T}\mathscr{G}$. The form ξ is defined as in (V.5), provided that the connection on P belongs to the $\mathscr{G}$-orbit passing through A.

The corresponding pulled-back ''connection'' on the bundle

$$P\times j_A^*\mathrm{T}\mathscr{A}\mapsto M\times j_A^*\mathrm{T}\mathscr{A}, \tag{VI.7}$$

is written again as

$$(A+c,\eta+\xi) \tag{VI.8}$$

and the corresponding ''curvature'' is

$$(F_A, d_A\eta + \tilde{\psi} + \tilde{\phi}). \tag{VI.9}$$

The Bianchi identities become

$$[d_{(A,\eta)} \pm \delta_{(c,\xi)}](F_A, d_A\eta + \tilde{\psi} + \tilde{\phi}) = 0$$

and altogether we obtain (see Ref. 1)

Theorem VI.1: *The transformation laws for the set of fields* $A,\eta,c,\xi,\tilde{\psi},\tilde{\phi}$ *given by the components of the connection (VI.8) and of the curvature (VI.9) are as follows*:

$$\delta A = d_A c, \tag{VI.10}$$

$$\delta\eta = -\tilde{\psi} + d_A\xi + [\eta,\ c], \tag{VI.11}$$

$$\delta F_A = [F_A,\ c], \tag{VI.12}$$

$$\delta(d_A\eta) = -d_A\tilde{\psi} + [F_A,\ \xi] + [d_A\eta,\ c], \tag{VI.13}$$

$$\delta c = -\tfrac{1}{2}[c,\ c], \tag{VI.14}$$

$$\delta\xi = \tilde{\phi} - [c,\ \xi], \tag{VI.15}$$

$$\delta\tilde{\psi} = -[\tilde{\psi},\ c] + d_A\tilde{\phi}, \tag{VI.16}$$

$$\delta\tilde{\phi} = [\tilde{\phi},\ c]. \tag{VI.17}$$

By comparing (VI.10), (VI.11) with (VI.5) we see that also this last BRST operator δ allowed us to overcome the problem of the lack of freedom of (VI.5). We have still to find how to read in our BRST complex the transformations of the field B corresponding to the action (VI.6). This will accomplished in the next section.

VII. A BRST COMPLEX THAT INCLUDES 2-FORMS

Now we will show that the BRST operator δ can consistently be extended to an operator s satisfying $s^2=0$ and that a double complex with operators (d,s) can be constructed with the following properties:

(1) s acts on the space $\Omega^2(M,\mathrm{ad}\ P)$;
(2) the gauge-equivariance is preserved, and
(3) the equations considered in Theorem VI.1 are preserved.

We use the synthetic notation $\mathscr{B} \triangleq \Omega^2(M,\mathrm{ad}\ P)$ and consider the tangent bundle $\mathrm{T}\mathscr{B} \sim \Omega^2(M,\mathrm{ad}\ P)\times\Omega^2(M,\mathrm{ad}\ P)$.

The group $\mathscr{G}$ acts on $\mathscr{A}\times\mathscr{B}$ yielding a $\mathscr{G}$-principal bundle. Moreover, the tangent map to the above action gives $\mathrm{T}\mathscr{A}\times\mathrm{T}\mathscr{B}$ the structure of a $\mathrm{T}\mathscr{G}$-principal bundle.

Explicitly this last action is given by

$$(A,\eta;C,E)\cdot(g,\zeta) = (A^g, \mathrm{Ad}_{g^{-1}}\eta + d_{A^g}\zeta; \mathrm{Ad}_{g^{-1}}C, \mathrm{Ad}_{g^{-1}}E + [\mathrm{Ad}_{g^{-1}}C,\ \zeta]). \tag{VII.1}$$

It is evident that the projection $\mathscr{A}\times\mathscr{B}\mapsto\mathscr{A}$ is a morphism of $\mathscr{G}$-bundles. Therefore, the connection c on (II.3) can also be considered as a connection on $\mathscr{A}\times\mathscr{B}$, and the connection (c,ξ) on (V.2) is also a connection on $\mathrm{T}\mathscr{A}\times\mathrm{T}\mathscr{B}$.

Moreover, $(A+c,\eta+\xi)$ is a (pulled-back) $(\mathfrak{g}\oplus_s\mathfrak{g})$-valued connection on the bundle

$$P\times\mathrm{T}\mathscr{A}\times\mathrm{T}\mathscr{B}\mapsto M\times\mathrm{T}\mathscr{A}\times\mathrm{T}\mathscr{B}. \tag{VII.2}$$

The corresponding covariant exterior derivative is given by (V.7). Forms on $P\times\mathrm{T}\mathscr{A}\times\mathrm{T}\mathscr{B}$ will be characterized by three indices (m,e,p) which represent the degree with respect to the three spaces P, $\mathrm{T}\mathscr{A}$, $\mathrm{T}\mathscr{B}$. The integer e is, as before, called the *ghost number*.

The pair $(C,E)\in\mathrm{T}\mathscr{B}$ is a $(\mathfrak{g}\oplus_s\mathfrak{g})$-valued (2,0,0)-form that is independent of $\mathrm{T}\mathscr{A}$.

We assume Convention i and Convention ii, and also the following:

Convention iii: We will omit the components of the forms on $P\times\mathrm{T}\mathscr{A}\times\mathrm{T}\mathscr{B}$ which have a degree higher than 0 as forms on $\mathrm{T}\mathscr{B}$.

Under the action of the covariant exterior derivative (V.7), the pair (C,E) is transformed into

$$(d_AC + [c,\ C], d_AE + [\eta,\ C] + [c,\ E] + [\xi,\ C]), \tag{VII.3}$$

owing to the fact that (C,E) does not depend on the space $\mathscr{A}$.

Definition VII.1: We define s to be equal to δ when computed on forms over $P\times\mathrm{T}\mathscr{A}$; moreover, we set for $(C,E)\in\mathrm{T}\mathscr{B}$,

$$s(C,E)\triangleq([C,c],[C,\xi]+[E,c]). \tag{VII.4}$$

We have hence set $s(C,E)$ to be equal, up to a sign, to $\delta_{(c,\xi)}(C,E)$. This takes care of requirement 2 (preservation of gauge-equivariance).

As a consequence we have

$$\delta^2_{(c,\xi)}(C,E)=[(\phi,\tilde{\phi}),(C,E)]=([\phi,C],[\tilde{\phi},C]+[\phi,E]),$$

where $(\phi,\tilde{\phi})$ is the curvature of the connection (c,ξ) on the $\mathrm{T}\mathscr{G}$ bundle $\mathrm{T}\mathscr{A}$. Here Convention i and Convention ii are always assumed.

In conclusion we have:

Theorem VII.2: *Let us assume Definition VII.1. The operator s is nilpotent in the following cases*:

(1) *always in the case of Eqs. (VI.4)*;
(2) *never in the case of the equations of Theorem V.4*;
(3) *only when pairs* $(0,E)\in \mathrm{T}_0\mathscr{B}$ *are considered in the case of the equations of Theorem VI.1*.

Remark VII.3: The reason why, when we consider the bundle (VII.2), we have nontrivial solutions for the compatibility problem of Theorem VII.2, is the fact that $\{1\}\times\mathfrak{g}\triangleleft G\ltimes\mathfrak{g}$ *in an Abelian normal subgroup.*

We now translate the field E and define

$$B\equiv E+d_A\eta. \tag{VII.5}$$

By combining (VI.13) with (VII.4) we find the following transformation property of B (see Refs. 1 and 9):

$$sB=-d_A\tilde{\psi}+[F_A,\xi]+[B,c]. \tag{VII.6}$$

Equation (VII.6) may be added to Eqs. (VI.10)→(VI.17), namely,

$$sA=d_Ac,\quad s\eta=-\tilde{\psi}+d_A\xi+[\eta,c],$$

$$sc=-\tfrac{1}{2}[c,c],\quad s\xi=\tilde{\phi}-[c,\xi],$$

$$s\tilde{\psi}=-[\tilde{\psi},c]+d_A\tilde{\phi},\quad s\tilde{\phi}=[\tilde{\phi},c].$$

While E is an element of $\mathrm{T}_0\mathscr{B}$, B is naturally an element of $\mathrm{T}_{F_A}\mathscr{B}$. In particular, triples (A,η,B) are elements of the pulled-back bundle,

$$K^*(\mathrm{T}\mathscr{A}\times\mathrm{T}\mathscr{B}),$$

where K is the curvature map

$$K:\mathscr{A}\mapsto\mathscr{A}\times\mathscr{B},\quad K(A)\triangleq(A,F_A). \tag{VII.7}$$

As a final remark, notice that once again we have overcome the problem of the lack of freedom of (VI.6).

VIII. INFINITE BRST SYMMETRIES

The procedure of the previous two sections can be iterated, so as to incorporate an arbitrary number of fields. More precisely, given any integer n we can construct field equations, similar to those considered in the previous section, depending on a connection A, on 2^n-1 fields $\gamma_i\in\Omega^1(M,\mathrm{ad}\,P)$, on 2^n fields $\eta_i\in\Omega^1(M,\mathrm{ad}\,P)$, on 2^n fields $B_i\in\Omega^2(M,\mathrm{ad}\,P)$, and on the relevant ghost-fields.

A binary notation turns out to be helpful to describe iterated tangent spaces. In fact given a manifold M we will describe an element $\mathbf{X}\in\mathrm{T}^nM$ by a 2^n-tuple as follows:

$$\mathbf{X} = \left(X_{\underbrace{0\ldots00}_{n-\text{times}}}, X_{\underbrace{0\ldots01}_{n-\text{times}}}, X_{\underbrace{0\ldots10}_{n-\text{times}}}, \ldots, X_{\underbrace{1\ldots11}_{n-\text{times}}} \right).$$

For instance in the case $n=3$, X_{000} denotes a point of M, (X_{000},X_{001}) denotes a point in $\mathrm{T}M$, $(X_{000},X_{001},X_{010},X_{011})$ denotes a point in $\mathrm{TT}M$ whose tangent vector is represented by $(X_{100},X_{101},X_{110},X_{111})$.

Elements in $\mathrm{Lie}(\mathrm{T}^nG)$ can analogously be represented as 2^n-tuples $\xi=(\xi_{i_{1,\ldots,i_n}})$, where each index i_p can be either 0 or 1, $\forall p\in\{1,\ldots,n\}$.

We now want to describe the bracket in $\mathrm{Lie}(\mathrm{T}^nG)$ induced by the bracket in $\mathfrak{g}$. We have

Theorem VIII.1: *The Lie bracket of* $\boldsymbol{\xi}$ *and* $\boldsymbol{\eta}$ *in* $\mathrm{Lie}(\mathrm{T}^nG)$ *is given by*

$$[\boldsymbol{\xi},\boldsymbol{\eta}]_{i_1\cdots i_n}=\sum_{j_i+k_i=i_i}[\xi_{j_1\cdots j_n},\eta_{k_1\cdots k_n}], \tag{VIII.1}$$

where the previous notation is understood.

Proof of Theorem VIII.1: We will prove (VIII.1) by induction on n. Formula (VIII.1) holds for $n=0$, i.e., for $\mathfrak{g}$. We assume now that it is true for n. We can represent any element $\boldsymbol{\xi}$ of $\mathrm{Lie}(\mathrm{T}^{n+1}G)$ as $(\xi_{0j_1\cdots j_n},\xi_{1j_1\cdots j_n})$ where the first component represents the base point in $\mathrm{Lie}(\mathrm{T}^nG)$, while the second component represents the relevant tangent vector. We can therefore use the expression of the bracket for $\mathrm{Lie}(\mathrm{T}G)\sim\mathfrak{g}\oplus_s\mathfrak{g}$ thus getting

$$[(\xi_{0j_1\cdots j_n},\xi_{1j_1\cdots j_n}),(\eta_{0k_1\cdots k_n},\eta_{1k_1\cdots k_n})]=([\xi_{0j_1\cdots j_n},\eta_{0k_1\cdots k_n}],[\xi_{0j_1\cdots j_n},\eta_{1k_1\cdots k_n}]+[\xi_{1j_1\cdots j_n},\eta_{0k_1\cdots k_n}]).$$

Therefore,

$$[\boldsymbol{\xi},\boldsymbol{\eta}]_{i_0i_1\cdots i_n}=\sum_{j_i+k_i=i_i}[\xi_{j_0j_1\ldots j_n},\ \eta_{k_0k_1\ldots k_n}].$$

□

We now take into account the iterated gauge group $\mathrm{T}^n\mathscr{G}$.

We can consider the Maurer–Cartan form for $\mathrm{T}^n\mathscr{G}$. This is a form with values in $\mathrm{Lie}(\mathrm{T}^n\mathscr{G})$, so it can be represented by a vector $\mathbf{c}$ with 2^n components each having ghost number one.

We set $c_0\equiv c_{0\cdots0}$, and $c_I\equiv c_{i_1\cdots i_n}$ for $I=\{i_1,\ldots,i_n\}\neq\{0\ldots0\}$, and define $I+J\triangleq\{i_1+j_1,\ldots,i_n+j_n\}$ (*not* modulo 2).

The *Maurer–Cartan* equations are as follows:

$$\delta c_0=-\tfrac{1}{2}[c_0,c_0], \tag{VIII.2}$$

$$\delta c_I=-\frac{1}{2}\sum_{J+K=I}[c_J,\ c_K]. \tag{VIII.3}$$

The group $\mathrm{T}^n\mathscr{G}$ acts (freely) on the iterated tangent space $\mathrm{T}^n\mathscr{A}$. We denote the corresponding fiber imbedding by

$$j^{(n)}_{A,\boldsymbol{\gamma}}:\mathrm{T}^n\mathscr{G}\to\mathrm{T}^n\mathscr{A},$$

where (A,γ) represents an element of $\mathrm{T}^n\mathscr{A}$ with $\boldsymbol{\gamma}\in\Omega^1(M,\mathrm{ad}\,P)^{\times 2^n-1}$.

In this section we consistently apply Convention i, Convention ii, and Convention iii. The equations describing the infinitesimal action of $\mathrm{T}^n\mathscr{G}$ and corresponding to (VI.4) are as follows:

$$\delta A=d_Ac_0, \tag{VIII.4}$$

$$\delta\gamma_I = d_A c_I + \sum_{J+K=I} [\gamma_J,\ c_K]. \tag{VIII.5}$$

In analogy with (VI.7) we apply the tangent functor once more and consider the bundle

$$P\times (j^{(n)}_{A,\boldsymbol{\gamma}})^*\mathrm{T}(\mathrm{T}^n\mathscr{A}) \to M\times (j^{(n)}_{A,\boldsymbol{\gamma}})^*\mathrm{T}(\mathrm{T}^n\mathscr{A}). \tag{VIII.6}$$

We have a vector $\boldsymbol{\eta}$ with 2^n components in $\Omega^1(M,\mathrm{ad}\,P)$ with ghost number zero and a vector $\boldsymbol{\xi}$ with 2^n components in $\Omega^0(M,\mathrm{ad}\,P)$ with ghost number one. In analogy with (VI.8) on (VIII.6) we have a (pulled-back) connection [We have to keep in mind that each of the four vectors $(A,\boldsymbol{\gamma});\boldsymbol{\eta};\mathbf{c};\boldsymbol{\xi}$ is a form on $P\times T^n\mathscr{A}$ with values in $\mathrm{Lie}(\mathrm{T}^nG)$.]

$$((A,\boldsymbol{\gamma})+\mathbf{c},\boldsymbol{\eta}+\boldsymbol{\xi}) \tag{VIII.7}$$

with values in $\mathrm{Lie}(\mathrm{T}^{n+1}G)$.

The curvature of (VIII.7) is given by

$$(F_A + d_A\boldsymbol{\gamma} + \tfrac{1}{2}[\boldsymbol{\gamma},\ \boldsymbol{\gamma}], d_A\boldsymbol{\eta} + [\boldsymbol{\gamma},\ \boldsymbol{\eta}] + \tilde{\boldsymbol{\psi}} + \tilde{\boldsymbol{\phi}}), \tag{VIII.8}$$

where the Ith component of the vector $[\boldsymbol{\gamma},\boldsymbol{\eta}]$ is defined to be $\Sigma_{J+K=I}[\gamma_J,\eta_K]$, the vector $\tilde{\boldsymbol{\psi}}$ has 2^n components in $\Omega^1(M,\mathrm{ad}\,P)$ and ghost number one, while the vector $\tilde{\boldsymbol{\phi}}$ has 2^n components, respectively, in $\Omega^0(M,\mathrm{ad}\,P)$ and ghost number two.

The results of the previous section, suggest us to introduce a vector $\mathbf{B}$ with 2^n components in $\Omega^2(M,\mathrm{ad}\,P)$ and ghost number zero.

By performing calculations similar to those carried on in the proof of Theorem VI.1 and (VII.6), we obtain the following:

Theorem VIII.2: The transformations for the set of fields A, $\boldsymbol{\gamma}$, $\boldsymbol{\eta}$, $\mathbf{c}$, $\boldsymbol{\xi}$, $\tilde{\boldsymbol{\psi}}$, $\tilde{\boldsymbol{\phi}}$, $\mathbf{B}$ *are given by (VIII.2), (VIII.3), (VIII.4), (VIII.5), and*

$$\delta\eta_I = -\tilde{\psi}_I + d_A\xi_I + \sum_{J+K=I}[\gamma_J,\ \xi_K] + \sum_{J+K=I}[\eta_J,\ c_K], \tag{VIII.9}$$

$$\delta B_I = -d_A\tilde{\psi}_I - \sum_{J+K=I}[\gamma_J,\ \tilde{\psi}_K] + [F_A,\ \xi_I] + \sum_{J+K=I}[d_A\gamma_J,\ \xi_K] + \sum_{J+K=I}[B_J,\ c_K], \tag{VIII.10}$$

$$\delta\xi_I = \tilde{\phi}_I - \sum_{J+K=I}[c_J,\ \xi_K], \tag{VIII.11}$$

$$\delta\tilde{\psi}_I = -\sum_{J+K=I}[\tilde{\psi}_J,\ c_K] + d_A\tilde{\phi}_I + \sum_{J+K=I}[\gamma_J,\ \tilde{\phi}_K], \tag{VIII.12}$$

$$\delta\tilde{\phi}_I = \sum_{J+K=I}[\tilde{\phi}_J,\ c_K]. \tag{VIII.13}$$

IX. THE BATALIN–VILKOVISKY ALTERNATIVE: TOPOLOGICAL *BF* THEORIES

In Secs. VI and VII we have considered the BRST structure of a field theory with fields $(A,\eta)\in\mathrm{T}\mathscr{A}$ and $B\in\mathscr{B}$ that is gauge invariant and can be considered *topological* only as far as the translations of the field η are concerned. Equivalently such a theory admits, as its basic symmetry group, the group $\mathscr{G}_{\mathrm{aff}}$.

For a full topological BF field theory, where translations in the space $\mathscr{A}$ have to be included as symmetries, one should consider instead the action of the group $\mathscr{G}_T$ on $\mathscr{A}$ given by (II.2) and extended to $\mathscr{A}\times\mathscr{B}$ as follows:

$$(A,B)\cdot(g,\tau) = (A^g+\tau, \mathrm{Ad}_{g^{-1}}B - d_{A^g}\tau - \tfrac{1}{2}[\tau,\ \tau]). \tag{IX.1}$$

Notice that (IX.1) implies that the action of $\mathscr{G}_{\mathrm{T}}$ on $B+F_A$ is simply the adjoint action of $\mathscr{G}$.

An example of such a theory is given by the action functional (I.2) when $t=1$, i.e., by

$$S_{BF,1}=\int_M \mathrm{Tr}(F_A\wedge B+\tfrac{1}{2}B\wedge B). \tag{IX.2}$$

Again the action (IX.1) is not free, but now this problem cannot be solved by considering the coboundary (BRST) operator of a principal bundle.

In fact one would have to extend the coboundary operator δ defined on (II.4) to a nilpotent operator s acting on B, while preserving the gauge equivariance.

This would mean to consider a covariant derivative acting on $\mathscr{B}$ corresponding to a connection c on $\mathscr{A}$. The requirement of the nilpotency of such an operator would then be equivalent to the requirement that, for any $B\in\mathscr{B}$, the following condition should hold:

$$[\phi,\ B]=0, \tag{IX.3}$$

where ϕ is the curvature of c.

But we know that condition (IX.3) is not satisfied.

The so-called Batalin–Vilkovisky mechanism[10] now comes into the picture by providing us with a nilpotent coboundary operator that has the same properties of a coboundary operator for a principal bundle.

The price we have to pay is that we have to introduce fields with negative ghost-number or, equivalently, that we have to consider fields that depend explicitly on the (functional integral with respect to the) action that we are considering.

The functional integral *formally* provides us with a volume form on the space of fields

$$\omega\equiv\exp(-S)*1\equiv\exp(-S)\Pi_x\mathscr{D}A(x)\mathscr{D}B(x), \tag{IX.4}$$

where S is the action functional (IX.2). The understanding that such a volume form exists is at the heart of the Batalin–Vilkovisky mechanism, which is the same to say that the Batalin–Vilkovisky mechanism is a device that allows *integration by parts in field theories*.

Let us denote by $\mathfrak{F}$ the ''manifold'' given by $\Pi_j\Pi_{x\in M}\mathscr{F}_j(x)$, where $\{\mathscr{F}_j\}$ is the set of all fields of the theory (e.g., $A^b,B^c,c^a,\psi^d,\phi^e$, with c,ψ,ϕ being defined as in Sec. II) and the indices a,b,c,d,e labeling a basis for the Lie algebra $\mathfrak{g}$. We work here in local coordinates as far as the bundle $P(M,G)$ is concerned.

We denote by the symbol B^* the ($\mathfrak{g}$-valued) contraction with respect to the vector field corresponding to the coordinate $B^a(x)$, $x\in M$ of the ''manifold'' $\mathfrak{F}$. Namely, we set

$$(B^*)^a\triangleq\frac{\partial}{\partial B^a(x)}. \tag{IX.5}$$

Being the ghost number defined as the degree of a form on $\mathfrak{F}$ (and particularly on the space of connections $\mathscr{A}$), a vector field on $\mathfrak{F}$ will have ghost number -1. More generally, given a field σ with form degree k (on M) and ghost number s, its antifield σ^* will have form degree $4-k$ and ghost number $-s-1$. The duality between the σ and σ^* will be given by the following condition:

$$\{(\sigma^*)^a(x),\sigma^b(y)\}=\delta^a_b\delta(x-y),$$

where the Dirac volume form δ on M has been used, and $\{\cdot,\cdot\}$ denotes the Poisson bracket for the cotangent bundle $T^*\mathfrak{F}$, which is mapped onto the tangent bundle via the metric (which gives the $*$-operator).

We now denote by δ the exterior derivative on $\mathfrak{F}$. By definition of B^* we have

$$\delta(B^*(*1))=0$$

and so

$$\delta(B^*\omega)=(-B(x)-F_A(x))\omega;$$

in other words we have the formal equation

$$\delta(B^*) = -B - F_A .$$

If we require equivarance, i.e., if we want to take into account the action of the group of gauge transformations $\mathscr{G}$, then we have to replace the exterior derivative with the covariant exterior derivative which we denote again by the symbol s. So we have

$$s(B^*) = -B - F_A - [B^*, c],$$

and the ensuing transformation

$$sB = [B,\ c] + d_A\psi - [B^*,\ \phi]. \tag{IX.6}$$

It is interesting to compare (IX.6) with (VII.6). The main difference between the two equations is that, in the second case, the operator s applied to B produces *only fields*, while it produces *both fields and antifields* in the first case. In the BV mechanism, antifields are added so to render the operator s nilpotent, i.e., so as to formally reconstruct a BRST operator. This is the case of the topological BF theory. On the contrary, in the BFYM theory, antifields are unnecessary since the BRST operator is nilpotent per se.

From the previous equations we have

$$\int [(B + F_A)\omega]\mathscr{D}\mathrm{A}\mathscr{D}B = 0,$$

and in particular,

$$\frac{\partial \exp S}{\partial B} \approx 0,$$

$$\begin{aligned} F_A \exp(-S) &= \exp\left(-\frac{1}{2}\int_M \mathrm{Tr}(B\wedge B)\right) B^*\left[\exp\left(-\int_M \mathrm{Tr}(B\wedge F_A)\right)\right] \\ &\approx -\exp\left(-\int_M \mathrm{Tr}(B\wedge F_A)\right) B^*\left[\exp\left(-\frac{1}{2}\int_M \mathrm{Tr}(B\wedge B)\right)\right] \\ &= -B\ \exp(-S), \end{aligned}$$

where $\approx$ means up to a total derivative. When the action functional is the topological BF action functional (IX.2), then $B^*(x)$ is equivalent to the transformation (concentrated at x)

$$F_A(x) \rightsquigarrow -B(x). \tag{IX.7}$$

We now include the fields (with negative ghost number) A^*, c^*, ψ^*, ϕ^* conjugate respectively to A, c, ψ, ϕ. The BV equations are written in the following double-complex:

4				$sc^* = [c^*,c] - d_A A^* + [B^*,B] - [\psi^*,\psi] - [\phi^*,\phi]$	$c^* = s\phi^* + [\phi^*,c] + d_A\psi^* + \frac{1}{2}[B^*,B^*]$	ϕ^*
3			$sA^* + [A^*,c] = -d_A B - [B^*,\psi] + [\psi^*,\phi]$	$A^* = -s\psi^* + [\psi^*,c] + d_A B^*$	ψ^*	
2		$sB + [c,B] = d_A\psi + [B^*,\phi]$	$-B = sB^* + [B^*,c] + F_A$	B^*		
1	$-s\psi - [c,\psi] = -d_A\phi$	$\psi = d_A c - sA$	A			
0	$\phi = sc + \frac{1}{2}[c,c]$	c				
	2	1	0	-1	-2	-3
			s			

The degrees corresponding to rows and columns in the above diagrams are, respectively, the form degree and the ghost number. Notice that the form

$$c+A+B^*+\psi^*+\phi^*$$

is formally a ''connection'' with ''curvature''

$$\phi+\psi-B+A^*+c^*.$$

So the field B^* allows the replacement, in the BV complex, of F_A with $-B$ in the structure equations. This is consistent with transformation (IX.7) and with integration by parts in the functional integral.

At the critical point $B=-F_A$, or equivalently, if we set $B^*=0$, we obtain, from the previous complex, Eqs. (II.9) and (II.10).

In conclusion topological field theories of the cohomological type are described by the structure equations and the Bianchi identities of a suitable bundle whose cohomology is some kind of equivariant cohomology. In topological field theories which are not of cohomological type, the above description is not possible, but the BV mechanism, with the introduction of fields with negative ghost number, allows us to recover, formally *off-shell*, the algebraic structure of equivariant cohomology.

X. GAUGE FIXING AND ORBITS

In this section we would like to report briefly on the gauge-fixing problem for the action functional (I.4).

The results of Secs. VI and VII imply that we have an exact BRST symmetry when we consider the space of fields $K^*(\mathrm{T}.\mathscr{A}\times\mathrm{T}.\mathscr{B})$ and the symmetry group $\mathrm{T}.\mathscr{G}$.

The action (I.4) is invariant under $\mathscr{G}_{\mathrm{aff}}$ and hence under its subgroup $\mathrm{T}.\mathscr{G}$.

So the action (I.4) is naturally defined on the space

$$\frac{K^*(\mathrm{T}.\mathscr{A}\times\mathrm{T}.\mathscr{B})}{\mathrm{T}.\mathscr{G}}=K^*\left(\frac{\mathrm{T}.\mathscr{A}\times\mathrm{T}.\mathscr{B}}{\mathrm{T}.\mathscr{G}}\right);$$

the last identity is a consequence of the fact that the curvature map K (VII.7) commutes with the action of $\mathscr{G}$ and hence descends to a map

$$K\colon \frac{\mathscr{A}}{\mathscr{G}}\to\frac{\mathscr{A}\times.\mathscr{B}}{\mathscr{G}}.$$

We notice that the following bundles are isomorphic:

$$\frac{K^*(\mathrm{T}.\mathscr{A}\times\mathrm{T}.\mathscr{B})}{\mathrm{T}.\mathscr{G}}\simeq\frac{K^*(\mathrm{H}.\mathscr{A}\times\mathrm{T}.\mathscr{B})}{\mathscr{G}},\tag{X.1}$$

the isomorphism being induced by the linear map

$$[A,\eta,B]_{\mathrm{T}.\mathscr{G}}\rightsquigarrow[A,\eta^{\mathrm{H}},B-d_A\eta^{\mathrm{V}}]_{\mathscr{G}}.\tag{X.2}$$

Here $\mathrm{H}.\mathscr{A}$ denotes the horizontal bundle defined by a connection c on $\mathscr{A}$ and the superscript V and H denote respectively the vertical and the horizontal projections.

In order to show that this map is well-defined on the equivalence classes we compute

$$\begin{aligned}&(A^g,\mathrm{Ad}_{g^{-1}}\eta+d_A\xi,\mathrm{Ad}_{g^{-1}}B+[F_{A^g},\xi])\\&\quad\rightsquigarrow(A^g,(\mathrm{Ad}_{g^{-1}}\eta)^{\mathrm{H}},\mathrm{Ad}_{g^{-1}}B+[F_{A^g},\xi]-d_{A^g}((\mathrm{Ad}_{g^{-1}}\eta)^{\mathrm{V}}+d_{A^g}\xi))\\&\quad=(A^g,(\mathrm{Ad}_{g^{-1}}\eta)^{\mathrm{H}},\mathrm{Ad}_{g^{-1}}B-\mathrm{Ad}_{g^{-1}}(d_A\eta^{\mathrm{V}})).\end{aligned}$$

It is immediate to check that (X.2) is injective and surjective.

The action functional (I.4) is also invariant under the subgroup of $\mathscr{G}_{\text{aff}}$ given by the translations by $\Omega^1(M,\text{ad } P)$,

$$(A,\eta,B)\rightsquigarrow(A,\eta+\tau,B+d_A\tau) \quad \tau\in\Omega^1(M,\text{ad } P). \tag{X.3}$$

When our space of fields is represented by $[K^*(\mathrm{H}\mathscr{A}\times\mathrm{T}\mathscr{B})]/\mathscr{G}$, then we have to consider triples (A,η,B) with $\eta\in\mathrm{H}_A\mathscr{A}$. The action (X.3) now becomes

$$(A,\eta,B)\rightsquigarrow(A,\eta+\tau^{\mathrm{H}},B+d_A\tau^{\mathrm{H}}) \quad \tau\in\Omega^1(M,\text{ad } P). \tag{X.4}$$

The above action is of course not free, but the space of orbits is still a manifold, namely it is

$$\frac{\mathscr{A}\times\mathscr{B}}{\mathscr{G}}\sim\frac{K_2^*\mathrm{T}\mathscr{B}}{\mathscr{G}}, \tag{X.5}$$

where K_2 denotes the second component of the curvature map (VII.7).

Different gauges are possible to describe the above orbit spaces. Let us clarify first what we mean by ''choice of the gauge'' in the present framework.

We have the vector bundle

$$\mathscr{V}\triangleq K^*(\mathrm{H}\mathscr{A}\times\mathrm{T}\mathscr{B})\to\mathscr{A} \tag{X.6}$$

which is isomorphic to the vector bundle

$$(\mathrm{H}\mathscr{A}\times\mathscr{B})\to\mathscr{A}.$$

The $\mathscr{G}$-invariant fiber metric in $\mathrm{H}\mathscr{A}$ and in $\mathscr{B}$ induces a $\mathscr{G}$-invariant fiber metric in $\mathscr{V}$.

Fixing a gauge means finding a vector bundle $\mathscr{W}$ so that we have a $\mathscr{G}$-equivariant splitting

$$\mathscr{V}=\mathrm{H}\mathscr{A}\oplus\mathscr{W}.$$

The first obvious choice is to choose

$$\mathscr{W}=\mathscr{A}\times\mathscr{B}. \tag{X.7}$$

In other words the gauge condition reads: $\eta=0$, meaning that the elements of $\mathscr{W}$ have zero projection on $\mathrm{H}\mathscr{A}$. We refer to the above gauge as to the *trivial gauge*.

In order to discuss the second choice of the gauge, we restrict A to belong to the open subset of $\mathscr{A}$, where the dimension of the space $\mathrm{Harm}^1_A(M,\text{ad } P)$ of harmonic 1-forms has the lowest dimension (possibly zero). Let us denote this open set by the symbol $\hat{\mathscr{A}}$.

The symmetry (X.4) indicates that we have at our disposal a second gauge fixing, namely, we can impose on B the following condition $\langle B,d_A\eta\rangle=0$, i.e., $\langle d_A^*B,\eta\rangle=0$, $\forall\,\eta\in\mathrm{H}\mathscr{A}$. Here $\langle\cdot,\cdot\rangle$ denotes the inner product in $\Omega^*(M,\text{ad } P)$.

Our second gauge fixing is then a condition on both η and $B\in\mathscr{B}$; namely, we require $\eta\in\mathrm{H}_A\hat{\mathscr{A}}$ and $B\in\hat{\mathscr{B}}$, where $\hat{\mathscr{B}}$ is a vector bundle of 2-forms over $\hat{\mathscr{A}}$ defined by the condition

$$\hat{\mathscr{B}}_A\triangleq\{B\in\mathscr{B}\,|\,d_A^*B\in\ \mathrm{Im}(d_A|_{\Omega^0(M,\text{ad } P)})\}. \tag{X.8}$$

This choice corresponds to defining

$$\mathscr{W}_A=(\mathrm{H}_A\hat{\mathscr{A}}\ominus\mathrm{Harm}^1_A(M,\text{ad } P))\oplus\hat{\mathscr{B}}_A\,.$$

Notice that the orthogonal projection of $\mathscr{W}_A$ on $\mathrm{H}_A\hat{\mathscr{A}}$ is not any more zero, but it is given by the orthogonal complement of the harmonic 1-forms.

We refer to the above gauge as the *covariant gauge*.

Finally we consider the *self-dual gauge*.

We start by considering the projection on self-dual 2-forms;[11] $P_+:\Omega^2(M,\text{ad } P)\to\Omega^2(M,\text{ad } P)^+$. We now restrict ourselves to the open set of connections where the operator $D_A\triangleq\sqrt{2}P_+d_A:\Omega^1(M,\text{ad } P)\to\Omega^2(M,\text{ad } P)^+$ is surjective. We denote by $\tilde{\mathscr{A}}$ such an open set.

If we define also

$$D_A \triangleq \sqrt{2} d_A : \Omega^2(M, \mathrm{ad}\ P)^+ \to \Omega^3(M, \mathrm{ad}\ P)$$

and

$$D_A \triangleq d_A : \Omega^0(M, \mathrm{ad}\ P) \to \Omega^1(M, \mathrm{ad}\ P),$$

then we can consider the forms that are harmonic with respect to the operator D_A, for which we use the notation $\widetilde{\mathrm{Harm}}^*_A(M, \mathrm{ad}\ P)$.

The self-dual gauge condition is now defined as follows: $\eta \in \mathrm{H}_A \cdot \widetilde{\mathscr{A}}$ and $P_+ B = 0$.

In this way we have defined

$$\mathscr{W}_A = (\mathrm{H}_A \cdot \widetilde{\mathscr{A}} \ominus \widetilde{\mathrm{Harm}}^1_A(M, \mathrm{ad}\ P)) \oplus \cdot \mathscr{B}^-,$$

where $\mathscr{B}^-$ is the space of anti-self-dual elements of $\mathscr{B}$.

Again the orthogonal projection of $\mathscr{W}_A$ on $\mathrm{H}_A \cdot \hat{\mathscr{A}}$ is not zero, but it is given by the orthogonal complement of the 1-forms that are harmonic with respect to the operator D_A.

Finally, we consider the equations of motion relevant to the action functional (I.4) and the corresponding extrema.

Taking the directional derivatives at (A, η, B) in the directions (τ, μ, C) we get the equations

$$-t\langle [\tau, \eta], B - d_A \eta \rangle + \langle B, *d_A \tau \rangle = 0,$$

$$\langle d_A \mu, B - d_A \eta \rangle = 0,$$

$$t\langle C, B - d_A \eta \rangle + \langle C, *F \rangle = 0.$$

Noticing that

$$\langle [\tau, \eta], U \rangle = -\langle \tau, *[*U, \eta] \rangle$$

for a generic 2-form U, we get

$$t[*B - *d_A \eta, \eta] + d_A B = 0,$$

$$d_A^*(B - d_A \eta) = 0,$$

$$t(B - d_A \eta) + *F_A = 0.$$

Owing to the Bianchi identity, the second equation is redundant and the first equation is equivalent to the Yang–Mills equation $d_A^* F_A = 0$. In summary, the equations of motions of (I.4) read

$$\begin{aligned} d_A^* F_A &= 0, \\ t(B - d_A \eta) + *F_A &= 0. \end{aligned} \tag{X.9}$$

At $t = 1$ the action functional (I.4) reads

$$S_{BF\mathrm{YM}, \eta} = \tfrac{1}{2}\langle B - d_A \eta + *F_A, B - d_A \eta + *F_A \rangle - \mathrm{YM}(A). \tag{X.10}$$

The points (A, η, B) satisfying the equation

$$B = d_A \eta - *F_A \tag{X.11}$$

are the minima of (X.10) once we have fixed the connection A.

When the condition (X.11) is satisfied, then (X.10) reduces to the Yang–Mills action functional (up to a sign).

XI. CONCLUSIONS

In this paper we have first discussed the differential geometry of the tangent bundle TP of a G-principal bundle P. It is known that TP is a TG-principal bundle.

We have shown that the group of gauge transformations of TP includes, as a proper subgroup, the tangent gauge group T$\mathcal{G}$, namely, the tangent bundle of the group of gauge transformations on P.

The tangent gauge group acts on the tangent bundle of the space of connections $\mathcal{A}$ of P, and we have identified this tangent bundle with a subspace of the space of connections of TP.

Then we have considered topological and nontopological quantum field theories that admit the tangent gauge group as their symmetry group.

It is known that:

(A) The structure equations and the Bianchi identities for the bundle

$$\frac{P\times\mathcal{A}}{\mathcal{G}}$$

can be interpreted as the BRST equations for a topological quantum field theory (see Ref. 3).

(B) By taking the restriction along a $\mathcal{G}$-fiber of the bundle $P\times\mathcal{A}$, one obtains from the above structure equations the BRST equations for the Yang–Mills theory.

In this paper we have first applied the ''tangent functor'' to the above cases (A) and (B). Moreover, a special mixing of these two cases has been considered by taking the restriction to the $\mathcal{G}$-orbit of the bundle T$P\times$T$\mathcal{A}$.

In this way we have defined a theory that is ''topological'' when we consider the fields that are represented by tangent vectors to $\mathcal{A}$ and coincides with the Yang–Mills theory when we consider the connection itself.

The remarkable fact is that, in the above ''semitopological'' theory, one is able to extend the BRST operator to fields represented by 2-forms. In other words one is allowed to consider field theories that include not only tangent vectors to the space of connections, but also tangent vectors to the space of the curvatures of connections.

The most important nontrivial example of these field theories is the four-dimensional BFYM theory, which, in a separate paper,[1] has been shown to be equivalent to the ordinary Yang–Mills theory. The fact that 2-forms are among the fields of this theory can be exploited by considering vacuum expectation values of observables depending on iterated loops (loops of loops) or on imbedded surfaces in a four-dimensional manifold.[4]

The gauge fixing problem for the BFYM theory is discussed in the last section. In particular the self-dual gauge and the covariant gauge are compared.

It is rather straightforward to extend all the above calculations to iterated tangent spaces. Hence we have constructed a BRST complex that includes—besides the connection A—$2^{n+1}-1$ fields which are 1-forms, 2^n fields which are 2-forms and the relevant ghost fields. We are investigating possible relations between this infinite BRST complex and SUSY models.

Finally, we have shown that (pure) *topological* field theories of the *BF* type do not have a BRST operator related to some Lie algebra cohomology. In other words the BRST operator considered in Ref. 3 does *not* extend to 2-forms. The way of dealing with topological *BF* theories, from a field-theoretical point of view, is to resort to the Batalin–Vilkovisky formalism.

ACKNOWLEDGMENTS

We would like to thank especially our collaborators of Ref. 1, namely, F. Fucito, M. Martellini, A. Tanzini, and M. Zeni for very useful discussions. The original motivation for this paper and some of the results reported here are a result of our common work. We also thank Jim Stasheff and S. Guerra for reading the manuscript and suggesting some corrections.

Discrete time adiabatic theorems for quantum mechanical systems

A. Dranov, J. Kellendonk, and R. Seiler
Fachbereich Mathematik, Technische Universität Berlin, 10623 Berlin, Germany

(Received 17 June 1997; accepted for publication 22 October 1997)

The theory of adiabatic asymptotics is adapted to systems with discrete time evolution. The corresponding theorems about the approximation of physical time evolution by the adiabatic time evolution are shown to hold true in a discrete setting.

I. INTRODUCTION

In recent years it has become more and more evident that many concepts and results of continuous analysis have interesting counterparts in a discrete setting typically on graphs or lattices. (A paradigm in this category is the discrete version of the theory of surfaces.[1]) An example of this kind is the one described here, the discrete version of the adiabatic theorem of quantum mechanics.

Originally formulated in the 1920s by Born and Fock,[2] the adiabatic theorem has evolved through a sequence of steps. Kato[3,4] has used the theorem in an important way for his analysis of perturbation theory of linear operators. Berry[5] and later Simon[6] noticed an interesting aspect of adiabatic dynamics: Adiabatic dynamics is typically geometric in the sense that it can be interpreted as parallel transport with respect to a natural connection. This point of view was important in an extension of this theorem which was motivated by the analysis of the Quantum Hall effect.[7] That article and a follow-up[8] are used in the present article as a guideline for the analysis of the discrete version of the adiabatic theorem.

In the continuous time-setting, adiabatic asymptotics applies to Hamiltonians which are time dependent in a particular way. It applies to those Hamiltonians for which there exists a large T such that the variation of the Hamiltonian in time depends essentially only on the rescaled time $s=t/T$. The time scale set up by T is supposed to be very large compared with the inverse frequencies corresponding to energy levels of the Hamiltonian at a fixed time t. It then makes sense to consider the limit $T\to\infty$, which is called the adiabatic limit.[2] For that, we have to consider a whole family $\{H(t,T)\}_T$ of time dependent Hamiltonians which is parametrized by T. The time dependent Schrödinger equation

$$i\partial_t U(t,T)=H(t,T)U(t,T), \quad U(0,T)=1,$$

is then more conveniently written in rescaled time $s=t/T$,

$$i\partial_s U_T(s)=TH_T(s)U_T(s), \quad U_T(0)=1, \tag{1}$$

where $U_T(s)=U(t,T)$ and $H_T(s)=H(t,T)$. In particular, $(d/ds)H_T(s)=T(d/dt)H(t,T)$. To repeat, the natural set up for adiabatic asymptotics is one in which $H_T(s)$ is independent of T.

The adiabatic theorems, which were considered in Refs. 7 and 8, apply to a situation in which the spectrum of $H(t,T)$ consists of two parts which are well separated by a gap. In that case one considers the adiabatic time evolution, which is the best approximation of the time evolution under the constraint that the spectral subspaces corresponding to the two parts are conserved. Its corresponding group of unitaries $U_T^A(s)$ is defined by the initial value problem

$$i\partial_s U_T^A(s)=TH_T^A(s)U_T^A(s), \quad U_T^A(0)=1, \tag{2}$$

where

 © 1998 American Institute of Physics

$$H_T^A(s)=H_T(s)+\frac{i}{T}[\partial_s P_T(s),P_T(s)], \tag{3}$$

and $P_T(s)$ is the spectral projection of $H_T(s)$ onto one part of the spectrum. Next to the result that $U_T^A{}^*U_T$ is of order T^{-1} the authors in Refs. 7 and 8 show that, under the additional requirement that $H_T(s)$ is infinitely often differentiable, the tunneling probability between the two parts of the spectrum is of order $T^{-\infty}$.

Our aim here is to develop the corresponding adiabatic theory for systems with discrete time evolution. For that we consider the discrete form of the Schrödinger equation, $n\in\mathbf{Z}$,

$$U(n+1,T)=W(n,T)U(n,T),\quad U(0,T)=1, \tag{4}$$

where $W(n,T)$ is a sequence of unitaries parametrized by T, and so is $U(n,T)$. The rescaled equation then reads, with $N=n/T$ and $W_T(N)=W(n,T)$,

$$U_T\left(N+\frac{1}{T}\right)=W_T(N)U_T(N),\quad U_T(0)=1. \tag{5}$$

One way to obtain a discrete system is by discretizing the solution of a continuous system. In fact, upon using the time ordered product ::,

$$W(n,T)=:e^{-i\int_n^{n+1}H(t,T)dt}: \tag{6}$$

gives by (4) the continuous solution at discrete times. This correspondence is useful to motivate our setup. [Alternatively, we could have started with the discrete form of equation (2) which is (5). The identity $W_T(N)=W(n,T)$ mirrors the identity $\int_N^{N+1/T}TH_T(s)ds=\int_{NT}^{NT+1}H(t,T)dt$ in the continuous version.]

Like in the continuous problem, adiabatic asymptotics makes sense if one considers the (adiabatic) limit $T\to\infty$ for a family of unitaries $W_T(N)$ which depend weakly enough on T. This will mean, as we will elaborate and specify, that $W_T(N+1/T)-W_T(N)$ is of order T^{-1}. It should be kept in mind that, in the adiabatic limit, the rescaled time $N=n/T$ remains finite.

To consider an adiabatic evolution in the discrete setting we assume that part of the spectrum of $W_T(N)$ is well separated from the rest by two gaps (in a sense specified below). Let $P_T(N)$ then denote the spectral projection onto that part. The group of unitaries $U_T^A(N)$ describing the adiabatic evolution associated with this spectral projection ought to be defined by

$$U_T^A\left(N+\frac{1}{T}\right)=W_T^A(N)U_T^A(N),\quad U_T^A(0)=1, \tag{7}$$

for a family of unitaries $W_T^A(N)$, which shall now be determined. As in the continuous setting U_T^A should preserve the eigenspace of $P_T(N)$, i.e.,

$$U_T^A(N)P_T(0)=P_T(N)U_T^A(N). \tag{8}$$

Furthermore, it should be close to U_T in the sense that for arbitrary N, $P_T(N)(U_T(N)-U_T^A(N))P_T(0)$ and $Q_T(N)(U_T(N)-U_T^A(N))Q_T(0)$ are of order T^{-1}. This can be achieved if we find an operator $v(N,M)$ such that, for arbitrary M and N, $v(N,M)-1$ is of order T^{-1} and

$$P_T(N)U_T(N)U_T^*(M)P_T(M)=P_T(N)v_T(N,M)U_T^A(N)U_T^{A*}(M)P_T(M),$$

$$Q_T(N)U_T(N)U_T^*(M)Q_T(M)=Q_T(N)v_T(N,M)U_T^A(N)U_T^{A*}(M)Q_T(M).$$

From equations (5) and (7) and the above ansatz one obtains

$$P_T\left(N+\frac{1}{T}\right)W_T(N)P_T(N)=P_T\left(N+\frac{1}{T}\right)v_T\left(N+\frac{1}{T},N\right)W_T^A(N)P_T(N),$$
$$Q_T\left(N+\frac{1}{T}\right)W_T(N)Q_T(N)=Q_T\left(N+\frac{1}{T}\right)v_T\left(N+\frac{1}{T},N\right)W_T^A(N)Q_T(N). \tag{9}$$

Provided that $v_T(N+1/T,N)$ is invertible, these equations are solved by

$$W_T^A(N)=v_T\left(N+\frac{1}{T},N\right)^{-1}S_T\left(N+\frac{1}{T},N\right)W_T(N), \tag{10}$$

where

$$S_T(N,M)=P_T(N)P_T(M)+Q_T(N)Q_T(M).$$

This follows since $W_T(N)$ commutes with its spectral projection $P_T(N)$ and $S_T(N,M)P_T(M)=P_T(N)P_T(M)$. In addition to solving (9) we want that $W_T^A(N)$ is unitary and satisfies $P_T(N+1/T)W_T^A(N)=W_T^A(N)P_T(N)$ (which insures (8)), and that $v_T(N+1/T,N)-1$ is of order T^{-2}. The latter then implies that $v_T(M,N)-1$ is of order T^{-1} for arbitrary M and N. This can all be achieved by setting $v_T(N,M)=\sqrt{S^*(N,M)S(N,M)}$. In fact,

$$V_T(N,M):=v_T(N,M)^{-1}S_T(N,M) \tag{11}$$

is then the unitary of the polar decomposition of $S_T(N,M)$. We will show below that the requirement on the dynamics, namely that $W_T(N+1/T)-W_T(N)$ is of order T^{-1}, implies for $P_T(N+1/T)-P_T(N)$ to be of order T^{-1} as well. The estimate $(1+\lambda^2)^{-1/2}=1+O(\lambda^2)$ then implies that $v_T(N+1/T,N)-1=\sqrt{1-(P_T(N)-P_T(N+1/T))^2}-1$ is of order T^{-2}. In particular, for large enough T, $v_T(M,N)$ is then invertible. The unitary operator $V_T(N,M)$ has been introduced by Kato.[4] It has been used also in Ref. 9 for the purpose of providing an explicit unitary equivalence between two projections P_1,P_2 which are close in the sense that $\|P_1-P_2\|<1$ (in the present case $P_1=P_T(N)$ and $P_2=P_T(M)$).

The main result of this article is the extension of the adiabatic theorems to the discrete setting. In particular, we shall first prove that the wave operator,

$$\Omega_T(N):=U_T^{A*}(N)U_T(N), \tag{12}$$

behaves in the adiabatic limit as $\Omega_T(N)=1+O(T^{-1})$. The notation $X=O(T^{-k})$ means, as usual, that there is a constant c such that $\|X\|\leqslant cT^{-k}$, one says that X is of order T^{-k}.

Second, defining for a sequence of operators $X(N)$, $N\in\mathbf{Z}/T$, the difference operator D as usual by

$$DX(N):=X\left(N+\frac{1}{T}\right)-X(N),$$

and $D^{(2)}=D\circ D$, etc., we shall prove that if, for any k, $D^{(k)}W_T(N)$ is of order T^{-k}, then the tunneling probability out of the spectral subspace is smaller than any inverse power of the time scale,

$$Q_T(0)\Omega_T(N)P_T(0)=O(T^{-\infty}). \tag{13}$$

II. ADIABATIC THEOREMS

A. The setup

We consider a sequence of unitary operators $W_T(N)$, $N\in\mathbf{Z}/T$, on some Hilbert-space $\mathscr{H}$ which is parametrized by a large time T. $N=n/T$ plays the role of a rescaled discrete time. This sequence is supposed to satisfy the following conditions.

(1) For a positive integer k, the value of which will be specified below, the k difference of W_T, $D^{(k)}W_T(N)$, is of order T^{-k}.

(2) The spectrum of $W_T(N)$ consists of two parts which are separated by two gaps in the following sense: There are two continuous functions $g_i:\mathbf{R}\to S^1$ and an $\epsilon>0$ such that, first, for all N and T,

$$\mathrm{dist}(\{g_1(N),g_2(N)\},\sigma(W_T(N)))>\epsilon,$$

and, second, g_1 and g_2 do not level-cross, i.e., $\forall r\in\mathbf{R}: g_1(r)\neq g_2(r)$. The two parts of the spectrum of $W_T(N)$ are then the parts which belong to the two different components of $S^1\setminus\{g_1(N),g_2(N)\}$.

Let us compare the above setup with the setup used in Ref. 7. In that work, a family of self-adjoint operators $H(s), s\in I\subset\mathbf{R}$, is investigated, the members of which are bounded from below, k times continuously differentiable and have gaps in the spectrum in the following sense: there are two continuous functions $g_i:\mathbf{R}\to\mathbf{R}$ and an $\epsilon>0$ such that, for all s, $\mathrm{dist}(\{g_1(s),g_2(s)\},\sigma(H(s)))>\epsilon$. These operators $H(s)$ are in fact nothing else than the $H_T(s)$ from (1), but they are, according to the natural adiabatic setup, independent of T.

The regularity conditions which ensure the existence of a unique dynamical evolution are already built in by requiring that all $W_T(N)$ are unitary operators. The natural adiabatic setup, in which H_T is independent of T, however does not lead to a sequence W_T of T-independent unitaries. In fact, assuming for simplicity that $H(t,T)$ commutes at different times, one obtains, formally, from (6)

$$W_T(N)=\exp(-iH_T(N)+O(T^{-1})), \tag{14}$$

the $O(T^{-1})$-term vanishing only under special circumstances. However, if $H(t,T)$ is independent of T (and differentiable), then (14) shows that $DW_T(N)=O(T^{-1})$. This is covered by our first condition with $k=1$. The first condition of our setup is also supported by the observation that boundedness of the kth derivative of $H_T(s)$ (w.r.t. s) requires the kth derivative of $H(t,T)$ (w.r.t. t) to be of order T^{-k}, and hence, to require that the k-difference of $W_T(N)$ be of order T^{-k} is the natural analog for the discrete case.

It is clear that, due to the topology of S^1, one needs two functions to separate a part of the spectrum. This is not really more restrictive than the gap condition in the continuous case, however, it should be mentioned that our second condition is *a priori* stronger than that gap condition in case the continuous Hamiltonian $H_T(s)$ were unbounded, because then the spectrum of $W_T(N)$ could be all of S^1.

B. Direct consequences of the setup

If $\Gamma_T(N)$ is a contour (traversed clockwise) around the part of spectrum of $W_T(N)$ which lies between $g_1(N)$ and $g_2(N)$, then the spectral projection $P_T(N)$ onto that part is given by the integral (which is to be understood in the strong sense)

$$P_T(N)=\frac{1}{2\pi i}\int_{\Gamma_T(N)} R_T(N,z)dz, \tag{15}$$

where $R_T(N,z)=(W_T(N)-z)^{-1}$ is the resolvent of $W_T(N)$. The large T behavior of $D^{(k)}P_T$ is of the same order in T as that of $D^{(k)}W_T$, since for large T

$$DP_T(N)=-\frac{1}{2\pi i}\int_{\Gamma_T} R_T\left(N+\frac{1}{T},z\right)DW_T(N)R_T(N,z)dz. \tag{16}$$

Here, due to condition 2 and in particular the continuity of g_i we can choose for large enough T either $\Gamma_T=\Gamma_T(N)$ or $\Gamma_T=\Gamma_T(N+1/T)$. This proves the case $k=1$, the one for larger k follows by a similar but more complicated argument.

Likewise the large T behavior of the k-differences of $V_T(N)=V_T(N+1/T,N)$ and $W_T^A(N)$ are of the same order in T as that of $D^{(k)}W_T$, as they are defined by infinitely differentiable functions

in P and one may use the discrete analog of the Leibniz rule, $D(XY)(N)=DX(N)Y(N+1/T)+X(N)DY(N)$. Furthermore, since $(1+\lambda^2)^{-1/2}=1+O(\lambda^2)$, the large T-behavior of $V_T(N)$ is given by

$$V_T(N)=1+\left(P_T\left(N+\frac{1}{T}\right)-P_T(N)\right)(2P_T(N)-1)+O(T^{-2}). \tag{17}$$

The unitary operator which describes the discrete time evolution of the wave operator,

$$\Theta_T(N):=\Omega_T\left(N+\frac{1}{T}\right)\Omega_T^*(N), \tag{18}$$

is easily shown to be

$$\Theta_T(N)=U_T^{A*}\left(N+\frac{1}{T}\right)V_T^*\left(N+\frac{1}{T},N\right)U_T^A\left(N+\frac{1}{T}\right). \tag{19}$$

Instead of using Θ_T we shall make use of the operator $K_T(N)=T(1-\Theta_T(N))$ and formulate equation (18) in the way $D\Omega_T=-T^{-1}K_T\Omega_T$, or, summed up,

$$\Omega_T\left(\frac{l}{T}\right)=1-\frac{1}{T}\sum_{n=0}^{l-1}K_T\left(\frac{n}{T}\right)\Omega_T\left(\frac{n}{T}\right). \tag{20}$$

Note that $K_T(N)=O(1)$.

C. The theorem about partial summing up

The theorem and corollary of this section furnish the technical basis of this work.

Theorem 1: *Let $W_T(N)$, $N\in\mathbf{Z}/T$, be a sequence of unitaries satisfying the conditions of our setup, condition 1 with $k=1$, and suppose that $X(N)$ and $Y(N)$ are sequences of operators such that $DX(N)$ and $DY(N)$ are of order T^{-1}. Let*

$$\widetilde{X}(N)=-\frac{1}{2\pi i}\int_{\Gamma_T(N)}R_T(N,z)X(N)R_T(N,z)dz, \tag{21}$$

where $R_T(N,z)$ is the resolvent of $W_T(N)$. Then

$$\sum_{n=1}^{l}Q_0U_T^{A*}\left(\frac{n}{T}\right)X\left(\frac{n}{T}\right)U_T^A\left(\frac{n}{T}\right)P_0Y\left(\frac{n}{T}\right)=\mathscr{B}+\frac{1}{T}\mathscr{S}, \tag{22}$$

where $P_0=P_T(0)$ and $Q_0=Q_T(0)$,

$$\mathscr{B}=Q_0U_T^{A*}(0)\widetilde{X}\left(\frac{1}{T}\right)U_T^A\left(\frac{1}{T}\right)P_0Y\left(\frac{1}{T}\right)-Q_0U_T^{A*}\left(\frac{l}{T}\right)\widetilde{X}\left(\frac{l+1}{T}\right)U_T^A\left(\frac{l+1}{T}\right)P_0Y\left(\frac{l+1}{T}\right) \tag{23}$$

is a boundary term and

$$\mathscr{S}=\sum_{n=1}^{l}Q_0U_T^{A*}\left(\frac{n}{T}\right)\left(Z\left(\frac{n}{T}\right)U_T^A\left(\frac{n}{T}\right)P_0Y\left(\frac{n}{T}\right)+\widetilde{X}\left(\frac{n+1}{T}\right)W_T^A\left(\frac{n}{T}\right)U_T^A\left(\frac{n}{T}\right)P_0TDY\left(\frac{n}{T}\right)\right) \tag{24}$$

is a sum, and

$$Z\left(\frac{n}{T}\right)=T\left(\left[\left(V_T^*\left(\frac{n}{T}\right)-1\right)W_T^A\left(\frac{n}{T}\right),\widetilde{X}\left(\frac{n}{T}\right)\right]+DW_T^A\left(\frac{n-1}{T}\right)\widetilde{X}\left(\frac{n}{T}\right)+D\widetilde{X}\left(\frac{n}{T}\right)W_T^A\left(\frac{n}{T}\right)\right). \tag{25}$$

Moreover, $Z(n/T)$ and $TDY(n/T)$ remain bounded in the adiabatic limit.

Proof: Note first the identity

$$Q_T(N)X(N)P_T(N) = -Q_T(N)[W_T(N),\widetilde{X}(N)]P_T(N) \tag{26}$$

which follows from

$$\begin{aligned}[W_T(N),\widetilde{X}(N)] &= -\frac{1}{2\pi i}\int_{\Gamma_T(N)}[W_T(N)-z,R_T(N,z)X(N)R_T(N,z)]dz \\ &= [P_T(N),X(N)].\end{aligned}$$

Substituting W_T by the expression of the adiabatic time evolution one gets

$$Q_T(N)X(N)P_T(N) = -Q_T(N)[W_T^A(N),\widetilde{X}(N)]P_T(N) + Q_T(N)[A(N),\widetilde{X}(N)]P_T(N), \tag{27}$$

where $A=(V_T^*-1)W_T^A=O(T^{-1})$. Using the intertwining properties (8) to obtain

$$Q_0U_T^{A^*}XU_T^AP_0 = Q_0U_T^{A^*}[W_T^A,\widetilde{X}]U_T^AP_0 + Q_0U_T^{A^*}[A,\widetilde{X}]U_T^AP_0$$

and the adiabatic equation of motion one arrives at

$$\begin{aligned}U_T^{A^*}\left(\frac{n}{T}\right)\left[W_T^A\left(\frac{n}{T}\right),\widetilde{X}\left(\frac{n}{T}\right)\right]U_T^A\left(\frac{n}{T}\right) &= U_T^{A^*}\left(\frac{n}{T}\right)W_T^A\left(\frac{n-1}{T}\right)\widetilde{X}\left(\frac{n}{T}\right)U_T^A\left(\frac{n}{T}\right) - U_T^{A^*}\left(\frac{n}{T}\right)\widetilde{X}\left(\frac{n}{T}\right)U_T^A\left(\frac{n+1}{T}\right) \\ &\quad + U_T^{A^*}\left(\frac{n}{T}\right)\left(W_T^A\left(\frac{n}{T}\right) - W_T^A\left(\frac{n-1}{T}\right)\right)\widetilde{X}\left(\frac{n}{T}\right)U_T^A\left(\frac{n}{T}\right) \\ &= U_T^{A^*}\left(\frac{n-1}{T}\right)\widetilde{X}\left(\frac{n}{T}\right)U_T^A\left(\frac{n}{T}\right) - U_T^{A^*}\left(\frac{n}{T}\right)\widetilde{X}\left(\frac{n+1}{T}\right)U_T^A\left(\frac{n+1}{T}\right) \\ &\quad + U_T^{A^*}\left(\frac{n}{T}\right)B\left(\frac{n}{T}\right)U_T^A\left(\frac{n}{T}\right),\end{aligned}$$

where

$$B\left(\frac{n}{T}\right) = (D\widetilde{X})\left(\frac{n}{T}\right)W_T^A\left(\frac{n}{T}\right) + (DW_T^A)\left(\frac{n-1}{T}\right)\widetilde{X}\left(\frac{n}{T}\right).$$

By hypothesis DX, and hence also $D\widetilde{X}$, and DW_T^A are of order T^{-1}. Thus $Z(n/T) = T([A(n/T),\widetilde{X}(n/T)]+B(n/T))$ is of order 1. Summing up yields the statement of the theorem. q.e.d.

Note that the sum $\mathscr{S}$ (24) is of the same form as the l.h.s. of (22). One might therefore apply the theorem iteratively if the boundary terms vanish. This is the content of the next corollary.

Corollary 1: Let in addition to the conditions of the last theorem $D^{(k)}W_T(N)$, $D^{(k)}X(N)$, and $D^{(k)}Y(N)$ be of order T^{-k} for all k and X or Y be supported inside $(0,s)$. Then for $l \geqslant sT$,

$$\frac{1}{T}\sum_{n=1}^{l} Q_0U_T^{A^*}\left(\frac{n}{T}\right)X\left(\frac{n}{T}\right)U_T^A\left(\frac{n}{T}\right)P_0Y\left(\frac{n}{T}\right) = O(T^{-\infty}). \tag{28}$$

Proof: Note first that, if $D^{(k)}W_T$, $D^{(k)}X$, and $D^{(k)}Y$ are of order T^{-k}, then $D^{(k-1)}Z$ is of order T^{-k+1}. Therefore one can in this case apply the above theorem k times iteratively, each time gaining one order in T^{-1}, provided the boundary terms $\mathscr{B}$ on the r.h.s. of (22) vanish. We assert that this is the case under the assumptions on the support of X or Y. For that, note that, for arbitrary X, $\mathrm{supp}X\subset[a,b]$, implies that $\mathrm{supp}DX\subset[a,b+1/T]$. By assumption, the support of X or that of Y is contained in $[\epsilon,s-\epsilon]$ for some $\epsilon>0$. This implies that $\mathrm{supp}Z\subset[\epsilon,s-\epsilon+1/T]$ or $\mathrm{supp}DY\subset[\epsilon,s-\epsilon+1/T]$. Therefore, if $\epsilon>1/T$, then the boundary terms on the r.h.s. of (22), which could arise upon one-fold application of the theorem, actually vanish. Inductively one concludes that if $T>k/\epsilon$, no boundary terms arise upon k-fold application of the theorem. Thus, after k-fold application of the theorem, the sum of interest has the form

$$\frac{1}{T}\sum_{n=1}^{l} Q_0 U_T^{A*}\left(\frac{n}{T}\right) X\left(\frac{n}{T}\right) U_T^{A}\left(\frac{n}{T}\right) P_0 Y\left(\frac{n}{T}\right) = \frac{1}{T^{k+1}}\sum_{i=1}^{2^k}\sum_{n=1}^{l} Q_0 U_T^{A*}\left(\frac{n}{T}\right) X_i\left(\frac{n}{T}\right) U_T^{A}\left(\frac{n}{T}\right) P_0 Y_i\left(\frac{n}{T}\right), \tag{29}$$

where X_i and Y_i are sequences of bounded operators, provided $T>k/\epsilon$. In particular, the large T behavior of the sum is bounded by any power of T^{-1}. q.e.d.

D. The first adiabatic theorem

The first adiabatic theorem states that the physical time evolution is approximated by the adiabatic time evolution. It is obtained upon estimating the large T behavior of Ω_T. For that we shall first investigate a sum of the form $T^{-1}\Sigma_{n=0}^{l-1}K_T(n/T)Y(n/T)$ where l is of the order of T.

Let us begin with the ''diagonal'' term $P_0K_T(n/T)P_0Y(n/T)$. Since, for any two projections p,q, holds $p(p-q)p=p(p-q)^2p$ equation (17) implies that $P_T(N)(1-V_T^*(N))P_T(N)=O(T^{-2})$, and therefore

$$\left\|\frac{1}{T}\sum_{n=0}^{[sT]} P_0K_T\left(\frac{n}{T}\right)P_0Y\left(\frac{n}{T}\right)\right\| = \left\|\sum_{n=1}^{[sT]+1} U_T^{A*}\left(\frac{n}{T}\right)P_T\left(\frac{n}{T}\right)\left(1-V^*\left(\frac{n}{T}\right)\right)P_T\left(\frac{n}{T}\right)U_T^{A}\left(\frac{n}{T}\right)Y\left(\frac{n-1}{T}\right)\right\|$$

$$\leqslant \frac{\text{const}}{T}\|Y\|_s, \tag{30}$$

where

$$\|Y\|_s = \sup_{0\leqslant n\leqslant sT}\left\|Y\left(\frac{n}{T}\right)\right\|. \tag{31}$$

The same estimate holds for the norm of $T^{-1}\Sigma_{n=0}^{[sT]}Q_0K_T(n/T)Q_0Y(n/T)$. To treat the ''off diagonal'' terms we apply Theorem 1, taking $X(N)=T(1-V_T^*(N))=TDP_T(N)(2P_T(N)-1)+O(T^{-1})$. In particular, $DX(N)$ is of order T^{-1} in the case W_T satisfies condition 1 with $k\geqslant 2$. The terms of

$$\frac{1}{T}\sum_{n=0}^{[sT]} Q_0K_T\left(\frac{n}{T}\right)P_0Y\left(\frac{n}{T}\right) = \frac{1}{T}\left(\mathscr{B}+\frac{1}{T}\mathscr{S}\right),$$

where $\mathscr{B}$ and $\mathscr{S}$ are as in Theorem 1, are bounded from above by

$$\|\mathscr{B}\|\leqslant \text{const}\|Y\|_s$$

and

$$\|\mathscr{S}\|\leqslant \text{const}T\|\|Y\|\|_s$$

with

$$\|\|Y\|\|_s = \max\{\|Y\|_s, T\|DY\|_s\}$$

and T-independent constants. Again, the same estimate holds for the norm of the other ''off diagonal'' $T^{-1}\Sigma_{n=0}^{[sT]}P_0K_T(n/T)Q_0Y(n/T)$. Summarizing we obtain

$$\left\|\frac{1}{T}\sum_{n=0}^{[sT]} K_T\left(\frac{n}{T}\right)Y\left(\frac{n}{T}\right)\right\| \leqslant \frac{\text{const}}{T}\|Y\|\|_s. \tag{32}$$

Theorem 2: *If $W_T(N)$, $N\in\mathbf{Z}/T$, is a sequence of unitaries satisfying the conditions of our setup, condition 1 with $k\geqslant 2$, then*

$$\Omega_T(N)=1+O(T^{-1}). \tag{33}$$

Proof: Define $\Omega_0 := 1$ and, for $j \geqslant 1$,

$$\Omega_j\left(\frac{l}{T}\right) := -\frac{1}{T}\sum_{n=0}^{l-1} K_T\left(\frac{n}{T}\right)\Omega_{j-1}\left(\frac{n}{T}\right). \tag{34}$$

Then, by (32) we have, for $j \geqslant 1$,

$$\left\|\Omega_j\left(\frac{l}{T}\right)\right\| \leqslant \frac{\text{const}}{T}\||\Omega_{j-1}\||_{l/T}\|. \tag{35}$$

But $D\Omega_j = -(1/T)K_T\Omega_{j-1}$ so that, for $j \geqslant 1$,

$$\||\Omega_j\||_s = \max\{\|\Omega_j\|_s, \|\Omega_{j-1}\|_s\}.$$

Since $\||\Omega_0\||_s = 1$ and hence, by (35), $\|\Omega_1\|_s = O(T^{-1})$, one obtains by induction on j, for all $j > 1$,

$$\|\Omega_{2j-1}\|_s + \|\Omega_{2j}\|_s = O(T^{-j}). \tag{36}$$

Furthermore, let

$$R_M := \Omega_T - \sum_{j=0}^{M} \Omega_j\,. \tag{37}$$

Then

$$\begin{aligned} R_M\left(\frac{l}{T}\right) &= -\frac{1}{T}\sum_{n=0}^{l-1} K_T\left(\frac{n}{T}\right)\Omega_T\left(\frac{n}{T}\right) + \frac{1}{T}\sum_{j=1}^{M}\sum_{n=0}^{l-1} K_T\left(\frac{n}{T}\right)\Omega_{j-1}\left(\frac{n}{T}\right) \\ &= -\frac{1}{T}\sum_{n=0}^{l-1} K_T\left(\frac{n}{T}\right)R_{M-1}\left(\frac{n}{T}\right), \end{aligned}$$

which shows that R_M satisfies the same equation as Ω_k. Hence, for $M \geqslant 1$,

$$\left\|R_M\left(\frac{l}{T}\right)\right\| \leqslant \frac{\text{const}}{T}\||R_{M-1}\||_{l/T}\,.$$

Since $R_0 = \Omega_T - 1$ is of order 1 in T and $DR_0 = -(1/T)K_T\Omega_T$ is of order T^{-1}, the above formula shows that R_1 is of order T^{-1} and, analogously, for all $M > 1$,

$$\|R_{2M-1}\|_s + \|R_{2M}\|_s = O(T^{-M}). \tag{38}$$

As $\Omega_T = 1 + R_1 + \Omega_1$, and $\|\Omega_T(N) - 1\| \leqslant \|\Omega_T - 1\|_N$, the statement of the theorem follows. q.e.d.

E. The second adiabatic theorem

We have just seen that the adiabatic time evolution approximates the physical time evolution. By construction, it preserves the spectral subspace corresponding to the projection $P_T(N)$. The quantities $\|Q_0\Omega_T P_0\|$ and $\|P_0\Omega_T Q_0\|$ are therefore upper bounds to the probabilities for the physical system to tunnel out and into, respectively, that spectral subspace. In case $D^{(k)}W_T(N)$ is of order T^{-k} for all k we shall show now that these probabilities are smaller than any inverse power of the time scale. For the remainder of this section we assume that $W_T(N)$, $N \in \mathbf{Z}/T$, is a sequence of unitaries satisfying the conditions of our setup, but condition 1 for all $k \geqslant 1$.

Recall that $\Omega_0 = 1$ and, for $j \geqslant 1$,

$$Q_0\Omega_j\left(\frac{l}{T}\right)P_0 = -\frac{1}{T}\sum_{n=1}^{l} Q_0 K_T\left(\frac{n-1}{T}\right)\Omega_{j-1}\left(\frac{n-1}{T}\right)P_0\,. \tag{39}$$

Lemma 1: Fix an integer $j \geqslant 1$. *Let* X *be supported inside* $(0,s)$ *and* $D^k X(N) = O(T^{-k})$ *for all* k, *and assume that, for* $l \geqslant sT$,

$$Q_0 \Omega_m\left(\frac{l}{T}\right) P_0 = O(T^{-\infty}) \quad \text{for all } 0 \leqslant m \leqslant j-1. \tag{40}$$

Then, for all $1 \leqslant j' \leqslant j$ *holds*

$$\begin{aligned}
&\sum_{n=1}^{l} Q_0 U_T^{A*}\left(\frac{n}{T}\right) X\left(\frac{n}{T}\right) U_T^A\left(\frac{n}{T}\right) \Omega_{j'-1}\left(\frac{n}{T}\right) P_0 \\
&\quad = \gamma(j')\frac{1}{T}\sum_{n=1}^{l} Q_0 U_T^{A*}\left(\frac{n}{T}\right) Z\left(\frac{n}{T}\right) U_T^A\left(\frac{n}{T}\right) \Omega_{j'-1}\left(\frac{n}{T}\right) P_0 + \gamma(j'-1)\frac{1}{T} \\
&\qquad \times \sum_{n=1}^{l} Q_0 U_T^{A*}\left(\frac{n}{T}\right) Z_1\left(\frac{n}{T}\right) U_T^A\left(\frac{n}{T}\right) \Omega_{j'-2}\left(\frac{n}{T}\right) P_0 + O(T^{-\infty}),
\end{aligned} \tag{41}$$

where $\gamma(j') = 1$ *for* $j' > 1$ *and* $\gamma(j') = 0$ *otherwise,*

$$Z_1\left(\frac{n}{T}\right) = \widetilde{X}\left(\frac{n+1}{T}\right) W_T^A\left(\frac{n}{T}\right) P_T\left(\frac{n}{T}\right) T\left(V_T^*\left(\frac{n-1}{T}\right) - 1\right),$$

and Z *and* $\widetilde{X}$ *are the same as in Theorem 1, cf. (21) and (25). Furthermore,* $D^k Z(n/T) = O(T^{-k})$ *and* $D^k Z_1(n/T) = O(T^{-k})$ *for all* k.

Proof: For $j' = 1$ the announced result is a special case of Corollary 1, namely that where $Y(N) = 1$ for all N. So let us consider the case $j' > 1$. Since $Q_0 \Omega_{j'-1}(n/T) P_0 = O(T^{-\infty})$,

$$\begin{aligned}
&\sum_{n=1}^{l} Q_0 U_T^{A*}\left(\frac{n}{T}\right) X\left(\frac{n}{T}\right) U_T^A\left(\frac{n}{T}\right) \Omega_{j'-1}\left(\frac{n}{T}\right) P_0 \\
&\quad = \sum_{n=1}^{l} Q_0 U_T^{A*}\left(\frac{n}{T}\right) X\left(\frac{n}{T}\right) U_T^A\left(\frac{n}{T}\right) P_0 \Omega_{j'-1}\left(\frac{n}{T}\right) P_0 + O(T^{-\infty}) \\
&\quad = \frac{1}{T}\sum_{n=1}^{l} Q_0 U_T^{A*}\left(\frac{n}{T}\right) Z\left(\frac{n}{T}\right) U_T^A\left(\frac{n}{T}\right) \Omega_{j'-1}\left(\frac{n}{T}\right) P_0 \\
&\qquad + \frac{1}{T}\sum_{n=1}^{l} Q_0 U_T^{A*}\left(\frac{n}{T}\right) \widetilde{X}\left(\frac{n+1}{T}\right) W_T^A\left(\frac{n}{T}\right) U_T^A\left(\frac{n}{T}\right) P_0 T D \Omega_{j'-1}\left(\frac{n}{T}\right) P_0 + O(T^{-\infty}),
\end{aligned}$$

the last equality following by Theorem 1 with $Y(n/T) = \Omega_{j'-1}(n/T) P_0$ provided T is large enough. In fact, as for Corollary 1 one shows that the boundary terms vanish if $T > 1/\epsilon$ where $\epsilon > 0$ is chosen such that $\mathrm{supp} X(N) \subset [\epsilon, s-\epsilon]$. Using that, for $j' > 1$, $D\Omega_{j'-1}(n/T) P_0 = -U_T^{A*}(n/T)(1 - V_T^*((n\text{-}1)/T)) U_T^A(n/T) \Omega_{j'-2}(n/T) P_0$ and the intertwining properties (8) one gets

$$\begin{aligned}
U_T^A\left(\frac{n}{T}\right) P_0 T D \Omega_{j'-1}\left(\frac{n}{T}\right) P_0 &= U_T^A\left(\frac{n}{T}\right) P_0 U_T^{A*}\left(\frac{n}{T}\right) T\left(V_T^*\left(\frac{n-1}{T}\right) - 1\right) U_T^A\left(\frac{n}{T}\right) \Omega_{j'-2}\left(\frac{n}{T}\right) P_0 \\
&= P_T\left(\frac{n}{T}\right) T\left(V_T^*\left(\frac{n-1}{T}\right) - 1\right) U_T^A\left(\frac{n}{T}\right) \Omega_{j'-2}\left(\frac{n}{T}\right) P_0 .
\end{aligned} \tag{42}$$

This shows (41) for $j' > 2$. If $j' = 2$ then we may apply Corollary 1 to the term containing $\Omega_{j'-2}(n/T)$, obtaining that this term is $O(T^{-\infty})$. It was already shown in the proof of Corollary 1 that $D^k Z(n/T) = O(T^{-k})$. That $D^k Z_1(n/T) = O(T^{-k})$ follows from the discrete Leibniz rule, since all factors satisfy this condition. q.e.d.

Theorem 3: *Suppose that* $W_T(N)$ *satisfies the conditions 1 and 2 for all* k *and that* $V_T^*(N)-1$ *be supported within* $(0,s)$. *Then for* $N\notin(0,s)$

$$Q_0\Omega_T(N)P_0=O(T^{-\infty}). \tag{43}$$

Proof: Recall that, for all M, $Q_0\Omega_T P_0=Q_0R_MP_0+\Sigma_{j=1}^{M}Q_0\Omega_jP_0$. We show by induction on j that, for $l\geqslant sT$ and $j\geqslant 1$,

$$Q_0\Omega_j\left(\frac{l}{T}\right)P_0=O(T^{-\infty}). \tag{44}$$

The theorem then follows from (38). Equation (44) is true for $j=1$, since, by Corollary 1 applied to $X=1-V_T^*$ and $Y=1$,

$$\begin{aligned}Q_0\Omega_1\left(\frac{l}{T}\right)P_0&=-\frac{1}{T}\sum_{n=1}^{l}Q_0K_T\left(\frac{n-1}{T}\right)P_0\\&=-\sum_{n=1}^{l}Q_0U_T^{A*}\left(\frac{n}{T}\right)\left[1-V_T^*\left(\frac{n}{T}\right)\right]U_T^{A}\left(\frac{n}{T}\right)P_0=O(T^{-\infty}).\end{aligned}$$

To prove (44) for $j>1$ we assume (40) and use Lemma 1 repeatedly. For that we take first, in view of (39), $X=V_T^*-1$, and in each further step apply that lemma separately with X being equal to the arising Z's and Z_1's from the last step. This is possible as long as the resulting Z and Z_1 satisfy also the remaining condition for the lemma, that is, as long as they have their support inside $(0,s)$. But as for Corollary 1 one shows that this is indeed the case if $T>k/\epsilon$, where $\mathrm{supp}X(N)\subset[\epsilon,s-\epsilon]$ for all N. Thus if $T>k/\epsilon$, k-fold application of Lemma 1 results in

$$Q_0\Omega_j\left(\frac{l}{T}\right)P_0=\frac{1}{T^k}\sum_{i=1}^{\min\{k,j-1\}}\sum_{n=1}^{l}Q_0U_T^{A*}\left(\frac{n}{T}\right)X_i\left(\frac{n}{T}\right)U_T^{A}\left(\frac{n}{T}\right)\Omega_{j-i}\left(\frac{n}{T}\right)P_0+O(T^{-\infty}), \tag{45}$$

where each X_i contains at most 2^k terms which all remain bounded in the adiabatic limit. Since also all Ω_j remain bounded in the adiabatic limit it follows that $Q_0\Omega_j(l/T)P_0=O(T^{-k})$ for all k. q.e.d.

That $P_0\Omega_T(N)Q_0=O(T^{-\infty})$ is proven likewise.

(Received 30 July 1997; accepted for publication 5 November 1997)

A description of the relative motion of neutrons and protons in strongly deformed even-even nuclei is reduced to that of two coupled triaxial rotors, one representing the neutrons and the other the protons, by using generating function methods. The two rotor theory is interpreted as a generalization of the Elliott SU(3) model with a neutron–proton direct product $SU_\nu(3)\times SU_\pi(3)$ substructure. The second order Casimir operator for this system is constructed and some of its eigenfunctions are found in explicit form in the Fock–Bargmann space representation. Analytical results for isovector $M1$ transitions probabilities are obtained and the results compared with experimental data and pseudo-SU(3) calculations. Graphs picturing the relative orientation of neutron-proton rotors in ^{22}Ne are presented. © *1998 American Institute of Physics.* [S0022-2488(98)03202-2]

I. INTRODUCTION

A ''giant resonance'' description of a nucleus[1,2] suggests the possible existence of new collective modes of excitations in deformed nuclei. In analogy with the relative vibrational motion between the proton and neutron distributions within a nucleus, which gives rise to the well-known giant dipole resonance ($E1$ mode), there is the possibility of relative angular oscillations of these two distributions. The simplest collective orbital excitation of this type has been denoted the ''scissors mode'' since the corresponding motion mimics the opening and closing of a scissors. The actual existence of the scissors mode in deformed nuclei was first predicted by Lo Iudice and Palumbo in terms of the Two Rotor Model (TRM).[3] In the TRM the protons and neutrons are assumed to rotate independently except for an interaction through a harmonic potential.

Approximately ten years ago the scissors mode was observed by high resolution inelastic electron scattering experiments as a low-lying collective 1^+ state.[4–6] The experiment results indicate that these states have mainly an orbital and not a spin-flip character, because corresponding peaks were not found in inelastic proton scattering data.[5,6] Following the announcement of the experimental findings, many studies were published attempting to explain the microscopic structure of this mode.[7–17] Models used in various efforts to describe these collective $M1$ excitations include the IBM,[7–9] pseudo-SU(3) model,[10] RPA,[11–13] quasiparticle RPA,[14] VPM[15] and SRA.[16] Some of these calculations even predict a fragmentation of the scissors mode.[10,11,13] Most of the theoretical descriptions assign an isovector character to the mode and emphasize the algebraic structure of the excitation.

The purpose of this paper is to begin to build a bridge between the algebraic and geometric pictures of the scissors mode in deformed nuclei. In so doing, the underlying geometry of the SU(3) model will emerge as a key ingredient in understanding the nature of these collective excitations, both the summed strength and its fragmentation across several final states. Subsequent papers will deal with more in depth analyses and applications of the theory.

The geometric TRM developed by Lo Iudice *et al.*[3,17] can be considered to be a semiclassical explanation of the nature of a new collective mode. The original version of the model describes a nucleus as simply a system of two axial rotors. The earliest version of the theory gives wave

functions for small values of the angle between the symmetry axes of the neutron and proton distributions. This picture also makes predictions for $B(M1)$ and $B(E2)$ strengths, excitation energies and TRM form-factors. Although the qualitative features of this version of the TRM are correct, the quantitative estimations for $B(M1)$ values often differ strongly the experimental data.[4]

A fully microscopic version of the TRM based on a systematic implementation of Fock–Bargmann space concepts has been recently developed in Refs. 18–20. In these studies the TRM is interpreted as a generalization of the Elliott SU(3) model.[21] Inasmuch as the simplest Elliott model describes the dynamics of only three collective degrees of freedom for the valence nucleons (whereas for the case of two rotors the number of degrees of freedom can range between four and six depending upon specifics of the two rotor geometries), it is necessary to extend the model to introduce a more sophisticated classification of the basis states. Basis states constructed as tensor products of the separate neutron and proton subdistributions, with the corresponding symmetry $\mathrm{SU}_\pi(3)\otimes\mathrm{SU}_\nu(3)$,[28] are required. A subsequent reduction of the tensor product with respect to SU(3) makes it possible to label the wave functions by the quantum numbers (λ,μ) characterizing the SU(3) symmetry of the neutron–proton system as a whole. The further reduction $\mathrm{SU}(3)\rightarrow\mathrm{SO}(3)$ results in an L,M,K classification of the states, where L is an orbital angular momentum, M is its projection on an external (laboratory) z-axis, and K is the angular momentum projection onto an intrinsic ζ-axis. (In general, when the λ and μ of both the proton and neutron subdistributions are nonzero, an additional label is required to uniquely identify the coupled SU(3) representation. This additional quantum number is called the outer multiplicity label. In this paper only multiplicity-free couplings will be considered; the physical significance of the multiplicity label will be considered separately.)

Since the Hamiltonian is always taken to be rotationally invariant and space is isotropic, the only exact symmetries of the system are the angular momentum L and its projection M in the laboratory system. In general, the projection of the angular momentum on the intrinsic axis, K, is not an integral of the motion so eigenstates are expected to be a superposition of states with different K values. It should be noted, however, that this label is only required when both λ and μ are greater than or equal to two, and in this case it can be chosen, for example, as the eigenvalue of the Bargmann-Moshinsky ω operator.[23,24] Indeed, it was shown by Elliott[21] that the (λ,μ) irreducible representation (irrep) can be reduced into irreps of SO(3) according to the following rule:

$$L=N,N+1,N+2,\ldots,N+B,$$

where $N=\min\{\lambda,\mu\}$, $\min\{\lambda,\mu\}-2$, $\min\{\lambda,\mu\}-4,\ldots,1$ or 0; and $B=\max\{\lambda,\mu\}$, except for the case $N=0$, when $L=B,B-2,\ldots,1$ or 0. In the present study we consider only the problem of configurations that do not require the use of the additional K quantum label.

In the present paper we extend the microscopic version of the TRM[18–20] to the case of two triaxial rotors. This extension, which is complementary to the pseudo-SU(3) approach, gives rise to a fragmentation of the scissors mode which is in keeping with experimental observations. The outline of the paper is as follows: In Sec. II we describe the basic ideas behind the generating function method. The construction procedure for the generators and second order Casimir operator of U(3) in the generating parameter space is considered in Sec. III. In Sec. IV some examples of basis states in Fock–Bargmann space are presented. In Sec. V we get reduced transition probabilities for the scissors mode in the multiplicity free case. In Sec. VI some pictures showing the relative orientation of one axial and one nonaxial rotor are discussed.

II. BASIC IDEAS BEHIND THE GENERATING FUNCTION METHOD

A microscopic analysis of the TRM can be established using the generating function method.[25–27] The analysis is limited to a consideration of only the collective modes of the valence nucleons within the same opened shell. A starting point for the analysis is an explanation of the way in which the dynamics of the relative motion of protons and neutrons can be reduced to a two rotor problem.

For this purpose consider the Slater determinant Φ constructed of proton

$$|i,\pi\rangle=H_{n_x}(\mathbf{u}_1\cdot\mathbf{r}_i)H_{n_y}(\mathbf{u}_2\cdot\mathbf{r}_i)H_{n_z}(\mathbf{u}_3\cdot\mathbf{r}_i)\exp(-r_i^2/2)\xi(\sigma_i) \tag{1}$$

and neutron

$$|i,\nu\rangle = H_{n_x}(\mathbf{v}_1\cdot\mathbf{r}_i)H_{n_y}(\mathbf{v}_2\cdot\mathbf{r}_i)H_{n_z}(\mathbf{v}_3\cdot\mathbf{r}_i)\exp(-r_i^2/2)\xi(\sigma_i) \tag{2}$$

orbitals in a harmonic oscillator potential. In these expressions the $H_n(x_i)$ are Hermite polynomials and the $\xi(\sigma_i)$ spin functions. We assume known rules for the filling of the shells[25] leading to a given SU(3) symmetry (λ_π,μ_π) for the proton subsystem and (λ_ν,μ_ν) for the neutron subsystem apply. The proton orbitals (1) contain a set of three orthonormalized vectors $\mathbf{u}_1,\mathbf{u}_2,\mathbf{u}_3$ (denoted $\mathbf{u}_s$, where $s=1,2,3$, below); likewise the orbitals for the neutrons (2) contain another set of three vectors $\mathbf{v}_1,\mathbf{v}_2,\mathbf{v}_3$ (denoted $\mathbf{v}_s$, where $s=1,2,3$, below) with the same properties. The Slater determinant is a generating function and can be written in the following form:

$$\begin{aligned}&\Phi(\{\mathbf{u}_s,\mathbf{v}_s\};\{\mathbf{r}_i,\sigma_i,\tau_i\})\\&=\sum_{L_1,\omega_1,M_1}\sum_{L_2,\omega_2,M_2}\sum_{K_1,K_2} C^{\omega_1\omega_2}(L_1K_1;L_2K_2)D^{L_1}_{K_1M_1}(\alpha_1\beta_1\gamma_1)D^{L_2}_{K_2M_2}(\alpha_2\beta_2\gamma_2)\\&=\sum_{\widetilde{K}_1\widetilde{K}_2}\widetilde{C}^{\omega_1\omega_2}(L_1\widetilde{K}_1;L_2\widetilde{K}_2)\Psi_{L_1\widetilde{K}_1M_1;L_2\widetilde{K}_2M_2}(\{\mathbf{r}_i,\sigma_i,\tau_i\}).\end{aligned} \tag{3}$$

As usual the τ_i is isospin label of i-th particle and the $D^{L_i}_{K_iM_i}(\alpha_i\beta_i\gamma_i)$ are spherical Wigner functions with $\alpha_1,\beta_1,\gamma_1$ and $\alpha_2,\beta_2,\gamma_2$ two sets of Euler angles defining, respectively, the orientation of the two sets of vectors $\mathbf{u}_1,\mathbf{u}_2,\mathbf{u}_3$ and $\mathbf{v}_1,\mathbf{v}_2,\mathbf{v}_3$, the letters ω_1,ω_2 are the additional quantum numbers (for instance, the Bargmann–Moshinsky integrals). This expansion (3) is of a great importance because it establishes the relation between many-particle basis functions

$$\sum_{\widetilde{K}_1\widetilde{K}_2}\widetilde{C}^{\omega_1\omega_2}(L_1\widetilde{K}_1;L_2\widetilde{K}_2)\Psi_{L_1\widetilde{K}_1M_1;L_2\widetilde{K}_2M_2}(\{\mathbf{r}_i,\sigma_i,\tau_i\})$$

and the images of this functions

$$\sum_{K_1,K_2} C^{\omega_1\omega_2}(L_1K_1;L_2K_2)D^{L_1}_{K_1M_1}(\alpha_1\beta_1\gamma_1)D^{L_2}_{K_2M_2}(\alpha_2\beta_2\gamma_2)$$

in the space of generating parameters which are the Euler angles α_1, β_1, γ_1, α_2, β_2, γ_2. The symbols $\widetilde{K}_1,\widetilde{K}_2$ are the angular momentum projections onto the intrinsic axis for the functions Ψ, defined in the usual coordinate space, and K_1,K_2 are the same, however for the function, defined in the generating parameter space. Finally, $\widetilde{C}^{\omega_1\omega_2}(L_1\widetilde{K}_1;L_2\widetilde{K}_2)$ and $C^{\omega_1\omega_2}(L_1K_1;L_2K_2)$ are the coefficients of the linear superposition for the wave function and its map.

In essence, the dynamical variables of the system are separated in the process of mapping these basis functions onto their images which are defined in Fock–Bargmann space.[28,27] The generating vector space can be identified with the Fock–Bargmann space if these vectors are considered as complex objects. Of course, the Euler angles will then be complex as well. However, there is no need to make such an extension to the complex space for the solving many problems. The latter applies here so we take all generating parameters to be real, even if this is not expressly stated. Note that the basis functions, which have a complicated form in a coordinate space, are much simpler in the Fock–Bargmann space, being homogeneous polynomials in the generating vectors $\{\mathbf{u}_s,\ \mathbf{v}_s\}$. The generating function Φ is a kernel of the integral transformation

$$\Psi(\{\mathbf{u}_s,\mathbf{v}_s\}) = \int\cdots\int \Phi(\{\mathbf{u}_s,\mathbf{v}_s\};\{\mathbf{r}_i,\sigma_i,\tau_i\})\Psi(\{\mathbf{r}_i,\sigma_i,\tau_i\})d\mathbf{r}_1\cdots d\mathbf{r}_A \tag{4}$$

that maps the model wave functions $\Psi(\{\mathbf{r}_i,\sigma_i,\tau_i\})$ onto their images $\Psi(\{\mathbf{u}_s,\mathbf{v}_s\})$ in the space of states reproducing the dynamics of the two rotors. The images of the basis functions can be interpreted as the wave functions of two (in general, triaxial) rotors. The angular momentum

values L_1, L_2 of these two rotors and their projections K_1, K_2 onto their respective internal symmetry axis are limited in accordance with the rules established by Elliott for basis states of the SU(3) irreps (λ_π, μ_π) and (λ_ν, μ_ν).

A study of the dynamics of two quantum rotors is a relatively simple, albeit physically significant problem that can be solved with the help of heuristic arguments focused on an analysis of the mechanics of such a system. It is very important to note, however, that the practical importance of the image concept is not restricted by going to this simplification. By further exploiting the image concept, a Hamiltonian for realistic nucleon-nucleon interactions can be written down, one that includes terms that may break the underlying unitary symmetries of the problem. This is important because it means the underlying microscopic substructure can be incorporated into the analysis.

The images and their normalized coefficients can actually be found from the overlap integral of the Slater determinant Φ with another determinant,

$$\widetilde{\Phi} = \Phi(\{\widetilde{\mathbf{u}}_s, \widetilde{\mathbf{v}}_s\}; \{\mathbf{r}_i, \sigma_i, \tau_i\}). \tag{5}$$

The six orthonormalized vectors in this last expression, $\{\widetilde{\mathbf{u}}_s, \widetilde{\mathbf{v}}_s\}$ differ in direction from the vectors of the generating function Φ. Then the overlap integral

$$\langle \widetilde{\Phi} | \Phi \rangle = \int \cdots \int \Phi(\{\widetilde{\mathbf{u}}_s, \widetilde{\mathbf{v}}_s\}; \{\mathbf{r}_i, \sigma_i, \tau_i\}). \Phi(\{\mathbf{u}_s, \mathbf{v}_s\}; \{\mathbf{r}_i, \sigma_i, \tau_i\}). d\mathbf{r}_1 \cdots d\mathbf{r}_A$$

can be calculated as a determinant of overlap integrals of single-particle orbitals. Most of its elements vanishes because of the orthogonality of the spin functions. The total generating overlap integral has a multiplicative form

$$\langle \widetilde{\Phi} | \Phi \rangle = \prod_k^{n^{open}} \langle \widetilde{\Phi}_k | \Phi_k \rangle,$$

where k, the oscillator shell number, runs over the n^{open} open shells and $\langle \widetilde{\Phi}_k | \Phi_k \rangle$ is an overlap integral of the k-th shell. It is important to note that the terms representing closed oscillator shells are constants. Thus the structure of the generating invariant $\langle \widetilde{\Phi} | \Phi \rangle$ is determined only by valence configurations of the system. It also means that nucleons in closed shells form an inert core in a very natural way with the dynamics determined only by the valence nucleons. While some approaches employ an artificial truncation of shell-model space, the present approach naturally leads to this type of factorization.

Taking into account the fact that protons and neutrons are filling different harmonic oscillator shells we obtain the very compact result

$$\langle \widetilde{\Phi} | \Phi \rangle = (\mathbf{u}_1 \cdot \widetilde{\mathbf{u}}_1)^{\lambda_\pi} (\mathbf{u}_3 \cdot \widetilde{\mathbf{u}}_3)^{\mu_\pi} (\mathbf{v}_1 \cdot \widetilde{\mathbf{v}}_1)^{\lambda_\nu} (\mathbf{v}_3 \cdot \widetilde{\mathbf{v}}_3)^{\mu_\nu}. \tag{6}$$

Notice that the overlap integral of generating functions $\widetilde{\Phi}$ and Φ with the Hamiltonian of a system supply us with constructions that are necessary for a complete study of the dynamics of the valence nucleons. They are matrix elements of the Hamiltonian in the basis states of the direct product $(\lambda_\pi, \mu_\pi) \times (\lambda_\nu, \mu_\nu)$. Working within the basis of SU(3) irreps and even-even nucleus we can assume that spin S_π of the proton and S_ν of the neutron subsystems are each zero. Therefore in this scheme orbital angular momentum L is an integral of motion and the overlap integral of generating functions can be written as

$$\langle \widetilde{\Phi} | \Phi \rangle = \sum_{\lambda \mu \nu} \sum_{L \omega M} \widetilde{\Psi}^{N \lambda \mu \nu}_{L \omega M} \Psi^{N \lambda \mu \nu}_{L \omega M}. \tag{7}$$

This expression is the realization of the well-known projection method of wave packet onto states with fixed values of angular momentum.

The overlap integral of these functions with the Hamiltonian is as follows:

$$\langle\tilde{\Phi}|\hat{H}|\Phi\rangle=\sum_{\tilde{\lambda}\tilde{\mu}\tilde{\nu}}\sum_{\lambda\mu\nu}\sum_{L\omega\tilde{\omega}M}\tilde{\Psi}^{N\tilde{\lambda}\tilde{\mu}\tilde{\nu}}_{L\tilde{\omega}M}\langle\tilde{\lambda}\tilde{\mu}\tilde{\nu}L\tilde{\omega}|\hat{H}|\lambda\mu\nu L\omega\rangle\Psi^{N\lambda\mu\nu}_{L\omega M}.$$

It is relatively easy to find the overlap integral $\langle\tilde{\Phi}|\hat{H}|\Phi\rangle$ even though the potential energy operator may include a sum of nucleon–nucleon interactions with the Coulomb interaction properly taken into account. However, to select a specific matrix element,

$$\langle\tilde{\lambda}\tilde{\mu}\tilde{\nu}L\tilde{\omega}|\hat{H}|\lambda\mu\nu L\omega\rangle,$$

from this overlap integral it is necessary to apply, for example, $\Psi^{N\lambda\mu\nu}_{L\omega M}$ to the result. The next goal of this study is to find a representation in which we can extract directly from the result required information for calculating isovector $M1$ transitions.

III. GENERATORS AND SECOND-ORDER CASIMIR OPERATOR OF U(3)

It is well-known that the quadrupole-quadrupole interaction is the simplest effective Hamiltonian for describing interactions among valence nucleons and that the corresponding eigenstates have good SU(3) symmetry.[21] In order to construct these states we should perform the reduction of the basis of direct products $(\lambda_\pi,\mu_\pi)\times(\lambda_\nu,\mu_\nu)$ onto the coupled (λ,μ) basis. The standard procedure for decomposing a product of two SU(3) representations into its irreducible parts is derived from the Littlewood rules for the coupling of two-rowed Young diagrams. This procedure is described in detail in Ref. 29. Note that our additional parameters differ from labels introduced in Ref. 29. In our scheme it is convenient to use the Young diagram assuming the following structure:

first row:	$f_1=\lambda_\nu+\lambda_\pi+\mu_{O\nu}+\mu_\pi-m-\nu_1-\nu_2$	boxes,
second row:	$f_2=\mu_\nu+\mu_\pi+m-k$	boxes,
third row:	$f_3=k+\nu_1+\nu_2$	boxes.

This is equivalent to

$$\lambda=\lambda_\nu+\lambda_\pi-2m-\nu_1-\nu_2+k,$$

$$\mu=\mu_\nu+\mu_\pi-2k-\nu_1-\nu_2+m,$$

$$\nu=k+\nu_1+\nu_2,$$

where (λ,μ) are the usual SU(3) irrep labels, and ν is the so-called background number of oscillator quanta. When we use only three parameters, we get

$$(\lambda,\mu)=(\lambda_\nu+\lambda_\pi-2(m-k)-\nu,\mu_\nu+\mu_\pi+(m-k)-\nu).$$

It is easy to see that total number of oscillator quanta N is

$$N=\lambda+2\mu+3\nu=\lambda_\nu+\lambda_\pi+2\mu_\nu+2\mu_\pi.$$

Note that m and k appear as a difference in these expressions and the final SU(3) representations are therefore the same for different combinations of m and $k$as long as their difference remains constant. But there is an additional source for this multiplicity; namely, the labels ν_1 and ν_2. The simplest case when we should use the label ν_1 is the reduction of the direct product $(\lambda_\pi,0)\otimes(0,\mu_\nu)$, when the irreps $(\lambda_\pi-\nu_1,\mu_\nu-\nu_1)$ appears. The direct product $(0,\mu_\pi)\otimes(\lambda_\nu,0)$ is the source for the irreps $(\lambda_\nu-\nu_2,\mu_\pi-\nu_2)$. We should employ both labels in the general case. Even though ν and k may be constant, the parameters ν_1 and ν_2 can vary. As an example, consider the ^{160}Gd nucleus with leading SU(3) irrep (28,8). In this case the following irreps contain the lowest scissors-like $J=1^+$ states:

$$(26,9)\rightarrow m=1,\quad \nu_1=0,\quad \nu_2=0,\quad k=0,$$

$$(27,7)\rightarrow m=0,\quad \nu_1=1,\quad \nu_2=0,\quad k=0,$$

$$(27,7)\rightarrow m=0,\quad \nu_1=0,\quad \nu_2=1,\quad k=0,$$

$$(29,6)\rightarrow m=0,\quad \nu_1=0,\quad \nu_2=0,\quad k=1.$$

The first case corresponds to an excitation that appears for two axial rotors with principal axis $\mathbf{u}_1$ and $\mathbf{v}_1$. States with (27,7) can be excited in two ways: $\nu_1=1,\nu_2=0$ or $\nu_1=0,\nu_2=1$. The fourth irrep is also a new one. It corresponds to the case of two axial rotors with symmetry axis directed along $\mathbf{u}_3$ and $\mathbf{v}_3$, respectively. (This reduction can also be achieved using Clebsch–Gordan series—here we choose to construct the basis functions with the quantum numbers $(\lambda,\mu);L,M,\nu$ in explicit form as functions of six variables describing the motion of two rotors.)

First we construct the generators of U(3) in the space of the three vectors $\mathbf{u}_1,\mathbf{u}_2,\mathbf{u}_3$. This is easy to do because these vectors are mutually orthogonal. It is enough to take vector $\mathbf{u}_1$ and add another to it, $\mathbf{w}^{\pi}$, which is related to $\mathbf{u}_3$ as follows:

$$\mathbf{u}_3=\mathbf{u}_1\times\mathbf{w}^{\pi}. \tag{8}$$

Then if we introduce Cartesian components of the vectors $\mathbf{u}_1$ and $\mathbf{w}$,

$$\mathbf{u}_1=\{x_1^{\pi},x_2^{\pi},x_3^{\pi}\},\quad \mathbf{w}^{\boldsymbol{\pi}}=\{y_1^{\pi},y_2^{\pi},y_3^{\pi}\}, \tag{9}$$

and define the generators $a_{i,j}$ of U(3) for protons in the following way:

$$a_{i,j}(\pi)=x_i^{\pi}\frac{\partial}{\partial x_j^{\pi}}+y_i^{\pi}\frac{\partial}{\partial y_j^{\pi}}. \tag{10}$$

In an analogous way we define the generators $a_{i,j}(\nu)$ of U(3) for the neutron subsystem. And finally we have the generators $A_{i,j}$ of U(3) for the neutron-proton system as a whole:

$$A_{i,j}=a_{i,j}(\pi)+a_{i,j}(\nu). \tag{11}$$

It is convenient to write generators $a_{i,j}(\pi)$, $a_{i,j}(\nu)$ and $A_{i,j}$ in the intrinsic coordinate frame defined by the directions of the vectors $\mathbf{u}_1,\mathbf{u}_3,\mathbf{v}_1,\mathbf{v}_3$. In Ref. 26 it is shown how this can be done using only the two vectors $\mathbf{u}_1$ and $\mathbf{v}_1$. The eigensystem $\{\xi,\eta,\zeta\}$ is defined as one where the two vectors $\mathbf{u}_1$ and $\mathbf{v}_1$ lie in the (ξ,η) plane and have the following components:

$$\mathbf{u}_1=\left\{u_1\cos\frac{\theta}{2},-u_1\sin\frac{\theta}{2},0\right\},\quad \mathbf{v}_1=\left\{v_1\cos\frac{\theta}{2},v_1\sin\frac{\theta}{2},0\right\}. \tag{12}$$

Obviously the ξ axis coincides with the bisectrix of the angle θ between $\mathbf{u}_1$ and $\mathbf{v}_1$. As for the vectors $\mathbf{u}_3$ and $\mathbf{v}_3$, their components in this system are parametrized as follows:

$$\begin{aligned}\mathbf{u_3}&=\left\{u_3\sin\frac{\theta}{2}\cos\phi_{\nu},u_3\cos\frac{\theta}{2}\cos\phi_{\nu},u_3\sin\phi_{\nu}\right\},\\ \mathbf{v_3}&=\left\{-v_3\sin\frac{\theta}{2}\cos\phi_{\pi},v_3\cos\frac{\theta}{2}\cos\phi_{\pi},v_3\sin\phi_{\pi}\right\}.\end{aligned} \tag{13}$$

As a result there are two additional angles ϕ_{ν}, ϕ_{π}. The orientation of the intrinsic frame is specified in the usual way by three Euler angles α, β, γ. Thus the rotation of the system as a whole is separated into external and internal degrees of freedom, the former being the Euler angles α, β, γ and the latter being θ, ϕ_{ν}, ϕ_{π}. We use these six dynamical variables, α, β, γ and θ, ϕ_{ν}, ϕ_{π}, as generating coordinates instead of the Euler angles α_1, β_1, γ_1, α_2, β_2, γ_2. In order to work

with generators of U(3) we ignore the fact that $\mathbf{u}_1,\mathbf{u}_3,\mathbf{v}_1,\mathbf{v}_3$ are unit vectors, that is, that u_1,u_3,v_1,v_3 are actually fixed and equal unity. Thus we have the following expressions for the U(3) generators for the proton subsystem:

$$a_{11}(1)=\cos^2\frac{\theta}{2}\,u_1\frac{\partial}{\partial u_1}-\cos\frac{\theta}{2}\sin\frac{\theta}{2}\left[\frac{\partial}{\partial\theta}+\frac{1}{2}M_\zeta\right]+\left(1-\cos^2\phi_\pi\sin^2\frac{\theta}{2}\right)u_3\frac{\partial}{\partial u_3}$$
$$+\sin^2\frac{\theta}{2}\sin\phi_\pi\cos\phi_\pi\frac{\partial}{\partial\phi_\pi};$$

$$a_{12}(1)=-\cos\frac{\theta}{2}\sin\frac{\theta}{2}\,u_1\frac{\partial}{\partial u_1}-\cos^2\frac{\theta}{2}\left[\frac{\partial}{\partial\theta}+\frac{1}{2}M_\zeta\right]-\cos\frac{\theta}{2}\sin\frac{\theta}{2}\cos^2\phi_\pi u_3\frac{\partial}{\partial u_3}$$
$$+\cos\frac{\theta}{2}\sin\frac{\theta}{2}\sin\phi_\pi\cos\phi_\pi\frac{\partial}{\partial\phi_\pi};$$

$$a_{13}(1)=\frac{1}{2}\cot\frac{\theta}{2}M_\xi+\frac{1}{2}M_\eta-\sin\frac{\theta}{2}\sin\phi_\pi\cos\phi_\pi u_3\frac{\partial}{\partial u_3}+\left[\sin\frac{\theta}{2}\sin^2\phi_\pi+\cos\frac{\theta}{2}\cot\theta\right]\frac{\partial}{\partial\phi_\pi}$$
$$+\frac{1}{2}\frac{1}{\sin\theta/2}\frac{\partial}{\partial\phi_\nu};$$

$$a_{21}(1)=-\cos\frac{\theta}{2}\sin\frac{\theta}{2}u_1\frac{\partial}{\partial u_1}+\sin^2\frac{\theta}{2}\left[\frac{\partial}{\partial\theta}+\frac{1}{2}M_\zeta\right]-\cos\frac{\theta}{2}\sin\frac{\theta}{2}\cos^2\phi_\pi u_3\frac{\partial}{\partial u_3}$$
$$+\cos\frac{\theta}{2}\sin\frac{\theta}{2}\sin\phi_\pi\cos\phi_\pi\frac{\partial}{\partial\phi_\pi};$$

$$a_{22}(1)=\sin^2\frac{\theta}{2}\,u_1\frac{\partial}{\partial u_1}+\cos\frac{\theta}{2}\sin\frac{\theta}{2}\left[\frac{\partial}{\partial\theta}+\frac{1}{2}M_\zeta\right]+\left(1-\cos^2\phi_\pi\cos^2\frac{\theta}{2}\right)u_3\frac{\partial}{\partial u_3}$$
$$+\cos^2\frac{\theta}{2}\sin\phi_\pi\cos\phi_\pi\frac{\partial}{\partial\phi_\pi};$$

$$a_{23}(1)=-\frac{1}{2}\tan\frac{\theta}{2}M_\eta-\frac{1}{2}M_\xi-\cos\frac{\theta}{2}\sin\phi_\pi\cos\phi_\pi u_3\frac{\partial}{\partial u_3}+\left[\cos\frac{\theta}{2}\sin^2\phi_\pi-\sin\frac{\theta}{2}\cot\theta\right]\frac{\partial}{\partial\phi_\pi}$$
$$-\frac{1}{2}\frac{1}{\cos\theta/2}\frac{\partial}{\partial\phi_\nu};$$

$$a_{31}(1)=-\sin\frac{\theta}{2}\sin\phi_\pi\cos\phi_\pi u_3\frac{\partial}{\partial u_3}-\sin\frac{\theta}{2}\cos^2\phi_\pi\frac{\partial}{\partial\phi_\pi};$$

$$a_{32}(1)=-\cos\frac{\theta}{2}\sin\phi_\pi\cos\phi_\pi u_3\frac{\partial}{\partial u_3}-\cos\frac{\theta}{2}\cos^2\phi_\pi\frac{\partial}{\partial\phi_\pi};$$

$$a_{33}(1)=\cos^2\phi_\pi u_3\frac{\partial}{\partial u_3}-\sin\phi_\pi\cos\phi_\pi\frac{\partial}{\partial\phi_\pi}.$$

(14)

The set of the generators for the neutron subsystem can be obtained from the above written ones (14) in a result of the simple substitution: $u_1\to v_1$, $u_3\to v_3$, $\theta\to-\theta$, $\phi_\pi\to\phi_\nu$, $\phi_\nu\to\phi_\pi$. The generators A_{ij} for the neutron–proton system as a whole can be put down in compact form:

$$A_{11}=\frac{1}{2}(1+t)(\lambda_\pi+\lambda_\nu)+(1-t^2)\frac{\partial}{\partial t}+\mu_\pi+\mu_\nu-\frac{1-t}{2}[\chi^+_{\tau_\pi}(\mu_\pi)+\chi^+_{\tau_\nu}(\mu_\nu)],$$

$$A_{12}=-\frac{1}{2}\{\sqrt{1-t^2}(\lambda_\pi-\lambda_\nu)+(1+t)M_\zeta+\sqrt{1-t^2}[\chi^+_{\tau_\pi}(\mu_\pi)-\chi^+_{\tau_\nu}(\mu_\nu)]\},$$

$$A_{13}=M_\eta-\sqrt{\frac{1-t}{2}}\,[\chi^-_{\tau_\pi}(\mu_\pi)-\chi^-_{\tau_\nu}(\mu_\nu)]\},$$

$$A_{21}=-\frac{1}{2}\{\sqrt{1-t^2}(\lambda_\pi-\lambda_\nu)-(1-t)M_\zeta+\sqrt{1-t^2}[\chi^+_{\tau_\pi}(\mu_\pi)-\chi^+_{\tau_\nu}(\mu_\nu)]\},$$

$$A_{22}=\frac{1}{2}(1-t)(\lambda_\pi+\lambda_\nu)-(1-t^2)\frac{\partial}{\partial t}+\mu_\pi+\mu_\nu-\frac{1+t}{2}[\chi^+_{\tau_\pi}(\mu_\pi)+\chi^+_{\tau_\nu}(\mu_\nu)], \tag{15}$$

$$A_{23}=-M_\xi-\sqrt{\frac{1+t}{2}}\,[\chi^-_{\tau_\pi}(\mu_\pi)+\chi^-_{\tau_\nu}(\mu_\nu)],$$

$$A_{31}=-\sqrt{\frac{1-t}{2}}\,[\chi^-_{\tau_\pi}(\mu_\pi)-\chi^-_{\tau_\nu}(\mu_\nu)],$$

$$A_{32}=-\sqrt{\frac{1+t}{2}}\,[\chi^-_{\tau_\pi}(\mu_\pi)+\chi^-_{\tau_\nu}(\mu_\nu)],$$

$$A_{33}=\chi^+_{\tau_\pi}(\mu_\pi)+\chi^+_{\tau_\nu}(\mu_\nu),$$

where $t=\cos\theta$, $\tau_\nu=\sin\phi_\nu$, $\tau_\pi=\sin\phi_\pi$, and

$$\chi^+_\tau(\mu)=(1-\tau^2)\left[\mu-\tau\frac{\partial}{\partial\tau}\right],\quad \chi^-_\tau(\mu)=\sqrt{1-\tau^2}\left[\mu\tau+(1-\tau^2)\frac{\partial}{\partial\tau}\right]. \tag{16}$$

The operators M_ξ, M_η, M_ζ are angular momentum projections.

The next step is the construction of the second order Casimir invariant C_2 of U(3) in terms of the U(3) group generators A_{ij}. This operator is a contraction of SU(3) generators:

$$C_2=d_{il}d_{km}A_{lm}d_{kj}d_{ir}A_{jr}, \tag{17}$$

where the d_{ij} are the elements of the transition matrix from the laboratory frame of reference into the intrinsic one. This expression is a second order differential form in terms of the internal variables and angular momentum projections M_ξ, M_η, M_ζ:

$$\begin{aligned}\hat{C}_2=2\Bigg\{&\chi^0_t(\lambda_\nu,\lambda_\pi)+\chi^0_{\tau_\nu}(\mu_\nu,\mu_\pi)+\chi^0_{\tau_\pi}(\mu_\nu,\mu_\pi)+\chi^+_t(\lambda_\nu)\chi^+_{\tau_\pi}(\mu_\pi)+\chi^+_t(\lambda_\pi)\chi^+_{\tau_\nu}(\mu_\nu)\\&+(1+t^2)\chi^+_{\tau_\nu}(\mu_\nu)\chi^+_{\tau_\pi}(\mu_\pi)+2t\chi^-_{\tau_\nu}(\mu_\nu)\chi^-_{\tau_\pi}(\mu_\pi)+\sqrt{\frac{1+t}{2}}\,[\chi^-_{\tau_\nu}(\mu_\nu)+\chi^-_{\tau_\pi}(\mu_\pi)]M_\xi\\&+\sqrt{\frac{1-t}{2}}\,[\chi^-_{\tau_\nu}(\mu_\nu)-\chi^-_{\tau_\pi}(\mu_\pi)]M_\eta+\frac{1}{2}\{\chi^-_{\tau_\nu}(\mu_\nu)-\chi^-_{\tau_\pi}(\mu_\pi)+\lambda_\nu-\lambda_\pi\}t\sqrt{1-t^2}M_\zeta\\&-\frac{1}{4}(1-t^2)M^2_\zeta\Bigg\}+(\lambda_\nu+\lambda_\pi+2)(\lambda_\nu+\lambda_\pi)+2(\mu_\nu+\mu_\pi)(\lambda_\nu+\lambda_\pi+\mu_\nu+\mu_\pi+1),\end{aligned} \tag{18}$$

where the operators $\chi^+_t(\lambda),\chi^-_t(\lambda)$ are defined by the relations (16) and

$$\chi^0_t(\lambda_\nu,\lambda_\pi)=(1-t^2)\left[(1-t^2)\frac{\partial^2}{\partial t^2}+(\lambda_\nu+\lambda_\pi-1)t\frac{\partial}{\partial t}-\lambda_\nu\lambda_\pi\right]. \tag{19}$$

The eigenfunctions of this differential form,

$$\Psi^{N\lambda\mu\nu}_{L\omega M}(\theta,\phi_\pi,\phi_\nu;\alpha,\beta,\gamma),$$

satisfy the following relation:

$$C_2\Psi^{N\lambda\mu\nu}_{L\omega M}=C^{\lambda\mu}_{\nu}\Psi^{N\lambda\mu\nu}_{L\omega M}, \tag{20}$$

where N is number of quanta, ν and ω are additional quantum numbers, and $C^{\lambda\mu}_{\nu}$ are eigenvalues of Casimir operator C_2:

$$C^{\lambda\mu}_{\nu}=\lambda^2+2\mu^2+2\lambda\mu+2(\lambda+\mu)+2\nu(\lambda+2\mu)+3\nu^2. \tag{21}$$

(Details involved in solving Eq. (20) are left for a more mathematical discussion of this matter.) In the next section we present some examples of basis functions for such a system.

IV. BASIS STATES IN FOCK–BARGMANN SPACE

In the present study we focus only on configurations that do not require the additional Bargmann–Moshinsky quantum number ω. For simplicity we denote

$$\Psi^{N\lambda\mu\nu}_{L\omega M}(\mathbf{u}_1,\mathbf{u}_3,\mathbf{v}_1,\mathbf{v}_3)\equiv\Psi^{N\lambda\mu\nu}_{L}.$$

As mentioned above, the eigenfunctions $\Psi^{N\lambda\mu\nu}_{L}$ are homogeneous polynomials in $\mathbf{u}_1,\mathbf{u}_3,\mathbf{v}_1,\mathbf{v}_3$ in Fock–Bargmann space. For example, the simplest solutions of Eq. (20) can be written in terms of the generating vectors:

$$\Psi^{2,2,0,0}_{0}=(\mathbf{v}_1\cdot\mathbf{u}_1),\quad \Psi^{3,0,0,1}_{0}=(\mathbf{v}_1\cdot\mathbf{u}_3),$$

$$\Psi^{3,0,0,1}_{0}=(\mathbf{v}_3\cdot\mathbf{u}_1),\quad \Psi^{2,0,2,0}_{0}=(\mathbf{v}_3\cdot\mathbf{u}_3),$$

$$\Psi^{4,2,2,0}_{0}=\sqrt{\frac{2}{3}}\left\{(\mathbf{v}_3\cdot\mathbf{u}_3)(\mathbf{v}_1\cdot\mathbf{u}_1)+\frac{1}{4}(\mathbf{v}_1\cdot\mathbf{u}_3)(\mathbf{v}_3\cdot\mathbf{u}_1)\right\},$$

$$\Psi^{6,1,1,1}_{1}=\sqrt{\frac{2}{5}}\,(\mathbf{v}_1\cdot\mathbf{u}_3)[\mathbf{v}_1\times\mathbf{u}_3].$$

To explain the normalization of the wave functions $\Psi^{N\lambda\mu\nu}_{L}$, we can go back to the overlap integral (3). Having defined the operator $\hat{\mathscr{A}}$

$$\hat{\mathscr{A}}=C_2-C^{\lambda_0\mu_0}_{0},$$

where $C^{\lambda_0\mu_0}_{0}$ is eigenvalue of Casimir operator for the leading SU(3) irrep

$$(\lambda_0,\mu_0)=(\lambda_\nu+\lambda_\pi,\mu_\nu+\mu_\pi),$$

and denoting

$$J(\lambda_\pi,\lambda_\nu,\mu_\pi,\mu_\nu)=(\mathbf{u}_1\cdot\tilde{\mathbf{u}}_1)^{\lambda_\pi}(\mathbf{u}_3\cdot\tilde{\mathbf{u}}_3)^{\mu_\pi}(\mathbf{v}_1\cdot\tilde{\mathbf{v}}_1)^{\lambda_\nu}(\mathbf{v}_3\cdot\tilde{\mathbf{v}}_3)^{\mu_\nu},$$

we observe that

$$\begin{aligned}\hat{\mathscr{A}}J(\lambda_\pi,\lambda_\nu,\mu_\pi,\mu_\nu)=&-\lambda_\pi\lambda_\nu[\mathbf{u}_1\times\mathbf{v}_1]\cdot[\tilde{\mathbf{u}}_1\times\tilde{\mathbf{v}}_1]J(\lambda_\pi-1,\lambda_\nu-1,\mu_\pi,\mu_\nu)\\&-\mu_\pi\mu_\nu[\mathbf{u}_3\times\mathbf{v}_3]\cdot[\tilde{\mathbf{u}}_3\times\tilde{\mathbf{v}}_3]J(\lambda_\pi,\lambda_\nu,\mu_\pi-1,\mu_\nu-1)\\&-\lambda_\nu\mu_\pi(\mathbf{u}_1\cdot\mathbf{v}_3)(\tilde{\mathbf{u}}_1\cdot\tilde{\mathbf{v}}_3)J(\lambda_\pi,\lambda_\nu-1,\mu_\pi-1,\mu_\nu)\\&-\lambda_\pi\mu_\nu(\mathbf{v}_1\cdot\mathbf{u}_3)(\tilde{\mathbf{v}}_1\cdot\tilde{\mathbf{u}}_3)J(\lambda_\pi-1,\lambda_\nu,\mu_\pi,\mu_\nu-1).\end{aligned} \tag{22}$$

On the other hand

$$J(\lambda_\pi,\lambda_\nu,\mu_\pi,\mu_\nu)=\sum_{\lambda,\mu} B^2_{mk\nu_1\nu_2}(\lambda,\mu)\langle(\lambda,\mu)|\widetilde{(\lambda,\mu)}\rangle, \tag{23}$$

where $B_{mk\nu_1\nu_2}(\lambda,\mu)$ are the weights of corresponding irreps. Therefore acting with the operator $\hat{\mathscr{A}}$ on expansion (23) and taking into account the relation (20) we have

$$\hat{\mathscr{A}}J(\lambda_\pi,\lambda_\nu,\mu_\pi,\mu_\nu)=\sum_{\lambda,\mu} B^2_{mk\nu_1\nu_2}(\lambda,\mu)(C^{\lambda,\mu}_\nu-C^{\lambda_0,\mu_0}_0)\langle(\lambda,\mu)|\widetilde{(\lambda,\mu)}\rangle, \tag{24}$$

where the overlap integral $\langle(\lambda,\mu)|\lambda,\mu)\rangle$ can be written as a product

$$|\mathbf{v}_1\times\mathbf{u}_1|^m|\mathbf{v}_3\times\mathbf{u}_3|^k(\mathbf{v}_1\cdot\mathbf{u}_3)^{\nu_1}(\mathbf{v}_3\cdot\mathbf{u}_1)^{\nu_2}\times|\tilde{\mathbf{v}}_1\times\tilde{\mathbf{u}}_1|^m|\tilde{\mathbf{v}}_3\times\tilde{\mathbf{u}}_3|^k(\tilde{\mathbf{v}}_1\cdot\tilde{\mathbf{u}}_3)^{\nu_1}(\tilde{\mathbf{v}}_3\cdot\tilde{\mathbf{u}}_1)^{\nu_2}I(\lambda,\mu). \tag{25}$$

In this expression $I(\lambda,\mu)$ is normalized so that when vectors $\mathbf{u}_1$ and $\mathbf{v}_1$, $\mathbf{u}_3$ and $\mathbf{v}_3$ are collinear, it takes on the well-known form first introduced by Elliott,[21]

$$I(\lambda,\mu)=d^\lambda_{11}d^\mu_{33}, \tag{26}$$

where $d_{ij}\equiv d_{ij}(\alpha',\beta',\gamma')$ are matrix elements of the transition matrix from the $\{\xi,\eta,\zeta\}$ coordinate frame into the $\{\tilde{\xi},\tilde{\eta},\tilde{\zeta}\}$ one.

Taking this property of the overlap integral into account and comparing relations (22) and (24), one can extract the coefficients $B^2_{mk\nu_1\nu_2}(\lambda,\mu)$. As an example, we now apply this procedure to find $B^2_{m=1}(\lambda,\mu)$. Using Eqs. (22), (18) and (25) we get

$$\begin{aligned}\lambda_\pi\lambda_\nu[\mathbf{u}_1\times\mathbf{v}_1]\cdot[\tilde{\mathbf{u}}_1\times\tilde{\mathbf{v}}_1]J(\lambda_\pi-1,\lambda_\nu-1,\mu_\pi,\mu_\nu)+\ldots\\ =\ldots+B^2_{m=1}(\lambda_0-2,\mu_0+1)(C_0^{\lambda_0-2,\mu_0+1}-C_0^{\lambda_0,\mu_0})\\ \times|\mathbf{u}_1\times\mathbf{v}_1||\tilde{\mathbf{u}}_1\times\tilde{\mathbf{u}}_1|I(\lambda_0-2,\mu_0+1)+\ldots,\end{aligned} \tag{27}$$

where dots denote the terms which do not contain the factor

$$|\mathbf{u}_1\times\mathbf{v}_1||\tilde{\mathbf{u}}_1\times\tilde{\mathbf{u}}_1|.$$

Putting in the functions $J(\lambda_\pi-1,\lambda_\nu-1,\mu_\pi,\mu_\nu)$ and $I(\lambda_0-2,\mu_0+1)$ with $(\mathbf{u}_1\cdot\mathbf{v}_1)=(\mathbf{u}_3\cdot\mathbf{v}_3)=1$ we find

$$B^2_{m=1}(\lambda_0-2,\mu_0+1)=\frac{\lambda_\nu\lambda_\pi}{\lambda_\nu+\lambda_\pi}.$$

Other weights can be found in the same way:

$$B^2_{k=1}(\lambda_0+1,\mu_0-2)=\frac{\mu_\nu\mu_\pi}{\mu_\nu+\mu_\pi},$$

$$B^2_{\nu_1=1}(\lambda_0-1,\mu_0-1)=\frac{\mu_\nu\lambda_\pi}{\mu_0+\lambda_0+1},\quad B^2_{\nu_2=1}(\lambda_0-1,\mu_0-1)=\frac{\mu_\pi\lambda_\nu}{\mu_0+\lambda_0+1}.$$

In the second step we project the overlap integral $\langle(\lambda,\mu)|\widetilde{(\lambda,\mu)}\rangle$ onto the states with certain values of orbital angular momentum L:

$$\langle(\lambda,\mu)|\widetilde{(\lambda,\mu)}\rangle=\sum_{L,M} A^2_{mk\nu_1\nu_1}(\lambda,\mu;L)\langle(\lambda,\mu);L,M|\widetilde{(\lambda,\mu)};L,M\rangle.$$

Passing from this expression to the Elliott case $((\mathbf{u}_1\cdot\mathbf{v}_1)=(\mathbf{u}_3\cdot\mathbf{v}_3)=1)$ we find the expansion coefficients $A_{mk\nu_1\nu_1}(\lambda,\mu;L)$:

$$A^2(\lambda_0,\mu_0;L=0)=\frac{1}{2\sqrt{\pi}}\frac{\Gamma((\lambda_0+1)/2)\Gamma((\lambda_0+\mu_0)/2+1)\Gamma((\mu_0+1)/2)}{\Gamma((\lambda_0)/2+1)\Gamma((\lambda_0+\mu_0+3)/2)\Gamma(\mu_0/2+1)};$$

$$A^2_{m=1}(\lambda_0-2,\mu_0+1;L=1)=\frac{3\lambda_0(\mu_0+1)}{(\lambda_0-1)(\mu_0+2)}A^2(\lambda_0,\mu_0;L=0);$$

$$A^2_{k=1}(\lambda_0+1,\mu_0-2;L=1)=\frac{3(\lambda_0+1)\mu_0}{(\lambda_0+2)(\mu_0-1)}A^2(\lambda_0,\mu_0;L=0); \tag{28}$$

$$A^2_{\nu_1=1,(\nu_2=1)}(\lambda_0-1,\mu_0-1;L=1)=\frac{3(\lambda_0+\mu_0+1)}{(\lambda_0+\mu_0)}A^2(\lambda_0,\mu_0;L=0).$$

Finally, we can write down expressions for the normalizing coefficients

$$N_{mk\nu_1\nu_1}(\lambda,\mu;L)=A_{mk\nu_1\nu_1}(\lambda,\mu;L)B_{mk\nu_1\nu_2}(\lambda,\mu).$$

Below we present one example of normalized wave function written in terms of dynamical variables θ, ϕ_ν, ϕ_π for $L=0$, $\mu_\nu=\mu_\pi=1$ and arbitrary even λ_ν,λ_π:

$$\begin{aligned}\Psi^{\lambda_0+4,(\lambda_0,2),0}_{L=0}=&\sqrt{\frac{\lambda_0+2}{2(\lambda_0+1)(\lambda_0+3)}}\Bigg\{\tau F\left(-\frac{\lambda_\nu}{2},-\frac{\lambda_\pi}{2},\frac{1}{2}-\frac{\lambda_0}{2};1-t^2\right)\\&+\frac{\lambda_\nu(\lambda_\nu-1)}{2(\lambda_0+2)(\lambda_0-1)}t(1-t^2)F\left(-\frac{\lambda_\nu}{2}+1,-\frac{\lambda_\pi}{2}+1,\frac{3}{2}-\frac{\lambda_0}{2};1-t^2\right)\\&\times\sqrt{1-\tau_\nu^2}\sqrt{1-\tau_\pi^2}\Bigg\}.\end{aligned} \tag{29}$$

In this expression the $F(a,b,c;z)$ are hypergeometric functions, $t=\cos\theta$, $\tau_\nu=\sin\phi_\nu$, $\tau_\pi=\sin\phi_\pi$ and $\tau=(\mathbf{u}_3\cdot\mathbf{v}_3)=\tau_\nu\tau_\pi+t\sqrt{1-\tau_\pi^2}\sqrt{1-\tau_\nu^2}$. The expression for the wave function for the most general case of arbitrary even μ_ν,μ_π, λ_ν,λ_π and $L=0$ is too spacious to be written wholly. Therefore we present here only first four terms of this function in order to show its structure:

$$\begin{aligned}\Psi^{N,(\lambda_0,\mu_0),0}_{L=0}=&F\left(-\frac{\mu_\pi}{2},-\frac{\mu_\nu}{2},\frac{1-\mu_0}{2};1-\tau^2\right)F\left(-\frac{\lambda_\pi}{2},-\frac{\lambda_\nu}{2},\frac{1-\lambda_0}{2};1-t^2\right)\\&+\frac{2\lambda_\pi\lambda_\nu\mu_\pi\mu_\nu}{(\lambda_0+\mu_0)(\lambda_0-1)(\mu_0-1)}(1-t^2)\sqrt{1-\tau_\pi^2}\sqrt{1-\tau_\nu^2}t\tau\\&\times F\left(-\frac{\lambda_\pi}{2}+1,-\frac{\lambda_\nu}{2}+1,\frac{3-\lambda_0}{2};1-t^2\right)F\left(-\frac{\mu_\pi}{2}+1,-\frac{\mu_\nu}{2}+1,\frac{3-\mu_0}{2};1-\tau^2\right)\\&-\frac{\lambda_\nu\mu_\pi(\lambda_\nu-1)(\mu_\pi-1)}{2(\lambda_0+\mu_0)(\lambda_0-1)(\mu_0-1)}(1-t^2)(1-\tau_\pi^2)\\&\times F\left(-\frac{\lambda_\pi}{2},-\frac{\lambda_\nu}{2}+1,\frac{3-\lambda_0}{2};1-t^2\right)F\left(-\frac{\mu_\pi}{2}+1,-\frac{\mu_\nu}{2},\frac{3-\mu_0}{2};1-\tau^2\right)\\&\times-\frac{\lambda_\pi\mu_\nu(\lambda_\pi-1)(\mu_\nu-1)}{2(\lambda_0+\mu_0)(\lambda_0-1)(\mu_0-1)}(1-t^2)(1-\tau_\nu^2)\end{aligned}$$

$$F\left(-\frac{\lambda_\pi}{2}+1,-\frac{\lambda_\nu}{2},\frac{3-\lambda_0}{2};1-t^2\right)F\left(-\frac{\mu_\pi}{2},-\frac{\mu_\nu}{2}+1,\frac{3-\mu_0}{2};1-\tau^2\right)+\ldots. \tag{30}$$

V. THE TRANSITION PROBABILITIES FOR THE SCISSORS MODE

To find transition probabilities, one must first construct the isovector operator $\mathbf{S}_M$ of the magnetic dipole transition. In the rotating frame this operator is connected with the angular momentum operators of the proton and neutron subsystems through the simple relation

$$\mathbf{S}_k=\mathbf{l}_k(\pi)-\mathbf{l}_k(\nu).$$

It is easy to obtain expressions for the spherical components of the operator $\mathbf{S}_k$ because the relation between operators $\mathbf{l}_k(\pi)$ and $\mathbf{l}_k(\nu)$ and the generators $a_{ij}(\pi)$ and $a_{ij}(\nu)$ are known:

$$\mathbf{l}_k(\pi)=e_{kij}a_{ij}(\pi)$$

and

$$\mathbf{l}_k(\nu)=e_{kij}a_{ij}(\nu).$$

Without giving details, we present the expression for the operator in the laboratory system that is necessary for the subsequent analysis. In going from the intrinsic to the laboratory frame of reference, the operator $\mathbf{S}_k$ transforms as components of a rank 1 tensor, that is,

$$\mathbf{S}'_M=\sum_k D^1_{M,k}\mathbf{S}_k.$$

Again, with the given details we now present an expression for the matrix elements of this operator. We confine ourselves to the analysis of the transitions (involving a change in the isospin) from the state with $L=0$ of the ground band $(\lambda_0,\mu_0)=(\lambda_\nu+\lambda_\pi,\mu_\nu+\mu_\pi)$ to the states with $L=1$ of the band with quantum numbers (λ_0-2,μ_0+1) and the band with (λ_0+1,μ_0-2), that is, we consider only multiplicity free cases for two triaxial rotors.

To find the matrix elements of a transition operator, it is necessary to extract functions $\Psi^{N,(\lambda_0-2,\mu_0+1),0}_{L=1}$ and $\Psi^{N,(\lambda_0+1,\mu_0-2),0}_{L=1}$ from a superposition of functions obtained as the result of the action of this operator on the normalized wave function $\Psi^{N\lambda_0\mu_0 0}_{L=0}$. We obtain

$$\mathbf{S}'_M\Psi^{N,(\lambda_0,\mu_0),0}_{L=0}=-i\frac{2\lambda_\nu\lambda_\pi}{(\lambda_\nu+\lambda_\pi-1)}\frac{N_0(\lambda_0,\mu_0;L=0)}{N_{m=1}(\lambda_0-2,\mu_0+1;L=1)}\Psi^{N,(\lambda_0-2,\mu_0+1),0}_{L=1}$$
$$-i\frac{2\mu_\nu\mu_\pi}{(\mu_\nu+\mu_\pi-1)}\frac{N_0(\lambda_0,\mu_0;L=0)}{N_{k=1}(\lambda_0+1,\mu_0-2;L=1)}\Psi^{N,(\lambda_0+1,\mu_0-2),0}_{L=1}+\ldots, \tag{31}$$

where $N_{mk\nu_1\nu_2}(\lambda,\mu;L)$ are normalizing coefficients and dots denote other functions. Taking into account the expressions given above we find

$$\langle(\lambda_0-2,\mu_0+1),L=1,M|\mathbf{S}'_M|(\lambda_0,\mu_0),L=0\rangle=-2i\sqrt{\frac{(\mu_\pi+\mu_\nu+2)\lambda_\nu\lambda_\pi}{3(\mu_\pi+\mu_\nu+1)(\lambda_\nu+\lambda_\pi-1)}}; \tag{32}$$

$$\langle(\lambda_0+1,\mu_0-2),L=1,M|\mathbf{S}'_M|(\lambda_0,\mu_0),L=0\rangle=-2i\sqrt{\frac{(\lambda_\nu+\lambda_\pi+2)\mu_\nu\mu_\pi}{3(\lambda_\nu+\lambda_\pi+1)(\mu_\nu+\mu-1)}}. \tag{33}$$

Using the well-known relation

$$\langle\alpha_2J_2M_2|Q_{\lambda,\mu}|\alpha_1J_1M_1\rangle=\frac{(J_1\lambda M_1\mu|J_2M_2)}{\sqrt{2J_2+1}}\langle\alpha_2J_2||Q_{\lambda,\mu}||\alpha_1J_1\rangle, \tag{34}$$

TABLE I. Theoretical and experimental M1 transition strengths from the ground state to the first excited 1^+ state. The results given in column Th^1 correspond to the approach used in this work and coincide with those of a pseudo-SU(3) theory. The SU(3) irrep (λ_0,μ_0) for the ground band and the irreps associated to the 1^+ states, (λ',μ'), for each is also given.

			$B(M1;0^+\to1^+)/(\mu_n^2)$	
Nucleus	(λ_0,μ_0)	(λ',μ')	Th^1	Exp
^{154}Sm	(30,0)	(28,1)	3.56	0.8(2)
^{156}Gd	(28,4)	(26,5)	1.91	1.5(3)
^{158}Gd	(28,8)	(26,9)	1.77	1.4(3)
		(29,6)	0.56	0.9(2)
^{160}Gd	(28,8)	(26,9)	1.77	0.8(2)
		(29,6)	0.56	0.60(17)
^{168}Er	(30,8)	(28,9)	1.83	
		(31,6)	0.56	0.9(2)
^{174}Yb	(32,6)	(30,7)	2.11	0.8(2)
^{232}Th	(42,6)	(40,7)	2.40	
		(43,4)	0.39	
$^{234-236}$U	(48,4)	(46,5)	3.29	
^{238}U	(54,0)	(52,1)	5.84	
^{242}Pu	(52,6)	(50,7)	3.27	

we also find the values of the reduced matrix elements of the transition operator. To calculate the reduced probabilities we use the well-known formula:

$$B(M1;1\to2)=\frac{3}{16\pi}\frac{1}{2J_1+1}|\langle\alpha_2J_2||\mathbf{S}'_M||\alpha_1J_1\rangle|^2\mu_n^2.$$

The reduced probabilities calculated by this formula have the values

$$B(M1;0^+\to1^+)=\frac{3}{4\pi}\left[\frac{\lambda_\nu\lambda_\pi}{(\lambda_\nu+\lambda_\pi-1)}\frac{(\mu_\pi+\mu_\nu+2)}{(\mu_\pi+\mu_\nu+1)}\right]\mu_n^2 \tag{35}$$

for the state $|(\lambda_\nu+\lambda_\pi-2,\mu_\nu+\mu_\pi+1),L=1,M\rangle$ and

$$B(M1;0^+\to1^+)=\frac{3}{4\pi}\left[\frac{\mu_\nu\mu_\pi}{(\mu_\nu+\mu_\pi-1)}\frac{(\lambda_\nu+\lambda_\pi+2)}{(\lambda_\nu+\lambda_\pi+1)}\right]\mu_n^2 \tag{36}$$

for the state $|(\lambda_\nu+\lambda_\pi+1,\mu_\nu+\mu_\pi-2),L=1,M\rangle$. The numerical values of $B(M1)$ strengths for the transitions $0^+\to1^+$ are the same that arise in a pseudo-SU(3) theory of collective M1 bands.[10] Note that proton and neutron g-factors are $g_p=1$ and $g_n=0$, respectively. The calculated strengths are given in Table I for some nuclei of the rare earth region and actinide species.

VI. RELATIVE ORIENTATION OF TWO ROTORS

We can analyze the dynamics of two rotors using the wave functions in explicit form. Here we study the dependence of basis states on the dynamical variables. An analysis of this dependence on the Euler angles α, β, γ is not of interest because these describe the well-studied rotation of the nucleus as a whole. Information about the relative motions of two rotors is, however, interesting. It can be obtained through an anlysis of the dependence of the basis states on the θ, ϕ_ν, and ϕ_π angles. As an example we consider in this section the nucleus ^{22}Ne $(\lambda_\nu=\lambda_\pi=4,\mu_\nu=2,\mu_\pi=0)$. We analyze the dependence of the density of the probability function on the θ and ϕ_ν angles. For this purpose we integrate the probability function

$$\rho^{L,M}_{(\lambda,\mu)}(\theta,\phi_\nu,\alpha,\beta,\gamma)\equiv|\Psi^{L,M}_{(\lambda,\mu)}|^2$$

over the Euler angles α, β, γ to get the function $\rho^{L}_{(\lambda,\mu)}(\theta,\phi_\nu)$. This function for ^{22}Ne for specific values of L,m,ν is

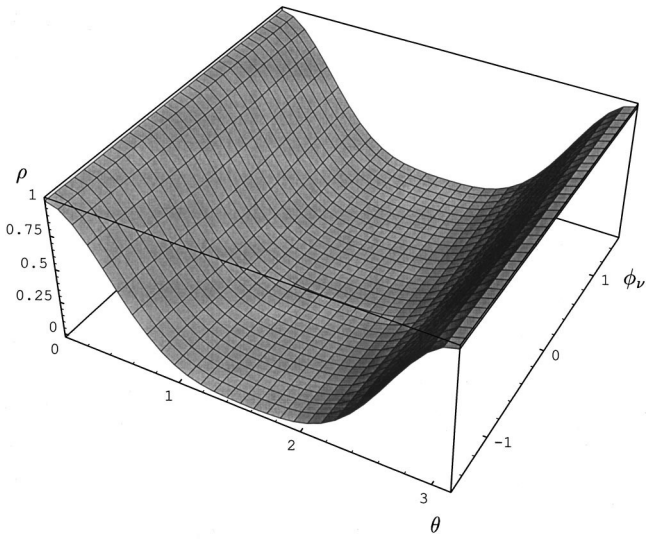

FIG. 1. The function $\rho^0_{(8,2)}(\theta,\phi_\nu)$ for ^{22}Ne.

$$\rho^0_{(8,2)}(\theta,\phi_\nu)=\left[1-\frac{8}{7}\sin^2\theta+\frac{8}{35}\sin^4\theta-\frac{6}{35}\sin^2\theta\cos^2\phi_\nu\left[1-\frac{4}{5}\sin^2\theta\right]\right]^2;$$

$$\rho^1_{(6,3)}(\theta,\phi_\nu)=\sin^2 2\theta\left[1-\frac{2}{5}\sin^2\theta-\frac{1}{5}\cos^2\phi_\nu-\frac{16}{175}\sin^2\theta\cos^2\phi_\nu\right]^2$$
$$+\frac{1}{400}\sin^2 2\phi_\nu\sin^2 2\theta\left[1-\frac{2}{5}\sin^2\theta\right]^2; \tag{37}$$

$$\rho^1_{(7,1)}(\theta,\phi_\nu)=\sin^2\theta\cos^2\phi_\nu\left\{\sin^2\phi_\nu\left(1-\frac{8}{7}\sin^2\theta+\frac{8}{35}\sin^4\theta\right)^2\right.$$
$$\left.+\cos^2\theta\cos^2\phi_\nu\left[1-\frac{4}{7}\sin^2\theta\right]^2\right\}$$

The behavior of these functions is shown in Figs. 1–3. {The values of $\rho^L_{(\lambda,\mu)}(\theta,\phi_\nu)$ are plotted on the vertical axis; the abscissa is the angle θ over the range $[0,\pi]$ where the ordinate is the angle

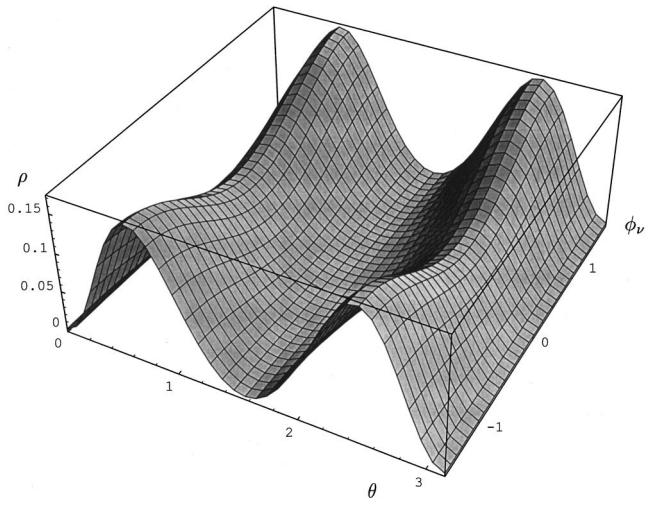

FIG. 2. The function $\rho^1_{(6,3)}(\theta,\phi_\nu)$ for ^{22}Ne.

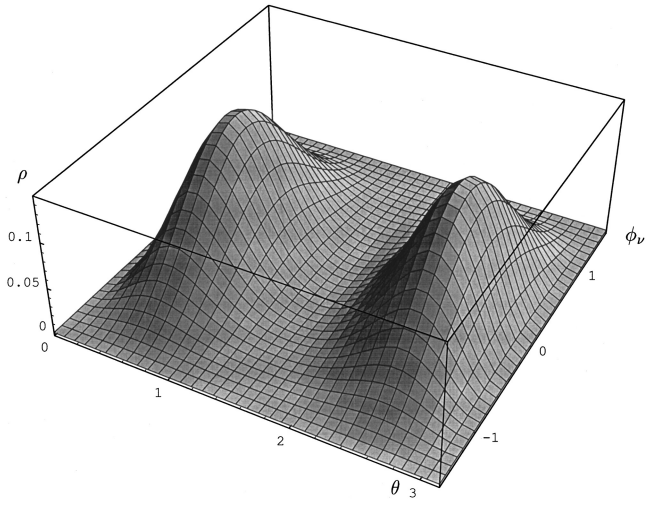

FIG. 3. The function $\rho^1_{(7,1)}(\theta,\phi_\nu)$ for ^{22}Ne.

ϕ_ν over the range $[-\pi/2,\pi/2]$.} Figure 1 indicates that the ground state corresponds to the maximum overlap of the proton and neutron distributions in the nucleus ($\theta=0$). In this case the function $\rho^0_{(\lambda,\mu)}(\theta,\phi_\nu)$ changes very slowly with angle ϕ_ν; nevertheless, it has maximum at $\phi_\nu=\pi/2$, which is difficult to observe in figures. The point $(\theta_{max},\phi_{\nu_{max}})=(0,\pi/2)$, for which $\rho^0_{(\lambda,\mu)}(\theta,\phi_\nu)$ has a maximum, corresponds to the limiting case when the system of one axial and one nonaxial rotor is transformed to one rotor.

The excitation of the nucleus to states with $L=1^+$ decreases the overlap of the two subsystems. The θ maximum of the $\rho^1_{(\lambda,\mu)}(\theta,\phi_\nu)$ function is shifted from $\theta=0$ to another θ_{max} in both the $m=1$ and $\nu_2=1$ cases. But one can see from Figs. 2 and 3 that the excited states with $m=1,\nu_2=0$ and $m=0,\nu_2=1$ differ one from another by the value of angle ϕ_ν ($\phi_{\nu_{max}}$) in which case $\rho^1_{(\lambda,\mu)}(\theta,\phi_\nu)$ has a maximum. When $m=1,\nu_2=0$ (state $|(\lambda_0-2,\mu_0+1),L=1,M\rangle$) the maximum is observed at $\phi_{\nu_{max}}=\pi/2$. This value of ϕ_ν corresponds to the transition from a system of one axial and one non-axial rotor into a system of two axial rotors. Actually, the state $|(\lambda-2,1),L=1,M\rangle$ appeared in the calculations of two axial rotors as the single lowest isovector state. The new state $|(\lambda_0-1,\mu_0-1),L=1,M\rangle$, that was absent in the case of two axial rotors is characterized by the maximum of the $\rho(\theta,\phi_\nu)$ function at $\phi_{\nu_{max}}=0$. This means that the most probable orientation of the neutron and proton subsystems is the one when $(\theta,\phi_\nu)=(\theta_{max},0)$, that is, when the three vectors $\mathbf{u}_1,\mathbf{v}_1,\mathbf{v}_3$ lie in a plane.

VII. CONCLUSION

In this paper we proposed a microscopic shell-model interpretation of the TRM. The theory is a neutron–proton version of the Elliott SU(3) model, where the final coupled SU(3) symmetry is constructed as a tensor product, $\mathrm{SU}_\pi(3)\otimes\mathrm{SU}_\nu(3)$. A basis for this new representation was constructed for $L=0$ and 1 states in Fock–Bargmann space. This representation is equivalent to a basis in coordinate space but has a simpler form that depends on only six variables. This simplification was achieved by constructing U(3) generators for the proton and neutron subsystems as well as for the total system. Through the construction of the second order Casimir operator of U(3) we were able to find by using generating function methods normalized wave functions for the ground state and two scissors-like states with $L=1^+$.

The efficiency of the method was illustrated with specific calculations for magnetic dipole transitions between nuclear states having quantum numbers $(\lambda_\nu+\lambda_\pi,\mu_\nu+\mu_\pi),L=0^+$, and $(\lambda_\nu+\lambda_\pi-2,\mu_\nu+\mu_\pi+1),L=1^+,M$, and $(\lambda_\nu+\lambda_\pi+1,\mu_\nu+\mu_\pi-2),L=1^+,M$. The results show that the approach predicts a fragmentation of the scissors mode into four transitions and we have obtained analytic expressions for the $B(M1)$–strengths corresponding to two of them. The results of calculations are compared with the corresponding pseudo-SU(3) predictions as well as experimental data for some rare earth and actinide nuclei.

We have also given a two rotor interpretation of the ground state and the excited isovector states and have connected changes in the underlying geometry with the transition operator. This has all been done without addressing the question of the excitation energies of the states involved. The reason is that it is known from Ref. 10 that there exists a simple Hamiltonian form built out of polynomial functions of the SU(3) generators that are SO(3) scalar that can be used to fit the experimental data. The Hamiltonian contains both kinetic (rotational spectrum within irreps) and potential (relative displacement of irreps) energy parts that can be used to reproduce rotor spectra, including a correct placement of the $M1$ band.

Only even–even nuclei have been considered in this paper. The approach can be extended to the general case when the total spin of a nucleus is nonzero. This case, as well as more complicated shapes that involve multiplicities, will be considered in a later publication.

Generalized annihilation operator coherent states

Gautam Ghosh[a)]
Saha Institute of Nuclear Physics, 1/AF Bidhannagar, Calcutta 700 064, India

(Received 21 July 1997; accepted for publication 4 September 1997)

A set of generalized coherent states as eigenstates of the annihilation operator is proposed. These states are analytic functions of a complex variable and admit a resolution of identity with positive measure. Guided by the classical action angle transformation and the correspondence principle a formalism is developed for the construction of the annihilation operator for a given Hamiltonian. © *1998 American Institute of Physics.* [S0022-2488(98)00603-3]

I. INTRODUCTION

The coherent states of the harmonic oscillator[1,2] are a set of states satisfying a large number of interesting and useful properties. They are (1) eigenfunctions of the annihilation operator, (2) entire functions of a complex variable, (3) a complete set of basis vectors and (4) minimum uncertainty states. Moreover, (5) these states can be constructed from the ground state by the action of a unitary displacement operator and (6) they are temporally stable, i.e., under time evolution they remain coherent. Historically, these states were introduced in an attempt to derive classical behavior viz., a nonspreading wave packet traveling coincidentally with the classical particle from the underlying quantum dynamics.[3] More general coherent states which include the oscillator coherent states as a special case were constructed. These are the generalized coherent states (GCS) of Perelomov and Gilmore,[4,5] the minimum uncertainty coherent states (MUCS) of Nieto and Simmons[6,7] and the very recent temporally stable coherent states (TSCS) of Klauder.[8] The GCS, defined through property (5), are richly endowed with a variety of interesting characteristics[9,10] including completeness arising from the group property of the unitary displacement operator. In general, they are neither minimum uncertainty states nor temporally stable. The TSCS of Klauder satisfy property (6) by construction and they are also complete. However like the GCS they are in general neither minimum uncertainty states nor eigenstates of the annihilation operator. The MUCS were proposed to have minimum uncertainty products with respect to operator pairs called natural quantum operators that are counterparts of classical variables which evolve like oscillator solutions. The MUCS have not been shown to be complete in general. Both the GCS and MUCS can be constructed for both finite and infinite spectra (including possible degeneracy) while the TSCS are defined only for infinite spectra.

In this work we propose a set of coherent states which are eigenstates of suitably constructed annihilation operators called generalized annihilation operators (GAO). The GAO can be obtained for both finite and infinite spectra through mappings to the linear spectrum of the oscillator so that they are direct generalizations of the oscillator annihilation operator. The coherent states defined only for infinite spectra will be analytic functions of complex variables and will be complete with respect to suitably chosen measures. Finally, these states will minimize the uncertainty products of operator pairs in a sense to be explained later.

II. FORMALISM

The construction of the GAO will be achieved within an action-angle framework. From the commutation relation (we take $\hbar=1$),

$$[J,\ e^{\pm i\phi}]=\pm e^{\pm i\phi}, \tag{1}$$

[a)]Electronic mail: gghosh@tnp.saha.ernet.in

 © 1998 American Institute of Physics

the eigenvalues (n) of J may be taken to be integers (modulo an inessential shift), unbounded both above and below while the unitary operators $e^{\pm i\phi}$ act as shift operators within the full eigenspace of J. However, identifying the ground state of the Hamiltonian with the state $n=0$, we note that the eigenspace ($\mathscr{H}:n\geqslant 0$) of the Hamiltonian is not invariant under the action of the shift operators. The problem is resolved for the oscillator where the creation and annihilation operators ($a^\dagger$ and a) turn out to be $\sqrt{J}e^{i\phi}$ and $e^{-i\phi}\sqrt{J}$ so that the ground state is indeed destroyed by a. The GAO are natural generalizations in the sense that for a given Hamiltonian we will look for operators of the form $e^{-i\phi}f(J)$ with the demand that $f(0)=0$, so as to ensure the aforementioned invariance and bypass the problem of the nonunitarity[11–16] of $e^{\pm i\phi}$ within $\mathscr{H}$. It turns out that the function $f(J)$ is essentially uniquely determined by the following requirements:

(i) The Hamiltonian operator must reduce to a function of J alone. This will directly lead to the spectra once J is replaced by n.

(ii) The relations between the quantum operators $(J,e^{\pm i\phi})$ and (x,p) must reduce to the classical relations in the leading order of J.

(iii)
$$e^{-in\phi}g(J)e^{in\phi}=g(J+n), \tag{2}$$

where $g(J)$ is any given function of J and $n\geqslant 0$. This is the same thing as (1) written in a form such that both the left- and right-hand sides of (2) are well defined in $\mathscr{H}$.

Once the generalized annihilation operator is constructed, the ground state in the coordinate representation may be obtained by solving a first order differential equation. Successive applications of the creation operator which is a first order differential operator then yields the excited state wave functions.[17] Since the formalism employs the classical action-angle transformation as the guiding principle, the construction of the GAO is limited to separable systems only. In the following we illustrate the method by working out the GAO and the corresponding coherent states in a number of standard problems involving an infinite number of bound states.

III. EXAMPLES OF COHERENT STATES

A. The harmonic oscillator with centripetal barrier (HOCB) potential

This potential supports a simple linear spectrum. The Hamiltonian (in appropriate units),

$$H=p^2/2+U\left(x-\frac{1}{x}\right)^2, \tag{3}$$

leads to the following classical relations between x, p and $J\equiv(1/2\pi)\oint p(E,x)dx$ and $\phi=(\partial/\partial J)\int^x p(J,x)dx$,

$$H=\sqrt{8U}J, \tag{4}$$

$$x^2=\left(1+\sqrt{\frac{2}{U}}\,J\right)+\sqrt{\frac{2}{U}}\,(J^2+\sqrt{2U}J)^{1/2}\sin\,\phi. \tag{5}$$

In conformity with the requirements mentioned above, we write the corresponding quantum relations as

$$H=\sqrt{8U}(J+\alpha), \tag{6}$$

$$x^2=a(J)+\frac{1}{2i}\,[b(J)e^{i\phi}-e^{-i\phi}b(J)], \tag{7}$$

where the constant α and the functions $a(J)$ and $b(J)$ are to be determined.

Equation (6) has been written so as to agree with (4) in the leading order in J, the term involving α having been introduced as a possible quantum correction. Similarly, the correspondence principle places restrictions on $a(J)$, $b(J)$ for $J\to\infty$. Furthermore for $b(J)\exp(i\phi)$ and $\exp(-i\phi)b(J)$ to be well defined in $\mathscr{H}$, $b(J)$ must satisfy $b(0)=0$.

The operators occurring on the left-hand side of (6) and (7) satisfy

$$[[H,\ x^2],\ x^2]=-4x^2 \tag{8a}$$

and

$$[H,\ x^2]^2=-4\{H,x^2\}+8U(x^2-1)^2-3, \tag{8b}$$

where {,} implies an anticommutator. Replacing these by corresponding operators on the right-hand side, and imposing (2) we get a set of consistency conditions determining the functions $a(J),b(J)$ through a set of difference equations. For instance, equating coefficients of $\exp(i\phi)$ in (8a) and (8b) one gets,

$$a(J)=1+\sqrt{\frac{2}{U}}\,(J+\alpha), \tag{9}$$

whereas equating the constants on both sides of (8a) and (8b) yields,

$$b(J)=\sqrt{\frac{2}{U}}\left[\left(J+\alpha+\sqrt{\frac{U}{2}}\right)\left(J+\alpha+\sqrt{\frac{U}{2}}-1\right)-\frac{U}{2}+\frac{3}{16}\right]^{1/2}, \tag{10}$$

so that the condition $b(0)=0$ yields,

$$\alpha=\frac{1}{2}\,(1-\sqrt{2U})+\left(\frac{U}{2}+\frac{1}{16}\right)^{1/2}. \tag{11}$$

It follows that (7) indeed reduces to the classical relation (5) in the leading order of J. We now define our GAO to be $e^{-i\phi}b(J)$ so that upon substitution for α from (11) in Eq. (10) we may write,

$$\mathscr{A}(J)\equiv\sqrt{\frac{2}{U}}\,e^{-i\phi}\sqrt{J(J+2\beta)}, \tag{12}$$

where $\beta=[(U/2)+(1/16)]^{1/2}$ and satisfying,

$$\mathscr{A}(J)|n\rangle=\sqrt{\frac{2}{U}}\,\sqrt{n(n+2\beta)}|n-1\rangle. \tag{13}$$

We can immediately write our desired coherent state as an eigenstate of $\mathscr{A}(J)$ belonging to eigenvalue z viz.

$$|z\rangle=[f(|z|^2)]^{-1/2}\sum\ \frac{z^n}{h_n}\,|n\rangle, \tag{14}$$

where $h_0\equiv 1$, $h_n=\Pi_{r=1}^{n}\sqrt{r(r+2\beta)}$ and the function f is defined as

$$f(s)=\sum_{n=0}^{\infty}\ \frac{s^n}{h_n^2}. \tag{15}$$

We see that (14) can be rewritten as,

$$|z\rangle=[f(|z|^2)]^{-1/2}f(z\mathscr{A}^{\dagger})|0\rangle. \tag{16}$$

The function f which embodies all the characteristics of the coherent state can be explicitly worked out to be,

$$f(s)=\Gamma(2\beta+1)\left(\frac{2}{Us}\right)^{\beta}I_{2\beta}(\sqrt{2Us}), \tag{17}$$

where $I_{2\beta}$ is the modified Bessel function of order 2β. In the coordinate representation Eq. (14) reads,

$$\psi_z(x)=\left[\frac{2\sqrt{2U}}{I_{2\beta}(|z|\sqrt{2U})}\right]^{1/2}\left(\frac{|z|}{z}\right)^{\beta}e^{\sqrt{U/2}(z-x^2)}\sqrt{x}J_{2\beta}(2x\sqrt{Uz}). \tag{18}$$

We now look for an isotropic weight function $\mu(|z|)$ such that the resolution of the identity operator reads,

$$\int |z\rangle\langle z|\mu(|z|)d^2z=1. \tag{19}$$

Taking diagonal matrix elements and using the orthonormality of the $|n\rangle$ states we find,

$$\int_0^{\infty}[f(s)]^{-1}s^n\mu(s)ds=\frac{h_n^2}{\pi}, \tag{20}$$

which is a moment problem for $\mu(s)/f(s)$ with $s=|z|^2$ and can be solved by the method of characteristic function to yield,

$$\mu(s)=\frac{U}{\pi}I_{2\beta}(\sqrt{2Us})K_{2\beta}(\sqrt{2Us}), \tag{21}$$

where $K_{2\beta}$ is another modified Bessel function.

The state so obtained is the same as the one obtained by Nieto and Simmons in their research on MUCS. To investigate the minimum uncertainty property of $\psi_z(x)$, we observe that an eigenstate of the operator $\mathscr{A}(J)$ minimizes the uncertainty product of the real and imaginary parts of $\mathscr{A}(J)$, i.e., if we write $\mathscr{A}(J)=A+iB$, where A and B are Hermitian operators, then $\Delta A\Delta B=\frac{1}{2}|\langle[A,B]\rangle|$, where the dispersions are calculated in the state $\psi_z(x)$. The operators A and B turn out to be $A=xp+px$ and $B=H-2Ux^2$ (modulo constant factors) which are essentially the same as the natural quantum operators of Nieto and Simmons.

As is expected the state $|z\rangle$ evolves as $|z(t)\rangle=|z(0)e^{-i\omega t}\rangle$, where $\omega(=\sqrt{8U})$ is the same as the classical angular frequency. We observe that mappings at the classical level (Nieto and Simmons) and quantum level (present work) yield the same coherent state for this linear spectrum case.

B. The Pöschl–Teller potential

This potential supports a quadratic spectrum and we will summarize our results below.

Classical:

$$H=\frac{p^2}{2}+U\ \mathrm{cosec}^2\ x=\frac{1}{2}\ (J+\sqrt{2U})^2,$$

$$\cos\ x=-\frac{[J^2+2\sqrt{2U}J]^{1/2}}{J+\sqrt{2U}}\ \sin\ \phi.$$

Quantum:

$$H=\tfrac{1}{2}\ (J+\alpha)^2,$$

$$\alpha=\tfrac{1}{2}\ (1+\sqrt{1+8U}),$$

$$\cos x=\frac{1}{2i}\,[b(J)e^{i\phi}-e^{-i\phi}b(J)],$$

$$b(J)=-\frac{\sqrt{J(J+2\alpha-1)}}{\sqrt{(J+\alpha)(J+\alpha-1)}}.$$

Dropping a minus sign in the definition, the GAO therefore satisfies,

$$\mathscr{A}(J)|n\rangle=\frac{\sqrt{n(n+2\alpha-1)}}{\sqrt{(n+\alpha)(n+\alpha-1)}}\,|n-1\rangle, \tag{22}$$

and the corresponding coherent state is written as,

$$|z\rangle=[f(|z|^2)]^{-1/2}\left[\frac{\Gamma(2\alpha)}{\Gamma(\alpha)\Gamma(\alpha+1)}\right]^{1/2}\sum_{n=0}^{\infty}\left[\frac{\Gamma(n+\alpha)\Gamma(n+\alpha+1)}{n!\Gamma(n+2\alpha)}\right]^{1/2}z^n|n\rangle, \tag{23}$$

where the normalization is given in terms of the hypergeometric function as,

$$f(s)={}_2F_1(\alpha,\alpha+1,2\alpha;s), \tag{24}$$

which diverges at $s=1$. The coherent states are therefore defined strictly within the unit circle ($|z|<1$).

The wave functions $\langle x|n\rangle$ involve Gegenbauer polynomials and the series in Eq. (23) can be summed by using a generating function of these polynomials[18] to yield the coordinate representation in the variable $y(=\cos x)$ viz.

$$\psi_z(y)\approx\frac{\Gamma(\alpha+1)}{[\pi\alpha 2^{1-2\alpha}\Gamma(2\alpha)]^{1/2}}\,(1-y^2)^{\alpha/2}(1-yz)^{-(\alpha+1)}{}_2F_1\left[\frac{\alpha+1}{2},\,\frac{\alpha+2}{2},\alpha+\frac{1}{2};\,\frac{(y^2-1)z^2}{(1-yz)^2}\right], \tag{25}$$

with the same normalization as in (23). To obtain a resolution of the identity we observe that the weight function satisfies the following well defined moment problem viz.,

$$\int_0^{\infty}g(s)s^n ds=\frac{1}{\pi}\,\frac{\Gamma(\alpha)\Gamma(\alpha+1)}{\Gamma(2\alpha)}\,\frac{n!\Gamma(n+2\alpha)}{\Gamma(n+\alpha)\Gamma(n+\alpha+1)},$$

where $g(s)[=\mu(s)/f(s)]$ is nonzero only in the interval $0\leqslant s<1$ and $s=|z|^2$. These coherent states differ from the MUCS of Nieto and Simmons. In fact these states minimize the uncertainty product of the operators $\cos x$ and $i[\sqrt{H},\cos x]$. However, like the MUCS the states in question do not remain coherent under time evolution, the equation of motion for the annihilation operator being given by,

$$\dot{\mathscr{A}}(J)=-i\mathscr{A}(J)(J-\tfrac{1}{2}+\alpha).$$

C. The Coulomb potential

We use squared parabolic coordinates[19] (μ,ν,ϕ) which are related to the rectangular coordinates (x,y,z) as,

$$x=\mu\nu\,\cos\,\phi,\;\; y=\mu\nu\,\sin\,\phi,\;\; z=\tfrac{1}{2}(\mu^2-\nu^2).$$

The Hamiltonian may therefore be written as,

$$H=\frac{1}{2}\,\frac{p_\mu^2+p_\nu^2}{\mu^2+\nu^2}+\frac{p_\phi^2}{2\mu^2\nu^2}-\frac{2e^2}{\mu^2+\nu^2}, \tag{26}$$

e being the electronic charge. Replacing p_ϕ by its quantized value m and remembering that $H=-E$ for a bound state we will consider the pair of Hamiltonians defined as,

$$H_\mu=\frac{p_\mu^2}{2}+\frac{m^2}{2\mu^2}+E\mu^2, \tag{27a}$$

$$H_\nu=\frac{p_\nu^2}{2}+\frac{m^2}{2\nu^2}+E\nu^2, \tag{27b}$$

with the condition that,

$$H_\mu+H_\nu=2e^2. \tag{28}$$

We recognize H_μ and H_ν to be a 2D harmonic oscillator Hamiltonians in polar coordinates. Proceeding along the lines by now familiar we obtain,

$$H_\mu=2\sqrt{2E}\left(J_\mu+\frac{1}{2}+\frac{|m|}{2}\right),$$

$$\mu^2=a(J_\mu)+\frac{1}{2i}\left[b(J_\mu)e^{i\phi_\mu}-e^{-i\phi_\mu}b(J_\mu)\right],$$

$$a(J_\mu)=\sqrt{\frac{2}{E}}\left(J_\mu+\frac{1}{2}+\frac{|m|}{2}\right),$$

$$b(J_\mu)=\sqrt{\frac{2}{E}}\left[J_\mu(J_\mu+|m|)\right]^{1/2},$$

and similar ones for the index ν. Imposition of (28) yields the energy eigenvalues. The coherent states are now constructed as eigenstates of the commuting GAO viz.,

$$\mathcal{A}(J_{\mu,\nu})=e^{-i\phi_{\mu,\nu}}[J_{\mu,\nu}(J_{\mu,\nu}+|m|)]^{1/2},$$

with eigenvalues z_1 and z_2, respectively.

The normalized state is obtained as

$$|z_1,z_2,m\rangle=\left[\frac{I_{|m|}(2|z_1|)I_{|m|}(2|z_2|)}{|z_1|^{|m|}|z_2|^{|m|}}\right]^{-1/2}\sum_{n_1n_2}\frac{z_1^{n_1}z_2^{n_2}}{\sqrt{n_1!n_2!(n_1+|m|)!(n_2+|m|)!}}|n_1,n_2,m\rangle, \tag{29}$$

where n_1 and n_2 are the eigenvalues of J_μ and J_ν, respectively. The resolution of the identity reads,

$$\sum_m\int d^2z_1d^2z_2\mu(z_1)\mu(z_2)|z_1,z_2,m\rangle\langle z_1,z_2,m|=1, \tag{30}$$

where the weight function μ is given by,

$$\mu(s)=\frac{2}{\pi}I_{|m|}(2|s|)K_{|m|}(2|s|). \tag{31}$$

IV. CONCLUDING REMARKS

In summary, the classical action angle transformation together with the correspondence principle has been used to transform to quantum action angle operators and thereby to construct the creation and annihilation operators and the corresponding coherent states for some exactly soluble and separable problems of quantum mechanics admitting infinite spectra. The states in question

are analytic functions of complex variables and form a complete set of basis vectors. In a non-confining potential with a finite number of bound states we could also construct coherent states as eigenstates of the GAO in the coordinate representation. However, these states will necessarily contain contributions from the continuum. The usual problems with the angle operator do not arise since the formulation involves only those operators that explicitly leave the Hilbert space of the problem invariant. The Coulomb coherent states have been defined for fixed m and should prove useful in the study of the highly excited states of atoms in magnetic fields.[20] Further investigations on these states as also relevant applications will be published elsewhere.

Radon–Nikodym derivatives of quantum instruments

A. S. Holevo[a)]
Steklov Mathematical Institute, Gubkina 8, 117966 Moscow, Russia

(Received 15 April 1997; accepted for publication 8 October 1997)

A convenient representation for Radon–Nikodym derivatives of completely positive (c.p.) instruments on $B(\mathscr{H})$ with respect to a scalar measure is suggested, similar to the Stinespring–Kraus representation for c.p. maps, but involving possibly nonclosable unbounded operators. The structure of covariant c.p. instruments is studied in detail. In particular, an exhaustive description is given to instruments covariant with respect to shifts or rotations, corresponding to ''position'' or ''angle'' measurements. © *1998 American Institute of Physics.*

I. INTRODUCTION

The notion of instrument was introduced by Davies and Lewis[1] in order to treat the repeatability issue for observables with continuous spectrum in quantum measurement theory. Ozawa[2] introduced complete positivity into the definition of Ref. 1 and showed that *any* completely positive (c.p.) instrument can be obtained from a measurement procedure consisting of interaction with apparatus and subsequent observation of the apparatus. Since then the notion of c.p. instrument was successfully applied in a number of concrete problems such as counting processes in quantum optics and quantum communication,[3] the standard quantum limit in high-precision experiments,[4] quantum Zeno paradox and time continuous measurement processes,[5,6] etc. The importance of the concept of instrument lies in the fact that it gives a condensed linear description, in terms of the system alone, of the measurement statistics and of posterior states of the system, i.e., the states conditioned upon certain outcome of the measurement. It should be stressed that the abstractness of the notion of instrument, which may count for disadvantage from point of view of a physicists, is due to the highly reduced nature of the statistical description of a measuring procedure[7] and is just the reverse side of its mathematical advantages. The property of complete positivity is crucial for relating the abstract notion of the instrument to a measurement process.

From a mathematical point of view, an instrument is a measure with values in the cone of operations—positive linear contractions of the algebra of observables.[8] In the case of finite-dimensional Hilbert space, a Radon–Nikodym theorem for such measures was proved by Davies,[9] giving operation-valued density (Radon–Nikodym derivative) with respect to a scalar measure. The main objective of this paper is to prove results of this type for c.p. instruments in arbitrary Hilbert space. The resulting density has structure formally similar to Stinespring–Kraus representation of c.p. maps, but involves in general nonclosable unbounded operators (Sec. II). Particularly interesting is the case where the instrument is covariant under unitary action of a symmetry group (Sec. III). As an important application, we give in Secs. IV and V an exhaustive description of instruments, covariant with respect to rotations and shifts, corresponding to quantum measurements of ''angle'' or ''position'' variables.

II. A GENERAL RADON–NIKODYM THEOREM FOR COMPLETELY POSITIVE INSTRUMENTS

Let $\mathscr{H}$ be a separable Hilbert space, $\mathscr{A}\subset B(\mathscr{H})$ be a von Neumann algebra with the predual $\mathscr{A}_*$, and $(\mathscr{X},\mathscr{B})$ be a Borel space (where $\mathscr{B}$ is σ-algebra of measurable subsets of the set $\mathscr{X}$). A *completely positive (c.p.) instrument in* $\mathscr{A}$ *with the value space* $\mathscr{X}$ is a measure $B\to\mathscr{M}(B)[\,\cdot\,]on\mathscr{B}$, whose values are bounded linear normal c.p. maps $X\to\mathscr{M}(B)[X]$ of $\mathscr{A}$, such that for

[a)]Electronic mail: holevo@genesis.mi.ras.ru

 © 1998 American Institute of Physics

any $S\in\mathcal{A}_*$, $X\in\mathcal{A}$, the scalar measure $B\to\langle S,\mathcal{M}(B)[X]\rangle$ is σ-additive; moreover, the measure $\mathcal{M}(\cdot)$ must satisfy the normalization condition $\mathcal{M}(\mathcal{X})[I]=I$, where I is the unit operator in $\mathcal{H}$.

In quantum measurement theory the notion of instrument is used as an equivalent description of the measurement probability distribution and posterior states for an arbitrary initial state of the system. If S is the initial state of the system, then the measurement probability distribution is

$$\mu_S(B)=\langle S,\mathcal{M}(B)[I]\rangle,\quad B\in\mathcal{B},$$

and is equivalently given by the associated *probability operator-valued measure* (p.o.m.)

$$M(B)=\mathcal{M}(B)[I],\quad B\in\mathcal{B}$$

(see Refs. 9 and 10). Posterior states S_x corresponding to measurement outcomes $x\in\mathcal{X}$ are determined from the relation

$$\langle S,\mathcal{M}(B)[X]\rangle=\int_B\langle S_x,X\rangle\mu_S(dx)$$

(see Ref. 11 for more detail).

The following result was proved in Ref. 2 (Proposition 4.2).

Proposition 1: For arbitrary c.p. instrument $\mathcal{M}$ there exists a Hilbert space $\mathcal{K}$, a spectral measure $E:B\to E(B)$, $B\in\mathcal{B}$, in $\mathcal{K}$; a nondegenerate normal $*$-representation $\pi:X\to\pi[X]$, $X\in\mathcal{A}$, in $\mathcal{K}$; and a linear isometry V from $\mathcal{H}$ to $\mathcal{K}$ such that

$$\mathcal{M}(B)[X]=V^*E(B)\pi[X]V, \tag{2.1}$$

$$E(B)\pi[X]=\pi[X]E(B), \tag{2.2}$$

for any $B\in\mathcal{B}$. $X\in\mathcal{A}$. □

In the case $\mathcal{A}=B(\mathcal{H})$, which will be our main concern, one has

$$\mathcal{K}=\mathcal{H}\otimes\mathcal{H}_0,\quad \pi[X]=X\otimes I_0,$$

where I_0 is the unit operator in $\mathcal{H}_0$ (see e.g., Ref. 9, Lemma 9.2.2). Then (2.2) implies

$$E(B)=I\otimes E_0(B),$$

where E_0 is a spectral measure in $\mathcal{H}_0$, so that the representation (2.1) reads

$$\mathcal{M}(B)[X]=V^*(X\otimes E_0(B))V. \tag{2.3}$$

By using this we can deduce the following analog of the Stinespring–Kraus representation of a c.p. map on $B(\mathcal{H})$ (for related results see also Ref. 12).

Theorem 1: There exist a positive σ-finite measure μ on $(\mathcal{X},\mathcal{B})$, a dense domain $\mathcal{D}\subset\mathcal{H}$, and a countable family of functions $x\to A_k(x)$ defined for almost all x, such that $A_k(x)$ are linear operators from $\mathcal{D}$ to $\mathcal{H}$, satisfying

$$\int_{\mathcal{X}}\sum_k\|A_k(x)\psi\|^2\mu(dx)=\|\psi\|^2,\quad \psi\in\mathcal{D}, \tag{2.4}$$

and

$$(\psi|\mathcal{M}(B)[X]\psi)=\int_B\sum_k(A_k(x)\psi|XA_k(x)\psi)\mu(dx),\quad \psi\in\mathcal{D}. \tag{2.5}$$

Proof: According to von Neumann's spectral theorem, $\mathcal{H}_0$ can be decomposed into the direct integral

$$\mathscr{H}_0 = \int_{\mathscr{X}}^{\oplus} \mathscr{H}(x)\mu(dx) \tag{2.6}$$

with respect to some positive σ-finite measure μ, diagonalizing the spectral measure E_0:

$$E_0(B)\phi = \int_B^{\oplus} \phi(x))\mu(dx), \tag{2.7}$$

where $\phi(x) \in \mathscr{H}(x)$ are the components of the vector $\phi \in \mathscr{H}_0$ in the decomposition (2.6). In what follows we shall fix a measurable field of orthonormal bases $\{e_{k,x}\}$ in the direct integral (2.6) and denote $\phi_k(x) = (e_{k,x}|\phi(x))$, where the inner product is in $\mathscr{H}(x)$ [note that $\phi_k(x)$ are defined μ-almost everywhere].

The tensor product $\mathscr{K} = \mathscr{H} \otimes \mathscr{H}_0$ has the direct integral decomposition

$$\mathscr{H} \otimes \mathscr{H}_0 = \int_{\mathscr{X}}^{\oplus} (\mathscr{H} \otimes \mathscr{H}(x))\mu(dx).$$

Let $\psi \in \mathscr{H}$. The decomposition of the vector $V\psi \in \mathscr{H} \otimes \mathscr{H}_0$ then reads

$$V\psi = \int_{\mathscr{X}}^{\oplus} \sum_k (V\psi)_k(x) e_{k,x}\mu(dx),$$

where $(V\psi)_k(x)$ are (equivalence classes of) μ-measurable functions with values in $\mathscr{H}$ satisfying

$$\int_{\mathscr{X}} \sum_k \|(V\psi)_k(x)\psi\|^2 \mu(dx) = \|\psi\|^2, \quad \psi \in \mathscr{H}, \tag{2.8}$$

since V is isometric. Since V is linear, we have for μ-almost all x

$$\left(V\left(\sum_j \lambda_j \psi_j \right) \right)_k (x) = \sum_j \lambda_j (V\psi_j)_k(x), \tag{2.9}$$

where $\{\psi_j\} \subset \mathscr{H}$ is a fixed countable system of vectors, and λ_j are complex numbers, only a finite number of which are nonzero.

Let us now fix an orthonormal basis $\{\psi_j\} \subset \mathscr{H}$ and let $\mathscr{D} = \mathrm{lin}\{\psi_j\}$ be its linear span. We define linear operators $A_k(x)$ on $\mathscr{D}$ by the relation

$$A_k(x)\left(\sum_j \lambda_j \psi_j \right) = \sum_j \lambda_j (V\psi_j)_k^0(x),$$

where $(V\psi_j)_k^0$ is a fixed representative of the equivalence class $(V\psi_j)_k$. Then by (2.9), for any fixed $\psi \in \mathscr{D}$ there is a subset $\mathscr{X}_\psi \subset \mathscr{X}$ such that $\mu(\mathscr{X} \setminus \mathscr{X}_\psi) = 0$ and

$$A_k(x)\psi = (V\psi)_k(x) \quad \text{for all } k, \quad \text{all } x \in \mathscr{X}_\psi. \tag{2.10}$$

Combining (2.3), (2.7), and (2.10), we obtain (2.5). The normalization condition (2.4) follows from (2.7) and (2.10). □

The representation (2.5) is especially convenient from the point of view of calculation of the measurement probability distribution and posterior states. Take pure initial state $S = |\psi)(\psi|$, where $\psi \in \mathscr{D}$. Then the probability distribution of outcomes is

$$\mu_\psi(B) = (\psi|\mathscr{M}(B)[I]\psi) = \int_B \sum_k \|A_k(x)\psi\|^2 \mu(dx). \tag{2.11}$$

The posterior state corresponding to the outcome x is

$$S_\psi(x)=\frac{\Sigma_k|A_k(x)\psi)(A_k(x)\psi|}{\Sigma_k\|A_k(x)\psi\|^2}. \tag{2.12}$$

In the case where the multiplicity of E_0 is one, the range of k is singleton, and formulas (2.5), (2.11), and (2.12) become

$$(\psi|\mathscr{M}(B)[X]\psi)=\int_B(A(x)\psi|XA(x)\psi)\mu(dx), \tag{2.13}$$

$$\mu_\psi(dx)=\|A(x)\psi\|^2\mu(dx), \tag{2.14}$$

$$S_\psi(x)=\frac{|A(x)\psi)(A(x)\psi|}{\|A(x)\psi\|^2}, \tag{2.15}$$

where $A(x)$ is a family of operators from $\mathscr{D}$ to $\mathscr{H}$, satisfying

$$\int\|A(x)\psi\|^2\mu(dx)=\|\psi\|^2,\quad \psi\in\mathscr{D}.$$

In this case the pure initial state gives rise to pure posterior states, and the corresponding instrument may be called *pure* (see Ref. 11 for an information-theoretic characterization of pure instruments).

Note that if the measure μ is nonatomic, operators $A_k(x)$ in the representation (2.5) need not be bounded, nor even closable, as the following example shows.

Example 1: The idea behind this example goes back to Gordon and Louisell[13] (see also Ref. 5). Let $\mathscr{H}=L^2(\mathrm{R})$ and Q be the position observable in $\mathscr{H}$ given by the operator of multiplication by the independent variable $x\in\mathrm{R}$. Let ψ_x, $x\in\mathrm{R}$, be a measurable family of unit vectors in $\mathscr{H}$. We take $\mathscr{D}=C_0(\mathrm{R})$ (the subspace of continuous functions with compact support), and define

$$A(x)\psi=\Psi_x\cdot\psi(x),\quad \psi\in\mathscr{D}. \tag{2.16}$$

In Dirac's notations $A(x)=|\Psi_x)(x|$, where $(x|$ is the linear unbounded nonclosable form on $\mathscr{D}$ satisfying $(x|\psi)=\psi(x)$ for $\psi\in\mathscr{D}$. The relation (2.13) with $\mu(dx)=dx$ defines a pure c.p. instrument, whose probability distribution is

$$\mu_\psi(dx)=\|\psi(x)\|^2\,dx$$

and the posterior states are

$$S_\psi(x)=|\psi_x)(\psi_x|.$$

This instrument thus corresponds to precise measurement of the position, accompanied by the preparation of the vector state ψ_x, depending on the outcome x of the measurement.

III. COVARIANT INSTRUMENTS

Let G be a locally compact second countable group, and $g\to V_g$ a continuous unitary representation of G in $\mathscr{H}$, leaving invariant the algebra $\mathscr{A}$. An instrument $\mathscr{M}$ with the value space G is called *covariant* if

$$V_g\mathscr{M}(B)[V_g^*XV_g]V_g^*=\mathscr{M}(gB)[X] \tag{3.1}$$

for all $g\in G$, $X\in\mathscr{A}$, $B\in\mathscr{B}$, where $\mathscr{B}$ is the σ-algebra of Borel subsets of G. The definition (in a slightly more general form, allowing a transitive G-space as the value space of the instrument) was given by Davies (see Ref. 9), who studied covariant (not necessarily c.p.) instruments in the case of compact G and $\dim\mathscr{H}<\infty$.

The importance of the condition of covariance lies in the fact that it provides a correspondence principle between classical kinematical variables and the quantum instruments. Let $g\in G$ be

such a variable. Then the transformation $x \to gx$, where $x \in G$, describes a motion in a classical space G. The representation V_g gives the corresponding transformation of quantum states $\psi \to \psi_g = V_g \psi$. Equation (3.1) is equivalent to the following properties of the measurement probability distribution and the posterior states:

$$\mu_{\psi_g}(B) = \mu_\psi(g^{-1}B),$$

$$S_{\psi_g}(x) = V_g S_\psi(g^{-1}x) V_g^*,$$

expressing the principle of correspondence.

The following result, proved in Ref. 14, specifies the representation (2.1) in the case of covariant c.p. instruments.

Proposition 2: If $\mathscr{M}$ is a covariant c.p. instrument, then the representation (2.1) can be chosen in such a way that there exists a continuous unitary representation $g \to \widetilde{V}_g$ of G in $\mathscr{K}$, such that

$$\widetilde{V}_g V = V V_g, \tag{3.2}$$

$$\pi[V_g^* X V_g] = \widetilde{V}_g^* \pi[X] \widetilde{V}_g, \tag{3.3}$$

$$\widetilde{V}_g E(B) \widetilde{V}_g^* = E(gB), \tag{3.4}$$

for all $g \in G$, $X \in \mathscr{A}$, $B \in \mathscr{B}$. □

In the case $\mathscr{A} = B(\mathscr{H})$ this leads to the representation (2.3) with V satisfying (3.2) where

$$\widetilde{V}_g = V_g \otimes D_g,$$

and $g \to D_g$ is a continuous representation of G in $\mathscr{H}_0$. This fulfills the condition (3.3), while (3.2) and (3.4) take the forms

$$(V_g \otimes D_g) V = V V_g, \tag{3.5}$$

$$D_g E_0(B) D_g^* = E_0(gB). \tag{3.6}$$

The last equation means that (D, E_0) is an *imprimitivity system* in $\mathscr{H}_0$ (see, e.g., Ref. 15). By the Mackey imprimitivity theorem (D, E_0) is unitarily equivalent to the special system in the space $L_h^2(G)$ of square integrable functions $f(x)$; $x \in G$, with values in a separable Hilbert space h, defined as

$$D_g f(x) = f(g^{-1}x), \quad E_0(B) f(x) = I_B(x) f(x),$$

where I_B is the indicator of a set $B \in \mathscr{B}$. Let us fix an orthonormal basis $\{e_k\}$ in h. Then $\mathscr{K} = \mathscr{H} \otimes L_h^2(G)$ is represented as the space of functions $\psi_k(x)$; $k = 1, \ldots, \dim h$; $x \in G$, with values in $\mathscr{H}$, satisfying

$$\int_G \sum_k \|\psi_k(x)\|^2 d_l x < \infty,$$

where $d_l x$ is the left Haar measure on G. The *intertwining equation* (3.5) is then equivalent to

$$V_g (V V_g^* \psi)_k(x) = (V\psi)_k(gx) \tag{3.7}$$

for all g and almost all $x \in G$.

We conjecture that at least in the case of a type I group G there exists a dense domain $\mathscr{D} \subset \mathscr{H}$, invariant under the representation and such that the functions $x \to (V\psi)_k(x)$ are continuous for $\psi \in \mathscr{D}$, and therefore have unambiguously defined values for every $x \in G$. Then there is a sequence of linear operators A_k from $\mathscr{D}$ to $\mathscr{H}$ such that

$$A_k \psi = (V\psi)_k(e), \quad \psi \in \mathscr{D},$$

TABLE I. Canonical pairs in quantum mechanics.

G	R		T		Z_n
$\hat{G}$	R		Z		Z_n
Λ	R	$-R_+$	Z	$-Z_+$	Z_n
x	position	time	angle	phase	discretized phase
A	momentum P	$-$energy $-H$	angular momentum	$-$number $-N$	$-$truncated number

where e is the neutral element of G, and the equation (3.7) has the unique solution

$$(V\psi)_k(g)=V_gA_kV_g^*\psi.$$

If this is so, we have the representation of the type (2.5) with explicitly covariant $A_k(x)=V_xA_kV_x^*$, where $\mu(dx)$ is the Haar measure on G.

In what follows we give the proofs of this conjecture for two particularly important cases, where G is a one-dimensional Lie group (i.e., T or R). The proof for the case $G=\mathrm{R}$ can be generalized to an arbitrary locally compact Abelian group by using techniques developed in Ref. 15. However, the case of the elementary locally compact Abelian groups is particularly important for quantum mechanical applications as it gives a key for quantization of principal canonical pairs (see Table I). In this table $x\in G$ is a classical kinematical parameter and $x\to V_x=\mathrm{e}^{-ixA}$ is a unitary representation with the generator A. The spectrum Λ of A is a subset of the dual group $\hat{G}$. For the description of quantum observables canonically conjugated to A in terms of covariant probability operator-valued measures, including generalizations of the canonical commutation relation and of the uncertainty relation, see Ref. 16. The last column where Z_n is the cyclic group of order n corresponds to the approximate approach to quantum oscillator phase proposed by Pegg and Barnett.[17]

IV. THE CASE $G=\mathrm{T}$

In this Section we find the general form of a c.p. instrument, covariant with respect to one-dimensional rotations, describing measurements of cyclic quantities like angle, phase, or any other periodic coordinate. Let $G=[0,2\pi)$ with the operation of addition modulo 2π, denoted as $\dot{+}$, and let $\theta\to V_0$; $\theta\in[0,2\pi)$, be a continuous unitary representation of G in $\mathscr{H}$. The intertwining equation (3.7) reads

$$V_0(VV_0^*\psi)_k(\phi)=(V\psi)_k(\phi\dot{+}\theta),\quad \theta\in[0,2\pi). \tag{4.1}$$

By Stone's theorem, $V_0=\exp(-i\theta L)$, where L is a self-adjoint operator with purely point spectrum $\Lambda\subset G=Z$. Then there is an orthonormal basis $\{|l,j);l\in\Lambda\}$ in $\mathscr{H}$, consisting of eigenvectors of L:

$$L|l,j)=l|l,j),\quad l\in\Lambda.$$

Theorem 2: Let $\mathscr{D}=\mathrm{lin}\{|l,j);l\in\Lambda\}$. An arbitrary c.p. instrument, covariant with respect to the representation $\theta\to V_\theta$, has the form

$$(\psi|\mathscr{M}(d\theta)[X]\psi)=\sum_k\,(A_k(\theta)\psi|XA_k(\theta)\psi)\,\frac{d\theta}{2\pi},\quad \psi\in\mathscr{D}, \tag{4.2}$$

where $A_k(\theta)=V_\theta\,A_kV_\theta^*$ and A_k are linear operators from $\mathscr{D}$ to $\mathscr{H}$, satisfying

$$\sum_k\,(\psi_{l,j,k}|\psi_{l,j',k})=\delta_{j,j'},\quad l\in\Lambda, \tag{4.3a}$$

with $\psi_{l,j,k}=A_k|l,j)$.

Proof: To simplify notations we assume throughout that *the multiplicity of the spectrum is one* (this assumption can be easily relaxed). Then we can drop the index j and relation (4.3a) takes the form

$$\sum_k \|A_k|l)\|^2 = I; \quad l \in \Lambda. \tag{4.3b}$$

Apparently $\mathscr{D}$ is invariant under V_θ. Consider the function

$$c_{m,l,k}(\theta) = (m|(V|l))_k(\theta). \tag{4.4}$$

The equation (4.1) implies

$$c_{m,l,k}(\phi \dot{+} \theta) = \mathrm{e}^{i\theta(l-m)} c_{m,l,k}(\phi) \tag{4.5}$$

for all $\theta \in [0,2\pi)$ and almost all ϕ. The normalization condition (2.8) with $\mu(d\theta) = d\theta/2\pi$ implies

$$\int_0^{2\pi} \sum_k \sum_m |c_{m,l,k}(\theta)|^2 \frac{d\theta}{2\pi} = 1, \quad l \in \Lambda. \tag{4.6}$$

Denoting

$$c^\epsilon_{m,l,k}(\theta) = \epsilon^{-1} \int_0^\epsilon c_{m,l,k}(\phi \dot{+} \theta) d\phi,$$

we have that $c^\epsilon_{m,l,k}(\theta)$ is continuous for every $\epsilon > 0$. By integrating Eq. (4.5) we see that

$$c^\epsilon_{m,l,k}(\theta) = \mathrm{e}^{i\theta(l-m)} c^\epsilon_{m,l,k}(0).$$

Since $c^\epsilon_{m,l,k}(\theta)$ converges to $c_{m,l,k}(\theta)$ in the mean as $\epsilon \to 0$, we have

$$|c^\epsilon_{m,l,k}(0) - c^{\epsilon'}_{m,l,k}(0)| \leqslant \int_0^{2\pi} |c^\epsilon_{m,l,k}(\theta) - c^{\epsilon'}_{m,l,k}(\theta)| \frac{d\theta}{2\pi} \to 0$$

as $\epsilon, \epsilon' \to 0$. Thus there exist $c_{m,l,k} = \lim_{\epsilon \to 0} c^\epsilon_{m,l,k}(0)$. Therefore $c^\epsilon_{m,l,k}(\theta)$ converges pointwise to $\mathrm{e}^{i(l-m)\theta} c_{m,l,k}$ and hence

$$c_{m,l,k}(\theta) = \mathrm{e}^{i(l-m)\theta} c_{m,l,k}. \tag{4.7}$$

From (4.6)

$$\sum_k \sum_m |c_{m,l,k}|^2 = 1, \quad l \in \Lambda.$$

Defining

$$\psi_{l,k} = \sum_{m \in \Lambda} c_{m,l,k} |m),$$

we have

$$\sum_k \|\psi_{l,k}\|^2 = 1, \quad l \in \Lambda. \tag{4.8}$$

The operators

$$A_k = \sum_{l \in \Lambda} |\psi_{l,k})(l| \tag{4.9}$$

are then defined on $\mathscr{D}$ and satisfy (4.3b). Moreover, for $\psi\in\mathscr{D}$

$$A_k(\theta)\psi=V_\theta A_k V_\theta^*\psi=\sum_{m,l\in\Lambda} c_{m,l,k}(\theta)|m)(l|\psi)=(V\psi)_k(\theta)$$

by (4.4). This proves (4.2). Note that the functions $A_k(\theta)\psi$ are norm continuous in θ for $\psi\in\mathscr{D}$.□

Let us consider two important particular cases: the minimum uncertainty instruments, and the instruments corresponding to an approximate von Neumann-type measurement process. The probability distribution of the instrument (4.2) is

$$\mu_\psi(d\theta)=\sum_k \|A_k V_\theta\psi\|^2\,\frac{d\theta}{2\pi}.$$

Let us look for the instruments minimizing the angular uncertainty[10,16]

$$\Delta_\psi(n)=n^{-2}[|\hat{\mu}_\psi(n)|^{-2}-1],$$

where

$$\hat{\mu}_\psi(n)=\int_0^{2\pi} e^{i\theta n}\mu_\psi(d\theta)=\sum_l\sum_k (\psi|l)(l+n|\psi)(\psi_{l,k}|\psi_{l+n,k})$$

is the characteristic function of the measurement probability distribution. Assuming $(l|\psi)\geqslant 0$, which can always be achieved via a gauge transformation choosing appropriate phase factors for elements of the basis $|l)$, the maximum under the condition (4.8) is attained if $\psi_{l,k}\equiv\Psi_k$, whence

$$A_k(\theta)=\sqrt{2\pi}V_\theta|\Psi_k)(\theta|,$$

where $(\theta|$ are unbounded nonclosable linear forms on $\mathscr{D}$, algebraically conjugate to antilinear forms

$$|\theta)=\frac{1}{\sqrt{2\pi}}\sum_{l\in\Lambda} e^{-i\theta l}|l). \tag{4.10}$$

This leads to a kind of instrument considered in Example 1. Its probability distribution is

$$\mu_\psi(d\theta)=\left|\sum_{l\in\Lambda} e^{i\theta l}(l|\psi)\right|^2\frac{d\theta}{2\pi}=|(\theta|\psi)|^2\,d\theta=\mathrm{Tr}\,S_\psi M(d\theta),$$

where

$$M(d\theta)=|\theta)(\theta|\,d\theta \tag{4.11}$$

is the p.o.m. representing the canonical angle observable.[10,16] The relations below involving integration with respect to such p.o.m.'s should be understood in the form sense. Notice that

$$(\theta|\theta')=\frac{1}{2\pi}\sum_{l\in\Lambda} e^{il(\theta-\theta')},$$

therefore this p.o.m. is the usual spectral measure only if $\Lambda=Z$, when this is a periodic delta-function.

We now develop another useful representation for the operators $A_k(0)$. For any $m\in Z$ and $l\in\Lambda$ we define

$$a_{m,k}(l)=\begin{cases}(l-m|\psi_{l,k}), & \text{if } l-m\in\Lambda,\\ 0, & \text{otherwise.}\end{cases} \tag{4.12}$$

If we represent $A_k(0)$ as a matrix in the basis $|l)$, these are the elements standing on the intersection of lth column with mth diagonal, $m>0$ corresponding to upper diagonals. Then

$$\psi_{l,k}=\sum_m a_{m,k}(l)|l-m).$$

Relation (4.8) implies

$$\sum_k \sum_m |a_{m,k}(l)|^2=1, \quad l\in\Lambda. \tag{4.13}$$

For any $m\in Z$ we define the partial isometry

$$P_m=\sum_{l:l\in\Lambda,l-m\in\Lambda} |l-m)(l|=\int_0^{2\pi} \mathrm{e}^{-i\theta m}M(d\theta), \tag{4.14}$$

satisfying the generalized canonical commutation relation (CCR):

$$V_\theta P_m=\mathrm{e}^{i\theta m}P_m V_\theta.$$

Then $\psi_{l,k}=\Sigma_m a_{m,k}(l)P_m|l)$ and

$$A_k(\theta)=\sum_m \mathrm{e}^{i\theta m}P_m a_{m,k}(L), \tag{4.15}$$

where $a_{m,k}(L)=\Sigma_{l\in\Lambda}a_{m,k}(l)|l)(l|$ is an essentially normal operator on the domain $\mathscr{D}$. The relation (4.15) gives the desired alternative form of the operators $A_k(\theta)$. It corresponds to special ordering when the action of L precedes the action of the canonically conjugated observable.

Example 2: Assume $\Lambda=Z$ (this is the case for measurements of the angle of rotation with infinite spin, neglecting inessential complications due to possible degeneracy of spectrum). In this case isometries (4.14) form the unitary group

$$P_m=U^m, \quad m\in \mathrm{Z}, \tag{4.16}$$

where $U=\Sigma_l|l-1)(l|$. By Stone's theorem,

$$U=\exp(-i\Theta), \tag{4.17}$$

where Θ is the self-adjoint operator

$$\Theta=\int_0^{2\pi}\theta M(d\theta), \tag{4.18}$$

with the spectral measure $M(d\theta)$ given by (4.11). The functions $A_k(\theta)$ in the representation (4.2) of the covariant instrument take the form

$$A_k(\theta)=\sum_m \mathrm{e}^{i\theta m}U^m a_{m,k}(L)=\sum_m \mathrm{e}^{i(\theta-\Theta)m}a_{m,k}(L). \tag{4.19}$$

Let us consider the particular case where $a_{m,k}(l)$ *do not depend on* l:

$$a_{m,k}(l)=a_{m,k}. \tag{4.20}$$

Then

$$A_k(\theta)=\tilde{a}_k(\theta-\Theta), \tag{4.21}$$

where

$$\tilde{a}_k(\theta)=\sum_m \mathrm{e}^{i\theta m}a_{m,k} \tag{4.22}$$

are the functions satisfying

$$\int_0^{2\pi}\sum_k |\tilde{a}_k(\theta)|^2\,\frac{d\theta}{2\pi}=1. \tag{4.23}$$

This structure of $A_k(\theta)$ is characteristic for approximate measurement of Θ, admitting a von Neumann type of realization described below (see Refs. 9 and 11 for the case $\theta\in\mathrm{R}$). Let $\mathscr{H}_0$ be a copy of the Hilbert space $\mathscr{H}$ spanned by the basis $\{|l)_0; l=0,1,...\}$. In $\mathscr{H}_0$ we can define the operator L_0 and the spectral measure $M_0(d\theta)=|\theta)_{0\ 0}(\theta|d\theta$ in a way similar to L and $M(d\theta)$. The space $\mathscr{H}_0$ will describe the measurement apparatus, the initial state of which is

$$S_0=\sum_k |a_k)_{0\ 0}(a_k|, \tag{4.24}$$

where

$$|a_k)_0=\sum_m a_{m,k}|m)_0. \tag{4.25}$$

Interaction between the system and the apparatus is given by the unitary operator

$$\mathscr{U}=\exp(-i\Theta\otimes L_0)=\sum_m U^m\otimes|m)_{0\ 0}(m|, \tag{4.26}$$

and the measured observable of the apparatus is

$$\Theta_0=\int_0^{2\pi}\theta M\ (d\theta).$$

From (4.19), (4.18), (4.25), and (4.26) it follows that

$$A_k(\theta)={}_0(\theta|\mathscr{U}|a_k)_0, \tag{4.27}$$

hence the described measurement process is a realization of the covariant instrument $\mathscr{M}(d\theta)$:

$$\sum_k (A_k(\theta)\psi|XA_k(\theta)\psi)\,\frac{d\theta}{2\pi}=\sum_k (\psi|\otimes{}_0(a_k|\mathscr{U}^*(X\otimes M_0(d\theta))\mathscr{U}|a_k)_0\otimes|\psi), \quad \psi\in\mathscr{D}. \tag{4.28}$$

Example 3: Let us try to apply a similar argument to the measurement of the phase of a harmonic oscillator. In this case $V_\phi=\mathrm{e}^{i\phi N}$, where N is the number operator. Thus $N=-L$ and $\Lambda=\{0,-1,...\}$. We have

$$P_m=\begin{cases}P^{*m}, & m=0,1,...,\\ P^{-m}, & m=-1,...,\end{cases}$$

where

$$P=\sum_{l=-\infty}^{-1}|l+1)(l|, \quad P^*=\sum_{l=-\infty}^{0}|l-1)(l|.$$

Here $|l)$ is the eigenvector of N such that $N|l)=-l|l)$ (in usual terms, it is the n-quanta vector with $n=-l$). Operator P^* is isometric, while P is co-isometric. Defining the p.o.m. $M(d\theta)$ by the relation (4.11), we have

$$\left.\begin{matrix} P \\ P^* \end{matrix}\right\} = \int_0^{2\pi} \mathrm{e}^{\pm i\theta} M(d\theta)$$

(see Refs. 10 and 16 for more detail).

A covariant instrument, corresponding to measurement of phase, has the form (4.2) with

$$A_k(\theta) = \sum_{m=0}^{\infty} \mathrm{e}^{im\theta} P^{*m} a_{m,k}(-N) + \sum_{m=-\infty}^{-1} \mathrm{e}^{im\theta} P^{-m} a_{m,k}(-N).$$

The ansatz (4.20) is compatible with the condition $a_{m,k}(l)=0$ for $l-m>0$ only if $a_{m,k}=0$ for $m<0$. Assuming this, we have

$$A_k(\theta) = \sum_{m=0}^{\infty} \mathrm{e}^{im\theta} P^{*m} a_{m,k} = \int_0^{2\pi} \tilde{a}_k(\theta-\theta') M(d\theta'), \tag{4.29}$$

where $\tilde{a}_k(\theta)$ are given by (4.22) with m running from 0 to ∞.

Let $\mathscr{H}_0$ be the Hilbert space spanned by the basis $\{|m)_0; m=0,1,...\}$. In this space we define the p.o.m. $M_0(d\theta)=|\theta)_{0\ 0}(\theta|d\theta$, where $|\theta)_0$ are determined by the relation (4.10) with l running from 0 to ∞. Defining also the isometric operator

$$\mathscr{U} = \sum_{m=0}^{\infty} P^{*m} \otimes |m)_{0\ 0}(m|,$$

in $\mathscr{H}\otimes\mathscr{H}_0$, we have the relation (4.27) for operators (4.29), and hence an analog of the realization (4.28) for the phase; however, this realization is not quite satisfactory because $\mathscr{U}$ is not unitary and $M_0(d\theta)$ is not a spectral measure.

If the spectrum Λ of L is bounded (e.g., in the case of measurement of the angle of rotation for a system with finite spin), the ansatz (4.20) is not compatible with the requirement $a_{m,k}(l)=0$ for $l-m\notin\Lambda$, and the construction of Example 2 cannot be directly transferred to this case.

V. THE CASE $G=\mathbf{R}$

Here we describe instruments, covariant with respect to one-dimensional shifts (which can be shifts in position, momentum, time, etc.) For definiteness, we speak of ''position''; at the end we shall make specific comments concerning time. In that case $G=\mathrm{R}$ and $x\to V_x$, $x\in\mathrm{R}$, is a continuous unitary representation of R in $\mathscr{H}$. The intertwining equation (3.7) for the isometry $V:\mathscr{H}\to\mathscr{H}\otimes L^2_h(\mathrm{R})$ reads

$$V_x(VV_x^*\psi)_k(\xi) = (V\psi)_k(\xi+x), \quad x\in\mathrm{R}. \tag{5.1}$$

By Stone's theorem, $V_x=\mathrm{e}^{-ixP}$, where P is a self-adjoint operator with the spectrum $\Lambda\subset\mathrm{R}$. In what follows we restrict ourselves to the case where P has a *purely Lebesgue spectrum with multiplicity one*. The restriction to the Lebesgue spectrum is necessary, since otherwise a covariant p.o.m. representing ''position'' observable does not exist (see Ref. 16); generalization to arbitrary multiplicity can be made easily with the help of techniques developed in Ref. 15. Under this assumption P is represented as multiplication by p in the space $\mathscr{H}=L^2(\Lambda)$ with generalized eigenvectors $|p)$, which are antilinear forms algebraically conjugate to the linear forms $(p|$, defined as $(p|\psi)=\psi(p)$ on the dense domain

$$\mathscr{D} = \{\psi\in\mathscr{H}: \text{the function } p\to(p|\psi) \text{is in } \mathrm{C}_0(\Lambda)\}. \tag{5.2}$$

Defining the family of partial isometries

$$U_y = \int_{\Lambda\cap(\Lambda+y)} |p-y)(p|\, dp, \quad y\in\mathrm{R}, \tag{5.3}$$

one can check the relation

$$V_x U_y = \mathrm{e}^{ixy} U_y V_x, \tag{5.4}$$

which has the form of the Weyl CCR.

By introducing the p.o.m.

$$M(dx) = |x)(x|\, dx,$$

where

$$|x) = \frac{l}{\sqrt{2\pi}} \int_\Lambda \mathrm{e}^{-ixp} |p)\, dp$$

are nonclosable antilinear forms defined on $\mathscr{D}$, we have

$$U_y = \int \mathrm{e}^{iyx} M(dx).$$

An operator with the domain $\mathscr{D}$ will be called a *kernel operator* if there is a measurable function $A(p,p')$ such that

$$\int_\Lambda \int_K |A(p,p')|^2\, dp\, dp < \infty$$

for any compact $K \subset \Lambda$ and

$$(p|A\psi) = \int A(p,p')(p'|\psi) dp'$$

for $\psi \in \mathscr{D}$. We denote

$$(p|\Lambda|p') \triangleq A(p,p')$$

and call it the *kernel* of the operator A.

Theorem 3: An arbitrary c.p. instrument, covariant with respect to the representation $x \to V_x$, has the form

$$(\psi|\mathscr{M}(dx)[X]\psi) = \sum_k (A_k(x)\psi|XA_k(x)\psi)\frac{dx}{2\pi}, \quad \psi \in \mathscr{D}, \tag{5.5}$$

where $A_k(x) = V_x A_k V_x^*$ and A_k are kernel operators satisfying

$$\int_\Lambda \sum_k |(p|A_k|p')|^2\, dp = l, \quad p' \in \Lambda. \tag{5.6}$$

Proof: In solving the equation (5.1), we shall use the method which is a modification of the one developed in Ref. 18 for characterization of covariant quantum Markovian evolutions.

Let B be a bounded Borel subset of R. Then the operator $\Delta_{B,k}: \mathscr{H} \to \mathscr{H} \otimes L_h^2(\mathrm{R})$, defined as

$$(\Delta_{B,k}\psi)_j(x) = \delta_{jk} \int_B \mathrm{e}^{ixy} U_y \psi\, dy,$$

is bounded and satisfies the same equation (5.1) as the operator V. This follows from the CCR (5.4). Hence the bounded operator $\Delta_{B,k}^* V: \mathscr{H} \to \mathscr{H}$ commutes with the representation $x \to V_x$, and therefore there exists a bounded Borel function $p \to A_{B,k}(p)$, $p \in \Lambda$, such that

$$\Delta_{B,k}^* V \psi = A_{B,k}(P)\psi, \quad \psi \in \mathscr{H}.$$

By writing this in P-representation, we have

$$A_{B,k}(p)(p|\psi)=\frac{1}{2\pi}\int_B\left\{\int \mathrm{c}^{-ixy}(p|U_y^*(V\psi)_k(x))dx\right\}dy.$$

This means that for all k and almost all $p\in\Lambda$, $B\to A_{B,k}(p)$ is a σ-finite complex measure, absolutely continuous with respect to the Lebesgue measure dy. Denoting the Radon–Nikodym derivative by $a_{y,k}(p)$, we have

$$a_{y,k}(p)(p|\psi)=\frac{1}{2\pi}\int \mathrm{e}^{-ixy}(p|U_y^*(V\psi)_k(x))dx=\frac{1}{2\pi}\int \mathrm{e}^{-ixy}(p-y|(V\psi)_k(x))\,dx, \quad (5.7)$$

if $p-y\in\Lambda$, and zero if $p-y\notin\Lambda$. It follows that

$$a_{y,k}(p+y)(p+y|\psi)=\frac{1}{2\pi}\int \mathrm{e}^{-ixy}(p|(V\psi)_k(x))\,dx, \quad (5.8)$$

if $p+y\in\Lambda$. Let us show that the right-hand side is equal to zero if $p+y\notin\Lambda$. Fixing such p and y, consider the function

$$f(x')=\frac{1}{2\pi}\int \mathrm{e}^{-ixy}(p|(VV_{x'}^*\psi)_k(x))\,dx.$$

By using Eq. (5.1), we see that $f(x')=\mathrm{e}^{ix'(p+y)}f(0)$, and we have to show that $f(0)=0$. Let us take

$$g(x)=\int_{\mathrm{R}\setminus\Lambda}\mathrm{e}^{ixp}\tilde{g}(p)dp,$$

where $\tilde{g}$ is an arbitrary C^∞-function with compact support in $\mathrm{R}\setminus\Lambda$. Then

$$\int \overline{g(x')}V_{x'}^*\psi\,dx'=0$$

and hence $\int\overline{g(x')}f(x')dx'=0$. However, this means that $\overline{\tilde{g}(p+y)}f(0)=0$, whence $f(0)=0$.

Since $V:\mathscr{H}\to\mathscr{H}\otimes L_h^2(R)$ is isometric,

$$\frac{1}{2\pi}\int\int_\Lambda\sum_k|(p|(V\psi)_k(x))|^2\,dp\,dx=\|\psi\|^2$$

[we take $dg=dx/2\pi$ in $L_h^2(\mathrm{R})$]. Hence by isometry of the Fourier transform (5.8),

$$\int\int_{\Lambda-y}\sum_k|a_{y,k}(p+y)|^2|(p+y|\psi)|^2\,dp\,dy=\|\psi\|^2.$$

By changing variables y,p to $y,p'=p+y$, we deduce

$$\int\sum_k|a_{y,k}(p)|^2\,dy=1,\quad p\in\Lambda. \quad (5.9)$$

It follows that the operators

$$a_{y,k}(P)=\int a_{y,k}(p)|p)(p|\,dp$$

are defined on $\mathscr{D}$. The relation (5.8) can then be written as

$$(p|U_y a_{y,k}(P)\psi)=\frac{1}{2\pi}\int \mathrm{e}^{-ixy}(p|(V\psi)_k(x))\,dx$$

for $\psi\in\mathscr{D}$. By inverting the Fourier transform, we obtain

$$(p|(V\psi)_k(x))=\int \mathrm{e}^{ixy}(p|U_y a_{y,k}(P)\psi)\,dy. \tag{5.10}$$

Let us show that for every $x\in\mathrm{R}$ the right-hand side defines the linear operator $A_k(x):\mathscr{D}\to\mathscr{H}$,

$$A_k(x)\psi=\int \mathrm{e}^{ixy}U_y a_{y,k}(P)\psi\,dy, \tag{5.11}$$

where the integral converges strongly for every $\psi\in\mathscr{D}$. This follows from the estimate

$$\begin{aligned}\|A_k(x)\psi\|^2&=\int\left|\int \mathrm{e}^{ixy}(p|U_y a_{y,k}(P)\psi)dy\right|^2 dp\\&=\int\left|\int \mathrm{e}^{ixy}a_{y,k}(p+y)\psi(p+y)dy\right|^2 dp\\&\leqslant\int\left\{\int |a_{y,k}(p+y)1_K(p+y)|^2\,dy\cdot\int|\psi(p+y)|^2\,dy\right\}dp\\&\leqslant\|\psi\|^2\int\int|a_{y,k}(p')|^2 1_K(p')dy\,dp'=\|\psi\|^2\mathrm{mes}\,K,\end{aligned}$$

where K is the support of ψ. A similar estimate shows that the function $x\to A_k(x)\psi$ is norm continuous.

The relation (5.11) is a continuous analog of (4.15). By CCR (5.4), $A_k(x)=V_xA_k(0)V_x^*$. From (5.11) it follows

$$(p|A_k(0)\psi)=\int_{\Lambda-y}a_{y,k}(p+y)(p+y|\psi)\,dy=\int_\Lambda a_{p'-p,k}(p')(p'|\psi)dp'.$$

Hence $A_k(0)$ is the kernel operator with the kernel

$$(p|A_k(0)|p')=a_{p'-p,k}(p').$$

Conversely,

$$a_{y,k}(p)=\begin{cases}(p-y|A_k(0)|p), & p-y\in\Lambda,\\ 0, & p-y\notin\Lambda.\end{cases} \tag{5.12}$$

The normalization condition (5.6) follows from (5.9). □

As in the case $G=\mathrm{T}$, there are two interesting particular cases corresponding to the minimum uncertainty and to von Neumann-type approximate measurements. The probability distribution of the instrument (5.5) is

$$\mu_\psi(dx)=\sum_k\|A_kV_x\psi\|^2\frac{dx}{2\pi}.$$

The variance of this probability distribution can be expressed in terms of the characteristic function as

$$\mathsf{D}_\psi=-\frac{1}{2}\frac{d^2}{dy^2}\bigg|_{y=0}\left|\int \mathrm{e}^{ixy}\mu_\psi(dx)\right|^2. \tag{5.13}$$

The modulus of the characteristic function is equal to

$$\left|\int\sum_k(\psi|p)(p+y|\psi)(\psi_{p,k}|\psi_{p+y,k})dp\right|,$$

where

$$\psi_{p,k} = \int |p')(p'|A_k(0)|p)dp',$$

and is uniformly (with respect to y) maximized by the choice $\psi_{p,k} \equiv \psi_k$ [provided $(p|\psi) \geqslant 0$]. It follows that this choice minimizes the variance (5.13). This gives

$$A_k(x) = \sqrt{2\pi} V_x |\psi_k)(x|,$$

which is a generalization of Example 1. From the inversion formula (5.12), $a_y(p) = (p-y|\Psi_0)$ in this case.

If $\Lambda = \mathrm{R}$, then $U_y = \mathrm{e}^{-iyQ}$, where $Q = \int xM(dx)$ is the self-adjoint position operator with the generalized eigenvectors $|x)$. This case is a continuous analog of the Example 2. In the case where $a_{y,k}(p) = a_{y,k}$ does not depend on p, we have $A_k(x) = \widetilde{a}_k(x-Q)$, where $\widetilde{a}_k(x) = \int \mathrm{e}^{ixy} a_{y,k}\, dy$. The instrument (5.5) then describes approximate measurement of Q admiting von Neumann-type realization, described in Ref. 11.

The case of the representation $t \to V_t = \mathrm{e}^{itH}$, $t \in \mathrm{R}$, where the self-adjoint operator $L = -H$ has nonpositive Lebesgue spectrum $\Lambda = (-\infty, 0)$, is an apparent continuous analog of Example 3. The instruments covariant with respect to this representation correspond to measurements of ''arrival time.'' The construction of Example 3 can be transformed to this case by using the description of the time observable given in Refs. 10 and 16, and by taking into account the multiplicity of the representation V_t.

p-adic stochastic hidden variable model

Andrew Khrennikov[a)]
Department of Mathematics, Statistics and Computer Sciences, University of Växjö, 35195, Växjö, Sweden

(Received 28 February 1996; accepted for publication 5 November 1997)

We propose stochastic hidden variables model in which hidden variables have a p-adic probability distribution $\rho(\lambda)$ and at the same time conditional probabilistic distributions $\mathbf{P}(U,\lambda)$, $U=A,A',B,B'$, are ordinary probabilities defined on the basis of the Kolmogorov measure-theoretical axiomatics. A frequency definition of p-adic probability is quite similar to the ordinary frequency definition of probability. p-adic frequency probability is defined as the limit of relative frequencies ν_n but in the p-adic metric. We study a model with p-adic stochastics on the level of the hidden variables description. But, of course, responses of macroapparatuses have to be described by ordinary stochastics. Thus our model describes a mixture of p-adic stochastics of the microworld and ordinary stochastics of macroapparatuses. In this model probabilities for physical observables are the ordinary probabilities. At the same time Bell's inequality is violated. © *1998 American Institute of Physics.* [S0022-2488(98)02802-3]

I. INTRODUCTION

Bell's inequality[1] and its numerous generalizations[2–5] provide very important predictions about properties of physical reality. It is quite surprising that these predictions have been obtained on the basis of a simple mathematical assumption. In fact, to prove Bell's inequality, we use only the assumption that *there exists a probability distribution[2] of hidden variables (HVs)*. (Of course, it is assumed that this probability distribution is defined in Kolmogorov's measure-theoretical framework.[4]) As a consequence we obtain, in particular, predictions about locality of the space–time.[5,6] It seems that it should be impossible to obtain such predictions, starting with this restricted initial information about a physical system.

It should be more natural to assume that information about the probability distribution of HVs can only give us new information about this probability distribution. In particular, all experiments for testing Bell's inequality can only give us information about the probability distribution of HVs. Thus, the violations of Bell's-type inequalities can only show us that the statement

HVs have a probability distribution described by usual theory of probability (i.e., by the system of Kolmogorov's axioms[6])

was not true. This idea is not new. There were many attempts to use this approach to understand the real consequences of the violations of Bell's inequality.[7–11] de Broglie[12] was one of the first who discussed the idea that ''classical'' and ''quantum'' probabilities had essentially different properties. Lochak[7,9] applied these considerations to the Einstein–Podolsky–Rosen[13] (EPR) paradox.

From the mathematical point of view, ''quantum'' behavior of probabilities implies that Kolmogorov's axiomatics must be changed to describe quantum phenomena. Kolmogorov's axiomatics contain the following axioms: *(1) probability yields values in the segment [0,1] of the field of real numbers* **R**; *(2) is a finite additive measure normalized by 1*. To use Lebesgue's integration theory, Kolmogorov proposed a stronger axiom: (2σ) *probability is a σ-additive measure*. In fact, Kolmogorov's axiomatics contain Bayes' formula for conditional probabilities as the additional axiom. [Kolmogorov motivated axioms (1) and (2) by using the properties of relative frequencies; see also the frequency probability theory of von Mises.[14] Bayes' formula can be motivated in the same way. On the other hand, σ additivity of probability has no frequency motivations. This is just

[a)]On leave from the Moscow Institute of Electronic Engineering.

the technical mathematical condition; see the corresponding discussion in Kolmogorov's book.[4]]

On the one hand, Kolmogorov's axiomatics strongly stimulate the development of probability theory, because it provides the rigorous mathematical foundations for this theory. On the other hand, this axiomatics essentially restrict the domain of probability theory, because it reduces all probability theories to the formalism of real-valued measures.

As we have already noticed, quantum theory implies that we need to change the probabilistic formalism. There are two possibilities to do this. The first possibility is to change formally one of Kolmogorov's axioms, i.e., to consider a theory in which, for example, probability is nonadditive, or additive, but not σ additive, or Bayes' formula can be violated or probability can yield values that do not belong to the segment $[0,1]$ of the field of real numbers. Another possibility is to start with one of the old probability formalisms (which has been used before Kolmogorov's axiomatics) and develop a new probability formalism. In this paper we will realize the latter possibility.

The idea of the formal change of Kolmogorov's axiomatics for solving the problem of quantum probabilities has been used by many authors. Feynman[15] proposed that the behavior of probabilities be described in the two slit experiment by using nonadditive probabilities. Accardi[8,9] investigated the same problem (and the EPR paradox) by using a probability formalism that does not contain Bayes' formula.

In fact, the same conclusion (i.e., Bayes' formula is the root of the EPR paradox) has been obtained by Bub.[16] He provided a careful analysis of probabilistic roots of the EPR paradox. His conclusion was that violations of Bell's inequality was not related in any way to locality of the space–time. These violations show that the standard probability formalism is violated in quantum theory. There by some (still unclear reasons) we cannot use the standard rule $\mathbf{P}(A_2)\mathbf{P}(A_1/A_2) = \mathbf{P}(A_1 \cap A_2)$ in quantum theory. For the compatible observables, x_j, $j=1,2$, i.e., $A_j = \{x_j \in S_j\}$, where S_j are the Borel subsets of R, this statement is the standard consequence of the quantum formalism. This is just because the probability $\mathbf{P}(A_1 \cap A_2)$ does not exist. However, Bub has shown that Bayes' formula could not be used for some compatible observables x_j, $j=1,2$. Here the probability $\mathbf{P}(A_1 \cap A_2)$ is well defined. Such compatible observables appear in the EPR experiments. This is the main probabilistic implication of the EPR experiment. Of course, Bub's investigation was just a chain of physical considerations. As we remarked, the idea that we have to consider a new (non-Kolmogorov) probability axiomatics for the description of this physical phenomenon has been proposed by Accardi.[8,9]

Dirac[17] has introduced negative probability distributions for solving a problem of the relativistic quantization of photons. Then negative probability distributions have been used in connection with the EPR paradox (see Refs. 10 and 11). But, as negative probabilities have not any reasonable interpretation, this solution of the EPR paradox has not been considered as a physical solution. (See, for example, Weizsäcker:[11] ''An indefinite measure on the Hilbert space has been considered frequently and is used concretely e.g., in quantum electrodynamics by the method of Bleuler and Gupta; also by Heisenberg's spinor-field theory. But since it has turned out impossible, to conceive negative probability in the visualizable sense, the indefinite measure was no longer understood as probability. If probability is defined, e.g., as the prediction of a relative frequency, clearly it has to be non-negative.'') In this paper we will provide a fruitful frequency interpretation of negative probabilities. Finally, we refer to papers of Pitowsky[18] in which nonmeasurable ''random variables'' are used for the description of the EPR experiment (see also Ref. 19).

Relative frequencies provide the unique connection between theoretical probabilities and the physical reality. We will also approximate negative (and other extended) probabilities by relative frequencies. The basis of such a theory is so called p-adic *frequency* theory of probability[20,21] (see Sec. II about fields of p-adic numbers $\mathbf{Q}_p$ and p-adic probabilities). From the first point of view these are quite exotic probabilities. But their definition is similar to the standard definition of frequency probabilities. It is evident that relative frequencies $\nu_n = n/N$ always belong to the field of rational numbers Q. Therefore their asymptotic can be studied, not only with respect to a real metric $\rho_\infty(x,y)$ on Q, but also with respect to other metrics $\rho(x,y)$ on Q, and, in particular, with respect to the p-adic metric $\rho_p(x,y)$. The limit with respect to a metric $\rho(x,y)$ (if it exists) is said to be a ρ probability. In particular, we can get probabilities belonging to $\mathbf{Q}_p$. Moreover, every p-adic number can be realized as such a frequency probability. As Q is a subset of $\mathbf{Q}_p$, then, in principle, every rational number can be a p-adic probability. Thus negative probability distribu-

tions can be interpreted as frequency objects. This frequency probability theory is a natural generalization of the theory of von Mises.[14]

p-adic probabilities (and, in particular, negative probabilities) can be also obtained by the extension of the standard proportional definition of probability. Let Ω be a finite population. Then for any subset (event) $A \subset \Omega$, probability is defined by

$$\mathbf{P}(A) = \frac{|A|}{|\Omega|}, \tag{1}$$

where for the set B, its cardinality is denoted by $|B|$. The measure-theoretical approach is in some sense a generalization of the proportional theory. However, the formula (1) has not been preserved there. p-adic numbers give a possibility to extend the proportional definition of probability to infinite populations Ω and at the same time to preserve the basic formula (1). However, we have to pay for this by p-adic and, in particular, negative probabilities.

Deterministic HV models with p-adic probability distributions have been presented in Ref. 22. In such models Bell's inequality can be violated.

However, the results of quantum measurements are described by usual statistics (based on Kolmogorov's axiomatics). How can we connect the p-adic probability description of HVs and the ordinary probability description of quantum measurements? The present paper is devoted to this problem. [Following Bohm, we understand that ''the so-called 'observables' are not properties belonging to the observed system alone, but instead potentialities whose precise development depends just as much on the observing apparatus as on the observed system.'' p-adic statistics of the (microworld) HV distribution is perturbated by the usual statistics of apparatus.]

The distribution $\rho(\lambda)$ of HVs can be a p-adic distribution corresponding to the properties of the (microworld) internal structure of a system, but responses of the macroequipment can have the ordinary Kolmogorov distributions $\mathbf{P}(A,\lambda)$ for every value λ of HV. These HV models have the mixed (real-p-adic) probability structure (mixed stochastic HV models). We will construct a mixed stochastic HV model in which a combination of p-adic stochastics of HVs and ordinary stochastics of apparatuses gives ordinary probabilities for all physical observables A, A', B, B' and their physical combinations AB, AB', $A'B$, $A'B'$, but Bell's-type inequalities are violated.

II. p-ADIC PROBABILITIES

The field of real numbers R is constructed as a completion of the field of rational numbers Q with respect to the metric $\rho(x,y)=|x-y|$, where $|\cdot|$ is the usual absolute value, norm. Fields of p-adic numbers $\mathbf{Q}_p$ are constructed in the same way. There is an infinite sequence of p-adic number fields; there is its own field for every prime number $p=2,3,5,\ldots$. A p-adic norm $|\cdot|_p$ is defined in the following way. At first, we define it for natural numbers. Every natural number n can be represented as the product of powers of prime numbers: $n=2^{r_2}3^{r_3}\cdots p^{r_p}\cdots$. Then $|n|_p = p^{-r_p}$, by the definition $|0|_p=0$, $|-n|_p=|n|_p$, and $|n/m|_p=|n|_p/|m|_p$. The completion of Q with respect to the metric $\rho_p(x,y)=|x-y|_p$ is a locally compact field $\mathbf{Q}_p$.

And it is an intrinsic fact of the theory of numbers[23] that there is the only possibility to introduce a norm on Q to use a real one $|\cdot|$ or one of p-adic valuations.

For any $x \in \mathbf{Q}_p$ we have a unique canonical expansion (converging in the $|\cdot|_p$ norm) of the form

$$x = a_{-s}/p^s + \cdots a_0 + \cdots + a_k p^k + \cdots = \cdots a_k \cdots a_0, a_{-1} \cdots a_{-s}, \tag{2}$$

where $a_j = 0,1,\ldots,p-1$, are the ''digits'' of the p-adic expansion. It is sufficiently natural (see Ref. 24) to interpret p-adic numbers x that have the infinite number of nonzero digits as infinitely large quantities.

As usual in metric space, we introduce balls in $\mathbf{Q}_p$: $U_r(a)=\{x \in \mathbf{Q}_p : |x-a|_p \leqslant r\}$, $r=p^n$, $n=0,\pm 1,\pm 2,\ldots$. These sets are closed and open at the same time (''clopen''). The unit ball $U_1(0)$ is denoted by $\mathbf{Z}_p$. It plays an important role in p-adic analysis. This is a ring. Elements of $\mathbf{Z}_p$ are called p-adic integers, because canonical expansions of elements of $\mathbf{Z}_p$ do not contain negative powers of p:

$$x=a_0+a_1p+\cdots+a_np^n+\cdots=\cdots a_n\cdots a_1a_0.$$

Elements that have infinite number of nonzero digits can be interpreted as infinitely large natural numbers.

As is well known, the frequency definition of probability proposed by von Mises in 1919 played an important role in the construction of the foundations of modern probability theory. This definition exerted a strong influence on the measure-theoretical axiomatic of Kolmogorov,[4] 1933. As the motivation of his axioms, Kolmogorov used the properties of limits of relative frequencies (see Ref. 4). We are interested in the manner in which one of Kolmogorov's axioms arose; in accordance with this axiom, the probability of any event E is a non-negative real number. In Ref. 4, Kolmogorov considers von Mises' definition[14] of probability as the limit of relative frequencies of occurrence of the event E. Further, since the relative frequencies are rational numbers that lie between zero and unity, their limits with respect to the real metric are real numbers between zero and unity.

It is probably necessary to recall in its general features the main propositions of von Mises' theory of probability.[14]

A basic object of Mises' theory is a *collective*. Let $\mathscr{S}$ be a random experiment and $T=\{\alpha_1,\ldots,\alpha_m\}$ be the set of all possible realizations of $\mathscr{S}$ (in the simplest case $T=\{0,1\}$). An infinite sequence of realizations of $\mathscr{S}$,

$$x=(x_1,\ldots,x_n,\ldots),\quad x_i\in T, \tag{3}$$

is said to be a collective if for every label $\alpha\in T$ there exists a limit of relative frequencies $\nu_n(\alpha)=k(\alpha)/n$: $\mathbf{P}(\alpha)=\lim_{n\to\infty}\nu_n(\alpha)$. This limit is said to be a probability of α.

Now a sequence (3) is said to be a p-adic collective[20,21] if a limit of relative frequencies exists with respect to the p-adic metric for every label $\alpha\in A$. This limit $\mathbf{P}(\alpha)=\lim_{n\to\infty}\nu_n(\alpha)$ is called a p-adic probability. In Refs. 20 and 21, p-adic collectives were considered from the theoretical and computer points of view.

A measure theoretical definition of p-adic probability is generated by the frequency definition. p-adic probability distributions are defined as $\mathbf{Q}_p$-valued measures with the normalization condition, $P(\Omega)=1$ (about $\mathbf{Q}_p$-valued measures, see Schikhov[23] and the Appendix).

Our interpretation of p-adic numbers,

$$N=l_0+l_1p+\cdots+l_sp^s+\cdots, \tag{4}$$

where $l_s=0,1,\ldots,p-1$, with an infinite number of nonzero digits l_s as infinitely large numbers gives the possibility of considering numerous actual infinities. Therefore we can study proportional probabilities on populations of an infinite volume. We shall study a population $\Omega=\Omega_N$ that has volume N, where N is the p-adic integer (4). If N is finite then Ω is the ordinary finite population; if N is infinite then Ω has essentially a p-adic structure. Consider a sequence of populations M_s having volumes l_sp^s, $s=0,1,\ldots$. Set $\Omega=\cup_{s=0}^{\infty}M_s$. Then $|\Omega|=N$.

We may imagine a population Ω as being the population of a tower $T=T_\Omega$, which has an infinite number of floors with the following distribution of population through floors: population of the sth floor is M_s. Set $T_k=\cup_{s=0}^{k}M_s$. This is population of the first $k+1$ floors.

Let $A\subset\Omega$ and let there exist

$$n(A)=\lim_{k\to\infty}n_k(A),\quad \text{where } n_k(A)=|A\cap T_k|. \tag{5}$$

We define the probability of A by the standard proportional relation:

$$\mathbf{P}(A)\equiv\mathbf{P}_\Omega(A)=\frac{n(A)}{N}. \tag{6}$$

Denote the family of all $A\subset\Omega$, for which (6) exists, by $\mathscr{F}=\mathscr{F}_\Omega$. The sets $A\in\mathscr{F}$ are said to be events. Later, we shall study some properties of the family of events. First we consider the set algebra F that consists of all finite subsets and their complements.

Proposition 2.1: $F\subset\mathscr{F}$.

Proof: Let A be a finite set. Then $n(A)=|A|$ and (6) has the form $\mathbf{P}(A)=|A|/|\Omega|$. Now let $B=\underline{A}$. Then $|B\cap T_k|=|T_k|-|A\cap \underline{T}_k|$. Hence there exists $\lim_{k\to\infty}|B\cap T_k|=N-|A|$. This equality implies the standard formula: $\mathbf{P}(\underline{A})=1-\mathbf{P}(A)$.

In particular, we have $\mathbf{P}(\Omega)=1$.

Proposition 2.2: Let $A_1,A_2\in\mathscr{F}$ *and* $A_1\cap A_2=\varnothing$. *Then* $A_1\cup A_2\in\mathscr{F}$ *and* $\mathbf{P}(A_1\cup A_2)=\mathbf{P}(A_1)+\mathbf{P}(A_2)$.

Proposition 2.3: Let $A_1,A_2\in\mathscr{F}$. *The following conditions are equivalent:*

$$(1)\ A_1\cup A_2\in\mathscr{F};\quad (2)\ A_1\cap A_2\in\mathscr{F};$$
$$(3)\ A_1\backslash A_2\in\mathscr{F};\quad (4)\ A_2\backslash A_1\in\mathscr{F}.$$

There are standard formulas:

$$\mathbf{P}(A_1\cup A_2)=\mathbf{P}(A_1)+\mathbf{P}(A_2)-\mathbf{P}(A_1\cap A_2); \tag{7}$$

$$\mathbf{P}(A_1\backslash A_2)=\mathbf{P}(A_1)-\mathbf{P}(A_1\cap A_2). \tag{8}$$

Proof: We have $n_k(A_1\cup A_2)=n_k(A_1)+n_k(A_2)-n_k(A_1\cap A_2)$. Therefore, if, for example, $A_1\cap A_2\in\mathscr{F}$ then there exists a limit of the right-hand side. It implies $A_1\cup A_2\in\mathscr{F}$ and (7) holds. Other implications are proved in the same way.

In general, $A_1,A_2\in\mathscr{F}$ does not imply $A_1\cup A_2\in\mathscr{F}$. To show this, by Proposition 2.3 it suffices to find $A_1,A_2\in\mathscr{F}$ such that $A_1\cap A_2\notin\mathscr{F}$. It is easy to do: let $A_1,A_2\in\mathscr{F}$ are such that $|A_1\cap A_2\cap M_s|=1$ for nonempty M_s (there is only one element $x\in A_1\cap A_2$ on each nonempty floor). If N is infinite then $\lim_{k\to\infty} n_k(A_1\cap A_2)$ does not exist. Therefore $\mathscr{F}$ is not a set algebra. It is closed only with respect to a finite unions of sets that have empty intersections. However, $\mathscr{F}$ is not closed with respect to countable unions of such sets: in general ($A_j\in\mathscr{F}$, $j=1,2,...$, $A_i\cap A_j=\varnothing$, $i\neq j$,) does not imply $U_{j=1}^{\infty}A_j\in\mathscr{F}$. The natural additional assumptions (a) $\Sigma_{j=1}^{\infty}\mathbf{P}(A_j)$ converges in $\mathbf{Q}_p$ or (a stronger assumption), (b) $\Sigma_{j=1}^{\infty}|\mathbf{P}(A_j)|_p<\infty$, also do not imply $A\in\mathscr{F}$.

Example 2.1: Let $m=2$, $N=-1=1+2+2^2+\cdots+2^n+\cdots$. Suppose that the sets A_j have the following structure: $|A_j\cap M_{3(j-1)}|=1$, $|A_j\cap M_{3j-1}|=2^{3j-1}-1$ and $A_j\cap M_i=\varnothing$, $i\neq 3(j-1)$, $3j-1$, i.e., the set A_j is located on two floors of the tower T. In particular, $A_i\cap A_j=\varnothing$, $i\neq j$. As $A_j\in F$, then $A_j\in\mathscr{F}$; the probability $\mathbf{P}(A_j)=-2^{3j-1}$, $j=1,2...$. The series $\Sigma_{j=1}^{\infty}|\mathbf{P}(A_j)|_2<\infty$. We show that $A=U_{j=1}^{\infty}A_j\notin\mathscr{F}$ We have

$$n_{3(j-1)}(A)=|A_j\cap T_{3(j-1)}|+|U_{s=1}^{j-1}A_s\cap T_{3(j-1)}|=1+\gamma,$$

where $|\gamma|_2<1$. Thus $|n_{3(j-1)}(A)|_2=1$. But $|n_{3j-1}(A)|_2<1$.

We note the following useful formula for computing probabilities: $\mathbf{P}(A)=\Sigma_{j=0}^{\infty}\mathbf{P}(A\cap M_j)$.

Definition 2.1: *The system* $\mathscr{P}=(\Omega,\mathscr{F},\mathbf{P})$ *is called p-adic proportional probability space for the population of the volume* $|\Omega|=N$.

In fact, any proportional probability space $\mathscr{P}$ can be approximated by proportional probability spaces $\mathscr{P}_k$ having populations of finite volumes. Set

$$N_k=l_0+l_1p+\cdots+l_kp^k,$$

for N, which has the expansion (4). Let l_s be the first nonzero digit in (4). Consider populations Ω_{N_k}, $k=s,s+1,...$, and proportional probability spaces $\mathscr{P}_{N_k}=(\Omega_{N_k},\mathscr{F}_{N_k},\mathbf{P}_{N_k})$. There $\mathscr{F}_{N_k}$ coincides with the algebra F_{N_k} of all subsets of Ω_{N_k} and

$$\mathbf{P}_{N_k}(A)=\frac{|A|}{|\Omega_{N_k}|},\quad A\in F_{N_k}. \tag{9}$$

Let us identify Ω_{N_k} with the population of the first $k+1$ floors of the tower T_{Ω}.

Proposition 2.4: Let $A\in\mathscr{F}_{\Omega}$. *Then*

$$\mathbf{P}(A)=\lim_{k\to\infty}\mathbf{P}_{N_k}(A\cap\Omega_{N_k}). \tag{10}$$

To prove (10) we have only used that $\mathbf{Q}_p$ is a topological group. This proposition has the natural frequency interpretation. In fact, the probabilities (10) are relative frequencies after a finite number N_k of trials. Therefore (10) is nothing other than the approximation of proportional probabilities by relative frequencies. The main difference from the usual results of such a kind is that this approximation depends essentially on the rule of a measurement, which is defined by the sequence $\{N_k\}$ corresponding to the volume of population. In principle, the change of this rule may change the limiting result. In this case the relative frequencies would not approximate the theoretical proportional probabilities. However, typically the limit is very stable with respect to the rule of a measurement; see Ref. 20 for the details.

Proposition 2.5: (The image of proportional probability). *The probability* $\mathbf{P}$ *maps* $\mathscr{F}_\Omega$ *into the ball* $U_{r_\Omega}(0)$, *where* $r_\Omega = 1/|N|_p$.

To study conditional probabilities we have to extend the notion of the p-adic proportional probability to consider more general populations.

Let Ω be the population of the tower T_Ω with an infinite number of floors M_j, $j=0,1,...$, and the following distribution of population: there are m_j elements on the jth floor, $m_j \in \mathbf{N}$ and the series $\Sigma_{j=1}^{\infty} m_j$ converges in $\mathbf{Z}_p$ to a nonzero number $N=|\Omega|$. We define the p-adic proportional probability of a set $A \subset \Omega$ by (5), (6); $\mathscr{F}$ is the corresponding family of events. It is easy to check that Propositions 2.1–2.5 hold for this more general proportional probability.

Let $A \in \mathscr{F}_\Omega$ and $\mathbf{P}(A) \neq 0$. We can consider elements of A as a new population and introduce the corresponding family of events $\mathscr{F}_A$.

Proposition 2.6 (conditional probability): Let $A \in \mathscr{F}_\Omega$, $\mathbf{P}(A) \neq 0$, *and* $B \in \mathscr{F}_A$. *Then* $B \in \mathscr{F}_\Omega$ *and Bayes' formula,*

$$\mathbf{P}_A(B) = \frac{\mathbf{P}_\Omega(B)}{\mathbf{P}_\Omega(A)}, \tag{11}$$

holds.

Proof: Set $M_{Aj} = A \cap M_j$, $j=0,1,...$, where M_j is population of the jth floor in the tower T_Ω. Then the tower T_A has the following population structure: there are M_{Aj} elements on the jth floor. In particular, $T_{Ak} = T_k \cap A$. Thus

$$n_{Ak}(B) = |B \cap T_{Ak}| = |B \cap T_k| = n_k(B), \tag{12}$$

for each $B \subset A$. Hence the existence of $n_A(B) = \lim_{k\to\infty} n_{Ak}(B)$ implies the existence of $n_\Omega(B) = \lim_{k\to\infty} n_k(B)$. Moreover, $n_\Omega(B) = n_A(B)$. Therefore,

$$\mathbf{P}_A(B) = \frac{n_A(B)}{n_\Omega(A)} = \frac{n_A(B)/|\Omega|}{n_\Omega(A)/|\Omega|}.$$

■

By (12) we obtain the following consequence.

Corollary 2.1: Let A, $B \in \mathscr{F}_\Omega$, $\mathbf{P}(A) \neq 0$, *and* $B \subset A$. *Then* $B \in \mathscr{F}_A$.

Thus, $\mathscr{F}_A = \{B \in \mathscr{F}_\Omega : B \subset A\}$.

Let A, B, $A \cap B \in \mathscr{F}_\Omega$, $\mathbf{P}(A) \neq 0$. We set by definition $\mathbf{P}_A(B) = \mathbf{P}_A(A \cap B)$. Then

$$\mathbf{P}_A(B) = \frac{\mathbf{P}_\Omega(B \cap A)}{\mathbf{P}_\Omega(A)}. \tag{13}$$

If we set $\mathbf{P}_A(B) = \mathbf{P}(B/A)$ and omit the index Ω for the probabilities for a population Ω then we obtain Bayes' formula.

Remark 2.1: We now discuss the domain of applications of Bayes' formula. This question has the exact and simple mathematical answer in the p-adic proportional probability theory. We can use Bayes' formula for events A and B iff $A \cap B$ is also the event, i.e., $A \cap B \in \mathscr{F}_\Omega$. Therefore in this formalism there are no restrictions for realizing incompatible physical observables X and Y as two random variables on the same proportional probability space. There are some events $A = \{X = t\}$ and $B = \{Y = s\}$ such that the event $A \cap B = \{X = t, Y = s\} \notin \mathscr{F}_\Omega$. Therefore the probability of this event is not defined.

III. *p*-ADIC PROBABILITY DISTRIBUTION OF HIDDEN VARIABLES

We study the simplest case of a discrete set of HVs, $\Lambda=\{\lambda_0,\ldots,\lambda_n,\ldots\}$. Suppose that weight of HV, λ_n, increases exponentially when n approaches infinity. For example, $\rho(\lambda_n)=2^n$, $n=0,1,2,\ldots$.

Remark 3.1: Note that this type of increasing will generate 2-adic structure of the corresponding probability distribution.

Thus, HVs with large numbers dominate very strongly over HVs with small numbers.

First we study this distribution on the basis of the ordinary theory of probability. Set $\Lambda_m=\{\lambda_0,\ldots,\lambda_m\}$. It is a finite approximation of HV set Λ. Compute the sum of all weights for Λ_m:

$$N_m=\rho(\lambda_0)+\cdots+\rho(\lambda_m)=2^{m+1}-1,$$

and probabilities

$$\mathbf{P}_m(\lambda_k)=\rho(\lambda_k)/N_m=2^k/(2^{m+1}-1),\quad k=0,1,\ldots,m.$$

But if $m\to\infty$, all these probabilities approach zero: $\lim_{m\to\infty}\mathbf{P}_m(\lambda_k)=0$, $k=0,1,\ldots,m$, in R. Thus, we cannot define the ordinary Kolmogorov distribution on the countable set Λ, corresponding to these quickly increasing sequence of weights.

But this model contains a natural 2-adic probability structure. We can normalize weights $\rho(\lambda_n)$ in Q_2:

$$N_\infty=\sum_{n=0}^{\infty}\rho(\lambda_n)=-1 \tag{14}$$

and

$$\mathbf{P}(\lambda_n)=\rho(\lambda_n)/N_\infty=-2^n. \tag{15}$$

There (-1) is the only 2-adic representation of an infinite number (14).

How would it be possible to image this 2-adic probability distribution in an intuitive way? The structure of HV distribution is the following one. For every HV, $\lambda=\lambda_k$, there exists HV $\lambda'=\lambda_{k+m}$ that dominates extremely over λ. A probability that a particle is described by HV, λ, is practically zero to compare with a probability that the particle is described by HV, λ'. But there exists another HV $\lambda''=\lambda_{k+m+l}$ with the same property with respect to λ'. By the Appendix about rules for working with proportional p-adic probabilities each probability $\mathbf{P}(\lambda_n)$ is infinitely small quantity with respect to the ''ordinary probabilities.'' Thus, in fact, we work on the set that has zero probability, but we can distinguish probabilities of elements of this set.

Remark 3.2: As it has been already remarked, we cannot define the ordinary Kolmogorov distribution on the countable set Λ corresponding the weights $\rho(\lambda_n)=2^n$, $n=0,1,2,\ldots$, because $\mathbf{P}_m(\lambda_k)\to 0$, $m\to\infty$. However, there exist the ordinary probability distributions with similar properties on the real line (for example, the Lebesgue measure on $[0,1]$). Therefore, the (possible) structure of the set Λ of hidden variables plays an important role in our example. In some sense we provide predictions on the topological structure of the set of hidden variables where violations of Bell's inequality are possible.

Remark 3.3: As we noted in the Introduction, the idea to use negative probability distributions to describe the violations of Bell's inequality is quite old. What is the main advantage of our approach? Why do we prefer to use p-adic realization of negative probabilities? The p-adic framework justifies the consideration of measures with nonpositive values as probabilities. We have the corresponding frequency and proportional interpretations. If we use the ordinary real-valued signed measures, we could not (at least at the moment) present any reason to regard these mathematical objects as probabilities.

IV. STOCHASTIC HIDDEN VARIABLE MODEL

As usual, we relax the requirement that each HV, λ, determines a unique measurement response (for example, $+1$ or -1), in favor of the idea that λ only determines the probability of

response. So we replace the response functions of determinism by the probability functions $\mathbf{P}(S,\lambda)$, where $\mathbf{P}(S,\lambda)$ gives the probability that observable S, measured in state λ, yields value $+1$. We have already discussed that it would be sufficiently natural to consider the situation where the distribution $\rho(\lambda)$ of HV is the p-adic one and responses of macroapparatus $\mathbf{P}(S,\lambda)$ are the ordinary Kolmogorov probabilities. We consider the typical EPR situation where S can be replaced by any of A, A', B, B' in $\mathbf{P}(S,\lambda)$ and also by complements $\bar{A},\ldots$. Then we require that

$$\mathbf{P}(S)=\int_{\Lambda}\mathbf{P}(S,\lambda)\rho(\lambda)d\lambda. \tag{16}$$

The same requirement is for all pairs of commuting variables $ST=AB$, $A'B$, AB', $A'B'$:

$$\mathbf{P}(ST)=\int_{\Lambda}\mathbf{P}(ST,\lambda)\rho(\lambda)d\lambda. \tag{17}$$

We also consider factorizable stochastic models: $\mathbf{P}(ST,\lambda)=\mathbf{P}(S,\lambda)\mathbf{P}(T,\lambda)$.

Now we use p-adic probability HV distribution of the previous section as the basis of the mixed stochastic HV model. It is a discrete model and it is convenient to use symbols $\mathbf{P}(S,n)$ and $\mathbf{P}(ST,n)$, $n=0,1,2,...$, instead of $\mathbf{P}(S,\lambda_n)$ and $\mathbf{P}(ST,\lambda_n)$. We have, instead of (16) and (17),

$$\mathbf{P}(S)=\sum_{n=0}^{\infty}\mathbf{P}(S,n)P(n), \tag{18}$$

where $\mathbf{P}(n)$ are the probabilities (15) and

$$\mathbf{P}(ST)=\sum_{n=0}^{\infty}\mathbf{P}(S,n)\mathbf{P}(T,n)\mathbf{P}(n), \tag{19}$$

as $\mathbf{P}(ST,n)=\mathbf{P}(S,n)\mathbf{P}(T,n)$.

We can always consider rational ordinary probabilities (in the Kolmogorov sense) in all physical applications. Thus, suppose that all probabilities of responses $\mathbf{P}(S,n)$ are rational numbers belonging to the segment $[0,1]$. We wish to prove that it is possible to choose these probabilities in such a way that all probabilities (18) and (19) are ordinary probabilities, rational numbers belonging to the segment $[0,1]$. But Bell's-type inequalities are not valid.

Suppose that all condition probabilities $\mathbf{P}(S,n)$ for the first k numbers n are the same, $\mathbf{P}(A,n)=\alpha$, $\mathbf{P}(B,n)=\beta$, $\mathbf{P}(A',n)=\alpha'$, and $\mathbf{P}(B',n)=\beta'$, $n=0,1,...,k$. In the same way, suppose that all condition probabilities for numbers $n>k$ are also equal and they differ from the first probabilities for $\epsilon>0$: $\mathbf{P}(A,n)=\alpha+\epsilon$, $\mathbf{P}(B,n)=\beta+\epsilon$, $\mathbf{P}(A')=\alpha'+\epsilon$, $\mathbf{P}(B',n)=\beta'+\epsilon$, $n=k+1,...$.

Remark 4.1: It is easy to generalize our considerations for different ϵ.

We consider the probability form of Bell's-type inequalities; see Clauser and Horne.[3] Set

$$\Delta=\mathbf{P}(AB)+\mathbf{P}(AB')+\mathbf{P}(A'B')-\mathbf{P}(A'B)-\mathbf{P}(A)-\mathbf{P}(B'). \tag{20}$$

We study the inequality

$$-1\leqslant\Delta\leqslant 0. \tag{21}$$

In our discrete case,

$$\Delta=\sum_{n=0}^{\infty}[\mathbf{P}(AB,n)+\mathbf{P}(AB',n)+\mathbf{P}(A'B',n)-\mathbf{P}(A'B,n)-\mathbf{P}(A,n)-\mathbf{P}(B',n)]\mathbf{P}(n).$$

Set

$$\Delta_1=\alpha\beta+\alpha\beta'+\alpha'\beta'-\alpha'\beta-\alpha-\beta',$$

and get also Δ_2 to add ϵ to all probabilities in Δ_1. Then we have $\Delta=(-2^{k+1}+1)\Delta_1+2^{k+1}\Delta_2 = 2^{k+1}(\Delta_2-\Delta_1)+\Delta_1$. If we set $\alpha=\beta'=0$, then

$$\Delta=-2^{k+2}\epsilon(1-\epsilon)+\Delta_1. \tag{22}$$

We can also consider the case $\alpha'=\beta=1-\delta$. Then $\Delta_1=-1+\delta_1$, where $\delta_1=2\delta-\delta^2$. Choose $\epsilon=g2^{-(k+2)}$. At the moment g is a rational parameter, $0<g<1$. Now

$$\Delta=-g[1-g2^{-(k+2)}]-1+\delta_1.$$

It is easy to find such g and δ that (21) is violated. We cannot discuss here the general solution of this problem. For example, we can choose $\delta=1/2$ and $g=7/8$. Here $\alpha'=\beta=1/2$ and $\Delta_1=-1/4$ and $\Delta=-9/8+(49/64)2^{-(k+2)}$. Now we can choose k so large that $\Delta<-1$.

But we have

$$\mathbf{P}(A)=\sum_{n=0}^{k}(-2^n)\alpha+\sum_{n=k+1}^{\infty}(-2^n)(\alpha+\epsilon)=\alpha+2^{k+1}(\alpha+\epsilon)=2^{k+1}\epsilon=7/16.$$

Remark 4.2: Roughly speaking, the result is based on the fact that Δ contains $2^{k+2}\epsilon$, (22), and probabilities contain $2^{k+1}\epsilon$.

Further, $\mathbf{P}(B')=7/16$, $\mathbf{P}(A')=\mathbf{P}(B)=15/16$ and

$$\mathbf{P}(AB)=\sum_{n=0}^{k}(-2^n)\alpha\beta+\sum_{n=k+1}(-2^n)(\alpha+\epsilon)(\beta+\epsilon)=2^{k+1}\epsilon(\beta+\epsilon)=7/32+49/2^{k+9}\approx 7/32,$$

for large k. As a consequence of $\beta=\alpha'$, we also have $\mathbf{P}(A'B')=\mathbf{P}(AA')=\mathbf{P}(AB)$. If k is large, then $\mathbf{P}(A'B)\approx 11/16$.

Of course, observables A, A', B, B' are not all mutually compatible in the usual EPR experiments. But we have obtained ordinary Kolmogorov probabilities also for these incompatible observables. It is impossible to compute probabilities $\mathbf{P}(AA')$ and $\mathbf{P}(BB')$ in EPR experiments, but these probabilities permit a statistical testing in our model. Probably we can interpret this property of our model as the possibility of a joint nonideal measurement of incompatible pairs of observables; see, for example, the review in Ref. 25. I think also that it is the only mathematical problem to construct such mixed stochastic HV models, where probabilities of incompatible pairs are non-Kolmogorovean and probabilities of compatible pairs are ordinary probabilities.

V. ON QUADRIVARIATE JOINT PROBABILITIES

Now it is well known that the existence of Bell's-type inequalities is equivalent to an existence of a quadrivariate joint probability distribution $\mathbf{P}(A,A',B,B')$; see Fine[10] and Rastall.[10] What about our model? Of course, there exists a p-adic quadrivariate distribution. But it cannot be an ordinary Kolmogorov distribution:

$$\mathbf{P}(\overline{A},\overline{A'},\overline{BB'})=(-2^{k+1}+1)/4+2^{k+1}(1-\epsilon)^2(1/2-\epsilon)^2\approx 1/4-(3/2)2^{k+1}\epsilon=-13/32,$$

for large k. Fine's paper[10] also contains the proof that a quadrivariate joint distribution can be constructed with the aid of joint distributions of three observables and two observables. This is why our model must also contain non-Kolmogorov probabilities for three observables, and it is so: $\mathbf{P}(A,\overline{B},B')\approx -3/8$ for large k.

VI. HYPOTHESIS OF REPRODUCIBILITY?

Now we try to consider our model from the experimental point of view. What are experimental consequences of p-adic HVs internal structure? Of course, we cannot realize an infinite HV space Λ in an experiment. That is why we must consider again finite approximations $\Lambda_m=\{\lambda_0,\ldots,\lambda_m\}$ of Λ and approximate probabilities $\mathbf{P}_m(\lambda_k)$. These probabilities are concentrated very quickly near λ_m. If m is large then $\mathbf{P}(\lambda_m)\approx 1/2$ and $\mathbf{P}(\lambda_{m-1})\approx 1/4$. Hence, if we consider

two finite sets of HV, Λ_m and Λ_s, where $m<s$ but not by very much, then the sets of HV that dominate in Λ_m, $\{\lambda_m,\lambda_{m-1},\lambda_{m-2}\}$, and in Λ_s, $\{\lambda_s,\lambda_{s-1},\lambda_{s-2}\}$, have the empty intersection.

Using this property of our mixed stochastic HV model, we can try to present some speculations on a hypothesis of reproducibility as a possible explanation of violations of a Bell's-type inequality in EPR experiments. It was discussed in papers[26,25] that to define quadrivariate distribution,

$$\mathbf{P}(A,A',B,B')=\int_\Lambda \mathbf{P}(A,\lambda)\mathbf{P}(A',\lambda)\mathbf{P}(B,\lambda)\mathbf{P}(B',\lambda)\rho(\lambda)d\lambda,$$

it is necessary to assume that the same value of λ can be prepared as an initial HV in different experiments. But it would be really impossible for our p-adic probability distribution of HVs because we can get different Λ_m in different experiments. Different HV, λ, strongly dominate in these experiments. Of course, it is only one of the possible interpretations.

VII. p-ADIC BELL'S-TYPE INEQUALITIES

Let Λ be a set of hidden variables λ distributed with a probability (usual Kolmogorov) density $\rho(\lambda)$. Then from the mathematical point of view all problems are concentrated in the integral

$$\langle AB\rangle=\int_\Lambda A(\lambda)B(\lambda)d\nu(\lambda), \tag{23}$$

where $A(\lambda)$ and $B(\lambda)$ are random variables with values $+1$ or -1 and $d\nu(\lambda)=\rho(\lambda)d\lambda$. We can easily estimate this integral:

$$|\langle AB\rangle|\leqslant\int_\Lambda |A(\lambda)B(\lambda)|d\nu(\lambda)\leqslant\int_\Lambda d\nu(\lambda)=1. \tag{24}$$

Can we get a p-adic-type Bell's inequality? Can we get some kind of Bell's estimate of the mean value (23) in the p-adically distributed case? Using properties of $\mathbf{Q}_p$-valued measures, we have

$$\left|\int_\Lambda A(\lambda)B(\lambda)\nu(d\lambda)\right|_p\leqslant\|\nu\|, \tag{25}$$

where $\|\nu\|$ is the norm (variation) of the probability measure ν. But this variation may be arbitrarily large also in the case of the normalized measure $\nu(\Lambda)=1$. Therefore, we need information about the variation of the p-adic probability distribution ν.

It does not seem surprising from the physical point of view. To prepare an experiment, we must have some initial information that will be tested during the experiment. The EPR experiments to verify Bell's inequality do not use any information about the probability distribution of hidden variables. In fact, these are not statistical experiments where some statistical hypothesis H about a form of a probability distribution must be verified. The only statistical hypothesis, which investigators try to verify during the EPR experiments is

$$H=\{\text{hidden variables have a Kolmogorov probability distribution}\}.$$

The result of numerous experiments is that $\bar{H}$ is right with a large probability.

VIII. CONCLUSIONS

(1) We have built the stochastic HV model where the probability distribution of HVs is sufficiently exotic from the point of view of the usual theory of probability. However, only the mathematical description is exotic (using the p-adic metric). We can create these distributions in real experiments.

(2) Despite the p-adic distribution of HVs, all probabilities that might be measured are usual Kolmogorov probabilities. It is a consequence of the stochastic structure of our HV model (responses of equipment destroy a p-adic probability structure of HVs).

(3) There is no Bell's inequality for this HV model. To say more rigorously, any p-adic ''Bell's-type inequality'' must be based on the information about the properties of the concrete distribution of hidden variables. However, it should be not natural to regard such types of inequalities as analogs of the Bell inequality, since the main reason of Bell's activity was to get inequality for the probability distribution of hidden variables that was not connected with any information about the concrete properties of the distribution of hidden variables.

(4) Our HV model might be realized as a real physical experiment with classical objects (for instance, colored balls). We should see that the ''essentially quantum'' structure of EPR-type experiments could have a classical internal structure. Only a probability distribution (for instance, of colors of the balls) must not be classical. Hence, all effects of the EPR experiment might be generated only by the unusual probability structure of HVs.

(5) Of course, we cannot justify our theoretical construction by statistical data of EPR-type experiments, because there are no statistics of HVs. However, we obtained some predictions on the behavior of HV. Probably, these predictions would be tested in some indirect measurements (without direct statistics of HVs). The main prediction is about a very unstable structure of HV distributions for the stochastic HV models, where Bell's inequality is violated (see the previous section).

(6) We hope that it will be possible to propose some physical experiments (not as complicated as EPR experiments), where we shall be able to test this behavior of HVs. The simplest situation is the case of two HVs, λ_1 and λ_2, which have a probability distribution of HVs such that relative frequencies of realizations of λ_j, $\nu(\lambda_j)$, oscillate with respect to the usual real metric.

(7) We understood that our HV model is probably only a toy model. The p-adic probabilities are the simplest non-Kolmogorovean probabilities. It would be possible to study another probability distributions with non-Kolmogorovean behavior. The p-adic model is very attractive from the analytic point of view. Here we have realized computations (in particular, the violation of Bell's inequality) that were not evident for other kinds of stochastics.

ACKNOWLEDGMENTS

APPENDIX A: p-ADIC MEASURES

Here we present the simplest variant of p-adic integration. Let X be compact open subset of $\mathbf{Q}_p$. Denote by $\Phi(X)$ the algebra of all clopen (i.e., at the same time open and closed) subsets of X. A measure is defined as a finite-additive set function $\mu:\Phi(X)\to\mathbf{Q}_p$, such that

$$\|\mu\|(A)=\sup\{|\mu(B)|_p : B\subset A, B\in\Phi(X)\}<\infty,$$

for each $A\in\Phi(X)$. In particular, the norm $\|\mu\|=\|\mu\|(X)$ is a finite number. Each measure defines a continuous $\mathbf{Q}_p$-linear functional $\mu:C(X)\to\mathbf{Q}_p$, where $C(X)$ is the space of continuous $\mathbf{Q}_p$-valued functions. Thus, the set of measures coincides with the dual space $C'(X)$. This functional (integral) is defined as a limit of Riemann sums. $S_u(f)=\Sigma_{i=1}^{k} f(a_i)\mu(U_i)$, where $u=(U_i)$, $U_i\in\Phi(X)$, $U_i\cap U_j=\emptyset$, $i\neq j$, is the cover of X. Then this integral is extended to a larger class of integrable functions.

APPENDIX B: RULES FOR WORKING WITH p-ADIC PROBABILITIES

One of the main tools of the ordinary theory of probability is based on the order structure on the field of real numbers $\mathbf{R}$. It gives the possibility of comparing probabilities of different events; events E with probabilities $\mathbf{P}(E)\ll 1$ are considered as negligible and events E with probabilities $\mathbf{P}(E)\approx 1$ are considered as practically certain. However, the use of these relations in concrete applications is essentially based on our (real) probability intuition. What is a large probability? What is a small probability? Moreover, it is not easy to compare two arbitrary probabilities. For

instance, do you prefer to win with the probability $\mathbf{P}(E_1)=11/17$ or $\mathbf{P}(E_2)=13/19$. Formally, because $\mathbf{P}(E_1)<\mathbf{P}(E_2)$, it would be better to choose E_2. But in practice this choice does not give many advantages. Thus, ordinary probability intuition is based more on centuries of human experiment than on exact mathematical theory.

If we want to work with p-adic probabilities we have to develop some kind of a p-adic probability intuition. However, there arises a mathematical problem that does not give the possibility of generalizing the real scheme directly. This is the absence of an order structure on $\mathbf{Q}_p$. Of course, we can also do something without an order structure. For example, we can classify (split) different events with the aid of their p-adic probabilities. For instance, it works sufficiently successfully in the frequency probability theory. If there are two ''random sequences'' x and y that are not collectives in the ordinary von Mises' frequency theory, then we could not split properties of x and y. Both these sequences seem to be totally chaotic from the real point of view. However, if they are p-adic collectives, then it would be possible to classify them with respect to p-adic probability distributions, $\mathbf{P}_x(s_i),\mathbf{P}_y(s_i)$. In the proportional approach different p-adic probabilities, $\mathbf{P}(E_1)\neq\mathbf{P}(E_2)$, mean that the events E_1 and E_2 have different volumes of population.

However, we could do much more with p-adic probabilities by using the partial order structure that exists on the ring of p-adic integers. Let $x=\cdots x_n\cdots x_1x_0$ and $y=\cdots y_n\cdots y_1y_0$ be the canonical expansions of two p-adic integers x, $y\in\mathbf{Z}_p$. We set $x<y$ if there exists n such that $x_n<y_n$ and $x_k\leqslant y_k$ for all $k>n$. This partial order structure on $\mathbf{Z}_p$ is the natural extension of the standard order structure on the set of natural numbers $\mathbf{N}$. It is easy to see that $x<y$ for any $x\in\mathbf{N}$ and $y\in\mathbf{Z}_p\backslash\mathbf{N}$, i.e., any finite natural number is less than any infinite number. But we could not compare any two infinite numbers.

Example 10.2: Let $x=\ldots0101....0101$, $z=\ldots.1010...1010$ and $y=\ldots1111...1000$, then $x<y$ and $z<y$, but the numbers x and z are incompatible.

It is important to remark that there exists the maximal number $N_{\max}\in\mathbf{Z}_p$. It is easy to see that

$$N_{\max}=-1=(p-1)+(p-1)p+\cdots+(p-1)p^n+\cdots .$$

Therefore the population Ω_{-1} is the largest population that can be considered in the p-adic framework.

Remark 10.3: It seems to be natural to suppose that the volume of the population increases with the increase of p, i.e., $|\Omega^p_{-1}|<|\Omega^q_{-1}|$, $p<q$.

Proposition 10.7: Let $N\neq0$ have the form (4). Then $\Omega_N\in\mathcal{F}_{\Omega_{-1}}$ and

$$\mathbf{P}_{\Omega_{-1}}(\Omega_N)=\frac{|\Omega_N|}{|\Omega_{-1}|}=-N. \tag{26}$$

Corollary 10.3: Let $N\in\mathbf{Z}_p$, $N\neq0$. Then $\mathcal{F}_{\Omega_N}\subset\mathcal{F}_{\Omega_{-1}}$ and probabilities $\mathbf{P}_{\Omega_N}(A)$ are calculated as conditional probabilities with respect to the subpopulation Ω_N of population Ω.

But $A\in\mathcal{F}_{\Omega_{-1}}$ does not imply $A\cap\Omega_N\in\mathcal{F}_{\Omega_N}$.

By Corollary 10.3 we can, in fact, restrict our considerations to the case of the maximal population Ω_{-1}. Therefore we shall study this case $\Omega\equiv\Omega_{-1}$.

Let $A,B\in\mathcal{F}$. By definition, $\mathbf{P}(A)<\mathbf{P}(B)$ iff $n(A)<n(B)$. Further, we study the properties of probabilities.

(1) As we have only a partial order structure we cannot compare probabilities of arbitrary two events A and B.

(2) As $x\leqslant-1$ for any $x\in\mathbf{Z}_p$, we have $\mathbf{P}(A)\leqslant1=\mathbf{P}(\Omega)$ for any $A\in\mathcal{F}$.

(3) As $0\leqslant x$ for any $x\in\mathbf{Z}_p$, we have $0\leqslant\mathbf{P}(A)$ for any $A\in\mathcal{F}$.

To illustrate further properties of p-adics we shall use the usual real order structure. In this case we shall say an ''r increase'' or an ''r decrease.'' We shall use the symbols $[a,b],\ldots,(a,b)$ for corresponding intervals of the real line.

(4) Set $F^f=\{A\in\mathcal{F}:n(A)\in\mathbf{N}\}$ (in particular, F^f contains all finite subsets of Ω). Because the partial order structure on $\mathbf{N}$ coincides with the standard order structure, we have the standard order relation for $n(A),n(B)$, $A,B\in F^f$. But $\mathbf{P}:F^f\to(-\infty,0)\cap\mathbf{Z}$ and $\mathbf{P}(A)$ is increasing to 1 if $\mathbf{P}(A)$ is r decreasing to $-\infty$. Therefore events with probabilities $\mathbf{P}(A)=-1$ or -3 are practically negligible with respect to events with probabilities $\mathbf{P}(B)=-100$ or -300 or with respect to the total

population Ω. An event A with probability $\mathbf{P}(A)=1000$ seems to be practically certain. Of course, the levels of negligible probabilities depend on the concrete model. An event with probability $\mathbf{P}(A)=-100$ may be negligible in one situation and not negligible in another. Further p-adic probability intuition must be developed from the results of experimental applications.

(5) Set $\overline{F^f}=\{B=\overline{A}:A\in F^f\}$ (in particular, $\overline{F^f}$ contains complements of all finite subsets of Ω). Then $\mathbf{P}:\overline{F^f}\to(1,\infty)\cap\mathbf{Z}$ and $\mathbf{P}(B)$ is decreasing to 0 if $\mathbf{P}(B)$ is r increasing to ∞. Therefore, events with probabilities $\mathbf{P}(E)=100$ or 200 are practically negligible with respect to events with probabilities $\mathbf{P}(C)=1$ or 2. An event C with probability 2 (or 3) seems to be practically certain. Of course, the level of negligible probabilities depends again on the concrete model.

We can use these rules for conditional probabilities. For example, let $\mathbf{P}(B)=100$, $\mathbf{P}(B')=200$, $\mathbf{P}(A)=2$, and $B,B'\subset A$. Then $\mathbf{P}(B/A)=50>\mathbf{P}(B'/A)=100$.

On the other hand, any event A with a probability $x\in(-\infty,0)\cap\mathbf{Z}$ is practically negligible with respect to any event B with a probability $y\in(1,\infty)\cap\mathbf{Z}$. For example, an event with probability -1000 is negligible with respect to an event with the probability 2.

By (4) and (5) we can work with probabilities belonging to $F^f\cup\overline{F^f}$.

(6) Now consider events $A\notin F^f\cup\overline{F^f}$. We can develop our intuition only by examples.

Example 10.3: Let $p=2$. Let $|A\cap M_{2k}|=2^{2k}$ and $A\cap M_{2k+1}=\emptyset$, $k=0,1,\ldots$. Then $n(A)=-1/3$ and $\mathbf{P}(A)=1/3$. Let $B\subset A$ and $B\cap M_{4k}=A\cap M_{4k}$, $B\cap M_j=\emptyset$, $j\neq 4k$. Then $n(B)=-1/15$ and $\mathbf{P}(B)=1/15$. It is evident that $-1/15<-1/4$ in $\mathbf{Z}_2$. Hence, $\mathbf{P}(B)=1/15<\mathbf{P}(A)=1/3$.

Thus it seems to be that the probabilistic relation on the set $[0,1]\cap\mathbf{Q}$ coincides with the standard real order. Moreover, it seems to be reasonable to use this relation also in the case where the numbers $n(A)$ and $n(B)$ are incompatible in $\mathbf{Z}_2$.

Example 10.4: Let p and A be the same as above. Let $|C\cap M_{2k+1}|=2^{2k+1}$, $C\cap M_{2k}=\emptyset$, $k=0,1,\ldots$. Then $n(C)=-2/3$ and $\mathbf{P}(C)=2/3$. The numbers $n(A)=-1/3$ and $n(C)=-2/3$ are incompatible in $\mathbf{Z}_2$. But heuristically it seems to be evident that we can use the r-order structure on $[0,1]$ to compare the probabilities of the events A and C. Therefore the probability of $\omega\in C$ is two times larger than the probability $\omega\in A$. These heuristic reasons were also confirmed by some frequency statistical models; see Ref. 20 for the details.

Further, we have that any set E with a probability $x\in(-\infty,0)\cap\mathbf{Z}$ is practically negligible with respect to any set A with a probability in $(0,1]\cap\mathbf{Q}$. For example, an event with probability -1000 is negligible with respect to an event with probability 1/3.

We can also use these rules for conditional probabilities. For example, let $\mathbf{P}(B)=1/15<\mathbf{P}(B')=2/15$, $\mathbf{P}(A)=1/5$, and $B,B'\subset A$. Then $\mathbf{P}(B/A)=1/3<\mathbf{P}(B'/A)=2/3$. Moreover, for example, let $\mathbf{P}(B)=-1<\mathbf{P}(B')=-5$, $\mathbf{P}(A)=-100$, and $B,B'\subset A$. Then $\mathbf{P}(B/A)=1/100<\mathbf{P}(B'/A)=1/20$. Thus the r-order structure on $(0,1]\cap\mathbf{Q}$ reproduces the rule (4).

Physical vertex operators in the Ramond sector

Seichi Naito
Department of Physics, Osaka City University, Sumiyoshiku, Osaka, Japan

(Received 17 September 1997; accepted for publication 1 December 1997)

Introducing *physical* string coordinate's modes as well as *physical* string coordino's modes, we derive the generating functional of *physical* vertex operators (GFPVO) of fermionic particles (in superstring), which is just equal to the one already proposed by using superconformal mapping in the Ramond sector. Inversely solving the superconformal mapping problem, we can derive general formulas, which give physical vertex operators of various fermionic particles up to arbitrarily excited mass levels. As an example, we explicitly derive some (Gliozzi–Scherk–Olive-allowed) low-lying physical vertex operators. © *1998 American Institute of Physics.* [S0022-2488(98)02703-0]

I. INTRODUCTION AND PRELIMINARIES

There exist two formulations of superstring: Ramond–Neveu–Schwarz (RNS) superstring[1,2] and Green–Schwarz superstring.[3] In our previous papers,[4,5] we have investigated RNS superstring, along the line proposed by Friedan, Martinec and Schenker (FMS).[6] The problem is how to construct all physical Ramond as well as Neveu–Schwarz vertex operators by using the common operators to both the R and NS sector. This problem has been solved, suggested by our previous paper[7] which has succeeded in constructing any physical vertex operator in the bosonic string. The strategy is using two different kinds of superconformal mappings, in constructing the generating functional of the physical vertex operator (GFPVO) for each R and NS sector. However, in Ref. 7, we have shown in the bosonic string case that GFPVO can be constructed by two methods. One method is using certain conformal mapping, while the other one is using DDF operators.[8] Furthermore, the equivalence of two methods has been explicitly shown. The former one is useful in explicitly obtaining all physical vertex operators, while the latter one is useful in clarifying the structure of the (thus constructed) physical Hilbert space. On the other hand, we have in Refs. 4 and 5 used only the former method in a RNS superstring.

A RNS superstring is described by the string coordinate $X^{\pm j}$ and the string coordino $\Psi^{\pm j} \equiv :\exp(\pm\phi^j):$ (for $j=0-4$). We construct physical string coordinate's modes $A^{\pm j}_{-m}$ and physical coordino's modes $\mathscr{D}^{\pm j}_{-m}$ [for $j=1-4$], which are, respectively, physical components of $X^{\pm j}$ and $\Psi^{\pm j}$ in the R sector. We prove that these physical operators satisfy the spectrum generating algebra proposed by Green and Schwarz.[3] With the help of these physical operators $A^{\pm j}_{-m}$ and $\mathscr{D}^{\pm j}_{-m}$, we construct GFPVO in the R sector, which is subsequently proved to be just equal to the previously proposed GFPVO in Ref. 4. Therefore we summarize the main results in Ref. 4 hereafter.

We introduce the light-cone operator $P_F^{\pm j\dagger}(w,\xi)$ $(j=1-4)$ in the R sector defined by

$$P_F^{\pm j^\dagger}(w,\xi) \equiv \frac{\xi}{w}\left(p^{\pm j}+\sum_{n=1}^{\infty} w^{-n}\alpha_{-n}^{\pm j}\right)+\frac{1}{\sqrt{w}}\left(\sum_{n=1}^{\infty} w^{-n} d_{-n}^{\pm j}\right) \tag{1.1}$$

$$(\equiv \xi\Pi_\alpha^{\pm j^\dagger}(w)+\pi_d^{\pm j^\dagger}(w)), \tag{1.1'}$$

where we have used light-cone (mode's) operators (for $j=1-4$), i.e., $p^{\pm j}$ (total energy-momentum operator), $\alpha_m^{\pm j}$'s, $\alpha_{-n}^{\pm j}$'s, $d_m^{\pm j}$'s, and $d_{-n}^{\pm j}$'s, which satisfy the following (anti-) commutation relations among themselves;

$$[\alpha_m^{\pm j}, \quad \alpha_{-n}^{\mp k}] = m\delta_{mn}\delta_{jk} \tag{1.2}$$

 © 1998 American Institute of Physics

and

$$\{d_m^{\pm j},\quad d_{-n}^{\mp k}\}=\delta_{mn}\delta_{jk}, \tag{1.3}$$

all other (anti-) commutators being zero.

