Proposition 6.2: There exist no nontrivial finite-dimensional subspaces of $L^2(\mathbf{R}^2)$ *left invariant by* $\mathscr{R}_{\mathbf{v},\mathbf{w},\mathbf{A}}$.

Proof: This follows from Proposition 2.6. ■

Proposition 6.3: Let $\mathbf{A}\in\mathscr{A}_{\mathbf{v},\mathbf{w}}(\mathbf{D})$ and $\mathbf{A}'\in\mathscr{A}_{\mathbf{v}',\mathbf{w}'}(\mathbf{D})$. *Suppose that* $C^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}-C^{\mathbf{A}'}_{\mathbf{v}',\mathbf{w}'}\notin 2\pi\mathbf{Z}/\alpha$. *Then* $\mathscr{R}_{\mathbf{v},\mathbf{w},\mathbf{A}}$ *and* $\mathscr{R}_{\mathbf{v}',\mathbf{w}',\mathbf{A}'}$ *are unitarily inequivalent.*

Proof: Suppose that there exists a unitary operator U on $L^2(\mathbf{R}^2)$ such that $UT^{\mathbf{A}}_{\mathbf{v}}U^{-1}=T^{\mathbf{A}'}_{\mathbf{v}'}$, $UT^{\mathbf{A}}_{\mathbf{w}}U^{-1}=T^{\mathbf{A}'}_{\mathbf{w}'}$. By (6.4) and the fact that $C^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}$ and $C^{\mathbf{A}'}_{\mathbf{v}',\mathbf{w}'}$ are constants, we have $\exp(-i\alpha C^{\mathbf{A}}_{\mathbf{v},\mathbf{w}})=\exp(-i\alpha C^{\mathbf{A}'}_{\mathbf{v}',\mathbf{w}'})$, which is equivalent to that $C^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}-C^{\mathbf{A}'}_{\mathbf{v},\mathbf{w}'}\in 2\pi\mathbf{Z}/\alpha$. Thus, the desired assertion follows. ■

Example 6.3: Let $\mathbf{A}$ be the vector potential given in Example 6.2. Then, by (6.3), we have

$$T^{\mathbf{A}}_{\boldsymbol{\omega}_1}T^{\mathbf{A}}_{\boldsymbol{\omega}_2}=e^{-2\pi i\alpha\Re c}T^{\mathbf{A}}_{\boldsymbol{\omega}_2}T^{\mathbf{A}}_{\boldsymbol{\omega}_1}. \tag{6.5}$$

Hence we have a one-parameter family $\mathscr{R}_c:=\mathscr{R}_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2,\mathbf{A}}$ of representations [on $L^2(\mathbf{R}^2)$] of rotation algebras (quantum planes). It follows from Proposition 6.3 that, if $\Re(c-c')\notin\mathbf{Z}/\alpha$, then the two representations $\mathscr{R}_c$ and $\mathscr{R}_{c'}$ are unitarily inequivalent to each other. Thus, associated with singular magnetic fields concentrated on $\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$, there exist infinitely many representations on $L^2(\mathbf{R}^2)$ of rotation algebras inequivalent to each other. ■

Remark 6.1: The same consideration as above applies to the algebra $\mathscr{R}^*_{\mathbf{v},\mathbf{w},\mathbf{A}}$ generated by $(T^{\mathbf{A}}_{\mathbf{v}})^*$ and $(T^{\mathbf{A}}_{\mathbf{w}})^*$, which is a representation of a rotation algebra. We can also consider the algebra generated by $T^{\mathbf{A}}_{\mathbf{v}}$, $T^{\mathbf{A}}_{\mathbf{w}}$, $(T^{\mathbf{A}}_{\mathbf{v}})^*$ and $(T^{\mathbf{A}}_{\mathbf{w}})^*$, which is a $*$-subalgebra of $\mathbf{B}(L^2(\mathbf{R}^2))$.

As is shown in Ref. 5, for any representation of a quantum plane where the generators are represented as bijections, one can construct a representation of the quantum group $U_q(sl_2)$. We can apply this method to the present case to construct, from $\mathscr{R}_{\mathbf{v},\mathbf{w},\mathbf{A}}$, representations of $U_q(sl_2)$ on $L^2(\mathbf{R}^2)$ with $q=e^{-i\alpha C^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}}$ or $q=e^{-i\alpha C^{\mathbf{A}}_{\mathbf{v},\mathbf{w}}/2}$ and analyze them in quite the same way as in Ref. 5. Here we only mention a basic feature of those representations: they have no weight vectors and hence no nontrivial finite-dimensional reductions (cf. Proposition 6.2). Note that this makes a big difference from the case of representations of $U_q(sl_2)$ constructed in terms of discrete magnetic translations on a lattice (Ref. 12), where finite-dimensional representations of $U_q(sl_2)$ appear (cf. also Ref. 13).

VII. REDUCTION TO LATTICE QUANTUM SYSTEMS

In this section we focus our attention on the case $\mathbf{D}=\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$ and consider the problem of reduction of the continuous magnetic translations,

$$T_j:=T^{\mathbf{A}}_{\boldsymbol{\omega}_j},\quad j=1,2, \tag{7.1}$$

to the closed subspace $L^2_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{R}^2)$, which is given by (1.19) and naturally identified with the Hilbert space $l^2(\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2))$.

A. General aspects

We denote by $\mathbf{S}^{(1)}_n$ (resp., $\mathbf{S}^{(2)}_m$) the open set between the straight lines $\{n\boldsymbol{\omega}_2+s\boldsymbol{\omega}_1|s\in\mathbf{R}\}$ (resp., $\{m\boldsymbol{\omega}_1+s\boldsymbol{\omega}_2|s\in\mathbf{R}\}$) and $\{(n+1)\boldsymbol{\omega}_2+s\boldsymbol{\omega}_1|s\in\mathbf{R}\}$ (resp., $\{(m+1)\boldsymbol{\omega}_1+s\boldsymbol{\omega}_2|s\in\mathbf{R}\}$).

Let

$$\phi^{\mathbf{A}}_j(\mathbf{r}):=\int_{\mathbf{r}}^{\mathbf{r}+\boldsymbol{\omega}_j}\mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}',\quad j=1,2. \tag{7.2}$$

Definition 7.1: We say that $\mathbf{A}$ is in the class $\mathscr{C}_j$ $(j=1,2)$ if, for each $n\in\mathbf{Z}$, $\phi_j^{\mathbf{A}}$ is constant on $\mathbf{S}_n^{(j)}$, i.e., there exists a constant $c_j(n)\in\mathbf{R}$, such that

$$\phi_j^{\mathbf{A}}(\mathbf{r})=c_j(n),\quad \mathbf{r}\in\mathbf{S}_n^{(j)},\quad n\in\mathbf{Z}. \tag{7.3}$$

Remark 7.1: It is easy to see that, if $\mathbf{A}\in\mathscr{C}_j$, then the function: $\mathbf{r}\to\mathbf{A}(\mathbf{r})\cdot\boldsymbol{\omega}_j$ is periodic on $\cup_{n\in\mathbf{Z}}\mathbf{S}_n^{(j)}$ with period $\boldsymbol{\omega}_j$. But the converse is not true.

Proposition 7.2: For each $j=1,2$, T_j and T_j^{-1} leave $L^2_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{R}^2)$ invariant if and only if $\mathbf{A}\in\mathscr{C}_j$.

Proof: By Theorem 3.2, we have, for all $\Psi\in L^2(\mathbf{R}^2)$,

$$(T_j\Psi)(\mathbf{r})=e^{-i\alpha\phi_j^{\mathbf{A}}(\mathbf{r})}(e^{i\overline{p\boldsymbol{\omega}_j}}\Psi)(\mathbf{r}),\quad \text{a.e.}\quad \mathbf{r}\in\mathbf{S}_n^{(j)}.$$

Note that $e^{\pm i\overline{p\boldsymbol{\omega}_j}}$ leave $L^2_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{R}^2)$ invariant. Hence, T_j leaves $L^2_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{R}^2)$ invariant if and only if $\phi_j^{\mathbf{A}}(r)$ is constant on $\mathbf{S}_{m,n}=\mathbf{S}_n^{(1)}\cap\mathbf{S}_m^{(2)}$ for all $m,n\in\mathbf{Z}$. Since $\mathbf{S}_n^{(j)}$ is connected and $\phi_j^{\mathbf{A}}$ is continuous on $\mathbf{S}_n^{(j)}$, it follows that $\phi_j^{\mathbf{A}}(\mathbf{r})$ is constant on $\mathbf{S}_{m,n}$ for all $m,n\in\mathbf{Z}$ if and only if it is constant on $\mathbf{S}_n^{(j)}$ for all $n\in\mathbf{Z}$. Thus, we obtain the desired result. ■

We set

$$\mathscr{C}=\mathscr{C}_1\cap\mathscr{C}_2. \tag{7.4}$$

As a corollary of Proposition 7.2, we have the following.

Theorem 7.3: *The four unitary operators T_1, T_1^{-1}, T_2 and T_2^{-1} leave $L^2_{\omega_1,\omega_2}(\mathbf{R}^2)$ invariant if and only if $\mathbf{A}\in\mathscr{C}$.*

By this theorem, if $\mathbf{A}\in\mathscr{C}$, then T_1, T_1^{-1}, T_2 and T_2^{-1} are reduced by $L^2_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{R}^2)$, and the restrictions

$$\hat{T}_j:=T_j\lceil L^2_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{R}^2),\quad \widehat{T_j^{-1}}:=T_j^{-1}\lceil L^2_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{R}^2),\quad j=1,2, \tag{7.5}$$

induce magnetic translations on the lattice $\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$ with $(\hat{T}_j)^{-1}=\widehat{T_j^{-1}}$. But, if these reduced magnetic translations have the trivial holonomy, i.e., $\hat{T}_1\hat{T}_2\hat{T}_1^{-1}\hat{T}_2^{-1}=I$, then they are uninteresting. Thus, we need to find conditions for the magnetic translations to have a nontrivial holonomy. The following proposition gives a necessary condition for that.

Proposition 7.4: Let $\mathbf{A}\in\mathscr{C}$. Suppose that A_1 and A_2 are continuous on $\mathbf{R}^2$. Then $T_1T_2=T_2T_1$.

Proof: By the condition $\mathbf{A}\in\mathscr{C}$, we have, for all $\mathbf{r}\in\mathbf{S}_{m,n}$,

$$\Phi^{\mathbf{A}}_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{r})=\phi_1^{\mathbf{A}}(\mathbf{r})+\phi_2^{\mathbf{A}}(\mathbf{r}+\boldsymbol{\omega}_1)-\phi_1^{\mathbf{A}}(\mathbf{r}+\boldsymbol{\omega}_2)-\phi_2^{\mathbf{A}}(\mathbf{r})=c_1(n)+c_2(m+1)-c_1(n+1)-c_2(m).$$

Since A_j is continuous on $\mathbf{R}^2$, so is $\phi_j^{\mathbf{A}}$. This implies that $c_j(n)=c_j(n+1)$ for all $n\in\mathbf{Z}$ and $j=1,2$. Hence $\Phi^A_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}=0$. By this fact and Theorem 3.3 we obtain the desired result. ■

Proposition 7.4 shows that, in the case $\mathbf{A}\in\mathscr{C}$, for the magnetic translations $\hat{T}_j,\hat{T}_j^{-1}$, $j=1,2$, to have a nontrivial holonomy, it is necessary for $\mathbf{A}$ to have singularities in $\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$.

We next show that, for a given vector potential $\mathbf{A}$ satisfying certain properties, we can construct an element in $\mathscr{C}$.

Definition 7.5: We say that $\mathbf{A}$ is in $\mathcal{D}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$ if there exist real sequences $\{\nu_j(n)\}_{n\in\mathbf{Z}}$, $j=1,2$, and real-valued continuous functions F_j on $\cup_{n\in\mathbf{Z}}\mathbf{S}_n^{(j)}$, such that

$$\phi_j^{\mathbf{A}}(\mathbf{r})+\int_0^1 F_j(\mathbf{r}+s\boldsymbol{\omega}_j)ds=\nu_j(n),\quad \mathbf{r}\in\mathbf{S}_n^{(j)},\quad j=1,2. \tag{7.6}$$

It is obvious that $\mathscr{C}\subset\mathcal{D}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$ [note that every element $\mathbf{A}\in\mathscr{C}$ satisfies (7.6) with $F_j=0$, $j=1.2$].

The matrix

$$W:=\begin{pmatrix}\omega_{11} & \omega_{12}\\ \omega_{21} & \omega_{22}\end{pmatrix} \tag{7.7}$$

is regular, since $\boldsymbol{\omega}_1$ and $\boldsymbol{\omega}_2$ are linearly independent.

Proposition 7.6: Suppose that $\mathbf{A}\in\mathcal{D}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$ *and let* $\nu_j(n)$, F_j *be as in Definition 7.5. Let*

$$\mathbf{F}:=(F_1,F_2), \tag{7.8}$$

$$\widetilde{\mathbf{A}}:=\mathbf{A}+W^{-1}\mathbf{F}. \tag{7.9}$$

Then $\widetilde{\mathbf{A}}\in\mathscr{C}$ *with*

$$\phi_j^{\widetilde{\mathbf{A}}}(\mathbf{r})=\nu_j(n),\quad \mathbf{r}\in\mathbf{S}_n^{(j)},\quad j=1,2. \tag{7.10}$$

Proof: We have, for all $\mathbf{r}\in\mathbf{S}_n^{(j)}$,

$$\phi_j^{\widetilde{\mathbf{A}}}(\mathbf{r})=\phi_j^{\mathbf{A}}(\mathbf{r})+\int_0^1 W^{-1}\mathbf{F}(\mathbf{r}+s\boldsymbol{\omega}_j)\cdot\boldsymbol{\omega}_j ds.$$

Since ${}^t(W^{-1})\boldsymbol{\omega}_j=\mathbf{e}_j$, we have $W^{-1}\mathbf{F}(\mathbf{r}+s\boldsymbol{\omega}_j)\cdot\boldsymbol{\omega}_j=F_j(\mathbf{r}+s\boldsymbol{\omega}_j)$. Hence, (7.10) follows. ■

Remark 7.2: The modified vector potential $\widetilde{\mathbf{A}}$ is not necessarily flat on $\mathbf{M}_\mathbf{L}$, even if $\mathbf{A}$ is flat on $\mathbf{M}_\mathbf{L}$. See the next section.

B. Construction of a subset of $\mathscr{C}$ from quasiperiodic functions

Definition 7.7: Let $f(z)$ be a holomorphic function on $\mathbf{C}\backslash\{\Omega_{m,n}\}_{m,n\in\mathbf{Z}}$ with possible poles at $z=\Omega_{m,n}$, $m,n\in\mathbf{Z}$. We say that f is in the class $\mathscr{C}$ if there exist constants $\xi_j:=\xi_{j1}+i\xi_{j2}\in\mathbf{C}$, $j=1,2$, such that

$$f(z+\omega_j)=f(z)+\xi_j,\quad j=1,2,\quad z\in\mathbf{C}\backslash\{\Omega_{m,n}\}_{m,n\in\mathbf{Z}}. \tag{7.11}$$

Remark 7.3: Every function $f\in\mathscr{C}$ is a primitive function of an elliptic function with periods ω_j, $j=1,2$. The constant ξ_j on the rhs of (7.11) is given by, e.g.,

$$\xi_j=f\left(\frac{\omega_j}{2}\right)-f\left(-\frac{\omega_j}{2}\right).$$

Let $f\in\mathscr{C}$ and A_j, $j=1,2$, be defined from f by (1.23). Set $\mathbf{A}=(A_1,A_2)$. Then the Cauchy–Riemann equation implies that $\mathbf{A}$ is flat on $\mathbf{M}_\mathbf{L}$ and

$$\partial_x A_1+\partial_y A_2=0,\quad \text{on}\quad \mathbf{M}_\mathbf{L}. \tag{7.12}$$

Let ξ_j be as in (7.11) and

$$\boldsymbol{\xi}_j:=(\xi_{j1},\xi_{j2}),\quad \boldsymbol{\xi}_j':=(\xi_{j2},\xi_{j1}),\quad j=1,2. \tag{7.13}$$

Proposition 7.8: For all $n\in\mathbf{Z}$, *there exist constants* $c_j(n)$, $j=1,2$, *such that*

$$\phi_j^{\mathbf{A}}(\mathbf{r})=\mathbf{r}\cdot\boldsymbol{\xi}_j'+c_j(n),\quad \mathbf{r}\in\mathbf{S}_n^{(j)}. \tag{7.14}$$

Proof: Let ω_j be as in (1.21) and $\theta_j:=\arg\omega_j$. Let $R(\theta)$ be defined by (2.10) and let

$$g_j(\mathbf{r}):=A(R(\theta_j)\mathbf{r})\cdot\boldsymbol{\omega}_j,\quad \phi_j'(\mathbf{r}):=\phi_j^{\mathbf{A}}(R(\theta_j)\mathbf{r}).$$

Then we have

$$\phi_j'(\mathbf{r})=\int_0^1 g_j(\mathbf{r}+s\boldsymbol{\omega}_j')ds,$$

where $\boldsymbol{\omega}_j' = |\omega_j|\mathbf{e}_1$. On the connected domain $R(-\theta_j)\mathbf{S}_n^{(j)}$, $g_j(\cdot + s\boldsymbol{\omega}_j')$, and ϕ_j' are infinitely many times differentiable with

$$\partial_x \phi_j'(\mathbf{r}) = \int_0^1 \partial_x g_j(\mathbf{r} + s\boldsymbol{\omega}_j') ds, \quad \mathbf{r} \in R(-\theta_j)\mathbf{S}_n^{(j)}.$$

It is easy to see that

$$\partial_x g_j(\mathbf{r} + s\boldsymbol{\omega}_j') = |\omega_j|^{-1} \frac{d}{ds} g_j(\mathbf{r} + s\boldsymbol{\omega}_j').$$

Hence

$$\partial_x \phi_j'(\mathbf{r}) = \frac{g_j(\mathbf{r} + \boldsymbol{\omega}_j') - g_j(\mathbf{r})}{|\omega_j|}.$$

On the other hand, we have, by (7.11) and (1.23),

$$\mathbf{A}(\mathbf{r} + \boldsymbol{\omega}_j) - \mathbf{A}(\mathbf{r}) = \boldsymbol{\xi}_j', \quad \mathbf{r} \in \mathbf{M}_\mathbf{L}. \tag{7.15}$$

Thus, we obtain

$$\partial_x \phi_j'(\mathbf{r}) = \frac{\boldsymbol{\omega}_j \cdot \boldsymbol{\xi}_j'}{|\omega_j|}, \quad \mathbf{r} \in U_{n \in \mathbf{Z}} R(-\theta_j)\mathbf{S}_n^{(j)}. \tag{7.16}$$

By the flatness of $\mathbf{A}$ on $\mathbf{M}_\mathbf{L}$ and (7.12), we can show that

$$\partial_y g_j(\mathbf{r}) = \partial_x \boldsymbol{\omega}_j \wedge \mathbf{A}(\mathbf{R}(\theta_j)\mathbf{r}).$$

Hence, in the same way as above, we obtain

$$\partial_y \phi_j'(\mathbf{r}) = \frac{\boldsymbol{\omega}_j \wedge \boldsymbol{\xi}_j'}{|\omega_j|}, \quad \mathbf{r} \in U_{n \in \mathbf{Z}} R(-\theta_j)\mathbf{S}_n^{(j)}. \tag{7.17}$$

It follows from (7.16) and (7.17) that there exist constants $c_j(n)$, $j = 1,2$, $n \in \mathbf{Z}$, such that

$$\phi_j^{\mathbf{A}}(\mathbf{r}) = \left[R(\theta_j) \left(\frac{\boldsymbol{\omega}_j \cdot \boldsymbol{\xi}_j'}{|\omega_j|}, \quad \frac{\boldsymbol{\omega}_j \wedge \boldsymbol{\xi}_j'}{|\omega_j|} \right) \right] \cdot \mathbf{r} + c_j(n), \quad \mathbf{r} \in \mathbf{S}_n^{(j)}.$$

The rhs of this equation is equal to the rhs of (7.14). ■

Theorem 7.9: *Let*

$$h_j(\mathbf{r}) := \left(\frac{\boldsymbol{\omega}_j}{2} - \mathbf{r} \right) \cdot \boldsymbol{\xi}_j', \quad \mathbf{r} \in \mathbf{R}^2, \quad j = 1,2, \quad \mathbf{h} = (h_1, h_2), \tag{7.18}$$

and

$$\tilde{\mathbf{A}} := \mathbf{A} + W^{-1}\mathbf{h}. \tag{7.19}$$

Then $\tilde{\mathbf{A}}$ *is in* $\mathscr{C}$ *with*

$$\phi_j^{\tilde{\mathbf{A}}}(\mathbf{r}) = c_j(n), \quad \mathbf{r} \in \mathbf{S}_n^{(j)}, \quad j = 1,2, \quad n \in \mathbf{Z}. \tag{7.20}$$

Moreover,

$$(T_{\boldsymbol{\omega}_j}^{\tilde{\mathbf{A}}})(\mathbf{r}) = e^{-i\alpha c_j(n)} \Psi(\mathbf{r} + \boldsymbol{\omega}_j), \quad \mathbf{r} \in \mathbf{S}_n^{(j)}, \quad j = 1,2, \quad n \in \mathbf{Z}. \tag{7.21}$$

Proof: By Proposition 7.8, (7.6) holds with $F_j = h_j$ and $\nu_j(n) = c_j(n)$. Hence, by Proposition 7.6, the desired assertion follows. Formula (7.21) follows from (3.5) and (7.20). ■

Theorem 7.9 establishes the existence of a mapping from $\mathscr{E}$ to a subset of $\mathscr{C}$ by the correspondence $f \to \widetilde{\mathbf{A}}$ defined by (7.19).

It is interesting to see when $\widetilde{\mathbf{A}}$ is flat on $\mathbf{M_L}$.

Lemma 7.10: The vector potential $\widetilde{\mathbf{A}}$ given by (7.19) is flat on $\mathbf{M_L}$ if and only if

$$\boldsymbol{\xi}_1' \cdot \boldsymbol{\omega}_2 = \boldsymbol{\xi}_2' \cdot \boldsymbol{\omega}_1 . \tag{7.22}$$

Proof: The magnetic field,

$$\widetilde{B}(\mathbf{r}) := D_x \widetilde{A}_2 - D_y \widetilde{A}_1 , \tag{7.23}$$

of the vector potential $\widetilde{\mathbf{A}}$ is constant, with

$$\widetilde{B}(\mathbf{r}) = \frac{\boldsymbol{\xi}_1' \cdot \boldsymbol{\omega}_2 - \boldsymbol{\xi}_2' \cdot \boldsymbol{\omega}_1}{\det W}, \quad \mathbf{r} \in \mathbf{M_L}. \tag{7.24}$$

Thus, the desired assertion follows. ■

We note the following fact.

Lemma 7.11: Let r_f be the residue of f at $z = \Omega_{m,n}$. Then r_f is independent of $m, n \in \mathbf{Z}$ and obeys the relation

$$\xi_1 \omega_2 - \xi_2 \omega_1 = 2\pi i r_f . \tag{7.25}$$

Proof: Let $a = (m - \frac{1}{2})\omega_1 + (n - \frac{1}{2})\omega_2$ and $C_{m,n}$ be the contour formed by the edges of the cell whose corners are $a, a + \omega_1, a + \omega_1 + \omega_2, a + \omega_2$, where the orientation of $C_{m,n}$ is taken to be anticlockwise. Then we have

$$\begin{aligned} 2\pi i r_f = \int_{C_{m,n}} f(z)dz &= \int_a^{a+\omega_1} \{f(z) - f(z+\omega_2)\}dz - \int_a^{a+\omega_2} \{f(z) - f(z+\omega_1)\}dz \\ &= -\xi_2 \omega_1 + \xi_1 \omega_2 , \end{aligned}$$

where we have used the quasiperiodicity (7.11) of f. Thus (7.25) is obtained. ■

The following proposition gives a complete characterization on the flatness of $\widetilde{\mathbf{A}}$ in terms of only f.

Proposition 7.12: The vector potential $\widetilde{\mathbf{A}}$ given by (7.19) is flat on $\mathbf{M_L}$ if and only if $\Re r_f = 0$.

Proof: We note that

$$\boldsymbol{\xi}_1' \cdot \boldsymbol{\omega}_2 - \boldsymbol{\xi}_2' \cdot \boldsymbol{\omega}_1 = \Im(\xi_1 \omega_2 - \xi_2 \omega_1).$$

By Lemma 7.11, the rhs is equal to $2\pi \Re r_f$. From this fact and Lemma 7.10, the desired result follows. ■

Remark 7.4: Let $f \in \mathscr{E}$ and $\Re r_f = 0$. Then, by Proposition 7.12, $\widetilde{\mathbf{A}}$ is flat on $\mathbf{M_L}$. We have $\Phi^{\mathbf{A}}_{\boldsymbol{\omega}_1, \boldsymbol{\omega}_2} = 2\pi \Re r_f = 0$ and

$$\Phi^{\widetilde{\mathbf{A}}}_{\omega_1, \omega_2} = \Phi^{\mathbf{A}}_{\omega_1, \omega_2} + \Phi^{W^{-1}\mathbf{h}}_{\boldsymbol{\omega}_1, \boldsymbol{\omega}_2} = 0.$$

Hence, in this case, the representations $\pi^{\mathbf{A}}_{\boldsymbol{\omega}_1, \boldsymbol{\omega}_2}$ and $\pi^{\widetilde{\mathbf{A}}}_{\boldsymbol{\omega}_1, \boldsymbol{\omega}_2}$ of CCR are unitarily equivalent to the Schrödinger representation and the algebras $\mathscr{R}_{\boldsymbol{\omega}_1, \boldsymbol{\omega}_2, \mathbf{A}}$ and $\mathscr{R}_{\boldsymbol{\omega}_1, \boldsymbol{\omega}_2, \widetilde{\mathbf{A}}}$ are commutative. Thus, for $f \in \mathscr{E}$, the case $\Re r_f = 0$ is uninteresting and only the case where $\widetilde{\mathbf{A}}$ is not flat on $\mathbf{M_L}$ may be interesting.

Example 7.1: Consider the case where $f(z)$ is the Weierstrass Zeta function:

$$f(z)=\zeta(z):=\frac{1}{z}+\sum_{(m,n)\in\mathbf{Z}^2\setminus\{0\}}\left\{\frac{1}{z-\Omega_{m,n}}+\frac{1}{\Omega_{m,n}}+\frac{z}{\Omega_{m,n}^2}\right\}. \tag{7.26}$$

It is well known (e.g., Ref. 22, Chap. XX, pp. 20–41) that

$$\zeta(z+\omega_j)=\zeta(z)+2\eta_j, \quad j=1,2, \tag{7.27}$$

where

$$\eta_j=\zeta(\omega_j/2). \tag{7.28}$$

Hence, $\zeta\in\mathscr{E}$. Since $r_\zeta=1$, Lemma 7.11 implies that, in the present case, $\widetilde{\mathbf{A}}$ is not flat on $\mathbf{M_L}$. By Lemma 7.11 we have

$$\eta_1\omega_2-\eta_2\omega_1=i\pi.$$

(This is a well-known formula: e.g., Ref. 22, Chap. XX, 20·411, pp. 446–447.) Hence

$$\boldsymbol{\eta}_1'\cdot\boldsymbol{\omega}_2-\boldsymbol{\eta}_2'\cdot\boldsymbol{\omega}_1=\pi.$$

Thus, in the present example,

$$\widetilde{B}(\mathbf{r})=\frac{2\pi}{\det W}\neq 0, \quad \mathbf{r}\in\mathbf{M_L}.$$

■

C. Derivation of Hamiltonians of the Hofstadter type from continuous systems

It is well known that some transport phenomena in two-dimensional solids can be modeled in part by Hamiltonians of the Hofstadter type, which are usually defined on two-dimensional infinite lattices (e.g., Ref. 13). It may be interesting to investigate if Hamiltonians of the Hofstadter type can be obtained as reductions of self-adjoint Hamiltonians of continuous quantum systems whose Hilbert spaces of state vectors are equal to $L^2(\mathbf{R}^2)$. For that purpose, we introduce a family $\{H^{\mathbf{A}}(t)\}_{t\in\mathbf{R}}$ of bounded self-adjoint operators,

$$\begin{aligned}H^{\mathbf{A}}(t):=&T^{\mathbf{A}}_{\boldsymbol{\omega}_1}(t)+\mu T^{\mathbf{A}}_{\boldsymbol{\omega}_2}(t)+\epsilon[T^{\mathbf{A}}_{\boldsymbol{\omega}_1}(t)^2+T^{\mathbf{A}}_{\boldsymbol{\omega}_2}(t)^2]+\lambda T^{\mathbf{A}}_{\boldsymbol{\omega}_1}(t)T^{\mathbf{A}}_{\boldsymbol{\omega}_2}(t)\\&+\nu T^{\mathbf{A}}_{\boldsymbol{\omega}_1}(t)T^{\mathbf{A}}_{\boldsymbol{\omega}_2}(t)^*+\gamma T^{\mathbf{A}}_{\boldsymbol{\omega}_1}(t)^*T^{\mathbf{A}}_{\boldsymbol{\omega}_2}(t)+\text{h.c.},\end{aligned} \tag{7.29}$$

where $\mu,\epsilon,\lambda,\nu,\gamma$ are complex parameters and h.c. means the Hermitian conjugate. The operator $H^{\mathbf{A}}(t)$ is a continuous version of Hamiltonians of the Hofstadter type. By Theorem 7.3, if $\mathbf{A}\in\mathscr{E}$, then

$$H^{\mathbf{A}}:=H^{\mathbf{A}}(1)=T_1+\mu T_2+\epsilon(T_1^2+T_2^2)+\lambda T_1T_2+\nu T_1T_2^*+\gamma T_1^*T_2+\text{h.c.}, \tag{7.30}$$

is reduced by $L^2_{\boldsymbol{\omega}_1,\boldsymbol{\omega}_2}(\mathbf{R}^2)\cong l^2(\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2))$ and its reduced part yields a Hamiltonian of the Hofstadter type on the lattice $\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$. This shows that, in the case $\mathbf{A}\in\mathscr{E}$, it is possible to obtain Hamiltonians of the Hofstatder type on $\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$ as reductions of Hamiltonians of the type $H^{\mathbf{A}}$. By Theorem 7.9, there exists a wide class of vector potentials $\mathbf{A}$ that give this kind of reduction for the Hamiltonian $H^{\mathbf{A}}$. We also remark that the reduction of $H^{\mathbf{A}}$ with $\mathbf{A}\in\mathscr{E}$ to the subspace $l^2(\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2))$ makes it possible to identify the spectrum of $H^{\mathbf{A}}$ in part by analyzing the spectra of Hamiltonians of the Hofstadter type on the lattice $\mathbf{L}(\boldsymbol{\omega}_1,\boldsymbol{\omega}_2)$ that may have interesting structures such as fractal ones (Ref. 13).

(Received 21 July 1997; accepted for publication 8 December 1997)

Canonical quantization of the isomonodromy solutions of equations integrable via the Inverse Scattering Transform leads to generalized Knizhnik–Zamolodchikov equations. One can solve these equations by the off-shell Bethe ansatz method provided the Knizhnik–Zamolodchikov equations are related with the highest weight representations of the corresponding Lie algebras: These solutions can be written in terms of multi-variable generalizations of special functions of the hypergeometric type. In this work, we consider a realization of the above scheme for the Maxwell–Bloch system with pumping: quantum states for this system are found in terms of the multi-variable confluent hypergeometric function. © *1998 American Institute of Physics.* [S0022-2488(98)03203-4]

I. INTRODUCTION

Some time ago Reshetikhin[1] introduced generalized Knizhnik–Zamolodchikov equations and noticed that they can be viewed as a quantization of the non-linear system of ordinary differential equations (ODEs) defining isomonodromy deformations of linear ODEs. In particular, the original system of the Knizhnik–Zamolodchikov[2] equations can be viewed as a quantization of the classical Schlesinger equations.[3] Later, Harnad[4] gave a more ''physical'' interpretation of this quantization procedure: By considering the Schlesinger equations as a multi-time Hamiltonian system, he has shown (using the standard quantum mechanical language) that the system of Knizhnik–Zamolodchikov equations can be viewed as a multi-time non-autonomous system of Schrödinger equations.

An attractive feature of this quantization is that the Knizhnik–Zamolodchikov equations on the Lie algebras with the finite weight representations can be solved in terms of the multi-variable hypergeometric functions,[5] so that one can get explicit formulas for the wave-functions, correlators, and so on. To make this quantization procedure closer to applications one has to find physical models which can be described in terms of solutions to the system of Schlesinger equations and/or their generalizations. One regular procedure is well-known: The system of the Schlesinger equations and their generalizations govern the so-called isomonodromy solutions of the equations integrable via the Inverse Scattering Transform (IST).[6] In particular, there are special classes of the isomonodromy solutions to the self-dual Yang–Mills equations, Einstein–Maxwell equations, and the Ernst equation, which can be written in terms of the solutions to the system of the Schlesinger equations.[7,8] In general, to fix a class of the isomonodromy solutions of a partial differential equation integrable via IST means to pick out a finite dimensional non-autonomous Hamiltonian system of its solutions which defines an isomonodromy deformation of some auxiliary linear ODE (see Sec. III for details). Most of the important solutions which are studied in the IST framework; solitons, finite-gap, or similarity, belong to the isomonodromy classes of solu-

tions. The quantization of the system of Schlesinger equations (or their generalizations) which governs one such isomonodromy subsystems means to associate with the classical system a spin-like non-autonomous finite dimensional quantum system. These systems usually contain some parameters, in particular the number of ''particle (waves),'' N, so that further one can study different scaling limits $N\to\infty$.

Korotkin and Nicolai[9] used the above ideas for the quantization of a special class of the isomonodromy solutions to the Ernst equation—the class which is governed by the classical Schlesinger equations. They found that for the further interpretation of the quantum model obtained as the model of quantum gravity one has to demand that the wave function belongs to the coset space $SL(2,\mathbb{R})/SO(2)$ and satisfies an additional constraint: like the vanishing of a total spin of the system. There are no (non-trivial) solutions of the corresponding Knizhnik–Zamolodchikov equations on the representations of $sl_2(\mathbb{R})$ with the highest weights which satisfy this constraint. There are two possibilities of continuation of these studies for the Ernst equation: (1) Instead of the principal discrete series of representations of $sl_2(\mathbb{R})$ one can try to use the principal continuous series. But the corresponding system of Knizhnik–Zamolodchikov equations becomes a rather complicated system of partial differential equations which is not investigated at the present time; (2) to study an application of this quantization scheme to other classes of isomonodromy solutions to the Ernst equation. In the last case, of course, we change the objects under quantization. The corresponding systems of Knizhnik–Zamolodchikov equations also change; probably they belong to the class of the generalized Knizhnik–Zamolodchikov equations which are introduced in Ref. 1.

In this paper we would like to draw attention to the fact that the quantization procedure briefly described above is applicable to isomonodromy solutions of any IST integrable (KdV-like) differential equation. The corresponding system of the generalized Knizhnik–Zamolodchikov equations can be solved via the off-shell Bethe ansatz method.[10,11] Since there is a rather big variety of the IST integrable equations, each of these equations possesses (infinitely) many classes of the isomonodromy solutions, and the same equation very often serves for a description of different physical models, so that the different classes of the isomonodromy solutions are really involved, we hope that this quantization procedure can appear to be quite reasonable for some physical models and therefore believe that it requires more wide attention and further studies.

In this work we consider the Maxwell–Bloch system with pumping (Sec. II). From the IST point of view this is an intermediate case between the systems integrable via IST with the variable spectral parameter and IST with the spectral parameter independent of the dynamical variables. The spectral parameter in this case depends on one (space) variable and is independent of time. It is worth mentioning that the wave function, the solution of a generalized system of Knizhnik–Zamolodchikov equations, is obtained in Sec. VI in terms of the multi-variable confluent hypergeometric function.

Probably, the Maxwell–Bloch system without pumping (Sec. II) would be physically the most reasonable example for further studies. The associated auxiliary ODE with respect to the spectral parameter, which plays a key role in the definition of the isomonodromy solutions (Sec. III), has an additional pole of the second order compared to the corresponding ODE studied in this work and is therefore the next complicated case to the one considered here.

II. MAXWELL–BLOCH SYSTEM WITH PUMPING

The Maxwell–Bloch system (without pumping)[12,13] describes the propagation of a sequence of electromagnetic pulses along the positive direction of the x-axis in the two level atomic medium. It is known to be integrable via the Inverse Scattering Transform.[14–16] The Maxwell–Bloch system with pumping was introduced by Burtsev, Zakharov, and Mikhailov[17] in the framework of the Inverse Scattering Transform with a variable spectral parameter as an integrable deformation (with the deformation parameter s) of the reduced Maxwell–Bloch system (RMB). More exactly, they considered the following system of linear differential equations:

$$\partial_\xi\psi=(z\sigma_3+U_0)\psi,\quad \left(\partial_\eta+\frac{s}{z}\partial_z\right)\psi=\frac{\hat\rho}{4z}\psi, \tag{2.1}$$

where $z \in \mathbb{C}$ is the auxiliary (spectral) parameter and the 2×2-matrices σ_3, U_0, and $i\hat{\rho} \in su_2$ have the following form:

$$\sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad U_0 = \frac{1}{2}\begin{pmatrix} 0 & E \\ -E^* & 0 \end{pmatrix}, \quad \hat{\rho} = \begin{pmatrix} N & -\rho \\ -\rho^* & -N \end{pmatrix}, \tag{2.2}$$

with the functions: $E = E(\xi, \eta), N = N(\xi, \eta)$, and $\rho = \rho(\xi, \eta)$ independent of z and (*) denoting the complex conjugation. The compatibility condition for the system (2.1) reads as

$$\partial_\eta E = \rho, \quad \partial_\xi \rho = NE, \quad \partial_\xi N + \frac{1}{2}(E\rho^* + E^*\rho) = 4s. \tag{2.3}$$

This non-linear system of partial differential equations is called the Maxwell–Bloch system with pumping (PMB). The physical meaning of the notations used is as follows: dimensionless variables η and ξ are related to the space, x, and time, t, variables:

$$\eta = \Omega \frac{x}{c}, \quad \xi = \Omega\left(t - \frac{x}{c}\right); \tag{2.4}$$

E and ρ are slowly varying complex amplitudes of the electric field and polarization, respectively; N is the population inversion, therefore $-1 \leqslant N \leqslant 1$; $\Omega > 0$ is a parameter characterizing the medium; and $s > 0$ represents the ''pumping,'' i.e., an additional excitation of the active medium as it was interpreted by the authors.[17] Note that the standard RMB equations are given by (2.3) and (2.4) with $s = 0$. From the mathematical viewpoint all the techniques related with IST, including the quantization which we present in this work, can be developed for the complex function N, and the parameters ω and s. However, here we follow the restrictions mentioned above. Further details about the system (2.3), (2.4) can be found in the works.[18–22] In fact the Maxwell–Bloch system is a semiclassical system: The medium is considered quantum-mechanically while the electromagnetic field is described via the classical Maxwell equations. The quantization scheme which is presented in this work can be considered as an attempt of quantization of the electromagnetic field interacting with the active medium.

III. ISOMONODROMY SOLUTIONS

The general notion of the isomonodromy solutions of the equations integrable via IST was formulated in the work.[6] It is applicable also to the equations integrable via IST with a variable spectral parameter. The ψ-function which corresponds to such solutions, possibly after some gauge-like transformations, solves together with the system (2.1) one more linear ODE, the ODE with respect to the spectral parameter,

$$\partial_z \psi = A(z)\psi, \tag{3.1}$$

where $A(z) = A(z, \xi, \eta) \in su_2$ is a rational function of the spectral parameter z. The compatibility condition of Eq. (3.1) with the system (2.1) does not uniquely define the matrix $A(z, \xi, \eta)$. This freedom is such that all the most important solutions to the equations integrable via IST (multisoliton, finite-gap, similarity) can be specified as the solutions of the isomonodromy class: the ψ-functions corresponding to them solve Eq. (3.1) with different matrices $A(z, \xi, \eta)$ for the solutions of the different types. Some solutions, which do not belong to the isomonodromy class, e.g., rapidly decaying solutions, also show an isomonodromy behavior in many interesting asymptotic regimes.

In our case the simple possible choice of $A(z, \xi, \eta)$ which is consistent with the system (2.1) reads as

$$A(z, \xi, \eta) = (\xi - \xi_0)\sigma_3 + \sum_{j=1}^{N} \frac{A_j}{z - z_j}, \quad z_j = \sqrt{2s\eta - k_j^2}, \tag{3.2}$$

where k_j^2, $\xi_0 \in \mathbb{R}$ are the parameters and the functions $A_j = A_j(\xi, \eta)$ are independent of z. In the following, to avoid technical details, we suppose that our system has a finite size, i.e.,

$$0 \leqslant \eta \leqslant L, \quad k_j^2 > 2sL \Rightarrow z_j^* = -z_j. \tag{3.3}$$

Proposition 1: If for $j=1,\ldots,N$ the matrix-functions $A_j \in su_2$ are such that the set $\{A_j\}_{j=1,\ldots,N}$ is a solution of the system

$$\partial_\xi A_j = [z_j\sigma_3 + U_0, A_j], \quad \partial_\eta A_j = \left[\frac{\hat{\rho}}{4z_j}, A_j\right], \tag{3.4}$$

$$U_0 = \frac{1}{\xi - \xi_0}\left(\sum_{l=1}^{N} A_l - i\theta_\infty\sigma_3\right), \quad i\theta_\infty\sigma_3 \equiv \operatorname{diag}\sum_{l=1}^{N} A_l, \quad \hat{\rho} = 4s\left((\xi-\xi_0)\sigma_3 - \sum_{l=1}^{N}\frac{A_l}{z_l}\right), \tag{3.5}$$

where the brackets, $[\cdot,\cdot]$, denote the commutator of two matrices; then $\theta_\infty \in \mathbb{R}, \partial_\xi\theta_\infty = \partial_\eta\theta_\infty = 0$, the matrix U_0 is off-diagonal, and the functions E, ρ, and N, which are defined by Eqs. (2.2) and (3.5), are the solutions of PMB (2.3).

The system (3.4), (3.5) defines the deformation (with the deformation parameters ξ and η) of the coefficients, A_j, of Eq. (3.1) with the matrix $A(z)$ given by (3.2), which preserves the monodromy group or, more generally, the monodromy data[23] of this equation. This comment ''explains'' the name isomonodromy solutions. Note that for $N=2$ the system (3.4), (3.5) reduces to the classical fifth Painlevé equation.[20]

To the N-soliton solution of PMB (2.3) corresponds a particular solution of the system (3.4), (3.5): The eigenvalues of all the matrices A_j are equal to $\pm 1/2$. To each soliton corresponds one (and only one) eigenvalue z_l. So, intuitively, one can think of the isomonodromy solutions defined by the system (3.4), (3.5) as an N-wave-like object, although the behavior of the general solution is much more complicated than the N-soliton train.

IV. HAMILTONIAN STRUCTURE

It is known that the equations which define isomonodromy deformations of the linear ODEs (3.1) where the matrix $A(z)$ is a rational function of z admit a Hamiltonian structure. The Poisson brackets between the matrix elements can be written in the following compact form:[24,25]

$$\{A(z) \overset{\otimes}{,} A(w)\} = [r(z-w), A(z)\otimes I + I\otimes A(w)], \tag{4.1}$$

where $r(z-w) = P/(z-w)$ with P the permutation operator on $\mathbb{C}^2 \otimes \mathbb{C}^2$. The corresponding Hamiltonians are generated by the so-called τ-function.[23] In our case Eq. (4.1) for the matrix elements, $(A_k)_{ab}$, reads as:[26]

$$\{(A_k)_{ab}, (A_j)_{cd}\} = \delta_{kj}((A_k)_{ad}\delta_{bc} - \delta_{ad}(A_k)_{cb}). \tag{4.2}$$

Proposition 2: The system (3.4), (3.5) can be written in the Hamiltonian form:

$$\partial_\xi A_j = \{A_j, H_\xi\}, \quad \partial_\eta A_j = \{A_j, H_\eta\}, \tag{4.3}$$

where the dynamics with respect to the variables ξ and η is defined by the following non-autonomous Hamiltonians:

$$H_\xi = \sum_{k=1}^{N} z_k \operatorname{tr}(A_k\sigma_3) + \frac{S^-S^+ + S^+S^-}{\xi - \xi_0}, \quad S^+ = \left(\sum_{k=1}^{N} A_k\right)_{12}, \quad S^- = \left(\sum_{k=1}^{N} A_k\right)_{21}, \tag{4.4}$$

$$H_\eta = \sum_{k=1}^{N} H_k \frac{\partial z_k}{\partial \eta} = \sum_{k=1}^{N} \frac{H_k}{z_k}, \quad H_k = (\xi-\xi_0)\operatorname{tr}(A_k\sigma_3) + \sum_{i\neq k}^{N} \frac{\operatorname{tr}(A_kA_i)}{z_k - z_i}, \quad k = 1,\ldots,N. \tag{4.5}$$

The compatibility of the system (4.3) follows from Proposition 3.

Proposition 3: $\{H_\xi, H_\eta\}=0$, $\partial H_\xi/\partial\eta=\partial H_\eta/\partial\xi$.

V. QUANTIZATION

We consider the N-particle sector of the Fock space,

$$\mathscr{H}_N=\otimes_{k=1}^N V_k, \tag{5.1}$$

where V_k are left su_2-modules corresponding to the spin m_k representations of su_2, i.e., V_k are isomorphic to $\mathbb{C}^{2m_k+1}$, $m_k\in\mathbb{Z}/2$. Denote by $s_k^a, a=1, 2, 3$, the linear operators, which generate in V_k these representations ($s_k^a\in su_2$):

$$[s_k^a, s_j^b]=i\delta_{kj}\epsilon^{abc}s_k^c, \quad a, b, c\in\{1, 2, 3\}, \quad s_k^3\omega_k=m_k\omega_k, \tag{5.2}$$

where ω_k is the highest weight vector. In particular, for the spin 1/2 representation $s_k^a=\frac{1}{2}\sigma_k^a$, where σ_k^1, σ_k^2, σ_k^3 are multiplications on the Pauli matrices. The natural extension of s_k^a to $\mathscr{H}_N$ is denoted by $\hat{s}_k^a$,

$$\hat{s}_k^a(g)=I\otimes\cdots\underbrace{s_k^a(g)}_{k-th}\cdots\otimes I\in\mathrm{End}(\mathscr{H}), \quad g\in su_2.$$

It is convenient to also introduce the following notations:

$$\hat{s}_k^\pm=\hat{s}_k^1\pm i\hat{s}_k^2, \quad \hat{S}^3=\sum_{k=1}^N \hat{s}_k^3, \quad \hat{S}^\pm=\sum_{k=1}^N \hat{s}_k^\pm.$$

In the Schrödinger picture, quantization of the classical observables A_k reads as

$$A_k\Rightarrow\hat{A}_k=i\hbar\begin{pmatrix}\hat{s}_k^3 & \hat{s}_k^+\\ \hat{s}_k^- & -\hat{s}_k^3\end{pmatrix}, \quad (\xi-\xi_0)\sigma_3\Rightarrow i\hbar(\xi-\xi_0)\sigma_3\otimes I.$$

The generator of the quantum observables [cf. (3.2)],

$$\hat{A}(z,\xi,\eta)=i\hbar(\xi-\xi_0)\begin{pmatrix}I & 0\\ 0 & -I\end{pmatrix}+\sum_{j=1}^N\frac{\hat{A}_j}{z-z_j}, \quad z_j=\sqrt{2s\eta-k_j^2}, \tag{5.3}$$

satisfies the following commutator relation [cf. (4.1)]:

$$[\hat{A}(z)\overset{\otimes}{,}\hat{A}(w)]=i\hbar[r(z-w), \quad \hat{A}(z)\otimes\hat{I}+\hat{I}\otimes\hat{A}(w)], \tag{5.4}$$

where $\hat{I}$ is the matrix with the identity operators on the main diagonal and the classical r-matrix above is the same as in the Poisson structure (4.1). The quantum Hamiltonians in the above notations can be written as follows:

$$\hat{H}_\xi=2(i\hbar)^2\sum_{j=1}^N z_j\hat{s}_j^3+\frac{(i\hbar)^2}{\xi-\xi_0}(\hat{S}^-\hat{S}^++\hat{S}^3),$$

$$\hat{H}_k=2(i\hbar)^2(\xi-\xi_0)\hat{s}_k^3+2(i\hbar)^2\sum_{j\neq k}^N\frac{\hat{s}_k^a\hat{s}_j^a}{z_k-z_j},$$

where in the last equation the summation on the superscript a is supposed.

The time evolution of the state-vector Ψ is governed by the Schrödinger equation,

$$i\hbar\kappa\frac{\partial\Psi}{\partial\xi}=\hat{H}_\xi\Psi, \tag{5.5}$$

where $\kappa \in \mathbb{R}$ plays a role of the dimension constant; note that our ''time-variable'' ξ is dimensionless! To be consistent with the classical picture we have to impose on the vector Ψ the system of N more ''Schrödinger'' equations,

$$i\hbar\kappa\frac{\partial\Psi}{\partial z_k}=\hat{H}_k\Psi, \quad k=1,\ldots,N, \tag{5.6}$$

which govern the dependence of the state-vector on the parameters z_k and so define the space-like dependence of the state vector. The necessity of the appearance of additional equations, system (5.6), is clear since we are quantizing the (soliton-) wave-like objects (see the last paragraph in Sec. III), whilst the Schrödinger equation (5.5) defines only the time dependence of the state-vector.

The system (5.5), (5.6) is compatible. It follows from Proposition 4.

Proposition 4: $[\hat{H}_\xi, \hat{H}_\eta]=0$, $\partial_\eta\hat{H}_\xi=\partial_\xi\hat{H}_\eta$.

The system (5.5), (5.6) is a generalized system of the Knizhnik–Zamolodchikov equations. In particular, the subsystem (5.6) for $\xi-\xi_0=0$ coincides with the classical Knizhnik–Zamolodchikov equations.[2]

VI. GENERALIZED KNIZHNIK–ZAMOLODCHIKOV EQUATIONS

In the previous section we have obtained the following system of generalized Knizhnik–Zamolodchikov equations:

$$\kappa\frac{\partial\Psi}{\partial\xi}=i\hbar\left(2\sum_{j=1}^{N}z_j\hat{s}_j^3+\frac{\hat{S}^-\hat{S}^++\hat{S}^3}{\xi-\xi_0}\right)\Psi, \tag{6.1}$$

$$\kappa\frac{\partial\Psi}{\partial z_k}=i\hbar\left(2(\xi-\xi_0)\hat{s}_k^3+2\sum_{j\neq k}^{N}\frac{\hat{s}_k^a\hat{s}_j^a}{z_k-z_j}\right)\Psi. \tag{6.2}$$

We have applied the off-shell Bethe ansatz method[10,11] to construct the general solution of this system. This method has a pure algebraic nature and that is why it works not only for the real values of the parameters: ξ, ξ_0, $\hbar$, iz_k, as is assumed in the setting related with the PMB, but also in the case when one allows arbitrary complex values ($z_k\neq z_j$ for $k\neq j$) for these parameters. Thus, the following formulae are valid for complex values of the parameters too.

Since the off-shell Bethe ansatz method has already been presented in the literature[10,11] and its application to system (6.1), (6.2) requires no essential modification, here we only write down the final answer.

The vacuum solution reads as

$$\Psi_0=\chi_0|0\rangle, \quad |0\rangle=\otimes_{k=1}^{N}\omega_k,$$

$$\chi_0=(\xi-\xi_0)^{i(\hbar/\kappa)\Sigma_{k=1}^{N}m_k}\prod_{1\leqslant k<j\leqslant N}(z_k-z_j)^{2i(\hbar/\kappa)m_km_j}\exp\left(2i\frac{\hbar}{\kappa}(\xi-\xi_0)\sum_{k=1}^{N}m_kz_k\right),$$

where m_k and ω_k are the highest weights and the highest weight vectors correspondingly (5.2). For each $m\in\mathbb{Z}$ satisfying the inequality, $1\leqslant m\leqslant 2\Sigma_{k=1}^{N}m_k$, the function

$$\Psi_m(\xi,\vec{z})=\oint_{\Delta_m}\chi_m(\vec{\mu}_m|\xi,\vec{z})\hat{\varphi}_m(\vec{\mu}_m|\xi,\vec{z})d\mu_1,\ldots,d\mu_m,$$

where $\vec{z}\equiv(z_1,\ldots,z_N)$, $\vec{\mu}_m\equiv(\mu_1,\ldots,\mu_m)$,

$$\chi_m(\vec{\mu}_m|\xi,\vec{z})=(\xi-\xi_0)^{(i\hbar/\kappa)\Sigma_{k=1}^N m_k-m)}\exp\left(\frac{2i\hbar}{\kappa}(\xi-\xi_0)\sum_{k=1}^N z_k m_k\right)\prod_{1\leqslant k<j\leqslant N}(z_k-z_j)^{(2i\hbar/\kappa)\, m_k m_j}$$

$$\times\prod_{\substack{1\leqslant\alpha\leqslant m\\ 1\leqslant k\leqslant N}}(z_k-\mu_\alpha)^{-(i\hbar/2\kappa)\, m_k}\prod_{1\leqslant\alpha<\beta\leqslant m}(\mu_\alpha-\mu_\beta)^{(i\hbar/2\kappa)}$$

$$\times\exp\left(-\frac{i\hbar}{\kappa}(\xi-\xi_0)\sum_{\alpha=1}^m\mu_\alpha\right),$$

$$\hat{\varphi}_m(\vec{\mu}_m|\xi,\vec{z})=\prod_{k=1}^m\hat{S}^-(\mu_k|\xi,\vec{z})|0>,\quad \hat{S}^-(\mu|\xi,\vec{z})=\sum_{k=1}^N\frac{\hat{s}_k^-}{\mu-z_k},$$

and the cycles Δ_m are defined by the following equation:

$$\sum_{k=1}^m\oint_{\Delta_m}\frac{d}{d\mu_k}\frac{\chi_m(\vec{\mu}_m|\xi,\vec{z})\ \hat{s}_j^-\,\hat{\varphi}_m^k(\vec{\mu}_m|\xi,\vec{z})}{z_j-\mu_k}\,d\mu_1,\ldots,d\mu_m=0,$$

$$\hat{\varphi}_m^k(\vec{\mu}_m|\xi,\vec{z})=\prod_{j\neq k}^N\hat{S}^-(\mu_j|\xi,\vec{z}),$$

solves the system (6.1), (6.2). The solution, Ψ_m, also should satisfy the quantum version of the second equation in (3.4),

$$(\hbar\hat{S}^3-\theta_\infty)\Psi_m=0\Rightarrow\hbar\left(m-\sum_{k=1}^N m_k\right)=\theta_\infty\,. \tag{6.3}$$

ACKNOWLEDGMENTS

This work was done during the authors' stay at Sonderforshungsbereich 288 in May 1995. Since then different versions were presented at seminars in FU Berlin, POMI (St. Petersburg), and INFN (Padova). It is our pleasure to thank A. I. Bobenko, L. D. Faddeev, I. R. Gabitov, M. Karowski, D. A. Korotkin, I. M. Krichever, P. A. Marchetti, M. Matone, H. Nicolai, R. Seiler, R. Schrader, and F. Toppan for discussions and useful comments. One of us (A. V. K.) is grateful to the Max-Planck-Insitut für Gravitationsphysik (Potsdam) for hospitality during the preparation of this work for publication. H. M. Babujian was partially supported by Grant No. 211-5291 YPI of the German Bundesministerium für Forshung und Technologie and Sonderforschungsbereich 288. A. V. Kitaev was supported by Sonderforschungsbereich 288 and the Alexander von Humboldt Foundation.

Geometry of the Batalin–Fradkin–Vilkovisky theorem

K. Bering[a)]
Institute of Theoretical Physics, Uppsala University,
P.O. Box 803, S-751 08 Uppsala, Sweden

(Received 15 October 1997; accepted for publication 24 November 1997)

We describe gauge fixing at the level of virtual paths in the path integral as a nonsymplectic BRST-type of flow on the path phase space. As a consequence, a gauge-fixed, nonlocal symplectic structure arises. Restoring of locality is discussed. A pertinent anti-Lie-bracket and an infinite dimensional group of gauge fermions are introduced. Generalizations to Sp(2)-symmetric BLT theories are made. © *1998 American Institute of Physics.* [S0022-2488(98)00804-4]

I. INTRODUCTION

Similar to the Lagrangian BRST symmetry[1] for Yang–Mills theory, Batalin, Fradkin, and Vilkovisky[2] developed a BRST formulation of an arbitrary Hamiltonian gauge theory with reducible first class constraints and possible open gauge algebra, now known as BFV-BRST quantization.[3] The crucial ingredients turn out to be two Grassmann odd objects, the nilpotent BRST charge Ω, and the gauge fermion ψ. The BFV theorem, which is the subject of this article, simply states that the partition function $\mathcal{Z}$ is independent of the choice of ψ.

The present work was originally motivated by a concern about the stability of time locality. It is a well-known fact that time has a special status in Hamiltonian theories. One assumes that all virtual paths in the path integral are parametrized by the one and same global time parameter. As a consequence, it makes sense to speak of equal-time Poisson brackets. In Hamiltonian theories, there is no interaction between two different time slices. In other words, the symplectic two-form $\omega(t)=\omega(z(t),t)$ is a *function* of the coordinates taken in the very same time. This is often referred to as saying that the phase space Poisson structure is ultra-local in time. So the symplectic structure does not depend on the past nor the future. Nevertheless, in the standard proof[2] for the BFV theorem one performs an infinitesimal flow generated by a bosonic BRST-type vector field

$$X(t)=\mu X_{\Omega(t)}, \tag{I.1}$$

where $\mu\sim\int_0^T dt\ \delta_{\mathrm{ext}\psi}(t)$ is a *functional*. The flow therefore carries information about the past and the future of the path. In a consistent geometric formulation such flows will violate the ultra-local ansatz for the two-form $\omega(t)=\omega(z(t),t)$. The BRST variation (I.1) is transporting well-defined ultra-local theories into nonlocal theories. Naively, one would expect that the pertinent BRST transformation would map ultra-local theories in ultra-local theories. However, this is not the case. Our analysis below shows that the nonlocality arising in the canonical measure factor, the Pfaffian, remarkably can be recast into an ultra-local form, which turns out to be the gauge-fixing term in the action. This solves our original posed question, and it shows that the formalism is consistent.

Besides the time-local problem mentioned above, we introduce and give a geometric description of the gauge fixing flow directly at the level of virtual paths in the path phase space.

The article is organized as follows: A pertinent anti-Lie-bracket, that turns the set of gauge fermions into an infinite-dimensional algebra is introduced in Sec. III. This algebra is interesting in its own right from a pure mathematical point of view. There we also discuss the realizations of the algebra of gauge fermions and its corresponding group. This paves the way for introduction of a gauge-fixing flow discussed in Sec. IV. With this in hand we can prove the BFV theorem in a path space formalism; see Sec. V. We have for completeness included in Sec. V C the infinitesimal gauge-fixing flow. Finally, in Sec. VI we generalize the construction to Sp(2)-symmetric

Hamiltonian theories.[4] Some of the results in this article have been reported on the NATO Advanced Research Workshop, 1997, Zakopane, ''New Developments in Quantum Field Theory.''

II. LIFT TO PATH SPACE

The basic philosophy is to consider the collection $\mathscr{P}\Gamma$ of all paths as an infinite-dimensional manifold, i.e., a geometric object that does not depend on the choice of coordinates. For instance, given a volume form, the partition function is an integral over this manifold weighted with the Boltzmann factor. Let us emphasize that both the Boltzmann factor and the volume form are scalar objects, which does not depend on the choice of coordinates. In this picture the BRST transformation (I.1) is a non-Hamiltonian (and nonlocal) vector field on the manifold $\mathscr{P}\Gamma$, i.e., it is not a symplectic or equivalently a canonical transformation. So the symplectic structure is affected by the BRST vector field (I.1) and it in general becomes nonlocal.

We see that the BRST-type transformation (I.1) forces us to consider a wider class of theories than the ultra-local ones. To include nonlocal theories, we have to lift the construction from phase space Γ to a *path* phase space $\mathscr{P}\Gamma$, thereby giving room for nontrivial Poisson bracket between different times. In general, nonlocal theories are senseless, but we shall see that we can give meaning to a restricted class of nonlocal theories.

We shall here discard global obstructions and assume that objects like the gauge fermion ψ and the symplectic potential ϑ exist globally. So, in particular, our considerations do not include Gribov problems. Also we will, for simplicity, consider the case where Γ does not have boundaries. Moreover, we assume that the path integral exists for the studied gauges.

Let us introduce a gauge-fixed symplectic two-form directly in the path space $\mathscr{P}\Gamma = \Pi_{t\epsilon[0,T]}\,\Gamma$:

$$\omega_\psi = \omega_\psi(\gamma) = \frac{1}{2}\int_\gamma\int_\gamma dt\ dt' dz^A(t)\omega_{\psi AB}(t,t')\wedge dz^B(t') = \frac{1}{2}\int_\gamma\int_\gamma dt\ dt'\ \omega_{\psi AB}(t,t')dz^B(t')\wedge dz^A(t)(-1)^{\epsilon_A+1}. \tag{II.1}$$

The basic picture is that acting with a BRST-type transformation (I.1) change the symplectic two-form depending on the gauge-fixing ψ. In other words, ω_ψ is a modified symplectic two-form, whose change is an accumulated effect of acting with a BRST-type of transformations (I.1). We shall derive the explicit formula later. Here we are only interested in the principle idea. The inverse $\omega_\psi^{AB}(t,t')$ gives rise to a gauge-fixed path space Poisson bracket

$$\{F,G\}_\psi = \{F,G\}_\psi(\gamma) = \int_\gamma\int_\gamma dt\ dt'\ F\ \frac{\overleftarrow{\delta}^r}{\delta z^A(t)}\ \omega_\psi^{AB}(t,t')\ \frac{\overrightarrow{\delta}^l}{\delta z^B(t')}\ G, \tag{II.2}$$

where $F,G:\mathscr{P}\Gamma\to\mathbb{C}$. For generic ψ the elements $\omega_{\psi AB}(t,t')$ are functionals of the path γ. More precisely, we allow for the following dependence: (A) It could be a *functional* of the full path γ, (B) it could be a function of the two path values $\gamma(t)$ and $\gamma(t')$, and finally (C) it could depend explicitly on the times t and t'. In symbols,

$$\omega_{\psi AB}(t,t') = \omega_{\psi AB}(\gamma,\gamma(t),\gamma(t'),t,t'). \tag{II.3}$$

As an obvious boundary condition, when the gauge fermion is turned off, $\psi=0$, the gauge-fixed symplectic structure should coincide with the original ultra-local symplectic structure. That is,

$$\omega = \omega(\gamma) = \frac{1}{2}\int_\gamma\int_\gamma dt\ dt'\ dz^A(t)\omega_{AB}(z(t),t)\,\delta(t-t')\wedge dz^B(t'). \tag{II.4}$$

In the same manner, instead of looking at classical observables $f:\Gamma\to\mathbb{C}$, let us consider classical observables $F:\mathscr{P}\Gamma\to\mathbb{C}$ that are functions on the *path* space $\mathscr{P}\Gamma$. The usual ultra-local classical observables F are of the form

$$F(\gamma)=\int_\gamma dt\ f(\gamma(t),t) \quad \text{or} \quad F(\gamma)=f(\gamma(t_1),t_1) \tag{II.5}$$

for some function $f:\Gamma\times[0,T]\to\mathbb{C}$ and $t_1\in[0,T]$. Examples are the BRST-improved Hamiltonian $H_{\mathrm{BRST}}(z(t),t)$ and the BRST charge $\Omega(z(t),t)$. The path space versions read

$$H_{\mathrm{BRST}}=H_{\mathrm{BRST}}(\gamma)=\int_\gamma dt H_{\mathrm{BRST}}(\gamma(t),t),$$

$$\Omega=\Omega(\gamma)=\int_\gamma dt\Omega(\gamma(t),t),$$

$$\{\Omega,\Omega\}=0, \quad \{\Omega,H_{\mathrm{BRST}}\}=0. \tag{II.6}$$

The classical observables of the form (II.5) are formally the fundamental building blocks for all classical observables, i.e., a classical observable F in path space is a formal powerseries of the type (II.5). As a particular example we allow that the gauge fermion $\psi:\mathscr{P}\Gamma\to\mathbb{C}$ is a power series of these building blocks.

III. THE SPACE OF GAUGE CHOICES

Let us analyze the set of gauge fermions in more detail. First of all, it turns out that we can define a Grassmann odd bracket structure among the gauge fermions. We have chosen here to start with this construction to emphasize its fundamental nature. We shall later see how this anti-algebra can be realized in the algebra of vector fields as BRST-like vector fields. When exponentiating to the corresponding groups we realize the corresponding BRST flow or—what turn out to be the same—the gauge-fixing flow; see Sec. IV.

A. An anti-Lie-bracket

An anti-Lie-bracket in the space $C^\infty(\mathscr{P}\Gamma)$ of ''classical'' observables is defined via the Poisson bracket and the BRST charge:

$$(F,G)=\frac{i}{\hbar}(-1)^{\epsilon_F}\{\Omega,FG\}=\frac{i}{\hbar}\{FG,\Omega\}(-1)^{\epsilon_G+1}=-(-1)^{(\epsilon_F+1)(\epsilon_G+1)}(G,F). \tag{III.1}$$

The anti-Lie-bracket is of odd Grassmann parity and it has ghost number $+1$. It satisfies the correct symmetry property, the Jacobi identity, but not the Poisson property.

B. Group of gauge fermions

The space of gauge fermions $\psi:\mathscr{P}\Gamma\to\mathbb{C}$ with ghost number -1 equipped with this anti-Lie-bracket is an infinite-dimensional Lie-algebra, which we denote $\mathscr{G}$. The corresponding group G is identified with precisely the same space of ghost number -1 functions $\Psi:\mathscr{P}\Gamma\to\mathbb{C}$, so $G=\mathscr{G}$. The group G is endowed with an associative product $\diamond:G\times G\to G$,

$$\Psi_1\diamond\Psi_2=\Psi_1+\Psi_2+\frac{i}{\hbar}\Psi_1\{\Omega,\Psi_2\}, \tag{III.2}$$

and an inversion map $\tau:G\to G$,

$$\tau(\Psi)=-\frac{\Psi}{1+(i/\hbar)\{\Omega,\Psi\}}=-\frac{\Psi}{1+B}=-\Psi e^{-b}. \tag{III.3}$$

We have for convenience introduced

$$b\equiv\frac{i}{\hbar}\{\Omega,\psi\}=\ln(1+B), \quad B\equiv\frac{i}{\hbar}\{\Omega,\Psi\}=e^b-1. \tag{III.4}$$

The algebra elements are in general denoted by a lowercase ψ and the group element are denoted by uppercase Ψ. They are connected via the *bijective* exponential map $\mathrm{Exp}:\mathscr{G}\to G$:

$$\Psi=\mathrm{Exp}(\psi)=\psi e(b),\quad \psi=\mathrm{Ln}(\Psi)=\Psi l(B), \tag{III.5}$$

where e and l are

$$e(b)=\int_0^1 d\alpha\ e^{\alpha b}=\frac{e^b-1}{b}=\frac{B}{b}=\sum_{n=1}^{\infty}\frac{b^{n-1}}{n!}, \tag{III.6}$$

$$l(B)=\frac{\ln(1+B)}{B}=\frac{b}{B}=\sum_{n=1}^{\infty}\frac{(-B)^{n-1}}{n}. \tag{III.7}$$

The neutral element of the Lie group is $\Psi=0$:

$$\Psi\diamond 0=\Psi=0\diamond\Psi,\quad \mathrm{Exp}(0)=0. \tag{III.8}$$

The exponential map obeys the Baker–Campbell–Hausdorff formula:

$$\mathrm{BCH}(u\psi_1,u\psi_2)=\mathrm{Ln}(\mathrm{Exp}(u\psi_1)\diamond\mathrm{Exp}(u\psi_2))=u\psi_1+u\psi_1+\tfrac{1}{2}(u\psi_1,u\psi_2)+\mathscr{O}(u^3),$$

$$\mathrm{Exp}(-\psi)=\tau(\mathrm{Exp}(\psi)). \tag{III.9}$$

This is easiest to prove in an algebra/group representation—a so-called realization—that we describe in the next section.

C. Group of diffeomorphisms

Consider the infinite dimensional Lie group $\mathrm{Diff}(\mathscr{P}\Gamma)$ of diffeomorphisms $\sigma:\mathscr{P}\Gamma\to\mathscr{P}\Gamma$. The corresponding infinite dimensional Lie algebra $\mathrm{Lie}(\mathrm{Diff}(\mathscr{P}\Gamma))$ is identified with the set of bosonic vector fields $X:C^\infty(\mathscr{P}\Gamma)\to C^\infty(\mathscr{P}\Gamma)$ with the usual Lie bracket

$$[X,Y][F]=X[Y[F]]-Y[X[F]]. \tag{III.10}$$

Here we have adapted the common definition[5] of a vector field X that it is a linear derivation on the space of functions $C^\infty(\mathscr{P}\Gamma)$, i.e., that it satisfies a graded Leibnitz' rule. Although this definition has the correct transformation properties under change of coordinate patches and it works in the general case, it has a complication that a more elementary definition of a vector field often doesn't have: It relates naturally to the *reversed* group $(\mathrm{Diff}(\mathscr{P}\Gamma),\overset{\mathrm{op}}{\circ})$ of opposite ordering, where $\sigma_1\overset{\mathrm{op}}{\circ}\sigma_2=\sigma_2\circ\sigma_1$ (or *vice-versa*, the Lie algebra of vector fields acting from the *right* corresponds to the group of usual ordering). To see this, let us write down the pertinent exponential map Exp from the algebra $(\mathrm{Lie}(\mathrm{Diff}(\mathscr{P}\Gamma)),[\cdot,\cdot])$ to the group $(\mathrm{Diff}(\mathscr{P}\Gamma),\overset{\mathrm{op}}{\circ})$. It is defined as follows. For each vector field $X\in\mathrm{Lie}(\mathrm{Diff}(\mathscr{P}\Gamma))$, there exists a unique one-parameter family solution $u\mapsto\sigma_X(u)$, to the first-order differential equation

$$\begin{cases}\dfrac{d}{du}\,\sigma_X(u)=X_{\sigma_X(u)}\\ \varphi_X(u=0)=\mathrm{id}_{\mathscr{P}\Gamma}\end{cases}. \tag{III.11}$$

In greater detail, this means that for all paths γ and functions $f\in C^\infty(\mathscr{P}\Gamma)$

$$\frac{d}{du}\,f\circ\sigma_X(u,\gamma)=X_{\sigma_{X(u,\gamma)}}[f]. \tag{III.12}$$

We shall not try to justify in this infinite dimensional problem that for a fixed path γ such solutions $\sigma_X(u,\gamma)$ exist in some interval $u\in[-\epsilon(\gamma),\epsilon(\gamma)]$. And even worse, these solutions should exist uniformly in γ over path space $\mathscr{P}\Gamma$ for $u\in[0,1]$. To do this properly, we should give a rigorous

definition of an infinite dimensional manifold $\mathscr{P}\Gamma$ of paths. But this would take us too far away from the main scope of this paper. We shall simply assume this can be done. Then the exponential map Exp is defined as $\mathrm{Exp}(X)\equiv\sigma_X(u=1)$. One may show that

$$\sigma_X(u)\circ\sigma_X(v)=\sigma_X(u+v),\quad \sigma_X(u)=\mathrm{Exp}(uX),$$

$$\mathrm{Exp}(uX)\circ\mathrm{Exp}(vX)=\mathrm{Exp}((u+v)X),\quad \mathrm{Exp}(X)^{-1}=\mathrm{Exp}(-X). \tag{III.13}$$

Note that (III.12) implies that

$$\frac{d}{du}\,(\mathrm{Exp}(uX)^*f)\big|_{u=0}=X[f]\equiv\mathscr{L}_X f. \tag{III.14}$$

Together with the boundary condition this yields formally

$$f\circ\mathrm{Exp}(uX)\equiv\mathrm{Exp}(uX)^*f=\sum_{n=0}^{\infty}\frac{1}{n!}(u\mathscr{L}(X))^n f\equiv e^{u\mathscr{L}(X)}f. \tag{III.15}$$

Hence, the formulas for the pull-back and the push-forward read

$$(\mathrm{Exp}(X))^*=e^{\mathscr{L}(X)},$$

$$(\mathrm{Exp}(X))_*Y=Y\circ\sum_{n=0}^{\infty}\frac{1}{n!}X^n\equiv Y\circ e^{\circ X}. \tag{III.16}$$

Moreover, from the reversing property of the pull-back $\sigma_1^*\sigma_2^*=(\sigma_2\circ\sigma_1)^*$, it follows that

$$\mathrm{Exp}(Y)\circ\mathrm{Exp}(X)=\mathrm{Exp}(X)\overset{\mathrm{op}}{\circ}\mathrm{Exp}(Y)=\mathrm{Exp}(\mathrm{BCH}(X,Y)). \tag{III.17}$$

This shows that the Lie algebra of vector fields which acts to the left is naturally associated with the Lie group of *opposite* ordering.

The exponential map $\mathrm{Exp}:\mathrm{Lie}(\mathrm{Diff}(\mathscr{P}\Gamma))\to\mathrm{Diff}(\mathscr{P}\Gamma)$ gives rise to a right action conventionally denoted by a dot

$$.:\mathscr{P}\Gamma\times:\mathrm{Lie}(\mathrm{Diff}(\mathscr{P}\Gamma))\to\mathscr{P}\Gamma. \tag{III.18}$$

Its definition and main properties are

$$\gamma.X=(\mathrm{Exp}(X))\,\gamma,\quad \gamma.0=\gamma,\quad (\gamma.X).Y=\gamma.(\mathrm{BCH}(X,Y)). \tag{III.19}$$

In particular, if the path space $\mathscr{P}\Gamma$ is a right $\mathrm{Lie}(\mathrm{Diff}(\mathscr{P}\Gamma))$ module, i.e., a $C^\infty(\mathscr{P}\Gamma)$ vector space endowed with an action

$$[\,\cdot\,,\cdot\,]:\mathscr{P}\Gamma\times\mathrm{Lie}(\mathrm{Diff}(\mathscr{P}\Gamma))\to\mathscr{P}\Gamma \tag{III.20}$$

satisfying

$$[\gamma,F\ X+G\ Y]=F(\gamma)[\gamma,X]+G(\gamma)[\gamma,Y],$$

$$[a\gamma_1+b\gamma_2,X]=a[\gamma_1,X]+b[\gamma_2,X],$$

$$[[\gamma,X],Y]-[[\gamma,Y]X]-[\gamma,[X,Y]]=0, \tag{III.21}$$

then the exponential map can be understood by simple Taylor expansion:

$$(\mathrm{Exp}(X))\,\gamma = \gamma e^{[\cdot,X]} = \sum_{n=0}^{\infty} \frac{1}{n!} \underbrace{[[\ldots,[\gamma,X],\ldots,X],X]}_{n \text{ commutators}}. \tag{III.22}$$

However, it is unnecessary to assume this.

IV. THE GAUGE-FIXING FLOW

We can now construct a Lie algebra homomorphism $X: \mathcal{G} \to \mathrm{Lie}(\mathrm{Diff}(\mathcal{P}\Gamma))$ that takes a gauge fermion ψ to a bosonic BRST-type vector field X^{ψ} by

$$X: \psi \mapsto X^{\psi} \equiv \frac{i}{\hbar} \psi X_{\Omega}, \quad [X^{\psi_1}, X^{\psi_2}] = X^{(\psi_1,\psi_2)}. \tag{IV.1}$$

The composition of two such vector fields is, remarkably, again a vector field of the same type

$$X^{\psi_1} \circ X^{\psi_2} = X^{\psi_1\{\psi_2,\Omega\}}, \tag{IV.2}$$

because the derivatives of second order cancel. The corresponding Lie group homomorphism

$$\sigma \equiv \mathrm{Exp} \circ X \circ \mathrm{Ln}: G \to \mathrm{Diff}(\mathcal{P}\Gamma) \tag{IV.3}$$

reads

$$\sigma: \Psi \mapsto \sigma_{\Psi} = \mathrm{id}_{\mathcal{P}\Gamma} + \frac{i}{\hbar}\, \Psi X_{\Omega},$$

$$\sigma_{\psi_1 \diamond \Psi_2} = \sigma_{\Psi_1} \overset{\mathrm{op}}{\circ} \sigma_{\Psi_2} = \sigma_{\Psi_2} \circ \sigma_{\psi_1},$$

$$\sigma_{\tau(\Psi)} = (\sigma_{\Psi})^{-1}. \tag{IV.4}$$

This is called a realization of G. As a very important consequence we have a gauge-fixing right group action

$$\diamond : \mathcal{P}\Gamma \times G \to \mathcal{P}\Gamma \tag{IV.5}$$

directly on the path space:

$$\gamma_{\Psi} = \gamma \diamond \Psi = \sigma_{\Psi}(\gamma) = \left(\mathrm{id}_{\mathcal{P}\Gamma} + \frac{i}{\hbar}\, \Psi X_{\Omega} \right) \gamma,$$

$$\gamma \diamond 0 = \gamma,$$

$$(\gamma \diamond \Psi_1) \diamond \Psi_2 = \gamma \diamond (\Psi_1 \diamond \Psi_2). \tag{IV.6}$$

This is the sought after geometric gauge-fixing. The gauge fixing can be understood at the level of paths as a modification of the individual paths!

Again, the expression $\sigma_{\Psi} = \mathrm{id}_{\mathcal{P}\Gamma} + (i/\hbar)\Psi X_{\Omega}$ is quite symbolic, but it is justified by the formula for the pull-back:

$$(\sigma_{\Psi})^{*} = \left(\mathrm{id}_{\mathcal{P}\Gamma} + \frac{i}{\hbar} \Psi X_{\Omega} \right)^{*} = 1 + \frac{i}{\hbar} \mathcal{S}(\Psi X_{\Omega}). \tag{IV.7}$$

The expression can be evaluated directly term by term on the manifold if the path space $\mathcal{P}\Gamma$ is a module wrt. the Lie algebra $(C^{\infty}(\mathcal{P}\Gamma), \{\cdot,\cdot\})$.

Before we carry on, let us for the sake of completeness also define the map

$$\sigma: \psi \mapsto \sigma_\psi = \mathrm{Exp}(X^\psi) = \mathrm{Exp}\left(\frac{1}{\hbar}\,\psi X_\Omega\right): \mathscr{G} \to \mathrm{Diff}(\mathscr{P}\Gamma),$$

$$(\sigma_\psi)^{-1} = \sigma_{-\psi}, \tag{IV.8}$$

and the corresponding right ''gauge-fixing action'' $\mathscr{P}\Gamma \times \mathscr{G} \to \mathscr{P}\Gamma$ on the path space $\mathscr{P}\Gamma$ from the Lie algebra $\mathscr{G}$:

$$\gamma.\psi = \sigma_\psi(\gamma) = \left(\mathrm{Exp}\left(\frac{i}{\hbar}\,\Psi X_\Omega\right)\right)\gamma,$$

$$\gamma.0 = \gamma,$$

$$(\gamma.\psi_1).\psi_2 = \gamma.(\mathrm{BCH}(\psi_1, \psi_2)). \tag{IV.9}$$

A. Gauge-fixed quantities

The gauge-fixed classical observables F_ψ are defined via the pull-back of the gauge-fixing map:

$$\begin{aligned} F_\psi(\gamma) &= (\sigma_\psi^* F)(\gamma) = F(\sigma_\psi(\gamma)) \\ &= F(\gamma) + \frac{i}{\hbar}\,\Psi(\gamma)\{\Omega(\gamma), F(\gamma)\} \\ &= e^{(i/\hbar)\psi(\gamma)\{\Omega(\gamma),\cdot\}} F(\gamma). \end{aligned} \tag{IV.10}$$

The BRST-improved Hamiltonian H_{BRST} and the BRST charge Ω are not changed by the gauge fixing flow, because of (II.6). The gauge-fixed symplectic two-form and the symplectic potential are remarkably simple, but clearly nonlocal:

$$\omega_\Psi = \sigma_\Psi^* \omega = \omega + \frac{i}{\hbar}\, d\Psi \wedge d\Omega, \tag{IV.11}$$

$$\vartheta_\Psi = \sigma_\Psi^* \vartheta = \vartheta + \frac{i}{\hbar}\,\Psi d\Omega + \frac{i}{\hbar}\, d[\Psi i_{X_\Omega}\vartheta]. \tag{IV.12}$$

The gauge-fixed Poisson bracket satisfies

$$\{F_\Psi, G_\Psi\}_\Psi = (\{F, G\})_\Psi, \tag{IV.13}$$

or written more explicitly

$$\begin{aligned} \{F,G\}_\Psi &= \sigma_\Psi^*(\{\sigma_{\tau(\Psi)}^* F, \sigma_{\tau(\Psi)}^* G\}) \\ &= \{F,G\} - \frac{i}{\hbar}\,\{F,\Psi\}\,\frac{1}{1+B}\,\{\Omega,G\} - \frac{i}{\hbar}\,\{F,\Omega\}\,\frac{1}{1+B}\,\{\Psi,G\} \\ &\quad + \left(\frac{i}{\hbar}\right)^2 \{F,\Omega\}\,\frac{\{\Psi,\Psi\}}{(1+B)^2}\,\{\Omega,G\} \\ &= \{F,G\} - \frac{i}{\hbar}\,\{F,\psi e(b)\} e^{-b}\{\Omega,G\} - \frac{i}{\hbar}\,\{F,\Omega\} e^{-b}\{e(b)\psi,G\} \\ &\quad + \left(\frac{i}{\hbar}\right)^2 \{F,\Omega\} e^{-b}\{e(b)\psi,\psi e(b)\} e^{-b}\{\Omega,G\}. \end{aligned} \tag{IV.14}$$

These formulas follow by straightforward application of (IV.10). The derivation becomes somewhat easier if one first derives (IV.14) for $G=F$ being Grassmann odd. Then one may use the polarization formula $\{F,G\}=\frac{1}{2}(\{F+G,F+G\}-\{F,F\}-\{G,G\})$ and finally linearity to extend to functions of both Grassmann-parities. An even simpler way is the following matrix calculation. Define, cf. (IV.11):

$$\omega_{\Psi AB}(t,t')=\omega_{AB}(t,t')+\Delta\omega_{AB}(t,t'),$$

$$\Delta\omega_{AB}(t,t')=\frac{i}{\hbar}\left(\frac{\vec{\delta}^l}{\delta z^A(t)}\,\Psi\right)\left(\Omega\,\frac{\overleftarrow{\delta}^r}{\delta z^B(t')}\right)+\frac{i}{\hbar}\left(\frac{\vec{\delta}^l}{\delta z^A(t)}\,\Omega\right)\left(\Psi\,\frac{\overleftarrow{\delta}^r}{\delta z^B(t')}\right). \tag{IV.15}$$

Then the inverse matrix is

$$[\omega_\Psi]^{-1}=([1]+[\omega]^{-1}[\Delta\omega])^{-1}[\omega]^{-1}$$

$$=\sum_{n=0}^{\infty}(-[\omega]^{-1}[\Delta\omega])^{-1})^n[\omega]^{-1}. \tag{IV.16}$$

It is easy to see that this sums up to (IV.14) with $F=z^A(t)$ and $G=z^B(t')$ substituted.

The BRST closed (and therefore BRST exact) quantities are constant under the BRST gauge-fixing flow. A BRST exact quantity

$$\{\Omega,F\}=\{\Omega,F_\psi\}_\psi,\quad \Omega_\psi=\Omega, \tag{IV.17}$$

can be written BRST exactly wrt. the gauge-fixed structure. As an important consequence the BRST cohomology is not affected by the gauge-fixing.

V. THE BFV PATH INTEGRAL

In this section we shall formally prove the BFV theorem in the path space formulation, by inspecting the various parts of the path integral. We have already argued that the BRST improved Hamiltonian $H_{\rm BRST}$ is not modified by the gauge fixing flow. Below we shall analyze the measure part and the kinetic part.

A. The volume form

Let us denote the volume form by $\Omega_{\rm vol}=\mathscr{D}z\,{\rm Pf}(\omega..)$. The gauge-fixed volume form can remarkably be written as

$$\sigma_\psi^*\Omega_{\rm vol}=\Omega_{\rm vol}\,\frac{1}{1+B}=\Omega_{\rm vol}e^{-(i/\hbar)\{\Omega,\psi\}}. \tag{V.1}$$

It is perhaps surprising that the gauge-fixing term, which can be view as a way to remove zero directions in the Hessian of the action, from a geometric point of view has little to do with the action. In fact, the above shows that it emerges from the measure part, completely dictated by the gauge-fixing flow. Because of the importance of (V.1), let us indicate a proof in the case of a finite number $2n$ of purely bosonic variables $z^A(t)=z^I$, where $(A,t)=I=1,...,2n$, so that

$$\Omega_{\rm vol}=\frac{1}{n!}\,\omega^{\wedge n}=\frac{1}{n!}\,\omega\wedge\cdots\wedge\omega. \tag{V.2}$$

If there are fermionic variables present, the volume form is no longer the nth exterior power of the symplectic two form, and the analysis becomes more involved. However, let's stick to the bosonic case. The gauge-fixed top-form is, cf. (IV.11),

$$\sigma_\Psi^*\Omega_{\rm vol}=\frac{1}{n!}\,\sigma_\Psi^*\Omega\wedge\cdots\wedge\sigma_\Psi^*\omega$$

$$
\begin{aligned}
&= \sum_{r=0}^{n} \frac{1}{(n-r)!r!}\, \omega^{\wedge(n-r)} \wedge \left(\frac{i}{\hbar}\, d\Psi \wedge d\Omega \right)^{\wedge r} \\
&= \sum_{r=0} \frac{1}{(n-r)!r!}\, \omega^{\wedge(n-r)} \wedge \sum_{I_1,\ldots,I_r} \left(\frac{i}{\hbar}\, dz^{I_1} \frac{\delta\Psi}{\delta z^{I_1}} \wedge d\Omega \right) \wedge \cdots \wedge \left(\frac{i}{\hbar}\, dz^{I_r} \frac{\delta\Psi}{\delta z^{I_r}} \wedge d\Omega \right).
\end{aligned}
\tag{V.3}
$$

Because of covariance, one may resort to Darboux coordinates $z^I=(q^i,p_i)$, $i=1,\ldots,n$. Then

$$
\{q^i,p_j\}=\delta^i_j, \quad \omega = dp_i \wedge dq^i. \tag{V.4}
$$

A simple combinatorial argument yields

$$
\begin{aligned}
\sigma^*_\Psi \Omega_{\mathrm{vol}} &= (dp_1 \wedge dq^1) \wedge \cdots \wedge (dp_n \wedge dq^n) \sum_{r=0}^{n} \sum_{i_1,\ldots,i_r} \left(-\frac{i}{\hbar} \right) \left(\frac{\delta\Psi}{\delta q^{i_1}} \frac{\delta\Omega}{\delta p_{i_1}} - \frac{\delta\Psi}{\delta p_{i_1}} \frac{\delta\Omega}{\delta q^{i_1}} \right) \\
&\quad \times \cdots \times \left(-\frac{i}{\hbar} \right) \left(\frac{\delta\Psi}{\delta q^{i_r}} \frac{\delta\Omega}{\delta p_{i_r}} - \frac{\delta\Psi}{\delta p_{i_r}} \frac{\delta\Omega}{\delta q^{i_r}} \right) \\
&= \Omega_{\mathrm{vol}} \sum_{r=0}^{n} (-B)^r = \Omega_{\mathrm{vol}}\, \frac{1-(-B)^{n+1}}{1+B}.
\end{aligned}
\tag{V.5}
$$

Now we formally take the $n=\infty$ limit to derive (V.1).

B. The kinetic part

We have already analyzed the variation of the Hamiltonian part and the measure under the gauge-fixing flow. Let us now draw our attention to the last piece of the path integral, namely the kinetic term. It is handy to introduce a vector field T that calculates the difference between the total time derivative and the explicit time derivative:

$$
T \equiv \frac{d}{dt} - \frac{\partial}{\partial t} = \int_\gamma dt\, \dot{\gamma}^A(t)\, \frac{\vec{\delta}^l}{\delta z^A(t)} : \; C^\infty(\mathscr{P}\Gamma) \to C^\infty(\mathscr{P}\Gamma). \tag{V.6}
$$

The kinetic term can be written as the contraction of the symplectic potential with this vector field:

$$
i_T \upsilon(\gamma) = \int_\gamma dt\; \vartheta_A(t)\, \dot{\gamma}^A(t), \quad \vartheta(\gamma) = \int_\gamma dt\; \vartheta_A(t) dz^A(t). \tag{V.7}
$$

We can now write the gauge-fixed BFV path integral as

$$
Z_\psi = \int \Omega_{\mathrm{vol}} e^{(i/\hbar)(i_T\vartheta - H_{\mathrm{BRST}} - \{\Omega,\psi\})}. \tag{V.8}
$$

We would like to only sum over paths in the path integral so that the kinetic term for these paths is left invariant under the gauge-fixing flow. In fact, if this is fulfilled, we have realized gauge-fixing as an internal diffeomorphism of the path integral. [Perhaps it is helpful at this point to recall that every integral $I=\int f(x)dx=\int f(\sigma(x))d\sigma(x)$ by the very definition is diffeomorphism invariant; x is just a dummy variable.] Thus the path integral cannot depend on the gauge fermion and we can conclude the BFV theorem. To achieve this conclusion, one should restrict the path space by only allowing for paths satisfying the following BRST boundary condition

$$
(i_{X_\Omega}\vartheta)(\gamma)\big|_{t=0} + \Omega(\gamma)\big|_{t=0} = (i_{X_\Omega}\vartheta)(\gamma)\big|_{t=T} + \Omega(\gamma)\big|_{t=T}. \tag{V.9}
$$

Because of the formula

$$i_{X_\Omega}\vartheta(\gamma)=\int_\gamma dt\ \vartheta_A(t)X^A_\Omega(t) \tag{V.10}$$

and because Ω is BRST invariant, we have

$$\begin{aligned} X_\Omega[i_{X_\Omega}\vartheta](\gamma)&=\int_\gamma\int_\gamma dt\ dt' X^B_\Omega(t')\ \frac{\overrightarrow{\delta}^l}{\delta z^B(t')}\,[\vartheta_A(t)X^A_\Omega(t)]\\ &=\frac{1}{2}\int_\gamma dt[X_\Omega,X_\Omega]^A(t)\vartheta_A(t)(-1)^{\epsilon_A}+\int_\gamma\int_\gamma dt\ dt' X^A_\Omega(t)X^B_\Omega(t')\ \frac{\overrightarrow{\delta}^l}{\delta z^B(t')}\ \vartheta_A(t)\\ &=\frac{1}{2}\int_\gamma dt\ X^A_{\{\Omega,\Omega\}}(t)\vartheta_A(t)(-1)^{\epsilon_A}+\frac{1}{2}\int_\gamma\int_\gamma dt\ dt' X^A_\Omega(t)X^B_\Omega(t')\omega_{BA}(t',t)=0. \end{aligned} \tag{V.11}$$

Together with $X_\Omega[\Omega]=0$ this yields that the above boundary condition on the paths is stabile under the gauge-fixing action of $\mathscr{G}$. We will assume that a vector field

$$X:\gamma\mapsto X_\gamma=\int_\gamma dt\ X^A(t)\ \frac{\overrightarrow{\delta}^l}{\delta z^A(t)} \tag{V.12}$$

has the following dependence on the path γ:

$$X^A(t)=X^A(\gamma,\gamma(t),t). \tag{V.13}$$

Under the assumption that the original symplectic potential $\vartheta_A(t)=\vartheta_A(\gamma(t))$ is ultra-local and that it has no explicit time dependence (and therefore the symplectic two form is also of that kind), one derives that a generic vector field X changes the kinetic term with

$$X[i_T\vartheta](\gamma)=i_X\vartheta|_{\gamma,\gamma(t=T),t=T}-i_X\vartheta|_{\gamma,\gamma(t=0),t=0}+\int_\gamma dt\ X^A(t)\omega_{AB}(t)\dot{z}^B(t). \tag{V.14}$$

Assuming that Ω is ultra-local and that it has no explicit time dependence and using the boundary condition (V.9), we therefore conclude that the kinetic term is invariant under the gauge-fixing flow $X=\psi X_\Omega$.

C. Infinitesimal gauge-fixing flow

Above we have argued from a formal point of view that turning on or turning off gauge fixing does not change the value of the path integral. In real applications, like quantum field theory, turning off gauge fixing makes the path integral ill-defined, as a result of integrating over an infinite gauge volume. That is why gauge fixing is introduced in the first place. It is therefore desirable to have an infinitesimal analysis.

Consider the map

$$L_{\mathrm{Exp}}:\mathscr{G}\to\mathrm{Aut}(G):\psi\mapsto L_{\mathrm{Exp}(\psi)}, \tag{V.15}$$

where L_Ψ is the left multiplication map with a fixed Ψ

$$L_\Psi(\Psi')=\Psi\diamond\Psi'. \tag{V.16}$$

Then by definition

$$L_{\mathrm{Exp}(0)}=\mathrm{id}_G. \tag{V.17}$$

Let us consider an infinitesimal change $\psi\to\psi+\delta\psi$ in the gauge fermion. The relevant object is the differential of L_{Exp} in $\psi=0$,

$$(L_{\mathrm{Exp}})_{*0}: T_0\mathscr{G} \to T_{\mathrm{id}_G}\mathrm{Aut}(G). \tag{V.18}$$

It reads

$$\Psi + \delta\Psi = ((L_{\mathrm{Exp}})_{*0}\delta\psi)(\Psi) = h_\Psi(\delta\psi) \diamond \Psi. \tag{V.19}$$

Here the function $h: \mathscr{G} \times T_0\mathscr{G} \to \mathscr{G}$ is

$$\begin{aligned} h_\psi(\delta\psi) &= (\Psi + \delta\Psi) \diamond \tau(\Psi) = \frac{\delta\Psi}{1+B} = \frac{\mathrm{Exp}_{*\psi}(\delta\psi)}{1+B} \\ &= e^{-b} e(b)\,\delta\psi + e^{-b} e'(b)\,\psi\{\Omega, \delta\psi\} \\ &= \frac{1-e^{-b}}{b}\,\delta\psi + \frac{b-1+e^{-b}}{b^2}\,\psi\{\Omega, \delta\psi\}. \end{aligned} \tag{V.20}$$

We have identified the tangent space $T_{\mathrm{id}_G}\mathrm{Aut}(G)$ with maps from the group G that to each element Ψ of the group G give an element in $\mathscr{G} \diamond \Psi$.

So the infinitesimal change in the gauge-fixing flow $\sigma_{\psi+\delta\psi} \circ \sigma_{-\psi}$ is governed by a BRST-type vector field, cf. (IV.6),

$$X^{h_\psi(\delta\psi)} = h_\psi(\delta\psi) X_\Omega. \tag{V.21}$$

Note that

$$\{\Omega, h_\psi(\mu)\} = \{\Omega, \mu\}, \quad h_{\alpha\psi}(\psi) = \alpha\psi. \tag{V.22}$$

We can now derive the infinitesimal change of various objects under an infinitesimal change $\psi \to \psi + \delta\psi$ of the gauge fermion caused by the vector field $X^{h_\psi(\delta\psi)}$. For instance, the measure changes according to

$$\mathrm{div}_\rho\, X^{h_\psi(\delta\psi)} = -\frac{i}{\hbar}\{\Omega, \delta\psi\}. \tag{V.23}$$

This is precisely the infinitesimal change in the gauge-fixed action.

VI. THE Sp(2) CASE

The whole construction can easily be extended to the Sp(2) case.[4] We shall thus be brief and just state the construction.

In the Sp(2) case we have two odd BRST charges Ω^a, $a = 1,2$, that are mutual orthogonal in the Poisson bracket sense:

$$\{\Omega^a, \Omega^b\} = 0. \tag{VI.1}$$

We define a Grassmann even bracket

$$[F, G] = Fk(G) - k(F)G = -(-1)^{\epsilon_F \epsilon_G}[G, F], \tag{VI.2}$$

where k is a Grassmann even nilpotent second order operator

$$k = \frac{i}{2\hbar}\,\epsilon_{ab} X_{\Omega^a} \circ X_{\Omega^b}, \quad k^2 = 0,$$

$$k(F) = \frac{i}{2\hbar}\,\epsilon_{ab}\{\Omega^a, \{\Omega^b, F\}\} = \frac{i}{2\hbar}\,\{\{F, \Omega^a\}, \Omega^b\}\epsilon_{ab}. \tag{VI.3}$$

The Grassmann even bracket satisfies the usual symmetry property, the Jacobi identity, but not the Poisson property. We define a degenerate metric structure (a covariant 2-tensor)

$$g(F,G)=k(F)G+Fk(G)-k(FG)$$
$$=\frac{i}{\hbar}\{F,\Omega^a\}\epsilon_{ab}\{\Omega^b,G\}$$
$$=+(-1)^{\epsilon_F\epsilon_G}g(G,F). \tag{VI.4}$$

k and g satisfy the following relations

$$g(k(F),G)=0,\quad k(g(F,G))=2k(F)k(G), \tag{VI.5}$$

$$g(F,g(G,H))=\tfrac{1}{2}\,g(F,G)k(H)+\tfrac{1}{2}\,g(F,H)k(G)(-1)^{\epsilon_G\epsilon_H}. \tag{VI.6}$$

We have a Jacobi-like identity:

$$g(F,g(G,H))-(-1)^{\epsilon_F\epsilon_G}g(G,g(F,H))=g([F,G],H). \tag{VI.7}$$

The gauge is now chosen by specifying a gauge *boson* ϕ. (Our gauge boson is *minus a half* of the BLT gauge boson.) The even bracket $[\,\cdot\,,\cdot\,]$ is a Lie-bracket in the algebra $\mathscr{G}$ of gauge bosons. The space $G=\mathscr{G}$ of gauge bosons becomes a Lie group by introducing a product and an inversion

$$\Phi_1\diamond\Phi_2=\Phi_1+\Phi_2+\Phi_1k(\Phi_2),$$
$$\tau(\Phi)=-\frac{\Phi}{1+B}=-\Phi e^{-\bar{b}}, \tag{VI.8}$$

where

$$\bar{b}=\frac{i}{2\hbar}\,\epsilon_{ab}\{\Omega^a,\{\Omega^b,\phi\}\}=k(\phi)=\mathrm{Ln}(1+\bar{B}),$$
$$\bar{B}=\frac{i}{2\hbar}\,\epsilon_{ab}\{\Omega^a,\{\Omega^b,\Phi\}\}=k(\Phi)=e^{\bar{b}}-1, \tag{VI.9}$$

and ϕ and Φ are connected via the bijective exponential map Exp: $\bar{\mathscr{G}}\to\bar{G}$

$$\Phi=\mathrm{Exp}(\phi)=\phi e(\bar{b}),\quad \phi=\mathrm{Ln}(\Phi)=\Phi l(\bar{B}). \tag{VI.10}$$

We can define a homomorphism $\Psi_a:\bar{\mathscr{G}}\to\mathscr{G}_a$ that transforms a gauge boson ϕ into a gauge fermion. [To be precise, $\Psi_a(\phi)=1/2\psi$ is *half* the corresponding gauge fermion of the standard BFV-BRST construction.] $\Psi_a(\phi)$ of the kind $a=1,2$ (corresponding to the generator Ω^a)

$$\Psi_a(\,\cdot\,)=\epsilon_{ab}X_{\Omega^b}(\,\cdot\,)$$
$$\Psi_a(F)=\epsilon_{ab}\{\Omega^b,F\}=(-1)^{\epsilon_F}\{F,\Omega^b\}\epsilon_{ba},$$
$$\Psi_a([\phi_1,\phi_2])=(\Psi_a(\phi_1),\Psi_a(\phi_2))^a,$$
$$\Psi_a(\Phi_1\diamond\Phi_2)=\Psi_a(\Phi_1)\diamond\Psi_a(\Phi_2) \tag{VI.11}$$

(no sum over a). Note that

$$\frac{i}{\hbar}\{\Omega^a,\Psi_b(F)\}=\delta^a_bk(F). \tag{VI.12}$$

The algebra homomorphism $\bar{X}:\bar{\mathscr{G}}\to\mathrm{Lie(Diff)}(\mathscr{P}\Gamma))$ is the sum of the two BRST homomorphisms

$$\overline{X}:\phi\mapsto\overline{X}^{\phi}\equiv g(\phi,\cdot)=\frac{i}{\hbar}\,\Psi_a(\phi)X_{\Omega^a},\quad [\overline{X}^{\phi_1},\overline{X}^{\phi_2}]=\overline{X}^{[\phi_1,\phi_2]}. \tag{VI.13}$$

The corresponding Lie group homomorphism $\overline{\sigma}\equiv\mathrm{Exp}\circ\overline{X}\circ\mathrm{Ln}:\overline{G}\to\mathrm{Diff}(\mathscr{P}\Gamma)$ reads

$$\begin{aligned}&\overline{\sigma}:\Phi\mapsto\overline{\sigma}_{\Phi}=\mathrm{id}_{\mathscr{P}\rho\Gamma}+g(\Phi,\cdot)+\tfrac{1}{2}\,g(\Phi,\Phi)k(\cdot),\\ &\overline{\sigma}_{\Phi_1\diamond\Phi_2}=\overline{\sigma}_{\Phi_1}\overset{\mathrm{op}}{\circ}\overline{\sigma}_{\Phi_2},\\ &\overline{\sigma}_{\tau(\Phi)}=(\overline{\sigma}_{\Phi})^{-1}.\end{aligned} \tag{VI.14}$$

The pull-back map $(\overline{\sigma}_{\Phi})^*$ is

$$(\overline{\sigma}_{\Phi})^*=1+\frac{i}{\hbar}\,\Psi_a(\Phi)\mathscr{L}(X_{\Omega^a})+\frac{i}{2\hbar}\,\epsilon_{ab}g(\Phi,\Phi)\mathscr{L}(X_{\Omega^a})\circ\mathscr{L}(X_{\Omega^b}). \tag{VI.15}$$

The gauge-fixed symplectic two form reads

$$\omega_{\Phi}=\overline{\sigma}_{\Phi}^{*}\omega=\omega+\frac{i}{\hbar}\,d\Psi_a(\Phi)\wedge d\Omega^a. \tag{VI.16}$$

The gauge-fixed volume form reads

$$\overline{\sigma}_{\phi}^{*}\Omega_{\mathrm{vol}}=\Omega_{\mathrm{vol}}\,\frac{1}{(1+\overline{B})^2}=\Omega_{\mathrm{vol}}e^{-(i/\hbar)\epsilon_{ab}\{\Omega^a,\{\Omega^b,\phi\}\}}. \tag{VI.17}$$

(Received 19 May 1997; accepted for publication 8 December 1997)

We consider a one-dimensional Stark–Wannier Hamiltonian, $H=-d^2/dx^2+p(x)-\epsilon x$, $x\in\mathbb{R}$, where p is a smooth periodic, finite-gap potential, and $\epsilon>0$ is small enough. We compute rigorously the imaginary parts of the spectral resonances. For this purpose we develop some related elements of the adiabatic approach to the equations of the form $-\psi''+p(x)\psi+q(\epsilon x)\psi=E\psi$, $\epsilon\to 0$. © *1998 American Institute of Physics.* [S0022-2488(98)03104-1]

I. INTRODUCTION

Stark–Wannier resonances are related with the operator H, which is defined by the expression

$$H=-\frac{d^2}{dx^2}+p(x)-\epsilon x, \quad x\in\mathbb{R}. \tag{1}$$

Here $p(x)$ is a smooth real-valued periodic function, $p(x+a)=p(x)$, and ϵ is a positive small parameter. The operator H is considered as self-adjoint in $L^2(\mathbb{R})$ on the natural domain. The operator has a simple absolutely continuous spectrum coinciding with all the real axis $\mathbb{R}$.

Let us describe the resolvent $R(E)=(H-E)^{-1}$. In Ref. 1 some solutions of the equation

$$-\psi''+p(x)-\epsilon x\psi=E\psi, \tag{2}$$

with characteristic behavior as $x\to\pm\infty$, have been constructed. Assume as in Ref. 1 that

$$\int_0^a p(x)dx=0. \tag{3}$$

Then there exists the solution $g_-=g_-(x,E)$, which possesses the following asymptotic behavior as $x\to-\infty$:

$$g_-\sim\frac{1}{2|\xi+E|^{1/4}}\,e^{-(2/3\epsilon)|\xi+E|^{3/2}}, \quad \xi=\epsilon x. \tag{4}$$

It is defined for $E\in\mathbb{C}$ and is an entire function of E. There exists also the solution $f_+=f_+(x,E)$ with the following behavior for $x\to+\infty$:

$$f_+\sim\frac{1}{\sqrt{2}|\xi+E|^{1/4}}\,e^{i(2/3\epsilon)|\xi+E|^{3/2}}, \quad \xi=\epsilon x. \tag{5}$$

It is defined as a continuous function of E for $\mathrm{Im}\,E\geqslant 0$ and is a holomorphic function for $\mathrm{Im}\,E>0$.

It is clear that

$$g_-=\overline{M}f_+ + M\overline{f_+}, \tag{6}$$

 © 1998 American Institute of Physics

where $M=M(E)$ is continuous for $\operatorname{Im} E\geqslant 0$ and is holomorphic for $\operatorname{Im} E>0$. The function M is periodic: $M(E+\epsilon a)=M(E)$.

The resolvent is the integral operator with the kernel

$$R(x,y,E)=iN(x,y,E)/M(E), \quad \operatorname{Im} E>0,$$
$$N(x,y,E)=g_-(x,E)f_+(y,E), \quad x\leqslant y. \tag{7}$$

We shall assume that $p(x)$ is holomorphic in the strip $|\operatorname{Im} x|<\alpha$. Then the solution f_+ and the function M admit an analytical continuation to the extended half-plane $\operatorname{Im} E>-\epsilon\alpha$. The function M does not have roots when $\operatorname{Im} E\geqslant 0$, but can have them in the strip $-\epsilon\alpha<\operatorname{Im} E<0$. Namely these roots are Stark–Wannier resonances. They create periodic lattices with the period ϵa.

The question of the existence of the resonances and of the description on their parameters has a long history. Comments on this account can be found in Ref. 2. In the last decade new works appeared, where the question was treated from several different points of view. Let us mention some of these works: Refs. 3–8. Studies begun in these works are being continued in the last years; see, for example, Refs. 9 and 10. We will not enter in the history in more detail. Our main aim is the development of the results of the paper in Ref. 1.

In Ref. 1 the potential p was assumed to be a finite-gap potential and the parameter ϵ to be small. As a confirmation of old results of theorists (which should be considered as conjectures from the math–physics point of view), it was proved that there is a correspondence between the spectral bands of the operator H_0 with periodic potential

$$H_0=-\frac{d^2}{dx^2}+p(x), \tag{8}$$

and the periodic ladders of Stark–Wannier resonances. Their real parts were described asymptotically by some quantization conditions. The problem of the description of the imaginary parts of the resonances is more subtle. In Ref. 1, it was shown that for the periodic ladder of resonances E_n^j, l is the number of the ladder, n is the number of the resonance:

$$\operatorname{Im} E_n^l\sim -a_l\epsilon e^{-(1/\epsilon)A_l}, \quad a_l,A_l>0. \tag{9}$$

However, this result was not strictly proved in Ref. 1, since the order of error obtained in Ref. 1 was worse than the order of the main asymptotical term itself.

The goal of the present work is the justification of formula (9). We will show that this result can be obtained by the methods of Ref. 1, after their natural development. We will use the present paper also in order to improve these methods in different directions, in particular, for the description of the solutions of Eq. (2) in vicinities of turning points. Another approach to the treatment of imaginary parts of the resonances was suggested recently in Ref. 10.