In the R sector of superstring [i.e., in the *fermionic* sector $s=F$], there exists FMS spinor[6] $S_{\{h\}}(z_0)$ at z_0, which is given by

$$S_{\{h\}}(z_0)\equiv :\exp(\tfrac{1}{2}\phi^0(z_0)):_\phi\times\prod_{j=1}^{4}:\exp(\epsilon_h^j\phi^j(z_0)):_\phi\quad(\text{with}\ \ \epsilon_\pm^j=\pm\tfrac{1}{2}). \tag{1.4}$$

Then any non-N operator $G(z)$ composed of $X^{\pm j}$ and $\Psi^{\pm j}$ is N-ized[4] into the N operator $G_N(z)$ by

$$\mathbf{R}\cdot G(z)S_{\{h\}}(z_0)\equiv G_N(z)\cdot S_{\{h\}}(z_0). \tag{1.5}$$

[Inversely, we state that the N operator G_N is changed into the non-N operator G.] For an example, we have that

$$\begin{aligned}\mathbf{R}\cdot :\exp(\pm\phi^j(z)):_\phi S_{\{h\}}(z_0)&=(z-z_0)^{\pm\epsilon_h^j}:\exp(\pm\phi^j(z))\cdot S_{\{h\}}(z_0):_\phi\\&=(z-z_0)^{\pm\epsilon_h^j}:\exp(\pm\phi_{Nh}^j(z)):_\phi S_{\{h\}}(z_0),\end{aligned} \tag{1.6}$$

$\mathbf{R}$ being radial ordering. In Eq. (1.6), $\phi_{Nh}^j(z)$ is the operator which has already been normally ordered with respect to FMS spinor $S_{\{h\}}(z_0)$. From Eq. (1.6), we have found that

$$\Psi^{\pm j}(z)\equiv :\exp(\pm\phi^j(z)):_\phi\overset{N}{\to}\Psi_N^{\pm j}(z)\equiv(z-z_0)^{\pm\epsilon_h^j}:\exp(\pm\phi_{Nh}^j(z)):_\phi, \tag{1.7}$$

$$\Psi_h^{\pm j}(z)\equiv(z-z_0)^{\mp\epsilon_h^j}:\exp(\pm\phi^j(z)):_\phi\overset{N}{\to}\Psi_{Nh}^{\pm j}(z)\equiv:\exp(\pm\phi_{Nh}^j(z)):_\phi, \tag{1.8}$$

and

$$X^{\pm j}(z,\theta)\equiv X^{\pm j}(z)+\theta\cdot\Psi^{\pm j}(z)\overset{N}{\to}X_N^{\pm j}(z,\theta)\equiv X^{\pm j}(z)+\theta\cdot(z-z_0)^{\pm\epsilon_h^j}\Psi_{Nh}^{\pm j}(z). \tag{1.9}$$

Then GFPVO $\Phi_{N\{h\}}^F(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)$ (in the N operator's form) can be constructed by

$$\begin{aligned}\Phi_{N\{h\}}^F(z_0,\theta_0;P_F^\dagger)(\equiv\Phi_{N\{h\}}^{F0}(z_0;P_F^\dagger)+\theta_0\cdot\Phi_{N\{h\}}^{F1}(z_0;P_F^\dagger))\equiv:\exp(\rho_{N+}^{0F}(z_0,\theta_0)+\rho_N^{1F}(z_0,\theta_0;P_F^\dagger)\\+\rho_{N\{h\}}^{2F}(z_0,\theta_0;P_F^\dagger)):_R.\end{aligned} \tag{1.10}$$

In Eq. (1.10), we have defined that

$$\rho_{N+}^{0F}(z_0,\theta_0)\equiv -ip^{+0}Y_{N+}^{-0}(z_0,\theta_0)-ip^{-0}X^{+0}(z_0) \tag{1.11}$$

$$(\text{with}\ \ Y_{N+}^{-0}(z_0,\theta_0)\equiv X^{-0}(z_0)+\theta_0\Psi_{N+}^{-0}(z_0)), \tag{1.11$'$}$$

$$\rho_N^{1F}(z_0,\theta_0;P_F^\dagger)\equiv-\sum_{\pm}\sum_{j=1}^{4}\ i\oint\frac{dw\ d\xi}{2\pi i}\ P_F^{\pm j^\dagger}(w,\xi)X_N^{\mp j}(z_{NF}(w,\xi),\theta_{NF}(w,\xi)), \tag{1.12}$$

with

$$X_N^{\mp j}(z_{NF}(w,\xi),\theta_{NF}(w,\xi))\equiv X^{\mp j}(z_{NF}(w,\xi))+\theta_{NF}(w,\xi)(z_{NF}(w,\xi)-z_0)^{\mp\epsilon_h^j}\cdot\Psi_{Nh}^{\mp j}(z_{NF}(w,\xi)), \tag{1.12$'$}$$

and

$$\rho^{2F}_{N\{h\}}(z_0,\theta_0;P^\dagger_F)$$

$$\equiv -\sum_{j=1}^{4}\oint\frac{dw\ d\xi}{2\pi i}P_F^{-j^\dagger}(w,\xi)\oint\frac{dw'\ d\xi'}{2\pi i}P_F^{+j^\dagger}(w',\xi')$$

$$\times\log\frac{z_{NF}(w,\xi)-z_{NF}(w',\xi')-([z_{NF}(w,\xi)-z_0]/[z_{NF}(w',\xi')-z_0])^{\epsilon^j_h}\theta_{NF}(w,\xi)\,\theta_{NF}(w',\xi')}{w-w'-(w/w')^{\epsilon^j_h}\cdot\xi\xi'},\tag{1.13}$$

where ϵ^j_h [i.e., $\epsilon^j_\pm\equiv\pm\frac{1}{2}$] is the constant used in $S_{\{h\}}(z_0)$ (1.4). In Eq. (1.10), $:\ :_R$ is the normal ordering in the R sector which is defined by

$$\mathbf{R}\cdot X^{\pm j}(z')X^{\mp k}(z)=\delta_{jk}\log(z'-z)+:X^{\pm j}(z')X^{\mp k}(z):_R\tag{1.14}$$

and

$$\mathbf{R}\cdot\Psi^{\pm j}_{Nh'}(z')\Psi^{\mp k}_{Nh}(z)=\frac{\delta_{jk}}{z'-z}+:\Psi^{\pm j}_{Nh'}(z')\Psi^{\mp k}_{Nh}(z):_R,\tag{1.15}$$

$\mathbf{R}$ being radial ordering. N operators $\theta_{NF}(w,\xi)$ and $z_{NF}(w,\xi)$ in Eqs. (1.12) and (1.13) can be expressed by

$$\theta_{NF}(w,\xi)\equiv J_{NF}(w)+\xi K_{NF}(w)\tag{1.16}$$

and

$$z_{NF}(w,\xi)-z_0\equiv L_{NF}(w)+\xi K_{NF}(w)J_{NF}(w),\tag{1.17}$$

and they are determined by inversely solving the following superconformal mapping in the R sector $(z_{NF},\theta_{NF})\to(w,\xi)$ [in the N operator's form];

$$z_{NF}-z_0-\sqrt{z_{NF}-z_0}\,\theta_{NF}\theta_0=w:\exp\left(\frac{X^{+0}_N(z_{NF},\theta_{NF})}{ip^{+0}}-\frac{X^{+0}(z_0)}{ip^{+0}}\right):_R\tag{1.18}$$

with the N operator $X^{+0}_N(z,\theta)$ being defined by Eq. (1.9), and

$$\xi(z_{NF},\theta_{NF})=(\partial_{z_{NF}}w(z_{NF},\theta_{NF}))^{-1/2}D_{\theta_{NF}}w(z_{NF},\theta_{NF}),\tag{1.19}$$

with $D_{\theta_{NF}}\equiv\partial_{\theta_{NF}}+\theta_{NF}\partial_{z_{NF}}$. It should be noticed that we have used in Eq. (1.18) only the string coordinate $X^{+0}(z_0)$ and *not* any string coordino $\Psi^{+0}_{N+}(z_0)$, while we have used $X^{+0}_N(z_{NF},\theta_{NF})$ (1.9). The inversely solved results $z_{NF}(w,\xi)$ and $\theta_{NF}(w,\xi)$ can be obtained as follows. First we consider operators $A^\pm_N(z)$ and $B^\pm_N(z)$, both of which are arbitrary functions of z analytic at $z=z_0$. With respect to $A^\pm_N(z_{NF})$ and $B^\pm_N(z_{NF})$, the function $[\quad]_{\xi=0}$ (which is the function of w) is defined by

$$[A^+_N(z_{NF})+\theta_{NF}\sqrt{z_{NF}-z_0}B^+_N(z_{NF})]_{\xi=0}$$

$$\equiv A^+_N(z_0)+\sum_{n=1}^{\infty}w^n\left(\sum_{k=1}^{n}\frac{1}{(k-1)!}R^{(n)}_{n-k}(z_0)\partial^{k-1}_{z_0}\left(\frac{1}{n}\,\partial_{z_0}A^+_N(z_0)+\theta_0B^+_N(z_0)\right)\right.$$

$$\left.+\sum_{k=2}^{n}\frac{1}{(k-2)!}R^{(n)}_{n-k}(z_0)\partial^{k-2}_{z_0}(V_N(z_0)B^+_N(z_0))\right)\tag{1.20}$$

and

$$
\begin{aligned}
&[\sqrt{z_{NF}-z_0}A_N^-(z_{NF})+\theta_{NF}B_N^-(z_{NF})]_{\xi=0}\\
&\quad\equiv\sum_{n=0}^{\infty}w^{n+1/2}\Bigg(\sum_{k=0}^{n}\frac{1}{k!}R_{n-k}^{(n+1/2)}(z_0)\partial_{z_0}^k\left(\frac{k+1/2}{n+1/2}A_N^-(z_0)+\theta_0B_N^-(z_0)\right)\\
&\qquad+\sum_{k=1}^{n}\frac{1}{(k-1)!}R_{n-k}^{(n+1/2)}(z_0)\partial_{z_0}^{k-1}(V_N(z_0)B_N^-(z_0))\Bigg),
\end{aligned}
\tag{1.21}
$$

where

$$
I(z_0)\equiv\frac{X^{+0}(z_0)}{ip^{+0}},
\tag{1.22}
$$

$$
R_m^{(n)}(z_0)\equiv\frac{1}{m!}\exp(-nI(z_0))\cdot\partial_{z_0}^m\exp(nI(z_0)),
\tag{1.23}
$$

and

$$
V_N(z_0)\equiv\frac{\Psi_{N+}^{+0}(z_0)}{ip^{+0}}.
\tag{1.24}
$$

Equipped with these preliminaries (1.20)–(1.24), we can state the theorem proved in Ref. 4.

Theorem: Superconformal mapping in the R sector in the N operator's form

N operators $F_N^{\pm}(z_{NF},\theta_{NF})$, given by

$$
F_N^+(z_{NF},\theta_{NF})\equiv A_N^+(z_{NF})+\theta_{NF}\sqrt{z_{NF}-z_0}B_N^+(z_{NF})
\tag{1.25}
$$

and

$$
F_N^-(z_{NF},\theta_{NF})\equiv\sqrt{z_{NF}-z_0}A_N^-(z_{NF})+\theta_{NF}B_N^-(z_{NF})
\tag{1.26}
$$

can be expressed as functions of w and ξ by the following formula:

$$
F_N^{\pm}(z_{NF},\theta_{NF})=[F_N^{\pm}(z_{NF},\theta_{NF})]_{\xi=0}+\xi K_{NF}(w)[D_{\theta_{NF}}F_N^{\pm}(z_{NF},\theta_{NF})]_{\xi=0},
\tag{1.27}
$$

with

$$
K_{NF}(w)=(\partial_w[z_{NF}-z_0]_{\xi=0}-(\partial_w[\theta_{NF}]_{\xi=0})[\theta_{NF}]_{\xi=0})^{1/2}.
\tag{1.28}
$$

By using the above theorem, the N operators $J_{NF}(w)$ in Eq. (1.16) and $L_{NF}(w)$ in Eq. (1.17) can be calculated by

$$
J_{NF}(w)=[\theta_{NF}]_{\xi=0}
\tag{1.29}
$$

and

$$
L_{NF}(w)=[z_{NF}-z_0]_{\xi=0},
\tag{1.30}
$$

as we shall see in this paper. [When Eq. (a.b) expressed in terms of non-N operators is N-ized into Eq. (a.b′) expressed in terms of N operators, we state that Eq. (a.b′) in the N operator's form is changed into Eq. (a.b) in non-N operator's form.]

In Sec. II, we introduce the *physical* string coordinate's mode $A_n^{\pm j}$ (for any integer n) as well as the *physical* string coordino's mode $\mathscr{D}_n^{\pm j}$ (for any integer n) in the R sector, and we prove that they generate *physical* Ramond states in superstring. Therefore we can construct the functional which generates all physical Ramond states. Thus the constructed functional is shown to be just equal to GFPVO $\Phi_{N\{h\}}^F(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)$ [given by Eqs. (1.4) and (1.10)]. Furthermore, our previous result[5] on OPE among GFPVO and the superstressino operator is shown to be easily derived by the new method in Sec. II. In Sec. III we derive various formulas (obtained by

superconformal mapping) with the help of which N operators ρ_N^{1F} (1.12) and $\rho_{N\{h\}}^{2F}$ (1.13) can be calculated up to an arbitrarily required number of terms. As an example, some (GSO-allowed[10]) physical vertex operators in the R sector of the superstring are explicitly given for some low-lying mass levels. With the help of the obtained vertex operators, we construct physical Ramond states in 1/2 picture. In Sec. IV, various results obtained in the R sector are summarized. On the other hand, we give various results in the NS sector without any proof, since these can be derived in a much simpler way. In Appendix A, we prove (anti-) commutation relations satisfied by $A_n^{\pm j}$ and $\mathscr{D}_n^{\pm j}$, which are used in Sec. II. In Appendix B, some terms of ρ_N^{1F} (1.12) and $\rho_{N\{h\}}^{2F}$ (1.13) are given explicitly.

II. NEW DERIVATION OF THE FORMULA (1.10) IN THE *R* SECTOR

In this section we shall derive the formula (1.10) in the R sector by using a new method different from our previous one;[5] For this purpose, we shall introduce [in the R sector] the *physical* string coordinate's mode $A_{-n}^{\pm j}$ (for any integer n) defined by

$$A_{-n}^{\pm j} \equiv -i \oint_0 \frac{dz\ d\theta}{2\pi i} D_\theta X^{\pm j}(z,\theta) \exp\left(\frac{nX^{+0}(z,\theta)}{ip^{+0}}\right), \tag{2.1}$$

as well as the *physical* string coordino's mode $\mathscr{D}_{-n}^{\pm j}$ (for any integer n) defined by

$$\mathscr{D}_{-n}^{\pm j} \equiv -i \oint_0 \frac{dz\ d\theta}{2\pi i} D_\theta X^{\pm j}(z,\theta) \frac{D_\theta[X^{+0}(z,\theta)/ip^{+0}]}{(-\partial_z[X^{+0}(z,\theta)/ip^{+0}])^{1/2}} \cdot \exp\left(\frac{nX^{+0}(z,\theta)}{ip^{+0}}\right),$$
$$\text{for } n=0,\pm 1,\pm 2,\ldots, \quad \text{and } j=1-4. \tag{2.2}$$

In Appendix A, operators (2.1) and (2.2) are shown to satisfy the following (anti-) commutation relations (for $n,m=0,1,2,\ldots$, and $j,k=1-4$):

$$[A_n^{\pm j},\ A_{-m}^{\mp k}]=n\delta_{jk}\delta_{nm}, \quad [A_n^{(\ )},\ \mathscr{D}_{-m}^{(\ )}]=0, \quad \text{and } \{\mathscr{D}_n^{\pm j},\ \mathscr{D}_{-m}^{\mp k}\}=\delta_{jk}\delta_{nm}, \tag{2.3}$$

[other (anti-) commutators being equal to zero] and that any of them (anti-) commutes with any of Virasoro generators $L_m^F(z_0)$ and $\mathscr{T}_m^F(z_0)$, which are defined by Eqs. (A4) and (A5);

$$[L_m^F(z_0),\ A_{-n}^{\pm j}]=[L_m^F(z_0),\ \mathscr{D}_{-n}^{\pm j}]=[\mathscr{T}_m^F(z_0),\ A_{-n}^{\pm j}]=\{\mathscr{T}_m^F(z_0),\mathscr{D}_{-n}^{\pm j}\}=0. \tag{2.4}$$

(Anti-) commutation relations (2.3) and (2.4) show that physical operators $A_{-n}^{\pm j}$ (2.1) and $\mathscr{D}_{-n}^{\pm j}$ (2.2) satisfy the spectrum generating algebra proposed by Green and Schwarz.[3]

We shall introduce the *basic* spinorial $\Sigma_{\{h\}}(z_0|\theta_0)$ defined by

$$\Sigma_{\{h\}}(z_0|\theta_0) \equiv :\exp\Bigg(-ip^{+0}Y_{N+}^{-0}(z_0,\theta_0)-ip^{-0}X^{+0}(z_0)$$
$$-\sum_{j=1}^{4} ip^{hj}Y_{Nh}^{-hj}(z_0,\theta_0)-\sum_{j=1}^{4} ip^{-hj}X^{+hj}(z_0)\Bigg) S_{\{h\}}(z_0):_R, \tag{2.5}$$

where we have used the FMS spinor (1.4) and Eq. (1.11′), together with

$$Y_{Nh}^{-hj}(z_0,\theta_0) \equiv X^{-hj}(z_0)+\theta_0\Psi_{Nh}^{-hj}(z_0). \tag{2.5′}$$

[Incidentally, $\Psi_{Nh}^{+hj}(z_0)$'s (for $j=0-4$) do not exist in Eq. (2.5).] Then we find with the help of contractions in the R sector[4] that

$$\mathbf{R}\cdot A_n^{\pm hj}\cdot\Sigma_{\{h\}}(z_0|\theta_0)\equiv -i\oint_{|z|>|z_0|}\frac{dz\ d\theta}{2\pi i}:\Big(D_\theta X_N^{\pm hj}(z,\theta)-ip^{\pm hj}D_\theta \times\log\Big(z-z_0-\begin{pmatrix}1\\0\end{pmatrix}\sqrt{z-z_0}\theta\theta_0\Big)\Big) \times\exp\left(\frac{-nX_N^{+0}(z,\theta)}{ip^{+0}}\right)(z-z_0-\sqrt{z-z_0}\theta\theta_0)^n\Sigma_{\{h\}}(z_0|\theta_0):_R \tag{2.6}$$

and

$$\mathbf{R}\cdot\mathscr{D}_n^{\pm hj}\cdot\Sigma_{\{h\}}(z_0|\theta_0)\equiv -i\oint_{|z|>|z_0|}\frac{dz\ d\theta}{2\pi i}:\Big(D_\theta X_N^{\pm hj}(z,\theta)-ip^{\pm hj}D_\theta\log\Big(z-z_0 -\begin{pmatrix}1\\0\end{pmatrix}\sqrt{z-z_0}\theta\theta_0\Big)\Big)\exp\left(\frac{-nX_N^{+0}(z,\theta)}{ip^{+0}}\right)(z-z_0\sqrt{z-z_0}\theta\theta_0)^n \times\left(\frac{D_\theta[X_N^{+0}(z,\theta)/ip^{+0}]-D_\theta\log(z-z_0-\sqrt{z-z_0}\theta\theta_0)}{(-\partial_z[X_N^{+0}(z,\theta)/ip^{+0}]+\partial_z\log(z-z_0-\sqrt{z-z_0}\theta\theta_0))^{1/2}}\right)\Sigma_{\{h\}} \times(z_0|\theta_0):_R, \tag{2.7}$$

which leads (for $n=1,2,...$) to

$$0=\lim_{z_0\to 0}\mathbf{R}\cdot A_n^{\pm hj}\cdot\Sigma_{\{h\}}(z_0|\theta_0)\cdot|0\rangle=\lim_{z_0\to 0}\mathbf{R}\cdot\mathscr{D}_n^{\pm hj}\cdot\Sigma_{\{h\}}(z_0|\theta_0)\cdot|0\rangle. \tag{2.8}$$

In Eqs. (2.6), (2.7), and hereafter, the integration contour in Eqs. (2.1) and (2.2) has been and will be deformed to satisfy the condition $|z|>|z_0|$ [z_0 being the one in Eq. (2.5)], so that we can use contractions in the R sector.[4] Therefore a complete set of *physical* ket states can be constructed by

$$|\{e_{\not}(n,\pm j)\},\{\tilde{e}_{\not}(n,\pm j)\},\{p\};\theta_0\rangle(\equiv|\not;\theta_0\rangle) \equiv\lim_{z_0\to 0}\left(\prod_{n=1}^{\infty}\prod_{\pm}\prod_{j=1}^{4}\frac{(iA_{-n}^{\pm j}/\sqrt{n})^{e_{\not}(n,\pm j)}}{\sqrt{e_{\not}(n,\pm j)!}}(i\mathscr{D}_{-n}^{\pm j})^{\tilde{e}_{\not}(n,\pm j)}\right)\Sigma_{\{h\}}(z_0|\theta_0)\cdot|0\rangle, \tag{2.9}$$

$e_{\not}(n,\pm j)$ being some non-negative integer and $\tilde{e}_{\not}(n,\pm j)$ is either 0 or 1, giving quantum numbers of $|\not;\theta_0\rangle$. Hereafter, $\{p\}$ in Eq. (2.5) is assumed to satisfy the *on-shell* condition

$$p^{+0}p^{-0}+\sum_{j=1}^{4}p^{+j}p^{-j}=0, \tag{2.10}$$

leading to the fact that the *basic* spinorial $\Sigma_{\{h\}}(z_0|0)$ in Eq. (2.9) is the primary operator of conformal weight 5/8. In the following, we shall prove the *theorem*

$$\mathbf{R}\cdot\exp\left(\sum_{n=1}^{\infty}\sum_{\pm}\sum_{j=1}^{4}\left(\frac{1}{n}\alpha_{-n}^{\pm j}\cdot A_{-n}^{\pm j}-d_{-n}^{\mp j}\cdot\mathscr{D}_{-n}^{\pm j}\right)\right)\cdot\Sigma_{\{h\}}(z_0|\theta_0) =:\exp(-ip^{+0}Y_{N+}^{-0}(z_0,\theta_0)-i\mathscr{P}^{-0}X^{+0}(z_0))\exp(\rho_N^{1F}(z_0,\theta_0;P_F^\dagger) +\rho_{N\{h\}}^{2F}(z_0,\theta_0;P_F^\dagger)):_R S_{\{h\}}(z_0)(\equiv\tilde{\Phi}_{N\{h\}}^{F}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)). \tag{2.11}$$

In Eq. (2.11), we have used $\rho_N^{1F}(z_0,\theta_0;P_F^\dagger)$ (1.12) and $\rho_{N\{h\}}^{2F}(z_0,\theta_0;P_F^\dagger)$ (1.13), while we have introduced the *operator* $\mathscr{P}^{-0}$ satisfying

$$\mathscr{P}^{-0}|\not{k};\theta_0\rangle=\mathscr{P}_{\not{k}}^{-0}|\not{k};\theta_0\rangle, \tag{2.12}$$

where $|\not{k};\theta_0\rangle$ is the state given by Eq. (2.9) and $\mathscr{P}_{\not{k}}^{-0}$ is the eigenvalue given by $\mathscr{P}_{\not{k}}^{-0}\equiv p^{-0}+N_{\not{k}}(p^{+0})^{-1}$ with

$$N_{\not{k}}\equiv\sum_{n=1}^{\infty}\sum_{\pm}\sum_{j=1}^{4} n(e_{\not{k}}(n,\pm j)+\tilde{e}_{\not{k}}(n,\pm j)). \tag{2.12'}$$

Therefore we have the following mass-shell condition for the state $|\not{k};\theta_0\rangle$ (2.9);

$$p^{+0}\mathscr{P}_{\not{k}}^{-0}+\sum_{j=1}^{4} p^{+j}p^{-j}=N_{\not{k}}. \tag{2.12''}$$

Proof: The left-hand side of Eq. (2.11) can be calculated by

$$\begin{aligned}
&\mathbf{R}\cdot\exp\left(\sum_{n=1}^{\infty}\sum_{\pm}\sum_{j=1}^{4}\frac{1}{n}\alpha_{-n}^{\mp j}\cdot A_{-n}^{\pm j}\exp\left(\frac{-nX^{+0}(z_0)}{ip^{+0}}\right)\right.\\
&\left.-\sum_{n=1}^{\infty}\sum_{\pm}\sum_{j=1}^{4} d_{-n}^{\mp j}\cdot\mathscr{D}_{-n}^{\pm j}\exp\left(\frac{-nX^{+0}(z_0)}{ip^{+0}}\right)\right)\cdot S_{\{h\}}(z_0|\theta_0)\\
&=\mathbf{R}\cdot\exp\left(\sum_{\pm}\sum_{j=1}^{4} i\oint_0\frac{dw\,d\xi}{2\pi i}P_F^{\mp j\dagger}(w,\xi)\oint\frac{dz\,d\theta}{2\pi i}D_\theta X^{\pm j}(z,\theta)\cdot U_F(w,\xi;z,\theta)\right)\\
&\times S_{\{h\}}(z_0|\theta_0).
\end{aligned} \tag{2.13}$$

In the last step of Eq. (2.13) we have introduced the following non-N operator U_F defined by

$$\begin{aligned}
U_F(w,\xi;z,\theta)\equiv&-\sum_{n=1}^{\infty}\frac{w^n}{n}\cdot\exp\left(\frac{nX^{+0}(z,\theta)}{ip^{+0}}-\frac{nX^{+0}(z_0)}{ip^{+0}}\right)\\
&-\xi\frac{D_\theta[X^{+0}(z,\theta)/ip^{+0}]}{(-\partial[X^{+0}(z,\theta)/ip^{+0}])^{1/2}}\left(\sum_{n=1}^{\infty}w^{n-1/2}\exp\left(\frac{nX^{+0}(z,\theta)}{ip^{+0}}-\frac{nX^{+0}(z_0)}{ip^{+0}}\right)\right)
\end{aligned} \tag{2.13'}$$

and the *excited* spinorial $S_{\{h\}}(z_0|\theta_0)$ defined by

$$S_{\{h\}}(z_0|\theta_0)\equiv:\exp(\sigma_{N+}^{0F}(z_0,\theta_0)):_R S_{\{h\}}(z_0), \tag{2.14}$$

with

$$\begin{aligned}
\sigma_{N+}^{0F}(z_0,\theta_0)\equiv&-ip^{+0}Y_{N+}^{-0}(z_0,\theta_0)-i\mathscr{P}^{-0}X^{+0}(z_0)-\sum_{j=1}^{4}ip^{hj}Y_{Nh}^{-hj}(z_0,\theta_0)-\sum_{j=1}^{4}ip^{-hj}X^{+hj}(z_0)\\
=&\tilde{\rho}_{N+}^{0F}(z_0,\theta_0)-\sum_{j=1}^{4}ip^{hj}Y_{Nh}^{-hj}(z_0,\theta_0)-\sum_{j=1}^{4}ip^{-hj}X^{+hj}(z_0).
\end{aligned} \tag{2.14'}$$

At this stage, we superconfomally map the c number (w,ξ) into the q number (z_F,θ_F) by using Eqs. (1.18) and (1.19) [changed into the non-N operator's form]. Then we have the radial ordered product among any operator $X^{+0}(z,\theta)$ in $U_F(w,\xi;z,\theta)$ (2.13') and any $Y_{N+}^{-0}(z_0,\theta_0)$ (1.11') in $S_{\{h\}}(z_0|\theta_0)$ (2.14). [Since $w=w(z_F,\theta_F)$ is the c number, any operator originating from $w=w(z_F,\theta_F)$ can be treated as the operator, which has already been normally ordered with respect to $Y_{N+}^{-0}(z_0,\theta_0)$.] We express this radial ordered product in terms of the normal ordered product in the R sector. The result is given by

$$\mathbf{R}\cdot U_F(w,\xi;z,\theta)\exp(-ip^{+0}Y_{N+}^{-0}(z_0,\theta_0))=:\widetilde{U}_F(w,\xi;z,\theta)\exp(-ip^{+0}Y_{N+}^{-0}(z_0,\theta_0)):_R \tag{2.15}$$

with

$$\begin{aligned}\widetilde{U}_F(w,\xi;z,\theta)\equiv&-\sum_{n=1}^{\infty}\frac{1}{n}\left(\frac{z_F-z_0-\sqrt{z_F-z_0}\theta_F\theta_0}{z-z_0-\sqrt{z-z_0}\theta\theta_0}\right)^n\cdot\exp\left(\frac{nX^{+0}(z,\theta)}{ip^{+0}}-\frac{nX^{+0}(z_F,\theta_F)}{ip^{+0}}\right)\\&-\xi\left(\frac{D_\theta[X^{+0}(z,\theta)/ip^{+0}]-D_\theta\log(z-z_0-\sqrt{z-z_0}\theta\theta_0)}{(-\partial_z[X^{+0}(z,\theta)/ip^{+0}]+\partial_z\log(z-z_0-\sqrt{z-z_0}\theta\theta_0))^{1/2}}\right)\\&\times\left(\sum_{n=1}^{\infty}w^{-1/2}\left(\frac{z_F-z_0-\sqrt{z_F-z_0}\theta_F\theta_0}{z-z_0-\sqrt{z-z_0}\theta\theta_0}\right)^n\exp\left(\frac{nX^{+0}(z,\theta)}{ip^{+0}}-\frac{nX^{+0}(z_F,\theta_F)}{ip^{+0}}\right)\right).\end{aligned} \tag{2.16}$$

Therefore the radial ordered product [in Eq. (2.13)] among $X^{\pm hj}(z,\theta),U_F(w,\xi;z,\theta)$ (2.13′), and any $\sigma_{N+}^{0F}(z_0,\theta_0)$ (2.14′) (in $S_{\{h\}}(z_0|\theta_0)$ (2.14)) is expressed [in terms of the normal ordered product] by

$$\begin{aligned}&\mathbf{R}\cdot D_\theta X^{\pm hj}(z,\theta)\cdot U_F(w,\xi;z,\theta):\exp(\sigma_{N+}^{0F}(z_0,\theta_0)):_R\\&=:\left(D_\theta X^{\pm hj}(z,\theta)-ip^{\pm hj}D_\theta\log\left(z-z_0-\begin{pmatrix}1\\0\end{pmatrix}\sqrt{z-z_0}\theta\theta_0\right)\right)\\&\quad\times\widetilde{U}_F(w,\xi;z,\theta)\exp(\sigma_{N+}^{0F}(z_0,\theta_0)):_R.\end{aligned} \tag{2.17}$$

Finally, applying N-izing given by Eq. (1.5), we find that

$$\begin{aligned}&\mathbf{R}\cdot D_\theta X^{\pm hj}(z,\theta)\cdot U_F(w,\xi;z,\theta)S_{\{h\}}(z_0|\theta_0)\\&=:\left(D_\theta X_N^{\pm hj}(z,\theta)-ip^{\pm hj}D_\theta\log\left(z-z_0-\begin{pmatrix}1\\0\end{pmatrix}\sqrt{z-z_0}\theta\theta_0\right)\right)\\&\quad\times\widetilde{U}_{NF}(w,\xi;z,\theta)):_RS_{\{h\}}(z_0|\theta_0),\end{aligned} \tag{2.18}$$

where the N operator $\widetilde{U}_{NF}(w,\xi;z,\theta)$ is N-ized from the non-N operator $\widetilde{U}_F(w,\xi;z,\theta)$ (2.16). In Eq. (2.18) we shall use

$$p^{\pm j}\left(\frac{1}{z-z_0-\sqrt{z-z_0}\theta\theta_0}\right)^n D_\theta\log(z-z_0-\sqrt{z-z_0}\theta\theta_0)=-\frac{1}{n}p^{\pm j}D_\theta\left(\frac{1}{z-z_0-\sqrt{z-z_0}\theta\theta_0}\right)^n \tag{2.19}$$

and

$$p^{\pm j}\left(\frac{1}{z-z_0-\sqrt{z-z_0}\theta\theta_0}\right)^n D_\theta\log(z-z_0)=-\frac{1}{n}p^{\pm j}\theta\partial_z\left(\frac{1}{z-z_0}\right)^n, \tag{2.20}$$

and then we partially integrate Eq. (2.13), which is thus found out to be given by

$$\begin{aligned}:\Bigg(\mathbf{R}\cdot\exp\Bigg(\sum_{\pm}\sum_{j=1}^{4}i\oint_0\frac{dw\,d\xi}{2\pi i}P_F^{\mp j^\dagger}(w,\xi)\oint_{|z|>|z_0|}\frac{dz\,d\theta}{2\pi i}\widetilde{H}_{NF}^{\pm j}(z,\theta)\Bigg)\\\times\exp(\sigma_{N+}^{0F}(z_0,\theta_0))\Bigg):_RS_{\{h\}}(z_0),\end{aligned} \tag{2.21}$$

where the N operators $\widetilde{H}_{NF}^{\pm hj}(z,\theta)$'s are given, respectively, by

$$\widetilde{H}_{NF}^{+hj}(z,\theta)=\left(D_\theta\left(X_N^{+hj}(z,\theta)-\frac{p^{+hj}}{p^{+0}}X_N^{+0}(z,\theta)\right)\right)\log(\widetilde{u}_{NF}(w,\xi;z,\theta))$$
$$+ip^{+hj}\xi w^{-1/2}D_\theta\left(\frac{D_\theta[X_N^{+0}(z,\theta)/ip^{+0}]-D_\theta\log(z-z_0-\sqrt{z-z_0}\theta\theta_0)}{(-\partial_z[X_N^{+0}(z,\theta)/ip^{+0}]+\partial_z\log(z-z_0-\sqrt{z-z_0}\theta\theta_0))^{1/2}}\right)$$
$$\times\log(\widetilde{v}_{NF}(w,\xi;z,\theta)) \tag{2.22}$$

and

$$\widetilde{H}_{NF}^{-hj}(z,\theta)=\left(D_\theta X_N^{-hj}(z,\theta)-\frac{p^{-hj}}{p^{+0}}\cdot\theta\partial_z X_N^{+0}(z,\theta)\right)\log(\widetilde{u}_{NF}(w,\xi;z,\theta))+ip^{-hj}\cdot\xi w^{-1/2}\theta$$
$$\cdot\partial_z\left(\frac{D_\theta[X_N^{+0}(z,\theta)/ip^{+0}]-D_\theta\log(z-z_0-\sqrt{z-z_0}\theta\theta_0)}{(-\partial_z[X_N^{+0}(z,\theta)/ip^{+0}]+\partial_z\log(z-z_0-\sqrt{z-z_0}\theta\theta_0))^{1/2}}\right)$$
$$\times\log(\widetilde{v}_{NF}(w,\xi;z,\theta)). \tag{2.23}$$

[We should notice that Eq. (2.21) has the radial ordering among N operators $\widetilde{H}_{NF}^{\pm hj}(z,\theta)$'s, while we have the normal ordered product in the R sector (denoted by $:\ :_R$) among any $\widetilde{H}_{NF}^{\pm hj}(z,\theta)$ and $S_{\{h\}}(z_0|\theta_0)$ (2.14).] In Eqs. (2.22) and (2.23), $\widetilde{u}_{NF}(w,\xi;z,\theta)$ and $\widetilde{v}_{NF}(w,\xi;z,\theta)$ are N operators obtained by N-izing [see Eq. (1.5)] the following non-N operators $\widetilde{u}_F(w,\xi;z,\theta)$ and $\widetilde{v}_F(w,\xi;z,\theta)$, respectively;

$$\widetilde{u}_F(w,\xi;z,\theta)\equiv 1-\frac{z_F-z_0-\sqrt{z_F-z_0}\theta_F\theta_0}{z-z_0-\sqrt{z-z_0}\theta\theta_0}\exp\left(\frac{X^{+0}(z,\theta)}{ip^{+0}}-\frac{X^{+0}(z_F,\theta_F)}{ip^{+0}}\right)$$
$$-\xi w^{-1/2}\left(\frac{D_\theta[X^{+0}(z,\theta)/ip^{+0}]-D_\theta\log(z-z_0-\sqrt{z-z_0}\theta\theta_0)}{(-\partial[X^{+0}(z,\theta)/ip^{+0}]+\partial_z\log(z-z_0-\sqrt{z-z_0}\theta\theta_0))^{1/2}}\right)$$
$$\times\exp\left(\frac{X^{+0}(z,\theta)}{ip^{+0}}-\frac{X^{+0}(z_F,\theta_F)}{ip^{+0}}\right) \tag{2.24}$$

and

$$\widetilde{v}_F(w,\xi;z,\theta)\equiv 1-\frac{z_F-z_0-\sqrt{z_F-z_0}\theta_F\theta_0}{z-z_0-\sqrt{z-z_0}\theta\theta_0}\cdot\exp\left(\frac{X^{+0}(z,\theta)}{ip^{+0}}-\frac{X^{+0}(z_F,\theta_F)}{ip^{+0}}\right). \tag{2.25}$$

[Incidentally, (z,θ) is just the *c number* integration variable, while the q number (z_F,θ_F) is the function of (w,ξ).] First, we find in the neighborhood of $z=z_0$ and $\theta=\theta_0$ that

$$\log(\widetilde{u}_F(w,\xi;z,\theta))=-\log(z-z_0-\sqrt{z-z_0}\theta\theta_0)+\mathrm{O}(1) \tag{2.26}$$

and

$$\log(\widetilde{v}_F(w,\xi;z,\theta))=-\log(z-z_0-\sqrt{z-z_0}\theta\theta_0)+\mathrm{O}(1). \tag{2.27}$$

Furthermore, we find from Eq. (1.18) [changed into non-N operator's form] that

$$f^F(z_F,\theta_F|z_0,\theta_0)\equiv\frac{X^{+0}(z_F,\theta_F)}{ip^{+0}}-\log(z_F-z_0-\sqrt{z_F-z_0}\theta_F\theta_0)=-\log w+\frac{X^{+0}(z_0)}{ip^{+0}}. \tag{2.28}$$

By using

$$D_{\theta_F}=\frac{1}{D_\xi\theta_F}D_\xi \tag{2.29}$$

we find successively the following formulas:

$$D_{\theta_F} f^F(z_F,\theta_F|z_0,\theta_0) = -\frac{\xi}{wD_\xi\theta_F} = -\frac{\xi}{wK_F(w)}, \tag{2.30}$$

$$\partial_{z_F} f^F(z_F,\theta_F|z_0,\theta_0) = -\frac{1}{w(D_\xi\theta_F)^2} - \frac{\xi\partial_w\theta_F}{w(D_\xi\theta_F)^3} = -\frac{1}{wK_F^2(w)} + \frac{\xi\partial_w J_F(w)}{wK_F^3(w)}, \tag{2.31}$$

and

$$\begin{aligned}\partial_{z_F} D_{\theta_F} f^F(z_F,\theta_F|z_0,\theta_0) &= \frac{\partial_w\theta_F}{w(D_\xi\theta_F)^4} + \xi\left(\frac{\partial_w\theta_F}{w^2(D_\xi\theta_F)^3} + \frac{\partial_w D_\xi\theta_F}{w(D_\xi\theta_F)^4}\right)\\ &= \frac{\partial_w J_F(w)}{wK_F^4(w)} + \xi\left(\frac{2\partial_w K_F(w)}{wK_F^4(w)} + \frac{1}{w^2K_F^3(w)}\right).\end{aligned} \tag{2.32}$$

Then by using the Taylor expansion at $z=z_F$ and $\theta=\theta_F$ [see Eq. (3.4) in Ref. 4], the first factor on the right-hand side of Eq. (2.24) is found to be given by

$$\begin{aligned}\tilde{v}_F(w,\xi;z,\theta) &= (\theta-\theta_F)\frac{\xi}{wK_F(w)} + (z-z_F-\theta\theta_F)\left(\frac{1}{wK_F^2(w)} - \frac{\xi\partial_w J_F(w)}{wK_F^3(w)}\right)\\ &\quad + \mathrm{O}((\theta-\theta_F)(z-z_F-\theta\theta_F)).\end{aligned} \tag{2.33}$$

On the other hand, the second one in Eq. (2.24) is found to be given by

$$-(\theta-\theta_F)\frac{\xi}{wK_F(w)} - (z-z_F-\theta\theta_F)\left(\frac{\xi\partial_w J_F(w)}{wK_F^3(w)}\right) + \mathrm{O}((\theta-\theta_F)(z-z_F-\theta\theta_F)). \tag{2.34}$$

Summing Eqs. (2.33) and (2.34), we finally obtain that

$$\tilde{u}_F(w,\xi;z,\theta) = (z-z_F-\theta\theta_F)\left(\frac{1}{wK_F^2(w)} - \frac{2\xi\partial_w J_F(w)}{wK_F^3(w)}\right) + \mathrm{O}((\theta-\theta_F)(z-z_F-\theta\theta_F)). \tag{2.35}$$

Substituting N-ized forms of Eqs. (2.26), (2.27), (2.33), and (2.35) into the N operator $\tilde{H}_{NF}^{+hj}(z,\theta)$ (2.22), we find by the partial integration that

$$\begin{aligned}\oint_{|z|>|z_0|}\frac{dz\,d\theta}{2\pi i}\,\tilde{H}_{NF}^{+hj}(z,\theta) &= -\oint_{|z|>|z_0|}\frac{dz\,d\theta}{2\pi i}\,(X^{+hj}(z)+\theta\sqrt{z-z_0}\Psi_{Nh}^{+hj}(z))\left(\frac{\theta-\theta_{NF}}{z-z_{NF}-\theta\theta_{NF}}\right.\\ &\quad\left.-\frac{\theta-\sqrt{z-z_0}\theta_0}{z-z_0-\sqrt{z-z_0}\theta\theta_0}\right) + \frac{p^{+hj}}{p^{+0}}\oint_{|z|>|z_0|}\frac{dz\,d\theta}{2\pi i}\,(X^{+0}(z)\\ &\quad + \theta\sqrt{z-z_0}\Psi_{N+}^{+0}(z))\left(\frac{\theta-\theta_{NF}}{z-z_{NF}-\theta\theta_{NF}} - \frac{\theta-\sqrt{z-z_0}\theta_0}{z-z_0-\sqrt{z-z_0}\theta\theta_0}\right)\\ &= -X_N^{+hj}(z_{NF},\theta_{NF}) + X^{+hj}(z_0) + \frac{p^{+hj}}{p^{+0}}\,(X_N^{+0}(z_{NF},\theta_{NF}) - X^{+0}(z_0)).\end{aligned} \tag{2.36}$$

By similar calculations, we find from the N operator $\tilde{H}_{NF}^{-hj}(z,\theta)$ (2.23) that

$$\oint_{|z|>|z_0|}\frac{dz\ d\theta}{2\pi i}\,\widetilde{H}_{NF}^{-hj}(z,\theta)=-\oint_{|z|>|z_0|}\frac{dz\ d\theta}{2\pi i}\left(X^{-hj}(z)+\theta\,\frac{\Psi_{Nh}^{-hj}(z)}{\sqrt{z-z_0}}\right)\left(\frac{\theta-\theta_{NF}}{z-z_{NF}-\theta\theta_{NF}}\right.$$
$$\left.-\frac{\theta-\sqrt{z-z_0}\theta_0}{z-z_0-\sqrt{z-z_0}\theta\theta_0}\right)+\frac{p^{-hj}}{p^{+0}}\oint_{|z|>|z_0|}\frac{dz\ d\theta}{2\pi i}$$
$$\times(X^{+0}(z)+\theta\sqrt{z-z_0}\Psi_{N+}^{+0}(z))\left(\frac{\theta}{z-z_{NF}}-\frac{\theta}{z-z_0}\right)$$
$$=-X_N^{-hj}(z_{NF},\theta_{NF})+Y_{Nh}^{-hj}(z_0,\theta_0)+\frac{p^{-hj}}{p^{+0}}\,(X^{+0}(z_{NF})-X^{+0}(z_0)),\tag{2.37}$$

where we have noticed from Eqs. (1.19) [changed into non-N operator's form] and (2.16) that

$$\left[\frac{D[X^{+0}(z,\theta)/ip^{+0}]-D_\theta\log(z-z_0-\sqrt{z-z_0}\theta\theta_0)}{(-\partial_z[X^{+0}(z,\theta)/ip^{+0}]+\partial_z\log(z-z_0-\sqrt{z-z_0}\theta\theta_0))^{1/2}}\right]_{z=z_F,\,\theta=\theta_F}\propto\xi,\tag{2.38}$$

together with

$$D_\theta\log(\widetilde{v}_F(w,\xi;z,\theta))=-\frac{\theta-\sqrt{z-z_0}\theta_0}{z-z_0-\sqrt{z-z_0}\theta\theta_0}+D_\theta\frac{X^{+0}(z,\theta)}{ip^{+0}}-\frac{\theta-\sqrt{z-z_0}\theta_0}{w}$$
$$+\mathrm{O}(z-z_0-\sqrt{z-z_0}\theta\theta_0).\tag{2.39}$$

With the help of the decomposition [into zero and nonzero modes]

$$P_F^{\mp j\dagger}(w,\xi)\equiv\frac{p^{\mp j}\xi}{w}+\mathscr{P}_F^{\mp j\dagger}(w,\xi)\tag{2.40}$$

we find [with respect to the integrand given by the right-hand side of Eq. (2.37)] that

$$-\sum_{j=1}^{4}i\oint_0\frac{dw\ d\xi}{2\pi i}\,P_F^{+hj\dagger}(w,\xi)\left(X_N^{-hj}(z_{NF}(w,\xi))-X^{-hj}(z_0)-\frac{p^{-hj}}{p^{+0}}\,(X^{+0}(z_{NF}(w,\xi))\right.$$
$$\left.-X^{+0}(z_0))+\theta_{NF}(w,\xi)\,\frac{\Psi_{Nh}^{-hj}(z_{NF}(w,\xi))}{(z_{NF}(w,\xi)-z_0)^{1/2}}-\theta_0\Psi_{Nh}^{-hj}(z_0)\right)$$
$$\equiv\sum_{j=1}^{4}\left(D_{F1}^{+hj}(\mathscr{P}_F^{+hj\dagger};X^{+0},\Psi_{N+}^{+0}|X^{-hj})-\frac{p^{-hj}}{p^{+0}}\,D_{F1}^{+hj}(\mathscr{P}_F^{+hj\dagger};X^{+0},\Psi_{N+}^{+0}|X^{+0})\right)$$
$$+\sum_{j=1}^{4}D_{F2}^{+hj}(\mathscr{P}_F^{+hj\dagger};X^{+0},\Psi_{N+}^{+0}|\Psi_{Nh}^{-hj})\tag{2.41}$$

and we find [with respect to the integrand given by the right-hand side of Eq. (2.36)] that

$$
\begin{aligned}
&-\sum_{j=1}^{4} i \oint_0 \frac{dw\ d\xi}{2\pi i} P_F^{-hj\dagger}(w,\xi)\Big(X^{+hj}(z_{NF}(w,\xi))-X^{+hj}(z_0)-\frac{p^{+hj}}{p^{+0}}\,(X^{+0}(z_{NF}(w,\xi))-X^{+0}(z_0)) \\
&\quad+\theta_{NF}(w,\xi)(z_{NF}(w,\xi)-z_0)^{1/2}\Psi_{Nh}^{+hj}(z_{NF}(w,\xi)) \\
&\quad-\frac{p^{+hj}}{p^{+0}}\cdot\theta_{NF}(w,\xi)(z_{NF}(w,\xi)-z_0)^{1/2}\Psi_{N+}^{+0}(z_{NF}(w,\xi))\Big) \\
&\equiv\sum_{j=1}^{4}\left(D_{F1}^{-hj}(\mathscr{P}_F^{-hj\dagger};X^{+0},\Psi_{N+}^{+0}|X^{+hj})-\frac{p^{+hj}}{p^{+0}}\,D_{F1}^{-hj}(\mathscr{P}_F^{-hj\dagger};X^{+0},\Psi_{N+}^{+0}|X^{+0})\right) \\
&\quad+\sum_{j=1}^{4}\left(D_{F3}^{-hj}(\mathscr{P}_F^{-hj\dagger};X^{+0},\Psi_{N+}^{+0}|\Psi_{Nh}^{+hj})-\frac{p^{+hj}}{p^{+0}}\,D_{F3}^{-hj}(\mathscr{P}_F^{-hj\dagger};X^{+0},\Psi_{N+}^{+0}|\Psi_{N+}^{+0})\right). \qquad (2.42)
\end{aligned}
$$

[Thus we find from Eqs. (2.41) and (2.42) that

$$
\begin{aligned}
\rho_N^{1F}(z_0,\theta_0;P_F^\dagger)&\equiv-\sum_{j=1}^{4} i\oint_0\frac{dw\ d\xi}{2\pi i}P_F^{\mp hj\dagger}(w,\xi)X_N^{\pm j}(z_{NF}(w,\xi),\theta_{NF}(w,\xi)) \\
&=-\sum_{j=1}^{4} ip^{+hj}Y_{Nh}^{-hj}(z_0,\theta_0)-\sum_{j=1}^{4} ip^{-hj}X^{+hj}(z_0) \\
&\quad+\sum_{\pm}\sum_{j=1}^{4} D_{F1}^{\pm hj}(\mathscr{P}_F^{\pm hj\dagger};X^{+0},\Psi_{N+}^{+0}|X^{\mp hj})+\sum_{j=1}^{4} D_{F2}^{+hj}(\mathscr{P}_F^{+hj\dagger};X^{+0}\Psi_{N+}^{+0}|\Psi_{Nh}^{-hj}) \\
&\quad+\sum_{j=1}^{4} D_{F3}^{-hj}(\mathscr{P}_F^{-hj\dagger};X^{+0},\Psi_{N+}^{+0}|\Psi_{Nh}^{+hj}). \qquad (2.43)
\end{aligned}
$$

Therefore with the help of Eqs. (2.13), (2.21), (2.36), (2.37), and (2.41)–(2.43), we find that Eq. (2.13) is reduced to be given by

$$
:(\mathbf{R}\cdot\ \exp(\rho_N^{1F}(z_0,\theta_0;P_F^\dagger)))\exp(\tilde{\rho}_{N+}^{0F}(z_0,\theta_0)+\sigma_N^{1F}(z_0,\theta_0;P_F^\dagger)):_R S_{\{h\}}(z_0), \qquad (2.44)
$$

with

$$
\begin{aligned}
\sigma_N^{1F}(z_0,\theta_0;P_F^\dagger)&\equiv-\sum_{\pm}\ \frac{p^{\mp hj}}{p^{+0}}\,D_{F1}^{\pm hj}(\mathscr{P}_F^{\pm hj\dagger};X^{+0},\Psi_{N+}^{+0}|X^{+0}) \\
&\quad-\frac{p^{+hj}}{p^{+0}}\,D_{F3}^{-hj}(\mathscr{P}_F^{-hj\dagger};X^{+0},\Psi_{N+}^{+0}|\Psi_{N+}^{+0}). \qquad (2.45)
\end{aligned}
$$

$D_{F(i)}^{\mp j}$'s (for $i=1-3$) in Eq. (2.43) are bilinear functionals of $\mathscr{P}_F^{\mp j\dagger}$ and $X^{\pm j}(\Psi_{Nh}^{\pm j})$. Therefore in Eq. (2.44), we have still the radial ordered product among N operators $\rho_N^{1F}(z_0,\theta_0;P_F^\dagger)$ (2.43). Hereafter, we express Eq. (2.44) in terms of overally normal-ordered products, by taking contractions in the R sector among $(X^{\pm j},\Psi_{Nh}^{\pm j})$. We denote thus obtained contracted terms by $E_{NF}(\mathscr{P}_F^{-j\dagger},\mathscr{P}_F^{+j\dagger}|X^{+0},\Psi_{N+}^{+0})$ [in N operator's form], which are bilinear terms in $\mathscr{P}_F^{-j\dagger}$ and $\mathscr{P}_F^{+j\dagger}$ (not including $p^{\mp j}$). [See the corresponding Eq. (2.11) in Ref. 7.] With the help of $\rho_{N\{h\}}^{2F}$ (1.13) and ρ_N^{1F} (2.43), we can show that E_{NF} is nothing but the one existing in the following formula:

$$
\begin{aligned}
&\rho^{2F}_{N\{h\}}(z_0,\theta_0;P^{\dagger}_F)\\
&\equiv -\sum_{j=1}^{4}\oint\frac{dw\ d\xi}{2\pi i}\left(\frac{p^{-j}\xi}{w}+\mathscr{P}_F^{-j^{\dagger}}(w,\xi)\right)\oint\frac{dw'\ d\xi'}{2\pi i}\left(\frac{p^{+j}\xi'}{w'}+\mathscr{P}_F^{+j^{\dagger}}(w',\xi')\right)\\
&\quad\times\log\frac{z_{NF}(w,\xi)-z_{NF}(w',\xi')-([z_{NF}(w,\xi)-z_0]/[z_{NF}(w',\xi')-z_0])^{\epsilon_h^j}\theta_{NF}(w,\xi)\theta_{NF}(w',\xi')}{w-w'-(w/w')^{\epsilon_h^j}\xi\xi'}\\
&=-\sum_{j=1}^{4}p^{+hj}\oint\frac{dw\ d\xi}{2\pi i}\mathscr{P}_F^{-hj^{\dagger}}(w,\xi)\cdot\log\frac{z_{NF}(w,\xi)-z_0-(z_{NF}(w,\xi)-z_0)^{1/2}\theta_{NF}(w,\xi)\theta_0}{w}\\
&\quad-\sum_{j=1}^{4}p^{-hj}\oint\frac{dw\ d\xi}{2\pi i}\mathscr{P}_F^{+hj^{\dagger}}(w,\xi)\cdot\log\frac{z_{NF}(w,\xi)-z_0}{w}\\
&\quad-\sum_{j=1}^{4}\oint\frac{dw\ d\xi}{2\pi i}\mathscr{P}_F^{-j^{\dagger}}(w,\xi)\oint\frac{dw'\ d\xi'}{2\pi i}\mathscr{P}_F^{+j^{\dagger}}(w',\xi')\log\Bigg(z_{NF}(w,\xi)-z_{NF}(w',\xi')\\
&\quad-\left(\frac{z_{NF}(w,\xi)-z_0}{z_{NF}(w',\xi')-z_0}\right)^{\epsilon_h^j}\theta_{NF}(w,\xi)\theta_{NF}(w',\xi')\Bigg)\\
&=\sigma_N^{1F}(z_0,\theta_0;P^{\dagger}_F)+\sum_{j=1}^{4}E_{NF}(\mathscr{P}_F^{-hj^{\dagger}},\mathscr{P}_F^{+hj^{\dagger}}|X^{+0},\Psi^{+0}_{N+}),
\end{aligned}
\tag{2.46}
$$

$\sigma_N^{1F}(z_0,\theta_0;P_F^{\dagger})$ being given by Eq. (2.45). In obtaining the last N operator E_{NF} in Eq. (2.46), we have used the following contraction in the R sector;

$$
\begin{aligned}
&\overbrace{\qquad\qquad R\qquad\qquad}\\
&X_N^{+j}(z_{NF}(w,\xi),\theta_{NF}(w,\xi))X_N^{-j}(z_{NF}(w',\xi'),\theta_{NF}(w',\xi'))\\
&\quad=\log\left(z_{NF}(w,\xi)-z_{NF}(w',\xi')-\left(\frac{z_{NF}(w,\xi)-z_0}{z_{NF}(w',\xi')-z_0}\right)^{\varepsilon_h^j}\theta_{NF}(w,\xi)\theta_{NF}(w',\xi')\right).
\end{aligned}
\tag{2.47}
$$

[Incidentally, we have also used in Eq. (2.46) that

$$
\log\frac{z_{NF}(w,\xi)-z_0}{w}=\frac{X^{+0}(z_{NF}(w,\xi))}{ip^{+0}}-\frac{X^{+0}(z_0)}{ip^{+0}},
\tag{2.48}
$$

which will be shown to be valid by using various formulas to be derived in the next section. First, we have from Eq. (1.17) that

$$
\log\frac{z_{NF}(w,\xi)-z_0}{w}=\log\frac{L_{NF}(w)}{w}+\xi K_{NF}(w)\frac{J_{NF}(w)}{L_{NF}(w)}.
\tag{2.49}
$$

Furthermore, comparing Eqs. (3.15) with (B17) (for $j=0$) leads to

$$
\log\frac{L_{NF}(w)}{w}=\left[\frac{X^{+0}(z_{NF})}{ip^{+0}}\right]_{\xi=0}-\frac{X^{+0}(z_0)}{ip^{+0}},
\tag{2.50}
$$

while comparing Eqs. (3.5), (3.19), and (3.20) with (B18) (for $j=0$) leads to

$$
\frac{J_{NF}(w)}{L_{NF}(w)}=\Gamma_N^{F2}(0,w)=\left[\theta_{NF}\partial_{z_{NF}}\frac{X^{+0}(z_{NF})}{ip^{+0}}\right]_{\xi=0}.
\tag{2.51}
$$

Therefore, Eqs. (2.49)–(2.51) together with Eq. (1.15) finally gives Eq. (2.48).] Therefore we find from Eqs. (2.44) and (2.46) that

$$
\begin{aligned}
&:(\mathbf{R}\cdot\exp(\rho_N^{1F}(z_0,\theta_0;P_F^\dagger)))\exp(\sigma_N^{1F}(z_0,\theta_0;P_F')):_R \\
&=:\exp\left(\rho_N^{1F}(z_0,\theta_0;P_F^\dagger)+\sigma_N^{1F}(z_0,\theta_0;P_F^\dagger)+\sum_{j=1}^{4} E_{NF}(\mathscr{P}_F^{+hj^\dagger},\mathscr{P}_F^{-hj^\dagger}|X^{+0},\Psi_{N+}^{+0})\right):_R \\
&=:\exp(\rho_N^{1F}(z_0,\theta_0;P_F^\dagger)+\rho_{N\{h\}}^{2F}(z_0,\theta_0;P_F^\dagger)):_R . \qquad (2.52)
\end{aligned}
$$

In conclusion, we find from Eqs. (2.44) and (2.52) that the left-hand side of Eq. (2.11) is given (in overally normal-ordered form) by $\Phi_{N\{h\}}^F(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)$ [i.e., Eqs. (1.10) and (1.14)] in the case of ''on-shell,'' provided we notice the fact that $\mathscr{P}^{-0}$ in $\tilde{\rho}_{N+}^{0F}$ [see Eq. (2.14′)] is just equal to p^{-0} in Eq. (1.11). [See also the on-shell condition (2.12″).] Without imposing the on-shell condition (2.10), we can easily prove Eq. (2.11) even in the off-shell case. (Q.E.D.)]

In the following, we shall prove OPE of GFPVO $\Phi_{N\{h\}}^F(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)$ with respect to the superstressino operator $(T_{NF},\mathscr{T}_{NF})$ (in the off-shell case); With respect to the stress operator $T_{NF}(z';z_0)$ which is N-ized [see Eq. (1.5)] from

$$
T_F(z')\equiv\sum_{j=0}^{4}\sum_{\pm}:\left(\frac{1}{2}\partial_{z'}X^{\pm j}(z')\partial_{z'}X^{\mp j}(z')+\frac{1}{2}\partial_{z'}\Psi^{\pm j}(z')\cdot\Psi^{\mp j}(z')\right):_R , \qquad (2.53)
$$

we easily find from Eq. (2.5) that

$$
\begin{aligned}
\mathbf{R}\cdot T_{NF}(z';z_0)\sum_{\{h\}}(z_0|\theta_0)&=\frac{-(p^{+0}p^{-0}+\Sigma_{j=1}^{4}p^{+j}p^{-j})}{(z'-z_0)^2}\cdot\sum_{\{h\}}(z_0|\theta_0)+\frac{1}{z'-z_0}\partial_{z_0}\sum_{\{h\}} \\
&\quad\times(z_0|\theta_0)+\mathrm{O}(1). \qquad (2.54)
\end{aligned}
$$

Applying OPE (2.54) to the left-hand side of Eq. (2.11), and taking account of mass relations (2.12)–(2.12″) and (anti-) commutation relations (2.4), we find that

$$
\begin{aligned}
&\mathbf{R}\cdot T_{NF}(z';z_0)\tilde{\Phi}_{N\{h\}}^F(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0) \\
&=\frac{1}{(z'-z_0)^2}\left(-\left(p^{+0}\mathscr{P}^{-0}+\sum_{j=1}^{4}p^{+j}p^{-j}\right)\tilde{\Phi}_{N\{h\}}^F(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)\right. \\
&\quad\left.+[N_F,\tilde{\Phi}_{N\{h\}}^F(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)]\right) \\
&\quad+\frac{1}{z'-z_0}\partial_{z_0}(\tilde{\Phi}_{N\{h\}}^F(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0))+O(1), \qquad (2.55)
\end{aligned}
$$

where we have used the light-cone number operator N_F defined by

$$
N_F\equiv\sum_{n=1}^{\infty}\sum_{\pm}\sum_{k=1}^{4}(\alpha_{-n}^{\mp k}\alpha_n^{\pm k}+nd_{-n}^{\mp k}d_n^{\pm k}). \qquad (2.56)
$$

On the other hand, with respect to the stressino operator $\mathscr{T}_{NF}(z';z_0)$ which is N-ized [see Eq. (1.5)] from

$$
\mathscr{T}_F(z')\equiv\sum_{j=0}^{4}\sum_{\pm}\partial_{z'}X^{\pm j}(z')\Psi^{\mp j}(z'), \qquad (2.57)
$$

we can easily find from Eq. (2.5) that

$$
\mathbf{R}\cdot\mathscr{T}_{NF}(z';z_0)\Sigma_{\{h\}}^0(z_0)=\frac{1}{(\sqrt{z'-z_0})^3}\Sigma_{\{h\}}^1(z_0)+O\left(\frac{1}{\sqrt{z'-z_0}}\right) \qquad (2.58)
$$

and

$$\mathbf{R}\cdot\mathscr{T}_{NF}(z';z_0)\Sigma^1_{\{h\}}(z_0)=\frac{-(p^{+0}p^{-0}+\Sigma_{j=1}^4 p^{+j}p^{-j})}{(\sqrt{z'-z_0})^3}\cdot\Sigma^0_{\{h\}}(z_0)+O\left(\frac{1}{\sqrt{z'-z_0}}\right), \quad (2.59)$$

where we have introduced

$$\Sigma_{\{h\}}(z_0|\theta_0)\equiv\Sigma^0_{\{h\}}(z_0)+\theta_0\Sigma^1_{\{h\}}(z_0). \quad (2.60)$$

On the other hand, Eq. (2.11) is rewritten into

$$\begin{aligned}&\mathbf{R}\cdot\ \exp\left(\sum_{n=1}^{\infty}\sum_{\pm}\sum_{j=1}^{4}\left(\frac{1}{n}\,\alpha_{-n}^{\mp j}\cdot A_{-n}^{\pm j}-d_{-n}^{\mp j}\cdot\mathscr{D}_{-n}^{\pm j}\right)\right)\cdot\Sigma^m_{\{h\}}(z_0)\\&\quad=\widetilde{\Phi}^{Fm}_{N\{h\}}(z_0;P_F^\dagger)S_{\{h\}}(z_0)\\&\qquad[\text{given by Eqs. (1.4) and (2.11), i.e., Eq. (1.10) with } \sim][\text{for } m=0,1].\end{aligned} \quad (2.61)$$

Applying OPE's (2.58) and (2.59) to the left-hand side of Eq. (2.61) and taking account of mass relations (2.12)–(2.12″) and (anti-) commutation relations (2.4), we find that

$$\mathbf{R}\cdot\mathscr{T}_{NF}(z';z_0)\widetilde{\Phi}^{F0}_{N\{h\}}(z_0;P_F^\dagger)S_{\{h\}}(z_0)=\frac{1}{(\sqrt{z'-z_0})^3}\,\widetilde{\Phi}^{F1}_{N\{h\}}(z_0;P_F^\dagger)S_{\{h\}}(z_0)+O\left(\frac{1}{\sqrt{z'-z_0}}\right) \quad (2.62)$$

and

$$\begin{aligned}&\mathbf{R}\cdot\mathscr{T}_{NF}(z';z_0)\widetilde{\Phi}^{F1}_{N\{h\}}(z_0;P_F^\dagger)S_{\{h\}}(z_0)\\&\quad=\frac{1}{(\sqrt{z'-z_0})^3}\left(-\left(p^{+0}\mathscr{P}^{-0}+\sum_{j=1}^{4}p^{+j}p^{-j}\right)\widetilde{\Phi}^{F0}_{N\{h\}}(z_0;P_F^\dagger)S_{\{h\}}(z_0)\right.\\&\qquad\left.+[N_F,\widetilde{\Phi}^{F0}_{N\{h\}}(z_0;P_F^\dagger)S_{\{h\}}(z_0)]\right)+O\left(\frac{1}{\sqrt{z'-z_0}}\right).\end{aligned} \quad (2.63)$$

[It should be noticed that the notation $\mathscr{P}^{-0}$ used in this section is just equal to the notation p^{-0} in Sec. I.]

Although we have exclusively investigated the R sector in this paper, the NS sector can be also analyzed in much the same way.

III. PHYSICAL VERTEX OPERATORS IN THE *R* SECTOR

In this section, we explicitly carry out the loop integrations over $w(w')$ and $\xi(\xi')$ in N operators ρ_N^{1F} (1.12) and $\rho_{N\{h\}}^{2F}$ (1.13), and we will obtain concrete results. With the help of formulas (1.16) and (1.17), we find that

$$\begin{aligned}&G_N^F(w,\xi;w',\xi')\\&\equiv\log\frac{z_{NF}(w,\xi)-z_{NF}(w',\xi')-([z_{NF}(w,\xi)-z_0]/[z_{NF}(w',\xi')-z_0])^{1/2}\theta_{NF}(w,\xi)\,\theta_{NF}(w',\xi')}{w-w'-(w/w')^{1/2}\xi\xi'}\end{aligned} \quad (3.1)$$

$$\begin{aligned}&=A_N^F(w,w')+\xi K_{NF}(w)\Gamma_N^{F1}(w,w')\\&\quad+\xi' K_{NF}(w')\Gamma_N^{F2}(w,w')-\xi\xi'\left(\frac{w}{w'}\right)^{1/2}C_N^F(w,w'),\end{aligned} \quad (3.2)$$

where

$$A_N^F(w,w')\equiv\log\frac{L_{NF}(w)-L_{NF}(w')-(L_{NF}(w)/L_{NF}(w'))^{1/2}J_{NF}(w)J_{NF}(w')}{w-w'} \tag{3.3}$$

$$\equiv\sum_{n,m=0}^{\infty} w^n w'^m A_{N,n,m}^F, \tag{3.3'}$$

$$\Gamma_N^{F1}(w,w')\equiv\sqrt{L_{NF}(w)}\,\frac{[J_{NF}(w)/\sqrt{L_{NF}(w)}]-[J_{NF}(w')/\sqrt{L_{NF}(w')}]}{L_{NF}(w)-L_{NF}(w')} \tag{3.4}$$

$$\equiv\sum_{n=0}^{\infty} w^{n+1/2}\left(\sum_{m=0}^{\infty} w'^m\Gamma_{N,n+1/2,m}^{F1}\right) \tag{3.4'}$$

and

$$\Gamma_N^{F2}(w,w')\equiv\frac{1}{\sqrt{L_{NF}(w')}}\cdot\frac{\sqrt{L_{NF}(w')}J_{NF}(w')-\sqrt{L_{NF}(w)}J_{NF}(w)}{L_{NF}(w')-L_{NF}(w)} \tag{3.5}$$

$$\equiv\sum_{m=-1}^{\infty} w'^{m+1/2}\left(\sum_{n=0}^{\infty} w^n\Gamma_{N,n,m+1/2}^{F2}\right). \tag{3.5'}$$

[We notice that general forms (3.3′)–(3.5′) are concluded from Eqs. (3.3)–(3.5), respectively.] On the other hand, we can calculate $C_N^F(w,w')$ by using

$$C_N^F(w,w')\equiv\frac{\exp(-(w-w')A_N^{F1}(w,w'))\exp((w-w')^2A_N^{F2}(w,w'))-1}{w-w'}. \tag{3.6}$$

In Eq. (3.6), $A_N^{F1(2)}(w,w')$ are functions obtained by

$$A_N^{F1}(w,w')\equiv\frac{A_N^F(w,w')-\log[L_{NF}(w)/w]-A_N^F(w',w)+\log[L_{NF}(w')/w']}{2(w-w')}$$

$$\equiv\sum_{n,m=0}^{\infty} w^n w'^m A_{N,n,m}^{F1} \tag{3.7}$$

and

$$A_N^{F2}(w,w')\equiv\frac{A_N^F(w,w)-A_N^F(w,w')-A_N^F(w',w)+A_N^F(w',w')}{2(w-w')^2}\equiv\sum_{n,m=0}^{\infty} w^n w'^m A_{N,n,m}^{F2}, \tag{3.8}$$

both of which are even under $w\leftrightarrow w'$. In Eq. (3.8), we have used the useful fact that Eqs. (1.28) and (3.3) lead to

$$K_{NF}(w)=\lim_{w'\to w}\left(\frac{L_{NF}(w)-L_{NF}(w')-J_{NF}(w)J_{NF}(w')}{w-w'}\right)^{1/2}=\exp\left(\frac{1}{2}A_N^F(w,w)\right). \tag{3.9}$$

In the following, we shall explain the method of how to calculate Eqs. (3.3)–(3.9) with the help of Eqs. (1.20)–(1.30).

First, Eq. (3.1) is rewritten into

$$G_N^F(w,\xi;w',\xi')=\log\frac{z_{NF}-z'_{NF}}{w-w'-(w/w')^{1/2}\xi\xi'}-\left(\frac{w}{w'}\right)^{1/2}\frac{\theta_{NF}\theta'_{NF}}{z_{NF}-z'_{NF}}\exp\left(-\frac{1}{2}I(z'_{NF})+\frac{1}{2}I(z_{NF})\right) \tag{3.10}$$

$$\begin{aligned}&=-\log\left(w-w'-\left(\frac{w}{w'}\right)^{1/2}\xi\xi'\right)+[\log(z_{NF}-z'_{NF})]_{\xi'=0}+\xi' K_{NF}(w')\\&\times\left[\frac{\theta'_{NF}}{z'_{NF}-z_{NF}}\right]_{\xi'=0}-\left(\frac{w}{w'}\right)^{1/2}\left[\frac{\theta'_{NF}\theta_{NF}}{z'_{NF}-z_{NF}}\exp\left(-\frac{1}{2}I(z'_{NF})+\frac{1}{2}I(z_{NF})\right)\right]_{\xi'=0}\\&-\left(\frac{w}{w'}\right)^{1/2}\xi' K_{NF}(w')\left[\frac{\theta_{NF}}{z'_{NF}-z_{NF}}\exp\left(-\frac{1}{2}I(z'_{NF})+\frac{1}{2}I(z_{NF})\right)\right]_{\xi'=0},\end{aligned} \tag{3.10$'$}$$

where we have used Eqs. (1.17), (1.27), and shorthand notations

$$z_{NF}\equiv z_{NF}(w,\xi),\quad z'_{NF}\equiv z_{NF}(w',\xi'),$$

and

$$\theta_{NF}\equiv\theta_{NF}(w,\xi),\quad \theta'_{NF}\equiv\theta_{NF}(w',\xi'). \tag{3.11}$$

In the case when $|w|>|w'|$, Eq. (3.10$'$) can be rewritten into

$$\begin{aligned}G_N^F(w,\xi;w',\xi')&=[\log(z_{NF}-z'_{NF})]_{\xi'=0}-\left(\frac{w}{w'}\right)^{1/2}\left[\exp\left(-\frac{1}{2}I(z'_{NF})+\frac{1}{2}I(z_{NF})\right)\frac{\theta'_{NF}\theta_{NF}}{z'_{NF}-z_{NF}}\right]_{\xi'=0}\\&-\log w+\sum_{n=1}^{\infty}\frac{1}{n}\left(\frac{w'}{w}\right)^n+\xi' K_{NF}(w')\left[\frac{\theta'_{NF}}{z'_{NF}-z_{NF}}\right]_{\xi'=0}-\xi' K_{NF}(w')\\&\times\left(\frac{w}{w'}\right)^{1/2}\left[\frac{\theta_{NF}}{z'_{NF}-z_{NF}}\exp\left(-\frac{1}{2}I(z'_{NF})+\frac{1}{2}I(z_{NF})\right)\right]_{\xi'=0}\\&+\xi\xi'\frac{1}{\sqrt{w'w}}\sum_{n=0}^{\infty}\left(\frac{w'}{w}\right)^n.\end{aligned} \tag{3.12}$$

First, we calculate Eq. (3.12) with the help of Eqs. (1.20), (1.21), and (1.27), using the shorthand notations (1.23) (for $k=0,1/2,1,...$) and

$$V_{k+1}\equiv\frac{1}{k!}\,\partial_{z_0}^k\frac{\Psi_{N+}^{+0}(z_0)}{ip^{+0}}. \tag{3.13}$$

The obtained result (in the zeroth order of both ξ and ξ') is compared with the general form (3.3$'$), leading to

$$\begin{aligned}&\sum_{n,m=0}^{\infty}w^n w'^m A_{N,n,m}^F-\log\frac{L_{NF}(w)}{w}\\&=\sum_{m=1}^{\infty}\frac{w'^m}{m}\left(\sum_{k=1}^{m}R_{m-k}^{(m)}(z_0)\frac{\partial_{z_0}^k I(z_0)}{(k-1)!}\right)+\sum_{m=1}^{\infty}\frac{w'^m}{m}\sum_{n=1}^{\infty}\frac{w^n}{n}\left(\sum_{k=1}^{m}kR_{m-k}^{(m)}(z_0)R_{n+k}^{(n)}(z_0)\right)\\&-\sum_{m=0}^{\infty}w'^m\sum_{n=0}^{\infty}w^n\left(\sum_{k=0}^{m}R_{m-k}^{(m)}(z_0)\left(\sum_{j=1}^{n+k}R_{n+k-j}^{(n)}(z_0)V_j\theta_0\right)\right)+\sum_{m=1}^{\infty}w'^m\sum_{n=0}^{\infty}w^n\\&\times\left(\sum_{k=1}^{m}R_{m-k}^{(m)}(z_0)\left(\sum_{J=1}^{k}R_{n+J-1}^{(n)}(z_0)V_{k-J+1}\theta_0+\sum_{J=2}^{n}R_{n-J}^{(n)}(z_0)\left(\sum_{j=1}^{k}V_{k-j+1}V_{J+j-1}\right)\right)\right)\end{aligned} \tag{3.14}$$

and

$$\log \frac{L_{NF}(w)}{w} = \sum_{n=1}^{\infty} \frac{w^n}{n} R_n^{(n)}(z_0). \tag{3.15}$$

The last term on the right-hand side of Eq. (3.14) has been derived from

$$\sum_{m=1}^{\infty} w'^m \sum_{n=0}^{\infty} w^n \Bigg(\sum_{k=1}^{m} R_{m-k}^{(m+1/2)}(z_0) \Bigg(\sum_{l=1}^{k} V_{k-l+1} \Bigg(\sum_{h=1}^{l} R_{l-h}^{(-1/2)}(z_0) \Bigg(R_{n+h-1}^{(n)}(z_0)\theta_0 + \sum_{j=1}^{n+h-1} R_{n+h-1-j}^{(n)}(z_0) V_j \Bigg) \Bigg) \Bigg) \Bigg), \tag{3.16}$$

which is subsequently rewritten by changing the order of summations in such a way that

$$\sum_{l=1}^{k} \sum_{h=1}^{l} = \sum_{h=1}^{k} \sum_{l=h}^{k}, \quad \text{etc.} \tag{3.17}$$

and by using the formulas such that

$$\sum_{k=l}^{m} R_{m-k}^{(p)}(z_0) R_{k-l}^{(q)}(z_0) = R_{m-l}^{(p+q)}(z_0). \tag{3.18}$$

Furthermore, comparing the coefficient of $\xi' K_{NF}(w')$ on both right-hand sides of Eqs. (3.2) and (3.10′), we find that

$$\Gamma_{N,n,-1/2}^{F2} = R_n^{(n)}(z_0)\theta_0 + \sum_{j=1}^{n} R_{n-j}^{(n)}(z_0) V_j \tag{3.19}$$

and

$$\begin{aligned} \Gamma_{N,n,m+1/2}^{F2} \quad (\text{for } m = 0,1,2,\ldots) = \sum_{k=0}^{m} R_{m-k}^{(m+1/2)}(z_0) \Bigg(& \delta_{n,0} \Bigg(\frac{\theta_0}{k!} \partial_{z_0}^{k+1} I(z_0) + \sum_{l=1}^{k} \frac{V_{k-l+1}}{(l-1)!} \partial_{z_0}^{l} I(z_0) \Bigg) \\ & + (1-\delta_{n,0}) \Bigg(\frac{k+1}{n} R_{n+k+1}^{(n)}(z_0)\theta_0 + \sum_{l=1}^{k} \frac{l}{n} V_{k-l+1} R_{n+l}^{(n)}(z_0) \Bigg) \Bigg) \\ & + \sum_{l=0}^{m+1} \frac{2l-1}{2m+1} \cdot R_{m+1-l}^{(m+1/2)}(z_0) \Bigg(R_{n+l}^{(n)}(z_0)\theta_0 \\ & + \sum_{j=1}^{n+l} R_{n+l-j}^{(n)}(z_0) V_j \Bigg), \end{aligned} \tag{3.20}$$

where we have used

$$\begin{aligned} \sum_{k=1}^{m+1} k R_{m+1-k}^{(m+1)}(z_0) \Bigg(\sum_{l=0}^{k} R_{k-l}^{(-1/2)}(z_0) f_l(z_0) \Bigg) = & \sum_{l=0}^{m+1} \frac{1}{2} \Bigg(\frac{-m-3/2}{m+1/2} (m+1-l) + m + 1 + l \Bigg) \\ & \times R_{m+1-l}^{(m+1/2)}(z_0) f_l(z_0). \end{aligned} \tag{3.21}$$

Instead of Eq. (3.10′), we first expand $z_{NF}(w,\xi)$ and then $z_{NF}(w',\xi')$ in $G_N^F(w,\xi;w',\xi')$ (3.1). Then, comparing the coefficient of $\xi K_{NF}(w)$ on both sides of Eqs. (3.1) and (3.2), we find that

$$\Gamma^{F1}_{N,1/2,m}=\left(\delta_{m,0}\partial_{z_0}I(z_0)+(1-\delta_{m,0})\,\frac{m+1}{m}\,R^{(m)}_{m+1}(z_0)\right)\theta_0+\sum_{j=1}^{m+1}R^{(m)}_{m+1-j}(z_0)V_j \tag{3.22}$$

and

$$\begin{aligned}\Gamma^{F1}_{N,n+1/2,m}\quad(\text{for } n=1,2,...)=&\sum_{k=0}^{n}R^{(n+1/2)}_{n-k}(z_0)\Bigg(\delta_{m,0}\Bigg(\frac{\theta_0}{k!}\,\partial^{k+1}_{z_0}I(z_0)+\sum_{l=1}^{k}\frac{V_{k-l+1}}{(l-1)!}\,\partial^{l}_{z_0}I(z_0)\Bigg)\\&+(1-\delta_{m,0})\Bigg(\frac{k+1}{m}\,R^{(m)}_{m+k+1}(z_0)\theta_0+\sum_{l=1}^{k}\frac{l}{m}\,V_{k-l+1}R^{(m)}_{m+l}(z_0)\Bigg)\Bigg)\\&+\sum_{l=0}^{n}\frac{2l+1}{2n+1}\,R^{(n+1/2)}_{n-l}(z_0)\Bigg(R^{(m)}_{m+l+1}(z_0)\,\theta_0\\&+\sum_{j=1}^{m+l+1}R^{(m)}_{m+l+1-j}(z_0)V_j\Bigg),\end{aligned} \tag{3.23}$$

where we have used

$$\sum_{k=1}^{n}kR^{(n)}_{n-k}(z_0)\Bigg(\sum_{l=0}^{k}R^{(1/2)}_{k-l}(z_0)f_l(z_0)\Bigg)=\sum_{l=0}^{n}\frac{1}{2}\left(\frac{-n+1/2}{n+1/2}\,(n-l)+n+l\right)R^{(n+1/2)}_{n-l}(z_0)f_l(z_0). \tag{3.24}$$

In the above formulas, we need various $R^{(n)}_m(z_0)$ (B1) and $R^{(n+1/2)}_m(z_0)$ (B1′), explicit expressions of which can be obtained (in Appendix B) in terms of I_m and I^n_m defined by Eq. (B2).

On the other hand, N operators ρ^{1F}_N (1.12) is found out to be given by

$$\rho^{1F}_N(z_0,\theta_0;P^\dagger_F)=\sum_{j=1}^{4}\rho^{1Fj}_N(z_0,\theta_0;P^\dagger_F), \tag{3.25}$$

where

$$\rho^{1Fj}_N(z_0,\theta_0;P^\dagger_F)=R^j_X+R^j_{\alpha Nh}+R^j_{dNh}. \tag{3.26}$$

In Eq. (3.26), we have defined that

$$\begin{aligned}R^j_X=&-\sum_{\pm}\,i\oint\frac{dw}{2\pi i}\,\Pi^{\pm j\dagger}_\alpha(w)[X^{\mp j}(z_{NF})]_{\xi=0}\\&+\sum_{\pm}\,i\oint\frac{dw}{2\pi i}\,\pi^{\pm j^\dagger}_d(w)K_{NF}(w)[\theta_{NF}\partial_{z_{NF}}X^{\mp j}(z_{NF})]_{\xi=0},\end{aligned} \tag{3.27}$$

$$\begin{aligned}R^j_{\alpha Nh}=&-i\oint\frac{dw}{2\pi i}\,\Pi^{-hj^\dagger}_\alpha(w)[\theta_{NF}\sqrt{z_{NF}-z_0}\Psi^{hj}_{Nh}(z_{NF})]_{\xi=0}\\&-i\oint\frac{dw}{2\pi i}\,\Pi^{hj^\dagger}_\alpha(w)\left[\theta_{NF}\,\frac{\Psi^{-hj}_{Nh}(z_{NF})}{\sqrt{z_{NF}-z_0}}\right]_{\xi=0}\end{aligned} \tag{3.28}$$

and

$$\begin{aligned}R^j_{dNh}=&\,i\oint\frac{dw}{2\pi i}\,\pi^{-hj^\dagger}_d(w)K_{NF}(w)[\sqrt{z_{NF}-z_0}\Psi^{hj}_{Nh}(z_{NF})]_{\xi=0}\\&+i\oint\frac{dw}{2\pi i}\,\pi^{hj\dagger}_d(w)K_{NF}(w)\left[\frac{\Psi^{-hj}_{Nh}(z_{NF})}{\sqrt{z_{NF}-z_0}}\right]_{\xi=0},\end{aligned} \tag{3.29}$$

where ''h'' is the same as the one in ϵ_h^j of $S_{\{h\}}(z_0)$ (1.4) and we have used the following light-cone operators:

$$\Pi_\alpha^{\pm j^\dagger}(w)=\frac{1}{w}\left(p^{\pm j}+\sum_{n=1}^{\infty}\alpha_{-n}^{\pm j}w^{-n}\right) \tag{3.30}$$

and

$$\pi_d^{\pm j^\dagger}(w)=\frac{1}{\sqrt{w}}\left(d_0^{\pm j}+\sum_{n=1}^{\infty}d_{-n}^{\pm j}w^{-n}\right). \tag{3.31}$$

Furthermore, substituting Eq. (3.2) into N operator $\rho_{N\{h\}}^{2F}$ (1.13), we find that

$$\rho_{N\{h\}}^{2F}(z_0,\theta_0;P_F^\dagger)\equiv\sum_{j=1}^{4}\rho_{Nh}^{2Fj}(z_0,\theta_0;P_F^\dagger), \tag{3.32}$$

where

$$\rho_{Nh}^{2Fj}(z_0,\theta_0;P_F^\dagger)=R_{\alpha\alpha Nh}^j+R_{\alpha dNh}^j+R_{d\alpha Nh}^j+R_{ddNh}^j. \tag{3.33}$$

In Eq. (3.33), we have defined that

$$R_{\alpha\alpha Nh}^j\equiv-\oint\frac{dw}{2\pi i}\,\Pi_\alpha^{-hj^\dagger}(w)\oint\frac{dw'}{2\pi i}\,\Pi_\alpha^{hj\dagger}(w')A_N^F(w,w'), \tag{3.34}$$

$$R_{\alpha dNh}^j\equiv\oint\frac{dw}{2\pi i}\,\Pi_\alpha^{-hj^\dagger}(w)\oint\frac{dw'}{2\pi i}\,\pi_d^{hj^\dagger}(w')K_{NF}(w')\Gamma_N^{F2}(w,w'), \tag{3.35}$$

$$R_{d\alpha Nh}^j\equiv\oint\frac{dw}{2\pi i}\,\pi_d^{-hj^\dagger}(w)\oint\frac{dw'}{2\pi i}\,\Pi_\alpha^{hj^\dagger}(w')K_{NF}(w)\Gamma_N^{F1}(w,w'), \tag{3.36}$$

and

$$R_{ddNh}^j\equiv\oint\frac{dw}{2\pi i}\,\pi_d^{-hj^\dagger}(w)\oint\frac{dw'}{2\pi i}\,\pi_d^{hj^\dagger}(w')C_N^F(w,w')\left(\frac{w}{w'}\right)^{1/2}, \tag{3.37}$$

where ''h'' is the same as the one in ϵ_h^j of $S_{\{h\}}(z_0)$ (1.4) and we have used $\Pi_\alpha^{\pm j^\dagger}$ (3.30) and $\pi_d^{\pm j^\dagger}$ (3.31). Finally, we have from Eq. (1.11) that

$$\rho_{N+}^{0F}(z_0,\theta_0)=\sum_{\pm}-ip^{\pm 0}X^{\mp 0}(z_0)-\theta_0 ip^{+0}\Psi_{N+}^{-0}(z_0). \tag{3.38}$$

Substituting ρ_N^{1F} (3.25), $\rho_{N\{h\}}^{2F}$ (3.32), and ρ_{N+}^{0F} (3.38) into the right-hand side of Eq. (1.10), we find that

$$\begin{aligned}&\Phi_{N\{h\}}^F(z_0,\theta_0;P_F^\dagger)(\equiv\Phi_{N\{h\}}^{F0}(z_0;P_F^\dagger)+\theta_0\Phi_{N\{h\}}^{F1}(z_0;P_F^\dagger))\\&\quad=:\exp\left(\sum_{j=1}^{4}Z_{Nh}^{Fj}(z_0,\theta_0;P_F^\dagger)\right)(1-\theta_0 ip^{+0}\Psi_{0,N+}^{-0})\exp\left(-\sum_{\pm}\sum_{j=0}^{4}ip^{\pm j}X^{\mp j}(z_0)\right):_R,\end{aligned} \tag{3.39}$$

with

$$Z^{Fj}_{Nh}(z_0,\theta_0;P^\dagger_F)=\rho^{1Fj}_N(z_0,\theta_0;P^\dagger_F)+\rho^{2Fj}_{Nh}(z_0,\theta_0;P^\dagger_F) \quad [\text{see Eqs. (3.26) and (3.33)}]. \tag{3.39$'$}$$

In giving formulas of Z^{Fj}_{Nh} in Eq. (3.39), we shall introduce the following shorthand notations (for $j=1-4$, $k=0,1,2,...$):

$$X^{\pm j}_k \equiv \frac{1}{k!}\,\partial^k_{z_0} X^{\pm j}(z_0), \tag{3.40}$$

$$\Psi^{\pm j}_{k+1,N\pm} \equiv \frac{1}{k!}\,\partial^k_{z_0}\Psi^{\pm j}_{N\pm}(z_0), \tag{3.41}$$

and

$$\Psi^{\mp j}_{k,N\pm} \equiv \frac{1}{k!}\,\partial^k_{z_0}\Psi^{\mp j}_{N\pm}(z_0), \tag{3.42}$$

together with the following notations $Q^{\pm hj}$ $(Q=\alpha,d,p,X,\Psi)$;

$$Q^{hj}=\begin{cases} Q^{+j} & \text{for } h=+ \\ Q^{-j} & \text{for } h=- \end{cases} \quad \text{and} \quad Q^{-hj}=\begin{cases} Q^{-j} & \text{for } h+ \\ Q^{+j} & \text{for } h=-, \end{cases} \tag{3.43}$$

where ''h'' is the same as the one in ϵ^j_h in $S_{\{h\}}(z_0)$ (1.4). Then we have from Z^{Fj}_{Nh} (3.39$'$) that

$$\sum_{j=1}^4 Z^{Fj}_{Nh}(z_0,\theta_0;P^\dagger_F)\equiv E_{N\{h\}}(z_0;P^\dagger_F)+\theta_0\mathscr{E}_{N\{h\}}(z_0;P^\dagger_F), \tag{3.44}$$

where

$$\begin{aligned}
E_{N\{h\}}(z_0;P^\dagger_F)=&-\sum_{j=1}^4 i\alpha^{hj}_{-1}(X^{-hj}_1-ip^{-hj}I_1+V_1\Psi^{-hj}_{0,Nh})-\sum_{j=1}^4 i\alpha^{-hj}_{-1}(X^{hj}_1-ip^{hj}I_1)\\
&+\sum_{j=1}^4 id^{hj}_{-1}(\Psi^{-hj}_{1,Nh}+\tfrac{1}{2}I_1\Psi^{-hj}_{0,Nh}-ip^{-hj}V_1)+\sum_{j=1}^4 id^{-hj}_{-1}(\Psi^{hj}_{1,Nh}-ip^{hj}V_1)\\
&-\sum_{j=1}^4 i\alpha^{hj}_{-2}(X^{-hj}_2+I_1X^{-hj}_1-ip^{-hj}(I_1^2+\tfrac{1}{2}I_2)+V_1\Psi^{-hj}_{1,NH}+(V_2+2I_1V_1)\Psi^{-hj}_{0,Nh})\\
&-\sum_{j=1}^4 i\alpha^{-hj}_{-2}(X^{hj}_2+I_1X^{hj}_1-ip^{hj}(I_1^2+\tfrac{1}{2}I_2)+V_1\Psi^{hj}_{1,Nh})\\
&+\sum_{j=1}^4 id^{hj}_{-2}(\Psi^{-hj}_{2,Nh}+\tfrac{3}{2}I_1\Psi^{-hj}_{1,Nh}+(\tfrac{7}{8}I_1^2+\tfrac{1}{2}I_2)\Psi^{-hj}_{0,Nh}-V_1X^{-hj}_1-ip^{-hj}(\tfrac{3}{2}I_1V_1+V_2))\\
&+\sum_{j=1}^4 id^{-hj}_{-2}(\Psi^{hj}_{2,Nh}+\tfrac{3}{2}I_1\Psi^{hj}_{1,Nh}-V_1X^{hj}_1-ip^{hj}(\tfrac{5}{2}I_1V_1+V_2))\\
&-\sum_{j=1}^4 \alpha^{-hj}_{-1}\alpha^{hj}_{-1}(\tfrac{1}{2}I_1^2+\tfrac{1}{2}I_2)+\sum_{j=1}^4 d^{-hj}_{-1}d^{hj}_{-1}\cdot\tfrac{1}{8}I_1^2+\sum_{j=1}^4 \alpha^{-hj}_{-1}d^{hj}_{-1}(\tfrac{3}{2}I_1V_1+V_2)\\
&+\sum_{j=1}^4 \alpha^{hj}_{-1}d^{-hj}_{-1}(I_1V_1+V_2)+\cdots
\end{aligned} \tag{3.45}$$

and

$$\mathscr{E}_{N\{h\}}(z_0;P_F^\dagger)=-\sum_{j=1}^{4} ip^{hj}\Psi_{0,Nh}^{-hj}-\sum_{j=1}^{4} i\alpha_{-1}^{hj}(\Psi_{1,Nh}^{-hj}+I_1\Psi_{0,Nh}^{-hj})-\sum_{j=1}^{4} i\alpha_{-1}^{-hj}(\Psi_{1,Nh}^{hj}-ip^{hj}V_1)$$
$$-\sum_{j=1}^{4} id_{-1}^{hj}(X_1^{-hj}+\tfrac{1}{2}V_1\Psi_{0,Nh}^{-hj}-\tfrac{3}{2}ip^{-hj}I_1)-\sum_{j=1}^{4} id_{-1}^{-hj}(X_1^{hj}-ip^{hj}I_1)$$
$$-\sum_{j=1}^{4} i\alpha_{-2}^{hj}(\Psi_{2,Nh}^{-hj}+2I_1\Psi_{1,Nh}^{-hj}+(2I_1^2+I_2)\Psi_{0,Nh}^{-hj})-\sum_{j=1}^{4} i\alpha_{-2}^{-hj}(\Psi_{2,Nh}^{hj}+2I_1\Psi_{1,Nh}^{hj}$$
$$-(2I_1V_1+V_2)ip^{hj})-\sum_{j=1}^{4} id_{-2}^{hj}(-2X_2^{-hj}-\tfrac{5}{2}I_1X_1^{-hj}-ip^{-hj}(\tfrac{11}{4}I_1^2+\tfrac{7}{4}I_2)$$
$$+\tfrac{1}{2}V_1\Psi_{1,Nh}^{-hj}+(\tfrac{7}{4}I_1V_1+V_2)\Psi_{0,Nh}^{-hj})-\sum_{j=1}^{4} id_{-2}^{-hj}(-2X_2^{hj}-\tfrac{5}{2}I_1X_1^{hj}+\tfrac{1}{2}V_1\Psi_{1,Nh}^{hj}$$
$$-ip^{hj}(\tfrac{5}{2}I_1^2+I_2))-\sum_{j=1}^{4} \alpha_{-1}^{-hj}\alpha_{-1}^{hj}(I_1V_1+V_2)-\sum_{j=1}^{4} d_{-1}^{-hj}d_{-1}^{hj}(\tfrac{5}{4}I_1V_1+V_2)$$
$$-\sum_{j=1}^{4} \alpha_{-1}^{-hj}d_{-1}^{hj}(\tfrac{3}{2}I_1^2+I_2)-\sum_{j=1}^{4} \alpha_{-1}^{hj}d_{-1}^{-hj}(I_1^2+I_2)+\cdots . \tag{3.46}$$

Then we obtain from Eqs. (3.39) and (3.44)–(3.46) that

$$\Phi_{N\{h\}}^{F0}(z_0;P_F^\dagger)=\exp(-E_{N\{h\}}(z_0;P_F^\dagger))-\exp\left(-\sum_{\pm}\sum_{j=0}^{4} ip^{\pm j}X^{\mp j}(z_0)\right) \tag{3.47}$$

and

$$\Phi_{N\{h\}}^{F1}(z_0;P_F^\dagger)=(\mathscr{E}_{N\{h\}}(z_0;P_F^\dagger)-ip^{+0}\Psi_{0,N+}^{-0})\exp(E_{N\{h\}}(z_0;P_F^\dagger))\exp\left(-\sum_{\pm}\sum_{j=0}^{4} ip^{\pm j}X^{\mp j}(z_0)\right). \tag{3.48}$$

Then we can expand $\Phi_{N\{h\}}^{Fm}(z_0;P_F^\dagger)$ (3.47) (for $m=0$) and (3.48) (for $m=1$) as

$$\Phi_{N\{h\}}^{Fm}(z_0;P_F^\dagger)S_{\{h\}}(z_0)\equiv\sum_{\not}\left(\prod_{n=1}^{\infty}\prod_{\pm}\prod_{j=1}^{4}\frac{(-i\alpha_{-n}^{\pm j}/\sqrt{n})^{e_{\not}(n,\pm j)}}{\sqrt{e_{\not}(n,\pm j)!}}(id_{-n}^{\pm j})^{\tilde{e}_{\not}(n,\pm j)}\right)$$
$$\times V^{m\not}(z_0)S_{\{h\}}(z_0). \tag{3.49}$$

Comparing the right-hand side of Eq. (3.49) with the left-hand side of Eq. (2.11), we find that $V^{m\not}(z_0)$ (for $m=0,1$) in the expansion (3.49) is just equal to

$$V^{m\not}(z_0)S_{\{h\}}(z_0)=(-)^{\not}\left(\prod_{n=1}^{\infty}\prod_{\pm}\prod_{j=1}^{4}\frac{(iA_{-n}^{\pm j}/\sqrt{n})^{e_{\not}(n,\pm j)}}{\sqrt{e_{\not}(n,\pm j)!}}(i\mathscr{D}_{-n}^{\pm j})^{\tilde{e}_{\not}(n,\pm j)}\right)\Sigma_{\{h\}}^{m}(z_0), \tag{3.50}$$

where the $\pm$ sign factor $(-)^{\not}$ is fixed for each $\not$. Then the Ramond state $|\not;\theta_0\rangle$ (2.9) is given by

$$|\not;\theta_0\rangle=(-)^{\not}(V^{0\not}(z_0)+\theta_0V^{1\not}(z_0))S_{\{h\}}(z_0)|0\rangle , \tag{3.51}$$

where p^{-0} is given by $\mathscr{P}_{\not}^{-0}(2.12)$. We can show that the BRST-invariant physical Ramond state[6] in 1/2 picture is given by

$$:\exp(+\sigma(0)):\exp(-1/2\phi(0)):V^{1/}(0)S_{\{h\}}(0)|0\rangle, \tag{3.52}$$

in the on-shell limit;

$$-\sum_{j=0}^{4} p^{+j}p^{-j}+N_{/}\to 0. \tag{3.53}$$

[Incidentally, the BRST-invariant physical Ramond state in $-1/2$ picture is given by

$$:\exp(+\sigma(0)):\exp(-3/2\phi(0)):V^{0/}(0)S_{\{h\}}(0)|0\rangle, \tag{3.54}$$

in the on-shell limit.] In Eq. (3.53), we have used the eigenvalue $N_{/}$ of the light-cone number operator (2.56) N_F, which is given by Eq. (2.12′). In Eq. (3.52), $:\exp(+\sigma(0)):$ is Grassman odd, while $:\exp(-1/2\phi(0)):$ is Grassman even. The GSO-allowed[10] physical vertex operator $V^{1/}$ is such that Eq. (3.52) is Grassman even in total, so that $V^{1/}(0)S_{\{h\}}(0)$ should be Grassman odd. Finally, we remark that the FMS spinor $S_{\{h\}}(0)$ is Grassman even or odd, depending on the values ϵ_h^j; The operator $:\exp(\frac{1}{2}\phi^0(z_0)):$ in Eq. (1.4) is taken to be Grassman even, and it will be called *spinon*. On the other hand, the other factor $\Pi_{j=1}^4:\exp(\epsilon_h^j\phi^0(z_0)):$ in Eq. (1.4) for the *odd* (*even*) value of $\Sigma_{j=1}^4\epsilon_h^j$ will be called *octino* (*octon*), and it is taken to be Grassman *odd* (*even*).

IV. CONCLUSIONS AND DISCUSSIONS

In this paper, we have derived GFPVO and OPE's (among GFPVO and the superstressino operator) by using a completely different method from the one presented in our previous papers:[4,5] In Sec. II, we have constructed both a *physical* string coordinate's mode $A_{-n}^{\pm j}$ (2.1) (for any integer n) and a *physical* string coordino's mode $\mathscr{D}_{-n}^{\pm j}$ (2.2) (for any integer n), in the R sector. We have proved that these operators satisfy (anti-)commutation relations (2.3) and (2.4) (i.e., the spectrum generating algebra[3]). On the other hand, in the NS sector, we can use the (Schwarz) physical string coordino's mode $\mathscr{B}_{-n+1/2}^{\pm j}$ defined by[9]

$$\mathscr{B}_{-n+1/2}^{\pm j}\equiv -i\oint_0 \frac{dz\,d\theta}{2\pi i}D_\theta X^{\pm j}(z,\theta)\,\frac{D_\theta[X^{+0}(z,\theta)/ip^{+0}]}{(-\partial_z[X^{+0}(z,\theta)/ip^{+0}])^{1/2}}$$
$$\cdot\ \exp\left(\frac{(n-1/2)X^{+0}(z,\theta)}{ip^{+0}}\right)\quad[\text{for } j=1-4 \text{ and } n=0,\pm 1,\pm 2,...]. \tag{4.1}$$

We point out that our $(A_m^{\pm j},\mathscr{D}_m^{\pm j})$ in the R sector and $(A_m^{\pm j},\mathscr{B}_{m-1/2}^{\pm j})$[9] in the NS sector are, respectively, representations of Green and Schwarz's (V_m^j,D_m^j) and (V_m^j,B_r^j), which satisfy the spectrum generating algebra.[3] [We remark that our operators $(A_m^{\pm j},\mathscr{D}_m^{\pm j})$ and $(A_m^{\pm j},\mathscr{B}_{m-1/2}^{\pm j})$ are constructed by using the string coordinate $X^{\pm j}$ and string coordino $\Psi^{\pm j}\equiv:\exp(\pm\phi^j):$ which are common to both the R and NS sectors.] With the help of these operators, we can construct a complete set of physical states $|/;\theta_0\rangle$ (2.9), which are generated by the left-hand side of Eq. (2.11). One of main results in this paper is that we have proved in Sec. II that the left-hand side of Eq. (2.11) is just equal to the right-hand side of Eq. (2.11), which is nothing but the GFPVO which has already been proposed[4,5] by using the superconformal mapping in the R sector. In proving Eq. (2.11), we extensively used various formulas [related with the superconformal mapping (in the R sector) given by Eqs. (1.18) and (1.19)] which have been derived and used in Refs. 4 and 5. Furthermore, we have succeeded in deriving OPE's (2.55), (2.62), and (2.63), respectively, from simple OPE's (2.54), (2.58), and (2.59), since the physical string coordinate's mode $A_m^{\pm j}$ (2.1) and physical string coordino's mode $\mathscr{D}_m^{\pm j}$ (2.2) are invariant under the super-Virasoro algebra. [See Eq. (2.4).] Compared with the previous derivation of these OPE's in Ref. 5, the new derivation in this paper is quite simple.

In Sec. III, we have calculated GFPVO (1.10) by using superconformal mapping in the R sector. Some results are given by $\Phi^{Fm}_{N\{h\}}(z_0;P^\dagger_F)$ (3.47) [for $m=0$] and (3.48) [for $m=1$], substituted with $E_{N\{h\}}(z_0;P^\dagger_F)$ (3.45) and $\mathscr{E}_{N\{h\}}(z_0;P^\dagger_F)$ (3.46). In these formulas, we have used the following notations;

$$I(z_0)\equiv\frac{X^{+0}(z_0)}{ip^{+0}},\quad I_m\equiv\partial^m_{z_0}I(z_0),\quad I^n_m\equiv(I_m)^n, \tag{4.2}$$

$$V_{k+1}\equiv\frac{1}{k!}\,\partial^k_{z_0}\,\frac{\Psi^{+0}_{N+}(z_0)}{ip^{+0}}, \tag{4.3}$$

$$X^{\pm j}_k\equiv\frac{1}{k!}\,\partial^k_{z_0}X^{\pm j}(z_0)\quad[\text{for } j=1-4], \tag{4.4}$$

and

$$\Psi^{hj}_{k+1,Nh}\equiv\frac{1}{k!}\,\partial^k_{z_0}\Psi^{hj}_{Nh}(z_0),\quad \Psi^{-hj}_{k,Nh}\equiv\frac{1}{k!}\,\partial^k_{z_0}\Psi^{-hj}_{Nh}(z_0)\quad[\text{for } j=1-4]. \tag{4.5}$$

How these formulas have been derived in Sec. III will be briefly summaried hereafter. N operators ρ^{1F}_N (1.12) and $\rho^{2F}_{N\{h\}}$ (1.13) can be calculated up to an arbitrarily required number of terms, by using ρ^{1F}_N (3.25)–(3.29) and $\rho^{2F}_{N\{h\}}$ (3.32)–(3.37), where we have used A^F_N (3.3) [given by Eqs. (3.14) and (3.15)], Γ^{F1}_N (3.4) [given by Eqs. (3.22) and (3.23)], Γ^{F2}_N (3.5) [given by Eqs. (3.19) and (3.20)] and C^F_N (3.6) [given by A^{F1} (3.7) and A^{F2} (3.8)].

The *physical* Ramond states (in 1/2 picture) are proposed to be constructed by Eq. (3.52), which are shown by OPE (2.63) to be annihilated by the Dirac operator $\mathscr{F}^F_0$, in the on-shell limit $L^F_0\to 0$. (Incidentally, this state can be shown to be BRST invariant.) In Appendix A we have proved (anti-)commutation relations (2.3) and (2.4) by using the normal ordering and the contraction in the R sector. In Appendix B, first some terms of ρ^{1F}_N (3.25) and $\rho^{2F}_{N\{h\}}$ (3.32) are obtained explicitly by using Eqs. (B27)–(B29) and (B23)–(B26), respectively.

In calculating physical scattering amplitudes among external physical states including more than six Ramond particles, we will find from FMS's work that that we need to picture-change[6] some physical Ramond states in 1/2 picture [later given by Eq. (5.12)] into those in 3/2 picture. These picture-changing calculations can be carried out by using the N operator $\hat\Phi^F_{N\{h\}}(z_0,\theta_0;P^\dagger_F)$ which we have in the following OPE (which has been derived in Ref. 5).

$$\begin{aligned}
&\mathbf{R}\cdot\mathscr{F}_F(z')\Phi^F_{\{h\}}(z_0,\theta_0;P^\dagger_F)S_{\{h\}}(z_0)\\
&\quad=-\frac{\theta_0}{(\sqrt{z'-z_0})^3}\cdot\Bigg(-\Bigg(\sum_{j=0}^{4}p^{+j}p^{-j}\Bigg)\Phi^F_{N\{h\}}(z_0,\theta_0;P^\dagger_F)S_{\{h\}}(z_0)\\
&\qquad+[N_F,\Phi^F_{N\{h\}}(z_0,\theta_0;P^\dagger_F)S_{\{h\}}(z_0)]\Bigg)+\frac{1}{(\sqrt{z'-z_0})^3}\cdot\partial_{\theta_0}\Phi^F_{N\{h\}}(z_0,\theta_0;P^\dagger_F)S_{\{h\}}(z_0)\\
&\qquad-\frac{\theta_0}{\sqrt{z'-z_0}}\cdot\partial_{z_0}(\Phi^F_{N\{h\}}(z_0,\theta_0;P^\dagger_F)S_{\{h\}}(z_0))+\frac{1}{\sqrt{z'-z_0}}\,\hat\Phi^F_{N\{h\}}(z_0,\theta_0;P^\dagger_F)S_{\{h\}}(z_0)\\
&\qquad+O(\sqrt{z'-z_0}),
\end{aligned}\tag{4.6}$$

where the N operator $\hat\Phi^F_{N\{h\}}(z_0,\theta_0;P^\dagger_F)$ is given by

$$\hat\Phi^F_{N\{h\}}(z_0,\theta_0;P^\dagger_F)(\equiv\hat\Phi^{F3}_{N\{h\}}(z_0;P^\dagger_F)+\theta_0\hat\Phi^{F4}_{N\{h\}}(z_0;P^\dagger_F))=\sum_{i=1}^{3}\hat\Phi^F_{N\{h\},i}(z_0,\theta_0;P^\dagger_F). \tag{4.7}$$

In Eq. (4.7), $\hat{\Phi}^F_{N\{h\},1}(z_0,\theta_0;P_F^\dagger)$ is given by

$$\begin{aligned}\hat{\Phi}^F_{N\{h\},1}(z_0,\theta_0;P_F^\dagger)=&-:\frac{\Psi^{+0}_{N+}(z_0)}{ip^{+0}}\left(\left(-\sum_{j=0}^{4}p^{+j}p^{-j}\right)\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)\right.\\&\left.+[N_F,\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)]\right):_R-:\left(\partial_{z_0}\frac{X^{+0}(z_0)}{ip^{+0}}\right)\partial_{\theta_0}\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger):_R\\&-:(\partial_{z_0}ip^{+0}\Psi^{-0}_{N+}(z_0)+\theta_0\partial_{z_0}ip^{-0}X^{+0}(z_0)+\partial_{z_0}X^{+0}(z_0)\\&\cdot\Psi^{-0}_{N+}(z_0))\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger):_R\\&-\sum_{\pm}\sum_{j=1}^{4}i\oint\frac{dw\,d\xi}{2\pi i}P_F^{\pm j^\dagger}(w,\xi):(\mathscr{H}_{NF}(w,\xi)X_N^{\mp j}(z_{NF},\theta_{NF}))\Phi^F_{N\{h\}}\\&\times(z_0,\theta_0;P_F^\dagger):_R-\sum_{j=1}^{4}\oint\frac{dw\,d\xi}{2\pi i}P_F^{-hj^\dagger}(w,\xi)\oint\frac{dw'\,d\xi'}{2\pi i}P_F^{+hj^\dagger}(w',\xi'):\\&\times\left((\mathscr{H}_{NF}(w,\xi)+\mathscr{H}_{NF}(w',\xi'))\log\left(z_{NF}-z'_{NF}-\left(\frac{z_{NF}-z_0}{z'_{NF}-z_0}\right)^{1/2}\theta_{NF}\theta'_{NF}\right)\right)\\&\times\Phi^F_{N\{h\}},\theta_0;P_F^\dagger):_R+O(\sqrt{z'-z_0}),\end{aligned}\tag{4.8}$$

where we have from Eq. (3.1) that

$$\log\left(z_{NF}-z'_{NF}-\left(\frac{z_{NF}-z_0}{z'_{NF}-z_0}\right)^{1/2}\theta_{NF}\theta'_{NF}\right)=G^F_N(w,\xi;w',\xi')+\log\left(w-w'-\left(\frac{w}{w'}\right)^{1/2}\xi\xi'\right).\tag{4.9}$$

In Eq. (4.8), $\mathscr{H}_{NF}(w,\xi)$ is the N operator given by

$$\begin{aligned}\mathscr{H}_{NF}(w,\xi)=&-\frac{J_{NF}(w)+\xi K_{NF}(w)}{(\sqrt{z_{NF}(w,\xi)-z_0})^3}\left(\frac{1}{2}\xi D_\xi+w\partial_w\right)+\frac{wK_{NF}(w)}{(\sqrt{z_{NF}(w,\xi)-z_0})^3}\cdot\partial_\xi\\&+\xi\left(\frac{\frac{1}{2}w\partial_W J_{NF}(w)}{(\sqrt{z_{NF}(w,\xi)-z_0})^3}+\frac{3}{4}wK^2_{NF}(w)\frac{J_{NF}(w)}{(\sqrt{z_{NF}(w,\xi)-z_0})^5}\right)\partial_\xi.\end{aligned}\tag{4.10}$$

Furthermore, $\hat{\Phi}^F_{N\{h\},i}(z_0,\theta_0;P_F^\dagger)$'s [for $i=2,3$] in Eq. (4.7) are given, respectively, by

$$\begin{aligned}\hat{\Phi}^F_{N\{h\},2}(z_0,\theta_0;P_F^\dagger)=:&\left(1/2\Psi^{+hj}_{Nh}(z_0)\Psi^{-hj}_{Nh}(z_0)+\frac{1}{2}i\oint\frac{dw\,d\xi}{2\pi i}P_F^{-hj^\dagger}(w,\xi)\right.\\&\times\frac{\theta_{NF}(w,\xi)}{\sqrt{z_{NF}(w,\xi)-z_0}}\cdot\Psi^{+hj}_{Nh}(z_0)\\&\left.-\frac{1}{2}i\oint\frac{dw\,d\xi}{2\pi i}P_F^{+hj^\dagger}(w,\xi)\frac{\theta_{NF}(w,\xi)}{(\sqrt{z_{NF}(w,\xi)-z_0})^3}\cdot\Psi^{-hj}_{Nh}(z_0)\right)\theta_0\\&\cdot\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger):_R+:\left(\frac{\frac{1}{2}\Psi^{+0}_{N+}(z_0)}{ip^{+0}}\right)\theta_0\partial_{\theta_0}\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger):_R\end{aligned}\tag{4.11}$$

and

$$\hat{\Phi}^F_{N\{h\},3}(z_0,\theta_0;P^\dagger_F)\equiv\sum_{j=1}^{4}:\left(\Psi^{-hj}_{Nh}(z_0)-i\oint\frac{dw\ d\xi}{2\pi i}P_F^{-hj^\dagger}(w,\xi)\frac{\theta_{NF}(w,\xi)}{\sqrt{z_{NF}(w,\xi)-z_0}}\right)\left(\partial_{z_0}X^{+hj}(z_0)\right.$$
$$\left.+i\oint\frac{dw\ d\xi}{2\pi i}P_F^{+hj^\dagger}(w,\xi)\frac{1}{z_{NF}(w,\xi)-z_0}\right)\Phi^F_{N\{h\}}(z_0,\theta_0;P^\dagger_F):_R. \tag{4.12}$$

In calculating N operator $\hat{\Phi}^F_{\{h\}}(z_0,\theta_0;P^\dagger_F)$ (4.7) by using Eqs. (4.8)–(4.12), we can use the various formulas in terms of N operators. Incidentally, we can use that

$$z_{NF}(w,\xi)-z_0=w\cdot\exp(G^F_N(0,0;w,\xi))\quad[\text{from Eq. (3.1)}] \tag{4.13}$$

and

$$J_{NF}(w)=\sum_{n=0}^{\infty}w^{n+1/2}\left(\theta_0R^{(n+1/2)}_n(z_0)+\sum_{k=1}^{\infty}R^{(n+1/2)}_{n-k}(z_0)V_k\right)\quad[\text{from Eqs. (1.16) and (1.21)}]. \tag{4.14}$$

In the mass shell limit [when the first term on the right-hand side of OPE (4.6) vanishes], we find that

$$\lim_{z'\to z_0}\sqrt{z'-z_0}\mathscr{F}(z')\Phi^{F1}_{N\{h\}}(z_0;P^\dagger_F)S_{\{h\}}(z_0)=\partial_{z_0}(\Phi^{F0}_{N\{h\}}(z_0;P^\dagger_F)S_{\{h\}}(z_0))-\hat{\Phi}^{F4}_{N\{h\}}(z_0;P^\dagger_F)S_{\{h\}}(z_0), \tag{4.15}$$

which can be used in picture-changing[5] Ramond states in 1/2 picture into those in 3/2 picture.

Finally, we can similarly analyze the *NS* sector. Therefore we only sketch various useful results in the *NS* sector; A complete and orthonormal infinite set of *physical NS* states can be constructed by

$$|\{e_{\mathscr{A}}(n,\pm j)\},\{\tilde{e}_{\mathscr{A}}(n-\tfrac{1}{2},\pm j)\},\{p\};\theta_0\rangle(\equiv|\mathscr{A};\theta_0\rangle)$$
$$\equiv\lim_{z_0\to0}\left(\prod_{n=1}^{\infty}\prod_{\pm}\prod_{j=1}^{4}\frac{(iA^{\pm j}_{-n}/\sqrt{n})^{e_{\mathscr{A}}(n,\pm j)}}{(e_{\mathscr{A}}(n,\pm j)!)^{1/2}}(i\mathscr{B}^{\pm j}_{-n+1/2})^{\tilde{e}_{\mathscr{A}}(n-1/2,\pm j)}\right)t(z_0|\theta_0)|0\rangle, \tag{4.16}$$

where we have introduced the *basic* tachynorial operator $t(z_0|\theta_0)$ defined by

$$t(z_0|\theta_0)\equiv:\exp\left(-\sum_{\pm}\sum_{j=0}^{4}ip^{\pm j}X^{\mp j}(z_0,\theta_0)\right):_{NS}. \tag{4.17}$$

In Eq. (4.16), $e_{\mathscr{A}}(n,\pm j)$ is some non-negative integer and $\tilde{e}_{\mathscr{A}}(n-\frac{1}{2},\pm j)$ is either 0 or 1. Hereafter, $p^{\pm j}$ [in Eq. (4.17)] is assumed to satisfy the *on-shell* condition

$$p^{+0}p^{-0}+\sum_{j=1}^{4}p^{+j}p^{-j}=-\frac{1}{2}, \tag{4.18}$$

leading to the fact that the basic tachynorial operator $t(z_0|0)$ (4.17) is the primary operator of conformal weight 1/2. On the other hand, we shall introduce the *operator* $\mathscr{P}^{-0}$ satisfying

$$\mathscr{P}^{-0}|\mathscr{A};\theta_0\rangle\equiv\mathscr{P}^{-0}_{\mathscr{A}}|\mathscr{A};\theta_0\rangle, \tag{4.19}$$

where $|\mathscr{A};\theta_0\rangle$ is the state given by Eq. (4.16) and $\mathscr{P}^{-0}_{\mathscr{A}}$ is the eigenvalue given by $\mathscr{P}^{-0}_{\mathscr{A}}\equiv p^{-0}+N_{\mathscr{A}}(p^{+0})^{-1}$ with

$$N_{\mathscr{E}} \equiv \sum_{n=1}^{\infty} \sum_{\pm} \sum_{j=1}^{4} (n \cdot e_{\mathscr{E}}(n, \pm j) + (n - \tfrac{1}{2}) \cdot \widetilde{e}_{\mathscr{E}}(n - \tfrac{1}{2}, \pm j)). \tag{4.20}$$

Therefore, we have the following mass-shell condition for the state $|\mathscr{E}; \theta_0\rangle$ (4.16);

$$p^{+0} \mathscr{P}_{\mathscr{E}}^{-0} + \sum_{j=1}^{4} p^{+j} p^{-j} = N_{\mathscr{E}} - \tfrac{1}{2}. \tag{4.21}$$

In much the same way as we have proved Eq. (2.11) in the R sector, we can prove the following *theorem* in the NS sector;

Theorem:

$$\mathbf{R} \cdot \exp\left(\sum_{n=1}^{\infty} \sum_{\pm} \sum_{j=1}^{4} \left(\frac{1}{n} \alpha_{-n}^{\mp j} \cdot A_{-n}^{\pm j} - b_{-n+1/2}^{\mp j} \cdot \mathscr{B}_{-n+1/2}^{\pm j} \right) \right) t(z_0 | \theta_0) = \widetilde{\Phi}^B(z_0, \theta_0; P_B^{\dagger}). \tag{4.22}$$

In Eq. (4.22), GFPVO $\widetilde{\Phi}^B(z_0, \theta_0; P_B^{\dagger})$ can be defined as follows: We introduce the light-cone operator $P_B^{\pm j\dagger}(w, \xi)$ in the NS sector by

$$P_B^{\pm j\dagger}(w, \xi) \equiv \frac{\xi}{w} \left(p^{\pm j} + \sum_{n=1}^{\infty} w^{-n} \alpha_{-n}^{\pm j} \right) + \frac{1}{\sqrt{w}} \left(\sum_{n=1}^{\infty} w^{-n+1/2} b_{-n+1/2}^{\pm j} \right), \tag{4.23}$$

where we have used light-cone (mode's) operators (for $j = 1-4$), i.e., $p^{\pm j}$ (total energy-momentum operator), $\alpha_m^{\pm j}$'s, $\alpha_{-n}^{\pm j}$'s, $b_{m-1/2}^{\pm j}$'s, and $b_{-n+1/2}^{\pm j}$'s, which satisfy the following (anti-)commutation relations among themselves;

$$[\alpha_m^{\pm j}, \alpha_{-n}^{\mp k}] = m \delta_{mn} \delta_{jk} \tag{4.24}$$

and

$$\{b_{m-1/2}^{\pm j}, b_{-n+1/2}^{\mp k}\} = \delta_{mn} \delta_{jk}, \tag{4.25}$$

all other (anti-)commutators being zero. Then we can define that

$$\widetilde{\Phi}^B(z_0, \theta_0; P_B^{\dagger}) \equiv :\exp(\widetilde{\rho}^{0B}(z_0, \theta_0) + \rho^{1B}(z_0, \theta_0; P_B^{\dagger}) + \rho^{2B}(z_0, \theta_0; P_B^{\dagger})):_{NS} \tag{4.26}$$

$$(\equiv \widetilde{\Phi}^{B0}(z_0; P_B^{\dagger}) + \theta_0 \widetilde{\Phi}^{B1}(z_0; P_B^{\dagger})). \tag{4.26'}$$

In Eq. (4.26), the normal ordering in the NS sector (denoted by $:\ :_{NS}$) is defined by

$$\mathbf{R} \cdot X^{\pm j}(z') X^{\mp k}(z) = \delta_{jk} \log(z' - z) + :X^{\pm j}(z') X^{\mp k}(z):_{NS} \tag{4.27}$$

and

$$\mathbf{R} \cdot \Psi^{\pm j}(z') \Psi^{\mp k}(z) = \frac{\delta_{jk}}{z' - z} + :\Psi^{\pm j}(z') \Psi^{\mp k}(z):_{NS}, \tag{4.28}$$

$\mathbf{R}$ being radial ordering. Furthermore, $\rho^{\iota B}$'s ($\iota = 0,1,2$) in Eq. (4.26) are given by

$$\widetilde{\rho}^{0B}(z_0, \theta_0) \equiv -ip^{+0} X^{-0}(z_0, \theta_0) - i\mathscr{P}^{-0} X^{+0}(z_0, \theta_0), \tag{4.29}$$

$$\rho^{1B}(z_0, \theta_0; P_B^{\dagger}) \equiv -\sum_{\pm} \sum_{j=1}^{4} i \oint \frac{dw\, d\xi}{2\pi i} P_B^{\pm j\dagger}(w, \xi) X^{\mp j}(z_B(w, \xi), \theta_B(w, \xi)) \tag{4.30}$$

and

$$\rho^{2B}(z_0,\theta_0;P_B^\dagger)\equiv-\sum_{j=1}^{4}\oint\frac{dw\ d\xi}{2\pi i}P_B^{+j^\dagger}(w,\xi)\oint\frac{dw'\ d\xi'}{2\pi i}P_B^{-j^\dagger}(w',\xi')$$
$$\times\log\frac{z_B(w,\xi)-z_B(w',\xi')-\theta_B(w,\xi)\theta_B(w',\xi')}{w-w'-\xi\xi'}. \tag{4.31}$$

In Eqs. (4.30) and (4.31), we have used

$$\theta_B(w,\xi)-\theta_0\equiv J_B(w)+\xi K_B(w) \tag{4.32}$$

and

$$z_B(w,\xi)-z_0-\theta_B(w,\xi)\theta_0\equiv L_B(w)+\xi K_B(w)J_B(w), \tag{4.33}$$

which are those to be determined by inversely solving the following superconformal mapping in the NS sector $(z_B,\theta_B)\to(w,\xi)$;

$$z_B-z_0-\theta_B\theta_0=w{:}\exp\left(\frac{X^{+0}(z_B,\theta_B)}{ip^{+0}}-\frac{X^{+0}(z_0,\theta_0)}{ip^{+0}}\right){:}_{NS} \tag{4.34}$$

and

$$\xi(z_B,\theta_B)=(\partial_{z_B}w(z_B,\theta_B))^{-1/2}D_{\theta_B}w(z_B,\theta_B), \tag{4.35}$$

with $D_{\theta_B}\equiv\partial_{\theta_B}+\theta_B\partial_{z_B}$. With the help of

$$t(z_0|\theta_0)\equiv t^0(z_0)+\theta_0 t^1(z_0) \tag{4.36}$$

Eq. (4.22) is rewritten into

$$\mathbf{R}\cdot\exp\left(\sum_{n=1}^{\infty}\sum_{\pm}\sum_{j=1}^{4}\left(\frac{1}{n}\alpha_{-n}^{\mp j}\cdot A_{-n}^{\pm j}-b_{-n+1/2}^{\mp j}\cdot\mathscr{B}_{-n+1/2}^{\pm j}\right)\right)t^m(z_0)=\widetilde{\Phi}^{Bm}(z_0;P_B^\dagger)\quad[\text{for } m=0,1]. \tag{4.37}$$

Then, we can expand $\widetilde{\Phi}^{Bm}(z_0;P_B^\dagger)$ in Eq. (4.26′) as

$$\widetilde{\Phi}^{Bm}(z_0;P_B^\dagger)\equiv\sum_{\mathscr{E}}\left(\prod_{n=1}^{\infty}\prod_{\pm}\prod_{j=1}^{4}\frac{(-i\alpha_{-n}^{\pm j}/\sqrt{n})^{e_{\mathscr{E}}(n,\pm j)}}{\sqrt{e_{\mathscr{E}}(n,\pm j)!}}(ib_{-n+1/2}^{\pm j})^{\tilde{e}_{\mathscr{E}}(n-1/2,\pm j)}\right)V^{m\mathscr{E}}(z_0)$$
$$[\text{for } m=0,1]. \tag{4.38}$$

Comparing the right-hand side of Eq. (4.38) with the left-hand side of Eq. (4.22), we find that $V^{m\mathscr{E}}(z_0)$ (for $m=0,1$) in the expansion (4.38) is just equal to

$$V^{m\mathscr{E}}(z_0)=(-)^{\mathscr{E}}\left(\prod_{n=1}^{\infty}\prod_{\pm}\prod_{j=1}^{4}\frac{(iA_{-n}^{\pm j}/\sqrt{n})^{e_{\mathscr{E}}(n,\pm j)}}{\sqrt{e_{\mathscr{E}}(n,\pm j)!}}(i.\mathscr{B}_{-n+1/2}^{\pm j})^{\tilde{e}_{\mathscr{E}}(n-1/2,\pm j)}\right)t^m(z_0), \tag{4.39}$$

where the $\pm$ sign factor $(-)^{\mathscr{E}}$ is fixed for each $|\mathscr{E};\theta_0\rangle$. Then the Neveu–Schwarz $|\mathscr{E};\theta_0\rangle$ (4.16) is given by

$$|\mathscr{E};\theta_0\rangle=(-)^{\mathscr{E}}(V^{0\mathscr{E}}(z_0)+\theta_0V^{1\mathscr{E}}(z_0))|0\rangle, \tag{4.40}$$

where $\mathscr{P}^{-0}$ is to be replaced with $\mathscr{P}_{\mathscr{E}}^{-0}$ (4.19). GSO-allowed[10] physical vertex operators $V^{0\mathscr{E}}$ in 0 picture ($V^{1\mathscr{E}}$ in 1 picture) are Grassman odd ones (Grassman even ones).

We consider the superstressino operator defined by

$$\mathscr{T}_B(z',\theta')\equiv\sum_{j=0}^{4}\sum_{\pm}:\frac{1}{2}\partial_{z'}X^{\pm j}(z',\theta')\cdot D_{\theta'}X^{\mp j}(z',\theta'):_{NS} \tag{4.41}$$

$$\equiv\tfrac{1}{2}\mathscr{T}_B(z')+\theta' T_B(z'). \tag{4.41'}$$

[The notation $\mathscr{T}_B(z',\theta')$ denoting the superstressino operator in the NS sector will be used instead of the notation $T_B(z',\theta')$ in Ref. 4.] From Eqs. (4.17) and (4.36), we can easily find the following OPE valid even in the off-shell case; With respect to the stress operator $T_B(z')$ (4.41′), we can easily find that

$$\mathbf{R}\cdot T_B(z')\cdot t^m(z_0)=\frac{\frac{1}{2}\delta_{m1}-(p^{+0}p^{-0}+\Sigma_{j=1}^{4}p^{+j}p^{-j})}{(z'-z_0)^2}\cdot t^m(z_0)+\frac{1}{z'-z_0}\partial_{z_0}t^m(z_0)+\mathrm{O}(1)$$

$$[\text{for } m=0,1]. \tag{4.42}$$

Applying OPE's (4.42) to the left-hand side of (4.37), and taking account of the mass relation (4.21) and invariance of $A_{-n}^{\pm j}$ (2.1) and $\mathscr{B}_{-n+1/2}^{\pm j}$ (4.1) under the super-Virasoro algebra (in the NS sector), we find that

$$\mathbf{R}\cdot T_B(z')\widetilde{\Phi}^{Bm}(z_0;P_B^\dagger)=\frac{1}{(z'-z_0)^2}\left(\left(\frac{1}{2}\delta_{m1}-p^{+0}\mathscr{P}^{-0}-\sum_{j=1}^{4}p^{+j}p^{-j}\right)\widetilde{\Phi}^{Bm}(z_0;P_B^\dagger)\right.$$

$$\left.+[N_B,\widetilde{\Phi}^{Bm}(z_0;P_B^\dagger)]\right)+\frac{1}{z'-z_0}\partial_{z_0}\widetilde{\Phi}^{Bm}(z_0;P_B^\dagger)+(\text{terms regular at } z'$$

$$=z_0)\quad[\text{for } m=0,1]. \tag{4.43}$$

In Eq. (4.43), we have used the light-cone number operator N_B defined by

$$N_B\equiv\sum_{n=1}^{\infty}\sum_{\pm}\sum_{k=1}^{4}(\alpha_{-n}^{\mp k}\alpha_n^{\pm k}+(n-\tfrac{1}{2})b_{-n+1/2}^{\mp k}b_{n-1/2}^{\pm k}) \tag{4.44}$$

and $\widetilde{\Phi}^{B0(1)}(z_0;P_B^\dagger)$ is the one defined by Eq. (4.26′). On the other hand, we find with respect to the stressino operator $\mathscr{T}_B(z')$ (4.41′) that

$$\mathbf{R}\cdot\mathscr{T}_B(z')\cdot t^0(z_0)=\frac{1}{z'-z_0}\partial_{z_0}t^1(z_0)+O(1) \tag{4.45}$$

and

$$\mathbf{R}\cdot\mathscr{T}_B(z')\cdot t^1(z_0)=\frac{-2(p^{+0}p^{-0}+\Sigma_{j=1}^{4}p^{+j}p^{-j})}{(z'-z_0)^2}\cdot t^0(z_0)+\frac{1}{z'-z_0}\partial_{z_0}t^0(z_0)+O(1). \tag{4.46}$$

Applying OPE's (4.45) and (4.46) to the left-hand side of (4.22), and taking account of the mass relation (4.21) and invariance of $A_{-n}^{\pm j}$ (2.1) and $\mathscr{B}_{-n+1/2}^{\pm j}$ (4.1) under the super-Virasoro algebra (in the NS sector), we find that

$$\mathbf{R}\cdot\mathscr{T}_B(z')\widetilde{\Phi}^{B0}(z_0;P_B^\dagger)=\frac{1}{z'-z_0}\widetilde{\Phi}^{B1}(z_0;P_B^\dagger)+(\text{terms regular at } z'=z_0) \tag{4.47}$$

and

$$\mathbf{R}\cdot\mathscr{T}_B(z')\widetilde{\Phi}^{B1}(z_0;P_B^\dagger)=\frac{2}{(z'-z_0)^2}\left(\left(-p^{+0}\mathscr{P}^{-0}-\sum_{j=1}^{4}p^{+j}p^{-j}\right)\widetilde{\Phi}^{B0}(z_0;P_B^\dagger)\right.$$
$$\left.+[N_B,\widetilde{\Phi}^{B0}(z_0;P_B^\dagger)]\right)+\frac{1}{z'-z_0}\partial_{z_0}\widetilde{\Phi}^{B0}(z_0;P_B^\dagger)$$
$$+(\text{terms regular at } z'=z_0). \tag{4.48}$$

APPENDIX A: PROOF OF (ANTI-)COMMUTATION RELATIONS (2.3) AND (2.4)

The *physical* operator $A_{-n}^{\pm j}$ (2.1) for any integer n is similar to the one (in the NS sector) introduced by Schwarz,[9] while we introduce in the R sector the *physical* operator $\mathscr{D}_{-n}^{\pm j}$ (2.2) for any integer n. [We notice that Schwarz introduced in the NS sector the *physical* operator $\mathscr{B}_{-n+1/2}^{\pm j}$ (4.1) for any integer n.] In the following, we shall prove (anti-)commutation relations (2.3) and (2.4) in the R sector by using the normal ordering and contractions in the R sector.[4]

We shall prove the last anti-commutation relation in Eq. (2.3) as an example. With the help of the contraction in the R sector given by[4]

$$\overbrace{X^{\pm j}(z,\theta)X^{\mp k}(z',\theta')}^{R}=\delta_{jk}\left(\log(z-z')-\frac{\theta\theta'}{z-z'}\left(\frac{z'-z_0}{z-z_0}\right)^{\mp\varepsilon_h^j}\right),$$

we find that

$$\overbrace{D_\theta^m X^{\pm j}(z,\theta)X^{\mp k}(z',\theta')}^{R}=\delta_{jk}D_\theta^m\log(z-z'-\theta\theta')$$
$$+\ (\text{terms regular at } z=z')\quad[\text{for } m=1,2]. \tag{A1}$$

Therefore we obtain that

$$\{\mathscr{D}_n^{\pm j},\mathscr{D}_{-m}^{\mp k}\}=\oint_{|z|>|z_0|}\frac{dz\,d\theta}{2\pi i}\oint_z\frac{dz'\,d\theta'}{2\pi i}\overbrace{D_\theta X^{\pm j}(z,\theta)D_{\theta'}X^{\mp k}(z',\theta')}^{R}$$
$$\times\frac{D_\theta[X^{+0}(z,\theta)/ip^{+0}]}{(-\partial_z[X^{+0}(z,\theta)/ip^{+0}])^{1/2}}\cdot\exp\left(\frac{-nX^{+0}(z,\theta)}{ip^{+0}}\right)$$
$$\times\frac{D_{\theta'}[X^{+0}(z',\theta')/ip^{+0}]}{(-\partial_{z'}[X^{+0}(z',\theta')/ip^{+0}])^{1/2}}\cdot\exp\left(\frac{mX^{+0}(z',\theta')}{ip^{+0}}\right)$$
$$=\delta_{jk}\oint_{|z|>|z_0|}\frac{dz\,d\theta}{2\pi i}\oint_z\frac{dz'\,d\theta'}{2\pi i}\frac{-1}{z'-z-\theta'\theta}$$
$$\times\frac{D_\theta[X^{+0}(z,\theta)/ip^{+0}]}{(-\partial_z[X^{+0}(z,\theta)/ip^{+0}])^{1/2}}\cdot\exp\left(\frac{-nX^{+0}(z,\theta)}{ip^{+0}}\right)$$
$$\times(\theta'-\theta)D_\theta\left(\frac{D_\theta[X^{+0}(z,\theta)/ip^{+0}]}{(-\partial_z[X^{+0}(z,\theta)/ip^{+0}])^{1/2}}\cdot\exp\left(\frac{mX^{+0}(z,\theta)}{ip^{+0}}\right)\right)$$
$$=-\delta_{jk}\oint_{|z|>|z_0|}\frac{dz\,d\theta}{2\pi i}D_\theta\frac{X^{+0}(z,\theta)}{ip^{+0}}\cdot\exp\left(\frac{(-n+m)X^{+0}(z,\theta)}{ip^{+0}}\right)$$
$$=\begin{cases}-\dfrac{1}{-n+m}\delta_{jk}\displaystyle\oint_{|z|>|z_0|}\frac{dz\,d\theta}{2\pi i}D_\theta\exp\left(\frac{(-n+m)X^{+0}(z,\theta)}{ip^{+0}}\right)=0 & [\text{for } -n+m\neq 0]\\ -\delta_{jk}\displaystyle\oint_{|z|>|z_0|}\frac{dz\,d\theta}{2\pi i}D_\theta\frac{X^{+0}(z,\theta)}{ip^{+0}}=\delta_{jk} & [\text{for } -\text{n}+\text{m}=0]\end{cases} \tag{A2}$$

(Q.E.D.)

As for Eq. (2.4), we first notice that the superstressino operator $\mathscr{T}_F(z',\theta')$ (normally ordered in the R sector) is given by

$$\mathscr{T}_F(z',\theta')\left(\equiv\frac{1}{2}\,\mathscr{T}_F(z')+\theta' T_F(z')\right)=\sum_{m=1}^{2}\sum_{j=0}^{4}:\frac{1}{2}\,D_{\theta'}^{3-m}X^{-j}(z',\theta')\cdot D_{\theta'}^{m}X^{+j}(z',\theta'):_R \tag{A3}$$

with

$$T_F(z')\equiv\frac{1}{(z'-z_0)z'}\left(\sum_{n=-\infty}^{\infty}L_n^F(z_0)z'^{-n}\right) \tag{A4}$$

and

$$\mathscr{T}_F(z')\equiv\frac{1}{(z'-z_0)^{1/2}z'}\left(\sum_{n=-\infty}^{\infty}\mathscr{T}_n^F(z_0)z'^{-n}\right). \tag{A5}$$

[Hereafter, we shall use the notation $\mathscr{T}_F(z',\theta')$ (instead of the notation $T_F(z',\theta')$ used in Ref. 4), in order to indicate that it is Grassman odd.] In the following, we shall prove that

$$[A_n^{+j},\mathscr{T}_F(z',\theta')]=0 \tag{A6}$$

and

$$\{\mathscr{D}_n^{+j}(z_0),\mathscr{T}_F(z',\theta')\}=0. \tag{A7}$$

Proof: First, we notice that

$$\begin{aligned}
&\overbrace{\sum_{m=1}^{2}X^{+j}(z,\theta)(D_{\theta'}^{3-m}X^{-j}(z',\theta')\cdot D_{\theta'}^{m}X^{+j}(z',\theta'))}^{R}\\
&=\overbrace{X^{+j}(z,\theta)(\partial_{z'}X^{-j}(z',\theta')D_{\theta'}X^{+j}(z',\theta'))}^{R}\\
&\quad+\overbrace{X^{+j}(z,\theta)(D_{\theta'}X^{-j}(z',\theta')\partial_{z'}X^{+j}(z',\theta'))}^{R}\\
&=\partial_{z'}\log\left(z-z'-\theta\theta'\left(\frac{z-z_0}{z'-z_0}\right)^{+\varepsilon_h^j}\right)\cdot D_{\theta'}X^{+j}(z',\theta')\\
&\quad+D_{\theta'}\log\left(z-z'-\theta\theta'\left(\frac{z-z_0}{z'-z_0}\right)^{+\varepsilon_h^j}\right)\cdot\partial_{z'}X^{+j}(z',\theta')\\
&\equiv\sum_{m=1}^{2}D_{\theta'}^{3-m}\log\left(z-z'-\theta\theta'\left(\frac{z-z_0}{z'-z_0}\right)^{+\varepsilon_h^j}\right)\cdot D_{\theta'}^{m}X^{+j}(z',\theta').
\end{aligned} \tag{A8}$$

Then, we find that

$$
\begin{aligned}
&i2[A_n^{+j}, \mathscr{F}_F(z',\theta')] \\
&= \sum_{m=1}^{2} \oint_{z'} \frac{dz\, d\theta}{2\pi i} : D_\theta X^{+j}(z,\theta) \exp\left(\frac{-nX^{+0}(z,\theta)}{ip^{+0}}\right) \\
&\qquad \overbrace{\qquad\qquad R \qquad\qquad} \\
&\quad \times \left(\frac{-nX^{+0}(z,\theta)}{ip^{+0}}\right) D_{\theta'}^{3-m} X^{-0}(z',\theta') \cdot D_{\theta'}^{m} X^{+0}(z',\theta') :_R \\
&\quad - \sum_{m=1}^{2} \oint_{z'} \frac{dz\, d\theta}{2\pi i} : D_\theta X^{+0}(z,\theta) \exp\left(\frac{-nX^{+0}(z,\theta)}{ip^{+0}}\right) \\
&\qquad \overbrace{\qquad\qquad R \qquad\qquad} \\
&\quad \times \left(\frac{-nX^{+j}(z,\theta)}{ip^{+0}}\right) D_{\theta'}^{3-m} X^{-j}(z',\theta') \cdot D_{\theta'}^{m} X^{+j}(z',\theta') :_R = 0,
\end{aligned}
\tag{A9}
$$

where we have used Eq. (A1). On the other hand, we notice that

$$
i2\{\mathscr{D}_n^{+j}, \mathscr{F}_F(z',\theta')\} = \sum_{m=1}^{4} H_m, \tag{A10}
$$

where H_m's $(m=1-4)$ are, respectively, given by

$$
\begin{aligned}
H_1 = \sum_{m=1}^{2} \oint_{z'} \frac{dz\, d\theta}{2\pi i} : &\left(D_\theta X^{+j}(z,\theta) \frac{D_\theta [X^{+0}(z,\theta)/ip^{+0}]}{(-\partial_z [X^{+0}(z,\theta)/ip^{+0}])^{1/2}} \right. \\
&\overbrace{\qquad\qquad R \qquad\qquad} \\
&\left. \times \exp\left(\frac{-nX^{+0}(z,\theta)}{ip^{+0}}\right)\right) \left(\frac{-nX^{+0}(z,\theta)}{ip^{+0}}\right) D_{\theta'}^{3-m} X^{-0}(z',\theta') \cdot D_{\theta'}^{m} X^{+0}(z',\theta') :_R ,
\end{aligned}
\tag{A11}
$$

$$
\begin{aligned}
H_2 = \sum_{m=1}^{2} \oint_{z'} \frac{dz\, d\theta}{2\pi i} : &\left(D_\theta X^{+j}(z,\theta) \frac{1}{(-\partial_z [X^{+0}(z,\theta)/ip^{+0}])^{1/2}} \right. \\
&\overbrace{\qquad\qquad R \qquad\qquad} \\
&\left. \times \exp\left(\frac{-nX^{+0}(z,\theta)}{ip^{+0}}\right)\right) D_\theta \frac{X^{+0}(z,\theta)}{ip^{+0}} \cdot D_{\theta'}^{3-m} X^{-0}(z',\theta') \cdot D_{\theta'}^{m} X^{+0}(z',\theta') :_R ,
\end{aligned}
\tag{A12}
$$

$$
\begin{aligned}
H_3 = \sum_{m=1}^{2} \oint_{z'} \frac{dz\, d\theta}{2\pi i} : &\left(D_\theta X^{+j}(z,\theta) \frac{\frac{1}{2} D_\theta [X^{+0}(z,\theta)/ip^{+0}]}{(-\partial_z [X^{+0}(z,\theta)/ip^{+0}])^{3/2}} \right. \\
&\overbrace{\qquad\qquad R \qquad\qquad} \\
&\left. \cdot \exp\left(\frac{-nX^{+0}(z,\theta)}{ip^{+0}}\right)\right) \partial_z \frac{X^{+0}(z,\theta)}{ip^{+0}} \cdot D_{\theta'}^{3-m} X^{-0}(z',\theta') \cdot D_{\theta'}^{m} X^{+0}(z',\theta') :_R
\end{aligned}
\tag{A13}
$$

and

$$
\begin{aligned}
H_4 = -\sum_{m=1}^{2} \oint_{z'} \frac{dz\, d\theta}{2\pi i} : &\left(\frac{D_\theta [X^{+0}(z,\theta)/ip^{+0}]}{(-\partial_z [X^{+0}(z,\theta)/ip^{+0}])^{1/2}} \right. \\
&\overbrace{\qquad\qquad R \qquad\qquad} \\
&\left. \times \exp\left(\frac{-nX^{+0}(z,\theta)}{ip^{+0}}\right)\right) D_\theta X^{+j}(z,\theta) D_{\theta'}^{3-m} X^{-j}(z',\theta') \cdot D_{\theta'}^{m} X^{+j}(z',\theta') :_R ,
\end{aligned}
\tag{A14}
$$

Then we obtain that

$$H_1=\sum_{m=1}^{2}-n(-)^m:D_{\theta'}^{2-m}\Bigg(D_{\theta'}\,\frac{X^{+j}(z',\theta')}{ip^{+0}}\cdot\frac{D_{\theta'}[X^{+0}(z',\theta')/ip^{+0}]}{(-\partial_{z'}[X^{+0}(z',\theta')/ip^{+0}])^{1/2}}\exp\Bigg(\frac{-nX^{+0}(z',\theta')}{ip^{+0}}\Bigg)\Bigg)D_{\theta'}^{m}X^{+0}(z',\theta'):_R \tag{A15}$$

$$H_2=\sum_{m=1}^{2}(-)^m:D_{\theta'}^{3-m}\Bigg(\frac{D_{\theta'}[X^{+j}(z',\theta')/ip^{+0}]}{(-\partial_{z'}[X^{+0}(z',\theta')/ip^{+0}])^{1/2}}\exp\Bigg(\frac{-nX^{+0}(z',\theta')}{ip^{+0}}\Bigg)\Bigg)D_{\theta'}^{m}X^{+0}(z',\theta'):_R \tag{A16}$$

$$H_3=-\sum_{m=1}^{3}(-)^m:D_{\theta'}^{4-m}\Bigg(D_{\theta'}\,\frac{X^{+j}(z',\theta')}{ip^{+0}}\cdot\frac{\frac{1}{2}D_{\theta'}[X^{+0}(z',\theta')/ip^{+0}]}{(-\partial_{z'}[X^{+0}(z',\theta')/ip^{+0}])^{3/2}}\exp\Bigg(\frac{-nX^{+0}(z',\theta')}{ip^{+0}}\Bigg)\Bigg)D_{\theta'}^{m}X^{+0}(z',\theta'):_R \tag{A17}$$

and

$$H_4=-\sum_{m=1}^{2}(-)^m:D_{\theta'}^{3-m}\times\Bigg(\frac{D_{\theta'}[X^{+0}(z',\theta')/ip^{+0}]}{(-\partial_{z'}[X^{+0}(z',\theta')/ip^{+0}])^{1/2}}\exp\Bigg(\frac{-nX^{+0}(z',\theta')}{ip^{+0}}\Bigg)\Bigg)D_{\theta'}^{m}X^{+j}(z',\theta'):_R. \tag{A18}$$

By straightforward calculations, we find that

$$\sum_{m=1}^{4}H_m=0 \tag{A19}$$

with the help of the following formula:

$$\begin{aligned}
&\partial_{z'}D_{\theta'}\Bigg(\frac{D_{\theta'}[X^{+0}(z',\theta')/ip^{+0}]}{(-\partial_{z'}[X^{+0}(z',\theta')/ip^{+0}])^{3/2}}\cdot\exp\Bigg(\frac{-nX^{+0}(z',\theta')}{ip^{+0}}\Bigg)\Bigg)\cdot D_{\theta'}\,\frac{X^{+0}(z',\theta')}{ip^{+0}}\\
&=\partial_{z'}D_{\theta'}\Bigg(\frac{D_{\theta'}[X^{+0}(z',\theta')/ip^{+0}]}{(-\partial_{z'}[X^{+0}(z',\theta')/ip^{+0}])^{3/2}}\cdot\exp\Bigg(\frac{-nX^{+0}(z',\theta')}{ip^{+0}}\Bigg)\cdot D_{\theta'}\,\frac{X^{+0}(z',\theta')}{ip^{+0}}\Bigg)\\
&\quad-\partial_{z'}\Bigg(\frac{D_{\theta'}[X^{+0}(z',\theta')/ip^{+0}]}{(-\partial_{z'}[X^{+0}(z',\theta')/ip^{+0}])^{3/2}}\cdot\exp\Bigg(\frac{-nX^{+0}(z',\theta')}{ip^{+0}}\Bigg)\Bigg)\cdot\partial_{z'}\,\frac{X^{+0}(z',\theta')}{ip^{+0}}\\
&\quad+D_{\theta'}\Bigg(\frac{D_{\theta'}[X^{+0}(z',\theta')/ip^{+0}]}{(-\partial_{z'}[X^{+0}(z',\theta')/ip^{+0}])^{3/2}}\cdot\exp\Bigg(\frac{-nX^{+0}(z',\theta')}{ip^{+0}}\Bigg)\Bigg)\cdot\partial_{z'}D_{\theta'}\,\frac{X^{+0}(z',\theta')}{ip^{+0}}\\
&\quad-\Bigg(\frac{D_{\theta'}[X^{+0}(z',\theta')/ip^{+0}]}{(-\partial_{z'}[X^{+0}(z',\theta')/ip^{+0}])^{3/2}}\cdot\exp\Bigg(\frac{-nX^{+0}(z',\theta')}{ip^{+0}}\Bigg)\Bigg)\cdot\partial_{z'}^{2}\,\frac{X^{+0}(z',\theta')}{ip^{+0}}.
\end{aligned}\tag{A20}$$

It should be noticed that the first term on the right-hand side of Eq. (A20) vanishes identically. (Q.E.D.)

APPENDIX B: SOME EXPLICIT FORMULAS IN THE *R* SECTOR

Functions $R_m^{(n)}(z_0)$'s and $R_m^{(n+1/2)}(z_0)$'s in Eq. (1.23) can be calculated, respectively, by using recursive relations

$$R_0^{(n)}(z_0)=1 \quad \text{and} \quad R_{m+1}^{(n)}(z_0)=\frac{1}{m+1}\,(\partial_{z_0}+nI_1)R_m^{(n)}(z_0), \tag{B1}$$

and

$$R_0^{(n+1/2)}(z_0)=1 \quad \text{and} \quad R_{m+1}^{(n+1/2)}(z_0)=\frac{1}{m+1}\,(\partial_{z_0}+(n+1/2)I_1)R_m^{(n+1/2)}(z_0), \tag{B1$'$}$$

in terms of

$$I_m\equiv\partial_{z_0}^m I(z_0) \quad \text{and} \quad I_m^n\equiv(I_m)^n \quad \text{with Eq. (1.22).} \tag{B2}$$

With the help of Eq. (B1), we find that

$$\begin{pmatrix} R_1^{(1)} \\ R_1^{(2)} \\ R_1^{(3)} \end{pmatrix}=\begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix} I_1, \tag{B3}$$

$$\begin{pmatrix} R_2^{(1)} \\ R_2^{(2)} \\ R_2^{(3)} \end{pmatrix}=\begin{pmatrix} \frac{1}{2} \\ 2 \\ \frac{9}{2} \end{pmatrix} I_1^2+\begin{pmatrix} \frac{1}{2} \\ 1 \\ \frac{3}{2} \end{pmatrix} I_2, \tag{B4}$$

$$\begin{pmatrix} R_3^{(1)} \\ R_3^{(2)} \\ R_3^{(3)} \end{pmatrix}=\begin{pmatrix} \frac{1}{6} \\ \frac{4}{3} \\ \frac{9}{2} \end{pmatrix} I_1^3+\begin{pmatrix} \frac{1}{2} \\ 2 \\ \frac{9}{2} \end{pmatrix} I_1I_2+\begin{pmatrix} \frac{1}{6} \\ \frac{1}{3} \\ \frac{1}{2} \end{pmatrix} I_3, \tag{B5}$$

and

$$\begin{pmatrix} R_4^{(1)} \\ R_4^{(2)} \\ R_4^{(3)} \end{pmatrix}=\begin{pmatrix} \frac{1}{24} \\ \frac{2}{3} \\ \frac{27}{8} \end{pmatrix} I_1^4+\begin{pmatrix} \frac{1}{4} \\ 2 \\ \frac{27}{4} \end{pmatrix} I_1^2I_2+\begin{pmatrix} \frac{1}{6} \\ \frac{2}{3} \\ \frac{3}{2} \end{pmatrix} I_1I_3+\begin{pmatrix} \frac{1}{8} \\ \frac{1}{2} \\ \frac{9}{8} \end{pmatrix} I_2^2+\begin{pmatrix} \frac{1}{24} \\ \frac{1}{12} \\ \frac{1}{8} \end{pmatrix} I_4, \tag{B6}$$

while we have from Eq. (B1$'$) that

$$\begin{pmatrix} R_1^{(1/2)} \\ R_1^{(1/2+1)} \\ R_2^{(1/2+2)} \end{pmatrix}=\begin{pmatrix} \frac{1}{2} \\ \frac{3}{2} \\ \frac{5}{2} \end{pmatrix} I_1 \tag{B7}$$

and

$$\begin{pmatrix} R_2^{(1/2)} \\ R_2^{(1/2+1)} \\ R_2^{(1/2+2)} \end{pmatrix}=\begin{pmatrix} \frac{1}{8} \\ \frac{9}{8} \\ \frac{25}{8} \end{pmatrix} I_1^2+\begin{pmatrix} \frac{1}{4} \\ \frac{3}{4} \\ \frac{5}{4} \end{pmatrix} I_2. \tag{B8}$$

Substituting Eqs. (B3)–(B8) into Eqs. (3.14) and (3.15) we find that

$$\begin{aligned} A_N^F(w,w')=&\,w(I_1+\theta_0V_1)+w'I_1+w^2(I_1^2+\tfrac{1}{2}I_2+\theta_0(V_2+2I_1V_1))+w'^2(I_1^2+\tfrac{1}{2}I_2)+ww'(\tfrac{1}{2}I_1^2+\tfrac{1}{2}I_2 \\ &+\theta_0(V_2+I_1V_1))+w^3(\tfrac{3}{2}I_1^3+\tfrac{3}{2}I_1I_2+\tfrac{1}{6}I_3+\theta_0(V_3+3I_1V_2+(\tfrac{9}{2}I_1^2+\tfrac{3}{2}I_2)V_1)) \\ &+w^2w'(\tfrac{2}{3}I_1^3+I_1I_2+\tfrac{1}{6}I_3+V_1V_2+\theta_0(V_3+3I_1V_2+2I_1^2V_1))+ww'^2(\tfrac{2}{3}I_1^3+I_1I_2+\tfrac{1}{6}I_3 \\ &+\theta_0(V_3+2I_1V_2+(2I_1^2+I_2)V_1))+w'^3(\tfrac{3}{2}I_1^3+\tfrac{3}{2}I_1I_2+\tfrac{1}{6}I_3)+\cdots \end{aligned} \tag{B9}$$

and

$$\log \frac{L_{NF}(w)}{w} = wI_1 + w^2(I_1^2 + \tfrac{1}{2}I_2) + w^3(\tfrac{3}{2}I_1^3 + \tfrac{3}{2}I_1I_2 + \tfrac{1}{6}I_3) + \cdots . \tag{B10}$$

Furthermore, Eqs. (3.19) and (3.20) together with Eqs. (B3)–(B8) give

$$\begin{aligned}\Gamma_N^{F2}(w,w') &= w'^{-1/2}\theta_0 + ww'^{-1/2}(V_1 + \theta_0 I_1) + w'^{-1/2+1}(V_1 + \tfrac{1}{2}\theta_0 I_1) + w^2 w'^{-1/2}(V_2 + 2I_1V_1 \\ &\quad + \theta_0(2I_1^2 + 2I_2)) + ww'^{-1/2+1}(V_2 + \tfrac{1}{2}I_1V_1 + \theta_0(\tfrac{1}{2}I_1^2 + I_2)) \\ &\quad + w^3 w'^{-1/2}(V_3 + 3I_1V_2 + (\tfrac{9}{2}I_1^2 + \tfrac{3}{2}I_2)V_1 + \theta_0(\tfrac{9}{2}I_1^3 + \tfrac{9}{2}I_1I_2 + \tfrac{1}{2}I_3)) \\ &\quad + w^2 w'^{-1/2+1}(V_3 + \tfrac{3}{2}I_1V_2 + (I_1^2 + I_2)V_1 + \theta_0(I_1^3 + \tfrac{5}{2}I_1I_2 + \tfrac{1}{2}I_3)) \\ &\quad + ww'^{-1/2+2}(V_3 + \tfrac{3}{2}I_1V_2 + (\tfrac{9}{8}I_1^2 + \tfrac{1}{4}I_2)V_1 + \theta_0(\tfrac{9}{4}I_1^3 + \tfrac{9}{4}I_1I_2 + \tfrac{1}{2}I_3)) \\ &\quad + w'^{-1/2+3}(V_3 + \tfrac{5}{2}I_1V_2 + (\tfrac{25}{8}I_1^2 + \tfrac{5}{4}I_2)V_1 + \theta_0(\tfrac{128}{48}I_1^3 + \tfrac{75}{24}I_1I_2 + \tfrac{5}{12}I_3)) + \cdots ,\end{aligned} \tag{B11}$$

while Eqs. (3.22) and (3.23) together with Eqs. (B3)–(B8) give

$$\begin{aligned}\Gamma_N^{F1}(w,w') &= w^{-1/2+1}(V_1 + \theta_0 I_1) + w^{-1/2+1}w'(V_2 + I_1V_1 + \theta_0(I_1^2 + I_2)) + w^{-1/2+2}(V_2 + \tfrac{3}{2}I_1V_1 \\ &\quad + \theta_0(\tfrac{3}{2}I_1^2 + I_2)) + w^{-1/2+1}w'^2(V_3 + 2I_1V_2 + (2I_1^2 + I_2)V_1 + \theta_0(2I_1^3 + 3I_1I_2 + \tfrac{1}{2}I_3)) \\ &\quad + w^{-1/2+2}w'(V_3 + \tfrac{3}{2}I_1V_2 + (I_1^2 + \tfrac{1}{2}I_2)V_1 + \theta_0(\tfrac{5}{12}I_1^3 + \tfrac{3}{4}I_1I_2 + \tfrac{1}{6}I_3)) \\ &\quad + w^{-1/2+3}(V_3 + \tfrac{5}{2}I_1V_2 + (\tfrac{29}{8}I_1^2 + \tfrac{5}{4}I_2)V_1 + \theta_0(\tfrac{25}{8}I_1^3 + \tfrac{15}{4}I_1I_2 + \tfrac{1}{2}I_3)) + \cdots .\end{aligned} \tag{B12}$$

Then we have from Eqs. (3.6)–(3.8), (B9), and (B10) that

$$\begin{aligned}\left(\frac{w}{w'}\right)^{1/2} C_N^F(w,w') &= w^{-1/2+1}w'^{-1/2}(\tfrac{1}{2}I_1 - \tfrac{1}{2}\theta_0 V_1) + w^{-1/2+2}w'^{-1/2}((\tfrac{7}{8}I_1^2 + \tfrac{1}{2}I_2) - \tfrac{3}{4}\theta_0 I_1V_1) \\ &\quad + w^{-1/2+1}w'^{-1/2+1}(\tfrac{1}{8}I_1^2 - \theta_0(V_2 + \tfrac{5}{4}I_1V_1)) + w^{-1/2+3}w'^{-1/2}(\tfrac{5}{6}I_1^3 + \tfrac{15}{8}I_1I_2 \\ &\quad + \tfrac{1}{4}I_3 + \tfrac{1}{2}V_1V_2 + \theta_0(\tfrac{1}{2}V_3 + \tfrac{3}{4}I_1V_2 - (I_1^2 + \tfrac{3}{8}I_2)V_1)) + w^{-1/2+2}w'^{-1/2+1} \\ &\quad \times(\tfrac{3}{4}I_1^3 + \tfrac{3}{4}I_1I_2 + \tfrac{1}{12}I_3 - \tfrac{1}{2}V_1V_2 - \theta_0(\tfrac{1}{2}V_3 + 2I_1V_2 + (\tfrac{9}{4}I_1^2 + \tfrac{1}{4}I_2)V_1)) \\ &\quad + w^{-1/2+1}w'^{-1/2+2}(-\tfrac{1}{6}I_1^3 - \tfrac{3}{8}I_1I_2 - \tfrac{1}{12}I_3 - \tfrac{1}{2}V_1V_2 - \theta_0(\tfrac{3}{2}V_3 + \tfrac{15}{4}I_1V_2 \\ &\quad + (\tfrac{7}{2}I_1^2 + \tfrac{9}{8}I_2)V_1)) + \cdots .\end{aligned} \tag{B13}$$

Then the function $K_{NF}(w)$ is evaluated by Eqs. (3.9) and (B9) as

$$\begin{aligned}K_{NF}(w) &= 1 + w(I_1 + \tfrac{1}{2}\theta_0 V_1) + w^2(\tfrac{7}{4}I_1^2 + \tfrac{3}{4}I_2 + \theta_0(V_2 + 2I_1V_1)) + w^3(\tfrac{43}{12}I_1^3 + \tfrac{13}{4}I_1I_2 + \tfrac{1}{3}I_3 + \tfrac{1}{2}V_1V_2 \\ &\quad + \theta_0(\tfrac{3}{2}V_3 + 5I_1V_2 + (\tfrac{53}{8}I_1^2 + \tfrac{13}{8}I_2)V_1)) + \cdots .\end{aligned} \tag{B14}$$

We find from Eqs. (B11) and (B14) that

$$\begin{aligned}\Gamma_N^{F2}(w,w')K_{NF}(w') &= w'^{-1/2}\theta_0 + ww'^{-1/2}(V_1 + \theta_0 I_1) + w'^{-1/2+1}(V_1 + \tfrac{3}{2}\theta_0 I_1) + w^2 w'^{-1/2}(V_2 \\ &\quad + 2I_1V_1 + \theta_0(2I_1^2 + 2I_2)) + ww'^{-1/2+1}(V_2 + \tfrac{3}{2}I_1V_1 + \theta_0(\tfrac{3}{2}I_1^2 + I_2)) \\ &\quad + w'^{-1/2+2}(V_2 + \tfrac{3}{2}I_1V_1 + \theta_0(\tfrac{11}{4}I_1^2 + \tfrac{7}{4}I_2)) + w^3 w'^{-1/2}(V_3 + 3I_1V_2 + (\tfrac{9}{2}I_1^2 \\ &\quad + \tfrac{3}{2}I_2)V_1 + \theta_0(\tfrac{9}{2}I_1^3 + \tfrac{9}{2}I_1I_2 + \tfrac{1}{2}I_3)) + w^2 w'^{-1/2+1}(V_3 + \tfrac{5}{2}I_1V_2 + (I_1^2 + I_2)V_1\end{aligned}$$

$$+\theta_0(\tfrac{5}{2}I_1^3+\tfrac{9}{2}I_1I_2+\tfrac{1}{2}I_3+\tfrac{1}{2}N_1N_2))+ww'^{-1/2+2}(V_3+\tfrac{3}{2}I_1V_2+(\tfrac{9}{8}I_1^2+\tfrac{1}{4}I_2)V_1$$
$$+\theta_0(\tfrac{9}{4}I_1^3+\tfrac{9}{4}I_1I_2+\tfrac{1}{2}I_3))+w'^{-1/2+3}(V_3+\tfrac{7}{2}I_1V_2+(\tfrac{39}{8}I_1^2+2I_2)V_1$$
$$+\theta_0(\tfrac{121}{16}I_1^3+\tfrac{31}{4}I_1I_2+\tfrac{1}{3}I_3))+\cdots, \tag{B15}$$

while Eqs. (B12) and (B14) lead to

$$\Gamma_N^{F1}(w,w')K_{NF}(w)=w^{-1/2+1}(V_1+\theta_0I_1)+w^{-1/2+1}w'(V_2+I_1V_1+\theta_0(I_1^2+I_2))+w^{-1/2+2}(V_2$$
$$+\tfrac{5}{2}I_1V_1+\theta_0(\tfrac{5}{2}I_1^2+I_2))+w^{-1/2+1}w'^2(V_3+2I_1V_2+(2I_1^2+I_2)V_1+\theta_0(2I_1^3$$
$$+3I_1I_2+\tfrac{1}{2}I_3))+w^{-1/2+2}w'(V_3+\tfrac{5}{2}I_1V_2+(2I_1^2+\tfrac{1}{2}I_2)V_1$$
$$+\theta_0(\tfrac{17}{12}I_1^3+\tfrac{7}{4}I_1I_2+\tfrac{1}{6}I_3+\tfrac{1}{2}V_1V_2))+w^{-1/2+3}(V_3+\tfrac{7}{2}I_1V_2+(\tfrac{63}{4}I_1^2+2I_2)V_1$$
$$+\theta_0(\tfrac{121}{16}I_1^3+\tfrac{31}{4}I_1I_2+\tfrac{1}{3}I_3))+\cdots. \tag{B16}$$

Moreover, with the help of Eq. (B14), we find that

$$[X^{\mp j}(z_{NF})]_{\xi=0}=X^{\mp j}(z_0)+\sum_{n=1}^{\infty}w^n\left(\sum_{k=0}^{n}\frac{k}{n}\cdot R_{n-k}^{(n)}(z_0)X_k^{\mp j}\right)$$
$$=X_0^{\mp j}+wX_1^{\mp j}+w^2(X_2^{\mp j}+I_1X_1^{\mp j})+\cdots, \tag{B17}$$

$$K_{NF}(w)[\theta_{NF}\partial_{z_{NF}}X^{\mp j}(z_{NF})]_{\xi=0}=K_{NF}(w)\sum_{n=0}^{\infty}w^{n+1/2}\left(\theta_0\left(\sum_{k=0}^{n}(k+1)R_{n-k}^{(n+1/2)}(z_0)X_{k+1}^{\mp j}\right)\right.$$
$$\left.+\sum_{k=1}^{n}R_{n-k}^{(n+1/2)}(z_0)\left(\sum_{l=1}^{k}l\cdot V_{k-l+1}X_l^{\mp j}\right)\right)$$
$$=w^{-1/2+1}\theta_0X_1^{\mp j}+w^{-1/2+2}(V_1X_1^{\mp j}+\theta_0(2X_2^{\mp j}+\tfrac{5}{2}I_1X_1^{\mp j}))$$
$$+w^{-1/2+3}(2V_1X_2^{\mp j}+(V_2+\tfrac{7}{2}I_1V_1)X_1^{\mp j}+\theta_0(3X_3^{\mp j}+7I_1X_2^{\mp j}$$
$$+(\tfrac{51}{8}I_1^2+2I_2)X_1^{\mp j}))+\cdots, \tag{B18}$$

$$[\theta_{NF}\sqrt{z_{NF}-z_0}\Psi_{N\pm}^{\pm J}(z_{NF})]_{\xi=0}=\sum_{n=1}^{\infty}w^n\left(\theta_0\left(\sum_{k=1}^{n}R_{n-k}^{(n)}(z_0)\Psi_{k,N\pm}^{\pm j}\right)+\sum_{k=2}^{n}R_{n-k}^{(n)}(z_0)\right.$$
$$\left.\times\left(\sum_{l=2}^{k}V_{k-l+1}\Psi_{l-1,N\pm}^{\pm j}\right)\right)$$
$$=w\theta_0\Psi_{1,N\pm}^{\pm j}+w^2(V_1\Psi_{1,N\pm}^{\pm j}+\theta_0(\Psi_{2,N\pm}^{\pm j}+2I_1\Psi_{1,N\pm}^{\pm j}))$$
$$+w^3(V_1\Psi_{2,N\pm}^{\pm j}+(V_2+3I_1V_1)\Psi_{1,N\pm}^{\pm j}+\theta_0(\Psi_{3,N\pm}^{\pm j}+3I_1\Psi_{2,N\pm}^{\pm j}$$
$$+(\tfrac{9}{2}I_1^2+\tfrac{3}{2}I_2)\Psi_{1,N\pm}^{\pm j}))+\cdots, \tag{B19}$$

$$K_{NF}(w)[\sqrt{z_{NF}-z_0}\Psi_{N\pm}^{\pm j}(z_{NF})]_{\xi=0}=K_{NF}(w)\sum_{n=0}^{\infty}w^{n+1/2}\left(\sum_{k=0}^{n}\frac{k+1/2}{n+1/2}\cdot R_{n-k}^{(n+1/2)}(z_0)\Psi_{k+1,N\pm}^{\pm j}\right)$$
$$=w^{-1/2+1}\Psi_{1,N\pm}^{\pm j}+w^{-1/2+2}(\Psi_{2,N\pm}^{\pm j}+\tfrac{3}{2}I_1\Psi_{1,N\pm}^{\pm j}+\tfrac{1}{2}\theta_0V_1\Psi_{1,N\pm}^{\pm j})$$
$$+w^{-1/2+3}(\Psi_{3,N\pm}^{\pm j}+\tfrac{5}{2}I_1\Psi_{2,N\pm}^{\pm j}+(\tfrac{23}{8}I_1^2+I_2)\Psi_{1,N\pm}^{\pm j}$$
$$+\theta_0(\tfrac{1}{2}V_1\Psi_{2,N\pm}^{\pm j}+(V_2+\tfrac{9}{4}I_1V_1)\Psi_{1,N\pm}^{\pm j}))+\cdots, \tag{B20}$$

$$\left[\theta_{NF}\frac{\Psi^{\mp j}_{N\pm}(z_{NF})}{\sqrt{z_{NF}-z_0}}\right]_{\xi=0}=\sum_{n=1}^{\infty}w^{n-1}\Bigg(\theta_0\Bigg(\sum_{k=1}^{n}R^{(n-1)}_{n-k}(z_0)\Psi^{\mp j}_{k-1,N\pm}\Bigg)+\sum_{k=2}^{n}R^{(n-1)}_{n-k}(z_0)\times\Bigg(\sum_{l=2}^{k}V_{k-l+1}\Psi^{\mp j}_{l-2,N\pm}\Bigg)\Bigg)$$
$$=\theta_0\Psi^{\mp j}_{0,N\pm}+w(V_1\Psi^{\mp j}_{0,N\pm}+\theta_0(\Psi^{\mp j}_{1,N\pm}+I_1\Psi^{\mp j}_{0,N\pm}))+w^2(V_1\Psi^{\mp}_{1,N\pm}+(V_2+2I_1V_1)\Psi^{\mp j}_{0,N\pm}+\theta_0(\Psi^{\mp j}_{2,N\pm}+2I_1\Psi^{\mp j}_{1,N\pm}+(2I_1^2+I_2)\Psi^{\mp j}_{0,N\pm}))+\cdots \tag{B21}$$

and

$$K_{NF}(w)\left[\frac{\Psi^{\mp j}_{N\pm}(z_{NF})}{\sqrt{z_{NF}-z_0}}\right]_{\xi=0}=K_{NF}(w)\sum_{n=0}^{\infty}w^{n-1/2}\Bigg(\sum_{l=0}^{n}\frac{2l-1}{2n-1}\cdot R^{(n-l/2)}_{n-l}(z_0)\Psi^{\mp j}_{l,N\pm}\Bigg)$$
$$=w^{-1/2}\Psi^{\mp j}_{0,N\pm}+w^{-1/2+1}(\Psi^{\mp j}_{1,N\pm}+\tfrac{1}{2}I_1\Psi^{\mp j}_{0,N\pm}+\tfrac{1}{2}\theta_0V_1\Psi^{\mp j}_{0,N\pm})+w^{-1/2+2}(\Psi^{\mp j}_{2,N\pm}+\tfrac{3}{2}I_1\Psi^{\mp j}_{1,N\pm}+(\tfrac{7}{8}I_1^2+\tfrac{1}{2}I_2)\Psi^{\mp j}_{0,N\pm}+\theta_0(\tfrac{1}{2}V_1\Psi^{\mp j}_{1,N\pm}+(V_2+\tfrac{7}{4}I_1V_1)\Psi^{\mp j}_{0,N\pm}))+\cdots . \tag{B22}$$

Finally, various R's defined by Eqs. (3.27)–(3.29) and (3.34)–(3.37) can be calculated as follows: We find from Eq. (3.34) substituted with Eqs. (3.30) and (B9) that

$$R^j_{\alpha\alpha Nh}=-\alpha^{-hj}_{-1}p^{hj}(I_1+\theta_0V_1)-p^{-hj}\alpha^{hj}_{-1}I_1-\alpha^{-hj}_{-2}p^{hj}(I_1^2+\tfrac{1}{2}I_2+\theta_0(V_2+2I_1V_1))-p^{-hj}\alpha^{hj}_{-2}(I_1^2+\tfrac{1}{2}I_2)-\alpha^{-hj}_{-1}\alpha^{hj}_{-1}(\tfrac{1}{2}I_1^2+\tfrac{1}{2}I_2+\theta_0(V_2+I_1V_1))-\alpha^{-hj}_{-3}p^{hj}(\tfrac{3}{2}I_1^3+\tfrac{3}{2}I_1I_2+\tfrac{1}{6}I_3+\theta_0(V_3+3I_1V_2+(\tfrac{9}{2}I_1^2+\tfrac{3}{2}I_2)V_1))-\alpha^{-hj}_{-2}\alpha^{hj}_{-1}(\tfrac{2}{3}I_1^3+I_1I_2+\tfrac{1}{6}I_3+V_1V_2+\theta_0(V_3+3I_1V_2+2I_1^2V_1))-\alpha^{-hj}_{-1}\alpha^{hj}_{-2}(\tfrac{2}{3}I_1^3+I_1I_2+\tfrac{1}{6}I_3+\theta_0(V_3+2I_1V_2+(2I_1^2+I_2)V_1))-p^{-hj}\alpha^{hj}_{-3}(\tfrac{3}{2}I_1^3+\tfrac{3}{2}I_1I_2+\tfrac{1}{6}I_3)+\cdots . \tag{B23}$$

On both sides of Eq. (B23), ''h'' is the one in ϵ^j_h in $S_{\{h\}}(z_0)$ (1.4). (We will use this notational convention hereafter.) With the help of Eq. (3.35) substituted with Eqs. (3.30), (3.31), and (B15), we find that

$$R^j_{\alpha dNh}=p^{-hj}d^{hj}_0\theta_0+\alpha^{-hj}_{-1}d^{hj}_0(V_1+\theta_0I_1)+p^{-hj}d^{hj}_{-1}(V_1+\tfrac{3}{2}\theta_0I_1)+\alpha^{-hj}_{-2}d^{hj}_0(V_2+2I_1V_1+\theta_0(2I_1^2+2I_2))+\alpha^{-hj}_{-1}d^{hj}_{-1}(V_2+\tfrac{3}{2}I_1V_1+\theta_0(\tfrac{3}{2}I_1^2+I_2))+p^{-hj}d^{hj}_{-2}(V_2+\tfrac{3}{2}I_1V_1+\theta_0(\tfrac{11}{4}I_1^2+\tfrac{7}{4}I_2))+\alpha^{-hj}_{-3}d^{hj}_0(V_3+3I_1V_2+(\tfrac{9}{2}I_1^2+\tfrac{3}{2}I_2)V_1+\theta_0(\tfrac{9}{2}I_1^3+\tfrac{9}{2}I_1I_2+\tfrac{1}{2}I_3))+\alpha^{-hj}_{-2}d^{hj}_{-1}(V_3+\tfrac{5}{2}I_1V_2+(I_1^2+I_2)V_1+\theta_0(\tfrac{5}{2}I_1^3+\tfrac{9}{2}I_1I_2+\tfrac{1}{2}I_3+\tfrac{1}{2}V_1V_2))+\alpha^{-hj}_{-1}d^{hj}_{-2}(V_3+\tfrac{3}{2}I_1V_2+(\tfrac{9}{8}I_1^2+\tfrac{1}{4}I_2)V_1+\theta_0(\tfrac{9}{4}I_1^3+\tfrac{9}{4}I_1I_2+\tfrac{1}{2}I_3))+p^{-hj}d^{hj}_{-3}(V_3+\tfrac{7}{2}I_1V_2+(\tfrac{39}{8}I_1^2+2I_2)V_1+\theta_0(\tfrac{121}{16}I_1^3+\tfrac{31}{4}I_1I_2+\tfrac{1}{3}I_3))+\cdots \tag{B24}$$

while Eq. (3.36) substituted with Eqs. (3.30), (3.31), and (B16) give

$$R^j_{d\alpha Nh}=d^{-hj}_{-1}p^{hj}(V_1+\theta_0 I_1)+d^{-hj}_{-1}\alpha^{hj}_{-1}(V_2+I_1V_1+\theta_0(I_1^2+I_2))+d^{-hj}_{-2}p^{hj}(V_2+\tfrac{5}{2}I_1V_1+\theta_0(\tfrac{5}{2}I_1^2+I_2))+d^{-hj}_{-1}\alpha^{hj}_{-2}(V_3+2I_1V_2+(2I_1^2+I_2)V_1+\theta_0(2I_1^3+3I_1I_2+\tfrac{1}{2}I_3))+d^{-hj}_{-2}\alpha^{hj}_{-1}(V_3+\tfrac{5}{2}I_1V_2+(2I_1^2+\tfrac{1}{2}I_2)V_1+\theta_0(\tfrac{17}{12}I_1^3+\tfrac{7}{4}I_1I_2+\tfrac{1}{6}I_3+\tfrac{1}{2}V_1V_2))+d^{-hj}_{-3}p^{hj}(V_3+\tfrac{7}{2}I_1V_2+(\tfrac{63}{4}I_1^2+2I_2)V_1+\theta_0(\tfrac{121}{16}I_1^3+\tfrac{31}{4}I_1I_2+\tfrac{1}{3}I_3))+\cdots . \tag{B25}$$

Furthermore, we have from Eq. (3.37) substituted with Eqs. (3.31) and (B13) that

$$R^j_{ddNh}=d^{-hj}_{-1}d^{hj}_{0}(\tfrac{1}{2}I_1-\tfrac{1}{2}\theta_0V_1)+d^{-hj}_{-2}d^{hj}_{0}(\tfrac{7}{8}I_1^2+\tfrac{1}{2}I_2-\tfrac{3}{4}\theta_0I_1V_1)+d^{-hj}_{-1}d^{hj}_{-1}(\tfrac{1}{8}I_1^2-\theta_0(V_2+\tfrac{5}{4}I_1V_1))+d^{-hj}_{-3}d^{hj}_{0}(\tfrac{5}{6}I_1^3+\tfrac{15}{8}I_1I_2+\tfrac{1}{4}I_3+\tfrac{1}{2}V_1V_2+\theta_0(\tfrac{1}{2}V_3+\tfrac{3}{4}I_1V_2-(I_1^2+\tfrac{3}{8}I_2)V_1))+d^{-hj}_{-2}d^{hj}_{-1}(\tfrac{3}{4}I_1^3+\tfrac{3}{4}I_1I_2+\tfrac{1}{12}I_3-\tfrac{1}{2}V_1V_2-\theta_0(\tfrac{1}{2}V_3+2I_1V_2+(\tfrac{9}{4}I_1^2+\tfrac{1}{4}I_2)V_1))+d^{-hj}_{-1}d^{hj}_{-2}(-\tfrac{1}{6}I_1^3-\tfrac{3}{8}I_1I_2-\tfrac{1}{12}I_3-\tfrac{1}{2}V_1V_2-\theta_0(\tfrac{3}{2}V_3+\tfrac{15}{4}I_1V_2+(\tfrac{7}{2}I_1^2+\tfrac{9}{8}I_2)V_1))+\cdots . \tag{B26}$$

On the other hand, Eq. (3.27) substituted with Eqs. (3.30), (3.31), (B17), and (B18) leads to

$$R^j_X=-\sum_{\pm} ip^{\pm j}X_0^{\mp j}-\sum_{\pm} i\alpha^{\pm j}_{-1}X_1^{\mp j}-\sum_{\pm} i\alpha^{\pm j}_{-2}(X_2^{\mp j}+I_1X_1^{\mp j})+\cdots+\sum_{\pm} id^{\pm j}_{-1}\theta_0X_1^{\mp j}+\sum_{\pm} id^{\pm j}_{-2}(V_1X_1^{\mp j}+\theta_0(2X_2^{\mp j}+\tfrac{5}{2}I_1X_1^{\mp j}))+\sum_{\pm} id^{\pm j}_{-3}(2V_1X_2^{\mp j}+(V_2+\tfrac{7}{2}I_1V_1)X_1^{\mp j}+\theta_0(3X_3^{\mp j}+7I_1X_2^{\mp j}+(\tfrac{51}{8}I_1^2+2I_2)X_1^{\mp j}))+\cdots . \tag{B27}$$

Furthermore, Eq. (3.28) substituted with Eqs. (3.30), (B19), and (B21) gives

$$R^j_{\alpha Nh}=-i\alpha^{-hj}_{-1}\theta_0\Psi^{hj}_{1,Nh}-i\alpha^{-hj}_{-2}(V_1\Psi^{hj}_{1,Nh}+\theta_0(\Psi^{hj}_{2,Nh}+2I_1\Psi^{hj}_{1,Nh}))-i\alpha^{-hj}_{-3}(V_1\Psi^{hj}_{2,Nh}+(V_2+3I_1V_1)\Psi^{hj}_{1,Nh}+\theta_0(\Psi^{hj}_{3,Nh}+3I_1\Psi^{hj}_{2,Nh}+(\tfrac{9}{2}I_1^2+\tfrac{3}{2}I_2)\Psi^{hj}_{1,Nh}))+\cdots-\theta_0ip^{hj}\Psi^{-hj}_{0,Nh}-i\alpha^{hj}_{-1}(V_1\Psi^{-hj}_{0,Nh}+\theta_0(\Psi^{-hj}_{1,Nh}+I_1\Psi^{-hj}_{0,Nh}))-i\alpha^{hj}_{-2}(V_1\Psi^{-hj}_{1,Nh}+(V_2+2I_1V_1)\Psi^{-hj}_{0,Nh}+\theta_0(\Psi^{-hj}_{2,Nh}+2I_1\Psi^{-hj}_{1,Nh}+(2I_1^2+I_2)\Psi^{-hj}_{0,Nh}))+\cdots . \tag{B28}$$

Finally, Eq. (3.29) substituted with Eqs. (3.31), (B20), and (B22) gives

$$R^j_{dNh}=+id^{-hj}_{-1}\Psi^{hj}_{1,Nh}+id^{-hj}_{-2}(\Psi^{hj}_{2,Nh}+\tfrac{3}{2}I_1\Psi^{hj}_{1,Nh}+\tfrac{1}{2}\theta_0V_1\Psi^{hj}_{1,Nh})+id^{-hj}_{-3}(\Psi^{hj}_{3,Nh}+\tfrac{5}{2}I_1\Psi^{hj}_{2,Nh}+(\tfrac{23}{8}I_1^2+I_2)\Psi^{hj}_{1,Nh}+\theta_0(\tfrac{1}{2}V_1\Psi^{hj}_{2,Nh}+(V_2+\tfrac{9}{4}I_1V_1)\Psi^{hj}_{1,Nh})+id^{hj}_{0}\Psi^{-hj}_{0,Nh}+id^{hj}_{-1}(\Psi^{-hj}_{1,Nh}+\tfrac{1}{2}I_1\Psi^{-hj}_{0,Nh}+\tfrac{1}{2}\theta_0V_1\Psi^{-hj}_{0,Nh})+id^{hj}_{-2}(\Psi^{-hj}_{2,Nh}+\tfrac{3}{2}I_1\Psi^{-hj}_{1,Nh}+(\tfrac{7}{8}I_1^2+\tfrac{1}{2}I_2)\Psi^{-hj}_{0,Nh}+\theta_0(\tfrac{1}{2}V_1\Psi^{-hj}_{1,Nh}+(V_2+\tfrac{7}{4}I_1V_1)\Psi^{-hj}_{0,Nh}))+\cdots . \tag{B29}$$

In *physical* Ramond states in $\frac{1}{2}$ picture (3.52), operators $d_0^{\pm j}$'s existing in Eqs. (B24), (B26), and (B29) vanish since light-cone states in the R sector are those satisfying[4]

$$d_0^{\pm j}|\{\hat{p}\};\{h\}\rangle_F=0 \quad (\text{for } \epsilon^j_h=\pm\tfrac{1}{2}). \tag{B30}$$

On topology and quantum mechanics

Karl-Georg Schlesinger
Department of Mathematics, University of Wuppertal, D-42097 Wuppertal, Germany

(Received 23 May 1997; accepted for publication 4 August 1997)

The relationship between topology and quantum mechanics is considered in two different ways. We suggest regarding quantum mechanics as a first-order approximation to topology theory on a fixed set. In this spirit, the approach of quantizing the lattice $\tau(X)$ of topologies on a set X [C. J. Isham, ''Quantum topology and quantization on the lattice of topologies,'' Class. Quantum. Grav. **6**, 1509–1534 (1989)] is shown to be easily applicable to a quantum mechanical lattice. In the main part of the paper we deal with the question of the quantization of the whole category of topological spaces and continuous injective maps. Ideas of the modern categorical approach to quantization, as known from topological quantum field theory, are invoked in this part. The final paragraphs are devoted to the problem of extending quantization, even to the level of the underlying set theory. © *1998 American Institute of Physics.* [S0022-2488(98)02302-0]

I. INTRODUCTION

In recent years, there have been several contributions to the question of the interplay between topology and quantum mechanics. Most prominent is certainly the use of quantum field theory to construct topological invariant of manifolds. On the other hand, the idea that topology itself should be quantized has been around for quite some time. Originating from Ref. 1, it has been first put into a rigorous mathematical form in Ref. 2 (see also Ref. 3). In this paper, we will deal with the relationship of topology and quantum mechanics in two different ways: First, we suggest that quantum mechanics may in some sense be regarded as a first-order version of the theory of topology (full topology theory is second order since it involves quantification over variables ranging over the power set of a given set). This is the content of Sec. II. As a consequence, it is tempting to quantize quantum mechanics along the lines Isham in Ref. 2 quantizes the lattice $\tau(X)$ of topologies on a given set X. We do this in Sec. III. At the end of this section, we shortly compare the result to the idea of second quantization. Second, in Sec. IV we generalize the idea of quantizing topology to the case of underlying sets of varying cardinality [while in the quantization of $\tau(X)$ the underlying set X is fixed]. We arrive at something like a kinematical structure for the general case by mixing the approach of Ref. 2 with some ideas of quantization by categorification (see Refs. 4–7). We compare the results to the mathematical structure known from topological quantum field theory (see the literature just cited above). Section V contains some final remarks. Parts of this work (especially Sec. II) are motivational in character and because of this the arguments are sometimes of a heuristic type.

Since the approach presented in Ref. 2 influenced some sections of this paper, we first mention briefly the concepts and results needed from there. For a fixed set X let $\tau(X)$ be the set of all topologies on X. $\tau(X)$ gains a lattice structure from the partial ordering $\leqslant$ defined by $\tau_1 \leqslant \tau_2$ iff the topology τ_2 is finer than τ_1. The lattice operations $\wedge$ and $\vee$ are then defined as the intersection and the topological span of τ_1 and τ_2, respectively. Configuration variables

$$R_\tau : \tau(X) \to \{0;1\}$$

are defined for $\tau \in \tau(X)$ by

$$R_\tau(\tau') = \begin{cases} 1, & \text{if } \tau \leqslant \tau', \\ 0, & \text{otherwise,} \end{cases} \tag{1}$$

 © 1998 American Institute of Physics

satisfying $R_{\tau_1}R_{\tau_2}=R_{\tau_1\vee\tau_2}$. The quantum theory of $\tau(X)$ then involves a representation of the algebra, generated by these functions, in terms of linear operators $\hat{R}_\tau$, $\tau\in\tau(X)$, on some suitable Hilbert space. While naively one might suspect the appropriate Hilbert space to consist of wave functions on $\tau(X)$, the spectral theory of the $\hat{R}_\tau$ shows that the domain space of the wave functions is actually not $\tau(X)$ itself but the set of ideals of the lattice $\tau(X)$ [in which $\tau(X)$ is naturally embedded]. Isham interprets the extra elements of the domain space as the analog of distributions appearing in the quantization of conventional field theories. Complementary variables M_τ with

$$M_\tau M_{\tau'}=M_{\tau\wedge\tau'}$$

are introduced by requiring that $\hat{M}_\tau$ should act on wave functions according to

$$(M_\tau\psi)(\tau')=\psi(\tau\wedge\tau') \tag{2}$$

and a suitable generalization to general ideals of $\tau(X)$.

II. QUANTUM MECHANICS AS FIRST-ORDER THEORY OF TOPOLOGY

For X as above, let $\alpha(X)$ be the sublattice of $\tau(X)$ containing the topologies generated by the singleton subsets of X, i.e., an element τ of $\alpha(X)$ is generated by a family

$$\{x_i\}_{i\in I},$$

with I an index set, $x_i\in X$, where the $\{x_i\}$ are open with respect to τ.

Lemma 1: *Let X be an arbitrary set, $\alpha(X)$ as above. There exists a pre-Hilbert space H with $\alpha(X)$ isomorphic to the lattice of subspaces of H generated by a fixed algebraic base of H.*

Proof: Let $\tau\in\alpha(X)$. Then τ is uniquely determined by a family of the form

$$\{x_i\}_{i\in I}, \tag{3}$$

$x_i\in X$. Define H to be the free complex vector space over X and a scalar product on H by

$$(x,y)=\begin{cases}1, & \text{if } x=y,\\ 0, & \text{if } x\neq y,\end{cases}$$

for x, $y\in X$ with the obvious extension to H. Then $\alpha(X)$ is isomorphic to the lattice of subspaces of H generated by X as a fixed base of H. □

Since H uniquely determines a Hilbert space $\overline{H}$ by completion, this means that $\alpha(X)$ determines an extension to a quantum-mechanical lattice of closed linear subspaces of a Hilbert space. Topologies in $\alpha(X)$ are determined by giving a family of points of X while for a general topology in $\tau(X)$ one has to give a family of subsets of X. So, $\alpha(X)$ may be considered as the first-order part of topology theory on X. It is tempting to speculate that including quantum superpositions of the elements of $\alpha(X)$ (which is mainly what happens when going to the subspace lattice of $\overline{H}$) might give some kind of first-order approximation to the full lattice $\tau(X)$. We will try to make this idea more precise now.

Let M be a smooth manifold (connected, Hausdorff, paracompact) with underlying set X. It is known that the C^∞-scalar functions on M generate the topology of M in the following sense (see, e.g., Ref. 8): Every open set of M has the form

$$\{y\in M\,|\,f(y)\neq 0\},$$

for some scalar function f. Since we can generate the same topology by restricting to scalar functions of compact support, we can generate the topology of M by the C^∞ functions, which are square integrable with respect to some suitable measure, too, i.e., by a very simple model of quantum mechanics on M (of course, on a topologically nontrivial manifold M, ''true'' quantum mechanics is not as simple as that).

Generalized wave functions in the form of Dirac delta distributions then generate the topologies belonging to $\alpha(X)$. Now, a square integrable wave function can be represented as a formal linear combination of delta distributions. So, the formal span of the delta distributions contains all the manifold topologies one can have on X. On the other hand, the relationship of the span of the delta distributions to $\alpha(X)$ is similar to the one of the subspace lattice of $\bar{H}$ to $\alpha(X)$ (The formal argument used here can be made precise by considering formal sums as words and going to a free vector space again.)

But the formal span of the delta distributions does not only contain the wave functions representing manifold topologies on X. It is also known that the C^* algebra of continuous complex-valued functions on a compact Hausdorff topological space allows for the reconstruction of the topology. So the argument above can be extended to compact nonmanifold topologies.

It is this sense—mediated by reinterpreting the lattice $\alpha(X)$ as representing the delta distributions on some manifold M—in which we regard the quantum-mechanical lattices as giving a first-order approximation (at least suitable for compact Hausdorff and manifold topologies) to topology theory, or put the other way around: $\tau(X)$ as the higher-order generalization of quantum mechanics. One may ask the question if the success with which quantum field theory can be applied to questions of topology can in the long run be understood as a consequence of a relationship like this between the two theories. Seen from this point of view, the idea of quantizing the lattice $\tau(X)$ itself, as followed in Ref. 2, appears to be very natural, reminding one of higher or iterative quantization. It is then tempting to apply the techniques, used in Ref. 2 to quantize $\tau(X)$, to a quantum-mechanical lattice. This is the content of the next section.

III. QUANTIZING QUANTUM MECHANICS

In a quantum-mechanical lattice L (i.e., a lattice of closed linear subspaces of a Hilbert space) the partial ordering $\leqslant$ is given by inclusion of subspaces and the lattice operations $\wedge$ and $\vee$ mean set–theoretic intersection and the closure of the linear span, respectively. We can again introduce functions,

$$R_\tau : L \to \{0;1\},$$

for $\tau \in L$ using (1). Again,

$$R_{\tau_1} \cdot R_{\tau_2} = R_{\tau_1 \vee \tau_2},$$

and therefore

$$R_\tau^2 = R_\tau.$$

As in Ref. 2, the spectral theory of the operators $\hat{R}_\tau$ shows that the domain space of the wave functions is the set $I(L)$ of ideals of the lattice L. So, the Hilbert space representing the kinematical structure of the quantum theory of L should be of the form

$$\mathscr{L}^2(I(L), d\mu),$$

for some measure μ. Remember that an ideal of L is a subset J of L satisfying the following:

(i) for $\tau_1, \tau_2 \in J$ we have $\tau_1 \vee \tau_2 \in J$;

(ii) if $\tau_1 \leqslant \tau_2$ and $\tau_2 \in J$ then $\tau_1 \in J$, too.

Since for $\tau \in L$,

$$\downarrow(\tau) := \{\tau' \in L \,|\, \tau' \leqslant \tau\}$$

is an ideal, L is naturally embedded in $I(L)$.

Again, complementary operators $\hat{M}_\tau$ satisfying

$$\hat{M}_{\tau_1} \hat{M}_{\tau_2} = \hat{M}_{\tau_1 \wedge \tau_2},$$

can be introduced by their action on wave functions ψ on $I(L)$ as

$$(\hat{M}_\tau \psi)(J) = \psi(\downarrow(\tau) \cap J), \tag{4}$$

for $J \in I(L)$. (4) is just the generalization of (2) to the ideals of L. In Ref. 2 the operation of $\hat{M}_\tau$ on some eigenstate $|J\rangle$ of the $\hat{R}_{\tau'}$ operators [the eigenstates of the $\hat{R}_{\tau'}$ operators have the elements of $I(L)$ as labels] is calculated to be

$$\hat{M}_\tau |J\rangle = \left(\frac{1}{\mu(J)}\right)^{1/2} \sum_{\{J' | \downarrow(\tau) \cap J' = J\}} (\mu(J'))^{1/2} |J'\rangle \tag{5}$$

[where the sum is understood to be zero if the condition on the sum cannot be fulfilled for any $J' \in I(L)$] for the quantization of $\tau(X)$, and X a finite set. Since a quantum-mechanical lattice L is never finite, the sum has to be replaced by an integral in this case. But the qualitative features can already be seen from (5): The operators $\hat{M}_\tau$ applied to a state $|J\rangle$ lead to a mixed state where any state $|J'\rangle$ compatible with the intersection requirement

$$\downarrow(\tau) \cap J' = J, \tag{6}$$

is present. For simplicity, consider the case where J' and J represent just elements of L, too. Then (6) can be reformulated as

$$\tau \cap J' = J.$$

This means that any subspace J' is present in the sum where the part belonging to τ is identical to J. Given the subspaces τ and J, the application of $\hat{M}_\tau$ therefore in some sense involves a maximal loss of information.

So, while the kinematical structure is in close analogy to conventional schemes of second quantization (we arrive at a Hilbert space of generalizations of wave functions on L), the operators involved in the quantization of a quantum-mechanical lattice allow for additional statistical effects beyond the usual quantum ones. This might give a suitable framework for generalizations of quantum field theory involving transitions between pure and mixed states.

IV. QUANTIZING THE CATEGORY OF TOPOLOGICAL SPACES AND CONTINUOUS INJECTIVE MAPS

In the last two sections, we have tried to motivate the following standpoint: We have suggested viewing quantum mechanics as a first-order approximation to topology theory on a set X and consequently argued to regard the quantization of $\tau(X)$ as a very natural step, related to second quantization. The ease with which the techniques of Ref. 2 for quantizing $\tau(X)$ translate to the case of a quantum-mechanical lattice L, in our opinion, give additional support to this view.

But the fact that the cardinality of the set X, underlying the topological spaces considered, remains fixed appears to be artificial to us. If we argue that quantum effects in general relativity might cause the topology to change, why should they preserve the identity of individual points? This is especially questionable since the points only get an identity in the physical sense after choosing a special solution of general relativity (see, e.g., Ref. 9), whereas quantization has to be applied to the whole space of solutions. In this section, we will present some ideas on quantizing the category of topological spaces, thereby getting rid of the restriction on the cardinality of X.

Determining a category means determining a class of objects and a class of morphisms. So, actually besides giving the objects (topological spaces) we should also make precise which maps between topological spaces we want to include. Since we want to generalize the structure of $\tau(X)$—where refinement of topology is the natural ordering relation—taking arbitrary continuous maps does not seem to be appropriate. In Ref. 2 the following partial ordering is suggested for the class of topological spaces:

$$(X_1, \tau_1) \prec (X_2, \tau_2),$$

iff there exists a continuous injection from (X_2, τ_2) to (X_1, τ_1). This clearly generalizes the case of $\tau(X)$. So, we take as category the category **Topi** of topological spaces and continuous injective maps (the ''*i*'' in **Topi** standing for ''injective'').

Of course, the totality of all topological spaces forms a proper class. In the sequel we will handle this class as just another mathematical object. At first sight this may cause some unease, but one should not forget that this is common practice in category theory. To stand on set-theoretically firm foundations, it is always possible to invoke type theory on classes (see Ref. 10) or alternatively to assume that what we call classes are actually sets of some inaccessible cardinality.

We start by introducing an algebra of functions from the class of objects of **Topi** to $\{0;1\}$. The spectral theory of this algebra should suggest the kinematical structure for the quantum theory of **Topi**. For (X,τ) a topological space, we define again

$$R_{(X,\tau)}((X',\tau'))=\begin{cases}1, & \text{if } (X,\tau)\prec(X',\tau'),\\ 0, & \text{otherwise.}\end{cases} \tag{7}$$

Observe that the functions $R_{(X,\tau)}$ naturally involve the morphism structure of **Topi** in their definition, too.

Since the functions $R_{(X,\tau)}$ take values only in the set $\{0;1\}$, it follows that

$$R^2_{(X,\tau)}=R_{(X,\tau)}. \tag{8}$$

Now, suppose $(X_1,\tau_1)\prec(X_2,\tau_2)$. Then

$$R_{(X_1,\tau_1)}R_{(X_2,\tau_2)}=R_{(X_2,\tau_2)}, \tag{9}$$

because

$$R_{(X_1,\tau_1)}((X',\tau'))R_{(X_2,\tau_2)}((X',\tau'))=1,$$

iff $(X_1,\tau_1)\prec(X',\tau')$ and $(X_2,\tau_2)\prec(X',\tau')$. But this is precisely the case if

$$(X_2,\tau_2)\prec(X',\tau').$$

Equation (9) shows that though the class of all topological spaces does not involve a lattice structure, the functions $R_{(X,\tau)}$ possess a natural absorption property with respect to the partial ordering $\prec$. This has to be expected if the operator analogs of these functions are projection operators on eigenstates of topology, as (8) suggests. The spectral theory of the operators $\hat{R}_{(X,\tau)}$ is what has to be considered next.

The operators $\hat{R}_{(X,\tau)}$ are commuting projection operators, so we should have a set of complete simultaneous eigenvectors $|h\rangle$ with

$$\hat{R}_{(X,\tau)}|h\rangle=h(X,\tau)|h\rangle,$$

and h taking values in $\{0;1\}$. It follows from (9) that the functions h have an absorption property, too:

$$h(X_1,\tau_1)h(X_2,\tau_2)=h(X_2,\tau_2), \tag{10}$$

for $(X_1,\tau_1)\prec(X_2,\tau_2)$. Let

$$J_h:=\{(X,\tau)|h(X,\tau)=1\}.$$

If again $(X_1,\tau_1)\prec(X_2,\tau_2)$ and $(X_2,\tau_2)\in J_h$, Eq. (10) implies

$$(X_1,\tau_1)\in J_h.$$

Conversely, let J be a subclass of the class of all topological spaces having the property that $(X_2,\tau_2)\in J$ implies $(X_1,\tau_1)\in J$ for every $(X_1,\tau_1)\prec(X_2,\tau_2)$. (We will call subclasses of this kind *downward directed*.) Then

$$h_J(X,\tau)=\begin{cases}1, & \text{if } (X,\tau)\in J,\\ 0, & \text{if } (X,\tau)\notin J,\end{cases}$$

has the absorption property (10). By definition,

$$h_{J_h}=h,$$

i.e., there is a one to one correspondence between the functions h and downward directed subclasses J of the class of all topological spaces. Again we can identify the space (X,τ) with

$$\downarrow(X,\tau):=\{(X',\tau')\,|\,(X',\tau')\prec(X,\tau)\}.$$

Clearly, $\downarrow(X,\tau)$ is a downward directed class.

We handled the spectral theory of the algebra generated by the operators $\hat{R}_{(X,\tau)}$ in a merely heuristic manner again. Our main aim was to get an idea what the kinematical structure of the quantum theory of **Topi** might look like. Having achieved this, we will now proceed in a category theoretic manner which we feel is the appropriate language for dealing with the quantization of **Topi**.

On the level of categories, the domain space of the quantum theory should involve all subcategories of **Topi** that are determined by a downward directed subclass of the class of all topological spaces. So, we take as domain space the 2-category **ST** of all full subcategories of **Topi**, the class of objects of which is a downward directed class J. The 1-morphisms are the functors, of course, and the 2-morphisms the natural transformations on these (for the definition of a 2-category, see e.g., Ref. 4).

Taking the downward directed classes J as the domain space of the quantum theory has a natural interpretation. It means that the quantum theory does not distinguish between a topological space and an extension thereof. This is plausible from a physical standpoint: In physics it does not seem to make much sense to distinguish between a space as such and the same space as embedded into a larger one. Since for topological spaces—in contrast to connected, Hausdorff, paracompact manifolds—there is no notion of maximal extension, this directly leads to the introduction of proper classes into the theory. Remember that the downward directed classes J are the analogs of the ideals of the lattice $\tau(X)$ or the distributional fields to be introduced in the quantization of conventional field theories. We regard it as interesting that the process of quantization automatically brings the notion of topological space (which is ultimately a model for the physical universe) close to the notion of mathematical universe (proper classes and categories as universe of discourse).

Now, the kinematical structure of the quantum theory should be given in terms of wave functions on the domain space. What are wave functions on ST? The generalization of the function concept to categories is the notion of functor, of course. On the level of 2-categories, we get 2-functors. At least on the level of the categorical analog of finite-dimensional linear algebra (see Refs. 4 and 7), the role of $\mathbb{C}$ is taken by the category **Vect** of finite-dimensional vector spaces. Since we have no reason to restrict to finite dimensions at the moment, we should replace this by the category **V** of vector spaces and linear maps. A module category over **V** is a category M with a symmetric monoidal structure $\oplus$ and a functor,

$$\otimes:\mathbf{V}\times M\to M,$$

such that $\oplus$ and $\otimes$ satisfy the axioms of a module up to natural isomorphisms that are subject to the usual coherence laws. Actually, we should introduce the categorical analog of a Hilbert space structure on M (this is possible; see Ref. 4), but for simplicity—in order to get the flavor of the general ideas involved—we restrict to the linear structure in this paper. The module categories over **V** and the functors preserving the module structure form a category **2-V**. Including structure preserving natural transformations, we get a 2-category (the ''2'' in the symbol **2-V** just points at the fact that we are dealing with the 2-categorical analog of the category of vector spaces).

So, wave functions on **ST** should be the 2-functors from **ST** to **2-V**. We have refrained from discussing the question of square integrability of wave functions, so far. It is not clear if an analog of measure theory can be introduced on **ST**, but it might well be that this is not necessary at all.

In ordinary quantum mechanics we need square integrability because we need normalized wave functions in order to give a probalistic interpretation to them. But there is a different possibility for interpreting a 2-functor,

$$\mathscr{F}:\mathbf{ST}\rightarrow\mathbf{2\text{-}V},$$

namely as a generalization of a topological quantum field theory. Remember that we can understand the functors $\mathscr{F}$ as resulting from a generalization of the ''naive quantization'' of **Topi**, where wave functions would just have been functors from **Topi** to **V**. But a functor from **Topi** to **V** generalizes the concept of topological quantum field theory (for the definition see the literature cited at the beginning) in a double sense: First, the domain category is generalized from differentiable manifolds to arbitrary topological spaces. Second, the codomain category is generalized from finite-dimensional vector spaces to the infinite-dimensional case.

Observe that the 2-category $\mathbf{2\text{-}V}^{\mathbf{ST}}$ of 2-functors from **ST** to **2-V** naturally inherits the structure of a module 2-category (the 2-categorical analog of a module category) from **2-V**. For the quantum theory of **Topi**, $\mathbf{2\text{-}V}^{\mathbf{ST}}$ has to be regarded as the analog of the Hilbert space of conventional quantum mechanics. So the state space of this theory appears to be a space of generalizations of topological quantum field theories. Compare this to recent results suggesting that the states of quantum gravity should be related to topological quantum field theories (see Refs. 5, 6, and 11).

Remark: A single topological space (X,τ) can itself be considered as a category, the objects being the open sets and the morphisms given by inclusion. Remembering our considerations of Sec. II and the role played by quantum field theoretic methods in constructing topological invariants, it is tempting to ask what a space of quantum theories on (X,τ) might look like. In a very general sense, giving a quantum (field) theory on (X,τ) should mean attaching Hilbert spaces to local regions of (X,τ), subject to the existence of inclusion maps between spaces for the inclusion of local regions. This means we have a functor from (X,τ) to **H** (the category of Hilbert spaces and linear maps). This is similar to the concept of presheaf on (X,τ) that abstractly formulated (see Ref. 12) is a functor from the opposite category of (X,τ) (i.e., all arrows reversed) to the category **Set** of sets and functions. Since reversing the arrows is not essential from a conceptual standpoint, we are dealing with something like *quantum presheaves* on (X,τ). A candidate for the space of quantum (field) theories on (X,τ) is then given by

$$\mathbf{H}^{(X,\tau)},$$

the category of functors from (X,τ) to **H**.

Observe the analogy between $\mathbf{H}^{(X,\tau)}$ and $\mathbf{2\text{-}V}^{\mathbf{ST}}$. On passing from a single topological space to the category **Topi**, we get a similar object one level of categorification higher (i.e., 2-categories instead of 1-categories). This is mainly due to the fact that we had to pass to a larger domain space (namely downward directed classes) when considering the quantum theory.

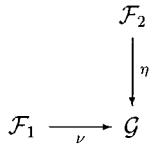
This level structure with respect to categorification is again known from (extended) topological quantum field theories, where it appears on passing to the cobordism category (i.e., the domain category of the topological quantum field theory) of the next higher dimension (see again Refs. 4, 5 and 6). □

The next step would be to introduce operators and commutation relations on $\mathbf{2\text{-}V}^{\mathbf{ST}}$. In the class of all topological spaces there is no natural candidate for variables complementary to the $R_{(X,\tau)}$. Besides this, the fact that the elements of $\mathbf{2\text{-}V}^{\mathbf{ST}}$ may have an interpretation (in terms of generalizations of topological quantum field theories) quite different from that of the state vectors of ordinary quantum mechanics, suggests that we should not necessarily expect sensible operators on $\mathbf{2\text{-}V}^{\mathbf{ST}}$ to reflect the properties of a classically given algebra. We plan to deal with these questions in detail in a later publication.

Consider $\mathbf{2\text{-}V}^{\mathbf{ST}}$ as a category for the moment (forgetting about the 2-morphism level of structure). Then the following lemma, needed in the sequel, holds.

Lemma 2: The category $\mathbf{2\text{-}V}^{\mathbf{ST}}$ *has pullbacks.*

Proof: Suppose for $\mathcal{F}_1, \mathcal{F}_2, \mathcal{G}$ functors from **ST** to **2-V** and ν, η natural transformations, a diagram of the following form is given:



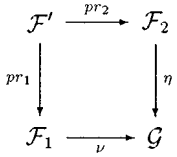
We define a new functor $\mathcal{F}'$ from **ST** to **2-V**. For C an object of **ST**, let $\mathcal{F}'(C)$ be the subcategory of $\mathcal{F}_1(C) \oplus \mathcal{F}_2(C)$ determined by the requirement that on $\mathcal{F}'(C)$, the functor identity

$$\nu_C \circ pr_1 = \eta_C \circ pr_2$$

holds, with pr_1 and pr_2 the projection functors of the Cartesian product (i.e., the direct sum). For a morphism f of **ST**, define

$$\mathcal{F}'(f) := \mathcal{F}_1(f) \oplus \mathcal{F}_2(f)|_{\mathcal{F}'(C)}.$$

Then the projection functors for each C together define a natural transformation from $\mathcal{F}'$ to $\mathcal{F}_1$ and from $\mathcal{F}'$ to $\mathcal{F}_2$, respectively. By construction, the diagram



commutes. The universality of $\mathcal{F}'$ is checked by calculation using the properties of the Cartesian product in **2-V**. □

There is one point in the quantization of **Topi** as presented above that remains somewhat unsatisfactory. We will deal with this in the rest of this section now.

When quantizing **Topi**, we quantized the topologies but we kept the underlying set theory in which the category **Topi** is formulated in the classical form. We remarked already above that in general relativity the set-theoretic level only gets physical meaning after the choice of a special solution while quantization is to be applied to the whole space of solutions. This might be taken as a hint that even the underlying set theory cannot remain in its classical form in a fully satisfactory quantization of Einstein's theory. The question on which level to apply quantization has been discussed by Isham several times (see, e.g., Refs. 13 and 14). To stop quantization at the level of topology and to leave set theory unchanged causes special unease because of the close interplay between classical topology and set theory.

Facing these problems, the question arises as to what the appropriate quantum set theory should look like. We take again the standpoint of the category theorist, interpreting this question as meaning what the appropriate category of sets replacing **Set** should be. The candidate first coming to mind is surely the category of Hilbert spaces. But there is another choice naturally suggesting itself that we prefer to take, namely the category $\mathbf{2\text{-}V}^{\mathbf{ST}}$.

We mentioned already that $\mathbf{2\text{-}V}^{\mathbf{ST}}$ is something like a category of quantum presheaves on **ST**. Classical categories of presheaves are known to be topoi (see Ref. 12), and therefore generalizations of set theory to the case of intuitionistic logic. Besides the interpretation as a space of generalizations of topological quantum field theories, $\mathbf{2\text{-}V}^{\mathbf{ST}}$ may thus be seen as a generalization of set theory, possibly involving elements of quantum and intuitionistic logic. We will deal with the details of set theory in $\mathbf{2\text{-}V}^{\mathbf{ST}}$ in a publication to follow and will for now restrict to the question of defining categories in $\mathbf{2\text{-}V}^{\mathbf{ST}}$. This is the first step toward defining an analog of **Topi** (or **ST**) in $\mathbf{2\text{-}V}^{\mathbf{ST}}$ and placing the whole quantization scheme in the context of our new set theory.

That it is possible to define categories in $\mathbf{2\text{-}V}^{\mathbf{ST}}$ is shown by Lemma 2. In a category $\mathcal{C}$ with pullbacks we can define categories in $\mathcal{C}$ by using the usual definition of category that can easily be formulated in arrow language in **Set** (see Ref. 12 for the details).

To understand what a category in **2-V**$^{\mathbf{ST}}$ looks like, consider first the case of a category in **2-V** (which has pullbacks too). First of all, **2-V** is a category of categories. So, a category in **2-V** surely has the structure of a double category. (A double category is defined to be a category in **Cat**, the category of (small) categories. It is the generalization of the 2-category notion to the case of rectangular arrow diagrams, whereas the arrow diagrams of 2-categories are spherical in nature. See Ref. 15 for an introduction.) Besides this, a category in **2-V** inherits a module structure from the objects of **2-V** that represent its object class and morphism class, respectively. So, a category in **2-V** is a module double category.

Now, let us return to the case of a category in **2-V**$^{\mathbf{ST}}$. A category in **2-V**$^{\mathbf{ST}}$ looks like a category in **2-V** varying with the objects of **ST**, where the variation is subject to certain compatibility relations. Observe that *every* category in **2-V**$^{\mathbf{ST}}$ has some topological flavor, it even resembles a manifold in the sense that it is locally a generalization of a module structure.

Placing the whole scheme of the quantization of **Topi** in the category **2-V**$^{\mathbf{ST}}$ now means that we have to consider wave functions in **2-V**$^{\mathbf{ST}}$ on some special category in **2-V**$^{\mathbf{ST}}$. In concluding this section, we will roughly sketch what this should look like.

Observe that a category in **V** (the category of vector spaces and linear maps) is a module category. Now, we argued above that wave functions on a module category $\mathscr{C}$ should be functors from $\mathscr{C}$ to **H** or—if we consider the linear structure only, again—from $\mathscr{C}$ to **V**. It is therefore suggestive to consider as wave functions on a category in **2-V**$^{\mathbf{ST}}$ something like functors from that category to **2-V**$^{\mathbf{ST}}$ itself. We say ''something like'' because at first sight functors are only defined between two different categories in **2-V**$^{\mathbf{ST}}$ and **2-V**$^{\mathbf{ST}}$ need not be representable as a category object in itself. This problem can be circumvented the following way: For the category **Set**, functors from a category in **Set** (which is just an ordinary category) to **Set** can be understood as split discrete opfibrations in **Set** (for details and the equivalence to **Set**-valued functors, see Ref. 12), a notion that readily generalizes to general categories with pullbacks. A split discrete opfibration (sometimes also called split discrete cofibration) in **2-V**$^{\mathbf{ST}}$ is a functor in **2-V**$^{\mathbf{ST}}$ between categories (C_0,C_1) and (D_0,D_1) in **2-V**$^{\mathbf{ST}}$ (where C_0 and D_0 are representing the classes of objects and C_1 and D_1 the classes of morphisms) having the property that

$$\begin{array}{ccc} D_1 & \longrightarrow & D_0 \\ {\scriptstyle \varphi_1}\downarrow & & \downarrow{\scriptstyle \varphi_0} \\ C_1 & \xrightarrow[d^\circ]{} & C_0 \end{array}$$

is a pullback square. Here, φ_0 and φ_1 denote the object and the morphism map of the functors, respectively, and d° is the domain map (assigning the domain to each morphism). If we want to be more precise, we talk about a split discrete opfibration over the category $\mathscr{C}=(C_0,C_1)$ in **2-V**$^{\mathbf{ST}}$.

In conclusion, we suggest that the wave functions on a category $\mathscr{C}$ in **2-V**$^{\mathbf{ST}}$ are the split discrete opfibrations over $\mathscr{C}$. We will deal with the implications of this suggestion in future work on set theory in **2-V**$^{\mathbf{ST}}$.

V. CONCLUSION

Starting from the idea that quantization of the lattice $\tau(X)$ of topologies on a fixed set X can be understood as a generalization of second quantization (which we take as a tiny hint that the abstract approach followed in this paper could have some physically interesting content), we went on to consider the problem of quantizing the whole category of topological spaces and continuous injective maps (getting rid of the assumption of a fixed set X). We found that our approach naturally suggested a further generalization, involving quantization, even of the underlying set theory.

One of the most interesting observations is surely that the approach developed in Ref. 2, which shows the need to enlarge the classical configuration space when considering the quantum theory, fits in with the hierarchy of categorical structures (1- and 2-categories) as known from topological quantum field theory.

Similarity and intertwining of Dirac operators

Barton L. Willis
Department of Mathematics and Statistics, University of Nebraska at Kearney, Kearney, Nebraska 68849-1110

(Received 26 August 1997; accepted for publication 19 November 1997)

Similarity and symmetry of quantum mechanical operators are the basic theoretical means for systematizing quantum dynamics. The classical counterparts of these concepts are canonical transformations and conservation laws. For operators, a concept called intertwining encompasses both similarity and symmetry. In this paper, we construct pairs of Dirac operators with noncentral potentials that are intertwined by multiplication operators. © *1998 American Institute of Physics.* [S0022-2488(98)01303-6]

I. INTRODUCTION

Operators H_1 and H_2 are said to be *intertwined* by Q if[1]

$$QH_1 - H_2Q = 0. \tag{1}$$

The operator Q need not be one-to-one; however, if it is, then we say that H_1 and H_2 are *similar*. Additionally, if $H_1 = H_2$, then Q commutes with H_1 and we say that Q is a *symmetry* of H_1. Thus the concept of intertwining encompasses similarity and symmetry. An important application of intertwining follows from the fact that if H_1 and H_2 are intertwined by Q and $\Psi \in \text{null}(H_1)$, then $Q\Psi \in \text{null}(H_2)$. To apply this result, the null-space (or at least one element of the null-space) of H_1 must be known; consequently, the aim is to intertwine H_1 and H_2 with H_1 being ''simple.''

Anderson[2] examined the intertwining of Dirac operators for *scalar* potentials. In this article, we investigate this problem for nonscalar potentials. Specifically, we consider four-vector potentials of the form

$$\boldsymbol{A} = (U, \sin(\theta)D, -\cos(\theta)D, 0), \tag{2}$$

where U and D are functions of the cylindrical coordinates r and z only. The electric and magnetic fields for vector potentials of this form are axially symmetric and their theta components are zero. In general, fields of this type have nonzero electric and magnetic dipole moments. We refer to the Dirac operator with mass m and vector potential given by Eq. (2) as $H_{[U,D,m]}$.

We offer three examples of how potentials of the form (2) arise in various physical problems. The first is the potential of a Penny trap with an electric quadrapole field and a constant magnetic field.[3] The second example is any atom whose nucleus has a nonvanishing electric dipole or quadrapole moment. The last example is the ''self-field quantum electrodynamics'' of Barut *et al.*[4] In this theory, the Dirac and Maxwell equations are coupled with the Dirac current serving as the electric current. Assuming this system has axially symmetric solutions, one is led to studying Dirac equations whose potential has the form given in Eq. (2).

For potentials of the form given by Eq. (2), the corresponding Dirac operator commutes with the z component of the angular momentum, but it does not in general commute with any other component. Further, the vector potential is time independent, so any Dirac spinor in the null-space of $H_{[U,D,m]}$ can be assumed to have the form

 © 1998 American Institute of Physics

$$\Psi = e^{i\omega t} e^{-in\theta}/\sqrt{r} \begin{pmatrix} e^{-i\theta} F_0 \\ F_1 \\ i e^{-i\theta} F_2 \\ i F_3 \end{pmatrix}, \tag{3}$$

where n is an integer and $F_0, \ldots, F_3$ are functions of r and z only. Using this form for the wave function, we find that the spinor (F_0, F_1, F_2, F_3) is in the null space of the ''reduced'' Dirac operator $\hat{H}_{[U,D,m]}$, where

$$\hat{H}_{[U,D,m]} = \partial_r + M\partial_z + (U-\omega)C_1 + \left(D - \frac{2n+1}{2r}\right) C_2 + mC_3, \tag{4}$$

and where the matrices M, C_1, C_2, and C_3 are given in 2×2 block form as

$$M = \begin{pmatrix} -i\sigma_y & 0 \\ 0 & -i\sigma_y \end{pmatrix}, \quad C_1 = \begin{pmatrix} 0 & \sigma_x \\ -\sigma_x & 0 \end{pmatrix},$$

$$C_2 = \begin{pmatrix} -\sigma_z & 0 \\ 0 & -\sigma_z \end{pmatrix}, \quad C_3 = \begin{pmatrix} 0 & \sigma_x \\ \sigma_x & 0 \end{pmatrix}.$$

These matrices pairwise anticommute and they satisfy $C_2^2 = C_3^2 = I, M^2 = C_1^2 = -I$, where I is the 4×4 identity matrix. The abbreviations

$$v_1 = U - \omega, \quad v_2 = D - (2n+1)/2r, \tag{5}$$

allow us to express the reduced Dirac operator as

$$\partial_r + M\partial_z + V_{[v_1, v_2, m]}, \tag{6}$$

where $V_{[v_1, v_2, m]}$ is the matrix (again, in 2×2 block form)

$$V_{[v_1, v_2, m]} = \begin{pmatrix} -v_2\sigma_z & (m+v_1)\sigma_x \\ (m-v_1)\sigma_x & -v_2\sigma_z \end{pmatrix}. \tag{7}$$

In Sec. II, we find all Dirac operators that are intertwined by a multiplication operator, and in Sec. III we present two examples.

II. MULTIPLICATION OPERATORS

Let Q be a multiplication operator and let H_1 and H_2 be the reduced Dirac operators

$$H_1 = \partial_r + M\partial_z + V_{[v_1, v_2, m]}, \tag{8}$$

$$H_2 = \partial_r + M\partial_z + V_{[w_1, w_2, \mu]}. \tag{9}$$

For the remainder of this paper, we use the notation

$$V_{[v1, v2, m]} = V, \quad V_{[w_1, w_2, \mu]} = W.$$

By commuting the derivative terms of the operator QH_1 to the right and by equating coefficients of like derivative operators, it follows that $QH_1 = H_2 Q$ if

$$[Q, M] = 0, \tag{10}$$

$$Q_r + MQ_z = QV - WQ, \tag{11}$$

where the subscripts indicate partial derivatives. To analyze these equations, we initially determine all matrices that commute with M. We find that Q commutes with M if and only if Q has the form

$$Q=\begin{pmatrix} q_{1,1} & -q_{1,0} & q_{1,3} & -q_{1,2} \\ q_{1,0} & q_{1,1} & q_{1,2} & q_{1,3} \\ q_{3,1} & -q_{3,0} & q_{3,3} & -q_{3,2} \\ q_{3,0} & q_{3,1} & q_{3,2} & q_{3,3} \end{pmatrix}, \tag{12}$$

where the q_{ij}'s are eight arbitrary functions of r and z.

We can derive one more algebraic condition on Q by using Eqs. (10) and (11) to show that M commutes with $QV-WQ$. To prove this, we need to remember that M is a constant matrix and that Q commutes with M. Imposing this condition on Q implies that the eight independent elements of Q satisfy eight homogeneous linear equations. These linear equations have a nontrivial solution if and only if either $v_2=w_2$ or if

$$0=v_2^2-v_1^2+m^2-w_2^2+w_1^2-\mu^2. \tag{13}$$

It can be shown that the condition $v_2=w_2$ gives no results that are not found from using the solvability condition given in Eq. (13).

The algebraic condition imposed by Eq. (13) can always be locally satisfied by a choice of gauge. Specifically, we can choose a gauge for which $0=m^2-v_1^2+v_2^2$ (and similarly for the other potential). In four-vector language, this choice corresponds to a gauge that specifies the value of $\boldsymbol{A}^{\mu}\boldsymbol{A}_{\mu}$.

We now have eight homogeneous linear equations and the solvability condition [Eq. (13)]. In solving these equations, we assume that $w_1\neq\mu$; a detailed calculation shows that if $w_1=\mu$, leads to inconsistent equations. Assuming $w_1\neq\mu$, we find

$$q_{1,0}=\frac{q_{3,1}v_2-q_{3,2}v_1+q_{3,2}m-q_{3,1}w_2}{w_1-\mu}, \tag{14}$$

$$q_{1,1}=\frac{q_{3,0}v_2+q_{3,3}v_1-q_{3,3}m+q_{3,0}w_2}{w_1-\mu}, \tag{15}$$

$$q_{1,2}=\frac{q_{3,3}v_2+q_{3,0}v_1+q_{3,0}m-q_{3,3}w_2}{w_1-\mu}, \tag{16}$$

$$q_{1,3}=\frac{q_{3,2}v_2-q_{3,1}v_1-q_{3,1}m+q_{3,2}w_2}{w_1-\mu}, \tag{17}$$

where q_{30},q_{31},q_{32}, and q_{33} are arbitrary. Making these substitutions for $q_{1,i}, 0\leqslant i\leqslant 3$ in Q we discover that $QV-WQ=0$. Thus the algebraic conditions on Q imply that Q intertwines V and W. This fact[5] reduces Eq. (11) to

$$Q_r+MQ_z=0. \tag{18}$$

The 16 components of Eq. (18) form four pairs of decoupled equations and each pair is a Cauchy–Riemann equation couple. We conclude from this that there are analytic functions F, G, J, and K for which

$$\begin{aligned} F&=q_{3,1}+iq_{3,0}, \quad G=q_{3,3}+iq_{3,2}, \\ J&=q_{1,1}+iq_{1,0}, \quad K=q_{1,3}+iq_{1,2}, \end{aligned} \tag{19}$$

where the complex variable is $r+iz$, where $q_{1,0},q_{1,1},q_{1,2}$, and $q_{1,3}$ are given by Eqs. (14)–(17). Defining a scalar ψ and a 2×2 matrix T by

$$\psi = -\frac{iv_2}{w_1-\mu}, \tag{20}$$

$$T = \frac{1}{w_1-\mu}\begin{pmatrix} iv_2 & -(v_1+\mu) \\ v_1-\mu & iv_2 \end{pmatrix}, \tag{21}$$

and defining column vectors $\boldsymbol{K}=(K,J)$ and $\boldsymbol{G}=(G,F)$, we can eliminate the eight $q'_{ij}s$ from Eqs. (14)–(17) and (19) to derive

$$\boldsymbol{K} = \psi\boldsymbol{G} + T\boldsymbol{G}^\star, \tag{22}$$

where the star is the complex conjugate. By supplementing Eq. (22) with its complex conjugate, we obtain (in 2×2 block form)

$$\begin{pmatrix} \boldsymbol{K} \\ \boldsymbol{G} \end{pmatrix} = \begin{pmatrix} \psi T & (1+\psi^2)T \\ T & \psi T \end{pmatrix}\begin{pmatrix} \boldsymbol{K} \\ \boldsymbol{G} \end{pmatrix}^\star. \tag{23}$$

Since $F,G,J,$ and K are analytic, Eq. (23) imposes onerous conditions on the analytic functions $F,G,J,$ and K. We offer two techniques to analyze these equations.

Our first technique is to find differential equations that the potentials must satisfy to guarantee that the analytic functions $F,G,J,$ and K exist. We start by representing Eq. (22) as $\boldsymbol{H}=\Phi\boldsymbol{H}^\star$, where Φ is a 4×4 matrix and $\boldsymbol{H}$ is a column vector of analytic functions. If $\boldsymbol{H}$ is analytic, then we can use the Cauchy–Riemann equations to derive a differential equation for $\boldsymbol{H}$

$$\partial_s\boldsymbol{H} + \Phi(\partial_{s^\star}\Phi)^\star\boldsymbol{H} = 0, \tag{24}$$

where the complex variable is $s=r+iz$ and $\partial_s^* = (\partial_r + i\partial_z)/2$. On the other hand, if the matrix $\Phi(\partial_{s^\star}\Phi)^\star$ is analytic, then Eq. (24) has a nontrivial analytic solution and further, $\boldsymbol{H}=\Phi\boldsymbol{H}^\star$. Thus our differential condition on the potentials is that $\Phi(\partial_{s^\star}\Phi)^\star$ must be analytic. This condition also can be stated as

$$0 = \partial_{s^*}(\Phi(\partial_{s^\star}\Phi)^\star).$$

We can reduce Eq. (24) to an algebraic problem by factoring the matrix Φ as $S^{-1}S^\star$, where S is analytic. Expressed in terms of S, the general solution to Eq. (24) is $\boldsymbol{H}=S^{-1}\boldsymbol{H}_o$, where $\boldsymbol{H}_o$ is an arbitrary constant vector. Thus the existence of a matrix S is an alternative condition for the existence of analytic functions $F,G,J,$ and K.

A second technique is to view Eqs. (22) as linear equations for the potentials. We have two equations for the four potentials (v_1,v_2,w_1,w_2); however, the potentials are real, so again we supplement Eq. (22) with its complex conjugate to obtain four *linear* equations for the potentials. The linear equations

$$\begin{pmatrix} -G^\star & -iF^\star & J & iF \\ -G & iF & J^\star & -iF^\star \\ F^\star & -iG^\star & K & iG \\ F & iG & K^\star & -iG^\star \end{pmatrix}\begin{pmatrix} v_1 \\ v_2 \\ w_1 \\ w_2 \end{pmatrix} = \begin{pmatrix} \mu J - mG^\star \\ \mu J^\star - mG \\ \mu K - mF^\star \\ \mu K^\star - mF \end{pmatrix} \tag{25}$$

must be solved subject to the solvability condition

$$m^2 - v_1^2 + v_2^2 = \mu^2 - w_1^2 + w_2^2. \tag{26}$$

If no restrictions are placed on the functions $F,G,J,$ and K (other than analyticity), then the only solution to these equations is the unacceptable $w_1=\mu$. To find other solutions, we demand that the determinant of the coefficient matrix in Eq. (25) be zero. This implies

$$F^2 + G^2 = (F^2 + G^2)^\star$$

or

$$FK-GJ=(FK-GJ)^{\star}.$$

Assuming $G\neq 0$, the second condition implies there is a *real* constant α and an analytic function P for which

$$F=PG+\alpha/K,\quad J=PK+\alpha/G.$$

Making these substitutions for F and J, we can find solutions to Eqs. (13) and (25). For example, if $\alpha=0$, $m=0$, and $\mu=1$, then we find

$$v_1=4\frac{\mathrm{Re}(GK^{\star})\ \mathrm{Im}(P)}{\mathrm{Im}((K^2+G^2)(1+P^2))}, \tag{27}$$

$$v_2=2\frac{\mathrm{Re}(GK^{\star})(|P|^2+1)}{\mathrm{Im}((K^2+G^2)(1+P^2))}, \tag{28}$$

$$w_1=\frac{\mathrm{Im}((K^2-G^2)(1+P^2))}{\mathrm{Im}((K^2+G^2)(1+P^2))}, \tag{29}$$

$$w_2=2\frac{\mathrm{Re}(GK(1+P^2))}{\mathrm{Im}((K^2+G^2)(1+P^2))}, \tag{30}$$

where Re and Im are the real and imaginary parts of a complex number, respectively. Setting $P=1$, we find solutions with $v_1=0$

$$v_1=0,\quad v_2=2\frac{\mathrm{Re}(GK^{\star})}{\mathrm{Im}(K^2+G^2)}, \tag{31}$$

$$w_1=\frac{\mathrm{Im}(K^2-G^2)}{\mathrm{Im}(K^2+G^2)},\quad w_2=2\frac{\mathrm{Re}(GK)}{\mathrm{Im}(K^2+G^2)}. \tag{32}$$

(Recall that it is desirable for v_1 and v_2 to be ''simple.'')

We now present two examples of these results.

III. EXAMPLES

For our first example we set

$$m=1,\quad \mu=1,\quad P=1,\quad G=iz+r,\quad K=i.$$

The potentials are given by

$$v_1=0,\quad v_2=(-z^2-2z+r^2-1)/2rz,$$

$$w_1=-(z+1)/z,\quad w_1=(z^2+2z+r^2+1)/2rz.$$

The intertwining matrix is

$$Q=\begin{pmatrix} 0 & -1 & 0 & -1 \\ 1 & 0 & 1 & 0 \\ r & -z & r & -z \\ z & r & z & r \end{pmatrix}, \tag{33}$$

and the matrix V is

$$V=\begin{pmatrix} -v_2 & 0 & 0 & 1+v_1 \\ 0 & v_2 & 1+v_1 & 0 \\ 0 & 1-v_1 & -v_2 & 0 \\ 1-v_1 & 0 & 0 & v_2 \end{pmatrix} \tag{34}$$

and similarly for W. For this example, the matrix Q is not one-to-one, so the Dirac operators are intertwined, but we cannot conclude that they are similar.

For the second example, we set

$$\alpha=-1, \quad \mu=0, \quad m=1, \quad P=0, \quad K=iz+r, \quad G=iz+r.$$

The potentials are

$$v_1=0, \quad w_1=0,$$

$$v_2=-(z^2+r^2)/2rz, \quad w_1=(z-r)(z+r)/2rz \tag{35}$$

and the intertwining matrix is

$$Q=\begin{pmatrix} r/\rho^2 & z/\rho^2 & r & -z \\ -z/\rho^2 & r/\rho^2 & z & r \\ -r/\rho^2 & -z/\rho^2 & r & -z \\ z/\rho^2 & -r/\rho^2 & z & r \end{pmatrix}, \tag{36}$$

where $\rho^2=z^2+r^2$. For this example, the intertwining matrix is one-to-one (its determinant is four) and consequently, the Dirac operators are similar.

IV. CONCLUSION

For a class of noncentral potentials, we have shown how to construct pairs of intertwined Dirac operators. We also determined a differential equation that the potentials of intertwined Dirac operators must satisfy.

In this paper, we considered intertwining by multiplication operators; however, it can be any combination of differential, integral, multiplication, or composition operators. Unless the intertwining operator is relatively simple, then it will not enable one to generate exactly solvable Dirac equations.

We finish by noting that even the concept of intertwining can be generalized. If there are operators Q and D for which $QH_1=H_2D$, then we still get a useful null-space result for H_1 and H_2. This avenue was not explored in the present study, because we can show that for multiplication operators we must have $D=Q$. For more complex operators, we may expect results with $Q \neq D$.

[1] Normally, the domain of $QH_1 - H_2Q$ is not the whole space, so we should write the intertwining condition as $QH_1 - H_2Q \subset 0$. We do not use this notation, so all equalities in this paper should be interpreted as ''equal on a nonempty set.''

Radiation principle for inhomogeneous media

D. Eidus
School of Mathematical Sciences, Sackler Faculty of Exact Sciences, Tel Aviv University, Tel Aviv 69978, Israel

(Received 12 May 1997; accepted for publication 10 October 1997)

The classical Sommerfeld radiation principle, well known for stationary oscillations in homogeneous media, is extended to a more general case where a smooth density $\rho=\rho(x)$, $x\in\mathbb{R}^N$, depends both on $r=|x|$ and on angular coordinates of the point x. We assume that the density behaves like a power r^m, $m>-2$, at infinity, and, moreover, that there exists a one-parameter family of closed asymptotic wave fronts. A Sommerfeld–Rellich-type radiation condition is obtained and a corresponding theorem of unique solvability of the stationary oscillation problem is proved under some conditions imposed on the asymptotic phase. Some examples are given which include the case of elliptic wave fronts. © *1998 American Institute of Physics.* [S0022-2488(98)00602-1]

I. INTRODUCTION

We are concerned with the extension of the classical Sommerfeld radiation principle to a general inhomogeneous medium. We assume that the free oscillation equation in the medium has the form

$$\rho(x)w_{tt}-\Delta w=0, \tag{1.1}$$

where $w=w(x,t)$, $t>0$, $x=(x^{(1)},\ldots,x^{(N)})$, is a point in the Euclidean space $\mathbb{R}^N$, $N\geqslant 2$, and $\rho=\rho(x)$ is a smooth positive function (density) defined on $\mathbb{R}^N$. The separation of the time variable t leads to the equation of stationary oscillations

$$\Delta u+k^2\rho(x)u=0, \tag{1.2}$$

where $k>0$ is the frequency. The corresponding equation of forced oscillations has the form

$$\Delta u+k^2\rho(x)u=f(x). \tag{1.3}$$

First let us assume for simplicity that $f(x)$ vanishes outside a sphere $|x|=r_1$ (i.e., it has a compact support). The case where

$$\rho(x)=\rho_0>0, \quad \rho_0=\text{const}, \tag{1.4}$$

outside a sphere was studied by Sommerfeld. It is known that for any $k>0$ there exists one and only one solution of (1.3) satisfying the following conditions at infinity:

$$u=O(r^{-(N-1)/2}), \tag{1.5}$$

$$u_r-ik\sqrt{\rho_0}u=o(r^{-(N-1)/2}) \tag{1.6}$$

as $r\to\infty$, where $r=|x|$, and u_r is a derivative with respect to r. This statement is called the radiation principle (RP) and the conditions (1.5) and (1.6) are the Sommerfeld radiation conditions (RC). Solutions of (1.3) satisfying RC have the following asymptotics at infinity:

$$u\sim\exp(ik\sqrt{\rho_0}r)g(r,\hat{x}), \quad r\to\infty, \tag{1.7}$$

where $\hat{x}=x/r$ and $g(r,\hat{x})$ behaves as $p(\hat{x})r^{-(N-1)/2}$ at infinity. These solutions are called outgoing because the functions

 © 1998 American Institute of Physics

$$w=e^{-ikt}u$$

are off-going waves described by the equation

$$\rho w_{tt}-\Delta w+e^{-ikt}f=0.$$

Vekua[1] has proved that it suffices to impose the condition (1.6) without (1.5), in order to guarantee the uniqueness of the solution u. Rellich[2] has shown that RC can be written in the following integral form:

$$\int |u_r-ik\sqrt{\rho_0}u|^2\,dx<\infty, \tag{1.8}$$

where we integrate over the whole $\mathbb{R}^N$. The uniqueness under RC (1.8) implies that the point $\lambda=k^2>0$ is not an eigenvalue of the equation (1.2) in H, where H is the space L^2 with the weight function ρ. So the existence of eigenvalues is not compatible with the RP in the above-defined form.

Much literature is devoted to the RP for general high-order equations with coefficients stabilizing fast enough at infinity. The strongest results were obtained by Vainberg (see Ref. 3 and references given there). There are also papers dealing with the RP for different boundary value problems in domains with noncompact boundaries (see Refs. 4 and 5 and the references in Ref. 3). We have to notice that RC can depend both on the equation and on the domain where the boundary value problem is treated.

There are also some results for the equation (1.3) where (1.4) is not valid. For the case of two homogeneous media with an infinite interface between them we can refer to Refs. 6–9. Many papers deal with the special case of stratified media (see Refs. 10–13). Some of these results were generalized recently by Jäger and Saito.[14,15]

Here we extend the RP to the case where the density $\rho(x)$ has the following asymptotics at infinity:

$$\rho(x)\sim\rho_0(\hat{x})r^{-2\alpha},\quad r\to\infty, \tag{1.9}$$

where $\alpha<1$ and $\rho_0(\hat{x})>0$ on the sphere

$$S^{N-1}:=\{x:x\in\mathbb{R}^N,|x|=1\}.$$

The restriction $\alpha<1$ is natural, because for $\alpha>1$ the spectrum of (1.2) in H (defined above) is discrete[16]—which is in contradiction to the RP.

Even for an exact equality (1.9) the variables in (1.2) could be separated only in the following two special cases: $\alpha=1$, which we have eliminated, and the case where

$$\rho_0(\hat{x})=\text{const.} \tag{1.10}$$

In the latter situation we have the exact solution of (1.2) depending on r only:

$$v(r)=r^{-(N-2)/2}H_p^{(1)}(c_0r^{1-\alpha}), \tag{1.11}$$

where c_0 and p are some positive constants. This function has the following asymptotics as $r\to\infty$:

$$v\sim c_1r^{-(N-1-\alpha)/2}\exp(ic_0r^{1-\alpha}) \tag{1.12}$$

[cf. with (1.7)]. This means that $v(r)$ describes an off-going wave and that the following RC is valid:

$$v_r-ik\sqrt{\rho}v=O(r^{-(N+1-\alpha)/2}),\quad r\to\infty. \tag{1.13}$$

Due to $\alpha<1$ the solution $v(r)$ satisfies RC (1.8).

Our first objective is to find a proper RC for densities ρ satisfying (1.9). To this end we apply the following heuristics. By the Dubye procedure[3] one can construct a formal asymptotic solution of (1.2) as $r\to\infty$. The dominant term of the corresponding asymptotic expansion has the following form:

$$\chi=g(r,\hat{x})\ \exp\ (ik\phi(x)), \tag{1.14}$$

where g behaves like $r^{-(N-1-\alpha)/2}$ as $r\to\infty$ and ϕ is a solution of the eikonal equation

$$|\nabla\phi|^2=\rho. \tag{1.15}$$

It is clear that (1.11) is a special case of (1.14). Set

$$\nu=|\nabla\phi|^{-1}\nabla\phi, \quad \chi_\nu=\partial\nu\partial\chi.$$

The function χ satisfies the RC

$$\int\ |\chi_\nu-ik\sqrt{\rho}\chi|^2\ dx<\infty, \tag{1.16}$$

which will be the basis of the RP for ρ satisfying (1.9). We leave out all standard calculations leading to (1.14) because this procedure is purely heuristic. The final results will be formulated in Sec. II and proved in Secs. III–V without using the Dubye method. Their concise description follows.

We assume the existence of an asymptotic solution ϕ (asymptotic phase) of the eikonal equation (1.15), which has a family of closed level surfaces (asymptotic wave fronts) in a neighborhood of infinity, and is increasing at infinity as $r^{1-\alpha}$, where α is the same number as in (1.9). Under these (and some additional) conditions imposed on ϕ, ρ, and f we prove that there exists one and only one solution (1.3) satisfying the RC

$$\int\ (1+r)^{\gamma-1}|u_\nu-ik\sqrt{\rho}u|^2\ dx<\infty, \tag{1.17}$$

where $\gamma=\text{const}$ and $\gamma\in(\alpha,1)$.

The imposed condition, that wave fronts are closed, is essential. For instance in the case where $\rho=\text{const}$, there exist nontrivial plane waves for which

$$u_\nu-ik\sqrt{\rho}u=0$$

in $\mathbb{R}^N$, where ν here is a normal to plane wave fronts.

We can see from the asymptotics (1.14) that the condition $\phi\to\infty$ as $r\to\infty$ in physical terms means that the wave is off-going.

Some of our results are similar to those obtained by Vogelsang in his paper[17] for a general self-adjoint elliptic operator of second order with variable coefficients [instead of Δ in (1.1)–(1.3)] and $\rho=\text{const}$. It might be interesting to combine them.

II. MAIN RESULTS AND EXAMPLES

Let us introduce some notation. For $r_2>r_1>0$ set

$$S(r_1)=\{x:x\in\mathbb{R}^N,|x|=r_1\},$$

$$\Omega(r_1)=\{x:x\in\mathbb{R}^N,|x|<r_1\},$$

$$\Omega_{r_1}=\{x:x\in\mathbb{R}^N,|x|>r_1\},$$

$$\Omega(r_1,r_2)=\{x:x\in\mathbb{R}^N,r_1<|x|<r_2\}.$$

By c and c_j, $j=0,1,...$, we denote positive constants. For $\mathbb{R}_+=\{\tau:\tau\in\mathbb{R},\tau>0\}$ and functions $a:\mathbb{R}^N\to\mathbb{R}$ and $b:\mathbb{R}^N\to\mathbb{R}_+$ we write $a=O(b)$, $r\to\infty$, if $|a(x)|\leqslant c_0 b(x)$ on some Ω_{r_1}, and $a\sim b$, $r\to\infty$, if $ab^{-1}\to 1$ as $r\to\infty$. By $(\xi^{(1)},\dots,\xi^{(N)})$ we denote coordinates of a vector $\xi\in\mathbb{C}^N$ in some orthogonal basis in $\mathbb{C}^N$, by (ξ,η) the inner product of vectors ξ,η in $\mathbb{C}^N$, by $\widehat{(\xi,\eta)}$ the angle between ξ, η, and by $|\xi|$ the norm of ξ in $\mathbb{C}^N$. Throughout the paper we use the tensor rule of summation over repeating indices.

By $\int g\,dx$ we denote the integration over $\mathbb{R}^N$. For derivatives we shall use the following notation:

$$u_j=\partial x_j\partial u,\quad \nabla u=(u_1,\dots,u_N),\quad u_r=\partial r\partial u,\quad r=|x|,$$

$$u_{jl}=\partial x_j\partial x_l\partial^2 u,\quad D^n u=\partial x_1^{n_1}\cdots\partial x_N^{n_N}\partial^{|n|},$$

where $n=(n_1,\dots,n_N)$ and $|n|=n_1+\cdots+n_N$. Denote by $L^2(\omega)$ and L^2_{loc} the sets of complex-valued functions square integrable over $\omega\subset\mathbb{R}^N$ and over every $\Omega(R)$, $R>0$, respectively; by $H^m(\omega)$; H^m_{loc}, $m=0,1,...$, we denote the sets of functions from $L^2(\omega)$, L^2_{loc} which have all distributional derivatives up to the order m belonging to $L^2(\omega)$, L^2_{loc}, respectively. Besides, $H^0=L^2$. Introduce the norm in $H^m(\omega)$:

$$\|g\|^2_{m,\omega}=\int\sum_{|n|=0,\dots,m}|D^n g|^2\,dx,\quad \|g\|_{0,\omega}=\|g\|_{L^2(\omega)}.$$

We say that the sequence $g_n\in H^m_{\mathrm{loc}}$ converges to $g\in H^m_{\mathrm{loc}}$ in H^m_{loc} if $g_n\to g$ in $H^m(\Omega(R))$ for any $R>0$. Let ρ be a given function $\rho:\mathbb{R}^N\to\mathbb{R}_+$. Let H be the Hilbert space of functions $u:\mathbb{R}^N\to\mathbb{C}$ with the norm

$$\|g\|^2=\int\rho|u|^2\,dx.$$

Set

$$H^1_\rho=\{g:g\in H^1_{\mathrm{loc}}\cap H,|\nabla g|\in L^2(\mathbb{R}^N)\},\quad l=-\rho^{-1}\Delta. \tag{2.1}$$

Let C_0^∞ be the set of functions from $C^\infty(\mathbb{R}^N)$ having compact supports, $\mathscr{L}$ be the Friedrichs extension in H of the operator l, initially defined on C_0^∞, and $\mathscr{D}(\mathscr{L})$ be the domain of $\mathscr{L}$. Then $\mathscr{L}$ is a self-adjoint operator in H,

$$\mathscr{D}(\mathscr{L})\subset H^1_\rho. \tag{2.2}$$

We shall assume that on $\mathbb{R}^N$

$$\rho(x)\geqslant c(1+r)^{-2\alpha},\quad \alpha<1. \tag{2.3}$$

Then[18]

$$\mathscr{D}(\mathscr{L})=\{u:u\in H^2_{\mathrm{loc}}\cap H,\ lu\in H\}. \tag{2.4}$$

The equation (1.3) can be written in the form

$$lu-\lambda u=F, \tag{2.5}$$

where $\lambda=k^2>0$, and

$$F=-\rho^{-1}f. \tag{2.6}$$

Definition 2.1: A function $u:\mathbb{R}^N\to\mathbb{C}$ is a solution of the equation (2.5) [or (1.3)] if $u\in H^2_{\mathrm{loc}}$ and (2.5) is valid a.e. on $\mathbb{R}^N$.

If $\lambda \in \mathbb{C}$ is a regular point of the self-adjoint operator $\mathscr{S}$, then for any $F \in H$ there exists one and only one solution of (2.5) belonging to $\mathscr{D}(\mathscr{S})$. So the equation (2.5) has a unique solution in $\mathscr{D}(\mathscr{S})$ for any $F \in H$ if $\lambda < 0$ or $\lambda = k^2 + \varepsilon i$, $\varepsilon \neq 0$.

Definition 2.2: A function $\phi: \Omega_{r_0} \to \mathbb{R}$, $\phi \in C^1$, belongs to the class U_τ, $\tau > 0$, if on some domain Ω_{r_1}, $r_1 \geqslant r_0$, we have $|\nabla \phi| > 0$,

$$0 < c_1 < r^{-\tau} \phi < c_2, \tag{2.7}$$

and there exists such a constant $c_0 > 0$ that for any $c > c_0$ the set

$$\Gamma(c) := \{x : x \in \mathbb{R}^N, \phi(x) = c\} \tag{2.8}$$

is a $(N-1)$-dimensional closed surface.

Note 2.1: Suppose $\phi \in U_\tau$, $\tau > 0$. Then for any $c > c_0$ the set

$$\Gamma_c := \{x : x \in \mathbb{R}^N, \phi(x) > c\} \tag{2.9}$$

is the exterior of the closed surface $\Gamma(c)$ and $\Gamma(c) \to \infty$ as $c \to +\infty$. Moreover, the vector

$$\nu = \nabla \phi / |\nabla \phi| \tag{2.10}$$

is determined at any point $x \in \Omega_{r_1}$ and coincides with the external normal to the corresponding surface $\Gamma(c)$ at the same point x.

Definition 2.3: Let $\rho: \mathbb{R}^N \to \mathbb{R}_+$. A function $\phi: \Omega_{r_0} \to \mathbb{R}$, $r_0 > 0$, $\phi \in C^1(\Omega_{r_0})$, is said to be an asymptotic phase for ρ if

$$|\nabla \phi|^2 \sim \rho, \quad r \to \infty,$$

and a δ-asymptotic phase, $\delta > 0$, if

$$\rho^{-1} |\nabla \phi|^2 = 1 + O(r^{-\delta}), \quad r \to \infty. \tag{2.11}$$

The corresponding surfaces (2.8) are said to be asymptotic (δ-asymptotic) wave fronts (cf. Refs. 19 and 20).

Note 2.2: If ϕ is an asymptotic phase for ρ, and on Ω_{r_0}, $r_0 > 0$,

$$0 < c_1 < r^{2\alpha} |\nabla \phi|^2 < c_2,$$

then on some Ω_{r_1}, $r_1 \geqslant r_0$,

$$0 < c_3 < r^{2\alpha} \rho < c_4.$$

Theorem 2.1: *Suppose* $\rho: \mathbb{R}^N \to \mathbb{R}_+$, $\rho \in C^1(\mathbb{R}^N)$ *and there exist such constants* $r_0 > 0$ *and* $\alpha < 1$ *that*

$$\rho r^{2\alpha} \geqslant c_0 > 0, \quad x \in \Omega_{r_0}, \tag{2.12}$$

$$Z := \lim_{R \to \infty} \inf_{r > R} (r(\log(r^{2\alpha} \rho))_r) > \alpha - 1. \tag{2.13}$$

Let $\phi \in C^1(\Omega_{r_1})$, $r_1 \geqslant r_0$, *be a corresponding asymptotic phase belonging to* U_τ, $\tau > 0$. *Then any solution* $u = u(x)$ *of (1.2) on* $\mathbb{R}^N$ *satisfying the RC*

$$\int_{\Omega_{R_1}} r^{\gamma - 1} |u_\nu - ik\sqrt{\rho} u|^2 \, dx < \infty, \tag{2.14}$$

where $\gamma = const$,

$$\gamma > \max\{\alpha, \alpha - Z\}, \tag{2.15}$$

and ν is defined by (2.10), vanishes a.e. on $\mathbb{R}^N$.

Corollary 2.1: Let u_1 and u_2 be solutions of (1.2) which satisfy the RC (2.14) with $\gamma=\gamma_1$ and $\gamma=\gamma_2$, respectively. Then $u_1=u_2$ a.e. on $\mathbb{R}^N$.

Note 2.3: The condition (2.13) actually coincides with the virial condition introduced by Agmon[21] (see also Ref. 17) for the Schrödinger equation.

Theorem 2.2: *Let $\rho=\rho(x)$ be a function satisfying the same condition as in Theorem 2.1 and, in addition, on Ω_{r_0},*

$$|\nabla\rho|\leqslant cr^{-2\alpha-1}. \tag{2.16}$$

Suppose that there exists a corresponding δ-asymptotic phase $\phi\in C^3(\Omega_{r_0})$, such that $\phi\in U_\tau$, $\tau=1-\alpha$, and

$$\delta>\max\{1-\alpha,1-\alpha-\tfrac{1}{2}Z\}, \tag{2.17}$$

$$|D^j\phi|\leqslant c_j r^{1-\alpha-|j|},\quad x\in\Omega_{r_0},\quad |j|=1,2,3. \tag{2.18}$$

Assume that there exists such a number γ that

$$\max\{\alpha,\alpha-Z\}<\gamma\leqslant\min\{1,2\delta+3\alpha-2\} \tag{2.19}$$

and for all pairs of vectors $(\xi,x)\in R^N\times\Omega_{r_0}$ the following inequality is valid:

$$G(x,\xi,\gamma)\geqslant c_0 r^{\gamma-1}|\xi|^2, \tag{2.20}$$

where $c_0>0$ is independent of x and *ξ,*

$$G(x,\xi,\gamma)=\phi^m(\phi_{lj}\xi^{(\ell)}\xi^{(j)}+m\phi^{-1}|\nabla\phi|^2((\xi,\nu)^2-\tfrac{1}{2}|\xi|^2)), \tag{2.21}$$

$$m=(\alpha+\gamma)/(1-\alpha). \tag{2.22}$$

Then for any $f\in V$, where

$$V=\left\{v: v\in L^2_{\mathrm{loc}}, \int (1+r)^{1+\gamma}|v|^2\,dx<\infty\right\}, \tag{2.23}$$

there exists one and only one solution of the problem (1.3) and (2.14).

Note 2.4: It follows from the conditions of Theorem 2.2 that in some Ω_{r_1}, $r_1>0$, we have

$$0<c_1\leqslant\rho r^{2\alpha}\leqslant c_2.$$

It is not easy, in general, to verify the condition (2.20). First let us deal with the simplest case where $\phi=\phi(r)$. Then

$$G(x,\xi,\gamma)=\phi^m(M_1|\xi|^2+M_2(|\xi|^2-(\xi,\hat{x})^2)),$$

where

$$M_1=\frac{m}{2}\,\phi^{-1}(\phi_r)^2+\phi_{rr},$$

$$M_2=r^{-1}\phi_r-\phi_{rr}-m\phi^{-1}(\phi_r)^2.$$

Thus the conditions $M_1>0$ and $M_2\geqslant 0$ are sufficient for (2.20).

Example 2.1: Let on Ω_{r_0}, $r_0>0$,

$$\phi(r)=(1-\alpha)^{-1}r^{1-\alpha},\quad \rho(x)=r^{-2\alpha}+\varphi(x),$$

where $\alpha<1$, and on Ω_{r_0}, for $|j|=0,1$,

$$|D^j\varphi|\leqslant cr^{-2\alpha-|j|-\delta} \tag{2.24}$$

and $\delta>1-\alpha$. Then

$$M_1=\tfrac{1}{2}(\gamma-\alpha)r^{-1-\alpha},\quad M_2=(1-\gamma)r^{-1-\alpha}.$$

By (2.24) ϕ is a δ-asymptotic phase for ρ and $Z=0$. Moreover (2.12), (2.13), and (2.16) hold, as does (2.20) for $\gamma\in(\alpha,1)$. So the assertion of Theorem 2.2 is valid for any $\gamma\in(\alpha,1)$.

Let us proceed to an example where ρ is weakly oscillating.

Example 2.2: Let on Ω_{r_0}, $r_0>0$,

$$\phi=(1-\alpha)^{-1}r^{1-\alpha}(A+\sin\log r),\quad \alpha<1,\quad A>0,$$

$$\rho=r^{-2\alpha}\left(A+\sin\log r+\frac{\cos\log r}{1-\alpha}\right)^2+\varphi(x),$$

where (2.24) holds with $\delta>\frac{3}{2}(1-\alpha)$. It is easy to see that ϕ is a δ-asymptotic phase for ρ, and for $A\to+\infty$

$$|\nabla\phi|^2=A^2r^{-2\alpha}(1+O(A^{-1})),$$

$$M_1=\tfrac{1}{2}A(\gamma-\alpha)r^{-1-\alpha}(1+O(A^{-1})),$$

$$M_2=A(1-\gamma)r^{-1-\alpha}(1+O(A^{-1})),$$

$$Z=O(A^{-1}).$$

Choose now some $\varepsilon\in(0,1-\alpha)$. Then for all sufficiently large A the inequality (2.12) is valid on some Ω_{r_1}, $r_1\geqslant r_0$, and

$$0<-Z<\varepsilon$$

[so (2.13) is also valid]. Now we can choose some $\gamma\in(\alpha+\varepsilon,1)\subset(\alpha-Z,1)$. Due to the choice of δ our γ satisfies (2.19) for all $A>A_0$, $A_0=A_0(\alpha)$. Now we can find such a number $A_1\geqslant A_0$, $A_1=A_1(\gamma,\alpha)$, that for $A>A_1$ the inequality (2.20) is valid. So the statement of Theorem 2.2 holds for all sufficiently large A.

Now we shall go on to another special case where the function ϕ is homogeneous of degree $1-\alpha$, $\alpha<1$. Here we obtain some geometric criteria for (2.20) imposed on wave fronts, which are quite verifiable. So let us assume that an asymptotic phase ϕ can be written in the form

$$\phi(x)=r^{1-\alpha}\hat{\phi}(\hat{x}),\quad \alpha<1, \tag{2.25}$$

where as above $r=|x|$, $\hat{x}=r^{-1}x$, and $\hat{\phi}:S^{N-1}\to\mathbb{R}_+$, and that $\phi\in C^3(\Omega_{r_0})$. By (2.25) the function ϕ is extended to the whole $\mathbb{R}^N$. The equation of each surface $\Gamma(c)$, $c>0$, can be written as follows:

$$r=c_1J(\hat{x}), \tag{2.26}$$

where $J>0$ on S^{N-1} and $c_1=c^{1/1-\alpha}$. The Euler identity for homogeneous functions

$$(x,\nabla\phi)=(1-\alpha)\phi \tag{2.27}$$

implies that for $x\neq0$,

$$|\nabla\phi|>0, \tag{2.28}$$

$$s:=\cos\psi>0, \tag{2.29}$$

where $\psi=(\widehat{x,\nu})$. By (2.25), (2.26), and (2.28) we can conclude that

$$\phi\in U_\tau,\quad \tau=1-\alpha. \tag{2.30}$$

All the functions $D^j\phi$, $|j|=1,2,3$, are homogeneous of degree $1-\alpha-|j|$ and could be written in the form analogous to (2.25). Hence the vector ν and the angle ψ depend only on $\hat{x}$ and do not depend on r. From (2.28) we have

$$0<c_1\leqslant r^{2\alpha}|\nabla\phi|^2\leqslant c_2,\quad x\in\Omega_{r_0},\quad r_0>0. \tag{2.31}$$

Set

$$\begin{gathered} s_0=\min_{\hat{x}\in S^{N-1}} s(\hat{x}),\\ \sigma=2s^2-1,\quad \sigma_0=2s_0^2-1. \end{gathered} \tag{2.32}$$

From (2.29)

$$s_0>0. \tag{2.33}$$

Definition 2.4: A smooth closed $(N-1)$-dimensional surface is said to be strongly convex if its second Gaussian quadratic form (with respect to the external normal) is negative definite at any point of the surface.

If the representation (2.25) for ϕ is valid, then all wave fronts $\Gamma(c)$, $c>0$, are homothetic. Therefore if one $\Gamma(c_1)$, $c_1>0$, is strongly convex, then all others $\Gamma(c)$, $c>0$, are too. Suppose it is the case and (g) is an $(N-1)$-dimensional tangential plane for a surface $\Gamma(c)$ at a point $x\in\Gamma(c)$. The Meunier formula for $\Gamma(c)$ can be written in the form

$$\phi_{ij}(x)g^{(i)}g^{(j)}=|\nabla\phi(x)|K(x,g), \tag{2.34}$$

where $g=(g^{(1)},\ldots,g^{(N)})\in(g),|g|=1$, and $K(x,g)$ is a positive curvature of the curve, which is the normal section of $\Gamma(c)$ at the point x by a two-dimensional plane of vectors ν, g. Due to (2.34)

$$K(x,g)=r^{-1}K_1(\hat{x},g), \tag{2.35}$$

where $K_1(\hat{x},g)$ is independent of r and will be called a normalized curvature for the direction $\hat{x}$ and the normal section defined by $g\in(g)$. Set

$$\beta=(\widehat{g,x}).$$

Then

$$\sin\beta\in[s,\,1]. \tag{2.36}$$

For $\sigma_0>0$ let us introduce

$$M=\min_{(\hat{x},g)\in Y}\frac{s(\hat{x})\sigma(\hat{x})K_1(\hat{x},g)}{\sigma(\hat{x})+\cos^2\beta}, \tag{2.37}$$

where $\beta=\beta(\hat{x},g)$ and Y is the following set of pairs $(\hat{x},g)$:

$$Y=\{(\hat{x},g):\hat{x}\in S^{N-1},g\in(g),|g|=1\}. \tag{2.38}$$

Theorem 2.3: *Let $\rho:\mathbb{R}^N\to\mathbb{R}_+$, $\rho\in C^1(\mathbb{R}^N)$ and (2.13) and (2.16) be satisfied where $\alpha<1$, $Z\geqslant 0$. Suppose that ϕ is a δ-asymptotic phase for ρ, its wave fronts are strongly convex, $\phi\in C^3(\Omega_{r_0})$, (2.25) is valid where $\hat{\phi}>0$ on S^{N-1}, $\alpha<1$, and*

$$2\delta>3(1-\alpha). \tag{2.39}$$

Then the following hold.

(i) *For any* $\alpha<0$ *there exists such* $\gamma\in(\alpha,1]$ *that for each* $f\in V$ *[see (2.23)], the problem (1.3) and (2.14) has one and only one solution.*

(ii) *For any* $\alpha\geqslant 0$ *such* γ *exists under the following additional conditions:*

$$\sigma_0>0, \tag{2.40}$$

$$\alpha<M\sigma_0(1+\sqrt{1-\sigma_0^2})^{-1}. \tag{2.41}$$

Corollary 2.2: Suppose that ϕ *satisfies the conditions of Theorem 2.3,* $\rho:\mathbb{R}^N\to\mathbb{R}_+$, $\rho\in C^1(\mathbb{R}^N)$, *and in* Ω_{r_0} *the function*

$$\varphi=\rho-|\nabla\phi|^2 \tag{2.42}$$

satisfies (2.24), where $|j|=0,1$, $2\delta>3(1-\alpha)$. *Then the statement of Theorem 2.3 holds.*

Note 2.5: The conditions (2.40) and (2.41) can be easily verified if

$$\phi=\phi_0^{1-\alpha},$$

where ϕ_0 is a homogeneous function of degree 1 and ϕ_0 does not depend on α. Then wave fronts and, consequently, σ_0 and M do not depend on α.

For instance, we can see, returning to Example 2.1, that $\Gamma(c)$ is a sphere $r=c$ and $\psi=0$, $s=1$, $\sigma=1$, $K_1=1$, and $\beta=\pi/2$ for all $\hat{x}$, g. Hence $M=1$ and conditions (2.40) and (2.41) are satisfied for any $\alpha\in[0,1)$.

Example 2.3: Let $N=2$, $\alpha<1$,

$$\phi(x)=(a_1^{-2}x_1^2+a_2^{-2}x_2^2)^{(1-\alpha)/2},$$

$\alpha,a_1,a_2=$const, and $a_1\geqslant a_2>0$. Then the wave fronts are ellipses:

$$a_1^{-2}x_1^2+a_2^{-2}x_2^2=c,\quad c>0. \tag{2.43}$$

Set $t=a_2^2a_1^{-2}$. It is easy to obtain that

$$\sigma_0=(1+t)^{-2}(6t-1-t^2), \tag{2.44}$$

$$M=(8t)^{-1}(6t-1-t^2)\quad\text{for}\quad t\in(3-2\sqrt{2},\tfrac{1}{3}), \tag{2.45}$$

$$M=t\quad\text{for}\quad t\in[\tfrac{1}{3},1]. \tag{2.46}$$

Thus $\sigma_0>0$ for $a_1^{-1}a_2\in(\sqrt{2}-1,1]$. Suppose that ρ satisfies the condition of Corollary 2.2. Then the RP is valid for $\alpha=0$ if $a_1^{-1}a_2\in(\sqrt{2}-1,1]$ and for $\alpha>0$ under the additional condition (2.41) where σ_0 and M are given by (2.44)–(2.46).

III. PROOF OF THEOREM 2.1

Lemma 3.1: Let $\varkappa,q\in\mathbb{R}$, $\rho:\mathbb{R}^N\to\mathbb{R}_+$, $u:\Omega_{r_0}\to\mathbb{C}$, $r_0>0$,

$$\int_{\Omega_{r_0}} r^{\varkappa}\rho|u|^2\,dx<\infty, \tag{3.1}$$

$$\rho r^{2\alpha}\geqslant c>0,\quad x\in\Omega_{r_0}. \tag{3.2}$$

(i) *If* $q\leqslant\min\{2-N,\varkappa+2(1-\alpha)\}$, *then*

$$\liminf_{R\to\infty} R^q\int_{S(R)}(\bar{u}u_r+u\bar{u}_r)\,ds\leqslant 0. \tag{3.3}$$

(ii) *If* $q>2-N$, $\ell\geqslant 2\alpha-N$, *then (3.3) holds.*

These statements can be obtained from the identity

$$\frac{d}{dr}\int_{S^{N-1}}|u|^2\,ds=\int_{S^{N-1}}(\overline{u}u_r+u\overline{u_r})ds. \tag{3.4}$$

Lemma 3.2: Let u *be a solution of the equation (1.2) on* Ω_{r_0}, $r_0>0$, *where (3.1) and (3.2) are satisfied with* $\alpha\leqslant 1$, $\ell=\gamma-1$, and $\gamma>0$. *Then*

$$\int_{\Omega_{r_0}} r^{\gamma-1}|\nabla u|^2\,dx<\infty. \tag{3.5}$$

Proof: By Lemma 3.1 we obtain (3.3) with $q=\gamma-1$. Multiply (1.2) by $r^{\gamma-1}\overline{u}$, pass to real parts, and integrate over $\Omega(r_0,R)$, $R>r_0$. The obtained equality, together with (3.3) where $q=\gamma-1$, implies (3.5). □

Lemma 3.3: Let u *be a solution of the equation (1.2) where* ρ: $\mathbb{R}^N\to\mathbb{R}_+$, $\rho\in C^1(\mathbb{R}^N)$. *Conditions (2.12) and (2.13) hold with* $\alpha<1$,

$$\int (1+r)^{\gamma-1}(\rho|u|^2+|\nabla u|^2)\,dx<\infty, \tag{3.6}$$

where $\gamma\in\mathbb{R}$, and γ *satisfies (2.15).*

Then $u=0$ *a.e. on* $\mathbb{R}^N$.

Proof: Without loss of generality we can assume that Im $u=0$ and, from (2.13) and (2.15), that $\gamma\leqslant 1$.

Multiply (1.2) by $r^{\gamma}u_r$ and integrate over Ω_{R_0}, $R_0>r_0>0$. Integrating by parts we can obtain by (3.6) the following equality:

$$\begin{aligned}
&R_0^{\gamma}\int_{S(R_0)}(u_r^2+1/2(k^2\rho u^2-|\nabla u|^2))\,dS+(1-\gamma)\\
&\quad\times\int_{\Omega_{R_0}} r^{\gamma-1}(|\nabla u|^2-u_r^2)\,dx+1/2(N-1-\alpha)\\
&\quad\times\int_{\Omega_{R_0}} r^{\gamma-1}(k^2\rho u^2-|\nabla u|^2)\,dx+k^2/2\\
&\quad\times\int_{\Omega_{R_0}} r^{\gamma-2\alpha}(r^{2\alpha}\rho)_r u^2\,dx+(\gamma-\alpha)/2\\
&\quad\times\int_{\Omega_{R_0}} r^{\gamma-1}(k^2\rho u^2+|\nabla u|^2)dx=0.
\end{aligned} \tag{3.7}$$

By (1.2), (2.12), (2.15), and (3.7) we obtain the inequality

$$\begin{aligned}
&\int_{\Omega_r} r^{\gamma-1}(|\nabla u|^2+k^2\rho u^2)\,dx\\
&\quad\leqslant c_1 r^{\gamma}\int_{S(r)}(|\nabla u|^2-k^2\rho u^2)\,dS-c_2 r^{\gamma-1}\int_{S(r)} uu_r\,dS,\quad c_1,c_2>0,
\end{aligned} \tag{3.8}$$

which is valid for all $r\geqslant r_1>0$ where r_1 is sufficiently large. Multiplying (3.8) by $r^{1-2\alpha}$ and integrating with respect to r from a fixed $r>r_1$ to $R>r$ we obtain

$$\int_r^R r^{1-2\alpha}\,dr\int_{\Omega_r} r^{\gamma-1}(|\nabla u|^2+k^2\rho u^2)\,dx$$

$$\leqslant c_1\int_{\Omega(r,R)} r^{1+\gamma-2\alpha}(|\nabla u|^2-k^2\rho u^2)\,dx-c_2\int_{\Omega(r,R)} r^{\gamma-2\alpha}uu_r\,dx. \tag{3.9}$$

After integration by parts we obtain by Lemma 3.1 that

$$I(r):=\int_{\Omega_r} r^{1+\gamma-2\alpha}(k^2\rho u^2+|\nabla u|^2)\,dx<\infty \tag{3.10}$$

and

$$I(r)\leqslant r^{2-2\alpha}\int_{\Omega_r} r^{\gamma-1}(k^2\rho u^2+\nabla u|^2)\,dx+c_3\int_{\Omega_r} r^{\gamma-1-2\alpha}u^2\,dx+c_4r^{\gamma-2\alpha}$$

$$\times\int_{S(r)} u^2\,dS-c_5r^{1+\gamma-2\alpha}\int_{S(r)} uu_r\,dS. \tag{3.11}$$

Multiply (3.11) by $r^{1-2\alpha}$ and integrate again with respect to r as above. It results in

$$\int_{\Omega_r} r^{\gamma-1+2p(1-\alpha)}(k^2\rho u^2+|\nabla u|^2)\,dx<\infty \tag{3.12}$$

where $p=2$. Repeating this process p times we obtain that (3.12) holds for any integer p.

Set

$$v(x,m)=r^m u,\quad m>0. \tag{3.13}$$

By (1.2) on Ω_{r_0}, $r_0>0$,

$$\Delta v-\frac{2m}{r}\,v_r+\left(k^2\rho+\frac{m(m-N+2)}{r^2}\right)v=0. \tag{3.14}$$

From (3.12) $\forall m>0$ we have

$$\int r^m(|\nabla v|^2+\rho v^2)\,dx<\infty. \tag{3.15}$$

Multiply (3.14) by rv_r and integrate over Ω_r. After integration by parts we obtain by (3.15)

$$I_1(r):=r\int_{S(r)}\left(v_r^2+\frac{1}{2}\left(\left(k^2\rho+\frac{m(m-N+2)}{r^2}\right)v^2-|\nabla v|^2\right)+\frac{N-2}{2}\left(\frac{m}{r^2}\,v^2-\frac{vv_r}{r}\right)\right)dS$$

$$=-\int_{\Omega_r}\left(2m\left(v_r^2-\frac{(N-2)^2}{4}\,\frac{v^2}{r^2}\right)+k^2\left(\rho+\frac{r\rho_r}{2}\right)v^2\right)dx. \tag{3.16}$$

By the Hardy inequality we have

$$\int_{\Omega_r}\left(v_r^2-\frac{(N-2)^2}{4}\,\frac{v^2}{r^2}\right)dx\geqslant 0. \tag{3.17}$$

The inequalities (3.16) and (3.17) together with (2.13) imply that for $r\geqslant r_2>0$, $\forall m>0$

$$I_1(r)\leqslant 0, \tag{3.18}$$

where r_2 is a sufficiently large number. Returning by (3.13) to the initial function u we can write $I_1(r)$ in the form

$$I_1(r)=r^{2m+1}(Am^2+Bm+C), \tag{3.19}$$

where $A=A(r)$, $B=B(r)$, and $C=C(r)$ are independent of m, and

$$A=r^{-2}\int_{S(r)} u^2\, dS. \tag{3.20}$$

Now (3.18)–(3.20) imply that $u=0$ a.e. on Ω_{r_2}, which in turn yields that $u=0$ a.e. on $\mathbb{R}^N$.[22] □

Note 3.1: Lemma 3.3 follows for some α, γ from a Rellich-type[2] lower estimate of solutions of the Schroedinger equation, given by Agmon.[21] For instance, suppose $Z=0$ (as for $\rho=r^{-2\alpha}$, $r>r_0>0$), $\alpha\in(0,1)$. Then the mentioned estimate together with (2.12) and (2.13) implies that Lemma 3.3 is valid for $\gamma>3\alpha$, which is more restrictive than (2.15).

Proof of Theorem 2.1: Integrate the identity

$$ik\phi^{-q}(\overline{u}u_\nu-u\overline{u_\nu})=\phi^{-q}\phi_\nu^{-1}(|u_\nu-ik\phi_\nu u|^2-|u_\nu|^2-k^2\phi_\nu^2|u|^2), \tag{3.21}$$

where

$$q=(1-\gamma)\tau^{-1}, \tag{3.22}$$

over a closed surface $\Gamma(c)$, $c\geqslant c_0$, where ν, defined by (2.10), is an external normal for $\Gamma(c)$ and ϕ_ν and u_ν are the corresponding derivatives. By the equation (1.2) and the definition of $\Gamma(c)$ we obtain

$$\int_{\Gamma(c)}\frac{|u_\nu|^2+k^2\phi_\nu^2|u|^2}{\phi_\nu\phi^q}\,dS=\int_{\Gamma(c)}\frac{|u_\nu-ik\phi_\nu u|^2}{\phi_\nu\phi^q}\,dS. \tag{3.23}$$

Integrate this identity with respect to c over the interval $c_1\leqslant c\leqslant c_2$, $c_1\geqslant c_0$. Setting

$$\Omega'(c_1,c_2)=\{x:x\in\mathbb{R}^N, c_1\leqslant\phi(x)\leqslant c_2\}$$

we obtain by (2.7) and

$$dx=\phi_\nu^{-1}ds\; dc$$

the following inequality:

$$\int_{\Omega'(c_1,c_2)} r^{\gamma-1}\phi_\nu^2|u|^2\, dx\leqslant b_0\int_{\Omega'(c_1,c_2)} r^{\gamma-1}|u_\nu-ik\phi_\nu u|^2\, dx, \tag{3.24}$$

where $b_0>0$ does not depend on c_1,c_2. Due to Definition 2.3 and Note 2.1 there exists such $c_3>c_0$ for any $\varepsilon>0$ that outside $\Gamma(c_3)$ we have

$$|\phi_\nu-\sqrt{\rho}|<\varepsilon\sqrt{\rho}. \tag{3.25}$$

Choose $\varepsilon>0$ such that

$$2b_0\varepsilon^2(1-\varepsilon)^{-2}<1. \tag{3.26}$$

Then (3.24) yields for $c_2>c_1>c_3$

$$\int_{\Omega'(c_1,c_2)} r^{\gamma-1}\rho|u|^2\, dx\leqslant b_1\int_{\Omega'(c_1,c_2)} r^{\gamma-1}|u_\nu-ik\sqrt{\rho}u|^2\, dx,$$

where b_1 does not depend c_2, $c_2>c_1$. Now (2.14) together with Lemmas 2.2 and 2.3 implies that $u=0$ a.e. on $\mathbb{R}^N$. □

IV. PROOF OF THEOREM 2.2

In order to prove the theorem we shall make use of the following limiting absorption method:[3] first we deal with the perturbed equation

$$\Delta u+(k^2+\varepsilon i)\rho u=f, \tag{4.1}$$

where the imaginary absorption term $i\varepsilon\rho u$, $\varepsilon=\text{const}>0$, is introduced. This equation can be written in the form (2.5) and (2.6); it was stated in Sec. II that, for $F\in H$, the equation (2.5) has a unique solution $u_\varepsilon\in\mathscr{D}(\mathscr{S})$. Moreover, from (2.2) we have

$$u_\varepsilon\in H^1_\rho. \tag{4.2}$$

Under condition (2.3) the set $\mathscr{D}(\mathscr{S})$ can be defined by (2.4). Imposing on F a condition more restrictive than $F\in H$, we shall prove that u_ε converges as $\varepsilon\to 0$, in a less restrictive space than H, and its limit u is a solution of the problem (1.3) and (2.14). To this end we have to obtain some estimates for u_ε analogous with those proved by Jäger.[23] Put

$$u_\varepsilon=e^{ik\phi(x)}v_\varepsilon. \tag{4.3}$$

From now on we write v instead of v_ε. Definition 2.3 together with (4.2) implies

$$v\in H^1_\rho. \tag{4.4}$$

By (4.1) a.e. on $\mathbb{R}^N$

$$\Delta v+2ki(\nabla v,\nabla\phi)+i(k\Delta\phi+\varepsilon\rho)v+k^2(\rho-|\nabla\phi|^2)v=e^{-ik\phi}f. \tag{4.5}$$

In particular (4.5) implies that $v\in\mathscr{D}(\mathscr{S})$. Choose some numbers δ_1, R_0, and R_1 so that $r_0<R_0<R_1$ and $0<\delta_1<\frac{1}{2}$, and on Ω_{R_0}

$$\begin{gathered}\phi(x)\geqslant 1,\\ 1-\delta_1\leqslant\rho/|\nabla\phi|^2\leqslant 1+\delta_1.\end{gathered} \tag{4.6}$$

Introduce a smooth cut-function $\theta:\mathbb{R}^N\to\mathbb{R}$, $0\leqslant\theta\leqslant 1$,

$$\theta=0 \quad \text{for } x\in\Omega(R_0), \tag{4.7}$$

$$\theta=1 \quad \text{for } x\in\Omega_{R_1}. \tag{4.8}$$

Now multiply (4.5) by $\theta\phi^s\overline{v}$, where $s=\text{const}$,

$$s<0, \tag{4.9}$$

pass to imaginary parts, and integrate over $\mathbb{R}^N$. After integration by parts we obtain

$$\begin{aligned}&\varepsilon\int\theta\phi^s\rho|v|^2\,dx-ks\int\theta\phi^{s-1}|\nabla\phi|^2|v|^2\,dx-\text{Im}\,s\int\theta\phi^{s-1}\overline{v}(\nabla v,\nabla\phi)\,dx\\ &\quad-\int\phi^s(|v|^2\,\text{Re}(\nabla\theta,\nabla\phi)+\text{Im}((\nabla v,\nabla\theta)\overline{v}))\,dx=\text{Im}\int\theta\phi^s f\overline{v}e^{-ik\phi}\,dx.\end{aligned} \tag{4.10}$$

Putting $s=1+\mu(1-\alpha)^{-1}$ into (4.10), where

$$\mu<-(1-\alpha), \tag{4.11}$$

we obtain that for μ satisfying (4.11)

$$\varepsilon\int (1+r)^{1+\mu-\alpha}\rho|v|^2\,dx+\int (1+r)^{\mu}\rho|v|^2\,dx$$
$$\leqslant c(\mu)\left(\int_{\Omega(R_1)}(|v|^2+|\nabla v|^2)\,dx+\int (1+r)^{\mu}|\nabla v|^2\,dx+\int (1+r)^{\mu+2}|f|^2\,dx\right), \tag{4.12}$$

where $c(\mu)$ is independent of ε, f.

Let $b:H_\rho\times\mathbb{R}_+\times V\to\mathbb{R}$, $B:\mathbb{R}_+\times V\to\mathbb{R}$, where $B(\varepsilon,f)=b(v,\varepsilon,f)\ \forall(\varepsilon,f)\in\mathbb{R}_+\times V$ where $v=v(\epsilon,f)\in H_\rho$ as above.