As a technical basis for the study of the resonances we will use the adiabatical approach to the equations of the form

$$-\psi''+v(x,\epsilon x)\psi=E\psi, \tag{10}$$

where $v(x,\xi)$ is a periodic function of the first argument, $v(x+a,\xi)=v(x,\xi)$. General initial facts about the adiabatical method and its spectral applications can be found in Refs. 2 and 11. The adiabatical method can be considered as a generalization of the standard Wentzel–Kramers–Brillouin (WKB) method for the equation

$$-\psi''+v(\epsilon x)\psi=E\psi. \tag{11}$$

In this approach, as in the standard WKB approach, the notion of the turning point is very essential. In such a point the character of the asymptotic behavior of solutions changes crucially. For a description of the asymptotics of the solutions in vicinities of the turning points in the standard WKB method there exist different approaches. We discuss here analogs of these approaches in more detail than in the previous publications.

The structure of the text is the following. In Sec. II we are reminded of some general properties of the solutions of the Schrödinger equation with purely periodic potentials. We represent these properties in a form that is the most suitable for the further applications to the adiabatic perturbations. In particular, we pay special attention to problems with some additional external parameter. Sections III A and III B contain a list of main properties of solutions of the adiabatically perturbed problem with the linear perturbing potential. We do not prove these properties in these sections and simply formulate them. In the rest of the section we use the listed properties in order to compute the imaginary parts of the resonances. The two last sections are devoted to the justifications of the used properties of the solutions of the adiabatically perturbed equations. Section IV contains a description of the formal asymptotic solutions in different circumstances: out of vicinities of the turning points and in the vicinities of such points. In the last section, Sec. V, we construct true solutions of the perturbed equation, which can be described asymptotically by the previously introduced formal solutions. Namely, these solutions and their asymptotics are used in Sec. III in order to compute the imaginary parts of the resonances.

II. THE SCHRÖDINGER EQUATION WITH PERIODIC POTENTIALS

This part contains some necessary information on the solutions of the equations with purely periodic potentials:

$$-u''+p(x)u=Eu. \tag{12}$$

We will also describe the notion of the isoenergy curve that appears for the equation

$$-u''+v(x,\xi)u=Eu, \tag{13}$$

with the periodic potential $v(x+a,\xi)=v(x,\xi)$ depending on the external parameter ξ.

A. The Schrödinger equation with periodic potentials

Consider the solutions of (12) of the form

$$u(x)=e^{ikx}\varphi(x), \tag{14}$$

where k is a given parameter (quasimomentum), $\varphi(x+a)=\varphi(x)$. For the fixed real k there exists a countable set of such solutions:

$$u_l(x,k)=e^{ikx}\varphi_l(x,k), \quad E=\mathscr{E}_l(k)\in\mathbb{R}, \quad l=1,2,\ldots . \tag{15}$$

The functions $\mathscr{E}_l(k)$ are periodic with the period $a^*=2\pi/a$, the solutions $u_l(x,k)$ can also be considered as periodic with respect to k. Properties of the plots of $\mathscr{E}_l$ are reflected by the Fig. 1.

Let $\min \mathscr{E}_l=E_{2(l-1)}$, $\max \mathscr{E}_l=E_{2l-1}$. For special potentials the equality $E_{2l-1}=E_{2l}$ is possible. Out of such levels:

$$\mathscr{E}_1(k)=E_0+\frac{1}{2M_0}k^2+\ldots, \quad \mathscr{E}_1(k)=E_1-\frac{1}{2M_1}(k-k^*)^2+\cdots,$$

$$\mathscr{E}_2(k)=E_2+\frac{1}{2M_2}(k-k^*)^2+\cdots, \quad \mathscr{E}_2(k)=E_3-\frac{1}{2M_3}k^2+\cdots,$$

$$k^*=\tfrac{1}{2}a^*, \quad M_0,M_1,\ldots>0. \tag{16}$$

Other critical points except 0 (mod k^*), are absent. The intervals $\Delta_l=[E_{2(l-1)},E_{2l-1}]$ are spectral intervals of Eq. (12) considered on the entire axis. The intervals $\Delta_0=(-\infty,E_0)$, $\Delta_l=(E_{2l-1},E_{2l})$ are the gaps in the spectrum of the equation. The number of the nonempty gaps can be finite. The corresponding potentials are called the finite-gap potentials. If the number of the finite gaps is Q, the potential is called the Q-gap potential. We will assume that the potential p is a finite-gap potential but shall not use the known explicit formulas for such potentials. For simplicity we will assume that the open gaps are the first gaps.

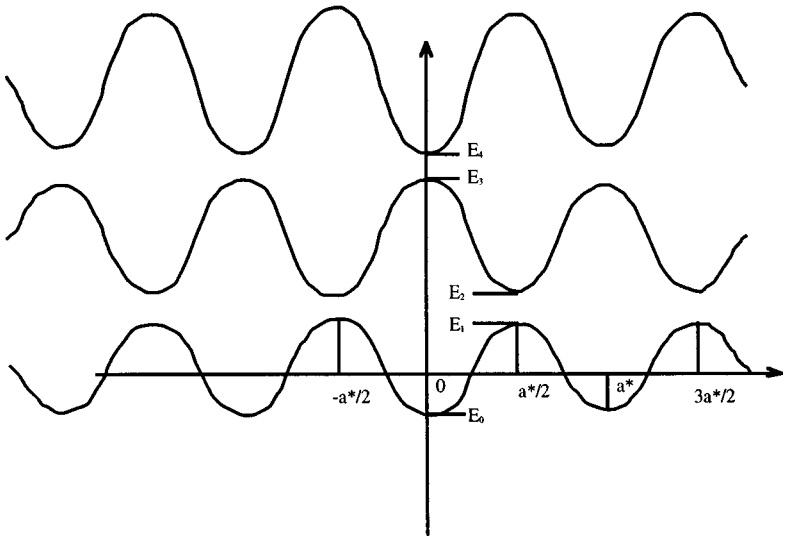

FIG. 1.

The function $\mathscr{E}_l$ can be continued analytically on the complex plane with some cuts; see Fig. 2. In fact, it is a function on the complex cylinder $\mathbb{C}/\{a^*\mathbb{Z}\}$ with the cuts. The parameters h_l, h_{l-1} depend on the potential p.

Consider the function $\mathscr{E}_l(k)$ on the intervals $((l-1)k^*, lk^*), (-lk^*, -(l-1)k^*)$. On the real axis some discontinuous function $\mathscr{E}(k)$ arises that can be analytically continued on the cut plane $\mathbb{K}$, with the cuts $it+k_l^*$, $k_l^*=lk^*$, $t\in(-h_l, h_l)$, $h_l\geqslant 0$; see Fig. 3.

The surface $\mathbb{K}$ is symmetrical with respect to the reflection $k\to -\overline{k}$. The shores of the cuts symmetrical with respect to this map should be identified. The function $\mathscr{E}(k)$ is real on the real axis and on the shores of the cuts (and only on this set). The function $\mathscr{E}(k)$ maps the broken line on Fig. 3 monotonously to the real line, and the image of the positive imaginary axis coincides with $(-\infty, E_0)$, the images of the real intervals are the spectral intervals, and the images of the loops around the cuts coincide with the gaps.

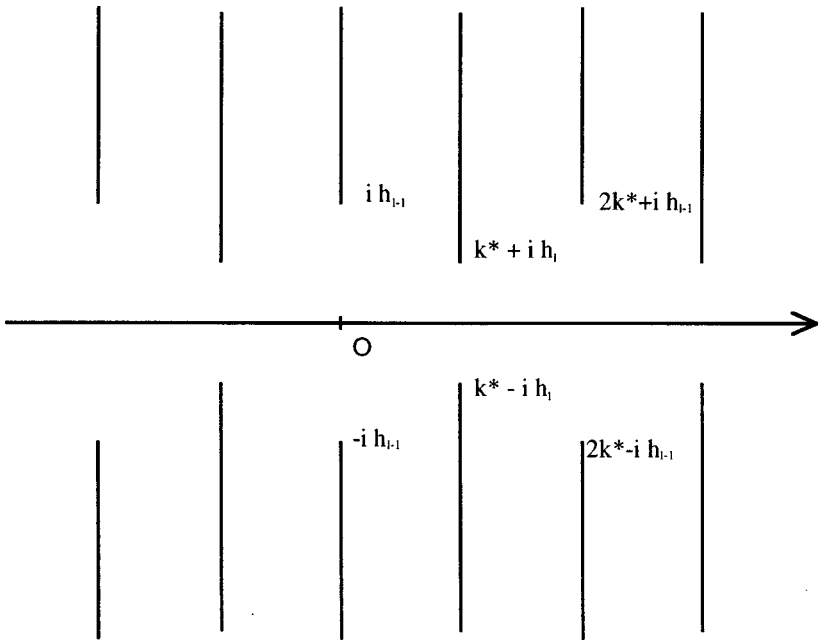

FIG. 2.

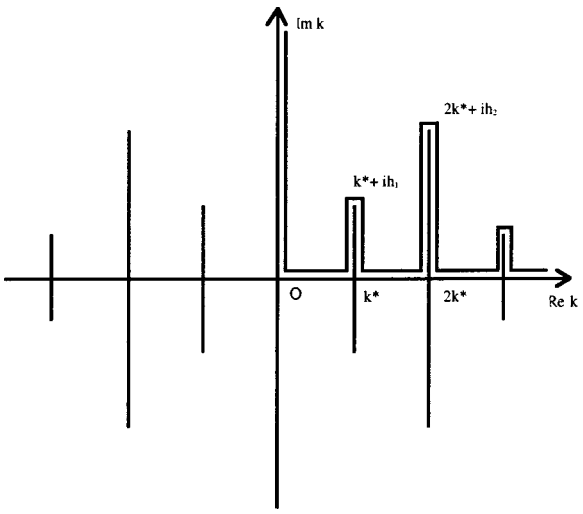

FIG. 3.

Asymptotically, when $k\to\infty$, $\mathscr{E}(k)\sim k^2$.

The solution $u_l(x,k)$ is defined by l and k up to the normalization. We can say that on the cut cylinder $\mathbb{C}/\{a^*\mathbb{Z}\}$ as a base, some bundle $\mathbb{P}_l$ is naturally defined. Also one can consider the bundle $\mathbb{P}$ over $\mathbb{K}$.

We can introduce special normalizations of $u_l(x,k)$ on $\mathbb{K}_l$ and $u(x,k)$ on $\mathbb{K}$ such that these functions will be defined as analytic functions of $k\in\mathbb{K}_l$ and $k\in\mathbb{K}$. These normalizations can be fixed appropriately such that $u(x,k)$ becomes real on the imaginary axis and $u(x,k)=e^{ikx}\varphi(x,k)\sim e^{ikx}$ as $k\to\infty$. The solutions can also be chosen real on the shores of the cuts. For all E except the boundaries of the intervals Δ_l, there are two linearly independent solutions $u(x,k)$ and $u(x,-k)$.

In order to avoid future misunderstandings it is worth mentioning that one of the real parts on the branches of the shores solutions that corresponds to a given real part nk^* of k, must have, at least, one zero in some point k of a shore; if it is chosen such that it does not have roots everywhere on the shores, it is not continuous in one of the points nk^*-0 or nk^*+0. However, this moment does not play any role in the following asymptotic constructions, since the continuity of the solutions in both the points nk^*+0 and nk^*-0 of the cut complex plane is not essential for them.

On the bundles $\mathbb{P}_l$ and $\mathbb{P}$ we can consider natural linear connections that are defined by the connection forms:

$$\omega_l=-\frac{\int_0^a\varphi_l(x,-k)d_k\varphi_l(x,k)dx}{\int_0^a\varphi(x,-k)\varphi(x,k)dx}, \tag{17}$$

$$\omega=-\frac{\int_0^a\varphi(x,-k)d_k\varphi(x,k)dx}{\int_0^a\varphi(x,-k)\varphi(x,k)dx}. \tag{18}$$

By this we can define the continuation of u_l/u along any oriented curve γ. If γ connects k_0 to k_1:

$$(u_l/u)(x,k_0)\to(u_l/u)(x,k_1)e^{\int_\gamma\omega}. \tag{19}$$

The forms are purely imaginary if $k\in\mathbb{R}$ and purely real on the imaginary axis and on the shores of the cuts.

Analogously, two similar forms corresponding to the expression

$$\widetilde{\omega}=-\frac{1}{a}\frac{\int_0^a\{u_2,d_ku_1\}dx}{\{u_2,u_1\}}, \tag{20}$$

will be useful. Here $\{f,g\}=fg'-f'g$ is the standard Wronskian and $u_1=u(x,k)$, $u_2=u(x,-k)$.

The following elementary formulas will be also essential:

$$\{u_1,u_2\}=-i\mathscr{E}'(k)\,\frac{1}{a}\int_0^a u_1u_2dx, \tag{21}$$

$$\widetilde{\omega}+i\,\frac{a}{2}\,dk=\omega-\frac{1}{2}\,d(\ln\,\mathscr{E}'). \tag{22}$$

B. Isoenergy curve

Here we will make some remarks on the structure of the curves on the ''phase plane'' defined by the equations

$$\mathscr{E}(k)+q(\xi)=E,\quad k\in\mathbb{K},\quad \xi\in\mathbb{R}, \tag{23}$$

$$\mathscr{E}_l(k)+q(\xi)=E,\quad k\in\mathbb{K}_l,\quad \xi\in\mathbb{R}. \tag{24}$$

Here $q(\xi)\in\mathbb{R}$ is a given smooth function. We will assume that on each finite interval the function q has only a finite number of nondegenerated critical points. Let us call these curves the isoenergy curves. For the Stark–Wannier case (2), $q(\xi)=-\xi$.

Consider the real plane $(\xi,\mathscr{E})$ and the curves $\mathscr{E}=E_m+q(\xi)$ on the plane. They generate on the plane some strips. The strip $\sigma(\underline{\Delta}_l)$, between $\mathscr{E}=E_{2l-2}+q(\xi)$ and $\mathscr{E}=E_{2l-1}+q(\xi)$, will be called admissible, and the strip $\sigma(\Delta_l)$, between $\mathscr{E}=E_{2l-1}+q(\xi)$ and $\mathscr{E}=E_{2l}+q(\xi)$, will be called forbidden.

Let us consider the straight line $\mathscr{E}=E$ with a fixed E, $E\in\mathbb{R}$. The values of ξ corresponding to the intersection points of this straight line and all the curves $\mathscr{E}=E_m+q(\xi)$ are called the turning points. They are solutions of the equations $E=E_m+q(\xi)$. A turning point ξ_1 is called a simple turning point if $q'(\xi_1)\neq 0$. The turning points play an essential role in the asymptotic theory of Eq. (10). In this text we will deal only with the simple turning points. For fixed E on each finite interval of the axis ξ, we can find only a finite number of the turning points.

Consider an interval between two neighboring simple turning points ξ_1 and ξ_2. As such, the intervals will be called the minimal intervals. Two cases are possible: either the points ξ_1,ξ_2 are the coordinates of the intersection of the straight line $\mathscr{E}=E$ with one curve $\mathscr{E}=E_m+q(\xi)$ [cases (a) and (b)], or they are the coordinates of the intersection with different curves $\mathscr{E}=E_m+q(\xi)$ and $\mathscr{E}=E_{m'}+q(\xi)$ [cases (c) and (d)], $m\neq m'$. Both the cases in their turn can be divided in two subcases: the line $\mathscr{E}=E$ between the intersections lies in an allowed strip [cases (a) and (c)] or it lies in a forbidden strip [cases (b) and (d)]; see Fig. 4, where the forbidden strips are striped.

Let us comment briefly on the figure. In Fig. 4(a), the straight line $\mathscr{E}=E$ intersects twice the same curve $\mathscr{E}=E_m+q(\xi)$, and its part between ξ_1,ξ_2 belongs to a forbidden strip. In Fig. 4(b), the line $\mathscr{E}=E$ again intersects the same curve, but now its part between ξ_1,ξ_2 belongs to an allowed strip. In Fig. 4(c), the line $\mathscr{E}=E$ intersects different curves and its part between ξ_1,ξ_2 belongs to a forbidden strip. In Fig. 4(d), the line $\mathscr{E}=E$ intersects different curves, but its part between ξ_1,ξ_2 belongs this time to an allowed strip.

Over the minimal interval on the plane $\mathbb{R}\times\mathbb{K}$ we can draw some branch of the isoenergy curve, and this curve has a very certain configuration. In general, properties of the configuration are in correspondence with the four indicated cases; see Fig. 5. The geometrical structure of the isoenergy curve corresponding to a forbidden strip does not depend on the case: for both cases (b) and (d) it is the same.

All the curves are symmetrical with respect to the axis ξ. The curves in Figs. 5(a) and 5(c) are real; they will be called the real branches of the isoenergy curve. The curves in Figs. 5(b) and 5(d) lie in the plane $\mathrm{Re}\,k=k_m$. They will be called the complex branches.

Let us consider the branches of the isoenergy curve over a minimal interval (ξ_1,ξ_2) up to the shift $k\to k+na^*$, $n\in\mathbb{Z}$. Then we obtain a smooth periodic curve that is, in fact, a curve on the cylinder $\mathbb{R}\times\mathbb{K}_l$. Let us denote it by γ_l if it is real and $\overline{\gamma_l}$ if it is complex.

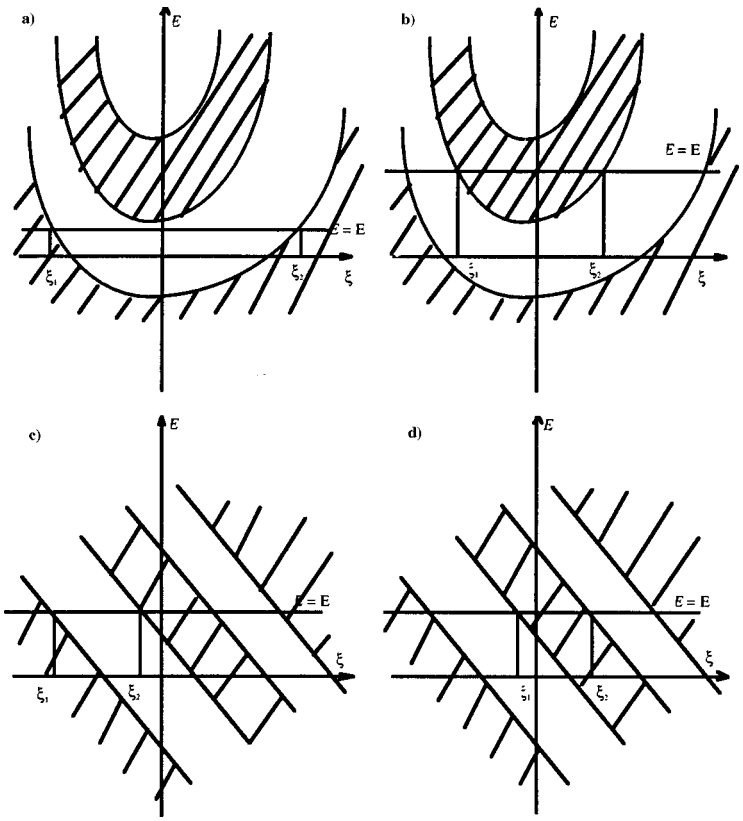

FIG. 4.

The closed curve γ_l corresponding to Fig. 5(a) can be continuously deformed to a point. The curve corresponding to Fig. 5(c) is a nontrivial cycle on the cylinder.

We make the following assumptions on the orientation: $\int_{\gamma_l}\xi d k>0$, γ_l real, $\int_{\overline{\gamma_l}}\xi(i d k)<0$, $\overline{\gamma_l}$ complex.

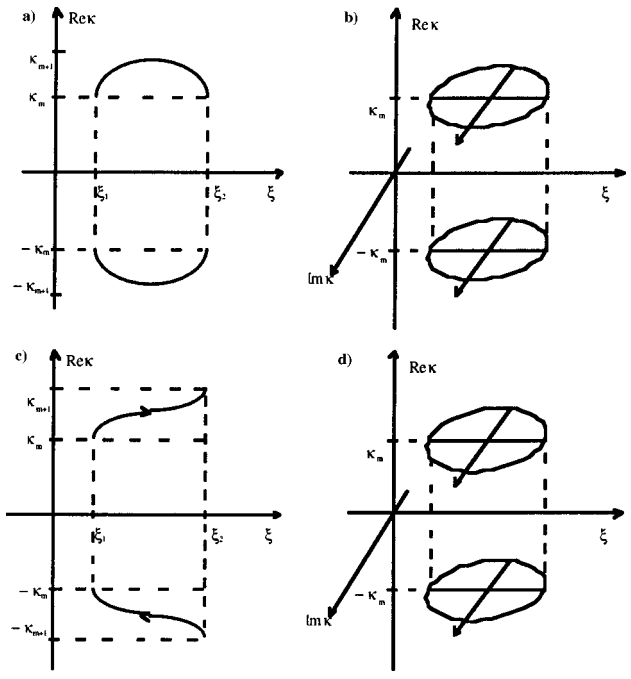

FIG. 5.

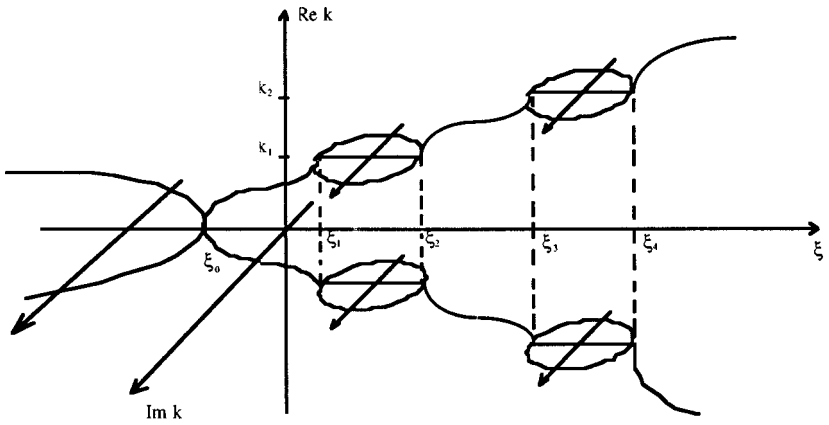

FIG. 6.

The entire axis ξ, in the general case, are divided by the turning points in a finite or an infinite number of the minimal intervals. Each of them is covered by the branch of the described type.

If p is a Q-gap potential and $q(\xi)=-\xi$, there are $2Q+1$ turning points $\xi_0<\xi_1<\cdots<\xi_{2Q}$, and $\xi_m=E_m-E$. The structure of the isoenergy curve, in the case $Q=2$, is given by Fig. 6.

III. STANDARD SOLUTIONS, TRANSITION MATRICES, IMAGINARY PARTS OF RESONANCES

A. Standard solutions and transition matrices

We begin with a short description of standard solutions of the equation

$$-\psi''+p(x)-\epsilon x\psi=E\psi, \tag{25}$$

and connections between them. The structure of such solutions and the justification of the connections between them is an object of the adiabatic approximation. A more detailed discussion of these solutions will be given in the next parts of the text.

Consider the turning points for the Q-gap potential p and for $q(\xi)=-\xi$. They are

$$\xi_m=E_m-E, \quad m=0,...,2Q. \tag{26}$$

Consider these points on the axis $\xi=\epsilon x$.

Put $\Omega_m=\Omega_m(\delta)=(\xi_{m-1}+\delta,\xi_{m+1}-\delta)$, where $\delta>0$ is fixed as a sufficiently small number such that Ω_m contains the turning point ξ_m. As ξ_{-1} and ξ_{2Q+1} we will also consider $-\infty$ and $+\infty$.

On the interval Ω_m we can construct three solutions of (25), which will be denoted by f_m, h_m, and g_m. They can be characterized by definite, relatively simple, asymptotic behavior for $\epsilon\to 0$ and $\xi\in\Omega_m$. These solutions cannot be defined uniquely, but their uncertainty is not an obstacle for our aims.

The solutions h_m, g_m are real (for $E\in\mathbb{R}$) and can be fixed such that

$$\{h_m,g_m\}=h_m g_m'-h_m' g_m=-1. \tag{27}$$

The solutions f_m and $\overline{f_m}$ are linearly independent:

$$\{f_m,\overline{f_m}\}=-i. \tag{28}$$

Two pairs of linearly independent solutions can be connected by the simple transition matrix:

$$\begin{pmatrix} h_m \\ g_m \end{pmatrix}=T\begin{pmatrix} f_m \\ \overline{f_m} \end{pmatrix}, \quad T=\frac{1}{\sqrt{2}}\begin{pmatrix} e^{-i(\pi/4)} & e^{i(\pi/4)} \\ e^{i(\pi/4)} & e^{-i(\pi/4)} \end{pmatrix}; \tag{29}$$

T is unitary, $\det T=-i$.

Our next question is the connection of the bases related with the different neighboring turning points ξ_m and ξ_{m+1}. The answer is different, depending on the nature of the interval (ξ_m,ξ_{m+1}): it can be admissible (covered by a real branch) or forbidden (covered by a complex branch).

Let the interval (ξ_m,ξ_{m+1}) be admissible and m be even. Let us put

$$\begin{pmatrix} h_{m+1} \\ g_{m+1} \end{pmatrix} = U_m \begin{pmatrix} h_m \\ g_m \end{pmatrix}. \tag{30}$$

Introduce the notation for the entries:

$$U_m = \begin{pmatrix} a_m & b_m \\ c_m & d_m \end{pmatrix}. \tag{31}$$

It is clear that U_m is real and $\det U_m=1$. Asymptotically, as $\epsilon\to 0$, U_m allows the representation

$$U_m \sim \begin{pmatrix} \cos\ \phi_m & -\sin\ \phi_m \\ \sin\ \phi_m & \cos\ \phi_m \end{pmatrix}, \tag{32}$$

where

$$\phi_m = \frac{\pi}{\epsilon a} E + \frac{1}{\epsilon} \sum_{n\geqslant 0} \epsilon^n \phi_{m,n}. \tag{33}$$

Here $\phi_{m,n}$ does not depend on E and principally can be computed, in particular,

$$\phi_{m,0}+\epsilon\phi_{m,1} = -\frac{1}{2}\int_0^{a^*} \mathscr{E}_l(k)\,dk + \frac{1}{2}\,\epsilon \int_{\gamma_l} \omega_l, \quad m=2l-2. \tag{34}$$

The formula (32) implies that for any N,

$$U_m = \begin{pmatrix} \cos\ \phi_m^N & -\sin\ \phi_m^N \\ \sin\ \phi_m^N & \cos\ \phi_m^N \end{pmatrix} + O(\epsilon^{N+1}), \tag{35}$$

where

$$\phi_m^N = \frac{\pi}{\epsilon a} E + \frac{1}{\epsilon} \sum_{n=0}^{N} \epsilon^n \phi_{m,n}. \tag{36}$$

Let now the interval (ξ_m,ξ_{m+1}) be forbidden and m be odd. Put

$$\begin{pmatrix} h_{m+1} \\ g_{m+1} \end{pmatrix} = V_m \begin{pmatrix} h_m \\ g_m \end{pmatrix}. \tag{37}$$

Again V_m is real and $\det V_m=1$. In fact, we can construct the solutions such that the diagonal elements of V_m are equal to 0:

$$V_m = \begin{pmatrix} 0 & -r_m^{-1} \\ r_m & 0 \end{pmatrix}. \tag{38}$$

The element r_m has the following asymptotic representation:

$$r_m \sim Z_m, \tag{39}$$

where

$$Z_m = 2e^{z_m}, \quad z_m = \frac{1}{\epsilon} \sum_{n \geqslant 0} z_{m,n} \epsilon^n. \tag{40}$$

$z_{m,n}$ do not depend on E, $z_{m,0} > 0$. For the main terms the explicit formula can be obtained:

$$z_{m,0} + \epsilon z_{m,1} = -\frac{1}{2} \int_{\bar{\gamma}_l} \xi(idk) + \frac{1}{2} \epsilon \int_{\bar{\gamma}_l} \omega_l, \quad m = 2l - 1. \tag{41}$$

The asymptotical sense of formula (39) is the following: for any N,

$$r_m = Z_m^N (1 + O(\epsilon^{N+1})), \quad Z_m^N = 2e^{z_m^N}, \quad z_m^N = \frac{1}{\epsilon} \sum_{n=0}^{N} \epsilon^n z_{m,n}. \tag{42}$$

B. Properties of g_-, f_+

The solutions f_0, h_0, g_0 with certain asymptotic behavior for $\xi \in (-\infty, \xi_1 - \delta)$, can be chosen, such that

$$g_- = Z_- h_0. \tag{43}$$

The coefficient $Z_- = e^{z_-}$ has the asymptotic expansion

$$z_- \sim \frac{1}{\epsilon} \sum_{n \geqslant 0} \epsilon^n z_{-,n}, \tag{44}$$

where

$$z_{-,0} + \epsilon z_{-,1} = \int_{-\infty}^{\xi_0} [ik - |E + \xi|^{1/2} \theta(-E - \xi)] d\xi - i\epsilon \int_{\xi_0}^{\infty} \omega. \tag{45}$$

The coefficients $z_{-,n}$ do not depend on E.

Similarly, the solutions f_{2Q}, h_{2Q}, g_{2Q} with certain asymptotic behavior on the interval $(\xi_{2Q-1} + \delta, \infty)$ can be chosen, such that

$$f_{2Q} = \alpha_+ f_+ + \beta_+ \bar{f}_+, \tag{46}$$

where $\alpha_+ = e^{i\varphi_+}$, φ_+ is real, allows the asymptotic expansion

$$\phi_+ \sim \frac{1}{\epsilon} \sum_{n \geqslant 0} \epsilon^n \phi_{+,n}, \tag{47}$$

and $\beta_+ = O(\epsilon^{N+1})$. For the main term one gets

$$\phi_{+,0} + \epsilon \phi_{+,1} = k_Q^* \xi_{2Q} + \int_{\xi_{2Q}}^{\infty} [k - \sqrt{(\xi + E)}\, \theta(\xi + E)] d\xi + \epsilon \int_{\xi_{2Q}}^{\infty} \omega. \tag{48}$$

There is only one term depending on E in ϕ_+; it enters in $k_Q^* \xi_{2Q} = k_Q^*(E_{2Q} - E)$.

We have described all the transition matrices and all their asymptotics for real E. The same asymptotic formulas are right for $|\mathrm{Im}\, E| < \epsilon\alpha' < \epsilon\alpha$.

C. Stark–Wannier resonances: One-gap potential

Now we have everything necessary for the description of the Stark–Wannier resonances, and, in particular, their imaginary parts. Let us begin with the one-gap potential.

Simultaneously with

$$g_- = \bar{M} f_+ + M \bar{f}_+, \tag{49}$$

consider

$$g_- = Kh_1 + Lg_1. \tag{50}$$

We will see that asymptotically the real parts of the resonances are defined by the roots of L and their imaginary parts are defined by the equation

$$L + \kappa K = 0, \tag{51}$$

with a small imaginary parameter κ.

Let us connect M with L and K. Express (h_1, g_1) in terms of $f_+, \overline{f}_+$:

$$\begin{aligned}\begin{pmatrix} h_1 \\ g_1 \end{pmatrix} &= V_1^{-1}\begin{pmatrix} h_2 \\ g_2 \end{pmatrix} = V_1^{-1}T\begin{pmatrix} f_2 \\ \overline{f}_2 \end{pmatrix} = V_1^{-1}T\begin{pmatrix} \alpha_+ & \beta_+ \\ \overline{\beta}_+ & \overline{\alpha}_+ \end{pmatrix}\begin{pmatrix} f_+ \\ \overline{f}_+ \end{pmatrix} \\ &= \frac{1}{\sqrt{2}}\begin{pmatrix} r_1^{-1}(\alpha_+ e^{i(\pi/4)} + \overline{\beta}_+ e^{-i(\pi/4)}) & r_1^{-1}(\beta_+ e^{i(\pi/4)} + \overline{\alpha}_+ e^{-i(\pi/4)}) \\ -r_1(\alpha_+ e^{-i(\pi/4)} + \overline{\beta}_+ e^{i(\pi/4)}) & -r_1(\beta_+ e^{-i(\pi/4)} + \overline{\alpha}_+ e^{i(\pi/4)}) \end{pmatrix}\begin{pmatrix} f_+ \\ \overline{f}_+ \end{pmatrix}.\end{aligned} \tag{52}$$

As a result,

$$M = -\frac{1}{\sqrt{2}}\, r_1(\beta_+ e^{-i(\pi/4)} + \overline{\alpha}_+ e^{i(\pi/4)})[L + \kappa K], \tag{53}$$

where

$$\kappa = -r_1^{-2}\,\frac{\beta_+ e^{i(\pi/4)} + \overline{\alpha}_+ e^{-i(\pi/4)}}{\beta_+ e^{-i(\pi/4)} + \overline{\alpha}_+ e^{i(\pi/4)}}. \tag{54}$$

The factor $(\beta_+ e^{-i(\pi/4)} + \overline{\alpha}_+ e^{i(\pi/4)})$ does not have roots on the real axis; moreover,

$$\beta_+ e^{-i(\pi/4)} + \overline{\alpha}_+ e^{i(\pi/4)} \sim \overline{\alpha}_+ e^{i(\pi/4)}. \tag{55}$$

It is clear that it does not have roots in the strip $|\mathrm{Im}\, E| < \epsilon\alpha' < \epsilon\alpha$.

As for κ, it is clear that asymptotically,

$$\kappa = i r_1^{-2}(1 + O(\epsilon^\infty)). \tag{56}$$

In order to complete the description of the resonances, i.e., roots of M, let us find the asymptotics of L and K. From the definition

$$g_- = Z_- h_0 = Z_-(d_0 h_1 - b_0 g_1); \tag{57}$$

see (30) (31); therefore

$$K = Z_- d_0, \quad L = -Z_- b_0, \tag{58}$$

and

$$M = \frac{e^{-i\phi_+}}{\sqrt{2}}\, Z_- r_1 e^{i(\pi/4)}(b_0 - \kappa d_0). \tag{59}$$

From (32),

$$b_0 \sim -\sin\,\phi_0, \quad d_0 \sim \cos\,\phi_0. \tag{60}$$

Now we can make the final conclusions on the locations of the roots E_n of M. Up to exponentially small corrections they are defined by the roots of b_0 and, therefore, admit the asymptotic expansion as $\epsilon \to 0$,

$$\phi_0 = n\pi, \quad n \in \mathbb{Z}. \tag{61}$$

In other words, asymptotically,

$$E_n + \frac{a}{\pi} \sum_{p \geqslant 0} \epsilon^p \phi_{0,p} = \epsilon a n. \tag{62}$$

These roots of b_0 are simple and, since b_0 is real on the real axis, are real. In the strip $|\mathrm{Im}\, E| < \epsilon\alpha' < \epsilon\alpha$, other roots are absent.

The formula (62) is the so-called quantization condition. It was discussed by many authors; see, for example, Ref. 2.

The shift ΔE of the root of b_0 under the influence of the small correction to b_0 is defined by the equation

$$\left.\frac{db_0}{dE}\right|_{E_n} \Delta E \simeq \kappa d_0|_{E_n}. \tag{63}$$

From this formula, asymptotically,

$$\Delta E \simeq -\frac{\epsilon a}{\pi}\, \kappa \simeq -i\, \frac{\epsilon a}{\pi}\, (Z_1^1)^{-2}, \tag{64}$$

Z_1^1 is described by (40)–(42). So we can conclude that the real parts of the roots are defined by the equation (62), and their imaginary parts are equal to

$$\mathrm{Im}\, E \sim -\frac{\epsilon a}{4\pi}\, e^{(1/\epsilon)(\int_{\overline{\gamma}_1} \xi(idk) - \epsilon \int_{\overline{\gamma}_1} \omega_1)}. \tag{65}$$

Let us remind the reader that the integral $\int_{\overline{\gamma}_1} \xi(idk)$ is negative; it is our assumption on the orientation of the $\overline{\gamma_l}$. In fact, this integral is nothing else than the area S_l surrounded by the closed complex curve $\overline{\gamma_l}$:

$$S_l = -\int_{\overline{\gamma}_l} \xi d(ik). \tag{66}$$

It is clear, from the analytical properties of all the objects, that the small corrections do not create additional roots in the strip $|\mathrm{Im}\, E| < \epsilon\alpha' < \epsilon\alpha$.

Let us remark that the real parts of the resonances can be localized only up to the error $O(\epsilon^\infty)$. In contrast, the imaginary part allows very fine localization; it is exponentially small. The result completely coincides with (9).

D. Many-gaps potentials

Consider, at last, the Q-gap potential. Principally, some definite ϵa-periodic ladder of the resonances corresponds to every spectral interval. The real parts of such ladders are described by the same quantization conditions as in the case of a one-gap potential; see Ref. 1,

$$\sin \phi_l = 0, \tag{67}$$

or

$$\phi_l = n\pi, \quad n \in \mathbb{Z}, \tag{68}$$

or

$$E + \frac{a}{\pi} \sum_{p \geqslant 0} \epsilon^p \phi_{l,p} = \epsilon a n. \tag{69}$$

This statement is not, however, unconditional. If the distances between the real parts of the resonances corresponding to two different spectral intervals, tend to zero, the independent description of these real parts becomes impossible. We are not interested here in the description of this more complicated situation and, therefore, as in Ref. 1, we assume that some condition is fulfilled that allows us to exclude such a situation. We have to consider under this condition only a special sequence of ϵ, tending to 0. Practically, it means that we assume that for all the spectral intervals except one, let its number be l, the corresponding $\sin \phi_m^1$, $m \neq 2l-2$, are uniformly bounded from zero:

$$|\sin \phi_m^1| \geqslant \nu > 0. \tag{70}$$

Under this condition we can describe the ladder corresponding to the lth spectral interval and compute its imaginary part.

As in the case $Q=1$ introduce the new real (if $E \in \mathbb{R}$) coefficients K, L:

$$g_- = Kh_{2l-1} + Lg_{2l-1}. \tag{71}$$

Let us express M in terms of K and L. It is clear that

$$\begin{pmatrix} h_{2l-1} \\ g_{2l-1} \end{pmatrix} = A_l T \begin{pmatrix} \alpha_+ & \beta_+ \\ \overline{\beta}_+ & \overline{\alpha}_+ \end{pmatrix} \begin{pmatrix} f_+ \\ \overline{f}_+ \end{pmatrix}, \tag{72}$$

where

$$A_l = V_{2l-1}^{-1} U_{2l-2}^{-1} \cdots U_{2Q-2}^{-1} V_{2Q-1}^{-1}. \tag{73}$$

Introduce the notations for A_l entries:

$$A_l = \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}. \tag{74}$$

It is easy to see that

$$M = \frac{1}{\sqrt{2}} [a_{21}(\beta_+ e^{-i(\pi/4)} + \overline{\alpha}_+ e^{i(\pi/4)}) + a_{22}(\beta_+ e^{i(\pi/4)} + \overline{\alpha}_+ e^{-i(\pi/4)})][L + \kappa K], \tag{75}$$

$$\kappa = \frac{a_{11}(\beta_+ e^{-i(\pi/4)} + \overline{\alpha}_+ e^{i(\pi/4)}) + a_{12}(\beta_+ e^{i(\pi/4)} + \overline{\alpha}_+ e^{-(\pi/4)})}{a_{21}(\beta_+ e^{-i(\pi/4)} + \overline{\alpha}_+ e^{i(\pi/4)}) + a_{22}(\beta_+ e^{i(\pi/4)} + \overline{\alpha}_+ e^{-i(\pi/4)})}. \tag{76}$$

Using the induction, we can prove that a single element of A, proportional to $Z_{2l-1} \cdots Z_{2Q-1}$, is a_{21}:

$$a_{21} \sim \sin \phi_{2l} \cdots \sin \phi_{2Q-2} Z_{2l-1} \cdots Z_{2Q-1} + \cdots. \tag{77}$$

Due to the condition (70) (for the E and ϵ considered) this term, indeed, defines the asymptotics of a_{21}. So we can declare that

$$\operatorname{Re} \kappa = O((Z_{2l-1}^0)^{-1} + \cdots + (Z_{2Q-1}^0)^{-1}). \tag{78}$$

As for the $\operatorname{Im} \kappa$, let us remark that because of $\det A_l = 1$,

$$\operatorname{Im} \kappa = \operatorname{Im}\left(\frac{\beta_+ e^{-i(\pi/4)} + \overline{\alpha}_+ e^{i(\pi/4)}}{\beta_+ e^{i(\pi/4)} + \overline{\alpha}_+ e^{-i(\pi/4)}} \right) \left| a_{21}\left(\frac{\beta_+ e^{-i(\pi/4)} + \overline{\alpha}_+ e^{i(\pi/4)}}{\beta_+ e^{i(\pi/4)} + \overline{\alpha}_+ e^{-i(\pi/4)}} \right) + a_{22} \right|^{-2}. \tag{79}$$

Asymptotically,

$$\frac{\beta_+ e^{-i(\pi/4)}+\overline{\alpha}_+ e^{i(\pi/4)}}{\beta_+ e^{i(\pi/4)}+\overline{\alpha}_+ e^{-i(\pi/4)}}\sim i+O(\epsilon^\infty); \tag{80}$$

therefore

$$\text{Im } \kappa=\frac{1+O(\epsilon^\infty)}{(\sin \phi_{2l}^1\cdots\sin \phi_{2Q-2}^1 Z_{2l-1}^1\cdots Z_{2Q-1}^1)^2}. \tag{81}$$

Simultaneously, it is clear that $[a_{21}(\beta_+ e^{-i(\pi/4)}+\overline{\alpha}_+ e^{i(\pi/4)})+a_{22}(\beta_+ e^{i(\pi/4)}+\overline{\alpha}_+ e^{-i(\pi/4)})]$ $\sim a_{21}\overline{\alpha}_+ e^{i(\pi/4)}$ does not have roots.

Preserving the control over the roots, we can write

$$M\sim\frac{1}{\sqrt{2}}\, a_{21}\overline{\alpha}_+ e^{i(\pi/4)}(L+\kappa K), \tag{82}$$

where κ asymptotically is described by (78) and (81).

The next step is to give the asymptotic formulas for L and K. We have

$$\begin{pmatrix} h_0 \\ g_0 \end{pmatrix}=B_l\begin{pmatrix} h_{2l-1} \\ g_{2l-1} \end{pmatrix}, \tag{83}$$

where

$$B_l=U_0^{-1}V_1^{-1}\cdots U_{2l-2}^{-1}. \tag{84}$$

Let

$$B_l=\begin{pmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{pmatrix}. \tag{85}$$

It is clear that

$$K=Z_- b_{11}, \quad L=Z_- b_{12}, \tag{86}$$

It gives

$$M\sim\frac{\alpha_+ Z_- a_{21} e^{i(\pi/4)}}{\sqrt{2}}\,(b_{12}+\kappa b_{11}). \tag{87}$$

The elements b_{21} and b_{11} contain terms proportional to $Z_1^0\cdots Z_{2l-3}^0$, asymptotically,

$$\begin{aligned} b_{11}&\sim(-1)^{l-2}Z_1\cdots Z_{2l-3}[\sin \phi_0\cdots\sin \phi_{2l-4}\cos \phi_{2l-2}+O((Z_1)^{-1}+\cdots+(Z_{2l-3})^{-1})], \\ b_{12}&\sim(-1)^{l-2}Z_1\cdots Z_{2l-3}[\sin \phi_0\cdots\sin \phi_{2l-2}+O((Z_1)^{-1}+\cdots+(Z_{2l-3})^{-1})]. \end{aligned} \tag{88}$$

As a result,

$$\begin{aligned} M\sim&\frac{1}{\sqrt{2}}\, a_{21}\overline{\alpha}_+ e^{i(\pi/4)}(-1)^{l-2}Z_1\cdots Z_{2l-3}Z_{2l-1}\cdots Z_{2Q-1} \\ &\times\sin \phi_0\cdots\sin \phi_{2l-4}\sin \phi_{2l}\cdots\sin \phi_{2Q-2}(1+O(Z_1^{-1}+\cdots+Z_{2Q-1}^{-1})) \\ &\times\Bigg[\sin \phi_{2l-2}+i\,\frac{1}{(\sin \phi_{2l}\cdots\sin \phi_{2Q-2}Z_{2l-1}\cdots Z_{2Q-1})^2}\cos \phi_{2l-2}(1+O(\epsilon^\infty)) \\ &+O(Z_1^{-1}+\cdots+Z_{2Q-1}^{-1})\Bigg]. \end{aligned} \tag{89}$$

It is essential that the second O term in [ ] is real, for $E\in\mathbb{R}$.

Repeating now the computations described in Sec. III C, we see that the real parts of the ladders are described by the quantization condition (68).

The imaginary part of this ladder is equal to

$$\operatorname{Im} E \sim -\frac{\epsilon a}{\pi} \frac{1}{(\sin \phi^1_{2l} \cdots \sin \phi^1_{2Q-2} Z^1_{2l-1} \cdots Z^1_{2Q-1})^2}, \tag{90}$$

where ϕ^1_{2m} is given in (34) and Z^1_{2m-1} in (42).

We can say that the shift of the ladder to the complex plane is induced by the tunneling of the lth spectral interval to the continuous spectrum (corresponding to the last infinite branch of the isoenergy curve) through all the intermediate gaps.

IV. FORMAL ASYMPTOTIC SOLUTIONS

Here we describe formal asymptotic solutions of the equation

$$-\psi'' + (p(x) + q(\epsilon x))\psi = E\psi. \tag{91}$$

We consider the formal solutions on the minimal intervals and more complicated solutions on the unification of two neighboring minimal intervals, including the turning point that separates them. In principal, these results do not differ from already known results; see Refs. 2 and 12; however, we describe them in a different form and it allows us to simplify the proof of properties of the transition matrices.

A. Formal solutions on the minimal interval

Fix a smooth branch γ of the isoenergy curve Γ covering the minimal interval bounded by simple turning points ξ_1, ξ_2. There exists a formal solution of the equation (91) corresponding to the branch γ, and it has the form

$$F(x, \xi, \epsilon) = e^{(i/\epsilon)\theta(\xi)} f(x, \xi, \epsilon), \quad \xi = \epsilon x, \tag{92}$$

where $\theta(\xi)$ is an integral of the differential form $k\, d\xi$ on the branch γ, $f(x, \xi, \epsilon)$ is periodic with respect to x with the period a, and the dependence on ϵ is characterized by the expansion

$$f(x, \xi, \epsilon) = \sum_{n \geqslant 0} \epsilon^n f_n(x, \xi), \quad f_0 \neq 0. \tag{93}$$

The equation (91) is equivalent to the following system of equations for f_n:

$$\left[\left(\frac{1}{i}\frac{\partial}{\partial x} + \theta'\right)^2 + p(x) + q(\xi) - E\right] f_n - i\left[2\left(\frac{1}{i}\frac{\partial}{\partial x} + \theta'\right)\frac{\partial}{\partial \xi} + \theta''\right] f_{n-1} - \frac{\partial^2}{\partial \xi^2} f_{n-2} = 0. \tag{94}$$

The equation for $n = 0$ gives

$$f_0 = N(\xi)\varphi(x, k), \quad k = \theta'(\xi). \tag{95}$$

The coefficient N can be characterized by the ''transport equation'' that arises as the condition of the existence of an a-periodic solution of the equation for f_1:

$$N(\xi) = |\mathscr{E}'(k)|^{-1/2} e^{\int \omega}, \tag{96}$$

where $\int \omega$ is an integral of the form ω on γ. As a result,

$$e^{(i/\epsilon)\theta} f_0 = c_0 |\mathscr{E}'(k)|^{-1/2} e^{(i/\epsilon)\theta(\xi)} \varphi(x, \xi) e^{\int \omega}. \tag{97}$$

This process can be continued and generates a solution F determined up to a constant factor of the form

$$c = e^{(i/\epsilon)\theta_0} \sum_{n \geqslant 0} \epsilon^n c_n . \tag{98}$$

In order to avoid misunderstandings, we should indicate that this form of the representation of f_0 is reasonable only for the case when γ is a real branch. In the internal points of this branch, $\mathscr{E}'(k) \neq 0$ and ω is purely imaginary. In the case of a complex branch the boundaries of the cuts $k = \pm 1/2na^* \pm ih_n$ are points where $(\mathscr{E}')^{-1/2}$ is finite (even zero), but not smooth. Simultaneously, in these points the solutions u_1, u_2 become orthogonal in $L_2(0,a)$, such that the form ω acquires singularities also. In order to compensate for both these singularities, it is necessary to combine the contributions of $\mathscr{E}'$ and ω in one joint expression, which is evidently smooth:

$$(\mathscr{E}')^{-1/2} e^{\int \omega} = N \exp\left[i \frac{a}{2} k + \int \tilde{\omega} \right], \tag{99}$$

where N is some constant; see (22). It is worth mentioning that ω is smooth in the ends of the cuts. Oppositely, $\tilde{\omega}$ is not smooth in these points: its singularities correspond to the singularities of $(\mathscr{E}')^{1/2.}$ Both the solutions u_1, u_2 are smooth functions of k and E in the ends of the cuts. The connection between E and k in these points is clear from Fig. 3: in particular, k is a smooth function of E. Since $\mathscr{E}(k) = E - q(\xi)$ is a smooth function of ξ, expression (99) is also smooth.

The solution F corresponding to a given branch γ of the isoenergy curve Γ can be replaced by the solution that is defined by the branch of Γ_l shifted on the period a^* with respect to k. Let us comment this declaration considering only the leading term (97). Let us assume that the solution $u(x,k)$ is a^* periodic with respect to k. Then $|\mathscr{E}'(k)|^{-1/2} e^{\int \omega}$ does not depend on the choice of a branch. The product $e^{(i/\epsilon)\theta(\xi)} \varphi(x,k)$ must be replaced by $e^{(i/\epsilon)\theta(\xi) + (i/\epsilon)a^* \xi} \varphi(x, k + a^*)$, which coincides with the initial product up to a constant factor. If $u(x,k)$ is not periodic, the transformations of $e^{\int \omega}$ and $e^{(i/\epsilon)\theta(\xi)} \varphi(x,k)$ compensate each other.

The minimal interval is covered by two branches γ_1, γ_2 of the isoenergy curve that cannot be connected by the shift $k \to k + la^*$, $l \in \mathbb{Z}$. For example, if $(k,\xi) \in \gamma_1$, then $(-k,\xi) \in \gamma_2$. Therefore, two solutions linearly independent over the field $\mathscr{A}$ of the series (98), exist on the minimal interval.

For two series F_1, F_2 of the form (92) one can consider their Wronskian:

$$\begin{aligned} \{F_1, F_2\} &= e^{(i/\epsilon)\theta_1 + (i/\epsilon)\theta_2} \left[f_1 \cdot \left(\frac{\partial}{\partial x} + \epsilon \frac{\partial}{\partial \xi} + i\theta_2' \right) f_2 - \left(\frac{\partial}{\partial x} + \epsilon \frac{\partial}{\partial \xi} + i\theta_1' \right) f_1 \cdot f_2 \right] \\ &= e^{(i/\epsilon)\theta_1 + (i/\epsilon)\theta_2} \sum_{n \geqslant 0} \epsilon^n \sum_{n_1 + n_2 = n} \left\{ f_{1,n_1} \cdot \left[\left(\frac{\partial}{\partial x} + i\theta_2' \right) f_{2,n_2} + \frac{\partial}{\partial \xi} f_{2,n_2 - 1} \right] \right. \\ &\quad \left. - \left[\left(\frac{\partial}{\partial x} + i\theta_1' \right) f_{1,n_1} + \frac{\partial}{\partial \xi} f_{1,n_1 - 1} \right] \cdot f_{2,n_2} \right\}. \end{aligned} \tag{100}$$

For any solutions this Wronskian is constant, i.e., an element of the field $\mathscr{A}$. If the solutions F_1, F_2 are linearly dependent over $\mathscr{A}$, the Wronskian is zero. If the solutions are linearly independent, the Wronskian does not equal zero.

It is easy to compute the main term of the Wronskian: if two branches γ_1, γ_2 are connected by the transformation $(k,\xi) \to (-k,\xi)$, then

$$\{f_1, f_2\} = e^{(i/\epsilon)\theta_1 + (i/\epsilon)\theta_2} |\mathscr{E}'(k)|^{-1} c_{01} c_{02} e^{\int_{\gamma_1} \omega + \int_{\gamma_2} \omega} \{u_1, u_2\}, \tag{101}$$

where $u_1 = e^{ikx} \varphi(x,k)$, $u_2 = e^{-ikx} \varphi(x,-k)$. The sum $\theta_1 + \theta_2 = \theta_0$ is constant,

$$e^{\int_{\gamma_1} \omega + \int_{\gamma_2} \omega} = N \left(\int_0^a u_1 u_2 dx \right)^{-1}, \tag{102}$$

where N is constant, and, therefore,

$$\{f_1,f_2\}\sim\frac{-2i}{a}\,e^{(i/\epsilon)\theta_0}\,\frac{\mathscr{E}'}{|\mathscr{E}'|}\,c_{01}c_{02}N; \tag{103}$$

here c_{01}, c_{02} are the corresponding constants in the formulas for the main terms of f_1,f_2.

If the branch γ (i.e., γ_1,γ_2) is real, the solutions F_1,F_2 can be normalized, such that

$$\overline{F_2}=F_1, \tag{104}$$

and $\{F_1,F_2\}$ becomes purely imaginary.

If the branch γ is complex, the solutions can be normalized such that they become real. Their Wronskian also become real.

Our last remark concerns the asymptotic character of the solutions (92).

If ξ_1,ξ_2 are simple turning points, the solution F possesses the asymptotic character on each subinterval $\delta\in(\xi_1,\xi_2)$ satisfying the condition $\mathrm{dist}(\xi_j,\delta)\geqslant\epsilon^{(2/3)(1-\gamma)}$, $\gamma>0$. It implies, more precisely, that

$$\epsilon^n|f_n(x,\xi)|\leqslant\epsilon^{\gamma n-1/6}. \tag{105}$$

On δ there exists a true solution $\mathscr{F}$ of the equation (91) for which F is its asymptotic expansion as $\epsilon\to0$:

$$\mathscr{F}=e^{(i/\epsilon)\theta}\left(\sum_{n=0}^{N}\epsilon^n f_n+o(\epsilon^{\gamma N-1/6})\right). \tag{106}$$

B. Formal solutions on the interval containing a turning point

In a vicinity of a simple turning point ξ_1, different formal solutions suitable for the asymptotic representation of the true solutions can be constructed.

The simplest one has the form

$$g=(\epsilon^{-1/6}wa+\epsilon^{1/6}w'b)e^{ik_mx}, \tag{107}$$

where $w=w(\epsilon^{-2/3}\zeta_0)$ is a solution of the Airy equation,

$$w''(z)=zw(z), \tag{108}$$

$$\zeta_0=(2M_mq'(\xi_1))^{1/3}(\xi-\xi_1); \tag{109}$$

M_m corresponds to E_m [see (16)] in the definition of the turning point, $E_m+q(\xi_1)=E$, a,b are characterized by the expansions

$$a=\sum_{n\geqslant0}\epsilon^{n/3}a_n(x,\zeta_0),\quad b=\sum_{n\geqslant0}\epsilon^{n/3}b_n(x,\zeta_0), \tag{110}$$

a_n,b_n are periodic or antiperiodic with respect to x (simultaneously with e^{ik_mx}) and are polynomials with respect to the second argument. The coefficients a,b do not depend on the choice of the solution w. In particular,

$$a_0=c_0\varphi(x,k_m). \tag{111}$$

If w is fixed, the solution g is defined up to the constant factor of the form

$$c=\sum_{n\geqslant0}\epsilon^{n/3}c_n. \tag{112}$$

The solution g has the asymptotic character on the interval $|\zeta_0|\leqslant\epsilon^{(1/2)(1+\delta)}$, $\delta>0$, where

$$\epsilon^{n/3}|a_n,b_n|\leqslant C_n\epsilon^{\delta n}. \tag{113}$$

On the same interval a true solution $\tilde{g}$ can be constructed for which g is its asymptotic expansion.

The solutions g were considered in Ref. 12; they were used there in order to describe the transformation of the solutions F in the point ξ_1. We will describe here also a different solution G that allows us to simplify essentially the description of this transformation. It is analogous to Olver's solution well known in the case of the standard WKB approach.[13]

But first let us describe shortly an analog of one more formal solution known in the standard WKB method. In Ref. 2 it was remarked that the general Maslov construction[14] can be applied also to Eq. (91), and to essentially more general partial differential equations. In particular, in vicinities of the simple turning point, the asymptotic behavior of the solutions of (91) can be described by the integrals of the form

$$\frac{e^{ik_m x}}{(2\pi\epsilon)^{1/2}} \int dp e^{(i/\epsilon)(\xi p - S(p))} \sum_{n\geqslant 0} \epsilon^n \tilde{f}_n(x,p), \quad \xi = \epsilon x, \tag{114}$$

where S is an integral of the form ξdp along the continuous branch of the isoenergy curve $\mathscr{E}(k_m+p)+q(\xi)=E$ containing the point (k_m,ξ_1); $\tilde{f}_n$ are periodic (antiperiodic) functions of x.

The asymptotic representations (107) and (114) have their own advantages and disadvantages. In particular, the representation (114) can be used on a finite (in ξ) vicinity of ξ_1. From the other side, representation (107) is more suitable for the description of the growing and decreasing solutions as ξ goes away from ξ_1 in the direction of the interval covered by the complex branch of the isoenergy curve. The Olver's-type solution possesses both these advantages.

C. Uniform asymptotics in a vicinity of the turning point

This solution has the form

$$G = (\epsilon^{-1/6} wA + \epsilon^{1/6} w' B) e^{ik_m x}, \tag{115}$$

where

$$w = w(\epsilon^{-2/3}\zeta),$$

$$A = A(x,\xi,\epsilon) = \sum_{n\geqslant 0} \epsilon^n A_n(x,\xi), \tag{116}$$

$$B = B(x,\xi,\epsilon) = \sum_{n\geqslant 0} \epsilon^n B_n(x,\xi). \tag{117}$$

In this formula w is again a solution of the Airy equation, A_n, B_n are smooth functions, periodic (antiperiodic) with respect to x, and the variable ζ is considered as a function of $\xi=\epsilon x$ defined by the equation

$$\mathscr{E}(k_m - i\sqrt{\zeta}\zeta') + q(\xi) = E. \tag{118}$$

As $\xi \to \xi_1, \zeta \sim \zeta_0$.

In order to find A_n, B_n, substitute the representation (115) to the equation (91):

$$\left[-\frac{d^2}{dx^2} + p + q - E \right] (\epsilon^{-1/6} wA + \epsilon^{1/6} w' B) e^{ik_m x} = e^{ik_m x} (\epsilon^{-1/6} wR_1 + \epsilon^{1/6} w' R_2), \tag{119}$$

$$R_1 = \sum_{n\geqslant 0} \epsilon^n R_{1,n}, \quad R_2 = \sum_{n\geqslant 0} \epsilon^n R_{2,n}; \tag{120}$$

here

$$R_{1,n}=\left[\left(\frac{1}{i}\frac{\partial}{\partial x}+k_m\right)^2+p+q-E-\zeta\zeta'^2\right]A_n-2i\zeta\zeta'\left(\frac{1}{i}\frac{\partial}{\partial x}+k_m\right)B_n-2i\left(\frac{1}{i}\frac{\partial}{\partial x}+k_m\right)\frac{\partial}{\partial\xi}A_{n-1}$$
$$-2\zeta\zeta'\frac{\partial}{\partial\xi}B_{n-1}-(\zeta\zeta')'B_{n-1}-\frac{\partial^2}{\partial\xi^2}A_{n-2}, \tag{121}$$

$$R_{2,n}=\left[\left(\frac{1}{i}\frac{\partial}{\partial x}+k_m\right)^2+p+q-E-\zeta\zeta'^2\right]B_n-2i\zeta'\left(\frac{1}{i}\frac{\partial}{\partial x}+k_m\right)A_n-2i\left(\frac{1}{i}\frac{\partial}{\partial x}+k_m\right)\frac{\partial}{\partial\xi}B_{n-1}$$
$$-2\zeta'\frac{\partial}{\partial\xi}A_{n-1}-\zeta''A_{n-1}-\frac{\partial^2}{\partial\xi^2}B_{n-2}. \tag{122}$$

This leads to the system for the definition of A_n, B_n:

$$R_{1,n}=0, \quad R_{2,n}=0. \tag{123}$$

In principal, the system can be studied quite analogously to system (94). The solution does not depend on the choice of w.

However, it turns out that the consideration of system (123) can be reduced almost directly to system (94).

In order to describe this reduction, consider the asymptotics of the solutions of the Airy equation as $z\to\infty$. Introduce some standard solutions of the Airy equation. There exists a unique solution w_1 with the following characteristic behavior as $z\to-\infty$:

$$w_1(z)\sim(-z)^{-1/4}e^{i(2/3)(-z)^{3/2}}\sum_{n\geqslant 0} i^n\alpha_n(-z)^{-3n/2}, \quad \alpha_0=1; \tag{124}$$

the coefficients α_n are real and can be computed explicitly. As a result,

$$w_1'(z)\sim -i(-z)^{1/4}e^{i(2/3)(-z)^{3/2}}\sum_{n\geqslant 0} i^n\beta_n(-z)^{-3n/2}, \quad \beta_0=1; \tag{125}$$

β_n can be computed in terms of α_n, α_{n-1}. The function $\overline{w_1}$ is also a solution.

The real solution,

$$v=\frac{1}{\sqrt{2}}\,(e^{-i(\pi/4)}w_1+e^{i(\pi/4)}\overline{w_1}), \tag{126}$$

is up to a constant factor a unique solution decreasing as $z\to+\infty$. It has the following asymptotic behavior:

$$v\sim\frac{1}{\sqrt{2}}\,z^{-1/4}e^{-2/3z^{3/2}}\sum_{n\geqslant 0}\alpha_n z^{-3n/2}, \tag{127}$$

$$v'\sim-\frac{1}{\sqrt{2}}\,z^{1/4}e^{-2/3z^{3/2}}\sum_{n\geqslant 0}\beta_n z^{-3n/2}. \tag{128}$$

Another real solution,

$$u=\frac{1}{\sqrt{2}}\,(e^{i(\pi/4)}w_1+e^{-i(\pi/4)}\overline{w_1}), \tag{129}$$

grows at infinity:

$$u\sim\sqrt{2}z^{-1/4}e^{2/3z^{3/2}}\sum_{n\geqslant 0}(-1)^n\alpha_n z^{-3n/2}, \tag{130}$$

$$u' \sim \sqrt{2} z^{1/4} e^{2/3 z^{3/2}} \sum_{n \geqslant 0} (-1)^n \beta_n z^{-3n/2}. \tag{131}$$

It is easy to see that

$$\{v, u\} = 2, \quad \{w_1, \overline{w_1}\} = 2i, \tag{132}$$

and

$$\begin{pmatrix} v \\ u \end{pmatrix} = T \begin{pmatrix} w_1 \\ \overline{w_1} \end{pmatrix}, \quad T = \frac{1}{\sqrt{2}} \begin{pmatrix} e^{-i(\pi/4)} & e^{i(\pi/4)} \\ e^{i(\pi/4)} & e^{-i(\pi/4)} \end{pmatrix}; \tag{133}$$

T is a unitary matrix, $\det T = -i$.

Therefore the following declarations are natural. The functions F^1, F^2,

$$\begin{aligned} F^1 &= e^{ik_m x + (i/\epsilon)(2/3)(-\zeta)^{3/2}} f^1, \quad f^1 = (-\zeta)^{-1/4} \alpha A - i(-\zeta)^{1/4} \beta B, \\ F^2 &= e^{ik_m x - (i/\epsilon)(2/3)(-\zeta)^{3/2}} f^2, \quad f^2 = (-\zeta)^{-1/4} \overline{\alpha} A + i(-\zeta)^{1/4} \overline{\beta} B, \end{aligned} \tag{134}$$

$$\alpha = \sum_{n \geqslant 0} (i\epsilon)^n \alpha_n (-\zeta)^{-3n/2}, \quad \beta = \sum_{n \geqslant 0} (i\epsilon)^n \beta_n (-\zeta)^{-3n/2},$$

satisfy system (94). The system for F^1 corresponds to the branch γ_1 of the isoenergy curve, where

$$k = k_m - (-\zeta)^{1/2} \zeta'; \tag{135}$$

F^2 corresponds to the branch γ_2, where

$$k = k_m + (-\zeta)^{1/2} \zeta'. \tag{136}$$

Since $\zeta(\xi_1) = 0$, these branches are fixed uniquely. They contain the point (ξ_1, k_m).

These branches are real. Consider now the complex branches containing the point (ξ_1, k_m).

Introduce two new series F^1, F^2,

$$F^1 = e^{ik_m x - (1/\epsilon)(2/3)\zeta^{3/2}} \frac{1}{\sqrt{2}} f^1, \quad f^1 = \zeta^{-1/4} \alpha_1 A - \zeta^{1/4} \beta_\perp B, \tag{137}$$

$$\alpha_1 = \sum_{n \geqslant 0} \epsilon^n \alpha_n \zeta^{-3n/2}, \quad \beta_1 = \sum_{n \geqslant 0} \epsilon^n \beta_n \zeta^{-3n/2},$$

$$\begin{aligned} F^2 &= e^{ik_m x + (1/\epsilon)(2/3)\zeta^{3/2}} \sqrt{2} f^2, \\ f^2 &= \zeta^{-1/4} \alpha_2 A + \zeta^{1/4} \beta_2 B, \end{aligned} \tag{138}$$

$$\alpha_2 = \sum_{n \geqslant 0} (-1)^n \epsilon^n \alpha_n \zeta^{-3n/2}, \quad \beta_2 = \sum_{n \geqslant 0} (-1)^n \epsilon^n \beta_n \zeta^{-3n/2}.$$

These solutions satisfy system (94), where correspondingly,

$$k = k_m + i\zeta^{1/2} \zeta', \quad k = k_m - i\zeta^{1/2} \zeta'. \tag{139}$$

Let us denote these branches again by γ_1, γ_2.

Let us discuss further the connection between the solutions F and G more concretely. Compute the coefficients of the series (134),

$$f^1=\sum_{n\geqslant 0}\epsilon^n f^1_n,\quad f^2=\sum_{n\geqslant 0}\epsilon^n f^2_n, \tag{140}$$

in terms of A_n, B_n:

$$f^1_n=\sum_{n_1+n_2=n} i^{n_1}(-\zeta)^{-3n_1/2}[(-\zeta)^{-1/4}\alpha_{n_1}A_{n_2}-i(-\zeta)^{1/4}\beta_{n_1}B_{n_2}], \tag{141}$$

$$f^2_n=\sum_{n_1+n_2=n} (-i)^{n_1}(-\zeta)^{-3n_1/2}[(-\zeta)^{-1/4}\alpha_{n_1}A_{n_2}+i(-\zeta)^{1/4}\beta_{n_1}B_{n_2}]. \tag{142}$$

Let us remark that we assume in that computation that solutions correspond to the real branches.

It can be checked that system (123) is equivalent to the systems (94) for f^1_n, f^2_n, respecting to the suitable branches of the isoenergy curve.

However, comparing systems (94) and (123) one has to keep in mind an essential detail principally affecting the set of the solutions of (123). In order to explain the detail, consider f^1_n, f^2_n for $n=0$:

$$f^1_0=[(-\zeta)^{-1/4}A_0-i(-\zeta)^{1/4}B_0], \tag{143}$$

$$f^2_0=[(-\zeta)^{-1/4}A_0+i(-\zeta)^{1/4}B_0]. \tag{144}$$

As a result,

$$A_0=\tfrac{1}{2}(-\zeta)^{1/4}(f^1_0+f^2_0), \tag{145}$$

$$B_0=\frac{1}{2i}(-\zeta)^{-1/4}(f^2_0-f^1_0). \tag{146}$$

With arbitrary solutions f^1_0, f^2_0, the functions A_0, B_0 satisfy the system (123) for $n=0$ everywhere except the point $\xi=\xi_1$, where f^1_0 and f^2_0 have singularities.

The solutions $f^{1,2}_0$ are fixed up to (independent) constant factors. It is essential that under the suitable choice of these constant factors, A_0 and B_0 become smooth for $\xi=\xi_1$ and are defined up to a common constant factor. The concrete structure of the singularities was briefly considered in Ref. 12, and reflected by formula (97). In order to estimate character of these singularities, remark that $\varphi(x,k)$ is a smooth function of k on the plane $\mathbb{K}$ with the cuts. Let us fix the integrals $\int_{\gamma_1}\omega$, $\int_{\gamma_2}\omega$ putting them to be zero in the point $(\xi_\perp, k_m)$. Then

$$e^{\int_{\gamma_1}\omega+\int_{\gamma_2}\omega}=\left(\int_0^a u_1(x,k_m)u_2(x,k_m)dx\right)\left(\int_0^a u_1(x,k)u_2(x,k)dx\right)^{-1}, \tag{147}$$

and

$$A_0=\tfrac{1}{2}(-\zeta)^{1/4}|\mathscr{E}'(k)|^{-1/2}[c_{01}\varphi(x,k)e^{\int_{\gamma_1}\omega}+c_{02}\varphi(x,2k_m-k)e^{\int_{\gamma_2}\omega}], \tag{148}$$

$$B_0=\frac{1}{2i}(-\zeta)^{-1/4}|\mathscr{E}'(k)|^{-1/2}[c_{02}\varphi(x,2k_m-k)e^{\int_{\gamma_2}\omega}-c_{01}\varphi(x,k)e^{\int_{\gamma_1}\omega}], \tag{149}$$

where $k=\theta_1'$. The first [ ] becomes an even function of $k-k_m$ and the second one an odd function if we put $c_{01}=c_{02}=c_0$. Both the functions A_0, B_0 become smooth even functions of $k-k_m$ and smooth functions of ξ. The coefficients are defined up to the common constant factor c_0.

We will not discuss further elementary details concerning A_n, B_n, $n\geqslant 1$. Finally, we can declare that formal solution (115) exists and is defined up to a factor of form (98). It exists on the unification of two minimal spectral intervals $\Delta=(\xi_0,\xi_1]\cup[\xi_1,\xi_2)$ containing the point ξ_1.

With any solution of system (123) we get the two-dimensional space of the solutions of (91) over the field $\mathscr{A}$ since the solution w of the Airy equation is arbitrary. The coefficients $\hat{A}=e^{ik_m x}A$ and $\hat{B}=e^{ik_m x}B$ can be found as real functions and the reality of G will be determined by the reality of w. The linear independence of G and $\overline{G}$ corresponding to w and $\overline{w}$ is also determined by the linear independence of $w,\overline{w}$.

In the conclusion of this section, consider the Wronskian of two solutions G_1,G_2:

$$\{G_1,G_2\}=G_1\frac{d}{dx}G_2-G_2\frac{d}{dx}G_1. \tag{150}$$

It is easy to show that

$$\{G_1,G_2\}=\{w_1,w_2\}[\hat{A},\hat{B}], \tag{151}$$

$$[\hat{A},\hat{B}]=\{\hat{A},\hat{B}\}+\zeta'(\hat{A}^2-\zeta\hat{B}^2), \tag{152}$$

where $\{w_1,w_2\}$ is the Wronskian of the corresponding w_1,w_2, with respect to their own argument, and $\{\hat{A},\hat{B}\}$ is the full standard Wronskian of $\hat{A},\hat{B}$ with respect to x. With an arbitrary choice of G_1,G_2 the combination $[\hat{A},\hat{B}]$ is an element of the field $\mathscr{A}$. $\{G_1,G_2\}$ equals zero if G_1 and G_2 are linearly dependent; it does not equal zero if G_1 and G_2 are independent. The expression $[\hat{A},\hat{B}]$ does not depend on the choice of w_1,w_2. Let us fix it such that

$$[\hat{A},\hat{B}]=-\tfrac{1}{2}. \tag{153}$$

This condition fixes $\hat{A},\hat{B}$ up to a common sign.

Compute the main term of the left side of (153):

$$[\hat{A},\hat{B}]\sim\frac{1}{2i}(\mathscr{E}')^{-1}c_0^2e^{\int\gamma_1\omega+\int\gamma_2\omega}\{u(x,k),u(x,2k_m-k)\}=-c_0^2\frac{1}{a}\int_0^a|u(x,k)|^2dx. \tag{154}$$

If we put

$$\int_0^a|u(x,k)|^2dx=a, \tag{155}$$

then $c_0^2=1/2$.

V. THE EXACT SOLUTIONS AND THE TRANSITION MATRICES

In this last section we construct the solutions that were used in Sec. III. We describe the asymptotic behavior of the solutions, consider the set of natural bases, and prove the asymptotic properties of the transition matrices.

A. Preliminary remarks

We remind the reader briefly of a standard idea that is used in order to prove the existence of the solution of an ordinary differential equation with a prescribed asymptotic expansion with respect to an external parameter.

Let u_1,u_2 be two formal asymptotic solutions of the equation

$$-\psi''+v(x,\epsilon)\psi=0, \tag{156}$$

where v depends on the external parameter $\epsilon,\epsilon\to 0$. Consider the finite sums of the asymptotic expansions and denote them u_1^N,u_2^N. Compute their Wronskian $\{u_1^N,u_2^N\}$. Since the formal Wronskian $\{u_1,u_2\}$ is a (formal) constant, the derivative $(d/dx)\{u_1^N,u_2^N\}$ should be small and, consequently,

$$\{u_1^N,u_2^N\}(x)=\{u_1^N,u_2^N\}(\tilde{x})+\int_{\tilde{x}}^{x}\frac{d}{dx}\{u_1^N,u_2^N\}dx \tag{157}$$

is close to a nonzero constant.

Introduce two almost new solutions:

$$y_1=\{u_1^N,u_2^N\}^{-1/2}u_1^N,\quad y_2=\{u_1^N,u_2^N\}^{-1/2}u_2^N. \tag{158}$$

Since $\{y_1,y_2\}=1$, both the functions y_1,y_2 have to satisfy the same equation,

$$-y''+\tilde{v}(x,\epsilon)y=0, \tag{159}$$

with a potential $\tilde{v}(x,\epsilon)$ close to $v(x,\epsilon)$.

Consider the integral equation

$$\psi(x)=y(x)+\int_{\tilde{x}}^{x}K(x,t)\psi(t)dt, \tag{160}$$

where $\tilde{x}$ is some fixed point, $y=\alpha y_1+\beta y_2$, α,β are some fixed constants, and

$$K(x,t)=(y_2(x)y_1(t)-y_1(x)y_2(t))(v(t,\epsilon)-\tilde{v}(t,\varepsilon)). \tag{161}$$

The solution of the integral equation satisfies the differential equation (156); its initial data in $\tilde{x}$ coincide with the initial data of y.

The kernel K is small in a suitable sense; therefore the integral equation should be effective for the asymptotic treatment of u_1,u_2.

If the asymptotic solutions possess different orders for different x, it is necessary to choose $\tilde{x}$ and α,β appropriately.

The last general remark: although the justification of the asymptotic expansion is limited by the choice of N (arbitrarily large), for the solution ψ of the integral equation the full asymptotic expansion, as $\epsilon\to 0$, can be obtained.

B. Solutions ψ_1 and ψ_2

Choose a turning point and construct real $\hat{A},\hat{B}$. Fix them such that

$$[\hat{A},\hat{B}]=-\tfrac{1}{2}. \tag{162}$$

Assume also that $\hat{A},\hat{B}$ do not contain exponential factors with respect to ϵ^{-1}. Consider four formal solutions $\mathbf{g},\mathbf{h},\mathbf{f},\overline{\mathbf{f}}$ taking as w, correspondingly, $u,v,w_1,\overline{w_1}$. It is evident that

$$\begin{pmatrix}\mathbf{h}\\ \mathbf{g}\end{pmatrix}=T\begin{pmatrix}\mathbf{f}\\ \overline{\mathbf{f}}\end{pmatrix}. \tag{163}$$

As it was shown in Sec. IV, as $\epsilon^{-2/3}\zeta\to+\infty$, the solutions $\mathbf{g},\overline{\mathbf{h}}$ can be reduced to solutions of the form F; analogously, as $\epsilon^{-2/3}\zeta\to-\infty$, the solutions $\mathbf{f},\overline{\mathbf{f}}$ can also be reduced to solutions of the form F.

Consider two neighboring turning points ξ_1,ξ_2, $\xi_1<\xi_2$. Let (ξ_1,ξ_2) be covered by a complex branch of the isoenergy curve. The minimal intervals (ξ_0,ξ_1) and (ξ_2,ξ_3) are covered by real branches. Consider in a vicinity of ξ_1 the solution $\mathbf{g}$ and denote it by $\mathbf{g}_1$. Up to a factor belonging to the field $\mathscr{A}$, it coincides (after the asymptotic reduction of w) with the solution $\mathbf{h}_2$ defined in a vicinity of ξ_2:

$$\mathbf{g}_1\sim -Z\mathbf{h}_2. \tag{164}$$

Since $\mathbf{g}_1,\mathbf{h}_2$ are fixed up to the sign, we can choose them such that $Z>0$ in the main order. Let us consider a smooth unit partition,

$$1=\theta_1+\theta_2, \tag{165}$$

where $\theta_1(\xi),\theta_2(\xi)$ differ from 0 or 1 only on a proper subinterval of (ξ_1,ξ_2). Introduce

$$\mathbf{r}=\mathbf{g}_1\theta_1-Z\mathbf{h}_2\theta_2. \tag{166}$$

Analogously, consider the solutions $\mathbf{g}_2$ and $\mathbf{h}_1$:

$$\mathbf{h}_1\sim Z_1\mathbf{g}_2, \tag{167}$$

and

$$\mathbf{s}=\mathbf{g}_2\theta_2+\frac{1}{Z_1}\,\mathbf{h}_1\theta_1. \tag{168}$$

It is easy to see that

$$\{\mathbf{r},\mathbf{s}\}=\{\mathbf{g}_1,\mathbf{h}_1\}\,\frac{1}{Z_1}=-Z\{\mathbf{h}_2,\mathbf{g}_2\}; \tag{169}$$

therefore

$$Z_1=\frac{1}{Z}, \tag{170}$$

and

$$\{\mathbf{r},\mathbf{s}\}=Z. \tag{171}$$

The factor Z will be discussed later, however, it is worth indicating here the exponential character of the dependence of Z on ϵ,

$$\ln Z=\frac{1}{\epsilon}\int_{\xi_1}^{\xi_2}|\mathrm{Im}\ k|d\xi+O(1). \tag{172}$$

Denote

$$Z_0=e^{(1/\epsilon)\int_{\xi_1}^{\xi_2}|\mathrm{Im}\ k|d\xi}. \tag{173}$$

Introduce new notations:

$$\rho_j^{\pm}(\xi)=\begin{cases} e^{\pm(2/3)\epsilon^{-1}|\zeta_j|^{3/2}}, & \zeta_j\geqslant 0,\\ 1, & \zeta_j\leqslant 0,\end{cases} \tag{174}$$

where ζ_j are the functions of the type ζ related to the points ξ_j.

Let us introduce the weights:

$$\rho_r(\xi)=\begin{cases}\rho_1^+(\xi), & \xi\leqslant\xi_2\\ Z_0\rho_2^-(\xi), & \xi\geqslant\xi_1,\end{cases}\quad \rho_s(\xi)=\begin{cases}\rho_2^+(\xi), & \xi\geqslant\xi_1,\\ Z_0\rho_1^-(\xi), & \xi\leqslant\xi_2.\end{cases} \tag{175}$$

They both are monotonous functions naturally defined for $\xi\in(\xi_0,\xi_3)$. It is clear that

$$\rho_r(\xi)\rho_s(\xi)=Z_0. \tag{176}$$

Return to the constructions of the previous section and take $\mathbf{r}$ and $\mathbf{s}$ as u_1,u_2. Then

$$|u_1^N|=|r^N|\leqslant C_N\rho_r,\quad |u_2^N|=|s^N|\leqslant C_N\rho_s, \tag{177}$$

$$\{u_1^N, u_2^N\} = \{r^N, s^N\} = Z_N + Z_0 O(\epsilon^{N+1}), \tag{178}$$

where Z_N is the cut series for Z.

It is easy to see that

$$|y_1| \leqslant C_N Z_0^{-1/2} \rho_r, \quad |y_2| \leqslant C_N Z_0^{-1/2} \rho_s,$$

$$|K| \leqslant C_N \epsilon^{N+1} Z_0^{-1} (\rho_r(\xi)\rho_s(\eta) + \rho_r(\eta)\rho_s(\xi)),$$

$$\xi = \epsilon x, \quad \eta = \epsilon t. \tag{179}$$

Consider now two exact solutions ψ_1 and ψ_2 taking as y, respectively, y_1 and y_2 and as $\widetilde{\xi}$ the points $\xi_0 + \delta, \xi_3 - \delta, \delta > 0, \delta$ is fixed.

It is almost immediately clear that on the interval $\xi \in [\xi_0 + \delta, \xi_3 - \delta]$,

$$\psi_1 = Z_N^{-1/2} r^N + Z_0^{-1/2} \rho_r(\xi) O(\epsilon^{N+1}), \tag{180}$$

$$\psi_2 = Z_N^{-1/2} s^N + Z_0^{-1/2} \rho_s(\xi) O(\epsilon^{N+1}), \tag{181}$$

$$\{\psi_1, \psi_2\} = 1 + O(\epsilon^{N+1}). \tag{182}$$

C. Solutions f, g, h

Consider the interval $(\xi_0 + \delta, \xi_3 - \delta)$. We have constructed on the interval two real solutions with a known asymptotic behavior and with a known Wronskian. As a result on finite vicinities of the turning points we have two linearly independent real solutions with a known asymptotic behavior. Introduce now on these vicinities sets of canonical solutions.

Consider on a vicinity of ξ_1 two solutions:

$$\widetilde{h}_1 = Z_N^{-1/2} \psi_2, \quad \widetilde{g}_1 = Z_N^{1/2} \psi_1. \tag{183}$$

On this vicinity, see the definition of **r** and **s**:

$$\begin{aligned} \widetilde{h}_1 &= (Z\mathbf{h}_1)^N Z_N^{-1} + \rho_1^- O(\epsilon^{N+1}) = h_1^N + \rho_1^- O(\epsilon^{N+1}), \\ \widetilde{g}_1 &= g_1^N + \rho_1^+ O(\epsilon^{N+1}), \end{aligned} \tag{184}$$

and

$$\{\widetilde{h}_1, \widetilde{g}_1\} = -\{\psi_1, \psi_2\} = -1 + O(\epsilon^{N+1}). \tag{185}$$

Let us renormalize $\widetilde{h}_1, \widetilde{g}_1$:

$$h_1 = \{\widetilde{g}_1, \widetilde{h}_1\}^{-1/2} \widetilde{h}_1, \quad g_1 = \{\widetilde{g}_1, \widetilde{h}_1\}^{-1/2} \widetilde{g}_1; \tag{186}$$

then

$$h_1 = h_1^N + \rho_1^- O(\epsilon^{N+1}), \quad g_1 = g_1^N + \rho_1^+ O(\epsilon^{N+1}), \quad \{h_1, g_1\} = -1. \tag{187}$$

Introduce f_1:

$$\begin{pmatrix} f_1 \\ \overline{f_1} \end{pmatrix} = T^{-1} \begin{pmatrix} h_1 \\ g_1 \end{pmatrix}. \tag{188}$$

It is clear that

$$f_1 = f_1^N + \rho_1^+ O(\epsilon^{N+1}), \quad \{f_1, \overline{f_1}\} = -i. \tag{189}$$

Analogously, on a vicinity of ξ_2 introduce

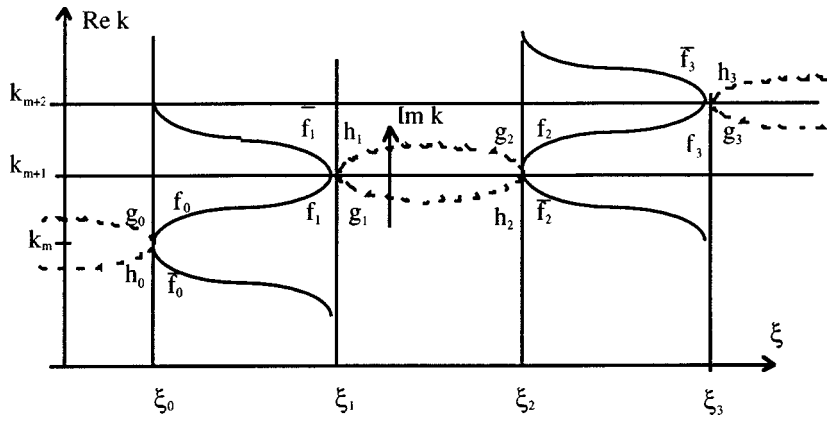

FIG. 7.

$$\widetilde{h}_2 = -Z_N^{-1/2}\psi_1, \quad \widetilde{g}_2 = Z_N^{1/2}\psi_2; \tag{190}$$

then $\{\widetilde{h}_2, \widetilde{g}_2\} = \{\psi_2, \psi_1\} = -1 + O(\epsilon^\infty)$. Consider

$$h_2 = \{\widetilde{g}_2, \widetilde{h}_2\}^{-1/2}\widetilde{h}_2, \quad g_2 = \{\widetilde{g}_2, \widetilde{h}_2\}^{-1/2}\widetilde{g}_2. \tag{191}$$

Then

$$h_2 = h_2^N + \rho_2^- O(\epsilon^{N+1}), \quad g_2 = g_2^N + \rho_2^+ O(\epsilon^{N+1}), \quad \{h_2, g_2\} = -1. \tag{192}$$

For f_2, defined by the formula

$$\begin{pmatrix} f_2 \\ \overline{f}_2 \end{pmatrix} = T^{-1}\begin{pmatrix} h_2 \\ g_2 \end{pmatrix}, \tag{193}$$

one has

$$f_2 = f_2^N + \rho_2^+ O(\epsilon^{N+1}), \quad \{f_2, \overline{f}_2\} = -i. \tag{194}$$

So one has to conclude that on a vicinity of each turning point ξ_m there exist three solutions f_m, h_m, g_m with all the set of the properties declared in Sec. III:

$$\begin{pmatrix} h_m \\ g_m \end{pmatrix} = T\begin{pmatrix} f_m \\ \overline{f}_m \end{pmatrix}, \quad f_m = f_m^N + \rho_m^+ O(\epsilon^{N+1}), \tag{195}$$

$$h_m = h_m^N + \rho_m^- O(\epsilon^{N+1}), \quad g_m = g_m^N + \rho_m^+ O(\epsilon^{N+1}),$$

$$\{f_m, \overline{f}_m\} = -i, \quad \{h_m, g_m\} = -1. \tag{196}$$

We have constructed here solutions with the finite asymptotic expansions, although N can be taken as an arbitrary natural number. These finite expansions are sufficient for the spectral applications considered in Sec. III. From the other side, it is not too difficult to complete the previous proof and to obtain solutions with the full asymptotic expansions. (See Fig. 7.)

D. Transition matrices

Now it is easy to connect two bases (h_1, g_1) and (h_2, g_2) if the minimal interval (ξ_1, ξ_2) is covered by a complex branch of the isoenergy curve. Indeed,

$$\begin{pmatrix} h_2 \\ g_2 \end{pmatrix} = \frac{1}{\{\psi_1, \psi_2\}^{1/2}}\begin{pmatrix} -Z_N^{-1/2}\psi_1 \\ Z_N^{1/2}\psi_2 \end{pmatrix} = \begin{pmatrix} -Z_N^{-1}g_1 \\ Z_N h_1 \end{pmatrix} = \begin{pmatrix} 0 & -Z_N^{-1} \\ Z_N & 0 \end{pmatrix}\begin{pmatrix} h_1 \\ g_1 \end{pmatrix}. \tag{197}$$

Let now (ξ_1,ξ_2) be separated by a minimal interval covered by a real branch of the isoenergy curve. Consider the relation

$$\begin{pmatrix} h_2 \\ g_2 \end{pmatrix} = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \begin{pmatrix} h_1 \\ g_1 \end{pmatrix}. \tag{198}$$

It is equivalent to the formula

$$\begin{pmatrix} f_2 \\ \overline{f_2} \end{pmatrix} = T^{-1} \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} T \begin{pmatrix} f_1 \\ \overline{f_1} \end{pmatrix}. \tag{199}$$

The entries of

$$\begin{pmatrix} \alpha_1 & \beta_1 \\ \overline{\beta_1} & \overline{\alpha_1} \end{pmatrix} = T^{-1} \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} T \tag{200}$$

should satisfy the relation

$$|\alpha_1|^2 - |\beta_1|^2 = 1. \tag{201}$$

They can be expressed in terms of Wronskians,

$$\alpha_1 = +i\{f_2, \overline{f_1}\}, \quad \beta_1 = -i\{f_2, f_1\}. \tag{202}$$

It is clear from the constructions for f_1, f_2 that

$$\mathbf{f}_2 = e^{-i\varphi}\mathbf{f}_1, \tag{203}$$

where φ is real,

$$\varphi \sim \frac{1}{\epsilon}\,\varphi^0 + \cdots. \tag{204}$$

We will discuss the structure of φ in the next section. From (202),

$$\alpha_1 = e^{-i\varphi^N}(1 + O(\epsilon^{N+1})), \quad \beta_1 = O(\epsilon^{N+1}). \tag{205}$$

Finally, one has

$$\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} = \begin{pmatrix} \cos\,\phi^N & -\sin\,\phi^N \\ \sin\,\phi^N & \cos\,\phi^N \end{pmatrix} + O(\epsilon^{N+1}). \tag{206}$$

E. Main asymptotic terms of φ and Z

Let us compute the main terms of the asymptotic expansions of φ and Z. Let us begin with φ. Remember the definition,

$$\mathbf{f}_2 = e^{-i\varphi}\mathbf{f}_1. \tag{207}$$

In a vicinity of the point ξ_1,

$$\mathbf{f}_1 \simeq \epsilon^{-1/6} w_1 \hat{A} + \epsilon^{1/6} w_1' \hat{B}, \tag{208}$$

where $\hat{A}$ and $\hat{B}$ are real. After the asymptotical reconstruction,

$$\mathbf{f}_1 \sim [(-\zeta_1)^{-1/4}\hat{A} - i(-\zeta_1)^{1/4}\hat{B}]e^{(i/\epsilon)(2/3)(-\zeta)^{3/2}} = c_{01}e^{ik_m x}e^{(i/\epsilon)\int_{\xi_1}^{\xi}(k-k_m)d\xi}(\mathscr{E}')^{-1/2}\varphi(x,k)e^{\int_{\xi_1}^{\xi}\omega}, \tag{209}$$

where c_{01} is real and fixed by the normalizing condition $c_{01}^2=1/2$.

Analogously,

$$\mathbf{f}_2\sim c_{02}e^{ik_{m'}x}e^{(i/\epsilon)\int_{\xi_2}^{\xi}(k-k_{m'})d\xi}(\mathscr{E}')^{-1/2}\varphi(x,k)e^{\int_{\xi_2}^{\xi}\omega}, \tag{210}$$

and again c_{02} is real and normalized by the condition $c_{02}^2=1/2$. We have to take $k_{m'}=k_m+1/2a^*$.

The connection between the signs of c_{01},c_{02} is not essential for the spectral applications; it is enough to compute the matrix V_m up to the sign. Nevertheless, we can put $c_{01}=c_{02}$. Then

$$e^{-i\varphi}\sim e^{(i/\epsilon)k_{m'}\xi_2-(i/\epsilon)k_m\xi_1-(i/\epsilon)\int_{\xi_1}^{\xi_2}kd\xi-\int_{\xi_1}^{\xi_2}\omega}=e^{-(i/\epsilon)(\pi/a)E+(i/\epsilon)\int_{k_m}^{k_{m'}}\mathscr{E}(k)dk-\int_{\xi_1}^{\xi_2}\omega}. \tag{211}$$

It coincides with formula (33) declared in Sec. III A.

Let us consider now the case when (ξ_1,ξ_2) is covered by a complex branch of the isoenergy curve. Then, after the reconstruction,

$$\mathbf{g}_1\sim\sqrt{2}[\zeta_1^{-1/4}\hat{A}_0+\zeta_1^{1/4}\hat{B}_0]e^{(2/3)(1/\epsilon)\zeta_1^{3/2}}=\pm c_{01}\sqrt{2}e^{ik_mx}e^{(1/\epsilon)\int_{\xi_1}^{\xi}|\mathrm{Im}\,k|d\xi}(-i\mathscr{E}')^{-1/2}\varphi(x,k)e^{\int_{\xi_1}^{\xi}\omega}. \tag{212}$$

On the branch of the integration $\mathrm{Im}\,k<0$, $(\pm)$ appeared since we do not control the sign of $(-i\mathscr{E}')^{1/2}$.

Analogously,

$$\mathbf{h}_2\sim\pm c_{02}\frac{1}{\sqrt{2}}e^{ik_mx}e^{(1/\epsilon)\int_{\xi_2}^{\xi}|\mathrm{Im}\,k|d\xi}(i\mathscr{E}')^{-1/2}\varphi(x,k)e^{\int_{\xi_2}^{\xi}\omega}. \tag{213}$$

Formulas (212) and (213) are valid for different ξ: in (212) $\xi<\hat{\xi}$, in (213) $\xi>\hat{\xi}$, and $\hat{\xi}$ corresponds to the end of the cut where $\mathscr{E}'=\infty$. Both the expressions cannot be continued directly through the point $\hat{\xi}$ since the integrals $\int\omega$ are singular at this point. However, the full expressions have finite limits, as $\xi\to\hat{\xi}$. It is easy to check that

$$\frac{\mathscr{E}'(\hat{\xi}-\epsilon)}{\mathscr{E}'(\hat{\xi}+\epsilon)}\to-1,\quad \epsilon\to0. \tag{214}$$

It implies that the full expression can be defined also for intervals containing $\hat{\xi}$. For this, the integral $\int\omega$ over the interval containing the point $\hat{\xi}$ must be defined in the sense of the principal value.

Let us come to Z. The constants here are the same as in the previous computations of φ. Therefore $c_{01}^2=c_{02}^2=\frac{1}{2}$. Since the solutions $\mathbf{g}_1,\mathbf{h}_2$ should be real and

$$g_1\sim-Zh_2, Z>0, \tag{215}$$

we have to choose c_{01} and c_{02} such that

$$Z\sim2e^{(1/\epsilon)\int_{\xi_1}^{\xi_2}|\mathrm{Im}\,k|d\xi+\int_{\xi_1}^{\xi_2}\omega}=2e^{-(1/2\epsilon)\int_{\overline{\gamma}_l}\xi(idk)+1/2\int_{\overline{\gamma}_l}\omega_l}\gg1. \tag{216}$$

F. Solutions g_-,f_+

The solutions g_- and f_+ were introduced in Sec. I. Their asymptotic behavior and their connections with the solutions f_i,g_i,h_i defined in the vicinity of the turning points ξ_0 and ξ_{2N} were described in Sec. III separately. Let us justify the results listed there.

Consider first g_-. Introduce the standard formal solutions $\mathbf{f}_0,\mathbf{g}_0,\mathbf{h}_0$ defined on the interval $(-\infty,\xi_1)$ containing the turning point ξ_0.

It is well known that

$$\mathscr{E}(k)=k^2+\cdots,\quad \psi(x,k)=e^{ikx}+\cdots,\quad k\to\infty. \tag{217}$$

Fix the complex branch $\overline{\gamma}$ of the isoenergy curve for $\xi<\xi_0$, where $k=-i|k|$. Consider the corresponding formal solution $\mathbf{g}$; its main term,

$$\mathbf{g}\sim c\sqrt{2}(i\mathscr{E}'(k))^{-1/2}\varphi(x,k)e^{\int_{\xi_0}^{\xi}\omega}e^{(i/\epsilon)\int_{\xi_0}^{\xi}kd\xi},\quad \text{Im } k<0, \tag{218}$$

can be simplified as $\xi\to-\infty$:

$$\mathbf{g}\sim\pm c|\xi+E|^{-1/4}e^{-(1/\epsilon)\int_{\xi}^{\xi_0}|\xi+E|^{1/2}d\xi}. \tag{219}$$

The sign can be fixed arbitrary. So the asymptotic behavior of the main term $\mathbf{g}$ coincides up to a constant factor with the asymptotic behavior of g_-.

Fix now this formal solution such that it would possess the asymptotic character simultaneously for $\epsilon\to0$ and $\xi\to-\infty$. More precisely, we can fix it such that its coefficients g_n will decrease at infinity as $|\xi+E|^{-1/4-n}$. To construct this solution one has to choose the arbitrary limits of integrations in all the solutions of the transport equations to be equal to $-\infty$. This solution is defined up to a simple constant c. Take this constant such that the main term of the solution, as $\xi\to-\infty$, coincides with the main term of the asymptotics of g_-.

It is clear that there exists an element Z_- of the field $\mathscr{A}$, such that (after the asymptotic reduction of $\mathbf{h}_0$)

$$\mathbf{g}_-\sim-Z_-\mathbf{h}_0; \tag{220}$$

compare with (164). The main term of Z_- is exponentially large for small ϵ.

Now we can construct $\mathbf{r}_-$, the analog of the solution $\mathbf{r}$; see (166). As the analog of $\mathbf{s}$ we can simply take $\mathbf{g}_0$.

Almost literally repeating the ideas of Sec. V A, we can find on the interval $(-\infty,\xi_1-\delta)$, containing one turning point ξ_0, the solutions f_0,h_0,g_0 with the asymptotics $f_0\sim\mathbf{f}_0$, $h_0\sim\mathbf{h}_0$, $g_0\sim\mathbf{g}_0$. As almost solutions we can use properly normalized r_-^N and g_0^N.

In the integral equation for the solution ψ_-, corresponding to $\mathbf{r}_-$, see Sec. V B, one has to take $\widetilde{\xi}=-\infty$. The coincidence of the main terms of the asymptotic behavior of r_-^N and g_-, as $\xi\to-\infty$, shows that ψ_-, and g_- should coincide up to a constant factor and, therefore, h_0 and g_- also coincide up to a constant factor. Asymptotically, as $\epsilon\to0$, this constant factor can be described by a series from the field $\mathscr{A}$. The explicit formula for the main term of this constant can be found by constructions similar to the constructions of Sec. V E. The result is given by (44). For the spectral applications one does not need any formula for the constant.

The solutions f_{2Q},g_{2Q},h_{2Q} with the standard properties can be constructed simultaneously with the solutions $f_{2Q-1},g_{2Q-1},h_{2Q-1}$, as usual. In particular, $f_{2Q}\sim\mathbf{f}_{2Q}$. They are defined on the interval $(\xi_{2Q-2}+\delta,R)$; R is fixed such that $R>\xi_{2Q}$.

The solution f_+ introduced in Sec. I, is characterized by its behavior, as $\xi\to+\infty$; see (5). Since $\{f_+,\overline{f}_+\}=-i$ there exist constants α_+,β_+ such that

$$f_{2Q}=\alpha_+f_++\beta_+\overline{f}_+. \tag{221}$$

We have to describe the asymptotic behavior of α_+,β_+, as $\epsilon\to0$.

In order to obtain this asymptotic behavior, introduce the formal solution $\mathbf{f}_+$, which has an asymptotic character simultaneously, as $\epsilon\to0$ and $\xi\to\infty$. The idea is absolutely similar to the idea used for the definition of $\mathbf{g}_-$, although now the point $\xi=-\infty$ should be replaced in all the integral's limits by the point $\xi=+\infty$. This formal solution is defined up to a simple constant factor, which should be fixed, such that $\mathbf{f}_+$ coincides asymptotically, as $\xi\to\infty$, with f_+.

We have two formal solutions $\mathbf{f}_+$ and $\mathbf{f}_+$. Now we can use f_+^N and $\overline{f}_+^N$ as almost solutions on the interval $\xi\geqslant\xi_{2Q}+\delta$. Notice that the Wronskian of these almost solutions equals $-i$ as well as for f_+ and f_+. It is clear from their asymptotic behavior at infinity. In the corresponding integral equations for the true solutions we have to set $\widetilde{\xi}=\infty$. If we take as y in the integral equation the almost solution f_+^N, we obtain a solution ψ_+ which has two properties: (1) by the construction $\psi_+\sim\mathbf{f}_+$; and (2) $\psi_+=f_+$, since they have the same asymptotics as $\xi\to\infty$. Therefore, as $\epsilon\to0$,

$$f_+\sim\mathbf{f}_+. \tag{222}$$

Two formal solutions $\mathbf{f}_{2Q}$ and $\mathbf{f}_+$ correspond to the same branch of the isoenergy curve and their Wronskians with the corresponding complex conjugated solutions coincide. Therefore

$$\mathbf{f}_{2Q}=e^{-i\varphi_+}\mathbf{f}_+, \tag{223}$$

where $e^{-i\varphi_+}\in\mathscr{A}$ (in a natural sense after reconstruction). Since

$$\alpha_+=i\{f_{2Q},\overline{f_+}\},\quad \beta_+=-i\{f_{2Q},f_+\}, \tag{224}$$

we obtain

$$\alpha_+\sim e^{-i\varphi_+}, \tag{225}$$

or

$$\alpha_+=e^{-i\varphi_+^N}+O(\epsilon^{N+1}); \tag{226}$$

N is arbitrary. For β_+ we have

$$\beta_+=O(\epsilon^N). \tag{227}$$

G. An important remark

All the asymptotical considerations of the two last sections were limited by the case of real E. In fact, all the obtained asymptotic formulas remain to be right if $|\mathrm{Im}\,E|<\epsilon\alpha'<\epsilon\alpha$. If we consider the equation for such complex E, we discover that all the constructions can be repeated without any changes. It can be explained by the fact that for such small $\mathrm{Im}\,E$, all the exponential factors in the asymptotic formulas have exactly the same character of increasing and decreasing as for the real E. The most convenient variant of the treatment of the complex E is to introduce the complex turning points defined again by the equation $E_m-\xi=E$ and to consider the equation on the straight line connecting them, in other words, on the line $\mathrm{Im}\,x=(1/\epsilon)\mathrm{Im}\,E$. Some special, but very natural, details concerning the interval $(\xi_{2Q},+\infty)$, can be found in Ref. 1.

(Received 2 June 1997; accepted for publication 11 February 1998)

The one-dimensional generalized Schrödinger equation for a system with smooth potential and *mass* step is resolved exactly. The wave function depends on the *Heun's* function, which is a solution of a second-order *Fuchsian* equation with four singularities. The behavior of the transmission coefficient as a function of energy is compared to that of the case of an abrupt potential and mass step. Two limiting cases are also studied: when the width of the mass step is vanishing, and when the smooth potential and mass step tend to an abrupt potential and mass step. © *1998 American Institute of Physics.* [S0022-2488(98)02505-5]

I. INTRODUCTION

Particular interest has been given to physical systems with position-dependent mass[1–5] in recent years. One example is the effective-mass model[6] (related to the envelope-function approximation),[7,8] used to study the dynamics of electrons in semiconductor heterostructures.[9–18] Since the mass and the momentum operator no longer commute, the generalization of the standard Hamiltonian[9–16,19–21] is not trivial. The basic problems are the following: the choice of a correct ordering of the operators for the kinetic energy so that the Hamiltonian is hermitic,[9,13,21] the Galilean invariance[16,22] related to the Bargmann's theorem, and the connection rules[7,8,10,11,17,18,23] for the wave functions across an abrupt heterojunction. It appears that a consensus was made in the majority of these works about the following form of the Hamiltonian:

$$H=\frac{1}{2}\left[p\,\frac{1}{m}\,p\right]+V. \tag{1.1}$$

With the help of this Hamiltonian we have calculated[24] the Green's function via the path integral formalism for systems with potential and mass both, step, rectangular barrier, and multi-barrier. We have also deduced the reflection and transmission coefficients for the first two cases, reproducing thus the results obtained by direct resolution of the Schrödinger equation.[25] But, these applications were made for systems with piecewise flat potentials and masses. However, it is also interesting to study models with continuous and smoothly variable potentials and masses. Indeed, they are obviously much more difficult to solve, but they allow us to study the crossing of the interfaces in a smooth and not in an abrupt way. Moreover, the cases with abrupt interfaces will be deduced as being limiting cases of these latter.

In this paper, we solve the one-dimensional generalized Schrödinger equation associated with the above-mentioned form of Hamiltonian (1.1) for a system with continuous potential and mass, both of the smooth step shape. In Sec. II we will show that, thanks to a change of the independent

variable (position), followed by a change of the dependent variable (wave function), the generalized Schrödinger equation is transformed into a second-order Fuchsian equation with four singularities, the so-called Heun's equation.[26–31] With the help of the solutions of this equation—the so-called Heun's functions—we will determine the general expression of the wave function. We will deduce the reflection and transmission coefficients by studying the asymptotic behavior of the wave function when $x \to \pm\infty$. We will show that the behavior of the transmission coefficient as a function of energy is similar to that of the case of an abrupt potential and mass step.[25] We will also recover the reflection and transmission coefficients of two limiting cases, namely, when the width of the mass step is vanishing,[32,33] and when the smooth potential and mass step tend to an abrupt potential and mass step.[25] Section III will feature a brief summing up and a conclusion. In Appendix A, we will build the functional relation between the z and $1\text{-}z$ argument Heun's functions, the relation required for the study of the asymptotic behavior of the wave function when $x \to \pm\infty$. Finally, in Appendix B, we will construct a relation between two *contiguous* Heun's functions, the relation necessary for the study of the transmission coefficient as a function of the energy, and for the study of the limiting case when the smooth potential and mass tend to an abrupt potential and mass step.

II. SCHRÖDINGER EQUATION

Let us adopt the following parametrization for the smooth potential[32,33] and mass step,

$$V(x) = \frac{V_0}{2}\left(1 + th\,\frac{x}{2r}\right), \tag{2.1}$$

$$m(x) = \overline{m} + \frac{\Delta m}{2}\,th\,\frac{x}{2r}, \tag{2.2}$$

where $\overline{m} = (m_1 + m_2)/2$, $\Delta m = m_2 - m_1$. Here V_0 and r are positive constants.

The potential (respectively, the mass) increases from the value $V = 0 (m = m_1)$ for $x = -\infty$ to the value $V = V_0 (m = m_2)$ for $x = +\infty$. The main rise occurring in the $-2r < x < 2r$ range,

$$V(-2r) = 0.119 V_0, \quad m(-2r) = 0.119 \Delta m;$$

$$V(2r) = 0.881 V_0, \quad m(2r) = 0.881 \Delta m.$$

The time-independent Schrödinger equation that follows from the generalized Hamiltonian (1.1) has the form

$$-\frac{\hbar^2}{2}\frac{d}{dx}\left(\frac{1}{m(x)}\frac{d\Psi(x)}{dx}\right) + V(x)\Psi(x) = E\Psi(x), \tag{2.3}$$

or

$$\frac{d^2\Psi(x)}{dx^2} - \frac{1}{m(x)}\left(\frac{dm(x)}{dx}\right)\frac{d\Psi(x)}{dx} + \frac{2m(x)}{\hbar^2}(E - V(x))\Psi(x) = 0. \tag{2.4}$$

The change of the independent variable,

$$z = \frac{1}{2}\left(1 - th\,\frac{x}{2r}\right), \tag{2.5}$$

maps the interval $x \in]-\infty, +\infty[$ to $z \in]0,1[$, and transforms the coefficients of the differential equation (2.4) into rational functions of the new variable z. Potential (2.1) and mass (2.2) can now be written as $V(z) = -V_0(z-1)$, $m(z) = -\Delta m(z-a)$, where

$$a = \frac{m_2}{m_2 - m_1}. \tag{2.6}$$

We come to the differential equation

$$\frac{d^2\Psi(z)}{dz^2}+\left[\frac{1}{z}+\frac{1}{z-1}-\frac{1}{z-a}\right]\frac{d\Psi(z)}{dz} + \left[-\omega^2 z-\frac{\nu^2 a}{z}+\frac{\mu^2(a-1)}{z-1}+a\omega^2+\nu^2-\mu^2\right]\frac{\Psi(z)}{z(z-1)(z-a)}=0, \tag{2.7}$$

where the following abbreviations have been used:

$$\nu^2=\frac{2m_2 r^2}{\hbar^2}(V_0-E), \quad \mu^2=-\frac{2m_1 r^2 E}{\hbar^2}, \quad \omega^2=\frac{2\Delta m r^2}{\hbar^2}V_0. \tag{2.8}$$

The resulting equation (2.7) is a Heun's-type equation, i.e., a second-order linear homogeneous differential equation with four singularities $z=0$, 1, a, ∞, all regular. Since all the singularities are regular, Eq. (2.7) belongs to the class of Fuchsian equations. In order to transform the equation (2.7) into its normal form, we introduce the following change of the dependent variable:

$$\Psi(z)=z^{\nu}(z-1)^{\mu}f(z). \tag{2.9}$$

A simple calculation leads to the normal form of the Heun's-type equation,

$$\frac{d^2 f(z)}{dz^2}+\left[\frac{2\nu+1}{z}+\frac{2\mu+1}{z-1}-\frac{1}{z-a}\right]\frac{df(z)}{dz}+[\{(\nu+\mu)^2-\omega^2\}z + a\{\omega^2-(\nu+\mu)(\nu+\mu+1)\}+\nu]\frac{f(z)}{z(z-1)(z-a)}=0. \tag{2.10}$$

The solution of Eq. (2.10), which is regular in the neighborhood of $z=0$ and belongs to the exponent *zero*, is the Heun's function defined by the series[34]

$$f_1(z)=CF(a,a[\omega^2-(\nu+\mu)(\nu+\mu+1)]+\nu;\nu+\mu+\omega,\nu+\mu-\omega,2\nu+1,-1;z) \equiv C\left\{1-\frac{a[\omega^2-(\nu+\mu)(\nu+\mu+1)]+\nu}{a(2\nu+1)}z+\sum_{s=2}^{\infty}c_s z^s\right\}. \tag{2.11}$$

Constant C will be determined by the boundary conditions. The c_s coefficients of the series (2.11) are determined by the difference equation

$$(s+2)(s+2+2\nu)ac_{s+2}=\{(s+1)^2(a+1)+(s+1)[2\nu-1+a(2\nu+2\mu+1)] +a[(\nu+\mu)(\nu+\mu+1)-\omega^2]-\nu\}c_{s+1} -(s+\nu+\mu+\omega)(s+\nu+\mu-\omega)c_s, \tag{2.12}$$

with the initial conditions

$$c_0=1, \quad c_1=\frac{a[(\nu+\mu)(\nu+\mu+1)-\omega^2]-\nu}{a(2\nu+1)}, \quad c_s=0, \quad \text{if} \quad s<0. \tag{2.13}$$

Series (2.11) converges inside a circle centered at the origin and whose radius is the distance from the origin to the nearer of the two singular points, $z=1$ and $z=a$. Thus, series (2.11) converges for $|z|<1$ if $|a|>1$, i.e., if $m_1<2m_2$ and $m_1\neq m_2$. In the case where $|a|<1$, i.e., $m_1>2m_2$, series (2.11) converges for $|z|<|a|$. In the latter case we can make an analytic continuation to ensure the convergence for $|z|<1$. The analytic continuation may be obtained by introducing into the differential equation (2.10) the change of the independent variable,

$$z'=1-z, \tag{2.14}$$

which leads to the following solution:

$$f_3(z)=C'F(1-a,(1-a)[\omega^2-(\nu+\mu)(\nu+\mu+1)] + \mu;\nu+\mu+\omega,\nu+\mu-\omega,2\mu+1,-1;1-z). \tag{2.15}$$

We first consider the limit $x\to\infty$ or $z\approx e^{-x/r}\to 0$; solution (2.11) becomes $f_1(0)=C$, or

$$\Psi(z)\to Cz^{\nu}\approx Ce^{-\nu x/r}. \tag{2.16}$$

Now two cases have to be distinguished.

(a) $E<V_0$, $\nu>0$ is real. Expression (2.16) vanishes exponentially, as would be expected for the $E<V_0$ case. We obtain $\Psi\to Ce^{-Kx}$, where

$$K^2=\frac{\nu^2}{r^2}=\frac{2m_2}{\hbar^2}(V_0-E). \tag{2.17}$$

(b) $E>V_0$, $\nu=-ik_2r$ is imaginary. Then $\Psi\to Ce^{ik_2x}$, where

$$k_2^2=\frac{2m_2}{\hbar^2}(E-V_0). \tag{2.18}$$

On the other hand, for $x\to-\infty$ or $z\to 1$, $1-z\approx e^{+x/r}\to 0$, we apply the formula (A15) of Appendix A, which links the z and $1-z$ argument Heun's functions. Thus, the Heun's function of relation (2.11) becomes

$$\begin{aligned}&F(a,a[\omega^2-(\nu+\mu)(\nu+\mu+1)]+\nu;\nu+\mu+\omega,\nu+\mu-\omega,2\nu+1,-1;z)\\ &\quad=C_1F(1-a,(1-a)[\omega^2-(\nu+\mu)(\nu+\mu+1)]-\mu;\nu+\mu-\omega,\nu+\mu+\omega,2\mu+1;1-z)\\ &\qquad+C_2(1-z)^{-2\mu}F(1-a,(1-a)[\omega^2-(\nu-\mu)(\nu-\mu+1)]\\ &\qquad-\mu;\nu-\mu+\omega,\nu-\mu-\omega,-2\mu+1;1-z),\end{aligned} \tag{2.19}$$

where constants C_1 and C_2 are

$$C_1=F(a,a[\omega^2-(\nu+\mu)(\nu+\mu+1)]+\nu;\nu+\mu-\omega,\nu+\mu+\omega,2\nu+1,-1;1), \tag{2.20}$$

$$C_2=F(a,a[\omega^2-(\nu-\mu)(\nu-\mu+1)]+\nu;\nu-\mu+\omega,\nu-\mu-\omega,2\nu+1,-1;1). \tag{2.21}$$

Since $1-z\approx e^{+x/r}$ when $x\to-\infty(1-z\to 0)$, the wave function behaves like

$$\Psi\to Ce^{i\pi\mu}\{C_1e^{\mu(x/r)}+C_2e^{-\mu(x/r)}\}. \tag{2.22}$$

Setting $\mu=ik_1r$, where

$$k_1^2=\frac{2m_1}{\hbar^2}E, \tag{2.23}$$

and

$$C=\frac{e^{i\pi\mu}}{C_1},\quad R=\frac{C_2}{C_1}, \tag{2.24}$$

wave function (2.11) can be written as

$$\Psi(x)=\left[\frac{1}{2}\left(1-th\,\frac{x}{2r}\right)\right]^{\nu}\left[\frac{1}{2}\left(1+th\,\frac{x}{2r}\right)\right]^{\mu} \times\frac{F\left(a,a[\omega^2-(\nu+\mu)(\nu+\mu+1)]+\nu;\nu+\mu+\omega,\nu+\mu-\omega,2\nu+1,-1;\frac{1}{2}\left(1-th\,\frac{x}{2r}\right)\right)}{F(a,a[\omega^2-(\nu+\mu)(\nu+\mu+1)]+\nu;\nu+\mu+\omega,\nu+\mu-\omega,2\nu+1,-1;1)}. \tag{2.25}$$

We can summarize the limits of the wave function when $x\to\pm\infty$ by

$$\Psi(x)=\begin{cases} e^{ik_1x}+\mathrm{Re}^{-ik_1x}, & \text{for} \quad x\to+\infty, \\ \begin{cases} Ce^{-Kx}, & \text{if } E>V_0, \quad \text{for} \quad x\to+\infty, \\ Ce^{ik_2x}, & \text{if } E<V_0, \quad \text{for} \quad x\to+\infty, \end{cases} \end{cases} \tag{2.26}$$

Thus, we recover the asymptotic behavior of a plane wave coming from the left-hand side. The quantity $|R|^2$ is the reflection coefficient,

$$|R|^2=\left|\frac{F(a,a[\omega^2-(\nu-\mu)(\nu-\mu+1)]+\nu;\nu-\mu+\omega,\nu-\mu-\omega,2\nu+1,-1;1)}{F(a,a[\omega^2-(\nu+\mu)(\nu+\mu+1)]+\nu;\nu+\mu-\omega,\nu+\mu+\omega,2\nu+1,-1;1)}\right|^2. \tag{2.27}$$

Again, we distinguish the two cases $E<V_0$ and $E>V_0$:

(a) $E<V_0$, $\mu=ik_1r$ is imaginary, $\nu>0$ is real, and ω is imaginary if $m_2<m_1$ or real if $m_2>m_1$. The numerator and denominator of the reflection coefficient (2.27) are complex conjugates, we have then $|R|^2=1$. We also recover this case of total reflection when $E=V_0$, $\nu=0$, ω imaginary or real.

(b) $E>V_0$, $\mu=ik_1r$ and $\nu=-ik_2r$ are imaginary.

Thanks to relation (B22) of Appendix B between two contiguous Heun's function, we can investigate the behavior of the transmission (or reflection) coefficient as a function of the energy E. For this purpose, let us rewrite expression (2.27) of the reflection coefficient in an equivalent form:

$$|R|^2=\left|\frac{F(a,a[\omega^2-(\nu-\mu)(\nu-\mu+1)]+\nu;\nu-\mu+\omega,\nu-\mu-\omega,2\nu+1,-1;1)}{F(a,a[\omega^2-(\nu+\mu)(\nu+\mu+1)]+\nu;\nu+\mu-\omega,\nu+\mu+\omega,2\nu+1,-1;1)}\right| \times\left|\frac{F(a,a[\omega^2-(\nu-\mu)(\nu-\mu+1)]+\nu;\nu-\mu-\omega,\nu-\mu+\omega,2\nu+1,-1;1)}{F(a,a[\omega^2-(\nu+\mu)(\nu+\mu+1)]+\nu;\nu+\mu-\omega,\nu+\mu+\omega,2\nu+1,-1;1)}\right|, \tag{2.28}$$

where we have used the fact that Heun's function is unaltered by the interchange of α and β arguments. Knowing that

$$\omega^2=\frac{\nu^2}{a}-\frac{\mu^2}{(a-1)}, \tag{2.29}$$

we apply now relation (B22) of Appendix B for each of the four Heun's functions of (2.28),

$$|R|^2=\frac{[(a-1)\nu+a\mu]^2}{[(a-1)\nu-a\mu]^2} \times\left|\frac{F(a,a[\omega^2-(\nu-\mu)(\nu-\mu+1)]+\mu-\omega,\nu-\mu+\omega,\nu-\mu-\omega+1,2\nu+2,0;1)}{F(a,a[\omega^2-(\nu+\mu)(\nu+\mu+1)]-\mu-\omega,\nu+\mu+\omega,\nu+\mu-\omega+1,2\nu+2,0;1)}\right| \times\left|\frac{F(a,a[\omega^2-(\nu-\mu)(\nu-\mu+1)]+\mu+\omega,\nu-\mu-\omega,\nu-\mu+\omega+1,2\nu+2,0;1)}{F(a,a[\omega^2-(\nu+\mu)(\nu+\mu+1)]-\mu+\omega,\nu+\mu-\omega,\nu+\mu+\omega+1,2\nu+2,0;1)}\right|. \tag{2.30}$$

(b1) The asymptotic value of the transmission coefficient when the energy goes to infinity. When $E\to\infty$ the reflection coefficient (2.30) is equivalent to

$$|R|^2 \underset{E\to\infty}{\approx} \left(\frac{\sqrt{m_1}-\sqrt{m_2}}{\sqrt{m_1}+\sqrt{m_2}}\right)^2 \left|\frac{F(a,-a(\nu-\mu)^2,\nu-\mu,\nu-\mu,2\nu,0;1)}{F(a,-a(\nu+\mu)^2,\nu+\mu,\nu+\mu,2\nu,0;1)}\right|^2.$$

Using Eq. (A16) of the Appendix A,

$$F(a,-a\alpha\beta;\alpha,\beta,\gamma,0;z)\equiv {}_2F_1(\alpha,\beta;\gamma;z),$$

and the following equivalence:

$${}_2F_1(\alpha,\alpha;\gamma;1) \underset{\alpha,\gamma\to\infty}{\approx} \exp\left(\frac{\alpha^2}{\gamma}\right),$$

we arrive at

$$|R|^2_{E\to\infty}=\left(\frac{\sqrt{m_1}-\sqrt{m_2}}{\sqrt{m_1}+\sqrt{m_2}}\right)^2. \tag{2.31}$$

Thus, the asymptotic value of the transmission coefficient is

$$|T|^2_{E\to\infty}=\frac{4\sqrt{m_1 m_2}}{(\sqrt{m_1}+\sqrt{m_2})^2}. \tag{2.32}$$

(b2) The value of the energy E for which the transmission coefficient reaches unity.

Relation (2.30) shows that $|R|^2=0$ (or $|T|^2=1$) when $(a-1)\nu+a\mu=0$, i.e., when the energy takes the value

$$E_t=\frac{m_1 V_0}{(m_1-m_2)}. \tag{2.33}$$

Hence, we see that the transmission coefficient reaches unity for the specific value E_t of the energy, only in the case $m_1>m_2$.

We come to the conclusion that the behavior of the transmission coefficient as a function of the energy E is similar to that of an abrupt potential and mass step,[25] setting

$$\tilde{k}=\sqrt{\frac{2|m_2-m_1|}{\hbar^2}\,V_0}. \tag{2.34}$$

(i) When $m_1<m_2$, $\omega=\tilde{k}r>0$ is real, we obtain

$$|R|^2=\left|\frac{F(a,ar^2[\tilde{k}^2+(k_1+k_2)^2]+ir[ak_1+(a-1)k_2];r[\tilde{k}-i(k_1+k_2)],-r[\tilde{k}+i(k_1+k_2)],1-2ik_2r,-1;1)}{F(a,ar^2[\tilde{k}^2+(k_1-k_2)^2]-ir[ak_1+(1-a)k_2];r[-\tilde{k}+i(k_1-k_2)],r[\tilde{k}+i(k_1-k_2)],1-2ik_2r,-1;1)}\right|^2. \tag{2.35}$$

The transmission coefficient increases from *zero* for $E=V_0$ to the asymptotic value (2.32) when $E\to\infty$, and never reaches unity.

(ii) When $m_1>m_2$, $\omega=i\tilde{k}r$ is imaginary, we have

$$|R|^2=\left|\frac{F(a,ar^2[-\tilde{k}^2+(k_1+k_2)^2]+ir[ak_1+(a-1)k_2];ir[\tilde{k}-k_1-k_2],-ir[\tilde{k}+k_1+k_2],1-2ik_2r,-1;1)}{F(a,ar^2[-\tilde{k}^2+(k_1-k_2)^2]-ir[ak_1+(1-a)k_2];ir[-\tilde{k}+k_1-k_2],ir[\tilde{k}+k_1-k_2],1-2ik_2r,-1;1)}\right|^2. \tag{2.36}$$

The transmission coefficient increases from *zero* for $E=V_0$, reaches unity for a specific value (2.33) of the energy, and then decreases to reach the asymptotic value (2.32).

Finally we consider the two following limiting cases.

(i) When the smooth potential and mass step tend to an abrupt potential and mass step, i.e., when the parameter r of definitions (2.1) and (2.2) tends to 0. Using the following special value of the Heun's function $F(a,0;0,1,2,0;1)=1$, we can see that each of the four Heun's functions of the relation (2.30) tend to 1 when $r\to 0$; then

$$|R|^2_{r\to 0}=\left(\frac{k_1/m_1-k_2/m_2}{k_1m_1+k_2/m_2}\right)^2. \tag{2.37}$$

Lévy-Leblond[25] found this result (2.37) by imposing, in the discontinuity of the abrupt potential and mass step, the continuity of the wave function and his derivative divided by the mass.

(ii) When the width of the mass step is vanishing, i.e., when the parameter a of the definition (2.6) tends to infinity. Using the following limit,[35] which gives one of the cases where the Heun's function degenerates into a hypergeometric function:

$$F(a,ac;\alpha,\beta,\gamma,\delta;z)_{a\to\infty}={}_2F_1(\eta+\sqrt{\eta^2+c},\eta-\sqrt{\eta^2+c};\gamma;z),$$

where

$$\eta=\frac{\alpha+\beta-\delta}{2} \quad \text{and} \quad \gamma\neq -n(n=0,1,2,...), \tag{2.38}$$

we recover all the results (wave function, reflection, and transmission coefficients) for a system with a constant mass and potential smooth step.[32] Particularly, and knowing that

$${}_2F_1(\alpha,\beta;\gamma;1)=\frac{\Gamma(\gamma)\Gamma(\gamma-\alpha-\beta)}{\Gamma(\gamma-\alpha)\Gamma(\gamma-\beta)},$$

reflection coefficient (2.27) tends to

$$|R|^2_{a\to\infty}=\left|\frac{{}_2F_1(\bar{\nu}-\bar{\mu},\bar{\nu}-\bar{\mu}+1;2\bar{\nu}+1;1)}{{}_2F_1(\bar{\nu}+\bar{\mu},\bar{\nu}+\bar{\mu}+1;2\bar{\nu}+1;1)}\right|^2=\left|\frac{\Gamma(+2\bar{\mu})\Gamma(\bar{\nu}-\bar{\mu})\Gamma(\bar{\nu}-\bar{\mu}+1)}{\Gamma(-2\bar{\mu})\Gamma(\bar{\nu}+\bar{\mu})\Gamma(\bar{\nu}+\bar{\mu}+1)}\right|^2=|\bar{R}|^2, \tag{2.39}$$

where

$$\bar{\nu}^2=\frac{2mr^2}{\hbar^2}(V_0-E), \quad \bar{\mu}^2=-\frac{2mr^2E}{\hbar^2}, \tag{2.40}$$

and $|\bar{R}|^2$ is the reflection coefficient for a system with a constant mass and potential smooth step obtained in Ref. 32.

III. CONCLUSION

We have succeeded in solving the one-dimensional generalized Schrödinger equation for a system with potential and mass, both of smooth step shape. We have found that the wave function depends on the Heun's function, which is a generalization of the hypergeometric function. We have shown that the behavior of the transmission coefficient as a function of the energy is similar to that of the case of an abrupt potential and mass step. We have also recovered the reflection and

transmission coefficients of two limiting cases, namely, when the width of the mass step is vanishing and when the smooth potential and mass step tend to an abrupt potential and mass step.

We think that our work may be used, in the future, for concrete computations in the area of semiconductor heterostructures, and more generally in that of the inhomogeneous crystals that is quickly developing.

APPENDIX A: RELATION BETWEEN THE z AND $1-z$ ARGUMENT HEUN'S FUNCTIONS

Let

$$y_1(z)=F(a,b;\alpha,\beta,\gamma,\delta;z), \tag{A1}$$

the Heun's function solution of the normal form of the Heun's equation,[36]

$$\frac{d^2y}{dz^2}+\left(\frac{\gamma}{z}+\frac{1+\alpha+\beta-\gamma-\delta}{z-1}+\frac{\delta}{z-a}\right)\frac{dy}{dz}+\frac{\alpha\beta z+b}{z(z-1)(z-a)}\,y=0, \tag{A2}$$

which is regular in the neighborhood of $z=0$ and belongs to the exponent *zero*. The two solutions linearly independent in the neighborhood of $z=1$ are[37]

$$y_3(z)=F(1-a,-b-\alpha\beta;\alpha,\beta,1+\alpha+\beta-\gamma-\delta,\delta;1-z), \tag{A3}$$

and

$$\begin{aligned} y_4(z)=(1-z)^{\gamma+\delta-\alpha-\beta}F(1-a,-b-\alpha\beta-[\gamma+\delta-\alpha-\beta][\gamma+\delta-a\gamma];\gamma \\ +\delta-\alpha,\gamma+\delta-\beta,1+\gamma+\delta-\alpha-\beta,\delta;1-z). \end{aligned} \tag{A4}$$

The solution $y_1(z)$ is a linear combination of the two solutions $y_3(z)$ and $y_4(z)$,

$$y_1(z)=C_1y_3(z)+C_2y_4(z), \tag{A5}$$

where C_1 and C_2 are independent of z, but depend on the other parameters. With the help of (A3) and (A4) the equation (A5) becomes

$$\begin{aligned} F(a,b;\alpha,\beta,\gamma,\delta;z)=C_1(a,b;\alpha,\beta,\gamma,\delta)F(1-a,-b-\alpha\beta;\alpha,\beta,1+\alpha+\beta-\gamma-\delta,\delta;1-z) \\ +C_2(a,b;\alpha,\beta,\gamma,\delta)(1-z)^{\gamma+\delta-\alpha-\beta}F(1-a,-b-\alpha\beta-[\gamma+\delta-\alpha-\beta] \\ \times[\gamma+\delta-a\gamma];\gamma+\delta-\alpha,\gamma+\delta-\beta,1+\gamma+\delta-\alpha-\beta,\delta;1-z). \end{aligned} \tag{A6}$$

Putting $z=1$ into the functional relation (A6) and knowing that $F(a,b;\alpha,\beta,\gamma,\delta;0)=1$, we obtain

$$C_1(a,b;\alpha,\beta,\gamma,\delta)=F(a,b;\alpha,\beta,\gamma,\delta;1). \tag{A7}$$

On the other hand, we have the relation[38]

$$F(a,b;\alpha,\beta,\gamma,\delta;z)=(1-z)^{\gamma+\delta-\alpha-\beta}F(a,b-a\gamma[\gamma+\delta-\alpha-\beta];\gamma+\delta-\alpha,\gamma+\delta-\beta,\gamma,\delta;z). \tag{A8}$$

The substitutions $\alpha\to\gamma+\delta-\alpha$, and $\beta\to\gamma+\delta-\beta$ into (A6) and (A8) give

$$\begin{aligned} F(a,b;\gamma+\delta-\alpha,\gamma+\delta-\beta,\gamma,\delta;z)=C_1(a,b;\gamma+\delta-\alpha,\gamma+\delta-\beta,\gamma,\delta)F(1-a,-b-[\gamma+\delta-\alpha] \\ \times[\gamma+\delta-\beta];\gamma+\delta-\alpha,\gamma+\delta-\beta,1+\gamma+\delta-\alpha-\beta,\delta;1-z) \\ +C_2(a,b;\gamma+\delta-\alpha,\gamma+\delta-\beta,\gamma,\delta)(1-z)^{\alpha+\beta-\gamma-\delta} \\ \times F(1-a,-b-\alpha\beta+a\gamma[\alpha+\beta-\gamma-\delta];\alpha,\beta,1 \\ +\alpha+\beta-\gamma-\delta,\delta;1-z), \end{aligned} \tag{A9}$$

and

$$F(a,b;\gamma+\delta-\alpha,\gamma+\delta-\beta,\gamma,\delta;z)$$
$$=(1-z)^{\alpha+\beta-\gamma-\delta}F(a,b+a\gamma[\gamma+\delta-\alpha-\beta];\alpha,\beta,\gamma,\delta;z). \tag{A10}$$

Applying the relation (A9) to the Heun's function of the right-hand side of (A10), Eq. (A10) takes the form

$$\begin{aligned}F(a,b;\gamma+\delta-\alpha,\gamma+\delta-\beta,\gamma,\delta;z)&\\ =(1-z)^{\alpha+\beta-\gamma-\delta}C_1(a,b+a\gamma[\gamma+\delta-\alpha-\beta];a,\beta,\gamma,\delta)F(1-a,-b&\\ -a\gamma[\gamma+\delta-\alpha-\beta]-\alpha\beta,\alpha,\beta,1+\alpha+\beta-\gamma-\delta,\delta;1-z)&\\ +C_2(a,b+a\gamma[\gamma+\delta-\alpha-\beta];\alpha,\beta,\gamma,\delta)F(1-a,-b-[\gamma+\delta-\alpha]&\\ \times[\gamma+\delta-\beta];\gamma+\delta-\alpha,\gamma+\delta-\beta,1+\gamma+\delta-\alpha-\beta,\delta;1-z).&\end{aligned} \tag{A11}$$

The comparison between (A9) and (A11) gives

$$C_1(a,b;\gamma+\delta-\alpha,\gamma+\delta-\beta,\gamma,\delta)=C_2(a,b+a\gamma[\gamma+\delta-\alpha-\beta];\alpha,\beta,\gamma,\delta), \tag{A12}$$

and

$$C_2(a,b;\gamma+\delta-\alpha,\gamma+\delta-\beta,\gamma,\delta)=C_1(a,b+a\gamma[\gamma+\delta-\alpha-\beta];\alpha,\beta,\gamma,\delta). \tag{A13}$$

With the help of (A7), relation (A13) can be written as

$$\begin{aligned}C_2(a,b;\alpha,\beta,\gamma,\delta)&=C_1(a,b-a\gamma[\gamma+\delta-\alpha-\beta];\gamma+\delta-\alpha,\gamma+\delta-\beta,\gamma,\delta)\\ &=F(a,b-a\gamma[\gamma+\delta-\alpha-\beta];\gamma+\delta-\alpha,\gamma+\delta-\beta,\gamma,\delta;1).\end{aligned} \tag{A14}$$

Finally, we obtain the functional relation between the z and $1-z$ argument Heun's functions,

$$\begin{aligned}F(a,b;\alpha,\beta,\gamma,\delta;z)&=F(a,b;\alpha,\beta,\gamma,\delta;1)F(1-a,-b-\alpha\beta;\alpha,\beta,1+\alpha+\beta-\gamma-\delta,\delta;1-z)\\ &+(1-z)^{\gamma+\delta-\alpha-\beta}F(a,b-a\gamma[\gamma+\delta-\alpha-\beta];\gamma+\delta-\alpha,\gamma+\delta-\beta,\gamma,\delta;1)\\ &\times F(1-a,-b-\alpha\beta-[\gamma+\delta-\alpha-\beta][\gamma+\delta-a\gamma];\gamma+\delta-\alpha,\gamma+\delta\\ &-\beta,1+\gamma+\delta-\alpha-\beta,\delta;1-z).\end{aligned} \tag{A15}$$

With[34]

$$F(a,-a\alpha\beta;\alpha,\beta,\gamma,0;z)={}_2F_1(\alpha,\beta;\gamma;z), \tag{A16}$$

we see that if we choose $b=-a\alpha\beta$ and $\delta=0$, Eq. (A15) is reduced to the well-known relation, which links the z and $1-z$ argument hypergeometric functions,

$$\begin{aligned}{}_2F_1(\alpha,\beta;\gamma;z)=&\frac{\Gamma(\gamma)\Gamma(\gamma-\alpha-\beta)}{\Gamma(\gamma-\alpha)\Gamma(\gamma-\beta)}\,{}_2F_1(\alpha,\beta;\gamma;1-z)\\ &+\frac{\Gamma(\gamma)\Gamma(\alpha+\beta-\gamma)}{\Gamma(\alpha)\Gamma(\beta)}(1-z)^{\gamma-\alpha-\beta}\,{}_2F_1(\gamma-\alpha,\gamma-\beta;1+\gamma-\alpha-\beta;1-z).\end{aligned} \tag{A17}$$

APPENDIX B: RELATION BETWEEN THE *CONTIGUOUS* HEUN'S FUNCTIONS $F(a,b;\alpha,\beta,\gamma,\delta;z)$ AND $F(a,b';\alpha,\beta+1,\gamma+1,\delta+1;z)$

In order to establish this relation, we follow the Heun's method.[39] To avoid notation problems of the Heun's functions, we adopt in this appendix the Heun's notations[26] (indexed by the letter H). In the end of this appendix, we restore the Snow's[28] notations (without indexes) of the Heun's functions that we have adopted in the bulk of this paper.

Let

$$y_0 = P\left\{ \begin{array}{cccccc} 0 & 1 & a & \infty & \\ 0 & 0 & 0 & \alpha & z \\ 1-\gamma & 1-\eta & 1-\epsilon_0 & \beta & \end{array} \right\}, \tag{B1}$$

where

$$\epsilon_0 = \alpha+\beta-\gamma-\eta+1, \tag{B2}$$

the Riemann's P symbol of the Heun's function,

$$y_0 = F_{\mathrm{H}}(a,q;\alpha,\beta,\gamma,\eta;z), \tag{B3}$$

where q is the —so-called— characteristic value. Heun's function y_0 is a solution of the following differential equation;

$$\psi \frac{d^2y_0}{dz^2} + \chi \frac{dy_0}{dz} + \widetilde{\omega} y_0 = 0, \tag{B4}$$

where

$$\psi = z(z-1)(z-a),$$

$$\chi = a\gamma - \{\alpha+\beta+a\gamma+(a-1)\eta+1\}z + (\alpha+\beta+1)z^2,$$

$$\widetilde{\omega} = \alpha\beta(z-q). \tag{B5}$$

Let

$$y = P\left\{ \begin{array}{cccccc} 0 & 1 & a & \infty & \\ 0 & 0 & 0 & \alpha & z \\ -\gamma & 2-\eta & 1-\epsilon & \beta+1 & \end{array} \right\}, \tag{B6}$$

where

$$\epsilon = \alpha+\beta-\gamma-\eta+2, \tag{B7}$$

the Riemann's P symbol of the Heun's function,

$$y = F_{\mathrm{H}}(a,q';\alpha,\beta+1,\gamma+1,\eta-1;z). \tag{B8}$$

The difference between the elements (exponents) of the P's symbols (B6) and (B1) gives the following matrix:

$$\Delta P \equiv \begin{pmatrix} 0 & 0 & 0 & 0 \\ -1 & 1 & -1 & 1 \end{pmatrix}.$$

Thus, the b_i's[39] parameters are, in our case,

$$b_1 = b_3 = -1, \quad b_2 = b_4 = 0 \quad \text{and} \quad D = b_1+b_2+b_3+b_4 = -2. \tag{B9}$$

We introduce then the change of the dependent variable,

$$y = z^{b_1}(z-1)^{b_2}(z-a)^{b_3}u = z^{-1}(z-a)^{-1}u. \tag{B10}$$

This change of variable yields to the following P symbol for the u function:

$$u = P\left\{\begin{array}{cccc} 0 & 1 & a & \infty \\ 1 & 0 & 1 & \alpha-2 \quad z \\ 1-\gamma & 2-\eta & 2-\epsilon & \beta-1 \end{array}\right\}. \tag{B11}$$

Therefore function u verifies the differential equation

$$z(z-a)\psi \frac{d^2u}{dz^2} + z(z-a)\widetilde{\theta} \frac{du}{dz} + \widetilde{\sigma} u = 0, \tag{B12}$$

where

$$\widetilde{\theta} = (\gamma-1)(z-1)(z-a) + (\eta-1)z(z-a) + (\alpha+\beta-\gamma-\eta)z(z-1),$$

$$\widetilde{\sigma} = -2\psi - (2z-a)\widetilde{\theta} + \alpha(\beta+1)z(z-a)(z-q'). \tag{B13}$$

Functions y_0 and u are related by

$$u = \varphi y_0 + \psi \frac{dy_0}{dz}, \tag{B14}$$

where φ is a polynomial of second degree. Combining the relations (B14), (B12) and (B4), we can eliminate the derivative d^2y_0/dz^2, the u function, and his derivatives d^2u/dz^2, du/dz. Thus, we arrive at the relation

$$\{[\widetilde{\sigma} - z(z-a)\widetilde{\omega}]\varphi + z(z-a)(\widetilde{\theta}\varphi' + \psi\varphi'') - z(z-a)[(\widetilde{\theta}-\chi)\widetilde{\omega} + (\psi\widetilde{\omega})']\}y_0$$
$$+ \{(\widetilde{\theta}-\chi)\varphi + 2\psi\varphi' + (\widetilde{\theta}-\chi)(\psi'-\chi) + \psi(\psi''-\chi'-\widetilde{\omega}) + (z-1)\widetilde{\sigma}\} \frac{dy_0}{dz} = 0. \tag{B15}$$

Relation (B15) implicates that the coefficient of y_0 and that of dy_0/dz must identically vanish, i.e.,

$$\left.\begin{array}{c} [\widetilde{\sigma} - z(z-a)\widetilde{\omega}]\varphi + z(z-a)(\widetilde{\theta}\varphi' + \psi\varphi'') - z(z-a)[(\widetilde{\theta}-\chi)\widetilde{\omega} + (\psi\widetilde{\omega})'] = 0, \\ (\widetilde{\theta}-\chi)\varphi + 2\psi\varphi' + (\widetilde{\theta}-\chi)(\psi'-\chi) + \psi(\psi''-\chi'-\widetilde{\omega}) + (z-1)\widetilde{\sigma} = 0. \end{array}\right\} \tag{B16}$$

All the terms with the same degree in z in the two equations of (B16) must be equal to *zero*. Collecting the terms with the same degree in z in the two equations of (B16), we arrive at a system of 11 equations. Resolution of this system gives, for the function φ of (B14),

$$\varphi = \beta z(z-a). \tag{B17}$$

Relation (B14) then takes the form

$$mF_{\mathrm{H}}(a,q';\alpha,\beta+1,\gamma+1,\eta-1;z) = \beta F_{\mathrm{H}}(a,q;\alpha,\beta,\gamma,\eta;z) + (z-1)\frac{d}{dz}F_{\mathrm{H}}(a,q,\alpha,\beta,\gamma,\eta;z). \tag{B18}$$

Constant m of this last relation is determined by setting $z=0$ in (B18),

$$m = \beta - \frac{\alpha\beta q}{\gamma a}. \tag{B19}$$

Relation (B18) then takes the final form

$$(\gamma a\beta-\alpha\beta q)F_{\mathrm{H}}(a,q';\alpha,\beta+1,\gamma+1,\eta-1;z)$$
$$=\gamma a\beta F(a,q;\alpha,\beta,\gamma,\eta;z)+\gamma a(z-1)\frac{d}{dz}F_{\mathrm{H}}(a,q;\alpha,\beta,\gamma,\eta;z). \tag{B20}$$

Putting $q=1$, $a=1$ in (B20), and knowing that

$$F_{\mathrm{H}}(a,q;\alpha,\beta,\gamma,\eta;z)_{a\to 1,q\to 1}={}_2F_1(\alpha,\beta;\gamma;z),$$

relation (B20) tends to the one of the Gauss' recursion functions,[40]

$$(\gamma-\alpha){}_2F_1(\alpha,\beta+1;\gamma+1;z)=\gamma\,{}_2F_1(\alpha,\beta;\gamma;z)+\alpha(z-1){}_2F_1(\alpha+1,\beta+1;\gamma+1;z). \tag{B21}$$

Finally, we can now rewrite the relation (B20) with Snow's notations, which we have adopted in our paper,

$$(\gamma a\beta+b)F(a,b-\alpha;\alpha,\beta+1,\gamma+1\,\delta+1;z)$$
$$=\gamma a\beta F(a,b;\alpha,\beta,\gamma,\delta;z)+\gamma a(z-1)\frac{d}{dz}F(a,b;\alpha,\beta,\gamma,\delta;z), \tag{B22}$$

where we have used the following correspondence rule between the two notations:

$$b\equiv-\alpha\beta q,\quad b'\equiv-\alpha(\beta+1)q'=-\alpha\beta q-\alpha q'-\alpha\beta(q'-q)=b-\alpha. \tag{B23}$$

These latter relations are deduced from the resolution of the system of 11 equations.

Intermediate level statistics with one-parameter random matrix ensembles

Hiroshi Hasegawa

Max-Planck Institut für Kern Physik, D-69117 Heidelberg, Germany

(Received 3 November 1997; accepted for publication 2 December 1997)

We discuss a formulation of the level statistics for quantum systems that lie in an intermediate regime between the integrability subject to Poisson statistics and the full chaos subject to Gaussian statistics of the typical random matrix theory (RMT). It is based on the idea initiated by Yukawa and also by Nakamura and Lakshmanan, namely, to transcribe the eigenvalue statistics into statistical mechanics of the completely integrable Calogero system with internal degrees of rotation. By analyzing the previous works of Gaudin and Forrester from this viewpoint, we answer the question raised by Mehta and Dyson in early RMT concerning the expectation of compressible level gas, which is realized now in such an intermediate regime. It indicates the general absence of a fractional power dependence of the two-level correlation function under the ordinary thermodynamic-limit procedure as the manifestation that a transition between localized and delocalized states does not occur. The predictability of the transition by modifying the theory is remarked. Two applications of the present scheme are shown: the information loss per level and the correlation hole of survival probability for intermediate circular unitary ensembles. © *1998 American Institute of Physics.* [S0022-2488(98)03105-3]

I. INTRODUCTION

The approach of energy level statistics has been applied in many branches of physics, such as complex nuclei,[1] quantum soft chaos,[2] and disordered electronic systems.[3] In some extreme cases (the strong-chaos regime or metallic region) quantum spectra have been shown[4] to follow the prediction of random matrix theories (RMT),[5] while in the opposite cases (classical integrability; insulator region) the Poisson statistics is applicable. The problem of interpolation between the Poisson and the RMT has long been discussed for quantifying the description of level statistics of intermediate situations between these extremes.

Theoretical efforts made thus far to approach the goal may be classified into two categories: In the first category, one wishes to extend the successful periodic-orbit theory of level statistics[6] and analyzes the structure of classical phase spaces depending on the degree of the softness of chaos.[7] In the second category, one wishes to find out a systematic means to generalize the underlying ensembles of random matrices from the typical RMT extremes; the approach that started in the paper by Berry and Robnik.[8]

In the present paper, we adopt the so-called *level dynamics* approach (its name taken from Haake's book[9]) in the second category: its first idea appeared in Pechukas,[10] as motivated from the early work of Dyson,[11] and then put into explicit formulations by Yukawa[12] and by Nakamura and Lakshmanan,[13] further followed by Haake and his co-workers,[9] Nakamura and Mikeska,[14] and Gaspard, Rice, Mikeska, and Nakamura.[15]

The common idea of the level dynamics approach quoted above is the observation that a random sequence of quantum levels whose correlations between each other are of a repulsive nature could be treated as a system of interacting (classical) particles arranged on a line; specifically, the Calogero–Moser system with the pair potential of the inverse square type (for which the line is extended to infinity) or the Calogero–Sutherland system with the pair potential of the inverse square *sine* function (for which the line becomes a circle, and hence the system is peri-

 © 1998 American Institute of Physics

odic). Strictly speaking, the Calogero–Moser/Sutherland system employed here is more complex than the original model,[16,17] in that the coefficient of each pair potential is not constant but subject to a dynamical law prescribed in accordance with a set of Poisson bracket relations that has analogy to angular momentum components in the N-dimensional space. Physically, it means that each constituent particle of the system has internal degrees of freedom associated with such a rotation induced by the angular momentum; hence, the name of *generalized Calogero–Moser* (g-CM)/*Sutherland* (g-CS) system.

Here, we present its Hamiltonian function in term of three sets of dynamical variables; the first two $\{x_n\}$, $\{p_n\}$; $(n=1,2,...,N)$, for the translation of N-particles, and the second $\{f_{n,m}\}$ for the N-dimensional rotation, respectively. Also, the relevant Poisson bracket relations among them are added in accordance with a description by Gaspard *et al.*:[15]

$$\mathscr{H}_{\text{g-CM}}=\frac{1}{2}\sum_n p_n^2+\frac{1}{2}\sum_{m\neq n}\frac{\|f_{mn}\|^2}{(x_m-x_n)^2}, \tag{1.1}$$

$$\mathscr{H}_{\text{g-CS}}=\frac{1}{2}\sum_n p_n^2+\frac{1}{2}\sum_{m\neq n}\frac{\|f_{mn}\|^2}{4\sin^2(\pi/L)(x_m-x_n)}, \tag{1.2}$$

$$\{x_m,p_n\}=c\,\delta_{mn}\quad (c=1 \text{ for g-CM, and } L/2\pi \text{ for g-CS}), \tag{1.3a}$$

$$\{x_m,x_n\}=\{p_m,p_n\}=\{x_m,f_{rs}\}=\{p_m,f_{rs}\}=0, \tag{1.3b}$$

$$\{f_{mn}^{(a)},f_{rs}^{(b)}\}=-\sum_{pqc} c_{mna,rsb}^{pqc} f_{pq}^{(c)} \tag{1.3c}$$

(Superscript a,b, etc. denotes the component of a complex number, i.e. *real* and *imaginary* part for a unitary ensemble (UE) and of a quaternion for a symplectic ensemble (SE), respectively (see below), and $\|f_{mn}\|^2=\sum_{a=1}^{\nu}|f_{mn}^{(a)}|^2$.)

It has been argued[13,14] that the set of equations of motion deduced from the above Hamiltonian function with Poisson bracket relations (1.3) is completely integrable, so that any solution of it may be obtained by quadrature in terms of the $2f$ initial values of the variables, where f is the degree of freedom of the system, i.e.

$$f=N+\frac{\nu}{2}N(N-1), \tag{1.4}$$

with $\nu=1$ for an orthogonal ensemble (OE), and $\nu=2,4$ unitary and symplectic ensembles (UE), (SE), respectively.

The following fact can easily be deduced:[9,12,18] *Let H_0 and V denote two arbitrary Hermitian* (*real symmetric for $\nu=1$, complex Hermitian for $\nu=2$, quaternion real Hermitian for $\nu=4$*) *matrices*. Then, all the matrix elements of

$$H_\lambda\equiv H_0+\lambda V,\quad \text{diag } V \quad\text{and}\quad [H_\lambda,V],\quad \text{on the } H_\lambda \text{ diagonal basis}, \tag{1.5}$$

which are denoted by x_n, p_n and f_{mn}, respectively, satisfy a set of equations of motion (with time variable λ) for the g-CM *system (1.1). Similarly, all the matrix elements of*

$$U_\lambda\equiv e^{-i\lambda V}e^{-iH_0},\quad \text{diag } V \quad\text{and}\quad i(e^{iH_0}Ve^{-iH_0}-V),\quad \text{on the } U_\lambda \text{ diagonal basis}, \tag{1.6}$$

which are denoted by $e^{i(2\pi/L)x_n}$, p_n and f_{mn}, respectively, satisfy a set of equations of motion for the g-CS *system (1.2).*

The question about the complete integrability of the g-CM/S system should be the converse of the above statement, namely, an affirmative answer to the question: *Is any solution of the set of equations of motion for the g-CM/S system so deduced from the prescription (1.1)–(1.3) repre-*

sentable in a matrix form H_λ in Eq. (1.5) or U_λ in Eq. (1.6), where all the matrix elements of H_0 and V give $2f$ initial values? It is by no means elementary to answer this question affirmatively, and here we want to state clearly that ''our answer is yes.'' [19]

Surely, therefore, these two dynamical systems are completely integrable. It implies the existence of precisely f independent, involutive global constants of motion associated with g-CM (1.1) and g-CS (1.2), each Hamiltonian function being only one of them. In his 1985 paper,[12] Yukawa proposed the construction of a statistical mechanics of the g-CM system by adding another constant of motion besides the Hamiltonian $\mathscr{H}=E$ (energy of the system), namely,

$$\mathscr{Q}=\frac{1}{2}\sum_{a=1}^{\nu}\sum_{m\neq n}|f_{mn}^{(a)}|^2 \tag{1.7}$$

(square of the angular momentum),

in the canonical ensemble of statistical mechanics; the form $e^{-\beta\mathscr{H}-\gamma\mathscr{Q}}$. Our first concern in this paper is to clarify the legitimacy of this ansatz for intermediate level statistics, and then its applications to actual problems.

We can observe that considerable interests have been focused recently on the universal correlation property of the particles in a one-dimensional system of the Calogero–Moser/Sutherland type (classical, quantum, and second-quantized sense). [This topic has been surveyed recently by Guhr, Müller-Groeling and Weidenmüller.[20]] Our aim in this paper is, by confining it to the classical g-CS system (which is more primitive than g-CM), to get a definite answer to the density correlation of the particles representing the levels in a random quantum spectrum within the above framework of level dynamics. A specific feature of the framework is that the complete integrability of the system necessarily modifies the ordinary basis of *ergodicity* for equilibrium statistical mechanics.

We therefore begin with an information theoretical formulation about the most probable canonical distribution, in Sec. II, which justifies Yukawa's one-parameter exponential family; a means to enlarge the classical RMT Gaussian ensembles that conforms to Balian.[21] In Sec. III, we discuss some general properties of the two-level correlation functions of this family. An exact one-parameter model of unitary ensembles studied by Gaudin in 1966[22] and reconsidered later by Forrester[23] turns out to be an integral reduction (equivalently, a coarse graining) of this family, and is used in Sec. IV to clarify the explicit form of this correlation function. It is significant to show a violation of the compatibility relations among the series of higher-order correlation functions, when the ordinary thermodynamic-limit procedure is adopted: this is discussed in Sec. V to provide a clear answer to the question of Mehta and Dyson in the beginning stage of RMT. This feature of the thermodynamic limiting at the cost of violating the compatibility in the second-order correlation function (the so-called ''sum rule'' [24]) affects the long-range behavior of the function as regards the metal–insulator transition. We further demonstrate some more applications of the present scheme of intermediate statistics in Sec. VI.

II. INFORMATION BASIS FOR THE G-CM/S CANONICAL DISTRIBUTION

The well-established N-level joint probability density function $P_N(\{x_n\})$ [or abbreviation $P_N(x)$] in RMT can be characterized by the standard *maximum entropy* principle as follows:[21] Let H denote an element of Hermitian matrix ensembles $\mathscr{E}_\nu$ ($N\times N$ and $\nu=1,2,4$ for OE, UE, SE, respectively, as before) and $P_\nu(H)d^\nu H$ a probability of the element to lie in an interval $(H,H+dH)$ in the matrix space $\mathscr{E}_\nu$, where $d^\nu H=\Pi_n dH_{nn}\times\Pi_{n<m}dH_{mn}^{(1)}\cdots dH_{mn}^{(\nu)}$, i.e., the product of all possible independent matrix-element increments. The Gaussian probability density $P_{\mathrm{G}\nu}(H)$ is determined uniquely from

$$\max_P\left[-\int_{\mathscr{E}_\nu}d^\nu H P(H)\log P(H)\right]=-\int_{\mathscr{E}_\nu}d^\nu H P_{\mathrm{G}}(H)\log P_{\mathrm{G}}(H), \tag{2.1}$$

under the constraint

$$\langle H_{mn}\rangle=0, \quad \text{and} \quad \langle H_{nn}^2\rangle=2\langle H_{mn}^{(a)2}\rangle(m\neq n)=\sigma^2, \quad \langle H_{mn}^{(a)}H_{rs}^{(b)}\rangle((m,n)\neq(r,s) \quad or \quad a\neq b)=0. \tag{2.2}$$

Briefly, among all possible distributions of H defined in $\mathscr{E}_\nu$ for which the first and second moment of the matrix random variable H exist, the Gaussian distribution,

$$P_{G\nu}(H)=\frac{1}{Z_\nu}e^{-(1/2\sigma^2)\mathrm{Tr}\,H^2}, \tag{2.3}$$

yields the most probable distribution of all those for which the first moments and the variances are prescribed uniformly as Eq. (2.2). The standard RMT N-level distribution,

$$P_N(x)dx_1dx_2\cdots dx_N=C_{N\nu}e^{-(1/2\sigma^2)\Sigma x_n^2}\prod_{m<n}|x_n-x_m|^\nu dx_1dx_2\cdots dx_N, \tag{2.4}$$

is known[5] to be deduced from the form $P_{G\nu}(H)d^\nu H$ by a change of the variables, such that

$$\{H_{mn}\}\to\{x_n\}(\text{all eigenvalues of } H), \tag{2.5}$$

and all other cyclic variables that do not enter.

A restricted nature of the standard RMT Gaussian distribution characterized above can be seen in the uniformity of constraint on the variance, i.e., the single constant factor in Eq. (2.3); a key word of enlarging the underlying matrix ensembles. A straightforward removal of such a uniformity may be seen in the idea of *band random matrix ensembles*.[25] Here, we discuss how to remove the ansatz of uniform variances for enlargement by analyzing possible canonical distribution of the g-CM/S system (1.1)/(1.2): Our assertion is as follows.

Among all the possible canonical distributions P of the form $Z(\{\gamma_j\})^{-1}\exp[-\Sigma_j\gamma_j\mathscr{Q}_j]$ for the g-CM/S system with f constants of motion $\{\mathscr{Q}_j\}$, the form

$$P_{\beta,\gamma}=\frac{1}{Z_{\beta,\gamma}}e^{-\beta\mathscr{H}-\gamma\mathscr{Q}} \tag{2.6}$$

yields the most probable canonical one by virtue of a certain entropy principle that we set up below.

We consider a conditional expectation value (i.e., a partial integration) of the entropy function $P(y)\log P(y)$ of two sets of variables y, $\{y_i\}=\mathscr{S}\times\mathscr{R}$;

$$\mathscr{R}=\{p_n\}\times\{f_{mn}\} \tag{2.7}$$

and

$$\mathscr{S}=\{x_n\}, \tag{2.8}$$

and the integration is carried out over the $\mathscr{R}$ variables that are irrelevant for information about the space $\mathscr{S}$; thus

$$h_P(x)\equiv-\int_{\mathscr{R}}dpdfP(x,p,f\,)\log\,P(x,p,f\,). \tag{2.9}$$

This is generally a function of the $\mathscr{S}$ variables. Then, our maximum entropy principle reads as

$$\max_P h_P(x)=h_m(x), \tag{2.10}$$

under the constraint, besides $\langle p\rangle_R=\langle f\rangle_R=0$,

$$\langle p_n^2\rangle_R,\langle|f_{mn}|^2\rangle_R=\text{prescribed as a function of } \{x_n\}.$$

We now show that the maximum entropy condition (2.10) under the following variance constraint determines the distribution (2.6) uniquely:

$$\langle p_n^2\rangle_R = 1/\beta, \quad \langle |V_{mn}|^2\rangle_R = \frac{1}{(x_n - x_m)^2}\langle |f_{mn}|^2\rangle_R = \frac{1}{2\beta}\,\frac{1}{1+(\gamma/\beta)(x_n-x_m)^2}, \tag{2.11}$$

for the g-CM system, and

$$\langle p_n^2\rangle_R = 1/\beta, \quad \langle |V_{mn}|^2\rangle_R = \frac{1}{4\sin^2(\pi/L)(x_n-x_m)}\langle |f_{mn}|^2\rangle_R = \frac{1}{2\beta}\,\frac{1}{1+(\gamma/\beta)4\sin^2(\pi/L)(x_n-x_m)}, \tag{2.12}$$

for the g-CS system. The reason for this result of the constraint in the present maximization problem is as follows.

(i) The special form of canonical distribution (Yukawa) (2.4) is Gaussian with respect to the subsystem $\mathscr{R}$, i.e., p and f variables, satisfying $\langle p\rangle_R = \langle f\rangle_R = 0$ and the variances given by Eq. (2.11)/(2.12).

(ii) Any canonical distribution of the form $Z^{-1}e^{-\Sigma_j \gamma_j \mathscr{Q}_j}$, if it is Gaussian with respect to the $\mathscr{R}$ variables with $\langle p\rangle_R = \langle f\rangle_R = 0$, must be identical to the form (2.6): in other words, expression (2.6) is the only Gaussian canonical distribution (with zero mean of the p and f variables) for the g-CM/S dynamics.

The strength of this latter statement can be verified immediately, if one proves the fact that $\mathscr{H}$ and $\mathscr{Q}$ are the only two constants of motion of the g-CM/S dynamics among $\{\mathscr{Q}_j\}$ that are quadratic with respect to all the matrix elements of V defining the solution H_λ in (1.5), or U_λ in (1.6). (See Ref. 18.)

From the second part of expression (2.11)/(2.12), which is identical to the averaged pair potential, we can observe the nature of the correlation between a pair of levels (particles in the system) and also the role of the added constant $\mathscr{Q}$ with coefficient γ: the correlation retains the inverse square type of the distance between the pair (on the entire line, or within the period L) inherent to the system, but it is depending on the ratio γ/β: when $\gamma/\beta = 0$, the averaged pair potential recovers the uniformity of the RMT ansatz (i.e., $\langle |V_{mn}|^2\rangle_R = 1/2\beta$), while in the opposite limit $\gamma/\beta = \infty$, it becomes a δ-function type ($\langle |f_{mn}|^2\rangle_R = 1/2\gamma$) showing a Poisson characteristic for the pair correlation.

The N-level joint distribution that has been determined above can be related to the maximized conditional entropy $h_m(x)$, such that

$$P_N(x) \equiv \int dp\,df\,P_{\beta,\gamma}(x,p,f) = C_N e^{h_m(x)}, \tag{2.13}$$

$h_m(x)$ being parametrized by the single ratio γ/β, and hence

$$C_N^{-1} = \int dx_1 dx_2 \cdots dx_N e^{h_m(x)} = C_N^{-1}(\gamma/\beta). \tag{2.14}$$

It is a one-parameter family of distributions, explicitly given by

$$P_N(x,\gamma/\beta) = C_{N\nu}(\gamma/\beta)\prod_{m<n}|x_m - x_n|^\nu [1+(\gamma/\beta)(x_m-x_n)^2]^{-\nu/2}, \quad \text{for g-CM}, \tag{2.15}$$

$$= C_{N\nu}(\gamma/\beta)\prod_{m<n}(2\sin(\pi/L)|x_m-x_n|)^\nu \times [1+(\gamma/\beta)4\sin^2(\pi/L)(x_m-x_n)]^{-\nu/2}, \quad \text{for g-CS}. \tag{2.16}$$

Our task, then, is to determine the correlation property of the particles subject to these distributions.

III. TWO-LEVEL CORRELATION FUNCTION

Following Dyson,[26] we define the n-level correlation function for the g-CS system in length L,

$$R_n(x_1,x_2,\ldots,x_n)=\frac{N!}{(N-n)!}\int_{(-L/2,L/2)}\cdots\int\left(\frac{2\pi}{L}\right)^{N-n}dx_{n+1}dx_{n+2}\cdots dx_N P(x_1,\ldots,x_N). \tag{3.1}$$

It is related to a set of cluster functions $T_n(x)$ such that every R_n can be decomposed into a sum of products of all lower-order T_n functions, as in the ordinary cluster-expansion theory.[27] Actually, Dyson used the angular variables θ in the range $[-\pi,\pi]$ instead of x in the range $[-L/2,L/2]$ by the assumed relation

$$\theta=\frac{2\pi}{L}x=\frac{2\pi}{N}\xi;\quad \xi=\rho x,\quad \rho\equiv\frac{N}{L} \tag{3.2}$$

(ξ denotes Dyson's scaled variable $\in[0,N)$: x becomes identical to ξ, if $\rho=1$),

so that $R_n(x)=R_n(\theta(x))$ holds. Let us write the relations between $\{T_n\}$ and $\{R_n\}$ for lower-order n's, as

$$T_1(x_1)=R_1(x_1)=\frac{N}{2\pi}, \tag{3.3a}$$

$$T_2(x_1,x_2)=-R_2(x_1,x_2)+R_1(x_1)R_1(x_2), \tag{3.3b}$$

$$T_3(x_1,x_2,x_3)=R_3(x_1,x_2,x_3)-[R_1(x_1)R_2(x_1,x_2)+c.p.(i=1,2,3)]+2R_1(x_1)R_1(x_2)R_1(x_3),\ \text{etc.} \tag{3.3c}$$

By definition (3.1), an integral identity holds involving R_n and R_{n-1}, such that

$$\int_{-L/2}^{L/2}R_n(x_1,\ldots,x_{n-1},x_n)\left(\frac{2\pi}{L}\right)dx_n=(N-n+1)R_{n-1}(x_1,\ldots,x_{n-1}), \tag{3.4}$$

which may be called the ''compatibility relation for R_n's.'' The corresponding compatibility relation for T_n's may read as

$$\int_{-L/2}^{L/2}T_n(x_1,\ldots,x_{n-1},x_n)\left(\frac{2\pi}{L}\right)dx_n=(n-1)T_{n-1}(x_1,\ldots,x_{n-1})\quad(n>1). \tag{3.5}$$

An issue about this compatibility, which was raised in the early RMT[28] (see Ref. 24), is whether or not this relation remains to hold in the thermodynamic limit of the N-particle system under consideration. If this is the case, one must have, in accordance with Dyson,[26]

$$\int_{-\infty}^{\infty}Y_n(x_1,\ldots,x_{n-1},x_n)dx_n=(n-1)Y_{n-1}(x_1,\ldots,x_{n-1})\quad(n>1), \tag{3.6a}$$

where

$$\lim_{N,L(\rho\ \text{fixed})\to\infty}\left(\frac{2\pi}{L}\right)^n T_n(x)\equiv Y_n(x),\quad \text{the limit called } \textit{thermodynamic limit}. \tag{3.6b}$$

In particular, the identity

$$\int_{-\infty}^{\infty}Y_2(x_1,x_2)dx_2=1\quad[Y_1(x_1)=1,\ \text{if } \rho=1,\ \text{called } \textit{unfolding scale}), \tag{3.7}$$

must hold, which has received considerable attention recently by the name of ''sum rule.'' [24] Toward this topic, we summarize some basic properties of the two-level correlation/cluster functions next.

A. Short-range property of R_2 function

One of the established fluctuation properties of quantum levels of classically chaotic systems is the level repulsion, i.e., the resistance of levels against crossings. This phenomenon is described by the behavior in small values of the nearest-neighbor spacing (NNS) distribution $P(s)$ for a given spacing value s [conditional probability density function $p(0;s)$ for the probability that there is no level in a given interval of length s, when its both end points are occupied]. It is computed from the N-level joint probability density function $P_N(x)$ via the ''hole probability'' $E(s)$ (=the unconditional probability that there is no level in a given interval of length s)[5]: Hereafter, we assume that 2π is absorbed in the system length L, but still retain the finiteness of L and ρ. Under the circumstance, the relation between $p(0;s)$ and $E(s)$ (Ref. 5) is modified as follows: [In the unfolded scale, i.e., in terms of Dyson's ξ, the NNS function $p(0;\xi)$ is given by $p(0;\xi)=(d^2/d\xi^2)E(\xi)$: in terms of the present variable, therefore, the second derivative must be multiplied by ρ^{-2}.]

$$
\begin{aligned}
p(0;s) &= \frac{1}{\rho^2}\frac{d^2}{ds^2}E(s) \\
&= \left(\frac{L}{N}\right)^2 \frac{d^2}{ds^2}\int_{(-L/2,-s/2)\cup(s/2,L/2)} P_N(x_1,x_2,\ldots,x_N)L^{-N}dx_1dx_2\cdots dx_N \\
&= \frac{N(N-1)}{N^2}\int_{(-L/2,-s/2)\cup(s/2,L/2)} P_N(-s/2,s/2,x_3,\ldots,x_N)L^{-(N-2)}dx_3\cdots dx_N, \qquad (3.8)
\end{aligned}
$$

where the factor $N(N-1)$ arises from $\frac{1}{2}N(N-1)$ pairs of the equal integrals and twice of the first pair ($x_1=-s/2$, $x_2=s/2$), and its interchange ($1\rightleftharpoons 2$). This suggests that we redefine the low-level correlation functions (3.1), omitting each fraction p/N; $p=1,\ldots,n-1$, by

$$
\begin{aligned}
r_n(x_1,\ldots,x_n) &= (1/N)^n R_n(x_1,\ldots,x_n) \\
&= \int_{(-L/2,L/2)}\cdots\int L^{-(N-n)}dx_{n+1}dx_{n+2}\cdots dx_N P(x_1,\ldots,x_N), \qquad (3.9a)
\end{aligned}
$$

and

$$
Y_n(x_1,\ldots,x_n)=\rho^{-n}\times Y_n(x), \quad \text{defined by Eq.(3.6b).} \qquad (3.9b)
$$

Our aim in this section is to show that the small-value behavior of the NNS function $p(0;s)$ can be represented very efficiently by that of the two-level correlation function $r_2(s)$. Namely, $p(0;s)=r_2(s)+[\text{terms of higher powers of } s]$, for $0<s\rightarrow 0$. More precisely, if the lowest-power term in s, $s\ll\bar{s}\equiv\int_0^\infty p(0;s)s\,ds$ [mean level spacing over $p(0;s)$] is $A_\nu s^\nu$ ($\nu>0$), then the lowest-power term of $r_2(s)$ is also $A_\nu s^\nu$, so that

$$
\lim_{s\rightarrow 0}\frac{p(0;s)-r_2(s)}{p(0;s)}=0. \qquad (3.10)
$$

The idea has been mentioned by Bohigas, Haq, and Pandey,[29] and we formulate it quantitatively, being motivated by a formula of Wigner:[30]

$$
p(0;s)=r_2(s)+\sum_{n=3}^{N}(-1)^n\frac{\rho^{n-2}}{(n-2)!}\int_{-s/2}^{s/2}\cdots\int_{-s/2}^{s/2}dx_3\cdots dx_n r_n\left(-\frac{s}{2},\frac{s}{2},x_3,\ldots,x_n\right). \qquad (3.11)
$$

This formula can be derived from Eq. (3.8) by employing the characteristic function for the integration region $(-L/2,-s/2)\cup(s/2,L/2)$, namely, $\Pi_{n=3}^{N}(1-a(x_n))$ with $a(x)=1$ for $|x|\leqslant s/2$, and $=0$ for $|x|>s/2$: we have an expansion,

$$\prod_{n=3}^{N}(1-a(x_n))=1-\sum_{n=3}^{N}a(x_n)+\cdots+(-1)^{N-2}a(x_3)\cdots a(x_N).$$

Property (3.10) certainly stems from the level repulsion, and can be verified for a class of N-level distributions, including (2.15) and (2.16), of the form

$$P_N(x)=\prod_{m<n}|x_n-x_m|^{\nu}\times F(x),\quad \nu>0,$$

$$F(x)=\text{a positive continuous function of } x(x_1,x_2,\ldots,x_N),\quad |x|<\infty.$$

By integrating the $P_N(x)$ in the above with respect to $N-n$ variables in the finite range $[-L/2,L/2]$ for each, we can get an estimate of the r_n function in (3.1) as

$$r_n(x_1,x_2,\ldots,x_n)\leqslant \text{const.}\prod_{i<j\leqslant n}|x_i-x_j|^{\nu},$$

and for

$$|x_i-x_j|\leqslant s,\quad r_n(x_1,x_2,\ldots,x_n)\leqslant C_n s^{(\nu/2)n(n-1)}. \tag{3.12}$$

Another continuity property of the r_n function (the mean-value theorem) enables us to rewrite the right-hand side of Eq. (3.11) as

$$p(0;s)=r_2(s)-\rho s r_3(-s/2,s/2,\epsilon s)+O(s^2 r_4(-s/2,s/2,\epsilon_1 s,\epsilon_2 s)),\quad (|\epsilon|,|\epsilon_n|<1/2),$$

the problem thus reducing to $O(sr_3)$, which can be combined to the estimate (3.12).

We therefore get

$$p(0;s)\propto s^{\nu},\quad \text{and}\quad \left|\frac{p(0;s)-r_2(s)}{p(0;s)}\right|<Cs^{2\nu+1}. \tag{3.13}$$

This is our precise efficiency estimation of the correlation expansion of the NNS function (3.11): when applied to the standard RMT, the lowest-power term in the difference $p(0;s)-r_2(s)$ is proportional to $s^{3\nu+1}$, that is, very efficiently s^4 for GOE, s^7 for GUE, and s^{13} for GSE. It is expected to hold in the thermodynamic-limit situation. A general proof of this result is difficult, even for the restricted present approach. In Sec. IV, we show the proof adapted to $\nu=2$ explicitly. However, the general validity of the estimate in (3.13) is certain for the systems (2.15) and (2.16) by virtue of (3.12) and the cancellation of the normalization factor, $C_{N,\nu}$, in the relative estimation (3.13).

B. Long-range properties of R_2 function—The number variance asymptote

Level fluctuations can be characterized also in terms of the long-range correlation between two levels. Let the mean level spacing $\overline{s}$ be chosen as unity (this is the ''unfolding'' procedure: for those systems that admit the hole probability $E(s)$, $\overline{s}=1/\rho$ holds so that the two definitions are identical). Then, the short-range and long-range properties of the correlation function are referred to for $s\ll 1$ and $s\gg 1$, respectively, and we have seen that the level repulsion is a typical short-range property represented in the $r_2(s)$ function. In order to see the role of the same function in the long-range property, we first note the probabilistic meaning of the $r_2(s)$ in terms of the spacing distributions:

$$r_2(s)=\sum_{n=0}^{\infty} p(n;s) \quad \text{(the sum of all } n\text{-level spacing distributions)}, \tag{3.14}$$

which can be regarded as a converse relation to Eq. (3.11) [Eq. (5.1.39) in Ref. 5 must be a misprint].

Two commonly used concepts for the long-range statistics are the number variance Σ^2 and the averaged spectral rigidity Δ_3, which are defined, respectively, by

$$\begin{aligned}\Sigma^2(S)&\equiv\overline{(N-\bar{N})^2} \quad \text{(in the interval of length } S\text{)}\\ &=\int_{-S/2}^{S/2}\int_{-S/2}^{S/2} dxdy[r_1(x)\delta(x-y)+r_2(x,y)]-\left[\int_{-S/2}^{S/2} dx r_1(x)\right]^2\end{aligned} \tag{3.15}$$

and

$$\overline{\Delta(L)}=\min_{A,B}\frac{1}{2L}\int_{-L/2}^{L/2}\overline{(N(x)-Ax-B)^2}dx. \tag{3.16}$$

By using the unfolded scale, the two-level cluster function $1-r_2(r)$ is given by $Y_2(r)$: then, in terms of this function,

$$\Sigma^2(S)=S-S^2+2\int_0^S (S-r)r_2(r)dr=S-2\int_0^S (S-r)Y_2(r)dr. \tag{3.17}$$

An integral expression of the $\overline{\Delta}(L)$ in terms of the number variance function $\Sigma^2(S)$ was established by Pandey,[31] which reads as

$$\overline{\Delta}(L)=\frac{2}{L^4}\int_0^L (L^3-2L^2S+S^3)\Sigma^2(S)dS. \tag{3.18}$$

Bohigas *et al.*[29] pointed out that for a large class of quantum level sequences the asymptotic behavior of the number variance function $\Sigma^2(S)$ can be represented by the formula

$$\Sigma^2(S)\simeq AS+2B\ \log\ S+C, \tag{3.19a}$$

where

$$A=1-\int_{-\infty}^{\infty} Y_2(r)dr, \tag{3.19b}$$

$$B=\text{coefficient of the inverse power expansion},$$

$$Y_2(r)=\frac{B}{r^2}+O\left(\frac{1}{r^3}\right), \quad r\gg 1, \tag{3.19c}$$

and

$$C=2\int_0^1 dS\int_S^{\infty} drY_2(r)-2B. \tag{3.19d}$$

Thus, the representation (3.19) can be characterized by the total area enclosed by the Y_2 function [which must be unity, provided the sum rule (3.7) holds] and its falloff of the inverse-square type (to which the g-CM, also the g-CS statistical model in a limited range, belongs): it may be regarded as a superposition of the Poisson linear line and the Gaussian-ensemble logarithmic line in RMT, namely,

$$\Sigma^2(S)_{\text{Poisson}}=S, \quad \Sigma^2(S)_{\text{GE}}\simeq \frac{2}{\nu\pi^2}[\log(2\pi S)+\gamma_\nu]+O\left(\frac{1}{S}\right), \tag{3.20}$$

where γ_ν is a constant, depending on $\nu=1$ (GOE), 2 (GUE), and 4 (GSE). This interpretation indicates that the present model (2.15) or (2.16) provides a general long-range statistics, in agreement with the prediction by the independent superposition theory (cf. Ref. 20), for example, the formula for superposed level sequences of Seligman and Verbaarshot,[32]

$$\Sigma^2(S)=\mu_1 S+\sum_{i=2}^{k}\Sigma^2_{\text{RMT}}(\mu_i S), \tag{3.21}$$

where μ_1 is the fraction of the phase space volume of the regular region and μ_i $(i\geqslant 2)$ that of the ith chaotic region. It supports the asymptotic correctness of the Berry–Robnik picture[8] on the product hole probability $E_2(s)=\Pi E_2(\mu_i s)$. However, there exists an important reservation before drawing the conclusion: it concerns a violation of the compatibility relation (3.5) in the thermodynamic limit $N\to\infty$, or that of the sum rule (3.7), and will be discussed after presenting a concrete, exact model, namely Gaudin's model in 1966.

IV. EXACT ANALYSIS ON POISSON-CUE INTERMEDIATE STATISTICS

The one-parameter family of distributions for the g-CS system given in Eq. (2.16) can be put into a more detailed analysis, if the symmetry is restricted to $\nu=2$, i.e., one-parameter unitary ensembles. It was proposed and studied by Gaudin in 1966:[22] he considered the following N-level distribution:

$$P(\phi_1,\phi_2,\ldots,\phi_N)=C'_N\prod_{j<k}\left|\frac{\epsilon_j-\epsilon_k}{\epsilon_j-Z\epsilon_k}\right|^2, \quad \epsilon_j=e^{i2\pi\phi_j}, \quad 0\leqslant Z\leqslant 1. \tag{4.1}$$

From the present viewpoint, this model is identical to the (integral reduction of) most probable g-CS canonical distribution, expression (2.16) with $\nu=2$, since the above $P(\phi)$ can be rewritten as

$$P(\phi_1,\phi_2,\ldots,\phi_N)=C'_N\left(\frac{e^\alpha}{\sinh\,\alpha}\right)^{N(N-1)}\prod_{m<n}\left[\frac{4\,\sin^2\,\pi(\phi_m-\phi_n)}{1+\sinh^{-2}\,\alpha\,\sin^2\,\pi(\phi_m-\phi_n)}\right], \tag{4.2a}$$

where the free parameter α is related to that in Eq. (4.1) through

$$Z=e^{-2\alpha}, \quad (0<\alpha\leqslant\infty). \tag{4.2b}$$

Thus, putting

$$4\gamma/\beta=\sinh^{-2}\,\alpha, \quad \phi_n=\frac{x_n}{L}, \tag{4.2c}$$

together with $C_N=C'_N(e^\alpha/\sinh\,\alpha)^{N(N-1)}$, we complete the identification between both families. They give an interpolation between the two limiting situations, such that

$$\alpha\to 0\,(\gamma/\beta\to\infty), \quad \text{Poisson limit;} \tag{4.3a}$$

$$\alpha\to\infty\,(\gamma/\beta\to 0), \quad \text{CUE limit.} \tag{4.3b}$$

The normalization factor of the distribution (4.1) or (4.2), i.e., the partition function, can be computed exactly by the formula[22]

$$\int_0^1\cdots\int_0^1 d\phi_1\ldots d\phi_N\prod_{m<n}\frac{\sin^2\,\pi(\phi_m-\phi_n)}{\sinh^2\,\alpha+\sin^2\,\pi(\phi_m-\phi_n)}=N!\,e^{-N(N-1)\alpha}\prod_{k=1}^{N}\frac{1-e^{-2\alpha}}{1-e^{-2k\alpha}}. \tag{4.4a}$$

After a more complicated analysis, Gaudin deduced an exact formula for the two-level correlation function $R_2(\phi_1,\phi_2)=R_2(\phi_1-\phi_2)$:

$$R_2(\phi_1-\phi_2)=N(N-1)-2\,\mathrm{Re}\sum_{\lambda<\mu}\prod_{k=\lambda}^{\mu-1}\left[1+\frac{e^{2\pi(s/L)}-1}{1-e^{-2\alpha k}}\right]^{-1},\quad \phi_1-\phi_2\equiv\frac{s}{L},$$

$$R_2(s)/N^2=r_2(s)\to 1-2\,\mathrm{Re}\int_{0<x<y<1}dxdy\,\exp\left[-2\pi\rho s\int_x^y d\xi\frac{1}{1-e^{-2\pi\rho a\xi}}\right],$$

where the parameter α is now replaced by

$$a=\alpha L/\pi,\quad \text{or}\quad \rho a=\alpha N/\pi. \tag{4.4b}$$

Therefore, the correlation function with an arbitrary density parameter, ρ, is given by

$$r_2(s)=1-\left|\int_0^1 dx\,\exp\left[i\frac{s}{a}\log(e^{2\pi a\rho x}-1)\right]\right|^2=1-Y_2(r), \tag{4.5}$$

where

$$Y_2(r)=\left|\int_0^1 dx\,\exp\left[i\frac{r}{a}\log(e^{2\pi\rho a x}-1)\right]\right|^2=\left(\frac{1}{2\pi\rho a}\right)^2\left|\int_\nu^\infty\frac{e^{-i\omega r/a}}{e^\omega+1}d\omega\right|^2,\quad \nu=-\log(e^{2\pi\rho a}-1), \tag{4.6}$$

on change of the integration variable, $x\to\omega=-\log(e^{2\pi\rho a x}-1)$.

On the other hand, Forrester[23] reconsidered Gaudin's model as the grand canonical ensemble of the g-CM system, which may be viewed as the proper thermodynamic limit of the g-CS. Thus, the results of Gaudin and Forrester are summarized (notations by Gaudin) as follows:

(a) *equation of state for grand canonical ensemble with fugacity* ζ,

$$2p=\int_0^\infty\log(1+\zeta e^{-2\pi a x})dx\quad\text{and}\quad\rho=\frac{1}{2\pi a}\log(1+\zeta); \tag{4.7}$$

(b) *hole probability* $E(s)$,

$$E(s)=\det|\mathbf{I}-\rho\mathbf{G}|=\sum_{p=0}^\infty\frac{(-1)^p}{p!}\int_{(-s/2,s/2)}\cdots\int\rho^p ds_1\cdots ds_p\,\det|g(s_j-s_k)|_p, \tag{4.8a}$$

where

$$g(s)=\frac{1}{2\pi\rho a}\int_\nu^\infty\frac{d\omega}{e^\omega+1}e^{-i\omega s/a}, \tag{4.8b}$$

$g(x-y)$ being the kernel of the integral operator $\mathbf{G}$ on a function space in $(-s/2,s/2)$.

Hereafter in this section (before a discussion of thermodynamics), we assume the unfolded scale:

$$\rho=1\quad(\overline{s}=1). \tag{4.9}$$

As demonstrated by Gaudin, one gets two simplified situations:

$$(i)\quad a\to 0,\quad Y_2(r)\cong\frac{a^2}{a^2+r^2}, \tag{4.10}$$

$$(ii)\quad a\to\infty,\quad Y_2(r)\cong\left(\frac{\sin\pi r}{\pi r}\right)^2. \tag{4.11}$$

Expressions (4.10) and (4.11) are deduced by replacing the integrand in the expression (4.6); $(e^{\omega}+1)^{-1}\to e^{-\omega}$, and $\to 1$, the integration range being $[\nu,\infty]$ and $[\nu(<0),0]$, respectively.[22] Here, we demonstrate the interpolation numerically and graphically by defining the following function:[33]

$$P(x,y;a)=\frac{1}{2a}\log\frac{e^{2\pi ax}-1}{e^{2\pi ay}-1}. \tag{4.12}$$

We can show, after a few manipulations, that both the short-range and the long-range behaviors of the two-level correlation function may be exhibited in terms of this function as follows:

$$r_2(s;a)|_{s\to 0}=A(a)s^2,\quad A(a)=2\int_0^1\int_0^1 dxdy\{P(x,y)\}^2 \tag{4.13}$$

and

$$\Sigma^2(s;a)=s-\int_0^1\int_0^1 dxdy\left\{\frac{\sin sP(x,y;a)}{P(x,y;a)}\right\}^2. \tag{4.14}$$

The parameter dependence of the resulting number variance and spectral rigidity (the Δ_3 function) is exhibited in Fig. 1. Result (4.13) shows that the repulsion is always (except $a=0$) of the GUE type (square dependence): For $a\to 0$ (Poisson limit), $A(a)$ diverges, and for $a\to\infty$ (CUE limit), $A(a)\to\pi^2/3$ [in agreement with $P_{\mathrm{GUE}}(s)$].

The above short-range property agrees with the prediction by Forrester,[23] who obtained the same square dependence of the nearest-neighbor spacing distribution $p(0;s)$.

Here, we add the validity of inequalities (3.12) and (3.13) in the power series expansion (3.11) explicitly for the present model by means of the third-order correlation function,[22,23]

$$r_p(s_1,\ldots,s_p)=\det|g(s_i-s_j)|_p,\quad p=3. \tag{4.15}$$

By the power series expansion of $r_3(s_1,s_2,s_3)$ with respect to two variables, $s\equiv s_1-s_2$ and $t\equiv s_1-s_3$ (hence $t-s=s_1-s_3$), one finds that the series starts with the lowest-power terms $s^2t^4+s^4t^2$ and s^3t^3, affirming (3.12) ($\nu=2$, $n=3$); also (3.13) by using $p(0;s)\propto s^2$.

In order to analyze Fig. 1, specifically, the asymptotic behavior of the number variance curve, we first note that the formulas by Bohigas *et al.* (3.19b)–(3.19d) hold here, because, first the cluster function Y_2 given by Eq. (4.6) satisfies

$$\int_{-\infty}^{\infty}Y_2(r)dr=\frac{1}{2\pi a}\int_{\nu}^{\infty}\frac{d\omega}{(e^{\omega}+1)^2}=1-\frac{1-e^{-2\pi a}}{2\pi a},\quad \nu=-\log(e^{2\pi\rho a}-1), \tag{4.16}$$

and second for the integral in (4.6), by means of an integration by parts,

$$\frac{1}{2\pi a}\int_{\nu}^{\infty}\frac{e^{-i\omega r/a}}{e^{\omega}+1}d\omega=\frac{e^{-i\nu r/a}}{2\pi ir}\left[\frac{1}{e^{\nu}+1}+e^{i\nu r/a}\int_{\nu}^{\infty}\left(\frac{1}{(e^{\omega}+1)(1+e^{-\omega})}\right)e^{-i\omega r/a}d\omega\right].$$

Hence

$$\left|\frac{1}{2\pi a}\int_{\nu}^{\infty}\frac{e^{-i\omega r/a}}{e^{\omega}+1}d\omega\right|^2=\frac{1}{(2\pi r)^2}\left|\frac{1}{e^{\nu}+1}+e^{i\nu r/a}C\right|^2, \tag{4.17a}$$

where C denotes the integral in the square bracket above, which can be estimated as

$$|C|=\left|\int_{\nu}^{\infty}\frac{e^{-i\omega r/a}d\omega}{(e^{\omega}+1)(1+e^{-\omega})}\right|\leqslant\int_{\nu}^{\infty}\frac{d\omega}{(e^{\omega}+1)(1+e^{-\omega})}=\frac{1}{e^{\nu}+1}=1-e^{-2\pi a}. \tag{4.17b}$$

We therefore have, for the number-variance asymptote,

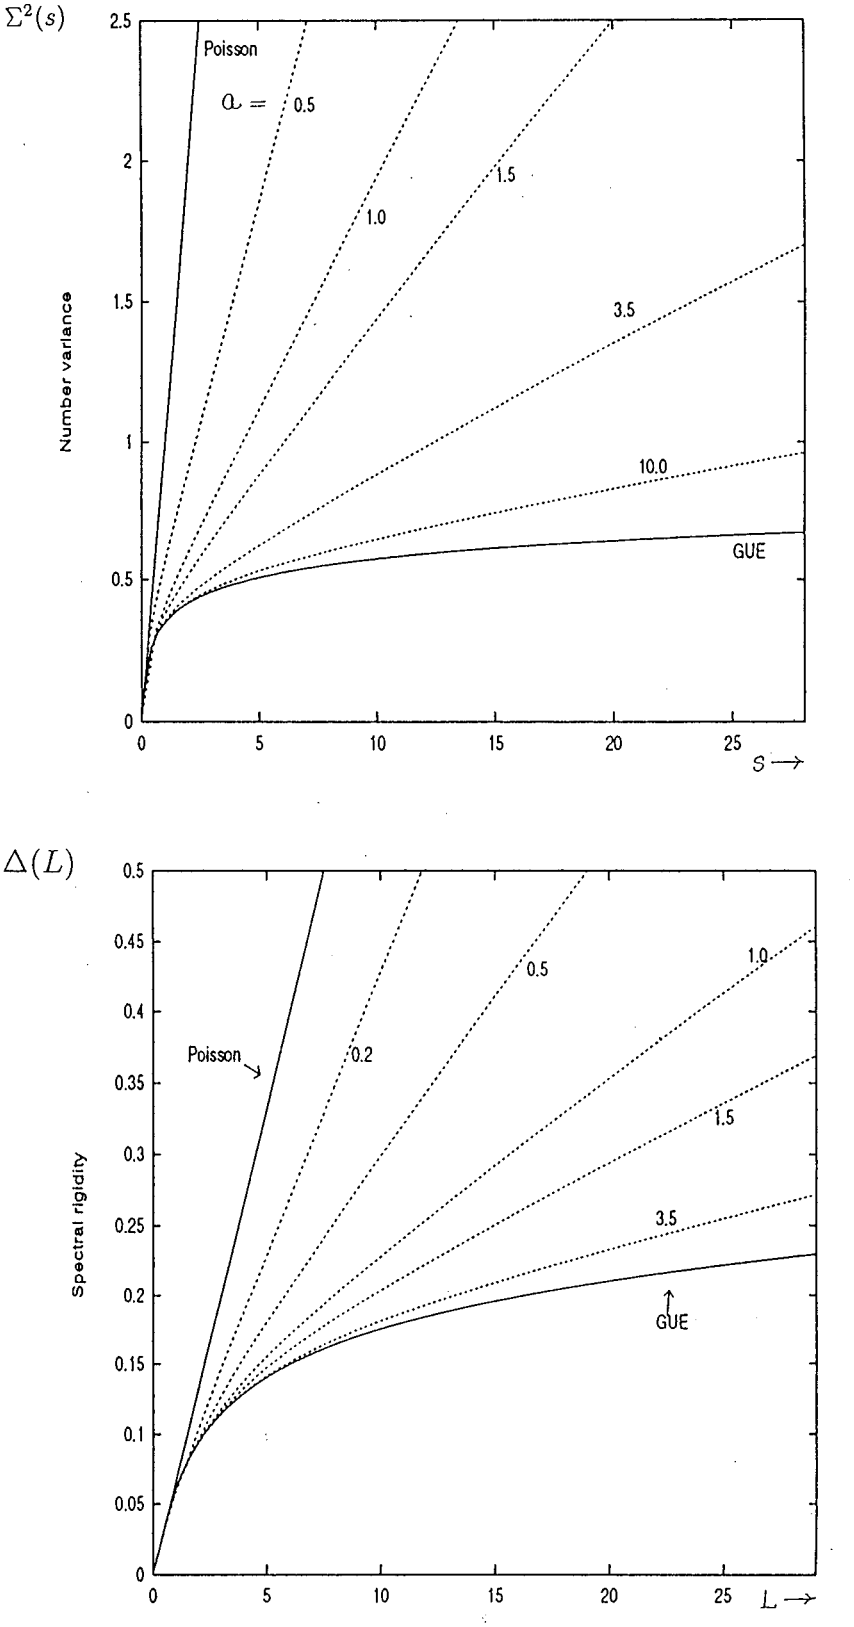

FIG. 1. Curves of number-variance $\Sigma^2(s)$ and Δ statistics $\Delta(L)$ for the exact Gaudin model (Refs. 22 and 33) of Poisson-CU ensembles.

$$\Sigma^2(S) \xrightarrow{S\to\infty} \frac{1-e^{-2\pi a}}{2\pi a}S+\frac{(1-e^{-2\pi a})^2+|C(a)|^2}{2\pi^2}(\log S+\text{const.}), \quad |C(a)|\leqslant 1-e^{-2\pi a}. \tag{4.18}$$

Result (4.16) indicates that the compatibility relation (3.7) (the sum rule) does not hold in the thermodynamic limit. The equation of state (4.7) provides its understanding from a viewpoint of compressible level gas: the presence of the linear term in the $\Sigma^2(S)$ asymptote above can be related to the isothermal compressibility of the one-dimensional interacting model gas as follows:

$$\frac{\partial}{\partial\rho}(\beta p)=\frac{d\zeta}{d\rho}\frac{\partial}{\partial\zeta}(\beta p)=\frac{2\pi a\rho}{1-e^{-2\pi a\rho}}, \tag{4.19}$$

$$\Sigma^2(S)_{\text{linear in } S}=\left(\frac{1}{\beta}\frac{d\rho}{dp}\right)S, \quad \text{with } \beta=2. \tag{4.20}$$

It corresponds to the Ornstein–Zernike formula[27] for the number variance of a three-dimensional gas in terms of the compressibility, as we discuss in more detail in Sec. V.

V. VIOLATION OF THE SUM RULE AND ABSENCE OF THE FRACTIONAL POWER LAW

The Ornstein–Zernike formula for the number variance of gas molecules in a big vessel of volume V reads[27] as

$$\langle(N-\langle N\rangle)^2\rangle=\langle N\rangle^2\frac{kT}{v}\kappa_T, \quad v\ll V, \tag{5.1}$$

where κ_T is the isothermal compressibility of the gas, given by

$$\kappa_T=-\frac{1}{v}\left(\frac{\partial\rho}{\partial p}\right)_{T,\langle N\rangle}=\frac{v}{\langle N\rangle}\left(\frac{\partial\rho}{\partial p}\right)_{T,\langle N\rangle} \quad \left(\rho=\frac{\langle N\rangle}{v}\right). \tag{5.2}$$

Hence, $\langle(N-\langle N\rangle)^2\rangle=kT(\partial\rho/\partial p)_{T,\langle N\rangle}\langle N\rangle$ holds.

For a one-dimensional level gas, it gives precisely the Poisson linear part of the $\Sigma^2(S)$ function, since $\langle N\rangle=S$, thus

$$\Sigma^2(S)_{\text{linear in } S}=\kappa S, \quad 0\leqslant\kappa\leqslant 1, \tag{5.3a}$$

where the compressibility κ now plays a role of the interpolation parameter:

$$\kappa=1: \quad \text{pure Poisson line} \quad \text{(the gas is fully compressible)}, \tag{5.3b}$$

$$\kappa=0: \quad \text{the Gaussian chaos} \quad \text{(the gas is fully incompressible)}. \tag{5.3c}$$

A contribution to the $\Sigma^2(S)$ function from the latter incompressible component is represented by a weaker logarithmic line (3.20) that originates from the inverse-square falloff of the $Y_2(r)$ function.

The feature summarized above is a necessary consequence of the violation of the sum rule (3.7), because as we have seen in the preceding sections the compressibility κ yields a measure of such a violation: $\kappa=1-\int_{-\infty}^{\infty}Y_2(r)dr$. It should be remarked that the violation $\kappa>0$ has resulted from the natural thermodynamic limit,

$$N\to\infty, \quad \text{and} \quad L\to\infty, \quad \text{with } \frac{N}{L}=\rho=\text{fixed}, \tag{5.4}$$

because for a finite g-CS level gas the integral identity must hold strictly in the form (3.5). This implies that for general compressible gases the integration and the thermodynamic limit $L\to\infty$ cannot be interchanged. This was first discussed by Mehta and Dyson[28] in early RMT without any quantitative conclusion: under the circumstance, one should adopt

$$\int_{-\infty}^{\infty} \lim_{N\to\infty}(N/L=\text{fixed}), \quad \text{rather than} \quad \lim_{N\to\infty}\int_{-L/2}^{L/2}, \tag{5.5}$$

which causes the nonvanishing linear component of the $\Sigma^2(S)$, (5.3).

One should not hasten to draw a conclusion that the above presentation be the only possible intermediate long-range statistics. There has been a prediction of a new one-parameter dependence in the Σ^2 function of the universal power type; $\Sigma^2(S)\propto S^{\gamma}$; $1>\gamma>0$, which we may call a ''fractional power law.'' The physical idea is to characterize a transition such as between insulating and metallic phases at the mobility edge,[24] and has been deduced based on the strict satisfaction of the sum rule (3.7). This behavior is certainly weaker than the Poisson straight line but weaker than the Gaussian logarithm, yielding another smooth interpolation between the two limits, as we demonstrated in Ref. 34) (cf. Ref. 20). Whether or not the fractional power law can be understood by the level dynamics is open.

VI. EXACT FORM FACTOR AND ITS APPLICATIONS

The two-level form factor $b(k)$ is defined as the Fourier transform of the (thermodynamic limit of) two-level cluster function $Y_2(x)$ [$n=2$ in (3.6b)], thus (without the unfolding, for generality)

$$b(k)=\int_{-\infty}^{\infty} Y_2(x)e^{ikx}\rho dx. \tag{6.1}$$

Gaudin's exact expression of this quantity for his linear interacting gas model (4.6) reads as

$$\begin{aligned} b(k)&=\frac{1}{2\pi a\rho}\int_{\nu}^{\infty}dx\int_{\nu}^{\infty}dx'\,\frac{\delta(x-x'-ka)}{(e^{x}+1)(e^{x'}+1)} \\ &=\frac{1}{2\sinh(|k|a/2)}\left(\frac{e^{|k|a/2}}{2\pi a\rho}\log[1+e^{-|k|a}(e^{2\pi a\rho}-1)]-e^{-|k|a/2}\right), \end{aligned} \tag{6.2}$$

where

$$b(0)=\lim_{k\to 0} b(k)=1-\frac{1}{2\pi a\rho}(1-e^{-2\pi a\rho}), \tag{6.3}$$

is in agreement with the preceding result (4.16) (if $\rho=1$).

Given a real symmetric, continuous function $f(x)$, $x\in\mathbf{R}$, which satisfies $\int_{-\infty}^{\infty}|f(x)|dx<\infty$. Then, the average of a quantity $(1/N)\Sigma_{m\neq n}f(x_m-x_n)$ over the reduced g-CS distribution (2.16), $\nu=2$, can be computed in terms of the Fourier transform of the f function $\mathscr{F}_f(k)$ and the two-level form factor $b(k)$ as follows:

$$\lim_{N\to\infty,\rho fixed}\left\langle\frac{1}{N}\sum_{m\neq n}f(x_m-x_n)\right\rangle=\rho\mathscr{F}_f(0)-\frac{1}{2\pi}\int_{-\infty}^{\infty}\mathscr{F}_f(k)b(k)dk,$$

$$\mathscr{F}_f(k)=\int_{-\infty}^{\infty}f(k)e^{ikx}dx. \tag{6.4}$$

As an example, we show the average of the potential function, $V(x-y)$, which is identified by rewriting the distribution (2.16) in the form $\exp[-\beta\Sigma_{m<n}V(x_m-x_n)]$: in the thermodynamic limit one finds that $V(s)=\frac{1}{2}\log(1+a^2/s^2)$, which is consistent with (4.10). Then,

$$\mathscr{F}_V(k)=\frac{1}{2}\int_{-\infty}^{\infty}\log(1+a^2/x^2)e^{ikx}\,dx=\frac{\pi(1-e^{-a|k|})}{|k|},$$

and the average potential energy per particle (level) is now given by

$$\left\langle\frac{1}{N}U\right\rangle=\frac{1}{2}\left(\pi a\rho-\int_0^{\infty}\frac{dk}{k}\left\{\frac{1}{2\pi a\rho}\log[1+(e^{2\pi a\rho}-1)e^{-k}]-e^{-k}\right\}\right). \tag{6.5}$$

A. Information loss per level of a circular unitary ensemble

Dyson[35] obtained an exact result on the statistical thermodynamics of eigenvalue sequences of a randomly chosen unitary matrix; what he named *circular ensembles*—orthogonal ($\nu=1$), unitary ($\nu=2$), and symplectic ($\nu=4$). The ordinary context of statistical mechanics, i.e., free energy and mean energy, yielded the entropy per single eigenvalue lying on a unit circle; thus,

$$\begin{aligned}\frac{S}{N}&=\frac{1}{2}(1-\gamma-\log\,\pi)=-0.361,\quad \nu=1,\\ &=-\gamma=-0.577,\quad \nu=2,\\ &=1-2\gamma-\log 2=-0.848,\quad \nu=4\\ &\quad(\gamma=\text{Euler's constant}).\end{aligned} \tag{6.6}$$

Dyson interpreted these numbers as a decrease of the degree of irregularity in the three kinds of eigenvalue sequences, $\nu=1$, 2, and 4, respectively: the negativity of the numbers indicates that each sequence carries an information content in comparison with the entirely random sequence (a negative information loss or, rather, an information gain) depending on the structure of the matrix symmetry: the larger the number ν, the less irregular the sequence.

The present status having the exact formula of the internal energy for Gaudin's model enables us to compute this information quantity as a continuous function of the parameter a from 0 to infinity. The free energy can be computed from the exact partition function (4.4a) with a change of the parameter (4.4b):

$$-\frac{\beta}{N}F=\frac{1}{N}\log N!-(N-1)\alpha+\log(1-e^{-2\alpha})-\frac{1}{N}\sum_{k=1}^{N}\log(1-e^{-2k\alpha}),\quad \beta=2.$$

For $N\gg 1$,

$$\begin{aligned}&=-\pi a\rho-1+\log(2\pi a\rho)-\frac{1}{\pi a\rho}\int_0^{\pi a\rho}\log(1-e^{-2u})du,\\ &=-\pi a\rho-1+\log\frac{2\pi a\rho}{1-e^{-2\pi a\rho}}+\frac{1}{\pi a\rho}\int_0^{\pi a\rho}\frac{2u\,du}{e^{2u}-1}.\end{aligned}$$

Hence, we get

$$\begin{aligned}\frac{1}{N}S=\frac{\beta}{N}(U-F)&=\log\left(\frac{2\pi a\rho}{1-e^{-2\pi a\rho}}\right)-1+\frac{1}{\pi a\rho}\int_0^{\pi a\rho}\frac{2u\,du}{e^{2u}-1}\\ &\quad-\int_0^{\infty}\left(\frac{1}{2\pi a\rho}\log[1+(e^{2\pi a\rho}-1)e^{-u}]-e^{-u}\right)\frac{du}{u}.\end{aligned} \tag{6.7}$$

It is not difficult to check the validity of the expected limits: $S\to 0$ for $a\to 0$, and $S\to -N\gamma$ for $a\to\infty$. The computed curve of this quantity versus a is shown in Fig. 2.

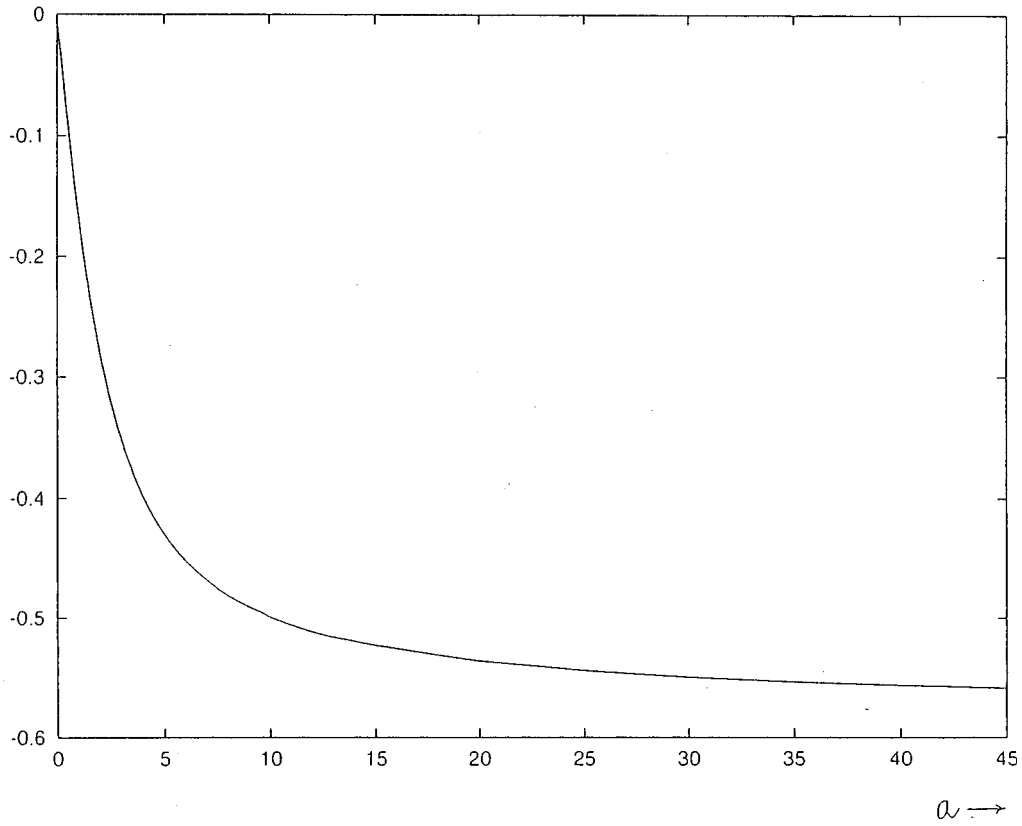

FIG. 2. Information-loss curve for the Gaudin model of Poisson-CU ensembles in accordance with Dyson (Ref. 35) computed by the formula of $b(k)$, Eq. (6.2).

B. Correlation hole of survival probability

We study a manifestation of level statistics on the so-called survival probability function (SPF), defined by

$$P(t)=|\langle\psi(0)|\psi(t)\rangle|^2, \tag{6.8}$$

i.e., the quantum probability that an initial state will return to itself after time t. It has been shown that the SPF, if averaged both over random initial states and over the Hamiltonian ensemble, exhibits a distinct difference between chaotic and regular systems. For integrable systems, the SPF decays monotonically to its long-time limit, while for chaotic systems the SPF curve exhibits a ''correlation hole,'' where the probability falls below its asymptotic value at finite times. These features can be explained in the framework of level statistics, as discussed by a number of authors.[36,37] Therefore, we investigate the intermediate situation of this phenomenon, where the present intermediate statistics is applicable, in particular, Gaudin's exact formula for intermediate circular unitary ensembles.

In Ref. 37, it was shown that the double-averaged SPF can be expressed, in terms of the two-level form factor $b(k)$ (6.2), as

$$\langle\langle P(t)\rangle\rangle=\frac{2}{N+1}+\frac{1}{N+1}\left[\frac{\sin^2(\pi\tau N)}{\pi^2\tau^2 N}-\int_{-\infty}^{\infty}dk\,b(k)\frac{\sin^2[\pi(\tau-k)N]}{\pi^2(\tau-k)^2 N}\right]. \tag{6.9}$$

Substituting the expression given by Eq. (6.2) into (6.9), we can plot the SPF, as shown in Fig. 3 for a fixed value of N $(=14)$ and four different values of the parameter a. One can see a smooth transition from the Poisson case, i.e., no correlation hole, to the GUE case, where the depth of the hole reaches its maximum. In the course of this transition, the area of the correlation hole is kept unchanged, while its depth increases as a increases. These are the manifestation of the level

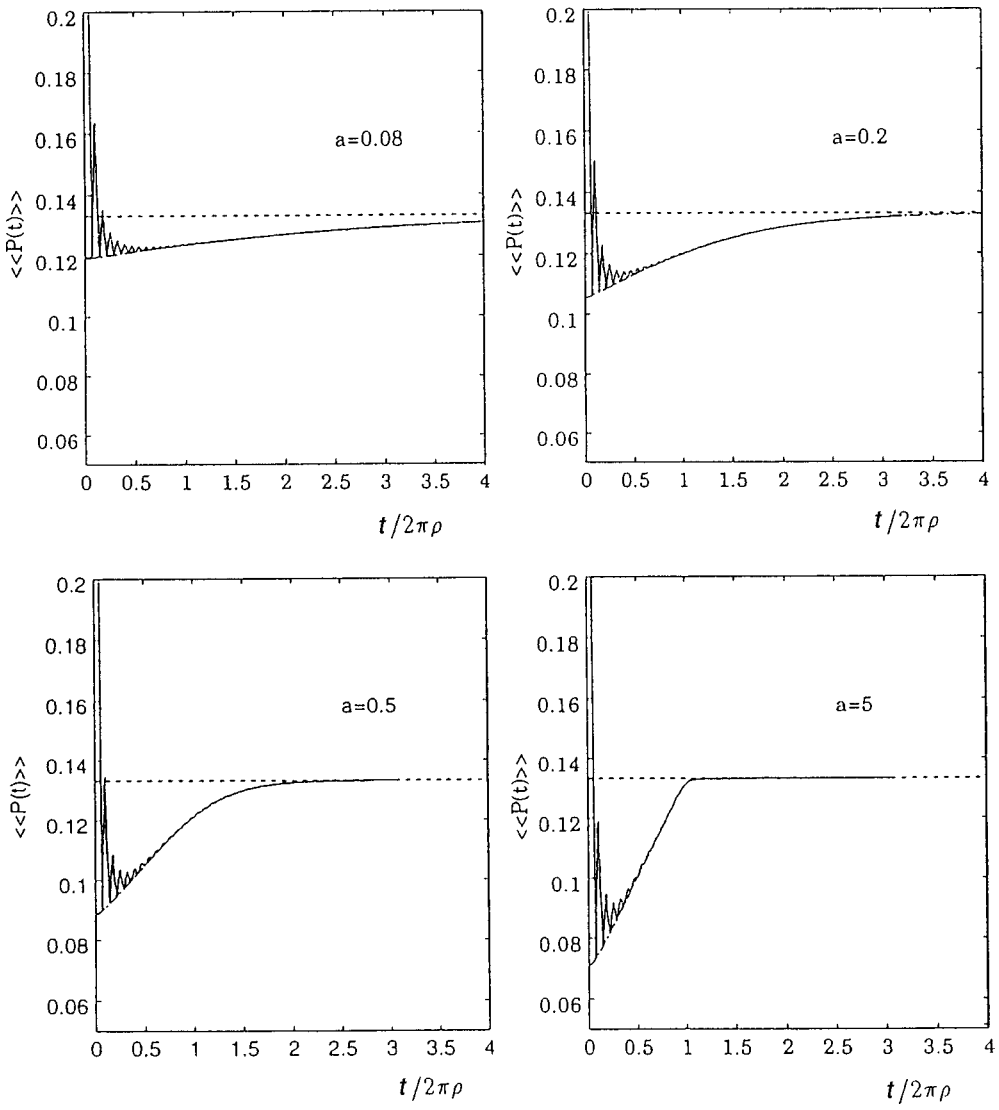

FIG. 3. Curves of survival probability for a simple quantum system without time reversal belonging to the Gaudin model (Ref. 37) of Poisson-CU ensembles.

repulsion and, in fact, due to an increase of the incompressibility of the level gas from the Poisson limit. Here, let us study another manifestation of the problem of the ''sum rule'' in the preceeding sections in the present Fourier transformed space. The depth H of the hole of SPF is given from (6.9) by

$$H(N)=\frac{1}{N+1}\left[\int_{-\infty}^{\infty}\mathrm{d}k b(k)\,\frac{\sin^2[\pi(\tau-k)N]}{\pi^2(\tau-k)^2N}\right]_{\tau=0}. \tag{6.10}$$

In deriving this expression, we have assumed that the bottom of the hole occurs close to $\tau=0$. Observe that a similar problem to that encountered in the asymptotic expansion of the number variance arises, namely, the noninterchangeability of the thermodynamic limit and other limits: If we take $\tau=0$, i.e., $t=0$ first, then we would obtain an identity for the SPF, given by

$$\langle\langle P(t=0)\rangle\rangle=1, \tag{6.11}$$

which corresponds to the exact sum rule. On the other hand, if we take the limit $N\to\infty$ first in the square bracket of Eq. (6.10), we would obtain

$$H(N)=\frac{1}{N+1}b(0) \tag{6.12}$$

which depends on the extent of the incompressibility of the level gas. Note that the conservation of the total area S of the hole is due to the identity

$$S=\frac{1}{N+1}\int_0^\infty b(\tau)d\tau=\frac{1}{2}Y_2(0). \tag{6.13}$$

Finally, we give a brief description about our ongoing investigation of the relation between the survival probability and the saturation of the long-range statistics, such as the spectral rigidity and the number variance. It was analytically shown by Berry[6] and later numerically and experimentally tested by various authors[38] that the spectral rigidity reaches a saturation value at a nonuniversal point $L_{\max}$, in contrast to the logarismic or the linear law, as predicted by the random matrix theory of treating infinitely many levels, for regular or chaotic systems, respectively. The value of $L_{\max}$ is determined by the shortest period of the corresponding classical periodic orbits. We find that in order to take into account the saturation effect the two-level form factor should be modified as

$$b(k)=1, \quad \text{if } k<k_{\text{sat}}, \tag{6.14}$$

and otherwise the same as given by the corresponding RMT model. Here, $k_{\text{sat}}\sim 1/L_{\max}$ is a nonuniversal quantity given by the classical feature of the system under consideration. Therefore, the manifestation of the saturation effect on the survival probability should be that the bottom of the correlation hole is of *finite* size, k_{sat}. The remaining question is whether or not the function $b(k)$ is discontinuous near the point k_{sat}, which must be treated separately.

VII. CONCLUDING REMARK

An important comment on the present work, which we consider as worthwhile to address in concluding it, is a possible unification of our framework of level dynamics and that of band random matrix theories (BRMT).[25,39] The common motivation in both frameworks is, being very close to each other, to take systematic account of the *structuredness* of level correlations such that a more distant pair of levels be less correlated. This nature is more pronounced in BRMT, since it starts with a straightforward destruction of the full permutation symmetry of levels (a kind of symmetry breaking of the symmetry group that is retained in our framework). It is not strange, therefore, that BRMT may be able to predict the metal–insulator transition with a fractional power law of the number variance asymptote, which should be studied.

(Received 21 November 1997; accepted for publication 29 December 1997)

We propose a path integral formulation of noncommutative generalizations of space–time manifold in even dimensions, characterized by a length scale λ_P. The commutative case is obtaind in the limit $\lambda_P=0$. © *1998 American Institute of Physics.* [S0022-2488(98)02904-1]

I. INTRODUCTION

It is commonly believed that the picture of space–time as a smooth pseudo-Riemannian manifold should break down at most at the Planck scale $\lambda_P \sim 10^{-33}$ cm, due to the effects of quantum gravity. Many arguments on operational limits on position and time measurements have been considered in literature,[1–4] suggesting that our description of space–time as a collection of points equipped with suitable topological and metric structures, should be modified in a way which is reminiscent of the quantization of phase space in ordinary quantum mechanics. In this case too, in fact, the classical phase space, seen as the joint spectrum of commuting position and momentum operators, turns into its fuzzy quantum version, where the notion of points is replaced, in a somehow intuitive way, by fundamental cells of area $\hbar$. This quantization procedure can be formalized by adopting a *dual* point of view, namely by considering the algebra of smooth functions over the phase space, generated by positions and momenta. This algebra contains, using Gelf'and–Naimark reconstruction theorem, all informations on the underlying space. Switching on the Planck constant then amounts to considering the noncommutative algebra still generated by positions and momenta, which are now considered noncommuting elements with usual commutation relations.

Quantum phase space is perhaps the most famous example of what is now usually called noncommutative geometry. While at the classical level the phase space can be described either *geometrically*, i.e., defining its structure as a topological manifold, or algebraically, its noncommutative quantum version can only be defined via the algebra of observables generated by positions and momenta, since the notion of ordinary manifold is lost. The algebraic description of noncommutative geometries has recently received new insights, in particular due to Connes.[5]

In this paper we will assume, as first considered long ago,[6] and as suggested by the previous considerations, that the effect of gravity at very short distances is such to render positions and time X^μ noncommutative,

$$[X^\mu, X^\nu] = i\lambda_P^2 Q^{\mu\nu}, \tag{1}$$

where the antisymmetric tensor $Q^{\mu\nu}$, depending in general on X^μ, should eventually be given by a satisfactory theory of quantum gravity. The space–time is described by the $*$-algebra $\mathscr{A}$ generated by regular representations of Eq. (1), whereas the notion of points is now lost. Here and in the following we will use upper case for the elements of $\mathscr{A}$ and lower case for their commutative limit, so for example, $F(X)$ is an element of $\mathscr{A}$ and $f(x)$ is instead an ordinary smooth function over the commutative space–time manifold. Many ansatzs for Eq. (1) have been considered, in different contexts.[3,4,7,8] They predict uncertainty relations among position and time operators which in turn imply that quantum field theories built upon these generalized space–times have a more regular behavior at small distances, and, in particular, may be free of ultraviolet divergences. See for example Refs. 3, 8–10.