Condition Q: The functional B satisfies the condition Q if there exists such a constant $\delta_1>0$ and a function $c(\delta_0)>0$, $\delta_0>0$, which are independent of ε, f, that for any $\delta_0>0$

$$|B|\leqslant\delta_0\int (1+r)^{\gamma-1}|\nabla v|^2\,dx+c(\delta_0)$$
$$\times\left(\int (1+r)^{\gamma-1-\delta_1}|\nabla v|^2\,dx+\int_{\Omega(R_1)}(|v|^2+|\nabla v|^2)\,dx+\int (1+r)^{1+\gamma}|f|^2\,dx\right). \tag{4.13}$$

Now multiply (4.5) by

$$\theta\phi^m((\nabla\phi,\nabla v)-(2k)^{-1}(k\Delta\phi+\varepsilon\rho)\overline{v}),$$

integrate over $\mathbb{R}^N$, and pass to real parts. After integration by parts we obtain

$$\sum_{j=0}^{11} I_j=0, \tag{4.14}$$

where I_j are the following integrals which are absolutely convergent because of $\alpha<1$, $\gamma\leqslant 1$, and (4.4):

$$I_0=\mathrm{Re}\int \phi^m\left((\nabla v,\nabla\theta)(\nabla\phi,\nabla v)-\frac{1}{2}(\nabla\theta,\nabla\phi)|\nabla v|^2+\frac{1}{2k}(\nabla\theta,\nabla v)(k\Delta\phi+\epsilon\rho)v\right)dx,$$

$$I_1=\int \theta(G(x,\nabla(\mathrm{Re}\ v),\gamma)+G(x,\nabla(\mathrm{Im}\ v),\gamma))\,dx,$$

$$I_2=\frac{m}{2}\,\mathrm{Re}\,i\int \phi^{m-1}\theta v(\nabla\phi,\nabla v)\Delta\phi\,dx,$$

$$I_3=\frac{\varepsilon m}{2k}\,\mathrm{Re}\int \theta\phi^{m-1}\rho v(\nabla\phi,\nabla v)\,dx,$$

$$I_4=\frac{1}{2}\,\mathrm{Re}\int \theta\phi^m v(\nabla(\Delta\phi),\nabla v)\,dx,$$

$$I_5=\frac{\varepsilon}{2k}\,\mathrm{Re}\int \theta\phi^m v(\nabla\rho,\nabla v)\,dx,$$

$$I_6=k^2\,\mathrm{Re}\int \theta\phi^m(|\nabla\phi|^2-\rho)(\nabla\phi,\nabla v)v\,dx,$$

$$I_7=\frac{k^2}{2}\,\mathrm{Re}\int \theta\phi^m(|\nabla\phi|^2-\rho)|v|^2\Delta\phi\,dx,$$

$$I_8=\frac{k\epsilon}{2}\int \theta\phi^m(|\nabla\phi|^2-\rho)\rho|v|^2\,dx,$$

$$I_9=\mathrm{Re}\int \theta\phi^m e^{-ik\phi}f(\nabla\phi,\nabla v)\,dx,$$

$$I_{10}=\frac{1}{2}\,\mathrm{Re}\int \theta\phi^m e^{-ik\phi}\overline{vf}\Delta\phi\,dx,$$

$$I_{11}=\frac{\varepsilon}{2k}\,\mathrm{Re}\int \theta\phi^m e^{-ik\phi}\rho\overline{vf}\,dx.$$

From (4.7) and (4.8) the integral I_0 satisfies the condition Q. Due to (2.20)

$$I_1\geqslant c\int_{\Omega_{R_1}} r^{\gamma-1}|\nabla v|^2\,dx. \tag{4.15}$$

By $\alpha<1$, $\gamma\leqslant 1$, $\phi\in U_{1-\alpha}$, and (2.18) we obtain

$$|I_2|\leqslant \delta_0\int (1+r)^{\gamma-1}|\nabla v|^2\,dx+c(\delta_0)\int (1+r)^{\mu}\rho|v|^2\,dx, \tag{4.16}$$

where $\delta_0>0$ is arbitrarily small, $c(\delta_0)$ does not depend on ε and f, and

$$\mu=\gamma-1+2(\alpha-1).$$

Since $\mu<\alpha-1$ we can apply the inequality (4.12) to the second integral in (4.16). So, we reach the conclusion that I_2 satisfies the condition Q. It is easy to see that

$$|I_3|\leqslant \delta_0\int (1+r)^{\gamma-1}|\nabla v|^2\,dx+\varepsilon^2c(\delta_0)\int (1+r)^{\gamma-1}\rho|v|^2\,dx. \tag{4.17}$$

By (4.1) we have

$$\varepsilon^2\int \rho|v|^2\,dx\leqslant\int \rho^{-1}|f|^2\,dx. \tag{4.18}$$

Now (4.17) and (4.18) imply that I_3 satisfies the condition Q. The terms I_4 and I_5 can be estimated in the same way as I_2 and I_3, respectively, so they also satisfy the condition Q.

By Definition 2.3 we obtain

$$|I_6|\leqslant \delta_0\int (1+r)^{\gamma-1}|\nabla v|^2\,dx+c(\delta_0)\int (1+r)^{\mu_1}\rho|v|^2\,dx, \tag{4.19}$$

where

$$\mu_1=1+\gamma-2\alpha-2\delta.$$

From (2.19)

$$\mu_1<\alpha-1,$$

and we can apply (4.12) to the last term in (4.19). As a result we obtain that I_6 satisfies the condition Q. Analogously we obtain the same for I_7, I_8, and I_9. Now

$$|I_{10}|\leqslant c\left(\int (1+r)^{\alpha-1-\delta_0}\rho|v|^2\,dx+\int (1+r)^{1+\gamma}|f|^2\,dx\right)$$

where

$$\delta_0=2-\alpha-\gamma>0.$$

It follows from (4.12) that I_{10} satisfies Q. From (4.18) the same holds for I_{11}. So because of (4.14) I_1 satisfies the condition Q, i.e., the inequality (4.13) is valid for $B=I_1$. This and (4.15) imply

$$c_1\int (1+r)^{\gamma-1}|\nabla v|^2\,dx\leqslant\delta_0\int (1+r)^{\gamma-1}|\nabla v|^2\,dx+c(\delta_0)\Bigg(\int (1+r)^{\gamma-1-\delta_1}|\nabla v|^2\,dx + \int_{\Omega(R_1)}(|v|^2+|\nabla v|^2)\,dx+\int (1+r)^{1+\gamma}|f|^2\,dx\Bigg). \tag{4.20}$$

Choose here a sufficiently small number $\delta_0>0$. Then

$$\int (1+r)^{\gamma-1}|\nabla v|^2\,dx\leqslant c_2\Bigg(\int (1+r)^{\gamma-1-\delta_1}|\nabla v|^2\,dx+\int_{\Omega(R_1)}(|v|^2+|\nabla v|^2)\,dx + \int (1+r)^{1+\gamma}|f|^2\,dx\Bigg), \tag{4.21}$$

where c_j do not depend on ε and f. From (4.21) we can choose a sufficiently large number $R_2>R_1$ and obtain the inequality

$$\int (1+r)^{\gamma-1}|\nabla v|^2\,dx\leqslant c\Bigg(\int_{\Omega(R_2)}(|v|^2+|\nabla v|^2)\,dx+\int (1+r)^{1+\gamma}|f|^2\,dx\Bigg), \tag{4.22}$$

where c is independent of ε and f. By (4.12) and (4.22) we have

$$\int (1+r)^{\alpha-1-\delta_0}\rho|v|^2\,dx\leqslant c(\delta_0)\Bigg(\int_{\Omega(R_2)}(|v|^2+|\nabla v|^2)\,dx+\int (1+r)^{1+\gamma}|f|^2\,dx\Bigg), \tag{4.23}$$

where δ_0 is an arbitrarily small positive number. Let us introduce the norm

$$\|g\|^2_{\delta_0}=\int ((1+r)^{\alpha-1-\delta_0}\rho|g|^2+(1+r)^{\gamma-1}|\nabla g|^2)\,dx.$$

Combining (4.22) and (4.23) we obtain

$$\|v_\epsilon\|^2_{\delta_0}\leqslant c(\delta_0)\Bigg(\int_{\Omega(R_2)}(|v|^2+|\nabla v|^2)\,dx+\int (1+r)^{1+\gamma}|f|^2\,dx\Bigg), \tag{4.24}$$

where $v_\varepsilon=v$ and $c(\delta_0)$ is independent of $(\varepsilon,f)\in(0,1)\times V$.

Now we shall prove that for fixed $\delta_0,k>0,f\in V$, the following inequality holds:

$$\|v_\varepsilon\|_{\delta_0}\leqslant c(\delta_0), \tag{4.25}$$

where $c(\delta_0)$ does not depend on $\varepsilon\in(0,1)$. Without loss of generality we can assume that $\delta_0<2(1-\alpha)$. Suppose that (4.25) is incorrect for some $(\delta_0,f)\in(0,2(1-\alpha))\times V$. Then there exists such a sequence $\varepsilon_n\to0$ as $n\to\infty$ that

$$N_n:=\|v_{\varepsilon_n}\|_{\delta_0}\to\infty. \tag{4.26}$$

Set $v_{\varepsilon_n}=v^{(n)}$,

$$w_n=v^{(n)}N_n^{-1},$$

$$U_n = w_n \exp(ik\phi). \tag{4.27}$$

Then

$$\Delta U_n + (k^2 + \varepsilon_n i)\rho U_n = f N_n^{-1}, \tag{4.28}$$

$$\|w_n\|_{\delta_0} = 1. \tag{4.29}$$

We shall make use of the following well-known inequality (see, e.g., Ref. 24):

$$\|g\|_{2,\Omega(R_1)} \leqslant c(R_1, R_2)(\|g\|_{0,\Omega(R_2)} + \|\Delta g\|_{0,\Omega(R_2)}), \tag{4.30}$$

where $0 < R_1 < R_2$, $g \in H^2_{\text{loc}}$, and $c(R_1, R_2)$ does not depend on g. From (4.28)–(4.30) we have

$$\|U_n\|_{2,\Omega(R)} \leqslant c(R), \tag{4.31}$$

which is valid for any $R > 0$ and $c(R)$ does not depend on n. It follows from (4.30) and (4.31) that there exists a subsequence U_{n_m} which converges, as $m \to \infty$, in H^2_{loc}, to a solution U of the equation

$$\Delta U + k^2 \rho U = 0 \tag{4.32}$$

on $\mathbb{R}^N$. In this connection we have from (4.27) that $w_{n_m} \to w$ in H^2_{loc} and

$$U = w \exp(ik\phi), \tag{4.33}$$

$$\|w\|_{\delta_0} \leqslant 1. \tag{4.34}$$

From (4.33)

$$U_\nu - ik\sqrt{\rho}U = e^{ik\varphi}(w_\nu + ikw(|\nabla\phi| - \sqrt{\rho})). \tag{4.35}$$

Due to the definition of δ-asymptotic phase

$$\big||\nabla\phi| - \sqrt{\rho}\big| \leqslant c r^{-\delta}\sqrt{\rho}, \quad x \in \Omega_{r_0},$$

hence

$$\int (1+r)^{\gamma-1} |U_\nu - ik\sqrt{\rho}U|^2 \, dx \leqslant c \int ((1+r)^{\gamma-1-2\delta}\rho|w|^2 + (1+r)^{\gamma-1}|\nabla w|^2) \, dx. \tag{4.36}$$

By (2.19) $\gamma - 1 - 2\delta \leqslant 3(\alpha - 1)$, and because of our choice of δ_0

$$\gamma - 1 - 2\delta < \alpha - 1 - \delta_0.$$

From (4.34) and (4.36) we have

$$\int (1+r)^{\gamma-1} |U_\nu - ik\sqrt{\rho}U|^2 \, dx \leqslant c\|w\|^2_{\delta_0} < \infty. \tag{4.37}$$

Theorem 2.1 together with (4.32) and (4.37) implies that $U = 0$ a.e. on $\mathbb{R}^N$. So $w_{n_m} \to 0$, as $m \to \infty$, in H^2_{loc}. On the other hand, from (4.24) we have

$$1 = \|w_n\|^2_{\delta_0} \leqslant c\left(\int_{\Omega(R_2)} (|w_n|^2 + |\nabla w_n|^2) \, dx + N_n^{-2} \int (1+r)^{1+\gamma} |f|^2 \, dx \right). \tag{4.38}$$

For $n = n_m$ the right side of (4.38) tends to zero as $m \to \infty$, which contradicts (4.38). So the inequality (4.25) is proved.

Now (4.1), where $u=u_\varepsilon$, and (4.25) and (4.30) yield

$$\|u_\varepsilon\|_{2,\Omega(R)}\leqslant c(R), \tag{4.39}$$

where $c(R)$ is independent of ε.

Therefore as above we can choose a sequence u_{ε_m} which converges in H^2_{loc}, and $\varepsilon_m\to 0$ as $m\to\infty$. The limit function u is a solution of (1.3). Moreover the sequence

$$v_{\varepsilon_m}=u_{\varepsilon_m}\exp(-ik\phi)$$

also has a limit v in H^2_{loc}. From (4.25) we obtain, as above for U, that the function u satisfies the radiation condition (2.14). □

V. PROOF OF THEOREM 2.3

Throughout this section we assume that the conditions of Theorem 2.3 are valid.

Lemma 5.1: Suppose $\sigma_0>0$ and M is defined by (2.37). Then $M\leqslant 1$.

Proof: Suppose $M>1$. By (2.37)

$$\begin{gathered}K_1(\hat{x},g)\geqslant(\sigma s)^{-1}M(\sigma+\cos^2\beta)\geqslant M,\\ K(x,q)=r^{-1}K_1\geqslant r^{-1}M.\end{gathered} \tag{5.1}$$

Let $c>0$ be a fixed number and $\gamma(c)$ be a one-dimensional curve on $\Gamma(c)$, which is an intersection of $\Gamma(c)$ and some two-dimensional plane (σ) passing through the origin $x=0$. Denote by ℓ the arc length on $\gamma(c)$, by $g_1(x)$ the unit tangent vector, and by $\kappa(x)$ the curvature of $\gamma(c)$ at the point $x\in\gamma(c)$. It is easy to see that

$$2\pi=\int_{\gamma(c)}\kappa\,d\ell\geqslant\int_{\gamma(c)}K(x,g_1(x))\,d\ell. \tag{5.2}$$

Passing to polar coordinates r, φ on the plane (σ) we obtain by (5.1)

$$\int_{\gamma(c)}K\,d\ell=\int_0^{2\pi}K\sqrt{r^2+r_\varphi^2}\,d\varphi\geqslant 2\pi M.$$

This together with (5.2) is in contradiction with our assumption. □

Proof of Theorem 2.3: Let us notice that because of (2.31) and Note 2.2 the condition (2.12) is valid. Therefore all the conditions of Theorem 2.1 are satisfied. The conditions (2.16) and (2.18) of Theorem 2.2 are also satisfied, and we have to verify its condition (2.20) only. For $Z\geqslant 0$ and (2.39) the interval (2.19) coincides with $(\alpha,1]$.

Let $x\in\mathbb{R}^N$ be a point belonging to some wave front $\Gamma(c)$, $c>0$. The vector ν and the plane (g) are defined at the point x as in Sec. II. Consider an arbitrary vector $\xi\in\mathbb{R}^N$ and expand it as follows:

$$\xi=\xi_x+\xi_g, \tag{5.3}$$

where $\xi_x=b_1x$, $\xi_g=b_2g$, $b_j\in\mathbb{R}$, $j=1,2$, and $g\in(g)$, $|g|=1$. For any two vectors ξ_1, $\xi_2\in\mathbb{R}^N$ put

$$\widetilde{\phi}(\xi_1,\xi_2)=\phi_{ij}(x)\xi_1^{(i)}\xi_2^{(j)},\quad \widetilde{\phi}(\xi)=\widetilde{\phi}(\xi,\xi).$$

From (2.34)

$$\widetilde{\phi}(\xi_g)=r^{-1}K_1(\hat{x},g)|\nabla\phi||\xi_g|^2. \tag{5.4}$$

The functions ϕ_i and ϕ_{ij} are homogeneous of degree $-\alpha$ and $-1-\alpha$, respectively. Therefore

$$\widetilde{\phi}(\xi_x) = -\alpha(1-\alpha)r^{-2}\phi|\xi_x|^2,$$

$$\widetilde{\phi}(\xi_x,\xi_g) = 0,$$

$$\widetilde{\phi}(\xi) = r^{-1}|\nabla\phi|K_1(\hat{x},g)|\xi_g|^2 - \alpha(1-\alpha)r^{-2}\phi|\xi_x|^2. \tag{5.5}$$

From (2.27) and (5.5)

$$G(x,\xi,\gamma) = \widetilde{A}_1|\xi_x|^2 + 2\widetilde{A}_2|\xi_x||\xi_g| + \widetilde{A}_3|\xi_g|^2. \tag{5.6}$$

where $\widetilde{A}_j = \chi A_j$,

$$\chi = \tfrac{1}{2}\phi^m|\nabla\phi|r^{-1}s^{-1},$$

$$A_1 = \sigma\gamma - \alpha,$$

$$A_2 = -(\alpha+\gamma)\cos\beta,$$

$$A_3 = 2K_1 s - \alpha - \gamma.$$

We have $\chi > 0$, hence it is sufficient to find $\gamma \in (\alpha,1]$ such that for any $(\hat{x},g) \in Y$ [see (2.38)]

$$A_1 > 0, \tag{5.7}$$

$$A_1A_3 - A_2^2 > 0. \tag{5.8}$$

These inequalities can be written as follows:

$$\sigma\gamma - \alpha > 0, \tag{5.9}$$

$$(\sigma+\cos^2\beta)\gamma^2 - 2\gamma(s\sigma K_1 + \alpha(\sin^2\beta - s^2)) + \alpha(2sK_1 - \alpha\sin^2\beta) < 0. \tag{5.10}$$

It is obvious that if $\alpha < 0$, then both (5.9) and (5.10) hold for all sufficiently small $|\gamma|$. If $\alpha = 0$, then it is sufficient for (5.9) and (5.10) that (2.40) and $\gamma \in (0,2M)$ are valid. Let us go on to a more complicated case $\alpha > 0$. By (2.41)

$$d := M^2 - 2\alpha\sigma_0^{-1}M + \alpha^2 > 0. \tag{5.11}$$

Consider the inequality

$$\gamma^2 - 2M\gamma + \alpha(2\sigma_0^{-1}M - \alpha) < 0, \tag{5.12}$$

which holds for all γ from the interval $(\gamma) := (\gamma_-,\gamma_+)$ where

$$\gamma_\pm = M \pm \sqrt{d}. \tag{5.13}$$

We shall prove that for these γ the inequalities (5.9) and (5.10) hold. First let us show that

$$\gamma_- \geqslant \alpha\sigma_0^{-1} \geqslant \alpha. \tag{5.14}$$

By (2.41) we have $M > \alpha\sigma_0^{-1}$. This and

$$(M - \alpha\sigma_0^{-1})^2 - d = \alpha^2(\sigma_0^{-2} - 1) \geqslant 0$$

imply (5.14), which in turn yields (5.9) for all $\gamma \in (\gamma)$, $\hat{x} \in S^{N-1}$. Rewrite (5.12) in the form

$$\gamma^2 - 2M(\gamma - \alpha\sigma_0^{-1}) - \alpha^2 < 0. \tag{5.15}$$

By (5.14), (2.36), and (2.37) we obtain from (5.15) that for all $\gamma \in (\gamma)$ and $(\hat{x},g) \in Y$ the following inequality holds:

$$\gamma^2-\frac{2s\sigma K_1}{\sigma+\cos^2\beta}(\gamma-\alpha\sigma_0^{-1})-\frac{\alpha^2\sin^2\beta}{\sigma+\cos^2\beta}-\frac{2\gamma\alpha(\sin^2\beta-s^2)}{\sigma+\cos^2\beta}<0,$$

which immediately implies (5.10). From (5.13) and Lemma 5.1 we have $\gamma_-<1$. This together with (5.14) leads to the conclusion that there exist points $\gamma\in(\alpha,1)$ such that (5.7) and (5.8) are valid for all $(\hat{x},g)\in Y$. So, the form $G(x,\xi,\gamma)$ is positive definite for these γ and $x\in\Omega_{r_0}$. Now by a continuity argument and by the obvious inequality

$$r^{1-\gamma}\chi\geqslant c_0>0,\quad x\in\Omega_{r_0}$$

we obtain the validity of (2.20) for chosen γ. □

On the electrodynamic group: The relativistic radiation reaction force

Angel Prieto[a)]
Physics Department, Birkbeck College, University of London, Malet Street, London WC1E 7HX, England

(Received 5 September 1996; accepted for publication 12 December 1997)

The relativistic force exerted by a classical electromagnetic field on an electron is examined from the point of view that associates the differential geometry of the space–time trajectory with a continuous group of transformations. The group relevant to this particular case is the group generated by the electromagnetic field tensor (electrodynamic group). This group is studied in some detail by treating separately the two parts of the Liénard–Wiechert expression for the tensor. The intrinsic differential equations of the space–time trajectories associated with the electrodynamic group are obtained by the Cartan method of the moving frame. These equations show that the curvature of the trajectory is associated only with the generalized Coulomb field and the hypertorsion with the radiation field. According to these equations, the relativistic force may have two components along orthogonal spacelike directions: The first, an apparent force, reduces to the Coulomb force in the nonrelativistic limit. The other is orthogonal to the four-momentum and to the apparent force; this is the radiation reaction force. In the nonrelativistic limit it manifests itself as a frictional force reducing the momentum. The approach also offers a point of view of the conventional treatment of radiation reaction in which the nonlocality in time emerges from the geometry of the problem. The implications pertaining to other areas of physics of the causal connection found between the hypertorsion and the radiation field are briefly considered. © *1998 American Institute of Physics.* [S0022-2488(98)03603-2]

I. INTRODUCTION

An important identity in the theory of relativity[1] relates the velocity vector, v^μ, of a free particle of mass m, with its energy-momentum vector, p^μ, by

$$p^\mu = mc^2 v^\mu, \tag{1}$$

where

$$v^\mu = \gamma\left(1, \frac{\mathbf{v}}{c}\right), \quad v^2 = 1, \tag{2}$$

$$p^\mu = (E, \mathbf{p}c). \tag{3}$$

In the rest frame of the particle, $(\mathbf{v}=0)$, (1) reduces to Einstein famous energy-mass[2] formula: $E_0 = mc^2$.

When the particle is subject to an external force, the relativistic dynamics involved requires one to consider the relativistic force, f^μ, which equals the (proper time) rate of change of p^μ,

$$f^\mu \equiv \dot{p}^\mu. \tag{4}$$

Equations (1) and (4) lead to

a)Present address: Departamento de Física, Facultad de Ciencias, Universidad Nacional Autónoma de México, Apdo. 40-147, México 06140, D. F. México; Electronic mail: apr@graef.fciencias.unam.mx

$$f^{\mu}=mc^{2}a^{\mu}, \tag{5}$$

where the acceleration a^{μ} is universally taken as

$$a^{\mu}\equiv\dot{v}^{\mu}=\frac{\gamma^{3}}{c^{3}}\,(\mathbf{v}\cdot\mathbf{a})v^{\mu}+\frac{\gamma^{2}}{c^{2}}\,(0,\mathbf{a}). \tag{6}$$

The operation used to obtain the right-hand side of (6) is considered in this paper from a novel point of view. We know that there is a continuous group of transformations invariably associated with a continuous curve, whatever the space in which the curve is embedded. This association determines the intrinsic differential equations of the curve in that space. If the curve represents the trajectory or world line of a point particle, the association, which in particular determines the rate of change of the tangent, by (1) and (4), determines also the relativistic force. In the case considered in this paper, the group and its relation with the curve, absolutely, cannot be ignored.

Now, let the particle be an electron and let the external force be produced by an electromagnetic field. The force (4), as described by (5) and (6), in this important case, can be shown to be incomplete. Specifically, it fails to account for the dynamical effects produced on the charge by the radiated field.[3,4] In fact, the conventional method of calculating the relativistic Larmor rate of radiated energy,[5] leads to

$$\dot{p}^{\mu}=\frac{2}{3}\,\frac{e^{2}}{4\pi}\,|a|^{2}v^{\mu}. \tag{7}$$

This expression, even if it appears as a rate of change of the momentum, cannot be accepted as a legitimate force because it is not orthogonal to the velocity. Following the conventional approach, the Schott[6] term, involving the third time derivative of the position, is added to this expression to produce the Abraham–Lorentz–Dirac force. The orthogonality problem is then corrected but new ones are introduced.

The operation employed to calculate the rate of change of the velocity (6) is based on the Euclidean group of rotations: The differentials with respect to the arclength are obtained in terms of the differentials with respect to ordinary time. This operation is only partially correct. There is, however, a group of space–time rotations which, if used instead, in addition to that result, produces also the radiation reaction force. This group is associated with the trajectories of electrons.

The relation between the curve followed in space-time by a (point) electron and this other group of rotations can be understood very easily. Let the initial position and momentum of the electron in a homogeneous electromagnetic field F be known. Denote by p the initial momentum vector and by p' the momentum vector after the electron has been subject for a time θ to the electromagnetic field. Both vectors p and p' are, necessarily, timelike, of norm $(mc^{2})^{2}$ and future pointing. Consequently, there is a restricted Lorentz transformation $\Lambda(\theta)$ such that: $p'(\theta)=\Lambda(\theta)p$. Clearly, this transformation depends also on the electromagnetic field. In fact, the transformation $\Lambda(F,\theta)=e^{\theta F}$ has already been studied.[7] Let Λ operate on p for a continuous range of values of the parameter θ, starting from zero. Then, p' describes a continuous path on the unit pseudosphere (a hyperboloid) centered at the origin of p. The curve associated with this rotation is fully defined if we also consider the translation of the base point of p' such that c times the length of the arc covered by the translation equals the proper time of the particle and such that the successive orientations of p' defined by θ, coincide in each point with the direction of the translation.

Lanczos, starting from a different point of view, arrives also at the similar conclusion that the Lorentz–Minkowski force implies that the electromagnetic field tensor is the infinitesimal generator of a Lorentz transformation.[8] Although these facts are known since long ago, nobody, as far as is known to the present author, has investigated the properties of the group generated by this tensor nor has used it to derive the intrinsic differential equations of the trajectories associated with it. This paper is devoted to the study of this particular group and the differential geometry of the curves associated with it, in Minkowski space. The findings that result from this study, however, because of their invariant nature, transcend the realm of electrodynamics.

The theory that studies the association between a given group and a specific differential geometry is of crucial importance to understand the point of view developed in this paper. As a reference, the method, due mainly to Cartan,[9] is reviewed succinctly in Appendix A.

II. THE ELECTRODYNAMIC GROUP

In this section a group of transformations of a continuous parameter is produced by considering the electromagnetic field tensor as the infinitesimal generator of the group. This group, defined in the space–time of special relativity (Lorentz space, also Minkowski space, $M^{3,1}$), has specific and unique characteristics. Some of these characteristics are investigated here.

Consider the transformations of the type[10]

$$\Lambda = I + \frac{\theta F}{1!} + \frac{(\theta F)^2}{2!} + \frac{(\theta F)^3}{3!} + \cdots = e^{\theta F}. \tag{8}$$

In (8), F is the electromagnetic field tensor and θ a continuous parameter. As F is antisymmetric, it is traceless. Therefore Λ is a Lorentz transformation: $\det \Lambda = e^{\theta \operatorname{tr} F} = 1$.

If θ is a real number and F is constant, the set represented by all Λ, for all possible values of θ has the structure of a group. I will refer to this group as the electrodynamic group.

To find the properties of the group, it is necessary to express F more specifically. We can express F using the electric and magnetic vector fields, **E** and **B**. However, this expression of F is not appropriate to investigate the differential geometry associated with the group because it is not possible to discriminate between the Coulomb and the radiation fields, as it is desirable. The expression of F using the retarded Liénard–Wiechert potentials allows for this discrimination very naturally. Of course, the results obtained using either of the two expressions of F are equivalent.

The well-known[11] expression for the electromagnetic field F produced by a trajectory $z(s)$ at the point x of space–time, calculated from the retarded Liénard–Wiechert potentials, is

$$F(x)^{\mu}{}_{\nu} = k\left(\frac{1}{\rho^3}\, d^{[\mu}\dot{z}_{\nu]}\right)_{\text{Coul}} + k\left[-\frac{(d^{\alpha}\ddot{z}_{\alpha})}{\rho^3}\, d^{[\mu}\dot{z}_{\nu]} + \frac{1}{\rho^2}\, d^{[\mu}\ddot{z}_{\nu]}\right]_{\text{rad}}. \tag{9}$$

The tensor F at the field point x depends exclusively on the retarded point of the trajectory, $z(s_0)$, that makes the distance $d = (x - z)$, a null distance: $d^2 = 0$. Here $\rho = d^{\alpha}\dot{z}_{\alpha}(s_0)$ and k is a positive constant. The first parentheses in (9) enclose the velocity fields, also known as the generalized Coulomb fields. The square brackets display the radiation or acceleration fields. They are the infinitesimal generators of the transformations of the group that we are developing.

To further investigate the properties of the electrodynamic group, we first insert (9) in (8). We find that, thanks to some recurrence relations in the powers of F, it is possible to express (8) in a more meaningful way. In fact, if we multiply F by itself n times, we easily find[12]

$$F^{2n} = \left(\frac{k}{\rho^2}\right)^{2(n-1)} F^2, \quad n = 1,2,3,... \tag{10}$$

and

$$F^{(2n+1)} = \left(\frac{k}{\rho^2}\right)^{2n} F, \quad n = 0,1,2,... . \tag{11}$$

Taking advantage of these relations we express the series expansion of the exponential, (8), as

$$\Lambda(x,\theta) = \left\{I - \frac{\rho^4}{k^2}\, F^2(x)\right\} + \left[\cosh\left(\frac{\theta k}{\rho^2}\right)\right]\left\{\frac{\rho^4}{k^2}\, F^2(x)\right\} + \left[\sinh\left(\frac{\theta k}{\rho^2}\right)\right]\left\{\frac{\rho^2}{k}\, F(x)\right\}. \tag{12}$$

The transformation $\Lambda(x,\theta)$, for a fixed value of θ, can now be understood as the simultaneous action of the three operators enclosed in braces. Each operator has a well-defined function in the transformation of a vector at the point x (the initial momentum, for example). The first produces the component of the transformed vector that remains unaffected by the transformation. The

second produces the component along the projection of the original vector on a three-plane. The third produces the component along a transversal direction on the same three-plane. We will investigate these transformations in more detail.

Λ operates on a vector having x as its point of origin. For a finite value of θ, Λ transforms this vector onto another vector of the same norm and of the same space. In other words, the transformation is a space–time rotation. In this respect, it may appear confusing when we operate below with Λ on a vector parallel to $\dot{z}(s_0)$. The fact that this vector has its origin at the point x is considered by the use of the null distance d that corresponds to x in the operators of Λ. The transformed vector, by the same reason, belongs also to this space. Nevertheless, this circumstance is recalled when necessarily changing s_0 to x, writing instead of $\dot{z}(s_0)$, $\dot{z}(x)$.

Let us now consider the Coulomb transformation by itself. The infinitesimal generator is

$$F_{\mathrm{Coul}}(x)=\frac{k}{\rho^3}\,(d^\mu \dot{z}_\nu - d_\nu \dot{z}^\mu). \tag{13}$$

This tensor produces the same recurrence relations as those found before, (10) and (11). The Coulomb transformation is then

$$\Lambda_{\mathrm{Coul}}(x,\theta)=e^{\theta F_{\mathrm{Coul}}(x)}=\left\{I-\frac{\rho^4}{k^2}\,F^2_{\mathrm{Coul}}(x)\right\}+\left[\cosh\left(\frac{\theta k}{\rho^2}\right)\right]\left\{\frac{\rho^4}{k^2}\,F^2_{\mathrm{Coul}}(x)\right\}$$
$$+\left[\sinh\left(\frac{\theta k}{\rho^2}\right)\right]\left\{\frac{\rho^2}{k}\,F_{\mathrm{Coul}}(x)\right\}. \tag{14}$$

It is convenient to express the three operators in braces in (14) with the aid of the retarded distance introduced by Synge[13] and defined, in his words, as follows: ''...from the point x drop the perpendicular x-b on the line of $\dot{z}(s_0)$. Then x-b is space-like, and has a length, say ρ. Let us call ρ the retarded distance of x from $z(s_0)$... .'' In the following, ρ will always be different from zero and from infinity. Let $\hat{r}$ denote a unit vector along the segment x-b, from the point b, on the line of $\dot{z}(s_0)$, to the field point x. The null vector d can now be expressed as

$$d^\mu=\rho(\hat{r}^\mu+\dot{z}^\mu), \tag{15}$$

with

$$\hat{r}^\alpha \dot{z}_\alpha=0, \quad \hat{r}^2=-1. \tag{16}$$

From (15) and (16) we have

$$d^\alpha \dot{z}_\alpha=\rho, \tag{17}$$

which justifies the notation used in (9) and,

$$d^\alpha \ddot{z}_\alpha=\rho(\hat{r}^\alpha \ddot{z}_\alpha)\equiv\rho\phi. \tag{18}$$

Using (15), the operators in the Coulomb transformation, (14), have the simple form

$$\frac{\rho^2}{k}\,F_{\mathrm{Coul}}(x)=(\hat{r}^\mu \dot{z}_\nu-\hat{r}_\nu \dot{z}^\mu), \tag{19}$$

and

$$\frac{\rho^4}{k^2}\,F^2_{\mathrm{Coul}}(x)=(-\hat{r}^\mu \hat{r}_\nu+\dot{z}^\mu \dot{z}_\nu). \tag{20}$$

It is clear from (19) and (20) that the transformation Λ_{Coul}, for a fixed and finite value of θ, produces a rotation on the $(\dot{z}^\mu(x)-\hat{r}^\mu)$-plane. This plane is timelike and cuts the light cone with vertex at x in the two lightlike directions: $\dot{z}^\mu(x)\pm\hat{r}^\mu$. The transformation leaves invariant the spacelike plane orthogonal to the plane of rotation (dual plane).

Consider at x a unit timelike vector, $\hat{v}$, on the plane of rotation

$$\hat{v}^{\mu}=a\hat{r}^{\mu}+b\dot{z}^{\mu}, \quad b^2-a^2=1, \quad b>0. \tag{21}$$

From (16), (19), and (20),

$$\left[I-\frac{\rho^4}{k^2}\,F^2_{\mathrm{Coul}}(x)\right]\hat{v}=0, \tag{22}$$

$$\frac{\rho^4}{k^2}\,F^2_{\mathrm{Coul}}(x)\hat{v}=\hat{v}, \tag{23}$$

and

$$\left[\frac{\rho^2}{k}\,F_{\mathrm{Coul}}(x)\right]\hat{v}=b\hat{r}^{\mu}+a\dot{z}^{\mu}. \tag{24}$$

We can now analyze the action of the operator Λ_{Coul} on the vector $\hat{v}$, as the sum of the actions of its three components, (22), (23), and (24). The operator in (23) projects the vector onto itself because $\hat{v}$ belongs to the $(\dot{z}^{\mu}-\hat{r}^{\mu})$-plane. The orientation of the transformed vector is the same as that of the original vector. Contrarily, the operator in (24) transforms timelike directions, as that of $\hat{v}$, into transversal directions. In fact, the transformed vector is spacelike: $(b\hat{r}^{\mu}+a\dot{z}^{\mu})^2=-1$. For a fixed and finite value of θ, $\Lambda_{\mathrm{Coul}}(x)$ rotates $\hat{v}$ from its original position towards the transversal direction by a hyperbolic angle that depends on the value of θ. For a continuous range of values of θ starting from zero, the end point or tip of the transformed vector describes a segment of a hyperbola drawn on the rotation plane, approaching asymptotically one of the two future null directions. In case the vector $\hat{v}$ has a component on the dual plane defined by the transformation, this component would remain unaffected, as seen from (22).

The radiation transformation seems to be more interesting, partly because it describes the dynamical process involved with the radiation, and partly because it deals with a peculiar type of Lorentz transformations. The infinitesimal generator is

$$F_{\mathrm{rad}}(x)=-\frac{k(d^{\alpha}\ddot{z}_{\alpha})}{\rho^3}\,(d^{\mu}\dot{z}_{\nu}-d_{\nu}\ddot{z}^{\mu})+\frac{k}{\rho^2}\,(d^{\mu}\ddot{z}_{\nu}-d_{\nu}\dot{z}^{\mu}). \tag{25}$$

The radiation generator is a nilpotent tensor of index three,[14]

$$F^3_{\mathrm{rad}}=0. \tag{26}$$

This property characterizes the uncommon type of Lorentz transformations known as intermediate.[15] The radiation transformation, using (18), is

$$\Lambda_{\mathrm{rad}}(x,\theta)\equiv e^{\theta F_{\mathrm{rad}}(x)}=I+\frac{\theta k}{\rho^2}\,d^{[\mu}(\ddot{z}-\phi\dot{z})_{\nu]}-\frac{\theta^2k^2}{2\rho^4}\,(\ddot{z}^2+\phi^2)d^{\mu}d_{\nu}. \tag{27}$$

This truncated series is a Lorentz transformation. To see this, one can take four orthogonal unit vectors at x and apply to them the transformation Λ_{rad}. It is easy to verify that the norm of each vector is preserved. Let us take, for example, the timelike vector of the tetrad to be parallel to $\dot{z}^{\mu}$. Then, using (15), (17), and (18),

$$[\Lambda_{\mathrm{rad}}(x,\theta)]\dot{z}^{\nu}(x)=\dot{z}^{\mu}-\frac{\theta k}{\rho}\,(\phi\hat{r}+\ddot{z})^{\mu}-\frac{\theta^2k^2}{2\rho^3}\,(\ddot{z}^2+\phi^2)d^{\mu}. \tag{28}$$

The square of this expression is one; therefore the norm is preserved. Similar results, except for the sign, are obtained for the two spatial unit vectors evidenced by (28), namely, $\hat{r}^{\mu}$ and $n(\phi\hat{r}+\ddot{z})^{\mu}$, ($n$ is a normalizing factor). The third spatial direction of the tetrad, being orthogonal to all the vectors that enter into the above expression, remains clearly invariant.

The locus of the tip of the transformed vector of $\dot{z}^\mu(x)$ by $\Lambda_{\rm rad}(x,\theta)$, as θ increases from zero, has two components, as shown by (28). The first is on a straight line that starts at the initial position of the $\dot{z}^\mu(x)$ tip, and runs parallel to the direction of the vector $-n(\phi\hat{r}+\ddot{z})^\mu$. Eventually, this component crosses the light cone with vertex at x. The second component, starting at the same initial point, is on a segment of parabola drawn on the timelike $(\dot{z}^\mu-\hat{r}^\mu)$-plane; it approaches the future direction defined by the null vector d^μ for large values of θ; it points to the future because, as is well known, the quantity $(-\ddot{z}^2-\phi^2)$ is positive definite.[16] In the composite curve described by the tip of the transformed vector, the first component dominates for small values of θ evolving towards the parabola for large values of θ. The curve is tridimensional, one of the dimensions being timelike.

Now we will find out how the individual transformations $\Lambda_{\rm Coul}$ and $\Lambda_{\rm rad}$ combine to produce $\Lambda_{\rm tot}$. Comparing $\Lambda_{\rm tot}$, (12), with $\Lambda_{\rm Coul}$, (14), we observe that the functional dependence on the parameter θ is the same for both transformations. From this we infer that θ, in the radiation transformation, has the fixed value ρ^2/k. In fact, it is easy to verify the relation

$$\Lambda_{\rm total}=e^{\theta F}\equiv e^{\theta(F_{\rm Coul}+F_{\rm rad})}=\Lambda_{\rm rad}^{-1}\Lambda_{\rm Coul}\Lambda_{\rm rad}, \tag{29}$$

where

$$\Lambda_{\rm rad}\equiv I+\frac{\rho^2}{k}F_{\rm rad}+\frac{1}{2}\frac{\rho^4}{k^2}F_{\rm rad}^2. \tag{30}$$

There are several ways to verify (29). One way is to carry out the operations indicated in the right-hand side using the commutator

$$[F_{\rm Coul},F_{\rm rad}]\equiv F_{\rm Coul}F_{\rm rad}-F_{\rm rad}F_{\rm Coul}=\frac{k}{\rho^2}F_{\rm rad}. \tag{31}$$

An easier way is by using the well-known relation between regular square matrices of the same order, A and B,

$$Be^AB^{-1}=e^{BAB^{-1}}. \tag{32}$$

Equation (29) helps us to understand how the transformations $\Lambda_{\rm Coul}$ and $\Lambda_{\rm rad}$ combine to produce $\Lambda_{\rm tot}$: While the Coulomb transformation produces the rotation on the timelike $(\dot{z}^\mu-\hat{r}^\mu)$-plane, the radiation transformation rotates this plane by a fixed amount around the axis given by the unit vector $\hat{e}^\mu_{(3)}$, towards the transversal direction given by minus $\hat{e}^\mu_{(2)}$, where

$$\hat{e}^\mu_{(2)}=n(\phi\hat{r}^\mu+\ddot{z}^\mu), \tag{33}$$

and

$$\hat{e}^\mu_{(3)}=\epsilon^{\mu\alpha\beta\gamma}\dot{z}_\alpha\hat{r}_\beta\hat{e}_{(2)\gamma}. \tag{34}$$

Finally, we will see that the electrodynamic group belongs to the restricted inhomogeneous Lorentz group, although this is already obvious. Let d be the null vector used above; $u(s_0)$ and $v(x)$ timelike vectors such that

$$u^\mu=d^\mu+v^\mu. \tag{35}$$

The null vector d is defined by the choice of the field point x and the given world line $z(s)$ through the retarded condition $d^2=0$. The point x represents any one of the field points. Then, the tips of the vectors u and d may be placed at any two points of the field. The norm of the difference, $u-d$ is, by (35), the norm of the vector $v(x)$, which is preserved because $\Lambda(x)$ is a Lorentz transformation. Therefore the electrodynamic group, in its Liénard–Wiechert potentials expression, belongs to the inhomogeneous Lorentz group. This is the group of transformations that preserves the distance between any two points of the space–time.

The transformations of the electrodynamic group preserve also the orientation of the vectors defined at x. Consider the transformation Λ_{tot}, (12). For the value zero of the parameter θ, the transformation is the identity; this clearly preserves the orientation. We can go from the identity to any other transformation of the group by varying continuously the parameter θ. Then, evidently, all the transformations of the group preserve the orientation of the vector space at x. The electrodynamic group, then, belongs to the restricted inhomogeneous Lorentz group.

III. THE INTRINSIC DIFFERENTIAL EQUATIONS OF THE CURVES ASSOCIATED WITH THE ELECTRODYNAMIC GROUP

Here we obtain the intrinsic differential equations of the curves associated with the electrodynamic group (characteristic curves) at an arbitrary point x of the space–time. They will be referred to the most representative tetrad (orthonormal set of four four-vectors) appearing in the expression of the electromagnetic tensor at that point. This tetrad qualifies as a tetrad of the group, as described below. Later, the group and the intrinsic differential equations will be expressed with reference to a tetrad attached intrinsically to the characteristic curve.

The electrodynamic group, as developed in the previous section, is a one parameter group. Consequently, the structure theorem reviewed in Appendix A applies to this group. According to this theorem, the components of the infinitesimal displacement of a tetrad of the group will depend on one parameter whatsoever. One can choose this parameter to be the arclength (proper time) of a curve associated with the group and going through the point x: One should remind, however, that the condition $d^2=0$ links the infinitesimal displacement of the point x to the corresponding one on the trajectory at the point $z(s_0)$.

If we observe the vectors appearing in the expression of the electromagnetic field tensor at x, (19) and (28), we identify the following basic tetrad

$$\begin{aligned}
\hat{e}^{\mu}_{(0)} &= \dot{z}^{\mu}, \\
\hat{e}^{\mu}_{(1)} &= \hat{r}^{\mu}, \\
\hat{e}^{\mu}_{(2)} &= n(\phi\hat{r}+\ddot{z})^{\mu}, \\
\hat{e}^{\mu}_{(3)} &= \epsilon^{\mu\alpha\beta\gamma}\hat{e}_{(0)\alpha}\ \hat{e}_{(1)\beta}\ \hat{e}_{(2)\gamma}.
\end{aligned} \tag{36}$$

The value n is a normalizing factor at the point x. The tetrad above is a tetrad of the group, according to this definition: A tetrad $T_0 \equiv (\hat{e}_{(0)}, \hat{e}_{(1)}, \hat{e}_{(2)}, \hat{e}_{(3)})$ is a tetrad of the group if for every transformation Λ_a of the group, with $\Lambda_a \neq I$, we have $\Lambda_a T_0 \neq T_0$.

Let us denote by T_0 the above tetrad of the group, (36). The components of the infinitesimal displacement of the tetrad, accounted from the field point x, are obtained immediately using (19) and (25): $dT_0 = (F_{\text{Coul}} + F_{\text{rad}})T_0 d\theta$, or, explicitly,

$$\frac{dx}{d\theta} \equiv \hat{e}_{(0)}, \tag{37}$$

$$\frac{d\hat{e}_{(0)}}{kd\theta} = \frac{1}{\rho^2}\,\hat{e}_{(1)} - \frac{\sqrt{-\ddot{z}^2-\phi^2}}{\rho}\,\hat{e}_{(2)}, \tag{38}$$

$$\frac{d\hat{e}_{(1)}}{kd\theta} = \frac{1}{\rho^2}\,\hat{e}_{(0)} + \frac{\sqrt{-\ddot{z}^2-\phi^2}}{\rho}\,\hat{e}_{(2)}, \tag{39}$$

$$\frac{d\hat{e}_{(2)}}{kd\theta} = -\frac{\sqrt{-\ddot{z}^2-\phi^2}}{\rho}\,\hat{e}_{(0)} - \frac{\sqrt{-\ddot{z}^2-\phi^2}}{\rho}\,\hat{e}_{(1)}, \tag{40}$$

$$\frac{d\hat{e}_{(3)}}{kd\theta} = 0. \tag{41}$$

This is the system of intrinsic differential equations that the characteristic curves of the electromagnetic field satisfy. Their relation to the electrodynamic group of rotations is essentially the same as that of the Frenet–Serret equations to the Euclidean group of rotations. The invariant factors may be expressed in different forms than those appearing above. Their expression depends on the tetrad of reference. At a given point x of the field, each invariant represents the norm of a vector at that point. We may denote these invariant factors, the curvature and the hypertorsion, by σ and η, respectively,

$$\sigma(x)=\frac{k}{\rho^2},$$
$$\eta(x)=\frac{k\sqrt{-\ddot{z}^2-\phi^2}}{\rho}. \tag{42}$$

Together with (37), these are the natural equations of the characteristic curves.

Using (37) and (42), Eqs. (38)–(41) can be recast into the more general form

$$\frac{d\hat{e}_{(0)}}{d\theta}= \quad \sigma\hat{e}_{(1)} \quad -\eta\hat{e}_{(2)}, \tag{43}$$
$$\frac{d\hat{e}_{(1)}}{d\theta}=\sigma\hat{e}_{(0)} \quad +\eta\hat{e}_{(2)}, \tag{44}$$
$$\frac{d\hat{e}_{(2)}}{d\theta}=-\eta\hat{e}_{(0)} \quad -\eta\hat{e}_{(1)}, \tag{45}$$
$$\frac{d\hat{e}_{(3)}}{d\theta}=0. \tag{46}$$

The expression of the invariants σ and η, depend on the specific realization of the group. The intrinsic equations, (43)–(46), which now refer to the relevant tetrad of the specific realization, are the same for all the realizations. These equations enclose all the essential information about the space–time curves associated with the electrodynamic group. As in the case of ordinary differential geometry, given the natural equations (42), with $\eta \geqslant 0$, there is, by the fundamental condition of equality,[17] one and only one space–time curve having these functions as its curvature and hypertorsion and having its tetrad oriented in a given form at one space–time point (satisfying the initial conditions). According to (46), the infinitesimal displacement of the tetrad along the curve is such that the vector $\hat{e}_{(3)}$, remains invariant. That is, the infinitesimal displacement of the tetrad is a rotation around the axis that contains this vector. Considering in (43) and (44) only those terms that contain σ, we see that σ represents the infinitesimal angle of a rotation on the timelike plane generated by the first two vectors of the tetrad. Finally, considering in (43), (44), and (45) only the terms that contain η, we find the infinitesimal characteristics of an intermediate transformation: The infinitesimal rotation of angle $(-\eta)$ on the timelike plane generated by the vectors $\hat{e}_{(0)}$ and $\hat{e}_{(2)}$ combined with the infinitesimal rotation of angle η on the space-like plane generated by the vectors $\hat{e}_{(1)}$ and $\hat{e}_{(2)}$.

Our next objective is to duplicate, or to realize, the electrodynamic group using a proper tetrad. A proper tetrad is the space–time version of the Frenet triad.[18] It is a tetrad attached intrinsically to a four-dimensional curve by means of a geometrical construction. Let us consider a curve parametrized by the arclength: $x=x(s)$. At a generic point of the curve, the first two vectors of the proper tetrad can be chosen along the tangent and along the first normal defined by the Euclidean group of rotations, (6), with their usual geometrical constructions,

$$\hat{e}^{\mu}_{(0)}\equiv v^{\mu}\equiv\frac{dx^{\mu}}{ds}, \tag{47}$$

$$\hat{e}^{\mu}_{(1)} \equiv \hat{a}^{\mu} = \frac{a^{\mu}}{|a|}. \tag{48}$$

As s is the arclength, the vector v^{μ} is of unit length and orthogonal to a^{μ}. Going back to the tetrad of the group, we see by (46) that the fourth vector of the tetrad remains invariant along the curve. In particular it remains invariant under the transformation that takes the vector $l=(1,0,0,0)$ onto the velocity vector v^{μ}, and vice versa. Then, the last two vectors of the proper tetrad can be defined as

$$\hat{e}^{\mu}_{(3)} \equiv s^{\mu} \equiv \epsilon^{\mu\nu\alpha\beta} l_{\nu} \hat{e}_{(1)\alpha} \hat{e}_{(0)\beta}, \tag{49}$$

$$\hat{e}^{\mu}_{(2)} \equiv t^{\mu} \equiv \epsilon^{\mu\nu\alpha\beta} \hat{e}_{(3)\nu} \hat{e}_{(1)\alpha} \hat{e}_{(0)\beta}. \tag{50}$$

It is easy to verify that the vector s remains invariant under the Lorentz transformations, $\underset{l\to v}{\Lambda}$ and $\underset{v\to l}{\Lambda}$.

Let α be the angle measured at the laboratory between the velocity **v** and the acceleration **a**, and v the norm of **v**. Then, the vectors s and t, (49) and (50), are given by

$$t^{\mu} = \frac{\gamma}{(\sin\alpha)\sqrt{\gamma^2\cos^2\alpha + \sin^2\alpha}} \left\{ \frac{v}{c}\sin^2\alpha, \hat{\mathbf{v}} - \hat{\mathbf{a}}\cos\alpha \right\}, \tag{51}$$

$$s^{\mu} = \frac{1}{\sqrt{a^2 v^2 \sin^2\alpha}} \{0, \mathbf{v}\times\mathbf{a}\} = \frac{1}{\sin\alpha} \{0, \hat{\mathbf{v}}\times\hat{\mathbf{a}}\}. \tag{52}$$

Let us denote by Ω the infinitesimal generators of the electrodynamic group when they are represented with elements of the proper tetrad $(v,\hat{a},t,s)$. From (19), (25), and (42) we have

$$\Omega_{\text{Coul}} = \sigma(\theta) \hat{a}^{[\mu} v_{\nu]}, \tag{53}$$

$$\Omega_{\text{rad}} = \eta(\sigma,\theta)(v+\hat{a})^{[\mu} t_{\nu]}. \tag{54}$$

Using the above infinitesimal generators in the place of F_{Coul} and F_{rad} as in Sec. II, it is possible to reproduce all the properties of the electrodynamic group. They reproduce also the differential equations (43)–(46). According to the fundamental theorem of equality, the curve described by means of the tetrad of the group (36) at the point x will be the same curve as that described by means of the proper tetrad, (47)–(50), if, having the same initial orientation the two tetrads ($\theta = s = 0$), their respective components of the infinitesimal displacements, σ and η, have the same values. These values are given in terms of the field by Eqs. (42). The meaning of the invariants with respect to the proper tetrad will be given in the next section.

The tetrad of the group (36), and the proper tetrad, (47)–(50), both belong to the same characteristic curve of the field. A proper tetrad can also be attached to an electron located in the field. If the initial velocity of the electron coincides with the timelike vector of the proper tetrad of the characteristic curve, then the trajectory of the electron will be the characteristic curve. If not, only the components of the proper tetrad of the electron lying on the rotation planes defined by the field will obey the differential equations.

IV. THE RELATIVISTIC FORCE ON THE ELECTRON

The rate of change of the velocity, that is, the acceleration in the inertial system of reference where the electromagnetic tensor is defined, is

$$\ddot{x} = \frac{d\hat{e}_{(0)}}{d\theta} = \sigma\hat{e}_{(1)} - \eta\hat{e}_{(2)}. \tag{43$'$}$$

This acceleration has two terms. Employing the terminology of classical kinematics, let us refer to the first term as the apparent acceleration and to the second as the radiation reaction acceleration. This suggests that the radiation reaction term is a kind of fictitious acceleration which can be cancelled out by a transformation of coordinates. This fact is expressed by (29). The length of the apparent acceleration is $-\sigma$. The invariant σ, referred to the tetrad of the group T_0, (36), is given by (42). If (43) refers to the proper tetrad of the characteristic curve at the same point in which we considered the tetrad T_0, then σ is also proportional to the inverse radius of curvature of the hyperbola of curvature as described by Minkowski in his famous address ''Space and Time.'' [19] The radius of curvature and the acceleration have the same direction and sense. Certainly, the value of σ, being an invariant, is the same referred to either one of the two tetrads. As the apparent acceleration is the acceleration that we observe at the laboratory in the absence of radiation, we may denote it by a^μ.

The radiation reaction acceleration, of length $-\eta$, arises from the relativistic considerations of the Liénard–Wiechert field acting on the tetrad of the group T_0, Sec. III. For small values of θ, it has the direction of a straight line (28): Its length can be approximated relating the hyperbola described by the tip of the velocity vector with the hyperbola described by the tip of the radiation acceleration vector as θ varies. We will consider this approximation later.

Referred to the proper tetrad, the radiation acceleration has the direction of the vector t. The direction of t and the magnitude $-\eta$ characterize this fictitious acceleration completely, however, it is convenient to obtain an expression for it in terms of successive differentials of the curve with respect to the arclength. We first notice that

$$\dot{x}^\mu = \hat{e}^\mu_{(0)} \tag{55}$$

and

$$a^\mu = \sigma e^\mu_{(1)}. \tag{56}$$

To replace the vector $\hat{e}_{(2)}$ in (43′) with differentials of the curve, we differentiate (43′) with respect to the arclength, using (44) and (45) and taking σ and η as constants. We find

$$\ddot{x}^\mu = \sigma(\sigma\hat{e}_{(0)} + \eta\hat{e}_{(2)}) - \eta(-\eta\hat{e}_{(0)} - \eta\hat{e}_{(1)}) = (\sigma^2+\eta^2)\dot{x}^\mu + \frac{\eta^2}{\sigma}\, a^\mu + \sigma\eta\hat{e}^\mu_{(2)}. \tag{57}$$

Using this result in (43′),

$$\frac{d\dot{x}}{d\theta} = \left(1+\frac{\eta^2}{\sigma^2}\right)a - \frac{1}{\sigma}\dddot{x} + \left(\frac{\sigma^2+\eta^2}{\sigma}\right)\dot{x}. \tag{58}$$

Comparing with (43′), we first observe that the apparent acceleration is now η^2/σ^2 larger. The second and third terms considered together, resemble the Abraham–Lorentz–Dirac (ALD) acceleration. We find the third-order derivative of the position and the necessary component along the velocity. Noting from (57) that $\ddot{x}^\alpha\dot{x}_\alpha = \sigma^2+\eta^2$ we find that, in fact, it is orthogonal to the velocity, a requirement fulfilled by an acceleration in general and by the ALD acceleration in particular. Except for the coefficients, they are equal.

The relativistic force, consequently, may be expressed in two equivalent forms, using either (43) or (58). If we use (1), (4), (43), and (50)

$$f = mc^2\sigma\hat{e}_{(1)} - mc^2\eta\hat{e}_{(2)} = mc^2 a - mc^2\eta t = f_a - \eta' t. \tag{59}$$

The first term is the apparent force f_a. The second term is the radiation reaction force. There is more than a simple similarity between the last force and the so-called fictitious forces. Fictitious forces, such as the Coriolis force, the centrifugal force, etc., are produced when the observer frame of reference is rotated with respect to a stationary frame where the force is initially considered. Both the fictitious forces and the radiation reaction force are produced by transformations of the Lorentz group. While the Coriolis force, for example, is produced by a rotation of the space, the radiation reaction force is produced by an intermediate transformation. They have a similar origin.

Let us now consider the equations of motion. Let an electron of known initial position (x) and velocity ($\dot{x}$) be subject to an external electromagnetic field whatsoever, F. The relativistic force on the electron is given by the Lorentz–Minkowski force:

$$f^{\mu}=eF^{\mu}{}_{\alpha}\dot{x}^{\alpha}. \tag{60}$$

The equation of motion, using the expression (59) for the force, is then

$$f_a{}^{\mu}-\eta' t^{\mu}=eF^{\mu}{}_{\alpha}\dot{x}^{\alpha}. \tag{61}$$

The field F at the space–time point x gives the values of invariants σ and η, that is, the natural equations of the curve: The trajectory is therefore defined from the initial conditions and the equation of motion is satisfactory in this sense. If we set the external field F equal to zero in (61), we have $a=\eta t=0$, and, by (43), we find that the momentum is a constant.

If we use the acceleration in the form (58) instead, we obtain the force

$$f=\left(1+\frac{\eta^2}{\sigma^2}\right)f_a-\frac{mc^2}{\sigma}\dddot{x}+mc^2\left(\frac{\sigma^2+\eta^2}{\sigma}\right)\dot{x}, \tag{62}$$

and the equation of motion

$$mc^2\left(1+\frac{\eta^2}{\sigma^2}\right)a-\frac{mc^2}{\sigma}\dddot{x}+mc^2\left(\frac{\sigma^2+\eta^2}{\sigma}\right)\dot{x}=eF\dot{x}. \tag{63}$$

Equations (61) and (63) are different expressions of the same equation of motion. Suppose now that we set $a=\ddot{x}$ in (63), introducing an error according to (43). Then (63) becomes the ALD equation, except for the coefficients. For an external field $F=0$, we also find self-accelerated solutions; imposing asymptotic conditions, we find preacceleration. In short, we find the nonlocality in time, characteristic of this equation of motion. Although the situation may seem to be more of the same, we have now some new information at our disposal: The apparent acceleration a is $\ddot{x}$ only if $\eta=0$. Then, the error that we introduced by making $a=\ddot{x}$ depends only on the radiation field and it is of the same order of magnitude as the radiation reaction force.

Now, consider (29). From it see that it is mathematically acceptable to approximate the real trajectory beginning from the trajectory due to the generalized Coulomb field alone, then, correcting it by switching on and off the radiation transformation for fixed values of the parameter. The concept introduced by Caldirola,[20] that the momentum of the electron, under the action of an external force, can only vary after a fixed interval of its proper time has elapsed finds here additional support: He calls this fundamental interval the chronon. This concept, which has been refined over the years,[21] is expressed relativistically by means of a differential-difference equation. This is in agreement with (30), where it is shown that the radiation transformation depends on a fixed value of the parameter θ.

We will now obtain an approximation of the length of the radiation reaction vector, the hypertorsion, in terms of the curvature. To avoid a long digression about the question of units, which was saved with the use of the constant k in the formulas, it will only be mentioned that the natural units of the Liénard–Wiechert field tensor (i.e., deleting all the proportionality constants) are, in our metric, those of an inverse squared length. In contrast, it has the dimensions of force per unit charge in the Lorentz–Minkowski force (60) (Heaviside–Lorentz units). If in (63) we express F in its natural units and absorb in the proportionality constant the factor mc^2 that is on the left, this constant becomes the classical electron radius. In that case the equation of motion (61) would be

$$a^{\mu}-\eta t^{\mu}=r_0F^{\mu}{}_{\alpha}\dot{x}^{\alpha}. \tag{64}$$

Using this proportionality constant in the tensor field to obtain the energy momentum tensor, instead of (7) one obtains

$$\dot{p}^{\mu}=r_0^2\left(\frac{8\pi}{3}\right)|\ddot{x}|^2\dot{x}^{\mu}. \tag{65}$$

The invariant η can be approximated with a hyperbola as follows: Let the direction of the radius of curvature be $-t$. Under the continuous action of the radiation field, the velocity vector $\dot{x}=\gamma(1,\mathbf{v}/c)$ will evolve towards the vector $l=(1,0,0,0)$. It will be translated and rotated. Refer the rotation to the base point of the velocity vector. The tip of the velocity vector for increasing values of the proper time will describe a hyperbola in the interior of the light cone with vertex at the base point of the vector. At the same time, the vector t, preserving its orthogonality with respect to the velocity vector, will describe an external hyperbola. The rotation of the velocity vector corresponds to the transformation

$$\Lambda\dot{x}=\dot{x}\ \cosh\ \vartheta-t\ \sinh\ \vartheta. \tag{66}$$

In particular, for the values

$$\cosh\ \vartheta=\gamma,$$

$$\sinh\ \vartheta=\gamma\,\frac{v}{c}, \tag{67}$$

Λ in (66) transforms the velocity vector $\dot{x}$ onto the laboratory vector l. Considering terms up to the second order in the series expansion of (66), we have

$$\Lambda\dot{x}\approx\dot{x}\left(1+\frac{1}{2!}\,\vartheta^2+\cdots\right)-t(\vartheta+\cdots). \tag{68}$$

We now identify the second term in the first parentheses of (68) with (65). This is not arbitrary because the energy momentum tensor is the projection operator in the transformation of the total electromagnetic field, (12). In particular, the energy momentum tensor corresponding to the so-called ''wave zone,'' is the last term in (27). This is the term that is used in the conventional treatment of radiation reaction to obtain (7).[22] Based on the commutator (31), but referred now to the proper tetrad, we set $\eta=|\ddot{x}|\,\vartheta$ and find

$$\eta=4\,\sqrt{\frac{2\,\pi}{3}}\,r_0|\ddot{x}|^2. \tag{69}$$

Let us now consider the nonrelativistic limit. From (63), with the modification that considers the apparent acceleration as $\ddot{x}$, one is lead to an equation of motion in ordinary space with the radiation reaction term $f_{\text{react}}\propto -d^3\mathbf{x}/dt^3$.

Contrarily, the radiation reaction force given by Eq. (61) reduces in the nonrelativistic limit to a typical frictional force. Consider a nonrelativistic electron moving along a characteristic curve such that $\mathbf{v}\cdot\mathbf{a}=0$. Then, from (51) we find

$$-t^\mu \xrightarrow[v\ll c]{} -\hat{\mathbf{v}}. \tag{70}$$

To end this section, (61) will be reduced to the case of a Coulomb force using the Liénard–Wiechert expression of F, (9) and (19). In this case: $\dot{z}=\dot{x}=(1,0,0,0)$ and $\ddot{z}=0$. First, we notice that the vectors s and t, by (49) and (50), are zero. Then we are left with

$$mc^2\ddot{x}^\mu=\frac{e^2}{4\,\pi}\,\frac{1}{\rho^2}\,(\hat{r}^\mu\dot{z}_\alpha-\hat{r}_\alpha\dot{z}^\mu)\dot{x}^\alpha. \tag{71}$$

In this case we find that $\hat{r}^\mu=(0,\hat{\mathbf{r}})$ and that the invariant ρ is the distance between the two electrons. From (6) and (16) we find the Coulomb law,

$$m\mathbf{a}=\frac{e^2}{4\,\pi r^2}\,\hat{\mathbf{r}}. \tag{72}$$

The Coulomb law expresses physically that the invariant σ given in terms of the tetrad of the group by (42) has the same value as the invariant given in terms of the proper tetrad, that is, as the norm of the ordinary acceleration.

V. CONCLUSIONS

The point of view of electrodynamics introduced in this paper leads one to consider the radiation reaction force as a fictitious force: as such, it can be canceled out by a transformation of the coordinates. From the mathematical viewpoint, there is a similarity with the case dealt with in the Larmor theorem, where the magnetic Lorentz force due to a constant magnetic field can be canceled out by the Coriolis force produced by a rotation of the space. The Abraham force or ALD force appears, except for the coefficients, as a constituent of this fictitious force: The ordinary force, however, becomes an apparent force and is modified when the force of radiation is also considered. It follows from this point of view that the source of the problems faced by the ALD equation resides not in the ALD force but in considering the apparent force as the total force.

The mathematical viewpoint employed in the paper asserts that the world-line curve, the group of transformations, and the intrinsic differential equations are different aspects of the same object: This also has an interesting consequence in the relativistic dynamics of an uncharged body. The electrodynamic group is contained in the restricted inhomogeneous Lorentz group and the characteristic curves associated with the electrodynamic group are embedded in the Minkowski space. We found that the hypertorsion of a space–time trajectory is accompanied by a radiation field and by a reduction of the momentum. These three characteristics occur simultaneously because they are manifestations of one and the same mathematical fact. This statement, which depends on the geometry and not on the charge, necessarily applies also to any space–time trajectory (the curve followed by any physical body, charged or uncharged). If this were not so, it would be possible to show that there is a contradiction between the laws that define the geometry associated with the electrodynamic group in Minkowski space, as the part contained in the whole, and the laws that define the geometry associated with the restricted inhomogeneous Lorentz group also in Minkowski space, as the whole that contains the part. Physically, this implies that if we constrain the motion of a massive, neutral body, to follow a trajectory in which the trajectory of its parts have a hypertorsion different from zero, we should expect, first, that a radiation field is produced and, second, the consequent reduction of the momentum. In other words, any body following a space–time trajectory with hypertorsion radiates.

ACKNOWLEDGMENTS

I want to thank Dr. Basil J. Hiley for his help and sensible guidance. I also thank Professor Clive W. Kilmister for valuable suggestions to a previous version of this paper. I am indebted to Dr. Luis de la Peña for accurate comments that improved the paper in general and, also, for his encouragement and help to proceed with the investigation introduced here. I acknowledge, with thanks, an observation made by the referee on a deficiency, now corrected, that motivated the rewriting of Sec. IV with considerable improvement.

APPENDIX A: THE CARTAN METHOD OF THE MOVING FRAME (REF. 23)

In Euclidean space, consider a set of three orthogonal ordered unit length vectors with common origin o. We will call any set like this a triad. Let $\mathbf{m}$ be a fixed point in the frame of reference defined by the triad and of coordinates (a,b,c). Now let the triad move continuously, but otherwise arbitrarily, from a given initial position in the frame $(\hat{\mathbf{e}}_1,\hat{\mathbf{e}}_2,\hat{\mathbf{e}}_3)$, and let its motion depend on n parameters, s_n. The point $\mathbf{m}$ moves fixed to the triad, i.e., its coordinates remain constant in that frame. The motion of the triad defines in the space a continuum of triads: the family E of triads. The most general infinitesimal variation in the coordinates of the point $\mathbf{m}$ due to an infinitesimal increment in all the parameters, referred this variation to the initial position of the triad, is given by the equations

$$
\begin{aligned}
d\mathbf{m} &= d\mathbf{o} + a\,d\hat{\mathbf{e}}_1 + b\,d\hat{\mathbf{e}}_2 + c\,d\hat{\mathbf{e}}_3,\\
d\mathbf{o} &= \omega_1\hat{\mathbf{e}}_1 + \omega_2\hat{\mathbf{e}}_2 + \omega_3\hat{\mathbf{e}}_3,\\
d\hat{\mathbf{e}}_1 &= \omega_{12}\hat{\mathbf{e}}_2 + \omega_{13}\hat{\mathbf{e}}_3,\\
d\hat{\mathbf{e}}_2 &= -\omega_{12}\hat{\mathbf{e}}_1 + \omega_{23}\hat{\mathbf{e}}_3,\\
d\hat{\mathbf{e}}_3 &= -\omega_{13}\hat{\mathbf{e}}_1 - \omega_{23}\hat{\mathbf{e}}_2.
\end{aligned}
\tag{A1}
$$

The ω's are known as connection forms. To get a quick idea of the meaning of these equations, suppose that all the forms are null except ω_1. In this case, Eqs. (A1) express that the infinitesimal displacement suffered by the point $\mathbf{m}$ is a translation parallel to $\hat{\mathbf{e}}_1$ and of infinitesimal magnitude ω_1. Suppose now that all the connection forms are null except ω_{12}. In this case, the motion of $\mathbf{m}$ is a rotation around the $\hat{\mathbf{e}}_3$ axis and of infinitesimal angle ω_{12}. Equations (A1) express, in the most general case, that the infinitesimal displacement of the point $\mathbf{m}$, due to infinitesimal increments in the n parameters, is a superposition of three infinitesimal translations parallel to the axes $\hat{\mathbf{e}}_1, \hat{\mathbf{e}}_2, \hat{\mathbf{e}}_3$, respectively, and three infinitesimal rotations around those same axes.

Let the point $\mathbf{m}$ coincide with the origin of the moving triad; Eqs. (A1) describe, in this case, the infinitesimal displacement of the triad itself.

Consider now two families of triads E and E' depending on the same number of parameters. Suppose that we can define a bijective mapping between the two families. This mapping defines homologous triads in E and E'. The fundamental condition of equality between the two families is expressed as follows: It is possible to superpose all homologous triads with the same transformation, if and only if, the bijective mapping produces components ω' of the infinitesimal change of a triad in E' equal to the components ω of the infinitesimal change of its homologous triad in E.

The problem simplifies substantially when the motion of the triad that generates the family is ruled by only one parameter. In this case we find the structure theorem: The components ω of the infinitesimal displacement of the moving triad, if its motion depends on only one parameter, are subject to no conditions of structure. In other words, the components ω depend on one variable whatsoever. This case applies directly to the study of the Euclidean space curves.

Let C be an oriented curve parametrized by the arclength, $\mathbf{x}=\mathbf{x}(s)$, with no inflexion points. At each point of the curve choose the triad satisfying the following: the origin of the triad coincides with that point of the curve, $\mathbf{o}=\mathbf{x}$; the first vector $\hat{\mathbf{e}}_1$ lies on the positive side of the tangent; the second vector $\hat{\mathbf{e}}_2$ lies on the principal normal pointing to the interior of the curve; the third vector $\hat{\mathbf{e}}_3$, the binormal, is the cross product $\hat{\mathbf{e}}_1 \times \hat{\mathbf{e}}_2$. This triad is known as the Frenet triad corresponding to that point of the curve. As the origin of the Frenet triad moves continuously along the positive direction of the arc, starting from an arbitrary initial point, the Frenet triad generates a family of triads.

The translation $\omega_1 = ds$, $\omega_2 = \omega_3 = 0$, gives in (A1) the usual definition of the tangent and of the arclength. The rotation $\omega_{13}=0$ gives the orientation of the principal normal. The other two rotations have the form: $\omega_{12} = \rho\, ds$, and $\omega_{23} = \kappa\, ds$. With these conditions Eqs. (A1) give the Frenet–Serret formulas. It follows from (A1) and the structure theorem that the curvature ρ and the torsion κ are positive functions of the parameter s.

The Frenet–Serret formulas can be put in the form

$$
d\mathbf{x} = ds\,\hat{\mathbf{e}}_1, \tag{A2}
$$

$$
d\hat{\mathbf{e}}_i = ds\,\Omega\hat{\mathbf{e}}_i, \tag{A3}
$$

$$
d\hat{\mathbf{e}}_{\mathrm{rot}} = ds\,\Omega\hat{\mathbf{e}}_{\mathrm{rot}} = ds\,\hat{\mathbf{e}}_{\mathrm{rot}}. \tag{A4}
$$

The operator Ω produces an infinitesimal rotation of the triad around the axis $\hat{\mathbf{e}}_{\mathrm{rot}}$, as shown by (A4). The velocity of the point $\mathbf{x}$ is defined by the translation (A2). The rate of change of the velocity is given by the infinitesimal rotation $\Omega\hat{\mathbf{e}}_1$. This is a rotation of the Euclidean group.

APPENDIX B: *F* IN TERMS OF THE LIÉNARD–WIECHERT POTENTIALS (REF. 24)

This is an outline of how to obtain the Liénard–Wiechert expression of the electromagnetic field tensor F. A field point is any point of the space–time, except those laying on the electron world line which is the source of the field. The coordinates of a field point will be represented by x^μ, or by x. The coordinates of the world line will be represented by z^μ, or by z. We are given, in parametric form, the four equations that define the world line of the point-electron, $z^\mu = z^\mu(s)$. The parameter (s) is, essentially, the proper time of the electron. The solution of the inhomogeneous wave equation, using this world line as the independent term, leads to the Liénard–Wiechert four potentials

$$A^\mu(x) = k \left. \frac{\dot{z}^\mu}{(x-z)^\alpha \dot{z}_\alpha} \right|_{(x-z)^2=0}. \tag{B1}$$

k is a positive constant. The characteristic property of these potentials is contained in the condition that defines the null vector

$$d^\mu \equiv (x^\mu - z^\mu), \quad d^2 = 0. \tag{B2}$$

The null distance d^μ is a function of x and z. To each field point x, there are two points on the world line $z(s)$ such that the condition $d^2=0$ is satisfied. Of the two points on the world line, we will take only the point $z(s_0)$ corresponding to a positive time component of d. With respect to the observation field point x, the potential from $z(s_0)$ is known as the retarded or causal solution. The condition $d^2=0$ allows us to express the time at the point x in terms of the time at $z(s_0)$ and the spatial distance between x and $z(s_0)$. The invariant in the denominator of (B1) has only one value for the retarded solution; It will be denoted by ρ. We have

$$A^\mu(x) = k \frac{\dot{z}^\mu(s_0)}{\rho}, \tag{B3}$$

with

$$\rho \equiv (x - z(s_0))^\alpha \dot{z}_\alpha(s_0). \tag{B4}$$

The condition $d^2=0$ embodies an essential property of the field. From this property it follows that to an infinitesimal increase in the coordinates of the field point x, it corresponds an infinitesimal increase in the coordinates on the world line z, and, consequently, also in (s). Then, to differentiate the potentials A^μ with respect to the field variables x^μ, we have to preserve the condition $d^2=0$. From (B2),

$$\partial^\mu d_\alpha d^\alpha = 2 d^\alpha (\delta^\mu_\alpha - \dot{z}_\alpha \partial^\mu s) = 0. \tag{B5}$$

Then

$$\partial^\mu s = \frac{d^\mu}{\rho}. \tag{B6}$$

The tensor F is defined by

$$F^\mu{}_\nu \equiv \partial^\mu A_\nu - \partial_\nu A^\mu \equiv \partial^{[\mu} A_{\nu]}. \tag{B7}$$

Using (B1), (B6), and (B7) it is easy to obtain

$$F(x)^\mu{}_\nu = k \left(\frac{1}{\rho^3} d^{[\mu} \dot{z}_{\nu]} \right)_{\text{Coul}} + k \left(-\frac{\Phi}{\rho^3} d^{[\mu} \dot{z}_{\nu]} + \frac{1}{\rho^2} d^{[\mu} \ddot{z}_{\nu]} \right)_{\text{rad}}, \tag{B8}$$

where

$$\Phi \equiv d^\alpha \ddot{z}_\alpha. \tag{B9}$$

APPENDIX C: THE RECURRENCE IN THE POWERS OF *F*

Calculating the square of (B8), using $d^\alpha \dot{z}_\alpha = \rho$, $d^\alpha \ddot{z}_\alpha = \Phi$, and $\ddot{z}^\alpha \dot{z}_\alpha = 0$, we have

$$\frac{F^2}{k^2} = \left[\frac{(1-\Phi)}{\rho^3}(d^\mu \dot{z}^\alpha - d^\alpha \dot{z}^\mu) + \frac{1}{\rho^2}(d^\mu \ddot{z}^\alpha - d^\alpha \ddot{z}^\mu)\right]\left[\frac{1-\Phi}{\rho^3}(d_\alpha \dot{z}_\nu - d_\nu \dot{z}_\alpha) + \frac{1}{\rho^2}(d_\alpha \ddot{z}_\nu - d_\nu \ddot{z}_\alpha)\right]$$

$$= \frac{(1-\Phi)^2}{\rho^6}(\rho d^\mu \dot{z}_\nu - d^\mu d_\nu + \rho d_\nu \dot{z}^\mu) + \frac{(1-\Phi)}{\rho^5}(\rho d^\mu \ddot{z}_\nu + \Phi d_\nu \dot{z}^\mu) + \frac{(1-\Phi)}{\rho^5}(\Phi d^\mu \dot{z}_\nu + d_\nu \ddot{z}^\mu)$$

$$+ \frac{1}{\rho^4}(\Phi d^\mu \ddot{z}_\nu - \ddot{z}^2 d^\mu d_\nu + \Phi \ddot{z}^\mu d_\nu) = \frac{(1-\Phi)^2}{\rho^5} d^{(\mu}\dot{z}_{\nu)} + \frac{(1-\Phi)\Phi}{\rho^5} d^{(\mu}\dot{z}_{\nu)} + \frac{(1-\Phi)}{\rho^4} d^{(\mu}\ddot{z}_{\nu)}$$

$$+ \frac{\Phi}{\rho^4} d^{(\mu}\ddot{z}_{\nu)} - \frac{1}{\rho^6}[(1-\Phi)^2 + \rho^2 \ddot{z}^2] d^\mu d_\nu .$$

Reducing, we arrive at the result,

$$\frac{F^2}{k^2} = \frac{1-\Phi}{\rho^5} d^{(\mu}\dot{z}_{\nu)} + \frac{1}{\rho^4} d^{(\mu}\ddot{z}_{\nu)} - \frac{1}{\rho^6}[(1-\Phi)^2 + \rho^2 \ddot{z}^2] d^\mu d_\nu . \tag{C1}$$

Repeating the process,

$$\frac{F^3}{k^3} = \left[\frac{1-\Phi}{\rho^5}(d^\mu \dot{z}^\alpha + d^\alpha \dot{z}^\mu) + \frac{1}{\rho^4}(d^\mu \ddot{z}^\alpha + d^\alpha \ddot{z}^\mu) - \frac{(1-\Phi)^2 + \rho^2 \ddot{z}^2}{\rho^6} d^\mu d^\alpha\right]\left[\frac{1-\Phi}{\rho^3}(d_\alpha \dot{z}_\nu - d_\nu \dot{z}_\alpha)\right.$$

$$\left. + \frac{1}{\rho^2}(d_\alpha \ddot{z}_\nu - d_\nu \ddot{z}_\alpha)\right] = \frac{(1-\Phi)^2}{\rho^5}(\rho d^\mu \dot{z}_\nu - d^\mu d_\nu - \rho \dot{z}^\mu d_\nu) + \frac{1-\Phi}{\rho^7}(\rho d^\mu \ddot{z}_\nu - \Phi \dot{z}^\mu d_\nu)$$

$$+ \frac{1-\Phi}{\rho^7}(\Phi d^\mu \dot{z}_\nu - \rho \ddot{z}^\mu d_\nu) + \frac{1}{\rho^6}(\Phi d^\mu \ddot{z}_\nu - \ddot{z}^2 d^\mu d_\nu - \Phi \ddot{z}^\mu d_\nu)$$

$$+ \frac{[(1-\Phi)^2 + \rho^2 \ddot{z}^2](1-\Phi)}{\rho^9} \rho d^\mu d_\nu + \frac{(1-\Phi)^2 + \rho^2 \ddot{z}^2}{\rho^8} \Phi d^\mu d_\nu = \frac{1}{\rho^7}[(1-\Phi)^2 + \Phi(1$$

$$- \Phi)] d^{[\mu}\dot{z}_{\nu]} + \frac{1}{\rho^6}[\Phi + (1-\Phi)] d^{[\mu}\ddot{z}_{\nu]} + \frac{1}{\rho^8}\{-(1-\Phi)^2 - \rho^2 \ddot{z}^2 + [(1-\Phi)^2 + \rho^2 \ddot{z}^2](1-\Phi)$$

$$+ \Phi[(1-\Phi)^2 + \rho^2 \ddot{z}^2]\} d^\mu d_\nu = \frac{1-\Phi}{\rho^7} d^{[\mu}\dot{z}_{\nu]} + \frac{1}{\rho^6} d^{[\mu}\ddot{z}_{\nu]} .$$

Comparing with (9), we find

$$F^3 = \left(\frac{k}{\rho^2}\right)^2 F. \tag{C2}$$

Multiplying both sides of (C2) by F, n times, using again (C2) and separating even from odd exponents, we arrive at (10) and (11).

APPENDIX D: CALCULATION OF F^3_{rad}

Eliminating the Coulomb terms from the process that leads to (C1) above, we find[25]

$$\frac{F^2_{\text{rad}}}{k^2} = -\frac{1}{\rho^4}\left(\ddot{z}^2 + \frac{\Phi^2}{\rho^2}\right) d^\mu d_\nu .$$

Using F_{rad} from (B8),

$$\frac{F^3_{\rm rad}}{k^3}=-\frac{1}{\rho^4}\left(\ddot{z}^2+\frac{\Phi^2}{\rho^2}\right)d^\mu d_\alpha\left[-\frac{\Phi}{\rho^3}\,(d^\alpha\dot{z}_\nu-d_\nu\dot{z}^\alpha)+\frac{1}{\rho^2}\,(d^\alpha\ddot{z}_\nu-d_\nu\ddot{z}^\alpha)\right]$$

$$=-\frac{1}{\rho^4}\left(\ddot{z}^2+\frac{\Phi^2}{\rho^2}\right)d^\mu\left(\frac{\rho\Phi}{\rho^3}\,d_\nu-\frac{1}{\rho^2}\,\Phi d_\nu\right)=0.$$

[1] Metric: $(+,-,-,-)$. Fundamental length: $ds^2=c^2dt^2-dx^2-dy^2-dz^2$. Dots refer to differentiation with respect to this length. Strictly, this length is proper time by a constant. An additional factor of c is produced in each differentiation. Matrix form of 4×4 tensors: $A=A^\mu{}_\nu$. In this form square of tensors equals matrix multiplication: $A^2=A^\mu{}_\alpha A^\alpha{}_\nu$. Four-vectors are called vectors throughout and denoted by a or a^μ. Components of vectors: $a=(a^\circ,\mathbf{a})$. Antisymmetric bivector $a^\mu b_\nu-a_\nu b^\mu=a^{[\mu}b_{\nu]}$. Symmetric bivector: $a^\mu b_\nu+a_\nu b^\mu=a^{(\mu}b_{\nu)}$. Planes generated by the two vectors a^μ and b^μ: $(a\text{-}b)$-plane. Totally antisymmetric tensor $e^{\alpha\beta\gamma\delta}=-e_{\alpha\beta\gamma\delta}$ and the Dirac delta δ with usual definitions. Formulas are given in Heaviside–Lorentz units.

Deriving the Hamilton equations of motion for a nonconservative system using a variational principle

Frank Thomas Tveter[a)]
Vidarsvei 21, N-1342 JAR, Norway

(Received 9 June 1997; accepted for publication 12 November 1997)

The classical derivation of the canonical transformation theory [H. Goldstein, *Classical Mechanics*, 2nd ed. (Addison–Wesley, Reading, 1981)] is based on Hamilton's principle which is only valid for conservative systems. This paper avoids this principle by using an approach that is basically reversed compared to the classical derivation. The Lagrange equations of motion are formulated in the undefined and *general* variable set $\{Q,P\}$, and the general Hamilton equations of motion are derived from the Lagrange equations by using a variational principle. The undefined *general* variables $\{Q,P\}$ are defined through a transformation to a *special* (defined) variable set $\{q,p\}$. The transformation equations connecting the two sets are derived by using the invariants property of the value of the Lagrangian. This approach results in a more general interpretation of the generator function. © *1998 American Institute of Physics.* [S0022-2488(98)00803-2]

I. INTRODUCTION

The classical Hamilton formalism focuses on solving conservative problems. This formalism has also been used as a starting point for a number of perturbation theories designed to solve nonconservative (or complicated conservative) problems. In the early 1960s, Hori and Brouwer[1] developed a perturbation theory which they used to solve the problem of a satellite orbiting a planet under the influence of air drag. They formulated an early version of the general Hamilton equations of motion (in Cartesian coordinates) and derived a canonical transformation theory which allowed transformations of the general equations from one set of canonical variables to another. The equations of motion were solved in an appropriate variable set by using a series approach.

Hori and Brouwer did not attempt to derive the general Hamilton equations of motion. Such an attempt was made by Tveter.[2] The derivation was based on direct manipulation of the differential equations, and resulted in long and complicated intermediate expressions. In a subsequent study[3] a more compact and more general derivation was presented. That derivation was also based on direct manipulation of the differential equations.

The derivation presented in this paper is based on a simple variational principle and an unfrequented property of the Lagrange equations of motion. The Lagrange equations of motion may be formulated in a redundant set of variables, giving a linearly dependent set of equations. This is referred to as the *redundancy property of the Lagrange equations of motion*. This property is used to provide the starting point for the derivation in this paper. The Lagrange equations of motion are formulated in the *general* variable set $\{Q,P\}$ (where the position vector may depend on the full set of variables, i.e., $\mathbf{r}(Q,P,t)$), before these variables have been defined. The Hamilton equations of motion are derived from the Lagrange equations by using a variational principle. The definitions introduced in the transformation from the Lagrange equations to the Hamilton equations also provide the general equations for defining the momenta $\{P\}$. These equations may be reduced to the classical definition of the momenta in the *special* variable set $\{q,p\}$ (where the position vector only depends on the coordinates $\{q\}$, i.e., $\mathbf{r}(q,t)$) when certain assumptions are made. The definitions introduced in the derivation of the Hamilton equations, together with the invariants of the Lagrangian, are used to derive the canonical transformation theory. The *general* variable set $\{Q,P\}$ is finally defined through a transformation from the *special* variable set $\{q,p\}$.

 © 1998 American Institute of Physics

The approach presented in this paper is basically reversed compared to the classical derivation e.g. Ref. 4, where the starting point is the Lagrange equations of motion formulated in a *special* variable set $\{q\}$ (where the position vector only depends on the coordinates, i.e., $\mathbf{r}(q,t)$). In the classical derivation, the Hamilton equations of motion are first derived in the *special* variable set. Starting with these equations, a canonical transformation theory is developed which gives the Hamilton equations of motion for a *general* variable set $\{Q,P\}$ (where the position vector may depend on the full set of variables, i.e., $\mathbf{r}(Q,P,t)$). The classical derivation of the transformation theory is only valid for conservative systems.

There are several differences between the classical derivation and the derivation presented in this paper. Here, the starting point is the Lagrange equations of motion formulated in a *general* and redundant variable set, before the variables have been defined. This is achieved by using the redundancy property of the Lagrange equations of motion. The variational principle is used to derive the Hamilton equations from the Lagrange equations, and not in the derivation of the transformation equations as it is in the classical derivation. The generator function, which is introduced with the variational principle, is therefore related to a variable set and not a transformation. In this paper the transformation theory is based on the invariants property of the value of the Lagrangian, and not Hamilton's principle (a variational principle that only is valid for conservative systems).

II. THE HAMILTON EQUATIONS OF MOTION FOR NONCONSERVATIVE PROBLEMS

The investigation is limited to one mass under influence of two forces (however the derivation may easily be extended to a system of particles). The first force is a conservative force $\mathbf{F}_0$ for which the force potential U_0 is known. The second is a force $\mathbf{F}$ for which there may not be a force potential. The force $\mathbf{F}$ may be nonconservative.

Let us first consider the motion of a mass under the influence of the conservative force $\mathbf{F}_0$ (referred to as *the original problem*). The Hamilton equations of motion in the canonical variable set $\{Q,P\}$ for that problem are

$$\dot{P}_i=-\left(\frac{\partial K}{\partial Q_i}\right)_{QPt}, \quad \dot{Q}_i=\left(\frac{\partial K}{\partial P_i}\right)_{QPt}, \tag{1}$$

where K is the Hamilton. The subscript in the partial derivative expressions indicates the functional dependency of K, and the nonindexed variables indicate the full subset of variables.

If the mass comes under the influence of a force $\mathbf{F}$ *in addition* to $\mathbf{F}_0$, the equations of motion may be written as[3]

$$\dot{P}_i=-\left(\frac{\partial K}{\partial Q_i}\right)_{QPt}+\mathbf{F}\cdot\left(\frac{\partial \mathbf{r}}{\partial Q_i}\right)_{QPt},$$

$$\dot{Q}_i=\left(\frac{\partial K}{\partial P_i}\right)_{QPt}-\mathbf{F}\cdot\left(\frac{\partial \mathbf{r}}{\partial P_i}\right)_{QPt}, \tag{2}$$

where $\mathbf{r}$ is the position vector and the definitions of the functions $K(Q,P,t)$, $\mathbf{r}(Q,P,t)$, and $\dot{\mathbf{r}}(Q,P,t)$ are the same as in the original problem.

III. THE LAGRANGE EQUATIONS OF MOTION

The Lagrange formalism is capable of handling nonconservative problems.

Consider a mass under the influence of the force $\mathbf{F}_0$ with the potential U_0 and the nonconservative force $\mathbf{F}$. The Lagrange equations of motion for that system are

$$\frac{d}{dt}\left[\left(\frac{\partial L}{\partial \dot{u}_i}\right)_{u\dot{u}t}\right]-\left(\frac{\partial L}{\partial u_i}\right)_{u\dot{u}t}=\mathbf{F}\cdot\left(\frac{\partial \mathbf{r}}{\partial u_i}\right)_{ut}, \tag{3}$$

where $\{u\}$ represents the variable set and L is the Lagrangian, defined as

$$L=\tfrac{1}{2}m\dot{\mathbf{r}}^2-U_0, \tag{4}$$

where m is the mass. Some variable sets allow the velocity vector to depend on $\{u,\dot{u}\}$ in several different ways. The velocity vector is defined as

$$\dot{\mathbf{r}}=\left(\frac{\partial \mathbf{r}}{\partial u_i}\right)_{ut}\dot{u}+\left(\frac{\partial \mathbf{r}}{\partial t}\right)_{ut} \tag{5}$$

in the Lagrange equations of motion. The force potential U_0 is found by solving the equation

$$\frac{d}{dt}\left[\left(\frac{\partial U_0}{\partial \dot{\mathbf{r}}}\right)_{\mathbf{r}\dot{\mathbf{r}}t}\right]-\left(\frac{\partial U_0}{\partial \mathbf{r}}\right)_{\mathbf{r}\dot{\mathbf{r}}t}=\mathbf{F}_0. \tag{6}$$

The only property required from the variable set $\{u\}$ in (3) is that it can be used to determine the position vector. The variable set may therefore be redundant. In other words, even though only three variables are needed to describe the position of a mass in free space, the Lagrange equations of motion may be formulated using six (or more) variables.

In the redundant variable set $\{u\}=\{Q,P\}$ *the Lagrange equations of motion* are

$$\begin{aligned}\frac{d}{dt}\left[\left(\frac{\partial L}{\partial \dot{Q}_i}\right)_{QP\dot{Q}\dot{P}t}\right]-\left(\frac{\partial L}{\partial Q_i}\right)_{QP\dot{Q}\dot{P}t}&=\mathbf{F}\cdot\left(\frac{\partial \mathbf{r}}{\partial Q_i}\right)_{QPt},\\ \frac{d}{dt}\left[\left(\frac{\partial L}{\partial \dot{P}_i}\right)_{QP\dot{Q}\dot{P}t}\right]-\left(\frac{\partial L}{\partial P_i}\right)_{QP\dot{Q}\dot{P}t}&=\mathbf{F}\cdot\left(\frac{\partial \mathbf{r}}{\partial P_i}\right)_{QPt}.\end{aligned} \tag{7}$$

This set of (six) equations is linearly dependent and contains only three independent equations. The variable set $\{Q,P\}$ is not defined at this point.

The definition of the potential U_0 does not involve any variables explicitly, only the physical variables $\{\mathbf{r},\dot{\mathbf{r}},t\}$. The value of U_0 is therefore the same in all variable sets, i.e., it is invariant to variable transformations. The Lagrangian, L, is defined using U_0 and $\dot{\mathbf{r}}$, and its value is therefore also invariant to variable transformations. This implies that the Lagrangian is transformed by simple variable substitution. For instance,

$$L(q,\dot{q},t)=L(q(Q,P,t),\dot{q}(Q,P,\dot{Q},\dot{P},t),t)=L(Q,P,\dot{Q},\dot{P},t), \tag{8}$$

transforms L from the variable set $\{q\}$ to the redundant variable set $\{Q,P\}$.

IV. THE HAMILTON EQUATIONS OF MOTION

Let us now introduce the auxiliary function f, the Hamilton $K(Q,P,t)$ and the generator function S. The auxiliary function f (and the Hamilton K) is defined according to the equation

$$f(Q,P,\dot{Q},\dot{P},t)=L(Q,P,\dot{Q},\dot{P},t)-P_i\dot{Q}_i+K(Q,P,t)-\frac{dS}{dt}\equiv 0. \tag{9}$$

The generator function may depend on any list of variables (including variables from other sets). It is important to note that the generator function here is associated with the variable set $\{Q,P\}$, and not with a specific transformation between two variable sets, as it is in the classical approach.

From Eq. (9) four sets of equations may be derived. The first two are derived using the variational principle

$$\delta\int f(Q,P,\dot{Q},\dot{P},t)dt=\delta\int 0\,dt=0, \tag{10}$$

which is equivalent to

$$\frac{d}{dt}\left[\left(\frac{\partial f}{\partial \dot{Q}_i}\right)_{QP\dot{Q}\dot{P}t}\right]-\left(\frac{\partial f}{\partial Q_i}\right)_{QP\dot{Q}\dot{P}t}=0,$$

$$\frac{d}{dt}\left[\left(\frac{\partial f}{\partial \dot{P}_i}\right)_{QP\dot{Q}\dot{P}t}\right]-\left(\frac{\partial f}{\partial P_i}\right)_{QP\dot{Q}\dot{P}t}=0. \tag{11}$$

Using (9) we find

$$\frac{d}{dt}\left[\left(\frac{\partial L}{\partial \dot{Q}_i}\right)_{QP\dot{Q}\dot{P}t}-P_i\right]-\left(\frac{\partial L}{\partial Q_i}\right)_{QP\dot{Q}\dot{P}t}-\left(\frac{\partial K}{\partial Q_i}\right)_{QPt}=0,$$

$$\frac{d}{dt}\left[\left(\frac{\partial L}{\partial \dot{P}_i}\right)_{QP\dot{Q}\dot{P}t}\right]-\left(\frac{\partial L}{\partial P_i}\right)_{QP\dot{Q}\dot{P}t}+\dot{Q}_i-\left(\frac{\partial K}{\partial P_i}\right)_{QPt}=0. \tag{12}$$

By using (7), these equations can easily be reduced to

$$\dot{P}_i=-\left(\frac{\partial K}{\partial Q_i}\right)_{QPt}+\mathbf{F}\cdot\left(\frac{\partial \mathbf{r}}{\partial Q_i}\right)_{QPt},$$

$$\dot{Q}_i=\left(\frac{\partial K}{\partial P_i}\right)_{QPt}-\mathbf{F}\cdot\left(\frac{\partial \mathbf{r}}{\partial P_i}\right)_{QPt}. \tag{13}$$

These are *the general Hamilton equations of motion*. Observe that the generator function, S, does not appear in these equations.

The next two sets of equations are found by taking the partial derivatives of (9) with respect to $\dot{Q}_i$ and $\dot{P}_i$. This gives

$$\left(\frac{\partial L}{\partial \dot{Q}_i}\right)_{QP\dot{Q}\dot{P}t}-P_i-\left(\frac{\partial}{\partial \dot{Q}_i}\left(\frac{dS}{dt}\right)\right)_{QP\dot{Q}\dot{P}t}=0,$$

$$\left(\frac{\partial L}{\partial \dot{P}_i}\right)_{QP\dot{Q}\dot{P}t}-\left(\frac{\partial}{\partial \dot{P}_i}\left(\frac{dS}{dt}\right)\right)_{QP\dot{Q}\dot{P}t}=0. \tag{14}$$

These are the general equations for defining the momenta. The direct use of Eqs. (14) should be the focus of a future study. In this paper these equations are solved in the special variable set $\{q,p\}$ where $(dS/dt)=0$, i.e., S is a constant S_0. This special variable set is then transformed to the general variable set $\{Q,P\}$.

For a variable set $\{q,p\}$ where $S=S_0$, Eqs. (14) are reduced to

$$\left(\frac{\partial L}{\partial \dot{q}_i}\right)_{qp\dot{q}\dot{p}t}-p_i=0,$$

$$\left(\frac{\partial L}{\partial \dot{p}_i}\right)_{qp\dot{q}\dot{p}t}=0. \tag{15}$$

The last set of equations implies that the Lagrangian cannot depend on $\dot{p}$. The Lagrangian is defined using the velocity vector (4), so the velocity vector in (5) may not depend on $\dot{p}$ either. This is only possible if the position vector itself is independent of p. If the position vector and the velocity vector are independent of p and $\dot{p}$, then the Lagrangian must be independent of them as well. This reduces (15) to the classical definition of the momenta

$$p_i=\left(\frac{\partial L}{\partial \dot{q}_i}\right)_{q\dot{q}t}. \tag{16}$$

If the coordinates q are defined so that they can be used to determine the position vector $\mathbf{r}(q,t)$, the Lagrangian $L(q,\dot{q},t)$ may be found, and the momenta p can be found by using (16). The Hamilton $H(q,p,t)$, which is the equivalent to $K(Q,P,t)$ for $S=S_0$, may then be found by using (9) (with $(dS/dt)=0$).

V. TRANSFORMATION PROPERTIES

The starting point for finding the transformation equations linking the variable set $\{q,p\}$ (where $S=S_0$) with the variable set $\{Q,P\}$ is the definition of the auxiliary function f in (9). This equation, formulated for the two variable sets, gives

$$L(q,\dot{q},t)-p_i\dot{q}_i+H(q,p,t)\equiv 0, \tag{17}$$

and

$$L(Q,P,\dot{Q},\dot{P},t)-P_i\dot{Q}_i+K(Q,P,t)-\frac{dS}{dt}\equiv 0. \tag{18}$$

The discussion which led to (8) concluded that the value of the Lagrangian is invariant to variable transformations. Eliminating the (invariant) Lagrangian from (17) and (18) gives

$$p_i\dot{q}_i-H(q,p,t)=P_i\dot{Q}_i-K(Q,P,t)+\frac{d(S-S_0)}{dt}, \tag{19}$$

where $S-S_0$ is the difference between the generator functions in the two variable sets. Equation (19) is the same equation as the one we used to find the transformation equations in the classical Hamilton formalism. In the classical formalism, the function $\Delta S=S-S_0$ is referred to *as the generator function of the transformation*. For instance, if this function is defined as $\Delta S=\Delta S(q,Q,t)$, (19) becomes

$$p_i\dot{q}_i-H(q,p,t)=P_i\dot{Q}_i-K(Q,P,t)+\left(\frac{\partial \Delta S}{\partial q_i}\right)_{qQt}\dot{q}_i+\left(\frac{\partial \Delta S}{\partial Q_i}\right)_{qQt}\dot{Q}_i+\left(\frac{\partial \Delta S}{\partial t}\right)_{qQt} \tag{20}$$

with a solution described by the following transformation equations:

$$p_i=\left(\frac{\partial \Delta S}{\partial q_i}\right)_{qQt}, \tag{21}$$

$$P_i=-\left(\frac{\partial \Delta S}{\partial Q_i}\right)_{qQt}, \tag{22}$$

$$K=H+\left(\frac{\partial \Delta S}{\partial t}\right)_{qQt}. \tag{23}$$

Notice that the perturbing force **F** appears only in the equations of motion, and that all other definitions are unaffected by the presence of this extra force.

VI. CONCLUSIONS

The main achievement of this study is the derivation of the Hamilton equations of motion for nonconservative systems using a variational principle. The study demonstrates how the Lagrange equations of motion may be formulated in a redundant variable set, and how the Hamilton equations of motion are directly linked to the Lagrange equations of motion. The study also shows how the invariants property of the value of the Lagrangian can be used to derive the canonical trans-

formation theory. This approach associates the generator function to the variable set, and not to a specific canonical transformation. The generator function is a constant for variable sets where the position vector is independent of the momenta.

ACKNOWLEDGMENTS

The redundancy property of the Lagrange equations of motion was first brought to the author's attention by Professor Jacques Henrard (Electronic mail: jhenrard@math.fundp.ac.be). The author is also grateful to Professor Egil Leer (Electronic mail: egil.leer@astro.uio.no) and Professor Jan Trulsen (Electronic mail: jan.trulsen@astro.uio.no) for their suggestions and criticism.

A classical large *N* hierarchical vector model in three dimensions: A nonzero fixed point and canonical decay of correlation functions

P. A. Faria da Veiga[a),b)]

(Received 4 September 1997; accepted for publication 2 December 1997)

We consider a hierarchical N-component classical vector model on a three-dimensional lattice $\mathbb{Z}^3$, for large N. The model differs from the usual one in that the kernel of the inverse Laplace operator is nontranslational invariant but has matrix elements which are positive and exhibit the same falloff as the inverse Laplacian in $\mathbb{Z}^3$. We introduce a renormalization group transformation and for $N=\infty$, corresponding to the leading order of the $1/N$ expansion, we construct explicitly a nonzero fixed point for this transformation and also obtain some correlation functions. The two-point function has canonical decay. For $1 \ll N < \infty$, we obtain the fixed point and the two-point function in the first $1/N$ approximation. Canonical decay is still verified, in contrast to what is reported for the full model. © *1998 American Institute of Physics.* [S0022-2488(98)04203-0]

I. INTRODUCTION

Hierarchical models are formulated to mimic systems of interest in statistical mechanics and euclidean quantum field theories. In particular, they have proved to be a good laboratory to test ideas and to develop tools that allow the rigorous analysis of the continuum and the thermodynamic limits in such systems.

In the case of boson lattice field theories, the hierarchical versions are defined by replacing, in the Gaussian (free) measure, the Laplace operator Δ in the inverse covariance by a hierarchical long-range Laplacian Δ_h. In general, although $(\Delta_h)^{-1}$ is not translational invariant on the lattice, it has matrix elements with the same canonical decay properties as for Δ^{-1}.

The main simplification involved in hierarchical models is of a technical nature and has to do with renormalization group transformations (RGT), which preserve locality of the interacting potential.

In Ref. 1, a given hierarchical version for the lattice real boson vector model, with a large number $N \in \mathbb{N}$ of components and in three euclidean dimensions, was considered that led to a recursion of the RGT which corresponds to the Wilson's (approximate) recursion when the value of the associated block-spin length, $L \in \mathbb{N}, L>1$, in the lattice $\Lambda \subset \mathbb{Z}^3$, equals two for each RGT step. In dimension $d \in \mathbb{N}$, the corresponding RGT is given by

$$e^{-\mathscr{T}V(\boldsymbol{\phi})} = \text{const} \int e^{-(1/2)L^d[V(L^{-(d-2)/2}\boldsymbol{\phi}+\mathbf{z})+V(L^{-(d-2)/2}\boldsymbol{\phi}-\mathbf{z})]} d\nu(\mathbf{z}), \tag{I.1}$$

where $\boldsymbol{\phi}=(\phi_1,\phi_2,\ldots,\phi_N) \in \mathbb{R}^N$ denotes the N-component field (a random process), V is the interacting potential, $\mathbf{z}$ describes the fluctuation field (another random process) and where

$$d\nu(\mathbf{z}) = \prod_{x \in \Lambda} e^{-(1/2)|\mathbf{z}(x)|^2} d\mathbf{z}(x)$$

for $d\mathbf{z}(x)$, at each lattice site x, being the product of Lesbesgue measures $dz_1(x)\cdots dz_N(x)$; is a normalized and mean zero Gaussian measure with unit covariance on $\Lambda \subset \mathbb{Z}^d$. In (I.1), the const factor is a normalization and $\mathscr{T}V$ describes the effective potential generated by this RGT.

In Ref. 1, a nonzero fixed point solution of the RGT (I.1) was constructed first for the $N = \infty$ regime, given by the leading order in the $1/N$ expansion for the model, and was then extended to the case $1 \ll N < \infty$. Physical stability, asymptotics and other properties of this solution have also been analyzed.

Recently, in a companion paper,[2] we reconsidered the previous analysis of Ref. 1 for the finite N fixed point and improved our understanding of this model by constructing the thermodynamic limit of some correlations. Even though the fixed point is nonzero, we have shown that the two-point function has canonical (nonanomalous) decay at large distances. The canonical decay is also checked for other correlations studied there. This behavior differs from what is reported to occur in the full model (see, e.g., Refs. 3, 4).

In this paper, we consider another hierarchical version for the same problem for which, as will be shown in the sequel, instead of the Wilson's transformation, the RGT in dimension d is given by (see Ref. 5)

$$e^{-\mathscr{T}V(\boldsymbol{\phi})} = \text{const} \int e^{-L^d[V(L^{-(d-2)/2}\boldsymbol{\phi}+\mathbf{z})]} d\nu(\mathbf{z}). \tag{I.2}$$

Due to the nonsymmetrical form of this transformation, in contrast with the Wilson's case given in Eq. (I.1), we will refer to the present model as the *nonsymmetrical* hierarchical model hereafter.

The point we will be focusing on is the decay of correlations at large distances. Precisely, we want to determine whether or not the correlation functions of the nonsymmetrical hierarchical model also have canonical decay.

The reason that justifies our motivation in performing this analysis lays in the fact that, while sharing the ''simplicity'' of a hierarchical model, it presents desirable features not found in the Wilson's symmetrical model (I.1), namely,

—the associated inverse hierarchical Laplacian ${\Delta_h}^{-1}$, on the lattice, has positive matrix elements as for the Laplacian Δ^{-1} in the full case;

—for $N=1$, as it will be shown in Sec. I C, in the case of a quadratic perturbation $V(\phi) = \mu\phi^2/2, \mu \geqslant 0$, associated with a nonzero Gaussian fixed point, noncanonical or anomalous behavior of the two-point function appears discontinuously in μ, at $\mu = 0$;

—working with the nonsymmetrical hierarchical classical vector model in dimension $d=3$ or higher, the Goldstone picture has been confirmed in Refs. 6, 7 by showing the change from canonical to noncanonical decay of the two-point function, depending on the considered field direction.

These facts make the nonsymmetrical model a better candidate to mimic the full model than Wilson's. Next, we give a detailed description of this model.

A. The model

Formally, the partition function for the N-component vector model on a lattice $\mathbb{Z}^d$ is taken as

$$Z = \int e^{-(1/2)\langle \boldsymbol{\phi}, \Delta\boldsymbol{\phi}\rangle - V(\boldsymbol{\phi})} \prod_x d\boldsymbol{\phi}(x), \tag{I.3}$$

where $\Delta = -\Delta_L$, Δ_L being the lattice Laplacian, $\boldsymbol{\phi} = (\phi_1, \ldots, \phi_N) \in \mathbb{R}^N, x \in \mathbb{Z}^d$.

We now define what we call the nonsymmetrical hierarchical model. With a view to our renormalization group (RG) analysis, it is convenient to introduce a sequence of unit lattices $\{\Lambda_j, j = 0,1,\ldots,l\}$, where

$$\Lambda_j = \left[-\frac{L^{l-j}}{2}, \frac{L^{l-j}}{2} \right]^d \cap \mathbb{Z}^d, \quad L > 1 \ \text{ odd}.$$

We also introduce N-component vector fields $\boldsymbol{\phi}^{(j)}(x^{(j)}) \in \mathbb{R}^N, x^{(j)} \in \Lambda_j$ and Gaussian measures $d\mu_j(\boldsymbol{\phi}^{(j)})$. $d\mu_j$ are normalized and mean-zero measures and have covariances G_j which are taken to be diagonal in the components of the vector field, being defined by

$$G_j(x^{(j)} = Lx^{(j+1)} + u, y^{(j)} = Ly^{(j+1)} + \bar{u}) = L^{-(d-2)} G_{j+1}(x^{(j+1)}, y^{(j+1)}) + \delta_{j+1}(x^{(j+1)}, y^{(j+1)}), \tag{I.4}$$

where the symbol δ denotes the Kronecker delta function, $G_l \equiv G_l(x^{(l)}, y^{(l)}) = [1 - L^{-(d-2)}]^{-1}$ and u, $\bar{u} \in B_0$, B_0 being the lattice block $[-\frac{L}{2}, \frac{L}{2}]^d \cap \mathbb{Z}^d$ containing L^d points of Λ_j.

Letting the site 0 denote the origin for the coordinate system on the lattice and e_1 the lattice unit vector for any given direction, it can be checked that, upon iteration, we have

$$G_0(0, L^k e_1) = \frac{1}{(1 - L^{-(d-2)})} \frac{1}{L^{k(d-2)}}; \quad k = 0,1,...,l-1, \tag{I.5}$$

that is, canonical decay for the covariances.

The partition function for the nonsymmetrical hierarchical vector model in the finite volume $\Lambda_0 \equiv \Lambda$ is taken as in (I.3) with the Gaussian part being given by $d\mu_0$, and for $x \equiv x^{(0)}$ and $\boldsymbol{\phi}(x) \equiv \boldsymbol{\phi}^{(0)}(x^{(0)})$, we have $V(\boldsymbol{\phi}) = \Sigma_{x^{(0)} \in \Lambda_0} V(\boldsymbol{\phi}^{(0)}(x^{(0)}))$. It reads

$$Z_0 \equiv Z_0(l) = \int e^{-V(\boldsymbol{\phi})} d\mu_0(\boldsymbol{\phi}). \tag{I.6}$$

The definition of the normalized p-point correlation functions follows in a similar way and is given by

$$\langle \phi_{i_1}(x_1) \phi_{i_2}(x_2) \cdots \phi_{i_p}(x_p) \rangle_l = (Z_0)^{-1} \int \phi_{i_1}(x_1) \phi_{i_2}(x_2) \cdots \phi_{i_p}(x_p) e^{-V(\boldsymbol{\phi})} d\mu_0(\boldsymbol{\phi}), \tag{I.7}$$

with $i_1, \ldots, i_p = 1,...,N$, and with Z_0 given by (I.6).

B. The nonsymmetrical RGT

In the context of the RG method, we now present some identities for the partition function, introduce the RGT, effective actions and give representations for correlation functions in terms of effective actions and effective spin (field) variables.

Corresponding to the decomposition (I.4) of the covariance, we introduce a decomposition for the fields given by

$$\boldsymbol{\phi}^{(j)}(x^{(j)} = Lx^{(j+1)} + u) = L^{-(d-2)/2} \boldsymbol{\phi}^{(j+1)}(x^{(j+1)}) + \boldsymbol{\eta}^{(j+1)}(x^{(j+1)}),$$

which yields to the fundamental identity, for any given function f_x,

$$\int \prod_{x \in \Lambda_j} f_x(\boldsymbol{\phi}^{(j)}) d\mu_j(\boldsymbol{\phi}^{(j)}) = \int \prod_{x \in \Lambda_{j+1}} \overline{f_x}(\boldsymbol{\phi}^{(j+1)}) d\mu_{j+1}(\boldsymbol{\phi}^{(j+1)}), \tag{I.8}$$

with

$$\overline{f_x}(\boldsymbol{\phi}) = \int \prod_{u \in B_0} f_{Lx+u}(L^{-(d-2)/2} \boldsymbol{\phi} + \boldsymbol{\zeta}) e^{-\xi^2/2} d\boldsymbol{\zeta},$$

where we adopt the convention that the $\boldsymbol{\zeta}$ integral includes the normalization factor $(2\pi)^{-N/2}$.

The fundamental identity (I.8) follows from the decomposition identity for the generating function of Gaussian measures. As it can be seen, repeated applications of (I.8) to the partition function $Z_0 \equiv Z_0(l)$ gives

$$Z_0 \equiv \int \prod_{x^{(0)} \in \Lambda_0} e^{-V(\boldsymbol{\phi}^{(0)}(x^{(0)}))} d\mu_0 = \int \prod_{x^{(1)} \in \Lambda_1} e^{-RV(\boldsymbol{\phi}^{(1)}(x^{(1)}))} d\mu_1$$

$$= \cdots = \int e^{-R^l V(\boldsymbol{\phi}^{(l)}(x^{(l)}))} d\mu_l \equiv Z_l ,$$

where, up to a normalization, the RGT is defined, in agreement with (I.2), by

$$e^{-RW(\boldsymbol{\phi})} = \int e^{-L^d W(L^{-(d-2)/2}\boldsymbol{\phi} + \boldsymbol{\eta})} e^{-\boldsymbol{\eta}^2/2} d\boldsymbol{\eta}. \tag{I.9}$$

Thus, it is clear that the effective actions remain local under this transformation.

Applying the fundamental identity (I.8) to both, the numerator and the denominator of the expression (I.7), we can represent the p-point functions in terms of effective spin variables. Doing this for the two-point function, and letting $I_i(\boldsymbol{\phi}) = \phi_i$, we get

$$\langle \boldsymbol{\phi}_i(0) \boldsymbol{\phi}_j(L^k e_1) \rangle_l$$

$$= (Z_1)^{-1} \int M_V I_i(\boldsymbol{\phi}^{(1)}(0)) M_V I_j(\boldsymbol{\phi}^{(1)}(L^{k-1} e_1)) \prod_{x^{(1)} \in \Lambda_1} e^{-RV(\boldsymbol{\phi}^{(1)}(x^{(1)}))} d\mu_1$$

$$= \cdots = (Z_k)^{-1} \int [(M_{R^{k-1}V} \cdots M_V I_i)(\boldsymbol{\phi}^{(k)}(0))][(M_{R^{k-1}V} \cdots M_V I_j)(\boldsymbol{\phi}^{(k)}(e_1))]$$

$$\times \prod_{x^{(k)} \in \Lambda_k} e^{-R^k V(\boldsymbol{\phi}^{(k)}(x^{(k)}))} d\mu_k$$

$$= \cdots = (Z_{k+1})^{-1} \int [M_{R^k V}[(M_{R^{k-1}V} \cdots M_V I_i)(M_{R^{k-1}V}$$

$$\times \cdots M_V I_j)]](\boldsymbol{\phi}^{(k+1)}(0)) \prod_{x^{(k+1)} \in \Lambda_{k+1}} e^{-R^{k+1} V(\boldsymbol{\phi}^{(k+1)}(x^{(k+1)}))} d\mu_{k+1}$$

$$= \cdots = (Z_l)^{-1} \int [M_{R^{l-1}V} \cdots M_{R^k V}[(M_{R^{k-1}V} \cdots M_V I_i)(M_{R^{k-1}V} \cdots M_V I_j)]](\boldsymbol{\phi}^{(l)})$$

$$\times e^{-R^{l-1} V(\boldsymbol{\phi}^{(l)})} d\mu_l , \tag{I.10}$$

where all the above partition functions carry an explicit dependence on l and M_W is the linear operator

$$[M_W f](\boldsymbol{\phi}) = \frac{\int f(L^{-(d-2)/2}\boldsymbol{\phi} + \boldsymbol{\eta}) e^{-W(L^{-(d-2)/2}\boldsymbol{\phi} + \boldsymbol{\eta})} e^{-(1/2)\boldsymbol{\eta}^2} d\boldsymbol{\eta}}{\int e^{-W(L^{-(d-2)/2}\boldsymbol{\phi} + \boldsymbol{\eta})} e^{-(1/2)\boldsymbol{\eta}^2} d\boldsymbol{\eta}}. \tag{I.11}$$

Remarks:

(1) In (I.10), after $(k-1)$ iterations, the points 0 and $L^k e_1$ belong to the same block, thus reducing the two corresponding fields to the same variable. After this, the action of M is global, on both fields.
(2) We can similarly derive expressions like (I.10) for other correlations.
(3) We note that in (I.11), apart from a normalization, when acting on a field $\boldsymbol{\phi}$, M_W gives the associated effective spin (field) corresponding obtained by integration over the corresponding fluctuation against an interacting potential W.
(4) Also, it is clear from Eq. (I.11) that, at a given point W, the operator M_W is L^{-d} times the linearized RGT associated with RW at this point. This observation is helpful in understanding the scaling behavior of the effective spin variables.

The above formalism appears in Refs. 6–8, and was used in Ref. 2 to compute the $N=\infty$ correlation functions. When $N=\infty$, at the nonzero fixed point, the spectral properties of the operator M_V turn out to be completely known for the symmetrical case.

The same method is, in principle, successful to treat any case whenever the spectral resolution of M_V can be obtained. Below, we illustrate how it works in another model. For $d>2$, we consider the case of a nonsymmetrical hierarchical scalar (one-component) model with a quadratic perturbation. This consists of an example of how an anomalous decay does appear within a hierarchical nonsymmetrical model.

C. A nonzero fixed point and anomalous decay: A nonsymmetrical hierarchical model with a quadratic potential

We are going to consider the case of a quadratic perturbation $V(\phi)=\frac{1}{2}\mu\phi^2$, $\mu\geqslant 0$, of a nonsymmetrical hierarchical model with a one-component field in dimension $d>2$. The RGT here reduces to [see Eq. (1.9)]

$$e^{-RV(\phi)}=\int e^{-(1/2)\mu L^d(L^{-(d-2)/2}\phi+\eta)^2}e^{-\eta^2/2}d\eta. \tag{I.12}$$

Let us first assume $\mu>0$. Simply by computing the above Gaussian integral we see that, under (I.12), $V(\phi)\mapsto V_1(\phi)\equiv[RV](\phi)=\frac{1}{2}(\mu L^2/(1+\mu L^d))\phi^2\equiv\mu L^2/(1+\mu L^d)$. Obviously, iteration of the RGT (I.12) gives

$$V_n(\phi)\equiv[R^nV](\phi)=\frac{1}{2}\,\mu_n\phi^2=\frac{1}{2}\,\frac{\mu_{n-1}L^2}{1+\mu_{n-1}L^d}\,\phi^2,$$

with

$$\mu_j\equiv\frac{\mu_{j-1}L^2}{(1+\mu_{j-1}L^d)},\quad j=1,\ldots,n-1.$$

Hence, for $\mu\equiv\mu_0>0$, we have the nonzero fixed point solution

$$\widetilde{V}(\phi)\equiv\lim_{n\to\infty}V_n(\phi)=\tfrac{1}{2}\widetilde{\mu}\phi^2,$$

where

$$\widetilde{\mu}=\frac{L^2-1}{L^d} \tag{I.13}$$

corresponds to the $n\to\infty$ limit of

$$\mu_n=\frac{L^{2n}\mu_0\widetilde{\mu}}{\widetilde{\mu}+(L^{2n}-1)\mu_0}. \tag{I.14}$$

Now, we will compute the infinite volume two-point function

$$\langle\phi(0)\phi(L^ke_1)\rangle_\infty\equiv\lim_{l\to\infty}\langle\phi(0)\phi(L^ke_1)\rangle_l.$$

This will be done using (I.10). To compute the action of the M-operator strings appearing in (I.10), taking the two points to the same block, we will use the formalism developed in Ref. 6. There it is shown that the action of each of these operator strings can be expressed *uniquely* in terms of the last step effective action. For the generic N-component case, we have (compare with equation (1.13) of Ref. 6)

$$[M_{R^{n-1}V}\cdots M_VI_k]_l(\boldsymbol{\phi})=L^{-n[(d-2)/2]}\phi_k-a_n\,\frac{\partial R^nV(\boldsymbol{\phi})}{\partial\phi_k}, \tag{I.15}$$

where the constant $a_n \equiv a_n(d)$ is given by

$$a_n = L^{-n((d+2)/2)}(L^{2n}-1)\tilde{\mu}^{-1}. \tag{I.16}$$

When $N=1$, (I.15) amounts to

$$[M_{R^{n-1}V}\cdots M_V\, I]_l(\phi) = L^{-n(d-2)/2}\phi - a_n \frac{\partial R^n V(\phi)}{\partial \phi},$$

for $I(\phi)=\phi$, reducing to $[(L^{-n[(d-2)/2]}-a_n\mu_n)\phi]$ after evaluation on R^nV. Applying this result to (I.10), setting $\phi^{(l)} \equiv \phi$, we then obtain

$$\begin{aligned}
\langle \phi(0)\phi(L^k e_1)\rangle_l &= (Z_l)^{-1}\int [M_{R^{l-1}V}\cdots M_{R^kV}(M_{R^{k-1}V}\cdots M_V I)(M_{R^{k-1}V}\cdots M_V I)](\phi) \\
&\quad \times e^{-R^{l-1}V(\phi)} d\mu_l \\
&= (Z_l)^{-1}\int M_{R^{l-1}V}\cdots M_{R^kV}[(L^{-k(d-2)/2}-a_k\mu_k)I]^2(\phi) e^{-R^{l-1}V(\phi)} d\mu_l \\
&= (Z_l)^{-1}\int [M_{R^{l-1}V}\cdots M_{R^kV}] \\
&\quad \times \left[\left(L^{-k(d+2)/2} + (L^{-k(d+2)/2}-L^{-k(d-2)/2})\left(\frac{\mu_k}{\tilde{\mu}}-1\right)\right) I\right]^2(\phi) \\
&\quad \times e^{-R^{l-1}V(\phi)} d\mu_l,
\end{aligned} \tag{I.17}$$

where, at each step, the partition function $Z_l \equiv Z_l(l)$ is given by the same integral with $M_{R^{l-1}V}\cdots M_{R^kV}[\ ]^2(\phi)$ replaced by one.

On the other hand, we can easily compute the action of the remaining M-string in (I.17) obtaining

$$(M_{R^{l-1}V}\cdots M_{R^kV})\phi^2 = \gamma_{l-k} + \xi_{l-k}\phi^2, \tag{I.18}$$

where

$$\gamma_{l-k} = L^{-2}\sum_{j=k}^{l-1} \xi_j \frac{\mu_{j-1}}{\mu_j} \quad ; \quad \xi_{l-k} = L^{-(d+2)(l-2k)}\left(\frac{\mu_{l-k}}{\mu_k}\right)^2. \tag{I.19}$$

With this, using (I.14) and performing the last integrals in (I.17), we get

$$\begin{aligned}
\langle \phi(0)\phi(L^k e_1)\rangle_l &= \left[L^{-[(d+2)/2]k} + L^{-[(d-4)/2]k}(1-L^{-3k})\frac{\tilde{\mu}-\mu_0}{\tilde{\mu}+(L^{2k}-1)\mu_0}\right]^2 \\
&\quad \times \left(\gamma_{l-k} + \xi_{l-k}\frac{1}{1-L^{-(d-2)}}\right).
\end{aligned} \tag{I.20}$$

As, from (I.13), $0<\tilde{\mu}<1$ and, according to (I.14),

$$\tilde{\mu} < \frac{(L^{2n}-1)\mu_0\tilde{\mu}}{\tilde{\mu}+(L^{2n}-1)\mu_0} < \mu_n < 2\tilde{\mu},$$

the behavior of both γ_{l-k} and ξ_{l-k} in (I.19) are controlled by the $L^{-(d+2)(l-2k)}$ factor. For this reason, only the constant term of (I.18) matters in, both, the thermodynamic limit at fixed k and the double limit $k,l\to\infty$ with $k\leqslant l$, the later corresponding to the limit of infinite separation.

Letting γ_∞ denote the limit $\lim_{l\to\infty}\gamma_{l-k}$ [see (I.19)], then the last observation applied to (I.20) gives, after taking the thermodynamic limit,

$$\langle \phi(0)\phi(L^k e_1)\rangle_\infty = \gamma_\infty \left[L^{-[(d+2)/2]k} + L^{-[(d-4)/2]k}(1-L^{-3k}) \frac{\tilde{\mu}-\mu_0}{\tilde{\mu}+(L^{2k}-1)\mu_0} \right]^2 \tag{I.21}$$

whenever $\mu_0 > 0$. As, for $\mu_0 = 0$ [check below (I.4)], corresponding to a starting model with no interacting potential, the model has a zero fixed point and the two-point function has canonical decay (scaling $L^{-(d-2)}$), we see in (I.21) that the two-point function for $\mu_0 > 0$ has a noncanonical decay as given by the scaling factor $L^{(d+2)/2}$. The appearance of this effect has thus a discontinuity at $\mu = 0$ and is associated with a change from one to γ_∞ in the wave-function renormalization (coefficient).

D. The large *N* nonsymmetrical hierarchical vector model in three dimensions: Definition and results

Going back to the N-component vector model, hereafter we set $d = 3$ and assume that the initial action is rotational invariant, so that the system has an $O(N)$ symmetry. In order to analyze this model when N is a finite but large integer, it is suitable to introduce the reduced variable $\varphi \in \mathbb{R}$, and fluctuation variables $s \in \mathbb{R}$ and $u \geqslant 0$ verifying

$$\boldsymbol{\phi} = N^{1/2}(\varphi, 0, ..., 0) \tag{I.22}$$

and

$$\mathbf{z} = N^{1/2}(s, \zeta_1, ..., \zeta_{N-1}), \quad {\zeta_1}^2 + \cdots + {\zeta_{N-1}}^2 = u. \tag{I.23}$$

Then, $d\mathbf{z} = u^{(N-3)/2} du\, ds\, d\Omega_{N-1}$. Further upon making the substitutions $V(\boldsymbol{\phi}) = v(\boldsymbol{\phi}^2) \to (N/2)v(\varphi^2)$ and $RV(\boldsymbol{\phi}) = Rv(\boldsymbol{\phi}^2) \to (N/2)v_1(\varphi^2)$, the RGT for the nonsymmetrical model (I.9) can be written as

$$e^{-(N/2)v_1} = N\Omega_{N-1} \int_{-\infty}^{\infty} ds \int_0^\infty du \;\; e^{-L^3(N/2)v(\psi)} e^{-(N/2)(s^2+u-\ln u)} e^{-(3/2)\ln u}, \tag{I.24}$$

where $\psi \equiv \psi(\varphi, s, u) = (L^{-1/2}\varphi + s)^2 + u$ and Ω_{N-1} is the $(N-1)$-dimensional solid angle.

Corresponding to the leading order of the (formal) $1/N$-expansion for (I.24), and letting $v(\varphi^2) \equiv v_{N=\infty}(\varphi^2)$ be independent of N, we define the $N = \infty$ RGT as

$$v_1 = \inf_{s,u} \; [L^3 v(\psi) + s^2 + u - \ln u] \equiv L^3 v(\psi_0) + s_0^2 + u_0 - \ln u_0 \tag{I.25}$$

for $s_0 \equiv s_0(\varphi^2)$ and $u_0 \equiv u_0(\varphi^2)$ being solutions of the variational equations

$$L^3 v'(\psi)(s + L^{-1/2}\varphi) + s = 0,$$

$$L^3 v'(\psi) + 1 - 1/u = 0, \tag{I.26}$$

where the prime denotes a derivative with respect to φ^2, and $\psi_0 \equiv \psi(\varphi, s_0, u_0)$.

Our first result describes a nonzero fixed point solution to (I.25). We have:

Theorem 1: *Let $\tau = v'$ and $t_0 = L/(L-1) \equiv (\varphi_0)^2$. Then, when $N = \infty$, there exists a fixed point $\tilde{v}_{N=\infty}$ of (I.25) given, in terms of t, the inverse function of $\tilde{v}'$, by*

$$t(\tau) = t_0 + t_0 L \tau \sum_{n=0}^{\infty} \frac{1}{L^n} \left[\frac{1-L^{-2}}{(1-L^{-2}) - (1-L^{-2n})L\tau} \right]^2 \left[\frac{1-L^{-2}}{(1-L^{-2}) - (1-L^{-2(n+1)})L\tau} \right] \tag{I.27}$$

for $\tau \neq \tau_n \equiv (1-L^{-2})/(L(1-L^{-2n}))$, $n = 0,1,...$. Thus, $t(\tau)$ extends to an analytic function in a disk centered at τ_0. Moreover, the potential $\tilde{v}_{N=\infty}(\varphi^2)$ is stable whenever φ is real, that is $t'(\tau) > 0$ for $\tau < (1-L^{-2})/L$, and $\tilde{v}'_{N=\infty}(\varphi^2)$ is analytic there. The fixed point $\tilde{v}_{N=\infty}$ is nonzero and has a unique minimum at $\varphi^2 = (\varphi_0)^2$, with $\tilde{v}''_{N=\infty}((\varphi_0)^2) = (2L\varphi_0^2)^{-1}$. Finally, normalizing $\tilde{v}_{N=\infty}$ so that $\tilde{v}_{N=\infty}(\varphi^2) = 0$ the following global bounds hold

$$a'+b'|\varphi|\leqslant\tilde{v}_{N=\infty}(\varphi^2)\leqslant a+b\varphi^2,\quad \varphi\in\mathbb{R} \tag{I.28}$$

for some real a and a' and positive b and b'.

Remark: The derivatives of the critical potential $\tilde{v}_{N=\infty}(\varphi^2)$ can be all computed, as an application of the analytic inverse function theorem. An integral representation for the inverse function is given in Ref. 9, and in Ref. 10 explicit formulas for the Taylor coefficients are obtained.

Concerning the two-point function, we note that because of the $O(N)$ symmetry of the model,

$$\langle\phi_i(0)\phi_j(L^k e_1)\rangle_l=\frac{\delta_{ij}}{N}\langle\boldsymbol{\phi}(0)\cdot\boldsymbol{\phi}(L^k e_1)\rangle_l, \tag{I.29}$$

the dot denoting the Euclidean inner product in $\mathbb{R}^n$.

Using in (I.29) the definition (I.10), and applying the relations $\Sigma_{i=1}^N\phi_i(\partial V/\partial\phi_i)=2N\varphi^2v'(\varphi^2)$ and $\nabla V\cdot\nabla V=4N\varphi^2[v'(\varphi^2)]^2$, to pass to the reduced variables (I.22) and (I.23), we obtain, for $I(\varphi^2)=\varphi^2$,

$$\begin{aligned}\langle\phi_i(0)\phi_j(L^k e_1)\rangle_l=\delta_{ij}(Z_l)^{-1}\int&[m_{l-k}[(L^{-k/2}I-a_kv'(I)I)^2(\varphi^2)]]\\&\times e^{-(N/2)v(\varphi^2)}e^{-(N/2)(1-L^{-1})\varphi^2}e^{(N-1)\ln\varphi}d\varphi,\end{aligned} \tag{I.30}$$

where, as in (I.11), for rotational invariant $f(\varphi^2)$, we define

$$[mf](\varphi^2)=\frac{\int_{-\infty}^{\infty}ds\int_0^{\infty}du\,f(\psi)e^{-(N/2)(s^2+u-\ln u)-(3/2)\ln u}e^{-(N/2)L^3v(\psi)}}{\int_{-\infty}^{\infty}ds\int_0^{\infty}du\,e^{-(N/2)(s^2+u-\ln u)-(3/2)\ln u}e^{-(N/2)L^3v(\psi)}}. \tag{I.31}$$

Note that, for $N=\infty$, we define the action of $m_\infty\equiv m_{N=\infty}$ of the operator m in (I.31), according to the Laplace method, as

$$[m_\infty f](\varphi^2)=f(\psi_0\equiv(L^{-1/2}\varphi+s_0)^2+u_0). \tag{I.32}$$

We can now state our second result, regarding the $N=\infty$ two-point functions

Theorem 2: *For $N=\infty$, the thermodynamic limit $l\to\infty$ of the two-point function exists and we have*

$$\langle\phi_i(0)\phi_j(L^k e_1)\rangle_{N=\infty,\infty}\equiv\lim_{l\to\infty}\langle\phi_i(0)\phi_j(L^k e_1)\rangle_{N=\infty,l}=\delta_{ij}L^{-k}\varphi_0^2. \tag{I.33}$$

Remarks:

(1) As it will become clear in the sequel, our techniques apply as well to other correlation functions. In particular, for the ''partially truncated'' (P.T.) functions defined below, we have,

$$\begin{aligned}&\frac{1}{N^{n+j}}\,\langle[(\boldsymbol{\phi}\cdot\boldsymbol{\phi})(0)]^n[(\boldsymbol{\phi}\cdot\boldsymbol{\phi})(L^k e_1)]^j\rangle_{N=\infty,\infty}^{\text{P.T.}}\\&\quad\equiv\lim_{l\to\infty}\Bigg(\frac{1}{N^{n+j}}\,\langle[(\boldsymbol{\phi}\cdot\boldsymbol{\phi})(0)]^n[(\boldsymbol{\phi}\cdot\boldsymbol{\phi})(L^k e_1)]^j\rangle_{N=\infty,l}\\&\qquad-\frac{1}{N^{n+j}}\,\langle[(\boldsymbol{\phi}\cdot\boldsymbol{\phi})(0)]^n\rangle_{N=\infty,l}\langle[(\boldsymbol{\phi}\cdot\boldsymbol{\phi})(L^k e_1)]^j\rangle_{N=\infty,l}\Bigg)=L^{-2k(n+j)}(\varphi_0)^{2(n+j)}.\end{aligned}$$

Though the coefficient φ_0^2 in (I.33) shows a change in the wave-function renormalization, as compared to the free case, all the above correlations have canonical decay, as $L^{-k}=|x|^{-1}$.

We do not know if Wick's theorem holds for expectations of all monomials.

Let us now consider the $1 \ll N < \infty$ regime and the model as described by the $1/N$ expansion. In this case, by extending the preceding analysis to the first $1/N$ correction, using the Laplace method to write an expansion for the integrals in (I.10), we can state our last result:

Theorem 3: *Let* $1 \ll N < \infty$. *Up to order* $1/N$:

(1) *The fixed point solution to (I.24) is given by*

$$\tilde{v} = \tilde{v}_{N=\infty} + \frac{1}{N}\tilde{r}, \tag{I.34}$$

where $\tilde{v}_{N=\infty}$ *is the* $N=\infty$ *nonzero fixed point solution of Theorem 1 and* $\tilde{r}$ *is given in Eq. (III.4) below, so that* $\tilde{v} \neq 0$ *for sufficiently large* N.

(2) *The (finite-volume) two-point function for extremely separated points 0 and* $L^{l-1}e_1$ *in the lattice* Λ_l, *for fixed* l *and at the fixed point* $\tilde{v}$ *of (I.34), has canonical decay and is given by*

$$\langle \phi_i(0)\phi_j(L^{l-1}e_1)\rangle_l = \delta_{ij} L^{-(l-1)}(\varphi_0)^2\left(1+\frac{c}{N}\right). \tag{I.35}$$

for some finite real constant c, *independent of* N *and* l.

Remark: The extreme separation condition should not be taken as an *a priori* limitation of the last result for the two-point function. Besides the fact c does not depend on l, as we saw in the case of the quadratic perturbation, accompanied by a change in the wave function renormalization, the two-point function has there the same noncanonical decay, no matter whether the thermodynamic limit is taken first, followed by the limit of infinite separation, or the separation taken to infinity, together with the volume.

In Sec. II, we treat the $N=\infty$ case and prove Theorems 1 and 2. Theorem 3 will be proven in Sec. III. We leave some final remarks for Sec. IV and, for completeness regarding the nonsymmetrical model, the spectral properties of the inverse Laplace operator $(\Delta_h)^{-1}$, as well as the falloff of the matrix elements of Δ_h, are presented in the Appendix.

II. THE $N=\infty$ MODEL: FIXED POINT AND CORRELATION FUNCTIONS

In this section, we consider the $N=\infty$ model. We derive and solve a functional equation for t appearing in Theorem 1, the inverse function of $\tilde{v}'_{N=\infty} \equiv d\tilde{v}_{N=\infty}/d\varphi^2$, where $\tilde{v}_{N=\infty} \equiv \tilde{v}_{N=\infty}(\varphi^2)$ is the fixed point solution of (I.25). Furthermore, we give bounds on the globally defined $\tilde{v}$, and also obtain correlation functions.

From the variational equations (I.26), we have

$$s_0 = (u_0 - 1)L^{-1/2}\varphi \tag{II.1}$$

and taking the derivative of (I.25) gives

$$v'_1 = h \cdot (v' \circ \mathscr{S}),$$

where the dot here means multiplication, ψ_0 is given below (I.26) and where we define

$$h = L^2 + \frac{L^{5/2}s_0}{\varphi}; \quad \mathscr{S}(\varphi^2) = \psi_0.$$

At the fixed point

$$v' = h \cdot (v' \circ \mathscr{S}). \tag{II.2}$$

Multiplying (II.2) by $1/h$, applying t, using (II.1) and (I.26), we obtain

$$t(v'/h) = L^{-1}u_0{}^2 + u_0. \tag{II.3}$$

We now introduce the parameter $\tau \equiv v'$. From (I.26) and (II.1), we have $u_0 = 1 - L\tau$ which, upon substituting in (II.3) yields

$$t(\tau)-\frac{L}{(1-L\tau)^2}\,t\left(\frac{\tau}{L^2(1-L\tau)}\right)=-\frac{L}{1-L\tau}. \tag{II.4}$$

From (II.4), we note that $t(0)=\varphi_0^2\equiv L/(L-1)$, so that introducing the linear operator $\mathscr{M}$ by

$$(\mathscr{M}f\,)(\tau)=\frac{L}{(1-L\tau)^2}\,f\left(\frac{\tau}{L^2(1-L\tau)}\right),$$

and, after subtracting $t(0)$, we rewrite (II.4) as

$$[(1-\mathscr{M})(t-t(0))](\tau)=\frac{L^2\tau}{(L-1)(1-L\tau)}. \tag{II.5}$$

Using in (II.5) the Neumann series for $(1-\mathscr{M})^{-1}$, we then obtain

$$t(\tau)=\frac{L}{L-1}\,\frac{1}{1-L\tau}+\frac{L^2}{L-1}\sum_{n=1}^{\infty}\left[\mathscr{M}^n\left(\frac{\cdot}{1-L\cdot}\right)\right](\tau). \tag{II.6}$$

It can be easily verified that

$$\left[\mathscr{M}^n\left(\frac{\cdot}{1-L\cdot}\right)\right](\tau)=\frac{\tau}{L^n}\,\frac{1}{[1-L(1+L^{-2}+\cdots+L^{-2(n-1)})]^2}\,\frac{1}{[1-L(1+L^{-2}+\cdots+L^{-2n})]} \tag{II.7}$$

which establishes (I.27). Thus, from (II.6) and (II.7), we see that $t(\tau)$ is meromorphic with poles at $\tau_n=L^{-1}[1+L^{-2}+\cdots+L^{-2n}]^{-1}$, $n=0,1,\ldots$, with an accumulation point at $\tau_\infty\equiv L^{-1}(1-L^{-2})$. Thus, the analytic inverse function theorem can be used to show analyticity of $\tilde{v}'$, as well as to compute $\tilde{v}''(\varphi_0^2)$.

It is clear from representation (II.6) that $t'\equiv dt(\tau)/d\tau$ is positive for $\tau\in[0,\tau_\infty)$, but we also have

Lemma 1: *The function t' satisfies $t'(\tau)>0$, for $\tau\in(-\infty,\tau_\infty)$.*

Proof: Notice that for

$$A_0\equiv 1;\quad A_n(\tau)\equiv\frac{\sigma}{\sigma-(1-L^{-2n}L\tau)},\quad n=1,\ldots,$$

with $\sigma=1-L^{-2}$, and with t_0 of Theorem 1, (II.6) can be written as

$$t(\tau)=t_0+t_0L\tau\sum_{n\geqslant 0}\frac{1}{L^n}\,[A_n(\tau)]^2A_{n+1}(\tau). \tag{II.8}$$

Next, using

$$\tau A_n'(\tau)=\frac{(1-L^{-2n})L\tau}{\sigma-(1-L^{-2n})L\tau}\,A_n(\tau),$$

we have from (II.8), by direct computation,

$$\frac{t'(\tau)}{t_0L}=[A_1(\tau)]^2+\sum_{n\geqslant 1}\frac{[A_n(\tau)]^2A_{n+1}(\tau)}{L^n}\,[2A_n(\tau)+A_{n+1}(\tau)-2]. \tag{II.9}$$

Then, we notice that A_n, $n>0$, has simple poles at p_n/L, where $\{p_n\equiv\sigma/(1-L^{-2n}),n\in\mathbb{N}\}$ is a decreasing sequence converging to $0<\sigma<1$. This ensures that the sequence $\{A_n,n\in\mathbb{N}\}=\{1/[1-p_n^{-1}],n\in\mathbb{N}\}$ converges to $A_\infty\equiv(\sigma/\sigma-L\tau)$, monotonically, being decreasing for $\tau<0$ and increasing for $0<\tau<\sigma/2$. This result can be used to get lower bounds on (II.9), taking the first or the last term of the sum, depending on the sign, and achieves the proof of Lemma 1. □

By Lemma 1, the analytic inverse function theorem, and the asymptotic behavior $\lim_{\tau\to-\infty}t(\tau)=-L$ and $\lim_{\tau\to\infty}t(\tau)=\infty$, there exists $v'(\varphi^2)$, monotone increasing and analytic in $(-L,\infty)$ with $v'(\varphi_0^2)=0$ and $\lim_{\varphi^2\to\infty} v'(\varphi^2)=(1-L^{-2})/L$. Normalizing v such that $v(\varphi_0^2)=0$, then $v(\varphi^2)$ has a Taylor expansion about φ_0^2 starting with $[1/(2L\varphi_0^2)](\varphi^2-\varphi_0^2)^2$. Moreover, we also have global upper and lower bounds for v given in:

Proposition 1: *Set* $a\equiv\varphi_0^2(2-L^{-2})\sigma^{-1}$ *and let* $\Phi^2=\varphi^2-\varphi_0^2$. *Then*

$$\frac{\sigma}{L}\left[\Phi^2-\frac{3a^{1/3}}{2}\left((\varphi^2)^{2/3}-(\varphi_0^2)^{2/3}\right)\right]\leqslant\tilde{v}_{N=\infty}(\varphi^2)\leqslant\frac{1}{L}\left[\Phi^2-\varphi_0^2\ln\frac{\varphi^2}{\varphi_0^2}\right]. \tag{II.10}$$

Proof: We note that if $f(\tau)>t(\tau)$ then, setting $h\equiv t^{-1}$, $v'(\varphi^2)<h(\varphi^2)$ which upon integration gives $v(\varphi^2)<\int_{\varphi_0^2}^{\varphi^2}h(\phi)d\phi$ and similarly for the lower bound. The upper bound in (II.10) follows by taking for f the first term in (II.6). For the lower bound, we note that the first term of $t(\tau)$ in (II.6) is $\varphi_0^2(1-L\tau)^{-1}$ and that the sum is bounded by $(\varphi^2\sigma)^{-1}\tau(1-\tau_\infty^{-1}\tau)^{-1}$. For f, we take $f=a(1-\tau_\infty^{-1}\tau)^{-3}$.

This concludes Proposition 1 and, as (II.10) gives (I.28), also the proof of Theorem 1. □

We now turn to the correlation functions. Iterating (II.2) p times gives

$$v'=H_p v'\circ\mathscr{G}^{(1)}\circ\cdots\circ\mathscr{G}^{(p)}, \tag{II.11}$$

where the upper indices count the number of compositions, and

$$H_p=\prod_{j=0}^{p-1}h_j$$

with $h_0\equiv h$ and

$$h_j(\varphi^2)=(h\circ\mathscr{G}^{(1)}\circ\cdots\circ\mathscr{G}^{(j)})(\varphi^2).$$

Multiplying (II.11) by $1/H_p$ and applying t yields

$$t\left(\frac{1}{H_p}\right)v'=\mathscr{G}^{(1)}\circ\cdots\circ\mathscr{G}^{(p)}. \tag{II.12}$$

Next, the linear operator m_∞ [see (I.32)] acting on $f(\varphi^2)$ gives

$$(m_\infty f)(\varphi^2)=f(\psi_0)\equiv(f\circ\mathscr{G})(\varphi^2) \tag{II.13}$$

so that $(m_\infty I)(\varphi^2)=\mathscr{G}(\varphi^2)$ and $m_\infty^n I=\mathscr{G}^{(1)}\circ\cdots\circ\mathscr{G}^{(n+1)}$. Thus, using (II.12) we get

$$m_\infty^n I=t\left(\frac{1}{H_{n+1}}v'\right)$$

and then, going back to (I.30), we obtain

$$\begin{aligned}\langle\phi_i(0)\phi_j(L^k e_1)\rangle_{N=\infty,\infty}&\equiv\lim_{l\to\infty}\langle\phi_i(0)\phi_j(L^k e_1)\rangle_{N=\infty,l}\\&=\delta_{ij}L^{-k}\lim_{n\to\infty}\left[t\left(\frac{1}{H_{n+1}}v'(\varphi^2)\right)\right]\\&=\delta_{ij}L^{-k}t(0)=\delta_{ij}L^{-k}\varphi_0^2,\end{aligned} \tag{II.14}$$

which corresponds to (I.33). Taking more general f's in (II.13) allows us to compute other correlation functions. We have now concluded the proof of Theorem 2. □

III. THE FIRST 1/*N* CORRECTION

In this section, we extend some of the $N=\infty$ results of Sec. II up to the first $1/N$ correction and prove Theorem 3. In the framework of the $1/N$ expansion, we write

$$v(\varphi^2)=v_{N=\infty}(\varphi^2)+\frac{1}{N}\,r(\varphi^2), \tag{III.1}$$

where $v_{N=\infty}$ is the N-independent leading order potential of Sec. II [see above Eq. (I.25)]. Doing the analogous decomposition for v_1 in (I.24), letting $w\equiv(s,u)\in\mathbb{R}\times[0,\infty)$ and for ψ defined below (I.24), we have

$$e^{-(N/2)(v_{N=\infty,1}+(1/N)r_1)}=N\Omega_{N-1}\int dw e^{-Nf(w)}e^{-g(w)}, \tag{III.2}$$

where, with an abuse of notation, we have

$$\begin{aligned} f(w)\equiv f(s,u)&=\tfrac{1}{2}L^3 v_{N=\infty}(\psi)+\tfrac{1}{2}(s^2+u-\ln u),\\ g(w)\equiv g(s,u)&=\tfrac{1}{2}L^3 r(\psi)+\tfrac{3}{2}\ln u. \end{aligned} \tag{III.3}$$

Applying the steepest descent method, we can compute an expansion for the integral in (III.2) about $w_0=(s_0,u_0)$, s_0 and u_0 being solutions of (I.26). Comparing terms of the same $1/N$ order gives back (I.25) and shows that, under the RGT (I.24), r transforms according to

$$r_1\varphi^2)=L^3 r(\psi_0)+3\ln u_0+\ln[(\det D^2 f\ )_0]$$

with ψ_0 defined below (I.24) and where $(\det D^2 f)_0$ is the Hessian of f at w_0. At the fixed point, we thus have

$$\tilde{r}(\varphi^2)=L^3\tilde{r}(\psi_0)+3\ln u_0+\ln[(\det D^2 f\ )_0] \tag{III.4}$$

which can already be used to calculate any derivative of $\tilde{r}$ at φ_0^2, assuming $\tilde{r}$ analytic. From (III.4), we also see that the $1/N$ order fixed point solution

$$\tilde{v}(\varphi^2)=\tilde{v}_{N=\infty}(\varphi^2)+\frac{1}{N}\,\tilde{r}(\varphi^2)$$

is nonzero for large enough N.

This shows part one of Theorem 3. To prove the second part, we go back to the two-point function (I.30) and, for technical simplification, we assume the points to have an extreme separation in the lattice. This is enough for our purposes here. The general case can be treated as well, following what is presented below.

Similar to f and g in (III.3), we define the functions $\hat{f}$ and $\hat{g}$ by

$$\begin{aligned} \hat{f}(\hat{w})\equiv\hat{f}(s,u,\varphi)&=f(w)+\frac{1-L^{-2}}{2}\,\varphi^2-\frac{1}{2}\ln\varphi^2,\\ \hat{g}(\hat{w})\equiv\hat{g}(s,u,\varphi)&=g(w)+\ln\varphi^2, \end{aligned} \tag{III.5}$$

with $\hat{w}\equiv(s,u,\varphi)\in\mathbb{R}\times[0,\infty)\times\mathbb{R}$. Now, letting

$$h(\hat{w})=\psi\left[L^{-l/2}\varphi-a_l\,\frac{dv(\psi)}{d\psi}\right]^2 \tag{III.6}$$

the two-point function (I.30), for extremely separated points 0 and $x=L^{l-1}e_1$ can be expressed as

$$\langle\phi_i(0)\phi_j(L^{l-1}e_1)\rangle_l=\delta_{ij}(Z_l)^{-1}\int d\hat{w}h(\hat{w})e^{-N\hat{f}(\hat{w})}e^{-\hat{g}(\hat{w})} \tag{III.7}$$

with Z_l given by the same integral with $h(\hat{w})$ replaced by one.

Direct calculation shows that the function $\hat{f}$ has a minimum at $\hat{w}_0=(s_0,u_0,\varphi_0)$ with the same s_0 and u_0 of (I.26), and $\varphi_0=\sqrt{L/(L-1)}$ given in Theorem 1. Hence, applying the steepest descent method to the integrals in (III.7), with $y=\sqrt{N}(\hat{w}-\hat{w}_0)$, we obtain

$$\begin{aligned}\langle \phi_i(0)\phi_j(L^{l-1}e_1)\rangle_l = \delta_{ij}h_0 + \frac{h_0'}{\sqrt{N}}\int y\, d\rho(y) - \frac{h_0'}{\sqrt{N}}\left(\int y\, d\rho(y)\right)\\ \times\left(\int\left[(T_0^{(3)}\hat{f}\,) + \frac{\hat{g}_0'}{\sqrt{N}}\,y\right]d\rho(y)\right)\\ + \int\left[-\frac{h_0'}{\sqrt{N}}\,y\left[(T_0^{(3)}\hat{f}\,) + \frac{\hat{g}_0'}{\sqrt{N}}\,y\right] + \frac{h_0''}{2N}\,y^2\right]d\rho(y) + \mathscr{O}(N^{-3/2}),\end{aligned} \tag{III.8}$$

where the zero subscript means evaluation at $\hat{w}=[\hat{w}_0+y/\sqrt{N}]_{y=0}=\hat{w}_0$, and $T^{(3)}$ is the third order Taylor operator, so that when acting on $\hat{f}$ produces an $\mathscr{O}(N^{-1/2})$ term. All the primes indicate derivatives within the multivariable context regarding $\hat{w}=(s,u,\varphi)$ entering in y, and $d\rho(y)$ is a normalized measure with Gaussian density $\exp(-\hat{f}_0''y^2/2-\hat{g}_0'y/\sqrt{N})$.

Applying a parity argument, all the linear terms in $s-s_0$ and $\varphi-\varphi_0$ in the $\int y\, d\rho(y)$ integrals vanish. Paying with an exponentially small factor $\mathscr{O}(e^{-\epsilon N})$, $\epsilon>0$, the same is verified for the integral of the linear $u-u_0$ term. This also ensures that only diagonal or product of diagonal terms (regarding the components of $\hat{w}$ and denoted below by $\mathscr{D}$) survive in the integrals of even powers of y so that (III.8) yields

$$\langle \phi_i(0)\phi_j(L^{l-1}e_1)\rangle_l = \delta_{ij}h_0 - \frac{\delta_{ij}}{N}\int\left[(h_0'y)[\hat{g}_0'y+(T_0^{(3)}\hat{f}\,)y^3] + \frac{h_0''}{2}\,y^2\right]_{\mathscr{D}} d\rho(y) + \mathscr{O}(N^{-3/2}). \tag{III.9}$$

Using (III.1), (III.5) and (III.6), and for a_n in (I.16), putting $b_n\equiv L^{n/2}a_n = L^3(1-L^{-2l})(L^2-1)^{-1}$, we have

$$\begin{aligned}h_0 &= \varphi_0^2 L^{-l}\left(1-\frac{2b_l}{N}\left(\frac{dr(\psi)}{d\psi}\right)_0\right)\\ h_0' &= L^{-l}\left(\frac{\partial\psi}{\partial y}\right)_0[1-2\varphi_0^2 b_l v_\infty''(\varphi_0^2)]\\ h_0'' &= L^{-l}\left\{\left(\frac{\partial^2\psi}{\partial y^2}\right)_0[1-4b_l v_\infty''(\varphi_0^2)-2\varphi_0^2 b_l v_\infty''(\varphi_0^2)] + 2\varphi_0^2 b_l\left(\frac{\partial\psi}{\partial y}\right)_0^2[b_l(v_\infty''(\varphi_0^2))^2 - v_\infty'''(\varphi_0^2)]\right\}.\end{aligned} \tag{III.10}$$

As $\hat{g}_0'$ and $\hat{f}_0'''$ do not depend on l, we see that the two-point function (III.9) presents the structure

$$\langle \phi_i(0)\phi_j(L^{l-1}e_1)\rangle_l = \delta_{ij}L^{-l}\varphi_0^2\left[1+\frac{1}{N}(K_1 b_l + K_2 b_l^2) + \mathscr{O}(N^{-3/2})\right]$$

for some constants K_1 and K_2, fixed essentially by Eqs. (III.10) and being independent of l and N. Hence, in the thermodynamic limit $l\to\infty$, we obtain

$$L^l\langle \phi_i(0)\phi_j(L^{l-1}e_1)\rangle_l \to \delta_{ij}\varphi_0^2\left[1+\frac{K}{N}+\mathscr{O}(N^{-3/2})\right]$$

for some finite K, uniform in N.

This shows (I.35) and concludes the proof of Theorem 3. □

Remark: With more work, the above analysis can be used to treat a generic two-point function and may be extended to compute other $2p$-point functions. It can also be used to obtain higher orders in $1/N$. It is likely that only even powers of $\sqrt{1/N}$ appear in the expansion for these functions.

IV. FINAL REMARKS

In the case of finite N, we have considered the fixed point and correlation functions only to order $1/N$, obtaining canonical decay for the two-point function. We expect this result to hold also without this restriction. The reason for this is that, due to the good properties of the $N=\infty$ fixed point solution, such as global stability and analyticity, we do not see any obstacles to carrying out a rigorous construction of a fixed point for N large, as in Ref. 1, and obtain the correlation functions as done in Ref. 2, for the symmetrical model.

There is the question of whether or not there exists some finite value N_0 of N where anomalous behavior sets in. For $N=1$, the existence of a nonzero fixed point in a hierarchical model is shown in Ref. 11, but the behavior of correlation functions is not determined. As our results show absence of anomalous decay (even though the fixed points are nonzero and the wave function renormalization is different from one) in both the symmetrical and the nonsymmetrical $O(N)$ vector hierarchical models, contrarily to what happens in the case of a one-component quadratic perturbation of Sec. I C and positive μ, it is certainly interesting to understand the full model from the point of view of configurations in a real space renormalization group approach.

APPENDIX: INFINITE LATTICE COVARIANCE

Here we obtain the spectral decomposition of the infinite lattice covariance operator G which is used to determine the long-range behavior of G^{-1}. G satisfies the recursion relation [see (I.4) and (I.5)], with $x,y\in\mathbb{Z}^d$, u_α, $\overline{u}_\alpha\in[0,L)$, $\alpha=1,\ldots,d$,

$$G(Lx+u,Ly+\overline{u})=L^{-(d-2)}G(x,y)+\delta(x,y).$$

We define the normalized block average operator $C:l_2(\mathbb{Z}^d)\to l_2(\mathbb{Z}^d)$ by

$$(Cf)(x)=L^{-d/2}\sum_{0\leqslant u_\alpha<L} f(Lx+u),$$

with Σ_u meaning the multiple sum over the d components of u. We find, for the adjoint C^*,

$$(C^*g)(Lx+u)=L^{-d/2}g(x),\quad 0\leqslant u_\alpha<L$$

and easily check that $CC^*=I$.

Now let, with $C_0=I$ and $C_n\equiv C^n$, $n\geqslant 1$,

$$\Gamma_n=C_n^*C_n-C_{n+1}^*C_{n+1}. \tag{A1}$$

We verify that

$$\Gamma_n\Gamma_m=\delta_{nm}\Gamma_n,\quad \Gamma_n^*=\Gamma_n$$

$$C_n^*\Gamma_nC_n=\Gamma_{n+1} \tag{A2}$$

$$C_{n+1}\Gamma_n=0. \tag{A3}$$

From (A1), we see that the functions in the range $R(\Gamma_n)$ of Γ_n are constant on the L^n blocks and, from (A3), we see that the average of $f\in R(\Gamma_n)$ over a L^{n+1} block is zero. Furthermore, $\{\Gamma_n\}$ furnishes a resolution of the identity, i.e., $I=\Sigma_{n=0}^{\infty}\Gamma_n$, and will be used in the spectral decomposition of G in $R(\Gamma_0)^{\perp}$ given by

Proposition 2: Let $\lambda_n=L^dL^{2(n-1)}(1-L^{-2n})/(1-L^{-2})$. *Then*

$$G=\sum_{n=0}^{\infty}\lambda_n\Gamma_n \tag{A4}$$

in the subspace $R(\Gamma_0)^{\perp}$. *Each* λ_n *has infinite multiplicity.*

Proof: It is easily shown that

$$G=L^2C^*GC+L^dC^*C. \tag{A5}$$

Write $G=\Sigma_{n=0}^{\infty}\beta_n\Gamma_n$, substitute in (A5) with $L^dC^*C=L^d[-\Gamma_0+\Sigma_{n=0}^{\infty}\Gamma_n]$ and use (A2). Equating coefficients of Γ_n we have

$$\beta_n=L^2\beta_{n-1}+L^d. \tag{A6}$$

Iterating (A6) with $\beta_0=0$ gives

$$\beta_n=L^d\sum_{j=0}^{n-1}L^{2j}=L^dL^{2(n-1)}\frac{1-L^{2n}}{1-L^2},$$

from which (A4) follows. □

From Proposition 2, the hierarchical Laplacian $\Delta_h=G^{-1}$ has a positive point spectrum $\{\lambda_n^{-1}\}$ with zero as the only point of accumulation.

We now determine the long-range behavior of

$$\Delta_h(0,L^ke)=\sum_n\lambda_n^{-1}\Gamma_n(0,L^ke), \tag{A7}$$

where we recall that $\Gamma_n=C_n^*C_n-C_{n+1}^*C_{n+1}$. Let $f(x)=\delta(x,0)$ and $g(y)=\delta(y,L^ke)$. Since $C_nf(x)=L^{-nd/2}\Sigma_{0\leqslant u<L^n}f(L^nx+u)$, $C_nf(x)$ only has support at $x=0$, and thus we only need $C_ng(0)=L^{-nd/2}\chi(k<n)$, where χ is the characteristic function. Substituting in (A7) gives

$$\Delta_h(0,L^ke)=\frac{L^d}{L^2-1}\sum_n(L^{2n}-1)[L^{-nd}\chi(k<n)-L^{-(n+1)d}\chi(k<(n+1))]$$

which, for large k, has a dominant const $L^{-k(d+2)}$ behavior.

The spectral decomposition of G can also be used to calculate directly the matrix elements of $(\Delta_h+\mu I)^{-1}=(G^{-1}+\mu I)^{-1}$, i.e., the two-point function of the hierarchical model with quadratic perturbation.

Note added in proof:

After the submission of this paper, we found that K. Gawedzki and A. Kupiainen [see ''Non-Gaussian scaling limits. Hierarchical model approximation,'' J. Stat. Phys. **35**, 267–284 (1984)] had already proven the main result of our companion work.[2] Neither did their method make use of our basic equations (I.10) and (I.15), nor did they solve the spectral properties of the linearized RGT at $N=\infty$.

(Received 5 May 1997; accepted for publication 6 November 1997)

A dynamic definition of a first-order phase transition is given. It is based on a master equation description of the time evolution of a system. When the operator generating that time evolution has an isolated near degeneracy there is a first-order phase transition. Conversely, when phenomena describable as first-order phase transitions occur in a system, the corresponding operator has near degeneracy. Estimates relating degree of degeneracy and degree of phase separation are given. This approach harks back to early ideas on phase transitions and degeneracy, but now enjoys greater generality because it involves an operator present in a wide variety of systems. Our definition is applicable to what have intuitively been considered phase transitions in nonequilibrium systems and to problematic near equilibrium cases, such as metastability. © *1998 American Institute of Physics.* [S0022-2488(98)01803-9]

I. INTRODUCTION

For systems out of equilibrium, much of the formal structure of thermodynamics and statistical mechanics is inapplicable. Numerous authors have addressed this problem, and our own efforts are found in Refs. 1 and 2. In the present article, we give a general theory of first-order phase transitions that holds in the nonequilibrium context, including systems that do not satisfy detailed balance. Our proposal is a natural offshoot of our approach, although we did find that some of the ''obvious'' assertions were not so easy to prove, even at the level of finite matrices. As could have been anticipated, the concept of analyticity of the partition function is of no use to us: there is in general no partition function. Rather, we focus on eigenvalue degeneracy, advocated by Kac among others. The limitation of this idea has been that many systems are not associated with linear operators. By going to dynamics we are able to use a nearly ubiquitous operator, the generator of the master equation, allowing application to a wide variety of equilibrium and nonequilibrium systems. In equilibrium models, eigenvalue degeneracy of this operator has been studied[3] in conjunction with a corresponding analytic structure. However, in that same article[3] an example of a natural boundary at a first-order phase transition was provided. In our present view, the simplicity of the eigenvalue degeneracy idea compares well with the variety of analytic structures that can occur at first-order transitions, coupled with the fact that even for so basic an example as the two-dimensional Ising model, no one knows what singularity appears at the first-order transition. (What is known about the singularity[4] provides evidence against the possibility of using analyticity in definitions of metastability; we comment further below.) In addition to analyticity there is another common idealization that we avoid, namely the thermodynamic limit. We discuss this below but we mention now that there are physical reasons why this concept should fail out of equilibrium, with metastability again providing a relevant example.

In our approach we assume that the dynamics can be formulated as stochastic dynamics. The system is described by states x,y in a state space X. The dynamics are defined by a transition probability R_{xy}, the probability that the system state is in x at time $t+1$, given that it was in y at time t. This context excludes some situations, but we expect that aside from mathematical niceties the important physical exclusions are systems where quantum interference plays a role and sys-

tems with infinite memory. By conservation of probability, R has an eigenvalue 1 and its associated right eigenvector p_0 is its stationary distribution. For simplicity, we assume that R is irreducible (otherwise split X and work with a reducible R) so that it has a unique stationary distribution. [Of course p_0 may not tell the whole story. Often though, a small modification of the dynamics can restore the focus on the stationary state. An example is above-threshold directed percolation, where the trivial absorbing state can be avoided with a vanishingly small (as size $\to\infty$) escape probability.]

Because of the close relation between our master equation approach and the theory of stochastic processes, our results may be of interest in that area as well. For example, issues related to those we raise here are discussed in Ref. 5.

In this article we establish the following two-way relation. (1) If the eigenvalue 1 of R is nearly degenerate and if other eigenvalues are distant (in a sense to be defined), then R is *nearly* reducible, that is, the support of its stationary state breaks into two pieces with hardly any transitions between them. (2) If two transition matrices, R and R' are close (i.e., $V\equiv R'-R$ is small in a certain sense), but have stationary states with nearly disjoint support, then the eigenvalue 1 for R is nearly degenerate. (This can describe critical points as well as first order transitions.) Furthermore, because the degenerate eigenvalue is a dynamic one, its (near-) degeneracy allows for the possibility of long-term phase coexistence. These results generalize to higher-order state multiplicities and eigenvalue degeneracies. Alternatively one could show the converse of item (1) above, namely, if the stationary measure breaks into pieces with a long transit time between them, then there is eigenvalue degeneracy. Running our proofs backward (in particular, the perturbation arguments of Sec. V) could establish this result, but we have instead chosen to focus on the instability aspect of a phase transition: small changes in external conditions lead to big changes in the system. Note that the notion of phase transition presented here implicitly involves the subtleties of asymptotic analysis. We speak of ''near degeneracy'' and ''near disjointness,'' etc. This is given practical meaning in terms of relations, such as Eq. (3.2) below, that allow the definition of time scales during which the transition is a recognizable physical phenomenon. Such an idea is certainly not new to physics, nor even to phase transitions,[6] but it is not the usual perception of an equilibrium phase transition. In particular this view is at odds with the notion of thermodynamic limit, for many a concept without which one cannot even contemplate a phase transition. However, as emphasized in Ref. 6, the relatively mild manifestation of nonequilibrium behavior in metastability arises precisely because volumes are finite; there are *two* large quantities: volume and droplet nucleation time.

As is implicit above, our *primitive* notion of a first-order phase transition is that there is a big change in the system for a small change in its dynamics. Our results establish a relation of this primitive notion to eigenvalue degeneracy for a dynamical operator that occurs in a wide variety of situations, equilibrium and nonequilibrium. As remarked, the significance of eigenvalue degeneracy was noted early in the study of phase transitions, [7–10] but given the frequent absence of a linear operator the idea was limited. Furthermore, results on analyticity breakdown in the thermodynamic limit made the latter concept appear to be the cleanest mathematical criterion for a phase transition. Notwithstanding the general satisfaction among workers in this field with notions of analyticity, phenomena such as metastability[11–17] never fit well with this picture.[18,6] In some of the referenced works on metastability a dynamical approach was taken and indeed the approach here may be considered an outgrowth of Refs. 3, 19, and 20. Moreover, metastability may be considered the gentlest of nonequilibrium phenomena. For the general nonequilibrium situation one can expect no help from ideas of analyticity, so that a dynamical approach is particularly suitable.

Another fundamental intuition for phase transitions is the coexistence of phases. As mentioned above, since the degenerate eigenvalue is dynamical, and since we show that the instability (''small change⇒big change'') implies degeneracy, we have as a corollary that there can be phase coexistence, not on an infinite time scale, but in the same asymptotic sense that underlies our other work.[21]

In Sec. II, we introduce our notation and general framework. Following that we detail assumptions germane to the problem at hand. In Sec. IV we establish basic identities and inequalities. In Sec. V this information is used to establish properties of individual phases, namely a measure of the degree of stability of each phase. This is continued in the following section, where exit times are calculated. In Sec. VII we use a method of two-time conditioning (similar to Ref.

19). In the next section we take up the converse: if there is a phase transition, does this imply degeneracy. We show (with technical assumptions) that it does. Finally in Sec. IX we deal with more than two phases.

We close with a comment on the issues of mathematical rigor and technical assumptions. We believe some of our assumptions are too restrictive and our results have greater generality. For example, Eq. (3.10) below probably assumes more than is needed.[22] But we also believe that for some systems and for certain limits the notions we propose really do break down, for physical reasons. Thus there are systems that are first-order phase transitions under our definition and in the physical sense as well (e.g., metastability) that lose definition in both senses for sufficiently large volume. We also mention that we sometimes do not provide full rigorous proofs, mainly because we did not consider it important at this stage, physically or mathematically, to define the additional hypotheses necessary for such proofs. An example is at the end of Sec. V. Finally, here and in our previous work[1,2] we have not addressed limitations due to assuming a finite, discrete state space and a discrete time. Although we do expect the basic idea to hold, for example, the Fokker–Planck equation for motion in a double well with a high barrier will show degeneracy, we also expect that the level of mathematical agony will increase considerably. And there may be cases where it really will make a difference.

II. NOTATION

Let R be a stochastic matrix on a space X. We assume it has only one eigenvalue of unit norm (to be called λ_0) and order the eigenvalues by decreasing modulus. For simplicity we assume that λ_1 is real. Thus the eigenvalues satisfy $\lambda_0 \equiv 1 > \lambda_1 \geqslant |\lambda_2| \geqslant \cdots$. The corresponding right and left eigenvectors are, respectively, p_k and A_k $(k=0,1,...)$, and satisfy

$$Rp_k = \lambda_k p_k, \quad A_k R = \lambda_k A_k.$$

We normalize

$$\langle A_k | p_l \rangle = \delta_{kl}, \tag{2.1}$$

p_0 is naturally normalized by

$$\sum p_0(x) = 1,$$

which fixes $A_0(x)=1$ for all x. (Thus $A_0 = \chi_X$, the characteristic function.) In the following we assume

$$p_0(x) > 0 \quad \text{for all } x \in X. \tag{2.2}$$

This corresponds to irreducibility and ergodicity assumptions on R. We normalize the left eigenstates by

$$\sup_{x \in X} |A_k(x)| = 1 \quad \text{for all } k. \tag{2.3}$$

For $t>0$ an integer, we denote by R^t the tth power of R; its eigenvalues satisfy $\lambda_0^t = 1 > \lambda_1^t \geqslant |\lambda_2^t| \geqslant \cdots$. We define two norms.

(1°) On left vectors, A,

$$\|A\|_L = \sup_{x \in X} |A(x)|.$$

(2°) On right vectors, q,

$$\|q\|_R = \sum_{x \in X} |q(x)|.$$

Accordingly, we define two norms on matrices, B,

$$\|B\|_R = \sup_{\|q\|_R \leqslant 1} \|Bq\|_R ,$$
$$\|B\|_L = \sup_{\|A\|_L \leqslant 1} \|AB\|_L , \tag{2.4}$$

III. ASSUMPTIONS CONCERNING NEAR DEGENERACY (2 PHASES)

We assume

$$1-\lambda_1 \ll 1-|\lambda_2| \tag{3.1}$$

and consider an intermediate time t such that

$$1-\lambda_1^t \sim \epsilon_1 ,$$
$$\lambda_2^t \quad \text{is small} \quad [\text{as specified in Eq. (3.10)}]. \tag{3.2}$$

We write

$$R^t = |p_0\rangle\langle A_0| + \lambda_1^t |p_1\rangle\langle A_1| + |\lambda_2^t| B^t, \tag{3.3}$$

where B^t is the remainder matrix

$$B^t = \sum_{k \geqslant 2} \frac{\lambda_k^t}{|\lambda_2^t|} |p_k\rangle\langle A_k|. \tag{3.4}$$

Although R need not be diagonalizable, the representation (3.3) is guaranteed by the nondegeneracy of λ_0 and λ_1. (Although for eigenvalues smaller than λ_1 a Jordan form may be needed, this would not affect our arguments below, since all we use is the orthogonality of the subspaces associated with those eigenvalues.) Because $\Sigma_x A_1(x) p_0(x) = 0$ and $p_0 > 0$, we deduce that

$$A_M \equiv \max_{x \in X} A_1(x) > 0 > A_m \equiv \min_{x \in X} A_1(x) \tag{3.5}$$

and we define accordingly the two states, which will correspond to the two phases of the system,

$$p_M^t(x) = p_0(x) + \lambda_1^t p_1(x) A_M + |\lambda_2^t| B_{xM}^t ,$$
$$p_m^t(x) = p_0(x) + \lambda_1^t p_1(x) A_m + |\lambda_2^t| B_{xm}^t . \tag{3.6}$$

Here B_{xM}^t (respectively B_{xm}^t) is the value of B_{xy}^t for some point $y(\equiv y_M)$ (respectively, y_m) such that $A_1(y) = A_M$ (respectively, A_m). From (3.6) we have

$$p_0(x) = \frac{A_M p_m^t(x) - A_m p_M^t(x)}{A_M - A_m} + |\lambda_2^t| \frac{A_m B_{xM}^t - A_M B_{xm}^t}{A_M - A_m},$$
$$p_1(x) = \frac{p_M^t(x) - p_m^t(x)}{\lambda_1^t (A_M - A_m)} + \frac{|\lambda_2^t|}{\lambda_1^t} \frac{B_{xm}^t - B_{xM}^t}{A_M - A_m}. \tag{3.7}$$

More generally, for any y we can define

$$p_y^t(x) = p_0(x) + \lambda_1^t p_1(x) A_1(y) + |\lambda_2^t| B_{xy}^t \equiv R_{xy}^t \tag{3.8}$$

so that, from Eqs. (3.7) and (3.8), we have

$$p_y^t(x) = C_M(y) p_M^t(x) + C_m(y) p_m^t(y) + q_{xy}^t \tag{3.9}$$

with

$$C_M(y)=\frac{\lambda_1^t A_1(y)-A_m}{A_M-A_m},\quad C_m(y)=\frac{A_M-\lambda_1^t A_m}{A_M-A_m},$$

and $q_{xy}=|\lambda_2^t|\times$ (combination of $B_{xM}^t, B_{xm}^t, B_{xy}^t$). Note that $C_M(y)$ and $C_m(y)$ are positive.

Our principal hypothesis is the following. We assume that B^t satisfies

$$|\lambda_2^t|\left|\sum_{y\in Y} B_{yx}^t\right|\leqslant \epsilon_2 \tag{3.10}$$

uniformly for any subset $Y\subset X$ and any point $x\in X$. In terms of the norms (2.4), this means that

$$|\lambda_2^t|\|B^t\|_R\leqslant \epsilon_2 .$$

For many interesting physical applications this assumption will not hold, although we expect our two-phase construction to be valid for systems more general than those obeying Eq. (3.10). Thus we consider the hypothesis to be needed for technical reasons.

IV. BASIC IDENTITIES AND INEQUALITIES

We take the scalar product of p_M^t and p_m^t with A_1. We have

$$\sum_x A_1(x)B_{xy}^t=0.$$

This follows from[23]

$$B^t=\sum_{k\geqslant 2}\frac{\lambda_k^t}{|\lambda_2^t|}|p_k\rangle\langle A_k|$$

and therefore

$$\sum_x A_1(x)p_M^t(x)=\lambda_1^t A_M,\quad \sum_x A_1(x)p_m^t(x)=\lambda_1^t A_m . \tag{4.1}$$

From (4.1) and the fact that $\Sigma p_M^t(x)=\Sigma p_m^t(x)=1$ we deduce the basic identity

$$1-\lambda_1^t=\sum_x p_M^t(x)\left(1-\frac{A_1(x)}{A_M}\right)=\sum_x p_m^t(x)\left(1-\frac{A_1(x)}{A_m}\right). \tag{4.2}$$

The foregoing identity is a fundamental statement about the structure of the two phases. It does not depend on the hypothesis of Eq. (3.10).

Let us now fix $a>0$ and consider the two subsets

$$\begin{aligned} I_M(a)&=\left\{x\in X\;\middle|\;\frac{A_M-A_1(x)}{A_M}<a\right\},\\ I_m(a)&=\left\{x\in X\;\middle|\;\frac{A_m-A_1(x)}{A_m}<a\right\}. \end{aligned} \tag{4.3}$$

These subsets will in fact turn out to be the two phases. We also define $E_M(a)\equiv\mathscr{C}I_M(a)$, $E_m(a)\equiv\mathscr{C}I_m(a)$ (where $\mathscr{C}$ indicates the complement of a set). We take $a<1$ and note that

$$a<1\Rightarrow I_M(a) \text{ and } I_m(a) \text{ disjoint.}$$

From the definition (4.3) of $I_M(a), E_M(a)$, and the identity (4.2), we deduce

$$\sum_{x\in I_M(a)} p_M^t(x) > 1-\frac{1-\lambda_1^t}{a},$$
$$\sum_{x\in E_M(a)} p_M^t(x) < \frac{1-\lambda_1^t}{a}, \tag{4.4}$$

with analogous inequalities for M replaced by m.

We next estimate the total weight of $I_M(a)\cup I_m(a)$ for p_0. From Eq. (3.7)

$$\sum_{x\in \mathcal{C}(I_M\cup I_m)} p_0(x) = \sum_{x\in E_M\cap E_m} p_0(x) \leqslant \frac{1}{A_M-A_m}\left[A_M\sum_{x\in E_m} p_m^t(x) - A_m\sum_{x\in E_M} p_M^t(x)\right]$$
$$+\frac{|\lambda_2^t|}{A_M-A_m}\sum_{x\in E_M\cap E_m}(A_mB_{xM}-A_MB_{xM}),$$

where $A_M>0$ and $A_m<0$ have been used. Thus from Eq. (4.4)

$$\sum_{x\in \mathcal{C}(I_M\cup I_m)} p_0(x) \leqslant \frac{1-\lambda_1^t}{a}+\frac{|\lambda_2^t|}{A_M-A_m}\sum_{x\in E_M\cap E_m}(A_mB_{xM}-A_MB_{xm}). \tag{4.5}$$

Now it may happen that in addition to the conditions we have already placed on ϵ_1 and ϵ_2, they further satisfy $\epsilon_2 \ll \epsilon_1$. In that case it follows from the basic hypothesis (3.10) that up to terms much less than ϵ_1

$$\sum_{x\in \mathcal{C}(I_M\cup I_m)} p_0(x) \leqslant \frac{(1-\lambda_1^t)}{a}, \tag{4.6}$$

which means that almost all the weight of the stationary state is on the union of the two phase regions. Note that for Eq. (4.6) to hold the quantity ''a'' used in it must be slightly smaller $[\mathrm{O}(\epsilon_2)]$ than the quantity by the same name in Eq. (4.5). In other words, we have eliminated the last term in Eq. (4.5), using the hypotheses of Eq. (3.2). On the other hand, if $\epsilon_2 \sim \epsilon_1$ or $\epsilon_2 > \epsilon_1$, then the bound on the sum in Eq. (4.6) may depend on both ϵ_1 and ϵ_2, and may also involve slight changes in ''a''.

A. p_M^t and p_m^t as approximate eigenstates of R

By definition

$$Rp_M^t = p_M^{t+1} = p_M^t + (p_M^{t+1}-p_M^t).$$

Now

$$p_M^{t+1}(x)-p_M^t(x) = (\lambda_1-1)\lambda_1^t p_1(x)A_M + \lambda_2^{t+1}B_{xM}^{t+1} - \lambda_2^t B_{xm}^t.$$

It follows that in the R-norm

$$\|p_M^{t+1}(x)-p_M^t(x)\| = \sum_x |(\lambda_1-1)\lambda_1^t p_1(x)A_M + \lambda_2^{t+1}B_{xM}^{t+1} - \lambda_2^t B_{xm}^t| \leqslant c(1-\lambda_1).$$

Thus $Rp_M^t = p_M^t + \mathrm{O}(1-\lambda_1)$. In fact, for any integer s of the same general size as t we also have

$$R^s p_M^t = p_M^t + \mathrm{O}(1-\lambda_1^s), \tag{4.7}$$

so that p_M^t is substantially unchanged by the action of R^s (for s of order t).

B. Estimation of p_1

We have seen that

$$p_1(x)=\frac{p_M^t(x)-p_m^t(x)}{\lambda_1^t(A_M-A_m)}+r(x), \tag{4.8}$$

where $r(x)=\lambda_2^t\times$ (linear combination of $B_{xM}^t, B_{x,m}^t$). From the basic identity (4.2), we deduce

$$\begin{aligned}\sum_{x\in I_M} p_1(x)&\geqslant \frac{1}{a\lambda_1^t(A_M-A_m)}+\epsilon,\\ \sum_{x\in I_m} p_1(x)&\leqslant \frac{-1}{a\lambda_1^t(A_M-A_m)}+\epsilon',\end{aligned} \tag{4.9}$$

where ϵ, ϵ' are $O(1-\lambda_1^t)$.

V. ALMOST DEGENERATE PERTURBATION THEORY

The phases I_M and I_m are disjoint, and their union, $I_m\cup I_M$, fills almost all X, as measured by p_0. We can define a new stochastic process that is the same as the original one within $I_m\cup I_M$, but which is killed if it steps outside this union. In other words, we consider the substochastic matrix $\widetilde{R}$ defined by

$$\widetilde{R}_{xy}=\begin{cases}R_{xy} & \text{if both } x \text{ and } y \text{ are in } I_M \text{ or both } x \text{ and } y \text{ are in } I_m\\ 0 & \text{otherwise}\end{cases}. \tag{5.1}$$

Because of the disjointness, $\widetilde{R}$ is reducible and will have two distinct non-negative eigenvectors. Each of these will be associated with the positive eigenvalue of the largest norm for vectors having support on the corresponding subspace. Thus we will have two distinct solutions to

$$\widetilde{R}\widetilde{p}=\widetilde{\lambda}_0\widetilde{p}_0 \tag{5.2}$$

with (possibly) different $\widetilde{\lambda}_0$s. Clearly,

$$\widetilde{p}_0(x)=0 \quad \text{for} \quad x\notin I_M\cup I_m.$$

We seek solutions to Eq. (5.2) by perturbing around the largest eigenvalue of R. We write

$$\widetilde{R}_{xy}=R_{xy}-T_{xy}, \tag{5.3}$$

so that

$$T_{xy}=\begin{cases}0 & \text{if both } x \text{ and } y \text{ are in } I_M \text{ or both } x \text{ and } y \text{ are in } I_m\\ R_{xy} & \text{otherwise}\end{cases}.$$

We use degenerate perturbation theory to solve (5.2), treating T as a perturbation. Namely, we write

$$\widetilde{\lambda}_0=1-\mu_1, \quad \widetilde{p}=p_0+\alpha_1 p_1+q,$$

where $q=\Sigma_{k\geqslant 2}\ \alpha_k p_k$. We formally consider μ_1, q, and T to be small. Equation (5.2) becomes

$$(R-T)(p_0+\alpha_1 p_1+q)=(1-\mu_1)(p_0+\alpha_1 p_1+q).$$

After rearrangement this gives the exact equation

$$(R-I)q=(T-\mu_1)p_0+\alpha_1(1-\lambda_1)p_1+\alpha_1(T-\mu_1)p_1+(T-\mu_1)q. \tag{5.4}$$

Our hypothesis (which must be checked later) is that $(T-\mu_1)_q$ is of second order, leading to the approximate equation

$$(R-I)q=(T-\mu_1)p_0+\alpha_1(1-\lambda_1)p_1+\alpha_1(T-\mu_1)p_1. \tag{5.5}$$

We want to solve Eq. (5.5) with $q=\Sigma_{k\geqslant 2}\ \alpha_k p_k$ so that the second member must be orthogonal to A_0 and A_1. Taking the scalar product of the second member of Eq. (5.5) with A_0 and A_1 gives

$$\langle A_0|Tp_0\rangle+\alpha_1\langle A_0|Tp_1\rangle=\mu_1, \tag{5.6}$$

$$\langle A_1|Tp_0\rangle+\alpha_1(1-\lambda_1)+\alpha_1\langle A_1|Tp_1\rangle-\alpha_1\mu_1=0. \tag{5.7}$$

Eliminating μ_1 between (5.6) and (5.7) yields an equation for α_1

$$-\alpha_1^2\langle A_0|Tp_1\rangle+\alpha_1[-\langle A_0|Tp_0\rangle+\langle A_1|Tp_1\rangle+1-\lambda_1]+\langle A_1|Tp_0\rangle=0. \tag{5.8}$$

Call $Q(\alpha_1)$ the trinomial on the left. It can be rewritten as

$$Q(\alpha_1)\equiv-\langle\alpha_1A_0-A_1|T(p_0+\alpha_1p_1)\rangle+\alpha_1(1-\lambda_1).$$

But

$$\alpha_1(1-\lambda_1)=\alpha_1\langle A_0|Rp_0\rangle-\alpha_1\langle A_1|Rp_1\rangle=\langle\alpha_1A_0-A_1|R(p_0+\alpha_1p_1)\rangle,$$

so that finally

$$Q(\alpha_1)=-\langle\alpha_1A_0-A_1|\widetilde{R}(p_0+\alpha_1p_1)\rangle. \tag{5.9}$$

A. Calculation of α_1

We use Eq. (3.7) so that

$$p_0(x)+\alpha_1p_1(x)=\frac{\alpha_1-\lambda_1^tA_m}{\lambda_1^t(A_M-A_m)}\,p_M^t(x)+\frac{\lambda_1^tA_M-\alpha_1}{\lambda_1^t(A_M-A_m)}\,p_m^t(x)+r(x),$$

where $r(x)=\lambda_2^t\times$ (combination of $B_{x,m},B_{x,M},\alpha_1$).

B. Solution of Eq. (5.9), $Q(\alpha_1)=0$

We first analyze the coefficients of the trinomial in Eq. (5.8) and prove that each coefficient is $O(1-\lambda_1^t)$. In the matrix elements of T, we have the sum only on x, y such that $T_{xy}\neq 0$, that is, x and y are not in the same phase. The sum therefore takes pairs from three disjoint subsets:

$$(x\in I_M,y\notin I_M),\quad (x\in I_m,y\notin I_m),\quad (x\notin I_M\cup I_m,y\in X).$$

Thus we examine in turn $\langle A_0|Tp_0\rangle$ [Eq. (5.10)], $\langle A_0|Tp_1\rangle$ [Eqs. (5.11) and (5.12)], and $\langle A_1|Tp_1\rangle$ [Eq. (5.13)].

$$\langle A_0|Tp_0\rangle=\sum_{x\in I_M}\left(\sum_{y\notin I_M}R_{xy}p_0(y)\right)+\sum_{x\in I_m}\left(\sum_{y\notin I_m}R_{xy}p_0(y)\right)+\sum_{x\notin I_M\cup I_m}\sum_{y\in X}R_{xy}p_0(y)$$

$$\leqslant\sum_{y\notin I_M}p_0(y)+\sum_{y\notin I_m}p_0(y)+\sum_{x\notin I_M\cup I_m}p_0(x)=O(1-\lambda_1^t), \tag{5.10}$$

$$\langle A_0|Tp_1\rangle=\sum_{x\notin I_M}\sum_{y\in I_M}R_{xy}p_1(y)+\sum_{x\notin I_m}\sum_{y\in I_m}R_{xy}p_1(y)+\sum_{x\in X}\sum_{y\notin I_M\cup I_m}R_{xy}p_1(y). \tag{5.11}$$

We replace $p_1(y)=(p_M^t(y)-p_m^t(y))/(A_M-A_m)$,

$$\sum_{x\notin I_M}\sum_{y\in I_M} R_{xy}p_m^t(y)\leqslant\sum_x\sum_{y\in I_M} R_{xy}p_m^t(y)=\sum_{y\in I_M} p_m^t(y)=\mathrm{O}(1-\lambda_1^t),$$

$$\sum_{x\notin I_M}\sum_{y\in I_M} R_{xy}p_M^t(y)\leqslant\sum_{x\notin I_M}\sum_y R_{xy}p_M^t(y)=\sum_{x\notin I_M} p_M^{t+1}(y)=\mathrm{O}(1-\lambda_1^t),$$

$$\left|\sum_{x\in X}\sum_{y\notin I_M\cup I_m} R_{xy}p_1(y)\right|\leqslant\sum_{y\notin I_M\cup I_m}|p_1(y)|=\mathrm{O}(1-\lambda_1^t)$$

so

$$\langle A_0|Tp_1\rangle=\mathrm{O}(1-\lambda_1^t). \tag{5.12}$$

Finally we examine the case $\Sigma_{x,y}A_1(x)T_{xy}p_1(y)$,

$$\left|\sum_{x,y} A_1(x)T_{xy}p_1(y)\right|\leqslant\max|A_1|\sum_{x,y} T_{xy}|p_1(y)|\leqslant\frac{\max|A_1|}{A_M-A_m}\sum_{x,y} T_{xy}(p_M^t(y)+p_m^t(y))+\mathrm{O}(1-\lambda_1^t), \tag{5.13}$$

where we have used the fact that

$$p_1=\frac{p_M^t-p_m^t}{\lambda_1^t(A_M-A_m)}+\cdots .$$

The same kind of reasoning as above for the estimate of $\langle A_0|Tp_1\rangle$ proves that

$$\sum_{x,y} T_{xy}(p_M^t(y)+p_m^t(y))=\mathrm{O}(1-\lambda_1^t)$$

and so

$$\langle A_1|Tp_1\rangle,\langle A_1|Tp_0\rangle=\mathrm{O}(1-\lambda_1^t). \tag{5.14}$$

As a consequence, all the coefficients of the trinomial $Q(\alpha_1)$ in Eq. (4.8) are $\mathrm{O}(1-\lambda_1^t)$ and one can solve $Q(\alpha_1)=0$ with two roots α_1',α_1'' which are order unity.

C. Calculation of μ_1

Equation (5.6) gives two possible values, μ_1' and μ_1'', one for each root α_1' and α_1''. Because of Eqs. (5.10)–(5.13) and (5.6) one obtains

$$\mu_1',\mu_1''=\mathrm{O}(1-\lambda_1^t). \tag{5.15}$$

D. Calculation of q

The equation for q is given by

$$Rq-q=V+(T-\mu_1)q, \tag{5.16}$$

[see Eq. (5.4)] where V is given by

$$V=(T-\mu_1)p_0+\alpha_1(1-\lambda_1)p_1+\alpha_1(T-\mu_1)p_1. \tag{5.17}$$

We approximate Eq. (5.16) by

$$Rq-q=V. \tag{5.18}$$

The conditions (5.6) and (5.7), which fix α_1 and μ_1, imply $\langle A_0|V\rangle=0$ and $\langle A_1|V\rangle=0$. Thus

$$V=\sum_{k\geqslant 2} v_k p_k, \quad v_k=\langle A_k|V\rangle$$

and

$$q=\sum_{k\geqslant 2} \frac{v_k}{\lambda_k-1}\, p_k.$$

On the other hand, it is easy to see that

$$|v_k|=|\langle A_k|V\rangle|\leqslant C(1-\lambda_t^1), \tag{5.19}$$

where C does not depend on k (for the normalization, $\max|A_k|=1$). The proof of (5.19) is exactly the same as the proof of Eqs. (5.10)–(5.13), because for $k\geqslant 2$ $\langle A_k|V\rangle=\langle A_k|Tp_0\rangle+\alpha_1\langle A_k|Tp_1\rangle$. One then uses the estimate for Tp_0, Tp_1, as before in the case $k=1$ above.

Remark: We have proved that $q=O(1-\lambda_1^t)$. To have a rigorous perturbation theory one would like to prove that $(T-\mu_1)q\ll O(1-\lambda_1^t)$. We do have control over $\mu_1 q$, since we know it to be $O((1-\lambda_1^t)^2)$. However, we do not have rigorous bounds for Tq.

Conclusion: We have obtained for $\tilde{R}$ two stationary states with eigenvalues $1-\mu_1'$ and $1-\mu_1''$, with μ_1' and $\mu_1''=O(1-\lambda_1^t)$. These have corresponding eigenstates $p_0+\alpha_1' p_1$ and $p_0+\alpha_1'' p_1$, where α_1', α_1'' are $O(1)$.

Remark: We expect the eigenstates of largest eigenvalue to look substantially like p_M and p_m and the corresponding left eigenvectors to look like the characteristic functions of I_M and I_m, except near the boundary.[24]

VI. EXIT TIME FROM ONE OF THE PHASE REGIONS

Let $T_M(x)$ be the average of the first exit time, starting from $x\in I_M$, of the phase region I_M

$$T_M(x)=E\{\inf\{t|X_t\notin I_M\}|X_0=x\},$$

where E is the expectation for the R process. It is easy to see that

$$T_M(x)=\begin{cases} 1+\sum_{y\in X} T_M(y)R_{yx} & \text{for } x\in I_M \\ 0 & \text{for } x\notin I_M \end{cases}. \tag{6.1}$$

The first line is derived by considering a single time step. The advantage of looking at the quantity $T_M(x)$ is that it is fairly constant inside I_M, except near the boundary of I_M, where it drops quickly to zero. One can also define a function $T_m(x)$ relative to the other phase I_m. One can then expand T_M, on the left eigenstates $\tilde{A}_{M,k}$ (eigenvalue $\tilde{\lambda}_{M,k}$) of $\tilde{R}$ relative to the phase I_M

$$T_M=\sum_{k\geqslant 0} \theta_{M,k}\tilde{A}_{M,k}, \tag{6.2}$$

where $\theta_{M,k}=\langle T_M|\tilde{p}_{M,k}\rangle$ and $\tilde{p}_{M,k}$ is the right eigenstate of $\tilde{R}$ relative to the phase I_M. In particular $\theta_{M,0}=\langle T_M|\tilde{p}_{M,0}\rangle>0$.

From Eq. (6.1), we see that

$$\theta_{M,0}\sim \frac{C}{1-\tilde{\lambda}_{M,0}}. \tag{6.3}$$

On the other hand, we have seen in Sec. IV, that

$$\tilde{\lambda}_{M,0}\sim 1-O(1-\lambda_1^t). \tag{6.4}$$

This means that

$$T_M \sim \mathrm{O}\left(\frac{1}{1-\lambda_1^t}\right). \tag{6.5}$$

Remark: Note that this is not a uniform estimate. T_M is in fact a function of $x \in X$ and for x near the boundary[24] we expect the otherwise almost constant $\tilde{A}(x)$ to vary, in particular to be small.

VII. DOUBLE CONDITIONING

In a previous publication[19] we found that a metastable phase could become fully well-defined by a method using two-time conditioning. In this method, the dynamical persistence of the metastable state, its characteristic feature, was the essential property that was used to define the concept of metastability. (This contrasts to analyticity oriented approaches to this problem). Inasmuch as our fundamental method in the present work (which follows Refs. 1 and 2) is dynamical, it is reasonable to expect the two-time conditioning approach to be applicable to the definition of phases of our R-degenerate system. We now show this to be the case.

For $x \in I_M$ define

$$\begin{aligned}\Theta_M(x,T) &= \mathrm{Prob}(X_T = x | [X_t \in I_M \text{ for all } 0 \leqslant t \leqslant 2T] \text{ and } [X_0 = M]) \\ &= \frac{\mathrm{Prob}(X_T = x,\ X_t \in I_M \text{ for all } 0 \leqslant t \leqslant 2T | X_0 = M)}{\mathrm{Prob}(X_t \in I_M \text{ for all } 0 \leqslant t \leqslant 2T | X_0 = M)}.\end{aligned} \tag{7.1}$$

The numerator is

$$\begin{aligned}&\mathrm{Prob}(X_T = x \text{ and } X_t \in I_M \forall t \leqslant T | X_0 = M) \\ &\quad \times \sum_{y \in I_M} \mathrm{Prob}(X_{2T} = y,\ X_t \in I_M \text{ for } T < t \leqslant 2T | X_T = x),\end{aligned}$$

so that

$$\Theta(x,T) = \frac{\tilde{R}^T_{xM} \Sigma_y \tilde{R}^T_{yx}}{\Sigma_z \tilde{R}^{2T}_{zM}}. \tag{7.2}$$

But for points in the M phase, we can expand

$$\tilde{R}_{xy} = \tilde{\lambda}_{M,0}\, \tilde{p}_{M,0}(x)\tilde{A}_{M,0}(y) + \cdots + \tilde{\lambda}_{M,k}\, \tilde{p}_{M,k}(x)\tilde{A}_{M,k}(y) + \cdots .$$

For $T \to \infty$, we expect that

$$\Theta(x,T) \sim \tilde{p}_{M,0}(x)\tilde{A}_{M,0}(x). \tag{7.3}$$

In particular, since $\Sigma \tilde{p}_{M,0}(x)\tilde{A}_{M,0}(x) = 1$, $\theta(x,T)$ is normalized.

Although we do not supply a rigorous proof of Eq. (7.3) we expect it to be true because the largest ''λ''s (excluding the single one for each phase near unity) will correspond to the relaxation times within the phases, namely, what we have been calling λ_2, and eigenvalues of yet smaller norm. As usual, in appropriate (or perhaps, inappropriate) departures from the intended physical situation (as in the thermodynamic limit described in Ref. 6) unphysical modes may be introduced by mathematical idealizations.

VIII. CONVERSE: PHASE TRANSITION IMPLIES DEGENERACY

We have shown that when a stochastic matrix is nearly degenerate (and satisfies certain other conditions) it will, to a good approximation, describe a system with two distinct stationary states. These stationary states are in many ways like the phases on either side of a first-order phase transition, but (unlike analyticity-based descriptions of phase transitions) have a natural place for the metastable phase. In the present section we deal with the converse: Suppose there is what one

might call, literally and by analogy, a phase transition. This would occur for two stochastic matrices that differ only slightly but whose respective invariant states are very different. What we show next is that this implies that for both these stochastic matrices the largest eigenvalue is nearly degenerate. This form of converse is not specific to first order phase transitions, and may apply to certain parameter variations about critical points. [Note that we only show near degeneracy of the largest eigenvalues, not that successive eigenvalues are distant in the sense of Eq. (3.1).]

Two stochastic matrices, R and R', are given, with

$$R' = R + V \tag{8.1}$$

so that $\Sigma_x V_{xy} = 0$. We denote by p_0 and p_0' the stationary states of R and R', and assume that both $p_0 > 0$ and $p_0' > 0$ everywhere. By the irreducibility of both R and R' we still have $A_0 = \chi_X = A_0'$. We denote by $(|)_{p_0}$ the scalar product

$$(w|v)_{p_0} = \sum_x p_0(x) w(x) v(x) \tag{8.2}$$

and by $(|)_{p_0'}$ the scalar product with respect to p_0'.

A. Hypotheses

(1) We assume that there exist disjoint subsets S and S' of X such that

$$\sum_{x \in S} p_0(x) = 1 - \mu, \quad \sum_{x \in S'} p_0'(x) = 1 - \mu' \tag{8.3}$$

and $S \cup S' = X$. It follows that

$$\sum_{x \in S} p_0'(x) = \mu', \quad \sum_{x \in S'} p_0(x) = \mu,$$

where μ and μ' are small.

(2) To say that a quantity (vector, operator) is small means that the norms, $\| \|_{p_0}$ and $\| \|_{p_0'}$, should be small. We assume that

$$\|V\|_{p_0}, \|V\|_{p_0'} \leqslant \delta, \tag{8.4}$$

where $\|V\|_{p_0}$ is the norm of the V matrix for the scalar product defined by p_0.

We want to prove that under these hypotheses R and R' have a near degeneracy in the sense that the eigenvalue of first excited state of R (respectively R') is λ_1 (respectively λ_1') with

$$1 - \lambda_1, 1 - \lambda_1' = \mathrm{O}(\mu, \mu', \delta).$$

We shall prove this for R'. We have to show that there exists a left vector $\hat{A}'$ such that

$$\hat{A}' \text{ is } \mathrm{O}(1) \text{ in the norm } \|\|_{p_0}, \tag{8.5}$$

$$\langle \hat{A}' | p_0' \rangle = 0, \tag{8.6}$$

and

$$\|\hat{A}'(1 - R')\|_{p_0}, \|\hat{A}'(1 - R')\|_{p_0'} = \mathrm{O}(\mu, \mu', \delta). \tag{8.7}$$

Before establishing the relations (8.5)–(8.7), we show that they in turn imply that R' has an eigenvalue (besides unity) whose difference from 1 is $\mathrm{O}(\mu, \mu', \delta)$.

More generally, let us assume that in a vector space E there are two vectors $x, y \in E$ and a matrix M such that

$$(M-I)x=y,$$

$$(M-I) \quad \text{is invertible,}$$

$$\|x\|=\mathrm{O}(1), \quad \|y\|=\mathrm{O}(\epsilon).$$

Then $x=(M-I)^{-1}y$ and it follows that the norm of $(M-I)^{-1}$ is of order $1/\epsilon$. By taking a Jordan expansion of M, we see that M has an eigenvalue within ϵ of 1.

In our situation, we choose for the vector space E the space of vectors A such that $\langle A|p_0\rangle=0$ and $M={}^t(R')$ (thereby satisfying the second condition above on E, using also the irreducibility of R). We take for ''x'' and ''y'' the vectors A and $(M-I)A$, respectively. Note too with respect to our upcoming application that it is sufficient to establish these conditions with respect to any particular norm, and for this purpose we have in mind the p_0 norm.

We now turn to establishing the conditions (8.5)–(8.7). Choose

$$\hat{A}'=\mu'\chi_{S'}-(1-\mu')\chi_S \tag{8.8}$$

so that Eq. (8.6) is satisfied and condition (8.5) is satisfied [for example, $\|\hat{A}\|_{p_0}=\mathrm{O}(1)$]. Now

$$-\hat{A}'(1-R')=-\mu'(\chi_{S'}-\chi_{S'}R')+(1-\mu')(\chi_S-\chi_SR)-(1-\mu')\chi_SV. \tag{8.9}$$

We also notice that $\chi_S+\chi_S{}'\equiv\chi_X\equiv A_0$ so that

$$\chi_S(1-R)=-\chi_{S'}(I-R). \tag{8.10}$$

B. Proof that $\|\chi_S-\chi_SR\|_{p_0}^2=\mathrm{O}(\mu)$

Using Eq. (8.10) we obtain

$$\langle\chi_S-\chi_SR|\chi_S-\chi_SR\rangle_{p_0}=-\langle\chi_{S'}(I-R)|\chi_S\rangle_{p_0}+\langle\chi_{S'}(I-R)|\chi_SR\rangle_{p_0}. \tag{8.11}$$

(1°) $\langle\chi_{S'}(I-R)|\chi_S\rangle_{p_0}=\mathrm{O}(\mu)$.

This is

$$\sum_{\substack{y\in S'\\ x\in S}}(\delta_{yx}-R_{yx})p_0(x)=-\sum_{\substack{y\in S'\\ x\in S}}R_{yx}p_0(x).$$

But

$$\sum_{\substack{y\in S'\\ x\in S}}R_{yx}p_0(x)\leqslant\sum_{\substack{y\in S'\\ x\in X}}R_{yx}p_0(x)=\sum_{y\in S'}p_0(y)=\mathrm{O}(\mu).$$

(2°) $\langle\chi_{S'}(I-R)|\chi_SR\rangle_{p_0}=\mathrm{O}(\mu)$.

This is

$$\sum_{y,z}p_0(y)\chi_S(z)R_{zy}\left(\chi_{S'}(y)-\sum_x\chi_{S'}(x)R_{xy}\right).$$

Now

$$\sum_{y,z}p_0(y)\chi_S(z)R_{zy}\chi_{S'}(y)\leqslant\sum_{z,y}R_{zy}\chi_{S'}(y)p_0(y)=\sum_{y\in S'}p_0(y)=\mathrm{O}(\mu),$$

$$\sum_{y,z,x}p_0(y)\chi_S(z)R_{zy}\chi_{S'}(x)R_{xy}\leqslant\sum p_0(y)R_{zy}\chi_{S'}(x)R_{xy}$$

$$=\sum p_0(y)\chi_{S'}(x)R_{xy}=\sum\chi_{S'}(x)p_0(x)=\mathrm{O}(\mu).$$

From (8.11) we deduce

$$\|\chi_S - \chi_S R\|_{p_0}^2 = O(\mu). \tag{8.12}$$

In the same way, we would obtain

$$\|\chi_{S'} - \chi_{S'} R'\|_{p_0'}^2 = O(\mu'). \tag{8.13}$$

C. Proof that $\|\chi_S - \chi_S R\|_{p_0'}^2 = O(\mu', \delta)$.

We use Eq. (8.10)

$$\|\chi_S - \chi_S R\|_{p_0'} = \|\chi_{S'} - \chi_{S'} R\|_{p_0'}.$$

Then we use $R' = R + V$.

$$\langle \chi_{S'} - \chi_{S'} R | \chi_{S'} - \chi_{S'} R \rangle_{p_0'} = \|\chi_{S'} - \chi_{S'} R'\|_{p_0'}^2 - 2\langle \chi_{S'} V | \chi_{S'}(I - R') \rangle_{p_0'} + \|\chi_{S'} V\|_{p_0'}^2.$$

Now our hypothesis on V says that

$$\|\chi_{S'} V\|_{p_0'}^2 \leqslant \|V\|_{p_0'}^2 \|\chi_{S'}\|_{p_0'}^2 = O(\delta^2). \tag{8.14}$$

Then

$$|\langle \chi_{S'} V | \chi_{S'}(I - R') \rangle_{p_0'}| \leqslant \|\chi_{S'} V\|_{p_0'} \|\chi_{S'}(I - R')\|_{p_0'} \leqslant C\delta\sqrt{\mu'}. \tag{8.15}$$

[We used Eqs. (8.13) and (8.14).] So from Eqs. (8.13), (8.15), and (8.14), we deduce

$$\|\chi_S - \chi_S R\|_{p_0'} = O(\mu', \delta). \tag{8.16}$$

D. Analysis of $\hat{A}'(I - R')$

We come back to Eq. (8.9) and study both norms $\|\hat{A}'(I - R')\|_{p_0}$ and $\|\hat{A}'(I - R')\|_{p_0'}$. The first term of Eq. (8.9) is already of order μ'. The second term is small because of Eq. (8.12) or (8.16). The last term is $\|\chi_S V\|_{p_0}$ or $\|\chi_S V\|_{p_0'}$, which is small by our hypotheses on V. This proves Eq. (8.7).

IX. SEVERAL PHASES

We now assume that the first p eigenvalues (after $\lambda_0 = 1$), $\lambda_1, \ldots, \lambda_p$, of R are real and satisfy

$$\lambda_1^t, \ldots, \lambda_p^t = O(1 - \epsilon_1)$$

but

$$\lambda_{p+1}^t \text{``} B^t \text{''} < \epsilon_2 \quad [\text{as in Eq. (3.10)}].$$

We further assume that $1 - \lambda_k^t$, $(1 \leqslant k \leqslant p)$, are of the same order of magnitude. The tth power of R can now be written [cf. Eq. (3.3)]

$$\begin{aligned} R^t &= |p_0\rangle\langle A_0| + \sum_{k=1}^{p} \lambda_k^t |p_k\rangle\langle A_k| + |\lambda_{p+1}^t| B^t, \\ B^t &= \sum_{k \geqslant p+1} \frac{\lambda_k^t}{|\lambda_{p+1}^t|} |p_k\rangle\langle A_k|. \end{aligned} \tag{9.1}$$

For any $y \in X$, $x \in X$ we define

$$p_y^t(x) = R_{xy}^t \tag{9.2}$$

so that p_y^t is a probability on x. For the two-phase case, the quantities A_M and A_m [cf. Eq. (3.5)] played an important role in our estimates. We must now find the corresponding quantities in the multiphase case. We represent the situation geometrically in $\mathbf{R}^p$: for any point $y \in X$ we consider the vector $(A_1(y),\ldots,A_p(y)) \in \mathbf{R}^p$ so that we obtain a set $\mathscr{A}$ of N vectors in $\mathbf{R}^p$, where N is the cardinality of X. We consider the convex envelope $\widehat{\mathscr{A}}$ of $\mathscr{A}$.

The first remark is that the vector (0,0,...,0) *is in this convex envelope* $\widehat{\mathscr{A}}$.

In fact we know that $\langle A_k | p_0 \rangle = 0$ for $1 \leqslant k \leqslant p$, so this means

$$\sum_{y \in X} p_0(y)(A_1(y),A_2(y),\ldots,A_p(y)) = (0,0,...,0)$$

and (0,...,0) is a convex combination of the vectors of $\mathscr{A}$. As a consequence, one can find $p+1$ points y_l^*, $1 \leqslant l \leqslant p+1$, which are extremal points of the convex set $\mathscr{A}$ and such that (0,0,...,0) is a convex combination of the vectors E_l,

$$E_l \equiv (A_1(y_l^*),A_2(y_l^*),\ldots,A_p(y_l^*)). \tag{9.3}$$

There may be several ways to choose these points y_l^*, but we shall prove that, in fact, the resulting vectors E_l $(1 \leqslant l \leqslant p+1)$ are uniquely defined. In particular, we can find μ_l, $1 \leqslant l \leqslant p+1$, with $0 \leqslant \mu_l \leqslant 1$, $\Sigma_{l=1}^{p+1} \mu_l = 1$ such that

$$\Sigma \mu_l E_l = 0 \quad \text{in} \quad \mathbf{R}^p. \tag{9.4}$$

Now, by definition, we have

$$\lambda_k^t A_k(y_l^*) = \langle A_k | p_{y_l^*}^t \rangle \tag{9.5}$$

so that for all l we have

$$(\lambda_1^t A_1(y_l^*),\lambda_2^t A_2(y_l^*),\ldots,\lambda_p^t A_p(y_l^*)) = \sum_{y \in X} p_{y_l^*}^t(y)(A_1(y),A_2(y),\ldots,A_p(y)). \tag{9.6}$$

Because $0 \leqslant \lambda_k < 1$, the vector on the left side of Eq. (9.6) is in the convex set $\widehat{\mathscr{A}}$; moreover, its distance to the extremal vector $E_l = (A_1(y_l^*,\ldots,A_p(y_l^*))$ is less than $1-\lambda_p^t$. Equation (9.6) says that this vector is a convex combination of the vectors of the set $\mathscr{A}$. Because $\Sigma_y p_{y_l^*}^t(y) = 1$, we have from Eq. (9.6)

$$E_l - (\lambda_1^t A_1(y_l^*),\lambda_2^t A_2(y_l^*),\ldots,\lambda_p^t A_p(y_l^*)) = \sum_y p_{y_l^*}^t(y)[E_l - (A_1(y),\ldots,A_p(y))]. \tag{9.7}$$

Now, consider the translated set $E_l - \mathscr{A}$ in $\mathbf{R}^p$, i.e., the set of vectors $E_l - (A_1(y),\ldots,A_p(y))$, $y \in X$. Then, the vector 0 is extremal for the convex set $E_l - \widehat{\mathscr{A}}$. We can transform our problem in the following way:

(i) We have a finite set of vectors $w(y)$ in $\mathbf{R}^p$ $(y \in X)$ such that the vector 0 is an extremal point of the convex envelope of this set.

(ii) We have a vector w_0 of norm $\|w_0\| < \epsilon$ which lies in the convex envelope. Here

$$w(y) = E_l - (A_1(y),\ldots,A_p(y)),$$

$$w_0 = E_l - (\lambda_1^t A_1(y),\ldots,\lambda_p^t A_p(y)),$$

$$\epsilon = 1 - \lambda_p^t.$$

We have a convex relation, with $0 \leqslant q(y) \leqslant 1$, $\Sigma q(y) = 1$

$$w_0=\sum_{y\in X} q(y)w(y). \tag{9.8}$$

Because 0 is extremal for the set of $w(y)$, there exist p linear forms $h_1,\ldots,h_p$ such that $h_j(w(y))>0$, except for y such that $w(y)=0$, and with coefficients $\leqslant 1$. Define

$$I(a)=\{y\in X | h_j(w(y))<a \quad \text{for all} \quad j=1,...,p\}. \tag{9.9}$$

Then from (9.8) we have

$$\sum_{y\notin I(a)} q(y)<\frac{p\epsilon}{a}.$$

In fact from (9.8) and the fact that h_j has coefficients $\leqslant 1$

$$\epsilon>h_j(w_0)>\sum_{y\in X} q(y)h_j(w(y))\geqslant a\sum_{\{y\in X|h_j(w(y))>a\}} q(y).$$

Thus

$$\sum_{y\notin I(a)} q(y)\leqslant\sum_{j=1}^{p}\left(\sum_{\{y\in X|h_j(w(y))>a\}} q(y)\right)\leqslant\frac{p\epsilon}{a}.$$

Coming back to our previous notation, we see that for any l, $1\leqslant l\leqslant p+1$, there exist p linear forms $h_{l,j}$ with coefficients $\leqslant 1$, such that if we define

$$I_l(a)=\{y\in X | h_{l,j}(E_l-(A_1(y),\ldots,A_p(y)))<a, j=1,...,p\} \tag{9.10}$$

then

$$\sum_{y\in I_l(a)} p^t_{y^*_l}(y)\geqslant 1-\frac{p}{a}(1-\lambda^t_p). \tag{9.11}$$

Moreover, we had certain $0\leqslant\mu_l\leqslant 1$, with $\Sigma\mu_l=1$, such that

$$\Sigma\mu_l E_l=1 \quad [\text{see Eq. (9.4)}].$$

This means that by (9.1), (9.2), and the definition of E_l

$$\sum_{l=1}^{p+1}\mu_l p^t_{y^*_l}(x)=p_0(x)+|\lambda^t_{p+1}|\sum_{l=1}^{p+1}\mu_l B^t_{xy^*_l}. \tag{9.12}$$

Now we assume that the B terms are small, i.e., for any $Y\subset X$ and all $x\in X$

$$|\lambda^t_{p+1}|\left|\sum_{y\in Y} B^t_{yx}\right|\ll 1-\lambda^t_p. \tag{9.13}$$

Then Eq. (9.12), and inequalities (9.11), (9.13) say that for some constant c, we have

$$\sum_{y\in\cup I_l(a)} p_0(y)\geqslant 1-c(1-\lambda^t_p). \tag{9.14}$$

The inequalities (9.11) and (9.14) say that the whole state space X breaks into subsets $I_l(a)$ which fill almost everything (with respect to p_0). This means that we have $p+1$ phases.

[21] The ''fundamental intuition'' of phase coexistence has been incorporated in other definitions of phase transition, some of them stemming from the C* algebra approach (Refs. 25 and 26). In this language a phase transition is expressed by the nonuniqueness of the infinite volume Gibbs measure. As indicated, we do not know how to bring infinite volume (the thermodynamic limit) into so mild a form of nonequilibrium as metastability, nor do we think that such a limit best reflects the physics (cf. Ref. 6).
[22] The ''remainder'' term in Eq. (3.10) (''B^t'') must be small in some sense for our phases to be well-defined, but the measure of smallness in that equation can probably be replaced by something weaker.
[23] The form for B^t in this equation is adopted for convenience only. In general B^t need *not* be writable as a sum of one-dimensional projections and a Jordan form would be required. See the remark following Eq. (3.4).
[24] By ''boundary'' of (say) I_M, we mean points $x \in I_M$ such that their distance, in terms of R, from any point in $\mathcal{C}I_M$ is small.

A stochastic method for Brownian-like optical transport calculations in anisotropic biosuspensions and blood

Steven Miller[a)]
Bioengineering Unit, University of Strathclyde, Glasgow G4ONW, Scotland

(Received 27 January 1997; accepted for publication 6 October 1997)

A generic stochastic method is presented that rapidly evaluates numerical bulk flux solutions to the one-dimensional integrodifferential radiative transport equation, for coherent irradiance of optically anisotropic suspensions of nonspheroidal bioparticles, such as blood. As Fermat rays or geodesics enter the suspension, they evolve into a bundle of random paths or trajectories due to scattering by the suspended bioparticles. Overall, this can be interpreted as a bundle of Markov trajectories traced out by a ''gas'' of Brownian-like point photons being scattered and absorbed by the homogeneous distribution of uncorrelated cells in suspension. By considering the cumulative vectorial intersections of a statistical bundle of random trajectories through sets of interior data planes in the space containing the medium, the effective equivalent information content and behavior of the (generally unknown) analytical flux solutions of the radiative transfer equation rapidly emerges. The fluxes match the analytical diffuse flux solutions in the diffusion limit, which verifies the accuracy of the algorithm. The method is not constrained by the diffusion limit and gives correct solutions for conditions where diffuse solutions are not viable. Unlike conventional Monte Carlo and numerical techniques adapted from neutron transport or nuclear reactor problems that compute scalar quantities, this vectorial technique is fast, easily implemented, adaptable, and viable for a wide class of biophotonic scenarios. By comparison, other analytical or numerical techniques generally become unwieldy, lack viability, or are more difficult to utilize and adapt. Illustrative calculations are presented for blood medias at monochromatic wavelengths in the visible spectrum. © *1998 American Institute of Physics.* [S0022-2488(98)00102-9]

I. INTRODUCTION

In this paper we present an approach to the mathematical problem of the scattering of a coherent light beam incident upon a slab or half-plane comprised of scattering–absorbing bioparticles in liquid suspension such as blood. Finding adequate mathematical solutions to this problem is relevant to a variety of technical biophysical and laser biology applications.[1–6] Part of the general mathematical difficulty arises from the complex optical and geometric properties of such medias. The shape, size, and number density of a homogeneous suspension of bioparticles, such as red blood cells, affects the rate of scattering and diffusion of the incident beam, the interior scattered flux profiles, and the scattered reflectance and transmittance. Blood is essentially a suspension of biconcave (dielectric) discoid cells or erythrocytes, each of which contains differing proportions or ratios of haemoglobins. These are haemoglobin and oxyhaemoglobin (Hb and HbO_2, respectively). The number density of suspended cells, their spatial geometry, and their inherent absorptive characteristics are therefore variables that can alter the optical properties in a complex way (red cells completely dominate the optical properties). Increasing the number of cells in suspension increases scattering since more scattering centers are now presented to an incident beam, but optical absorbancy is simultaneously increased since the relative amount of absorbing haemoglobins present is also increased. Furthermore, haemoglobin and oxyhaemoglobin have different optical absorbancy characteristics at the same optical wavelength.[7–9]

In most problems of multiple light scattering and diffusion in suspensions of particulate medias, the wavelength of the light λ, the scatter mean-free path l, and the thickness d of the sample obey the inequality $\lambda \ll l \ll d$. Also, if L is the effective dimension of the scatterer (e.g., diameter), then we will have either $L \ll \lambda, L \sim \lambda$, or $L \gg \lambda$. Multiple scattering of scalar waves in such particulate medias can be described by the following levels of theoretical description.

(i) The macroscopic approach[10] resides in solving an effective (Helmholtz) diffusion equation, which gives spatiotemporal variations in the scalar diffuse intensity or fluence $\phi(\mathbf{x},t)$ at points $\mathbf{x}$ at time t, or $\phi(\mathbf{x})$ in the steady state. This approximation is excellent in the bulk of the medium on length scales much larger than the mean-free path l, and when the particles scatter strongly and isotropically with little or no absorption. However, it is invalid in dealing with subsurface or ''quasidiffuse'' light scattered to low-order, strong anisotropy, coherent sources and strong absorption and combinations of these.

(ii) The mesoscopic approach[10–12] utilized in astrophysics and nuclear engineering, is based on radiative transfer theory (RTT). Spatiotemporal variations in radiance or intensity $\psi(\mathbf{x},\hat{\boldsymbol{\omega}},t)$ at all points $\mathbf{x}$ within the medium from propagation direction $\hat{\boldsymbol{\omega}}$, are described by an integrodifferential balance equation, structurally similar to the Boltzmann equation of kinetic theory. The approach is essentially heuristic and deals directly with the transport of scattered energy or power. The formulation is flexible and can be applied to a wide variety of physical and technological problems.[10] However, the general solutions are not known, even in one dimension; most approaches to the equation are therefore a compromise between mathematical and computational tractability and accuracy. The macroscopic diffusion approach is recovered in the limit of length scales larger than l when the particles are highly scattering.

(iii) The microscopic or analytical approach begins with Maxwell's equations or wave equations and the scattering–absorption characteristics of particles. Appropriate differential or integral equations are developed for statistical quantities such as correlation functions and field variances. This approach has a mathematically rigorous structure and can, in principle, include all possible wave related phenomenology.[10] However, the various theories that can provide solutions are all approximate, each being viable within specific ranges of parameters. The diagram method, the Dyson and Bethe–Salpeter equations, and Twersky's theory are theories of this type.[10] The approach is compatible with (ii) and can recover the RTE.

Each of these viewpoints represents a qualitative improvement on the previous one and are applicable to biosuspensions and blood medias. Twersky[13] developed a mathematical formalism as in (iii) to describe scattering of plane electromagnetic waves by large, low refracting, and absorbing particles. Anderson and Sekelj[14] demonstrated the application of this theory to a blood cell suspension. Twersky[15] later applied his own model to biological suspensions. However, the inherent complexity of the theory precludes the possibility of any pragmatic solutions for a biophysical application. It is possible to obtain an optical density formula for scattering in whole blood, but the coefficients within the equation have to empirically fitted from experimental data.[13] The more tractable alternative for blood and biosuspension is via the radiative transfer or diffusion approaches of (i) and (ii). However, again we have the difficulty that general solutions of the transport equation in closed form are unknown, even in one-dimensional geometry.[10,11] Analytical and numerical solutions are possible in the diffusion approximation of (ii) when the medium is isotropic and thick and the suspended particles are assumed to be more scattering than absorbing, however, these conditions do not always generally hold for biosuspensions or blood.

Cohen and Longini[16] initially applied similar principles of semiconductor electron diffusion to the analogous optical diffusion problem in a turbid blood medium. Johnson,[17] Reynolds,[18] and Turnbull and Barbenel,[19,20] developed the same diffusion theory for boundaries and geometries relevant to their biophysical experiments, leading to complex expressions with no analytical solutions. Mathematical techniques included the SDD model (surface distributed dipole source) and the IDCT models (internal distributed cylindrical column of twin pole sources). A concise review is presented by Barbenel.[20] Recent mathematical work in bio-optics and biophotonics has focused on numerically solving or simulating the transport and diffusion equations of approaches (i) and (ii) directly borrowing techniques utilized in nuclear engineering and astrophysics.[1] These include discrete ordinates, Gauss quadrature, higher-order spherical harmonic P_n approximations, finite

element diffusion methods, and standard Monte Carlo simulation methods adapted from neutron diffusion theory.[1,21–24] However, while these techniques are viable and effective for many problems, all such methods generally require sophisticated application software and extensive computational or supercomputer facilities. This is often superfluous and detrimental when one essentially requires simple and fast but accurate quantitative flux or dosimetry solutions that are relevant to a variety of experimental or biological contexts.

In this paper, I develop a simple, yet effective and practical generic stochastic based mathematical approach that encompasses the regimes described by (i) and (ii), for the case of homogeneous suspensions of uncorrelated, anisotropic scattering and absorbing bioparticles. The method is specifically demonstrated for the case of whole blood and red cell suspensions. Given the basic scattering and absorbing properties of the cells (which are known), the technique rapidly ascertains the steady-state numerical solutions for scattered radiant flux, arising from wide beam coherent irradiance of the sample. The information content is equivalent to that which would be provided by the general analytical solutions of the RTE, which are unknown. In particular, the generation and decay of anisotropic multiply scattered light, arising from coherent beam decay, can be studied in detail for all possible optical conditions and for thin samples or films where the diffusive limit is generally not viable. Unlike conventional numerical and Monte Carlo algorithms for anisotropic transport,[22] this alternative formalism can be incorporated into very compact and simple computer codes, with many accurate and practical computations being completed rapidly. For the class of biophysical problems considered, the method has some advantages over all other methods.

II. CROSS SECTIONS AND OPTICAL COEFFICIENTS FOR BIOPARTICLES AND BLOOD CELLS

We consider a homogeneous and isotropic liquid suspension of N red blood cells or erythrocytes, which are uncorrelated and randomly oriented. The cells can be viewed as nonspheroidal or biconcave dielectric discoids, which scatter light due a refractive index continuity at their surface, separating the interior from the surrounding (transparent) plasma. The suspension is irradiated with a wide coherent monochromatic beam in the visible spectrum. Since $L \sim 8\ \mu$m and λ is normally 700–660 nm, $L \gg \lambda$. We first consider the scattering and absorption characteristics of a single erythrocyte, then consider the cumulative macroscopic or bulk optical properties arising statistically from many cells in suspension. The generic properties of scattering particles have been exhaustively presented in the literature.[10,25–27]

To make this paper self-contained and as a necessary prerequisite for the development of the method, we briefly summarize and define what is directly relevant for generic bioparticles and blood cells. If a linearly polarized, monochromatic, electromagnetic wave propagates in a medium with dielectric constant ϵ_0, then the electric field is $\mathbf{E}_i(\mathbf{x}) = \hat{\mathbf{e}}_i \exp(ik\hat{\boldsymbol{\omega}},\mathbf{x})$, where $\hat{\boldsymbol{\omega}}$ is a unit vector in the direction of propagation, $\hat{\mathbf{e}}_i$ is a unit vector in the direction of polarization, and $k = 2\pi\lambda^{-1}$, where λ is the wavelength. The wave is incident upon a particle or cell suspended within the translucent liquid, with relative dielectric constant $\epsilon_{\text{rel}}(\mathbf{x}) = \epsilon(\mathbf{x})/\epsilon_0$, where $\epsilon_{\text{rel}}(\mathbf{x}) \in \mathbb{C}$. The field at a distance R, from a reference point $\mathbf{x}$ within the cell, in direction $\hat{\boldsymbol{\omega}}$, is comprised of the incident field $\mathbf{E}_i$ and the scattered field $\mathbf{E}_s$. Within $R < L^2\lambda^{-1}$, the (near) field $\mathbf{E}_s$ has complicated amplitude and phase variations due to interference between contributions from different spatial regions of the cell. However, in the farfield $R > L^2\lambda^{-1}$, $\mathbf{E}_s$ behaves as a spherical wave and

$$\mathbf{E}_s(\mathbf{x}) = R^{-1} f(\hat{\boldsymbol{\omega}}, \hat{\boldsymbol{\omega}}') \exp(ikR), \tag{2.1}$$

where the function $f(\hat{\boldsymbol{\omega}}, \hat{\boldsymbol{\omega}}') \in \mathbb{C}$ represents the phase and amplitude of the scattered wave in the farfield in direction $\hat{\boldsymbol{\omega}}'$, when the cell is illuminated by a plane wave initially in along $\hat{\boldsymbol{\omega}}$. If $\mathcal{F}_s$ is the scattered power flux density at R from the particle along unit vector $\hat{\boldsymbol{\omega}}'$, due to an incident flux density $\mathcal{F}_i$, then the differential scattering cross section of the cell is

$$\chi_{\text{diff}}(\hat{\boldsymbol{\omega}}, \hat{\boldsymbol{\omega}}') = \lim_{R \to \infty} [\mathcal{F}_i^{-1}(R^2 \mathcal{F}_s)] = |f(\hat{\boldsymbol{\omega}}, \hat{\boldsymbol{\omega}}')|^2 = (\chi_t/4\pi)\mathcal{P}(\hat{\boldsymbol{\omega}}, \hat{\boldsymbol{\omega}}'), \tag{2.2}$$

where $\mathscr{P}(\hat{\boldsymbol{\omega}},\hat{\boldsymbol{\omega}}') \in [0,1] \subset \mathbb{R}$ is the phase function and χ_t is the total cross section (to be defined below). The total power scattered into all solid angles around the cell is related to the scattering cross section χ_s:

$$\chi_s = \int_{4\pi} \chi_{\text{diff}}\, d\omega = \int_{4\pi} |f(\hat{\boldsymbol{\omega}},\hat{\boldsymbol{\omega}}')^2\, d\omega = (\chi_t/4\pi) \int_{4\pi} \mathscr{P}(\hat{\boldsymbol{\omega}},\hat{\boldsymbol{\omega}}') d\omega. \tag{2.3}$$

The ratio $a(0)=(\chi_s/\chi_t)$ is the albedo of a single particle, so clearly $a(0) = \chi_t \int |f(\hat{\boldsymbol{\omega}},\hat{\boldsymbol{\omega}}')|^2\, d\omega = (4\pi)^{-1} \int \mathscr{P}(\hat{\boldsymbol{\omega}},\hat{\boldsymbol{\omega}}') d\omega$. If the scatterer is lossless then no power is absorbed and the total power loss is due to scattering with $\chi_t = \chi_s$. This would be the case for clear cells such as platelets. For blood cells, the haemoglobin molecules within the cell can absorb energy from the incident wave that is quantified by χ_a, the absorption cross section. Hence, $\chi_t = \chi_s + \chi_a$. The optical theorem[10] then defines the total χ_t to the imaginary part of the amplitude $f(\hat{\boldsymbol{\omega}},\hat{\boldsymbol{\omega}})$ as $\chi_t = (4\pi/k)\text{Im}[f(\hat{\boldsymbol{\omega}},\hat{\boldsymbol{\omega}})] \cdot \hat{\mathbf{e}}_i$. If the cellular geometry is spherical, the exact solutions for amplitude f, χ_a, and χ_s for electromagnetic waves incident on a dielectric sphere are derived from Mie theory.[10,27] For more complex biconcave and ellipsoidal geometries, relevant to biological particles, the method is still tractable.[27,28] For red cells, values of $\chi_s(\lambda)$ and $\chi_a(\lambda)$ have been derived for various optical wavelengths λ, using both experimental and theoretical methods.[18,29]

Given the microscopic optical properties of a single cell, the macroscopic bulk optical properties of a homogeneous suspension of a large number N of such red cells in a volume V can be ascertained. If $\eta = (N/V)$ is the number density, then the haematrocrit is $h = \eta \nu_e^{-1}$, where ν_e is the volume of a single erythrocyte and $h \in [0,1]$. The bulk macroscopic absorption coefficient $a(h) = \eta \chi_a$ of the suspension (in cm^{-1}) has a linear functional dependence on h:

$$a(h) = \eta \chi_a = h \nu_e^{-1} \chi_a. \tag{2.4}$$

However, since erythrocytes contain a binary mixture of Hb and HbO_2, the cross section χ_a also varies with the ratio of the molecular concentrations within the cell, since Hb and HBO_2 have different absorption spectra (except at isosbestic points at around $\lambda = 805$ nm). If $c[\text{Hb}]$ is the molecular concentration of Hb and $c[\text{HbO}_2]$ that of HbO_2 (in moles/cm^3), then the haemoglobin saturation $\mathscr{S}$ is defined as $\mathscr{S} = c[\text{HbO}_2]/[c[\text{HbO}_2] + c[\text{Hb}]]$ with $\mathscr{S} \in [0,1]$. As $\mathscr{S} \to 1$, the cells are fully oxygen saturated, and as $\mathscr{S} \to 0$, they are deoxygenated. In any suspension, all N cells will generally have equal $\mathscr{S}$. The coefficient $a(h,\mathscr{S})$ for any $0 < h < 1$ and $0 < \mathscr{S} < 1$ then has a linear functional dependence on h and $\mathscr{S}$:

$$a(h,\mathscr{S}) = h \nu_e^{-1} [\mathscr{S} \chi_{ao} + (1-\mathscr{S}) \chi_{ar}], \tag{2.5}$$

where χ_{ao} is the Mie absorption cross section for fully oxygenated cells ($\mathscr{S} = 1$) and χ_{ar} that for reduced cells with $\mathscr{S} = 0$ at a specific monochromatic wavelength λ. The function $a(h,\mathscr{S})$ is essentially the inverse probability per unit length (cm^{-1}) for light being absorbed along a rectilinear path. $a(h,\mathscr{S})$ can also be written as $a(h,\mathscr{S}) = [\mathscr{S} q_1 + (\mathscr{S}-1) q_2] h$, where the wavelength-dependent constants, q_1 and q_2, can be determined empirically.[9]

The macroscopic scattering coefficient $b = b(h)$ in cm^{-1} is functionally dependent only on h. For small h ($h <= 0.2$), we have $b(h) = \eta \chi_s = h \nu_e^{-1} \chi_s$, but as h increases the cells become more densely packed. As $h \to 1$ (the dense packing limit) the cells conglomerate and refractive index discontinuities $\epsilon_{\text{rel}}(x)$ between cell and plasma are gradually eliminated. Optically, the medium is then equivalent to a dense solution of haemoglobin with no scattering and the farfield approximation $R > L^2 \lambda^{-1}$ becomes invalid as $R \to 0$ as $h \to 1$. However, for all $h > 0$ and $h < 0.7 = 0.9$, the condition $R > L^2 \lambda^{-1}$ is satisfied. Since $b(h) \to 0$ as $h \to 0$ or 1, the scattering coefficient has a parabolic functional dependence on h:

$$b(h) = \chi_s \nu_e^{-1} h(1-h) = \eta \chi_s. \tag{2.6}$$

A correction has been presented as $b(h) = \chi_s \nu_e^{-1} h(1-h)(1.4-h)$,[3] but the parabolic term $h(1-h)$ is the essential feature.

Since $L \gg \lambda$, the coefficient $b(h)$ is not very dependent on λ. A useful formula on the full optical spectrum is $b(h) = (54.1 - 38.97h)h(1-h)$, which has been empirically determined.[9]

The dense packing limit as $h \to 1$ is only possible due to the elastic deformation properties of cells. For a suspension of hard spheres of volume ν, h cannot exceed 0.64[30] and $b(h) = h\chi_s \nu^{-1} \zeta(h)$, where $\zeta(h)$ is a monotone decreasing function of h with $\zeta(0) = 0$ and $\zeta(0.64) = 0$. These generic formulas are viable for all types of biosuspensions with a given number density and Mie cross sections.

III. BIOSCATTERING AMPLITUDES AND ANISOTROPIC PHASE FUNCTIONS

Since the red cell geometry is biconcave, this deviation from spherical symmetry suggests that the cells will not scatter flux isotropically. Deviations from spherically symmetric or isotropic scatter will be quantified by the complex bioscattering amplitude $f(\hat{\boldsymbol{\omega}}, \hat{\boldsymbol{\omega}}')$ defined in Eq. (3.1), and the optical theorem for a single cell. Consider a specific intensity or radiance $\psi(\mathbf{x}, \hat{\boldsymbol{\omega}})$ incident upon a cylindrical volume of the suspension of cells of saturation $\mathscr{S}$, with unit cross section and length $d\xi$. The volume $d\xi$ contains $\eta\, d\xi$ cells, where η is the homogeneous number density of cells in the suspension. Each cell in the volume will then absorb the power $[\chi_{ao} \mathscr{S} + (\mathscr{S} - 1)\chi_{ar}]\psi(\mathbf{x}, \hat{\boldsymbol{\omega}})$ and scatter the power $\chi_s \psi(\mathbf{x}, \hat{\boldsymbol{\omega}})$, so the differential variational decrease $d\psi$ within the volume $d\xi$ is

$$d\psi(\mathbf{x}, \hat{\boldsymbol{\omega}}) = -d\xi[\chi_s + \chi_{ao} \mathscr{S} + (1 - \mathscr{S})\chi_{ar}]\psi(\mathbf{x}, \hat{\boldsymbol{\omega}}) = -\eta\, d\xi\, \chi_t . \tag{3.1}$$

Radiance $\psi(\mathbf{x}, \hat{\boldsymbol{\omega}})$ also increases due to contributions scattered into this direction from all possible directions $\hat{\boldsymbol{\omega}}'$. For a wave incident in direction $\hat{\boldsymbol{\omega}}'$ on a cell, the incident flux density through a small solid angle is $\mathscr{F}_i = \psi(\mathbf{x}, \hat{\boldsymbol{\omega}}')d\omega$. The power flux density $\mathscr{F}_s$ scattered by a cell in the direction $\hat{\boldsymbol{\omega}}$ at distance R from the cell is $\mathscr{F}_s = [|f(\hat{\boldsymbol{\omega}}, \hat{\boldsymbol{\omega}}')|^2 R^{-2}]\mathscr{F}_i$. The scattered intensity in direction $\hat{\boldsymbol{\omega}}$ due to $\mathscr{F}_i$ is therefore $\mathscr{F}_s R^2 = |f(\hat{\boldsymbol{\omega}}, \hat{\boldsymbol{\omega}}')|^2 \mathscr{F}_1 = |f(\hat{\boldsymbol{\omega}}, \hat{\boldsymbol{\omega}}')|^2 \psi(\mathbf{x}, \hat{\boldsymbol{\omega}}')d\omega'$. Summing over all contributions from all directions $\hat{\boldsymbol{\omega}}'$, the radiance scattered in direction $\hat{\boldsymbol{\omega}}$ by $\eta\, d\xi$ cells in volume $d\xi$ is

$$\int_{4\pi} \eta\, d\xi |f(\hat{\boldsymbol{\omega}}, \hat{\boldsymbol{\omega}}')|^2 \psi(\mathbf{x}, \hat{\boldsymbol{\omega}}')d\boldsymbol{\omega}'. \tag{3.2}$$

This equation can be expressed using the real cellular phase function $\mathscr{P}(\hat{\boldsymbol{\omega}}, \hat{\boldsymbol{\omega}}')$ of (2.3):

$$\mathscr{P}(\hat{\boldsymbol{\omega}}, \hat{\boldsymbol{\omega}}') = (4\pi/\chi_t)|f(\hat{\boldsymbol{\omega}}, \hat{\boldsymbol{\omega}}')|^2. \tag{3.3}$$

If the vector orientation $\hat{\boldsymbol{\omega}}$ is given by (Θ, φ) with $\Theta \in [0, \pi]$, $\varphi \in [0, 2\pi]$ and that of $\hat{\boldsymbol{\omega}}'$ given by (Θ', φ'), then $\mathscr{P}(\hat{\boldsymbol{\omega}}, \hat{\boldsymbol{\omega}}') = \mathscr{P}(\Theta, \varphi | \Theta', \varphi')$, where $\cos\Theta = \hat{\boldsymbol{\omega}}.\hat{\boldsymbol{\omega}}'$, with respect to the incident beam axis along $+z$ or $\Theta_0 = \pi/2$. If scattering is symmetric about the incident wave, then the phase function is dependent only on Θ and can be expanded in Legendre polynomials $\mathscr{L}_n(\cos\Theta)$[10,31,32] for anisotropic scattering:

$$\mathscr{P}(\Theta, \varphi | \Theta', \varphi') = \mathscr{P}(\cos\Theta) = \sum_{n=0}^{\infty} A(n) \mathscr{L}_n(\cos\Theta), \tag{3.4}$$

where $A(0) = 1$ is the albedo of the cell. Given $\mathscr{P}(\hat{\boldsymbol{\omega}}, \hat{\boldsymbol{\omega}}')$, the effects of anisotropy or weighting of the scatter direction are embodied in the anisotropy parameter $g = \langle \cos\Theta \rangle = \langle \hat{\boldsymbol{\omega}}.\hat{\boldsymbol{\omega}}' \rangle$, defined as

$$g = \langle \cos\Theta \rangle = \left(\int_0^{\pi} \oint \mathscr{P}(\cos\Theta) \cos\Theta' \sin\Theta\ \delta\Theta'\ \delta\varphi' \right) \times \left(\int_0^{\pi} \oint \mathscr{P}(\cos\Theta) \sin\Theta' \delta\Theta' \delta\varphi' \right)^{-1}. \tag{3.5}$$

For isotropic scattering, $g = 0$ and $\mathscr{P}(\cos\Theta) = 1$; anisotropy increases as $g \to 1$. Possibilities for one-parameter scattering functions for blood cell suspensions[29] include the binomial law $\mathscr{P}(\cos\Theta) = \pi^{-1}[(i+1)/2^{i+1}][1 + \cos\Theta]$ and the ellipsoidal law $\mathscr{P}(\cos\Theta) = j[2\pi(1 - j\cos\Theta)]^{-1}[\mathrm{Ln}(1+j) - \mathrm{Ln}(1+j)]^{-1}$, where $i = \text{const}$ and $0 < j < 1$. Theoretically each of these

is viable. However, the experiment has demonstrated that the astrophysical Henyey–Greenstein function is the most convenient one-parameter function,[6,19,33,34] and is a very acceptable approximation to (3.4) for generic anisotropic scattering. Although initially applied to diffusion of radiation in the galaxy,[33] it also provides an adequate description of blood, particulate suspensions, and most other random medias. The function deviates from Mie theory calculations for high anisotropy ($g>0.9$ and $g<1$) with very small scatter angles.[34] However, this can be corrected.[34] For the purposes of this paper, it can be utilized as the paradigmatic example of a viable one-parameter phase function $\mathscr{P}(\Theta)$ for the bulk scattering properties of generic, anisotropic, optical systems comprised of discrete particulate constituents. It can be expressed as

$$\mathscr{P}(\cos\,\Theta)=\frac{1}{2\pi}\,\beta_1[\beta_2-\cos\,\Theta]^{-3/2}. \tag{3.6}$$

Here $\beta_1=(1+g^2)/2g$, $\beta_2=(1-g^2)/2g$. A valuable property of this function is that it is easily integrated. The scattering Mie cross sections of the cells can be related to $\mathscr{P}(\cos\,\Theta)$.[29] If χ_s is the total Mie scattering cross section, then the purely forward and backward scattering Mie cross sections $\chi_s(+)$ and $\chi_s(-)$ can be computed with good accuracy from:[29]

$$\chi_s(+)\sim\chi_s\int_0^1\beta_1(\beta_2-\cos\,\Theta)^{-3/2}d(\cos\,\Theta), \tag{3.7a}$$

$$\chi_s(-)\sim\chi_s\int_{-1}^0\beta_1(\beta_2-\cos\,\Theta)^{-3/2}d(\cos\,\Theta). \tag{3.7b}$$

The ratio $|\chi_s(+)/\chi_s(-)|$ is determined by the geometric shape of the cell, so that $|\chi_s(+)/\chi_s(-)|>1$ for $g>0$ and $|\chi(+)/\chi(-)|=1$ for $g=0$.

IV. STATEMENT OF THE PROBLEM: TRANSPORT THEORY AND PATH INTEGRALS

Adding the equations (3.1) (3.2) and using (3.3), we obtain the integro-differential radiative transfer equation for beam propagation within the blood cell suspension:

$$\frac{d\psi(\mathbf{x},\hat{\boldsymbol{\omega}})}{d\xi}=-\eta[\chi_s+\mathscr{S}\chi_{ao}+(1-\mathscr{S})\chi_{ar}]\psi(\mathbf{x},\hat{\boldsymbol{\omega}})$$
$$+\left(\frac{\eta[\chi_s+\mathscr{S}\chi_{ao}+(1-\mathscr{S})\chi_{ar}]}{4\pi}\right)\int_{4\pi}\mathscr{P}(\hat{\boldsymbol{\omega}},\hat{\boldsymbol{\omega}}')\psi(\mathbf{x},\hat{\boldsymbol{\omega}}')d\boldsymbol{\omega}'. \tag{4.1}$$

The left side can be written as a gradient or divergence operator since $d\psi(\mathbf{x},\hat{\boldsymbol{\omega}})/d\xi=\hat{\boldsymbol{\omega}}\cdot\boldsymbol{\nabla}\psi(\mathbf{x},\hat{\boldsymbol{\omega}})=\hat{\boldsymbol{\omega}}\cdot[\psi(\mathbf{x},\hat{\boldsymbol{\omega}})\hat{\boldsymbol{\omega}}]$ and $\hat{\boldsymbol{\omega}}$ is solenoidal in that $\boldsymbol{\nabla}\cdot\hat{\boldsymbol{\omega}}=0$. Writing $\hat{\boldsymbol{\omega}}=(\Theta,\varphi)$ with $\Theta\in[0,\pi]$ and $\varphi[0,2\pi]$ and using the macroscopic definitions (2.5) and (2.6):

$$[\hat{\boldsymbol{\omega}},\boldsymbol{\nabla}+(a(h,\mathscr{S})+b(h))]\psi(\mathbf{x},\Theta,\varphi)$$
$$=\left(\frac{a(h,\mathscr{S})+b(h)}{4\pi}\right)\int_0^{\pi}\oint\mathscr{P}(\Theta,\varphi|\Theta',\varphi')\psi(\mathbf{x},\Theta',\varphi')\sin\,\Theta'\;\delta\Theta'\;\delta\varphi'. \tag{4.2}$$

We consider flat wide beam coherent irradiance of a finite slab of thickness d, bounded by planes $z=0$ and $z=d$ (this geometry is adequate for realistic samples within thin cuvettes and laser biology problems). However, the transport equation has no general solution, even in this geometry. Since the beam is coherent, the radiance is the linear superposition of coherent and scattered components $\psi=\psi_c+\psi_s$. The coherent intensity ψ_c decays according to $d\psi_c(z,\hat{\boldsymbol{\omega}})/dz=-[a(h,\mathscr{S})+b(h)]\psi_c(z,\hat{\boldsymbol{\omega}})$, where $\hat{\boldsymbol{\omega}}$ is along the beam axis and perpendicular to $z=0$. The solution is simply the Beer–Lambert law:

$$\psi(z,\hat{\boldsymbol{\omega}})=\psi_0\,\exp[-(a(h,\mathscr{S})+b(h))z]. \tag{4.3}$$

The scattered component ψ_s satisfies

$$\hat{\boldsymbol{\omega}}\cdot\nabla\psi_s(\mathbf{x},\Theta,\varphi)=-[a(h,\mathscr{S})+b(h)]\psi_s(\mathbf{x},\Theta,\varphi)+\left(\frac{a(h,\mathscr{S})+b(h)}{4\pi}\right)\int_0^{\pi}\oint\mathscr{P}(\Theta,\varphi|\Theta',\varphi')\psi_s(\mathbf{x},\Theta',\varphi')+\psi_c(\mathbf{x},\Theta',\varphi'))\sin\Theta'\,\delta\Theta'\,\delta\varphi'. \tag{4.4}$$

Exponential decay of ψ_c acts as an additional source term for the generation of ψ_s and ψ_s must be zero at the surface planes $z=0$ or $z=d$ when $\hat{\boldsymbol{\omega}}$ is pointed into the suspension. Let $\mathscr{E}$ be a plane or surface within the medium (in the mathematical sense) and let $d\mathscr{E}$ be an element of the surface with unit normal $\hat{\boldsymbol{\omega}}_0$. The net forward scattered flux intersecting $\mathscr{E}$ is given by a solid angle integral over ψ_s in the forward range $(0<=\Theta<=\pi/2)$: when the blood is described by $(h,\mathscr{S})$, it can be written as $\mathscr{F}(+,\mathscr{E}:h,\mathscr{S})d\mathscr{E}$. The net backscattered radiant flux in $(\pi/2<\Theta<=0)$ is similarly $\mathscr{F}(-,\mathscr{E}:h,\mathscr{S})d\mathscr{E}$, where the forward and back flux densities are

$$\mathscr{F}(+,\mathscr{E}:h,\mathscr{S})=\int_0^{\pi/2}\oint\psi_s(\mathscr{E},\Theta,\varphi)\cos\Theta\,\sin\Theta\,\delta\Theta\,\delta\varphi, \tag{4.5a}$$

$$\mathscr{F}(-,\mathscr{E}:h,\mathscr{S})=\int_{\pi/2}^{0}\oint\psi_s(\mathscr{E},\Theta,\varphi)\cos\Theta\sin\Theta\,\delta\Theta\,\delta\varphi, \tag{4.5b}$$

where $\cos\Theta=\hat{\boldsymbol{\omega}}\cdot\hat{\boldsymbol{\omega}}_0$. The coherent radiant flux density follows directly from (4.3) since $\hat{\boldsymbol{\omega}}$ is perpendicular to $z=\mathscr{E}$, so that $\mathscr{F}_c(+,\mathscr{E};h,\mathscr{S})=\mathscr{F}_0\exp[-(a(h,\mathscr{S})+b(h))\mathscr{E}]$, where $\mathscr{F}_0$ is the incident flux density at plane $z=0$.

The rotational symmetry of the RTE is broken when a solution is constructed on the basis of initial data, as is the case, for example, with slab geometry. The initial data are the radiance $\psi(z=0;\hat{\boldsymbol{\omega}}_0)=\psi\ (z=0;\Theta_0,\varphi_0)$ at boundary $z=0$, where the unit vector $\hat{\boldsymbol{\omega}}_0$ is normal to plane $z=0$ for incident coherent or Fermat light $(\Theta_0=\pi/2)$ and points into the medium.

In Refs. 35 and 36, a solution was constructed for the initial value problem of deriving the forward scattered radiance ψ_s at any plane $z=$const below the initial data plane at $z=0$. The radiance solution is expressed in terms of a path integral kernal over a measure spanning all paths that scattered light can take from the initial angular direction $\hat{\boldsymbol{\omega}}_0$ at data plane $z=0$, to z at direction $\hat{\boldsymbol{\omega}}$. However, the path kernal cannot take into account backscattering and is restricted to very small angle forward scatterings and low absorption. The path kernal cannot be evaluated analytically and requires a Gaussian approximation. Nevertheless, this interpretation of mesoscopic RTT is of considerable efficacy.

Given initial data at $\psi(\mathbf{x}',\Theta',\varphi')$ at $\mathbf{x}=\mathbf{x}'$, the radiance $\psi(\mathscr{E};\Theta,\varphi)$ at an interior data plane $z=\mathscr{E}$ in direction (Θ,φ) is given by Huygen's principle in terms of the point spread Green's function or kernal $G(\mathscr{E},\Theta,\varphi|0,\Theta_0,\varphi_0)$:

$$\psi(\mathscr{E},\Theta,\varphi)=\int\delta\mathbf{x}'\int\delta\Theta'\int\delta\varphi'G(\mathscr{E},\Theta,\varphi|\mathbf{x}',\Theta',\varphi')\psi(\mathbf{x}',\Theta',\varphi'). \tag{4.6}$$

The radiance $\psi(\mathscr{E},\Theta,\varphi)$ at surface $\mathscr{E}$ is due to all optical paths generated by multiple scattering, intersecting $\mathscr{E}$ in direction (Θ,φ) having begun from $z=0$:

$$\psi(\mathscr{E},\Theta,\varphi)=\int\int\int\cdots\prod_{n>0}\delta\mathbf{x}_n\,\delta\Theta_n\,\delta\varphi_nG(\mathbf{x}_{n+1},\Theta_{n+1},\varphi_{n+1}|\mathbf{x}_n,\Theta_n,\varphi_n)\psi(\mathbf{x}=0,\Theta_0\varphi_0). \tag{4.7}$$

This is essentially a path integral over all possible optical paths that can contribute to $\psi(\mathscr{E},\Theta,\varphi)$, and G satisfies Kolmogorov equations:

$$G(\mathbf{x}_{n+1},\Theta_{n+1},\varphi_{n+1}|\mathbf{x}_{n-1},\Theta_{n-1},\varphi_{n-1})$$

$$=\int\int\int G(\mathbf{x}_{n-1},\Theta_{n+1},\varphi_{n+1}|\mathbf{x}_n,\Theta_n,\varphi_n)$$

$$\times G(\mathbf{x}_n,\Theta_n,\varphi_n|\mathbf{x}_{n-1},\Theta_{n-1},\varphi_{n-1})\,\delta x_n\,\sin\,\Theta_n\,\delta\Theta_n\,\delta\varphi_n. \tag{4.8}$$

The forward scattered radiant flux $\mathscr{F}(+,\mathscr{E}{:}h,\mathscr{S})$ through $\mathscr{E}$ is then explicitly expressed as

$$\mathscr{F}(+,\mathscr{E}{:}h,\mathscr{S})=\int_0^{\pi/2}\oint\Bigg[\cdots\int\delta\mathbf{x}_{n+1}\int\delta\Theta_{n+1}\int\delta\varphi_{n+1}\int\delta\mathbf{x}_n\int\delta\Theta_n\int\delta\varphi_n\cdots$$

$$\times\int\delta\mathbf{x}_2\int\delta\Theta_2\int\delta\varphi_2\int\delta\mathbf{x}_1\int\delta\Theta_1\int\delta\varphi_1\cdots G(\mathbf{x}_{n+1},\Theta_{n+1},\varphi_{n+1}|\mathbf{x}_n,\Theta_n,\varphi_n)$$

$$\times G(\mathbf{x}_n\Theta_n\varphi_n|\mathbf{x}_{n-1},\theta_{n-1},\varphi_{n-1})\cdots G(\mathbf{x}_2,\Theta_2,\varphi_2|\mathbf{x}_1,\Theta_1,\varphi_1)$$

$$\times G(\mathbf{x}_1,\Theta_1,\varphi_1|\mathbf{x}_2,\theta_1,\varphi_1)$$

$$\times G(\mathbf{x}_1,\Theta_1,\varphi_1|0,\Theta_0,\varphi_0)\psi(0,\Theta_0,\varphi_0)\Bigg]\cos\,\Theta\,\sin\Theta\,\delta\Theta\,\delta\varphi, \tag{4.9}$$

and similarly for the back flux $\mathscr{F}(-,\mathscr{E}{:}h,\mathscr{S})$. $\mathscr{F}(\pm,\mathscr{E};h,\mathscr{S})$ as a path integral, can be interpreted as a consequence of all possible vectorial intersections of all optical trajectories through surface $\mathscr{E}$, in the forward half-space. These are essentially all possible optical trajectories $\{\gamma\}$ that can evolve within the suspension, in biological state $(h,\mathscr{S})$ due to scattering, from Fermat paths or rays entering normal ($\Theta_0=\pi/2$) to the initial data plane at $z=0$. The rays propagate in the translucent plasma in rectilinear steps $\|\delta\mathbf{x}_n\|$ from cell to cell ($\mathbf{x}_{n-1}\rightarrow\mathbf{x}_n\rightarrow\mathbf{x}_{n+1}$) with $\delta\mathbf{x}_n=\mathbf{x}_{n+1}-\mathbf{x}_n$, where they experience either scattering and deflection or absorption. Overall, each optical trajectory within the biosuspension is constructed from such sequences of rectilinear steps or vectors $\delta\mathbf{x}_n=\mathbf{x}_{n+1}-\mathbf{x}_n$, each pointing in a random direction due to refraction from cellular index discontinuities [in (4.9) the integration measure $|\Pi_n\,\delta\mathbf{x}_n$ is over all possible $\delta\mathbf{x}_n$]. A statistical bundle of such trajectories $\{\gamma\}$ vectorially intersecting any interior surface $\mathscr{E}$, effectively gives rise to a stable scattered flux density $\mathscr{F}(\pm,\mathscr{E})$ through the surface.

The probability of any path γ vectorially intersecting $\mathscr{E}$ in direction Θ, φ, from scattering at $\mathbf{x}_n$ is not dependent on the previous random history of the path that resulted in its eventual arrival at $\mathbf{x}_n$. Any optical migration or trajectory γ is then essentially a Markov chain, since it has no memory of its past for a given present,[36] as exemplified by the Kolmogorov equation (4.8). At the level of description, (ii), as described in Sec. I, radiative transfer can be interpreted statistically as a bundle of such optical Markov trajectories being randomly traced out by a ''gas'' or ensemble of Brownian-like point photons being scattered rectilinearly from cell to cell and/or being absorbed in the cells. A single optical Markov migration or chain γ, from the ensemble defined by the path sum in (4.9), can be expressed as (dropping integrals for a single optical path).

$$G(\mathscr{E},\Theta,\varphi|\Theta,\theta_0,\varphi_0)=G(\mathscr{E},\Theta,\varphi|\mathbf{x}_n,\Theta_n,\varphi_n)\times G(\mathbf{x}_n,\Theta_n,\varphi_n|\mathbf{x}_{n-1},\Theta_{n-1}\varphi_{n-1})\times\cdots$$

$$\times G(\mathbf{x}_1,\Theta_1,\varphi_1|0,\Theta_0\varphi_0), \tag{4.10}$$

where $G(\mathbf{x}_{n+1},\Theta_{n+1},\varphi_{n+1}|\mathbf{x}_n,\Theta_n,\varphi_n)$ is the transition probability or the Green's function for being scattered to the nth order from $\mathbf{x}_n$ with incident direction (Θ_n,φ_n) to $\mathbf{x}_{n+1}$ in direction $(\Theta_{n+1},\varphi_{n+1})$. Since G cannot be ascertained (outside the Gaussian or diffusion approximation), any single optical migration or random path γ can be represented as a dataset of stochastic variables:

$$\left[\left(0,\frac{\pi}{2},0\right),(R_1,\Theta_1,\varphi_1),\langle R_2,\Theta_2,\varphi_2\rangle,\ldots,(R_{n-1},\Theta_{n-1},\varphi_{n-1}),(R_n,\Theta_n,\varphi_n)\ldots\right], \tag{4.11}$$

where $R_n \equiv \|\delta \mathbf{x}_n\| = \|\mathbf{x}_{n+1} - \mathbf{x}_n\|$, and $(z, \Theta_0, \varphi_0) = (0, \pi/2, 0)$ is the initial dataset for all Fermat rays entering the suspension at the initial data plane $z = 0$. The total length of the path is $\Sigma_n \|\delta \mathbf{x}_n\| = \Sigma_n R_n^{(s)} + R^{(a)}$.

V. THE METHOD

The path integral flux expression in (4.9) is statistically approximated by an ensemble or bundle of u Brownian-like or Markov optical trajectories:

$$[\gamma(1), \gamma(2), \ldots \gamma(p) \ldots \gamma(u)].$$

The algorithm generates u random stochastic datasets of the form (4.11), from a bundle of u Fermat rays entering at $z = 0$, all with initial specification $(z, \Theta_0, \varphi_0) = (0, \pi/2, 0)$ on the data surface $z = 0$. Given any $h \in (1,0)$, $\mathscr{S} \in [1,0]$ and $g \in [0,1)$, for the suspension, the probability densities that constrain the allowed stochastic variable sets $\{(R_n, \Theta_n, \varphi_n)\}$, are easily determined, and are functionally dependent on variations in h, $\mathscr{S}$, or g. By sampling these densities, the stochastic datasets $\{(R, \Theta, \varphi)\}$ describing a random optical migration γ, can be generated. The probability of a rectilinear propagation distance $R^{(s)}$ in the translucent plasma between cells, without being scattered by a cell is $\mathscr{P}(R^{(s)})$. Similarly, the probability of rectilinear propagation $R^{(a)}$ in plasma without being absorbed by a cell is $\mathscr{P}(R^{(a)})$. We must have $\mathscr{P}: R \to [0,1]$:

$$\mathscr{P}(R^{(s)}) = b(h) \exp[-b(h) R^{(s)}], \tag{5.1a}$$

$$\mathscr{P}(R^{(a)}) = a(h, \mathscr{S}) \exp[-a(h, \mathscr{S}) R^{(a)}]. \tag{5.1b}$$

Clearly, $\mathscr{P}(R^{(s)}) \to 0$ and $\mathscr{P}(R^{(a)}) \to 0$ as $R^{(s)}$ and $R^{(a)}$ increase. $R^{(s)} \to 0$ as $b(h) \to 0$ as $h \to 1$. However, the ''farfield'' limit $R^{(s)} > L^2 \lambda^{-1}$ generally holds for $h < 0.7 - 0.9$ (above these values scattering can be ignored anyway). These densities are necessarily normalized as

$$\int_0^\infty \mathscr{P}(R^{(s)}) dR^{(s)} = 1, \tag{5.2a}$$

$$\int_0^\infty \mathscr{P}(R^{(a)}) dR^{(a)} = 1, \tag{5.2b}$$

so that for all finite interaction steps $R^{(s)}$ and $R^{(a)}$:

$$\int_0^{R^{(s)}} \mathscr{P}(R^{(s)}) dR^{(s)} = \zeta^{(1)} < 1, \tag{5.3a}$$

$$\int_0^{R^{(a)}} \mathscr{P}(R^{(a)}) dR^{(a)} = \zeta^{(2)} < 1. \tag{5.3b}$$

Integrating and solving for $R^{(s)}$ and $R^{(a)}$ gives the generator formulas:

$$R^{(s)} = -(b(h))^{-1} \text{ Ln } \zeta^{(1)}, \tag{5.4a}$$

$$R^{(a)} = -(a(h, \mathscr{S}))^{-1} \text{ Ln } \zeta^{(2)}. \tag{5.4b}$$

If $\zeta^{(1)}$ and $\zeta^{(2)}$ are pure, uncorrelated random numbers on (1,0), the set $(\zeta^{(1)}, \zeta^{(2)})$ generates the stochastic pair $(R^{(s)}, R^{(a)})$. The weighted anisotropic density $\mathscr{P}(\cos \Theta)$ or $\mathscr{P}(\Theta)$ for stochastic scatter angles is given by Eq. (3.6). Using this Greenstein form, we also have the necessary renormalization:

$$\int_0^\pi \oint \beta_1 (\beta_2 - \cos \Theta)^{-3/2} \sin \Theta \, d\Theta \, d\varphi = 1, \tag{5.5a}$$

$$\int_0^{\theta} \oint \beta_1(\beta_2-\cos\Theta)^{-3/2}\sin\Theta\, d\Theta\, d\varphi=\zeta^3<1. \tag{5.5b}$$

The integration can be done and inverted to give

$$\Theta=\frac{1}{2\pi}\left[\frac{g}{2}\left(\beta_1-\beta_2\left(1-g-2g\zeta^3\right)\right]\right]. \tag{5.6}$$

If $\zeta^{(3)}$ is a random number on (1,0), then the generator (5.6) gives a stochastic variable Θ on $[0,\pi]$. The stochastic polar angles φ are trivially sampled by $\varphi=2\pi\zeta^{(4)}$ with $\zeta^{(4)}\in(0,1)$.

Consider the nth-order scattering of any optical Brownian path γ within a cell at $\mathbf{x}_n$, which is then randomly scattered to another cell randomly located $\mathbf{x}_{n+1}$. A dataset of stochastic variables is generated for the nth scatter event:

$$(\zeta_n^{(1)},\zeta_n^{(2)},\zeta_n^{(3)},\zeta_n^{(4)})\rightarrow(R_n^{(s)},R_n^{(a)},\Theta_n,\varphi_n).$$

Since the shortest rectilinear step from the pair $(R_n{}^{(s)},R_n{}^{(a)}$ is the most probable, the following inequalities and operations are considered.

(1) If $R_n{}^{(s)}<R_n{}^{(a)}$, then $R_n{}^{(s)}$ is selected.

The optical migration γ then stochastically evolves by propagating a rectilinear distance $R_n{}^{(s)}$ in the translucent plasma, before encountering another cell at random location $\mathbf{x}_{n+1}$ such that $R_n{}^{(s)}=\|\mathbf{x}_{n+1}-\mathbf{x}_n\|$. Since $R_n{}^{(s)}$ is a stochastic scatter step, the optical path undergoes another Brownian-like scatter from a cell at $\mathbf{x}_{n+1}$.

(2) If $R_n{}^{(a)}<R_n{}^{(s)}$, then $R_n{}^{(a)}$ is selected.

The optical migration γ then evolves by propagating a rectilinear distance $R_n{}^{(a)}$ in the translucent plasma, before encountering another cell at random location $\mathbf{x}_{n+1}$ such that $R_n{}^{(a)}=\|\mathbf{x}_{n+1}-\mathbf{x}_n\|$. Since $R_n{}^{(a)}$ is a stochastic absorption step or terminal step, the optical trajectory terminates at $\mathbf{x}_{n+1}$. A new trajectory is then generated. If the suspension of particles is lossless, then $A=0$, and only scatter steps are relevant (for example, translucent cells); the trajectory can only terminate by leaving the space containing the particles.

The orientation of the resultant vector $\delta\mathbf{x}_n=\mathbf{x}_{n+1}-\mathbf{x}_n$ is determined by the stochastic angles sampled from the integrated phase function in (3.6). If the optical trajectory approached the cell at $\mathbf{x}_n$ in direction $(\Theta_{n-1},\varphi_{n-1})$, then it is scattered in a random direction (Θ_n,φ_n) toward $\mathbf{x}_{n+1}$. Since the phase function is weighted by the factor $g>0$, optical trajectories are preferentially scattered into the forward half-space $(0<\Theta<\pi/2)$, if the incidence direction was in the forward half-space. If $R_n{}^{(s)}<R_n{}^{(a)}$ then a new dataset of stochastic variables is generated at $\mathbf{x}_{n+1}$:

$$(\zeta_{n+1}^{(1)},\zeta_{n+1}^{(2)},\zeta_{n+1}^{(3)},\zeta_{n+1}^{(4)})\rightarrow(R_{n+1}^{(s)},R_{n+1}^{(a)},\Theta_{n+1},\varphi_{n+1}).$$

This iteration continues until an absorption step is sampled or the trajectory leaves the space containing the suspension.

Any generic random optical trajectory γ contributing to the flux path integral in (4.9) can then be expressed as a dataset of sampled stochastic variables:

$$\gamma:[(0,1/2\pi,0),(R_1^{(s)},\Theta_1,\varphi_1),(R_2^{(s)},\Theta_2,\varphi_2),\ldots,(R_n^{(s)},\Theta_n,\varphi_n)\ldots].$$

Sequential vectors $\mathbf{x}_{n+1}$ and $\mathbf{x}_n$ are related by a linear matrix transformation $\Gamma[R_n{}^{(s)},\Theta_n,\varphi_n]$:

$$\mathbf{x}_{n+1}=\Gamma[R_n{}^{(s)},\Theta_n,\varphi_n]\mathbf{x}_n,\quad \text{if } R_n{}^{(s)}<R_n{}^{(a)}, \tag{5.7a}$$

$$\mathbf{x}_{n+1}=\Gamma[R_n{}^{(a)},\Theta_n,\varphi_n]\mathbf{x}_n,\quad \text{if } R_n{}^{(a)}<R_n{}^{(s)}. \tag{5.7b}$$

Using these rules, the bundle of u optical trajectories $\{\gamma(1)\cdots\gamma(u)\}$ representing the flux path integral (4.9) can be generated. The comparison of inequalities $R^{(a)}<R^{(s)}$ and $R^{(s)}<R^{(a)}$ functions as a roulette. The relative statistical probabilities of either outcome is determined by the ratio $a(h,\mathscr{S})b^{-1}(h)$. The $R^{(s)}$ become shorter on average as h increases from zero. If $\mathscr{S}$ is varied on [1,0] then only $a(h,\mathscr{S})$ and $\mathscr{P}(R^{(a)})$ are varied relative to fixed $b(h)$ and $\mathscr{P}(R^{(s)})$. Varying h

on (0,1) and $\mathscr{S}$ on [0,1] in any combination shifts the ratio $\mathscr{P}(R^{(a)})\mathscr{P}^{-1}(R^{(s)})$ and alters the relative probabilities of $R^{(a)}$ being preferentially selected at any scatter event, relative to $R^{(s)}$. The densities $\mathscr{P}(R^{(s)})$ and $\mathscr{P}(R^{(a)})$ illustrate that the shortest of the rectilinear optical interaction steps is always most probable, which is why it is selected from the sampled pair $(R^{(s)},R^{(a)})$.

In neutron transport simulation, mathematical and statistical optimization techniques were developed by Metropolis and Ulam.[23] The neutron path segments are sampled using the total inverse attenuation $(a+b)^{-1}$. All initial particles have a statistical weight w_0 of unity that is reduced by factor $b(a+b)^{-1}$ at each scatter event so that $w_n=w_0b^n(a+b)^{-n}\rightarrow 0$ as $n\rightarrow\infty$. Random migrations are terminated once $w_n<=w_{\text{th}}$, where w_{th} is a threshold weight. The problem is in accurately determining values for the threshold; an incorrect cutoff will skew the statistical acceptability. A correct application does improve statistics for very thick medias and for cases where particles undergo deep penetration with many hundreds or thousands of scattering events, such as in nuclear reactor and radiation shielding problems.[31,32] It is also tailored toward computing scalars like the average diffuse intensity. However, these techniques are superfluous and a hindrance for the optical vector flux calculations in biosuspensions of finite depth, which are also absorbing as well as scattering. For most biological applications, the depth is typically $d=0.5$ mm to 5 cm, so that trajectories in such medias can be generated and terminated more rapidly and efficiently using the alternative method, while maintaining adequate statistics. In this alternative formalism, vectorial fluxes $\mathscr{F}(\pm,\mathscr{E}:h,\mathscr{S})$ are ascertained more rapidly and effectively than a scalar fluence $\phi(\mathscr{E})$. In addition, the absorption effects of cells can be separated out from their scattering effects.

VI. VECTORIAL INTERSECTIONS OF DATA SURFACES

Given the radiance $\psi(0,\pi/2,0)$ on the initial data plane $z=0$, the scattered flux density $\mathscr{F}(+,\mathscr{E}:h,\mathscr{S})$ through data surface $z=\mathscr{E}$ is given by the flux path integral in (4.9). Since the bundle of optical paths $\{\gamma(p)\}$ vectorially intersects the data plane $\mathscr{E}$, one can easily ascertain the radiant flux densities $\mathscr{F}(\pm,\{\mathscr{E}\}:h,\mathscr{S})$ throughout the medium, by defining a complete set of data planes $\{\mathscr{E}\}$. If any optical trajectory scatters from $\mathbf{x}_n$ to $\mathbf{x}_{n+1}$, then the vector $\delta\mathbf{x}_n=\mathbf{x}_{n+1}-\mathbf{x}_n$ will vectorially intersect or pierce a subset of these data planes, consecutively and in either the net forward half-space ($0<\Theta_n<\pi/2$ and $0<\varphi_n<2\pi$) or the back half-space ($\pi/2<\Theta_n<0$ and $0<\varphi_n<2\pi$). In generating the stochastic set of optical Markov trajectories $[\gamma(1),\gamma(2),\ldots\gamma(p)\ldots\gamma(u)]$, the algorithm can record the vectorial intersections $\{\delta\mathbf{x}_n^{(p)}\}\cap(\mathscr{E})$, due to all successive scatterings of all $p=1$ to u trajectories with all specified interior data planes $\{\mathscr{E}\}$.

Given the spatial region $0<z<d$ containing the suspension, define a set of data planes as $\{\mathscr{E}\}=\{z(q)\}=\{z(1),z(2),\ldots z(q)\ldots z(v)\}$, for $q=1$ to integer v. These are simply generated by $z(q)=(q\times d\times v^{-1})$ for all $q=1$ to v. They are therefore parallel and equidistantly spaced along the interval $[0,d]$, and normal to the incident Fermat rays at $z=0$ that have $(z,\Theta_0,\varphi_0)=(0,\pi/2,0)$. The density of surfaces is determined by v and $d=z(v)$. Scattered flux densities $\mathscr{F}(\pm,q:h,\mathscr{S})$ exist through all these data surfaces for any given $1>h>0$ and $0<=\mathscr{S}<=1$. To each data plane $z(q)$ in the set $\{z(q)\}$, there is then assigned a set of real matrix elements $\{M(+,q:h,\mathscr{S})\}$, $\{M(-,q:h,\mathscr{S})\}$ and $\{C(+,q:h,\mathscr{S})\}$, for all $q=1$ to v, so that

$$\{M(+,q:h,\mathscr{S})\}=\{M(+,1:h,\mathscr{S}),M(+,2:h,\mathscr{S})\cdots M(+,q:h,\mathscr{S})\cdots M(+,v:h,\mathscr{S})\},$$

$$\{M(-,q:h,\mathscr{S})\}=\{M(-,1:h,\mathscr{S}),M(-,2:h,\mathscr{S})\cdots M(-,q:h,\mathscr{S})\cdots M(-,v:h,\mathscr{S})\},$$

$$\{C(+,q:h,\mathscr{S})\}=\{C(+,1:h,\mathscr{S}),C(-,2:h,\mathscr{S})\cdots C(+,q;h,\mathscr{S})\cdots C(+,v:h,\mathscr{S})\}.$$

The matrix elements $\{M(+,q:h,\mathscr{S})\}$ score all possible vectorial intersections of all stochastic optical trajectories $\{\gamma(p)\}$ for $p=1$ to u, through all $\{z(q)\}$ for $q=1$ to v, in the forward half-space for some combination $h>0$ and $0<=\mathscr{S}<=1$. Matrix elements $\{M(-,q:h,\mathscr{S})\}$ score all vectorial intersections of all stochastic optical trajectories $\{\gamma(p)\}$ for $p=1$ to u, through all $\{z(q)\}$ for $q=1$ to v, in the back half-space. Matrix elements $C(+,q:h,\mathscr{S})$ score all vectorial intersections normal to any $\{z(q)\}$ due to incident Fermat rays, which have $\Theta_0=\pi/2$. Initially, $\{M(+,q:h,\mathscr{S})\}=\{0,0,\ldots\}$, $M(-q:h,\mathscr{S})=\{0,0,\ldots\}$ and $C(+,q:h,\mathscr{S})=\{0,0,\ldots\}$.

To examine how the matrix elements are incremented within the sequence of operations for generating $\{\gamma(1)\cdots\gamma(p)\cdots\gamma(u)\}$, consider the nth-order scattering of the pth optical or Markovian trajectory $\gamma(p)$ in a red cell biosuspension whose biological state is described by h and $\mathscr{S}$. Then $\mathbf{x}_n^{(p)}\rightarrow\mathbf{x}_{n+1}^{(p)}$. The stochastic set $\{R_n^{(s)},R_n^{(a)},\theta_n,\varphi_n\}$ is generated. Suppose $R_n^{(s)}<R_n^{(a)}$, then from (5.7),

$$\mathbf{x}_{n+1}^{(p)}=\Gamma[R_n^{(s)},\theta_n,\varphi_n]\mathbf{x}_n^{(p)}.$$

Let $\mathbf{x}_{n+1}^{(p)}=(x_{n+1}^{(p)},y_{n+1}^{(p)},z_{n+1}^{(p)})$ and $\mathbf{x}_n=(x_n^{(p)},y_n^{(p)},z_n^{(p)})$ and consider the qth data surface $z(q)$. The following inequalities and operations are implemented:

$$\text{if } z_{n+1}^{(p)}>z(q)>z_n^{(p)} \text{ then } M(+,q{:}h,\mathscr{S})=M(+,q{:}h,\mathscr{S})+1;$$

$$\text{if } z_{n+1}^{(p)}<z(q)<z_n^{(p)} \text{ then } M(-,q{:}h,\mathscr{S})=M(-,q{:}h,\mathscr{S})+1;$$

$$\text{if } z_{n+1}^{(p)}>z_n^{(p)}>z(q) \text{ then } M(\pm,q{:}h,\mathscr{S})=M(\pm,q{:}h,\mathscr{S});$$

$$\text{if } z(q)>z_{n+1}^{(p)}>z_n^{(p)} \text{ then } M(\pm,q;h,\mathscr{S})=M(\pm,q{:}h,\mathscr{S});$$

$$\text{if } z_{n+1}^{(p)}<z_n^{(p)}<z(q) \text{ then } M(\pm,q{:}h,\mathscr{S})=M(\pm,q{:}h,\mathscr{S});$$

$$\text{if } z(q)<z_{n+1}^{(p)}<z_n^{(p)} \text{ then } M(\pm,q{:}h,\mathscr{S})=M(\pm,q{:}h,\mathscr{S});$$

$$\text{if } z_1^{(p)}>z(q)>0 \text{ then } C(+,q{:}h,\mathscr{S})=C(+,q{:}h,\mathscr{S})+1, \quad \text{for } n=1 \text{ only.}$$

This sequence is repeated for all data surfaces $\{z(q)\}$ for $q=1$ to v, for all scatterings of all $p=1$ to u optical Markov trajectories (although sequential, the process is inherently parallel). For sufficiently large u, the complete matrix elements $\{M(+,q{:}h,\mathscr{S})\}$ and $\{M(-,q{:}h,\mathscr{S})\}$ contain the equivalent information of the (unknown) flux solutions $\mathscr{F}(+,q{:}h,\mathscr{S})$ and $\mathscr{F}(-,q{:}h,\mathscr{S})$ of the radiative transfer equation. In addition, one has the option of filtering out scattering beyond a given order m, by only scoring vector intersections for $n<=m$. In this way, specific flux contributions of lower-order multiply scattered light can be separated out from the total flux.

If $\mathscr{F}_0$ is the incident flux density at initial data plane $z=0$, the solutions for scattered anisotropic fluxes $\mathscr{F}(\pm,q{:}h,\mathscr{S})$ through any data surface $z(q)$, for any suspension in state $(h,\mathscr{S},g)$, are

$$\begin{aligned}\mathscr{F}(+,q{:}h,\mathscr{S})&=\int_0^{\pi/2}\oint\psi_s(q,\Theta,\varphi)\cos\Theta\,\sin\Theta\,\delta\Theta\,\delta\varphi\\&=u^{-1}\mathscr{F}_0[M(+,q{:}h,\mathscr{S})\pm V(+,q{:}h,\mathscr{S})],\\\mathscr{F}(-,q{:}h,\mathscr{S})&=\int_{\pi/2}^{0}\oint\psi_s(q,\Theta,\varphi)\cos\Theta\,\sin\Theta\,\delta\Theta\,\delta\varphi\\&=u^{-1}\mathscr{F}_0[M(-,q{:}h,\mathscr{S})\pm V(+,q{:}h,\mathscr{S})],\end{aligned}$$

$$\mathscr{F}_c(+,q{:}h,\mathscr{S})=u^{-1}\mathscr{F}_0C(+,q{:}h,\mathscr{S})=\mathscr{F}_0\exp[-(a(h,\mathscr{S})+b(h))z(q)],$$

$$\mathfrak{T}(+,v{:}h,\mathscr{S})=u^{-1}[M(+,v{:}h,\mathscr{S})\pm V(+,v{:}h,\mathscr{S})],$$

$$\mathfrak{R}(-,0{:}h,\mathscr{S})=u^{-1}[M(-,0{:}h,\mathscr{S})\pm V(-,0{:}h,\mathscr{S})],$$

where the matrix elements $C(+,q{:}h,\mathscr{S})$ match the Beer–Lambert extinction law and $\mathfrak{T}(+,v{:}h,\mathscr{S})$ and $\mathfrak{R}(-,0{:}h,\mathscr{S})$ are the scattered transmittance and reflectance, respectively, at $z=z(v)=d$ and $z(0)=0$. The matrix elements $V(\pm,q{:}h,\mathscr{S})$ are the flux statistical variances or fluctuations due to u being finite. These variances can be computed from the positive and negative residuals of $M(+,q{:}h,\mathscr{S})$ and $M(-,q{:}h,\mathscr{S})$, with respect to the means $\langle M(+,q{:}h,\mathscr{S})\rangle$ and $\langle M(-,q{:}h,\mathscr{S})\rangle$ over a number of repeated calculations using the same input parameters. From

these, one can estimate variances. For typical computations they range from 2% to 5% (typically less than the symbol size for graphical representation). The $V(\pm,q{:}h,\mathscr{S})$ only begin to grow unacceptably large for very deep penetrations $z(q)$, which is avoided since d is finite or negligible for realistic problems. The collective ensemble behavior of the individual stochastic elements $\{\gamma(p)\}$ gives rise to stable macroscopic behavior, in this case the quantative flux solutions.