The key observation of the present paper is that the analogy with ordinary quantum mechanics and quantization of phase space can also be pursued to establish a path integral formulation of these noncommutative geometries, taking the point of view that a class of linear functionals over $\mathcal{A}$, which turn into evaluation maps in the commutative limit, can be expressed as integrals, with a suitable measure, of ordinary functions over the classical, commutative space–time manifold. It is well known in fact that quantization of phase space can be introduced either in the canonical approach, namely, by defining a representation for positions and momenta as self-adjoint operators on a separable Hilbert space, or via Feynman sum over paths in classical phase space. In this case, to evaluate matrix elements of time ordered polynomials in position and momenta one should average over all trajectories with fixed boundary conditions, $q(t_0)=q_0$ and $q(t_f)=q_f$, with measure $\exp(iS/\hbar)$. For one degree of freedom

$$\langle q_f,t_f|T[Q(t_1)P(t_2)\ldots]|q_0,t_0\rangle=\int D[q]D[p]e^{iS/\hbar}(q(t_1)p(t_2)\ldots), \tag{2}$$

where T denotes time ordering and the action S is the integral over the considered path of the one-form $pdq-H(p,q)dt$. Equation (2) defines a set of linear functionals over the algebra generated by Q and P in the Heisenberg representation. In particular for $q_0=q_f$, of the two terms in S, the first one measures for each closed trajectory γ in the phase space the area of the surface Γ with boundary γ normalized to $\hbar$, i.e., the surface integral of the symplectic form $dp\wedge dq$ over Γ. Actually, the picture of quantum phase space as composed by fundamental cells of area $\hbar$ is already emerging from this term, independently of which particular dynamical system we are considering, defined by a particular choice for the Hamilton function $H(p,q)$.

These considerations suggest that a noncommutative structure of space–time could be introduced starting with the classical commutative manifold equipped with a symplectic form Ω. A path integral formalism similar to Eq. (2) may then provide a way of evaluating a class of linear functionals over polynomials of the deformed noncommutative position and time operators X^μ. Of course this will restrict our analysis to the case of even dimensional spacetime manifolds M^{2n}, in order that a nondegenerate, closed two-form Ω exists. This construction requires the introduction of a parameter with dimension of length, λ_P, which plays a role analogous of $\hbar$ in ordinary quantum mechanics. In particular in the limit $\lambda_P\to 0$ all functionals we will consider reduce to evaluation maps of the commutative algebra of smooth functions over M^{2n}. For finite λ_P instead, position and time operators X^μ satisfy nontrivial commutation relations of the form of Eq. (1) with $Q^{\mu\nu}$ related in a simple way to Ω.

II. PATH INTEGRAL OVER SPACE–TIMES

We start considering the pair (R^{2n},Ω), with Ω a symplectic form and the following generating functional:

$$Z(x_0,J)=N\int D[\gamma]\exp[i\lambda_P^{-2}(\Sigma[x_0,\gamma]+(x,J))], \tag{3}$$

where N is a normalization constant, J an arbitrary source, the integration is carried over all closed curves γ in R^{2n} with base point $x_0\in R^{2n}$ and we define

$$\Sigma[x_0,\gamma]=\int_\Gamma \Omega_{\mu\nu}(x)dx^\mu\wedge dx^\nu, \tag{4}$$

$$(x,J)=\int_\gamma x^\mu(\tau)J_\mu(\tau)d\tau, \tag{5}$$

where we have introduced a parameterization, γ: $\tau\mapsto x^\mu(\tau)$ and Γ is any two-dimensional surface with boundary γ. Finally, the antisymmetric matrix $\Omega_{\mu\nu}(x)$ is the representation of the symplectic form in the coordinate basis x^μ and, in general, explicitly depends on x^μ. Here we will assume for simplicity that $\Omega_{\mu\nu}(x)$ is a slowly varying function of x on the scale λ_P, and we consider only zero order terms in Taylor expansion around the base point x_0 in integrals (4), $\Omega_{\mu\nu}(x)$

$\sim\Omega_{\mu\nu}(x_0)$. This assumption simplifies the explicit evaluation of $Z(x_0,J)$, which is our main aim in this paper, but is not necessary. The general case will be considered elsewhere. In this case $\Sigma[x_0,\gamma]$ can therefore be written as

$$\Sigma[x_0,\gamma]=\int_\gamma x^\mu(\tau)\Omega_{\mu\nu}(x_0)\,\frac{d}{d\tau}\,x^\nu(\tau)d\tau. \tag{6}$$

$Z(x_0,J)$ is invariant under curve reparameterization, as is easy to verify, provided we redefine the arbitrary external source J. In the following we will consider $\tau\in[0,1]$.

Equation (3) is clearly inspired by the expression of path integral in phase space with external sources. However it is worth pointing out that there is one main difference with ordinary path integral approach to quantum mechanics of Eq. (2), even for $q_0=q_f$. In this case, in fact, the variables q and p are treated on different grounds, since integration is carried over all curves with boundary conditions on positions only, while momenta run over all possible values. In case of Eq. (3), instead, all curves γ should have equal end points x_0^μ for all x^μ's, $\mu=1,...,2n$.

The generating functional $Z(x_0,J)$ defines a one parameter family of (noncommutative) algebras $\mathscr{A}(\tau)$ generated by $2n$ elements $X^\mu(\tau)$, implicitly defined via the introduction of a set of linear functionals ρ_{x_0} as follows:

$$\begin{aligned}\rho_{x_0}(P[X^\mu(\tau_1)\ldots X^\nu(\tau_k)])&\equiv NZ(x_0,0)^{-1}\int D[\gamma]e^{i\Sigma[x_0,\gamma]/\lambda_P^2}x^\mu(\tau_1)\ldots x^\nu(\tau_k)\\&=(-i\lambda_P^2)^kZ(x_0,0)^{-1}\frac{\delta}{\delta J_\mu(\tau_1)}\cdots\frac{\delta}{\delta J_\nu(\tau_k)}\,Z(x_0,J)\Big|_{J=0},\end{aligned} \tag{7}$$

where P stands for path ordering, defined analogously to time ordering in quantum mechanics. Once defined on all polynomials in the X^μ, Eq. (7) can be applied to the entire algebra of continuous functions $F(X)$ in the weak topology.

To better understand Eq. (7) we consider the *classical* limit $\lambda_P\to 0$. The integral over curves γ is then dominated by the contribution at stationary points satisfying $\delta\Sigma[x_0,\gamma]=0$, i.e., $\Omega_{\mu\nu}(x_0)dx^\nu/d\tau=0$. Since Ω is not degenerate, the leading contribution satisfying $x^\mu(0)=x^\mu(1)=x_0^\mu$, is therefore given by the curve $x^\mu(\tau)=x_0^\mu$, $\forall\tau$, so that we get

$$\rho_{x_0}(P[X^\mu(\tau_1)\cdots X^\nu(\tau_k)])\to x^\mu\cdots x^\nu|_{x_0}+O(\lambda_P^2). \tag{8}$$

Thus, the maps ρ_{x_0} reduce to the evaluation maps of the commutative algebra of smooth functions over R^{2n}, $\rho_{x_0}:f(x)\mapsto f(x_0)$, independently of τ, and thus completely reconstruct R^{2n} as a topological manifold. For finite λ_P, instead, all closed curves whose projection on the $x^\mu-x^\nu$ plane enclose surfaces with area of the order $\Omega_{\mu\nu}(x_0)^{-1}\lambda_P^2$ give a relevant contribution to the right-hand side of Eq. (7), and evaluation maps are smeared over cells in R^{2n} with projection on the $x^\mu-x^\nu$ plane of this order of magnitude. It is worth mentioning that stationary phase method requires Hessian to be nondegenerate at stationary points. As for the case of wave packets of zero mass particles, this aspect deserves a careful analysis in the case under consideration, since the self-adjoint extension of the operator $\Omega_{\mu\nu}(x_0)d/d\tau$ admits zero modes. We will deal with this problem by using in the following a customary $i\epsilon$ prescription which renders the above operator invertible.

We start evaluating $Z(x_0,J)$ for the case $n=1$. Use of Darboux theorem allows for a straightforward generalization to arbitrary n. In two dimensions we write $\Omega_{\mu\nu}(x_0)$ as $\omega(x_0)\epsilon_{\mu\nu}$, with $\omega(x_0)$ a nonvanishing function on R^2. Furthermore all closed curves $x^\mu(\tau)$ with end points at x_0^μ can be written as $x^\mu(\tau)=x_0^\mu+y^\mu(\tau)$, where $y^\mu(0)=y^\mu(1)=0$. Substituting in (3) we get

$$Z(x_0,J)=N\int D[y]\exp\left[i\lambda_P^{-2}\left(\omega(x_0)\int_0^1 y^\mu(\tau)\epsilon_{\mu\nu}\,\frac{d}{d\tau}\,y^\nu(\tau)d\tau+(x_0,J)+(y,J)\right)\right]. \tag{9}$$

The operator $\epsilon_{\mu\nu}d/d\tau$ is self-adjoint with respect to the scalar product (5) on the domain of periodic two component functions $y^\mu(\tau)$. Its spectrum is given by $\mu_m=2m\pi$, $m\in Z$. To each eigenvalue correspond the two eigenfunctions, normalized to λ_P,

$$y_m^{(+)}(\tau)=\lambda_P\begin{pmatrix}\cos(\mu_m\tau)\\ \sin(\mu_m\tau)\end{pmatrix},\quad y_m^{(-)}(\tau)=\lambda_P\begin{pmatrix}\sin(\mu_m\tau)\\ -\cos(\mu_m\tau)\end{pmatrix}. \tag{10}$$

Expanding the functions $y^\mu(\tau)$ in the basis (10), $Z(x_0,J)$ becomes a usual pseudo-Gaussian integral over the Fourier components $c_m^{(\pm)}=\lambda_P^{-1}(y_m^{\pm},y)$. As mentioned before, we will introduce a $i\epsilon$ prescription as a regularization of the singularity due to the presence of a zero mode, namely shifting in the complex plane $\mu_m\to\mu_m+i\epsilon$. In this way we get, integrating over $c_m^{(\pm)}$

$$Z(x_0,J)=N'\ \exp\Bigg[i\lambda_P^{-2}x_0^\mu\int_0^1 J_\mu(\tau)d\tau-(4\epsilon\lambda_P^2)^{-1}\delta^{\mu\nu}\int_0^1 J_\mu(\tau)d\tau\int_0^1 J_\nu(\tau')d\tau'$$
$$-i\sum_{m\neq 0}(4\mu_m\omega(x_0)+i\epsilon)^{-1}((J_m^{(+)})^2+(J_m^{(-)})^2)\Bigg], \tag{11}$$

where $J_m^{(\pm)}=\lambda_P^{-1}(x_m^{(\pm)},J)$ are the Fourier components of $J_\mu(\tau)$ and notice that the zero mode does not contribute to the sum, so we can safely neglect the $i\epsilon$ term in this case. Using (10) and performing the sum over m we finally obtain

$$Z(x_0,J)=N'\ \exp\Bigg[i\lambda_P^{-2}x_0^\mu\int_0^1 J_\mu(\tau)d\tau-(4\epsilon\lambda_P^2)^{-1}\delta^{\mu\nu}\int_0^1 J_\mu(\tau)d\tau\int_0^1 J_\nu(\tau')d\tau'$$
$$+i\lambda_P^{-2}\int_0^1 d\tau\int_0^1 d\tau'\,\Omega^{-1\mu\nu}(x_0)J_\mu(\tau)J_\nu(\tau')\Delta(\tau-\tau')\Bigg], \tag{12}$$

where the kernel $\Delta(t)$ is given by

$$8\Delta(t)=\begin{cases}2t-1 & t\in\,]0,1[\\ 2t+1 & t\in\,]-1,0[\end{cases} \tag{13}$$

which is discontinuous at $t=0$. We can now proceed to explicitly evaluate the action of the maps ρ_{x_0} on path ordered polynomials of X^μ. Up to second order polynomials we get

$$\rho_{x_0}(X^\mu(\tau))=x_0^\mu,\quad \rho_{x_0}(P[X^\mu(\tau)X^\nu(\tau')])=x_0^\mu x_0^\nu+\frac{\lambda_P^2}{2\epsilon}\,\delta^{\mu\nu}-2i\lambda_P^2\Omega^{-1\mu\nu}(x_0)\Delta(\tau-\tau'). \tag{14}$$

Actually, since $Z(x_0,J)$ only contains linear and quadratic terms in J, all other higher order polynomials can be evaluated, up to combinatorial factors, in terms of these expressions.

We see from (14) that ρ_{x_0} simply associates to $X^\mu(\tau)$ the value x_0^μ, independently of τ. In fact the only dependence on the τ variable is contained in the function $\Delta(\tau-\tau')$, appearing for path ordered products of $X^1(\tau)X^2(\tau')$. As long as arbitrary polynomials $X^\mu(\tau_1)\cdots X^\mu(\tau_k)$ in only one of the X^μ operators are considered, the dependence on the parameters τ_i drops out. We also notice that we get for the *uncertainty* functional

$$\rho_{x_0}(X^\mu(\tau)X^\mu(\tau'))-\rho_{x_0}(X^\mu(\tau))\rho_{x_0}(X^\mu(\tau'))=\frac{\lambda_P^2}{2\epsilon}\ \forall\,\tau,\tau'. \tag{15}$$

These results have a customary interpretation by looking at ρ_{x_0} as corresponding to states $|x_0\rangle$ in a Hilbert space with respect to which $X^\mu(\tau)$ have mean value x_0^μ and squared uncertainty as in (15). For the equal τ commutator we find

$$\rho_{x_0}([X^\mu,X^\nu](\tau))=\lim_{\delta\to 0^+}(\rho_{x_0}(X^\mu(\tau+\delta)X^\nu(\tau))-\rho_{x_0}(X^\nu(\tau+\delta)X^\mu(\tau)))$$
$$=\frac{i}{2}\,\lambda_P^2\Omega^{-1\mu\nu}(x_0),\quad \forall\,\tau. \tag{16}$$

As expected, the commutator is proportional to the inverse symplectic form Ω^{-1} and using notation of Eq. (1), we see that $X^\mu(\tau)$ generates a noncommutative algebra with, for any τ, $\rho_{x_0}(Q^{\mu\nu}(\tau))=\Omega^{-1\mu\nu}(x_0)/2$.

The uncertainties (15) diverge if one lets the regularizing parameter ϵ go to zero. This means that in this limit the states $|x_0\rangle$ are no longer in the domain of X^μ. However, the $1/\epsilon$ singularity can be removed if one defines a *renormalized* set of linear functionals $\tilde{\rho}_{x_0}$ which satisfy the first of Eqs. (14), Eq. (16), and have minimal squared uncertainties compatible with Eq. (16), and equals for both $X^1(\tau)$ and $X^2(\tau)$, namely $\lambda_P^2(4\omega(x_0))^{-1}$. Equation (14) then becomes

$$\tilde{\rho}_{x_0}(X^\mu(\tau))=x_0^\mu, \quad \tilde{\rho}_{x_0}(P[X^\mu(\tau)X^\nu(\tau')])=x_0^\mu x_0^\nu+\frac{\lambda_P^2}{4\omega(x_0)}\,\delta^{\mu\nu}-2i\lambda_P^2\Omega^{-1\mu\nu}(x_0)\Delta(\tau-\tau'). \tag{17}$$

Accordingly, the corresponding generating functional $\tilde{Z}(x_0,J)$ is obtained from Eq. (12) by substituting ϵ with $2\omega(x_0)$. The states corresponding to this new set of linear functionals would be analogous to coherent states for ordinary quantum mechanics. They would also correspond to the states of maximal localization introduced in Ref. 8. Notice also that $\tilde{\rho}_{x_0}$ gives finite results when applied to arbitrary higher order polynomials in $X^\mu(\tau)$, which, as already stressed, can all be expressed in terms of (17).

The above results can be easily generalized to the $2n$ dimensional case. We start again with Eqs. (3)–(5), written now on R^{2n}. As before, we will consider in Eq. (4) only zero terms in the Taylor expansion of $\Omega(x)$. By the Darboux theorem it is always possible to reduce $\Omega(x_0)$, for any x_0, to the canonical form

$$\omega=\begin{pmatrix} 0 & 1_n \\ -1_n & 0 \end{pmatrix} \tag{18}$$

with a suitable coordinate transformation $z^\mu=(A^{-1})^\mu_\nu(x_0)y^\nu$. In these new coordinates and within the approximation $\Omega(x)\sim\Omega(x_0)$, $\Sigma[x_0,\gamma]$ is simply the sum of n bidimensional integrals like the first term in Eq. (9) and $Z(x_0,J)$ factorizes into the product of n bidimensional generating functionals depending on the sources $J'_\mu=(A^T)^\nu_\mu(x_0)J_\nu$, with A^T the transpose of A. Carrying out the pseudo-Gaussian integrals and transforming back the result in terms of J_μ we therefore obtain

$$Z(x_0,J)=N'\,\exp\Bigg[i\lambda_P^{-2}x_0^\mu\int_0^1 J_\mu(\tau)d\tau-(4\epsilon\lambda_P^2)^{-1}(AA^T)^{\mu\nu}(x_0)\int_0^1 J_\mu(\tau)d\tau\cdot\int_0^1 J_\nu(\tau')d\tau'$$
$$+i\lambda_P^{-2}\int_0^1 d\tau\int_0^1 d\tau'\,\Omega^{-1\mu\nu}(x_0)J_\mu(\tau)J_\nu(\tau')\Delta(\tau-\tau')\Bigg] \tag{19}$$

which gives

$$\rho_{x_0}(X^\mu(\tau))=x_0^\mu, \tag{20}$$

$$\rho_{x_0}(P[X^\mu(\tau)X^\nu(\tau')])=x_0^\mu x_0^\nu+\frac{\lambda_P^2}{2\epsilon}\,(AA^T)^{\mu\nu}(x_0)-2i\lambda_P^2\Omega^{-1\mu\nu}(x_0)\Delta(\tau-\tau'), \tag{21}$$

and for the equal τ commutator again Eq. (16).

It is worth noticing that a constant Ω in four dimensions corresponds to the case considered in Ref. 3, where the following algebra has been studied:

$$[X^\mu,X^\nu]=i\lambda_P^2Q^{\mu\nu}, \quad [X^\mu,Q^{\mu\nu}]=0,$$

$$Q_{\mu\nu}Q^{\mu\nu}=0, \quad (\tfrac{1}{8}\,\epsilon_{\mu\nu\rho\sigma}Q^{\mu\nu}Q^{\rho\sigma})^2=I. \tag{22}$$

Actually the condition $\rho_{x_0}([X^\mu,Q^{\mu\rho}](\tau))=0$, $\forall\tau$ can be easily verified using Eq. (19), while the constraint $\rho_{x_0}(\epsilon_{\mu\nu\rho\sigma}Q^{\mu\nu}Q^{\rho\sigma}(\tau))=\pm 8$ is equivalent, up to a suitable normalization, to require Ω

to be nondegenerate. The procedure of describing a noncommutative geometry with a path integral approach outlined in this paper cover, however, more general cases, since the commutator may depend on x_0, as is clear from Eqs. (16) and (19). Moreover, if one does not assume that $\Omega(x)$ is a slowly varying function of x and that for each x_0 one can approximate $\Omega(x)\sim\Omega(x_0)$ in the phase $\Sigma[x_0,\gamma]$, one may consider, at least in principle, a completely general case, although the corresponding generating functional could be difficult to handle. Nevertheless, even if $Z(x_0,J)$ is not exactly solvable for more involved choices of Ω, applications of perturbation techniques, as in ordinary path integral in quantum mechanics, may provide some information on the underlying noncommutative space–time.

III. PATH INTEGRAL OVER SPACE–TIMES WITH NONTRIVIAL TOPOLOGIES

In the previous section we considered the path integral construction of noncommutative generalizations of space–times for the case of R^{2n} as the underlying classical manifold. When the method outlined there is applied to manifolds M^{2n} with nontrivial topologies, in particular when the first and/or second homology groups are nontrivial, there are (however) two aspects which one should take into account. First of all, if $H^1(M^{2n})\neq\{0\}$, there are closed curves contributing to the sum over paths which are not boundaries of any surface, so the surface integral of the assigned symplectic form is not defined for these paths. In these cases the introduction of a one-form A, such that locally $\Omega=dA$ is a better starting point. Moreover, if $H^2(M^{2n})\neq\{0\}$, the integral $\Sigma[x_0,\gamma]$ for any γ is in general a multivalued function, since the integral of Ω over two surfaces Γ and Γ', both with boundary γ, may be different if $\Gamma-\Gamma'$ is a nontrivial 2-cycle (of course this problem is absent if Ω is exact). The ambiguity in the choice of the surface, however, can be removed by requiring *quantization* conditions on the integral of Ω over a set of generators of $H^2(M^{2n})$ such that $\exp(i\Sigma[x_0,\gamma]\lambda_P^{-2})$ is single valued, analogous to the one introduced to quantize the motion of a charged particle in the field of a magnetic charge. We will illustrate these points in two bidimensional simple examples, the sphere S^2 and the torus $S^1\times S^1$, and discuss the generalization to general cases.

Let us consider the pair (S^2,Ω). Any closed curve γ will divide S^2 into two surfaces, and therefore the value of $\Sigma[x_0,\gamma]$ of Eq. (4) will be defined only up to the integral of Ω over S^2. The measure in the path integral will be, nevertheless, single valued if the latter is a multiple of 2π, in unit λ_P^2,

$$\int_{S^2}\Omega=2n\pi\lambda_P^2. \tag{23}$$

A path integral over S^2 was already considered in Ref. 11, as a way to quantize a classical particle with spin.

Incidentally, we observe that condition (23) could have an intriguing relationship with the idea that the black hole horizon area is quantized and its spectrum is uniformly spaced.[12] In our approach, this quantization in unit of λ_P^2, would be intimately related to the fact that positions and time are noncommuting operators and their commutator is of the form reported in Eq. (1). Actually black hole physics is one of the best scenarios where the noncommutative nature of space–time at small scales, otherwise unobservable, could be felt well above the Planck length.

The ambiguity in the definition of the measure in path integral and the necessity of a *quantization* condition (23) is due to the fact that the second homology group of S^2 is nontrivial. A similar ambiguity in defining the *action* $\Sigma[x_0,\gamma]$ corresponding to a path γ on a manifold M^{2n}, and therefore the generating functional (3), will arise whenever $H^2(M^{2n})\neq\{0\}$. In particular, if its 2-Betti number is equal to $b_2(M^{2n})=k$, and denoting with Γ_i, $i=1,...,k$, a set of generators of $H^2(M^{2n})$, the measure $\exp(i\Sigma[x_0,\gamma]\lambda_P^{-2})$ will be single valued if Ω satisfies the following conditions:

$$\int_{\Gamma_i}\Omega=2n_i\pi\lambda_P^2,\quad i=1,...,k, \tag{24}$$

which of course do not depend on the choice for the elements of the basis Γ_i.

As a second example of a nontrivial topological manifold, we consider the bidimensional torus $T^2=S^1\times S^1$. In this case there are closed curves which are not boundaries of any surface and therefore the construction outlined in the previous section cannot be applied. Nevertheless it is still possible to construct a path integral over T^2 and the generating functional $Z(x_0,J)$ starting with a one-form A such that (locally) $\Omega=dA$. Let us denote with $\gamma_i(x_0)$, $i=1,2$ two generators of the T^2 1-homology group passing through the point x_0 and define

$$I_i(x_0)=\lambda_P^{-2}\int_{\gamma_i(x_0)}A. \tag{25}$$

The path integral measure we will introduce soon, will be single valued only if the values of $I_i(x_0)$ only differ for a factor $2n\pi$ when the curve γ_i is continuously moved around the manifold and go back to the original path after a complete cycle. For example, in the angular coordinates θ and ϕ on T^2, taking $A=r_1r_2(\theta d\phi-\phi d\theta)$, with r_1,r_2 the two radii, and choosing $\gamma_1(\theta_0,\phi_0)$: $\{\theta=\theta_0\}$ and $\gamma_2(\theta_0,\phi_0)$: $\{\phi=\phi_0\}$, the values of $I_1(x_0)$ for the identified points θ_0 and $\theta_0+2\pi$, and analogously for $I_2(x_0)$, will be the same up to a factor $2n\pi$ provided that

$$\int_{T^2}dA=8\pi^2r_1r_2=2n\pi\lambda_P^2. \tag{26}$$

This condition also ensures, as we have seen for the S^2 case, that for all curves which are instead boundaries of surfaces, the corresponding contribution to the generating functional is single valued. Defining

$$\Sigma[x_0,\gamma]=\int_\gamma A \tag{27}$$

the contribution to $Z(x_0,J)$ of a generic path γ on T^2 can be written as

$$\exp[i\lambda_P^{-2}\Sigma[x_0,\gamma]]=\exp\left[in_1I_1(x_0)+in_2I_2(x_0)+i\lambda_P^{-2}\int_{\gamma'}A\right] \tag{28}$$

for some integers n_1 and n_2 and with γ' a boundary of some bidimensional surface, so the generating functional takes the form

$$Z(x_0,J)=N\sum_{n_1,n_2}\int D[\gamma']\exp(in_1I_2(x_0)+in_2I_2(x_0))\exp\left(i\lambda_P^{-2}\int_\Gamma dA\right)\exp(i\lambda_P^{-2}(x,J)), \tag{29}$$

where the integration is over all 1-boundaries γ' with base point x_0 and $\partial\Gamma=\gamma'$.

This expression can now be easily generalized to an arbitrary manifold M^{2n} with Betti numbers $b_1=p$, $b_2=q$. Consider the pair (M^{2n},A), a set of basis $\gamma_i(x_0)$ and a base Γ_j, for $H^1(M^{2n})$ and $H^2(M^{2n})$, respectively. The fact that the path integral measure should be single valued enforces q integral conditions on $\Omega=dA$,

$$\int_{\Gamma_j}\Omega=2m_j\pi\lambda_P^2,\quad j=1,...,q, \tag{30}$$

and defining, as in (25)

$$I_i(x_0)=\lambda_P^{-2}\int_{\gamma_i(x_0)}A,\quad i=1,...,p, \tag{31}$$

we may introduce the generating functional as follows:

$$Z(x_0,J)=N\prod_{i=1}^{p}\sum_{n_i}\int D[\gamma']\exp(in_iI_i(x_0))\exp\left(i\lambda_P^{-2}\int_\Gamma\Omega\right)\exp(i\lambda_P^{-2}(x,J)), \tag{32}$$

where $\partial\Gamma=\gamma'$. Equation (32) represents the generalization of Eq. (3) to a generic topological manifold M^{2n}.

IV. CONCLUSIONS AND OUTLOOK

In this paper we have described a path integral approach to noncommutative geometries. In particular, using the analogy with ordinary quantum mechanics, we have described a way of expressing a set of linear functionals over noncommutative generalizations, in even dimensions, of the algebra generated by position and time operators in terms of ordinary functions over the classical manifold, which represents its commutative classical geometry. In particular all these linear functionals reduce in the limit $\lambda_P=0$ to evaluation maps over the commutative algebra of smooth functions over the manifold.

There are several points related to this approach which deserve further studies.

We have considered in more detail the simple case of a classical starting manifold with trivial first and second homology groups. It would be interesting to perform a deeper study of the properties of the generating functional over manifolds with more involved topological properties, which has been discussed in Sec. III, and of the corresponding deformed noncommutative geometries.

Another important issue is that this approach may give the possibility of introducing a differential calculus over noncommutative generalizations of the algebra of functions over classical space–times using all customary results for a commutative geometry. In particular, quite relevant is to look for a consistent definition of a metric structure, connections and curvature. Of course, when λ_P is switched on, one expects that dramatic changes affect all these structures. Nevertheless, to have a simple way of relating the algebra generated by the X^μ's to its commutative counterpart, could be a powerful way to look for their generalization.

The role of the parameter τ should be better understood. While it has a clear meaning as the parameter of closed curves over M^{2n}, its role for the noncommutative algebras $\mathcal{A}(\tau)$ is not transparent. Actually all dependence on τ is contained in the kernel $\Delta(\tau-\tau')$. One possibility is, of course, that each of these algebras, for fixed τ, is already sufficient to describe a noncommutative space–time, so that the role of the parameter τ in this case would be only auxiliary. On the other hand, the analogy with quantum phase space we started with, suggests that it could also have an intrinsic nontrivial meaning.

(Received 25 June 1997; accepted for publication 6 November 1997)

Turbiner's one-dimensional, quasi-exactly soluble potentials can be interpreted as central potentials in *N* dimensions. Using a particular transformation, one shows how these potentials convert to seemingly unrelated isolated solutions of other Schrödinger equations, including solutions of the combined Coulomb plus harmonic oscillator system. © *1998 American Institute of Physics.*
[S0022-2488(98)03803-1]

I. INTRODUCTION

Quasi-analytic solutions of the one-dimensional Schrödinger equation were first pointed out by Turbiner.[1] These involve one-dimensional systems subject to the potentials

$$V(x)=2x^2[(x^2+\beta)^2-(2n+r+\tfrac{3}{2})], \quad n=0,1,2..., \quad r=0, \text{ or } 1. \tag{1}$$

For a given value of n, i.e., a particular quasi-exactly soluble potential, one can directly obtain the first $n+1$ eigenvalues and the corresponding eigenfunctions. The remaining solutions cannot be obtained analytically, hence the nomenclature ''quasi-exactly soluble potentials.''

In this paper one uses the generalization of Turbiner's work to N dimensions. Applying a recently discussed transformation,[2] to the resulting N-dimensional Schrödinger equation, it is shown to transform into other, seemingly unrelated Schrödinger equations and potentials. This yields new isolated solutions of various Schrödinger equations, including solutions of the interesting combined Coulomb plus harmonic oscillator system.

II. GENERALIZATION OF TURBINER'S RESULTS TO *N*-DIMENSIONAL SPACES

The following N-dimensional central potential $V(r)$:

$$V(r)=2r^2\left[(r^2+\beta)^2-\left(2n+\frac{k_1}{2}+1\right)\right], \quad n=0,1,2,..., \tag{2}$$

when inserted into the N-dimensional Schrödinger equation:[3]

$$\left[-\frac{1}{2}\left(\frac{d^2}{dr^2}-\frac{(k_1-1)(k_1-3)}{4r^2}\right)+V(r)-E\right]u_1(r)=0, \tag{3}$$

where $m=\hbar=c=1$, $k_1=N+2l$, and $\int_0^\infty u_1^2(r)dr=1$, $(u_1(0)=0)$ can be seen to be the N-dimensional generalization of the one-dimensional quasi-exactly soluble potentials Eq. (1) introduced by Turbiner.[1] Turbiner's one-dimensional cases are obtained from the above by setting $k_1=1(\Rightarrow N=1,\ l=0)$ or $3(\Rightarrow N=3,\ l=0)$. Equation (3) then reduces to the one-dimensional Schrödinger equation and Eq. (2) becomes equivalent to Eq. (1) for the two cases $r=0,1$. Equation (2) is a sextic potential. The factors in Eq. (1) are slightly different from those in Turbiner's papers because he works without the factor 1/2 in the first term of Eq. (3), etc.

If one assumes solutions of the form:

$$u_1(r)=Cr^{(k_1-1)/2}e^{-(r^2+\beta)^2/2}f(r), \tag{4}$$

 © 1998 American Institute of Physics

and substitutes back in Eq. (3), this yields for $f(r)$:

$$\left\{ f''(r) - \left[4r(r^2+\beta) - \frac{k_1-1}{r} \right] f'(r) - 2(\beta k_1 - 4nr^2 - E) f(r) \right\} = 0. \tag{5}$$

The $n+1$ $f(r)$'s and corresponding E's can be obtained by substituting in Eq. (5) a polynomial in r^2 of order n, i.e.,

$$f(r) = \sum_{q=0}^{n} c_q r^{2q}. \tag{6}$$

As in the one-dimensional case, the remaining solutions are unobtainable.

Special cases:

The case $n=0$ involves one exact solution:

$$E = \beta k_1, \quad f(r) = 1. \tag{7}$$

The case $n=1$ involves two exact solutions:

$$E = \beta(k_1=2) \mp 2\sqrt{\beta^2+k_1}, \quad f(r) = 1 - 2(\beta \mp \sqrt{\beta^2+k_1})\, \frac{r^2}{k_1}. \tag{8}$$

The case $n=2$ involves the three exact solutions, whose energies and coefficients c_q are obtained by solving the cubic equation:

$$E^3 - 3\beta(k_1+4)E^2 + (3\beta^2 k_1^2 + 24\beta^2 k_1 + 32\beta^2 - 16k_1 - 16)E$$

$$- \beta k_1(\beta^2 k_1^2 + 12\beta^2 k_1 + 32\beta^2 - 16k_1 - 80) = 0,$$

where

$$c_0 = 1, \quad c_1 = \beta - E/k_1, \quad c_2 = \{-8 + (\beta - E/k_1)(4\beta + \beta k_1 - E)\}/(2k_1+4). \tag{9}$$

Thus for three-dimensional systems, given the potential

$$V(r) = 2r^2[(r^2+\beta)^2 - (l+9/2)], \tag{10}$$

one has two solutions:

$$E = \beta(5+2l) \mp 2\sqrt{\beta^2+3+2l},$$

$$u_1(r) = Cr^{l+1} e^{-(r^2+\beta)^2/2} \left\{ 1 - 2(\beta \mp \sqrt{\beta^2+3+2l})\, \frac{r^2}{3+2l} \right\}, \tag{11}$$

and so on for higher n.

III. TRANSFORMATION OF TURBINER'S RESULTS

If one applies the transformation:[2] $r = \rho^m$, $u_1(r) = \rho^{(m-1)/2} u_m(\rho)$, to Eq. (3), it transforms into

$$\left[-\frac{1}{2} \left(\frac{d^2}{d\rho^2} - \frac{(k_m-1)(k_m-3)}{4\rho^2} \right) + m^2 \rho^{2(m-1)} \{V(\rho^m) - E\} \right] u_m(\rho) = 0, \tag{12}$$

where $k_m = m(k_1-2)+2$. In other words Eq. (3) transforms into a Schrödinger equation in a different dimension, with a potential and energy $v(\rho) - \epsilon = m^2 \rho^{2(m-1)} \{V(\rho^m) - E\}$.

An interesting special case to consider for the potential of Eq. (2) is $m = 1/2$. One then obtains the Schrödinger equation:

$$\left[-\frac{1}{2}\left(\frac{d^2}{d\rho^2}-\frac{(k_{1/2}-1)(k_{1/2}-3)}{4\rho^2}\right)+\frac{1}{2}(\rho+\beta)^2-\frac{E}{4\rho}-\frac{1}{2}(2n+k_{1/2})\right]u_{1/2}(\rho)=0, \tag{13}$$

with $k_{1/2}=k_1/2+1$, where $\int_0^\infty u_{1/2}^2(\rho)d\rho=1$ and $u_{1/2}(0)=0$.

One notes that for this value of m, part of Eq. (2), the generalized Turbiner potential $[-2r^2[2n+k_{1/2}]]$ has been transformed into an energy term in Eq. (13) [namely, $\frac{1}{2}(2n+k_{1/2})$]. The remainder of Turbiner's generalized potential [namely, $2r^2(r^2+\beta^2)^2$] transforms into the oscillator potential $\frac{1}{2}(\rho+\beta)^2$. The energy term (E) in Eq. (3) has meanwhile been absorbed into the new effective potential (as $-E/4\rho$). By suitable identifications one thus has a Schrödinger equation in the space specified by $k_{1/2}=N'+2l'$, with

$$v(\rho)=\frac{1}{2}(\rho+\beta)^2-\frac{E}{4\rho}, \tag{14}$$

$$\epsilon=\frac{1}{2}(2n+k_{1/2}). \tag{15}$$

For a particular n in Eq. (15), i.e., a particular ϵ, one thus has in this case from Eq. (3), $n+1$ solutions $u_1(r)$ [using Eqs. (4) and (6)] and hence directly determines the corresponding E's. Thus if $n=0$, 1, or 2, the $u_1(r)$'s and E's are given by Eqs. (7), (8), or (9), etc. Each of these particular E's then completely specifies the related potential $v(\rho)$ in Eq. (14). From the corresponding $u_1(r)$ one can also obtain the appropriate eigenfunction $u_{1/2}(\rho)=\rho^{1/4}u_1(\rho^{1/2})$ for that potential and energy.

This particular choice $m=1/2$ is of interest since it results in the potential given by Eq. (14) which includes both a (displaced if $\beta\neq 0$) harmonic oscillator and a Coulomb potential (of a specific sign and strength), treated on equal footing. If one makes the right identification (albeit isolated) solutions for this system can then be obtained. Consider, for example, the case $n=1$. For this choice of n,

$$\epsilon=\frac{1}{2}(2+k_{1/2}),\rightarrow E=2\beta k_{1/2}\mp 2\sqrt{\beta^2+2k_{1/2}-2}, \tag{16}$$

and

$$v(\rho)=\frac{1}{2}(\rho+\beta)^2-\frac{[\beta k_{1/2}\mp\sqrt{\beta^2+2k_{1/2}-2}]}{2\rho}, \tag{17}$$

with isolated solutions

$$u_{1/2}(\rho)=C\rho^{(k_{1/2}-1)/2}e^{-(\rho+\beta)^2/2}\left[1-(\beta\mp\sqrt{\beta^2+2k_{1/2}-2})\,\frac{\rho}{k_{1/2}-1}\right], \tag{18}$$

where $k_{1/2}>1$ so that $u_{1/2}(\rho)\xrightarrow[\rho\rightarrow 0]{}0$ and Eq. (18) has no singularities. If β is zero, Eq. (18) can be normalized analytically as will be shown in the two special cases discussed below. Otherwise the normalization constant C can be obtained numerically.

One notes that the two solutions of Eq. (18) have the same energy ϵ given by Eq. (16). However they are obviously not degenerate states since they correspond to the two different potentials of Eq. (17). For a particularly simple illustration consider the case $k_{1/2}=3$, i.e., $k_1=4$, and $\beta=0$, i.e., the oscillator is centered at the origin $\rho=0$. In this case, if $n=1$:

$$\epsilon=\frac{5}{2},\ \rightarrow E=\mp 4 \tag{19}$$

while

$$v(\rho)=\frac{1}{2}\,\rho^2\pm\frac{1}{\rho}, \tag{20}$$

with isolated solutions:

$$u^{\pm}_{1/2}(\rho)=C^{\pm}_1\rho e^{-\rho^2/2}[1\pm\rho]. \tag{21}$$

As required, the wave functions of Eq. (21) satisfy the condition $u_{1/2}(0)=0$. Normalizing with the condition $\int_0^\infty u^2_{1/2}(\rho)d\rho=1$, one obtains

$$C^{\pm}_1=\frac{1}{\sqrt{(5\sqrt{\pi}/8)\pm 1}}, \quad \text{i.e.,} \quad C^{+}_1\sim 0.69,\ C^{-}_1\sim 3.05.$$

One notes from Eq. (20) that one has here the two cases of a repulsive and of an attractive Coulomb potential, respectively, in addition to the harmonic oscillator.

If the quadratic potential in Eq. (13) is not displaced (i.e., $\beta=0$) and $E=0$, this equation reduces to the isotropic oscillator problem. For the n defined in Eq. (1) this yields acceptable solutions $\epsilon=n+(k_{1/2}/2)$, for $n=$an even integer or zero.

For $n=2$ (i.e., $\epsilon=7/2$), $k_{1/2}=3$ (i.e., $k_1=4$), and $\beta=0$, one has from Eq. (9) that

$$E=0, \quad E=\mp 4\sqrt{5}, \tag{22}$$

i.e.,

$$v(\rho)=\frac{1}{2}\,\rho^2, \quad v(\rho)=\frac{1}{2}\,\rho^2\pm\frac{\sqrt{5}}{\rho}, \tag{23}$$

the former is the pure harmonic oscillator potential, with solution:

$$u_{1/2}(\rho)=C_2\rho e^{-\rho^2/2}[1-\tfrac{2}{3}\rho^2], \tag{24}$$

and the latter, the harmonic oscillator plus a (repulsive or attractive) Coulomb potential, with exact solutions:

$$u^{\pm}_{1/2}(\rho)=C^{\pm}_3\rho e^{-\rho^2/2}[1\pm\sqrt{5}\rho+\rho^2]. \tag{25}$$

Normalizing one obtains

$$C_2=\left(\frac{6}{\sqrt{\pi}}\right)^{1/2}, \quad C^{\pm}_3=\left[\left(\frac{61}{16}\,\sqrt{\pi}\pm 3\sqrt{5}\right)\right]^{-1/2}.$$

Other choices of m yield different potentials and related isolated solutions. For instance, if $m=2$,

$$\left[-\frac{\hbar^2}{2m}\left(\frac{d^2}{d\rho^2}-\frac{(k_2-1)(k_2-3)}{4\rho^2}\right)+8\rho^6\left\{(\rho^4+\beta)^2-\left(2n+\frac{k_2}{4}+\frac{3}{2}\right)\right\}-4\rho^2E\right]u_2(\rho)=0, \tag{26}$$

where $k_2=2k_1-2$. Thus by the method outlined above one obtains isolated solutions of a potential of the form

$$v(\rho)=A\rho^{14}+B\rho^{10}+C\rho^6+D\rho^2, \tag{27}$$

for particular values of A, B, C, and D. If $m=3/2$, one obtains isolated solutions for a potential of the form

$$v(\rho)=F\rho^{10}+G\rho^7+H\rho^4+I\rho, \tag{28}$$

for particular values of F, G, H, and I, etc.

IV. CONCLUSIONS

The generalization to N dimensions of Turbiner's one-dimensional quasi-exactly soluble potentials is discussed in this paper, and a few specific N-dimensional solutions are listed. Applying a suitable transformation, these potentials are shown to be related to the (possibly displaced) isotropic oscillator plus Coulomb potential system. Some normalized isolated solutions for this system are obtained.

Leibnizstrasse 10, 38678 Clausthal-Zellerfeld, Germany

(Received 16 July 1997; accepted for publication 23 December 1997)

We present new perturbation algorithms for time-dependent quantum systems. These new methods make use of a time-dependent averaging method and are based on analogies with the Poincaré–von Zeipel (PvZ) and Kolmogorov–Arnold–Moser (KAM) expansions. Application to a simple example shows that the PvZ as well as the KAM expansion are superior to the standard quantum mechanical time-dependent perturbation method (Dyson expansion). © *1998 American Institute of Physics.* [S0022-2488(98)01404-2]

I. INTRODUCTION

The use of HAMILTONian or *symplectic methods* has been very fruitful in dynamical systems in general and in classical mechanics in particular. It has produced deep structural insights (e.g., KAM-Theorem) as well as techniques (e.g., reduction of systems with symmetries) and algorithms (e.g., canonical perturbation theories).

Quantum mechanics, on the other hand, has mostly been treated using the tools of *functional analysis*, although it is fairly well known that the SCHRÖDINGER equation may be written as an infinite-dimensional HAMILTONian system.[1] What seems to prevent the transfer of HAMILTONian methods known in classical mechanics to quantum mechanics is the fact that classical mechanics lives on a finite-dimensional symplectic manifold, whereas quantum mechanics on an infinite-dimensional HILBERT space. This, however, is only an obstacle if the classical information is formulated in a coordinate-dependent manner. At least formally most geometric concepts of classical HAMILTONian systems can be transferred to quantum mechanics. Loosely speaking, the *basic philosophy* behind this program is the following:

P_1: formulate the classical theory in as *purely geometric* a fashion as possible
P_2: formulate the SCHRÖDINGER equation as an *infinite-dimensional* HAMILTONian system
P_3: repeat the geometric constructions of P_1 for the system in P_2.

It turns out that this program applied to the realm of *perturbation theories using the averaging method* is extremely fruitful. The method of averaging has been well known in classical mechanics and is used there to construct perturbation theories free of so called *secular terms*.[2] It is only quite recently, however, that this method has been extended to self-adjoint operators by the author, and with the help of this method analogues of the classical POINCARÉ–VON ZEIPEL[3] as well as of KOLMOGOROV's perturbation theory,[4,5] which is used in the proof of the KOLMOGOROV–ARNOLD–MOSER (KAM) theorem, have been obtained for time-independent (i.e., autonomous) systems.

In this paper we present P_1-P_3 of the above program for POINCARÉ–VON ZEIPEL as well as KAM perturbation theories of time-dependent (i.e., non-autonomous) systems. That is, two perturbation algorithms are constructed in complete analogy to the theories in classical mechanics for time-dependent quantum systems. For such systems both POINCARÉ–VON ZEIPEL, as well as the KAM algorithm, yield *new* perturbation theories which are free of secular terms and in all examples tested perform far better than the DYSON expansion which is the standard time-dependent perturbation method for quantum systems. A short outline of these algorithms has been given for the POINCARÉ–VON ZEIPEL method in Ref. 6 and for the KAM algorithm in Ref. 7. The main purpose of this paper is to present on the formal level the following:

a)Electronic mail: ptws@pt.tu-clausthal.de

 © 1998 American Institute of Physics

- the *ideas* originating from classical HAMILTONian systems as they are translated to quantum systems using *geometrization* as a crucial ingredient of the theory since this enables one to avoid the use of local coordinates which prevents copying classical methods to quantum mechanics.
- the *algorithmic procedures* in a fashion suitable to immediate applications.

This means in particular, that *functional analytic issues* such as domain questions, operator topologies, convergence, etc. will be mostly ignored in this exposition. They are currently under investigation and will be dealt with in the future.

POINCARÉ-type normal form algorithms for time-dependent quantum systems have been constructed before by KUMMER and GOMPA[8,9] and KAM-type algorithms by BELLISSARD,[10,11] COMBESCURE,[12,13] and, building on their work, recently by DUCLOT and STOVICEK.[14] While there is a certain kinship of ideas the approach presented here differs from these in that it emphasises the geometric similartity of the quantum situation with the classical one. This way the construction is more general but still only formally so and the ongoing investigation of convergence (see the remark above) will reveal how much of that generality can be maintained.

This paper is organized as follows.

In Section II the geometric formulation of time-dependent classical and quantum mechanical HAMILTONian systems is presented rather extensively. In this Section all tools necessary to construct the two perturbation algorithms are provided. This includes the notion of extended phase space (Section II B) and time-dependent averaging in classical mechanics (Section II C) as well as quantum mechanics (Sections II D and II E). Transformations on constant time slices are introduced in Section II F. These transformations which use the perturbation parameter as a flow parameter are used in the two perturbation methods (once in the POINCARÉ–VON ZEIPEL method and iteratively in the KAM method) to transform the perturbed HAMILTONian to a HAMILTONian which is such that the computation of its flow is reduced to solving a *time-independent* initial value problem.

Equipped with the averaging construction we then turn to the perturbation algorithms beginning with the POINCARÉ–VON ZEIPEL method in Section III where we first present the classical theory in Section III B and then the quantum theory in Section III C. Since the quantum theory is new it is summarized in an algorithmic fashion suitable to immediate application in Section III D.

The second perturbation method copied from classical mechanics is the time-dependent version of the KAM algorithm which is presented in Section IV beginning again with the classical case in Section IV B and continuing with the quantum case in Section IV C which is summarized in algorithmic fashion in Section IV D.

The two methods—POINCARÉ–VON ZEIPEL, and KAM—along with the standard quantum mechanical method and a numerical calculation using the Mathematica package are then applied to a simple system consisting of a spin-$\frac{1}{2}$ particle in an oscillating magnetic field in Section V and the results for a transition probability are compared in Section V E.

We conclude this paper with a discussion of the methods and associated problems in Section VI.

II. TIME-DEPENDENT HAMILTONIAN SYSTEMS

A. Introduction

The main subject of interest here are HAMILTONian systems whose HAMILTONian depends ''explicitly'' on t. Using the concept of *extended phase-space*[15,16] we shall first recall the geometric description of HAMILTONian systems of this type in Section II B, their time evolution, and the averaging method for them in Section II C. The quantum analogues of these are given in Section II D and in Section II E. The time-dependent version of the non-autonomous ε-transformations is then introduced in Section II F for classical and quantum systems.

A somewhat related approach to time-dependent quantum systems has been introduced by SAMBE,[17] HOWLAND,[18,19] and YAJIMA.[20,21] They, however, define an extended HILBERT space as the tensor product of certain functions of time with the original HILBERT space, whereas here the extended HILBERT space is built in close analogy to the classical situation by adding time and its conjugate coordinate energy to the original HILBERT space viewed as a symplectic manifold.

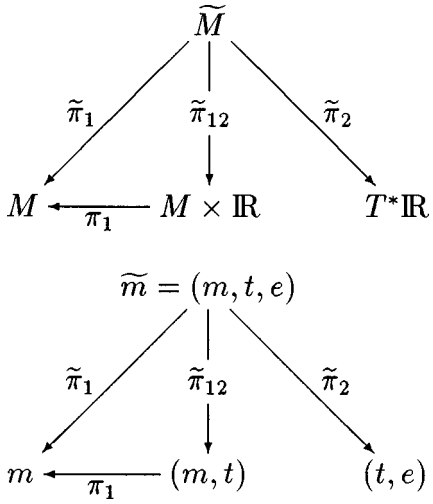

FIG. 1. Projections from extended phase space.

B. Extended phase space

Let M be a symplectic manifold whose points are denoted by m and whose symplectic form is ω and let

$$f: M \times \mathbb{R} \to \mathbb{R}, \quad (m,t) \mapsto f(m,t), \tag{2.1}$$

be a time-dependent HAMILTONian which for each $t \in \mathbb{R}$ defines a function

$$f_t: M \to \mathbb{R}, \quad m \mapsto f(m,t). \tag{2.2}$$

The time-dependent vector field generated by f is then defined as

$$X_f(\cdot,t): M \to TM, \quad m \mapsto X_f(m,t) := X_{f_t}(m), \tag{2.3}$$

where X_{f_t} is defined in the usual way such that for each $t \in \mathbb{R}$,

$$\imath(X_{f_t})\omega = -df_t. \tag{2.4}$$

Here $\imath(Z)\omega$ denotes the one-form $Y \mapsto \omega(Z,Y)$. The flow φ_f of this vector field is the solution of the following non-autonomous initial value problem,

$$\frac{d}{dt}\varphi_f(t,t_0)(m) = X_f(\varphi_f(t,t_0)(m),t), \quad \varphi_f(t_0,t_0)(m) = m, \tag{2.5}$$

which we assume to be unique. This flow still satisfies

$$\varphi_f(t_2,t_1) \circ \varphi_f(t_1,t_0) = \varphi_f(t_2,t_0), \tag{2.6}$$

but it is no longer time-translationally invariant, i.e., in general

$$\varphi_f(t+t_1,t_1) \neq \varphi_f(t+t_0,t_0), \quad \text{if } t_1 \neq t_0. \tag{2.7}$$

With the help of the extended phase space one is able to construct a flow on that space which does have this property and ''includes'' φ_f.[16] We define the extended phase space as

$$\widetilde{M} := M \times T^*\mathbb{R} \ni \widetilde{m} := (m,t,e), \tag{2.8}$$

where t is the base coordinate and e the fiber coordinate in $T^*\mathbb{R}$. This provides us with the projections depicted in Fig. 1. We will mostly consider the following classes of functions on $\widetilde{M}$.

- Lifted functions,
$$C_L(\widetilde{M}) \coloneqq \widetilde{\pi}_1^* C^\infty(M) \cup \widetilde{\pi}_{12}^* C^\infty(M \times \mathbb{R}), \tag{2.9}$$
i.e., functions $f,g,h,w,\ldots$, which are initially defined only on M (resp., $M\times\mathbb{R}$) and will be lifted with $\widetilde{\pi}_1^*$ (resp., $\widetilde{\pi}_{12}^*$) to functions on $\widetilde{M}$. But for the sake of notational sanity we shall not always write out these pull-backs and denote the functions on $\widetilde{M}$ still by the same letter. So, whenever necessary, the application of the pull-backs should be understood.
- Extended functions,
$$C_E(\widetilde{M}) \coloneqq \left\{ \begin{array}{ll} \widetilde{h}\colon & \widetilde{M} \to \mathbb{R} \\ & \widetilde{m} = (m,t,e) \mapsto h(m,t) - e \end{array} \;\middle|\; h \in C_L(\widetilde{M}) \right\}. \tag{2.10}$$

On $\widetilde{M}$ we define the symplectic form

$$\widetilde{\omega} \coloneqq \widetilde{\pi}_1^* \omega - \widetilde{\pi}_2^*(de \wedge dt). \tag{2.11}$$

For lifted functions $f \in C_L(\widetilde{M})$ we have thus the HAMILTONian vector fields,

$$\widetilde{X}_f(\widetilde{m}) = X_{f_t}(m) + \frac{\partial f}{\partial t}(m,t)\, \frac{\partial}{\partial e}, \tag{2.12}$$

where X_{f_t} is given as in (2.4) and the right hand side is to be understood as follows. The tangent maps of the projections $\widetilde{\pi}_1$ and $\widetilde{\pi}_2$ provide us with an isomorphism between $T\widetilde{M}$ and the product bundle $TM \times T^*\mathbb{R}$ over $\widetilde{M}$.[22] Using this isomorphism we may then consider $(X_{f_t}, (\partial f/\partial t) \times (\partial/\partial e))$ as a vector field on $\widetilde{M}$. For extended functions $\widetilde{f} \in C_E(\widetilde{M})$ one finds the HAMILTONian vector fields,

$$\widetilde{X}_{\widetilde{f}}(\widetilde{m}) = \widetilde{X}_f(\widetilde{m}) + \frac{\partial}{\partial t}. \tag{2.13}$$

For $f,g \in C_L(\widetilde{M})$ and $\widetilde{f},\widetilde{g} \in C_E(\widetilde{M})$ we obtain

$$\widetilde{ad}_{\widetilde{f}}(\widetilde{g}) \coloneqq \{\widetilde{\widetilde{f},\widetilde{g}}\} = \{f_t, g_t\} + \frac{\partial g}{\partial t} - \frac{\partial f}{\partial t}, \tag{2.14}$$

$$\widetilde{ad}_{\widetilde{f}}(g) \coloneqq \{\widetilde{\widetilde{f},g}\} = \{f_t, g_t\} + \frac{\partial g}{\partial t}, \tag{2.15}$$

$$\widetilde{ad}_f(g) \coloneqq \{\widetilde{f,g}\} = \{f_t, g_t\}, \tag{2.16}$$

where $\{\widetilde{\cdot,\cdot}\}$ is the POISSON bracket associated with $\widetilde{\omega}$, $\{\cdot,\cdot\}$ the one associated with ω, and, as usual, the lifts in the expressions on the right hand side are to be understood. This means that for $f,g \in C_L(\widetilde{M})$ one has originally $\{f_t,g_t\} \in C^\infty(M)$ but with its dependence on t $\{f_t,g_t\}$ may be viewed as an element of $C^\infty(\widetilde{M})$ and as such it can be lifted to an element of $C_L(\widetilde{M})$. To avoid an overburdened notation we shall thus henceforth most often write just $\{f,g\}$ for $\{f_t,g_t\}$ where $\{f,g\}$ is to be understood in the sense outlined above.

C. Time evolution and averaging on extended phase space

We will now show how to recover the flow φ_h of a time-dependent HAMILTONian h on M from the flow on $\widetilde{M}$ generated by the extended function $\widetilde{h} = h - e$. Let

$$\widetilde{\varphi}_{\widetilde{h}}\colon \mathbb{R} \times \widetilde{M} \to \widetilde{M}, \quad (\tau,\widetilde{m}) \mapsto \widetilde{\varphi}_{\widetilde{h}}(\tau)(\widetilde{m}), \tag{2.17}$$

be the flow generated by the extended function $\widetilde{h}$. It satisfies

$$\frac{d}{d\tau}\,\widetilde{\varphi}_{\widetilde{h}}(\tau)(\widetilde{m})=\widetilde{X}_{\widetilde{h}}(\widetilde{\varphi}_{\widetilde{h}}(\tau)(\widetilde{m})),\quad \widetilde{\varphi}_{\widetilde{h}}(0)(\widetilde{m})=\widetilde{m},\tag{2.18}$$

and if we project it with the $\widetilde{\pi}$'s and use the similar decomposition for the vector field given by (2.13) and (2.12), we can write the differential equation in (2.18) as

$$\frac{d}{d\tau}\begin{pmatrix}\widetilde{\pi}_1\circ\widetilde{\varphi}_{\widetilde{h}}(\tau)(\widetilde{m})\\ t(\tau)(\widetilde{m})\\ e(\tau)(\widetilde{m})\end{pmatrix}=\begin{pmatrix}X_{h_t}(\widetilde{\pi}_1\circ\widetilde{\varphi}_{\widetilde{h}}(\tau)(\widetilde{m}))\\ 1\\ \dfrac{\partial h}{\partial t}(\widetilde{\pi}_{12}(\widetilde{m}))\end{pmatrix},\tag{2.19}$$

where $t(\tau)(\widetilde{m})$ and $e(\tau)(\widetilde{m})$ are the projections down to $\mathbb{R}^2\simeq T^*\mathbb{R}$. Consequently, the extended flow is given by

$$\widetilde{\varphi}_{\widetilde{h}}(\tau)\left(\begin{pmatrix}m\\ t\\ e\end{pmatrix}\right)=\begin{pmatrix}\varphi_h(\tau+t,t)(m)\\ \tau+t\\ e+h(\varphi_h(\tau+t,t)(m),\tau+t)-h(m,t)\end{pmatrix},\tag{2.20}$$

and its projection to M is the original dynamical evolution generated by the time-dependent function h. Note that

$$\widetilde{\varphi}_{\widetilde{h}}(\tau_1+\tau_2)=\widetilde{\varphi}_{\widetilde{h}}(\tau_1)\circ\widetilde{\varphi}_{\widetilde{h}}(\tau_2)\quad\text{and}\quad\widetilde{\varphi}_{\widetilde{h}}(\tau)^*\widetilde{h}=\widetilde{h}.\tag{2.21}$$

If we choose the initial point $\widetilde{m}$ such that $e=h(m,t)$ then the motion is confined to the level set,

$$\widetilde{\Sigma}_0^{\widetilde{h}}:=\{\widetilde{m}\in\widetilde{M}\,|\,\widetilde{h}(\widetilde{m})=0\},\tag{2.22}$$

and the evolution of the coordinate e then gives the value of the energy of the time-dependent system, which is now no longer constant.

We can now present the averaging constructions for time-dependent systems in purely geometric terms.

For any map $\widetilde{\varphi}:\widetilde{M}\to\widetilde{M}$ we define its pull-back action on functions on $\widetilde{M}$,

$$\widetilde{\varphi}^*:C^\infty(\widetilde{M})\to C^\infty(\widetilde{M}),$$

$$f\mapsto\widetilde{\varphi}^*f:=f\circ\widetilde{\varphi},\tag{2.23}$$

and for any function $g\in C^\infty(\widetilde{M})$ we have

$$\frac{d}{d\tau}\,\widetilde{\varphi}_{\widetilde{f}}(\tau)^*g=\widetilde{\varphi}_{\widetilde{f}}(\tau)^*\circ\widetilde{ad}_{\widetilde{f}}(g),\quad\widetilde{\varphi}_{\widetilde{f}}(0)^*g=g,\tag{2.24}$$

as well as for the reverse flow,

$$\frac{d}{d\tau}\,\overset{-1}{\widetilde{\varphi}}_{\widetilde{f}}(\tau)^*g=-\widetilde{ad}_{\widetilde{f}}\circ\overset{-1}{\widetilde{\varphi}}_{\widetilde{f}}(\tau)^*(g),\quad\overset{-1}{\widetilde{\varphi}}_{\widetilde{f}}(0)^*g=g.\tag{2.25}$$

Let $\widetilde{f}\in C_E(\widetilde{M})$, $g\in C_L(\widetilde{M})$ and let $\widetilde{\varphi}_{\widetilde{f}}(\tau):\widetilde{M}\to\widetilde{M}$ be the flow generated by $\widetilde{f}$. Suppose $\widetilde{f}$ and g are such that

$$\lim_{T\to\infty}\frac{\overset{-1}{\widetilde{\varphi}}_{\widetilde{f}}(T)^*g-g}{T}=0\tag{2.26}$$

and

$$\overline{g^{(\tilde f)}} := \lim_{T\to\infty} \frac{1}{T} \int_0^T d\sigma\ \overset{-1}{\tilde\varphi}_{\tilde f}(\sigma)^* g \in C_L(\widetilde M), \tag{2.27}$$

$$s^{(\tilde f)}(g) := \lim_{T\to\infty} \frac{1}{T} \int_0^T d\tau \int_0^\tau d\sigma\ \overset{-1}{\tilde\varphi}_{\tilde f}(\sigma)^* (g - \overline{g^{(\tilde f)}}) \in C_L(\widetilde M), \tag{2.28}$$

exist. Then it follows that

$$g - \widetilde{ad}_{\tilde f}(s^{(\tilde f)}(g)) = \overline{g^{(\tilde f)}}, \tag{2.29}$$

$$\widetilde{ad}_{\tilde f}(\overline{g^{(\tilde f)}}) = 0, \tag{2.30}$$

which means

$$g - \{f, s^{(\tilde f)}(g)\} - \frac{\partial s^{(\tilde f)}(g)}{\partial t} = \overline{g^{(\tilde f)}}, \tag{2.31}$$

$$\{f, \overline{g^{(\tilde f)}}\} + \frac{\partial \overline{g^{(\tilde f)}}}{\partial t} = 0. \tag{2.32}$$

We first prove (2.30), i.e. (2.32). Using (2.15) one has

$$\{f, \overline{g^{(\tilde f)}}\} + \frac{\partial \overline{g^{(\tilde f)}}}{\partial t} = \widetilde{ad}_{\tilde f}(\overline{g^{(\tilde f)}}) = \lim_{T\to\infty} \frac{1}{T} \int_0^T d\sigma\ \widetilde{ad}_{\tilde f}(\overset{-1}{\tilde\varphi}_{\tilde f}(\sigma)^* g),$$

where we have assumed sufficiently nice convergence properties of the limit and the integral in (2.27) such that pulling $\widetilde{ad}_{\tilde f}$ inside is permitted. From (2.25) it follows that then

$$\{f, \overline{g^{(\tilde f)}}\} + \frac{\partial \overline{g^{(\tilde f)}}}{\partial t} = -\lim_{T\to\infty} \frac{1}{T} \int_0^T d\sigma\ \frac{d}{d\sigma}\ \overset{-1}{\tilde\varphi}_{\tilde f}(\sigma)^* g = -\lim_{T\to\infty} \frac{\overset{-1}{\tilde\varphi}_{\tilde f}(T)^* g - g}{T} = 0,$$

where the last line is a consequence of the assumed property (2.26) and (2.30) is thus established. Now we prove (2.31). Similar to the steps above we have

$$\{f, s^{(f)}(g)\} + \frac{\partial s^{(f)}(g)}{\partial t} = \widetilde{ad}_{\tilde f}(s^{(f)}(g)) = \lim_{T\to\infty} \frac{1}{T} \int_0^T d\tau \int_0^\tau d\sigma\ \widetilde{ad}_{\tilde f}(\overset{-1}{\tilde\varphi}_{\tilde f}(\sigma)^* g),$$

where we have used already (2.30) in the last line. Using (2.25) once more gives

$$\begin{aligned}
\{f, s^{(f)}(g)\} + \frac{\partial s^{(f)}(g)}{\partial t} &= -\lim_{T\to\infty} \frac{1}{T} \int_0^T d\tau \int_0^\tau d\sigma \frac{d}{d\sigma}\ \overset{-1}{\tilde\varphi}_{\tilde f}(\sigma)^* g \\
&= \lim_{T\to\infty} \frac{1}{T} \int_0^T d\tau (g - \overset{-1}{\tilde\varphi}_{\tilde f}(\tau)^* g) \\
&= g - \overline{g^{(\tilde f)}},
\end{aligned}$$

which proves (2.31), i.e., (2.29).

These proofs are identical (in geometric terms) to the ones for the time-independent case.[3–5] It should be noted, however, that while the functions $\overline{g^{(\tilde{f})}}$ and $\widetilde{s}^{(\tilde{f})}(g)$ do not depend on the extended flow parameter τ, they *do depend on* t. Equations (2.26)–(2.30) constitute the *time-dependent averaging equations* and as in the time-independent theory[3–5] they will be at the heart of the time-dependent perturbation algorithms to be constructed in the following sections.

The averaging equations above may be formulated for more general functions $f,g\in C^\infty(\widetilde{M})$ but we shall not need this generalization. Finally, we define the constant-time slices,

$$\widetilde{\Sigma}_t := \{(m,t,e)\in\widetilde{M}\,|\,m\in M, e\in\mathbb{R}\}\subset\widetilde{M}, \tag{2.33}$$

which are moved by the extended flow,

$$\widetilde{\varphi}_{\tilde{h}}(\tau)(\widetilde{\Sigma}_t)\subset\widetilde{\Sigma}_{\tau+t}. \tag{2.34}$$

D. Time-dependent Hamiltonian quantum mechanics

In this Section we will show how to transfer the geometrical concepts of Sections II B and II C to the quantum mechanical setting. This will be done on a purely formal level. Nevertheless, we will restrict the exposition to bounded operators and smooth time-dependence to avoid the otherwise omnipresent domain questions for operators. For a rigorous treatment of the geometry on HILBERT spaces in general we refer the reader to Ref. 23, Chaps. 1.1–1.4 and to Ref. 1 for the symplectic geometry on HILBERT spaces in particular. Let $\mathbb{H}$ be a HILBERT space whose vectors are denoted by ψ,ϕ. The BANACH space of linear, *bounded, and self-adjoint* operators on $\mathbb{H}$ is denoted by $\mathscr{S}_{sa}(\mathbb{H})$. Since $\mathbb{H}$ is a linear space, its tangent space $T_\phi\mathbb{H}$ at $\phi\in\mathbb{H}$ is $\mathbb{H}$ itself and we have for its tangent bundle $T\mathbb{H}\simeq\mathbb{H}\times\mathbb{H}$. Viewing a vector field $X\in\mathscr{X}(\mathbb{H})$ as a section in $T\mathbb{H}$, we write it as $X=\{(\phi,X(\phi))\,|\,\phi\in\mathbb{H}\}\subset\mathbb{H}\times\mathbb{H}$ and call $X(\phi)$ the principal part of X at ϕ. If $\mathscr{F}:\mathbb{H}\to\mathbb{R}$ is a function on $\mathbb{H}$ the action of the vector field $X=(\phi,X(\phi))$ on $\mathscr{F}$ is given by

$$X\cdot\mathscr{F}(\phi) := \frac{d}{ds}\,\mathscr{F}(\phi+sX(\phi))\Big|_{s=0}, \tag{2.35}$$

and the differntial $d\mathscr{F}_\phi$ of $\mathscr{F}$ at $\phi\in\mathbb{H}$ is the map

$$d\mathscr{F}_\phi : T_\phi\mathbb{H}\simeq\mathbb{H}\to\mathbb{R},$$
$$\psi\mapsto\frac{d}{ds}\,\mathscr{F}(\phi+s\psi)\Big|_{s=0}. \tag{2.36}$$

The imaginary part of the scalar product $\langle\cdot\,|\,\cdot\rangle$ in $\mathbb{H}$ (which is assumed anti-linear in the first and linear in the second argument) furnishes us with a constant symplectic structure Ω defined as

$$\Omega_\phi(\psi_1,\psi_2) := -2\hbar\ \mathrm{Im}\langle\psi_1|\psi_2\rangle, \tag{2.37}$$

for $\psi_1,\psi_2\in T_\phi\mathbb{H}\simeq\mathbb{H}$. The associated POISSON bracket is defined as usual.[15]

This symplectic structure leads to a nice identification between its canonical linear transformations and unitary transformations:[1]

$$\Phi:\mathbb{H}\to\mathbb{H},\ \textit{linear},\ \Phi^*\Omega=\Omega\ \Leftrightarrow\ \Phi\ \textit{unitary}. \tag{2.38}$$

We can now combine this with the results of the previous Sections and describe quantum systems whose observables depend explicitly on time as a HAMILTONian system. For simplicity we consider only *smooth* time-dependent operators $\mathbb{R}\ni t\mapsto F(t)\in\mathscr{S}_{sa}(\mathbb{H})$ which are viewed as elements of the linear space $\mathscr{C}_{sa}(\mathbb{H})$ of smooth curves in the BANACH space $\mathscr{S}_{sa}(\mathbb{H})$ of bounded self-adjoint operators on $\mathbb{H}$,

$$\mathscr{C}_{sa}(\mathbb{H}) := C^\infty(\mathbb{R},\mathscr{S}_{sa}(\mathbb{H})), \tag{2.39}$$

such that their time derivative $(\partial F/\partial t)(t)$ exists and is again an element of the space of these curves.

In $\mathscr{C}_{sa}(\mathbb{H})$ we introduce the (natural) LIE-product,

$$[F,G]_{\mathscr{C}_{sa}(\mathbb{H})}(t) := \frac{i}{\hbar}[F(t),G(t)] =: \frac{i}{\hbar}[F,G], \tag{2.40}$$

where the last equation introduces a convenient shorthand notation for the left-hand sides. Equation (2.40) makes $\mathscr{C}_{sa}(\mathbb{H})$ into a LIE-algebra.

Given such a time-dependent operator F it defines the following function on $\mathbb{H}\times\mathbb{R}$:

$$\langle F\rangle : \mathbb{H}\times\mathbb{R}\to\mathbb{R}, \quad (\psi,t)\mapsto\langle\psi|F(t)\psi\rangle, \tag{2.41}$$

which for each t defines the function

$$\langle F\rangle_t : \mathbb{H}\to\mathbb{R}, \quad \psi\mapsto\langle F\rangle(\psi,t). \tag{2.42}$$

Mathematically the definition given for $\langle F\rangle$ in (2.42) makes sense only for bounded F. For unbounded F we have to restrict the domain of $\langle F\rangle$ to the form domain of the quadratic form associated to F (Ref. 24, Chap. VIII.6). Similar to the classical case we may then define the time-dependent vector field generated by $\langle F\rangle$ as

$$X_{\langle F\rangle}(\cdot,t) : \mathbb{H}\to T\mathbb{H}, \quad \psi\mapsto X_{\langle F\rangle}(\psi,t) := X_{\langle F\rangle_t}(\psi), \tag{2.43}$$

where $X_{\langle F\rangle_t}(\psi)$ is given for each t by

$$\imath(X_{\langle F\rangle_t})\Omega = -d\langle F\rangle_t, \tag{2.44}$$

and due to the bilinearity of the generating function this vector field at $\phi\in\mathbb{H}$ and time t turns out to be essentially the application of $F(t)$ to ϕ,

$$X_{\langle F\rangle_t}(\phi) = -\frac{i}{\hbar}F(t)\phi. \tag{2.45}$$

Consequently the HAMILTONian equation satisfied by the flow $\Phi_{\langle F\rangle}(t,t_0)$ of $X_{\langle F\rangle}(\cdot,t)$ is nothing but the *time-dependent* SCHRÖDINGER-equation:

$$\frac{d}{dt}\Phi_{\langle F\rangle}(t,t_0)\phi = -\frac{i}{\hbar}F(t)\Phi_{\langle F\rangle}(t,t_0)\phi, \quad \Phi_{\langle F\rangle}(t_0,t_0)\phi = \phi. \tag{2.46}$$

We will henceforth denote this flow simply by $\Phi_F(t,t_0)$.

The extended quantum mechanical phase space is then constructed in complete analogy to the classical case outlined in Section II C. Essentially this amounts to replacing M by $\mathbb{H}$ in Section II B which yields the extended HILBERT space,

$$\widetilde{\mathbb{H}} := \mathbb{H}\times T^*\mathbb{R} \ni \widetilde{\psi} := (\psi,t,e), \tag{2.47}$$

and the symplectic form

$$\widetilde{\Omega} := \widetilde{\pi}_1^*\Omega - \widetilde{\pi}_2^*(de\wedge dt). \tag{2.48}$$

Analogous to (2.9) and (2.10) we define the lifted $C_L(\widetilde{\mathbb{H}})$ and extended functions,

$$C_E(\widetilde{\mathbb{H}}) \ni \widetilde{\langle F\rangle}(\widetilde{\psi}) := \langle F\rangle(\psi,t) - e = \langle\psi|F(t)\psi\rangle - e, \tag{2.49}$$

such that the analogues of (2.12) and (2.13) become

$$\widetilde{X}_{\langle F\rangle}(\widetilde{\psi}) = -\frac{i}{\hbar}F(t)\psi + \left\langle\psi\left|\frac{\partial F(t)}{\partial t}\psi\right\rangle\right. \frac{\partial}{\partial e}, \tag{2.50}$$

$$\widetilde{X}_{\widetilde{\langle F\rangle}}(\widetilde{\psi})=\widetilde{X}_{\langle F\rangle}(\widetilde{\psi})+\frac{\partial}{\partial t}. \tag{2.51}$$

We also have the following POISSON bracket relations:

$$\widetilde{\mathscr{AD}}_{\widetilde{\langle F\rangle}}(\widetilde{\langle G\rangle}):=\{\widetilde{\langle F\rangle},\widetilde{\langle G\rangle}\}=\left\langle\frac{i}{\hbar}[F,G]+\frac{\partial G}{\partial t}-\frac{\partial F}{\partial t}\right\rangle, \tag{2.52}$$

$$\widetilde{\mathscr{AD}}_{\widetilde{\langle F\rangle}}(\langle G\rangle):=\{\widetilde{\langle F\rangle},\widetilde{\langle G\rangle}\}=\left\langle\frac{i}{\hbar}[F,G]+\frac{\partial G}{\partial t}\right\rangle, \tag{2.53}$$

$$\widetilde{\mathscr{AD}}_{\langle F\rangle}(\langle G\rangle):=\{\widetilde{\langle f\rangle},\widetilde{\langle g\rangle}\}=\left\langle\frac{i}{\hbar}[F,G]\right\rangle. \tag{2.54}$$

As in the classical case (2.20) the flow,

$$\widetilde{\Phi}_{\widetilde{H}}(\tau):\mathbb{R}\times\widetilde{\mathbb{H}}\to\widetilde{\mathbb{H}},$$

$$(\tau,\widetilde{\psi})\mapsto\widetilde{\Phi}(\tau)(\widetilde{\psi}), \tag{2.55}$$

of the vector field $\widetilde{X}_{\widetilde{\langle F\rangle}}$ generated by an extended function $\widetilde{\langle H\rangle}$ ''contains'' the time-dependent flow (2.46):

$$\widetilde{\Phi}_{\widetilde{H}}(\tau)\begin{pmatrix}\psi\\ t\\ e\end{pmatrix}=\begin{pmatrix}\Phi_H(\tau+t,t)\psi\\ \tau+t\\ e+\langle H\rangle(\Phi_H(\tau+t,t)\psi,\tau+t)-\langle H\rangle(\psi,t)\end{pmatrix}. \tag{2.56}$$

E. Time-dependent quantum averaging

In the previous Sections we have developed the general averaging-scheme for time-dependent HAMILTONian systems (Section II C) and have given a HAMILTONian formulation of time-dependent quantum mechanics using bilinear functions $\widetilde{\langle F\rangle}$ on $\widetilde{\mathbb{H}}$ (Section II D). In this Section we develop the formalism necessary to lift these concepts to time-dependent self-adjoint operators alone (rather than their associated function).

For each $F\in\mathscr{C}_{sa}(\mathbb{H})$ we define the following derivations on $\mathscr{C}_{sa}(\mathbb{H})$:

$$\widetilde{\mathscr{AD}}_F:\mathscr{C}_{sa}(\mathbb{H})\to\mathscr{C}_{sa}(\mathbb{H}),$$

$$G\mapsto\frac{i}{\hbar}[F,G], \tag{2.57}$$

$$\widetilde{\mathscr{AD}}_{\widetilde{F}}:\mathscr{C}_{sa}(\mathbb{H})\to\mathscr{C}_{sa}(\mathbb{H}),$$

$$G\mapsto\frac{i}{\hbar}[F,G]+\frac{\partial G}{\partial t}. \tag{2.58}$$

From (2.53) and (2.54) we infer that choice of notation in (2.57) and (2.58) is justified since $\langle\cdot\rangle$ intertwines the two $\widetilde{\mathscr{AD}}$-actions:

$$\widetilde{\mathscr{AD}}_{\widetilde{\langle F\rangle}}(\langle G\rangle)=\langle\widetilde{\mathscr{AD}}_{\widetilde{F}}(G)\rangle, \tag{2.59}$$

$$\widetilde{\mathscr{AD}}_{\langle F\rangle}(\langle G\rangle)=\langle\widetilde{\mathscr{AD}}_F(G)\rangle. \tag{2.60}$$

From (2.56) we see that

$$(\widetilde{\Phi}_{\widetilde{F}}(\tau)^*\langle G\rangle)(\psi,t)=\langle\psi|\Phi_F(\tau+t,t)^\dagger G(\tau+t)\Phi_F(\tau+t,t)\psi\rangle, \tag{2.61}$$

which prompts us to define the following action on $\mathscr{C}_{sa}(\mathbb{H})$ of flows generated by self-adjoint operators:

$$\widetilde{\Phi}_{\widetilde{F}}(\tau)^{*}G(t) := \Phi_F(\tau+t,t)^{\dagger}G(\tau+t)\Phi_F(\tau+t,t). \tag{2.62}$$

An immediate consequence of the definitions (2.58) and (2.62) is

$$\frac{d}{d\tau}\overset{-1}{\widetilde{\Phi}}_{\widetilde{F}}(\tau)^{*}G := -\widetilde{\mathscr{AD}}_{\widetilde{F}} \circ \overset{-1}{\widetilde{\Phi}}_{\widetilde{F}}(\tau)^{*}G, \quad \overset{-1}{\widetilde{\Phi}}_{\widetilde{F}}(0)^{*}G = G, \tag{2.63}$$

which allows us to do averaging for time-dependent operators as in the time-dependent classical case, provided the operator analogues of the equations (2.26)–(2.30) are well defined. Let $F,G \in \mathscr{C}_{sa}(\mathbb{H})$ such that

$$\lim_{T\to\infty} \frac{\overset{-1}{\widetilde{\Phi}}_{\widetilde{F}}(T)^{*}G - G}{T} = 0 \tag{2.64}$$

and

$$\overline{G}^{(\widetilde{F})} := \lim_{T\to\infty} \frac{1}{T}\int_0^T d\sigma\ \overset{-1}{\widetilde{\Phi}}_{\widetilde{F}}(\sigma)^{*}G \in \mathscr{C}_{sa}(\mathbb{H}), \tag{2.65}$$

$$S^{(\widetilde{F})}(G) := \lim_{T\to\infty} \frac{1}{T}\int_0^T d\tau \int_0^\tau d\sigma\ \overset{-1}{\widetilde{\Phi}}_{\widetilde{F}}(\sigma)^{*}(G-\overline{G}^{(\widetilde{F})}) \in \mathscr{C}_{sa}(\mathbb{H}), \tag{2.66}$$

exist. Then it follows that

$$G - \widetilde{\mathscr{AD}}_{\widetilde{F}}(S^{(\widetilde{F})}(G)) = \overline{G}^{(\widetilde{F})}, \tag{2.67}$$

$$\widetilde{\mathscr{AD}}_{\widetilde{F}}(\overline{G}^{(\widetilde{F})}) = 0. \tag{2.68}$$

Again the proof of these statements makes repeated use of (2.63) and proceeds otherwise as in the classical case in Section II C, but they may also be verified by direct computations. Note that $\overline{G}^{(\widetilde{F})}$ as well as $S^{(\widetilde{F})}(G)$ are elements of $\mathscr{C}_{sa}(\mathbb{H})$ and as such in general time-dependent. In fact, using (2.62) we can display this time-dependence explicitly as

$$\overline{G}^{(\widetilde{F})}(t) = \lim_{T\to\infty} \frac{1}{T}\int_0^T d\sigma\ \Phi_F(t-\sigma,t)^{\dagger}G(t-\sigma)\Phi_F(t-\sigma,t),$$

$$S^{(\widetilde{F})}(G)(t) = \lim_{T\to\infty} \frac{1}{T}\int_0^T d\tau \int_0^\tau d\sigma (\Phi_F(t-\sigma,t)^{\dagger}G(t-\sigma)\Phi_F(t-\sigma,t) - \overline{G}^{(\widetilde{F})}(t)).$$

Moreover, (2.67) and (2.68) may be stated in terms commonly used in quantum mechanics, as follows:

$$G - \frac{i}{\hbar}[F, S^{(\widetilde{F})}(G)] - \frac{\partial S^{(\widetilde{F})}(G)}{\partial t} = \overline{G}^{(\widetilde{F})}, \tag{2.69}$$

$$\frac{i}{\hbar}[F, \overline{G}^{(\widetilde{F})}] + \frac{\partial \overline{G}^{(\widetilde{F})}}{\partial t} = 0. \tag{2.70}$$

It should be noted that even for the case of bounded operators treated here the existence of $S^{(\widetilde{F})}(G)$ as defined in (2.66) is not always assured. General conditions on F and G which imply the validity of the averaging constructions (2.64)–(2.66) are currently being investigated.

F. Transformations on constant time slices

We now also introduce non-autonomous flows depending on some additional parameter ε which will later play the role of the perturbation parameter. The generating functions of these flows, however, are assumed to be only lifted functions, i.e., they do not depend on e, which implies that the canonical transformations they generate do not leave the constant time slices. We begin with the classical situation. Let

$$v:\widetilde{M}\times I\to\mathbb{R},\quad (\widetilde{m},\varepsilon)\mapsto v(m,t,\varepsilon), \tag{2.71}$$

where $I:=]\varepsilon_>,\varepsilon_<[\subset\mathbb{R}$ with some $\varepsilon_>\leqslant 0\leqslant\varepsilon_<$. For each $\varepsilon\in I$ this defines a function $v_\varepsilon\in C_L(\widetilde{M})$,

$$v_\varepsilon:\widetilde{M}\to\mathbb{R},\quad m\mapsto v(m,t,\varepsilon). \tag{2.72}$$

The non-autonomous vector field generated by v is then defined as

$$\widetilde{X}_v(\cdot,\varepsilon):\widetilde{M}\to T\widetilde{M},\quad \widetilde{m}\mapsto\widetilde{X}_v(\widetilde{m},\varepsilon):=\widetilde{X}_{v_\varepsilon}(\widetilde{m}), \tag{2.73}$$

where $\widetilde{X}_{v_\varepsilon}$ is defined in the usual way such that for each $\varepsilon\in I$,

$$\imath(\widetilde{X}_{v_\varepsilon})\widetilde{\omega}=-dv_\varepsilon. \tag{2.74}$$

The non-autonomous flow $\widetilde{\varphi}_v$ of this vector field is the solution of the following initial value problem:

$$\frac{d}{d\varepsilon}\widetilde{\varphi}_v(\varepsilon,\varepsilon_0)(\widetilde{m})=\widetilde{X}_v(\widetilde{\varphi}_v(\varepsilon,\varepsilon_0)(\widetilde{m}),\varepsilon),\quad \widetilde{\varphi}_v(\varepsilon_0,\varepsilon_0)(\widetilde{m})=\widetilde{m}, \tag{2.75}$$

which we assume to be unique. For each t and ε, v also gives a function on M,

$$v_{t,\varepsilon}:M\to\mathbb{R},\quad m\mapsto v(m,t,\varepsilon), \tag{2.76}$$

which generates the vector field $X_{v_{t,\varepsilon}}\in\mathscr{X}(M)$ which in turn generates the non-autonomous ε-flow φ_{v_t} such that

$$\frac{d}{d\varepsilon}\varphi_{v_t}(\varepsilon,\varepsilon_0)(m)=X_{v_{t,\varepsilon}}(\varphi_{v_t}(\varepsilon,\varepsilon_0)(m)),\quad \varphi_{v_t}(\varepsilon_0,\varepsilon_0)(m)=m. \tag{2.77}$$

From (2.12) we see that

$$\widetilde{X}_v(\widetilde{m},\varepsilon)=X_{v_{t,\varepsilon}}(m)+\frac{\partial v_\varepsilon}{\partial t}(m,t)\frac{\partial}{\partial e}, \tag{2.78}$$

and we can make a similar decomposition used to arrive at (2.19) to obtain

$$\frac{d}{d\tau}\begin{pmatrix}\widetilde{\pi}_1\circ\widetilde{\varphi}_v(\varepsilon,\varepsilon_0)((\widetilde{m}))\\ t(\varepsilon,\varepsilon_0)(\widetilde{m})\\ h(\varepsilon,\varepsilon_0)(\widetilde{m})\end{pmatrix}=\begin{pmatrix}X_{v_{t,\varepsilon}}(\widetilde{\pi}_1\circ\widetilde{\varphi}_v(\varepsilon,\varepsilon_0)((\widetilde{m})))\\ 0\\ \dfrac{\partial v_\varepsilon}{\partial t}(m,t)\end{pmatrix}. \tag{2.79}$$

Hence, the action of the extended ε-flow is given by

$$\widetilde{\varphi}_v(\varepsilon,\varepsilon_0)\left(\begin{pmatrix} m \\ t \\ e \end{pmatrix}\right)=\begin{pmatrix} \varphi_{v_t}(\varepsilon,\varepsilon_0)(m) \\ t \\ e+\int_{\varepsilon_0}^{\varepsilon} d\lambda\, \dfrac{\partial v}{\partial t}(\varphi_{v_t}(\lambda,\varepsilon_0)(m),t,\lambda) \end{pmatrix}. \tag{2.80}$$

Evidently, functions of the type (2.71) generate flows which do not leave the constant time slices:

$$\widetilde{\varphi}_v(\varepsilon,\varepsilon_0)(\widetilde{\Sigma}_t)\subset\widetilde{\Sigma}_t, \quad \forall t\in\mathbb{R}. \tag{2.81}$$

In our applications to time-dependent perturbation problems it will be useful to have the above formulae for the following special cases. If for some function v as in (2.71) we define

$$\widetilde{\varphi}(\varepsilon):=\overset{-1}{\widetilde{\varphi}}_{-v}(\varepsilon,0) \quad \text{and} \quad \varphi_t(\varepsilon):=\overset{-1}{\varphi}_{-v_t}(\varepsilon,0), \tag{2.82}$$

then (2.80) becomes

$$\widetilde{\varphi}^{-1}(\varepsilon)\begin{pmatrix} m \\ t \\ e \end{pmatrix}=\begin{pmatrix} \overset{-1}{\varphi}_t(\varepsilon)(m) \\ t \\ e-\int_0^{\varepsilon} d\lambda\, \overset{-1}{\varphi}_t(\lambda)^*\dfrac{\partial v_{t,\lambda}}{\partial t}(m) \end{pmatrix}, \tag{2.83}$$

and for the inverse we have

$$\widetilde{\varphi}(\varepsilon)\begin{pmatrix} m \\ t \\ e \end{pmatrix}=\begin{pmatrix} \varphi_t(\varepsilon)(m) \\ t \\ e+\varphi_t(\varepsilon)^*\int_0^{\varepsilon} d\lambda\, \overset{-1}{\varphi}_t(\lambda)^*\dfrac{\partial v_{t,\lambda}}{\partial t}(m) \end{pmatrix}. \tag{2.84}$$

Note that $\widetilde{\varphi}(\varepsilon)^*$ satisfies

$$\frac{d}{d\varepsilon}\,\widetilde{\varphi}(\varepsilon)^*g=\widetilde{ad}_{v_\varepsilon}\circ\widetilde{\varphi}(\varepsilon)^*g, \quad \widetilde{\varphi}(0)^*g=g, \quad \forall g\in C^\infty(\widetilde{M}). \tag{2.85}$$

Turning to the quantum mechanical case, suppose that we have an operator V on $\mathbb{H}$ which in addition to time also depends on some additional parameter $\varepsilon\in I:=]\varepsilon_>,\varepsilon_<[\subset\mathbb{R}$ with some $\varepsilon_>\leqslant 0\leqslant\varepsilon_<$,

$$V:\mathbb{R}\times I\to\mathscr{L}_{sa}(\mathbb{H}), \quad (t,\varepsilon)\mapsto V(t,\varepsilon). \tag{2.86}$$

Similar to the classical definitions (2.72) and (2.76) we thus define

$$\begin{matrix} V_\varepsilon:\mathbb{R}\to\mathscr{L}_{sa}(\mathbb{H}) \\ t\mapsto V(t,\varepsilon) \end{matrix} \quad \in\mathscr{C}_{sa}(\mathbb{H}), \tag{2.87}$$

and

$$V_{t,\varepsilon}\in\mathscr{L}_{sa}(\mathbb{H}). \tag{2.88}$$

Repeating the constructions of Section II F for the extended quantum mechanical phase space, we obtain for

$$\widetilde{\Phi}(\varepsilon) := \overset{-1}{\widetilde{\Phi}}_{-V}(\varepsilon,0) \quad \text{and} \quad \Phi_t(\varepsilon) := \overset{-1}{\Phi}_{-V_t}(\varepsilon,0) \tag{2.89}$$

the following action on $\widetilde{\mathbb{H}}$:

$$\widetilde{\Phi}(\varepsilon)\begin{pmatrix}\psi\\ t\\ e\end{pmatrix} = \begin{pmatrix}\Phi_t(\varepsilon)\psi\\ t\\ e + \left\langle \Phi_t(\varepsilon)^* \int_0^\varepsilon d\lambda \overset{-1}{\Phi}_t(\lambda)^* \frac{\partial V}{\partial t}\right\rangle\end{pmatrix}. \tag{2.90}$$

Note that $\Phi_t(\varepsilon)$ is the solution of

$$\frac{d}{d\varepsilon}\Phi_t(\varepsilon) = -\frac{i}{\hbar}\Phi_t(\varepsilon)V(t,\varepsilon), \quad \text{and} \quad \Phi_t(0) = \mathbb{1}, \quad \forall t \in \mathbb{R}. \tag{2.91}$$

III. POINCARÉ–VON ZEIPEL PERTURBATION THEORY

A. Introduction

Having established the geometric description of time-dependent systems both classical and quantum mechanical, we now turn to the construction of time-dependent perturbation theories. Since the time evolution of such non-autonomous systems has been formulated as HAMILTONian on extended phase space we might as well ''copy'' the geometric constructions of the time-independent constructions given in Refs. 3–5 and this is essentially what we shall do.

The aim of POINCARÉ–VON ZEIPEL perturbation theory is to provide approximations (or, if possible, exact solutions) of the flow generated by a perturbed HAMILTONian $\widetilde{h(\varepsilon)} = \widetilde{h_0} + \varepsilon h_1 + \ldots$ where $\widetilde{h_0}$ is the unperturbed part whose flow $\varphi_{h_0}(t,t_0)$ is assumed known and ε is the perturbation parameter. This is accomplished with a suitable canonical transformation $\widetilde{\varphi}(\varepsilon)$ to a new HAMILTONian $\widetilde{k(\varepsilon)} = \widetilde{h_0} + \varepsilon k_1 + \cdots$ such that $\widetilde{ad}_{\widetilde{h_0}}(k_p) = 0$. That this equation can be satisfied is assured by the averaging constructions. Moreover, this latter equation allows us to reduce the computation of the flow of $\widetilde{k(\varepsilon)}$ to a *time-independent* problem which in most cases is more amenable to exact solutions. The knowledge of the flow of $\widetilde{k(\varepsilon)}$ and of the canonical transformation $\widetilde{\varphi}(\varepsilon)$ then gives the desired flow of $\widetilde{h(\varepsilon)}$.

For HAMILTONian systems in general, time-dependent POINCARÉ–VON ZEIPEL is constructed in Section III B, whereas the quantum mechanical case is treated in Section III C, and its algorithm is summarized in Section III D.

B. General theory

Let

$$h(\varepsilon) := h_0 + \sum_{p=1}^{\infty} \frac{\varepsilon^p}{p!} h_p : M \times \mathbb{R} \to \mathbb{R},$$

$$(m,t) \mapsto h(\varepsilon)(m,t), \tag{3.1}$$

be a time-dependent HAMILTONian as in (2.1), where the flow $\varphi_{h_0}(t,t_0)$ of the unperturbed (but possibly time-dependent) part h_0 is known. With $h(\varepsilon)$ we construct the extended function

$$\widetilde{h(\varepsilon)} := h(\varepsilon) - e, \tag{3.2}$$

on $\widetilde{M}$. Let v, v_ε, and $v_{t,\varepsilon}$ be as in (2.71), (2.72), and (2.76), respectively and v_ε with an expansion,

$$v_\varepsilon := \sum_{p=0}^{\infty} \frac{\varepsilon^p}{p!} w_{p+1}, \tag{3.3}$$

in terms of ε-independent lifted functions $w_p \in C_L(\widetilde{M})$ and let $\widetilde{\varphi}(\varepsilon)$ and $\varphi_t(\varepsilon)$ be defined as in (2.82). The pull-back action of $\widetilde{\varphi}(\varepsilon)$ satisfies (2.85) and the pull-back of $\varphi_t(\varepsilon)$ which acts on functions on M satisfies

$$\frac{d}{d\varepsilon}\varphi_t(\varepsilon)^* g = ad_{v_{t,\varepsilon}} \circ \varphi_t(\varepsilon)^* g, \quad \varphi_t(0)^* g = g, \quad \forall g \in C^\infty(M), \tag{3.4}$$

and is assumed to permit the expansion

$$\varphi_t(\varepsilon)^* = \sum_{p=0}^{\infty} \frac{\varepsilon^p}{p!} t_p, \tag{3.5}$$

in terms of time-dependent differential operators acting on functions on M which may be computed recursively from

$$t_0 = id_{C^\infty(M)}, \quad t_{p+1} = \sum_{l=0}^{p} \binom{p}{l} ad_{w_{l+1}} \circ t_{p-l}. \tag{3.6}$$

Applying $\widetilde{\varphi}(\varepsilon)^*$ to $\widetilde{h(\varepsilon)}$ we find from (2.84),

$$\begin{aligned}
\widetilde{\varphi}(\varepsilon)^* \widetilde{h(\varepsilon)}(\widetilde{m}) &= h(\varepsilon)(\varphi_t(\varepsilon)(m), t) - \varphi_t(\varepsilon)^* \int_0^\varepsilon d\lambda\, \overset{-1}{\varphi_t}(\lambda)^* \frac{\partial v_{t,\lambda}}{\partial t}(m) - e \\
&=: k(\varepsilon)(m,t) - e \\
&=: \widetilde{k(\varepsilon)}(\widetilde{m}).
\end{aligned} \tag{3.7}$$

This defines the new HAMILTONian,

$$k(\varepsilon) = \varphi_t(\varepsilon)^* \left(h(\varepsilon)(m,t) - \int_0^\varepsilon d\lambda\, \overset{-1}{\varphi_t}(\lambda)^* \frac{\partial v_{t,\lambda}}{\partial t}(m) \right), \tag{3.8}$$

which we assume to have the ε-expansion

$$k(\varepsilon) = h_0 + \sum_{p=1}^{\infty} \frac{\varepsilon^p}{p!} k_p, \tag{3.9}$$

in terms of lifted functions k_p. We thus have

$$\begin{aligned}
\frac{d}{d\varepsilon}k(\varepsilon) &= \left(\frac{d}{d\varepsilon}\varphi_t(\varepsilon)^*\right)\left(h(\varepsilon)(m,t) - \int_0^\varepsilon d\lambda\, \overset{-1}{\varphi_t}(\lambda)^* \frac{\partial v_{t,\lambda}}{\partial t}(m) \right) - \frac{\partial v_{t,\varepsilon}}{\partial t} + \varphi_t(\varepsilon)^* \frac{d}{d\varepsilon} h(\varepsilon) \\
&= ad_{v_{t,\varepsilon}} \circ \varphi_t(\varepsilon)^* h(\varepsilon) - \frac{\partial v_{t,\varepsilon}}{\partial t} + \varphi_t(\varepsilon)^* \frac{d}{d\varepsilon} h(\varepsilon) \\
&= \varphi_t(\varepsilon)^* \frac{d}{d\varepsilon} h(\varepsilon) - \widetilde{ad}_{\widetilde{k(\varepsilon)}}(v_\varepsilon),
\end{aligned} \tag{3.10}$$

and arrive at the following recursive formulae for the k_p:

$$k_0 := h_0, \tag{3.11}$$

$$k_p = f_p - ad_{h_0}(w_p) - \frac{\partial w_p}{\partial t} = f_p - \widetilde{ad}_{\tilde{h}_0}(w_p), \quad \forall p \geqslant 1, \tag{3.12}$$

$$f_1 := h_1, \tag{3.13}$$

$$f_p := h_p + \sum_{l=0}^{p-2} \binom{p-1}{l} (ad_{w_{l+1}}(k_{p-l-1}) + t_{p-l-1} h_{l+1}), \quad \forall p \geqslant 2. \tag{3.14}$$

Here the h_p, k_p, and w_p are lifted functions and the expressions on the right-hand side like $ad_{w_{p+1}}(k_{p-l-1}) = \{(w_p)_t, (k_{p-l-1})_t\}$ are defined as in (2.16). How are we now to choose the w_p? We will now show that the requirement

$$\widetilde{ad}_{\tilde{h}_0}(k_p) = ad_{h_0}(k_p) + \frac{\partial k_p}{\partial t} = 0, \tag{3.15}$$

not only helps to determine the w_p but also implies a useful property for the k_p. Using the results about time-dependent averaging in Section II C we can satisfy (3.15) by the choice

$$w_p = s^{(\tilde{h}_0)}(f_p), \tag{3.16}$$

which also gives us

$$k_p = \overline{f_p}^{(\tilde{h}_0)}, \tag{3.17}$$

where the right hand sides are defined as in (2.27) and (2.28). Note that w_p as well as k_p are in general time-dependent. However, due to their construction, the time dependence of the k_p is essentially trivial since by using (2.15) and (2.13) equation (3.15) becomes

$$\{h_0, k_p\} + \frac{\partial k_p}{\partial t} = \widetilde{X}_{\tilde{h}_0} k_p = 0, \tag{3.18}$$

such that

$$(k_p)_t(m) := k_p(m,t) \tag{3.19}$$

$$= \overset{-1}{\varphi}_{h_0}(t,t_0)^*(k_p)_{t_0}(m), \tag{3.20}$$

for each p and some (arbitrarily chosen) $t_0 \in \mathbb{R}$ and hence

$$(k(\varepsilon))_t(m) := k(\varepsilon)(m,t) \tag{3.21}$$

$$= \overset{-1}{\varphi}_{h_0}(t,t_0)^*(k(\varepsilon))_{t_0}(m), \tag{3.22}$$

for $k(\varepsilon)$ as a whole. Using this we find

$$\frac{d}{dt}(\overset{-1}{\varphi}_{h_0}(t,t_0) \circ \varphi_{k(\varepsilon)}(t,t_0)(m)) = X_{\Sigma_{p=1}^{\infty}(\varepsilon^p/p!)(k_p)_{t_0}}(\overset{-1}{\varphi}_{h_0}(t,t_0) \circ \varphi_{k(\varepsilon)}(t,t_0)(m)), \tag{3.23}$$

where $\varphi_{k(\varepsilon)}(t,t_0)$ is the flow of the non-autonomous vector field generated by $k(\varepsilon)$. On the other hand, t_0 in (3.23) is arbitrary but fixed and $X_{\Sigma_{p=1}^{\infty}(\varepsilon^p/p!)(k_p)_{t_0}}$ *is an autonomous vector field*. Let us suppose then that $\varphi_{(k(\varepsilon)-h_0)_{t_0}}$ is a solution of the autonomous initial value problem,

$$\frac{d}{dt}\varphi_{(k(\varepsilon)-h_0)_{t_0}}(t)(m)=X_{\Sigma_{p=1}^{\infty}(\varepsilon^p/p!)\,(k_p)_{t_0}}(\varphi_{(k(\varepsilon)-h_0)_{t_0}}(t)(m)),\quad \varphi_{(k(\varepsilon)-h_0)_{t_0}}(t_0)(m)=m. \tag{3.24}$$

From (3.23) and (3.24) we infer that the flow generated by $k(\varepsilon)$ is given by

$$\varphi_{(k(\varepsilon))_t}(t,t_0)=\varphi_{h_0}(t,t_0)\circ\varphi_{(k(\varepsilon)-h_0)_{t_0}}(t). \tag{3.25}$$

Knowing this flow means that we can reconstruct the extended flow,

$$\widetilde{\varphi_{\widetilde{k(\varepsilon)}}}(\tau)\begin{pmatrix}\begin{pmatrix}m\\t\end{pmatrix}\\e\end{pmatrix}=\begin{pmatrix}\varphi_{k(\varepsilon)}(\tau+t,t)(m)\\ \tau+t\\ e+k(\varepsilon)(\varphi_{k(\varepsilon)}(\tau+t,t)(m),\tau+t)-k(\varepsilon)(m,t)\end{pmatrix}, \tag{3.26}$$

generated by $\widetilde{k(\varepsilon)}$. Knowing $\widetilde{\varphi}_{\widetilde{k(\varepsilon)}}(\tau)$ means that we also know $\widetilde{\varphi}_{\widetilde{h(\varepsilon)}}(\tau)$ since $\widetilde{k(\varepsilon)}=\widetilde{\varphi}(\varepsilon)^*\widetilde{h(\varepsilon)}$ implies

$$\widetilde{\varphi}_{\widetilde{h(\varepsilon)}}(\tau)=\widetilde{\varphi}(\varepsilon)\circ\widetilde{\varphi}_{\widetilde{k(\varepsilon)}}(\tau)\circ\widetilde{\varphi}^{-1}(\varepsilon). \tag{3.27}$$

Finally the knowledge of $\widetilde{\varphi}_{\widetilde{h(\varepsilon)}}(\tau)$ implies that we have the desired non-autonomous flow $\varphi_{h(\varepsilon)}(t,t_0)$ simply by taking the projection of the motion in M. Using (2.20), (2.83), (2.84), and (3.25) in (3.27) and taking the projection on M we find then that the desired flow is given by

$$\varphi_{h(\varepsilon)}(t,t_0)=\varphi_t(\varepsilon)\circ\varphi_{h_0}(t,t_0)\circ\varphi_{(k(\varepsilon)-h_0)_{t_0}}(t)\circ\varphi_{t_0}^{-1}(\varepsilon). \tag{3.28}$$

Here $\varphi_t(\varepsilon)$ is defined as in (2.82). Equation (3.28) shows that in order to get the desired flow one first transforms on the initial time slice $\widetilde{\Sigma}_{t_0}$, evolves with the autonomous flow $\varphi_{(k(\varepsilon)-h_0)_{t_0}}(t)$, then with the *a priori* known (possibly non-autonomous) flow of the unperturbed HAMILTONian, and finally within the final time slice $\widetilde{\Sigma}_t$.

The strategy to find the flow of the time-dependent perturbed HAMILTONian $h(\varepsilon)$ is then as follows:

- construct $\widetilde{\varphi}(\varepsilon)$, i.e., calculate successively the f_p of (3.14), the w_p according to (3.16), and the k_p according to (3.17)
- find $\varphi_{(k(\varepsilon)-h_0)_{t_0}}(t)$, i.e., solve the autonomous initial value problem (3.24)
- compute $\varphi_{h(\varepsilon)}(t,t_0)$ as in (3.28).

Note that (3.24) is a time-independent (autonomous) problem and thus may be treated by means of time-independent perturbation techniques given in Refs. 3–5. In general, however, it may not be possible to compute w_p, f_p, k_p for all $p\in\mathbb{N}$ but only up to some finite N, or it may not be possible to solve (3.24) but only up to order $\mathcal{O}(\varepsilon^N)$, i.e., we may have only the following approximations available:

$$\varphi_t^N(\varepsilon):=\varphi_t(\varepsilon)+\mathcal{O}(\varepsilon^N), \tag{3.29}$$

$$\varphi^N_{(k(\varepsilon)-h_0)_{t_0}}(t):=\varphi_{(k(\varepsilon)-h_0)_{t_0}}(t)+\mathcal{O}(\varepsilon^N), \tag{3.30}$$

such that (3.28) has to be modified to

$$\varphi_{h(\varepsilon)}(t,t_0)=\varphi_t^N(\varepsilon)\circ\varphi_{h_0}(t,t_0)\circ\varphi^N_{(k(\varepsilon)-h_0)_{t_0}}(t)\circ\varphi_{t_0}^{N\,-1}(\varepsilon)+\mathcal{O}(\varepsilon^N). \tag{3.31}$$

C. Quantum mechanical case

Suppose now that we are given a time-dependent operator which also depends on the perturbation parameter ε in the usual way,

$$H(\varepsilon)=H_0+\sum_{p=1}^{\infty}\frac{\varepsilon^p}{p!}H_p\in\mathscr{C}_{sa}(\mathbb{H}), \tag{3.32}$$

where the flow $\Phi_{H_0}(t,t_0)$ generated by the unperturbed (but possibly time-dependent) part H_0 is assumed known. The aim of the quantum mechanical version of time-dependent POINCARÉ–VON ZEIPEL perturbation theory is to find or approximate the time evolution generated by $H(\varepsilon)$.

Let V be an ε and time-dependent operator as in (2.86) and V_ε as in (2.87) with an ε-expansion,

$$V_\varepsilon=\sum_{p=0}^{\infty}\frac{\varepsilon^p}{p!}W_{p+1}\in\mathscr{C}_{sa}(\mathbb{H}), \tag{3.33}$$

in terms of ε-independent time-dependent operators $W_p\in\mathscr{C}_{sa}(\mathbb{H})$. Let $\widetilde{\Phi}(\varepsilon)$ and $\Phi_t(\varepsilon)$ be generated by V (resp., V_t) and defined as in (2.89). For each t and ε, $\Phi_t(\varepsilon)$ defines the transformation

$$\Phi_t(\varepsilon)^*:\mathscr{C}_{sa}(\mathbb{H})\to\mathscr{C}_{sa}(\mathbb{H}),$$

$$F\mapsto\Phi_t(\varepsilon)^\dagger F\Phi_t(\varepsilon). \tag{3.34}$$

Similarly to what was done in Section III B, this transformation is expanded in terms of time-dependent linear operators T_p acting now on $\mathscr{C}_{sa}(\mathbb{H})$,

$$\Phi_t(\varepsilon)^*=\sum_{p=0}^{\infty}\frac{\varepsilon^p}{p!}T_p, \tag{3.35}$$

where the T_p are then recursively defined through $T_0=\mathbb{1}_{\mathscr{C}_{sa}(\mathbb{H})}$ and

$$T_{p+1}=\sum_{l=0}^{p}\binom{p}{l}.\mathscr{AD}_{W_{l+1}}\circ T_{p-l}. \tag{3.36}$$

Moreover, we define

$$\widetilde{\Phi}(\varepsilon)^*:\mathscr{C}_{sa}(\mathbb{H})\to\mathscr{C}_{sa}(\mathbb{H}),$$

$$F\mapsto\widetilde{\Phi}(\varepsilon)^*F, \tag{3.37}$$

where

$$\widetilde{\Phi}(\varepsilon)^*F(t)\coloneqq\Phi_t(\varepsilon)^\dagger\left(F(t)-\int_0^\varepsilon d\lambda\,\Phi_t(\lambda)\,\frac{\partial V}{\partial t}(t,\lambda)\Phi_t(\lambda)^\dagger\right)\Phi_t(\varepsilon) \tag{3.38}$$

$$=\Phi_t(\varepsilon)^*\left(F(t)-\int_0^\varepsilon d\lambda\,\Phi_t(\lambda)\,\frac{\partial V}{\partial t}(t,\lambda)\Phi_t(\lambda)^\dagger\right). \tag{3.39}$$

With the help of this transformation we define the new HAMILTONian,

$$K(\varepsilon)\coloneqq\widetilde{\Phi}(\varepsilon)^*H(\varepsilon)\in\mathscr{C}_{sa}(\mathbb{H}), \tag{3.40}$$

which is assumed to have the usual ε-expansion,

$$K(\varepsilon)=\sum_{p=0}^{\infty}\frac{\varepsilon^p}{p!}K_p, \tag{3.41}$$

in terms of time-dependent operators K_p. Calculations similar to the ones performed in Section III B lead to

$$\frac{d}{d\varepsilon}K(\varepsilon)=\Phi_t(\varepsilon)^*\frac{d}{d\varepsilon}H(\varepsilon)-\mathscr{AD}_{K(\varepsilon)}(V_{t,\varepsilon})-\frac{\partial V_{t,\varepsilon}}{\partial t} \tag{3.42}$$

$$=\Phi_t(\varepsilon)^*\frac{d}{d\varepsilon}H(\varepsilon)-\widetilde{\mathscr{AD}}_{K(\varepsilon)}(V_{t,\varepsilon}), \tag{3.43}$$

and from these we derive the following recursive formulae for the operators K_p:

$$K_0=H_0, \tag{3.44}$$

$$K_p=F_p-\mathscr{AD}_{H_0}(W_p)-\frac{\partial W_p}{\partial t}=F_p-\widetilde{\mathscr{AD}}_{\tilde{H}_0}(W_p),\quad \forall p\geqslant 1, \tag{3.45}$$

$$F_1:=H_1, \tag{3.46}$$

$$F_p:=H_p+\sum_{l=0}^{p-2}\binom{p-1}{l}(\mathscr{AD}_{W_{l+1}}(K_{p-l-1})+T_{p-l-1}H_{l+1}),\quad \forall p\geqslant 2. \tag{3.47}$$

Once again we determine the W_p and thus the K_p by the requirement

$$\widetilde{\mathscr{AD}}_{\tilde{H}_0}(K_p)=\mathscr{AD}_{H_0}(K_p)+\frac{\partial K_p}{\partial t}=\frac{i}{\hbar}[H_0,K_p]+\frac{\partial K_p}{\partial t}=0. \tag{3.48}$$

Using the results about time-dependent averaging in Section II C we can satisfy (3.48) by the choice

$$W_p=S^{(\tilde{H}_0)}(F_p), \tag{3.49}$$

which also gives us

$$K_p=\overline{F_p}^{(\tilde{H}_0)}, \tag{3.50}$$

where the right hand sides are defined as in (2.65) and (2.66). As in the classical case this implies that each time-dependent operator $K_p\in\mathscr{C}_{sa}(\mathbb{H})$ is invariant under the transformation $\tilde{\Phi}_{\tilde{H}_0}(\tau)^*$, $\forall\tau\in\mathbb{R}$ and thus $K(\varepsilon)$ as a whole is also invariant. In particular we may choose a fixed $t_0\in\mathbb{R}$ and set $\tau=t-t_0$ which leads to

$$(K(\varepsilon))_t=\overset{-1}{\Phi}_{H_0}(t,t_0)^\dagger(K(\varepsilon))_{t_0}\overset{-1}{\Phi}_{H_0}(t,t_0) \tag{3.51}$$

$$=(\overset{-1}{\Phi}_{H_0}(t,t_0))^*(K(\varepsilon))_{t_0}, \tag{3.52}$$

the last equation being the equivalent of (3.22). This invariance of $K(\varepsilon)$ implies that

$$\frac{d}{dt}(\overset{-1}{\Phi}_{H_0}(t,t_0)\circ\Phi_{K(\varepsilon)}(t,t_0))=-\frac{i}{\hbar}\sum_{p=1}^{\infty}\frac{\varepsilon^p}{p!}(K_p)_{t_0}(\overset{-1}{\Phi}_{H_0}(t,t_0)\circ\Phi_{K(\varepsilon)}(t,t_0)), \tag{3.53}$$

where $\Phi_{H_0}(t,t_0)$ and $\Phi_{K(\varepsilon)}(t,t_0)$ are the quantum mechanical time evolutions generated by the time-dependent HAMILTONian operators H_0 and $K(\varepsilon)$. On the other hand $\Sigma_{p=1}^{\infty}(\varepsilon^p/p!)(K_p)_{t_0}$

does not depend on t and, as in the classical case, (3.53) constitutes an autonomous problem. Let us suppose then that $\Phi_{(K(\varepsilon)-H_0)_{t_0}}$ is a solution of the autonomous initial value problem,

$$\frac{d}{dt}\Phi_{(K(\varepsilon)-H_0)_{t_0}}(t)=-\frac{i}{\hbar}\sum_{p=1}^{\infty}\frac{\varepsilon^p}{p!}(K_p)_{t_0}\Phi_{(K(\varepsilon)-H_0)_{t_0}}(t),\quad \Phi_{(K(\varepsilon)-H_0)_{t_0}}(t_0)=\mathbb{1}_{\mathrm{H}}. \tag{3.54}$$

The time evolution generated by $K(\varepsilon)$ is thus given by

$$\Phi_{K(\varepsilon)}(t,t_0)=\Phi_{H_0}(t,t_0)\circ\Phi_{(K(\varepsilon)-H_0)_{t_0}}(t). \tag{3.55}$$

Recalling (2.56), i.e., that

$$\widetilde{\Phi}_{\widetilde{K(\varepsilon)}}(\tau)\begin{pmatrix}\psi\\ t\\ e\end{pmatrix}=\widetilde{\Phi}_{\widetilde{\langle K(\varepsilon)\rangle}}(\tau)\begin{pmatrix}\psi\\ t\\ e\end{pmatrix}=\begin{pmatrix}\Phi_{K(\varepsilon)}(\tau+t,t)\psi\\ \tau+t\\ e+\langle K(\varepsilon)\rangle(\Phi_{K(\varepsilon)}(\tau+t,t)\psi,\tau+t)-\langle K(\varepsilon)\rangle(\psi,t)\end{pmatrix},$$

we see that a solution of (3.54) allows us to construct the extended flow $\widetilde{\Phi}_{\widetilde{\langle K(\varepsilon)\rangle}}(\tau)$. Using moreover that

$$\widetilde{\langle H(\varepsilon)\rangle}=\widetilde{\langle\widetilde{\Phi}^{-1}(\varepsilon)*K(\varepsilon)\rangle}=\widetilde{\Phi}^{-1}(\varepsilon)*\widetilde{\langle K(\varepsilon)\rangle}, \tag{3.56}$$

we may thus deduce via the following chain of equalities:

$$\widetilde{\Phi}_{\widetilde{H(\varepsilon)}}(\tau)=\widetilde{\Phi}_{\widetilde{\langle H(\varepsilon)\rangle}}(\tau) \tag{3.57}$$

$$=\widetilde{\Phi}^{-1}_{\widetilde{\Phi}(\varepsilon)*\widetilde{\langle K(\varepsilon)\rangle}}(\tau) \tag{3.58}$$

$$=\widetilde{\Phi}(\varepsilon)\circ\widetilde{\Phi}_{\widetilde{\langle K(\varepsilon)\rangle}}(\tau)\circ\widetilde{\Phi}^{-1}(\varepsilon) \tag{3.59}$$

$$=\widetilde{\Phi}(\varepsilon)\circ\widetilde{\Phi}_{\widetilde{K(\varepsilon)}}(\tau)\circ\widetilde{\Phi}^{-1}(\varepsilon), \tag{3.60}$$

that the desired non-autonomous flow $\Phi_{H(\varepsilon)}(t,t_0)$ is given by

$$\Phi_{H(\varepsilon)}(t,t_0)=\Phi_t(\varepsilon)\circ\Phi_{K(\varepsilon)}(t,t_0)\circ\overset{-1}{\Phi}_{t_0}(\varepsilon) \tag{3.61}$$

$$=\Phi_t(\varepsilon)\circ\Phi_{H_0}(t,t_0)\circ\Phi_{(K(\varepsilon)-H_0)_{t_0}}(t,t_0)\circ\overset{-1}{\Phi}_{t_0}(\varepsilon). \tag{3.62}$$

Equation (3.62) describes how $\Phi_{H(\varepsilon)}(t,t_0)$ can be obtained from the knowledge of the W_p and the solution of the autonomous initial value problem (3.54). However, as in the classical case, it may not be possible to compute W_p, F_p, K_p for all $p\in\mathbb{N}$ but only up to some finite $N\in\mathbb{N}$, or it may be impossible to solve (3.54) exactly, but only approximately up to $\mathcal{O}(\varepsilon^N)$, i.e., we may have only the left hand sides of

$$\Phi^N_t(\varepsilon)=\Phi_t(\varepsilon)+\mathcal{O}(\varepsilon^N), \tag{3.63}$$

$$\Phi^N_{(K(\varepsilon)-H_0)_{t_0}}(t)=\Phi_{(K(\varepsilon)-H_0)_{t_0}}(t)+\mathcal{O}(\varepsilon^N), \tag{3.64}$$

available, such that we have to modify (3.62) to the approximation

$$\Phi_{H(\varepsilon)}(t,t_0)=\Phi^N_t(\varepsilon)\circ\Phi_{H_0}(t,t_0)\circ\Phi^N_{(K(\varepsilon)-H_0)_{t_0}}(t,t_0)\circ\overset{-1}{\Phi}{}^N_{t_0}(\varepsilon)+\mathcal{O}(\varepsilon^N). \tag{3.65}$$

In fact, since in quantum mechanics we are dealing with a linear flow, we can write down an approximation $\Phi_t^N(\varepsilon)$ with the help of the W_p. Let

$$\Phi_t^N(\varepsilon) := \sum_{p=0}^{N} \frac{\varepsilon^p}{p!} \Phi_p, \tag{3.66}$$

where each $\Phi_p \in \mathscr{C}_{sa}(\mathbb{H})$ is, according to (2.91), given by the recursive relation

$$\Phi_{p+1} = -\frac{i}{\hbar} \sum_{l=0}^{p} \binom{p}{l} \Phi_{p-l} W_{l+1}, \quad \Phi_0 = \mathbb{1}_{\mathbb{H}}, \tag{3.67}$$

where only now Φ_p, $W_p \in \mathscr{C}_{sa}(\mathbb{H})$.

In general it will be only the approximation (3.65) which can be computed. As a fairly straightforward example shows (see Section V) this approximation is different from standard time-dependent perturbation theory.

D. Summary of time-dependent quantum mechanical Poincaré–von Zeipel perturbation theory

Below is a summary of the quantum mechanical time-dependent POINCARÉ–VON ZEIPEL perturbation theory developed in Section III C in an algorithmic fashion suitable to immediate application by practitioners.

Let

$$H(\varepsilon) = \sum_{p=0}^{\infty} \frac{\varepsilon^p}{p!} H_p \tag{3.68}$$

be given and suppose $\Phi_{H_0}(t,t_0)$ is known.

Step 1: Starting with $p=1$ do the following loop:

(1) Compute

$$F_p := \begin{cases} H_1, & \text{if } p=1, \\ H_p + \sum_{l=0}^{p-2} \binom{p-1}{l} (\mathscr{AD}_{W_{l+1}}(K_{p-l-1}) + T_{p-l-1} H_{l+1}), & \forall p \geqslant 2 \end{cases} \tag{3.69}$$

where $\mathscr{AD}_{W_{l+1}}(K_{p-l-1}) = i/\hbar\,[W_{l+1}, K_{p-l-1}]$.

(2) Compute

$$K_p = \overline{F_p}^{(H_0)} = \lim_{T\to\infty} \frac{1}{T} \int_0^T d\sigma\; \Phi_{H_0}(t-\sigma,t)^\dagger F_p(t-\sigma) \Phi_{H_0}(t-\sigma,t). \tag{3.70}$$

(3) Compute

$$W_p := S^{(H_0)}(F_p) = \lim_{T\to\infty} \frac{1}{T} \int_0^T d\tau \int_0^\tau d\sigma\; (\Phi_{H_0}(t-\sigma,t)^\dagger F_p(t-\sigma) \Phi_{H_0}(t-\sigma,t) - \overline{F_p}^{(\tilde{H}_0)}(t)). \tag{3.71}$$

(4) Using $T_0 = \mathbb{1}_{\mathscr{C}_{sa}(\mathbb{H})}$ compute

$$T_{p+1} = \sum_{l=0}^{p} \binom{p}{l} \mathscr{AD}_{W_{l+1}} \circ T_{p-l}. \tag{3.72}$$

(5) Using $\Phi_0 = \mathbb{1}_{\mathbb{H}}$ compute

$$\Phi_{p+1} = -\frac{i}{\hbar} \sum_{l=0}^{p-1} \binom{p-1}{l} \Phi_{p-l-1} W_{l+1}, \tag{3.73}$$

until $p = N =$ desired order of approximation.

Step 2: Compute

$$\Phi_t^N(\varepsilon)=\sum_{p=0}^{N}\frac{\varepsilon^p}{p!}\Phi_p(t). \tag{3.74}$$

Step 3: Find the solution $\Phi^N_{(K(\varepsilon)-H_0)_{t_0}}(t)$ of the autonomous initial value problem,

$$\frac{d}{dt}\Phi^N_{(K(\varepsilon)-H_0)_{t_0}}(t)=\left(-\frac{i}{\hbar}\sum_{p=1}^{N}\frac{\varepsilon^p}{p!}(K_p)_{t_0}\right)\Phi^N_{(K(\varepsilon)-H_0)_{t_0}}(t),\quad \Phi^N_{(K(\varepsilon)-H_0)_{t_0}}(t_0)=\mathbb{1}_{\mathbb{H}}. \tag{3.75}$$

Step 4: With the results of Steps 1–3 compute

$$\Phi_t^N(\varepsilon)\circ\Phi_{H_0}(t,t_0)\circ\Phi^N_{(K(\varepsilon)-H_0)(t_0)}(t,t_0)\circ\overset{-1}{\Phi}{}^N_{t_0}(\varepsilon)=\Phi_{H(\varepsilon)}(t,t_0)+\mathcal{O}(\varepsilon^{N+1}). \tag{3.76}$$

This is the desired Nth-order approximation for time evolution generated by the time-dependent HAMILTONian (3.68).

IV. TIME-DEPENDENT KAM ALGORITHM

A. Introduction

Once the time-dependent version of POINCARÉ–VON ZEIPEL is available, it is rather straightforward to construct the KAM method. This is done in analogy to the time-independent case[3–5] by a successive application of canonical transformations $\widetilde{\varphi}^n(\varepsilon)$, $n=1,2,\ldots$, with a suitable choice of generators w_p^n.

The time-dependent KAM method for HAMILTONian systems in general is presented in Section IV B, whereas the quantum mechanical case is given in Section IV C, and its algorithm summarized in Section IV D.

B. General theory

Let $h(\varepsilon)$ be given as in (3.1). Since we are going to transform successively to new HAMILTONians, we shall denote this original perturbed HAMILTONian, whose flow we would like to find (or approximate), by $h^0(\varepsilon):=h(\varepsilon)$ and accordingly $h_p^0:=h_p$ such that $h_0^0=h_0$ is our unperturbed HAMILTONian whose flow is assumed known. Moreover, for $n=1,2,\ldots$, we let v^n, v^n_ε, and $v^n_{t,\varepsilon}$ be as in (2.71), (2.72), and (2.76), respectively, and v^n_ε with an expansion,

$$v^n_\varepsilon:=\sum_{p=0}^{\infty}\frac{\varepsilon^p}{p!}w^n_{p+1}, \tag{4.1}$$

in terms of ε-independent lifted functions $w_p^n\in C_L(\widetilde{M})$ and let $\widetilde{\varphi^n}(\varepsilon)$ and $\varphi_t^n(\varepsilon)$ be defined as in (2.82). The pull-back action of $\widetilde{\varphi^n}(\varepsilon)$ satisfies (2.85) and the pull-back of $\varphi_t^n(\varepsilon)$ which acts on functions on M satisfies

$$\frac{d}{d\varepsilon}\varphi_t^n(\varepsilon)^*g=ad_{v^n_{t,\varepsilon}}\circ\varphi_t^n(\varepsilon)^*g,\quad \varphi_t^n(0)^*g=g,\quad \forall g\in C^\infty(M), \tag{4.2}$$

and is assumed to permit the expansion

$$\varphi_t^n(\varepsilon)^*=\sum_{p=0}^{\infty}\frac{\varepsilon^p}{p!}t_p^n, \tag{4.3}$$

in terms of time-dependent differential operators t_p^n acting on functions on M which may be computed recursively from

$$t_0^n=id_{C^\infty(M)},\quad t_{p+1}^n=\sum_{l=0}^{p}\binom{p}{l}ad_{w^n_{l+1}}\circ t^n_{p-l}. \tag{4.4}$$

Let $\widetilde{k^1(\varepsilon)}$ be the extended HAMILTONian obtained by pulling back the extended original perturbed HAMILTONian $\widetilde{h^0(\varepsilon)}$ with $\widetilde{\varphi^1}(\varepsilon)$,

$$\widetilde{k^1(\varepsilon)} := \widetilde{\varphi^1}(\varepsilon)^* \widetilde{h^0(\varepsilon)}. \tag{4.5}$$

This defines

$$k^1(\varepsilon) = \varphi^1_t(\varepsilon)^* \left(h^0(\varepsilon)(m,t) - \int_0^\varepsilon d\lambda \overset{-1}{\varphi^1_t}(\lambda)^* \frac{\partial v^1_{t,\lambda}}{\partial t}(m) \right), \tag{4.6}$$

which we assume to have the ε-expansion,

$$k^1(\varepsilon) = h^0_0 + \sum_{p=1}^{\infty} \frac{\varepsilon^p}{p!} k^1_p, \tag{4.7}$$

in terms of lifted functions k^1_p. Calculations similar to (3.10) lead to

$$k^1_0 := h^0_0, \tag{4.8}$$

$$k^1_p = f^1_p - ad_{h^0_0}(w^1_p) - \frac{\partial w^1_p}{\partial t} = f^1_p - \widetilde{ad}_{h^0_0}(w_p), \quad \forall p \geqslant 1, \tag{4.9}$$

$$f^1_1 := h^0_1, \tag{4.10}$$

$$f^1_p := h^0_p + \sum_{l=0}^{p-2} \binom{p-1}{l} (ad_{w^1_{l+1}}(k^1_{p-l-1}) + t^1_{p-l-1} h^0_{l+1}), \quad \forall p \geqslant 2. \tag{4.11}$$

So far we have just done POINCARÉ–VON ZEIPEL with $\widetilde{\varphi^1}(\varepsilon)$. Now, however, we shall choose the w^1_p differently:

$$w^1_1 = s^{(\widetilde{h^0_0})}(f^1_1), \tag{4.12}$$

$$w^1_p = 0, \quad \forall p \geqslant 2, \tag{4.13}$$

which implies

$$k^1_1 = \overline{h^0_0}^{(\widetilde{h^0_0})}, \tag{4.14}$$

$$k^1_{p+1} = ad_{w^1_1}(k^1_p) + \sum_{l=0}^{p} \binom{p}{l} (ad_{w^1_1})^{p-l}(h^0_{l+1}), \quad \forall p \geqslant 1. \tag{4.15}$$

After this first transformation we introduce the HAMILTONian $h^1(\varepsilon)$ which is considered as the perturbed HAMILTONian of the unperturbed part $h^0_0 + \varepsilon \overline{h^0_1}^{(\widetilde{h^0_0})}$:

$$h^1(\varepsilon) := k^1(\varepsilon) = \underbrace{h^0_0 + \varepsilon \overline{h^0_1}^{(\widetilde{h^0_0})}}_{} + \sum_{p=2}^{\infty} \frac{\varepsilon^p}{p!} k^1_p \tag{4.16}$$

$$= \quad h^1_0 \quad + \sum_{p=2}^{\infty} \frac{\varepsilon^p}{p!} h^1_p, \tag{4.17}$$

such that

$$h^1_0(\varepsilon) = h^0_0 + \varepsilon \overline{h^0_1}^{(\widetilde{h^0_0})}, \quad h^1_1 = 0, \quad h^1_p = k^1_p, \quad \forall p \geqslant 2, \tag{4.18}$$

and $h^1(\varepsilon)$ has no perturbation of first order in ε. The extended version of (4.16)–(4.17) reads as

$$\widetilde{h^1(\varepsilon)} := \widetilde{k^1(\varepsilon)} = \underbrace{\widetilde{h_0^0} + \varepsilon \overline{h_1^0}^{(\widetilde{h_0^0})}} + \sum_{p=2}^{\infty} \frac{\varepsilon^p}{p!} k_p^1 \tag{4.19}$$

$$= \widetilde{h_0^1} + \sum_{p=2}^{\infty} \frac{\varepsilon^p}{p!} h_p^1. \tag{4.20}$$

By construction $\widetilde{h_0^1}$ is invariant under $\widetilde{\varphi}_{\widetilde{h_0^0}}(\tau)$ which is equivalent to [see the discussion following (3.15)]

$$(h_0^1)_t = \overset{-1}{\varphi}_{h_0^0}(t,t_0)^*(h_0^1)_{t_0}, \tag{4.21}$$

for some $t_0 \in \mathbb{R}$ and thus

$$\frac{d}{dt}(\overset{-1}{\varphi}_{h_0^0}(t,t_0)\circ\varphi_{h_0^1}(t,t_0)(m)) = X_{(h_0^1(\varepsilon)-h_0^0)_{t_0}}(\overset{-1}{\varphi}_{h_0^0}(t,t_0)\circ\varphi_{h_0^1}(t,t_0)(m)), \tag{4.22}$$

which helps us to find the flow of h_0^1. Let $\varphi_{(h_0^1(\varepsilon)-h_0^0)_{t_0}}(t)$ be the solution of the *autonomous* initial value problem,

$$\frac{d}{dt}\varphi_{(h_0^1(\varepsilon)-h_0^0)_{t_0}}(t)(m) = X_{(h_0^1(\varepsilon)-h_0^0)_{t_0}}(\varphi_{(h_0^1(\varepsilon)-h_0^0)_{t_0}}(t)(m)), \quad \varphi_{(h_0^1(\varepsilon)-h_0^0)_{t_0}}(t_0)(m) = m; \tag{4.23}$$

then (4.22) implies

$$\varphi_{h_0^1}(t,t_0) = \varphi_{h_0^0}(t,t_0)\circ\varphi_{(h_0^1(\varepsilon)-h_0^0)_{t_0}}(t). \tag{4.24}$$

Now we do a second transformation $\widetilde{\varphi^2}(\varepsilon)$ on $\widetilde{h^1(\varepsilon)}$ such that

$$\widetilde{k^2(\varepsilon)} := \widetilde{\varphi^2}(\varepsilon)^*\widetilde{h^1(\varepsilon)}, \tag{4.25}$$

$$= \widetilde{k_0^2} + \sum_{p=1}^{\infty} \frac{\varepsilon^p}{p!} k_p^2, \tag{4.26}$$

and in the same manner as before one finds that

$$k_0^2 = h_0^1, \tag{4.27}$$

$$k_{p+1}^2 = \sum_{l=0}^{p} \binom{p}{l} (ad_{w_{l+1}^2}(k_{p-l}^2) + t_{p-l}^2(h_{l+1}^1)), \quad \forall p \geqslant 1. \tag{4.28}$$

Here we choose the generating function $v^2(\varepsilon)$ such that

$$w_1^2 = 0, \tag{4.29}$$

$$w_p^2 = s^{(\widetilde{h_0^1})}(h_p^1), \quad p = 2,3, \tag{4.30}$$

$$w_p^2 = 0, \quad \forall p \geqslant 4, \tag{4.31}$$

which implies

$$k_1^2 = 0, \tag{4.32}$$

$$k_2^2=\widetilde{\overline{h_2^1}^{(h_0^1)}}, \tag{4.33}$$

$$k_3^2=\widetilde{\overline{h_3^1}^{(h_0^1)}}, \tag{4.34}$$

$$k_{p+1}^2=\binom{p}{2}ad_{w_2^2}(k_{p-1}^2)+\binom{p}{3}ad_{w_3^2}(k_{p-2}^2)+\sum_{l=1}^{p}\binom{p}{l}t_{p-l}^2(h_{l+1}^1). \tag{4.35}$$

Note that $k_0^2=h_0^1=h_0^0+\varepsilon\widetilde{\overline{h_1^1}^{(h_0^0)}}$ is the unperturbed HAMILTONian after the first step whose flow is found with the help of (4.24) using the solution of (4.23). Moreover, different from the POINCARÉ–VON ZEIPEL algorithm it is now $h_0^1=h_0^0+\varepsilon\widetilde{\overline{h_1^1}^{(h_0^0)}}$ (and *not* h_0^0 as in the POINCARÉ–VON ZEIPEL method) along whose flow we now compute the averages and which is used to construct w_p^2 in (4.29).

After the second transformation we introduce the HAMILTONian $\widetilde{h^2}(\varepsilon)$ which is considered as the perturbed HAMILTONian of the unperturbed part $h_0^1+(\varepsilon^2/2!)\widetilde{\overline{h_2^1}^{(h_0^1)}}+(\varepsilon^3/3!)\widetilde{\overline{h_3^1}^{(h_0^1)}}$:

$$h^2(\varepsilon):=k^2(\varepsilon)=\underbrace{h_0^0+\varepsilon\widetilde{\overline{h_1^0}^{(h_0^0)}}+\frac{\varepsilon^2}{2!}\widetilde{\overline{h_2^1}^{(h_0^1)}}+\frac{\varepsilon^3}{3!}\widetilde{\overline{h_3^1}^{(h_0^1)}}}_{=\,h_0^2}+\sum_{p=2^2}^{\infty}\frac{\varepsilon^p}{p!}k_p^2 \tag{4.36}$$

$$=h_0^2+\sum_{p=2^2}^{\infty}\frac{\varepsilon^p}{p!}h_p^2, \tag{4.37}$$

such that

$$h_0^2(\varepsilon)=h_0^0+\varepsilon\widetilde{\overline{h_1^0}^{(h_0^0)}}+\frac{\varepsilon^2}{2!}\widetilde{\overline{h_2^1}^{(h_0^1)}}+\frac{\varepsilon^3}{3!}\widetilde{\overline{h_3^1}^{(h_0^1)}}, \tag{4.38}$$

$$h_p^2=0, \quad \text{if } 1\leqslant p<2^2, \tag{4.39}$$

$$h_p^1=k_p^1, \quad \text{if } p\geqslant 2^2, \tag{4.40}$$

and $h^2(\varepsilon)$ has no perturbation up to order ε^3. Now one proceeds as before to compute the flow of h_0^2, etc.

The procedure for general n runs as follows.

Starting with $n=1$ we have after $n-1$ transformations the following HAMILTONian:

$$h^{n-1}(\varepsilon)=h_0^{n-1}+\sum_{p=2^{n-1}}^{\infty}\frac{\varepsilon^p}{p!}h_p^{n-1}, \tag{4.41}$$

such that

$$h_p^{n-1}=0, \quad \forall 1\leqslant p<2^{n-1}, \tag{4.42}$$

and the flow $\varphi_{h_0^{n-1}}(t,t_0)$ generated by h_0^{n-1} is known. To the extension of h_0^{n-1} we apply the transformation $\widetilde{\varphi^n}(\varepsilon)$ to obtain

$$\widetilde{k^n(\varepsilon)}=\widetilde{\varphi^n}(\varepsilon)*\widetilde{h^{n-1}(\varepsilon)}, \tag{4.43}$$

$$=\widetilde{k_0^n}+\sum_{p=1}^{\infty}\frac{\varepsilon^p}{p!}k_p^n. \tag{4.44}$$

The w_p^n generating $\widetilde{\varphi^n}(\varepsilon)$ are chosen as

$$w_p^n=\begin{cases}0, & \text{if } p<2^{n-1},\\ s^{(\widetilde{h_0^{n-1}})}(h_p^{n-1}), & \text{if } 2^{n-1}\leqslant p<2^n,\\ 0, & \text{if } 2^n\leqslant p,\end{cases} \tag{4.45}$$

which implies

$$k_p^n=\begin{cases}h_0^{n-1}, & \text{if } p=0,\\ 0, & \text{if } 1\leqslant p<2^{n-1},\\ \overline{h_p^{n-1}}^{(\widetilde{h_0^{n-1}})}, & \text{if } 2^{n-1}\leqslant p<2^n,\\ \displaystyle\sum_{l=2^{n-1}-1}^{p-1}\binom{p-1}{l}(ad_{w_{l+1}^n}(k_{p-l-1}^n)+t_{p-l-1}^n(h_{l+1}^{n-1})), & \text{if } 2^n\leqslant p.\end{cases} \tag{4.46}$$

Thus we have

$$h^n(\varepsilon)=h_0^n+\sum_{p=2^n}^{\infty}\frac{\varepsilon^p}{p!}h_p^n, \tag{4.47}$$

where

$$h_0^n=h_0^{n-1}+\sum_{p=2^{n-1}}^{2^n-1}\frac{\varepsilon^p}{p!}\overline{h_p^{n-1}}^{(\widetilde{h_0^{n-1}})}, \tag{4.48}$$

$$h_p^n=k_p^n,\quad \forall p\geqslant 2^n. \tag{4.49}$$

Next, solve the autonomous initial value problem,

$$\frac{d}{dt}\varphi_{(h_0^n(\varepsilon)-h_0^{n-1}(\varepsilon))_{t_0}}(t)(m)=X_{(h_0^n(\varepsilon)-h_0^{n-1}(\varepsilon))_{t_0}}(\varphi_{(h_0^n(\varepsilon)-h_0^{n-1}(\varepsilon))_{t_0}}(t)(m)), \tag{4.50}$$

$$\varphi_{(h_0^n(\varepsilon)-h_0^n(\varepsilon))_{t_0}}(t_0)(m)=m. \tag{4.51}$$

This solution permits us to write down $\varphi_{h_0^n}$ explicitly:

$$\begin{aligned}\varphi_{h_0^n}(t,t_0)&=\varphi_{h_0^{n-1}}(t,t_0)\circ\varphi_{(h_0^n(\varepsilon)-h_0^{n-1}(\varepsilon))_{t_0}}(t)\\ &\ \ \vdots\\ &=\varphi_{h_0^0}(t,t_0)\circ\varphi_{(h_0^1(\varepsilon)-h_0^0)_{t_0}}(t)\circ\cdots\circ\varphi_{(h_0^n(\varepsilon)-h_0^{n-1}(\varepsilon))_{t_0}}(t).\end{aligned} \tag{4.52}$$

This way we can find the flow of $h_0^n(\varepsilon)$, but what about the original object of desire, namely the flow of $h^0(\varepsilon)$? Since

$$\widetilde{h^n(\varepsilon)}=\widetilde{\varphi^n}(\varepsilon)*\widetilde{h^{n-1}(\varepsilon)}, \tag{4.53}$$

$$=(\widetilde{\varphi^1}(\varepsilon)\circ\cdots\circ\widetilde{\varphi^n}(\varepsilon))*\widetilde{h^0(\varepsilon)}, \tag{4.54}$$

it follows from arguments similar to those used after (3.27) that

$$\varphi_{h^0(\varepsilon)}(t,t_0)=(\varphi_t^1(\varepsilon)\circ\cdots\circ\varphi_t^n(\varepsilon))\circ\varphi_{h^n(\varepsilon)}(t,t_0)\circ(\varphi_{t_0}^1(\varepsilon)\circ\cdots\circ\varphi_{t_0}^n(\varepsilon))^{-1}, \tag{4.55}$$

and since

$$\varphi_{h^n(\varepsilon)}(t,t_0)=\varphi_{h_0^n(\varepsilon)}(t,t_0)+\mathcal{O}(\varepsilon^{2^n}), \tag{4.56}$$

we deduce

$$\varphi_{h^0(\varepsilon)}(t,t_0)=(\varphi_t^1(\varepsilon)\circ\cdots\circ\varphi_t^n(\varepsilon))\circ\varphi_{h_0^0}(t,t_0)\circ\varphi_{(h_0^1(\varepsilon)-h_0^0)_{t_0}}(t)\circ\cdots\circ\varphi_{(h_0^n(\varepsilon)-h_0^{n-1}(\varepsilon))_{t_0}}(t)$$
$$\circ(\varphi_{t_0}^1(\varepsilon)\circ\cdots\circ\varphi_{t_0}^n(\varepsilon))^{-1}+\mathscr{O}(\varepsilon^{2^n}), \tag{4.57}$$

which constitutes the desired approximation to the flow of $h^0(\varepsilon)$.

C. Quantum mechanical case

Suppose now that, as in Section III C, we are given a time-dependent operator which also depends on the perturbation parameter ε in the usual way,

$$H^0(\varepsilon)=H_0^0+\sum_{p=1}^{\infty}\frac{\varepsilon^p}{p!}H_p^0\in\mathscr{C}_{sa}(\mathbb{H}), \tag{4.58}$$

where the flow $\Phi_{H_0^0}(t,t_0)$ generated by the unperturbed (but possibly time-dependent) part H_0^0 is assumed known.

For $n=1,2,\ldots$, let V^n be an ε and time-dependent operator as in (2.86) and V_ε^n as in (2.87) with an ε-expansion,

$$V_\varepsilon^n=\sum_{p=0}^{\infty}\frac{\varepsilon^p}{p!}W_{p+1}^n\in\mathscr{C}_{sa}(\mathbb{H}), \tag{4.59}$$

in terms of ε-independent time-dependent operators $W_p^n\in\mathscr{C}_{sa}(\mathbb{H})$. Let $\widetilde{\Phi^n}(\varepsilon)$ and $\Phi_t^n(\varepsilon)$ be generated by V^n (resp., V_t^n) and defined as in (2.89). Each t and ε $\Phi_t^n(\varepsilon)$ defines a transformation $\Phi_t^n(\varepsilon)^*$ on $\mathscr{C}_{sa}(\mathbb{H})$ as given in (3.34). As in (3.35) this transformation is expanded in terms of time-dependent linear operators T_p^n acting on $\mathscr{C}_{sa}(\mathbb{H})$,

$$\Phi_t^n(\varepsilon)^*=\sum_{p=0}^{\infty}\frac{\varepsilon^p}{p!}T_p^n, \tag{4.60}$$

where the T_p^n are then recursively defined through $T_0^n=\mathbb{1}_{\mathscr{C}_{sa}(\mathbb{H})}$ and

$$T_{p+1}^n=\sum_{l=0}^{p}\binom{p}{l}.\mathscr{AD}_{W_{l+1}^n}\circ T_{p-l}^n. \tag{4.61}$$

For each n we define

$$\widetilde{\Phi^n}(\varepsilon)^*:\mathscr{C}_{sa}(\mathbb{H})\to\mathscr{C}_{sa}(\mathbb{H}),$$
$$F\mapsto\widetilde{\Phi^n}(\varepsilon)^*F, \tag{4.62}$$

where

$$\widetilde{\Phi^n}(\varepsilon)^*F(t):=\Phi_t^n(\varepsilon)^\dagger\left(F(t)-\int_0^\varepsilon d\lambda\,\Phi_t^n(\lambda)\,\frac{\partial V^n}{\partial t}(t,\lambda)\Phi_t^n(\lambda)^\dagger\right)\Phi_t^n(\varepsilon), \tag{4.63}$$

$$=\Phi_t^n(\varepsilon)^*\left(F(t)-\int_0^\varepsilon d\lambda\,\Phi_t^n(\lambda)\,\frac{\partial V^n}{\partial t}(t,\lambda)\Phi_t^n(\lambda)^\dagger\right). \tag{4.64}$$

With the help of $\widetilde{\Phi^1}(\varepsilon)$ we define the new HAMILTONian,

$$K^1(\varepsilon):=\widetilde{\Phi^1}(\varepsilon)^*H^0(\varepsilon)\in\mathscr{C}_{sa}(\mathbb{H}), \tag{4.65}$$

which is assumed to have the usual ε-expansion,

$$K^1(\varepsilon)=\sum_{p=0}^{\infty}\frac{\varepsilon^p}{p!}K^1_p, \tag{4.66}$$

in terms of time-dependent operators K^n_p. As shown in Section III C this leads to

$$K^1_0=H^0_0, \tag{4.67}$$

$$K^1_p=F^1_p-\mathscr{AD}_{H_0}(W^1_p)-\frac{\partial W^1_p}{\partial t}=F^1_p-\widetilde{\mathscr{AD}}_{H^0_0}(W^1_p),\quad \forall p\geqslant 1, \tag{4.68}$$

$$F^1_1:=H^0_1, \tag{4.69}$$

$$F^1_p:=H^0_p+\sum_{l=0}^{p-2}\binom{p-1}{l}(\mathscr{AD}_{W^1_{l+1}}(K^1_{p-l-1})+T^1_{p-l-1}H^0_{l+1}),\quad \forall p\geqslant 2. \tag{4.70}$$

As in the general theory the generator of $\widetilde{\Phi^1}(\varepsilon)$ is chosen as

$$W^1_1=S^{(\widetilde{H^0_0})}(F^1_1), \tag{4.71}$$

$$W^1_p=0,\quad \forall p\geqslant 2, \tag{4.72}$$

where $S^{(\widetilde{H^0_0})}(F^1_1)$ is defined as in (2.66). This implies

$$K^1_1=\overline{H^{0(\widetilde{H^0_0})}_0}, \tag{4.73}$$

$$K^1_{p+1}=\mathscr{AD}_{W^1_1}(K^1_p)+\sum_{l=0}^{p}\binom{p}{l}(\mathscr{AD}_{W^1_1})^{p-l}(H^0_{l+1}),\quad \forall p\geqslant 1. \tag{4.74}$$

After this first transformation we introduce the HAMILTONian $H^1(\varepsilon)$ which is considered as the perturbed HAMILTONian of the unperturbed part $H^0_0+\varepsilon\overline{H^{0(\widetilde{H^0_0})}_1}$:

$$H^1(\varepsilon):=K^1(\varepsilon)=\underbrace{H^0_0+\varepsilon\overline{H^{0(\widetilde{H^0_0})}_1}}+\sum_{p=2}^{\infty}\frac{\varepsilon^p}{p!}K^1_p \tag{4.75}$$

$$=\quad H^1_0\quad +\sum_{p=2}^{\infty}\frac{\varepsilon^p}{p!}H^1_p, \tag{4.76}$$

such that

$$H^1_0(\varepsilon)=H^0_0+\varepsilon\overline{H^{0(\widetilde{H^0_0})}_1},\quad H^1_1=0,\quad H^1_p=K^1_p,\quad \forall p\geqslant 2, \tag{4.77}$$

and $H^1(\varepsilon)$ has no perturbation of first order in ε.

By construction $\widetilde{H^1_0}$ is invariant under $\widetilde{\Phi}_{\widetilde{H^0_0}}(\tau)$ which is equivalent to [see the discussion following (3.15)]

$$(H^1_0)_t=\overset{-1}{\Phi}_{H^0_0}(t,t_0)^*(H^1_0)_{t_0}=\Phi_{H^0_0}(t_0,t)^\dagger(H^1_0)_{t_0}\Phi_{H^0_0}(t_0,t), \tag{4.78}$$

for some $t_0\in\mathbb{R}$ and thus

$$\frac{d}{dt}(\overset{-1}{\Phi}_{H^0_0}(t,t_0)\circ\Phi_{H^1_0}(t,t_0))=-\frac{i}{\hbar}(H^1_0(\varepsilon)-H^0_0)_{t_0}(\overset{-1}{\Phi}_{H^0_0}(t,t_0)\circ\Phi_{H^1_0}(t,t_0)). \tag{4.79}$$

Of course, $H_0^1(\varepsilon)-H_0^0=\varepsilon\widetilde{H_1^{0(H_0^0)}}$ but we retain the form on the left-hand side in the expressions here such that their generalization to $n\geqslant 2$ is not obscured. The property (4.79) helps us to find the flow of H_0^1. Let $\Phi_{(H_0^1(\varepsilon)-H_0^0)_{t_0}}(t)$ be the solution of the *autonomous* initial value problem,

$$\frac{d}{dt}\Phi_{(H_0^1(\varepsilon)-H_0^0)_{t_0}}(t)=-\frac{i}{\hbar}(H_0^1(\varepsilon)-H_0^0)_{t_0}(\Phi_{(H_0^1(\varepsilon)-H_0^0)_{t_0}}(t)),\quad \Phi_{(H_0^1(\varepsilon)-H_0^0)_{t_0}}(t_0)=\mathbb{1}_{\mathbb{H}};\tag{4.80}$$

then (4.79) implies

$$\Phi_{H_0^1}(t,t_0)=\Phi_{H_0^0}(t,t_0)\circ\Phi_{(H_0^1(\varepsilon)-H_0^0)_{t_0}}(t).\tag{4.81}$$

Now we do a second transformation $\widetilde{\Phi^2}(\varepsilon)$ on $H^1(\varepsilon)$ such that

$$K^2(\varepsilon):=\widetilde{\Phi^2}(\varepsilon)*H^1(\varepsilon),\tag{4.82}$$

$$=K_0^2+\sum_{p=1}^{\infty}\frac{\varepsilon^p}{p!}K_p^2.\tag{4.83}$$

We choose the generating operator $V^2(\varepsilon)$ of $\widetilde{\Phi^2}(\varepsilon)$ as follows:

$$W_1^2=0,\tag{4.84}$$

$$W_p^2=S^{(\widetilde{H_0^1})}(H_p^1),\quad p=2,3,\tag{4.85}$$

$$W_p^2=0,\quad \forall p\geqslant 4,\tag{4.86}$$

which implies

$$K_0^2=H_0^1,\tag{4.87}$$

$$K_1^2=0,\tag{4.88}$$

$$K_2^2=\widetilde{H_2^{1(H_0^1)}},\tag{4.89}$$

$$K_3^2=\widetilde{H_3^{1(H_0^1)}},\tag{4.90}$$

$$K_{p+1}^2=\binom{p}{2}ad_{W_2^2}(K_{p-1}^2)+\binom{p}{3}ad_{W_3^2}(K_{p-2}^2)+\sum_{l=1}^{p}\binom{p}{l}T_{p-l}^2(H_{l+1}^1).\tag{4.91}$$

Here $K_0^2=H_0^1=H_0^0+\varepsilon\widetilde{H_1^{1(H_0^0)}}$ is the unperturbed Hamiltonian after the first step whose flow is found with the help of (4.81) using the solution of (4.80).

After the second transformation we introduce the HAMILTONian $H^2(\varepsilon)$, which is considered as the perturbed HAMILTONian of the unperturbed part $H_0^1+(\varepsilon^2/2!)\widetilde{H_2^{1(H_0^1)}}+(\varepsilon^3/3!)\widetilde{H_3^{1(H_0^1)}}$:

$$H^2(\varepsilon)=K^2(\varepsilon)=H_0^1+\frac{\varepsilon^2}{2!}\widetilde{H_2^{1(H_0^1)}}+\frac{\varepsilon^3}{3!}\widetilde{H_3^{1(H_0^1)}}+\sum_{p=2^2}^{\infty}\frac{\varepsilon^p}{p!}K_p^2 \tag{4.92}$$

$$= \underbrace{\qquad\qquad H_0^2 \qquad\qquad}+\sum_{p=2^2}^{\infty}\frac{\varepsilon^p}{p!}H_p^2, \tag{4.93}$$

such that $H_p^2=K_p^2$, $\forall p\geqslant 2^2$ and $H^2(\varepsilon)$ has no perturbation of second and third order in ε. Again by construction H_0^2 is invariant under $\widetilde{\Phi}_{H_0^1}(\tau)$ and thus [see the discussion following (3.15)]

$$\frac{d}{dt}(\overset{-1}{\Phi}_{H_0^1}(t,t_0)\circ\Phi_{H_0^2}(t,t_0))=-\frac{i}{\hbar}(H_0^2(\varepsilon)-H_0^1(\varepsilon))_{t_0}(\overset{-1}{\Phi}_{H_0^1}(t,0)\circ\Phi_{H_0^2}(t,t_0)), \tag{4.94}$$

the solution of which permits us to compute

$$\Phi_{H_0^2}(t,t_0)=\Phi_{H_0^1}(t,t_0)\circ\Phi_{(H_0^2(\varepsilon)-H_0^1(\varepsilon))_{t_0}}(t). \tag{4.95}$$

Now transform $H^2(\varepsilon)$ with a third transformation $\widetilde{\Phi^3}(\varepsilon)\ldots$, and so on and so forth.

D. Summary of time-dependent quantum mechanical KAM algorithm

Let us summarize the algorithmic procedure of the time-dependent KAM method. Let N be the desired order of approximation. After $n-1$ transformations we have a HAMILTONian,

$$H^{n-1}(\varepsilon)=H_0^{n-1}(\varepsilon)+\sum_{p=2^{n-1}}^{\infty}\frac{\varepsilon^p}{p!}H_p^{n-1}, \tag{4.96}$$

where we know the time evolution $\Phi_{H_0^{n-1}(\varepsilon)}(t,t_0)$ generated by the unperturbed part after the nth step. Starting with $n=1$ do the following loop.

Step 1: For $2^{n-1}\leqslant p<\min(N,2^n)$ compute

$$S^{\widetilde{(H_0^{n-1})}}(H_p^{n-1})=\lim_{T\to\infty}\frac{1}{T}\int_0^T d\tau\int_0^\tau d\sigma\ \Phi_{H_0^{n-1}(\varepsilon)}(t-\sigma,t)^\dagger H_p^{n-1}(t-\sigma)\Phi_{H_0^{n-1}(\varepsilon)}(t-\sigma,t), \tag{4.97}$$

and set

$$W_p^n=\begin{cases}S^{\widetilde{(H_0^{n-1})}}(H_p^{n-1}), & \text{if } 2^{n-1}\leqslant p<2^n,\\ 0 & \text{otherwise}\end{cases}. \tag{4.98}$$

Step 2: For $p=1,\ldots,N$ compute the T_p^n from $T_0^n=\mathbb{1}_{\mathscr{C}_{sa}(\mathbb{H})}$ and

$$T_{p+1}^n=\sum_{l=0}^{p}\binom{p}{l}.\mathscr{AD}_{W_{l+1}^n}\circ T_{p-l}^n. \tag{4.99}$$

Step 3: For $p=0,\ldots,N$ set

$$K_0^n=H_0^{n-1}\quad\text{and}\quad K_p^n=0,\quad\text{if } 1\leqslant p<2^{n-1}, \tag{4.100}$$

and compute successively the right-hand side of

$$K_p^n=\begin{cases} \overline{H_p^{n-1}(\widetilde{H_0^{n-1}})}, & \text{if } 2^{n-1}\leqslant p<2^n,\\ \displaystyle\sum_{l=2^{n-1}-1}^{p-1}\binom{p-1}{l}(\mathscr{AD}_{W_{l+1}^n}(K_{p-l-1}^n)+T_{p-l-1}^n(H_{l+1}^{n-1})), & \text{if } 2^n\leqslant p\leqslant N,\end{cases} \tag{4.101}$$

where

$$\overline{H_p^{n-1}}(\widetilde{H_0^{n-1}})=\lim_{T\to\infty}\frac{1}{T}\int_0^T d\tau\,\Phi_{H_0^{n-1}(\varepsilon)}(t-\tau,t)^\dagger H_p^{n-1}(t-\tau)\Phi_{H_0^{n-1}(\varepsilon)}(t-\tau,t). \tag{4.102}$$

Step 4: Set

$$H_0^n=H_0^{n-1}+\sum_{p=2^{n-1}}^{2^n-1}\frac{\varepsilon^p}{p!}\overline{H_p^{n-1}}(\widetilde{H_0^{n-1}}), \tag{4.103}$$

$$H_p^n=K_p^n,\quad \text{for } 2^n\leqslant p\leqslant N, \tag{4.104}$$

and find the solution $\Phi_{(H_0^n(\varepsilon)-H^{n-1}(\varepsilon))_{t_0}}(t)$ of the autonomous initial value problem,

$$\frac{d}{dt}\Phi_{(H_0^n(\varepsilon)-H_0^{n-1}(\varepsilon))_{t_0}}(t)=\left(-\frac{i}{\hbar}(H_0^n(\varepsilon)-H_0^{n-1}(\varepsilon))_{t_0}\right)\Phi_{(H_0^n(\varepsilon)-H_0^{n-1}(\varepsilon))_{t_0}}(t),$$

$$\Phi_{(H_0^n(\varepsilon)-H^{n-1}(\varepsilon))_{t_0}}(t_0)=\mathbb{1}_{\mathrm{H}}, \tag{4.105}$$

and compute the flow of $H_0^n(\varepsilon)$ as

$$\Phi_{H_0^n(\varepsilon)}(t,t_0)=\Phi_{H_0^{n-1}(\varepsilon)}(t,t_0)\Phi_{(H_0^n(\varepsilon)-H_0^{n-1}(\varepsilon))_{t_0}}(t). \tag{4.106}$$

Step 5: Find the solution $\Phi_t^n(\varepsilon)$ of

$$\frac{d}{d\varepsilon}\Phi_t^n(\varepsilon)=-\frac{i}{\hbar}V^n(t,\varepsilon)\Phi_t^n(\varepsilon),\quad \Phi_t^n(0)=\mathbb{1}_{\mathrm{H}}, \tag{4.107}$$

and its inverse $\overset{-1}{\Phi}_t(\varepsilon)$ or, if no such solution can be found approximate this solution by computing successively for $p=1,\ldots,N-1$,

$$(\Phi_{p+1}^n)_t=-\frac{i}{\hbar}\sum_{l=0}^{p}\binom{p}{l}(\Phi_{p-l}^n)_t(W_{l+1}^n)_t, \tag{4.108}$$

starting with $(\Phi_0^n)_t=\mathbb{1}_{\mathrm{H}}$. $\Phi_t^n(\varepsilon)$ is then approximated by

$$\Phi_t^n(\varepsilon)=\underbrace{\sum_{p=0}^{N}\frac{\varepsilon^p}{p!}(\Phi_p^n)_t}_{=:\Phi_t^n(\varepsilon)^N}+\mathscr{O}(\varepsilon^{N+1}). \tag{4.109}$$

Step 6: If $N=$desired order$>2^n$ replace n by $n+1$ and start over with *Step 1* otherwise compute the desired approximation to the time-evolution generated by $H(\varepsilon)$ as

$$\Phi_t^1(\varepsilon)\cdots\Phi_t^n(\varepsilon)\Phi_{H_0^0}(t,t_0)\Phi_{(H_0^1-H_0^0)_{t_0}}(t)\cdots\Phi_{(H_0^n-H_0^{n-1})_{t_0}}(t)\overset{-1}{\Phi}{}^n_{t_0}(\varepsilon)\cdots\overset{-1}{\Phi}{}^1_{t_0}(\varepsilon)$$
$$=\Phi_{H(\varepsilon)}(t,t_0)+\mathcal{O}(\varepsilon^{N+1}). \tag{4.110}$$

V. EXAMPLE: SPIN RESONANCE

A. The system

As an illustration of the methods we apply the POINCARÉ–VON ZEIPEL and KAM methods as well as the standard DYSON expansion and a numerical integration to a simple system consisting of a spin $\frac{1}{2}$-particle in an oscillating magnetic field. More precisely, we have $\mathbb{H}=\mathbb{C}^2\ni\psi$ and

$$i\hbar\frac{d}{dt'}\psi(t',t_0')=-\mu\vec{S}\cdot\vec{B}(t')\psi(t',t_0'), \tag{5.1}$$

where μ is some constant with units $s^{-1}\cdot\text{Gauss}^{-1}$, $\vec{S}=(\hbar/2)\vec{\sigma}$ is the spin-operator expressed with the help of the PAULI-matrices σ_j, $j=1,2,3$, and

$$\vec{B}(t')\coloneqq\begin{pmatrix}B_{0x}\cos(\omega t')\\0\\B_{0z}\end{pmatrix},\quad B_{0x},B_{0z}=\text{const} \tag{5.2}$$

is the magnetic field.

Such a system has also been investigated with more standard techniques and in lower orders by SHIRLEY[25] and SAMBE.[17]

We shall only consider the ''initial time'' $t_0'=0$ and use the abbreviation $\psi(t')=\psi(t',0)$. In this system $-\mu B_{0z}S_3$ is the unperturbed part and $-\mu B_{0x}\cos(\omega t')S_1$ is the perturbation whose strength is proportional to B_{0x} and which depends on the frequency ω as an additional parameter.

Using the dimensionless variable $t=\omega t'$, the dimensionless parameters $a\coloneqq-\mu B_{0z}/\omega$ and $\varepsilon\coloneqq-\mu B_{0x}/\omega$, and $\chi(t)\coloneqq\psi(t/\omega)$ the system (5.1) may be written as

$$i\hbar\frac{d}{dt}\chi(t)=(\underbrace{aS_3}_{=:H_0}+\varepsilon\underbrace{S_1\cos(t)}_{=:H_1(t)})\chi(t) \tag{5.3}$$

and it is this system which we will investigate with the approximations presented in the previous Sections. Note that a is inversely proportional to the perturbation frequency ω and that $a=1$ is a resonant case which leads to strongly divergent behavior in all perturbation methods described below.

The unperturbed system is time-independent and its flow is

$$\Phi_{H_0}(t,0)=\exp\left(-\frac{iat}{\hbar}S_3\right)=\begin{pmatrix}e^{(-iat/2)}&0\\0&e^{(iat/2)}\end{pmatrix}. \tag{5.4}$$

Let us now turn to the different perturbation methods applied to the HAMILTONian $H(\varepsilon)=H_0+\varepsilon H_1(t)$.

B. Standard time-dependent perturbation theory

The standard perturbative approach to time-dependent problems of this kind in quantum mechanics can be found in most textbooks on quantum mechanics[26,27] and is commonly referred to as the DYSON expansion.

Suppose we know the flow $\Phi_{H_0}(t,t_0)$ of $H_0\in\mathscr{C}_{sa}(\mathbb{H})$ and would like to find the flow of the perturbed HAMILTONian $H(\varepsilon)\coloneqq H_0+\varepsilon H_1$ where $H_1\in\mathscr{C}_{sa}(\mathbb{H})$ is the perturbation. Time-dependent quantum mechanical perturbation theory consists of an iteration of the integral version of the time-dependent SCHRÖDINGER equation (2.46) in the interaction picture and leads to the following approximation to the time evolution:

$$\Phi_{H(\varepsilon)}(t,t_0)=\Phi_{H_0}(t,t_0)+\sum_{p=1}^{\infty}\varepsilon^p\Phi(t,t_0)^{(p)}_{STAN}, \tag{5.5}$$

where the operator $\Phi(t,t_0)^{(p)}_{STAN}$ is given by

$$\begin{aligned}\Phi(t,t_0)^{(p)}_{STAN}=&\frac{1}{(i\hbar)^p}\int_{t_0}^{t}dt_p\int_{t_0}^{t_p}dt_{p-1}\cdots\int_{t_0}^{t_2}dt_1\Phi_{H_0}(t,t_p)H_1(t_p)\\&\times\Phi_{H_0}(t_p,t_{p-1})\cdots\Phi_{H_0}(t_2,t_1)H_1(t_1)\Phi_{H_0}(t_1,t_0).\end{aligned} \tag{5.6}$$

To illustrate the so called secular terms it is sufficient to consider the following trivial example. Let H_0 be time-independent such that $\Phi_{H_0}(t,t_0)=\exp\{-[i(t-t_0)/\hbar\,]H_0\}$ and $H_1=H_0$. Obviously then

$$\Phi(t,t_0)^{(1)}_{STAN}=\exp\left(-\frac{i(t-t_0)}{\hbar}H_0\right)\left(-\frac{i(t-t_0)}{\hbar}H_0\right), \tag{5.7}$$

which is, of course, the first order term in the expansion,

$$\exp\left(-\frac{i(t-t_0)}{\hbar}(1+\varepsilon)H_0\right)=\exp\left(-\frac{i(t-t_0)}{\hbar}H_0\right)\left(\mathbb{1}-\varepsilon\,\frac{i(t-t_0)}{\hbar}H_0+\cdots\right), \tag{5.8}$$

of the exact solution but which is an unbounded (operator valued) function of t. Hence this method of approximating the true time evolution can only be reliable for fairly short time-differences $t-t_0$ and it will in general *violate unitarity* for sufficiently large times. It is the absence of this feature which makes the perturbation methods based on time-dependent averaging which we have presented in this paper so rather attractive. It is straightforward to compute the approximations $\Phi(t,0)^{(p)}_{STAN}$ in the expansion (5.5) for the example at hand and one finds

$$\begin{aligned}&\Phi(t,0)^{(1)}_{STAN}\\&=\frac{1}{2(a^2-1)}\begin{pmatrix}0 & ae^{(-iat/2)}-(a\,\cos(t)-i\,\sin(t))e^{(iat/2)}\\(a\,\cos(t)+i\,\sin(t))e^{(-iat/2)}-ae^{(iat/2)} & 0\end{pmatrix},\end{aligned} \tag{5.9}$$

for the first order term, still free of secular terms. The second order term has the form

$$\Phi(t,0)^{(2)}_{STAN}=\frac{-1}{16(a^2-1)^2}\begin{pmatrix}\Phi(t,0)^{(2)}_{11} & 0\\0 & \Phi(t,0)^{(2)}_{22}\end{pmatrix}, \tag{5.10}$$

where the matrix entries are

$$\begin{aligned}\Phi(t,0)^{(2)}_{11}=&e^{(-iat/2)}(1+3a^2+4ae^{(iat)}(i\,\sin(t)-a\,\cos(t))\\&+(a^2-1)(\cos(2t)+ia\,\sin(2t)+\underline{2iat})),\end{aligned} \tag{5.11}$$

$$\begin{aligned}\Phi(t,0)^{(2)}_{22}=&e^{(iat/2)}(1+3a^2-4ae^{(-iat)}(i\,\sin(t)+a\,\cos(t))\\&+(a^2-1)(\cos(2t)-ia\,\sin(2t)-\underline{2iat}))\end{aligned} \tag{5.12}$$

and we have underlined the *secular* terms which are proportional to t in this order which will lead to terms proportional to $t^2,t^3,\ldots,$ in higher orders.

C. Time-dependent Poincaré–von Zeipel

Let us now apply the POINCARÉ–VON ZEIPEL algorithm as outlined in Section III D to the system (5.3). Calculating up to $N=2$ one finds easily for the terms in *Step 1*: (in Section III D)

$$K_1 = 0_{2\times 2}, \tag{5.13}$$

$$W_1 = \frac{1}{a^2-1}(a\ \cos(t)S_2 - \sin(t)S_1), \tag{5.14}$$

$$F_2 = \frac{a\ \cos^2(t)}{a^2-1}S_3 = \frac{\cos^2(t)}{a^2-1}H_0, \tag{5.15}$$

$$K_2 = \frac{a}{2(a^2-1)}S_3 = \frac{1}{2(a^2-1)}H_0, \tag{5.16}$$

$$W_2 = \frac{a\ \sin(2t)}{4(a^2-1)}S_3 = \frac{\sin(2t)}{4(a^2-1)}H_0. \tag{5.17}$$

For $\Phi_t^2(\varepsilon)$ in *Step 2* we find

$$\Phi_t^2(\varepsilon) = \left(1 - \frac{\varepsilon^2\ \cos^2(t)}{4} - \frac{1}{4(a^2-1)}\right)\mathbb{1} - \frac{i\varepsilon a\ \cos(t)}{2(a^2-1)}\sigma_2 + \frac{i\varepsilon\ \sin(t)}{2(a^2-1)}\sigma_1 - \frac{i\varepsilon^2 a\ \sin(2t)}{8(a^2-1)}\sigma_3. \tag{5.18}$$

For $N=2$ the solution requested in *Step 3* is

$$\Phi^2_{(K(\varepsilon)-H_0)_0}(t,0) = \begin{pmatrix} e^{[-(iat)/2]-\varepsilon^2\{(iat)/[8(a^2-1)]\}} & 0 \\ 0 & e^{[(iat)/2]+\varepsilon^2\{(iat)/[8(a^2-1)]\}} \end{pmatrix}, \tag{5.19}$$

and it is now straightforward to calculate (though tedious to write down which is why we shall not do so) the second-order approximation to the time evolution as given in *Step 4*:

$$\Phi_{H(\varepsilon)}(t,0) = \Phi_t^2(\varepsilon)\circ\Phi_{H_0}(t,0)\circ\Phi^2_{(K(\varepsilon)-H_0)_0}(t,0)\circ\overset{-1}{\Phi}{}_0^2(\varepsilon) + \mathcal{O}(\varepsilon^3), \tag{5.20}$$

by insertion of the relevant terms from (5.18) and (5.19). From this it also follows that, in contrast to the second order approximation (5.11) calculated in standard perturbation theory, the second order approximation computed from the time-dependent POINCARÉ–VON ZEIPEL *is bounded as a function of* t.

D. KAM algorithm

Let us briefly summarize the results of *Step 1–Step 4* for the KAM algorithm up to $N=2$:

$$\widetilde{\overline{H_1^{0(H_0^0)}}} = 0_{2\times 2}, \tag{5.21}$$

$$W_1^1 = \frac{1}{a^2-1}(a\ \cos(t)S_2 - \sin(t)S_1), \tag{5.22}$$

$$H_2^1 = \frac{a\ \cos^2(t)}{a^2-1}S_3, \tag{5.23}$$

$$\widetilde{\overline{H_2^{1(H_0^1)}}} = \frac{a}{2(a^2-1)}S_3, \tag{5.24}$$

$$H_0^2 = \left(a + \varepsilon^2\frac{a}{4(a^2-1)}\right)S_3, \tag{5.25}$$

$$W_2^2=\frac{a\ \sin(2t)}{4(a^2-1)}S_3, \tag{5.26}$$

$$\Phi_{H_0^1}(t,0)=\Phi_{H_0^0}(t,0), \tag{5.27}$$

$$\Phi_{H_0^2}(t,0)=\begin{pmatrix} e^{[-(iat)/2]-\varepsilon^2\{(iat)/[8(a^2-1)]\}} & 0 \\ 0 & e^{[(iat)/2]+\varepsilon^2\{(iat)/[8(a^2-1)]\}} \end{pmatrix}, \tag{5.28}$$

$$=\Phi_{H_0^0}(t,0)\Phi_{(H_0^1(\varepsilon)-H_0^0)_0}(t)\Phi_{(H_0^2(\varepsilon)-H_0^1(\varepsilon))_0}(t), \tag{5.29}$$

which so far is equivalent to the POINCARÉ–VON ZEIPEL results. However, because of the choice (4.98) for the W_p^1 we can find the exact solution $\Phi_t^1(\varepsilon)$ of (4.107) as

$$\Phi_t^1(\varepsilon)=\cos\left(\frac{\varepsilon\sqrt{a^2\ \cos^2(t)+\sin^2(t)}}{2(a^2-1)}\right)\mathbb{1}-\frac{2i\ \sin\left(\frac{\varepsilon\sqrt{a^2\ \cos^2(t)+\sin^2(t)}}{2(a^2-1)}\right)}{\sqrt{a^2\ \cos^2(t)+\sin^2(t)}}(a\ \cos(t)S_3-\sin(t)S_1). \tag{5.30}$$

Hence, the KAM approximation up to second order,

$$\Phi_{H(\varepsilon)}(t,t_0)=\Phi_t^1(\varepsilon)\Phi_t^2(\varepsilon)\Phi_{H_0^0}(t,0)\Phi_{(H_0^1-H_0^0)_0}(t)\Phi_{(H_0^2-H_0^1)_0}(t)\overset{-1}{\Phi}{}_0^2(\varepsilon)\overset{-1}{\Phi}{}_0^1(\varepsilon)+\mathcal{O}(\varepsilon^3), \tag{5.31}$$

differs from the POINCARÉ–VON ZEIPEL approximation and, as can be seen in Section V E, this difference seems to further improve the quality of the approximation.

E. Comparing the transition-probability

Suppose that at the initial time $t_0=0$ the system is in a spin-up eigenstate,

$$\chi(0)\coloneqq\begin{pmatrix}1\\0\end{pmatrix}. \tag{5.32}$$

We can then compute the state at a later time t,

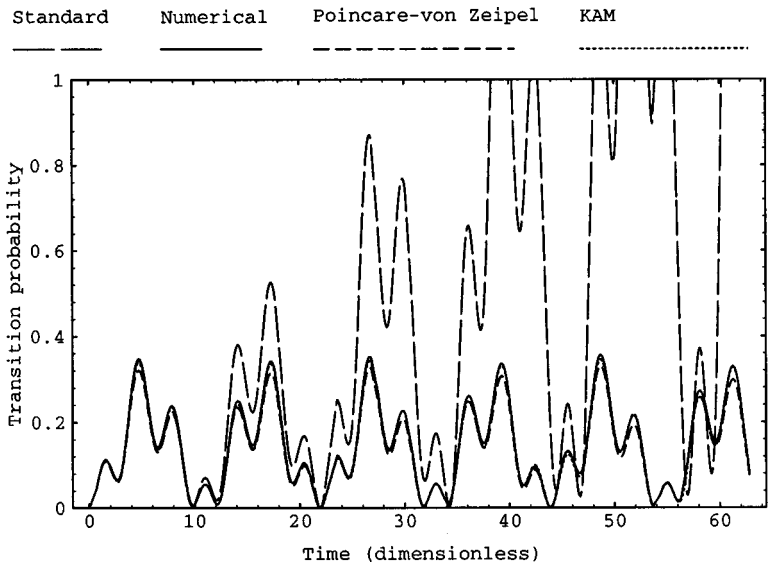

FIG. 2. Transition probability $|\chi_-(t)|^2$ for $a=0.5$ and $\varepsilon=0.7$ computed by different methods.

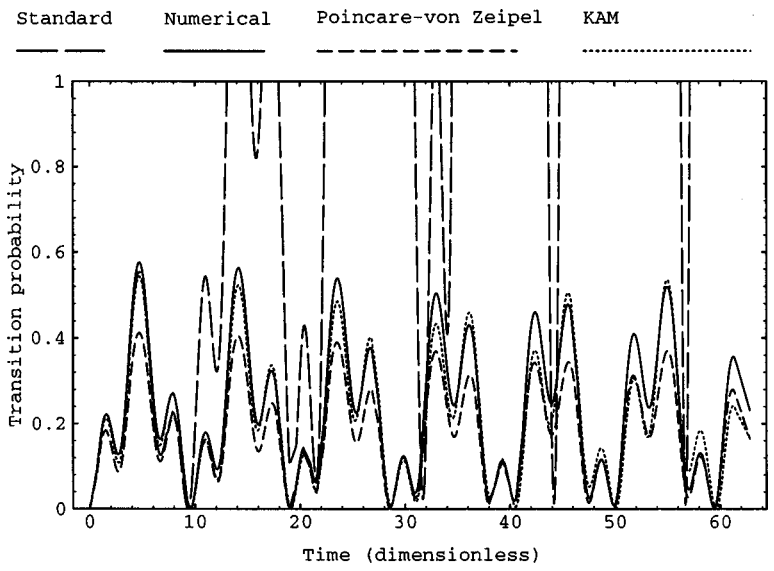

FIG. 3. Transition probability $|\chi_-(t)|^2$ for $a=0.5$ and $\varepsilon=1$ computed by different methods.

$$\chi(t) \coloneqq \begin{pmatrix} \chi_+(t) \\ \chi_-(t) \end{pmatrix} = \Phi_{H(\varepsilon)}(t,0)\chi(0), \tag{5.33}$$

to a desired order in ε with the various approximations to the time evolution given in the previous Sections. In what follows we shall compare the results for the *transition-probability*,

$$P_{+\to-}(t) = |\chi_-(t)|^2, \tag{5.34}$$

from the initial spin-up state to the spin-down state computed up to *fourth order* in ε with the standard, POINCARÉ–VON ZEIPEL and the KAM algorithm and compare it furthermore with a numerical solution of (5.3) using a numerical algorithm contained in the Mathematica package.

Figures 2–4 show $|\chi_-(t)|^2$ for $a=0.5$ and increasing perturbation $\varepsilon=0.7,1,1.3$. Figure 2 shows that the standard perturbation result is quite good for short times $t\leqslant 11$ but then increasingly deviates from the numerical result and violates unitarity due to the presence of secular terms, whereas POINCARÉ–VON ZEIPEL as well as the KAM method reproduce the numerical result with

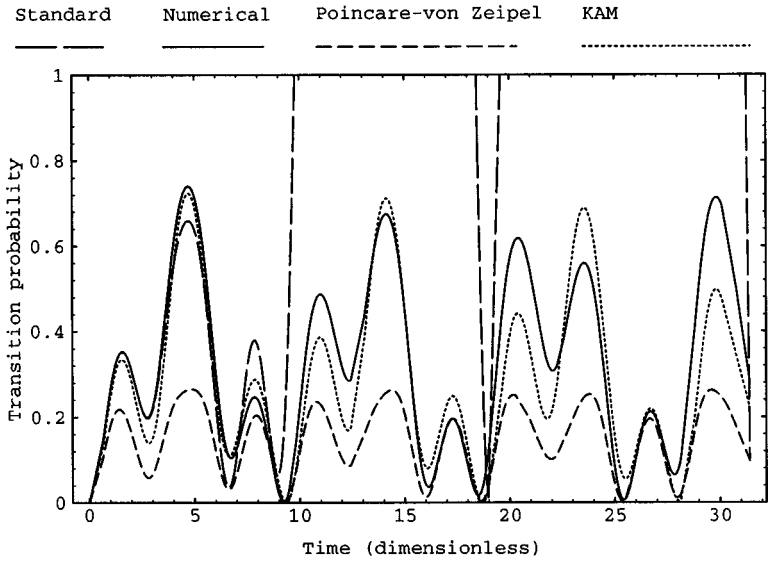

FIG. 4. Transition probability $|\chi_-(t)|^2$ for $a=0.5$ and $\varepsilon=1.3$ computed by different methods.

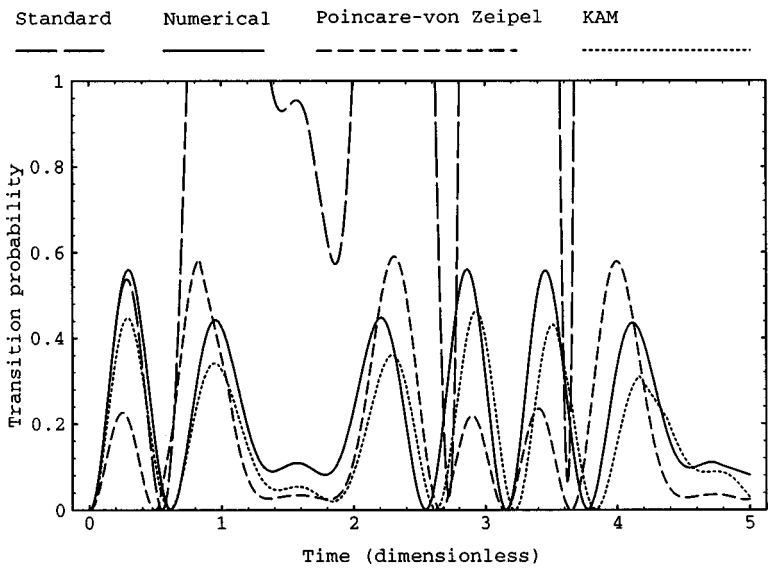

FIG. 5. Transition probability $|\chi_-(t)|^2$ for $a=7$ and $\varepsilon=8$ computed by different methods.

great accuracy and for arbitrarily long times in the case of small perturbation $\varepsilon=0.7$. As the perturbation increases in strength ($\varepsilon=1$ in Fig. 3 and $\varepsilon=1.3$ in Fig. 4) POINCARÉ–VON ZEIPEL deviates more strongly from the numerical result while the KAM method remains still close to it. This behavior is also reproduced for smaller perturbing frequencies (i.e., larger a) as can be seen from Fig. 5. As is evident from all figures, the time-span of reliability for the standard result decreases with increasing perturbation.

VI. CONCLUSION

Using time-dependent averaging we have constructed POINCARÉ–VON ZEIPEL and KAM perturbation methods originating from classical systems for self-adjoint operators. Unlike the time-independent case[3–5] here *both* algorithms give rise to *new* perturbation theories.

The POINCARÉ–VON ZEIPEL algorithm consists of constructing one ε-dependent transformation $\widetilde{\Phi}(\varepsilon)$ on the extended phase space. This transformation is built up successively by an appropriate choice of the generating function V and if projected down to the non-extended phase space it yields different transformations $\Phi_{t_0}(\varepsilon)$ at t_0 and $\Phi_t(\varepsilon)$ at t. The new HAMILTONian $K(\varepsilon)$ is then invariant under the unperturbed flow and its flow can be found by solving a time-independent initial value problem. If we can determine $\Phi_t(\varepsilon)$ exactly and find the flow of $(K(\varepsilon)-H_0)_{t_0}$, then the problem is exactly solved by

$$\Phi_t(\varepsilon)\Phi_{H_0}(t,t_0)\Phi^{-1}_{(K(\varepsilon)-H_0)_{t_0}}(t)\Phi_{t_0}(\varepsilon). \tag{6.1}$$

This, for example, is the case in an application of the theory to a driven harmonic oscillator[28] where one can show inductively that all W_p and K_p vanish for big enough p. In such a case the method tells us immediately that we must have the exact solution.

In general, however, $\Phi_t(\varepsilon)$ cannot be determined exactly, since it may be that not all W_p can be computed or we might not be able to solve (2.91). One may resort to an approximation of the type (3.74) which, however, does not respect unitarity. A unitary approximation to $\Phi_t(\varepsilon)$ can be obtained by attempting to solve

$$\frac{d}{d\varepsilon}\Phi^N_t(\varepsilon)=-\frac{i}{\hbar}\Phi_t(\varepsilon)\sum_{p=0}^{N}\frac{\varepsilon^p}{p!}W_p \quad \text{and} \quad \Phi^N_t(0)=\mathbb{1}, \quad \forall t\in\mathbb{R}. \tag{6.2}$$

Note that in general the approximation (6.1) contains all orders of ε through $\Phi_{(K(\varepsilon)-H_0)_{t_0}}(t)$ [they may also enter by solving (6.2)].

An approximation similar to the POINCARÉ–VON ZEIPEL method has also been constructed by KUMMER and GOMPA using the normal form approach.[8,9] They use this method to transform to a new HAMILTONian by algebraic means and derive rigorous bounds on the deviation from the true time evolution. Their algebraic construction requires solutions of operator equations which are provided by our time-dependent averaging.

The time-dependent KAM method consists of an iterative application of the POINCARÉ–VON ZEIPEL algorithm with a judicious choice of the generators W_p^n. The approximation to the time evolution is then

$$\Phi_t^1(\varepsilon)\cdots\Phi_t^n(\varepsilon)\Phi_{H_0^0}(t,t_0)\Phi_{(H_0^1-H_0^0)_{t_0}}(t)\cdots\Phi_{(H_0^n-H_0^{n-1})_{t_0}}(t)\overset{-1}{\Phi}{}_{t_0}^n(\varepsilon)\cdots\overset{-1}{\Phi}{}_{t_0}^1(\varepsilon). \tag{6.3}$$

Here the particular choice of the W_p^n, as given in (4.98), makes it much easier to solve for the $\Phi_t^n(\varepsilon)$ in

$$\frac{d}{d\varepsilon}\Phi_t^n(\varepsilon)=-\frac{i}{\hbar}\Phi_t(\varepsilon)V^n(t,\varepsilon) \quad \text{and} \quad \Phi_t^n(0)=\mathbb{1}, \quad \forall t\in\mathbb{R}. \tag{6.4}$$

In particular $\Phi_t^1(\varepsilon)$ can always be found by integration. Thus, if all Φ_t^n up to some N can be found and the flows of the autonomous HAMILTONians $(H_0^n-H_0^{n-1})_{t_0}$ [which are simpler than $K(\varepsilon)-H_0$ above as well] can be found, then we have an approximation to the time evolution respecting unitarity.

The applicability of the resulting theories is not confined to just quantum mechanics—or quantum field theory for that matter—but *includes any self-adjoint operator* on a complex HILBERT space for which the solution of a SCHRÖDINGER-type flow equation (2.46) is sought.

These theories are thus *generic* in the sense that they are completely independent of the particular form of the operator and, as far as the general theory is concerned, the phrases ''in quantum mechanics, in the quantum case,'' etc. are synonymous with ''for self-adjoint operators.'' From the physicist's point of view, however, it is indeed quantum theory which comprises the most prominent application of these theories.

The lack of rigorous convergence results is certainly something to be remedied in the future. In particular it will have to be established for which operators the averaging construction (2.64)–(2.66) can be defined rigorously and for which perturbations the resulting series converges to a well defined operator-valued function of ε. It would be futile, however, to insist on such results at this stage. The purpose of this work is to develop the complete formalisms suitable for immediate applications. Only now that these theories are available on the formal level, it becomes fully clear which questions have to be answered by mathematics and which tools might be most suited for that purpose.

A uniqueness theorem for distributions and its application to nonlocal quantum field theory

M. A. Soloviev[a)]
Department of Theoretical Physics, P. N. Lebedev Physical Institute, Leninsky prosp. 53, Moscow 117924, Russia

(Received 15 July 1997; accepted for publication 5 November 1997)

It is shown that if a distribution $u \in \mathscr{D}'(\mathbb{R}^n)$ has support in a convex cone not containing a straight line and its Fourier transform is carried by a closed cone K different from the whole space, i.e., $\tilde{u} \in \tilde{\mathscr{D}}'(K)$, $K \neq \mathbb{R}_n$, then u is zero. This result leads to a new and most general proof of the PCT theorem which covers nonlocal quantum fields with arbitrary high-energy behavior. © *1998 American Institute of Physics.* [S0022-2488(98)03504-X]

I. INTRODUCTION

In the classical derivation[1,2] of the PCT theorem, quantum fields are assumed to have a finite order of singularity in the space–time variables, or equivalently, to grow in momentum space no faster than a polynomial. Such behavior is inherent in the terms of formal perturbation expansions rather than in exact solutions of relativistic quantum field theories,[3] but this assumption does not give rise to serious omissions since the theorem is directly extendable to Jaffe's strictly localizable theory[4] as well as to the most general formulation of local QFT in terms of hyperfunctions,[5] which allow for the possibility that the off-mass-shell amplitudes behave at high energies worse (the polynomial bound is changed for an exponential one), but leave the analyticity properties of the vacuum expectation values in coordinate space unaltered, and these properties play a leading role in the proof set forth in Refs. 1 and 2. Nevertheless, it is of principal interest to examine the case of arbitrary singularity, when the domain of analyticity is empty, first of all in order to more deeply understand to what extent locality is essential for the existence of the fundamental PCT symmetry. This problem was raised in important papers[6,7] by Lücke who proposed using the momentum-space analyticity properties of the expectation values in overcoming it and analyzed the relevant envelopes of holomorphy. Here we present an alternative proof of the generalized PCT theorem which covers nonlocal fields with arbitrary ultraviolet behavior and which is based on the employment of the analytic wave front set notion[8] and a new type of uniqueness theorem for distributions.

As in Ref. 7, we suppose the fields under study to be averaged with the test functions whose Fourier transform is just the Shwartz space $\mathscr{D}$ of infinitely differentiable functions of compact support, and we use the notation S^0 in place of $\tilde{\mathscr{D}}$, which is intended to stress that this is the smallest space among the Gelfand–Shilov[9] spaces S^β, $0 \leqslant \beta < 1$, traditionally used in nonlocal QFT. (So S^0 gives the widest framework for the treatment of field models with singular behavior in the ultraviolet domain.) The space $S^0(\mathbb{R}^n)$ consists of (the restrictions to $\mathbb{R}^n$ of) entire analytic functions on $\mathbb{C}^n$ with the property that

$$|f(z)| \leqslant C_f (1+|x|)^{-N} e^{b|y|}, \quad (z = x + iy) \tag{1}$$

for some f-dependent $b > 0$ and each $N = 1,2,\ldots$. For definiteness, we take the norm $|\cdot|$ in $\mathbb{R}^n$ to be Euclidean and, as usual, we shall use a prime to label the continuous dual space of a topological vector space. The main problem in dealing with the generalized functions belonging to S'^0 is to correctly generalize the notion of support because its conventional definition breaks down in this case, and so does the local commutativity (microcausality) axiom for the fields with configuration-space test functions in S^0. At this point our definitions and designations differ somewhat from

[a)]Electronic mail: soloviev@td.lpi.ac.ru

 © 1998 American Institute of Physics

those used in Refs. 6 and 7, with the correlation shown in Sec. VI. Namely, first we assign a related space $S^0(U)$ to every open cone $U\subset\mathbb{R}^n$. It consists of all entire functions satisfying the inequality

$$|f(z)|\leqslant C_f(1+|x|)^{-N}e^{b|y|+bd(x,U)}, \tag{2}$$

where $d(\cdot,U)$ is the distance of the point from U, and is regarded as the inductive limit[10] of the family of countably normed spaces $S^{0,b}(U)$ whose norms are defined by

$$\|f\|_{U,b,N}=\sup_z|f(z)|(1+|x|)^N e^{-b|y|-bd(x,U)}. \tag{3}$$

For each closed cone K, we also define a space $S^0(K)$ by taking another inductive limit through those U which contain the set $K\backslash 0$ and shrink to it. A closed cone $K\subset\mathbb{R}^n$ is said to be a *carrier* of a generalized function $w\in S'^0(\mathbb{R}^n)$ if w has a continuous extension to the space $S^0(K)$. We refer to previous papers[11,12] for a motivation of these definitions and for their connection with the theory of hyperfunctions. It is essential in particular that they are in accordance with the usual definition of support of tempered distribution, in the sense that if this support is contained in K, then the restriction of the distribution to S^0 is carried by K. When applied to QFT, the notion of carrier cone leads to the corresponding generalizations of local commutativity and weak local commutativity which we call asymptotic commutativity and weak asymptotic commutativity (WAC), respectively. The main purpose of the present work is to prove the equivalence of the latter condition to the PCT invariance.

In Sec. II, the precise formulations of the WAC condition and of the generalized PCT theorem are given. In Sec. III, we show that the space S^0 is dense in every $S^0(K)$, deriving this fact (important in what follows) as a consequence of an analogous property previously established[13] for the second Gelfand–Shilov scale of test function spaces S^0_α which provides the widest framework for construction of gauge models with singular infrared behavior.[14] In Sec. IV, a relation between the analytic wave front set of Schwartz distributions and the carrier cones of their Fourier transforms is established, which improves Lemma 8.4.17 of Ref. 8. In the next section, it is used in proving a uniqueness theorem which is central in our derivation of the PCT invariance and replaces the uniqueness properties of analytic functions exploited in the usual derivation. The last section is devoted to concluding remarks.

II. GENERALIZED PCT THEOREM

We follow the notation of Ref. 2 and assume that the fields $\varphi_1,\varphi_2,\ldots$ under consideration transform according to general irreducible representations $\mathscr{D}^{(j/2,k/2)}$ of the group $SL(2,\mathbb{C})$ covering the proper Lorentz group. Recall that a point $(\xi_1,\ldots,\xi_n)\in\mathbb{R}^{4n}$, is called a Jost point if the vector $\Sigma\lambda_i\xi_i\in\mathbb{R}^4$ is spacelike for all non-negative numbers λ_i such that $\Sigma\lambda_i>0$. These points form an open cone denoted by J_n. In the conventional formalism dealing with tempered distribution fields, J_n is contained in the analyticity domain of the Wightman functions

$$W_{\mu\ldots\nu}(\xi_1,\ldots,\xi_n)=\langle\Psi_0,\varphi_\mu(x_1)\ldots\varphi_\nu(x_{n+1})\Psi_0\rangle,\quad \xi_i=x_i-x_{i+1}. \tag{4}$$

In these points, all vectors x_i-x_j, $i\neq j$, are spacelike and Jost's version of the PCT theorem says that a field theory (of tempered growth) is PCT invariant if and only if

$$\langle\Psi_0,\varphi_\mu(x_1)\ldots\varphi_\nu(x_{n+1})\Psi_0\rangle=i^F\langle\Psi_0,\varphi_\nu(x_{n+1})\ldots\varphi_\mu(x_1)\Psi_0\rangle, \tag{5}$$

where F is the number of fields with half-integer spins involved in the vacuum expectation value. This relation is referred to as the weak local commutativity (WLC) condition and it takes the form

$$W_{\mu\ldots\nu}(\xi_1,\ldots,\xi_n)-i^F W^{\mathrm{rev}}_{\nu\ldots\mu}(-\xi_n,\ldots,-\xi_1)=0,\quad \xi\in J_n, \tag{6}$$

in terms of the Wightman functions depending on the relative coordinates ξ_i.

Definition: Let $\varphi_1,\varphi_2,\ldots$ be quantum fields with configuration-space test functions in $S^0(\mathbb{R}^4)$. Then we say that they satisfy the weak asymptotic commutativity (WAC) condition if, for any n, the left-hand side of Eq. (6) is carried by the cone $\mathsf{C}J_n$ complementary to the Jost cone.

Theorem 1: A quantum field theory defined over the test function space $S^0(\mathbb{R}^4)$ and satisfying all the Wightman axioms except for locality is PCT invariant if and only if the WAC condition is fulfilled.

Proof: Recall that in terms of the Wightman functions the PCT invariance is expressed by the relation

$$W_{\mu\ldots\nu}(\xi_1,\ldots,\xi_n)=i^F(-1)^J W^{\mathrm{rev}}_{\nu\ldots\mu}(\xi_n,\ldots,\xi_1), \tag{7}$$

where $J=j_1+\cdots+j_n$ is the total number of unpointed indices of the fields involved in the vacuum expectation value. Under the usual temperedness assumption, the conversion WLC$\rightarrow$(7) is carried out in two steps. First, since the proper complex Lorentz group $L_+(\mathbb{C})$ contains the total space–time reflection, the equality $W(\zeta)=(-1)^J W(-\zeta)$ holds in the analyticity domain extended by the Bargman–Hall–Wightman theorem, which enables one to convert the WLC condition to the form (7) in the Jost points. Second, since the distributions occurring in (7) are boundary values of analytic functions from the same tube, this implies their coincidence everywhere by the uniqueness properties of analytic functions. In our case, the analyticity domain is empty. Nevertheless, the difference

$$T=W(\xi)-(-1)^J W(-\xi) \tag{8}$$

is carried by the cone $\mathsf{C}J_n$ due to the Lorentz covariance and by virtue of the spectral condition

$$\mathrm{supp}\ \widetilde{W}\subset \overline{V_+}\times\cdots\times\overline{V_+}\,. \tag{9}$$

One can make sure of this by using the regularization of the high-energy behavior by multiplication with a Lorentz invariant function $h((\Sigma p_i)^2/\Lambda^2)$, where $h\in\mathscr{D}(\mathbb{R}^1)$ and $h(t)=1$ for $|t|\leqslant 1$. Then the generalized function (8) turns into a tempered distribution which has support in $\mathsf{C}J_n$ by the BHW theorem and hence belongs to $S'^0(\mathsf{C}J_n)$. On the other hand, $\widetilde{T}_\Lambda$ coincides with $\widetilde{T}$ in a neighborhood of the origin which enlarges indefinitely as $\Lambda\rightarrow\infty$, and this fact enables T to be extended to the space $S^0(\mathsf{C}J_n)$. However, here the denseness of S^0 in $S^0(U)$ is of prime importance and we put off the details of this extension up to the end of the next section. Writing the difference of the left-hand and right-hand sides of Eq. (7) as

$$\begin{aligned}W_{\mu\ldots\nu}(\xi_1,\ldots,\xi_n)-(-1)^J W_{\mu\ldots\nu}(-\xi_1,\ldots,-\xi_n)+(-1)^J[W_{\mu\ldots\nu}(-\xi_1,\ldots,-\xi_n)\\ -i^F W^{\mathrm{rev}}_{\nu\ldots\mu}(\xi_n,\ldots,\xi_1)],\end{aligned}$$

and taking into account the symmetry property $-J_n=J_n$, we conclude that this difference is carried by $\mathsf{C}J_n$ if the WAC condition is fulfilled. Theorem 4 established below shows that such a carrier property is compatible with the spectral condition (9) only if the difference is zero, which means the PCT invariance. Conversely, the relation (7) implies the fulfillment of the WAC condition by the same argument.

III. RELEVANT APPROXIMATION THEOREM

Theorem 2: For any open cone $U\subset\mathbb{R}^n$ and for each pair of positive numbers b', b such that $b'>2neb$, the space $S^{0,b'}$ is dense in $S^{0,b}(U)$ under the topology of $S^{0,b'}(U)$. As a consequence, S^0 is dense in $S^0(U)$.

An analogous theorem has been proved in Ref. 13 for the Banach spaces $S^{0,b}_{\alpha,a}(U)$, $\alpha>1$, whose norms are defined by a formula obtainable from (3) by the replacement $(1+|x|)^N\rightarrow\exp\{|x/a|^{1/\alpha}\}$. The assertion we now are interested in results from it and from the simple fact that the space $S^0_\alpha(U)=\mathrm{inj\ lim}\, S^{0,b}_{\alpha,a}(U)$ is dense in $S^0(U)$. The latter can be demonstrated in the following way. Let $f\in S^{0,b}(U)$ and $1<\alpha'<\alpha$. We choose a function $g\in S^{0,1}_{\alpha',1}$ such that $g(0)=1$ and consider the sequence $f_\nu(z)=f(z)g(z/\nu)$. If $\epsilon>0$ and $\nu>1/\epsilon$, then

$$|f_\nu(z)|\leqslant C_\nu\ \exp\{-|x|^{1/\alpha}+(b+\epsilon)|y|+bd(x,U)\}$$

and so $f_\nu \in S^{0,b+\epsilon}_{\alpha,1}(U)$. Let us show that under the condition $b' > b+\epsilon$ the sequence f_ν tends to f in every norm of $S^{0,b'}(U)$. We have

$$\|f-f_\nu\|_{U,b',N} \leqslant \|f\|_{U,b,N+1} \sup_z |1-g(z/\nu)|(1+|x|)^{-1}e^{-\epsilon|y|}.$$

Suppose that $\nu > 2/\epsilon$. Then $|1-g(z/\nu)| \leqslant C \exp\{\epsilon|y|/2\}$. Choose R so that the supremum over $|z| \geqslant R$ is less than $\delta\|f\|^{-1}_{U,b,N+1}$, and let ν be so large that the supremum over $|z| < R$ does not exceed the same number. Then $\|f-f_\nu\|_{U,b',N} < \delta$ as was to be shown. By Theorem 5 of Ref. 13, for any $b' > 2ne(b+\epsilon)$ and $a > 1$, the functions f_ν can be approximated in the topology of $S^{0,b'}_{\alpha,a}(U)$ by functions belonging to $S^{0,b'}_{\alpha,a}$, which completes the proof of Theorem 2 since this topology is finer than that of $S^{0,b'}(U)$ and ϵ can be taken arbitrarily small.

Corollary: The generalized function $T \in S'^0(\mathbb{R}^{4n})$ defined by (8) allows a unique continuous extension to the space $S^0(CJ_n)$.

Proof: Let us denote by T_Λ the result of the regularization specified in Sec. II. As already remarked, $T_\Lambda \in S'^0(U)$, with U any open cone such that $(\complement J_n)\backslash 0 \subset U$. By construction, the regularization does not change the value of $\tilde{T}$ on the functions belonging to $\mathscr{D}$ $(|p| < \Lambda/\sqrt{n})$. Set $\Lambda(b) = 10n^{3/2}eb$, $b' = 9neb$ and denote by $\hat{T}_b$ the restriction $T_\Lambda | S^{0,b}(U)$. Then T_Λ coincides with T on the elements of $S^{0,b'}$ since the Fourier transformation converts these into functions having support in the ball of radius b'. Let $f \in S^{0,b}(U)$ and let $B > b$. Applying Theorem 2 and choosing $f_\nu \in S^{0,b'}$ so that $f_\nu \to f$ in $S^{0,b'}(U)$, we get $(\hat{T}_B, f) = \lim(T, f_\nu) = (\hat{T}_b, f)$. By the definition of inductive limit topology, a family of linear forms coordinated in this manner determines an element $\hat{T} \in S'^0(U)$, and so we have obtained the desired result.

IV. ANALYTIC WAVE FRONT SET AND CARRIER CONES

We refer to Hörmander for definition of the analytic wave front set $\mathrm{WF}_A(u)$ of a distribution $u \in \mathscr{D}'(\mathscr{O})$, $\mathscr{O} \in \mathbb{R}^n$. This is a closed subset of $\mathscr{O} \times (\mathbb{R}^n \backslash 0)$ conic relative to the second variable, that is, invariant under multiplication of it by the positive numbers. The projection of $\mathrm{WF}_A(u)$ onto $\mathscr{O}$ consists of those points that have no neighborhood wherein u is an analytic function, and the cone attached to such a point is just the set of ''high-frequency'' directions responsible for the appearance of a singularity at this point, that is, of those relevant directions in which the Fourier transform $\tilde{u}$ behaves badly at infinity.

Recall that if V is a cone in $\mathbb{R}^n$, then its dual cone is defined by $V^* = \{\eta : \eta x \geqslant 0, \text{ for all } x \in V\}$. The cone V^* is closed and convex and has a nonempty interior int V^* if and only if V is proper, that is, the closure of its convex hull does not contain a straight line. A cone V is said to be compact in another cone V' if $\overline{V \backslash 0} \subset V'$, in which case the notation $V \Subset V'$ is used.

Theorem 3: If $u \in \mathscr{D}'$ and $\tilde{u}$ is carried by a closed cone K, then

$$WF_A(u) \subset \mathbb{R}^n \times K. \tag{10}$$

Proof: We denote $\tilde{u}$ by w and at first we suppose that K is properly convex. Under the condition $\mathrm{Im}\ \zeta \in \mathrm{int}\ K^*$, the exponential $e^{iz\zeta}$ belongs to $S^0(K)$ and we can consider the (inverse) Laplace transformation

$$w \to u(\zeta) = (2\pi)^{-n}(w, e^{iz\zeta}).$$

If $\mathrm{Im}\ \zeta$ lies in a cone $V \Subset \mathrm{int}\ K^*$ (we will assume V to be open and convex) and if $|\zeta|$ is bounded, then $u(\zeta)$ satisfies

$$|u(\zeta)| \leqslant C|\mathrm{Im}\ \zeta|^{-N}. \tag{11}$$

This estimate can easily be derived in the regular way analogous to that used, for instance, in proving a Paley–Wiener–Schwartz-type theorem of Ref. 13 for generalized functions of the class S'^0_α. Namely, we choose a pair of open cones U, U' so that $K \Subset U \Subset U' \Subset \mathrm{int}\ V^*$. This is possible because $V \Subset \mathrm{int}\ K^*$ implies $K \Subset \mathrm{int}\ V^*$. For any b and some (b-dependent) N, we have

$$|u(\zeta)| \leqslant (2\pi)^{-n} \|w\|_{U,b,N} \|e^{iz\zeta}\|_{U,b,N} \tag{12}$$

and, with $\zeta = \xi + i\eta$,

$$\|e^{iz\zeta}\|_{U,b,N} = \sup_{x,y} \exp\{-x\eta - y\xi + N \ln(1+|x|) - b|y| - bd(x,U)\}.$$

Let us suppose that $|\xi| < b$ and drop the terms involving y. If $x \notin U'$, then $d(x,U) > \delta|x|$ with some positive δ and, assuming that $|\eta| < b\delta$, the exponent can be majorized by a constant. At last, by virtue of the inclusion $U' \Subset \operatorname{int} V^*$, we have the inequality

$$x\eta \geqslant \delta'|x||\eta|, \quad \text{for all} \quad x \in U', \quad \eta \in V,$$

which immediately yields (11). A simple estimation shows that, under the same restrictions on ζ, the difference quotients corresponding to the partial derivatives $\partial e^{iz\zeta}/\partial\zeta_j$ converge in the topology of $S^{0,b}(U)$ and hence the function $u(\zeta)$ is analytic in $\mathbb{R}^n + \operatorname{int} K^*$. According to Theorem 3.1.15 of Ref. 8 it has a boundary value belonging to $\mathscr{D}'(|\xi| < b)$ which is just (the restriction of) the initial distribution u because the correspondence $S'^0(K) \to \mathscr{D}'(|\xi| < b)$ is continuous due to the factor $\|w\|_{U,b,N}$ in (12) and coincides with the continuous operator $\mathscr{F}^{-1}$ on the dense subspace of $S'^0(K)$ consisting of the tempered distributions supported by K. (Indeed, even the subspace consisting of all finite linear combinations of δ-function and its derivatives is dense in $S'^0(K)$.) Taking into account that b is arbitrarily large and applying Theorem 8.4.8 of the same treatise, we obtain the inclusion $WF_A(u) \subset \mathbb{R}^n \times V^*$ which changes into (10) for this particular case as V approaches K^* since $K^{**} = K$ under the above assumptions.

In the general case, we cover the cone $K\backslash 0$ by a finite number of open circular cones U_j so that their union is close to $K\backslash 0$. Let us denote by $S^{0,b+}(U)$ the countably normed space obtained by the replacement $b \to b + 1/N$ on the right-hand side of the definition (3), whereupon the natural injections $S^{0,b,N+1}(U) \to S^{0,b,N}(U)$ turn out to be compact for any pair of adjacent spaces with the modified norms as may be proved by standard arguments based on the Montel theorem (and similar to those used in deriving Theorem 5.5 of Ref. 12.) As a consequence, the projective limit $S^{0,b+}(U)$ is a Fréchet–Schwartz (FS) space. We claim that the linear functional w regarded as an element of $S'^{0,b+}(\cup U_j)$ allows a decomposition $w = \Sigma w_j$, where $w_j \in S'^{0,b+}(U_j)$. It suffices to make sure of this for the case of two cones. Let us consider the sequence of natural mappings

$$0 \to S^{0,b+}(U_1 \cup U_2) \to S^{0,b+}(U_1) \oplus S^{0,b+}(U_2) \to S^{0,b+}(U_1 \cap U_2), \tag{13}$$

where the last arrow maps a pair (f_1, f_2) into the difference $f_1 - f_2$. The sequence (13) is exact since $d(x, U_1 \cup U_2) = \min\{d(x,U_1), d(x,U_2)\}$. Therefore, the image of $S^{0,b+}(U_1 \cup U_2)$ in the direct sum, being the kernel of a continuous mapping, is closed. So it is a FS space under the topology induced by that of the sum (see, e.g., Komatsu[15]) and, by the open mapping theorem, this topology coincides with the original topology of $S^{0,b+}(U_1 \cup U_2)$. By the Hahn–Banach theorem w has a continuous extension $\hat{w}$ to the whole sum and we obtain the desired decomposition by setting $w(f) = \hat{w}(f,0) + \hat{w}(0,f)$. Now let us consider the Laplace transform of w_j in the domain $|\xi| < \underline{b}, \eta \in V_j \Subset \operatorname{int} U_j^*, |\eta| < b\delta_j$. By the above argument we have the inclusion $\mathrm{WF}_A(u_j) \subset \mathbb{R}^n \times U_j$ for its boundary value $u_j \in \mathscr{D}'(|\xi| \leqslant \underline{b})$. Therefore, the wave front set of the restriction $u|\mathscr{D}(|\xi| < b) = \Sigma u_j$ is contained in $\mathbb{R}^n \times \cup U_j$. Since b can be taken arbitrarily large and $\cup U_j$ is arbitrarily close to K, the proof is finished.

V. UNIQUENESS THEOREM

Theorem 4: Let $u \in \mathscr{D}'(\mathbb{R}^n)$ be a nontrivial distribution whose support is contained in some proper cone V. Then only the whole of $\mathbb{R}^n$ can be a carrier cone of $\tilde{u}$.

Proof: At first we assume that $0 \in \operatorname{supp} u$. Then $(0,x)$ is an external normal to supp u for any $x \in -V^*\backslash 0$ and hence $(0, x_1 - x_2) \in \mathrm{WF}_A(u)$ for all unequal $x_1, x_2 \in V^*$ by a theorem due to Kashiwara, see Ref. 8, Corollary 9.6.8. However $V^* - V^* = \mathbb{R}^n$ since int V^* is nonempty. Therefore, $\tilde{u}$ cannot be carried by a cone different from $\mathbb{R}^n$ by virtue of Theorem 3.

The case $0 \notin \operatorname{supp} u$ may be reduced to the foregoing one by a series of suitable contractions. As before, denote $\tilde{u}$ by w. Let us suppose that a nontrivial carrier exists and so there is an open

cone U such that $\overline{U}\neq\mathbb{R}^n$ and $w\in S'^0(U)$. We may assume without loss of generality that w is bounded in the norm $\|\cdot\|_{U,b,0}$ for each b. In fact, after regularizing by a multiplier $\widetilde{h}_\Lambda(x)=\widetilde{h}(x/\Lambda)$, where $0\leqslant h\in\mathscr{D}(|\xi|<1)$, $\int h\,d\xi=1$, this property is ensured because

$$|(w,\widetilde{h}_\Lambda f)|\leqslant\|w\|_{U,B,N_B}\|\widetilde{h}_\Lambda f\|_{U,B,N_B}\leqslant C\|f\|_{U,b,0}\sup_{x,y}\frac{(1+|x|)^{N_B}}{(1+|x/\Lambda|)^N}\times\exp\{(b-B)(|y|+d(x,U))+|y/\Lambda|\},$$

and the supremum on the right-hand side is finite if $B>b+1/\Lambda$ and $N>N_B$. Furthermore, for Λ large enough, the function $u^{\mathrm{reg}}=u*h_\Lambda$ has support in a proper cone and is nontrivial because it tends to u. Denote $u_\nu(\xi)=u^{\mathrm{reg}}(\nu\xi)$, $w_\nu=\widetilde{u}_\nu$. The homothetic transformation leaves the support of distribution in the same cone and, being an isomorphism of the spaces over cones, does not alter the carrier cones of its Fourier transform. Let us consider the series

$$\sum_{\nu=1}^{\infty}a_\nu w_\nu \tag{14}$$

with positive coefficients subject to the condition

$$a_\nu\leqslant 1/(\nu^2\|w_\nu\|'_{U,\nu,0}), \tag{15}$$

where $\|w\|'_{U,\nu,0}=\sup\{|(w,f)|:f\in S^{0,\nu}(U),\|f\|_{U,\nu,0}\leqslant 1\}$. The dual norm is stronger, the greater is ν and, the strong dual space of a normed space being complete, the condition (15) ensures the absolute convergence of the series (14) in every norm $\|\cdot\|'_{U,b,0}$ and all the more its weak convergence in $S'^0(U)$ to an element which we denote by $\widetilde{\mathscr{U}}$. Now let us show that under some additional restrictions on a_ν the support of $\mathscr{U}$ contains the origin and so we return to the situation examined at first. Assume that the distance of supp u_1 from 0 is equal to 1, and let ξ_0 be its point nearest 0. For each $\mu=1,2,...$, there exists a function $g_\mu\in\mathscr{D}$ with support in the ball $|\xi-\xi_0/\mu|<(1/2)(1/\mu-1/(\mu+1))$ and such that $(u_\mu,g_\mu)=1$. Note that supp $u_\nu\cap$ supp $g_\mu=0$ for $\nu<\mu$. We specify the coefficients a_ν sequentially imposing the conditions

$$a_\nu|(u_\nu,g_\mu)|\leqslant a_\mu/2^\nu\quad\text{for}\quad\mu<\nu \tag{16}$$

in addition to (15). Then for each μ,

$$(\mathscr{U},g_\mu)=a_\mu+\sum_{\nu>\mu}a_\nu(u_\nu,g_\mu)\neq 0,$$

since the sum of the last series does not exceed $a_\mu/2$ in absolute value. Thus $0\in$ supp $\mathscr{U}$ and the proof is completed.

VI. WEAK ESSENTIAL LOCALITY VS WEAK ASYMPTOTIC COMMUTATIVITY

In Ref. 7, Lücke examined the PCT invariance of the theory of a neutral scalar field defined on the test function space $S^0(\mathbb{R}^4)$ and subject to an essential locality condition originally formulated[16] for quantum fields of any class S'^β, $0\leqslant\beta<1$. In conformity to the case $\beta=0$ of particular interest this formulation looks as follows.

(i) Let $Q\subset S^0(\mathbb{R}^n)$ and let M be a closed subset of $\mathbb{R}^n$. Then Q is called locally bounded on M if there is a positive number b such that $\sup\{\|f\|_{M,b,N}:f\in Q\}<\infty$ for every $N=1,2,...$.

(ii) A generalized function $w\in S'^0$ is said to be locally continuous on M (with respect to S^0) if $\sup\{|(w,f)|:f\in Q\}<\infty$ for each locally bounded Q.

(iii) Let φ be a scalar Hermitian field with configuration space test functions in $S^0(\mathbb{R}^4)$. Then φ is called essentially local if the generalized function $\langle\Phi,[\varphi(x),\varphi(x')]\Psi\rangle$ is locally continuous on $\{(x,x')\in\mathbb{R}^8:(x-x')^2\geqslant 0\}$ for all vectors Φ, Ψ belonging to its dense invariant domain in the Hilbert space of states.

Accordingly, the weak essential locality means that the generalized function

$$W(\xi_1,\ldots,\xi_n)-W(-\xi_n,\ldots,-\xi_1)$$

is locally continuous on the cone $\mathsf{C}J_n\subset\mathbb{R}^{4n}$, and this property certainly follows from the essential locality.

It should be noted that the definition of spaces $S^{\beta}(\mathbb{R}^n)$ used in Refs. 7 and 16 is expressed in terms of real variables and outwardly differs from the definition given above in terms of complex variables, but such a reformulation is natural for $\beta<1$ as long ago pointed out by Gelfand and Shilov. In Refs. 11 and 12, we have argued that for $\beta<1$ it is also natural to consider cones instead of arbitrary sets M and then the definition of norms $\|\cdot\|_{M,b,N}$ exploited by Bümmerstede and Lücke admits a similar restatement. Specifically, if M is a closed cone with nonempty interior, then the local boundedness (i) means that Q is contained in some space $S^{0,b}(\mathrm{int}\,M)$ and is bounded in each of its norm determined by (3).

Theorem 5: Let M be a closed cone with nonempty interior U. Then $w\in S'^0$ is locally continuous on M if and only if it is continuous under the topology induced on S^0 by that of $S^0(U)$.

Proof: The boundedness of a linear form on a countably normed space is equivalent to its continuity. Therefore, in standard terminology of the topological vector space theory, the condition (ii) means that every restriction $w|L^b$, where $L^b=S^0\cap S^{0,b}(U)$, is continuous; i.e., it is equivalent to the continuity of w under the topology of inductive limit of the subspaces L^b endowed by the norms of $S^{0,b}(U)$. This topology is not coarser than that induced on S^0 as a subspace of $S^0(U)$ but need not *a priori* coincide with the latter. However, the denseness property established in Theorem 2 ensures their coincidence by the following simple arguments. Let $\mathscr{T}$ and τ denote the topologies in question ($\mathscr{T}\geqslant\tau$) and let $\hat{S}^0(U)$ be the completion of the Hausdorff space $(S^0,\mathscr{T})$. By the definition of inductive limit topology, every mapping $L^b\to\hat{S}^0(U)$ is continuous. Since $L^{b'}$ is dense in $S^{0,b}(U)$, we are able to extend $L^{b'}\to\hat{S}^0(U)$ to a mapping $S^{0,b}(U)\to\hat{S}^0(U)$ continuous under the topology of $S^{0,b'}(U)$ and under that of $S^{0,b}(U)$ all the more. The image of $f\in S^{0,b}(U)$ in $\hat{S}^0(U)$ obtained by the extension exploiting $L^{b''}\supset L^{b'}$ is the same because if $f_\nu\in L^{b'}$ and $f_\nu\to f$ in $S^{0,b'}(U)$, then $f_\nu\to f$ in $S^{0,b''}(U)$. Thus the mappings $S^{0,b}(U)\to\hat{S}^0(U)$ are compatible and determine a homomorphism $S^0(U)\to\hat{S}^0(U)$ which is again continuous by the very definition of inductive topology. Considering its restriction to S^0, we conclude that changing from $\mathscr{T}$ to τ preserves continuity of the canonical mapping $S^0\to\hat{S}^0(U)$. This completes the proof.

Thus, the weak essential locality is a little more restrictive condition than the weak asymptotic commutativity since the space $S^0(\mathrm{int}\,\mathsf{C}J_n)$ is larger than the space $S^0(\mathsf{C}J_n)$ defined with the help of an additional inductive limit operation (whose usefulness is also explained in Refs. 11 and 12), and their dual spaces are inversely related. Therefore, the derivation of the PCT invariance set forth in the present paper covers the essentially local fields.