VII. COMPARISON IN THE DIFFUSION LIMIT

Since there are no general analytical solutions for $\mathscr{F}(\pm,q{:}h,\mathscr{S})$, the scattered flux solutions (6.1) are tested in the macroscopic diffusion limit, for a set of conditions where the diffusion limit is valid. This requires $b(h)\gg a(h,\mathscr{S})$ and weak anisotropy. The radiance of the transport equation (4.4) is expanded out as

$$\psi_s(\mathbf{x},\hat{\omega})=\phi(\mathbf{x})+(3/4\pi)D(\mathbf{x})\cdot\hat{\omega}, \tag{7.1}$$

where $\phi(x)$ is the average diffuse scalar intensity and $D(\mathbf{x})$ is the diffuse vectorial flux. When the generic phase function $\mathscr{P}(\theta)$ is a function of the angle θ only, a standard calculation[6,10] will give the linear Helmholtz scalar diffusion equation for $\phi(z)$ (for slab geometry). For an anisotropic blood cell suspension described by $(h,\mathscr{S},g)$, irradiated at plane $z=0$ by a coherent flux density $\mathscr{F}_0$, $\phi(z)$ satisfies

$$\frac{\partial^2\phi(z)}{\partial z^2}-\zeta^2\phi(z)=-\Lambda_0\exp[-(a(h,\mathscr{S})+b(h))z], \tag{7.2}$$

where $\zeta=\sqrt{[a(h,\mathscr{S})\times b(h)]}$ and where

$$\Lambda_0=[3b(h)b(h)+3(1-g)b(h)a(h,\mathscr{S})+3gb(h)(b(h)+a(h,\mathscr{S}))][\mathscr{F}_0/4\pi]. \tag{7.3}$$

The boundary conditions are

$$\phi(z)+\alpha\frac{\partial}{\partial z}\phi(z)+\frac{\Lambda_1(z)}{2\pi}=0,\quad \text{at } z=0, \tag{7.4a}$$

$$\phi(z)-\alpha\frac{\partial}{\partial z}\phi(z)+\frac{\Lambda_1(z)}{2\pi}=0,\quad \text{at } z=d, \tag{7.4b}$$

where $\Lambda_1=[b(\mathscr{S})g]/[a(h,\mathscr{S})+(1-g)b(h))]\mathscr{F}_0\exp[-(a(h,\mathscr{S})+b(h))z]$ and $\alpha=2/[3a(h,\mathscr{S})+3(1-g)b(h)]$. The general scalar solution is the sum of a particular solution $\phi_{\text{par}}(z)$ and a complimentary solution $\phi_{\text{com}}(z)$ so $\phi(z)=\phi_{\text{com}}(z)+\phi_{\text{par}}(z)$. The solution $\phi_{\text{com}}(z)$ must satisfy $d^2\phi_{\text{com}}(z)/dz^2-\zeta^2\phi_{\text{com}}(z)=0$, so that

$$\phi_{\text{com}}(z)=\xi_1\exp(\zeta z)+\xi_2\exp(-\zeta z), \tag{7.5}$$

with ξ_1 and ξ_2 constants. The particular solution $\phi_{\text{par}}(z)$ is found by $\phi_{\text{par}}(z)=\xi_3\exp[-(a(h,\mathscr{S})+b(h))z]$ and substituting back into (7.2) to obtain $\xi_3=-\Lambda_0[(a(h,\mathscr{S})+b(h))^2-\zeta^2]$. The complete solution is then

$$\phi(z)=\xi_1\exp(\zeta z)+\xi_2\exp(-\zeta z)+\xi_3\exp[-(a(h,\mathscr{S})+b(h))z], \tag{7.6}$$

where constants ξ_1, ξ_2, ξ_3 are derived from the boundary conditions at planes $z=0$ and $z=d$. The diffuse fluxes through the same set of data planes $\{z(q)\}$ for all $q=1$ to v, as previously defined, are then

$$\phi(q)=\xi_1\exp(\zeta z(q))+\xi_2\exp(-\zeta z(q))+\xi_3\exp[-(a(h,\mathscr{S})+b(h))z(q)], \tag{7.7a}$$

$$D(+,q{:}h,\mathscr{S})=2\pi[\phi(q)+\Omega(q)], \tag{7.7b}$$

$$D(-,q{:}h,\mathscr{S})=2\pi[\phi(q)-\Omega(q)], \tag{7.7c}$$

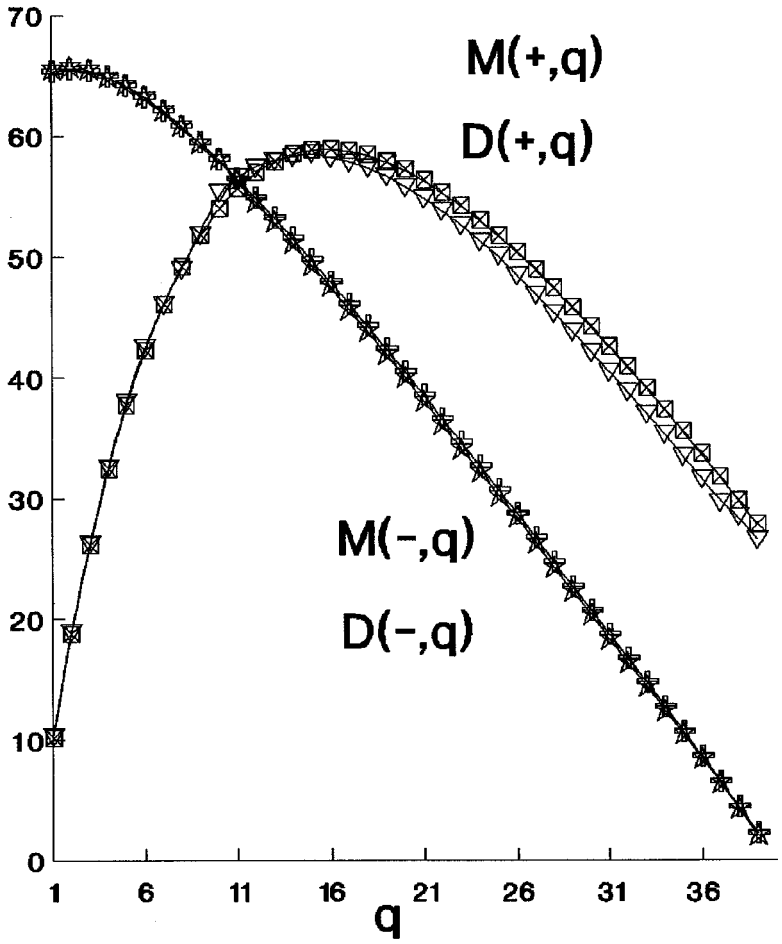

FIG. 1. Comparison of matrix elements $M(\pm,q)$ with diffusion theory solutions $D(\pm,q)$ when the diffusion approximation is strictly satisfied.

where $\Omega(z)=-(1/2\xi_2)d\phi(z)/dz$ and $\Omega(q)$ is the value at data plane $z=z(q)$. In the diffusive limit, the solutions should match the vectorial flux solutions $\mathscr{F}(\pm,q{:}h,\mathscr{S})$ computed from the stochastic algorithm:

$$D(+,q{:}h,\mathscr{S})=u^{-1}\mathscr{F}_0[M(+,q{:}h,\mathscr{S})\pm V(+,q{:}h,\mathscr{S})], \tag{7.8a}$$

$$D(-,q{:}h,\mathscr{S})=u^{-1}\mathscr{F}_0[M(-,q{:}h,\mathscr{S})\pm V(-,q{:}h,\mathscr{S})]. \tag{7.8b}$$

VIII. VERIFICATION AND ILLUSTRATIVE CALCULATIONS

The method was transformed to a compact computer code (using the language *C*) and Eq. (7.8) verified in the diffusive limit. Figure 1 shows a comparison of $D(\pm,q)$ and $M(\pm,q)$ for $a=0.1\ \mathrm{cm}^{-1}$, $b=99\ \mathrm{cm}^{-1}$, $g=0$, and $d=0.04$ cm with $u=10^4$ for $q=1-40$. This is for a set of generic test results where diffusion solutions (7.8) are strictly satisfied. These data were utilized in Ref. 37 to compare optical diffusion theory with a modified discrete ordinates algorithm adapted from nuclear engineering algorithms, for the purpose of computing laser generated thermal source profiles. The comparison is illustrated in Fig. 1, where $\mathscr{F}_0/u=1$. Here, $M(\pm,q)$ give the same solutions with as much accuracy as discrete ordinates, but far more easily, and with greatly reduced computational requirements. Unlike the $D(\pm,q)$ solutions, the $M(\pm,q)$ solutions can be derived for all possible optical and anisotropy conditions. Figures 2 and 3 quickly illustrate typical scattered flux computations into blood medias and erythrocytic suspensions using $a(h,\mathscr{S})$ and

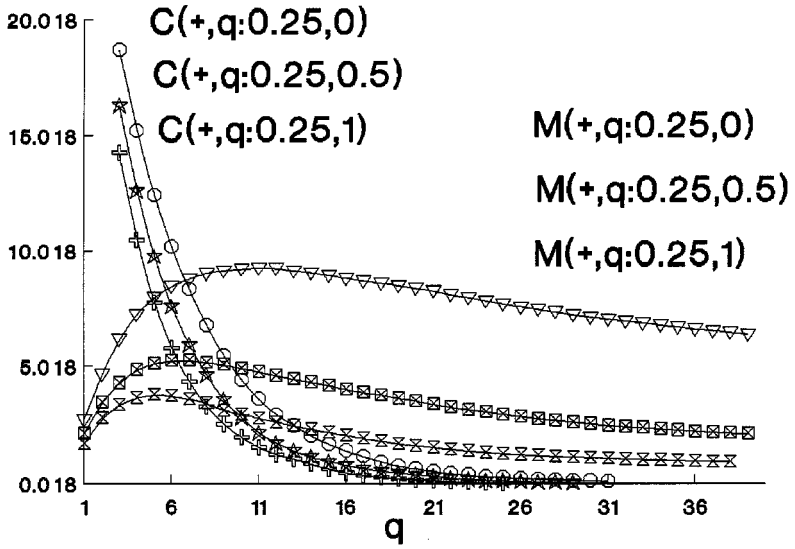

FIG. 2. Penetration of coherent or Fermat fluxes $C(+,q{:}h,\mathscr{S})$ and generation and transport of forward scattered fluxes $M(+,q{:}h,\mathscr{S})$ in a dilute anisotropic red cell suspension.

$b(h)$ data from Ref. 9 and with $g \gg 0$. Fluxes $D((\pm,q{:}h,\mathscr{S}))$ break down for some of these conditions. The effects on $M(+,q{:}h,\mathscr{S})$ of varying h and $\mathscr{S}$ on the intervals (0,1) and [0,1] are illustrated.

Figure 2 illustrates the generic decay of coherent optical beam $C(+,q{:}h,\mathscr{S})$ and generation of scattered fluxes $M(+,q;h,\mathscr{S})$ in a dilute erythrocytic suspension of depth $d=8$ mm, with fixed $h=0.25$, $g=0.9$, $u=3\times10^4$, with $\mathscr{S}=1$, $\frac{1}{2}$, 0 (at 695 nm) for all $q=1$ to $v=40$. As the Fermat beam decays due to scattering and absorption by suspended cells, scattered fluxes $M(+,q;h,\mathscr{S})$ are generated, which are equivalent to the exact solution $\mathscr{T}(+,q;h,\mathscr{S})$ of the radiative transport equation defined on data surfaces $\{z(q)\}$ for $q=1$ to v. The x axis is labeled by q (y-axis units are arbitrary). The effect of cell oxygenation $\mathscr{S}$ does not affect the scattering or

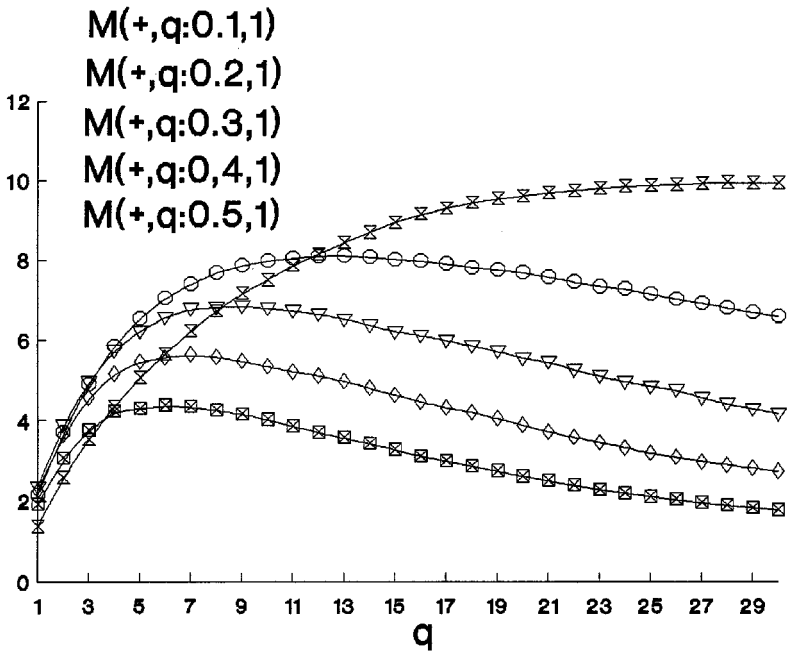

FIG. 3. Generation and transport of scattered fluxes $M(+,q{:}h,\mathscr{S})$ in anisotropic red cell suspension for various h at fixed $\mathscr{S}$.

the rate of generation of the scattered fluxes. The diffusion solution, however, breaks down for these conditions. The scattered beam penetrates through the sample since $g=0.9$ implies high anisotropy. As $\mathscr{S}$ is decreased on [0,1], the fluxes are monotonically reduced along all $z(q)$ for $q=1$ to v. Figure 3 illustrates the effect of varying h on (0,1) with fixed $\mathscr{S}$, for the forward scattered fluxes $M(+,q;h,\mathscr{S})$ for all $q=1$ to 30 along a depth of $d=8$ mm. Here, $\mathscr{S}=1$, $g=0.9$, $u=3\times10^4$, and $h=0.1$, 0.2, 0.3, 0.4, 0.5 at $\lambda=735$ nm. For $h=0.1$, the red cell suspension is dilute and so the scattered forward beam builds up more slowly through the $\{z(q)\}$ since the coherent source beam decays slowly due to the dilute number density of suspended cells. For $h=0.2$, the scattered beam builds up a maximum more rapidly since the density of suspended cellular scatter centers presented to the incident Fermat beam is greater. However, the amount of absorbing HbO_2 present also increases so the suspension is simultaneously more absorptive. Consequently, the scattered flux $M(+,q;h,\mathscr{S})$ decays more rapidly with depth. The effect is increased as h increases ($h=0.4$ corresponds to normal blood). The variances $V(+,q:h,\mathscr{S})$ for these computations are typically less than the graphical symbol size for $u>=10^4$. These conditions and dimensions are typical of many biophysical and biomedical optical/laser applications. Most accurate computations can be done in less than several minutes of cpu time using a typical UNIX mainframe.

IX. CONCLUSIONS

A stochastic-based vectorial method for finding equivalent statistical flux solutions to the radiative transfer equation for beam irradiation of suspensions or thin films of erythrocytes was developed. Although demonstrated explicitly for red blood cells, the general method should be applicable to many scattering problems related to biological or artificial suspensions of scattering–absorbing particles. The method works well for dilute suspensions as $h\rightarrow0.1$ and less, thin films ($d\rightarrow1$) and for calculating the flux contributions of multiscattered or quasi-Fermat light through both films and thick samples. The advantage over the diffusion approximation is that this approximation is not always satisfied for such medias, especially for cells or particles with nonspheroidal geometries and/or strong absorption properties, such as blood cells. The stochastic approach adapts easily to changes in boundary conditions and source beam profiles and is valid for all optical conditions. The method is also valid near the surface or the source where scattered flux begins to be generated. The advantage over Gaussian quadrature and discrete ordinates is in reduced software complexity and computing requirements. The method presented in this paper can be implemented in under 60–70 lines of compact code. Standard Monte Carlo techniques for photon transport adapted from nuclear physics deposit statistical weight in voxels and cut off photon trajectories via a roulette. This conventional method is specifically tailored toward computing scalars like fluence and average intensity in very thick medias, and requires very long computation time for even simple calculations. However, fluxes are usually more relevent. The alternative formalism will perform very many useful calculations with accuracy in typically 1–5 mins. The simple Brownian-like vectorial intersection method also enables a stochastic evaluation of the smooth scattered flux profiles to be deduced more efficiently and rapidly than the scalar fluence. The method begins to become less accurate as d increases, however, most blood vessels, laser biotargets, and realistic samples and cuvettes have $d<4$ cm, for which the method remains fast, accurate and adaptable.

A note on Tauber's expanding universe in conformally flat coordinates

Geoffrey Endean[a)]
University of Durham, Old Shire Hall, Durham, DH1 3HP, England

(Received 16 June 1997; accepted for publication 29 October 1997)

The solutions given by Tauber, based on conformally flat space–time, of Einstein's field equations for the Friedmann–Robertson–Walker, closed topology, dust model are corrected. The corrected solutions are shown to reduce to the standard textbook solutions obtained directly in Friedmann–Robertson–Walker coordinates, with the parameter identified as a component of the transformation to conformally flat space–time coordinates. The general significance of Tauber's work and its relationship to more recent papers by Endean on this subject are discussed. © *1998 American Institute of Physics.* [S0022-2488(98)04103-6]

I. INTRODUCTION

The principles of cosmology in conformally flat space-time (CFS) were laid down by Infeld and Schild.[1] In a recent series of papers, Endean[2–4] has developed these principles and has concluded that the Friedmann–Robertson–Walker (FRW), closed topology, dust model formulated in CFS coordinates provides a good fit with recent observations, as well as resulting in further observational predictions. In a much earlier paper, Tauber[5] solved Einstein's field equations for FRW space–time directly in CFS. This note reconciles Tauber's solutions for the closed topology, dust model with the standard textbook results and establishes the relationship of Tauber's contribution to Endean's more recent work.

II. BASIC EQUATIONS AND NOTATION

In Infeld and Schild's[1] notation, the FRW line element ds for the case of closed three-dimensional space topology may be written

$$ds^2 = d\tau'^2 - R_1^2 d\sigma^2,$$

$$\tau = \int d\tau'/R_1(\tau'),$$

$$R(\tau) = R_1(\tau');$$

$$ds^2 = R^2(\tau)(d\tau^2 - d\sigma^2),$$

$$d\sigma^2 = d\rho'^2 + \sin^2\ \rho'(d\theta^2 + \sin^2\ \theta.d\phi^2), \tag{2.1}$$

where ρ' is FRW radius. The prime has been added to the symbol so as not to confuse it with mass density for which the same symbol is used later in this paper. The CFS line element in Infeld and Schild's[1] notation is

$$ds^2 = \gamma(t,r)\{dt^2 - [dr^2 + r^2(d\theta^2 + \sin^2\ \theta.d\phi^2)]\}. \tag{2.2}$$

The finite transformation from (2.1) to (2.2) given by Infeld and Schild[1] may be expressed as

$$(t \pm r) = \tan[(\tau \pm \rho')/2]. \tag{2.3}$$

[a)]Electronic mail: 100710.2100@compuserve.com

 © 1998 American Institute of Physics

As explained below, apart from a factor of 2 and a change of symbol from τ to S, this agrees with Endean's[2] Eq. (8) combined with his Table I.

It is unfortunate that Infeld and Schild,[1] Tauber,[5] and Endean[2] have used different notations for the CFS metric function. Endean,[2] Eq. (2); Infeld and Schild,[1] Eq. (3.1) and Table III, Type 1; and Tauber,[5] Eqs. (1.5) and (1.6), define the metric function for closed topology, CFS coordinates, respectively, by

$$g^2(r,t)=\gamma(r,t)=F(r,t)=f(\tan S)/w^2, \tag{2.4}$$

where S is the function of the conformally flat radius and time coordinates r and t defined by Endean's[2] Eq. (8) combined with his Table I and

$$w=1-\tfrac{1}{4}(t^2-r^2). \tag{2.5}$$

Tauber[5] agrees with Endean[2] on the definition of the CFS coordinates r and t but, as stated in Tauber's[5] footnote (7), this definition differs by a factor of 2 from that of Infeld and Schild.[1] Also, it should be noted that Endean[2] does not explicitly define the function f.

There are further differences of notation relating to the FRW scale factor R. Endean,[2] Eq. (6), defines

$$\frac{dS(\tau)}{d\tau}=\frac{1}{R(\tau)}, \tag{2.6}$$

whereas Infeld and Schild,[1] Eq. (4.11) and see also Eq. (2.1) above, define

$$\frac{d\tau}{d\tau'}=\frac{1}{R(\tau)}, \tag{2.7}$$

while Tauber,[5] Eq. (1.2), defines

$$\frac{d\tau}{dT}=\frac{1}{R(\tau)}. \tag{2.8}$$

It may be noted that all three assign the same meaning to R, while Endean's[2] S is exactly the same variable as the τ of both Infeld and Schild[1] and of Tauber.[5] In the rest of this paper, S is used to signify this variable in preference to τ, while τ is taken to be the unmodified FRW time as in Endean.[2]

Infeld and Schild's[1] Eq. (4.41) and Tauber's[5] unnumbered equation between Eqs. (1.7a) and (1.7b), are the same basic equation which applies to the closed topology model. It may be expressed

$$R^2=\sec^2(S)f(\tan S). \tag{2.9}$$

Endean[2] does not repeat this result. However, combining this equation with Eq. (2.4) above produces

$$g(r,t)=R\cos S/w, \tag{2.10}$$

while Endean,[2] in Eq. (12), does give the following result for closed topology

$$g(r,t)=R\sin\rho'/r. \tag{2.11}$$

Equations (2.10) and (2.11) are consistent with each other provided that

$$\frac{r}{w}=\frac{\sin\rho'}{\cos S}. \tag{2.12}$$

Remembering that the prime has been added to FRW radius so as not to confuse it with mass density, it is easily confirmed that Eq. (2.12) is indeed an identity by using Eq. (8) of Endean.[2]

III. SOLUTION OF THE FIELD EQUATIONS

Tauber[5] solves Einstein's field equations directly in conformally flat coordinates. He gives, for the solution in the case of the closed topology dust model, his equations (3.12) and (3.12a) for the effective metric function and the density, respectively,

$$f^{1/4}(\sinh\ \theta) = \text{const}\ \cosh(\tfrac{1}{2}\theta)/\cosh\ \theta, \tag{3.1}$$

$$\rho = \rho_0[\cosh\ \theta/(1+\cosh\ \theta)]^3. \tag{3.2}$$

[In these equations, the variable θ is clearly not the same as the polar coordinate θ which appears in Eqs. (2.1) and (2.2).] It can be seen by the inspection of Tauber's[5] Figs. 3 and 4 that these solutions are suspect. Attempts to prove that they are correct by substituting back into his equations shows that they are not. The correct solutions of his equations for this case may be confirmed by checking with the equations to be

$$f^{1/4}(\sinh\ \theta) = \text{const}\ \sinh(\tfrac{1}{2}\theta)/\cosh\ \theta, \tag{3.3}$$

$$\rho = \rho_0[\cosh\ \theta/(\cosh\ \theta - 1)]^3. \tag{3.4}$$

The differences are small in terms of typing, the sort of errors that are easily missed in proofreading. But they are crucial to the reconciliation of Tauber's analysis with standard theory and Endean's work.

Taking the square of Eq. (3.3) and making the substitution $\sinh\theta = \tan S$ (checking through Tauber[5] confirms that this is the correct substitution), so that $\cosh\theta = \sec S$, one obtains

$$f^{1/2}(\tan\ S) = \text{const}(1-\cos\ S)\cos\ S, \tag{3.5}$$

so that, from Eq. (2.9)

$$R = K(1-\cos\ S), \tag{3.6}$$

where K is a constant. Combining this result with Eq. (2.6) gives

$$\tau = K(S-\sin\ S). \tag{3.7}$$

On the same basis, one obtains from Eq. (3.4)

$$\rho = \rho_0/(1-\cos\ S)^3 = \text{const}/R^3, \tag{3.8}$$

where use has been made of Eq. (3.6).

IV. DISCUSSION

Now Eqs. (3.6) and (3.7) are given in standard textbooks[6] but with S identified only as a parameter. Endean[2] made the identification between the CFS transformation variable S and the parameter in the open topology case and continued with the identification for the closed topology case in Endean.[3] Tauber[5] did not make this identification but he might have if his solutions had been correct. It was because he was aware of the identification that Endean was able, without too much difficulty, to spot the errors in Tauber's solutions. Equation (3.8) is also given in standard textbooks.[6]

The presence of the error in the determination of f would also have prevented Tauber from obtaining a correct formula for the closed topology, dust model, metric function in CFS. Finally, in the open topology case, while pointing out that his closed topology analysis could easily be transferred across, Tauber considered a different transformation. Reconciliation of the results based on this different transformation with the standard, open topology transformation and with standard, open topology theory requires further work.

V. CONCLUSION

The paper of Tauber[5] is most valuable, not only because when its solutions have been corrected it provides independent confirmation of standard theory and the basis for Endean's[2–4] work, but also because it applies, not just to the dust model, but to a range of equations of state for which analytical solutions are not available in standard textbooks. While Tauber[5] extends his analysis to calculate the Hubble factor in FRW coordinates, he does not deal with redshift in CFS coordinates. Indeed, the work of Endean[2–4] in identifying the CFS coordinates as the true time and distance coordinates and working out the consequences could not be said to have been anticipated by Tauber[5] at all. In one sense this is disappointing because there was always the possibility that Tauber might have provided more independent confirmation of the correctness of Endean's analysis.

Fast and slow solutions in General Relativity: The initialization procedure

(Received 9 June 1997; accepted for publication 3 November 1997)

We apply recent results in the theory of PDE, specifically in problems with two different time scales, to Einstein's equations near their Newtonian limit. The results imply a justification to post-Newtonian approximations when initialization procedures to different orders are made on the initial data. We determine up to what order initialization is needed in order to detect the contribution to the quadrupole moment due to the slow motion of a massive body as distinct from initial data contributions to fast solutions and prove that such initialization is compatible with the constraint equations. Using the results mentioned, the first post-Newtonian equations and their solutions in terms of Green's functions are presented in order to indicate how to proceed in calculations with this approach. © *1998 American Institute of Physics.* [S0022-2488(98)02902-8]

I. INTRODUCTION

A rigorous justification of the Newtonian limit approximation in General Relativity has been given in recent papers (Refs. 1 and 2). Assuming either symmetric hyperbolic equations for the matter (including appropriate boundary conditions for it), Ref. 1, or Vlasov type matter[2] it has been shown that given a Newtonian solution, there exists a nearby general relativistic solution for a time interval which is independent of the limiting parameter. The proofs of these results rely on ideas pioneered by Kreiss on dynamical systems with different time scales which, in turn, rely on energy estimates for symmetric hyperbolic systems.

The above mentioned results are based on an initialization procedure, that is, the proximity of full relativistic solutions to the Newtonian ones is obtained by choosing the initial data in a very special way, basically ensuring that the time derivatives of the solutions at the initial surface stay bounded in that limit. This initialization procedure is only needed to a finite order on the limiting parameter (which is taken to be one over the speed of light; rigorously it can be taken as $\varepsilon = v/c$, where v is a characteristic velocity of the matter fields, for example, the speed of sound) implying that the fast behaving parts of solutions stay under control order by order along the evolution.

In this paper we advance further into this problem by showing two things: first, that the General Relativity equations can be cast into a form on which the standard theory of different time scales applies (c.f. Refs. 3, 4, and 5). This substantially improves the results of Ref. 1, because it avoids singular terms outside the principal part which had to be dealt with in a very involved way. This gives further information on the behavior of the fast part of the solutions, which is the part that comes from the failure to initialize data to all orders. In particular, it gives the equations that the leading order fast behaving parts of the solutions satisfy and so its bulk behavior. This result should be important in studying the scattering of gravitational waves on slow varying sources.

To be able to apply these standard results (estimates) we shall assume that the sources for Einstein's equations also satisfy symmetric hyperbolic equations which are regular in the limit, and, if boundary conditions are needed to deal with them, that they are of such a nature as to allow for the estimates to hold. Admittedly there may be some problems to grant this to hold for some specific cases, but that is a problem on our understanding of the description of normal matter, and

is not very much related to the dynamics of the gravitional degrees of freedom, so we do not address this issue further.

Second, that the initialization procedure can be done to higher enough orders so that the quadrupole formula should follow. The initialization procedure implies some relations between initial data, besides the one implied by the constraint equations, and so the above mentioned results imply that we have to show that certain elliptic systems of equations have solutions with the appropriate asymptotic behavior. The result is only an argument, for the method used does not allow us to have estimates, and so to control evolution, all the way up to some portion of future null infinity, the region where the quadrupole formula should hold. A rigorous result for that issue should follow by studying evolution either along null cones, as considered by Winicour,[6] or along asymptotically null surfaces as studied by Friedrich.[7]

The plan of the paper is as follows: in Section II we introduce the general theory of different time scales systems and quote the relevant theorem. We then follow Ref. 1 and cast Einstein's equations as a symmetric–hyperbolic–elliptic system. By assigning units to the fields appearing in those equations, one can determine how the parameter ε appears in the system and in this way the solutions become a one parameter family of solutions to Einstein's equations. A further rescaling of the fields is needed so that the structure of the equations is in the form assumed in the hypothesis of the mentioned theorem.

In Section III we calculate the flux of energy coming from the slow part of the solution (i.e., the contribution to the flux of energy due to the slow motion of a massive body), and the flux of energy coming from the initial data without sources, that is the contribution from fast solutions. We conclude that one should initialize up to order three in ε, in order to isolate the contribution to the energy flux coming from the slow part of the solution. We further prove a Lemma stating that such initialization is consistent with the constraint equations, and so that solutions with these characteristics exists.

In an Appendix we look at the solution to the initialized data to order ε, and obtain an explicit solution in terms of the shift vector N^a and the source S^{ab}. This is done in order to illustrate how the general setting of the theory of different time scales produces the correct post-Newtonian equations to that order, and how to proceed if one wishes to compute higher order corrections.

II. PRELIMINARIES

The study of systems with different time scales reduces to the study of systems of partial differential equations which are singular in the limit of one of these time scales going to zero. The study of such a limit distinguishes between different classes of solutions according to their limiting behavior. Solutions which behave smoothly on the limit are called slow, they move according to the time scale which remains finite, those which do not have a well defined limit are called fast, they have dependence on the time scale we are setting to zero. As an example we consider the following system:

$$u_t = \frac{1}{\varepsilon}(u_x - v_x), \tag{1}$$

$$v_t = v_x . \tag{2}$$

Since the system is linear we can consider its Fourier modes, with the ansatz

$$\begin{pmatrix} u \\ v \end{pmatrix}(x,t) = \begin{pmatrix} u_0 \\ v_0 \end{pmatrix} \mathrm{e}^{i(kx-\omega t)},$$

we obtain

$$\begin{pmatrix} u \\ v \end{pmatrix}(x,t) = u_0 \begin{pmatrix} 1 \\ 0 \end{pmatrix} \mathrm{e}^{ik(x+t/\varepsilon)} + v_0 \begin{pmatrix} \dfrac{\varepsilon}{1-\varepsilon} \\ 1 \end{pmatrix} \mathrm{e}^{ik(x+t)}.$$

It is clear that the first term in this expression is a fast solution, while the second term is a slow one. Notice that for a solution to be slow it is necessary that its time derivative stay bounded, in particular at $t=0$. One of the main results of the theory of different time scales is that, under some circumstances, this condition is also sufficient. In particular this allow us to pick slow solutions from initial data requiring that a number of consecutive time derivatives at the initial time are bounded; this procedure is called initialization. Another interesting output of the theory is that it gives precise information on the evolution of the fast and slow parts.

We turn now to the general setting and quote the main results of the theory in the following theorem.

Theorem II.1 (Ref. 8; see also Ref. 9): *Let*

$$A^0{}_{ij}(\varepsilon u^k)\frac{\partial}{\partial t}u^j=\left(\frac{1}{\varepsilon}K^a{}_{ij}+A^a_{1ij}(u^k,\varepsilon)\right)\partial_a u^j+B_i(u^k,\varepsilon), \tag{3}$$

be a symmetric-hyperbolic system containing the small parameter ε; i.e., let the matrices K^a, A^a_1, and A^0 be symmetric and A^0 positive definite. Assume that the matrices A^a_1 and the vector B are continuous in ε uniformly in u for bounded u, and are C^s in u uniformly in ε with $s\geqslant s_0\equiv[n/2]+2$ and that the initial data $u(0,x,\epsilon)=(q_{ab}(x,0),p_{ab}(x,0),r^a{}_{bc}(x,0))$ lies in $H^s(\mathbf{R}^n)$. Then the solution $u(t,x,\epsilon)$ exists for a time T independent of ε. Moreover if the initial data for (3) is

$$u(0,x,\epsilon)=u_0(x)+\varepsilon\ \ u_1(x)+\mathcal{O}(\varepsilon^2),$$

where

$$K^a\partial_a u_0=0;$$

then

$$u(t,x,\epsilon)=u^0(t,x)+\epsilon[v^0(t,x)+\tilde{u}(t,x,\epsilon)]+\mathcal{O}(\epsilon^2),$$

with u^0 and $\tilde{u}$ satisfying

$$\begin{aligned} A^0(0)u^0_t+A^a_1(u^0,0)\partial_a u^0+K^a\partial_a v^0&=B_0,\\ K^a\partial_a u^0&=0,\\ u^0(0,x)&=u_0(x), \end{aligned} \tag{4}$$

and

$$\begin{aligned} [A^0(0)+\varepsilon u^0A^0_u(0)]\tilde{u}_t+A^a_1(u^0,0)\partial_a\tilde{u}+\frac{1}{\varepsilon}K^a\partial_a\tilde{u}&=B_1,\\ \tilde{u}(0,x)&=u_1(x)-v^0(0,x), \end{aligned} \tag{5}$$

respectively,

$$\begin{aligned} B_0&=B(t,x,u^0,0),\\ B_1&=B_\varepsilon(t,x,u^0,0)+(v^0+\tilde{u})B_u(t,x,u^0)\\ &\quad-(v^0+\tilde{u})A^a_u(u^0,0)\partial_a u^0-A^0(0)v^0_t-A^a(u^0,0)\partial_a v^0, \end{aligned}$$

and v^0 chosen in such a way that $K^a\partial_a u^0=0$.

The solutions of (5) are fast solutions depending on the choice of the initial data. There exists further local (in $\mathbf{T}^n$) refinements of these results, that give us information about the behavior of

these fast solutions; see, for example, Refs. 10, 11, and 5. These results should be a useful tool for the understanding of problems like the scattering of gravitational waves by slow moving bodies.

If we wanted the fast solution to appear in the second order of ε, u^0, and u^1 would have to satisfy equations similar to (4) and $\tilde{u}$ one similar to (5) (with different sources), so that u_t and u_{tt} remain bounded when $\varepsilon\to 0$ at $t=0$. Summarizing we can suppress the fast part up to $\mathcal{O}(\varepsilon^n)$, demanding that n-time derivatives stay bounded when $\varepsilon\to 0$.This procedure is called *initialization*; for more details see Refs. 8 and 3. Note that in the case of General Relativity the choice of initial data for the initialization procedure is not trivial for it must be consistent with the constraint equations.

In order to give a formulation of the post-Newtonian limit in General Relativity as an initialization procedure, we use the variables given in Ref. 1, such that the Einstein equations can be put as a symmetric hyperbolic–elliptic system. Defining the lapse function as

$$N\equiv\frac{1}{1-\varepsilon^2 U}, \tag{6}$$

with U being the Newtonian potential and

$$r^{ab}{}_c\equiv\frac{1}{2\varepsilon^3}\left(\partial_c q^{ab}-\frac{1}{2}q^{ab}q_{ed}\partial_c q^{ed}\right)\equiv\frac{1}{2\varepsilon^3\sqrt{q}}\partial_c(\sqrt{q}q^{ab}), \tag{7}$$

$$p^{ab}\equiv\frac{1}{\varepsilon^2}\bar{\pi}^{ab}, \tag{8}$$

where ∂_c is the derivative operator associated to a flat three-metric e^{ab} and q_{ab} is the three-metric induced on the hypersurfaces $t=$const. The evolution equations become

$$\begin{aligned}\dot{q}^{ab}=&-8\varepsilon^2 q^{ab}N\dot{U}+2\varepsilon^2(1-4\varepsilon^2U)N^3q^{1/2}(q^{ab}p-p^{ab})\\&-2\varepsilon^2q^{1/2}N\bar{D}^{(a}N^{b)}+2\varepsilon^2q^{ab}\bar{D}_cN^c,\end{aligned} \tag{9}$$

$$\begin{aligned}\dot{p}^{ab}=&-q^{3/4}N^{1/2}\frac{1}{\varepsilon}(q^{cd}\partial_d r^{ab}{}_c-2q^{c(a}\partial_c r^{b)d}{}_d)-2q^{1/2}\frac{1}{\varepsilon^2}q^{ab}(\Delta U-\rho)\\&+2S^{ab}+\varepsilon^2N^c\partial_c p^{ab}+\varepsilon F^{ab}(\varepsilon,r^{de}{}_c,p^{de},\partial_c U,\partial_c N^d),\end{aligned} \tag{10}$$

$$\begin{aligned}\dot{r}^{ab}{}_c=&-\frac{N^{1/2}}{q^{1/4}}\frac{1}{\varepsilon}(\partial_c p^{ab}-2\delta^{(a}_c\partial_d p^{b)d})+\frac{1}{\varepsilon}\{q^{ab}\partial_c\partial_d N^d-q^{d(b}\partial_c\partial_d N^{a)}\\&+\frac{4N^{1/2}}{q^{1/4}}\frac{1}{\varepsilon}\delta^{(a}_c J^{b)}+\frac{2}{\varepsilon}q^{ab}\partial_c(N\dot{U})+\varepsilon^2N^d\partial_d r^{ab}{}_c-2\varepsilon Nq^{ab}N^d\partial_c\partial_d U\\&+\varepsilon F^{ab}{}_c(\varepsilon,r^{ab}{}_c,p^{ab},\partial_c U,\dot{U},\partial_c N^a),\end{aligned} \tag{11}$$

where N^a is the shift, $\bar{D}_a$ is the covariant derivative associated with $\bar{q}_{ab}$, $\Delta\equiv\bar{q}^{ab}\partial_a\partial_b$, $F^{ab}=F^{ab}(\varepsilon,r^{ab}{}_c,p^{ab},\partial_c U,\partial_c N^a)$, $F^{ab}{}_c=F^{ab}{}_c(\varepsilon,r^{ab}{}_c,p^{ab},\partial_c U,\dot{U},\partial_c N^a)$, and all F's in the equations are smooth pointwise functions of all their arguments and the quadratic terms in $r^{ab}{}_c$ and p^{ab} are the highest powers the factors will appear in and are $\mathcal{O}(\varepsilon^2)$.

In these variables, the constraint equations become

$$\Delta U-\frac{1}{2}\varepsilon\partial_c r^{cd}{}_d=\rho+\varepsilon^2F(\varepsilon,r^{ab}{}_c,p^{ab},\partial_c U), \tag{12}$$

$$-2\partial_c p^{ca}=4J^a+\varepsilon^2F^a(\varepsilon,r^{ab}{}_c,p^{ab},\partial_c U), \tag{13}$$

$$r^{ab}{}_c=\frac{1}{2\varepsilon^3\sqrt{q}}\partial_c(\sqrt{q}q^{ab}). \tag{14}$$

The system (10)–(11) is symmetric hyperbolic, and has an energy estimate finite for fixed ε . In order to have an energy estimate bounded in the limit when $\varepsilon\to 0$ the authors in Ref. 1, choose a gauge (i.e., a selection of lapse and shift) that makes $r^{ab}{}_b\equiv 0$ and $\dot{r}^{ab}{}_b=0$. As a matter of fact one could relax this gauge choice to $r^{ab}{}_b\equiv\mathcal{O}(\varepsilon^\beta)$ and $\dot{r}^{ab}{}_b=\mathcal{O}(\varepsilon^\beta)$ where β is an arbitrary positive number that guarantees that the energy estimates stay bounded even when $\varepsilon\to 0$. In this paper we choose $\beta=3$, the reason for this choice depends on the initialization procedure and it shall become clear in the next Section.

This choice implies the following equations for N^a:

$$\partial_c D^c N^b-\partial^b D_c N^c-4(J^b+\partial^b N\dot{U})+2\varepsilon^2 q^{cb}N^d\partial_c\partial_d U-\varepsilon^2 G^b=0, \tag{15}$$

$$D_d N^d=-2N\dot{U}; \tag{16}$$

combining equations (15) and (16) we get

$$\partial_c D^c N^b+\partial^b D_c N^c-4J^b+2\varepsilon^2 q^{cb}N^d\partial_c\partial_d U-\varepsilon^2 G^b=0, \tag{17}$$

and the constraint equation (12) becomes

$$\Delta U=\rho+\varepsilon^2 F(\varepsilon,r^{ab}{}_c,p^{ab},\partial_c U). \tag{18}$$

Thus the system given by (10), (11), (13), (14), (17), and (18) constitutes a symmetric hyperbolic–elliptic system; the hyperbolic and elliptic part are given by the equations (10), (11) and (17), (18), respectively.

By inspection one can see that the source $B_i(u^k,\varepsilon)$ in (10) and (11) takes the form $B_i(u^k,\varepsilon)=(C_{ij}/\varepsilon)\,u^j+F_i(u^k,\varepsilon)$, where C_{ij} is a constant matrix. Since we want to apply Theorem II on this system, the source has to be smooth in ϵ, thus we rescale the variables (a similar rescaling is used in Ref. 2) in the following way:

$$\overline{r}^{ab}_c=\varepsilon r^{ab}_c, \quad \overline{p}^{ab}=\varepsilon p^{ab}, \quad \text{and} \quad q^{ab}=e^{ab}+\varepsilon^2\hat{h}^{ab}. \tag{19}$$

Since F^{ab} and F^{ab}_c have quadratic terms in the variables r^{ab}_c and p^{ab} , we obtain a system such as (3) with a source term depending smoothly on ε, namely,

$$\begin{aligned}\dot{q}^{ab}=&-8\varepsilon^2 q^{ab}N\dot{U}+2\varepsilon(1-4\varepsilon^2 U)N^3 q^{1/2}(q^{ab}\overline{p}-\overline{p}^{ab})\\&-2\varepsilon^2 q^{1/2}N\overline{D}^{(a}N^{b)}+2\varepsilon^2 q^{ab}\overline{D}_c N^c,\end{aligned} \tag{20}$$

$$\begin{aligned}\dot{\overline{p}}^{ab}=&-q^{3/4}N^{1/2}\frac{1}{\varepsilon}(q^{cd}\partial_d\overline{r}^{ab}{}_c-2q^{c(a}\partial_c\overline{r}^{b)d}{}_d)-2q^{1/2}\frac{1}{\varepsilon}q^{ab}(\Delta U-\rho)\\&+2\varepsilon S^{ab}+\varepsilon^2 N^c\partial_c\overline{p}^{ab}+\varepsilon F^{ab}(\varepsilon,\overline{r}^{de}{}_c,\overline{p}^{de},\partial_c U,\partial_c N^d),\end{aligned} \tag{21}$$

$$\begin{aligned}\dot{\overline{r}}^{ab}{}_c=&-\frac{N^{1/2}}{q^{1/4}}\frac{1}{\varepsilon}(\partial_c\overline{p}^{ab}-2\,\delta^{(a}_c\partial_d\overline{p}^{b)d})+q^{ab}\partial_c\partial_d N^d-q^{d(b}\partial_c\partial_d N^{a)}\\&+\frac{4N^{1/2}}{q^{1/4}}\delta^{(a}_c J^{b)}+2q^{ab}\partial_c(N\dot{U})+\varepsilon^2 N^d\partial_d\overline{r}^{ab}{}_c-2\varepsilon^2 N q^{ab}N^d\partial_c\partial_d U\\&+\varepsilon^2 F^{ab}{}_c(\varepsilon,\overline{r}^{ab}{}_c,\overline{p}^{ab},\partial_c U,\dot{U},\partial_c N^a).\end{aligned} \tag{22}$$

In the same gauge as before, the constraint equations and the equation for the shift vector become

$$\Delta U = \rho + \varepsilon^2 F(\varepsilon, \overline{r^{ab}}_c, \overline{p^{ab}}, \partial_c U), \tag{23}$$

$$-2\partial_c \overline{p^{ca}} = 4\epsilon J^a + \varepsilon^2 F^a(\varepsilon, \overline{r^{ab}}_c, \overline{p^{ab}}, \partial_c U), \tag{24}$$

$$\overline{r^{ab}}_c = \frac{1}{2\varepsilon^2\sqrt{q}}\partial_c(\sqrt{q}q^{ab}), \tag{25}$$

and

$$\partial_c D^c N^b + \partial^b D_c N^c - 4J^b + 3\varepsilon F^b + \varepsilon^2(4Nq^{cb}N^d\partial_c\partial_d U - F^{ab}{}_b) = 0. \tag{26}$$

From now on, to simplify the notation, we will work without bars on the variables p^{ab} and $r^{ab}{}_c$. As stated in the Introduction we assume that the above system is part of a bigger symmetric hyperbolic system which includes the equations for the sources. These are assumed to be regular in ε and of such a type that global estimates can be obtained.

The existence of a smooth one parameter family of solutions is guaranteed because the energy estimates corresponding to the hyperbolic part of the system stay bounded when $\varepsilon \to 0$ via a particular gauge choice, the elliptic variables satisfy a Gårding estimate in terms of the hyperbolic ones, and the boundedness in time of the solutions is guaranteed via the initialization procedure.

Another interesting problem which can be tackled with these techniques is whether for each given fast post-Newtonian solution (i.e., a fixed slow background solution and a highly oscillating part), there exists a solution to the full Einstein equations in the *same interval of existence* and that it remains close for that whole interval to the first one in some norm. In other words, whether the solution to (3) exists and converges to the solution of the limit equation for as long as the General Relativistic solution exists.

III. THE POST-NEWTONIAN LIMIT AS AN INITIALIZATION PROCEDURE

The Theorem quoted above implies that solutions to Einstein's equations [the system given by (20) to (22)], can be split into slow and fast ones, and this is dictated by the choice of initial data.

In the context of General Relativity, the slow part of the solution contains information about the matter fields that are moving with velocity much lower than c, that is with their own time scale, while the fast part contains information essentially due to the arbitrariness of initial data and so is not related directly to the sources.

In the context of symmetric–hyperbolic systems, this means that on the post-Newtonian approximations the highly oscillatory part (fast part) of the solution should be suppressed up to higher order of ε. For example, if we initialize (choose initial data such that the time derivative of the solution is bounded independently of ε at $t=0$) up to order ε, the slow part appears at zeroth order and the fast one at first order. The degree of initialization needed depends on the problem at hand. In this Section we show that to get the quadrupole formula one needs to initialize up to order ε^3. This guarantees that no contribution from fast solutions will be present in the gravitational radiation flux, to that order. We then show that such an initialization is possible.

To know to which order of ε we have to initialize, we estimate the contribution to the energy flux at $\mathscr{I}^+$ from both sources and vacuum (pure initial data) solutions. Since we are only interested in the order of ε at which these contributions appear, it is enough to estimate them in linearized gravity, for example see Ref. 12.

To this end we keep the physical units in the Einstein equations (i.e., $k = G \neq 1$), and we check the power at which ε appears in the radiation due to the matter (quadrupole contribution, with zero initial data) and in the radiation due to the initial data (without sources).

In this approximation,

$$g_{\mu\nu} = \eta_{\mu\nu} + \delta g_{\mu\nu},$$

and, in the absence of matter, the energy flux in the x^1 direction due to the initial data can be calculated as

$$ct^{01}=\frac{1}{32\pi k\varepsilon^3}\left[\delta\dot{g}_{23}^2+\frac{1}{4}(\delta\dot{g}_{22}-\delta\dot{g}_{33})^2\right],$$

where the dot means a time derivative. In the presence of matter, with initial data $\delta g_{\mu\nu}=\delta\dot{g}_{\mu\nu}=0$, we can use the same formula as above because at a large distance from the bodies the matter waves can be considered as plane waves. By (19) $\delta g_{ij}=\varepsilon^2\hat{h}_{ij}$, the flux of energy becomes

$$ct^{01}=\frac{\varepsilon}{32\pi k}\left[\dot{\hat{h}}_{23}{}^2+\frac{1}{4}(\dot{\hat{h}}_{22}-\dot{\hat{h}}_{33})^2\right],$$

Thus choosing the initial data $\hat{h}_{ij}=\varepsilon^\alpha f_{ij}$, the flux becomes $ct^{01}=\mathcal{O}(\varepsilon^{2\alpha+1})$, while the flux due to the matter is calculated as $ct^{01}=\mathcal{O}(\varepsilon^5)$ (see the Appendix). We conclude that initializing up to order ε^3, the fast part of the solution will contribute at a higher order in ε to the flux. This means that the initial data will be chosen as

$$u|_{t=0}=u_0+\varepsilon u_1+\varepsilon^2u_2+\varepsilon^3u_3+\mathcal{O}(\varepsilon^4).$$

This is equivalent to demanding that the first four time derivatives of the solution stay bounded in $t=0$ when $\varepsilon\to0$ (c.f. Ref. 3).

Besides a hyperbolic system, Eintein's equations also include a constraint system, that is, equations which relate the otherwise arbitrary initial data fields with each other. Thus it must be checked that these constraints are consistent with the initialization procedure. To do that, we add to the equations arising from the initialization the constraint equations, and show that in the resulting system the hierarchy of elliptic systems admits solutions with the correct asymptotic fall off.

Defining the pseudotensor h^{ab},

$$\sqrt{q}q^{ab}=\sqrt{e}e^{ab}+\varepsilon^2h^{ab}, \tag{27}$$

and from the definition of $r^{ab}{}_c$ given by (25), we obtain

$$r^{ab}{}_c=\frac{1}{2\sqrt{q}}\partial_c(h^{ab}).$$

Choosing the gauge condition $r^{ab}{}_b=0$ and $\dot{r}^{ab}{}_b=0$ up to order ε^3, and demanding boundedness of the first four time derivatives, we get that $p_i{}^{ab}$ and $h_i{}^{ab}$, $i=0,1,2,3$ should satisfy at $t=0$ the following differential equations:

$$\begin{aligned}
&\Delta_0h_0{}^{ab}=0,\\
&\partial_cp_0{}^{ab}=0,\\
&\Delta_0h_1{}^{ab}=0,\\
&\Delta_0(p_1{}^{ab}+\partial^{(a}N_0{}^{b)})=0,\\
&\Delta_0(p_2{}^{ab}+\partial^{(a}N_1{}^{b)})=0,\\
&\Delta_0h_2{}^{ab}=2S_0{}^{ab}+F_0{}^{ab}+\partial^{(a}\dot{N}_0{}^{b)}-e^{ab}F_0,\\
&\Delta_0(p_3{}^{ab}+\partial^{(a}N_2{}^{b)})=-2\dot{S}_0{}^{ab}-\dot{F}_0{}^{ab}+2e^{ab}\dot{F}_0-\partial^{(a}\ddot{N}_0{}^{b)}+\partial^dF_0{}^{ab}{}_d\\
&\qquad\qquad-\partial^{(a}F_1{}^{b)}-2e^{ab}\partial^e(N_0{}^d\partial_e\partial_dU_0),\\
&\Delta_0h_3{}^{ab}=2S_1{}^{ab}-F_1{}^{ab}+\partial^{(a}\dot{N}_1{}^{b)}-2e^{ab}F_1,
\end{aligned}\tag{28}$$

where $\Delta_0 = e^{ab}\partial_a\partial_b$. These equations are consistent with the constraint up to order ε^3, for they have been included in the set. Thus we can prove the following

Lemma III.1: The equation system for the initial data given by (28) admits a solution.

Proof: From the first five equations, we can choose

$$p_0{}^{ab}=0,\ r_0{}^{ab}{}_c=0,\ \ r_1{}^{ab}{}_c=0,\ p_1{}^{ab}=-\partial^{(a}N_0{}^{b)}, \tag{29}$$

and

$$p_2{}^{ab}=-\partial^{(a}N_1{}^{b)}. \tag{30}$$

Therefore, in order to guarantee the existence of solutions, it is sufficient to prove that the sources in the three last equations in (28) have the decay $\mathcal{O}(1/r^3)$ (cf. Ref. 13).

Due to the choice made in (29), the functions $F_0{}^{ab}$, F_0, $F_0{}^{ab}{}_c$, F_1, $F_1{}^a$, and $F_1{}^{ab}$ are all linear functions of $\partial_a(U_0N_0{}^b)$. Similarly $\dot{F}_0$ and $\dot{F}_0{}^{ab}$ depend linearly on $\partial_t\partial_a(U_0N_0{}^b)$. But the vector fields $N_0{}^a$ and $N_1{}^a$ and the function U_0 satisfy the following differential equations:

$$\Delta_0 N_0{}^a+\partial^a\partial_c N_0{}^c=4J_0{}^a,$$

$$\Delta_0 N_1{}^a+\partial^a\partial_c N_1{}^c=4J_1{}^a,$$

$$\Delta_0 U_0=\rho_0.$$

Thus, because of the compactness of the support of the sources, the standard theory of elliptic systems in $\mathbf{R}^n$ (cf. Ref. 13) assures that U_0, $N_0{}^a$, and $N_1{}^a$, and their time and spatial derivatives decay as $\mathcal{O}(1/r)$ and $\mathcal{O}(1/r^2)$ respectively. Hence we conclude that the sources decay fast enough as to ensure the existence of solutions for $h_2{}^{ab}$, $h_3{}^{ab}$, and $p_3{}^{ab}+\partial^{(a}N_2{}^{b)}$.

In order to have a well defined $p_3{}^{ab}$, it remains to prove that $N_2{}^a$ exists. Note that the gauge condition implies that $N_2{}^a$ must satisfy

$$\Delta_0 N_2{}^a+\partial^a\partial_c N_2{}^c=4J_2{}^a-3F_1{}^a-4N_0{}^d\partial_d\partial^a U_0+2F_0{}^{ab}{}_b,$$

and that the source in this equation has a fast enough decay. Thereby the existence of $N_2{}^a$ and so of $p_3{}^{ab}$ is assured. □

This Lemma proves that we can initialize at least up to order ε^3, hence by Theorem II.1 we can assure that the fast solution appears in an order higher than ε^3

APPENDIX: THE EVOLUTION OF THE INITIALIZED DATA

In order to exemplify the initialization procedure, we initialize up to order ε and solve explicitly the equation for u^0, u^1, and v^0, choosing the initial data u_0 and u_1 as in (29). In fact this choice gives that $\tilde{u}$ becomes a slow solution suppressing the fast one to an higher order of ϵ.

Claim: *Given the initial data*

$$u(0,x)=\varepsilon\begin{pmatrix} p_1^{ab} \\ r_{1c}{}^{ab}\end{pmatrix}(x)+\mathcal{O}(\varepsilon^2)$$

$$=\varepsilon\begin{pmatrix} -\partial^{(a}N^{b)} \\ 0\end{pmatrix}(x)+\mathcal{O}(\varepsilon^2),$$

where $N^a(x)$ is the solution of the elliptic equation (32) for $t=0$, the solution of (21) and (22) can be written as

$$u(t,x)=\varepsilon\begin{pmatrix} p_1^{ab} \\ r_{1c}{}^{ab} \end{pmatrix}+\mathcal{O}(\varepsilon^2)$$

$$=\varepsilon\begin{pmatrix} \tilde{p}^{ab}+v^{ab} \\ \tilde{r}^{ab}{}_c+v^{ab}{}_c \end{pmatrix}+\mathcal{O}(\varepsilon^2),$$

with

$$v=\begin{pmatrix} -\partial^{(a}N^{b)} \\ 0 \end{pmatrix}$$

and

$$\tilde{p}^{ab}=\int_{|\mathbf{x}-\mathbf{x}'|\leqslant t/\varepsilon}\frac{\Gamma_1^{ab}(t-\varepsilon|\mathbf{x}-\mathbf{x}'|,\mathbf{x}')}{|\mathbf{x}-\mathbf{x}'|}\,d^3x'+\partial^{(a}N^{b)},$$

$$\tilde{r}_c^{ab}=\varepsilon\,\partial_c\int_{|\mathbf{x}-\mathbf{x}'|\leqslant t/\varepsilon}\frac{\Gamma_2^{ab}(t-\varepsilon|\mathbf{x}-\mathbf{x}'|,\mathbf{x}')}{|\mathbf{x}-\mathbf{x}'|}\,d^3x',$$

where $\Gamma_1^{ab}=-(\Delta\partial^{(a}N^{b)})+2\varepsilon^2\dot{S}^{ab}$ *and* $\Gamma_2^{ab}=\partial^{(a}\dot{N}^{b)}+2S^{ab}$, ρ *and* J^a *have compact support in* R^3. *Furthermore, the asymptotic behavior of* $\tilde{u}$ *is* $\mathcal{O}(1/r)$.

Proof: Since $u_0=0$ and thereby $K^a\partial_a u_0=0$, Theorem II.1 assures that

$$u(t,x,\epsilon)=u^0(t,x)+\epsilon[v(t,x)+\tilde{u}(t,x,\epsilon)]+\mathcal{O}(\epsilon^2).$$

By applying (4) and (5) on the equations system given by (21) and (22), we obtain that u^0, and v will satisfy

$$\begin{aligned} &\dot{p}_0^{ab}+\partial^c v^{ab}{}_c-2\,\partial^{(a}v^{b)d}{}_d=0,\\ &\dot{r}_{0c}{}^{ab}+\partial_c v^{ab}-2\,\delta_c^{(a}\partial_d v^{b)d}=-\partial_c\partial^{(b}N^{a)}+4\,\delta_c^{(a}J^{b)},\\ &K^a\partial_a u^0=0. \end{aligned}\tag{A1}$$

At this order of ε the constraint equations and the gauge become

$$\begin{aligned} &\Delta U=\rho,\\ &-2\,\partial_c p_0^{ca}=0,\\ &r_{0c}{}^{ab}=\frac{1}{2}\partial_c h_0^{ab},\\ &\partial_c\partial^c N^b+\partial^b\partial_c N^c=4J^b, \end{aligned}\tag{A2}$$

where h^{ab} is a pseudotensor defined in (27). Choosing

$$v=\begin{pmatrix} -\partial^{(a}N^{b)} \\ 0 \end{pmatrix},$$

the system (A1) becomes

$$\begin{aligned} &u_t^0=0,\\ &K^a\partial_a u^0=0, \end{aligned}\tag{A3}$$

$$u_0(x)=0,$$

which is trivially satisfied by $u^0(t,x)=0$.

Considering now the equation for $\tilde{u}$, namely

$$\tilde{u}_t+\frac{1}{\varepsilon}K^a\partial_a\tilde{u}=B_1, \tag{A4}$$

$$\tilde{u}(0,x)=u_1(x)-v^0(0,x)=0,$$

with

$$B_1=\begin{pmatrix} 2S^{ab}+\partial^{(a}\dot{N}^{b)} \\ 0 \end{pmatrix},$$

we obtain the following system:

$$\dot{\tilde{p}}^{ab}+\frac{1}{\varepsilon}\partial^c\tilde{r}^{ab}{}_c=2S^{ab}+\partial^{(a}\dot{N}^{b)}, \tag{A5}$$

$$\dot{\tilde{r}}^{ab}{}_c+\frac{1}{\varepsilon}\partial_c\tilde{p}^{ab}=0, \tag{A6}$$

and the constraint and the gauge become

$$\Delta U=\rho,$$

$$\partial_c p_1^{ca}=-2J^a,$$

$$r_{1c}{}^{ab}=\frac{1}{2}\partial_c h_1^{ab},$$

$$\partial_c\partial^c N^b+\partial^b\partial_c N^c=4J^b. \tag{A7}$$

Since $\tilde{p}^{ab}=p_1^{ab}-v^{ab}$ and $\tilde{r}_c{}^{ab}=r_{1c}{}^{ab}$, instead of (A5) we consider the differential equations

$$\dot{p}_1^{ab}+\frac{1}{\varepsilon}\partial^c r_{1c}{}^{ab}=2S^{ab},$$

$$\dot{r}_{1c}{}^{ab}+\frac{1}{\varepsilon}\partial_c p_1^{ab}=-\frac{1}{\varepsilon}\partial_c\partial^{(a}\dot{N}^{b)}. \tag{A8}$$

The equations system (A8) is clearly consistent with the gauge (A7). Taking the time derivative to the system above, we obtain

$$\Box p_1^{ab}=-(\Delta\partial^{(a}N^{b)}+2\varepsilon^2\dot{S}^{ab}),$$

$$\Box h_1^{ab}=2\varepsilon(\partial^{(a}\dot{N}^{b)}+2S^{ab}) \tag{A9}$$

$$:=2\varepsilon\Gamma_2^{ab}$$

and the solution of the second equation in (A9) can be written as

$$h_1^{ab}=2\varepsilon\int_{|\mathbf{x}-\mathbf{x}'|\leqslant t/\varepsilon}\frac{\Gamma_2^{ab}(t-\varepsilon|\mathbf{x}-\mathbf{x}'|,\mathbf{x}')}{|\mathbf{x}-\mathbf{x}'|}\,d^3x'.$$

Because of the decay of the source, when $|\mathbf{x}| \gg |\mathbf{x}'|$, we write $|\mathbf{x}-\mathbf{x}'| \approx |\mathbf{x}| - \hat{n}\cdot\mathbf{x}'$, where $\hat{n} = \mathbf{x}/|\mathbf{x}|$. Hence in this first approximation we have

$$h_1^{ab} \approx \frac{2\varepsilon}{r} \int_{|\mathbf{x}-\mathbf{x}'| \leqslant t/\varepsilon} \Gamma_2^{ab}(t - \varepsilon r + \varepsilon \hat{n}\cdot\mathbf{x}', \mathbf{x}') d^3x',$$

similarly we calculate p_1^{ab}. □

Following this procedure we can generate the solution that has as initial data (28) and the functions $u^2(t,x)$ and $u^3(t,x)$ obey more similar equations than do $u^0(t,x)$ and $u^1(t,x)$.

Remark III.1: In the calculus of the flux of energy due to the matter fields, we use the pseudotensor field calculated above instead of the spatial components of the perturbation of the metric. The difference between them can be calculated using equations (19) and (25), and because they have the same expansion in ε they can be considered as equal.

(Received 14 July 1997; accepted for publication 7 November 1997)

It is shown that higher-weighted representations of rotation groups can be constructed using multilinear functions in geometric algebra. Methods for obtaining the irreducible representations are found, and applied to the spatial rotation group, SO(3), and the proper Lorentz group, $SO^+(1,3)$. It is also shown that the representations can be generalized to non-linear functions, with applications to relativistic wave equations describing higher-spin particles, such as the Rarita–Schwinger equations. The internal spin degrees of freedom and the external space–time degrees of freedom are handled within the same mathematical structure. © *1998 American Institute of Physics.* [S0022-2488(98)00903-7]

I. INTRODUCTION

The vector and spinor representations of rotation groups are well known. In this paper we show that it is possible to extend these to higher-weighted representations by using multilinear functions of vector variables. Our representations are constructed using the language of geometric algebra, an introduction to which is given in the following subsection.

First we show how to construct the representations of an arbitrary rotation group $SO^+(p,q)$ and demonstrate the methods for finding their irreducible components. The most important method is monogenic decomposition,[1] which can be refined by considering the symmetry between the arguments of the function. A monogenic function belongs to the null space of the vector derivative (the Dirac operator). Analysis of the monogenic properties of functions forms an important part of Clifford analysis.

We use these methods to find the irreducible representations of the rotation group of Euclidean 3-space SO(3) and the proper Lorentz group $SO^+(1,3)$. In both cases we show how to find all the integral- and half-integral-spin representations of the groups. These are useful in constructing wave equations describing higher-spin particles.

In the last section we examine the Dirac equation and its generalizations to higher-spin wave equations, such as the Rarita–Schwinger equations. We show that the multilinear representations can be extended to encompass non-linear functions, and these can be used to construct the wavefunctions. This provides a unified method for describing the internal and external degrees of freedom of a higher-spin particle. In using geometric algebra we are able to overcome one of the deficiencies in the matrix formulation of linear algebra, that it is not easily able to relate linear and non-linear methods. Polynomial projection[1] enables us to immediately construct the non-linear functions which form the basis of the space–time part of the wavefunction from the multilinear functions derived earlier for the spin part of the wavefunction.

A. Geometric algebra

Geometric algebra is based upon Clifford algebra with an emphasis on the geometric interpretation of elements of the algebra rather than their matrix representations. Here we present a brief introduction to geometric algebra and the conventions that are used in this paper. More comprehensive introductions can be found in Hestenes and Sobczyk[2] and Gull, Lasenby and Doran.[3]

Geometric algebra is a graded algebra in which the fundamental product is the geometric product. Vectors, which have grade 1, will be written in lower case Roman letters (a, b, etc.). The geometric product of vectors ab can be split into its symmetric and antisymmetric parts,

$$ab = a \cdot b + a \wedge b, \tag{1}$$

where

$$\begin{aligned} a \cdot b &\equiv \tfrac{1}{2}(ab + ba), \\ a \wedge b &\equiv \tfrac{1}{2}(ab - ba). \end{aligned} \tag{2}$$

The inner product $a \cdot b$ is scalar-valued (grade 0). The outer product $a \wedge b$ represents a directed plane segment produced by sweeping a along b. This new element is called a bivector and has grade 2. By introducing more vectors, higher-grade elements can be constructed, trivectors (grade 3) $a \wedge b \wedge c$ represent volumes and so on, up to the dimension of the space under consideration. A grade-r element of the algebra is called an r-vector and a general element of the geometric algebra, possibly consisting of many grades, is called a multivector. If we multiply an r-vector A_r by an s-vector B_s the geometric product can be expanded as follows:

$$A_r B_s = \langle A_r B_s \rangle_{r+s} + \langle A_r B_s \rangle_{r+s-2} + \cdots + \langle A_r B_s \rangle_{|r-s|}, \tag{3}$$

where $\langle C \rangle_t$ denotes projecting out the grade-t elements of C. The notation for inner and outer products is retained for the lowest and highest grade elements in this expansion,

$$\begin{aligned} A_r \wedge B_s &\equiv \langle A_r B_s \rangle_{r+s}, \\ A_r \cdot B_s &\equiv \langle A_r B_s \rangle_{|r-s|}. \end{aligned} \tag{4}$$

We use the convention that inner and outer products take precedence over geometric products in expressions.

In addition we define the commutator product, which is equal to half the commutator bracket,

$$A \times B = \tfrac{1}{2}(AB - BA) = \tfrac{1}{2}[A, B]. \tag{5}$$

Reversion is the operation by which the order of vectors in a geometric product is reversed, it is defined by

$$\widetilde{AB} = \widetilde{B}\widetilde{A}, \tag{6}$$

where a vector reverses to give itself, $\widetilde{a} = a$.

Although geometric algebra can be constructed in an entirely basis-free form, in many applications it is useful to introduce a set of basis vectors. The geometric algebra with signature (p,q) which will be denoted as $\mathcal{G}_{p,q}$ has $n = p + q$ orthonormal basis vectors, $e_i, i = 1, \ldots, n$ which obey

$$e_i \cdot e_j = \begin{cases} 1, & i = j = 1, \ldots, p, \\ -1, & i = j = p+1, \ldots, p+q, \\ 0, & i \neq j. \end{cases} \tag{7}$$

The grade-r space in this algebra is denoted $\mathcal{G}^{\,r}_{p,q}$.

The highest grade element that can be formed from this basis has grade n and is called the pseudoscalar. It is defined by

$$I \equiv e_1 \wedge e_2 \wedge \cdots \wedge e_n = e_1 e_2 \cdots e_n. \tag{8}$$

All grade-n elements must be a scalar multiple of the pseudoscalar.

In this paper we make use of some results of geometric calculus, which is based on the vector derivative. If we write a vector in terms of its components, $a=a^i e_i$, then the vector derivative with respect to a is defined as

$$\partial_a \equiv e^i \frac{\partial}{\partial a^i}, \tag{9}$$

where the reciprocal vectors are defined by

$$e^i \equiv (-1)^{i-1}(e_1 \wedge \cdots \wedge \check{e}_i \wedge \cdots \wedge e_n) I^{-1}, \tag{10}$$

and the check on $\check{e}_i$ denotes that it is omitted from the product. The vector derivative, besides being an operator, also inherits the properties of a vector from a. The vector derivative with respect to position x is given the symbol ∇,

$$\nabla \equiv \partial_x . \tag{11}$$

In this paper we use the properties of multilinear functions which are functions in geometric algebra that are linear in all of their arguments. A function,

$$M(a_1, \ldots, a_k), \tag{12}$$

which takes values in any part of the geometric algebra and is linear in its k vector arguments will be called k-linear.

There are two geometric algebras, the Pauli algebra and the space–time algebra, which for reasons of convention have their own notation.

B. The Pauli algebra

The Pauli algebra $\mathcal{G}_{3,0}$ is the geometric algebra of three dimensional Euclidean space. The three basis vectors are σ_1, σ_2 and σ_3, which satisfy

$$\sigma_j \cdot \sigma_k = \delta_{jk} . \tag{13}$$

The pseudoscalar of the algebra is

$$i \equiv \sigma_1 \sigma_2 \sigma_3 . \tag{14}$$

The algebra has eight basis elements,

1	$\{\sigma_k\}$	$\{i\sigma_k\}$	i
1 scalar	3 vectors	3 bivectors	1 pseudoscalar
grade 0	grade 1	grade 2	grade 3

(15)

C. The space–time algebra

The space–time algebra (STA) is the geometric algebra of Minkowski space–time, $\mathcal{G}_{1,3}$. The basis vectors are γ_0, γ_1, γ_2 and γ_3, which satisfy

$$\gamma_\mu \cdot \gamma_\nu = \eta_{\mu\nu} = \mathrm{diag}(+---). \tag{16}$$

We also define the bivectors,

$$\sigma_k = \gamma_k \gamma_0 \quad (k=1,2,3), \tag{17}$$

and the pseudoscalar,

$$i=\gamma_0\gamma_1\gamma_2\gamma_3=\sigma_1\sigma_2\sigma_3. \tag{18}$$

These definitions are compatible with those for the Pauli algebra given above, because the Pauli algebra is a sub-algebra of the STA. The STA has 16 basis elements,

1	$\{\gamma_\mu\}$	$\{\sigma_k, i\sigma_k\}$	$\{i\gamma_\mu\}$	i
1 scalar	4 vectors	6 bivectors	4 trivectors	1 pseudoscalar
grade 0	grade 1	grade 2	grade 3	grade 4

(19)

Vectors in the STA have a projective relation to those in the Pauli algebra,

$$a\gamma_0=a_0+\mathbf{a}, \tag{20}$$

where $a_0=a\cdot\gamma_0$ and $\mathbf{a}=a\wedge\gamma_0$. The bivector $\mathbf{a}$ in the STA corresponds to the vector in the Pauli algebra relative to the frame defined by the unit timelike vector γ_0.

II. REPRESENTATIONS OF ROTATION GROUPS

In this section we shall develop the formalism we need to describe higher-weighted representations of the rotation group $\mathrm{SO}^+(p,q)$ and find its irreducible representations.

A. The representations

Any rotation belonging to the group $\mathrm{SO}^+(p,q)$ leaves the inner product of two vectors in the geometric algebra $\mathcal{G}_{p,q}$ unchanged. Such a rotation is described by a rotor R, an even-graded element of the algebra which satisfies

$$R\tilde{R}=1. \tag{21}$$

Rotors are used to define the two types of representation of the the rotation group. The one-sided representations, which will be denoted as $\hat{\mathrm{U}}_R$, in which the rotor acts one-sidedly on a multivector ψ,

$$\hat{\mathrm{U}}_R[\psi]=R\psi, \tag{22}$$

and the two-sided representations, which will be denoted as $\hat{\mathrm{V}}_R$, in which the rotor R acts two-sidedly on a multivector M,

$$\hat{\mathrm{V}}_R[M]=RM\tilde{R}. \tag{23}$$

The group $\mathrm{Spin}^+(p,q)$ of which the one-sided representations are members is a double covering of the group $\mathrm{SO}^+(p,q)$. This follows from the fact that in the two-sided representations, the rotation represented by a rotor R could equally well be represented by $-R$,

$$\hat{\mathrm{V}}_{(-R)}=\hat{\mathrm{V}}_R,$$

but this does not hold for the one-sided representations.

We extend the carrier spaces of these two types of representations to multilinear functions of vector variables by defining their actions on k-linear functions to be

$$\hat{\mathrm{U}}_R[\psi(a_1,\ldots,a_k)]=R\psi(\tilde{R}a_1R,\ldots,\tilde{R}a_kR), \tag{24}$$

$$\hat{\mathrm{V}}_R[M(a_1,\ldots,a_k)]=RM(\tilde{R}a_1R,\ldots,\tilde{R}a_kR)\tilde{R}. \tag{25}$$

Most rotors can be written in the form

$$R=\exp\left(\frac{1}{2}C\right), \tag{26}$$

where C is a bivector. If C is a simple bivector then it defines the plane in which the rotation occurs. The algebra of the bivectors $\mathcal{G}^2_{p,q}$, which is closed under the commutator product (5), is equivalent to the Lie algebra so(p,q) of the rotation group.[4]

By writing the operator $\hat{\mathrm{U}}_R$ in a form similar to (26) we can define the linear operator $\hat{\mathrm{L}}_C$ which corresponds to C,

$$\hat{\mathrm{U}}_R\equiv\exp\left(\frac{1}{2}\hat{\mathrm{L}}_C\right). \tag{27}$$

Take for example a linear function $\psi(a)$ which transforms under $\hat{\mathrm{U}}_R$. In order to find the action of $\hat{\mathrm{L}}_C$ on $\psi(a)$ we write $C=\alpha B$, where α is a scalar and use (26) to substitute for R,

$$\hat{\mathrm{U}}_R[\psi(a)]=\exp\left(\frac{1}{2}\alpha\hat{\mathrm{L}}_B\right)\psi(a)=e^{(1/2)\,\alpha B}\psi(e^{-(1/2)\,\alpha B}ae^{(1/2)\,\alpha B}). \tag{28}$$

Differentiating with respect to α and setting $\alpha=0$, we find that

$$\tfrac{1}{2}\,\hat{\mathrm{L}}_B\psi(a)=\tfrac{1}{2}B\psi(a)+\psi(a\cdot B). \tag{29}$$

The factors of $\frac{1}{2}$ in this equation arise naturally from the definition of the rotor (26). The set of operators $\hat{\mathrm{L}}_B$ form a representation of the Lie algebra which obeys the commutation relation

$$[\hat{\mathrm{L}}_B,\hat{\mathrm{L}}_C]=\hat{\mathrm{L}}_{[B,C]}, \tag{30}$$

or writing the same expression using the commutator product,

$$\hat{\mathrm{L}}_B\times\hat{\mathrm{L}}_C=\hat{\mathrm{L}}_{B\times C}. \tag{31}$$

The geometric algebra $\mathcal{G}_{p,q}$ has $\frac{1}{2}n(n-1)$ linearly-independent bivectors, thus SO(p,q) has $\frac{1}{2}n(n-1)$ generators.

Extending $\hat{\mathrm{L}}_B$ to act on functions with k arguments is straightforward,

$$\frac{1}{2}\,\hat{\mathrm{L}}_B[\psi(\cdots)]=\frac{1}{2}B\psi(\cdots)+\sum_{i=1}^{k}\psi(\ldots,a_i\cdot B,\ldots); \tag{32}$$

each argument makes a contribution of one term to the expression. A similar procedure gives the action of $\hat{\mathrm{L}}_B$ on functions which transform two-sidedly,

$$\frac{1}{2}\,\hat{\mathrm{L}}_B[M(\cdots)]=B\times M(\cdots)+\sum_{i=1}^{k}M(\ldots,a_i\cdot B,\ldots). \tag{33}$$

B. Invariant subspaces

We must find the irreducible representations of the rotation group. To this end we now seek the invariant subspaces of the representations.

The simplest kind of invariant subspace is one in which elements have a definite symmetry among their arguments. An operator $\hat{\mathrm{T}}_{ij}$ can be defined which exchanges the ith and jth arguments of a function,

$$\hat{\mathrm{T}}_{ij}\psi(\ldots,a_i,\ldots,a_j,\ldots)=\psi(\ldots,a_j,\ldots,a_i,\ldots), \tag{34}$$

which is used to construct operators which symmetrize or antisymmetrize between the ith and jth arguments of a function,

$$\hat{\mathrm{S}}_{ij} \equiv \tfrac{1}{2}(1+\hat{\mathrm{T}}_{ij}),$$
$$\hat{\mathrm{A}}_{ij} \equiv \tfrac{1}{2}(1-\hat{\mathrm{T}}_{ij}). \tag{35}$$

These operators commute with the action of the group, so if a function has symmetric or antisymmetric arguments, the action of the group does not change this property. Combinations of $\hat{\mathrm{S}}_{ij}$ and $\hat{\mathrm{A}}_{ij}$ can be constructed to represent all distinct symmetries between the arguments of a k-linear function. A general product of these operators will be denoted as $\hat{\mathrm{Y}}$. It can be shown that there is a one-to-one correspondence between these functions and the order-k Young tableaux.

A two-sided representation preserves the grade of an object which it transforms. This property can be shown by considering the action of $\hat{\mathrm{V}}_R$ on an r-vector $A_r = a_1 \wedge a_2 \wedge \cdots \wedge a_r$ where $a_1, a_2, \ldots, a_r$ are vectors. Since $R\widetilde{R}=1$,

$$\hat{\mathrm{V}}_R[A_r] = RA_r\widetilde{R} = (Ra_1\widetilde{R}) \wedge (Ra_2\widetilde{R}) \wedge \cdots \wedge (Ra_r\widetilde{R}), \tag{36}$$

which is also be an r-vector, so $\hat{\mathrm{V}}_R$ preserves the grades of all r-vectors, formally,

$$\hat{\mathrm{V}}_R[\mathscr{G}^{\,r}_{p,q}] = \mathscr{G}^{\,r}_{p,q}. \tag{37}$$

A one-sided representation does not preserve the grade of an object, however, since rotors are even-graded elements of the algebra, this representation separates the space of multivectors into even and odd grades, formally,

$$\hat{\mathrm{U}}_R[\mathscr{G}^{+}_{p,q}] = \mathscr{G}^{+}_{p,q},$$
$$\hat{\mathrm{U}}_R[\mathscr{G}^{-}_{p,q}] = \mathscr{G}^{-}_{p,q}. \tag{38}$$

We shall call a one-sided irreducible representation a spinor representation. A spinor representation can also accommodate an ideal structure. A spinor or spinor-valued function ψ can be multiplied on the right by an idempotent element of the algebra $E=E^2$ to project it into a right ideal of the algebra,

$$\psi = \psi E. \tag{39}$$

The ideal structure is preserved by the action of $\hat{\mathrm{U}}_R$ since the rotor acts only on the left.

Another property that is not changed by the action of the group is that of monogenicity. If a function $\mathscr{M}(a_1, \ldots, a_k)$ is monogenic, it has the property

$$\partial_{a_j}\mathscr{M}(a_1, \ldots, a_k) = 0, \tag{40}$$

for all $j=1,2,\ldots,k$. This property is unchanged by the action of a rotor. Take, for example, a function which transforms under $\hat{\mathrm{U}}_R$,

$$\partial_{a_j}\hat{\mathrm{U}}_R[\mathscr{M}(a_1, \ldots, a_k)] = \partial_{a_j} R\mathscr{M}(a'_1, \ldots, a'_k), \tag{41}$$

where $a'_j = \widetilde{R}a_jR$. Using the chain rule to rearrange the transformed function,

$$\partial_{a_j} R\mathscr{M}(a'_1, \ldots, a'_k) = \partial_{a_j}(\widetilde{R}a_jR)\cdot\partial_{a'_j} R\mathscr{M}(a'_1, \ldots, a'_k)$$
$$= R\partial_{a'_j}\mathscr{M}(a'_1, \ldots, a'_k). \tag{42}$$

Thus, under the action of $\hat{U}_R$, the monogenic properties of a function are not changed,

$$\hat{U}_R[\partial_{a_j}\mathscr{M}(a_1,\ldots,a_k)]=R\partial_{a'_j}\mathscr{M}(a'_1,\ldots,a'_k). \tag{43}$$

A similar argument applies to the double-sided transformation (25). From this, it can be shown that monogenicity is also preserved under the action of elements of the Lie algebra. We shall denote any monogenic function by the primary label $\mathscr{M}$.

The grade-invariance property of the two-sided transformation and monogenic invariance do not define mutually exclusive invariant subspaces and so cannot be used simultaneously to find the irreducible representations. We conclude that the irreducible representations of rotation groups consist of basis functions which have distinct symmetry among their arguments. For functions which transform one-sidedly, they correspond to particular terms in the monogenic decomposition and possibly have an ideal structure or, for functions which transform two-sidedly, they possess a definite grade.

C. Monogenic decomposition

In the last section we proved that the monogenic properties of a function are not changed by the action of the rotation group or its Lie algebra. Arbitrary k-linear functions can be decomposed into monogenic and non-monogenic parts in a similar manner to Taylor decomposition of functions in one dimension.

An inner product can be defined between two k-linear functions, ξ and η,

$$\langle\xi|\,\eta\rangle=\langle\xi(\partial_{a_1},\ldots,\partial_{a_k})\,\tilde{\eta}(a_1,\ldots,a_k)\rangle, \tag{44}$$

which is invariant under the action of both types of representation of the rotation group. A complex structure can always be added to this inner product. The functions are orthogonal if $\langle\xi|\,\eta\rangle=0$. For simplicity it will be assumed that at least one of the functions is not null. A function $\psi(a_1,\ldots,a_k)$ can be decomposed into a monogenic part and a part orthogonal to it:

$$\psi(a_1,\ldots,a_k)=\mathscr{M}(a_1,\ldots,a_k)+M(a_1,\ldots,a_k), \tag{45}$$

where

$$M(a_1,\ldots,a_k)=a_1\psi_1(a_2,\ldots,a_k)+a_2\psi_2(a_1,a_3,\ldots,a_k)+\cdots+a_k\psi_k(a_1,\ldots,a_{k-1}). \tag{46}$$

The fact that each term in M is orthogonal to $\mathscr{M}$ follows easily from the definition of the inner product, since for any function $\xi(a_1,\ldots,a_{j-1},a_{j+1},\ldots,a_k)$ which does not depend on a_j,

$$\begin{aligned}&\langle a_j\xi(a_1,\ldots,a_{j-1},a_{j+1},\ldots,a_k)|\mathscr{M}(a_1,\ldots,a_k)\rangle\\&\quad=\langle\xi(a_1,\ldots,a_{j-1},a_{j+1},\ldots,a_k)|\partial_{a_j}\mathscr{M}(a_1,\ldots,a_k)\rangle=0,\end{aligned} \tag{47}$$

by the monogenic properties of $\mathscr{M}$. Recursive use of the partial decomposition produces the complete monogenic decomposition,

$$\psi(a_1,\ldots,a_k)=\sum_{l=0}^{k}M_l(a_1,\ldots,a_k), \tag{48}$$

where

$$\begin{aligned}M_0(a_1,\ldots,a_k)&=\mathscr{M}(a_1,\ldots,a_k),\\M_l(a_1,\ldots,a_k)&=\sum_{\pi}a_{\pi(1)}\ldots a_{\pi(l)}\mathscr{M}_{\pi}(a_{\pi(l+1)},\ldots,a_{\pi(k)}),\end{aligned} \tag{49}$$

where the sum runs over all permutations π of the numbers $1,\ldots,k$. The decomposition is unique and the M_l are orthogonal,

$$\langle M_j|M_l\rangle=0, \quad \text{for } j\neq l. \tag{50}$$

Under the action of $\hat{\mathrm{U}}_R$, the function M_l transforms as

$$\hat{\mathrm{U}}_R[M_l(a_1,\ldots,a_k)]=\sum_{\pi} a_{\pi(1)}\ldots,a_{\pi(l)}\hat{\mathrm{U}}_R[\mathscr{M}_{\pi}(a_{\pi(l+1)},\ldots,a_{\pi(k)})], \tag{51}$$

similarly for $\hat{\mathrm{V}}_R$. This shows that only the monogenic part of the function is transformed, the polynomial of vectors remaining unchanged.

We conclude that any arbitrary k-linear function can be constructed out of monogenic functions as in (48).

The symmetry between the arguments can be used to refine the monogenic decomposition,

$$\psi(a_1,\ldots,a_k)=\sum_{l=0}^{k}\sum_{\hat{\mathrm{Y}}}\hat{\mathrm{Y}}M_l(a_1,\ldots,a_k), \tag{52}$$

where M_l is defined as before (49) and the decomposition is summed over all possible symmetries among the arguments, $\hat{\mathrm{Y}}$. This is known as the Fischer decomposition.[1]

III. REPRESENTATIONS OF SO(3)

In this section we will investigate the multilinear representations of the rotation group of Euclidean space, SO(3).

A. Generators and eigenstates

The Pauli algebra $\mathscr{G}_{3,0}$ has three linearly-independent bivectors, $i\sigma_1$, $i\sigma_2$ and $i\sigma_3$, so SO(3) has three generators, for which the following notation is introduced:

$$\hat{\mathrm{J}}_k\equiv\tfrac{1}{2}\hat{\mathrm{L}}_{i\sigma_k}, \tag{53}$$

for $k=1,2,3$. Since $i\sigma_k^2=-1$ these are compact generators. The $\{\hat{\mathrm{J}}_k\}$ obey the commutation relation

$$[\hat{\mathrm{J}}_k,\hat{\mathrm{J}}_l]=-\epsilon_{klm}\hat{\mathrm{J}}_m. \tag{54}$$

This relation differs from the usual convention because the generators are related to the bivectors of the Pauli algebra, rather than the vectors as in more conventional treatments.

The representations will be classified as eigenstates of the generators. To do this we need to introduce a complex structure, but rather than using the scalar imaginary we shall use an operation within the real geometric algebra to play the same role. The geometric operation that we choose will be denoted by $\hat{\mathrm{J}}$.

The spin of a particle is described by two quantum numbers which give the total spin and the spin in a particular plane. The 'total spin' operator is the Casimir operator of the group,

$$\hat{\mathbf{J}}^2\equiv\hat{\mathrm{J}}_1{}^2+\hat{\mathrm{J}}_2{}^2+\hat{\mathrm{J}}_3{}^2. \tag{55}$$

Denoting this as the square of a vector is somewhat misleading, but we shall retain this notation for the sake of convention. One of the generators must be chosen to complete our commuting set of operators. The conventional choice is $\hat{\mathrm{J}}_3$ which measures the spin in the $i\sigma_3$ plane. The states are described in terms of the eigenstates of these two operators, the eigenvalues of which are s and m, respectively. Acting on an abstract state $|sm\rangle$,

$$\hat{\mathbf{J}}^2|sm\rangle=-s(s+1)|sm\rangle, \tag{56}$$

$$\hat{\mathrm{J}}_3|sm\rangle=\hat{\jmath}m|sm\rangle. \tag{57}$$

The raising and lowering operators are the same as in conventional treatments,

$$\hat{\mathrm{J}}_{\pm}=\hat{\mathrm{J}}_1\pm\hat{\jmath}\hat{\mathrm{J}}_2. \tag{58}$$

The spin-s irreducible representation will be referred to as $D(s)$. Products of the representations obey the familiar Clebsch–Gordon decomposition,

$$D(s_1)\otimes D(s_2)\equiv D(s_1+s_2)\oplus\cdots\oplus D(|s_1-s_2|). \tag{59}$$

B. The spin-$\frac{1}{2}$ representation

The spin-$\frac{1}{2}$ representation is the fundamental spinor representation which could take values in the even or odd sectors of the algebra. It is more convenient to let spinor ψ take values in the even sub-algebra $\mathcal{G}^{+}_{3,0}$, of which the basis elements are

$$\{1,i\sigma_1,i\sigma_2,i\sigma_3\}. \tag{60}$$

Translating the conventional representation into geometric algebra[5,6] it is found that the spin-$\frac{1}{2}$ representation is complexified by right-multiplication by $i\sigma_3$,

$$\hat{\jmath}\psi\equiv\psi i\sigma_3. \tag{61}$$

The even sub-algebra is closed under this operation.

Using the raising and lowering operators (58) the spin-up and spin-down basis states $\chi_{\pm}$ are found to be

$$\begin{aligned}\chi_{+}&=1,\\ \chi_{-}&=i\sigma_1.\end{aligned} \tag{62}$$

Coefficients of these states are defined over the ''complex'' field, $\{1,\hat{\jmath}\}$ so a general state takes values over the whole even sub-algebra. The convention for the basis states used here differs slightly from those of Doran *et al.*[6] since we have adopted a different convention for the generators.

C. The spin-1 representation

The vector space of the Pauli algebra $\mathcal{G}^{1}_{3,0}$ has three basis vectors which could form a basis for the spin-1 representation $D(1)$. We cannot use the same complexification operation as the spin-$\frac{1}{2}$ representation here, but we note that the space of bivectors $\mathcal{G}^{2}_{3,0}$ could also form a suitable basis for $D(1)$. So to complexify this representation we employ an *ad hoc* construction: the pseudoscalar $i=\sigma_1\sigma_2\sigma_3$, which has a negative square, is used to complexify the representation

$$\hat{\jmath}A\equiv iA. \tag{63}$$

A consequence of this is that the $D(1)$ representation is vector- and bivector-valued and has 3 complex or 6 real degrees of freedom. The complexification operations we have defined for the spin-$\frac{1}{2}$ and the spin-1 representations at first sight appear to be incompatible, but later we shall show that they can be reconciled.

Using the raising and lowering operators the three basis states A_{sm} can be constructed,

$$\begin{aligned}A_{1,1}&=\frac{1}{\sqrt{2}}(\sigma_1+i\sigma_2),\\ A_{1,0}&=-i\sigma_3,\end{aligned} \tag{64}$$

$$A_{1,-1}=\frac{1}{\sqrt{2}}(\sigma_1-i\sigma_2),$$

the coefficients of which take values over the ''complex'' field $\{1,\hat{\mathrm{j}}\}$.

D. Relating spin-$\frac{1}{2}$ and spin-1 representations

Here we shall attempt to relate the spin-$\frac{1}{2}$ representations to the spin-1 representations and reconcile the differing complexification operators. This process will be very useful later in constructing higher-spin representations.

We can attempt to construct a spin-1 state from two spin-$\frac{1}{2}$ states, ψ_1 and ψ_2, in the form

$$M=\psi_1\Gamma\tilde{\psi}_2, \tag{65}$$

where Γ is a fixed multivector to be determined. If the spinors are transformed under $\hat{\mathrm{U}}_R$ we find that

$$\psi_1\Gamma\tilde{\psi}_2\overset{R}{\mapsto}\hat{\mathrm{U}}_R[\psi_1]\Gamma\hat{\mathrm{U}}_R[\tilde{\psi}_2]=R\psi_1\Gamma(R\psi_2)\tilde{}=R\psi_1\Gamma\tilde{\psi}_2\tilde{R}=\hat{\mathrm{V}}_R[\psi_1\Gamma\tilde{\psi}_2], \tag{66}$$

so M transforms like an integral-spin representation. Taking the product of the representations, M will transform as

$$D\left(\frac{1}{2}\right)\otimes D\left(\frac{1}{2}\right)=D(1)\oplus D(0). \tag{67}$$

Since Γ is a multivector, M will take values in all possible grades of the algebra. The scalar and pseudoscalar parts can be identified with the spin-0 representation, since these grades are invariant under rotation,

$$\phi=\langle\psi_1\Gamma\tilde{\psi}_2\rangle_{0,3}, \tag{68}$$

and the vector and bivector parts are identified with the spin-1 representation as in the previous section,

$$A=\langle\psi_1\Gamma\tilde{\psi}_2\rangle_{1,2}. \tag{69}$$

Inserting the spin-$\frac{1}{2}$ basis states into (69), we find that Γ is

$$\Gamma\equiv(1+\sigma_3)\sigma_1. \tag{70}$$

The presence of the idempotent $\frac{1}{2}(1+\sigma_3)$ in Γ ensures that the differing complexification operators defined earlier are consistent.

E. Half-integral-spin representations

To find a general half-integral-spin representation, we will be looking for spinor-valued functions which transform under $\hat{\mathrm{U}}_R$. The complexification operator for these functions is the same as that for the spinor representation.

Consider a spinor-valued linear function, $\psi(a)$, which transforms under $\hat{\mathrm{U}}_R$. The monogenic decomposition (48) can be used to analyze the transformation properties of the function,

$$\psi(a)=\mathscr{M}(a)+a\chi, \tag{71}$$

where $\mathscr{M}(a)$ is the monogenic part of the function, and the second term is the residual component which is defined by

$$\chi = \tfrac{1}{3}\partial_a \psi(a), \tag{72}$$

which will take values in the odd-graded part of the algebra $\mathscr{G}_{3,0}$. This function will transform as the

$$D\left(\frac{1}{2}\right)\otimes D(1) = D\left(\frac{3}{2}\right)\oplus D\left(\frac{1}{2}\right) \tag{73}$$

representation. Under the action of $\hat{\mathrm{U}}_R$, $\psi(a)$ transforms to

$$R\psi(\widetilde{R}aR) = R\mathscr{M}(\widetilde{R}aR) + aR\chi. \tag{74}$$

It can be seen that the second term transforms with one rotor like the spin-$\frac{1}{2}$ representation, so the monogenic part of the function can be identified with the spin-$\frac{3}{2}$ representation.

To construct the higher-spin representations we will need some ''complex''-valued functions of a vector variable from which to construct the contributions of the arguments,

$$\begin{aligned}
\phi_1(a) &= \frac{1}{\sqrt{2}}(a\cdot\sigma_1 + a\cdot\sigma_2\hat{\mathrm{j}}),\\
\phi_0(a) &= -a\cdot\sigma_3\hat{\mathrm{j}},\\
\phi_{-1}(a) &= \frac{1}{\sqrt{2}}(a\cdot\sigma_1 - a\cdot\sigma_2\hat{\mathrm{j}}).
\end{aligned} \tag{75}$$

These are closely related to the spin-1 basis states. They have been written using $\hat{\mathrm{j}}$ since they will be useful in constructing both integral and half-integral-spin states.

The spin-$\frac{3}{2}$ multiplet can be constructed from these functions and the spin-$\frac{1}{2}$ basis states $\chi_\pm$ (62),

$$\begin{aligned}
\psi_{3/2,\,3/2}(a) &= \chi_+\phi_1(a),\\
\psi_{3/2,\,1/2}(a) &= \frac{1}{\sqrt{3}}(\chi_-\phi_1(a) + \sqrt{2}\chi_+\phi_0(a)),\\
\psi_{3/2,\,-1/2}(a) &= \frac{1}{\sqrt{3}}(\chi_+\phi_{-1}(a) + \sqrt{2}\chi_-\phi_0(a)),\\
\psi_{3/2,\,-3/2}(a) &= \chi_-\phi_{-1}(a).
\end{aligned} \tag{76}$$

These four basis states are monogenic functions. The associated spin-$\frac{1}{2}$ doublet consists of the residual functions from the monogenic decomposition,

$$\begin{aligned}
\psi_{1/2,\,1/2}(a) &= \frac{1}{\sqrt{3}}(\sqrt{2}\chi_-\phi_1(a) - \chi_+\phi_0(a)) = \frac{1}{\sqrt{3}}ai,\\
\psi_{1/2,\,-1/2}(a) &= \frac{1}{\sqrt{3}}(-\sqrt{2}\chi_+\phi_{-1}(a) + \chi_-\phi_0(a)) = -\frac{1}{\sqrt{3}}a\sigma_1.
\end{aligned} \tag{77}$$

These functions are orthonormal under the functional inner product (44).

Now consider a spinor-valued bilinear function, $\psi(a,b)$, which will transform under $\hat{\mathrm{U}}_R$ as

$$D\left(\frac{1}{2}\right)\otimes D(1)\otimes D(1)=D\left(\frac{5}{2}\right)\oplus 2D\left(\frac{3}{2}\right)\oplus 2D\left(\frac{1}{2}\right). \tag{78}$$

The monogenic decomposition of $\psi(a,b)$ is

$$\psi(a,b)=\mathscr{M}(a,b)+a.\mathscr{M}'(b)+b.\mathscr{M}''(a)+ab\xi_1+ba\xi_2. \tag{79}$$

The symmetry between the arguments need not be taken into account since there cannot be any antisymmetric monogenic functions in $\mathscr{G}_{3,0}$. If there were such a monogenic $\mathscr{M}_A(a,b)$, it could be written as a function of a bivector $\mathscr{M}_A(a\wedge b)$. By linearity,

$$\partial_a.\mathscr{M}_A(a\wedge b)=\partial_a(a\wedge b)\cdot\partial_B.\mathscr{M}_A(B)=0, \tag{80}$$

where the chain rule has been applied. Expanding B over the bivector basis elements, this becomes

$$b\cdot i\sigma_1.\mathscr{M}_A(i\sigma_1)+b\cdot i\sigma_2.\mathscr{M}_A(i\sigma_2)+b\cdot i\sigma_3.\mathscr{M}_A(i\sigma_3)=0, \tag{81}$$

which must hold for all values of b. It is easy to show that this implies that each of the components of $\mathscr{M}_A(a\wedge b)$ vanishes. It follows that in 3 dimensions a k-linear monogenic cannot be antisymmetric in any two of its arguments; it therefore must be totally symmetric.

Under the action of $\hat{\mathrm{U}}_R$, $\psi(a,b)$ transforms to

$$\begin{aligned}R\psi(\widetilde{R}aR,\widetilde{R}bR)=R.\mathscr{M}(\widetilde{R}aR,\widetilde{R}bR)+aR.\mathscr{M}'(\widetilde{R}bR)\\ +bR.\mathscr{M}''(\widetilde{R}aR)+abR\xi_1+baR\xi_2.\end{aligned} \tag{82}$$

Again it can be seen that it is the monogenic part which behaves as the irreducible representation with the highest spin, in this case spin-$\frac{5}{2}$. There are also two spin-$\frac{3}{2}$ and two spin-$\frac{1}{2}$ representations, as predicted in (78). The $m=\frac{5}{2}$ state will be

$$\psi_{5/2\,,\,5/2}(a,b)=\chi_+\phi_1(a)\phi_1(b), \tag{83}$$

and the remaining basis states of the $D(\frac{5}{2})$ representation can be constructed using the lowering operator.

The properties of a function which corresponds to a general half-integral-spin irreducible representation can now be deduced. Consider a spinor-valued k-linear function,

$$\psi(a_1,\ldots,a_k), \tag{84}$$

which transforms under $\hat{\mathrm{U}}_R$ as

$$D\left(\frac{1}{2}\right)\otimes\underbrace{D(1)\otimes\ldots\otimes D(1)}_{k\text{ times}}=D\left(k+\frac{1}{2}\right)\oplus D\left(k-\frac{1}{2}\right)\oplus\ldots\oplus D\left(\frac{1}{2}\right). \tag{85}$$

The monogenic part of this function,

$$\mathscr{M}(a_1,\ldots,a_k), \tag{86}$$

which must be totally symmetric, will correspond to the $D(k+\frac{1}{2})$ irreducible representation. The $m=k+\frac{1}{2}$ basis state will be

$$\psi_{k+(1/2)\,,k+(1/2)}(a_1,\ldots,a_k)=\chi_+\phi_1(a_1)\cdots\phi_1(a_k). \tag{87}$$

The rest of the spin-$(k+\frac{1}{2})$ basis states can be constructed from this using the lowering operator.

F. Integral-spin representations

In the same way as we constructed the spin-1 representation from the spin-$\frac{1}{2}$ representation, we can construct any integral-spin representation from the half-integral-spin representations deduced above. A linear function which transforms under $\hat{\mathrm{V}}_R$ can be constructed from a spinor-valued linear function $\psi_1(a)$ and a spinor ψ_2,

$$M(a)=\psi_1(a)\Gamma\tilde{\psi}_2, \tag{88}$$

where $\Gamma=(1+\sigma_3)\sigma_1$ as before (70). $M(a)$ will be multivector-valued, and it will belong to the

$$D\left(\frac{1}{2}\right)\otimes D(1)\otimes D\left(\frac{1}{2}\right) \tag{89}$$

representation. If $\psi_1(a)$ is restricted to be monogenic $\mathscr{M}(a)$, then the function

$$M'(a)=\mathscr{M}(a)\Gamma\tilde{\psi}_2 \tag{90}$$

belongs to the

$$D\left(\frac{3}{2}\right)\otimes D\left(\frac{1}{2}\right)=D(2)\oplus D(1) \tag{91}$$

representation. This can be restricted further by selecting the vector and bivector part,

$$A(a)=\langle\mathscr{M}(a)\Gamma\tilde{\psi}_2\rangle_{1,2}, \tag{92}$$

which will transform as the $D(2)$ irreducible representation. The scalar and pseudoscalar part of $M'(a)$ will transform as $D(1)$. Inserting the $D(\frac{3}{2})$ and $D(\frac{1}{2})$ basis states from (62) and (76) the basis states of the $D(2)$ irreducible representation are

$$A_{2,2}(a)=A_1\phi_1(a),$$

$$A_{2,1}(a)=\frac{1}{\sqrt{2}}(A_1\phi_0(a)+A_0\phi_1(a)),$$

$$A_{2,0}(a)=\frac{1}{\sqrt{6}}(A_1\phi_{-1}(a)+A_{-1}\phi_1(a)+2A_0\phi_0(a)), \tag{93}$$

$$A_{2,-1}(a)=\frac{1}{\sqrt{2}}(A_{-1}\phi_0(a)+A_0\phi_{-1}(a)),$$

$$A_{2,-2}(a)=A_{-1}\phi_{-1}(a).$$

where A_1, A_0 and A_{-1} are shorthand for the $m=1$, $m=0$ and $m=-1$ basis states of the $D(1)$ representation, respectively.

This procedure can now be generalized to find the properties of a function which corresponds to any integral-spin irreducible representation. Consider a k-linear function which transforms under $\hat{\mathrm{V}}_R$, constructed from a k-linear spinor-valued function $\psi_1(a_1,\ldots,a_k)$ and a spinor ψ_2,

$$M(a_1,\ldots,a_k)=\psi_1(a_1,\ldots,a_k)\Gamma\tilde{\psi}_2. \tag{94}$$

It will transform as

$$D\left(\frac{1}{2}\right)\otimes\underbrace{D(1)\otimes\ldots\otimes D(1)}_{k\text{ times}}\otimes D\left(\frac{1}{2}\right)=D(k+1)\oplus D(k)\oplus\ldots\oplus D(0) \tag{95}$$

If $\psi_1(a_1,\ldots,a_k)$ is restricted to be a monogenic then the function

$$M'(a)=\mathscr{M}(a_1,\ldots,a_k)\Gamma\tilde{\psi}_2 \tag{96}$$

will transform as the

$$D\left(k+\frac{1}{2}\right)\otimes D\left(\frac{1}{2}\right)=D(k+1)\oplus D(k) \tag{97}$$

representation. Again if this is restricted to the vector and bivector parts, the resulting function,

$$A(a_1,\ldots,a_k)=\langle\mathscr{M}(a_1,\ldots,a_k)\Gamma\tilde{\psi}_2\rangle_{1,2}, \tag{98}$$

corresponds to the $D(k+1)$ irreducible representation.

We have now identified the functions which correspond to all of the irreducible representations of $SO(3)$ and in the process discovered many monogenic functions in the Pauli algebra.

IV. REPRESENTATIONS OF THE LORENTZ GROUP

We now turn our attention the the proper Lorentz group $\mathrm{SO}^+(1,3)$. The representations we find in this section will be useful in describing relativistic wave equations.

A. Generators

The space–time algebra has six linearly-independent bivectors, $\{\sigma_k, i\sigma_k\}$, therefore the Lorentz group has six generators, for which we introduce the following shorthand notation:

$$\hat{\mathrm{J}}_k=\frac{1}{2}\hat{\mathrm{L}}_{i\sigma_k},\quad \hat{\mathrm{K}}_k=\frac{1}{2}\hat{\mathrm{L}}_{\sigma_k}, \tag{99}$$

where $k=1,2,3$. These operators obey the commutation relations

$$[\hat{\mathrm{J}}_i,\hat{\mathrm{J}}_j]=-\epsilon_{ijk}\hat{\mathrm{J}}_k,\quad [\hat{\mathrm{K}}_i,\hat{\mathrm{K}}_j]=\epsilon_{ijk}\hat{\mathrm{J}}_k,\quad [\hat{\mathrm{J}}_i,\hat{\mathrm{K}}_j]=\epsilon_{ijk}\hat{\mathrm{K}}_k. \tag{100}$$

The $\{\hat{\mathrm{J}}_k\}$ form a closed sub-algebra, which is identical to the Lie algebra of SO(3) in the previous section. Again these relations differ slightly from conventional treatments.

B. Classification of irreducible representations

We shall introduce a complex structure to the Lorentz group within the real STA, using the operator $\hat{\mathrm{j}}$ to stand for the complexification operation and deducing its action on the representations. The complex structure can be used to define two sets of generators from the generators of the Lorentz group:[7]

$$\hat{\mathrm{A}}_k=\tfrac{1}{2}(\hat{\mathrm{J}}_k+\hat{\mathrm{j}}\hat{\mathrm{K}}_k),\quad \hat{\mathrm{B}}_k=\tfrac{1}{2}(\hat{\mathrm{J}}_k-\hat{\mathrm{j}}\hat{\mathrm{K}}_k), \tag{101}$$

where $k=1,2,3$. These operators have the following commutation relations:

$$[\hat{\mathrm{A}}_k,\hat{\mathrm{A}}_l]=-\epsilon_{klm}\hat{\mathrm{A}}_m,\quad [\hat{\mathrm{B}}_k,\hat{\mathrm{B}}_l]=-\epsilon_{klm}\hat{\mathrm{B}}_m,\quad [\hat{\mathrm{A}}_k,\hat{\mathrm{B}}_l]=0. \tag{102}$$

The operators form two uncoupled sets of generators which individually behave like the generators of SO(3). The group generated by these uncoupled operators will therefore behave as a direct product of two copies of SO(3). If s_a is the spin of the $\hat{\mathrm{A}}_k$ irreducible representation and s_b is the

spin of the $\hat{\mathrm{B}}_k$ irreducible representation then their direct product space, which can be described by a pair of spin weights (s_a, s_b), will have $(2s_a+1)(2s_b+1)$ complex degrees of freedom. An eigenstate will be equivalent to the product of two SO(3) eigenstates,

$$|s_a\, s_b\, m_a\, m_b\rangle \cong |s_a\, m_a\rangle \otimes |s_b\, m_b\rangle. \tag{103}$$

The operators,

$$\hat{\mathbf{A}}^2 = \hat{\mathrm{A}}_1{}^2 + \hat{\mathrm{A}}_2{}^2 + \hat{\mathrm{A}}_3{}^2, \tag{104}$$

$$\hat{\mathbf{B}}^2 = \hat{\mathrm{B}}_1{}^2 + \hat{\mathrm{B}}_2{}^2 + \hat{\mathrm{B}}_3{}^2, \tag{105}$$

are the Casimir operators of the group, where the ''vector'' notation has again been used. These can be written in terms of the $\hat{\mathrm{J}}_k$ and $\hat{\mathrm{K}}_k$ operators by taking the sum and difference,

$$\hat{\mathbf{A}}^2 + \hat{\mathbf{B}}^2 = \tfrac{1}{2}(\hat{\mathbf{J}}^2 - \hat{\mathbf{K}}^2), \tag{106}$$

$$\hat{\mathbf{A}}^2 - \hat{\mathbf{B}}^2 = -\hat{\mathrm{j}}\hat{\mathbf{J}} \cdot \hat{\mathbf{K}}. \tag{107}$$

It will be found that a particular irreducible representation can be distinguished from other representations with the same $s = s_a + s_b$ by its grade or algebraic properties. We shall refer to all such representations as spin-s representations, for example, $(\frac{1}{2}, \frac{1}{2})$ and $(1,0)\oplus(0,1)$ are both spin-1 representations.

Because the representations have a direct product structure, the Lorentz group analogue of the Clebsh–Gordon decomposition is quite simple,

$$(s_{a_1}, s_{b_1}) \otimes (s_{a_2}, s_{b_2}) = \sum_{s_a, s_b} \oplus (s_a, s_b), \tag{108}$$

where the sum runs independently over the values

$$\begin{aligned} s_a &= s_{a_1} + s_{a_2}, s_{a_1} + s_{a_2} - 1, \ldots, |s_{a_1} - s_{a_2}|, \\ s_b &= s_{b_1} + s_{b_2}, s_{b_1} + s_{b_2} - 1, \ldots, |s_{b_1} - s_{b_2}|. \end{aligned} \tag{109}$$

Now that we have identified the irreducible representations, we can classify their basis states. The basis states will be expressed as eigenstates of the operators $\hat{\mathrm{J}}_3$ and $\hat{\mathrm{K}}_3$ with eigenvalues m and n, respectively, because these are related to simple bivector generators. These states will still be eigenstates of $\hat{\mathrm{A}}_3$ and $\hat{\mathrm{B}}_3$; the eigenvalues are related by

$$m = m_a + m_b, \tag{110}$$

$$n = m_a - m_b. \tag{111}$$

The basis states are thus characterized by four spin quantum numbers, s_a, s_b, m and n. Operating on an eigenstate $|s_a s_b m n\rangle$ we find

$$\hat{\mathbf{A}}^2 |s_a s_b m n\rangle = -s_a(s_a+1)|s_a s_b m n\rangle, \tag{112}$$

$$\hat{\mathbf{B}}^2 |s_a s_b m n\rangle = -s_b(s_b+1)|s_a s_b m n\rangle, \tag{113}$$

$$\hat{\mathrm{J}}_3 |s_a s_b m n\rangle = \hat{\mathrm{j}} m |s_a s_b m n\rangle, \tag{114}$$

$$\hat{\mathrm{K}}_3 |s_a s_b m n\rangle = n |s_a s_b m n\rangle. \tag{115}$$

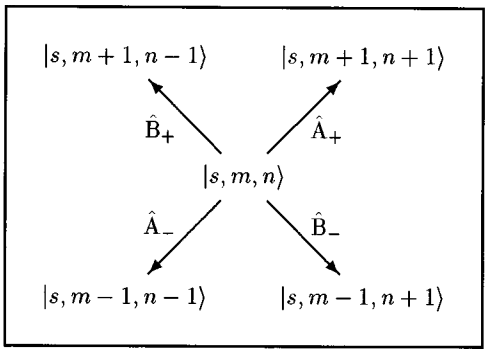

FIG. 1. Raising and lowering operators for spin-s irreducible representation of the Lorentz group.

The raising and lowering operators

$$\hat{\mathrm{A}}_\pm = \hat{\mathrm{A}}_1 \pm \hat{\mathrm{j}}\hat{\mathrm{A}}_2, \qquad \hat{\mathrm{B}}_\pm = \hat{\mathrm{B}}_1 \pm \hat{\mathrm{j}}\hat{\mathrm{B}}_2, \tag{116}$$

which raise and lower the m_a and m_b quantum numbers, respectively, can be used to move between the basis states of the representation, which is shown in terms of the m and n states in Figure 1.

An alternative, incomplete method of classifying the irreducible representations of the Lorentz group is to decompose them into representations of the subgroup SO(3), as eigenstates of $\hat{\mathbf{J}}^2$. The (s_a, s_b) representation contains the

$$D(s_a)\otimes D(s_b) = D(s_a+s_b)\oplus\cdots\oplus D(|s_a-s_b|) \tag{117}$$

representations of SO(3) and the $(s_a, s_b)\oplus(s_b, s_a)$ representation will contain two copies of each of these subgroup representations. The operator $\hat{\mathrm{J}}_3$ will be used to find the eigenstates of these subgroup representations. The alternative quantum numbers which correspond to the eigenstates of $\hat{\mathbf{J}}^2$ and $\hat{\mathrm{J}}_3$ are j and m,

$$(\hat{\mathbf{J}}^2 - \hat{\mathbf{K}}^2)|s_a s_b j m\rangle = -2(s_a(s_a+1)+s_b(s_b+1))|s_a s_b j m\rangle, \tag{118}$$

$$\hat{\mathbf{J}}^2|s_a s_b j m\rangle = -j(j+1)|s_a s_b j m\rangle, \tag{119}$$

$$\hat{\mathrm{J}}_3|s_a s_b j m\rangle = \hat{\mathrm{j}} m|s_a s_b j m\rangle. \tag{120}$$

These are not a complete set of operators because $\hat{\mathbf{J}}^2$ does not commute with $\hat{\mathbf{J}}\cdot\hat{\mathbf{K}}$. Also $\hat{\mathrm{K}}_3$ commutes with $\hat{\mathrm{J}}_3$ but not with $\hat{\mathbf{J}}^2$, so it does not behave as a lowering or raising operator, but mixes the $|s_a s_b j m\rangle$ state with all the other possible j eigenstates leaving the eigenvalue s unchanged (Figure 2).

C. The spin-$\frac{1}{2}$ representation

The Lorentz group has one spin-$\frac{1}{2}$ irreducible representation, $(\frac{1}{2},0)\oplus(0,\frac{1}{2})$. Translating the Dirac spinor into the STA we find it most convenient if it takes values in the even sub-algebra.[5,6] The complexification operation is identical to that of the non-relativistic spin-$\frac{1}{2}$ representation, multiplication on the right by $i\sigma_3$,

$$\hat{\mathrm{j}}\psi \equiv \psi i\sigma_3. \tag{121}$$

The basis states ψ_{mn} of this representation are

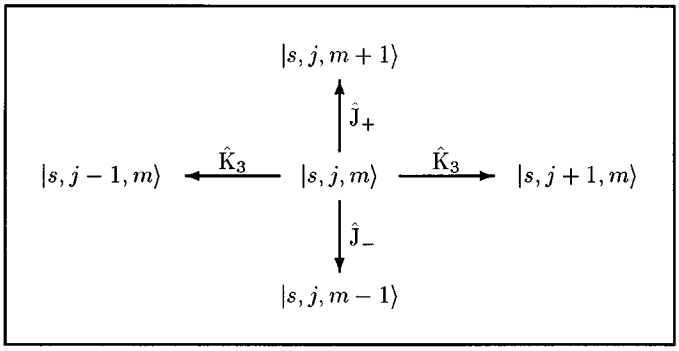

FIG. 2. Alternative raising and lowering operators for spin-s irreducible representation of the Lorentz group.

$$\psi_{1/2,\,1/2}=\frac{1}{2}(1+\sigma_3)\quad \psi_{1/2,\,-1/2}=\frac{1}{2}(1-\sigma_3),$$
$$\psi_{-1/2,\,1/2}=i\sigma_1\frac{1}{2}(1-\sigma_3)\quad \psi_{-1/2,\,-1/2}=i\sigma_1\frac{1}{2}(1+\sigma_3). \tag{122}$$

These basis states have an ideal structure, therefore they correspond most closely to the Weyl representation.

Decomposing the $(\frac{1}{2},0)\oplus(0,\frac{1}{2})$ irreducible representation in terms of the SO(3) subgroup,

$$\left(\frac{1}{2},0\right)\oplus\left(0,\frac{1}{2}\right)\cong D\left(\frac{1}{2}\right)\oplus D\left(\frac{1}{2}\right), \tag{123}$$

there are two $D(\frac{1}{2})$ doublets which are transformed into each other by the action of $\hat{\mathrm{K}}_3$,

$$\begin{aligned}\chi_+&=1, &&\xi_+=\sigma_3,\\ &&&\overset{\hat{\mathrm{K}}_3}{\leftrightarrow}\\ \chi_-&=i\sigma_1, &&\xi_-=\sigma_2.\end{aligned} \tag{124}$$

The $\chi_\pm$ doublet is identical to the $D(\frac{1}{2})$ representation of $SO(3)$; the $\xi_\pm$ doublet is new, coming from the action of $\hat{\mathrm{K}}_3$ on the $\chi_\pm$ doublet.

D. The spin-1 representations

The Lorentz group has two spin-1 representations, $(\frac{1}{2},\frac{1}{2})$ and $(1,0)\oplus(0,1)$. Like the integral-spin representations of SO(3), we can construct the spin-1 representations from the spinor representation. We use the same form,

$$M=\psi_1\Gamma\tilde{\psi}_2, \tag{125}$$

where Γ is an arbitrary multivector to be chosen later. Since the STA and the Pauli Algebra share the same pseudoscalar we can use the same construction as before to complexify these representations,

$$\hat{\mathrm{j}}M\equiv iM. \tag{126}$$

In general, M will transform under $\hat{\mathrm{V}}_R$ as the

$$\left[\left(\frac{1}{2},0\right)\oplus\left(0,\frac{1}{2}\right)\right]\otimes\left[\left(\frac{1}{2},0\right)\oplus\left(0,\frac{1}{2}\right)\right]=2(0,0)\oplus 2\left(\frac{1}{2},\frac{1}{2}\right)\oplus[(1,0)\oplus(0,1)] \tag{127}$$

representation.

The $(\frac{1}{2},\frac{1}{2})$ irreducible representation is obtained by choosing

$$\Gamma = \gamma_1 + i\gamma_2, \tag{128}$$

which restricts M to be vector- and trivector-valued. Inserting the $(\frac{1}{2},0)\oplus(0,\frac{1}{2})$ basis states from (122) it is found that the basis states A_{mn} of the $(\frac{1}{2},\frac{1}{2})$ representation are

$$\begin{aligned} A_{0,1} &= \gamma_0 + \gamma_3, \quad A_{0,-1} = \gamma_0 - \gamma_3, \\ A_{1,0} &= \gamma_1 + i\gamma_2, \quad A_{1,-1,0} = \gamma_1 - i\gamma_2, \end{aligned} \tag{129}$$

which is identical to the null tetrad $(l,n,m,\overline{m})$ of Penrose and Rindler.[8,9]

If Γ is chosen to be

$$\Gamma = \sigma_1 + i\sigma_2, \tag{130}$$

then M will be even-valued. Further restricting (125) to the symmetric part,

$$F = \tfrac{1}{2}(\psi_1 \Gamma \widetilde{\psi}_2 + \psi_2 \Gamma \widetilde{\psi}_1), \tag{131}$$

then F will be bivector-valued, which corresponds to the $(1,0)\oplus(0,1)$ irreducible representation.

We have chosen the operation (126) to perform the complexification. Multiplication by the pseudoscalar, i, also generates the duality operation, so by this process we only obtain the self-dual set of basis states for F. Inserting the spin-$\frac{1}{2}$ basis states from (122) the basis states F_{mn} are found to be

$$\begin{aligned} F_{1,1} &= \sigma_1 + i\sigma_2, \\ F_{0,0} &= i\sigma_3, \\ F_{-1,-1} &= \sigma_1 - i\sigma_2. \end{aligned} \tag{132}$$

Instead, if we had chosen $\hat{\jmath}M = -iM$ to be the complexification operation, which is consistent with choosing $\Gamma = \sigma_1 - i\sigma_2$, we would obtain the anti-self-dual set of basis states.

The corresponding antisymmetric part of (125),

$$\phi = \tfrac{1}{2}(\psi_1 \Gamma \widetilde{\psi}_2 - \psi_2 \Gamma \widetilde{\psi}_1), \tag{133}$$

is scalar- and pseudoscalar-valued, which is invariant under the action of $\hat{\mathrm{V}}_R$. This corresponds to the scalar (0,0) irreducible representation.

Above, identifying the grades of a multivector with the representations, we have only obtained half of the irreducible representations that should be contained in the decomposition of the complete multivector representation (127). This is a consequence of the minimalist route we have chosen, introducing complexification as a geometric operation.

E. Half-integral-spin representations

We now search for half-integral-spin irreducible representations, which we expect to be multilinear spinor-valued functions. Consider a linear spinor-valued function $\psi(a)$ which transforms under $\hat{\mathrm{U}}_R$. Its monogenic decomposition is

$$\psi(a) = \mathscr{M}(a) + a\chi, \tag{134}$$

where the first term is monogenic and the second is the residual term in which χ is defined by $\chi = \frac{1}{4}\partial_a \psi(a)$. The function $\psi(a)$ belongs to the

$$\left[\left(\frac{1}{2},0\right)\oplus\left(0,\frac{1}{2}\right)\right]\otimes\left(\frac{1}{2},\frac{1}{2}\right)=\left[\left(1,\frac{1}{2}\right)\oplus\left(\frac{1}{2},1\right)\right]\oplus\left[\left(\frac{1}{2},0\right)\oplus\left(0,\frac{1}{2}\right)\right] \tag{135}$$

representation. The second term of the monogenic decomposition (134) transforms like the $(\frac{1}{2},0)\oplus(0,\frac{1}{2})$ irreducible representation so the monogenic component is identified with the $(1,\frac{1}{2})\oplus(\frac{1}{2},1)$ irreducible representation, a ''spin-$\frac{3}{2}$'' representation:

$$\left(1,\frac{1}{2}\right)\oplus\left(\frac{1}{2},1\right)\leftrightarrow\mathscr{M}(a),$$

$$\left(\frac{1}{2},0\right)\oplus\left(0,\frac{1}{2}\right)\leftrightarrow\chi.$$

The monogenic functions which form the basis states for the $(1,\frac{1}{2})\oplus(\frac{1}{2},1)$ representation can be constructed from the spin-$\frac{1}{2}$ basis states and ''complex''-valued linear functions derived from the $(\frac{1}{2},\frac{1}{2})$ representation. For example,

$$\psi_{1/2\,,\,3/2}(a)=\psi_{1/2\,,\,1/2}\phi_{0,1}(a) \tag{136}$$

is monogenic, where $\phi_{0,1}(a)=a\cdot(\gamma_0+\gamma_3)$.

Now consider a bilinear spinor-valued function $\psi(a,b)$ which transforms under $\hat{\mathrm{U}}_R$. Its monogenic decomposition is

$$\psi(a,b)=\mathscr{M}(a,b)+a.\mathscr{M}'(b)+b.\mathscr{M}''(a)+ab\chi_1+ba\chi_2, \tag{137}$$

which can be further refined by taking into account the symmetry between the arguments:

$$\begin{aligned}\psi(a,b)=&\mathscr{M}_S(a,b)+\mathscr{M}_A(a,b)+a.\mathscr{M}_S'(b)+b.\mathscr{M}_S'(a)\\&+a.\mathscr{M}_A'(b)-b.\mathscr{M}_A'(a)+a\cdot b\chi_S+a\wedge b\chi_A,\end{aligned} \tag{138}$$

where the subscripts S and A denote the symmetric and antisymmetric parts, respectively,

$$\begin{aligned}\mathscr{M}_S(a,b)&=\mathscr{M}_S(b,a),\\ \mathscr{M}_A(a,b)&=-\mathscr{M}_A(b,a).\end{aligned} \tag{139}$$

The function $\psi(a,b)$ belongs to the

$$\begin{aligned}&\left[\left(\frac{1}{2},0\right)\oplus\left(0,\frac{1}{2}\right)\right]\otimes\left(\frac{1}{2},\frac{1}{2}\right)\otimes\left(\frac{1}{2},\frac{1}{2}\right)\\&\quad=\left[\left(\frac{3}{2},1\right)\oplus\left(1,\frac{3}{2}\right)\right]\oplus\left[\left(\frac{3}{2},0\right)\oplus\left(0,\frac{3}{2}\right)\right]\oplus2\left[\left(1,\frac{1}{2}\right)\oplus\left(\frac{1}{2},1\right)\right]\\&\qquad\oplus2\left[\left(\frac{1}{2},0\right)\oplus\left(0,\frac{1}{2}\right)\right]\end{aligned} \tag{140}$$

representation. The are two new terms in this decomposition compared to that of a linear spinor-valued function, $(\frac{3}{2},1)\oplus(1,\frac{3}{2})$ and $(\frac{3}{2},0)\oplus(0,\frac{3}{2})$. Counting the degrees of freedom, we make the following identifications:

$$\left(\frac{3}{2},1\right)\oplus\left(1,\frac{3}{2}\right)\leftrightarrow\mathscr{M}_S(a,b),$$

$$\left(\frac{3}{2},0\right)\oplus\left(0,\frac{3}{2}\right)\leftrightarrow\mathscr{M}_A(a,b),$$

$$\left(1,\frac{1}{2}\right)\oplus\left(\frac{1}{2},1\right)\leftrightarrow\mathscr{M}'_S(a),\mathscr{M}'_A(a),$$

$$\left(\frac{1}{2},0\right)\oplus\left(0,\frac{1}{2}\right)\leftrightarrow\chi_S,\chi_A.$$

We can now proceed to find a general half-integral-spin representation. Consider a spinor-valued k-linear function,

$$\psi(a_1,\ldots,a_k), \tag{141}$$

which will transform under the action of the group as

$$\left[\left(\frac{1}{2},0\right)\oplus\left(0,\frac{1}{2}\right)\right]\otimes\underbrace{\left(\frac{1}{2},\frac{1}{2}\right)\otimes\ldots\otimes\left(\frac{1}{2},\frac{1}{2}\right)}_{k\text{ times}}. \tag{142}$$

The highest-spin representation in the decomposition will be a symmetric monogenic function which will correspond to the $((k+1)/2,k/2)\oplus(k/2,(k+1)/2)$ irreducible representation. This is confirmed by counting the degrees of freedom in this function. A symmetric spinor-valued function in 4 dimensions has $8[(k+3)!/3!k!]$ real degrees of freedom. A monogenic version of the same therefore has

$$8\left(\frac{(k+3)!}{3!k!}-\frac{(k+2)!}{3!(k-1)!}\right)=4(k+2)(k+1) \tag{143}$$

real degrees of freedom which is exactly the number contained in the $((k+1)/2,k/2)\oplus(k/2,(k+1)/2)$ irreducible representation.

F. Integral-spin representations

Again the integral-spin representations can be constructed from half-integral-spin representations. Consider a multivector-valued linear function constructed in the form

$$T(a)=\psi_1(a)\Gamma\widetilde{\psi}_2. \tag{144}$$

In general, $T(a)$ will belong to the

$$\left[\left(\frac{1}{2},0\right)\oplus\left(0,\frac{1}{2}\right)\right]\otimes\left(\frac{1}{2},\frac{1}{2}\right)\otimes\left[\left(\frac{1}{2},0\right)\oplus\left(0,\frac{1}{2}\right)\right] \tag{145}$$

representation. If $\psi_1(a)$ is restricted to be monogenic, then the function will belong to the

$$\left[\left(1,\frac{1}{2}\right)\oplus\left(\frac{1}{2},1\right)\right]\otimes\left[\left(\frac{1}{2},0\right)\oplus\left(0,\frac{1}{2}\right)\right] \tag{146}$$

representation which contains the $(1,1)$ and $(\frac{3}{2},\frac{1}{2})\oplus(\frac{1}{2},\frac{3}{2})$ irreducible representations as the highest-spin irreducible representations. Using $\Gamma=\gamma_1+i\gamma_2$ projects out the vector and trivector part which corresponds to the $(1,1)$ representation,

$$A(a)=\psi_1(a)(\gamma_1+i\gamma_2)\widetilde{\psi}_2, \tag{147}$$

and choosing $\Gamma=\sigma_1+i\sigma_2$ and projecting out the bivector part corresponds to the $(\frac{3}{2},\frac{1}{2})\oplus(\frac{1}{2},\frac{3}{2})$ representation,

$$F(a)=\langle\psi_1(a)(\sigma_1+i\sigma_2)\widetilde{\psi}_2\rangle_2. \tag{148}$$

We can now generalize to an arbitrary integral-spin representation,

$$T(a_1,\ldots,a_k)=\psi_1(a_1,\ldots,a_k)\Gamma\widetilde{\psi}_2, \tag{149}$$

which belongs to the

$$\left[\left(\frac{1}{2},0\right)\oplus\left(0,\frac{1}{2}\right)\right]\otimes\underbrace{\left(\frac{1}{2},\frac{1}{2}\right)\otimes\ldots\otimes\left(\frac{1}{2},\frac{1}{2}\right)}_{k\text{ times}}\otimes\left[\left(\frac{1}{2},0\right)\oplus\left(0,\frac{1}{2}\right)\right] \tag{150}$$

representation. If we select the monogenic, totally-symmetric part of the function, we can restrict it to the

$$\left[\left(\frac{k+1}{2},\frac{k}{2}\right)\oplus\left(\frac{k}{2},\frac{k+1}{2}\right)\right]\otimes\left[\left(\frac{1}{2},0\right)\oplus\left(0,\frac{1}{2}\right)\right] \tag{151}$$

representation which contains the $((k+1)/2,(k+1)/2)$ and $((k+2)/2,k/2)\oplus(k/2,(k+2)/2)$ irreducible representations as the highest-spin irreducible representations, which again correspond to the vector–trivector and bivector parts, respectively. These are both ''spin-$(k+1)$'' representations.

We have now found the method for identifying the irreducible representations of the Lorentz group with multilinear functions.

V. WAVE EQUATIONS

So far we have restricted our attention to describing higher-weighted representations of rotation groups with multilinear functions. The wavefunction describing a quantum-mechanical particle depends in an arbitrary non-linear fashion on the position vector x. The method described in this paper can be generalized to include non-linear arguments, and thus handle these ''external'' spatial or space–time degrees of freedom within the same mathematical structure as the ''internal'' spin degrees of freedom.

Consider a function which transforms under $\hat{\mathrm{U}}_R$ which has linear arguments $a_1,\ldots,a_k$ and non-linear arguments $x_1,\ldots,x_l$; we shall separate the linear and non-linear arguments with a semi-colon,

$$\psi(a_1,\ldots,a_k;x_1,\ldots,x_l). \tag{152}$$

The non-linear arguments transform under rotation in the same manner as the linear ones,

$$\hat{\mathrm{U}}_R[\psi(a_1,\ldots,a_k;x_1,\ldots,x_l)]=R\psi(\widetilde{R}a_1R,\ldots,\widetilde{R}a_kR;\widetilde{R}x_1R,\ldots,\widetilde{R}x_lR), \tag{153}$$

but the action of the Lie group is modified,

$$\begin{aligned}\frac{1}{2}\hat{\mathrm{L}}_B[\psi(\ldots;\ldots)]&=\frac{1}{2}B\psi(\ldots;\ldots)+\sum_{i=1}^{k}\psi(\ldots,a_i\cdot B,\ldots;\ldots)\\&\quad-\sum_{i=1}^{l}B\cdot(x_i\wedge\partial_{x_i})\psi(\ldots;\ldots).\end{aligned} \tag{154}$$

Each non-linear argument x_i makes a contribution,

$$-B\cdot(x_i\wedge\partial_{x_i})=(x_i\cdot B)\cdot\partial_{x_i}, \tag{155}$$

to $\frac{1}{2}\hat{\mathrm{L}}_B$. If x_i were a linear argument then this would reduce to the same form as for a linear argument, so this generalization is consistent with our earlier definitions. This operator (155) could also be interpreted as finding the component of angular momentum, $-\hat{\mathrm{j}}(x\wedge\nabla)$, in the plane defined by B.

A similar generalization can be made for functions which transform under $\hat{\mathrm{V}}_R$, only the external transformation properties of the function differ from those transforming under $\hat{\mathrm{U}}_R$.

The Dirac equation written in the STA is

$$\nabla\psi(x)i\sigma_3=m\psi(x)\gamma_0. \tag{156}$$

This has been investigated extensively elsewhere.[10,6] The wavefunction $\psi(x)$ is a spinor function of position x. Some of the functions which form a basis for the Dirac wavefunction can be obtained from multilinear functions by polynomial projection.[1] The l-th order contribution can be made by setting all the arguments of a l-linear function equal to x,

$$\psi_l(x)=\prod_{i=1}^{l}(x\cdot\partial_{a_i})\psi(a_1,\ldots,a_l). \tag{157}$$

Only the symmetric part of the function will survive this procedure; the antisymmetric parts vanish. The complete wavefunction can be expressed as a sum over all orders of these functions.

Using the representations of the Lorentz group we found earlier, we can investigate higher-spin wave equations. The Rarita–Schwinger equations[11] describe half-integral-spin particles. Translating these into geometric algebra, the equation describing a spin-$\frac{3}{2}$ particle becomes

$$\nabla\psi(a;x)i\sigma_3=m\psi(a;x)\gamma_0, \tag{158}$$

with the additional condition

$$\partial_a\psi(a;x)=0, \tag{159}$$

which ensures that the spin part of $\psi(a;x)$ belongs to the $(1,\frac{1}{2})\oplus(\frac{1}{2},1)$ representation. In general, a spinor-valued k-linear wavefunction which is symmetric in its arguments represents a spin-$(k+\frac{1}{2})$ particle; it obeys

$$\nabla\psi_S(a_1,\ldots,a_k;x)i\sigma_3=m\psi_S(a_1,\ldots,a_k;x)\gamma_0, \tag{160}$$

$$\partial_{a_1}\psi_S(a_1,\ldots,a_k;x)=0, \tag{161}$$

where the additional condition restricts the spin part of the wavefunction to the $((k+1)/2,k/2)\oplus(k/2,(k+1)/2)$ representation.

The basis functions of the k-linear wavefunction can also be obtained by polynomial projection. The l-th order contribution to the wavefunction is obtained by setting l arguments of a suitable $(k+l)$-linear function equal to x,

$$\psi_l(a_1,\ldots,a_k;x)=\prod_{i=1}^{l}(x\cdot\partial_{a_{(k+i)}})\psi(a_1,\ldots,a_{k+l}). \tag{162}$$

The symmetry among the first k arguments must be correct for the wavefunction that is being described. Again, the complete wavefunction will be a sum over all orders of these functions.

Different relativistic wave equations with spin corresponding to different representations of the Lorentz group can be explored by selecting the appropriate multilinear wavefunctions. This presents opportunities for further investigation.

(Received 6 February 1997; accepted for publication 3 December 1997)

A new method is presented to obtain the anomalous dimension in the solution of the Barenblatt's equation. The result is the same as that in the renormalization group (RG) approach. It gives us insight on the perturbative solution of the Barenblatt's equation in the RG approach. Based on this discussion, an improvement is made to take into account, in a more complete way, the nonlinear effect, which is included in the Heaviside function in higher orders. This improved result is better than that in the RG approach. © *1998 American Institute of Physics.* [S0022-2488(98)02903-X]

I. INTRODUCTION

Renormalization and the renormalization group (RG) method are powerful mathematical physics tools in quantum field theory and condensed matter physics.[1,2] Recently, it has been found that there are also important applications in dynamical process, asymptotic analysis, and perturbation theory.[3–5] The fractal and chaos behaviors have been studied with the RG approach.[3] The introduction of the intermediate asymptotic idea is very useful. It can help us to search for the connection between the similarity, fractal, and anomalous dimension of the RG theory.[3] But there are still ambiguities in some aspects. For example, in quantum field theory and in dynamical theory, it is well known that the RG approach can improve the results of the perturbation calculation.[1–5] It can remove the divergence and lead to higher leading-order behavior from a lower-order perturbation calculation. It is also clear that the divergence and the renormalization are physical requirements for some theories. But some of the divergences occur without apparent physical reasons. One question involves the improvement that arises from the RG perturbative calculations. In this paper we study this problem by analyzing a typical example.

Barenblatt's equation has many good characteristics. It has a strong physical background and appears in many different disciplines.[6] It has been studied by applying the method of similarity analysis. It can be solved in terms of the parabolic cylinder functions in the intermediate asymptotic region. Its perturbation solution is divergent and has an anomalous dimension in its asymptotic behavior. It is renormalizable and can be treated with the renormalization and RG approaches.[3,4] But there are still some ambiguities, as mentioned above.

In this paper we study improvements on the perturbation solution of the Barenblatt's equation by renormalization and RG treatment, and attempt to expose some general principles through the discussion of this example. Based on the above analysis, an improved result is obtained by considering the nonlinear effect, which is included in the Heaviside function in higher orders, in a more complete way.

II. ANOMALOUS DIMENSION CALCULATION BY THE RG METHOD

In this section; we repeat some results that are well known, for consistency in notation and discussion style.

We consider the Barenblatt's equation in one space dimension,

---

 © 1998 American Institute of Physics

$$\partial_t u(x,t) - \frac{1}{2}\,\partial_x^2 u(x,t) = \frac{\epsilon}{2}\,\theta(-\partial_t u(x,t))\partial_x^2 u(x,t), \tag{1}$$

with a symmetrical initial condition. It describes a nonlinear diffusive process with a nonconservative ''mass.''

Introduce a change of variables,

$$\xi = \xi(x,t) = \frac{x}{\sqrt{t+l^2}} \quad \textit{and} \quad T = T(x,t) = t + l^2. \tag{2}$$

Then Eq. (1) reads as

$$\partial_T u(\xi,T) - \frac{\xi}{2T}\,\partial_\xi u(\xi,T) - \frac{1}{2T}\,\partial_\xi^2 u(\xi,T) = \frac{\epsilon}{2T}\,\theta\left(\left(-\partial_T + \frac{\xi}{2T}\,\partial_\xi\right)u(\xi,T)\right)\partial_\xi^2 u(\xi,T). \tag{3}$$

We use an initial condition of $u(\xi,T)$ as

$$u(\xi,l^2) = \frac{m_0}{\sqrt{2\pi l^2}}\exp\left(-\frac{\xi^2}{2}\right). \tag{4}$$

It corresponds to the initial condition for $u(x,t)$ in the variables x and t as follows:

$$u(x,0) = \frac{m_0}{\sqrt{2\pi l^2}}\exp\left(-\frac{x^2}{2l^2}\right). \tag{5}$$

For a general diffusion equation, there is a finite solution under this initial condition. In this case, the initial condition is singular when l^2 approaches zero as a δ function. m_0 is a finite constant. But it is not so in the case of Barenblatt's equation.[3,4,6] It must be renormalized to get a finite solution. The m_0 is no longer a constant when the l^2 changes. It becomes infinite when the support of the initial state approaches zero. We will discuss that in the end of this section.

Introducing the expansion

$$u(\xi,T) = u_0(\xi,T) + \epsilon u_1(\xi,T) + \cdots, \tag{6}$$

one has a sequence of equations:

$$2T\partial_T u_0(\xi,T) - \xi\partial_\xi u_0(\xi,T) - \partial_\xi^2 u_0(\xi,T) = 0, \tag{7}$$

$$2T\partial_T u_1(\xi,T) - \xi\partial_\xi u_1(\xi,T) - \partial_\xi^2 u_1(\xi,T) = \theta\left(\left(-\partial_T + \frac{\xi}{2T}\,\partial_\xi\right)u_0(\xi,T)\right)\partial_\xi^2 u_0(\xi,T), \tag{8}$$

and so on.

Further, we assume that the initial condition of the $u_0(\xi,T)$ is

$$u_0(\xi,l^2) = \frac{m_0}{\sqrt{2\pi l^2}}\exp\left(-\frac{\xi^2}{2}\right). \tag{9}$$

Then the initial condition of the $u_n(\xi,T)$ is

$$u_n(\xi,l^2) = 0, \quad n \geqslant 1. \tag{10}$$

The solution of the zeroth-order approximation is

$$u_0(\xi,T) = \frac{m_0}{\sqrt{2\pi T}}\exp\left(-\frac{\xi^2}{2}\right). \tag{11}$$

Since one has

$$\left(-\partial_T+\frac{\xi}{2T}\,\partial_\xi\right)u_0(\xi,T)=\left(\frac{1}{2T}-\frac{\xi^2}{2T}\right)u_0(\xi,T), \tag{12}$$

one obtains

$$\theta\left(\left(-\partial_T+\frac{\xi}{2T}\,\partial_\xi\right)u_0(\xi,T)\right)=\theta(1-|\xi^2|). \tag{13}$$

This is the Heaviside function of the Barenblatt's equation in its lowest order. We can write the first-order equation as

$$2T\partial_T u_1(\xi,T)-\xi\partial_\xi u_1(\xi,T)-\partial_\xi^2 u_1(\xi,T)=\theta(1-|\xi^2|)\partial_\xi^2 u_0(\xi,T). \tag{14}$$

From the similarity analysis we know that the solution of the Barenblatt's equation can be written in a form of variable separation:

$$u(\xi,T)=F(T)G(\xi). \tag{15}$$

It is adequate when we are only interested in the behavior of the solution in the intermediate asymptotic region.

Expanding

$$F(T)=F_0(T)+\epsilon F_1(T)+\ldots \tag{16}$$

and

$$G(\xi)=G_0(\xi)+\epsilon G_1(\xi)+\ldots, \tag{17}$$

we have

$$u_0(\xi,T)=F_0(T)G_0(\xi) \tag{18}$$

and

$$u_1(\xi,T)=F_0(T)G_1(\xi)+F_1(T)G_0(\xi). \tag{19}$$

We now take

$$F_0(T)=\frac{m_0}{\sqrt{2\pi T}}\quad \textit{and}\quad G_0(\xi)=\exp\left(-\frac{\xi^2}{2}\right). \tag{20}$$

The solution in the first-order approximation is

$$u^{(1)}(\xi,T)=F_0(T)G_0(\xi)+\epsilon(F_0(T)G_1(\xi)+F_1(T)G_0(\xi)). \tag{21}$$

It tells us that the approximation solution cannot be expressed in the form of variable separation in finite order of the perturbative theory. But we will see that the RG solution is in this form. Thus, we shall pursue along this line and accept a corresponding approximation, so that we can use the variable separation solution.

Inserting Eq. (19) into Eq. (14) yields

$$2T(F_1'G_0+F_0'G_1)-\xi(F_1G_0'+F_0G_1')-(F_1G_0''+F_0G_1'')=\theta(1-|\xi|)F_0G_0'', \tag{22}$$

where

$$F_i'=\frac{d}{dT}\,F_i(T),\quad G_i'=\frac{d}{d\xi}\,G_i(\xi),\quad \textit{and}\quad G_i''=\frac{d^2}{d\xi^2}\,G_i(\xi),\quad i=0,1. \tag{23}$$

Now, we search for the solution of the $F_1(T)$. Integrate this equation with respect to the ξ from $-\infty$ to $+\infty$ and let

$$\int_{-\infty}^{\infty} G_1(\xi)d\xi = a. \tag{24}$$

After simple integral calculation and the application of the conditions

$$\lim_{\xi\to\pm\infty} \xi G_1(\xi) = 0 \quad \textit{and} \quad \lim_{\xi\to\pm\infty} G_1'(\xi) = 0, \tag{25}$$

one obtains

$$2aF_1(T)TF_0'(T) + 2\sqrt{2\pi}TF_1'(T) + aF_0(T) + \sqrt{2\pi}F_1(T) = -\frac{2}{\sqrt{e}}F_0(T). \tag{26}$$

Substituting $F_0(T) = m_0/\sqrt{2\pi T}$ and $F_0'(T) = -F_0(T)/2T$ into Eq. (26), we get

$$TF_1'(T) + \frac{1}{2}F_1(T) + \frac{1}{\sqrt{2\pi e}}F_0(T) = 0. \tag{27}$$

The solution of Eq. (27) is

$$F_1(T) = -F_0(T)\beta \ln\frac{T}{l^2}, \tag{28}$$

where

$$\beta = \frac{1}{\sqrt{2\pi e}}. \tag{29}$$

For obtaining this solution, we have made use of the initial condition

$$F_n(l^2) = 0, \quad n \geqslant 1. \tag{30}$$

The first-order approximation of $F(T)$ is

$$F^{(1)}(T) = F_0(T)\left(1 - \alpha \ln\frac{T}{l^2}\right), \tag{31}$$

where

$$\alpha = \epsilon\beta = \frac{\epsilon}{\sqrt{2\pi e}}. \tag{32}$$

It is the anomalous dimension and is well known in the solution of the Barenblatt's equation in the intermediate asymptotic region by application of the RG approach.[3,4]

In the following discussion, we keep the $G(\xi)$ in its zeroth-order approximation without considering the higher-order corrections. That is, to put $G_n(\xi) = 0$, $n \geqslant 1$. Then the solution of the first order is

$$u^{(1)}(\xi, T) = F_0(T)G_0(\xi)\left(1 - \alpha \ln\frac{T}{l^2}\right). \tag{33}$$

It has been proved that this approximation does not have any effect on the function $F^{(1)}(T)$ when we make the RG treatment. We will discuss the space behavior in a separate paper.

For getting a finite but nonzero asymptotic solution, the ''mass,''

$$m_0 = \int_{-\infty}^{\infty} dx u(x,t), \tag{34}$$

cannot remain a constant. It is necessary to approach infinity when the support of the initial function approaches zero. To obtain a finite solution of Barenblatt's equation, the $u(x,0)$ must be more singular than the δ function. It is different from the diffusive equation in regular cases. Moreover, the values of the non-zeroth-order terms are not small, but instead, very large in the intermediate asymptotic region. The renormalization is required. It is well known that the renormalization and RG approaches not only remove the divergence but also improve the perturbation expansion solution to higher leading order.[1–5]

Let

$$m_0 = m_R(\mu) Z(\mu, l^2) \tag{35}$$

and

$$Z(\mu, l^2) = 1 + \alpha \ln \frac{\mu}{l^2}. \tag{36}$$

From the work of Goldenfeld *et al.*,[3,4] we know that the result of the renormalization and RG treatment is

$$u_R^{(1)}(\xi, T) = \frac{m_R(l^2)}{\sqrt{2\pi T}} \left(\frac{l^2}{T}\right)^{\alpha} \exp\left(-\frac{\xi^2}{2}\right). \tag{37}$$

It is easy to check that the initial condition, the boundary conditions, and the connection condition are all satisfied when the l^2 is taken in a nonzero value. But we must remember that the renormalization mass will approach the infinite when $l^2 \to 0$, in order to keep the solution finite. Usually we require

$$m_R(l^2) \times l^{2\alpha} = \text{finite}. \tag{38}$$

There is an explanation for the improvement of the RG approach.[7] But the whole case is not very clear yet. We will discuss some aspects of it in the following sections.

III. ANOMALOUS DIMENSION CALCULATION BY SUMMING $F(T)$ TO THE INFINITE ORDER

Now we discuss the improvement to the perturbative solution of the Barenblatt's equation in the RG approach. We do this by using the approximation suggested in the previous section. We are especially interested in the behavior of the intermediate asymptotic region, in which ξ and t are far from the zero point but not infinite. We shall prove that the result of the renormalization and RG approach is equivalent to the infinite sum of the series of $F(T)$.

We assume the solution of Eq. (3) in a form of variable separation in any order. We have known that it is not a suitable form when the approximation order n is finite. But, the higher the approximation order is taken, the better the proposed form is. As the first step, we keep the dependence on space in its lowest order. Thus we set

$$u_n(\xi, T) = f_n(T) u_0(\xi, T). \tag{39}$$

At the same time, we also neglect a part of the nonlinear effects. We keep the Heaviside function in its lowest order as $\theta(1 - |\xi^2|)$. Therefore we have the form of perturbation expansion of the Barenblatt's equation,

$$2T\partial_T u_n(\xi, T) - \xi \partial_\xi u_n(\xi, T) - \partial_\xi^2 u_n(\xi, T) = \theta\left(\left(-\partial_T + \frac{\xi}{2T}\,\partial_\xi\right) u_0(\xi, T)\right) \partial_\xi^2 u_{n-1}(\xi, T), \quad n \geqslant 1. \tag{40}$$

We will prove that the RG anomalous dimension is just the result of summing up the $F(T)$ series to infinite order in the above approximation.

Inserting Eqs. (13) and (39) into Eq. (40) yields

$$2Tu_0(\xi,T)\,\frac{d}{dT}\,f_n(T)=\theta(1-|\xi^2|)f_{n-1}(T)\partial_\xi^2 u_0(\xi,T),\quad n\geqslant 1. \tag{41}$$

The initial condition,

$$u_n(\xi,l^2)=0,\quad n\geqslant 1, \tag{42}$$

becomes

$$f_n(l^2)=0,\quad n\geqslant 1. \tag{43}$$

When $n=1$, one has

$$2Tu_0(\xi,T)\,\frac{d}{dT}\,f_1(T)=\theta(1-|\xi^2|)\partial_\xi^2 u_0(\xi,T). \tag{44}$$

Integrating it with respect to ξ from $-\infty$ to $+\infty$ gives

$$T\,\frac{d}{dT}\,f_1(T)=-\frac{1}{\sqrt{2\pi e}}=-\beta. \tag{45}$$

Using $f_n(l^2)=0$, $n\geqslant 1$, the solution of Eq. (45) is

$$f_1(T)=-\frac{1}{\sqrt{2\pi e}}\ln\frac{T}{l^2}=\ln\left(\frac{T}{l^2}\right)^{-\beta}. \tag{46}$$

When $n=2$, one has

$$2Tu_0(\xi,T)\,\frac{d}{dT}\,f_2(T)=\theta(1-|\xi^2|)f_1(T)\partial_\xi^2 u_0(\xi,T). \tag{47}$$

Doing the same integration as we have done to Eq. (44), we obtain

$$2T\,\frac{m_0}{\sqrt{T}}\,\frac{d}{dT}\,f_2(T)=f_1(T)\int_{-1}^{1}d\xi\partial_\xi^2 u_0(\xi,T). \tag{48}$$

Due to the identity

$$2T\,\frac{m_0}{\sqrt{T}}\,\frac{d}{dT}\,f_1(T)=\int_{-1}^{1}d\xi\partial_\xi^2 u_0(\xi,T), \tag{49}$$

we have

$$\frac{d}{dT}\,f_2(T)=f_1(T)\,\frac{d}{dT}\,f_1(T). \tag{50}$$

Making use of $f_n(l^2)=0$, $n\geqslant 1$, we obtain

$$f_2(T)=\frac{1}{2}\,[f_1(T)]^2. \tag{51}$$

Using the principle of mathematical induction, we now prove that

$$f_m(T)=\frac{1}{m!}[f_1(T)]^m. \tag{52}$$

Suppose that Eq. (52) is true for $m=n-1$, that is to say,

$$f_{n-1}(T)=\frac{1}{(n-1)!}[f_1(T)]^{n-1}. \tag{53}$$

We are going to prove that it is true for $m=n$. Integrating Eq. (41) with respect to ξ from $-\infty$ to $+\infty$ gives

$$2T\frac{m_0}{\sqrt{T}}\frac{d}{dT}f_n(T)=f_{n-1}(T)\int_{-1}^{1}d\xi\partial_\xi^2 u_0(\xi,T). \tag{54}$$

Due to Eq. (49), one has

$$\frac{d}{dT}f_n(T)=f_{n-1}(T)\frac{d}{dT}f_1(T). \tag{55}$$

Substituting Eq. (53) into it gives

$$\frac{d}{dT}f_n(T)=\frac{1}{(n-1)!}[f_1(T)]^{n-1}\frac{d}{dT}f_1(T). \tag{56}$$

Because $f_n(l^2)=0$, the solution of Eq. (56) is

$$f_n(T)=\frac{1}{n!}[f_1(T)]^n. \tag{57}$$

It is true for $m=1$ and $m=2$. Thus we have proved the proposition for any m.

In the infinite limit, we have

$$u(\xi,T)=\left[1+\sum_{n=1}^{\infty}\frac{\epsilon^n}{n!}[f_1(T)]^n\right]u_0(\xi,T). \tag{58}$$

Inserting Eq. (46) into it yields

$$u(\xi,T)=\left[1+\sum_{n=1}^{\infty}\frac{1}{n!}\left[-\epsilon\beta\ln\frac{T}{l^2}\right]^n\right]u_0(\xi,T), \tag{59}$$

that is,

$$u(\xi,T)=\exp\left[-\epsilon\beta\ln\frac{T}{l^2}\right]u_0(\xi,T)=\left[\frac{T}{l^2}\right]^{-\alpha}u_0(\xi,T), \tag{60}$$

where

$$\alpha=\epsilon\beta=\frac{\epsilon}{\sqrt{2\pi e}}, \tag{61}$$

which is just the anomalous dimension given by the renormalization and RG approaches.

IV. AN IMPROVEMENT ON THE CALCULATION OF THE ANOMALOUS DIMENSION

In the previous section, we have kept the Heaviside function and the function $G(\xi)$ in their lowest order in our calculation of the $F(T)$ to higher orders. It has led a partial loss of the nonlinear effect which is included in the Heaviside function. Now we show that the calculation of

the anomalous dimension can be improved by the infinite summing of the function $F(T)$ without the approximation of keeping the Heaviside function in its lowest order to take account of a part of the lost nonlinear effect. Now we still keep the solution in the form of variable separation as Eq. (15), but only let the function $G(\xi)$ in it lowest order. We shall use a trick that makes an analytic treatment possible.

Take the approximation solution obtained in the previous section,

$$u(\xi,T)=\left(\frac{T}{l^2}\right)^{-\alpha} u_0(\xi,T), \tag{62}$$

as an initial solution. After inserting it into the Heaviside function, we solve the $u_n(\xi,T)$ and search for its infinite sum. Thus we obtain the first iterative result.

We put the first iterative solution into the Heaviside function to solve the equation secondly.

In this way, we search for the limit of the iterative solution to infinite. If the limit exists, we can obtain the solution.

An important observation is that the form of the solution remains unchanged in the iterative process,

$$u^{(k)}(\xi,T)=\left(\frac{T}{l^2}\right)^{-\alpha^{(k)}} u_0(\xi,T). \tag{63}$$

The only change is the value of the anomalous dimension $\alpha^{(k)}$. It simplifies the analysis considerably.

We rewrite α as $\alpha^{(0)}$,

$$\alpha=\epsilon\beta=\frac{\epsilon}{\sqrt{2\pi e}}\rightarrow\alpha^{(0)}=\epsilon\beta^{(0)}. \tag{64}$$

The $\alpha^{(k)}=\epsilon\beta^{(k)}$ represents the results after the kth iteration.

We still need to solve the problem by summing up the infinite expansion series, in each step of the iterative process.

Putting Eq. (63) into the Heaviside function of the nth-order equation, we obtain the nth order and $(k+1)$th iteration equation,

$$2Tu_0(\xi,T)\,\frac{d}{dT}\,f_n^{(k+1)}(T)=\theta\left(\left(-\partial_T+\frac{\xi}{2T}\,\partial_\xi\right)\left(\left(\frac{T}{l^2}\right)^{-\alpha^{(k)}} u_0(\xi,T)\right)\right) f_{n-1}^{(k+1)}(T)\partial_\xi^2 u_0(\xi,T), \tag{65}$$

where the super-index (k) represents the result of the kth iteration and the subindex n represents the nth order in the perturbation expansion. The initial condition remains in the form of Eq. (43).

When $k=1$ and $n=1$, one has

$$2Tu_0(\xi,T)\,\frac{d}{dT}\,f_1^{(1)}(T)=\theta\left(\left(-\partial_T+\frac{\xi}{2T}\,\partial_\xi\right)\left(\left(\frac{T}{l^2}\right)^{-\alpha^{(0)}} u_0(\xi,T)\right)\right)\partial_\xi^2 u_0(\xi,T), \tag{66}$$

where $f_0^{(k)}(T)=1$ has been used. Because of the identity

$$\left(-\partial_T+\frac{\xi}{2T}\,\partial_\xi\right)\left(\left(\frac{T}{l^2}\right)^{-\alpha^{(0)}} u_0(\xi,T)\right)=[2\alpha^{(0)}-(\xi^2-1)]\,\frac{1}{2T}\left(\frac{T}{l^2}\right)^{-\alpha^{(0)}} u_0(\xi,T), \tag{67}$$

one has

$$\theta\left(\left(-\partial_T+\frac{\xi}{2T}\,\partial_\xi\right)\left(\left(\frac{T}{l^2}\right)^{-\alpha^{(0)}} u_0(\xi,T)\right)\right)=\theta(2\alpha^{(0)}+1-\xi^2). \tag{68}$$

Substituting it into Eq. (66) and integrating it with respect to ξ from $-\infty$ to $+\infty$ yields

$$2T\frac{m_0}{\sqrt{T}}\frac{d}{dT}f_1^{(1)}(T)=\int_{-\infty}^{\infty}\theta(2\alpha^{(0)}+1-\xi^2)\partial_\xi^2 u_0(\xi,T)$$

$$=\frac{m_0}{\sqrt{2\pi T}}\left[-2\sqrt{(1+2\alpha^{(0)})}\exp\left(-\frac{1+2\alpha^{(0)}}{2}\right)\right], \tag{69}$$

that is,

$$\frac{d}{d\ln T}f_1^{(1)}(T)=\frac{1}{\sqrt{2\pi}}\left[-\sqrt{(1+2\alpha^{(0)})}\exp\left(-\frac{1+2\alpha^{(0)}}{2}\right)\right]. \tag{70}$$

Using $f_1^{(1)}(l^2)=0$, we can obtain the solution of Eq. (70)

$$f_1^{(1)}(T)=\frac{-\sqrt{(1+2\alpha^{(0)})}}{\sqrt{2\pi e^{(1+2\alpha^{(0)})}}}\ln\frac{T}{l^2}=-\beta^{(1)}\ln\frac{T}{l^2}, \tag{71}$$

where

$$\beta^{(1)}=\frac{\sqrt{(1+2\alpha^{(0)})}}{\sqrt{2\pi e^{(1+2\alpha^{(0)})}}}. \tag{72}$$

When $k=1$ and $n=2$, one has

$$2Tu_0(\xi,T)\frac{d}{dT}f_2^{(1)}(T)=\theta(2\alpha^{(0)}+1-\xi^2)f_1^{(1)}(T)\partial_\xi^2 u_0(\xi,T). \tag{73}$$

Integrating it with respect to ξ from $-\infty$ to $+\infty$ yields

$$\frac{d}{dT}f_2^{(1)}(T)=f_1^{(1)}(T)\frac{d}{dT}f_1^{(1)}(T). \tag{74}$$

Making use of $f_n^{(1)}(l^2)=0$, $n\geqslant 2$, the solution of Eq. (74) is

$$f_2^{(1)}(T)=\frac{1}{2}[f_1^{(1)}(T)]^2. \tag{75}$$

Using the principle of mathematical induction, it is easy to prove that

$$f_m^{(1)}(T)=\frac{1}{m!}[f_1^{(1)}(T)]^m. \tag{76}$$

Suppose it is true for $m=n-1$, that is to say

$$f_{n-1}^{(1)}(T)=\frac{1}{(n-1)!}[f_1^{(1)}(T)]^{n-1}. \tag{77}$$

We are going to prove that it is true for $m=n$. We know that

$$2Tu_0(\xi,T)\frac{d}{dT}f_n^{(1)}(T)=\theta(2\alpha^{(0)}+1-\xi^2)f_{n-1}^{(1)}(T)\partial_\xi^2 u_0(\xi,T). \tag{78}$$

Integrating it with respect to ξ from $-\infty$ to $+\infty$ gives

$$\frac{d}{dT}f_n^{(1)}(T)=f_{n-1}^{(1)}(T)\frac{d}{dT}f_1^{(1)}(T). \tag{79}$$

Substituting Eq. (77) into it yields

$$\frac{d}{dT} f_n^{(1)}(T) = \frac{1}{(n-1)!} [f_1^{(1)}(T)]^{n-1} \frac{d}{dT} f_1^{(1)}(T). \tag{80}$$

On account of $f_n^{(1)}(l^2)=0$, one can solve Eq. (80) and obtain

$$f_n^1(T) = \frac{1}{n!} [f_1^{(1)}(T)]^n. \tag{81}$$

We have proved that it is true for $m=1$ and $m=2$. Thus the proposition is true for any m.

Now we sum the infinite series

$$u^{(1)}(\xi,T) = \left[1 + \sum_{n=1}^{\infty} \frac{\epsilon^n}{n!} [f_1^{(1)}(T)]^n \right] u_0(\xi,T). \tag{82}$$

Inserting the expression of $f_1^{(1)}(T)$ into it, we obtain

$$u^{(1)}(\xi,T) = \left[1 + \sum_{n=1}^{\infty} \frac{1}{n!} \left[-\epsilon\beta^{(1)} \ln \frac{T}{l^2} \right]^n \right] u_0(\xi,T). \tag{83}$$

That is,

$$u^{(1)}(\xi,T) = \left[\frac{T}{l^2} \right]^{-\alpha^{(1)}} u_0(\xi,T), \tag{84}$$

where

$$\alpha^{(1)} = \epsilon\beta^{(1)} \quad \textit{and} \quad \beta^{(1)} = \frac{\sqrt{(1+2\alpha^{(0)})}}{\sqrt{2\pi e^{(1+2\alpha^{(0)})}}}. \tag{85}$$

The $\alpha^{(1)}$ is the anomalous dimension corrected to the first order of the $F(T)$. Now, we have finished the first iterative calculation.

When we make the kth iteration, the process is the same as the $(k-1)$th one. The only difference is that we will use $\beta^{(k)}$ in place of the $\beta^{(k-1)}$. Then it is easy to prove that

$$u^{(k)}(\xi,T) = \left[\frac{T}{l^2} \right]^{-\alpha^{(k)}} u_0(\xi,T), \tag{86}$$

where

$$\alpha^{(k)} = \epsilon\beta^{(k)} \quad \textit{and} \quad \beta^{(k)} = \frac{\sqrt{(1+2\alpha^{(k-1)})}}{\sqrt{2\pi e^{(1+2\alpha^{(k-1)})}}}. \tag{87}$$

The $\alpha^{(k)}$ is the anomalous dimension corrected to the kth order of the $F(T)$.

If the iterative process is convergent, the limit exists. Let $\lim_{k\to\infty} \beta^{(k)} = \beta^{(\infty)}$, which leads to

$$\beta^{(\infty)} = \frac{\sqrt{(1+2\epsilon\beta^{(\infty)})}}{\sqrt{2\pi e^{(1+2\epsilon\beta^{(\infty)})}}}. \tag{88}$$

Then one has

$$u^{(\infty)}(\xi,T) = \left[\frac{T}{l^2} \right]^{-\alpha^{(\infty)}} u_0(\xi,T), \tag{89}$$

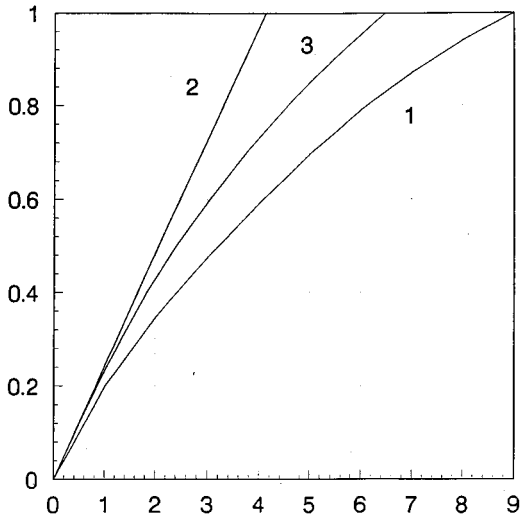

FIG. 1. The function $\alpha(\epsilon)$ vs ϵ, with (1) the numerical result from Barenblatt by similarity analysis; (2) the RG result from Goldenfeld *et al.*; and (3) our result by using an infinite sum of the $F(T)$.

where

$$\alpha^{(\infty)}=\epsilon\beta^{(\infty)} \tag{90}$$

and

$$\alpha^{(\infty)}=\frac{\epsilon\sqrt{(1+2\alpha^{(\infty)})}}{\sqrt{2\pi e^{(1+2\alpha^{(\infty)})}}}. \tag{91}$$

It is obvious that Eq. (91) has a finite solution, which is the anomalous dimension corrected by considering the nonlinear effect of $F(T)$ to infinite order.

The justification of the iterative method and its initial value is that the solution is convergent and satisfies the Barenblatt's equation in our approximation.

We can compare the improved result with the numerical one given by Barenblatt and the result obtained by the RG approach, as shown in Fig. 1. The improved result $\alpha^{(\infty)}$ is better than $\alpha^{(0)}$.

V. CONCLUSION

We have calculated the anomalous dimension by summing the $F(T)$ to infinite order. When we keep the Heaviside function and the space-dependent function $G(\xi)$ in their lowest order, the anomalous dimension is the same as the RG result. When the approximation of the Heaviside function in its lowest order is removed, the value of the anomalous dimension can be improved. It is expressed in Eq. (91) and Fig. 1.

(Received 5 September 1996; accepted for publication 20 October 1997)

We characterize, in the case of $\widehat{\mathrm{sl}}(2)$, the crystal base of the Demazure module $E_w(\Lambda)$ in terms of extended Young diagrams or paths for any dominant integral weight Λ and Weyl group element w. Its character is evaluated via two expressions, ''bosonic'' and ''fermionic.'' © *1998 American Institute of Physics.* [S0022-2488(98)00503-9]

I. INTRODUCTION

Our purpose in this work is to characterize the crystal bases of the Demazure modules of $\widehat{\mathrm{sl}}(2)$ in terms of ''paths,'' or extended Young diagrams, and obtain explicit expressions for their full characters. There are two ways to motivate this work: one can motivate it from the viewpoint of certain recent developments in mathematical physics, or from the viewpoint of representation theory.

A. One-point functions in exactly solvable models

Certain physical quantities in exactly solvable two-dimensional lattice models, namely, the so-called ''one-point functions'' can be evaluated using Baxter's corner transfer matrix method. (For an introduction to exactly solvable models, and to the corner transfer matrix method, we refer to Ref. 1.) This method reduces the computation of one-point functions to a computation of a weighted sum. This sum is over combinatorial objects called ''paths,'' one-dimensional configurations, defined on the half-line. They will be discussed in detail in the sequel. The weight of a path is the evaluation, on that path, of an ''energy'' functional defined on the set of all paths. The weighted sum is the generating function of the number of paths of a certain weight.

One way to evaluate this generating function is by solving a recursion relation for the generating function that counts the number of paths defined on a finite segment, of length L, of the half-line. The recursion is with respect to L. The $L\to\infty$ limit of the result, which is the generating function of all paths, turns out to be the character of a highest weight module of an infinite-dimensional algebra: an affine, or Virasoro algebra. (For an introduction to the algebraic approach to exactly solvable models, we refer to Ref. 2.) The result obtained by solving a recursion relation typically has a form that, for physical reasons, is called ''bosonic.'' (For an explanation of the origin of this terminology, we refer to Ref. 3.)

B. Rogers–Ramanujan-type *q*-series identities

More recently, the same physical objects were evaluated in a completely different way, using Bethe Ansatz methods.[3] In that case, the results turn out to have a completely different form, that, for the same physical reasons as above, is referred to as ''fermionic.''

Equating the bosonic and fermionic expressions for the same objects, one obtains Rogers–Ramanujan-type identities between q series. Strictly speaking, such identities are conjectures, since the methods used to obtain them are indirect, and involve certain ''physical assumptions.''

(What we have in mind are the various assumptions involved in the derivation of the corner transfer matrix method, and the ''string hypothesis.'') What one needs are direct proofs.

C. Schur-type polynomial identities

One method to obtain direct proofs, which dates back to Schur, is to work at the level of the generating functions of all paths that live on a segment of the half-line of length L. These are polynomials that depend on L. Once we can prove the boson-fermion identities for finite L, we take the limit $L\to\infty$, and obtain the original q-series identities.

The following question now arises: If the original infinite q series are characters of highest weight modules of infinite-dimensional algebras, are the finite-L polynomials the characters of anything? Do they have a meaning in mathematics? Or are they just convenient objects that appear in intermediate steps?

The reason why this question arises is that rigorous proofs in exactly solvable models are typically obstructed by the fact that we have to deal with infinite series, and infinite-dimensional quantities. The reason why we typically have to do that, is that only in the limit $L\to\infty$ do these models exhibit invariance under infinite-dimensional algebras, and this invariance is an essential ingredient in solvability. Thus, we have the following problem: we need to work in the $L\to\infty$ limit in order to be able to obtain exact solutions, but in that limit we cannot provide rigorous proofs.

This is the reason why it is very interesting to try to understand as much of the structure of exactly solvable models as possible at the level of finite L. The hope is that we can find algebraic structures at finite L that are sufficiently strong to provide rigorous proofs and solutions. A typical object to investigate are the L-restricted generating functions.

What we find in this work, is that these objects do have a mathematical significance, or are directly related to objects that do. We find that the L-restricted generating functions are closely related to the characters of Demazure modules.

D. Demazure modules

From the viewpoint of representation theory, we can motivate our work in the evaluation of the characters of Demazure modules. The Demazure module is characterized by its highest weight Λ and Weyl group element w, and is denoted by $E_w(\Lambda)$. In Refs. 4–5, a formula for computing the Demazure character $\mathrm{ch}\, E_w(\Lambda)=\Sigma_{\mu\in P}\dim(E_w(\Lambda))_\mu e^\mu$ is given as follows. For $\mu\in P, i=0,1$, define the operator $D_i:\mathbb{Z}[P]\to\mathbb{Z}[P]$ by

$$D_i(e^\mu)=\frac{e^{\mu+\rho}-e^{r_i(\mu+\rho)}}{1-e^{-\alpha_i}}\,e^{-\rho}.$$

Let $w=r_{i_n}\cdots r_{i_2}r_{i_1}\in W$ be a reduced expression. For the terminologies of $\widehat{\mathrm{sl}}(2)$ see Sec. II A. Then, the Demazure character formula states that

$$\mathrm{ch}\, E_w(\Lambda)=D_{i_n}\cdots D_{i_2}D_{i_1}(e^\Lambda).$$

As elegant as this character formula is, it is anything but combinatorial. Hence, using this formula it is very difficult to get any information about specific weight spaces. In Ref. 6, Sanderson used Littelmann's path model[7] and gave nice expressions for the ''real'' characters of $E_w(\Lambda)$ for all Λ and the ''principal'' characters of $E_w(\Lambda)$ for $\Lambda=s\Lambda_0$. We point out that the real (resp., principal) character of $E_w(\Lambda)$ is the specialization of $e^{-\Lambda}\,\mathrm{ch}\, E_w(\Lambda)$, where $e^{-\alpha_0}=q$, $e^{-\delta}=1$ (resp., $e^{-\alpha_0}=q$, $e^{-\delta}=q^2$).

E. Crystal bases

In 1990, Kashiwara brought a notion of crystal base in the representation theory of the quantum group.[8] This notion is quite powerful in the combinatorial aspect of representation theory. As an example, we find Ref. 9, in which the Littlewood–Richardson-type rules for the classical Lie algebras are given in a purely combinatorial way. Kashiwara also obtained the crystal

bases of the Demazure modules as subsets of those of the corresponding highest weight modules.[10] His algorithm is given in a recursive way. Consequently he got a new proof of the Demazure character formula.

Since we know that in the case of affine Lie algebra the crystal base of the highest weight module is described in terms of paths,[11,12] it is natural to try to characterize the crystal base of the Demazure module in this language. For the affine algebra of type A we have yet another notion to describe the crystal base, that is, an extended Young diagram.[13,14]

F. Main results

What we have done in our work is the characterization of Demazure crystal bases in terms of extended Young diagrams (Theorem 2). One of the advantages to do so is that we can make the most of earlier efforts toward the evaluations of so-called one-dimensional configuration sums.[15,16] Recent results on fermionic expressions are also available. We would like to note here that after we had obtained the fermionic expression (Theorem 3), we came to know Schilling also had the same result.[17] However, we have included our proof since it is different from that of Schilling. As a corollary of the characterization theorem, we evaluate the characters of Demazure modules (Theorems 4 and 5).

G. Outline of paper

In Sec. II, we define the basic combinatorial objects in this work: paths and extended Young diagrams. We then describe the crystal structure of the integrable highest weight module of $U_q(\hat{\mathfrak{sl}}(2))$. In Sec. III, we introduce the Demazure modules, and characterize their crystals via paths or extended Young diagrams. In Sec. IV, we review one-dimensional configuration sums and rewrite them into fermionic forms. Using them we can express Demazure characters. We also discuss some specializations and compare them with Sanderson's results. Section V contains a short discussion.

II. PATHS AND EXTENDED YOUNG DIAGRAMS

In this section we recall the basic combinatorial objects used in this work: the paths and extended Young diagrams. Next, we outline the realization of the crystal base of an integrable $\hat{\mathfrak{sl}}(2)$ module in terms of these objects. We also list some properties of the crystal base that we will need in the sequel.

A. Preliminaries

Consider the affine Lie algebra $\hat{\mathfrak{sl}}(2)$.[18] Let $\{\alpha_0,\alpha_1\}$, $\{h_0,h_1\}$, and $\{\Lambda_0,\Lambda_1\}$ be the simple roots, simple coroots, and fundamental weights, respectively. They satisfy $\Lambda_i(h_j)=\delta_{ij}$ and $\alpha_i(h_j)=2(-1)^{1+\delta_{ij}}$ for $i,j=0,1$. $\delta=\alpha_0+\alpha_1$, $c=h_0+h_1$ are the null root and canonical central element, respectively. The sets $P=\mathbb{Z}\Lambda_0\oplus\mathbb{Z}\Lambda_1\oplus\mathbb{Z}\delta$, and $Q=\mathbb{Z}\alpha_0\oplus\mathbb{Z}\alpha_1$ are the weight and root lattices, respectively. Let $\rho\in\mathfrak{h}^*$ be such that $\rho(h_i)=1$ for $i=0,1$.

Let $U_q(\hat{\mathfrak{sl}}(2))$ denote the quantized universal enveloping algebra associated with $\hat{\mathfrak{sl}}(2)$. For its precise definition and Hopf algebra structure, we refer to Ref. 14. For $\Lambda\in P,\Lambda(c)$ is the level of Λ. The set $P^+=\{\Lambda\in P|\Lambda(h_i)\geqslant 0,i=0,1\}$ is the set of dominant weights. For $\Lambda\in P^+$, let $V(\Lambda)$ denote the unique (up to isomorphism) integrable highest weight $U_q(\hat{\mathfrak{sl}}(2))$ module. Since $V(\Lambda+k\delta)\simeq V(\Lambda)\otimes V(k\delta)$ and $\dim V(k\delta)=1$, it suffices to assume that $\Lambda=s\Lambda_0+t\Lambda_1$ for some $s,t\in\mathbb{Z}_{\geqslant 0}$. Let $\Lambda(c)=s+t=k$ be the level of Λ.

B. Paths

For convenience, we extend the subscript i of Λ_i to $i\in\mathbb{Z}$, by setting $\Lambda_i=\Lambda_{i'}$ for $i\equiv i'\pmod 2$. We also set $\hat{i}=\Lambda_{i+1}-\Lambda_i(i=0,1)$. For $k\in\mathbb{Z}_{\geqslant 0}$, we define a set of level k weights P_k by $P_k=\{a_0\Lambda_0+a_1\Lambda_1|a_0,a_1\in\mathbb{Z},a_0+a_1=k\}$.

Definition 1 [path on P_k]: Fixing $k,L\in\mathbb{Z}_{\geqslant 0}$ we define a path p of length L as a sequence $p=(p_0,\ldots,p_L,p_{L+1})$, with all $p_i\in P_k$ and $p_{i+1}-p_i\in\{k\hat{0},(k-1)\hat{0}+\hat{1},\ldots,k\hat{1}\}$.

Definition 2 [set of paths $\mathscr{P}_L(\Lambda)$]: For $L\in\mathbb{Z}_{\geqslant 0}$ and a dominant weight $\Lambda=s\Lambda_0+t\Lambda_1(s+t=k)$, we set

$$\mathscr{P}_L(\Lambda)=\left\{p=(p_0,\ldots,p_L,p_{L+1})\,\middle|\,\begin{array}{l}p \ \text{is a path on} \ P_k,\\ p_i=s\Lambda_i+t\Lambda_{i+1}, \quad \text{for} \ \ i=L,L+1\end{array}\right\}.$$

To the set $\mathscr{P}_L(\Lambda)$, we associate a special path $\overline{p}$, called the ground-state path, defined as follows:

Definition 3 [ground-state path $\overline{p}$]:

$$\overline{p}=(\overline{p_0}\ldots,\overline{p_L},\overline{p_{L+1}}), \quad \overline{p_i}=s\Lambda_i+t\Lambda_{i+1}, \quad \text{for all} \ \ i.$$

The relevance of the ground-state path will become clear in the sequel.

For $k\in\mathbb{Z}_{\geqslant 0}$ set $\mathscr{A}_k^+=\{a_0\epsilon_0+a_1\epsilon_1|a_0,a_1\in\mathbb{Z}_{\geqslant 0},a_0+a_1=k\}$. Here we consider ϵ_0 and ϵ_1 as symbols. Just as in the case of Λ_i, we extend the subscript i of ϵ_i to $i\in\mathbb{Z}$ by setting $\epsilon_i=\epsilon_{i'}$ for $i\equiv i'(\mathrm{mod}\ 2)$. We encode a path in terms of a sequence of elements in $\mathscr{A}_k^+$ as follows.

Definition 4 [sequence of elements $\iota(p)$]: Let $\Lambda=s\Lambda_0+t\Lambda_1(s+t=k)$. For a path $p=(p_0,\ldots,p_L,p_{L+1})\in\mathscr{P}_L(\Lambda)$ we define a sequence $\iota(p)=(\iota(p)_0,\ldots,\iota(p)_L)$ by $\iota(p)_i=m_i\epsilon_0+(k-m_i)\epsilon_1\in\mathscr{A}_k^+$, where for each i, m_i is determined by $p_{i+1}-p_i=m_i\hat{0}+(k-m_i)\hat{1}$.

For the ground-state path $\overline{p}$, $\iota(\overline{p})$ is given by $\iota(\overline{p})_i=s\epsilon_i+t\epsilon_{i+1}$. We remark that the data $\iota(p)$ uniquely determine $p\in\mathscr{P}_L(\Lambda)$.

Define a function $\mu:\mathscr{A}_k^+\to\{0,1,\ldots,k\}$ by

$$\mu(m\epsilon_0+(k-m)\epsilon_1)=m.$$

Using μ, we define the energy, and the weight of a path p as follows:

Definition 5 [energy of a path $E(p)$]:

$$E(p)=\sum_{j=1}^{L} j(H(\iota(p)_{j-1},\iota(p)_j)-H(\iota(\overline{p})_{j-1},\iota(\overline{p})_j)),$$

where

$$H(\epsilon,\epsilon')=\max(k-\mu(\epsilon),\mu(\epsilon')), \quad \text{for} \ \ \epsilon,\epsilon'\in\mathscr{A}_k^+. \tag{1}$$

Definition 6 [weight of a path wt *p]:*

$$\mathrm{wt}\ p=p_0-E(p)\delta.$$

We note that for the ground-state path $\overline{p}\in\mathscr{P}_L(\Lambda)$ we have $E(\overline{p})=0$ and wt $\overline{p}=\Lambda$. We will need the following lemma in the sequel.

Lemma 1: Let $\Lambda=s\Lambda_0+t\Lambda_1(s+t=k)$. For the ground-state path $\overline{p}\in\mathscr{P}_L(\Lambda)$, we have

$$\sum_{j=1}^{L} jH(\iota(\overline{p}_{j-1}),\iota(\overline{p}_j))=\left(\frac{L+\epsilon^{(L)}}{2}\right)^2 k+(-1)^{\epsilon^{(L)}}\frac{L+\epsilon^{(L)}}{2}s.$$

Here $\epsilon^{(L)}$ is defined by

$$\epsilon^{(L)}=\begin{cases}0 & (L:\textit{even}),\\ 1 & (L:\textit{odd}).\end{cases} \tag{2}$$

Proof: Note that $\iota(\overline{p}_j)=s\epsilon_j+t\epsilon_{j+1}$. From (1) we obtain the following expression to calculate:

$$\sum_{\substack{j=1\\ j:\mathrm{odd}}}^{L} jt+\sum_{\substack{j=1\\ j:\mathrm{even}}}^{L} js,$$

which is evaluated easily. ■

So far, we fixed the length of paths L. Next, we consider two lengths L and $L'(L\leqslant L')$. Let $\Lambda=s\Lambda_0+t\Lambda_1$. Then there is an injection given by

$$\mathscr{P}_L(\Lambda)\to\mathscr{P}_{L'}(\Lambda)$$

$$p=(p_0,\ldots,p_L,p_{L+1})\mapsto p'=(p'_0,\ldots,p'_{L'},p'_{L'+1}),$$

where $p'_i=p_i(0\leqslant i\leqslant L+1),=s\Lambda_i+t\Lambda_{i+1}(L+1\leqslant i\leqslant L'+1)$. Let $\overline{p'}$ be the ground-state path of $\mathscr{P}_{L'}(\Lambda)$. The image of $\mathscr{P}_L(\Lambda)$ in $\mathscr{P}_{L'}(\Lambda)$ is characterized by the paths $\{p'\}$ such that $p'_i=\overline{p'_i}(i\geqslant L)$. Note that the energy and weight of a path are unchanged by this injection. We have the following inductive system:

$$\mathscr{P}_0(\Lambda)\to\mathscr{P}_1(\Lambda)\to\cdots\to\mathscr{P}_L(\Lambda)\to\cdots .$$

We define the set of all paths $\mathscr{P}(\Lambda)$ as follows.

Definition 7 [$\mathscr{P}(\Lambda)$]:

$$\mathscr{P}(\Lambda)=\lim_{\to}\mathscr{P}_L(\Lambda).$$

C. Extended Young diagrams

An extended Young diagram Y is an infinite sequence $(y_j)_{j\geqslant 0}$ of integers, such that $y_j\leqslant y_{j+1}$ for all j and $y_j=y_\infty$ (a fixed integer) for sufficiently large j.[15,13,14] In other words, the sequence stabilizes after a finite (though arbitrarily large) number of elements. The number y_∞ is called the ''charge'' of Y. In this paper, we only consider extended Young diagrams of charge $\gamma=0$ or 1.

We can view an extended Young diagram $Y=(y_j)_{j\geqslant 0}$ as a diagram drawn on the lattice in the right-half-plane with sites $\{(m,n)\in\mathbb{Z}\times\mathbb{Z}|m\geqslant 0\}$, where y_j denotes the depth of the jth column. If $y_j\neq y_{j+1}$, for some j, then there will be concave (''⌈''), and convex (''⌋'') corners. A corner located at site (m,n) has diagonal number $d=m+n$.

1. A coloring scheme

We assign each corner of $Y=(y_j)_{j\geqslant 0}$ one of two colors: 0=''white,'' or 1=''black'' as follows: A d-diagonal corner is white (resp., black), if d is even (resp., odd). A white (resp., black) corner will also be called a 0-corner (resp., 1-corner).

Thus, we can also view an extended Young diagram $Y=(y_j)_{j\geqslant 0}$ of charge 0 (resp., 1) as a usual Young diagram, but with its nodes alternately colored ''white'' and ''black,'' such that the top leftmost node has color ''white'' (resp., ''black'').

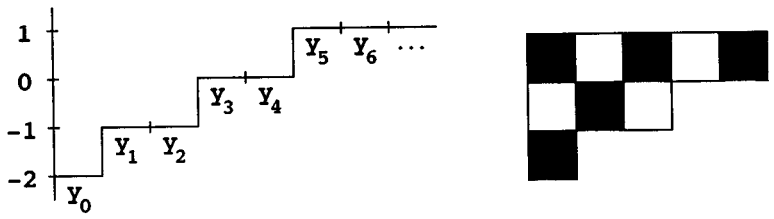
We define the weight wt Y of an extended Young diagram Y of charge i $(=0$ or $1)$ to be

$$\text{wt } Y=\Lambda_i-k_0\alpha_0-k_1\alpha_1,$$

where k_0 is the number of white nodes in Y and k_1 is the number of of black nodes. We also define the ''width of Y,'' $|Y|$, to be the number of nodes in the first row of Y. Equivalently, $|Y|=L$ if and only if $y_L=y_\infty$ (=charge of Y) but $y_{L-1}<y_L$.

2. Example

Consider the extended Young diagram $Y=(y_j)_{j\geqslant 0}=(-2,-1,-1,0,0,1,1,1,\ldots)$ of charge 1. Y has convex 1-corners at sites $(1,-2)$ and $(5,0)$, a convex 0-corner at site $(3,-1)$, a concave 1-corner at site $(3,0)$, and a concave 0-corner at site $(1,-1)$. Also note that wt $Y=\Lambda_1-4\alpha_0-5\alpha_1$ and $|Y|=5$.



D. From paths to extended Young diagrams

Let us define a ''pattern'' to be a map,

$$t:\mathbb{Z}\times\mathbb{Z}_{\geqslant 0}\to\mathbb{Z},$$

$$(i,j)\mapsto t_{ij},$$

such that (i) for all i, $(t_{ij})_{j\geqslant 0}$ is an extended Young diagram; (ii) $t_{ij}\leqslant t_{i+1j}$ for all i and j; (iii) $t_{i+k\,j}=t_{ij}+2$ for all i and j.

We say the pattern t is normalized if $0\leqslant\gamma_1\leqslant\cdots\leqslant\gamma_k<2$, where $\gamma_i=t_{i\infty}$ is the charge of $(t_{ij})_{j\geqslant 0}$. We call $\gamma=(\gamma_1,\ldots,\gamma_k)$ the charge of t. Viewing condition (iii) we can identify the pattern t with a k-tuple $\mathbf{Y}=(Y_1,\ldots,Y_k)$ of extended Young diagrams $Y_i=(t_{ij})_{j\geqslant 0}$. In terms of extended Young diagrams, (ii) is equivalent to the following inclusion rule:

$$Y_1\supset Y_2\supset\cdots\supset Y_k\supset Y_1[2], \tag{3}$$

where $Y_1[2]$ denotes the extended Young diagram that is obtained by shifting Y_1 upward two units on the lattice in the right-half-plane. Let $\Lambda=s\Lambda_0+t\Lambda_1(s+t=k)$. Denote the set of patterns with charge $\gamma=(\underbrace{0,\ldots,0}_{s},\underbrace{1,\ldots,1}_{t})$ by $\mathscr{T}(\Lambda)$. Then we have a map,

$$\pi:\mathscr{T}(\Lambda)\to\mathscr{P}(\Lambda),$$

$$t=(t_{ij})\mapsto p,$$

where p is determined from $\iota(p)_j=\epsilon_{t_{1j}+j}+\cdots+\epsilon_{t_{kj}+j}$. For a path $p\in\mathscr{P}(\Lambda)$ we say t is a ''lift'' of p if $t\in\pi^{-1}(p)$. Among lifts of $p\in\mathscr{P}(\Lambda)$ there exists a unique normalized lift $t=(t_{ij})\in\mathscr{T}(\Lambda)$ such that $t_{ij}\geqslant t'_{ij}$ for all i,j for any $t'=(t'_{ij})\in\pi^{-1}(p)$ (Proposition 3.4 in Ref. 14). $t(p)$ is called the ''highest lift'' of p. Let $\mathbf{Y}=(Y_1,\ldots,Y_k)$ be the k-tuple of extended Young diagrams corresponding to the highest lift of p. Then we have (Theorem 5.7 in Ref. 15)

$$\text{wt } p=\text{wt } Y_1+\cdots+\text{wt } Y_k.$$

E. The crystal $B(\Lambda)$

Let $(L(\lambda),B(\Lambda))$ be the crystal base of $V(\lambda)$. In this section we give the combinatorial rules used to construct the crystal $B(\Lambda)$, following the work of Refs. 14 and 13.

1. The rules

Let $\Lambda=s\Lambda_0+t\Lambda_1\in P^+$ of level $k=s+t$. We order the elements of $\mathbb{Z}\times\{1,2,\ldots,k\}$ as follows. For (d,j), $(d',j')\in\mathbb{Z}\times\{1,2,\ldots,k\}$, we say

$$(d,j)>(d',j') \text{ if and only if } d>d' \text{ or } d=d' \text{ and } j<j'.$$

Let $\mathscr{Y}(\Lambda)$ denote the set of k-tuples of extended Young diagrams $\mathbf{Y}=(Y_1,\ldots,Y_s,Y_{s+1},\ldots,Y_k)$, such that Y_j has charge 0 (resp., 1) for $1\leqslant j\leqslant s$ (resp., $s+1\leqslant j\leqslant k$). For $\mathbf{Y}\in\mathscr{Y}(\Lambda)$ and fixed i $(=0$ or $1)$, we define the i signature of $\mathbf{Y}$ to be the sequence $\varepsilon=(\varepsilon_1,\varepsilon_2,\ldots,\varepsilon_m)$ (Note that we distinguish ε_j from ϵ_j, which has appeared in Definition 5), such that we see the following:

(A1) $\Sigma_{j=1}^{k}\sharp\{i\text{-corners of } Y_j\}=m$;
(A2) each ε_r is either 0 or 1;
(A3) we can define $j(r)(1\leqslant j(r)\leqslant k)$ and $d(r)$ in such a way that $Y_{j(r)}$ has a $d(r)$-diagonal i-corner;
(A4) if $\varepsilon_r=0$ (resp., 1) then $Y_{j(r)}$ has a $d(r)$-diagonal concave (resp., convex) i-corner;
(A5) if $r_1<r_2$, then $(d(r_1),j(r_1))>(d(r_2),j(r_2))$.

For fixed i signature $\varepsilon=(\varepsilon_1,\varepsilon_2,\ldots,\varepsilon_m)$ we partition the set $\{1,2,...,m\}=J\sqcup K_1\sqcup\cdots\sqcup K_r$ into disjoint subsets by the following procedure:
(B1) if there is no j such that $(\varepsilon_j,\varepsilon_{j+1})=(0,1)$ define $J=\{1,2,...,m\}$,
(B2) if there is some j such that $(\varepsilon_j,\varepsilon_{j+1})=(0,1)$ define $K_1=\{j,j+1\}$,
(B3) apply (B1) and (B2) above to $\{1,2,...,m\}\backslash K_1$ to choose J or K_2 and repeat this as necessary to choose J and $K_1,\ldots,K_r$.

Let $\varepsilon_J=(\varepsilon_{j_1},\ldots,\varepsilon_{j_r})$, where $J=\{j_1,\ldots,j_r\}$ and $j_1<\cdots<j_r$. We call a 0 or 1 in the i-signature ''relevant'' if and only if it is in ε_J.

For fixed $i\in\{0,1\}$ and $\mathbf{Y}$, $\mathbf{Y}'\in\mathscr{Y}(\Lambda)$ suppose that the following conditions hold: (C1) $\varepsilon=(\varepsilon_1,\ldots,\varepsilon_m)$ and $\varepsilon'=(\varepsilon'_1,\ldots,\varepsilon'_m)$ are the i-signatures of $\mathbf{Y}$ and $\mathbf{Y}'$ respectively; (C2) the partition $\{1,2,...,m\}=J\sqcup K_1\sqcup\cdots\sqcup K_r$ is the same for both ε and ε'; and (C3) there exists $l\in J$ such that $\varepsilon_l=0$, $\varepsilon'_l=1$, and $\varepsilon_j=\varepsilon'_j=1$ (resp., 0) if $j\in J$ and $j<l$ (resp., $j>l$).

We define $\tilde{f}_i\mathbf{Y}=\mathbf{Y}'$ and $\tilde{e}_i\mathbf{Y}'=\mathbf{Y}$ if and only if the above conditions hold. If there exists no such $\mathbf{Y}'$ (resp., $\mathbf{Y}$) for $\mathbf{Y}$ (resp., $\mathbf{Y}'$), we define $\tilde{f}_i\mathbf{Y}=0$ (resp., $\tilde{e}_i\mathbf{Y}'=0$).

2. Example

Let $\Lambda=\Lambda_0+\Lambda_1$ and take $\mathbf{Y}=(Y_1,Y_2)\in\mathscr{Y}(\Lambda)$, where $Y_1=(-2,-2,-1,-1,0,0,...)$ is of charge 0 and $Y_2=(-1,0,0,1,1,...)$ is of charge 1.

$$\mathbf{Y}=(Y_1,Y_2)=\Big(\ ,\ \Big).$$

The 0-signature of $\mathbf{Y}$ is $\varepsilon=(0,0,1,1,0)$. So using rule B, $\varepsilon_J=(0)$. Hence by using rule C we have

$$\tilde{f}_0\mathbf{Y}=\mathbf{Y}'=\Big(\ ,\ \Big)\quad\text{and}\quad\tilde{e}_0\mathbf{Y}=0.$$

However, the 1-signature of $\mathbf{Y}$ is $\varepsilon=(1,1,0,0,0)$ and by rule B, $\varepsilon_J=\varepsilon$. So by rule C we have

$$\tilde{f}_1\mathbf{Y}=\Big(\ ,\ \Big)\quad\text{and}\quad\tilde{e}_1\mathbf{Y}=\Big(\ ,\ \Big).$$

Thus, in general, $\tilde{e}_i,\tilde{f}_i(i=0,1)$ are well-defined maps from $\mathscr{Y}(\Lambda)$ to $\mathscr{Y}(\Lambda)\sqcup\{0\}$. Now let $\Phi=(\phi_1,\ldots,\phi_s,\phi_{s+1},\ldots,\phi_k)\in\mathscr{Y}(\Lambda)$ be the k-tuple of empty extended Young diagrams, where ϕ_j has charge 0 (resp., 1) for $1\leqslant j\leqslant s$ (resp., $s+1\leqslant j\leqslant k$). Note that wt $\Phi=\Lambda=s\Lambda_0+t\Lambda_1$, and $\tilde{e}_i\Phi=0$ for $i=0,1$. We call Φ the highest weight vector (or vacuum) of weight Λ.

We now define the set $B(\Lambda)\subset\mathscr{Y}(\Lambda)$ as

$$B(\Lambda)=\{\tilde{f}_{i_1}\tilde{f}_{i_2}\cdots\tilde{f}_{i_k}\Phi\,|\,k\geqslant 0,i_j=0,1\}\backslash\{0\}.$$

For $\mathbf{Y}\in B(\Lambda)$, $i=0,1$, define

$$\varepsilon_i(\mathbf{Y})=\max\{m\geqslant 0\,|\,\tilde{e}_i^m\mathbf{Y}\in B(\Lambda)\},$$

$$\varphi_i(\mathbf{Y})=\max\{m\geqslant 0\,|\,\tilde{f}_i^m\mathbf{Y}\in B(\Lambda)\}.$$

Thus, $\varepsilon_i, \varphi_i : B(\Lambda) \to \mathbb{Z}$. (We use this new definition of ε_i only here. We hope this will not cause any confusion.) We also have the map $\mathrm{wt}: B(\Lambda) \to P$ given by $\mathbf{Y} \mapsto \mathrm{wt}\,\mathbf{Y}$. The set $B(\Lambda)$ equipped with these maps $\tilde{e}_i$, $\tilde{f}_i$, ε_i, φ_i, and wt turns out to be the ''crystal'' (see Refs. 19 and 20) associated with the integrable highest weight module $V(\Lambda)$. In particular, for $i=0,1$ we have

$$\tilde{e}_i(B(\Lambda)) \subseteq B(\Lambda) \sqcup \{0\} \quad \text{and} \quad \tilde{f}_i(B(\Lambda)) \subseteq B(\Lambda) \sqcup \{0\}.$$

Moreover, $B(\Lambda)$ turns out to be the set of k-tuples of extended Young diagrams corresponding to the highest lifts of $\mathscr{P}(\Lambda)$ (Proposition 3.12 in Ref. 14).

The crystal $B(\Lambda)$ has the structure of an oriented colored graph with elements of $B(\Lambda)$ as the set of vertices and for $\mathbf{Y}, \mathbf{Y}' \in B(\Lambda), \mathbf{Y} \overset{i}{\to} \mathbf{Y}' (i=0,1)$ if and only if $\tilde{f}_i \mathbf{Y} = \mathbf{Y}'$. As a graph, $B(\Lambda)$ is connected. In particular, for $\mathbf{Y} \in B(\Lambda)$ we have (see Proposition 3.11 in 14)

$$\mathbf{Y} \neq \Phi \Rightarrow \tilde{e}_0 \mathbf{Y} \neq 0 \quad \text{or} \quad \tilde{e}_1 \mathbf{Y} \neq 0. \tag{4}$$

As a consequence of (3), we have

$$|Y_1| \geqslant \cdots \geqslant |Y_s| \quad \text{and} \quad |Y_{s+1}| \geqslant \cdots \geqslant |Y_k|.$$

Now we have the following simple but important observations.

Proposition 1: Let $\mathbf{Y} = (Y_1, \ldots, Y_s, Y_{s+1}, \ldots, Y_k) \in B(\Lambda)$ *and* $\mathbf{Y} \neq \Phi$. *Then* $|Y_1| \neq |Y_{s+1}|$.

Proof: Suppose $|Y_1| = |Y_{s+1}|$. Since Y_1 has charge 0 and Y_{s+1} has charge 1, the last nodes in the first rows of Y_1 and Y_{s+1} will have opposite color. Also by (3), the second rows of Y_1 and Y_{s+1} have at least one node less than their first rows. Consequently, we have two convex corners of opposite colors corresponding to the last nodes in the first rows of Y_1 and Y_{s+1}. One of these convex corners will contribute a 1 to the 0-signature of $\mathbf{Y}$ and the other will contribute a 1 to the 1-signature of $\mathbf{Y}$. However, in both cases this 1 will not be relevant as it will be preceded by at least one 0 in each signature. Therefore, by applying $\tilde{e}_0$ and $\tilde{e}_1$ successively we will obtain $\mathbf{Y}' = (Y_1', \ldots, Y_s', Y_{s+1}', \ldots, Y_k') \in B(\Lambda)$, such that

$$\mathbf{Y}' = \hat{e}_{i_m} \tilde{e}_{i_{m-1}} \cdots \tilde{e}_{i_1} \mathbf{Y}, \quad \text{for some } m \quad \text{and} \quad i_j \in \{0,1\},$$

$$\tilde{e}_0 \mathbf{Y}' = 0, \quad \tilde{e}_1 \mathbf{Y}' = 0,$$

$$|Y_1'| = |Y_1| = |Y_{s+1}| = |Y_{s+1}'|.$$

Since $\mathbf{Y} \neq \Phi$ and $|Y_1'| = |Y_1|$, we also have $\mathbf{Y}' \neq \Phi$. So by (4), either $\tilde{e}_0 \mathbf{Y}' \neq 0$ or $\tilde{e}_1 \mathbf{Y}' \neq 0$, which is a contradiction. Hence $|Y_1| \neq |Y_{s+1}|$. ■

Proposition 2: Let $\mathbf{Y} = (Y_1, \ldots, Y_s, Y_{s+1}, \ldots, Y_k) \in \mathscr{Y}(\Lambda)$. *Suppose that* $\tilde{f}_i^n \mathbf{Y} = \mathbf{Y}' = (Y_1', \ldots, Y_s', Y_{s+1}', \ldots, Y_k')$ *for some* $n > 0$ *and* $i = 0$ *or 1. Then* $|Y_j'| \leqslant |Y_j| + 1$ *for all* $1 \leqslant j \leqslant k$.

Proof: Let $\varepsilon = (\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_m)$ be the i-signature of $\mathbf{Y}$ and $\varepsilon_J = (\varepsilon_{j_1}, \ldots, \varepsilon_{j_r})$ be the relevant part of ε. By definition of $\tilde{f}_i$ action (see rule C), $\tilde{f}_i^n \mathbf{Y} = \mathbf{Y}' \neq 0$ implies that $\varepsilon_{j_{r-n+1}} = \varepsilon_{j_{r-n+2}} = \cdots = \varepsilon_{j_r} = 0$. Also recall that each relevant 0 in ε_J corresponds to a unique concave i-corner in some Y_j, $1 \leqslant j \leqslant k$, and each application of $\tilde{f}_i$ changes only one relevant 0 to a relevant 1 without affecting the partition of ε. Hence the first row of each Y_j' can have at most one more i-color node than that of Y_j for $1 \leqslant j \leqslant k$. Therefore, the proposition follows. ■

III. CRYSTALS OF DEMAZURE MODULES

A. Demazure modules

The affine Lie algebra $\hat{\mathfrak{sl}}(2)$ has a triangular decomposition $\mathfrak{n}^- \oplus \mathfrak{h} \oplus \mathfrak{n}^+$, where $\mathfrak{h} = \mathrm{span}\{h_0, h_1, d\}$ is the Cartan subalgebra and $\mathfrak{n}^+$ (resp., $\mathfrak{n}^-$) denote the sum of the positive (resp., negative) root spaces (see Ref. 18). The subalgebra $\mathfrak{b} = \mathfrak{h} + \mathfrak{n}^+$ is the Borel subalgebra of $\hat{\mathfrak{sl}}(2)$. Let r_0, r_1 denote the simple reflections corresponding to the simple roots α_0, α_1, respectively. Recall that $r_i \mu = \mu - \mu(h_i)\alpha_i$ for all $\mu \in P$. Let W denote the Weyl group of $\hat{\mathfrak{sl}}(2)$ generated by r_0, r_1. For $w \in W$ let $l(w)$ denote the length of w and let $\prec$ denote the Bruhat order on W. For Λ

$=s\Lambda_0+t\Lambda_1\in P^+$, $k=s+t$, as before we consider the integrable highest weight $U_q(\widehat{\mathrm{sl}}(2))$-module $V(\Lambda)$. It is known that for $w\in W$, the extremal weight space $V(\Lambda)_{w\Lambda}$ is one dimensional. Let $E_w(\Lambda)$ denote the $U_q(\mathfrak{b})$-module generated by $V(\Lambda)_{w\Lambda}$. These modules $E_w(\Lambda)$, $w\in W$ are called the Demazure modules. They are finite-dimensional subspaces of $V(\Lambda)$ and have the following property: For $w,w'\in W, w\preceq w'$, we have $E_w(\Lambda)\subseteq E_{w'}(\Lambda)$, and $\cup_{w\in W}E_w(\Lambda)=V(\Lambda)$.

B. Demazure crystals

It is known that for $\widehat{\mathrm{sl}}(2)$, the Weyl group is

$$W=\{(r_1r_0)^m,r_0(r_1r_0)^m,(r_0r_1)^m,r_1(r_0r_1)^m|m\in\mathbb{Z}_{\geqslant 0}\}.$$

In particular, for each integer $L>0$, the Weyl group W has two distinct elements of length L:

$$w_L^+=\underbrace{\cdots r_0r_1r_0}_{L}\quad\text{and}\quad w_L^-=\underbrace{\cdots r_1r_0r_1}_{L}.$$

Let $W^+=\{1,w_L^+|L>0\}$ and $W^-=\{1,w_L^-|L>0\}$. Note that on each set W^+ and W^- the Bruhat order is a total order. Also note that $W^+\cup W^-=W$ and $W^+\cap W^-=\{1\}$. For $\Lambda=s\Lambda_0+t\Lambda_1\in P^+$, Kashiwara[10] has defined the crystals $B_w(\Lambda)$ for the Demazure modules $E_w(\Lambda)$ as a suitable subset of the crystal $B(\Lambda)$. For our purpose it suffices to recall the following recursive property of $B_w(\Lambda)$: If $r_iw<w$, then

$$B_w(\Lambda)=\{\tilde{f}_i^m b|m\geqslant 0,b\in B_{r_iw}(\Lambda),\tilde{e}_ib=0\}\backslash\{0\},\tag{5}$$

which can be used to construct $B_w(\Lambda)$ starting from the vacuum $\Phi\in B(\Lambda)$.

For example, if $\Lambda=2\Lambda_0$ and $w=r_1r_0$, the graph of the crystal $B_w(\Lambda)$ can be easily seen in Fig. 1.

Since $w_{L-1}^+<w_L^+, w_{L-1}^-<w_L^-, w_{L-1}^+<w_{L-1}^+r_1=w_L^-$ and $w_{L-1}^-<w_{L-1}^-r_0=w_L^+$, the following result is an immediate consequence of Proposition 3.2.4 in Ref. 10.

Proposition 3: For $L>0$ and $\Lambda\in P^+$ we have

(i) $B_{w_{L-1}^+}(\Lambda)\subseteq B_{w_L^+}(\Lambda)$,
(ii) $B_{w_{L-1}^-}(\Lambda)\subseteq B_{w_L^-}(\Lambda)$,
(iii) $B_{w_{L-1}^+}(\Lambda)\subseteq B_{w_L^-}(\Lambda)$,
(iv) $B_{w_{L-1}^-}(\Lambda)\subseteq B_{w_L^+}(\Lambda)$.

C. Realizations of $B_{w_L^+}(\Lambda)$ and $B_{w_L^-}(\Lambda)$

We define an extended Young diagram $Y=(y_j)_{j\geqslant 0}$ of charge γ ($=0$ or 1) to be *maximal of width L* if

$$|Y|=L\quad\text{and}\quad y_{j+1}=y_j+1\quad\text{for } 0\leqslant j\leqslant L-1.$$

We also define, for $\Lambda=s\Lambda_0+t\Lambda_1\in P^+$, $k=s+t$,

$$B_L(\Lambda)=\{\mathbf{Y}=(Y_1,\ldots,Y_s,Y_{s+1},\ldots,Y_k)\in B(\Lambda)||Y_j|\leqslant L,1\leqslant j\leqslant k\}.$$

Noting that the weight multiplicities of $w_L^+\Lambda$ and $w_L^-\Lambda$ are one, we define extremal vectors as follows:

Definition 8 [extremal vectors]: $b_{w_L^+\Lambda}$ (resp., $b_{w_L^-\Lambda}$) is defined as the element of $B(\Lambda)$ that has the weight $w_L^+\Lambda$ (resp., $w_L^-\Lambda$).

The following theorem characterizes the extremal vectors.

Theorem 1: *Let $\Lambda=s\Lambda_0+t\Lambda_1$, $k=s+t$ and $L>0$. Then we have the following.*

(i) $b_{w_L^+\Lambda}=(Y_1,\ldots,Y_s,Y_{s+1},\ldots,Y_k)\in B(\Lambda)$ *where $Y_1=\cdots=Y_s$ are maximal of width L and charge 0, and $Y_{s+1}=\cdots=Y_k$ are maximal of width $L-1$ and charge 1.*

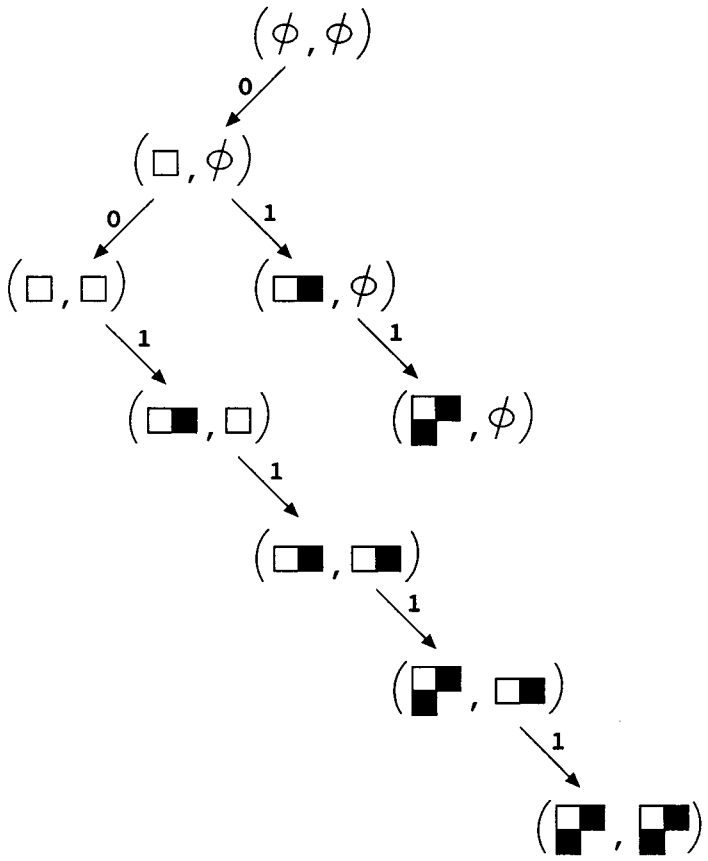


FIG. 1. The crystal graph of $B_{r_1 r_0}(2\Lambda_0)$.

(ii) $b_{w_L^- \Lambda} = (Y_1, \ldots, Y_s, Y_{s+1}, \ldots, Y_k) \in B(\Lambda)$ *where* $Y_1 = \cdots = Y_s$ *are maximal of width* $L-1$ *and charge 0, and* $Y_{s+1} = \cdots = Y_k$ *are maximal of width* L *and charge 1.*

Proof: We use induction on L. If $L=1$, then $w_L^+ = r_0$ and $w_L^+ \Lambda = r_0(s\Lambda_0 + t\Lambda_1) = \Lambda - s\alpha_0$. Also, it is easy to see that the 0-signature of the vacuum $\Phi \in B(\Lambda)$ is $\epsilon = (\epsilon_1, \ldots, \epsilon_s)$, where $\epsilon_j = 0$ for $1 \leqslant j \leqslant s$. Hence

$$b_{r_0 \Lambda} = \tilde{f}_0^s \Phi = (\square, \ldots, \square, \phi, \ldots, \phi) \in B(\Lambda),$$

and (i) holds for $L=1$. Now assume (i) for $L-1$. Observe that $b_{w_{L-1}^+ \Lambda}$ has convex and concave corners of opposite colors. Furthermore, $b_{w_{L-1}^+ \Lambda}$ has exactly $sL + t(L-1)$ numbers of concave i-corners where $L-1 \equiv i \pmod 2$. Also,

$$w_L^+ \Lambda = r_i(w_{L-1}^+ \Lambda) = w_{L-1}^+ \Lambda - (w_{L-1}^+ \Lambda)(h_i)\alpha_i = w_{L-1}^+ \Lambda - (sL + t(L-1))\alpha_i .$$

Since applying $\tilde{f}_i$ to $b_{w_{L-1}^+ \Lambda}(sL + t(L-1))$ times we add one i-color box to each row of each diagram in $b_{w_{L-1}^+ \Lambda}$, we have

$$b_{w_L^+ \Lambda} = \tilde{f}_i^{sL + t(L-1)} b_{w_{L-1}^+ \Lambda} = (Y_1, \ldots, Y_s, Y_{s+1}, \ldots, Y_k) \in B(\Lambda),$$

where $Y_1 = \cdots = Y_s$ are maximal of width L and $Y_{s+1} = \cdots = Y_k$ are maximal of width $L-1$. This proves (i). Proof of (ii) is similar to that of (i). ■

The following theorem characterizes the crystals of the Demazure modules.

Theorem 2: *Let* $\Lambda = s\Lambda_0 + t\Lambda_1$, $k = s+t$ *and* $L > 0$. *Then we have*

$$B_{w_L^+}(\Lambda)=\{(Y_1,\ldots,Y_s,Y_{s+1},\ldots,Y_k)\in B(\Lambda)\,||Y_1|\leqslant L,|Y_{s+1}|\leqslant L-1\},$$

$$B_{w_L^-}(\Lambda)=\{(Y_1,\ldots,Y_s,Y_{s+1},\ldots,Y_k)\in B(\Lambda)\,||Y_1|\leqslant L-1,|Y_{s+1}|\leqslant L\}.$$

Proof: Let

$$S_L=\{(Y_1,\ldots,Y_s,Y_{s+1},\ldots,Y_k)\in B(\Lambda)\,||Y_1|\leqslant L,|Y_{s+1}|\leqslant L-1\},$$

$$T_L=\{(Y_1,\ldots,Y_s,Y_{s+1},\ldots,Y_k)\in B(\Lambda)\,||Y_1|\leqslant L-1,|Y_{s+1}|\leqslant L\}.$$

We use induction on L. First we will show that $B_{w_L^+}(\Lambda)\subseteq S_L$ and $B_{w_L^-}(\Lambda)\subseteq T_L$. This is clear for $L=1$, since by (5), $B_{r_0}(\Lambda)=\{\tilde{f}_0^m\Phi|0\leqslant m\leqslant s\}$ and $B_{r_1}(\Lambda)=\{\tilde{f}_1^m\Phi|0\leqslant m\leqslant t\}$. Assume that $B_{w_{L-1}^+}(\Lambda)\subseteq S_{L-1}$ and $B_{w_{L-1}^-}(\Lambda)\subseteq T_{L-1}$. Since $w_L^+=r_i w_{L-1}^+$ where $L-1\equiv i(\mathrm{mod}\,2)$ by (5), we have

$$B_{w_L^+}(\Lambda)=\{\tilde{f}_i^m b|m\geqslant 0,b\in B_{w_{L-1}^+}(\Lambda),\tilde{e}_i b=0\}\backslash\{0\}.$$

Since $B_{w_{L-1}^+}(\Lambda)\subseteq S_{L-1}$, by Proposition 2 we have $B_{w_L^+}(\Lambda)\subseteq S_L$. Similarly $B_{w_L^-}(\Lambda)\subseteq T_L$.

Now we proceed to show that $S_L\subseteq B_{w_L^+}(\Lambda)$ and $T_L\subseteq B_{w_L^-}(\Lambda)$. As before, this is clear for $L=1$. Assume that $S_{L-1}\subseteq B_{w_{L-1}^+}(\Lambda)$ and $T_{L-1}\subseteq B_{w_{L-1}^-}(\Lambda)$. Let $\mathbf{Y}=(Y_1,\ldots,Y_s,Y_{s+1},\ldots,Y_k)\in S_L$. By Proposition 1, $|Y_1|\neq|Y_{s+1}|$. If $|Y_1|\leqslant L-1$ and $|Y_{s+1}|\leqslant L-2$, then $\mathbf{Y}\in S_{L-1}\subseteq B_{w_{L-1}^+}(\Lambda)\subseteq B_{w_L^+}(\Lambda)$ by (i) of Proposition 3. If $|Y_1|\leqslant L-2$ and $|Y_{s+1}|\leqslant L-1$, then $\mathbf{Y}\in T_{L-1}\subseteq B_{w_{L-1}^-}(\Lambda)\subseteq B_{w_L^+}(\Lambda)$ by (iv) of Proposition 3.

Finally, if $|Y_1|=L$ and $|Y_{s+1}|\leqslant L-1$, then Y_1 will have a convex i-corner corresponding to the last node of the first row of Y_1, where $L-1\equiv i(\mathrm{mod}\,2)$. Furthermore, this convex i-corner will contribute a relevant 1 to the i-signature of $\mathbf{Y}$. Therefore, $\tilde{e}_i\mathbf{Y}\neq 0$. Now, we can choose m such that $\tilde{e}_i^m\mathbf{Y}=\mathbf{Y}'=(Y_1',\ldots,Y_s',Y_{s+1}',\ldots,Y_k')\in B(\Lambda)$ and $\tilde{e}_i\mathbf{Y}'=0$. Then $|Y_1'|=L-1$, and $|Y_{s+1}'|\leqslant L-2$ by Proposition 1. Thus $\mathbf{Y}'\in S_{L-1}\subseteq B_{w_{L-1}^+}(\Lambda)$. Hence by (5), $\mathbf{Y}=\tilde{f}_i^m\mathbf{Y}'\in B_{r_i w_{L-1}^+}(\Lambda)=B_{w_L^+}(\Lambda)$. This proves that $S_L\subseteq B_{w_L^+}(\Lambda)$. Similarly $T_L\subseteq B_{w_L^-}(\Lambda)$ and the theorem holds. ■

The following result is an immediate consequence of Theorem 2.

Corollary 1: For $\Lambda=s\Lambda_0+t\Lambda_1$, we have

$$(i)\quad B_{w_L^+}(\Lambda)\cup B_{w_L^-}(\Lambda)=B_L(\Lambda),$$

$$(ii)\quad B_{w_L^+}(\Lambda)\cap B_{w_L^-}(\Lambda)=B_{L-1}(\Lambda).$$

Let us consider the extreme cases $s=0$ or $t=0$. Assume $\Lambda=k\Lambda_0$. Noting $w_L^-\Lambda=w_{L-1}^+\Lambda$, we have $B_{w_L^-}(\Lambda)=B_{w_{L-1}^+}(\Lambda)$. Similarly, if $\Lambda=k\Lambda_1$, we have $B_{w_L^+}(\Lambda)=B_{w_{L-1}^-}(\Lambda)$. Combining Proposition 3 and the previous corollary, we have the following.

Corollary 2:

$$B_L(\Lambda)=\begin{cases}B_{w_L^+}(\Lambda), & \text{if } \Lambda=k\Lambda_0,\\ B_{w_L^-}(\Lambda), & \text{if } \Lambda=k\Lambda_1.\end{cases}$$

IV. CHARACTERS

A. One-dimensional configuration sum

We summarize the one-dimensional (1-D) configuration sum that have already appeared in the study of exactly solvable SOS models.[15] It will be used in the evaluation of the character for $\mathscr{P}_L(\Lambda)$ in the following section.

Fixing a positive integer k, let us call a pair of integers (b,c) *weakly admissible* if $b-c=-k,-k+2,...,k$. For a weakly admissible pair (b,c) and $L\in\mathbb{Z}_{\geqslant 0}$, let $f_L^{(k)}(b,c)$ denote the unique solution to the following linear difference equation:

$$f_L^{(k)}(b,c)=\sum_d{}' \; f_{L-1}^{(k)}(d,b)q^{L|d-c|/4}, \tag{6}$$

$$f_0^{(k)}(b,c)=\delta_{b0}. \tag{7}$$

Here the sum Σ' is taken over d such that the pair (d,b) is weakly admissible. If (b,c) is not weakly admissible, $f_L^{(k)}(b,c)$ is set to be 0. Note that N,m in Ref. 15 are replaced with k,L, respectively. $f_L^{(k)}(b,c)$ enjoys the following properties: Reflection symmetry:

$$f_L^{(k)}(b,c)=f_L^{(k)}(-b,-c);$$

support property:

$$f_L^{(k)}(b,c)=0, \quad \text{unless} \quad |b|\leqslant Lk, |c|\leqslant (L+1)k \quad \text{and} \quad b\equiv Lk \bmod 2.$$

Given an integer μ, set

$$R_\mu=\{b\in\mathbb{Z}|(\mu-1)k\leqslant b\leqslant(\mu+1)k\},$$

where the left (resp., right) equality sign is taken if $\mu-1\leqslant 0$ (resp., $\mu+1\geqslant 0$). We also set $R_{\mu,\nu}=R_\mu\times R_\nu$. For a weakly admissible pair (b,c) and integer $L(\geqslant 1)$, let $\mu,\nu(=\mu\pm 1)$ be integers such that

$$(b,c)\in R_{\mu,\nu}, \quad \mu\equiv L+1, \nu\equiv L+2 \bmod 2.$$

The above equation uniquely determines μ and ν, except when $b=0$ $(\mu=\pm 1)$ or $c=0$ $(\nu=\pm 1)$, in which case either choice is allowed.

Let us recall standard notations in q analysis (see Ref. 21, for example). We set

$$(z;q)_m=\begin{cases}\displaystyle\prod_{j=1}^{m}(1-zq^{j-1}) & (m\geqslant 1),\\ 1 & (m=0).\end{cases}$$

If there is no danger of confusion, we abbreviate it as $(z)_m$. The *q-multinomial coefficient* is defined as

$$\begin{bmatrix} M \\ m_1\ldots m_n\end{bmatrix}_q=\begin{cases}\dfrac{(q)_M}{\Pi_{j=1}^n(q)_{m_j}}, & \text{if } m_1,\ldots,m_n\geqslant 0 \quad \text{and} \quad m_1+\cdots+m_n=M,\\ 0, & \text{otherwise.}\end{cases} \tag{8}$$

$\left[\begin{smallmatrix} M \\ m_1m_2\end{smallmatrix}\right]_q$ is often written as $\left[\begin{smallmatrix} M \\ m_1\end{smallmatrix}\right]_q$ and called the *Gaussian polynomial*. In both cases, if the subscript is omitted, we understand it as q.

For later use we extend the definition of the Gaussian polynomial $\left[\begin{smallmatrix} M \\ i\end{smallmatrix}\right]$ with $M\geqslant 0, i\in\mathbb{Z}$ to the case of $M,i\in\mathbb{Z}$, by setting

$$\begin{bmatrix} M \\ i\end{bmatrix}=\begin{cases}\dfrac{(q^{M-i+1})_i}{(q)_i}, & \text{if } i\geqslant 0,\\ 0, & \text{otherwise.}\end{cases} \tag{9}$$

Similarly, for $M<0$ we define $(z)_M$ to be $(q^Mz)_{-M}^{-1}$.

Lemma 2: For $M,N,n\in\mathbb{Z}$ we have

$$(z)_M=\sum_i (-z)^i q^{i(i-1)/2}\begin{bmatrix} M \\ i \end{bmatrix}, \tag{10}$$

$$\begin{bmatrix} M+N \\ n \end{bmatrix}=\sum_i q^{(n-i)(M-i)}\begin{bmatrix} M \\ i \end{bmatrix}\begin{bmatrix} N \\ n-i \end{bmatrix}, \tag{11}$$

where the sums are taken over all integers.

Proof: The first equation reduces to (3.3.6) or (3.3.7) in Ref. 21 depending on whether $M \geqslant 0$ or $M<0$.

Next, note that the following equation holds for $M,N\in\mathbb{Z}$:

$$(z)_{M+N}=(z)_M(q^M z)_N. \tag{12}$$

The second equation can be proved by using (10) on both sides of (12) and comparing the coefficients of z^n. ■

We call the following expression bosonic.

Proposition 4 (Theorem 4.1.1 in Ref. 15): For any weakly admissible pair $(b,c)\in R_{\mu,\nu}$ and integers $L,k\geqslant 1$,

$$(q)_{L-1}f_L^{(k)}(b,c)=\left(\sum_{\substack{i>(L+\nu)/2\\ j\leqslant(L+\mu-1)/2}}-\sum_{\substack{i<(L+\nu)/2-1\\ j\geqslant(L+\mu+1)/2}}\right)(-1)^{i+j}q^{Q_{i,j}^{(L)}(b,c)}\begin{bmatrix} L-1 \\ i \end{bmatrix}\begin{bmatrix} L \\ j \end{bmatrix}, \tag{13}$$

$$Q_{i,j}^{(L)}(b,c)=\frac{1}{2}(i-j)(i-j+1)-\left(i-\frac{L-1}{2}\right)\left(j-\frac{L}{2}\right)k+\frac{b}{2}\left(i-\frac{L-1}{2}\right)+\frac{c}{2}\left(j-\frac{L}{2}\right).$$

B. Fermionic expression

In this section we rewrite the bosonic expression to the fermionic expression, which involves q multinomials. At the first step we show the following.

Proposition 5: For any weakly admissible pair $(b,c)\in R_{\mu,\nu}$ satisfying $b\geqslant -Lk$ and integers $L,k\geqslant 1$,

$$\begin{aligned} q^{[L(L-1)k+(L-1)b+Lc]/4}f_L^{(k)}(b,c)=&\sum_{j\in\mathbb{Z}}(-1)^j q^{(1/2)j(j-1)+[(L-1)/2]jk+(c/2)j}\begin{bmatrix} L \\ j \end{bmatrix}\\ &\times\begin{bmatrix} L-j-1-\left(j-\frac{L}{2}\right)k+\frac{b}{2} \\ L-1 \end{bmatrix}\\ &-\sum_{j\in\mathbb{Z}}(-1)^j q^{(1/2)j(j+1)+(L/2)jk+(b/2)j}\begin{bmatrix} L-1 \\ j \end{bmatrix}\\ &\times\begin{bmatrix} L-j-2-\left(j-\frac{L-1}{2}\right)k+\frac{c}{2} \\ L-1 \end{bmatrix}(1-q^{L-j-1-[j-(L-1)/2]k+c/2}). \end{aligned}$$

Proof: Rewrite the sum

$$\left(\sum_{\substack{i>(L+\nu)/2\\ j\leqslant(L+\mu-1)/2}}-\sum_{\substack{i<(L+\nu)/2-1\\ j\geqslant(L+\mu+1)/2}}\right)$$

in (13) as

$$\left(\sum_{\substack{i\in\mathbb{Z}\\ j\leqslant(L+\mu-1)/2}}-\sum_{\substack{i\leqslant(L+\nu)/2-1\\ j\in\mathbb{Z}}}\right).$$

Applying (10) for the sum over $i \in \mathbb{Z}$ or $j \in \mathbb{Z}$, we obtain

$$q^{[L(L-1)k+(L-1)b+Lc]/4} f_L^{(k)}(b,c) = \sum_{j \leqslant (L+\mu-1)/2} (-1)^j q^{(1/2)j(j-1)+[(L-1)/2]jk+(c/2)j} \times \begin{bmatrix} L \\ j \end{bmatrix} \frac{(q^{-j+1-(j-L/2)k+b/2})_{L-1}}{(q)_{L-1}} - \sum_{i \leqslant (L+\nu)/2-1} (-1)^i q^{(1/2)i(i+1)+(L/2)ik+(b/2)i} \times \begin{bmatrix} L-1 \\ i \end{bmatrix} \frac{(q^{-i-[i-(L-1)/2]k+c/2})_L}{(q)_{L-1}}.$$

Recall that we have assumed $b \geqslant -Lk$. Noticing $(\mu-1)k \leqslant b \leqslant (\mu+1)k$, $(\nu-1)k \leqslant c \leqslant (\nu+1)k$ with $\mu \geqslant 1-L$, $\nu \geqslant -L$, we get $L-j-1-(j-L/2)k+b/2 < m-1$ and $L-i-2-[i-(L-1)/2]k+c/2 < m-1$ if $j > (L+\mu-1)/2$ and $i > (L+\nu)/2-1$. Therefore, recalling the definition (9), we have

$$\begin{bmatrix} L-j-1-\left(j-\frac{L}{2}\right)k+\frac{b}{2} \\ L-1 \end{bmatrix} = \begin{cases} \dfrac{(q^{-j+1-(j-L/2)k+b/2})_{L-1}}{(q)_{L-1}}, & \text{if } j \leqslant \dfrac{L+\mu-1}{2} \\ 0, & \text{otherwise,} \end{cases}$$

$$\begin{bmatrix} L-i-2-\left(i-\frac{L-1}{2}\right)k+\frac{c}{2} \\ L-1 \end{bmatrix} = \begin{cases} \dfrac{(q^{-i-[i-(L-1)/2]k+c/2})_{L-1}}{(q)_{L-1}}, & \text{if } i \leqslant \dfrac{L+\nu}{2}-1 \\ 0, & \text{otherwise.} \end{cases}$$

Thus we arrive at the desired result. ■

Proposition 6: For any weakly admissible pair $(b,c) \in R_{\mu,\nu}$ *satisfying* $b \geqslant 0$, $c \neq b+k$ *and integers* $L \geqslant 0$, $k \geqslant 2$, *we have*

$$f_L^{(k)}(b,c) = \sum_{0 \leqslant i \leqslant L} q^{L(L-1)/4-[(k-1)i^2+(2L+b+c-1)i]/4} \times \begin{bmatrix} L \\ i \end{bmatrix} f_{L-i}^{(k-1)}(b+(k+1)i-L, c+(k+1)i-L+1).$$

Proof: If $L=0$, the formula is shown easily from the initial condition (7). We assume $L \geqslant 1$.

Notice that from the assumption $f_{L-i}^{(k-1)}(b+(k+1)i-L, c+(k+1)i-L+1)=0$ when $i=L$. Since the right-hand side of the formula in Proposition 5 is formally zero when $L=0$, we can use it for convenience of our proof. Check that the assumption allows us to use Proposition 5. Setting

$$a_L^{(k)}(b,c;j) = q^{-[L(L-1)k+(L-1)b+Lc]/4+[(L-1)/2]jk+(c/2)j} \begin{bmatrix} L \\ j \end{bmatrix} \begin{bmatrix} L-j-1-\left(j-\frac{L}{2}\right)k+\frac{b}{2} \\ L-1 \end{bmatrix},$$

$$b_L^{(k)}(b,c;j) = q^{-[L(L-1)k+(L-1)b+Lc]/4+(L/2)jk+(b/2)j} \begin{bmatrix} L-1 \\ j \end{bmatrix} \begin{bmatrix} L-j-2-\left(j-\frac{L-1}{2}\right)k+\frac{c}{2} \\ L-1 \end{bmatrix} \times (1-q^{L-j-1-[j-(L-1)/2]k+c/2}),$$

we have to show

$$\sum_{j\in\mathbb{Z}}(-1)^j(q^{(1/2)j(j-1)}a_L^{(k)}(b,c;j)-q^{(1/2)j(j+1)}b_L^{(k)}(b,c;j))$$

$$=\sum_{i=0}^{L}q^{L(L-1)/4-[(k-1)i^2+(2L+b+c-1)i]/4}\begin{bmatrix}L\\ i\end{bmatrix}$$

$$\times\sum_{j\in\mathbb{Z}}(-1)^j(q^{(1/2)j(j-1)}a_{L-i}^{(k-1)}(b',c';j)-q^{(1/2)j(j+1)}b_{L-i}^{(k-1)}(b',c';j)),$$

where $b'=b+(k+1)i-L$, $c'=c+(k+1)i-L+1$. In fact, we can show that the recurrence relation holds term by term, that is,

$$a_L^{(k)}(b,c;j)=\sum_{i=0}^{L}q^{L(L-1)/4-[(k-1)i^2+(2L+b+c-1)i]/4}\begin{bmatrix}L\\ i\end{bmatrix}$$

$$\times a_{L-i}^{(k-1)}(b+(k+1)i-L,c+(k+1)i-L+1;j), \tag{14}$$

and the same for $b_L^{(k)}(b,c;j)$. After some calculation, (14) reduces to

$$\begin{bmatrix}L\\ j\end{bmatrix}\begin{bmatrix}L-j-1-\left(j-\frac{L}{2}\right)k+\frac{b}{2}\\ L-1\end{bmatrix}=\sum_i q^{(L-i-1)(L-i-j)}\begin{bmatrix}L\\ i\end{bmatrix}\begin{bmatrix}L-i\\ j\end{bmatrix}\begin{bmatrix}-1-\left(j-\frac{L}{2}\right)k+\frac{b}{2}\\ L-i-1\end{bmatrix}.$$

Noting that

$$\begin{bmatrix}L\\ i\end{bmatrix}\begin{bmatrix}L-i\\ j\end{bmatrix}=\begin{bmatrix}L\\ j\end{bmatrix}\begin{bmatrix}L-j\\ i\end{bmatrix},$$

we can cancel the factor $\left[\begin{smallmatrix}L\\ j\end{smallmatrix}\right]$. Thus we arrive at (11) with $M=L-j$, $N=-1-(j-L/2)k+b/2$, $n=L-1$.

Similarly, (14) with $a_L^{(k)}(b,c;j)$ replaced by $b_L^{(k)}(b,c;j)$ reduces to

$$\begin{bmatrix}L-1\\ j\end{bmatrix}\begin{bmatrix}L-j-2-\left(j-\frac{L-1}{2}\right)k+\frac{c}{2}\\ L-1\end{bmatrix}(1-q^{L-j-1-[j-(L-1)/2]k+c/2})$$

$$=\sum_i q^{(L-i)(L-i-j-1)}\begin{bmatrix}L\\ i\end{bmatrix}\begin{bmatrix}L-i-1\\ j\end{bmatrix}\begin{bmatrix}-1-\left(j-\frac{L-1}{2}\right)k+\frac{c}{2}\\ L-i-1\end{bmatrix}$$

$$\times(1-q^{-[j-(L-1)/2]k+c/2}). \tag{15}$$

Set $N=-[j-(L-1)/2]k+c/2$. Noting that

$$\begin{bmatrix}L-1\\ j\end{bmatrix}\begin{bmatrix}L-j+N-2\\ L-1\end{bmatrix}(1-q^{L-j+N-1})=\begin{bmatrix}L\\ j\end{bmatrix}\begin{bmatrix}L-j+N-1\\ L\end{bmatrix}(1-q^{L-j}),$$

$$\begin{bmatrix}L\\ i\end{bmatrix}\begin{bmatrix}L-i-1\\ j\end{bmatrix}\begin{bmatrix}N-1\\ L-i-1\end{bmatrix}(1-q^N)=\begin{bmatrix}L\\ j\end{bmatrix}\begin{bmatrix}N\\ L-i\end{bmatrix}\begin{bmatrix}L-j-1\\ i\end{bmatrix}(1-q^{L-j}),$$

and cancelling the factor $\left[\begin{smallmatrix}L\\ j\end{smallmatrix}\right](1-q^{L-j})$, (15) reduces again to (11) with $M=L-j-1$, $n=L$. ■

This recurrence relation with respect to k leads us to an expression of $f_L^{(k)}(b,c)$ in terms of the q-multinomial coefficient (8). The next theorem is a generalization of Theorem 4.2.5 in Ref. 15.

Theorem 3: *For any weakly admissible pair $(b,c)\in R_{\mu,\nu}$ and integers $L\geqslant 0$, $k\geqslant 1$, we have the following expression for $f_L^{(k)}(b,c)$:*

$$f_L^{(k)}(b,c)=\sum q^{\mathcal{C}\left[\begin{smallmatrix}L\\ x_0\cdots x_k\end{smallmatrix}\right]}, \tag{16}$$

$$\mathcal{Q}=\frac{L^2k-L(b-c+k)+b}{4}-\sum_{0\leqslant a\leqslant a'\leqslant k}(a'-a)x_a x_{a'}+\sum_{(c-b+k)/2\leqslant a\leqslant k}\left(a-\frac{c-b+k}{2}\right)x_a .$$

The sum in (16) is taken over all non-negative integers $x_0,\ldots,x_k$, satisfying

$$\sum_{a=0}^{k}x_a=L,\quad \sum_{a=0}^{k}ax_a=\frac{Lk-b}{2}.$$

Proof: We prove by induction on k. If $k=1$, (16) reduces to

$$f_L^{(1)}(b,c)=q^{bc/4}\begin{bmatrix} L \\ \frac{L+b}{2}\ \frac{L-b}{2}\end{bmatrix}.$$

This trivially satisfies (7). Checking (6) reduces to the following identity of Gaussian polynomials:

$$\begin{bmatrix} M \\ i\end{bmatrix}=\begin{bmatrix} M-1 \\ i-1\end{bmatrix}+q^i\begin{bmatrix} M-1 \\ i\end{bmatrix}=q^{M-i}\begin{bmatrix} M-1 \\ i-1\end{bmatrix}+\begin{bmatrix} M-1 \\ i\end{bmatrix}.$$

Thus, the theorem is correct when $k=1$.

Now assume $k\geqslant 2$. If $c=b+k$, (16) turns out to be equivalent to Theorem 4.2.5 [also see Eq. (4.2.1)] in Ref. 15. Therefore we can assume $c\neq b+k$. First suppose $b\geqslant 0$. From Proposition 6 and the assumption of the induction, we obtain

$$f_L^{(k)}(b,c)=\sum_{x_k=0}^{L}\sum q^{\mathcal{Q}}\begin{bmatrix} L \\ x_k\end{bmatrix}\begin{bmatrix} L-x_k \\ x_0\cdots x_{k-1}\end{bmatrix}, \tag{17}$$

with

$$\mathcal{Q}=\frac{L(L-1)}{4}-\frac{(k-1)x_k^2+(2L+b+c-1)x_k}{4}+\mathcal{Q}',$$

$$\mathcal{Q}'=\frac{(L-x_k)^2(k-1)-(L-x_k)(b'-c'+k-1)+b'}{4}-\sum_{0\leqslant a<a'\leqslant k-1}(a'-a)x_a x_{a'}$$
$$+\sum_{(c'-b'+k-1)/2\leqslant a\leqslant k-1}\left(a-\frac{c'-b'+k-1}{2}\right)x_a ,$$

$$b'=b+(k+1)x_k-L,\quad c'=c+(k+1)x_k-L+1,$$

and the inner sum in (17) is taken over non-negative integers $x_0,\ldots,x_{k-1}$ such that $\Sigma_{a=0}^{k-1}x_a=L-x_k$, $\Sigma_{a=0}^{k-1}ax_a=[(L-x_k)(k-1)-b']/2$. Calculating the power of q, and noting that

$$\begin{bmatrix} L \\ x_k\end{bmatrix}\begin{bmatrix} L-x_k \\ x_0\cdots x_{k-1}\end{bmatrix}=\begin{bmatrix} L \\ x_0\cdots x_k\end{bmatrix},$$

we arrive at (16).

For the proof of the case $b<0$, it suffices to check Reflection symmetry on the right-hand side of (16). The check is easily done by the variable change $x_j\to x_{k-j}$ $(0\leqslant j\leqslant k)$ in the summand of (16). ■

C. Character of $\mathcal{P}_L(\Lambda)$

We define the character for $\mathcal{P}_L(\Lambda)$.

Definition 9 [character of $\mathcal{P}_L(\Lambda)$]:

$$\mathrm{ch}_L(\Lambda)=\mathrm{ch}_L(\Lambda)(z,q)=\sum_{p\in\mathscr{P}_L(\Lambda)} z^{(\Lambda-p_0|\Lambda_1)}q^{E(p)}.$$

Then we have the following expression for $\mathrm{ch}_L(\Lambda)$.

Proposition 7:

$$\mathrm{ch}_L(\Lambda)=\sum_{j\in\mathbb{Z}} z^{-j}q^{j/2}f_L^{(k)}(\epsilon^{(L)}(s-t)-2j,\epsilon^{(L+1)}(s-t)-2j).$$

Here $\epsilon^{(L)}$ is given in (2).

Proof: First, for $a\Lambda_0+b\Lambda_1\in P_k$, we set $\nu(a\Lambda_0+b\Lambda_1)=b$. Then we have

$$\mu(\iota(p)_j)=\frac{\nu(p_{j+1})-\nu(p_j)+k}{2}.$$

From the definition of H (Definition 5), we have

$$H(\iota(p)_{j-1},\iota(p)_j)=\frac{k}{2}+\frac{|\nu(p_{j-1})-\nu(p_{j+1})|}{4}+\frac{\nu(p_{j-1})-2\nu(p_j)+\nu(p_{j+1})}{4},$$

and therefore

$$\sum_{j=1}^{L} jH(\iota(p)_{j-1},\iota(p)_j)=\frac{k}{2}\frac{L(L+1)}{2}+\sum_{j=1}^{L} j\,\frac{|\nu(p_{j-1})-\nu(p_{j+1})|}{4}+\frac{\nu(p_0)-(L+1)\nu(p_L)+L\nu(p_{L+1})}{4}.$$

Thus, we have

$$E(p)=\frac{\nu(p_0)-\nu(\bar{p_0})}{4}+\sum_{j=1}^{L} j\,\frac{|\nu(p_{j-1})-\nu(p_j)|}{4}.$$

Using this and parametrizing p_0 by $\Lambda+j\alpha_1$ $(j\in\mathbb{Z})$, we can rewrite the character (Definition 9) as

$$\mathrm{ch}_L(\Lambda)=\sum_{j\in\mathbb{Z}} z^{-j}q^{(\nu(p_0)-\nu(\bar{p_0}))/4}K_{L,j},$$

$$K_{L,j}=\sum_{\substack{p\in\mathscr{P}_L(\Lambda)\\ p_0=\Lambda+j\alpha_1}} q^{\sum_{J=1}^{L} j|\nu(p_{j-1})-\nu(p_{J+1})|/4}.$$

Noting that $K_{L,j}$ satisfies the same difference equation as $f_L^{(k)}(\nu(p_L)-\nu(p_0),\nu(p_{L+1})-\nu(p_0))$, we have

$$\mathrm{ch}_L(\Lambda)=\sum_{j\in\mathbb{Z}} z^{-j}q^{(\nu(p_0)-\nu(\bar{p_0}))/4}f_L^{(k)}(\nu(p_L)-\nu(p_0),\nu(p_{L+1})-\nu(p_0)),$$

with $p_0=\Lambda+j\alpha_1$. Evaluating $\nu(p_j)$ $(j=0,L,L+1)$ explicitly, we have the desired result. ■

Now we have the final result on the character of $\mathscr{P}_L(\Lambda)$.

Theorem 4: *Let $\Lambda=s\Lambda_0+t\Lambda_1$ $(s+t=k)$, C be the Cartan matrix of $sl(k)$, that is, $C_{ij}=2\delta_{ij}-\delta_{ij+1}-\delta_{ij-1}$ $(1\leqslant i,j\leqslant k-1)$. Set $x^t=(x_1,\ldots,x_{k-1})$ and let e_i be the $k-1$-dimensional ith unit vector $(e_0=e_k=0)$. Define $F_{j,L}(\Lambda)$ by*

$$\mathrm{ch}_L(\Lambda)=\sum_{j\in\mathbb{Z}} z^{-j}F_{j,L}(\Lambda).$$

Then we have the following expression for $F_{j,L}(\Lambda)$. *If* L *is even,*

$$F_{j,L}(\Lambda)=\sum_{\Sigma_{i=1}^{k-1} i x_i \in j+k\mathbb{Z}} q^{x^t C^{-1} x - x^t C^{-1} e_s + j(j+t)/k} \begin{bmatrix} L \\ x_0 \cdots x_k \end{bmatrix},$$

where

$$x_0=\frac{L}{2}-\frac{1}{k}\left(\sum_{i=1}^{k-1}(k-i)x_i+j\right), \quad x_k=\frac{L}{2}-\frac{1}{k}\left(\sum_{i=1}^{k-1} i x_i - j\right).$$

If L *is odd,*

$$F_{j,L}(\Lambda)=\sum_{\Sigma_{i=1}^{k-1} i x_i \in j+t+k\mathbb{Z}} q^{x^t C^{-1} x - x^t C^{-1} e_t + J(j+t)/k} \begin{bmatrix} L \\ x_0 \cdots x_k \end{bmatrix},$$

where

$$x_0=\frac{L+1}{2}-\frac{1}{k}\left(\sum_{i=1}^{k-1}(k-i)x_i+j+t\right), \quad x_k=\frac{L-1}{2}-\frac{1}{k}\left(\sum_{i=1}^{k-1} i x_i - j - t\right).$$

Proof: Suppose L is even, from Theorem 3 and Proposition 7; we obtain

$$F_{j,L}(\Lambda)=\sum_{\Sigma_{i=0}^{k} i x_i = Lk/2+j} q^{\frac{L^2 k}{4}-\frac{Lt}{2}-\Sigma_{0\leqslant i\leqslant i'\leqslant k}(i'-i)x_i x_{i'}+\Sigma_{s\leqslant i\leqslant k}(i-s)x_i} \begin{bmatrix} L \\ x_0 \cdots x_k \end{bmatrix}.$$

Solving $\Sigma_{i=0}^{k} x_i = L$ and $\Sigma_{i=0}^{k} i x_i = Lk/2+j$ for x_0 and x_k, we get $x_0=L/2-(1/k)(\Sigma_{i=1}^{k-1}(k-i)x_i+j)$, $x_k=L/2-(1/k)(\Sigma_{i=1}^{k-1} i x_i - j)$. Substitute these expressions into the power of q, and note that $(C^{-1})_{ij}=i(k-j)/k$ (for $i\leqslant j$), $j(k-i)/k$ (for $i>j$). Noticing that the sum restriction changes into $\Sigma_{i=1}^{k-1} i x_i \in j+k\mathbb{Z}$, we obtain the desired expression.

The case of L odd is similar. ■

D. Character of Demazure module

As we have seen in Sec. III, crystals of Demazure modules can be realized as subsets of the crystal $B(\Lambda)$ or equivalently $\mathscr{P}(\Lambda)$. Now it is easy to see that the characters of Demazure modules admit the following definition.

Definition 10:

$$\mathrm{ch}_L^{\pm}(\Lambda)=\mathrm{ch}_L^{\pm}(\Lambda)(z,q)=\sum_{p\in B_{w_L^{\pm}}(\Lambda)} z^{(\Lambda - p_0|\Lambda_1)} q^{E(p)}.$$

A natural question to ask is the following: Is it possible to express $\mathrm{ch}_L^{\pm}(\Lambda)$ in terms of $\mathrm{ch}_L(\Lambda)$? The answer is given by the following theorem.

Theorem 5: Let $\Lambda=s\Lambda_0+t\Lambda_1$, $s+t=k$. *We have*

$$\mathrm{ch}_L^{+}(\Lambda)=\sum_{i=0}^{s} z^{-\epsilon^{(L)}(s-i)} q^{[(L+\epsilon^{(L)})/2](s-i)} \mathrm{ch}_{L-1}(\Lambda^{(i)}),$$

$$\mathrm{ch}_L^{-}(\Lambda)=\sum_{i=0}^{t} z^{\epsilon^{(L)}(t-i)} q^{[(L-\epsilon^{(L)})/2](t-i)} \mathrm{ch}_{L-1}(\Lambda^{(k-i)}).$$

Here $\epsilon^{(L)}$ *is given in (2) and* $\Lambda^{(i)}=i\Lambda_0+(k-i)\Lambda_1$.

Proof: First we prove the expression for $\mathrm{ch}_L^{+}(\Lambda)$. Let us suppose L is even. Interpreting Theorem 2 in terms of paths, for any $p\in B_{w_L^{+}}(\Lambda)$ we have $\iota(p)_{L-1}=(k-i)\epsilon_0+i\epsilon_1$, where $i=0,1,\ldots,s$. For each i consider the following subset of $\mathscr{P}_L(\Lambda)$:

$$S^{(i)}=\{p\in\mathscr{P}_L(\Lambda)|p_{L-1}=\Lambda-((k-i)\hat{0}+i\hat{1})\}.$$

Noting that $\Lambda-((k-i)\hat{0}+i\hat{1})-\Lambda^{(k-i)}=\Lambda-\Lambda^{(i)}$, we see that

$$\{(p_j-(\Lambda-\Lambda^{(i)}))_{j=0,\ldots,L}|p\in S^{(i)}\}$$

can be identified with $\mathscr{P}_{L-1}(\Lambda^{(i)})$. Defining $\overline{p^{(i)}}$ as the ground-state path of $\mathscr{P}_{L-1}(\Lambda^{(i)})$, we have

$$\mathrm{ch}_{L-1}(\Lambda^{(i)})=\sum_{\substack{p\in B_{w_L^+}(\Lambda)\\ p_{L-1}=\Lambda-((k-i)\hat{0}+i\hat{1})}} z^{(\Lambda^{(i)}-(p_0-(\Lambda-\Lambda^{(i)}))|\Lambda_1)} \times q^{\sum_{j=1}^{L-1} j(H(\iota(p)_{j-1},\iota(p)_j)-H(\iota(\overline{p^{(i)}})_{j-1},\iota(\overline{p^{(i)}})_j))}.$$

Therefore,

$$\mathrm{ch}_L^+(\Lambda)=\sum_{i=0}^{s} q^{\sum_{j=1}^{L-1} j(H(\iota(\overline{p^{(i)}})_{J-1},\iota(\overline{p^{(i)}})_J)-H(\iota(\overline{p})_{j-1},\iota(\overline{p})_j))} \times q^{L(H(\iota_{L-1}^{(i)},\iota_L^{(i)})-H(\iota_{L-1},\iota_L))}\,\mathrm{ch}_{L-1}(\Lambda^{(i)}).$$

Here $\iota_{L-1}^{(i)}=(k-i)\epsilon_0+i\epsilon_1$, $\iota_{L-1}=\iota_{L-1}^{(s)}$, $\iota_L^{(i)}=\iota_L=s\epsilon_0+t\epsilon_1$. Using Lemma 1 we get the result. The case of L odd is similar.

For $\mathrm{ch}_L^-(\Lambda)$ we utilize the Dynkin diagram symmetry:

$$\mathrm{ch}_L^-(\Lambda)=\mathrm{ch}_L^+(t\Lambda_0+s\Lambda_1)(qz^{-1},q)$$
$$=\sum_{i=0}^{t}(qz^{-1})^{-\epsilon^{(L)}(t-i)}q^{[(L+\epsilon^{(L)})/2](t-i)}\,\mathrm{ch}_{L-1}(\Lambda^{(i)})(qz^{-1},q).$$

Noting that $\mathrm{ch}_{L-1}(\Lambda^{(i)})(qz^{-1},q)=\mathrm{ch}_{L-1}(\Lambda^{(k-i)})(z,q)$, we get the result. ■

E. Some specializations

In this section, we consider two specializations of Demazure characters, and compare with Sanderson's results.[6]

First we consider ''real characters.'' These are obtained by setting $e^{-\alpha_0}=q$, $e^{-\alpha_1}=q^{-1}$. We have the following.

Corollary 3: Let $\Lambda=s\Lambda_0+t\Lambda_1$, $s+t=k$:

$$\mathrm{ch}_L^+(\Lambda)(q^{-1},1)=q^{-(L-\epsilon^{(L)})k/2}[s+1][k+1]^{L-1}.$$

Here $[a]=(1-q^a)/(1-q)$.

Proof: From Theorem 4 we easily get

$$f_L^{(k)}(b,c;1)=\sum_{\sum_{i=0}^{k} ix_i=(Lk-b)/2}\binom{L}{x_0\cdots x_k}.$$

Here $\binom{L}{x_0\cdots x_k}$ denotes the usual multinomial coefficient. Assume L is even. From Proposition 7 we have

$$\begin{aligned}\mathrm{ch}_L(\Lambda)(q^{-1},1)&=\sum_{j\in\mathbb{Z}} q^j \sum_{\Sigma_{i=0}^k i x_i = Lk/2+j} \begin{pmatrix} L \\ x_0\cdots x_k \end{pmatrix} \\ &= q^{-Lk/2} \sum_{x_0,\ldots,x_k} q^{\Sigma_{i=0}^k i x_i} \begin{pmatrix} L \\ x_0\cdots x_k \end{pmatrix} \\ &= q^{-Lk/2}(1+q+\ldots+q^k)^L \\ &= q^{-Lk/2}[k+1]^L.\end{aligned}$$

Similarly, for L odd we have

$$\mathrm{ch}_L(\Lambda)(q^{-1},1)=q^{-(Lk-s+t)/2}[k+1]^L.$$

Using Theorem 5, we obtain the desired result. ■

Next, we consider ''principal characters'' obtained by setting $e^{-\alpha_0}=e^{-\alpha_1}=q$. In considering this case, we restrict ourselves to the extreme case $t=0$.

Corollary 4: Let $\Lambda=k\Lambda_0$:

$$\mathrm{ch}_L^+(\Lambda)(q,q^2)=\sum_{x_0,\ldots,x_k} q^{2x^tC^{-1}x+(k/2)\mathscr{S}(\mathscr{S}+1)} \begin{bmatrix} L \\ x_0\cdots x_k \end{bmatrix}_{q^2},$$

where we have set

$$\mathscr{S}=\frac{1}{k}\sum_{i=0}^{k}(k-2i)x_i. \tag{18}$$

Proof: Note from Corollary 2 that when $\Lambda=k\Lambda_0$ we have $\mathrm{ch}_L^+(\Lambda)=\mathrm{ch}_L(\Lambda)$. Using Theorem 4 we obtain

$$\mathrm{ch}_L^+(\Lambda)(q,q^2)=\sum_{j\in\mathbb{Z}} q^{-j} \sum_{\Sigma_{i=1}^{k-1} i x_i \in j+k\mathbb{Z}} q^{2x^tC^{-1}x+2j^2/k} \begin{bmatrix} L \\ x_0\cdots x_k \end{bmatrix}_{q^2}, \tag{19}$$

where

$$x_0=\left[\frac{L+1}{2}\right]-\frac{1}{k}\left(\sum_{i=1}^{k-1}(k-i)x_i+j\right), \quad x_k=\left[\frac{L}{2}\right]-\frac{1}{k}\left(\sum_{i=1}^{k-1} i x_i-j\right), \tag{20}$$

with [ ] being the Gauss symbol: $[x]$ is the largest integer that does not exceed x. Since the condition $\Sigma_{i=1}^{k-1} i x_i \in j+k\mathbb{Z}$ is equivalent to the condition that all x_k are integers, we can rewrite the expression in (19) as

$$\sum_{x_0,\ldots,x_k} q^{2x^tC^{-1}x+2j^2/k-j} \begin{bmatrix} L \\ x_0\cdots x_k \end{bmatrix}_{q^2}.$$

Solving (20) with respect to j, we get

$$j=\frac{k}{2}\left(\left[\frac{L+1}{2}\right]-\left[\frac{L}{2}\right]-\mathscr{S}\right).$$

Noting that $[(L+1)/2]-[L/2]=\epsilon^{(L)}$ and substituting this into the expression, we arrive at

$$\sum_{x_0,\ldots,x_k} q^{2x^tC^{-1}x+(k/2)\mathscr{S}(\mathscr{S}+1-2\epsilon^{(L)})} \begin{bmatrix} L \\ x_0\cdots x_k \end{bmatrix}_{q^2}.$$

If L is odd, we can make the variable change $x_i\to x_{k-i}$, which amounts to $\mathscr{S}\to-\mathscr{S}$. Thus we get the desired result. ■

In Ref. 6, Sanderson has evaluated the same character involving the q-multinomial coefficient with argument q, as opposed to our expression with q^2. Accordingly, we get the following new q-multinomial identity:

$$\sum_{x_0,\ldots,x_k} q^{2x^tC^{-1}x+(k/2)\mathscr{S}(\mathscr{S}+1)} \begin{bmatrix} L \\ x_0 \cdots x_k \end{bmatrix}_{q^2}$$
$$= \sum_{0\leqslant i_1\leqslant \ldots \leqslant i_k\leqslant L} q^{i_1(i_1+1)/2+\ldots+i_k(i_k+1)/2} \begin{bmatrix} L \\ L-i_ki_k-i_{k-1}\cdots i_2-i_1i_1 \end{bmatrix}_q, \tag{21}$$

where $\mathscr{S}$ is defined in (18). As pointed out by Andrews, changing q to q^{-1} in (21) for $k=1$ reduces to

$$\sum_{x_1=0}^{L} q^{x_1} \begin{bmatrix} L \\ x_1 \end{bmatrix}_{q^2} = \prod_{j=1}^{L} (1+q^j), \tag{22}$$

which is a known classical identity due to Watson. Thus (21) can be thought of as the higher level generalization of Watson's identity (22).

V. DISCUSSION

We characterized all Demazure crystals associated with $\widehat{\mathrm{sl}}(2)$ in terms of paths. We then obtained explicit expressions for their full characters. Our results extend Sanderson's results, and reduce to hers when specialized to certain limits. Our derivations are based on ideas and techniques that originated in computations of certain physical quantities in exactly solvable lattice models, particularly Baxter's corner transfer matrix method, and the combinatorial structures related to it.

Since the very same methods and techniques are available, we expect that our approach can be used for the cases of other affine algebras too. Let us consider the $\widehat{\mathrm{sl}}(n)$ case. In the case we treated in this work, the affine Weyl group W had two subsets W^+ and W^- satisfying $W^+\cup W^-=W$, $W^+\cap W^-=\{1\}$. On each subset the Bruhat order was a total order. But if $n>2$ the Weyl group does not have such a property. Thus, it is very difficult to treat the Demazure modules corresponding to all Weyl group elements. But for some particular type of elements there does exist a correspondence between Demazure crystals and paths, which we would like to report in the near future.

As for one-dimensional configuration sums in the higher rank case, few results are available, except the level 1 case.[16] We would like to push forward these studies. Along this line we note the works by Kuniba–Nakanishi–Suzuki[22] and Georgiev.[23] In Ref. 22 they presented conjectures of fermionic expressions for string functions of vacuum modules $V(k\Lambda_0)$ when the affine algebra is of type $X_r^{(1)}$. Georgiev proved the conjecture in the $A_r^{(1)}$ case. For our purpose we have to ''finitize'' their conjecture or result, since we need generating functions of paths of finite length. This would be a challenging problem.

Our approach can be also extended to types other than $\widehat{\mathrm{sl}}(n)$. In these cases we do not have descriptions of crystals by extended Young diagrams or similar notions yet. We might have to work directly on paths. We have so far discussed the cases of affine algebra modules. There are definitely the cases of coset modules left. We also would like to understand the representation theoretical meaning of the truncated generating functions.

ACKNOWLEDGMENTS

We wish to thank S. Dasmahapatra, A. Kuniba, and S. O. Warnaar for discussions and interest in this work. This work was started while K.M. and M.O. were visiting the University of Melbourne in July, 1995, and continued while O.F. was visiting the University of Utrecht. We thank the Australian Research Council, and the Netherlands Organization for Scientific Research (NWO) for their financial support of these visits. O.F. was supported in part by the Australian Research Council (ARC), and the Netherlands Organization for Scientific Research (NWO). K.C.M. was

supported in part by NSA/MSP Grant No. MDA904-96-1-0013. Masato Okado was supported in part by a Grant-in-Aid for Scientific Research on Priority Areas, the Ministry of Education, Science and Culture, Japan.

L operators and Drinfeld's generators

Norifumi Hayaishi and Kei Miki
Department of Mathematics, Graduate School of Science, Osaka University, Toyonaka 560, Japan

(Received 27 May 1997; accepted for publication 29 October 1997)

Utilizing the multiplicative formula of universal R matrices, the correspondence between the L operators and Drinfeld's generators is explicitly calculated for quantum group $U_q(g)$ with $g=A_l^{(1)},B_l^{(1)},C_l^{(1)},D_l^{(1)}$. © *1998 American Institute of Physics.* [S0022-2488(98)00103-0]

I. INTRODUCTION

By Drinfeld[1,2] and Jimbo,[3] a quantum group was invented by quantizing the universal enveloping algebras of Kac–Moody algebras. It was defined by deforming the defining relations for Chevally generators. Later Drinfeld found another realization of quantum group for affine Kac–Moody algebras in Ref. 4. Finally, Faddeev, Reshetikhin and Takhtatjan[5] defined quantum group by the $RLL=LLR$ relations, which deforms the matrix realization of finite dimensional simple Lie algebras. This was later generalized to the affine case by Reshetikhin and Semenov-Tian-Shansky.[6] Up to now, the relations among these three definitions are clarified as follows. The universal R matrix by Drinfeld[2] gives the map from the third formulation to the first.[5,6] In the original paper,[4] the isomorphism from the first definition to the second is given. (See Ref. 7 for the explicit verification.) Later in the nontwisted affine case, the map in the opposite direction is obtained in Ref. 8, without the use of the Braid group, and in Ref. 9 by using the Braid group actions. The correspondence between the second and third definitions is found by Ding and Frenkel[10] for $g=\widehat{gl_n}$. The purpose of this paper is to generalize the last result to $g=A_l^{(1)},B_l^{(1)},C_l^{(1)},D_l^{(1)}$ by utilizing the multiplicative formula of the universal R matrix. [See Ref. 11 for a similar calculation in the case $\widehat{DY(sl_2)}$.] This formula in the nontwisted affine case is already obtained in Ref. 12 without the use of the Braid group. In this paper, we follow the approach by Beck[9,13] and Lusztig.[14] Their results easily give the multiplicative formula, and this formula immediately yields the desired correspondence. The results in this paper would be well known conceptually. We only hope that the explicit expressions here help to clarify the problem.

This paper is organized as follows. In section II, we fix our notations. In section III, we determine the defining relations of quantum group in the L operator formalism for $g=A_l^{(1)}$, $B_l^{(1)}$, $C_l^{(1)}$, $D_l^{(1)}$, $A_{2l}^{(2)}$, $A_{2l-1}^{(2)}$, $D_{l+1}^{(2)}$, since we cannot find the proof in literature. Here we also consider the twisted case since the proof is essentially the same as the one in the nontwisted case. In section IV, after a review of the result by Beck, we write down the multipilcative formula of the universal R matrix for nontwisted affine Kac–Moody algebras. In section V, utilizing the result in section III, the multiplicative formula and the result by Beck, we calculate the correspondence between the L operators and Drinfeld's generators for $g=A_l^{(1)}$, $B_l^{(1)}$, $C_l^{(1)}$, $D_l^{(1)}$. The work by Edwards, announced in Ref. 15, would immediately generalize the results here to the twisted case.

II. NOTATIONS

A. Root data

Let g be an affine Kac–Moody algebra over $\mathbf{Q}$ and $(a_{ij})_{0\leqslant i,j\leqslant l}$ its generalized Cartan matrix. Let further $a_0,\ldots,a_l$ and $a_0^\vee,\ldots,a_l^\vee$ be relatively prime positive integers such that $\Sigma_i a_i^\vee a_{ij}=0$ and $\Sigma_j a_{ij}a_j=0$, respectively. We set $h^\vee=\Sigma_{i=0}^l a_i^\vee$. We follow the enumeration of the vertices of the Dynkin diagram in Ref. 16, Chap. 4 except in the $A_{2l}^{(2)}$ case, in which we enumerate them in reverse order. In our notation, $a_0=1$ for any g and $a_0^\vee=2$ for $g=A_{2l}^{(2)}$, $=1$ otherwise. We denote the finite type Kac–Moody algebra corresponding to the Cartan matrix $(a_{ij})_{1\leqslant i,j\leqslant l}$ by $\overline{g}$.

 © 1998 American Institute of Physics

Let h^* be a $\mathbf{Q}$ vector space with basis $\alpha_0,\ldots,\alpha_l,\Lambda_0$. Let further $d_0,\ldots,d_l$ be relatively prime positive integers such that $d_i a_{ij}=d_j a_{ji}$. We introduce a symmetric bilinear form $(\ |\ ):h^*\times h^*\to\mathbf{Q}$ by $(\alpha_i|\alpha_j)=d_i a_{ij}$, $(\alpha_i|\Lambda_0)=d_i\delta_{i0}$ and $(\Lambda_0|\Lambda_0)=0$. Set $\delta=\Sigma_{i=0}^{l}a_i\alpha_i$ and $\alpha_i^\vee=\alpha_i/d_i$ $(0\leqslant i\leqslant l)$. Define ω_i and $\omega_i^\vee\in h^*$ $(1\leqslant i\leqslant l)$ by $(\alpha_j^\vee|\omega_i)=\delta_{ij}$ $(1\leqslant j\leqslant l)$, $(\delta|\omega_i)=(\Lambda_0|\omega_i)=0$ and $\omega_i^\vee=\omega_i/d_i$. We further define several $\mathbf{Z}$ submodules of h^* by $Q=\oplus_{i=0}^{l}\mathbf{Z}\alpha_i$, $\Sigma=Q\oplus\mathbf{Z}\Lambda_0/d_0$, $\Gamma=\Sigma+p\mathbf{Z}\omega_1$ and $\overline{Q}=\oplus_{i=1}^{l}\mathbf{Z}\alpha_i$. Here and hereafter $p=2$ for $g=A_2^{(2)}$ and $=1$ otherwise. Finally, as usual, we introduce an order relation on Q by $\lambda\geqslant\mu\Leftrightarrow\lambda-\mu\in Q_+=\oplus_{i=0}^{l}\mathbf{Z}_{\geqslant 0}\alpha_i$.

B. F algebra $U_q^\Gamma(g)$

Let q be an indeterminate and set $F=\mathbf{Q}(q)$. Following Refs. 1 and 3, let $\mathscr{U}=U_q^\Gamma(g)$ be the F algebra generated by e_i, f_i $(0\leqslant i\leqslant l)$ and k_λ $(\lambda\in\Gamma)$ with the relations

$$k_\lambda k_\mu=k_{\lambda+\mu},\quad k_0=1, \tag{2.1}$$

$$k_\lambda e_i k_{-\lambda}=q^{(\lambda|\alpha_i)}e_i,\quad k_\lambda f_i k_{-\lambda}=q^{-(\lambda|\alpha_i)}f_i, \tag{2.2}$$

$$[e_i,f_j]=\delta_{ij}\frac{k_i-k_i^{-1}}{q_i-q_i^{-1}}, \tag{2.3}$$

$$\sum_{r=0}^{1-a_{ij}}(-1)^r e_i^{(r)}e_j e_i^{(1-a_{ij}-r)}=0\quad(i\neq j), \tag{2.4}$$

$$\sum_{r=0}^{1-a_{ij}}(-1)^r f_i^{(r)}f_j f_i^{(1-a_{ij}-r)}=0\quad(i\neq j), \tag{2.5}$$

where $k_i^{\pm 1}=k_{\pm\alpha_i}$ and

$$q_i=q^{d_i},\quad x_i^{(n)}=\frac{x_i}{[n]_i!}\ \ (x=e,f),\quad [n]_i=\frac{q_i^n-q_i^{-n}}{q_i-q_i^{-1}},\quad [n]_i!=\prod_{k=1}^{n}[k]_i.$$

This algebra has the following Hopf algebra structure:

$$\Delta(e_i)=e_i\otimes 1+k_i\otimes e_i,\quad \Delta(f_i)=f_i\otimes k_i^{-1}+1\otimes f_i,$$

$$\Delta(k_\lambda)=k_\lambda\otimes k_\lambda,$$

$$S(e_i)=-k_i^{-1}e_i, S(f_i)=-f_i k_i,\quad S(k_\lambda)=k_{-\lambda},$$

$$\epsilon(e_i)=\epsilon(f_i)=0,\quad \epsilon(k_\lambda)=1. \tag{2.6}$$

We define several subalgebras of $\mathscr{U}$ by

$$\mathscr{U}^+=\langle e_i|0\leqslant i\leqslant l\rangle,\quad \mathscr{U}^-=\langle f_i|0\leqslant i\leqslant l\rangle,\quad \mathscr{U}^0=\langle k_\lambda|\lambda\in\Gamma\rangle,$$

$$\mathscr{U}^{\geqslant 0}=\mathscr{U}^0\mathscr{U}^+,\quad \mathscr{U}^{\leqslant 0}=\mathscr{U}^-\mathscr{U}^0.$$

Then $\mathscr{U}^\pm=\oplus_{\mu\in Q_+}\mathscr{U}^\pm_{\pm\mu}$ where

$$\mathscr{U}^\pm_\mu=\{x\in\mathscr{U}^\pm|\ k_\lambda x k_{-\lambda}=q^{(\lambda|\mu)}x\ \ (\forall\lambda\in\Gamma)\}.$$

Moreover the following is known.

Proposition 1:[17,18,14]

(1) *The multiplication map* $\mathscr{U}^-\otimes\mathscr{U}^0\otimes\mathscr{U}^+\to\mathscr{U}$ *induces an isomorphism of vector spaces.*

(2) $(k_\lambda)_{\lambda\in\Gamma}$ *forms a basis of* $\mathscr{U}^0$.

(3) $\dim_F \mathscr{U}^{\pm}_{\pm\mu} = \mathscr{P}(\mu)$, *where* $\mathscr{P}(\mu)$ *is Kostant's partition function for* g.

Similarly we define $U = U_q^{\Sigma}(g)$, $U' = U_q^{Q}(g)$ and $\overline{U} = U_q^{\overline{Q}}(\overline{g})$. We identify U (resp., U') with the subalgebra of $\mathscr{U}$ (resp., U). Then $\mathscr{U}^{\pm} = U^{\pm} = U'^{\pm}$.

C. Finite dimensional $U_q^Q(g)$ module (ρ, V)

Hereafter to the end of the next section, we consider $g = A_l^{(1)}$ $(l \geqslant 1)$, $B_l^{(1)}$ $(l \geqslant 3)$, $C_l^{(1)}$ $(l \geqslant 2)$, $D_l^{(1)}$ $(l \geqslant 4)$, $A_{2l}^{(2)}$ $(l \geqslant 1)$, $A_{2l-1}^{(2)}$ $(l \geqslant 3)$, $D_{l+1}^{(2)}$ $(l \geqslant 2)$. For a $\overline{U}$ module M, we shall call $v \in M$ a weight vector with weight $\mu \in \overline{P} = \oplus_{1 \leqslant i \leqslant l} \mathbf{Z}\omega_i$ if $k_\lambda v = q^{(\lambda|\mu)} v$ for any $\lambda \in \overline{Q}$. Let $V(p\omega_1)$ be the irreducible highest weight module with highest weight $p\omega_1$ of $\overline{U}$. Let further v_i $[1 \leqslant i \leqslant \dim V(p\omega_1)]$ be a basis of this module consisting of weight vectors such that $i < j$ if $\eta_i - \eta_j > 0$, where η_i is the weight of v_i as a $\overline{U}$ module. $V(\omega_1) \oplus F$ in the case $g = D_{l+1}^{(2)}$, and $V(p\omega_1)$ otherwise can be made into representations of U', on which $k_{\pm\delta}$ acts as 1. We shall denote them by (ρ, V) and set $N = \dim V$. In the case $g = D_{l+1}^{(2)}$, by v_N and η_N we denote the basis vector of the trivial representation as a $\overline{U}$ module and its weight 0, respectively. The representations (ρ, V) are the same as the ones used in Ref. 19 and, in the limit $q = 1$, reduce to the ones in Ref. 16, Chapters 7 and 8. Let τ_b $(b \in F^\times)$ be the automorphism of $\mathscr{U}$ determined by $\tau_b(e_i) = b^{\delta_{i0}} e_i$, $\tau_b(f_i) = b^{-\delta_{i0}} f_i$ and $\tau_b(k_\lambda) = k_\lambda$. Put $\rho_b = \rho \circ \tau_b|_{U'}$. Set $M = l + 1$ and $b_i = q^{-2(i-1)}$ $(1 \leqslant i \leqslant M)$ for $g = A_l^{(1)}$. In other cases, set $M = 2$ and $b_1 = 1$, $b_2 = \sigma q_0^{-h^\vee/a_0^\vee}$. Here $\sigma = -1$ for $g = A_{2l}^{(2)}$, $A_{2l-1}^{(2)}$ and $= 1$ otherwise. Then in $(\rho_{b_1} \otimes \cdots \otimes \rho_{b_M}, V^{\otimes M})$, there exists a trivial representation of U'. We denote its basis vector by w. In the case $M = 2$, we define a matrix $J = (J_{ij})_{1 \leqslant i,j \leqslant N}$ by $w = \Sigma_{i,j} J_{ij} v_i \otimes v_j$. See Appendix A for the explicit expressions of N, η_i, (ρ, V) and w. Below we identify $\mathrm{End}V$ with $M_N(F)$ through the basis $v_1, \cdots, v_N$ normalized as in Appendix A.

D. R matrix and L operators

Let Θ be the quasi-universal R matrix of U.[2,20,14] This is an invertible element of (an appropriate completion of) $U \otimes U$ uniquely determined by

$$\Theta = \sum_{\mu \geqslant 0} \Theta_\mu, \quad \Theta_\mu \in U_\mu^+ \otimes U_{-\mu}^-, \quad \Theta_0 = 1 \otimes 1,$$

$$\iota \circ \Delta(x) \Theta = \Theta \Psi \circ \Delta(x) \quad (x \in U). \tag{2.7}$$

Here $\iota(x \otimes y) = y \otimes x$, and Ψ is the automorphism of $U \otimes U$ defined by

$$\Psi(e_i \otimes 1) = e_i \otimes k_i^{-1}, \quad \Psi(f_i \otimes 1) = f_i \otimes k_i,$$

$$\Psi(k_\lambda \otimes k_\mu) = k_\lambda \otimes k_\mu, \quad \Psi = \iota \circ \Psi \circ \iota.$$

This element further satisfies

$$\Theta_{\alpha_i} = -(q_i - q_i^{-1}) e_i \otimes f_i \quad (0 \leqslant i \leqslant l), \tag{2.8}$$

$$(1 \otimes \Delta)\Theta = \Theta_{13} \Psi_{13}(\Theta_{12}), \quad (\Delta \otimes 1)\Theta = \Theta_{13} \Psi_{13}(\Theta_{23}), \tag{2.9}$$

$$\Theta_{12} \Psi_{12}(\Theta_{13}) \Theta_{23} = \Theta_{23} \Psi_{23}(\Theta_{13}) \Theta_{12}, \tag{2.10}$$

where Θ_{13}, for example, denotes $\Sigma_i x_i \otimes 1 \otimes y_i$ for $\Theta = \Sigma_i x_i \otimes y_i$ as usual.

For Θ^{-1}, define $(\Theta^{-1})_\mu$ $(\mu \in Q_+)$ as for Θ. Let z be a formal variable. Let us introduce $\hat{\mathscr{L}}^{\pm}(z) \in (M_N(F) \otimes U^{\mp})[[z^{\pm 1}]]$ and $\mathscr{R}(z) \in (M_N(F) \otimes M_N(F))[[z]]$ by

$$\hat{\mathscr{S}}^{+}(z)=\sum_{\mu\geqslant 0}(\rho\otimes 1)(\Theta_{\mu})\ z^{(\Lambda_0|\mu)/d_0},$$

$$\hat{\mathscr{S}}^{-}(z)=\sum_{\mu\geqslant 0}(\rho\otimes 1)(((\Theta_{21})^{-1})_{\mu})\ z^{-(\Lambda_0|\mu)/d_0},$$

$$\mathscr{R}(z)=(1\otimes\rho)\mathscr{S}^{+}(z). \tag{2.11}$$

We further introduce L operators and an R matrix by

$$\hat{L}^{+}(z)=\hat{\mathscr{S}}^{+}(z)\hat{\mathscr{T}}^{-1},\quad \hat{L}^{-}(z)=\hat{\mathscr{T}}\hat{\mathscr{S}}^{-}(z),$$

$$R(z)=\mathscr{R}(z)T^{-1}=\sum_{n\geqslant 0}\sum_{1\leqslant i_1,i_2,j_1,j_2\leqslant N}R[n]^{i_1j_1}_{i_2j_2}E_{i_1i_2}\otimes E_{j_1j_2}z^{n}, \tag{2.12}$$

where

$$\hat{\mathscr{T}}^{\pm 1}=\sum_{1\leqslant i\leqslant N}E_{ii}\otimes k_{\pm\eta_i},\quad T^{\pm 1}=\sum_{1\leqslant i,j\leqslant N}q^{\pm((\eta_i|\eta_j)-(\eta_1|\eta_1))}E_{ii}\otimes E_{jj},$$

and E_{ij} is a matrix unit.

Finally we state the simple properties of R matrix, which we shall need in the next section. Let $(\dot{\rho},\mathbf{Q}^N)$ denote the representation of $g'=[g,g]$ obtained by taking the limit $q=1$ of $\rho(\cdot)\in M_N(F)$. Let $r(z)\in(\dot{\rho}(g')\otimes_{\mathbf{Q}}\dot{\rho}(g'))[[z]]$ be the trigonometric classical r matrix[21] of type g normalized by the condition that the diagonal part of the z^0 component of $r(z)$ is $\Sigma_{1\leqslant i,j\leqslant N}[(\eta_i|\eta_j)/2]E_{ii}\otimes E_{jj}(=:r_0)$. Let further A be the $\mathbf{Q}$ subalgebra of F consisting of the elements which have no pole at $q=1$.

Lemma 1:

(1) $R[0]^{i_1j_1}_{i_2j_2}\neq 0$ only if $i_1\leqslant i_2$ and $j_1\geqslant j_2$.

(2) $\eta_{i_1}+\eta_{j_1}=\eta_{i_2}+\eta_{j_2}$, $i_1=i_2\Leftrightarrow j_1=j_2$ when $R[n]^{i_1j_1}_{i_2j_2}\neq 0$.

(3) $\mathscr{R}(z)=1-(q-q^{-1})(r(z)-r_0)$ mod $(q-q^{-1})^2(M_N(A)\otimes_A M_N(A))[[z]]$.

Proof: (3) Let r_μ $(\mu>0)$ be the elements of $M_N(\mathbf{Q})\otimes_{\mathbf{Q}}M_N(\mathbf{Q})$ uniquely determined by the following conditions:

$$r_{\alpha_i}=d_i\dot{\rho}(e_i)\otimes\dot{\rho}(f_i)\quad(0\leqslant i\leqslant l),$$

$$[1\otimes\dot{\rho}(e_i),r_\mu]+[\dot{\rho}(e_i)\otimes 1,r_{\mu-\alpha_i}]=0\quad(\mu(\neq\alpha_i)>0,\ 0\leqslant i\leqslant l),$$

$$[\dot{\rho}(f_i)\otimes 1,r_\mu]+[1\otimes\dot{\rho}(f_i),r_{\mu-\alpha_i}]=0\quad(\mu(\neq\alpha_i)>0,\ 0\leqslant i\leqslant l),$$

$$\sum_{k=1}^{M}(r_\mu)_{k\,M+1}\dot{w}\otimes 1_{\mathbf{Q}^N}=0\quad(\mu>0),\quad\text{for } g\neq A^{(2)}_{2l},A^{(2)}_{2l-1},$$

$$(\mathrm{tr}\otimes 1)(r_\mu)=0\quad(\mu>0),\quad\text{for } g=A^{(2)}_{2l},A^{(2)}_{2l-1},$$

where $\dot{w}=w|_{q=1}$. (See Ref. 16, Proposition 8.3.a.) Then $r(z)=\Sigma_{\mu\geqslant 0}r_\mu z^{(\Lambda_0|\mu)/d_0}$. Hence by considering the equations from (2.7), (2.8) and (2.9) in the limit $q=1$, the claim can be easily proven by induction on $\mathrm{ht}\mu$. In the case $g=A^{(2)}_{2l}$, $A^{(2)}_{2l-1}$, we also use (3.14) below with $l_{ij}[-n]=-\hat{\mathscr{S}}^{+}_{ij}[-n]/(q-q^{-1})$. (In the nontwisted case, it is also possible to use the multiplicative formula of Θ below. See Ref. 9, Section 6 and Ref. 22, Section 1.)

III. *L* OPERATOR FORMALISM

A. *F* algebra $\mathscr{A}(g)$

Let g, (ρ,V), N, η_i $(1\leqslant i\leqslant N)$, $R(z)$, M, b_i $(1\leqslant i\leqslant M)$ and w as before. Following Refs. 5, 6, 10, 23, let $\mathscr{A}=\mathscr{A}(g)$ be the F algebra generated by $L_{ij}^{+}[0]$ $(1\leqslant i\leqslant j\leqslant N)$, $L_{ij}^{-}[0]$ $(1\leqslant j\leqslant i\leqslant N)$, $L_{ij}^{\pm}[\mp n]$ $(1\leqslant i,j\leqslant N, n\in\mathbf{Z}_{>0})$, $C^{\pm 1}$ and $D^{\pm 1}$ with the relations

$$L_{ii}^{\pm}[0]L_{ii}^{\mp}[0]=C^{\pm 1}C^{\mp 1}=D^{\pm 1}D^{\mp 1}=1, \tag{3.1}$$

$$L_{ii}^{\pm}[0]=1, \text{ for } i \text{ such that } \eta_i=0, \tag{3.2}$$

$$C^{\pm 1} \text{ central}, \tag{3.3}$$

$$DL_{ij}^{\pm}[\mp n]D^{-1}=q^{\mp n}L_{ij}^{\pm}[\mp n], \tag{3.4}$$

$$R_{12}(Cz_1/z_2)L_1^{+}(z_1)L_2^{-}(z_2)=L_2^{-}(z_2)L_1^{+}(z_1)R_{12}(C^{-1}z_1/z_2), \tag{3.5}$$

$$R_{12}(z_1/z_2)L_1^{\pm}(z_1)L_2^{\pm}(z_2)=L_2^{\pm}(z_2)L_1^{\pm}(z_1)R_{12}(z_1/z_2), \tag{3.6}$$

$$L_1^{\pm}(b_1z)\cdots L_M^{\pm}(b_Mz)w\otimes 1=w\otimes 1, \tag{3.7}$$

$$(G\otimes 1)L^{\pm}(z)(G^{-1}\otimes 1)=L^{\pm}(-z), \quad \text{for } g=D_{l+1}^{(2)}. \tag{3.8}$$

Here $L^{\pm}(z)$ is defined in terms of the generating series $L_{ij}^{\pm}(z)=\Sigma_{n\geqslant 0}L_{ij}^{\pm}[\mp n]z^{\pm n}$ as

$$L^{\pm}(z)=\sum_{1\leqslant i,j\leqslant N}E_{ij}\otimes L_{ij}^{\pm}(z)\in(M_N(F)\otimes\mathscr{A})[[z^{\pm 1}]];$$

$L_i^{\pm}(z)$ denotes $L^{\pm}(z)$ whose matrix part acts on the ith space, z_1 and z_2 are formal variables, and

$$G=\operatorname{diag}(1,\ldots,1,-1)\in M_N(F).$$

It is well known and easy to check that $\mathscr{A}$ has the following Hopf algebra structure:

$$\Delta(L_{ij}^{+}(z))=\sum_{k=1}^{N}L_{kj}^{+}(C_2^{-1}z)\otimes L_{ik}^{+}(z), \quad \Delta(L_{ij}^{-}(z))=\sum_{k=1}^{N}L_{kj}^{-}(z)\otimes L_{ik}^{-}(C_1^{-1}z),$$

$$\Delta(C^{\pm 1})=C^{\pm 1}\otimes C^{\pm 1}, \quad \Delta(D^{\pm 1})=D^{\pm 1}\otimes D^{\pm 1},$$

$$\epsilon(L_{ij}^{\pm}(z))=\delta_{ij}, \quad \epsilon(C^{\pm 1})=\epsilon(D^{\pm 1})=1,$$

$$(1\otimes S)(L^{\pm}(z))={}^{t}(({}^{t}L^{\pm}(Cz))^{-1}), \quad S(C^{\pm 1})=C^{\mp 1}, \quad S(D^{\pm 1})=D^{\mp 1}, \tag{3.9}$$

where $C_1=C\otimes 1$, $C_2=1\otimes C$ and ^{t} denotes the matrix transpose in the first space of the tensor product. It is also well known and easy to check that there is a surjective Hopf algebra homomorphism $\phi:\mathscr{A}\to\mathscr{U}$ defined by

$$L^{\pm}(z)\mapsto\hat{L}^{\pm}(z), \quad C^{\pm 1}\mapsto k_{\pm\delta}, \quad D^{\pm 1}\mapsto k_{\pm\Lambda_0/d_0}.$$

In the next subsection, we shall show the injectivity of ϕ by the standard specialization argument at $q=1$.[18,22] The only subtlety appears in the case $A_{2l}^{(2)}$, $A_{2l-1}^{(2)}$.

B. Proof of the isomorphism $\mathscr{A}(g)\simeq U_q^{\Gamma}(g)$

Set

$$\mathscr{L}^{+}(z)=L^{+}(z)\mathscr{T}, \quad \mathscr{L}^{-}(z)=\mathscr{T}^{-1}L^{-}(z), \quad \mathscr{T}^{\pm 1}=\sum_{1\leqslant i\leqslant N}E_{ii}\otimes L_{ii}^{\mp}[0], \tag{3.10}$$

and define the components $\mathscr{L}_{ij}^{\pm}[\mp n]$ as before. We further define subalgebras of $\mathscr{A}$ by

$$\mathscr{A}^{\pm}=\langle \mathscr{L}_{ij}^{\mp}[\mp n] | 1\leqslant i,j\leqslant N,\ n\geqslant 0\rangle, \quad \mathscr{A}^{0}=\langle L_{ii}^{\pm}[0], C^{\pm 1}, D^{\pm 1} | 1\leqslant i\leqslant N\rangle,$$

and, for $\mu\in Q$, we set

$$\mathscr{A}_{\mu}^{\pm}=\{x\in\mathscr{A}^{\pm} | L_{ii}^{-}[0]xL_{ii}^{+}[0]=q^{(\eta_i|\mu)}x \quad (1\leqslant i\leqslant N), \quad DxD^{-1}=q^{(\Lambda_0|\mu)/d_0}x\}.$$

Lemma 2:
(1) $L_{kk}^{-}[0]L_{ij}^{\pm}[\mp n]=q^{-(\eta_k|\eta_i-\eta_j)}L_{ij}^{\pm}[\mp n]L_{kk}^{-}[0]$.
(2) $\mathscr{A}^{0}$ is commutative.
(3) $\Pi_{i=1}^{N}L_{ii}^{\pm}[0]^{n_i}=1$ if $\Sigma_i n_i\eta_i=0$.
(4) $\mathscr{A}=\mathscr{A}^{-}\mathscr{A}^{0}\mathscr{A}^{+}$.

Proof: (3) follows from (3.2) and the z^0 components of (3.7) and (3.8).

Lemma 3: $\mathscr{A}^{\pm}=\oplus_{\mu\in Q_+}\mathscr{A}_{\pm\mu}^{\pm}$ and $\dim_F\mathscr{A}_{\pm\mu}^{\pm}\leqslant\mathscr{P}(\mu)$.

Proof: This can be proven as in Ref. 22, Proposition 1.13.

Let $\mathscr{N}$ be the F algebra generated by $\mathscr{L}_{ij}[0]$ $(1\leqslant i<j\leqslant N)$ and $\mathscr{L}_{ij}[-n]$ $(1\leqslant i,j\leqslant N,\ n>0)$ with the relations

$$\mathscr{R}_{12}(z_1/z_2)T_{12}^{-1}\mathscr{L}_1(z_1)T_{12}\mathscr{L}_2(z_2)=\mathscr{L}_2(z_2)T_{12}\mathscr{L}_1(z_1)T_{12}^{-1}\mathscr{R}_{12}(z_1/z_2), \tag{3.11}$$

$$\mathscr{L}_1(b_1z)T_{12}\mathscr{L}_2(b_2z)T_{12}^{-1}\cdots T_{1;M}\mathscr{L}_M(b_Mz)T_{1;M}^{-1}w\otimes 1=w\otimes 1, \tag{3.12}$$

$$(G\otimes 1)\mathscr{L}(z)(G^{-1}\otimes 1)=\mathscr{L}(-z), \quad \text{for } g=D_{l+1}^{(2)}, \tag{3.13}$$

where $T_{1;k}=T_{1k}\cdots T_{k-1\,k}$, and $\mathscr{L}(z)$ are defined as $L^{+}(z)$ with $\mathscr{L}_{ii}[0]=1$. Next let $\mathscr{N}_A$ be the A algebra generated by $l_{ij}[0]$ $(1\leqslant i<j\leqslant N)$ and $l_{ij}[-n]$ $(1\leqslant i,j\leqslant N,\ n>0)$ with the following relations. Let $l(z)$ be defined as before with $l_{ii}[0]=0$. First substitute $\mathscr{L}(z)=1-(q-q^{-1})l(z)$ into (3.11)–(3.13) and then divide (3.11) by $(q-q^{-1})^2$ and the rest by $q-q^{-1}$. We take the thus obtained equations as the defining relations of $\mathscr{N}_A$. In the case $g=A_{2l}^{(2)},A_{2l-1}^{(2)}$, we impose another relation,

$$\frac{\operatorname{tr} l(b_2z)-\operatorname{tr} l(b_2^{-1}z)}{q-q^{-1}}=\operatorname{tr}\ \tilde{l}(z)^2-\operatorname{tr} l(z)^2+(q-q^{-1})(\operatorname{tr} l(z)^2\tilde{l}(b_2z)-\operatorname{tr} l(b_2^{-1}z)\tilde{l}(z)^2), \tag{3.14}$$

where $\tilde{l}(z)=\Sigma_{n\geqslant 0}\Sigma_{ij}E_{ij}\otimes(u_i/u_j)\,q^{(\eta_i|\eta_i-\eta_j)}l_{N+1-j\ N+1-i}[-n]z^n$ (see Sec. 3 in Appendix A for the u_i) and tr denotes the trace of the matrix part. Finally let n^{-} be the subalgebra of g generated by the f_i in the notations of Ref. 16 and $U(n^{-})$ its enveloping algebra. $U(n^{-})$ can be defined by the generators $l_{ij}[0]$ $(1\leqslant i<j\leqslant N)$, $l_{ij}[-n]$ $(1\leqslant i,j\leqslant N,\ n>0)$ and the relations

$$\begin{gathered}
[r_{12}(z_1/z_2),l_1(z_1)+l_2(z_2)]+[l_1(z_1),l_2(z_2)]+[(r_0)_{12},l_1(z_1)-l_2(z_2)]=0,\\
l(z)(\dot{J}\otimes 1)+(\dot{J}\otimes 1)\,{}^{t}l(\sigma z)=0, \quad \text{for } g\neq A_l^{(1)},\\
\operatorname{tr}\ l(z)=0, \quad \text{for } g=A_l^{(1)},\ A_{2l}^{(2)},\ A_{2l-1}^{(2)},\\
(G\otimes 1)l(z)(G^{-1}\otimes 1)=l(-z), \quad \text{for } g=D_{l+1}^{(2)},
\end{gathered} \tag{3.15}$$

where $\dot{J}=J|_{q=1}$. (See Ref. 16, Chapters 7 and 8.)

Set $\mathscr{N}_F=\mathscr{N}_A\otimes_A F$ and $\mathscr{N}_{\mathbf{Q}}=\mathscr{N}_A\otimes_A\mathbf{Q}$, where A acts on F naturally and on $\mathbf{Q}$ via $q\mapsto 1$. In the case $g=A_{2l}^{(2)},A_{2l-1}^{(2)}$, (3.14) follows from (3.12) in $\mathscr{N}$. Thanks to Lemma 1 (3), in the limit $q=1$ the relations of $\mathscr{N}_A$ reduce to (3.15); cf. Refs. 6 and 23. Therefore

$$\begin{gathered}
\mathscr{N}_{\mathscr{F}}\xrightarrow{\sim}\mathscr{N} \quad (l_{ij}[-n]\otimes 1\mapsto -\mathscr{L}_{ij}[-n]/(q-q^{-1})),\\
\mathscr{N}_{\mathbf{Q}}\xrightarrow{\sim}U(n^{-}) \quad (l_{ij}[-n]\otimes 1\mapsto l_{ij}[-n]).
\end{gathered} \tag{3.16}$$

As easily checked, $\mathcal{N}_A$ is a Q-graded algebra by assigning $\eta_j-\eta_i-n\delta\in Q$ to $l_{ij}[-n]$ and each homogeneous component $(\mathcal{N}_A)_\mu$ $(\mu\in Q)$ is finitely generated over A. Moreover there is a surjective F algebra homomorphism from $\mathcal{N}$ to $\mathcal{A}^-$ which maps $\mathcal{L}_{ij}[-n]$ to $\mathcal{L}_{ij}^+[-n]$. Therefore, thanks to (3.16) we obtain $\dim_F\mathcal{A}^-_{-\mu}\leqslant\dim_F(\mathcal{N}_A)_{-\mu}\otimes_A F\leqslant\dim_{\mathbf{Q}}(\mathcal{N}_A)_{-\mu}\otimes_A\mathbf{Q}=\mathcal{P}(\mu)$. The case $\mathcal{A}^+$ can be similarly proven.

Theorem 1: *For $g=A_l^{(1)}, B_l^{(1)}, C_l^{(1)}, D_l^{(1)}, A_{2l}^{(2)}, A_{2l-1}^{(2)}, D_{l+1}^{(2)}$, $\phi:\mathcal{A}(g)\to U_q^\Gamma(g)$ is a Hopf algebra isomorphism.*

Proof: Clearly $\phi(\mathcal{A}^0)=\mathcal{U}^0$ and $\phi(\mathcal{A}^\pm_{\pm\mu})=\mathcal{U}^\pm_{\pm\mu}$. Since $\Gamma=\oplus_{i=1}^l\mathbf{Z}\eta_i\oplus\mathbf{Z}\delta\oplus\mathbf{Z}\Lambda_0/d_0$, Proposition 1 (2), Eq. (3.1) and Lemma 2 (2), (3) show that $\phi|_{\mathcal{A}^0}$ is injective. Proposition 1 (3) and Lemma 3 prove that $\phi|_{\mathcal{A}^\pm}:\mathcal{A}^\pm\to\mathcal{U}^\pm$ are isomorphisms. Hence Proposition 1 (1) and Lemma 2 (4) yield the claim.

Remark: In the case $g=A_l^{(1)}$, we can replace (3.7) in the definition of $\mathcal{A}(g)$ by the following well known conditions for quantum determinants,

$$\sum_{\gamma\in\mathcal{S}_{l+1}}(-q)^{l(\gamma)}L^\pm_{1\,\gamma(1)}(b_1z)\cdots L^\pm_{l+1\,\gamma(l+1)}(b_{l+1}z)=1,$$

where $l(\gamma)$ denotes the length function of $\mathcal{S}_{l+1}$. For the above relation is contained in (3.7) and is sufficient to give Lemma 2 (3) and tr $l(z)=0$ in (3.15).

IV. MULTIPLICATIVE FORMULA OF Θ

A. Review of the result by Beck

In this section, we shall consider nontwisted affine Kac–Moody algebra g. In this subsection, for completeness and a later purpose, we review the result by Beck[9] on the isomorphism of U and Drinfeld's realization $\mathcal{D}$ (see below). We slightly change the notations in order to do without the square root of the central element. See Ref. 9 and references therein for further details.

Set $\overline{P}^\vee=\oplus_{i=1}^l\mathbf{Z}\omega_i^\vee$ and $\overline{Q}^\vee=\oplus_{i=1}^l\mathbf{Z}\alpha_i^\vee$. Let $\overline{W}$ and W be the Weyl groups of $\overline{g}$ and g, respectively. Set $\widetilde{W}=\overline{W}\ltimes\overline{P}^\vee$, where $\overline{W}$ acts on $\overline{P}^\vee$ naturally. $\widetilde{W}$ is known to be isomorphic to $\Pi\ltimes W$. Here Π is a subgroup of the automorphism group of the Dynkin diagram of type g, which is isomorphic to $\overline{P}^\vee/\overline{Q}^\vee$, and $\pi\in\Pi$ acts on s_i, a simple reflection with respect to α_i, as $\pi s_i\pi^{-1}=s_{\pi(i)}$. $\widetilde{W}$ acts on Q. Its action is given by $\widetilde{w}(\alpha)=\overline{w}(\alpha)-(\alpha|x)\delta=\pi(w(\alpha))$, where $\widetilde{w}=\overline{w}x=\pi w\in\widetilde{W}$ $(\overline{w}\in\overline{W},x\in\overline{P}^\vee,\pi\in\Pi,w\in W)$, $\alpha\in Q$ and $\pi(\alpha_i)=\alpha_{\pi(i)}$.

Let T_i $(0\leqslant i\leqslant l)$[14] and T_π $(\pi\in\Pi)$ be the automorphisms of U' defined by

$$T_i(e_i)=-f_ik_i,\quad T_i(f_i)=-k_i^{-1}e_i,\quad T_i(k_\lambda)=k_{s_i(\lambda)},$$

$$T_i(e_j)=\mathrm{ad}(e_i^{(-a_{ij})})\cdot e_j,\quad T_i(f_j)=f_j\cdot\widetilde{\mathrm{ad}}(f_i^{(-a_{ij})})\quad(i\neq j),$$

$$T_\pi(e_i)=e_{\pi(i)},\quad T_\pi(f_i)=f_{\pi(i)},\quad T_\pi(k_{\alpha_i})=k_{\alpha_{\pi(i)}}.$$

Here ad (resp., $\widetilde{\mathrm{ad}}$) is a left (resp., right) adjoint action defined by

$$\mathrm{ad}(x)\cdot y=\sum x^{(1)}yS(x^{(2)}),\quad y\cdot\widetilde{\mathrm{ad}}(x)=\sum S(x^{(1)})yx^{(2)},$$

with $x,y\in U$ and $\Delta(x)=\Sigma x^{(1)}\otimes x^{(2)}$. For $\widetilde{w}\in\widetilde{W}$, we say an expression $\widetilde{w}=\pi s_{i_1}\cdots s_{i_n}$ $(\pi\in\Pi)$ is reduced if $s_{i_1}\cdots s_{i_n}$ is so in W. For any reduced expression $\widetilde{w}=\pi s_{i_1}\cdots s_{i_n}$, we can set $T_{\widetilde{w}}=T_\pi T_{i_1}\cdots T_{i_n}$. Then $T_{\widetilde{w}}$ $(\widetilde{w}\in\widetilde{W})$ gives a Braid group action on U'. Let Ω be the $\mathbf{Q}$ algebra anti-automorphism of U' defined by

$$e_i\mapsto f_i,\quad f_i\mapsto e_i,\quad k_\lambda\mapsto k_{-\lambda},\quad q\mapsto q^{-1}.$$

This satisfies $\Omega T_{\widetilde{w}}=T_{\widetilde{w}}\Omega$.

Fix $o(i)\in\{-1,1\}$ $(1\leqslant i\leqslant l)$ such that $o(i)=-o(j)$ if $a_{ij}<0$. Let us define $x_{i,k}^{(\pm)}$, $h_{i,r}\in U$ $(1\leqslant i\leqslant l,\ k\in\mathbf{Z},\ r\in\mathbf{Z}-\{0\})$ by

$$x_{i,k}^{(+)}=o(i)^k T_{\omega_i^\vee}^{-k}(e_i),\quad x_{i,k}^{(-)}=\Omega(x_{i,-k}^{(+)}), \tag{4.1}$$

$$k_i^{\mp 1}\exp\left(\mp(q_i-q_i^{-1})\sum_{r>0}h_{i,\mp r}z^{\pm r}\right)=\sum_{r\geqslant 0}\phi_{i,\mp r}^{\pm}z^{\pm r}, \tag{4.2}$$

where

$$\phi_{i,0}^{-}=k_i,\quad \phi_{i,r}^{-}=(q_i-q_i^{-1})k_{r\delta}\ [e_i,x_{i,r}^{(-)}]\quad (r>0),\quad \phi_{i,-r}^{+}=\Omega(\phi_{i,r}^{-})\quad (r\geqslant 0). \tag{4.3}$$

Let $\mathscr{D}=\mathscr{D}(g)^4$ be the F algebra generated by $x_{i,k}^{(\pm)}$, $h_{i,r}$, $k_i^{\pm 1}$, $C^{\pm 1}$, $D^{\pm 1}$ $(1\leqslant i\leqslant l,\ k\in\mathbf{Z},\ r\in\mathbf{Z}-\{0\})$ with the relations

$$k_i^{\pm 1}k_i^{\mp 1}=C^{\pm 1}C^{\mp 1}=D^{\pm 1}D^{\mp 1}=1, \tag{4.4}$$

$$C^{\pm 1}\ \text{central}, \tag{4.5}$$

$$[k_i,k_j]=[k_i,D]=[k_i,h_{j,r}]=0, \tag{4.6}$$

$$[h_{i,r},h_{j,s}]=\delta_{r+s,0}\frac{[ra_{ij}]_i}{r}\frac{C^r-C^{-r}}{q_j-q_j^{-1}}, \tag{4.7}$$

$$k_i x_{j,k}^{(\pm)}k_i^{-1}=q^{\pm(\alpha_i|\alpha_j)}x_{j,k}^{(\pm)}, \tag{4.8}$$

$$Dx_{i,k}^{(\pm)}D^{-1}=q^k x_{i,k}^{(\pm)},\quad Dh_{i,r}D^{-1}=q^r h_{i,r}, \tag{4.9}$$

$$[h_{i,r},x_{j,k}^{(\pm)}]=\pm\frac{[ra_{ij}]_i}{r}C^{(r\mp|r|)/2}x_{j,r+k}^{(\pm)}, \tag{4.10}$$

$$[x_{i,m}^{(+)},x_{j,n}^{(-)}]=\frac{\delta_{ij}}{q_i-q_i^{-1}}(C^{-n}\phi_{i,m+n}^{-}-C^{-m}\phi_{i,m+n}^{+}), \tag{4.11}$$

$$x_{i,m+1}^{(\pm)}x_{j,n}^{(\pm)}-q^{\pm(\alpha_i|\alpha_j)}x_{j,n}^{(\pm)}x_{i,m+1}^{(\pm)}=q^{\pm(\alpha_i|\alpha_j)}x_{i,m}^{(\pm)}x_{j,n+1}^{(\pm)}-x_{j,n+1}^{(\pm)}x_{i,m}^{(\pm)}, \tag{4.12}$$

$$\mathrm{Sym}_{m_1,\cdots,m_r}\sum_{s=0}^{r}(-1)^s\frac{[r]_i!}{[s]_i![r-s]_i!}x_{i,m_1}^{(\pm)}\cdots x_{i,m_s}^{(\pm)}x_{j,n}^{(\pm)}x_{i,m_{s+1}}^{(\pm)}\cdots x_{i,m_r}^{(\pm)}=0\quad (i\neq j,\ r=1-a_{ij}), \tag{4.13}$$

where $\phi_{i,\mp r}^{\pm}$ $(r\geqslant 0)$ is expressed in terms of $k_i^{\pm 1}$ and $h_{i,r}$'s by (4.2).

Theorem 2:[9] *For nontwisted affine Kac–Moody algebra g, there exists an algebra isomorphism $\psi:\mathscr{D}(g)\to U_q^{\Sigma}(g)$ determined by*

$$x_{i,k}^{(\pm)}\mapsto x_{i,k}^{(\pm)},\quad h_{i,r}\mapsto h_{i,r},\quad k_i^{\pm 1}\mapsto k_i^{\pm 1},\quad C^{\pm 1}\mapsto k_{\pm\delta},\quad D^{\pm 1}\mapsto k_{\pm\Lambda_0/d_0}.$$

B. Multiplicative formula of Θ

In this subsection, we shall write down the multiplicative formula of Θ, following the approach by Beck[9,13] and Lusztig.[14] Most of the necessary results have already been obtained by them.

Firstly we shall describe their results. Fix $x=\omega_{j_K}^\vee\cdots\omega_{j_1}^\vee\in\overline{Q^\vee}\subset W$ such that $(x|\alpha_i)>0$ $(1\leqslant i\leqslant l)$. Let $s_{i_L}\cdots s_{i_1}$ be one of its reduced expressions obtained by the concatenation of reduced presentations of $\omega_{j_k}^\vee$'s and canceling the elements of Π. Let us define β_k $(k\in\mathbf{Z})$ by

$$\beta_k = s_{i_1}\cdots s_{i_{k-1}}(\alpha_{i_k}) \ \ (1\leqslant k\leqslant L), \quad \beta_{k\pm rL} = \pm x^{\mp r}(\beta_k) \ \ (1\leqslant k\leqslant L,\ r>0).$$

Then they are distinct and run over the whole set of positive real roots of g. Moreover β_k is a positive (resp., negative) root of $\overline{g}$ mod $\mathbf{Z}\delta$ if $k>0$ (resp., $k\leqslant 0$). We define $E_k \in U^+_{\beta_k}$ and $F_k \in U^-_{-\beta_k}$ $(k\in\mathbf{Z})$ by

$$E_{k+rL} = T_x^{-r}T_{i_1}^{-1}\cdots T_{i_{k-1}}^{-1}(e_{i_k}) \ \ (1\leqslant k\leqslant L, r\geqslant 0),$$

$$E_{k-rL} = k_{\beta_{k-rL}}T_x^r T_{i_1}^{-1}\cdots T_{i_{k-1}}^{-1}(f_{i_k}) \ \ (1\leqslant k\leqslant L,\ r>0),$$

$$F_k = \Omega(E_k), \tag{4.14}$$

and set

$$E^{\mathbf{m}} = (E_1^{m_1}E_2^{m_2}\cdots)\prod_{\substack{1\leqslant i\leqslant l\\ r>0}} h_{i,r}^{m_{i,r}}(\cdots E_{-1}^{m_{-1}}E_0^{m_0}), \quad F^{\mathbf{m}} = (F_1^{m_1}F_2^{m_2}\cdots)\prod_{\substack{1\leqslant i\leqslant l\\ r>0}} h_{i,-r}^{m_{i,r}}(\cdots F_{-1}^{m_{-1}}F_0^{m_0}). \tag{4.15}$$

Here $h_{i,\pm r}\in U^{\pm}_{\pm r\delta}$ $(r>0)$ is defined in (4.2), and $\mathbf{m}=(m_k, m_{j,r})_{k\in\mathbf{Z},1\leqslant j\leqslant l,r>0}$ is a family of nonnegative integers such that they all vanish except for a finite number of them. For $k\in\mathbf{Z}$ we let $\overline{k}$ denote the integer which is between 1 and L, and equal to k mod L. Finally, let $(\ ,\ ): U^{\geqslant 0}\times U^{\leqslant 0}\to F$ be the Hopf pairing (Ref. 2 and Ref. 20, Proposition 2.1.1) determined by bilinearity and the following:

$$(k_\lambda, k_\mu) = q^{-(\lambda|\mu)}, \quad (e_i, k_\lambda) = (k_\lambda, f_i) = 0, \quad (e_i, f_j) = -\delta_{ij}/(q_i - q_i^{-1}),$$

$$(x, y_1y_2) = (\Delta(x), y_1\otimes y_2), \quad (x_1x_2, y) = (x_2\otimes x_1, \Delta(y)) \tag{4.16}$$

$$(x, x_1, x_2\in U^{\geqslant 0},\ y, y_1, y_2\in U^{\leqslant 0}).$$

Reference 13, Proposition 3 and Ref. 14, Proposition 40.2.4 give the following.

Proposition 2:[13,14]

(1) $(E^{\mathbf{m}})_{\mathbf{m}}$ and $(F^{\mathbf{m}})_{\mathbf{m}}$ form a basis of U^+ and U^-, respectively.

(2) $(E^{\mathbf{m}}, F^{\mathbf{n}}) = (\Pi_{\substack{1\leqslant i\leqslant l\\ r>0}} h_{i,r}^{m_{i,r}}, \Pi_{\substack{1\leqslant i\leqslant l\\ r>0}} h_{i,-r}^{n_{i,r}})\times\Pi_{k\in\mathbf{Z}}\delta_{m_k,n_k}(e_{i_k}^{m_k}, f_{i_k}^{m_k})$.

Therefore we have only to show the following. For $r\in\mathbf{Z}_{>0}$, let $(C_{ij}(r))_{1\leqslant i,j\leqslant l}$ be the inverse matrix of $([ra_{ij}]_i(q-q^{-1})/r(q_j-q_j^{-1}))_{1\leqslant i,j\leqslant l}$ and set $\tilde{h}_{i,-r} = \Sigma_{j=1}^l C_{ij}(r)h_{j,-r}$.

Lemma 4:

$$\left(\prod_{i,r} h_{i,r}^{m_{i,r}}, \prod_{i,r}\tilde{h}_{i,-r}^{n_{i,r}}\right) = \prod_{i,r}\delta_{m_{i,r},n_{i,r}} m_{i,r}!\left(\frac{-1}{q-q^{-1}}\right)^{m_{i,r}}.$$

Proof: Let $\langle\ ,\ \rangle: U\times U\to F(q^{1/2})$ be the Killing form introduced in Ref. 20. This form is bilinear and has the following properties:

$$\langle \mathrm{ad}(u)\cdot v_1, v_2\rangle = \langle v_1, v_2\cdot\widetilde{\mathrm{ad}}(u)\rangle \ \ (u, v_1, v_2\in U), \tag{4.17}$$

$$\langle xk_\lambda, yk_\mu\rangle = (x,y)q^{-(\lambda|\mu)/2} \ \ (x\in U^+, y\in U^-), \tag{4.18}$$

$$\langle U^{\geqslant 0}U^-_{-\mu}, U^{\leqslant 0}\rangle = \{0\} \ \ (\mu>0). \tag{4.19}$$

In particular, (4.18) implies that $\langle x, yk_\lambda\rangle$ is independent of $\lambda\in\Sigma$ if $x\in U^+$ and $y\in U^{\leqslant 0}$. Since $\tilde{h}_{i,-r}\in U^-_{-r\delta}$,[9]

$$\Delta(\tilde{h}_{i,-r}) = 1\otimes\tilde{h}_{i,-r} + \tilde{h}_{i,-r}\otimes k_{-r\delta} \ \ \mathrm{mod} \ \ \oplus_{r\delta>\beta>0}U^-_{-(r\delta-\beta)}\otimes U^-_{-\beta}U^0.$$

Noting the above and (4.7), we obtain from (4.17) with $u=\tilde{h}_{j,-s}$, $v_1=\Pi_{i,r}h_{i,r}^{m_{i,r}}$ and $v_2=\Pi_{i,r}\tilde{h}_{i,-r}^{n_{i,r}}\cdot k_\lambda$,

$$(q^{-(\lambda|s\delta)}-1)\left\{\left(\prod_{i,r}h_{i,r}^{m_{i,r}},\tilde{h}_{j,-s}\prod_{i,r}\tilde{h}_{i,-r}^{n_{i,r}}\right)\right.$$
$$\left.+\frac{m_{j,s}}{q-q^{-1}}\left(h_{j,s}^{m_{j,s}-1}\prod_{(i,r)\neq(j,s)}h_{i,r}^{m_{i,r}},\prod_{i,r}\tilde{h}_{i,-r}^{n_{i,r}}\right)\right\}=\sum_{s\delta>\beta\geqslant 0}q^{-(\lambda|\beta)}x_\beta.$$

Here x_β's are the elements of F independent of λ. Since the above equality holds for any $\lambda\in\Sigma$, the inside of the curly bracket vanishes. From this, the lemma follows.

The following is essentially due to Beck and Lusztig, cf. Refs. 8, 12, 24, 25. Set

$$\Theta^0=\exp\left(-(q-q^{-1})\sum_{\substack{1\leqslant i,j\leqslant l\\ r>0}}C_{ij}(r)h_{i,r}\otimes h_{j,-r}\right),\quad \Theta^+=\Theta_1\Theta_2\cdots,\quad \Theta^-=\cdots\Theta_{-1}\Theta_0,\tag{4.20}$$

where

$$\Theta_k=\sum_{m\geqslant 0}(-1)^m q_i^{-m(m-1)/2}\frac{(q_i-q_i^{-1})^m}{[m]_i!}E_k^m\otimes F_k^m\quad (i=i_{\bar{k}}).$$

Proposition 3:

(1) $\Theta=\Theta^+\Theta^0\Theta^-$.

(2) *Let* $i\in\{1,\ldots,l\}$. *If* $\beta_k=\alpha_i+m\delta$ $(k>0,\ m\geqslant 0)$, *then* $E_k\otimes F_k=x_{i,m}^{(+)}\otimes x_{i,-m}^{(-)}$. *If* $\beta_k=-\alpha_i+m\delta$ $(k\leqslant 0,\ m>0)$, *then* $E_k\otimes F_k=\Psi(x_{i,m}^{(-)}\otimes x_{i,-m}^{(+)})$.

Proof: (1) Since Θ_μ is the canonical element of $(\ ,\ )|_{U_\mu^+\times U_{-\mu}^-}$,[2,20] the claim follows from Proposition 2 and Lemma 4.

(2) Let x_i denote e_i or f_i. When $1\leqslant k\leqslant L$, $T_{i_1}^{-1}\cdots T_{i_{k-1}}^{-1}(x_{i_k})=T_{\omega_{j_1}^\vee}^{-1}\cdots T_{\omega_{j_{r-1}}^\vee}^{-1}\times T_{p_1}^{-1}\cdots T_{p_{s-1}}^{-1}(x_{p_s})$ for some r, s, where $\pi s_{p_t}\cdots s_{p_1}$ is the reduced expression of $\omega_{j_r}^\vee$. Since among the roots $s_{p_1}\cdots s_{p_{s-1}}(\alpha_{p_s})|1\leqslant s\leqslant t$ only $\alpha_{p_1}=\alpha_{j_r}$ has the form $\pm\alpha_i+m\delta$ $(1\leqslant i\leqslant l, m\geqslant 0)$, (2) follows from $T_{\omega_i^\vee}T_{\omega_j^\vee}=T_{\omega_j^\vee}T_{\omega_i^\vee}$ and $T_{\omega_i^\vee}x_j=x_j$ $(1\leqslant i\neq j\leqslant l)$.[9]

V. *L* OPERATORS AND DRINFELD'S GENERATORS

In the rest of the paper, we shall consider only $g=A_l^{(1)},B_l^{(1)},C_l^{(1)},D_l^{(1)}$. Let $L^\pm(z)=L^{\pm,u}(z)L^{\pm,d}(z)L^{\pm,l}(z)$ be the unique decomposition of the L operators such that $L^{\pm,a}(z)\in(M_N(F)\otimes\mathscr{A})[[z^{\pm 1}]]\simeq M_N(\mathscr{A}[[z^{\pm 1}]])$ $(a=u,d,l)$, $L^{\pm,d}(z)$ is diagonal, and $L^{\pm,u}(z)$ [resp., $L^{\pm,l}(z)$] is upper (resp., lower) triangular with identity elements on the diagonal.[10] For Θ^a $(a=\pm,0)$, define $((\Theta^a)^{\pm 1})_\mu$ $(\mu\in Q_+)$ as for Θ. Let us introduce $\hat{L}^{\pm,a}(z)\in(M_N(F)\otimes\mathscr{U})\times[[z^{\pm 1}]]$ $(a=u,d,l)$ by

$$\hat{L}^{+,u}(z)=\hat{\mathscr{L}}^{+,u}(z),\quad \hat{L}^{+,d}(z)=\hat{\mathscr{L}}^{+,d}(z).\hat{\mathscr{T}}^{-1},\quad \hat{L}^{+,l}(z)=.\hat{\mathscr{T}}\hat{\mathscr{L}}^{+,l}(z).\hat{\mathscr{T}}^{-1},$$
$$\hat{L}^{-,u}(z)=.\hat{\mathscr{T}}\hat{\mathscr{L}}^{-,u}(z).\hat{\mathscr{T}}^{-1},\quad \hat{L}^{-,d}(z)=.\hat{\mathscr{T}}\hat{\mathscr{L}}^{-,d}(z),\quad \hat{L}^{-,l}(z)=\hat{\mathscr{L}}^{-,l}(z)\tag{5.1}$$

where

$$\hat{\mathscr{L}}^{+,a}(z)=\sum_{\mu\geqslant 0}(\rho\otimes 1)(\Theta_\mu^{a'})z^{(\Lambda_0|\mu)/d_0},\quad \hat{\mathscr{L}}^{-,a}(z)=\sum_{\mu\geqslant 0}(\rho\otimes 1)(((\Theta_{21}^{a''})^{-1})_\mu)z^{-(\Lambda_0|\mu)/d_0},$$

with $u'=l''=+$, $d'=d''=0$ and $l'=u''=-$. Noting the property of β_k as a root of $\overline{g}$ mod $\mathbf{Z}\delta$ and the weight of $h_{i,r}$, we obtain the following.

Proposition 4: If we identify $\mathscr{A}$ with $\mathscr{U}$ by the map ϕ, then $L^{\pm,a}(z)=\hat{L}^{\pm,a}(z)$ $(a=u,d,l)$.

This, together with Proposition 3 and Theorem 2, gives the relation between the L operators and Drinfeld's generators. Before we state the results, we prepare some notations. For $1 \leqslant i \leqslant l$, set

$$e_i^+(z) = \sum_{m>0} x_{i,-m}^{(+)} z^m, \quad f_i^+(z) = \sum_{m \geqslant 0} x_{i,-m}^{(-)} z^m, \quad \phi_i^+(z) = \sum_{m \geqslant 0} \phi_{i,-m}^+ z^m,$$

$$e_i^-(z) = \sum_{m \geqslant 0} x_{i,m}^{(+)} z^{-m}, \quad f_i^-(z) = \sum_{m>0} x_{i,m}^{(-)} z^{-m}, \quad \phi_i^-(z) = \sum_{m \geqslant 0} \phi_{i,m}^- z^{-m}. \tag{5.2}$$

Let $\rho_{\pm 1}(x_i)$ $(x = e, f)$ denote the expressions $x_i^{\pm}$ in Sec. 2 Appendix A. Let further $\epsilon(i)$ $(1 \leqslant i \leqslant N)$ denote i for $\epsilon = +1$ and $N+1-i$ for $\epsilon = -1$. For $L^{\pm,a}(z)$ $(a = u, l)$, let $\equiv$ denote the equality modulo $\oplus'_{i,j}(FE_{ij} \otimes \mathscr{A})[[z^{\pm 1}]]$, where the sum is taken over i, j such that $\eta_i - \eta_j \neq 0, \epsilon\alpha_k$ $(1 \leqslant k \leqslant l$, $\epsilon = +1$ for $a = u$, $= -1$ for $a = l)$. Finally, define $b \in F^{\times}$ by $-o(l)b = q^{-(l+1)}$ for $g = A_l^{(1)}$, $= x/y \times q_0^{-h^{\vee}/2}$ [see (A3) for x and y] for $g = B_l^{(1)}$ and $= q_0^{-h^{\vee}/2}$ for $g = C_l^{(1)}, D_l^{(1)}$. (b is an inessential constant determined by the correspondence between the e_j and $x_{i,1}^{(-)}$).

By direct calculations, we obtain

Theorem 3: *Let g be $A_l^{(1)}$, $B_l^{(1)}$, $C_l^{(1)}$ or $D_l^{(1)}$. If we identify $\mathscr{D}(g)$ with the subalgebra of $\mathscr{A}(g)$ via $(\tau_b \circ \phi)^{-1}|_{U_q^{\Sigma}(g)} \circ \psi$, the following holds.*

(1) $g = A_l^{(1)}$:

$$\mp(L^{\pm,u}(z) - 1) \equiv (q - q^{-1}) \sum_{1 \leqslant i \leqslant l} \rho(e_i) \otimes f_i^{\pm}(q^i C^{-(1 \mp 1)/2} z),$$

$$\mp(L^{\pm,l}(z) - 1) \equiv (q - q^{-1}) \sum_{1 \leqslant i \leqslant l} \rho(f_i) \otimes e_i^{\pm}(q^i C^{-(1 \pm 1)/2} z),$$

$$L_{ii}^{\pm,d}(z) L_{i+1\,i+1}^{\pm,d}(z)^{-1} = \phi_i^{\pm}(q^i z) \quad (1 \leqslant i \leqslant l).$$

(2) $g = B_l^{(1)}, C_l^{(1)}, D_l^{(1)}$:

$$\mp(L^{\pm,u}(z) - 1) \equiv \sum_{\substack{1 \leqslant i \leqslant l-1 \\ \epsilon = \pm 1}} (q_i - q_i^{-1}) \rho_{\epsilon}(e_i) \otimes f_i^{\pm}(q_i^{\epsilon i} q_0^{-\epsilon h^{\vee}/2} C^{-(1 \mp 1)/2} z) + (q_l - q_l^{-1})$$
$$\times \begin{cases} \sum_{\epsilon = \pm 1} \rho_{\epsilon}(e_l) \otimes f_l^{\pm}(q_l^{\epsilon} C^{-(1 \mp 1)/2} z), & \text{for } g = B_l^{(1)} \\ \rho(e_l) \otimes f_l^{\pm}(C^{-(1 \mp 1)/2} z), & \text{for } g = C_l^{(1)}, D_l^{(1)}, \end{cases}$$

$$\mp(L^{\pm,l}(z) - 1) \equiv \sum_{\substack{1 \leqslant i \leqslant l-1 \\ \epsilon = \pm 1}} (q_i - q_i^{-1}) \rho_{\epsilon}(f_i) \otimes e_i^{\pm}(q_i^{\epsilon i} q_0^{-\epsilon h^{\vee}/2} C^{-(1 \pm 1)/2} z) + (q_l - q_l^{-1})$$
$$\times \begin{cases} \sum_{\epsilon = \pm 1} \rho_{\epsilon}(f_l) \otimes e_l^{\pm}(q_l^{\epsilon} C^{-(1 \pm 1)/2} z), & \text{for } g = B_l^{(1)} \\ \rho(f_l) \otimes e_l^{\pm}(C^{-(1 \pm 1)/2} z), & \text{for } g = C_l^{(1)}, D_l^{(1)}, \end{cases}$$

$$L_{\epsilon(i)\,\epsilon(i)}^{\pm,d}(z)^{\epsilon}\ L_{\epsilon(i+1)\,\epsilon(i+1)}^{\pm,d}(z)^{-\epsilon} = \phi_i^{\pm}(q_i^{\epsilon i} q_0^{-\epsilon h^{\vee}/2} z) \quad (1 \leqslant i \leqslant l-1,\ \epsilon = \pm 1),$$

$$L_{\epsilon(l)\,\epsilon(l)}^{\pm,d}(z)^{\epsilon}\ L_{\epsilon(l+1)\,\epsilon(l+1)}^{\pm,d}(z)^{-\epsilon} = \phi_l^{\pm}(q_l^{\epsilon} z) \quad (\epsilon = \pm 1), \quad \text{for } g = B_l^{(1)},$$

$$L_{ll}^{\pm,d}(z) L_{l+1\,l+1}^{\pm,d}(z)^{-1} = \phi_l^{\pm}(z), \quad \text{for } g = C_l^{(1)},$$

$$L_{l-1\,l-1}^{\pm,d}(z) L_{l+1\,l+1}^{\pm,d}(z)^{-1} = L_{ll}^{\pm,d}(z) L_{l+2\,l+2}^{\pm,d}(z)^{-1} = \phi_l^{\pm}(z) \quad \text{for } g = D_l^{(1)}.$$

Remark: In Ref. 25, another Hopf algebra structure of the quantum group found by Drinfeld is shown to be obtained by the twisting by $\mathscr{F}=(\Theta_{21}^{+})^{-1}$ (in our notation). The above correspondence between the L operators and Drinfeld's generators gives an intuitive explanation of its comultiplication formula as follows. After the twist, $\Theta^{\mathscr{F}}=\Theta^{0}\Theta^{-}\Psi(\Theta_{21}^{+})$. Define $\hat{L}^{\pm,\mathscr{F}}(z)$ for $\Theta^{\mathscr{F}}$ as before. Then $\hat{L}^{+,\mathscr{F}}(z)=\hat{L}^{+,d}(z)\hat{L}^{+,l}(z)\hat{L}^{-,l}(k_{-\delta}z)^{-1}$ and $\hat{L}^{-,\mathscr{F}}(z)=\hat{L}^{+,u}(k_{-\delta}z)^{-1}\times\hat{L}^{-,u}(z)\hat{L}^{-,d}(z)$. These have the lower and upper triangular forms, respectively, and satisfy the comultiplication formula in (3.9) for $\Delta^{\mathscr{F}}(\cdot)=\mathscr{F}\Delta(\cdot)\mathscr{F}^{-1}$. From this, the comultiplication formula for Drinfeld's generators easily follows. The above argument is formal, but the justification would be possible.

APPENDIX A: U' MODULE (ρ,V) AND w

1. N and $\eta=(\eta_1,\ldots,\eta_N)$

(1) $A_l^{(1)}$ $(l\geqslant 1)$: $N=l+1$, $\eta=\left(\epsilon_1,\cdots,\epsilon_l,-\sum_{i=1}^{l}\epsilon_i\right)$.

(2) $B_l^{(1)}$ $(l\geqslant 3)$, $A_{2l}^{(2)}$ $(l\geqslant 1)$: $N=2l+1$, $\eta=(\epsilon_1,\ldots,\epsilon_l,0,-\epsilon_l,\ldots,-\epsilon_1)$.

(3) $C_l^{(1)}$ $(l\geqslant 2)$, $A_{2l-1}^{(2)}$ $(l\geqslant 3)$, $D_l^{(1)}$ $(l\geqslant 4)$: $N=2l$, $\eta=(\epsilon_1,\ldots,\epsilon_l,-\epsilon_l,\ldots,-\epsilon_1)$.

(4) $D_{l+1}^{(2)}$ $(l\geqslant 2)$: $N=2l+2$, $\eta=(\epsilon_1,\ldots,\epsilon_l,0,-\epsilon_l,\ldots,-\epsilon_1,0)$.

Here $\epsilon_i=p\omega_1-(\alpha_1+\cdots\alpha_{i-1})$ $(1\leqslant i\leqslant l)$. (Note that in the case $g=D_l^{(1)}$, v_l and v_{l+1} can be interchanged.)

2. (ρ,V)

We give the matrix representations of e_i and f_i $(0\leqslant i\leqslant l)$ with repect to the basis $v_1,\ldots,v_N$. Below E_{ij} is a matrix unit and ${}^tf_i$ denotes the transpose of f_i. $x_i^{B_l}$ and $x_i^{C_l}$ $(x=e,f,\ 1\leqslant i\leqslant l)$ stand for the expressions x_i given for $B_l^{(1)}$ and $C_l^{(1)}$, respectively.

(1) $A_l^{(1)}$: $e_i=E_{i\,i+1}={}^tf_i$ $(1\leqslant i\leqslant l)$, $e_0=E_{N1}={}^tf_0$. (A1)

(2) $B_l^{(1)}, C_l^{(1)}, D_l^{(1)}$:

(i) $1\leqslant i<l$: $e_i=e_i^{+}+e_i^{-}$, $f_i=f_i^{+}+f_i^{-}$,

$$e_i^{+}=E_{i\,i+1}={}^tf_i^{+},\quad e_i^{-}=-E_{N-i\ N+1-i}={}^tf_i^{-}. \tag{A2}$$

(ii) $i=l,0$:

$B_l^{(1)}$: $e_l=e_l^{+}+e_l^{-}$, $f_l=f_l^{+}+f_l^{-}$, $e_0=E_{N-1\,1}-E_{N\,2}={}^tf_0$,

$$x^{-1}e_l^{+}=E_{l\,l+1}=y^{-1}{}^tf_l^{+},\quad x^{-1}e_l^{-}=-E_{l+1\,l+2}=y^{-1}{}^tf_l^{-},$$

$$x,y\in A,\ \text{such that } xy=[2]_l. \tag{A3}$$

$$C_l^{(1)}:\ e_l=E_{l\,l+1}={}^tf_l,\ e_0=E_{N1}={}^tf_0. \tag{A4}$$

$$D_l^{(1)}:\ e_l=E_{l-1\,l+1}-E_{l\,l+2}={}^tf_l,\ e_0=E_{N-1\,1}-E_{N2}={}^tf_0. \tag{A5}$$

(3) $A_{2l}^{(2)}$: $x_i=Mx_i^{B_l}M^{-1}$ $(x=e,f,\ 1\leqslant i\leqslant l)$, $e_0=E_{N1}={}^tf_0$,

$$M=\mathrm{diag}(\overbrace{1\cdots 1}^{l+1},-1,1,\ldots,(-1)^l). \tag{A6}$$

(4) $A_{2l-1}^{(2)}$: $x_i = M x_i^{C_l} M^{-1}$ $(x=e,f,\ 1\leqslant i\leqslant l)$, $e_0 = E_{N-1\,1} + E_{N2} = {}^t f_0$,

$$M = \mathrm{diag}(\overbrace{1\cdots 1}^{l+1}, -1, 1, \ldots, (-1)^{l-1}). \tag{A7}$$

(5) $D_{l+1}^{(2)}$: $x_i = x_i^{B_l}$ $(x=e,f,\ 1\leqslant i\leqslant l)$, $x^{-1}e_0 = E_{N1} + E_{N-1\,N} = y^{-1}{}^t f_0$,

$$x,y\in A, \text{ such that } xy=[2]_0. \tag{A8}$$

3. w

(1) $g = A_l^{(1)}$: $w = \sum_{\gamma\in\mathcal{J}_{l+1}} (-q)^{l(\gamma)} v_{\gamma(1)}\otimes\cdots\otimes v_{\gamma(l+1)}$ ($l(\gamma)$: length function).

(2) $g\neq A_l^{(1)}$: $w = \sum_{1\leqslant i,j\leqslant N} J_{ij} v_i\otimes v_j$,

$$J_{ij} = u_i\delta_{i+j,N+1} \text{ for } g\neq D_{l+1}^{(2)}, \quad = u_i\delta_{i+j,N} + u_N\delta_{iN}\delta_{jN} \text{ for } g = D_{l+1}^{(2)}.$$

List of $(u_1,\ldots,u_N)$

(i) $B_l^{(1)}$: $(q^{-(2l-1)},\ldots,q^{-3},q^{-1},q,q,q^3,\ldots,q^{2l-1})$

(ii) $C_l^{(1)}$: $(-q^{-l},\ldots,-q^{-2},-q^{-1},q,q^2,\ldots,q^l)$

(iii) $D_l^{(1)}$: $(q^{-(l-1)},\cdots,q^{-1},1,1,q,\cdots,q^{l-1})$

(iv) $A_{2l}^{(2)}$: $((-1)^l q^{-(2l-1)},\ldots,q^{-3},-q^{-1},q,-q,q^3,\ldots,(-1)^l q^{2l-1})$

(v) $A_{2l-1}^{(2)}$: $((-1)^l q^{-l},\ldots,q^{-2},-q^{-1},q,-q^2,\ldots,(-1)^{l-1} q^l)$

(vi) $D_{l+1}^{(2)}$: $(q^{-(2l-1)},\ldots,q^{-3},q^{-1},q,q,q^3,\ldots,q^{2l-1},-q)$.

Transformations of strongly causal space–times preserving null geodesics

Wen-ling Huang
Universität Hamburg, Bundesstrasse 55, 20146 Hamburg, Germany

(Received 11 September 1997; accepted for publication 11 November 1997)

Let $(\mathscr{M},g)$ be a strongly causal space–time, $\dim\mathscr{M}\geqslant 3$. Let $f:\mathscr{M}\to\mathscr{M}$ be a bijection such that images and pre-images of null geodesics (as point sets) are null geodesics. Then f is a conformal transformation. © *1998 American Institute of Physics.* [S0022-2488(98)02603-6]

I. INTRODUCTION

A conformal diffeomorphism of an n-dimensional, strongly causal space–time $(\mathscr{M},g)$, $n\geqslant 3$, *can be characterized as a homeomorphism of* $(\mathscr{M},g)$ *which takes null geodesic curves (as point sets) to null geodesic curves.*

This theorem has been shown by Hawking.[1] Peleska has generalized this result of Hawking to arbitrary Pseudo-Riemannian manifolds.[2] According to a theorem of Alexandrov,[3,4] the hypothesis of homeomorphy can be omitted in Minkowski space.

Any bijective transformation f of at least three-dimensional Minkowski space M which preserves the Minkowski distance 0 *in both directions is a conformal mapping of Minkowski space.*

It is a natural question whether the homeomorphy condition in Hawking's theorem is necessary or not. Lester has examined Alexandrov-type transformations for Robertson–Walker space–times,[5] for Einstein's cylinder universe,[6] and for de Sitter space–time.[7] In Schwarzschild space–time the following result is known.[8]

Let $n\geqslant 3$. *Let f be a bijective mapping from n-dimensional Schwarzschild space–time to itself such that f and* f^{-1} *preserve inextendible null geodesic curves (as point sets). Then f is an isometry.*

We show that the homeomorphy condition in Hawking's theorem can be omitted if we demand that also the inverse mapping takes null geodesic curves (as point sets) to null geodesic curves.

Theorem: *Let* $(\mathscr{M},g)$ *be a strongly causal space–time,* $\dim\mathscr{M}\geqslant 3$. *Let* $f:\mathscr{M}\to\mathscr{M}$ *be a bijection which satisfies the following condition.*

For any null geodesic curve $\gamma:\mathscr{E}\to\mathscr{M}$ *there are null geodesic curves* $\gamma_1:\mathscr{E}_1\to\mathscr{M}$ *and* $\gamma_2:\mathscr{E}_2\to\mathscr{M}$ *such that*

$$f(\gamma(\mathscr{E}))=\gamma_1(\mathscr{E}_1) \quad \text{and} \quad f^{-1}(\gamma(\mathscr{E}))=\gamma_2(\mathscr{E}_2).$$

Then f is a homeomorphism and, by Hawking's theorem, a conformal transformation.

The physical meaning of the condition used in this theorem to characterize conformal transformations is clear: *Images and pre-images of paths which photons travel between emission and absorption should again be such paths.*

II. PRELIMINARIES

Let $n\in\mathbb{N}$, $n\geqslant 2$. A *space–time* $(\mathscr{M},g)$ is an n-dimensional, time oriented, connected C^∞-Hausdorff manifold with a Lorentz metric g (i.e., the signature of g is $n-2$) together with the Levi-Civita connection of g on $\mathscr{M}$.

In a space–time $(\mathscr{M},g)$ a non-zero tangent vector X at $x\in\mathscr{M}$ is called *timelike*, *null*, or *spacelike* if $g_x(X,X)$ is negative, zero, or positive, respectively. A future directed timelike (non-spacelike) curve is a C^1-curve $\gamma:\mathscr{E}\to\mathscr{M}$ whose tangent vectors are all timelike (non-spacelike) and future directed. Here and henceforth $\mathscr{E}$ is an open, not necessarily bounded interval of $\mathbb{R}$.

 © 1998 American Institute of Physics

Let $U\subseteq\mathscr{M}$ and $x\in\mathscr{M}$. A point $y\in\mathscr{M}$ is said to be in the *chronological future* $I_U^+(x)$ of x relative to U, $x\ll_U y$, if there is a future directed timelike curve section $\gamma:[0,1]\to U$ connecting $x=\gamma(0)$ and $y=\gamma(1)$. If $x\ll_U y$, then x is in the *chronological past* $I_U^-(y)$ of y relative to U. The point y is said to be in the *causal future* $J_U^+(x)$ of x relative to U, and x is in the *causal past* $J_U^-(y)$ of y relative to U, $x\leqslant_U y$, if there is a future directed non-spacelike curve section $\gamma:[0,1]\to U$ connecting $x=\gamma(0)$ and $y=\gamma(1)$. In this paper we write $x\to_U y$ if there is a future directed **null geodesic** in U from $x\in U$ to $y\in U$. (This definition is different from that used in Ref. 9, p. 182.) Let $C_U^+(x):=\{y\in\mathscr{M}|x\to_U y\}$ and $C_U^-(x):=\{y\in\mathscr{M}|y\to_U x\}$. If $U=\mathscr{M}$ we simply write $I^+(x)$, $x\ll y$, etc. A space–time is called *strongly causal*, if the set of all $I^+(x)\cap I^-(y)$, $x,y\in\mathscr{M}$, is a basis of the ordinary topology of $(\mathscr{M},g)$. In a strongly causal space–time $(\mathscr{M},g)$, each point $x\in\mathscr{M}$ possesses a convex normal neighborhood U such that no non-spacelike curve intersects U more than once.

For $x\in\mathscr{M}$, $X\in T_x(M)$ there is a unique inextendible geodesic γ_X with $\gamma_X(0)=x$, $\dot{\gamma}_X(0)=X$. If $\gamma_X(1)$ exists, we write $\exp_x X:=\gamma_X(1)$ (Ref. 9, p. 33). An open neighborhood $N_x\subset T_xM$ of the origin in the tangent space T_xM of $x\in\mathscr{M}$ is said to be *normal* if $\exp_x|_{N_x}$ is defined and is a diffeomorphism onto its image. We call the image $U_x:=\exp_x(N_x)$ a normal neighborhood of x. If a normal neighborhood U_x is a normal neighborhood for any point $y\in U_x$, then we call it a *convex normal* neighborhood. Hence, in a convex normal neighborhood U, any two points $x,y\in U$ can be joined by a unique inextendible geodesic $\gamma:\mathscr{E}\to U$, $\gamma(0)=x$, $\gamma(1)=y$, (Ref. 10, p. 149). In a convex normal neighborhood U we define the *energy function* $\Phi:U\times U\to\mathbb{R}$,

$$\Phi(x,y):=g_x(\exp_x^{-1}y,\exp_x^{-1}y).$$

$\Phi(x,y)$ is negative, zero, or positive if the unique geodesic γ connecting x and y is timelike, lightlike, or spacelike, respectively.

Proposition 1: Let $(\mathscr{M},g)$ be a space–time. Let $U\subseteq\mathscr{M}$ be open and $x,y,z\in U$. Then either $x\ll_U y\leqslant_U z$ or $x\leqslant_U y\ll_U z$ imply $x\ll_U z$ (cf. Ref. 9, p. 183).

Proposition 2: Let $U\subseteq\mathscr{M}$ be a convex normal neighborhood of $x\in\mathscr{M}$. Let $\gamma:(a,c)\to U$ be a future directed null geodesic such that $x\notin\gamma((a,c))$. There is at most one point $y=\gamma(b)$, $b\in(a,c)$ with $\Phi(x,y)=0$, i.e., there is at most one null geodesic in U which contains x and intersects $\gamma((a,c))$. If y exists, then the set of points in $\gamma((a,c))$ which are chronologically related to x is $\gamma((a,b))$ if $y\to_U x$, and $\gamma((b,c))$ if $x\to_U y$.

Proof: Define $\Phi_x:U\to\mathbb{R}$, $\Phi_x(z):=\Phi(x,z)$ for all $z\in U$. $\Phi_x\circ\gamma:(a,c)\to\mathbb{R}$ is a C^∞-function, and $(\Phi_x\circ\gamma)'(t)=2\,g_{\gamma(t)}(\dot{\gamma}(t),\dot{\alpha}(1))$ where $\alpha:[0,1]\to U$ denotes the geodesic section from $x=\alpha(0)$ to $\gamma(t)=\alpha(1)$ (Ref. 11, p. 127). If there is a $b\in(a,c)$ with $\Phi_x\circ\gamma(b)=0$, then

$$(\Phi_x\circ\gamma)'(b)=2\,g_{\gamma(b)}(\dot{\gamma}(b),\dot{\alpha}(1))\begin{cases}<0, & \text{if } \alpha \text{ is future directed,}\\ >0, & \text{if } \alpha \text{ is past directed.}\end{cases}$$

Since there are no null geodesic triangles in a convex normal neighborhood, $\Phi_x\circ\gamma$ is 0 only at b. In the case $(\Phi_x\circ\gamma)'(b)<0$, i.e., $x\to_U y$, we have $\Phi_x\circ\gamma(t)<0$ for all $t\in(b,c)$, and $\Phi_x\circ\gamma(t)>0$ for all $t\in(a,b)$. In the case $(\Phi_x\circ\gamma)'(b)>0$, i.e., $y\to_U x$, we have $\Phi_x\circ\gamma(t)<0$ for all $t\in(a,b)$, and $\Phi_x\circ\gamma(t)>0$ for all $t\in(b,c)$. □

Proposition 3: Let $U\subseteq\mathscr{M}$ be a convex normal neighborhood.Let $x,y\in U$ be two points with $x\to_U y$. Let α,β be two future directed inextendible null geodesics in U with $x=\alpha(0)$ and $y=\beta(0)$ such that y, resp., x is not contained in the image of α resp. β. Then there are two points $\alpha(t_1)$, $\beta(t_2)$ in U, $0<t_1,t_2$, so that $\alpha(t_1)\to_U\beta(t_2)$ and the map $\lambda:(0,t_1)\to(0,t_2)$ defined by $\alpha(t)\to_U\beta(\lambda(t))$ is a bijection (figure 1).

Proof: It follows from Proposition 2 that $\Phi(y,\alpha(t))>0$ and $\Phi(x,\beta(t))<0$ for all $t>0$. Choose arbitrary $t_\alpha,t_\beta>0$ in the domains of α and β. If $\Phi(\alpha(t_\alpha),\beta(t_\beta))=0$ let $t_1:=t_\alpha$ and $t_2:=t_\beta$; then $\alpha(t_1)\to_U\beta(t_\beta)$.

If $\Phi(\alpha(t_\alpha),\beta(t_\beta))>0$ then there is some $t_1\in(0,t_\alpha)$ satisfying $\Phi(\alpha(t_1),\beta(t_\beta))=0$. Since $x\to_U y$ and since α,β are both future directed, we have $\alpha(t_1)\to_U\beta(t_2)$ for $t_2:=t_\beta$. If

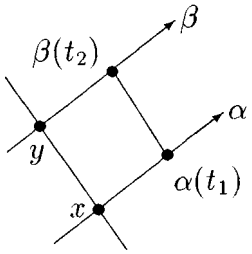

FIG. 1. Proposition 3.

$\Phi(\alpha(t_\alpha),\beta(t_\beta))<0$ then there is some $t_2\in(0,t_\beta)$ satisfying $\Phi(\alpha(t_\alpha),\beta(t_2))=0$, and we obtain $\alpha(t_1)\rightarrow_U\beta(t_2)$ for $t_1:=t_\alpha$. Therefore, we have shown the existence of $t_1,t_2>0$ with $\alpha(t_1)\rightarrow_U\beta(t_2)$.

Let $t\in(0,t_1)$. Since $x\rightarrow_U y$ and $x\rightarrow_U\alpha(t)$, we obtain from Proposition 2 that $\Phi(\alpha(t),\beta(t_2))<0$ and $\Phi(\alpha(t),y=\beta(0))>0$. $\Phi(\alpha(t),\beta(\cdot))$ is continuous, hence there is a $\bar{t}\in(0,t_2)$ with $\Phi(\alpha(t),\beta(\bar{t}))=0$. From Proposition 2, $\bar{t}$ is uniquely determined. Similarly, for $\bar{t}\in(0,t_2)$, we obtain $\Phi(\alpha(t_1),\beta(\bar{t}))>0$ and $\Phi(\alpha(0),\beta(\bar{t}))<0$, and there is a $t\in(0,t_1)$ which satisfies $\Phi(\alpha(t),\beta(\bar{t}))=0$. Hence the mapping $\lambda:(0,t_1)\rightarrow(0,t_2)$ is a bijection. □

Corollary 1: Let $x,z\in U$ be two points in a convex normal neighborhood U with $x\ll_U z$. If there exists some $y\in U$ satisfying $\Phi(x,y)=\Phi(y,z)=0$, then, from Proposition 2, we have $x\rightarrow_U y\rightarrow_U z$.

Proposition 4: Let $(\mathscr{M},g)$ be strongly causal. Let $\gamma:\mathscr{E}\rightarrow\mathscr{M}$ be an inextendible null geodesic, and let $\alpha:\mathscr{E}'\rightarrow\mathscr{M}$ be a null geodesic such that $\alpha(\mathscr{E}')\subset\gamma(\mathscr{E})$. Then there exists an interval $\mathscr{E}_1\subset\mathscr{E}$ with $\gamma(\mathscr{E}_1)=\alpha(\mathscr{E}')$.

Proof: Choose an arbitrary point $x\in\alpha(\mathscr{E}')$. Let U be a sufficiently small normal neighborhood of x such that α and γ intersect U only once, i.e., there are intervals $I\subset\mathscr{E}'$ and $J\subset\mathscr{E}$ with $\alpha(I)=\alpha(\mathscr{E}')\cap U$, $\gamma(J)=\gamma(\mathscr{E})\cap U$, and such that $\alpha(I)=\gamma(J)$. Since U is normal, $\alpha|_J$ and $\gamma|_J$ are the same null geodesics up to an affine reparametrization. Let t,s be affine parameters for α and γ, respectively. Then there are $k_1\neq0$, $k_2\in\mathbb{R}$ so that $k_1t+k_2=s$ and $\alpha(t)=\gamma(k_1t+k_2)$ for all $t\in\mathscr{E}'$. Hence $\alpha(\mathscr{E}')=\gamma(\mathscr{E}_1)$ for $\mathscr{E}_1:=\{k_1t+k_2\mid t\in\mathscr{E}'\}$. □

III. PROOF OF THE THEOREM

(3.1) Let $\alpha:\mathscr{E}_1\rightarrow\mathscr{M}$, $\beta:\mathscr{E}_2\rightarrow\mathscr{M}$ be two inextendible null geodesics with affine parameters t,s, respectively, and satisfying $f\circ\alpha(\mathscr{E}_1)=\beta(\mathscr{E}_2)$. Then the mapping $\mathscr{E}_1\rightarrow\mathscr{E}_2$, $t_0\mapsto s_0$ defined by $f\circ\alpha(t_0)=\beta(s_0)$ is monotone.

Proof: Since $(\mathscr{M},g)$ is strongly causal, α and β are one to one. For $t_1<t_2<t_3$, $t_i\in\mathscr{E}_1$, let $s_i\in\mathscr{E}_2$ satisfy $\beta(s_i)=f\circ\alpha(t_i)$, $i=1,2,3$. Let $I\subset\mathscr{E}_1$ be an open interval containing t_1 and t_2 but not t_3. Since $f\circ\alpha|_I$ is a null geodesic, from Proposition 4 there is an interval $J\subset\mathscr{E}_2$ such that $f\circ\alpha(I)=\beta(J)$. Since β is one to one, we have $s_1,s_2\in J$, $s_3\notin J$. Hence $s_1<s_2<s_3$ or $s_3<s_2<s_1$.

From (3.1) follows immediately (3.2).

(3.2) Let $\alpha:\mathscr{E}_1\rightarrow\mathscr{M}$, $\beta:\mathscr{E}_2\rightarrow\mathscr{M}$ be two future directed inextendible null geodesics with $f\circ\alpha(\mathscr{E}_1)=\beta(\mathscr{E}_2)$. Let $x,y\in\alpha(\mathscr{E}_1)$ be two points, $x\rightarrow y$. Let $z\in\alpha(\mathscr{E}_1)$, $x\rightarrow z$. If $f(x)\rightarrow f(y)$, then $f(x)\rightarrow f(z)$; and $f(z)\rightarrow f(x)$ otherwise.

(3.3) Let $x\in\mathscr{M}$ be a point. Let U, resp. V, be convex normal neighborhoods of x, resp., $f(x)$ such that no non-spacelike curve intersects U, resp. V, more than once. Let $X\in T_x(\mathscr{M})$ be a null vector with $y:=\exp_x X\in U$. If $\exp_{f(x)}Y:=f(y)\in V$, $Y\in T_{f(x)}(\mathscr{M})$, then Y is a null vector and

$$\{f\circ\exp_x(tX)\mid t\in[0,1]\}=\{\exp_{f(x)}(tY)\mid t\in[0,1]\}. \tag{1}$$

Proof: Since f takes null geodesics to null geodesics, there is a null geodesic $\gamma:\mathscr{E}\rightarrow\mathscr{M}$ connecting $f(x)$ and $f(y)$. Let I be an interval with $\gamma(I)=\gamma(\mathscr{E})\cap V$. Since V is convex normal

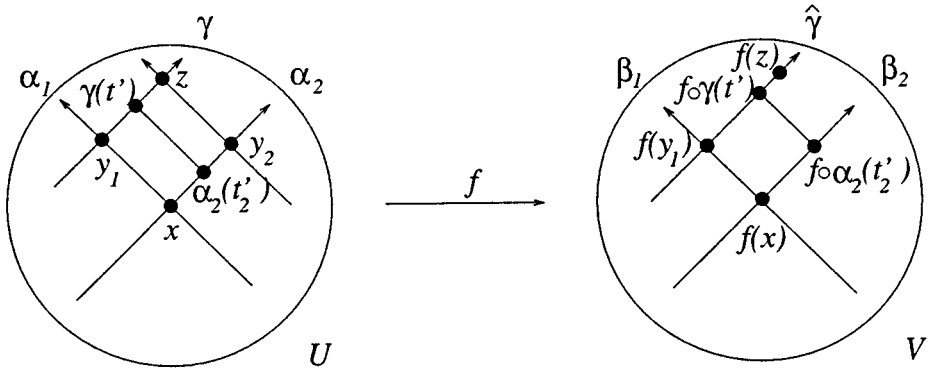

FIG. 2. Proof of (3.4).

we can choose an interval J such that $\gamma|_I: I \to V$ and $\exp_{f(x)}(tY): J \to V$ are the same geodesics, up to a reparametrization. Therefore Y is a null vector. From (3.1) we obtain (1).

(3.4) Let $x \in \mathscr{M}$. Then $\{f(C^+(x)), f(C^-(x))\} = \{C^+(f(x)), C^-(f(x))\}$.

Proof: Choose a convex normal neighborhood U of x such that no non-spacelike curve intersects U more than once.

We take two future directed null geodesics α_1, α_2 with $x = \alpha_1(0) = \alpha_2(0)$ so that $f \circ \alpha_1(t)$, $f \circ \alpha_2(t)$ are both contained in $C^+(f(x))$ or in $C^-(f(x))$ for $t > 0$. Without loss of generality we may assume that $f \circ \alpha_i(t) \in C^+(f(x))$, $i = 1,2$. Let V be a convex normal neighborhood of $f(x)$ such that no non-spacelike curve intersects V more than once. There are intervals I_i with $0 \in I_i$ and $\alpha_i(I_i) \subset U$, $f \circ \alpha_i(I_i) \subset V$, $i = 1,2$. Let $\beta_i: J_i \to V$ be future directed null geodesics with $\beta_i(J_i) \subset V$ and $f \circ \alpha_i(I_i) = \beta_i(J_i)$, $i = 1,2$. Let $0 < t_1 \in I_1$ and $y_1 := \alpha_1(t_1)$. Let γ be a future directed null geodesic from $y_1 = \gamma(0)$ such that $\dot{\gamma}(0)$, $\dot{\alpha}_1(t_1)$ are linearly independent. Then there is an interval I with $\gamma(I) \subset U$ and $f \circ \gamma(I) \subset V$. Let $\hat{\gamma}: J \to U$ denote a future directed null geodesic with $\hat{\gamma}(J) = f \circ \gamma(I)$ and $\hat{\gamma}(0) = y_1$. According to Proposition 3, there are $0 < t_0 \in I$ and $0 < t_2 \in I_2$ such that $z := \gamma(t_0)$ and $y_2 := \alpha_2(t_2)$ are connected by a null geodesic in U. For $0 < t' < t_0$ there is a $0 < t_2' < t_2$ such that $\gamma(t')$, $\alpha_2(t_2')$ are connected by a null geodesic in U. Then $f \circ \gamma(t') =: \hat{\gamma}(s_1)$ and $f \circ \alpha_2(t_2') =: \beta_2(t_2^*)$ are connected by a null geodesic in V (see figure 2).

We claim $f(z) \in C_V^+(f(y_1))$. If not, then $s_2 < s_1 < 0$, where s_2 is defined by $\hat{\gamma}(s_2) := f(z)$. This implies $\Phi(\beta_2(t_2^*), \hat{\gamma}(s_2)) > 0$, $\Phi(\beta_2(t_2^*), \hat{\gamma}(0)) > 0$ and thus $\Phi(\beta_2(t_2^*), \hat{\gamma}(s_1)) > 0$, a contradiction to $\Phi(f \circ \alpha_2(t_2'), f \circ \gamma(t')) = \Phi(\beta_2(t_2^*), \hat{\gamma}(s_1)) = 0$. So $f(z) \in C_V^+(f(y_1)) \subset J_V^+(f(x))$.

Let α_3 be a future directed null geodesic with $\alpha_3(0) = x$ and such that $\dot{\alpha}_3(0)$, $\dot{\alpha}_1(0)$ are linearly independent. Let I_3 be an interval with $x \in \alpha_3(I_3) \subset U$ and $f \circ \alpha_3(I_3) \subset V$. From Proposition 3, we can find $y_3 \in \alpha(I_3)$, $x \to y_3$, and $z^* \in \gamma(I)$, $y_1 \to z^*$, such that $y_3 \to z^*$. From $f(z^*) \in I_V^+(f(x))$ and Corollary 1 follows $f(y_3) \in C_V^+(f(x))$. We obtain from (3.2) that $f(C^+(x)) \subseteq C^+(f(x))$. Since f^{-1} has the same properties as f, we have $f(C^+(x)) = C^+(f(x))$. It is now obvious that $f(C^-(x)) = C^-(f(x))$.

(3.5) Let $x \in \mathscr{M}$ and $\{\epsilon, \epsilon'\} = \{-, +\}$ such that $f(C^+(x)) = C^\epsilon(f(x))$. Then $f(I^+(x)) = I^\epsilon(f(x))$ and $f(I^-(x)) = I^{\epsilon'}(f(x))$.

Proof: Assume $f(C^+(x)) = C^+(f(x))$. For $y \in I^+(x)$ there are $x_0, \ldots, x_k$, $k \geqslant 2$,

$$x = x_0 \to x_1 \to \cdots \to x_k = y,$$

and we can choose x_1, x_2 such that x_0, x_1, x_2 are not joined by a null geodesic. Then

$$f(x) = f(x_0) \to f(x_1) \to \cdots \to f(x_k) = f(y),$$

and $f(x_0), f(x_1), f(x_2)$ are not joined by a null geodesic. $f(x_0)$ and $f(x_2)$ can be joined by a timelike curve (cf. Ref. 9, p. 113). Hence $f(x_0) \ll f(x_2) \leqslant f(y)$. From Proposition 1 we have

$f(y)\in I^+(f(x))$ and thus $f(I^+(x))\subset I^+(f(x))$. Applying the same arguments to f^{-1}, we obtain $f(I^+(x))=I^+(f(x))$. The case $f(C^+(x))=C^-(f(x))$ is treated similarly.

(3.6) Let $x\in\mathscr{M}$ and $\{\epsilon,\epsilon'\}=\{-,+\}$ such that $f(I^+(x))=I^\epsilon(f(x))$. Then $f(I^-(y))=I^{\epsilon'}(f(y))$ for all $y\in J(x)$.

Proof: We have $J(x)=I(x)\cup C(x)\cup\{x\}$ (cf. Ref. 9, p. 184). (3.4) and (3.5) imply $f(J^+(x))=J^\epsilon(f(x))$ and $f(J^-(x))=J^{\epsilon'}(f(x))$. Since $x\in J(y)$, applying (3.4) and (3.5) again yields $f(I^-(y))=I^{\epsilon'}(f(y))$.

(3.7) f is a homeomorphism.

Proof: Let $x,y\in\mathscr{M}$. If $y\notin J(x)$, then $I^+(x)\cap I^-(y)=\varnothing$. If $y\in J(x)$, let $f(I^+(x))=I^\epsilon(f(x))$, $\{\epsilon,\epsilon'\}=\{-,+\}$. Then $f(I^-(y))=I^{\epsilon'}(f(y))$, and $f(I^+(x)\cap f(I^-(y))=I^\epsilon(f(x))\cap I^{\epsilon'}(f(y))$. Thus the basis $\{I^+(x)\cap I^-(y)\mid x,y\in\mathscr{M}\}$ of the topology of $\mathscr{M}$ is preserved under f and f^{-1}. □

The spherical curl transform of a linear force-free magnetic field

Malcolm A. MacLeod
Air Force Research Laboratory, Hanscom Air Force Base, Massachusetts 01731-3010

(Received 18 October 1996; accepted for publication 28 October 1997)

The description of linear force-free magnetic fields in terms of the Moses eigenfunctions of the curl operator begun previously is here completed by the derivation of a general expression for the field's spherical curl transform. This enables the transform space representation of a given field to be determined and compared with that of other fields, assisting the analysis and classification of this type of magnetic field as well as providing a basis for generalization. The result obtained gives the spherical curl transform as a weighted projection of the vector Radon transform of the field on the appropriate curl eigenvector. The process is exemplified by the determination of the transforms of three fields: the simplest force-free magnetic field, and the Lundquist and classical spheromak fields. The latter two are both of interest as models of the magnetic fields of solar magnetic clouds, while the classical spheromak field is relevant to the design of nuclear fusion reactors as well. The use of the transform in generalizing the Lundquist field is briefly discussed. As before, all results apply equally well to the description of the Trkalian subset of Beltrami fields in fluid dynamics. © *1998 American Institute of Physics.* [S0022-2488(98)01103-7]

I. INTRODUCTION

Recent work has led to a new mathematical description of linear force-free magnetic fields (FFMFs), one that provides a unifying scheme for exploring this distinct class of fields as well as providing fresh insight into the solution of practical problems. Both of these characteristics will be illustrated below, but the primary goal of the present work is to present an improved method for determining the spherical curl transform of a given force-free magnetic field.

The essence of the new description is that a general linear FFMF is defined entirely in terms of a scalar function on the unit sphere in transform space, reducing a three-dimensional vector problem in physical space effectively to a two-dimensional scalar problem in transform space [MacLeod,[1] referred to as (I) below]. Of course, to obtain the physical field requires performing a specific vector transform whose mathematical evaluation is typically nontrivial, but the *spherical curl transform* (SCT) defined on the sphere in transform space holds the key to the general linear FFMF. In (I) the transform was considered to be given and a discussion of the various types of resulting fields was sketched. In a subsequent work [MacLeod,[2] referred to as (II) below] the inverse case was considered, resulting in a workman-like, but not entirely satisfactory, determination of the SCT from a given field. The formula presented here for the spherical curl transform completes the new description of these fields by providing a satisfactory general inverse.

The basic idea is to expand the general linear FFMF in terms of the eigenfunctions of the curl operator introduced by Moses,[3] leading to the discovery that such a field requires only one curl eigenfunction whose helicity sense matches the sign of the parameter α appearing in the defining system of the FFMF. The curl eigenfunction expansion of a general vector field is outlined in Sec. II and the required direct and inverse transforms are introduced in order to define and clarify terms. This expansion is specialized to describe linear FFMFs in Sec. III, and the spherical curl transform introduced and defined. The general expression for the SCT is derived in Sec. IV in terms of a weighted projection of the vector Radon transform of the field on the appropriate curl eigenvector, and two alternative expressions for the inverse SCT are shown to be equivalent and to produce the original field. To illustrate the process and its results, the derivation of specific SCTs is carried out in Sec. V for three FFMFs: the simplest FFMF, the Lundquist field, and the

 © 1998 American Institute of Physics

classical spheromak field. While the first of these computations is intended merely to exemplify the process without obscuring it with mathematical details, the latter two computations treat fields of current practical interest. Both the Lundquist field (Burlaga[4]) and the classical spheromak (Ivanov and Harshiladze[5]) have been proposed as models of the magnetic fields of solar magnetic clouds (SMCs), while the latter is still of some interest in the magnetic fusion community (Wright[6]). Moreover, the development of the Lundquist field SCT led directly to a generalization that is being investigated as a more flexible fit to the fields of SMCs (MacLeod[7]). In the final section the main points are recapitulated and several potentially fruitful directions for further work outlined.

II. REPRESENTING A GENERAL VECTOR FIELD BY CURL EIGENFUNCTION EXPANSION

Moses[3] showed that a general (three-dimensional) vector field $\mathbf{F}(\mathbf{x})$ could be represented as an expansion in terms of the three eigenfunctions of the curl operator,

$$\boldsymbol{\chi}_\lambda(\mathbf{x}|\mathbf{k}) \equiv (2\pi)^{-3/2} e^{i\mathbf{k}\cdot\mathbf{x}} \mathbf{Q}_\lambda(\mathbf{k}), \tag{2.1}$$

where the curl eigenvectors $\mathbf{Q}_\lambda(\mathbf{k})$ are given explicitly in Appendix A and the index λ takes on the values $(0,\pm 1)$ reflecting the sense of the helicity of the corresponding eigenfunction. Such an expansion has the form

$$\mathbf{F}(\mathbf{x}) = \sum_\lambda \int d^3k \; \boldsymbol{\chi}_\lambda(\mathbf{x}|\mathbf{k}) f_\lambda(\mathbf{k}), \tag{2.2}$$

which is fundamentally a type of Fourier transform. The vector transform of the original function may be obtained explicitly by multiplying (2.2) by an appropriate exponential and integrating over space:

$$f(\mathbf{k}') \equiv \sum_\lambda \mathbf{Q}_\lambda(\mathbf{k}') f_\lambda(\mathbf{k}') = (2\pi)^{-3/2} \int d^3x \; \mathbf{F}(\mathbf{x}) e^{-i\mathbf{k}'\cdot\mathbf{x}}. \tag{2.3}$$

We consider the spatial field $\mathbf{F}(\mathbf{x})$ to be primary here, so that (2.3) represents the *direct* transform of the field, while (2.2) is the *inverse* transform of the field. So far this is standard Fourier fare. If we now take the scalar product of (2.3) with the conjugate curl eigenvector $\mathbf{Q}^*_\mu(\mathbf{k}')$ and use the orthogonality of the curl eigenvectors, we generate the components of the *curl transform* of $\mathbf{F}(\mathbf{x})$:

$$f_\mu(\mathbf{k}') = \mathbf{Q}^*_\mu(\mathbf{k}') \cdot \mathbf{f}(\mathbf{k}') = (2\pi)^{-3/2} \mathbf{Q}^*_\mu(\mathbf{k}') \cdot \int d^3x \; \mathbf{F}(\mathbf{x}) e^{-i\mathbf{k}'\cdot\mathbf{x}}, \tag{2.4}$$

which in the most general case has three nonzero components corresponding to a field possessing divergence and two nonaligned helicity components ($\mu = 0, +1, -1$). Thus, the μ component of the curl transform is the scalar product of the μ curl eigenvector with the Fourier transform of the field. Note that the curl transform is a *scalar* quantity derived from a *vector* field. The inverse curl transform is (2.2), with three vector components indexed by λ corresponding to the terms of the summation:

$$\mathbf{F}_\lambda(\mathbf{x}) = \int d^3k \; \boldsymbol{\chi}_\lambda(\mathbf{x}|\mathbf{k}) f_\lambda(\mathbf{k}). \tag{2.5}$$

The curl eigenfunction expansion of a linear force-free magnetic field is distinguished by its comparative simplicity: the appearance of only one component of the three required for the general vector field.

III. CURL EIGENFUNCTION EXPANSION OF A LINEAR FORCE-FREE MAGNETIC FIELD

A plasma magnetic field is defined to be force-free if its Lorentz force is zero, implying that the field is parallel to the plasma current density vector. Since the current density is proportional to the field vorticity in the absence of displacement current, the equations defining a FFMF become

$$\nabla \times \mathbf{B} = \alpha \mathbf{B}, \qquad \nabla \cdot \mathbf{B} = 0. \tag{3.1}$$

The proportionality factor α is constant for the linear FFMF case that we consider here (see Sturrock[8] for a discussion of linear versus nonlinear FFMFs). The first of Eqs. (3.1) shows the linear FFMF to be an eigenfunction of the curl operator, and it was shown in (I) that it is represented entirely by the integral over one rotational curl eigenfunction,

$$\mathbf{B}_\lambda(\mathbf{x}) = \int d^3k \ \boldsymbol{\chi}_\lambda(\mathbf{x}|\mathbf{k}) b_\lambda(\mathbf{k}), \tag{3.2}$$

for which the sign of λ matches that of α, and whose curl transform is restricted to the sphere $k = \lambda\alpha$ in transform space,

$$b_\lambda(\mathbf{k}) = \frac{\delta(k - \lambda\alpha)}{k^2} s_\lambda(\mathbf{k}), \tag{3.3}$$

leading to the final expression for a general linear FFMF:

$$\mathbf{B}_\lambda(\mathbf{x}) = (2\pi)^{-3/2} \int d\Omega \ e^{i\lambda\alpha\boldsymbol{\kappa}\cdot\mathbf{x}} \mathbf{Q}_\lambda(\boldsymbol{\kappa}) s_\lambda(\lambda\alpha\boldsymbol{\kappa}). \tag{3.4}$$

Here the integration is over the transform sphere, $\boldsymbol{\kappa} \equiv \mathbf{k}/k$ defines the unit position vector in transform space, and we have indicated the fact that the curl eigenvector does not depend on the magnitude of $\mathbf{k}$. We call the function s_λ the *spherical curl transform* to distinguish it from the full curl transform $b_\lambda(\mathbf{k})$. The relation (3.4), which defines the inverse curl transform of the field, allows one to calculate the field for given curl transforms, and an introductory exploration of this was carried out in (I). Since there is only one curl eigenfunction component of the linear FFMF, the curl transform of the field, i.e., the inverse of the relation (3.2), is unique and is given by the analog of Eq. (2.4):

$$b_\lambda(\mathbf{k}) = (2\pi)^{-3/2} \mathbf{Q}^*_\lambda(\boldsymbol{\kappa}) \cdot \int d^3x \ \mathbf{B}_\lambda(\mathbf{x}) e^{-i\mathbf{k}\cdot\mathbf{x}} = \int d^3x \ \boldsymbol{\chi}^*_\lambda(\mathbf{x}|\mathbf{k}) \cdot \mathbf{B}_\lambda(\mathbf{x}). \tag{3.5}$$

In words: the curl transform of a linear FFMF is given by the projection of the Fourier transform of the field on the corresponding curl eigenvector, or, in other words, by the integral of the projection of the field on the corresponding curl eigenfunction. This relation enables the transform space behavior of known FFMFs to be computed and compared. As such, it would seem to be potentially more useful from a theoretical, classificatory standpoint than as a practical aid, though we shall point out below a case that belies that conclusion. Note that (3.5), as the analog of the general vector relation (2.4), has only made use of the unique curl eigenfunction decomposition of the linear FFMF, without taking into account the restriction of the curl transform to the sphere in transform space, as given in (3.3). When this is done the determination of the curl transform can be taken one step farther, and this was done in (II). The principal result of that paper was an expression for the curl transform, which, while demonstrated to be workable, lacked clarity of interpretation and was clumsy of execution. Our aim in the present paper is two-fold: to remedy these two features and to exhibit the curl transforms of some nontrivial linear FFMFs.

IV. THE SPHERICAL CURL TRANSFORM OF A LINEAR FORCE-FREE MAGNETIC FIELD

In this section we derive a general expression for the SCT in a form that lends itself to facile interpretation and demonstrate that its inverse leads back to the original field. Additionally we show that the Radon transform formalism produces an alternative representation of this inverse, which in another form was the main result of (I).

A. The direct spherical curl transform

In order to derive an expression for the spherical curl transform of a linear FFMF that makes explicit the restriction of the curl transform to the sphere in transform space, substitute Eq. (3.3) into the formula (3.5), producing the relation (II.4.2),

$$\frac{\delta(k-\lambda\alpha)}{k^2}\, s_\lambda(\mathbf{k}) = (2\pi)^{-3/2}\mathbf{Q}^*_\lambda(\boldsymbol{\kappa})\cdot\int d^3x\ \mathbf{B}_\lambda(\mathbf{x})e^{-i\mathbf{k}\cdot\mathbf{x}} = \int d^3x\ \boldsymbol{\chi}^*_\lambda(\mathbf{x}|\mathbf{k})\cdot\mathbf{B}_\lambda(\mathbf{x}). \quad (4.1)$$

The presence of the delta function on the left-hand side implies that the right-hand side has a latent distributional character. This can be brought out more clearly by experimenting with different test function factors in the realizing integration that must be performed to utilize the delta function. While a complete functional analysis investigation of this relation properly involves a discussion of the function spaces to which it is applicable, we defer this to later investigation and proceed in a purely formal way.

The delta function was in origin a radial delta function; indeed, the fact that the product $\lambda\ \alpha$ must be positive is an essential feature of the curl eigenfunction description of FFMFs (I). Taking k^2 as a test function factor and integrating (4.1) over positive k leads down the path taken in (II):

$$\int_0^\infty k^2\ dk\ \frac{\delta(k-\lambda\alpha)}{k^2}\, s_\lambda(\mathbf{k}) = s_\lambda(\lambda\alpha\mathbf{k}) = (2\pi)^{-3/2}\mathbf{Q}^*_\lambda(\boldsymbol{\kappa})\cdot\int_0^\infty k^2\ dk\int d^3x\mathbf{B}_\lambda(\mathbf{x})e^{-i\mathbf{k}\cdot\mathbf{x}}, \quad (4.2)$$

culminating in the expressions (4.10) and (4.11) of that paper, which see for further details on this approach. The development detailed there lacked elegance, and the resulting expressions lacked the transparency of interpretation that we develop below for an alternative path.

Introducing the function e^{ikp} as a test function factor and integrating both sides of (4.1) over k (with a doubly infinite range) leads to the following expressions for the spherical curl transform:

$$\begin{aligned} s_\lambda(\lambda\alpha\boldsymbol{\kappa}) &= \frac{\alpha^2}{(2\pi)^{3/2}}\, e^{-i\lambda\alpha p}\mathbf{Q}^*_\lambda(\boldsymbol{\kappa})\cdot\int d^3x\ \mathbf{B}_\lambda(\mathbf{x})\int_{-\infty}^{+\infty} dk\ e^{ik(p-\boldsymbol{\kappa}\cdot\mathbf{x})} \\ &= \frac{\alpha^2}{(2\pi)^{1/2}}\, e^{-i\lambda\alpha p}\mathbf{Q}^*_\lambda(\boldsymbol{\kappa})\cdot\int d^3x\ \mathbf{B}_\lambda(\mathbf{x})\,\delta(p-\boldsymbol{\kappa}\cdot\mathbf{x}). \end{aligned} \quad (4.3)$$

These are easily recognized as the (weighted) projection of the vector Radon transform of the FFMF on the corresponding curl eigenvector,

$$s_\lambda(\lambda\alpha\boldsymbol{\kappa}) = \frac{\alpha^2}{(2\pi)^{1/2}}\, e^{-i\lambda\alpha p}\mathbf{Q}^*_\lambda(\boldsymbol{\kappa})\cdot\mathbf{B}^R_\lambda(\mathbf{p}), \quad (4.4)$$

where the vector Radon transform is defined in Appendix B:

$$\mathbf{B}^R_\lambda(\mathbf{p}) = \mathbf{B}^R_\lambda(p,\boldsymbol{\kappa}) = \int d^3x\ \mathbf{B}_\lambda(\mathbf{x})\,\delta(p-\boldsymbol{\kappa}\cdot\mathbf{x}). \quad (4.5)$$

For computational purposes the delta function is typically replaced by its integral exponential form, as in the first of equations (4.3). The final result giving the spherical curl transform of a general linear FFMF in explicit form may then be written as

$$s_\lambda(\lambda\alpha\boldsymbol{\kappa}) = \frac{\alpha^2}{(2\pi)^{3/2}}\, e^{-i\lambda\alpha p}\mathbf{Q}_\lambda^*(\boldsymbol{\kappa})\cdot\int_{-\infty}^{+\infty} dk\; e^{ikp}\int d^3x\; \mathbf{B}_\lambda(\mathbf{x})e^{-ik\boldsymbol{\kappa}\cdot\mathbf{x}}, \tag{4.6}$$

where the Radon transform is represented as the doubly infinite integral over the radial direction of the FFMF Fourier transform (Deans[9]).

We now calculate the inverse transform to verify the above result.

B. The inverse spherical curl transform

The intimate relation found above between the spherical curl transform and the Radon transform gives a new perspective to the specification of the FFMF field in terms of an integral transform as well as providing an alternative path for deriving the inverse spherical curl transform, i.e., determining the field in terms of its transform. The starting point for such an exercise could be either transform since they are interconvertible using the relation (4.4),

$$s_\lambda(\lambda\alpha\boldsymbol{\kappa}) = \frac{\alpha^2}{(2\pi)^{1/2}}\, e^{-i\lambda\alpha p}\mathbf{Q}_\lambda^*(\boldsymbol{\kappa})\cdot\mathbf{B}_\lambda^R(\mathbf{p}), \tag{4.4}$$

and (C2),

$$\mathbf{B}_\lambda^R(p,\boldsymbol{\kappa}) = \frac{(2\pi)^{1/2}}{\alpha^2}\,[e^{i\lambda\alpha p}\mathbf{Q}_\lambda(\boldsymbol{\kappa})s_\lambda(\lambda\alpha\boldsymbol{\kappa}) + e^{-i\lambda\alpha p}\mathbf{Q}_\lambda(-\boldsymbol{\kappa})s_\lambda(-\lambda\alpha\boldsymbol{\kappa})]. \tag{4.7}$$

In the first case we substitute the expression (4.4) in the integral relation (3.4), whereas in the second case we operate on (4.7) with the standard inverse Radon transform operator (Deans[9]),

$$\mathbf{B}(\mathbf{x}) = -\frac{1}{8\pi^2}\,\nabla_x^2\int_S d\Omega\; \mathbf{B}^R(\boldsymbol{\kappa}\cdot\mathbf{x},\boldsymbol{\kappa}). \tag{4.8}$$

The two results must be equivalent, and we show that by reducing the first case to (4.8), then showing that (4.8) reproduces the correct field. Note clearly that the point to carrying out the latter effort is not to verify the general formula for inverting the Radon transform, but to prove that our expression for the Radon transform of the linear FFMF (4.7) gives the correct field when inverted.

Begin by substituting the spherical curl transform expression (4.4) into Eq. (3.4), which inverts the transform to produce the general linear FFMF:

$$\mathbf{B}_\lambda(\mathbf{x}) = \frac{\alpha^2}{4\pi^2}\int d\Omega\; e^{-i\lambda\alpha(p-\boldsymbol{\kappa}\cdot\mathbf{x})}\mathbf{Q}_\lambda(\boldsymbol{\kappa})\mathbf{Q}_\lambda^*(\boldsymbol{\kappa})\cdot\mathbf{B}_\lambda^R(\mathbf{p}). \tag{4.9}$$

The completeness relation for the curl eigenvectors, (A2b), allows the vector expression occurring here to be written as the dyadic projection,

$$\mathbf{Q}_\lambda\mathbf{Q}_\lambda^*\cdot\mathbf{B}_\lambda^R = \mathfrak{I}\cdot\mathbf{B}_\lambda^R - (\mathbf{Q}_{-\lambda}\mathbf{Q}_{-\lambda}^* + \mathbf{Q}_0\mathbf{Q}_0^*)\cdot\mathbf{B}_\lambda^R, \tag{4.10}$$

where $\mathfrak{I}$ is the unit dyadic. The projections of the $\mathbf{Q}_\lambda$ dyads on the Radon transform can only reproduce the corresponding pieces of (4.7); [$\mathbf{Q}_\lambda(-\boldsymbol{\kappa})$ can be written in terms of $\mathbf{Q}_{-\lambda}(\boldsymbol{\kappa})$ using (A5) and (A3c)], so that (4.10) reduces to

$$\mathbf{Q}_\lambda\mathbf{Q}_\lambda^*\cdot\mathbf{B}_\lambda^R = \mathfrak{I}\cdot\mathbf{B}_\lambda^R - \mathbf{Q}_{-\lambda}\mathbf{Q}_{-\lambda}^*\cdot\mathbf{B}_\lambda^R. \tag{4.11}$$

It is shown in Appendix D that the integrals over the sphere of the two $\mathbf{Q}$ dyadic projections on the Radon transform are equal, so that

$$\int d\Omega\; e^{-i\lambda\alpha(p-\boldsymbol{\kappa}\cdot\mathbf{x})}\mathbf{Q}_\lambda(\boldsymbol{\kappa})\mathbf{Q}_\lambda^*(\boldsymbol{\kappa})\cdot\mathbf{B}_\lambda^R(\mathbf{p}) = \frac{1}{2}\int d\Omega rs\; e^{-i\lambda\alpha(p-\boldsymbol{\kappa}\cdot\mathbf{x})}\mathfrak{I}\cdot\mathbf{B}_\lambda^R(\mathbf{p}), \tag{4.12}$$

and (4.9) becomes

$$\mathbf{B}_\lambda(\mathbf{x}) = \frac{\alpha^2}{8\pi^2} \int d\Omega\ e^{-i\lambda\alpha(p-\boldsymbol{\kappa}\cdot\mathbf{x})} \mathbf{B}^R_\lambda(\mathbf{p}). \tag{4.13}$$

By introducing the Laplacian and specializing the magnitude of $\mathbf{p}$ to $\boldsymbol{\kappa}\cdot\mathbf{x}$, we regain the standard expression for the inverse Radon transform (4.8). Thus, we have shown that the inverse spherical curl transform (3.4) reduces to the inverse Radon transform (4.8).

The demonstration that the curl eigenfunction expansion of the FFMF Radon transform (4.7) satisfies (4.8) to reproduce the field now follows easily. Substitute (4.7) into (4.8) to find

$$\begin{aligned}\mathbf{B}_\lambda(\mathbf{x}) &= -\frac{1}{2(2\pi)^{3/2}\alpha^2} \nabla_x^2 \int d\Omega[e^{i\lambda\alpha\boldsymbol{\kappa}\cdot\mathbf{x}} \mathbf{Q}_\lambda(\boldsymbol{\kappa}) s_\lambda(\lambda\alpha\boldsymbol{\kappa}) + e^{-i\lambda\alpha\boldsymbol{\kappa}\cdot\mathbf{x}} \mathbf{Q}_\lambda(-\boldsymbol{\kappa}) s_\lambda(-\lambda\alpha\boldsymbol{\kappa})] \\ &= \frac{1}{2(2\pi)^{3/2}} \int d\Omega[e^{i\lambda\alpha\boldsymbol{\kappa}\cdot\mathbf{x}} \mathbf{Q}_\lambda(\boldsymbol{\kappa}) s_\lambda(\lambda\alpha\boldsymbol{\kappa}) + e^{-i\lambda\alpha\boldsymbol{\kappa}\cdot\mathbf{x}} \mathbf{Q}_\lambda(-\boldsymbol{\kappa}) s_\lambda(-\lambda\alpha\boldsymbol{\kappa})]. \end{aligned} \tag{4.14}$$

The second integral is just the first evaluated with the coordinates inverted, whence the expression for the FFMF in terms of the inverse spherical curl transform [(3.4); (I.8)] becomes apparent,

$$\mathbf{B}_\lambda(\mathbf{x}) = \frac{1}{(2\pi)^{3/2}} \int d\Omega\ e^{i\lambda\alpha\boldsymbol{\kappa}\cdot\mathbf{x}} \mathbf{Q}_\lambda(\boldsymbol{\kappa}) s_\lambda(\lambda\alpha\boldsymbol{\kappa}). \tag{4.15}$$

Thus, the description of the spherical curl transform in terms of the Radon transform is both necessary and sufficient; they are completely equivalent representations.

V. EXAMPLES OF LINEAR FFMF SPHERICAL CURL TRANSFORMS

A significant part of the rationale for introducing the curl eigenfunction expansion of FFMFs was to explore possible advantages in using the transform space representation. The viewpoint of (I) was from the transform space: what physical space fields correspond to given curl transforms. The viewpoint taken here is from the physical space: what curl transforms correspond to given FFMFs. The availability of the curl transform expressions above will ease the development of such representations and the comparison with existing FFMFs, processes that are necessary for the exploration of the representation technique. To illustrate the process we have chosen to derive the curl transforms for three fundamental fields: the simplest FFMF, the Lundquist field, and the classical spheromak field.

The notation below follows that of (I, II); physical space spherical coordinates are denoted by (r,θ,φ), while the corresponding coordinates in transform space are denoted by (k,η,ψ) [see Fig. 1 of (II)].

A. The simplest FFMF

This field, which is simply a particular type of standing vector plane wave, corresponds to a curl transform that is a delta function at a point on the transform sphere. It is represented in physical space by the complex wave [see (I)],

$$\mathbf{B}(\mathbf{x}) = \mathbf{B}_0 e^{i\mathbf{k}_0\cdot\mathbf{x}}, \tag{5.1}$$

whose wave vector must be transverse to satisfy the divergence-free condition (3.1b),

$$\mathbf{k}_0\cdot\mathbf{B}_0 = 0, \tag{5.2}$$

and have magnitude α to satisfy (3.1a):

$$k_0 = \lambda\alpha, \quad \lambda = \pm 1. \tag{5.3}$$

Its Radon transform is

$$\mathbf{B}_\lambda^R(p,\boldsymbol{\kappa}) = \frac{1}{2\pi}\int_{-\infty}^{+\infty} dk\ e^{ikp}\int d^3x\ \mathbf{B}_\lambda(\mathbf{x})e^{-ik\boldsymbol{\kappa}\cdot\mathbf{x}}$$

$$= \frac{\mathbf{B}_0}{2\pi}\int_{-\infty}^{+\infty} dk\ e^{ikp}\int d^3x\ e^{i(\mathbf{k}_0-k\boldsymbol{\kappa})\cdot\mathbf{x}}$$

$$= \mathbf{B}_0\int_{-\infty}^{+\infty} dk\ e^{ikp}\delta(\mathbf{k}_0-k\boldsymbol{\kappa})$$

$$= \mathbf{B}_0\int_{-\infty}^{+\infty} dk\ e^{ikp}\frac{\delta(k_0-k)}{k^2}\ \delta(\boldsymbol{\kappa}_0-\boldsymbol{\kappa}) = \frac{\mathbf{B}_0}{k_0^2}\,e^{ik_0p}\delta(\boldsymbol{\kappa}_0-\boldsymbol{\kappa}), \tag{5.4}$$

from which the curl transform is obtained according to (4.4), after substituting the value of k_0 from (5.3):

$$s_\lambda(\lambda\alpha\boldsymbol{\kappa}) = (2\pi)^{-3/2}\mathbf{Q}_\lambda^*(\boldsymbol{\kappa})\cdot\mathbf{B}_0\,\delta(\boldsymbol{\kappa}_0-\boldsymbol{\kappa}) = s_{\lambda 0}\,\delta(\boldsymbol{\kappa}-\boldsymbol{\kappa}_0). \tag{5.5}$$

This agrees with (I.9); it is simply a complex amplitude delta function acting at the point $\boldsymbol{\kappa}_0 = \mathbf{k}_0/k_0$ on the unit sphere in transform space, and as such is a representative of the class of point transform fields discussed briefly there.

B. The Lundquist field

The Lundquist field is significant for two reasons: it was the first FFMF (constructed by Lundquist[10] in 1950), and it has been used as a model for the fields of solar magnetic clouds (Burlaga[4]). Its spherical curl transform turns out to be relatively simple, though its derivation is somewhat lengthy.

According to the formula developed above in (4.6), the spherical curl transform of the Lundquist field, $\mathbf{B}_\mathrm{L}$, may be written as the projection on the corresponding curl eigenvector of the doubly infinite radial Fourier integral in transform space of the three-dimensional (3-D) Fourier transform of the field:

$$s_{\mathrm{L}\lambda}(\lambda\alpha\boldsymbol{\kappa}) = \frac{\alpha^2}{(2\pi)^{3/2}}\,e^{-i\lambda\alpha p}\mathbf{Q}_\lambda^*(\boldsymbol{\kappa})\cdot\int_{-\infty}^{+\infty} dk\ e^{ikp}\int d^3x\ \mathbf{B}_{\mathrm{L}\lambda}(\mathbf{x})e^{-ik\boldsymbol{\kappa}\cdot\mathbf{x}}. \tag{5.6}$$

While the Lundquist field has cylindrical symmetry, it is convenient to express its vector form in Cartesian components to simplify the integration, while retaining its functional form in terms of the circular cylindrical components (r,φ,z):

$$\mathbf{B}_\mathrm{L} = B_0\{-J_1(\alpha r)\sin\varphi,\ J_1(\alpha r)\cos\varphi,\ J_0(\alpha r)\}. \tag{5.7}$$

Recall that the helicity is given by λ (the sign of α), so that it could be explicitly shown as follows:

$$\mathbf{B}_{\mathrm{L}\lambda} = B_{\lambda 0}\{-\lambda J_1(\lambda\alpha r)\sin\varphi,\ \lambda J_1(\lambda\alpha r)\cos\varphi,\ J_0(\lambda\alpha r)\}, \tag{5.8}$$

by taking the parity of the Bessel functions into account and demanding that the Bessel function arguments be positive. To simplify the algebra we carry the form (5.7) through and convert to an explicit helicity form at the end.

The Fourier transform of the Lundquist field is evaluated in Appendix E to be

$$\mathbf{B}_{\mathrm{L}\lambda}^F(\mathbf{k}) = (2\pi)^{+1/2}iB_{\lambda 0}\delta(k_z)\frac{\delta(k-\lambda\alpha)}{\lambda\alpha}\,[\lambda\sin\psi\,\mathbf{i}_x - \lambda\cos\psi\,\mathbf{i}_y - i\mathbf{i}_z]. \tag{5.9}$$

Taking the Fourier transform of this over k simply adds an exponential factor,

$$\int_{-\infty}^{+\infty} dk\ e^{ikp}\mathbf{B}_{\mathrm{L}\lambda}^F(\mathbf{k}) = (2\pi)^{+1/2}iB_{\lambda 0}\delta(k_z)\,\frac{e^{i\lambda\alpha p}}{\lambda\alpha}\,[\lambda\sin\psi\,\mathbf{i}_x - \lambda\cos\psi\,\mathbf{i}_y - i\mathbf{i}_z], \tag{5.10}$$

whose purpose it is to cancel the inverse factor in the spherical curl transform expression (5.6):

$$s_{L\lambda}(\lambda\alpha\boldsymbol{\kappa})=\frac{\alpha i}{2\pi}B_{\lambda 0}\delta(k_z)\mathbf{Q}^*_\lambda(\boldsymbol{\kappa})\cdot[\sin\psi\,\mathbf{i}_x-\cos\psi\,\mathbf{i}_y-i\lambda\mathbf{i}_z]. \tag{5.11}$$

The general form for the conjugate curl eigenvector expression as a Cartesian vector in terms of cylindrical components is

$$\mathbf{Q}^*_\lambda=-\frac{\lambda}{\sqrt{2}}\frac{k_r e^{-i\lambda\psi}}{k+k_z}\left(\frac{\mathbf{k}}{k}+\mathbf{i}_z\right)+\frac{\lambda}{\sqrt{2}}(\mathbf{i}_x-i\lambda\mathbf{i}_y), \tag{5.12}$$

but anticipating the effect of the k_z delta function reduces this effectively to

$$\mathbf{Q}^*_\lambda=-\frac{\lambda}{\sqrt{2}}[e^{-i\lambda\psi}(\cos\psi\,\mathbf{i}_x+\sin\psi\,\mathbf{i}_y+\mathbf{i}_z)-(\mathbf{i}_x-i\lambda\mathbf{i}_y)], \tag{5.13}$$

leading to the final expression for the spherical curl transform of the Lundquist field:

$$s_{L\lambda}(\lambda\alpha\boldsymbol{\kappa})=-\frac{\alpha}{\sqrt{2}\pi}B_{\lambda 0}\delta(k_z)e^{-i\lambda\psi}. \tag{5.14}$$

This SCT is a member of the class of line transforms [see (I), Sec. 3. B] and lives on the equatorial circle of the transform sphere with an amplitude that is a simple complex exponential function of the azimuthal angle ψ. It is capable of immediate generalization by associating it with the class of circle transforms sketched in (I) that have constant amplitude over a small circle of the sphere. This has led to a family of fields related to the Lundquist field that has two additional parameters and is expected to find an application in interplanetary magnetohydrodynamics by providing a more flexible model for solar magnetic cloud fields (MacLeod[7]).

C. The classical spheromak field

The classical spheromak field is significant for consideration here because it has found an application both in interplanetary magnetohydrodynamics and in nuclear fusion work. It was first constructed and introduced by Rosenbluth and Bussac[11] in order to investigate the stability properties of a family of fusion devices proposed as alternatives to the tokamak (see Wright[6] for a review of spheromak work and Sheffield[12] to cast this in the perspective of nuclear fusion work in general; Goldenbaum[13] gives a useful presentation of spheromak physics). The magnetic field of the simplest of this family is the classical spheromak, which bears a strong resemblance to Hill's spherical vortex in fluid mechanics. More recently this field has been proposed as a model of the magnetic field of solar magnetic clouds (Ivanov and Harshiladze,[5] Vandas, Fischer, and Geranios;[14] see Farrugia *et al.*[15] for an extensive review and comparison with the Lundquist field model). (This field also serves as a simple introduction to the use of spherical harmonic expansions as a general means for describing FFMFs, since any reasonably behaved function on the transform sphere may be so expanded.)

We adopt the form of the classical spheromak field given by Farrugia *et al.*[15] in spherical coordinates and components as

$$\mathbf{B}_\lambda(r,\theta,\varphi)=B_{\lambda 0}\left\{\frac{2}{\alpha r}j_1(\lambda\alpha r)\cos\theta\,\mathbf{i}_r+\frac{1}{\alpha r}[j_1(\lambda\alpha r)-\sin(\lambda\alpha r)]\sin\theta\,\mathbf{i}_\theta+\lambda j_1(\lambda\alpha r)\sin\theta\,\mathbf{i}_\varphi\right\}, \tag{5.15}$$

where we have replaced the signed parameter α by its magnitude $\lambda\,\alpha$, as well as making use of the parity of the spherical Bessel functions to show the helicity λ explicitly. Now rewrite this for ease of calculation in spherical coordinates and Cartesian components:

$$\mathbf{B}_\lambda(r,\theta,\varphi)=\frac{B_{\lambda 0}}{3}\{[-j_2(\lambda\alpha r)P_2^1(\mu)\cos(\varphi)+3\lambda j_1(\lambda\alpha r)P_1^1(\mu)\sin(\varphi)]\mathbf{i}_x$$
$$-[j_2(\lambda\alpha r)P_2^1(\mu)\sin(\varphi)+3\lambda j_1(\lambda\alpha r)P_1^1(\mu)\cos(\varphi)]\mathbf{i}_y$$
$$+2[j_2(\lambda\alpha r)P_2(\mu)+j_0(\lambda\alpha r)P_0(\mu)]\mathbf{i}_z\}, \tag{5.16}$$

where we have converted to the Legendre function description in terms of the variable $\mu\equiv\cos\theta$. Note that the helicity affects only the sign of the azimuthal component, as is clear from (5.15).

Once again, the first step in calculating the spherical curl transform is to evaluate the Fourier transform of the field. We choose to do this by utilizing the spherical harmonic expansion of the exponential kernel (Stratton[16]):

$$e^{-ik\cdot x}=e^{-ikr\cos\omega}=\sum_{n=0}^{\infty}(-i)^n(2n+1)j_n(kr)[pa_n(\mu,\eta)+pb_n(\mu,\eta,\varphi,\psi)],$$

$$pa_n(\mu,\eta)\equiv P_n(\mu)P_n(\cos\eta), \tag{5.17}$$

$$pb_n(\mu,\eta,\varphi,\psi)\equiv 2\sum_{m=1}^{n}\frac{(n-m)!}{(n+m)!}P_n^m(\mu)P_n^m(\cos\eta)\cos m(\varphi-\psi),$$

which reduces the problem to the evaluation of a small number of elementary integrals; the calculation is outlined in Appendix F.

The resulting expression for the Fourier transform of the classical spheromak field is

$$\mathbf{b}_\lambda(\mathbf{k})=\frac{\lambda}{3}\sqrt{\frac{\pi}{2}}B_{\lambda 0}\frac{\delta(k-\lambda\alpha)}{k\alpha}\{[P_2^1(\mu')\cos\psi-3i\lambda P_1^1(\mu')\sin\psi]\mathbf{i}_x$$
$$+[P_2^1(\mu')\sin\psi+3i\lambda P_1^1(\mu')\cos\psi]\mathbf{i}_y+2[-P_2(\mu')+P_0(\mu')]\mathbf{i}_z\}, \tag{5.18}$$

where $\mu'\equiv\cos(\eta)$. The essence of taking the Fourier transform of this expression over k (i.e., forming the Radon transform of the field) is the evaluation of the integral

$$\int_{-\infty}^{+\infty}dk\ e^{ikp}\frac{\delta(k-\lambda\alpha)}{\lambda k\alpha}=\frac{e^{i\lambda\alpha p}}{\alpha^2}, \tag{5.19}$$

again with the result of annihilating the exponential factor in the spherical curl transform formula (4.6), and the SCT takes the form

$$s_\lambda(\lambda\alpha\boldsymbol{\kappa})=\frac{\sqrt{2\pi}}{6}B_{\lambda 0}\{[P_2^1(\mu')\cos\psi-3i\lambda P_1^1(\mu')\sin\psi]\mathbf{Q}_\lambda^*(\boldsymbol{\kappa})\cdot\mathbf{i}_x$$
$$+[P_2^1(\mu')\sin\psi+3i\lambda P_1^1(\mu')\cos\psi]\mathbf{Q}_\lambda^*(\boldsymbol{\kappa})\cdot\mathbf{i}_y+2[-P_2(\mu')+P_0(\mu')]\mathbf{Q}_\lambda^*(\boldsymbol{\kappa})\cdot\mathbf{i}_z\}. \tag{5.20}$$

The recognition that the Legendre functions can be factored,

$$P_2^1(\mu')=3\mu'P_1^1(\mu')=3P_1(\mu')P_1^1(\mu'), \tag{5.21}$$

and rewritten as

$$-P_2+P_0=\frac{3}{2}(P_1^1)^2, \tag{5.22}$$

reducing the form (5.20) to

$$s_\lambda(\lambda\alpha\boldsymbol{\kappa}) = \frac{\sqrt{2\pi}}{2} B_{\lambda 0} P_1^1(\mu')\{[P_1(\mu')\cos\psi - i\lambda\sin\psi]\mathbf{Q}_\lambda^*(\boldsymbol{\kappa})\cdot\mathbf{i}_x$$
$$+[P_1(\mu')\sin\psi + i\lambda\cos\psi]\mathbf{Q}_\lambda^*(\boldsymbol{\kappa})\cdot\mathbf{i}_y + P_1^1(\mu')\mathbf{Q}_\lambda^*(\mathbf{k})\cdot\mathbf{i}_z\} \tag{5.23}$$

simplifies the subsequent algebra. Now evaluating the conjugate curl eigenvector dot products using (A1), we find

$$\mathbf{Q}_\lambda^*\cdot\mathbf{i}_x = -\frac{\lambda}{\sqrt{2}}[(1-P_1)\cos\psi\, e^{-i\lambda\psi} - 1],$$

$$\mathbf{Q}_\lambda^*\cdot\mathbf{i}_y = -\frac{\lambda}{\sqrt{2}}[(1-P_1)\sin\psi\, e^{-i\lambda\psi} + i\lambda], \tag{5.24}$$

$$\mathbf{Q}_\lambda^*\cdot\mathbf{i}_z = \frac{\lambda}{\sqrt{2}} P_1^1 e^{-i\lambda\psi}.$$

Substituting (5.24) in (5.23), the final form for the spherical curl transform of the classical spheromak field reduces to (!!)

$$s_\lambda(\lambda\alpha\boldsymbol{\kappa}) = -\lambda\sqrt{\pi} B_{\lambda 0} P_1^1(\mu') e^{-i\lambda\psi}. \tag{5.25}$$

Thus, this SCT is a member of the class of areal transforms [see (I), Sec. 3.C] and lives on the whole sphere with an amplitude varying with the sine of the polar angle [i.e., $P_1^1(\cos\eta)$] and as a complex exponential in the azimuthal angle.

VI. SUMMARY AND OUTLOOK

The description of the general linear force-free magnetic field in terms of the Moses curl eigenfunctions begun previously by the derivation of an expression giving the physical field in terms of an integral over the transform sphere has been completed by deriving a general expression for the inverse operator that enables the spherical curl transform to be determined in terms of the physical field. This inverse may be represented as a weighted projection of the vector Radon transform of the field on the appropriate curl eigenvector. The process was exemplified by the determination of the transforms of three fields: the simplest force-free magnetic field, and the Lundquist and classical spheromak fields. The use of the SCT in generalizing a given type of FFMF was briefly sketched for the Lundquist field.

The point that the spherical curl transforms found above are considerably simpler in functional form than their corresponding fields in physical space cannot be overemphasized. One way of looking at the effect is to say that the use of the curl eigenvectors to shoulder the responsibility of describing the field geometry in the Fourier transform has simplified the problem considerably. It has, in fact, reduced the vector three-dimensional problem in physical space to a scalar two-dimensional problem on the sphere in transform space. It has, so far, used simpler functions to describe the transform than are used to describe the physical field. Of course, one tends to doubt that the latter is a universal feature of the representation, but the fact is that this has been a prominent feature of the fields considered to date, and, as seen above, these have included some nontrivial fields. To demonstrate this difference in complexity, examples of field/transform pairs are shown in Table I. These have been taken from the three classes of point, line, and areal transforms outlined in (I), including the three pairs discussed above. This suggests that a considerable advantage may be gained in the study of FFMFs by working in transform space, though further techniques are needed to reduce this to practice, such as the development of a Green's function approach to solve specific boundary value problems.

It would be interesting to reconsider the FFMFs found by Richter from symmetry considerations (Richter[17]) from the standpoint of the curl eigenfunction representation to see what light they might shed on the complexity issue. Surely the group symmetries found by Emets' and Kovbasenko[18] and Richter[19] can contribute to the elucidation of this facet of the problem.

TABLE I. The relative simplicity of the expressions for the spherical curl transforms compared to their corresponding fields. [For details on the circle line and constant areal transforms and their parameters see (I).]

Field type/Name	Field expression	Spherical curl transform
Point transform/Simplest:	$\mathbf{B}_0 e^{i\mathbf{k}_0\cdot\mathbf{x}}$	$(2\pi)^{-3/2}\mathbf{Q}^*_\lambda(\boldsymbol{\kappa})\cdot\mathbf{B}_0\delta(\boldsymbol{\kappa}_0-\boldsymbol{\kappa})$
Line transform/Circle:	$\frac{B_{\lambda 0}}{2\pi^{1/2}} e^{iz/L_z}[(\cos\eta_0+1)J_0(r/L_r)\mathbf{i}_\lambda-(\cos\eta_0-1)J_2(r/L_r)e^{i2\lambda\varphi}\mathbf{i}^*_\lambda - \sqrt{2}\lambda i\sin\eta_0 J_1(r/L_r)e^{i\lambda\varphi}\mathbf{i}_z]$	$B_{\lambda 0}\frac{\delta(\eta-\eta_0)}{\sin\eta}$
Line transform/Lundquist:	$B_{\lambda 0}[\lambda J_1(\lambda\alpha r)\mathbf{i}_\varphi+J_0(\lambda\alpha r)\mathbf{i}_z]$	$-\frac{\alpha}{\sqrt{2}\pi}B_{\lambda 0}\delta(k_z)e^{-i\lambda\psi}$
Areal transform/Constant:	$(2\pi)^{-1/2}B_{\lambda 0}\text{-}\varnothing\Big\{[j_0(\alpha r)+ij_1(\alpha r)P_1(\mu)]\mathbf{i}_\lambda - \pi^{-1/2}\lambda i P^1_1(\mu)e^{i\lambda\varphi}j_1(\alpha r)\mathbf{k}-\sqrt{\frac{2}{\pi}}\sum_{n=2}^{\infty}(-i)^n \times(2n+1)j_\pi(\alpha r)\frac{(n-2)!}{(n+2)!}P^2_n(\mu)e^{i2\lambda\varphi}\mathbf{i}^*_\lambda\Big\}$	$B_{\lambda 0}$
Areal transform/Classical spheromak:	$B_{\lambda 0}\Big\{\frac{2}{\alpha r}j_1(\lambda\alpha r)\cos\theta\mathbf{i}_r+\frac{1}{\alpha r}[j_1(\lambda\alpha r)-\sin(\lambda\alpha r)] \times\sin\theta\mathbf{i}_\theta+\lambda j_1(\lambda\alpha r)\sin\theta\mathbf{i}_\varphi\Big\}$	$-\lambda\sqrt{\pi}B_{\lambda 0}P^1_1(\mu)e^{-i\lambda\psi}$

Another path to explore is the use of alternative formulas for the Radon transform. Moses and Prosser[20] showed that it is sufficient to integrate over a ''canonical hemisphere'' for the inverse Radon transform, reducing the well-known double covering of x space to a single covering. (Similar considerations have been discussed previously. The Radon transform literature is extensive; see, e.g., Ludwig[21] and Guillemin[22]). A tantalizing aspect of this is the thought that the Radon transform and the curl eigenfunctions are both aspects of a particular Hopf fibration that could both simplify and generalize our understanding of these concepts and their interrelations by lifting the description to one in four dimensions, in spite of the fact that the curl operator lives in three dimensions.

Finally, it must be emphasized again that, although the entire discussion above has been couched in terms of force-free magnetic fields, the results apply equally well [with the caveat mentioned in (I)] to the description of the Trkalian class of Beltrami flows in fluid dynamics.

ACKNOWLEDGMENTS

Once again, the assistance of the staff of the nonpareil Geophysics Research Library, especially Ms. Susan Benzer, is gratefully acknowledged, as is the continued support of Gary Mullen.

APPENDIX A: PROPERTIES OF THE MOSES CURL EIGENVECTORS

The $\mathbf{Q}_\lambda(\mathbf{k})$ vectors introduced above in the definition of the curl eigenfunctions were defined by Moses[3] in Cartesian coordinates as follows:

$$\mathbf{Q}_0(\mathbf{k})\equiv-\frac{\mathbf{k}}{k},$$

$$\mathbf{Q}_\lambda(\mathbf{k})\equiv-\frac{\lambda}{\sqrt{2}}\left[\frac{k_1(k_1+i\lambda k_2)}{k(k+k_3)}-1,\ \frac{k_2(k_1+i\lambda k_2)}{k(k+k_3)}-i\lambda,\ \frac{k_1+i\lambda k_2}{k}\right]\quad(\lambda=\pm1). \tag{A1}$$

They possess the following useful properties:

$$\mathbf{Q}_\lambda^*(\mathbf{k})\cdot\mathbf{Q}_\mu(\mathbf{k})=\delta_{\lambda\mu}\quad(\lambda,\mu=0,\pm1),$$
$$\sum_\lambda \mathbf{Q}_{\lambda i}^*(\mathbf{k})\cdot\mathbf{Q}_{\lambda j}(\mathbf{k})=\delta_{ij}\quad(i,j=1,2,3), \tag{A2}$$

which provide the foundation for the orthogonality and completeness of the curl eigenfunctions. Three other relations are useful in simplifying expressions:

$$\mathbf{k}\times\mathbf{Q}_\lambda(\mathbf{k})=-i\lambda k\mathbf{Q}_\lambda(\mathbf{k})\quad(\lambda,\mu=0,\pm1),$$
$$\mathbf{Q}_\mu^*(\mathbf{k})\times\mathbf{Q}_\lambda(\mathbf{k})=-i\lambda\ \delta_{\lambda\mu}\mathbf{Q}_0(\mathbf{k})=-i\lambda\delta_{\lambda\mu}\frac{\mathbf{k}}{k}\quad(\lambda=\pm1), \tag{A3}$$
$$\mathbf{Q}_\lambda^*(\mathbf{k})=-\mathbf{Q}_{-\lambda}(\mathbf{k})\quad(\lambda=\pm1).$$

Note that, although the curl eigenvectors are invariant under a positive scale change of their argument,

$$\mathbf{Q}_\lambda(\mathbf{k})=\mathbf{Q}_\lambda(\boldsymbol{\kappa})=\mathbf{Q}_\lambda(\beta\boldsymbol{\kappa}),\quad \beta>0, \tag{A4}$$

a negative scale change introduces a phase factor and transforms a rotational eigenvector to its counterpart with opposite helicity:

$$\mathbf{Q}_\lambda(-\beta\boldsymbol{\kappa})=-\left(\frac{\kappa_1+i\lambda\kappa_2}{\kappa_1-i\lambda\kappa_2}\right)\mathbf{Q}_\lambda^*(\beta\boldsymbol{\kappa})=\left(\frac{\kappa_1+i\lambda\kappa_2}{\kappa_1-i\lambda\kappa_2}\right)\mathbf{Q}_{-\lambda}(\beta\boldsymbol{\kappa})=e^{i2\lambda\psi}\mathbf{Q}_{-\lambda}(\boldsymbol{\kappa}), \tag{A5}$$

while the same operation reverses the sign of $\mathbf{Q}_0(\mathbf{k})$.

N.B.: The k factor on the right-hand side of (A3a) was inadvertently omitted from the corresponding list in both (I) and (II).

APPENDIX B: VECTOR RADON AND FOURIER TRANSFORMS

The three-dimensional scalar Radon transform,

$$f^R(\mathbf{p})\equiv\int d^3x\ f(\mathbf{x})\,\delta(p-\boldsymbol{\kappa}\cdot\mathbf{x}), \tag{B1}$$

and its inverse,

$$f(\mathbf{x})=\frac{1}{8\pi^2}\nabla_x^2\int d\Omega\ f^R(\boldsymbol{\kappa}\cdot\mathbf{x},\boldsymbol{\kappa}) \tag{B2}$$

(Deans[9]), as well as the corresponding Fourier transforms, are easily converted to vector transforms given in terms of the Cartesian components,

$$\mathbf{f}(\mathbf{x})=\sum_{j=1}^{3} f_j\mathbf{i}_j, \tag{B3}$$

by replacing the scalar functions by vector functions:

$$\mathbf{f}^R(\mathbf{p})\equiv\int d^3x\ \mathbf{f}(\mathbf{x})\,\delta(p-\boldsymbol{\kappa}\cdot\mathbf{x}) \tag{B4}$$

(and similarly for the other transforms). Here we have used the linearity of their integral operators and, in the case of the inverse Radon transform, recalled that the vector Laplacian is equivalent to the scalar Laplacian acting on the Cartesian components (Morse and Feshbach[23]).

The relation between the Radon and Fourier transforms depends, however, on the specific definition of the Fourier transform. Since we have adopted the symmetrical definition of Moses

that differs from that which commonly appears in the Radon transform literature (Deans,[9] Helgason[24]), we must rederive the interrelation of the two transforms. Following Deans, p. 97, write the Fourier transform as

$$\mathbf{f}^F(\mathbf{k}) = (2\pi)^{-3/2} \int_{-\infty}^{+\infty} dt \int d^3x \; \mathbf{f}(\mathbf{x}) e^{-it} \delta(t - \mathbf{k}\cdot\mathbf{x}). \tag{B5}$$

Now change variables as follows:

$$\mathbf{k} = s\boldsymbol{\kappa}, \quad t = sp.$$

After substituting these values and rearranging, we find the Fourier transform in terms of the Radon transform; then inverting this relation, the Radon transform in terms of the Fourier transform:

$$\begin{aligned} \mathbf{f}^F(s\boldsymbol{\kappa}) &= (2\pi)^{-3/2} \int_{-\infty}^{+\infty} dp \; e^{-isp} \mathbf{f}^R(p\boldsymbol{\kappa}), \\ \mathbf{f}^R(q\boldsymbol{\kappa}) &= (2\pi)^{1/2} \int_{-\infty}^{+\infty} ds \; e^{isq} \mathbf{f}^F(s\boldsymbol{\kappa}). \end{aligned} \tag{B6}$$

APPENDIX C: THE RADON TRANSFORM OF A LINEAR FORCE-FREE MAGNETIC FIELD

The Radon transform of the FFMF introduced in Sec. IV has a subtlety in its derivation that we explain here. If we set about to develop the Radon transform of the linear FFMF by inserting the expression (3.4) into the vector Radon transform definition (4.5), introducing the integral exponential representation of the delta function and rearranging leads to

$$\begin{aligned} \mathbf{B}^R_\lambda(p,\mathbf{u}) &= \int d^3x \left[(2\pi)^{-3/2} \int d\Omega \; e^{i\lambda\alpha\boldsymbol{\kappa}\cdot\mathbf{x}} \mathbf{Q}_\lambda(\boldsymbol{\kappa}) s_\lambda(\lambda\alpha\boldsymbol{\kappa}) \right] \delta(p - \mathbf{u}\cdot\mathbf{x}) \\ &= (2\pi)^{-5/2} \int d^3x \int d\Omega \; e^{i\lambda\alpha\boldsymbol{\kappa}\cdot\mathbf{x}} \mathbf{Q}_\lambda(\boldsymbol{\kappa}) s_\lambda(\lambda\alpha\boldsymbol{\kappa}) \int_{-\infty}^{\infty} dt \; e^{it(p-\mathbf{u}\cdot\mathbf{x})} \\ &= (2\pi)^{-5/2} \int d\Omega \; \mathbf{Q}_\lambda(\boldsymbol{\kappa}) s_\lambda(\lambda\alpha\boldsymbol{\kappa}) \int_{-\infty}^{\infty} dt \; e^{itp} \int d^3x \; e^{i\mathbf{x}\cdot(\lambda\alpha\boldsymbol{\kappa} - t\mathbf{u})} \\ &= (2\pi)^{1/2} \int d\Omega \; \mathbf{Q}_\lambda(\boldsymbol{\kappa}) s_\lambda(\lambda\alpha\boldsymbol{\kappa}) \int_{-\infty}^{\infty} dt \; e^{itp} \delta(\lambda\alpha\boldsymbol{\kappa} - t\mathbf{u}). \end{aligned} \tag{C1}$$

Given that $\lambda\alpha > 0$ and that $\mathbf{u}$ has a specific orientation, this delta function contributes to the integral twice: when the sign of $\boldsymbol{\kappa}$ matches that of $\mathbf{u}$ and t is positive, and when the sign of $\boldsymbol{\kappa}$ is oppositely directed to $\mathbf{u}$ and t is negative:

$$\begin{aligned} \mathbf{B}^R_\lambda(p,\mathbf{u}) &= (2\pi)^{1/2} \int d\Omega \; \mathbf{Q}_\lambda(\boldsymbol{\kappa}) s_\lambda(\lambda\alpha\boldsymbol{\kappa}) \left[\int_0^{\infty} dt \; e^{itp} \delta(\lambda\alpha\boldsymbol{\kappa} - t\mathbf{u}) + \int_0^{\infty} dt \; e^{-itp} \delta(\lambda\alpha\boldsymbol{\kappa} + t\mathbf{u}) \right] \\ &= (2\pi)^{1/2} \left[\int_0^{\infty} dt \; e^{itp} \frac{\delta(t - \lambda\alpha)}{t^2} \int d\Omega \; \mathbf{Q}_\lambda(\boldsymbol{\kappa}) s_\lambda(\lambda\alpha\boldsymbol{\kappa}) \delta(\boldsymbol{\kappa} - \mathbf{u}) \right. \\ &\quad \left. + \int_0^{\infty} dt \; e^{-itp} \frac{\delta(t + \lambda\alpha)}{t^2} \int d\Omega \; \mathbf{Q}_\lambda(\boldsymbol{\kappa}) s_\lambda(\lambda\alpha\boldsymbol{\kappa}) \delta(\boldsymbol{\kappa} + \mathbf{u}) \right] \\ &= \frac{(2\pi)^{1/2}}{\alpha^2} \left[e^{i\lambda\alpha p} \mathbf{Q}_\lambda(\mathbf{u}) s_\lambda(\lambda\alpha\mathbf{u}) + e^{-i\lambda\alpha p} \mathbf{Q}_\lambda(-\mathbf{u}) s_\lambda(-\lambda\alpha\mathbf{u}) \right]. \end{aligned} \tag{C2}$$

As a check on this result, note that it obviously satisfies the two main symmetries of the Radon transform [which reflect the symmetries of the delta function in the definition (4.5)]:

$$\begin{aligned}\mathbf{B}^R_\lambda(-p,-\mathbf{u})&=\mathbf{B}^R_\lambda(p,\mathbf{u}),\\ \mathbf{B}^R_\lambda(-p,\mathbf{u})&=\mathbf{B}^R_\lambda(p,-\mathbf{u}).\end{aligned}\tag{C3}$$

Thus the Radon transform of a linear FFMF contains within it the essence of both helicities of the field. Comparing (C2) with (3.4), the Radon transform for which $p=\boldsymbol{\kappa}\cdot\mathbf{x}$ is seen to be proportional to the mean of the spherical Fourier transforms of the two helicity components.

APPENDIX D: THE EQUIVALENCE OF CERTAIN INTEGRAL EXPRESSIONS

The essential step in developing (4.12) is to show that the projections of the $\mathbf{Q}_\lambda\mathbf{Q}^*_\lambda$ and $\mathbf{Q}_{-\lambda}\mathbf{Q}^*_{-\lambda}$ dyads on the FFMF Radon transform are equal when integrated over the sphere:

$$\int d\Omega\; e^{-i\lambda\alpha(p-\boldsymbol{\kappa}\cdot\mathbf{x})}\mathbf{Q}_\lambda(\boldsymbol{\kappa})\mathbf{Q}^*_\lambda(\boldsymbol{\kappa})\cdot\mathbf{B}^R_\lambda(\mathbf{p})=\int d\Omega\; \mathbf{e}^{i\lambda\alpha(p-\boldsymbol{\kappa}\cdot\mathbf{x})}\mathbf{Q}_{-\lambda}(\boldsymbol{\kappa})\mathbf{Q}^*_{-\lambda}(\boldsymbol{\kappa})\cdot\mathbf{B}^R_\lambda(\mathbf{p}).\tag{D1}$$

Transform the right-hand integral by inverting the coordinates, replacing the resulting negative argument $\mathbf{Q}$ dyad by its positive counterpart using (A5), flip the argument signs of the Radon transform using (C3b), and substitute the expression (C2) for the FFMF Radon transform to obtain sequentially

$$\begin{aligned}\int d\Omega\; e^{i\lambda\alpha(p-\boldsymbol{\kappa}\cdot\mathbf{x})}\mathbf{Q}_{-\lambda}(\boldsymbol{\kappa})\mathbf{Q}^*_{-\lambda}(\boldsymbol{\kappa})\cdot\mathbf{B}^R_\lambda(\mathbf{p})&=\int d\Omega\; e^{i\lambda\alpha(p+\boldsymbol{\kappa}\cdot\mathbf{x})}\mathbf{Q}_{-\lambda}(-\boldsymbol{\kappa})\mathbf{Q}^*_{-\lambda}(-\boldsymbol{\kappa})\cdot\mathbf{B}^R_\lambda(p,-\boldsymbol{\kappa})\\ &=\int d\Omega\; e^{i\lambda\alpha(p+\boldsymbol{\kappa}\cdot\mathbf{x})}\mathbf{Q}_\lambda(\boldsymbol{\kappa})\mathbf{Q}^*_\lambda(\boldsymbol{\kappa})\cdot\mathbf{B}^R_\lambda(p,-\boldsymbol{\kappa})\\ &=\int d\Omega\; e^{i\lambda\alpha(p+\boldsymbol{\kappa}\cdot\mathbf{x})}\mathbf{Q}_\lambda(\boldsymbol{\kappa})\mathbf{Q}^*_\lambda(\boldsymbol{\kappa})\cdot\mathbf{B}^R_\lambda(-p,\boldsymbol{\kappa})\\ &=\frac{\sqrt{2\pi}}{\alpha^2}\int d\Omega\; e^{i\lambda\alpha\boldsymbol{\kappa}\cdot\mathbf{x}}\mathbf{Q}_\lambda(\boldsymbol{\kappa})s_\lambda(\lambda\alpha\boldsymbol{\kappa}).\end{aligned}\tag{D2}$$

Now replace the Radon transform on the left-hand side of (D1) using (C2) to find

$$\int d\Omega\; e^{-i\lambda\alpha(p-\boldsymbol{\kappa}\cdot\mathbf{x})}\mathbf{Q}_\lambda(\boldsymbol{\kappa})\mathbf{Q}^*_\lambda(\boldsymbol{\kappa})\cdot\mathbf{B}^R_\lambda(\mathbf{p})=\frac{\sqrt{2\pi}}{\alpha^2}\int d\Omega\; e^{i\lambda\alpha\boldsymbol{\kappa}\cdot\mathbf{x}}\mathbf{Q}_\lambda(\boldsymbol{\kappa})s_\lambda(\lambda\alpha\boldsymbol{\kappa}),\tag{D3}$$

and the relation (D1) is seen to be true, leading to (4.12).

APPENDIX E. THE FOURIER TRANSFORM OF THE LUNDQUIST FIELD

The Fourier transform of the Lundquist field has the general form

$$\begin{aligned}\mathbf{B}^F_{\mathrm{L}\lambda}(\mathbf{k})=(2\pi)^{-3/2}\int d^3x\,\mathbf{B}_{\mathrm{L}\lambda}(\mathbf{x})e^{-i\mathbf{x}\cdot\mathbf{k}}&=(2\pi)^{-3/2}B_{\lambda 0}\int d^3x[-J_1(\alpha r)\sin\varphi\;\mathbf{i}_x\\ &+J_1(\alpha r)\cos\varphi\;\mathbf{i}_\mathbf{y}+J_0(\alpha r)\mathbf{i}_z]e^{-i\mathbf{x}\cdot\mathbf{k}}.\end{aligned}\tag{E1}$$

The scalar product appearing in the exponential argument is (in circular cylindrical coordinates)

$$\mathbf{k}\cdot\mathbf{x}=k_r r\,\cos(\varphi-\psi)+k_z z,\tag{E2}$$

where (k_r,ψ,k_z) refer to transform space and (r,φ,z) refer to physical space. The integral over z is immediate:

$$\mathbf{B}^F_{\mathrm{L}\lambda}(\mathbf{k}) = (2\pi)^{-1/2} B_{\lambda 0}\delta(k_z)\int r\ dr\ d\varphi[-J_1(\alpha r)\sin\ \varphi\ \mathbf{i}_x + J_1(\alpha r)\cos\ \varphi\ \mathbf{i}_y + J_0(\alpha r)\mathbf{i}_z]e^{-ik_r r\ \cos(\varphi-\psi)}. \tag{E3}$$

The integral over the azimuthal angle requires some care. It is composed of three integrals of the form

$$I_{s/c/1}(\beta,\psi) \equiv \int_0^{2\pi} d\varphi[\sin\ \varphi/\cos\ \varphi/1]e^{i\beta\ \cos(\varphi-\psi)}, \tag{E4}$$

where here $\beta = -k_r r$. These integrals are closely related to Bessel's original definition of the Bessel coefficients and can each be shown to have the form of Hansen's integral formula for the $J_m(z)$ Bessel function (Korn and Korn[25]):

$$J_m(z) = \frac{(-i)^m}{\pi}\int_0^{\pi} dt\ e^{iz\ \cos t}\cos(mt). \tag{E5}$$

Rewriting the angular argument in (E4) as $\varphi - \psi \equiv \varphi'$ changes the limits and expands the trig function factors of $I_{s/c}$ to give both sine and cosine contributions, of which only the cosine pieces survive the integration. The integral values are easily shown to be insensitive to the limit shifts and the surviving integrals evaluated by splitting the integration range and recognizing the Bessel functions from Hansen's formula:

$$I_s(\beta,\psi) = \sin\ \psi\int_0^{2\pi} d\varphi'\ \cos\ \varphi' e^{-i\beta\ \cos\ \varphi'} = \pi i\ \sin\ \psi[J_1(\beta) - J_1(-\beta)] = 2\pi i\ \sin\ \psi\ J_1(\beta), \tag{E6}$$

$$I_c(\beta,\psi) = \cos\ \psi\int_0^{2\pi} d\varphi'\ \cos\ \varphi' e^{-i\beta\ \cos\ \varphi'} = 2\pi i\ \cos\ \psi\ J_1(\beta), \tag{E7}$$

$$I_1(\beta,\psi) = \int_0^{2\pi} d\varphi'\ e^{-i\beta\ \cos\ \varphi'} = 2\pi i J_0(\beta). \tag{E8}$$

Thus, the complete φ integral becomes

$$\begin{aligned}\mathbf{B}^{\mathrm{F}}_{\mathrm{L}\lambda}(\mathbf{k}) &= (2\pi)^{-1/2} B_{\lambda 0}\delta(k_z)\int_0^{\infty} r\ dr[-J_1(\alpha r)I_s\mathbf{i}_x + J_1(\alpha r)I_c\mathbf{i}_y + J_0(\alpha r)I_1\mathbf{i}_z] \\ &= (2\pi)^{+1/2} i B_{\lambda 0}\delta(k_z)\int_0^{\infty} r\ dr[J_1(\alpha r)J_1(kr)\sin\ \psi\ \mathbf{i}_x - J_1(\alpha r)J_1(kr)\cos\ \psi\ \mathbf{i}_y \\ &\quad - iJ_0(\alpha r)J_0(kr)\mathbf{i}_z].\end{aligned} \tag{E9}$$

The remaining integrals are all instances of the delta function according to the familiar formula (Korn and Korn,[25] Eqs. (21.8–22.9):

$$\int_0^{\infty} r\ dr\ J_1(kr)J_1(k'r) = \frac{\delta(k-k')}{k'}, \tag{E10}$$

where $k,\ k' \geqslant 0$. Now making use of the explicit helicity expression analogous to (5.8) and integrating, the Fourier transform of the Lundquist field becomes

$$\mathbf{B}^F_{\mathrm{L}\lambda}(\mathbf{k}) = (2\pi)^{+1/2} i B_{\lambda 0}\delta(k_z)\int_0^\infty r\, dr[\lambda J_1(kr)J_1(\lambda\alpha r)\sin\psi\,\mathbf{i}_x$$
$$-\lambda J_1(kr)J_1(\lambda\alpha r)\cos\psi\,\mathbf{i}_y - iJ_0(kr)J_0(\lambda\alpha r)\mathbf{i}_z]$$
$$= (2\pi)^{+1/2} i B_{\lambda 0}\delta(k_z)\,\frac{\delta(k-\lambda\alpha)}{\lambda\alpha}\,[\lambda\,\sin\psi\,\mathbf{i}_x - \lambda\,\cos\psi\,\mathbf{i}_y - i\mathbf{i}_z]. \tag{E11}$$

APPENDIX F: THE FOURIER TRANSFORM OF THE CLASSICAL SPHEROMAK FIELD

Using the expansion of the exponential kernel outlined in Sec. V C, the Fourier transform of the classical spheromak field takes the form

$$\mathbf{b}_\lambda(\mathbf{k}) = (2\pi)^{-3/2}\sum_{n=0}^{\infty}(-i)^n(2n+1)\int d^3x\; j_n(kr)[pa_n(\mu,\mu') + pb_n(\mu,\mu',\varphi,\psi)]\mathbf{B}_\lambda(\mathbf{x}). \tag{F1}$$

Rewriting (5.16) as

$$B_x(r,\mu,\varphi) = B_1\,\cos\varphi + B_2\,\sin\varphi,$$
$$B_y(r,\mu,\varphi) = B_1\,\sin\varphi - B_2\,\cos\varphi, \tag{F2}$$
$$B_z(r,\mu) = B_3,$$

where we have defined

$$B_1 \equiv -\tfrac{1}{3}\,B_0 j_2(\alpha r)P_2^1(\mu),$$
$$B_2 \equiv B_0 j_1(\alpha r)P_1^1(\mu), \tag{F3}$$
$$B_3 \equiv \tfrac{2}{3}\,B_0[j_2(s)P_2(\mu) + j_0(s)P_0(\mu)],$$

clarifies the integration operations. In integrating (F1) over φ, the orthogonality of the trig functions forces the pa contribution to zero except for that from B_3 with $m=0$, and the pb contribution to zero except for that from B_1 and B_2 with $m=1$:

$$\mathbf{b}_\lambda(\mathbf{x}) = (2\pi)^{-1/2}\int_0^\infty r^2\, dr\sum_{n=0}^{\infty} i^n(2n+1)j_n(kr)$$
$$\times[(I_1\,\cos\psi + I_2\,\sin\psi)\mathbf{i}_x + (I_1\,\sin\psi - I_2\,\cos\psi)\mathbf{i}_y + I_3\mathbf{i}_z]. \tag{F4}$$

Here the integrals over μ have been explicitly indicated by

$$I_1 \equiv \int_{-1}^{+1} d\mu\; pb_n(\mu,\mu')\delta_{m1}B_1,$$
$$I_2 \equiv \int_{-1}^{+1} d\mu\; pb_n(\mu,\mu')\delta_{m1}B_2, \tag{F5}$$
$$I_3 \equiv \int_{-1}^{+1} d\mu\; pa_n(\mu,\mu')\delta_{m0}B_3.$$

Fortunately, the Kronecker deltas force the m values of the pb Legendre functions to coincide with those of the B_i, and the orthogonality of the Legendre functions then collapses the n values to coincide with those of the B_i:(2;1;0,2), so that the Fourier transform takes the form

$$\mathbf{b}_\lambda(\mathbf{k}) = \frac{2}{15}(2\pi)^{-1/2} B_0 \sum_{n=0}^{\infty} (-i)^n (2n+1) \int_0^\infty r^2\, dr\; j_n(kr)\{[-j_2(\alpha r) P_2^1(\mu')\delta_{n2} \cos\psi + 5 j_1(\alpha r) P_n^1(\mu')\delta_{n1} \sin\psi]\mathbf{i}_x - [j_2(\alpha r) P_2^1(\mu')\delta_{n2} \sin\psi + 5 j_1(\alpha r) P_n^1(\mu')\delta_{n1} \cos\psi]\mathbf{i}_y + 2[j_2(\alpha r) P_n(\mu')\delta_{n2} + 5 j_0(\alpha r) P_n(\mu')\delta_{n0}]\mathbf{i}_z\}. \tag{F6}$$

Thanks to the Kronecker deltas, the radial integrals are now all of the form

$$\int_0^\infty r^2\, dr\; j_n(kr) j_n(\alpha r) = \frac{\pi}{2} \frac{\delta(k-\alpha)}{k\alpha}. \tag{F7}$$

Note, however, that this formula assumes that k and α are both positive; since α may be negative, the following modified formula is necessary:

$$\int_0^\infty r^2\, dr\; j_n(kr) j_n(\alpha r) = \lambda^n \int_0^\infty r^2\, dr\; j_n(kr) j_n(\lambda\alpha r) = \lambda^n \frac{\pi}{2} \frac{\delta(k-\lambda\alpha)}{\lambda k \alpha}, \tag{F8}$$

in which we have taken account of the parity of the spherical Bessel functions. Making use of this formula in (F6), we obtain the final form of the classical spheromak Fourier transform:

$$\mathbf{b}_\lambda(\mathbf{k}) = \frac{\lambda}{3}\sqrt{\frac{\pi}{2}} B_0 \frac{\delta(k-\lambda\alpha)}{k\alpha}\{[P_2^1(\mu')\cos\psi - 3i\lambda P_1^1(\mu')\sin\psi]\mathbf{i}_x + [P_2^1(\mu')\sin\psi + 3i\lambda P_1^1(\mu')\cos\psi]\mathbf{i}_y + 2[-P_2(\mu') + P_0(\mu')]\mathbf{i}_z\}. \tag{F9}$$

The identities of the algebraic invariants of the four-dimensional Riemann tensor. II.

G. E. Sneddon[a)]
School of Computer Science, Mathematics and Physics, James Cook University, Townsville, 4811, Australia

(Received 11 September 1997; accepted for publication 28 October 1997)

This paper makes use of several known results from invariant theory to further investigate the invariants of the Riemann tensor and the identities between them. The work also relies on the idea of expressing the Riemann tensor in terms of two complex matrices in the space of self-dual bivectors. It is shown that all invariants that are of even degree in the trace-free Ricci tensor can be written as polynomial functions of a set of 28 invariants. It is believed that this set is a complete set for this type of invariant. Several identities for matrix polynomials of 3×3 matrices are also obtained. These are used to find a large number of the identities between the 28 invariants. While some of these identities are quite complicated, it is shown how, in the general case, they might be used to obtain all invariants from a knowledge of a smaller set. © *1998 American Institute of Physics.*

I. INTRODUCTION

Existing classifications of the Riemann tensor depend on separate classifications of the Weyl tensor and the Ricci tensor. In turn, the classification of these tensors depends on the relationships between their algebraic invariants. Any attempt to classify the Riemann tensor as a whole can therefore be expected to depend on an understanding of all of the invariants of the Riemann tensor and the relationships between them. It is known that fourteen of these invariants are independent and it is not too difficult to write down a set of fourteen such invariants. However, as noted by Carminati and McLenaghan,[1] in many situations it is important to have a complete set of invariants. Any other invariant can be written as a polynomial function of the elements of such a set. This will ensure that this set is sufficient to determine any other invariant in any algebraically special case as well as in the general case. The task of finding such a set and the relationships between these invariants has been hampered by a lack of understanding of how these relationships may be obtained and (no doubt) by the considerable algebra involved.

Previous discussions of this problem have used either the tensor representation,[2] or the spinor representation[1,3,4] or a complex bivector representation[5,6] of the Riemann tensor. The latter approach was also taken by Sneddon,[7,8] who made use of the formalism developed by Buchdahl[9] to express the problem in the space of self-dual bivectors. Buchdahl referred to self-dual bivectors as rotors and a brief summary of his procedure is given in Ref. 8. The main advantage of expressing the invariants in terms of self-dual bivectors is that they become essentially the invariants of a pair of complex 3×3 matrices under a given group of transformations. One of these matrices, Ψ, corresponds to the Weyl tensor, and the other, Γ, corresponds to the trace-free part of the Ricci tensor. Sneddon[8] has given a complete solution for the invariants of two symmetric 3×3 matrices under similarity transformations. However, in the present case, the matrix corresponding to the trace-free part of the Ricci tensor is Hermitian and undergoes the transformation $\Gamma\rightarrow S\Gamma\overline{S}^{-1}$. This fact complicates the process of determining the relationships between the invariants quite considerably, as the preliminary investigations indicate.

Much of this work has been carried out without taking full account of known results in invariant theory. Indeed, since some of the results are quite fundamental properties of matrices, it is perhaps not surprising that many of them have appeared in the literature previously. Before pro-

ceeding to find a complete set of invariants for the Riemann tensor, it is important to take account of these earlier results. Section II describes some of the results from invariant theory that have particular relevance for the task of describing the invariants of the Riemann tensor. In Sec. III, some of the results presented in Ref. 8 are revisited with these ideas in mind. Also, the relationship between the invariants of non-symmetric matrices is presented. In Sec. IV, a number of identities between matrix products are investigated, and it is shown that there must be relationships between them (identities of identities). This feature is also well known and has important implications for later work. Furthermore, some of these identities can be found, and it is shown that there must be an even higher level of identities (''identities cubed''). The problem of finding a complete set of invariants for the Riemann tensor is addressed in Sec. V. A set containing 28 elements is given which is believed to be a complete set for the invariants of even degree in the Ricci tensor. It can be shown that this set must contain a complete set, but it has yet to be proved that no proper subset can be complete. In Sec. VI, several identities are found for these invariants. A study of these helps to see how the new invariants are related to those used previously.

A number of the identities obtained are identities for matrix polynomials. A matrix product of a set of R matrices, A_i, can be written as $A_{i_1}^{\alpha_1}A_{i_2}^{\alpha_2}\cdots A_{i_e}^{\alpha_e}$, where each of the subscripts lies between 1 and R and each of the indices is a positive integer. The total degree of the matrix product in the matrices A_i is $\alpha=\alpha_1+\alpha_2+\cdots+\alpha_e$. The partial degree of a given matrix, A, in the matrix product is the sum of the indicies α_k for which $A_{i_k}=A$. The degree of a trace can be defined similarly. A matrix polynomial is a sum of terms, each of which is a matrix product multiplied by a coefficient which is either a constant or the product of one or more traces of matrices. (Spencer and Rivlin[10] referred to these as *isotropic* matrix polynomials.) The degree of each such term is the sum of the degrees of the matrix product and its coefficient. The degree of a matrix polynomial is the degree of the term with the largest degree.

Consider a matrix polynomial, P, for which α is the total degree of the matrix product of largest total degree. Then P is reducible if it can be re-expressed as a matrix polynomial, Q, for which each matrix product has total degree less than α. This shall be denoted by $P\approx 0$, and the notation $P_1\approx P_2$ shall indicate that the difference of the two matrix polynomials is reducible. Similarly, the trace, T, of a matrix (or matrix polynomial) is said to be reducible if it can be written as a polynomial whose arguments are each traces of lower total degree than T. Again, this shall be written as $T\approx 0$.

Square brackets will be used to denote the trace of a matrix. Thus $[AB]$ is the trace of the matrix AB. Indices $i,j,\ldots$ will range from 1 to 4, while bivector indices $A,B,\ldots$ will range from 1 to 3.

II. RESULTS FROM INVARIANT THEORY

The study of invariant theory dates back to the middle of the last century. At that time, attention was concentrated on the invariants of homogeneous polynomials and forms. Towards the end of the century, Hilbert produced the main results in this area. These results could also be applied to invariants of sets of vectors and tensors in general. Throughout, there are two fundamental problems, namely (i) the nature of the invariants and (ii) the nature of the relationships between them. Before describing the results, it is important to review various definitions that are needed.

Definition: An *invariant* of a set of tensors in n dimensions is a polynomial function of the components of those tensors that is invariant under some group of transformations of the tensors.

Such an invariant is often referred to as a polynomial invariant. The allowable invariants can depend on the group chosen. Often it will be the full group of linear transformations, $GL(n)$. However, if the Lorentz group is used, then the invariants can automatically involve the metric tensor, η_{ij}. Similarly, if the proper Lorentz group is used, then the Levi-Civita tensor density (ε_{ijkl} or ε^{ijkl}) can also be involved, even though this entity transforms as a tensor density rather than a tensor under $GL(n)$. It is common practice to include invariants formed using this tensor density amongst the invariants of the four dimensional Riemann tensor. This means that the quantities to be considered will be invariant under the proper Lorentz group.

A complete set may be defined as follows.

Definition: A *complete* set of invariants, $\{I_1, \ldots, I_m\}$, is one for which any other invariant I can be written as a polynomial function of $\{I_1, \ldots, I_m\}$, but no element of the set can be written as a polynomial function of the others.

Therefore, with a complete set of invariants, it will always be possible to calculate any other invariant. This will be the case even in algebraically special sub-cases where some invariants may vanish.

Definition: An *independent* set of invariants, $\{I_1, \ldots, I_m\}$, is one for which $f(I_1, \ldots, I_m)=0$ implies that f is the trivial function, $f \equiv 0$.

An independent set can be maximal in the sense that, for any other invariant I, there is a function g such that $g(I, I_1, \ldots, I_m)=0$. Even if this is the case, it may not be possible to calculate all other invariants in some algebraically special cases. For example, a calculation could involve division by an invariant that became zero in the algebraically special case. This feature has been seen in the invariants of the Riemann tensor.[1] On the other hand, a complete set may require such a large number of elements that its usefulness is limited. For this reason, Zakhary and McIntosh[4] and Carminati and McLenaghan[11] have considered other possible requirements for a convenient set to work with. In general, a complete set will not be independent. In those cases where it is not, there must be identities (syzygies) between the invariants in the set. An example of this is the identity given in Ref. 8 connecting the invariants of two symmetric 3×3 matrices.

With these ideas in mind, we can now turn to the main theorems.

(a) **The first fundamental theorem:** Any polynomial invariant of a set of tensors can be expressed as a linear combination of complete contractions of products of those tensors (together with the metric or $\varepsilon_{i_1 \cdots i_n}$ as appropriate).

This result is discussed by Weyl[12] and also by Gurevich.[13] It tells what form the invariants can take. Also, the Hilbert Finiteness Theorem states that the invariants are finitely generated. That is, a complete set will have a finite number of elements. The second fundamental theorem indicates the form of any identities between the invariants.

(b) **The second fundamental theorem:** Any identity between the invariants of a set of tensors in n dimensions can be obtained as a consequence of the fact that skew-symmetrizing over $n+1$ indicies will annihilate any tensor.

This refers to identities that are additional to those that can be obtained from the symmetries of the tensors themselves. The theorem can also be extended to matrix identities. In some cases, the identities themselves might also satisfy certain identities and these identities in turn may be related by further identities, etc. The Hilbert Syzygy theorem[14] states that this process must terminate and that the total number of identities is finite.

Special cases of the second fundamental theorem have been known for some time. In the case of sets of vectors, the proof was given by Weyl.[12] For sets of $n\times n$ matrices, which is the case to be considered here, the result has been obtained by Procesi.[15] The result for general tensors has recently been obtained by Gover.[16] He also allows for the possibility that the tensors themselves may have existing symmetries. He has shown that any identity between the invariants is an algebraic consequence of such symmetries, together with the identities which arise from the result that skew-symmetrizing over $n+1$ indicies annihilates any tensor in n dimensions. These results are obtained for the groups $O(g)$ and $SO(g)$, with the metric g unspecified, so they will be valid for the Lorentz group. The method is quite general and so should also apply to tensors with dotted indicies.

In a series of papers,[10,17,18] Spencer and Rivlin obtained several specific results for 3×3 matrices. They were dealing with stress tensors in isotropic continua and these tensors were expressed in terms of a number of tensors representing the strain. Their work was prompted by the need to simplify the the form of the various products of these strain tensors. They showed how to express products of up to five 3×3 matrices in terms of a comparatively small ''basis set'' of such products. In so doing, they made extensive use of the relationship

$$AB^2+B^2A+BAB-[A]B^2-[B](AB+BA)+\tfrac{1}{2}([B]^2-[B^2])A+([A][B]-[AB])B-([AB^2]$$
$$-[B][AB]+\tfrac{1}{2}([A][B]^2-[A][B^2]))I=0, \tag{1}$$

which follows from

$$X^{[A}{}_AY^B{}_BZ^C{}_C\delta^{D]}{}_E=0 \tag{2}$$

by putting $X=Y=A$, and $Z=B$. They were able to show that any matrix polynomial involving only two matrices could be written in terms of a set of 17 matrix products. (Only nine matrix products are needed if the matrices and matrix polynomial are symmetric.) Equation (2) contains the Cayley–Hamilton equation as a special case, but it can also be deduced from the Cayley-Hamilton theorem by a ''polarization'' process.[10] Of course, it is also an example of where skew-symmetrizing over $n+1$ indicies can lead to matrix identities as well as trace identities. The basis set obtained by Spencer and Rivlin was equivalent to the set

$$\begin{gathered} I \\ A,\ B \\ A^2,\ AB,\ BA,\ B^2 \\ A^2B,\ AB^2,\ BA^2,\ B^2A \\ A^2B^2,\ A^2BA,\ B^2AB,\ B^2A^2 \\ A^2B^2A,\ B^2A^2B. \end{gathered} \tag{3}$$

If A and B are symmetric, then any symmetric matrix polynomial can be written in terms of the matrices

$$\begin{gathered} I \\ A,\ B \\ A^2,\ AB+BA,\ B^2 \\ A^2B+BA^2,\ AB^2+B^2A \\ A^2B^2+B^2A^2. \end{gathered} \tag{4}$$

The sets (3) and (4) shall be referred to as $\mathscr{M}$ and $\mathscr{S}$ respectively. Spencer and Rivlin gave equations that could be used to write any other matrix polynomial in terms of the elements of one of these sets as appropriate. Often the final result was quite lengthy and was not given explicitly. For example, the expression for A^2B^2AB in terms of the set (3) requires 78 terms. This expression is given in Appendix A for the case where both A and B are trace-free. This still requires 22 terms.

Spencer and Rivlin also obtained many of the identities between the traces of matrix products (of up to five 3×3 matrices) that can be obtained by skew-symmetrizing over four indicies. Since the components of the Riemann tensor can be written in terms of the components of 3×3 matrices, their work is particularly relevant. In fact, it will be shown that their results can be used to find a complete set of invariants of the Riemann tensor.

Initially, these results were used to show that the set

$$\begin{array}{cccc} & [A] & [A^2] & [A^3] \\ [B] & [AB] & [A^2B] & \\ [B^2] & [AB^2] & [A^2B^2] & \\ [B^3] & & & \end{array} \tag{5}$$

forms a complete set for the invariants of two symmetric 3×3 matrices under similarity transformations. This result was re-derived by Sneddon,[8] who also obtained the identity $S_0=0$, where

$$S_0=c_3[A^2B^2]^3+c_2[A^2B^2]^2+c_1[A^2B^2]+c_0, \tag{6}$$

and

$$c_3 = -4,$$

$$c_2 = [AB]^2 + 5[A^2][B^2],$$

$$c_1 = 2[B^2][A^2B]^2 + 2[A^2][AB^2]^2 - 2[AB][AB^2][A^2B] - 2[A^2][B^3][A^2B] - 2[A^3][B^2][AB^2] - [A^2][B^2][AB]^2 + 2[A^3][B^3][AB] - 2[A^2]^2[B^2]^2,$$

$$\begin{aligned} c_0 = &-\tfrac{4}{3}([B^3][A^2B]^3 + [A^3][AB^2]^3) + [A^2B]^2[AB^2]^2 \\ &- \tfrac{1}{2}[A^2][B^2]([B^2][A^2B]^2 + [A^2][AB^2]^2) + 2[A^3][B^3][A^2B][AB^2] \\ &- \tfrac{4}{9}[A^3][B^3][AB]^3 + \tfrac{2}{3}[AB]^2([A^3][B^2][AB^2] + [A^2][B^3][A^2B]) \\ &+ \tfrac{1}{3}[AB]([A^2]^2[B^3][AB^2] + [A^3][B^2]^2[A^2B]) \\ &+ \tfrac{2}{3}[A^2][B^2]([A^3][B^2][AB^2] + [A^2][B^3][A^2B]) - \tfrac{2}{3}[A^2][A^3][B^2][B^3][AB] \\ &+ \frac{1}{4}[A^2]^3[B^2]^3 + \tfrac{1}{18}([A^3]^2[B^2]^3 + [A^2]^3[B^3]^2) - \tfrac{1}{3}[A^3]^2[B^3]^2. \end{aligned}$$

This identity is valid for all trace-free, symmetric matrices. The corresponding equation for the case where the matrices are not trace-free can also be obtained. A simple counting argument on the number of independent components remaining after all the coordinate freedom is used up, shows that nine of the invariants in (5) must be independent. This means that the relationship $S_0 = 0$ (or its generalization if the traces are non-zero) is the one relationship between the elements of the complete set for the invariants of a pair of symmetric matrices. The set (5) shall be denoted by $\mathscr{I}$.

If either A or B is not symmetric, $\mathscr{I}$ needs to be augmented with either $[A^2B^2AB]$ or $[B^2A^2BA]$ (or their difference) to form a complete set. Since only ten of these invariants can be independent, there must again be a relationship connecting them. This relationship is obtained in the next section.

Finally, identities such as (2), which rely explicitly on skew-symmetrizing over $n+1$ indicies, have been used in general relativity on other occasions. Lovelock[19] showed that a number of well known identities in general relativity are consequences of this procedure. Also Harvey[2] used this property in his work on invariants, and Edgar and co-workers (see Ref. 20 for example) have used the property to obtain equations for the Lanczos tensor and the Weyl tensor. Lovelock referred to such identities as ''dimensionally dependent'' identities.

III. TRACE IDENTITIES

The results of the previous section raise a number of questions concerning the trace identities of 3×3 matrices. Some of these questions are relevant to the aim of understanding the invariants of the Riemann tensor.

Firstly, the second fundamental theorem states that all trace identities can be obtained by skew-symmetrizing over four indicies. It is clear that this is the case for the identities obtained by Spencer and Rivlin. However, it is not obviously the case for the identity $S_0 = 0$. This identity was obtained in Ref. 8 by two brute force methods, neither of which made use of this theorem. It needs to be confirmed that this identity can also be obtained by skew-symmetrizing over four indicies. Secondly, in the case that A and B are not symmetric, it would be of interest to obtain an identity that connects $[A^2B^2AB]$ with the set $\mathscr{I}$. This would be a relationship between the elements of a complete set for the invariants of two 3×3 matrices under similarity transformations.

It is best to answer the second question first. The answer to the first then follows easily. It has been conjectured[8] that the required identity could possibly be obtained from

$$[C]^3 - 3[C][C^2] + 2[C^3] - 6\det C = 0 \tag{7}$$

with $C=A^2B^2AB$ and $\det C$ replaced by $(\det A\ \det B)^3$. This was partly because a cubic expression for $[A^2B^2AB]$ was expected. However, it was found that the left-hand side (LHS) of (7) actually factorizes and that one of these factors gives the correct identity, which is a quadratic in $[A^2B^2AB]$. It should be possible to obtain this identity as the single solution of some equation.

In view of the second fundamental theorem, it can be expected that this identity will result from an equation such as

$$X^{[A}{}_{A}Y^{B}{}_{B}Z^{C}{}_{C}W^{D]}{}_{D}=0 \tag{8}$$

with an appropriate choice for X,Y,Z and W. Also, it is clear that it will be sufficient to choose these matrices from amongst those in the basis set found by Spencer and Rivlin. In order to find a suitable choice, a multiplication table was set up for the matrices in $\mathscr{M}$ together with A^2B^2AB and B^2A^2BA. It was assumed that both matrices were trace-free to reduce the amount of algebra. The results for the general case could be deduced if needed. Initially, expressions were found for the product of each of these matrices with A and B. Each such product was expressed in terms of the matrices in this set. These calculations were carried out largely by hand, using identities such as (1). Once this was done, a full multiplication table could be produced. An algebraic computing package was needed for this second step as the algebra required for some products was quite considerable, even with the trace-free assumption. (The package actually used was MATHEMATICA.) For example, the expression for $A^2BA\times B^2A^2B$ contains 45 terms. Subsequently, the expressions for A^2B^2AB and B^2A^2BA in terms of $\mathscr{M}$ were found.

With this table available, Eq. (8) can be written out in full and various choices of matrices can be tried. In fact there are many combinations that will give the required identity. Perhaps the simplest choice is to put

$$X=A^2B^2,$$

$$Y=A^2B^2,$$

$$Z=AB,$$

$$W=AB.$$

The resulting identity is

$$\Delta^2=-(c_3[A^2B^2]^3+c_2[A^2B^2]^2+c_1[A^2B^2]+c_0), \tag{9}$$

where $\Delta=[A^2B^2AB]-[B^2A^2BA]$ and the coefficients c_i are the ones that follow Eq. (6). This equation can be generalized to the case where A and B are not trace-free. Thus we have a complete set of invariants for a pair of matrices, and (9) (or its generalization) gives the relationship between them.

It is now straightforward to see how to obtain the identity for symmetric matrices. If A and B are symmetric, then $[A^2B^2AB]=[B^2A^2BA]$ and so $\Delta=0$. Therefore

$$S_0=c_3[A^2B^2]^3+c_2[A^2B^2]^2+c_1[A^2B^2]+c_0=0.$$

Therefore, this equation can be obtained by skew-symmetrizing over four indices as predicted by the second fundamental theorem.

Finally, while this method of deriving this identity may seem more elegant than the previous approaches, it is no less cumbersome. In fact, the calculations required in setting up the multiplication table mean that probably more work is required. It does have the advantage though that, once constructed, the multiplication table can be used for other things.

IV. MATRIX-VALUED IDENTITIES

Identities such as (1) are matrix-valued identities. They can be used to give expressions for products of matrices in terms of the basis set $\mathscr{M}$. For example, Eq. (1) itself can be used to give BAB in terms of AB^2 and B^2A and the other elements of $\mathscr{M}$. Since the coefficient of BAB does

not involve any of the invariants, this equation can always be solved for BAB. There are, however, a number of other matrix identities where the coefficient of each matrix product involves some of the invariants. The solution of these equations for one of its matrix products is not guaranteed, as it may involve division by zero in some cases. Consideration of the basis set $\mathscr{M}$ also suggests that there must be further identities between these matrix products. That is, while there are 17 elements of that set, only nine can be independent as there are only nine independent components of a 3×3 matrix. Similar comments will apply to the elements of $\mathscr{S}$ as there can be only six independent symmetric matrices.

The task then is to find some of these additional matrix identities for the elements of $\mathscr{M}$. This can be done using the equation

$$X^{[A}{}_{A}Y^{B}{}_{B}Z^{C}{}_{C}W^{D]}{}_{E}=0.$$

and replacing X, Y, Z and W with different elements of $\mathscr{M}$ in turn. Equivalently, Eq. (2) could be used, and any identity obtained could be multiplied by a matrix W. In fact, *any* further identity can be obtained in this fashion. Of course, a large number of identities have already been used in the construction of the multiplication tables, and so some of the choices for X, Y, Z and W will simply give the trivial identity. The new identities obtained in this fashion can be characterized by their partial degrees in A and B. Also, for given degrees of A and B, the identities can be separated into a symmetric part and a skew-symmetric part. It appears that this classification is sufficient to identify each of these identities. For example, the symmetric identity of degree six in A and degree four in B is unique to within a constant multiple and the possible addition of multiples of identities of lower total degree. This identity can therefore be referred to as $M^{64}{}_{s}$. The corresponding skew-symmetric identity will be $M^{64}{}_{a}$ and so on.

Now, the only syzygy connecting elements of $\mathscr{T}$ is of sixth degree in A and B, and the elements of $\mathscr{M}$ that are of largest degree are A^2B^2A and B^2A^2B. It follows that any further matrix identity must be of at least the third degree in A and fourth degree in B or vice versa. (Any identity of lower degree would have to be the trivial identity, as the trace of its product with any matrix product would have to be zero.) Choosing $X=B$, $Y=AB$, $Z=A^2B^2$ and $W=I$ gives M^{34}. M^{43} can be obtained similarly. These identities are skew-symmetric, thus removing the need for the subscript. Several more identities can now be obtained, either by different choices of X, Y, Z and W, or by multiplying existing identities such as M^{34} and M^{43} by A or B, etc. From above, it is expected that there would be eight such matrix identities connecting the 17 ''basis'' matrix products. The difficulty now is that, rather than having too many matrix products, there appears to be too many identities between them. Therefore some of these matrix identities must be dependent. In fact, the situation is a little more subtle than that. This will be illustrated by letting A and B be symmetric and considering $M^{nn}{}_{s}$, the identities between symmetric matrix polynomials. These considerations will also assist in understanding the relationships between the invariants of the Riemann tensor.

The basis, $\mathscr{S}$, for symmetric matrix polynomials formed from symmetric matrices is given by Eq. (4). Since there are nine elements in this set, and there are six independent symmetric 3×3 matrices, there should be exactly three independent relations between them. These equations could then be solved to give, say, $A^2B^2+B^2A^2$, A^2B+BA^2 and AB^2+B^2A in terms of the other matrices in $\mathscr{S}$. However, the foregoing procedure actually produces nine identities that appear to be independent. These are

$$\begin{matrix} M^{44}{}_{s} & M^{54}{}_{s} & M^{64}{}_{s} \\ M^{45}{}_{s} & M^{55}{}_{s} & M^{65}{}_{s} \\ M^{46}{}_{s} & M^{56}{}_{s} & M^{66}{}_{s}. \end{matrix} \tag{10}$$

Once again, there seems to be too many identities. We shall look more closely at $M^{44}{}_{s}$, $M^{45}{}_{s}$, $M^{54}{}_{s}$ and $M^{55}{}_{s}$. For brevity, these identities will be written as $S_i=0$. They are given in Appendix A for the case $[A]=[B]=0$. At first glance, they appear to be independent. For example, these identities can be viewed as a system of four equations to determine $A^2B^2+B^2A^2$, A^2B+BA^2, AB^2+B^2A and $AB+BA$ in terms of the other matrices. The determinant of the coefficient matrix can be calculated, and it is a polynomial expression in the invariants $\mathscr{T}$. Surprisingly, this expres-

sion is not identically zero, which suggests that the equations are independent. However, it turns out that the expression for the determinant factorizes, and that one of the factors is the expression S_0 defined in Eq. (6). This cubic is known to be identically zero when A and B are symmetric 3×3 matrices. Therefore, the equations are actually dependent. This must also be the situation for other sets of four equations.

Since these identities are dependent, there should be invariant expressions a_i such that $\Sigma_{i=1}^{4} a_i S_i = 0$. However, the term on the LHS can be zero only as a consequence of the cubic identity $S_0 = 0$. Therefore, the equation must read

$$\sum_{i=1}^{4} a_i S_i = -a_0 S_0, \tag{11}$$

where a_0 is a symmetric matrix polynomial. Such an equation would show clearly the relationship between the syzygies $S_i = 0$. It would be a syzygy of syzgyies. In order to find this equation, the highest power of $[A^2B^2]$ in each of the a_i can be assumed to be two. The equation $S_0 = 0$ could be used to remove any higher powers. Thus the coefficients a_i can be written as $x_i[A^2B^2]^2 + y_i[A^2B^2] + z_i$. The LHS of Eq. (11) can then be expanded, and the coefficients of the powers of $[A^2B^2]$ can be collected. If the equation $S_0 = 0$ is again used to replace any powers higher than the second, the resulting expression must be zero. Furthermore each coefficient of the remaining powers of $[A^2B^2]$ must be identically zero and, within each such coefficient, the coefficients of each of the matrices in $\mathscr{S}$ must be zero. This gives 27 linear homogeneous equations for the 12 unknowns x_i, y_i, z_i, but it turns out that only nine are independent. Therefore, there are three different solutions for (x_i, y_i, z_i) and each of these gives rise to a different solution for a_i. Each of these solutions can be checked by substituting into the LHS of (11) and expanding. This time, the higher powers of $[A^2B^2]$ are not replaced. Instead, the resulting expression should factorize, with S_0 being one of the factors. In this fashion, it can be verified that each of the three choices for a_i gives a solution for (11). It should be noted that some of these calculations were carried out for the special case where $[AB] = [AB^2] = 0$ (as well as $[A] = [B] = 0$) in order to reduce the amount of algebra involved. As has been seen previously,[8] this special case is sufficient to construct the general result.

The fact that there are three solutions of (11) is a surprise at first. It suggests that there are actually three identities between the four relationships $S_i = 0$, when only one was expected. The only possible resolution of this is if these identities themselves also satisfy certain syzygies. These will be syzygies of syzygies of syzygies (or (syzygies)^3!). The possibility of such a hierarchy of syzygies is well known. There is a discussion in the recent publication of Hilbert's lectures on invariant theory.[14] Indeed, Hilbert's Syzygy Theorem states that, under fairly general conditions, such a chain of syzygies must be finite. In the present case, it is not too difficult to see the origin of these ''(syzygies)^3.'' Any particular identity of the type

$$a_1 S_1 + a_2 S_2 + a_3 S_3 + a_4 S_4 = -a_0 S_0$$

can be multiplied by $[A^2B^2]$. Each of the terms $a_i \times [A^2B^2]$ can be expanded and the higher powers of $[A^2B^2]$ can again be replaced. The resulting relationship will differ from the initial one and so must be some combination of the three relationships. This will most probably give one of the (syzygies)^3. Multiplication of the initial identity by $[A^2B^2]^2$ and repeating the process will most likely give the second.

Finally, it is clear that these results are not complete. There will be a hierarchy of syzygies connecting all the identities of (10). The present results simply provide a glimpse of the complexity of the problem. These same complexities arise in considering the invariants of the Riemann tensor. The results just presented will help in the understanding of that case.

V. THE INVARIANTS OF THE RIEMANN TENSOR

The invariants of the Riemann tensor can be expressed in terms of two complex 3×3 matrices. These are a trace-free symmetric matrix, Ψ, and a Hermitian matrix, Γ. (The Ricci scalar is excluded from consideration here.) From Ref. 9, if the components of the Riemann tensor undergo a Lorentz transformation, the elements of the bivector space (the rotors) undergo a complex

orthogonal transformation. That is, $\Psi \to S\Psi S^{-1}$ and $\Gamma \to S\Gamma \overline{S^{-1}}$ where $SS^T = I$. There are two consequences of this when compared with the work in the previous sections, where S could be a general non-singular matrix. Firstly, since the metric tensor is left invariant by the transformation, the transpose of matrices can appear in the invariants. Consequently, invariants such as $[AB^T]$ should also be considered. Secondly, since the Levi-Civita tensor density, ε_{ABC}, is left unchanged, it can also be used in the construction of the invariants. Since the matrices to be considered are symmetric, the first problem won't arise. Also, as discussed below, invariants containing ε_{ABC} will be excluded from consideration.

Two special subsets of the invariants of the Riemann tensor can be identified. They are (i) those invariants in which Γ appears only in the combination $\Gamma\overline{\Gamma}$ and (ii) those invariants which are of even degree in Γ. The first case was dealt with in Ref. 8, and further results for that case have been given in the preceding sections. This section will discuss the invariants of the second type. Clearly this set contains the elements of the first type. The second type of invariant can also be described as those that are also left unchanged by the transformation $\Gamma \to -\Gamma$. It turns out that the invariants that are not contained in this set are those that involve ε_{ABC}. For example, $\varepsilon_{ABC}\varepsilon^{\dot{A}\dot{B}\dot{C}}\Gamma^A{}_{\dot{A}}\Gamma^B{}_{\dot{B}}\Gamma^C{}_{\dot{C}}$ and $\varepsilon_{ABC}\varepsilon^{\dot{A}\dot{B}\dot{C}}\Psi^A{}_D\Gamma^D{}_{\dot{A}}\Gamma^B{}_{\dot{E}}\overline{\Psi}^{\dot{E}}{}_{\dot{B}}\Gamma^C{}_{\dot{C}}$ would be excluded. In the tensor representation it would mean that the invariant $R^i{}_j R^j{}_k R^k{}_i$ was not included. While these are no less important than the other invariants, it is felt that their inclusion at this stage would simply add to the complexity. In any case, the squares of these invariants will be included in this class of invariants, as will be the product of any two of them. In this sense, all invariants can be accounted for to within a minus sign.

Invariants of the first type were investigated by introducing matrices $A = \Psi$ and $B = L$, where L is the trace-free part of $K = \Gamma\overline{\Gamma}$. Even though the results obtained assumed that both matrices were trace-free, they could be used to construct the general results. A means is needed for describing invariants of the second type. They will be formed from the traces of products of matrices such as Ψ, $\overline{\Psi}$, K, $\overline{K}$, Γ, and $\overline{\Gamma}$. In these matrix products, there will need to be either a Γ or a $\overline{\Gamma}$ separating either of the matrices Ψ and K from the matrices $\overline{\Psi}$ and $\overline{K}$. Once again, the Cayley–Hamilton theorem guarantees that matrix powers higher than the second should not be included. These considerations suggest that any such invariant can be expressed in terms of the traces of products of the matrices

$$A = \Psi,$$

$$B = K,$$

$$C = \Gamma\overline{\Psi}\overline{\Gamma},$$

$$D = \Gamma\overline{\Psi}^2\overline{\Gamma}.$$

Note that A is trace-free, but there seems to be no advantage in choosing B to be the trace-free part of K, as the presence of Γ will mean that $[K]$ will appear in the final equations in any case. It is also important to note that each of these matrices is symmetric. Thus the earlier results for symmetric matrices will apply to any pair of these matrices (after allowing for the fact that they are not all trace-free).

Even though these matrices are not fully independent, there is no further simplification that can be made at this stage. For example, $C^2 = \Gamma\overline{\Psi}K\overline{\Psi}\overline{\Gamma}$ and the appropriate modification of Eq. (1) implies $\overline{\Psi}\overline{K}\overline{\Psi} \approx -(\overline{\Psi}^2\overline{K} + \overline{K}\overline{\Psi}^2)$. Therefore $C^2 \approx -(DB + BD)$. However, this does not provide a means to express D simply in terms of C^2. There seems to be no alternative other than to look at the invariants of these four matrices.

Fortunately, much of the work required here has already been done by Spencer and Rivlin.[17] They gave details of complete sets for the invariants of up to five symmetric 3×3 matrices. These results can be summarized as follows:

1. For two symmetric matrices A and B, a complete set is given by $\mathscr{T}$.
2. For three symmetric matrices A, B and C, a complete set consists of

TABLE I. Any invariant of Ψ and Γ that is of even degree in Γ can be written as a polynomial function of these invariants.

Real invariants	Complex invariants
$[B]=[K]$	
$[B^2]=[K^2]$	$[A^2]=[\Psi^2]$
$[B^3]=[K^3]$	$[A^3]=[\Psi^3]$
	$[AB]=[\Psi K]=\overline{[C]}$
	$[AB^2]=[\Psi K^2]=\overline{[BC]}$
	$[A^2B]=[\Psi^2K]=\overline{[D]}$
	$[A^2B^2]=[\Psi^2K^2]=\overline{[BD]}$
$[AC]=[\Psi\Gamma\overline{\Psi}\,\overline{\Gamma}]$	$[AD]=[\Psi\Gamma\overline{\Psi}^2\overline{\Gamma}]$
$[ABC]=[\Psi K\Gamma\Psi\Gamma]$	$=\overline{[A^2C]}$
$[AB^2C]=[\Psi K^2\Gamma\overline{\Psi}\,\overline{\Gamma}]$	$[ABD]=[\Psi K\Gamma\overline{\Psi}^2\overline{\Gamma}]$
$[A^2D]=[\Psi^2\Gamma\overline{\Psi}^2\overline{\Gamma}]$	$=\overline{[A^2BC]}$
$[A^2BD]=[\Psi^2K\Gamma\overline{\Psi}^2\overline{\Gamma}]$	$[AB^2D]=[\Psi K^2\Gamma\overline{\Psi}^2\overline{\Gamma}]$
$[A^2B^2D]=[\Psi^2K^2\Gamma\overline{\Psi}^2\overline{\Gamma}]$	$=\overline{[A^2B^2C]}$
$[A^2BACD]=[\Psi^2K\Psi\Gamma\overline{\Psi}\overline{K}\overline{\Gamma}^2\overline{\Gamma}]$	

(a) all elements of the complete sets of each of the three pairs of matrices that can be selected from A, B and C,
(b) the invariant $[ABC]$,
(c) the invariants $[ABC^2]$, $[BCA^2]$, $[CAB^2]$ and
(d) the invariants $[AB^2C^2]$, $[BC^2A^2]$, $[CA^2B^2]$.

3. For four symmetric matrices A, B, C and D, a complete set consists of

(a) all elements of the complete sets of each of the four sets of three matrices that can be selected from A, B, C and D,
(b) the invariants $[ABCD]$, $[ABDC]$,
(c) the invariants $[ABCD^2]$, $[ACBD^2]$, $[DABC^2]$, $[DBAC^2]$, $[CDAB^2]$, $[CADB^2]$, $[BCDA^2]$, $[BDCA^2]$,
(d) the invariants $[ABC^2D^2]$, $[ACB^2D^2]$, $[ADB^2C^2]$, $[BCA^2D^2]$, $[BDA^2C^2]$, $[CDA^2B^2]$ and
(e) the invariants $[BACDA^2]$, $[CBDAB^2]$, $[DCABC^2]$, $[ADBCD^2]$.

Initially, the task of writing out all these invariants, let alone making sense of them, seems quite formidable. However, there a number of simplifications available. Some of these are as follows:

1. Since $C^2\approx-(BD+DB)$, any invariants involving C^2 can be removed from the list. Similarly, $D^2\approx0$ so any invariant involving D^2 can also be removed. A similar simplification can not be made for CD, but the fact that $CD\approx-DC$ can be used.
2. Sometimes, when an invariant, or its complex conjugate, is written explicitly in terms of Ψ, K and Γ it is obvious that it is reducible. For example, $\overline{[B^2C]}=[K^3\Psi]$ is obviously reducible as it contains K^3.
3. The fact that the complex conjugate of an invariant doesn't appear on the list of Spencer and Rivlin is evidence that the invariant is reducible. $[ACD]$ is not obviously reducible, but its complex conjugate, $[A^2BAC]$, is not on the list given by Spencer and Rivlin. A little manipulation shows that $[A^2BAC]\approx-[ABA^2C]=-[A^2BAC]$. The first step follows from Eq. (1) and the second is true since the matrices are symmetric. Therefore, $2[A^2BAC]\approx0$ and $[ACD]$ can be removed from the list.

Once these simplifications are made, the remaining invariants can be listed. There are 28 of them, some of which appear in complex conjugate pairs. These invariants are given in Table I and shall be denoted by $\mathscr{J}$. The invariants contained in $\mathscr{I}$ are, of course, amongst these, but note that, since $A=\Psi$ which is trace-free, it is understood that, in any reference to $\mathscr{I}$, $[A]$ will be zero.

It is claimed that this set of invariants forms a complete set for the invariants of the Riemann tensor (excluding the Ricci scalar of course) that are of even degree in the trace-free Ricci tensor. Certainly any other invariant can be expressed as a polynomial function of the invariants in this set. However, it is not yet certain that this could not be achieved with a smaller set. The term that seems most likely to be reducible is $[A^2BACD]$. It is possible to obtain a number of syzygies containing this term, and this is discussed in the next section. However, none of these syzygies suggests that it might be possible to find an expression for $[A^2BACD]$. Even if such a relationship did exist, there would still be a large number of invariants in a complete set of invariants of the Riemann tensor. The inclusion of invariants that are of odd degree in the Ricci tensor may improve the situation, but this is unlikely. Whatever the situation, there may be some advantage in relaxing the requirement of a polynomial dependence, and looking for smaller sets of invariants that can still be used to calculate all other invariants in most situations.

It should also be noted that the above considerations are valid even if Ψ and $\overline{\Psi}$ are independent of each other. In some cases, it is best to regard them as independent, and also regard each complex invariant in Table I as being independent of its complex conjugate. Then, if $[\overline{\Psi}^2]$ and $[\overline{\Psi}^3]$ are included amongst the invariants, there will be a total of 28 independent terms representing the invariants in the set. These terms will include $[AB]$, $[C]$, $[ABD]$, $[A^2BC]$ etc. as independent invariants. In this fashion, the real invariants appear only once, and the complex invariants will appear in pairs which are complex conjugates when Ψ and $\overline{\Psi}$ are complex conjugates.

Finally, many of the ''new'' mixed invariants have appeared before. For example, $[AC]$ and $[A^2C]$ are essentially the invariants m_3 and m_5 defined by Carminati and McLenaghan. Their invariant m_4, as expressed by Sneddon,[8] contains the invariants $[ABC]$ and $[AB^2C]$. The expression M_4 defined by Haddow[4] is just $[A^2D]$.

VI. SYZYGIES OF THE INVARIANTS

The next step is to look for syzygies connecting elements of this set. Clearly, there will be a large number of these, and the connections between them can be quite complex. Rather than find all such syzygies, the initial aim will be to find a sufficient number to enable all the invariants in $\mathscr{J}$ to be calculated from those in $\mathscr{I}$ (at least in the general case). As may be expected, the equations needed to do this will be polynomial equations and their solution will not be unique. An alternative approach is to look for a set that is larger than $\mathscr{I}$, but from which the invariants in $\mathscr{J}$ can be calculated uniquely. Either of these two approaches gives some understanding of the relationships between the invariants and the syzygies. In general, even though the syzygies obtained are quite complex, they have a simple structure if the invariants in $\mathscr{I}$ are regarded as known quantities.

One method for finding syzygies would be first to produce a ''basis set'' for matrix polynomials formed from the four matrices A, B, C and D. Then construct a multiplication table for the elements of this basis set and use Eq. (8) to generate the syzygies. This would be a considerable task, especially when, at least in the first instance, only some of the simpler syzygies are required. A better approach would be to start with one of the matrix identities of Sec. IV, multiply this by another matrix such as C or D and take the trace. Provided all the traces can be written in terms of the elements of $\mathscr{J}$, a new syzygy should result. One other method is to start with a known identity and replace one of the matrices, A say, with a ''perturbed'' matrix, $A+\epsilon C$ say. The coefficient of ϵ in this perturbed identity will often be a new identity. This is equivalent to the method of polarization which is well known in invariant theory.[12] Both of these latter methods are used below.

The simplest method for generating syzygies is to start with the matrix identities M^{nn}, multiply by C and take the trace. Each of the trace terms can be expressed in terms of $\mathscr{J}$. Since C is symmetric, the only new identities will come from $M^{nn}{}_s$. Therefore, there will be nine such identities which can be labeled as T_c^{nn}. Initially, they can be regarded as a set of homogeneous, linear equations for the nine invariants

$$
\begin{array}{ccc}
[\overline{\Psi}] & [AC] & [A^2C] \\
[C] & [ABC] & [A^2BC] \\
[BC] & [AB^2C] & [A^2B^2C].
\end{array}
$$

These identities will be subject to the same relationships as the corresponding matrix identities. Thus, only three of them will be independent, and it will be sufficient to consider simply T_c^{44}, T_c^{45} and T_c^{54}. On the other hand, if the invariants $\mathscr{I}$ are known, then $[\overline{\Psi}]$, $[C]$ and $[BC]$ are also known and these identities are linear equations for the six invariants $[AB^mC]$ and $[A^2B^mC]$. The complex conjugates of these equations, denoted by $\overline{T_c^{nn}}$, will be linear equations for $[AB^mC]$ and $[AB^mD]$.

These procedures also follow if we multiply the matrix identities by D and take the trace. The identities T_d^{nn} give equations for $[AB^mD]$ and $[A^2B^mD]$. Their complex conjugates, $\overline{T_d^{nn}}$, are equations for $[A^2B^mC]$ and $[A^2B^mD]$. Altogether, there are twelve equations for twelve unknowns. However, it turns out that only nine of these are independent. Also, none of these equations involves $[A^2BACD]$. This means that at least four more equations are needed.

The next set of identities can be obtained by multiplying the matrix identities by CD and taking the trace. In this case, some work is needed to write some of the traces in terms of the set $\mathscr{I}$, and several of the calculations draw significantly on the work of Spencer and Rivlin. Since $(CD)^T=DC$ and $CD+DC\approx 0$, identities found by this method will effectively come from the skew-symmetric part of the matrix identities, namely $M^{43}{}_a$, $M^{34}{}_a$, $M^{44}{}_a$, etc. These trace identities can be labeled T_{cd}^{43}, T_{cd}^{34} and T_{cd}^{44} and so on. The invariant $[A^2BACD]$ appears linearly in each of these equations and the invariants $[A^nB^mC]$ and $[A^nB^mD]$ appear quadratically. Once again, there will be a chain of identities of identities for these equations, but no attempt has been made to find these.

The other technique that has been successful in obtaining new identities is equivalent to a polarization procedure. Of the several possibilities that were tried, the ''transformation'' $A \rightarrow A+\epsilon C$ seemed to provide the simplest identities. Other choices either did not give new identities, or gave identities of higher degree than have already been found. In carrying out this transformation, the matrices Ψ and $\overline{\Psi}$ were treated as independent, so that C and D were unchanged. The transformation was carried out on each invariant in a given identity and the coefficient of ϵ in the resulting equation then gave a new identity. Also, since A was being transformed into a matrix that was not trace-free, it was neccessary to start with each identity in a form that included $[A]$. $[A]$ could again be set to zero once the new identity had been obtained.

A number of identities have been generated in this fashion. These have been provisionally labeled according the the total degree of Ψ, $K=\Gamma\overline{\Gamma}$ and $\overline{\Psi}$ in the identity. For this purpose, the matrix $C=\Gamma\overline{\Psi}\,\overline{\Gamma}$ was regarded as being of first degree in both K and $\overline{\Psi}$. Thus T^{362} is the name given to the identity generated from T_c^{44} etc. Some care should be taken however, as it is not certain that this notation will identify an identity uniquely in general. Some of the identities obtained from the equations seen so far are

$$
\begin{array}{ll}
T_c^{44}\rightarrow T^{362}, & T_d^{44}\rightarrow T^{363}, \\
T_c^{45}\rightarrow T^{372}, & T_d^{45}\rightarrow T^{373}, \\
T_c^{54}\rightarrow T^{462}, & T_d^{54}\rightarrow T^{463}.
\end{array}
$$

Each of these identities is quadratic in $[A^nB^mC]$ and $[A^nB^mD]$, but none of them contains $[A^2BACD]$. The procedure applied to the equations $\overline{T_c^{nn}}$ gave the null identity, while applied to $\overline{T_d^{nn}}$ it gave identities whose complex conjugates are linear in C and so must be combinations of the identities T_c^{nn}.

Each of these identities could be checked quickly by choosing random numerical values for Ψ and Γ. These were substituted into the LHS of the identity which was then evaluated to check that the result was zero. (This procedure also helped to detect many errors at early stage.)

It remains now to confirm that there are sufficient equations to determine all invariants in $\mathscr{J}$ from a knowledge of $\mathscr{I}$. We start by looking more closely at the structure of some of the identities. Introduce the notation

$$\boldsymbol{u}=\begin{pmatrix}[AC]\\ [ABC]\\ [AB^2C]\end{pmatrix};\quad \boldsymbol{v}=\begin{pmatrix}[A^2C]\\ [A^2BC]\\ [A^2B^2C]\end{pmatrix};\quad \boldsymbol{w}=\begin{pmatrix}[A^2D]\\ [A^2BD]\\ [A^2B^2D]\end{pmatrix},$$

where $\boldsymbol{u}$ and $\boldsymbol{w}$ are real and $\boldsymbol{v}$ is complex. The sets of equations T_c^{nn} and $\overline{T_d^{nn}}$ can then be written as

$$\begin{aligned} M\boldsymbol{u}+N\boldsymbol{v}&=\boldsymbol{s},\\ M\bar{\boldsymbol{v}}+N\boldsymbol{w}&=\boldsymbol{t},\end{aligned} \tag{12}$$

where M and N are matrices whose coefficients are functions of the invariants $\mathscr{I}$, and $\boldsymbol{s}$ and $\boldsymbol{t}$ are vectors of invariants. The expressions for M and N are given in Appendix A. The equations T_{cd}^{nn} have the form

$$d[A^2BACD]+\boldsymbol{v}^TF\bar{\boldsymbol{v}}-\boldsymbol{u}^TF\boldsymbol{w}+\boldsymbol{f}^T\boldsymbol{u}+\boldsymbol{g}^T\boldsymbol{v}+\boldsymbol{h}^T\bar{\boldsymbol{v}}+\boldsymbol{k}^T\boldsymbol{w}=m, \tag{13}$$

where d and m are invariants, F is a matrix and $\boldsymbol{f}$, $\boldsymbol{g}$, $\boldsymbol{h}$ and $\boldsymbol{k}$ are vectors of invariants. Expressions for d and the matrix F for T_{cd}^{34} are given in Appendix A. The equations T^{362} and T^{372} each have the form

$$\boldsymbol{u}^TF\boldsymbol{u}+\boldsymbol{u}^TG\boldsymbol{v}+\boldsymbol{f}^T\boldsymbol{u}+\boldsymbol{g}^T\boldsymbol{v}+\boldsymbol{h}^T\bar{\boldsymbol{v}}=m. \tag{14}$$

The equations in (12) each have about 100 terms. Equations of the type T_{cd}^{nn} and T^{nnn} (at least those that have been calculated) have about 200–300 terms.

Equations (12) show how all the invariants of $\mathscr{J}$ can be determined from only a small number of them. For example, if the three real invariants in $\boldsymbol{u}$ are known, and $\det N\neq 0$, the first equation can be solved to give $\boldsymbol{v}$. Once this is known, the second equation can be solved for $\boldsymbol{w}$. The fact that this value for $\boldsymbol{w}$ must always be real is a further indication that Eqs. (12) must be dependent. Finally, T_{cd}^{34} can be solved to give $[A^2BACD]$.

On the other hand, if only the invariants $\mathscr{I}$ are to be used to find all those in Table I, it will be neccessary to find equations to calculate $\boldsymbol{u}$ first. In principle, this can be done as follows. Equation (12) can be used to write $\boldsymbol{v}=N^{-1}(\boldsymbol{s}-M\boldsymbol{u})$ and $\boldsymbol{w}=N^{-1}\boldsymbol{t}-N^{-1}M\overline{N}^{-1}\overline{\boldsymbol{s}}+N^{-1}M\overline{N}^{-1}\overline{M}\boldsymbol{u}$. These expressions can then be substituted into identities such as T^{362}, T^{372} and T^{462} which are quadratic in $\boldsymbol{u}$, $\boldsymbol{v}$ and $\boldsymbol{w}$. The final result will be a set of three quadratic equations for the three components of $\boldsymbol{w}$. Once these equations are solved, the other invariants can be found. Unfortunately, things are not quite that simple. Trials with specific numerical values for the set $\mathscr{I}$ suggest that the identities T^{362}, T^{372} and T^{462} are actually dependent. The identity T^{363} also does not provide any further information. To obtain an extra equation, $[A^2BACD]$ can be eliminated from T_{cd}^{34} and T_{cd}^{43}. By this means, independent quadratic equations for $[AC]$, $[ABC]$ and $[AB^2C]$ can be obtained. These equations can progressively be reduced to a single eighth degree equation for one of the variables, $[AC]$ say. The eight solutions of this equation can be found numerically.

This procedure was tested by giving random values to the matrices Ψ and Γ and calculating the invariants in $\mathscr{I}$. The above procedures were then followed to calculate the value of $[AC]$ and the other components of $\boldsymbol{u}$ from the values of $\mathscr{I}$ only. The final equation for $[AC]$ will have complex coefficients in general. In those examples tried, typically two or four of the eight solutions of this equation were real—or at least the imaginary part was several orders of magnitude less than the real part. Since $[AC]$ has to be real, these are the only solutions that will be suitable. In each different trial, the ''correct'' value for $[AC]$ was amongst these real solutions. However, in some cases, it wasn't clear that the imaginary part was small enough to deem some of the solutions to be real. It is likely that, in these cases, the set of equations was somewhat ill-conditioned. The situation often improved by increasing the precision of the calculations. Another approach was to use small integer values for the components of Ψ and Γ and then carry out the

calculations using integer arithmetic. Any approximation was delayed until the final step when the eighth degree polynomial was solved. In this fashion, the solutions were either clearly complex, or the order of magnitude of the imaginary part was 10^{-14} times that of the real part. An example of this is given in Appendix B. Despite these numerical difficulties, it is clear that, at least in principle, the invariants $\mathscr{I}$ can be used to determine the invariants in $\boldsymbol{u}$, and then those in Table I, and, consequently, all invariants of even degree in Γ.

One final observation can be made here. The procedures used to solve the equations that give the value of $\boldsymbol{u}$ indicate that the only non-linear equation to be solved is the eighth degree polynomial for $[AC]$. Once this has been solved, the equations needed to calculate $[ABC]$ and $[AB^2C]$ are linear. However, the expressions for these equations in terms of the invariants $\mathscr{I}$ (rather than particular numerical values) will be quite complex.

VII. CONCLUSION

There has been a considerable number of papers directed towards understanding the invariants of the Riemann tensor. It seems that, in some cases at least, these papers have not taken full account of relevant results from invariant theory. One of the purposes of this paper has been to bring some of these results to the attention of other workers in the field. It has been seen that they can be very useful in obtaining a complete set of invariants and the relationships between them.

These results, particularly those of Spencer and Rivlin, have been combined with the idea of expressing the Riemann tensor in terms of matrices in a complex three dimensional space. This has produced a set of invariants of the Riemann tensor which is believed to be complete (at least for invariants that are of even degree in the trace-free Ricci tensor and does not involve the Ricci scalar). At the same time, a large number of syzygies have been found which show how the invariants of this set are related.

The final results are not quite as simple as one might have hoped. It appears that a complete set for the invariants of the Riemann tensor may require 29 elements (if the Ricci scalar is included). This is certainly larger than expected. Also, the syzygies that connect these invariants typically have a few hundred terms. While such equations can be handled easily with modern computer algebra packages, it is still difficult to get any real understanding of them. On the other hand, it appears that the invariants $\mathscr{I}$, together with $\boldsymbol{u}$ and the Ricci scalar will be sufficient to determine all other invariants uniquely in the general case. There are a total of 19 such invariants which is close to the number that Carminati and McLenaghan[11] have estimated will be needed to calculate the other invariants.

ACKNOWLEDGMENTS

This work was carried out while the author was on sabbatical leave at the Queensland University of Technology during the first semester of 1997. I would like to thank Professor Sean McElwain and the School of Mathematics at QUT for their hospitality and the use of their facilities during that period. I am particularly grateful to Rod Gover of QUT for drawing my attention to the relevant work in invariant theory and for a number of illuminating discussions.

APPENDIX A: EXAMPLES OF IDENTITIES

This appendix contains some of the identities that have been found in this paper. This is primarily to give an indication of the nature of these identities, rather than to give a complete list. The full identities are available from the author in an electronic form suitable for input into most computer algebra packages. The identities are written in terms of the determinants of matrices, rather than the trace of the cube. Thus throughout, $[A^3]$ is replaced by the appropriate expression involving $\det A$.

The first equation is the expression for A^2B^2AB in terms of $\mathscr{M}$. It is assumed that $[A]=[B]=0$.

$$
\begin{aligned}
12A^2B^2AB=&\,2B^2AB[A^2]-8AB^2[A^2B]-4B^2A[A^2B]+8A^2B^2[AB]+4B^2A^2[AB]\\
&-4B^2[A^2][AB]+4A^2B[AB^2]-4BA^2[AB^2]\\
&-2A^2BA[B^2]-2A^2[AB][B^2]\\
&+B(2[A^2][AB^2]+2\ \det A[B^2])+AB(8[A^2B^2]-2[A^2][B^2])\\
&+BA(4[A^2B^2]-[A^2][B^2])+A(-2\ \det B[A^2]+4[A^2B][B^2])\\
&+I(4[A^2B^2AB]-8[A^2B^2][AB]+4[A^2B][AB^2]+3[A^2][AB][B^2]).
\end{aligned}
$$

The next group of equations gives four of the identities satisfied by symmetric matrix polynomials. Once again $[A]=[B]=0$. The identity $M^{44}{}_s$ is $S_1=0$ where

$$
\begin{aligned}
6S_1=&\,B^2(-2[A^2B]^2+2[A^2][A^2B^2]-[A^2][AB]^2+6\ \det A[AB^2])\\
&+\tfrac{1}{2}(AB^2+B^2A)(-4\,[A^2B][AB]+2\,[A^2][AB^2]+6\ \det A[B^2])\\
&+\tfrac{1}{2}(A^2B^2+B^2A^2)(-12\,[A^2B^2]+4\,[AB]^2+2\,[A^2][B^2])\\
&+\tfrac{1}{2}(A^2B+BA^2)(6\ \det B[A^2]-4\,[AB][AB^2]+2\,[A^2B][B^2])\\
&+B(-2\ \det B[A^2]^2+2\,[A^2B][A^2B^2]+[A^2][AB][AB^2]\\
&-[A^2][A^2B][B^2]-\det A[AB][B^2])+\tfrac{1}{2}(AB+BA)(-18\ \det A\ \det B\\
&+2\,[A^2B^2][AB]+2\,[A^2B][AB^2]-[A^2][AB][B^2])\\
&+A^2(6\ \det B[A^2B]-2\,[AB^2]^2+2\,[A^2B^2][B^2]-[AB]^2[B^2])\\
&+I(-4\ \det B[A^2][A^2B]+4\,[A^2B^2]^2+6\ \det A\ \det B[AB]\\
&-2\,[A^2B^2][AB]^2+2\,[A^2B][AB][AB^2]-2\,[A^2][A^2B^2][B^2]\\
&+[A^2][AB]^2[B^2]-4\ \det A[AB^2][B^2])+A(-(\det B[A^2][AB])\\
&+2\,[A^2B^2][AB^2]+[A^2B][AB][B^2]-[A^2][AB^2][B^2]-2\ \det A[B^2]^2).
\end{aligned}
$$

The identity $M^{45}{}_s$ is $S_2=0$ where

$$
\begin{aligned}
24\,S_2=&\,\tfrac{1}{2}(A^2B^2+B^2A^2)(-12\ \det B[A^2]+8\,[AB][AB^2]-4\,[A^2B][B^2])\\
&+B^2(4\ \det B[A^2]^2-4\,[A^2B][A^2B^2]-2\,[A^2][AB][AB^2]\\
&+2\,[A^2][A^2B][B^2]+2\ \det A[AB][B^2])+\tfrac{1}{2}(AB^2+B^2A)(36\ \det A\ \det B\\
&-4\,[A^2B^2][AB]-4\,[A^2B][AB^2]+2\,[A^2][AB][B^2])\\
&+B(-4\ \det B[A^2][A^2B]+4\,[A^2B^2]^2-12\ \det A\ \det B[AB]+2\,[A^2][AB^2]^2\\
&-2\,[A^2][A^2B^2][B^2]+2\ \det A[AB^2][B^2])\\
&+\tfrac{1}{2}(AB+BA)(-4\ \det B[A^2][AB]\\
&+8\,[A^2B^2][AB^2]-2\,[A^2][AB^2][B^2]-2\ \det A[B^2]^2)
\end{aligned}
$$

$$
\begin{aligned}
&+\tfrac{1}{2}(A^2B+BA^2)(24\ \det B[A^2B]-8\,[AB^2]^2-4\,[A^2B^2][B^2]+2\,[A^2][B^2]^2)\\
&+A^2(-12\ \det B[A^2B^2]+4\ \det B[AB]^2+8\ \det B[A^2][B^2]\\
&-4\,[AB][AB^2][B^2]\\
&+2\,[A^2B][B^2]^2)+I(-8\ \det B[A^2B]^2+8\ \det B[A^2][A^2B^2]\\
&-12\ \det A\ \det B[AB^2]-4\,[A^2B^2][AB][AB^2]+4\,[A^2B][AB^2]^2\\
&-4\ \det B[A^2]^2[B^2]+4\,[A^2B][A^2B^2][B^2]+2\,[A^2][AB][AB^2][B^2]\\
&-2\,[A^2][A^2B][B^2]^2)+B(-4\ \det B[A^2B][AB]+2\ \det B[A^2][AB^2]\\
&-12\ \det A\ \det B[B^2]+2\,[A^2B^2][AB][B^2]+2\,[A^2B][AB^2][B^2]\\
&-[A^2][AB][B^2]^2).
\end{aligned}
$$

The identity $M^{54}{}_s$ can be deduced from $M^{45}{}_s$ by interchanging A and B. The identity $M^{55}{}_s$ is $S_4=0$, where

$$
\begin{aligned}
12\,S_4=&\tfrac{1}{2}(AB^2+B^2A)(2\ \det B[A^2]^2-8\,[A^2B][A^2B^2]+2\,[A^2][A^2B][B^2]+4\ \det A[AB][B^2])\\
&+\tfrac{1}{2}(A^2B^2+B^2A^2)(-36\ \det A\ \det B+4\,[A^2B^2][AB]+4\,[A^2B][AB^2]\\
&-2\,[A^2][AB][B^2])\\
&+B^2(12\ \det A\ \det B[A^2]-2\,[A^2][A^2B^2][AB]-2\,[A^2][A^2B][AB^2]\\
&+4\ \det A[AB][AB^2]-2\ \det A[A^2B][B^2]+[A^2]^2[AB][B^2])\\
&+B(12\ \det A\ \det B[A^2B]-2\ \det B[A^2]^2[AB]+4\,[A^2][A^2B^2][AB^2]\\
&-4\ \det A[AB^2]^2-2\ \det A[A^2B^2][B^2]-[A^2]^2[AB^2][B^2])\\
&+\tfrac{1}{2}(A^2B+BA^2)(4\ \det B[A^2][AB]-8\,[A^2B^2][AB^2]+2\,[A^2][AB^2][B^2]\\
&+2\ \det A[B^2]^2)+\tfrac{1}{2}(AB+BA)(4\ \det B[A^2][A^2B]+8\,[A^2B^2]^2-24\ \det A\ \det B[AB]\\
&-6\,[A^2][A^2B^2][B^2]+4\ \det A[AB^2][B^2]+[A^2]^2[B^2]^2)+A(-4\ \det B[A^2B]^2\\
&-2\ \det B[A^2][A^2B^2]+12\ \det A\ \det B[AB^2]+4\,[A^2B][A^2B^2][B^2]\\
&-[A^2][A^2B][B^2]^2-2\ \det A[AB][B^2]^2)+A^2(4\ \det B[A^2B][AB]\\
&-2\ \det B[A^2][AB^2]+12\ \det A\ \det B[B^2]-2\,[A^2B^2][AB][B^2]\\
&-2\,[A^2B][AB^2][B^2]+[A^2][AB][B^2]^2)+I(12\ \det A\ \det B[A^2B^2]\\
&-4\ \det B[A^2][A^2B][AB]-4\,[A^2B^2]^2[AB]+8\ \det A\ \det B[AB]^2\\
&+4\,[A^2B][A^2B^2][AB^2]-8\ \det A\ \det B[A^2][B^2]+4\,[A^2][A^2B^2][AB][B^2]\\
&-4\ \det A[AB][AB^2][B^2]-[A^2]^2[AB][B^2]^2).
\end{aligned}
$$

The equations T_c^{nn} and T_d^{nn} are given by Eq. (12). The matrices M and N in those equations are as follows:

$$72M_{11} = -12\det B[A^2][AB] + 24[A^2B^2][AB^2] + 72\det A\ \det B[B] - 24[A^2B^2][AB][B]$$
$$-24[A^2B][AB^2][B] + 12[A^2B][AB][B]^2 + 12[A^2][AB^2][B]^2 - 6[A^2][AB][B]^3$$
$$-12\det A[B]^4 + 12[A^2B][AB][B^2] - 12[A^2][AB^2][B^2] + 6[A^2][AB][B][B^2]$$
$$+36\det A[B]^2[B^2] - 24\det A[B^2]^2,$$

$$72M_{12} = -216\det A\ \det B + 24[A^2B^2][AB] + 24[A^2B][AB^2] - 24[A^2][AB^2][B]$$
$$+12[A^2][AB][B]^2 + 36\det A[B]^3 - 12[A^2][AB][B^2] - 84\det A[B][B^2],$$

$$72M_{13} = -48[A^2B][AB] + 24[A^2][AB^2] - 24\det A[B]^2 + 72\det A[B^2],$$

$$72M_{21} = -12\det B[A^2B][AB] + 6\det B[A^2][AB^2] + 4\det B[A^2][AB][B]$$
$$-8[A^2B^2][AB^2][B] + 24\det A\ \det B[B]^2 + 2[A^2B^2][AB][B]^2$$
$$+2[A^2B][AB^2][B]^2 + 2[A^2B][AB][B]^3 - [A^2][AB^2][B]^3 - [A^2][AB][B]^4$$
$$-2\det A[B]^5 - 36\det A\ \det B[B^2] + 6[A^2B^2][AB][B^2]$$
$$+6[A^2B][AB^2][B^2]$$
$$-10[A^2B][AB][B][B^2] + [A^2][AB^2][B][B^2] + 4[A^2][AB][B]^2[B^2]$$
$$+6\det A[B]^3[B^2] - 3[A^2][AB][B^2]^2 - 4\det A[B][B^2]^2,$$

$$72M_{22} = -12\det B[A^2][AB] + 24[A^2B^2][AB^2] - 72\det A\ \det B[B] - 8[A^2B^2][AB][B]$$
$$-8[A^2B][AB^2][B] + 2[A^2][AB^2][B]^2 + 2[A^2][AB][B]^3 + 6\det A[B]^4$$
$$-6[A^2][AB^2][B^2] - 2[A^2][AB][B][B^2] - 8\det A[B]^2[B^2] - 6\det A[B^2]^2,$$

$$72M_{23} = 108\det A\ \det B - 12[A^2B^2][AB] - 12[A^2B][AB^2] + 16[A^2B][AB][B]$$
$$+4[A^2][AB^2][B] - 6[A^2][AB][B]^2 - 10\det A[B]^3 + 6[A^2][AB][B^2]$$
$$+18\det A[B][B^2],$$

$$72M_{31} = 6\det\ B[A^2][A^2B] + 12[A^2B^2]^2 - 36\det A\ \det B[AB] - 24[A^2B][A^2B^2][B]$$
$$+6[A^2B]^2[B]^2 + 6[A^2][A^2B^2][B]^2 + 12\det A[AB^2][B]^2 - 3[A^2][A^2B][B]^3$$
$$-6\det A[AB][B]^3 + 6[A^2B]^2[B^2] - 6[A^2][A^2B^2][B^2] - 12\det A[AB^2][B^2]$$
$$+3[A^2][A^2B][B][B^2] + 6\det A[AB][B][B^2],$$

$$72M_{32} = -6\det B[A^2]^2 + 24[A^2B][A^2B^2] - 48\det A[AB^2][B] - 6[A^2][A^2B][B]^2$$
$$+36\det A[AB][B]^2 + 3[A^2]^2[B]^3 - 6[A^2][A^2B][B^2] - 12\det A[AB][B^2]$$
$$-3[A^2]^2[B][B^2],$$

$$72M_{33} = -24[A^2B]^2 - 12[A^2][A^2B^2] + 72\det A[AB^2] + 24[A^2][A^2B][B]$$
$$-48\det A[AB][B] - 6[A^2]^2[B]^2 + 6[A^2]^2[B^2].$$

$$72N_{11}=72\det B[A^2B]-24\,[AB^2]^2-48\det B[A^2][B]+48\,[AB][AB^2][B]$$
$$-24\,[A^2B^2][B]^2-12\,[AB]^2[B]^2+12\,[A^2B][B]^3+24\,[A^2B^2][B^2]$$
$$-12\,[AB]^2[B^2]-12\,[A^2B][B][B^2],$$

$$72N_{12}=72\det B[A^2]-48\,[AB][AB^2]+96\,[A^2B^2][B]-72\,[A^2B][B]^2+12\,[A^2][B]^3$$
$$+24\,[A^2B][B^2]-12\,[A^2][B][B^2],$$

$$72N_{13}=-144\,[A^2B^2]+48\,[AB]^2+96\,[A^2B][B]-24\,[A^2][B]^2+24\,[A^2][B^2],$$

$$72N_{21}=-36\det B[A^2B^2]+12\det B[AB]^2+8\,[AB^2]^2[B]-8\det B[A^2][B]^2$$
$$-4\,[AB][AB^2][B]^2+2\,[A^2B^2][B]^3-2\,[AB]^2[B]^3+2\,[A^2B][B]^4$$
$$+24\det B[A^2][B^2]-12\,[AB][AB^2][B^2]$$
$$-2\,[A^2B^2][B][B^2]+10\,[AB]^2[B][B^2]$$
$$-8\,[A^2B][B]^2[B^2]+6\,[A^2B][B^2]^2,$$

$$72N_{22}=72\det B[A^2B]-24\,[AB^2]^2+16\,[AB][AB^2][B]+4\,[A^2B^2][B]^2-12\,[A^2B][B]^3$$
$$+2\,[A^2][B]^4-12\,[A^2B^2][B^2]+28\,[A^2B][B][B^2]-8\,[A^2][B]^2[B^2]+6\,[A^2][B^2]^2,$$

$$72N_{23}=-36\det B[A^2]+24\,[AB][AB^2]-16\,[AB]^2[B]+4\,[A^2B][B]^2+2\,[A^2][B]^3$$
$$-12\,[A^2B][B^2]-2\,[A^2][B][B^2],$$

$$72N_{31}=6\det B[A^2][AB]-12\,[A^2B^2][AB^2]-36\det A\ \det B[B]+12\,[A^2B^2][AB][B]$$
$$+12\,[A^2B][AB^2][B]-6\,[A^2B][AB][B]^2-6\,[A^2][AB^2][B]^2+3\,[A^2][AB][B]^3$$
$$+6\det A[B]^4-6\,[A^2B][AB][B^2]+6\,[A^2][AB^2][B^2]-3\,[A^2][AB][B][B^2]$$
$$-18\det A[B]^2[B^2]+12\det A[B^2]^2,$$

$$72N_{32}=108\det A\ \det B-12\,[A^2B^2][AB]-12\,[A^2B][AB^2]+12\,[A^2][AB^2][B]$$
$$-6\,[A^2][AB][B]^2-18\det A[B]^3+6\,[A^2][AB][B^2]+42\det A[B][B^2],$$

$$72N_{33}=24\,[A^2B][AB]-12\,[A^2][AB^2]+12\det A[B]^2-36\det A[B^2].$$

The equation for T^{34}_{cd} is given by (13). The expressions for d and F in that equation are as follows:

$$54\,d=-54\det B+5\,[B]^3-9\,[B][B^2],$$

$$54F=\begin{pmatrix}[B]^4-5\,[B]^2[B^2]+6\,[B^2]^2, & -[B]^3+3\,[B][B^2], & 3\,[B]^2-9\,[B^2]\\ -[B]^3+3\,[B][B^2], & -3\,[B]^2+9\,[B^2], & 0\\ 3\,[B]^2-9\,[B^2], & 0, & 0\end{pmatrix}.$$

APPENDIX B: AN EXAMPLE FOR CALCULATING $\mathscr{J}$ FROM $\mathscr{I}$

The following is a simple example of the calculation of the invariants $\boldsymbol{u}$ from a knowledge of those in $\mathscr{I}$. The following values were chosen for Ψ and Γ,

$$\Psi=\begin{pmatrix} -2i, & 2, & i \\ 2, & 1-2i, & -i \\ i, & -i, & -1+4i \end{pmatrix};\quad \Gamma=\begin{pmatrix} ; & -2, & i, & 1+2i \\ ; & -i, & 0, & -2-2i \\ & 1-2i, & -2+2i, & -1 \end{pmatrix}.$$

Calculation of the invariants $\mathscr{I}$ gives the following:

$$[\Psi^2]=-18-12i \qquad \det\Psi=21-34i$$
$$[K]=-3 \qquad [\Psi K]=83-12i \qquad [\Psi^2K]=-66+198i$$
$$[K^2]=-195 \quad [\Psi K^2]=-114-254i \quad [\Psi^2K^2]=2979-374i$$
$$\det K=169.$$

The task now is to find the value of $[AC]$ using the values of these invariants, and not the values of Ψ and Γ. The solutions of Eq. (12) can be approximated to give

$$[A^2C]=889.895-544.891i+(0.0612686-0.00125164i)[AB^2C]$$
$$-(0.423424-0.132449i)[ABC]+(2.95822+0.328379i)[AC],$$
$$[A^2BC]=-5473.47+3719.81i+(0.211712-0.0662243i)[AB^2C]$$
$$+(1.37951-0.0107651i)[ABC]+(28.8703-6.90351i)[AC],$$
$$[A^2B^2C]=39493.2+21031.8i-(6.14016-0.514248i)[AB^2C]$$
$$+(5.13792-5.86159i)[ABC]-(384.532-22.5566i)[AC],$$
$$[A^2D]=889.895+544.891i+(0.0612686+0.00125164i)[AB^2C]$$
$$-(0.423424+0.132449i)[ABC]+(2.95822-0.328379i)[AC],$$
$$[A^2BD]=-5473.47-3719.81i+(0.211712+0.0662243i)[AB^2C]$$
$$+(1.37951+0.0107651i)[ABC]+(28.8703+6.90351i)[AC],$$
$$[A^2B^2D]=39493.2-21031.8i-(6.14016+0.514248i)[AB^2C]$$
$$+(5.13792+5.86159i)[ABC]-(384.532+22.5566i)[AC].$$

These can be substituted into T^{34}_{cd}, T^{43}_{cd}, T^{362} and T^{372} to give the following equations for $[AC]$, $[ABC]$ and $[AB^2C]$:

$$0=1.23009\ 10^9-2.99669\ 10^9i+(27126.9-57662.\ i)[AB^2C]$$
$$+(2.40324-1.10915\ i)[AB^2C]^2-(740633.-1.654\ 10^6\ \ i)[ABC]$$
$$+(6.79429-5.6801\ i)[AB^2C][ABC]+(131.37-262.435\ i)[ABC]^2$$
$$+(682518.-1.17136\ 10^6\ \ i)[AC]+(375.736-569.387\ i)[AB^2C][AC]$$
$$+(841.824-1576.45\ i)[ABC][AC]+(12572.-26212.1\ i)[AC]^2,$$
$$0=-1.835\ 10^9-2.75287\ 10^8\ \ i+(132810.+267227.\ i)[AB^2C]$$
$$-(1.40933+0.621754\ i)[AB^2C]^2+(1.79147\ 10^6+382792.\ i)[ABC]$$
$$-(60.9006+75.3397\ i)[AB^2C][ABC]-(439.4-0.988063\ i)[ABC]^2$$

$$+(1.88299\,10^{7}-2.54068\,10^{6}\ i)[AC]-(256.321+234.499\,i)[AB^{2}C][AC]$$
$$-(7861.13-2139.7\,i)[ABC][AC]-(12470.5+20978.4\,i)[AC]^{2},$$
$$0=2.63922\,10^{11}-2.21063\,10^{11}i-(9.04512\,10^{6}-7.57629\,10^{6}\ i)[AB^{2}C]$$
$$+(73.4438-61.5173\,i)[AB^{2}C]^{2}-(2.00194\,10^{8}-1.67685\,10^{8}\ i)[ABC]$$
$$+(3972.51-3327.41\,i)[AB^{2}C][ABC]+(38266.4-32052.3\,i)[ABC]^{2}$$
$$-(6.72171\,10^{8}-5.63018\,10^{8}\ i)[AC]+(30039.6-25161.5\,i)[AB^{2}C][AC]$$
$$+(316964.-265492.\,i)[ABC][AC]+(1.88052\,10^{6}-1.57514\,10^{6}\ i)[AC]^{2}.$$

These equations can be reduced to the following eighth degree polynomial for $[AC]$:

$$0=6.57264-9.68351\,i+(0.286771-0.270973\,i)[AC]$$
$$+(0.00323485-0.00165287\,i)[AC]^{2}-(4.05461\,10^{-6}$$
$$-0.0000112074\,i)[AC]^{3}$$
$$-(2.04805\,10^{-7}-1.05828\,10^{-7}i)[AC]^{4}-(1.50569\,10^{-10}$$
$$+2.43893\,10^{-10}i)[AC]^{5}$$
$$+(6.7192\,10^{-12}-3.54656\,10^{-12}i)[AC]^{6}+(1.85497\,10^{-14}$$
$$-7.37274\,10^{-15}i)[AC]^{7}$$
$$-(1.04906\,10^{-17}+1.30311\,10^{-18}i)[AC]^{8}.$$

The solutions of this polynomial for $[AC]$ are

$$\begin{array}{cc}-187.475-4.76682\,i & -154.602\\ -114.192+40.8714\,i & -89.+2.85274\,10^{-13}\ i\\ -62.7669+21.187\,i & 142.82+62.1616\,i\\ 142.82-62.1616\,i & 1977.78-965.713\,i.\end{array}$$

The only real values are -154.602 and $-89.+2.85274\,10^{-13}\ i$ (which is deemed to be real). The corresponding values for $[ABC]$ and $[AB^{2}C]$ can be calculated from the earlier equations. The value of -89 is the ''correct'' value, and will lead to the correct values for the other invariants.

On a class of distributions of interest in quantum field theory

Launey J. Thomas, III and Eyvind H. Wichmann
Department of Physics, University of California, Berkeley, California 94720

(Received 13 February 1997; accepted for publication 11 November 1997)

A class of tempered distributions studied by Araki is considered. These distributions are of interest in quantum field theory since they include certain matrix elements of commutators or anticommutators of local quantum field operators. A number of results concerning the null regions in spacetime of such distributions are presented, for the cases when the null regions are causal complements of closed, convex, causally complete subsets of spacetime. Applications to quantum field theory are discussed, and some immediate applications to the theory of the Klein–Gordon equation and the wave equation are noted. © *1998 American Institute of Physics.* [S0022-2488(98)03103-X]

I. INTRODUCTION

In this paper we will discuss a class of tempered distributions (on test functions on Minkowski spacetime) which have been discussed before by Araki.[1] They are of great interest in quantum field theory, and also in the theory of the wave equation and the Klein–Gordon equation. We will discuss applications to quantum field theory in this paper (in Section V), within the framework formulated by Wightman and others.[2–5] In a subsequent paper we will discuss applications to the theory of *local nets* of von Neumann algebras.[5,6] Many of the results in the present paper apply with minor modifications to the theory of local nets.

This work incorporates a number of results from the doctoral thesis of one of us (L. J. T.).[7]

For the formulation and study of the conditions of causality and local independence in quantum field theory the *causal structure* of Minkowski spacetime is of great importance. In an earlier paper,[8] *hereafter referred to as* TW-I, we have discussed the geometry of Minkowski spacetime and its causal structure in considerable detail. For the reader's convenience, and in order to establish notation, we briefly review some basic notions. Minkowski spacetime M is parametrized by the usual Cartesian coordinates $x=(x_1,x_2,x_3,x_4)=(\mathbf{x},t)$, with $t=x_4$ and $\mathbf{x}=(x_1,x_2,x_3)$, with reference to some particular inertial frame. The Minkowski scalar product is denoted $x\cdot y=x_4y_4-\mathbf{x}\cdot\mathbf{y}$, where $\mathbf{x}\cdot\mathbf{y}$ is the usual scalar product on the Euclidean subspace R^3. If R is any subset of M, we denote the closure of R by $\overline{R}$, the interior of R by R^o, the complement of R by $\widetilde{R}$, and the boundary of R by ∂R. The *causal complement* R^c of R is defined as the set of all points of M which are spacelike relative to all points of R. The set $R^{cc}=(R^c)^c$ is called the *causal completion of* R, and we say that a subset R of M is *causally complete* if and only if $R^{cc}=R$. For a detailed discussion of these notions we refer to TW-I.[8] (See, in particular, Section II of the quoted paper.) We here recall some notions which are basic for the present paper.

Definition 1.1: (a) For any $x\in\mathsf{M}$ we denote by $V_+(x)$ the *open forward lightcone* with x as apex, and we denote by $V_-(x)$ the *open backward lightcone* with x as apex.

(b) We denote by $\mathscr{W}$ the set of all open wedge-regions W which are Poincaré-equivalent with the particular wedge-region $W_R=\{x|x_3>|x_4|\}$, i.e., an element $W\in\mathscr{W}$ is any open subset of M bounded below by a characteristic plane π' and bounded above by another characteristic plane π'' not parallel with π'. We write $W(\pi',\pi'')$ for such a wedge in $\mathscr{W}$. We employ the term *causal wedge* for any $W\in\mathscr{W}$ or for its closure $\overline{W}$.

(c) For any two points $x,y\in\mathsf{M}$ such that $y\in V_+(x)$ we define the *closed double cone* $D(x,y)$ with x and y as apices by $D(x,y)=\overline{V}_+(x)\cap\overline{V}_-(y)$, and we denote by $\mathscr{D}$ the set of all such double cones. Note that with this definition every double cone $D\in\mathscr{D}$ has a nonempty interior. The intersection $\partial V_-(y)\cap\partial V_+(x)$ is contained in a unique spacelike plane σ, and it can be regarded

 © 1998 American Institute of Physics

as a sphere. The set $B=\sigma\cap D(x,y)$ is called the *base* of the closed double cone $D(x,y)$, and the set $B_o=\sigma\cap D(x,y)^o$ is the base of the open double cone $D(x,y)^o$.

(d) We define $\mathscr{K}_E$ as the set of all *closed, convex, causally complete* subsets K of M which satisfy the condition that there exist four characteristic planes π_1,π_2,π_3 and π_4 in a *general relative position*, i.e., the normals of these planes are linearly independent, such that K lies *below* π_1 and π_2 and *above* π_3 and π_4.

(e) We define the subset $\mathscr{K}_C$ of $\mathscr{K}_E$ as the set of all *compact* sets $K\in\mathscr{K}_E$, i.e., $\mathscr{K}_C$ is the set of all *compact, convex, causally complete* subsets of M. We regard the empty set $\varnothing$ as an element of $\mathscr{K}_C\subset\mathscr{K}_E$. We have $\mathscr{D}\subset\mathscr{K}_C$.

We say that two wedges W_1 and W_2 are in a *general relative position* if the four boundary planes are in a general relative position. We easily see that the set $\mathscr{K}_E$ can also be described as follows. A closed, convex, and causally complete set K is in $\mathscr{K}_E$ if and only if there exist two wedges $W_1,W_2\in\mathscr{W}$ in a general relative position such that $K\subset W_1\cap W_2$. We note that the sets $\mathscr{K}_E$ and $\mathscr{K}_C$ are closed under intersections (in contrast to what the situation is for the set $\mathscr{D}$ of double cones). Furthermore, if $K\subset\mathsf{M}$ is closed, convex, and causally complete, then $K\cap K_e\in\mathscr{K}_E$ if $K_e\in\mathscr{K}_E$, and $K\cap K_c\in\mathscr{K}_C$ if $K_c\in\mathscr{K}_C$. We also note that the sets $\mathscr{K}_E$ and $\mathscr{K}_C$ include subsets K of M with empty interiors. For a detailed discussion of the sets in $\mathscr{K}_E$ we refer to Section III in TW-I.[8]

In Section II we discuss general features of a class of tempered distributions studied by Araki.[1] We denote this class, specified in Definition 2.1, by $\mathscr{S}'_A(\mathsf{M})$. These distributions appear in quantum field theory in the following context. Let X be a local field operator and let $X(x)=T(x)XT(x)^{-1}$ be the translated operator obtained from X by a conjugation with the unitary operator $T(x)$ representing a translation by x. Let Y be some other operator, and let Φ_1 and Φ_2 be two vectors in the Hilbert space $\mathscr{H}$ of physical states with *compact* support in momentum space. The matrix element $\langle\Phi_1|[Y,X(x)]\Phi_2\rangle=\xi(x)$ is then a function on M which can be regarded as a distribution in the class $\mathscr{S}'_A(\mathsf{M})$. We have here ignored questions of domains for the possibly unbounded operators: in Section V we give a more cautious formulation. The support of the Fourier transform $\hat{\xi}(p)$ of $\xi(x)$ is then contained in the union of some forward lightcone and some backward lightcone in momentum space, and if the operator Y is in some sense ''local,'' then the *null region* $N(\xi)$ of the matrix element $\xi(x)$ is, in general, nonempty. Matrix elements of this kind have been much studied in the past, and we note here the papers by Jost and Lehmann[9] and by Dyson.[10] In our paper we follow the approach of Araki,[1] since our geometrical considerations are similar in spirit to the considerations in his paper. We are concerned with the following kind of problem. Given that the null region of $\xi(x)$ contains a subset S of M, where else does $\xi(x)$ vanish? This problem was also central in Araki's paper, in which a partial solution was given. His main result is here quoted in Lemma 2.7 in Section II. The ultimate aim is to determine the null region of the *commutator* $[Y,X(x)]$, and to get a handle on this problem one considers matrix elements of the above nature. If we consider *vacuum expectation values* of the commutator $[Y,X(x)]$, we are led to a class of *special* Araki distributions $\xi(x)$ for which the support of the Fourier transform $\hat{\xi}(p)$ is contained in the lightcone.

In the case of two fermion operators one considers anticommutators instead of commutators, but the corresponding modifications in the theory are of a trivial nature.

A solution $\psi(x)$ of the Klein–Gordon equation (or the wave equation) can be regarded as an element of $\mathscr{S}'_A(\mathsf{M})$ provided that it satisfies certain growth conditions in the asymptotic region. Every result about the nature of the support of a distribution in $\mathscr{S}'_A(\mathsf{M})$ thus applies to ''asymptotically well-behaved'' solutions of the Klein–Gordon equation. Concerning the null region of an ordinary solution of the Klein–Gordon equation there are certain ''classical'' principles which have been known for a long time, namely the following: I) If $\psi(x)$ vanishes on a neighborhood of a timelike (straight) line segment, then $\psi(x)$ also vanishes on the double cone with the endpoints of the segment as apices. II) If $\psi(x)$ and its gradient vanishes on the base of an open double cone, then $\psi(x)$ also vanishes on the open double cone.[11] In view of these principles it is natural to define an ''envelope'' $\mathscr{E}(S)$ of any open $S\subset\mathsf{M}$ as the smallest subset of M which contains S, and which contains an open double cone $D^o=D(x',x'')^o$ if it contains either the base of D^o or the line segment (x',x''). If $\psi(x)$ is a solution of the Klein–Gordon equation, we thus have the result that $N(\psi)\supset\mathscr{E}(S)$ whenever $N(\psi)\supset S$. The first one of the above ''classical'' principles also applies to

the distributions in $\mathscr{S}'_A(\mathsf{M})$, but the second principle does not apply in general, i.e., it is not true that if S is an arbitrary open subset of M on which a distribution $\xi(x) \in \mathscr{S}'_A(\mathsf{M})$ vanishes, then also $N(\xi) \supset \mathscr{E}(S)$. Araki's theory leads to a set-mapping $S \to a(S)$ of open sets to open sets such that $N(\xi) \supset a(S)$ whenever $N(\xi) \supset S$, and in general the set $a(S)$ is *smaller* than $\mathscr{E}(S)$. For any open subset S of M we thus have three different ''envelopes:'' the *Araki envelope* $a(S)$, the *envelope of uniqueness* $\mathscr{E}(S)$, and the causal completion S^{cc} of S. In Section II we show that we always have $S \subset a(S) \subset \mathscr{E}(S) \subset (S^{cc})^o$. Hence we have $S = a(S) = \mathscr{E}(S)$ if S is *causally complete.*

Much of the discussion in this paper depends on the following general result stated in Theorem 2.11. If $S = \cup\{S_\alpha | \alpha \in \mathscr{T}\}$ is the union of any family of open sets S_α, such that for each α in the index set $\mathscr{T}$ the set S_α consists of all points which lie *below* a characteristic plane π''_α and *above* a characteristic plane π'_α, then $a(S) = \mathscr{E}(S)$. In particular this result applies if S is the union of any family of wedges in $\mathscr{W}$. Section III is devoted to a discussion of this situation. The issue is now under what *additional* premises can we conclude that $\mathscr{E}(S) = (S^{cc})^o$, and hence that $a(S) = (S^{cc})^o$. For a variety of sets $S \subset \mathsf{M}$ it is the case that $\mathscr{E}(S) = (S^{cc})^o$, and these sets are thus of particular interest, but this relation does not hold generally, as we show by examples. Theorem 3.6 and Propositions 3.8 and 3.9 are our main results in Section III. The most important part of Theorem 3.6 says that if $\mathscr{F}$ is any family of wedges in $\mathscr{W}$ which contains at least two wedges in a general relative position, then $a(S) = \mathscr{E}(S) = S^{cc}$, with $S = \cup\{W | W \in \mathscr{F}\}$. Furthermore we have $S^c \in \mathscr{K}_E$. The same conclusions hold in certain other cases, as stated in Theorem 3.6 and Proposition 3.8. These results are optimal, in the sense described in Proposition 4.4 in Section IV. In Proposition 3.9 we state and prove an ''intersection property.'' In particular, if $K_1, K_2 \in \mathscr{K}_E$, then $a(K_1^c \cup K_2^c) = (K_1 \cap K_2)^c$. Note that we have $a(K_1^c) = K_1^c$ and $a(K_2^c) = K_2^c$ since K_1^c and K_2^c are causally complete. The relation $a(K_1^c \cup K_2^c) = (K_1 \cap K_2)^c$ does *not* hold for two arbitrary closed causally complete subsets K_1 and K_2 of M, as we show by Example 4.10 in Section IV.

In Section IV we consider solutions of the Klein–Gordon equation (for an arbitrary mass $m \geqslant 0$), including the special case of the wave equation (with $m = 0$). A solution $\psi(x)$ which does not grow too rapidly as x tends to infinity can be regarded as a distribution in $\mathscr{S}'_A(\mathsf{M})$, and all of our results in Section III are directly applicable to the study of the support of $\psi(x)$. We present a few rather trivial conclusions of this category, but our purpose is not to enrich the theory of the Klein–Gordon equation, but rather to illustrate the general results in Sections II and III. The solutions of this equation provide concrete and tangible examples, as well as counterexamples against unwarranted ''extensions.''

In Proposition 4.4 and Example 4.5 (which concern solutions of the Klein–Gordon equation) we show that the largest *common* null region $\nu(S)$ of *all* distributions $\xi \in \mathscr{S}'_A(\mathsf{M})$ which vanish on an open set S can never be larger than $(S^{cc})^o$. It can, of course, be equal to $(S^{cc})^o$ since $a(S) = \mathscr{E}(S) = S$ if S is causally complete. Example 4.7 shows that for an arbitrary open set S the set $a(S)$ is in general smaller than $\mathscr{E}(S)$.

The solutions $\psi(x)$ of the Klein–Gordon equation in $\mathscr{S}'_A(\mathsf{M})$ have the property, not shared by Araki distributions in general, that $\psi(x) = 0$ on $\mathscr{E}(S)$ if $\psi(x) = 0$ on S. Moreover, a solution $\psi(x)$ is determined everywhere by the initial data on a suitable spacelike surface, and the initial data in two disjoint closed subsets of the surface are independent. Examples 4.18 and 4.19 illustrate some implications of these features for a solution of the Klein–Gordon equation for $m > 0$. We have $\psi(x) = 0$ on certain open sets $S = \mathscr{E}(S)$, and we show that in these cases we have $\psi(x) = 0$ on S^{cc} although $\mathscr{E}(S)$ is strictly smaller than S^{cc}. In Example 4.19, S is the union of two disjoint sets S_1 and S_2 such that $\mathscr{E}(S_1) = S_1$ and $\mathscr{E}(S_2) = S_2$. Both S_1 and S_2 are null regions for some solutions, but their union is not.

The class of special Araki distributions $\xi(x)$ mentioned before, for which the support of $\hat{\xi}(p)$ is contained in the lightcone, are somewhat more akin to solutions of the Klein–Gordon equation than the general Araki distributions. We present some results for these special distributions which do not hold for arbitrary distributions in $\mathscr{S}'_A(\mathsf{M})$. In Lemma 4.12 we consider an Araki distribution $\xi(x)$ such that the support of $\hat{\xi}(p)$ is contained in the *open* lightcone $V(0)$, and we prove that if $\xi(x)$ vanishes on an open ''tube-region'' with an isotropic ''axis,'' then $\xi(x)$ vanishes *identically*. In Lemma 4.14 we show that if $\xi(x)$ vanishes on the region obtained when a bounded portion is removed from the above tube-region, then $\xi(x)$ vanishes identically, *provided* that $\xi(x)$ now satisfies the slightly stronger condition that $\mathrm{supp}(\hat{\xi}(p)) \subset \{p | p \cdot p \geqslant m^2\}$ for some $m > 0$.

In Section V we discuss various applications of the results in Sections II–IV to quantum field theory. Specifically we consider the *weak commutant* $\mathscr{P}_0(R)^w$ of the algebra $\mathscr{P}_0(R)$ of all quantum field operators associated with various regions $R\subset\mathsf{M}$. The set $\mathscr{P}_0(R)^w$ is a weakly closed linear manifold of *bounded* operators B which satisfy the weak commutation relations $X^{**}B\supset BX$ and $X^{**}B^*\supset B^*X$ for all $X\in\mathscr{P}_0(R)$. It is not known at present whether the weak commutants are (nontrivial) von Neumann algebras without additional conditions on the quantum fields, but if they are, they define a local net of von Neumann algebras with which the field operators are affiliated. Results about weak commutants are thus relevant for the theory of local nets, which is one reason why we discuss these objects here.

The necessary and sufficient condition for a bounded operator B to be in $\mathscr{P}_0(R)^w$ is that certain expressions of the form $\langle B^*\Phi'|\varphi_\mu(x)\Phi''\rangle-\langle\varphi_\mu^\dagger(x)\Phi'|B\Phi''\rangle$ must vanish on R^o. Here Φ' and Φ'' are arbitrary vectors of *compact* support in momentum space, and the expressions are then Araki distributions. The results in Sections II and III are thus applicable when we try to determine the largest region R_e such that $B\in\mathscr{P}_0(R_e)^w$ whenever $B\in\mathscr{P}_0(R)^w$, for a given $R\subset\mathsf{M}$. In particular we have $\mathscr{P}_0(S)^w=\mathscr{P}_0(a(S))^w$ for any open S (Lemma 5.6), and hence $\mathscr{P}_0(S)^w=\mathscr{P}_0(\mathscr{E}(S))^w$ whenever $\mathscr{E}(S)=a(S)$, and $\mathscr{P}_0(S)^w=\mathscr{P}_0(S^{cc})^w$ whenever $(S^{cc})^o=a(S)$.

If $K\subset\mathsf{M}$ is a closed causally complete set, it is rather natural to associate the weak commutant $\mathscr{P}_0(K^c)^w$ with K, and hence we write $\mathscr{C}(K)=\mathscr{P}_0(K^c)^w$. In Propositions 5.8 and 5.9 we state some obvious properties of the objects $\mathscr{C}(K)$. We are particularly interested in the case when K is also convex. Theorems 5.10 and 5.11 are main results in Section V. The most important part of Theorem 5.10 states that if $\mathscr{F}$ is any family of wedges in $\mathscr{W}$ which contains at least two wedges in a general relative position, then $\mathscr{C}(K)=\cap\{\mathscr{C}(W^c)|W\in\mathscr{F}\}$, with $K=\cap\{W^c|W\in\mathscr{F}\}$. Or, equivalently stated, $\mathscr{P}_0(S^{cc})^w=\mathscr{P}_0(S)^w$, with $S=\cup\{W|W\in\mathscr{F}\}=K^c$, since we trivially have $\mathscr{P}_0(S)^w=\cap\{\mathscr{P}_0(W)^w|W\in\mathscr{F}\}$. Theorem 5.11 also states an ''intersection property.'' In particular, if $K_1,K_2\in\mathscr{K}_E$, then $K_1\cap K_2\in\mathscr{K}_E$ and $\mathscr{C}(K_1\cap K_2)=\mathscr{C}(K_1)\cap\mathscr{C}(K_2)$. This relation most definitely does not hold for two *arbitrary* closed causally complete subsets of M. We show this by counterexamples within the theory of a single free Hermitian scalar field (see Example 5.13 and Proposition 5.18). The theory of a free scalar field is closely related to the theory of the Klein–Gordon equation, and the examples and counterexamples in Section V are based on the examples and counterexamples in Section IV, in the manner explained in Lemma 5.12.

We also consider vacuum expectation values of commutators, corresponding to the ''special'' Araki distributions discussed in Section IV. Theorem 5.16, Lemma 5.17 and Proposition 5.18 are proved on the basis of properties of these special distributions. These results *cannot* be obtained on the basis of the results in Sections II and III alone: the proofs depend on additional features of a quantum field theory. Proposition 5.18 concerns the weak commutants of the field operators associated with two wedges W_1 and W_2 in $\mathscr{W}$, and it gives a complete description of the cases which can occur.

We conclude Section V by showing, in Example 5.20, that the weak commutant $\mathscr{C}(K)$ for a compact, convex, causally complete set $K\subset\mathsf{M}$ with an *empty* interior can be nontrivial. The relevant example is within the theory of a free scalar field.

In Section VI we make some general remarks about our results, and about the limitations of our methods, which are based on very general features of quantum field theories. Whether such a general theory always satisfies a physically reasonable condition of causality is not known. One might suspect that what is missing is some kind of ''dynamical principle'' which would imply a strong condition of causality.

II. ON A CLASS OF TEMPERED DISTRIBUTIONS DISCUSSED BY ARAKI

We denote by $\mathscr{S}'(\mathsf{M})$ the set of all tempered distributions defined on the set $\mathscr{S}(\mathsf{M})$ of Schwartz functions $f(x)$ on Minkowski spacetime. For any $\xi(x)\in\mathscr{S}'(\mathsf{M})$ we define the Fourier transform $\hat{\xi}(p)$ (which is also a tempered distribution) by

$$\hat{\xi}(p)=\frac{1}{(2\pi)^2}\int_{(\infty)}d^4(x)\,\xi(x)\,\exp(-ip\cdot x). \tag{2.1}$$

Here $p \cdot x$ stands for the Lorentz scalar product of p and x. For the inverse Fourier transform we thus have

$$\xi(x) = \frac{1}{(2\pi)^2} \int_{(\infty)} d^4(p) \hat{\xi}(p) \exp(ix \cdot p).$$

The above formulas, in which we employ the symbolic ''function notation,'' are to be understood in the sense of distribution theory.

We now define a special class of distributions in $\mathscr{S}'(\mathsf{M})$, introduced by Araki.[1] As we said in the Introduction, and as discussed in detail in Araki's paper, we are led to these distributions within quantum field theory when we consider matrix elements of commutators (or anticommutators) of field operators between vector states of compact support in momentum space.

Definition 2.1: The set $\mathscr{S}'_A(\mathsf{M})$ of tempered distributions is the set of all $\xi(x) \in \mathscr{S}'(\mathsf{M})$ for which the Fourier transform satisfies the condition

$$\mathrm{supp}(\hat{\xi}(p)) \subset \overline{V}_+(p'') \cup \overline{V}_-(p')$$

for *some* elements p' and p'' of four-momentum space.

It is well known that the support of a distribution is not independent of the support of its Fourier transform. A principal issue in this paper, as well as in Araki's paper, is the nature of the null regions of the distributions in $\mathscr{S}'_A(\mathsf{M})$. By the *null region* $N(\xi)$ of any $\xi \in \mathscr{S}'_A(\mathsf{M})$ we understand the open complement of the support of ξ (in the sense of distribution theory). Let S be an open subset of M. It can well happen that S is not the null region of any element of $\mathscr{S}'_A(\mathsf{M})$, and in general there will exist an open set $\nu(S)$, strictly larger than S, such that $N(\xi) \supset \nu(S)$ for *all* $\xi \in \mathscr{S}'_A(\mathsf{M})$ for which $N(\xi) \supset S$. (We always have $(S^{cc})^o \supset \nu(S)$: see Proposition 4.4 in Section IV. As an important example of this phenomenon we here state a result originally due to Borchers,[12] in the following form.

Lemma 2.2: Let $\xi(x) \in \mathscr{S}'_A(\mathsf{M})$, and let $N(\xi)$ be the null region of $\xi(x)$. If $N(\xi)$ includes the closed *timelike* line segment $[x', x'']$, then $N(\xi)$ includes the closed double cone $D(x', x'')$.

This result, which follows readily from the general theory of Araki,[1] has turned out to be a very useful ''extension principle.'' We will depend on this principle in our paper, and before we discuss Araki's theory further we will pursue the implications of this lemma to some length. First we present an elaboration which follows readily from the above lemma. See also a similar result by Kraus.[13]

Proposition 2.3: Let $s \to x(s)$ be a continuous mapping of $[-1,1]$ into M such that the vector $x(s) - x(-s)$ is in $\overline{V}_+$ for all $s \in [0,1]$. Let $\xi \in \mathscr{S}'_A(\mathsf{M})$ be such that the curve $C = \{x(s) | s \in [-1,1]\}$ is contained in the null region $N(\xi)$. Then the line segment $[x(-1), x(1)]$ is also contained in $N(\xi)$, and there exists a double cone $D \in \mathscr{D}$, contained in $N(\xi)$, which contains the points $x(-1)$ and $x(1)$.

Proof: (1) We first consider the case when $x(s) - x(-s)$ is *strictly forward timelike* for all $s \in (0,1]$. For any $s \in [0,1]$, let $L(s)$ be the line segment $[x(-s), x(s)]$, which is thus timelike for all $s \in (0,1]$. For any $s \in (0,1]$, let $D(s)$ be the double cone in $\mathscr{D}$ with apices $x(-s)$ and $x(s)$. With reference to Lemma 2.2 we note that if $L(s) \subset N(\xi)$, then $D(s) \subset N(\xi)$.

We have $L(0) = x(0) \in N(\xi)$, and since C is continuous and $N(\xi)$ is open, it follows that there exists an $s_0 \in (0,1]$ such that $L(s) \subset N(\xi)$ for all $s \in [0, s_0)$. Let s_m be the largest such s_0. We then have $(x(-s_m), x(s_m)) \subset \cup \{D(s) | s_m > s > 0\} \subset N(\xi)$, and since $x(-s_m) \in N(\xi)$ and $x(s_m) \in N(\xi)$ by the premises, it follows that $L(s_m) \subset N(\xi)$, and hence also $D(s_m) \subset N(\xi)$. If $s_m = 1$, there is nothing to prove, and we thus consider the possibility that $1 > s_m > 0$. Since $D(s_m)$ is compact and $N(\xi)$ is open, there must exist an open double cone D^o such that $L(s_m) \subset D(s_m) \subset D^o \subset N(\xi)$. For a sufficiently small $\delta > 0$ we obviously have $L(s) \subset D^o \subset N(\xi)$ for all $s \in (s_m, s_m + \delta)$, which contradicts the definition of s_m. Hence $L(1) \subset N(\xi)$.

(2) We now consider the general case. Let v be a forward timelike vector. For any $p > 0$ we define the function $x_p(s)$ on $[-1,1]$ with range in M by $x_p(s) = x(s) + spv$. Since the curve C is compact it follows that $C_p = \{x_p(s) | s \in [-1,1]\} \subset N(\xi)$ for all sufficiently small $p > 0$. Let $p > 0$ be such that $C_p \subset N(\xi)$. We have $x_p(s) - x_p(-s) \in V_+$ for all $s \in (0,1]$, and by the result in step

(1) we conclude that the double cone D with apices $x_p(-1)$ and $x_p(1)$ is contained in $N(\xi)$. By the construction of the function $x_p(s)$, it readily follows that the line segment $[x(-1),x(1)]$ is in D, and hence in $N(\xi)$. This completes the proof.

A special case arises when the above function $x(s)$ is such that $x(s)=x(0)$ for all $s\in[-1,0]$. The points $x_0=x(0)$ and $x_1=x(1)$ are then joined by the continuous curve $C_1=\{x(s)|s\in[0,1]\}$. If $x-x_0\in\overline{V}_+$ for all $x\in C_1$, and if $C_1\subset N(\xi)$, then $[x_0,x_1]\subset N(\xi)$.

We remark here that the principle in Proposition 2.3 is valid for a Minkowski-type spacetime of *arbitrary* dimensionality, because Araki's derivation of Lemma 2.2 (on which the conclusion in the proposition is based) is generally valid for such a space. Concerning the premises in the proposition we note the following. Let x_1 and x_{-1} be two points such that $x_1\in\overline{V}_+(x_{-1})$, and let C be a continuous curve with these points as end points. Suppose that $\xi(x)\in\mathscr{S}'_A(\mathsf{M})$, with a null region $N(\xi)\supset C$. In a *two*-dimensional spacetime one can *always* find a parametrization of the curve C which satisfies the premises in Proposition 2.3, and hence it follows that $[x_{-1},x_1]\subset N(\xi)$. In a spacetime of higher dimensionality it can well happen that *no* parametrization which satisfies the premises in Proposition 2.3 exists for a *given* curve C. In Section IV we will show by an explicit example (in which $\xi(x)$ is a suitable solution of the Klein–Gordon equation) that the conclusion in the proposition can fail in such a situation (see Example 4.11).

We think that Proposition 2.3 is of a certain general interest, with other potential applications than those in this paper. Before we pursue the implications of this proposition we quote the following result from TW-I[8] (see Lemma 4.4 and Proposition 4.3):

Lemma 2.4: Let $l'=\{x'-\lambda u'|\lambda\in\mathsf{R}^1\}$ and $l''=\{x''+\lambda u''|\lambda\in\mathsf{R}^1\}$ be two isotropic lines, where u' and u'' are *forward* isotropic. Let π' be the unique characteristic plane which contains l', and let π'' be the unique characteristic plane which contains l''. We write $x'(\lambda)=x'-\lambda u'$ and $x''(\lambda)=x''+\lambda u''$, and we define S to be the *open* region (possibly empty) bounded *above* by π'' and bounded *below* by π'. Then S is nonempty if and only if there exists a λ_0 such that $x''(\lambda_0)-x'(\lambda_0)$ is *forward timelike,* and if this is the case, then

$$S=\cup\{D(x'(\lambda),x''(\lambda))^o|\lambda\geqslant\lambda_1\}=\mathscr{E}(S) \tag{2.2}$$

for any $\lambda_1\geqslant\lambda_0$.

The meaning of the symbol $\mathscr{E}(S)$ was explained in the Introduction: see also Lemma 2.6 below. For the time being we only need to know that the first two members in (2.2) are equal. As we discussed in TW-I,[8] the above conclusion holds in any Minkowski-type space M_n of dimensionality n. We are interested in the case $\mathsf{M}_4=\mathsf{M}$ (physical spacetime) and in the present section also in the case M_5. On the basis of Proposition 2.3 and Lemma 2.4 we can now obtain the following results.

Proposition 2.5: (a) Let $[x',x'']$ be a *timelike* interval, with $x''\in V_+(x')$. Let u' and u'' be two *forward isotropic* vectors, and let h_+ and h_- be two closed half-lines defined by $h_+=\{x''+\lambda u''|\lambda\geqslant 0\}$ and $h_-=\{x'-\lambda u'|\lambda\geqslant 0\}$. Let π'' be the unique characteristic plane containing h_+, let π' be the unique characteristic plane containing h_-, and let S be the *open* region consisting of all points x which lie *below* π'' and lie *above* π'. Hence $S=W(\pi',\pi'')\in\mathscr{W}$ if u' and u'' are not parallel, and S is an open ''slab-region'' between two characteristic planes if u' and u'' are parallel. Let C be the continuous curve $C=h_-\cup[x',x'']\cup h_+$.

Let $\xi\in\mathscr{S}'_A(\mathsf{M})$, with null region $N(\xi)$. If $N(\xi)\supset C$, then $N(\xi)\supset S$.

(b) If u' and u'' are not parallel, then the above conclusion also holds in the case $x'=x''$.

(c) Let $D^o=D(x',x'')^o$ be an open double cone, and let u be a forward isotropic vector. We define the open ''tube-region'' T by $T=\{x+\lambda u|x\in D^o,\lambda\in\mathsf{R}^1\}$. Let π'' be the unique characteristic plane passing through x'', with normal u, and let π' be the plane parallel with π'' passing through x'. Let S be the ''slab-region'' bounded above by π'' and bounded below by π'.

Let $\xi\in\mathscr{S}'_A(\mathsf{M})$, with null region $N(\xi)\supset T$. Then $N(\xi)\supset S$.

Proof: (1) We consider part (a). Let $x_0\in(x',x'')$, $C_+=C\cap V_+(x_0)$, and $C_-=C\cap V_-(x_0)$. We have $C=C_-\cup\{x_0\}\cup C_+$, and if $y'\in C_-$ and $y''\in C_+$, then $y''\in V_+(y')$. By an obvious application of Proposition 2.3 we conclude that $D(y',y'')\subset N(\xi)$. Hence with $x'(\lambda)=x'-\lambda u'$ and $x''(\lambda)=x''+\lambda u''$ we have $D(x'(\lambda),x''(\lambda))^o\subset N(\xi)$ for all $\lambda\geqslant 0$, and it then follows from Lemma 2.4 that $S\subset N(\xi)$.

(2) The assertion in part (b) follows trivially from what has been said above. We consider part (c). Let $x'(\lambda)=x'-\lambda u$ and $x''(\lambda)=x''+\lambda u$. With the stated premises we have $x''(\lambda) \in V_+(x'(\lambda))$ and $(x'(\lambda),x''(\lambda))\subset T\subset N(\xi)$, for all $\lambda\geqslant 0$. Hence $D(x'(\lambda),x''(\lambda))^o\subset N(\xi)$ for $\lambda\geqslant 0$, and it then follows from Lemma 2.4 that $S\subset N(\xi)$. This completes the proof.

This proposition provides further examples of the ''enlargement'' of a region contained in a null region $N(\xi)$ on the basis of the principle in Lemma 2.2, and in some cases the extent of the enlargement can be rather surprising.

The principle in Lemma 2.2 is just one aspect of the general problem of determining the common null region of all distributions $\xi\in\mathscr{S}'_A(\mathsf{M})$ which satisfy the condition that $N(\xi)$ includes some particular ''given'' $S\subset\mathsf{M}$. Before we outline Araki's approach to this problem, we consider the analogous problem for the solutions of the Klein–Gordon equation. Let $\phi(x)$ be a C_2-solution of the Klein–Gordon equation for mass $m\geqslant 0$ on an n-dimensional Minkowski-type space M_n (with $n-1\geqslant 1$ spatial dimensions and one temporal dimension), and let $N(\phi)$ be the null region of $\phi(x)$. There are two well-known ''classical'' principles concerning the support of the solution:[11] I) If $N(\phi)$ contains an open timelike segment (x',x''), then $N(\phi)$ contains the open double cone $D(x',x'')^o$. II) If $N(\phi)$ contains the base of an open double cone D^o, then $N(\phi)$ contains D^o. Stated in this form the two principles apply equally well to distribution-valued solutions of the Klein–Gordon equation. According to Lemma 2.2 the Principle I also applies to tempered distributions in the set $\mathscr{S}'_A(\mathsf{M})$, but this is in general *not* the case for Principle II. We note here that a C_2-solution $\phi(x)$ of the Klein–Gordon equation for M with $m\geqslant 0$ can be identified with a distribution in $\mathscr{S}'_A(\mathsf{M})$ provided that $\phi(x)$ satisfies certain growth conditions as x tends to infinity. This implies constraints on the extensions S_e of S in the case of the Araki distributions $\mathscr{S}'_A(\mathsf{M})$: an extension S_e can never be larger than it can be in the case of solutions of the Klein–Gordon equation of the stated kind.

As we discussed in Section IV in TW-I,[8] the above principles motivate the consideration of an *envelope of uniqueness* $\mathscr{E}(S)$ of any open set $S\subset\mathsf{M}$. We here state the relevant facts as a lemma for later reference. (See Definition and Proposition 4.2 in TW-I.[8])

Lemma 2.6: (a) Let S be an *open* subset of Minkowski spacetime M. There then exists a unique *smallest* subset X of M which satisfies the following three conditions: I) $X\supset S$. II) If X contains the base B_0 of an open double cone $D^o\subset\mathsf{M}$, then X contains D^o. III) If X contains the open timelike line segment (x',x''), then X contains the open double cone $D^o=D(x',x'')^o$ with x' and x'' as apices.

Here, and throughout this paper, we denote this smallest set by $\mathscr{E}(S)$, *for any open* $S\subset\mathsf{M}$.

(b) The set $\mathscr{E}(S)$ is *open*, and it satisfies the conditions $\mathscr{E}(S)\subset(S^{cc})^o\subset S^{cc}=\mathscr{E}(S)^{cc}$. If S is *causally complete*, then $\mathscr{E}(S)=S$.

Furthermore, $\mathscr{E}(\mathscr{E}(S))=\mathscr{E}(S)$, and $\mathscr{E}(S_1)\supset\mathscr{E}(S_2)$ if $S_1\supset S_2$.

(c) If the *open* set S contains either the base B of a closed double cone $D=D(x',x'')\in\mathscr{D}$, or else the closed timelike line segment $[x',x'']$, then $\mathscr{E}(S)$ contains D.

(d) If S_1 and S_2 are two open subsets of M such that $\mathscr{E}(S_1)=S_1$ and $\mathscr{E}(S_2)=S_2$, then $\mathscr{E}(S_1\cap S_2)=S_1\cap S_2$. If S_1 and S_2 are *disjoint*, then $\mathscr{E}(S_1\cup S_2)=S_1\cup S_2$.

The properties of the mapping $S\to\mathscr{E}(S)$ were discussed in considerable detail in TW-I,[8] and we will not repeat this discussion here. The mapping $S\to\mathscr{E}(S)$ can obviously be defined in the same manner for any Minkowski space M_n. What was said above about the null region $N(\phi)$ of a C_2-solution of the Klein–Gordon equation can now be rephrased as follows. We have $\mathscr{E}(N(\phi))=N(\phi)$, and if $S\subset N(\phi)$, and S is open, then $\mathscr{E}(S)\subset N(\phi)$. The same conclusion holds for distribution-valued solutions.

We now outline the ideas in Araki's paper.[1] We regard Minkowski spacetime M as corresponding to a timelike hyperplane in a five-dimensional Minkowski space $\mathsf{M}_5=\mathsf{M}\times\mathsf{R}^1$. A point $\hat{x}$ in M_5 is the pair $\hat{x}=(x,s)$, with $x\in\mathsf{M}$ and $s\in\mathsf{R}^1$, and with the ''metric'' on M_5 defined by $\hat{x}\cdot\hat{x}=x\cdot x-s^2$, i.e., the added dimension is spacelike. We denote by Γ the one-one mapping of M into M_5 defined by $\Gamma x=(x,0)$ for any $x\in\mathsf{M}$, and we write $\Gamma X=\{(x,0)|x\in X\}$ for any $X\subset\mathsf{M}$. The inverse mapping is thus

$$\Gamma^{-1}Y=\{x|x\in\mathsf{M},\quad (x,0)\in Y\}$$

for any $Y \subset \mathsf{M}_5$. The four-dimensional Minkowski spacetime is thus in effect identified with the hyperplane $\Gamma\mathsf{M} = \{(x,0) | x \in \mathsf{M}\}$ in M_5, and the image of any $Y \subset \mathsf{M}_5$ under Γ^{-1} depends only on the intersection of Y with this hyperplane.

Let $\xi(x) \in \mathscr{S}'_A(\mathsf{M})$. Somewhat heuristically described the idea is now to associate with $\xi(x)$ a solution $\phi(x,s)$ of the (massless) wave equation on M_5 such that $\phi(x,s) = \phi(x,-s)$ and $\phi(x,0) = \xi(x)$. If X is in the null region $N(\xi)$ of ξ, then ΓX is in the null region $N(\phi)$ of ϕ, and if $Y \subset N(\phi)$, then $\Gamma^{-1} Y \subset N(\xi)$. The two principles concerning the null region apply to ϕ (in M_5), and the second principle thus applies in an *indirect* fashion to the null region of $\xi(x)$. The construction of $\phi(x,s)$ is rather straightforward if the support of the Fourier transform $\hat{\xi}(p)$ of $\xi(x)$ is contained in the lightcone $\overline{V}(0)$ in momentum space (as we will discuss in Section V), but in view of Definition 2.1 this is not necessarily the case, and the above description is not quite right, although the basic ideas are as stated. The *rigorous* approach to this issue involves a number of not entirely trivial questions of detail, and for the discussion and settlement of these we refer to Araki's paper.[1] In our paper we depend on a specific result in Araki's paper, which we state in the form of a lemma.

Lemma 2.7: Let four-dimensional Minkowski spacetime M be related to five-dimensional Minkowski space M_5 as described above. For any *open* $S \subset \mathsf{M}$, let $E(S) \subset \mathsf{M}_5$ be the smallest set in M_5 which contains ΓS and satisfies the condition that it contains the open double cone $D_5^o \subset \mathsf{M}_5$ if it contains *either* the base of D_5^o, *or* the open timelike line segment with the apices of D_5^o as its endpoints. We define the subset $a(S)$ of M by $a(S) = \Gamma^{-1} E(S)$. Then $S \subset a(S)$, and $a(S)$ is *open*.

Let $\xi(x) \in \mathscr{S}'_A(\mathsf{M})$, and let $S \subset \mathsf{M}$ be contained in the null region $N(\xi)$. Then $a(S) \subset N(\xi)$.

In what follows we refer to the set $a(S)$ as the *Araki envelope of* S. We note that, given an arbitrary open region S, it is not at all immediately obvious what the region $a(S)$ ''looks like.'' It is not, however, difficult to see that Lemma 2.2 does follow immediately from Lemma 2.7. Since Lemma 2.2 involves an important principle we wanted to state it explicitly, lest it be obscured by the geometric complications in Lemma 2.7.

For the visualization of the sets $E(S)$ and $a(S)$ it is useful to think about the mapping $S \to E(S)$ as arising in two steps. Let $S \subset \mathsf{M}$ be open. To S corresponds the *relatively open* subset ΓS of the 4-plane $\Gamma\mathsf{M}$ in M_5. We first ''fatten'' ΓS a little bit to obtain an open subset of M_5, and then apply the mapping in Lemma 2.6 to this subset to obtain $E(S)$. It is worthwhile to formulate this idea precisely as follows.

Lemma 2.8: Let the premises and notation be as in Lemma 2.7 above, and let $R \to \mathscr{E}_5(R)$ be the mapping in Lemma 2.6, for the five-dimensional space M_5. For any open $S \subset \mathsf{M}$ we define the region $E_0(S)$ in M_5 by

$$E_0(S) = \cup \{E(D^o) | D \in \mathscr{D},\ D^o \subset S\}. \tag{2.3}$$

Then $E_0(S)$ and $E(S)$ are *open*, and $\Gamma^{-1} E_0(S) = S$. Furthermore,

$$\mathscr{E}_5(E(S)) = E(S) = \mathscr{E}_5(E_0(S)). \tag{2.4}$$

Proof: We consider an open double cone $D^o = D(x',x'')^o \subset \mathsf{M}$. Then $E(D^o)$ is obviously an open double cone $D_5^o \subset \mathsf{M}_5$ with apices $\hat{x}' = (x',0)$ and $\hat{x}'' = (x'',0)$, and we have $\Gamma^{-1} D_5^o = D^o$. It follows that the set $E_0(S)$ in (2.3) is open, and since the open set S is the union of all open double cones which it contains, it follows that $\Gamma^{-1} E_0(S) = S$. We have $E(S) \supset E_0(S) \supset \Gamma S$, and in view of the definition of $E(S)$ we conclude that $E(S) = \mathscr{E}_5(E_0(S))$. This implies that $E(S)$ is open, and since $\mathscr{E}_5(\mathscr{E}_5(R)) = \mathscr{E}_5(R)$ for any open $R \subset \mathsf{M}_5$, we have $\mathscr{E}_5(E(S)) = \mathscr{E}_5(E_0(S)) = E(S)$. This completes the proof.

We note that it follows from this that $a(S) = \Gamma^{-1} E(S)$ is open since $E(S)$ is open.

Before we discuss the determination of the Araki envelope $a(S)$ in particular cases it will be useful to consider another mapping between the spaces M and M_5. We define the set-mapping Λ of subsets of M to subsets of M_5 by $\Lambda X = \{(x,s) | x \in X, s \in \mathsf{R}^1\}$, for any $X \subset \mathsf{M}$. For a singleton we write $\Lambda x = \{(x,s) | s \in \mathsf{R}^1\}$. A point $x \in \mathsf{M}$ is thus mapped onto the line in M_5 which passes through the point $(x,0)$ and is parallel with the 5-axis. We note that $\Gamma^{-1} \Lambda X = X$ for any $X \subset \mathsf{M}$. Every set

ΛX is, of course, mapped onto itself by any translation in the 5-direction, and, conversely, every set $Y \subset \mathsf{M}_5$ invariant under translations in the 5-direction is of the form ΛX, with $X = \Gamma^{-1} Y$, and for such a set we thus have $Y = \Lambda \Gamma^{-1} Y$.

Lemma 2.9: Let Λ be the mapping of subsets of M to subsets of M_5 defined above. Let the mapping $S \to \mathscr{E}(S)$ for M be defined as in Lemma 2.6, and let $R \to \mathscr{E}_5(R)$ be the corresponding mapping for M_5. Then:

(a) If $X \subset \mathsf{M}$, then $\Lambda X \subset \mathsf{M}_5$ is open if and only if X is open.

(b) The mapping Λ commutes with causal complementation and causal completion, in the sense that for any $X \subset \mathsf{M}$,

$$(\Lambda X)^c = \Lambda(X^c), \quad (\Lambda X)^{cc} = \Lambda(X^{cc}). \tag{2.5}$$

(c) If $S \subset \mathsf{M}$ is open, then

$$\mathscr{E}_5(\Lambda S) = \Lambda \mathscr{E}(S). \tag{2.6}$$

Proof: (1) The assertion in part (a) is trivial. We consider part (b). Let $X \subset \mathsf{M}$. The set ΛX is invariant under any translation in the 5-direction, and the set $(\Lambda X)^c \subset \mathsf{M}_5$ obviously has the same property. Hence $(\Lambda X)^c = \Lambda Y$, with $Y = \Gamma^{-1}((\Lambda X)^c) \subset \mathsf{M}$. Let $\hat{x} = (x, s_1) \in \Lambda X$, and let $\hat{y} = (y, s_2) \in \mathsf{M}_5$. We then have $(x,s) \in \Lambda X$ for all s, and the separation between $\hat{y}$ and (x,s) is spacelike (within M_5) for all s if and only if the separation between (x,s_2) and $\hat{y} = (y,s_2)$ is spacelike, but this is the case if and only if the separation between x and y is spacelike (within M). It follows that $Y = X^c$, and hence $(\Lambda X)^c = \Lambda(X^c)$. The second relation in (2.5) then follows readily.

(2) We consider part (c), assuming that $S \subset \mathsf{M}$ is open. Since ΛS is invariant under all translations in the 5-direction it follows trivially that $\mathscr{E}_5(\Lambda S)$ has the same property, and we thus have $\mathscr{E}_5(\Lambda S) = \Lambda S_1$, with $S_1 = \Gamma^{-1} \mathscr{E}_5(\Lambda S) \supset \Gamma^{-1} \Lambda S = S$. We consider the open double cone $D_4^o = D(x,y)^o \subset \mathsf{M}$ and the open double cone $D_5^o = D_5(\hat{x}, \hat{y})^o = E_0(D_4^o) \subset \mathsf{M}_5$, with $\hat{x} = (x,0)$ and $\hat{y} = (y,0)$. Let B_{04} be the base of D_4^o and let B_{05} be the base of D_5^o. It is trivial that: (a) ΛS_1 contains D_5^o if and only if S_1 contains D_4^o, (b) ΛS_1 contains B_{05} if and only if S_1 contains B_{04}, and (c) ΛS_1 contains $(\hat{x}, \hat{y})$ if and only if S_1 contains (x,y). From this we conclude that $\mathscr{E}(S_1) = S_1$, since $\mathscr{E}_5(\Lambda S_1) = \mathscr{E}_5(\mathscr{E}_5(\Lambda S)) = \mathscr{E}_5(\Lambda S) = \Lambda S_1$. Since $S_1 \supset S$ it follows that $\mathscr{E}(S_1) = S_1 \supset \mathscr{E}(S)$, and hence we have $\mathscr{E}_5(\Lambda S) \supset \Lambda \mathscr{E}(S)$.

(3) In the continuation of the proof we will depend on the following rather plausible result from TW-I:[8] If X is a bounded open convex subset of M, then $\mathscr{E}(X) = X^{cc}$. (See Lemma 4.7 in the quoted paper.)

Let now X_5 be a bounded, open convex subset of M_5, and let $X_{5\Lambda}$ be defined by $X_{5\Lambda} = \{\hat{x} + (0,\lambda) | \hat{x} \in X_5, \lambda \in \mathsf{R}^1\}$, and let $X_4 = \Gamma^{-1} X_{5\Lambda}$. We can regard ΓX_4 as the orthogonal projection of X_5 into $\Gamma \mathsf{M}$, and we have $X_{5\Lambda} = \Lambda X_4$. The set $X_{5\Lambda}$ is obviously open and convex, and the set X_4 is open and convex and bounded. Hence we have $\mathscr{E}(X_4) = X_4^{cc}$, and in view of (2.5) we have $\Lambda \mathscr{E}(X_4) = \Lambda(X_4^{cc}) = (\Lambda X_4)^{cc} = X_{5\Lambda}^{cc} \supset \mathscr{E}_5(X_{5\Lambda}) \supset \mathscr{E}_5(X_5)$.

Suppose now that the above set X_5 is included in $\Lambda \mathscr{E}(S)$, and hence $\Lambda X_4 = X_{5\Lambda} \subset \Lambda \mathscr{E}(S)$. This implies that $X_4 \subset \mathscr{E}(S)$, and hence $\mathscr{E}(X_4) \subset \mathscr{E}(S)$. By the above it then follows that $\mathscr{E}_5(X_5) \subset \Lambda \mathscr{E}(X_4) \subset \Lambda \mathscr{E}(S)$.

(4) Let $D = D(\hat{x}', \hat{x}'')$ be a closed double cone in M_5 with base B. Suppose that $B \subset \Lambda \mathscr{E}(S)$. It is obvious that there then exists a bounded open convex set X_5 such that $B \subset X_5 \subset \Lambda \mathscr{E}(S)$, and it then follows from the result in step (3) that $D \subset \Lambda \mathscr{E}(S)$. Suppose instead that $[\hat{x}', \hat{x}''] \subset \Lambda \mathscr{E}(S)$. There then exists a bounded open convex set X_5 such that $[\hat{x}', \hat{x}''] \subset X_5 \subset \Lambda \mathscr{E}(S)$, and it then follows, in this case too, that $D \subset \Lambda \mathscr{E}(S)$. These results imply that $\Lambda \mathscr{E}(S) = \mathscr{E}_5(\Lambda \mathscr{E}(S))$. Since $\Lambda \mathscr{E}(S) \supset \Lambda S$ we have $\mathscr{E}_5(\Lambda \mathscr{E}(S)) \supset \mathscr{E}_5(\Lambda S)$, and in view of the result in step (2) the equality in (2.6) follows. This completes the proof.

For an arbitrary open set $S \subset \mathsf{M}$ the Araki envelope $a(S)$ is in general *smaller* than the envelope $\mathscr{E}(S)$. An example of substantial physical interest is an open set T consisting of all points between two parallel *spacelike* planes. Such a region is called *a time-slice* in quantum field

theory. We trivially have $\mathscr{E}(T)=\mathsf{M}$, but $a(T)=T$, as one easily sees. We will have more to say about this later. At this point we note some simple inclusion relations involving the mappings a and $\mathscr{E}$.