Theorem 5 was actually used (without a proof) by Lücke[17] in deriving a Roumieu-type representation for the generalized functions locally continuous on M through Borel measures supported by M. When being exploited in Ref. 7, this representation provides a means for the decomposition $w=\Sigma w_j$, $w_j\in S'^0(U_j)$ subordinated to a partition of the quasisupport of w. We have seen in Sec. IV that a weaker version of decomposition ensured by the exactness of the sequence (13) is sufficient to prove the generalized PCT theorem. I do not know any way to prove Theorem 5 without exploiting the denseness property. The point is that subspaces of bornologic spaces (see Ref. 10 for definition) are not necessarily bornologic. This implies that the continuity of a linear form under the topology τ induced on S^0 by that of $S^0(U)$ cannot *a priori* be expressed in simple sequential terms originally used by Gelfand and Shilov for S^0 itself. Proceeding along the same lines as in Lemma 5.2 of Ref. 12 (in particular, using the acyclicity and, as a consequence, the regularity of the injective sequence of spaces $S^{0,b}(U)$, $b=1,2,\ldots$), one can easily show that $\mathscr{T}$ is just the bornologic topology associated with τ but this fact is yet insufficient to be sure that the dual space $(S^0,\mathscr{T})'$ is not larger than $(S^0,\tau)'$. (This is the case if and only if $\mathscr{T}$ is the Mackey topology associated with τ, see Sec. IV. 3. 2 of Ref. 10.) It is also worth noting that, in deriving the Roumieu-type representation, the difficulty connected with two possible topologiza-

tions of subspaces of inductive limits occurs once again, this time in embedding $S^0(U)$ into a space of multi-index sequences of continuous functions by the correspondence $f \to f_q = \partial^q f$, as is clear from some Komatsu's considerations[18] applied at this point. The simple denseness arguments are unsuitable now since this mapping is of closed range and, in my opinion, this matter calls for a more close examination.

VII. CONCLUDING REMARKS

Analogs of Theorems 3 and 4 are valid for the ultradistributions defined on the spaces S_0^α, $\alpha > 1$. In some respects their proofs are even easier since one can apply a decomposition theorem[19] and a Paley–Wiener–Schwartz-type theorem previously established in Ref. 13. Moreover, in deriving the relevant Roumieu-type representation one can easily obviate the difficulty mentioned above because the topological aspect is simpler in this case. However, some new specific problems present themselves and we shall discuss them in an accompanying work for these results taken together with the previous ones give a consistent analytical formalism for construction and treatment of gauge models in a generic covariant gauge.

In the present paper, we have restricted ourselves to the generalized functions of class S'^0 primarily because these are traditionally used in nonlocal QFT and theoretical physicists are familiar with the Schwartz distributions into which S'^0 is converted by the Fourier transformation. From the mathematical point of view, it is also of interest that the employment of the presheaf of spaces $S^0(U)$ over cones enables one to improve considerably the well-known relation between the wave front set of a tempered distribution and the support property of its Fourier transform. A more precise version of decomposition as well as a PWS-type theorem can actually be derived in this case too but with the help of more sophisticated tools which have luckily turned out unnecessary for the purpose of this paper. Finally, it should be noted that the approach proposed here is applicable as well to the derivation of the connection between spin and statistics for the quantum fields smeared with test functions in S^0 (or S_α^0) and satisfying the asymptotic commutativity condition. Further applications, e.g., to generalization of the Borchers equivalence concept, are also possible and such studies are in progress.

Standard forms of local nets in quantum field theory

Launey J. Thomas, III and Eyvind H. Wichmann
Department of Physics, University of California, Berkeley, California 94720

(Received 22 August 1997; accepted for publication 15 January 1998)

Nets of von Neumann algebras, with local algebras associated with all compact, convex, causally complete subsets of spacetime, are constructed, assuming a particular kind of net considered by Bisognano and Wichmann. The properties of such nets are discussed, within the general framework of algebraic quantum field theory, with an emphasis on the relation between the geometry of spacetime and the structure of the nets. An ''intersection property'' for the local algebras is stated and proved. The structure of subnets of such nets is discussed. A number of particular possible features of the nets are shown to be hereditary in the sense that the subnets have the same features. Possible further extensions of the domain of definition of these nets are discussed briefly. © *1998 American Institute of Physics.*

I. INTRODUCTION

This study is within the framework of algebraic quantum field theory. A paper published in 1964 by Haag and Kastler[1] can be regarded as the seminal paper of this subject. We refer to the monographs by Haag,[2] and by Horuzhy,[3] for detailed descriptions of this approach, and for extensive references to the literature. The characteristic feature of such a theory is the existence of a *local net*, by which is understood an association of C^* - or von Neumann algebras with subsets of Minkowski spacetime M in a ''suitable'' family $\mathscr{R}$ of subsets. In this paper we will assume that the algebras are von Neumann algebras on a Hilbert space $\mathscr{H}$. We assume that $\mathscr{H}$ carries a strongly continuous unitary representation of the covering group of the Poincaré group, and that $\mathscr{H}$ contains a unique vacuum vector. We are thus only concerned with the vacuum representation of the algebras in the net. For the choice of the family of subsets one can imagine a great variety of possibilities. The family $\mathscr{R}$ should always include a sufficiently large set of *bounded* regions, and the operators in the von Neumann algebras associated with these bounded regions are the *local* operators of the net. In Section II we review some features of the theory of local nets in general. (See, in particular, Definition 2.1, which describes the notion of a local net which we adhere to in this paper.)

In Section II we also review a *specific* structure discussed by Bisognano and Wichmann,[4] and by Wichmann.[5] The subsets of M for which the von Neumann algebras are defined are the causal wedges and the closed double cones (with nonempty interiors) in M, as well as the causal complements of these double cones. Our aim in this paper is to define local nets for *larger* classes of subsets of Minkowski spacetime, and to discuss the properties of such extended nets. Our starting point is a net of the kind discussed by Bisognano and Wichmann, which we then embed in a net with a suitable larger domain of subsets of M. This involves no new assumptions, and the properties of the extended nets are thus already implicit in the structure of the ''original'' net.

A main theme of this paper is the relationship between geometric features of Minkowski spacetime and the structures of local nets. In an earlier paper,[6] hereafter referred to as TW-I, we have discussed the causal structure of Minkowski spacetime, and in a subsequent paper,[7] hereafter referred to as TW-II, we have discussed a class of tempered distributions of interest in quantum field theory, with reference to the geometric theory in TW-I. In the present paper we discuss the implications of this causal structure for the structure of local algebras, and our theory thus depends in an essential manner on the results in TW-I and TW-II. We follow the notation and terminology in these papers, to which the reader is referred for details which are not spelled out here. For the reader's convenience we briefly review here some points of particular importance.

For any subset R of Minkowski spacetime M, we denote the closure of R by $\overline{R}$, the interior of

 © 1998 American Institute of Physics

R by R^o, the complement of R in M by $\widetilde{R}$, and the boundary of R by ∂R. The *causal complement* R^c of R is defined as the set of all point of M which are spacelike relative to all points of R. The set $R^{cc}=(R^c)^c$ is called the *causal completion of* R, and we say that a subset R of M is *causally complete* if and only if $R^{cc}=R$. For a detailed discussion of these notions we refer to TW-I.[6]

We describe here the kinds of subsets of Minkowski spacetime with which we will be particularly concerned.

Definition 1.1: (a) For any $x\in\mathsf{M}$ we denote by $V_+(x)$ the *open forward lightcone*, and by $V_-(x)$ the *open backward lightcone*, with x as the apex.

(b) For any two points $x,y\in\mathsf{M}$ such that $y\in V_+(x)$ we define the *closed double cone* $D(x,y)$ with x and y as apices by $D(x,y)=\overline{V}_+(x)\cap\overline{V}_-(y)$, and we denote by $\mathscr{D}$ the set of all such double cones. Note that with this definition every double cone $D\in\mathscr{D}$ has a nonempty interior.

(c) We denote by $\mathscr{W}$ the set of all open wedge-regions W which are Poincaré-equivalent with the particular wedge-region $W_R=\{x|x_3>|x_4|\}$, i.e., an element $W\in\mathscr{W}$ is any open subset of M bounded below by a characteristic plane π' and bounded above by another characteristic plane π'' not parallel with π'.

(d) We denote by $\mathscr{K}$ the set of all *closed, convex, causally complete* subsets K of M such that K^c has a *nonempty* interior.

(e) We define $\mathscr{K}_E$ as the set of all *closed, convex, causally complete* subsets K of M which satisfy the condition that there exist four characteristic planes π_1, π_2, π_3, and π_4 in a *general relative position*, i.e., the normals of these planes are linearly independent, such that K lies *below* π_1 and π_2 and *above* π_3 and π_4.

(f) We define the subset $\mathscr{K}_C$ of $\mathscr{K}_E$ as the set of all *compact* sets $K\in\mathscr{K}_E$, i.e., $\mathscr{K}_C$ is the set of all *compact, convex, causally complete* subsets of M. We regard the empty set $\varnothing$ as an element of $\mathscr{K}_C\subset\mathscr{K}_E$. We have $\mathscr{D}\subset\mathscr{K}_C$.

(g) We denote by $\mathscr{K}_B$ the set of all *compact, causally complete* subsets K of M.

(h) We say that two wedges W_1 and W_2 are in a *general relative position* if the four boundary planes are in a general relative position. The set $\mathscr{K}_E$ can also be described as follows: A closed, convex, causally complete set K is in $\mathscr{K}_E$ if and only if there exist two wedges $W_1,W_2\in\mathscr{W}$ in a general relative position such that $K\subset W_1\cap W_2$.

In Section II we give a precise definition of what we here call a *basic local net* (see Definition 2.3). Such a net is of the kind discussed by Bisognano and Wichmann,[4] with von Neumann algebras $\mathscr{A}_o(W)$, $\mathscr{B}_o(D)$, and $\mathscr{A}_o(D^c)$ defined for all $W\in\mathscr{W}$ and all $D\in\mathscr{D}$, but we add some specific assumptions. In particular we assume that the vacuum vector Ω is cyclic for the algebra $\mathscr{B}_o(D)$ associated with any double cone $D\in\mathscr{D}$. We do assume that the algebras $\mathscr{A}_o(W)$ associated with the causal wedges W in $\mathscr{W}$ satisfy the *condition of duality*, but not necessarily the so-called *special condition of duality* discussed by Bisognano and Wichmann (see Definition 2.4). The notion of a local net is a very general notion, and it hardly makes sense to try to pursue a large number of variants. Our aim was to select a reasonable starting point for the discussion in this paper.

Sections III and IV incorporate, and depend substantially on results from the doctoral thesis of one of us (L.J.T.).[8] In Section III we discuss the construction of a specific extended local net, for which we employ the term *regular net* as a technical term in this paper, starting from a *basic net*. This extended net consists of von Neumann algebras $\mathscr{A}(W)$, $\mathscr{B}(K)$, and $\mathscr{A}(K^c)$, defined for all $W\in\mathscr{W}$, for all $K\in\mathscr{K}_C$. For any $K\in\mathscr{K}_C$ the algebra $\mathscr{B}(K)$ is defined as the intersection of *all* algebras $A_o(W)$ for which W contains K. We show that the extended net has reasonable properties. It satisfies all the usual conditions of a local net, as well as the condition of duality. Furthermore the set of all *local* operators of the extended net is equal to the set of all local operators of the original basic net. One can thus say that the extension merely amounts to a more refined association of the local operators with bounded subsets of M. The extended net is also *maximal* in the sense that the algebras $\mathscr{B}(K)$ cannot be larger without violating the condition of locality. This corresponds to a general principle which we have followed in this paper: to arrange it so that the *local* algebras are as large as they can be, consistent with the condition of locality. The extension which we describe depends in an essential way on the feature that the sets $K\in\mathscr{K}_C$ are convex, compact, and causally complete. We also discuss a rather natural association of algebras with

other closed, convex, causally complete subsets of M, but this further extended system of algebras is not necessarily a local net.

In Section IV we discuss various properties of *regular* nets. We first state and prove some continuity properties for the mapping of subsets of M into the set of von Neumann algebras. We next show that an algebra $\mathscr{B}(K)$ can be nontrivial for a $K\in\mathscr{K}_C$ with an empty interior, but that the algebra *is* trivial if K is contained in a *two*-dimensional linear manifold. Furthermore we discuss various *intersection properties*. Among other things we show that if $K_1,K_2\in\mathscr{K}_C$, then $\mathscr{B}(K_1)\cap\mathscr{B}(K_2)=\mathscr{B}(K_1\cap K_2)$. To prove this statement in full generality we have to assume that the basic net satisfies the *condition of additivity for wedges* (see Definition 2.5). However, this condition is not needed for the conclusion that $\mathscr{B}(K_1)$ and $\mathscr{B}(K_2)$ have only multiples of the identity in common if K_1 and K_2 are spacelike separated. Our discussion of intersection properties is closely related to a similar discussion in Section V in our earlier paper TW-II.[7] There the object of interest was the *weak commutant* $\mathscr{C}(K)$ of the quantum field operators in the causal complement of K, and it was shown that $\mathscr{C}(K_1)\cap\mathscr{C}(K_2)=\mathscr{C}(K_1\cap K_2)$ if $K_1,K_2\in\mathscr{K}_C$. It is not known whether the weak commutants are von Neumann algebras for an arbitrary field theory, but there is a particularly pleasing scenario in which this is the case. For *Bose fields* we then have $\mathscr{B}(K)=\mathscr{C}(K)$, and in particular this is the case for a *free* Bose field. In the present paper we do not make any assumption about associated quantum fields, and hence we cannot depend on the results in TW-II[7] concerning intersection properties.

In Section V we discuss local subnets of a regular net. This generalizes an earlier study by Wichmann[5] of subnets of a basic net. In this discussion the *special condition of duality* is assumed. There is a natural standard form of such a subnet for which the vacuum representation of the subnet is a regular local net which also satisfies the special condition of duality. We discuss a number of possible special properties of a regular net which are also inherited by the vacuum representation of the subnet. Finally we show that for any local operator B there is an *intrinsic* smallest $K\in\mathscr{K}_C$ such that $B\in\mathscr{B}(K)$.

In Section VI we briefly discuss possible further extensions of a *regular* net. The goal is to define local algebras $\mathscr{B}_e(K)$ for every K in the set $\mathscr{K}_B$ of all compact causally complete subsets of M. The methods in Section III are not applicable, because the sets in $\mathscr{K}_B$ are not all convex, and hence other procedures for the extension must be employed. We show that it is always possible to construct a particular ''standard'' extension to a local net with von Neumann algebras $\mathscr{A}_S(W)$, $\mathscr{B}_S(K)$, and $\mathscr{A}_S(K^c)$, defined for all $W\in\mathscr{W}$, for all $K\in\mathscr{K}_B$. This extension satisfies a number of reasonable conditions, but it is definitely not as canonical as the extension to a regular net in Section III. We cannot show that it is maximal or that a unique maximal extension exists, but we show that the local algebras $\mathscr{B}_e(K)$ of any maximal extension satisfy the condition $\mathscr{B}_e(K)\supset\mathscr{B}_S(K)$. We discuss some features of these extensions of regular nets. Among other things we show that the intersection properties discussed in Section IV *cannot* hold generally for the extended nets.

Finally it is worth stating that our discussion refers *specifically* to four-dimensional Minkowski spacetime. Our reasoning depends on results in our earlier papers,[6,7] some of which are specific for a four-dimensional spacetime, and not necessarily valid for other (model) spacetimes.

II. GENERALITIES ABOUT LOCAL NETS OF VON NEUMANN ALGEBRAS

Minkowski spacetime M is parameterized by the usual Cartesian coordinates $x=(x^1,x^2,x^3,x^4)=(\mathbf{x},t)$, with $t=x^4$, $\mathbf{x}=(x^1,x^2,x^3)$, with reference to some particular inertial frame. The Minkowski scalar product is denoted $x\cdot y=x^4y^4-\mathbf{x}\cdot\mathbf{y}$, where $\mathbf{x}\cdot\mathbf{y}$ is the usual scalar product on the Euclidean subspace R^3.

We denote the universal covering group of the Poincaré group by $\hat{\mathsf{P}}$, and its elements by $\lambda=\lambda(x,g)$, where $g\in SL(2,C)$ and $x\in\mathsf{M}$. The element $\lambda(x,g)=\lambda(x,I)\lambda(0,g)$ thus describes a homogeneous transformation g followed by a translation by x. In the interpretation of g we follow the usual conventions. The states of the physical system are described in terms of a separable Hilbert space $\mathscr{H}$, which carries a strongly continuous unitary representation $\lambda\to U(\lambda)$ of $\hat{\mathsf{P}}$. We will also denote the translations by $T(x)\equiv U(\lambda(x,I))=U(x,I)$, and we assume the usual spectrum condition for $T(x)$, i.e., the support of the spectral measure μ_T of $T(x)$ is contained in the closed

forward lightcone $\overline{V}_+$. We assume the existence of a normalized vacuum state vector Ω, uniquely determined (up to a factor of modulus unity) by the condition $U(\lambda)\Omega=\Omega$, for all $\lambda\in\hat{\mathsf{P}}$. We also assume the existence of a *PCT*-operator θ, which satisfies the usual conditions[9–11] relative to the $U(\lambda)$, and relative to the local algebras under discussion.

To deal efficiently with the commutation and anticommutation relations which appear in the locality conditions, we employ a device of Bisognano and Wichmann.[4] We denote the unitary operator which describes a rotation by angle 2π about any axis by $U_0=U(0,-I)$, and we define the unitary operator Z by

$$Z=\frac{I+iU_0}{1+i},$$

and we then have

$$U_0^2=I,\quad Z^2=U_0,\quad U_0\Omega=\Omega=Z\Omega,\quad \theta Z\theta^{-1}=Z^{-1},\quad U(\lambda)Z=ZU(\lambda),$$

for all $\lambda\in\hat{\mathsf{P}}$.

For any operator Q, and any set $\mathscr{S}$ of operators we write

$$Q^z=ZQZ^{-1},\quad \mathscr{S}^z=\{Q^z|Q\in\mathscr{S}\}.$$

We refer to operators which commute with the involution U_0 as *boson operators*, and we refer to operators which anticommute with U_0 as *fermion operators*. If X is a boson operator and Y is a fermion operator we thus have $X^z=ZXZ^{-1}=X$ and $Y^z=ZYZ^{-1}=iU_0Y$. Every operator Q has a unique representation as a sum of a boson operator Q_b and a fermion operator Q_f,

$$Q=Q_b+Q_f,\quad Q_b=\tfrac{1}{2}(Q+U_0QU_0),\quad Q_f=\tfrac{1}{2}(Q-U_0QU_0).$$

It is important that this resolution ''respects the locality'' of an operator. If Q is a local operator associated with some region R, then Q_b and Q_f are local operators associated with the *same* region, because the *algebra* $\mathscr{M}(R)$ of the operators associated with the region is invariant under conjugation by U_0. The *condition of locality* can now be stated as follows. If X and Y are two local operators associated with two *spacelike* separated regions, then $[X,Y^z]=0=[X^z,Y]$.

For any $R\subset\mathsf{M}$ and any $\lambda\in\hat{\mathsf{P}}$ we write $R_{(\lambda)}$ for the image of R under the usual action of λ on Minkowski spacetime. Corresponding to the *PCT* operator θ we have the mapping $R\to R_{(\theta)}=\{-x|x\in R\}$.

Throughout this paper we will assume the above structure, and follow the above notation. We next give a general description of a *local net*,[1–4] within the framework of our paper. We note that our notion of a local net is, in some respects, less general than in the papers by Haag and Kastler,[1] and by Haag and Schroer.[12]

Definition 2.1: Let $\mathscr{R}$ be a set of subsets of M, such that if $R\in\mathscr{R}$, then $R_{(\theta)}\in\mathscr{R}$, and $R_{(\lambda)}\in\mathscr{R}$ for all $\lambda\in\hat{\mathsf{P}}$. Furthermore we assume that $\mathscr{R}$ contains a subset $\mathscr{R}_L$ of *bounded* subsets of M such that if $R_1,R_2\in\mathscr{R}_L$, then there exists an $R\in\mathscr{R}_L$ such that $R\supset R_1\cup R_2$.

(a) By a *local net* $\mathscr{N}$ *with domain* $\mathscr{R}$ we understand the following structure.

I. To every $R\in\mathscr{R}$ corresponds a von Neumann algebra $\mathscr{M}(R)$ of operators on $\mathscr{H}$.

II. The net $\mathscr{N}$ satisfies the *condition of isotony*, in the sense that $\mathscr{M}(R_i)\subset\mathscr{M}(R)$ if $R_i,R\in\mathscr{R}$ and $R_i\subset R$.

III. The net $\mathscr{N}$ is *Poincaré covariant*, in the sense that $\mathscr{M}(R_{(\lambda)})=U(\lambda)\mathscr{M}(R)U(\lambda)^{-1}$ for all $R\in\mathscr{R}$ and all $\lambda\in\hat{\mathsf{P}}$.

IV. The net $\mathscr{N}$ is *local*, in the sense that $\mathscr{M}(R_1)^z\subset\mathscr{M}(R_2)'$ whenever $R_1,R_2\in\mathscr{R}$ and $R_1\subset R_2^c$. Here the prime indicates the commutant.

V. The net $\mathscr{N}$ *is determined by its local operators* in the sense that $\mathscr{M}(R)\subset\mathscr{U}''$ for all $R\in\mathscr{R}$, where $\mathscr{U}=\cup\{\mathscr{M}(R)|R\in\mathscr{R}_L\}$ is the set of all *local operators* of the net $\mathscr{N}$.

(b) In *addition* a net may, or may not, satisfy any one of the following conditions.

VI. The net $\mathscr{N}$ is *PCT-covariant*, in the sense that $\mathscr{M}(R_{(\theta)})=\theta\mathscr{M}(R)\theta^{-1}$ for all $R\in\mathscr{R}$.

VII. The net $\mathcal{N}$ is *irreducible*, in the sense that the set of operators $\cup\{\mathcal{M}(R)|R\in\mathcal{R}\}$ is1 irreducible, which is the case if and only if $\mathcal{U}''=\mathsf{B}(\mathcal{H})$. Here $\mathsf{B}(\mathcal{H})$ denotes the set of all bounded operators on $\mathcal{H}$.

VIII. The net $\mathcal{N}$ satisfies the *condition of duality*, in the sense that $R^c\in\mathcal{R}$ whenever $R\in\mathcal{R}$, *and* $\mathcal{M}(R)^z=\mathcal{M}(R^c)'$ for all $R\in\mathcal{R}$.

IX. The net has a *strictly local structure*, in the sense that $R=\cup\{R_b|R_b\in\mathcal{R}_L,\ R_b\subset R\}$ and $\mathcal{M}(R)=\{\mathcal{M}(R_b)|R_b\in\mathcal{R}_L,\ R_b\subset R\}''$, for all $R\in\mathcal{R}$.

(c) Let $\mathcal{N}$ be a local net as above, with domain $\mathcal{R}$, and let $\mathcal{N}_s$ be another local net with algebras $\mathcal{M}_s(R)$ defined on the *same* domain $\mathcal{R}$. We say that $\mathcal{N}_s$ is a *subnet of* $\mathcal{N}$ if and only if $\mathcal{M}_s(R)\subset\mathcal{M}(R)$ for all $R\in\mathcal{R}$, and we can express this relationship by the symbolism $\mathcal{N}_s<\mathcal{N}$ or $\mathcal{N}>\mathcal{N}_s$.

The purpose of the above definition is to summarize some *general* properties of local nets for later reference. The ''essence'' of a local net is, of course, the function $\mathcal{M}$. We employ the symbol $\mathcal{N}$, rather than $\mathcal{M}$, for a net as a symbol for the *entire* structure described above.

The question of how the domain $\mathcal{R}$ should be chosen is here left open temporarily. In this paper we will discuss some specific choices as explained later, but other choices can be imagined. Conditions I–IV are always imposed on local nets, and the physical motivation for these conditions is obvious. We include Condition V as a condition that there are ''enough'' *local* operators in the sense that the von Neumann algebra generated by these contains all the operators in the net. Note that the set $\mathcal{U}$ is a *unital* **-algebra* under the stated conditions. Condition IX is a much stronger condition than Condition V. The nets discussed in Sections III–V will satisfy this condition, as well as the condition of duality. One could argue that the *proper* statement of the condition of duality is that *both* Conditions VIII and IX should be satisfied. In the original formulation by Haag and Schroer[12] the condition of duality is a condition on the *local* operators of a net. We illustrate this for the case of a local net with the domain $\mathcal{R}=\mathcal{D}$. The condition that

$$\mathcal{M}(D)^z=\{\mathcal{M}(D_o)|D_o\in\mathcal{D},\ D_o\subset D^c\}', \tag{2.1}$$

for all $D\in\mathcal{D}$ involves only local operators, and a condition of this nature is commonly referred to as *Haag duality*. If we now extend the domain of the net to include all causal complements D^c of the double cones D by defining $\mathcal{M}(D^c)=\{\mathcal{M}(D_o)|D_o\in\mathcal{D},\ D_o\subset D^c\}''$ it follows that both Conditions VIII and IX are satisfied if the condition in (2.1) holds. The duality condition in (2.1) implies that the local algebras are *maximal*, i.e., if $\{\mathcal{M}_1(D)|D\in\mathcal{D}\}$ are the algebras of another local net with the same domain $\mathcal{D}$, and such that $\mathcal{M}_1(D)\supset\mathcal{M}(D)$, then $\mathcal{M}_1(D)=\mathcal{M}(D)$.

We note here a simple relationship between the condition of duality (in *our* formulation) and the conditions of isotony and locality, which we express as follows.

Lemma 2.2: Let $\mathcal{R}$ be a set of subsets of M such that $R^c\in\mathcal{R}$ whenever $R\in\mathcal{R}$. Let there be given a von Neumann algebra $\mathcal{M}(R)$ for each $R\in\mathcal{R}$, and suppose that the mapping $R\to\mathcal{M}(R)$ satisfies the *condition of duality* $\mathcal{M}(R)^z=\mathcal{M}(R^c)'$ for all $R\in\mathcal{R}$. Then the mapping satisfies the *condition of isotony*, i.e., $\mathcal{M}(R_i)\subset\mathcal{M}(R)$ whenever $R_i\subset R$, if and only if the mapping satisfies the *condition of locality*, i.e., $\mathcal{M}(R_1)^z\subset\mathcal{M}(R_2)'$ whenever $R_1\subset R_2^c$.

This trivial observation is of interest when we want to verify that a mapping $R\to\mathcal{M}(R)$ is a local net.

In a ''local theory'' we are naturally interested in local nets which are *irreducible*. Subnets of such a net are also of interest, and they are in general *reducible*. In Section V we will discuss subnets and their (irreducible) *vacuum representations*.

As we said in the Introduction, we will *assume* the existence of a local net of the kind discussed in Bisognano and Wichmann,[4] and in Wichmann.[5] The set $\mathcal{R}$ of subsets of M for which the von Neumann algebras are defined are the wedges in $\mathcal{W}$ and the closed double cones D (with *nonempty* interiors) in $\mathcal{D}$, as well as the causal complements D^c of these double cones. In the quoted papers such a local net was called an *AB-system* (to distinguish it from other kinds of local nets). In this paper we will add some specific conditions, and refer to such a net as a *basic (local) net*. This is to distinguish it from the nets which we will construct by extending the domain $\mathcal{R}$ of the mapping $\mathcal{M}$.

Definition 2.3: By an *irreducible basic local net* $\mathcal{N}_o$ is understood a system of von Neumann algebras of operators on $\mathcal{H}$ with the following properties.

(a) To every $W \in \mathscr{W}$ corresponds a von Neumann algebra $\mathscr{A}_o(W) = \mathscr{M}(W)$, and to every $D \in \mathscr{D}$ correspond two von Neumann algebras $\mathscr{B}_o(D) = \mathscr{M}(D)$ and $\mathscr{A}_o(D^c) = \mathscr{M}(D^c)$. These algebras constitute a local net $\mathscr{N}_o$ which satisfies *all* the Conditions I–IX in Definition 2.1, specifically the following:

(b) The von Neumann algebras of the net $\mathscr{N}_o$ are related by

$$\mathscr{B}_o(D) = \cap\{\mathscr{A}_o(W) | W \in \mathscr{W},\ \overline{W} \supset D\}, \quad \mathscr{A}_o(D^c) = \{\mathscr{A}_o(W) | W \in \mathscr{W},\ W \subset D^c\}'', \tag{2.2}$$

$$\mathscr{A}_o(W) = \{\mathscr{B}_o(D) | D \in \mathscr{D},\ D \subset W\}'', \quad \mathscr{A}_o(D^c) = \{\mathscr{B}_o(D_i) | D_i \in \mathscr{D},\ D_i \subset D^c\}'', \tag{2.3}$$

for all $D \in \mathscr{D}$, and all $W \in \mathscr{W}$.

(c) The net $\mathscr{N}_o$ satisfies the *condition of duality* in the sense that

$$\mathscr{A}_o(W)^z = \mathscr{A}_o(\overline{W^c})', \quad \mathscr{B}_o(D)^z = \mathscr{A}_o(D^c)', \tag{2.4}$$

for all $D \in \mathscr{D}$, and all $W \in \mathscr{W}$.

(d) For any $D \in \mathscr{D}$ we have

$$\overline{\mathscr{B}_o(D)\Omega} = \mathscr{H}. \tag{2.5}$$

(e) We denote by $\mathscr{U}_o$ the *algebra of all local operators of the net*, defined as $\mathscr{U}_o = \cup\{\mathscr{B}_o(D) | D \in \mathscr{D}\}$. The net $\mathscr{N}_o$ is *irreducible*, and hence

$$\mathscr{U}_o' = \{\mathscr{B}_o(D) | D \in \mathscr{D}\}'' = \{\mathscr{A}_o(W) | W \in \mathscr{W}\}'' = \mathsf{B}(\mathscr{H}),$$

where $\mathsf{B}(\mathscr{H})$ denotes the set of all bounded operators on $\mathscr{H}$.

The reader will note that the above is a description of a scenario, rather than a statement of a minimal set of assumptions. The various stated conditions on the net $\mathscr{N}_o$ are obviously by no means independent. It is worthwhile to discuss here some aspects of the logical structure of this scenario.

In the papers by Bisognano and Wichmann,[4] and by Wichmann,[5] the algebras $\mathscr{B}_o(D)$ and $\mathscr{A}_o(D^c)$ were in *defined* in terms of the ''wedge-algebras'' $\mathscr{A}_o(W)$, essentially as in (2.2). With this construction it follows at once that *if* the algebras $\mathscr{A}_o(W)$ satisfy the applicable conditions of Poincaré covariance, *PCT*-covariance, isotony, and locality, as was assumed in these papers, *then* the algebras $\mathscr{B}_o(D)$ and $\mathscr{A}_o(D^c)$ satisfy the corresponding conditions relevant for the regions D and D^c of these algebras.

We note here that it follows trivially from the strong continuity of the representation of the translation group that

$$\mathscr{A}_o(W) = \cap\{\mathscr{A}_o(W_o) | W_o \in \mathscr{W},\ W_o \supset \overline{W}\} = \{\mathscr{A}_o(W_i) | W_i \in \mathscr{W},\ \overline{W}_i \subset W\}''. \tag{2.6}$$

The expression in the second member could be regarded as the algebra corresponding to the *closed* wedge $\overline{W}$, properly denoted by $\mathscr{B}_o(\overline{W})$, but since it is equal to $\mathscr{A}_o(W)$ we do not employ the notation $\mathscr{B}_o(\overline{W})$. As discussed in the quoted papers, it follows that the algebras $\mathscr{B}_o(D)$ are ''continuous from the outside,'' and the algebras $\mathscr{A}_o(D^c)$ are ''continuous from the inside,'' in the sense that

$$\mathscr{B}_o(D) = \cap\{\mathscr{B}_o(D_o) | D_o \in \mathscr{D},\ D_o^o \supset D\}, \quad \mathscr{A}_o(D^c) = \{\mathscr{A}_o(D_i^c) | D_i \in \mathscr{D},\ D^c \supset \overline{D_i^c}\}''. \tag{2.7}$$

The wedge-algebras $\mathscr{A}_o(W) = \mathscr{B}_o(\overline{W})$ are continuous from both sides, in view of (2.6). Furthermore we have

$$\mathscr{B}_o(D) = \cap\{\mathscr{A}_o(W) | W \in \mathscr{W},\ W \supset D\}, \quad \mathscr{A}_o(D^c) = \{\mathscr{A}_o(W) | W \in \mathscr{W},\ \overline{W} \subset D^c\}''. \tag{2.8}$$

It is thus a matter of taste whether we define the algebras $\mathscr{B}_o(D)$ and $\mathscr{A}_o(D^c)$ through (2.2) or through (2.8). The above relations have a certain obvious *geometric* basis, which we do not

think we have to describe explicitly here. Note here that the isotony conditions include the condition that $\mathscr{B}(D)\subset\mathscr{A}(W)$ whenever $D\subset\overline{W}$, as is also implied by (2.2).

The construction of the basic net in Bisognano and Wichmann[4] was based on the premise that the vacuum vector Ω is cyclic for any wedge-algebra $\mathscr{A}_o(W)$. By a well-known argument within quantum field theory[9–11] it then follows that the set of operators $\cup\{\mathscr{A}_o(W)|W\in\mathscr{W}\}$ is irreducible, but this *does not* imply the condition in (2.5), or the relations in (2.3). Within the framework of the Bisognano–Wichmann theory it might conceivably happen that $\mathscr{B}_o(D)=\mathbf{C}^1\cdot I$ for all $D\in\mathscr{D}$, but such a theory would not be a physically sensible theory of *local* operators. Another possibility is that the algebra $\mathscr{U}_o$ is *irreducible*, but that the relation $\overline{\mathscr{B}_o(D)\Omega}=\mathscr{H}$ does not hold for *all* $D\in\mathscr{D}$. In particular one could imagine the situation in which $\mathscr{B}_o(D)=\mathbf{C}^1\cdot I$ for all ''sufficiently small'' double cones D. Such a theory would thus involve a notion of a *fundamental length*. We know of no explicit examples of such a net, and we will therefore not consider this possibility. In this paper we thus *assume* the condition in (2.5), from which it follows that the algebra $\mathscr{U}_o$ of all local operators is irreducible.

We *assume* that the net satisfies the condition of duality, as stated in Definition 2.3. The condition of duality at left in (2.4) is, of course, stronger than the condition of locality for the algebras $\mathscr{A}_o(W)$. We note that this condition of duality for the algebras $\mathscr{A}_o(W)$ implies the duality condition at right in (2.4). As far as we know the *wedge duality* $\mathscr{A}_o(W)^z=\mathscr{A}_o(\overline{W^c})'$ does not follow from the *Haag duality* in (2.1), with $\mathscr{A}_o(W)$ *defined* by (2.3) in terms of the local algebras $\mathscr{B}_o(D)=\mathscr{M}(D)$.

In the papers of Bisognano and Wichmann,[4] and Wichmann,[5] the nets were subject to a very specific further condition, called the *special condition of duality*, which we here state as follows, within the framework of the Tomita–Takesaki theory.[13]

Definition 2.4: Let the premises and notation be as in Definition 2.3. We say that the *basic* net $\mathscr{N}_o$ satisfies the *special condition of duality* if and only if the antiunitary involution $J=Z\theta U(0,\exp(-i\pi\sigma_3/2)$ is the modular conjugation, and the one-parameter group $\{V(\tau)|\tau\in\mathbf{R}^1\}$, with $V(\tau)=U(0,\exp(\tau\sigma_3/2))$, of all velocity transformations in the 3-direction (within the Poincaré group) is the modular automorphism group, for the algebra $\mathscr{A}_o(W_R)$, relative to the cyclic and separating vector Ω.

We refer to the quoted papers, as well as to the papers by Borchers,[14,15] and by Brunetti, Guido, and Longo,[16] for discussions of the implications of this condition, and of its plausibility and standing. The ''origin'' of this condition is a property of quantum fields, within the framework of local quantum field theory.[9–11] We refer to such fields as *Wightman fields*. There are good reasons to believe[4,17] that the special condition of duality holds for local nets which are ''locally related'' to an irreducible system of (finite-component) local Wightman fields, but the condition may have a more general validity. For discussions of the connection between quantum fields and local nets, we refer to the papers by Driessler, Summers, and Wichmann,[17] and by Borchers and Yngvason.[18,19] The general idea is that the unbounded local field operators have closed extensions affiliated with the local von Neumann algebras in the net. It was shown by Summers and Wichmann[20] that a local net which is related to Wightman fields in such a manner also satisfies a particular condition of *additivity*, which we state as follows.

Definition 2.5: Let $\mathscr{N}$ be a local net, with algebras $\mathscr{A}(W)$, $\mathscr{A}(D^c)$, and $\mathscr{B}(D)$ defined for all $W\in\mathscr{W}$ and $D\in\mathscr{D}$. We say that the net $\mathscr{N}$ satisfies the *condition of additivity for wedges* if and only if

$$\mathscr{A}(W)\subset\{\mathscr{B}(D)|D\in\mathscr{F}\}''$$

for any $\mathscr{F}\subset\mathscr{D}$ such that

$$W\subset\cup\{D^o|D\in\mathscr{F}\},$$

where D^o denotes the interior of D.

In the quoted paper it was explicitly proved that this condition holds for an irreducible local net locally associated with a single Hermitian scalar field, but the reasoning applies equally well, with minor modifications, to the case of any irreducible set of (finite-component) Wightman fields. For some of the conclusions in our paper we will require this additional property of the local net,

and when this is so, we will refer to this assumption explicitly. We note here that if the condition of additivity for wedges holds for a net, then Ω is a cyclic vector for $\mathscr{B}_o(D)$, for *all* $D \in \mathscr{D}$, if and only if the net is irreducible.

If a *basic* net $\mathscr{N}_o$ satisfies the *special condition of duality* in Definition 2.4, then the net has the somewhat surprising property that

$$\mathscr{A}_o(W_R) = \{V(\tau).\mathscr{B}_o(D)V(\tau)^{-1} | \tau \in \mathsf{R}^1\}'',$$

for *any* double cone $D \subset W_R$. This is suggestive, but as far as we know, the condition of additivity for wedges does *not* follow from the conditions in Definition 2.3, even if amended by the special condition of duality.

We want to contrast the above condition of additivity for wedges with the following apparently much stronger *condition of additivity for double cones*: For every $D \in \mathscr{D}$ we have $\mathscr{B}_o(D) \subset \{\mathscr{B}_o(D_c) | D_c \in \mathscr{F}\}''$ for any family $\mathscr{F}$ of doubles cones such that $D \subset \cup\{D_c^o | D_c \in \mathscr{F}\}$. It obviously implies the condition in Definition 2.5 if we also have $\mathscr{A}_o(W) = \{.\mathscr{B}_o(D) | D \in \mathscr{D}, D \subset W\}''$. This stronger condition does hold for the local nets generated by a system of free fields, and it describes a physically reasonable feature, but it is not known whether it holds for local nets $\mathscr{N}_o$ in general, under the conditions in Definition 2.3. One may thus have doubts about the validity of the condition of additivity for double cones, whereas we feel that the condition of additivity for wedges is much more plausible. In this paper we will not depend in any way on the stronger condition.

The condition of additivity for wedges trivially implies the relations in (2.3). If the condition of duality also holds, then it follows from these relations that

$$\mathscr{A}_o(W) = \cap\{.\mathscr{A}_o(D^c) | D \in \mathscr{D},\ D^c \supset \overline{W}\}, \quad \mathscr{B}_o(D) = \cap\{.\mathscr{A}_o(D_o^c) | D_o \in \mathscr{D},\ D_o^c \supset D\}, \tag{2.9}$$

for all $D \in \mathscr{D}$, and all $W \in \mathscr{W}$. Conversely the relations in (2.9) imply the relations in (2.3), if the condition of duality holds. With the situation as described in Definition 2.3 the net $\mathscr{N}_o$ is thus completely determined by the *local* algebras $\mathscr{B}_o(D)$. The relation $\mathscr{A}_o(W) = \{.\mathscr{B}_o(D) | D \in \mathscr{D}, D \subset W\}''$ in (2.3) does *not* follow from the other conditions in Definition 2.3. However, it does follow from the special condition of duality in Definition 2.4, *and* the condition that $\overline{\mathscr{B}_o(D)\Omega} = \mathscr{H}$ for at least one $D \in \mathscr{D}$.

We conclude this section with two lemmas which will be of use later. Both lemmas depend on the assumed spectrum condition on the translation group.

Lemma 2.6: (a) Let u be a *timelike* or *isotropic* four-vector. Let A and B be two bounded operators which satisfy the condition

$$\langle \Omega | [B, T(su)AT(su)^{-1}]\Omega \rangle = 0, \tag{2.10}$$

for all real s. Then,

$$\langle \Omega | BT(su)A\Omega \rangle = \langle \Omega | BA\Omega \rangle = \langle \Omega | B\Omega \rangle \langle \Omega | A\Omega \rangle,$$

for all real s.

(b) Let $\mathscr{B}_o(D)$ be the algebra of a *basic net* $\mathscr{N}_o$ corresponding to the double cone $D \in \mathscr{D}$. If A is a bounded operator which satisfies the condition in (2.10) for all $B \in \mathscr{B}_o(D)$, then $A\Omega = a\Omega$, $A^*\Omega = a^*\Omega$, with $a = \langle \Omega | A\Omega \rangle$. If furthermore $A \in \mathscr{B}_o(D_0)'$ for some $D_0 \in \mathscr{D}$, then $A = aI$.

Proof: The assertion in part (a) is a well-known result within quantum field theory, which follows from the spectrum condition on the translation group, and from the fact that the weak limit of $T(x)$ equals the vacuum projection $|\Omega\rangle\langle\Omega|$ as x tends to infinity along any fixed direction.

Under the premises in part (b) the relation $\langle B^*\Omega | A\Omega \rangle = a\langle B^*\Omega | \Omega \rangle$ holds for all $B \in .\mathscr{B}_o(D)$, and since $\mathscr{B}_o(D)\Omega$ is dense in $\mathscr{H}$, it follows that $A\Omega = a\Omega$, and similarly that $A^*\Omega = a^*\Omega$. If also $A \in \mathscr{B}_o(D_0)'$, then it follows that $A = aI$ since Ω is separating for $\mathscr{B}_o(D_0)'$.

Lemma 2.7: Let $W_1, W_2 \in \mathscr{W}$ be such that $W_1 \cap W_2 = \varnothing = W_1^c \cap W_2^c$. Let A and B be two bounded operators which satisfy the condition

$$\langle\Omega|[B,T(x)AT(x)^{-1}]\Omega\rangle=0, \tag{2.11}$$

for all $x\in W_1\cup W_2$. Then the relation in (2.11) holds for *all* x, and

$$\langle\Omega|BT(x)A\Omega\rangle=\langle\Omega|BA\Omega\rangle=\langle\Omega|B\Omega\rangle\langle\Omega|A\Omega\rangle, \tag{2.12}$$

for all $x\in\mathsf{M}$.

Proof: Under the stated premises the edges of the two wedges must be parallel, and the upper plane of one of the wedges must lie *above* the lower plane of the other. Without any loss of generality we assume that the upper plane of W_1 lies above the lower plane of W_2. The lower plane of W_1 then either coincides with the upper plane of W_2, or else lies above the upper plane of W_2. With a suitable choice of a standard coordinate system the two wedges can then be described by

$$W_1=\{x|x_3+\rho>|x_4-\tau|\},\quad W_2=\{x|x_3-\rho<-|x_4+\tau|\},$$

for some $\tau>0$, with $\rho=\tau$ if the lower plane of W_1 coincides with the upper plane of W_2, and $\rho=0$ if the lower plane of W_1 lies above the upper plane of W_2. We will depend on a result in Lemma 5.17 in TW-II,[7] and in order to conform to the notation in the quoted paper we introduce the two wedges $W_3=\{x|x_3>|x_4-\tau|+\tau/2\}$ and $W_4=\{x|x_3<-|x_4+\tau|-\tau/2\}$. We easily see that we then have $W_3\cup W_4\subset W_1\cup W_2$, for $\rho=\tau$ as well as for $\rho=0$.

We consider the function $\eta(A,B;x)=\langle B^*\Omega|T(x)A\Omega\rangle-\langle A^*\Omega|T(-x)B\Omega\rangle$. By the condition in (2.11) we have $\eta(A,B;x)=0$ for all $x\in W_3\cup W_4$. The function $\eta(A,B;x)$ is analogous to the function denoted $\eta(X,B;x)$ in the quoted paper, and the reasoning which led to the conclusion that $\eta(X,B;x)=0$ for all x also applies in the present case. We thus have $\eta(B,A;x)=0$ for all x, and from this the relations in (2.12) follow by Lemma 2.6.

III. CONSTRUCTION OF EXTENDED LOCAL NETS

In this section we discuss various extensions of the basic net $\mathscr{N}_o$ described in Definition 2.3. Our primary interest is in extensions in which we associate von Neumann algebras with the sets K and K^c, for all $K\in\mathscr{K}_C$. We recall from Definition 1.1 that $\mathscr{K}_C$ is the set of all compact, convex, causally complete subsets of M. We define a particularly canonical net of this nature as follows.

Definition 3.1: By a *regular net* $\mathscr{N}$ is understood a system of von Neumann algebras of operators on $\mathscr{H}$ with the following properties.

(a) To every $W\in\mathscr{W}$ corresponds a von Neumann algebra $\mathscr{A}(W)=\mathscr{M}(W)$, and to every $K\in\mathscr{K}_C$ correspond two von Neumann algebras $\mathscr{B}(K)=\mathscr{M}(K)$ and $\mathscr{A}(K^c)=\mathscr{M}(K^c)$. These algebras constitute an irreducible local net which satisfies *all* the Conditions I–IX in Definition 2.1.

(b) The von Neumann algebras of the net $\mathscr{N}$ are related by

$$\mathscr{B}(K)=\cap\{\mathscr{A}(W)|W\in\mathscr{W},\ \overline{W}\supset K\},\quad \mathscr{A}(K^c)=\{\mathscr{A}(W)|W\in\mathscr{W},\ W\subset K^c\}'', \tag{3.1}$$

$$\mathscr{A}(W)=\{\mathscr{B}(K)|K\in\mathscr{K}_C,\ K\subset W\}'', \tag{3.2}$$

for all $K\in\mathscr{K}_C$, and all $W\in\mathscr{W}$.

(c) The net $\mathscr{N}$ satisfies the *condition of duality* in the sense that

$$\mathscr{A}(W)'=\mathscr{A}(\overline{W^c})^z,\quad \mathscr{B}(K)'=\mathscr{A}(K^c)^z, \tag{3.3}$$

for all $W\in\mathscr{W}$ and all $K\in\mathscr{K}_C$.

(d) For any $K\in\mathscr{K}_C$ the vector Ω is *separating* for $\mathscr{B}(K)$ and *cyclic* for $\mathscr{A}(K^c)$. If K has a nonempty interior, then Ω is also *cyclic* for $\mathscr{B}(K)$ and *separating* for $\mathscr{A}(K^c)$. The vector Ω is *cyclic* and *separating* for every wedge-algebra $\mathscr{A}(W)$.

(e) We denote by $\mathscr{U}$ the *algebra of all local operators of the net*, defined as $\mathscr{U}=\cup\{\mathscr{B}(K)|K\in\mathscr{K}_C\}$. The net $\mathscr{N}$ is *irreducible* in the sense that the algebra $\mathscr{U}$ is irreducible, and hence

$$\mathscr{U}''=\{\mathscr{B}(K)|K\in\mathscr{K}_C\}''=\{\mathscr{A}(W)|W\in\mathscr{W}\}''=\mathsf{B}(\mathscr{H}),\quad \mathscr{B}(\varnothing)=\mathsf{C}^1\cdot I.$$

Like Definition 2.3 the above is also a description of a scenario. Some additional features are described in Proposition 3.6. In what follows we will mostly deal with nets so described. The term ''regular net'' has no official standing, but for the purposes of this paper we will employ it as a convenient technical term.

We now want to prove that every *basic* net has a unique extension to a *regular* net, as described in the above definition. This extension depends crucially on certain geometric relationships discussed in TW-I,[6] which we here state in the form of two propositions and two lemmas. For the proofs we refer to the quoted paper. The second proposition describes relevant characteristics of the sets $\mathscr{K}_E$ and $\mathscr{K}_C$, and the first proposition is intended to provide a more general perspective on the issues. The two lemmas which follow are of a more technical nature.

Proposition 3.2: (a) Let K be a closed, convex, causally complete subset of M such that K^c has a nonempty interior. Then

$$K=\cap\{\overline{W}|W\in\mathscr{W},\ \overline{W}\supset K\}=\cap\{W^c|W\in\mathscr{W},\ W\subset K^c\},$$

$$(K^c)^o=\cup\{W|W\in\mathscr{W},\ W^c\supset K\}=\cup\{W|W\in\mathscr{W},\ W\subset K^c\},$$

and

$$((K^c)^o)^c=K,\quad \overline{(K^c)^o}=\overline{K^c},\quad (\overline{K^c})^o=(K^c)^o.$$

The set K has an empty interior if and only if it is contained in some characteristic plane.

(b) Let $\{K_\alpha|\alpha\in A\}$ be a family of subsets of M which satisfy the premises in part (a). Then $K=\cap\{K_\alpha|\alpha\in A\}$ also satisfies the premises in part (a).

(c) Let $\mathscr{F}$ be any family of wedges in $\mathscr{W}$, and let $S=\cup\{W|W\in\mathscr{F}\}$. Then $K=\cap\{W^c|W\in\mathscr{F}\}=S^c$ satisfies the premises in part (a).

(d) Let K be a closed, convex, causally complete *proper* subset of M. Then K^c has an empty interior if and only if K contains an isotropic (straight) line, and if this is the case, then both K and K^c are contained in some characteristic plane.

The above proposition is a slightly abbreviated version of Theorem 3.2 in TW-I.[6]

Proposition 3.3: (a) Every set $K\in\mathscr{K}_E$ satisfies the premises in part (a) of Proposition 3.2, and specifically K^c is nonempty and *open.*

(b) If K_0 is any closed, convex, causally complete subset of M, then $K_0\cap K\in\mathscr{K}_E$ if $K\in\mathscr{K}_E$, and $K_0\cap K\in\mathscr{K}_C$ if $K\in\mathscr{K}_C$.

(c) If $\mathscr{F}_c\subset\mathscr{K}_C$, then $\cap\{K|K\in\mathscr{F}_c\}\in\mathscr{K}_C$. If $\mathscr{F}_e\subset\mathscr{K}_E$, then $\cap\{K|K\in\mathscr{F}_e\}\in\mathscr{K}_E$, and if at least one of the elements in $\mathscr{F}_e$ is in $\mathscr{K}_C$, then $\cap\{K|K\in\mathscr{F}_e\}\in\mathscr{K}_C$.

(d) If $K\in\mathscr{K}_E$, then there exist two *spacelike* 3-planes σ' and σ'' such that K lies *below* σ' and *above* σ''.

(e) If $K\in\mathscr{K}_E$, then K contains *no* (infinite) line, and *no* timelike or isotropic half-line.

This proposition is a verbatim quote of Proposition 3.4 in TW-I.[6] For a detailed discussion of the sets $\mathscr{K}_E$ and $\mathscr{K}_C$ we refer to Section III in the quoted paper. We note here the rather trivial fact, stated in the proposition, that the sets $\mathscr{K}_E$ and $\mathscr{K}_C$ are closed under intersections, in contrast to what the situation is for the set $\mathscr{D}$ of double cones. We also note that the sets $\mathscr{K}_E$ and $\mathscr{K}_C$ include subsets K of M with empty interiors, which are then necessarily contained in some characteristic plane.

Lemma 3.4: Let $K\in\mathscr{K}_C$, i.e., K is a compact, convex, causally complete subset of M. Then:

(a)

$$K=\cap\{D^o|D\in\mathscr{D},\ D^o\supset K\}=\cap\{D|D\in\mathscr{D},\ D\supset K\}.$$

(b) If $W\in\mathscr{W}$ and $W\supset K$, then there exists a double cone $D\in\mathscr{D}$, such that $W\supset D\supset D^o\supset K$.

The above lemma is a verbatim quote of Proposition 3.8 in TW-I.[6]

Lemma 3.5: (a) Let R be a nonempty convex subset of M, and let S be a nonempty *open* convex subset of M, such that $S\subset R^c$, and hence $R\subset S^c$. There then exists a wedge $W\in\mathscr{W}$ such that $S\subset W$ and $R\subset R^{cc}\subset W^c$.

(b) Let $K_1, K_2 \in \mathscr{K}_E$ be such that $K_1 \subset K_2^c$. Suppose furthermore that K_1 and K_2 are not both *unbounded* subsets of the *same* characteristic plane. There then exists a wedge $W \in \mathscr{W}$ such that $K_1 \subset \overline{W}$ and $K_2 \subset W^c$.

In particular a wedge W with the stated property always exists if $K_1, K_2 \in \mathscr{K}_C$.

Part (a) of this lemma is a verbatim quote of Proposition 3.1, and part (b) is a verbatim quote of Proposition 3.7 in TW-I.[6] We note here that the conclusion in part (b) can actually fail if K_1 and K_2 lie in the same characteristic plane, and neither K_1 nor K_2 is in $\mathscr{K}_C$. An example of this is given in the quoted paper.

Before we describe the construction of a regular net from a basic net we note some trivial features of a regular net.

Proposition 3.6: Let $\mathscr{N}$ be a *regular net*, with algebras $\mathscr{A}(W)$, $\mathscr{B}(K)$, and $\mathscr{A}(K^c)$ for all $W \in \mathscr{W}$ and all $K \in \mathscr{K}_C$, as in Definition 3.1. Then:

(a) The set of algebras $\{\mathscr{A}(W) | W \in \mathscr{W}\}$ and $\{\mathscr{B}(D), \mathscr{A}(D^c) | D \in \mathscr{D}\}$ are the algebras of a *basic net*, as described in Definition 2.3, and we have

$$\mathscr{A}(W) = \{\mathscr{B}(K) | K \in \mathscr{K}_C,\ K \subset W\}'' = \{\mathscr{B}(D) | D \in \mathscr{D},\ D \subset W\}''. \tag{3.4}$$

(b) Furthermore,

$$\mathscr{A}(K^c) = \{\mathscr{B}(K_i) | K_i \in \mathscr{K}_C,\ K_i \subset K^c\}'' = \{\mathscr{B}(D) | D \in \mathscr{D},\ D \subset K^c\}'', \tag{3.5}$$

$$\mathscr{A}(W) = \cap\{\mathscr{A}(K^c) | K \in \mathscr{K}_C,\ K^c \supset W\} = \cap\{\mathscr{A}(D^c) | D \in \mathscr{D},\ D^c \supset W\}, \tag{3.6}$$

$$\mathscr{B}(K) = \cap\{\mathscr{A}(K_i^c) | K_i \in \mathscr{K}_C,\ K_i^c \supset K\} = \cap\{\mathscr{A}(D^c) | D \in \mathscr{D},\ D^c \supset K\}, \tag{3.7}$$

$$\mathscr{B}(K) = \cap\{\mathscr{A}(W) | W \in \mathscr{W},\ W \supset K\}, \quad \mathscr{A}(K^c) = \{\mathscr{A}(W) | W \in \mathscr{W},\ \overline{W} \subset K^c\}'', \tag{3.8}$$

for all $W \in \mathscr{W}$ and all $K \in \mathscr{K}_C$.

(c) For any $K \in \mathscr{K}_C$ we have

$$\mathscr{B}(K) = \cap\{\mathscr{B}(D) | D \in \mathscr{D},\ D^o \supset K\}. \tag{3.9}$$

(d) Two regular nets are equal if their algebras are equal on the subdomain $\mathscr{W}$, or on the subdomain $\mathscr{D}$.

Proof: (1) We consider part (a). Comparing the Definitions 2.3 and 3.1 we see that the only issue to settle is whether the relation in (3.2) implies the relation at left in (2.3), i.e., whether the equality of the first two members in (3.4) implies that they are equal to the third member. We first note that since $\mathscr{D} \subset \mathscr{K}_C$ it follows that $\mathscr{A}(W) = \{\mathscr{B}(K) | K \in \mathscr{K}_C,\ K \subset W\}'' \supset \{\mathscr{B}(D) | D \in \mathscr{D},\ D \subset W\}''$. Let $K \in \mathscr{K}_C$ and $K \subset W$. By Lemma 3.4 there then exists a double cone D such that $K \subset D \subset W$. By isotony this implies that $\{\mathscr{B}(K) | K \in \mathscr{K}_C,\ K \subset W\}'' \subset \{\mathscr{B}(D) | D \in \mathscr{D},\ D \subset W\}''$, and hence we have $\mathscr{A}(W) = \{\mathscr{B}(D) | D \in \mathscr{D},\ D \subset W\}''$.

(2) We consider part (b). The identities in (3.5) follow from the identities in (3.4) and the relation at right in (3.1). The identities in (3.6) are equivalent with the identities in (3.4) under duality, and the identities in (3.7) are equivalent with the identities in (3.5) under duality. In view of the continuity relations in (2.6) for wedge-algebras, the relations in (3.1) trivially imply the relations in (3.8), and *vice versa.*

(3) We consider part (c). Let $K \in \mathscr{K}_C$, and let $W \in \mathscr{W}$ and $W \supset K$. By Lemma 3.4 there then exists a double cone $D_W \in \mathscr{D}$ such that $W \supset D_W \supset D_W^o \supset K$. By isotony we have $\mathscr{A}(W) \supset \mathscr{B}(D_W) \supset \cap\{\mathscr{B}(D) | D \in \mathscr{D},\ D^o \supset K\} \supset \mathscr{B}(K)$, and it follows that $\mathscr{B}(K) = \cap\{\mathscr{A}(W) | W \in \mathscr{W},\ W \supset K\} \supset \cap\{\mathscr{B}(D) | D \in \mathscr{D},\ D^o \supset K\} \supset \mathscr{B}(K)$. This proves the relation in (3.9).

The assertions in part (d) are trivial in view of the definitions in (3.1), and in view of what has been shown. This completes the proof.

We are now prepared for the extension of an ''original'' *basic* net $\mathscr{N}_o$.

Theorem 3.7: Let $\mathscr{N}_o$ be a *basic net*, with algebras $\mathscr{A}_o(W)$, $\mathscr{B}_o(D)$, and $\mathscr{A}_o(D^c)$, as described in Definition 2.3. There then exists a *unique regular net* $\mathscr{N}$, with algebras $\mathscr{A}(W)$, $\mathscr{B}(K)$, and $\mathscr{A}(K^c)$, as described in Definition 3.1, such that $\mathscr{B}(D) = \mathscr{B}_o(D)$ for all $D \in \mathscr{D}$. The

net $\mathscr{N}$ is an *extension* of the net $\mathscr{N}_o$ in the sense that we also have $\mathscr{A}(D^c)=\mathscr{A}_o(D^c)$ for all $D\in\mathscr{D}$, and $\mathscr{A}(W)=\mathscr{A}_o(W)$ for all $W\in\mathscr{W}$. Furthermore, with $\mathscr{U}_o$ as in Definition 2.3, we have $\mathscr{U}=\mathscr{U}_o$, i.e.,

$$\cup\{\mathscr{B}(K)\,|\,K\in\mathscr{K}_C\}=\cup\{\mathscr{B}_o(D)\,|\,D\in\mathscr{D}\}, \tag{3.10}$$

and the *local* operators of $\mathscr{N}$ and $\mathscr{N}_o$ are thus precisely the same.

The extension $\mathscr{N}$ is also uniquely determined by the condition that $\mathscr{N}$ is a regular net which satisfies the condition $\mathscr{A}(W)=\mathscr{A}_o(W)$ for some $W\in\mathscr{W}$.

Proof: (1) For each $W\in\mathscr{W}$ we write $\mathscr{A}(W)=\mathscr{A}_o(W)$, and for each $K\in\mathscr{K}_C$ we define the von Neumann algebras $\mathscr{B}(K)$ and $\mathscr{A}(K^c)$ by

$$\mathscr{B}(K)=\cap\{\mathscr{A}_o(W)\,|\,W\in\mathscr{W},\ \overline{W}\supset K\},\quad \mathscr{A}(K^c)=\{\mathscr{A}_o(W)\,|\,W\in\mathscr{W},\ W\subset K^c\}''. \tag{3.11}$$

We want to show that the system $\mathscr{N}$ of algebras so defined is a regular net, related to the net $\mathscr{N}_o$ as described above. We first note that we have $\mathscr{B}(D)=\mathscr{B}_o(D)$ and $\mathscr{A}(D^c)=\mathscr{A}_o(D^c)$ for any $D\in\mathscr{D}\subset\mathscr{K}_C$, in view of (2.2) and the definitions in (3.11). It is trivial that the system $\mathscr{N}$ is irreducible, since the net $\mathscr{N}_o$ is irreducible.

The Poincaré- and *PCT*-covariance of the system $\mathscr{N}$ follows trivially from the Poincaré- and *PCT*-covariance of the mapping $W\to\mathscr{A}_o(W)=\mathscr{A}(W)$. We next have to show that the system $\mathscr{N}$ satisfies the conditions of isotony, locality, and duality.

(2) We consider the condition of isotony. The relation $\mathscr{A}(W_1)\subset\mathscr{A}(W_2)$ if $W_1\subset W_2$ is included in the premises. It follows at once from the definitions in (3.11) that if $K_1,K_2\in\mathscr{K}_C$ and $K_1\supset K_2$ (and hence $K_1^c\subset K_2^c$), then $\mathscr{B}(K_1)\supset\mathscr{B}(K_2)$ and $\mathscr{A}(K_1^c)\subset\mathscr{A}(K_2^c)$. It is trivial that $\mathscr{B}(K)\subset\mathscr{A}(W)$ if $K\subset\overline{W}$, and that $\mathscr{A}(W)\subset\mathscr{A}(K^c)$ if $W\subset K^c$. Suppose now that $K_1,K_2\in\mathscr{K}_C$ and $K_1\subset K_2^c$. By Lemma 3.5 there then exists a wedge $W\in\mathscr{W}$ such that $K_1\subset\overline{W}$ and $K_2\subset W^c$. The latter relation is equivalent with the relation $W\subset K_2^c$. By the definitions in (3.11) we then have $\mathscr{B}(K_1)\subset\mathscr{A}(W)\subset\mathscr{A}(K_2^c)$. Since we cannot have $W\subset K$, or $K^c\subset W$, or $K^c\subset K_1$ for any $K,K_1\in\mathscr{K}_C$ and any $W\in\mathscr{W}$, we have thus proved all the isotony relations.

(3) To prove the conditions of locality, we have to consider a number of different cases, as in the case of isotony. The locality condition for the case of two spacelike separated wedges in $\mathscr{W}$ is included in the premises. Suppose now that $K\in\mathscr{K}_C$ and $W\in\mathscr{W}$, and that $K\subset W^c$. We then have $\mathscr{B}(K)^z\subset\mathscr{A}((W^c)^o)^z\subset\mathscr{A}(W)'$, taking into account the fact that $(W^c)^o=\overline{W^c}$, and the locality condition thus holds for this case. We next consider the case when $K_1,K_2\in\mathscr{K}_C$ and $K_1\subset(K_2^c)^c=K_2$. Let $W\subset K_2^c$, and hence $K_1\subset K_2\subset W^c$. By the above we thus have $\mathscr{A}(W)\subset(\mathscr{B}(K_1)^z)'$, and since this holds for every $W\subset K_2^c$ it follows from the definition at right in (3.11) that $\mathscr{A}(K_2^z)\subset(\mathscr{B}(K_1)^z)'$, which proves the locality condition in this case.

Let $K_1,K_2\in\mathscr{K}_C$, and $K_1\subset K_2^c$. By Lemma 3.5 there then exists a wedge $W\in\mathscr{W}$ such that $K_1\subset\overline{W}$ and $K_2\subset W^c$. By the above we have $\mathscr{B}(K_2)^z\subset\mathscr{A}(W)'$, and since $\mathscr{B}(K_1)\subset\mathscr{A}(W)$, and hence $\mathscr{A}(W)'\subset\mathscr{B}(K_1)'$, it follows that $\mathscr{B}(K_2)^z\subset\mathscr{B}(K_1)'$. This proves the locality condition for two spacelike separated subsets $K_1,K_2\in\mathscr{K}_C$.

It remains to consider the cases of two regions K^c or a wedge W and a region K^c. The salient point is now that the question of locality *does not apply* to such configurations. If $K\in\mathscr{K}_C$ and $W\in\mathscr{W}$, then W cannot be spacelike separated from K^c. The relation $K^c\subset W^c$ would imply that $W\subset K$, which is impossible, and the relation $K_1^c\subset(K_2^c)^c=K_2$ is likewise impossible since K_1^c is a union of wedges in $\mathscr{W}$.

(4) We next prove that the extended net satisfies the condition of duality in part (c) in Definition 3.1. The relation at left in (3.3) is included in the premises. To prove the relation at right in (3.3) we form the commutant of both members in the relation at right in (3.11), and we obtain $\mathscr{A}(K^c)'=\cap\{\mathscr{A}(W)'\,|\,W\in\mathscr{W},\ W\subset K^c\}=\cap\{\mathscr{A}(\overline{W^c})^z\,|\,W\in\mathscr{W},\ W\subset K^c\}$. With $W_1=\overline{W^c}$ the relation $W\subset K^c$ is equivalent with the relation $\overline{W_1}\supset K$, and hence we obtain $\mathscr{A}(K^c)'=(\cap\{\mathscr{A}(W_1)\,|\,W_1\in\mathscr{W},\ \overline{W_1}\supset K\})^z=\mathscr{B}(K)^z$.

(5) We have now shown that the system $\mathscr{N}$ is a local net. By (2.3) we have $\mathscr{A}(W)=\{\mathscr{B}(D)\,|\,D\in\mathscr{D},\ D\subset W\}''$, and it then follows from the relation at right in (3.11) that we also

have $\mathscr{A}(K^c)=\{\mathscr{B}(D)|D\in\mathscr{D},\ D\subset K^c\}''$ for any $K\in\mathscr{K}_C$. Hence the net $\mathscr{N}$ satisfies Condition IX in Definition 2.1, and we conclude from the above that $\mathscr{N}$ satisfies *all* the Conditions I–IX in Definition 2.1.

We have $\mathscr{A}(W)\supset\{\mathscr{B}(K)|K\in\mathscr{K}_C,\ K\subset W\}''\supset\{\mathscr{B}(D)|D\in\mathscr{D},\ D\subset W\}''=\mathscr{A}(W)$, which proves the relations in (3.4). Since every $K\in\mathscr{K}_C$ is contained in some double cone $D\in\mathscr{D}$, and since we obviously have $\cup\{\mathscr{B}(K)|K\in\mathscr{K}_C\}\supset\cup\{\mathscr{B}(D)|D\in\mathscr{D}\}$, the identity in (3.10) follows.

It is trivial that the net of $\mathscr{N}$ satisfies the conditions in part (d) of Definition 3.1. Hence $\mathscr{N}$ is a *regular* net. The asserted uniqueness of a *regular* extension of $\mathscr{N}_o$ follows trivially from Proposition 3.6. This completes the proof.

As we see from the above, the extension of the basic net to a regular net, as described in Theorem 3.7, is not at all an ''enlargement'' of the set $\mathscr{U}_o$ of local operators. What is involved is rather a more refined assignment of the operators in $\mathscr{U}_o$ to subsets of Minkowski spacetime M. The set $\mathscr{U}_o=\mathscr{U}$ is, in fact, *maximal* in the sense that we cannot add any new local operator Q to the set. Such an operator would have to be in the commutant of one of the algebras $\mathscr{A}_o(D^c)^z$, and hence in $\mathscr{B}_o(D)\subset\mathscr{U}_o$. The existence of a unique regular net, as described in Definition 3.1, is thus *implicit* in the notion of a basic net, as described in Definition 2.3, and involves no new assumptions.

We could have shortened the above somewhat pedantic proof by relying on Lemma 2.2, according to which the conclusions in step (3) follow from the results in steps (2) and (4), but we felt that it is of interest to see in detail how the properties of isotony and locality follow from the corresponding properties of the set of wedge-algebras, independently of duality. We note that the locality condition involving two spacelike separated sets K_1 and K_2 is not entirely trivial, since the conclusion depends on the facts stated in Lemma 3.5, but the locality conditions for all the other possible configurations are indeed trivial. Likewise the proof of the corresponding isotony relation $\mathscr{B}(K_1)\subset\mathscr{A}(K_2^c)$ involves Lemma 3.5, whereas all the other isotony relations are trivial.

A *regular* net is completely determined by its ''wedge-algebras'' $\mathscr{A}(W)$, in view of the relations (3.1) or (3.8). It is also completely determined by the particular local algebras $\mathscr{B}(D)$, with $D\in\mathscr{D}$, in view of (3.4). The idea behind our notation in this paper is that a $\mathscr{B}$-algebra of a (closed) set $K\in\mathscr{K}_C$ is the intersection of all the $\mathscr{A}$-algebras of the (open) sets which contain K, and that an $\mathscr{A}$-algebra of an open region R is the von Neumann algebra generated by all $\mathscr{B}$-algebras of the closed sets in $\mathscr{K}_C$ contained in R. [We noted before the slight inconsistency in that we write $\mathscr{A}(W)$ for $\mathscr{B}(\overline{W})$.] The local $\mathscr{B}$-algebras are, in a sense, the objects of primary interest, and the $\mathscr{A}$-algebras can be regarded as ''auxiliary'' objects. The important point is that the $\mathscr{A}$-algebras are generated by the local operators which they contain, as shown in (3.4) and (3.5). The duality condition relates the $\mathscr{B}$-algebras to the $\mathscr{A}$-algebras, but since the net $\mathscr{N}$ has a *strictly local structure* in the sense of Condition IX in Definition 2.1, the duality condition is really a condition on the *local* algebras, i.e., *Haag duality* obtains for the net.

Since the algebra $\mathscr{U}$ of all local operators for the extended net $\mathscr{N}$ is the same as the algebra $\mathscr{U}_o$ for the original basic net $\mathscr{N}_o$, we expect that the algebra $\mathscr{B}(K)$ for any $K\in\mathscr{K}_C$ can be obtained ''directly'' from the algebras $\mathscr{B}(D)=\mathscr{B}_o(D)$ associated with double cones. That this is so is shown by the relation (3.9) in Proposition 3.6.

The extension principle in Theorem 3.7 has a more general applicability, which we illustrate as follows.

Proposition 3.8: Let $\mathscr{N}_a$ be a local net (not necessarily irreducible) with domain $\mathscr{D}$, with von Neumann algebras $\mathscr{B}_a(D)$. The net $\mathscr{N}_a$ thus satisfies Conditions I–V in Definition 2.1.

We define the von Neumann algebras $\mathscr{B}_e(K)$, $\mathscr{A}_e(W)$, and $\mathscr{A}_e(K^c)$ by

$$\mathscr{A}_e(W)=\{\mathscr{B}_a(D)|D\in\mathscr{D},\ D\subset W\}'' \tag{3.12}$$

and

$$\mathscr{B}_e(K)=\cap\{\mathscr{A}_e(W)|W\in\mathscr{W},\ \overline{W}\supset K\},\quad \mathscr{A}_e(K^c)=\{\mathscr{A}_e(W)|W\in\mathscr{W},\ W\subset K^c\}'', \tag{3.13}$$

for all $K\in\mathscr{K}_C$ and all $W\in\mathscr{W}$. Then:

(a) The algebras $\mathcal{B}_e(K)$, $\mathcal{A}_e(W)$, and $\mathcal{A}_e(K^c)$ are the von Neumann algebras of a local net $\mathcal{N}_e$ which satisfies Conditions I–V and IX in Definition 2.1. Furthermore the net satisfies the condition

$$\mathcal{A}_e(W)=\{\mathcal{B}_e(K)|K\in\mathcal{K}_C,\ K\subset W\}''=\{\mathcal{B}_e(D)|D\in\mathcal{D},\ D\subset W\}'', \tag{3.14}$$

for all $W\in\mathcal{W}$. The net $\mathcal{N}_e$ satisfies the condition of *PCT*-covariance if the net $\mathcal{N}_a$ satisfies this condition.

(b) The nets $\mathcal{N}_e$ and $\mathcal{N}_a$ are related by

$$\mathcal{B}_e(D)\subset\mathcal{B}_a(D), \tag{3.15}$$

for all $D\in\mathcal{D}$.

We write $\mathcal{U}_a=\cup\{\mathcal{B}_a(D)|D\in\mathcal{D}\}$ for the algebra of all local operators of the net $\mathcal{N}_a$, and we write $\mathcal{U}_e=\cup\{\mathcal{B}_e(K)|K\in\mathcal{K}_C\}$ for the algebra of all local operators of the net $\mathcal{N}_e$. We then have

$$\mathcal{U}_e\supset\mathcal{U}_a,\quad \mathcal{U}_a''=\mathcal{U}_e=\mathcal{A}_e(\mathsf{M}). \tag{3.16}$$

(c) The sub-Hilbert space $\mathcal{H}_a=\overline{\mathcal{U}_a\Omega}$ is Poincaré-invariant, and we have

$$\overline{\mathcal{A}_e(W)\Omega}=\overline{\mathcal{A}_e(K^c)\Omega}=\overline{\mathcal{U}_e\Omega}=\overline{\mathcal{U}_a\Omega}=\mathcal{H}_a, \tag{3.17}$$

for all $W\in\mathcal{W}$ and all $K\in\mathcal{K}_C$.

(d) Suppose that a local net $\mathcal{N}_b$ with domain $\mathcal{K}_C$, with von Neumann algebras $\mathcal{B}_b(K)$ defined for all $K\in\mathcal{K}_C$, is an *extension* of the net $\mathcal{N}_a$ such that $\mathcal{B}_b(D)=\mathcal{B}_a(D)$ for all $D\in\mathcal{D}$. We then have $\mathcal{U}_b=\mathcal{U}_a$, with $\mathcal{U}_b=\cup\{\mathcal{B}_b(K)|K\in\mathcal{K}_C\}$, and

$$\mathcal{A}_e(W)=\{\mathcal{B}_b(K)|K\in\mathcal{K}_C,\ K\subset W\}'', \tag{3.18}$$

$$\mathcal{B}_e(K)\supset\mathcal{B}_b(K), \tag{3.19}$$

for all $W\in\mathcal{W}$ and all $K\in\mathcal{K}_C$.

Proof: (1) The Poincaré-covariance of the mapping $W\to\mathcal{A}_e(W)$ follows from the Poincaré-covariance of the net $\mathcal{N}_a$, in view of the definition in (3.12). The Poincaré-covariance of the system N_e then follows, in view of the definitions in (3.13). Similarly we conclude that the system $\mathcal{N}_e$ satisfies the condition of *PCT*-covariance if the net $\mathcal{N}_a$ satisfies this condition.

From the definition in (3.12) it also follows trivially that the mapping $W\to\mathcal{A}_e(W)$ satisfies the conditions of isotony and locality. By the same reasoning as in steps (2) and (3) in the proof of Theorem 3.7 we then conclude that the system $\mathcal{N}_e$ satisfies all the relevant conditions of isotony and of locality.

(2) By (3.12) and (3.13) we have $\mathcal{B}_a(D)\subset\cap\{\mathcal{A}_e(W)|W\in\mathcal{W},\ \overline{W}\supset D\}=\mathcal{B}_e(D)$, for every $D\in\mathcal{D}$. Hence we have $\mathcal{U}_e\supset\mathcal{U}_a$, and we also readily conclude that $\mathcal{U}_a''=\mathcal{A}_e(\mathsf{M})=\mathcal{U}_e''$. With the results in step (1) this implies that $\mathcal{N}_e$ is a local net.

Since $\mathcal{B}_e(D)\subset\mathcal{A}_e(W)$ if $D\subset W$ it follows that $\mathcal{A}_e(W)\supset\{\mathcal{B}_e(D)|D\in\mathcal{D},\ D\subset W\}''\supset\{\mathcal{B}_a(D)|D\in\mathcal{D},\ D\subset W\}''=\mathcal{A}_e(W)$. The relation (3.14) follows, and in view of the definition of the algebras $\mathcal{A}_e(K^c)$ we conclude that the net $\mathcal{N}$ satisfies Condition IX in Definition 2.1. We have thus proved the assertions in parts (a) and (b).

(3) We consider part (c). The subspace $\mathcal{H}_a$ is trivially Poincaré-invariant. The relation $\overline{\mathcal{U}_e\Omega}=\overline{\mathcal{U}_a\Omega}$ follows from the relation $\mathcal{U}_a''=\mathcal{U}_e''$. The remaining relations in (3.17) follow by a well-known argument involving the *Reeh–Schlieder Principle*.

(4) We consider part (d). Let $K\in\mathcal{K}_C$, $W\in\mathcal{W}$, and $K\subset W$. By Lemma 3.4 there then exists a double cone D such that $K\subset D\subset W$. Hence $\mathcal{B}_b(K)\subset\mathcal{B}_b(D)=\mathcal{B}_a(D)\subset\mathcal{A}_e(W)$. From this we conclude that $\mathcal{U}_b\subset\mathcal{U}_a$, and since the opposite inclusion is trivial, it follows that $\mathcal{U}_b=\mathcal{U}_a$. Furthermore we conclude that the left member in (3.18) includes the right member, and since the latter obviously includes the right member in (3.12), we obtain the identity in (3.18). The inclusion relation in (3.19) is proved by the same reasoning as in the proof of the relation in (3.15). This completes the proof.

The net $\mathcal{N}_e$ is a rather natural extension of an original local net $\mathcal{N}_a$ with domain $\mathcal{D}$, or of an original local net $\mathcal{N}_b$ with domain $\mathcal{K}_C$. It is easy to construct examples for which $\mathcal{B}_a(D)$ is smaller than $\mathcal{B}_e(D)$. It can also happen that $\mathcal{U}_a$ is smaller than $\mathcal{U}_e$. Examples of this possibility can be constructed within the theory of generalized free fields. The local operators in $\mathcal{U}_e$ are, however, implicit in the net $\mathcal{N}_a$, ''hidden'' in the wedge-algebras $\mathcal{A}_e(W)$ constructed as in (3.12), and the relations (3.16) and (3.17) are always valid. If we apply the proposition to the case when the net $\mathcal{N}_a$ is the restriction of a *basic net* $\mathcal{N}_o$ to the domain $\mathcal{D}$, the extension $\mathcal{N}_e$ will be equal to the *regular net* $\mathcal{N}$ in Theorem 3.7. This circumstance, and the fact that the net $\mathcal{N}_e$ satisfies the relations (3.13) and (3.14), provide justification for regarding such a net as a *standard form* of a local net with a domain consisting of all wedges in $\mathcal{W}$ and all $K \in \mathcal{K}_C$ and their causal complements K^c.

In Theorem 3.7 we noted the trivial fact that the basic net $\mathcal{N}_o$ and the extended net $\mathcal{N}$ have the same set of local operators. The proposition which follows illustrates the ''rigid structure'' of the set of local operators of a regular net under certain circumstances.

Proposition 3.9: Let $\mathcal{N}$ be a *regular* net which satisfies the *special condition of duality*, as described in Definition 2.4. Let $\mathcal{N}_e$, with von Neumann algebras $\mathcal{A}_e(W)$, $\mathcal{B}_e(K)$, and $\mathcal{A}_e(K^c)$ for all $W \in \mathcal{W}$ and all $K \in \mathcal{K}_C$, be another local net (relative to the *same* representation of the group $\hat{\mathsf{P}}$, on the same Hilbert space). We assume that $\mathcal{N}_e$ is of the *standard form* described in Proposition 3.8, i.e., the net satisfies the conditions in (3.13) and in (3.14). Let $\mathcal{U}$ be the set of all local operators of the net $\mathcal{N}$, and similarly, let $\mathcal{U}_e = \cup\{\mathcal{B}_e(K) | K \in \mathcal{K}_C\}$. Suppose that Ω is *cyclic* for the set $\mathcal{S} = \mathcal{U} \cap \mathcal{U}_e$. Then $\mathcal{N} = \mathcal{N}_e$.

Proof: Let $B \in \mathcal{S}$. We then have $B \in \mathcal{B}(D_1) \cap \mathcal{B}_e(D_2)$ for some $D_1, D_2 \in \mathcal{D}$. There then exists a nonempty open subset X_B of W_R such that the translates of D_1 and D_2 by any $x \in X_B$ are contained in W_R, and hence $T(x)BT(x)^{-1} \in \mathcal{A}(W_R) \cap \mathcal{A}_e(W_R)$ for all $x \in X_B$. From this we conclude, by the *Reeh–Schlieder Principle*, that Ω is cyclic for $\mathcal{A}(W_R) \cap \mathcal{A}_e(W_R) = \mathcal{A}_R$, since Ω is cyclic for the set $\mathcal{S} = \mathcal{U} \cap \mathcal{U}_e$. The algebra $\mathcal{A}_R$ is obviously invariant under conjugation by any velocity transformation $V(\tau)$ in the 3-direction. Since the net $\mathcal{N}$ satisfies the *special condition of duality*, and since $\mathcal{A}_R \subset \mathcal{A}(W_R)$, it follows that $\mathcal{A}_R = \mathcal{A}(W_R)$, and hence $\mathcal{A}_e(W_R) \supset \mathcal{A}(W_R)$. Similarly we have $\mathcal{A}_e(W_L) \supset \mathcal{A}(W_L)$, and hence $\mathcal{A}_e(W_R)^z \subset \mathcal{A}_e(W_L)' \subset \mathcal{A}(W_L)' = \mathcal{A}(W_R)^z$. We conclude that $\mathcal{A}_e(W_R) = \mathcal{A}(W_R)$, from which it follows readily that $\mathcal{N}_e = \mathcal{N}$, i.e., we also have $\mathcal{B}_e(K) = \mathcal{B}(K)$ and $\mathcal{A}_e(K^c) = \mathcal{A}(K^c)$. This completes the proof.

That two irreducible local nets of the standard form should be identical if they have ''sufficiently many'' local operators in common seems rather plausible, and this conclusion does hold if at least one of the nets satisfies the *special condition of duality*, but the conclusion might possibly fail if this is not the case. The above proposition rules out any ''reassignment'' of regions for the local operators. We have $B \in \mathcal{B}_e(K)$ if and only if $B \in \mathcal{B}(K)$. Note that this was *not* assumed in the premises, for the operators in $\mathcal{S}$.

We next consider a proposition which provides a framework for possible further extensions of a basic net.

Proposition 3.10: Let $\mathcal{N}$ be a *regular* net as described in Definition 3.1, with algebras $\mathcal{A}(W)$, $\mathcal{B}(K)$, and $\mathcal{A}(K^c)$. Let $\mathcal{K}$ be the set of all *closed, convex, causally complete* subsets K of M, such that K^c has a *nonempty* interior. For each $K \in \mathcal{K}$ we define the von Neumann algebras $\mathcal{B}^\sharp(K)$ and $\mathcal{A}^\sharp(K^c)$ by

$$\mathcal{B}^\sharp(K) = \cap\{\mathcal{A}(W) | W \in \mathcal{W},\ \overline{W} \supset K\}, \quad \mathcal{A}^\sharp(K^c) = \{\mathcal{A}(W) | W \in \mathcal{W},\ W \subset K^c\}'', \tag{3.20}$$

and hence we have $\mathcal{B}^\sharp(K) = \mathcal{B}(K)$ and $\mathcal{A}^\sharp(K^c) = \mathcal{A}(K^c)$ for all $K \in \mathcal{K}_C$, and $\mathcal{A}^\sharp(W) = \mathcal{A}(W) = \mathcal{B}^\sharp(\overline{W})$ for all $W \in \mathcal{W}$. We refer to the algebras $\mathcal{B}^\sharp(K)$ and $\mathcal{A}^\sharp(K^c)$ as the *associated algebras of the net* $\mathcal{N}$, and we denote this system of algebras by $\mathcal{N}^\sharp$. Then:

(a) The mappings $K \to \mathcal{B}^\sharp(K)$ and $K^c \to \mathcal{A}^\sharp(K^c)$ are Poincaré-covariant and *PCT*-covariant.

(b) The associated algebras satisfy the duality condition

$$\mathcal{B}^\sharp(K)^z = \mathcal{A}^\sharp(K^c)', \tag{3.21}$$

for all $K \in \mathscr{K}$.

(c) If $K_s, K_l \in \mathscr{K}$, and $K_s \subset K_l$, and hence $K_s^c \supset K_l^c$, then

$$\mathscr{B}^\sharp(K_s) \subset \mathscr{B}^\sharp(K_l) = (\mathscr{A}^\sharp(K_l^c)^z)', \quad (\mathscr{B}^\sharp(K_l)^z)' = \mathscr{A}^\sharp(K_l^c) \subset \mathscr{A}^\sharp(K_s^c). \tag{3.22}$$

(d) If $K_1, K_2 \in \mathscr{K}$, and $K_1 \subset K_2^c$, and if either K_1 or K_2 has a *nonempty interior*, then

$$\mathscr{B}^\sharp(K_1)^z \subset \mathscr{B}^\sharp(K_2)', \quad \mathscr{B}^\sharp(K_1) \subset \mathscr{A}^\sharp(K_2^c). \tag{3.23}$$

(e) The algebras $\mathscr{A}^\sharp(K^c)$ are generated by the *local* operators which they contain, and specifically,

$$\mathscr{A}^\sharp(K^c) = \{\mathscr{B}(D) | D \in \mathscr{D},\ D \subset K^c\}'' = (\mathscr{A}^\sharp(K^c) \cap \mathscr{U})'', \tag{3.24}$$

for any $K \in \mathscr{K}$. Here $\mathscr{U} = \cup\{\mathscr{B}(K) | K \in \mathscr{K}_C\}$ is the algebra of all local operators of the net $\mathscr{N}$.

(f) If the locality relation at left in (3.23) holds for *all* $K_1, K_2 \in \mathscr{K}$ such that $K_1 \subset K_2^c$, then the system $\mathscr{N}^\sharp$ of algebras is an irreducible local net which satisfies all the Conditions I–VIII in Definition 2.1.

Proof: (1) The duality condition in (3.21) is proved by the same kind of reasoning as in step (4) in the proof of Theorem 3.7. The conclusions in parts (a) and (c) then follow trivially from the defining relations in (3.20).

(2) We consider part (d). The proof of the *particular* locality condition at left in (3.23) is based on part (a) of Lemma 3.5. Suppose that K_1 has a nonempty interior. The interior K_1^o is convex since K_1 is convex, and we have $\overline{K_1^o} = K_1$ and $(K_1^o)^c \supset K_2$. By Lemma 3.5 there then exists a wedge $W \in \mathscr{W}$ such that $K_1^o \subset W$ and $K_2 \subset W^c$. Hence $K_1 \subset \overline{W}$ and $\mathscr{B}^\sharp(K_1) \subset \mathscr{A}(W)$, $\mathscr{B}^\sharp(K_2) \subset \mathscr{A}(\overline{W^c})$, from which the relation at left in (3.23) follows by the duality relation $\mathscr{A}(W)^z = \mathscr{A}(\overline{W^c})'$ for the wedge-algebras. The relation at right in (3.23) is equivalent with the relation at left, in view of the duality relation (3.21).

(3) The relations in (3.24) follow readily from the defining relation at right in (3.20), and from the relation $\mathscr{A}(W) = \{\mathscr{B}(D) | D \in \mathscr{D},\ D \subset W\}''$ which holds for the regular net $\mathscr{N}$.

(4) We consider part (f). If $K_1, K_2 \in \mathscr{K}$, then K_1^c and K_2^c *cannot* be spacelike separated unless *both* K_1^c and K_2^c are wedges in $\mathscr{W}$. This means that the locality relations in (3.22) and (3.23) include all applicable locality conditions for the system $\mathscr{N}^\sharp$, and with the premise in part (f) the system $\mathscr{N}^\sharp$ thus satisfies the condition of locality. Since it also satisfies the condition of duality it follows, by Lemma 2.2, that it satisfies the condition of isotony, and hence $\mathscr{N}^\sharp$ is a local net of the asserted kind. This completes the proof.

We are *not* suggesting that the system $\mathscr{N}^\sharp$ is a local net in general. We have no proof, and no counterexample. The geometric basis for the above construction is described in Proposition 3.2. It is worth noting that the causal complement K^c of a set $K \in \mathscr{K}$ is not necessarily open, but it is ''close'' to its interior in the sense that $((K^c)^o)^c = K$ and $(\overline{K^c})^o = (K^c)^o$. The algebras of the system $\mathscr{N}^\sharp$ are interesting objects to consider, and the proposition which follows supports this view.

Proposition 3.11: Let $\mathscr{N}$ be a *regular net*, with algebras $\mathscr{A}(W)$, $\mathscr{B}(K)$, and $\mathscr{A}(K^c)$ for all $W \in \mathscr{W}$ and all $K \in \mathscr{K}_C$. Let $\mathscr{N}^\sharp$ be the system of *associated algebras*, as described in Proposition 3.10. Let $\mathscr{K}_X$ be a Poincaré- and *PCT*-invariant subset of $\mathscr{K}$ which contains $\mathscr{K}_C$.

(a) Suppose that there exists a local net $\mathscr{N}_X$, with algebras $\mathscr{A}_X(W)$, $\mathscr{B}_X(K)$, and $\mathscr{A}_X(K^c)$ for all $W \in \mathscr{W}$ and all $K \in \mathscr{K}_X$, which satisfies *all* the Conditions I–IX in Definition 2.1. Suppose furthermore that the net $\mathscr{N}_X$ is an extension of the net $\mathscr{N}$ in the sense that $\mathscr{A}_X(W) = \mathscr{A}(W)$, $\mathscr{B}_X(K) = \mathscr{B}(K)$, and $\mathscr{A}_X(K^c) = \mathscr{A}(K^c)$ for all $W \in \mathscr{W}$ and all $K \in \mathscr{K}_C$. We then have $\mathscr{B}_X(K) = \mathscr{B}^\sharp(K)$ and $\mathscr{A}_X(K^c) = \mathscr{A}^\sharp(K^c)$ for all $K \in \mathscr{K}_X$, and an extension with the domain of $\mathscr{N}_X$ is thus *unique*.

(b) An extension of the kind described in (a) exists if and only if

$$\mathscr{B}^\sharp(K) = \{\mathscr{B}(K_c) | K_c \in \mathscr{K}_C,\ K_c \subset K\}'', \tag{3.25}$$

for all $K \in \mathscr{K}_X$.

Proof: (1) We consider part (a). Let $K \in \mathscr{K}_X$. By (3.24) we have $\mathscr{A}^\sharp(K^c) = \{\mathscr{B}(K_i) | K_i \in \mathscr{K}_C,\ K_i \subset K^c\}''$. Since the net satisfies Condition IX in Definition 2.1, we have $\mathscr{A}_X(K^c) = \{\mathscr{B}(K_i) | K_i \in \mathscr{K}_C,\ K_i \subset K^c\}''$, and hence $\mathscr{A}_X(K^c) = \mathscr{A}^\sharp(K^c)$ for all $K \in \mathscr{K}_X$. Since both the net $\mathscr{N}_X$ and the system $\mathscr{N}^\sharp$ satisfies the condition of duality, it follows that also $\mathscr{B}_X(K) = \mathscr{B}^\sharp(K)$.

(2) We consider part (b). That the condition in (3.25) is necessary follows from the assumption that $\mathscr{N}_X$ satisfies Condition IX in Definition 2.1. To prove the sufficiency we assume that this condition holds. Let $K_1, K_2 \in \mathscr{K}_X$, and $K_1 \subset K_2^c$. Let $K_{1c}, K_{2c} \in \mathscr{K}_C$, and such that $K_{1c} \subset K_1$ and $K_{2c} \subset K_2$. We then have $K_{1c} \subset K_{2c}^c$, and hence $\mathscr{B}(K_{1c})^z \subset \mathscr{B}(K_{2c})'$. With reference to (3.25) we then conclude that $\mathscr{B}^\sharp(K_1)^z \subset \mathscr{B}^\sharp(K_2)'$, which means that the system $\mathscr{N}^\sharp$ restricted to the domain of $\mathscr{N}_X$ satisfies *all* the applicable conditions of locality. Since the restricted system satisfies the condition of duality, it follows by Lemma 2.2 that the restricted system also satisfies all applicable conditions of isotony, and hence the restricted system is a local net $\mathscr{N}_X$, which satisfies the premises in part (a). This completes the proof.

The existence of an extension of the kind described above is thus implicit in the structure of the net $\mathscr{N}$, or of the basic net $\mathscr{N}_o$ of which $\mathscr{N}$ is the extension, and if it exists, it is unique. It is interesting to consider the possibility that such an extension exists for $\mathscr{K}_X$ equal to the set $\mathscr{K}_E$ in Definition 1.1. We recall that $\mathscr{K}_E$ is the set of all elements K of $\mathscr{K}$ which are contained in the intersection of some pair of wedges in $\overline{\mathscr{W}}$ which are in a general relative position. In particular $\mathscr{K}_E$ contains all sets of the form $\overline{W_1 \cap W_2}$ where W_1 and W_2 are in a general relative position. The intersection of two closed causal wedges which are *not* in a general relative position is in $\mathscr{K}$, but *not* in $\mathscr{K}_E$. The issue is then whether the locality condition at left in (3.23) holds for *all* $K_1, K_2 \in \mathscr{K}_E$. We easily see, on the basis of part (b) in Lemma 3.5, that this condition holds, with the possible exception of the case when *both* K_1 and K_2 are *unbounded* subsets of the *same* characteristic plane. This is a rather singular exceptional case, but we do not know whether this obstacle is real or illusory. For a net of algebras generated by a massive free Hermitian scalar field the set of all $\mathscr{B}$-algebras (with domain $\mathscr{K}_E$) is indeed local, and we have no example of a possible failure of this locality condition.

If an element $K \in \mathscr{K}$ has an empty interior it is always a subset of a characteristic plane. As we show in the next section, the von Neumann algebra $\mathscr{B}^\sharp(K)$ associated with such a set is not necessarily trivial, and these sets K can therefore not be dismissed outright as ''unphysical,'' although they are, in a sense, mildly pathological. We can avoid the pathology by excluding the algebras $\mathscr{B}^\sharp(K)$ and $\mathscr{A}^\sharp(K^c)$ for every $K \in \mathscr{K}$ which has an empty interior, and we then obtain a unique local net $\mathscr{N}_I$ from a regular net $\mathscr{N}$. We describe this in the theorem below. The proof follows trivially from Proposition 3.10, and we feel that we can omit the details.

Theorem 3.12: Let the premises and notation be as in Proposition 3.10. Let $\mathscr{K}_I$ be the set of all $K \in \mathscr{K}$ which have a *nonempty interior*, i.e., $\mathscr{K}_I$ is the set of all *closed convex* subsets K of M such that both K and K^c have *nonempty interiors*. Then the system $\mathscr{N}_I$ of von Neumann algebras $\{\mathscr{B}_I(K), \mathscr{A}_I(K^c) | K \in \mathscr{K}_I\}$, defined by $\mathscr{B}_I(K) = \mathscr{B}^\sharp(K)$ and $\mathscr{A}_I(K) = \mathscr{A}^\sharp(K^c)$ for all $K \in \mathscr{K}_I$, is a local net which satisfies *all* the Conditions I–VIII in Definition 2.1. Furthermore the net $\mathscr{N}_I$ satisfies the condition

$$\mathscr{A}_I(K^c) = \{\mathscr{B}_I(K_i) | K_i \in \mathscr{K}_I,\ K_i \subset K^c\}'' = \{\mathscr{B}_I(D) | D \in \mathscr{D},\ D \subset K^c\}'', \tag{3.26}$$

for all $K \in \mathscr{K}_I$. The net $\mathscr{N}_I$ is the *unique* net with the above domain which satisfies the condition in (3.26) and the condition that $\mathscr{B}_I(D) = \mathscr{B}(D)$ for all $D \in \mathscr{D}$.

We can again regard the $\mathscr{B}_I$-algebras as the primary objects of interest, and the $\mathscr{A}_I$-algebras as ''auxiliary'' constructs. It is then interesting to note that the local net with domain $\mathscr{K}_I$ consisting of the algebras $\mathscr{B}_I(K)$ satisfies a condition analogous to *Haag duality*, in view of (3.26) and the duality condition $\mathscr{A}_I(K^c) = (\mathscr{B}_I(K)^z)'$. Note also that we are *not* asserting that the net $\mathscr{N}_I$ satisfies Condition IX in Definition 2.1. The relation in (3.26) is *part* of this condition, but it might happen that the algebra $\mathscr{B}_I(K)$ for some unbounded $K \in \mathscr{K}_I$ is *not* generated by the local operators it contains.

IV. SOME PROPERTIES OF REGULAR NETS

In this section we consider some properties of a *regular* net $\mathscr{N}$, as described in Definition 3.1. Some of the properties of the algebras of such a net are shared by the associated algebras $\mathscr{B}^\sharp(K)$

and $\mathcal{A}^{\sharp}(K^c)$ of the net defined in Proposition 3.10, when K is an element of the set $\mathcal{K}_E$ in Definition 1.1, and we felt it worthwhile to state such results when applicable. The reader is warned, however, that these result might *not* be valid for an arbitrary K in the larger set $\mathcal{K}$. In many respects the elements of $\mathcal{K}_E$ are ''better behaved'' than arbitrary elements in $\mathcal{K}$.

As we noted in Section II, the algebras $\mathcal{B}_o(D)$ of a *basic* net are continuous from the outside, whereas the algebras $\mathcal{A}_o(D^c)$ are continuous from the inside, i.e., we have the relations in (2.7). A *regular* net has similar features, and one aspect of this can be stated as follows.

Proposition 4.1: Let $\mathcal{N}$ be a *regular* net, i.e., an irreducible local net as described in Definition 3.1, with algebras $\mathcal{A}(W)$, $\mathcal{A}(K^c)$, and $\mathcal{B}(K)$ defined for all $W \in \mathcal{W}$ and all $K \in \mathcal{K}_C$. Let the associated algebras $\mathcal{A}^{\sharp}(K^c)$ and $\mathcal{B}^{\sharp}(K)$ be defined by

$$\mathcal{B}^{\sharp}(K) = \cap\{\mathcal{A}(W) \mid W \in \mathcal{W},\ \overline{W} \supset K\}, \quad \mathcal{A}^{\sharp}(K^c) = \{\mathcal{A}(W) \mid W \in \mathcal{W},\ W \subset K^c\}'', \tag{4.1}$$

for all $K \in \mathcal{K}$, as in Proposition 3.10. Hence $\mathcal{B}^{\sharp}(K) = \mathcal{B}(K)$ and $\mathcal{A}^{\sharp}(K^c) = \mathcal{A}(K^c)$ for all $K \in \mathcal{K}_C$.

Let $K \in \mathcal{K}_E$, and let K_n, $n \in \mathbb{Z}_+$, be a nested sequence of sets $K_n \in \mathcal{K}_E$ such that $K_n \supset K_{n+1}$ for all positive n. Then

$$K = \cap\{K_n \mid n \in \mathbb{Z}_+\}, \tag{4.2}$$

if and only if

$$K^c = \cup\{K_n^c \mid n \in \mathbb{Z}_+\}, \tag{4.3}$$

and if this is the case, then

$$\mathcal{B}^{\sharp}(K) = \cap\{\mathcal{B}^{\sharp}(K_n) \mid n \in \mathbb{Z}_+\}, \quad \mathcal{A}^{\sharp}(K^c) = \{\mathcal{A}^{\sharp}(K_n^c) \mid n \in \mathbb{Z}_+\}''. \tag{4.4}$$

Proof: (1) It is trivial that the relation in (4.3) implies the relation in (4.2). To prove the converse we assume that the equality in (4.2) obtains. We first note that since $K_1 \in \mathcal{K}_E$, it follows from part (d) of Proposition 3.3 that there exist two *spacelike* 3-planes σ' and σ'' such that K_1 lies *below* σ' and *above* σ''. It follows readily from this that the set $\overline{V}(x) \cap K_1$ is *compact* for any $x \in \mathsf{M}$. Suppose now that $x \in K^c$, in which case we have $\overline{V}(x) \cap K = \varnothing$. By the assumed nesting, and by (4.2), we then have $\overline{V}(x) \cap K_1 \supset \overline{V}(x) \cap K_n \supset \overline{V}(x) \cap K_{n+1}$ and $\cap\{\overline{V}(x) \cap K_n \mid n \in \mathbb{Z}_+\} = \overline{V}(x) \cap K = \varnothing$. We cannot have $\overline{V}(x) \cap K_n \neq \varnothing$ for all n, because we would then have $\overline{V}(x) \cap K \neq \varnothing$, since $\overline{V}(x) \cap K_1$ is compact. Hence $\overline{V}(x) \cap K_m = \varnothing$ for some m, which means that $x \in K_m^c \subset \cup\{K_n^c \mid n \in \mathbb{Z}_+\}$. We have thus shown that $K^c \subset \cup\{K_n^c \mid n \in \mathbb{Z}_+\}$. Since it follows trivially from (4.2) that $K^c \supset \cup\{K_n^c \mid n \in \mathbb{Z}_+\}$ we then have the equality in (4.3).

(2) We now assume that the relations in (4.2) and (4.3) hold. Let $D \in \mathcal{D}$ be such that $D \subset K^c = \cup\{K_n^c \mid n \in \mathbb{Z}_+\}$. Since D is compact it follows that $D \subset K_m^c$ for some m, and hence $\mathcal{B}(D) \subset \mathcal{A}^{\sharp}(K_m^c) \subset \{\mathcal{A}^{\sharp}(K_n^c) \mid n \in \mathbb{Z}_+\}''$. By Proposition 3.10 we then have $\mathcal{A}^{\sharp}(K^c) = \{\mathcal{B}(D) \mid D \in \mathcal{D},\ D \subset K^c\}'' \subset \{\mathcal{A}^{\sharp}(K_n^c) \mid n \in \mathbb{Z}_+\}''$. We trivially have $\mathcal{A}^{\sharp}(K^c) \supset \{\mathcal{A}^{\sharp}(K_n^c) \mid n \in \mathbb{Z}_+\}''$ since $K^c \supset K_n^c$ for all n, and hence we obtain the equality at right in (4.4). The equality at left then follows by duality. This completes the proof.

Within free-field theories one can give examples (as we will do below) of local nets for which the algebras $\mathcal{B}(K)$ are *nontrivial* for certain sets $K \in \mathcal{K}_C$ with an empty interior, and for such a net the $\mathcal{B}$-algebras can obviously not be continuous from the *inside*. Within free-field theories the algebras $\mathcal{B}(K)$ *are* continuous from the inside when K has a nonempty interior, but it is not known whether this might be true for local nets in general.

We will next show, among other things, that if $K \in \mathcal{K}_C$, with K contained in a *two*-dimensional linear manifold, then the algebra $\mathcal{B}(K)$ is trivial.

Proposition 4.2: Let $\mathcal{N}$ be a *regular* net, with algebras $\mathcal{A}(W)$, $\mathcal{A}(K^c)$, and $\mathcal{B}(K)$ defined for all $W \in \mathcal{W}$ and all $K \in \mathcal{K}_C$. Then:

(a) For every $W \in \mathcal{W}$ we have

$$\mathcal{A}(W) \cap \mathcal{A}(W)' = \mathcal{A}(W) \cap \mathcal{A}(\overline{W^c})^z = \mathbb{C}^1 \cdot I, \quad \mathcal{A}(W) \cap \mathcal{A}(\overline{W^c}) = \mathbb{C}^1 \cdot I, \tag{4.5}$$

and $\mathscr{A}(W)$ is thus a factor.

(b) If $K \in \mathscr{K}_C$ is a subset of a *two*-dimensional linear submanifold of M, then $\mathscr{B}(K) = \mathsf{C}^1 \cdot I$, and hence $\mathscr{A}(K^c) = \mathsf{B}(\mathscr{H})$.

In particular we have $\mathscr{B}(\{x\}) = \mathsf{C}^1 \cdot I$ for any singleton $\{x\}$, and $\mathscr{B}([x', x'']) = \mathsf{C}^1 \cdot I$ for any isotropic or spacelike (finite) line segment.

(c) If $K \in \mathscr{K}_C$ is a subset of a characteristic plane in M, then it can happen that $\mathscr{B}(K)$ contains elements which are *not* multiples of the identity (provided that K is not a subset of a two-plane). The vector Ω is *not* cyclic for $\mathscr{B}(K)$, and hence *not* separating for $\mathscr{A}(K^c)$.

Proof: (1) We consider part (a). Let $W \in \mathscr{W}$. With a suitable choice of a standard coordinate system we can write $W = W_R = \{x | x \in \mathsf{M},\ x_3 > |x_4|\}$. Let u be the isotropic vector $u = (0,0,1,1)$. Let $B \in \mathscr{A}(W) \cap \mathscr{A}(W)'$. Since $W(su) = \{su + x | x \in W\} \subset W$ for all $s \geqslant 0$ we then have $T(su)BT(su)^{-1} \in \mathscr{A}(W)$, and hence $[B^*, T(su)BT(su)^{-1}] = 0$ for all $s \geqslant 0$. Similarly we have $[B, T(su)B^*T(su)^{-1}] = 0$ for all $s \geqslant 0$, and it follows that $[B^*, T(su)BT(su)^{-1}] = 0$ for *all* real s. By Lemma 2.6 we then have $\langle \Omega | B^*B\Omega \rangle = |\langle \Omega | B\Omega \rangle|^2$, which implies that $(B - cI)\Omega = 0$, for some complex c, and since Ω is separating for $\mathscr{A}(W)$ it follows that $B = cI$. This proves the identities at left in (4.5).

Let B be a *boson* operator in $\mathscr{A}(W) \cap \mathscr{A}(\overline{W^c})$. Since $\mathscr{A}(\overline{W^c})$ and $\mathscr{A}(W)' = \mathscr{A}(\overline{W^c})^z$ have precisely the same boson operators, it follows from the above that B is a multiple of the identity.

Suppose that A is a *fermion* operator in $\mathscr{A}(W) \cap \mathscr{A}(\overline{W^c})$. We then have $A^*A + AA^* = 0$ by locality, and hence $A = 0$. We have thus proved the relations in (4.5).

(2) We consider part (b), and assume that $K \in \mathscr{K}_C$ is a subset of a *two*-dimensional linear manifold ω, which is then necessarily a submanifold of a characteristic plane π, since K cannot contain two timelike separated points. If ω is *spacelike*, then ω is the common edge of two wedges, $\omega = \overline{W} \cap W^c$. Since $K \subset \overline{W} \cap W^c$ we then have $\mathscr{B}(K) \subset \mathscr{A}(W) \cap \mathscr{A}(\overline{W^c}) = \mathsf{C}^1 \cdot I$ by the result in part (a).

We now consider the case when $\omega \subset \pi$ is *not* spacelike. With a suitable choice of a standard coordinate system we can write $\pi = \{x | x \in \mathsf{M},\ x_4 = x_3\}$ and $\omega = \{x | x \in \mathsf{M};\ x_4 = x_3,\ x_1 = 0\}$. Let Q be a self-adjoint operator in $\mathscr{B}(K)$. Let $K(x)$ be obtained from K by a translation by x, i.e., $K(x) = \{x + y | y \in K\}$. Let $u = (0,0,1,1)$ and $v = (1,0,0,0)$. Then $K \subset K(rv + su)^c$, and hence $[Q^z, T(rv + su)QT(rv + su)^{-1}] = 0$, for any s and any $r \neq 0$. By continuity we then have $[Q^z, T(su)QT(su)^{-1}] = 0$ for all s. By Lemma 2.6 it follows that $\langle \Omega | Q^z Q\Omega \rangle = \langle \Omega | Q^z \Omega \rangle \times \langle \Omega | Q\Omega \rangle$. If Q is a fermion operator we conclude from this that $Q = 0$, and if Q is a boson operator we conclude that Q is a multiple of the identity, and hence $\mathscr{B}(K) = \mathsf{C}^1 \cdot I$, as asserted.

(3) We consider part (c), and assume that $K \in \mathscr{K}_C$ is a subset of a characteristic plane π. To show that $\mathscr{B}(K)$ is not necessarily trivial, we depend on a result in TW-II:[7] see Example 5.20 in Section V. The example in question concerns the theory of a single Hermitian *free* scalar field $\varphi(x)$. We consider the subset $K_e = \{x | \tau \geqslant x_3 = x_4 \geqslant -\tau,\ x_1^2 + x_2^2 \leqslant \rho^2\}$ of the characteristic plane $\pi = \{x | x_3 = x_4\}$, with $\tau > 0$, $\rho > 0$. We then have $K_e \in \mathscr{K}_C$ and K_e has an empty interior. It was shown in the quoted paper that there exists a unitary operator B, not equal to a multiple of the identity, which commutes with $\varphi(x)$ for all $x \in K_e^c$. For a *free*-field theory this implies that $B \in \mathscr{B}(K_e)$.

(4) We continue the discussion of part (c), and assume that $K \in \mathscr{K}_C$ is a subset of the characteristic plane $\pi = \{x | x_3 = x_4\}$. Let $u = (0,0,1,1)$ and $v = (1,0,0,0)$, and let $K(x) = \{x + y | y \in K\}$ for any $x \in \mathsf{M}$. For any $x, y \in \pi$ we have $-(x - y) \cdot (x - y) = (x_1 - y_1)^2 + (x_2 - y_2)^2$. Since $K \subset \pi$ is compact it follows that for a sufficiently large λ the displaced set $K(\lambda v + su)$ is spacelike separated from K for *all* s. We chose such a λ, fixed in what follows. Suppose that $Q \in \mathscr{B}(K)$ is not a multiple of the identity. Let $B = T(\lambda v)QT(\lambda v)^{-1} - \langle \Omega | Q\Omega \rangle \cdot I$. For any $A \in \mathscr{B}(K)$ we then have $[A^*, T(su)B^zT(su)^{-1}] = 0$ for all s, and hence $\langle A\Omega | B^z\Omega \rangle = 0$, by Lemma 2.6. Since Ω is separating for $\mathscr{B}(K(\lambda v))$ we must have $B^z\Omega \neq 0$, and we conclude that Ω cannot be cyclic for $\mathscr{B}(K)$. This completes the proof.

That $\mathscr{A}(W)$ is a factor is a well-known old result. Part (b) of the proposition extends a result by Driessler and Summers.[21] The result in part (c) is intuitively reasonable. If $K \in \mathscr{K}_C$ has an empty interior, and hence is a subset of a characteristic plane, then $\mathscr{B}(K)$ is not necessarily trivial, but such an algebra is indeed ''smaller'' than an algebra associated with any set with a nonempty interior, in the sense that $\mathscr{B}(K)\Omega$ is not dense in $\mathscr{H}$.

We will now consider ''intersection properties'' of a *regular* net, and its associated algebras. The issue is the nature of the intersection of two or several algebras in a (regular) net $\mathcal{N}$, and how it might correspond to geometric relationships. We first consider the very simple case of two parallel wedges. We believe the result is widely known, but we present it here anyway for the sake of completeness.

Proposition 4.3: Let $W_1, W_2 \in \mathscr{W}$ be such that W_2 is obtained from W_1 by a *parallel displacement*. Let $\mathcal{A}(W)$ denote the wedge-algebras of a *regular* net. Then $(W_1 \cup W_2)^{cc} = W_u \in \mathscr{W}$, $W_1^c \cap W_2^c = W_u^c$, and

$$\mathcal{A}(\overline{W}_1^c) \cap \mathcal{A}(\overline{W}_2^c) = \mathcal{A}(\overline{W}_1^c \cap \overline{W}_2^c) = \mathcal{A}(\overline{W}_u^c), \tag{4.6}$$

$$(\mathcal{A}(W_1) \cup \mathcal{A}(W_2))'' = \mathcal{A}((W_1 \cup W_2)^{cc}) = \mathcal{A}(W_u). \tag{4.7}$$

Proof: It is trivial that $(W_1 \cup W_2)^{cc} = W_u \in \mathscr{W}$. Specifically the lower plane of W_u is the lower one of the lower planes of W_1 and W_2, and the upper plane of W_u is the upper one of the upper planes of W_1 and W_2. The relations (4.6) and (4.7) are equivalent under duality, and they are trivial if one of the wedges is contained in the other. We thus consider the case when W_2 is obtained from W_1 by a *timelike* displacement. With a suitable choice of a standard coordinate system we then have the configuration

$$W_1 = \{x | x_3 - \tau > |x_4 + \tau|\}, \quad W_2 = \{x | x_3 - \tau > |x_4 - \tau|\}, \quad W_u = \{x | x_3 > |x_4|\},$$

for some $\tau > 0$.

Let $B \in (\mathcal{A}(W_1) \cup \mathcal{A}(W_2))'$, and let $A \in \mathcal{A}(W_u)$. We write $A(x) = T(x) A T(x)^{-1}$ for the translate of A by any $x \in \mathsf{M}$. We then have $A(x) \in \mathcal{A}(W_1) \cup \mathcal{A}(W_2)$, and hence $[B, A(x)] = 0$, for any $x \in W_1 \cup W_2$, and in particular when x is in the region $\{x | x \in \mathsf{M}, x_3 > |x_4|, x_3 > 2\tau\}$. It then follows readily from the results in a paper by Araki[22] that $[B, A(x)] = 0$ for all $x \in W_u$. By the continuity of $A(x)$ we have $[A, B] = 0$. This implies that $B \in \mathcal{A}(W_u)'$, and we thus have $\mathcal{A}(W_u)' \supset (\mathcal{A}(W_1) \cup \mathcal{A}(W_2))'$, and $\mathcal{A}(W_u) \subset (\mathcal{A}(W_1) \cup \mathcal{A}(W_2))''$. By isotony we have $\mathcal{A}(W_u) \supset (\mathcal{A}(W_1) \cup \mathcal{A}(W_2))''$, and hence the relation (4.7) holds. This completes the proof.

We next discuss what amounts to an elaboration of a result by Borchers.[23]

Proposition 4.4: Let $\mathcal{N}$ be a *regular* net, with algebras $\mathcal{A}(W)$, $\mathcal{B}(K)$, and $\mathcal{A}(K^c)$. Let $K_1, K_2 \in \mathscr{K}_C$ be such that $K_1 \subset K_2^o$. Then:

(a) $\mathcal{B}(K_1) \cap \mathcal{B}(K_2)' = \mathsf{C}^1 \cdot I$, and hence $(\mathcal{B}(K_2) \cup \mathcal{B}(K_1)')'' = \mathsf{B}(\mathscr{H})$;

(b) $\mathcal{B}(K_1) \cap \mathcal{A}(K_2^c) = \mathsf{C}^1 \cdot I$, and hence $(\mathcal{B}(K_2) \cup \mathcal{A}(K_1^c))'' = \mathsf{B}(\mathscr{H})$.

Proof: (1) We consider part (a). The salient point is that K_1 is ''movable'' within K_2, since K_1 is compact and contained in the interior of K_2. Let u be a forward timelike vector. In view of the above there exists a $\tau_0 > 0$ such that $T(tu) \mathcal{B}(K_1) T(tu)^{-1} \subset \mathcal{B}(K_2)$ whenever $|t| < \tau_0$.

Let E be a self-adjoint projection in $\mathcal{B}(K_1) \cap \mathcal{B}(K_2)'$, and let $E^\perp = I - E$. We then have $E E^\perp = 0$, and $[T(tu) E T(tu)^{-1}, E^\perp] = 0$ whenever $|t| < \tau_0$. By Borchers' theorem this implies that $T(tu) E T(tu)^{-1} E^\perp = 0$ for *all* t. This result is a consequence of the spectrum condition on the one-parameter translation group $\{T(tu) | t \in \mathsf{R}^1\}$. From this we readily conclude that E is a multiple of the identity, which implies the conclusion in part (a).

(2) We consider part (b). The algebras $\mathcal{B}(K_1)$ and $\mathcal{A}(K_2^c)$ cannot have any nonzero fermion element Q in common, since Q would then anticommute with its adjoint. The boson elements of $\mathcal{A}(K_2^c)$ and $\mathcal{B}(K_2)' = \mathcal{A}(K_2^c)^z$ are the same, and by the result in (a), the only common boson elements of $\mathcal{B}(K_1)$ and $\mathcal{A}(K_2^c)$ are the multiples of the identity. This completes the proof.

In the further study of the intersection properties we depend on a number of results from TW-I[6] and TW-II.[7] We first consider the important notion of the *envelope of uniqueness* $\mathscr{E}(S)$ of any open subset S of M.

Lemma 4.5: Let S be an *open* subset of Minkowski spacetime M. There then exists a unique *smallest* subset X of M which satisfies the following three conditions: (I) $X \supset S$. (II) If X contains the base B_0 of an open double cone $D^o \subset \mathsf{M}$, then X contains D^o. (III) If X contains the open timelike line segment (x', x''), then X contains the open double cone $D^o = D(x', x'')^o$ with x' and x'' as apices. Here, and throughout this paper, we denote this smallest set by $\mathscr{E}(S)$, for any open $S \subset \mathsf{M}$.

See Section IV in TW-I[6] for the (trivial) proof, and for a detailed discussion of the mapping $S \to \mathscr{E}(S)$. We will not repeat this discussion here, but we note a few simple facts. The set $\mathscr{E}(S)$ is (obviously) *open*, and it satisfies the conditions $\mathscr{E}(S) \subset (S^{cc})^o \subset S^{cc} = \mathscr{E}(S)^{cc}$. If S is *causally complete*, then $\mathscr{E}(S) = S$. In general $\mathscr{E}(S)$ is smaller that S^{cc}, but for certain kinds of (physically interesting) regions S we do have $\mathscr{E}(S) = S^{cc}$, as shown in Lemma 4.6 below. The above definition of $\mathscr{E}(S)$ refers to *open* double cones, but it is obvious that if S contains either the base B of a closed double cone $D = D(x', x'') \in \mathscr{D}$, or else the closed timelike line segment $[x', x'']$, then $\mathscr{E}(S)$ contains D. The envelope $\mathscr{E}(S)$ is of interest in the theory of the Klein–Gordon equation, in view of the following well-known principle. If $\phi(x)$ is a solution of this equation which vanishes throughout S, then $\phi(x)$ vanishes throughout $\mathscr{E}(S)$. In this sense $\mathscr{E}(S)$ is an ''envelope of uniqueness.''

We state here some properties of the mapping $\mathscr{E}$ for later reference.

Lemma 4.6: (a) Let $W_1, W_2 \in \mathscr{W}$ be such that $W_1 \cap W_2 \neq \emptyset$. Then $\mathscr{E}(W_1 \cup W_2) = (W_1 \cup W_2)^{cc}$.

(b) Let $\mathscr{F}$ be a family of wedges in $\mathscr{W}$, and let $S = \{W | W \in \mathscr{F}\}$. Suppose that the normals of the boundary planes of these wedges spans M, and that $\mathscr{F}$ contains at least two wedges for which no two of the four boundary planes are parallel. Then $\mathscr{E}(S) = S^{cc}$. In particular this holds if $\mathscr{F}$ contains at least two wedges in a general relative position, i.e., if the normals of the four boundary planes are linearly independent.

(c) Let $S \subset \mathsf{M}$ be *open*, and let S_n, $n \in \mathsf{Z}_+$, be a sequence of *open* subsets of S such that $S_{n+1} \supset S_n$ for all n, and $S = \cup\{S_n | \ n \in \mathsf{Z}_+\}$. Then $\mathscr{E}(S) = \cup\{\mathscr{E}(S_n) | \ n \in \mathsf{Z}_+\}$.

For the proof of part (a), see Proposition 5.6; for the proof of part (b), see Theorem 5.7, and for the proof of part (c), see Proposition 4.12 in TW-I.[6]

We next state an important lemma which is based on some results in TW-II,[7] and ultimately on the theory of Araki referred to earlier.[22]

Lemma 4.7: Let $\{S_\alpha | \alpha \in \mathscr{I}\}$, where $\mathscr{I}$ is some index set, be a family of open regions $S_\alpha \subset \mathsf{M}$ such that S_α is bounded above by the characteristic plane π''_α and below by the characteristic plane π'_α. Let $S = \cup\{S_\alpha | \alpha \in \mathscr{I}\}$. We denote by $\mathscr{E}(S)$ the envelope of uniqueness of S, as in Lemma 4.5.

Let $\mathscr{N}$ be a *regular* net as in Definition 3.1. Let D be a double cone in $\mathscr{D}$. We denote by $D(x)$ the image of D under a translation by x. Then

$$\{\mathscr{B}(D(x)) | x \in S\}'' = \{\mathscr{B}(D(x)) | x \in \mathscr{E}(S)\}''. \tag{4.8}$$

In particular the identity in (4.8) obtains if S is the union of any family of wedges in $\mathscr{W}$.

Proof: Since $S \subset \mathscr{E}(S)$, it is trivial that the left member in (4.8) is included in the right member. We thus have to prove the opposite inclusion.

Let $A \in \{\mathscr{B}(D(x)) | x \in S\}'$ and let $B \in \mathscr{B}(D)$. We then have $[A, T(x)BT(x)^{-1}] = 0$ for all $x \in S$, and we have to prove that the commutator also vanishes for all $x \in \mathscr{E}(S)$. Let Ψ' and Ψ'' be two vectors in $\mathscr{H}$ with compact support in four-momentum space, and let $\xi(x)$ be the function on M defined by $\xi(x) = \langle \Psi' | [A, T(x)BT(x)^{-1}]\Psi'' \rangle$. This function is continuous and bounded, and it can be regarded as a tempered distribution in $\mathscr{S}'(\mathsf{M})$. We easily see that the support of the Fourier transforms $\hat{\xi}(p)$ of this distribution is contained in a region of the form $\overline{V}_+(p') \cup \overline{V}_-(p'')$, for some points p' and p'' in four-momentum space. The distribution $\xi(x)$ is in a special class of distributions studied by Araki,[22] denoted by $\mathscr{S}'_A(\mathsf{M})$ in TW-II.[7] We have $\xi(x) = 0$ for all $x \in S$, and it then follows by Theorem 2.11 in TW-II[7] that $\xi(x) = 0$ for all $x \in \mathscr{E}(S)$. Since this holds for all vectors Ψ' and Ψ'' of compact support in four-momentum space, it follows that $[A, T(x)BT(x)^{-1}] = 0$ for all $x \in \mathscr{E}(S)$. This completes the proof.

We want to state here explicitly that it is *not* true in general that if S is an open set, and if $\xi(x)$ is a distribution in the class $\mathscr{S}'_A(\mathsf{M})$ such that $\xi(x) = 0$ on S, then $\xi(x) = 0$ also on $\mathscr{E}(S)$. It is easy to find counterexamples, and some are given in TW-II.[7] On the basis of the general assumptions in *this* paper we *cannot* conclude that the relation (4.8) holds for *arbitrary* open sets S, although the relation does hold for a free-field theory. With our approach the special nature of the set S stated in the premises is crucial.

The lemma which follows is an important tool in our investigation. It depends on Lemma 4.7 and on some simple facts concerning the geometry of Minkowski spacetime.

Lemma 4.8: Let $\mathscr{F}$ be a family of wedges in $\mathscr{W}$. We write $S=\cup\{W|W\in\mathscr{F}\}$ and $K=\cap\{W^c|W\in\mathscr{F}\}=S^c$.

Let $q\in V_+$. For any wedge $W=W(\pi',\pi'')\in\mathscr{W}$ with lower plane π' and upper plane π'' we define $W[q]=W(\pi'(q),\pi''(-q))$ as the wedge in $\mathscr{W}$ with lower plane $\pi'(q)=\{x+q|x\in\pi'\}$ and upper plane $\pi''(-q)=\{x-q|x\in\pi''\}$. We write $S[q]=\cup\{W[q]|W\in\mathscr{F}\}$ and $K[q]=S[q]^c=\cap\{W[q]^c|W\in\mathscr{F}\}$.

Let $D_q=D(-q,q)\in\mathscr{D}$ be the double cone with apices $-q$ and q, and for any $x\in\mathsf{M}$, let $D_q(x)=\{x+y|y\in D_q\}$ be the double cone obtained by a displacement of D_q by x. Then:

(a) For any $W\in\mathscr{W}$ we have $D_q(x)\subset W$ if and only if $x\in W[q]$.

(b) $D_q(x)\subset S$ if and only if $x\in S[q]$.

(c) If $1>\theta>0$, then $K[q]\supset K[\theta q]\supset K$ and $S[q]\subset S[\theta q]\subset S$. Furthermore we have

$$K=\cap\{K[q/n]|n\in\mathsf{Z}_+\},\quad S=\cup\{S[q/n]|n\in\mathsf{Z}_+\},\tag{4.9}$$

$$\mathscr{E}(S)=\cup\{\mathscr{E}(S[q/n]|n\in\mathsf{Z}_+\}.\tag{4.10}$$

(d) Let $\mathscr{N}$ be a *regular net* with algebras $\mathscr{A}(W)$, $\mathscr{B}(K)$, and $\mathscr{A}(K^c)$, as in Definition 3.1. Then

$$\{\mathscr{B}(D_q(x))|x\in\mathscr{E}(S[q])\}''\subset\{\mathscr{A}(W)|W\in\mathscr{F}\}''.\tag{4.11}$$

Proof: (1) Let $W=W(\pi',\pi'')\in\mathscr{W}$. Since W is causally complete, W contains $D_q(x)$ if and only if W contains the apices $x-q$ and $x+q$ of $D_q(x)$, and hence if and only if $x+q$ lies *below* the plane π'' and $x-q$ lies *above* the plane π'. These two conditions are precisely the conditions for x to be in $W[q]$, and hence we arrive at the conclusion in part (a). From this the conclusion in part (b) follows trivially, in view of the definition of the sets S and $S[q]$.

(2) We consider part (c). The inclusion relations $K[q]\supset K[\theta q]\supset K$ and $S[q]\subset S[\theta q]\subset S$, as well as the relations in (4.9), are trivial if $\mathscr{F}$ consists of a single wedge $W\in\mathscr{W}$, in which case we have $S=W$ and $K=W^c$. That these relations hold *generally*, for an arbitrary $\mathscr{F}$, then follows readily from the definitions of K, $K[q]$, S, and $S[q]$. By part (c) of Lemma 4.6 the relation in (4.10) then follows from the relation at right in (4.9).

(3) We consider part (d). Suppose that $x\in S[q]=\cup\{W[q]|W\in\mathscr{F}\}$. There thus exists a $W\in\mathscr{F}$ such that $x\in W[q]$, and hence $D_q(x)\subset W$ and $\mathscr{B}(D_q(x))\subset\mathscr{A}(W)$. We thus have $\{\mathscr{B}(D_q(x))|x\in S[q]\}''\subset\{\mathscr{A}(W)|W\in\mathscr{F}\}''$, and the relation in (4.11) follows from the identity in (4.8). This completes the proof.

It is worth noting here that the double cones $D_q(x)$ contained in a $W\in\mathscr{W}$ do not in general ''sweep out'' W, i.e., the set $\cup\{D_q(x)|x\in W[q]\}$ is *smaller* than W, unless q lies in the span of the normals u' and u''. This is in contrast to the analogous (completely trivial) scenario in a *two*-dimensional spacetime.

We also note that the open set S in the lemma is not, in general, causally complete. In particular it can happen for some $S\neq\mathsf{M}$, that $K=S^c$ is empty, in which case $S^{cc}=K^c=\mathsf{M}$. We also note here the following somewhat subtle point. Let $\mathscr{F}^*=\{W|W\in\mathscr{W},\ W^c\supset K\}$. We then have $\mathscr{F}^*\supset\mathscr{F}$ and $K=\cap\{W^c|W\in\mathscr{F}^*\}$. Let $K^*[q]=\cap\{W[q]^c|W\in\mathscr{F}^*\}$. Now one may think that $K[q]=K^*[q]$, but this is not necessarily so. The set $K^*[q]$ is in general *smaller* than the set $K[q]$, as one can see by considering examples in which $\mathscr{F}$ consists of just two intersecting wedges.

It was shown by Landau,[24] and it also follows from Proposition 4.4, that the algebras associated with two *spacelike* separated double cones have only multiples of the identity in common. The algebras associated with two regions which are merely disjoint can very well have a nontrivial intersection, but for certain special pairs of regions the intersection *is* trivial, as shown in the theorem which follows.

Theorem 4.9: Let $\mathscr{N}$ be a *regular* net, with algebras $\mathscr{A}(W)$, $\mathscr{B}(K)$, and $\mathscr{A}(K^c)$, defined for all $W\in\mathscr{W}$ and all $K\in\mathscr{K}_C$.

(a) If $K_1,K_2\in\mathscr{K}_C$ are such that $K_1\cap K_2=\varnothing$, then $\mathscr{B}(K_1)\cap\mathscr{B}(K_2)=\mathsf{C}^1\cdot I$, and, equivalently, $(\mathscr{A}(K_1^c)\cup\mathscr{A}(K_2^c))''=\mathsf{B}(\mathscr{H})$.

(b) If $K_1 \in \mathscr{K}_C$ and $W_2 \in \mathscr{W}$ are such that $K_1 \cap \overline{W}_2 = \varnothing$, then $\mathscr{B}(K_1) \cap \mathscr{A}(W_2) = \mathsf{C}^1 \cdot I$, and, equivalently, $(\mathscr{A}(K_1^c) \cup \mathscr{A}(\overline{W}_2^c))'' = \mathsf{B}(\mathscr{H})$.

(c) If $W_1, W_2 \in \mathscr{W}$ are such that $\overline{W}_1 \cap \overline{W}_2 = \varnothing$, then $\mathscr{A}(W_1) \cap \mathscr{A}(W_2) = \mathsf{C}^1 \cdot I$, and, equivalently, $(\mathscr{A}(\overline{W}_1^c) \cup \mathscr{A}(\overline{W}_2^c))'' = \mathsf{B}(\mathscr{H})$.

Proof: (1) In this proof we follow the notation in Lemma 4.8. We consider part (a). Let $\mathscr{F}_1 = \{W | W \in \mathscr{W},\ W^c \supset K_1\}$, $\mathscr{F}_2 = \{W | W \in \mathscr{W},\ W^c \supset K_2\}$, and $\mathscr{F} = \mathscr{F}_1 \cup \mathscr{F}_2$. We write $K_1[q] = \cap\{W[q]^c | W \in \mathscr{F}_1\}$ and $K_2[q] = \cap\{W[q]^c | W \in \mathscr{F}_2\}$ for any $q \in V_+$. We easily see that since K_1 is compact there exists a $q \in V_+$ such that $K_1[q] \cap K_2[q] = \varnothing$. Let q be so chosen. We write $S[q] = \cup\{W[q] | W \in \mathscr{F}\}$, and we then have $S[q]^c = K_1[q] \cap K_2[q] = \varnothing$ and $S[q]^{cc} = \mathsf{M}$. Since $\mathscr{F}$ obviously contains two wedges in a general relative position it follows from part (b) of Lemma 4.6 that $\mathscr{E}(S[q]) = S[q]^{cc} = \mathsf{M}$.

By (4.11) we then have $\{\mathscr{B}(D_q(x)) | x \in \mathsf{M}\}'' \subset \{\mathscr{A}(W) | W \in \mathscr{F}\}'' = (\mathscr{A}(K_1^c) \cup \mathscr{A}(K_2^c))''$. By Lemma 2.6 the left member of this inclusion relation equals $\mathsf{B}(\mathscr{H})$, and hence the relation $(\mathscr{A}(K_1^c) \cup \mathscr{A}(K_2^c))'' = \mathsf{B}(\mathscr{H})$ follows. The relation $\mathscr{B}(K_1) \cap \mathscr{B}(K_2) = \mathsf{C}^1 \cdot I$ then follows by duality.

(2) We consider part (b), and we define $\mathscr{F}_1$ and $\mathscr{F}$ as above, with $\mathscr{F}_2 = \{\overline{W}_2^c\}$. Since K_1 is compact we can obviously find a $q \in V_+$ such that $K_1[q] \cap \overline{W}_2[q] = \varnothing$. Let q be so chosen. The family $\mathscr{F}$ again contains two wedges in a general relative position, and by the same kind of reasoning as in step (1) we conclude that $\{\mathscr{A}(W) | W \in \mathscr{F}\}'' = (\mathscr{A}(K_1^c) \cup \mathscr{A}(\overline{W}_2^c))'' = \mathsf{B}(\mathscr{H})$. The first assertion in part (b) then follows by duality.

(3) We consider part (c). It will be convenient to introduce the wedges $W_a, W_b \in \mathscr{W}$ by $W_a = \overline{W}_1^c$ and $W_b = \overline{W}_2^c$, and the premise is thus that $W_a^c \cap W_b^c = \varnothing$. The two cases $W_a \cap W_b \neq \varnothing$ and $W_a \cap W_b = \varnothing$ have to be considered separately, and we first consider the case when $W_a \cap W_b \neq \varnothing$. Let $x_i \in W_a \cap W_b$. Since the set $W_a \cap W_b$ is open we can select a $q \in V_+$ such that the closed timelike line segment $[x_i - q, x_i + q]$ is included in $W_a \cap W_b$. Let q be so chosen. As in Lemma 4.8 we consider the wedges $W_a[q] \subset W_a$ and $W_b[q] \subset W_b$, and we obviously have $x_i \in W_a[q] \cap W_b[q]$, and hence $W_a[q] \cap W_b[q] \neq \varnothing$. We assert that $W_a[q]^c \cap W_b[q]^c = \varnothing$, and to prove this we consider the possibility that there exists a point $y \in W_a[q]^c \cap W_b[q]^c$. Let l be the line passing through the points x_i and y. This line is *spacelike*, since $x_i \in W_a[q]$ and $y \in W_a[q]^c$, and its intersections with $W_a[q]^c$ and W_a^c are half-infinite intervals which do not contain x_i. Similarly the intersections of l with $W_b[q]^c$ and W_b^c are half-infinite intervals which do not contain x_i. It follows that $W_a^c \cap W_b^c$ contains a half-infinite interval on l, which is a contradiction since $W_a^c \cap W_b^c = \varnothing$. We conclude that $W_a[q]^c \cap W_b[q]^c = \varnothing$.

By the above, and by part (a) of Lemma 4.6, we then have $\mathscr{E}(W_a[q] \cup W_b[q]) = (W_a[q] \cup W_b[q])^{cc} = (W_a[q]^c \cap W_b[q]^c)^c = \mathsf{M}$. We write $S = W_a \cup W_b$ and $S[q] = W_a[q] \cup W_b[q]$. We then have $D_q(x) \subset S$, and hence $\mathscr{B}(D_q(x)) \subset (\mathscr{A}(W_a) \cap \mathscr{A}(W_b))''$, whenever $x \in S[q]$. By (4.11) we then conclude that $(\mathscr{A}(\overline{W}_1^c) \cup \mathscr{A}(\overline{W}_2^c))'' = (\mathscr{A}(W_a) \cap \mathscr{A}(W_b))'' = \mathsf{B}(\mathscr{H})$, and, by duality, that $\mathscr{A}(W_1) \cap \mathscr{A}(W_2) = \mathsf{C}^1 \cdot I$.

(4) It remains to consider the case when $W_a \cap W_b = \varnothing$ and $W_a^c \cap W_b^c = \varnothing$. The upper plane of W_a is then parallel with the lower plane of W_b, and the lower plane of W_a is parallel with the upper plane of W_b. There obviously exists a $q \in V_+$ such that $W_a[q]^c \cap W_b[q]^c = \varnothing$. Let q be so chosen. We trivially have $W_a[q] \cap W_b[q] = \varnothing$. We have $D_q(x) \subset W_a \cup W_b$, and hence $\mathscr{B}(D_q(x)) \subset \mathscr{A}(W_a) \cup \mathscr{A}(W_b)$, whenever $x \in W_a[q] \cup W_b[q]$. Let $B \in \mathscr{A}(W_1) \cap \mathscr{A}(W_2) = (\mathscr{A}(W_a)^z \cup \mathscr{A}(W_b)^z)'$ and let $A \in \mathscr{B}(D_q)^z$. We then have $[B, T(x) A T(x)^{-1}] = 0$ whenever $x \in W_a[q] \cup W_b[q]$, and by Lemma 2.7 we conclude that $\langle \Omega | BA\Omega \rangle = \langle \Omega | B\Omega \rangle \langle \Omega | A\Omega \rangle$. Since Ω is cyclic for $\mathscr{B}(D_q)^z$ it follows that $B^* \Omega = b\Omega$, for some constant b, and since Ω is separating for $\mathscr{A}(W_1) \cap \mathscr{A}(W_2)$ it follows that $B = bI$. This completes the proof.

In the discussion up to this point we have made no assumptions about the *condition of additivity for wedges*. For the discussion which follows we will need to assume this condition.

Theorem 4.10: Let $\mathscr{N}$ be a *regular* net, as described in Definition 3.1, with algebras $\mathscr{A}(W)$, $\mathscr{A}(K^c)$, and $\mathscr{B}(K)$ defined for all $W \in \mathscr{W}$ and all $K \in \mathscr{K}_C$. Let the associated algebras $\mathscr{A}^\sharp(K^c)$ and $\mathscr{B}^\sharp(K)$ be defined as in (4.1) for all $K \in \mathscr{K}$. In addition we assume that the net $\mathscr{N}$ satisfies the *condition of additivity for wedges*, in accordance with Definition 2.5.

Let $\mathscr{F}$ be a family of wedges in $\mathscr{W}$. We write $S=\cup\{W|W\in\mathscr{F}\}$ and $K=\cap\{W^c|W\in\mathscr{F}\}$. Let $\mathscr{E}(S)$ be defined as in Lemma 4.5.

(a) Suppose that $\mathscr{F}$ contains two wedges in a *general relative position*. Then K is an element of the set $\mathscr{K}_E$ as described in Definition 1.1, and we have $\mathscr{E}(S)=S^{cc}=K^c$, and

$$\cap\{\mathscr{A}(\overline{W}^c)|W\in\mathscr{F}\}=\mathscr{B}^\sharp(K),\quad \{\mathscr{A}(W)|W\in\mathscr{F}\}''=\mathscr{A}^\sharp(S^{cc}). \tag{4.12}$$

(b) Suppose instead that the normals of the boundary planes of the wedges in $\mathscr{F}$ span M, and suppose furthermore that $\mathscr{F}$ contains two wedges such that no two of the boundary planes of these wedges are parallel. Then the conclusions are the same as in part (a).

Proof: (1) We note that the premises in part (a) imply the premises in part (b), and it thus suffices to consider part (b). By Definition 1.1 we have $K\in\mathscr{K}_E$, and by part (b) of Lemma 4.6 we have $\mathscr{E}(S)=S^{cc}$.

Let $q\in V_+$. We define $W[q]$, as in Lemma 4.8, for any $W\in\mathscr{W}$, and we write $S[q]=\cup\{W[q]|W\in\mathscr{F}\}$. By Lemma 4.8 we then have

$$S^{cc}=\mathscr{E}(S)=\cup\{\mathscr{E}(S[q/n])|n\in\mathsf{Z}_+\}. \tag{4.13}$$

(2) Let $D_q\in\mathscr{D}$ be the double cone with apices $(-q,q)$, and let $D_q(x)=\{x+y|y\in D_q\}$, as in Lemma 4.8. We write $\mathscr{A}_S=\{\mathscr{A}(W)|W\in\mathscr{F}\}''$, and by Lemma 4.8 we then have

$$\{\mathscr{B}(D_q(x))|x\in\mathscr{E}(S[q])\}''\subset\mathscr{A}_S. \tag{4.14}$$

Let $q\in V_+$ be fixed. Let $W\in\mathscr{W}$, $\overline{W}\subset S^{cc}$, and let $x\in\overline{W}$. In view of (4.13) there then exists a positive integer n (dependent on x) such that $x\in\mathscr{E}(S[q/n])$, and by replacing q in (4.14) by q/n we conclude that $\mathscr{B}(D_{q/n}(x))\subset\mathscr{A}_S$. By the assumed condition of additivity for wedges it follows that $\mathscr{A}(W)\subset\mathscr{A}_S$. Since the wedge-algebras are continuous from the inside, as expressed in (2.6), the relation $\mathscr{A}(W)\subset\mathscr{A}_S$ also holds for all $W\in\mathscr{W}$ such that $W\subset S^{cc}$, and since $\mathscr{A}^\sharp(S^{cc})=\{\mathscr{A}(W)|W\in\mathscr{W},\ W\subset S^{cc}\}''$ by (4.1) it follows that $\mathscr{A}^\sharp(S^{cc})\subset\mathscr{A}_S$.

Since $\mathscr{F}\subset\{W|W\in\mathscr{W},\ W\subset S^{cc}\}$ it follows that $\mathscr{A}_S\subset\{\mathscr{A}(W)|W\in\mathscr{W},\ W\subset S^{cc}\}''=\mathscr{A}^\sharp(K^c)$, and hence we obtain the identity at right in (4.12). The identity at left then follows by duality. This completes the proof.

Let $\mathscr{F}^*\subset\mathscr{W}$ be defined by $\mathscr{F}^*=\{W|W\in\mathscr{W},W\supset K\}$, in which case we have $\mathscr{F}\subset\mathscr{F}^*$, and $\mathscr{B}^\sharp(K)=\cap\{\mathscr{A}(W)|W\in\mathscr{F}^*\}$ by the definition of $\mathscr{B}^\sharp(K)$. The point of the theorem is that $\mathscr{F}$ can be ''very much smaller'' than $\mathscr{F}^*$, and in general the set $S^{cc}=\cup\{W|W\in\mathscr{F}^*\}$ is strictly larger than the set $S=\cup\{W|W\in\mathscr{F}\}$. The conclusion is therefore not trivial.

Theorem 4.11: Let $\mathscr{N}$ be a *regular* net with algebras $\mathscr{A}(W)$, $\mathscr{A}(K^c)$, and $\mathscr{B}(K)$, and associated algebras $\mathscr{A}^\sharp(K^c)$ and $\mathscr{B}^\sharp(K)$, as in Theorem 4.10. In addition we assume that the net $\mathscr{N}$ satisfies the *condition of additivity for wedges*, as in Definition 2.5.

(a) Let $K_0\in\mathscr{K}_C$, and let $\mathscr{F}$ be any family of wedges in $\mathscr{W}$. We write $K=(\cap\{W^c|W\in\mathscr{F}\})\cap K_0$. Then $K\in\mathscr{K}_C$ and

$$\mathscr{B}(K)=(\cap\{\mathscr{A}(\overline{W}^c)|W\in\mathscr{F}\})\cap\mathscr{B}(K_0). \tag{4.15}$$

More generally, if $K_0\in\mathscr{K}_E$, and K is defined in terms of K_0 and $\mathscr{F}$ as above, then $K\in\mathscr{K}_E$ and

$$\mathscr{B}^\sharp(K)=(\cap\{\mathscr{A}(\overline{W}^c)|W\in\mathscr{F}\})\cap\mathscr{B}^\sharp(K_0). \tag{4.16}$$

(b) Let $\mathscr{T}_K$ be any subset of $\mathscr{K}_C$, and let $K_i=\cap\{K|K\in\mathscr{T}_K\}$. Then $K_i\in\mathscr{K}_C$ and

$$\mathscr{B}(K_i)=\cap\{\mathscr{B}(K)|K\in\mathscr{T}_K\}. \tag{4.17}$$

More generally, if $\mathscr{T}_K$ is a subset of $\mathscr{K}_E$, then $K_i=\cap\{K|K\in\mathscr{T}_K\}\in\mathscr{K}_C$ and

$$\mathscr{B}^\sharp(K_i)=\cap\{\mathscr{B}^\sharp(K)|K\in\mathscr{T}_K\}. \tag{4.18}$$

Proof: (1) Suppose that $K_0 \in \mathscr{K}_E$. Let $\mathscr{T}_0 = \{W | W \in \mathscr{W},\ W \subset K_0^c\}$ and let $\mathscr{T}_u = \mathscr{T} \cup \mathscr{T}_0$. We have $K_0 = \cap\{W^c | W \in \mathscr{T}_0\}$, $\mathscr{B}^\sharp(K_0) = \cap\{.\mathscr{A}(\overline{W^c}) | W \in \mathscr{T}_0\}$, and $K = \cap\{W^c | W \in \mathscr{T}_u\}$. Since $K_0 \in \mathscr{K}_E$, the family $\mathscr{T}_0$ contains two wedges in a general relative position, and the same then holds for the family $\mathscr{T}_u$. By Theorem 4.10 we have $\mathscr{B}^\sharp(K) = \cap\{.\mathscr{A}(\overline{W^c}) | W \in \mathscr{T}_u\}$, and the relation (4.16) follows. If K_0 is in the subset $\mathscr{K}_C$ of $\mathscr{K}_E$ we have $K \in \mathscr{K}_C$, and the relation (4.16) can then be written in the form in (4.15), since $\mathscr{B}^\sharp(K) = \mathscr{B}(K)$ for all $K \in \mathscr{K}_C$.

(2) Suppose that $\mathscr{T}_K \subset \mathscr{K}_E$. For each $K \in \mathscr{T}_K$ we define the family $\mathscr{T}[K]$ of wedges by $\mathscr{T}[K] = \{W | W \in \mathscr{W},\ W^c \supset K\}$. With $\mathscr{T} = \cup\{\mathscr{T}[K] | K \in \mathscr{T}_K\}$ we have $K_i = \cap\{W^c | W \in \mathscr{T}\}$, and the relation (4.18) follows readily on the basis of Theorem 4.10. The relation (4.17) refers to the special case when $\mathscr{T}_K \subset \mathscr{K}_C$, in which case we also have $K_i \in \mathscr{K}_C$. This completes the proof.

The special case of part (b) when $\mathscr{T}_K$ contains just two elements $K_1, K_2 \in \mathscr{K}_C$ is of particular interest. We then have the simple conclusion that $\mathscr{B}(K_1) \cap .\mathscr{B}(K_2) = \mathscr{B}(K_1 \cap K_2)$. If $K_1 \cap K_2 = \varnothing$ we have $\mathscr{B}(K_1) \cap .\mathscr{B}(K_2) = \mathsf{C}^1 \cdot I$, which is also the conclusion in Theorem 4.9, *without* the assumption that the net $\mathscr{N}$ satisfies the condition of additivity for wedges. The condition for a *regular* net that Ω is cyclic for $\mathscr{B}(D)$ for *any* $D \in \mathscr{D}$, was, however, crucial for the proof of Theorem 4.9. The condition of additivity for wedges is stronger than this condition, and the question arises as to whether it is a necessary premise of Theorem 4.11 or of Theorem 4.10. It is not hard to see that the intersection property $\mathscr{B}(K_1) \cap .\mathscr{B}(K_2) = .\mathscr{B}(K_1 \cap K_2)$ can be proved without the additivity condition for certain *special* configurations. Suppose that $D_1 = D(x', x'')$ and $D_2 = D(y', y'')$ are two double cones so located that $x'' \in D_2^o$ and $y' \in D_1^o$. We then have $D_1 \cap D_2 = D(y', x'')$, and it is easily seen that the relation $\mathscr{B}(D_1) \cap .\mathscr{B}(D_2) = .\mathscr{B}(D_1 \cap D_2)$ can be proved just on the basis of Proposition 4.3. There are, however, other configurations for which, as far as we know, the intersection properties *cannot* be proved without the condition of additivity for wedges (or some similar condition).

We next consider the intersection of two wedge-algebras.

Theorem 4.12: Let the premises and notation be as in Theorem 4.11. Let $W_1, W_2 \in \mathscr{W}$. We write $S = W_1 \cup W_2$ and $K = W_1^c \cap W_2^c = S^c$, and hence $K \in \mathscr{K}$ and we have $\mathscr{B}^\sharp(K) = \cap\{.\mathscr{A}(W) | W \in \mathscr{W},\ \overline{W} \supset K\}$ and $\mathscr{A}^\sharp(S^{cc}) = \{.\mathscr{A}(W) | W \in \mathscr{W},\ W \subset S^{cc}\}''$ in accordance with (4.1).

(a) If $W_1 \cap W_2 \neq \varnothing$, then

$$\mathscr{A}(\overline{W_1^c}) \cap .\mathscr{A}(\overline{W_2^c}) = \mathscr{B}^\sharp(W_1^c \cap W_2^c), \quad (.\mathscr{A}(W_1) \cup .\mathscr{A}(W_2))'' = \mathscr{A}^\sharp((W_1 \cup W_2)^{cc}). \tag{4.19}$$

In particular this applies if W_1 and W_2 are in a general relative position.

(b) If $K = W_1^c \cap W_2^c = \varnothing$, then the relations in (4.19) also hold, and we have $\mathscr{B}(K) = \mathsf{C}^1 \cdot I$ and $\mathscr{A}(S^{cc}) = \mathsf{B}(\mathscr{H})$.

(c) If the span of the normals of the boundary planes of the wedges W_1 and W_2 is *two-dimensional*, then the relations in (4.19) hold.

(d) If $W_1 \cap W_2 = \varnothing$, and if the span of the normals of the boundary planes of the wedges is *three-dimensional*, then $K = W_1^c \cap W_2^c \neq \varnothing$, and the relations in (4.19) *do not* hold generally.

Proof: (1) By Proposition 3.10 the two relations in (4.19) are equivalent by duality. We write $\mathscr{A}_i = (.\mathscr{A}(W_1) \cup .\mathscr{A}(W_2))''$, and we note that we trivially have $\mathscr{A}_i \subset \mathscr{A}^\sharp((W_1 \cup W_2)^{cc})$, and we thus have to prove the opposite inclusion. We first note that the conclusion in part (b) follows at once from part (c) of Theorem 4.9.

(2) We consider part (a), assuming that $W_1 \cap W_2 \neq \varnothing$. Theorem 4.10 is not directly applicable if W_1 and W_2 are *not* in a general relative position, but by part (a) of Lemma 4.6 we have $S^{cc} = \mathscr{E}(S)$, and the relation (4.13) holds as stated. The reasoning in step (2) of the proof of Theorem 4.10 is therefore also applicable to the case at hand, and we can conclude that the relations in (4.19) hold.

(3) We consider part (c). There are two possibilities. Either W_2 is obtained by a parallel displacement of W_1, or else W_2 is obtained by a parallel displacement of $\overline{W_1^c}$. In the first case the conclusion follows readily from Proposition 4.3. We consider the second case, and we can now assume that $K = W_1^c \cap W_2^c \neq \varnothing$, in view of the result in part (b). It is then easily seen that $W \supset K$ if and only if either $W \supset W_1^c$ or else $W \supset W_2^c$, and the relation at left in (4.19) then follows trivially.

(4) We consider part (d). For a counterexample which shows that the relations in (4.19) cannot be generally valid, we refer to Proposition 5.18 in TW-II,[7] and specifically to part (d) of that

proposition. The counterexample concerns the theory of a single free Hermitian massive scalar field. The von Neumann algebra $A(W)$ is then the *weak commutant* denoted $\mathscr{C}(W)$ in the quoted paper, for any $W\in\mathscr{W}$, and with the notation in the paper we have $\mathscr{C}(W_1^c\cap W_2^c)=\cap\{\mathscr{A}(W)|W\in\mathscr{W},\ W\supset W_1^c\cap W_2^c\}$. An example is presented for which $\mathscr{C}(W_1^c\cap W_2^c)\neq\mathscr{C}(W_1^c)\cap\mathscr{C}(W_2^c)$, and hence the relations in (4.19) fail to hold in this case. This completes the proof.

The relation at left in (4.19) describes an ''intersection property,'' and as we have seen, it can fail in a free-field theory for certain configurations of two wedges. When it does fail to hold, we necessarily also have

$$\mathscr{A}(\overline{W}_1^c)\cap\mathscr{A}(\overline{W}_2^c)\neq\{\mathscr{B}(K_0)|K_0\in\mathscr{K}_C,\ K_0\subset W_1^c\cap W_2^c\}'', \tag{4.20}$$

because it is easily seen that if equality obtains in (4.20), then the relation at left in (4.19) follows. The algebra $\mathscr{A}(\overline{W}_1^c)\cap\mathscr{A}(\overline{W}_2^c)$ is, of course, in the weak closure of the set $\mathscr{U}$ of *all* local operators, but it is *not* in the weak closure of the set of all local operators ''localized'' within the region $W_1^c\cap W_2^c$, contrary to what one might expect at first.

We note here that the relations in (4.19) follow at once from Theorem 4.10 in the case when W_1 and W_2 are in a general relative position, i.e., when the normals of the boundary planes of the wedges span M, in which case we have $K=W_1^c\cap W_2^c\in\mathscr{K}_E$. Thus the ''pathology'' can only occur for configurations which are essentially ''three-dimensional.'' In these cases K is an element of $\mathscr{K}$ but *not* an element of $\mathscr{K}_E$.

We conclude this section by noting a simple implication of the condition of additivity for wedges.

Proposition 4.13: Let $\mathscr{N}$ be a *regular* net, as described in Definition 3.1, with algebras $\mathscr{A}(W)$, $\mathscr{A}(K^c)$, and $\mathscr{B}(K)$. In addition we assume that the net $\mathscr{N}$ satisfies the *condition of additivity for wedges*, in accordance with Definition 2.5. Let $D\in\mathscr{D}$ be *fixed*. We denote by $D(x)$ the double cone obtained from D by a translation by any $x\in\mathsf{M}$. Then

$$\mathscr{A}(W)=\{\mathscr{B}(D(x))|x\in\mathsf{M},\ D(x)\subset W\}'',\quad \mathscr{A}(K^c)=\{\mathscr{B}(D(x))|x\in\mathsf{M},\ D(x)\subset K^c\}'',$$

for any $W\in\mathscr{W}$, and any $K\in\mathscr{K}_C$.

Proof: The relation at right follows immediately from the relation at left, since $\mathscr{A}(K^c)=\{\mathscr{A}(W)|W\in\mathscr{W},\ W\subset K^c\}''$. It thus suffices to prove the relation at left. We write $\mathscr{A}=\{\mathscr{B}(D(x))|x\in\mathsf{M},\ D(x)\subset W\}''$. We trivially have $\mathscr{A}(W)\supset\mathscr{A}$, and we thus have to prove the opposite inclusion.

With a suitable choice of standard coordinates we have $W=\{x|x\in\mathsf{M},\ x_3>|x_4|\}$, and without any essential loss of generality we can consider the double cone $D\in\mathscr{D}$ with apices $\pm(\mathbf{y},\tau)$ for some $\mathbf{y}\in\mathsf{R}^3$ and some $\tau>|\mathbf{y}|$. Let $\tau>\delta>0$, and let $W_{u,\delta}=\{x|x\in\mathsf{M},\ x_3-\tau>|x_4-\tau+\delta|\}$ and $W_{l,\delta}=\{x|x\in\mathsf{M},\ x_3-\tau>|x_4+\tau-\delta|\}$. We easily see that we then have

$$W_{u,\delta}\cup W_{l,\delta}\subset\cup\{D^o(x)|x\in\mathsf{M},\ D(x)\subset W\},$$

and hence $\mathscr{A}(W_{u,\delta})\cup\mathscr{A}(W_{l,\delta})\subset\mathscr{A}$ by the condition of additivity. We trivially have $(W_{u,\delta}\cup W_{l,\delta})^{cc}=\{x|x\in\mathsf{M},\ x_3-\delta>|x_4|\}=W_\delta$, and it then follows by Proposition 4.3 that $\mathscr{A}(W_\delta)\subset\mathscr{A}$. Since δ can be selected arbitrarily small it follows from the continuity relations in (2.6) that $\mathscr{A}(W)\subset\mathscr{A}$. This completes the proof.

The point is that the set $\cup\{D^o(x)|x\in\mathsf{M},\ D(x)\subset W\}$ is in general *smaller* than W, i.e., the double cones $D(x)$ contained in W do not in general ''sweep out'' the wedge, and hence the conclusion is not immediately obvious.

V. ABOUT SUBNETS OF REGULAR NETS

In this section we will discuss local subnets of *regular nets* which satisfy the *special condition of duality*. Before we do that we make some general observations. We refer to part (c) in Definition 2.1 for the general (obvious) notion of a subnet $\mathscr{N}_s$ of a local net $\mathscr{N}$. Let $\mathscr{N}$ be an *irreducible* local net, with algebras $\mathscr{A}(W)$, $\mathscr{B}(K)$, and $\mathscr{A}(K^c)$ for all $W\in\mathscr{W}$ and $K\in\mathscr{K}_C$. Let $\mathscr{N}_s$ be a *subnet* of $\mathscr{N}$ with von Neumann algebras $\mathscr{A}_s(W)\subset\mathscr{A}(W)$, $\mathscr{B}_s(K)\subset\mathscr{B}(K)$, and $\mathscr{A}_s(K^c)\subset\mathscr{A}(K^c)$ for all $W\in\mathscr{W}$ and $K\in\mathscr{K}_C$. Both nets $\mathscr{N}$ and $\mathscr{N}_s$ thus satisfy the basic

Conditions I–V in Definition 2.1. These include the condition of Poincaré-covariance, but not *PCT*-covariance, as it could happen that a subnet $\mathcal{N}_s$ of a *PCT*-covariant net is not *PCT*-covariant.

We consider the algebra $\mathcal{U}=\cup\{\mathcal{B}(K)|K\in\mathcal{K}_C\}=\cup\{\mathcal{B}(D)|D\in\mathcal{D}\}$ of all local operators of $\mathcal{N}$, and the algebra $\mathcal{U}_s=\cup\{\mathcal{B}_s(K)|K\in\mathcal{K}_C\}=\cup\{\mathcal{B}_s(D)|D\in\mathcal{D}\}$ of all local operators of $\mathcal{N}_s$. Our particular notion of a local net requires that $\mathcal{A}(\mathsf{M})=\mathcal{U}''$ and $\mathcal{A}_s(\mathsf{M})=\mathcal{U}_s''$. Since we assumed that the net $\mathcal{N}$ is irreducible we have $\mathcal{A}(\mathsf{M})=\mathsf{B}(\mathcal{H})$, but in general $\mathcal{A}_s(\mathsf{M})$ is smaller than $\mathsf{B}(\mathcal{H})$, and Ω is not cyclic for $\mathcal{A}_s(\mathsf{M})$. We remark here that it could happen that there exists a system of sub-algebras of the algebras of a local net (in our sense) which satisfies all the other conditions on a local net, except for the condition $\mathcal{A}_s(\mathsf{M})=\mathcal{U}_s''$. This is an interesting possibility about which we have nothing to say here.

We define the sub-Hilbert space $\mathcal{H}_s$ by $\mathcal{H}_s=F_s\mathcal{H}=\overline{\mathcal{A}_s(\mathsf{M})\Omega}$, where F_s is the self-adjoint projection onto $\mathcal{H}_s$. Hence $\mathcal{A}_s(\mathsf{M})\subset\{F_s\}'$. The subspace $\mathcal{H}_s$ is Poincaré-invariant, i.e., $U(\lambda)F_s=F_sU(\lambda)$ for all $\lambda\in\hat{\mathsf{P}}$. Corresponding to the decomposition of $\mathcal{H}$ as the direct sum $\mathcal{H}=\mathcal{H}_s\oplus\mathcal{H}_s^{\perp}$ of the two orthogonal subspaces $\mathcal{H}_s$ and $\mathcal{H}_s^{\perp}$, we can write any bounded operator X on $\mathcal{H}$ in the block-matrix form

$$X=\begin{bmatrix}\rho(X), & \alpha(X)\\ \beta(X), & \gamma(X)\end{bmatrix},\quad F_s=\begin{bmatrix}I, & 0\\ 0, & 0\end{bmatrix},\tag{5.1}$$

and $\rho(X)$ is thus the restriction of the operator F_sXF_s to $\mathcal{H}_s$. Hence $\rho(X)^*=\rho(X^*)$. For any set $\mathcal{S}$ of operators on $\mathcal{H}$ we will write $\rho(\mathcal{S})=\{\rho(X)|X\in\mathcal{S}\}$. The mapping $\lambda\to U_s(\lambda)=\rho(U(\lambda))$ is a (strongly continuous) unitary representation of the group $\hat{\mathsf{P}}$ on $\mathcal{H}_s$. We have $\rho(X^z)=Z_s\rho(X)Z_s^{-1}$, with $Z_s=\rho(Z)$, and we will write $\rho(X)^z=\rho(X^z)$. With reference to this representation of $\hat{\mathsf{P}}$, the sets $\hat{\mathcal{A}}_s(W)=\rho(\mathcal{A}_s(W))$, $\hat{\mathcal{B}}_s(K)=\rho(\mathcal{B}_s(K))$, and $\hat{\mathcal{A}}_s(K^c)=\rho(\mathcal{A}_s(K^c))$, for $W\in\mathcal{W}$ and $K\in\mathcal{K}_C$, are the von Neumann algebras of an irreducible local net $\hat{\mathcal{N}}_s$, called the *vacuum representation* of the subnet $\mathcal{N}_s$.

The general Conditions I–V in Definition 2.1 leave a considerable latitude for the structure of a net. As we showed in Proposition 3.8 it is always possible to construct a ''standard net'' which satisfies the conditions in (3.13) and (3.14) from a given net, and this new net then satisfies Condition IX in Definition 2.1, i.e., it has a *strictly local structure*. If the irreducible net $\mathcal{N}$ has this structure, it is natural to consider subnets $\mathcal{N}_s$ which also have this structure. For a particular subnet $\mathcal{N}_s$ the operators in the set $\mathcal{A}_s(\mathsf{M})\cap\mathcal{U}$ are *local* operators (of the original net $\mathcal{N}$), and we want to arrange it so that they are identified as local operators of the subnet, i.e., we should have $\mathcal{U}_s=\mathcal{A}_s(\mathsf{M})\cap\mathcal{U}$. An arbitrary subnet does not necessarily have this property.

Let $\mathcal{G}$ be a group of *local internal symmetries* for a *regular* net $\mathcal{N}$, i.e., $\mathcal{G}$ is a group of unitary operators such that $G\Omega=\Omega$, and $G\mathcal{B}(K)G^{-1}=\mathcal{B}(K)$ for all $G\in\mathcal{G}$ and all $K\in\mathcal{K}_C$. The set $\mathcal{N}_s$ of algebras defined by $\mathcal{B}_s(K)=\mathcal{B}(K)\cap\mathcal{G}'$, $\mathcal{A}_s(K^c)=\mathcal{A}(K^c)\cap\mathcal{G}'$, and $\mathcal{A}_s(W)=\mathcal{A}(W)\cap\mathcal{G}'$, for all $K\in\mathcal{K}_C$ and all $W\in\mathcal{W}$, is then, what we will call below, a *regular* subnet of $\mathcal{N}$. This is an important ''mechanism'' for the production of subnets, which has been discussed extensively by Doplicher, Haag, and Roberts.[25] For a subnet of this kind one can derive many of the results discussed in what follows *without* assuming the special condition of duality. One can show by examples, however, that a subnet is not always obtained in this fashion. See also the discussion by Araki[26] of subnets in general.

An interesting general question concerns those properties of the net $\mathcal{N}$ which are *hereditary* in the sense that they are also properties of the *reduced* subnet $\hat{\mathcal{N}}_s$. Among such properties we can consider the condition of *PCT*-covariance, the condition of duality, the property that Ω is cyclic for $\mathcal{B}(K)$ for every $K\in\mathcal{K}_C$ with a nonempty interior, or the properties discussed in Section IV. It is obvious that an *arbitrary* reduced subnet $\hat{\mathcal{N}}_s$ does not necessarily inherit such special properties of $\mathcal{N}$.

Throughout the remainder of this section we will assume that $\mathcal{N}$ is a *regular* net which satisfies the *special condition of duality*. This assumption leads to a particular satisfactory theory of subnets, and the basic reason for this is that the modular operators for the wedge-algebras (relative to the vacuum vector Ω) are of a ''geometric nature,'' i.e., related to the Poincaré group and the *PCT*-operator, as described in Definition 2.4. The three theorems which follow depend

substantially on results in a paper by Wichmann[5] on subnets of local nets. The first describes important features of a ''regular'' subnet, the second describes the generation of such a subnet by any set of local operators, and the third describes properties of the reduced subnet. It will be convenient to combine the proof of these three theorems.

Theorem 5.1: Let $\mathcal{N}$ be a *regular* net, as in Definition 3.1, with algebras $\mathcal{A}(W)$, $\mathcal{B}(K)$, and $\mathcal{A}(K^c)$ for all $W\in\mathcal{W}$ and $K\in\mathcal{K}_C$. Furthermore we assume that $\mathcal{N}$ satisfies the *special condition of duality*, in accordance with Definition 2.4. Let $\mathcal{N}_s$ be a subnet of $\mathcal{N}$, with von Neumann algebras $\mathcal{A}_s(W)\subset\mathcal{A}(W)$, $\mathcal{B}_s(K)\subset\mathcal{B}(K)$, and $\mathcal{A}_s(K^c)\subset\mathcal{A}(K^c)$, which satisfy the conditions

$$\mathcal{B}_s(K)=\cap\{\mathcal{A}_s(W)\,|\,W\in\mathcal{W},\ \overline{W}\supset K\},\quad \mathcal{A}_s(K^c)=\{\mathcal{A}_s(W)\,|\,W\in\mathcal{W},\ W\subset K^c\}'', \tag{5.2}$$

and

$$\mathcal{A}_s(W)=\{\mathcal{B}_s(D)\,|\,D\in\mathcal{D},\ D\subset W\}'' \tag{5.3}$$

for all $K\in\mathcal{K}_C$, and all $W\in\mathcal{W}$. With these premises we say that $\mathcal{N}_s$ is a *regular subnet* of $\mathcal{N}$.

Let $\mathcal{U}=\cup\{\mathcal{B}(K)\,|\,K\in\mathcal{K}_C\}$ and $\mathcal{U}_s=\cup\{\mathcal{B}_s(K)\,|\,K\in\mathcal{K}_C\}$. Hence $\mathcal{A}_s(\mathsf{M})=\mathcal{U}_s''$. Let $\mathcal{H}_s=\overline{\mathcal{A}_s(\mathsf{M})\Omega}=F_s\mathcal{H}$, where F_s is the self-adjoint projection onto $\mathcal{H}_s$. Then:

(a) The subnet $\mathcal{N}_s$ is *PCT*-covariant, and the subspace $\mathcal{H}_s$ is Poincaré- and *PCT*-invariant.

(b)

$$\mathcal{A}_s(W)=\mathcal{A}(W)\cap\mathcal{A}_s(\mathsf{M})=\mathcal{A}(W)\cap\{F_s\}',\quad \mathcal{B}_s(K)=\mathcal{B}(K)\cap\mathcal{A}_s(\mathsf{M})=\mathcal{B}(K)\cap\{F_s\}', \tag{5.4}$$

for all $W\in\mathcal{W}$ and all $K\in\mathcal{K}_C$, and hence $\mathcal{U}_s=\mathcal{U}\cap\mathcal{A}_s(\mathsf{M})=\mathcal{U}\cap\{F_s\}'$.

Furthermore,

$$\mathcal{A}_s(K^c)=\mathcal{A}(K^c)\cap\mathcal{A}_s(\mathsf{M})=\mathcal{A}(K^c)\cap\{F_s\}', \tag{5.5}$$

for all $K\in\mathcal{K}_C$ with a *nonempty* interior.

(c) We have $\mathcal{A}_s(\mathsf{M})\Omega=\mathcal{H}_s$, and

$$\overline{\mathcal{B}_s(K)\Omega}=\mathcal{H}_s,$$

for every $K\in\mathcal{K}_C$ with a *nonempty* interior.

(d) If $\mathcal{H}_s=\mathcal{H}$, then $\mathcal{N}_s=\mathcal{N}$, i.e., $\mathcal{A}_s(W)=\mathcal{A}(W)$, $\mathcal{B}_s(K)=\mathcal{B}(K)$, and $\mathcal{A}_s(K^c)=\mathcal{A}(K^c)$.

Theorem 5.2: Let $\mathcal{N}$ be a *regular* net, as in Definition 3.1, with algebras $\mathcal{A}(W)$, $\mathcal{B}(K)$, and $\mathcal{A}(K^c)$ for all $W\in\mathcal{W}$ and $K\in\mathcal{K}_C$, which satisfies the *special condition of duality*. Let $\mathcal{U}=\cup\{\mathcal{B}(K)\,|\,K\in\mathcal{K}_C\}$ be the algebra of all local operators in $\mathcal{N}$.

(a) Let $\mathcal{S}$ be a subset of $\mathcal{U}$. Let $\mathcal{P}_s$ be the *smallest Poincaré-invariant* *-algebra which contains $\mathcal{S}$. We define the von Neumann algebras $\mathcal{A}_s(W)$, $\mathcal{B}_s(K)$, and $\mathcal{A}_s(K^c)$ by

$$\mathcal{A}_s(W)=\{\mathcal{P}_s\cap\mathcal{B}(D)\,|\,D\in\mathcal{D},\ D\subset W\}'', \tag{5.6}$$

for all $W\in\mathcal{W}$, and by (5.2) for all $K\in\mathcal{K}_C$. Then this system of algebras are the von Neumann algebras of a *regular* subnet $\mathcal{N}_s$ of $\mathcal{N}$, which satisfies the premises in Theorem 5.1, and hence all the conclusions in that theorem apply. Furthermore,

$$\mathcal{P}_s\subset\mathcal{U}_s,\quad \mathcal{P}_s''=\mathcal{U}_s''=\mathcal{A}_s(\mathsf{M}),\quad \overline{\mathcal{P}_s\Omega}=\overline{\mathcal{A}_s(\mathsf{M})\Omega}=\mathcal{H}_s, \tag{5.7}$$

where $\mathcal{U}_s=\cup\{\mathcal{B}_s(K)\,|\,K\in\mathcal{K}_C\}$, and where the sub-Hilbert space $\mathcal{H}_s$ is defined as in Theorem 5.1.

We say that the subnet $\mathcal{N}_s$ is *generated by* the set of local operators $\mathcal{S}$, and we express this by the notation $\mathcal{N}_s=\mathcal{N}(\mathcal{S})$ when appropriate.

(b) Let $\mathcal{S}_1$ be another subset of $\mathcal{U}$, and let $\mathcal{H}_{s1}$ be the corresponding subspace of $\mathcal{H}$, constructed in terms of $\mathcal{S}_1$ as above. Then $\mathcal{N}(S_1)=\mathcal{N}(S)$ if $\mathcal{H}_{s1}=\mathcal{H}_s$.

Theorem 5.3: Let the premises and notation be as in Theorem 5.1. As before, we denote by $\rho(X)$ the restriction of $F_s X F_s$ to $\mathscr{H}_s$ for any bounded linear or antilinear operator X on $\mathscr{H}$, and we write $\rho(\mathscr{Q})=\{\rho(X)|X\in\mathscr{Q}\}$ for any set $\mathscr{Q}$ of such operators. Then:

(a) The sets $\hat{\mathscr{A}}_s(W)=\rho(\mathscr{A}_s(W))$, $\hat{\mathscr{B}}_s(K)=\rho(\mathscr{B}_s(K))$, and $\hat{\mathscr{A}}_s(K^c)=\rho(\mathscr{A}_s(K^c))$, for all $W\in\mathscr{W}$ and all $K\in\mathscr{K}_C$, are the von Neumann algebras of a *regular* local net $\hat{\mathscr{N}}_s$ which satisfies the *special condition of duality* (with respect to the representation $\lambda\to U_s(\lambda)=\rho(U(\lambda))$ of the group $\hat{\mathsf{P}}$).

In particular, the net $\hat{\mathscr{N}}_s$ is *PCT*-covariant, with the *PCT*-operator $\theta_s=\rho(\theta)$, and the vector Ω, regarded as a vector in $\mathscr{H}_s$, is *cyclic and separating* for $\hat{\mathscr{B}}_s(K)$ for every $K\in\mathscr{K}_C$ with a nonempty interior.

(b) Suppose that $K\in\mathscr{K}_C$ has a *nonempty* interior. Hence the vector $\Omega\in\mathscr{H}$ is cyclic and separating for $\mathscr{B}(K)$. Let $\{V_K(\tau)|\tau\in\mathsf{R}^1\}$ be the modular automorphism group, and let J_K be the modular conjugation, for the algebra $\mathscr{B}(K)$ relative to Ω. Then the self-adjoint projection F_s commutes with $V_K(\tau)$ and with J_K, and we have

$$V_K(\tau).\mathscr{B}_s(K)V_K(\tau)^{-1}=\mathscr{B}_s(K),\quad V_K(\tau).\mathscr{A}_s(K^c)V_K(\tau)^{-1}=\mathscr{A}_s(K^c),$$

for all real τ. Furthermore,

$$J_K.\mathscr{B}_s(K)J_K=\mathscr{A}_s(K^c)^z.$$

We write $J_{sK}=\rho(J_K)$ and $V_{sK}(\tau)=\rho(V_K(\tau))$. Then $\{V_{sK}(\tau)|\tau\in\mathsf{R}^1\}$ is the modular automorphism group, and J_{sK} is the modular conjugation, for the algebra $\hat{\mathscr{B}}_s(K)$, relative to Ω.

(c) As equalities between sets, we have

$$\rho(\mathscr{A}(W))=\rho(\mathscr{A}_s(W)),\quad \rho(\mathscr{B}(K))=\rho(\mathscr{B}_s(K)),\quad \rho(\mathscr{A}(K^c))=\rho(\mathscr{A}_s(K^c)),\tag{5.8}$$

for all $W\in\mathscr{W}$ and all $K\in\mathscr{K}_C$.

(d) Let $\mathscr{S}$ be any subset of $\mathscr{U}$ such that $\mathscr{N}(\mathscr{S})=\mathscr{N}_s$, with the notation in Theorem 5.2, and let $\hat{\mathscr{S}}=\rho(\mathscr{S})$. Then $\mathscr{N}(\hat{\mathscr{S}})=\hat{\mathscr{N}}_s$.

Proof of Theorems 5.1, 5.2, and 5.3: (1) Assertions very similar to the assertions in the above theorems were proved in a paper by Wichmann[5] for the case of subnets of a local net with domain $\mathscr{R}=\{D,D^c|D\in\mathscr{D}\}\cup\mathscr{W}$. We are now concerned with the rather trivial extension of these results to the kind of extended net described in Definition 3.1. We will not repeat the detailed reasoning in the earlier paper, but instead we discuss the modifications required in the present scenario. We largely follow the notation in the quoted paper, but note that the double cones are there denoted by K, rather than by D as in the present paper, and most of the formulas thus (deceptively) have the same appearance.

(2) We first consider part (a) of Theorem 5.2. The von Neumann algebras defined by $\mathscr{B}_a(D)=(\mathscr{P}_s\cap\mathscr{B}(D))''$ for all $D\in\mathscr{D}$ are the algebras of a local net $\mathscr{N}_a$ with domain $\mathscr{D}$. Let $\mathscr{N}_e$ be the net constructed from the net $\mathscr{N}_a$ as in Proposition 3.8. By (5.6) we trivially have $\mathscr{A}_s(W)=\{\mathscr{B}_a(D)|D\in\mathscr{D},\ D\subset W\}''=\mathscr{A}_e(W)$, and we thus have $\mathscr{B}_s(K)=\mathscr{B}_e(K)$ and $\mathscr{A}_s(K^c)=\mathscr{A}_e(K^c)$ for the algebras defined by (5.2). Hence $\mathscr{N}_s=\mathscr{N}_e$ is a local net which satisfies the relation (5.3) in view of the relation (3.14). Since $\mathscr{B}_a(D)\subset\mathscr{B}(D)$, and hence $\mathscr{A}_s(W)\subset\mathscr{A}(W)$, it follows that $\mathscr{N}_s$ is a subnet of $\mathscr{N}$ which thus satisfies the premises of Theorem 5.1. The relations in (5.7) follow from Proposition 3.8.

(3) Suppose that a subnet $\mathscr{N}_s$ of a *regular* net $\mathscr{N}$ satisfies all the premise in Theorem 5.1. We want to apply Theorem 4 in Wichmann,[5] with $\mathscr{S}=\mathscr{U}_s=\cup\{\mathscr{B}_s(D)|D\in\mathscr{D}\}=\mathscr{P}_s$, and with $\mathscr{S}(K)$ in the theorem given by $\mathscr{S}(K)=\mathscr{B}_s(K)$ for all $K\in\mathscr{D}$. In view of (5.3) and (5.2) the conclusions in parts (a) and (d) of Theorem 5.1, and in part (b) of Theorem 5.2, follow immediately from the quoted theorem. The relations at left in (5.4) also follow from this theorem. We now note that the reasoning in the quoted paper depends on certain geometric properties of double cones, which also obtain for all $K\in\mathscr{K}_C$, namely that every such K is compact and is the intersection of the wedges $W\in\mathscr{W}$ which contain K, and that K^c is a union of the wedges contained in K^c. (See, in particular, Proposition 6 in the paper.) The relations at right in (5.4) are thus valid for *all* $K\in\mathscr{K}_C$, and the relations in (5.5) hold as stated. It was not assumed in the quoted paper that $\mathscr{B}(D)\Omega$ is dense in

$\mathscr{H}$ for *all* $D \in \mathscr{D}$, but our Definition 3.1 of a *regular* net incorporates this assumption, and hence $\mathscr{B}(K)\Omega$ is dense in $\mathscr{H}$, and $\mathscr{B}_s(K)\Omega$ is dense in $\mathscr{H}_s$, for every $K \in \mathscr{K}_C$ with a nonempty interior.

(4) For all $W \in \mathscr{W}$ and all $K \in \mathscr{K}_C$ we define the von Neumann algebras $\hat{\mathscr{A}}_w(W)$, $\hat{\mathscr{B}}_w(K)$, and $\hat{\mathscr{A}}_w(K^c)$ of operators on $\mathscr{H}_s$ by $\hat{A}_w(W) = \{\rho(\mathscr{S}(D)) | D \in \mathscr{D},\ D \subset W\}''$ and by $\hat{\mathscr{B}}_w(K) = \cap\{\hat{A}_w(W) | W \in \mathscr{W},\ W \supset K\}$ and $\hat{\mathscr{A}}_w(K^c) = \{\hat{A}_w(W) | W \in \mathscr{W},\ W \subset K^c\}''$, with $\mathscr{S}(D) = \mathscr{B}_s(D)$ as above. Note that the algebras $\hat{\mathscr{A}}_w(W)$ are denoted by $\hat{\mathscr{A}}_s(W)$ in the quoted paper, and that the algebras $\hat{\mathscr{B}}_w(K)$ and $\hat{\mathscr{A}}_w(K^c)$ are denoted by $\hat{\mathscr{B}}_s(K)$, respectively $\hat{\mathscr{A}}_s(K^c)$, for $K \in \mathscr{D}$. This (temporary) deviation from the notation in the paper is necessary in view of the different definition of the sets $\hat{\mathscr{A}}_s(W)$, $\hat{\mathscr{B}}_s(K)$, and $\hat{\mathscr{A}}_s(K^c)$ in part (a) of Theorem 5.3. By Theorem 4 in the paper we then have $\hat{\mathscr{A}}_w(W) = \rho(\mathscr{A}_s(W))$ for $W \in \mathscr{W}$, and $\hat{\mathscr{B}}_w(K) = \rho(\mathscr{B}_s(K))$ and $\hat{\mathscr{A}}_w(K^c) = \rho(\mathscr{A}_s(K^c))$ for $K \in \mathscr{D}$. The reasoning in the paper by which the last two identities are proved is, however, valid for *all* $K \in \mathscr{K}_C$, and we thus have $\hat{\mathscr{A}}_w(W) = \hat{\mathscr{A}}_s(W)$, $\hat{\mathscr{B}}_w(K) = \hat{\mathscr{B}}_s(K)$, and $\hat{\mathscr{A}}_w(K^c) = \hat{\mathscr{A}}_s(K^c)$ for all $W \in \mathscr{W}$ and all $K \in \mathscr{K}_C$. Likewise the identities in (5.8) hold as stated. By Theorem 4 in the paper, the net $\hat{\mathscr{N}}_s$ is *PCT*-covariant and satisfies the special condition of duality, and the set $\hat{\mathscr{B}}_s(K)\Omega$ is dense in $\mathscr{H}_s$ for every $K \in \mathscr{K}_C$ with a nonempty interior. We conclude that $\hat{\mathscr{N}}_s$ is a *regular* net. By the above, and by Theorem 4 in the quoted paper, all the other conclusions in Theorem 5.3 follow readily. This completes the proof.

The subnet $\mathscr{N}_s$ in Theorem 5.1 is of the standard form (of the net $\mathscr{N}_e$) described in Proposition 3.8. The term ''regular subnet'' for such a subnet is justified by the fact that the reduced subnet $\hat{\mathscr{N}}_s$ is a *regular* net in the sense of Definition 3.1.

An examination of the reasoning in the proof of Theorems 5.1 and 5.3 shows that a key point is that a wedge-algebra $\mathscr{A}_s(W)$ of the subnet $\mathscr{N}_s$ is invariant under the modular automorphism group of the algebra $\mathscr{A}(W)$ of the original net $\mathscr{N}$. This is the case when the net $\mathscr{N}$ satisfies the *special condition of duality*, and then it follows, among other things, that the subnet is *PCT*-covariant. If we relax the condition that the net $\mathscr{N}$ satisfies the *special condition of duality*, and merely assume duality, then a particular subnet might not have the above features (as far as we know). However, if we *assume* that the subnet is such that any wedge-algebra $\mathscr{A}_s(W)$ of the subnet $\mathscr{N}_s$ is invariant under the modular automorphism group of the algebra $\mathscr{A}(W)$ of the original net $\mathscr{N}$, then we arrive at results similar to those of Theorems 5.1 and 5.3, except that nothing can be concluded about the *PCT*-covariance of the subnet.

We continue the study of regular subnets of regular nets.

Proposition 5.4: Let the premises and notation be as in Theorem 5.1. Furthermore we assume that $\mathscr{H}_s$ is a *proper* subspace of $\mathscr{H}$.

Let $\mathscr{H}_s^\perp = F^\perp \mathscr{H}$ be the orthogonal complement of $\mathscr{H}_s$, with the projection $F^\perp = I - F_s$. As in (5.1) we denote by $\gamma(X)$ the restriction of the operator $F^\perp X F^\perp$ to $\mathscr{H}_s^\perp$, for any bounded operator X on $\mathscr{H}$.

(a) Let $K \in \mathscr{K}_C$, with a *nonempty interior*. Then

$$\|X\| = \|\rho(X)\| = \|\gamma(X)\|, \tag{5.9}$$

for every $X \in \mathscr{A}_s(K^c)$. In particular these relations hold for every $X \in \mathscr{U}_s$.

(b) For every $X \in \mathscr{U}$ there exists a *unique* element $\xi(X) \in \mathscr{U}_s$ such that

$$F_s X \Omega = \xi(X)\Omega,$$

or, equivalently stated, such that $\rho(X) = \rho(\xi(X))$.

If $X \in \mathscr{B}(K)$ for some $K \in \mathscr{K}_C$, then $\xi(X) \in \mathscr{B}_s(K) \subset \mathscr{B}(K)$.

(c) As a mapping of $\mathscr{U}$ onto $\mathscr{U}_s$ the mapping ξ is a *conditional expectation*, i.e., the mapping is *linear* on $\mathscr{U}$, and it satisfies the conditions

$$\xi(I) = I, \quad \xi(X^*) = \xi(X)^*, \tag{5.10}$$

$$\xi(\xi(X)) = \xi(X), \quad \xi(X)\xi(Y) = \xi(X\xi(Y)) = \xi(\xi(X)Y), \tag{5.11}$$

$$\xi(X)=\xi(X)^*\geqslant 0, \quad \text{if } X=X^*\geqslant 0, \tag{5.12}$$

$$\|\xi(X)\|\leqslant\|X\|, \tag{5.13}$$

for all $X,Y\in\mathscr{U}$.

Furthermore, we actually have $\xi(X)>0$ if $X=X^*>0$.

(d) The mapping ξ can be extended by norm-continuity to a mapping of the C^*-algebra $\mathscr{C}=\overline{\mathscr{U}}$ *onto* the C^*-algebra $\mathscr{C}_s=\overline{\mathscr{U}}_s$, which is also a conditional expectation, i.e., the extended (linear) mapping (denoted by the same symbol ξ) also satisfies the conditions in (5.10)–(5.13). The mapping ξ commutes with the adjoint actions on $\mathscr{C}$ of θ and of $U(\lambda)$ for all $\lambda\in\hat{\mathsf{P}}$.

Proof: (1) We consider part (a), and assume that $X\in\mathscr{A}_s(K^c)$, and that $K\in\mathscr{K}_C$ has a nonempty interior. We have $\alpha(X)=\beta(X)=0$, and hence $\|X\|=\max\{\|\rho(X)\|,\|\gamma(X)\|\}$. It clearly suffices to prove the equalities in (5.9) for the special case when $X=X^*>0$, and we thus assume that X is self-adjoint and positive.

We first consider the possibility that $\|\rho(X)\|<\|\gamma(X)\|$. There then exists a self-adjoint spectral projection $E\neq 0$ of X such that $\rho(E)=0$, and hence $E\Omega=0$. Since $E\in\mathscr{A}_s(K^c)$, and since Ω is separating for $\mathscr{A}_s(K^c)$ whenever K has a nonempty interior, we have $E=0$, which is a contradiction.

(2) We next consider the possibility that $\|\rho(X)\|>\|\gamma(X)\|$. We can then find a spectral projection E_0 of X which satisfies the conditions $\rho(E_0)>0$, $\gamma(E_0)=0$. Since $E_0\in\mathscr{A}_s(K^c)$ we also have $\alpha(E_0)=0=\beta(E_0)$. Let $D\in\mathscr{D}$ be such that $D\subset K^c$, and let $Y\in\mathscr{B}(D)$ but $Y\notin\mathscr{B}_s(D)$. Such a Y certainly exists, since we assumed that $\mathscr{N}\neq\mathscr{N}_s$. By (5.8) there then exists a $Y_s\in\mathscr{B}_s(D)\subset\mathscr{B}(D)$ such that $\rho(Y)=\rho(Y_s)$. We write $Q=Y-Y_s$, and hence we have $Q\in\mathscr{B}(D)$ and $\rho(Q)=0$. With the notation in (5.1) we then have

$$E_0Q=\begin{bmatrix}0, & \rho(E_0)\alpha(Q)\\ 0, & 0\end{bmatrix}, \quad E_0Q\Omega=0.$$

Since $E_0Q\in\mathscr{A}(K^c)$, and since Ω is separating for $\mathscr{A}(K^c)$, it follows that $E_0Q=0$. Let $\mathsf{N}\subset\mathsf{M}$ be a neighborhood of $0\in\mathsf{M}$ such that $D_{(x)}=\{x+y|y\in D\}\subset K^c$ for all $x\in\mathsf{N}$. Hence $T(x)QT(x)^{-1}\in\mathscr{A}(K^c)$, and $E_0T(x)Q\Omega=0$, which implies that $E_0T(x)Q=0$, for all $x\in\mathsf{N}$. We thus have $\langle\Omega|E_0T(x)QQ^*\Omega\rangle=0$ for all $x\in\mathsf{N}$, which implies that this relation holds for *all* $x\in\mathsf{M}$. Letting x tend to infinity we obtain the relation $\|E_0\Omega\|\cdot\|Q^*\Omega\|=0$. Since $E_0\Omega\neq 0$, and since Ω is separating for $\mathscr{A}(K^c)$, we obtain $Q=0$, which entails a contradiction. The assumption that $\|\rho(X)\|>\|\gamma(X)\|$ is thus untenable, and in view of the result in step (1) we conclude that $\|\rho(X)\|=\|\gamma(X)\|$, and we have thus proved the relations in (5.9) for every $X\in\mathscr{A}_s(K^c)$.

(3) Suppose that $X\in\mathscr{U}_s$. We then have $X\in\mathscr{B}_s(D)$ for some $D\in\mathscr{D}$, and since we can always find a $K\in\mathscr{K}_C$ with a nonempty interior such that $D\subset K^c$, and hence $X\in\mathscr{A}_s(K^c)$, it follows that the relations in (5.9) hold for all $X\in\mathscr{U}_s$.

(4) We consider part (b). Let $X\in\mathscr{U}$, and hence $X\in\mathscr{B}(K)$ for some $K\in\mathscr{K}_C$. By (5.9) there then exists an $X_s\in\mathscr{B}_s(K)\subset\mathscr{U}_s$ such that $\rho(X)=\rho(X_s)$. Let $X_1\in\mathscr{U}_s$ be such that $\rho(X)=\rho(X_1)$. We then have $\rho(X_s-X_1)=0$, $X_s-X_1\in\mathscr{U}_s$, and hence $(X_s-X_1)\Omega=0$. Since Ω is separating for $\mathscr{U}_s\subset\mathscr{U}$, it follows that $X_1=X_s$, and hence $X_s=\xi(X)$ is unique.

(5) We consider part (c). The assertions in (5.10) are trivial. For any $X\in\mathscr{U}$ we have $\xi(\xi(X))\Omega=F_s\xi(X)\Omega=F_sF_sX\Omega=\xi(X)\Omega$, and since $\xi(\xi(X))$, $\xi(X)\in\mathscr{U}$, and since Ω is separating for $\mathscr{U}$, it follows that $\xi(\xi(X))=\xi(X)$.

Let $X,Y\in\mathscr{U}$. We then have $\xi(X)\xi(Y)F_s=\xi(X)F_sYF_s=F_s\xi(X)YF_s=\xi(\xi(X)Y)F_s$. Hence $\xi(X)\xi(Y)\Omega=\xi(\xi(X)Y)\Omega$, and it follows that $\xi(X)\xi(Y)=\xi(\xi(X)Y)$. Forming the adjoints of both members we arrive at the relation $\xi(X)\xi(Y)=\xi(X\xi(Y))$, for all $X,Y\in\mathscr{U}$. This proves the relations in (5.11).

Suppose now that $X\in\mathscr{U}$, and $X=X^*>0$, and that $\xi(X)=0$, which implies that $\rho(X)=0$. With the notation as in (5.1) we must then have $\alpha(X)=0=\beta(X)$, since X is non-negative and self-adjoint. This implies that $X\Omega=0$, which is impossible since Ω is separating for $\mathscr{U}$. Hence we conclude that $\xi(X)>0$ if $X=X^*>0$.

To prove the inequality in (5.13) we merely note that $\|X\| \geqslant \|\rho(X)\| = \|\rho(\xi(X))\| = \|\xi(X)\|$ for any $X \in \mathscr{U}$, since the equalities in (5.9) then hold for $\xi(X) \in \mathscr{U}_s$. The assertions in part (d) are trivial. This completes the proof.

If the algebras of the subnet $\mathscr{N}_s$ are the invariance-algebras of a *compact* group $\mathscr{G}$ of local internal symmetries, i.e., $\mathscr{B}_s(K) = \mathscr{B}(K) \cap \mathscr{G}'$, $\mathscr{A}_s(K^c) = \mathscr{A}(K^c) \cap \mathscr{G}'$, and $\mathscr{A}_s(W) = \mathscr{A}(W) \cap \mathscr{G}'$, then the conditional expectation ξ is given by averaging over the group.[25]

As we have seen, certain features of a net are *hereditary* under the premises of Theorems 5.1 and 5.2, namely *PCT*-covariance; that the net satisfies the special condition of duality, and the property that Ω is cyclic for $\mathscr{B}(K)$ for every $K \in \mathscr{K}_C$ with a nonempty interior. We next consider some other properties of a net which are also hereditary.

Proposition 5.5: Let the premises and notation be as in Theorems 5.1 and 5.3. Hence $\hat{\mathscr{N}}_s$ is a *reduced regular subnet* of a *regular* net $\mathscr{N}$ which satisfies the *special condition of duality*.

Suppose that the net $\mathscr{N}$ has the property that

$$\mathscr{B}(K) = \cap\{\mathscr{B}(K_f) | K_f \in \mathscr{F}\}, \tag{5.14}$$

for any $K \in \mathscr{K}_C$ and any subset $\mathscr{F}$ of $\mathscr{K}_C$ such that $K = \cap\{K_f | K_f \in \mathscr{F}\}$. Then the nets $\mathscr{N}_s$ and $\hat{\mathscr{N}}_s$ have the same property, i.e.,

$$\mathscr{B}_s(K) = \cap\{\mathscr{B}_s(K_f) | K_f \in \mathscr{F}\}, \quad \hat{\mathscr{B}}_s(K) = \cap\{\hat{\mathscr{B}}_s(K_f) | K_f \in \mathscr{F}\}. \tag{5.15}$$

Proof: (1) The equality at left in (5.15) follows immediately if we form the intersections of both members in (5.14) with $\mathscr{A}_s(\mathsf{M})$.

(2) Let $\hat{B} \in \cap\{\hat{\mathscr{B}}_s(K_f) | K_f \in \mathscr{F}\}$, and let $K_1, K_2 \in \mathscr{F}$. There then exist two unique operators, $B_1 \in \mathscr{B}_s(K_1)$ and $B_2 \in \mathscr{B}_s(K_2)$, such that $\rho(B_1) = \hat{B} = \rho(B_2)$. We have $(B_1 - B_2)\Omega = 0$, and since Ω is trivially separating for the set $\mathscr{B}_s(K_1) \cup \mathscr{B}_s(K_2) \subset \mathscr{U}$, it follows that $B_1 = B_2$. From this we conclude that there exists a unique operator $B \in \mathscr{B}_s(K)$ such that $\rho(B) = \hat{B}$. This implies that $\rho(\mathscr{B}_s(K)) = \hat{\mathscr{B}}_s(K) \supset \cap\{\hat{\mathscr{B}}_s(K_f) | K_f \in \mathscr{F}\}$, and since the opposite inclusion follows trivially from isotony, we arrive at the identity at right in (5.15). This completes the proof.

The intersection property presented in Theorem 4.11 is thus hereditary. In that theorem the intersection property was based on the condition of additivity for wedges. In the above it is immaterial whether this condition holds or does not hold, but it is of interest to note that *this* condition is also hereditary, as we will show in Proposition 5.7 below. In preparation for this we first consider a lemma which will also permit some other interesting conclusions.

Lemma 5.6: Let the premises and notation be as in Theorems 5.1 and 5.3. Let $\mathscr{F}$ be a subset of $\mathscr{K}_C$ such that every element $K \in \mathscr{F}$ has a *nonempty* interior K^o, and such that the set $S = \cup\{K^o | K \in \mathscr{F}\}$ is *connected*. Let $\mathscr{A}_s = \cap\{\mathscr{A}_s(K^c) | K \in \mathscr{F}\}$. Then

$$\rho(\mathscr{A}_s) = \cap\{\hat{\mathscr{A}}_s(K^c) | K \in \mathscr{F}\}. \tag{5.16}$$

Proof: (1) Let $K_a, K_b \in \mathscr{F}$. Since S is open and connected it is also path-connected, and we readily conclude that there exists a finite chain, $\{K_j | j = 1,2,\ldots,n\} \subset \mathscr{F}$ such that $K_a = K_1$, $K_b = K_n$, and $K_k^o \cap K_{k+1}^o \neq \varnothing$ for $k = 1,2,\ldots,n-1$. The vector Ω is then cyclic for the algebras $\mathscr{B}(K_k)^z \cap \mathscr{B}(K_{k+1})^z$, and hence separating for the sets $\mathscr{A}_s(K_k^c) \cup \mathscr{A}_s(K_{k+1}^c) \subset \mathscr{A}(K_k^c) \cup \mathscr{A}(K_{k+1}^c)$, for $k = 1,2,\ldots,n-1$.

(2) Let $\hat{B} \in \cap\{\hat{\mathscr{A}}_s(K^c) | K \in \mathscr{F}\}$, and hence $\hat{B} \in \hat{\mathscr{A}}_s(K_j^c)$ for $j = 1,2,\ldots,n$. For each j there then exists a unique operator $B_j \in \mathscr{A}_s(K_j^c)$ such that $\rho(B_j) = \hat{B}$. We have $(B_k - B_{k+1})\Omega = 0$, and since Ω is separating for the sets $\mathscr{A}_s(K_k^c) \cup \mathscr{A}_s(K_{k+1}^c)$ it follows that $B_j = B_1 = B_n$ for all j. From this we conclude that there exists a *unique* operator $B \in \mathscr{A}_s$ such that $\rho(B) = \hat{B}$, and hence $\hat{B} \in \rho(\mathscr{A}_s)$. This proves that $\rho(\mathscr{A}_s) \supset \cap\{\hat{\mathscr{A}}_s(K^c) | K \in \mathscr{F}\}$, and since the opposite inclusion is trivial, the equality in (5.16) follows.

Proposition 5.7: Let the premises and notation be as in Theorems 5.1 and 5.3. Hence $\hat{\mathscr{N}}_s$ is a *reduced regular subnet* of a *regular* net $\mathscr{N}$ which satisfies the *special condition of duality*. In addition we assume that the net $\mathscr{N}$ satisfies the *condition of additivity for wedges*, in accordance with Definition 2.5. Then the reduced subnet $\hat{\mathscr{N}}_s$ satisfies the same condition.

Proof: Let $W \in \mathscr{W}$, and let $\mathscr{F} \subset \mathscr{D}$ be such that $W \subset \cup\{D^o | D \in \mathscr{F}\}$. Without any essential loss of generality we can assume that $D \cap W \neq \varnothing$ for all $D \in \mathscr{F}$, and hence the set $S = \cup\{D^o | D \in \mathscr{F}\}$ is *connected*. By the condition of additivity we have $\mathscr{A}(W) \subset \{\mathscr{B}(D) | D \in \mathscr{F}\}''$. This relation is, by duality, equivalent with the relation

$$\mathscr{A}(\overline{W}^c) \supset \cap\{\mathscr{A}(D^c) | D \in \mathscr{F}\}.$$

Forming the intersections of both members with $\mathscr{A}_s(\mathsf{M})$ we obtain the relation $\mathscr{A}_s(\overline{W}^c) \supset \cap\{\mathscr{A}_s(D^c) | D \in \mathscr{F}\}$. By Lemma 5.6 we have $\rho(\mathscr{A}_s) = \cap\{\hat{\mathscr{A}}_s(D^c) | D \in \mathscr{F}\}$, with $\mathscr{A}_s = \cap\{\mathscr{A}_s(D^c) | D \in \mathscr{F}\}$, and since $\hat{\mathscr{A}}_s(\overline{W}^c) = \rho(\mathscr{A}_s(\overline{W}^c)$ it follows that

$$\hat{\mathscr{A}}_s(\overline{W}^c) \supset \cap\{\hat{\mathscr{A}}_s(D^c) | D \in \mathscr{F}\}. \tag{5.17}$$

The reduced subnet $\hat{\mathscr{N}}_s$ satisfies the condition of duality, and hence the relation (5.17) is equivalent with the relation

$$\hat{\mathscr{A}}_s(W) \subset \{\hat{\mathscr{B}}_s(D) | D \in \mathscr{F}\}''.$$

The reduced subnet $\hat{\mathscr{N}}_s$ thus satisfies the condition of additivity for wedges, as asserted.

By similar reasoning we can also show that if the net $\mathscr{N}$ satisfies the *condition of additivity for double cones*, mentioned in Section II, then the reduced subnet $\hat{\mathscr{N}}_s$ also satisfies this condition.

We next show that a certain causality condition is hereditary.

Proposition 5.8: Let the premises and notation be as in Theorems 5.1 and 5.3. Hence $\hat{\mathscr{N}}_s$ is a *reduced regular subnet* of a *regular* net $\mathscr{N}$ which satisfies the *special condition of duality*. In addition we assume that the net $\mathscr{N}$ satisfies the following particular *condition of causality:*

$$\{\mathscr{B}(D) | D \in \mathscr{D},\ D \subset S\}'' = \{\mathscr{B}(D) | D \in \mathscr{D},\ D \subset \mathscr{E}(S)\}'', \tag{5.18}$$

for every open *connected* subset S of M. Here $\mathscr{E}(S)$ is the envelope of uniqueness of S, defined as in Lemma 4.5.

Then the net $\hat{\mathscr{N}}_s$ satisfies the same causality condition.

Proof: The relation in (5.18) is, by duality, equivalent with the relation

$$\cap\{\mathscr{A}(D^c) | D \in \mathscr{D},\ D \subset S\} = \cap\{\mathscr{A}(D^c) | D \in \mathscr{D},\ D \subset \mathscr{E}(S)\}.$$

Forming the intersections of both members with $\mathscr{A}_s(\mathsf{M})$ we obtain the relation

$$\cap\{\mathscr{A}_s(D^c) | D \in \mathscr{D},\ D \subset S\} = \cap\{\mathscr{A}_s(D^c) | D \in \mathscr{D},\ D \subset \mathscr{E}(S)\}. \tag{5.19}$$

Since the set S is connected the set $\mathscr{E}(S)$ is also connected. We have $S = \cup\{D^o | D \subset S\}$ and $\mathscr{E}(S) = \cup\{D^o | D \subset \mathscr{E}(S)\}$. By an obvious application of Lemma 5.6 to both members in (5.19) we obtain the relation

$$\cap\{\hat{\mathscr{A}}_s(D^c) | D \in \mathscr{D},\ D \subset S\} = \cap\{\hat{\mathscr{A}}_s(D^c) | D \in \mathscr{D},\ D \subset \mathscr{E}(S)\},$$

which, by duality, is equivalent with the relation

$$\{\hat{\mathscr{B}}_s(D) | D \in \mathscr{D},\ D \subset S\}'' = \{\hat{\mathscr{B}}_s(D) | D \in \mathscr{D},\ D \subset \mathscr{E}(S)\}''.$$

Hence the reduced subnet $\hat{\mathscr{N}}$ satisfies the same causality condition. This completes the proof.

The above rather strong causality condition holds for a local net $\mathscr{N}$ generated by a free Hermitian scalar field associated with a single massive particle, but it is not known whether it holds more generally. The above proposition shows that counterexamples, if there are such, cannot be manufactured within the framework of finite-component free-field theories. A variety of other weaker causality conditions can be considered, and among these we note the so-called *time-slice condition*.[9,12] (This condition says that the algebra generated by all local operators associated with

a region bounded by two parallel spacelike planes is irreducible.) By the same kind of reasoning as above we see at once that the time-slice condition is also hereditary (under the general premises in the above proposition).

The algebras $\mathscr{B}(K)$ of a regular net $\mathscr{N}$ are continuous from the *outside*, but not necessarily from the inside. However, if the algebra $\mathscr{B}(K_0)$ is continuous from the inside, for some particular $K_0 \in \mathscr{K}_C$, then this property if also hereditary.

Proposition 5.9: Let the premises and notation be as in Theorems 5.1 and 5.3. Hence $\hat{\mathscr{N}}_s$ is a *reduced regular subnet* of a *regular* net $\mathscr{N}$ which satisfies the *special condition of duality*. Suppose that the algebra $\mathscr{B}(K_0)$, for some $K_0 \in \mathscr{K}_C$ with a nonempty interior, is *continuous from the inside* in the sense that

$$\mathscr{B}(K_0) = \{\mathscr{B}(K) | K \in \mathscr{K}_C,\ K \subset K_0^o\}''. \tag{5.20}$$

Then the algebra $\hat{\mathscr{B}}_s(K_0)$ of the reduced subnet $\hat{\mathscr{N}}_s$ has the same property.

Proof: Let $\mathscr{T}_0$ be the set of all $K \in \mathscr{K}_C$ with a *nonempty interior*, and such that $K \subset K_0^o$. We obviously have $\mathscr{B}(K_0) = \{\mathscr{B}(K) | K \in \mathscr{T}_0\}''$ if the relation in (5.20) holds. By duality this implies that $\mathscr{A}(K_0^c) = \cap\{\mathscr{A}(K^c) | K \in \mathscr{T}_0\}$, and from this it follows that $\mathscr{A}_s(K_0^c) = \cap\{\mathscr{A}_s(K^c) | K \in \mathscr{T}_0\}$. By Lemma 5.6 we then conclude that $\hat{\mathscr{A}}_s(K_0^c) = \cap\{\hat{\mathscr{A}}_s(K^c) | K \in \mathscr{T}_0\}$. By duality this relation is equivalent with the relation $\hat{\mathscr{B}}_s(K_0) = \{\hat{\mathscr{B}}_s(K) | K \in \mathscr{T}_0\}''$. Since we clearly have $\hat{\mathscr{B}}_s(K_0) \supset \{\hat{\mathscr{B}}_s(K) | K \in \mathscr{K}_C,\ K \subset K_0^o\}'' \supset \{\hat{\mathscr{B}}_s(K) | K \in \mathscr{T}_0\}''$, it follows that

$$\hat{\mathscr{B}}_s(K_0) = \{\hat{\mathscr{B}}_s(K) | K \in \mathscr{K}_C,\ K \subset K_0^o\}'',$$

as asserted. This completes the proof.

The so-called *condition of nuclearity* was discussed in a paper by Buchholz and Wichmann[27] as a physically motivated additional condition on the local algebras. We will not discuss this condition here, but we remark that it is trivial that it is also hereditary.

We conclude this section by showing that there is a unique $K \in \mathscr{K}_C$ associated with every local operator, under certain premises.

Proposition 5.10: Let the premises and notation be as in Theorems 5.1 and 5.3. Hence $\hat{\mathscr{N}}_s$ is a *reduced regular subnet* of a *regular* net $\mathscr{N}$ which satisfies the *special condition of duality*. In addition we assume that the net $\mathscr{N}$ has the *intersection property* described in Proposition 5.5. In particular the net $\mathscr{N}$ has this property if it satisfies the *condition of additivity for wedges* in Definition 2.5.

Let $B \in \mathscr{U} = \cup\{\mathscr{B}(K) | K \in \mathscr{K}_C\}$. There then exists a unique *smallest* $K_B \in \mathscr{K}_C$ such that $B \in \mathscr{B}(K_B)$, i.e., $K_B \subset K$ if $B \in \mathscr{B}(K)$. Furthermore, we have $\rho(B) \in \hat{\mathscr{B}}_s(K_B)$, and if $B \in \mathscr{U}_s$, then K_B is the *smallest* $K \in \mathscr{K}_C$ such that $\rho(B) \subset \hat{\mathscr{B}}_s(K)$. In particular this applies when $\mathscr{N}_s = \mathscr{N}(\{B\})$, i.e., the subnet $\mathscr{N}_s$ is *generated* by B in the sense described in Theorem 5.2.

Proof: For any $B \in \mathscr{U}$ we define K_B by $K_B = \cap\{K | K \in \mathscr{K}_C,\ B \in \mathscr{B}(K)\}$, and K_B is then the unique smallest K such that $B \in \mathscr{B}(K)$. By part (b) of Proposition 5.4 we then have $\rho(B) = \rho(\xi(B)) \in \hat{\mathscr{B}}_s(K_B)$. Suppose now that $B \in \mathscr{U}_s$, and that $\rho(B) \in \hat{\mathscr{B}}_s(K)$. We then have $B \in \mathscr{B}_s(K) \subset \mathscr{B}(K)$, and hence $K \supset K_B$, and it follows that K_B is the smallest $K \in \mathscr{K}_C$ such that $\rho(B) \subset \hat{\mathscr{B}}_s(K)$. This completes the proof.

The case when $\mathscr{N}_s = \mathscr{N}(\{B\})$ is interesting. By the above proposition K_B is the unique smallest compact, convex, causally complete subset K of M such that $[B^z, U(\lambda) B U(\lambda)^{-1}] = 0$ and $[B^z, U(\lambda) B^* U(\lambda)^{-1}] = 0$ for all $\lambda \in \hat{\mathsf{P}}$ such that $K_{(\lambda)} \subset K^c$. The region K_B is thus an *intrinsic* feature of the local operator B in the sense that it can in principle be determined without reference to the other local operators in the net.

VI. ABOUT POSSIBLE FURTHER EXTENSIONS OF SYSTEMS OF LOCAL ALGEBRAS

Given a *regular* local net $\mathscr{N}$, a rather natural project is to try to extend the domain of the $\mathscr{B}$-algebras to the set $\mathscr{K}_B$ of *all* compact causally complete subsets of M. We want to discuss this issue briefly here. For any $K \in \mathscr{K}_B$ the set K^c is open and causally complete, and we thus also like to extend the domain of the $\mathscr{A}$-algebras to include all such K^c. The *local* algebras satisfy the

condition of *Haag duality* if and only if the extended net satisfies *both* Conditions VIII and IX in Definition 2.1, and if this is the case, then the *local* algebras are maximal. We are *not* asserting here that such an extension always exists for a given regular net $\mathcal{N}$, or that it is unique if it exists. We are merely describing a desirable goal, and we have no proof one way or the other.

As in the construction of a regular net from a basic net in Section III, the set $\mathcal{U}$ of all *local* operators of the extended net remains unchanged, for the simple reason that every $K \in \mathcal{K}_B$ is contained in some double cone. To the extended net thus corresponds a particular association of the local operators with the regions in $\mathcal{K}_B$. The set $\mathcal{K}_B$ contains compact sets of considerable geometric complexity. A set $K \in \mathcal{K}_B$ may thus be a union of any number of disjoint connected components, and any component may be multiply connected. Similarly for the regions K^c. The *convex* sets in $\mathcal{K}_C$ are very much simpler. We were able to show (assuming the condition of additivity for wedges) that to each local operator B corresponds a unique smallest $K \in \mathcal{K}_C$ such that $B \in \mathcal{B}(K)$. Without a suitable ''intersection property'' for algebras corresponding to the regions in $\mathcal{K}_B$ we cannot show that there corresponds a unique smallest $K_b \in \mathcal{K}_B$ to each local operator, and it is not obvious to us that such a correspondence exists.

We will here describe the construction of a particular extended net. The main issue is the extension of the system of *local* algebras, and we will first show that given any such an extension, the extension of the domain of the auxiliary $\mathcal{A}$-algebras is then rather trivial.

Lemma 6.1: Let $\mathcal{N}$ be a *regular* local net, as in Definition 3.1, with algebras $\mathcal{A}(W)$, $\mathcal{B}(K)$, and $\mathcal{A}(K^c)$ for all $W \in \mathcal{W}$ and $K \in \mathcal{K}_C$. Let $\mathcal{K}_B$ be the set of all *compact and causally complete* subsets K of M. Let $\mathcal{N}_{loc}$ be a *PCT-covariant local net*, with von Neumann algebras $\mathcal{B}_e(K)$ defined for all $K \in \mathcal{K}_B$. We thus assume that the net $\mathcal{N}_{loc}$ satisfies Conditions I–VI in Definition 2.1. Furthermore we assume that $\mathcal{B}_e(K_c) = \mathcal{B}(K_c)$ for all $K_c \in \mathcal{K}_C$.

We write $\mathcal{A}_e(K^c) = (\mathcal{B}_e(K)^z)'$ for every $K \in \mathcal{K}_B$, and we write $\mathcal{A}_e(W) = \mathcal{A}(W)$ for every $W \in \mathcal{W}$. Then:

(a) $\mathcal{B}_e(K) \subset \mathcal{A}(W)$ for any $K \in \mathcal{K}_B$, $W \in \mathcal{W}$, such that $K \subset W$, and we have

$$\mathcal{A}_e(W) = \{\mathcal{B}_e(K) | K \in \mathcal{K}_B,\ K \subset W\}'' = \cap(\mathcal{A}_e(K^c) | K \in \mathcal{K}_B,\ K^c \supset W\}, \tag{6.1}$$

for every $W \in \mathcal{W}$.

(b) The system $\mathcal{N}_e$ of the von Neumann algebras $\mathcal{A}_e(W)$, $\mathcal{B}_e(K)$, and $\mathcal{A}_e(K^c)$, defined above for all $W \in \mathcal{W}$ and all $K \in \mathcal{K}_B$, is an irreducible local net, which satisfies *all* the Conditions I–VIII in Definition 2.1 (but not necessarily Condition IX). We have

$$\mathcal{B}_e(K) = \mathcal{B}(K), \quad \mathcal{A}_e(K^c) = \mathcal{A}(K^c), \quad \text{for all } K \in \mathcal{K}_C, \tag{6.2}$$

and the net $\mathcal{N}_e$ is thus an *extension of the net* $\mathcal{N}$ since we also have $\mathcal{A}_e(W) = \mathcal{A}(W)$.

(c) The nets $\mathcal{N}_e$ and $\mathcal{N}$ have precisely the same *local* operators, i.e., we have $\cup\{\mathcal{B}_e(K) | K \in \mathcal{K}_B\} = \mathcal{U} = \cup\{\mathcal{B}(K_c) | K_c \in \mathcal{K}_C\}$.

Proof: (1) It is trivial that the system $\mathcal{N}_e$ is Poincaré- and *PCT*-covariant. Furthermore the system satisfies the conditions of duality, namely $\mathcal{B}_e(K)^z = \mathcal{A}_e(K^c)'$ for all $K \in \mathcal{K}_B$ and $\mathcal{A}_e(W)^z = \mathcal{A}_e(\overline{W^c})'$ for all $W \in \mathcal{W}$, by the definitions of the algebras $\mathcal{A}_e(K^c)$ and $\mathcal{A}_e(W)$. The relation at right in (6.2) then follows by duality from the assumed relation at left.

Let $K \subset W$, with $K \in \mathcal{K}_B$ and $W \in \mathcal{W}$. Since K is compact there certainly exists a $K_c \in \mathcal{K}_C$ such that $K \subset K_c \subset W$. In particular we can select K_c as a double cone in $\mathcal{D}$. By the condition at left in (6.2), and by isotony, we then have $\mathcal{B}_e(K) \subset \mathcal{B}_e(K_c) = \mathcal{B}(K_c) \subset \mathcal{A}(W)$. From this it follows that $\mathcal{A}(W) \supset \{\mathcal{B}_e(K) | K \in \mathcal{K}_B,\ K \subset W\}'' \supset \{\mathcal{B}(K) | K \in \mathcal{K}_C,\ K \subset W\}'' = \mathcal{A}(W)$. This proves the equality of the first two members in (6.1). The equality of the first and third members then follows by duality. The remaining assertions are easily proved, and we omit the details. Note that two regions K_1^c and K_2^c can never be spacelike separated if $K_1, K_2 \in \mathcal{K}_B$, and hence the condition of locality does not apply to the pair of algebras $\mathcal{A}_e(K_1^c)$ and $\mathcal{A}_e(K_2^c)$. This completes the proof.

Condition IX in Definition 2.1 is at least *partly* satisfied, in view of the relations in (6.1). It is also easily seen that we have $\mathcal{A}_e(K^c) = \{\mathcal{B}_e(K_i) | K_i \in \mathcal{K}_B,\ K_i \subset K^c\}''$ for all $K \in \mathcal{K}_C$, but it might well happen that this relation does not hold for *all* $K \in \mathcal{K}_B$. As we said before, the goal is to find an extension such that this relation does hold for all $K \in \mathcal{K}_B$, which means that the net $\mathcal{N}_e$ satisfies *all* the Conditions I–IX.

We have arranged it so that the net $\mathcal{N}_e$ satisfies the duality condition. We could also have defined the $\mathcal{A}_e$-algebras by $\mathcal{A}_e(K^c)=\{\mathcal{B}_e(K_i)|K_i\in\mathcal{K}_B,\ K_i\subset K^c\}''$, in which case Condition IX would hold, but then our duality condition might fail. If the net $\mathcal{N}$ has no extension which satisfies all the Conditions I–IX, it becomes a matter of choice of how the auxiliary $\mathcal{A}_e$-algebras are defined. One might feel that an *essential* feature of duality is that Condition IX should also hold, and that the duality of the net $\mathcal{N}_e$ is of a ''cheap'' kind if the extension does not satisfy this condition. However, the net $\mathcal{N}_e$ does satisfy this condition for wedges, and its restriction to the domain of $\mathcal{N}$ is a net which does satisfy *all* the Conditions I–IX. These features of the net $\mathcal{N}_e$ are *not* ''cheap.''