Proposition 2.10: Let the premises and notation be as in Lemma 2.7, and let $S\to\mathscr{E}(S)$ be the mapping in Lemma 2.6. If $S\subset\mathsf{M}$ is *open*, then

$$(S^{cc})^o\supset\mathscr{E}(S)=a(\mathscr{E}(S))=\mathscr{E}(a(S))\supset a(S)\supset S. \tag{2.7}$$

Proof: By Lemma 2.6 we have $(S^{cc})^o\supset\mathscr{E}(S)\supset S$, and it is trivial that $a(S)\supset S$ and that $\mathscr{E}(a(S))\supset a(S)$. We follow the notation in Lemmas 2.8 and 2.9. We trivially have $\Lambda D^o\supset E_0(D^o)$ for any open double cone $D^o\subset\mathsf{M}$, and hence $\Lambda S\supset E_0(S)$ for any open $S\subset\mathsf{M}$. In view of (2.4) and (2.6) we have $\Lambda\mathscr{E}(S)=\mathscr{E}_5(\Lambda S)\supset\mathscr{E}_5(E_0(S))=E(S)$, and hence $\mathscr{E}(S)=\Gamma^{-1}\Lambda\mathscr{E}(S)\supset\Gamma^{-1}E(S)=a(S)$. Forming the $\mathscr{E}$-envelope of all members in the relation $\mathscr{E}(S)\supset a(S)\supset S$ we obtain $\mathscr{E}(S)=\mathscr{E}(a(S))$, since $\mathscr{E}(\mathscr{E}(S))=\mathscr{E}(S)$. Finally we note that $a(\mathscr{E}(S))=\Gamma^{-1}E(\mathscr{E}(S))\subset\Gamma^{-1}\Lambda\mathscr{E}(S)=\mathscr{E}(S)$. Since $a(\mathscr{E}(S))\supset\mathscr{E}(S)$ we conclude that $a(\mathscr{E}(S))=\mathscr{E}(S)$. This completes the proof.

It is worth noting that it follows from (2.7) that if S happens to be such that $\mathscr{E}(S)=S$, then $a(S)=S$. In particular, if S is open and causally complete, then $a(S)=\mathscr{E}(S)=S$.

In this paper we are particularly interested in regions S which are unions of wedges in $\mathscr{W}$. In this special situation we depend on a result which we will now derive from Lemmas 2.4 and 2.7, and from Proposition 2.10.

Theorem 2.11: Let $\{S_\alpha|\alpha\in\mathscr{I}\}$, where $\mathscr{I}$ is some index set, be a family of open regions $S_\alpha\subset\mathsf{M}$ such that S_α is bounded above by the characteristic plane π''_α and below by the characteristic plane π'_α. Let $S=\cup\{S_\alpha|\alpha\in\mathscr{I}\}$. We define the Araki envelope $a(S)$ as in Lemma 2.7, and we define the open set $\mathscr{E}(S)$ as in Lemma 2.6. Then

$$a(S)=\mathscr{E}(S)\subset(S^{cc})^o \tag{2.8}$$

and if $\xi(x)\in\mathscr{S}'_A(\mathsf{M})$, with null region $N(\xi)\supset S$, then $N(\xi)\supset\mathscr{E}(S)$.

Proof: (1) We follow the notation in Lemmas 2.6–2.9. We first show that for each $\alpha\in\mathscr{I}$ we have

$$E(S_\alpha)=\Lambda S_\alpha, \tag{2.9}$$

and that $E(S_\alpha)$ is the region in M_5 bounded by the characteristic 4-planes

$$\Lambda\pi'_\alpha=\{(x,s)|x\in\pi'_\alpha,s\in\mathsf{R}^1\},\quad \Lambda\pi''_\alpha=\{(x,s)|x\in\pi''_\alpha,s\in\mathsf{R}^1\},$$

such that $E(S_\alpha)$ is below $\Lambda\pi''_\alpha$ and above $\Lambda\pi'_\alpha$. We assume that $S_\alpha\neq\varnothing$, since the relation (2.9) is otherwise trivial. Let $l'=\{x'-\lambda u'|\lambda\in\mathsf{R}^1\}$ be an isotropic line in π'_α, and let $l''=\{x''+\lambda u''|\lambda\in\mathsf{R}^1\}$ be an isotropic line in π''_α, where the vectors u' and u'' are chosen as *forward* isotropic. We write $x'(\lambda)=x'-\lambda u'$ and $x''(\lambda)=x''+\lambda u''$, for $\lambda\in\mathsf{R}^1$. By Lemma 2.4 there then exists a λ_0 such that $x''(\lambda)-x'(\lambda)$ is forward timelike for all $\lambda\geqslant\lambda_0$, and for such a λ we have $(x'(\lambda),x''(\lambda))\subset S_\alpha$.

The sets $\Gamma l'$ and $\Gamma l''$ are isotropic lines in M_5, and it is easily seen that $\Lambda\pi'_\alpha$ is the unique characteristic plane which contains $\Gamma l'$, and that $\Lambda\pi''_\alpha$ is the unique characteristic plane which contains $\Gamma l''$. The region ΛS_α is thus the region bounded below by $\Lambda\pi'_\alpha$ and bounded above by $\Lambda\pi''_\alpha$. For any $\lambda\geqslant\lambda_0$ the open timelike line segment $(\Gamma x'(\lambda),\Gamma x''(\lambda))$ is in ΓS_α, and hence in $E(S_\alpha)$. By the definition of $E(S_\alpha)$ this implies that the open double cone $D(\Gamma x'(\lambda),\Gamma x''(\lambda))^o$ is in $E(S_\alpha)$. Since this holds for all $\lambda\geqslant\lambda_0$, it follows from Lemma 2.4 that $\Lambda S_\alpha\subset E(S_\alpha)$.

It is easily seen that $S_\alpha=\mathscr{E}(S_\alpha)$ if the planes π'_α and π''_α are parallel. If π'_α and π''_α are not parallel, then $S_\alpha=W(\pi'_\alpha,\pi''_\alpha)$, and hence $S_\alpha=\mathscr{E}(S_\alpha)$. We thus always have $S_\alpha=\mathscr{E}(S_\alpha)$, and hence, by (2.6), $\Lambda S_\alpha=\Lambda\mathscr{E}(S_\alpha)=\mathscr{E}_5(\Lambda S_\alpha)$. With the notation in Lemma 2.8 we have $\Lambda S_\alpha\supset E_0(S_\alpha)$, and hence $\Lambda S_\alpha=\mathscr{E}_5(\Lambda S_\alpha)\supset\mathscr{E}_5(E_0(S_\alpha))=E(S_\alpha)$, by Lemma 2.8. In view of what was shown above we conclude that $\Lambda S_\alpha=E(S_\alpha)$, as asserted in (2.9).

(2) By (2.9) we obtain $E(S)\supset\cup\{E(S_\alpha)|\alpha\in\mathscr{I}\}=\cup\{\Lambda S_\alpha|\alpha\in\mathscr{I}\}=\Lambda S$, since $S=\cup\{S_\alpha|\alpha\in\mathscr{I}\}$. By (2.4) we have $E(S)=\mathscr{E}_5(E(S))$, and hence $E(S)=\mathscr{E}_5(E(S))\supset\mathscr{E}_5(\Lambda S)$. By (2.6) we

have $\mathscr{E}_5(\Lambda S)=\Lambda\mathscr{E}(S)$. Hence $E(S)\supset\Lambda\mathscr{E}(S)$, and it follows that $a(S)=\Gamma^{-1}E(S)\supset\Gamma^{-1}\Lambda\mathscr{E}(S)=\mathscr{E}(S)$. By (2.7) we have $a(S)\subset\mathscr{E}(S)\subset(S^{cc})^o$, and the relation (2.8) follows. This completes the proof.

The virtue of this theorem is that it will now not be necessary to make any further excursions into five-dimensional Minkowski space when we want to find the envelope $a(S)$ for a union S of *wedges*. Rather than working with Lemma 2.7 we will depend on Theorem 2.11, in which the five-dimensional space is not mentioned explicitly. For an arbitrary $R\subset\mathsf{M}$ it is in general much easier to find (and visualize) the envelope $\mathscr{E}(R)$ than the Araki envelope $a(R)$. It is important to understand what it is that is so special about a union of *wedges*. The salient point is that the relation (2.9) holds *only* for the kind of set S_α described in the premises, or for a *disjoint* union of such sets, but for *no* other open subset R of M. On the basis of this observation it is not hard to see that the relation $E(S)=\mathscr{E}_5(\Lambda S)$ in step (2) of the proof holds *only* if S is the kind of set described in the premises, which includes the union of any set of wedges in $\mathscr{W}$. This relation, in turn, is crucial for the conclusion in (2.8), which at first sight seems to say that the second principle concerning the null region of a solution of the Klein–Gordon equation, discussed before Lemma 2.6, is applicable after all to the distributions in the set $\mathscr{S}'_A(\mathsf{M})$. Note, however, that to be able to conclude that a double cone D^o is included in $N(\xi)$, given that the base B_0 of the double cone is included in $N(\xi)$, we must know that B_0 is included in the *subset* S of $N(\xi)$, as described in the premises of the theorem. If we are only given that $B_0\subset N(\xi)$, we *cannot* in general conclude that $D^o\subset N(\xi)$.

In the next section we discuss a number of interesting implications of Theorem 2.11. We conclude this section with a discussion of certain properties of the mappings $S\to\mathscr{E}(S)$ and $S\to a(S)$ which are of interest in quantum field theory.

Proposition 2.12: Let $S\subset\mathsf{M}$ be *open*, and let S_n, $n\in\mathsf{Z}_+$, be a sequence of *open* subsets of S such that $S_{n+1}\supset S_n$ for all n, and such that $S=\cup\{S_n|n\in\mathsf{Z}_+\}$. Then $\mathscr{E}(S)=\cup\{\mathscr{E}(S_n)|n\in\mathsf{Z}_+\}$ and $a(S)=\cup\{a(S_n)|n\in\mathsf{Z}_+\}$.

Proof: The relation $\mathscr{E}(S)=\cup\{\mathscr{E}(S_n)|n\in\mathsf{Z}_+\}$ was proved in TW-I.[8] (See Proposition 4.12 in the quoted paper.) It holds for a Minkowski-type space M_n of any dimensionality n.

Let the notation be as in Lemma 2.8. With reference to (2.3) it is immediately obvious that $E_0(S)=\cup\{E_0(S_n)|n\in\mathsf{Z}_+\}$, and we trivially have $E_0(S_{n+1})\supset E_0(S_n)$ for all n. It then follows that $E(S)=\mathscr{E}_5(E_0(S))=\cup\{\mathscr{E}_5(E_0(S_n))|n\in\mathsf{Z}_+\}=\cup\{E(S_n)|n\in\mathsf{Z}_+\}$, and hence $a(S)=\Gamma^{-1}E(S)=\cup\{\Gamma^{-1}E(S_n)|n\in\mathsf{Z}_+\}=\cup\{a(S_n)|n\in\mathsf{Z}_+\}$. This completes the proof.

III. ABOUT ARAKI DISTRIBUTIONS WHICH VANISH ON A UNION OF CAUSAL WEDGES

In this section we will be mostly concerned with the common null region of all distributions in $\mathscr{S}'_A(\mathsf{M})$ which are known to vanish on a union S of wedges in $\mathscr{W}$. It follows from Theorem 2.11 that the common null region also includes the set $\mathscr{E}(S)$. For some configurations of wedges we have $\mathscr{E}(S)=(S^{cc})^o$, and we want to identify these configurations. When S is a union of wedges the causal complement $K=S^c$ of S is a closed, convex, causally complete subset of M, and the converse is *almost* true. In TW-I[8] we discussed the nature of closed, convex, causally complete subsets of M and their causal complements in considerable detail. For convenient reference we here quote as a theorem some results which are relevant and important for the discussion in the present paper. Parts (a), (c), (d), and (e) are verbatim quotes from Theorem 3.2 in TW-I,[8] and the (trivial) statements in part (b) are from Proposition 3.4 in that paper.

Theorem 3.1: (a) Let K be a closed, convex, causally complete subset of M such that K^c has a nonempty interior. Then

$$K=\cap\{\overline{W}|W\in\mathscr{W},\ \overline{W}\supset K\}=\cap\{W^c|W\in\mathscr{W},\ W\subset K^c\},$$

$$(K^c)^o=\cup\{W|W\in\mathscr{W},\ W^c\supset K\}=\cup\{W|W\in\mathscr{W},\ W\subset K^c\},$$

and

$$((K^c)^o)^c=K,\ \ \overline{(K^c)^o=K^c},\quad \overline{(K^c)^o}=(K^c)^o.$$

The set K has an empty interior if and only if it is contained in some characteristic plane.

(b) Every set $K \in \mathscr{K}_E$ (with $\mathscr{K}_E$ as described in Definition 1.1) satisfies the premises in part (a) above, and specifically K^c is nonempty and *open*.

(c) Let $\{K_\alpha | \alpha \in A\}$ be a family of subsets of M which satisfy the premises in part (a). Then $K = \cap\{K_\alpha | \alpha \in A\}$ also satisfies the premises in part (a).

(d) Let $\mathscr{F}$ be any family of wedges in $\mathscr{W}$, and let $S = \cup\{W | W \in \mathscr{F}\}$. Then $K = \cap\{W^c | W \in \mathscr{F}\} = S^c$ satisfies the premises in part (a).

If $\mathscr{F}$ is a *finite* family, then the set K^c is *open*.

(e) Let K be a closed, convex, causally complete subset of M. Then K^c has an empty interior if and only if K contains an isotropic line. If K is a *proper* subset of M containing an isotropic line l, then K is a closed convex union of a set of isotropic lines, all contained in the characteristic plane π containing l (and hence all parallel with l). The set K^c is then the relative (set) complement of K in π, and hence the union of all isotropic lines in π which do not intersect K.

This geometric theorem provides a framework for the discussion in this section, and the statement in part (d) is particularly relevant. In the ''favorable'' cases when we have $\mathscr{E}(S) = (S^{cc})^o$ the Araki envelope $a(S)$ is thus equal to the interior of the causal complement of a closed, convex, causally complete subset K of M, which is a useful and transparent description of $a(S)$.

In view of the discussion in the preceding section the problem of determining the Araki envelope $a(S)$ when S is a union of wedges is essentially a *geometric* problem, involving the determination of the envelope $\mathscr{E}(S)$ defined in Lemma 2.6. The latter problem was discussed in considerable detail in TW-I,[8] and we will depend on various results from that paper. We first quote, as a theorem, some results which will turn out to be useful in the study of unions of wedges, although wedges are not mentioned explicitly. This theorem is also of considerable of interest in its own right.

Theorem 3.2: Let $\Pi' = \{\pi'_\alpha | \alpha \in \mathscr{I}'\}$ and $\Pi'' = \{\pi''_\beta | \beta \in \mathscr{I}''\}$, where $\mathscr{I}'$ and $\mathscr{I}''$ are two index sets, be two families of *characteristic* planes in M. For each $\alpha \in \mathscr{I}'$ and $\beta \in \mathscr{I}''$, let $S_{\alpha\beta}$ be the *open* subset of M (possibly empty) which is bounded below by π'_α and bounded above by π''_β, and let $S = \cup\{S_{\alpha\beta} | \alpha \in \mathscr{I}', \beta \in \mathscr{I}''\}$ and $K = S^c$. The set S is thus the set of all points $x \in \mathsf{M}$ which lie *below* at least one of the planes in Π'' and lie *above* at least one of the planes in Π'. Furthermore we assume that for each $\alpha \in \mathscr{I}'$ there exists a $\beta \in \mathscr{I}''$ such that $S_{\alpha\beta} \neq \varnothing$, and that for each $\beta \in \mathscr{I}''$ there exists an $\alpha \in \mathscr{I}'$ such that $S_{\alpha\beta} \neq \varnothing$. Then:

(a) The set $K = S^c$ is *closed*, *convex*, and *causally complete*.

(b) Let the Araki envelope $a(S)$ be defined as in Lemma 2.7, and let the envelope $\mathscr{E}(S)$ be defined as in Lemma 2.6. Then

$$a(S) = \mathscr{E}(S).$$

If $\xi(x) \in \mathscr{S}'_A(\mathsf{M})$, with null region $N(\xi) \supset S$, then $N(\xi) \supset \mathscr{E}(S)$.

(c) The following cases can occur:

Case I: $K \neq \varnothing$, and hence $S^{cc} \neq \mathsf{M}$. We then have

$$\mathscr{E}(S) = (S^{cc})^o = (K^c)^o.$$

Case II: $K = \varnothing$ and $S^{cc} = \mathsf{M} = \mathscr{E}(S)$.

Case IIIa: $K = \varnothing$, $S^{cc} = \mathsf{M}$, and $\mathscr{E}(S)$ is an open half-space bounded below by a characteristic plane π', in which case all the planes in Π' are parallel with π'.

Case IIIb: $K = \varnothing$, $S^{cc} = \mathsf{M}$, and $\mathscr{E}(S)$ is an open half-space bounded above by a characteristic plane π'', in which case all the planes in Π'' are parallel with π''.

Case IV: $K = \varnothing$, $S^{cc} = \mathsf{M}$, and $\mathscr{E}(S)$ is an open ''slab-region'' bounded above by a characteristic plane π'' and bounded below by a characteristic plane π' parallel with π'', in which case all the planes in $\Pi' \cup \Pi''$ are parallel with the planes π' and π''.

(d) If each one of the sets Π' and Π'' contains at least two nonparallel planes, then $\mathscr{E}(S) = S^{cc} = K^c$ and S^{cc} is *open*. If Π' and Π'' satisfy the *additional* condition that the set of normals of the planes in $\Pi' \cup \Pi''$ spans M, then $K \in \mathscr{K}_E$.

Proof: The statements in parts (a), (c), and (d) are quoted verbatim from Theorem 4.11 in TW-I,[8] and we will not repeat the proofs here. The set S satisfies the premises of Theorem 2.11 in the preceding section, and hence the assertions in part (b) follow.

For a discussion of various geometric features of the above configurations we refer to the proof of Theorem 4.11 in TW-I[8] and to Proposition 3.6 in the same paper. We consider a configuration for which there exists a plane $\pi'_\mu \in \Pi'$ such that $S_{\mu\beta}=\emptyset$ for *all* $\beta \in \mathscr{T}''$. The plane π'_μ is then *irrelevant* in the sense that it has no effect on the region S, and without loss of generality we can rule out such configurations, as we have done in the statement of premises. Note that we necessarily have $S\neq\emptyset$ with our premises. The case $S=\emptyset$ is naturally totally uninteresting.

In the next section we will show that the above result is the best possible, in the sense that $\mathscr{E}(S)$ is the largest common null region of *all* Araki distributions which vanish throughout S.

We now consider a result concerning two *intersecting* wedges.

Proposition 3.3: Let $W_1=W(\pi'_1,\pi''_1)$ and $W_2=W(\pi'_2,\pi''_2)$ be two wedges in $\mathscr{W}$ such that $W_1\cap W_2\neq\emptyset$. We write $S=W_1\cup W_2$ and $K=S^c=W_1^c\cap W_2^c$. Let $\mathscr{E}(S)$ be the envelope in Lemma 2.6, and let $a(S)$ be the Araki envelope in Lemma 2.7. Then:

(a) The set $S^{cc}=K^c$ is open, and

$$\mathscr{E}(S)=a(S)=S^{cc}=K^c. \tag{3.1}$$

Hence if $\xi\in\mathscr{S}'_A(\mathsf{M})$ with null region $N(\xi)\supset S$, then $N(\xi)\supset S^{cc}$.

(b) If π'_1 is not parallel with π''_2, then $W(\pi'_1,\pi''_2)\subset\mathscr{E}(S)$, and if π'_2 is not parallel with π''_1, then $W(\pi'_2,\pi''_1)\subset\mathscr{E}(S)$.

(c) If π'_1 is parallel with π''_2, or if π'_2 is parallel with π''_1, then $\mathscr{E}(S)=\mathsf{M}$.

Proof: It was shown in TW-I[8] that $\mathscr{E}(S)=S^{cc}$ with S defined as above, and the assertions in parts (b) and (c) were also proved. (See Proposition 5.6 in that paper.) By Theorem 2.11 we have $a(S)=\mathscr{E}(S)$, and hence the equalities in (3.1) obtain.

As was noted in TW-I,[8] it is *essential* that the wedges W_1 and W_2 have a nonempty intersection. If this is *not* the case, the conclusions can fail to hold. (See Examples 3.12 and 3.14 below.)

The above proposition has an obvious generalization to the case of any family $\mathscr{F}$ of wedges in $\mathscr{W}$ which satisfies the special condition that $W_1\cap W_2\neq\emptyset$ for *all* pairs $\{W_1,W_2\}$ of wedges in $\mathscr{F}$.

Proposition 3.4: Let $\mathscr{F}=\{W_\alpha=W(\pi'_\alpha,\pi''_\alpha)\,|\,\alpha\in\mathscr{T}\}$, where $\mathscr{T}$ is an index set, be a family of wedges in $\mathscr{W}$, such that $W_\alpha\cap W_\beta\neq\emptyset$ for *all* $\alpha,\beta\in\mathscr{T}$. For $\alpha,\beta\in\mathscr{T}$ we denote by $S_{\alpha\beta}$ the open region bounded below by π'_α and bounded above by π''_β. We define the sets S_0, S, and K by $S_0=\cup\{W_\alpha\,|\,\alpha\in\mathscr{T}\}$, $S=\cup\{S_{\alpha\beta}\,|\,\alpha,\beta\in\mathscr{T}\}$, and $K=S^c$. Then:

(a) The families $\Pi'=\{\pi'_\alpha\,|\,\alpha\in\mathscr{T}\}$ and $\Pi''=\{\pi''_\alpha\,|\,\alpha\in\mathscr{T}\}$ satisfy the premises in Theorem 3.2, and all the conclusions concerning S^{cc} and $\mathscr{E}(S)$ in that theorem apply. Furthermore,

$$a(S_0)=a(S)=\mathscr{E}(S_0)=\mathscr{E}(S)\subset(S_0^{cc})^o=(S^{cc})^o,\quad K=S^c=S_0^c,$$

and if $\xi(x)\in\mathscr{S}'_A(\mathsf{M})$, with null region $N(\xi)\supset S_0$, then $N(\xi)\supset\mathscr{E}(S)$.

(b) In particular we have $a(S_0)=S_0^{cc}$ if the family $\mathscr{F}$ contains at least two wedges with nonparallel upper planes, and at least two wedges with nonparallel lower planes.

Proof: (1) Let $\alpha,\beta\in\mathscr{T}$. By Proposition 3.3 we have $W(\pi'_\alpha,\pi''_\beta)=S_{\alpha\beta}\subset\mathscr{E}(W_\alpha\cup W_\beta)=(W_\alpha\cup W_\beta)^{cc}$ if π'_α is not parallel with π''_β, whereas we have $\mathscr{E}(W_\alpha\cup W_\beta)=(W_\alpha\cup W_\beta)^{cc}=\mathsf{M}$ if π'_α is parallel with π''_β. In both cases we have $S_{\alpha\beta}\subset\mathscr{E}(W_\alpha\cup W_\beta)\subset\mathscr{E}(S_0)$. Since this holds for all $\alpha,\beta\in\mathscr{T}$, it follows that $S\subset\mathscr{E}(S_0)$, and from this it follows that $\mathscr{E}(S)\subset\mathscr{E}(\mathscr{E}(S_0))=\mathscr{E}(S_0)$. We trivially have $\mathscr{E}(S)\supset\mathscr{E}(S_0)$ since $S\supset S_0$, and hence $\mathscr{E}(S_0)=\mathscr{E}(S)$. In view of Theorem 2.11 we then have $a(S_0)=\mathscr{E}(S_0)=\mathscr{E}(S)=a(S)$.

(2) We want to show that $S^c=S_0^c$, which is equivalent to the relation $S^{cc}=S_0^{cc}$. By Lemma 2.6 we have $R^{cc}=\mathscr{E}(R)^{cc}$ for any open $R\subset\mathsf{M}$. Hence $S_0^{cc}=\mathscr{E}(S_0)^{cc}=\mathscr{E}(S)^{cc}=S^{cc}$, and since $\mathscr{E}(S_0)=\mathscr{E}(S)$ we conclude that $S_0^{cc}=S^{cc}$. This completes the proof.

The point of this proposition is that the set S_0 is, in general, *smaller* than the set S, but nevertheless we have $S_0^{cc}=S^{cc}$ and $\mathscr{E}(S_0)=\mathscr{E}(S)$. We emphasize that the condition that $W_\alpha\cap W_\beta\neq\emptyset$, for all $\alpha,\beta\in J$, is *crucial*. If the family $\mathscr{F}$ contains a pair of wedges with an empty intersection, the conclusions may fail to hold.

We now consider a very special class of configurations of wedges to which Proposition 3.4 applies.

Proposition 3.5: Let $\mathscr{F}\subset\mathscr{W}$, and let $S_0=\cup\{W\,|\,W\in\mathscr{F}\}$ and $K=S_0^c=\cap\{W^c\,|\,W\in\mathscr{F}\}$.

(a) Suppose that all the *lower* planes of the wedges $W \in \mathscr{F}$ are *parallel*. Then the premises in Proposition 3.4 are satisfied, and the conclusions in part (a) of the proposition apply. Any one of the Cases I, II, IIIa, or IIIb in Theorem 3.2 can obtain. The set K is *not* in $\mathscr{K}_E$ if $K \neq \emptyset$.

(b) Suppose that all the *upper* planes of the wedges $W \in \mathscr{F}$ are *parallel*. Then the conclusions are the same as in part (a).

Proof: We only consider part (a) since very similar considerations apply to part (b). We first note the obvious fact that if the lower planes of two wedges in $\mathscr{W}$ are parallel, then the two wedges have a nonempty intersection. Since all the lower planes of the wedges in $\mathscr{F}$ are parallel it follows that the configuration is within the purview of Proposition 3.4. It is very easy to find examples which show that any one of the Cases I, II, IIIa, or IIIb can indeed obtain, and we feel that we can omit these details. (See, however, Example 3.10 below for some illustrations.)

We next consider a class of configurations of particular interest in quantum field theory. In the theorem and proposition which follow we depend on some geometric results in Section V of TW-I.[8]

Theorem 3.6: Let $\mathscr{F}$ be a family of wedges in $\mathscr{W}$. We write $S = \cup\{W | W \in \mathscr{F}\}$ and $K = \cap\{W^c | W \in \mathscr{F}\}$. Let $\mathscr{E}(S)$ be defined as in Lemma 2.6, and let the Araki envelope $a(S)$ be defined as in Lemma 2.7.

(a) Suppose that $\mathscr{F}$ contains two wedges in a *general relative position*. Then K is an element of the set $\mathscr{K}_E$ described in Definition 1.1, and we have

$$a(S) = \mathscr{E}(S) = S^{cc} = K^c. \tag{3.2}$$

If $\xi \in \mathscr{S}'_A(\mathsf{M})$, with null region $N(\xi) \supset S$, then $N(\xi) \supset S^{cc}$.

(b) Suppose instead that the normals of the boundary planes of the wedges in $\mathscr{F}$ span M, and suppose furthermore that $\mathscr{F}$ contains two wedges such that no two of the boundary planes of these wedges are parallel. Then the conclusions are the same as in part (a).

Proof: Under the stated premises in part (a) or in part (b) we have $\mathscr{E}(S) = S^{cc} = K^c$ and $K \in \mathscr{K}_E$ by Theorem 5.7 in TW-I,[8] and by Theorem 2.11 in the present paper we have $a(S) = \mathscr{E}(S)$. This establishes the conclusions in the theorem.

The configurations in part (a) are obviously just special cases of the configurations in part (b), since the premise in part (a) trivially implies the premises in part (b). The assertions in part (a) are thus ''superfluous,'' but we wanted to state these assertions explicitly since they concern what can be regarded as the *simplest* case. The situation when two ''arbitrary'' wedges are *not* in a general relative position is ''exceptional'' in the sense that the normals of the boundary planes of the two wedges must then be linearly dependent. We might thus regard a family $\mathscr{F}$ of wedges as ''normal'' if it contains some pairs of wedges in a general relative position. Part (a) of the theorem then applies to such a family, and in particular we have $K \in \mathscr{K}_E$. However, it can happen that a family $\mathscr{F}$ contains *no* two wedges in a general relative position, although the family is such that $K \in \mathscr{K}_E$. It is worthwhile to consider a specific example here, similar to an example given in Section III in TW-I.[8]

Example 3.7: Let the index set $\mathscr{I}$ in the above theorem be the set of all unit vectors $\mathbf{u} \in \mathsf{R}^3$. Let $q > 0$. For each unit vector $\mathbf{u}$ we define the wedge $W_{\mathbf{u}}$ by $W_{\mathbf{u}} = \{(\mathbf{x},t) | \mathbf{x}\cdot\mathbf{u} - q > |t|\}$, and we define the family $\mathscr{F}$ by $\mathscr{F} = \{W_{\mathbf{u}} | \mathbf{u} \in \mathscr{I}\}$. We have $K = \cap\{W_{\mathbf{u}}^c | \mathbf{u} \in \mathscr{I}\} = D((\mathbf{0},-q),(\mathbf{0},q)) \in \mathscr{D} \subset \mathscr{K}_C \subset \mathscr{K}_E$, but $\mathscr{F}$ contains no two wedges in a general relative position. The premises in part (b) of the theorem are, however, satisfied, and hence the equalities in (3.2) hold.

This example shows that an ''abnormal'' family need not be particularly ''pathological'' at all. Part (b) of the theorem is intended to deal with some configurations of this kind. The proposition which follows seemingly deals with configurations for which the premises in part (b) of Theorem 3.6 might not be satisfied. However, by Proposition 5.8 in TW-I[8] these premises are *in fact* satisfied. Hence we have the following result.

Proposition 3.8: Let $\mathscr{F}$ be a family of wedges in $\mathscr{W}$. We write $S = \cup\{W | W \in \mathscr{F}\}$ and $K = \cap\{W^c | W \in \mathscr{F}\}$, and we assume that $K \neq \emptyset$ and that S is *connected*.

(a) Suppose that $K \in \mathscr{K}_E$. Then the family $\mathscr{F}$ satisfies the premises in part (b) of Theorem 3.6, and hence $a(S) = \mathscr{E}(S) = S^{cc} = K^c$.

(b) Suppose instead that $\mathscr{F}$ contains at least two wedges with nonparallel lower planes, and at least two wedges with nonparallel upper planes. Suppose furthermore that the normals of the

boundary planes of the wedges in $\mathscr{F}$ span M. Then $K \in \mathscr{K}_E$ and the conclusion is as in part (a).

We will not repeat here the proofs of Theorem 5.7 and Proposition 5.8 in TW-I,[8] but some comments about what is involved are in order. The *nontrivial* issue in Theorem 3.6 (and in Proposition 3.8) is the relation $\mathscr{E}(S) = S^{cc}$, since the relation $a(S) = \mathscr{E}(S)$ follows at once from Theorem 2.11. We consider Theorem 3.6. Corresponding to the family $\mathscr{F}$ we define the set $S \subset \mathsf{M}$ by $S = \cup\{W | W \in \mathscr{F}\}$, as in the theorem. We define a new family $\mathscr{F}^*$ of wedges in $\mathscr{W}$ by $\mathscr{F}^* = \{W | W \in \mathscr{W}, W \subset \mathscr{E}(S)\}$ and we write $S_e = \cup\{W | W \in \mathscr{F}^*\}$. We clearly have $\mathscr{F}^* \supset \mathscr{F}$ and $\mathscr{E}(S) \supset S_e \supset S$. It follows readily that $\mathscr{E}(S) = \mathscr{E}(S_e)$ and $\mathscr{E}(S)^{cc} = S_e^{cc} = S^{cc}$. We also easily see that the ''enlarged'' family $\mathscr{F}^*$ satisfies the same premises as the family $\mathscr{F}$. What is not quite so obvious is that $\mathscr{F}^*$ always contains at least two wedges in a general relative position, even in the case when the ''original'' family $\mathscr{F}$ does not have this property. (See the proof of Theorem 5.7 in TW-I[8]).

Given any family $\mathscr{F}$ of wedges, the crux of the matter is really whether the ''enlarged'' family $\mathscr{F}^*$, defined in terms of $\mathscr{F}$ as above, contains two wedges in a general relative position. It is desirable to find criteria for this to be the case in terms of reasonably transparent conditions on the ''primary family'' $\mathscr{F}$. Such conditions are given in part (b) of Theorem 3.6 and in Proposition 3.8.

In Theorem 3.6 and in Proposition 3.8 the family $\mathscr{F}$ is such that the set $K = \cap\{W^c | W \in \mathscr{F}\}$ is an element of the (well-behaved) family $\mathscr{K}_E$ described in Definition 1.1. One aspect of this is that the set of all normals of the boundary planes of the wedges in $\mathscr{F}$ span M. Proposition 3.4 also concerns a family $\mathscr{F}$ of wedges. It is not required in the premises of this proposition that the normals span M, but instead it is required that $W_\alpha \cap W_\beta \neq \varnothing$ for *every* pair $\{W_\alpha, W_\beta\} \subset \mathscr{F}$. It can well happen that the normals of all the upper and lower planes span a *three*-dimensional or *two*-dimensional subspace of M, and in this case K is *not* an element of $\mathscr{K}_E$. The premises are thus quite different in Proposition 3.4 and Theorem 3.6, although it can happen that a particular family $\mathscr{F}$ satisfies the premises of both.

What is, perhaps, not so obvious at this point is to what extent these premises are necessary for the stated conclusions in Theorem 3.6 or in Propositions 3.3 or 3.8 about the null regions of Araki distributions $\xi(x)$, namely that $N(\xi) \supset (S^{cc})^o$ if $N(\xi) \supset S$. This question has two aspects. One is the purely geometric problem of when $\mathscr{E}(S) = (S^{cc})^o$, and the other is within the purview of distribution theory and concerns the question of whether *every* distribution $\xi(x) \in \mathscr{S}'_A(\mathsf{M})$ which vanishes on some open set S might in fact vanish on a *larger* open set than $a(S)$. We will discuss the second question in Section IV. In the present section we will illustrate the *geometric* aspects of the issue with some examples, but before we present these examples we want to draw some simple but important conclusions from Theorem 3.6. The proposition which follows will be of particular interest in our discussion of nets of local algebras in a subsequent paper. In Section V we will consider its implications in quantum field theory.

Proposition 3.9: (a) Let $K_1 \in \mathscr{K}_E$, and let $\mathscr{F}_2 \subset \mathscr{W}$ be any family of wedges. We write $K_2 = \cap\{W^c | W \in \mathscr{F}_2\}$ and $S_2 = \cup\{W | W \in \mathscr{F}_2\}$. Then $K_1 \cap K_2 \in \mathscr{K}_E$, and $a(K_1^c \cup S_2) = \mathscr{E}(K_1^c \cup S_2) = (K_1 \cap K_2)^c = (K_1^c \cup S_2)^{cc}$.

(b) Let $K_1 \in \mathscr{K}_E$, and let K_2 be a closed, convex, causally complete subset of M, such that K_2^c has a nonempty interior $(K_2^c)^o = S_2$. Then $K_1 \cap K_2 \in \mathscr{K}_E$, and $a(K_1^c \cup S_2) = \mathscr{E}(K_1^c \cup S_2) = (K_1^c \cup S_2)^{cc} = (K_1 \cap K_2)^c$.

(c) Let $\mathscr{K}_S \subset \mathscr{K}_E$, $\mathscr{K}_S \neq \varnothing$, and let $S = \cup\{K^c | K \in \mathscr{K}_S\}$ and $K_S = \cap\{K | K \in \mathscr{K}_S\} = S^c$. Then $K_S \in \mathscr{K}_E$ and $a(S) = \mathscr{E}(S) = S^{cc} = K_S^c$.

Proof: (1) We consider part (a), and we write $\mathscr{F}_1 = \{W | W \in \mathscr{W}, W^c \supset K_1\}$ and $\mathscr{F} = \mathscr{F}_1 \cup \mathscr{F}_2$. By Theorem 3.1 we have $K_1 = \cap\{W^c | W \in \mathscr{F}_1\}$ and $K^c = \cup\{W | W \in \mathscr{F}_1\}$. Hence $K_1 \cap K_2 = \cap\{W^c | W \in \mathscr{F}\}$ and $\mathscr{E}(K_1^c \cup K_2^c) \supset \cup\{W | W \in \mathscr{F}\}$. By the definition of $\mathscr{K}_E$ the set $\mathscr{F}_1$ contains two wedges in a general relative position, and hence this is also the case for the set $\mathscr{F}$. The set $\mathscr{F}$ thus satisfies the premise in part (a) of Theorem 3.6, and the conclusion follows at once.

(2) We consider part (b). By Theorem 3.1 we have $S_2^c = ((K_2^c)^o)^c = K_2$. The conclusion in part (b) then follows from the result in part (a) when we select $\mathscr{F}_2 = \{W | W \in \mathscr{W}, W^c \supset K_2\}$, in which case we have $S_2 = \cup\{W | W \in \mathscr{W}, W^c \supset K_2\}$.

(3) To prove part (c) we define the family $\mathscr{F} \subset \mathscr{W}$ by $\mathscr{F} = \cup\{\{W | W \in \mathscr{W}, W \supset K\} | K \in \mathscr{K}_S\}$. Let $K_1 \in \mathscr{K}_S \subset \mathscr{K}_E$. We then have $\{W | W \in \mathscr{W}, W \supset K_1\} \subset \mathscr{F}$, and it follows that $\mathscr{F}$ contains two wedges in a general relative position. The conclusion then follows from Theorem 3.6.

Note that the set K_2 in part (a) is not necessarily in $\mathscr{K}_E$. The simplest case in part (c) is the

case of just two sets $K_1, K_2 \in \mathscr{K}_E$. (Part (b) also applies to this case.) We then have $K = K_1 \cap K_2 \in \mathscr{K}_E$ and $a(S) = a(K_1^c \cup K_2^c) = (K_1^c \cup K_2^c)^{cc}$. If $\xi(x) \in \mathscr{S}'_A(\mathsf{M})$, with null region $N(\xi) \supset K_1^c \cup K_2^c$, we thus have $N(\xi) \supset (K_1^c \cup K_2^c)^{cc}$. The significance of this result is that $(K_1^c \cup K_2^c)^{cc}$ is in general *larger* (and in some cases ''very much larger'') than $K_1^c \cup K_2^c$.

We now discuss some examples. At this point the reader may want to go ahead of the discussion and look at Examples 4.8 and 4.9 in the next section.

Example 3.10: Let π' be a characteristic plane, and let Π'' be a family of characteristic planes not parallel with π'. We consider the family $\mathscr{F} \subset \mathscr{W}$ defined by $\mathscr{F} = \{W(\pi', \pi'') \,|\, \pi'' \in \Pi''\}$, and we write $S = \cup\{W \,|\, W \in \mathscr{F}\}$ and $K = S^c$. We then have $K = \cap\{\overline{W}(\pi'', \pi') \,|\, \pi'' \in \Pi''\}$. The set K is *not* in $\mathscr{K}_E$, since $\mathscr{F}$ contains no two wedges with nonparallel lower planes. The span of the normals of the planes in $\Pi'' \cup \{\pi'\}$ can be two-, three-, or four-dimensional. The set S is *connected* but the premises in Theorem 3.6 or in Proposition 3.8 are not satisfied. Proposition 3.5 is obviously applicable. In this kind of example we have just two possibilities: I) $K \neq \varnothing$ and $a(S) = \mathscr{E}(S) = (S^{cc})^o$. This case obtains in particular if the family Π'' is *finite*. II) $K = \varnothing$, $S^{cc} = \mathsf{M}$, but $\mathscr{E}(S)$ is the open half-space bounded below by π'. An example of Case II is the configuration when Π'' consists of *all* characteristic planes which are not parallel with π'.

Similar considerations apply to any family $\mathscr{F}$ of wedges with a common *upper* plane π''. With $S = \cup\{W \,|\, W \in \mathscr{F}\}$ we then have two possibilities: I) $K = S^c \neq \varnothing$ and $a(S) = \mathscr{E}(S) = (S^{cc})^o$. II) $K = S^c = \varnothing$, $S^{cc} = \mathsf{M}$, but $\mathscr{E}(S)$ is the open half-space bounded above by π''.

Example 3.11: Let π' and π'' be two parallel characteristic planes such that π' lies *above* π''. Let $\Pi_u{}'$ and Π_l' be two (nonempty) sets of characteristic planes which are *not* parallel with π'' (and π'). We define the family $\mathscr{F}_u$ of wedges by $\mathscr{F}_u = \{W(\pi', \pi_u'') \,|\, \pi_u'' \in \Pi_u{}'\}$, and similarly we define the family $\mathscr{F}_l$ by $\mathscr{F}_l = \{W(\pi_l', \pi'') \,|\, \pi_l' \in \Pi_l'\}$. We write $S_u = \cup\{W \,|\, W \in \mathscr{F}_u\}$, $K_u = S_u^c$, $S_l = \cup\{W \,|\, W \in \mathscr{F}_l\}$, and $K_l = S_l^c$. Proposition 3.5 applies to each one of the families $\mathscr{F}_u$ and $\mathscr{F}_l$ separately, and the family $\mathscr{F}_u$ is as described in Example 3.10. The set $\mathscr{E}(S_u)$ lies *above* the plane π' and the set $\mathscr{E}(S_l)$ lies *below* the plane π''.

Let $\mathscr{F} = \mathscr{F}_u \cup \mathscr{F}_l$ and $S = \cup\{W \,|\, W \in \mathscr{F}\} = S_u \cup S_l$. The set $K = S^c = K_u \cap K_l$ is contained in the closed ''slab-region'' between the planes π' and π''. The sets S_u and S_l are disjoint, and hence S is not connected. The set S^{cc} is connected if and only if S_u contains a point x'' and S_l contains a point x' such that the interval $[x', x'']$ is timelike, which is the case if and only if S_u is *not* included in S_l^c. If $S_u \subset S_l^c$, then $S^{cc} = S_u^{cc} \cup S_l^{cc}$. The sets $\mathscr{E}(S_u)$ and $\mathscr{E}(S_l)$ are also disjoint, and we have $\mathscr{E}(S) = \mathscr{E}(S_u) \cup \mathscr{E}(S_l)$. Hence we always have $\mathscr{E}(S) \neq (S^{cc})^o$ if S^{cc} is connected.

Proposition 3.4 is not applicable, since $\mathscr{F}$ contains pairs of wedges with an empty intersection. The span of the normals of the boundary planes of the wedges in $\mathscr{F}$ can be two-, three-, or four-dimensional. Every pair of wedges in the family $\mathscr{F}$ is such that one of the boundary planes of one of the wedges is parallel with one of the boundary planes of the other, and in particular $\mathscr{F}$ contains no two wedges in a general relative position. Theorem 3.6 is accordingly not applicable. Proposition 3.8 is not applicable since S is not connected.

As described in Example 3.10 we have two main cases for each one of the sets S_u and S_l. If either $S_u^{cc} = \mathsf{M}$ or $S_l^{cc} = \mathsf{M}$ we have $S^{cc} = \mathsf{M} \neq \mathscr{E}(S)$. If $S_u^{cc} \neq \mathsf{M}$ *and* $S_l^{cc} \neq \mathsf{M}$, we may, or may not, have $\mathscr{E}(S) = (S^{cc})^o$ depending on whether $S_u \subset S_l^c$ or not.

We consider some special configurations within the general class described in Example 3.11.

Example 3.12: (a) Suppose that Π_u'' consists of a single plane π_1'', and that Π_l'' also consists of a single plane π_1', parallel with π_1''. Hence $S_u = W(\pi', \pi_1'') = \mathscr{E}(S_u)$ and $S_l = W(\pi_1', \pi'') = \mathscr{E}(S_l)$. This configuration is ''two-dimensional'' in the sense that the span of the normals of the boundary planes of the wedges in $\mathscr{F}$ is two-dimensional. It is invariant under all translations in a two-dimensional group of spacelike translations. We have $K = S^c = W(\pi', \pi_1'')^c \cap W(\pi_1', \pi'')^c$ and $\mathscr{E}(S) = S$. If π_1'' lies *above* π_1', then $K = \varnothing$ and $S^{cc} = \mathsf{M}$. If π_1'' does *not* lie above π_1', then $K \neq \varnothing$ and $S^{cc} = S = \mathscr{E}(S)$. Proposition 3.3 is not applicable since $W(\pi', \pi_1'') \cap W(\pi_1', \pi'') = \varnothing$.

(b) Suppose that $\Pi_u{}'$ consists of a single plane π_1'', and that $\Pi_l{}'$ also consists of a single plane π_1', *not* parallel with π_1''. This configuration is ''three-dimensional'' in an obvious sense. We have $S = \mathscr{E}(S) = W(\pi', \pi_1'') \cup W(\pi_1', \pi'') \neq S^{cc}$ and $K = W(\pi', \pi_1'')^c \cap W(\pi_1', \pi'')^c \neq \varnothing$. The set S^{cc} is *connected*, and we have $W(\pi_1', \pi_1'') \subset S^{cc}$. Proposition 3.3 is not applicable since $W(\pi', \pi_1'') \cap W(\pi_1', \pi'') = \varnothing$.

Example 3.13: Let the premises and notation be as in Example 3.11. Let $x' \in \pi'$ and x''

$\in \pi''$ be two points, such that $x' \in V_+(x'')$. Hence the closed double cone $D(x'',x')$ lies in the closed ''slab-region'' R between the planes π' and π''. Let Π'_l consist of all characteristic planes which pass through x' and which are not parallel with π' (and π''), and let Π''_u consist of all characteristic planes which pass through x'' and which are not parallel with π'. We then have $K=D(x'',x') \in \mathscr{D} \subset \mathscr{K}_E$, but Proposition 3.8 is not applicable since S is not connected. The set $S^{cc}=K^c=(S^{cc})^o$ is connected, but $\mathscr{E}(S)$ is not connected, and hence $\mathscr{E}(S) \neq (S^{cc})^o$.

We consider a pair of wedges $W_1=W(\pi'_1,\pi''_1)$ and $W_2=W(\pi'_2,\pi''_2)$ in $\mathscr{W}$. Let $u'_j=(\mathbf{u}'_j,1)$ and $u''_j=(\mathbf{u}''_j,1)$ be the normals of the boundary planes in the standard form. Each one of the intersections $W_1 \cap W_2$ and $W_1^c \cap W_2^c$ can be empty or nonempty, and we distinguish between four kinds of configurations which can occur on this basis. It is not hard to show (see Proposition 5.1 in TW-I[8]) that at least one of these intersections is empty if and only if there exist two numbers $\theta', \theta'' \in [0,1]$ such that $\theta' u'_1+(1-\theta')u'_2=\theta'' u''_1+(1-\theta'')u''_2$. If the normals span M, then both intersections are nonempty, and Proposition 3.3 is applicable. Suppose that the normals span a *three*-dimensional space. One easily sees that at least one of the intersections $W_1 \cap W_2$ and $W_1^c \cap W_2^c$ must then be nonempty. In Example 3.12 we have examples of configurations for which $W_1 \cap W_2=\varnothing$ but $W_1^c \cap W_2^c \neq \varnothing$. In these examples the lower plane of one of the wedges is parallel with and lies above the upper plane of the other. It is of interest to present an example in which no two boundary planes are parallel. Such a configuration is presented in Example 4.17 in the next section, but we here give another example which is simpler to analyze.

Example 3.14: We consider four characteristic planes defined by

$$\pi'_1=\{x|t\sqrt{2}=-x_2-x_3+1\}, \quad \pi''_1=\{x|t\sqrt{2}=-x_2+x_3-1\},$$

$$\pi'_2=\{x|t\sqrt{2}=x_2+x_3+1\}, \quad \pi''_2=\{x|t\sqrt{2}=x_2-x_3-1\},$$

and we write $W_1=W(\pi'_1,\pi''_1)$, $W_2=W(\pi'_2,\pi''_2)$, $S=W_1 \cup W_2$, and $K=S^c=W_1^c \cap W_2^c$. It is trivial that $0 \in K$, and hence $K \neq \varnothing$. By the above criteria we then conclude that $W_1 \cap W_2=\varnothing$, as one can also easily see directly by an examination of the relevant inequalities implied by the equations for the four planes. We have $W_1 \cup W_2 \cup W(\pi'_1,\pi''_2) \cup W(\pi'_2,\pi''_1) \subset S^{cc}$, but $\mathscr{E}(S)=S \neq S^{cc}$. The span of the normals of the four planes is trivially three-dimensional. No two of the four planes are parallel. Proposition 3.3 is not applicable since $W_1 \cap W_2=\varnothing$, and hence we cannot conclude that $W(\pi'_1,\pi''_2) \cup W(\pi'_2,\pi''_1) \subset N(\xi)$, given that $N(\xi) \supset W_1 \cup W_2$ for a distribution $\xi(x) \in \mathscr{S}'_A(\mathsf{M})$. As shown in Example 4.17 there exist, in fact, distributions ξ such that $N(\xi) \supset W_1 \cup W_2$ but such that $W(\pi'_1,\pi''_2) \cup W(\pi'_2,\pi''_1)$ is *not* included in $N(\xi)$.

We note that W_1 and W_2 are not separated by any *characteristic* plane. To see this we consider the edges $E_1=\{x|-x_2+x_3-1=t\sqrt{2}=-x_2-x_3+1\}$ and $E_2=\{x|x_2-x_3-1=t\sqrt{2}=x_2+x_3+1\}$ of the wedges W_1, respectively W_2. If a hyperplane π separates W_1 from W_2, then π must contain a linear 2-manifold parallel with E_1, and a linear 2-manifold parallel with E_2. We easily see that π must then contain a *timelike* line, and hence π cannot be a characteristic hyperplane.

We also note the trivial fact that if l is any *isotropic* line, then l necessarily contains a half-line which is *not* in $W_1 \cup W_2$. The same is true for the configuration in Example 3.13.

IV. ABOUT THE KLEIN–GORDON EQUATION AND A CLASS OF SPECIAL ARAKI DISTRIBUTIONS

In this section we consider (among other things) *tempered* distributions $\psi(x) \in \mathscr{S}'(\mathsf{M})$ which satisfy the *Klein–Gordon equation*

$$\frac{\partial^2 \psi(x)}{\partial t^2}-\Delta \psi(x)+m^2\psi(x)=0. \tag{4.1}$$

Here $m \geqslant 0$, and we thus include the case of the *wave equation* corresponding to $m=0$. We denote the set of tempered distributions which satisfy the equation (4.1) for a particular m by Ψ_m. Every such distribution is trivially in the Araki-class $\mathscr{S}'_A(\mathsf{M})$. Every ''ordinary'' C_2-solution $\psi(x)$ of the Klein–Gordon equation which satisfies certain asymptotic growth conditions can also be regarded as a distribution of this kind if we define $\psi[f]$ for any test function $f(x)$ by

$$\psi[f]=\int_{(\infty)} d^4(x)\ f(x)\psi(x). \tag{4.2}$$

Specifically a C_2-solution $\psi(x)$ of (4.1) is in $\mathscr{S}'_A(\mathsf{M})$ if and only if $|\psi(x)|<C(1+|\mathbf{x}|+|t|)^n$ for some constants C and n.

Suppose that the complex-valued functions $g_+(\mathbf{p})$ and $g_-(\mathbf{p})$ on R^3 are elements of the Hilbert space $L_2(\mathsf{R}^3)$. Then the integral at right in

$$\psi(x)=\frac{1}{(2\pi)^{3/2}}\int_{(\infty)}\frac{d^3(\mathbf{p})}{\sqrt{2\omega}}(g_+(\mathbf{p})e^{-ix\cdot p}+g_-(\mathbf{p})e^{ix\cdot p}) \tag{4.3}$$

where $\omega=\omega(\mathbf{p})=\sqrt{m^2+|\mathbf{p}|^2}$ and $p=(\mathbf{p},\omega)$, makes sense and defines a solution $\psi(x)$ of (4.1) in $\mathscr{S}'_A(\mathsf{M})$. Solutions of this kind are of interest in quantum field theory, *and in what follows we denote this class of solutions by* Ψ^H_m. If $\psi(x)$ is a C_2-solution of (4.1) such that $\psi(x)$ and its time derivative $\partial_t\psi(x)$ restricted to the spacelike 3-plane $\sigma_0=\{(\mathbf{x},0)|\mathbf{x}\in\mathsf{R}^3\}$ are functions of compact support, then $\psi(x)\in\Psi^H_m$. If $\psi(x)$ is a C_2-solution of (4.1) such that $\psi(x)$ and its time derivative $\partial_t\psi(x)$ restricted to the spacelike 3-plane σ_0 are in the test function space $\mathscr{S}(\mathsf{R}^3)$, then $\psi(x)\in\Psi^H_m$, and $\psi(x)$ is infinitely differentiable.

All the results in Section III apply as such to the elements of $\Psi_m\subset\mathscr{S}'_A(\mathsf{M})$. Moreover, if $\psi(x)\in\Psi_m$, with null region $N(\psi)$, then $N(\psi)\supset\mathscr{E}(S)$ whenever $N(\psi)\supset S$, and we have $\mathscr{E}(N(\psi))=N(\psi)$. As we remarked earlier, these ''classical'' principles *do not* in general apply to the elements of $\mathscr{S}'_A(\mathsf{M})$. The following is a statement within the framework of our paper of a well-known result concerning the ''region of dependence.''

Proposition 4.1: Let $\psi(x)$ be a C_2-solution of (4.1), with null region $N(\psi)$. Let σ be a spacelike plane, and let K_σ be a closed subset of σ which contains the supports of the restrictions of $\psi(x)$ and its normal derivative to σ. Let S_σ be the relative complement of K_σ in σ. We write $K=K^{cc}_\sigma$ and $S=S^{cc}_\sigma$. Then:

(a) S is *open* and K is *closed*, and we have $S^c=K$ and $N(\psi)\supset S=K^c$.

(b) If $W\in\mathscr{W}$ and $W^c\supset K_\sigma$, then $N(\psi)\supset W$.

About the Proof: The statement that $N(\psi)\supset S^{cc}_\sigma$ is the ''classical'' result.[11] The remaining assertions are of a geometric character, and we omit the simple proofs.

The above can be combined with our Proposition 3.9 as follows.

Proposition 4.2: Let $\mathscr{T}\subset\mathscr{W}$ be a family of wedges. We write $K=\cap\{W^c|W\in\mathscr{T}\}$ and $S=\cup\{W|W\in\mathscr{T}\}$. Let $\psi(x)$ be a C_2-solution of (4.1) such that the supports of the restrictions of $\psi(x)$ and its normal derivative to some spacelike plane σ are *compact*. Suppose furthermore that the null region $N(\psi)$ of $\psi(x)$ contains S. Then $N(\psi)\supset K^c=S^{cc}$.

Proof: Let K_σ be a closed subset of σ which contains the supports of the restrictions of $\psi(x)$ and its normal derivative to σ. There then exists a $K_1\in\mathscr{K}_E$ such that $K_1\supset K_\sigma$ and hence $K_1=K^{cc}_1\supset K^{cc}_\sigma$. By Proposition 4.1 we have $N(\psi)\supset K^c_1$ and it then follows by Proposition 3.9 that $N(\psi)\supset a(K^c_1\cup K^c)=(K^c_1\cup K^c)^{cc}\supset K^c$, which proves the assertion.

In Proposition 4.1 the ''initial-value surface'' σ is a spacelike 3-plane. It is well known that a solution of (4.1) can be uniquely specified by the initial values on other kinds of surfaces, and we here give an example of this.

Proposition 4.3: Let Σ be a hypersurface in M defined by $\Sigma=\{(\mathbf{x},g(\mathbf{x}))|\mathbf{x}\in\mathsf{R}^3\}$, where $g(\mathbf{x})$ is a C_2-function on R^3 which satisfies the condition $|g(\mathbf{x})-g(\mathbf{y})|\leqslant\theta|\mathbf{x}-\mathbf{y}|$ for all $\mathbf{x},\mathbf{y}\in\mathsf{R}^3$, for some fixed $\theta\in(0,1)$. Let K_0 be a closed subset of Σ, and let Σ_0 be its relative complement (within Σ). Let $\psi(x)$ be a C_2-solution of (4.1), such that the supports of the restrictions of $\psi(x)$ and its gradient to Σ are contained in K_0. Then Σ^{cc}_0 is open, and $N(\psi)\supset\Sigma^{cc}_0=K^c_0$, where $N(\psi)$ is the null region of $\psi(x)$.

About the Proof: The statement that $N(\psi)\supset\Sigma^{cc}_0$ is again a ''classical'' result. That Σ^{cc}_0 is open and that $\Sigma^{cc}_0=K^c_0$ was proved in Proposition 2.8 in TW-I.[8]

If $\psi(x)$ is a C_2-solution of the Klein–Gordon equation, and if $S\subset N(\psi)$, then we obviously have $(\overline{S})^o\subset N(\psi)$, and it follows that the null region must satisfy the condition $(\overline{N(\psi)})^o=N(\psi)$. Similar considerations apply to the initial values of $\psi(x)$ on some suitable spacelike surface, and we have, in particular, the following result. Let $W\in\mathscr{W}$, and suppose that the C_2-solution $\psi(x)$ of

(4.1) satisfies the condition that $N(\psi)\supset W\cup(W^c)^o$. Then $\psi(x)=0$ on M. To see this we note that the initial values of $\psi(x)$ vanish identically on any spacelike 3-plane which contains the edge $\overline{W}\cup W^c$ of the wedge W. These properties of C_2-solutions are naturally not shared with more discontinuous distribution solutions of (4.1).

It is not our intention to try to give a complete description of the null regions of solutions of the Klein–Gordon equation here. As far as we know such a description is actually not known at present. As we will see, the matter cannot be settled by the above-mentioned ''classical'' principles alone. We will, however, consider the theory of Sections II and III in the light of known properties of the solutions of equation (4.1). We first note that for any $m>0$ and any point $y\in\mathsf{M}$ there exist solutions whose support (in x-space) is precisely the closed lightcone $\overline{V}(y)$. We consider the ''causal function'' $\Delta_0(x-y;m)$, familiar from quantum field theory, which is proportional to the vacuum expectation value $\langle\Omega|[\varphi(x),\varphi(y)]\Omega\rangle$ of the commutator of two free Hermitian scalar field operators. We regard y as a fixed ''parameter,'' and write $\zeta_y(x)=\Delta_0(x-y;m)$. The ''function'' $\zeta_y(x)$ is a tempered distribution in $\mathscr{S}'_A(\mathsf{M})$ which satisfies equation (4.1). We have the (symbolic) integral representation

$$\zeta_y(x)=\Delta_0(x-y;m)=\frac{1}{(2\pi)^3}\int_{(\infty)}d^3(\mathbf{p})\,\frac{\sin(\omega(t-s))}{\omega}\,\exp(i(\mathbf{x}-\mathbf{y})\cdot\mathbf{p}) \tag{4.4}$$

with $x=(\mathbf{x},t)$, $y=(\mathbf{y},s)$, $p=(\mathbf{p},\omega)$, and $\omega=\sqrt{m^2+|\mathbf{p}|^2}$.

When $m>0$ the support of $\zeta_y(x)$ is precisely the closed lightcone $\overline{V}(y)$, and when $m=0$ the support is precisely $\partial V(y)$. From this we can now draw a simple conclusion, which is worth a formal statement.

Proposition 4.4: (a) Let S be an open subset of M, and let $\nu(S)$ be the *largest* open set such that $N(\xi)\supset\nu(S)$ for *every* $\xi\in\mathscr{S}'_A(\mathsf{M})$ for which $N(\xi)\supset S$. Then $(S^{cc})^o\supset\nu(S)\supset a(S)$.

(b) Under the premises in Theorem 3.6, or in Propositions 3.3 or 3.8, we have $S^{cc}=\nu(S)=\mathscr{E}(S)=a(S)$.

Proof: Let S be an open subset of M, and suppose that $\xi(x)\in\mathscr{S}'_A(\mathsf{M})$, with null region $N(\xi)\supset S$. For any point $y\in S^c$ it might then happen that the support of $\xi(x)$ is equal to the light cone $\overline{V}(y)$, as would be the case if $\xi(x)=\zeta_y(x)$, with $\zeta_y(x)$ as in (4.4) for some $m>0$. The set $\cup\{\overline{V}(y)|y\in S^c\}$ is the (set) complement of the causal completion S^{cc} of S, and hence the largest possible *common* null region $\nu(S)$ for the set of *all* $\xi(x)$ which vanish on S cannot exceed $(S^{cc})^o$.

With the premises in Theorem 3.6, or in Propositions 3.3 or 3.8, we have the conclusion that $S^{cc}=\mathscr{E}(S)=a(S)$, and hence we have the conclusion in part (b) above.

The results in Theorem 3.6, or in Propositions 3.3 or 3.8, are thus optimal in the sense that S^{cc} is *precisely* the common null region $\nu(S)$ of all $\xi(x)\in\mathscr{S}'_A(\mathsf{M})$ which vanish on S: no ''improvement'' is possible.

Example 4.5: The distribution $\zeta_y(x)$ considered above is not in the class Ψ^H_m. Since it is of interest to see what one can say about the support of functions in this class, we consider the following. Let S be an open subset of M. The causal complement S^c is then closed. We consider the special case when S^c is equal to the closure of its interior. Let σ be a spacelike 3-plane which intersects the interior of S^c, and let $B\subset\sigma\cap(S^c)^o$ be the base of a double cone $D\in\mathscr{D}$. Hence $D\subset S^c$. Let g be a C_∞-function on σ with support equal to B. For any particular $m\geqslant 0$ there then exists a (unique) C_∞-solution $\psi_{g,m}(x)$ of the Klein–Gordon equation (4.1) such that the restriction of $\psi_{g,m}(x)$ to σ agrees with the function g, and such that the normal derivative (relative to σ) of $\psi_{g,m}(x)$ vanishes on σ. This solution is in Ψ^H_m, and it has the representation in (4.3). By the construction we have $N(\psi_{g,m})\supset D^c\supset S^c$, and its support includes B. From what has been said we can then conclude that $(S^{cc})^o$ is the largest possible *common* null region of *all* functions $\psi(x)\in\Psi^H_m$ which vanish on S.

For an open $S\subset\mathsf{M}$ it can happen that $K=S^c$ has an empty interior. The case when S^c is a subset of a characteristic plane with a nonempty relative interior is of interest.

Example 4.6: Let $\pi=\{x|x_3=t\}$, and let K be the subset of this characteristic plane defined by $K=\{x|\tau\geqslant x_3=t\geqslant-\tau, x_1^2+x_2^2\leqslant\rho^2\}$, with $\tau>0$ and $\rho>0$. We then have $K\in\mathscr{K}_C$, i.e., K is compact, convex, and causally complete, and the set $S=K^c$ is *open*. We want to construct a function

$\psi(x) \in \Psi_m^H$, for $m>0$, such that $\psi(x)=0$ on S. The idea is to ''average'' the distribution $\zeta_y(x)$ in (4.4) with a suitable function $f(y)$ on K, and we thus consider the representation of $\psi(x)$ by an integral of the form

$$\psi(x)=\int_K d_3(y)\Delta_0(x-y;m)f_1(s)f_2(y_1,y_2) \tag{4.5}$$

with $y=(y_1,y_2,s,s)$ and $d_3(y)=dy_1dy_2ds$. We select $f_2(y_1,y_2)$ as an infinitely differentiable function on R^2 with support in the closed ball $\{(y_1,y_2)|y_1^2+y_2^2\leqslant\rho^2\}$. To achieve our goal we select $f_1(s)$ as an infinitely differentiable function on R^1 with support in the interval $[-\tau,\tau]$, and with the additional property that the integral of $f_1(s)$ over the interval vanishes. We thus express $f_1(s)$ as the derivative

$$f_1(s)=\frac{df_0(s)}{ds} \tag{4.6}$$

of an infinitely differentiable function $f_0(s)$ on R^1 with support in $[-\tau,\tau]$. Although this is not essential for the construction, we will assume that both $f_2(y_1,y_2)$ and $f_0(s)$ are *real* functions.

For any function $h(\mathbf{x})$ on R^n we define its Fourier transform $\hat{h}(\mathbf{p})$ by

$$\hat{h}(\mathbf{p})=\frac{1}{(2\pi)^{n/2}}\int_{(\infty)} d^n(\mathbf{x})h(\mathbf{x})\ \exp(-i\mathbf{x}\cdot\mathbf{p}). \tag{4.7}$$

By (4.6) we have $\hat{f}_1(q)=iq\hat{f}_0(q)$, and since the functions f_0 and f_2 are real, we have $\hat{f}_0(q)^*=\hat{f}_0(-q)$ and $\hat{f}_2(p_1,p_2)^*=\hat{f}_2(-p_1,-p_2)$. By a simple computation, based on the integral representation in (4.4), we then find that the function $\psi(x)$ in (4.5) is of the form in (4.3) with $g_+(\mathbf{p})$ and $g_-(\mathbf{p})$ given by

$$g_+(\mathbf{p})=\frac{(\omega-p_3)}{\sqrt{2\omega}}\hat{f}_0(p_3-\omega)\hat{f}_2(p_1,p_2), \quad g_-(\mathbf{p})=g_+(\mathbf{p})^*.$$

We have $\hat{f}_0(q)\in\mathscr{S}(\mathsf{R}^1)$ and $\hat{f}_2(p_1,p_2)\in\mathscr{S}(\mathsf{R}^2)$, and it is easily seen that $g_-(\mathbf{p}),g_+(\mathbf{p})\in L_2(\mathsf{R}^3)$. Hence $\psi(x)\in\Psi_m^H$, and the function $\psi(x)$ is *real* as a consequence of the reality of the functions f_0 and f_2. By the construction we have $\psi(x)=0$ on $S=K^c$. This example has implications for quantum field theory, as we will discuss in Section V. It also has implications for the theory of nets of local algebras, as we will discuss in a subsequent paper. It implies that nontrivial algebras of observables can be associated with a set such as K, with an *empty* interior, and such sets can therefore not be dismissed as ''unphysical,'' although one may at first be tempted to do so.

We next consider an example which involves the issues in Lemma 2.7 and Theorem 2.11.

Example 4.7: We want to construct an Araki distribution $\xi(x)$ from a solution $\phi(x,s)$ of the Klein–Gordon equation

$$\frac{\partial^2\phi(x,s)}{\partial t^2}-\sum_{\alpha=1}^{3}\frac{\partial^2\phi(x,s)}{\partial x_\alpha^2}-\frac{\partial^2\phi(x,s)}{\partial s^2}+m^2\phi(x,s)=0 \tag{4.8}$$

on a *five*-dimensional Minkowski-type space M_5. Let M_5 and the four-dimensional Minkowski spacetime M be related as in Lemma 2.7. We will consider a solution $\phi(x,s)$ which satisfies the condition $\phi(x,-s)=\phi(x,s)$, and we will define $\xi(x)$ by $\xi(x)=\phi(x,0)$. In the case when $m=0$ this is kind of a reversal of Araki's construction.[1] We will, however, consider the more general situation of any $m\geqslant 0$.

Let $\tau>\rho>0$, and let $h(\mathbf{x},s)$ be an infinitely differentiable function on R^4 (with Cartesian coordinates $(\mathbf{x},s)=(x_1,x_2,x_3,s)$) with support equal to $K_0=\{(\mathbf{x},s)||\mathbf{x}|^2+(s-\tau)^2\leqslant\rho^2\}\cup\{(\mathbf{x},s)||\mathbf{x}|^2+(s+\tau)^2\leqslant\rho^2\}$, and such that $h(\mathbf{x},-s)=h(\mathbf{x},s)$. We interpret the domain R^4 of this function as the spacelike hyperplane $\sigma_{05}=\{((\mathbf{x},0),s)|\mathbf{x}\in\mathsf{R}^3,s\in\mathsf{R}^1\}$ in M_5. The set K_0 is

thus the union of two closed balls of radii ρ, centered at the points $(\mathbf{0},\tau)$ and $(\mathbf{0},-\tau)$. Since we assumed that $\tau>\rho$, these balls are disjoint and do not intersect the timelike hyperplane $\Gamma\mathsf{M}=\{(x,0)|x\in\mathsf{M}\}$. Let $m\geqslant 0$. There then exists a unique solution $\phi(x,s)$ of the equation in (4.8) such that $\phi((\mathbf{x},0),s)=h(\mathbf{x},s)$, and such that the derivative of $\phi(x,s)$ with respect to t vanishes on σ_{05}, and this solution is a *bounded* C_∞-function. The function $\xi(x)=\phi(x,0)$ is then also a bounded C_∞-function, which we can identify with a tempered distribution in accordance with (4.2). Its Fourier transform $\hat{\xi}(p)$, as given by (2.1), is also a tempered distribution. The support of the Fourier transform $\hat{\phi}(p,q)$ (which is a tempered distribution) is in the set $\{(p,q)|p\cdot p=m^2+q^2, p\in\mathsf{M}, q\in\mathsf{R}^1\}$. It follows that $\mathrm{supp}(\hat{\xi}(p))\subset\{p|p\cdot p\geqslant m^2\}$, and hence $\xi(x)\in\mathscr{S}'_A(\mathsf{M})$. The Araki distribution $\xi(x)$ is, however, ''special'' in the sense that $\mathrm{supp}(\hat{\xi}(p))\subset\overline{V}(0)$.

On the basis of the analog of Proposition 4.1 for a five-dimensional spacetime we find, by a simple computation, that

$$\mathrm{supp}(\xi(x))\subset R=\{x|\rho+|t|\geqslant\sqrt{\tau^2+|\mathbf{x}|^2}\}. \tag{4.9}$$

For a suitable choice of the initial-value function $h(\mathbf{x},s)$ the support of $\xi(x)$ is *precisely* the above closed set R. We write $S=\widetilde{R}$, and hence $N(\xi)\supset S$. We note that S contains the *time-slice* $T=\{x|\tau-\rho>t>-(\tau-\rho)\}$, and hence we have $S^{cc}\supset T^{cc}=\mathsf{M}$, and $\mathscr{E}(S)\supset\mathscr{E}(T)=\mathsf{M}$. The set S is *not* a union of wedges, and Theorem 2.11 is thus *not* applicable. It is not hard to see that the Araki envelope $a(S)$ in Lemma 2.7 is actually equal to S in this case, and hence strictly smaller than $\mathscr{E}(S)$. For a region $S=\widetilde{R}$, with R as given in (4.9), we thus have the result that the largest *common* null region of all distributions in $\mathscr{S}'_A(\mathsf{M})$ which vanish on S is equal to $S=a(S)$. The implications of examples of this kind for quantum field theory have been discussed by Haag and Schroer.[14]

The function $\xi(x)$ constructed above can be regarded as a superposition of solutions of Klein–Gordon equations for different masses ranging from m to infinity. Any solution of a Klein–Gordon equation which vanishes on the time-slice T vanishes identically. The function $\xi(x)$ behaves very differently, and it turns out that the essential feature for this behavior of $\xi(x)$ is that $\mathrm{supp}(\hat{\xi}(p))$ includes arbitrarily large values of $p\cdot p$.

Let $S_0=\cup\{W|W\in\mathscr{W}, W\subset S\}$. We easily see that $S_0=D^c$, where D is the closed double cone with apices $(\mathbf{0},-\rho)$ and $(\mathbf{0},\rho)$. We trivially have $a(S_0)=\mathscr{E}(S_0)=S_0=S_0^{cc}$, and Theorem 2.11 is applicable to the set S_0, but as we said before, not to the strictly larger set S.

We next consider examples in which the null region of an Araki distribution includes a ''slab-region'' between two parallel *characteristic* planes.

Example 4.8: Let $f(s)$ be a twice differentiable bounded function on R^1. The function $\psi(x)=f(t-x_3)$ on M is then a bounded solution of the wave equation (4.1) for $m=0$, and we have $\psi(x)\subset\mathscr{S}'_A(\mathsf{M})$. We consider four special cases.

(a) $\mathrm{supp}(f)=[-\tau,\tau]$, for some $\tau>0$. The support of ψ is thus the closed ''slab-region'' R bounded above by the characteristic plane $\pi'=\{x|t=x_3+\tau\}$, and bounded below by the plane $\pi''=\{x|t=x_3-\tau\}$. Let S_u be the open half-space bounded below by π', and let S_l be the open half-space bounded above by π''. The sets S_u, S_l and $S_u\cup S_l=S_0$ are unions of wedges, and hence Theorem 2.11 is applicable. We have $a(S_0)=\mathscr{E}(S_0)=S_0\neq S_0^{cc}=\mathsf{M}$, and $N(\psi)=S_0$, $\mathrm{supp}(\psi)=\widetilde{S_0}=R$.

(b) $\mathrm{supp}(f)=[-\infty,\tau]$. With the notation as in (a) we have $a(S_u)=\mathscr{E}(S_u)=S_u\neq S_u^{cc}=\mathsf{M}$, and $N(\psi)=S_u$, $\mathrm{supp}(\psi)=\widetilde{S_u}$.

(c) $\mathrm{supp}(f)=[-\tau,+\infty]$. In this case we have $a(S_l)=\mathscr{E}(S_l)=S_l\neq S_l^{cc}=\mathsf{M}$, and $N(\psi)=S_l$, $\mathrm{supp}(\psi)=\widetilde{S_l}$.

(d) $\mathrm{supp}(f)=[-\infty,-\tau]\cup[\tau,+\infty]$. With $S_s=\{x|x_3+\tau>t>x_3-\tau\}$ we have $a(S_s)=\mathscr{E}(S_s)=S_s\neq S_s^{cc}=\mathsf{M}$, and $N(\psi)=S_s$, $\mathrm{supp}(\psi)=\widetilde{S_s}$.

In view of the above examples (b)–(d) we conclude the following. If S is an open half-space bounded above or below by a characteristic plane, then there exist distributions $\xi(x)\in\mathscr{S}'_A(\mathsf{M})$ such that $N(\xi)=S=a(S)=\mathscr{E}(S)$. The same conclusion obtains if S is an open ''slab-region'' bounded by two parallel characteristic planes. In both cases $S^{cc}=\mathsf{M}$ is strictly larger than $a(S)$, and we have trivial examples showing that $N(\xi)\supset S$ does not in general imply that $N(\xi)\supset S^{cc}$. We

can now conclude that under the premises in Theorem 3.2 the largest *common* null region $\nu(S)$ of *all* distributions $\xi(x)\in\mathscr{S}'_A(\mathsf{M})$ which vanish on S is just $\nu(S)=a(S)=\mathscr{E}(S)$.

(e) With $f(s)$ as above we consider the function $\psi_1(x)=f(t-x_3)\exp(mx_1)$ on M, for $m>0$. This function satisfies the Klein–Gordon equation (4.1) for the mass m, and its support is equal to the support of the function $\psi(x)$, but it is *not* in the class $\mathscr{S}'_A(\mathsf{M})$ since it grows exponentially in some directions. As we will see a bit later, there are actually *no* nonzero Araki distributions which satisfy the equation (4.1) for some $m>0$, and have a null region which includes a nonempty slab-region between two parallel characteristic planes.

Example 4.9: The distribution $\eta(x)=\delta(x_4-x_3)$, with Fourier transform $\hat{\eta}(p)=2\pi\delta(p_1)\delta(p_2)\delta(p_3-p_4)$, is an element of $\mathscr{S}'_A(\mathsf{M})$. It can be regarded as a limiting case of the distributions in Example 4.8(a) above, in which the planes π' and π'' coincide and the closed ''slab-region'' R becomes a characteristic plane. We have $N(\xi)=\widetilde{R}=S_u\cup S_l$, with S_u and S_l defined as in Example 4.8.

Let R be the ''slab-region'' as in Example 4.8, or the plane $R=\pi'=\pi''$ in the present example. Let $\xi\subset\mathscr{S}'_A(\mathsf{M})$, with null region $N(\xi)\supset S_c=S_a\cup S_b$, where S_a lies *above* R and S_b lies *below* R. Our simple examples show that the largest *common* null region $\nu(S_c)$ of *all* distributions $\xi(x)\in\mathscr{S}'_A(\mathsf{M})$ which vanish on S_c *must* be contained in $\widetilde{R}=S_u\cup S_l$. In particular we have $a(S_c)\subset\mathscr{E}(S_c)=\mathscr{E}(S_a)\cup\mathscr{E}(S_b)\subset\nu(S_c)\subset S_u\cup S_l$. This is relevant for the configurations in Examples 3.11–3.13 in Section III. We also see that the conclusion in Proposition 3.8 can fail if the set S is not connected. Similarly we see that the conclusion in Proposition 3.3 can fail if $W_1\cap W_2=\varnothing$.

We next consider two examples which have to do with the issues in Propositions 2.3 and 3.9. The geometric considerations are mildly complicated, and the reader may find it useful to follow the discussion by drawing suitable symbolic diagrams.

Example 4.10: Let $f(s)$ be an infinitely differentiable function on R^1 whose support is the interval $[-\tau,\tau]$, with $\tau>0$. Let $m\geqslant 0$ be fixed in what follows. The function $\psi(x)=f(t-x_3)\exp(mx_1)$ on M is then an infinitely differentiable solution of the equation (4.1) for mass m, and we have $\mathrm{supp}(\psi)=R=\{x|x_3+\tau\geqslant t\geqslant x_3-\tau\}$. We will construct other solutions of the equation (4.1) from the solution $\psi(x)$, specifying the initial values on the spacelike surface $\sigma_0=\{(\mathbf{x},0)|\mathbf{x}\in\mathsf{R}^3\}$. We write $R_0=R\cap\sigma_0=\{(\mathbf{x},0)|\tau\geqslant x_3\geqslant-\tau\}$. Let $u(\mathbf{x})$ be an infinitely differentiable function on R^3 such that $u(\mathbf{x})=1$ when $|\mathbf{x}|\leqslant 3\tau$ and $u(\mathbf{x})=0$ when $|\mathbf{x}|\geqslant 4\tau$. Let $\psi_1(x)$ be the unique solution of the equation (4.1) such that $\psi_1(\mathbf{x},0)=u(\mathbf{x})\psi(\mathbf{x},0)$ and $(\partial_t\psi_1)(\mathbf{x},0)=u(\mathbf{x})\times(\partial_t\psi)(\mathbf{x},0)$, and let $\psi_2(x)$ be the unique solution of the equation (4.1) such that $\psi_2(\mathbf{x},0)=(1-u(\mathbf{x}))\psi(\mathbf{x},0)$ and $(\partial_t\psi_1)(\mathbf{x},0)=(1-u(\mathbf{x}))(\partial_t\psi)(\mathbf{x},0)$. We thus have $\psi(x)=\psi_1(x)+\psi_2(x)$ for all $x\in\mathsf{M}$, and since the initial values of $\psi_1(x)$ on σ_0 are infinitely differentiable and of compact support, it follows that $\psi_1(x)\in\Psi^H_m$. We write $R_{01}=\{(\mathbf{x},0)|\tau\geqslant x_3\geqslant-\tau,|\mathbf{x}|\leqslant 4\tau\}$ and $R_{02}=\{(\mathbf{x},0)|\tau\geqslant x_3\geqslant-\tau,|\mathbf{x}|\geqslant 3\tau\}$. The subset R_{01} of σ_0 thus contains the supports of the initial values of $\psi_1(x)$, and R_{02} contains the supports of the initial values of $\psi_2(x)$. By Proposition 4.1 we then have $N(\psi_1)\supset R^c_{01}$ and $N(\psi_2)\supset R^c_{02}$. Let S_u and S_l be defined as in Example 4.8, i.e., $S_u=\{x|t>x_3+\tau\}$ and $S_l=\{x|t<x_3-\tau\}$. Since $\psi(x)=\psi_1(x)+\psi_2(x)$, and since $N(\psi)=\widetilde{R}=S_u\cup S_l$, it follows that

$$N(\psi_1)\supset R^c_{01}\cup(R^c_{02}\cap(S_u\cup S_l))=R^c_{01}\cup(R^c_{02}\cap S_u)\cup(R^c_{02}\cap S_l)\equiv S_1. \tag{4.10}$$

We consider the four open double cones $D^o_l=D(x'_l,x''_l)^o$, $D^o_i=D(x''_l,x'_u)^o$, $D^o_u=D(x'_u,x''_u)$, and $D^o=D(x'_l,x''_u)^o$, with the apices $x'_l=(\mathbf{0},-3\tau)$, $x''_l=(\mathbf{0},-\tau)$, $x'_u=(\mathbf{0},\tau)$, and $x''_u=(\mathbf{0},3\tau)$. The apices thus all lie on the time axis, and such that D^o_l lies below D^o_i which lies below D^o_u. The two double cones D^o_l and D^o_u are thus *timelike* separated, and we have $D^o_l\cup D^o_i\cup D^o_u\subset D^o$ and $D^o=(D^o_l\cup D^o_u)^{cc}$. By the above definitions of R_{02} and $\psi_2(x)$ we have $D^o\subset R^c_{02}$, and hence $\psi_2(x)=0$ and $\psi_1(x)=\psi(x)$ for all $x\in D^o$. In view of the nature of the support R of $\psi(x)$ it then follows that

$$\mathrm{supp}(\psi_1)\supset\overline{D^o_i},\quad N(\psi_1)\supset D^o_l\cup D^o_u. \tag{4.11}$$

We can now draw some interesting and important conclusions from the above.

Proposition 3.9 says (among other things) that if K_1 and K_2 are two subsets of M in the set $\mathscr{K}_E$, and if $\xi(x)\in\mathscr{S}'_A(\mathsf{M})$, with null region $N(\xi)$, then $N(\xi)\supset(K_1\cap K_2)^c$ whenever $N(\xi)\supset K_1^c\cup K_2^c$. We can think about this as expressing an ''intersection property'' of the causal complements of certain sets contained in the null region of $\xi(x)$. Now it is important to understand that this intersection property is definitely *not* valid for two *arbitrary* closed, causally complete subsets K_l and K_u of M. Let $K_l=(D_l^o)^c$ and $K_u=(D_u^o)^c$. These sets are closed and causally complete, and we have $(K_l\cap K_u)^c=(D_l^o\cup D_u^o)^{cc}=D^o\supset\overline{D_i^o}$. In view of (4.11) the set $(K_l\cap K_u)^c$ is *not* contained in $N(\psi_1)$, whereas $N(\psi_1)\supset D_l^o\cup D_u^o=K_l^c\cup K_u^c$. For the consideration of this issue in quantum field theory, or in the theory of local nets, it is of importance that the example involves distributions in $\mathscr{S}'_A(\mathsf{M})$ which are functions $\psi_1(x)$ in Ψ_m^H, for an arbitrary $m\geqslant 0$. Note that we can clearly find *real-valued* functions of this nature if we like.

Example 4.11: We continue the above discussion, and we consider the two timelike separated points $z'=(\mathbf{0},-2\tau)\in D_l^o\subset S_1$ and $z''=(\mathbf{0},2\tau)\in D_u^o\subset S_1$, with $S_1\subset N(\psi_1)$ as defined in (4.10). We thus have $z',z''\in N(\psi_1)$, but $[z',z'']$ is *not* in $N(\psi_1)$ since $[x_l'',x_u']\subset[z',z'']$ and since $\mathrm{supp}(\psi_1)\supset[x_l',x_{u\prime}]$ by (4.11). We will now give a particular example of a continuous curve $C\subset S_1\subset N(\psi_1)$ with z' and z'' as endpoints. The curve C is composed of five arcs, $C=C_1\cup C_2\cup C_3\cup C_4\cup C_5$ as follows. $C_1=[z',z_1]$ with $z_1=(0,0,2\tau,0)$, $C_2=[z_1,z_2]$ with $z_2=(0,0,5\tau,0)$, $C_3=\{(0,5\tau\sin\theta,5\tau\cos\theta,0)\,|\,\theta\in[0,\pi]\}$, $C_4=[z_3,z_4]$ with $z_3=(0,0,-5\tau,0)$ and $z_4=(0,0,-2\tau,0)$, and $C_5=[z_4,z'']$. We easily see that $C_1\subset D^o\cap S_l\subset R_{02}^c\cap S_l$; $C_5\subset D^o\cap S_u\subset R_{02}^c\cap S_u$; $C_2\subset R_{02}^c\cap S_l$; $C_4\subset R_{02}^c\cap S_u$; and $C_3\subset R_{01}^c$, and in view of (4.10) it follows that $C\subset S_1\subset N(\psi_1)$. The curve C does not satisfy the conditions of the curve C in Proposition 2.3, and as our example shows, the conclusion in the proposition can then fail to hold. We remark that the set S_1 is, in fact, connected, but we need not prove this here.

With the premises in Theorem 3.6, or in Propositions 3.3 or 3.8 we have $N(\xi)\supset S^{cc}$ if $N(\xi)\supset S$, but this conclusion depends on the very special nature of S in these propositions, and it is definitely not valid for arbitrary subsets S of M, as our many examples clearly show. Concerning the results in Theorem 3.2 about the null regions of distributions in $\mathscr{S}'_A(\mathsf{M})$, our Example 4.8 shows that these results can in general not be ''improved'' in the sense that we could find a *larger* region than $\mathscr{E}(S)$ which is always included in the null region $N(\xi)$ of such a distribution ξ, given that $N(\xi)\supset S$. There is, however, a physically interesting *subset* of $\mathscr{S}'_A(\mathsf{M})$ for which we *can* obtain stronger results, and we will now consider this subset.

Lemma 4.12: Let u be a forward isotropic vector, and let $S\subset\mathsf{M}$ be a nonempty open set which is invariant under all translations in the direction u, i.e., we have $S=\{x+\tau u\,|\,x\in S,\tau\in\mathsf{R}^1\}$. Let $\eta(x)\in\mathscr{S}'(\mathsf{M})$, with null region $N(\eta)\supset S$, be such that the support of the Fourier transform of $\eta(x)$ is contained in the open lightcone, i.e., $\mathrm{supp}(\hat{\eta}(p))\subset V(0)$. Then $\eta=0$.

In particular this applies to the case when S is a ''slab-region'' bounded by two parallel characteristic planes, or when S is a half-space bounded by a characteristic plane.

Proof: (1) Let C be a compact subset of S with a nonempty interior. There then exists a nonempty open set S_1 such that the translated set $C_y=\{x+y\,|\,x\in C\}$ is included in S for all $y\in S_1$. We then have $C_{y+\tau u}\subset S$ for all $y\in S_1$ and all $\tau\in\mathsf{R}^1$.

Let $g(x)$ be an infinitely differentiable function on M with support in C, with Fourier transform $\hat{g}(p)$. For any $y\in\mathsf{M}$ we define the function $g_y(x)$ (of x in M) by $g_y(x)=g(x-y)$, and we define the function $f(y)$ by

$$f(y)=\eta[g_y]=\int_{(\infty)}d^4(x)\,\eta(x)g_y(x)=\int_{(\infty)}d^4(p)\,\hat{\eta}(p)\hat{g}(-p)\exp(iy\cdot p).$$

Since $\eta(x)=0$ on S, it follows from the above constructions that $f(y+\tau u)=0$ for all $y\in S_1$, and all $\tau\in\mathsf{R}^1$.

(2) Since $\mathrm{supp}(\hat{\eta}(p))\subset V(0)$ we can write $f(y)$ as the sum $f(y)=f_+(y)+f_-(y)$, with

$$f_+(y)=\int_{V_+(0)}d^4(p)\,\hat{\eta}(p)\hat{g}(-p)\exp(iy\cdot p),\quad f_-(y)=\int_{V_-(0)}d^4(p)\,\hat{\eta}(p)\hat{g}(-p)\exp(iy\cdot p).\tag{4.12}$$

Both functions are infinitely differentiable functions of y, and since η is a *tempered* distribution we have

$$|f_+(y)|<C\cdot(1+|\mathbf{y}|+|y_4|)^{n-1},\quad |f_-(y)|<C\cdot(1+|\mathbf{y}|+|y_4|)^{n-1},$$

for some positive integer n independent of g, and some constant C.

With $y\in S_1$ temporarily fixed we consider the functions $h_+(\tau)=f_+(y+\tau u)$ and $h_-(\tau)=f_-(y+\tau u)$, as functions of τ on R^1. We have $h_+(\tau)+h_-(\tau)=f(y+\tau u)=0$ for all real τ. It follows at once from (4.12) that the supports of the Fourier transforms of these two functions (regarded as distributions in $\mathscr{S}'(\mathsf{R}^1)$) have only the point 0 in common, and hence $h_+(\tau)=h_-(\tau)$ is a polynomial in τ, of a degree not exceeding $n-1$. Hence $\partial_\tau^n h_+(\tau)=0=\partial_\tau^n h_-(\tau)$, and we thus conclude that $(u\cdot\partial)^n f_+(y)=0$ and $(u\cdot\partial)^n f_-(y)=0$ for all $y\in S_1$. Here ∂ denotes the gradient operator.

(3) We define the *open forward imaginary tube* $\mathscr{T}_{i+}$ in complex Minkowski space by $\mathscr{T}_{i+}=\{y'+iy''|y'\in\mathsf{M},y''\in V_+(0)\}$. By inspection of the expression for $f_+(y)$ in (4.12) we see that the integral defines a (jointly) continuous function of the complex variable y on the closed forward imaginary tube $\overline{\mathscr{T}}_{i+}$, which is analytic on the open tube. Since $(u\cdot\partial)^n f_+(y)$ vanishes on the nonempty open set $S_1\subset\mathsf{M}$, it follows that $(u\cdot\partial)^n f_+(y)$ vanishes on $\overline{\mathscr{T}}_{i+}$, and in particular for all real $y\in\mathsf{M}$. In a similar fashion we conclude that $(u\cdot\partial)^n f_-(y)$ vanishes on M, and hence $(u\cdot\partial)^n\eta[g_y]=(u\cdot\partial)^n f(y)=0$ for all $y\in\mathsf{M}$. Since this holds for all $g(x)\in\mathscr{S}(\mathsf{M})$ with support in S_1, and for all $y\in\mathsf{M}$, it follows that $(u\cdot p)^n\hat{\eta}(p)=0$. Since $u\cdot p\neq 0$ on supp$(\hat{\eta})$, it follows that $\eta=0$. This completes the proof.

The considerations in Example 4.8 show that the conclusion in the lemma can fail for distributions in $\mathscr{S}'_A(\mathsf{M})$ which do not satisfy the condition that supp$(\hat{\eta}(p))\subset V(0)$, as well as for solutions of the Klein–Gordon equation for $m>0$ which are not in $\mathscr{S}'_A(\mathsf{M})$.

We recall here part (c) of Proposition 2.5, according to which $\xi(x)=0$ on a ''slab-region'' if $\xi(x)=0$ on a ''tube-region'' of the form $S=\{x+\tau u|x\in D^o,\tau\in\mathsf{R}^1\}$, where D^o is an open double cone. *This* conclusion holds for *all* distributions in $\mathscr{S}'_A(\mathsf{M})$, and does not depend on the assumption in the present lemma that supp$(\hat{\eta}(p))\subset V(0)$.

The above result leads to an immediate ''improvement'' of Theorem 3.2 for the Araki distributions which satisfy the special condition that supp$(\hat{\eta}(p))\subset V(0)$, as follows.

Proposition 4.13: Let the premises and notation be as in Theorem 3.2. Let $\eta(x)\in\mathscr{S}'(\mathsf{M})$ be such that supp$(\hat{\eta}(p))\subset V(0)$. Let $N(\eta)$ be the null region of η, and suppose that $N(\eta)\supset S$. Then $N(\eta)\supset(S^{cc})^o$.

Proof: We have $\eta(x)\in\mathscr{S}'_A(\mathsf{M})$. By Theorem 3.2 we either have $\mathscr{E}(S)=(S^{cc})^o$, or else $S^{cc}=\mathsf{M}$ *and* $\mathscr{E}(S)$ contains an open slab-region bounded by two parallel characteristic planes. In the latter case we have $N(\eta)=\mathsf{M}$ by Lemma 4.12 above, and hence $N(\eta)\supset(S^{cc})^o$ in all cases.

As we have said, we are led to the Araki distributions in $\mathscr{S}'_A(\mathsf{M})$ if we consider matrix elements of commutators of field operators between two states of compact support in momentum space. If we consider *vacuum expectation values* of commutators of field operators in a theory with no massless particles, we are led to the distributions $\eta(x)\in\mathscr{S}'_A(\mathsf{M})$ which satisfy the additional condition that supp$(\hat{\eta}(p))\subset V(0)$.

Lemma 4.12 and Proposition 4.13 apply in particular to those solutions of the Klein–Gordon equation for $m>0$ which can be regarded as elements in $\mathscr{S}'_A(\mathsf{M})$. For C_2-solutions this means that the solution can grow no faster than some power of $(|\mathbf{x}|+|t|)$ as $x=(\mathbf{x},t)$ tends to infinity. As we see from Example 4.8, the conclusions can fail for C_2-solutions which grow exponentially as x tends to infinity in some direction. The conclusions can also fail in the case of the *wave equation*, i.e., the Klein–Gordon equation for $m=0$.

We next consider a stronger result than in Lemma 4.12, but with a slightly stronger condition on the support of $\hat{\eta}(p)$. It is now given that the distribution vanishes throughout a region obtained when we remove a portion ''in the middle'' from a ''tube-region'' of the kind described in Proposition 2.5.

Lemma 4.14: Let $\rho>0$, and let D^o_ρ be the open double cone with apices $x'_\rho=(\mathbf{0},-\rho)$ and $x''_\rho=(\mathbf{0},\rho)$. We define the open ''tube-region'' $T(\rho)$ in Minkowski spacetime by

$$T(\rho)=\{(x_1,x_2,x_3+s,x_4+s)|x\in D_\rho^o, s\in \mathsf{R}^1\}.$$

Let $\tau>0$, and let $S=S(\rho,\tau)$ be the region

$$S(\rho,\tau)=\{x|x\in T(\rho),\ |x_3+x_4|>\tau\}. \tag{4.13}$$

Let $\eta\in\mathscr{S}'(\mathsf{M})$, with null region $N(\eta)\supset S$, and with a Fourier transform $\hat{\eta}$ such that $\text{supp}(\hat{\eta}(p))\subset\{p|p\in\mathsf{M}, p\cdot p\geqslant m^2\}$ for some $m>0$. Then $\eta=0$.

Proof: (1) Let $D=D(x',x'')$ be the double cone with apices $x'=(\mathbf{0},-\rho/2)$ and $x''=(\mathbf{0},\rho/2)$, and let $g(x)\in\mathscr{S}(\mathsf{M})$, with $\text{supp}(g(x))\subset D(x',x'')$. We consider the convolution of η with g,

$$\zeta(x)=(\eta\star g)(x)=\int_{(\infty)} d^4(y)\ \ \eta(x-y)g(y). \tag{4.14}$$

The object $\zeta(x)$ is a C_∞-function on M, which we can also regard as a distribution in $\mathscr{S}'(\mathsf{M})$. We thus have, for all $x\in\mathsf{M}$,

$$|\zeta(x)|<k\cdot(1+|\mathbf{x}|+|x_4|)^{n'} \tag{4.15}$$

for some positive integer n' and some constant k.

Since the Fourier transform of $g(x)$ is an entire function of p, we have $\text{supp}(\hat{\zeta}(p))=\text{supp}(\hat{\eta}(p))\subset\{p|p\in\mathsf{M}, p\cdot p\geqslant m^2\}$. Considering the supports of $\eta(x)$ and $g(x)$ we easily see that $N(\zeta)\supset S(\rho_0,\tau_0)$ with $\rho_0=\rho/2$ and $\tau_0=\tau+\rho/2$. The distribution ζ thus satisfies the same kind of conditions as the original distribution η. Our strategy of proof will be to show that $N(\eta)\supset T(\rho_0)$, and it will then follow from Lemma 4.12 that $\eta=0$. Now $\eta=0$ on $T(\rho_0)$ if and only if $\zeta(0,0,s,s)=0$ for all C_∞-functions $g(x)$ with support in $D(x',x'')$ and for all $s\in\mathsf{R}^1$. In order to show that ζ has this property we will show that

$$\int_{-\tau_0}^{\tau_0} ds\,\zeta(0,0,s/2,s/2)s^l=0 \tag{4.16}$$

for every non-negative integer l and for all g. In view of the nature of the support of $\zeta(x)$ discussed above we have $\zeta(0,0,s/2,s/2)=0$ when $|s|\geqslant\tau_0$. Since $\zeta(0,0,s/2,s/2)$ is continuous, and since the powers of s form a total set in $L^2([-\tau_0,\tau_0])$, it follows from (4.16) that we also have $\zeta(0,0,s/2,s/2)=0$ when $|s|\leqslant\tau_0$, and hence $\zeta(0,0,s/2,s/2)=0$ for all real s.

(2) Let $g(x)$ be a C_∞-function with support in $D(x',x'')$, and let l be a non-negative integer. In what follows we regard $g(x)$ and l as fixed. With $\zeta(x)$ defined as in (4.14) we define the function $A(r,s)$ of the two real variables r and s by

$$A(r,s)=\zeta\left(0,0,\frac{s-r}{2},\frac{s+r}{2}\right)s^l. \tag{4.17}$$

The function $A(r,s)$ is an infinitely differentiable function on R^2, and it follows from (4.15) that

$$|A(r,s)|<k_0(1+\rho_0 m^2(|s|+|r|))^n \tag{4.18}$$

for some constant k_0 and some positive integer n. (The optional multiplier $\rho_0 m^2>0$ of $|s|+|r|$ is inserted for convenience, in anticipation of what will follow.) Since $N(\zeta)\supset S(\rho_0,\tau_0)$, it follows that

$$A(r,s)=0,\quad \text{if } |r|\leqslant\rho_0 \quad\text{and } |s|\geqslant\tau_0. \tag{4.19}$$

The function $A(r,s)$ can be regarded as a tempered distribution in $\mathscr{S}'(R^2)$, and we consider its Fourier transform $\hat{A}(q_1,q_2)$ defined by

$$\hat{A}(q_1,q_2)=\frac{1}{2\pi}\int_{-\infty}^{\infty}dr\int_{-\infty}^{\infty}dsA(r,s)\ \exp(-irq_1-isq_2).$$

Since $\mathrm{supp}(\hat{\zeta}(p))\subset\{p|p\in\mathsf{M},p\cdot p\geqslant m^2\}$ we conclude, by a simple computation, that

$$\hat{A}(q_1,q_2)=0,\quad \text{if}\ \ 4q_1q_2<m^2. \tag{4.20}$$

(3) Let $f_1(s),f_2(s)\in\mathscr{S}(\mathsf{R}^1)$, with Fourier transforms $\hat{f}_1(q)$ and $\hat{f}_2(q)$ defined as in (4.7), be such that

$$\int_{-\infty}^{\infty}dsf_1(s)=1,\quad f_2(0)=1,\quad \mathrm{supp}(\hat{f}_1(q))=\mathrm{supp}(\hat{f}_2(q))\subset(-1/2,1/2). \tag{4.21}$$

For $\lambda>0$ we define $h_\lambda(r,s)\in\mathscr{S}(\mathsf{R}^2)$ by

$$h_\lambda(r,s)=\lambda f_1(\lambda r)f_2(m^2s/\lambda), \tag{4.22}$$

and we then have

$$\begin{aligned}A[h_\lambda]&=\int_{-\infty}^{\infty}dr\int_{-\infty}^{\infty}dsA(r,s)h_\lambda(r,s)\\&=\frac{\lambda}{m^2}\int_{-\infty}^{\infty}dq_1\int_{-\infty}^{\infty}dq_2\hat{A}(q_1,q_2)\hat{f}_1(-q_1/\lambda)\hat{f}_2(-\lambda q_2/m^2).\end{aligned}$$

By (4.21) we have $\hat{f}_1(-q_1/\lambda)\hat{f}_2(-\lambda q_2/m^2)=0$ *unless* $|q_1|<\lambda/2$ *and* $|q_2|<m^2/(2\lambda)$, and hence *unless* $|q_1q_2|<m^2/4$. In view of (4.20) the supports of the distribution $\hat{A}(q_1,q_2)$ and the test function $\hat{f}_1(-q_1/\lambda)\hat{f}_2(-\lambda q_2/m^2)$ are thus *disjoint*, and it follows that $A[h_\lambda]=0$ for all $\lambda>0$.

(4) We next note that

$$\lim_{\lambda\to+\infty}\int_{-\rho_0}^{\rho_0}dr\int_{-\infty}^{\infty}dsA(r,s)h_\lambda(r,s)=\int_{-\tau_0}^{\tau_0}ds\zeta(0,0,s/2,s/2)s^l. \tag{4.23}$$

The range of the s-integration in the expression at left is actually the interval $[-\tau_0,\tau_0]$ in view of (4.19), and the result in (4.23) then follows readily in view of (4.17), (4.21), and (4.22).

We write

$$A_0[h_\lambda]=\int_{-\infty}^{-\rho_0}dr\int_{-\infty}^{\infty}dsA(r,s)h_\lambda(r,s)+\int_{\rho_0}^{\infty}dr\int_{-\infty}^{\infty}dsA(r,s)h_\lambda(r,s). \tag{4.24}$$

We will show that $A_0(h_\lambda)$ tends to zero as λ tends to $+\infty$, and since $A[h_\lambda]=0$ by the result in step (3), it then follows that the right member in (4.23) equals zero, as we promised to show.

For the test functions $f_1(s)$ and $f_2(s)$ we have estimates of the form

$$|f_1(r)|<\frac{k_1}{(1+|r|)^{n+6}},\quad |f_2(s)|<\frac{k_2}{(1+|s|)^{n+4}}, \tag{4.25}$$

for some constants k_1 and k_2. Suppose now that $|r|\geqslant\rho_0$ and that $\lambda>\rho_0m^2$. We then have $(1+\lambda|r|)(1+m^2|s|/\lambda)\geqslant1+\lambda|r|+m^2|rs|>1+\rho_0m^2(|r|+|s|)$, and, trivially, $(1+\lambda|r|)\geqslant1+\lambda\rho_0$. From this, and from the estimates in (4.18) and (4.25), we then obtain the inequality

$$|A(r,s)h_\lambda(r,s)|<\frac{\lambda k_0k_1k_2}{(1+\lambda\rho_0)^2(1+\rho_0m^2(|r|+|s|))^4},$$

which holds for all s and all r such that $|r| \geqslant \rho_0$, provided only that $\lambda > \rho_0 m^2$. On the basis of this estimate we obtain the inequality $|A_0[h_\lambda]| < k_3/\lambda$, where k_3 is some constant, for the quantity in (4.24) when $\lambda > \rho_0 m^2$, and it follows that $A_0(h_\lambda)$ tends to zero as λ tends to $+\infty$. This completes the proof.

This lemma is immediately applicable to solutions of the Klein–Gordon equation for mass $m > 0$. If such a solution $\psi(x)$ vanishes throughout the region $S = S(\rho, \tau)$ defined in the lemma, and if the solution can be regarded as an element of $\mathscr{S}'(\mathsf{M})$, i.e., if it grows no faster than a polynomial in x for large x, then it vanishes on M. We note that we obviously have $\mathscr{E}(S) \neq \mathsf{M}$, and the conclusion that $\psi(x)$ vanishes identically cannot be drawn on the basis of the two ''classical'' principles alone. We also note, with reference to the discussion in Example 4.8, that the conclusion can fail in the case of solutions which grow exponentially for large x. It can also fail for the wave equation, with $m = 0$.

On the basis of Lemma 4.14 we obtain the following interesting (and plausible) result.

Proposition 4.15: Let $W_1, W_2 \in \mathscr{W}$ be such that $W_1^c \cap W_2^c = \varnothing$. Let $\eta(x) \in \mathscr{S}'(\mathsf{M})$, with null region $N(\eta) \supset W_1 \cup W_2$, have a Fourier transform which satisfies the condition that $\mathrm{supp}(\hat{\eta}(p)) \subset \{p | p \in \mathsf{M},\ p \cdot p \geqslant m^2\}$, for some $m > 0$. Then $\eta = 0$.

Proof: If $W_1 \cap W_2 \neq \varnothing$, the conclusion follows from Proposition 3.3. We thus consider the case when $W_1 \cap W_2 = \varnothing$. The upper plane of either wedge is then parallel with the lower plane of the other wedge, and the upper plane of one of the wedges must lie *above* the lower plane of the other. Suppose that the upper plane π_2'' of the wedge $W_2 = W(\pi_2', \pi_2'')$ lies above the lower plane π_1' of the wedge $W_1 = W(\pi_1', \pi_1'')$. The ''slab-region'' R bounded above by π_2'' and bounded below by π_1' then contains a ''cut'' tube-region S, which is Poincaré equivalent to the region $S(\rho, \tau)$ in (4.13), and such that $N(\eta) \supset S$. On the basis of Lemma 4.14 we then conclude that $\eta = 0$. This completes the proof.

We recall again Proposition 3.3, which played an important role in our discussion in Section III. Let $W_1 = W(\pi_1', \pi_1'')$ and $W_2 = W(\pi_2', \pi_2'')$ be two wedges in $\mathscr{W}$, and let $S = W_1 \cup W_2$. Suppose that $W_1 \cap W_2 \neq \varnothing$. The proposition asserts that we then have $a(S) = \mathscr{E}(S) = S^{cc}$, and hence, if $\xi(x) \in \mathscr{S}_A'(\mathsf{M})$, with null region $N(\xi) \supset S$, then $N(\xi) \supset S^{cc}$. In particular, if π_1' is not parallel with π_2'' we have $W(\pi_1', \pi_2'') \subset S^{cc}$, and hence $N(\xi) \supset W(\pi_1', \pi_2'')$. Suppose now that $W_1 \cap W_2 = \varnothing$. We then have $a(S) = \mathscr{E}(S) = S = W_1 \cup W_2$, but S^{cc} is strictly larger than $\mathscr{E}(S)$ unless $W_1 \subset W_2^c$, and the question arises whether it might nevertheless be true that $N(\xi) \supset S^{cc}$ if $N(\xi) \supset S$. This is an important question in view of the nature of our reasoning in the proofs of the propositions and theorems in Section III, in which it was a constant concern whether the configurations of wedges contained a ''sufficiently large'' set of pairs of *intersecting* wedges.

If $W_1 \cap W_2 = \varnothing$, then the normals of the boundary planes of the wedges span either a three-dimensional space, or else a two-dimensional space. In the latter case the lower plane of W_1 is parallel with the upper plane of W_2, and the upper plane of W_1 is parallel with the lower plane of W_2. If $W_1^c \cap W_2^c \neq \varnothing$, then $a(S) = \mathscr{E}(S) = S = S^{cc}$, and by the discussion in Example 4.8, S is the largest common null region $\nu(S)$ of all $\xi \in \mathscr{S}_A'(\mathsf{M})$ for which $N(\xi) \supset S$. If $W_1^c \cap W_2^c = \varnothing$, then $S^{cc} = \mathsf{M}$. As shown in Examples 4.8 and 4.9 we can easily find nonzero distributions $\xi(x) \in \mathscr{S}_A'(\mathsf{M})$ for which $N(\xi) \supset W_1 \cup W_2$, but for the *restricted* class of distributions $\eta(x)$ considered in Proposition 4.15 we do have $N(\eta) = \mathsf{M}$ if $N(\eta) \supset S$.

We consider the situation when $W_1 \cap W_2 = \varnothing$ and when the normals of the boundary planes of the wedges span a *three*-dimensional space. Without any essential loss of generality we can then assume that the plane π_1' is *not* parallel with the plane π_2''. We will now present an example of a solution $\psi_1(x)$ of the Klein–Gordon equation (for any mass $m \geqslant 0$) such that $N(\psi_1)$ includes $S = W_1 \cup W_2$, but *not* $W(\pi_1', \pi_2'')$. Since we have $W(\pi_1', \pi_2'') \subset S^{cc}$ this example shows conclusively that if $\xi(x) \in \mathscr{S}_A'(\mathsf{M})$ and $N(\xi) \supset S = W_1 \cup W_2$, then it does not follow that $N(\xi) \supset S^{cc}$, even for $\xi(x)$ in the restricted class in Proposition 4.15. This is in marked contrast to the situation for the configuration of wedges in that proposition.

Example 4.16: (1) Let $h(s)$ be a real-valued infinitely differentiable function on R^1 with $\mathrm{supp}(h) = [-\tau, \tau]$, with $\tau > 0$. Let $m \geqslant 0$, $\rho_2 > \rho_1 > 0$, and let $g(q)$ be a real-valued infinitely differentiable function on R^1 with $\mathrm{supp}(g) = [\rho_1, \rho_2]$. We define the function $f(x_1, x_2)$ on R^2 by

$$f(x_1, x_2) = \int_{\rho_1}^{\rho_2} dq\, g(q) \exp(x_2 \sqrt{q^2 + m^2}) \cos(q x_1). \tag{4.26}$$

The function $\psi(x)$ on M defined by

$$\psi(x)=f(x_1,x_2)h(x_3-t)$$

is then a *real-valued* C_∞-solution of the Klein–Gordon equation (4.1), for mass m.

We define H_+ as the open half-space bounded below by the characteristic plane $\pi_2'=\{x|t=x_3+\tau\}$, and we define H_- as the open half-space bounded above by the characteristic plane $\pi_1''=\{x|t=x_3-\tau\}$. The integral in (4.26) defines an entire analytic function of the variables x_1 and x_2, and hence $\mathrm{supp}(\psi(x))=\{x|x\in\mathsf{M},x_3+\tau\geqslant t\geqslant x_3-\tau\}=\widetilde{H}_+\cap\widetilde{H}_-$.

(2) Let $c(s)$ be a real-valued infinitely differentiable function such that $c(s)=0$ for $s\leqslant 0$ and $c(s)=1$ for $s\geqslant s_0>0$, with s_0 a constant. Let $\psi_1(x)$ and $\psi_2(x)$ be the unique solutions of the Klein–Gordon equation for mass m which satisfy the initial conditions

$$\psi_1(\mathbf{x},0)=(1-c(x_2))\psi(\mathbf{x},0),\quad (\partial_t\psi_1)(\mathbf{x},0)=(1-c(x_2))(\partial_t\psi)(\mathbf{x},0),$$

$$\psi_2(\mathbf{x},0)=c(x_2)\psi(\mathbf{x},0),\quad (\partial_t\psi_2)(\mathbf{x},0)=c(x_2)(\partial_t\psi)(\mathbf{x},0),$$

on the spacelike 3-plane $\sigma_0=\{(\mathbf{x},0)|\mathbf{x}\in R^3\}$. With this construction we have the following obvious properties of the solutions ψ_1 and ψ_2. (a) $\psi_1(x)+\psi_2(x)=\psi(x)$, for all $x\in\mathsf{M}$. (b) The supports of the initial values $\psi_1(\mathbf{x},0)$ and $(\partial_t\psi_1)(\mathbf{x},0)$ of $\psi_1(x)$ are contained in the subset $\sigma_{0,1}=\{(\mathbf{x},0)|x_2\leqslant s_0,|x_3|\leqslant\tau\}$ of the plane σ_0, and the supports of the initial values $\psi_2(\mathbf{x},0)$ and $(\partial_t\psi_2)(\mathbf{x},0)$ of $\psi_2(x)$ are contained in the subset $\sigma_{0,2}=\{(\mathbf{x},0)|x_2\geqslant 0,|x_3|\leqslant\tau\}$ of the plane σ_0. (c) The initial values $\psi_1(\mathbf{x},0)=(1-c(x_2))f(x_1,x_2)h(x_3)$ and $(\partial_t\psi_1)(\mathbf{x},0)=-(1-c(x_2))f(x_1,x_2)h'(x_3)$ are in the space of functions $\mathscr{S}(\mathsf{R}^3)$, and hence $\psi_1(x)$ is a real-valued infinitely differentiable solution of the Klein–Gordon equation in the set $\Psi_m^H\subset\mathscr{S}_A'(\mathsf{M})$. (The solution $\psi_2(x)$ is obviously *not* in $\mathscr{S}_A'(\mathsf{M})$ since it grows exponentially in the positive 2-direction.)

(3) We define the two characteristic planes π_1' and π_2'' by $\pi_1'=\{(\mathbf{x},t)|t=x_2\}$ and $\pi_2''=\{(\mathbf{x},t)|t=-x_2\}$. We then have $\sigma_{0,2}\subset\overline{W}(\pi_1'',\pi_1')=W(\pi_1',\pi_1'')^c$, and it follows that $\psi_2(x)=0$ on $W(\pi_1',\pi_1'')$. Now $W(\pi_1',\pi_1'')\subset H_-$, and since $\psi_1(x)+\psi_2(x)=\psi(x)=0$ on H_-, we conclude that $\psi_1(x)=0$ on $W(\pi_1',\pi_1'')=W_1$. Similarly we conclude that $\psi_1(x)=0$ on $W(\pi_2',\pi_2'')=W_2$.

We have $\sigma_{0,2}\subset\overline{W}(\pi_2'',\pi_1')=W(\pi_1',\pi_2'')^c$, and hence $\psi_2(x)=0$ on $W(\pi_1',\pi_2'')$, which implies that $\psi_1(x)=\psi(x)$ on $W(\pi_1',\pi_2'')$. We easily see that $W(\pi_1',\pi_2'')\cap\mathrm{supp}(\psi)=W(\pi_1',\pi_2'')\cap\mathrm{supp}(\psi_1)$ is *nonempty*. In particular this set contains the open double cone $D^o=D(x',x'')^o$ with apices $x'=(0,-\tau,0,-\tau)$ and $x''=(0,-\tau,0,\tau)$.

(4) In summary we have the following situation. The *real-valued* solution $\psi_1(x)\in\Psi_m^H$ vanishes throughout $W_1\cup W_2$. The upper plane π_1'' of the wedge $W_1=W(\pi_1',\pi_1'')$ is parallel with the lower plane π_2' of the wedge $W_2=W(\pi_2',\pi_2'')$ and lies *below* π_2'. Hence $W_1\cap W_2=\varnothing$. The function $\psi_1(x)$ *does not* vanish throughout the wedge $W(\pi_1',\pi_2'')$, and hence does not vanish throughout $(W_1\cup W_2)^{cc}$. This is the example we promised above.

Example 4.17: In the above example the upper plane of the wedge W_1 is parallel with the lower plane of the wedge W_2. It is of interest to find an example in which no two boundary planes are parallel, and we can do this with a minor modification of Example 4.16. Let the premises and notation be as in that example. We define the two characteristic planes π_3' and π_3'' by $\pi_3'=\{x|t\sqrt{2}=\tau+s_0-x_2-x_3\}$ and $\pi_3''=\{x|t\sqrt{2}=x_2+x_3-\tau-s_0\}$. We easily see that $\sigma_{0,1}\subset\overline{W}(\pi_3'',\pi_3')=W(\pi_3',\pi_3'')^c$, and hence we have $\psi_1(x)=0$ on $W_3=W(\pi_3',\pi_3'')$. We next note that the point $x=(0,-s_0,2\tau+2s_0,0)$ lies *above* the planes π_1' and π_3', and *below* the planes π_1'' and π_3''. Hence $W_1\cap W_3\neq\varnothing$, and by Proposition 3.3 we conclude that $\psi_1(x)=0$ on $W(\pi_1',\pi_3'')$. The situation is thus as follows. No two boundary planes of the wedges $W(\pi_1',\pi_3'')$ and $W(\pi_2',\pi_2'')$ are parallel. We have $\psi_1(x)=0$ on $W(\pi_1',\pi_3'')\cup W(\pi_2',\pi_2'')$, but $\psi_1(x)$ does *not* vanish throughout the subset $W(\pi_1',\pi_2'')$ of $(W(\pi_1',\pi_3'')\cup W(\pi_2',\pi_2''))^{cc}$. Note that we necessarily have $W(\pi_1',\pi_3'')\cap W(\pi_2',\pi_2'')=\varnothing$, because otherwise we would have $N(\psi_1)\supset W(\pi_1',\pi_2'')$, by Proposition 3.3. It is not hard to show by a direct computation that the intersection is indeed empty. The configuration of the two wedges $W(\pi_1',\pi_3'')$ and $W(\pi_2',\pi_2'')$ is of the same nature as the configuration in Example 3.14 in Section III, and the remarks about that example apply here, too.

We conclude this section with two simple examples which show that the common null region of all solutions of the Klein–Gordon equation in Ψ_m, with $m>0$, which vanish on certain open sets S can be *larger* than $\mathscr{E}(S)$ (but, of course, *never* larger than $(S^{cc})^o$, in view of the discussion in Proposition 4.4). The salient point in these examples is that the solutions can be expressed in terms of the initial values on any (suitable) spacelike hypersurface.

Example 4.18: Let $\tau>0$, and let S be the open subset of M defined by $S=\{x|t>-x_3, x_3>t>x_3-\tau\}$. The region S thus consists of all points in the slab-region S_0 between the two characteristic planes $\pi''=\{x|t=x_3\}$ and $\pi'=\{x|t=x_3-\tau\}$ which lie *above* the characteristic plane $\pi=\{x|t=-x_3\}$. We then have $\mathscr{E}(S)=S$, but $S^{cc}=W_R=W(\pi,\pi'')=\{x|x_3>|t|\}$. Let $m>0$. Let $\psi(x)$ be a C_∞-solution of the Klein–Gordon equation for mass m in the space $\Psi_m\subset\mathscr{S}'_A(\mathsf{M})$, and suppose that $N(\psi)\supset S$. We will show that we then have $N(\psi)\supset S^{cc}=W_R$.

We consider the initial values of $\psi(x)$ on the spacelike 3-plane $\sigma_0=\{(\mathbf{x},0)|\mathbf{x}\in\mathsf{R}^3\}$, and we note that these vanish on the ''strip'' $\{(\mathbf{x},0)|\tau>x_3>0\}$. Let $\psi_R(x)$ be the (unique) solution of the Klein–Gordon equation for mass m determined by the initial conditions $\psi_R(\mathbf{x},0)=\psi(\mathbf{x},0)$ and $(\partial_t\psi_R)(\mathbf{x},0)=(\partial_t\psi)(\mathbf{x},0)$ when $x_3\geqslant\tau$, and $\psi_R(\mathbf{x},0)=0=(\partial_t\psi_R)(\mathbf{x},0)$ when $x_3<\tau$. We write $\psi_L(x)=\psi(x)-\psi_R(x)$, and we then have $\psi_L(\mathbf{x},0)=0=(\partial_t\psi_L)(\mathbf{x},0)$ when $x_3>0$. We easily see that $\psi_R(x),\psi_L(x)\in\Psi_m$. In view of the supports of the initial values we then have $N(\psi_L)\supset W_R$ and $N(\psi_R)\supset W_{L,\tau}=\{x|x_3<\tau-|t|\}$. Since $S\subset W_R$ and since $\psi(x)=\psi_L(x)+\psi_R(x)=0$ on S it follows that $\psi_R(x)=0$ on S. Now $S_0\subset S\cup W_{L,\tau}$, and hence $\psi_R(x)=0$ on S_0. By Lemma 4.12 we then have $\psi_R(x)=0$ identically, and hence $\psi(x)=\psi_L(x)$ for all x, which establishes that $N(\psi)\supset S^{cc}=W_R$.

We now consider the case when $\eta(x)$ is an *arbitrary* solution of the Klein–Gordon equation in the set $\Psi_m\subset\mathscr{S}'_A(\mathsf{M})$ which satisfies the condition that $N(\eta)\supset S$. We consider the convolution $\psi(x)=(\eta\star c)(x)$ of $\eta(x)$ with a C_∞-function $c(x)$ with support in the double cone $D_\lambda=D((\mathbf{0},-\lambda),(\mathbf{0},\lambda))$, for a ''small'' $\lambda>0$. The function $\psi(x)$ then satisfies the premises in the example (but with a ''slightly smaller'' null region than the null region of $\eta(x)$). Since λ can be selected as small as we like, we easily arrive at the above result $N(\psi)\supset S^{cc}=W_R$ for the distribution $\eta(x)$.

Example 4.19: Let $\tau>\rho>0$, and let $S=S_u\cup S_l$ be the open subset of M defined by $S_u=\{x|\rho>|t-\tau|+|x_3-\tau|\}$ and $S_l=\{x|\rho>|t+\tau|+|x_3+\tau|\}$. We have $S_u\cap S_l=\varnothing$ and we easily see that $\mathscr{E}(S_u)=S_u$, $\mathscr{E}(S_l)=S_l$, and $\mathscr{E}(S)=S$. However, $S^{cc}=\{x|x_3>|t+\tau|-\tau-\rho, x_3<\tau+\rho-|t-\tau|\}$ is strictly larger than $\mathscr{E}(S)$. We first consider the case when $\psi(x)$ is a C_∞-solution of the Klein–Gordon equation for mass $m>0$ in the space $\Psi_m\subset\mathscr{S}'_A(\mathsf{M})$, such that $N(\psi)\supset S$. We will show that we then have $N(\psi)\supset S^{cc}$. The reasoning has many similarities with the reasoning in Example 4.18, but we now consider *two* ''initial-value planes,'' $\sigma_+=\{(\mathbf{x},\tau)|\mathbf{x}\in\mathsf{R}^3\}$ and $\sigma_-=\{(\mathbf{x},-\tau)|\mathbf{x}\in\mathsf{R}^3\}$. We note that the initial values of $\psi(x)$ on σ_+ vanish when $|x_3-\tau|<\rho$, and that the initial values of $\psi(x)$ on σ_- vanish when $|x_3+\tau|<\rho$. Let $\psi_R(x)$ be the unique solution of the Klein–Gordon equation for m such that the initial values of $\psi_R(x)$ and $\psi(x)$ on σ_+ are equal for $x_3\geqslant\tau-\rho$, and such that the initial values of $\psi_R(x)$ equal zero for $x_3<\tau-\rho$. Let $\psi_L(x)$ be the unique solution of the Klein–Gordon equation for m such that the initial values of $\psi_L(x)$ and $\psi(x)$ on σ_- are equal for $x_3<-\tau+\rho$, and such that the initial values of $\psi_L(x)$ equal zero for $x_3>-\tau+\rho$. We then have $\psi_R(x)=\psi(x)$ and $\psi_L(x)=0$ on $W_+=\{x|x_3>\tau-\rho+|t-\tau|\}$ and $\psi_L(x)=\psi(x)$ and $\psi_R(x)=0$ on $W_-=\{x|x_3<-\tau+\rho-|t+\tau|\}$. We write $\psi_0(x)=\psi(x)-\psi_R(x)-\psi_L(x)$, and by the above we then have $\psi_0(x)=0$ on $W_+\cup W_-$. We easily see that $\psi_0(x)\in\Psi_m$, and it then follows by Proposition 4.15 that $\psi_0(x)=0$ throughout M. Since $\psi_L(x)=0$ for $x_3>|t+\tau|-\tau-\rho$, and since $\psi_R(x)=0$ for $x_3<\tau+\rho-|t-\tau|$, we conclude that $\psi(x)=0$ on S^{cc}.

By the same kind of reasoning as in Example 4.18 we conclude that $N(\eta)\supset S^{cc}$ for an *arbitrary* $\eta(x)\in\Psi_m\subset\mathscr{S}'_A(\mathsf{M})$ which satisfies the condition that $N(\eta)\supset S$.

We note that the conclusions in the above two examples can fail for the *wave equation* ($m=0$), and that they can also fail for solutions of the Klein–Gordon equation for mass $m>0$ which are *not* in the space $\Psi_m\subset\mathscr{S}'_A(\mathsf{M})$.

V. LOCAL ALGEBRAS OF QUANTUM FIELD OPERATORS, AND THEIR WEAK COMMUTANTS

In this section we will discuss the implications of the results in Sections III and IV for quantum field theory. We follow the formulation of field theory in the monograph by Streater and Wightman:[2] see in particular Chapter 3. We denote the field operators by $\varphi_\mu(x)$, where μ is in

some index set $\mathscr{I}$, and we denote a field operator averaged with the test function $f \in \mathscr{S}(\mathsf{M})$ by $\varphi_\mu[f]$. These field operators thus satisfy all the general conditions in Ref. 2. Specifically we assume that the field operators form an irreducible system. We regard the domain D_1 (see Sections 3.1 and 3.2 in Ref. 2) as the domain of the operators $\varphi_\mu[f]$, and the Hermitian conjugate $\varphi_\mu[f]^\dagger$ of the operator $\varphi_\mu[f]$ is the restriction of the adjoint of the operator to D_1. The domain D_1 is dense in the Hilbert space $\mathscr{H}$, it is Poincaré invariant, it contains the (normalized) vacuum vector Ω, and it is mapped into itself by the operators $\varphi_\mu[f]$ and $\varphi_\mu[f]^\dagger$. Let R be any subset of M. We denote by $\mathscr{P}_0(R)$ the smallest unital algebra which contains $\varphi_\mu[f]$ and $\varphi_\mu[f]^\dagger$ for all $\mu \in \mathscr{I}$, and all test functions $f(x)$ with support in R. We thus have $X\mathsf{D}_1 \subset \mathsf{D}_1$ for all $X \in \mathscr{P}_0(R)$. Every $X \in \mathscr{P}_0(R)$ is closable, and we denote by $X^\dagger$ the restriction of X^* to D_1. The algebra $\mathscr{P}_0(R)$ is thus a *-algebra, with Hermitian conjugation ''†'' as the *-operation. The condition that the field operators form an irreducible system is equivalent to the condition that the vacuum vector Ω is cyclic for the algebra $\mathscr{P}_0(\mathsf{M})$, and if this is the case then it follows from the Reeh–Schlieder Principle that Ω is cyclic for $\mathscr{P}_0(R)$ for every $R \subset \mathsf{M}$ with a nonempty interior.

With the above definition of $\mathscr{P}_0(R)$ we have $\mathscr{P}_0(R) = \mathscr{P}_0(R^o)$ for any $R \subset \mathsf{M}$. This follows from the fact that for any closed $K \subset \mathsf{M}$ the space of test functions in $\mathscr{S}(\mathsf{M})$ with support in K is equal to the closure, in the test-function space topology, of the space of all test functions with support in the interior K^o of K. With our definition we thus have $\mathscr{P}_0(R) = \mathsf{C}^1 \cdot I$ if R has an empty interior.

For later reference we here state as a lemma a well-known important property of the domain D_1.

Lemma 5.1: Let $g(p) \in \mathscr{S}(\mathsf{M})$, and let P denote the four-momentum operator. Then $g(P)\mathsf{D}_1 \subset \mathsf{D}_1$, and the linear manifold $\mathsf{D}_c = \mathrm{span}\{g(P)\phi | g \in \mathscr{D}(\mathsf{M}), \phi \in \mathsf{D}_1\}$ is a core for the closure X^{**} of every $X \in \mathscr{P}_0(\mathsf{M})$. Here $\mathscr{D}(\mathsf{M})$ denotes the space of all functions in $\mathscr{S}(\mathsf{M})$ of compact support.

We also have the following result due to Borchers and Zimmermann.[15]

Lemma 5.2: Let S be any nonempty open subset of M. Then the linear manifold $\mathscr{P}_0(S)\Omega$ is a core for the closure X^{**} of every $X \in \mathscr{P}_0(\mathsf{M})$.

The *condition of locality* in a quantum field theory is usually stated in terms of the vanishing of commutators *or* anticommutators of two fields with spacelike separated arguments, depending on whether the fields are bose fields or fermi fields. We here assume what is known as the ''normal connection between spin and statistics.'' Following Bisognano and Wichmann[16] we can express all the locality conditions with reference to *commutators*, as follows. We denote the unitary operator which describes a rotation by angle 2π about any axis by U_0, and we define the unitary operator Z by $Z = (I + iU_0)/(1+i)$. We then have $U_0^2 = I$, $Z^2 = U_o$, $U_0\Omega = \Omega = Z\Omega$, and $U_0\mathsf{D}_1 = \mathsf{D}_1 = Z\mathsf{D}_1$. For any operator Q, and any region $R \in \mathsf{M}$ we write $Q^z = ZQZ^{-1}$, $\mathscr{P}_0(R)^z = \{X^z | X \in \mathscr{P}_0(R)\}$, and the condition of locality for the quantum fields can then be stated as follows. If $X \in \mathscr{P}_0(R_1)$ and $Y \in \mathscr{P}_0(R_2)$, and if R_1 and R_2 are *spacelike separated*, then $[X, Y^z] = 0$ *on the domain* D_1. We refer to operators which commute with the involution U_0 as *boson operators*, and we refer to operators which anticommute with U_0 as *fermion operators*. If X is a boson operator and Y is a fermion operator, we thus have $ZXZ^{-1} = X$ and $ZYZ^{-1} = iU_0Y$. For any $R \subset \mathsf{M}$, every $X \in \mathscr{P}_0(R)$ has a unique representation as a sum of a boson operator X_b and a fermion operator X_f, where $X_b, X_f \in \mathscr{P}_0(R)$.

Definition 5.3: We define the *weak commutant* $\mathscr{P}_0(R)^w$ of the algebra $\mathscr{P}_0(R)$ as the set of all *bounded* operators B which satisfy the condition

$$\langle B^*\Phi' | X\Phi'' \rangle = \langle X^\dagger \Phi' | B\Phi'' \rangle \tag{5.1}$$

for all $\Phi', \Phi'' \in \mathsf{D}_1$ and all $X \in \mathscr{P}_0(R)$. Equivalently stated: $\mathscr{P}_0(R)^w$ is the set of all bounded operators B such that $X^*B \supset BX^\dagger$ for all $X \in \mathscr{P}_0(R)$.

The weak commutant is a weakly and strongly closed linear manifold of operators, closed under the adjoint-operation. Under special *additional* conditions on the system of fields it is a von Neumann algebra,[16] but it is not known whether it is an algebra in general. In this paper we make no assumptions about this point. We will depend on the following simple (and well-known) fact about the weak commutant.

Lemma 5.4: A bounded operator B is in $\mathscr{P}_0(R)^w$ if and only if

$$\langle B^*\Phi'|\varphi_\mu[f]\Phi''\rangle=\langle\varphi_\mu[f]^\dagger\Phi'|B\Phi''\rangle \tag{5.2}$$

for all $\Phi',\Phi''\in\mathsf{D}_c$, all $\mu\in\mathscr{T}$, and all $f(x)\in\mathscr{S}(\mathsf{M})$ with support in R.

We omit the trivial proof: the conclusion follows readily from Lemma 5.1 and the definition of the algebra $\mathscr{P}_0(R)$. The condition in (5.2) is seemingly much weaker than the condition in (5.1) since we only demand that the relation in (5.1) holds for all Φ' and Φ'' in the *smaller* domain D_c, and for the operators in $\mathscr{P}_0(R)$ which are *linear* in the field operators, but the condition in the lemma actually implies the condition in the definition.

With $\Phi',\Phi''\in\mathsf{D}_c$ fixed, and with B a fixed bounded operator, the (linear) mappings $f\to\langle B^*\Phi'|\varphi_\mu[f]\Phi''\rangle$ and $f\to\langle\varphi_\mu[f]^\dagger\Phi'|B\Phi''\rangle$ of $\mathscr{S}(\mathsf{M})$ into C^1 are, for all $\mu\in\mathscr{T}$, tempered distributions. Employing the generalized function notation we can thus define the distribution $A_{\mu;\Phi',\Phi''}(B;x)$ by

$$A_{\mu;\Phi',\Phi''}(B;x)=\langle B^*\Phi'|\varphi_\mu(x)\Phi''\rangle-\langle\varphi_\mu^\dagger(x)\Phi'|B\Phi''\rangle \tag{5.3}$$

for any $\Phi',\Phi''\in\mathsf{D}_c$, any $\mu\in\mathscr{T}$, and any bounded operator B. This distribution is then in the set $\mathscr{S}'_A(\mathsf{M})$, since the vectors Φ' and Φ'' are of compact support in momentum space.[1] *Heuristically* we have $T_{\mu;\Phi'\Phi'}(B;x)=\langle\Phi'|[B,\varphi_\mu(x)]\Phi''\rangle$, but the matrix element of the commutator is not well defined (as it is written) unless $B\Phi'\in\mathsf{D}_1$, which we do not want to assume is necessarily the case.

We can now paraphrase Lemma 5.4 as follows.

Lemma 5.5: A bounded operator B is in $\mathscr{P}_0(R)^w$ if and only if $A_{\mu;\Phi'\Phi''}(B;x)=0$ throughout the interior R^o of R for all $\mu\in\mathscr{T}$, and all $\Phi',\Phi''\in\mathsf{D}_c$.

Looking at the weak commutants from this point of view the results in Sections II and III are immediately applicable to the study of these objects. We first state a lemma which is essentially Araki's result,[1] although here stated in a somewhat different context.

Lemma 5.6: Let $S\subset\mathsf{M}$ be *open*. Let $a(S)$ be the Araki envelope defined in Lemma 2.7. Then

$$\mathscr{P}_0(S)^w=\mathscr{P}_0(a(S))^w. \tag{5.4}$$

Proof: We clearly have $\mathscr{P}_0(S)^w\supset\mathscr{P}_0(a(S))^w$ since $S\subset a(S)$. Let $B\in\mathscr{P}_0(S)^w$. With $A_{\mu;\Phi',\Phi''}(B;x)$ defined as in (5.3) we then have, $A_{\mu;\Phi',\Phi''}(B;x)=0$ on S, and hence, by Lemma 2.7, $A_{\mu;\Phi',\Phi''}(B;x)=0$ on $a(S)$, for all $\Phi',\Phi''\in\mathsf{D}_c$ and all $\mu\in\mathscr{T}$. This is precisely the condition that $B\in\mathscr{P}_0(a(S))^w$. We thus have $\mathscr{P}_0(S)^w\subset\mathscr{P}_0(a(S))^w$, and the identity in (5.4) follows.

We also note the following trivial fact. Let $\{S_\alpha|\alpha\in\mathscr{T}\}$ be any family of *open* subsets of M, and let $S=\cup\{S_\alpha|\alpha\in\mathscr{T}\}$. It follows immediately from Lemma 5.5 that we then have $\mathscr{P}_0(S)^w=\cap\{\mathscr{P}_0(S_\alpha)^w|\alpha\in\mathscr{T}\}$.

On the basis of the important Theorem 2.11 we obtain the following general result.

Theorem 5.7: Let $\{S_\alpha|\alpha\in\mathscr{T}\}$, where $\mathscr{T}$ is some index set, be a family of open regions $S_\alpha\subset\mathsf{M}$ such that S_α is bounded above by the characteristic plane π''_α and below by the characteristic plane π'_α. Let $S=\cup\{S_\alpha|\alpha\in\mathscr{T}\}$. We define the open set $\mathscr{E}(S)$ as in Lemma 2.6. Then

$$\mathscr{P}_0(S)^w=\mathscr{P}_0(a(S))^w=\mathscr{P}_0(\mathscr{E}(S))^w\supset\mathscr{P}_0(S^{cc})^w. \tag{5.5}$$

Proof: By Theorem 2.11 we have $a(S)=\mathscr{E}(S)$ under the stated premises, and in view of (5.4) the first three members in (5.5) are equal. Since $\mathscr{E}(S)\subset(S^{cc})^o$ it obviously follows that $\mathscr{P}_0(\mathscr{E}(S))^w\supset\mathscr{P}_0(S^{cc})^w$. This completes the proof.

We *always* have $\mathscr{P}_0(S)^w=\mathscr{P}_0(a(S))^w\supset\mathscr{P}_0(\mathscr{E}(S))^w\supset\mathscr{P}_0(S^{cc})^w$, since $a(S)\subset\mathscr{E}(S)\subset(S^{cc})^o$, for any open $S\subset\mathsf{M}$. There now emerge two interesting questions. Under what conditions is it the case that $\mathscr{P}_0(S)^w=\mathscr{P}_0(\mathscr{E}(S))^w$, and under what conditions is it the case that $\mathscr{P}_0(S)^w=\mathscr{P}_0(S^{cc})^w$? The equality $\mathscr{P}_0(S)^w=\mathscr{P}_0(S^{cc})^w$ trivially implies the equality $\mathscr{P}_0(S)^w=\mathscr{P}_0(\mathscr{E}(S))^w$ (for a particular open $S\subset\mathsf{M}$), but the converse is not necessarily true if $\mathscr{E}(S)\neq(S^{cc})^o$, as we will see by an explicit example. We will also see, through examples, that for a given open set S there does not exist any open set R *larger* than $(S^{cc})^o$ such that $\mathscr{P}_0(S)^w=\mathscr{P}_0(R)^w$. Theorem 5.7 states a *sufficient* condition for the equality $\mathscr{P}_0(S)^w=\mathscr{P}_0(\mathscr{E}(S))^w$ to hold, and in particular this equality holds if S is a union of wedges in $\mathscr{W}$. The question of for what other sets S this equality may hold is more delicate, and we will return to this issue later.

If the (open) region R is *causally complete*, it is rather natural to regard the operators in $\mathscr{P}_0(R)^w$ as ''locally associated'' with the (closed) causal complement R^c of R. We pursue this idea as follows.

Proposition 5.8: Let K be a closed causally complete subset of M. We define the linear manifold of bounded operators $\mathscr{C}(K)$ by

$$\mathscr{C}(K)=\mathscr{P}_0(K^c)^w. \tag{5.6}$$

(a) The above mapping $K\to\mathscr{C}(K)$ satisfies the condition of *isotony*, i.e., if $K_1,K_2\subset\mathsf{M}$ are closed and causally complete, then $\mathscr{C}(K_1)\supset\mathscr{C}(K_2)$ whenever $K_1\supset K_2$.

(b) The mapping is *Poincaré covariant*, i.e., $U(\lambda)\mathscr{C}(K)U(\lambda)^{-1}=\mathscr{C}(K_{(\lambda)})$, where $U(\lambda)$ is the unitary operator which represents the element λ in the universal covering group of the Poincaré group, and where $K_{(\lambda)}$ is the image of K under the action of λ on Minkowski spacetime.

We omit the trivial proof. A closely related object, denoted $\mathscr{C}_w(K)$, was considered by Bisognano and Wichmann[16] (see Section V in the quoted paper). This object is related to our $\mathscr{C}(K)$ by $\mathscr{C}_w(K)=Z\mathscr{C}(K)Z^{-1}=\mathscr{C}(K)^z$, where Z is defined as above. If the $\mathscr{C}(K)$ happen to be von Neumann algebras (which we do not assume here), then the algebras $\mathscr{C}_w(K)$ are natural objects to consider, because (at least for some subsets K) they can be regarded as ''generated'' by the field operators associated with K. We will not pursue these issues here. We felt that the introduction of the operator Z might just obscure the topics we want to discuss, and hence we consider the objects defined in (5.6). $\mathscr{C}(K)$ is thus simply the weak commutant of the operators in $\mathscr{P}_0(K^c)$.

The following results in TW-I[8] are of interest in connection with the definition of $\mathscr{C}(K)$ in (5.6) (see Proposition 2.6 in the quoted paper). If K is a closed causally complete *proper* subset of M, then K^c is not necessarily open, but if K^c has a *nonempty interior*, then $(K^c)^o$ is ''very close'' to K^c in the sense that $((K^c)^o)^c=K$, and $\overline{(K^c)^o}=\overline{K^c}$. It can also happen that K^c has an empty interior, but this case is rather ''pathological'' in the sense that both K and K^c are then confined to some characteristic plane. This case can only occur if K contains an isotropic line.

We are particularly interested in the objects $\mathscr{C}(K)$ when K is a closed, convex, causally complete set in the family $\mathscr{K}_E$ (which includes all compact, convex, causally complete subsets of M). For *these* sets we have certain *intersection properties*, which we will now discuss. We first state a rather trivial result.

Proposition 5.9: Let $K\in\mathscr{K}_E$, with $\mathscr{K}_E$ as described in Definition 1.1. Then $\mathscr{C}(K)=\cap\{\mathscr{C}(W^c)|W\in\mathscr{W},W^c\supset K\}$.

Proof: By Proposition 3.1 we have $K^c=\cup\{W|W\in\mathscr{W},W^c\supset K\}$, and hence $\mathscr{C}(K)=\mathscr{P}_0(K^c)^w=\cap\{\mathscr{P}_0(W)^w|W\in\mathscr{W},W^c\supset K\}=\cap\{\mathscr{C}(W^c)|W\in\mathscr{W},W^c\supset K\}$, which proves the assertion.

On the basis of Theorem 3.6 and Proposition 3.8 we obtain the following result.

Theorem 5.10: Let $\mathscr{C}(K)$ be defined in terms of K as in Proposition 5.8. Let $\mathscr{F}$ be a family of wedges in $\mathscr{W}$. We write $S=\cup\{W|W\in\mathscr{F}\}$ and $K=\cap\{W^c|W\in\mathscr{F}\}=S^c$.

(a) Suppose that the normals of the boundary planes of the wedges in $\mathscr{F}$ span M, and suppose furthermore that $\mathscr{F}$ contains two wedges such that no two of the boundary planes of these wedges are parallel. Then K is an element of the set $\mathscr{K}_E$ as described in Definition 1.1, and we have

$$\mathscr{C}(K)=\cap\{\mathscr{C}(W^c)|W\in\mathscr{F}\}. \tag{5.7}$$

(b) In particular the premises and conclusions in part (a) obtain if $\mathscr{F}$ contains two wedges in a *general relative position*.

(c) Suppose instead that the family $\mathscr{F}$ satisfies the conditions in part (a) or part (b) of Proposition 3.8. Then the relation (5.7) holds.

Proof: By Theorem 5.7 we have $\mathscr{P}_0(S)^w=\mathscr{P}_0(\mathscr{E}(S))^w$, and by Theorem 3.6 we have $\mathscr{E}(S)=S^{cc}$ under the premises in parts (a) or (b), and by Proposition 3.8 we have $\mathscr{E}(S)=S^{cc}$ under the premises in part (c). Hence $\mathscr{P}_0(S)^w=\mathscr{P}_0(S^{cc})^w=\mathscr{C}(K)$. Since $S=\cup\{W|W\in\mathscr{F}\}$ we have $\mathscr{P}_0(S)^w=\cap\{\mathscr{P}_0(W)^w|W\in\mathscr{F}\}=\cap\{\mathscr{C}(W^c)|W\in\mathscr{F}\}$, and the relation (5.7) follows. This completes the proof.

Note carefully the difference between this theorem and Proposition 5.9. We write $\mathscr{F}_K=\{W|W\in\mathscr{W},W^c\supset K\}$, and by Proposition 5.9 we then have $\mathscr{C}(K)=\cap\{\mathscr{C}(W^c)|W\in\mathscr{F}_K\}$. The

same conclusion follows by Theorem 5.10, since the family $\mathscr{F}_K$ satisfies the premises in part (a) of this theorem. However, for a particular $K\in\mathscr{K}_E$ the family $\mathscr{F}$ in Theorem 5.10 might be *smaller* than the ''maximal family'' $\mathscr{F}_K$, and Theorem 5.10 is therefore much stronger than the rather trivial Proposition 5.9.

One of the goals of this paper is the proof of the following *intersection property* for certain pairs of weak commutants.

Theorem 5.11: Let $\mathscr{C}(K)$ be defined in terms of K as in Proposition 5.8. Let $K_1\in\mathscr{K}_E$, with $\mathscr{K}_E$ as described in Definition 1.1, and let K_2 be closed, convex and causally complete, and such that K_2^c has a nonempty interior. Then $K_1\cap K_2\in\mathscr{K}_E$ and

$$\mathscr{C}(K_1)\cap\mathscr{C}(K_2)=\mathscr{C}(K_1\cap K_2). \tag{5.8}$$

In particular (5.8) holds for any two $K_1,K_2\in\mathscr{K}_E$.

Proof: Let $S_2=(K_2^c)^o$. By Proposition 3.9 we have $K_1\cap K_2\in\mathscr{K}_E$ and $\mathscr{E}(K_1^c\cup S_2)=(K_1^c\cup S_2)^{cc}=(K_1\cap K_2)^c$. Taking into account (5.5) we then have $\mathscr{C}(K_1)\cap\mathscr{C}(K_2)=\mathscr{P}_0(K_1^c)^w\cap\mathscr{P}_0(S_2)^w=\mathscr{P}_0(K_1^c\cup S_2)^w=\mathscr{P}_0(\mathscr{E}(K_1^c\cup S_2))^w=\mathscr{P}_0((K_1\cap K_2)^c)^w=\mathscr{C}(K_1\cap K_2)$. This completes the proof.

We here note the following. Let $\mathscr{T}_1=\{W|W\in\mathscr{W},W^c\supset K_1\}$, $\mathscr{T}_2=\{W|W\in\mathscr{W},W^c\supset K_2\}$, and $\mathscr{T}=\{W|W\in\mathscr{W},W^c\supset K_1\cap K_2\}$. The family $\mathscr{T}$ is in general *larger* than the family $\mathscr{T}_1\cup\mathscr{T}_2$, and hence the relation (5.8) *does not* follow directly from Proposition 5.9, as one might, perhaps, think at first.

This theorem has an obvious generalization to the case of an arbitrary family $\{K_\alpha|\alpha\in\mathscr{I}\}$ of closed, convex, causally complete sets K_α, such that K_α^c has a nonempty interior, and such that at least one of these sets is an element of $\mathscr{K}_E$.

The intersection property in (5.8) *does not* hold generally for two *arbitrary* closed and causally complete sets K_1 and K_2. We show this by a counterexample after the next lemma. This lemma is a useful tool in the manufacture of examples and counterexamples. It is within the theory of free fields, which is our only available source for such things.

Lemma 5.12: We consider the quantum field theory of a single free Hermitian scalar field $\varphi(x)$, associated with a scalar particle of mass $m>0$. Let $\psi(x)$ be a *real* solution of the Klein–Gordon equation (4.1) with the integral representation in (4.3), such that $g_+(\mathbf{p})=g_-(\mathbf{p})^*=g(\mathbf{p})\in L_2(\mathsf{R}^3)$. There then exists a bounded operator B, not equal to a multiple of the identity, such that $B\in\mathscr{P}_0(S)^w$ for an *open* $S\subset\mathsf{M}$ if and only if $S\subset N(\psi)$.

Proof: (1) We have the familiar symbolic representation

$$\varphi(x)=\frac{1}{(2\pi)^{3/2}}\int_{(\infty)}\frac{d^3(\mathbf{p})}{\sqrt{2\omega(\mathbf{p})}}(a^\dagger(\mathbf{p})e^{ix\cdot p}+a(\mathbf{p})e^{-ix\cdot p})$$

of the field, where $p=(\mathbf{p},\omega)$, $\omega=\omega(\mathbf{p})=\sqrt{|\mathbf{p}|^2+m^2}$. The creation and destruction operators $a^\dagger(\mathbf{p})$ and $a(\mathbf{p})$, regarded as operator-valued tempered distributions, satisfy the usual canonical commutation relations on D_1. In discussing the free field it is convenient to regard the field operators as defined on a larger domain than D_1, namely the domain D_N which is the intersection of the domains of all positive powers of the number operator N. For any $g(\mathbf{p})\in L_2(\mathsf{R}^3)$ we write

$$a^\dagger[g]=\int_{(\infty)}d^3(\mathbf{p})a^\dagger(\mathbf{p})g(\mathbf{p}),\quad a[g]=\int_{(\infty)}d^3(\mathbf{p})a(\mathbf{p})g(\mathbf{p})^*=(a^\dagger[g])^\dagger.$$

These symbolic integrals make good sense, and the operators $a^\dagger[g]$ and $a[g]$ are closable operators on D_N which map D_N into D_N in a well-known fashion. The operator $Q[g]=i(a^\dagger[g]-a[g])$ is Hermitian, and we have

$$[iQ[g],\varphi(x)]=\frac{1}{(2\pi)^{3/2}}\int_{(\infty)}\frac{d^3(\mathbf{p})}{\sqrt{2\omega(\mathbf{p})}}(g(\mathbf{p})^*e^{ix\cdot p}+g(\mathbf{p})e^{-ix\cdot p})\cdot I\equiv\psi(x)\cdot I$$

on the domain D_N. The right member is thus a solution $\psi(x)$ of the Klein–Gordon equation in the space Ψ_m^H, times the identity operator I on $\mathscr{H}$.

(2) The operator Q is essentially self-adjoint on D_N (and on D_1), and we can define the unitary Weyl operator B by $B=\exp(iQ[g]^{**})$, where $Q[g]^{**}$ denotes the self-adjoint closure of $Q[g]$. It then follows that $A_{\Phi',\Phi''}(B;x)=\langle B^*\Phi'|\varphi(x)\Phi''\rangle-\langle\varphi(x)\Phi'|B\Phi''\rangle=\psi(x)\langle\Phi'|B\Phi''\rangle$ for any $\Phi',\Phi''\in\mathsf{D}_c$, which means that $B\in\mathscr{P}_0(N(\psi))^w$.

If $\Phi'=\Phi''=\Omega$, we have $A_{\Omega,\Omega}(B;x)=\psi(x)\langle\Omega|B\Omega\rangle$, and since $\langle\Omega|B\Omega\rangle\neq 0$ it follows that $N(A_{\Omega,\Omega}(B;x))=N(\psi(x))$, which implies that if $B\in\mathscr{P}_0(S)^w$ for some open $S\subset\mathsf{M}$, then $S\subset N(\psi)$. This completes the proof.

We now return to the issue of the intersection property in (5.8).

Example 5.13: We consider the particular solution $\psi_1(x)$ of the Klein–Gordon equation constructed in Example 4.10 in Section IV. This solution is of the form in (4.3), with $g_-(\mathbf{p})^*=g_+(\mathbf{p})=g(\mathbf{p})\in\mathscr{S}(\mathsf{R}^3)$, and hence Lemma 5.12 is applicable. The function $\psi_1(x)$ vanishes on $D_u^o\cup D_l^o$, with the notation employed in Example 4.10, but it does not vanish throughout $(D_u^o\cup D_l^o)^{cc}$. With $K_1=(D_u^o)^c$ and $K_2=(D_l^o)^c$ the relation in (5.8) thus fails to hold. In this case the sets K_1 and K_2 are not compact, but this is not an essential feature of the counterexample, as we can show as follows, with reference to Example 4.10. Let $D_4=D(z_4',z_4'')$ be the closed double cone with apices $z_4'=(\mathbf{0},-4\tau)$ and $z_4''=(\mathbf{0},4\tau)$. By the construction of the solution $\psi_1(x)$ in Example 4.10 we then have $\psi_1(x)=0$ on D_4^c, and hence $\psi_1(x)=0$ on $S_1\cup S_2$, with $S_1=D_4^c\cup D_u^o$ and $S_2=D_4^c\cup D_l^o$. The sets $S_1^c=D_4\cap(D_u^o)^c$ and $S_2^c=D_4\cap(D_l^o)^c$ are then *compact* and causally complete. The solution $\psi_1(x)$ does not vanish throughout $(S_1\cup S_2)^{cc}$ since $(S_1\cup S_2)^{cc}\supset\overline{D_l^o}$, and hence we have $\mathscr{C}(S_1^c)\cap\mathscr{C}(S_2^c)\neq\mathscr{C}(S_1^c\cap S_2^c)$. This does not contradict Theorem 5.11, since the sets S_1^c and S_2^c are not in $\mathscr{K}_E$.

We will now consider Araki distributions which are essentially vacuum expectation values of commutators. Let $X\in\mathscr{P}_0(\mathsf{M})$ and let B be a bounded operator. We denote by $T(x)$ the unitary operator which describes a translation by x. We write $X(x)=T(x)XT(x)^{-1}$ for the operator obtained from X by the translation by x, and we consider the expression

$$\eta(X,B;x)=\langle B^*\Omega|X(x)\Omega\rangle-\langle X^\dagger(x)\Omega|B\Omega\rangle=\langle B^*\Omega|T(x)X\Omega\rangle-\langle X^\dagger\Omega|T(-x)B\Omega\rangle. \quad (5.9)$$

The function $\eta(x)=\eta(X,B;x)$ is obviously an infinitely differentiable bounded function of x on M, such that all its partial derivatives are bounded. It can be regarded as an Araki distribution, and we have $\mathrm{supp}(\hat{\eta})\subset\overline{V}(0)$. It is in many respects ''better behaved'' than an arbitrary element of $\mathscr{S}_A'(\mathsf{M})$. One aspect of this is that we have a trivial association of $\eta(x)$ with a solution $\phi(x,s)$ of the wave equation on the five-dimensional space M_5, corresponding to Araki's construction discussed in Section II. This solution is given by

$$\phi(x,s)=\langle B^*\Omega|\cos(s\sqrt{P\cdot P})T(x)X\Omega\rangle-\langle X^\dagger\Omega|\cos(s\sqrt{P\cdot P})T(-x)B\Omega\rangle,$$

where P is the four-momentum operator. The function $\phi(x,s)$ is bounded and infinitely differentiable on M_5, and all its partial derivatives are bounded. We trivially have $\phi(x,-s)=\phi(x,s)$ and $\phi(x,0)=\eta(x)$.

It is well known[17,18] that $T(x)=U(x,I)$ converges weakly to the vacuum projection $|\Omega\rangle\langle\Omega|$ as x tends to infinity along any direction, i.e.,

$$w-\lim_{\lambda\to\infty}T(\lambda u)=|\Omega\rangle\langle\Omega| \quad (5.10)$$

for any nonzero four-vector u. From this it follows that the function $\eta(X,B;x)$ in (5.9) tends to zero as x tends to infinity along any direction, and that $\langle B^*\Omega|X(x)\Omega\rangle$ and $\langle X^\dagger(x)\Omega|B\Omega\rangle$ both tend to $\langle\Omega|B\Omega\rangle\langle\Omega|X\Omega\rangle$.

For a bounded operator B the condition that $\langle B^*\Phi'|X\Phi''\rangle-\langle X^\dagger\Phi'|B\Phi''\rangle=0$ for all $\Phi',\Phi''\in\mathsf{D}_1$ for a *particular* operator X is, of course, much stronger than the condition that $\langle B^*\Omega|X\Omega\rangle-\langle X^\dagger\Omega|B\Omega\rangle=0$. We note, however, the following rather trivial fact.

Proposition 5.14: Let R be a subset of M, and let S_0 be a *nonempty open* subset of R. Let B be a bounded operator such that $B\in\mathscr{P}_0(S_0)^w$ and such that

$$\langle B^*\Omega|X\Omega\rangle-\langle X^\dagger\Omega|B\Omega\rangle=0 \quad (5.11)$$

for all $X \in \mathscr{P}_0(R)$. Then $B \in \mathscr{P}_0(R)^w$.

Proof: Let $X \in \mathscr{P}_0(R)$, and let $Y_1, Y_2 \in \mathscr{P}_0(S_0)$. We then have $Y_1^\dagger X Y_2 \in \mathscr{P}_0(R)$, and hence, by (5.11), $\langle B^*\Omega | Y_1^\dagger X Y_2 \Omega\rangle = \langle Y_2^\dagger X^\dagger Y_1 \Omega | B\Omega\rangle$. Since $B \in \mathscr{P}_0(S_0)^w$ we have $\langle B^*\Omega | Y_1^\dagger X Y_2\Omega\rangle = \langle B^* Y_1\Omega | X Y_2\Omega\rangle$ and $\langle Y_2^\dagger X^\dagger Y_1\Omega | B\Omega\rangle = \langle X^\dagger Y_1\Omega | B Y_2\Omega\rangle$, and it follows that $\langle B^* Y_1\Omega | X Y_2\Omega\rangle = \langle X^\dagger Y_1\Omega | B Y_2\Omega\rangle$, for all $X \in \mathscr{P}_0(R)$ and all $Y_1, Y_2 \in \mathscr{P}_0(S_0)$. By Lemma 5.2 the set $\{Y\Omega | Y \in \mathscr{P}_0(S_0)\}$ is a core for the closure of X, and hence $X^* B^* \supset B^* X^\dagger$ for all $X \in \mathscr{P}_0(R)$, which means that $B \in \mathscr{P}_0(R)^w$, as asserted.

We can think about the relation in (5.11) as saying that the vacuum expectation value of the commutator of B with every operator $X \in \mathscr{P}_0(R)$ vanishes. This by itself does *not* imply that the commutator of B with every operator $X \in \mathscr{P}_0(R)$ vanishes, but this conclusion *does* follow if B satisfies the additional condition that it commutes with all the local operators in $\mathscr{P}_0(S_0)$.

We remark here that all the conclusions in this paper about quantum fields and their weak commutants could have been obtained through a study of the *special* Araki distributions in (5.9). Proposition 5.14 is a key element in such an approach.[7] In addition we need the result that if S is a union of wedges in $\mathscr{W}$, and if $\eta(x)$ is a distribution of the form in (5.9), then $N(\eta) \supset \mathscr{E}(S)$ whenever $N(\eta) \supset S$. One can regard this as a simplification, since the validity of Araki's prescription in Lemma 2.7 is completely trivial for the distributions in (5.9). We felt, however, that the results in Sections II and III, which concern general Araki distributions, are of interest as such. Furthermore the proofs of Theorems 5.7, 5.10, and 5.11 are particularly simple on the basis of the results in Section III.

As we remarked the distributions in (5.9) have special properties which are not shared by arbitrary distributions in $\mathscr{S}'_A(\mathsf{M})$. This permits some interesting conclusions about weak commutants which go beyond what can be obtained on the basis of the results in Section III alone. We first present a result which we believe is widely known and part of the folklore of quantum field theory.

Lemma 5.15: Let S_0 be a nonempty open subset of M, and let u be a forward isotropic vector. We define the ''tube-like'' (open) set S by $S = \{x + su | x \in S_0, s \in \mathsf{R}^1\}$. Then $\mathscr{P}_0(S)^w = \mathsf{C}^1 \cdot I$.

Proof: (1) Let $B \in \mathscr{P}_0(S)^w$ and let $X \in \mathscr{P}_0(S)$. We introduce $B_0 \in \mathscr{P}_0(S)^w$ by $B_0 = B - I \cdot \langle \Omega | B\Omega\rangle$, and hence $\langle \Omega | B_0\Omega\rangle = 0$. We denote $X_u(s) = T(su) X T(su)^{-1}$, where $T(x)$ is the unitary translation operator. Let $f_1(s) = \langle B_0^*\Omega | X_u(s)\Omega\rangle = \langle B_0^*\Omega | T(su) X\Omega\rangle$ and $f_2(s) = \langle X_u(s)^\dagger \Omega | B_0\Omega\rangle = \langle X^\dagger\Omega | T(-su) B_0\Omega\rangle$. We then have $f_1(s) = f_2(s)$ for all real s, since $X(s) \in \mathscr{P}_0(S)$ for all real s. Furthermore it follows from (5.10) that

$$\lim_{|s|\to\infty} f_1(s) = \lim_{|s|\to\infty} f_2(s) = \langle \Omega | B_0\Omega\rangle \langle \Omega | X\Omega\rangle = 0.$$

(2) The functions $f_1(s)$ and $f_2(s)$ are bounded and continuous on R^1, and we can regard them as tempered distributions in $\mathscr{S}'(\mathsf{R}^1)$. It follows from the spectrum condition on the translation group that the support of the Fourier transform of $f_1(s)$ has only the point 0 in common with the support of the Fourier transform of $f_2(s)$, and hence the bounded functions $f_1(s)$ and $f_2(s)$ are independent of s. We thus have $f_1(s) = 0 = f_2(s)$ for all real s, and hence we have

$$\langle B_0^*\Omega | X\Omega\rangle = 0 = \langle X^\dagger\Omega | B_0\Omega\rangle$$

for all $X \in \mathscr{P}_0(S)$. Setting $X = X_1^\dagger X_2$, with $X_1, X_2 \in \mathscr{P}_0(S)$, we obtain $\langle X_1\Omega | B_0 X_2\Omega\rangle = \langle \Omega | B_0 X_1^\dagger X_2\Omega\rangle = 0$, and since this holds for all $X_1, X_2 \in \mathscr{P}_0(S)$ it follows that $B_0 = 0$. Hence B is a complex multiple of the identity. This completes the proof.

This lemma is obviously closely related to Lemma 4.12, but we note the following. In the premises of Lemma 4.12 it was assumed that the support of the Fourier transform $\hat{\eta}(p)$ of $\eta(x)$ is contained in $V(0)$. No such assumption was made about the function $\eta(B, X; x)$ in the present lemma, but instead we depended on the fact in (5.10).

With this lemma we can now obtain a definitive result for the configurations described in Theorem 3.2.

Theorem 5.16: Let $\Pi' = \{\pi'_\alpha | \alpha \in \mathscr{T}'\}$ and $\Pi'' = \{\pi''_\beta | \beta \in \mathscr{T}''\}$, where $\mathscr{T}'$ and $\mathscr{T}''$ are two index sets, be two families of *characteristic* planes in M. For each $\alpha \in \mathscr{T}'$ and $\beta \in \mathscr{T}''$, let $S_{\alpha\beta}$ be the *open* subset of M (possibly empty) which is bounded below by π'_α and bounded above by π''_β,

and let $S=\cup\{S_{\alpha\beta}|\alpha\in\mathscr{T}',\beta\in\mathscr{T}''\}$ and $K=S^c$. The set S is thus the set of all points $x\in\mathsf{M}$ which lie *below* at least one of the planes in Π'' and lie *above* at least one of the planes in Π'. Then

$$\mathscr{P}_0(S)^w=\mathscr{P}_0(S^{cc})^w=\mathscr{C}(K) \tag{5.12}$$

and the set $K=S^c$ is *closed, convex, and causally complete*.

Proof: (1) If S is empty the conclusion is trivial, and we thus assume that S is nonempty. If an $\alpha\in\mathscr{T}'$ is such that $S_{\alpha\beta}=\varnothing$ for all $\beta\in\mathscr{T}''$, then the index α can be omitted from $\mathscr{T}'$ since it is irrelevant for S. Similarly we can omit any index $\beta\in\mathscr{T}''$ such that $S_{\alpha\beta}=\varnothing$ for all $\alpha\in\mathscr{T}'$, and without any loss of generality we can thus assume that the configuration of characteristic planes is precisely as in Theorem 3.2. According to Theorem 3.2 we either have $\mathscr{E}(S)=(S^{cc})^o$ or else $S^{cc}=\mathsf{M}\neq\mathscr{E}(S)$ and $\mathscr{E}(S)$ contains an open slab-region bounded by two parallel characteristic planes.

(2) By Theorem 5.7 we have $\mathscr{P}_0(S)^w=\mathscr{P}_0(\mathscr{E}(S))^w$. If $\mathscr{E}(S)=(S^{cc})^o$, then the conclusion in (5.12) follows at once. We thus consider the case when $S^{cc}=\mathsf{M}\neq\mathscr{E}(S)$. The set $\mathscr{E}(S)$ then contains a ''tube-region'' S_T of the kind considered in Lemma 5.15, and we have $\mathscr{P}_0(S)^w=\mathscr{P}_0(\mathscr{E}(S))^w\supset\mathscr{P}_0(S_T)^w=\mathsf{C}^1\cdot I$. Since $K=\varnothing$ we have $\mathscr{C}(K)=\mathscr{C}(\varnothing)=\mathsf{C}^1\cdot I$, and the conclusion in (5.12) holds in this case too. This completes the proof.

This theorem is obviously related to Lemma 4.12, and the remark following the proof of Lemma 5.15 is relevant here too.

We can now state a definitive result for all possible configurations of *two* wedges. In preparation for this we first consider a special case.

Lemma 5.17: Let $W_1,W_2\in\mathscr{W}$ be such that $W_1\cap W_2=\varnothing=W_1^c\cap W_2^c$. Then $\mathscr{C}(W_1^c)\cap\mathscr{C}(W_2^c)=\mathsf{C}^1\cdot I$.

Proof: (1) Under the stated premises the edges of the two wedges must be parallel, and the upper plane of one of the wedges must lie *above* the lower plane of the other. Without any loss of generality we assume that the upper plane of W_1 lies above the lower plane of W_2. The lower plane of W_1 then either coincides with the upper plane of W_2, or else lies above the upper plane of W_2. With a suitable choice of standard coordinates the two wedges can then be described by

$$W_1=\{x|x_3+\rho>|x_4-\tau|\},\quad W_2=\{x|x_3-\rho<-|x_4+\tau|\}$$

for some $\tau>0$, with $\rho=\tau$ if the lower plane of W_1 coincides with the upper plane of W_2, and $\rho=0$ if the lower plane of W_1 lies above the upper plane of W_2. Let $D^o=D(x',x'')^o$ be the open double cone with apices $x'=(\mathbf{0},-\tau/2)$, $x''=(\mathbf{0},\tau/2)$, and let D^o_{-x} be the double cone obtained from D^o by the translation by $-x$. We easily see that $D^o_{-x}\subset W_1\cup W_2$ for all $x\in W_3\cup W_4$, where W_3 and W_4 are the wedges

$$W_3=\{x|x_3>|x_4-\tau|+\tau/2\},\quad W_4=\{x|x_3<-|x_4+\tau|-\tau/2\}.$$

Let $X\subset\mathscr{P}_0(D^o)$ and $B\in\mathscr{P}_0(W_1\cup W_2)^w$. Let $\eta(X,B;x)=\langle B^*\Omega|T(x)X\Omega\rangle-\langle X^\dagger\Omega|T(-x)B\Omega\rangle$, as in (5.9). We then have $\eta(X,B;x)=0$ for all $x\in W_3\cup W_4$. We have $W_3^c\cap W_4^c=\varnothing=W_3\cap W_4$, and we would naturally now like to apply Proposition 4.15, but it is not directly applicable since the support of the Fourier transform $\hat{\eta}(p)$ of $\eta(x)=\eta(X,B;x)$ might *not* be included in any set of the form $\{p|p\in\mathsf{M},p\cdot p\geqslant m^2\}$ for some $m>0$ (whereas it *is* contained in $\overline{V}(0)$). We overcome this difficulty as follows.

(2) Let $m>0$ and let $g(s)\in\mathscr{S}(\mathsf{R}^1)$ be such that the support of the Fourier transform $\hat{g}(q)$ of $g(s)$ *does not* intersect the interval $[-m,m]$. We consider the function $\eta_g(x)$ on M defined by

$$\eta_g(x_1,x_2,x_3,x_4)=\int_{-\infty}^{\infty}ds\,g(s)\,\eta(s,x_2,x_3,x_4). \tag{5.13}$$

Both functions $\eta(x)$ and $\eta_g(x)$ are bounded and infinitely differentiable, and can thus be regarded as distributions in $\mathscr{S}'(\mathsf{M})$. We trivially have $\eta_g(x)=0$ for all $x\in W_3\cup W_4$. Note that

$\eta_g(x)$ is actually independent of x_1. Since $\mathrm{supp}(\hat{\eta}) \subset \overline{V}(0)$ it follows from the definition in (5.13) that $\mathrm{supp}(\hat{\eta}_g) \subset \{p | p_4^2 - p_3^2 - p_2^2 \geq m^2, p_1 = 0\}$, and hence $\mathrm{supp}(\hat{\eta}_g) \subset \{p | p \cdot p \geq m^2\}$. Proposition 4.15 is now applicable to η_g, and we conclude that $\eta_g(x) = 0$ for all x.

(3) Let $h(x_2, x_3, x_4) \in \mathscr{S}(R^3)$, and let

$$\xi(s) = \int_{-\infty}^{\infty} dx_2 \int_{-\infty}^{\infty} dx_3 \int_{-\infty}^{\infty} dx_4 \, h(x_2, x_3, x_4) \, \eta(s, x_2, x_3, x_4).$$

The function $\xi(s)$ is bounded and continuous, and can be interpreted as a distribution in $\mathscr{S}'(R^1)$. By the result in step (2) we have $\xi[g] = 0$ for every test function $g(s)$ such that $\hat{g}(q) = 0$ when $q \in [-m, m]$. Since $m > 0$ is arbitrary, it follows that $\mathrm{supp}(\hat{\xi}(q)) = \{0\}$. It follows from (5.10) that the function $\xi(s)$ tends to zero as s tends to infinity, and we can then conclude that $\xi(s) = 0$ for all s, which in turn implies that $\eta(x) = \eta(X, B; x) = 0$ for all $x \in \mathsf{M}$. We have thus shown that $\langle B^* \Omega | X(x) \Omega \rangle - \langle X^\dagger(x) \Omega | B \Omega \rangle = 0$ for all $x \in \mathsf{M}$ and all $X \in \mathscr{P}_0(D^o)$, but this implies that $B \in \mathscr{P}_0(\mathsf{M})^w$, and hence we have $B = c \cdot I$ for some complex c. Since this holds for all $B \in \mathscr{P}_0(W_1 \cup W_2)^w$, we conclude that $\mathscr{C}(W_1^c) \cap \mathscr{C}(W_2^c) = \mathscr{P}_0(W_1 \cup W_2)^w = \mathsf{C}^1 \cdot I$. This completes the proof.

Proposition 5.18: Let $W_1, W_2 \in \mathscr{W}$.

(a) If $W_1 \cap W_2 \neq \varnothing$, then

$$\mathscr{C}(W_1^c) \cap \mathscr{C}(W_2^c) = \mathscr{P}_0(W_1 \cup W_2)^w = \mathscr{P}_0((W_1 \cup W_2)^{cc})^w = \mathscr{C}(W_1^c \cap W_2^c). \tag{5.14}$$

(b) If $W_1^c \cap W_2^c = \varnothing$, then the relations in (5.14) also hold, with $\mathscr{C}(W_1^c) \cap \mathscr{C}(W_2^c) = \mathscr{P}_0(W_1 \cup W_2)^w = \mathsf{C}^1 \cdot I$.

(c) If the span of the normals of the boundary planes of the wedges is either *four-dimensional* or *two-dimensional*, then the relations in (5.14) hold.

(d) If the span of the normals of the boundary planes of the wedges is *three-dimensional*, and if $W_1 \cap W_2 = \varnothing$, then $W_1^c \cap W_2^c \neq \varnothing$, and the intersection property $\mathscr{C}(W_1^c) \cap \mathscr{C}(W_2^c) = \mathscr{C}(W_1^c \cap W_2^c)$ *does not* hold generally.

Proof: (1) We consider part (a), and we thus assume that $W_1 \cap W_2 \neq \varnothing$. By Proposition 3.3 we then have $\mathscr{C}(W_1 \cup W_2) = (W_1 \cup W_2)^{cc} = (W_1^c \cap W_2^c)^c$, and hence, by Theorem 5.7, $\mathscr{P}_0(W_1 \cup W_2)^w = \mathscr{P}_0(\mathscr{C}(W_1 \cup W_2))^w = \mathscr{P}_0((W_1 \cup W_2)^{cc})^w = \mathscr{P}_0((W_1^c \cap W_2^c)^c)^w$, which proves the equalities in (5.14) in this case.

(2) If the span of the normals of the boundary planes is four-dimensional, then the premise and conclusion in part (a) obtain. If the span is three-dimensional, then at least one of the sets $W_1 \cap W_2$ or $W_1^c \cap W_2^c$ is nonempty. Hence, if $W_1^c \cap W_2^c = \varnothing$, then the result in part (a) applies.

Suppose now that the span of the normals is three-dimensional, and that $W_1 \cap W_2 = \varnothing$. In Examples 4.16 and 4.17 we considered such a configuration of wedges, and we gave an example of a real-valued solution $\psi_1(x) \in \Psi_m^H$ of the Klein–Gordon equation for mass $m \geq 0$, with the property that $\psi_1(x) = 0$ on $W_1 \cup W_2$ but *not* throughout $(W_1 \cup W_2)^{cc}$. We consider a theory of a single free Hermitian scalar field of mass m. By Lemma 5.12 there then exists a bounded operator B, not equal to a multiple of the identity, such that $B \in \mathscr{P}_0(W_1 \cup W_2)^w$ but $B \notin \mathscr{P}_0((W_1 \cup W_2)^{cc})^w$. Hence $\mathscr{P}_0(W_1 \cup W_2)^w \neq \mathscr{P}_0((W_1 \cup W_2)^{cc})^w$, or, equivalently, $\mathscr{C}(W_1^c) \cap \mathscr{C}(W_2^c) \neq \mathscr{C}(W_1^c \cap W_2^c)$. We have thus proved the assertions in part (d), and we have also accounted for all the configurations for which the span of the normals is either four- or three-dimensional.

(3) It remains to consider the cases when the span of the normals is two-dimensional *and* $W_1 \cap W_2 = \varnothing$. The upper plane of W_1 is then parallel with the lower plane of W_2, and the upper plane of W_2 is parallel with the lower plane of W_1. We first consider the case when $W_1^c \cap W_2^c \neq \varnothing$. We then have $\mathscr{C}(W_1 \cup W_2) = (W_1 \cup W_2)^{cc} = W_1 \cup W_2$, and the equalities in (5.14) follow readily.

(4) We finally consider the case when $W_1^c \cap W_2^c = \varnothing$ (and also $W_1 \cap W_2 = \varnothing$). By Lemma 5.17 we then have $\mathscr{C}(W_1^c) \cap \mathscr{C}(W_2^c) = \mathsf{C}^1 \cdot I$. Since $(W_1 \cup W_2)^{cc} = \mathsf{M}$, we have $\mathscr{P}_0(W_1 \cup W_2)^w = \mathscr{P}_0((W_1 \cup W_2)^c)^w = \mathscr{P}_0(\mathsf{M})^w = \mathsf{C}^1 \cdot I$, and the equalities in (5.14) obtain. This completes the proof.

The above result that $\mathscr{C}(W_1^c)\cap\mathscr{C}(W_2^c)=C_1\cdot I$ if $W_1^c\cap W_2^c=\varnothing$ is eminently plausible. We might also expect that the conclusion is the same if W_1^c and W_2^c only have a common *edge*, and this is indeed the case. See also the related discussion by Driessler and Summers.[19]

Proposition 5.19: (a) Let $W_1, W_2\in\mathscr{W}$ be such that $\overline{W_2}=W_1^c$, and hence $\overline{W_1}=W_2^c$, i.e., the two wedges W_1 and W_2 have the common edge $E=\overline{W_1}\cap W_1^c=\overline{W_2}\cap W_2^c$. Then $\mathscr{C}(E)=\mathscr{P}_0(W_1\cup W_2)^w=\mathsf{C}^1\cdot I$.

(b) Let $K\subset\mathsf{M}$ be closed and causally complete, and such that K is contained in a *spacelike* 2-plane. Then $\mathscr{C}(K)=\mathsf{C}^1\cdot I$.

Proof: The pair of wedges $\{W_1, W_2\}$ is Poincaré equivalent with the pair $\{W_R, W_L\}$, with $W_R=\{x|x_3>|t|\}$ and $W_L=\{x|x_3<-|t|\}$, and we thus prove the assertion in part (a) for the latter pair. We now depend on some results of Bisognano and Wichmann.[16] (See, in particular, part (c) of Lemma 11, and note that the set $\mathscr{C}_w(W_R)$ in the quoted paper is equal to the set $Z\mathscr{C}(W_R)Z^{-1}$ in the present paper.) For any $B\in\mathscr{C}(W_R)=\mathscr{P}_0(W_L)^w$ we thus have

$$V(i\pi)ZB\Omega=JZB^*\Omega. \tag{5.15}$$

Here $V(i\pi)$ is a self-adjoint operator obtained by an analytic continuation of the operators in the Abelian group $\{V(\lambda)|\lambda\in\mathsf{R}^1\}$ of all velocity transformations in the 3-direction, and J is the antiunitary involution $J=ZU_0\theta_0$ where θ_0 is the *PCT*-operator and U_0 is the operator which represents a rotation by angle 2π about any axis. The operator Z is given by $Z=(I+iU_0)/(1+i)$.

For any $B_L\in\mathscr{C}(W_L)=\mathscr{P}_0(W_R)^w$ we have

$$V(-i\pi)ZB_L\Omega=U_0JZB_L^*\Omega. \tag{5.16}$$

Suppose that $B\in\mathscr{C}(W_R)\cap\mathscr{C}(W_L)$. Then $B=B_L$ satisfies *both* the relations (5.15) and (5.16), and since Z commutes with $V(\lambda)$ and U_0 we have $V(-i\pi)B\Omega=U_0V(i\pi)B\Omega$, which implies that $B\Omega$ is an eigenvector of $U_0V(2\pi i)$ (with eigenvalue $+1$). Since Ω is the only eigenvector of $U_0V(2\pi i)$ it follows that $B\Omega=c\Omega$, with $c=\langle\Omega|B\Omega\rangle$. For any $X_1, X_2\in\mathscr{P}_0(W_L)$ we then have $\langle X_1\Omega|BX_2\Omega\rangle=\langle X_2^\dagger X_1\Omega|B\Omega\rangle=c\langle X_1\Omega|X_2\Omega\rangle$, and we thus conclude that $B=cI$. This proves the assertion in part (a). The conclusion in part (b) follows from the trivial fact that a spacelike 2-plane is always the edge of some wedge.

It can well happen that $\mathscr{C}(K)\neq\mathsf{C}^1\cdot I$ for a closed causally complete set K with an empty interior. Such a set K is necessarily a subset of some characteristic plane if it is also convex. We conclude this section with an example of this kind.

Example 5.20: As in Example 4.6 we define K as the subset $K=\{x|\tau\geqslant x_3=t\geqslant-\tau, x_1^2+x_2^2\leqslant\rho^2\}$ of the characteristic plane $\pi=\{x|x_3=t\}$, with $\tau>0$, $\rho>0$. We then have $K\in\mathscr{K}_C$ and K has an empty interior. Let $\psi(x)$ be the solution of the Klein–Gordon equation, for some $m>0$, constructed in Example 4.6, and let B be the unitary operator related to $\psi(x)$ as in Lemma 5.12. We then have $B\in\mathscr{P}_0(K^c)^w$ since $\psi(x)=0$ on K^c, and the operator B is not a multiple of the identity.

VI. CONCLUDING REMARKS

In our discussion of quantum field theories in Section V two basic questions emerge, as we noted before. Given an open set $S\subset\mathsf{M}$, when do we have the equality $\mathscr{P}_0(S)^w=\mathscr{P}_0(\mathscr{E}(S))^w$ and when do we have the equality $\mathscr{P}_0(S)^w=\mathscr{P}_0(S^{cc})^w$? The second equality trivially implies the first, since $S\subset\mathscr{E}(S)\subset(S^{cc})^o$, but as was demonstrated conclusively in Example 5.13, the first equality does not imply the second, and the second equality *cannot* be generally true. As we have also seen, the *intersection property* $\mathscr{C}(K_1)\cap\mathscr{C}(K_2)=\mathscr{C}(K_1\cap K_2)$ for the weak commutants, which might seem plausible at first sight, *cannot* be generally true, for two arbitrary closed causally complete subsets K_1, K_2 of M. In this paper we have shown that one has a rather satisfactory theory for the weak commutants $\mathscr{C}(K)$ when K is in the set $\mathscr{K}_E$, and thus equal to an intersection of closed causal wedges. This is related to the fact that open regions S which are unions of wedges have special features which are not shared by ''arbitrary'' open sets. In particular the relations $\mathscr{P}_0(S)^w=\mathscr{P}_0(\mathscr{E}(S))^w$ and $a(S)=\mathscr{E}(S)$ always hold for these special sets. Our demonstration of these facts was based on Araki's theory,[1] which in turn is based on the spectrum condition for the

translation operators, and on the commutation or anticommutation relations expressing the locality condition in quantum field theory. These conditions are very general, and one might regard the input of our theory as rather ''meager.''

We have shown that the intersection property $\mathscr{E}(K_1)\cap\mathscr{E}(K_2)=\mathscr{E}(K_1\cap K_2)$ does hold for compact, convex, causally complete sets K_1 and K_2 (and also a bit more generally), but it is hard to believe that *convexity* is the real essence of the matter. The convexity is, however, essential for our methods, and without additional input we do not expect that one can do much better.

The status of the relation $\mathscr{P}_0(S)^w=\mathscr{P}_0(\mathscr{E}(S))^w$ is presently clouded. With the weak commutant defined as in our paper the counterexample of Haag and Schroer[14] shows conclusively that the relation cannot hold generally, since the *time-slice condition* does not hold in their example. The example involves a single generalized free field, and the considerations are closely related to the considerations in our Example 4.7. However, if we enlarge the set of field operators to include *all* (generalized free) fields in the Borchers class of the ''original'' generalized free field, then the counterexample evaporates, and the relation $\mathscr{P}_0(S)^w=\mathscr{P}_0(\mathscr{E}(S))^w$ now holds generally, for all open sets S. In view of this one could argue that our definition of the weak commutants is defective: we should first enlarge the set of quantum fields to include all fields in the Borchers class of the ''given'' fields, and then define the weak commutants with respect to this enlarged set. There is some reason to believe that this would not affect the weak commutants $\mathscr{E}(K)$ associated with sets $K\in\mathscr{K}_C$, but that it would in general lead to *smaller* weak commutants $\mathscr{P}_0(R)^w$ for *bounded* sets R. To our knowledge there does not exist, at this time, any convincing counterexample ruling out the general validity of the relation $\mathscr{P}_0(S)^w=\mathscr{P}_0(\mathscr{E}(S))^w$ for such an extended field algebra. This relation is obviously of the nature of a *causality condition*, and one might argue that it ought to be valid in a physically satisfactory theory. It is thus of interest to see how our results would be improved if we *assume* that the equality holds.

Let K_1 and K_2 be two closed, causally complete sets such that K_1^c and K_2^c are open. We then have $\mathscr{P}_0(K_1^c)^w\cap\mathscr{P}_0(K_2^c)^w=\mathscr{P}_0(K_1^c\cup K_2^c)^w$ and $\mathscr{P}_0(K_1^c\cup K_2^c)^w=\mathscr{P}_0(\mathscr{E}(K_1^c\cup K_2^c))^w$ with our additional assumption. As we discussed in Section IV in TW-I,[8] it is the case that $\mathscr{E}(S)=(S^{cc})^o$ for a large class of ''reasonable'' open sets S, although this relation most definitely does not hold generally. We gave the necessary and sufficient conditions on S for the relation to be valid, and we also gave a number of examples for which it does not hold. An obvious absolute requirement is that $\mathscr{E}(S)$ must be *timelike convex*, which means that $\mathscr{E}(S)$ contains the timelike (or isotropic) interval $[x',x'']$ whenever $\mathscr{E}(S)$ contains the endpoints x' and x''. It is easily seen that $\mathscr{E}(S)$ is timelike convex if S is timelike convex. Note that the counterexample in Example 5.13 does involve a case when neither $K_1^c\cup K_2^c$ nor $\mathscr{E}(K_1^c\cup K_2^c)$ is timelike convex. Timelike convexity by itself is not sufficient for the conclusion that $\mathscr{E}(S)=(S^{cc})^o$, but if S is also bounded, then the conclusion follows. (See Lemma 4.7 and Theorem 4.8 in TW-I[8]). Suppose now that the above sets K_1 and K_2 are such that $\mathscr{E}(K_1^c\cup K_2^c)=(K_1^c\cup K_2^c)^{cc}=(K_1\cap K_2)^c$. The intersection property $\mathscr{P}_0(K_1^c)^w\cap\mathscr{P}_0(K_2^c)^w=\mathscr{P}_0((K_1\cap K_2)^c)^w$ then holds for the weak commutants associated with the sets K_1 and K_2. The intersection property would thus hold for all pairs K_1 and K_2 which satisfy the condition that $\mathscr{E}(K_1^c\cup K_2^c)=(K_1^c\cup K_2^c)^{cc}$, which is a very much stronger result than our result in Theorem 5.11. In particular there is no requirement that the sets K_1 or K_2 be convex, nor is there any requirement that these sets be connected.

In the preceding section we have considered *bounded* operators B which commute in the weak sense of Definition 5.3 with the operators in $\mathscr{P}_0(R)$, for some R. It should be clear that very similar conclusions can be drawn about *unbounded* operators Q which commute in some ''weak'' sense with the operators in $\mathscr{P}_0(R)$. If Q is unbounded, attention has to be given to questions of domains. One possibility is that we are given that Q is defined and closable on the domain D_1, in which case we would consider expressions of the form $\langle Q^*\Phi'|X\Phi''\rangle-\langle X^\dagger\Phi'|Q\Phi''\rangle$, or of the form $A_{\mu;\Phi',\Phi''}(Q;x)=\langle Q^*\Phi'|\varphi_\mu(x)\Phi''\rangle-\langle\varphi_\mu^\dagger(x)\Phi'|Q\Phi''\rangle$, as corresponding to matrix elements of commutators. It is not required that Q and $Q^\dagger$ map D_1 into D_1. If we consider operators Q which satisfy the additional conditions that $Q\mathsf{D}_1\subset\mathsf{D}_1$ and $Q^\dagger\mathsf{D}_1\subset\mathsf{D}_1$, then the commutators $[X,Q]$ and $[\varphi_\mu(x),Q]$ make sense on D_1, and the set of all operators Q which commute with all $X\in\mathscr{P}_0(R)$ on D_1 for some $R\subset\mathsf{M}$ form a unital *-algebra. Other possibilities can be considered, with Q and the field operators defined on some ''natural'' domain *larger* than D_1. If the reasoning depends on features such as those described in Lemmas 5.1 or 5.2, one must check that analogous principles are actually valid in the case at hand. We did not want to burden the discussion with

domain questions, and hence we discussed weak commutants consisting of bounded operators. Furthermore weak commutants of this kind are of particular interest in connection with the question of whether the local field operators may have closed extensions affiliated with von Neumann algebras in a local net. In the most favorable case the weak commutants would *equal* these algebras.

Gauge fixing in the partition function for generalized quantum dynamics

Stephen L. Adler
Institute for Advanced Study, Princeton, New Jersey 08540

(Received 29 September 1997; accepted for publication 10 November 1997)

We discuss the problem of gauge fixing for the partition function in generalized quantum (or trace) dynamics, deriving analogs of the De Witt–Faddeev–Popov procedure and of the BRST invariance familiar in the functional integral context.

I. INTRODUCTION, AND THE GAUGE THEORY AXIAL GAUGE PARTITION FUNCTION

Generalized quantum (or trace) dynamics[1] is a generalization of classical mechanics, in which the Lagrangian and Hamiltonian are constructed as the trace of multinomials in noncommutative operator or matrix variables. This new form of analytic mechanics has a number of interesting properties. When the fermions are realized in the conventional manner as Grassmann matrices, generalized quantum dynamics incorporates and generalizes all rigid supersymmetry theories, such as[2] the Wess–Zumino and supersymmetric Yang–Mills theories, and also[3] the recently much discussed ''matrix model for M theory.'' In addition, one can formulate a statistical mechanics for generalized quantum dynamics, in both the canonical[4] and microcanonical[5] ensembles. Recent work suggests[4,6] that this statistical mechanics can behave as a prequantum mechanics, with the Heisenberg commutation relations holding for statistical averages over the canonical ensemble of the underlying operator variables.

This prior work on the statistical mechanics of generalized quantum dynamics has assumed either that one is dealing with an unconstrained system, or that the constraints have been explicitly integrated out. In the generic case for an unconstrained system, the canonical ensemble takes the form[4–6]

$$\rho = Z^{-1}\exp(-\tau\mathbf{H}-\mathrm{Tr}\lambda\widetilde{C}),$$

$$Z=\int d\mu\ \exp(-\tau\mathbf{H}-\mathrm{Tr}\lambda\widetilde{C}), \tag{1a}$$

with $d\mu$ the invariant matrix (or operator) phase space measure provided[4] by Liouville's theorem, with $\mathbf{H}$ the conserved total trace Hamiltonian, and with $\widetilde{C}$ the conserved operator

$$\widetilde{C}=\sum_r{}_{\text{bosons}}[q_r,p_r]-\sum_r{}_{\text{fermions}}\{q_r,p_r\}. \tag{1b}$$

In order to apply Eq. (1a) directly to a constrained system, one must first explicitly integrate out the constraints. A simple example where this is possible, that forms the focus of this paper, is provided by the generalized quantum dynamics form of non-Abelian gauge theory,[1] which has a full operator valued gauge invariance group. Let A_ν be an anti-self-adjoint operator or matrix valued gauge potential, let $F_{\mu\nu}$ be the corresponding gauge field strength defined by

$$F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu+[A_\mu,A_\nu], \tag{2a}$$

and let $\mathbf{L}$ be the total trace Lagrangian defined by

$$\mathbf{L}=\frac{1}{4}\mathrm{Tr}F_{\mu\nu}F^{\mu\nu}. \tag{2b}$$

 © 1998 American Institute of Physics

As is well known, Eqs. (2a) and (2b) define a constrained dynamical system. Introducing the canonical momenta

$$p_{A_l} = -F_{0l}, \quad l = 1,2,3, \tag{3a}$$

and the covariant derivative

$$D_\mu X = \partial_\mu X + [A_\mu, X], \tag{3b}$$

the constraint equation for the system of Eqs. (2a) and (2b) takes the form

$$\sum_{l=1}^{3} D_l p_{A_l} = 0. \tag{3c}$$

Since in axial gauge, where $A_3 = 0$, the covariant derivative D_3 simplifies to $D_3 = \partial_3$, the constraint of Eq. (3c) is readily integrated out, giving as the explicit expression for the total trace Hamiltonian,

$$\begin{aligned} \mathbf{H} &= \mathrm{Tr}\left[-\frac{1}{2}\sum_{l=1}^{3} p_{A_l}^2 - \frac{1}{4}\sum_{l,m=1}^{3} F_{lm}^2 \right] \\ &= \int d^3x \frac{1}{2}\mathrm{Tr}\left[-\sum_{l=1}^{2} p_{A_l}^2 - F_{03}^2 - F_{12}^2 - \sum_{l=1}^{2} (\partial_3 A_l)^2 \right], \end{aligned} \tag{4a}$$

with F_{03} given by the line integral

$$F_{03} = \int dz' \frac{1}{2} \frac{z - z'}{|z - z'|} \left(\sum_{l=1}^{2} D_l p_{A_l} \right) \Bigg|_{z'}. \tag{4b}$$

The conserved operator $\tilde{C}$ takes the form, in a general gauge,

$$\tilde{C} = \int d^3x \sum_{l=1}^{3} [A_l, p_{A_l}] = \sum_{l=1}^{3} \left(\int d^3x D_l p_{A_l} - \int dS_l p_{A_l} \right), \tag{5a}$$

with dS_l the surface element of the sphere at infinity. To specialize Eq. (5a) to axial gauge, one sets A_3 equal to zero and evaluates p_{A_3} using Eqs. (3a) and (4b). The axial gauge partition function is then given by Eq. (1a), with the phase space measure $d\mu$ given by

$$d\mu_{\mathrm{axial}} = \prod_{\vec{x}} \prod_{l=1}^{2} dA_l(\vec{x}) dp_{A_l(\vec{x})}. \tag{5b}$$

The problem we wish to address in this paper is how to generalize the axial gauge partition function to other gauges in which it may not be possible to explicitly integrate out the constraint. This is a familiar problem in the theory of path integrals, and we shall use methods similar to the ones employed there to give a solution. However, since the partition function singles out a Lorentz frame, we will have to make a restriction not encountered in the Lorentz scalar path integral case, namely we will consider only nontemporal gauge conditions that do not involve the scalar potential A_0. This will still allow us to consider gauge transformations that rotate the axial gauge axis, or that transform to rotationally invariant gauges such as Coulomb gauge. We will also make the further assumption that the allowed gauge transformations leave invariant the surface integral contribution to $\mathrm{Tr}\tilde{\lambda}\tilde{C}$ arising from the second term on the right hand side of Eq. (5a), which places a restriction on the constant of integration that governs the gauge transformation at the point at infinity. [Although the volume integral in the first term on the right hand side of Eq. (5a) is generically gauge covariant rather than gauge invariant, this causes no problem because its integrand is proportional to the constraint of Eq. (3c).] In Sec. II we develop an analog of the standard

DeWitt–Faddeev–Popov method to write the axial gauge partition function in a general nontemporal gauge, subject to the surface term restriction just stated. Since we have shown[2,3] that trace dynamics incorporates rigid supersymmetry, and since BRST invariance is a particular rigid supersymmetry transformation, it is not surprising that the generalized expression for the partition function, when reexpressed in terms of ghost fermions, admits a BRST invariance, and this is demonstrated in Sec. III. In the analysis that follows, we do not attempt to address the issue of convergence of the partition function, which may well require significant restrictions on the class of trace Hamiltonians being considered.

II. GENERAL NONTEMPORAL GAUGES AND THE DE WITT–FADDEEV–POPOV PROCEDURE

To express the partition function in a general nontemporal gauge, we follow closely the treatment of the De Witt–Faddeev–Popov construction in the familiar functional integral case, as given in the text of Weinberg.[7] Let us consider the integral

$$Z_G = \int d\mu B[f(A_l)]\,\delta(D)\det \mathscr{F}[A_l]\exp(-\pi\mathbf{H} - \mathrm{Tr}\tilde{\lambda}\tilde{C}),$$

$$d\mu = \prod_{\vec{x}} \prod_{l=1}^{3} dA_l(\vec{x}) dp_{A_l(\vec{x})}, \tag{6a}$$

with $\mathbf{H}$ given by the first line of Eq. (4a) [which is valid in a general gauge on the constraint surface $D=0$ selected by the delta function in Eq. (6a)], with $\tilde{C}$ given by Eq. (5a), and with D defined by $D \equiv \Sigma_{l=1}^{3} D_l p_{A_l}$. The delta function of the anti-self-adjoint matrix valued argument D appearing in Eq. (6a) is given, in terms of ordinary delta functions of the real (R) and imaginary (I) parts of the matrix elements, by

$$\delta(D) = \prod_{m<n} \delta((D_R)_{mn}) \prod_{m\leqslant n} \delta((D_I)_{mn}), \tag{6b}$$

and the integration measure over the anti-self-adjoint matrix A_l is defined by

$$dA_l = \prod_{m<n} d(A_{lR})_{mn} \prod_{m\leqslant n} d(A_{lI})_{mn}, \tag{6c}$$

and similarly for dp_{A_l}. The function $B[f]$ is an arbitrary integrable scalar valued function of the matrix valued argument $f(A_l)$, which is used to specify the gauge condition. We shall treat f as a column vector f_α with α a composite index formed from the matrix row and column indices m,n; the argument $\mathscr{F}$ of the De Witt–Faddeev–Popov determinant is then given in terms of f by the expression

$$\mathscr{F}_{\alpha\vec{x},\beta\vec{y}}[A_l] \equiv \left.\frac{\delta f_\alpha(A_l(\vec{x}) + D_l\Lambda(\vec{x}))}{\delta\Lambda_\beta(\vec{y})}\right|_{\Lambda=0}, \tag{6d}$$

where δ is the usual functional derivative and β is the composite of the row and column indices of the infinitesimal gauge transformation matrix Λ.

We now demonstrate two properties of the integral Z_G defined in Eq. (6a): (i) first, we show that when the gauge fixing functions $B[f]$ and $f(A_l)$ are chosen to correspond to the axial gauge condition, then Eq. (6a) reduces (up to an overall constant) to the axial gauge partition function of Sec. I; (ii) second, we show that Z_G is in fact independent of the function $f(A_l)$, and depends on the function $B[f]$ only through an overall constant. These two properties together imply that Z_G gives the wanted extension of the axial gauge partition function to general nontemporal gauges.

To establish property (i), we make the conventional axial gauge choice

$$B[f(A_l)]=\delta(A_3)=\prod_{m<n}\delta((A_{3R})_{mn})\prod_{m\leqslant n}\delta((A_{3I})_{mn}) \tag{7a}$$

so that

$$\int dA_3 B[f(A_l)]=\int dA_3\delta(A_3)=1. \tag{7b}$$

With this gauge choice,

$$D_3 p_{A_3}=\partial_3 p_{A_3}, \tag{7c}$$

which implies that

$$\begin{aligned}\delta(D)&=\delta\left(\partial_3 p_{A_3}+\sum_{l=1}^{2} D_l p_{A_l}\right)\\&=|\partial_3|^{-1}\delta\left(p_{A_3}+\int^z dz'\sum_{l=1}^{2} D_l p_{A_l}\right);\end{aligned} \tag{8a}$$

hence the integral over p_{A_3} in Z_G can be done explicitly, giving (up to an overall constant factor coming from the Jacobian $|\partial_3|^{-1}$) the expression

$$Z_G=\int d\mu_{\text{axial}}\ \exp\ (-\tau\mathbf{H}-\mathrm{Tr}\tilde{\lambda}\tilde{C})|_{A_3=0;p_{A_3}=-\int^z dz'\Sigma_{l=1}^{2}D_l p_{A_l}}, \tag{8b}$$

which agrees with the axial gauge partition function of Sec. I.

To establish property (ii), we first examine the gauge transformation properties of the various factors in the integral defining Z_G. We begin with the integration measure $d\mu$. Under the infinitesimal gauge transformation (with Λ anti-self-adjoint)

$$A_l\rightarrow A_l+D_l\Lambda=A_l+\partial_l\Lambda+[A_l,\Lambda], \tag{9a}$$

the inhomogeneous term $\partial_l\Lambda$ does not contribute to the transformation of the differential dA_l, and so dA_l obeys the homogeneous transformation law $dA_l\rightarrow dA_l+\Delta_l$, with

$$\Delta_l\equiv[dA_l,\Lambda]. \tag{9b}$$

Hence to first order in Λ, the Jacobian of the transformation is

$$\begin{aligned}J&=1+\sum_{m<n}\frac{\partial(\Delta_{lR})_{mn}}{\partial(dA_{lR})_{mn}}+\sum_{m\leqslant n}\frac{\partial(\Delta_{lI})_{mn}}{\partial(dA_{lI})_{mn}}\\&=1+\left(\sum_{m<n}+\sum_{m\leqslant n}\right)[(\Lambda_R)_{nn}-(\Lambda_R)_{mm}]=1,\end{aligned} \tag{9c}$$

since the anti-self-adjointness of Λ implies that $(\Lambda_R)_{nm}=-(\Lambda_R)_{mn}$, and so the diagonal matrix elements $(\Lambda_R)_{nn}$ are all zero. Thus each factor $dA_l(\vec{x})$ in the integration measure is gauge invariant. A similar argument applies to each factor $dp_{A_l(\vec{x})}$ in the integration measure, and also to the factor $\delta(D)$ in the integrand, since D obeys the homogeneous gauge transformation law $D\rightarrow D+[D,\Lambda]$. Turning to the exponential, the terms $\mathrm{Tr}p_{A_l}^2$ and $\mathrm{Tr}F_{lm}^2$ are gauge invariant, and so the trace Hamiltonian $\mathbf{H}$ is gauge invariant. From Eq. (5a), the volume integral term in $\tilde{C}$ vanishes by virtue of the integrand factor $\delta(D)$, and so $\mathrm{Tr}\tilde{\lambda}\tilde{C}$ receives a contribution only from the surface term in Eq. (5a), which by hypothesis is left invariant by the class of gauge transformations under consideration. In sum, we see that the integral Z_G has the form

$$Z_G = \int d\mu \mathcal{G}[A_l] B[f(A_l)] \det \mathcal{F}[A_l], \tag{10a}$$

with the integration measure $d\mu$ and the integrand factor

$$\mathcal{G}[A_l] = \delta(D) \exp(-\tau \mathbf{H} - \mathrm{Tr} \tilde{\lambda} \tilde{C}) \tag{10b}$$

both gauge invariant. Hence Z_G has exactly the form assumed in the discussion of Weinberg,[7] and the proof given there completes the demonstration of property (ii).

III. GHOSTS AND BRST INVARIANCE OF THE GENERALIZED PARTITION FUNCTION

Let us continue to follow the standard path integral analysis, and represent the De Witt–Faddeev–Popov determinant $\det \mathcal{F}[A_l]$ as an integral over fermionic ghosts, by writing

$$\det \mathcal{F}[A_l] = \int d\omega^* d\omega \exp\left(\int d^3x d^3y \omega^*_\alpha(\vec{x}) \mathcal{F}_{\alpha\vec{x},\beta\vec{y}}[A_l] \omega_\beta(\vec{y}) \right), \tag{11a}$$

with

$$d\omega = \prod_{\vec{x}} \prod_{m,n} d\omega_{mn}(\vec{x}), \quad d\omega^* = \prod_{\vec{x}} \prod_{m,n} d\omega^*_{mn}(\vec{x}). \tag{11b}$$

Let us also take for $B[f]$ the usual Gaussian

$$B[f] = \exp\left(-\frac{1}{2\xi} \int d^3x \mathrm{Tr} f(A_l(\vec{x}))^2 \right), \tag{11c}$$

and for $f(A_l)$ the linear gauge condition

$$f(A_l) = \sum_l L^l A_l, \tag{11d}$$

in which L^l can be either a fixed vector (such as δ_{l3} in axial gauge) or a differential operator (such as ∂_l in Coulomb gauge), and a summation of l from 1 to 3 is understood. With this choice of $f(A_l)$, we find from Eq. (6d) that

$$\begin{aligned} \mathcal{F}_{nm\vec{x},pq\vec{y}}[A_l] &= \frac{\delta f_{nm}(A_l(\vec{x}) + D_l \Lambda(\vec{x}))}{\delta \Lambda_{pq}(\vec{y})} \\ &= \sum_l L^l_{\vec{x}} \left(\frac{\partial \delta(\vec{x}-\vec{y})}{\partial x^l} \delta_{np}\delta_{mq} + \delta(\vec{y}-\vec{y})[(A_l)_{np}\delta_{mq} - \delta_{np}(A_l)_{qm}] \right), \end{aligned} \tag{12a}$$

which when substituted into the exponent in Eq. (11a) gives, after integrations by parts,

$$\int d^3x d^3y \omega^*_\alpha(\vec{x}) \mathcal{F}_{\alpha\vec{x},\beta\vec{y}}[A_l] \omega_\beta(\vec{y})) = \int d^3x \mathrm{Tr} \bar{\omega}(\vec{x}) \sum_l L^l D_l \omega(\vec{x}), \tag{12b}$$

where we have defined $\bar{\omega}_{mn} = \omega^*_{nm}$. Hence the expression of Eq. (10a) for Z_G becomes

$$Z_G = \int d\mu d\bar{\omega} d\omega \mathcal{G}[A_l] \exp\left[-\int d^3x \mathrm{Tr} \left(\frac{1}{2\xi} \left(\sum_l L^l A_l \right)^2 - \bar{\omega}(\vec{x}) \sum_l L^l D_l \omega(\vec{x}) \right) \right]. \tag{13a}$$

An alternative way of writing Eq. (13a), that is convenient for exhibiting the BRST invariance, is to introduce an auxilliary self-adjoint matrix field h and to reexpress Eq. (13a) as

$$Z_G=\int d\mu dh d\bar{\omega} d\omega \mathcal{G}[A_l]\exp\left[-\int d^3x \mathrm{Tr}\left(\frac{\xi}{2}h^2+ih\sum_l L^l A_l-\bar{\omega}(\vec{x})\sum_l L^l D_l\omega(\vec{x})\right)\right]. \tag{13b}$$

Starting from Eq. (13b), we can now show that Z_G has a BRST invariance of the familiar form. Let θ be an $\vec{x}$-independent c-number Grassmann parameter (i.e., a 1×1 Grassmann matrix), and consider the variations defined by

$$\begin{aligned}\delta\omega&=\omega^2\theta,\\ \delta A_l&=D_l\omega\theta,\\ \delta\bar{\omega}&=-ih\theta,\\ \delta h&=0.\end{aligned} \tag{14}$$

We begin by showing that Eq. (14) defines a nilpotent transformation, in the sense that the second variations of all quantities are zero. To verify this, we show that the variations of ω^2 and $D_l\omega$ are zero (the variations of h and of 0 are trivially 0), as follows:

$$\begin{aligned}\delta\omega^2&=\{\delta\omega,\omega\}=\{\omega^2\theta,\omega\}=\omega^2\{\omega,\theta\}=0,\\ \delta D_l\omega&=[\delta A_l,\omega]+D_l\delta\omega=[D_l\omega\theta,\omega]+D_l\omega^2\theta=-\{D_l\omega,\omega\}\theta+\{D_l\omega,\omega\}\theta=0.\end{aligned} \tag{15a}$$

To see that Z_G is invariant, we note that the action on A_l of the BRST transformation of Eq. (14) is just a gauge transformation (albeit with a Grassmann valued parameter), and so the gauge invariance analysis of Sec. II shows that the factors $d\mu$ and $\mathcal{G}[A_l]$ are invariant. The measure dh is trivially invariant, and the measure $d\bar{\omega}$ is invariant because $\delta\bar{\omega}$ has no dependence on $\bar{\omega}$. Since

$$\delta(d\omega)=d(\delta\omega)=d(\omega^2\theta)=(\omega d\omega+d\omega\omega)\theta, \tag{15b}$$

we have

$$(\delta(d\omega))_{mn}=(\omega_{mm}d\omega_{mn}+d\omega_{mn}\omega_{nn})\theta+\cdots=d\omega_{mn}(\omega_{nn}-\omega_{mm})\theta+\cdots, \tag{15c}$$

with $\ldots$ denoting terms that contain matrix elements $d\omega_{m'n'}$ with $(m',n')\neq(m,n)$. Hence the Jacobian of transformation for $d\omega$ differs from unity by a term proportional to

$$\sum_{nm}(\omega_{nn}-\omega_{mm})\theta=0, \tag{15d}$$

and so the measure $d\omega$ is also invariant. Hence to complete the demonstration that Z_G is BRST invariant, we have to show that the gauge fixing part of the Hamiltonian,

$$\mathbf{H}_G\equiv\int d^3x \mathrm{Tr}\left(\frac{\xi}{2}h^2+ih\sum_l L^l A_l-\bar{\omega}\sum_l L^l D_l\omega\right), \tag{16a}$$

is BRST invariant. Since we have already seen that $D_l\omega$ is invariant, and since h is trivially invariant, we have only to verify that

$$0=\int d^3x \mathrm{Tr}\left[ih\sum_l L^l\delta A_l-(\delta\bar{\omega})\sum_l L^l D_l\omega\right]=\int d^3x \mathrm{Tr} ih\sum_l L^l D_l\{\omega,\theta\}, \tag{16b}$$

which checks, completing the demonstration of BRST invariance of the generalized partition function.

Geometric approach to inverse scattering for hydrogen-like systems in a homogeneous magnetic field

Silke Arians[a)]
Institut für Reine und Angewandte Mathematik, RWTH Aachen, D-52056 Aachen, Germany

(Received 23 June 1997; accepted for publication 8 January 1998)

We consider the Hamiltonian of one quantum particle in a homogeneous magnetic field and a scalar potential in three space dimensions. For a given magnetic field the high velocity limit of the scattering operator uniquely determines the scalar potential if it is of short range. If, in addition, long-range potentials are present, some knowledge of (the far out tail of) the long-range part is needed to define a modified Dollard wave operator and a scattering operator. Again its high velocity limit uniquely determines the total scalar potential for a given magnetic field. We generalize our results to a system of two interacting quantum particles with opposite electric charges. © *1998 American Institute of Physics.* [S0022-2488(98)02704-2]

I. INTRODUCTION

We study a system of one quantum particle in a homogeneous magnetic field in $\nu=3$ dimensions. As an example of such a one-body system we mention a hydrogen atom with an infinitely heavy proton. The interactions are given by a vector potential $\mathbf{A}$ with $\mathbf{rotA}=\mathbf{B}$ and a scalar potential V. We chose the coordinates $(x,y,z)\in\mathbb{R}^3$ such that the magnetic field is pointed along the z-axis, i.e., $\mathbf{B}=(0,0,b)$ for $b>0$ constant. In a transversal gauge a corresponding vector potential is

$$\mathbf{A}(\mathbf{r})=(-by/2,bx/2,0) \text{ for a vector } \mathbf{r}=(x,y,z)\in\mathbb{R}^3. \tag{1.1}$$

A classical particle with mass m, charge e and velocity $\mathbf{v}$ in a constant magnetic field $\mathbf{B}$ moves in helixes with the Larmor radius

$$\mathbf{R}(t)=-\frac{m}{e}\frac{\mathbf{v}(t)\times\mathbf{B}}{\mathbf{B}^2}, \tag{1.2}$$

i.e., $|\mathbf{R}(t)|=(\mathbf{v}_x^2(t)+\mathbf{v}_y^2(t))^{1/2}m|e|/b$ and the radius is proportional to the velocity in the (x,y)-direction. Then in the high velocity limit the radius tends to infinity, such that the particle moves in a straight line. The Larmor frequency is

$$\boldsymbol{\omega}=-\frac{e\mathbf{B}}{m}, \tag{1.3}$$

such that the minimal period of the particle $|T|=|2\pi/\boldsymbol{\omega}|=2\pi m/(|e|b)$ is independent of the velocity. Thus for increasing velocity the particle moves in circles with increasing radius, but needs the same time for each circle. Therefore we have to assume that the particle moves parallel to the magnetic field with velocity $|\mathbf{v}_z|>0$, such that the potential is hit only once.

Let $H_0:=(1/2m)\,\mathbf{p}^2$ be the free Hamiltonian. By

$$H_A:=\frac{1}{2m}(\mathbf{p}-\mathbf{A}(\mathbf{r}))^2 \tag{1.4}$$

a)Electronic mail: arians@iram.rwth-aachen.de

 © 1998 American Institute of Physics

we denote the Hamiltonian with the magnetic field alone and by $H=H_A+V$ we denote the interacting Hamiltonian with mass m, charge $e=1$, momentum $\mathbf{p}=-i\nabla_{\mathbf{r}}$ and position $\mathbf{r}$. We abbreviate the first and second components of the position $\mathbf{r}$ with $\boldsymbol{\rho}$ and of the momentum $\mathbf{p}$ with $\boldsymbol{\pi}$:

$$\boldsymbol{\rho}:=(x,y) \text{ and } \boldsymbol{\pi}:=(\mathbf{p}_x,\mathbf{p}_y). \tag{1.5}$$

It is useful to introduce the following representation (see Ref. 1 for the notation):

$$H_A=H_0+\frac{1}{2m}\left\{\frac{b^2}{4}\left(\frac{\mathbf{B}}{|\mathbf{B}|}\times\mathbf{r}\right)^2-\mathbf{B}\mathbf{L}\right\} \tag{1.6}$$

$$=H_0+\frac{1}{2m}\left\{\frac{b^2}{4}(x^2+y^2)-b\mathbf{L}_z\right\} \tag{1.7}$$

$$=\frac{1}{2m}\mathbf{p}_z^2+H_{osc}-\frac{1}{2m}b\mathbf{L}_z \tag{1.8}$$

with the z-component of the angular momentum $\mathbf{L}_z=x\mathbf{p}_y-y\mathbf{p}_x$ and the harmonic oscillator

$$H_{osc}=\frac{1}{2m}\left\{(\mathbf{p}_x^2+\mathbf{p}_y^2)+\frac{b^2}{4}(x^2+y^2)\right\}. \tag{1.9}$$

We consider H acting on $\mathscr{H}=L^2(X)$ for $X=\mathbb{R}^3$. It is known (see Ref. 2 for details) that $H_{xy}=H_{osc}-(1/2m)\,b\mathbf{L}_z$, acting on the Hilbert space $L^2(\mathbb{R}^2)$, has a complete set of eigenfunctions $\{\Theta_{ln}(x,y)\}_{l=0,\pm1,\ldots;n=0,1,\ldots}$ with corresponding eigenvalues

$$E_{ln}=(2m)^{-1}b(2n+|l|-l+1), \tag{1.10}$$

where E_{ln} and Θ_{ln} are often referred to as Landau energy levels and Landau orbits. As H_{xy} does not act on the z-variable, we have $\exp[-iH_At]=\exp[-iH_{xy}t]\exp[-i\mathbf{p}_z^2/(2m)]$.

The scalar potential can be split into a short-range and a long-range part: $V=V^s+V^l$. V^s is assumed to be short range: $V^s\in\mathscr{V}_{SR}$ with

$$\mathscr{V}_{SR}:=\{V^s\,|\,|V^s(\mathbf{r})|\leqslant\text{const}(1+|\mathbf{r}|)^{-(1+\varepsilon)}\}. \tag{1.11}$$

We mention that our results remain valid for unbounded short-range potentials (see Section VI).

Here V^l is assumed to be long range: $V^l\in\mathscr{V}_{LR}$ with

$$\mathscr{V}_{LR}:=\{V^l\,|\,V^l\in C^1(\mathbb{R}^3), V^l \text{ tends to zero for } |\mathbf{r}|\to\infty \text{ and}$$

$$|\nabla V^l(\mathbf{r})|\leqslant\text{const}(1+|\mathbf{r}|)^{-\gamma} \text{ with } \gamma>3/2\}. \tag{1.12}$$

The splitting into short- and long-range parts is not unique. But without loss of generality we can make it in such a way that in addition

$$|D^\alpha V^l(\mathbf{r})|\leqslant\text{const}(1+|\mathbf{r}|)^{-1-|\alpha|(\delta+1/2)} \tag{1.13}$$

for $1\leqslant|\alpha|\leqslant4$, $0<\delta<1/2$ (see Ref. 3).

We remark that for the proof of the asymptotics of the scattering operators (1.17), (1.24) and (1.25) we only need decay of the potentials in the z-direction. The decay in all directions is needed for the reconstruction of the scalar potentials.

Under these assumptions the interacting Hamiltonian is self-adjoint on its domain $\mathscr{D}(H)=\mathscr{D}(H_A)=W^{2,2}(X)$ in $\mathscr{H}=L^2(X)$.

In the special case, when V is of short range the following wave operators, which measure for a given $\mathbf{A}$ the additional effect on scattering due to V^s,

$$\Omega_\pm:=\Omega_\pm(\mathbf{A}):=\underset{t\to\pm\infty}{\text{s-lim}}\ e^{iHt}e^{-iH_At} \tag{1.14}$$

exist and are complete (see Ref. 2, Chapter 4). The scattering operator S is

$$S:=S(\mathbf{A};V^s):=(\Omega_+)^*\Omega_-. \tag{1.15}$$

As wave functions we chose asymptotic configurations $\Phi_0\in\mathscr{H}=L^2(X)$ with compact momentum support in the ball around the origin with radius $m\eta$, $\eta>0$, and momentum space wave function $\hat{\phi}_0\in C_0^\infty(B_{m\eta}(0))$. These functions are dense in $\mathscr{H}$ and we can find a function $g\in C_0^\infty(\mathbb{R}^3)$ with $\Phi_0=g(\mathbf{p})\Phi_0$ and especially a function $f\in C_0^\infty(\mathbb{R})$ with $\Phi_0=f(\mathbf{p}_z)\Phi_0$.

By $\Phi_\mathbf{v}$ we denote the boosted configuration translated by $m\mathbf{v}$ in momentum space, where $\mathbf{v}=(\mathbf{v}_x,\mathbf{v}_y,\mathbf{v}_z)$ is the velocity:

$$\Phi_\mathbf{v}=e^{im\mathbf{v}\mathbf{r}}\Phi_0\Leftrightarrow\hat{\phi}_\mathbf{v}(\mathbf{p})=\hat{\phi}_0(\mathbf{p}-m\mathbf{v}),\quad \mathbf{v}_z\neq 0, \tag{1.16}$$

where $\Phi_\mathbf{v}$ has compact velocity support in $B_\eta(\mathbf{v})$. Let $v:=|\mathbf{v}|$. We will obtain asymptotics of S for the high velocity limit in an arbitrary direction $\hat{\mathbf{v}}=(\hat{\mathbf{v}}_x,\hat{\mathbf{v}}_y,\hat{\mathbf{v}}_z):=\mathbf{v}/v$, $v\to\infty$ with $\hat{\mathbf{v}}_z\neq 0$.

Regarding S as a mapping from the set of short-range potentials $\mathscr{V}_{SR}$ into the set of bounded operators $L(\mathscr{H})$ we have the following:

Theorem 1: Suppose that $V^s\in\mathscr{V}_{SR}$ and $V^l=0$. *Then the following reconstruction formula holds for all* $\Phi_\mathbf{v},\Psi_\mathbf{v}$ *as in Eq. (1.16):*

$$\lim_{v\to\infty} iv((S-\mathbb{1})\Phi_\mathbf{v},\Psi_\mathbf{v})=\int_{-\infty}^{\infty}(V^s(\mathbf{r}+\tau\hat{\mathbf{v}})\Phi_0,\Psi_0)d\tau. \tag{1.17}$$

In particular, the scattering map

$$S(\mathbf{A};\cdot):\mathscr{V}_{SR}\to L(\mathscr{H})$$

is injective.

The modified Dollard wave operators

$$\Omega_\pm^D:=\Omega_\pm^D(\mathbf{A}):=\operatorname*{s-lim}_{t\to\pm\infty} e^{iHt}U^D(t) \tag{1.18}$$

with

$$U^D(t):=\exp\left[-iH_At-i\int_0^t V^l(\hat{\boldsymbol{\rho}}_\mathbf{v}(s),s\mathbf{p}_z/m)ds\right] \tag{1.19}$$

where

$$\hat{x}_\mathbf{v}(s):=\omega^{-1}\{\mathbf{v}_x\sin(\omega s)+\mathbf{v}_y(1-\cos(\omega s))\}, \tag{1.20}$$

$$\hat{y}_\mathbf{v}(s):=\omega^{-1}\{\mathbf{v}_y\sin(\omega s)-\mathbf{v}_x(1-\cos(\omega s))\} \tag{1.21}$$

and

$$\hat{\boldsymbol{\rho}}_\mathbf{v}(s):=(\hat{x}_\mathbf{v}(s),\hat{y}_\mathbf{v}(s)) \tag{1.22}$$

with $\omega:=|\boldsymbol{\omega}|=b/m$ exist and are complete (see Ref. 1, Theorem 7.1) for a Dollard correction with $\hat{\boldsymbol{\rho}}_\mathbf{v}=0$. We remark that we introduced a velocity dependent correction (1.22) which corresponds to the classical behavior of a particle in a harmonic oscillator:

$$S^D:=S^D(\mathbf{A},V^l;V^s):=(\Omega_+^D)^*\Omega_-^D \tag{1.23}$$

is the scattering operator S^D. Since the splitting of V into a short- and a long-range part is not unique the Dollard wave operators are not uniquely defined. Nevertheless, the scalar potential is uniquely obtained from *any* of the scattering operators S^D.

Theorem 2: *Suppose that* $V^s \in \mathscr{V}_{SR}$ *and* $V^l \in \mathscr{V}_{LR}$. *Then the following reconstruction formula holds for all* $\Phi_{\mathbf{v}}, \Psi_{\mathbf{v}}$ *as in Eq. (1.16):*

$$\lim_{v\to\infty} iv((S^D-\mathbb{1})\Phi_{\mathbf{v}},\Psi_{\mathbf{v}}) - (\{V^l(\mathbf{r}+\tau\hat{\mathbf{v}}) - V^l(\tau\hat{\mathbf{v}})\}\Phi_0,\Psi_0)$$
$$= \int_{-\infty}^{\infty} (V^s(\mathbf{r}+\tau\hat{\mathbf{v}})\Phi_0,\Psi_0)\,d\tau. \tag{1.24}$$

In particular, for a given long-range potential V^l *the scattering map*

$$S^D(\mathbf{A},V^l;\cdot): \mathscr{V}_{SR} \to L(\mathscr{H})$$

is injective.

Moreover, the following formula holds for all $\Phi_{\mathbf{v}}, \Psi_{\mathbf{v}}$ *as in Eq. (1.16):*

$$\lim_{v\to\infty} iv([S^D,\mathbf{p}_z]\Phi_{\mathbf{v}},\Psi_{\mathbf{v}}) = \int_{-\infty}^{\infty} \{(V^s(\mathbf{r}+\tau\hat{\mathbf{v}})\mathbf{p}_z\Phi_0,\Psi_0) - (V^s(\mathbf{r}+\tau\hat{\mathbf{v}})\Phi_0,\mathbf{p}_z\Psi_0)$$
$$+ i((\partial_z V^l)(\mathbf{r}+\tau\hat{\mathbf{v}})\Phi_0,\Psi_0)\}\,d\tau. \tag{1.25}$$

In particular, any of the scattering operators S^D *uniquely determines the total potential* V.

Remark 3: We only need the knowledge of $\mathbf{B}$, *in particular of* b, *and fix a gauge* $\mathbf{A}$ *for the definition of the wave operators* $\Omega_{\pm}^{(D)}$ *and the scattering operator* $S^{(D)}$. *The reconstruction formulae (1.17), (1.24) and (1.25) are independent of* $\mathbf{B}$.

Remark 4: The reconstruction formulae of Theorem 1 and 2 for $\mathbf{B}=0$ *are the same as in the case without magnetic field obtained by Enss and Weder in Ref. 4.*

Remark 5: Our results are also valid for a system of two interacting quantum particles with opposite charges (see Section V).

Our proofs use a geometric, time-dependent method developed by Enss and Weder. This method has been used by them in Ref. 4 to prove Theorems 1 and 2 in the case without magnetic field.

As previous works on inverse scattering theory without magnetic fields we mention the works of Faddeev,[5] Berezanskii[6] and Saito[7] who previously proved the uniqueness result of Theorem 1 in the two-body case with stationary methods. The last author proved it for bounded short-range continuous potentials. Also a stationary proof of uniqueness at fixed energy was given by Ramm[8] and Novikov[9] for potentials of compact support. For exponentially decreasing potentials a stationary proof of uniqueness at fixed energy was given by Novikov.[10] Wang[11] proved uniqueness with stationary methods in the N-body case with regular short-range potentials. Moreover, Isozaki and Kitada[12] studied the two-body case with C^∞ long-range potential and proved that the potential is uniquely determined by a particular scattering operator with time-independent modifier. For additional information about multidimensional inverse scattering see Weder,[13] Eskin and Ralston,[14] Newton,[15] and Chadan and Sabatier.[16]

To our knowledge the case with decaying magnetic fields was previously treated by Novikov and Khenkin in Ref. 17 where they proved that bounded, rapidly decreasing and sufficiently smooth potentials are uniquely obtained from the scattering operator at fixed energy. Eskin and Ralston proved in Ref. 18 that the scattering operator at fixed energy uniquely determines the magnetic field and the scalar potential by stationary phase methods for exponentially decaying $\mathbf{A}$ and V^s. By stationary methods Nicoleau proves in Ref. 19 that the high energy limit uniquely determines the magnetic field and the scalar potential, where the potentials have to be C^∞ - functions with decay assumptions on the potentials and all derivatives. In Refs. 20 and 21 we prove a similar result with less decay assumptions on the scalar potential with the geometric, time-dependent method.

As far as we know, there are no rigorous results on inverse scattering for one-body and many-body (including two-body) systems in a homogeneous magnetic field.

II. PROOF IN THE SHORT-RANGE CASE $V=V^s$

Since $S-\mathbb{1}=(\Omega_+-\Omega_-)^*\Omega_-$ we obtain

$$v((S-1)\Phi_{\mathbf{v}},\Psi_{\mathbf{v}})=\underbrace{v((\Omega_--1)\Phi_{\mathbf{v}},(\Omega_+-\Omega_-)\Psi_{\mathbf{v}})}_{=:R(\mathbf{v})}+\underbrace{v(\Phi_{\mathbf{v}},(\Omega_+-\Omega_-)\Psi_{\mathbf{v}})}_{=:l(\mathbf{v})}. \tag{2.1}$$

In the following we will show that $R(\mathbf{v})=\mathcal{O}(v^{-1})$ and that the high velocity limit $\lim_{v\to\infty}l(\mathbf{v})$ exists. For that purpose we need the following Lemma which is a propagation property expressing the fact that the solutions of the (one-dimensional) free Schrödinger equation have rapid decay away from the classically allowed region. In the following $F(z\in\mathcal{M})$ denotes the multiplication operator with the characteristic function $\chi_{\{z\in\mathcal{M}\}}(z)$.

Lemma 6: For any $f\in C_0^\infty(\mathbb{R}^1)$ with $\mathrm{supp}f\subset B_{m\eta}(0)$, for some $\eta>0$ and any $l=1,2,3,\ldots,$ there is a constant C_l such that

$$\|F(z\in\mathcal{M})e^{-i(1/2m)\mathbf{p}_z^2t}f(\mathbf{p}_z-m\mathbf{v}_z)F(z\in\mathcal{M}')\|\leq C_l(1+s+|t|)^{-l} \tag{2.2}$$

for every $\mathbf{v}_z,t\in\mathbb{R}$ and any measurable sets $\mathcal{M}$ and $\mathcal{M}'$ with distance $s:=\mathrm{dist}(\mathcal{M},\mathcal{M}'+\mathbf{v}_zt)-\eta|t|\geq 0$.

Proof: See Ref. 22, Proposition 2.10.

Proposition 7: Assume that $V^s\in\mathcal{V}_{SR}$. Then for all $\Phi_{\mathbf{v}}$ as in Eq. (1.16)

$$\|(\Omega_\pm-\mathbb{1})\Phi_{\mathbf{v}}\|=\mathcal{O}(v^{-1}). \tag{2.3}$$

Proof: We compute the difference

$$\begin{aligned}(\Omega_\pm-\mathbb{1})\Phi_{\mathbf{v}}&=\int_0^{\pm\infty}dt\,\frac{d}{dt}(e^{iHt}e^{-iH_At})\Phi_{\mathbf{v}}\\&=\int_0^{\pm\infty}dt\,e^{iHt}i(H-H_A)e^{-iH_At}\Phi_{\mathbf{v}}\\&=v^{-1}\int_0^{\pm\infty}d\tau\,e^{iH\tau/v}iV^s(\mathbf{r})e^{-iH_A\tau/v}\Phi_{\mathbf{v}}\end{aligned} \tag{2.4}$$

with the substitution $\tau=vt$. If we can show that the norm of the integrand in (2.4) is bounded by an integrable function $h\in L^1((\pm\infty,0],d\tau)$, we have finished the proof. To show integrability we will use $f(\mathbf{p}_z-m\mathbf{v}_z)\Phi_{\mathbf{v}}=\Phi_{\mathbf{v}}$ and $\|(1+|z|)^2\Phi_{\mathbf{v}}\|\leq\mathrm{const}<\infty$. In addition, we use that the particle moves in the direction parallel to the magnetic field with velocity $|\mathbf{v}_z|=v|\hat{\mathbf{v}}_z|>0$. Then

$$\begin{aligned}&\|V^s(\mathbf{r})e^{-iH_A\tau/v}\Phi_{\mathbf{v}}\|\\&\leq\|V^s(\mathbf{r})e^{-iH_{xy}\tau/v}e^{-i\frac{1}{2m}\mathbf{p}_z^2\tau/v}f(\mathbf{p}_z-m\mathbf{v}_z)(1+|z|)^{-2}\|\|(1+|z|)^2\Phi_{\mathbf{v}}\|\\&\leq\mathrm{const}\{\|F(|z|>|\tau\hat{\mathbf{v}}_z|/4)(1+|z|)^{-2}\|\end{aligned} \tag{2.5}$$

$$+\|F(|z-\tau\hat{\mathbf{v}}_z|\geq|\tau\hat{\mathbf{v}}_z|/2)e^{-i\frac{1}{2m}\mathbf{p}_z^2\tau/v}f(\mathbf{p}_z-m\mathbf{v}_z)F(|z|\leq|\tau\hat{\mathbf{v}}_z|/4)\| \tag{2.6}$$

$$+\|V^s(\mathbf{r})F(|z-\tau\hat{\mathbf{v}}_z|<|\tau\hat{\mathbf{v}}_z|/2)\|\} \tag{2.7}$$

$$\leq h(|\tau\hat{\mathbf{v}}_z|) \tag{2.8}$$

since $(2.5)\leq\mathrm{const}(1+|\tau\hat{\mathbf{v}}_z|)^{-2}\leq h_1(|\tau\hat{\mathbf{v}}_z|)$, $(2.6)\leq h_2(|\tau\hat{\mathbf{v}}_z|)$ for $v\geq 8\eta/|\hat{\mathbf{v}}_z|$ because of Lemma 6 and $(2.7)\leq\|V^s(\mathbf{r})F(|z|\geq|\tau\hat{\mathbf{v}}_z|/2)\|\leq h_3(|\tau\hat{\mathbf{v}}_z|)$ because V^s is of short range. Equation (2.8) follows with $h=h_1+h_2+h_3$. ■

The following Lemma expresses the translation in position and momentum space.

Lemma 8: For all measurable bounded or polynomial functions f on suitable domains and all $s\in\mathbb{R}$ we have

$$e^{i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}s}f(\mathbf{r})e^{-i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}s}=f(\mathbf{r}+s\hat{\mathbf{v}}) \tag{2.9}$$

and

$$e^{i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}s}f(\mathbf{p})e^{-i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}s}=f(\mathbf{p}+s(\mathbf{B}\times\hat{\mathbf{v}})/2)). \tag{2.10}$$

Proof: The translation in position space (2.9) can be obtained from

$$\begin{aligned}e^{i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}s}\mathbf{r}e^{-i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}s}&=e^{i\mathbf{p}\hat{\mathbf{v}}s}e^{-i\mathbf{A}\hat{\mathbf{v}}s}\mathbf{r}e^{-i\mathbf{A}\hat{\mathbf{v}}s}e^{-i\mathbf{p}\hat{\mathbf{v}}s}\\&=e^{i\mathbf{p}\hat{\mathbf{v}}s}\mathbf{r}e^{-i\mathbf{p}\hat{\mathbf{v}}s}=\mathbf{r}+s\hat{\mathbf{v}},\end{aligned} \tag{2.11}$$

where in (2.11) $i[\mathbf{p}\hat{\mathbf{v}},\mathbf{A}\hat{\mathbf{v}}]=(b/2)\hat{\mathbf{v}}_x\hat{\mathbf{v}}_y+(-b/2)\hat{\mathbf{v}}_y\hat{\mathbf{v}}_x=0$ is used.

The translation in momentum space (2.10) can be obtained from

$$e^{i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}s}\mathbf{p}e^{-i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}s}=e^{-i\mathbf{A}\hat{\mathbf{v}}s}\mathbf{p}e^{i\mathbf{A}\hat{\mathbf{v}}s} \tag{2.12}$$

$$=\mathbf{p}+s(\mathbf{B}\times\hat{\mathbf{v}})/2. \tag{2.13}$$

The last equality can be proven by showing that the derivatives in s of (2.12) and (2.13) are equal. To show this we use $i[\mathbf{p},\mathbf{A}\hat{\mathbf{v}}]=(b\hat{\mathbf{v}}_y/2,-b\hat{\mathbf{v}}_x/2,0)=(\mathbf{B}\times\hat{\mathbf{v}})/2$. ■

To prove the next Proposition, where we compute the high velocity limit of the wave operators, we need the following Lemma:

Lemma 9: Assume that $V^s\in\mathscr{V}_{SR}$. Then for fixed $\tau\in\mathbb{R}$

$$\operatorname*{s-lim}_{v\to\infty}e^{i(H/v+(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}})\tau}=e^{i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}\tau}=\operatorname*{s-lim}_{v\to\infty}e^{i(H_A/v+(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}})\tau}. \tag{2.14}$$

Proof: We show the first equality for H which implies the second with $V^s=0$ and compute the difference

$$\begin{aligned}&e^{i(H/v+(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}})\tau}-e^{i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}\tau}\\&\quad=\{e^{i(H/v+(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}})\tau}e^{-i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}\tau}-1\}e^{i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}\tau}\\&\quad=\int_0^\tau ds\,e^{i(H/v+(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}})(\tau-s)}(-iH/v)e^{i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}s}.\end{aligned}$$

Then we obtain

$$\|\{e^{i(H/v+(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}})\tau}-e^{i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}\tau}\}\Psi_0\|\leqslant v^{-1}\int_0^\tau ds\|He^{i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}s}\Psi_0\| \tag{2.15}$$

and, if we can show that the integrand in (2.15) is bounded by a constant, we have finished the proof. Because of Lemma 8 the integrand in (2.15) is bounded by

$$\begin{aligned}&\|\{[\mathbf{p}-s(\mathbf{B}\times\hat{\mathbf{v}})/2-\mathbf{A}(\mathbf{r}-s\hat{\mathbf{v}})]^2/(2m)+V^s(\mathbf{r}-s\hat{\mathbf{v}})\}\Psi_0\|\\&\quad=\|\{[\mathbf{p}-\mathbf{A}(\mathbf{r})]^2/(2m)+V^s(\mathbf{r}-s\hat{\mathbf{v}})\}\Psi_0\|,\end{aligned}$$

where both sides are equal because of the transversal gauge. The second term is bounded by a constant because our dense set of states Ψ_0 are localized in position and momentum space. ■

Proposition 10: Assume that $V^s\in\mathscr{V}_{SR}$. Then for all $\Psi_{\mathbf{v}}$ as in Eq. (1.16)

$$\|(\Omega_+-\Omega_-)\Psi_{\mathbf{v}}\|=\mathscr{O}(v^{-1}) \tag{2.16}$$

and

$$\lim_{v\to\infty} e^{im\mathbf{v}\mathbf{r}} v(\Omega_+ - \Omega_-)\Psi_{\mathbf{v}} = \int_{-\infty}^{\infty} d\tau i V^s(\mathbf{r}+\tau\hat{\mathbf{v}})\Psi_0. \tag{2.17}$$

Proof: Similarly to the proof of Proposition 7 we compute the difference

$$(\Omega_+ - \Omega_-)\Psi_{\mathbf{v}} = v^{-1}\int_{-\infty}^{\infty} d\tau e^{iH\tau/v} i V^s(\mathbf{r}) e^{-iH_A\tau/v}\Psi_{\mathbf{v}} \tag{2.18}$$

and use that the norm of the integrand in (2.18) is bounded by an integrable function $h\in L^1((-\infty,\infty),d\tau)$ [see (2.4)–(2.8)]. Hence (2.16) is proven.

Now we calculate the high velocity limit (2.17). In the following we will use

$$e^{-im\mathbf{v}\mathbf{r}} f(\mathbf{p}) e^{im\mathbf{v}\mathbf{r}} = f(\mathbf{p}+m\mathbf{v}) \tag{2.19}$$

for measurable and bounded functions f and Lemma 8. Because of the dominated convergence theorem we can interchange the limit and the integral:

$$\begin{aligned}
&\lim_{v\to\infty} e^{im\mathbf{v}\mathbf{r}} v(\Omega_+ - \Omega_-)\Psi_{\mathbf{v}} \\
&\quad = \lim_{v\to\infty} \int_{-\infty}^{\infty} d\tau e^{i(H+(\mathbf{p}-\mathbf{A})\mathbf{v})\tau/v} i V^s(\mathbf{r}) e^{-i(H_A+(\mathbf{p}-\mathbf{A})\mathbf{v})\tau/v}\Psi_0 \\
&\quad = \int_{-\infty}^{\infty} d\tau e^{i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}\tau} i V^s(\mathbf{r}) e^{-i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}\tau}\Psi_0 \qquad (2.20)\\
&\quad = \int_{-\infty}^{\infty} d\tau i V^s(\mathbf{r}+\tau\hat{\mathbf{v}})\Psi_0, \qquad (2.21)
\end{aligned}$$

where we used Lemma 9 in (2.20) and (2.9) in (2.21). ■

With the help of Propositions 7 and 10 we calculate the following limit:

$$\begin{aligned}
&\lim_{v\to\infty} iv((S-\mathbb{1})\Phi_{\mathbf{v}},\Psi_{\mathbf{v}}) \\
&\quad = \lim_{v\to\infty} iv((\Omega_- - \mathbb{1})\Phi_{\mathbf{v}},(\Omega_+ - \Omega_-)\Psi_{\mathbf{v}}) + iv(\Phi_{\mathbf{v}},(\Omega_+ - \Omega_-)\Psi_{\mathbf{v}}) \\
&\quad = \int_{-\infty}^{\infty} d\tau (V^s(\mathbf{r}+\tau\hat{\mathbf{v}})\Phi_0,\Psi_0),
\end{aligned}$$

which is the desired reconstruction formula in Theorem 1.

We remark that we proved the reconstruction formula for all $\hat{\mathbf{v}}\in S^2$ with $\hat{\mathbf{v}}_z\neq 0$, i.e. for almost all $\hat{\mathbf{v}}\in S^2$, which is enough for the reconstruction of the scalar potential.

The injectivity of the scattering map results from the fact that the reconstruction of the potential V^s can be reduced to the inversion of the Radon transform of a bounded, continuous, square integrable function on $\mathbb{R}^2$ (see Ref. 4, Proof of Theorem 1.1) which uniquely determines the function (see Ref. 23, Chapter I, Theorem 2.17). Hence Theorem 1 is proved. ■

III. PROOF IN THE LONG-RANGE CASE $V = V^s + V^l$

Similarly to (2.1) we obtain

$$v((S^D-\mathbb{1})\Phi_{\mathbf{v}},\Psi_{\mathbf{v}}) = \underbrace{v((\Omega_-^D-\mathbb{1})\Phi_{\mathbf{v}},(\Omega_+^D-\Omega_-^D)\Psi_{\mathbf{v}})}_{=:R^D(\mathbf{v})} + \underbrace{v(\Phi_{\mathbf{v}},(\Omega_+^D-\Omega_-^D)\Psi_{\mathbf{v}})}_{=:I^D(\mathbf{v})}. \tag{3.1}$$

In the following we will show that $R^D(\mathbf{v})=\mathcal{O}(v^{-1})$ and that the high velocity limit $\lim_{v\to\infty} l^D(\mathbf{v})$ exists. For that purpose we need the following Lemma which is a propagation property for the Dollard correction $\tilde{U}(t)$ with

$$\tilde{U}(t)=\exp\left[-i\int_0^t V^l(\hat{\boldsymbol{\rho}}_{\mathbf{v}}(s),s\mathbf{p}_z/m)ds\right] \tag{3.2}$$

and $\hat{\boldsymbol{\rho}}_{\mathbf{v}}(s)$ given in (1.20) – (1.22).

Lemma 11: For any $f\in C_0^\infty(\mathbb{R}^1)$ *with* $\mathrm{supp} f\subset B_{m\eta}(0)$ *and* $\mathbf{v}_z\in\mathbb{R}^1$ *with* $|\mathbf{v}_z|\geqslant 2\eta$ *the following estimates are true:*

$$\|z\tilde{U}(t)f(\mathbf{p}_z-m\mathbf{v}_z)(1+|z|^2)^{-1/2}\|\leqslant C(1+|\mathbf{v}_z|^{-2}|\mathbf{v}_z t|^{2-\gamma})\leqslant C(1+|\mathbf{v}_z t|)^{2-\gamma}, \tag{3.3}$$

$$\|F(|z|\geqslant|\mathbf{v}_z t|/4)\tilde{U}(t)f(\mathbf{p}_z-m\mathbf{v}_z)(1+|z|^2)^{-2}\|\leqslant C(1+|\mathbf{v}_z t|)^{-(2+\varepsilon)} \tag{3.4}$$

for some $\varepsilon>0$.

Proof: The estimates can be proven in the same way as the estimates for $\hat{\boldsymbol{\rho}}_{\mathbf{v}}=0$ in Ref. 4, Proposition 3.1 because $\hat{\boldsymbol{\rho}}_{\mathbf{v}}$ commutes with $\mathbf{p}_z$. ■

To show the boundedness of the norm of $\{\boldsymbol{\rho}-\hat{\boldsymbol{\rho}}_{\mathbf{v}}(t)\}e^{-iH_{xy}t}\Phi_{\mathbf{v}}$ we need an explicit expression of $e^{-iH_{xy}t}\boldsymbol{\rho}e^{-iH_{xy}t}$:

Proposition 12: With $\boldsymbol{\rho}^\perp:=(y,-x)$ *and* $\boldsymbol{\pi}^\perp:=(\mathbf{p}_y,-\mathbf{p}_x)$ *and* $\omega=b/m$ *the following equality holds:*

$$\begin{aligned}e^{-iH_{xy}t}\boldsymbol{\rho}e^{-iH_{xy}t}=&\boldsymbol{\rho}\{1+\cos(\omega t)\}/2+\boldsymbol{\rho}^\perp\sin(\omega t)/2\\&+\boldsymbol{\pi}\omega^{-1}\sin(\omega t)+\boldsymbol{\pi}^\perp\omega^{-1}\{1-\cos(\omega t)\}\end{aligned} \tag{3.5}$$

on the domain $(\boldsymbol{\rho}^2+\boldsymbol{\pi}^2)^{-1/2}\mathscr{H}$.

Proof: Let us denote the left hand side of the equation (3.5) with $f(t)$ and the right hand side with $g(t)$. We calculate derivatives in t of $f(t)$ by computing a series of commutators $i[H_{xy},\boldsymbol{\rho}]$ and of $g(t)$ and observe that $f'''=-\omega^2 f', g'''=-\omega^2 g'$ and $f'(0)=g'(0), f''(0)=g''(0)$, which implies $f'=g'$. In addition we know that $f(0)=g(0)$, which implies $f=g$. ■

Corollary 13: For $\Phi_{\mathbf{v}}$ *as in Eq. (1.16) and* $\hat{\boldsymbol{\rho}}_{\mathbf{v}}(t)$ *given in (1.20)–(1.22) the following expression is uniformly bounded in time* t *and velocity* $\mathbf{v}$*:*

$$\|\{\boldsymbol{\rho}-\hat{\boldsymbol{\rho}}_{\mathbf{v}}(t)\}e^{-iH_{xy}t}\Phi_{\mathbf{v}}\|\leqslant\text{const.} \tag{3.6}$$

Proof: Using Proposition 12 and the localization in position and momentum space we obtain the boundedness uniformly in time and velocity. ■

Proposition 14: Assume that $V^s\in\mathscr{V}_{SR}$ *and* $V^l\in\mathscr{V}_{LR}$. *Then for all* $\Phi_{\mathbf{v}}$ *as in Eq. (1.16)*

$$\|(\Omega_\pm^D-\mathbb{1})\Phi_{\mathbf{v}}\|=\mathcal{O}(v^{-1}). \tag{3.7}$$

Proof: We compute the difference

$$(\Omega_{\pm}^{D}-\mathbb{1})\Phi_{\mathbf{v}}=\int_0^{\pm\infty} dt\,\frac{d}{dt}(e^{iHt}U^D(t))\Phi_{\mathbf{v}}$$

$$=\int_0^{\pm\infty} dt e^{iHt} i(H-H_A-V^l(\hat{\boldsymbol{\rho}}_{\mathbf{v}}(t),t\mathbf{p}_z/m))U^D(t)\Phi_{\mathbf{v}}$$

$$=v^{-1}\int_0^{\pm\infty} d\tau e^{iH\tau/v} i\{V^s(\mathbf{r})+V^l(\mathbf{r})-V^l(\hat{\boldsymbol{\rho}}_{\mathbf{v}}(\tau/v),\tau\mathbf{p}_z/(vm))\}$$

$$\times U^D(\tau/v)\Phi_{\mathbf{v}}. \tag{3.8}$$

If we can show that the norm of the integrand in (3.8) is bounded by an integrable function $h \in L^1((\pm\infty,0],d\tau)$, we have finished the proof.

Since $i[\mathbf{p}_z,(\mathbf{p}-\mathbf{A})^2]=0$, the components in U^D commute and $U^D(t)=\exp[-iH_At]\widetilde{U}(t)$. Let $\overline{f}\in C_0^\infty(\mathbb{R})$ with $\overline{f}\equiv 1$ on the support of f. We use that the particle moves in the direction parallel to the magnetic field with velocity $|\mathbf{v}_z|=v|\hat{\mathbf{v}}_z|>0$. We show the integrability for the term with V^s and then for the term with V^l:

$$\|V^s(\mathbf{r})e^{-iH_A\tau/v}\widetilde{U}(\tau/v)\Phi_{\mathbf{v}}\| \tag{3.9}$$

$$=\|V^s(\mathbf{r})e^{-i\,(1/2m)\,\mathbf{p}_z^2\tau/v}e^{-iH_{xy}\tau/v}\widetilde{U}(\tau/v)\Phi_{\mathbf{v}}\|$$

$$\leqslant \text{const}\{\|F(|z|>|\tau\hat{\mathbf{v}}_z|/4)\widetilde{U}(\tau/v)f(\mathbf{p}_z-m\mathbf{v}_z)(1+|z|^2)^{-2}\| \tag{3.10}$$

$$+\|F(|z-\tau\hat{\mathbf{v}}_z|\geqslant|\tau\hat{\mathbf{v}}_z|/2)e^{-i\,(1/2m)\,\mathbf{p}_z^2\tau/v}\overline{f}(\mathbf{p}_z-m\mathbf{v}_z)F(|z|\leqslant|\tau\hat{\mathbf{v}}_z|/4)\| \tag{3.11}$$

$$+\|V^s(\mathbf{r})F(|z-\tau\hat{\mathbf{v}}_z|<|\tau\hat{\mathbf{v}}_z|/2)\|\}. \tag{3.12}$$

Then (3.10)$\leqslant h(|\tau\hat{\mathbf{v}}_z|)$ with Lemma 11 for $v\geqslant 2\eta/|\hat{\mathbf{v}}_z|$, and (3.11) and (3.12) are the same terms as (2.5) and (2.7), respectively. Thus (3.9) is bounded by an integrable function.

To show integrability for the term with the difference of V^l, we introduce a cutoff function $\chi\in C^\infty(\mathbb{R})$ with $0\leqslant\chi\leqslant 1$, $\chi(\lambda)=1$ for $\lambda\geqslant 1/2$, and $\chi(\lambda)=0$ for $\lambda\leqslant 1/4$, and define $V_\tau^l(\boldsymbol{\rho},z):=V^l(\boldsymbol{\rho},z)\chi(|z|/|\tau\hat{\mathbf{v}}_z|)$. Then it follows from (1.13) that

$$\|\nabla V_\tau^l\|=\sup|\nabla V_\tau^l(\mathbf{r})|\leqslant\text{const}|\tau\hat{\mathbf{v}}_z|^{-\gamma},\quad \gamma>3/2, \tag{3.13}$$

$$\|D^{(0,0,2)}V_\tau^l\|\leqslant\text{const}|\tau\hat{\mathbf{v}}_z|^{-(2+\delta)},\quad \delta>0. \tag{3.14}$$

We remark that $V^l(\hat{\boldsymbol{\rho}}_{\mathbf{v}}(\tau/v),\tau\mathbf{p}_z/(vm))=V_\tau^l(\hat{\boldsymbol{\rho}}_{\mathbf{v}}(\tau/v),\tau\mathbf{p}_z/(vm))$ on the support of $f(\mathbf{p}_z-m\mathbf{v}_z)$. Then

$$\|\{V^l(\mathbf{r})-V^l_\tau(\hat{\boldsymbol{\rho}}_\mathbf{v}(\tau/v),\tau\mathbf{p}_z/(vm))\}e^{-iH_A\tau/v}\tilde{U}(\tau/v)\Phi_\mathbf{v}\| \tag{3.15}$$

$$=\|\{V^l(\mathbf{r})-V^l_\tau(\hat{\boldsymbol{\rho}}_\mathbf{v}(\tau/v),\tau\mathbf{p}_z/(vm))\}e^{-i\frac{1}{2m}\mathbf{p}_z^2\tau/v}e^{-iH_{xy}\tau/v}\tilde{U}(\tau/v)\Phi_\mathbf{v}\|$$

$$\leqslant \text{const}\{\|F(|z|>|\tau\hat{\mathbf{v}}_z|/4)\tilde{U}(\tau/v)f(\mathbf{p}_z-m\mathbf{v}_z)(1+|z|^2)^{-2}\| \tag{3.16}$$

$$+\|\{V^l(\mathbf{r})-V^l_\tau(\mathbf{r})\}e^{-iH_{xy}\tau/v}e^{-i(1/2m)\mathbf{p}_z^2\tau/v}\overline{f}(\mathbf{p}_z-m\mathbf{v}_z)F(|z|\leqslant|\tau\hat{\mathbf{v}}_z|/4)\|$$

$$+\|\{V^l_\tau(\mathbf{r})-V^l_\tau(\hat{\boldsymbol{\rho}}_\mathbf{v}(\tau/v),\tau\mathbf{p}_z/(vm))\}e^{-i(1/2m)\mathbf{p}_z^2\tau/v}e^{-iH_{xy}\tau/v}\tilde{U}(\tau/v)\Phi_\mathbf{v}\|\}$$

$$\leqslant h_1(|\tau\hat{\mathbf{v}}_z|)+\text{const}\{\|F(|z-\tau\hat{\mathbf{v}}_z|\geqslant|\tau\hat{\mathbf{v}}_z|/2)e^{-i(1/2m)\mathbf{p}_z^2\tau/v}\overline{f}(\mathbf{p}_z-m\mathbf{v}_z)$$

$$\times F(|z|\leqslant|\tau\hat{\mathbf{v}}_z|/4)\| \tag{3.17}$$

$$+\|\{V^l_\tau(\boldsymbol{\rho},z+\tau\mathbf{p}_z/(vm))-V^l_\tau(\hat{\boldsymbol{\rho}}_\mathbf{v}(\tau/v),\tau\mathbf{p}_z/(vm))\}$$

$$\times e^{-iH_{xy}\tau/v}\tilde{U}(\tau/v)\Phi_\mathbf{v}\|\}, \tag{3.18}$$

where (3.16)$\leqslant h_1(|\tau\hat{\mathbf{v}}_z|)$ with Lemma 11 for $v\geqslant 2\eta/|\hat{\mathbf{v}}_z|$ and (3.17)$\leqslant h_2(|\tau\hat{\mathbf{v}}_z|)$ with Lemma 6 for $v\geqslant 8\eta/|\hat{\mathbf{v}}_z|$. We used $\exp[i\mathbf{p}_z^2t/(2m)]f(\boldsymbol{\rho},z)\exp[-i\mathbf{p}_z^2t/(2m)]=f(\boldsymbol{\rho},z+t\mathbf{p}_z/m)$ to obtain (3.18). Finally (3.18) can be calculated using the Baker–Campbell–Hausdorff formula

$$\exp[-i\mathbf{q}(\boldsymbol{\rho},z+t\mathbf{p}_z/m)]\exp[i\mathbf{q}(s\boldsymbol{\rho}+(1-s)\hat{\boldsymbol{\rho}}_\mathbf{v}(t),sz+t\mathbf{p}_z/m)]$$

$$=\exp[-i\mathbf{q}(\boldsymbol{\rho}-\hat{\boldsymbol{\rho}}_\mathbf{v}(t),z)(1-s)]\exp[it\mathbf{q}_z^2(1-s)/(2m)]$$

for all $\mathbf{q}\in\mathbb{R}^3$. Then for the difference of V^l_τ in (3.18) we obtain

$$V^l_\tau(\boldsymbol{\rho},z+\tau\mathbf{p}_z/(vm))-V^l_\tau(\hat{\boldsymbol{\rho}}_\mathbf{v}(\tau/v),\tau\mathbf{p}_z/(vm))$$

$$=\int_0^1 ds\left\{-(\boldsymbol{\nabla}V^l_\tau)(s\boldsymbol{\rho}+(1-s)\hat{\boldsymbol{\rho}}_\mathbf{v}(\tau/v),sz+\tau\mathbf{p}_z/(vm))[\mathbf{r}-(\hat{\boldsymbol{\rho}}_\mathbf{v}(\tau/v),z)]\right.$$

$$\left.+\frac{i}{2m}(D^{(0,0,2)}V^l_\tau)(s\boldsymbol{\rho}+(1-s)\hat{\boldsymbol{\rho}}_\mathbf{v}(\tau/v),sz+\tau\mathbf{p}_z/(vm))\tau/v\right\}.$$

With (3.13), (3.14), Corollary 13 and Lemma 11 integrability of (3.18) is proven. ■

Lemma 15: For $\hat{\boldsymbol{\rho}}_\mathbf{v}(t)$ given in (1.20) – (1.22) and all fixed $\tau\in\mathbb{R}$ the following high velocity limit holds:

$$\text{s-lim}_{v\to\infty}\, V^l(\hat{\boldsymbol{\rho}}_\mathbf{v}(\tau/v),\tau(\mathbf{p}_z+m\mathbf{v}_z)/(mv))=V^l(\tau\hat{\mathbf{v}}). \tag{3.19}$$

Proof: As V^l is continuous, decays at infinity and for fixed τ $\lim_{v\to\infty}\hat{x}_\mathbf{v}(\tau/v)=\tau\hat{\mathbf{v}}_x$, $\lim_{v\to\infty}\hat{y}_\mathbf{v}(\tau/v)=\tau\hat{\mathbf{v}}_y$ and $\lim_{v\to\infty}\mathbf{p}_z\tau/(mv)=0$ in the strong resolvent sense we obtain (3.19). ■

Proposition 16: Assume that $V^s\in\mathscr{K}_{SR}$ and $V^l\in\mathscr{K}_{LR}$. Then for all $\Psi_\mathbf{v}$ as in Eq. (1.16)

$$\|(\Omega^D_+-\Omega^D_-)\Psi_\mathbf{v}\|=\mathscr{O}(v^{-1}) \tag{3.20}$$

and

$$\lim_{v\to\infty}e^{im\mathbf{v}\mathbf{r}}v(\Omega^D_+-\Omega^D_-)\Psi_\mathbf{v}=\int_{-\infty}^{\infty}d\tau i\{V^s(\mathbf{r}+\tau\hat{\mathbf{v}})$$

$$+V^l(\mathbf{r}+\tau\hat{\mathbf{v}})-V^l(\tau\hat{\mathbf{v}})\}\Psi_0. \tag{3.21}$$

Proof: Similarly to the proof of Proposition 14 we compute the difference

$$(\Omega_+^D-\Omega_-^D)\Psi_{\mathbf{v}}=v^{-1}\int_{-\infty}^{\infty}d\tau e^{iH\tau/v}i\{V^s(\mathbf{r})+V^l(\mathbf{r})-V^l(\hat{\boldsymbol{\rho}}_{\mathbf{v}}(\tau/v),\tau\mathbf{p}_z/(vm))\}\times U^D(\tau/v)\Psi_{\mathbf{v}} \tag{3.22}$$

and can show that the norm of the integrand in (3.22) is bounded by an integrable function $h\in L^1((-\infty,\infty),d\tau)$. Hence (3.20) is proven.

Now we calculate the high velocity limit (3.21). Because of the dominated convergence theorem we can interchange the limit and the integral and obtain similarly to (2.21):

$$\begin{aligned}
&\lim_{v\to\infty}e^{im\mathbf{vr}}v(\Omega_+^D-\Omega_-^D)\Psi_{\mathbf{v}}\\
&\quad=\lim_{v\to\infty}\int_{-\infty}^{\infty}d\tau e^{i(H+(\mathbf{p}-\mathbf{A})\mathbf{v})\tau/v}i\{V^s(\mathbf{r})+V^l(\mathbf{r})-V^l(\hat{\boldsymbol{\rho}}_{\mathbf{v}}(\tau/v),\tau(\mathbf{p}_z+m\mathbf{v}_z)/(vm))\}\\
&\qquad\times e^{-i(H_A+(\mathbf{p}-\mathbf{A})\mathbf{v})\tau/v-i\int_0^{\tau/v}V^l(\hat{\boldsymbol{\rho}}_{\mathbf{v}}(s),s(\mathbf{p}_z+m\mathbf{v}_z)/m)ds}\Psi_0\\
&\quad=\int_{-\infty}^{\infty}d\tau e^{i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}\tau}i\{V^s(\mathbf{r})+V^l(\mathbf{r})-V^l(\tau\hat{\mathbf{v}})\}e^{-i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}\tau}\Psi_0\\
&\quad=\int_{-\infty}^{\infty}d\tau i\{V^s(\mathbf{r}+\tau\hat{\mathbf{v}})+V^l(\mathbf{r}+\tau\hat{\mathbf{v}})-V^l(\tau\hat{\mathbf{v}})\}\Psi_0,
\end{aligned}\tag{3.23}$$

where in (3.23) $\text{s-lim}_{v\to\infty}\exp[i(H/v+(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}})\tau]=\exp[i(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}}\tau]=\text{s-lim}_{v\to\infty}\exp[i(H_A/v+(\mathbf{p}-\mathbf{A})\hat{\mathbf{v}})\tau+i\int_0^{\tau/v}V^l(\hat{\boldsymbol{\rho}}_{\mathbf{v}}(s),s(\mathbf{p}_z+m\mathbf{v}_z)/m)ds]$ for fixed τ is used. This can similarly be shown as the equality in the short-range case in Lemma 9. ■

With the help of Propositions 14 and 16 we calculate the following limit:

$$\begin{aligned}
&\lim_{v\to\infty}iv((S^D-\mathbb{1})\Phi_{\mathbf{v}},\Psi_{\mathbf{v}})\\
&\quad=\lim_{v\to\infty}iv((\Omega_-^D-\mathbb{1})\Phi_{\mathbf{v}},(\Omega_+^D-\Omega_-^D)\Psi_{\mathbf{v}})+iv(\Phi_{\mathbf{v}},(\Omega_+^D-\Omega_-^D)\Psi_{\mathbf{v}})\\
&\quad=\int_{-\infty}^{\infty}d\tau(V^s(\mathbf{r}+\tau\hat{\mathbf{v}})\Phi_0,\Psi_0)+\int_{-\infty}^{\infty}d\tau(\{V^l(\mathbf{r}+\tau\hat{\mathbf{v}})-V^l(\tau\hat{\mathbf{v}})\}\Phi_0,\Psi_0),
\end{aligned}\tag{3.24}$$

which is the reconstruction formula (1.24) in Theorem 2. The injectivity has already been shown in the short-range case above.

A short computation for the commutator of S^D with the third component of the momentum $\mathbf{p}_z$ gives (1.25). Then the total potential V can be computed from (1.25) (see Ref. 4, Proof of Theorem 1.2). Hence Theorem 2 is proved. ■

IV. ERROR BOUNDS

All formulae hold in the high velocity limit. For large, but fixed, v we obtain an error term of order $\mathcal{O}(|\mathbf{v}_z|^{-1})$. We remark that the order is not uniformly bounded in $\mathbf{v}$ if we consider all velocities $\mathbf{v}$ with $\hat{\mathbf{v}}\in S^2$ and $\hat{\mathbf{v}}_z\neq 0$ because the order $|\mathbf{v}_z|^{-1}=|\hat{\mathbf{v}}_z|^{-1}v^{-1}$ tends to infinity for $\hat{\mathbf{v}}_z\to 0$. But if the scalar potential is L^1 and compactly supported we only have to know the x-ray transform for infinitely many directions $\hat{\mathbf{v}}$, but not for all, to uniquely determine the potential from its x-ray transform (see Ref. 24, Theorem 5.2). Then, e.g., velocities with $|\hat{\mathbf{v}}_z|\geqslant 1/2$ are sufficient for the reconstruction and the error terms $|R(\mathbf{v})|$ and $|R^D(\mathbf{v})|$ can be calculated from (2.1) and (3.1), respectively, and are of order $\mathcal{O}(|\mathbf{v}|^{-1})$.

V. THE TWO-BODY CASE

Now we study a system of two interacting quantum particles with opposite charges in a homogeneous magnetic field. As the most important example of such a system we note the hydrogen atom (see Ref. 1 and references there). Let $H_0 := \Sigma_{i=1,2} (1/2m_i)\, \mathbf{p}_i^2$ be the free Hamiltonian. By

$$H_A := \sum_{i=1,2} \frac{1}{2m_i} (\mathbf{p}_i - e_i \mathbf{A}(\mathbf{r}_i))^2 \tag{5.1}$$

we denote the Hamiltonian with the magnetic field alone and by $H = H_A + V$ the interacting Hamiltonian with mass m_i, momentum $\mathbf{p}_i = -i\nabla_{\mathbf{r}_i}$, electric charge e_i and position $\mathbf{r}_i$ of the ith particle, where we will assume that $e_1 = -e_2$. As in the one-body case it is useful to introduce the following representation (see Ref. 1 for the notation):

$$H_A = H_0 + \sum_{i=1,2} \frac{1}{2m_i} \left\{ \frac{b^2}{4} \left(\frac{\mathbf{B}}{|\mathbf{B}|} \times \mathbf{r}_i \right)^2 - e_i \mathbf{B} \mathbf{L}_i \right\} \tag{5.2}$$

$$= H_0 + \sum_{i=1,2} \frac{1}{2m_i} \left\{ \frac{b^2}{4} (x_i^2 + y_i^2) - e_i b \mathbf{L}_{z,i} \right\} \tag{5.3}$$

$$= \sum_{i=1,2} \left\{ \frac{1}{2m_i} \mathbf{p}_{z,i}^2 + H_{osc,i} - \frac{1}{2m_i} e_i b \mathbf{L}_{z,i} \right\} \tag{5.4}$$

with the z-component of the angular momentum $\mathbf{L}_{z,i} = x_i \mathbf{p}_{y,i} - y_i \mathbf{p}_{x,i}$ of the ith particle and

$$H_{osc,i} = \frac{1}{2m_i} \left\{ (\mathbf{p}_{x,i}^2 + \mathbf{p}_{y,i}^2) + \frac{b^2}{4} (x_i^2 + y_i^2) \right\}. \tag{5.5}$$

As $H_{osc,i}$ and $\mathbf{L}_{z,i}$ do not act on the z-variable, we can separate the center of mass motion in the z-direction as usual. For that purpose we consider H acting on $\mathscr{H} = L^2(X)$ with

$$X = \{(\mathbf{r}_1, \mathbf{r}_2) \subset \mathbb{R}^6 | m_1 z_1 + m_2 z_2 = 0\}$$

instead of $L^2(\mathbb{R}^6)$, and write $z = z_1 - z_2$. The momentum space is

$$\hat{X} = \{(\mathbf{u}_1, \mathbf{u}_2) \subset \mathbb{R}^6 | \mathbf{u}_{z,1} + \mathbf{u}_{z,2} = 0\}.$$

It is known (see Ref. 2 for details) that $H_{osc,i} - (1/2m_i)\, e_i b \mathbf{L}_{z,i}$, acting on the Hilbert space $L^2(\mathbb{R}^2)$, has a complete set of eigenfunctions $\{\Theta_{ln}(x_i, y_i)\}_{l=0,\pm 1,\ldots;n=0,1,\ldots}$ with corresponding eigenvalues

$$E_{ln,i} = (2m_i)^{-1} b (2n + |l| - e_i l + 1), \tag{5.6}$$

where $E_{ln,i}$ and Θ_{ln} are often referred to as Landau energy levels and Landau orbits. Therefore the spectrum of $H_{xy} = \Sigma_{i=1,2} H_{osc,i} - (1/2m_i)\, e_i b \mathbf{L}_{z,i}$ acting on $L^2(\mathbb{R}^4)$ consists of infinitely degenerated eigenvalues $\{E_\beta\}_{\beta=(l,n,l',n')}$, $l, l' = 0, \pm 1, \ldots, n, n' = 0, 1, \ldots$, with

$$E_\beta = \frac{b}{2m_1} (2n + |l| - e_1 l + 1) + \frac{b}{2m_2} (2n' + |l'| - e_2 l' + 1) \tag{5.7}$$

and corresponding eigenfunctions $\theta_\beta((x_1, y_1), (x_2, y_2)) = \theta_{ln}(x_1, y_1) \times \theta_{l'n'}(x_2, y_2)$. From now on we assume that $e_1 = -e_2 = 1$.

We will use some notation similar to that commonly used in many-body scattering theory:

$$\mathbf{r} := \mathbf{r}_1 - \mathbf{r}_2, \quad \mathbf{p} := (\mathbf{p}_1/m_1 - \mathbf{p}_2/m_2) m, \tag{5.8}$$

with reduced mass $m=m_1m_2/(m_1+m_2)$, where $\mathbf{r}$ denotes the relative coordinate of $\mathbf{r}_1$ and $\mathbf{r}_2$ and $\mathbf{p}$ its conjugate momentum. As again H_{xy} does not act on the z-variable, we have $\exp[-iH_At]=\exp[-iH_{xy}t]\exp[-i\mathbf{p}_z^2/(2m)]$.

Then the theorems for the two-body case of Theorems 1 and 2 can be proven in the same way as in the one-body case where we use that the propagation properties of Lemma 6 and 11 are also true in the two-body case and that all other statements can be proven as before now using the new relative coordinates $\mathbf{r}$ and $\mathbf{p}$ [see (5.8)]. Finally we obtain the following Theorems for the two-body case:

Theorem 17: Two-Body Case with $V=V^s$: *Suppose that $V^s\in\mathscr{V}_{SR}$ and $V^l=0$. Then the following reconstruction formula holds for all $\Phi_{\mathbf{v}},\Psi_{\mathbf{v}}$ as in Eq. (1.16):*

$$\lim_{v\to\infty} iv((S-1)\Phi_{\mathbf{v}},\Psi_{\mathbf{v}})=\int_{-\infty}^{\infty}(V^s(\mathbf{r}+\tau\hat{\mathbf{v}})\Phi_0,\Psi_0)d\tau. \tag{5.9}$$

In particular, the scattering map

$$S(\mathbf{A};\cdot):\mathscr{V}_{SR}\to L(\mathscr{H})$$

is injective.

Theorem 18: Two-Body Case with $V=V^s+V^l$: *Suppose that $V^s\in\mathscr{V}_{SR}$ and $V^l\in\mathscr{V}_{LR}$. Then the following reconstruction formula holds for all $\Phi_{\mathbf{v}},\Psi_{\mathbf{v}}$ as in Eq. (1.16):*

$$\begin{aligned}\lim_{v\to\infty} iv((S^D-1)\Phi_{\mathbf{v}},\Psi_{\mathbf{v}})&-(\{V^l(\mathbf{r}+\tau\hat{\mathbf{v}})-V^l(\tau\hat{\mathbf{v}})\}\Phi_0,\Psi_0)\\&=\int_{-\infty}^{\infty}(V^s(\mathbf{r}+\tau\hat{\mathbf{v}})\Phi_0,\Psi_0)d\tau.\end{aligned} \tag{5.10}$$

In particular, for a given long-range potential V^l the scattering map

$$S^D(\mathbf{A},V^l;\cdot):\mathscr{V}_{SR}\to L(\mathscr{H})$$

is injective.

Moreover, the following formula holds for all $\Phi_{\mathbf{v}},\Psi_{\mathbf{v}}$ as in Eq. (1.16):

$$\begin{aligned}\lim_{v\to\infty} iv([S^D,\mathbf{p}_z]\Phi_{\mathbf{v}},\Psi_{\mathbf{v}})&\\&=\int_{-\infty}^{\infty}\{(V^s(\mathbf{r}+\tau\hat{\mathbf{v}})\mathbf{p}_z\Phi_0,\Psi_0)-(V^s(\mathbf{r}+\tau\hat{\mathbf{v}})\Phi_0,\mathbf{p}_z\Psi_0)\\&\quad+i((\partial_zV^l)(\mathbf{r}+\tau\hat{\mathbf{v}})\Phi_0,\Psi_0)\}d\tau.\end{aligned} \tag{5.11}$$

In particular, any of the scattering operators S^D uniquely determines the total potential V.

VI. GENERALIZATION

It is possible to generalize the results such that unbounded short-range V^s (i.e., V^s is only Kato-small and unbounded in the direction parallel to the field) are included. The decay assumption (1.11) can be weakened such that

$$\|V^s(\mathbf{r})(\mathbf{p}_z^2+1_z)^{-1}F(|\mathbf{r}|\geqslant R)\|\in L^1([0,\infty),dR) \tag{6.1}$$

is sufficient for the reconstruction of V^s in Theorems 1 and 17 and of $V=V^s+V^l$ in Theorems 2 and 18 because V^s can be regularized with $f(\mathbf{p}_z-m\mathbf{v}_z)$ which commutes with e^{-iH_At} and $U^D(t)$.

ACKNOWLEDGMENTS

I thank Professor V. Enss and Professor R. Weder for their encouragement and helpful conversations. As this paper was written during my visit at the Institute for Advanced Study in

Princeton, I would like to thank the Institute for their hospitality. This research was supported by a grant from Deutsche Forschungsgemeinschaft, hereby gratefully acknowledged, and is in partial fulfillment of the requirements for a Ph.D. degree at the RWTH Aachen.

Phase-space representation of quantum state vectors

Masashi Ban
Advanced Research Laboratory, Hitachi, Ltd., Akanuma 2520, Hatoyama, Saitama 350-0395, Japan

(Received 22 October 1997; accepted for publication 12 January 1998)

Phase-space representation of quantum state vectors is obtained within the framework of the relative-state formulation. For this purpose, the Hilbert space of a quantum system is enlarged by introducing an auxiliary quantum system. Relative-position state and relative-momentum state are defined in the extended Hilbert space of the composite quantum system and expressions of basic operators such as canonical position and momentum operators, acting on these states, are obtained. Phase-space functions which represent a state vector of the relevant quantum system are obtained in terms of the relative-position states and the relative-momentum states. The absolute-square of the phase-space function represents the probability distribution of the phase-space variables. Time-evolution of a quantum system is investigated in terms of the phase-space functions. The relations to the phase-space representations formulated by the other methods are obtained. © *1998 American Institute of Physics.* [S0022-2488(98)02804-7]

I. INTRODUCTION

Classical mechanics and classical statistical mechanics can use the phase space to describe dynamical and statistical properties of physical systems.[1,2] When we consider an n-dimensional system, the phase space of a physical system becomes a $2n$-dimensional space. An arbitrary point in the phase space that represents a state of the system is given by $(\mathbf{x},\mathbf{p})$, where $\mathbf{x}=(x_1,x_2,\ldots,x_n)$ and $\mathbf{p}=(p_1,p_2,\ldots,p_n)$ are vectors of the canonical position and momentum of the system. Time-evolution of the system can be described by the trajectory $\mathbf{l}(t)=(\mathbf{x}_t,\mathbf{p}_t)$ in the phase space, where $\mathbf{x}_t=\mathbf{x}(t)$ and $\mathbf{p}_t=\mathbf{p}(t)$ are solutions of the Hamiltonian equations of motion.[1] Statistical properties of the system are determined by distribution of the phase-space points, where the probability distribution $P_c(\mathbf{x},\mathbf{p})$ completely characterizes the statistical properties of the system.[2] Therefore the phase space is useful for describing the properties of physical systems in classical mechanics and classical statistical mechanics. However it is well known that there is not such a phase-space description of physical systems in quantum mechanics. Because of the uncertainty relation of canonical position and momentum, physical systems cannot simultaneously take the definite values of position and momentum. Thus individual points in the phase space cannot have the physical meaning in quantum mechanics. This fact makes it impossible to define the phase-space probability distribution of the system.

There are the several phase-space functions which describe the properties of physical systems in quantum mechanics. The most important are the Wigner function,[3,4] the Glauber-Sudarshan function,[5–7] and the Husimi function.[8,9] Although the Wigner function $W(x,p)$ has the correct marginal distributions of position and momentum variables of a quantum system, it does not become positive definite.[10,11] Hence the Wigner function cannot be considered a phase-space probability distribution. The Husimi function defined by $Q(x,p)=\pi^{-1}\langle x,p|\hat{\rho}|x,p\rangle$ with a coherent state $|x,p\rangle=|\alpha\rangle$ $(\alpha=(x+ip)/\sqrt{2})$ is suitable for describing the heterodyne detection and the simultaneous measurement of position and momentum.[11–16] The Glauber-Sudarshan function becomes the most singular function for nonclassical states such as the photon-number state. In quantum optics, the degree of the singularity of this function is used to characterize the nonclassicality, such as the nonclassical depth, of quantum states.[17] The generalization of these phase-space functions has been considered by several authors.[18–22] The operational phase-space probability distributions have been also introduced,[23–27] which are closely related to quantum measurement performed on physical systems. The underlying idea of the operational phase-space probability distribution is equivalent to that of the fuzzy-space formulation of quantum

 © 1998 American Institute of Physics

mechanics.[28–31] The fussy or unsharp observables include the additional fluctuation due to the finite accuracy of a measurement apparatus.[32] Such a fluctuation is indispensable for introducing the phase-space probability distribution in quantum mechanics.

To investigate the properties of physical and chemical systems, Torres-Vega and Frederick[33] and Harriman[34] have recently formulated the phase-space representations of quantum state vectors that make it possible to define the phase-space probability distribution. Using their results, the quantum-classical correspondence[35] and the relation to the coherent state representation[36] have been investigated. Furthermore the numerical analysis for physical and chemical systems has been performed by means of the phase-space functions.[37–39] Their methods for formulating the phase-space representations are useful and convenient, but rather abstract. In their methods, some state vector and transformation kernel have been introduced without proving their existence. The present author has recently formulated the relative-state formulation[40,41] to introduce a phase operator in quantum optical systems.[42–47] Therefore, in this paper we will formulate the phase-space representation of quantum state vectors by means of the relative-state formulation. Furthermore it will be shown that under certain conditions, our phase-space representation becomes equivalent to those obtained by Torres-Vega and Frederick[33] and by Harriman.[34] Hence it is considered that the results obtained in this paper give some physical and mathematical basis for their phase-space representations.

This paper is organized as follows. In Sec. II, we briefly summarize the phase-space representations of quantum state vectors that have been formulated by Torres-Vega and Frederick[33] and by Harriman.[34] The method by Torres-Vega and Frederick introduces a complete orthonormal system which depends on the phase-space variables while the method by Harriman uses a linear transformation between the phase space and the position (momentum) space. In Sec. III, we introduce the relative-state formulation of quantum systems in a convenient way for obtaining the phase-space representation of quantum state vectors. Using the relative-state formulation, we define relative-position states and relative-momentum states and then we obtain the expressions of basic operators, such as position and momentum operators, acting on these state vectors. In Sec. IV, we obtain the phase-space representation of quantum state vectors by means of the relative-state formulation. It is shown that under certain conditions, our phase-space representation becomes equivalent to those obtained by Torres-Vega and Frederick[33] and by Harriman.[34] The quantum dynamics in the phase-space representation is also considered. In Sec. V, we summarize our results.

II. PHASE-SPACE REPRESENTATION OF QUANTUM STATE VECTORS

In this section, we briefly summarize the two phase-space representations of quantum state vectors of physical systems. One obtained by Torres-Vega and Frederick[33] uses the Hilbert-space-vector approach and the other by Harriman[34] uses the linear transformation approach. The two phase-space representations become equivalent under certain conditions.

A. Hilbert-space-vector approach

We now consider the phase-space representation of quantum state vectors by means of the Hilbert-space-vector approach. According to Torres-Vega and Frederick,[33] we first introduce a state vector $|\Gamma\rangle$ which is the eigenstate of a Hermitian phase-space operator $\hat{\Gamma}$ with eigenvalue Γ. It is assumed that the set of the state vectors becomes a complete orthonormal system in the Hilbert space $\mathscr{H}$ of a quantum system,[48]

$$\langle\Gamma|\Gamma'\rangle=\delta(\Gamma-\Gamma'),\quad \int_{\mathscr{C}} d\Gamma|\Gamma\rangle\langle\Gamma|=\hat{I}, \tag{2.1}$$

where $\mathscr{C}$ stands for the set of all possible values of Γ and $\hat{I}$ is an identity operator defined on the Hilbert space $\mathscr{H}$. Here it is not necessary to consider which observable quantity the Hermitian operator $\hat{\Gamma}$ represents. Using the completeness relation, an arbitrary state vector $|\psi\rangle$ in the Hilbert space $\mathscr{H}$ is expanded as $|\psi\rangle=\int_{\mathscr{C}} d\Gamma\Psi(\Gamma)|\Gamma\rangle$, where $\Psi(\Gamma)=\langle\Gamma|\psi\rangle$ is a square-integrable function normalized as $\int_{\mathscr{C}} d\Gamma|\Psi(\Gamma)|^2=1$. In the formulation by Torres-Vega and Frederick,[33] it is assumed that the eigenvalue Γ represents a point in a two-dimensional phase space. In this case,

we have $\mathscr{C}=\mathbf{R}^2$, where $\mathbf{R}$ is the set of all real numbers. Thus we can set $\Gamma=(x,p)$ and $\int_{\mathscr{C}} d\Gamma F(\Gamma)=\int_{-\infty}^{\infty} dx \int_{-\infty}^{\infty} dp F(x,p)$ for any function F of Γ, and Eq. (2.1) becomes

$$\langle \Gamma|\Gamma'\rangle=\delta(x-x')\,\delta(p-p'), \quad \int_{-\infty}^{\infty} dx \int_{-\infty}^{\infty} dp\,|\Gamma\rangle\langle\Gamma|=\hat{I}. \tag{2.2}$$

To describe the quantum mechanical properties of physical systems in terms of the state vector $|\Gamma\rangle$, we have to specify the properties of the state vector $|\Gamma\rangle$. To this end, recall that the basic operators of a quantum system are canonical position and momentum operators, $\hat{x}$ and $\hat{p}$, which satisfy the canonical commutation relation $[\hat{x},\hat{p}]=i$. We set $\hbar=1$ throughout this paper. Any physical quantity $\hat{\mathscr{O}}$ can be expressed in terms of these operators, for example, $\hat{\mathscr{O}}=\Sigma_m \Sigma_n \mathscr{O}(m,n)\hat{x}^m \hat{p}^n$. This fact indicates that to describe a quantum system in terms of the state vectors $|\Gamma\rangle$, we have to know how the canonical operators $\hat{x}$ and $\hat{p}$ act on this state vector. According to Torres-Vega and Frederick,[33] we choose the following representation of the position and momentum operators,

$$\langle \Gamma|\hat{x}|\psi\rangle=\left(\alpha x+i\beta\frac{\partial}{\partial p}\right)\Psi(x,p), \tag{2.3}$$

$$\langle \Gamma|\hat{p}|\psi\rangle=\left(\gamma p+i\delta\frac{\partial}{\partial x}\right)\Psi(x,p), \tag{2.4}$$

where $|\psi\rangle$ is an arbitrary state vector of the quantum system and $\Psi(x,p)=\langle\Gamma|\psi\rangle$ is the phase-space function of the state vector $|\psi\rangle$. The real parameters α, β, γ and δ must satisfy the relation $\beta\gamma-\alpha\delta=1$ for Eqs. (2.3) and (2.4) to be consistent with the canonical commutation relation. The relations given by Eqs. (2.2)–(2.4) make it possible to describe the quantum mechanical properties of physical systems in terms of the state vector $|\Gamma\rangle$. The description of physical systems in terms of the phase-space function $\Psi(x,p)$ and the differential operators $\alpha x+i\beta\partial/\partial p$ and $\gamma p+i\delta\partial/\partial x$ is called the phase-space representation of quantum state vectors.

We next consider the relation between the phase-space representation and the usual wave-function representation of quantum state vectors. In the position (momentum) space, a quantum state vector $|\psi\rangle$ is represented by the wave function $\psi(x)=\langle x|\psi\rangle$ [$\tilde{\psi}(p)=\langle p|\psi\rangle$], where $|x\rangle$ and $|p\rangle$ are the eigenstates of the position and momentum operators. Since $\{|x\rangle|x\in\mathbf{R}\}$ and $\{|\Gamma\rangle|\Gamma\in\mathbf{R}^2\}$ are complete orthonormal systems in the Hilbert space $\mathscr{H}$, the relation between the phase-space function $\Psi(x,p)$ and the wave function $\psi(x)$ is given by the linear transformation,

$$\Psi(x,p)=\int_{-\infty}^{\infty} dx'\,\mathscr{K}(x,p|x')\,\psi(x'), \tag{2.5}$$

$$\psi(x)=\int_{-\infty}^{\infty} dx' \int_{-\infty}^{\infty} dp'\,\mathscr{K}^*(x',p'|x)\Psi(x',p'), \tag{2.6}$$

where the transformation kernel $\mathscr{K}(x,p|x')=\langle\Gamma|x'\rangle$ satisfies the differential equation,

$$\left(\alpha x+i\beta\frac{\partial}{\partial p}\right)\mathscr{K}(x,p|x')=x'\,\mathscr{K}(x,p|x'), \tag{2.7}$$

which yields the solution,

$$\mathscr{K}(x,p|x')=\exp\left[-i\frac{p}{\beta}(x'-\alpha x)\right]\mathscr{G}(x|x'). \tag{2.8}$$

The function $\mathscr{G}(x|x')$ of x and x' cannot be determined unless we impose further conditions on the transformation kernels.

In the same way, we can obtain the linear transformation between the phase-space function $\Psi(x,p)$ and the wave function $\tilde{\psi}(p)$ in the momentum space,

$$\Psi(x,p)=\int_{-\infty}^{\infty}dp'.\tilde{\mathscr{K}}(x,p|p')\tilde{\psi}(p'), \tag{2.9}$$

$$\tilde{\psi}(p)=\int_{-\infty}^{\infty}dx'\int_{-\infty}^{\infty}dp'.\tilde{\mathscr{K}}^{*}(x',p'|p)\psi(x',p'), \tag{2.10}$$

where the transformation kernel $.\tilde{\mathscr{K}}(x,p|p')=\langle\Gamma|p'\rangle$ is given by

$$.\tilde{\mathscr{K}}(x,p|p')=\exp\left[-i\frac{x}{\delta}(p'-\gamma p)\right]\tilde{\mathscr{G}}(p|p'). \tag{2.11}$$

Here the function $\tilde{\mathscr{G}}(p|p')$ does not depend on x. Since the position eigenstate $|x\rangle$ is obtained from the momentum eigenstate $|p\rangle$ by the Fourier transformation, the transformation kernels $.\mathscr{K}(x,p|x')$ and $.\tilde{\mathscr{K}}(x,p|p')$ are also related by the Fourier transformation,

$$.\mathscr{K}(x,p|x')=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}dp'\exp(-ip'x').\tilde{\mathscr{K}}(x,p|p'). \tag{2.12}$$

Substituting Eqs. (2.8) and (2.11) into this equation, we obtain the relation between the functions $\mathscr{G}(x|x')$ and $\tilde{\mathscr{G}}(p|p')$,

$$\mathscr{G}(x|x')=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}dp'\exp\left[-i\left(p'-\frac{p}{\beta}\right)\left(x'+\frac{x}{\delta}\right)\right]\tilde{\mathscr{G}}(p|p'), \tag{2.13}$$

where we have used the relation $\beta\gamma-\alpha\delta=1$. When $\tilde{\mathscr{G}}(p|p')$ is a function of $p'-p/\beta$, that is, $\tilde{\mathscr{G}}(p|p')=\tilde{\mathscr{G}}(p'-p/\beta)$, we obtain from Eq. (2.13),

$$\mathscr{G}(x|x')=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}dp\ \exp\left[-ip\left(x'+\frac{x}{\delta}\right)\right]\tilde{\mathscr{G}}(p)=\mathscr{G}(x'+x/\delta), \tag{2.14}$$

where the function $\mathscr{G}(x)$ is the Fourier transformation of the function $\tilde{\mathscr{G}}(p)$. In this case, the transformation kernels given by Eqs. (2.8) and (2.11) become

$$.\mathscr{K}(x,p|x')=\mathscr{G}(x'+x/\delta)\exp\left[-i\frac{p}{\beta}(x'-\alpha x)\right], \tag{2.15}$$

$$.\tilde{\mathscr{K}}(x,p|p')=\tilde{\mathscr{G}}(p'-p/\beta)\exp\left[-i\frac{x}{\delta}(p'-\gamma p)\right]. \tag{2.16}$$

These results indicate that when we set the function $\mathscr{G}(x|x')$ $[\tilde{\mathscr{G}}(p|p')]$ and fix the real parameters α, β, γ and δ, there is the one-to-one correspondence between the phase-space function and the wave function in the position (momentum) space. The detailed properties and applications of the phase-space representation have been investigated in Refs. 33–39.

B. Linear transformation approach

We have introduced the state vector $|\Gamma\rangle$ in the Hilbert space to formulate the phase-space representation of quantum state vectors. However, there is another method to introduce the phase-space representation. The method obtained by Harriman[34] uses the linear transformation between the position (momentum) space and the phase space. According to Harriman,[34] let us consider the following linear transformations,

$$\Phi(x,p)=\int_{-\infty}^{\infty}dx'\,\mathscr{U}(x,p|x')\,\psi(x')=\int_{-\infty}^{\infty}dp'\,\mathscr{T}(x,p|p')\,\tilde{\psi}(p'),\tag{2.17}$$

where $\psi(x)=\langle x|\psi\rangle$ and $\tilde{\psi}(p)=\langle p|\psi\rangle$ are the wave functions of a quantum state vector $|\psi\rangle$ in the position and momentum representations. It should be noted that the phase-space function $\Phi(x,p)$ is defined by these transformations. Thus the transformation kernels $\mathscr{U}(x,p|x')$ and $\mathscr{T}(x,p|p')$ determine the phase-space representation of a quantum state vector $|\psi\rangle$. Here it is assumed that the transformation kernels $\mathscr{U}(x,p|x')$ and $\mathscr{T}(x,p|p')$ satisfy the orthogonality relations,

$$\int_{-\infty}^{\infty}dx\int_{-\infty}^{\infty}dp\,\mathscr{U}(x,p|x_1)\,\mathscr{U}^*(x,p|x_2)=\delta(x_1-x_2),\tag{2.18}$$

$$\int_{-\infty}^{\infty}dx\int_{-\infty}^{\infty}dp\,\mathscr{T}(x,p|p_1)\,\mathscr{T}^*(x,p|p_2)=\delta(p_1-p_2).\tag{2.19}$$

Since the wave function $\psi(x)$ is obtained from $\tilde{\psi}(p)$ by the Fourier transformation, the transformation kernel $\mathscr{T}(x,p|p')$ is connected to $\mathscr{U}(x,p|x')$ by the Fourier transformation,

$$\mathscr{T}(x,p|p')=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}dx'\exp(ip'x')\,\mathscr{U}(x,p|x').\tag{2.20}$$

The relations given by Eqs. (2.17)–(2.19) are not sufficient to determine the phase-space representation of the quantum state vector $|\psi\rangle$. Thus Harriman imposed the following conditions on the transformation kernel $\mathscr{U}(x,p|x')$,

$$\left(\tilde{\alpha}x+i\tilde{\beta}\frac{\partial}{\partial p}\right)\mathscr{U}(x,p|z)=z\,\mathscr{U}(x,p|z),\tag{2.21}$$

$$\left(\tilde{\alpha}p-i\tilde{\beta}\frac{\partial}{\partial x}\right)\mathscr{U}(x,p|z)=i\frac{\partial}{\partial z}\mathscr{U}(x,p|z),\tag{2.22}$$

where $\tilde{\alpha}$ and $\tilde{\beta}$ are real parameters satisfying the relation $\tilde{\alpha}\tilde{\beta}=\frac{1}{2}$ which ensures the canonical commutation relation. The conditions on the transformation kernel $\mathscr{T}(x,p|z)$ are derived from Eqs. (2.21) and (2.22) by Eq. (2.20). Using Eqs. (2.17)–(2.22), we can obtain the phase-space representation of quantum state vectors of physical systems.[34]

From Eqs. (2.20)–(2.22), we can express the transformation kernels $\mathscr{U}(x,p|z)$ and $\mathscr{T}(x,p|z)$ in the following forms,[34]

$$\mathscr{U}(x,p|z)=\mathscr{W}(z-x/\tilde{\beta})\exp\left(-i\frac{p}{\tilde{\beta}}z+i\frac{px}{2\tilde{\beta}^2}\right),\tag{2.23}$$

$$\mathscr{T}(x,p|z)=\tilde{\mathscr{W}}(z-p/\tilde{\beta})\exp\left(i\frac{x}{\tilde{\beta}}z-i\frac{px}{2\tilde{\beta}^2}\right),\tag{2.24}$$

where the functions $\mathscr{W}(x)$ and $\tilde{\mathscr{W}}(x)$ are related by the Fourier transformation. Comparing Eqs. (2.15) and (2.16) with these equations, we find that the phase-space representation obtained by Torres-Vega and Frederick[33] becomes equal to that obtained by Harriman[34] when we set $\alpha=1/(2\tilde{\beta})$, $\beta=\tilde{\beta}$, $\gamma=1/(2\tilde{\beta})$ and $\delta=-\tilde{\beta}$. If we require the equality $\mathscr{W}(x)=\tilde{\mathscr{W}}(x)$, the transformation kernels become Gaussian functions,

$$\mathscr{U}(x,p|z)=\frac{1}{\tilde{\beta}\sqrt{2\pi}}\mathscr{W}_0(x/\tilde{\beta},p/\tilde{\beta};z),\tag{2.25}$$

$$\mathscr{T}(x,p|z)=\frac{1}{\tilde{\beta}\sqrt{2\pi}}\mathscr{W}_0(p/\tilde{\beta},-x/\tilde{\beta};z), \tag{2.26}$$

where the function $\mathscr{W}_0(x,y;z)$ is given by

$$\mathscr{W}_0(x,y;z)=\pi^{-1/4}\exp[-\tfrac{1}{4}(z-x)^2-iyz+\tfrac{1}{2}ixy]. \tag{2.27}$$

The detailed properties of the phase-space representation by means of the linear transformations have been investigated in Ref. 34.

III. RELATIVE-STATE FORMULATION OF QUANTUM SYSTEMS

We have reviewed the phase-space representations of quantum state vectors formulated by Torres-Vega and Frederick[33] and by Harriman.[34] The state vector $|\Gamma\rangle$ in the Hilbert-space-vector approach and the transformation kernels $\mathscr{U}(x,p|z)$ and $\mathscr{T}(x,p|z)$ in the linear transformation approach are essential for obtaining the phase-space representations. However their existence has been assumed without proof. In this section, we present the relative-state formulation in a suitable way for introducing the phase-space representation. The relative-state formulation gives some physical and mathematical basis for their phase-space representations.

A. Relevant and reference quantum systems

We consider the relative-state formulation of quantum systems that was originally obtained for quantum systems characterized by discrete quantum numbers.[40] The relative-state formulation makes it possible to introduce a phase operator in quantum optical systems. We first suppose that a quantum state of physical system is characterized by means of single real parameter $z\in\mathbf{R}$. We denote a basic state vector as $|z\rangle$ which is an element of the Hilbert space $\mathscr{H}$ of the quantum system.[48] Furthermore we assume that the set $\mathscr{S}=\{|z\rangle|z\in\mathbf{R}\}$ becomes a complete orthonormal system in the Hilbert space $\mathscr{H}$, which satisfies $\langle z_1|z_2\rangle=\delta(z_1-z_2)$ and $\int_{-\infty}^{\infty}dz|z\rangle\langle z|=\hat{I}$, where $\hat{I}$ is an identity operator defined on the Hilbert space $\mathscr{H}_r$. Thus any state vector $|\psi\rangle$ of the quantum system can be expressed as $|\psi\rangle=\int_{-\infty}^{\infty}dzf(z)|z\rangle$, where the expansion coefficient $f(z)=\langle z|\psi\rangle$ is a square-integrable function normalized as $\int_{-\infty}^{\infty}dz|f(z)|^2=1$. We next introduce an auxiliary quantum system to construct the relative-state formulation of the quantum system. We assume that any state vector of the auxiliary quantum system can be expressed in terms of state vectors $|z\rangle_r$ and that the set $\mathscr{S}_r=\{|z\rangle_r|z\in\mathbf{R}\}$ becomes a complete orthonormal system in the Hilbert space $\mathscr{H}_r$ of the auxiliary quantum system, which satisfies ${}_r\langle z_1|z_2\rangle_r=\delta(z_1-z_2)$ and $\int_{-\infty}^{\infty}dz|z\rangle_{rr}\langle z|=\hat{I}_r$, where $\hat{I}_r$ is an identity operator defined on the Hilbert space $\mathscr{H}_r$ of the auxiliary system. An arbitrary state vector $|\psi\rangle_r$ is expressed as $|\psi\rangle_r=\int_{-\infty}^{\infty}dzg(z)|z\rangle_r$, where the function $g(z)={}_r\langle z|\psi\rangle_r$ is normalized as $\int_{-\infty}^{\infty}dz|g(z)|^2=1$. In the following, we refer to the original and auxiliary quantum systems as the relevant and reference quantum systems, and we denote quantities of the reference quantum system by adding subscript r such as $|\psi\rangle_r$ and $\hat{x}_r$.

When we consider the composite system of the relevant and reference quantum systems, we have to treat quantum state vectors in the extended Hilbert space $\hat{\mathscr{H}}=\mathscr{H}\otimes\mathscr{H}_r$. The complete orthonormal system of the extended Hilbert space $\hat{\mathscr{H}}$ is given by

$$\hat{\mathscr{S}}=\{|z,z'\rangle\rangle=|z\rangle\otimes|z'\rangle_r||z\rangle\in\mathscr{S},|z'\rangle_r\in\mathscr{S}_r\}, \tag{3.1}$$

which satisfies the relations,

$$\langle\langle z_1,z_1'|z_2,z_2\rangle\rangle=\delta(z_1-z_2)\,\delta(z_1'-z_2'), \tag{3.2}$$

$$\int_{-\infty}^{\infty}dz\int_{-\infty}^{\infty}dz'|z,z'\rangle\rangle\langle\langle z,z'|=\hat{I}\otimes\hat{I}_r. \tag{3.3}$$

We denote a state vector in the extended Hilbert space $\hat{\mathscr{H}}$ by using ''double bra'' and ''double ket'' such as $\langle\langle\Phi|$ and $|\Psi\rangle\rangle$ to emphasize that it belongs to the extended Hilbert space $\hat{\mathscr{H}}$. Thus an arbitrary state vector $|\Psi\rangle\rangle$ of the relevant and reference quantum systems can be expressed in terms of the basic vectors $|z,z'\rangle\rangle$ in the Hilbert space $\hat{\mathscr{H}}$,

$$|\Psi\rangle\rangle=\int_{-\infty}^{\infty}dz\int_{-\infty}^{\infty}dz'F(z,z')|z,z'\rangle\rangle, \tag{3.4}$$

where we set $F(z,z')=\langle\langle z,z'|\psi\rangle\rangle$ which is normalized as $\int_{-\infty}^{\infty}dz\int_{-\infty}^{\infty}dz'|F(z,z')|^2=1$. The function $F(z,z')$ characterizes the composite state of the relevant and reference quantum systems in terms of the individual parameters, z and z', of the respective quantum systems.

We now introduce a state vector $|\omega(z_r,z;s)\rangle\rangle$ in the extended Hilbert space $\hat{\mathscr{H}}$,

$$|\omega(z_r,z;s)\rangle\rangle=|z+\tfrac{1}{2}(1+s)z_r\rangle\otimes|z-\tfrac{1}{2}(1-s)z_r\rangle_r, \tag{3.5}$$

where s is a real parameter. When we set $|\omega(z_r,z;s)\rangle\rangle=|u\rangle\otimes|v\rangle_r$ with $u=z+\frac{1}{2}(1+s)z_r$ and $v=z-\frac{1}{2}(1-s)z_r$, we obtain the relations,

$$z_r=u-v,\quad z=\tfrac{1}{2}(1-s)u+\tfrac{1}{2}(1+s)v. \tag{3.6}$$

Thus it is seen that in the state vector $|\omega(z_r,z;s)\rangle\rangle$ the parameter z_r represents the difference between the individual system-parameters and the parameter z represents the weighted sum of the individual system-parameters. Furthermore the set $\hat{\mathscr{S}}_r=\{|\omega(z_r,z;s)\rangle\rangle|z_r,z\in\mathbf{R}\}$ becomes a complete orthonormal system in the extended Hilbert space $\hat{\mathscr{H}}$,

$$\langle\langle\omega(z_r,z;s)|\omega(z_r',z';s)\rangle\rangle=\delta(z_r-z_r')\,\delta(z-z'), \tag{3.7}$$

$$\int_{-\infty}^{\infty}dz_r\int_{-\infty}^{\infty}dz|\omega(z_r,z;s)\rangle\rangle\langle\langle\omega(z_r,z;s)|=\hat{I}\otimes\hat{I}_r. \tag{3.8}$$

Thus an arbitrary state vector $|\Psi\rangle\rangle$ of the relevant and reference quantum systems can be expressed in terms of the state vectors $|\omega(z_r,z;s)\rangle\rangle$,

$$|\Psi\rangle\rangle=\int_{-\infty}^{\infty}dz_r\int_{-\infty}^{\infty}dz\mathscr{F}(z_r,z)|\omega(z_r,z;s)\rangle\rangle, \tag{3.9}$$

where the function $\mathscr{F}(z_r,z)=\langle\langle\omega(z_r,z;s)$ is normalized as $\int_{-\infty}^{\infty}dz_r\int_{-\infty}^{\infty}dz|\mathscr{F}(z_r,z)|^2=1$. The function $\mathscr{F}_s(z_r,z)$ characterizes the composite state of the relevant and reference quantum systems in terms of the parameter-difference z_r and the weighted parameter-sum z of the relevant and reference quantum systems. Therefore it is reasonable that we refer to the vector $|\omega(z_r,z;s)\rangle\rangle$ as the relative-parameter state.

B. Relative-position state and its properties

Suppose that a quantum system is described in terms of the position eigenstates $|x\rangle$. Then the reference quantum system is assumed to be described in terms of the position eigenstates $|x\rangle_r$. In this case we obtain a relative-position state $|\omega(r,x;s)\rangle\rangle$ of the relevant and reference quantum systems,

$$|\omega(r,x;s)\rangle\rangle=|x+\tfrac{1}{2}(1+s)r\rangle\otimes|x-\tfrac{1}{2}(1-s)r\rangle_r. \tag{3.10}$$

The set $\{|\omega(r,x;s)\rangle\rangle|r,x\in\mathbf{R}\}$ becomes a complete orthonormal system in the extended Hilbert space $\hat{\mathscr{H}}=\mathscr{H}\otimes\mathscr{H}_r$. The same relations as those given by Eqs. (3.7)–(3.9) are obtained for the relative-position state by replacing the parameters z_r and z with r and x. Note that the relative-position state $|\omega(r,x;s)\rangle\rangle$ satisfies the eigenvalue equations,

$$(\hat{x}-\hat{x}_r)|\omega(r,x;s)\rangle\rangle = r|\omega(r,x;s)\rangle\rangle, \tag{3.11}$$

$$\tfrac{1}{2}(\hat{x}+\hat{x}_r)|\omega(r,x;s)\rangle\rangle = (x+\tfrac{1}{2}sr)|\omega(r,x;s)\rangle\rangle. \tag{3.12}$$

It is found from Eq. (3.11) that the parameter r in the state vector $|\omega(r,x;s)\rangle\rangle$ represents the relative position between the relevant and reference quantum systems. Furthermore, since we obtain the relations,

$$\hat{x}|\omega(r,x;s)\rangle\rangle = [x+\tfrac{1}{2}(1+s)r]|\omega(r,x;s)\rangle\rangle, \tag{3.13}$$

$$\hat{x}_r|\omega(r,x;s)\rangle\rangle = [x-\tfrac{1}{2}(1-s)r]|\omega(r,x;s)\rangle\rangle, \tag{3.14}$$

it is easy to see that if we set the parameter $s=1$, 0, or -1, the parameter x in the state vector $|\omega(r,x;s)\rangle\rangle$ respectively represents the position of the reference quantum system, the center between the relevant and reference quantum systems, or the position of the relevant quantum system.

We next introduce a state vector $|\omega(r,k;s)\rangle\rangle$ by the Fourier transformation of the relative-position state $|\omega(r,x;s)\rangle\rangle$ with respect to the parameter x,

$$|\omega(r,k;s)\rangle\rangle = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} dx|\omega(r,x;s)\rangle\rangle \exp(ikx), \tag{3.15}$$

which is also referred to as the relative-position state. This state vector plays an important role in formulating the phase-space representation of quantum state vectors. Since the Fourier transformation is unitary, the set $\{|\omega(r,k;s)\rangle\rangle|r,k\in\mathbf{R}\}$ becomes a complete orthonormal system in the extended Hilbert space $\hat{\mathscr{H}}$,

$$\langle\langle\omega(r,k;s)|\omega(r',x';s)\rangle\rangle = \delta(r-r')\,\delta(x-x'), \tag{3.16}$$

$$\int_{-\infty}^{\infty} dr\int_{-\infty}^{\infty} dk|\omega(r,k;s)\rangle\rangle\langle\langle\omega(r,k;s)| = \hat{I}\otimes\hat{I}_r. \tag{3.17}$$

Furthermore it is found from Eqs. (3.10) and (3.15) that the transformed relative-position state $|\omega(r,k;s)\rangle\rangle$ is the simultaneous eigenstate of the relative-position operator $\hat{x}-\hat{x}_r$ and the momentum-sum operator $\hat{p}+\hat{p}_r$, with eigenvalues r and k,

$$(\hat{x}-\hat{x}_r)|\omega(r,k;s)\rangle\rangle = r|\omega(r,k;s)\rangle\rangle, \tag{3.18}$$

$$(\hat{p}+\hat{p}_r)|\omega(r,k;s)\rangle\rangle = k|\omega(r,k;s)\rangle\rangle. \tag{3.19}$$

Here, $\hat{p}$ and $\hat{p}_r$ are the canonical momentum operators of the relevant and reference quantum systems. The operators $\hat{x}-\hat{x}_r$ and $\hat{p}+\hat{p}_r$ commute with each other, $[\hat{x}-\hat{x}_r,\hat{p}+\hat{p}_r]=0$. It is important to note that the dependence of the transformed relative-position state $|\omega(r,k;s)\rangle\rangle$ on the parameter s appears only in its phase factor. In fact, substituting Eq. (3.10) into Eq. (3.15), we obtain

$$|\omega(r,k;s)\rangle\rangle = |\omega(r,k)\rangle\rangle \exp[\tfrac{1}{2}i(1-s)kr], \tag{3.20}$$

where the state vector $|\omega(r,k)\rangle\rangle$ which does not depend on the parameter s is given by

$$|\omega(r,k)\rangle\rangle = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} dx|x+r\rangle\otimes|x\rangle_r \exp(ikr). \tag{3.21}$$

Finally, we express the relative-position state $|\omega(r,k;s)\rangle\rangle$ in terms of bosonic annihilation and creation operators of the relevant and reference quantum systems. These operators are defined in terms of the position and momentum operators,

$$\hat{a}=\frac{\hat{x}+i\hat{p}}{\sqrt{2}},\quad \hat{a}^{\dagger}=\frac{\hat{x}-i\hat{p}}{\sqrt{2}},\quad \hat{a}_r=\frac{\hat{x}_r+i\hat{p}_r}{\sqrt{2}},\quad \hat{a}_r^{\dagger}=\frac{\hat{x}_r-i\hat{p}_r}{\sqrt{2}}. \tag{3.22}$$

To obtain the expression, recall the fact that the position eigenstate $|x\rangle$ is expressed as

$$|x\rangle=\pi^{-(1/4)}\exp[-\tfrac{1}{2}x^2+\sqrt{2}x\hat{a}^{\dagger}-\tfrac{1}{2}(\hat{a}^{\dagger})^2]|0\rangle, \tag{3.23}$$

where $|0\rangle$ is the vacuum state defined by the relation $\hat{a}|0\rangle=0$. Substituting Eq. (3.23) into Eq. (3.21) and performing the integration, we can obtain

$$|\omega(r,k;s)\rangle\rangle=\frac{1}{\sqrt{2\pi}}\exp\left(-\frac{1}{2}|\mu|^2+\mu\hat{a}^{\dagger}-\mu^{*}\hat{a}_r^{\dagger}+\hat{a}^{\dagger}\hat{a}_r^{\dagger}-\frac{1}{2}iskr\right)|0,0\rangle, \tag{3.24}$$

where we set $|0,0\rangle\rangle=|0\rangle\otimes|0\rangle_r$ and the complex parameter μ is given by

$$\mu=\frac{r+ik}{\sqrt{2}}. \tag{3.25}$$

The expression given by Eq. (3.24) is referred to as the Fock-space representation of the relative-position state $|\omega(r,k;s)\rangle\rangle$. It should be noted that by setting $s=0$ in Eq. (3.24), the Fock-state representation becomes equivalent to that obtained by Fan Hong-yi and Klauder[49] in connection with the EPR problem[50]

C. Relative-momentum state and its properties

We have introduced the relative-position states $|\omega(r,x;s)\rangle\rangle$ and $|\omega(r,k;s)\rangle\rangle$ to describe an arbitrary state of the relevant and reference quantum systems. We now consider another state vector obtained by replacing the parameters z_r and z in Eq. (3.5) with momentum variables. In this case, we obtain a relative-momentum state of the relevant and reference quantum systems,

$$|\tilde{\omega}(k,p;s)\rangle\rangle=|p+\tfrac{1}{2}(1+s)k\rangle\otimes|p-\tfrac{1}{2}(1-s)k\rangle_r, \tag{3.26}$$

where $|p\rangle$ and $|p\rangle_r$ are the momentum eigenstates of the relevant and reference quantum systems. It is easy to see that the set $\{|\tilde{\omega}(k,p;s)\rangle\rangle|k,p\in\mathbf{R}\}$ is a complete orthonormal system in the extended Hilbert space $\hat{\mathscr{H}}$. The same relations as those given by Eqs. (3.7)–(3.9) are also established for the relative-momentum states by replacing the parameters z_r and z with k and p. Note that the relative-momentum state $|\omega(k,p;s)\rangle\rangle$ is the simultaneous eigenstate of $\hat{p}-\hat{p}_r$ and $\hat{p}+\hat{p}_r$,

$$(\hat{p}-\hat{p}_r)|\tilde{\omega}(k,p;s)\rangle\rangle=k|\tilde{\omega}(k,p;s)\rangle\rangle, \tag{3.27}$$

$$\tfrac{1}{2}(\hat{p}+\hat{p}_r)|\tilde{\omega}(k,p;s)\rangle\rangle=(p+\tfrac{1}{2}sk)|\tilde{\omega}(k,p;s)\rangle\rangle. \tag{3.28}$$

The parameter k in $|\tilde{\omega}(k,p;s)\rangle\rangle$ represents the relative momentum between the relevant and reference quantum systems, and for $s=1$, 0, or -1, the parameter p in $|\tilde{\omega}(k,p;s)\rangle\rangle$ respectively represents the momentum of the reference quantum system, the arithmetic mean of the momenta of the relevant and reference quantum systems, or the momentum of the relevant quantum system.

As we have done for the relative-position state $|\omega(r,x;s)\rangle\rangle$, we introduce another relative-momentum state $|\tilde{\omega}(k,r;s)\rangle\rangle$ by the Fourier transformation of the state vector $|\tilde{\omega}(k,p;s)\rangle\rangle$ with respect to the parameter p,

$$|\widetilde{\omega}(k,r;s)\rangle\rangle=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}dp|\widetilde{\omega}(k,p;s)\rangle\rangle\exp(-ipr), \tag{3.29}$$

which is the simultaneous eigenstate of the position-sum operator $\hat{x}+\hat{x}_r$ and the momentum-difference operator $\hat{p}-\hat{p}_r$,

$$(\hat{p}-\hat{p}_r)|\widetilde{\omega}(k,r;s)\rangle\rangle=k|\widetilde{\omega}(k,r;s)\rangle\rangle, \tag{3.30}$$

$$(\hat{x}+\hat{x}_r)|\widetilde{\omega}(k,r;s)\rangle\rangle=r|\widetilde{\omega}(k,r;s)\rangle\rangle. \tag{3.31}$$

Because of the unitarity of the Fourier transformation, the set $\{|\widetilde{\omega}(k,r;s)\rangle\rangle|k,r\in\mathbf{R}\}$, becomes a complete orthonormal system in the extended Hilbert space $\hat{\mathscr{H}}$,

$$\langle\langle\widetilde{\omega}(k,r;s)|\widetilde{\omega}(k',r';s)\rangle\rangle=\delta(r-r')\,\delta(k-k'), \tag{3.32}$$

$$\int_{-\infty}^{\infty}dr\int_{-\infty}^{\infty}dk|\widetilde{\omega}(k,r;s)\rangle\rangle\langle\langle\widetilde{\omega}(k,r;s)|=\hat{I}\otimes\hat{I}_r. \tag{3.33}$$

It is found that the dependence of the transformed relative-momentum state $|\widetilde{\omega}(k,r;s)\rangle\rangle$ on the parameter s appears only in its phase factor and the following relation is obtained

$$|\widetilde{\omega}(k,r;s)\rangle\rangle=|\widetilde{\omega}(k,r)\rangle\rangle\exp[-\tfrac{1}{2}i(1-s)kr], \tag{3.34}$$

where the state vector $|\widetilde{\omega}(k,r)\rangle\rangle$ which does not depend on the parameter s is given by

$$|\widetilde{\omega}(k,r)\rangle\rangle=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}dp|p+k\rangle\otimes|p\rangle_r\,\exp(-ipr). \tag{3.35}$$

Furthermore, using the fact that the momentum eigenstate $|p\rangle$ is expressed as

$$|p\rangle=\pi^{-(1/4)}\exp[-\tfrac{1}{2}p^2+i\sqrt{2}p\hat{a}^\dagger+\tfrac{1}{2}(\hat{a}^\dagger)^2]|0\rangle, \tag{3.36}$$

we can obtain the Fock-space representation of the transformed relative-momentum state,

$$|\widetilde{\omega}(k,r;s)\rangle\rangle=\frac{1}{\sqrt{2\pi}}\,\exp\left(-\frac{1}{2}|\mu|^2+\mu\hat{a}^\dagger+\mu^*\hat{a}_r-\hat{a}^\dagger\hat{a}_r^\dagger+\frac{1}{2}iskr\right)|0,0\rangle, \tag{3.37}$$

where the complex parameter μ is given by Eq. (3.25).

D. Expressions for basic operators

Before closing this section, we obtain the expressions of the position, momentum, annihilation and creation operators when they act on the relative-position state $|\omega(r,k;s)\rangle\rangle$ and the relative-momentum state $|\widetilde{\omega}(k,r;s)\rangle\rangle$. For an arbitrary state vector $|\Psi\rangle\rangle$ of the relevant and reference quantum systems, we define the following functions,

$$\mathscr{F}_s(r,k)=\langle\langle\omega(r,k;s)|\Psi\rangle\rangle,\quad \widetilde{\mathscr{F}}_s(r,k)=\langle\langle\widetilde{\omega}(k,r;s)|\Psi\rangle\rangle, \tag{3.38}$$

which are referred to as the relative-state representation of the quantum state vector $|\Psi\rangle\rangle$. For the relative-position states $|\omega(r,k;s)\rangle\rangle$, the expressions of the position and momentum operators are obtained from Eqs. (3.10) and (3.15),

$$\langle\langle\omega(r,k;s)|\hat{x}|\psi\rangle\rangle=\left[\frac{1}{2}(1+s)r+i\frac{\partial}{\partial k}\right]\mathscr{F}_s(r,k)=\hat{\mathscr{X}}_s(r;k)\mathscr{F}_s(r,k), \tag{3.39}$$

$$\langle\langle \omega(r,k;s)|\hat{p}|\psi\rangle\rangle = \left[\frac{1}{2}(1-s)k - i\frac{\partial}{\partial r}\right].\mathscr{F}_s(r,k) = .\hat{\mathscr{X}}^*_{-s}(k;r).\mathscr{F}_s(r,k), \tag{3.40}$$

$$\langle\langle \omega(r,k;s)|\hat{x}_r|\psi\rangle\rangle = -\left[\frac{1}{2}(1-s)r - i\frac{\partial}{\partial k}\right].\mathscr{F}_s(r,k) = -.\hat{\mathscr{X}}^*_{-s}(r;k).\mathscr{F}_s(r,k), \tag{3.41}$$

$$\langle\langle \omega(r,k;s)|\hat{p}_r|\psi\rangle\rangle = \left[\frac{1}{2}(1+s)k + i\frac{\partial}{\partial r}\right].\mathscr{F}_s(r,k) = .\hat{\mathscr{X}}_s(k;r).\mathscr{F}_s(r,k), \tag{3.42}$$

where $.\hat{\mathscr{X}}_s(x;y) = \frac{1}{2}(1+s)x + i\partial/\partial y$. Using the complex parameter μ defined by Eq. (3.25), we can obtain the expressions of the annihilation and creation operators,

$$\langle\langle \omega(r,k;s)|\hat{a}|\psi\rangle\rangle = \left[\frac{1}{2}(\mu + s\mu^*) + \frac{\partial}{\partial \mu^*}\right].\mathscr{F}_s(\mu) = .\hat{\mathscr{M}}^{(+)}_s(\mu).\mathscr{F}_s(\mu), \tag{3.43}$$

$$\langle\langle \omega(r,k;s)|\hat{a}^\dagger|\psi\rangle\rangle = \left[\frac{1}{2}(\mu^* + s\mu) - \frac{\partial}{\partial \mu}\right].\mathscr{F}_s(\mu) = .\hat{\mathscr{M}}^{(-)}_s(\mu^*).\mathscr{F}_s(\mu), \tag{3.44}$$

$$\langle\langle \omega(r,k;s)|\hat{a}_r|\psi\rangle\rangle = -\left[\frac{1}{2}(\mu^* - s\mu) + \frac{\partial}{\partial \mu}\right].\mathscr{F}_s(\mu) = -.\hat{\mathscr{M}}^{(+)}_{-s}(\mu^*).\mathscr{F}_s(\mu), \tag{3.45}$$

$$\langle\langle \omega(r,k;s)|\hat{a}^\dagger_r|\psi\rangle\rangle = -\left[\frac{1}{2}(\mu - s\mu^*) - \frac{\partial}{\partial \mu^*}\right].\mathscr{F}_s(\mu) = -.\hat{\mathscr{M}}^{(-)}_{-s}(\mu).\mathscr{F}_s(\mu), \tag{3.46}$$

where $\mathscr{F}_s(\mu) = \mathscr{F}_s(r,k)$ and $.\hat{\mathscr{M}}^{(\pm)}_s(\mu) = \frac{1}{2}(\mu + s\mu^*) \pm \partial/\partial\mu^*$.

For the relative-momentum state $|\widetilde{\omega}(k,r;s)\rangle\rangle$, we can obtain the expressions of the position and momentum operators from Eqs. (3.26) and (3.29),

$$\langle\langle \widetilde{\omega}(k,r;s)|\hat{x}|\psi\rangle\rangle = \left[\frac{1}{2}(1-s)r + i\frac{\partial}{\partial k}\right].\widetilde{\mathscr{F}}_s(r,k) = .\hat{\mathscr{X}}_{-s}(r;k).\widetilde{\mathscr{F}}_s(r,k), \tag{3.47}$$

$$\langle\langle \widetilde{\omega}(k,r;s)|\hat{p}|\psi\rangle\rangle = \left[\frac{1}{2}(1+s)k - i\frac{\partial}{\partial r}\right].\widetilde{\mathscr{F}}_s(r,k) = .\hat{\mathscr{X}}^*_s(k;r).\widetilde{\mathscr{F}}_s(r,k), \tag{3.48}$$

$$\langle\langle \widetilde{\omega}(k,r;s)|\hat{x}_r|\psi\rangle\rangle = \left[\frac{1}{2}(1+s)r - i\frac{\partial}{\partial k}\right].\widetilde{\mathscr{F}}_s(r,k) = .\hat{\mathscr{X}}^*_s(r;k).\widetilde{\mathscr{F}}_s(r,k), \tag{3.49}$$

$$\langle\langle \widetilde{\omega}(k,r;s)|\hat{p}_r|\psi\rangle\rangle = -\left[\frac{1}{2}(1-s)k + i\frac{\partial}{\partial r}\right].\widetilde{\mathscr{F}}_s(r,k) = -.\hat{\mathscr{X}}_{-s}(k;r).\widetilde{\mathscr{F}}_s(r,k). \tag{3.50}$$

Furthermore the annihilation and creation operators are expressed in the following forms:

$$\langle\langle \widetilde{\omega}(k,r;s)|\hat{a}|\psi\rangle\rangle = \left[\frac{1}{2}(\mu - s\mu^*) + \frac{\partial}{\partial \mu^*}\right].\widetilde{\mathscr{F}}_s(\mu) = .\hat{\mathscr{M}}^{(+)}_{-s}(\mu).\widetilde{\mathscr{F}}_s(\mu), \tag{3.51}$$

$$\langle\langle \widetilde{\omega}(k,r;s)|\hat{a}^\dagger|\psi\rangle\rangle = \left[\frac{1}{2}(\mu^* - s\mu) - \frac{\partial}{\partial \mu}\right].\widetilde{\mathscr{F}}_s(\mu) = .\hat{\mathscr{M}}^{(-)}_{-s}(\mu^*).\widetilde{\mathscr{F}}_s(\mu), \tag{3.52}$$

$$\langle\langle \widetilde{\omega}(k,r;s)|\hat{a}_r|\psi\rangle\rangle = \left[\frac{1}{2}(\mu^* + s\mu) + \frac{\partial}{\partial \mu}\right].\widetilde{\mathscr{F}}_s(\mu) = .\hat{\mathscr{M}}^{(+)}_s(\mu^*).\widetilde{\mathscr{F}}_s(\mu), \tag{3.53}$$

$$\langle\langle \widetilde{\omega}(k,r;s)|\hat{a}^\dagger_r|\psi\rangle\rangle = \left[\frac{1}{2}(\mu + s\mu^*) - \frac{\partial}{\partial \mu^*}\right].\widetilde{\mathscr{F}}_s(\mu) = .\hat{\mathscr{M}}^{(-)}_s(\mu).\widetilde{\mathscr{F}}_s(\mu), \tag{3.54}$$

where we set $\tilde{\mathscr{F}}_s(\mu)=\tilde{\mathscr{F}}_s(r,k)$. Using these expressions of the basic operators, we can investigate the quantum mechanical properties of physical systems in terms of the relative-position and relative-momentum states.

IV. PHASES-PACE REPRESENTATION IN THE RELATIVE-STATE FORMULATION

In this section, we obtain the phase-space representation of quantum state vectors of the relevant system by means of the relative-state formulation. It is shown that under certain conditions, our phase-space representation becomes equivalent to those obtained by Torres-Vega and Frederick[33] and by Harriman.[34] Using the results, we investigate the time-evolution of a free particle and harmonic oscillator in the phase space.

A. Reduction of the Hilbert space

We have introduced the relative-state formulation of quantum systems and obtained the expressions of the basic operators acting on the relative-position state $|\omega(r,k;s)\rangle\rangle$ and the relative-momentum state $|\tilde{\omega}(k,r;s)\rangle\rangle$. In the formulation, we have extended the Hilbert space as $\mathscr{H}\rightarrow\hat{\mathscr{H}}=\mathscr{H}\otimes\mathscr{H}_r$ by introducing the reference quantum system. However, when we investigate the properties of the relevant quantum system, we need only the description of the relevant quantum system. To obtain the reduced description, we assume that the state vector of the reference quantum system remains unchanged and there is no correlation between the relevant and reference quantum systems. We denote such a state vector of the reference quantum system as $|\phi\rangle_r$. Fixing the state vector of the reference quantum system corresponds to projecting a state vector in the extended Hilbert space $\hat{\mathscr{H}}=\mathscr{H}\otimes\mathscr{H}_r$ into the subspace $\hat{\mathscr{H}}'=\mathscr{H}\otimes\{|\phi\rangle_r\}\subset\hat{\mathscr{H}}$. In this reduced description, the state vectors $|\omega(r,k;s)\rangle\rangle={}_r\langle\phi|\omega(r,k;s)\rangle\rangle$ and $|\tilde{\omega}(k,r;s)\rangle\rangle={}_r\langle\phi|\tilde{\omega}(k,r;s)\rangle\rangle$ in the Hilbert space $\mathscr{H}$ are considered the relative-position state and the relative-momentum state of the relevant quantum system. The reduced description depends on the state vector $|\phi\rangle_r$ of the reference quantum system. Therefore, we have arbitrariness in the choice of the state vector $|\phi\rangle_r$ of the reference quantum system. However it should be noted that such arbitrariness also appears in the phase-space representations by Torres-Vega and Frederick[33] and by Harriman.[34] In fact, the functions $\mathscr{G}(z)$ and $\tilde{\mathscr{G}}(z)$ in Eqs. (2.15) and (2.16) and the functions $\mathscr{W}(z)$ and $\tilde{\mathscr{W}}(z)$ in Eqs. (2.23) and (2.24) are arbitrary unless we impose further conditions on them.

From Eqs. (3.15) and (3.29), we obtain the reduced relative-position state $|\omega(r,k;s)\rangle$ and the reduced relative-momentum state $|\tilde{\omega}(k,r;s)\rangle$ of the relevant quantum system,

$$|\omega(r,k;s)\rangle=\frac{1}{\sqrt{2\pi}}e^{-i(1+s)kr/2}\int_{-\infty}^{\infty}dx|x\rangle\phi^*(x-r)e^{ikx}, \tag{4.1}$$

$$|\tilde{\omega}(k,r;s)\rangle=\frac{1}{\sqrt{2\pi}}e^{i(1+s)kr/2}\int_{-\infty}^{\infty}dp|p\rangle\tilde{\phi}^*(p-k)e^{-ipr}, \tag{4.2}$$

where $\phi(x)={}_r\langle x|\phi\rangle_r$ and $\tilde{\phi}(p)={}_r\langle p|\phi\rangle_r$ are the wave functions of the reference quantum system in the position and momentum spaces. The sets $\{|\omega(r,k;s)\rangle|r,k\in\mathbf{R}\}$ and $\{|\tilde{\omega}(k,r;s)\rangle|r,k\in\mathbf{R}\}$ are overcomplete systems in the Hilbert space $\mathscr{H}$,

$$\int_{-\infty}^{\infty}dr\int_{-\infty}^{\infty}dk|\omega(r,k;s)\rangle\langle\omega(r,k;s)|=\int_{-\infty}^{\infty}dr\int_{-\infty}^{\infty}dk|\tilde{\omega}(k,r;s)\rangle\langle\tilde{\omega}(k,r;s)|=\hat{I}, \tag{4.3}$$

$$\langle\omega(r,k;s)|\omega(r',k';s)\rangle=\frac{1}{2\pi}e^{i(1+s)(kr-k'r')/2}\int_{-\infty}^{\infty}dx\,\phi(x-r)\phi^*(x-r')e^{-i(k-k')x}, \tag{4.4}$$

$$\langle\tilde{\omega}(k,r;s)|\tilde{\omega}(k',r';s)\rangle=\frac{1}{2\pi}e^{-i(1+s)(kr-k'r')/2}\int_{-\infty}^{\infty}dp\,\tilde{\phi}(p-k)\tilde{\phi}^*(p-k')e^{ip(r-r')}. \tag{4.5}$$

The normalization conditions for the reduced states are given by $\langle\omega(r,k;s)|\omega(r,k;s)\rangle=\langle\tilde{\omega}(k,r;s)|\tilde{\omega}(k,r;s)\rangle=(2\pi)^{-1}$. The nonorthogonality of these state vectors is due to the restriction of the extended Hilbert space $\hat{\mathscr{H}}$. The degree of the nonorthogonality of the reduced states $|\omega(r,k;s)\rangle$ and $|\tilde{\omega}(k,r;s)\rangle$ depends on the wave function of the reference quantum system. When we set $k=k'$ or $r=r'$ in Eq. (4.4), we obtain the relations,

$$\langle\omega(r,k;s)|\omega(r',k;s)\rangle=\frac{1}{2\pi}e^{i(1+s)k(r-r')/2}\int_{-\infty}^{\infty}dx\,\phi(x-r)\,\phi^*(x-r'), \tag{4.6}$$

$$\langle\omega(r,k;s)|\omega(r,k';s)\rangle=\frac{1}{2\pi}e^{-i(1-s)(k-k')r/2}\int_{-\infty}^{\infty}dp\,\tilde{\phi}(p-k')\,\tilde{\phi}^*(p-k). \tag{4.7}$$

Let ℓ_x and ℓ_p be the spreads of the wave functions $\phi(x)$ and $\tilde{\phi}(p)$ in the position and momentum spaces, where the inequality $\ell_x\ell_p\geqslant 1/2$ should be satisfied because of the Heisenberg uncertainty relation. Thus we find from Eqs. (4.6) and (4.7),

$$\langle\omega(r,k;s)|\omega(r',k;s)\rangle=0 \quad \text{for } |r-r'|>\ell_x,$$

$$\langle\omega(r,k;s)|\omega(r,k';s)\rangle=0 \quad \text{for } |k-k'|>\ell_p.$$

The same result can be obtained for the reduced relative-momentum state $|\tilde{\omega}(k,r;s)\rangle$. The completeness relation given by Eq. (4.3) is essential for obtaining the phase-space representation of state vectors of the relevant quantum system. For example, when the state vector $|\phi\rangle_r$ is a Glauber coherent state $|\alpha^*\rangle_r$ with complex amplitude α^*, the reduced relative-position and relative-momentum states become

$$|\omega(r,k;s)\rangle=\frac{1}{\sqrt{2\pi}}e^{i[\mathrm{Im}(\alpha^*\mu)-skr/2]}|\mu+\alpha\rangle, \tag{4.8}$$

$$|\tilde{\omega}(k,r;s)\rangle=\frac{1}{\sqrt{2\pi}}e^{-i[\mathrm{Im}(\alpha^*\mu)-skr/2]}|\mu-\alpha\rangle, \tag{4.9}$$

where $\mu=(r+ik)/\sqrt{2}$. In this case, the reduced relative-position and relative-momentum states are Glauber coherent states, except for the normalization.

In the reduced description of the relevant quantum system, the position, momentum, annihilation and creation operators acting on the reduced state vectors $|\omega(r,k;s)\rangle$ and $|\tilde{\omega}(k,r;s)\rangle$ are expressed in the same forms as those obtained in Sec. III D. In fact, we obtain the expressions of the position and momentum operators,

$$\langle\omega(r,k;s)|\hat{x}|\psi\rangle=\left[\frac{1}{2}(1+s)r+i\frac{\partial}{\partial k}\right]\psi_s(r,k)=\hat{\mathscr{X}}_s(r;k)\,\psi_s(r,k), \tag{4.10}$$

$$\langle\omega(k,r;s)|\hat{p}|\psi\rangle=\left[\frac{1}{2}(1-s)k-i\frac{\partial}{\partial r}\right]\psi_s(r,k)=\hat{\mathscr{X}}^*_{-s}(k;r)\,\psi_s(r,k), \tag{4.11}$$

$$\langle\tilde{\omega}(k,r;s)|\hat{x}|\psi\rangle=\left[\frac{1}{2}(1-s)r+i\frac{\partial}{\partial k}\right]\tilde{\psi}_s(r,k)=\hat{\mathscr{X}}_{-s}(r;k)\,\psi_s(r,k), \tag{4.12}$$

$$\langle\tilde{\omega}(k,r;s)|\hat{p}|\psi\rangle=\left[\frac{1}{2}(1+s)k-i\frac{\partial}{\partial r}\right]\tilde{\psi}_s(r,k)=\hat{\mathscr{X}}^*_s(k;r)\,\psi_s(r,k), \tag{4.13}$$

where we set $\psi_s(r,k)=\langle\omega(r,k;s)|\psi\rangle$ and $\tilde{\psi}_s(r,k)=\langle\tilde{\omega}(k,r;s)|\psi\rangle$ which are referred to as the phase-space functions of the quantum state vector $|\psi\rangle$ of the relevant quantum system. We can describe the properties of the relevant quantum system in terms of the phase-space function

$\psi_s(r,k)$ $[\tilde{\psi}_s(r,k)]$ and the differential operators $\hat{\mathscr{X}}_s(r;k)$ and $\hat{\mathscr{X}}^*_{-s}(k;r)$ $[\hat{\mathscr{X}}_{-s}(r;k)$ and $\hat{\mathscr{X}}^*_s(k;r)]$. This description is the phase-space representation of quantum state vectors of the relevant system by means of the relative-state formulation.

Before proceeding further, we consider the relation between the reduced relative-position state $|\omega(r,k;s)\rangle$ and the reduced relative-momentum state $|\tilde{\omega}(k,r;s)\rangle$. Since the wave function $\tilde{\phi}(p)$ is derived from the wave function $\phi(x)$ by the Fourier transformation, the reduced relative-momentum state $|\tilde{\omega}(k,r;s)\rangle$ given by Eq. (4.2) is expressed as

$$|\tilde{\omega}(k,r;s)\rangle = \frac{1}{\sqrt{2\pi}} e^{-i(1-s)kr/2} \int_{-\infty}^{\infty} dx |x\rangle \phi^*(r-x) e^{ikx}. \tag{4.14}$$

Comparing this expression with Eq. (4.1), we see that if the wave function $\phi(x)$ is even with respect to x, the following relation is established

$$|\omega(r,k;s)\rangle = |\tilde{\omega}(k,r;-s)\rangle. \tag{4.15}$$

For example, when the reference quantum system is in the vacuum state $|0\rangle_r$, we obtain this relation since the wave function of the vacuum state is $\phi(x)=\pi^{-(1/4)}\exp(-x^2/2)$. In fact, from Eqs. (4.8) and (4.9), we obtain the reduced states $|\omega(r,k;s)\rangle=(2\pi)^{-(1/2)}e^{-iskr/2}|\mu\rangle$ and $|\tilde{\omega}(k,r;s)\rangle=(2\pi)^{-(1/2)}e^{iskr/2}|\mu\rangle$ which satisfy Eq. (4.15).

B. Phase-space function of quantum system vector

We now consider the phase-space functions which represent a state vector of the relevant quantum system and investigate their properties in detail. We also discuss the relations to the phase-space functions obtained by Torres-Vega and Frederick[33] and by Harriman.[34] Suppose that a quantum state of the relevant system is described by state vector $|\psi\rangle$. Using the completeness relations of the reduced relative-position state $|\omega(r,k;s)\rangle$ and the relative-momentum state $|\tilde{\omega}(k,r;s)\rangle$ in the Hilbert space $\mathscr{H}$, we can expand the state vector $|\psi\rangle$ in the following form:

$$|\psi\rangle = \int_{-\infty}^{\infty} dr \int_{-\infty}^{\infty} dk \psi_s(r,k) |\omega(r,k;s)\rangle \tag{4.16}$$

$$= \int_{-\infty}^{\infty} dr \int_{-\infty}^{\infty} dk \tilde{\psi}_s(r,k) |\tilde{\omega}_s(k,r;s)\rangle, \tag{4.17}$$

where $\psi_s(r,k)=\langle\omega(r,k;s)|\psi\rangle$ and $\tilde{\psi}_s(r,k)=\langle\tilde{\omega}(k,r;s)|\psi\rangle$ are the phase-space functions which represent the state vector $|\psi\rangle$ of the relevant quantum system. Conversely, if a phase-space function $\psi_s(r,k)$ or $\tilde{\psi}_s(r,k)$ is given, the corresponding state vector of the relevant quantum system is obtained by Eq. (4.16) or (4.17). The phase-space functions, $\psi_s(r,k)$ and $\tilde{\psi}_s(r,k)$, are normalized as

$$\int_{-\infty}^{\infty} dr \int_{-\infty}^{\infty} dk |\psi_s(r,k)|^2 = \int_{-\infty}^{\infty} dr \int_{-\infty}^{\infty} dk |\tilde{\psi}_s(r,k)|^2 = 1. \tag{4.18}$$

Thus, the functions $|\psi_s(r,k)|^2$ and $|\tilde{\psi}_s(r,k)|^2$ can be interpreted as the probability distributions of the phase-space variables r and k.

To consider the meaning of the phase-space probability distributions $|\psi_s(r,k)|^2$ and $|\tilde{\psi}_s(r,k)|^2$, let us calculate the average values of the phase-space variables r and k,

$$\langle r^m k^n\rangle_\psi \equiv \int_{-\infty}^{\infty} dr \int_{-\infty}^{\infty} dk r^m k^n |\psi_s(r,k)|^2 = \langle (\hat{x}-\hat{x}_r)^m (\hat{p}+\hat{p}_r)^n\rangle, \tag{4.19}$$

$$\langle r^m k^n\rangle_{\tilde{\psi}} \equiv \int_{-\infty}^{\infty} dr \int_{-\infty}^{\infty} dk r^m k^n |\tilde{\psi}_s(r,k)|^2 = \langle (\hat{x}+\hat{x}_r)^m (\hat{p}-\hat{p}_r)^n\rangle, \tag{4.20}$$

where we set $\langle \hat{A}\rangle = \langle \Psi|\hat{A}|\Psi\rangle\rangle$ with $|\Psi\rangle\rangle = |\psi\rangle\otimes|\phi\rangle_r$. Thus the functions $|\psi_s(r,k)|^2$ and $|\tilde{\psi}_s(r,k)|^2$ represent the probability distributions of the eigenvalues of the operators $\hat{x}\mp\hat{x}_r$ and $\hat{p}\pm\hat{p}_r$. For example, when the state vector $|\phi\rangle_r$ of the reference quantum system is the vacuum state $|0\rangle_r$, we find that

$$\langle r\rangle_\psi = \langle r\rangle_{\tilde{\psi}} = \langle \psi|\hat{x}|\psi\rangle, \quad \langle (\Delta r)^2\rangle_\psi = \langle (\Delta r)^2\rangle_{\tilde{\psi}} = \langle \psi|(\Delta\hat{x})^2|\psi\rangle + \tfrac{1}{2}, \tag{4.21}$$

$$\langle k\rangle_\psi = \langle k\rangle_{\tilde{\psi}} = \langle \psi|\hat{p}|\psi\rangle, \quad \langle (\Delta k)^2\rangle_\psi = \langle (\Delta k)^2\rangle_{\tilde{\psi}} = \langle \psi|(\Delta\hat{p})^2|\psi\rangle + \tfrac{1}{2}, \tag{4.22}$$

where we set $\langle (\Delta r)^2\rangle_\psi = \langle r^2\rangle_\psi - \langle r\rangle_\psi^2$, $\langle \psi|(\Delta\hat{x})^2|\psi\rangle = \langle \psi|\hat{x}^2|\psi\rangle - \langle \psi|\hat{x}|\psi\rangle^2$ and so on. In general, the fluctuations of the phase-space variables satisfy the inequality,

$$\Delta_\psi r \Delta_\psi k \geqslant 1, \quad \Delta_{\tilde{\psi}} r \Delta_{\tilde{\psi}} k \geqslant 1, \tag{4.23}$$

where we set $\Delta_\psi r = \sqrt{\langle (\Delta r)^2\rangle_\psi}$, $\Delta_{\tilde{\psi}} r = \sqrt{\langle (\Delta r)^2\rangle_{\tilde{\psi}}}$ and so on. These inequalities are called the operational uncertainty relation.[51]

When we have a state vector $|\psi\rangle$ of the relevant quantum system, we obtain the wave functions $\psi(x) = \langle x|\psi\rangle$ and $\tilde{\psi}(p) = \langle p|\psi\rangle$ in the position and momentum spaces, $|\psi(x)|^2$ and $|\tilde{\psi}(p)|^2$ being the probability distributions of the position and momentum of the quantum system. We first investigate the relation between the phase-space function $\psi_s(r,k)$ and the wave function $\psi(x)$. Since the sets $\{|\omega(r,k;s)\rangle | r,k\in\mathbf{R}\}$ and $\{|x\rangle | x\in\mathbf{R}\}$ are complete in the Hilbert space $\mathscr{H}$, the phase-space function $\psi_s(r,k)$ and the wave function $\psi(x)$ which represent the same state vector $|\psi\rangle$ are connected by the linear transformation,

$$\psi_s(r,k) = \int_{-\infty}^{\infty} dx . \mathscr{T}_s(r,k|x)\psi(x), \tag{4.24}$$

$$\psi(x) = \int_{-\infty}^{\infty} dr \int_{-\infty}^{\infty} dk . \mathscr{T}_s^*(r,k|x)\psi_s(r,k), \tag{4.25}$$

where the transformation kernel $\mathscr{T}_s(r,k|x)$ is given by

$$\mathscr{T}_s(r,k|x) = \langle \omega(r,k;s)|x\rangle = \frac{1}{\sqrt{2\pi}}\phi(x-r)e^{-ik[x-(1+s)r/2]}, \tag{4.26}$$

which satisfies the relations,

$$\int_{-\infty}^{\infty} dr \int_{-\infty}^{\infty} dk . \mathscr{T}_s(r,k|x) . \mathscr{T}_s^*(r,k|x') = \delta(x-x'), \tag{4.27}$$

$$\int_{-\infty}^{\infty} dx . \mathscr{T}_s(r,k|x) . \mathscr{T}_s^*(r',k'|x) = \langle \omega(r,k;s)|\omega(r',k';s)\rangle. \tag{4.28}$$

The right-hand side of the last equation is given by Eq. (4.4).

We consider the relation of the transformation kernel $\mathscr{T}_s(r,k|x)$ to those obtained by Harriman and by Torres-Vega and Frederick. Recall that in the phase-space representation by Harriman,[34] the transformation kernel [see Eq. (2.23)] is given by

$$\mathscr{U}(r,k|x) = \mathscr{W}(x-r/\tilde{\beta})\exp\left[-i\frac{k}{\tilde{\beta}}\left(x-\frac{r}{2\tilde{\beta}}\right)\right]. \tag{4.29}$$

Comparing this equation with Eq. (4.26), we find that when we set the parameter $s=0$ in Eq. (4.26) and $\tilde{\beta}=1$ in Eq. (4.29), the transformation kernels $\mathscr{T}_s(r,k|x)$ and $\mathscr{U}(r,k|x)$ become equivalent. In this case, the function $\mathscr{W}(x)$ corresponds to the wave function $\phi(x)={}_r\langle x|\phi\rangle_r$ of the reference quantum system. On the other hand, in the phase-space representation by Torres-Vega and Frederick,[33] the transformation kernel [see Eq. (2.15)] is given by

$$\mathscr{K}(r,k|x)=\mathscr{G}(x+r/\delta)\exp\left[-i\frac{k}{\beta}(x-\alpha r)\right]. \tag{4.30}$$

It is easy to see from Eqs. (4.26) and (4.30) that when we set the parameters $\alpha=\frac{1}{2}(1+s)$, $\beta=1$, $\gamma=\frac{1}{2}(1-s)$ and $\delta=-1$ $(\beta\gamma-\alpha\delta=1)$ in this equation, the transformation kernel $\mathscr{T}_s(r,k|x)$ is equivalent to $\mathscr{K}(r,k|x)$. Therefore when we appropriately choose the parameters, the phase-space representation by means of the relative-state formulation becomes equivalent to those obtained by Torres-Vega and Frederick[33] and by Harriman.[34]

In the same way, the phase-space function $\psi_s(r,k)$ and the wave function $\tilde{\psi}(p)$ in the momentum space are connected by the linear transformation,

$$\psi_s(r,k)=\int_{-\infty}^{\infty}dp.\tilde{\mathscr{T}}_s(r,k|p)\tilde{\psi}(p), \tag{4.31}$$

$$\tilde{\psi}(p)=\int_{-\infty}^{\infty}dr\int_{-\infty}^{\infty}dk.\tilde{\mathscr{T}}_s^*(r,k|p)\psi_s(r,k), \tag{4.32}$$

where the transformation kernel $\tilde{\mathscr{T}}_s(r,k|p)$ is given by

$$\tilde{\mathscr{T}}_s(r,k|x)=\langle\omega(r,k;s)|p\rangle=\frac{1}{\sqrt{2\pi}}\tilde{\phi}(k-p)e^{i[p-(1-s)k/2]r}, \tag{4.33}$$

which satisfies the relations,

$$\int_{-\infty}^{\infty}dr\int_{-\infty}^{\infty}dk.\tilde{\mathscr{T}}_s(r,k|p).\tilde{\mathscr{T}}_s^*(r,k|p')=\delta(p-p'), \tag{4.34}$$

$$\int_{-\infty}^{\infty}dp.\tilde{\mathscr{T}}_s(r,k|p).\tilde{\mathscr{T}}_s^*(r',k'|p)=\langle\omega(r,k;s)|\omega(r',k';s)\rangle. \tag{4.35}$$

Comparing Eq. (2.24) with Eq. (4.33), we find the equivalence of the transformation kernels $\tilde{\mathscr{T}}_s(r,k|p)$ and $\mathscr{V}(r,k|p)$ when we set the parameters $s=0$ and $\tilde{\beta}=1$. Furthermore it is found from Eqs. (2.16) and (4.33) that the equivalence of the transformation kernels $\tilde{\mathscr{T}}_s(r,k|p)$ and $\mathscr{K}(r,k|x)$ is established when we set the parameters $\alpha=\frac{1}{2}(1+s)$, $\beta=1$, $\gamma=\frac{1}{2}(1-s)$ and $\delta=-1$ in Eq. (2.16). For example, if the state vector $|\phi\rangle_r$ of the reference quantum system is the vacuum state $|0\rangle_r$ which yields the wave function $\phi(x)=\pi^{-(1/4)}\exp(-x^2/2)$, the transformation kernels $\mathscr{T}_s(r,k|x)$ and $\tilde{\mathscr{T}}_s(r,k|p)$ becomes Gaussian,

$$\mathscr{T}_s(r,k|x)=\frac{1}{\sqrt{2\pi^{3/2}}}\exp\left[-\frac{1}{2}(x-r)^2-ikx+\frac{1}{2}i(1+s)kr\right], \tag{4.36}$$

$$\tilde{\mathscr{T}}_s(r,k|p)=\frac{1}{\sqrt{2\pi^{3/2}}}\exp\left[-\frac{1}{2}(p-k)^2+ipr-\frac{1}{2}i(1-s)kr\right], \tag{4.37}$$

which are equal to Eqs. (2.25) and (2.26) if we set the parameters $s=0$ and $\tilde{\beta}=1$.

Next we consider the relation between the phase-space function $\tilde{\psi}_s(r,k)$ and the wave function $\psi(x)$ $[\tilde{\psi}(p)]$. Using the completeness relations of the state vectors, we can obtain the linear transformations,

$$\tilde{\psi}_s(r,k)=\int_{-\infty}^{\infty}dx.\mathscr{R}_s(r,k|x)\psi(x)=\int_{-\infty}^{\infty}dp.\tilde{\mathscr{R}}_s(r,k|p)\tilde{\phi}(p), \tag{4.38}$$

$$\psi(x)=\int_{-\infty}^{\infty}dr\int_{-\infty}^{\infty}dk.\mathscr{R}_s^*(r,k|x)\tilde{\psi}_s(r,k), \tag{4.39}$$

$$\tilde{\psi}(p)=\int_{-\infty}^{\infty}dr\int_{-\infty}^{\infty}dk.\tilde{\mathscr{R}}_s^*(r,k|p)\tilde{\psi}_s(r,k), \tag{4.40}$$

where the transformation kernels $.\mathscr{R}_s(r,k|x)$ and $.\tilde{\mathscr{R}}_s(r,k|p)$ are given by

$$.\mathscr{R}_s(r,k|x)=\langle\tilde{\omega}(k,r;s)|x\rangle=\frac{1}{\sqrt{2\pi}}\phi(r-x)e^{-ik[x-(1-s)r/2]}, \tag{4.41}$$

$$.\tilde{\mathscr{R}}_s(r,k|p)=\langle\tilde{\omega}(k,r;s)|p\rangle=\frac{1}{\sqrt{2\pi}}\tilde{\phi}(p-k)e^{i[p-(1+s)k/2]r}, \tag{4.42}$$

which satisfy the relations,

$$\int_{-\infty}^{\infty}dr\int_{-\infty}^{\infty}dk.\mathscr{R}_s(r,k|x).\mathscr{R}_s^*(r,k|x')=\delta(x-x'), \tag{4.43}$$

$$\int_{-\infty}^{\infty}dr\int_{-\infty}^{\infty}dk.\tilde{\mathscr{R}}_s(r,k|p).\tilde{\mathscr{R}}_s^*(r,k|p')=\delta(p-p'), \tag{4.44}$$

$$\int_{-\infty}^{\infty}dx.\mathscr{R}_s(r,k|x).\mathscr{R}_s^*(r',k'|x)=\langle\tilde{\omega}(k,r;s)|\tilde{\omega}(k',r';s)\rangle, \tag{4.45}$$

$$\int_{-\infty}^{\infty}dp.\tilde{\mathscr{R}}_s(r,k|p).\tilde{\mathscr{R}}_s^*(r',k'|p)=\langle\tilde{\omega}(k,r;s)|\tilde{\omega}(k',r';s)\rangle. \tag{4.46}$$

From Eqs. (2.23) and (2.24), the equivalence of $.\mathscr{R}_s(r,k|x)$ and $\mathscr{U}(r,k|x)$ and the equivalence of $.\tilde{\mathscr{R}}_s(r,k|p)$ and $\tilde{\mathscr{V}}(r,k|p)$ are found if we set the parameters $s=0$ and $\tilde{\beta}=1$. Furthermore, from Eqs. (2.15) and (2.16), the equivalence of $.\mathscr{R}_s(r,k|x)$ and $.\mathscr{K}(r,k|x)$ and the equivalence of $.\tilde{\mathscr{R}}_s(r,k|p)$ and $.\tilde{\mathscr{K}}(r,k|p)$ are also found if we set the parameters $\alpha=\frac{1}{2}(1-s)$, $\beta=1$, $\gamma=\frac{1}{2}(1+s)$ and $\delta=-1$. In particular, when the reference quantum system is in the vacuum state, the transformation kernels $.\mathscr{R}_s(r,k|x)$ and $.\tilde{\mathscr{R}}_s(r,k|p)$ are calculated to be

$$.\mathscr{R}_s(r,k|x)=\frac{1}{\sqrt{2\pi^{3/2}}}\exp\left[-\frac{1}{2}(x-r)^2-ikx+\frac{1}{2}i(1-s)kr\right], \tag{4.47}$$

$$.\tilde{\mathscr{R}}_s(r,k|p)=\frac{1}{\sqrt{2\pi^{3/2}}}\exp\left[-\frac{1}{2}(p-k)^2+ipr-\frac{1}{2}i(1+s)kr\right], \tag{4.48}$$

which are equal to Eqs. (2.25) and (2.26) if we set the parameters $s=0$ and $\tilde{\beta}=1$.

We summarize the relations among the transformation kernels in the phase-space representations. When we set the parameters $s=0$ and $\tilde{\beta}=1$ and the functions $\mathscr{W}(x)=(2\pi)^{-(1/2)}\phi(x)$ and $\tilde{\mathscr{W}}(p)=(2\pi)^{-(1/2)}\tilde{\phi}(p)$, we obtain the relations,

$$\mathscr{T}_s(r,k|x)=\mathscr{R}_s(-r,-k|-x)=\mathscr{U}(r,k|x), \tag{4.49}$$

$$\tilde{\mathscr{T}}_s(-r,-k|-x)=\tilde{\mathscr{R}}_s(r,k|x)=\mathscr{V}(r,k|x). \tag{4.50}$$

On the other hand, if we set the parameters $\alpha=\frac{1}{2}(1+s)$, $\beta=1$, $\gamma=\frac{1}{2}(1-s)$ and $\delta=-1$, and the functions $\mathscr{G}(x)=(2\pi)^{-(1/2)}\phi(x)$, we obtain the relations,

$$\mathscr{T}_s(r,k|x)=\mathscr{K}(r,k|x), \quad \tilde{\mathscr{T}}_s(r,k|p)=\tilde{\mathscr{K}}(-r,-k|-p), \tag{4.51}$$

and if we set the parameters $\alpha=\frac{1}{2}(1-s)$, $\beta=1$, $\gamma=\frac{1}{2}(1+s)$ and $\delta=-1$, and the functions $\tilde{\mathscr{G}}(p)=(2\pi)^{-(1/2)}\tilde{\phi}(p)$, we obtain the relations,

$$\mathscr{R}_s(r,k|x)=\mathscr{K}(-r,-k|-x), \quad \tilde{\mathscr{R}}_s(r,k|p)=\tilde{\mathscr{K}}(r,k|p). \tag{4.52}$$

These results indicate that the phase-space representation of quantum state vectors by means of the relative-state formulation is equivalent to those obtained by Torres-Vega and Frederick[33] and by Harriman.[34]

We finally consider the relations among our transformation kernels. It is easily found from Eqs. (4.26), (4.33), (4.41) and (4.42) that the following relations are established

$$\mathscr{T}_s(r,k|x)=\mathscr{R}_{-s}(-r,-k|-x), \quad \tilde{\mathscr{T}}_s(r,k|-p)=\tilde{\mathscr{R}}_{-s}(-r,-k|-p). \tag{4.53}$$

Let us suppose that the wave function $\phi(x)={}_r\langle x|\phi\rangle_r$ of the reference quantum system is an even function of x. In this case, since there is the relation between the reduced relative-position state $|\omega(r,k;s)\rangle$ and the reduced relative-momentum state $|\tilde{\omega}(k,r;s)\rangle$ [see Eq. (4.15)], we can obtain the following relations among the transformation kernels,

$$\mathscr{R}_s(r,k|x)=\mathscr{T}_{-s}(r,k|x)=e^{-iskr}\mathscr{T}_s(r,k|x), \tag{4.54}$$

$$\tilde{\mathscr{R}}_s(r,k|p)=\tilde{\mathscr{T}}_{-s}(r,k|p)=e^{-iskr}\tilde{\mathscr{T}}_s(r,k|p). \tag{4.55}$$

In fact, it is easy to check that the transformation kernels given by Eqs. (4.36), (4.37), (4.47) and (4.48) satisfy these relations.

C. Time-evolution of phase-space function

We investigate the time-evolution of the phase-space function $\psi_s(r,k;t)$ which represents a state vector of the relevant quantum system. Let $H(\hat{x},\hat{p})$ be a Hamiltonian of the system and let $|\psi(t)\rangle$ be a state vector of the quantum system at time t. Then the equation of motion for the state vector $|\psi(t)\rangle$ is given by the Schrödinger equation ($\hbar=1$),

$$\frac{\partial}{\partial t}|\psi(t)\rangle=-iH(\hat{x},\hat{p})|\psi(t)\rangle. \tag{4.56}$$

Using Eqs. (4.10) and (4.11), we obtain the equation of motion for the phase-space function $\psi_s(r,k;t)=\langle\omega(r,k;s)|\psi(t)\rangle$,

$$\frac{\partial}{\partial t}\psi_s(r,k;t)=-iH\left[\frac{1}{2}(1+s)r+i\frac{\partial}{\partial k},\frac{1}{2}(1-s)k-i\frac{\partial}{\partial r}\right]\psi_s(r,k;t). \tag{4.57}$$

It is important to note that the initial condition for the phase-space function $\psi_s(r,k;0)=\psi_s(r,k)$ depends not only on the initial state vector of the relevant quantum system but also on the state vector $|\phi\rangle_r$ of the reference quantum system. When we obtain the solution $\psi_s(r,k;t)$ of the equation of motion given by Eq. (4.57), we can calculate the average value of any physical quantity $A(\hat{x},\hat{p})$ at time t in the phase space,

$$\langle A(t)\rangle=\langle\psi(t)|A(\hat{x},\hat{p})|\psi(t)\rangle$$

$$= \int_{-\infty}^{\infty} dr \int_{-\infty}^{\infty} dk \psi_s^*(r,k;t) A\left[\frac{1}{2}(1+s)r + i\frac{\partial}{\partial k}, \frac{1}{2}(1-s)k - i\frac{\partial}{\partial r}\right]\psi_s(r,k;t). \quad (4.58)$$

In the following, we will consider the properties of the phase-space function $\psi_s(r,k;t)$ for a free particle and harmonic oscillator in one-dimensional space.

1. Free particle

We first consider the time-evolution of the phase-space function which represents a quantum state vector of a free particle with unit mass in one-dimensional space. We suppose that the initial state of the particle is given by the Gaussian wave packet, $\psi(x) = \pi^{-(1/4)}\exp(-x^2/2)$. Since we have to fix the state vector of the reference quantum system to obtain the phase-space representation, we assume that the reference quantum system is in the vacuum state $|0\rangle_r$, for the sake of simplicity. In this case, we have $\phi(x) = \pi^{-(1/4)}\exp(-x^2/2)$. Thus the phase-space function of the initial state of the free particle is given by

$$\psi_s(r,k;0) = \frac{1}{\sqrt{2\pi}}\exp\left[-\frac{1}{4}(r^2+k^2) + \frac{1}{2}iskr\right]. \quad (4.59)$$

Since the Hamiltonian of the free particle is given by $H(\hat{p}) = \hat{p}^2/2$, the equation of motion for the phase-space function $\psi_s(r,k)$ becomes

$$\frac{\partial}{\partial t}\psi_s(r,k;t) = -\frac{1}{2}i\left[\frac{1}{2}(1-s)k - i\frac{\partial}{\partial r}\right]^2\psi_s(r,k;t). \quad (4.60)$$

Solving this equation of motion under the initial condition (4.59), we can obtain the phase-space function at time t,

$$\psi_s(r,k;t) = \frac{1}{\sqrt{\pi(2+it)}}\exp\left[-\frac{r^2+(1+it)k^2+2i(1+it)kr}{2(2+it)} + i\frac{1+s}{2}kr\right]. \quad (4.61)$$

Then the phase-space probability distribution is given by

$$|\psi_s(r,k;t)|^2 = \frac{1}{\pi\sqrt{4+t^2}}\exp\left[-\frac{2}{4+t^2}\left(r-\frac{1}{2}kt\right)^2 - \frac{1}{2}k^2\right]. \quad (4.62)$$

Thus the probability distribution of the phase-space variables r and k is the Gaussian distribution. In the position representation, the wave function at time t is obtained

$$\psi(x;t) = \frac{1}{\sqrt{\pi^{1/2}(1+it)}}\exp\left[-\frac{x^2}{2(1+it)}\right], \quad (4.63)$$

and the probability distribution of the position of the free particle becomes

$$|\psi(x;t)|^2 = \frac{1}{\sqrt{\pi(1+t^2)}}\exp\left(-\frac{x^2}{1+t^2}\right). \quad (4.64)$$

It is easy to check that the phase-space function $\psi_s(r,k;t)$ and the wave function $\psi(x;t)$ are connected by the linear transformation with the kernel function given by Eq. (4.36).

Using the results, we calculate the average values and fluctuations of the phase-space variables r and k,

$$\langle r\rangle_t = \langle k\rangle_t = 0, \quad (\Delta r)_t^2 = \tfrac{1}{2}(2+t^2), \quad (\Delta k)_t^2 = 1, \quad (4.65)$$

while we obtain the average values and fluctuations of the position and momentum variables,

$$\langle \hat{x} \rangle_t = \langle \hat{p} \rangle_t = 0, \quad (\Delta x)_t^2 = \tfrac{1}{2}(1+t^2), \quad (\Delta p)_t^2 = \tfrac{1}{2}. \tag{4.66}$$

The enhancement of the fluctuations in the phase space is due to the vacuum-fluctuation of the reference quantum system.

2. Harmonic oscillator

We next consider the phase-space function which represents a quantum state of a harmonic oscillator with unit mass and unit frequency in one-dimensional space. We here assume that the reference quantum system is in the vacuum state, $|\phi\rangle_r = |0\rangle_r$. The Hamiltonian of the harmonic oscillator is given by $\hat{H} = \frac{1}{2}(\hat{x}^2 + \hat{p}^2) = \hat{a}^\dagger \hat{a} + \frac{1}{2}$. Before considering the time-evolution of the phase-space function, let us investigate the property of the phase-space function of the energy eigenstate. Since the energy eigenstate of the harmonic oscillator is given by $|\psi_n\rangle = (1/n!)\hat{a}^{\dagger n}|0\rangle$, where $\hat{H}|\psi_n\rangle = (n+\frac{1}{2})|\psi_n\rangle$ $(n=0,1,2,\ldots)$, the corresponding phase-space function $\psi_s(r,k|n)$ becomes

$$\psi_s(r,k|n) = \frac{1}{\sqrt{2\pi n!}} \mu^{*n} \exp\left[-\frac{1}{2}|\mu|^2 + \frac{1}{4}s(\mu^2 - \mu^{*2}) \right], \tag{4.67}$$

where the complex parameter μ is given by $\mu = (r+ik)/\sqrt{2}$. In deriving Eq. (4.67), we have assumed the reference quantum system to be in the vacuum state. Thus the phase-space probability distribution of the energy eigenstate becomes

$$|\psi_s(r,k|n)|^2 = \frac{1}{2\pi n!}\left[\frac{1}{2}(r^2+k^2) \right]^n \exp\left[-\frac{1}{2}(r^2+k^2) \right]. \tag{4.68}$$

Since the classical Hamiltonian of the harmonic oscillator is given by $H_{\rm cl}(x,p) = \frac{1}{2}(x^2+p^2)$, we can express the phase-space probability distribution in the following form:

$$|\psi_s(r,k|n)|^2 = \frac{1}{2\pi n!}[H_{\rm cl}(r,k)]^n \exp[-H_{\rm cl}(r,k)]. \tag{4.69}$$

This result indicates that the most probable path of the energy eigenstate in the phase space is obtained by solving the equation $H_{\rm cl}(r,k) = n$ which corresponds to the condition of the semiclassical quantization of the harmonic oscillator.

Let us now consider the time-evolution of the phase-space function of the harmonic oscillator, where we assume that the initial state of the harmonic oscillator is a coherent state $|\alpha\rangle$ with complex amplitude $\alpha = (q+ip)/\sqrt{2}$. Since we have $|\alpha(t)\rangle = \exp(-i\hat{H}t)|\alpha\rangle = |\alpha e^{-it}\rangle$ for the harmonic oscillator Hamiltonian $\hat{H}$, the phase-space function $\psi_s(r,k;t) = \langle \psi_s(r,k;s)|\alpha(t)\rangle$ is given by

$$\psi_s(r,k;t) = \frac{1}{\sqrt{2\pi}} \exp\left[-\frac{1}{4}(r-q_t)^2 - \frac{1}{4}(k-p_t)^2 + \frac{1}{2}i(p_t r - q_t k + skr) \right], \tag{4.70}$$

where the functions q_t and p_t are the solutions of the classical equations of motion for the harmonic oscillator, that is, $q_t = q\cos t + p\sin t$ and $p_t = p\cos t - q\sin t$. The probability distribution of the phase-space variables of the harmonic oscillator becomes

$$|\psi_s(r,k;t)|^2 = \frac{1}{2\pi}\exp\left[-\frac{1}{2}(r-q_t)^2 - \frac{1}{2}(k-p_t)^2 \right], \tag{4.71}$$

which means that the most probable path of the coherent state is identical with the classical trajectory $\mathbf{l}(t) = (q_t, p_t)$ in the phase space of the harmonic oscillator. The detailed investigations of the phase-space functions have been done by the Hilbert-space-vector approach[33] and by the linear transformation approach.[34]

V. SUMMARY

We have obtained the phase-space representation of quantum state vectors by means of the relative-state formulation.[40,41] The phase-space representation of quantum state vectors is useful for investigating the properties of physical and chemical systems.[33–39] In the relative-state formulation, the Hilbert space is extended by introducing the reference quantum system. The relative-position and relative-momentum states are defined in the extended Hilbert space. The basic operators such as position and momentum operators are expressed as the differential operators acting on these states. After obtaining the relative-position state, the relative momentum state and the expressions of the basic operators, we restrict the extended Hilbert space to the original Hilbert space of the relevant quantum system since we need only the description of the relevant quantum system. Hence we obtain the phase-space representation of quantum state vectors of the relevant system within the framework of the relative-state formulation. Furthermore we have found the linear transformations between the phase-space function and the wave function in the position (momentum) space, which are equivalent to those obtained by Torres-Vega and Frederick[33] and by Harriman[34] under certain conditions. Although in this paper we have confined ourselves to considering the phase-space representation of pure quantum states, it is straightforward to generalize the results in the case that a physical system is in a mixed quantum state described by a statistical operator.

[48] In mathematical sense, a state vector $|\chi\rangle$ which is an eigenstate of any unbounded operator with continuous spectrum, such as canonical position and momentum operators, cannot be an element of the Hilbert space $\mathscr{H}$. In fact, the state $|\chi\rangle$ obeys the δ-function normalization and cannot have the finite value of norm. To define such a state vector rigorously, we have to introduce the Gel'fand triplets or the rigged Hilbert space [see A. Böhm, *The Rigged Hilbert Space and Quantum Mechanics* (Springer, Berlin, 1978); A. Böhm and M. Gadella, *Dirac Kets, Gamov Vectors, and Gel'fand triplets* (Springer, Berlin, 1989)]. In our treatment, however, there is no problem even if the state vector $|\chi\rangle$ is assumed to be an element of the usual Hilbert space $\mathscr{H}$.

Feynman integral in regularized nonrelativistic quantum electrodynamics

Z. Haba
Institute of Theoretical Physics, University of Wroclaw, Wroclaw, Poland

(Received 8 March 1996; accepted for publication 15 October 1997)

We express the unitary time evolution in nonrelativistic regularized quantum electrodynamics at zero and positive temperature by a Feynman integral defined in terms of a complex Brownian motion. An average over the quantum electromagnetic field determines the form of the quantum mechanics in an environment of a quantum black body radiation. In this nonperturbative formulation of quantum electrodynamics we prove the existence of the classical limit $\hbar \to 0$. We estimate an error to some approximations commonly applied in quantum radiation theory. © *1998 American Institute of Physics.* [S0022-2488(98)02003-9]

I. INTRODUCTION

Quantum electrodynamics (nonrelativistic as well as relativistic) has been formulated in terms of a path integral by Feynman himself.[1] Starting from the Feynman integral, the conventional perturbation series in powers of the fine structure constant $\alpha = e^2(\hbar c)^{-1}$ is derived. It is a common attitude among physicists to treat the Feynman integral just as a tool for the generation of the perturbation series. However, it is well known that the imaginary time (Euclidean) version of the Feynman integral has a mathematical meaning beyond the perturbation theory. In fact, the Euclidean two-dimensional quantum electrodynamics (QED) has been constructed by means of the path integral.[2,3] The path integral for Euclidean regularized QED at finite temperature in any dimension has been discussed in Ref. 4. Although, in principle, the Euclidean correlation functions can be continued analytically to the Minkowski space,[5] in practice, this is an inconvenient approach to dynamics.

Perturbative QED agrees perfectly well with experiments. Its nonperturbative effects have not been discovered yet. However, the photons form an inevitable environment for all events in nature at least in the form of the heat or (much weaker) cosmic microwave background. The permanent influence of radiation may have a profound effect on mesoscopic phenomena. A lot of theoretical studies has been done investigating the effect of an infinite environment on a finite microscopic system (see, e.g., Refs. 6–8). However, the mathematical model of the heat bath could not be identified with any physical environment. The quantum electromagnetic field constitutes such a physical environment. There are suggestions[9] that Leggett's model approximates the effect of the quantum electromagnetic field. However, we think that this is quite a rough approximation, completely out of control. The approximations commonly applied[10–16] neglect the spatial dependence of the electromagnetic field. The neglect of the spatial dependence is hard to justify in QED where the electromagnetic field has singular vacuum correlation functions.

In this paper we apply to QED our earlier mathematical formulation of the Feynman integral[17,18] (see also Refs. 19 and 20). Such a formulation makes it possible to discuss the dynamics directly in the real time. Working with physical time is indispensable in problems concerning finite time dynamics e.g., decoherence[6,21] and radiation reaction. We consider the Dirac model[22] of a finite number of particles interacting by means of the Coulomb forces and additionally with the quantum electromagnetic field. This is the first approximation to the relativistic quantum field theory of interacting quantum electromagnetic field (in the radiation gauge) and matter fields. As pointed out already by Feynman,[1] a minor modification of the path integral defines the complete relativistic model. For this reason the nonrelativistic theory has a similar perturbative expansion in powers of the fine structure constant α. At the moment we are mainly interested in an application of the quantum electromagnetic field as a model of an environment to the conventional nonrelativistic quantum mechanics. For this reason we include a discussion of

 © 1998 American Institute of Physics

mixed states corresponding to a finite temperature. The main virtue of a rigorous formulation of the Feynman integral is an opportunity to estimate an error to formal calculations. In this paper we discuss the radiation damping and quasiclassical expansion. In the perturbative approach to QED we encounter a serious difficulty with the classical limit (see Ref. 23), because α tends to infinity when $\hbar \to 0$. So, a nonperturbative formulation of this problem is required.

The paper is organized as follows. In Sec. II we define the model in terms of the Hamiltonian in a finite mode approximation for the quantum electromagnetic field. In Sec. III we derive the Feynman formula for the time evolution operator in this model. The finite temperature QED is expressed by the functional integral in Sec. IV. In Sec. V we integrate over the quantum electromagnetic field in order to describe the quantum mechanical particles in equilibrium with a radiation background. We consider the limit of an infinite volume and infinite number of modes in Sec. VI. We define the Feynman kernel for the evolution operator in Sec. VII. We prove semiclassical asymptotics for the Feynman kernel in Sec. VIII. In Sec. IX we discuss the approximation of a slowly varying quantum electromagnetic field (the dipole approximation).[10,11,13,14] Finally, Sec. X contains a summary and perspectives for further research.

We put more emphasis on the precise description of quantum dynamics than on the details of the proofs. This is so because the method of the probabilistic representation of the quantum dynamics has been described in our earlier papers[17,18] together with detailed proofs. Our approach in this paper, starting with a finite mode approximation, is a repetition of methods in our earlier work.

II. THE HAMILTONIAN

We consider the electromagnetic field in a finite volume V. We expand the vector potential A in eigenmodes $g(k,\mathbf{x})$:

$$\omega(k)^2 g(k,\mathbf{x}) = c^2 \Delta g(k,\mathbf{x}).$$

In this formula $\omega(k)$ denotes the eigenfrequencies and k numerates the eigenmodes (so k is a vector if V is a parallelepiped; this will be tacitly assumed further on, but we write some formulas in a way suggesting cavities of a general shape). We assume that $g(k,x)$ are real (see, e.g., Refs. 24 and 25 for such a choice of eigenmodes), normalized as follows:

$$\int_V g(k,\mathbf{x}) g(k',\mathbf{x})\, dx = \delta(k,k') V.$$

The δ-function is equal to 1 for the same g and equal to 0 if the eigenmodes are different. The expansion in eigenmodes takes the form

$$A_j(x) = \sum_{k,\nu} \sqrt{\frac{2\pi\hbar}{\omega(k)V}}\, c f(k) \mathscr{E}_j(k,\nu)(a(k,\nu) + a(k,\nu)^+) g(k,x). \tag{1}$$

In Eq. (1) $\mathscr{E}$ is the polarization transversal to k,

$$\sum_{\nu=1,2} \mathscr{E}_j(k,\nu)\mathscr{E}_l(k,\nu) \overset{\text{def}}{=} \delta^{tr}_{jl} = \delta_{jl} - k_j k_l |\mathbf{k}|^{-2},$$

$a(k,\nu)$ and $a(k,\nu)^+$ are the amplitudes fulfilling the commutation relations for creation and annihilation operators, and $f(k)$ is a formfactor regularizing the electromagnetic field. Such a formfactor has been introduced already by Pauli and Fierz[26] [we choose $f(k)$ real; with no regularization $f(k)=1$].

The free Hamiltonian is

$$H_R = \sum_{k,\nu} \hbar\omega(k) a(k,\nu)^+ a(k,\nu) = \sum_{k,\nu} \frac{1}{2\mu(k)} p(k,\nu)^2 + \frac{1}{2}\mu(k)\omega(k)^2 y(k,\nu)^2, \tag{2}$$

where we defined

$$a(k,\nu)=\sqrt{\frac{\mu(k)\omega(k)}{2\hbar}}\,y(k,\nu)+\sqrt{\frac{1}{2\mu(k)\omega(k)\hbar}}\,ip(k,\nu)$$

with

$$\mu(k)=\frac{4\pi f(k)^2}{\omega(k)^2 V}.$$

In this way we have expressed the radiation Hamiltonian as a sum of the Hamiltonians for harmonic oscillators. We consider the system's Hamiltonian describing an interaction of the rth particle with an external potential u_r, the interaction with photons (the coupling e_r/c, where e_r denotes an electric charge and c the light velocity), and the Coulomb interaction ϕ between the particles. The Coulomb interaction is related to the quantum radiation by the gauge invariance

$$\phi(\mathbf{x}_r,\mathbf{x}_s)=4\pi\sum_k\ f(k)^2c^2\omega(k)^{-2}g(k,\mathbf{x}_r)g(k,\mathbf{x}_s).$$

Now, the system's Hamiltonian reads

$$H_P=\sum_r\ \frac{1}{2m_r}\left(\mathbf{p}_r+\frac{e_r}{c}\,\mathbf{A}(\mathbf{x}_r)\right)^2+\sum_{r,s}\ e_re_s\phi(\mathbf{x}_r,\mathbf{x}_s)+\sum_r\ u_r(\mathbf{x}_r). \tag{3}$$

When the number of modes is finite, then the Hamiltonian H_R+H_P is defined as a self-adjoint operator in a tensor product of a finite number of $L^2(dy)$ Hilbert spaces.

III. PROBABILISTIC REPRESENTATION OF QUANTUM DYNAMICS

If we restrict ourselves to a finite number of modes and quantize the Hamiltonian $H=H_R+H_P$ canonically, then we obtain a second-order [in $\mathbf{x}_r$ and $y(k,\nu)$] differential operator. A probabilistic representation of the unitary group generated by H has been discussed in our earlier papers.[17]

Let us consider first a single harmonic oscillator. Denote its Hamiltonian by H_k. The ground state χ_k of H_k is

$$\chi_k(y)=\exp\left(-\frac{\mu(k)\omega(k)y^2}{2\hbar}\right). \tag{4}$$

Let us define the Brownian motion as the Gaussian process with the covariance

$$E[b_tb_s]=\min(t,s).$$

Let $q(t,y)$ be the solution of the stochastic equation

$$dq=-i\omega(k)q\,dt+\lambda\sigma_k db \tag{5}$$

with the initial condition y. Here

$$\lambda=\frac{1}{\sqrt{2}}\,(1+i)$$

and

$$\sigma_k=\sqrt{\frac{\hbar}{\mu(k)}}.$$

Then, the Schrödinger time evolution of the state $\psi=\chi_k\Phi$ can be expressed in the form

$$\psi_t(y)\equiv\left(\exp\left(-iH_k\frac{t}{\hbar}\right)\psi\right)(y)=\chi_k(y)E[\Phi(q(t,y))]. \tag{6}$$

The free electromagnetic field is just a collection of harmonic oscillators. Let χ be the ground state of H_R, i.e., $H_R\chi=0$. Let again $\psi=\chi\Phi$. Then

$$\psi_t(\mathbf{A})\equiv\left(\exp\left(-iH_R\frac{t}{\hbar}\right)\psi\right)(\mathbf{A})=\chi(\mathbf{A})E[\Phi(\mathscr{A}(t,\mathbf{A}))], \tag{7}$$

where

$$\mathbf{A}=\sum_{k,\nu}\sqrt{4\pi\mu(k)}cf(k)\mathscr{E}(k,\nu)y(k,\nu)g(k,\mathbf{x})$$

and

$$\mathscr{A}(t,\mathbf{A})=\sum_{k,\nu}\sqrt{4\pi\mu(k)}cf(k)\mathscr{E}(k,\nu)q(t;y,k,\nu)g(k,\mathbf{x}), \tag{8}$$

where

$$q(t;y,k,\nu)=\exp(-i\omega(k)t)y(k,\nu)+\lambda\sigma_k\int_0^t\exp(-i\omega(k)(t-\tau))\,db(\tau;k,\nu)$$

is the solution of Eq. (5) with the initial condition $y(k,\nu)$ (now each Brownian motion has an index numerating the eigenmodes of the electromagnetic field; the Brownian motions corresponding to different indices are independent).

In order to derive a probabilistic representation of the Schrödinger evolution for H_R+H_P we need some additional cutoffs. So, let us assume at the beginning that the number of modes is finite. Next, we need to bound the behavior of $\mathbf{A}(\mathbf{x})$ as well as $\phi(\mathbf{x}_r,\mathbf{x}_s)$ for complex $\mathbf{x}$. In Ref. 17 we have bounded $\mathbf{A}$ and ϕ in the Feynman integral, multiplying these functions by a Gaussian damping factor depending on the Brownian motion. We introduce here an alternative regularization which is useful in QED. We regularize the modes $g(k,\mathbf{x})$ as follows:

$$g(k,\mathbf{x})\to g_\delta(k,\mathbf{x})=\exp(-\delta^2|\mathbf{x}|^8)g(k,\mathbf{x}). \tag{9}$$

Here $\mathbf{A}$ with the g_δ modes replacing g does not fulfill the sourceless Maxwell equations. For this reason the replacement $g\to g_\delta$ is treated as a regularization which subsequently is to be removed. The regularization (9) can be related to the one of our earlier papers[17] by means of the Laplace transform

$$\exp(-\delta^2|\mathbf{x}|^8)=\int_0^\infty ds h(s)\exp(-s\sqrt{\delta}|\mathbf{x}|^2), \tag{10}$$

where $h(s)$ is determined by the inverse Laplace transform [we made use of $(iy)^4=y^4$]

$$h(s)=\frac{1}{2\pi}\int_{-\infty}^{\infty}dy\,\exp(-y^4+iys).$$

It follows from Eq. (10) that h is a real, square integrable, and bounded function on $\mathbb{R}$.

We consider an analytic wave function $\psi(\lambda\mathbf{x})$ at $\lambda\mathbf{x}\in\mathbb{C}^3$, where $\lambda=\sqrt{i}$. In such a case $(\lambda(\mathbf{x}+\sigma\mathbf{b}))^8=(\mathbf{x}+\sigma\mathbf{b})^8$. Hence, in the representation (10) if $\mathbf{x}\to\lambda(\mathbf{x}+\sigma\mathbf{b})$, then on the rhs of Eq. (10) we obtain $\exp(-s\sqrt{\delta}(\mathbf{x}+\sigma\mathbf{b})^2)$. Then, the regularization (9) is equivalent to the one of our earlier paper.[17] Applying the methods of that paper we now obtain the following Feynman formula.

Theorem 1: Consider the Hamiltonian H_R+H_P [Eqs. (2) and (3)], where the number of modes is finite and $g(k,\mathbf{x})$ are replaced by $g_\delta(k,\mathbf{x})$ (this Hamiltonian is denoted H_δ). Assume that $g_\delta(k,\mathbf{x})$ can be analytically extended to the region V_C,

$$V_C=(\mathbf{z}\in\mathbb{C}^3:\mathbf{z}=\mathbf{x}+(1+i)\mathbf{y},\mathbf{x}\in V,\mathbf{y}\in\mathbb{R}^3),$$

and remain bounded analytic functions in V_C. Assume that the external potentials u_r are also analytic and bounded in V_C. Let us consider the initial state of the form $\chi\Phi$ where χ is the ground state of H_R and Φ is square integrable. Then, the unitary semigroup U_t^δ $(t\geqslant 0)$ generating the Schrödinger time evolution has for a sufficiently small time t the probabilistic representation

$$\begin{aligned}(U_t^\delta\psi)(\mathbf{A},\lambda\mathbf{x})\equiv(\exp(-iH_\delta t/\hbar)\psi)(\mathbf{A},\lambda\mathbf{x})=\chi(\mathbf{A})E\Bigg[\exp\Bigg(i\sum_r\frac{e_r}{\hbar c}\int_0^t\mathscr{A}_\delta(\tau,\lambda\mathbf{x}_r\\ +\lambda\sigma_r\mathbf{b}_r(\tau))\lambda\sigma_r d\mathbf{b}_r(\tau)\Bigg)\exp\Bigg(-\frac{i}{\hbar}\sum_{r,s}e_re_s\int_0^t\phi_\delta(\lambda\mathbf{x}_r+\lambda\sigma_r\mathbf{b}_r(\tau),\lambda\mathbf{x}_s\\ +\lambda\sigma_s\mathbf{b}_s(\tau))\,d\tau-\frac{i}{\hbar}\sum_r\int_0^t u_r(\lambda\mathbf{x}_r+\lambda\sigma_r\mathbf{b}_r(\tau))\,d\tau\Bigg)\Phi(\mathscr{A}_\delta(t,\mathbf{A}),\lambda\mathbf{x}+\lambda\sigma\mathbf{b}(t))\Bigg].\end{aligned}\tag{11}$$

Remarks:

(1) The index δ at the potentials $\mathscr{A}$ and ϕ means that in their definitions we made the replacement $g\to g_\delta$.
(2) It does not matter whether the stochastic integral in Eq. (11) is in the Stratonovitch or Ito sense[27] because both integrals are equal for transverse vector potentials.
(3) If V is a parallelepiped, then $\cos(\mathbf{kx})$ and $\sin(\mathbf{kx})$ constitute the eigenmodes, hence $g_\delta(k,\mathbf{x})$ are analytic and bounded in V_C.
(4) The wave function in the theorem describes the quantum electromagnetic field interacting with the n-particle system. We denoted the coordinates in the argument of ψ and Φ collectively by $\mathbf{x}$ and $\mathbf{b}$.
(5) We may write $U_t=(U_{t/n})^n$, where the natural number n is chosen large enough. In such a case we can obtain a probabilistic representation for arbitrarily large time through a repetition of the formula (11).
(6) We consider here only $t\geqslant 0$. The evolution for $t\leqslant 0$ can be obtained by time reflection as discussed in Ref. 17.

Proof: The proof is based on general methods of the construction of semigroups.[28] First, the formula (11) holds true if there is no interaction between the particles and the photons (i.e., when $u_r=0$ and $e_r=0$) as shown in Ref. 17. Then, the factor in the expectation value in Eq. (11) is an example of a nonanticipating multiplicative functional. Such a multiplicative functional defines a semigroup. There remains to prove that the multiplicative functional is integrable [so that the expression (11) is finite] and that the generator of the semigroup is $(i/\hbar)H_\delta$. The integrability results from our assumptions implying that ϕ_δ and $\mathscr{A}_\delta$ are bounded. Then, for each $\mathscr{A}_\delta$,

$$\exp\Bigg(z\int_0^t\mathscr{A}_\delta(\tau,\lambda\mathbf{x}+\lambda\sigma\mathbf{b}(\tau))\lambda\sigma\,d\mathbf{b}(\tau)\Bigg)$$

is integrable for any complex z on the basis of an estimate proved in Ref. 29 and discussed in our earlier paper.[17] There remains the Gaussian integral over $\mathscr{A}_\delta$. Owing to the δ-regularization the covariance of $\mathscr{A}_\delta$ is a bounded continuous function. Hence, the $\mathscr{A}_\delta$-integral is bounded by an exponential of a continuous bilinear form in the Brownian motion $\mathbf{b}$ (this bilinear form is discussed in more detail in Sec. V). The expectation value of such an exponential is finite for a sufficiently small time (see Refs. 17 and 27). We can refer now to the Fubini theorem in order to perform first the $\mathscr{A}_\delta$-integral and to conclude that the expectation value in Eq. (11) is finite. Finally, the computation of the generator involves the limit $t\to 0$. In such a case the calculations are reduced to an elementary stochastic calculus[27] which does not depend on whether the poten-

tials are real or complex. Let us only explain in more detail the quantum electromagnetic part which constitutes a new ingredient in comparison to Ref. 17. In the differentiation of $\mathscr{A}_\delta(t,\mathbf{x})$ over t we expand $\mathscr{A}_\delta$ in $q(t;k,\nu)$. Then, the differentiation of q is determined by Eq. (5). As a result of the $q(t;k,\nu)$ differentiation we obtain the photon part of H:

$$\chi^{-1}H_R\chi=-\sum_{k,\nu}\left(\frac{\hbar^2}{2\mu(k)}\frac{\partial^2}{\partial y(k,\nu)\partial y(k,\nu)}+\hbar\omega(k)y(k,\nu)\frac{\partial}{\partial y(k,\nu)}\right).$$

The remaining terms result from differentiation in time in the same way as in the conventional form of the Feynman–Kac formula.[27] □

Let us mention the imaginary time (Euclidean) version of Eqs. (5) and (11) (the Feynman–Kac formula). The Feynman–Kac formula can be applied to more singular potentials. However, there are stronger conditions on the possible decrease of the scalar potential to minus infinity. The imaginary time version can be useful in a study of the spectrum, but is unsuitable for an investigation of dynamics. So, the imaginary time version of Eq. (5) reads

$$dq(t;k,\nu)=-\omega(k)q(t;k,\nu)dt+\sigma_k db(t;k,\nu), \tag{12}$$

whereas the imaginary time version of Eq. (11) takes the form

$$\begin{aligned}\left(\exp\left(-H\frac{t}{\hbar}\right)\psi\right)(\mathbf{A},\mathbf{x})=\chi(\mathbf{A})E\Bigg[&\exp\left(i\sum_r\frac{e_r}{\hbar c}\int_0^t\mathscr{A}(\tau,\mathbf{x}_r+\sigma_r\mathbf{b}_r(\tau))\sigma_r\,d\mathbf{b}_r(\tau)\right)\\&\times\exp\left(-\frac{1}{\hbar}\sum_{r,s}e_re_s\int_0^t\phi(\mathbf{x}_r+\sigma_r\mathbf{b}_r(\tau),\mathbf{x}_s+\sigma_s\mathbf{b}_s(\tau))\,d\tau\right.\\&\left.-\frac{1}{\hbar}\sum_r\int_0^t u_r(\mathbf{x}_r+\sigma_r\mathbf{b}_r(\tau))d\tau\right)\Phi(\mathscr{A}(t,\mathbf{A}),\mathbf{x}+\sigma\mathbf{b}(t))\Bigg],\end{aligned} \tag{13}$$

where $\mathscr{A}(t,\mathbf{x})$ is expressed by $q(t;k,\nu)$ in the same way as in the real time case [Eq. (8)]. Equation (13) holds true under the assumption that the number of modes is finite and $g(k,\mathbf{x})$ are bounded functions on $\mathbb{R}^3$ (in such case no δ-regularization is needed). It is easy to take the limit of an infinite number of modes if the formfactors $f(k)$ decay sufficiently fast for large k (e.g., $|f(k)|\leqslant\text{const}|\mathbf{k}|^{-2}$).

IV. PROBABILISTIC DESCRIPTION OF QUANTUM DYNAMICS AT FINITE TEMPERATURE

A mixed state can be described as a random pure state. Let us begin with one degree of freedom. Assume that the (classical) probability ρ_n of a state $|n\rangle$ is given. We introduce a random variable w such that

$$E[\overline{w^n}w^m]=\delta_{mn}n!\rho_n.$$

Then, the density matrix can be expressed in the form

$$\rho=E[|\chi\rangle\langle\chi|], \tag{14}$$

where

$$|\chi\rangle=\sum_{n=0}^{\infty}\frac{1}{\sqrt{n!}}w^n|n\rangle. \tag{15}$$

Let us consider the quantum harmonic oscillator with the frequency $\omega(k)$ at temperature T. If $|n\rangle$ is the nth excited energy eigenstate of the oscillator, then the Gibbs distribution is

$$\rho_n=(1-\exp(-\beta\hbar\omega(k)))\,\exp(-\beta\hbar\omega(k)n),$$

where $\beta=(KT)^{-1}$ and K is the Boltzman constant. It is easy to see that the expectation value (14) can be realized by the Gaussian distribution

$$\mathrm{Tr}(\rho F)=\mathrm{Tr}(E[|\chi\rangle\langle\chi|F])=(1-\exp(-\beta\hbar\omega(k)))\mathrm{Tr}\left(\int d\rho_k(w)F|\chi\rangle\langle\chi|\right),$$

where $d\rho_k$ is the Gaussian probability measure

$$d\rho_k(w)=\pi^{-1}dwd\bar{w}\exp(\beta\hbar\omega(k))\exp(-|w|^2\exp(\beta\hbar\omega(k))).$$

We can sum up the series (15). In the coordinate representation we obtain an expression for the coherent state

$$\langle y|\chi_k(z)\rangle=\left(\frac{\eta_k}{\pi}\right)^{1/4}\exp\left(-\frac{1}{2}\eta_k y^2-\frac{1}{4\eta_k}(z^2+|z|^2)+zy\right),$$

where

$$\eta_k=\frac{\mu(k)\omega(k)}{\hbar}$$

and we defined

$$z=\sqrt{2\eta_k}w.$$

Under the time evolution

$$\chi_k(t,y)\equiv\langle y|\exp\left(-iH_k\frac{t}{\hbar}\right)|\chi(z)\rangle=\langle y|\chi(\exp(-i\omega(k)t)z)\rangle. \tag{16}$$

According to our general scheme[30] the time evolution of the wave function $|\chi\rangle$ [Eq. (15)] determines the correlation functions in the mixed state ρ. In more detail, we define first the stochastic process $(0\leqslant\tau\leqslant t)$

$$dq(\tau)=\frac{i\hbar}{m}\chi(t-\tau,q)^{-1}\nabla\chi(t-\tau,q)d\tau+\lambda\sigma\, db(\tau) \tag{17}$$

where m is the mass of a particle and

$$\sigma=\sqrt{\frac{\hbar}{m}}.$$

Then, the correlation functions of Heisenberg operators can be expressed by the solution $q(t,y)$ of the stochastic equation with the initial condition y, e.g.,

$$\mathrm{Tr}(y(t)y(0)\rho)=E\left[\int dy|\chi_t(y)|^2 y q_t(y)\right]. \tag{18}$$

In the case of the coherent state χ_k, Eq. (17) reads

$$dq(\tau)=-i\omega(k)qd\tau+\frac{i\hbar}{\mu(k)}z\exp(-i\omega(k)(t-\tau))d\tau+\lambda\sigma_k\, db(\tau). \tag{19}$$

Its solution entering formula (18) is

$$q(t;y,z)=\exp(-i\omega(k)t)y+\frac{i\hbar}{\mu(k)\omega(k)}z\exp(-i\omega(k)t)\sin(\omega(k)t)$$
$$+\lambda\sigma_k\int_0^t\exp(-i\omega(k)(t-\tau))db(\tau). \tag{20}$$

The correlation functions in Eq. (18) can easily be computed from Eqs. (16) and (20):

$$\mathrm{Tr}(y(t)y(0)\rho)=(1-\exp(-\beta\hbar\omega(k)))\int d\rho_k(w)dy|\langle y|\chi_k(\exp(-i\omega(k)t)w)\rangle|^2$$
$$\times\left(\exp(-i\omega(k)t)y^2+i\sqrt{\frac{2}{\eta_k}}\sin(\omega(k)t)\exp(-i\omega(k)t)wy\right)$$
$$=\frac{\hbar}{2\mu(k)\omega(k)}\left(\mathrm{cth}\left(\frac{1}{2}\beta\hbar\omega(k)\right)\cos(\omega(k)t)-i\sin(\omega(k)t)\right). \tag{21}$$

According to formulas (2) and (8), the free quantum electromagnetic field is a sum of oscillators. The density matrix is a product of the density matrices with different masses and frequencies. Hence, we obtain directly from Eqs. (8) and (21)

$$\mathrm{Tr}\,(A_j(t,\mathbf{x})A_l(0,\mathbf{x}')\rho)\equiv G_\beta(\mathbf{x},\mathbf{x}';t)_{jl}=\frac{2\pi\hbar c}{V}\sum_k\frac{f(k)^2}{|\mathbf{k}|}\delta^{tr}_{jl}g(k,\mathbf{x})g(k,\mathbf{x}')$$
$$\times\left(\mathrm{cth}\left(\frac{1}{2}\beta\hbar\omega(k)\right)\cos(\omega(k)t)-i\sin(\omega(k)t)\right). \tag{22}$$

The expectation value in the ground state χ of the free electromagnetic field in a cavity is a special case of Eq. (22) corresponding to the limit $\beta\to\infty$ $(t\geqslant 0)$

$$D_{jl}(\mathbf{x},\mathbf{x}';t)\equiv\langle\chi|A_j(t,\mathbf{x})A_l(0,\mathbf{x}')|\chi\rangle=\frac{2\pi\hbar c}{V}\sum_k\frac{f(k)^2}{|\mathbf{k}|}\delta^{tr}_{jl}g(k,\mathbf{x})g(k,\mathbf{x}')\exp(-i\omega(k)t). \tag{23}$$

The expression for correlation functions of an n-particle system in equilibrium with the black body radiation at temperature T described by the Hamiltonian H_R+H_P (2) and (3) follow directly from our description (14) of a mixed state as a random pure state. In this way we obtain directly from Theorem 1

$$\mathrm{Tr}(U_t^+\Phi_1(\mathbf{A},\lambda\mathbf{x})U_t\Phi_2(\mathbf{A},\lambda\mathbf{x})\rho)=\lambda^3\int\prod_{k,\nu}dy(k,\nu)d\mathbf{x}\;\Phi_1(\mathbf{A},\lambda\mathbf{x})E\Big[\Phi_2(\mathscr{A}^z_\delta(t,\mathbf{A}),\lambda\mathbf{x}$$
$$+\lambda\sigma\mathbf{b}(t))\exp\left(i\sum_r\frac{e_r}{\hbar c}\int_0^t\mathscr{A}^z_\delta(\tau,\lambda\mathbf{x}_r\right.$$
$$\left.+\lambda\sigma_r\mathbf{b}_r(\tau))\lambda\sigma_r\,d\mathbf{b}_r(\tau)\right)\exp\left(-\frac{i}{\hbar}\sum_{r,s}e_re_s\int_0^t\phi_\delta(\lambda\mathbf{x}_r\right.$$
$$+\lambda\sigma_r\mathbf{b}_r(\tau),\lambda\mathbf{x}_s+\lambda\sigma_s\mathbf{b}_s(\tau))\,d\tau-\frac{i}{\hbar}\sum_r\int_0^t u_r(\lambda\mathbf{x}_r$$
$$\left.+\lambda\sigma_r\mathbf{b}_r(\tau))d\tau\right)\Big]. \tag{24}$$

In Eq. (24) $\mathscr{A}^z$ means that in the expression (8) for $\mathscr{A}$ we insert the solution (20), depending on the coherent state random variable z_k as well as on the initial condition $y(k,\nu)$. Then, in Eq. (24) the average is taken over the Brownian motion the random variables z_k as well as over the initial values $y(k,\nu)$ defining $\mathbf{A}$. Note that the left-hand side of Eq. (24) is simple if $\Phi_1=1$, whereas the right-hand side is quite complicated even if $\Phi_1=1$. This is so because the unitarity condition applied at the left-hand side when expressed by a path integral takes a complicated form (a condition of a time invariance of the expectation value is an analog of unitarity).

V. QUANTUM MECHANICS IN QED ENVIRONMENT

In quantum mechanics we usually consider idealized systems consisting of a finite number of particles. However, real systems are open and interact in an uncontrollable way with an infinite

environment. It is believed that if the interaction with the environment is weak, then it is negligible. A model suggested by Caldeira and Leggett[6] indicates that this may be not the case concerning processes on the mesoscopic scale. In particular, the disappearance of the quantum interference may be a result of an interaction with an environment (besides the Caldeira and Leggett papers see also Refs. 21, 31, and 32. However, the model of an environment discussed in the above-mentioned papers does not come from any concrete physical environment (the claims in Refs. 9 and 33 that such an environment can be considered as an approximation to QED are rather unconvincing). There appeared some suggestions[34,35] that QED (e.g., in the form of the black body radiation) constitutes the environment enforcing the appearance of classical properties of macroscopic systems. Unfortunately, the quantum electrodynamics discussed in these papers has been considered in such a rough approximation that a conclusion concerning its effect was rather unfounded.

A restriction to observables associated with a system of particles means that we take an average over all states of the quantum radiation field. Let us note first that the random electromagnetic field (8) consists of two parts: the $\hbar$-independent part (which we call $\mathscr{A}^{\mathrm{vac}}$) depending on the initial values $y(k,\nu)$,

$$\mathscr{A}^{\mathrm{vac}}(t,\mathbf{x})=\sum_{k,\nu}\ \sqrt{4\pi\mu(k)}cf(k)\mathscr{E}(k,\nu)\exp(-i\omega(k)t)y(k,\nu)g(k,\mathbf{x}), \tag{25}$$

and the rest

$$\mathscr{A}^{Q}\equiv\mathscr{A}-\mathscr{A}^{\mathrm{vac}}.$$

An easy computation gives

$$\begin{aligned}E[\mathscr{A}_j^Q(\tau,\mathbf{x})\mathscr{A}_l^Q(\tau',\mathbf{x}')]&=\frac{2\pi\hbar c}{V}\sum_k\ \frac{f(k)^2}{|\mathbf{k}|}\,\delta_{jl}^{tr}g(k,\mathbf{x})g(k,\mathbf{x}')(\exp(-i\omega(k)|\tau'-\tau|)\\&\quad-\exp(-i\omega(k)(\tau'+\tau)))\\&\equiv D_{jl}(\mathbf{x},\mathbf{x}';|\tau'-\tau|)-D_{jl}^{\mathrm{vac}}(\mathbf{x},\mathbf{x}';\tau'+\tau),\end{aligned} \tag{26}$$

where we divided the correlation function (26) into a time-translation invariant part and the rest. If the δ-regularization $g\to g_\delta$ is inserted in Eq. (26), then the corresponding correlation function is denoted D^δ.

We can now calculate transition amplitudes in quantum mechanics in a QED environment. Let $\chi(\mathbf{A})$ be the Fock vacuum for the radiation field. Assume that Φ_1 and Φ_2 are entire analytic functions and depend only on the particle positions. In such a case we can rotate the $\mathbf{x}$ integral into the complex hyperplane $\mathbb{C}^3$. Then, the transition amplitudes can be expressed in the form

$$\begin{aligned}(\Phi_1\chi,U_t\Phi_2\chi)&=\exp\left(\frac{3i\pi}{4}\right)\int d\mathbf{x}\overline{\Phi}_1(\lambda\mathbf{x})E\Big[\Phi_2(\lambda\mathbf{x}+\lambda\sigma\mathbf{b}(t))\\&\quad\times\exp\Big(-i\sum_{rs}\ \frac{e_r\sigma_re_s\sigma_s}{2\hbar^2c^2}\int_0^t\int_0^t d\mathbf{b}_r(\tau)d\mathbf{b}_s(\tau')D^\delta(\lambda\mathbf{x}_r\\&\quad+\lambda\sigma_r\mathbf{b}_r(\tau),\lambda\mathbf{x}_s+\lambda\sigma_s\mathbf{b}_s(\tau');|\tau-\tau'|)\Big)\exp\Big(-\frac{i}{\hbar}\sum_{r,s}\ e_re_s\int_0^t\phi_\delta(\lambda\mathbf{x}_r\\&\quad+\lambda\sigma_r\mathbf{b}_r(\tau),\lambda\mathbf{x}_s+\lambda\sigma_s\mathbf{b}_s(\tau))\,d\tau-\frac{i}{\hbar}\sum_r\ \int_0^t u_r(\lambda\mathbf{x}_r+\lambda\sigma_r\mathbf{b}_r(\tau))d\tau\Big)\Big],\end{aligned} \tag{27}$$

where $d\mathbf{b}d\mathbf{b}D$ means a sum over vector indices of D and vector indices of the Brownian motions of individual particles.

Remarks:

(1) The conditions for applicability of the Fubini theorem are fulfilled in the regularized theory for a sufficiently small time (cf. Theorem 1). Double stochastic integrals are discussed in Refs. 36 and 37.

(2) It is remarkable that the ''vacuum part'' in the exponential of the expectation value (27) is absent. The ''vacuum part'' of Eq. (26) cancelled with the contribution from the expectation value of $\mathscr{A}^{\mathrm{vac}}$ and what remains is the time translation invariant part of the expression (26).

The corresponding formula at finite temperature reads

$$\begin{aligned}\mathrm{Tr}(U_t^+\Phi_1(\lambda\mathbf{x})U_t\Phi_2(\lambda\mathbf{x})\rho)=\exp\left(\frac{3i\pi}{4}\right)\int d\mathbf{x}\ \Phi_1(\lambda\mathbf{x})E\Bigg[\Phi_2(\lambda\mathbf{x}+\lambda\sigma\mathbf{b}(t))\\ \times\exp\Bigg(-i\sum_{rs}\ \frac{e_r\sigma_r e_s\sigma_s}{2\hbar^2c^2}\int_0^t\int_0^t d\mathbf{b}_r(\tau)d\mathbf{b}_s(\tau')G_\beta^\delta(\lambda\mathbf{x}_r\\ +\lambda\sigma_r\mathbf{b}(\tau),\lambda\mathbf{x}_s+\lambda\sigma_s\mathbf{b}_s(\tau');|\tau-\tau'|)\Bigg)\\ \times\exp\Bigg(-\frac{i}{\hbar}\sum_{r,s}\ e_re_s\int_0^t\phi_\delta(\lambda\mathbf{x}_r+\lambda\sigma_r\mathbf{b}_r(\tau),\lambda\mathbf{x}_s\\ +\lambda\sigma_s\mathbf{b}_s(\tau))d\tau-\frac{i}{\hbar}\sum_r\ \int_0^t u_r(\lambda\mathbf{x}_r+\lambda\sigma_r\mathbf{b}_r(\tau))d\tau\Bigg)\Bigg],\end{aligned}\tag{28}$$

where G_β^δ is the finite temperature correlation function (22) with $g\to g_\delta$.

We can see from Eq. (27) that the quantum electromagnetic environment contributes an additional nonlocal interaction (described by D) between particles of the system. One could say that the particles interact through an exchange of photons from the environment. As D (at zero temperature) is proportional to $\hbar$ the additional interaction is of the order of the fine structure constant α. From Eq. (22) we can see that at high temperature the interaction becomes proportional to the temperature. However, because of the light velocity in the denominator, this interaction seems negligible at the room temperatures. Nevertheless, it should be realized that such a comparison of the strength of interactions makes sense only for interactions of the same type. The interaction induced by the QED environment is of different type than the Coulomb interaction ϕ and the external potential u. It depends on velocities and is nonlocal. Such interactions may be relevant on the large time and space scale.

VI. REMOVAL OF CUTOFFS AND REGULARIZATIONS

We restricted ourselves until now to a finite number of modes (an ultraviolet cutoff) in a finite volume V and we introduced additionally the δ-regularization which is demanded by the functional integral representation in the real time (it would be superfluous in the Feynman–Kac formula). Together with a finite number of modes we considered also the formfactor $f(k)$ which can describe a finite distribution of the charge. We can allow the number of modes to increase to infinity if the formfactor decreases sufficiently fast (in k). In such a case the formfactor fulfills the role of the ultraviolet cutoff. We restrict ourselves from now on to the case when V is a cube. Then, $g(k,\mathbf{x})$ consist of pairs $(\cos(\mathbf{kx}),\sin(\mathbf{kx}))$ (with a certain restriction on $\mathbf{k}$ ensuring that the basis is orthogonal, see Refs. 24 and 25). Hence,

$$g(k,\mathbf{x})g(k,\mathbf{x}')\to\cos(\mathbf{kx})\cos(\mathbf{kx}')+\sin(\mathbf{kx})\sin(\mathbf{kx}')=\cos(\mathbf{kx}-\mathbf{kx}')\tag{29}$$

and

$$\omega(k)=c|\mathbf{k}|\,.$$

It can be seen from Eqs. (26) and (27) that in a cube (with periodic boundary conditions) the interaction is invariant under space and time translations. Moreover, if the temperature is equal to

zero, the cube tends to $\mathbb{R}^3$ and the ultraviolet regularization is removed $[f(k)=1]$, then the interaction becomes relativistic invariant (in such a case D coincides with the conventional D_+). It is well known that in the relativistic theory D_+ is singular on the light cone. The origin of this singularity can be seen from Eqs. (26) and (29); the oscillating factor becomes a constant on the light cone, hence the sum over wave vectors tends to infinity. In such a case the double stochastic integral in Eq. (27) is infinite. The ultraviolet problem is unavoidable in QED and presumably can only be solved perturbatively through an expansion of the exponential in power series (which is a power series in α). We consider in this section the remaining regularizations.

Theorem 2: Let V be a cube. Assume that the number of modes is finite. Assume also that the external potentials u_r are bounded on V_C (defined in Theorem 1). Then, the limit $\delta\to 0$ of $\exp(-iH_\delta t/\hbar)\psi(\mathbf{A},\lambda\mathbf{x})$ exists for each $\mathbf{A}$ and $\mathbf{x}$ and sufficiently small t. The limit $\delta\to 0$ defines a unitary evolution solving the Schrödinger equation

$$i\hbar\,\partial_t\psi_t=(H_R+H_P)\psi_t$$

with the initial condition ψ. As a consequence the limits $\delta\to 0$ of the transition amplitude (27) and the finite temperature correlation functions (28) also exist for a sufficiently small time.

Proof: We apply the representation (9) and (10) to the δ-regularization. We expand the exponentials in Eq. (11) in power series in e. Then, it follows from the results of Ref. 17 (Theorem 3) and from the Lebesgue dominated convergence theorem (because $\mathscr{A}_\delta$ and ϕ_δ are bounded) that for each $\mathscr{A}^Q$ the limit $\delta\to 0$ is exchangeable with the sum. There remains the Gaussian integral over $\mathscr{A}^Q$ in the power series. From estimates of the combinatorial factor in front of the term $(\mathscr{A}^Q)^n$ done in Ref. 17 (based on Ref. 29) it follows that it is bounded by $1/\sqrt{n!}$. Hence, after the Gaussian integration of the term $(\mathscr{A}^Q)^n$ (which contributes $\sqrt{n!}$) this term becomes bounded by $c(t)^n$ where $c(t)$ is proportional to t because the upper limit in the stochastic integration is equal to t. Hence, if t is sufficiently small, then the power series is bounded by a convergent geometric series. The proof of the convergence of the power series for the transition amplitude (27) and the correlation functions (28) is similar. In the proof we obtain the Gaussian integral with the covariance (26) instead of the Gaussian integral with the covariance (23). □

Corollary 3: Assume that there exist $a>0$ and $R(a)>0$ such that

$$|f(k)|\leqslant R(a)\exp(-a|\mathbf{k}|^2). \tag{30}$$

(i) Let N be the number of modes. Then, the limit $N\to\infty$ of the transition amplitude (27) and the finite temperature correlation functions (28) exists uniformly in δ for a sufficiently small time t. The limits $N\to\infty$ and $\delta\to 0$ are exchangeable and can be taken simultaneously.

(ii) If time t is sufficiently small, then after $N\to\infty$ the limit $V\to\mathbb{R}^3$ of the transition amplitude and the same limit of the finite temperature correlation functions can be performed according to the rule

$$\frac{1}{V}\sum_k \to \frac{1}{(2\pi)^3}\int d^3k.$$

The limit $V\to\mathbb{R}^3$ is uniform in δ. Hence, the limits $V\to\mathbb{R}^3$ and $\delta\to 0$ are exchangeable.

Remark: We could define directly the evolution operator U_t (11) for an infinite number of modes and a sufficiently small time by the same argument which we apply in the proof below. In principle, an operator can be recovered from the transition amplitude.

Proof: It is sufficient to note that with the bound on the formfactor $f(k)$ the limits considered in the Corollary can be taken at each order of the perturbation series in e. This is so, because according to the results of Ref. 17 (proven under a condition equivalent to the bound on the formfactor assumed here) and Theorem 2 the perturbation series is convergent. Then, the existence of the limit $N\to\infty$ is easy to show at each order of the perturbation expansion. The infinite volume limit and the convergence of the sum over k to an integral is a consequence of Riemann's definition of an integral. □

We approached QED starting from a well-defined Hamiltonian consisting of a finite number of modes of the quantum electromagnetic field in a finite volume. This is a model often studied in quantum optics. However, we could consider the final formula (27) where the limits $\delta\to 0$, N

$\to\infty$ and $V\to\mathbb{R}^3$ are performed directly under the expectation value on the right-hand side in the exponential factor. We would obtain an expression defined by the stochastic integrals of D and ϕ. This could be considered as a definition of QED. In fact, if we first integrated over $\mathscr{A}$ in the (imaginary time) Feynman–Kac formula and afterwards performed in a formal way the analytic continuation on the path space, then we would arrive at the formula (27). In Theorem 2 and Corollary 3 we have shown that the limits on the right-hand side exist for a sufficiently small time and define a limit of an evolution operator. If the limits are performed under the expectation value, then the expectation value may be infinite or, even if it is finite, we may lose a connection with the Hamiltonian formalism. In the rest of this section we investigate the double stochastic integral of the formula (27), treating the right-hand side as a definition of the Feynman integral representation of the left-hand side. We emphasize the following result of Ref. 37.

Lemma 4: The sufficient conditions required for a definition of the double stochastic integral in Eq. (27) as an almost surely finite random variable read

$$E\left[\int_0^t d\tau \int_0^\tau d\tau' \ |D(\mathbf{b}(\tau),\mathbf{b}(\tau');\tau-\tau')|^2\right]<\infty \tag{31}$$

and

$$E\left[\int_0^t d\tau \ |D(\mathbf{b}(\tau),\mathbf{b}(\tau);0)|^2\right]<\infty.$$

Applying Lemma 4 we can show the following.

Lemma 5: Under the assumption (30) the double stochastic integral is defined as an almost surely finite random variable.

Proof: Under our assumptions the correlation function D for equal times is a finite constant. It remains to be proven that the integral (31) is finite. The expectation value (31) is equal to

$$\int_0^t d\tau \int_0^\tau d\tau' \ d^3x \ d^3y \ d^3k \ d^3k' (2\pi)^{-3} (\tau'(\tau-\tau'))^{-3/2}$$
$$\times \exp\left(-\frac{\mathbf{x}^2}{2\tau'}-\frac{(\mathbf{y}-\mathbf{x})^2}{2(\tau-\tau')}\right)(|\mathbf{k}||\mathbf{k}'|)^{-1} \ f(k)^2$$
$$\times \exp(-ic(|\mathbf{k}|+|\mathbf{k}'|)(\tau-\tau')+\lambda\sigma(\mathbf{k}\mathbf{y}-\mathbf{k}\mathbf{x})+\overline{\lambda}\sigma(\mathbf{k}'\mathbf{y}-\mathbf{k}'\mathbf{x})).$$

We change variables $(\mathbf{x},\mathbf{y})\to(\mathbf{x},\mathbf{z})$ where

$$\mathbf{x}-\mathbf{y}=\sqrt{\tau-\tau'}\,\mathbf{z}.$$

After such a change of variables and a calculation of the $\mathbf{x}$-integral the integrand becomes regular in τ and τ' whereas the integrability at large k and k' is ensured by the assumption (30). □

Finally, we consider an explicit example

$$f(k)=\exp\left(-\frac{a}{2}|\mathbf{k}|\right). \tag{32}$$

(where $a>0$) which does not fulfill the assumption (30). Nevertheless, we can show the following.

Proposition 6: (i) If $f(k)$ is defined by Eq. (32), then the function D (the case of an infinite volume) has an analytic continuation to the region $V_C(0)=(\mathbf{z}\in\mathbb{C}^3:\mathbf{z}=(1+i)\mathbf{y},\mathbf{y}\in\mathbb{R}^3)$. Moreover, D is bounded in this region.

(ii) Assume that the external potential u is bounded by a quadratic form in the region V_C of Theorem 1. Then, the functional integral (27) with the formfactor (32) is finite for a sufficiently small time.

Proof: A direct calculation from Eq. (23) [see also Eq. (26)] gives

$$D_{jl}(\mathbf{x},\mathbf{x}';\tau-\tau')=\frac{\delta^{tr}_{jl}}{4\pi}\,((a+ic|\tau-\tau'|)^2+(\mathbf{x}-\mathbf{x}')^2)^{-1}.$$

For a single particle the function D in the double stochastic integral of Eq. (27) takes the form

$$D_{jl}(\lambda\mathbf{x}+\lambda\sigma\mathbf{b}(\tau),\lambda\mathbf{x}'+\lambda\sigma\mathbf{b}(\tau');\tau-\tau')$$
$$\equiv\delta^{tr}_{jl}D=\frac{1}{4\pi}\,\delta^{tr}_{jl}(a^2-c^2(\tau-\tau')^2+2iac|\tau-\tau'|+i\sigma^2(\mathbf{x}-\mathbf{x}'+\mathbf{b}(\tau)-\mathbf{b}(\tau'))^2)^{-1}.$$

Here δ^{tr} is a bounded operator. So, it is sufficient to discuss the scalar function D behind δ^{tr} (a more detailed demonstration would involve an application of the Ito formula; we express the stochastic integral with respect to the longitudinal modes by an ordinary integral which would be bounded owing to the regularization). It is easy to see that D is bounded because, if

$$|\tau-\tau'|c\leqslant\frac{a}{2},$$

then $|D|\leqslant(3\pi a^2)^{-1}$ because the real part of the denominator of D is different from zero. If

$$|\tau-\tau'|c\geqslant\frac{a}{2},$$

then $|D|\leqslant(3\pi a^2)^{-1}$, because the imaginary part of the denominator of D is different from zero.

When D is a bounded continuous function and the potential u is quadratically bounded, then the integrand (27) can be bounded by a Gaussian factor. In such a case the well-known theorems (see, e.g., Ref. 27; **b** can be expressed by independent Gaussian random variables) show the integrability proving (ii). □

Even if D is bounded it may be not easy to prove integrability in Eq. (27) for arbitrarily large time. We have to show that the negative part of D decreases sufficiently fast when $|\tau-\tau'|$ grows. If this is not the case we have to continue the formula (27) beyond the time interval where it loses its meaning. We encounter this problem already for a harmonic oscillator. A solution of the problem is well known in this case. For an anharmonic oscillator it is usually discussed in a semiclassical approximation (Maslov indices).

VII. THE FEYNMAN KERNEL OF THE EVOLUTION OPERATOR

We wish to derive an explicit Feynman integral formula for the evolution kernel of the operator (11). We mainly discuss in this section a finite number of modes. However, in principle there is no difficulty in defining an evolution kernel in an infinite number of dimensions. There is no Lebesgue measure in an infinite number of dimensions. For this reason we define a kernel K as a transformation of a set of measures $\mathscr{G}$ into a set of functions $L^2(d\mu)$ integrable with respect to a certain measure μ. In QED we choose for μ a measure defined on vector fields which gives a realization of the Fock space of the transversal electromagnetic free field, i.e., μ is the Gaussian measure with the covariance

$$\hbar\,\delta^{tr}_{jl}(-\Delta)^{-1}.$$

If Φ_1 and Φ_2 belong to $L^2(d\mu)$, then we define the kernel K_t of the unitary evolution U_t by the formula

$$(\Phi_1,U_t\Phi_2)=(\Phi_1,K_t\Phi_2 d\mu)\equiv\int d^3x\; d\mu(\mathbf{C})\overline{\Phi_1}(\mathbf{C},\mathbf{x})K(t,\mathbf{C},\mathbf{x};0,\mathbf{B},\mathbf{x}')\Phi_2(\mathbf{B},\mathbf{x}')d\mu(\mathbf{B})d^3x'.$$

We have obtained a Feynman formula for the kernel of a quantum mechanical Hamiltonian evolution in the case without the quantum electromagnetic field in Ref. 18. In order to extend this formula to the quantum electromagnetic field let us start with a definition of the Gaussian process $0\leqslant\tau\leqslant t$,

$$Q^t(\tau;k,\nu)=\alpha^t(\tau;k,\nu)+\lambda\sigma_k\gamma^t(\tau;k,\nu), \tag{33}$$

where α^t (we shall sometimes conceal some indices which are inessential at the moment) is the solution of the oscillator equation

$$\left(\frac{\partial^2}{\partial\tau^2}+\omega(k)^2\right)\alpha^t(\tau)=0. \tag{34}$$

with the boundary conditions $\alpha^t(0)=X$ and $\alpha^t(t)=Y$. Explicitly

$$\alpha^t(\tau)=\frac{\sin(\omega(k)(t-\tau))}{\sin(\omega(k)t)}X+\frac{\sin(\omega(k)\tau)}{\sin(\omega(k)t)}Y.$$

Here γ^t is the Gaussian process fulfilling the zero boundary conditions $\gamma^t(0)=\gamma^t(t)=0$ with the mean zero and the covariance

$$E[\gamma^t(\tau)\gamma^t(\tau')]=\mathscr{M}(\tau,\tau'), \tag{35}$$

where

$$\mathscr{L}_\tau\mathscr{M}(\tau,\tau')\equiv\left(-\frac{\partial^2}{\partial\tau^2}-\omega(k)^2\right)\mathscr{M}(\tau,\tau')=\delta(\tau-\tau'), \tag{36}$$

i.e., $\mathscr{L}\mathscr{M}=1$. Here $\mathscr{M}$ is the Green's function of the operator $\mathscr{L}$ with the Dirichlet boundary conditions on the interval $[0,t]$. For $t<\pi\omega(k)$, the kernel $\mathscr{M}$ is positive definite, because for such a t the operator $\mathscr{L}$ is positive definite. This is so because the lowest eigenvalue of $-\partial^2$ is $(\pi/t)^2$. In such a case the random variable γ^t is real. The explicit formula for $\mathscr{M}$ reads

$$\begin{aligned}\mathscr{M}(\tau,\tau')=&\frac{1}{\omega(k)}\,\theta(\tau'-\tau)(\sin(\omega(k)(t-\tau'))\cos(\omega(k)(t-\tau))\\&-\operatorname{ctg}(\omega(k)t)\sin(\omega(k)(t-\tau))\sin(\omega(k)(t-\tau')))+\frac{1}{\omega(k)}\,\theta(\tau-\tau')\\&\times(\sin(\omega(k)(t-\tau))\cos(\omega(k)(t-\tau'))\\&-\operatorname{ctg}(\omega(k)t)\sin(\omega(k)(t-\tau))\sin(\omega(k)(t-\tau'))),\end{aligned}$$

where θ is the Heaviside step function.

We can express the process γ^t by the Brownian motion

$$\gamma^t(\tau)=\sin(\omega(k)(t-\tau))\int_0^\tau(\sin(\omega(k)(t-u)))^{-1}db(u). \tag{37}$$

When $\tau<\pi/\omega$, then the integral (37) is well defined, proving that the kernel $\mathscr{M}$ is positive definite.

We insert Q^t (33) into the expansion (8) of the electromagnetic field $\mathscr{A}$ into eigenmodes. We obtain

$$\mathscr{A}(\tau,\mathbf{x};t,\mathbf{B},\mathbf{C})=\mathscr{A}^{cl}(\tau,\mathbf{x};t,\mathbf{B},\mathbf{C})+\lambda\mathscr{H}^t(\tau,\mathbf{x}), \tag{38}$$

where $\mathscr{A}^{cl}$ is the solution of the wave equation

$$\left(\frac{1}{c^2}\frac{\partial^2}{\partial\tau^2}-\Delta\right)\mathscr{A}^{cl}=0.$$

with the two-point boundary condition $\mathscr{A}^{cl}(0,\mathbf{x};t,\mathbf{B},\mathbf{C})=\mathbf{B}(\mathbf{x})$ and $\mathscr{A}^{cl}(t,\mathbf{x};t,\mathbf{B},\mathbf{C})=\mathbf{C}(\mathbf{x})$. $\mathscr{H}^t$ is a quantum fluctuation. Note that the two-point boundary value problem (34) has the unique solution only if $t<\pi/\omega(k)$ for every k. In terms of the initial condition of Eq. (34) **B** has the form

$$\mathbf{B}=\sum_{k,\nu}\sqrt{4\pi\mu(k)}cf(k)\mathscr{E}(k,\nu)X(k,\nu)g(k,\mathbf{x}).$$

We have a similar formula for $\mathbf{C}$ in terms of $Y(k,\nu)$. The decomposition of the quantum field $\mathscr{A}$ (38) into a solution of a classical boundary value problem and a random fluctuation resembles Boyer's stochastic electrodynamics.[38] However, our random fluctuation $\mathscr{H}$ is multiplied by a complex number λ.

The construction of the random electromagnetic field (38) fulfilling the two-point boundary condition is a generalization of the construction of the Brownian bridge v.[27] This is the Gaussian process defined on the interval $[0,1]$ with zero two-point boundary condition and the covariance

$$E[v_j(\tau)v_l(\tau')]=\delta_{jl}(\theta(\tau-\tau')\tau'(1-\tau)+\theta(\tau'-\tau)\tau(1-\tau')).$$

The bridge connecting the points $\lambda\mathbf{x}$ and $\lambda\mathbf{x}'$ which we apply in the Feynman formula has the form

$$\mathbf{p}(\tau;t,\mathbf{x},\mathbf{x}')=\lambda\mathbf{x}'\ \frac{\tau}{t}+\lambda\ \frac{t-\tau}{t}\ \mathbf{x}+\lambda\sigma\sqrt{t}\mathbf{v}\left(\frac{\tau}{t}\right). \tag{39}$$

We can now express the evolution kernel by the bridge as follows.

Theorem 7: (i) Let $0\leqslant t<\min_k(\pi/\omega(k))$. Then the integral kernel of the unitary semigroup U_t of Theorem 1 (under the assumptions of this theorem) has the representation

$$\begin{aligned}K^{\delta}(t,\mathbf{C},\lambda\mathbf{x};0,\mathbf{B},\lambda\mathbf{x}')&=K^{\text{free}}(t,\mathbf{C};0,\mathbf{B})E\left[\exp\left(i\sum_r\ \frac{e_r}{\hbar c}\ \int_0^t\mathscr{A}_{\delta}(\tau,\mathbf{p}_r(\tau);t,\mathbf{B},\mathbf{C})d\mathbf{p}_r(\tau)\right)\right.\\&\left.\times\exp\left(-\frac{i}{\hbar}\sum_{r,s}\ e_re_s\int_0^t\phi_{\delta}(\mathbf{p}_r(\tau),\mathbf{p}_s(\tau))d\tau-\frac{i}{\hbar}\sum_r\ \int_0^t u_r(\mathbf{p}_r(\tau))d\tau\right)\right]\\&\equiv K^{\text{free}}\mathscr{R},\end{aligned} \tag{40}$$

where K^{free} is the Feynman kernel of $\exp(-iH_R\,t/\hbar)$:

$$\begin{aligned}K^{\text{free}}(t,\mathbf{C};0,\mathbf{B})=\prod_k\ (2\pi i\sigma_k^2\ \sin(\omega(k)t))^{-1}\prod_{k,\nu}\ \exp\left(\frac{i}{2\sigma_k^2}\ (X(k,\nu)ctg(\omega(k)t)X(k,\nu)\right.\\\left.+Y(k,\nu)ctg(\omega(k)t)Y(k,\nu)-2X(k,\nu)(\sin(\omega(k)t))^{-1}Y(k,\nu))\right).\end{aligned}$$

(ii) Assume that (i) holds true. Then under the assumptions of Theorem 2 there exists the limit $\delta\to 0$ of $K^{\delta}(t,\mathbf{C},\lambda\mathbf{x};0,\mathbf{B},\lambda\mathbf{x}')$ for each $\mathbf{x}$, $\mathbf{x}'$, $\mathbf{B}$, and $\mathbf{C}$ if t is sufficiently small.

(iii) The limit $V\to\mathbb{R}^3$ exists for a sufficiently small time if $f(k)=0$ for $|\mathbf{k}|>\kappa$ with a certain ultraviolet cutoff κ.

Remarks:

(1) The allowed time in (ii) and (iii) may be smaller than in (i) because we additionally require a convergence of the perturbation series in powers of the electric charge.
(2) The formula for arbitrary time can in principle be derived by a composition of kernels for a small time.

Proof: In (i) we can repeat the argument of Ref. 18 in order to represent the kernel of the evolution operator of Theorem 1 [Eq. (11)] in terms of the corresponding bridge joining the initial and the final points. Here, for the electromagnetic field we apply the bridge (33) corresponding to the harmonic oscillator instead of the v-bridge corresponding to a free particle used in our earlier paper[18] (the imaginary time version of the oscillator bridge is discussed in Ref. 39). In part (ii) we repeat the proof of Theorem 2, showing that the perturbation series is convergent uniformly in δ and that the δ-regularization can be removed term by term. In part (iii) we apply the same argument as in (ii) of Corollary 3 to show that a sum over wave vectors $\mathbf{k}$ converges to an integral

when $V \to \mathbb{R}^3$. This is possible only if the denominator in the bridge Q^t (33) is different from zero. For this reason we assumed the sharp ultraviolet cutoff in (iii). □

It seems that Eq. (40) remains true for any $t \neq \pi/\omega(k)$. A rough argument is as follows: it could be proved in an independent way under our assumptions that the evolution kernel of $H_R + H_P$ has a convergent expansion around the evolution kernel of H_R (see Ref. 40 for a closely related theorem). On the other hand, Eq. (40) defines such an expansion for any $t \neq \pi/\omega(k)$. Hence, it is sufficient to compare the expansion coefficients. These expansion coefficients must be the same because both kernels fulfill the same equation. Another argument which could be applied comes from the fact that an imaginary time version of Eq. (40) [cf. Eq. (13)] holds true for arbitrarily large time. For an operator bounded from below an analytic continuation in time exists (see a discussion in Ref. 41). At points where the right-hand side of Eq. (40) is regular it must coincide with the integral kernel of the analytic continuation of the semigroup $\exp(-Ht/\hbar)$.

VIII. THE SEMICLASSICAL EXPANSION

A nonperturbative construction of QED is necessary for a demonstration of a classical limit of QED. This is so because the conventional perturbative QED involves an expansion in the fine structure constant α, where $\alpha \to \infty$ when $\hbar \to 0$ (see a discussion of some problems concerning this limit in Ref. 23). We could obtain the conventional perturbation expansion expanding Eq. (27) in powers of the electric charge [see Ref. 1 for a relativistic generalization of Eq. (27)]. In this section we obtain a semiclassical form of the Feynman kernel (40) through an expansion in $\hbar$ (the semiclassical expansion of the Feynman kernel in quantum mechanics with a rigorous version of the Feynman integral is discussed in Refs. 18, 42, and 43; for a version without the Feynman integral see Ref. 44). In such an approach the role of the two-point boundary value problem and its quantum correction (38) become visible. After a derivation of the quasiclassical form of the Feynman kernel other versions of the classical limit can be obtained through an expression of the time evolution by the Feynman kernel. In particular, one can see more explicitly the difference between QED and Boyer's stochastic electrodynamics.[38] In the derivation of the semiclassical expansion we follow our earlier paper.[18] The first step is a shift of variables $\gamma \to \gamma + \zeta\beta$ and $\mathbf{v} \to \mathbf{v} + z\mathbf{w}$, where z and ζ are complex numbers.

Lemma 8: Let $\beta(\tau)$ and $\mathbf{w}(\tau)$ be differentiable and their derivatives square integrable on the intervals $[0,t]$ and $[0,1]$, respectively. Moreover, assume that β and $\mathbf{w}$ are equal to zero on the ends of the respective intervals. Then, with the assumptions and notation of (i) of Theorem 7 we have the following identity:

$$\begin{aligned}\mathscr{R} = E\Bigg[\exp\Bigg(&-\frac{1}{2}\int_0^t \sum_{k,\nu} \zeta(k,\nu)^2 \beta(\tau;k,\nu)\mathscr{L}\beta(\tau;k,\nu)\,d\tau - \int_0^t \sum_{k,\nu} \zeta(k,\nu)\mathscr{L}\beta(\tau;k,\nu)\gamma(\tau;k,\nu)\,d\tau \\ &- \int_0^1 \sum_r z_r \frac{d\mathbf{w}_r}{d\tau}\,d\mathbf{v}_r(\tau) - \frac{1}{2}\int_0^1 \sum_r z_r^2 \frac{d\mathbf{w}_r}{d\tau}\frac{d\mathbf{w}_r}{d\tau}\,d\tau + i\sum_r \frac{e_r}{\hbar c}\int_0^t \mathscr{A}_\delta\Big(\tau, \mathbf{p}_r(\tau) \\ &+ \lambda\sqrt{t}\sigma_r z_r \mathbf{w}_r\Big(\frac{\tau}{t}\Big); t, \mathbf{B}+\mathbf{F}, \mathbf{C}\Big) d\Big(\mathbf{p}_r(\tau) + \lambda\sqrt{t}\sigma_r z_r \mathbf{w}_r\Big(\frac{\tau}{t}\Big)\Big)\Bigg) \exp\Bigg(-\frac{i}{\hbar}\sum_{r,s} e_r e_s \int_0^t \phi_\delta\Big(\mathbf{p}_r(\tau) \\ &+ \lambda\sqrt{t}\sigma_r z_r \mathbf{w}_r\Big(\frac{\tau}{t}\Big), \mathbf{p}_s(\tau) + \lambda\sqrt{t}\sigma_s z_s \mathbf{w}_s\Big(\frac{\tau}{t}\Big)\Big) d\tau - \frac{i}{\hbar}\sum_r \int_0^t u_r\Big(\mathbf{p}_r(\tau) + \lambda\sqrt{t}\sigma_r z_r \mathbf{w}_r\Big(\frac{\tau}{t}\Big)\,d\tau\Big)\Bigg],\end{aligned} \tag{41}$$

where $\mathscr{L}$ is defined in Eq. (36) and

$$\mathscr{A}_\delta(\tau;\mathbf{x};t,\mathbf{B}+\mathbf{F},\mathbf{C}) \equiv \mathscr{A}_\delta(\tau;\mathbf{x};t,\mathbf{B},\mathbf{C}) + \mathscr{F}_\delta(\tau,\mathbf{x})$$

with

$$\mathscr{F}_\delta(\tau,\mathbf{x}) = \sum_{k,\nu} \sqrt{4\pi\mu(k)}\, c f(k) \mathscr{E}(k,\nu) \lambda \sigma_k \zeta(k,\nu) \beta(\tau;k,\nu) g_\delta(k,\mathbf{x}).$$

Proof: If z and ζ are real, then Eq. (41) [cf. the definition of $\mathscr{R}$ in Eq. (40)] is a version of the Cameron–Martin formula expressing the transformation of the Gaussian integral under a shift of variables. The validity of the formula (41) for complex z and ζ follows by analytic continuation; this has been discussed first in Ref. 43 and then in Ref. 18. □

Now, we choose $z_r=(\lambda\sigma_r)^{-1}$ and $\zeta(k,\nu)=(\lambda\sigma_k)^{-1}$. We study the limit $\hbar\to 0$ of the wave function $(U_l^{\delta}\psi)(\lambda\mathbf{x})$ of Theorem 1 defined on the complex hyperplane in $\mathbb{C}^3$. When $\lambda\mathbf{x}\to\mathbf{x}$, then we obtain the conventional semiclassical limit with real fields and real trajectories. Let us introduce a field [see Eq. (38) for a definition of $\mathscr{A}^{cl}$]

$$\mathscr{A}^I(\tau,\mathbf{x})\equiv\mathscr{A}^{cl}(\tau,\mathbf{x};t,\mathbf{B},\mathbf{C})+\mathscr{F}(\tau,\mathbf{x}) \tag{42}$$

and a trajectory (it becomes real if $\lambda\mathbf{x}\to\mathbf{x}$ and $\lambda\mathbf{x}'\to\mathbf{x}'$)

$$\mathbf{x}(\tau)=\lambda\mathbf{x}'\,\frac{\tau}{t}+\lambda\,\frac{t-\tau}{t}\,\mathbf{x}+\sqrt{t}\mathbf{w}\left(\frac{\tau}{t}\right).$$

Let us choose $\mathbf{w}_r$ in such a way that $\mathbf{x}_r(\tau)$ is the solution of the Lorentz equation

$$m_r\frac{d^2\mathbf{x}_r}{d\tau^2}=-e_r\boldsymbol{\nabla}_r\sum_s\, e_s\phi(\mathbf{x}_r,\mathbf{x}_s)-\boldsymbol{\nabla}_r u_r(\mathbf{x}_r)-\frac{1}{c}\,\partial_\tau\mathscr{A}^I(\tau,\mathbf{x}_r)+e_r\,\frac{d\mathbf{x}_r}{d\tau}\times\boldsymbol{\nabla}\times\mathscr{A}^I(\tau,\mathbf{x}_r) \tag{43}$$

with the two-point boundary condition $\mathbf{x}(0)=\lambda\mathbf{x}$ and $\mathbf{x}(t)=\lambda\mathbf{x}'$. For a sufficiently small time t (what we assume here) the two-point boundary value problem (43) has the unique solution.[45]

The field $\mathscr{A}^I$ is constructed from the amplitudes $\beta(\tau;k,\nu)$. Let us define

$$\xi(\tau;k,\nu)=\alpha(\tau;k,\nu)+\beta(\tau;k,\nu), \tag{44}$$

where α is defined below Eq. (34). Then, $\mathscr{A}^I$ of Eq. (42) is defined by ξ:

$$\mathscr{A}^I(\tau,\mathbf{x})=\sum_{k,\nu}\,\sqrt{4\pi\mu(k)}cf(k)\mathscr{E}(k,\nu)\xi(\tau;k,\nu)g(k,\mathbf{x}).$$

Now, we choose $\beta(\tau;k,\nu)$ in such a way that $\xi(\tau;k,\nu)$ is the solution of the equation

$$(\partial_\tau^2+\omega(k)^2)\xi(\tau;k,\nu)=\sqrt{\frac{4\pi}{\mu(k)}}\,f(k)\sum_r\, e_r\mathscr{E}(k,\nu)\,\frac{d\mathbf{x}_r(\tau)}{d\tau}\,g(k,\mathbf{x}(\tau)) \tag{45}$$

with the two-point boundary condition $\xi(0;k,\nu)=X(k;\nu)$ and $\xi(t;k,\nu)=Y(k;\nu)$. Equation (45) implies the usual equation for a vector potential of a given particle current

$$\left(\frac{1}{c^2}\frac{\partial^2}{\partial\tau^2}-\Delta\right)\mathscr{A}^I(\mathbf{x})=\frac{4\pi}{c}\sum_r\, e_r\,\frac{d\mathbf{x}_r}{d\tau}\,\delta_f(\mathbf{x}_r(\tau),\mathbf{x}), \tag{46}$$

where

$$\delta_f(\mathbf{x},\mathbf{y})=\frac{1}{V}\sum_k\, f(k)^2g(k,\mathbf{x})g(k,\mathbf{y}).$$

Equation (46) is solved with the two-point boundary condition $\mathscr{A}^I(\tau=0,\mathbf{x})=\mathbf{B}(\mathbf{x})$ and $\mathscr{A}^I(\tau=t,\mathbf{x})=\mathbf{C}(\mathbf{x})$. When $f(k)\to 1$, then we obtain the classical electrodynamics of point charges. We wrote Eqs. (43) and (46) without the δ-regularization (9). As a first step we insert again the δ-regularization and prove the semiclassical expansion. Subsequently, we show that the δ-regularization can be removed.

Theorem 9: Let us assume that V is a cube and the number of modes is finite. Define the classical action [where x and ξ solve the classical equations of motion (43) and (45)]

$$S_\delta=\sum_r \int_0^t\left(\frac{m_r 1}{2}\left(\frac{d\mathbf{x}_r}{d\tau}\right)^2-u_r(\mathbf{x}_r(\tau))\right)d\tau-\sum_{r,s}\int_0^t e_r e_s \phi_\delta(\mathbf{x}_r,\mathbf{x}_s)d\tau$$
$$+\sum_{k,\nu}\int_0^t\left(\frac{\mu(k)}{2}\left(\frac{d\xi(k,\nu)}{d\tau}\right)^2-\frac{1}{2}\mu(k)\omega(k)^2\xi(k,\nu)^2\right)d\tau$$
$$+\sum_r \frac{e_r}{c}\int_0^t \mathscr{A}^I_\delta(\tau,\mathbf{x}_r(\tau))d\mathbf{x}_r(\tau). \tag{47}$$

Then (i) for a sufficiently small time t

$$K_\delta(t,\mathbf{C},\lambda\mathbf{x};0,\mathbf{B},\lambda\mathbf{x}')\exp\left(-i\frac{S_\delta}{\hbar}\right)\equiv\Omega_\delta(t,\hbar) \tag{48}$$

is bounded in $\hbar$.

(ii) The limit $S_\delta\to S$ as $\delta\to 0$ exists if t is small enough.

(iii) For a sufficiently small time Ω_δ can be expanded in a power series in the electric charge and the limit $\delta\to 0$ of each term exists uniformly in $\hbar$. Hence, the limits $\delta\to 0$ and $\hbar\to 0$ in $\Omega_\delta(t,\hbar)$ exist and are exchangeable.

Proof: We expand K_δ in powers of $\sqrt{\hbar}$ according to Eq. (41). S_δ of Eq. (47) constitutes the singular part of the expansion. Equations of motion (43) and (45) result from the condition of the cancellation of the terms of order $(\sqrt{\hbar})^{-1}$. There remains to bound the remainder. In the cube $g(k,\mathbf{x})$ are the sine and cosine functions. In such a case the problem of the estimate of the remainder is very similar to the estimate of the remainder for trigonometric interactions done in Ref. 18 (Theorem 6.2). So, after a subtraction of the term S_δ from K_δ we expand the exponentials in Eq. (41) in power series in the electric charge. The series is convergent for a sufficiently small time. We show that the singular terms of order $(\sqrt{\hbar})^{-1}$ cancel identically in the series if the classical equations of motion (43) and (45) are fulfilled. The remaining terms in the series are already bounded in $\hbar$ and δ. As a consequence, the series is convergent uniformly in $\hbar$ and δ. Hence, the limit $\delta\to 0$ can be performed term by term in the convergent power series. The part (ii) of the theorem is an easy consequence of the continuity of solutions of differential equations with respect to variation of parameters if the fields are regular and the time is small enough. The part (iii) follows from our discussion of the expansion of Ω_δ in the power series. □

We can solve the linear equation (45) and insert the solution into Eq. (43). In such a case we obtain an integro-differential equation describing particles interacting by Coulomb forces and additionally under the interaction of the retarded magnetic field produced by their movements. We would obtain this equation if we performed the classical limit in Eq. (27) where the functional integral over the quantum electromagnetic field has been calculated. The double stochastic integral in the exponential of Eq. (27) describes the quantum radiation reaction. Equations (43) and (45) lead to the classical expression for the radiation reaction.[46,47] We have shown in Theorem 9 that the quantum radiation reaction has a classical limit for a sufficiently small time. It is well known that we encounter serious acausal effects with both the classical and quantum radiation reaction (see a clarification of some difficulties in Ref. 48). However, these problems involving a large time behavior are beyond the scope of this paper.

IX. SOME APPROXIMATIONS IN QED

It is quite difficult to obtain nonpertubative results in QED without further approximations. It is often argued (see, e.g., Refs. 11 and 22) that because the electron in an atom is localized around the nucleus and the wavelength involved in the light–atom interaction is large in comparison to the atom size, then in quantum radiation theory we may neglect the spatial dependence of quantum electromagnetic field (such an assumption is also applied in mathematical physics papers[13,14]). Although this argument is convincing classically it would be very difficult to justify it in a complete relativistic quantum theory of the electromagnetic field. In a relativistic theory the propagator D in Eq. (27) is singular on the light cone. Hence, an expansion in coordinates of this

propagator in Eq. (27) could not be justified. We could consider the ultraviolet cutoff in D as an expression of the belief that the high-frequency atom–photon interactions are not relevant to atomic physics.

We intend to formulate this short-range approximation in a particular case. Let us consider the formfactor

$$f(k)^2=\int_0^\infty ds\varsigma(s)\exp(-\epsilon s|\mathbf{k}|). \tag{49}$$

We wish to compare the transition amplitude (27) with the one where the spatial dependence of D is neglected. Let us note that (see the propagator D of Proposition 6)

$$D(\mathbf{x},\mathbf{x}';|\tau-\tau'|)-D(0,0;|\tau-\tau'|)=\frac{1}{4\pi}\,\delta^{tr}\int_0^\infty \varsigma(s)(\mathbf{x}-\mathbf{x}')^2(\epsilon s+ic|\tau-\tau'|)^{-2}$$
$$\times((\epsilon s+ic|\tau-\tau'|)^2+(\mathbf{x}-\mathbf{x}')^2)^{-1}. \tag{50}$$

Hence, with a proper choice of ς this difference can be a bounded function of $\mathbf{x}-\mathbf{x}'$.

Proposition 10: Consider the transition amplitude (27) for a single particle in $\mathbb{R}^3$. Assume that $\int_0^\infty s^{-2}\varsigma(s)ds<\infty$. Then, for a sufficiently small time t,

$$|(\Phi_1\chi,U_t\Phi_2\chi)-(\Phi_1\chi,U_t\Phi_2\chi)_0|\leqslant \text{const}\,\frac{e^2}{\hbar c}\,t, \tag{51}$$

where $(,)_0$ denotes the transition amplitude computed with the propagator $D(0,0;|\tau-\tau'|)$ where the spatial dependence is neglected.

Proof: We note that under the assumptions of the Proposition the difference of the propagators $D(\lambda\sigma\mathbf{b}(\tau),\lambda\sigma\mathbf{b}(\tau');|\tau-\tau'|)-D(0,0;|\tau-\tau'|)$ is a bounded function of $\mathbf{b}$ and $\tau-\tau'$. Then, in Eq. (27) the exponential of the double stochastic integral $\int db\ db(D-D_0)$ (where the propagator without the spatial dependence is denoted D_0) can be expanded in power series, which is convergent for a sufficiently small time. The first term $\int db\ db(D-D_0)$ in the series (51) is estimated by the rhs of Eq. (51). Then, the estimate of the Proposition is a consequence of the convergence of the series. □

The proposition says that under our assumptions an error of the neglect of the spatial dependence is of the order of the fine structure constant. Such a result can be considered as a first step of a more systematic investigation. The substantial result should hold true for arbitrarily large time. However, this would be quite difficult to prove. The difficulty results from the problem of integrability for arbitrarily large time of the exponential of the double stochastic integral. The approximations to the double stochastic integral are interesting from the point of view of the quantum theory of radiation reaction. The well-known formula for classical radiation reaction of a point charge[46] confirmed by approximate quantum calculations[48,49] can be obtained by a neglect of spatial dependence. In order to investigate the problem from the point of view of the Feynman integral (for a Hamiltonian formulation see Ref. 50) let us introduce the decomposition $D=D^0+D^1$ for the zero temperature propagator and $G=G^0+G^1$ for the finite temperature propagator (22), where the index zero means that the spatial coordinates are set equal to zero. In the infinite volume we have (the factor $\frac{2}{3}$ comes from the replacement of δ^{tr} by δ)

$$D^0_{jl}(t)=\frac{2}{3}\,\delta_{jl}\,\frac{\hbar c}{\pi}\int_0^\infty dk\ kf(k)^2\ \exp(-ickt)$$

and

$$G^0(t)_{jl}=\frac{2}{3}\,\delta_{jl}\,\frac{\hbar c}{\pi}\int_0^\infty dk\ kf(k)^2\left(cth\left(\frac{1}{2}\,\beta\hbar ck\right)\cos(ckt)-i\,\sin(ckt)\right).$$

When $f(k)\to 1$, then $\mathrm{Im}\,D^0(t)_{jl}\to(2/3c)\hbar\,\delta_{jl}\delta'(t)$ (where Im denotes the imaginary part). Inserting this result into Eq. (27) we obtain the standard expression for the radiation reaction [strictly

speaking the integral (27) becomes divergent and requires a renormalization]. We can take the radiation reaction into account explicitly by means of a transformation of paths. Let us introduce an operator in $L^2([0,t])$,

$$\mathscr{K}=1+\frac{e^2}{\hbar c^2 m}\,\mathrm{Im}\,D^0,$$

where by $\mathrm{Im}\,D^0$ we denoted the integral operator defined by the kernel $\mathrm{Im}\,D^0$. A transformation

$$d\mathbf{b}\to d\mathbf{b}\equiv\mathscr{K}^{1/2}d\mathbf{b}$$

expresses the functional integral (27) in terms of a new Brownian motion which contains the effect of the radiation reaction. Such a transformation is mathematically correct if $\mathrm{Im}\,D^0$ is a Hilbert–Schmidt operator and moreover if $\mathscr{K}$ is positive definite. For a positive temperature it is useful to note that $G-D$ is real. So, the heat bath does not contribute to the classical radiation reaction. In order to see some effects of the temperature we perform another transformation upon the functional integral. For any functional Φ of the Brownian motion defined on the interval $[0,t]$ we have the Cameron–Martin identity

$$E[\Phi(\mathbf{b})]=E\left[\exp\left(-\int_0^t\frac{d\mathbf{f}}{d\tau}\,d\mathbf{b}(\tau)-\frac{1}{2}\int_0^t\left(\frac{d\mathbf{f}}{d\tau}\right)^2 d\tau\right)\Phi(\mathbf{b}+\mathbf{f})\right]$$

for any $\mathbf{f}$ with a square integrable derivative. We choose now

$$\frac{d\mathbf{f}}{d\tau}=\frac{ie}{\hbar c}\,\lambda\sigma\mathscr{A}^z(0,\tau)$$

in Eq. (24) (for simplicity restricted to a single particle). Then in Eq. (24) $\Phi_2(\mathbf{x}+\lambda\sigma\mathbf{b}(t))\to\Phi_2(\mathbf{q}_t(\mathbf{x}))$ where $\mathbf{q}_t(\mathbf{x})$ is the solution of the equation

$$d\mathbf{q}=-\frac{e}{m}\,\mathscr{A}^z(0,\tau)d\tau+\lambda\sigma d\mathbf{b}(\tau). \tag{52}$$

Using Eqs. (52) and (21) we can compute the correlation functions of q. In this way, for a large temperature and $f(k)=1$ we obtain

$$E\left[\frac{dq_j}{d\tau}\,\frac{dq_l}{d\tau'}\right]=\frac{e^2}{m^2}\,KT\delta_{jl}\delta(\tau-\tau')$$

plus less singular terms. So, the charged particle in equilibrium with a black body radiation behaves like a Brownian particle in a fluid of temperature T. This result is approximate, because we neglected the change of the covariance of the electromagnetic field caused by the Cameron–Martin transformation. We could approach in this way in the framework of QED the model discussed first by Einstein and Hopf[51] and later on in Refs. 52 and 53. Let us note that the behavior of the correlation functions of the quantum particle in equilibrium with the radiation is in qualitative agreement with the requirements of the ''quantum Brownian motion'' due to Benguria and Kac[54] (see also Ref. 6).

X. DISCUSSION AND OUTLOOK

In this paper we concentrated mainly on the precise formulation of regularized QED dynamics. In some cases we were able to show that the expressions were finite only for a small time. Such a requirement resulted from a demand of a convergence of the perturbation series. In principle, we can prolong the dynamics to a larger time using the group property of the time evolution. In practice, the multiple integration involved in such a procedure may be inconvenient. The results of Sec. VII may indicate a way out of this difficulty. The formula for the propagation kernel of a harmonic oscillator holds true for arbitrarily large time (except of the moments equal to the classical periods) in spite of the fact that the functional integral loses its sense already when

t tends to the first period. In another approach to the harmonic oscillator we have obtained in Sec. III the dynamics for an arbitrarily large time through an application of stochastic differential equations [see Eq. (5)]. We have discussed the method of stochastic differential equations for nonlinear quantum systems in Refs. 17 and 55. This method could be applied to QED. The first step has been done in Eq. (52). A nonlinear transformation (discussed for quantum mechanics in Ref. 55) can be applied to formulate exactly the dynamics in QED as a random dynamics. We intend to discuss this method in a subsequent publication.

The dependence on the formfactor (ultraviolet cutoff) constitutes another unsatisfactory aspect of the theory. A nonperturbative removal of the cutoff is a difficult problem. However, some results may be insensitive to the cutoff. One may believe that phenomena on a large time and space scale involving low energies should not depend on the ultraviolet cutoff. We consider the formulation of this paper as a substantial step towards a control over approximations made in QED, quantum optics, and quantum radiation theory. In principle, in Sec. IX we were able to estimate an error involed in a dipole approximation. In Sec. VIII we are able to estimate subsequent terms in the semiclassical expansion.

Note added in proof: After the submission of this paper we have learned about the work of L. H. Ford[56] studying the effect of QED on quantum coherence and the paper of F. Hiroshima[57] who constructs the path integral in QED.

Semidirect product of CCR and CAR algebras and asymptotic states in quantum electrodynamics

Andrzej Herdegen[a)]
Institute of Physics, Jagiellonian University, Reymonta 4, 30-059 Cracow, Poland

(Received 3 March 1997; accepted for publication 17 October 1997)

A C^*-algebra containing the CCR and CAR algebras as its subalgebras and naturally described as the semidirect product of these algebras is discussed. A particular example of this structure is considered as a model for the algebra of asymptotic fields in quantum electrodynamics in which Gauss' law is respected. The appearance in this algebra of a phase variable related to electromagnetic potential leads to the universal charge quantization. Translationally covariant representations of this algebra with energy-momentum spectrum in the future lightcone are investigated. It is shown that vacuum representations are necessarily nonregular with respect to total electromagnetic field. However, a class of translationally covariant, irreducible representations is constructed explicitly, which remain as close as possible to the vacuum, but are regular at the same time. The spectrum of energy-momentum fills the whole future lightcone, but there are no vectors with energy-momentum lying on a mass hyperboloid or in the origin. © *1998 American Institute of Physics.* [S0022-2488(98)01703-4]

I. INTRODUCTION AND SUMMARY

In this paper we continue the study of the algebra of asymptotic fields in quantum electrodynamics, in the framework developed earlier in Ref. 1 (and motivated by the classical asymptotic structure discussed in Ref. 2). However, the present work is self-contained: the main results of Ref. 2 are recalled and the construction of Ref. 1 is restated here in a modified form.

The existence of, and the algebraic relations between, the asymptotic (''in'' or ''out'') observables and fields in quantum electrodynamics is a question of great physical interest. In the asymptotic limit, on the one hand, the details and full complication of the dynamics should lose their importance. On the other hand, the consequences of Gauss' law and of the long-range character of the electromagnetic interaction must survive. Suppose a closed algebra of asymptotic fields in quantum electrodynamics may be constructed. This should imply, at least, that (some) states over this algebra are approached in the asymptotic limit by the expectation values of actual fields in physical states. Therefore, the infrared and charged structure of the full theory should be encoded in the asymptotic algebra, and physical insight into this structure may be gained by investigating representations of this algebra.

Investigations into the infrared structure and asymptotic fields of electrodynamics have a long history (see Refs. 3–5 for a review). They have led to the discovery of such structures and effects as superselection sectors of the local observables, the infraparticle problem, and spontaneous breaking of the Lorentz symmetry. However, a clear formulation of a closed algebraic structure of asymptotic fields has not been achieved, although there do exist various partial answers to this problem, with varying balance of mathematical rigor on the one hand and physical concreteness on the other (the asymptotic dynamics of Kulish and Faddeev[6] and Zwanziger,[7] the dressed electron states of Fröhlich,[8] the asymptotic electromagnetic fields[9] and particle weights[10] of Buchholz). The difficulties are twofold. First, we do not have a complete, mathematically sound formulation of QED. Second, the complete asymptotic separation of matter and electromagnetic field may not be expected. These difficulties are not of purely technical nature. The physical factor playing the decisive role in the infrared structure of electrodynamics is the presence of constraints, the Gauss' law. It is not clear at all, in our opinion, to what degree the experience gained by the

quantization of simpler, unconstrained, and short-range interactions may be taken over to the formulation of quantum electrodynamics. In fact, the analysis of Refs. 6 and 8 shows that the usual canonical quantization on hypersurfaces of constant, finite time leads to the asymptotic evolution which in the limit takes the states out of the space in which the theory is defined for finite times. This may be understood as an indication that this method of obtaining a quantum theory may not be best suited for electrodynamics. Also, the localization properties of observables which form the base of the axiomatic algebraic approach to quantum field theory problems still need justification in the case of electrodynamics, and may seem somewhat artificial in the version considered there (localization in spacelike cones).

The above remarks should not be understood as an attempt to question *a priori* the standard wisdom on the subject. We would like, rather, to indicate that the problem of the algebraic structure of quantum electrodynamics may still be validly regarded as open. This view is also supported by the failure of the standard electrodynamics to explain such striking and universal physical fact as the observed spectrum of charge.[11]

In the present work we follow the approach of Refs. 1 and 2 to formulate and investigate a concrete C^*-algebra of asymptotic fields in electrodynamics. The basic idea of the approach consists of interchanging the order of ''quantization'' and ''asymptotic limit.'' (Quantization of free electromagnetic field along these lines has been discussed in Refs. 12 and 13. Our approach develops the ideas of Ref. 13 and extends the program to include charged fields.) In Ref. 2 the asymptotic structure of the classical field electrodynamics (the Maxwell–Dirac system) has been discussed. In Ref. 1 then a class of models of the asymptotic algebra has been obtained by the quantization of this classical structure by the correspondence principle. The Gauss' law is naturally implemented on the algebraical level. Now we develop the approach further in the following ways.

(i) We restrict attention to the technically simplest of the models introduced in Ref. 1, the one in which only the Coulomb field is undetachable from a particle [the possibility (b) of Sec. VI in Ref. 1]. While not rejecting other possibilities at this stage, we observe that this model is also the one following most naturally by the quantization of the classical structure. In this case the construction of Ref. 1 may be simplified to yield the asymptotic algebra in the form of a particular instant of a semidirect product of the CCR (canonical commutation relations) and CAR (canonical anticommutation relations) algebras. The definition and the discussion of some mathematical aspects of this structure comprise the self-contained Sec. II of the paper.

(ii) In the course of quantization we bring into play a new factor, which is present at the classical level in Ref. 2, but has not been properly taken into account in the quantization procedure in Ref. 1. It has been shown in Ref. 2 that one of the asymptotic variables has a natural interpretation as a phase variable. The quantization of the classical structure which properly respects the phase character of this variable leads unambiguously to the quantization of the physical charge spectrum in units of elementary charge. As the phase variable is connected with the free electromagnetic potential, this quantization law is universal: it has to be respected by any carriers of charge. (For similar reasoning, but with a different identification of the phase variable, see the works by Staruszkiewicz.[11]) The classical asymptotic structure, its quantization, and the resulting algebra are discussed in Sec. III, including the action of the Poincaré group on the algebra and the identification of observables.

(iii) Section IV contains some general results on physically admissible representations of the asymptotic algebra. It is argued that the representations should be regular with respect to all Weyl operators, as otherwise the Coulomb field part of the total field is lost. In representations satisfying Borchers' criterion (the spectrum of energy-momentum in the future lightcone) the Gauss constraint, which is hidden in the commutation relations on the abstract algebraic level, is shown to be recovered in the functional form.

(iv) More special representations are investigated in Sec. VI with the use of technical tools discussed in Sec. V (some technical material is shifted to the Appendix). All vacuum representations are shown to be nonregular with respect to the Weyl operators with infrared-singular test functions, which is a handicap as explained earlier. Also, superselec-

tion sectors with respect to regular operators are distinguished by the *free* field spacelike asymptotic, which is not what one would expect in a physical state.[14] There exists a Poincaré-invariant vacuum on the field algebra (sectors transform into each other under Lorentz transformations), whose GNS representation space contains charge-one vector states with the energy-momentum on the mass hyperboloid (no infraparticle problem in this vacuum). A class of representations satisfying Borchers' criterion is constructed, which remain as close as possible to this representation, but are regular at the same time. The nonexistence of charged states on the mass hyperboloid follows here from nonexistence of a vacuum vector state. It is not known at present whether there do exist regular Poincaré covariant representations satisfying Borchers' criterion (standard arguments[15,14] do not apply here).

II. SEMIDIRECT PRODUCT OF CCR AND CAR ALGEBRAS

In this section we discuss a generalization of the direct product of CCR and CAR algebras.[33] We also give a class of representations of the resulting C^*-algebra.

Suppose we are given the following constructs:

(i) a complex Hilbert space $\mathscr{K}$ and the *-algebra *CAR generated by the elements $a(f)$ depending antilinearly on $f\in\mathscr{K}$ and by the identity E, according to the CAR relations [(Eqs. (2.2) below];

(ii) an Abelian group X (with the additive notation of the group multiplication) equipped with a symplectic form $X\times X\ni(x,y)\to\{x,y\}\in\mathbf{R}$;

(iii) a representation of the group X in the automorphism group of the *-algebra *CAR,

$$X\ni x\to\beta_x\in \text{Aut } {}^*\text{CAR}, \quad \beta_x\beta_y=\beta_{x+y}.$$

We consider the *-algebra $\mathscr{B}$ generated by the elements $a(f)$ $(f\in\mathscr{K})$, $W(x)$ $(x\in X)$, and the identity E according to the relations:

$$W(x)^*=W(-x), \quad W(0)=E, \quad W(x)W(y)=e^{-(i/2)\{x,y\}}W(x+y), \tag{2.1}$$

$$[a(f),\, a(g)]_+=0, \quad [a(f),\, a(g)^*]_+=(f,g)E, \tag{2.2}$$

$$W(x)C=\beta_x(C)W(x) \quad \forall C\in {}^*\text{CAR}. \tag{2.3}$$

With the use of (2.3) every element of $\mathscr{B}$ may be given the form $\Sigma_{i=1}^n C_i W(x_i)$, where $C_i\in{}^*\text{CAR}$.

Proposition 2.1: (i) If $x_i\neq x_k$ for $i\neq k$ and $C_i\neq 0$ in *CAR, *then* $\Sigma_{i=1}^n C_i W(x_i)\neq 0$. *Every nonzero element of $\mathscr{B}$ is uniquely represented in this way.*

*(ii) The *-algebra $\mathscr{B}$ has a faithful representation by bounded operators in a Hilbert space.*

Proof: Let π_f be a representation of *CAR in a Hilbert space $\mathscr{H}$ (e.g., the Fock representation). Let $\pi(W(y))$ and $\pi(C)$ be operators acting in the direct sum Hilbert space $\oplus_{x\in X}\mathscr{H}_x$, $\mathscr{H}_x=\mathscr{H}$, defined by

$$[\pi(W(y))\psi]_x=e^{(i/2)\{x,y\}}\psi_{x-y}, \quad [\pi(C)\psi]_x=\pi_f(\beta_{-x}C)\psi_x,$$

where $\psi=\oplus_x\psi_x$. One easily shows that these bounded operators satisfy the relations (2.1)–(2.3) and part (i) of the proposition. This implies part (ii). □

This representation defines a C^*-norm on the algebra $\mathscr{B}$. All C^*-norms on $\mathscr{B}$ are jointly bounded, as for each such norm p there is $p(W(x))=1$ and $p(a(f))=\|f\|_{\mathscr{K}}$. Therefore, the set of C^*-norms contains the maximal element defined by $\|A\|:=\sup_p p(A)$.[16]

*Definition 2.1: The field algebra $(\mathscr{F},\|.\|)$ is the C^*-completion of the *-algebra $\mathscr{B}$ in the norm $\|.\|$.*

Remarks: (i) The elements $a(f)$ [resp. $W(x)$] generate a C^*-subalgebra of $\mathscr{F}$ which will be called the CAR (resp. the CCR, or the Weyl) algebra in this article.

(ii) The construction would be slightly more general if the CAR algebra with its automorphisms instead of *CAR and β_x were used. This, however, would not be convenient for our purposes.

Corollary 2.2: (i) Every Hilbert space representation of $\mathscr{B}$ is given in terms of bounded operators and extends to a representation of $\mathscr{F}$.

(ii) Every positive linear functional on $\mathscr{B}$ defines via the GNS construction a Hilbert space representation of $\mathscr{B}$ and extends to a positive linear functional on $\mathscr{F}$.

*(iii) Every *-automorphism of $\mathscr{B}$ extends to a *-automorphism of $\mathscr{F}$.*

We omit a simple proof. The corollary establishes the 1:1 correspondence between the positive functionals and representations of $\mathscr{F}$ on the one hand, and of $\mathscr{B}$ on the other hand. It also gives a class of automorphisms of $\mathscr{F}$ in simple terms. We shall repeatedly (and tacitly, mostly) take advantage of these simplifications in what follows.

An important class of automorphisms of $\mathscr{B}$ is given as follows. Let T be a symplectic additive mapping in X:

$$T(x+y)=Tx+Ty, \quad \{Tx,Ty\}=\{x,y\}. \tag{2.4}$$

Let, further, τ be an automorphism of *CAR satisfying for each $x\in X$

$$\tau\beta_x=\beta_{Tx}\tau. \tag{2.5}$$

Define $\tau(W(x))=W(Tx)$. Then τ extends to an automorphism of $\mathscr{B}$ (and $\mathscr{F}$). This is a Bogoliubov transformation when restricted to the Weyl algebra.

In the following sections the constructions outlined above will be needed in a special case. Both β_x and τ will be Bogoliubov transformations given by

$$\beta_x a(f)=a(S_x f), \quad \tau a(f)=a(Rf), \tag{2.6}$$

where S_x is a unitary representation of X in $\mathscr{K}$ and R is a unitary operator in $\mathscr{K}$. The condition (2.5) now takes the form

$$RS_x=S_{Tx}R. \tag{2.7}$$

In the remaining part of this section we introduce a particular class of representations of $\mathscr{B}$. We pose, namely, the following question. Suppose ω_f and ω_r are states on the CAR and the Weyl algebra, respectively. When does $\omega(CW(x))=\omega_f(C)\omega_r(W(x))$ define a state on $\mathscr{F}$? The hermiticity of ω implies that $(\omega_f(\beta_x C)-\omega_f(C))\omega_r(W(x))=0$ for every $C\in\mathrm{CAR}$ and $x\in X$. This condition is satisfied, in particular, in each of the following two cases:

$$\omega_f(\beta_x C)=\omega_f(C) \quad \text{for all } x\in X, \quad C\in\mathrm{CAR}, \tag{2.8}$$

$$\omega_r(W(x))=0 \quad \text{if } \beta_x\neq \mathrm{id}. \tag{2.9}$$

One easily shows that in each of these cases ω is also positive on $\mathscr{B}$, hence it is a state on $\mathscr{F}$. We generalize this construction and give the explicit prescription for the resulting representation in terms of π_r and π_f in the following theorem.

Proposition 2.3: Suppose π_f and π_r are representations of the CAR algebra and the Weyl *algebra in Hilbert spaces $\mathscr{H}_f$ and $\mathscr{H}_r$, respectively. Define operators $\pi(A)$, acting in the space $\mathscr{H}_f\otimes\mathscr{H}_r$, in the following two cases:*

(i) π_f has a cyclic vector Ω_f, such that the expectation values in that state satisfy (2.8). *Then*

$$\begin{aligned}\pi(C)&:=\pi_f(C)\otimes\mathbf{1}_r,\\ \pi(W(x))[\pi_f(B)\Omega_f\otimes\varphi]&:=\pi_f(\beta_x B)\Omega_f\otimes\pi_r(W(x))\varphi.\end{aligned} \tag{2.10}$$

(ii) π_r has a cyclic vector Ω_r, such that the expectation values in that state satisfy (2.9). *Then*

$$\pi(W(x)) := \mathbf{1}_f \otimes \pi_r(W(x)),$$
$$\pi(C)[\psi \otimes \pi_r(W(y))\Omega_r] := \pi_f(\beta_{-y}C)\psi \otimes \pi_r(W(y))\Omega_r; \tag{2.11}$$

Then π defines a representation of the algebra $\mathscr{B}$ (and $\mathscr{F}$) in each of the two cases.

Proof: Part (i) is immediately verified if one observes that $\pi(W(x)) = U_x \otimes \pi_r(W(x))$, where U_x canonically implement β_x in the representation generated by ω_f. To prove (ii) one has to show that $\pi(C)$ in (2.11) is well defined as a linear operator. Once this is established, the verification of the algebraic properties is a simple exercise, which we omit. Let $\Sigma_{i=1}^n \psi_i \otimes \pi_r(W(x_i))\Omega_r = 0$. Without loss of generality $\beta_{x_i} = \beta_{x_k}$ $(i,k = 1,...,n)$, as otherwise the vectors are orthogonal. Then $\Sigma_i \pi_f(\beta_{-x_i}C)\psi_i \otimes \pi_r(W(x_i))\Omega_r = \pi_f(\beta_{-x_1}C) \otimes \mathbf{1}_r \Sigma_{i=1}^n \psi_i \otimes \pi_r(W(x_i))\Omega_r = 0$, which justifies the definition of $\pi(C)$. □

The following result will be needed later.

Proposition 2.4: Let τ be an automorphism of $\mathscr{F}$ satisfying (2.4) *and* (2.5), *and let π be a representation of $\mathscr{F}$ of the type* (2.10). *The following two conditions are equivalent.*

(i) The symmetry τ is implementable in the representation π by a unitary operator leaving the subspace $\Omega_f \otimes \mathscr{H}_r$ invariant:

$$\pi(\tau A) = U\pi(A)U^* \quad \forall A \in \mathscr{F}, \tag{2.12}$$

$$U(\Omega_f \otimes \mathscr{H}_r) \subset \Omega_f \otimes \mathscr{H}_r. \tag{2.13}$$

(ii) The state ω_f is invariant under τ,

$$\omega_f(\tau C) = \omega_f(C) \quad \forall C \in \mathrm{CAR}, \tag{2.14}$$

and τ is implementable in the representation π_r

$$\pi_r(\tau A) = U_r \pi_r(A) U_r^* \quad \forall A \in \mathrm{CCR}. \tag{2.15}$$

If these conditions are satisfied, there is a 1:1 correspondence between operators U and U_r given by

$$U = U_f \otimes U_r, \quad \textit{where} \quad U_f \pi_f(C)\Omega_f := \pi_f(\tau C)\Omega_f. \tag{2.16}$$

If, moreover, $G \ni g \to \tau_g \in \mathrm{Aut}\,\mathscr{F}$ is a symmetry group, then $U(g)$ is a representation of G iff $U_r(g)$ is.

Proof: (i)⇒(ii). If U satisfies (2.13), then the equation $U(\Omega_f \otimes \varphi) = \Omega_f \otimes U_r\varphi$ defines a unitary operator U_r. Then, by (2.10) and (2.12), $\Omega_f \otimes U_r\pi_r(W(x))\varphi = U\pi(W(x))(\Omega_f \otimes \varphi) = \Omega_f \otimes \pi_r(\tau W(x))U_r\varphi$, which is equivalent to (2.15). Moreover, again by (2.10) and (2.12), $U(\pi_f(C)\Omega_f \otimes \varphi) = U\pi(C)(\Omega_f \otimes \varphi) = \pi_f(\tau C)\Omega_f \otimes U_r\varphi$, hence U has the form (2.16). Finally, $\omega_f(\tau C) = (\Omega_f, \pi_f(\tau C)\Omega_f) = \omega_f(C)$.

(ii)⇒(i). Choose U as in (2.16). Then (2.12) for $A \in \mathrm{CAR}$ is obvious from (2.10). Moreover, by (2.10) and (2.5),

$$\begin{aligned} U\pi(W(x))U^*(\pi_f(C)\Omega_f \otimes \varphi) &= \pi_f(\tau\beta_x\tau^{-1}C)\Omega_f \otimes U_r\pi_r(W(x))U_r^*\varphi \\ &= \pi_f(\beta_{Tx}C)\Omega_f \otimes \pi_r(W(Tx))\varphi = \pi(W(Tx))(\pi_f(C)\Omega_f \otimes \varphi). \end{aligned}$$

If τ_g is a symmetry group, then $U_f(g)$ is a representation of G, which implies the last equivalence of the proposition. □

A similar proposition holds for the representations of the type (2.11).

III. THE ASYMPTOTIC FIELD ALGEBRA

We turn in this section to the proper task of this article, the investigation of an asymptotic algebra of fields for charged particles in interaction with an electromagnetic field, as outlined in the Introduction. For this purpose it is necessary to review the asymptotic structure of the classical field electrodynamics (the Maxwell–Dirac system) discussed in Ref. 2 (see also Ref. 13). This

paper contains, more precisely, rigorous results for both external field problems and supplies plausibility arguments for the persistence of the resulting structures in the fully interacting theory. (For recent rigorous results on the dynamics of the classical Maxwell–Dirac system obtained by the adaptation of a modified Dollard method[17] see Ref. 18; our approach is different.) Here we only briefly sketch the results without bothering about regularity assumptions or the exact sense of limits, with the purpose of merely identifying the asymptotic variables. For more details we refer the reader to Ref. 2. On the other hand, it should be clear that quantization by the correspondence principle is a heuristic procedure itself, so there is no need for excessive formalization of this point.

Due to the difference in propagation of the electromagnetic field on the one hand, and massive fields on the other, the natural asymptotic directions are also different in the two cases, lightlike in the first and timelike in the second case, respectively. Consider the electromagnetic field first. Let l_a be a null, future-pointing vector ($a,b,$ etc. are space–time indices). Then the leading asymptotic term in this direction of the electromagnetic potential in a Lorentz gauge $A_a(x)$ is given by

$$A_a(x+Rl)\sim\frac{1}{R}\,V_a(x\cdot l,l)\quad\text{for}\quad R\to\infty, \tag{3.1}$$

where x is any space–time point, $V_a(s,l)$ is a real, space–time-vector-valued function of a real variable s and a null vector l, and $x\cdot l$ denotes the scalar product with signature $(+,-,-,-)$. Different gauges yield V's differing by the transformation $V_a(s,l)\to V_a(s,l)+l_a\alpha(s,l)$, which will also be referred to as gauge transformation, but determine the same electromagnetic field asymptotic

$$F_{ab}(x+Rl)\sim\frac{1}{R}\,(l_a\dot{V}_b(x\cdot l,l)-l_b\dot{V}_a(x\cdot l,l))\quad\text{for}\quad R\to\infty, \tag{3.2}$$

where the dot over V denotes differentiation with respect to s. The functions $V_a(s,l)$ are homogeneous of degree -1,

$$V_a(\mu s,\mu l)=\mu^{-1}V_a(s,l),\quad \mu>0, \tag{3.3}$$

satisfy

$$l\cdot V(s,l)=Q, \tag{3.4}$$

where Q is the total charge of the system as measured by the integrated electric flux in spacial infinity, and tend to the limit functions $V_a(\pm\infty,l)$ for $s\to\pm\infty$. The homogeneity implies that $V_a(s,l)$ is determined by its values for l's on a manifold cutting each null direction once. In each Minkowski frame, if l's are scaled to satisfy $t\cdot l=1$ (where t is the timelike basis vector of the frame), then $\dot{V}_a(s,l)$ falls off componentwise for $|s|\to\infty$ at least as $|s|^{-(1+\epsilon)}$, for some $\epsilon>0$. Differentiations with respect to independent variables in the null vector l (i.e., differentiations in directions tangent to the lightcone) are conveniently carried out with the use of the operator $L_{ab}:=l_a\partial_b-l_b\partial_a$, $\partial_a:=\partial/\partial l^a$. With this notation the limit functions $V_a(\pm\infty,l)$ satisfy the differential condition

$$L_{[ab}V_{c]}(\pm\infty,l)=0. \tag{3.5}$$

The limit function $V_a(-\infty,l)$ has a clear physical meaning. For any spacelike vector y there is

$$\lim_{R\to\infty}R^2F_{ab}(x+Ry)=\frac{1}{2\pi}\int(l_aV_b(-\infty,l)-l_bV_a(-\infty,l))\delta'(y\cdot l)d^2l, \tag{3.6}$$

where $\delta'(\cdot)$ is the derivative of the Dirac delta-function and d^2l is the Lorentz-invariant measure on the set of null directions applicable to functions homogeneous in l of degree -2. (If l's are scaled to $t\cdot l=1$, then d^2l is the spherical angle measure on the unit sphere in the hyperplane

orthogonal to t.) Therefore, $l \wedge V(-\infty,l)$ is responsible for the long-range part of the electromagnetic field. The physical content of the property (3.5) of $V(-\infty,l)$ is that the long-range field is of purely electrical type. The physical meaning of the limit function $V(+\infty,l)$ and its property (3.5) will become clear in the sequel.

Consider now the timelike asymptotic of the Dirac field, in the sense of asymptotic behavior for $\lambda \to \infty$ of $\psi(\lambda v)$, where v lies on the future part of the unit hyperboloid. In the Dirac equation choose the electromagnetic potential in a local gauge A^{tr}, related (locally) to a Lorentz potential A by $A^{\mathrm{tr}}_a(x) = A_a(x) - \boldsymbol{\nabla}_a S(x)$, with the condition that for $x^2 \to +\infty$, $x^0 > 0$, the leading term of $S(x)$ is $\ln \sqrt{x^2}\, x \cdot A$. Then the leading asymptotic term of the Dirac field in this gauge, $\psi^{\mathrm{tr}}(x) = e^{-ieS(x)}\psi(x)$, is

$$\psi^{\mathrm{tr}}(\lambda v) \sim -i\lambda^{-3/2} e^{-i(m\lambda + \pi/4)\gamma \cdot v} f(v) \quad \text{for} \quad \lambda \to \infty, \tag{3.7}$$

where γ^a are the Dirac matrices. The function $f(v)$ is a $\mathbf{C}^4$-valued function with finite norm squared $\int \overline{f(v)}\gamma \cdot v f(v)\, d\mu(v)$, where the bar denotes the usual Dirac conjugation and $d\mu(v)$ is the invariant measure d^3v/v^0. The merit of the above asymptotics lies in its simplicity and form-independence of the potential, as long as the latter lies in the distinguished class. This does not contradict the modified Dollard asymptotic dynamics,[6,17,18] as here the asymptotic sequence of hyperboloids rather than spacelike hyperplanes is considered, and a special class of gauges is used.

The asymptotic variables $V_a(s,l)$ and $f(v)$ have well-defined transformation properties under the action of the Poincaré group. The element (x,A) of its universal covering group [x is a space–time vector and $A \in \mathrm{SL}(2,\mathbf{C})$] transforms the Lorentz (covariant) gauge fields by $A_a(y) \to \Lambda(A)_a{}^b A_b(\Lambda^{-1}(y-x))$, $\psi(y) \to S(A)\psi(\Lambda^{-1}(y-x))$, where $S(A)$ is the bispinor representation and $\Lambda(A)$ is the representation of $\mathrm{SL}(2,\mathbf{C})$ in $\mathscr{L}^{\uparrow}_{+}$ [with the notation $(\Lambda y)^a = \Lambda^a{}_b y^b$]. The field $\psi^{\mathrm{tr}}(y)$ transforms noncovariantly, but the noncovariant phase factors are shown to cancel out in the limit. The asymptotics transform then by the representations of the Poincaré group

$$[T_{x,A}V]_a(s,l) = \Lambda(A)_a{}^b V_b(s - x \cdot l, \Lambda^{-1} l), \tag{3.8}$$

$$[R_{x,A} f](v) = e^{imx \cdot v \gamma \cdot v} S(A) f(\Lambda^{-1} v). \tag{3.9}$$

Let us introduce the following structures on the space of asymptotic variables: the symplectic form

$$\{V_1, V_2\} = \frac{1}{4\pi} \int (\dot{V}_1 \cdot V_2 - \dot{V}_2 \cdot V_1)(s,l)\, ds\, d^2 l, \tag{3.10}$$

and the scalar product

$$(f_1, f_2) = \int \overline{f_1(v)}\gamma \cdot v f_2(v)\, d\mu(v) \tag{3.11}$$

(both of them are well defined). Then $T_{x,A}$ is a symplectic transformation, and $R_{x,A}$ a unitary one:

$$\{T_{x,A}V_1, T_{x,A}V_2\} = \{V_1, V_2\}, \quad (R_{x,A}f_1, R_{x,A}f_2) = (f_1, f_2). \tag{3.12}$$

The generators of these transformations defined by

$$T_{x,A} - \mathbf{1} \approx x^a r_a - \frac{1}{2}\omega^{ab} n_{ab}, \quad R_{x,A} - \mathbf{1} \approx i x^a p_a - \frac{i}{2}\omega^{ab} m_{ab},$$

for infinitesimal x^a and ω^{ab}, where $\Lambda^a{}_b \approx g^a_b + \omega^a{}_b$, are

$$(r_a V)_c(s,l) = -l_a \dot{V}_c(s,l), \quad (n_{ab}V)_c(s,l) = -L_{ab}V_c(s,l) - g_{ca}V_b(s,l) + g_{cb}V_a(s,l),$$

$$(p_a f)(v) = m v_a \gamma \cdot v f(v), \quad (m_{ab} f)(v) = \left(v_a i\delta_b - v_b i\delta_a + \frac{i}{4}[\gamma_a, \gamma_b] \right) f(v),$$

where δ_a is the derivative tangent to the hyperboloid, $\delta_a f(v) := (\nabla_a - x_a x^c \nabla_c) f(x)|_{x=v}$, and on the rhs any extension of $f(v)$ to the local neighborhood of the hyperboloid is used.

The discussion of Ref. 2 suggests that the asymptotic variables $V(s,l)$ and $f(v)$ form a causally complete set, in the sense that they determine the state of the system at any space–time point (this has not been proved in the present approach, but cf. Ref. 18). The total energy-momentum and angular momentum are shown to be sums of two terms, the first one describing the respective quantity going out in timelike directions and expressed in terms of $f(v)$ only, and the second one describing the respective quantity going out in lightlike directions and expressed in terms of $V_a(s,l)$ only. (For angular momentum this is, actually, the natural and well-defined way for extending the definition of this quantity to the infrared-singular case; the standard integral over a Cauchy surface, as resulting from Noether theorem, is ill defined.) Explicitly, they may be put into the form

$$P_a = (f, p_a f\ ) + \tfrac{1}{2}\{V, r_a V\}, \tag{3.13}$$

$$M_{ab} = (f, m_{ab} f\ ) + \tfrac{1}{2}\{V, n_{ab} V\}. \tag{3.14}$$

[The first terms in these formulas are those of Eqs. (5.15) and (5.16) in Ref. 2, while the second ones are the tensor forms of the expressions (3.13) and (3.14) in the same reference.] Note that the local gauge freedom of the Dirac field is lost in the asymptotic limit as defined in the present approach—a change of phase of $f(v)$ by a nonconstant function of v spoils the form of the angular momentum. The electromagnetic terms are separately gauge invariant, although the symplectic form (3.10) depends on gauges of $V_{\mathrm{i}a}(-\infty,l) - V_{\mathrm{i}a}(+\infty,l)$, i=1,2, (cf. below).

The conditions of relativistic quantization for the quantum variables V^{q} and f^{q} corresponding to the classical ones are[19]

$$\begin{gathered}[P_a,\ V_c^{\mathrm{q}}] = i(r_a V^{\mathrm{q}})_c, \quad [M_{ab},\ V_c^{\mathrm{q}}] = i(n_{ab} V^{\mathrm{q}})_c, \\ [P_a,\ f^{\mathrm{q}}] = -p_a f^{\mathrm{q}}, \quad [M_{ab},\ f^{\mathrm{q}}] = -m_{ab} f^{\mathrm{q}},\end{gathered} \tag{3.15}$$

where in the generators also the respective quantum variables should be substituted. Suppose, that the variables V^{q} and f^{q} commute, $[V^{\mathrm{q}}, f^{\mathrm{q}}] = 0$, and all fundamental (anti)commutators are c-numbers. This assumption remains in concord with the standard wisdom on canonical quantization in local gauges (on which the derivation of both variables is based) and fixes the quantization rules uniquely:

$$[\{V_1, V^{\mathrm{q}}\}, \{V_2, V^{\mathrm{q}}\}] = i\{V_1, V_2\}, \tag{3.16}$$

$$[(f_1, f^{\mathrm{q}}), (f_2, f^{\mathrm{q}})]_+ = 0, \quad [(f_1, f^{\mathrm{q}}), (f_2, f^{\mathrm{q}})^*]_+ = (f_1, f_2). \tag{3.17}$$

The above quantization relations must be considered as merely the first step towards our aim, as up to now we have not taken into account the constraints between the asymptotic variables. To remedy this deficiency we return to the discussion of the classical structure. The symplectic form (3.10) is invariant under the constant gauge transformation $V_a(s,l) \to V_a(s,l) + l_a \alpha(l)$. One shows that with the appropriate choice of this gauge there is

$$V_a(+\infty, l) = \int n(v) V_a^e(v,l)\ d\mu(v). \tag{3.18}$$

where $n(v) = \overline{f(v)}\, \gamma \cdot v f(v)$ is the asymptotic density of particles moving with velocity v and $V_a^e(v,l) = e v_a / v \cdot l$ is the null asymptotic (3.1) of the Lorentz potential of the Coulomb field surrounding a particle with charge e, moving with constant velocity v. Therefore, the above relation is the implementation of the Gauss constraint on the space of classical asymptotic variables. The relation (3.5) for this limit function is now seen to be satisfied identically. Let, furthermore, $A_a^{\mathrm{adv}}(x)$ be the advanced field of the sources. It turns out that the asymptotic (3.1) of this field is given by $V_a^{\mathrm{adv}}(s,l) = V_a(+\infty, l)$. Hence, the asymptotic of the free outgoing field potential, standardly defined by $A^{\mathrm{out}} = A - A^{\mathrm{adv}}$, is determined by $V_a^{\mathrm{out}}(s,l) = V_a(s,l) - V_a(+\infty, l)$. The ''out'' field is recovered from its asymptotic by the formula

$$A_b^{\text{out}}(x) = -\frac{1}{2\pi}\int \dot{V}_b^{\text{out}}(x\cdot l, l)\; d^2 l. \tag{3.19}$$

The connection of this formula with the Fourier representation

$$A_b^{\text{out}}(x) = \frac{1}{\pi}\int a_b(k)\,\delta(k^2)\,\epsilon(k^0) e^{-ix\cdot k}\; d^4 k \tag{3.20}$$

is supplied by the relation $a_b(\omega l) = -\omega^{-1}\tilde{V}_b^{\text{out}}(\omega, l)$, where the following one-dimensional Fourier transformation has been introduced:

$$\tilde{h}(\omega, l) = \frac{1}{2\pi}\int h(s,l) e^{i\omega s}\; ds. \tag{3.21}$$

The limit function $V^{\text{out}}(-\infty, l) = -2\pi\tilde{V}^{\text{out}}(0,l)$ describes the long-range (infrared-singular) part of A^{out}, the limit function at $s\to\infty$ vanishes, and the charge in formula (3.4) is zero.

The infrared characteristic $V^{\text{out}}(-\infty, l)$ has a simple representation, to become of importance below. Equations (3.3), (3.4) (with $Q=0$), and (3.5) satisfied by $V^{\text{out}}(-\infty, l)$ imply that there exists a homogeneous of degree 0 function $\Phi(l)$ such that

$$l_a V_b^{\text{out}}(-\infty, l) - l_b V_a^{\text{out}}(-\infty, l) = L_{ab}\Phi(l). \tag{3.22}$$

The function $\Phi(l)$ is determined up to an additive constant, but one of the solutions is distinguished by being determined linearly and Lorentz-covariantly by $V_a^{\text{out}}(-\infty, l)$:

$$\Phi_{V^{\text{out}}}(l) = \frac{1}{4\pi}\int \frac{l\cdot V^{\text{out}}(-\infty, l')}{l\cdot l'}\; d^2 l'. \tag{3.23}$$

[This explicit formula appears here for the first time; it may be obtained by a technique similar to that used in Appendix to prove (A8).] This new variable transforms by an addition of a constant with the gauge transformation of the potential: if $V_a^{\text{out}}(s,l) \to V_a^{\text{out}}(s,l) + \alpha(s,l) l_a$, then $\Phi_{V^{\text{out}}}(l) \to \Phi_{V^{\text{out}}}(l) + (1/4\pi)\int \alpha(-\infty, l')\; d^2 l'$. The solution (3.23) is the only one which satisfies (as shown by a simple calculation)

$$\int \frac{\Phi_{V^{\text{out}}}(l)}{(v\cdot l)^2}\; d^2 l = \int \frac{v\cdot V^{\text{out}}(-\infty, l)}{v\cdot l}\; d^2 l \tag{3.24}$$

for any velocity v.

Next, we want to determine the outgoing Dirac field which may be regarded as independent of V^{out} from the point of view of Poincaré generators. To this end put $V(s,l) = V^{\text{out}}(s,l) + V(+\infty, l)$ into (3.13) and (3.14). One finds $\frac{1}{2}\{V, r_a V\} = \frac{1}{2}\{V^{\text{out}}, r_a V^{\text{out}}\}$, but $\frac{1}{2}\{V, n_{ab} V\} = \frac{1}{2}\{V^{\text{out}}, n_{ab} V^{\text{out}}\} + \{V^{\text{out}}, n_{ab} V(+\infty, .)\}$. Substituting (3.18) for $V(+\infty, l)$ and using the identity $(n_{ab} V^e)_c(v,l) = (v_a\delta_b - v_b\delta_a) V_c^e(v,l)$ we obtain $\{V^{\text{out}}, n_{ab} V(+\infty, .)\} = \int n(v)(v_a i\delta_b - v_b i\delta_a) i\{V^e(v, .), V^{\text{out}}\} d\mu(v)$. Finally, introducing a new variable

$$g(v) = e^{i\{V^e(v,.), V^{\text{out}}\}} f(v), \tag{3.25}$$

we bring the generators to the form

$$P_a = (g, p_a g) + \tfrac{1}{2}\{V^{\text{out}}, r_a V^{\text{out}}\}, \tag{3.26}$$

$$M_{ab} = (g, m_{ab} g) + \tfrac{1}{2}\{V^{\text{out}}, n_{ab} V^{\text{out}}\}. \tag{3.27}$$

Now, define the free outgoing Dirac field by

$$\psi^{\text{out}}(x) = \left(\frac{m}{2\pi}\right)^{3/2}\int e^{-imx\cdot v\,\gamma\cdot v}\gamma\cdot v\, g(v)\; d\mu(v), \tag{3.28}$$

which is a special, concise form of the Fourier representation and which implies the asymptotic of the form (3.7) with $f(v)$ replaced by $g(v)$. Then the generators (3.26) and (3.27) turn out to be the sums of the conserved quantities for free fields $\psi^{\text{out}}(x)$ and $F^{\text{out}}_{ab}(x)$. Therefore, $\psi^{\text{out}}(x)$ should be interpreted as the field describing free particles *together with their Coulomb fields.* We have seen that the new separation of variables (3.26) and (3.27) forced the explicit appearance of a gauge-dependent quantity $\{V^e(v,.),V^{\text{out}}\}$, but only as a phase transformation. With the use of (3.24) the phase factor in (3.25) takes the form

$$e^{i\{V^e(v,.),V^{\text{out}}\}}=\exp\left(\frac{ie}{4\pi}\int\frac{\Phi_{V^{\text{out}}}(l)}{(v\cdot l)^2}\,d^2l\right), \tag{3.29}$$

and this is the only way in which a gauge-dependent quantity appears in the classical asymptotic structure. It is natural and economic, therefore, to assume that the additive constant in $e\Phi_{V^{\text{out}}}(l)$ is a phase variable. Consequently, we put into one class gauges V^{out}_1 and V^{out}_2 such that $l\wedge V^{\text{out}}_1(s,l)=l\wedge V^{\text{out}}_2(s,l)$ and $\Phi_{V^{\text{out}}_2}(l)-\Phi_{V^{\text{out}}_1}(l)=n2\pi/e,\ n\in\mathbf{Z}$.

With the above knowledge of the classical structure we can now return to the problem of taking into account the Gauss constraint on the quantum level. The form (3.18) of this constraint is not suited for the translation to an abstract algebraic level. However, the physical interpretation prompts an indirect solution. Instead of either the pair $(V,f\,)$ or (V^{out},g) it is natural to work with the pair of variables having the direct physical meaning: the asymptotic total electromagnetic field V and the asymptotic field of charged particles, with their Coulomb fields included, g. The commutation relations (3.16) and (3.17) will be now reformulated in terms of these variables with the use of the relation

$$g(v)=e^{i\{V^e(v,.),V\}}f(v), \tag{3.30}$$

which is equivalent to (3.25) by $\{V^e(v,.),V(+\infty,.)\}=0$. Two circumstances have to be taken into account. First, on the classical level the Gauss constraint has been completely solved, so for the electromagnetic test field asymptotic the free field part only should be taken. Second, the quantization has to be consistent with our identifying the gauges differing by $n2\pi$ in $e\Phi(l)$. This problem is solved, as is easily seen from (3.16) and (3.17), by using the electromagnetic variable in the form $e^{-i\{V^{\text{out}}_1,V^{\text{q}}\}}$ only. Then, the relations (3.16) take the form

$$e^{-i\{V^{\text{out}}_1,V^{\text{q}}\}}e^{-i\{V^{\text{out}}_2,V^{\text{q}}\}}=e^{-i(1/2)\{V^{\text{out}}_1,V^{\text{out}}_2\}}e^{-i\{V^{\text{out}}_1+V^{\text{out}}_2,V^{\text{q}}\}}, \tag{3.31}$$

the relations (3.17) remain true for g^{q}, but now the two variables do not commute:

$$e^{-i\{V^{\text{out}}_1,V^{\text{q}}\}}g^{\text{q}}(v)=e^{+i\{V^{\text{out}}_1,V^e(v,.)\}}g^{\text{q}}e^{-i\{V^{\text{out}}_1,V^{\text{q}}\}}. \tag{3.32}$$

The last relation has an obvious physical interpretation: the element $g^{\text{q}}(v)$, besides its fermionic role, annihilates the Coulomb field with the asymptotic $V^e(v,l)$. This is, clearly, the implementation of Gauss' law on the quantum level. Note, also, that by (3.29) the relation is indeed consistent with our identification of gauge classes. Observe, furthermore, that the element $e^{-i\{V^{\text{out}}_1,V^{\text{q}}\}}$ creates the field with the asymptotic $V^{\text{out}}_1(s,l)$. The use of only free fields as test fields reflects the fact that the Coulomb field is fastened to a particle, which is a neat confirmation of the consistency of our scheme. Nevertheless, the element $e^{-i\{V^{\text{out}}_1,V^{\text{q}}\}}$ is a functional of the *total* field V^{q}, as assumed in the construction. This is seen from (3.32), and also from

$$\{V^{\text{out}}_1,V\}=\{V^{\text{out}}_1,V^{\text{out}}\}-\frac{1}{4\pi}\int V^{\text{out}}_1(-\infty,l)\cdot V(+\infty,l)d^2l. \tag{3.33}$$

It is clear from both arguments that in order to ''catch'' the whole field, it is absolutely necessary that all free test fields are admitted, also those infrared-singular, for which $V^{\text{out}}(-\infty,l)\neq 0$. This fact is to become of crucial importance for the interpretation of further results.

The quantum structure thus obtained will be now given an unobjectionable algebraic form, formulated in terms of elements heuristically identified by

$$W(V)=e^{-i\{V,V^{\mathrm{q}}\}},\quad B(g)=(g,g^{\mathrm{q}}),$$

where from now on all the test fields $V(s,l)$ are free fields, so we omit the superscript ''out.'' We have to specify the scope of the test functions. Let $\mathscr{K}$ be the Hilbert space of (equivalence classes of) $\mathbf{C}^4$-valued functions $g(v)$ on the hyperboloid $v^2=1$, $v^0>0$, with the scalar product (3.11). Let $\mathscr{V}$ be the linear space of homogeneous of degree -1 [Eq. (3.3)] functions $V_a(s,l)$, infinitely differentiable in both variables outside $l=0$ (differentiations with respect to l in the sense of the action of the operator L_{ab}) and satisfying the conditions

$$l\cdot V(s,l)=0, \tag{3.34}$$

$$|L_{b_1c_1}\cdots L_{b_kc_k}\dot{V}_a(s,l)|<\frac{\mathrm{const}(k)}{(t\cdot l)^2(1+|s|/t\cdot l)^{1+\epsilon}},\quad k=0,1,..., \tag{3.35}$$

$$V_a(+\infty,l)=0, \tag{3.36}$$

$$L_{[ab}V_{c]}(-\infty,l)=0, \tag{3.37}$$

where the second condition holds for some (V- and k-dependent) $\epsilon>0$ and for an arbitrarily chosen unit timelike, future-pointing vector t; the bounds are then true for any other such vector [with some other constants const(k)]. These bounds guarantee the existence of the limit functions as infinitely differentiable, homogeneous functions of degree -1. Let L be the Abelian additive group of elements (V) defined as pairs

$$(V)=(l\wedge V(s,l),\Phi_V(l)\bmod 2\pi/e), \tag{3.38}$$

where $V\in\mathscr{V}$ and Φ_V is defined by (3.23). In other words, L is the quotient of the additive group $\mathscr{V}$ through the equivalence relation $\sim$, $L=\mathscr{V}/\sim$, where

$$V_1\sim V_2\quad\text{iff}\quad V_2(s,l)-V_1(s,l)=l\alpha(s,l)\quad\text{and}\quad\frac{1}{4\pi}\int\alpha(-\infty,l)d^2l=n\,\frac{2\pi}{e}. \tag{3.39}$$

The group L inherits from $\mathscr{V}$ the symplectic form (3.10). Denote, also, for later use, $\mathscr{V}_0:=\{V\in\mathscr{V}\,|\,l\wedge V(-\infty,l)=0\}$ and $L_0:=\mathscr{V}_0/\sim$.

The symplectic group L and the Hilbert space $\mathscr{K}$ supply the test fields for the elements $W(V)$, $(V)\in L$ [the parenthesis in the symbol (V) appearing as an argument of W or of the symplectic form will be omitted], and $B(f)$, $f\in\mathscr{K}$, which generate a particular *-algebra $\mathscr{B}$ of Sec. II according to the relations

$$W(V)^*=W(-V),\quad W(0)=E,\quad W(V_1)W(V_2)=e^{-(i/2)\{V_1,V_2\}}W(V_1+V_2), \tag{3.40}$$

$$[B(g_1),\,B(g_2)]_+=0,\quad [B(g_1),\,B(g_2)^*]_+=(g_1,g_2)E, \tag{3.41}$$

$$W(V)B(g)=\beta_{\Phi_V}(B(g))W(V), \tag{3.42}$$

where

$$\beta_\Phi(B(g))=B(S_\Phi g),\quad (S_\Phi g)(v)=\exp\left(i\,\frac{e}{4\pi}\int\frac{\Phi(l)}{(v\cdot l)^2}\,d^2l\right)g(v). \tag{3.43}$$

Definition 3.1: The asymptotic field algebra is the C-algebra* $(\mathscr{F},\|.\|)$ *obtained from the above *-algebra* $\mathscr{B}$ *according to Definition 2.1.*

Let us consider the role of elements $W((0,c \bmod 2\pi/e))$, which form an Abelian one-parameter group $W((0,c_1 \bmod 2\pi/e))W((0,c_2 \bmod 2\pi/e))=W((0,c_1+c_2 \bmod 2\pi/e))$. The relations (3.4) and (3.33) suggest that in any representation in which $\pi(W((0,c \bmod 2\pi/e)))$ are strongly continuous and written as e^{icQ_π}, the operator Q_π has the interpretation of the charge operator. This interpretation is confirmed by the action of the automorphism γ_c of $\mathscr{F}$,

$$A \to \gamma_c(A) := W((0,c \bmod 2\pi/e))AW((0,c \bmod 2\pi/e))^* \tag{3.44}$$

on the basic elements:

$$\gamma_c(W(V)) = W(V), \quad \gamma_c(B(g)) = e^{-iec}B(g).$$

Now, as $2\pi/e = 0 (\mathrm{mod}\, 2\pi/e)$, there is $e^{i2\pi Q_\pi/e} = \mathbf{1}$, which implies that the spectrum of charge is contained in the set $\{ne | n \in \mathbf{Z}\}$. The variable $e\Phi(l)$ is connected with the free electromagnetic field, so bringing into play other carriers of charge should respect the phase character of the additive constant in this function. This means that the assumption in the following corollary is well founded.

Corollary 3.1: If a C-algebra of asymptotic fields contains the subalgebra generated by elements* $W((0,c \bmod 2\pi/e))$, *then the charge is quantized in units of* e.

In the following definition particular elements of $\mathscr{F}$ are distinguished as observables in the obvious way.

Definition 3.2: The algebra of observables $\mathscr{A}$ *is the C*-subalgebra of* $\mathscr{F}$ *of elements invariant under the gauge transformation (3.44).*

One has to stress at this point that all the Weyl elements are therefore (functions of) observables. Denying the elements with infrared-singular test functions $[V(-\infty, l) \neq 0]$ the status of observables one would deprive the total electromagnetic field of its Coulomb part, as discussed earlier. We shall return to this important point when discussing representations of our algebra. Also, all elements $B(f)^*B(g)$ are in $\mathscr{A}$.

The restricted Poincaré group (or rather its covering group) is represented in the group of automorphisms of the field algebra $\mathscr{F}$. One easily shows that the operators (3.8) and (3.9) [the variable $g(v)$ undergoes the same transformations as $f(v)$] satisfy the consistency condition (2.7), namely,

$$R_{x,A}S_\Phi = S_{T_{x,A}\Phi}R_{x,A},$$

where the transformation $[T_{x,A}\Phi](l) = \Phi(\Lambda^{-1}l)$ is implied by (3.8) and (3.23). Therefore, the action of the Poincaré group on $\mathscr{F}$ may be consistently defined by

$$\alpha_{x,A}(W(V)) = W(T_{x,A}V), \quad \alpha_{x,A}(B(g)) = B(R_{x,A}g).$$

We end this section with the demonstration that for free test fields the symplectic structure discussed above is an extension of the structure used in more traditional algebraic formulations. To see this we find the connection with the work of Roepstorff.[20] This author uses the electromagnetic test fields of the form $F_{ab}(x) = 4\pi \int D(x-y)(\nabla_a \varphi_b(y) - \nabla_b \varphi_a(y))\, d^4y$, where $D(x)$ is the Pauli–Jordan function and $\varphi_a(x) = \nabla^b \varphi_{ab}(x)$ for some antisymmetric test function of compact support $\varphi_{ab}(x)$. With the use of representation $D(x) = (1/8\pi^2)\int \delta'(x \cdot l)\, d^2l$ a Lorentz gauge potential for this field takes the form (3.19), with

$$V_a(s,l) = \int \delta(s - y \cdot l)\varphi_a(y)\, d^4y. \tag{3.45}$$

Substituting two functions of this form in (3.10) one has

$$\{V_1, V_2\} = 4\pi \int \varphi_1^a(x) D(x-y) \varphi_{2a}(y)\, d^4x\, d^4y. \tag{3.46}$$

The rhs is the symplectic form used by Roepstorff (up to multiplicative constants due to electromagnetic conventions). However, the space of test fields is smaller in this formulation. It is obvious from (3.45) that $V_a(-\infty, l) = 0$, so all these fields are infrared-regular (the spacelike asymptotic of F_{ab} has no $1/r^2$ term). In fact, even a stronger regularity property holds. There is $V_a(s, l) = \dot{J}_a(s, l)$, where $J_a(s, l)$ is a smooth function vanishing outside a compact region (for a fixed scaling $t \cdot l = 1$), given by $J_a(s, l) = \int \delta(s - y \cdot l) l^b \varphi_{ab}(y)\, d^4y$. It will prove convenient to reformulate the above formulas in the Fourier-transformed version. It is shown in Sec. V below that

$$\{V_1,V_2\}=i\mathrm{P}\int \overline{\tilde{V}_1}\cdot\tilde{V}_2(\omega,l)\,\frac{d\omega}{\omega}\,d^2l, \tag{3.47}$$

where P denotes the principal value. If $\tilde{V}_a(\omega,l)$ vanishes for $\omega\to 0$ sufficiently fast (e.g., as $|\omega|^{\epsilon}$), then the principal value sign may be omitted. This is true, in particular, for V given by (3.45). In this case $\tilde{V}_a(\omega,l)=\hat{\varphi}_a(\omega l)$, where $\hat{\varphi}(p)=(1/2\pi)\int\varphi(x)e^{ip\cdot x}\,d^4x$, and then $\tilde{V}_a(\omega,l)=-i\omega\hat{\varphi}_a(\omega l)$. On the other hand, the last equation shows that our general field satisfies the condition of Roepstorff's space L_1.

IV. EXISTENCE OF CHARGE AND ENERGY-MOMENTUM, AND THE REGULARITY OF REPRESENTATIONS

In the present section we investigate the consequences of putting some physical restrictions on representations. The following definitions, the second of which is standard,[5] will simplify the formulation of propositions.

Definition 4.1: (i) A representation π of $\mathscr{T}$ will be called a charge-representation of $\mathscr{T}$ iff the one-parameter group $\mathbf{R}\ni c\to\pi(W((0,c \bmod 2\pi/e)))$ is strongly continuous.

(ii) A representation π of the algebra $\mathscr{T}$ acting in the Hilbert space $\mathscr{H}$ is said to satisfy Borchers' criterion iff there exists a unitary, strongly continuous representation of the translation group $U(x)$ acting in $\mathscr{H}$, with the spectrum contained in the closed forward lightcone, Spec $U(x)\subset\overline{V_+}$, *and implementing translations of all $A\in\mathscr{T}$*:

$$\pi(\alpha_x A)=U(x)\,\pi(A)\,U(-x). \tag{4.1}$$

(iii) A representation π of the algebra $\mathscr{T}$ will be said to satisfy Borchers' criterion with respect to $\mathscr{A}$ (wrt observables) iff the restriction of π to the subalgebra $\mathscr{A}$ satisfies Borchers' criterion.

The defining properties of (i) and (iii) are necessary requirements for a physically admissible representation. We analyze their implications.

Proposition 4.1: If π is a charge-representation of $\mathscr{T}$, then it has one of the following properties (or is a direct sum of these three types):

(i) The charge takes on all the values ke, $k\in\mathbf{Z}$, and each charge eigenspace is cyclic.

(ii) [resp. (iii)] The subspace of vectors satisfying $\pi(B(g))\psi=0\ \ \forall g\in\mathscr{K}$ [resp. $\pi(B(g)^*)\psi=0\ \ \forall g\in\mathscr{K}$] is cyclic.

Proof: Given $\pi(\mathscr{T})$ on $\mathscr{H}$ let $\mathscr{H}_k\subset\mathscr{H}$ be the subspace of all charge eigenvectors to the eigenvalue ke for a given $k\in\mathbf{Z}$, and let $\mathscr{H}'_k=[\pi(\mathscr{T})\mathscr{H}_k]$ [the closed linear subspace spanned by vectors in $\pi(\mathscr{T})\mathscr{H}_k$]. Then $\mathscr{H}=\mathscr{H}'_k\oplus\mathscr{H}'^{\perp}_k$, where both subspaces are invariant. Moreover, if we split $\mathscr{H}'^{\perp}_k=\mathscr{H}'_{k+}\oplus\mathscr{H}'_{k-}$, where the spectrum of charge goes from $(k+1)e$ upwards on $\mathscr{H}'_{k+}$ and from $(k-1)e$ downwards on $\mathscr{H}'_{k-}$, then both subspaces are separately invariant. This occurs because the generating elements $\pi((W(V)))$, $\pi(B(g))$ and $\pi(B(g)^*)$ carry charge 0 or $\pm e$, so they cannot match the gap between $\mathscr{H}'_{k+}$ and $\mathscr{H}'_{k-}$.

The representations $\pi(\mathscr{T})|_{\mathscr{H}'_{k+}}$ and $\pi(\mathscr{T})|_{\mathscr{H}'_{k-}}$ have the properties (ii) and (iii), respectively. To see this, let $\mathscr{H}''_{k+}$ be the subspace of $\mathscr{H}'_{k+}$ of vectors satisfying the equation in (ii). Let ψ be an element of the invariant subspace $\mathscr{H}'_{k+}\cap[\pi(\mathscr{T})\mathscr{H}''_{k+}]^{\perp}$, with a bounded spectral content of charge [these vectors form a dense subspace as $e^{icQ_\pi}\in\pi(\mathscr{T})$]. If $\psi\neq 0$, then there exists such $f\in\mathscr{K}$ that $\pi(B(f))\psi\neq 0$. Continuing in this way one can lower the charge spectral content of the vector unlimitedly. This contradicts the charge content of $\mathscr{H}'_{k+}$. A similar proof holds for $\pi(\mathscr{T})|_{\mathscr{H}'_{k-}}$.

The rest of the proof is simple inductive reasoning. Let the set of integers $\mathbf{Z}$ be organized into a sequence $\{k_n\}$. Suppose that for $\pi(\mathscr{T})$ on $\mathscr{H}(n)$ the charge eigensubspaces $\mathscr{H}_{k_1},\ldots,\mathscr{H}_{k_n}$ are cyclic. Take the next charge eigenspace $\mathscr{H}_{k_{n+1}}$ and decompose $\mathscr{H}(n)$ according to the above prescription: $\mathscr{H}(n)=\mathscr{H}'_{k_{n+1}}\oplus\mathscr{H}'_{k_{n+1}+}\oplus\mathscr{H}'_{k_{n+1}-}$. The representations $\pi(\mathscr{T})|\mathscr{H}'_{k_{n+1}\pm}$ satisfy the properties (ii) and (iii), respectively. By construction $\mathscr{H}_{k_{n+1}}$ is cyclic for $\pi(\mathscr{T})$ on $\mathscr{H}(n+1):=\mathscr{H}'_{k_{n+1}}$. As each of the subspaces $\mathscr{H}'_{k_{n+1}}$, $\mathscr{H}'_{k_{n+1}+}$, and $\mathscr{H}'_{k_{n+1}-}$ is invariant, in particular with respect to charge operator, so $\mathscr{H}_{k_i}=(\mathscr{H}_{k_i}\cap\mathscr{H}'_{k_{n+1}})\oplus(\mathscr{H}_{k_i}\cap\mathscr{H}'_{k_{n+1}+})$

$\oplus(\mathscr{H}_{k_i}\cap\mathscr{H}'_{k_{n+1}-})$, and the spaces $\mathscr{H}_{k_i}\cap\mathscr{H}(n+1)$ are cyclic in $\mathscr{H}(n+1)$ for $i=1,...,n$. Continuing in this way we obtain a direct sum of representations satisfying the properties (ii) or (iii) and a representation on $\mathscr{H}=\cap_{n=1}^{\infty}\mathscr{H}(n)$, which satisfies the property (i) by construction. □

If, in addition to the charge, physical energy-momentum observables are assumed to exist, then one has the following result.

Proposition 4.2: The charge spectrum consists of all values ke, $k\in\mathbf{Z}$, and eigenspace to each charge value is cyclic for a charge-representation of $\mathscr{F}$ satisfying Borchers' criterion with respect to observables.

The proof of the proposition will be based on the following observation.

Lemma 4.3: If the representation π of $\mathscr{F}$ has the property (ii) of Proposition 4.1, then it is unitarily equivalent to a representation of type (2.10), where π_f is the Fock representation based on the cyclic vector Ω_f satisfying $\pi_f(B(g))\Omega_f=0\ \forall g\in\mathscr{K}$.

An analogous result holds for representations satisfying the property (iii) of Proposition 4.1. [In that case π_f is the Fock representation based on the cyclic vector satisfying $\pi_f(B(g)^*)\Omega_f=0\ \forall g\in\mathscr{K}$. We use the term Fock representation in the wider sense, referring to any of the representations differing by a Bogoliubov transformation from the one appearing in the lemma.]

Proof: Let the representation π act in $\mathscr{H}$ and denote the respective cyclic subspace by $\mathscr{H}_r$. If $C\in{}^*\mathrm{CAR}$, then it may be represented as $C=\omega_F(C)E+C'$, where ω_F is the Fock state and C' is a sum of elements having $B(f)$ on the right and/or $B(g)^*$ on the left. Therefore for $\varphi,\ \psi\in\mathscr{H}_r$ there is $(\varphi,\pi(C)\psi)=\omega_F(C)(\varphi,\psi)$. $\mathscr{H}_r$ is invariant under $\pi(W(V))$, hence the vectors $\Sigma_{k=1}^{N}\pi(C_k)\varphi_k$, $\varphi_k\in\mathscr{H}_r$, are dense in $\mathscr{H}$. Let π_r be the restriction of π to the Weyl algebra and to the space $\mathscr{H}_r$. We map $\mathscr{H}$ onto $\mathscr{H}_F\otimes\mathscr{H}_r$ ($\mathscr{H}_F$ is the Hilbert space of the Fock representation π_F) by the rule $\Sigma_k\pi(C_k)\varphi_k\to\Sigma_k\pi_F(C_k)\Omega_F\otimes\varphi_k$. It is now easy to show this is a unitary map providing the claimed equivalence of representations. □

Proof of Proposition 4.2: In view of the result of Proposition 4.1 one has to show that a representation of the type described in the lemma cannot be a subrepresentation of a representation satisfying the assumptions of Proposition 4.2. By a general theorem by Borchers[21] (see also Ref. 5) the representation $U(x)$ may be chosen to lie in $\pi(\mathscr{A})''$, hence it suffices to show that for the representation of the lemma itself there is no $U(x)$ in $\pi(\mathscr{A})''$ implementing translations of observables and satisfying the spectral condition. Suppose the converse is true. Then for any $C\in\mathrm{CAR}\cap\mathscr{A}$ there is $U(x)\pi(C)U(-x)=\pi(\alpha_x C)=\pi_F(\alpha_x C)\otimes\mathbf{1}_r=[U_F(x)\otimes\mathbf{1}_r][\pi_F(C)\otimes\mathbf{1}_r]\times[U_F(-x)\otimes\mathbf{1}_r]$, where $U_F(x)$ is the unitary representation of translations in the Fock representation. This means that $U(x)[U_F(-x)\otimes\mathbf{1}_r]\equiv R(x)$ commutes with $\pi_F(C)\otimes\mathbf{1}_r$ for all $C\in\mathrm{CAR}\cap\mathscr{A}$. The representation $\pi_F(\mathrm{CAR}\cap\mathscr{A})$ acts irreducibly on each of the subspaces $\mathscr{H}_n\subset\mathscr{H}_F$ spanned by all vectors $\pi_F(B(g_1)^*\cdots B(g_n)^*)\Omega_F$, and all spaces $\mathscr{H}_n\otimes\mathscr{H}_r$ are invariant with respect to $R(x)$ [as they are invariant with respect to $\pi(\mathscr{A})$]. Hence, $U(x)|_{\mathscr{H}_n\otimes\mathscr{H}_r}=U_F(x)|_{\mathscr{H}_n}\otimes U_{r,n}(x)$, where $U_{r,n}$ is a strongly continuous representation of translations in $\mathscr{H}_r$. However, the Fock representation π_F appearing in this construction is not ''the right'' Fock representation of the free Dirac field [$B(g)$ contains both positive and negative frequencies], and the energy spectrum of $U_F(x)|_{\mathscr{H}_n}$ is not bounded from below for $n\geqslant 1$, which contradicts the assumption. □

The existence of a charge operator is a necessary, but by far not a sufficient condition for the operators $\pi(W(V))$ to have a clear physical interpretation. We recall that, as explained in the previous section, in our algebra all these Weyl operators should be understood as observables, more precisely, as exponentials of (unbounded) observable electromagnetic field operators. The test function set L is an Abelian group rather than a vector space, so a direct multiplication of V by a parameter is not possible. However, it is sufficient to find a map $\mathbf{R}\ni\lambda\to(V^\lambda)\in L$, such that $(V^0)=(0)$, $(V^1)=(V)$, $(V^\lambda)+(V^\nu)=(V^{\lambda+\nu})$, and $-(V^\lambda)=(V^{-\lambda})$. Then $W(V^\lambda)$ is a one-parameter group and the above condition on the representation may be formulated as the strong continuity of $\pi(W(V^\lambda))$ in λ. Let $(V)=(l\wedge V,\Phi \bmod 2\pi/e)$. Then it is easily shown that for each choice of the representant Φ from the class $\Phi \bmod 2\pi/e$ the map

$$\mathbf{R}\ni\lambda\to(V^\lambda)_\Phi:=(l\wedge\lambda V,\lambda\Phi \bmod 2\pi/e) \tag{4.2}$$

satisfies the listed requirements.

Definition 4.2: Representation π of the algebra $\mathscr{T}$ (or of a subalgebra of $\mathscr{T}$) will be called regular iff all one-parameter groups $\mathbf{R}\ni\lambda\to\pi(W((V^\lambda)_\Phi))$ are strongly continuous.

Remarks: (i) If π is regular, then it is a charge representation. This follows by the special choice $(V)=(0,c \bmod 2\pi/e)$.

(ii) The generators of the groups $\pi(W((V^\lambda)_{\Phi'}))$ and $\pi(W((V^\lambda)_\Phi))$, where $\Phi' \in \Phi \bmod 2\pi/e$, differ by a multiple of the charge operator. This follows from $W((V^\lambda)_{\Phi'}) = W((V^\lambda)_\Phi)W((0,\lambda 2k\pi/e \bmod 2\pi/e))$ for $\Phi'=\Phi+2k\pi/e$.

We are now prepared to partly characterize the representations satisfying the condition of Definition 4.1 (ii). For the positive energy Fock representation π_F of the algebra CAR let us denote $\pi_F(B(g))=\int \overline{g(v)}\gamma\cdot v b(v)\, d\mu(v)$ and let :...: denote the standard normal ordering.

Theorem 4.4: *(i) A representation π of the algebra $\mathscr{T}$ satisfies Borchers' criterion if, and only if, it is unitarily equivalent to a representation of type (2.10), where $\pi_f=\pi_F$ is the positive energy Fock representation of* CAR *and π_r is a representation of the Weyl algebra satisfying Borchers' criterion.*

For representations of this type, the Gauss constraint in the form (3.18) is recovered in the von Neumann algebra $\pi(\mathscr{A})''$:

$$\pi(W(V))=\exp\left(-i\int :\overline{b(v)}\gamma\cdot v b(v):\{V,V^e(v,\cdot)\}d\mu(v)\right)\otimes\pi_r(W(V)). \tag{4.3}$$

(ii) π is irreducible iff π_r is irreducible.

(iii) π is regular iff π_r is regular.

Remark: For $\pi(\mathscr{T})$ in the form given by (i) the operator $\mathbf{1}\otimes\pi_r(W(V))$ has the interpretation of the free field exponent, and one sees once more the essentiality of the regularity assumption.

Proof: If the unitary equivalence is proved, then (4.3) follows by simple calculation. This formula then implies (ii) by irreducibility of the Fock representation [and the identity[22] $(\mathscr{L}(\mathscr{H}_F)\otimes\pi_r(\mathrm{CCR}))'=\mathbf{C}\mathbf{1}_F\otimes\pi_r(\mathrm{CCR})'$] and (iii) by $\{(V^\lambda)_\Phi,V^e(v,\cdot)\}=-\lambda(e/4\pi)\times\int(\Phi(l)/(v\cdot l)^2)\, d^2l$. The equivalence of representations is proved by adapting to the present case the idea of Ref. 23. Let $g\in\mathscr{K}$. The positive and negative frequency parts of g are easily extracted from g by $g_\pm=P_\pm g$, where $P_\pm$ are projection operators in $\mathscr{K}$ defined by $(P_\pm g)(v)=P_\pm(v)g(v)$, $P_\pm(v)=\frac{1}{2}(1\pm\gamma\cdot v)$. Let π satisfy Borchers' criterion. From translational covariance one shows in standard way that $\pi(B(g_+))$ and $\pi(B(g_-))^*$ [resp. $\pi(B(g_+))^*$ and $\pi(B(g_-))$] lower (resp. raise) the energy content of a vector by at least m (the mass of the fermion). Let $\mathscr{H}_r$ be the subspace of the representation space formed by all vectors φ satisfying $\pi(B(g_+))\varphi=\pi(B(g_-))^*\varphi=0\,\forall g\in\mathscr{K}$. The subspace $\mathscr{H}_r$ is invariant under U and the subspaces $[\pi(\mathscr{T})\mathscr{H}_r]$ and $[\pi(\mathscr{T})\mathscr{H}_r]^\perp$ are invariant both under π and U. Let $\psi\neq 0$ lie in the dense subspace of finite energy vectors in $[\pi(\mathscr{T})\mathscr{H}_r]^\perp$. Then for some $g\in\mathscr{K}$ there is $\pi(B(g_+))\psi\neq 0$ or $\pi(B(g_-))^*\psi\neq 0$. By recurrence, this gives the way for reaching negative energies, which contradicts the assumption. Hence $\mathscr{H}_r$ is cyclic for $\pi(\mathscr{T})$. The unitary equivalence to a representation of type (2.10) follows now as in the proof of Lemma 4.3. However, the Fock representation appearing in the construction is in the present case ''the right,'' positive energy Fock representation. The use of Proposition 2.4 finishes the proof. From this proposition also the ''if'' statement of (i) follows easily. □

Our next objectives are the characterization of vacuum states on our algebra, and the construction of a class of physically meaningful regular representations. The first problem is solved by the adaptation to the present situation of standard analytical methods. We shall have to discuss some properties of the symplectic space of test functions. For $V\in\mathscr{V}$ let us denote by $[\dot V]$ the respective *field* test function, i.e., the equivalence class of $\dot V$ with respect to the equivalence

$$\dot V'\approx\dot V \ \text{ iff } \ l\wedge\dot V'=l\wedge\dot V. \tag{4.4}$$

The vector space of these classes will be denoted by L^f, and its subspace of classes $[\dot V]$ with $l\wedge V(-\infty,l)=0$ by L^f_0. The space L^f inherits the symplectic form from $\mathscr{V}$, $\{[\dot V_1],[\dot V_2]\}=\{V_1,V_2\}$. Now the analytical properties of this space needed for the characterization of vacuum

states will also play a role for its extension $\hat{L}^f$ to be used in the construction of regular representations. Therefore, in the next section we introduce this auxiliary symplectic space and formulate the necessary properties in this wider setting.

V. EXTENSION AND ANALYTICAL PROPERTIES OF SYMPLECTIC STRUCTURE

The first step towards extension of the symplectic space of test fields L^f will be generalizing the falloff condition (3.35) for $k=0$. We do it first for scalar functions. Consider the real Hilbert space $L^2_{\epsilon,t}$ of (equivalence classes of) real, measurable functions $f(s,l)$, homogeneous of degree -2, with finite norm

$$\|f\|^2_{\epsilon,t}=\int f^2(\tau t\cdot l,l)(|\tau|+1)^{1+\epsilon}(t\cdot l)^2\, d\tau\, d^2l, \tag{5.1}$$

where $\epsilon>0$ and t is a unit future-pointing vector. If $\tilde{t}$ is another future-pointing vector and $c_{\tilde{t}\cdot t}\equiv\tilde{t}\cdot t+\sqrt{(\tilde{t}\cdot t)^2-1}$, then for every null vector l there is $c^{-1}_{\tilde{t}\cdot t}\leqslant\tilde{t}\cdot l/t\cdot l\leqslant c_{\tilde{t}\cdot t}$. Using these bounds one shows that $c^{-2-\epsilon}_{\tilde{t}\cdot t}\|f\|^2_{\epsilon,t}\leqslant\|f\|^2_{\epsilon,\tilde{t}}\leqslant c^{2+\epsilon}_{\tilde{t}\cdot t}\|f\|^2_{\epsilon,t}$. Therefore $L^2_{\epsilon,t}$ does not depend on t when considered as a linear topological space. Components of smooth functions satisfying (3.35) obviously lie in this space.

If $f\in L^2_{\epsilon,t}$ then for $\delta<\epsilon$

$$\begin{aligned}&\int |f(\tau t\cdot l,l)|(|\tau|+1)^{\delta/2}|f(st\cdot l,l)|(|s|+1)^{\delta/2}(t\cdot l)^2 d\tau\, ds\, d^2l\\ &\leqslant\left(\int\left[\int|f(\tau t\cdot l,l)|^2(t\cdot l)^2d^2l\right]^{1/2}(|\tau|+1)^{\delta/2}\,d\tau\right)^2\leqslant\frac{2}{\epsilon-\delta}\|f\|^2_{\epsilon,t}.\end{aligned}$$

Consequently, the integral $\int|f(\tau t\cdot l,l)|(|\tau|+1)^{\delta/2}\,d\tau\, t\cdot l$ is finite d^2l-almost everywhere and as a function of l (homogeneous of degree -1) is square integrable with respect to d^2l. In particular, the Fourier transform of $f(s,l)$ with respect to s is defined by the integral (3.21), satisfies

$$\int\left|\tilde{f}\left(\frac{\omega}{t\cdot l},l\right)\right|^2 d^2l\leqslant\frac{1}{2\pi^2\epsilon}\|f\|^2_{\epsilon,t}, \tag{5.2}$$

and

$$\int\left|\tilde{f}\left(\frac{\omega}{t\cdot l},l\right)\right|^2 d\omega=\frac{1}{2\pi}\int f^2(\tau t\cdot l,l)d\tau(t\cdot l)^2. \tag{5.3}$$

The function $\tilde{f}(\omega/t\cdot l,l)$ depends continuously on ω, both pointwise in l and as an element of the Hilbert space $L^2(d^2l)$. In fact, even stronger conditions are satisfied. With the use of the bound $|e^{ix}-1|<2|x|^\alpha$ for $0\leqslant\alpha<1$, one finds for any $\delta\in\langle 0,\min\{2,\epsilon\}\rangle$

$$\left|\tilde{f}\left(\frac{\omega'}{t\cdot l},l\right)-\tilde{f}\left(\frac{\omega}{t\cdot l},l\right)\right|\leqslant\frac{1}{\pi}\,|\omega'-\omega|^{\delta/2}\int|\tau|^{\delta/2}|f(\tau t\cdot l,l)|d\tau\,t\cdot l, \tag{5.4}$$

and then

$$\int\left|\tilde{f}\left(\frac{\omega'}{t\cdot l},l\right)-\tilde{f}\left(\frac{\omega}{t\cdot l},l\right)\right|^2 d^2l\leqslant\frac{2}{(\epsilon-\delta)\pi^2}\,\|f\|^2_{\epsilon,t}|\omega'-\omega|^{\delta}. \tag{5.5}$$

This implies, with the use of (5.2),

$$\left|\int\left|\tilde{f}\left(\frac{\omega'}{t\cdot l},l\right)\right|^2 d^2l-\int\left|\tilde{f}\left(\frac{\omega}{t\cdot l},l\right)\right|^2 d^2l\right|\leqslant\frac{2}{\pi^2\sqrt{\epsilon(\epsilon-\delta)}}\,\|f\|^2_{\epsilon,t}|\omega'-\omega|^{\delta/2}. \tag{5.6}$$

Next, we derive some integral identities. Let $\tilde{K}_{\alpha,\beta}(\omega)=\omega^{-1}\chi_{\alpha,\beta}(\omega)$, where $\chi_{\alpha,\beta}$ is the characteristic function of the set $\langle-\beta,-\alpha\rangle\cup\langle\alpha,\beta\rangle$, and let $f,g\in L^2_{\epsilon,t}$. For almost all l the function $(1/(2\pi)^2)f(\tau,l)\tilde{K}_{\alpha,\beta}(\omega)e^{-i\omega(\tau-s)}g(s,l)$ is absolutely integrable with respect to $d\tau\,ds\,d\omega$, so the iterated integrals are equal, i.e.,

$$\frac{1}{(2\pi)^2}\int f(\tau,l)K_{\alpha,\beta}(\tau-s)g(s,l)d\tau\,ds=\int_{|\omega|\in\langle\alpha,\beta\rangle}\overline{\tilde{f}(\omega,l)}\tilde{g}(\omega,l)\,\frac{d\omega}{\omega}. \tag{5.7}$$

$K_{\alpha,\beta}(s)$ is uniformly bounded and $\lim_{\alpha\to0}\lim_{\beta\to\infty}K_{\alpha,\beta}(s)=-i\pi\epsilon(s)$, so

$$\frac{1}{4\pi}\int f(\tau,l)\epsilon(\tau-s)g(s,l)d\tau\,ds=i\mathrm{P}\int\overline{\tilde{f}(\omega,l)}\tilde{g}(\omega,l)\,\frac{d\omega}{\omega}, \tag{5.8}$$

where P denotes the principal value operation. Integrating over d^2l we obtain

$$\frac{1}{4\pi}\int d^2l\int f(\tau,l)\epsilon(\tau-s)g(s,l)d\tau\,ds=i\int d^2l\,\mathrm{P}\int\overline{\tilde{f}(\omega,l)}\tilde{g}(\omega,l)\,\frac{d\omega}{\omega}. \tag{5.9}$$

Another form of the Fourier representation of this integral will be useful. We integrate $f(\tau' t\cdot l,l)\tilde{K}_{\alpha,\beta}(\omega)e^{-i\omega(\tau'-s')}g(s' t\cdot l,l)(t\cdot l)^2$ over $ds'\,d\tau'\,d^2l d\omega$, and then calculate the limits (in the same order as before). Changing the variables τ',s' back to τ,s we have

$$\frac{1}{4\pi}\int d^2l\int f(\tau,l)\epsilon(\tau-s)g(s,l)d\tau\,ds=i\mathrm{P}\int\frac{d\omega'}{\omega'}\int\overline{\tilde{f}\left(\frac{\omega'}{t\cdot l},l\right)}\tilde{g}\left(\frac{\omega'}{t\cdot l},l\right)d^2l. \tag{5.10}$$

Consider now the linear space of vector functions $u_a(\tau,l)$ such that $l\cdot u(\tau,l)=0$ and each component of u_a (in any Minkowski frame) is an element of the space $L^2_{\epsilon,t}$. Divide this space into classes with respect to the equivalence relation (4.4): $[u_a]=u_a(\tau,l)$ mod $\alpha(s,l)l_a$. We denote this factor space by $\mathscr{T}_\epsilon$. For decreasing ϵ the spaces $\mathscr{T}_\epsilon$ form an increasing family of vector spaces. Their union $\mathscr{T}:=\cup_{\epsilon>0}\mathscr{T}_\epsilon$ is therefore again a vector space. We now list some properties of $\mathscr{T}$ and of some structures on it. Simple proofs based on the preceding discussion are omitted.

$\mathscr{T}$ becomes a symplectic space with the form

$$\begin{aligned}\{[u_1],[u_2]\}&=\frac{1}{4\pi}\int d^2l\int u_{1a}(\tau,l)\epsilon(\tau-s)u_2^a(s,l)d\tau\,ds\\&=-i\mathrm{P}\int\frac{d\omega'}{\omega'}\int\left[-\overline{\tilde{u}_{1a}\left(\frac{\omega'}{t\cdot l},l\right)}\tilde{u}^a_2\left(\frac{\omega'}{t\cdot l},l\right)\right]d^2l.\end{aligned} \tag{5.11}$$

The form is nondegenerate on $\mathscr{T}$. Consider, further, the linear space of real, measurable vector functions $f_a(l)$ on the cone, homogeneous of degree -1, orthogonal to $l, l\cdot f(l)=0$, and such that each

component is an element of the Hilbert space $L^2(d^2l)$. Divide this space into equivalence classes $[f_a](l):=f_a(l)\text{mod }\beta(l)l_a$. This factor space is a real Hilbert space, denoted by $\mathscr{H}_0$, with the scalar product

$$([f_1],[f_2])_0=\int [-f_{1a}(l)f_2^a(l)]d^2l. \tag{5.12}$$

Now, one easily shows with the use of (5.2) that if $[u]\in\mathscr{T}$, then $[\tilde{u}(0,\cdot)]\in\mathscr{H}_0$. The map

$$\mathscr{T}\ni[u]\to p([u])=[\tilde{u}(0,\cdot)]\in\mathscr{H}_0 \tag{5.13}$$

is linear and onto, $p(\mathscr{T})=\mathscr{H}_0$ {for a given $[f]\in\mathscr{H}_0$ put $u_a(s,l)=f_a(l)(t\cdot l)^{-1}h(s/t\cdot l)$, with h of compact support and $\tilde{h}(0)=1$; then $p([u])=[f]$}. If at least one of the pair of functions $[u_i]\in\mathscr{T}$, $i=1,2$, satisfies $p([u_i])=0$, then, by (5.4), the following integral is well defined:

$$F([u_1],[u_2])=\int_{\omega\geqslant 0}[-\overline{\tilde{u}_{1a}(\omega,l)}\tilde{u}_2^a(\omega,l)]\,\frac{d\omega}{\omega}\,d^2l, \tag{5.14}$$

and the symplectic form may be expressed by

$$\{[u_1],[u_2]\}=2\,\text{Im}\,F([u_1],[u_2]), \tag{5.15}$$

where the hermiticity of F has been used:

$$\overline{F([u_1],[u_2])}=F([u_2],[u_1]). \tag{5.16}$$

For almost all l the integral $U_a(s,l)=-\int_s^{+\infty}u_a(\tau,l)\,d\tau$ is well defined for all s, and for almost all s there is $(\partial/\partial_s)U_a(s,l)=u_a(s,l)$. It is now easy to see that the functions $U_a(s,l)$ generalize the test functions $V_a(s,l)$, and the symplectic form (5.11) extends the form (3.10). The limit values at $-\infty$ may be expressed by $U_a(-\infty,l)=-2\pi\tilde{u}_a(0,l)$. The only essential property of V_a which has not been taken into account yet is (3.22), $l_{[a}\tilde{V}_{b]}(0,l)=-(1/2\pi)l_{[a}\partial_{b]}\Phi(l)$. In order to formulate its generalization for U_a consider the Hilbert subspace $\mathscr{H}_{IR}$ of $\mathscr{H}_0$ obtained as the closure of the linear subspace of elements $[\partial_a\phi]$, where ϕ is a real smooth homogeneous function of degree 0 {different extensions of $\phi(l)$ outside the cone yield $\partial_a\phi(l)$ on the cone in one class $[\partial_a\phi]$},

$$\mathscr{H}_{IR}:=\overline{\{[\partial_a\phi]\in\mathscr{H}_0|\,\phi\in\mathscr{C}^\infty\}}^{\mathscr{H}_0}. \tag{5.17}$$

For $\phi\in\mathscr{C}^\infty$ the class $[\partial_a\phi]$ determines ϕ uniquely up to a constant. With the notation $[\phi]\equiv\phi$ mod const, the map $[\partial_a\phi]\to[\phi]$ is linear and injective. We show in the Appendix that this map extends canonically to an injective map j of $\mathscr{H}_{IR}$ into the space of classes $[\phi]$ with ϕ square-integrable with respect to any (and all) of the measures $d^2l/(t\cdot l)^2$. In this way every element of $\mathscr{H}_{IR}$ corresponds uniquely to some $[\phi]\in j(\mathscr{H}_{IR})$, and may be written in this generalized sense as $[\partial_a\phi]$.

The extended symplectic space is now chosen as the subspace of $\mathscr{T}$ given by $\hat{L}^f:=p^{-1}(\mathscr{H}_{IR})$, with p defined in (5.13), and equipped with the symplectic form (5.11). The elements of $\hat{L}^f$ satisfying $p([u])=0$ form a linear subspace, denoted by $\hat{L}_0^f$. These structures extend the field test functions spaces $L^f\subset\hat{L}^f$ and $L_0^f=L^f\cap\hat{L}_0^f$.

The following properties of the form $F(.,.)$ will be needed for the characterization of vacuum states.

Lemma 5.1: (i) For each pair $[u_i]\in\hat{L}^f$, $i=1,2$, *the function* $x\to F([u_1],[T_xu_2-u_2])$ *is the boundary value for* $\text{Im}\,z=0$ *of the function*

$$\mathbf{R}^4+i\overline{V_+}\ni z\to F([u_1],[T_zu_2-u_2]):=-\int_{\omega\geqslant 0}(e^{i\omega l\cdot z}-1)\overline{\tilde{u}_1}\cdot\tilde{u}_2(\omega,l)\,\frac{d\omega}{\omega}\,d^2l,$$

which is continuous on its domain and analytic on $\mathbf{R}^4+iV_+$.
The following bounds (ii)–(iv) hold on the whole domain $z=x+iy\in\mathbf{R}^4+i\overline{V_+}$.

(ii) For any fixed, unit, future-pointing vector t,

$$|e^{F([u_1],[T_zu_2-u_2])}|\leqslant C(t,[u_1],[u_2])[(1+y^0+|\vec{y}|)^2+(|x^0|+|\vec{x}|)^2]^{(1/2)\int \tilde{u}_1\cdot\tilde{u}_2(0,l)\,\theta(\tilde{u}_1\cdot\tilde{u}_2(0,l))d^2l},$$

where $y^0\equiv y\cdot t$, $|\vec{y}|\equiv\sqrt{(y\cdot t)^2-y^2}$ *(and the same for x), and* $\theta(\cdot)$ *is the Heaviside step function.*

(iii) If $\tilde{u}_1\cdot\tilde{u}_2(0,l)\leqslant 0$ d^2l*-almost everywhere, then*

$$|e^{F([u_1],[T_zu_2-u_2])}|\leqslant C(t,[u_1],[u_2])[(1+y^0-|\vec{y}|)^2+\theta(x\cdot x)(|x^0|-|\vec{x}|)^2]^{-(1/2)\int|\tilde{u}_1\cdot\tilde{u}_2(0,l)|d^2l}.$$

(iv) If $\tilde{u}_1\cdot\tilde{u}_2(0,l)\geqslant 0$ d^2l*-almost everywhere, then*

$$|e^{-F([u_1],[T_zu_2-u_2])}|\leqslant C(t,[u_1],[u_2]).$$

(v) If $p([u_1+u_2])=0$, *then for* $x\in\mathbf{R}^4$

$$F([u_1+T_xu_2],[u_1+T_xu_2])=F([u_1],[T_xu_2-u_2])+F([T_xu_2-u_2],[u_1])+F([u_1+u_2],[u_1+u_2]).$$

(vi) The Fourier representation (5.14) of $F(.,.)$ *is the usual one-photon scalar product when restricted to* $\hat{L}_0^f$, *which yields a dense subspace of the one-photon Hilbert space, and*

$$F([T_xu_1],[T_xu_2])=F([u_1],[u_2]).$$

Proof: If $z\in\mathbf{R}^4+iV_+$, then for any $k\in\mathbf{R}^4$ the function $\mathbf{C}\ni\xi\to F([u_1],[T_{z+\xi k}u_2-u_2])$ is analytic in some neighborhood of $\xi=0$, which implies (i) by Hartog's theorem. Properties (ii)–(iv) follow easily from the bound

$$\left|F([u_1],[T_zu_2-u_2])-\int\tilde{u}_1\cdot\tilde{u}_2(0,l)\ln\left|1-i\,\frac{z\cdot l}{t\cdot l}\right|d^2l\right|\leqslant\text{const}(t,[u_1],[u_2]),$$

and the inequalities $1\leqslant(1+y^0-|\vec{y}|)^2+\theta(x\cdot x)(|x^0|-|\vec{x}|)^2\leqslant|1-iz\cdot l/t\cdot l|^2\leqslant(1+y^0+|\vec{y}|)^2+(|x^0|+|\vec{x}|)^2$. To prove the bound we split F into two parts

$$F([u_1],[T_zu_2-u_2])=-\int_{\omega\geqslant 0}(e^{i\omega l\cdot z}-1)[\overline{\tilde{u}_1}\cdot\tilde{u}_2(\omega,l)-\tilde{u}_1\cdot\tilde{u}_2(0,l)e^{-\omega t\cdot l}]\,\frac{d\omega}{\omega}\,d^2l$$
$$-\int\left[\tilde{u}_1\cdot\tilde{u}_2(0,l)\int_0^\infty\left(\exp\left(i\omega'\,\frac{z\cdot l}{t\cdot l}\right)-1\right)e^{-\omega'}\,\frac{d\omega'}{\omega'}\right]d^2l.$$

The first term is absolutely bounded by $2\int|\overline{\tilde{u}_1}\cdot\tilde{u}_2(\omega,l)-\tilde{u}_1\cdot\tilde{u}_2(0,l)e^{-\omega t\cdot l}|(d\omega/\omega)d^2l<\infty$. The second term is equal to $\int\tilde{u}_1\cdot\tilde{u}_2(0,l)\ln(1-iz\cdot l/t\cdot l)d^2l$. The imaginary part of $\ln(1-iz\cdot l/t\cdot l)$ yields a term bounded in z, which ends the proof of the bound. Property (v) is easily proved by straightforward calculation in the special case $u_1=-u_2$, and then the general case follows from $u_1+T_xu_2=(u_1+u_2)+(T_xu_2-u_2)$. Statement (vi) follows from our discussion of the relation of the present formulation with the traditional one, ending Sec. III. □

VI. VACUUM VERSUS REGULAR, POSITIVE ENERGY REPRESENTATIONS

Now we can take up the study of physical representations of the asymptotic algebra. First of all, vacuum states have to be characterized.

Theorem 6.1: *(i) If a cyclic representation* π *of the algebra* $\mathscr{T}$ *satisfies Borchers' criterion with respect to the Weyl algebra of the electromagnetic field, and* $U(x)\Omega=\Omega$ *for some choice of the pertinent representation of translations* $U(x)$ *and of the cyclic vector* Ω, *then for each* $C\in\text{CAR}$

$$(\Omega,\pi(CW(V))\Omega)=0\quad if\quad l\wedge V(-\infty,l)\neq 0. \tag{6.1}$$

(ii) A cyclic representation π of the algebra $\mathscr{F}$ satisfies Borchers' criterion and $U(x)\Omega=\Omega$ for some choice of the pertinent representation of translations $U(x)$ and of the cyclic vector Ω if, and only if, there is $(\Omega,\pi(CW(V))\Omega)=\omega_F(C)\omega_r(W(V))$, where ω_F is the positive energy Fock state on CAR *and ω_r is the state on* CCR *given by*

$$\omega_r(W(V))=\begin{cases}0, & if \quad l\wedge V(-\infty,l)\neq 0,\\ f(V)e^{-(1/2)F([\dot V],[\dot V])}, & if \quad l\wedge V(-\infty,l)=0,\end{cases} \tag{6.2}$$

where $f:L_0\to\mathbf{C}$ is a function of positive type, satisfying the condition

$$f(V_1+(T_x-1)V_2)=f(V_1) \quad \forall (V_1)\in L_0,(V_2)\in L,x\in M. \tag{6.3}$$

Proof: (i) Using the algebraic relations (3.40) and (3.42) and the relation (5.15) one finds

$$e^{F([\dot V_1],[T_x\dot V_2-\dot V_2])}CW(V_1)W(T_xV_2)=e^{-i\{V_1,V_2\}}\overline{e^{F([\dot V_1],[T_x\dot V_2-\dot V_2])}}W(T_xV_2)\beta_{-\Phi_2}(C)W(V_1).$$

It follows now from the invariance of Ω under $U(x)$ and from the spectral properties of $U(x)$ that the value of $\omega(.):=(\Omega,\pi(.)\Omega)$ on the lhs of this identity is the boundary value for Im $z=0$ of the function

$$R^4+i\overline{V_+}\ni z\to e^{F([\dot V_1],[T_z\dot V_2-\dot V_2])}(\Omega,\pi(CW(V_1))U(z)\pi(W(V_2))\Omega),$$

continuous on its domain and analytic inside. By Lemma 5.1(ii) this function is polynomially bounded. The expectation value of the rhs of the above identity has similar properties in the time-reflected region $\mathbf{R}^4-i\overline{V_+}$. By the edge of the wedge theorem there is an open region containing $\mathbf{R}^4+i\overline{V_+\cup V_-}$ and a function analytic in this region which is the analytic continuation of both these functions. This function is polynomially bounded on $\mathbf{R}^4+i\overline{V_+\cup V_-}$, hence it is a polynomial. To prove this implication let $h(z)$ be a function with the stated properties, and choose a basis of Minkowski vector space consisting of four unit future-pointing vectors t_i, $i=1,...,4$. For fixed real α^2, α^3, α^4 the function $\mathbf{C}\ni\xi\to h(\xi t_1+\alpha^2t_2+\alpha^3t_3+\alpha^4t_4)$ is analytic and polynomially bounded, hence by Cauchy inequality for analytic functions it is a polynomial in ξ. Therefore, by repeated use of the implication, $h(x)$ is a polynomial, hence $h(z)$ is the same polynomial for complex z. We have thus proved that

$$e^{F([\dot V_1],[T_x\dot V_2-\dot V_2])}\omega(CW(V_1)W(T_xV_2))=P_{C,V_1,V_2}(x), \tag{6.4}$$

where P_{C,V_1,V_2} is a polynomial. If $p([\dot V_1])=p([\dot V_2])\neq 0$, then by Lemma 5.1(iii) $P_{C,V_1,V_2}(x)=0$ (take $|\vec x|=$const and $|x^0|\to+\infty$). For $x=0$, $[\dot V_1]=[\dot V_2]=\frac{1}{2}[\dot V]$, $p([\dot V])\neq 0$ we get $\omega(CW(V))=0$, which ends the proof if (i).

(ii) If $U(x)$ implement translations and $U(x)\Omega=\Omega$ for cyclic Ω, then writing each $C\in{}^*\mathrm{CAR}$ in the form $C=\omega_F(C)E+C'$, where ω_F is the positive energy Fock state and C' is a sum of elements having $B(g_+)$, $B(g_-)^*$ on the right and/or $B(g_+)^*$, $B(g_-)$ on the left, one finds that $\omega(CW(V))=\omega_F(C)\omega(W(V))$. By (3.40), (5.15), and Lemma 5.1(v), for $p([\dot V_1+\dot V_2])=0$ Eq. (6.4) is now equivalent to

$$f(V_1+T_xV_2)=P'_{V_1,V_2}(x), \tag{6.5}$$

where P'_{V_1,V_2} is a polynomial and f is a function on L_0 defined by

$$f(V)=\omega(W(V))e^{(1/2)F([\dot V],[\dot V])}. \tag{6.6}$$

By Lemma 5.1(vi) $f(V_1+T_xV_2)$ is absolutely bounded as a function of x for fixed (V_1), $(V_2)\in L_0$. Hence, by (6.5),

$$f(V_1+T_xV_2)=f(V_1+V_2) \quad \text{for } (V_1),(V_2)\in L_0. \tag{6.7}$$

The positivity of $\omega(A^*A)$ for $A=\Sigma_{i=1}^{n}\alpha_i W(V_i)$, for $(V_i)\in L_0$ and all sequences of complex numbers $\{\alpha_i\}_{i=1}^{n}$, is equivalent to the condition $\Sigma_{i,k=1}^{n}\overline{\beta_i}\beta_k e^{F([V_i],[V_k])}f(V_k-V_i)\geqslant 0$ for all sequences of complex numbers $\{\beta_i\}_{i=1}^{n}$. Following Ref. 24 we replace all V_i in this condition by $(1/N)\Sigma_{k=0}^{N-1}\underline{T_x^k V_i}$ and take the limit $N\to\infty$. Then by (6.7), Lemma 5.1(vi), and the ergodic theorem one has $\Sigma\overline{\beta_i}\beta_k f(V_k-V_i)\geqslant 0$, hence f is of positive type [the remaining conditions, $f(0)=1$ and $\overline{f(V)}=f(-V)$, are obviously satisfied]. Consequently, f is bounded and, by (6.5), (6.7) is satisfied for all (V_1), $(V_2)\in L$ with $(V_1+V_2)\in L_0$. This is equivalent to (6.3), which ends the proof that the state ω has the form given in (ii).

Conversely, let ω_r be a linear functional of the form given by (ii). Then it is a state (one uses the fact that if A and B are two Hermitian positive matrices $n\times n$, then the matrix C defined by $C_{ik}=A_{ik}B_{ik}$ is also positive). Translations are implemented in π_r by the canonically defined representation of translations $U_r(x)$ (ω_r is translationally invariant). This representation is strongly continuous and satisfies the spectrum condition. To show this, it is sufficient to demonstrate that for any pair (V_1), $(V_2)\in L$ the function $x\to\omega_r(W(V_1)W(T_xV_2))$ is continuous, and its Fourier transform has support in $\overline{V_+}$. If $(V_1+V_2)\notin L_0$, then this function vanishes identically. For $(V_1+V_2)\in L_0$, we have by (5.15) and the Lemma 5.1(v)

$$\begin{aligned}\omega_r(W(V_1)W(T_xV_2))&=e^{-(i/2)\{V_1,V_2\}}e^{-(i/2)\{V_1,T_xV_2-V_2\}}\omega_r(W(V_1+T_xV_2))\\&=\omega_r(W(V_1)W(V_2))e^{-F([\dot V_1],[T_x\dot V_2-\dot V_2])}.\end{aligned}$$

The function $\mathbf{R}^4+i\overline{V_+}\ni z\to e^{-F([u_1],[T_zu_2-u_2])}$ is analytic and, by Lemma 5.1(iv), bounded on its domain. Therefore it is the Laplace transform of a distribution with support in $\overline{V_+}$.[25] Now, the Fock state ω_F on CAR satisfies (2.8), so the state on $\mathscr{T}$ defined by $\omega(CW(V))=\omega_F(C)\omega_r(W(V))$ generates a representation unitarily equivalent to a representation of the type (2.10). Translations are implemented in this representation by $U_F(x)\otimes U_r(x)$, where $U_F(x)$ is the representation canonically correlated to ω_F, which ends the proof. □

Let us denote by $\mathscr{T}_0$ the subalgebra of $\mathscr{T}$ generated by CAR and by elements $W(V)$ with $(V)\in L_0$. The representation space $\mathscr{H}$ of a vacuum representation, as implied by the general result (i) of the above theorem, is easily seen to be the uncountable direct sum of the space $[\pi(\mathscr{T}_0)\Omega]$ and spaces derived from it by the action of operators $\pi(W(V))$; if $l\wedge V_1(-\infty,l)=l\wedge V_2(-\infty,l)$ the respective spaces are equal, in other cases they are orthogonal. In consequence, vacuum representations are nonregular with respect to the Weyl operators with infrared-singular test functions $[l\wedge V(-\infty,l)\neq 0]$. Now, the derivation of our asymptotic algebra has led unambiguously to its interpretation, as explained in Secs. III and IV. From the point of view of this interpretation the above structure does not seem a physically justified idealization, for two reasons:

(i) The infrared singular Weyl operators, being degraded to operators intertwining between different representations of $\mathscr{T}_0$, no longer describe the electromagnetic field observable. However, the regular Weyl operators, as discussed earlier, are functions of the free outgoing field only, and the Coulomb field is lost. If the vacuum is of the form (ii) of the theorem, one can separately *define* it by the first term in (4.3), but this is done ''by hand,'' and the information on the unique way in which the Coulomb field and the ''out'' field add to form the total field is lost.

(ii) The superselection sectors with respect to regular observables $\mathscr{A}_0:=\mathscr{T}_0\cap\mathscr{A}$ are labeled by the spacelike asymptotic of the *free* field (and, of course, by total charge, if it exists), so that even the standard wisdom does not apply here. The spacelike asymptotic of electromagnetic field according to Buchholz[14] yields in the subspace $[\pi(W(V))\pi(\mathscr{T}_0)\Omega]$ the field (3.6), which is a free field for free field asymptotic V. Moreover, $\mathscr{A}_0$ should not be interpreted as the algebra of local observables: creation or annihilation of a charged particle together with its Coulomb field is a nonlocal operation, so $B(g)^*B(f)\in\mathscr{A}_0$ is a nonlocal observable.

Consider the particular, Poincaré-invariant vacuum state as given by Theorem 6.1(ii) with $f\equiv 1$. In this representation there is no infraparticle problem: all one-particle states $\pi(B(g_+)^*)\Omega$, $\pi(B(g_-))\Omega$ have energy-momentum on the mass hyperboloid. We want to construct representations which remain as close in their structure to this vacuum representation, but which are regular

at the same time. The obvious idea how to do it is to try to integrate the superselection sectors of this vacuum into a direct integral Hilbert space. As the representation is of the form determined by Theorem 4.4, it is sufficient to confine attention to the electromagnetic part of the representation, π_r. However, for measure-theoretical reasons one has to extend the scope of sectors which are to be integrated. It is now that the extension of the symplectic space introduced in Sec. V will be needed. This extension allows us to consider the Weyl algebra $\widehat{\mathrm{CCR}}$ generated uniquely (due to nondegeneracy of the symplectic form[26]) by elements $\hat{W}([u])$, $[u]\in\hat{L}^f$,

$$\hat{W}([u_1])\hat{W}([u_2])=e^{-(i/2)\{[u_1],[u_2]\}}\hat{W}([u_1+u_2]).$$

The elements $\hat{W}([u])$ with $[u]$ from the subspace $\hat{L}^f_0$ generate a C^*-subalgebra, which we denote $\widehat{\mathrm{CCR}}_0$. The Poincaré transformations act on the algebra $\widehat{\mathrm{CCR}}$ by

$$\alpha_{x,A}\hat{W}([u])=\hat{W}([T_{x,A}u]),$$

$$(T_{x,A}u)_a(s,l)=\Lambda(A)_a{}^b u_b(s-x\cdot l,\Lambda^{-1}l).$$

The Poincaré-invariant vacuum state is easily obtained:

$$\hat{\omega}(\hat{W}([u]))=\begin{cases}0, & \text{if } p([u])\neq 0,\\ e^{-(1/2)F([u],[u])}, & \text{if } p([u])=0.\end{cases}$$

The representation space $\hat{\mathscr{H}}$ of the representation $\hat{\pi}$ canonically obtained from $\hat{\omega}$ is the uncountable direct sum $\hat{\mathscr{H}}=\oplus_{[f]\in\mathscr{H}_{IR}}\hat{\mathscr{H}}_{[f]}$, where $\hat{\mathscr{H}}_{[f]}$ is the subspace spanned by the vectors $\hat{\pi}(\hat{W}([u]))\hat{\Omega}$ with $p([u])=[f]$. The restriction of the representation $\hat{\pi}$ to the subalgebra $\widehat{\mathrm{CCR}}_0$ and to the subspace $\hat{\mathscr{H}}_{[f]}$ is a coherent state representation,[20] $\hat{\pi}_{[f]}(\widehat{\mathrm{CCR}}_0):=\hat{\pi}(\widehat{\mathrm{CCR}}_0)|_{\hat{\mathscr{H}}_{[f]}}$. Two representations $\hat{\pi}_{[f_i]}$, $i=1,2$, are disjoint for $[f_1]\neq[f_2]$.[20] In particular, $\hat{\pi}_{[0]}(\widehat{\mathrm{CCR}}_0)$ is the (positive energy) Fock representation. Each subspace $\hat{\mathscr{H}}_{[f]}$ is invariant under the action of translations $\hat{U}(x)$, thus $\hat{U}(x)=\oplus_{[f]\in\mathscr{H}_{IR}}\hat{U}_{[f]}(x)$, each component representation being a positive energy representation, Spec $\hat{U}_{[f]}(x)\subset\overline{V_+}$.

Suppose we are given a cylindrical σ-additive measure μ on the Hilbert space $\mathscr{H}_{IR}$ (5.17).[27] Let $\psi([f])$ vary over the set of all measurable functions $\mathscr{H}_{IR}\to\hat{\mathscr{H}}_{[0]}$ [i.e., the set of functions for which $(\varphi,\psi([f]))_{\hat{\mathscr{H}}_{[0]}}$ is measurable for all $\varphi\in\hat{\mathscr{H}}_{[0]}$ (Ref. 22)]. Let further $h(s,l)$ vary over the set of smooth homogeneous functions of degree -1, satisfying for some $\epsilon>0$ and all $k=0,1,\ldots$ the bounds

$$|L_{b_1c_1}\cdots L_{b_kc_k}h(s,l)|\leqslant\frac{\mathrm{const}(k)}{(|s|+1)^{1+\epsilon}}\tag{6.8}$$

(for any gauge $t\cdot l=1$) and such that $\tilde{h}(0,l)=1$. Then $[fh]\in\hat{L}^f$ and $p([fh])=[f]$ for any $[f]\in\mathscr{H}_{IR}$. Consider the set Γ of all functions of the form

$$\mathscr{H}_{IR}\ni[f]\to\Psi([f])=\hat{\pi}(\hat{W}([fh]))\psi([f])\in\hat{\mathscr{H}}_{[f]}.\tag{6.9}$$

Lemma 6.2: For any fixed h every function in Γ has a unique representation (6.9).

Proof: If h' is another function satisfying the same conditions as h, then

$$\hat{\pi}(\hat{W}([fh']))\psi([f])=\hat{\pi}(\hat{W}([fh]))e^{(i/2)\{[fh],[fh']\}}\hat{\pi}_{[0]}(\hat{W}([f(h'-h)]))\psi([f]).$$

It has to be shown that if $\psi([f])$ is measurable, then $\psi'([f])=e^{(i/2)\{[fh],[fg]\}}\times\hat{\pi}_{[0]}(\hat{W}([fg]))\psi([f])$, where $g\equiv h'-h$, is also measurable. It is sufficient to show that $(e_i,\psi'([f]))$ are measurable for a basis $\{e_i\}$ of $\hat{\mathscr{H}}_{[0]}$. If one chooses for $\{e_i\}$ the finite ''particle'' number basis, then these products have the following form: $e^{(i/2)\{[fh],[fg]\}-(1/2)F([fg],[fg])}\sum_{k=1}^{\infty}(e_k,\psi([f]))C_k([f])$, where $C_k([f])$ are linear combinations of products of expressions $F([fg],[\chi])$ and their complex conjugations, where $[\chi]\in\hat{L}^f_0$ are profiles

of the photons in the basis vectors. Now, the expressions $F([fg],[\chi])$, $\{[fh],[fg]\}$, and $F([fg],[fg])$ are easily seen to be absolutely bounded as functions of $[f]$, the first by const$\|[f]\|_{\mathscr{K}_{IR}}$, the other two by const$\|[f]\|^2_{\mathscr{K}_{IR}}$. Hence, the first may be written as $([f],[k])$, $[k] \in \mathscr{K}_{IR}$, and the other two as $([f],B[f])_{\mathscr{K}_{IR}}$, where B is a bounded operator on $\mathscr{K}_{IR}$. Both expressions are measurable functions of $[f]$, which ends the proof. □

The set Γ thus has the natural structure of a vector space, and the pair $(\{\hat{\mathscr{H}}_{[f]}\}_{[f]\in\mathscr{K}_{IR}},\Gamma)$ is easily seen to form a μ-measurable family of Hilbert spaces.[22] This family determines the direct integral Hilbert space $\mathscr{H}=\int_{\oplus}\hat{\mathscr{H}}_{[f]}d\mu([f])$, with its elements denoted by $\Psi = \int_{\oplus}\Psi([f])\, d\mu([f])$. It is necessary for our purposes to assume that μ is quasi-invariant with respect to translations by smooth elements of $\mathscr{K}_{IR}$. This set, more exactly the set of elements in $\mathscr{K}_{IR}$ having smooth representants, will be denoted by $\mathscr{C}^{\infty}_{IR}$. Hence, we demand that

$$\mu_{[k]}(B) := \mu(B-[k]) = 0 \Leftrightarrow \mu(B) = 0 \quad \forall \text{ measurable } B,\ [k] \in \mathscr{C}^{\infty}_{IR}. \tag{6.10}$$

(This was the reason for the need to extend L^f to $\hat{L}^f$, and consequently $\mathscr{C}^{\infty}_{IR}$ to $\mathscr{K}_{IR}$: there are no measures on function spaces quasi-invariant with respect to all translations.[27]) Then, by Radon–Nikodym theorem, $d\mu_{[k]}([f]) = (d\mu_{[k]}/d\mu)([f])d\mu([f])$, where $(d\mu_{[k]}/d\mu)([f])$ and $[(d\mu_{[k]}/d\mu)([f])]^{-1}$ are integrable, non-negative functions.

Formula (6.9) may be used to define, for each fixed h, an isomorphism of the space $\mathscr{H}$ with the tensor product space $L^2(\mathscr{K}_{IR},\mu)\otimes\hat{\mathscr{H}}_{[0]}$. Namely, we put by definition

$$\mathscr{U}_h : L^2(\mathscr{K}_{IR},\mu)\otimes\hat{\mathscr{H}}_{[0]} \to \mathscr{H},$$

$$\chi\otimes\psi \to \Psi = \int_{\oplus}\Psi([f])\, d\mu([f]), \tag{6.11}$$

$$\Psi([f]) = \hat{\pi}(\hat{W}([fh]))\chi([f])\psi.$$

This is a noncanonical isomorphism, as it depends on the choice of the function h, which has no intrinsic meaning. The use of the isomorphism will be restricted to technical purposes only.

We now define in $\mathscr{H}$ a new representation of CCR. Note that if V is a test function of $W(V)$, then by (3.35) $\tilde{V}(\omega,l)$ is a smooth function of l for each ω. Therefore $p([\dot{V}])$ is a smooth element of $\mathscr{K}_{IR}$ [has a smooth representant $\tilde{V}(0,l)$].

Theorem 6.3: *The linear operators on $\mathscr{H}$ introduced by*

$$[\pi_r(W(V))\Psi]([f]) := \left(\frac{d\mu_{p([\dot{V}])}}{d\mu}([f])\right)^{1/2}\hat{\pi}(\hat{W}([\dot{V}]))\Psi([f]-p([\dot{V}])) \tag{6.12}$$

define a representation π_r of CCR *satisfying Borchers' criterion. The unitary representation of translations defined by*

$$[U_r(x)\Psi]([f]) := \hat{U}_{[f]}(x)\Psi([f]) \tag{6.13}$$

implements translations in the representation π_r and satisfies Spec $U(x) = \overline{V_+}$.

Proof: A straightforward calculation shows that π_r and U_r satisfy the algebraic conditions of representations and that $U_r(x)$ implement translations in the representation π_r. From the strong continuity and spectral properties of each of $\hat{U}_{[f]}(x)$ it follows that also $U_r(x)$ is strongly continuous and Spec $U_r(x)\subset\overline{V_+}$. The proof will be now completed by showing that Spec $\hat{U}_{[0]}(x)$ $\subset$ Spec $U_r(x)$ ($\hat{U}_{[0]}$ is the standard transformation of the Fock representation, hence Spec $\hat{U}_{[0]}(x) = \overline{V_+}$). Take $\Psi = \mathscr{U}_h(\chi\otimes\psi)$, with $\|\chi\|_{L^2(\mathscr{K}_{IR},\mu)} = 1$, $\|\psi\|_{\hat{\mathscr{H}}_{[0]}} = 1$. Then

$$(\Psi, U_r(x)\Psi) = \int |\chi([f])|^2 e^{(i/2)\{[fh],[fT_xh]\}}(\psi, \hat{\pi}_{[0]}(\hat{W}([f(T_xh-h)]))\hat{U}_{[0]}(x)\psi)\, d\mu([f]).$$

Let $\Psi_k=\mathscr{U}_{h_k}(\chi\otimes\psi)$ $(k=1,2,...)$, with $h_k(s,l)=k^{-1}h(k^{-1}s,l)$. Then

$$\lim_{k\to\infty} F([fh_k],[f(T_xh_k-h_k)])=0, \quad \lim_{k\to\infty} F([f(T_xh_k-h_k)],[f(T_xh_k-h_k)])=0$$

and

$$\mathrm{w}-\lim_{k\to\infty} \hat{\pi}_{[0]}(\hat{W}([f(T_xh_k-h_k)]))=1.$$

By Lebesgue's theorem

$$\lim_{k\to\infty}(\Psi_k, U_r(x)\Psi_k)=(\psi,\hat{U}_{[0]}(x)\psi).$$

Hence Spec $\hat{U}_{[0]}(x)\subset$Spec $U_r(x)$. □

Further properties of the representation π_r are discussed after finding its unitarily equivalent form $\mathscr{U}_h^{-1}\pi_r\mathscr{U}_h$ by (6.11). Let $V_a(s,l)$ be any test function of $W(V)$. The integral

$$-\frac{1}{4\pi}\int h(s,l)\epsilon(s-\tau)\dot{V}_a(\tau,l)ds\ d\tau=-i\mathrm{P}\int \overline{\tilde{h}(\omega,l)}\tilde{V}_a(\omega,l)\ \frac{d\omega}{\omega}$$

is a real smooth vector function orthogonal to l, and a representant of an element of $\mathscr{H}_0$ [defined before (5.12)]. The orthogonal projection of this element to the subspace $\mathscr{H}_{IR}$ of $\mathscr{H}_0$ will be denoted by $r_h([\dot{V}])$. We show in the Appendix that the orthogonal projection to $\mathscr{H}_{IR}$ of a smooth element of $\mathscr{H}_0$ is smooth, hence $r_h([\dot{V}])\in\mathscr{C}^\infty_{IR}$. Let ccr be the Weyl algebra over the vector space $\mathscr{C}^\infty_{IR}\oplus\mathscr{C}^\infty_{IR}$ with the symplectic form $\{[g_1]\oplus[k_1],[g_2]\oplus[k_2]\}_{IR}:=([g_1],[k_2])_{\mathscr{H}_{IR}}-([k_1],[g_2])_{\mathscr{H}_{IR}}$. This algebra is generated by elements $w([g]\oplus[k])$ satisfying

$$\begin{gathered} w([g_1]\oplus[k_1])w([g_2]\oplus[k_2])=e^{-(i/2)\{[g_1]\oplus[k_1],[g_2]\oplus[k_2]\}_{IR}}w([g_1+g_2]\oplus[k_1+k_2]),\\ w([g]\oplus[k])^*=w(-([g]\oplus[k])). \end{gathered} \tag{6.14}$$

(This algebra is unambiguously defined as the symplectic form is nondegenerate.[26])

Theorem 6.4: *(i) The following definition determines a representation π_μ of the algebra* ccr *on the Hilbert space $L^2(\mathscr{H}_{IR},\mu)$:*

$$(\pi_\mu(w([g]\oplus[k]))\chi)([f]):=\left(\frac{d\mu_{[g]}}{d\mu}([f])\right)^{1/2}e^{i([f]-(1/2)[g],[k])_{\mathscr{H}_{IR}}}\chi([f-g]). \tag{6.15}$$

The vector $\Omega_\mu([f])=1$ is cyclic in $L^2(\mathscr{H}_{IR},\mu)$ for the representation π_μ restricted to the subalgebra generated by elements $w([0]\oplus[k])$.

(ii) The representation π_r goes over under the unitary transformation $\mathscr{U}_h$ of representation space to

$$\mathscr{U}_h^{-1}\pi_r(W(V))\mathscr{U}_h=\pi_\mu(w(p([\dot{V}])\oplus r_h([\dot{V}])))\oplus\hat{\pi}_{[0]}(\hat{W}([\dot{V}-\tilde{\dot{V}}(0,.)h])). \tag{6.16}$$

(iii) $(\mathscr{U}_h^{-1}\pi_r(\mathrm{CCR})\mathscr{U}_h)''=\pi_\mu(\mathrm{ccr})''\otimes\mathscr{L}(\hat{\mathscr{H}}_{[0]})$ (the von Neumann tensor product), where $\mathscr{L}(\hat{\mathscr{H}}_{[0]})$ is the algebra of bounded operators on $\hat{\mathscr{H}}_{[0]}$. Therefore, π_r is irreducible iff π_μ is irreducible.

(iv) π_r is regular iff π_μ is regular.

Proof: (i) The algebraic properties needed for π_μ to be a representation of ccr are checked by direct calculation. For any $\chi\in L^2(\mathscr{H}_{IR},\mu)$ there is

$$(\chi,\pi_\mu(w([0]\oplus[k]))\Omega_\mu)=\int\overline{\chi([f])}e^{i([f],[k])}\,d\mu([f]),$$

If this integral vanishes for all smooth $[k]$, then by continuity in $[k]$ it vanishes for all $[k]\in\mathscr{H}_{IR}$, and then $\chi=0$, which shows that Ω_μ is cyclic.

(ii) A direct calculation gives

$$[\pi_r(W(V))\mathscr{U}_h(\chi\otimes\psi)]([f])=\hat{\pi}(\hat{W}([fh]))\left(\frac{d\mu_{p([\dot V])}}{d\mu}([f])\right)^{1/2}e^{i\{[(f-(1/2)\tilde{\dot V}(0,.))h],[\dot V]\}}$$
$$\times\chi([f]-p([\dot V]))\hat{\pi}_{[0]}(\hat{W}([\dot V-\tilde{\dot V}(0,.)h]))\psi.$$

Denote $f'\equiv f-\frac{1}{2}\tilde{\dot V}(0,.)$. The symplectic form in the exponent of the last formula is evaluated by

$$\{[f'h],[\dot V]\}=-\int f'_a(l)\left(-i\mathrm{P}\int\overline{\tilde h(\omega,l)}\tilde{\dot V}^a(\omega,l)\,\frac{d\omega}{\omega}\right)d^2l$$
$$=([f'],r_h([\dot V]))_{\mathscr{H}_{IR}}=([f]-\tfrac{1}{2}p([\dot V]),r_h([\dot V]))_{\mathscr{H}_{IR}}.$$

Transforming back with $\mathscr{U}_h^{-1}$ one obtains (6.16).

(iii) Let $(V')\in L_0$. Further, let $f_a(l)$ be a smooth function representing an element $[f]\in\mathscr{H}_{IR}$ and put $\dot V_a(s,l)=f_a(l)h(s,l)+\dot V'_a(s,l)$. Then $(V)\in L$, $p([\dot V])=[f]$, and

$$\mathscr{U}_h^{-1}\pi_r(W(V))\mathscr{U}_h=\pi_\mu(w([f]\oplus r_h([\dot V'])))\otimes\hat{\pi}_{[0]}(\hat{W}([\dot V'])). \tag{6.17}$$

The functions $\tilde{\dot V}'$ are dense in the Hilbert space of test functions of the Fock representation, which is irreducible. Therefore, to prove the equality in (iii) it is sufficient to show that all operators $\pi_\mu(w([f]\oplus[g]))\otimes\mathbf{1}_{[0]}$ are in $(\mathscr{U}_h^{-1}\pi_r(\mathrm{CCR})\mathscr{U}_h)''$. The second statement of (iii) then follows from $(\mathscr{U}_h^{-1}\pi_r(\mathrm{CCR})\mathscr{U}_h)'=\pi_\mu(\mathrm{ccr})'\otimes\mathbf{C1}_{[0]}$ (see Ref. 22).

To fill the missing step consider for $\beta\in(0,\epsilon)$ a one-parameter family of functions $\tilde N_\beta(\omega,l)=\tilde\kappa_\beta(\omega t\cdot l)\tilde h(\omega,l)$, where $\tilde\kappa_\beta(\omega)=ie^{-|\omega|}|\omega|^\beta\,\mathrm{sgn}(\omega)$. Then $N_\beta(s,l)$ are real homogeneous functions of degree -1 given by

$$N_\beta(s,l)=\frac{1}{2\pi t\cdot l}\int\kappa_\beta\left(\frac{s-\tau}{t\cdot l}\right)h(\tau,l)\,d\tau,$$

with $\kappa_\beta(s)=2\Gamma(1+\beta)(s^2+1)^{-(1+\beta)/2}\sin((1+\beta)\mathrm{arctg}\,s)$. With the use of bounds (6.8) one shows that $N_\beta(s,l)$ are smooth and also satisfy bounds of the form (6.8), with ϵ replaced by β. Consider the smooth homogeneous function of degree 0 given by the integral

$$c_\beta(l)=-\frac{1}{4\pi}\int h(\tau,l)\epsilon(\tau-s)N_\beta(s,l)\,d\tau\,ds=2\int_0^\infty\left|\tilde h\left(\frac{\omega'}{t\cdot l},l\right)\right|^2e^{-\omega'}\omega'^{\beta-1}\,d\omega',$$

the last equality by (5.8). From the bound of the form (5.4) satisfied by $\tilde h$ and the condition $\tilde h(0,l)=1$ we know that there is a positive u, such that $|\tilde h(\omega'/t\cdot l,l)|^2e^{-\omega'}>\frac{1}{2}$ for $\omega'\in\langle 0,u\rangle$. On the other hand, the function $|\tilde h(\omega'/t\cdot l,l)|^2$ is bounded by a constant from above. Hence, $(u^\beta/\beta)<c_\beta(l)<\mathrm{const}\,\Gamma(\beta)$. Therefore, the new auxiliary function defined by $n_\beta(s,l)=N_\beta(s,l)/c_\beta(l)$ is smooth, has all the properties listed above for $N_\beta(s,l)$, and in addition satisfies

$$-\frac{1}{4\pi}\int h(\tau,l)\epsilon(\tau-s)n_\beta(s,l)\,d\tau\,ds=1. \tag{6.18}$$

Now, choose a smooth element $[g]$ in $\mathscr{H}_{IR}$ and put $\dot V'_{\beta a}(s,l)=g_a(l)n_\beta(s,l)$. These V'_β satisfy the conditions for a test function V' in (6.17) and, by (6.18), yield $r_h([\dot V'_\beta])=[g]$. For $\dot V_{\beta a}(s,l)=f_a(l)h(s,l)+\dot V'_{\beta a}(s,l)$ Eq. (6.17) reads

$$\mathscr{U}_h^{-1}\pi_r(W(V_\beta))\mathscr{U}_h=\pi_\mu(w([f]\oplus[g]))\otimes\hat{\pi}_{[0]}(\hat{W}([\dot V'_\beta])). \tag{6.19}$$

By a straightforward calculation one obtains

$$F([\dot{V}'_\beta],[\dot{V}'_\beta]) = \int d^2l \frac{-g^2(l)}{c^2_\beta(l)} \int_0^\infty \left| \tilde{h}\left(\frac{\omega'}{t\cdot l}, l\right)\right|^2 e^{-2\omega'} \omega'^{2\beta-1}\, d\omega'$$

$$< \int (-g^2(l)) \frac{c_{2\beta}(l)}{2c^2_\beta(l)}\, d^2l$$

$$< \text{const}\, \frac{\beta^2\Gamma(2\beta)}{u^{2\beta}} \int (-g^2(l)) d^2l = \text{const}\, \frac{\Gamma(1+2\beta)}{u^{2\beta}}\, \beta.$$

Hence $\lim_{\beta\to 0} F([\dot{V}'_\beta],[\dot{V}'_\beta]) = 0$, and then $\mathrm{w}-\lim_{\beta\to 0} \hat{\pi}_{[0]}(\hat{W}([\dot{V}'_\beta])) = \mathbf{1}$. Then, by (6.19), $\mathrm{w}-\lim_{\beta\to 0} \mathscr{U}_h^{-1} \pi_r(W(V_\beta)) \mathscr{U}_h = \pi_\mu(w([f]\oplus[g])) \otimes \mathbf{1}$, which ends the proof of (iii).

(iv) This is obvious by regularity of the Fock representation and by

$$\mathscr{U}_h^{-1} \pi_r(W((V^\lambda)_\Phi)) \mathscr{U}_h = \pi_\mu(\omega(\lambda(p([\dot{V}]) \oplus r_h([\dot{V}])))) \otimes \hat{\pi}_{[0]}(\hat{W}(\lambda[\dot{V} - \tilde{\dot{V}}(0,.)h])). \qquad \square$$

Remarks: (i) Theorems 4.4, 6.3, and 6.4 together characterize a class of regular, irreducible representations of the algebra $\mathscr{F}$ satisfying Borchers' criterion. When restricted to CCR$\cap\mathscr{F}_0$ the representations decompose into direct integral of coherent state representations and in this respect resemble the scattering representations considered in Ref. 15. However, here the infrared clouds are independent of the charged particles (they are there even if there are no such particles present). In particular, the arguments of this reference for the Lorentz symmetry breaking do not apply here.

(ii) The vacuum vector is replaced here by ''infravacua,'' and states with finite charged particle number are obtained by the action of creation operators on any such state. (The ''infravacua'' are not of the KPR type,[28] which does not lead to coherent states.) There are no vectors with the energy-momentum on mass hyperboloid, but the arguments of Ref. 14 do not apply here either: the asymptotic of electromagnetic field according to Buchholz catches only the free field part, and does not characterize states by classical distribution of electric flux.

(iii) The operators $\pi(W(V))$ with $l\wedge V(-\infty,l)\neq 0$ representing the exponentials of total electromagnetic field do not commute with $\pi(B(g))$, which reflects the fact that creation or annihilation of a charged particle together with its Coulomb field is a nonlocal operation. They do not commute with nonlocal observables $\pi(B(g)^*B(f))$ either.

A particular representation in the class thus characterized is given whenever a measure μ is chosen, such that the condition (6.10) is satisfied and the representation π_μ is regular and irreducible. Explicit characterization of such measures may be given in the subclass of Gaussian measures. For any positive, trace-class operator B in the Hilbert space $\mathscr{H}_{IR}$ the characteristic function

$$\int e^{i([f],[g])}\, d\mu_B([f]) = e^{-(1/2)([g],B[g])}$$

defines a cylindrical, σ-additive measure, a Gaussian measure with covariance B.[29] The following proposition is obtained by the application of general standard results.

Proposition 6.5: (i) A Gaussian measure with covariance B satisfies the quasi-invariance condition (6.10) iff

$$\mathscr{C}^\infty_{IR} \subset B^{1/2}.\mathscr{H}_{IR} \tag{6.20}$$

(*hence* Ker $B^{1/2}=\{0\}$, *as* $\overline{\mathscr{C}^\infty_{IR}}^{\mathscr{H}_{IR}} = \mathscr{H}_{IR}$). *Then the representation* π_μ *is regular and it is unitarily equivalent to the GNS representation of the quasi-free state*

$$\omega_\mu(w([g]\oplus[k])) = e^{-(1/4)s([g]\oplus[k],[g]\oplus[k])}, \tag{6.21}$$

where s is a bilinear, positive definite form on $\mathscr{C}^\infty_{IR}\oplus\mathscr{C}^\infty_{IR}$ *satisfying the defining condition of a quasi-free state*

$$|\{[g_1]\oplus[k_1],[g_2]\oplus[k_2]\}_{IR}|^2 \leqslant s([g_1]\oplus[k_1],[g_1]\oplus[k_1])\, s([g_2]\oplus[k_2],[g_2]\oplus[k_2]) \tag{6.22}$$

and given explicitly by

$$s([g_1]\oplus[k_1],[g_2]\oplus[k_2])=\tfrac{1}{2}(B^{-1/2}[g_1],B^{-1/2}[g_2])+2(B^{1/2}[k_1],B^{1/2}[k_2]). \tag{6.23}$$

(ii) If (6.20) is satisfied, then π_μ is irreducible iff $\overline{B^{-1/2}\mathscr{C}^\infty_{IR}}^{\mathscr{H}_{IR}}=\mathscr{H}_{IR}$. The state (6.21) then yields a Fock representation. Otherwise π_μ is nonfactor.

Proof: (i) A Gaussian measure on a Hilbert space $\mathscr{H}_{IR}$ and with covariance B is equivalent to its translation by an element $[g]\in\mathscr{H}_{IR}$ if, and only if, $[g]\in B^{1/2}\mathscr{H}_{IR}$ (see Ref. 29), which proves the first statement of (i). If this is the case, then

$$\frac{d\mu_{[g]}}{d\mu}([f])=e^{-(1/2)\|B^{1/2}[g]\|^2+([f],B^{-1}[g])},$$

where $([f],B^{-1}[g])$ is to be understood in the sense of a measurable linear functional on $\mathscr{H}_{IR}$.[29] As the vector Ω_μ is cyclic for π_μ, this representation is unitarily equivalent to the GNS representation obtained from the state $\omega_\mu(A):=(\Omega_\mu,\pi_\mu(A)\Omega_\mu)$. The relations (6.21)–(6.23) are now verified by calculation. By the results of Ref. 30 ω_μ is a quasi-free state, which always yields a regular representation.

(ii) By the results of Ref. 30 the state ω_μ is primary iff the extension $\{.,.\}^s_{IR}$ of the symplectic form $\{.,.\}_{IR}$ to the completion of $\mathscr{C}^\infty_{IR}\oplus\mathscr{C}^\infty_{IR}$ with respect to s is nondegenerate. This completed space is a real Hilbert space $\mathscr{H}_s$. In our case $\mathscr{H}_s=\mathscr{H}_-\oplus\mathscr{H}_+$, where $\mathscr{H}_-$ (resp. $\mathscr{H}_+$) is the completion of $\mathscr{C}^\infty_{IR}$ with respect to the norm $\|[f]\|_-:=\|B^{-1/2}[f]\|$ (resp. $\|[f]\|_+:=\|B^{1/2}[f]\|$), and s is extended to $(x_1\oplus y_1,x_2\oplus y_2)=\frac{1}{2}(x_1,x_2)_-+2(y_1,y_2)_+$. The linear operator U_- (resp. U_+) on $\mathscr{C}^\infty_{IR}$ defined by $U_-[f]:=B^{-1/2}[f]$ (resp. by $U_+[f]:=B^{1/2}[f]$) maps $\mathscr{C}^\infty_{IR}$ as a subspace of $\mathscr{H}_-$ (resp. of $\mathscr{H}_+$) isometrically into $\mathscr{H}_{IR}$. By continuity $U_\mp$ extend to isometric operators $U_\mp:\mathscr{H}_\mp\to\mathscr{H}_{IR}$. By restricting arguments in the following equation to smooth elements one sees that the extension of $\{.,.\}_{IR}$ to $\{.,.\}^s_{IR}$ is given by $\{x_1\oplus y_1,x_2\oplus y_2\}^s_{IR}=(U_-x_1,U_+y_2)_{IR}-(U_-x_2,U_+y_1)_{IR}$. This form is nondegenerate iff $U_-\mathscr{H}_-=U_+\mathscr{H}_+$. However, $U_+\mathscr{H}_+=\overline{B^{1/2}\mathscr{C}^\infty_{IR}}^{\mathscr{H}_{IR}}=\mathscr{H}_{IR}$ (as Ker $B^{1/2}=\{0\}$). Therefore, ω_μ is primary iff $U_-\mathscr{H}_-\equiv\overline{B^{-1/2}\mathscr{C}^\infty_{IR}}^{\mathscr{H}_{IR}}=\mathscr{H}_{IR}$. If this is the case, then it is checked by direct calculation that $(x_1\oplus y_1,x_2\oplus y_2)_s=\{x_1\oplus y_1,A(x_2\oplus y_2)\}^s_{IR}$, where $A(x\oplus y):=(-2U_-^{-1}U_+y)\oplus(\frac{1}{2}U_+^{-1}U_-x)$. The operator A satisfies the equation $A^2=-1$, which is a necessary and sufficient condition for ω_μ to be pure.[30] □

Concrete examples of trace-class operators B satisfying the conditions of Proposition 6.5 (i) and (ii) are most easily constructed in the unitarily equivalent version of the space $\mathscr{H}_{IR}$, the Hilbert space $\mathscr{H}_{\partial^2}$ discussed in the Appendix. Let $\widetilde{B}_\alpha=[((t\cdot l)^2\partial^2)^{-1}]^{1+\alpha}$, $\alpha>0$, where $((t\cdot l)^2\partial^2)^{-1}$ is the positive operator on $\mathscr{H}_{\partial^2}$ defined in Appendix [Eq. (A10) and the following discussion]. It follows from the spectral properties of this operator that each of the operators $\widetilde{B}_\alpha$ may serve as an example of the transformed covariance operator.

ACKNOWLEDGMENTS

I am grateful to Professor Andrzej Staruszkiewicz for discussions and support, to Professor Detlev Buchholz for helpful correspondence and to Walter Kunhardt for discussions and critical reading of an early version of the manuscript.

APPENDIX: HOMOGENEOUS FUNCTIONS ON THE LIGHTCONE

In this Appendix we briefly discuss some structures and operations on spaces of homogeneous functions on the future lightcone. Let, first, $\phi(l)$, $\phi_1(l)$, and $\phi_2(l)$ be smooth ($\mathscr{C}^\infty$ in the sense of differentiation by $L_{ab}=l_a\partial_b-l_b\partial_a$) functions, homogeneous of degree 0. Take, for the sake of differentiation, extensions of these functions which remain homogeneous in some neighborhood of the cone. Straightforward calculation then gives on the cone

$$L_a{}^bL_{cb}\phi=*L_c{}^b*L_{ab}\phi=-L_{ac}\phi+l_al_c\partial^2\phi, \tag{A1}$$

$$*L_a{}^bL_{cb}\phi=-L_c{}^b*L_{ab}\phi=-*L_{ac}\phi, \tag{A2}$$

$$L_a{}^b\phi_1 L_{cb}\phi_2 = {}^*L_c{}^b\phi_1 {}^*L_{ab}\phi_2 = l_a l_c \partial\phi_1\cdot\partial\phi_2, \tag{A3}$$

where ${}^*L_{ab}=\frac{1}{2}e_{abcd}L^{cd}$ and $\partial^2=\partial_a\partial^a$. As the action of L_{ab} is extension independent (this is the tangent derivative), these formulas give extension-independent meanings of $\partial^2\phi$ and $\partial\phi_1\cdot\partial\phi_2$, which in this form were calculated for a homogeneous (but otherwise arbitrary) extensions. Contracting (A1) and (A3) with $t^a t^c$, where t is any unit future-pointing vector, one obtains

$$\partial^2\phi=(t\cdot l)^{-2}{}^*L_0{}^b{}^*L_{0b}\phi, \tag{A4}$$

$$\partial\phi_1\cdot\partial\phi_2=(t\cdot l)^{-2}{}^*L_0{}^b\phi_1{}^*L_{0b}\phi_2, \tag{A5}$$

where ${}^*L_{0b}=t^a{}^*L_{ab}$. If ψ is any differentiable function, homogeneous of degree -2, then

$$\int L_{ab}\psi(l)d^2l=0. \tag{A6}$$

Using this identity one obtains from (A4) and (A5) by integration by parts (and taking into account ${}^*L_{0b}t\cdot l=0$)

$$\int \phi_1\partial^2\phi_2\ d^2l=-\int \partial\phi_1\cdot\partial\phi_2\ d^2l. \tag{A7}$$

Therefore, $\int\phi\ \partial^2\phi\ d^2l\geqslant 0$ and $\int\phi\ \partial^2\phi\ d^2l=0$ iff $\phi=$const. Thus $\partial^2\phi=0$ iff $\phi=$const. This positivity of ∂^2 is also seen from the identity (A4), which says that ∂^2, when applied to a homogeneous function of degree 0, is the ''orbital angular momentum squared'' in each Minkowski frame.

The action of ∂^2 may be explicitly reversed. For each smooth, homogeneous of degree 0 function ϕ the function $\psi=\partial^2\phi$ is smooth, homogeneous of degree -2, and satisfies $\int\psi\ d^2l=0$. Conversely, if ψ is any function with these properties, then the formula

$$\phi_t(l)=-\frac{1}{4\pi}\int \ln\frac{l\cdot l'}{t\cdot l'}\ \psi(l')d^2l' \tag{A8}$$

gives the unique such smooth function that $\partial^2\phi_t=\psi$, and with the additive constant chosen such that

$$\int \frac{\phi_t(l)}{(t\cdot l)^2}\ d^2l=0. \tag{A9}$$

Smoothness of $\phi_t(l)$ is proved by showing that for $\epsilon\searrow 0$ the functions

$$\phi_{t\epsilon}(l)=-\frac{1}{4\pi}\int \ln\frac{l\cdot l'+\epsilon t\cdot l t\cdot l'}{t\cdot l'}\ \psi(l')\ d^2l'$$

converge uniformly to $\phi_t(l)$, and $L_{ab}\phi_{t\epsilon}(l)$ converge uniformly to

$$-\frac{1}{4\pi}\int \ln\frac{l\cdot l'}{t\cdot l'}\ L'_{ab}\psi(l')d^2l'+\frac{1}{4\pi}\int\frac{l'_a t_b-l'_b t_a}{t\cdot l'}\ \psi(l')d^2l'.$$

Then it remains to show that

$$-\frac{1}{4\pi(t\cdot l)^2}\int \ln\frac{l\cdot l'+\epsilon t\cdot l t\cdot l'}{t\cdot l'}\ {}^*L'_0{}^b{}^*L'_{0b}\psi(l')d^2l'=\frac{2\epsilon+\epsilon^2}{4\pi}\int\left(\frac{t\cdot l'}{l\cdot l'+\epsilon t\cdot l t\cdot l'}\right)^2\psi(l')d^2l'$$

converges to $\psi(l)$ pointwise, which is an easy exercise.

Consider now the linear space $[\mathscr{C}^\infty]$ of equivalence classes $[\phi]=\{\phi'\,|\,\phi'=\phi+\text{const}\}$ of smooth, homogeneous of degree 0, functions ϕ. On this space the operators $[\phi]\to[(t\cdot l)^2\partial^2\phi]$ and $[\phi]\to[((t\cdot l)^2\partial^2)^{-1}\phi_t]$, where ϕ_t is the representant satisfying (A9), and

$$(((t\cdot l)^2\partial^2)^{-1}\phi_t)(l)=-\frac{1}{4\pi}\int \ln\frac{l\cdot l'}{t\cdot l'}\,\frac{\phi_t(l')}{(t\cdot l')^2}\,d^2l', \tag{A10}$$

are bijective, mutually inverse maps. Moreover, it is easily seen that the operator $((t\cdot l)^2\partial^2)^{-1}$ is bounded with respect to the norm of the scalar product on $[\mathscr{C}^\infty]$ defined by

$$([\phi_1],[\phi_2])_t=\int \frac{\phi_{1t}\phi_{2t}(l)}{(t\cdot l)^2}\,d^2l, \tag{A11}$$

that is

$$\|[((t\cdot l)^2\partial^2)^{-1}\phi_t]\|_t\leqslant c\|[\phi_t]\|_t. \tag{A12}$$

The expression (A7) introduces another scalar product on $[\mathscr{C}^\infty]$:

$$([\phi_1],[\phi_2])_{\partial^2}=\int \phi_1\partial^2\phi_2(l)d^2l. \tag{A13}$$

By (A11)–(A13) we have

$$\begin{aligned}\|[\phi]\|_t^2&=([\phi],[((t\cdot l)^2\partial^2)^{-1}\phi_t])_{\partial^2}\leqslant\|[\phi]\|_{\partial^2}\|[((t\cdot l)^2\partial^2)^{-1}\phi_t]\|_{\partial^2}\\&=\|[\phi]\|_{\partial^2}\sqrt{([\phi],[((t\cdot l)^2\partial^2)^{-1}\phi_t])_t}\leqslant\sqrt{c}\|[\phi]\|_{\partial^2}\|[\phi]\|_t,\end{aligned}$$

hence

$$\|[\phi]\|_t\leqslant\sqrt{c}\|[\phi]\|_{\partial^2}, \tag{A14}$$

and

$$\|[((t\cdot l)^2\partial^2)^{-1}\phi_t]\|_{\partial^2}\leqslant c\|[\phi_t]\|_{\partial^2}, \tag{A15}$$

that is, the operator (A10) is bounded with respect to this norm as well. Furthermore, for any sequence $[\phi_n]\in[\mathscr{C}^\infty]$ there is

$$\|[\phi_n]\|_{\partial^2}^2\leqslant\|[\phi_n-\phi_m]\|_{\partial^2}^2+2([\phi_n],[\phi_m])_{\partial^2}\leqslant\|[\phi_n-\phi_m]\|_{\partial^2}^2+2\|[\phi_n]\|_t\|[(t\cdot l)^2\partial^2\phi_m]\|_t.$$

Suppose $\lim_{m,n\to\infty}\|[\phi_m-\phi_n]\|_{\partial^2}=0$ and $\lim_{n\to\infty}\|[\phi_n]\|_t=0$. For $\epsilon>0$ let $\|[\phi_m-\phi_n]\|<\epsilon$ for all $m,n\geqslant N$. Put $m=N$ and let $N'\geqslant N$ be such that for all $n\geqslant N'$ there is $2\|[\phi_n]\|_t\|[(t\cdot l)^2\partial^2\phi_N]\|<\epsilon^2$. Then for all $n\geqslant N'$ there is $\|[\phi_n]\|_{\partial^2}^2<2\epsilon^2$, hence $\lim_{n\to\infty}\|[\phi_n]\|_{\partial^2}=0$. Summing up, the norm $\|.\|_{\partial^2}$ is stronger than $\|.\|_t$ and these norms are compatible.[31] This implies that the Hilbert space $\mathscr{H}_{\partial^2}$ obtained from $[\mathscr{C}^\infty]$ by completion with respect to $\|.\|_{\partial^2}$ is (may be canonically identified with) a subspace of the completion of $[\mathscr{C}^\infty]$ with respect to $\|.\|_t$. The latter space is the Hilbert space L_t^2 of equivalence classes of homogeneous of degree 0, measurable functions modulo constant for which $\|[\phi]\|_t<\infty$. This space does not depend on t when considered as a vector space. All elements of $\mathscr{H}_{\partial^2}$ are therefore equivalence classes $[\phi]$ of such functions.

The operator (A10) extends to a bounded, self-adjoint, positive operator on $\mathscr{H}_{\partial^2}$. In view of the comment following (A7) this is a compact operator with eigenvalues $(j(j+1))^{-1}$ of multiplicity $2j+1$, where $j=1,2,...$, and eigenspaces $\mathscr{H}_j$ contained in $[\mathscr{C}^\infty]$.

With the use of the Hilbert space $\mathscr{H}_{\partial^2}$ the operation of projecting $\mathscr{H}_0$ to $\mathscr{H}_{IR}$ needed in Sec. V may be described more explicitly. Let, first, $f_a(l)$ be a smooth function, homogeneous of degree -1 and orthogonal to l^a, which means that $[f_a]$ is a smooth element of $\mathscr{H}_0$. For every such function there are smooth, homogeneous of degree 0 functions $\phi(l)$ and $\psi(l)$, unique up to additive constants, such that

$$l_af_b(l)-l_bf_a(l)=L_{ab}\phi(l)-{}^*L_{ab}\psi(l). \tag{A16}$$

This is shown most easily with the use of the spinor formalism, which we do not intend to discuss here and refer the reader to Ref. 32, and to Ref. 2 for application to related problems. Within this formalism it is a simple result that $o^{A'}f_{A'A}(l)=(\partial/\partial o^A)\chi(l)$, where o^A is the spinor of the null

vector l^a and $\chi(l)$ is a smooth complex function, homogeneous of degree 0, determined by this equation up to an additive constant. The equivalent form of this equation in the tensor language is ${}^-(l_a f_b - l_b f_a) = {}^-L_{ab}\chi$, where ${}^-G_{ab}$ for an antisymmetric tensor G_{ab} denotes its anti-self-dual part ${}^-G_{ab} = \frac{1}{2}(G_{ab} + i{}^*G_{ab})$. Solving this equation for $l_a f_b - l_b f_a$ one obtains (A16), with $\phi = \mathrm{Re}\,\chi$ and $\psi = \mathrm{Im}\,\chi$. Now, let f_1 and f_2 be two such smooth functions represented as in (A16). Then by (A16) and the first equality in (A3)

$$f_1 \cdot f_2(l) = (t\cdot l)^{-2} t^a t^c (l_a f_{1b} - l_b f_{1a})(l_c f_2^b - l^b f_{2c})$$
$$= (t\cdot l)^{-2}({}^*L_{0b}\phi_1 {}^*L_0{}^b\phi_2 + {}^*L_{0b}\psi_1 {}^*L_0{}^b\psi_2 - {}^*L_{0b}\psi_1 L_0{}^b\phi_2 - L_{0b}\phi_1 {}^*L_0{}^b\psi_2).$$

Now integrate this identity with respect to $d^2 l$, integrate one ${}^*L$ in each term by parts and use (A1) and (A2) to obtain

$$([f_1],[f_2])_0 = ([\phi_1],[\phi_2])_{\partial^2} + ([\psi_1],[\psi_2])_{\partial^2}. \tag{A17}$$

Therefore, the map $(\phi,\psi)\to f$ given by (A16) for smooth elements extends to a unitary map $\mathscr{H}_{\partial^2}\oplus\mathscr{H}_{\partial^2}\to\mathscr{H}_0$. The space $\mathscr{H}_{IR}$ is the image of the subspace $\mathscr{H}_{\partial^2}\oplus 0$ in this map.

(Received 8 December 1997; accepted for publication 6 January 1998)

We discuss the use of histories labelled by a continuous time in the approach to consistent-histories quantum theory in which propositions about the history of the system are represented by projection operators on a Hilbert space. This extends earlier work by two of us [C. J. Isham and N. Linden, J. Math. Phys. **36**, 5392–5408 (1995)] where we showed how a continuous time parameter leads to a history algebra that is isomorphic to the canonical algebra of a quantum *field* theory. We describe how the appropriate representation of the history algebra may be chosen by requiring the existence of projection operators that represent propositions about the time average of the energy. We also show that the history description of quantum mechanics contains an operator corresponding to velocity that is quite distinct from the momentum operator. Finally, the discussion is extended to give a preliminary account of quantum field theory in this approach to the consistent histories formalism. © *1998 American Institute of Physics.* [S0022-2488(98)03304-0]

I. INTRODUCTION

The consistent histories approach to quantum theory can be formulated in several different ways. In the original scheme,[1–3] the crucial object is the decoherence function written as

$$d(\alpha,\beta)=\mathrm{tr}(\widetilde{C}_\alpha^\dagger \rho \widetilde{C}_\beta), \tag{1}$$

where ρ is the initial density-matrix, and where the *class operator* $\widetilde{C}_\alpha$ is defined in terms of the standard Schrödinger-picture projection operators α_{t_i} as

$$\widetilde{C}_\alpha := U(t_0,t_1)\alpha_{t_1}U(t_1,t_2)\alpha_{t_2}\ldots U(t_{n-1},t_n)\alpha_{t_n}U(t_n,t_0), \tag{2}$$

where $U(t,t')=e^{-i(t-t')H/\hbar}$ is the unitary time-evolution operator from time t to t'. Each projection operator α_{t_i} represents a proposition about the system at time t_i, and the class operator $\widetilde{C}_\alpha$ represents the composite history proposition ''α_{t_1} is true at time t_1, and then α_{t_2} is true at time t_2, and then $\ldots$, and then α_{t_n} is true at time t_n.''

As a product of (generically, non-commuting) projection operators, the class-operator $\widetilde{C}_\alpha$ is not itself a projector. This difference between the representation of propositions in standard quantum mechanics and in the history theory is avoided in the alternative approach[4,5] to the latter in which the history proposition ''α_{t_1} is true at time t_1, and then α_{t_2} is true at time t_2, and

then . . . , and then α_{t_n} is true at time t_n'' is represented by the *tensor product* $\alpha_{t_1}\otimes\alpha_{t_2}\otimes\cdots\otimes\alpha_{t_n}$ which, unlike $\widetilde{C}_\alpha$, *is* a genuine projection operator. In this 'history projection operator' (HPO) scheme, the decoherence function can be written as

$$d(\alpha,\beta)=\mathrm{tr}_{\mathscr{V}\otimes\mathscr{V}}(\alpha\otimes\beta X) \tag{3}$$

for a suitable operator X (independent of α and β) defined on $\mathscr{V}\otimes\mathscr{V}$.[6] Here, $\mathscr{V}$ denotes the 'history space' $\mathscr{H}_{t_1}\otimes\mathscr{H}_{t_2}\otimes\cdots\otimes\mathscr{H}_{t_n}$ on which the history-proposition projectors α and β are defined, where, for each t_i, $\mathscr{H}_{t_i}$ is a copy of the Hilbert space $\mathscr{H}$ of the standard quantum theory. The representation of history propositions with projection operators has clear advantages when discussing logical operations; in our case, quantum temporal logic. It could also be applicable in quantum gravity situations where there is no background concept of time and where, therefore, the construction of a class operator is particularly problematic: in this case, history propositions could still be represented by projection operators, but on a Hilbert space that does not arise as a temporal tensor product.

The introduction of a *continuous* time clearly poses difficulties for both approaches to the consistent history theory: in the class-operator scheme one has to define continuous products of projection operators; in the HPO approach, the problem is to define a continuous *tensor* product of projection operators.

In an earlier paper by two of us,[7] the latter problem was tackled by exploiting the well-known existence of continuous tensor products of coherent states. However, several interesting issues were sidestepped in the process. For example, the natural history propositions in this scheme are represented by continuous tensor products of projectors onto coherent states, and these do not have a transparent physical interpretation. On the other hand, the formalism as given was not well-equipped to handle the more physically-motivated history propositions about continuous time averages.

In the present paper we take a fresh look at the question of continuous time in the HPO formalism. As in our earlier work, the starting point is the *history group*: a history analogue of the canonical group used in standard quantum mechanics. The key idea is that a unitary representation of the history group leads to a self-adjoint representation of its Lie algebra, the spectral projectors of which are to be interpreted as propositions about the histories of the system. Thus we employ a history group whose associated projection operators represent propositions about continuous-time histories. It transpires that the history algebra for one-dimensional quantum mechanics is *infinite* dimensional—in fact, it is isomorphic to the canonical commutation algebra of a standard quantum *field* theory in one spatial dimension. This suggests that it might be profitable to study the history theory using tools that are normally employed in quantum field theory. This we shall do; in particular, we show that the physically appropriate representation of the history algebra can be selected by requiring the existence of operators that represent propositions about the time-averaged values of the energy. The Fock space thus constructed is related to the notion of a continuous tensor product as used in our earlier paper, thus establishing the link with the idea of continuous temporal logic. We also introduce the continuous-time history analogue of the Heisenberg picture, and we discuss the role of velocity in the history theory. Finally, the discussion is extended to include the case of a free relativistic quantum field.

In what follows we have deliberately adopted a 'physicist's approach' to the analytical problems that arise in the theory; for example, we frequently use unsmeared commutation relations, and domains of operators are not discussed. This enables us to present the essential physical ideas without getting lost in mathematical detail. However, nothing of real importance is hidden thereby since only Fock space representations of the history algebra are used, and the full mathematical theory of these is well-known from normal quantum field theory and poses no major problems.

II. THE HISTORY SPACE

A. The history group

We start by considering the HPO version of the quantum theory of a particle moving on the real line $\mathbb{R}$. As explained above, the history proposition ''α_{t_1} is true at time t_1, and then α_{t_2} is true

at time t_2, and then ... , and then α_{t_n} is true at time t_n'' is represented by the projection operator $\alpha_{t_1}\otimes\alpha_{t_2}\otimes\cdots\otimes\alpha_{t_n}$ on the n-fold tensor product $\mathscr{V}_n=\mathscr{H}_{t_1}\otimes\mathscr{H}_{t_2}\otimes\cdots\otimes\mathscr{H}_{t_n}$ of n-copies of the Hilbert-space $\mathscr{H}$ of the canonical theory. Since $\mathscr{H}$ carries a representation of the Heisenberg–Weyl group with Lie algebra

$$[x,p]=i\hbar, \tag{4}$$

the Hilbert space $\mathscr{V}_n$ carries a unitary representation of the n-fold product group whose generators satisfy

$$[x_k,x_m]=0, \tag{5}$$

$$[p_k,p_m]=0, \tag{6}$$

$$[x_k,p_m]=i\hbar\,\delta_{km}, \tag{7}$$

with $k,m=1,2,\ldots,n$. Thus the Hilbert space $\mathscr{V}_n$ carries a representation of the 'history group' whose Lie algebra is defined to be that of Eqs. (5)–(7). However, we can also turn the argument around and *define* the history version of n-time quantum mechanics by starting with Eqs. (5)–(7). In this approach, $\mathscr{V}_n$ arises as a representation space for Eqs. (5)–(7), and tensor products $\alpha_{t_1}\otimes\alpha_{t_2}\otimes\cdots\otimes\alpha_{t_n}$ that correspond to sequential histories about the values of position or momentum (or linear combinations of them) are then elements of the spectral representations of this Lie algebra.

We shall employ this approach to discuss continuous-time histories. Thus, motivated by Eqs. (5)–(7), we start with the history-group whose Lie algebra (referred to in what follows as the 'canonical history algebra', or CHA for short) is[7]

$$[x_{t_1},x_{t_2}]=0, \tag{8}$$

$$[p_{t_1},p_{t_2}]=0, \tag{9}$$

$$[x_{t_1},p_{t_2}]=i\hbar\,\delta(t_1-t_2), \tag{10}$$

where $-\infty\leqslant t_1,t_2\leqslant\infty$. Note that these operators are in the *Schrödinger* picture: they must not be confused with the Heisenberg-picture operators $x(t),p(t)$ of normal quantum theory.

An important observation is that Eqs. (8)–(10) are mathematically the same as the canonical commutation relations of a quantum *field* theory in one space dimension:

$$[\phi(x_1),\phi(x_2)]=0, \tag{11}$$

$$[\pi(x_1),\pi(x_2)]=0, \tag{12}$$

$$[\phi(x_1),\pi(x_2)]=i\hbar\,\delta(x_1-x_2). \tag{13}$$

This analogy will be exploited fully in the present paper. For example, the following two issues arise immediately. First—to be mathematically well-defined—equations of the type Eqs. (8)–(10) must be smeared with test functions to give

$$[x_f,x_g]=0, \tag{14}$$

$$[p_f,p_g]=0, \tag{15}$$

$$[x_f,p_g]=i\hbar\int_{-\infty}^{\infty}f(t)g(t)dt, \tag{16}$$

which leads at once to the question of which class τ of test functions to use. The minimal requirement for the right hand side of Eq. (16) to make sense is that τ must be a linear subspace of the space $L^2(\mathbb{R},dt)$ of square integrable functions on $\mathbb{R}$. For the moment we shall leave τ unspecified beyond this.

The second issue is concerned with finding the physically appropriate representation of the CHA Eqs. (14)–(16), bearing in mind that infinitely many unitarily inequivalent representations are known to exist in the analogous case of Eqs. (11)–(13). Note that this problem does not arise in standard quantum mechanics, or in the history version of quantum mechanics with propositions defined at a finite number of times, since—by the Stone–von Neumann theorem—there is a unique representation of the corresponding algebra up to unitarily equivalence.

Of course, from the perspective of the history theory the physically appropriate representation is expected to involve some type of continuous tensor product; this was the path followed in our earlier work.[7] On the other hand, in standard quantum field theory there is a folk lore, going back at least to a famous paper by Araki,[8] to the effect that requiring the Hamiltonian to exist as a proper self-adjoint operator is sufficient to select a unique representation; for example, the representations appropriate for a free boson field with different masses are unitarily inequivalent. In our case, this suggests that the appropriate representation of the algebra Eqs. (14)–(16) should be chosen by requiring the existence of operators that represent history propositions about (time-averaged) values of the energy. As we shall see, this is indeed the case.

B. The Hamiltonian algebra

We start with the ubiquitous example of the one-dimensional, simple harmonic oscillator with Hamiltonian

$$H=\frac{p^2}{2m}+\frac{m\omega^2}{2}x^2. \tag{17}$$

The naïve idea behind the HPO theory is that to each time t there is associated a Hilbert space $\mathscr{H}_t$ that carries propositions appropriate to that time (the 'naïvety' refers to the fact that, in a *continuous* tensor product $\otimes_{t\in\mathbb{R}}\mathscr{H}_t$, the individual Hilbert spaces $\mathscr{H}_t$ do not strictly exist as subspaces; this is related to the need to smear operators). Thus we expect to have a one-parameter family of operators

$$H_t:=\frac{p_t^2}{2m}+\frac{m\omega^2}{2}x_t^2 \tag{18}$$

that represent the energy at time t.

As it stands, the right hand side of Eq. (18) is not well-defined, just as in normal canonical quantum field theory it is not possible to define products of field operators at the same spatial point. However, the commutators of H_t with the generators of the CHA can be computed formally as

$$[H_t,x_s]=-\frac{i\hbar}{m}\delta(t-s)p_s, \tag{19}$$

$$[H_t,p_s]=i\hbar m\omega^2\delta(t-s)x_s, \tag{20}$$

$$[H_t,H_s]=0, \tag{21}$$

and are the continuous-time, history analogues of the familiar result in standard quantum theory:

$$[H,x]=-\frac{i\hbar}{m}p, \tag{22}$$

$$[H,p]=i\hbar m\omega^2 x. \tag{23}$$

In standard quantum theory, the spectrum of the Hamiltonian operator can be computed directly from the algebra of Eqs. (22) and (23) augmented with the requirement that the underlying representation of the canonical commutation relations Eq. (4) is irreducible. This suggests that we try to *define* the history theory by requiring the existence of a family of operators H_t that satisfy the relations Eqs. (19)–(21) and where the representation of the canonical history algebra Eqs. (8)–(10) is irreducible. More precisely, we augment the CHA with the algebra (in semi-smeared form)

$$[H(\chi),x_t]=-\frac{i\hbar}{m}\chi(t)p_t, \tag{24}$$

$$[H(\chi),p_t]=i\hbar m\omega^2\chi(t)x_t, \tag{25}$$

$$[H(\chi_1),H(\chi_2)]=0, \tag{26}$$

where $H(\chi)$ is the history energy-operator, time averaged with the function χ; heuristically, $H(\chi)=\int_{-\infty}^{\infty}dt\chi(t)H_t$.

It is useful to integrate these equations in the following sense. *If* self-adjoint operators $H(\chi)$ exist satisfying Eqs. (24)–(26), we can form the unitary operators $e^{iH(\chi)/\hbar}$, and these satisfy

$$e^{iH(\chi)/\hbar}x_te^{-iH(\chi)/\hbar}=\cos[\omega\chi(t)]x_t+\frac{1}{m\omega}\sin[\omega\chi(t)]p_t, \tag{27}$$

$$e^{iH(\chi)/\hbar}p_te^{-iH(\chi)/\hbar}=-m\omega\sin[\omega\chi(t)]x_t+\cos[\omega\chi(t)]p_t. \tag{28}$$

However, it is clear that the right hand sides of Eqs. (27) and (28) defines an *automorphism* of the canonical history algebra Eqs. (8)–(10). Thus the task at hand can be rephrased as that of finding an irreducible representation of the CHA in which these automorphisms are unitarily implementable: the self-adjoint generators of the corresponding unitary operators will then be the desired time-averaged energy operators $H(\chi)$ [strictly speaking, weak continuity is also necessary, but this poses no additional problems in the cases of interest here].

C. The Fock representation

It is natural to contemplate the use of a Fock representation of the CHA since this plays such a central role in the analogue of a free quantum field in one spatial dimension. To this end, we start by defining the 'annihilation operator'

$$b_t:=\sqrt{\frac{m\omega}{2\hbar}}x_t+i\sqrt{\frac{1}{2m\omega\hbar}}p_t \tag{29}$$

in terms of which the CHA (8)–(10) becomes

$$[b_t,b_s]=0, \tag{30}$$

$$[b_t,b_s^\dagger]=\delta(t-s). \tag{31}$$

Note that

$$\hbar\omega b_t^\dagger b_s=\frac{1}{2m}p_tp_s+\frac{m\omega^2}{2}x_tx_s-\frac{\hbar\omega}{2}\delta(t-s), \tag{32}$$

which suggests that there exists an additively renormalized version of the operator H_t in Eq. (18) of the form $\hbar\omega b_t^\dagger b_t$. In turn, this suggests strongly that a Fock space based on Eq. (29) should provide the operators we seek.

To make this explicit we recall that the bosonic Fock space $\mathscr{F}[\mathscr{H}]$ associated with a Hilbert space $\mathscr{H}$ is defined as

$$\mathscr{F}[\mathscr{H}]:=\mathbb{C}\oplus\mathscr{H}\oplus(\mathscr{H}\otimes_S\mathscr{H})\oplus\cdots, \tag{33}$$

where $\mathscr{H}\otimes_S\mathscr{H}$ denotes the symmetrized tensor product of $\mathscr{H}$ with itself. Any unitary operator U on the 'one-particle' space $\mathscr{H}$ gives a unitary operator $\Gamma(U)$ on $\mathscr{F}[\mathscr{H}]$ defined by

$$\Gamma(U):=1\oplus U\oplus(U\otimes U)\oplus\cdots. \tag{34}$$

Furthermore, if $U=e^{iA}$ for some self-adjoint operator A on $\mathscr{H}$, then $\Gamma(U)=e^{id\Gamma(A)}$ where

$$d\Gamma(A):=0\oplus A\oplus(A\otimes 1+1\otimes A)\oplus\cdots. \tag{35}$$

The implications for us of these well-known constructions are as follows. Consider the Fock space $\mathscr{F}[L^2(\mathbb{R},dt)]$ that is associated with the Hilbert space $L^2(\mathbb{R},dt)$ via the annihilation operator b_t defined in Eq. (29); i.e., the space built by acting with (suitably smeared) operators $b_t^\dagger$ on the 'vacuum state' $|0\rangle$ that satisfies $b_t|0\rangle=0$ for all $t\in\mathbb{R}$. The equations (27) and (28) show that, *if* it exists, the operator $e^{iH(\chi)/\hbar}$ acts on the putative annihilation operator b_t as

$$e^{iH(\chi)/\hbar}b_te^{-iH(\chi)/\hbar}=e^{-i\omega\chi(t)}b_t. \tag{36}$$

However, thought of as an action on $L^2(\mathbb{R},dt)$, the operator $U(\chi)$ defined by

$$(U(\chi)\psi)(t):=e^{-i\omega\chi(t)}\psi(t) \tag{37}$$

is unitary for any measurable function χ. Hence, using the result mentioned above, it follows that in this particular Fock representation of the CHA the automorphism on the right hand side of Eq. (36) *is* unitarily implementable, and hence the desired self-adjoint operators exist. Note that $H(\chi)=\hbar\omega d\Gamma(\hat{\chi})$, where the self-adjoint operator $\hat{\chi}$ is defined on $L^2(\mathbb{R},dt)$ as

$$(\hat{\chi}\psi)(t):=\chi(t)\psi(t). \tag{38}$$

In summary, we have shown that the Fock representation of the CHA Eqs. (8)–(10) associated with the annihilation operator b_t of Eq. (29) is such that there exists a family of self-adjoint operators $H(\chi)$ for which the algebra Eqs. (24)–(26) is satisfied. This Fock space is the desired carrier of the history propositions in our theory. Note that, in this case, the natural choice for the test function space $\tau\subseteq L^2(\mathbb{R},dt)$ used in Eqs. (14)–(16) is simply $L^2(\mathbb{R},dt)$ itself.

The position history variable x_t can be written in terms of b_t and $b_t^\dagger$ as

$$x_t=\sqrt{\frac{\hbar}{2m\omega}}(b_t+b_t^\dagger) \tag{39}$$

and has the correlation function

$$\langle 0|x_tx_s|0\rangle=\frac{\hbar}{2m\omega}\,\delta(t-s). \tag{40}$$

Thus the carrier space of our history theory is Gaussian white noise.

Finally, we note that the formalism discussed above can be extended to a wide class of Hamiltonian operators by employing the types of argument used by axiomatic field theorists to construct Euclidean quantum field theories in one space plus one time dimension.[9] In particular, the underlying Gaussian stochastic process of our history theory of the simple harmonic oscillator can be successfully perturbed by the addition to H_t of a wide class of polynomial functions of the configuration variable x_t.

D. The '*n*-particle' history propositions

The Fock space construction produces a natural collection of history propositions: namely, those represented by the projection operators onto what, in a normal quantum field theory, would be called the 'n-particle states.' To see what these correspond to physically in our case we note first that a δ-function normalized basis for $\mathscr{F}[L^2(\mathbb{R},dt)]$ is given by the vectors $|0\rangle$, $|t_1\rangle$, $|t_1,t_2\rangle$,

. . . , where $|t_1\rangle := b^\dagger_{t_1}|0\rangle$, $|t_1,t_2\rangle := b^\dagger_{t_1}b^\dagger_{t_2}|0\rangle$, etc. (of course, properly normalized vectors are of the form $|\phi\rangle := b^\dagger_\phi|0\rangle$, etc., for suitable smearing function ϕ). The physical meaning of the projection operators of the form $|t\rangle\langle t|$ (or, more rigorously, $|\phi\rangle\langle\phi|$), $|t_1,t_2\rangle\langle t_1,t_2|$, etc., can be seen by studying the equations

$$H(\chi)|0\rangle = 0, \tag{41}$$

$$H(\chi)|t\rangle = \hbar\omega\chi(t)|t\rangle, \tag{42}$$

$$H(\chi)|t_1,t_2\rangle = \hbar\omega[\chi(t_1)+\chi(t_2)]|t_1,t_2\rangle, \tag{43}$$

or, in totally unsmeared form,

$$H_t|0\rangle = 0, \tag{44}$$

$$H_t|t_1\rangle = \hbar\omega\,\delta(t-t_1)|t_1\rangle, \tag{45}$$

$$H_t|t_1,t_2\rangle = \hbar\omega[\,\delta(t-t_1)+\delta(t-t_2)]|t_1,t_2\rangle. \tag{46}$$

It is clear from the above that, for example, the projector $|t_1,t_2\rangle\langle t_1,t_2|$ represents the proposition that there is a unit of energy $\hbar\omega$ concentrated at the time point t_1 and another unit concentrated at the time point t_2. Note that $H(\chi)|t,t\rangle = 2\hbar\omega\chi(t)|t,t\rangle$, and hence $|t,t\rangle\langle t,t|$ represents the proposition that there are two units of energy concentrated at the *single* time point t (thus exploiting the bose-structure of the canonical history algebra!). This interpretation of projectors like $|t_1,t_2\rangle\langle t_1,t_2|$ is substantiated by noting that the time-averaged energy obtained by choosing the averaging function χ to be 1 acts on these vectors as

$$\int_{-\infty}^{\infty} ds H_s|t\rangle = \hbar\omega|t\rangle, \tag{47}$$

$$\int_{-\infty}^{\infty} ds H_s|t_1,t_2\rangle = 2\hbar\omega|t_1,t_2\rangle, \tag{48}$$

and so on. This is the way in which the HPO account of the simple harmonic oscillator recovers the integer-spaced energy spectrum of standard quantum theory.

Finally, we note in passing that

$$\frac{1}{\hbar\omega}\int_{-\infty}^{\infty} ds\,s H_s|t_1,t_2,\ldots,t_n\rangle = (t_1+t_2+\cdots+t_n)|t_1,t_2,\ldots,t_n\rangle \tag{49}$$

so that $(1/\hbar\omega)\int_{-\infty}^{\infty} ds\,s H_s$ acts as a 'total time' or 'center-of-time' operator.

E. The Heisenberg picture

It is interesting to investigate the analogue of the Heisenberg picture in our continuous-time HPO theory. In standard quantum theory, the Heisenberg picture version of an operator A is defined with respect to a time origin $t=0$ as

$$A_H(s) := e^{isH/\hbar}Ae^{-isH/\hbar}. \tag{50}$$

In particular, for the simple harmonic oscillator we have

$$x(s) = \cos[\omega s]x + \frac{1}{m\omega}\sin[\omega s]p, \tag{51}$$

$$p(s) = -m\omega\sin[\omega s]x + \cos[\omega s]p. \tag{52}$$

The Heisenberg picture operator $x(s)$ satisfies the classical equation of motion

$$\frac{d^2x(s)}{ds^2}+\omega^2x(s)=0, \tag{53}$$

and the commutator of these operators is

$$[x(s_1),x(s_2)]=\frac{i\hbar}{m\omega}\sin[\omega(s_1-s_2)], \tag{54}$$

which, on using the equation of motion

$$p:=m\left.\frac{dx(s)}{ds}\right|_{s=0}, \tag{55}$$

reproduces the familiar canonical commutation relation Eq. (4).

In trying to repeat this construction for the history theory we might be tempted to define the Heisenberg picture analogue of, say, x_t as

$$x_{H,t}(s):=e^{isH_t/\hbar}x_te^{-isH_t/\hbar}. \tag{56}$$

However, this expression is not well-defined since it corresponds to choosing the test-function in Eq. (27) as $\chi(t'):=s\delta(t-t')$, which leads to ill-defined products of $\delta(t-t')$.

What is naturally suggested instead is to define 'time-averaged' Heisenberg quantities

$$x_{\kappa,t}:=e^{iH(\kappa)/\hbar}x_te^{-iH(\kappa)/\hbar}=\cos[\omega\kappa(t)]x_t+\frac{1}{m\omega}\sin[\omega\kappa(t)]p_t \tag{57}$$

for suitable test functions κ. The analogue of the equation of motion (53) is the functional differential equation

$$\frac{\delta^2x_{\kappa,t}}{\delta\kappa(s_1)\delta\kappa(s_2)}+\delta(t-s_1)\delta(t-s_2)\omega^2x_{\kappa,t}=0, \tag{58}$$

while the history analogue of Eq. (55) is

$$\delta(t-s)p_t=m\left.\frac{\delta x_{\kappa,t}}{\delta\kappa(s)}\right|_{\kappa=0}, \tag{59}$$

and the analogue of the 'covariant commutator' Eq. (54) is

$$[x_{\kappa_1,t_1},x_{\kappa_2,t_2}]=\frac{i\hbar}{m\omega}\delta(t_1-t_2)\sin[\omega(\kappa_1(t_1)-\kappa_2(t_2)], \tag{60}$$

which correctly reproduces the canonical history algebra.

It is worth remarking that we could have proceeded in a slightly different way by starting with a set of operators $x_t(s)$ that satisfy a postulated history version of the covariant commutator Eq. (54):

$$[x_{t_1}(s_1),x_{t_2}(s_2)]=\frac{i\hbar}{m\omega}\delta(t_1-t_2)\sin[\omega(s_1-s_2)] \tag{61}$$

and with the standard Schrödinger canonical history operators then being *defined* as $x_t:=x_t(0)$ and $p_t:=m[dx_t(s)/ds]|_{s=0}$. However, in fact, this is just a special case of the first scheme with the test function κ chosen to be $\kappa(t):=s$ for all t; i.e., the 'Heisenberg picture' operators $x_t(s)$ are generated by the time-averaged energy in the form

$$x_t(s):=e^{is\int drH_r/\hbar}x_te^{-is\int drH_r/\hbar}. \tag{62}$$

In our HPO formalism, the Heisenberg picture operators—unlike those in the Schrödinger picture—have no obvious direct physical interpretation and their main use is likely to be mathematical. Therefore, there is no *a priori* reason for rejecting the simple time-averaged quantity in Eq. (62). What *is* clear however is that—whichever version is used—*two* different time labels appear: the 'external' label t that specifies the time at which a proposition is asserted, and the 'internal' label s that specifies the time parameter in the Heisenberg picture associated with the copy of standard quantum theory on the Hilbert space $\mathscr{H}_t$.

F. The relation with continuous temporal logic

Relating the construction above to the idea of 'continuous temporal logic' involves showing that

$$\otimes_{t\in\mathbb{R}} L^2_t(\mathbb{R},dx) \simeq \mathscr{F}[L^2(\mathbb{R},dt)], \tag{63}$$

where $L^2(\mathbb{R},dx)$ is the Hilbert space of the standard quantum theory of a particle moving in one dimension. For completeness we shall summarize here the discussion of this relation given in our earlier paper.[7]

At a heuristic level, the inner product between two continuous tensor product vectors $|\otimes_{t\in\mathbb{R}} u_t\rangle$ and $|\otimes_{t\in\mathbb{R}} v_t\rangle$ is required to be

$$\langle \otimes_{t\in\mathbb{R}} u_t | \otimes_{t\in\mathbb{R}} v_t\rangle_{\otimes_t \mathscr{H}_t} = \prod_{t\in\mathbb{R}} \langle u_t | v_t\rangle_{\mathscr{H}_t} := \exp\int_{-\infty}^{\infty} dt \log\langle u_t | v_t\rangle_{\mathscr{H}_t}. \tag{64}$$

Since $\langle u_t | v_t\rangle$ is a complex number the logarithm on the right hand side of Eq. (64) is generally not well-defined. However, consider the special case of trying to construct the continuous tensor product of copies of a *Fock* space $\mathscr{F}[K]$ for some Hilbert space K. In particular, consider the *coherent states* $|\exp\phi\rangle$, $|\phi\rangle \in K$, defined as

$$|\exp\phi\rangle := \oplus_{n=0}^{\infty} \frac{1}{n!} (\otimes |\phi\rangle)^n, \tag{65}$$

where $(\otimes|\phi\rangle)^n$ denotes the tensor product of $|\phi\rangle$ with itself n times (and with the convention that $(|\phi\rangle)^0 := 1$). Then

$$\langle \exp\phi | \exp\psi\rangle_{\mathscr{F}[K]} = \exp\langle \phi | \psi\rangle_K \tag{66}$$

and hence, using Eq. (64),

$$\langle \otimes_t \exp\phi_t | \otimes_t \exp\psi_t\rangle_{\otimes_t \mathscr{F}[K]_t} = \exp\int_{-\infty}^{\infty} dt \langle \phi_t | \psi_t\rangle_{K_t} \tag{67}$$

which *is* well-defined. But the exponent on the right hand side of Eq. (67) is just the inner product in the direct integral $\int^{\oplus} K_t dt$ of the Hilbert spaces K_t, and hence we arrive at the basic isomorphism

$$\otimes_{t\in\mathbb{R}} \mathscr{F}[K]_t \simeq \mathscr{F}\left[\int^{\oplus} K_t dt\right], \quad \otimes_t |\exp\phi_t\rangle \mapsto |\exp\phi(\cdot)\rangle. \tag{68}$$

However, the single-time Hilbert space of our theory—$L^2(\mathbb{R},dx)$—can be written as the Fock space for the one-dimensional Hilbert space $\mathbb{C}$ via the isomorphism

$$\mathscr{F}[\mathbb{C}] \simeq L^2(\mathbb{R},dx), \tag{69}$$

$$|\exp z\rangle \mapsto \langle x | \exp z\rangle := (2\pi)^{-1/4} e^{zx - (1/2)z^2 - (1/4)x^2}, \tag{70}$$

where the right hand side involves the familiar coherent states in $L^2(\mathbb{R},dx)$. Thus the isomorphism Eq. (68) becomes

$$\otimes_{t\in\mathbb{R}} L^2_t(\mathbb{R},dx) \simeq \mathscr{F}\left[\int^{\oplus} \mathbb{C}_t dt\right]. \tag{71}$$

But the direct integral $\int^{\oplus}\mathbb{C}_t dt$ is isomorphic to $L^2(\mathbb{R},dt)$ via the map that takes the parametrized family of complex numbers λ_t to the *function* $\lambda(\cdot)$ in $L^2(\mathbb{R},dt)$ [i.e., $\lambda(t):=\lambda_t$]. Hence we arrive at the desired isomorphism in Eq. (63).

G. The extension to three dimensions

The extension of the formalism above to a particle moving in three spatial dimensions appears at first sight to be unproblematic. The analogue of the history algebra Eqs. (8)–(10) is

$$[x^i_{t_1}, x^j_{t_2}] = 0, \tag{72}$$

$$[p^i_{t_1}, p^j_{t_2}] = 0, \tag{73}$$

$$[x^i_{t_1}, p^j_{t_2}] = i\hbar\,\delta^{ij}\delta(t_1 - t_2), \tag{74}$$

$i,j=1,2,3$, while the formal expression Eq. (18) for the energy at time t becomes

$$H_t := \frac{\underline{p}_t\cdot\underline{p}_t}{2m} + \frac{m\omega^2}{2}\underline{x}_t\cdot\underline{x}_t. \tag{75}$$

It is straightforward to generalize the discussion above to this situation and, in particular, to find a Fock representation of Eqs. (72)–(74) in which the rigorous analogues of Eq. (75) exist as *bona fide* self-adjoint operators. However, an interesting issue then arises that has no analogue in one-dimensional quantum theory. Namely, we expect to have angular-momentum operators whose formal expression is

$$L^i_t := \epsilon^i{}_{jk} x^j_t p^k_t \tag{76}$$

and whose commutators can be computed heuristically as

$$[L^i_t, L^j_s] = i\hbar\,\epsilon^{ij}{}_k \delta(t-s) L^k_t. \tag{77}$$

Such operators L^i_t can be constructed rigorously using, for example, the method employed for the energy operators H_t: viz., compute the automorphisms of the canonical history algebra that are formally induced by the angular-momentum operators and then see if these automorphisms can be unitarily implemented in the given Fock representation. However, the interesting observation is that, even if this can be done (which is the case, see below), this does not guarantee *a priori* that the commutators in Eq. (77) will be reproduced: in particular, it is necessary to check directly if a c-number *central extension* is present since we know from other branches of theoretical physics that algebras of the type in Eq. (77) are prone to such anomalies.

An obvious technique for evaluating such a commutator would be to define the angular momentum operators by point-splitting in the form

$$L^i_{t,\epsilon} := i\hbar\,\epsilon^i{}_{jk}(b^j_t)^\dagger b^k_{t+\epsilon} \tag{78}$$

so that the commutator in Eq. (77) is the analogue of an equal-time commutator in standard quantum field theory, and the point splitting is the analogue of spatial point splitting. It is then straightforward to compute the commutators of these point-split operators and take the limit $\epsilon\to 0$. The result is the anticipated algebra Eq. (77).

However, in standard quantum field theory it is known that the limit of the commutator has to be considered at unequal times (i.e., using Heisenberg picture operators), and that there is a subtle relation between the two limits of the times becoming equal and the spatial point splitting tending to zero.[10] Therefore, in order to calculate correctly the commutator in our case it seems appropriate to consider the analogue of an unequal time commutator, namely,

$$[L^i_{\chi,t,\epsilon}, L^j_{0,s,\epsilon}], \tag{79}$$

where

$$L^i_{\chi,t,\epsilon} := i\hbar\,\epsilon^i{}_{jk}(b^j_{\chi,t})^\dagger b^k_{\chi,t+\epsilon}, \tag{80}$$

and where

$$b^k_{\chi,t} := e^{iH(\chi)} b^k_t e^{-iH(\chi)} = e^{-i\omega\chi(t)} b^k_t \tag{81}$$

is a time-averaged Heisenberg picture operator of the type defined earlier.

It is not difficult to show that

$$[L^i_{\chi,t,\epsilon}, L^j_{0,s,\epsilon}] = -\hbar^2 e^{i\omega(\chi(t)-\chi(t+\epsilon))}[\,\delta(t-s+\epsilon)((b^j_t)^\dagger b^i_{t+2\epsilon} - \delta^{ij}(b^m_t)^\dagger b^m_{t+2\epsilon})$$
$$-\delta(t-s-\epsilon)((b^i_{t-\epsilon})^\dagger b^j_{t+\epsilon} - \delta^{ij}(b^m_{t-\epsilon})^\dagger b^m_{t+\epsilon})], \tag{82}$$

and then, by evaluating the matrix element of the commutator in the vacuum state, one sees that there is no central extension in this case. Furthermore, by considering the matrix element of the commutator in general coherent states, one can check that the limits of $\epsilon \to 0$ and $\chi \to 0$ are straightforward, and that as long as the test functions are smooth, the angular momentum generators do indeed satisfy the heuristic commutator Eq. (77) in the limit.

H. The role of the velocity operator

The HPO approach to the consistent histories theory has the striking feature that, formally, there exists an operator that corresponds to propositions about the *velocity* of the system: namely, $\dot{x}_t := (d/dt)\,x_t$. More rigorously, we can adopt the procedure familiar from standard quantum field theory and define

$$\dot{x}_f := -x_{\dot{f}}, \tag{83}$$

which is meaningful provided that (i) the test-function f is differentiable; and (ii) f 'vanishes at infinity' so that the implicit integration by parts used in Eq. (83) is allowed; i.e., heuristically, $x_f = \int_{-\infty}^{\infty} dt\, x_t f_t$.

The rigorous existence of $\dot{x}_t$ depends on the precise choice of test-function space used in the smeared form of the CHA in Eqs. (14)–(16). In the analogous situation in normal quantum field theory, the test-functions are chosen so that the spatial derivatives of the quantum field exist, this being necessary to define the Hamiltonian operator. In our case, the situation is somewhat different since the energy operator H_t [see Eq. (18)] does not depend on $\dot{x}_t$ and hence there is no *a priori* requirement for $\dot{x}_t$ to exist. However, what *is* clear from Eq. (8) is that *if* $\dot{x}_t$ exists, then

$$[x_t, \dot{x}_s] = 0 \tag{84}$$

and hence our theory allows for history propositions that include assertions about the position of the particle and its velocity at the same time; in particular, the velocity $\dot{x}_t$ and momentum p_t are not related. In this context it should be emphasized once more that x_t, $t \in \mathbb{R}$, is a one-parameter family of *Schrödinger* picture operators—it is *not* a Heisenberg picture operator, and the equations of motion do not enter at this level.

The existence of a velocity operator that commutes with position is a striking property of the HPO approach to consistent histories and raises some intriguing questions. For example, a classic paper by Park and Margenau[11] contains an interesting discussion of the uncertainty relations, including a claim that it *is* possible to measure position and momentum simultaneously provided the latter is defined using time-of-flight measurements. The existence in our formalism of the vanishing commutator Eq. (84) throws some new light on this old discussion. Also relevant in this respect is Hartle's discussion of the operational meaning of momentum in a history theory.[12] In particular, he emphasizes that an accurate measurement of momentum requires a long time-of-

flight, whereas—on the other hand—our definition of velocity as the time-derivative of the history variable x_t clearly involves a vanishingly small time interval. Presumably this is the operational difference between momentum and velocity in the HPO approach to consistent histories.

The potential existence of $\dot{x}_t$ also raises the interesting possibility of defining a 'velocity-extended' version of the energy H_t as

$$H_t := \frac{p_t^2}{2m} + \frac{m}{2}(\omega^2 x_t^2 + \lambda \dot{x}_t^2) \tag{85}$$

for some real parameter $\lambda \geqslant 0$. Note that in the one-dimensional quantum field theory analogue in which x_t and p_t are replaced by $\phi(x)$ and $\pi(x)$, respectively, for an appropriate choice of λ the expression in Eq. (85) becomes the usual Hamiltonian density $H(x)$ for a massive scalar field (the $\lambda = 0$ case of Eq. (18) then corresponds to an *ultralocal* quantum field). Guided by this observation, we can try to repeat our earlier analysis and look for a representation of the canonical history algebra in which a suitably smeared version of this new energy exists as a proper operator. The quantum field theory analogue suggests that the appropriate replacement for Eq. (29) is

$$c_t := \left(\frac{m\sqrt{\omega^2 - \lambda D^2}}{2\hbar}\right)^{1/2} x_t + i\left(\frac{1}{2m\hbar\sqrt{\omega^2 - \lambda D^2}}\right)^{1/2} p_t, \tag{86}$$

where D denotes the differential operator d/dt. Note that $-D^2$ is a positive semi-definite operator on $L^2(\mathbb{R}, dt)$, and hence the square-root of $\omega^2 - \lambda D^2$ is well-defined; of course, to make all this rigorous a suitably-smeared form of Eq. (86) should be used.

We note that

$$[c_t, c_s^\dagger] = \delta(t-s) \tag{87}$$

and that, *if* it existed, the smeared form $H(\chi)$ of the velocity-extended Hamiltonian would generate the CHA automorphism

$$e^{iH(\chi)/\hbar} c_t e^{-iH(\chi)/\hbar} = \exp[-i\chi(t)\sqrt{\omega^2 - \lambda D^2}]c_t. \tag{88}$$

For the special case in which χ is a *constant*, the right hand side corresponds to a unitary transformation on the 'one-particle' space $L^2(\mathbb{R}, dt)$, and hence the time-averaged energy $\int_{-\infty}^{\infty} dt H_t$ exists as a genuine operator on the associated Fock space. Of course, the eigenvalues and eigenvectors of this operator are well-known for the quantum field theory analogue of the total Hamiltonian operator $\int dx H(x)$; in the history theory, the associated projection operators correspond to appropriate propositions about the value of the time average of the energy.

Note that the relation between x_t and the new annihilation and creation operators is non-local in time:

$$x_t = \left(\frac{\hbar}{2m\sqrt{\omega^2 - \lambda D^2}}\right)^{1/2} (c_t + c_t^\dagger). \tag{89}$$

In particular, the correlation function is

$$\langle 0 | x_t x_s | 0 \rangle = \left(\frac{\hbar}{2m\sqrt{\omega^2 - \lambda D^2}}\right) \delta(t-s), \tag{90}$$

where the non-local quantity on the right hand side is the Green's function of the elliptic partial differential operator $\sqrt{\omega^2 - \lambda D^2}$. Thus we still have a Gaussian stochastic process but it is 'softer' than the one constructed earlier whose correlation function was Eq. (40). Of course, existence of non-local terms is a common occurrence in normal relativistic quantum field theory, but there the non-locality is in space, not time. It remains to be seen whether the 'velocity-extended' Hamiltonian in Eq. (85) has any real physical application in the consistent histories theory.

III. QUANTUM FIELD THEORY

A. The canonical history algebra

We wish now to extend the discussion to the HPO theory of a free scalar field. Hartle[13] proposed a consistent histories approach to quantum field theory based on path integrals, and Blencowe[14] gave a careful analysis of the use of class operators. However, almost nothing has been said about the HPO scheme in this context, and we shall now briefly present the necessary developments. The resemblance of the history version of quantum mechanics ('field theory in zero spatial dimensions') to a canonical field theory in one spatial dimension suggests that the history version of quantum field theory in three spatial dimensions should resemble canonical quantum field theory in *four* spatial dimensions. We shall see that this expectation is fully justified.

The first step in constructing a HPO version of quantum field theory is to foliate four-dimensional Minkowski space–time with the aid of a timelike vector n^μ that is normalized by $\eta_{\mu\nu}n^\mu n^\nu=1$, where the signature of the Minkowski metric $\eta_{\mu\nu}$ has been chosen as $(+,-,-,-)$. The canonical commutation relations for a standard bosonic quantum field theory (the analogue of Eq. (4)) in three spatial dimensions are

$$[\phi(\underline{x}_1),\phi(\underline{x}_2)]=0, \tag{91}$$

$$[\pi(\underline{x}_1),\pi(\underline{x}_2)]=0, \tag{92}$$

$$[\phi(\underline{x}_1),\pi(\underline{x}_2)]=i\hbar\,\delta^3(\underline{x}_1-\underline{x}_2), \tag{93}$$

where x_1 and x_2 are three-vectors that are spatial with respect to the foliation vector n. In constructing the associated HPO theory we shall assume that the passage from the canonical algebra Eq. (4) to the history algebra Eqs. (8)–(10) is reflected in the field theory case by passing from Eqs. (91)–(93) to

$$[\phi_{t_1}(\underline{x}_1),\phi_{t_2}(\underline{x}_2)]=0, \tag{94}$$

$$[\pi_{t_1}(\underline{x}_1),\pi_{t_2}(\underline{x}_2)]=0, \tag{95}$$

$$[\phi_{t_1}(\underline{x}_1),\pi_{t_2}(\underline{x}_2)]=i\hbar\,\delta(t_1-t_2)\,\delta^3(\underline{x}_1-\underline{x}_2), \tag{96}$$

where, for each $t\in\mathbb{R}$, the fields $\phi_t(x)$ and $\pi_t(x)$ are associated with the spacelike hypersurface (n,t) whose normal vector is n and whose foliation parameter is t; in particular, the three-vector x in $\phi_t(x)$ or $\pi_t(x)$ denotes a vector in this space.

In using this algebra, we have in mind a representation that is some type of continuous tensor product $\otimes_{t\in\mathbb{R}}\mathscr{H}_t$ where each $\mathscr{H}_t$ carries a representation of the standard canonical commutation relations Eqs. (91)–(93) for a scalar field theory associated with the given space–time foliation. However, to emphasize the underlying space–time picture it is convenient to rewrite Eqs. (94)–(96) in terms of four-vectors X and Y as

$$[\phi(X),\phi(Y)]=0, \tag{97}$$

$$[\pi(X),\pi(Y)]=0, \tag{98}$$

$$[\phi(X),\pi(Y)]=i\hbar\,\delta^4(X-Y). \tag{99}$$

In relating these expressions to those in Eqs. (94)–(96) the three-vector x may be equated with a four-vector x_n that satisfies $n\cdot x_n=0$ (the dot product is taken with respect to the Minkowski metric $\eta_{\mu\nu}$) so that the pair $(t,x)\in\mathbb{R}\times\mathbb{R}^3$ is associated with the space–time point $X=tn+x_n$ (in particular, $t=n\cdot X$). Note, however, that the covariant-looking nature of these expressions is deceptive and it is not correct to assume *a priori* that the fields $\phi(X)$ and $\pi(Y)$ transform as space–time scalars under the action of some 'external' space–time Poincaré group that acts on the X and Y labels—as things stand there is an implicit n label on both ϕ and π. We shall return to this question later.

B. The Hamiltonian algebra

The key idea of our HPO approach to quantum field theory is that the physically-relevant representation of the canonical history algebra Eqs. (94)–(96) [or, equivalently, Eqs. (97)–(99)] is to be selected by requiring the existence of operators that represent history propositions about temporal averages of the energy defined with respect to the chosen space–time foliation. Thus, for a fixed foliation vector n, we seek a family of 'internal' Hamiltonians $H_{n,t}$, $t\in\mathbb{R}$, whose explicit formal form (i.e., the analogue of Eq. (18)) can be deduced from the standard quantum field theory expression to be

$$H_{n,t}:=\frac{1}{2}\int d^4X\{\pi(X)^2+(n^\mu n^\nu-\eta^{\mu\nu})\partial_\mu\phi(X)\partial_\nu\phi(X)+m^2\phi(X)^2\}\delta(t-n\cdot X). \quad (100)$$

The analogous, temporally-averaged object is

$$\begin{aligned} H_n(\chi):&=\int_{-\infty}^{\infty}dt\chi(t)H_{n,t}\\ &=\frac{1}{2}\int d^4X\{\pi(X)^2+(n^\mu n^\nu-\eta^{\mu\nu})\partial_\mu\phi(X)\partial_\nu\phi(X)+m^2\phi(X)^2\}\chi(n\cdot X) \end{aligned} \quad (101)$$

where χ is a real-valued test function.

As in the discussion above of the simple harmonic oscillator, the next step is to consider the commutator algebra that would be satisfied by the operators $H_n(\chi)$ *if* they existed. These field-theoretic analogues of Eqs. (24)–(26) are readily computed as

$$[H_n(\chi),\phi(X)]=-i\hbar\chi(n\cdot X)\pi(X), \quad (102)$$

$$[H_n(\chi),\pi(X)]=i\hbar\chi(n\cdot X)K_n\phi(X), \quad (103)$$

$$[H_n(\chi_1),H_n(\chi_2)]=0, \quad (104)$$

where K_n denotes the partial differential operator

$$(K_nf)(X):=[(\eta^{\mu\nu}-n^\mu n^\nu)\partial_\mu\partial_\nu+m^2]f(X). \quad (105)$$

The exponentiated form of Eqs. (102)–(103) is

$$e^{iH_n(\chi)/\hbar}\phi(X)e^{-iH_n(\chi)/\hbar}=\cos[\chi(n\cdot X)\sqrt{K_n}]\phi(X)+\frac{1}{\sqrt{K_n}}\sin[\chi(n\cdot X)\sqrt{K_n}]\pi(X), \quad (106)$$

$$e^{iH_n(\chi)/\hbar}\pi(X)e^{-iH_n(\chi)/\hbar}=-\sqrt{K_n}\sin[\chi(n\cdot X)\sqrt{K_n}]\phi(X)+\cos[\chi(n\cdot X)\sqrt{K_n}]\pi(X), \quad (107)$$

where the square-root operator $\sqrt{K_n}$, and functions thereof, can be defined rigorously using the spectral theory of the self-adjoint, partial differential operator K_n on the Hilbert space $L^2(\mathbb{R}^4,d^4X)$. Note that the expression $\chi(n\cdot X)\sqrt{K_n}$ is unambiguous since, viewed as an operator on $L^2(\mathbb{R}^4,d^4X)$, multiplication by $\chi(n\cdot X)$ commutes with K_n.

C. The Fock space representation

The right hand side of Eqs. (106) and (107) defines an automorphism of the CHA Eqs. (97)–(99) and the task is to find a representation of the latter in which these automorphisms are unitarily implemented. To this end, define new operators

$$q(X):=K_n^{1/4}\phi(X), \quad (108)$$

$$p(X):=K_n^{-1/4}\pi(X), \quad (109)$$

and

$$b(X) := \frac{1}{\sqrt{2}}(q(X)+ip(X)) = \frac{1}{\sqrt{2}}(K_n^{1/4}\phi(X)+iK_n^{-1/4}\pi(X)), \tag{110}$$

which satisfy

$$[b(X),b(Y)]=0, \tag{111}$$

$$[b^\dagger(X),b^\dagger(Y)]=0, \tag{112}$$

$$[b(X),b^\dagger(Y)]=\hbar\,\delta^4(X-Y). \tag{113}$$

Then

$$e^{iH_n(\chi)/\hbar}q(X)e^{-iH_n(\chi)/\hbar} = \cos[\chi(n\cdot X)\sqrt{K_n}]q(X)+\sin[\chi(n\cdot X)\sqrt{K_n}]p(X), \tag{114}$$

$$e^{iH_n(\chi)/\hbar}p(X)e^{-iH_n(\chi)/\hbar} = -\sin[\chi(n\cdot X)\sqrt{K_n}]q(X)+\cos[\chi(n\cdot X)\sqrt{K_n}]p(X), \tag{115}$$

and so

$$e^{iH_n(\chi)/\hbar}b(X)e^{-iH_n(\chi)/\hbar} = e^{-i\chi(n\cdot X)\sqrt{K_n}}b(X). \tag{116}$$

However, the operator defined on $L^2(\mathbb{R}^4)$ by

$$(U(\chi)\psi)(X) := e^{-i\chi(n\cdot X)\sqrt{K_n}}\psi(X) \tag{117}$$

is unitary, and hence—using the same type of argument invoked earlier for the simple harmonic oscillator—we conclude that the desired quantities $H_n(\chi)$ exist as self-adjoint operators on the Fock space $\mathscr{F}[L^2(\mathbb{R}^4,d^4X)]$ associated with the creation and annihilation operators $b^\dagger(X)$ and $b(X)$. The spectral projectors of these operators then represent propositions about the time-averaged value of the energy in the spacetime foliation determined by n.

D. The question of external Lorentz invariance

An important part of standard quantum field theory is a proof of invariance under the Poincaré group—something that, in the canonical formalism, is not totally trivial since the Schrödinger picture fields depend on the reference frame (i.e., the space–time foliation). The key ingredient is a construction of the generators of the Poincaré group as explicit functions of the canonical field variables; in practice, the first step is often to construct the Heisenberg picture fields with the aid of the Hamiltonian, and then to demonstrate manifest Poincaré covariance within that framework. The canonical fields associated with any spacelike surface in a particular Lorentz frame can then be obtained by restricting the Heisenberg fields (and their normal derivatives) to the surface.

When considering the role of the Poincaré group in the HPO picture of consistent histories, the starting point is the observation that, heuristically speaking, for a given foliation vector n—and for each value of the associated time t—there will be a Hilbert space $\mathscr{H}_t$ carrying an independent copy of the standard quantum field theory. In particular, therefore, for fixed n, there will be a representation of the Poincaré group associated with each spacelike slice (n,t), $t\in\mathbb{R}$. Thus if A_a, $a=1,2,\ldots,10$, denote the generators of the Poincaré group, there should exist a family of operators A_t^a which, for each $t\in\mathbb{R}$, generate the '*internal*' Poincaré group $\mathscr{P}_{n,t}$ associated with the slice (n,t). These operators will satisfy a 'temporally gauged' version of the Poincaré algebra. More precisely, if $C^{ab}{}_c$ are the structure constants of the Poincaré group, so that

$$[A^a,A^b]=iC^{ab}{}_cA^c, \tag{118}$$

then the algebra satisfied by the history theory operators A_t^a is

$$[A_t^a,A_s^b]=i\,\delta(t-s)C^{ab}{}_cA_t^c, \tag{119}$$

which, of course, reflects the way in which the canonical commutation relations Eqs. (91)–(93) are replaced by Eqs. (94)–(96) in the history theory.

As always in quantum theory, the energy operator is of particular importance, and in the present case we have a family of Hamiltonian operators $H_{n,t}$, $t\in\mathbb{R}$, which are related to the generators $P^{\mu}_{n,t}$ of translations for the quantum field theory associated with the hypersurface (n,t) by

$$H_{n,t}=n_{\mu}P^{\mu}_{n,t}. \tag{120}$$

In fact, it is straightforward to show that

$$P^{\mu}_{n,t}=n^{\mu}H_{n,t}+\int d^4X\,\delta(t-n\cdot X)(n^{\mu}n\cdot\partial\phi-\partial^{\mu}\phi)\pi, \tag{121}$$

which suggests that, as would be expected, the components of $P^{\mu}_{n,t}$ normal to n are the generators of spatial translations in the hypersurface (n,t). Indeed, Eq. (102) generalizes to

$$[P^{\mu}_{n}(\chi),\phi(X)]=-i\hbar\chi(n\cdot X)\{n_{\mu}\pi(X)+(\partial_{\mu}\phi(X)-n_{\mu}n\cdot\partial\phi(X))\}. \tag{122}$$

Similarly, the 'temporally gauged' Lorentz generators satisfy

$$[J^{\mu\nu}_{n,t},\phi(X)]=i\hbar\,\delta(t-n\cdot X)\{X^{\mu}(\partial^{\nu}\phi-n^{\nu}n\cdot\partial\phi)-X^{\nu}(\partial^{\mu}\phi-n^{\mu}n\cdot\partial\phi)-(X^{\mu}n^{\nu}-X^{\nu}n^{\mu})\pi\}. \tag{123}$$

As emphasized above, each generator of the group $\mathscr{P}_{n,t}$ acts 'internally' in the Hilbert space $\mathscr{H}_t$; in particular, this is true of the Hamiltonian, which (modulo the need to smear in t) generates translations along an 'internal' time label s that is to be associated with each leaf (n,t) of the foliation. It is important to note that $H_{n,t}$ does *not* generate translations along the 'exernal' time parameter t that appears in the CHA Eqs. (94)–(96) and which labels the spacelike surface (of course, there is an analogous statement for the Hamiltonians H_t in the HPO model of the simple harmonic oscillator considered earlier). The existence of these internal Poincaré groups is sufficient to guarantee covariance of physical quantities, such as transition amplitudes, that can be calculated in the class operator version of the theory.

However, the HPO formalism admits an additional type of Poincaré group—what we shall call the '*external*' Poincaré group—which is defined to act on the pair of labels (x,t) that appear in the CHA Eqs. (94)–(96). Thus these labels include the 'external' time parameter t that specifies the leaf (n,t) of the foliation associated with the timelike vector n. In the context of the covariant-looking version Eqs. (97)–(99) of the CHA, the main question is whether the fields $\phi(X)$ and $\pi(X)$ transform in a covariant way under this external group.

As far as the field $\phi(X)$ is concerned it seems reasonable to consider the possibility that this may be an external scalar in the sense that there exists a unitary representation $U(\Lambda)$ of the external Lorentz group $U(\Lambda)$ such that

$$U(\Lambda)\phi(X)U(\Lambda)^{-1}=\phi(\Lambda X). \tag{124}$$

The spectral projectors of the (suitably smeared) operators $\phi(X)$ then represent propositions about the values of the space–time field in a covariant way.

However, the situation for the field momentum $\pi(X)$ is different since this is intrinsically associated with the timelike vector n. Indeed, the natural thing would be to require the existence of a *family* of operators $\pi_n(X)$ where n lies in the hyperboloid of all timelike (future-pointing) vectors, and such that

$$U(\Lambda)\pi_n(X)U(\Lambda)^{-1}=\pi_{\Lambda n}(\Lambda X). \tag{125}$$

The next step in demonstrating external Poincaré covariance would be to extend the algebra (97)–(99) to include the n parameter on the π field; in particular, one would need to specify the commutator $[\pi_n(X),\pi_m(Y)]$, but it is not obvious *a priori* what this should be.

Another possibility would be to try to combine the Heisenberg picture—and its associated 'internal' time s—with the external time parameter t of the space–time foliation to give some scheme that was manifestly covariant in the context of a five-dimensional space with signature $(+++,--)$ associated with the variables (x,t,s). However, we do not know if this is possible and the demonstration of external Poincaré covariance, if it exists, remains the subject for future research.

IV. CONCLUSIONS

We have discussed the introduction of continuous-time histories within the 'HPO' version of the consistent histories formalism in which propositions about histories of the system are represented by projection operators on a 'history' Hilbert space. The history algebra (whose representations specify this space) for a particle moving in one dimension is isomorphic to the canonical commutation relations for a one-dimensional quantum field theory, thus allowing the history theory to be studied using techniques drawn from quantum field theory. In particular, we have shown how the problem of the existence of infinitely many inequivalent representations of the history algebra can be solved by requiring the existence of operators whose spectral projectors represent propositions about time-averages of the energy.

We have shown how the Heisenberg picture is changed in the HPO formalism in such a way that the familiar, partial-differential equations of motion are replaced by functional differential equations; these operators are used in the proof that the angular momentum operators of the three-dimensional theory are anomaly free. The question of potential anomalies in the history algebra is rather intriguing and it would be interesting to study a theory in which such things might be expected, such as a fermionic system.

A striking property of the HPO formalism is the potential existence of a velocity operator that commutes with the position operators, thus opening up a new perspective on the old debate about the operational meaning of the Heisenberg uncertainty relations between position and momentum. The introduction of the velocity operator suggests a number of topics for future work: for example, it would be most interesting to see if some thing like the action functional of the classical action has a natural role to play in the HPO theory.

Finally, we have shown how the HPO scheme can be extended to the history version of canonical quantum field theory. We discussed the difference between the 'internal' and 'external' Poincaré groups and indicated how the former are implemented in the formalism. A major challenge for future research is to construct an HPO quantum field theory which is manifestly covariant under this external symmetry group.

Classical limits for quantum maps on the torus

Andrzej Lesniewski, Ron Rubin, and Nathan Salwen
Lyman Laboratory of Physics, Harvard University, Cambridge, Massachusetts 02138-2901

(Received 11 March 1997; accepted for publication 26 March 1997)

We provide a rigorous canonical quantization for the following toral automorphisms: cat maps, generalized kicked maps, and generalized Harper maps. For each of these systems we construct a unitary propagator and prove the existence of a well-defined classical limit. We also provide an alternative derivation of Hannay and Berry results for the cat map propagator on the plane. © *1998 American Institute of Physics.* [S0022-2488(98)02404-9]

I. INTRODUCTION

The burgeoning field of ''quantum chaos'' or, more precisely, the quantum mechanics of classically chaotic dynamics has opened the door to several issues in quantization (see e.g., Ref. 1). One of these is the quantization of classical maps.[2–5]

Classical maps arise naturally in the study of chaos. In the Poincaré surface of section maps (see Ref. 6), for instance, the flow on a d-dimensional phase space is ''reduced'' to a $(d-1)$-dimensional map by considering the discrete evolution of points of intersection of the trajectory with a co-dimension of one hypersurface. Chaotic properties of the flow typically leave tell-tale signs on the surface of section. It is clear that the two problems are intimately connected, and numerical results indicate this. Another typical way in which classical flows lead to maps is via a coarse graining of Hamilton's equation,

$$p'=p+f(x)\Delta t, \quad x'=x+p',$$

where $f(x)=-\nabla_x u(x)$ is the classical force function for the Hamiltonian $H=p^2/2+u(x)$, and where in the second equation p' is used rather than p to ensure the map is area preserving. For maps corresponding to integrable flows, the parameter Δt is a type of ''order parameter'' for the transition to chaos in the corresponding family of maps. Typically for large Δt, the system is completely chaotic, while for small Δt, the system mimics its continuous time progenitor and remains on regular trajectories for all time. (Examples abound. See, e.g., Ref. 6.)

The quantization of classically chaotic maps has recently become an interesting issue in its own right. Hannay and Berry[3] provide a quantization of the cat map

$$(x',p')=\beta(x,p) \mod 1, \quad \beta\in SL(2,\mathbb{Z}), \tag{1}$$

using a semiclassical argument. First they impose the integrality condition of Planck's constant $h=1/N$. Then argue that on the torus the Hilbert space has dimension N. This is semiclassical in that it corresponds to the quantization condition

$$\oint p\,dx=nh. \tag{2}$$

For the unit torus, the left-hand side of (2) is unity, and the integrality condition for Planck's constant follows. In fact, this is also the integrality condition of geometric quantization which requires the symplectic form divided by Planck's constant to define a deRham cohomology class with integer coefficients.[7] With the Hannay–Berry prescription for quantization, a further restriction was necessary: only a subset of $SL(2,\mathbb{Z})$, the so-called ''checkerboard'' matrices

$$\begin{pmatrix} odd & even \\ even & odd \end{pmatrix}, \quad \begin{pmatrix} even & odd \\ odd & even \end{pmatrix} \tag{3}$$

 © 1998 American Institute of Physics

could be quantized.

In Refs. 8, 4, and 5, a different approach toward quantizing the cat maps was introduced, in which the dynamics is described in the Heisenberg picture as the evolution of a noncommutative algebra of observables. The Hilbert space remains infinite dimensional, and no restrictions on Planck's constant or the allowed classical maps are made. The quantum torus is constructed by deforming the classical algebra of observables. We let

$$U=Q_\hbar(e^{2\pi ix}), \quad V=Q_\hbar(e^{2\pi ip}),$$

where $Q_\hbar(\sigma)$ is an operator on the Hilbert space $\mathscr{H}$ corresponding to the classical symbol σ, and the algebra of observables $\mathfrak{A}_\hbar$ is then generated by $\{U,V,U^\dagger,V^\dagger\}$. Technically, the algebra is given with an appropriate closure. For example, taking $\mathfrak{A}_\hbar=\{U,V,U^\dagger,V^\dagger\}''$, where R'' is the bicommutant of R, the algebra generated is a von Neumann algebra. The quantum dynamics is implemented as a discrete automorphism group of $\mathfrak{A}_\hbar$ generated by a unitary operator (called the propagator) F such that as $\hbar\to 0$, $F^\dagger Q_\hbar(\sigma)F\to Q_\hbar(\sigma\circ\beta)$ in a suitable topology.

A quantization scheme of the kind just described was given in Refs. 4 and 5 for the cat map, along with the connection to the original quantization proposed by Hannay and Berry. In this paper, we extend the results to three classes of maps.

We divide the remainder of the paper into three sections, corresponding to the different maps. In Sec. II, we review the relevant results of Refs. 4 and 5 for the cat maps, and also provide a canonical derivation of the propagator *on the plane* obtained by Ref. 3 using a ''discrete time path integral.'' In Sec. III, we provide a quantization scheme for ''generalized kick maps'' $\kappa(x,p)=(x',p')$, with

$$p'=p+\epsilon f(x), \quad x'=x+p'. \tag{4}$$

Here ϵ is a real constant, and f is a continuous real function (the force function) on the unit circle with Fourier coefficients f_k obeying the bound

$$\sum_{k\in\mathbb{Z}} k^2|f_k|<\infty. \tag{5}$$

In Sec. IV, we quantize ''generalized Harper maps'': $\eta(x,p)=(x',p')$, with

$$p'=p+\epsilon_1 f(x), \quad x'=x+\epsilon_2 g(p'), \tag{6}$$

where ϵ_1 and ϵ_2 are real constants, and f and g are real functions on the unit circle with Fourier coefficients satisfying the bound:

$$\sum_j j^2|f_j|<\infty, \quad \sum_k k^2|g_k|\exp\left(2\pi\epsilon_1 k\left(\sum_j |f_j|\right)\right)<\infty.$$

Note for generic f in kick maps, and generic f and g in Harper maps, the coefficients ϵ and ϵ_1, ϵ_2 are the parameters which induce a transition to chaos as they are increased in magnitude.

II. THE CAT MAP REVISITED

The cat map (1) has become a paradigm for the study of quantum chaos (see, e.g., Ref. 9). The first quantization scheme for the cat map was given by Hannay and Berry[3] in which a path integral argument from continuous time linear dynamics was used to write down the propagator for quantum evolution. In Ref. 4, a canonical quantization was proposed using Toeplitz operators in Bargmann space, and an explicit integral kernel for the unitary one-step evolution on the entire complex plane was given. Recall that Bargmann space $\mathscr{H}^2(\mathbb{C},d\mu_\hbar)\subset L^2(\mathbb{C},d\mu_\hbar)$ is the Hilbert space of entire functions on $\mathbb{C}$ which are square integrable with respect to the measure $d\mu_\hbar(z)=(\pi\hbar)^{-1}\exp(-|z|^2/\hbar)d^2z$. Formally, Toeplitz quantization $T_\hbar$ of a symbol over phase space is the operator of multiplication on $L^2(\mathbb{C},d\mu_\hbar)$ by this symbol followed by a projection onto $\mathscr{H}^2(\mathbb{C},d\mu_\hbar)$. For calculations, we must simply note that this gives an anti-Wick ordering of the corresponding quantum operator: $T_\hbar=(z^n\overline{z^m})=T_\hbar(\overline{z^m})T_\hbar(z^n)$. The quantum torus is then con-

structed by restricting the algebra of observables to be the Toeplitz quantization of Fourier series with classical generators $\exp(2\pi ix)$ and $\exp(2\pi ip)$. As in Refs. 4 and 5, we define the unitary operators U and V on $\mathscr{H}^2(\mathbb{C},d\mu_\hbar)$ to be the quantization of classical generators for $f\in C(\mathbb{T}^2)$, i.e.,

$$U=\exp(2\pi i\hat{x})=\exp(\pi^2\hbar)T_\hbar(\exp(2\pi ix)),$$

$$V=\exp(2\pi i\hat{p})=\exp(\pi^2\hbar)T_\hbar(\exp(2\pi ip)),$$

where $\hat{x}=T_\hbar(x)$, $\hat{p}=T_\hbar(p)$, and $z=(1/\sqrt{2})(x-ip)$. Observe also that the canonical position and momentum variables on the plane satisfy the usual Heisenberg relation $[\hat{x},\hat{p}]=i\hbar$, and so

$$UV=e^{-4\pi^2\hbar i}VU. \tag{7}$$

Bargmann space is natural in that a phase space dynamics is given a phase space quantization. However, it is clear from the isomorphism between $\mathscr{H}^2(\mathbb{C},d\mu_\hbar)$ and $L^2(\mathbb{R},dx)$ (see Ref. 10) that we should be able to reformulate the problem in $L^2(\mathbb{R})$. Following Ref. 4, to the classical cat map β defined in Eq. (1) we assign a corresponding quantum propagator C. For linear dynamics *on the torus* we have the following result.

Theorem 1: *There exists a unique (up to a phase) unitary quantum propagator C satisfying the following properties*:

(1)

$$C^\dagger\hat{x}C=a\hat{x}+b\hat{p}=\hat{x}', \quad C^\dagger\hat{p}C=c\hat{x}+d\hat{p}=\hat{p}', \tag{8}$$

where $\left(\begin{smallmatrix}a&b\\c&d\end{smallmatrix}\right)\in SL(2,\mathbb{Z})$, *such that C maps the harmonic oscillator ground state into the unique ground state of the transformed coordinates.*

(2) The mapping $U\to U'=C^\dagger UC$, *and* $V\to V'=C^\dagger VC$ *extends to an automorphism of the von Neumann algebra* $\mathfrak{A}_\hbar$.

(3) For $\sigma\in C(\mathbb{T}^2)$,

$$\|C^\dagger T_\hbar(\sigma)C-T_\hbar(\sigma\circ\beta)\|\to 0 \quad \text{as} \quad \hbar\to 0.$$

(4) Acting on a state $\Phi\in L^2(\mathbb{R})$, *C can be written explicitly as*

$$C\Phi(x)=\left(\frac{1}{hb}\right)^{1/2}\int_{\mathbb{R}} e^{i(ay^2-2yx+dx^2)/2b}\Phi(y)dy. \tag{9}$$

Remark 1: $C(x,y)=(1/hb)^{1/2}e^{i(ay^2-2yx+dx^2)/2b}$ *is precisely the integral kernel proposed in Ref. 3 using a semiclassical path integral argument.*

Proof: The proofs of (1), (2), and (3) are given in Ref. 4.

We prove statement (4). Following Ref. 10, the isomorphism between $\mathscr{H}^2(\mathbb{C},d\mu_\hbar)$ and $L^2(\mathbb{R})$ is implemented by the Bargmann transform. For $x\in\mathbb{R}$, and $z\in\mathbb{C}$, the integral kernel $B:L^2(\mathbb{R})\to\mathscr{H}^2(\mathbb{C},d\mu_\hbar)$ is given by

$$B(z,x)=\left(\frac{1}{\pi\hbar}\right)^{1/4}\exp(\sqrt{2}xz/\hbar-x^2/2\hbar-z^2/2\hbar).$$

Note also that

$$B^{-1}(z,x)=B(\overline{z},x).$$

The integral kernel for the linear dynamics on the plane in Bargmann representation was found in Ref. 4 to be

$$F(z,w)=\frac{1}{\sqrt{|\alpha|}}\exp\left\{-\frac{\overline{\beta}z^2}{2\hbar\alpha}+\frac{\overline{w}z}{\hbar\alpha}+\frac{\beta\overline{w}^2}{2\hbar\alpha}\right\},$$

where

$$\alpha=\tfrac{1}{2}(a+d+i(b-c)),\quad \beta=\tfrac{1}{2}(a-d+i(b+c)).$$

Then

$$C(x,y)=\int B(\overline{z},x)F(z,w)B(w,y)d\mu_\hbar(w)d\mu_\hbar(z)$$

$$=\frac{1}{\sqrt{\pi\hbar|\alpha|}}\int \exp(\sqrt{2}x\overline{z}/\hbar-x^2/2\hbar-\overline{z}^2/2\hbar-\overline{\beta}\overline{z}^2/2\hbar\alpha+\overline{w}z/\hbar\alpha+\beta\overline{w}^2/2\hbar\alpha$$
$$+\sqrt{2}yw/\hbar-y^2/2\hbar-w^2/2\hbar-|z|^2/\hbar-|w|^2/\hbar)d^2zd^2w.$$

This integral is a straightforward but tedious Gaussian integral. It can be calculated directly with the following result. For complex numbers A, B, C, D, E such that $\mathrm{Re}\,A>0$ and $(\mathrm{Re}\,A)^2>(\mathrm{Re}\,B+\mathrm{Re}\,C)^2+(\mathrm{Im}\,B-\mathrm{Im}\,C)^2$, we find

$$\int_C \exp(-A|z|^2+Bz^2+C\overline{z}^2+Dz+E\overline{z})d^2z$$

$$=\frac{\pi}{\sqrt{A^2-4BC}}\exp\frac{(D+E)^2(A^2-4BC)-(A(D-E)+2(EB-CD))^2}{4(A-B-C)(A^2-4BC)}.$$

Applying this formula twice to the above integral gives the desired result. ■

III. QUANTUM KICK MAPS

We provide here a procedure for quantizing another class of automorphisms of the torus described in Sec. I. Exponentiating (4), we have for the classical maps on the torus

$$e^{2\pi ix'}=e^{2\pi i(x+p')},\quad e^{2\pi ip'}=e^{2\pi i(p+\epsilon f(x))}. \tag{10}$$

In fact, we let (10) also give the quantum evolution, that is, we find a quantum propagator such that the one-step dynamics is given by (4) exactly, with x and p replaced by the Toeplitz operators $\hat{x}$ and $\hat{p}$. However, it is not immediately clear that such a map will give a well-defined automorphism of the quantum algebra $\mathfrak{A}$ on the torus. We now demonstrate this.

Lemma 2: Let f be a real valued function satisfying (5). Then the sum $\Sigma_{k\in Z}\widetilde{f}_kU^k$, where

$$\widetilde{f}_k=\left(\frac{1-e^{-i\lambda k}}{i\lambda k}\right)f_k \tag{11}$$

defines a bounded self-adjoint operator.

Proof: This is an immediate consequence of the estimate

$$\sum_k \|\widetilde{f}_kU^k\|\leqslant\sum_k|\widetilde{f}_k|\leqslant\sum_k|f_k|<\infty.$$

The second inequality follows from (19), while the last bound on the Fourier coefficients is by assumption. ■

We now define the quantum map corresponding to (10),

$$U'=e^{-i\lambda/2}V'U,\quad V'=V\exp\left(2\pi i\epsilon\sum_{k\in\mathbb{Z}}\widetilde{f}_kU^k\right), \tag{12}$$

where

$$\lambda=4\pi^2\hbar.$$

In the following we use the standard functional calculus for self-adjoint operators to define functions of the operators $\hat{x}$ and $\hat{p}$.

Lemma 3: With the above definitions,

$$U' = \exp(2\pi i(\hat{x} + \hat{p}')), \quad V' = \exp 2\pi i(\hat{p} + \epsilon f(\hat{x})). \tag{13}$$

Proof: Using Trotter's formula (see, e.g., Ref. 11), for T an integer,

$$\exp 2\pi i(\hat{p} + \epsilon f(\hat{x})) = \lim_{T\to\infty} (\exp[2\pi i\hat{p}/T]\exp[2\pi i\epsilon f(\hat{x})/T])^T, \tag{14}$$

where the limit is meant in the strong operator topology. Using

$$e^{-2\pi i\hat{p}/T}\hat{x}e^{2\pi i\hat{p}/T} = \hat{x} - 2\pi\hbar/T,$$

we see that the right-hand side of (14) reduces to

$$\begin{aligned}
&\exp(2\pi i\hat{p}) \lim_{T\to\infty} \exp \frac{2\pi i\epsilon}{T} \sum_{j=0}^{T-1} \sum_k f_k \exp[2\pi ik(\hat{x} - 2\pi j\hbar/T)] \\
&= \exp(2\pi i\hat{p}) \lim_{T\to\infty} \exp\left(\frac{2\pi i\epsilon}{T} \sum_k f_k \exp[2\pi ik\hat{x}] \frac{1 - \exp(-4\pi^2\hbar ik)}{1 - \exp(4\pi^2\hbar ik/T)} \right) \\
&= \exp(2\pi i\hat{p}) \exp\left(2\pi i\epsilon \sum_k \widetilde{f}_k \exp(2\pi ik\hat{x}) \right) = V',
\end{aligned}$$

where $\widetilde{f}_k$ is defined in (11). We also find

$$\exp(2\pi i(\hat{x} + \hat{p}')) = \exp(2\pi i\hat{p}')\exp(2\pi i\hat{x})\exp(-2\pi^2[\hat{x}, \hat{p}']) = V'UE^{-i\lambda/2} = U',$$

and the claim follows. ∎

Theorem 4: *Let f be a real valued function satisfying (5).*

(1) There exists a unitary operator (the quantum propagator) which implements (12), i.e.,

$$U' = K^\dagger UK, \quad V' = K^\dagger VK.$$

Explicitly, this operator is given by

$$K = e^{-i\hat{p}^2/2\hbar} e^{i\epsilon u(\hat{x})/\hbar}, \tag{15}$$

where u is a real differentiable function on the unit circle defined (up to a real constant) by $du(x)/dx = f(x)$.

(2) The map $U \to U'$, $V \to V'$ defined above extends to an automorphism of the von Neumann algebra of observables on the quantized torus. We call this automorphism the quantized kick map.

(3) The quantum dynamics has a well-defined classical limit in the norm topology. For $\sigma \in C(\mathbb{T}^2)$, we have

$$\|K^{-1}T_\hbar(\sigma)K - T_\hbar(\sigma\circ\kappa)\| \to 0, \text{ as } \hbar \to 0,$$

where $\kappa(x,p) = (p',x')$ is defined in Eq. (4).

Proof: (1) This is a straightforward calculation. Observe for K as in (15),

$$\begin{aligned}
K^\dagger VK &= \exp(2\pi iK^\dagger\hat{p}K) = \exp[2\pi i\{\exp(-i\epsilon u(\hat{x})/\hbar)\hat{p}\ \exp(i\epsilon u(\hat{x})/\hbar)\}] \\
&= \exp\left[2\pi i\left(\hat{p} + \epsilon \frac{du}{dx}(\hat{x}) \right) \right] = V',
\end{aligned}$$

where in the last step we have used Lemma 3. Likewise,

$$K^\dagger UK = \exp[2\pi i(\exp(-i\epsilon u(\hat{x})/\hbar)\exp(i\hat{p}^2/2\hbar)\hat{x}\ \exp(-i\hat{p}^2/2\hbar)\exp(i\epsilon u(\hat{x})/\hbar))]$$
$$= \exp[2\pi i(\hat{p}' + \hat{x})] = U'.$$

(2) It follows easily from part (1) that U' and V' satisfy (7). Since U and V can be expressed in terms of $U'$and V', namely,

$$U = e^{i\lambda} V'^\dagger U', \quad V = V'\ \exp\left(-2\pi i\epsilon \sum_{k\in\mathbb{Z}} \tilde{f}_k (e^{i\lambda} V'^\dagger U')^k\right),$$

this implies that U' and V' generate $\mathfrak{A}_\hbar$. The map is thus an automorphism of the algebra $\mathfrak{A}_\hbar$.

(3) As the proof of (3) is somewhat involved, we divide it into steps.

Step 1. We first calculate the terms in (3) for the case of the pure harmonic

$$\sigma_{mn}(x,p) := \exp(2\pi i(mx+np)).$$

Applying the Toeplitz quantization to the symbol σ_{mn} and using the Baker–Hausdorff–Campbell relation in the last step, we get

$$T_\hbar(\sigma_{mn}) = T_\hbar(\exp(\sqrt{2}\pi i(m-ni)\overline{z})\exp(\sqrt{2}\pi i(m+ni)z))$$
$$= \exp(\pi i(m-ni)(\hat{x}+i\hat{p}))\exp(\pi i(m+ni)(\hat{x}-i\hat{p}))$$
$$= V^n U^m\ \exp(-\pi^2\hbar(n^2+m^2+2inm)). \tag{16}$$

Thus, using (14) once again, we find

$$K^\dagger T_\hbar(\sigma_{mn}) K = (V')^n (U')^m\ \exp(-\pi^2\hbar(n^2+m^2+2inm))$$
$$= (V')^{n+m} U^m\ \exp(-i\lambda m/2)\exp(-i\lambda[m(m-1)]/2)\exp(-\pi^2\hbar(n^2+m^2+2inm))$$
$$= V^{n+m} U^m\ \exp(-\lambda(n^2+m^2+2inm+2im^2)/4)$$
$$\times \exp\left(2\pi i\epsilon \sum_k\ (m+n)\tilde{f}_k(m+n) U^k\right), \tag{17}$$

where, for any integer n,

$$\tilde{f}_k(n) = \left(\frac{1-\exp(-i\lambda kn)}{i\lambda kn}\right) f_k. \tag{18}$$

Expanding the right-hand side of (17), we have

$$K^\dagger T_\hbar(\sigma_{mn})K = V^{m+n}U^m \exp(-\lambda(n^2+m^2+2inm+2im^2)/4) \times \sum_{l=0}^{\infty} \frac{(2\pi i\epsilon)^l (m+n)^l}{l!} \sum_{k_1,\ldots,k_l} \prod_{j=1}^{l} \tilde{f}_{k_j}(m+n)U^{k_j}.$$

We want to compare this last expression with

$$T_\hbar(\sigma_{mn}\circ\kappa(x,p)) = T_\hbar(\exp(2\pi i[n(p+\epsilon f(x))+m(x+p+\epsilon f(x))])) = T_\hbar\left(\exp 2\pi i((m+n)p+mx)\sum_{l=0}^{\infty} \frac{[2\pi i(m+n)\epsilon(\Sigma_{k\in\mathbb{Z}} f_k e^{2\pi ikx})]^l}{l!}\right).$$

Using (16) to expand the right-hand side of the equation above, we find

$$T_\hbar(\sigma_{mn}\circ\kappa(x,p)) = V^{m+n}U^m \exp\left(-\frac{\lambda}{4}[(m+n)^2+2i(m^2+mn)]\right) \times \sum_{l=0}^{\infty} \frac{(2\pi i\epsilon)^l (m+n)^l}{l!} \sum_{k_1,\ldots,k_l} \prod_{j=1}^{l} f_{k_j}U^{k_j} \times \exp\left(-\frac{\lambda}{4}[(m+k_1+\cdots+k_l)^2+2i(m+n)(k_1+\cdots+k_l)]\right).$$

Step 2. Next we prove (3) for the case of a pure harmonic. Since $\tilde{f}_{k_j}(n)$ approaches f_k as $\hbar \to 0$, it is clear that term by term (in powers of V^pU^q) the difference $K^\dagger T_\hbar(\sigma_{mn})K$ and $T_\hbar(\sigma_{mn}\circ\kappa)$ vanishes as $\hbar\to 0$. To show the entire sum vanishes requires a little more work.

We shall see that this indeed happens provided the force function f satisfies our assumption. To this end, we define the following norm of f:

$$\|f\|_2 := \sum_k (1+|k|)^2|f_k| < \infty.$$

Notice first of all the difference

$$\|K^\dagger T_\hbar(\sigma_{mn})K - T_\hbar(\sigma_{mn}\circ\kappa)\| \leq \Bigg\| \exp\left(-\frac{\lambda}{4}(n^2+m^2+2inm+2im^2)\right) \times \sum_{l=0}^{\infty} \frac{(2\pi i\epsilon)^l (m+n)^l}{l!} \sum_{k_1,\ldots,k_l} \prod_{j=1}^{l} \tilde{f}_{k_j}(m+n)U^{k_j} - \exp\left(-\frac{\lambda}{4}[(m+n)^2+2i(m^2+mn)]\right) \times \sum_{l=0}^{\infty} \frac{(2\pi i\epsilon)^l (m+n)^l}{l!} \sum_{k_1,\ldots,k_l} \prod_{j=1}^{l} f_{k_j}U^{k_j} \times \exp -\frac{\lambda}{4}[(m+k_1+\cdots+k_l)^2+2i(m+n)(k_1+\cdots+k_l)]\Bigg\|,$$

where we have used the fact that $\|U\| = \|V\| = 1$. We next use a simple argument to eliminate the exponentials preceding the sums in both terms on the right-hand side of the above expression. We see that

$$\begin{aligned}\|K^\dagger T_\hbar(\sigma_{mn})K - T_\hbar(\sigma_{mn}\circ\kappa)\| \leqslant & \left\| \left(1-\exp-\frac{\lambda}{4}(n^2+m^2+2inm-2im^2)\right)\right. \\ & \left.\times\sum_{l=0}^{\infty}\frac{(2\pi i\epsilon)^l(m+n)^l}{l!}\sum_{k_1,\ldots,k_l}\prod_{j=1}^{l}\widetilde{f}_{k_j}(m+n)U^{k_j}\right\| \\ & +\left\|\sum_{l=0}^{\infty}\frac{(2\pi i\epsilon)^l(m+n)^l}{l!}\sum_{k_1,\ldots,k_l}\prod_{j=1}^{l}U^{k_j}\left(\sum_{j=1}^{l}\widetilde{f}_{k_j}(m+n)-\prod_{j=1}^{l}f_{k_j}\right.\right. \\ & \left.\left.\times\exp-\frac{\lambda}{4}[(m+k_1+\cdots+k_l)^2+2i(m+n)(k_1+\cdots+k_l)]\right)\right\| \\ & +\left\|\left(1-\exp-\frac{\lambda}{4}((m+n)^2+2i(m^2+mn))\right)\right. \\ & \times\sum_{l=0}^{\infty}\frac{(2\pi i\epsilon)^l(m+n)^l}{l!}\sum_{k_1,\ldots,k_l}\prod_{j=1}^{l}f_{k_j}U^{k_j} \\ & \left.\times\exp-\frac{\lambda}{4}((m+k_1+\cdots+k_l)^2+2i(m+n)(k_1+\cdots+k_l))\right\|.\end{aligned}$$

The first and third terms on the right-hand side are both of the form $\|(1-\exp-a\lambda)F\|$, where F is a bounded operator as $\lambda\to 0$ and $\mathrm{Re}(a)>0$. From the mean value theorem, it follows that

$$|1-\exp(-a\lambda)|\leqslant|a|\lambda, \tag{19}$$

so that these two terms are both $O(\lambda)$. Thus

$$\begin{aligned}&\|K^\dagger T_\hbar(\sigma_{mn})K - T_\hbar(\sigma_{mn}\circ\kappa)\| \\ &\quad\leqslant O(\lambda)+\left\|\sum_{l=0}^{\infty}\frac{(2\pi i\epsilon)^l(m+n)^l}{l!}\sum_{k_1,\ldots,k_l}U^{k_j}\left(\prod_{j=1}^{l}\widetilde{f}_{k_j}(m+n)-\prod_{j=1}^{l}f_{k_j}\right.\right. \\ &\qquad\left.\left.\times\exp-\frac{\lambda}{4}((m+k_1+\cdots+k_l)^2+2i(m+n)(k_1+\cdots+k_l))\right)\right\|.\end{aligned}$$

An only slightly more complicated telescoping argument eliminates the exponentials inside the remaining sums. We see

$$\begin{aligned}&\|K^\dagger T_\hbar(\sigma_{mn})K - T_\hbar(\sigma_{mn}\circ\kappa)\| \\ &\quad\leqslant O(\lambda)+\left\|\sum_{l=0}^{\infty}\frac{(2\pi i\epsilon)^l(m+n)^l}{l!}\sum_{k_1,\ldots,k_l}U^{k_j}\left(\prod_{j=1}^{l}\widetilde{f}_{k_j}(m+n)-\prod_{j=1}^{l}f_{k_j}\right)\right\| \\ &\qquad+\left\|\sum_{l=0}^{\infty}\frac{(2\pi i\epsilon)^l(m+n)^l}{l!}\sum_{k_1,\ldots,k_l}\prod_{j=1}^{l}U^{k_j}f_{k_j}\right. \\ &\qquad\left.\times\left[1-\exp-\frac{\lambda}{4}((m+k_1+\cdots+k_l)^2+2i(m+n)(k_1+\cdots+k_l))\right]\right\|.\end{aligned}$$

Consider the last set of terms only in the above expression. We have, using (19) once again

$$\begin{aligned}
&\left\| \sum_{l=0}^{\infty} \frac{(2\pi i\epsilon)^l (m+n)^l}{l!} \right. \\
&\qquad \left. \times \sum_{k_1,\ldots,k_l} \prod_{j=1}^{l} U^{k_j} f_{k_j} \left[1 - \exp - \frac{\lambda}{4} \left((m+k_1+\cdots+k_l)^2 + 2i|m+n|(k_1+\cdots+k_l) \right) \right] \right\| \\
&\leqslant \frac{\lambda}{4} \sum_{l=0}^{\infty} \frac{(2\pi\epsilon)^l (|n|+|m|)^l}{l!} \sum_{k_1,\ldots,k_l} \prod_{j=1}^{l} |f_{k_j}| \\
&\qquad \times \left| (m+k_1+\cdots+k_l)^2 + 2(|m|+|n|)(k_1+\cdots+k_l) \right| \\
&\leqslant \frac{\lambda}{4} \sum_{l=0}^{\infty} \frac{(2\pi\epsilon)^l (|n|+|m|)^l}{l!} \sum_{k_1,\ldots,k_l} \prod_{j=1}^{l} |f_{k_j}| \\
&\qquad \times (m^2 + l(k_1^2+\cdots+k_l^2) + (4|m|+2|n|)(k_1+\cdots+k_l)) \\
&\leqslant \frac{\lambda}{4} \sum_{l=0}^{\infty} \frac{(2\pi\epsilon)^l (|n|+|m|)^l}{l!} (m^2 + 4|m| + 2|n| + l) \|f\|_2^l \\
&\leqslant \frac{\lambda}{4} (m^2 + 4|m| + 2|n| + 2\pi\epsilon(|n|+|m|)\|f\|_2) \exp 2\pi\epsilon(|n|+|m|)\|f\|_2 = O(\lambda).
\end{aligned}$$

Combining all of this, we have reduced our estimate to

$$\begin{aligned}
&\|K^\dagger T_\hbar(\sigma_{mn}) K - T_\hbar(\sigma_{mn} \circ \kappa)\| \\
&\qquad \leqslant O(\lambda) + \sum_{l=0}^{\infty} \frac{(2\pi\epsilon)^l (|n|+|m|)^l}{l!} \\
&\qquad\qquad \times \sum_{k_1,\ldots,k_l} \left| 1 - \left(\prod_{j=1}^{l} \frac{1 - \exp(-i\lambda k_j (m+n))}{i\lambda k_j (m+n)} \right) \right| |f_{k_1}| \cdots |f_{k_l}|. \qquad (20)
\end{aligned}$$

By Taylor's theorem with remainder, we know that for $\alpha \in \mathbb{R}$,

$$|1 - i\alpha - e^{-i\alpha}| = \left| \frac{\alpha^2}{2} (\cos\beta_1 - i\cos\beta_2) \right| \leqslant |\alpha^2|, \qquad (21)$$

where β_1 and β_2 are between 0 and α. Similarly, $|1 - e^{-i\alpha}| \leqslant |\alpha|$. Using these two bounds, we see that

$$\begin{aligned}
\left| 1 - \prod_{j=1}^{l} \frac{1 - \exp(-i\lambda k_j (m+n))}{i\lambda k_j (m+n)} \right| &\leqslant \left| 1 - \frac{1 - \exp(-i\lambda k_1 (m+n))}{i\lambda k_1 (m+n)} \right| + \left| \frac{1 - \exp(-i\lambda k_1 (m+n))}{i\lambda k_1 (m+n)} \right| \\
&\quad \times \left| 1 - \frac{1 - \exp(-i\lambda k_2 (m+n))}{i\lambda k_2 (m+n)} \right| + \cdots \\
&\quad + \left| \frac{1 - \exp(-i\lambda k_1 (m+n))}{i\lambda k_1 (m+n)} \right| \cdots \left| 1 - \frac{1 - \exp(-i\lambda k_l (m+n))}{i\lambda k l (m+n)} \right| \\
&\leqslant \lambda (m+n)(|k_1| + \cdots + |k_l|).
\end{aligned}$$

Putting this back in (20) yields

$$\|K^\dagger T_\hbar(\sigma_{mn}) K - T_\hbar(\sigma_{mn} \circ \kappa)\| \leqslant O(\lambda) + \lambda (2\pi\epsilon)(|n|+|m|)^2 \|f\|_2 e^{2\pi\epsilon(|n|+|m|)\|f\|_2} = O(\lambda).$$

The right-hand side vanishes as $\lambda \to 0$. This completes the proof for a pure harmonic σ_{mn}.

Step 3. We can now complete the proof for any classical symbol $\sigma \in C(\mathbb{T}^2)$ with a simple application of the Stone–Weierstrass theorem. For such σ there exists a trigonometric polynomial P such that given $\delta > 0$,

$$\|\sigma - P\|_\infty \leqslant \delta/3,$$

where $\|\sigma\|_\infty = \sup_z |\sigma(z)|$ is the sup-norm. Now, since the operator norm of a Toeplitz operator does not exceed the sup-norm of the symbol, i.e., $\|T_\hbar(\sigma)\| \leqslant \|\sigma\|_\infty$ (see Ref. 10), we find

$$\|T_\hbar(\sigma) - T_\hbar(P)\| \leqslant \delta/3.$$

Since P is a linear combination of finitely many simple harmonics, by part Step 2, we can find γ (depending on P) such that for $\hbar < \gamma$

$$\|K^\dagger T_\hbar(P) K - T_\hbar(P \circ \kappa)\| \leqslant \delta/3.$$

Thus

$$\begin{aligned}\|K^\dagger T_\hbar(\sigma) K - T_\hbar(\sigma \circ \kappa)\| &\leqslant \|K^\dagger T_\hbar(\sigma) K - K^\dagger T_\hbar(P) K\| + \|K^\dagger T_\hbar(P) K - T_\hbar(P \circ \kappa)\| + \|T_\hbar(P \circ \kappa) \\ &\quad - T_\hbar(\sigma \circ \kappa)\| \leqslant \|T_\hbar(\sigma) - T_\hbar(P)\| + \delta/3 + \|(P - \sigma) \circ \kappa\|_\infty \leqslant \delta.\end{aligned}$$

This completes the proof of the theorem. ■

IV. GENERALIZED HARPER MAPS

We complete the class of quantizations of toral automorphisms with the generalized Harper maps. Exponentiating (6), we find

$$e^{2\pi i x'} = e^{2\pi i (x + \epsilon_2 g(p'))}, \quad e^{2\pi i p'} = e^{2\pi i (p + \epsilon_1 f(x))}. \tag{22}$$

As before, we let (22) give the quantum evolution. That is, we are led to the following definition of the quantum Harper dynamics:

$$U' = \exp\left(2\pi i \epsilon_2 \sum_{k \in \mathbb{Z}} (V')^k \widetilde{g}_k \right) U, \quad V' = V \exp\left(2\pi i \epsilon_1 \sum_{k \in \mathbb{Z}} \widetilde{f}_k U^k \right), \tag{23}$$

where

$$\widetilde{g}_k = \left(\frac{1 - \exp(-i\lambda k)}{i\lambda k} \right) g_k, \quad \widetilde{f}_k = \left(\frac{1 - \exp(-i\lambda k)}{i\lambda k} \right) f_k,$$

and

$$g(\hat{p}) = \frac{dv}{dp}(\hat{p}) = \sum_{k \in \mathbb{Z}} g_k V^k, \quad f(\hat{x}) = \frac{du}{dx}(\hat{x}) = \sum_{k \in \mathbb{Z}} f_k U^k.$$

Calculations similar to the kick map case show that

$$U' = e^{2\pi i (\hat{x} + \epsilon_2 g(\hat{p} + \epsilon_1 f(\hat{x})))}, \quad V' = e^{2\pi i (\hat{p} + \epsilon_1 f(\hat{x}))}.$$

We have the following theorem, which shows that the map above indeed yields a well-defined quantum dynamics.

Theorem 5: *(1) There exists a unitary quantum propagator which implements (23), namely,*

$$H=\exp(i\epsilon_2 v(\hat{p})/\hbar)\exp(-i\epsilon_1 u(\hat{x})/\hbar).$$

(2) The quantum Harper map defined by (23) extends to an automorphism of the von Neumann algebra $\mathfrak{A}_\hbar$ of observables on the quantized torus.

(3) For maps with f and g satisfying

$$\sum_j j^2|f_j|<\infty, \quad \sum_k k^2|g_k|\exp\left(2\pi\epsilon_1 k\sum_j |f_j|\right)<\infty,$$

the quantum propagator has a well-defined classical limit:

$$\|H^\dagger T_\hbar(\sigma)H-T_\hbar(\sigma\circ\eta)\|\to 0 \quad \text{as} \quad \hbar\to 0,$$

where $\eta(p,x)=(p',x')$ is the classical evolution defined in (6).

Proof: (1) Observe

$$H^\dagger UH=\exp(i\epsilon_l u(\hat{x})/\hbar)\exp(-i\epsilon_2 v(\hat{p})/\hbar)U\ \exp(i\epsilon_2 v(\hat{p})/\hbar)\exp(-i\epsilon_1 u(\hat{x})/\hbar)$$

$$=\exp(i\epsilon_1 u(\hat{x})/\hbar)\exp(2\pi i(\hat{x}+\epsilon_2 g(\hat{p})))\exp(-i\epsilon_1 u(\hat{x})/\hbar)=\exp(2\pi i(\hat{x}+\epsilon_2 g(\hat{p}'))).$$

Similarly we see $H^\dagger VH=V'$.

(2) The proof that the mapping is an automorphism of the algebra $\mathfrak{A}_\hbar$ follows that of the kick map. We omit the details here.

(3) We break the proof of (3) into the same steps as in the proof for the kick map.

Step 1. First we calculate $H^\dagger T_\hbar(\sigma_{mn})H=(V')^n(U')^m\exp-\pi^2\hbar(m^2+n^2+2imn)$. Then using Trotter's formula, we get

$$(V')^n=V^n\ \exp 2\pi i\epsilon_1 n\sum_{k\in\mathbb{Z}}\tilde{f}_k(n)U^k,$$

and

$$(U')^m=\exp\left(2\pi i\epsilon_2 m\sum_{k\in\mathbb{Z}}\tilde{g}_k(m)(V')^k\right)U^m,$$

where $\tilde{f}_k(n)$ and $\tilde{g}_k(n)$ are defined as in (18). Thus

$$\begin{aligned}H^\dagger T_\hbar(\sigma_{mn})H=&\sum_{l=0}^{\infty}\sum_{k_1,\ldots,k_l}\frac{(2\pi i\epsilon_2 m)^l}{l!}\tilde{g}_{k_1}(m)\cdots\tilde{g}_{k_l}(m)V')^{n+k_1+\cdots+k_l}U^m\\&\times\exp(-\pi^2\hbar(m^2+n^2+2imn))\\=&\sum_{l=0}^{\infty}\sum_{k_1,\ldots,k_l}\frac{(2\pi i\epsilon_2 m)^l}{l!}\tilde{g}_{k_1}(m)\cdots\tilde{g}_{k_l}(m)V^{n+k_1+\cdots+k_l}\\&\times\sum_{q=0}^{\infty}\sum_{j_1,\ldots,j_q}\frac{(2\pi i\epsilon_1(n+k_1+\cdots+k_l))^q}{q!}\left(\prod_{i=1}^{q}\tilde{f}_{j_i}(n+k_1+\cdots+k_l)\right)\\&\times U^{m+j_1+\cdots+j_q}\exp(-\pi^2\hbar(m^2+n^2+2imn)).\end{aligned}$$

Next, we calculate

$$
\begin{aligned}
T_\hbar(\sigma_{mn}\circ\eta) &= T_\hbar(\exp[2\pi i(mx'+np')]) \\
&= \sum_{l=0}^{\infty}\sum_{k_1,\ldots,k_l}\sum_{q=0}^{\infty}\sum_{j_1,\ldots,j_q} T_\hbar\Bigg(\frac{(2\pi i\epsilon_2 m)^l}{l!}\, g_{k_1}\cdots g_{k_l} \\
&\quad \times\frac{(2\pi i\epsilon_1(n+k_1+\cdots+k_l))^q}{q!}\, f_{j_1}\cdots f_{j_q} \\
&\quad \times\exp\{2\pi i((m+j_1+\cdots+j_q)x+(n+k_1+\cdots+k_l)p)\}\Bigg) \\
&= \sum_{l=0}^{\infty}\sum_{k_1,\ldots,k_l}\sum_{q=0}^{\infty}\sum_{j_1,\ldots,j_q} \frac{(2\pi i\epsilon_2 m)^l}{l!}\, g_{k_1}\cdots g_{k_l} \\
&\quad \times\frac{(2\pi i\epsilon_1(n+k_1+\cdots+k_l))^q}{q!}\, f_{j_1}\cdots f_{j_q} V^{n+k_1+\cdots+k_l}U^{m+j_1+\cdots-j_q} \\
&\quad \times\exp[(n+k_1+\cdots+k_l)^2+(m+j_1+\cdots+j_q)^2 \\
&\quad +2i(n+k_1+\cdots+k_l)(m+j_1+\cdots+j_q)].
\end{aligned}
$$

It is obvious that term by term (in powers of U^pV^q) that the previous two expressions approach each other as $\hbar\to 0$. The proof that the sums converge is very similar to the analogous proof for the kick map in the previous section. An outline of the results is as follows. We find that

$$
\|H^\dagger T_\hbar(\sigma_{mn})H - T_\hbar(\sigma_{mn}\circ\kappa)\| \leqslant D_1+D_2+D_3,
$$

where (writing $\overline{n}=n+k_1+\cdots+k_l$, $\overline{m}=m+j_1+\cdots+j_q$)

$$
\begin{aligned}
D_1 &= \Bigg\| \sum_{l=0}^{\infty}\sum_{k_1,\ldots,k_l}\sum_{q=0}^{\infty}\sum_{j_1,\ldots,j_q} \frac{(2\pi i\epsilon_2 m)^l(2\pi i\epsilon_1\overline{n})^q}{l!q!}\, V^{\overline{n}}U^{\overline{m}} \\
&\quad \times g_{k_1}\cdots g_{k_l} f_{j_1}\cdots f_{j_q}(e^{-\pi^2\hbar(\overline{n}^2+\overline{m}^2+2i\overline{nm})}-1)\Bigg\|,
\end{aligned}
$$

$$
\begin{aligned}
D_2 &= \Bigg\| \sum_{l=0}^{\infty}\sum_{k_1,\ldots,k_l}\sum_{q=0}^{\infty}\sum_{j_1,\ldots,j_q} \frac{(2\pi i\epsilon_2 m)^l(2\pi i\epsilon_1\overline{n})^q}{l!q!}\, V^{\overline{n}}U^{\overline{m}} g_{k_1}\cdots g_{k_l} f_{j_1}\cdots f_{j_q} \\
&\quad -\widetilde{g}_{k_1}(m)\cdots\widetilde{g}_{k_l}(m)\widetilde{f}_{j_1}(\overline{n})\cdots\widetilde{f}_{j_q}(\overline{n})\Bigg\|,
\end{aligned}
$$

$$
\begin{aligned}
D_3 &= \Bigg\| \sum_{l=0}^{\infty}\sum_{k_1,\ldots,k_l}\sum_{q=0}^{\infty}\sum_{j_1,\ldots,j_q} \frac{(2\pi i\epsilon_2 m)^l(2\pi i\epsilon_1\overline{n})^q}{l!q!}\, V^{\overline{n}}U^{\overline{m}}\widetilde{g}_{k_1}(m)\cdots\widetilde{g}_{k_l}\widetilde{f}_{j_1}(\overline{n})\cdots\widetilde{f}_{j_q}(\overline{n}) \\
&\quad \times(e^{-\pi^2\hbar(m^2+n^2+2inm)}-1)\Bigg\|.
\end{aligned}
$$

Using (19) once again, we see that D_3 is $O(\lambda)$. To show that D_1 and D_2 go to zero we set

$$
\|g\|_{2,f} := \sum_{k\in\mathbb{Z}} (1+|k|)^2|g_k|\exp(2\pi\epsilon_1 k\|f\|_2) < \infty,
$$

and with these bounds,

$$
\begin{aligned}
D_1 \leqslant & \frac{\lambda}{4} \sum_{l=0}^{\infty} \sum_{k_1,\ldots,k_l} \sum_{q=0}^{\infty} \sum_{j_1,\ldots,j_q} \frac{(2\pi\epsilon_2|m|)^l (2\pi\epsilon_1|\overline{n}|)^q}{l!q!} |g_{k_1}|\cdots|g_{k_l}||f_{j_1}|\cdots|f_{j_q}| \\
& \times (\overline{n}^2 + m^2 + 2m(j_1+\cdots+j_q) + q(j_1^2+\cdots+j_q^2) + 2\overline{n}(m+j_1+\cdots+j_q)) \\
\leqslant & \frac{\lambda}{4} \sum_{l=0}^{\infty} \sum_{k_1,\ldots,k_l} \frac{(2\pi\epsilon_2|m|)^l}{l!} |g_{k_1}|\cdots|g_{k_6}| \exp(2\pi\epsilon_1|\overline{n}|\|f\|_2) \\
& \times (\overline{n}^2 + m^2 + 2|m| + 2\pi\epsilon_1\overline{n}\|f\|_2 + 2|\overline{n}|(|m|+1)) \\
\leqslant & \frac{\lambda}{4} \exp(2\pi\epsilon_1|n|\|f\|_2) \exp(2\pi\epsilon_2 m\|g\|_{2,f}) ((|m|+|n|)^2 + 4(|n|+|m|) + 2\pi\epsilon_2|m|\|g\|_{2,f} \\
& + 2\pi\epsilon_1\|f\|_2(|n|+1)+2) = O(\lambda),
\end{aligned}
$$

while using (21),

$$
\begin{aligned}
D_2 \leqslant & \sum_{l=0}^{\infty} \sum_{k_1,\ldots,k_l} \sum_{q=0}^{\infty} \sum_{j_1,\ldots,j_q} \frac{(2\pi\epsilon_2|m|)^l (2\pi\epsilon_1|\overline{n}|)^q}{l!q!} |g_{k_1}|\cdots|g_{k_l}||f_{j_1}|\cdots|f_{j_q}| \\
& \times \left(\left| 1 - \prod_{r=1}^{l} \left| \frac{\widetilde{g}_{k_r}(m)}{g_{k_r}} \right| \right| + \left| 1 - \prod_{r=1}^{l} \left| \frac{\widetilde{g}_{k_r}(m)}{g_{k_r}} \right| \right| \left| 1 - \prod_{r=1}^{l} \left| \frac{\widetilde{f}_{j_s}(\overline{n})}{f_{j_s}} \right| \right| + \left| 1 - \prod_{r=1}^{l} \left| \frac{\widetilde{f}_{j_s}(\overline{n})}{f_{j_s}} \right| \right| \right) \\
\leqslant & \sum_{l=0}^{\infty} \sum_{k_1,\ldots,k_l} \sum_{q=0}^{\infty} \sum_{j_1,\ldots,j_q} \frac{(2\pi\epsilon_2|m|)^l (2\pi\epsilon_1|\overline{n}|)^q}{l!q!} |g_{k_1}|\cdots|g_{k_l}||f_{j_1}|\cdots|f_{j_q}| (\lambda|m|(|k_1|+\cdots \\
& + |k_l|) + \lambda|\overline{n}|(|j_1|+\cdots+|j_q|)\lambda m(|k_1|+\cdots+|k_l|) + \lambda|\overline{n}|(|j_1|+\cdots+|j_q|)) \\
= & \lambda \sum_{l=0}^{\infty} \sum_{k_1,\ldots,k_l} \frac{(2\pi\epsilon_2|m|)^l}{l!} |g_{k_1}|\cdots|g_{k_l}| \exp(2\pi\epsilon_1\overline{n}\|f\|_2)(|m|(|k_1|+\cdots+|k_l|) \\
& + \lambda|\overline{n}|m(|k_1|+\cdots+|k_l|)) + |\overline{n}| \\
= & \lambda \exp(2\pi\epsilon_1|n|\|f\|_2) \exp(2\pi\epsilon_2|m|\|g\|_{2,f})(|m| + \lambda|m|(|n| + 2\pi\epsilon_2 m\|g\|_{2,f}) \\
& + (|n|+1)) = O(\lambda).
\end{aligned}
$$

We have thus shown that $\|H^\dagger T_\hbar(\sigma_{mn})H - T_\hbar(\sigma_{mn}\circ\eta)\| = O(\lambda)$. The proof is completed for a general symbol $\sigma \in C(\mathbb{T}^2)$ by referring to Step 3 in the proof of the analogous theorem for the kick map. ■

(Received 10 February 1997; accepted for publication 29 December 1997)

We explain in detail how to derive the operator product expansions (OPEs) among generating functionals of physical vertex operators (GFPVO) of fermionic particles (i.e., GFPVO in the Ramond sector of superstring) and the stress operators. As for OPEs among GFPVO of bosonic particles (i.e., in the Neveu–Schwarz sector of superstring) and the stress operators, they are those simply obtained by super-generalizing OPEs among GFPVO (in bosonic string) and the stress operator. © *1998 American Institute of Physics.* [S0022-2488(98)01704-6]

I. INTRODUCTION AND PRELIMINARIES

In the preceding paper,[1] we have explained in detail how to construct the generating functionals of physical vertex operators (GFPVO) of both fermionic and bosonic particles (i.e., in both Ramond[2] and Neveu–Schwarz[3] sectors of superstring). However, operator product expansions (OPEs) among GFPVO and the superstressino operator have been given without any proof. Since these OPEs play very important roles in calculating physical scattering amplitudes,[4] these OPEs should be proved explicitly. In this paper, we explain in detail how we can derive these OPEs [i.e., (4.18)–(4.21) and (5.26) in Ref. 1].

In the following, we shall briefly review how GFPVO in the R (NS) sector can be constructed. (See Ref. 1 for more details.) We introduce the light-cone operator $P_F^{\pm j\dagger}(w,\xi)$ $(j=1-4)$ in the R sector defined by

$$P_F^{\pm j\dagger}(w,\xi)\equiv \frac{\xi}{w}\left(p^{\pm j}+\sum_{n=1}^{\infty} w^{-n}\alpha_{-n}^{\pm j}\right)+\frac{1}{\sqrt{w}}\left(d_0^{\pm j}+\sum_{n=1}^{\infty} w^{-n}d_{-n}^{\pm j}\right) \tag{1.1}$$

$$\times(\equiv \xi\Pi_{\alpha}^{\pm j\dagger}(w)+\pi_d^{\pm j\dagger}(w)), \tag{1.1'}$$

where we have used light-cone (mode's) operators (for $j=1-4$) i.e., $p^{\pm j}$ (total energy–momentum operator), $\alpha_m^{\pm j}$'s, $\alpha_{-n}^{\pm j}$'s, $d_m^{\pm j}$'s, and $d_{-n}^{\pm j}$'s, which satisfy the following (anti) commutation relations among themselves;

$$[\alpha_m^{\pm j},\alpha_{-n}^{\mp k}]=m\,\delta_{mn}\delta_{jk} \tag{1.2}$$

and

$$\{d_m^{\pm j},d_{-n}^{\mp k}\}=\delta_{mn}\delta_{jk}, \tag{1.3}$$

all other (anti) commutators being zero.

In the R sector of superstring (i.e., in the *fermionic* sector $s=F$), there exists the Friedan, Martinee, and Schenker (FMS) spinor[5] $S_{\{h\}}(z_0)$ at z_0, which is given by

$$S_{\{h\}}(z_0)\equiv :\exp(1/2\phi^0(z_0)):_{\phi}\times\prod_{j=1}^{4} :\exp(\epsilon_h^j\phi^j(z_0)):_{\phi}, \tag{1.4}$$

$$(\text{with } \epsilon_{\pm}^j=\pm 1/2)$$

Then, any non-N operator $G(z)$ composed of $X^{\pm j}$ and $\psi^{\pm j}$ is N-ized into the N operator $G_N(z)$ by

$$\vec{R}\cdot G(z)S_{\{h\}}(z_0)\equiv G_N(z)\cdot S_{\{h\}}(z_0). \tag{1.5}$$

 © 1998 American Institute of Physics

(Inversely, we state that the N operator G_N is changed into the non-N operator G.) For an example, we have that

$$\begin{aligned}\vec{R}\cdot :\exp(\pm\phi^j(z)):_\phi S_{\{h\}}(z_0) &= (z-z_0)^{\pm\epsilon_h^j} :\exp(\pm\phi^j(z))\cdot S_{\{h\}}(z_0):_\phi \\ &= (z-z_0)^{\pm\epsilon_h^j} :\exp(\pm\phi_{Nh}^j(z)):_\phi S_{\{h\}}(z_0),\end{aligned} \tag{1.6}$$

with $\vec{R}$ being radial ordering. In Eq. (1.6), $\phi_{Nh}^j(z)$ is the operator which has already been normally ordered with respect to the FMS spinor $S_{\{h\}}(z_0)$. From Eq. (1.6), we have found that

$$\Psi^{\pm j}(z) \equiv :\exp(\pm\phi^j(z)):_\phi \overset{N}{\to} \Psi_N^{\pm j}(z) \equiv (z-z_0)^{\pm\epsilon_h^j} :\exp(\pm\phi_{Nh}^j(z)):_\phi , \tag{1.7}$$

$$\Psi_h^{\pm j}(z) \equiv (z-z_0)^{\mp\epsilon_h^j} :\exp(\pm\phi^j(z)):_\phi \overset{N}{\to} \Psi_{Nh}^{\pm j}(z) \equiv :\exp(\pm\phi_{Nh}^j(z)):_\phi , \tag{1.8}$$

and

$$X^{\pm j}(z,\theta) \equiv X^{\pm j}(z) + \theta\cdot\Psi^{\pm j}(z) \overset{N}{\to} X_N^{\pm j}(z,\theta) \equiv X^{\pm j}(z) + \theta\cdot(z-z_0)^{\pm\epsilon_h^j}\cdot\Psi_{Nh}^{\pm j}(z). \tag{1.9}$$

The normal ordering in the R sector is denoted by $: :_R$ and it is defined by

$$\vec{R}\cdot X^{\pm j}(z')X^{\mp k}(z) = \delta_{jk}\log(z'-z) + :X^{\pm j}(z')X^{\mp k}(z):_R \tag{1.10}$$

and

$$\vec{R}\cdot\Psi_{Nh'}^{\pm j}(z')\Psi_{Nh}^{\mp k}(z) = \frac{\delta_{jk}}{z'-z} + :\Psi_{Nh'}^{\pm j}(z')\Psi_{Nh}^{\mp k}(z):_R , \tag{1.11}$$

$\vec{R}$ being radial ordering. In the R sector of superstring (i.e., in fermionic sector $s=F$), GFPVO $\vec{R}\cdot\Phi_{\{h\}}^F(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)$ (in non-N operator's form) was proposed to be constructed by

$$\Phi_{\{h\}}^F(z_0,\theta_0;P_F^\dagger) \equiv :\exp(\rho_{N+}^{0F}(z_0,\theta_0) + \rho^{1F}(z_0,\theta_0;P_F^\dagger) + \rho_{\{h\}}^{2F}(z_0,\theta_0;P_F^\dagger)):_R \tag{1.12}$$

$$(\equiv \Phi_{\{h\}}^{F0}(z_0;P_F^\dagger) + \theta_0\Phi_{\{h\}}^{F1}(z_0;P_F^\dagger)). \tag{1.12'}$$

In Eq. (1.12), $: :_R$ is the normal ordering in the R sector and we have used

$$\rho_{N+}^{0F}(z_0,\theta_0) \equiv -ip^{+0}Y_{N+}^{-0}(z_0,\theta_0) - ip^{-0}X^{+0}(z_0), \tag{1.13}$$

$$(\text{with}^1\ \ Y_{N+}^{-0}(z_0,\theta_0) \equiv X^{-0}(z_0) + \theta_0\Psi_{N+}^{-0}(z_0)), \tag{1.13'}$$

$$\rho^{1F}(z_0,\theta_0;P_F^\dagger) \equiv -\sum_{\pm}\sum_{j=1}^{4} i\oint\frac{dwd\xi}{2\pi i}P_F^{\pm j^\dagger}(w,\xi)X^{\mp j}(z_F(w,\xi),\theta_F(w,\xi)) \tag{1.14}$$

and

$$\rho^{2F}_{\{h\}}(z_0,\theta_0;P^{\dagger}_F)\equiv-\sum_{j=1}^{4}\oint\frac{dwd\xi}{2\pi i}P_F^{-j^{\dagger}}(w,\xi)\oint\frac{dw'd\xi'}{2\pi i}P_F^{+j^{\dagger}}(w',\xi')$$
$$\times\log\frac{z_F(w,\xi)-z_F(w',\xi')-\left(\frac{z_F(w,\xi)-z_0}{z_F(w',\xi')-z_0}\right)^{\epsilon^j_h}\theta_F(w,\xi)\theta_F(w',\xi')}{w-w'-\left(\frac{w}{w'}\right)^{\epsilon^j_h}\xi\xi'},\tag{1.15}$$

where ϵ^j_h is the constant (i.e., $\epsilon^j_+\equiv+\frac{1}{2}$ and $\epsilon^j_-\equiv-\frac{1}{2}$) in the FMS spinor $S_{\{h\}}(z_0)$ defined by Eq. (1.4). In Eqs. (1.14) and (1.15), we have used various non-N operators

$$\theta_F(w,\xi)\equiv J_F(w)+\xi K_F(w)\tag{1.16}$$

and

$$z_F(w,\xi)-z_0\equiv L_F(w)+\xi K_F(w)J_F(w),\tag{1.17}$$

which are those determined by inversely solving the following superconformal mapping in the R sector $(z_F,\theta_F)\to(w,\xi)$;

$$z_F-z_0-\sqrt{z_F-z_0}\cdot\theta_F\theta_0=w{:}\exp\left(\frac{X^{+0}(z_F,\theta_F)}{ip^{+0}}-\frac{X^{+0}(z_0)}{ip^{+0}}\right){:}_R\tag{1.18}$$

and

$$\xi(z_F,\theta_F)=(\partial_{z_F}w(z_F,\theta_F))^{-1/2}D_{\theta_F}w(z_F,\theta_F),\tag{1.19}$$

with $D_{\theta_F}\equiv\partial_{\theta_F}+\theta_F\partial_{z_F}$. Various functions in Eqs. (1.16) and (1.17) can be obtained by using the following theorem.

Theorem: (superconformal mapping in the R sector)

In the case when non-N operators $A^{\pm}(z)$ and $B^{\pm}(z)$ are analytic at $z=z_0$, the functions $F^{\pm}(z_F,\theta_F)$ given by

$$F^{+}(z_F,\theta_F)\equiv A^{+}(z_F)+\theta_F\sqrt{z_F-z_0}B^{+}(z_F)\tag{1.20}$$

and

$$F^{-}(z_F,\theta_F)\equiv\sqrt{z_F-z_0}A^{-}(z_F)+\theta_F B^{-}(z_F)\tag{1.21}$$

can be expressed as the functions of w and ξ by the following formulas:

$$F^{\pm}(z_F,\theta_F)=[F^{\pm}(z_F,\theta_F)]_{\xi=0}+\xi K_F(w)[D_{\theta_F}F^{\pm}(z_F,\theta_F)]_{\xi=0},\tag{1.22}$$

with

$$K_F(w)=\left(\partial_w[z_F-z_0]_{\xi=0}-(\partial_w[\theta_F]_{\xi=0})[\theta_F]_{\xi=0}\right)^{1/2}.\tag{1.23}$$

In Eqs. (1.22) and (1.23), we have used the functions $[\ ]_{\xi=0}$ defined by

$$[A^{+}(z_F)+\theta_F\sqrt{z_F-z_0}B^{+}(z_F)]_{\xi=0}\equiv A^{+}(z_0)+\sum_{n=1}^{\infty}\frac{w^n}{(n-1)!}e^{-nI(z_0)}\lim_{z\to z_0}\left[\partial_z^{n-1}\left(e^{nI(z)}\left(\frac{1}{n}\partial_z A^{+}(z)\right.\right.\right.$$
$$\left.\left.\left.+\left((z-z_0)\frac{\Psi^{+0}_{+}(z;z_0)}{ip^{+0}}+\theta_0\right)B^{+}(z)\right)\right)\right]\tag{1.24}$$

and

$$[\sqrt{z_F-z_0}A^-(z_F)+\theta_F B^-(z_F)]_{\xi=0}$$

$$\equiv\sum_{n=0}^{\infty}\frac{w^{n+1/2}}{n!}e^{-(n+1/2)I(z_0)}\lim_{z\to z_0}\Bigg[\partial_z^n\Bigg(e^{(n+1/2)I(z)}\Bigg(\times\sqrt{z-z_0}\partial_z\Bigg(\sqrt{z-z_0}\,\frac{A^-(z)}{n+1/2}\Bigg)+\Bigg((z-z_0)\,\frac{\Psi_+^{+0}(z;z_0)}{ip^{+0}}+\theta_0\Bigg)B^-(z)\Bigg)\Bigg)\Bigg],\tag{1.25}$$

with the help of shorthand notations

$$I(z)\equiv\frac{X^{+0}(z)}{ip^{+0}},\quad\text{and}\quad\Psi_+^{+0}(z;z_0)\equiv\frac{\Psi^{+0}(z)}{\sqrt{z-z_0}}.\tag{1.26}$$

On the other hand, we introduce the light-cone operator $P_B^{\pm j\dagger}(w,\xi)$ in the NS sector by

$$P_B^{\pm j\dagger}(w,\xi)\equiv\frac{\xi}{w}\left(p^{\pm j}+\sum_{n=1}^{\infty}w^{-n}\alpha_{-n}^{\pm j}\right)+\frac{1}{\sqrt{w}}\left(\sum_{n=1}^{\infty}w^{-n+1/2}b_{-n+1/2}^{\pm j}\right)\tag{1.27}$$

$$(\equiv\xi\Pi_\alpha^{\pm j\dagger}(w)+\pi_b^{\pm j\dagger}(w)).\tag{1.27$'$}$$

where we have used light-cone (mode's) operators (for $j=1-4$), i.e., $p^{\pm j}$ (total energy–momentum operator), $\alpha_m^{\pm j}$'s, $\alpha_{-n}^{\pm j}$'s, $b_{m-1/2}^{\pm j}$'s, and $b_{-n+1/2}^{\pm j}$'s, which satisfy the following (anti)-commutation relations among themselves:

$$[\alpha_m^{\pm j},\alpha_{-n}^{\mp k}]=m\delta_{mn}\delta_{jk}\tag{1.28}$$

and

$$\{b_{m-1/2}^{\pm j},b_{-n+1/2}^{\mp k}\}=\delta_{mn}\delta_{jk},\tag{1.29}$$

all other (anti)commutators being zero. In the NS sector of superstring (i.e., in bosonic sector $s=B$), GFPVO $\Phi^B(z_0,\theta_0;P_B^\dagger)$ was proposed to be constructed by

$$\Phi^B(z_0,\theta_0;P_B^\dagger)\equiv:\exp(\rho^{0B}(z_0,\theta_0)+\rho^{1B}(z_0,\theta_0;P_B^\dagger)+\rho^{2B}(z_0,\theta_0;P_B^\dagger)):_{\rm NS}\tag{1.30}$$

$$(\equiv\Phi^{B0}(z_0;P_B^\dagger)+\theta_0\Phi^{B1}(z_0;P_B^\dagger)).\tag{1.30$'$}$$

In Eq. (1.30), $:\ :_{\rm NS}$ is the normal ordering in the NS sector defined by

$$\vec{R}\cdot X^{\pm j}(z')X^{\mp k}(z)=\delta_{jk}\log(z'-z)+:X^{\pm j}(z')X^{\mp k}(z):_{\rm NS}\tag{1.31}$$

and

$$\vec{R}\cdot\Psi^{\pm j}(z')\Psi^{\mp k}(z)=\frac{\delta_{jk}}{z'-z}+:\Psi^{\pm j}(z')\Psi^{\mp k}(z):_{\rm NS},\tag{1.32}$$

$\vec{R}$ being radial ordering. Furthermore, $\rho^{\iota B}$'s ($\iota=0,1,2$) in Eq. (1.30) are given by

$$\rho^{0B}(z_0,\theta_0)\equiv\sum_{\pm}-ip^{\pm 0}X^{\mp 0}(z_0,\theta_0),\tag{1.33}$$

$$\rho^{1B}(z_0,\theta_0;P_B^\dagger)\equiv-\sum_{\pm}\sum_{j=1}^{4}i\oint\frac{dwd\xi}{2\pi i}P_B^{\pm j\dagger}(w,\xi)X^{\mp j}(z_B(w,\xi),\theta_B(w,\xi))\tag{1.34}$$

and

$$\rho^{2B}(z_0,\theta_0;P_B^\dagger)\equiv-\sum_{j=1}^{4}\oint\frac{dwd\xi}{2\pi i}P_B^{+j^\dagger}(w,\xi)\oint\frac{dw'd\xi'}{2\pi i}P_B^{-j^\dagger}(w',\xi')$$
$$\times\log\frac{z_B(w,\xi)-z_B(w',\xi')-\theta_B(w,\xi)\theta_B(w',\xi')}{w-w'-\xi\xi'}. \tag{1.35}$$

In Eqs. (1.34) and (1.35), we have used

$$\theta_B(w,\xi)-\theta_0\equiv J_B(w)+\xi K_B(w) \tag{1.36}$$

and

$$z_B(w,\xi)-z_0-\theta_B(w,\xi)\theta_0\equiv L_B(w)+\xi K_B(w)J_B(w), \tag{1.37}$$

which are those to be determined by inversely solving the following superconformal mapping in the NS sector $(z_B,\theta_B)\to(w,\xi)$:

$$z_B-z_0-\theta_B\theta_0=w{:}\exp\left(\frac{X^{+0}(z_B,\theta_B)}{ip^{+0}}-\frac{X^{+0}(z_0,\theta_0)}{ip^{+0}}\right){:}_{\rm NS} \tag{1.38}$$

and

$$\xi(z_B,\theta_B)=(\partial_{z_B}w(z_B,\theta_B))^{-1/2}D_{\theta_B}w(z_B,\theta_B), \tag{1.39}$$

with $D_{\theta_B}\equiv\partial_{\theta_B}+\theta_B\partial_{z_B}$. {Various function in Eqs. (1.36) and (1.37) can be obtained by using the theorem [superconformal mapping in the NS sector] which has been proved in Ref. 1.}

In Sec. II, we introduce the modified superconformal mapping in the R sector, with the help of which we can derive the contractions (in the R sector) of non-N operators $\theta_F(w,\xi)$ (1.16) and $z_F(w,\xi)$ (1.17) with respect to non-N-operator $\lambda\cdot ip^{+0}Y_+^{-0}(z',\theta';z_0)$. Furthermore, we derive z_0 and θ_0 dependence of non-N operators θ_F (1.16) and z_F (1.17). With the help of various formulas derived in Sec. II, we can derive in Sec. III the operator product expansions (OPEs) among $\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)$ and the superstressino operator. Especially in Sec. IV, we derive (in the R sector) the next leading terms in OPE among GFPVO and stressino operator. In Sec. V, we discuss our obtained results in the R sector, while derivation of OPEs among GFPVO in the NS sector [i.e., $\Phi^B(z_0,\theta_0;P_B^\dagger)$ (1.30)] and the superstressino operator is only briefly commented upon, since this can be done in a much simpler way. In Appendices A–E, we give various formulas which are necessary in obtaining the final results on OPEs among $\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)$ (in N-operator's form) and the stress operators.

II. CONTRACTIONS AND z_0 AND θ_0 DEPENDENCE OF z_F AND θ_F

In order to derive the operator product expansions (OPEs) among GFPVO $\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)$ and the stress operators, we shall need explicit expressions (in the non-N operator's form) for the following contractions in the R sector with respect to $Y_+^{-0}(z',\theta';z_0)$ $(\equiv X^{-0}(z')+\theta'\sqrt{z'-z_0}\Psi^{-0}(z'))$:

$$\lambda\cdot ip^{+0}\overbrace{Y_+^{-0}(z',\theta';z_0)z_F(w,\xi)}^{R}\equiv\delta z_F(w,\xi) \tag{2.1}$$

and

$$\lambda\cdot ip^{+0}\overbrace{Y_+^{-0}(z',\theta';z_0)\theta_F(w,\xi)}^{R}\equiv\delta\theta_F(w,\xi). \tag{2.2}$$

Furthermore, we shall need the following z_0 and θ_0 dependence of non-N operators:

$$\partial_{z_0}z_F-\partial_{z_0}\theta_F\cdot\theta_F,\quad \partial_{z_0}\theta_F \tag{2.3}$$

and

$$D_{\theta_0} z_F - D_{\theta_0}\theta_F \cdot \theta_F, \quad D_{\theta_0}\theta_F, \tag{2.4}$$

with $D_{\theta_0} \equiv \partial_{\theta_0} + \theta_0 \partial_{z_0}$. In the following, we obtain explicit formulas for Eqs. (2.1) and (2.2): First, we have the following contractions (in the R sector) among non-N operators $X^{+0}(z,\theta)$, $X^{+0}(z_0)$, and $\lambda \cdot ip^{+0} Y_+^{-0}(z',\theta';z_0)$:

$$\lambda \cdot ip^{+0} \overbrace{Y_+^{-0}(z',\theta';z_0) X^{+0}(z,\theta)}^{R} \equiv \delta X^{+0}(z,\theta) \tag{2.5}$$

$$= \lambda ip^{+0} \log(z' - z - \sqrt{z - z_0}\,\theta'\theta) \tag{2.5'}$$

and

$$\lambda \cdot ip^{+0} \overbrace{Y_+^{-0}(z',\theta';z_0) X^{+0}(z_0)}^{R} \equiv \delta X^{+0}(z_0) \tag{2.6}$$

$$= \lambda ip^{+0} \log(z' - z_0), \tag{2.6'}$$

provided that any of (z',θ'), (z,θ), and z_0 is c number. Therefore, we modify the superconformal mapping in the R sector (1.18) by the following replacements:

$$X^{+0}(z_F,\theta_F) \to X^{+0}(z_F,\theta_F) + \delta X^{+0}(z_F,\theta_F) \tag{2.7}$$

and

$$X^{+0}(z_0) \to X^{+0}(z_0) + \delta X^{+0}(z_0). \tag{2.8}$$

[In Eq. (2.7), $\delta X^{+0}(z_F,\theta_F)$ is the one obtained from Eq. (2.5′) by replacing c number (z,θ) with q number (z_F,θ_F).] Thus, we are lead to consider the following modified superconformal mapping in the R sector:

$$\begin{aligned} & z_F(w,\xi;\lambda) - z_0 - \sqrt{z_F(w,\xi;\lambda) - z_0}\cdot \theta_F(w,\xi;\lambda)\,\theta_0 \\ & = w : \exp\left(\frac{X^{+0}(z_F(w,\xi;\lambda),\theta_F(w,\xi;\lambda))}{ip^{+0}} - \frac{X^{+0}(z_0)}{ip^{+0}} \right. \\ & \qquad \left. + \lambda \log \frac{z' - z_F(w,\xi;\lambda) - \sqrt{z_F(w,\xi;\lambda) - z_0}\cdot \theta'\,\theta_F(w,\xi;\lambda)}{z' - z_0} \right) :_R, \end{aligned} \tag{2.9}$$

while the superpartner $\xi(z_F,\theta_F;\lambda)$ for $w(z_F,\theta_F;\lambda)$ (2.9) should be determined by

$$\xi = (\partial_{z_F} w(z_F,\theta_F;\lambda))^{-1/2} D_{\theta_F} w(z_F,\theta_f;\lambda). \tag{2.10}$$

In the limit $\lambda \to 0$, Eqs. (2.9) and (2.10) are reduced to Eqs. (1.18) and (1.19), respectively. In this $\lambda = 0$ limit, we have proved[1] the theorem (superconformal mapping in the R sector) i.e., Eqs. (1.20)–(1.25). Similarly, we we can prove the following generalized theorem, which is valid even for $\lambda \neq 0$.

Theorem: (modified superconformal mapping in the R sector)

Non-N operators $F^{\pm}(z_F(w,\xi;\lambda),\theta_F(w,\xi;\lambda))$ can be expressed as the function of w and ξ by using the same functions (1.22) and (1.23), provided that we modify the factors $I(z)$, $I(z_0)$ and $\Psi_+^{+0}(z;z_0)/ip^{+0}$ [which are to be used on the right-hand sides of Eqs. (1.24) and (1.25)] by the following replacements;

$$I(z) \to I(z) + \lambda \log(z' - z), \tag{2.11}$$

$$I(z_0) \to I(z_0) + \lambda \log(z' - z_0), \tag{2.11'}$$

and

$$\frac{\Psi_+^{+0}(z;z_0)}{ip^{+0}} \to \frac{\Psi_+^{+0}(z;z_0)}{ip^{+0}} + \frac{\lambda\,\theta'}{z'-z_0}. \tag{2.12}$$

Expanding thus obtained non-N operators $z_F(w,\xi;\lambda)$ and $\theta_F(w,\xi;\lambda)$ up to the first-order (of λ) term, these operators are expressed by

$$z_F(w,\xi;\lambda) = z_F(w,\xi;0) + \delta z_F(w,\xi) + O(\lambda^2)(\equiv z_F + \delta z_F + O(\lambda^2)) \tag{2.13}$$

and

$$\theta_F(w,\xi;\lambda) = \theta_F(w,\xi;0) + \delta\theta_F(w,\xi) + O(\lambda^2)(\equiv \theta_F + \delta\theta_F + O(\lambda^2)). \tag{2.14}$$

It is remarkable that the first-order (in λ) term δz_F (2.13) and $\delta\theta_F$ (2.14) are found to be equal to those given by Eqs. (2.1) and (2.2), respectively. [This can be seen from the above theorem, especially from Eqs. (2.11), (2.11′), and (2.12).] Furthermore, $(\delta z_F, \delta\theta_F)$ can be calculated explicitly as shown hereafter; First, we notice that

$$\begin{aligned}\delta G &\equiv G(z_F(w,\xi;\lambda),\theta_F(w,\xi;\lambda);\lambda) - G(z_F(w,\xi;0),\theta_F(w,\xi;0);0)\\ &= (\delta\theta_F) D_{\theta_F} G(z_F,\theta_F;0) + (\delta z_F - \delta\theta_F\cdot\theta_F)\partial_{z_F} G(z_F,\theta_F;0)\\ &\quad + \lambda[\partial_\lambda G(z_F(w,\xi;0),\theta_F(w,\xi;0);\lambda)]_{\lambda=0} + O(\lambda^2).\end{aligned} \tag{2.15}$$

Expressing $\log w$ and ξ in terms of z_F, θ_F, z_0, θ_0, and λ with the help of $w \equiv w(z_F,\theta_F;\lambda)$ (2.9), $\xi \equiv \xi(z_F,\theta_F;\lambda)$ (2.10), we apply Eq. (2.15) to $G=\log w$ and $G=\xi$, by noticing that

$$\delta \log w = \delta\xi = 0, \tag{2.16}$$

which result from the fact that both w and ξ are just c numbers, so that they do not have any contraction with $\lambda\cdot ip^{+0}Y_+^{-0}(z',\theta';z_0)$. Then, Eq. (2.16) leads to both

$$(\delta\theta_F) D_{\theta_F} \log w + (\delta z_F - \delta\theta_F\cdot\theta_F)\partial_{z_F} \log w = \lambda \log \frac{z'-z_F-(z_F-z_0)^{1/2}\theta'\,\theta_F}{z'-z_0} \tag{2.17}$$

and

$$\begin{aligned}(\delta\theta_F) D_{\theta_F}\xi + (\delta z_F - \delta\theta_F\cdot\theta_F)\partial_{z_F}\xi &= \lambda w(\partial_{z_F} w)^{-1/2} D_{\theta_F} \log(z'-z_F-(z_F-z_0)^{1/2}\theta'\,\theta_F)\\ &\quad + \lambda\xi\left(\begin{array}{l}\dfrac{1}{2}\log\dfrac{z'-z_F-(z_F-z_0)^{1/2}\theta'\,\theta_F}{z'-z_0}\\ \qquad -\dfrac{\frac{1}{2}w}{\partial_{z_F} w}\,\partial_{z_F}\log(z'-z_F-(z_F-z_0)^{1/2}\theta'\,\theta_F)\end{array}\right).\end{aligned} \tag{2.18}$$

On the other hand, applying

$$D_{\theta_F} = \frac{1}{D_\xi\theta_F}\, D_\xi, \tag{2.19}$$

we find that

$$D_{\theta_F}\log w = \frac{\xi/w}{D_\xi\theta_F}, \quad \partial_{z_F}\log w = \frac{1}{w(D_\xi\theta_F)^2} + \frac{\dfrac{\xi}{w}\,\partial_w\theta_F}{(D_\xi\theta_F)^3},$$

$$D_{\theta_F}\xi=\frac{1}{D_\xi\theta_F},\quad \partial_{z_F}\xi=-\frac{\partial_w\theta_F}{(D_\xi\theta_F)^3},\tag{2.20}$$

and

$$(\partial_{z_F}w)^{-1/2}=D_\xi\theta_F-\tfrac{1}{2}\xi\partial_w\theta_F.\tag{2.20'}$$

Therefore, we have from Eqs. (2.20) and (2.20′) the following identity:

$$(\delta z_F-\delta\theta_F\cdot\theta_F)\frac{1}{w(D_\xi\theta_F)^2}=((\delta\theta_F)D_{\theta_F}\log w+(\delta z_F-\delta\theta_F\cdot\theta_F)\partial_{z_F}\log w)+\frac{\xi}{w}((\delta\theta_F)D_{\theta_F}\xi+(\delta z_F-\delta\theta_F\cdot\theta_F)\partial_{z_F}\xi).\tag{2.21}$$

Substituting Eqs. (2.17) and (2.18) into the right-hand side of Eq. (2.21), we find that

$$\frac{1}{\lambda}(\delta z_F-\delta\theta_F\cdot\theta_F)=w(D_\xi\theta_F)^2\log\frac{z'-z_F-(z_F-z_0)^{1/2}\theta'\theta_F}{z'-z_0}+\xi wK_F^3(w)D_{\theta_F}\log(z'-z_F-(z_F-z_0)^{1/2}\theta'\theta_F),\tag{2.22}$$

where we have used Eq. (1.16). Finally, substituting Eq. (2.22) into the left-hand side of Eq. (2.18), we find that

$$\begin{aligned}\frac{1}{\lambda}(\delta\theta_F)=&(\tfrac{1}{2}\xi D_\xi\theta_F+w\partial_w\theta_F)\log\frac{z'-z_F-(z_F-z_0)^{1/2}\theta'\theta_F}{z'-z_0}\\&+(wK_F^2(w)+\tfrac{1}{2}\xi wK_F(w)\partial_wJ_F(w))D_{\theta_F}\log(z'-z_F-(z_F-z_0)^{1/2}\theta'\theta_F)\\&-\tfrac{1}{2}\xi wK_F^3(w)\partial_{z_F}\log(z'-z_F-(z_F-z_0)^{1/2}\theta'\theta_F).\end{aligned}\tag{2.23}$$

Next, we calculate Eqs. (2.3) and (2.4), which show z_0 and θ_0 dependence of non-N-operators z_F and θ_F; we express non-N-operators θ_F (1.16) and z_F (1.17) by $\theta_F(w,\xi;z_0,\theta_0)$ and $z_F(w,\xi;z_0,\theta_0)$, respectively. If we define

$$\Delta\theta_F\equiv\theta_F(w,\xi;z_0+\Delta z_0,\theta_0+\Delta\theta_0)-\theta_F(w,\xi;z_0,\theta_0)\tag{2.24}$$

and

$$\Delta z_F\equiv z_F(w,\xi;z_0+\Delta z_0,\theta_0+\Delta\theta_0)-z_F(w,\xi;z_0,\theta_0),\tag{2.25}$$

we obtain

$$\begin{aligned}\Delta F(z_F,\theta_F,z_0,\theta_0)\equiv&F(z_F+\Delta z_F,\theta_F+\Delta\theta_F,z_0+\Delta z_0,\theta_0+\Delta\theta_0)-F(z_F,\theta_F,z_0,\theta_0)\\=&(\Delta z_0-\Delta\theta_0\cdot\theta_0)((\partial_{z_0}z_F-\partial_{z_0}\theta_F\cdot\theta_F)\partial_{z_F}+(\partial_{z_0}\theta_F)D_{\theta_F}+\partial_{z_0})F(z_F,\theta_F,z_0,\theta_0)\\&+\Delta\theta_0((D_{\theta_0}z_F-D_{\theta_0}\theta_F\cdot\theta_F)\partial_{z_F}+(D_{\theta_0}\theta_F)D_{\theta_F}+D_{\theta_0})F(z_F,\theta_F,z_0,\theta_0)\\&+O(\Delta^2).\end{aligned}\tag{2.26}$$

Expressing $\log w$ and ξ in terms of z_F, θ_F, z_0, and θ_0 with the help of $w\equiv w(z_F,\theta_F,z_0,\theta_0)$ (1.18) and $\xi\equiv\xi(z_F,\theta_F;z_0,\theta_0)$ (1.19), we can apply Eq. (2.26) to $G=\log w$ and $G=\xi$, by noticing that

$$\Delta\log w=\Delta\xi=0,\tag{2.27}$$

which result from the fact that w and ξ are *independent of* both z_0 and θ_0. In much the same way as conditions (2.16) lead to explicit results (2.22) and (2.23), conditions (2.27) are shown to lead to the explicit results [for Eqs. (2.3) and (2.4)] by the following steps: (First, we should notice that z_0 dependence of non-N operators is *different* from that of N operators.) With the help of w (1.18), ξ (1.19) (given in terms of non-N operators), we calculate $\Delta \log w$ and $\Delta\xi$ by using Eq. (2.26). Then we find from Eq. (2.27) the following four formulas in terms of non-N operators; As for ∂_{z_0}, we have

$$(\partial_{z_0} z_F - \partial_{z_0}\theta_F \cdot \theta_F)\partial_{z_F} \log w + (\partial_{z_0}\theta_F) D_{\theta_F} \log w = \frac{1}{z_F - z_0} + \frac{\frac{1}{2}\theta_F\theta_0}{(\sqrt{z_F - z_0})^3} - \partial_{z_0}\frac{X^{+0}(z_0)}{ip^{+0}}, \tag{2.28}$$

and

$$(\partial_{z_0} z_F - \partial_{z_0}\theta_F \cdot \theta_F)\partial_{z_F}\xi + (\partial_{z_0}\theta_F) D_{\theta_F}\xi = \frac{w}{\sqrt{\partial_{z_F} w}}\left(-\frac{\theta_F}{(z_F - z_0)^2} + \frac{\frac{1}{2}\theta_0}{(\sqrt{z_F - z_0})^3}\right) + \frac{1}{2}\,\xi\left(\begin{array}{l} \dfrac{1}{z_F - z_0} + \dfrac{\frac{1}{2}\,\theta_F\theta_0}{(\sqrt{z_F - z_0})^3} - \partial_{z_0}\dfrac{X^{+0}(z_0)}{ip^{+0}} \\ + wK_F^2(w)\left(\dfrac{1}{(z_F - z_0)^2} + \dfrac{\frac{3}{4}\,\theta_F\theta_0}{(\sqrt{z_F - z_0})^5}\right) \end{array}\right). \tag{2.29}$$

Furthermore, as for D_{θ_0}, we have

$$(D_{\theta_0} z_F - D_{\theta_0}\theta_F \cdot \theta_F)\partial_{z_F} \log w + (D_{\theta_0}\theta_F) D_{\theta_F} \log w = -\frac{\theta_F}{\sqrt{z_F - z_0}} + \frac{\theta_0}{z_F - z_0} - \theta_0\partial_{z_0}\frac{X^{+0}(z_0)}{ip^{+0}} \tag{2.30}$$

and

$$(D_{\theta_0} z_F - D_{\theta_0}\theta_F \cdot \theta_F)\partial_{z_F}\xi + (D_{\theta_0}\theta_F) D_{\theta_F}\xi = \frac{w}{\sqrt{\partial_{z_F} w}}\left(\frac{1}{\sqrt{z_F - z_0}} + \frac{\theta_F\theta_0}{(z_F - z_0)^2}\right) + \frac{1}{2}\,\xi\left(\begin{array}{l} \dfrac{\theta_F}{\sqrt{z_F - z_0}} - \dfrac{\theta_0}{z_F - z_0} + \theta_0\partial_{z_0}\dfrac{X^{+0}(z_0)}{ip^{+0}} \\ + wK_F^2(w)\left(\dfrac{\frac{1}{2}\,\theta_F}{(\sqrt{z_F - z_0})^3} - \dfrac{\theta_0}{(z_F - z_0)^2}\right) \end{array}\right). \tag{2.31}$$

In Eqs. (2.28)–(2.31), we have used Eq. (1.16). First, solving Eqs. (2.28) and (2.29) leads to

$$\partial_{z_0} z_F - \partial_{z_0}\theta_F \cdot \theta_F = w(D_\xi\theta_F)^2\left(\frac{1}{z_F - z_0} + \frac{\frac{1}{2}\theta_F\theta_0}{(\sqrt{z_F - z_0})^3} - \partial_{z_0}\frac{X^{+0}(z_0)}{ip^{+0}}\right) - \xi w K_F^3(w)\left(\frac{\theta_F}{(z_F - z_0)^2} - \frac{\frac{1}{2}\theta_0}{(\sqrt{z_F - z_0})^3}\right) \tag{2.32}$$

and

$$\partial_{z_0}\theta_F=\left(\frac{1}{2}\,\xi D_\xi\theta_F+w\partial_w\theta_F\right)\left(\frac{1}{z_F-z_0}+\frac{\frac{1}{2}\theta_F\theta_0}{(\sqrt{z_F-z_0})^3}-\partial_{z_0}\frac{X^{+0}(z_0)}{ip^{+0}}\right)$$
$$+\left(wK_F^2(w)+\frac{1}{2}\,\xi wK_F(w)\partial_w J_F(w)\right)\left(-\frac{\theta_F}{(z_F-z_0)^2}+\frac{\frac{1}{2}\theta_0}{(\sqrt{z_F-z_0})^3}\right)$$
$$+\frac{1}{2}\,\xi wK_F^3(w)\left(\frac{1}{(z_F-z_0)^2}+\frac{\frac{3}{4}\theta_F\theta_0}{(\sqrt{z_F-z_0})^5}\right). \tag{2.33}$$

Finally, Eqs. (2.30) and (2.31) lead to

$$D_{\theta_0}z_F-D_{\theta_0}\theta_F\cdot\theta_F=w(D_\xi\theta_F)^2\left(\frac{\theta_0}{z_F-z_0}-\frac{\theta_F}{\sqrt{z_F-z_0}}-\theta_0\partial_{z_0}\frac{X^{+0}(z_0)}{ip^{+0}}\right)$$
$$-\xi wK_F^3(w)\left(\frac{\theta_F\theta_0}{(z_F-z_0)^2}+\frac{1}{\sqrt{z_F-z_0}}\right) \tag{2.34}$$

and

$$D_{\theta_0}\theta_F=\left(\frac{1}{2}\,\xi D_\xi\theta_F+w\partial_w\theta_F\right)\left(-\frac{\theta_0}{z_F-z_0}+\frac{\theta_F}{\sqrt{z_F-z_0}}+\theta_0\partial_{z_0}\frac{X^{+0}(z_0)}{ip^{+0}}\right)$$
$$+\left(wK_F^2(w)+\frac{1}{2}\,\xi wK_F(w)\partial_w J_F(w)\right)\left(\frac{\theta_F\theta_0}{(z_F-z_0)^2}+\frac{1}{\sqrt{z_F-z_0}}\right)$$
$$+\frac{1}{2}\,\xi wK_F^3(w)\left(-\frac{\theta_0}{(z_F-z_0)^2}+\frac{\frac{1}{2}\theta_F}{(\sqrt{z_F-z_0})^3}\right). \tag{2.35}$$

III. OPERATOR PRODUCT EXPANSIONS (OPEs) IN THE RAMOND SECTOR

In order to derive the operator product expansions (OPEs) among GFPVO $\vec{R}\cdot\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)$ and the stress operators, we shall not use the jth component $\mathscr{F}^{jF}(z',\theta')$ of the superstressino operator defined by

$$\mathscr{F}^{jF}(z',\theta')\equiv\tfrac{1}{2}\mathscr{F}^{jF}(z')+\theta' T^{jF}(z') \tag{3.1}$$

$$=\sum_{\pm}1/2{:}\partial_{z'}X^{\pm j}(z',\theta')D_{\theta'}X^{\mp j}(z',\theta'){:}_R\,, \tag{3.1$'$}$$

since the double-valued stressino operator $\mathscr{F}^{jF}(z')$ is not easily treated. [We shall hereafter use the notation $\mathscr{F}^{jF}(z',\theta')$ instead of $T^{jF}(z',\theta')$ in Ref. 1.] We shall use the following (single-valued) new operator $\tau^j(z',\theta';z_0)$ defined by

$$\tau^j(z',\theta';z_0)\equiv\theta' T_F^j(z')+\frac{1}{2}\left(\sqrt{z'-z_0}+\frac{1}{\sqrt{z'-z_0}}\right)\frac{1}{2}\,\mathscr{F}_F^j(z'). \tag{3.2}$$

N operator $\tau_N^j(z',\theta';z_0)$ is obtained from non-N operator $\tau^j(z',\theta';z_0)$ (3.2) by replacing the non-N operator

$$X^{\pm j}(z,\theta)\equiv X^{\pm j}(z)+\theta{:}\exp(\pm\phi^j(z)){:}_\phi \tag{3.3}$$

with the (N-ized) N operator

$$X_N^{\pm j}(z,\theta;z_0)\equiv X^{\pm j}(z)+\theta(z-z_0)^{\pm\epsilon_h^j}{:}\exp(\pm\phi_{Nh}^j(z)){:}_\phi\,. \tag{3.3$'$}$$

This process was called N-izing in Ref. 1. [See Eq. (1.5).]; Non-N operator $\tau^j(z',\theta';z_0)$ is N-ized into N operator $\tau^j_N(z',\theta';z_0)$ by N-izing $X^{\pm j}(z',\theta')$ (3.3) into $X^{\pm j}_N(z',\theta';z_0)$ (3.3′).

First, we can show that

$$\tau^j(z',\theta';z_0)=\tau^j_+(z',\theta';z_0)=\tau^j_-(z',\theta';z_0), \tag{3.4}$$

where the new non-N operator $\tau^j_h(z',\theta';z_0)$ is the one defined by

$$\begin{aligned}\tau^j_h(z',\theta';z_0)&(\equiv \tau^j_h(z',\theta';z_0)_1+\tau^j_h(z',\theta';z_0)_2+\tau^j_h(z',\theta';z_0)_3)\\ &\equiv\sum_{\pm}\ :\tfrac{1}{2}\,\partial_{z'}Y^{\pm j}_h(z',\theta';z_0)D_{\theta'}Y^{\mp j}_h(z',\theta';z_0):_R+\epsilon^j_h\\ &\quad\cdot\frac{\theta'}{z'-z_0}:\Psi^{+j}_h(z';z_0)\Psi^{-j}_h(z';z_0):_R+\sum_{\pm}\ \tfrac{1}{4}\,((z'-z_0)^{\mp 2\epsilon^j_h}-1)\partial_{z'}X^{\pm j}(z')\\ &\quad\cdot\Psi^{\mp j}_h(z';z_0),\quad \text{for } j=0-4 \text{ and } h=\pm.\end{aligned} \tag{3.5}$$

Non-N operator $\tau^j_h(z',\theta';z_0)$ is N-ized [see Eq. (1.5)] into N operator $\tau^j_{Nh}(z',\theta';z_0)$ (for $h=+,-$) by using the following N-izing denoted by $\overset{N}{\rightarrow}$:

$$\begin{aligned}&\text{non-}N\ \text{operators} && \overset{N}{\rightarrow}\ N\ \text{operators}\\ &\Psi^{\pm j}_h(z;z_0)\equiv(z-z_0)^{\mp\epsilon^j_h}:\exp(\pm\phi^j(z)):_\phi && \overset{N}{\rightarrow}\Psi^{\pm j}_{Nh}(z)\equiv:\exp(\pm\phi^j_{Nh}(z)):_\phi\\ &Y^{\pm j}_h(z,\theta;z_0)\equiv X^{\pm j}(z)+\theta\Psi^{\pm j}_h(z;z_0) && \overset{N}{\rightarrow}Y^{\pm j}_{Nh}(z,\theta)\equiv X^{\pm j}(z)+\theta\Psi^{\pm j}_{Nh}(z).\end{aligned} \tag{3.6}$$

Then, we can easily see that τ^j_{Nh} has no branch point at $z'=z_0$. Similar to Eq. (3.4), we can also show that

$$\tau^j_N(z',\theta';z_0)=\tau^j_{N+}(z',\theta';z_0)=\tau^j_{N-}(z',\theta';z_0). \tag{3.7}$$

Since non-N operators $\tau^j_\pm(z',\theta';z_0)$ are single valued, we hereafter investigate radially ordered products among the non-N operator $\Phi^F_{\{h\}}(z_0,\theta_0;P^\dagger_F)$ (1.12), FMS spinor $S_{\{h\}}(z_0)$ (1.4), and the (single-valued) non-N-operator $\tau^j_\pm$ (3.5), where τ^j_h should be used when $S_{\{h\}}(z_0)$ has the factor $:\exp(\epsilon^j_h\phi^j(z_0)):_\phi$. By using Wick's theorem, the radially ordered product can be rewritten in terms of the normal ordered products in the R sector (denoted by $:\ :_R$), with the help of the following contractions in the R sector (for $j,k=1-4$):

$$\begin{aligned}&ip^{+0}\overbrace{Y^{-0}_+(z',\theta';z_0)X^{\pm j}(z_F,\theta_F)}^{R}+ip^{+0}\overbrace{Y^{-0}_+(z',\theta';z_0)X^{\pm j}(z_F,\theta_F)}^{R}\\ &=\frac{1}{\lambda}(\delta z_F-\delta\theta_F\cdot\theta_F)\partial_{Z_F}X^{\pm j}(z_F,\theta_F)+\frac{1}{\lambda}(\delta\theta_F)D_{\theta_F}X^{\pm j}(z_F,\theta_F),\end{aligned} \tag{3.8}$$

$$\begin{aligned}&\overbrace{Y^{+0}_+(z',\theta';z_0)Y^{-0}_{N+}(z_0,\theta_0)}^{R}=\log(z'-z_0-\theta'\theta_0),\\ &\overbrace{Y^{-0}_+(z',\theta';z_0)X^{+0}(z_0)}^{R}=\log(z'-z_0)\end{aligned} \tag{3.9}$$

and

$$\overbrace{Y^{\pm j}_h(z',\theta';z_0)X^{\mp k}(z_F,\theta_F)}^{R}=\delta^{jk}\log(z'-z_F-(z_F-z_0)^{\mp\epsilon^j_{h'}}\cdot\theta'\theta_F), \tag{3.10}$$

which are valid when (z',θ') is a c number. [On the right-hand side of Eq. (3.8), we can use Eqs. (2.22) and (2.23).]

In Appendix A, we find the following OPE:

$$\begin{aligned}\vec{R}\cdot\tau_+^0(z',\theta';z_0):&\exp(\rho_{N+}^{0F}(z_0,\theta_0))\exp(\rho^{1F}(z_0,\theta_0;P_F^\dagger)):_R\\ =:&\left(\tau_+^0(z',\theta';z_0)+G_+^F(z_0,\theta_0|z',\theta')-\sum_{\pm}\sum_{j=1}^{4} i\oint\frac{dwd\xi}{2\pi i}P_F^{\pm j\dagger}(w,\xi)G^{\mp jF}(w,\xi|z',\theta')\right)\\ &\times\exp(\rho_{N+}^{0F}(z_0,\theta_0))\exp(\rho^{1F}(z_0,\theta_0;P_F^\dagger)):_R\end{aligned}\tag{3.11}$$

and those obtained from Eq. (3.11) by

$$\left.\begin{aligned}\tau_+^0(z',\theta';z_0)&\to\tau_+^0(z',\theta';z_0)_\iota,\\ G_+^F(z_0,\theta_0|z',\theta')&\to G_+^F(z_0,\theta_0|z',\theta')_\iota\\ G^{\mp jF}(w,\xi|z',\theta')&\to G^{\mp jF}(w,\xi|z',\theta')_\iota,\end{aligned}\right\}[\text{for }\ \iota=1-3],\tag{3.11$'$}$$

so that we have from Eq. (3.5)

$$\begin{aligned}G_+^F(z_0,\theta_0|z',\theta')&=\sum_{\iota=1}^{3}G_+^F(z_0,\theta_0|z',\theta')_\iota,\\ G^{\mp jF}(w,\xi|z',\theta')&=\sum_{\iota=1}^{3}G^{\mp jF}(w,\xi|z',\theta')_\iota.\end{aligned}\tag{3.11$''$}$$

In Eq. (3.11$'$), non-N operators $G_+^F(\ )_\iota$ and $G^{\mp jF}(\ )_\iota$ (for $\iota=1-3$) are calculated by Eqs. (A1)–(A3) and (A4)–(A6), respectively. Furthermore, non-N operator $G^{\mp jF}$ in OPE (3.11) is given by

$$G^{\mp jF}(w,\xi|z',\theta')=(G^{F1/2}(w,\xi|z',\theta')\partial_{z_F}+G^{F1}(w,\xi|z',\theta')D_{\theta_F})X^{\mp j}(z_F,\theta_F),$$

$$\text{with }\ z_F\equiv z_F(w,\xi)\quad\text{and}\quad\theta_F\equiv\theta_F(w,\xi)\tag{3.12}$$

and we have those obtained from Eq. (3.12) by

$$\left.\begin{aligned}G^{\mp jF}(w,\xi|z',\theta')&\to G^{\mp jF}(w,\xi|z',\theta')_\iota,\\ G^{F(1/2)(1)}(w,\xi|z',\theta')&\to G^{F(1/2)(1)}(w,\xi|z',\theta')_\iota,\end{aligned}\right\}[\text{for }\ \iota=1-3],\tag{3.12$'$}$$

so that we have from Eq. (3.11$''$)

$$G^{F(1/2)(1)}(w,\xi|z',\theta')=\sum_{\iota=1}^{3}G^{F(1/2)(1)}(w,\xi|z',\theta')_\iota.\tag{3.12$''$}$$

In Eq. (3.12$'$), non-N operators $G^{F1/2}(\ )_\iota$ and $G^{F1}(\ )_\iota$ (for $\iota=1-3$) are given by Eqs. (A8)–(A10) and (A11)–(A13), respectively.

In Appendix B, we find that

$$\vec{R}\cdot\tau_h^j(z',\theta';z_0):\exp(\rho^{1F}(z_0,\theta_0;P_F^\dagger)):_R$$

$$=:\Bigg(\tau_h^j(z',\theta';z_0)-\sum_{\pm}\sum_{j=1}^{4} i\oint\frac{dwd\xi}{2\pi i}P_F^{\pm j^\dagger}(w,\xi)g_h^{\mp jF}(w,\xi|z',\theta')$$

$$-\sum_{j=1}^{4}\oint\frac{dwd\xi}{2\pi i}P_F^{-j^\dagger}(w,\xi)\oint\frac{dw'd\xi'}{2\pi i}P_F^{+j}(w',\xi')g_h^{jjF}(w,\xi;w',\xi'|z',\theta')\Bigg)$$

$$\times\exp(\rho^{1F}(z_0,\theta_0;P_F^\dagger)):_R \tag{3.13}$$

and those obtained from Eq. (3.13) by

$$\left.\begin{aligned}\tau_h^j(z',\theta';z_0)&\to\tau_h^j(z',\theta';z_0)_\iota,\\ g_h^{\mp jF}(w,\xi|z',\theta')&\to g_h^{\mp jF}(w,\xi|z',\theta')_\iota\\ g_h^{jjF}(w,\xi;w',\xi'|z',\theta')&\to g_h^{jjF}(w,\xi;w',\xi'|z',\theta')_\iota\end{aligned}\right\}[\text{for }\ \iota=1-3], \tag{3.13$'$}$$

so that we have from Eq. (3.5)

$$g_h^{\mp jF}(w,\xi|z',\theta')=\sum_{\iota=1}^{3}g_h^{\mp jF}(w,\xi|z',\theta')_\iota,$$

$$g_h^{jjF}(w,\xi;w',\xi'|z',\theta')=\sum_{\iota=1}^{3}g_h^{jjF}(w,\xi;w',\xi'|z',\theta')_\iota. \tag{3.13$''$}$$

In Eq. (3.13), non-N operator $g_h^{\mp jF}(\ )_\iota$ [for $\iota=1-3$] is given by Eqs. (B1)–(B3), while $g_h^{jjF}(\ )_\iota$ [for $\iota=1-3$] is given by Eqs. (B4)–(B6).

In Appendix C, we find the following OPE:

$$\vec{R}\cdot\tau_+^0(z',\theta';z_0):\exp(\rho_{\{h\}}^{2F}(z_0,\theta_0;P_F^\dagger))\exp(-ip^{+0}Y_{N+}^{-0}(z_0,\theta_0)):_R$$

$$=:\Bigg(\tau_+^0(z',\theta';z_0)-\sum_{j=1}^{4}\oint\frac{dwd\xi}{2\pi i}P_F^{-j^\dagger}(w,\xi)\oint\frac{dw'd\xi'}{2\pi i}P_F^{+j^\dagger}(w',\xi')$$

$$\times G_h^{jjF}(w,\xi;w',\xi'|z',\theta')\Bigg)\exp(\rho_{\{h\}}^{2F}(z_0,\theta_0;P_F^\dagger))\exp(-ip^{+0}Y_{N+}^{-0}(z_0,\theta_0)):_R, \tag{3.14}$$

where non-N operator G_h^{jjF} is given by Eq. (C2).

Previously obtained OPEs (3.11), (3.13), and (3.14) will be summarized into OPE among GFPVO $\vec{R}\cdot\Phi_{\{h\}}^F(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)$ and

$$\tau(z',\theta';z_0)\equiv\sum_{j=0}^{4}\tau^j(z',\theta';z_0). \tag{3.15}$$

Thus obtained OPE (in non-N operator's form) is given as follows:

$$\vec{R}\cdot\tau(z',\theta';z_0)\Phi^F_{\{h\}}(z_0,\theta_0;P^\dagger_F)S_{\{h\}}(z_0)$$

$$=\vec{R}:\Bigg(\tau(z',\theta';z_0)+G^F_+(z_0,\theta_0|z',\theta')-\sum_{\pm}\sum_{j=1}^{4} i\oint\frac{dwd\xi}{2\pi i}P_F^{\pm j^\dagger}(w,\xi)H_h^{\mp jF}(w,\xi|z',\theta')$$

$$-\sum_{j=1}^{4}\oint\frac{dwd\xi}{\pi i}P_F^{-j^\dagger}(w,\xi)\oint\frac{dw'd\xi'}{2\pi i}P_F^{+j^\dagger}(w',\xi')H_h^{jjF}(w,\xi;w',\xi'|z',\theta')\Bigg)$$

$$\times\Phi^F_{\{h\}}(z_0,\theta_0;P^\dagger_F):_R S_{\{h\}}(z_0), \tag{3.16}$$

where

$$H_h^{\mp jF}=G^{\mp jF}+g_h^{\mp jF}$$

$$H_h^{jjF}\equiv G_h^{jjF}+g_h^{jjF}. \tag{3.17}$$

In Eqs. (3.16) and (3.17), we have used G^F_+ and $G^{\mp jF}$ in OPE (3.11), $g_h^{\mp jF}$ and g_h^{jjF} in OPE (3.13), and G_h^{jjF} in OPE (3.14). On the right-hand side of OPE (3.16), there exist two types of singularities, i.e., type (A): those at $z'=z_F,z'_F$ and type (B): those at $z'=z_0$. For the time being, we shall investigate singularies of type (A); Singular terms of type (A) in F will be denoted by $(F)_{\text{sing.}}$, hereafter. Then, non-N operator $(g_h^{\mp j}(\ ))_{\text{sing.}}$ in OPE (3.13) is expanded as

$$(g_h^{\mp jF}(w,\xi|z',\theta'))_{\text{sing.}}\equiv((g_h^{F1/2}(w,\xi|z',\theta'))_{\text{sing.}}\partial_{z_F}+(g_h^{F1}(w,\xi|z',\theta'))_{\text{sing.}}D_{\theta_F})X^{\mp j}(z_F,\theta_F) \tag{3.18}$$

and we have also those obtained from Eq. (3.18) by

$$\left.\begin{aligned}(g_h^{\mp jF}(w,\xi|z',\theta'))_{\text{sing.}}&\to(g_h^{\mp jF}(w,\xi|z',\theta')_\iota)_{\text{sing.}}\\ (g_h^{F1(1/2)}(w,\xi|z',\theta'))_{\text{sing.}}&\to(g_h^{F1(1/2)}(w,\xi|z',\theta')_\iota)_{\text{sing.}}\end{aligned}\right\}\ [\text{for}\ \ \iota=1-3]. \tag{3.18$'$}$$

Therefore, we have from Eq. (3.13″)

$$(g_h^{F1(1/2)}(w,\xi|z',\theta'))_{\text{sing.}}=\sum_{i=1}^{3}(g_h^{F1(1/2)}(w,\xi|z',\theta')_\iota)_{\text{sing.}}. \tag{3.18$''$}$$

Non-N operator $(g_h^{F1(1/2)}(\ )_\iota)_{\text{sing.}}$ [for $\iota=1-3$] in Eq. (3.18′) is given by Eqs. (D4)–(D6) [(D7) and (D8)], so that non-N operator $(g_h^{F1(1/2)}(\ ))_{\text{sing.}}$ in Eq. (3.18″) is found out to be given by Eq. (D10) [(D9)]. On the other hand, non-N operator $(g_h^{jjF}(\ )_\iota)_{\text{sing.}}$ (for $\iota=1-3$) in Eq. (3.13′) is given by Eqs. (D12)–(D14), so that $(g_h^{jjF}(\ ))_{\text{sing.}}$ in Eq. (3.13″) is given by Eq. (D15). Therefore, with the help of Eqs. (D9), (D10), and (D15), we find the important relation

$$\begin{aligned}(g_h^{jjF}(w,\xi;w',\xi'|z',\theta'))_{\text{sing.}}=&((g_h^{F1/2}(w,\xi|z',\theta'))_{\text{sing.}}\partial_{z_F}+(g_h^{F1}(w,\xi|z',\theta'))_{\text{sing.}}D_{\theta_F}\\&+(g_h^{F1/2}(w',\xi'|z',\theta'))_{\text{sing.}}\partial_{z'_F}\\&+(g_h^{F1}(w',\xi'|z',\theta'))_{\text{sing.}}D_{\theta'_F})\log\left(z_F-z'_F-\left(\frac{z_F-z_0}{z'_F-z_0}\right)^{\epsilon_h^j}\theta_F\theta'_F\right).\end{aligned} \tag{3.19}$$

Therefore, Eq. (3.17) together with Eqs. (3.12) and (3.18) gives

$$(H_h^{\mp jF}(w,\xi|z',\theta'))_{\text{sing.}}\equiv((H_h^{F1/2}(w,\xi|z',\theta'))_{\text{sing.}}\partial_{z_F}+(H_h^{F1}(w,\xi|z',\theta'))_{\text{sing.}}D_{\theta_F})X^{\mp j}(z_F,\theta_F), \tag{3.20}$$

while Eq. (3.17) together with Eqs. (C2) and (3.19) gives

$$
\begin{aligned}
&(H_h^{jjF}(w,\xi;w',\xi'|z',\theta'))_{\text{sing.}}\\
&\quad=((H_h^{F\,1/2}(w,\xi|z',\theta'))_{\text{sing.}}\partial_{z_F}+(H_h^{F1}(w,\xi|z',\theta'))_{\text{sing.}}D_{\theta_F}+(H_h^{F1/2}(w',\xi'|z',\theta'))_{\text{sing.}}\partial_{z'_F}\\
&\qquad+(H_h^{F1}(w',\xi'|z',\theta'))_{\text{sing.}}D_{\theta'_F})\log\left(z_F-z'_F-\left(\frac{z_F-z_0}{z'_F-z_0}\right)^{\epsilon_h^j}\theta_F\theta'_F\right),
\end{aligned}
\tag{3.21}
$$

where we have

$$
(H_h^{F1(1/2)}(\ ))_{\text{sing.}}\equiv(G^{F1(1/2)}(\ ))_{\text{sing.}}+(g_h^{F1(1/2)}(\ ))_{\text{sing.}}. \tag{3.22}
$$

In Appendix E, we can prove Eqs. (E20) and (E21) among $(G^{F\,1/2(1)}(\ ))_{\text{sing.}}$ and $(g_h^{F\,1/2(1)}(\ ))_{\text{sing.}}$, which lead to the essential fact that $(H_h^{F\,1/2(1)}(\ ))_{\text{sing.}}$ in Eqs. (3.20) and (3.21) is just equal to zero. This fact together with

$$
\theta' T^{0F}(z')=\tau^0(z',\theta';z_0)-\tau^0(z',0;z_0) \tag{3.23}
$$

and

$$
\mathscr{T}^{0F}(z')=4\left(\sqrt{z'-z_0}+\frac{1}{\sqrt{z'-z_0}}\right)^{-1}(1-\theta'\partial_{\theta'})\tau^0(z',\theta';z_0) \tag{3.24}
$$

shows that the radially ordered product among $T_F(\mathscr{T}_F)$, $\Phi^F_{\{h\}}$, and $S_{\{h\}}$ does not have any singularity at $z'=z_F,z'_F$, but it has singularities (*only*) at $z'=z_0$.

Hereafter, we shall investigate the singularities of type (B) (i.e., those at $z'=z_0$) on the right-hand side of the following OPE [which is obtained from (3.11) and (3.14)];

$$
\begin{aligned}
&\vec{R}\cdot\tau_+^0(z',\theta';z_0)\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)\\
&\quad=\vec{R}\cdot:\Bigg(\tau_+^0(z',\theta';z_0)+G^F_{N+}(z_0,\theta_0|z',\theta')\\
&\qquad-\sum_{\pm}\sum_{j=1}^{4} i\oint\frac{dwd\xi}{2\pi i}P_F^{\pm j^\dagger}(w,\xi)G^{\mp jF}(w,\xi|z',\theta')\\
&\qquad-\sum_{j=1}^{4}\oint\frac{dwd\xi}{2\pi i}P_F^{-j^\dagger}(w,\xi)\oint\frac{dw'd\xi'}{2\pi i}P_F^{+j^\dagger}\\
&\qquad\times(w',\xi')G_h^{jjF}(w,\xi;w',\xi'|z',\theta')\Bigg)\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger):_R S_{\{h\}}(z_0).
\end{aligned}
\tag{3.25}
$$

{In OPE (3.25), we have used N operator G_{N+}, which is N-ized [see Eq. (1.5)] from non-N operator G_+ in OPE (3.11).} Then, singular terms at $z'=z_0$ in G^F_{N+} and $G^{F1(1/2)}$ can be obtained after tedious but straightforward calculations, as follows: in the neighborhood of $z'=z_0$, $G^F_{N+}(\ )$ is easily expanded at $z'=z_0$. We can express G^F_{N+} in Eq. (3.25) by

$$
G^F_{N+}(z_0,\theta_0|z',\theta')=\theta'\cdot M^F_{N+}(z_0,\theta_0|z')+N^F_{N+}(z_0,\theta_0|z'). \tag{3.26}
$$

In the neighborhood of $z'=z_0$, the singular terms in M^F_{N+} in Eq. (3.26) are found to be

$$
M^F_{N+}(z_0,\theta_0|z')=-\frac{p^{+0}p^{-0}}{(z'-z_0)^2}+\frac{1}{z'-z_0}(\partial_{z_0}\rho^{0F}_{N+}(z_0,\theta_0)+\tfrac{1}{2}\theta_0\partial_{z_0}ip^{+0}\Psi^{-0}_{N+}(z_0))+O(1). \tag{3.27}
$$

Similarly, in the neighborhood of $z'=z_0$, the singular terms in N^F_{N+} in Eq. (3.26) are found out to be

$$4\left(\sqrt{z'-z_0}+\frac{1}{\sqrt{z'-z_0}}\right)^{-1} N^F_{N+}(z_0,\theta_0|z')(\equiv \mathscr{N}^F_{N+}(z_0,\theta_0|z'))$$

$$=\frac{1}{(\sqrt{z'-z_0})^3}\,(p^{+0}p^{-0}\theta_0+\partial_{\theta_0}\rho^{0F}_{N+}(z_0,\theta_0))+\frac{1}{\sqrt{z'-z_0}}$$
$$\times\left(\frac{\Psi^{+0}_{N+}(z_0)}{ip^{+0}}\,p^{+0}p^{-0}-\theta_0\partial_{z_0}\rho^{0F}_{N+}(z_0,\theta_0)-\partial_{z_0}ip^{+0}\Psi^{-0}_{N+}(z_0)-\theta_0\partial_{z_0}ip^{-0}X^{+0}(z_0)\right)$$
$$+O(\sqrt{z'-z_0}). \tag{3.28}$$

On the other hand, in order to analyze singular terms (at $z'=z_0$) of non-N operators $G^{F(1/2)(1)}$ {calculated by summing up Eqs. (A8)–(A10) [(A11)–(A13)]}, non-N operator $f_+(z',\theta'|z_0,\theta_0)$ in Eqs. (A8)–(A13) must be N-ized [see Eq. (1.5)] into N operator $f_{N+}(z',\theta'|z_0,\theta_0)$ (A7′), which can be expanded at $z'=z_0$. Thus, we obtain

$$G^{F\,1/2}(w,\xi|z',\theta')\partial_{z_F}+G^{F1}(w,\xi|z',\theta')D_{\theta_F}=\theta'(M^{F\,1/2}(w,\xi|z')\partial_{z_F}+M^{F1}(w,\xi|z')D_{\theta_F})$$
$$+N^{F\,1/2}(w,\xi|z')\partial_{z_F}+N^{F1}(w,\xi|z')D_{\theta_F}, \tag{3.29}$$

where we have found that

$$M^{F\,1/2}(w,\xi|z')\partial_{z_F}+M^{F1}(w,\xi|z')D_{\theta_F}=\frac{1}{(z'-z_0)^2}\,(\tfrac{1}{2}\xi D_\xi+w\partial_w)$$
$$+\frac{1}{z'-z_0}\left(\partial_{z_0}-\frac{\frac{1}{2}\Psi^{+0}_{N+}(z_0)}{ip^{+0}}\,\partial_{\theta_0}\right)+O(1) \tag{3.30}$$

and

$$4\left(\sqrt{z'-z_0}+\frac{1}{\sqrt{z'-z_0}}\right)^{-1}(N^{F\,1/2}(w,\xi|z')\partial_{z_F}+N^{F1}(w,\xi|z')D_{\theta_F})(\equiv \mathscr{N}^{F\,1/2}(w,\xi|z')\partial_{z_F}$$
$$+\mathscr{N}^{F1}(w,\xi|z')D_{\theta_F})$$
$$=\frac{1}{(\sqrt{z'-z_0})^3}\,(-\theta_0(\tfrac{1}{2}\xi D_\xi+w\partial_w)+\partial_{\theta_0})$$
$$+\frac{1}{\sqrt{z'-z_0}}\left(-\frac{\Psi^{+0}_{N+}(z_0)}{ip^{+0}}\,(\tfrac{1}{2}\xi D_\xi+w\partial_w)-\left(\theta_0\partial_{z_0}+\partial_{z_0}\frac{X^{+0}(z_0)}{ip^{+0}}\,\partial_{\theta_0}\right)\right.$$
$$\left.-\oint_{z_0}\frac{dz}{2\pi i}\,\frac{ip^{+0}}{(z-z_0)^2}\,\Psi^{-0}_{N+}(z)\otimes\right)+O(\sqrt{z'-z_0}). \tag{3.31}$$

Our results have been rewritten into final expressions of Eqs. (3.30) and (3.31), by using the following identities:

$$(D_{\theta_0}z_F-D_{\theta_0}\theta_F\cdot\theta_F)\partial_{z_F}F(z_F,\theta_F)+(D_{\theta_0}\theta_F)D_{\theta_F}F(z_F,\theta_F)=D_{\theta_0}F(z_F,\theta_F) \tag{3.32}$$

and

$$(\partial_{z_0}z_F-\partial_{z_0}\theta_F\cdot\theta_F)\partial_{z_F}F(z_F,\theta_F)+(\partial_{z_0}\theta_F)D_{\theta_F}F(z_F,\theta_F)=\partial_{z_0}F(z_F,\theta_F). \tag{3.33}$$

We remark that D_{θ_0} and ∂_{z_0} on the left-hand sides of Eqs. (3.32) and (3.33) have appeared by using relations (2.32)–(2.35). Furthermore, we have used the identity

$$w(D_\xi\theta_F)^2\partial_{z_F}F(z_F,\theta_F)+(\tfrac{1}{2}\xi D_\xi\theta_F+w\partial_w\theta_F)D_{\theta_F}F(z_F,\theta_F)=(\tfrac{1}{2}\xi D_\xi+w\partial_w)F(z_F,\theta_F), \tag{3.34}$$

together with the following formulas in non-N operator's form:

$$\begin{aligned}\partial_{\theta_0}z_F-\partial_{\theta_0}\theta_F\cdot\theta_F&=(D_{\theta_0}z_F-D_{\theta_0}\theta_F\cdot\theta_F)-\theta_0(\partial_{z_0}z_F-\partial_{z_0}\theta_F\cdot\theta_F)\\&=-w(D_\xi\theta_F)^2\,\frac{\theta_F}{\sqrt{z_F-z_0}}-\frac{\xi wK_F^3(w)}{\sqrt{z_F-z_0}}\end{aligned} \tag{3.35}$$

and

$$\begin{aligned}\partial_{\theta_0}\theta_F&=D_{\theta_0}\theta_F-\theta_0(\partial_{z_0}\theta_F)=(\tfrac{1}{2}\xi D_\xi\theta_F+w\partial_w\theta_F)\,\frac{\theta_F}{\sqrt{z_F-z_0}}+(wK_F^2(w)\\&\quad+\tfrac{1}{2}\xi wK_F(w)\partial_wJ_F(w))\,\frac{1}{\sqrt{z_F-z_0}}+\frac{1}{4}\,\xi wK_F^3(w)\,\frac{\theta_F}{(\sqrt{z_F-z_0})^3},\end{aligned} \tag{3.36}$$

which result from Eqs. (2.32) to (2.35). Moreover, we have defined the operator $A\otimes$ which operates on adjacent operator B as

$$A\otimes B\equiv\overbrace{A\quad B}^{R}, \tag{3.37}$$

so that we have

$$\begin{aligned}&-\oint_{z_0}\frac{dz}{2\pi i}\frac{ip^{+0}}{(z-z_0)^2}\;\Psi_{N+}^{-0}(z)\otimes X^{\mp j}(z_F,\theta_F)\\&\equiv-\oint_{z_0}\frac{dz}{2\pi i}\frac{ip^{+0}}{(z-z_0)^2}\,\overbrace{\Psi_{N+}^{-0}(z)X^{\mp j}}^{R}(z_F,\theta_F)\\&=\left(-w(D_\xi\theta_F)^2\,\frac{\theta_F}{(\sqrt{z_F-z_0})^3}-\xi\,\frac{wK_F^3(w)}{(\sqrt{z_F-z_0})^3}\right)\partial_{z_F}X^{\mp j}(z_F,\theta_F)\\&\quad+\left((\tfrac{1}{2}\xi D_\xi\theta_F+w\partial_w\theta_F)\,\frac{\theta_F}{(\sqrt{z_F-z_0})^3}+(wK_F^2(w)+\tfrac{1}{2}\,\xi wK_F(w)\partial_wJ_F(w))\,\frac{1}{(\sqrt{z_F-z_0})^3}\right.\\&\quad\left.+\frac{3}{4}\,\xi wK_F^3(w)\,\frac{\theta_F}{(\sqrt{z_F-z_0})^5}\right)D_{\theta_F}X^{\mp j}(z_F,\theta_F)\end{aligned} \tag{3.38}$$

resulting from contractions in the R sector (2.22) and (2.23).

At this stage, it should be noticed that light-cone operators α's and d's in $P_F^{\pm j}$ (1.1) satisfy the following (anti) commutation relations:

$$[\alpha_m^{\pm j},\alpha_{-n}^{\mp k}]=m\,\delta_{mn}\delta^{jk}\quad\text{for }\ j,k=1-4\quad\text{and }\ n,m=1,2,3,\ldots. \tag{3.39}$$

and

$$\{d_m^{\pm j},d_{-n}^{\mp k}\}=\delta_{mn}\delta^{jk}\quad\text{for }\ j,k=1-4\quad\text{and }\ n,m=0,1,2,\ldots. \tag{3.40}$$

Then, the light-cone number operator N_F defined by

$$N_F \equiv \sum_{n=1}^{\infty} \sum_{\pm} \sum_{k=1}^{4} \left(\alpha_{-n}^{\mp k} \alpha_n^{\pm k} + n d_{-n}^{\mp k} d_n^{\pm k} \right) \tag{3.41}$$

satisfies the following commutation relation:

$$[N_F, P_F^{\pm j\dagger}(w,\xi)] = -\partial_w (w P_F^{\pm j\dagger}(w,\xi)) + \tfrac{1}{2} \partial_\xi (\xi P_F^{\pm j\dagger}(w,\xi)). \tag{3.42}$$

Furthermore, we have the identity

$$1 = (\tfrac{1}{2}\, \xi \partial_\xi + w \partial_w + \tfrac{1}{2}\, \xi' \partial_{\xi'} + w' \partial_{w'}) \log \left(w - w' - \left(\frac{w'}{w} \right)^{\pm 1/2} \xi \xi' \right). \tag{3.43}$$

With the help of Eqs. (3.42) and (3.43), we obtain the following relations:

$$-\sum_{\pm} \sum_{j=1}^{4} i \oint \frac{dw d\xi}{2\pi i} P_F^{\pm j\dagger}(w,\xi) (\tfrac{1}{2}\, \xi \partial_\xi + w \partial_w) X^{\mp j}(z_F, \theta_F) = [N_F, \rho^{1F}(z_0, \theta_0; P_F^\dagger)] \tag{3.44}$$

and

$$\begin{aligned} &-\sum_{j=1}^{4} \oint \frac{dw d\xi}{2\pi i} P_F^{-j\dagger}(w,\xi) \oint \frac{dw' d\xi'}{2\pi i} P_F^{+j\dagger}(w',\xi') \\ &\quad \times (\tfrac{1}{2}\, \xi \partial_\xi + w \partial_w + \tfrac{1}{2}\, \xi' \partial_{\xi'} + w' \partial_{w'}) \log \left(z_F - z_F' - \left(\frac{z_F - z_0}{z_F' - z_0} \right)^{\epsilon_h^j} \theta_F \theta_F' \right) \\ &\quad = [N_F, \rho_{\{h\}}^{2F}(z_0, \theta_0; P_F^\dagger)] - \left(\sum_{j=1}^{4} p^{+j} p^{-j} \right). \end{aligned} \tag{3.45}$$

Since we have $T^{OF}(z')$ by using Eq. (3.23), we finally obtain [from Eq. (3.25) substituted with both Eq. (3.27) in Eq. (3.26) and Eq. (3.30) in Eq. (3.29)] the following operator product expansion (OPE):

$$\begin{aligned} \vec{R} \cdot T^{0F}(z') \Phi_{\{h\}}^F(z_0, \theta_0; P_F^\dagger) S_{\{h\}}(z_0) &= \frac{1}{(z' - z_0)^2} \vec{R} \cdot \left(-\left(\sum_{j=0}^{4} p^{+j} p^{-j} \right) \Phi_{\{h\}}^F(z_0, \theta_0; P_F^\dagger) S_{\{h\}}(z_0) \right. \\ &\quad \left. + [N_F, \Phi_{\{h\}}^F(z_0, \theta_0; P_F^\dagger) S_{\{h\}}(z_0)] \right) + \frac{1}{z' - z_0} \vec{R} \\ &\quad \cdot (\partial_{z_0} \Phi_{\{h\}}^F(z_0, \theta_0; P_F^\dagger)) S_{\{h\}}(z_0) + \frac{1}{z' - z_0} \vec{R} \\ &\quad \cdot : \left(\tfrac{1}{2} \Psi_{N+}^{+0}(z_0) \Psi_{N+}^{-0}(z_0) + \tfrac{1}{2} \theta_0 (\partial_{z_0} i p^{+0} \Psi_{N+}^{-0}(z_0)) \right. \\ &\quad \left. - \frac{\tfrac{1}{2}\, \Psi_{N+}^{+0}(z_0)}{i p^{+0}} \partial_{\theta_0} (\rho^{1F}(z_0, \theta_0; P_F^\dagger) + \rho_{\{h\}}^{2F}(z_0, \theta_0; P_F^\dagger)) \right) \\ &\quad \times \Phi_{\{h\}}^F(z_0, \theta_0; P_F^\dagger) :_R S_{\{h\}}(z_0) + O(1), \end{aligned} \tag{3.46}$$

where $S_{\{h\}}(z_0)$ is the FMS spinor (1.4). In the following, we shall prove that the last term on the right-hand side of Eq. (3.46) can be rewritten into the term on the left-hand side of the following Eq. (3.48):

Proof: Since we have

$$:\exp(-\phi^0_{N+}(z_0)):_\phi :(\partial_{z_0}\phi^0(z_0)\exp(\tfrac{1}{2}\phi^0(z_0))):_\phi$$

$$=:(\exp(-\phi^0(z_0))\partial_{z_0}\phi^0(z_0)\exp(\tfrac{1}{2}\phi^0(z_0))):_\phi$$

$$=:(\exp(-\phi^0_{N+}(z_0))\partial_{z_0}\phi^0_{N+}(z_0)):_\phi :\exp(\tfrac{1}{2}\phi^0(z_0)):_\phi , \tag{3.47}$$

we find that

$$\frac{1}{z'-z_0}\vec{R}\cdot :\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger)(\partial_{z_0}:\exp(\tfrac{1}{2}\phi^0(z_0)):_\phi)\left(\prod_{j=1}^{4}:\exp(\epsilon_h^j\phi^j(z_0)):_\phi\right)$$

$$=\frac{1}{z'-z_0}\vec{R}\cdot :(\exp(\rho^{0F}_{N+}(z_0,\theta_0))\tfrac{1}{2}\partial_{z_0}\phi^0_{N+}(z_0)):_\phi :(\exp(\rho^{1F}(z_0,\theta_0;P_F^\dagger)$$
$$+\rho^{2F}_{\{h\}}(z_0,\theta_0;P_F^\dagger))):_R S_{\{h\}}(z_0), \tag{3.48}$$

the right-hand side of which can be calculated as follows. First, we notice that

$$\vec{R}\cdot :(\exp(\rho^{0F}_{N+}(z_0,\theta_0))\tfrac{1}{2}\partial_{z_0}\phi^0_{N+}(z_0)):_\phi :(\exp(\rho^{1F}(z_0,\theta_0;P_F^\dagger)+\rho^{2F}_{\{h\}}(z_0,\theta_0;P_F^\dagger))):_R$$
$$=:(\tfrac{1}{2}\partial_{z_0}\phi^0_{N+}(z_0)\exp(\rho^{0F}_{N+}(z_0,\theta_0)+\rho^{1F}(z_0,\theta_0;P_F^\dagger)+\rho^{2F}_{\{h\}}(z_0,\theta_0;P_F^\dagger))):_R+:((\tfrac{1}{2}\partial_{z_0}\phi^0_{N+}(z_0)$$
$$\otimes(\rho^{1F}(z_0,\theta_0;P_F^\dagger)+\rho^{2F}_{\{h\}}(z_0,\theta_0;P_F^\dagger)))\exp(\rho^{0F}_{N+}(z_0,\theta_0)+\rho^{1F}(z_0,\theta_0;P_F^\dagger)$$
$$+\rho^{2F}_{\{h\}}(z_0,\theta_0;P_F^\dagger))):_R , \tag{3.49}$$

where we have used the operation $\otimes$ defined by Eq. (3.37). With the help of

$$:\Psi^{+j}_{Nh}(z')\Psi^{-j}_{Nh}(z'):_R=\partial_{z'}\phi^j_{Nh}(z') \quad \text{for } j=0-4, \tag{3.50}$$

we find in the second term on the right-hand side of Eq. (3.49) that

$$\tfrac{1}{2}\partial_{z_0}\phi^0_{N+}(z_0)\otimes(\rho^{1F}(z_0,\theta_0;P_F^\dagger)+\rho^{2F}_{\{h\}}(z_0,\theta_0;P_F^\dagger))$$

$$=:\tfrac{1}{2}\Psi^{+0}_{N+}(z_0)\left(\overbrace{\Psi^{-0}_{N+}(z_0)0\rho^{1F}}^{R}(z_0,\theta_0;P_F^\dagger)+\overbrace{\Psi^{-0}_{N+}(z_0)\rho^{2F}_{\{h\}}}^{R}(z_0,\theta_0;P_F^\dagger)\right):_R . \tag{3.51}$$

By calculating the contractions in the R sector [i.e., $ip^{+0}\Psi^{-0}_{N+}(z_0)\otimes$ in Eq. (3.51)] with the help of Eqs. (2.22) and (2.23), Eq. (3.51) is reduced to

$$-:\left(\frac{\tfrac{1}{2}\Psi^{+0}_{N+}(z_0)}{ip^{+0}}\,\partial_{\theta_0}(\rho^{1F}(z_0,\theta_0;P_F^\dagger)+\rho^{2F}_{\{h\}}(z_0,\theta_0;P_F^\dagger))\right):_R , \tag{3.51$'$}$$

where we have used the partial derivative ∂_{θ_0} given by Eqs. (3.35) and (3.36). Furthermore, we have from Eqs. (1.13) and (3.47)

$$:(\tfrac{1}{2}\partial_{z_0}\phi^0_{N+}(z_0)\exp(\rho^{0F}_{N+}(z_0,\theta_0))):_R=:\tfrac{1}{2}\partial_{z_0}\phi^0_{N+}(z_0)(1-\theta_0 ip^{+0}\exp(-\phi^0_{N+}(z_0)))$$
$$\times\exp\left(-\sum_{\pm} ip^{\pm 0}X^{\mp 0}(z_0)\right):_R$$
$$=:\exp\left(-\sum_{\pm} ip^{\pm 0}X^{\mp 0}(z_0)\right)$$
$$\times(\tfrac{1}{2}\partial_{z_0}\phi^0_{N+}(z_0)+\tfrac{1}{2}\theta_0\partial_{z_0}ip^{+0}\Psi^{-0}_{N+}(z_0)):_R. \tag{3.52}$$

On the other hand, we have from Eq. (1.3)

$$:\exp(\rho^{0F}_{N+}(z_0,\theta_0))\cdot\tfrac{1}{2}\Psi^{+0}_{N+}(z_0)\Psi^{-0}_{N+}(z_0):_R=:\exp\left(-\sum_{\pm} ip^{\pm 0}X^{\mp 0}(z_0)\right)\tfrac{1}{2}\Psi^{+0}_{N+}(z_0)\Psi^{-0}_{N+}(z_0):_R$$
$$=:\exp\left(-\sum_{\pm} ip^{\pm 0}X^{\mp 0}(z_0)\right)\tfrac{1}{2}\partial_{z_0}\phi^0_{N+}(z_0):_R, \tag{3.53}$$

which is just equal to the first term on the right-hand side of Eq. (3.52). Therefore, we find from Eqs. (3.52) and (3.53)

$$:\exp(\rho^{0F}_{N+}(z_0,\theta_0))\tfrac{1}{2}\partial_{z_0}\phi^0_{N+}(z_0):_R=:\exp(\rho^{0F}_{N+}(z_0,\theta_0))(\tfrac{1}{2}\Psi^{+0}_{N+}(z_0)\Psi^{-0}_{N+}(z_0)$$
$$+\tfrac{1}{2}\theta_0\partial_{z_0}ip^{+0}\Psi^{-0}_{N+}(z_0)):_R. \tag{3.54}$$

Substituting Eq. (3.51′) [(3.54)] into the second (first) term on the right-hand side of Eq. (3.49), we find that the right-hand side of Eq. (3.48) is just equal to the last term on the right-hand side of Eq. (3.46). (Q.E.D.)

On the other hand, we find

$$\vec{R}\cdot\left(\sum_{j=1}^{4} T^{jF}(z')\right)\Phi^F_{\{h\}}(z_0,\theta_0;P^\dagger_F)S_{\{h\}}(z_0)$$
$$=\frac{1}{z'-z_0}\vec{R}\cdot\Phi^F_{\{h\}}(z_0,\theta_0;P^\dagger_F):\exp(\tfrac{1}{2}\phi^0(z_0)):_\phi\partial_{z_0}$$
$$\times\left(\prod_{j=1}^{4}:\exp(\epsilon^j_h\phi^j(z_0)):_\phi\right)+O(1). \tag{3.55}$$

In summing Eqs. (3.46) and (3.55), the following factor appears:

$$\vec{R}\cdot(\partial_{z_0}\Phi^F_{\{h\}}(z_0,\theta_0;P^\dagger_F))S_{\{h\}}(z_0)+\vec{R}\cdot\Phi^F_{\{h\}}(z_0,\theta_0;P^\dagger_F)(\partial_{z_0}S_{\{h\}}(z_0))$$
$$=\partial_{z_0}(\Phi^F_{N\{h\}}(z_0,\theta_0;P^\dagger_F)S_{\{h\}}(z_0)). \tag{3.56}$$

We should notice that we must use non-N operator $\Phi^F_{\{h\}}(z_0,\theta_0;P^\dagger_F)$ in each term on the left-hand side of Eq. (3.56), while we can use N operator $\Phi^F_{N\{h\}}(z_0,\theta_0;P^\dagger_F)$ on the right-hand side of Eq. (3.56). With respect to $T_{NF}(z';z_0)$ which is N-ized [see Eq. (1.5)] from

$$T_F(z')\equiv\sum_{j=0}^{4} T^{jF}(z') \tag{3.57}$$

[see Eq. (3.1)], we finally find the following OPE in N operator's form:

$$\vec{R}\cdot T_{NF}(z';z_0)\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)=\frac{1}{(z'-z_0)^2}\left(-\left(\sum_{j=0}^{4}p^{+j}p^{-j}\right)\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)\right.$$
$$\left.+[N_F,\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)]\right)$$
$$+\frac{1}{z'-z_0}\,\partial_{z_0}(\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0))+O(1). \tag{3.58}$$

With the help of Eq. (3.24), the following OPE [with respect to the stressino operator $\mathscr{F}^{0F}(z')$] is obtained (in non-N operator's form) by substituting both N^F_{N+} (3.28) (in Eq. (3.26)) and $N^{F1/2(1)}$ (3.31) [in Eq. (3.30)] into OPE (3.26);

$$\vec{R}\cdot\mathscr{F}^{0F}(z')\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)$$
$$=-\frac{\theta_0}{(\sqrt{z'-z_0})^3}\,\vec{R}$$
$$\cdot\left(-\left(\sum_{j=0}^{4}p^{+j}p^{-j}\right)\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)+[N_F,\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)]\right)$$
$$+\frac{1}{(\sqrt{z'-z_0})^3}\,\vec{R}\cdot\partial_{\theta_0}\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)+O\left(\frac{1}{\sqrt{z'-z_0}}\right). \tag{3.59}$$

On the other hand, we have

$$\vec{R}\cdot\left(\sum_{j=1}^{4}\mathscr{F}^{jF}\right)\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)=O\left(\frac{1}{\sqrt{z'-z_0}}\right). \tag{3.60}$$

With respect to $\mathscr{F}_{NF}(z';z_0)$ which is N-ized [see Eq. (1.5)] from

$$\mathscr{F}_F(z')\equiv\sum_{j=0}^{4}\mathscr{F}^{jF}(z') \tag{3.61}$$

[see Eq. (3.1)], we finally find the following OPE in N operator's form;

$$\vec{R}\cdot\mathscr{F}_{NF}(z';z_0)\Phi^{F0}_{N\{h\}}(z_0;P_F^\dagger)S_{\{h\}}(z_0)=\frac{1}{(\sqrt{z'-z_0})^3}\,\Phi^{F1}_{N\{h\}}(z_0;P_F^\dagger)S_{\{h\}}(z_0)+O\left(\frac{1}{\sqrt{z'-z_0}}\right) \tag{3.62}$$

and

$$\vec{R}\cdot\mathscr{F}_{NF}(z';z_0)\Phi^{F1}_{N\{h\}}(z_0;P_F^\dagger)S_{\{h\}}(z_0)=\frac{1}{(\sqrt{z'-z_0})^3}\left(-\left(\sum_{j=0}^{4}p^{+j}p^{-j}\right)\Phi^{F0}_{N\{h\}}(z_0;P_F^\dagger)S_{\{h\}}(z_0)\right.$$
$$\left.+[N_F,\Phi^{F0}_{N\{h\}}(z_0;P_F^\dagger)S_{\{h\}}(z_0)]\right)+O\left(\frac{1}{\sqrt{z'-z_0}}\right). \tag{3.63}$$

IV. NEXT LEADING TERMS IN OPEs (3.59)–(3.63)

In calculating physical scattering amplitudes among external physical states including more than six Ramond particles, we will find from FMS's work that that we need to picture change[5] some physical Ramond states in 1/2 picture [later given by Eq. (5.12)] into those in 3/2 picture. These picture-changing calculations can be carried out by using the N operator $\hat{\Phi}^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)$ which we have in the following OPE:

$$\begin{aligned}\vec{R}\cdot\mathscr{F}_F(z')\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)=&-\frac{\theta_0}{(\sqrt{z'-z_0})^3}\left(-\left(\sum_{j=0}^{4}p^{+j}p^{-j}\right)\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)\right.\\&\left.+[N_F,\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)]\right)+\frac{1}{(\sqrt{z'-z_0})^3}\\&\cdot\partial_{\theta_0}\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)-\frac{\theta_0}{\sqrt{z'-z_0}}\\&\cdot\partial_{z_0}(\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0))\\&+\frac{1}{\sqrt{z'-z_0}}\hat{\Phi}^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)+O(\sqrt{z'-z_0}).\end{aligned}\tag{4.1}$$

In the following, the explicit formula of the N operator $\hat{\Phi}^F_{N\{h\}}$ [in OPE (4.1)] will be derived by using various formulas given in Sec. III: We have investigated the OPE among GFPVO and the jth stressino operator $\mathscr{F}^{jF}(z')$ defined by

$$\mathscr{F}^{jF}(z')\equiv\sum_{\pm}\partial_{z'}X^{\pm j}(z')\cdot\Psi^{\mp j}(z')\quad(\text{for } j=0-4).\tag{4.2}$$

Then, we find from Eqs. (3.24) to (3.26), (3.12), and (C2) that

$$\begin{aligned}&\vec{R}\cdot\mathscr{F}^{0F}(z')\cdot\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)\\&=\vec{R}\cdot\left(\mathscr{F}^{0F}(z')+\mathscr{N}^F_{N+}(z_0,\theta_0|z')-\sum_{\pm}\sum_{j=1}^{4}i\oint\frac{dwd\xi}{2\pi i}P_F^{\pm j^\dagger}(w,\xi)\right.\\&\times((\mathscr{N}^{F\,1/2}(w,\xi|z')\partial_{z_F}+\mathscr{N}^{F1}(w,\xi|z')D_{\theta_F})X^{\mp j}(z_F,\theta_F))-\sum_{j=1}^{4}\oint\frac{dwd\xi}{2\pi i}P_F^{-j^\dagger}(w,\xi)\\&\times\oint\frac{dw'd\xi'}{2\pi i}P_F^{+j^\dagger}(w',\xi')(\mathscr{N}^{F\,1/2}(w,\xi|z')\partial_{z_F}+\mathscr{N}^{F1}(w,\xi|z')D_{\theta_F}+\mathscr{N}^{F\,1/2}(w',\xi'|z')\partial_{z'_F}\\&\left.+\mathscr{N}^{F1}(w',\xi'|z')D_{\theta'_F})\log\left(z_F-z'_F-\left(\frac{z_F-z_0}{z'_F-z_0}\right)^{\epsilon_h^j}\cdot\theta_F\theta'_F\right)\right)\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0).\end{aligned}\tag{4.3}$$

In the neighborhood of $z'=z_0$, the singular terms in $\mathscr{N}^F_{N+}$ are found from Eq. (3.28), while the singular terms in $\mathscr{N}^{F\,1/2}$ and $\mathscr{N}^{F1}$ in OPE (4.3) are found from Eq. (3.31). In Eq. (4.3), we have used the operator $\Psi^{-0}_{N+}(z)\otimes$ which operates on adjacent operator B as Eq. (3.37) and we have found Eq. (3.38).

On the other hand, we find from Eqs. (2.19) and (1.16) that

$$D_{\theta_F}=\left(\frac{1}{K_F(w)}-\frac{\xi\partial_w J_F(w)}{K_F^2(w)}\right)D_\xi\tag{4.4}$$

and

$$\partial_{z_F}=D_{\theta_F}\cdot D_{\theta_F}=-\frac{1}{K_F^3(w)}\,(\partial_w J_F(w)+\xi\partial_w K_F(w))D_\xi+\frac{1}{K_F^2(w)}\left(1-\frac{2\xi\partial_w J_F(w)}{K_F(w)}\right)\partial_w\,. \tag{4.5}$$

Substituting Eqs. (4.4), (4.5), and (1.16) into Eq. (3.38), we find

$$\begin{aligned}
&-\oint_{z_0}\frac{dz}{2\pi i}\,\frac{ip^{+0}}{(z-z_0)^2}\,\Psi_{N+}^{-0}(z)\otimes(\equiv\mathscr{H}_F(w,\xi))\\
&\quad=-\frac{\theta_F}{(\sqrt{z_F-z_0})^3}\,(\tfrac{1}{2}\xi D_\xi+w\partial_w)+\frac{wK_F(w)}{(\sqrt{z_F-z_0})^3}\,\partial_\xi\\
&\qquad+\xi\left(\tfrac{1}{2}w\partial_w J_F(w)\cdot\frac{1}{(\sqrt{z_F-z_0})^3}+\frac{3}{4}\,wK_F^2(w)\,\frac{\theta_F}{(\sqrt{z_F-z_0})^5}\right)\partial_\xi\,.
\end{aligned}\tag{4.6}$$

Then, OPE (4.3) substituted with Eqs. (3.28), (3.31), and (4.6) leads to

$$\begin{aligned}
\vec{R}\cdot\mathscr{F}^{0F}(z')\cdot\Phi_{\{h\}}^F(z_0\theta_0;P_F^\dagger)S_{\{h\}}(z_0)=&\frac{1}{(\sqrt{z'-z_0})^3}\,(\cdots)-\frac{\theta_0}{\sqrt{z'-z_0}}\cdot\vec{R}\cdot(\partial_{z_0}\Phi_{\{h\}}^F(z_0,\theta_0;P_F^\dagger))S_{\{h\}}\\
&\times(z_0)+\frac{1}{\sqrt{z'-z_0}}\,\hat{\Phi}_{N\{h\},1}^F(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)\\
&+O(\sqrt{z'-z_0}),
\end{aligned}\tag{4.7}$$

with

$$\begin{aligned}
&\hat{\Phi}_{N\{h\},1}^F(z_e,\theta_0;P_F^\dagger)\\
&=-:\frac{\Psi_{N+}^{+0}(z_0)}{ip^{+0}}\left(\left(-\sum_{j=0}^{4}p^{+j}p^{-j}\right)\Phi_{N\{h\}}^F(z_0,\theta_0;P_F^\dagger)+[N_F,\Phi_{N\{h\}}^F(z_0,\theta_0;P_F^\dagger)]\right):_R\\
&\quad-:\left(\partial_{z_0}\frac{X^{+0}(z_0)}{ip^{+0}}\right)\partial_{\theta_0}\Phi_{N\{h\}}^F(z_0,\theta_0;P_F^\dagger):_R-:(\partial_{z_0}ip^{+0}\Psi_{N+}^{-0}(z_0)\\
&\quad+\theta_0\partial_{z_0}ip^{-0}X^{+0}(z_0)+\partial_{z_0}X^{+0}(z_0)\cdot\Psi_{N+}^{-0}(z_0))\Phi_{N\{h\}}^F(z_0,\theta_0;P_F^\dagger):_R\\
&\quad-\sum_{\pm}\sum_{j=1}^{4}i\oint\frac{dwd\xi}{2\pi i}\,P_F^{\pm j^\dagger}(w,\xi):(\mathscr{H}_{NF}(w,\xi)X_N^{\mp j}(z_{NF},\theta_{NF}))\Phi_{N\{h\}}^F(z_0,\theta_0;P_F^\dagger):_R\\
&\quad-\sum_{j=1}^{4}\oint\frac{dwd\xi}{2\pi i}\,P_F^{-j^\dagger}(w,\xi)\oint\frac{dw'd\xi'}{2\pi i}\,P_F^{+j^\dagger}(w',\xi'):\\
&\quad\times\left((\mathscr{H}_{NF}(w,\xi)+\mathscr{H}_{NF}(w',\xi'))\log\left(z_{NF}-z'_{NF}-\left(\frac{z_{NF}-z_0}{z'_{NF}-z_0}\right)^{\epsilon_h^j}\cdot\theta_{NF}\theta'_{NF}\right)\right)\\
&\quad\times\Phi_{N\{h\}}^F(z_0,\theta_0;P_F^\dagger):_R+O(\sqrt{z'-z_0}).
\end{aligned}\tag{4.8}$$

In Eq. (4.8), $\mathscr{H}_{NF}(w,\xi)$ is the N operator which is N-ized [see Eq. (1.5)] from $\mathscr{H}_F(w,\xi)$ (4.6), so that it is given by

$$\mathscr{H}_{NF}(w,\xi)=-\frac{J_{NF}(w)+\xi K_{NF}(w)}{(\sqrt{z_{NF}(w,\xi)-z_0})^3}\,(\tfrac{1}{2}\xi D_\xi+w\partial_w)+\frac{wK_{NF}(w)}{(\sqrt{z_{NF}(w,\xi)-z_0})^3}\cdot\partial_\xi$$
$$+\xi\left(\frac{\frac{1}{2}w\partial_w J_{NF}(w)}{(\sqrt{z_{NF}(w,\xi)-z_0})^3}+\frac{3}{4}\,wK_{NF}^2(w)\,\frac{J_{NF}(w)}{(\sqrt{z_{NF}(w,\xi)-z_0})^5}\right)\partial_\xi. \tag{4.9}$$

We should notice that the right-hand side of OPE (4.7) still has the non-N operator $\vec{R}\cdot(\partial_{z_0}\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger))S_{\{h\}}(z_0)$, which can be expressed in terms of N operators as follows: First, we find from Eqs. (3.47) to (3.56) [together with Eq. (1.13)] that

$$\vec{R}\cdot(\partial_{z_0}\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger))S_{\{h\}}(z_0)=-\vec{R}$$
$$\cdot(\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger):\exp(\tfrac{1}{2}\phi^0(z_0)):)\partial_{z_0}\left(\prod_{j=1}^4:\exp(\epsilon_h^j\phi^j(z_0)):\right)$$
$$-:\Bigg(\tfrac{1}{2}\theta_0(\partial_{z_0}ip^{+0}\Psi^{-0}_{N+}(z_0))$$
$$-\frac{\frac{1}{2}\Psi^{+0}_{N+}(z_0)}{ip^{+0}}\,\partial_{\theta_0}\Bigg)\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger):_R S_{\{h\}}(z_0)$$
$$+\partial_{z_0}(\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)\cdot S_{\{h\}}(z_0)) \tag{4.10}$$

In order to express the first term [which is the only one non-N operator on the right-hand side of Eq. (4.10)] in terms of N operators, it should be noticed that we have derived Eq. (3.55) as

$$\vec{R}:(\partial_{z'}\Psi^{+hj}(z')\cdot\Psi^{-hj}(z')+\partial_{z'}\Psi^{-hj}(z')\cdot\Psi^{+hj}(z')):_R:\exp(\epsilon_h^j\phi^j(z_0)):$$
$$=:\Bigg(\partial_{z'}(\sqrt{z'-z_0}\Psi^{+hj}_{Nh}(z'))\cdot\frac{1}{\sqrt{z'-z_0}}\,\Psi^{-hj}_{Nh}(z')+\partial_{z'}\left(\frac{1}{\sqrt{z'-z_0}}\,\Psi^{-hj}_{Nh}(z')\right)$$
$$\cdot\sqrt{z'-z_0}\Psi^{+hj}_{Nh}(z')\Bigg):_R:\exp(\epsilon_h^j\phi^j(z_0)):$$
$$=\frac{1}{z'-z_0}:\Psi^{+hj}_{Nh}(z_0)\Psi^{-hj}_{Nh}(z_0):_R:\exp(\epsilon_h^j\phi^j(z_0)):+O(1), \tag{4.11}$$

which is reduced to

$$\frac{1}{z'-z_0}\,2\epsilon_h^j\cdot\partial_{z_0}\phi_{Nh}(z_0):\exp(\epsilon_h^j\phi^j(z_0)):+O(1), \tag{4.12}$$

by using Eq. (3.50). Therefore, we find

$$\vec{R}\cdot(\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger):\exp(\tfrac{1}{2}\phi^0(z_0)):)\partial_{z_0}\left(\prod_{j=1}^4:\exp(\epsilon_h^j\phi^j(z_0)):\right)$$
$$=:\Bigg(1/2\Psi^{+hj}_{Nh}(z_0)\Psi^{-hj}_{Nh}(z_0)+\tfrac{1}{2}i\oint\frac{dwd\xi}{2\pi i}\,P_F^{-hj^\dagger}(w,\xi)\,\frac{\theta_{NF}(w,\xi)}{\sqrt{z_{NF}(w,\xi)-z_0}}\cdot\Psi^{+hj}_{Nh}(z_0)$$
$$-\tfrac{1}{2}i\oint\frac{dwd\xi}{2\pi i}\,P_F^{+hj^\dagger}(w,\xi)\,\frac{\theta_{NF}(w,\xi)}{(\sqrt{z_{NF}(w,\xi)-z_0})^3}\cdot\Psi^{-hj}_{Nh}(z_0)\Bigg)\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger):_R S_{\{h\}}(z_0), \tag{4.13}$$

the right-hand side of which is given in terms of N operators. Finally, we obtain from Eqs. (4.10) and (4.13)

$$-\vec{R}\cdot(\theta_0\partial_{z_0}\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger))S_{\{h\}}(z_0)$$
$$=-\partial_{z_0}{:}(\theta_0\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)\cdot S_{\{h\}}(z_0)){:}_R+\hat{\Phi}^F_{N\{h\},2}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0), \tag{4.14}$$

with

$$\hat{\Phi}^F_{N\{h\},2}(z_0,\theta_0;P_F^\dagger)={:}\Bigg(1/2\Psi^{+hj}_{Nh}(z_0)\Psi^{-hj}_{Nh}(z_0)+\tfrac{1}{2}i$$
$$\times\oint\frac{dwd\xi}{2\pi i}P_F^{-hj^\dagger}(w,\xi)\frac{\theta_{NF}(w,\xi)}{\sqrt{z_{NF}(w,\xi)-z_0}}\cdot\Psi^{+hj}_{Nh}(z_0)-\tfrac{1}{2}i$$
$$\times\oint\frac{dwd\xi}{2\pi i}P_F^{+hj^\dagger}(w,\xi)\frac{\theta_{NF}(w,\xi)}{(\sqrt{z_{NF}(w,\xi)-z_0})^3}\cdot\Psi^{-hj}_{Nh}(z_0)\Bigg)$$
$$\times\theta_0\cdot\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger){:}_R$$
$$+{:}\left(\frac{\frac{1}{2}\Psi^{+0}_{N+}(z_0)}{ip^{+0}}\right)\theta_0\partial_{\theta_0}\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger){:}_R. \tag{4.15}$$

On the other hand, from the following OPE:

$$\vec{R}\cdot\mathscr{F}^{jF}(z'){:}\exp(\epsilon^j_h\phi^j(z_0)){:}=\frac{1}{\sqrt{z'-z_0}}\partial_{z_0}X^{+hj}(z_0)\cdot\Psi^{-hj}_{Nh}(z_0){:}\exp(\epsilon^j_h\phi^j(z_0)){:}+O(\sqrt{z'-z_0}), \tag{4.16}$$

we can derive that

$$\sum_{j=1}^4\vec{R}\cdot\mathscr{F}^{jF}(z')\cdot\Phi^F_{\{h\}}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)=\frac{1}{\sqrt{z'-z_0}}\hat{\Phi}^F_{N\{h\},3}(z_0,\theta_0;P_F^\dagger)S_{\{h\}}(z_0)+O(\sqrt{z'-z_0}), \tag{4.17}$$

with

$$\hat{\Phi}^F_{N\{h\},3}(z_0,\theta_0;P_F^\dagger)\equiv\sum_{j=1}^4{:}\Bigg(\Psi^{-hj}_{Nh}(z_0)-i\oint\frac{dwd\xi}{2\pi i}P_F^{-hj^\dagger}(w,\xi)\frac{\theta_{NF}(w,\xi)}{\sqrt{z_{NF}(w,\xi)-z_0}}\Bigg)$$
$$\times\Bigg(\partial_{z_0}X^{+hj}(z_0)$$
$$+i\oint\frac{dwd\xi}{2\pi i}P_F^{+hj^\dagger}(w,\xi)\frac{1}{z_{NF}(w,\xi)-z_0}\Bigg)$$
$$\times\Phi^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger){:}_R. \tag{4.18}$$

With the help of OPE (4.7), Eq. (4.14), and OPE (4.17), we finally find that the N operator $\hat{\Phi}^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)$ in OPE (4.1) is given by

$$\hat{\Phi}^F_{N\{h\}}(z_0,\theta_0;P_F^\dagger)(\equiv\hat{\Phi}^{F3}_{N\{h\}}(z_0;P_F^\dagger)+\theta_0\hat{\Phi}^{F4}_{N\{h\}}(z_0;P_F^\dagger))=\sum_{i=1}^3\hat{\Phi}^F_{N\{h\},i}(z_0,\theta_0;P_F^\dagger). \tag{4.19}$$

with $\hat{\Phi}^F_{N\{h\},i}(z_0,\theta_0;P_F^\dagger)$ (4.8) [for $i=1$], (4.15) [for $i=2$], and (4.18) [for $i=3$]. In the mass shell limit [when the first term on the right-hand side of OPE (4.1) vanishes], we find

$$\lim_{z'\to z_0}\sqrt{z'-z_0}\mathscr{T}(z')\Phi^{F1}_{N\{h\}}(z_0;P^\dagger_F)S_{\{h\}}(z_0)=\partial_{z_0}(\Phi^{F0}_{N\{h\}}(z_0;P^\dagger_F)S_{\{h\}}(z_0))-\hat{\Phi}^{F4}_{N\{h\}}(z_0;P^\dagger_F)S_{\{h\}}(z_0), \tag{4.20}$$

which can be used in picture-changing Ramond states in 1/2 picture into those in 3/2 picture.

V. CONCLUSIONS AND DISCUSSIONS

In Ref. 1, we have proposed GFPVO $\Phi^B(z_0,\theta_0;P^\dagger_B)$ (1.30) in the NS sector of superstring, which can be easily obtained by simply supergeneralizing GFPVO in bosonic string theory [i.e., Eq. (2.6) in Ref. 4]. It is easily *imagined* that GFPVO $\Phi^B(z_0,\theta_0;P^\dagger_B)$ might satisfy our proposed OPE (5.26) in Ref. 1], since it is the one obtained by supergeneralizing OPE (3.10) in Ref. 4. On the other hand, we have proposed[1] GFPVO $\Phi^F_{N\{h\}}(z_0,\theta_0;P^\dagger_F)S_{\{h\}}(z_0)$ (1.12) in the R sector, which is quite unfamiliar and typical of superstring theory. The fact that our $\Phi^F_{N\{h\}}(z_0,\theta_0;P^\dagger_F)S_{\{h\}}(z_0)$ [given by Eqs. (1.12) and (1.4)] actually satisfy our proposed OPEs (4.18)–(4.20) in Ref. 1 might not be easily imagined. Therefore, in this paper, we have explained in detail how to derive OPEs (3.58) and (4.1), giving so many new materials necessary in proving these OPEs. The proof is straightforward but extremely tedious; In Sec. II, the contractions (in the R sector) of $\theta_F(w,\xi)$ (1.16) and $z_F(w,\xi)$ (1.17) with respect to $\lambda\cdot ip^{+0}Y^{-0}_+(z',\theta';z_0)$ are denoted by $\delta\theta_F(w,\xi)$ (2.2) and $\delta z_F(w,\xi)$ (2.1), respectively. These quantities are calculated with the help of the modified superconformal mapping in the R sector given by Eqs. (2.9) and (2.10); Since (w,ξ) is just c number, there is not any contraction with $\lambda\cdot ip^{+0}Y^{-0}_+(z',\theta';z_0)$, so that we have Eq. (2.16), which leads to explicit formulas (2.22) and (2.23). Furthermore, we can derive z_0 and θ_0 dependence of θ_F (1.16) and z_F (1.17). Since (w,ξ) is independent of z_0 and θ_0, we have Eq. (2.27), which leads to explicit formulas (2.32)–(2.35). With the help of various formulas already obtained in Sec. II, we investigate in Sec. III the OPE among GFPVO in the R sector and the superstressino operator. For this purpose, it is not helpful to use double-valued $\mathscr{T}^{jF}(z',\theta')$ (3.1). On the other hand, $\tau^j(z',\theta';z_0)$ defined by Eq. (3.2) is single valued. Therefore, we investigate OPE among GFPVO and $\tau(z',\theta';z_0)$ (3.15), thus obtaining OPE (3.16) by straightforward calculations. Denoting singular terms of F (in the neighborhood of $z'=z_F,z'_F$) by $(F)_{\text{sing.}}$, we find $(H^{\mp j}_h)_{\text{sing.}}$ (3.20) and $(H^{jjF}_h)_{\text{sing.}}$ (3.21). It is essential that $(H^{F1/2(1)}_h)_{\text{sing.}}$ (3.22) is shown to be zero, by proving Eqs. (E20) and (E21). Thus, we have only to investigate singularities at $z'=z_0$ on the right-hand side of OPE (3.16). Then, with the help of identities (3.23) [(3.24)], OPE (3.25) leads to OPE (3.46) [(3.59)] among GFPVO and $T^{0F}(\mathscr{T}^{0F})$. Finally, summing OPE (3.46) [(3.59)] and OPE (3.55) [(3.60)] gives OPE (3.58) [(3.62) and (3.63)] among GFPVO in the R sector and $T_{NF}(\mathscr{T}_{NF})$. However, the term proportional to $(z'-z_0)^{-1/2}$ in OPEs (3.60)–(3.63) are not obtained explicitly. On the other hand, in Sec. IV, the next leading term $\hat{\Phi}^F_{N\{h\}}(z_0,\theta_0;P^\dagger_F)$ in OPE (4.1) is found out to be given by Eq. (4.19). This term is related with the picture changing, as seen from Eq. (4.20). In Appendices A–E, we derive various formulas needed in proving OPEs among GFPVO $\Phi^F_{N\{h\}}(z_0,\theta_0;P^\dagger_F)\cdot S_{\{h\}}(z_0)$ and the stress operators; In Appendix A, operators G^F_+ and $G^{\mp jF}$ in OPE (3.11) are explicitly derived. In Appendix B, operators $g^{\mp jF}_h$ and g^{jjF}_h in OPE (3.13) are explicitly derived. In Appendix C, operators G^{jjF}_h in OPE (3.14) are explicitly derived. In Appendix D, singularities at $z'=z_F,z'_F$ in $g^{\mp jF}_h$ and g^{jjF}_h in OPE (3.13) are analyzed, and results are given by Eqs. (D4)–(D10) and (D12)–(D15), respectively. In Appendix E, both $H^{F1/2}_h$ and H^{F1}_h in Eqs. (3.20) and (3.21) are shown to be free of singularities at $z'=z_F,z'_F$, by proving Eqs. (E20) and (E21).

In the following, we investigate the operator product expansion (OPE) among GFPVO $\Phi^B(z_0,\theta_0;P^\dagger_B)$ (1.30) and the superstressino operator $\mathscr{T}_B(z',\theta')$ in the NS sector, which is defined by

$$\mathscr{T}_B(z',\theta')\equiv\sum_{\pm}\sum_{j=0}^{4}:\tfrac{1}{2}\partial_{z'}X^{\pm j}(z',\theta')D_{\theta'}X^{\mp j}(z',\theta'):_{\text{NS}} \tag{5.1}$$

$$(\equiv\tfrac{1}{2}\mathscr{T}_B(z')+\theta' T_B(z')). \tag{5.1'}$$

[Hereafter, we shall use the notation $\mathscr{T}_B(z',\theta')$ instead of the notation $T_B(z',\theta')$ in Ref. 1.] In Eq. (5.1), $:\ :_{\mathrm{NS}}$ is the normal ordering in the NS sector[1] and the supervector field is given by

$$X^{\pm j}(z',\theta')\equiv X^{\pm j}(z')+\theta'\Psi^{\pm j}(z'). \tag{5.2}$$

Then, in a much simpler way than the one described (in detail) in Sec. III, we can derive the following OPE, by using the techniques given in Sec. III:

$$\begin{aligned}\vec{R}\cdot\mathscr{T}_B(z',\theta')\Phi^B(z_0,\theta_0;P_B^\dagger)=&\frac{\theta'-\theta_0}{(z'-z_0-\theta'\theta_0)^2}\left(-\left(\sum_{j=0}^{4}p^{+j}p^{-j}\right)\Phi^B(z_0,\theta_0;P_B^\dagger)\right.\\&\left.+[N_B,\Phi^B(z_0,\theta_0;P_B^\dagger)]\right)+\frac{1/2}{z'-z_0-\theta'\theta_0}D_{\theta_0}\Phi^B(z_0,\theta_0;P_B^\dagger)\\&+\frac{\theta'-\theta_0}{z'-z_0-\theta'\theta_0}\partial_{z_0}\Phi^B(z_0,\theta_0;P_B^\dagger)+(\text{terms regular at } z'=z_0),\end{aligned} \tag{5.3}$$

where we have used the light-cone number operator N_B defined by

$$N_B\equiv\sum_{n=1}^{\infty}\sum_{\pm}\sum_{k=1}^{4}(\alpha_{-n}^{\mp k}\alpha_n^{\pm k}+(n-1/2)b_{-n+1/2}^{\mp k}b_{n-1/2}^{\pm k}). \tag{5.4}$$

With the help of Eqs. (1.30′) and (5.1′), OPE (5.3) can be rewritten as

$$\begin{aligned}\vec{R}\cdot T_B(z')\Phi^{Bm}(z_0;P_B^\dagger)=&\frac{1}{(z'-z_0)^2}\left(\left(\tfrac{1}{2}\delta_{m1}-\sum_{j=0}^{4}p^{+j}p^{-j}\right)\Phi^{Bm}(z_0;P_B^\dagger)+[N_B,\Phi^{Bm}(z_0;P_B^\dagger)]\right)\\&+\frac{1}{z'-z_0}\partial_{z_0}\Phi^{Bm}(z_0;P_B^\dagger)+(\text{terms regular at } z'=z_0),\\&[\text{for } m=0,1],\end{aligned} \tag{5.5}$$

$$\vec{R}\cdot\mathscr{T}_B(z')\Phi^{B0}(z_0;P_B^\dagger)=\frac{1}{z'-z_0}\Phi^{B1}(z_0;P_B^\dagger)+(\text{terms regular at } z'=z_0) \tag{5.6}$$

and

$$\begin{aligned}\vec{R}\cdot\mathscr{T}_B(z')\Phi^{B1}(z_0;P_B^\dagger)=&\frac{2}{(z'-z_0)^2}\left(\left(-\sum_{j=0}^{4}p^{+j}p^{-j}\right)\Phi^{B0}(z_0;P_B^\dagger)+[N_B,\Phi^{B0}(z_0;P_B^\dagger)]\right)\\&+\frac{1}{z'-z_0}\partial_{z_0}\Phi^{B0}(z_0;P_B^\dagger)+(\text{terms regular at } z'=z_0).\end{aligned} \tag{5.7}$$

Finally, we discuss how our results can be used in quantum superstring field theory. $\Phi^{Fm}_{N\{h\}}(z_0;P_F^\dagger)$ [for $m=0,1$] given by Eqs. (1.2′) can be expanded as sums of following terms:

$$\sum\ \text{const.}\,\alpha\cdots\alpha d\cdots d\times V^m_{\alpha\cdots\alpha d\cdots d}(z_0)\quad(\text{for } m=0,1). \tag{5.8}$$

Hereafter, the physical vertex operator $V^m_{\alpha\cdots\alpha d\cdots d}(z_0)$ will be simply denoted by $V^{m\not{}}(z_0)$, $\not{}$ representing quantum numbers. [How to fix ''const.'' in Eq. (5.8) and how to select out GSO-allowed[6] physical vertex operators will be discussed in our succeeding paper.[7]] Then, we can construct the state given by $V^{0\not{}}(0)S_{\{h\}}(0)|0\rangle$, which constitutes the complete system, in the following on-shell limit of the state $|\not{}\rangle$:

$$-\sum_{j=0}^{4}p^{+j}p^{-j}+N_{\not{}}\to 0\quad(\text{i.e., } L_0^F\to 0), \tag{5.9}$$

$N_{\not}$ being the eigenvalue [of the light-cone number operator N_F (3.41)] determined by

$$[N_F, \alpha\cdots\alpha d\cdots d] = N_{\not}\alpha\cdots\alpha d\cdots d. \tag{5.10}$$

Unfortunately, this state does not satisfy the Dirac equation, since we find from OPE (3.62) that

$$\mathscr{F}^F_{N0}(V^{0\not}(0)S_{\{h\}}(0)|0\rangle) = V^{1\not}(0)S_{\{h\}}(0)|0\rangle \neq 0, \tag{5.11}$$

even in the on-shell limit, $\mathscr{F}^F_{N0}$ being the Dirac operator. Using the technique used in calculating the norm given by Eq. (3.29) of Ref. 8, we can find the following state constructed by

$$V^{1\not}(0)S_{\{h\}}(0)|0\rangle \tag{5.12}$$

has the nonvanishing norm, where we have used $V^{1\not}$ given by Eq. (5.8).

Similarly, $\Phi^{Bm}(z_0; P_B^\dagger)$ [for $m=0,1$] given by Eq. (1.30′) can be expressed as sums of following terms:

$$\sum \text{ const.}\, \alpha\cdots\alpha b\cdots b \times V^m_{\alpha\cdots\alpha b\cdots b}(z_0) \quad (\text{for } m=0,1). \tag{5.13}$$

Hereafter, the physical vertex operator $V^m_{\alpha\cdots\alpha b\cdots b}(z_0)$ will be simply denoted by $V^{m\not\ell}(z_0)$, $\not\ell$ representing quantum numbers. Then, the *physical* Neveu–Schwarz state $|\not\ell\rangle$ is given by $V^{0\not\ell}(0)|0\rangle$, which constitutes the orthonormal complete system, in the following on-shell limit of the state $|\not\ell\rangle$:

$$-\sum_{j=0}^{4} p^{+j}p^{-j} + N_{\not\ell} \longrightarrow 1/2 \quad (\text{i.e., } L_0^B \to 1/2). \tag{5.14}$$

$N_{\not\ell}$ being the eigenvalue $N_{\not\ell}$ [for the light-cone number operator N_B (4.4)] determined by

$$[N_B, \alpha\cdots\alpha b\cdots b] = N_{\not\ell}\alpha\cdots\alpha b\cdots b. \tag{5.15}$$

[How to fix ''const.'' in Eq. (5.13) and how to select out GSO-allowed[6] physical vertex operator will be discussed in our succeeding paper.[7]] On the other hand, we find from OPEs (5.6) and (5.7) that

$$\mathscr{F}^B_{-1/2}\cdot V^{0\not\ell}(0)|0\rangle = V^{1\not\ell}(0)|0\rangle \tag{5.16}$$

and

$$\mathscr{F}^B_{1/2}\cdot V^{1\not\ell}(0)|0\rangle = V^{0\not\ell}(0)|0\rangle, \tag{5.17}$$

with

$$\{\mathscr{F}^B_{1/2}, \mathscr{F}^B_{-1/2}\} = 2L_0^B. \tag{5.18}$$

In RNS superstring theory, Friedan, Martinec, and Schenker[5] have originally succeeded in constructing physical vertex operators for massless fermions and bosons, with the help of conformal field theoretical techniques.[9] For this purpose, they had to introduce various ghost fields (which we did not discuss in this paper). They have also given the picture changing operator X. FMS have shown that the operator X plays important roles in obtaining physical scattering amplitudes in RNS superstring theory. Based on their ideas, quantum superstring field theory has been proposed by Witten,[10] where there exist interactions among BRST invariant R states (in 1/2 picture) given by

$$\exp(+\sigma(0))\exp(-\tfrac{1}{2}\phi(0))\cdot(V^{1\not}(0)S_{\{h\}}(0)|0\rangle), \tag{5.19}$$

and BRST invariant NS states (in 0 picture) given by

$$\exp(+\sigma(0))\exp(-\phi(0))\cdot V^{0\not{\prime}}(0)|0\rangle. \tag{5.20}$$

However, Wendt[11] has pointed out that Witten's quantum superstring field theory is plagued with divergences induced by colliding of two *local* picture changing operators. To overcome this difficulty, Preitshopf, Thorn, and Jost[12] have investigated quantum superstring field theory using BRST invariant NS states in one picture, which are created by

$$(\exp(+\sigma(0))\cdot V^{1\not{\prime}}(0)-\tfrac{1}{2}\gamma(0)\cdot V^{0\not{\prime}}(0))|0\rangle, \tag{5.21}$$

γ being the ghost operator of conformal weight $-1/2$, introduced and discussed by FMS.[5] We should notice that there exist physical vertex operators $V^{1\not{\prime}}$ and $V^{1\not{\prime}}$ in Eqs. (5.8) and (5.13), which are generated by $\Phi^{F1}(z_0;P_F^\dagger)$ and $\Phi^{B1}(z_0;P_B^\dagger)$, respectively.

In Ref. 13, we have introduced various techniques in quantum bosonic string field theory, which make it possible to calculate physical scattering amplitudes, by using the generating functional for physical vertex operators (GFPVO). Physical scattering amplitudes among N excited particles can be obtained by Eq. (7.3) [with Eqs. (7.4)–(7.7) and (7.28) in Ref. 13.] It should be noticed that Eq. (7.3) can be calculated by using c number conformal mapping (7.30) (in Ref. 13), which is obtained from q number conformal mapping (7.10). In Eq. (7.30), we have the effective c number field (7.31), which is induced by the presence of external particles at various punctures. (See Ref. 13, for more details.) Thus, GFPVO [given by Eq. (7.8) in Ref. 13] in bosonic string theory has played important roles in calculating physical particles. Therefore, we can imagine that similar situations occur also in superstring theory. However, we have two types of formalisms in superstring theory. Historically, Ramond[2]–Neveu–Schwarz[3] superstring was at first formulated and then Green–Schwarz[7,14] superstring was formulated. In this paper, we only investigated RNS superstring, where we have only string coordinate $X^{\pm j}$ and string coordino $\Psi^{\pm j}$, both of which are vectors in ten-dimensional space-time. Therefore, it is extremely important in RNS superstring to know how we can construct (all) fermionic Ramond states (described by spinor fields). We have shown in this paper that physical R states can be constructed by Eq. (5.12). {Incidentally, physical NS states in 0 (1) picture can be constructed by Eq. (5.20) [(5.21)]}. On the other hand, Green and Schwarz[8] have analyzed physical fermionic and bosonic states in GS superstring, by using the spectrum generating algebras (SGA) for each fermionic sector and bosonic sector. We shall see in our succeeding papers[7] that our physical states states (5.12), (5.20), and (5.21) can be actually generated by physical string coordinate modes and physical string coordino modes which satisfy SGA. Thus, our approach gives new insight into the relation between RNS superstring and GS superstring. [Incidentally, this relation has been discussed by Berkovits.[15]]

APPENDIX A: NON-N OPERATORS G_+^F AND $G^{\mp jF}$ IN EQ. (3.11)

In this Appendix, explicit expressions for non-N operators $G_+^F(\ )_\iota$ and $G^{\mp jF}(\ )_\iota$ in OPE (3.11′) are given. Applying contractions in the R sector (3.9) to ρ_{N+}^{0F} (1.3), we find that the non-N operator $G_+^F(\ )_\iota$ (for $\iota=1-3$) in OPE (3.11′) is obtained as follows:

$$\begin{aligned}
G_+^F(z_0,\theta_0|z',\theta')_1=&\frac{\theta'-\theta_0}{(z'-z_0-\theta'\theta_0)^2}\,(-p^{+0}p^{-0})+\frac{1/2}{z'-z_0-\theta'\theta_0}\,D_{\theta'}\\
&\times\left(\sum_{\pm}\,-ip^{\pm 0}Y_+^{\mp 0}(z',\theta';z_0)\right)+\frac{\frac{1}{2}(\theta'-\theta_0)}{z'-z_0-\theta'\theta_0}\,\partial_{z'}\\
&\times\left(\sum_{\pm}\,-ip^{\pm 0}Y_+^{\mp 0}(z',\theta';z_0)\right)+p^{+0}p^{-0}\left(-\frac{\frac{1}{2}\theta'\theta_0}{(z'-z_0)^2}\cdot\frac{\Psi_+^{+0}(z';z_0)}{ip^{+0}}\right.\\
&\left.-\frac{\frac{1}{2}\theta_0}{(z'-z_0)^2}+\frac{\frac{1}{2}\theta_0}{z'-z_0}\,\partial_{z'}\,\frac{Y_+^{+0}(z',\theta';z_0)}{ip^{+0}}\right),
\end{aligned}\tag{A1}$$

$$G_+^F(z_0,\theta_0|z',\theta')_2=\frac{\frac{1}{2}\theta'\theta_0}{(z'-z_0)^2}\,ip^{+0}\Psi_+^{-0}(z';z_0), \tag{A2}$$

and

$$G_+^F(z_0,\theta_0|z',\theta')_3=p^{+0}p^{-0}\frac{\theta_0}{(z'-z_0)^2}\left(\sum_{\pm}\frac{1}{4}((z'-z_0)^{\pm 1}-1)\right)$$
$$-\frac{\theta_0}{z'-z_0}\left(\sum_{\pm}\frac{1}{4}((z'-z_0)^{\pm 1}-1)\partial_{z'}(-ip^{\pm 0}X^{\mp 0}(z'))\right)$$
$$+\frac{1}{z'-z_0}\left(\sum_{\pm}\frac{1}{4}((z'-z_0)^{\mp 1}-1)(-ip^{\pm 0}\Psi_+^{\mp 0}(z';z_0))\right)$$
$$+\frac{p^{+0}p^{-0}}{4}\left(\frac{1}{z'-z_0}-1\right)\left(-\frac{\theta_0}{(z'-z_0)^2}+\frac{\theta_0}{z'-z_0}\,\partial_{z'}\,\frac{X^{+0}(z')}{ip^{+0}}\right). \quad \text{(A3)}$$

Furthermore, non-N operator $G^{\mp jF}(\ )_\iota$ [for $\iota=1-3$] in Eq. (3.11′) is found by applying contraction in the R sector (3.8) to ρ^{1F} (1.14);

$$G^{\mp jF}(w,\xi|z',\theta')_1=\tfrac{1}{2}(D_{\theta'}f_+^F(z',\theta'|z_0,\theta_0)\partial_{z'}+\partial_{z'}f_+^F(z',\theta'|z_0,\theta_0)D_{\theta'})\frac{1}{\lambda}((\delta z_F-\delta\theta_F\cdot\theta_F)\partial_{z_F}$$
$$+\delta\theta_F D_{\theta_F})X^{\mp j}(z_F,\theta_F), \quad \text{(A4)}$$

$$G^{\mp jF}(w,\xi|z',\theta')_2=\frac{\frac{1}{2}\theta'}{z'-z_0}(D_{\theta'}f_+^F(z',\theta'|z_0,\theta_0))_{\theta'=0}\frac{1}{\lambda}((D_{\theta'}(\delta z_F-\delta\theta_F\cdot\theta_F))_{\theta'=0}\partial_{z_F}$$
$$+(D_{\theta'}\delta\theta_F)_{\theta'=0}D_{\theta_F})X^{\mp j}(z_F,\theta_F) \quad \text{(A5)}$$

and

$$G^{\mp jF}(w,\xi|z',\theta')_3=\frac{1}{4}(z'-z_0-1)(D_{\theta'}f_+^F(z',\theta'|z_0,\theta_0))_{\theta'=0}\frac{1}{\lambda}((\partial_{z'}(\delta z_F-\delta\theta_F\cdot\theta_F))_{\theta'=0}\partial_{z_F}$$
$$+(\partial_{z'}\delta\theta_F)_{\theta'=0}D_{\theta_F})X^{\mp j}(z_F,\theta_F)+\frac{1}{4}\left(\frac{1}{z'-z_0}-1\right)$$
$$\times(\partial_{z'}f_+^F(z',\theta'|z_0,\theta_0))_{\theta'=0}\frac{1}{\lambda}((D_{\theta'}(\delta z_F-\delta\theta_F\cdot\theta_F))_{\theta'=0}\partial_{z_F}$$
$$+(D_{\theta'}\delta\theta_F)_{\theta'=0}D_{\theta_F})X^{\mp j}(z_F,\theta_F). \quad \text{(A6)}$$

The second term on the right-hand side of the following non-N operator:

$$f_+^F(z',\theta'|z_0,\theta_0)\equiv\frac{Y_+^{+0}(z',\theta';z_0)}{ip^{+0}}-\log(z'-z_0-\theta'\theta_0) \quad \text{(A7)}$$

[existing in Eqs. (A4)–(A6),) has arisen from the contraction (3.9) in the R sector. [Incidentally, Eq. (A7) is N-ized into

$$f_{N+}^F(z',\theta'|z_0,\theta_0)\equiv\frac{Y_{N+}^{+0}(z',\theta')}{ip^{+0}}-\log(z'-z_0-\theta'\theta_0), \quad \text{(A7′)}$$

which will be useful in analyzing singularities at $z'=z_0$.]

Substituting Eqs. (2.22) and (2.23) into Eqs. (A4)–(A6), we shall find the following explicit formulas for non-N operator functions $G^{F1/2}(\ )_\iota$'s and $G^{F1}(\ )_\iota$'s in Eq. (3.12′). As for $G^{F1/2}(\ )_\iota$'s (for $\iota=1-3$) in Eq. (3.12′), we have

$$G^{F1/2}(w,\xi|z',\theta')_1=\tfrac{1}{2}D_{\theta'}f_+^F(z',\theta'|z_0,\theta_0)\Bigg(w(D_\xi\theta_F)^2\Bigg(\frac{1}{z'-z_F-\sqrt{z_F-z_0}\,\theta'\theta_F}-\frac{1}{z'-z_0}\Bigg)$$
$$+\xi wK_F^3(w)\,\frac{\theta_F-\sqrt{z_F-z_0}\,\theta'}{(z_F-z')^2}\Bigg)+\tfrac{1}{2}\partial_{z'}f_+^F(z',\theta'|z_0,\theta_0)$$
$$\times\Bigg(w(D_\xi\theta_F)^2\Bigg(\frac{\theta'-\sqrt{z_F-z_0}\,\theta_F}{z'-z_F}-\frac{\theta'}{z'-z_0}\Bigg)$$
$$+\xi wK_F^3(w)\Bigg(\frac{\theta_F\theta'}{(z_F-z')^2}+\frac{\sqrt{z_F-z_0}}{z_F-z'}\Bigg)\Bigg),\tag{A8}$$

$$G^{F1/2}(w,\xi|z',\theta')_2=\frac{\frac{1}{2}\theta'}{z'-z_0}\,(D_{\theta'}f_+^F(z',\theta'|z_0,\theta_0))_{\theta'=0}\Bigg(-w(D_\xi\theta_F)^2\cdot\,\frac{\sqrt{z_F-z_0}\,\theta_F}{z'-z_F}$$
$$-\xi wK_F^3(w)\,\frac{\sqrt{z_F-z_0}}{z'-z_F}\Bigg)\tag{A9}$$

and

$$G^{F\,1/2}(w,\xi|z',\theta')_3=\frac{1}{4}\,(z'-z_0-1)(D_{\theta'}f_+^F(z',\theta'|z_0,\theta_0))_{\theta'=0}\Bigg(w(D_\xi\theta_F)^2\Bigg(\frac{1}{z'-z_F}-\frac{1}{z'-z_0}\Bigg)$$
$$+\xi wK_F^3(w)\,\frac{\theta_F}{(z_F-z')^2}\Bigg)+\frac{1}{4}\,\Bigg(\frac{1}{z'-z_0}-1\Bigg)(\partial_{z'}f_+^F(z',\theta'|z_0,\theta_0))_{\theta'=0}$$
$$\times\Bigg(-w(D_\xi\theta_F)^2\cdot\,\frac{\sqrt{z_F-z_0}}{z'-z_F}\,\theta_F-\xi wK_F^3(w)\,\frac{\sqrt{z_F-z_0}}{z'-z_F}\Bigg).\tag{A10}$$

Furthermore, as for $G^{F1}(\ )_\iota$ (for $\iota=1-3$) in Eq. (3.12′), we have

$$G^{F1}(w,\xi|z',\theta')_1=\ \tfrac{1}{2}D_{\theta'}f_+^F(z',\theta'|z_0,\theta_0)$$
$$\times\Bigg(\begin{array}{l}\Bigg(\dfrac{1}{2}\,\xi D_\xi\theta_F+w\partial_w\theta_F\Bigg)\Bigg(\dfrac{1}{z'-z_F-\sqrt{z_F-z_0}\,\theta'\theta_F}-\dfrac{1}{z'-z_0}\Bigg)\\ +\Bigg(wK_F^2(w)+\dfrac{1}{2}\,\xi wK_F(w)\partial_wJ_F(w)\Bigg)\,\dfrac{\theta_F-\sqrt{z_F-z_0}\,\theta'}{(z_F-z')^2}\\ +\dfrac{1}{2}\,\xi wK_F^3(w)\Bigg(\begin{array}{c}\dfrac{2\sqrt{z_F-z_0}\,\theta'\theta_F}{(z_F-z')^3}\\ -\dfrac{1}{(z_F-z')^2}-\dfrac{\frac{1}{2}\theta'\theta_F}{(z_F-z')^2\sqrt{z_F-z_0}}\end{array}\Bigg)\end{array}\Bigg)$$
$$+\frac{1}{2}\,\partial_{z'}f_+^F(z',\theta'|z_0,\theta_0)$$
$$\times\Bigg(\begin{array}{c}\Bigg(\dfrac{1}{2}\,\xi D_\xi\theta_F+w\partial_w\theta_F\Bigg)\Bigg(-\dfrac{\theta'-\sqrt{z_F-z_0}\,\theta_F}{z'-z_F}+\dfrac{\theta'}{z'-z_0}\Bigg)\\ +\Bigg(wK_F^2(w)+\dfrac{1}{2}\,\xi wK_F(w)\partial_wJ_F(w)\Bigg)\Bigg(\dfrac{\theta'\theta_F}{(z'-z_F)^2}+\dfrac{\sqrt{z_F-z_0}}{z'-z_F}\Bigg)\\ +\dfrac{1}{2}\,\xi wK_F^3(w)\Bigg(\dfrac{\frac{1}{2}\theta_F}{(z_F-z')\sqrt{z_F-z_0}}+\dfrac{\theta'-\sqrt{z_F-z_0}\,\theta_F}{(z'-z_F)^2}\Bigg)\end{array}\Bigg),\tag{A11}$$

$$G^{F1}(w,\xi|z',\theta')_2=\frac{\frac{1}{2}\theta'}{z'-z_0}\,(D_{\theta'}f_+^F(z',\theta'|z_0,\theta_0))$$
$$\times\begin{pmatrix}\left(\frac{1}{2}\,\xi D_\xi\theta_F+w\partial_w\theta_F\right)\frac{\sqrt{z_F-z_0}\theta_F}{z'-z_F}\\ +\left(wK_F^2(w)+\frac{1}{2}\,\xi wK_F(w)\partial_w J_F(w)\right)\frac{\sqrt{z_F-z_0}}{z'-z_F}\\ +\frac{1}{2}\,\xi wK_F^3(w)\left(\frac{\frac{1}{2}\theta_F}{(z_F-z')\sqrt{z_F-z_0}}-\frac{\sqrt{z_F-z_0}\theta_F}{(z_F-z')^2}\right)\end{pmatrix},\tag{A12}$$

and