We will now discuss a simple extension of a regular net. The strategy is to first construct algebras $\mathcal{B}_S(K)$ for all $K\in\mathcal{K}_B$, which are as large as we can make them, after which we apply Lemma 6.1 to complete the extension. A natural first step is to define a von Neumann algebra $\mathcal{B}_0(K)$ by $\mathcal{B}_0(K)=\{\mathcal{B}(K_i)|K_i\in\mathcal{K}_C,\ K_i\subset K\}''$ for every $K\in\mathcal{K}_B$. These algebras form a local net with domain $\mathcal{K}_B$, but it is possible that this net is not maximal. There is a well-known standard construction which may lead to an enlargement of these algebras, which we now describe in general terms.

Lemma 6.2: Let $\mathcal{M}$ be any mapping of $\mathcal{K}_B$ into the set of von Neumann algebras in $\mathsf{B}(\mathcal{H})$. We define the *dual mapping* $\mathcal{M}^\star$ of $\mathcal{K}_B$ into the set of von Neumann algebras by

$$\mathcal{M}^\star(K)=\{\mathcal{M}(K_i)^z|K_i\in\mathcal{K}_B,\ K_i\subset K^c\}', \tag{6.3}$$

for all $K\in\mathcal{K}_B$, and we define $\mathcal{M}^{\star\star}$ as $(\mathcal{M}^\star)^\star$ and $\mathcal{M}^{\star\star\star}$ as $(\mathcal{M}^{\star\star})^\star=(\mathcal{M}^\star)^{\star\star}$. Then:

(a) For all $K\in\mathcal{K}_B$,

$$\mathcal{M}^{\star\star}(K)\supset\mathcal{M}(K),\quad \mathcal{M}^\star(K)=\mathcal{M}^{\star\star\star}(K). \tag{6.4}$$

(b) If $\mathcal{M}$ satisfies the conditions of isotony, Poincaré-covariance, and *PCT*-covariance, then $\mathcal{M}^\star$ and $\mathcal{M}^{\star\star}$ satisfy the same conditions.

(c) If $\mathcal{M}$ is a local net with domain $\mathcal{K}_B$, then $\mathcal{M}^{\star\star}$ is also a local net with domain $\mathcal{K}_B$. Furthermore we have $\mathcal{M}^\star(K)\supset\mathcal{M}^{\star\star}(K)$ for all $K\in\mathcal{K}_B$.

Proof: (1) The inclusion relation $\mathcal{M}^{\star\star}(K)\supset\mathcal{M}(K)$ follows trivially from the definition in (6.3). Replacing $\mathcal{M}$ by $\mathcal{M}^\star$ we have $\mathcal{M}^{\star\star\star}(K)\supset\mathcal{M}^\star(K)$. Let $\mathcal{M}_l$ and $\mathcal{M}_s$ be two mappings of the stated kind, such that $\mathcal{M}_l(K)\supset\mathcal{M}_s(K)$ for all $K\in\mathcal{K}_B$. By (6.3) we then have $\mathcal{M}_l^\star(K)\subset\mathcal{M}_s^\star(K)$ for all $K\in\mathcal{K}_B$. Applying this to the relation $\mathcal{M}^{\star\star}(K)\supset\mathcal{M}(K)$ we obtain $\mathcal{M}^{\star\star\star}(K)\subset\mathcal{M}^\star(K)$, and hence the relation at right in (6.4) follows.

(2) The assertions in part (b) follow trivially from the fact that causal complementation commutes with all Poincaré transformations, and with inversion, and from the fact that $R_l^c\subset R_s^c$ whenever $R_l\supset R_s$.

(3) We consider part (c). The locality condition for $\mathcal{M}$ trivially implies that $\mathcal{M}^\star(K)\supset\mathcal{M}(K)$, in view of the definition in (6.3). By (6.4) it then follows that $\mathcal{M}^\star(K)\supset\mathcal{M}^{\star\star}(K)$. In view of (6.3) this implies that $\mathcal{M}^{\star\star}$ is a local net. This completes the proof.

In the present context *Haag duality* for a local net $\mathcal{M}$ is the condition that $\mathcal{M}^\star=\mathcal{M}$. The weaker condition that $\mathcal{M}^\star=\mathcal{M}^{\star\star}$, which is the condition that $\mathcal{M}^\star$ is local, is referred to as *essential duality* in the literature.

We are now prepared for the specific extension which we want to discuss.

Theorem 6.3: Let $\mathcal{N}$ be a *regular* local net, as in Definition 3.1, with algebras $\mathcal{A}(W)$, $\mathcal{B}(K)$, and $\mathcal{A}(K^c)$ for all $W\in\mathcal{W}$ and $K\in\mathcal{K}_C$. For each $K\in\mathcal{K}_B$ we define the von Neumann algebra $\mathcal{B}_0(K)$ by $\mathcal{B}_0(K)=\{\mathcal{B}(K_i)|K_i\in\mathcal{K}_C,\ K_i\subset K\}''$. We define the mappings $\{\mathcal{B}_0(K)\}\to\{\mathcal{B}_0^\star(K)\}$ and $\{\mathcal{B}_0(K)\}\to\{\mathcal{B}_0^{\star\star}(K)\}$ as in Lemma 6.2.

We write $\mathcal{A}_S(W)=\mathcal{A}(W)$ for $W\in\mathcal{W}$, and for each $K\in\mathcal{K}_B$ we define the von Neumann algebras $\mathcal{B}_S(K)$ and $\mathcal{A}_S(K^c)$ by $\mathcal{B}_S(K)=\mathcal{B}_0^{\star\star}(K)$ and $\mathcal{A}_S(K^c)=(\mathcal{B}_S(K)^z)'$. Then:

(a) The set of algebras $\mathcal{A}_S(W)$, for $W\in\mathcal{W}$, and $\mathcal{B}_S(K)$ and $\mathcal{A}_S(K^c)$, for $K\in\mathcal{K}_B$, forms a local net $\mathcal{N}_S$ which satisfies all the Conditions I–VIII in Definition 2.1, but possibly *not* Condition IX. It is an extension of the net $\mathcal{N}$, and we have

$$\mathscr{B}_S(K)=\mathscr{B}(K), \quad \mathscr{A}_S(K^c)=\mathscr{A}(K^c), \quad \text{for all } K\in\mathscr{K}_C,$$

and

$$\mathscr{A}_S(W)=\{\mathscr{B}_S(K)|K\in\mathscr{K}_B,\ K\subset W\}''=\cap(\mathscr{A}_S(K^c)|K\in\mathscr{K}_B,\ K^c\supset W\}.$$

The nets $\mathscr{N}$ and $\mathscr{N}_S$ have the same set of local operators, i.e.,

$$\mathscr{U}_S=\cup\{\mathscr{B}_S(K)|K\in\mathscr{K}_B\}=\mathscr{U}=\cup\{\mathscr{B}(K)|K\in\mathscr{K}_C\}.$$

(b) Let $\mathscr{N}_m$ be a local net, with von Neumann algebras $\mathscr{A}_m(W)=\mathscr{A}(W)$, $\mathscr{B}_m(K)$, and $A_m(K^c)$ for all $W\in\mathscr{W}$ and all $K\in\mathscr{K}_B$. Suppose that $\mathscr{N}_m$ is an extension of $\mathscr{N}$ such that $\mathscr{B}_m(K)=\mathscr{B}(K)$ and $\mathscr{A}_m(K^c)=\mathscr{A}(K^c)$ for all $K\in\mathscr{K}_C$, and suppose furthermore that $\mathscr{B}_m^{\star\star}(K)=\mathscr{B}_m(K)$ for all $K\in\mathscr{K}_B$. We then have

$$\mathscr{B}_0^{\star}(K)=\mathscr{B}_S^{\star}(K)\supset\mathscr{B}_m(K)\supset\mathscr{B}_S(K), \tag{6.5}$$

for all $K\in\mathscr{K}_B$.

(c) The net $\mathscr{N}_S$ satisfies Condition IX in Definition 2.1, i.e.,

$$\mathscr{A}_S(K^c)=\{\mathscr{B}_S(K_i)|K_i\in\mathscr{K}_B,\ K_i\subset K^c\}'', \tag{6.6}$$

for all $K\in\mathscr{K}_B$, if and only if $\mathscr{B}_0^{\star}(K)=\mathscr{B}_S(K)$ for all $K\in\mathscr{K}_B$, which is the case if and only if the set of algebras $\{\mathscr{B}_0^{\star}(K)|K\in\mathscr{K}_B\}$ is a *local net* with domain $\mathscr{K}_B$. If these conditions hold, then $\mathscr{N}_S$ is the *unique* extension of $\mathscr{N}$ which satisfies *all* the Conditions I–IX in Definition 2.1, and the *local* algebras $\mathscr{B}_S(K)$ are *maximal*.

(d) The mapping $K\to\mathscr{B}_0^{\star}(K)$ satisfies the conditions of isotony, Poincaré-covariance and *PCT*-covariance. We have $\mathscr{B}_0^{\star}(K)\subset\mathscr{U}$ for all $K\in\mathscr{K}_B$, and $\mathscr{B}_0^{\star}(K_c)=\mathscr{B}(K_c)$ for all $K_c\in\mathscr{K}_C$. Furthermore we have $\mathscr{B}_0^{\star}(K)\subset\mathscr{A}(W)$ for any $K\in\mathscr{K}_B$ and $W\in\mathscr{W}$ such that $K\subset W$.

Proof: (1) It follows trivially from the definition of the algebras $\mathscr{B}_0(K)$ that the mapping $K\to\mathscr{B}_0(K)$ is a local net with domain $\mathscr{K}_B$, which satisfies the condition that $\mathscr{B}_0(K_c)=\mathscr{B}(K_c)$ for all $K_c\in\mathscr{K}_C$. The conclusions in part (a) then follow readily on the basis of Lemmas 6.1 and 6.2.

(2) By part (c) of Lemma 6.2 we have $\mathscr{B}_0^{\star}(K)\supset\mathscr{B}_0^{\star\star}(K)\supset\mathscr{B}_0(K)$ for all $K\in\mathscr{K}_B$, and in particular for all $K\in\mathscr{K}_C$. Let $K_c\in\mathscr{K}_C$. Since $\mathscr{K}_C\subset\mathscr{K}_B$ it follows from (6.3) that we have $\mathscr{B}_0^{\star}(K^c)\subset\{\mathscr{B}(K_i)^z|K_i\in\mathscr{K}_C,\ K_i\subset K_c^c\}'=(\mathscr{A}(K_c^c)^z)'=\mathscr{B}(K_c)$, and hence we have $\mathscr{B}_0^{\star}(K_c)=\mathscr{B}(K_c)=\mathscr{B}_0(K_c)$ for all $K_c\in\mathscr{K}_C$. From this we conclude that $\mathscr{B}_0^{\star}(K_c)=\mathscr{B}_0^{\star\star}(K_c)=\mathscr{B}(K_c)$ for all $K_c\in\mathscr{K}_C$. Let $K\in\mathscr{K}_B$ and $W\in\mathscr{W}$ be such that $K\subset W$. There then obviously exists a $K_c\in\mathscr{K}_C$ such that $K\subset K_c\subset W$, and by the isotony of the mapping $\mathscr{B}_0^{\star}$ it follows that $\mathscr{B}_0^{\star}(K)\subset\mathscr{B}(K_c)\subset\mathscr{A}(W)$. Since every $K\in\mathscr{K}_B$ is contained in some $K_c\in\mathscr{K}_C$, we also conclude that $\mathscr{B}_0^{\star}(K)\subset\mathscr{U}$ for all $K\in\mathscr{K}_B$. We have thus proved the assertions in part (d).

(3) We consider part (b). By the isotony of the extended net $\mathscr{N}_m$ we have $\mathscr{B}_m(K)\supset\mathscr{B}_0(K)$, and hence $\mathscr{B}_m^{\star\star}\supset\mathscr{B}_0^{\star\star}=\mathscr{B}_S(K)$ and $\mathscr{B}_0^{\star}(K)\supset\mathscr{B}_m^{\star}(K)\supset\mathscr{B}_m^{\star\star}(K)$ for all $K\in\mathscr{K}_B$. Since it was also assumed that $\mathscr{B}_m(K)=\mathscr{B}_m^{\star\star}(K)$ we obtain the inclusion relations in (6.5).

(4) We consider part (c). We have $\mathscr{B}_S^{\star}(K)=\mathscr{B}_0^{\star\star\star}(K)=\mathscr{B}_0^{\star}(K)$, in view of Lemma 6.2. By the duality condition for the net $\mathscr{N}_S$ the relation (6.6) is equivalent with the relation $\mathscr{B}_S(K)=\{\mathscr{B}_S(K_i)^z|K_i\in\mathscr{K}_B,\ K_i\subset K^c\}'$, and with reference to (6.3) we conclude that the relation (6.6) holds for all $K\in\mathscr{K}_B$ if and only if $\mathscr{B}_0^{*}(K)=\mathscr{B}_S(K)=\mathscr{B}_0^{\star\star}(K)$ for all $K\in\mathscr{K}_B$. The latter relation is the condition that the mapping $K\to\mathscr{B}_0^{\star}(K)$ is a local net. If these relations hold, the stated uniqueness of the extension $\mathscr{N}_S$ then follows from the inclusion relations in (6.5), and it is trivial that the local algebras are maximal. This completes the proof.

As we see, the algebras $\mathscr{B}_0^{\star}(K)$ do consist of *local* operators in the ''original'' set $\mathscr{U}$ of local operators, but the conditions of locality involving two $\mathscr{B}_0^{\star}$-algebras might not hold for *all* relevant configurations of causally disjoint sets in $\mathscr{K}_B$, although they obviously hold for some configurations since we have $\mathscr{B}_0^{\star}(K_c)=\mathscr{B}(K_c)$ for all $K_c\in\mathscr{K}_C$. We note here that the mapping $K\to\mathscr{B}_0^{\star}(K)$ constructed from a regular net $\mathscr{N}$ associated with a *free* massive scalar field is indeed a local net with domain $\mathscr{K}_B$, and in this case $\mathscr{N}_S$ is the unique extension of $\mathscr{N}$, which satisfies *all* the Conditions I–XI in Definition 2.1.

We note that an extended net $\mathscr{N}_m^{\cdot}$ for which the local algebras $\mathscr{B}_m(K)$ are maximal trivially satisfies the premises in part (b), and this is in particular the case if the net $\mathscr{N}_m^{\cdot}$ satisfies all the Conditions I–IX. The algebras $\mathscr{B}_m(K)$ are then always pinned between the algebras $\mathscr{B}_0^{\star}(K)$ and $\mathscr{B}_S(K)$. As we said before, we have no proof that a unique extension exists which satisfies *all* the Conditions I–IX in Definition 2.1, and we tend to believe that the question cannot be decided without additional conditions on the net $\mathscr{N}^{\cdot}$. The extension $\mathscr{N}_S^{\cdot}$ described above can, in any case, be regarded as a rather natural *standard* extension, already implicit for a *basic* net as described in Definition 2.3.

It is worth noting that the construction of the extended local net $\mathscr{N}_S^{\cdot}$ depends essentially on the circumstance that the $\mathscr{B}$-algebras are defined for *compact* subsets of M. If we try to apply the above scheme to define the algebras $\mathscr{B}_S(K)$ for *all* causally complete closed sets K, it could happen that the algebras $\mathscr{A}_S(K^c)=(\mathscr{B}_S(K)^z)'$ do not satisfy *all* the conditions of locality among themselves. This issue does not arise in our case, since K_1^c and K_2^c cannot be spacelike separated if K_1 and K_2 are compact.

In Section IV we discussed various ''intersection properties'' for a *regular* net. The question arises whether similar properties can be established for an extended local net $\mathscr{N}_e^{\cdot}$ of the kind considered in this section. The results in Proposition 4.4 can indeed be generalized. Suppose that $K_1, K_0 \in \mathscr{K}_B$ are such that $K_1 \subset K_0^o$. By the same reasoning as in the proof of Proposition 4.4, based on Borchers' theorem,[23] we easily conclude that $\mathscr{B}_e(K_1) \cap \mathscr{A}_e(K_0^c) = \mathsf{C}^1 \cdot I$. This implies in particular that $\mathscr{B}_e(K_1) \cap \mathscr{B}_e(K_2) = \mathsf{C}^1 \cdot I$ if $K_1, K_2 \in \mathscr{K}_B$ are *spacelike* separated.

We also proved other ''intersection properties,'' as in Theorem 4.11, for which the convexity of the regions in $\mathscr{K}_E$ played an important role. We are inclined to believe that these results cannot be generalized, without additional conditions on the net $\mathscr{N}_e^{\cdot}$, beyond the basic assumptions in this paper. Let $K_1, K_2 \in \mathscr{K}_B$. The relation

$$\mathscr{B}_e(K_1) \cap \mathscr{B}_e(K_2) = \mathscr{B}_e(K_1 \cap K_2) \tag{6.7}$$

is, by duality, equivalent with the relation

$$(\mathscr{A}_e(K_1^c) \cup \mathscr{A}_e(K_2^c))'' = \mathscr{A}_e((K_1 \cap K_2)^c). \tag{6.8}$$

Suppose now that the extended net $\mathscr{N}_e^{\cdot}$ satisfies *all* the Conditions I–IX in Definition 2.1, the *condition of additivity*, as well as the particular *causality condition* that

$$\{\mathscr{B}_e(K) | K \in \mathscr{K}_B,\ K \subset S\}'' = \{\mathscr{B}_e(K) | K \in \mathscr{K}_B,\ K \subset \mathscr{E}(S)\}'', \tag{6.9}$$

for any open set S. For certain sets $K_1, K_2 \in \mathscr{K}_B$ it is the case that $(K_1 \cap K_2)^c = (K_1^c \cup K_2^c)^{cc} = \mathscr{E}(K_1^c \cup K_2^c)$, and if this is the case, then the relations in (6.8) and (6.7) follow from (6.9), i.e., the intersection property holds for the pair K_1, K_2. However, the intersection property in (6.7) *cannot* hold generally, for two *arbitrary* $K_1, K_2 \in \mathscr{K}_B$. For a counterexample within the theory of a free Hermitian scalar field $\varphi(x)$ associated with a massive particle, we refer to Example 5.13 in TW-II.[7] In the quoted paper the objects of interest are the *weak commutants* $\mathscr{C}(K)$ of the field operators in K^c, rather than the local von Neumann algebras, but for a free scalar field we do have $\mathscr{B}_e(K) = \mathscr{C}(K)$, as we noted earlier. The counterexample involves two particular causally complete open sets S_1 and S_2 such that $K_1 = S_1^c \in \mathscr{K}_B$, and $K_2 = S_2^c \in \mathscr{K}_B$, and such that $\mathscr{E}(S_1 \cup S_2) \neq (S_1 \cup S_2)^{cc}$. The condition in (6.9) holds for a free-field theory, but the relation in (6.7) fails to hold. This involves no contradiction to what was said above, since we have $(K_1^c \cup K_2^c)^{cc} \neq \mathscr{E}(K_1^c \cup K_2^c)$ in the counterexample.

Within the theory of a free scalar field associated with a *massless* particle one can also easily construct examples of two *disjoint* sets $K_1, K_2 \in \mathscr{K}_B$, such that $\mathscr{B}_e(K_1)$ and $\mathscr{B}_e(K_2)$ have elements in common which are not multiples of the identity. The sets K_1 and K_2 can then not be spacelike separated.

We will not pursue these issues further, since the condition in (6.9) is outside the scope of our paper.

Hyperfinite-dimensional representations of canonical commutation relation

Hideyasu Yamashita
Graduate School of Human Informatics, Nagoya University, Nagoya 464-01, Japan

(Received 11 June 1997; accepted for publication 28 October 1997)

This paper presents some methods of representing canonical commutation relations in terms of hyperfinite-dimensional matrices, which are constructed by nonstandard analysis. The first method uses representations of a nonstandard extension of the finite Heisenberg group, called hyperfinite Heisenberg group. The second is based on hyperfinite-dimensional representations of $so(3)$. Then, the cases of infinite degree of freedom are argued in terms of the algebra of hyperfinite para-Fermi oscillators, which is mathematically equivalent to a hyperfinite-dimensional representation of $so(n)$. © *1998 American Institute of Physics.*

I. INTRODUCTION

In the field of mathematical foundations of quantum physics, especially of infinite degrees of freedom, it is often argued that we need any extensions of separable Hilbert space as the fundamental mathematical tools, such as the linear space of generalized functions.

In recent years, another alternative, the *nonstandard-analytical extension* method, is developed by some authors.[1–4] The present paper adopts an approach in use of hyperfinite-dimensional linear spaces, constructed by nonstandard analysis[5,6] (see the Appendix to find the basic definitions).

This approach also is closely related with that of *finite-dimensional quantum physics*;[7–10] nonstandard extensions of finite-dimensional models in quantum physics turn out to be the powerful tools for the approach.

The purpose of the present paper is to represent the canonical commutation relation (CCR) $[Q,P]=i$ (let us take the natural unit $\hbar=1$), or equivalently, $[a,a^{\dagger}]=1$, where $a=(Q+iP)/\sqrt{2}$, in a hyperfinite-dimensional linear space. Let ν be an infinite hypernatural number, and Q and P internal $\nu\times\nu$ Hermitian matrices. Q and P act on the ν-dimensional internal linear space ${}^{\star}\mathbf{C}^{\nu}$ as internal linear operators. No standard finite-dimensional matrices satisfy the CCR. By the transfer principle in nonstandard analysis, the fact also holds for any internal hyperfinite-dimensional matrices, so we have $[Q,P]\neq i$. Thus we must arrange the standard CCR for hyperfinite-dimensional matrices. First we consider the following weaker version of CCR: $[Q,P]\approx i$, that is, $\|[Q,P]-i\|_{\infty}\approx 0$, where $\|A\|_{\infty}$ is given by

$$\|A\|_{\infty}=\sup\{\|A\xi\|:\|\xi\|\leqslant 1,\xi\in{}^{\star}\mathbf{C}^{\nu}\}.$$

This is equivalent to the condition that for any $\xi\in{}^{\star}\mathbf{C}^{\nu}$ with finite norm, $[Q,P]\xi\approx i\xi$ (i.e., $\|([Q,P]-i)\xi\|\approx 0$, where $\|\cdot\|$ is the norm on ${}^{\star}\mathbf{C}^{\nu}$ defined by $\|(\xi_1,\ldots,\xi_{\nu})\|=\sqrt{|\xi_1|^2+\cdots+|\xi_{\nu}|^2}$. We see that the condition never holds as follows. Suppose the condition holds. Then any eigenvalue λ of $[Q,P]$ satisfies $\lambda\approx i$. This contradicts $\mathrm{Tr}([Q,P])=0$. Now, let us define the still weaker notion of representation of the CCR by limiting the domain of the operators Q and P.

Definition 1.1: Let Q_k, P_k be $\nu\times\nu$ internal Hermitian matrices ($k=1,2,\ldots<\infty$), and S be an external subspace of ${}^{\star}\mathbf{C}^{\nu}$ which consists only of the vectors with finite norm. The set of the triples (Q_k,P_k,S) (or of pairs (a_k,S) where $a_k=(Q_k+iP_k)/\sqrt{2}$) is called a *quasirepresentation of the CCR* if

$$[Q_k,P_l]\xi\approx i\delta_{kl}\xi,\quad [Q_k,Q_l]\xi\approx[P_k,P_l]\xi\approx 0$$

 © 1998 American Institute of Physics

for any $\xi \in S$ and $k,l=1,2,...<\infty$. A quasirepresentation of the CCR (Q_k,P_k,S) is called a *representation of CCR* if S is invariant respect to Q_k, P_k (i.e., $Q_kS,P_kS\subseteq S$).

Hereafter, we will use the following notations:

(1) $\star$ is the mapping of nonstandard extension.
(2) $\mathbf{N}(^\star\mathbf{N})$ is the set of natural (hypernatural) numbers.
(3) $\mathbf{Z}(^\star\mathbf{Z})$ is the set of integers (hyperintegers).
(4) $\mathbf{R}(^\star\mathbf{R})$ is the set of real (hyperreal) numbers.
(5) $\mathbf{C}(^\star\mathbf{C})$ is the set of complex (hypercomplex) numbers.

II. $so(3)$-REPRESENTATION OF THE CCR

Let J_1, J_2, and J_3 be an irreducible set of $(p+1)\times(p+1)$ Hermitian matrices which satisfy

$$[J_k,J_l]=i\epsilon_{klm}J_m,$$

where ϵ_{klm} is the Levi-Civita symbol. iJ_1,iJ_2, and iJ_3 generate a $p+1$ dimensional irreducible representation of Lie algebra $so(3)$. It is known that J_k has eigenvalues

$$\frac{p}{2},\quad \frac{p}{2}-1,...,\quad 1-\frac{p}{2},\quad -\frac{p}{2}$$

and corresponding eigenvectors are given by

$$\left|J_3;\frac{p}{2}\right\rangle,\quad J_-\left|J_3;\frac{p}{2}\right\rangle,...,\quad J_-^p\left|J_3;\frac{p}{2}\right\rangle,$$

where $|J_3;(p/2)\rangle$ is a normalized eigenvector with eigenvalue $p/2$ and $J_-=J_1-iJ_2$. Let $j=p/2$ and $|J_3;m\rangle=J_-^{j-m}|J_3;j\rangle/\|J_-^{j-m}|J_3;j\rangle\|$. It is shown that

$$\langle J_3;m'|J_-|J_3;m\rangle=\delta_{m',m-1}\sqrt{(j+m)(j-m+1)}.$$

We consider the nonstandard version of this representation; let p be an infinite hypernatural number, and J_k be the internal matrices satisfying the above commutation relations. Define Q and P by $Q=J_1/\sqrt{j}$, $P=J_2/\sqrt{j}$.

Theorem 2.1: Let $S\subset{}^\star\mathbf{C}^\nu$ be the subspace finitely spanned by $|J_3;j-k\rangle$, $(k=0,1,...<\infty)$, i.e.,

$$S=\left\{\sum_{k=0}^{n}c_k|J_3;j-k\rangle:\quad c_k\in{}^\star\mathbf{C},|c_k|<\infty,n\in\mathbf{N}\right\}.$$

S is an invariant subspace of P and Q, and

$$[Q,P]|\xi\rangle\approx i|\xi\rangle$$

for each $|\xi\rangle\in S$, and hence (Q,P,S) is a representation of the CCR.

Proof: The invariance of S is seen from

$$\begin{aligned}Q|J_3;j-k\rangle&=\frac{1}{\sqrt{j}}\frac{1}{2}(J_-+J_-^\dagger)|J_3;j-k\rangle\\&=\frac{1}{2}\sqrt{(2-k/j)(k+1)}|J_3;j-k-1\rangle+\frac{1}{2}\sqrt{k(2-k/j+1/j)}|J_3;j-k+1\rangle\in S,\end{aligned}$$

$$\begin{aligned}P|J_3;j-k\rangle&=\frac{1}{\sqrt{j}}\frac{i}{2}(J_-^\dagger-J_-)|J_3;j-k\rangle\\&=\frac{i}{2}\sqrt{(2-k/j)(k+1)}|J_3;j-k-1\rangle-\frac{i}{2}\sqrt{k(2-k/j+1/j)}|J_3;j-k+1\rangle\in S.\end{aligned}$$

And we have $[Q,P]|J_3;j-k\rangle=(i/j)J_3|J_3;j-k\rangle=i(1-k/j)|J_3;j-k\rangle\approx i|J_3;j-k\rangle$. Q.E.D.

We find the rotation covariance of these operators,

$$Q\ \cos\ \theta+P\ \sin\ \theta=e^{i\theta J_3}Qe^{-i\theta J_3}.$$

Moreover, it turns out that this representation is convenient in dealing with coherent states. Let $R(\theta,\phi)$ denote the rotation matrix

$$R(\theta,\phi)=e^{i\theta(J_1\ \sin\ \phi-J_2\ \cos\ \phi)}.$$

$R(\theta,\phi)$ has also the expression[11]

$$R(\theta,\phi)=e^{\mu J_-}e^{-\log(1+|\mu|^2)J_3}e^{-\mu^* J_-^\dagger},$$

where $\mu=e^{i\phi}\tan(\theta/2)$. Define $|\theta,\phi\rangle$ by $|\theta,\phi\rangle=R(\theta,\phi)|J_3;j\rangle$. It is shown that

$$|\theta,\phi\rangle=\frac{1}{(1+|\mu|^2)^j}\sum_{k=0}^{2j}\binom{2j}{k}^{1/2}\mu^k|J_3;j-k\rangle.$$

If $|\mu|\sqrt{j}<\infty$ and $k<\infty$,

$$\frac{1}{(1+|\mu|^2)^j}\approx e^{-j|\mu|^2},\quad \binom{2j}{k}^{1/2}\mu^k\approx\frac{(\sqrt{2j}\mu)^k}{\sqrt{k!}}.$$

Thus we find

$$\langle J_3;j-k|\theta,\phi\rangle\approx e^{-|z|^2/2}\frac{z^k}{k!},$$

where $z=\mu\sqrt{2j}$. Corresponding standard coherent state $|z\rangle$ satisfies

$$\langle k|z\rangle=e^{-|z|^2/2}\frac{z^k}{k!},$$

where $|k\rangle=a^{\dagger k}|0\rangle/\|a^{\dagger k}|0\rangle\|$, $a^\dagger$ being the standard bose creation operator and $|0\rangle$ the vacuum state.

III. REPRESENTATIONS OF $so(n)$

The hyperfinite-dimensional representation of the CCR which has more general rotation covariance is constructed by hyperfinite-dimensional representation of $so(n)$. This section reviews the method of *spin representation* in use of Clifford algebra. Let $C(\mathbf{R}_-^n)$ be the $\mathbf{R}$-vector space the base of which is the 2^n elements

$$1,\ e_1,\ldots,e_n,\quad e_1e_2,\ldots,e_ie_j(i<j),\ldots,e_{n-1}e_n,\ldots,$$

$$e_{i_1}\ldots,e_{i_k}(i_1<\cdots<i_k),\ldots,e_1\ldots e_n.$$

Define the product of these elements by

$$(e_{i_1}\cdots e_{i_k})(e_{j_1}\cdots e_{j_l})=e_{i_1}\cdots e_{i_k}e_{j_1}\cdots e_{j_l}$$

and require the relation

$$e_i^2=-1,\ (i=1,\ldots,n),\ e_ie_j=-e_je_i(i\neq j),\ (\lambda 1)e_i=e_i(\lambda 1)\quad(\lambda\in\mathbf{R}).$$

Assume that 1 is the unit of the product, and that the product is associative. Now, $C(\mathbf{R}_-^n)$ is the 2^n-dimensional $\mathbf{R}$-algebra. $C(\mathbf{R}_-^n)$ is called *Clifford algebra.*

Let us identify $(\lambda_1,\ldots,\lambda_n)\in\mathbf{R}^n$ with $\Sigma_{k=1}^n\lambda_k e_k$. Then we have $S^{n-1}\subset\mathbf{R}^n\subset C(\mathbf{R}^n_-)$ (S^{n-1} is the unit sphere in $\mathbf{R}^n$). The following fact is shown.

Theorem 3.1: $Spin(n)$ defined by

$$Spin(n)=\{\alpha\in C(\mathbf{R}^n_-)\,|\,\alpha=a_1\ldots a_m, a_i\in S^{n-1}, m=2,4,\ldots\}$$

is a topological group, and isomorphic to the covering group of $so(n)$. $e_{ij}=e_ie_j$ $(i,j=1,\ldots,n)$ is a base (of a representation) of $so(n)$.

If $n=2\nu+1$, $e_1,\ldots,e_n$ is represented by $2^\nu\times 2^\nu$ matrices as follows. Let $V_k\simeq\mathbf{C}^2$ $(k=1,\ldots,\nu)$. Pauli matrices $\sigma_{1,k}$, $\sigma_{2,k}$, $\sigma_{3,k}$ that act on V_k are represented as

$$\sigma_{1,k}=\begin{pmatrix}0&1\\1&0\end{pmatrix},\quad \sigma_{2,k}=\begin{pmatrix}0&-i\\i&0\end{pmatrix},\quad \sigma_{3,k}=\begin{pmatrix}1&0\\0&-1\end{pmatrix}.$$

Define V by

$$V=V_1\otimes\cdots\otimes V_\nu,$$

and define $\hat\sigma_{c,k}$ and γ_i that acts on V by

$$\hat\sigma_{c,k}=\overbrace{1\otimes\cdots\otimes 1}^{k-1}\otimes\sigma_{c,k}\otimes 1\otimes\cdots\otimes 1,\quad c=1,2,3,$$

$$\gamma_{2k-1}=\hat\sigma_{2,k}\hat\sigma_{3,k+1}\cdots\hat\sigma_{3,\nu},$$

$$\gamma_{2k}=-\hat\sigma_{1,k}\hat\sigma_{3,k+1}\cdots\hat\sigma_{3,\nu},$$

$$\gamma_{2\nu+1}=\hat\sigma_{3,1}\hat\sigma_{3,2}\cdots\hat\sigma_{3,\nu}.$$

Direct calculations show the following relations:

$$\{\gamma_i,\gamma_j\}=2\delta_{ij},\quad i,j=1,\ldots,2\nu.$$

Thus, we can take $e_j=i\gamma_j$ (this is called the *spin representation*). Moreover we have the tensor product representation of $so(n)$ from one constructed above,

$$\tilde e_{ij}=\sum_{l=0}^{p-1}\overbrace{1\otimes\cdots\otimes 1}^{l}\otimes e_{ij}\otimes\overbrace{1\otimes\cdots\otimes 1}^{p-l-1}$$

also generate a representation of $so(n)$.

In the next section, we introduce a hyperfinite representation of $so(n)$, using these mathematical tools.

IV. HYPERFINITE PARA-FERMI REPRESENTATION

In this section, we construct a hyperfinite-dimensional representation of the algebra of standard infinite bose oscillators, that is, the algebra generated by bose annihilation operators $a_1,a_2,\ldots$ satisfying $[a_j,a_k^\dagger]=\delta_{jk}$ and $[a_j,a_k]=0$, with the condition that the nonzero vector $|0\rangle$ that satisfies $a_k|0\rangle=0$ is unique except the scalar multiples (*the uniqueness of vacuum*). This representation is constructed by using hyperfinite internal representations of the algebra of para-Fermi oscillators, which is mathematically equivalent to the hyperfinite-dimensional spin representation of $so(n)$.

Definition 4.1:[12,13] Let $\nu\in\mathbf{N}$, and suppose that for some $d\in\mathbf{N}$, $b_1,\ldots,b_\nu\in M(d,\mathbf{C})$ (i.e., $b_1,\ldots,b_\nu$ are finite-dimensional matrices). $b_1,\ldots,b_\nu$ is called *annihilation operators* of para-Fermi oscillators of order $p\in\mathbf{N}$ if they satisfy

$$[b_k,[b_l^\dagger,b_m]]=2\delta_{kl}b_m,$$

$$[b_k,[b_l^\dagger,b_m^\dagger]]=2\delta_{kl}b_m^\dagger-2\delta_{km}b_l^\dagger,$$

$$[b_k,[b_l,b_m]]=0,$$

and the uniqueness of vacuum $|0\rangle$, and,

$$b_kb_l^\dagger|0\rangle=\delta_{kl}p|0\rangle.$$

$b_1^\dagger,\ldots,b_\nu^\dagger$ are called *creation operators* of para-Fermi oscillators of order p. *Hyperfinite annihilation operators* of para-Fermi oscillators are the internal matrices defined in the above definition by substituting ${}^\star\mathbf{N}$ and ${}^\star\mathbf{C}$ for $\mathbf{N}$ and $\mathbf{C}$, respectively.

Green[12] has given a class of representations of the above commutation relations of para-Fermi creation and annihilation operators. In the so-called *Green representation* for the cases of order p, the para-Fermi operators b_k are expressed by the form

$$b_k=\sum_{\alpha=1}^{p} b_k^{(\alpha)},$$

where the *Green-component* operators $b_k^{(\alpha)}$ satisfy the commutation relations

$$\{b_k^{(\alpha)},b_l^{(\alpha)^\dagger}\}=\delta_{kl},\quad \{b_k^{(\alpha)},b_l^{(\alpha)}\}=0,$$

$$[b_k^{(\alpha)},b_l^{(\beta)^\dagger}]=[b_k^{(\alpha)},b_l^{(\beta)}]=0,\quad (\alpha\neq\beta),$$

where $\{A,B\}=AB+BA$, and the uniqueness of vacuum $|0\rangle$ such that

$$b_k^{(\alpha)}|0\rangle=0 \text{ for all } k,\alpha.$$

Green representation is essentially equivalent to the tensor product representation of Clifford algebra representation of $so(2\nu)$. In fact, we easily verify that $e_1,\ldots,e_{2\nu}$ defined by $e_{2k-1}=i(b_k^\dagger+b_k)$, $e_{2k}=b_k^\dagger-b_k$ form the generator of a Clifford algebra (i.e., $e_i^2=-1$ and $e_ie_j=-e_je_i$ $(i\neq j)$ hold). Thus, we can construct a $2^{p\nu}$-dimensional representation of Green components by using a spin representation of the Clifford algebra as follows. Let $V_k^{(\alpha)}\simeq\mathbf{C}^2$ $(k=1,\ldots,\nu,$ $\alpha=1,\ldots,p)$. Pauli matrices $\sigma_{1,k}^{(\alpha)}$, $\sigma_{2,k}^{(\alpha)}$, and $\sigma_{3,k}^{(\alpha)}$ that act on $V_k^{(\alpha)}$ are represented as

$$\sigma_{1,k}^{(\alpha)}=\begin{pmatrix}0&1\\1&0\end{pmatrix},\ \sigma_{2,k}^{(\alpha)}=\begin{pmatrix}0&-i\\i&0\end{pmatrix},\ \sigma_{3,k}^{(\alpha)}=\begin{pmatrix}1&0\\0&-1\end{pmatrix}.$$

Define $V^{(\alpha)}$ by

$$V^{(\alpha)}=V_1^{(\alpha)}\otimes\cdots\otimes V_\nu^{(\alpha)},$$

and define $\hat\sigma_{c,k}^{(\alpha)}$ and $\gamma_i^{(\alpha)}$ $(k=1,\ldots,\nu,\ i=1,\ldots,2\nu)$ that acts on $V^{(\alpha)}$ by

$$\hat\sigma_{c,k}^{(\alpha)}=\overbrace{1\otimes\cdots\otimes 1}^{k-1}\otimes\sigma_{c,k}^{(\alpha)}\otimes 1\otimes\cdots\otimes 1,\quad c=1,2,3,$$

$$\gamma_{2k-1}^{(\alpha)}=\hat\sigma_{2,k}^{(\alpha)}\hat\sigma_{3,k+1}^{(\alpha)}\cdots\hat\sigma_{3,\nu}^{(\alpha)},$$

$$\gamma_{2k}^{(\alpha)}=-\hat\sigma_{1,k}^{(\alpha)}\hat\sigma_{3,k+1}^{(\alpha)}\cdots\hat\sigma_{3,\nu}^{(\alpha)}.$$

Operators $b_k^{(\alpha)}$ $(k=1,\ldots,\nu)$ defined by

$$b_k^{(\alpha)}=\tfrac{1}{2}(\gamma_{2k-1}^{(\alpha)}-i\gamma_{2k}^{(\alpha)}),$$

satisfy the relations

$$\{b_k^{(\alpha)}, b_l^{(\alpha)\dagger}\} = \delta_{kl}, \quad \{b_k^{(\alpha)}, b_l^{(\alpha)}\} = 0,$$

for all $k,\ l = 1,...,\nu$.

Define V and $\tilde{b}_k^{(\alpha)}$ $(k = 1,...,\nu)$ acting on V by

$$V = V^{(1)} \otimes \cdots \otimes V^{(p)},$$

$$\tilde{b}_k^{(\alpha)} = \overbrace{1 \otimes \cdots \otimes 1}^{\alpha-1} \otimes b_k^{(\alpha)} \otimes 1 \otimes \cdots \otimes 1.$$

We see that for all $k,\ l = 1,...,\nu$,

$$\{\tilde{b}_k^{(\alpha)}, \tilde{b}_l^{(\alpha)\dagger}\} = \delta_{kl}, \quad \{\tilde{b}_k^{(\alpha)}, \tilde{b}_l^{(\alpha)}\} = 0,$$

$$[\tilde{b}_k^{(\alpha)}, \tilde{b}_l^{(\beta)\dagger}] = [\tilde{b}_k^{(\alpha)}, \tilde{b}_l^{(\beta)}] = 0, \quad (\alpha \neq \beta).$$

Let $|0\rangle_k^{(\alpha)} \in V_k^{(\alpha)}$ denote the normalized vector such that $b_k^{(\alpha)}|0\rangle_k^{(\alpha)} = 0$. Define $|0\rangle^{(\alpha)}$ and $|0\rangle$ by

$$|0\rangle^{(\alpha)} = |0\rangle_1^{(\alpha)} \otimes \cdots \otimes |0\rangle_\nu^{(\alpha)},$$

$$|0\rangle = |0\rangle^{(\alpha)} \otimes \cdots \otimes |0\rangle^{(p)}.$$

Now, we find that $\tilde{b}_1^{(\alpha)}, \ldots, \tilde{b}_\nu^{(\alpha)}$ are $2^{p\nu}$-dimensional representations of Green components and $|0\rangle$ is the vacuum. Thus, $b_k = \Sigma_{\alpha=1}^p \tilde{b}_k^{(\alpha)}$, $(k = 1,...,\nu)$ are $2^{p\nu}$-dimensional representations of annihilation operators of ν para-Fermi oscillators of order p. Let us call the above representation of the algebra of para-Fermi oscillators *spin representation*.

Define $\sigma_{\pm,k}^{(\alpha)}$ by

$$\sigma_{\pm,k}^{(\alpha)} = (\sigma_{1,k}^{(\alpha)} \pm i\sigma_{2,k}^{(\sigma)})/2$$

and $|1\rangle_k^{(\alpha)} \in V_k^{(\alpha)}$ by

$$|1\rangle_k^{(\alpha)} = \sigma_{+,k}^{(\alpha)}|0\rangle_k^{(\alpha)},$$

$$\{(|e_1^{(1)}\rangle_1^{(1)} \cdots |e_\nu^{(1)}\rangle_\nu^{(1)}) \cdots (|e_1^{(p)}\rangle_1^{(p)} \cdots |e_\nu^{(p)}\rangle_\nu^{(p)}) : e_k^{(\alpha)} = 0,1\}$$

($\otimes$'s are omitted) is a complete orthonormal system of V. We write the vectors simply as $|\{e_k^{(\alpha)}\}\rangle$.

Number operator N on V and the related operators N_k, $N^{(\alpha)}$ are defined as follows:

$$N_k^{(\alpha)} = \frac{1}{2}(1 + \sigma_{3,k}^{(\alpha)}) = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix},$$

$$\hat{N}_k^{(\alpha)} = \overbrace{1 \otimes \cdots \otimes 1}^{k-1} \otimes N_k^{(\alpha)} \otimes \overbrace{1 \otimes \cdots \otimes 1}^{\nu-k},$$

$$\tilde{N}_k^{(\alpha)} = \overbrace{1 \otimes \cdots \otimes 1}^{\alpha-1} \otimes \hat{N}_k^{(\alpha)} \otimes \overbrace{1 \otimes \cdots \otimes 1}^{p-\alpha},$$

$$N_k = \sum_{\alpha=1}^{p} \tilde{N}_k^{(\alpha)}, \quad N^{(\alpha)} = \sum_{k=1}^{\nu} \tilde{N}_k^{(\alpha)}, \quad N = \sum_{\alpha=1}^{p} N^{(\alpha)}.$$

We see that

$$N|\{e_k^{(\alpha)}\}\rangle = n|\{e_k^{(\alpha)}\}\rangle,$$

where n is the number of $e_k^{(\alpha)}$'s that is equal to 1. It is easily shown that

$$\tilde{b}_k^{(\alpha)\dagger}\tilde{b}_k^{(\alpha)} = \tilde{N}_k^{(\alpha)}, \quad \tilde{b}_k^{(\alpha)}\tilde{b}_k^{(\alpha)\dagger} = 1 - \tilde{N}_k^{(\alpha)}, \quad N_k = \tfrac{1}{2}([b_k^\dagger, b_k] + p),$$

$$[N_k, N_l] = 0, \quad N_k b_k = b_k(N_k - 1), \quad N_k b_k^\dagger = b_k^\dagger(N_k + 1), \quad \text{etc.}$$

Lemma 4.1: Suppose that hyperfinite para-Fermi annihilation operators $b_1, \ldots, b_\nu$ are represented by spin representation, and that their order p is an infinite hypernatural number ($b_1, \ldots, b_\nu$ are $2^{p\nu} \times 2^{p\nu}$ internal matrices acting on ${}^\star\mathbf{C}^{2^{p\nu}}$). If $|\xi\rangle \in {}^\star\mathbf{C}^{2^{p\nu}}$ satisfies $\langle\xi|\xi\rangle$, $\langle\xi|N^2|\xi\rangle < \infty$, and $k \neq l$ $(k, l = 1, 2, \ldots, \nu)$, then

(i) $[\beta_k, \beta_l]|\xi\rangle \approx [\beta_k, \beta_l^\dagger]|\xi\rangle \approx 0.$
(ii) $[\beta_k, \beta_k^\dagger]|\xi\rangle \approx |\xi\rangle.$
(iii) $\beta_k \beta_k^{\dagger n}|\xi\rangle \approx (\beta_k^{\dagger n}\beta_k + n\beta_k^{\dagger n-1})|\xi\rangle,$

where $\beta_k = p^{-1/2} b_k$ (*normalization of* b_k) and $n < \infty$.

Proof:

(i) Notice that

$$[\beta_k, \beta_l] = \frac{2}{p}\sum_{\alpha=1}^{p} \tilde{b}_k^{(\alpha)}\tilde{b}_l^{(\alpha)}, \quad [\beta_k, \beta_l^\dagger] = \frac{2}{p}\sum_{\alpha=1}^{p} \tilde{b}_k^{(\alpha)}\tilde{b}_l^{(\alpha)\dagger}.$$

Direct calculations show that

$$b_k^{(\alpha)} b_l^{(\alpha)} = \begin{cases} -\hat{\sigma}_{3,k+1}^{(\alpha)} \cdots \hat{\sigma}_{3,l}^{(\alpha)} \hat{\sigma}_{-,k}^{(\alpha)} \hat{\sigma}_{-,l}^{(\alpha)} & (l > k) \\ -\hat{\sigma}_{3,l+1}^{(\alpha)} \cdots \hat{\sigma}_{3,k}^{(\alpha)} \hat{\sigma}_{-,k}^{(\alpha)} \hat{\sigma}_{-,l}^{(\alpha)} & (k > l) \end{cases},$$

$$b_k^{(\alpha)} b_l^{(\alpha)^\dagger} = \begin{cases} \hat{\sigma}_{3,k+1}^{(\alpha)} \cdots \hat{\sigma}_{3,l}^{(\alpha)} \hat{\sigma}_{+,k}^{(\alpha)} \hat{\sigma}_{-,l}^{(\alpha)} & (l > k) \\ \hat{\sigma}_{3,l+1}^{(\alpha)} \cdots \hat{\sigma}_{3,k}^{(\alpha)} \hat{\sigma}_{+,k}^{(\alpha)} \hat{\sigma}_{-,l}^{(\alpha)} & (k > l) \end{cases}.$$

Hence, using $N_k^{(\alpha)} + N_l^{(\alpha)} - 2N_k^{(\alpha)} N_l^{(\alpha)} = (N_k^{(\alpha)} - N_l^{(\alpha)})^2 \geqslant 0$,

$$\|\tilde{b}_k^{(\alpha)}\tilde{b}_l^{(\alpha)}|\xi\rangle\|^2 = \langle\xi|\tilde{\sigma}_{+,k}^{(\alpha)}\hat{\sigma}_{+,l}^{(\alpha)}\tilde{\sigma}_{-,l}^{(\alpha)}\tilde{\sigma}_{-,k}^{(\alpha)}|\xi\rangle = \langle\xi|\tilde{N}_k^{(\alpha)}\tilde{N}_l^{(\alpha)}|\xi\rangle \leqslant \frac{1}{2}\langle\xi|\tilde{N}_k^{(\alpha)} + \tilde{N}_l^{(\alpha)}|\xi\rangle \leqslant \frac{1}{2}\langle\xi|\tilde{N}^{(\alpha)}|\xi\rangle.$$

Thus,

$$\|[\beta_k, \beta_l]|\xi\rangle\| = \left\| \frac{2}{p}\sum_{\alpha=1}^{p} \tilde{b}_k^{(\alpha)}\tilde{b}_l^{(\alpha)}|\xi\rangle \right\| \leqslant \frac{2}{p}\sum_{\alpha=1}^{p} \|\tilde{b}_k^{(\alpha)}\tilde{b}_l^{(\alpha)}|\xi\rangle\| \leqslant \frac{2}{p}\sum_{\alpha=1}^{p} \sqrt{\frac{1}{2}\langle\xi|\tilde{N}^{(\alpha)}|\xi\rangle} \approx 0.$$

The last equation is seen from $\Sigma_{\alpha=1}^{p}\langle\xi|N^{(\alpha)}|\xi\rangle = \langle\xi|N|\xi\rangle < \infty$; under this condition we find that the number of α's such that $\langle\xi|N^{(\alpha)}|\xi\rangle \not\approx 0$ is finite.

In a similar way, it is shown that

$$\|[\beta_k, \beta_l^\dagger]|\xi\rangle\| \leqslant \frac{2}{p}\sum_{\alpha=1}^{p} \|\tilde{b}_k^{(\alpha)}\tilde{b}_l^{(\alpha)\dagger}|\xi\rangle\| \leqslant \frac{2}{p}\sum_{\alpha=1}^{p} \sqrt{\langle\xi|\tilde{N}_l^{(\alpha)}(1 - \tilde{N}_k^{(\alpha)})|\xi\rangle} \leqslant \frac{2}{p}\sum_{\alpha=1}^{p} \sqrt{\langle\xi|\tilde{N}_l^{(\alpha)}|\xi\rangle} \approx 0.$$

(ii) A direct calculation shows that

$$[\beta_k, \beta_k^\dagger] = -\frac{1}{p}\sum_{\alpha=1}^{p} \tilde{\sigma}_{3,k}^{(\alpha)},$$

$$([\beta_k, \beta_k^\dagger] - 1)^2 = \frac{4}{p^2}\left(\sum_{\alpha=1}^{p} N_k^{(\alpha)}\right)^2.$$

Hence,

$$\|[\beta_k, \beta_k^\dagger]|\xi\rangle - |\xi\rangle\|^2 = \frac{4}{p^2}\langle\xi|\left(\sum_{\alpha=1}^{p} N_k^{(\alpha)}\right)|\xi\rangle.$$

$$\leqslant \frac{4}{p^2}\langle\xi|N^2|\xi\rangle \approx 0.$$

(iii) is shown by the induction for n, using (ii). Q.E.D.

Suppose the number of para-Fermi oscillators ν and their order p are infinite hypernatural numbers. When n_i is a non-negative integer for any $i=1,2,...<\infty$, and the number of n_i's such that $n_i \neq 0$ is finite, we will define $|n_1,n_2,\ldots\rangle$ by

$$|n_1,n_2,\ldots\rangle = \frac{b_1^{\dagger n_1} b_2^{\dagger n_2} \ldots |0\rangle}{\| b_1^{\dagger n_1} b_2^{\dagger n_2} \ldots |0\rangle \|}.$$

$b_1^{\dagger n_1} b_2^{\dagger n_2} \ldots$ is the product of a finite number of operators, so it is well-defined. $N_k|n_1,n_2,\ldots\rangle = n_k|n_1,n_2,\ldots\rangle$ is easily shown, and hence, since N_k is Hermitian, the set of the vectors of the form $|n_1,n_2,\ldots\rangle$ is an orthonormal system.

Lemma 4.2:

(i) $\beta_k^\dagger \beta_k |n_1,n_2,\ldots\rangle \approx n_k |n_1,n_2,\ldots\rangle$,
(ii) $\beta_k \beta_k^\dagger |n_1,n_2,\ldots\rangle \approx (n_k+1)|n_1,n_2\ldots\rangle$,
(iii) $\| \beta_1^{\dagger n_1} \beta_2^{\dagger n_2} \ldots |0\rangle \| \approx \sqrt{n_1! n_2! \cdots}$,
(iv) $\beta_k^\dagger |n_1,n_2,\ldots\rangle \approx \sqrt{n_k+1}\,|n_1,n_2,\ldots n_k+1,\ldots\rangle$,
(v) $\beta_k |n_1,n_2,\ldots\rangle \approx \sqrt{n_k}\,|n_1,n_2,\ldots,n_k-1,\ldots\rangle$.

Proof: (i) and (ii) are shown by Lemma 4.1 (i)–(iii). (iii) is shown by the induction for $n_1,n_2,\ldots$, using (ii) and Lemma 4.1 (i). (iv) and (v) are shown by (iii) and Lemma 4.1 (i) (iii). Q.E.D.

Define a set $D \subset {}^\star\mathbf{C}^{2^{p\nu}}$ by

$$D = \left\{ \left. \frac{\beta_{k_1}^\dagger \cdots \beta_{k_n}^\dagger |0\rangle}{\| \beta_{k_1}^\dagger \cdots \beta_{k_n}^\dagger |0\rangle \|} \right| n,k_1,\ldots,k_n \in \mathbf{N} \right\} \cup \{|0\rangle\}.$$

Clearly, every vector in D is a normalized eigenvector of the number operator N with a finite eigenvalue. Let S denote the external subspace of ${}^\star\mathbf{C}^{2^{p\nu}}$ spanned by D, i.e.,

$$S = \left\{ \sum_{i=1}^{n} c_i |\xi\rangle : c_i \in {}^\star\mathbf{C}, |c_i| < \infty, n \in \mathbf{N}, |\xi\rangle \in D \right\}.$$

Theorem 4.3: (β_k, S) $(k \in \mathbf{N})$ is a representation of the CCR of a countably-infinite degree of freedom, i.e., S is invariant with respect to β_k and $\beta_k^\dagger$ for every $k \in \mathbf{N}$, and

$$[\beta_k, \beta_l]|\xi\rangle \approx 0,$$

$$[\beta_k, \beta_l^\dagger]|\xi\rangle \approx \delta_{kl}|\xi\rangle,$$

for any $|\xi\rangle \in S$. Moreover, the uniqueness of the vacuum is satisfied in the following sense: if $|\xi\rangle \in S$, $\langle\xi|\xi\rangle = 1$, and $\beta_k|\xi\rangle \approx 0$ for all $k \in \mathbf{N}$, then $|\langle\xi|0\rangle| \approx 1$.

APPENDIX: NONSTANDARD ANALYSIS

This section briefly outlines the basic notions of nonstandard analysis along Hurd and Loeb,[6] and reviews some development in the field of hyperfinite-, dimensional linear space theory. Let X be a set and $\mathscr{P}(X)$ the power set of X, that is, the set of all subsets of X. The *superstructure over* X, denoted by $V(X)$, is defined by the following recursion:

$$V_0(X) = X, V_{n+1}(X) = V_n(X) \cup \mathscr{P}(V_n(X)),$$

$$V(X) = \bigcup_{n \in \mathbf{N}} V_n(X).$$

Let us regard any element of X as a nonset here; hence $x \in V(X)$ is a set iff $x \in V(X)\backslash X$. Let $\mathbf{C}$ be the set of complex numbers. $V(\mathbf{C})$ contains all the structures that we usually use in quantum physics, for instance, separable Hilbert space $\mathscr{H}$.

$V(X)$ is called a *nonstandard extension of* $V(\mathbf{C})$ if there exists a map $\star$: $V(\mathbf{C}) \to V(X)$ satisfying the following conditions:

(1) $\star$ is an injective mapping from $V(\mathbf{C})$ to $V(X)$;
(2) ${}^\star\mathbf{C} = X$;
(3) (Transfer Principle) Let ϕ be a sentence in terms of $V(\mathbf{C})$, and ${}^\star\phi$ the sentence ''transferred'' from ϕ by mapping $\star$. ϕ is true iff ${}^\star\phi$ is true.

The Transfer Principle needs more explanation. Although the exact description of it needs more definitions of some notions in mathematical logic, one can find the intuitive meaning of it without them, in an example. A sentence in terms of $V(\mathbf{C})$ is constructed from the symbols for logical connectives $\neg$, $\wedge$, $\vee$, $\Rightarrow$, $\Leftrightarrow$, quantifiers $\forall$, $\exists$, individual variables $x,y,z,\ldots$, two predicates $=$, $\in$, parentheses $(,)$, and elements of $V(\mathbf{C})$. We will consider an example. Let $\mathbf{R}$ denote the set of real numbers. Define $G_< \in V(\mathbf{C})$ by $G_< = \{(x,y) | x,y \in \mathbf{R}, x<y\}$, where (x,y) is identified as $\{\{x\},y\}$,

$$(\forall x)(\forall y)(x \in \mathbf{R} \wedge y \in \mathbf{R} \wedge (x,y) \in G_< \Rightarrow (\exists z)(z \in \mathbf{R} \wedge (x,z) \in G_< \wedge (z,y) \in G_<))$$

is a sentence in terms of $V(\mathbf{C})$ because $\mathbf{R}$, $G_< \in V(\mathbf{C})$. Let ϕ denote this sentence. ϕ means that $\mathbf{R}$ is dense, and hence ϕ is true. The ''transferred'' sentence ${}^\star\phi$ is as follows:

$$(\forall x)(\forall y)(x \in {}^\star\mathbf{R} \wedge y \in {}^\star\mathbf{R} \wedge (x,y) \in {}^\star G_< \Rightarrow (\exists z)(z \in {}^\star\mathbf{R} \wedge (x,z) \in {}^\star G_< \wedge (z,y) \in {}^\star G_<)).$$

By transfer principle, ${}^\star\phi$ is true (${}^\star\mathbf{R}$ is called $\star$-dense).

$u \in V(X)$ is called *standard* if there is $x \in V(\mathbf{C})$ such that $u = {}^\star x$, and called *internal* if there is $x \in V(\mathbf{C})$ such that $u \in {}^\star x$. ${}^\star V(\mathbf{C})$ is the set of all internal sets. Let A and B be internal sets. Function $f: A \to B$ is called *internal* if the graph of f (i.e., $\{(x,f(x)) | x \in A\}$) is internal. $V(X)$ is called a *countably saturated extension* of $V(\mathbf{C})$ if it satisfies the following condition:

(Saturation Principle) If countable sequence of internal sets $A_j \in V(X)\backslash X$ satisfies

$$\bigcap_{j=1}^{k} A_j \neq \phi (k = 1,2,\ldots),$$

then

$$\bigcap_{j=1}^{\infty} A_j \neq \phi.$$

Let $A \in V(\mathbf{C})\backslash\mathbf{C}$. From the Saturation Principle, we can show that if A is an infinite set, ${}^s A$ defined by

$${}^s A = \{{}^\star a | a \in A\}$$

is a proper subset of ${}^\star A$. Hence ${}^\star A$ is an extended structure of A. ${}^\star A$ is called the *nonstandard extension of* A. By renaming the elements of X, we can assume without loss of generality that $\mathbf{C}$ is a subset of ${}^\star\mathbf{C}$ and ${}^\star x = x$ for each $x \in \mathbf{C}$.

Given any subset $U \subseteq V(\mathbf{C})$, define ${}^\star U$ by

$${}^\star U = \bigcup_{n \in \mathbf{N}} {}^\star(U \cap V_n(\mathbf{C})).$$

Let $F(\mathbf{C}) \subseteq V(\mathbf{C})$ be the set of finite sets, i.e.,

$$F(\mathbf{C}) = \{A \in V(\mathbf{C})\backslash\mathbf{C} | A \text{ is a finite set}\}.$$

An element of ${}^\star F(\mathbf{C})$ is called a *hyperfinite set*. It is shown that if A is a hyperfinite set, then there is an initial segment $J=\{n\in{}^\star\mathbf{N}|n\leqslant j\}$ for some $j\in{}^\star\mathbf{N}$ and a one-to-one, onto internal mapping $f:J\to A$. Thus, we will often write a hyperfinite set A as $A=\{a_1,a_2,\ldots,a_j\}$, where $a_k=f(k)$, $k\in J$.

Any element of ${}^\star\mathbf{C}({}^\star\mathbf{R})$ is called a *hypercomplex (hyper-real)* number. We assume that ${}^\star\mathbf{R}\subseteq{}^\star\mathbf{C}$. ${}^\star\mathbf{C}$ is a proper extension field of $\mathbf{C}$, and ${}^\star\mathbf{R}$ is an ordered extension of $\mathbf{R}$. An element of ${}^\star\mathbf{N}({}^\star\mathbf{Z})$ is called a *hypernatural number (hyperinteger)*. A hypercomplex number x is called *infinite* if $|x|>n$ for any $n\in\mathbf{N}$, *finite*, $|x|<\infty$, if there is some $n\in\mathbf{N}$ such that $|x|<n$, and *infinitesimal* if $|x|<(1/n)$ for any $n\in\mathbf{N}$.

For any $x,y\in{}^\star\mathbf{C}$, we will write $x\approx y$ if $|x-y|$ is infinitesimal. For any finite hypercomplex number x, there is a unique complex number z such that ${}^\star z\approx x$; this z is called the *standard part* of x and denoted by ${}^\circ x$.

Let $\mathscr{A}$ be an internal normed linear space with norm $\|\cdot\|$. The *principal galaxy* $\mathrm{fin}(\mathscr{A})$ and the *principal monad* $\mu(0)$ are defined by

$$\mathrm{fin}(\mathscr{A})=\{x\in\mathscr{A}|\|x\|<\infty\},$$

$$\mu(0)=\{x\in\mathscr{A}|\|x\|\approx 0\}.$$

Both of them are linear spaces over $\mathbf{C}$. The *nonstandard hull of* $\mathscr{A}$ is the quotient linear space $\hat{\mathscr{A}}=\mathrm{fin}(\mathscr{A})/\mu(0)$ equipped with the norm given by

$$\|{}^\circ x\|={}^\circ\|x\|$$

for all $x\in\mathrm{fin}(\mathscr{A})$, where ${}^\circ x=x+\mu(0)$. It is shown by the Saturation Principle that $\hat{\mathscr{A}}$ is a Banach space.[6]

Let ν be an infinite hypernatural number, i.e., $\nu\in{}^\star\mathbf{N}\backslash\mathbf{N}$. Define ${}^\star\mathbf{C}^\nu$ by

$${}^\star\mathbf{C}^\nu=\{f|f:\{1,\ldots,\nu\}\to{}^\star\mathbf{C};\text{internal}\}.$$

${}^\star\mathbf{C}^\nu$ is a ν-dimensional internal inner product space with the natural inner product and the internal norm $\|\cdot\|$ derived by the inner product. Define $\mathbf{M}=M({}^\star\mathbf{C},\nu)$, the set of $\nu\times\nu$ internal matrices over ${}^\star\mathbf{C}$, by

$$\mathbf{M}=\{f|f:\{1,\ldots,\nu\}^2\to{}^\star\mathbf{C};\text{internal}\}.$$

Naturally $\mathbf{M}$ acts on ${}^\star\mathbf{C}^\nu$ as the internal linear operators. Let p_∞ be the operator norm on $\mathbf{M}$, i.e., $p_\infty(A)=\sup\{\|A\xi\||\|\xi\|\leqslant 1,\xi\in{}^\star\mathbf{C}^\nu\}$. Denote by $A^\star$ the adjoint of $A\in\mathbf{M}$. Let τ be the internal normalized trace on $\mathbf{M}$, i.e.,

$$\tau(A)=\frac{1}{\nu}\sum_{i=1}^{\nu}A_{ii}$$

for $A=(A_{ij})\in\mathbf{M}$. Then τ defines an internal inner product $(\cdot|\cdot)$ on $\mathbf{M}$ by $(A|B)=\tau(A^\star B)$, for A, $B\in\mathbf{M}$. Its derived norm called the normalized Hilbert–Schmidt norm is denoted by p_2, i.e., $p_2(A)=\tau(A^\star A)^{1/2}$ for $A\in\mathbf{M}$. Denoted by $(\mathbf{M},p_\infty)$ and $(\mathbf{M},p_2)$ the normed linear spaces are equipped with these respective norms. The principal galaxies $\mathrm{fin}_\infty(\mathbf{M})$ of $(\mathbf{M},p_\infty)$ and $\mathrm{fin}_2(\mathbf{M})$ of $(\mathbf{M},p_2)$ are defined as follows:

$$\mathrm{fin}_\infty(\mathbf{M})=\{A\in\mathbf{M}|p_\infty(A)<\infty\},$$

$$\mathrm{fin}_2(\mathbf{M})=\{A\in\mathbf{M}|p_2(A)<\infty\}.$$

The principal monads $\mu_\infty(0)$ of $(\mathbf{M},p_\infty)$ and $\mu_2(0)$ of $(\mathbf{M},p_2)$ are defined as follows:

$$\mu_\infty(0)=\{A\in\mathbf{M}|p_\infty(A)\approx 0\},$$

$$\mu_2(0)=\{A\in\mathbf{M}|p_2(A)\approx 0\}.$$

The nonstandard hull $\hat{\mathbf{M}}_2 = \mathrm{fin}_2(\mathbf{M})/\mu_2(0)$ turns out to be a Hilbert space with the inner product $\langle \cdot | \cdot \rangle$ and the norm $\| \cdot \|_2$ defined by

$$\langle A + \mu_2(0) | B + \mu_2(0) \rangle = {}^\circ(A|B)$$

and

$$\| A + \mu_2(0) \|_2 = p_2(A)$$

for $A, B \in \mathrm{fin}_2(\mathbf{M})$.

The nonstandard hull $\hat{\mathbf{M}}_\infty = \mathrm{fin}_\infty(\mathbf{M})/\mu_\infty(0)$ of $(\mathbf{M}, p_\infty)$ turns out to be a $C^\star$-algebra equipped with norm $\hat{p}_\infty$ defined by

$$\hat{p}_\infty(A + \mu_\infty(0)) = {}^\circ p_\infty(A)$$

for $A \in \mathrm{fin}_\infty(\mathbf{M})$.

Hinokuma and Ozawa[14] showed that another quotient space $\hat{\mathbf{M}}$ defined by

$$\hat{\mathbf{M}} = \mathrm{fin}_\infty(\mathbf{M})/(\mu_2(0) \cap \mathrm{fin}_\infty(\mathbf{M})).$$

is a von Neumann algebra of type II_1 factor.

Solutions of the modified chiral model in (2+1) dimensions

T. Ioannidou and W. J. Zakrzewski
Department of Mathematical Sciences, University of Durham, Durham DH1 3LE, United Kingdom

(Received 25 June 1997; accepted for publication 21 January 1998)

In this paper we deal with classical solutions of the modified chiral model on $\mathbf{R}^{2+1}$. Such solutions are shown to correspond to products of various factors which we call time-dependent unitons. Then the problem of solving the system of second-order partial differential equations for the chiral field is reduced to solving a sequence of systems of first-order partial differential equations for the unitons. © *1998 American Institute of Physics.* [S0022-2488(98)00505-2]

I. INTRODUCTION

As is well known,[1,2] some physical phenomena (relativity, particle physics, etc.) lead, in their mathematical description, to nonlinear partial differential equations. Some of these equations are elliptic (when we deal with time-independent problems), others are hyperbolic or parabolic. However, with few exceptions, nonlinear partial differential equations are hard to solve (especially when they involve more than one spatial variable). Although in some cases static solution can be found the generalization to the time dependent problems often presents a formidable task.

A simple model which exemplifies many of the points mentioned above is the so-called relativistic chiral model in (2+1) dimensions. This model involves a chiral field $J(x,y,t)$ which takes its values in $SU(N)$. The equation of motion for this field is given by

$$\partial_\mu(J^{-1}\,\partial^\mu J)=0, \quad J\in SU(N), \tag{1}$$

and is, in fact, the Euler–Lagrange equation corresponding to the Lagrangian density,

$$\mathscr{L}=\tfrac{1}{2}\,\mathrm{tr}[(J^{-1}\partial_\mu J)(J^{-1}\partial^\mu J)]. \tag{2}$$

Here the indices μ,ν,α range over the values 0,1,2, with $x^\mu=(t,x,y)$ and ∂_μ denotes partial differentiation with respect to x^μ. Thus J describes maps of $\mathbf{R}^{2+1}$ into $SU(N)$ and, when we restrict our attention to static fields, we have maps from $\mathbf{R}^2$ into $SU(N)$. If we restrict our attention further and consider only static fields whose energy is finite (see below) then the problem reduces to finding harmonic maps of $\mathbf{S}^2\to SU(N)$.

Such harmonic maps were studied by Uhlenbeck[3] who, in a seminal paper, showed how to construct these maps in an explicit form. Her construction involved the introduction of the concept of a uniton. She then showed how starting from a given solution one can find a new one by ''the addition of a uniton.'' This observation allowed her to demonstrate that all solutions can be obtained from the trivial ones (i.e., $J=$const) by the addition of a certain number [in fact $\leqslant(N-1)$] of unitons.

This beautiful result relied heavily on the integrability of the chiral model in (2+0) dimensions (for more details see Ref. 4). When we consider the same model in (2+1) dimensions, i.e., when we want to solve (1) we immediately run into a problem as (1) is not integrable and so Uhlenbeck's method does not apply.

Some time ago Ward[5] presented a model in (2+1) dimensions which is an integrable generalization of the static chiral model in (2+0) dimensions. The model involves an $SU(N)$ valued chiral field whose equation of motion now takes the form

$$(\eta^{\mu\nu}+\varepsilon^{\mu\nu\alpha}V_\alpha)\partial_\mu(J^{-1}\partial_\nu J)=0. \tag{3}$$

 © 1998 American Institute of Physics

Here the tensor $\eta^{\mu\nu}$ is the inverse Minkowski metric, given by $\eta^{\mu\nu}=\mathrm{diag}(-1,1,1)$; $\varepsilon^{\mu\nu\alpha}$ is the fully antisymmetric tensor with $\varepsilon^{012}=1$; and V_α is the constant unit vector pointing in the x-direction, $V_\alpha=(0,1,0)$.

Notice that although (3) is not relativistically covariant (as V_α is nonzero) the solutions of Uhlenbeck are static solutions of (3). As the model is integrable many solutions of (3) can be easily found. The first solutions of this model[5] exhibited many properties seen in other integrable models (like wave-like behavior with a phase shift, soliton-like structures passing through each other, etc.). Recently, Ward,[6] Ioannidou[7] and even more recently Anand[8] have found further interesting solutions of (3). These solutions described the evolution of soliton-like extended structures whose properties were quite similar to properties of solitonic objects in the $O(3)$ sigma model (i.e., they exhibit the 90° scattering).

The approach of Ward and Ioannidou involved treating fields of the model as the limiting cases of the Riemann problem with zeros. In this paper we return to Uhlenbeck's construction of static solutions and show that her construction can be generalized to give, in general nonstatic, solutions of the modified chiral model of Ward [i.e., of (3)]. Our approach reproduces the solutions reported in Refs. 6 and 7 and presents an unusual but interesting application of Uhlenbeck's approach.

II. THE MODIFIED MODEL

As shown by Ward[5] the modified chiral model (3) has the same conserved energy density as the original chiral model (1) and this energy is given by

$$\mathscr{E}=-\tfrac{1}{2}\,\mathrm{tr}[(J^{-1}J_t)^2+(J^{-1}J_x)^2+(J^{-1}J_y)^2]. \tag{4}$$

To specify the problem of finding solutions of (3) completely we have to state the boundary conditions satisfied by J. Thus in order to ensure the finiteness of energy of the solutions, we require

$$J=J_c+J_\theta(\theta)\ r^{-1}+O(r^{-2}),\quad r\to\infty, \tag{5}$$

where $z=r\ e^{i\theta}$ (with $z=x+iy$), J_c is a constant matrix and J_θ is independent of t.

Equation (3) is completely integrable, in the sense that it can be written as the compatibility condition for a pair of linear equations involving a spectral parameter λ. Define

$$A_z=\tfrac{1}{2}J^{-1}(\partial_z-\tfrac{1}{2}i\partial_t)J,\quad A_{\bar z}=\tfrac{1}{2}J^{-1}(\partial_{\bar z}+\tfrac{1}{2}i\partial_t)J, \tag{6}$$

where A_z, $A_{\bar z}$ are $N\times N$ matrices depending on x,y,t but not on λ.

Then the pair of linear operators,

$$\vartheta_{\bar z}+(1-\lambda)A_{\bar z},\quad \vartheta_z+(1-\lambda^{-1})A_z, \tag{7}$$

with $\vartheta_z=\partial_z+\frac{1}{2}\,i\lambda^{-1}\partial_t$, $\vartheta_{\bar z}=\partial_{\bar z}-\frac{1}{2}\,i\lambda\partial_t$, commute for all $\lambda\in\mathbf{C}^*=\mathbf{C}-\{0\}$, as a consequence of (3). Therefore one can find a solution, E_λ, of the equations

$$\vartheta_z E_\lambda=(1-\lambda^{-1})E_\lambda A_z,\quad \vartheta_{\bar z}E_\lambda=(1-\lambda)E_\lambda A_{\bar z}. \tag{8}$$

Theorem 1: If $J:\mathbf{R}^{2+1}\to SU(N)$ *is harmonic, then there exists a* $GL(N,\mathbf{C})$*-valued function* E_λ *of (8) which is analytic, holomorphic in* $\lambda\in\mathbf{C}^*$ *and unitary for* $|\lambda|=1$ *or* $\bar\lambda=\lambda^{-1}$ *such that* $E_{-1}=J$ *and*

$$E_\lambda=(E_{\bar\lambda}^{-1})^\dagger, \tag{9}$$

where † *denotes complex conjugate transpose. Conversely, if* E_λ *is holomorphic and analytic; and* A_z, $A_{\bar z}$ *defined by* (6) *are independent of* λ, *then* $J=E_{-1}$ *is harmonic.*

This follows from Ref. 3 and E_λ is called an extended solution corresponding to J. System (8) is overdetermined and in order for a solution E_λ to exist, A_z and $A_{\bar z}$ have to satisfy integrability conditions,

$$\begin{aligned}(\partial_z+\tfrac{1}{2}i\partial_t)A_{\bar z}+(\partial_{\bar z}-\tfrac{1}{2}i\partial_t)A_z=0,\\ (\partial_z-\tfrac{1}{2}i\partial_t)A_{\bar z}-(\partial_{\bar z}+\tfrac{1}{2}i\partial_t)A_z-2[A_{\bar z},A_z]=0.\end{aligned}\tag{10}$$

Notice that the first equation of (10) is equivalent to (3).

III. UHLENBECK'S CONSTRUCTION

It has been known for some time that all static solutions of Grassmannian models are also solutions of the static chiral model;[9] although not much is known about other solutions. However, Uhlenbeck[3] proved that any harmonic map from the Riemann sphere $\mathbf{S}^2$ to the unitarity group $U(N)$ can be factorized into a product of a finite number of factors (so-called unitons) involving maps into Grassmannians $G_k(\mathbf{C}^N)$ each of which satisfies a system of first-order partial differential equations. Thus the problem of solving a system of second-order partial differential equations for a static harmonic map has been reduced to having to solve a sequence of systems of first-order partial differential equations for the unitons. This observation can be generalized to the nonstatic case (3).

We will seek solutions of (8) of the form

$$E_\lambda=\prod_{k=0}^{n}(1+(\lambda-1)R_k),\tag{11}$$

for some n, where R_k are Hermitian projectors of the form $R_k=(q_k^\dagger\otimes q_k)/|q_k|^2$ (R_0 is a constant matrix, i.e., 0-uniton), which satisfy some first-order differential equations; and q_k are N-dimensional vectors which, in general, depend on $z,\bar z,t$ and $|q_k|^2=q_k\cdot q_k^\dagger$. Note that a constant E_λ is a 0-uniton. Then, following Uhlenbeck, we consider

$$\tilde E_\lambda=E_\lambda(1+(\lambda-1)R_n),\tag{12}$$

and find the following:

Theorem 2: *Let* $E_\lambda:\mathbf{C}^*\times\mathbf{R}^{2+1}\to GL(N,\mathbf{C})$ *be an extended harmonic map* $E_\lambda:\mathbf{R}^{2+1}\to SU(N)$ *for* $|\lambda|=1$. *Then* $\tilde E_\lambda=E_\lambda(1+(\lambda-1)R_n)$ *is an extended map for a Hermitian projection* (R_n) *if and only if*

$$\begin{aligned}(1-R_n)(\partial_t R_n-2iA_{\bar z}R_n)=0,\\ R_n(\partial_{\bar z}R_n-A_{\bar z}(1-R_n))=0,\end{aligned}\tag{13}$$

where $A_{\bar z}=-(A_z)^\dagger$ *given by* (6).

From the definition of the extended solution, $\tilde A_{\bar z}=(1-\lambda)^{-1}\tilde E_\lambda^{-1}\,\partial_{\bar z}\tilde E_\lambda$ and so

$$\tilde A_{\bar z}=(1+(\lambda^{-1}-1)R_n)(A_{\bar z}(1+(\lambda-1)R_n)-(\partial_{\bar z}-\tfrac{1}{2}i\lambda\partial_t)R_n),\tag{14}$$

using the fact that $\tilde E_\lambda^{-1}=(1+(\lambda^{-1}-1)R_n)E_\lambda^{-1}$ and $A_{\bar z}=(1-\lambda)^{-1}E_\lambda\,\partial_{\bar z}E_\lambda^{-1}$. But, from Theorem 1 we know that $\tilde E_\lambda$ is an extended solution if the λ and λ^{-1} terms vanish, which leads to the system (13).

Next we observe the following theorem:

Theorem 3: *Suppose that* E_λ *is an extended solution and so is* $\tilde E_\lambda=E_\lambda(1+(\lambda-1)R_n)$. *Then if* $A_{\bar z}=\frac{1}{2}E_\lambda^{-1}\,\partial_{\bar z}E_\lambda$ *and* $\tilde A_{\bar z}=\frac{1}{2}\tilde E_\lambda^{-1}\,\partial_{\bar z}\tilde E_\lambda$, *they are related by*

$$\tilde A_{\bar z}=A_{\bar z}-\partial_{\bar z}R_n+\tfrac{1}{2}i\partial_t R_n.\tag{15}$$

This follows automatically from the terms in (14) which do not contain λ. In general, by induction, one can show that

$$A_{zn}^{-}=\left(-\partial_{z}^{-}+\frac{1}{2}i\partial_{t}\right)\sum_{k=0}^{n}R_{k}, \tag{16}$$

and so, that the corresponding R_k satisfy the following equations:

$$\begin{aligned}&(1-R_n)\left(\partial_t R_n-2i\sum_{k=0}^{n-1}\left(-\partial_z^{-}+\frac{1}{2}i\partial_t\right)R_kR_n\right)=0,\\ &R_n\left(\partial_z^{-}R_n-\sum_{k=0}^{n-1}\left(-\partial_z^{-}+\frac{1}{2}i\partial_t\right)R_k\,(1-R_n)\right)=0.\end{aligned} \tag{17}$$

Observe that for $n=1$, system (17) gives $\partial_t R_1\ R_1=0$ and $R_1\partial_z^{-}R_1=0$; i.e., the equations for the holonomic static solutions (instantons) of the Grassmannian models. This is the case as

$$\partial_t R_1\ R_1\equiv q_1\ q_1^{\dagger}\ \frac{\partial_t q_1^{\dagger}\otimes q_1}{|q_1|^4}-\partial_t q_1^{\dagger}\ q_1\ \frac{q_1^{\dagger}\otimes q_1}{|q_1|^4}=0, \tag{18}$$

which is satisfied, if and only if, q_1 is independent of t. Using the same argument for $R_1\partial_z^{-}R_1=0$ we deduce that $q_1=q_1(z)$. For $n\neq 1$, we have more general and, in general t-dependent, solutions.

Now, let us concentrate on (3) and discuss the construction of its solutions. If we set $\widetilde{E}_{-1}=J$ and $E_{-1}=J_0$ in (12), then the chiral field J (due to Theorem 2) is of the form

$$J=J_0(1-2R_n), \tag{19}$$

and satisfies (3) if J_0 does and if R_n satisfies (13). This describes a time-dependent multi-soliton solution of (3) since it satisfies (10), i.e.,

$$\begin{aligned}\left(\partial_z+\frac{i}{2}\partial_t\right)\widetilde{A}_z^{-}+\left(\partial_z^{-}-\frac{i}{2}\partial_t\right)\widetilde{A}_z&\equiv\left(\partial_z+\frac{i}{2}\partial_t\right)\left(-(1-2R_n)\left(\partial_z^{-}+\frac{i}{2}\partial_t\right)R_n+(1-2R_n)A_z^{-}(1-2R_n)\right)\\&\quad+\left(\partial_z^{-}-\frac{i}{2}\partial_t\right)\left((1-2R_n)\left(\partial_z-\frac{i}{2}\partial_t\right)R_n+(1-2R_n)A_z(1-2R_n)\right)\\&=\left(\partial_z+\frac{i}{2}\partial_t\right)\left(A_z^{-}-\left(\partial_z^{-}-\frac{i}{2}\partial_t\right)R_n\right)\\&\quad+\left(\partial_z^{-}-\frac{i}{2}\partial_t\right)\left(A_z+\left(\partial_z+\frac{i}{2}\partial_t\right)R_n\right)=0,\end{aligned} \tag{20}$$

using equations (6), (13) and (19).

So, to construct time-dependent solutions of the $SU(N)$ model (3), one can start from a constant solution (zero-uniton) and add to it a one-uniton. This solution will be nonconstant — but it is static. Then, to this one uniton, one can add a second uniton, then a third one and so on. As we are going to see, the number of soliton-like structures in an n-uniton configuration is not related to n (i.e., the procedure of the ''addition of a uniton'' can both increase or decrease the number of solitons). In the static chiral model (1) Uhlenbeck's theorem shows that for $U(N)$ the largest uniton number is less than N. In our case, the t-dependence of the system (17) invalidates this argument; the number of unitons can be arbitrary. In the static $SU(2)$ case considered by Uhlenbeck the only solutions are those described by constant matrices (0-unitons) and factors constructed from holomorphic functions (1-unitons). In the modified chiral model the 0- and 1-uniton solutions are the same but then, in addition, we have further solutions corresponding to

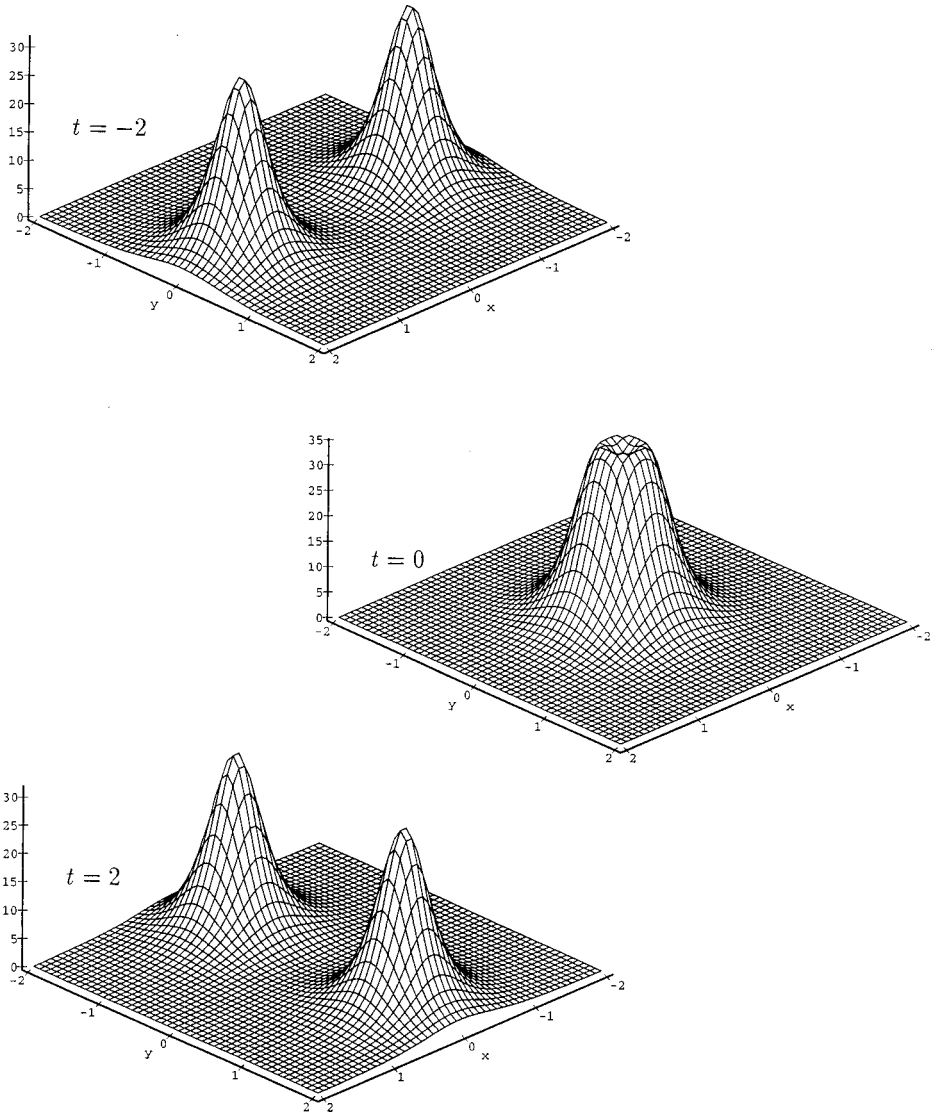

FIG. 1. Energy density of the embedding of $SU(2)$ solitons, at increasing times.

two and more unitons. These additional solutions are nonstatic. We do not know, at this stage, whether there is any bound on the uniton number so that all solutions correspond to field configurations of up to this number.

IV. THE $SU(2)$ AND $SU(3)$ CASES

In this section we shall construct and discuss, as an example, a 2-uniton solution of the $SU(3)$ model (3). First of all, observe that all fields of the $SU(2)$ model can be embedded into the $SU(3)$ model so that the $SU(2)$ solutions are automatically also solutions of the $SU(3)$ model. In what follows we will recover some of them as special cases of the derived expressions.

Let us observe that the following expression describes a nonstatic 2-uniton solution:

$$J=K\left(1-2\frac{q_1^{\dagger}\otimes q_1}{|q_1|^2}\right)\left(1-2\frac{q_2^{\dagger}\otimes q_2}{|q_2|^2}\right), \tag{21}$$

where q_i for $i=1,2$ are the three-dimensional vectors given by

$$q_1=(1,f,g), \tag{22}$$

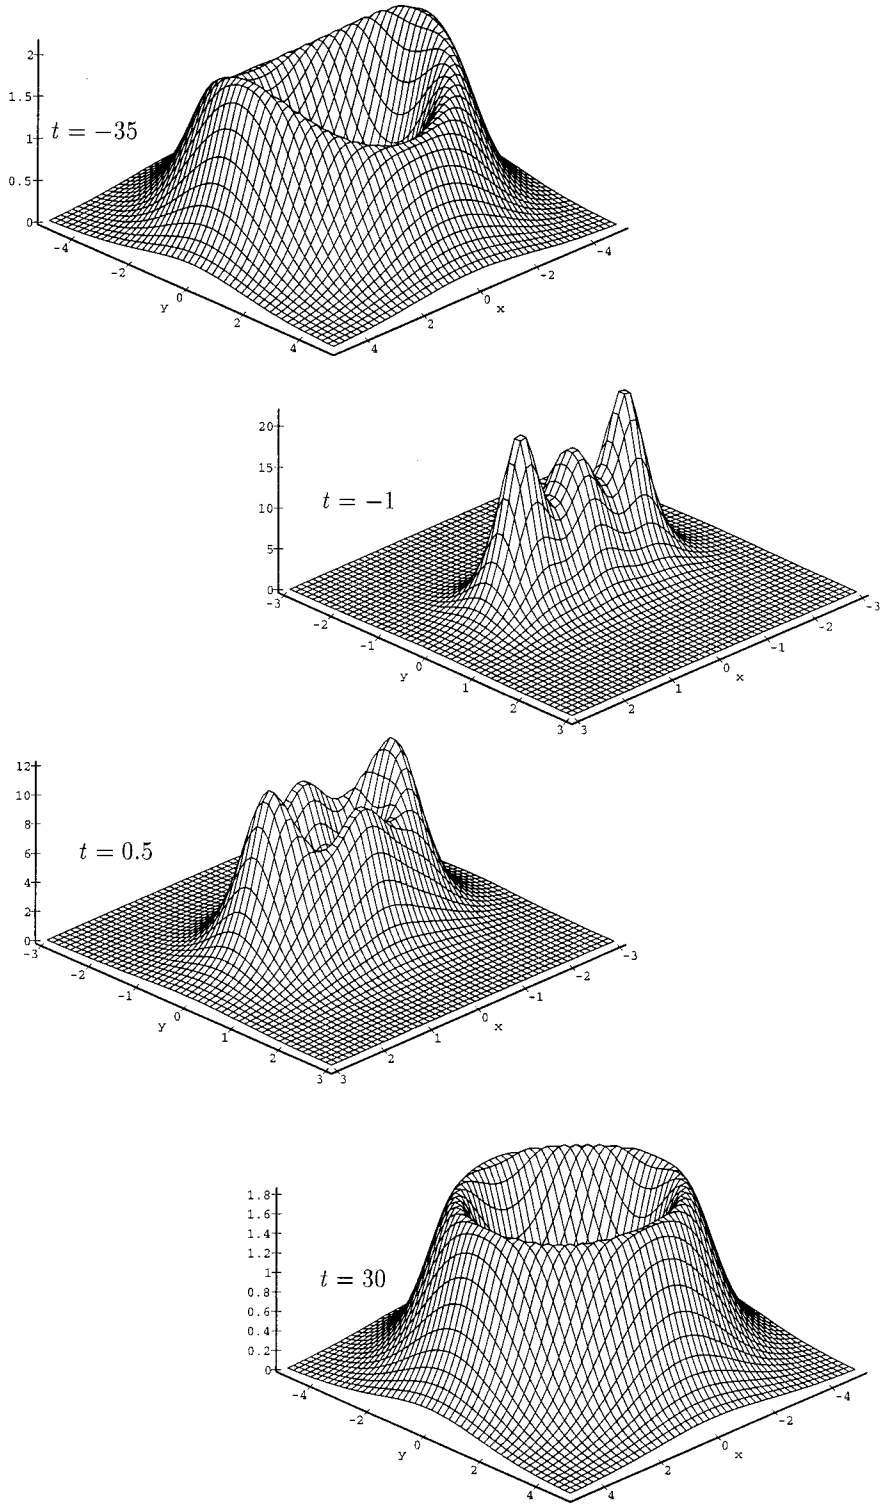

FIG. 2. Energy density at increasing times, for three ring-shaped solitons.

$$q_2=(1+|f|^2+|g|^2)(1,f,g)-2i(tf'+h)(\overline{f},-(1+|g|^2),g\overline{f})-2i(tg'+h_1)(\overline{g},\overline{g}\overline{f},-(1+|f|^2)),$$

and K is a constant matrix. Here f and g are rational meromorphic functions of z. The field J takes values in $SU(3)$, is smooth everywhere in $\mathbf{R}^{2+1}$ (as the two vectors q_i are nowhere zero). It satisfies the boundary condition (9) and the equation of motion (3).

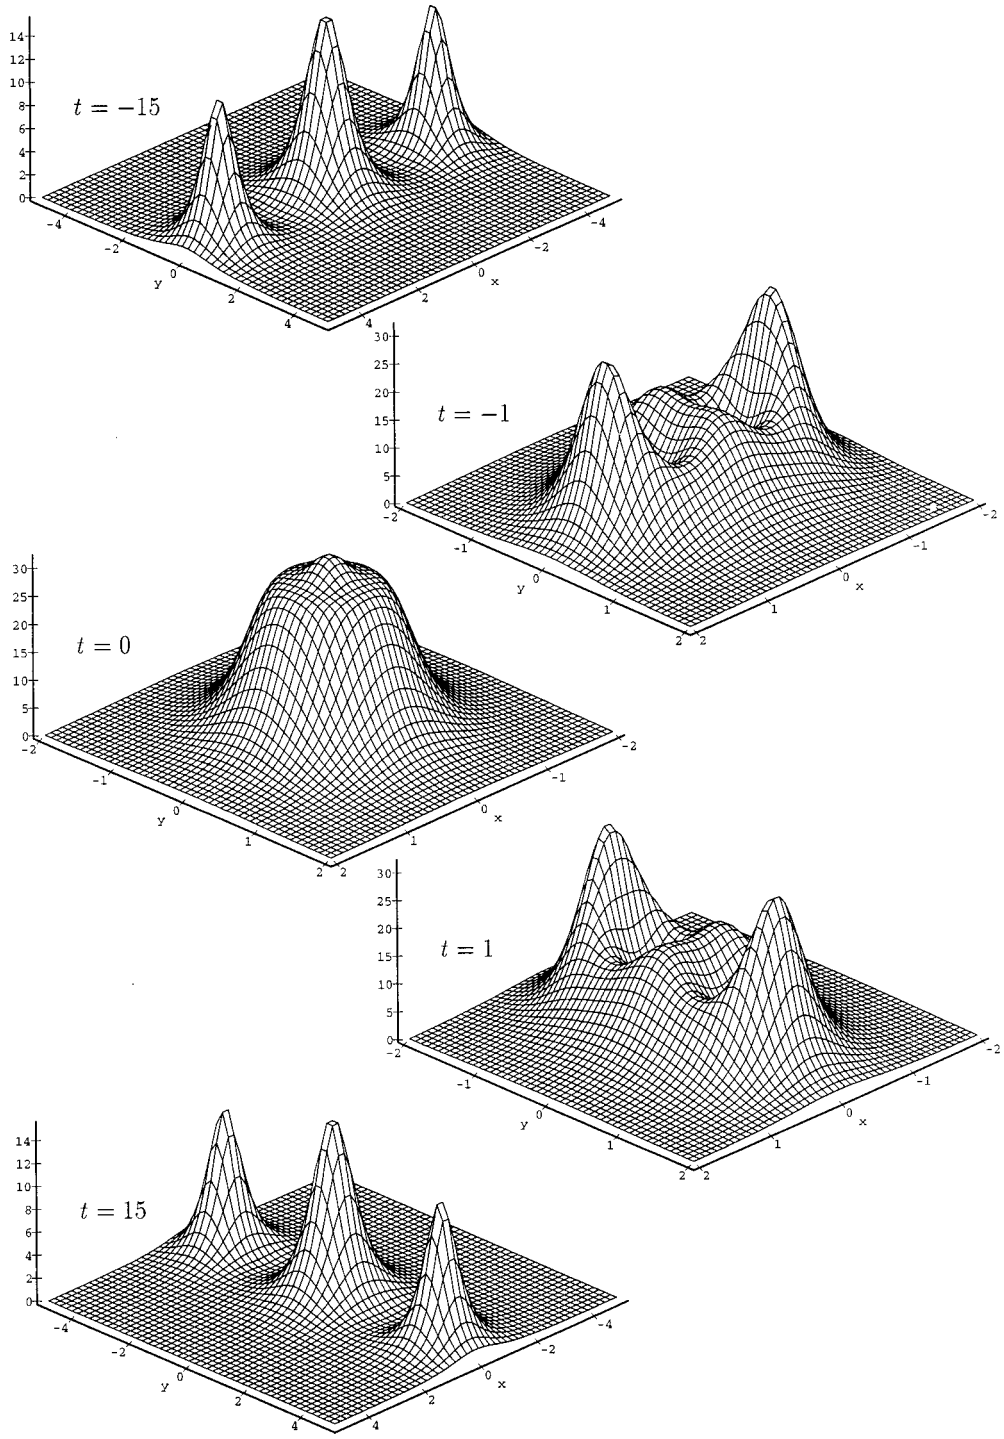

FIG. 3. Energy density at increasing times showing a 90° scattering between pure $SU(3)$ solitons.

Now let indicate how the solution (21) was constructed and how further solutions can be obtained. One way of proceeding is to take the q_i vectors of the form $q_i=(1,u_i,v_i)$. Then, for the 1-uniton solution corresponding to (17), the q_1 vector $q_1=(1,u_1,v_1)$ (as we have shown) is given in terms of the complex variable z. Thus we write $q_1=(1,f,g)$ where f and g are functions of z only. Then the system (17) for $n=2$ reduces to the following first-order differential equations for the function u_2 and v_2:

$$\partial_{\bar{z}}u_2=\frac{G}{(1+|f|^2+|g|^2)}(-u_2+f), \quad \partial_{\bar{z}}v_2=\frac{G}{(1+|f|^2+|g|^2)}(-v_2+f), \tag{23}$$

where $G=\overline{f}'(-u_2+f)+\overline{g}'(-v_2+g)+(u_2g-v_2f)(\overline{f}\overline{g}'-\overline{f}'\overline{g})$ and

$$\partial_t u_2=2i\frac{(1+u_2\overline{f}+v_2\overline{g})}{(1+|f|^2+|g|^2)}(u_2(\overline{f}f'+\overline{g}g')+\overline{g}(f'g-g'f)+f'),$$
$$\partial_t v_2=2i\frac{(1+u_2\overline{f}+v_2\overline{g})}{(1+|f|^2+|g|^2)}(v_2(\overline{f}f'+\overline{g}g')-\overline{f}(f'g-g'f)+g'), \tag{24}$$

and $'$ denotes the derivative with respect to z. A few lines of algebra allow us to show that q_2 of (22) is the general solution of the equations of the above system. Notice that when $v_i=0$ (i.e., $g=0$), (21) corresponds to the field J of the $SU(2)$ model (3).

Calculating the energy density for (21) we find

$$\mathscr{E}=\mathscr{E}_0+4\ \mathrm{tr}\left(\left(\partial_{\bar z}-\frac{i}{2}\partial_t\right)R_2\left(\partial_z+\frac{i}{2}\partial_t\right)R_2\right)-4\ \mathrm{tr}\left(\left(\partial_{\bar z}-\frac{i}{2}\partial_t\right)R_2\partial_z R_2 R_2\right)$$
$$-4\ \mathrm{tr}\left(\left(\partial_z+\frac{i}{2}\partial_t\right)R_2R_2\partial_{\bar z}R_2\right), \tag{25}$$

where $\mathscr{E}_0$ is the energy density of the 1-uniton (i.e., static) field. As is well known[3] $\mathscr{E}_0$ is a total derivative and so, probably, also is $\mathscr{E}$, but so far, we have not managed to prove this. However, we have looked at some special cases and have found that the total energy E, obtained by integrating $\mathscr{E}$, is quantized in units of 8π, i.e., is given by $E=8N\pi$. N appears to be related to the number of topological structures.

Let us discuss some special cases.

(*a*) The embedding of $SU(2)$ solitons, where we set

$$g=f, \quad h=h_1. \tag{26}$$

Such soliton solutions are localized along the direction of motion; they are not, however, of constant size. Their height (maximum of $\mathscr{E}$), is time dependent. In fact, for ($\deg f\geqslant\deg h$) no scattering occurs, i.e., the solitons are located at the center-of-mass forming a totally symmetric ring configuration. Otherwise, there are ($\deg f-1$) static solitons at the center-of-mass of the system accompanied by $N=\deg h-\deg f+1$ solitons (located at $t+z^N=0$; since J departs from its asymptotic value J_c when $tf'+h=0$) accelerating towards the solitons in the center, scattering at an angle of π/N, and then decelerating as they separate. This phenomenon has been observed, firstly, in the $SU(2)$ model (3) (cf. Refs. 6 7) and is a feature of systems (with nontrivial topology) admitting topological solitons.

As an example, let us take $f(z)=z$ and $h(z)=z^2$. The corresponding field represents a configuration of two solitons that undergo a 90° scattering. The energy density of this solution is

$$\mathscr{E}=32\frac{1+12r^2+12r^4+32r^2t^2+8t^2-16(x^2-y^2)t}{[1+12r^4+4r^2+16(x^2-y^2)t+1+8t^2]^2}, \tag{27}$$

and is symmetric under the interchange $t\to -t$, $x\to y$, $y\to x$. Figure 1 illustrates what happens close to $t=0$.

(*b*) In a more general case, i.e., for arbitrary values of our parameters, the configuration represents a multi-soliton solution that is localized close to the center of mass and deforms as the time passes. As an example, let us present a typical case by taking $f(z)=z$, $g(z)=2z$, $h(z)=z^2$ and $h_1(z)=3$. In this time-dependent solution, which corresponds to a configuration of three solitons, the energy density of the field, for large (negative) t, is in the shape of a ring which, as time passes, deforms to three peaks and then expands again to a ring. Figure 2 presents pictures of the corresponding energy densities at some representative values of time.

Returning to the scattering of our soliton-like structures we have seen that an embedding of the $SU(2)$ model provides an example of such a scattering. A further example is provided by a genuine $SU(3)$ case when we take

$$f=\rho^2(z), \quad g=\sqrt{2}\ \rho(z), \tag{28}$$

where $\rho(z)$ is an arbitrary function.

One example is presented in Figure 3, where we have chosen $\rho=z$, $h=z^3$ and $h_1=0$. This configuration can be seen to consist of two static solitons at the center-of-mass accompanied by two solitons accelerating towards the center, scattering at right angles and then decelerating as they separate.

V. CONCLUSIONS AND FURTHER COMMENTS

In this paper we have shown how to adapt Uhlenbeck's construction of uniton solutions of the chiral model in $(2+0)$ dimensions to the, time-dependent, uniton-like solutions of the modified chiral model in $(2+1)$ dimensions. It seems likely that there are many more interesting solutions still to be found. One could, for example, investigate the existence of time-dependent solutions based on other static ones constructed by Uhlenbeck.

As for static fields both models are the same, all Uhlenbeck's solutions are also solutions of the modified chiral model. However, at the level of two unitons and beyond, our construction has given us genuine time-dependent solutions of the modified chiral model. Looking at some examples we have seen that, in some cases, their field configurations can be thought of as representing scatterings of some soliton-like objects, sometimes accompanied also by static structures. The total energy appears to be quantized — thus showing that during their scattering the soliton-like structures must change their size.

We have not succeeded yet in gaining the full understanding of various properties of our solutions. These problems are currently being investigated.

Alternative potentials for the electromagnetic field

Shaun N. Mosley
Sunnybank, Albert Road, Nottingham NG3 4JD, England

(Received 24 November 1997; accepted for publication 5 February 1998)

The source-free electromagnetic field can be expressed in terms of two complex potentials α,β, which are related to the Debye potentials. The potentials $\{\alpha,\beta\}$ corresponding to various fields are discussed. A conserved radiation density ρ can be constructed in terms of these potentials, this density is positive (negative) for positive (negative) helicity radiation. © *1998 American Institute of Physics.* [S0022-2488(98)01605-3]

I. INTRODUCTION

The source-free electromagnetic field has only two degrees of freedom per space-time point. Some economy is achieved by reducing the six components of the electric and magnetic fields $(\mathbf{E},\mathbf{B})$ to the usual four potentials $(\Phi,\mathbf{A})$ which must satisfy the covariant Lorentz condition $\partial_t\Phi + \boldsymbol{\nabla}\cdot\mathbf{A}=0$, or the Φ component may be dispensed with provided that the three potentials $\mathbf{A}$ satisfy the non-covariant Coulomb gauge $\boldsymbol{\nabla}\cdot\mathbf{A}=0$. The most economical way to express the two degrees of freedom of the free electromagnetic field is in terms of the two Debye potentials[1,2] (ψ_1,ψ_2). The electric and magnetic fields are expressed in terms of these potentials by

$$\begin{bmatrix}\mathbf{E}\\ \mathbf{B}\end{bmatrix}=\begin{bmatrix}-(\mathbf{x}\times\boldsymbol{\nabla})\partial_t\\ \boldsymbol{\nabla}\times(\mathbf{x}\times\boldsymbol{\nabla})\end{bmatrix}\psi_1+\begin{bmatrix}-\boldsymbol{\nabla}\times(\mathbf{x}\times\boldsymbol{\nabla})\\ -(\mathbf{x}\times\boldsymbol{\nabla})\partial_t\end{bmatrix}\psi_2, \tag{1}$$

where ψ are solutions of the wave equation

$$(\partial_t^2-\nabla^2)\psi=0. \tag{2}$$

The standard textbooks may not refer to the Debye potentials by that name,[3] but use either ψ or $L^2\psi$ in their analysis of multipole radiation fields, where ψ are spherical solutions of the wave equation—see, for example pp. 432–433 of Reitz,[4] or pp. 745–746 of Jackson.[5] The paper by Boukamp and Casimir[6] discusses the various essentially equivalent approaches to multipole radiation, while Refs. 2, 7 show that any field $(\mathbf{E},\mathbf{B})$ outside the source region can be expressed in terms of the potentials ψ_1,ψ_2.

We express (1) more concisely by defining the complex field $\mathbf{F}\equiv\mathbf{E}+i\mathbf{B}$, then

$$\begin{aligned}\mathbf{F}&=[-(\mathbf{x}\times\boldsymbol{\nabla})\partial_t+i\boldsymbol{\nabla}\times(\mathbf{x}\times\boldsymbol{\nabla})](\psi_1+i\psi_2),\\ \mathbf{F}&=[i\partial_t+\boldsymbol{\nabla}\times]\mathbf{L}\psi,\end{aligned} \tag{3}$$

where $\mathbf{L}\equiv -i\mathbf{r}\times\boldsymbol{\nabla}$ is the angular momentum operator and $\psi\equiv-(\psi_1+i\psi_2)$. Conversely

$$\mathbf{r}\cdot\mathbf{F}=\mathbf{r}\cdot\boldsymbol{\nabla}\times\mathbf{L}\psi=iL^2\psi \tag{4}$$

and the operator L^2 is, in principle, invertible.[8] The source-free Maxwell's equations are

$$[i\partial_t-\boldsymbol{\nabla}\times]\mathbf{F}=0, \tag{5a}$$

$$\boldsymbol{\nabla}\cdot\mathbf{F}=0. \tag{5b}$$

It is readily verified that substituting (3) into the above yields an identity, given (2).

Despite the fact that the two Debye potentials (or the single complex Debye potential ψ) precisely contain the two degrees of freedom of the electromagnetic field, they are seldom used outside magnetostatics and multipole field analysis. Some disadvantages spring to mind:

 © 1998 American Institute of Physics

(a) the field $\mathbf{F}\equiv\mathbf{E}+i\mathbf{B}$ is expressed by second order differential operators acting on the potentials, so then for example the usual energy density of the field $(\mathbf{F}^*\mathbf{F})$ is a cumbersome expression in terms of ψ;
(b) there is no regular closed form potential ψ representing a plane wave field. The standard texts[9] express the plane wave potential as an infinite sum over l of the spherical harmonics $Y_{l,\pm 1}$, although this actually represents plane waves outgoing in each direction from the $(\theta=\pi/2)$ plane;
(c) the Debye potential formalism is ill suited to coping with point singularities representing charged particles in the field, i.e., there is no regular potential ψ representing the monopole field at the origin, as can be seen immediately from (4). See Ref. 1 for irregular potentials ψ representing the monopole field.

We will now show that, given (3), the field $\mathbf{F}$ can be expressed in terms of two complex potentials α,β acted on by first order differential operators. These potentials $\{\alpha,\beta\}$ admit charged particle solutions, for static and moving charges, and the potentials representing the plane wave fields are fairly simple. From (3) we calculate the field $(\mathbf{F}+i\hat{\mathbf{x}}\times\mathbf{F})$ in terms of ψ, where $\hat{\mathbf{x}}\equiv\mathbf{x}/r$. We use the operator identities[2]

$$\boldsymbol{\nabla}\times\mathbf{L}=(-i\mathbf{x}\nabla^2+i\boldsymbol{\nabla}(\partial_r r)),\quad \hat{\mathbf{x}}\times\mathbf{L}=i(\boldsymbol{\nabla}r-\partial_r\mathbf{x}),\quad \hat{\mathbf{x}}\times(\boldsymbol{\nabla}\times\mathbf{L})=-\mathbf{L}(\partial_r r).$$

Then

$$\mathbf{F}+i\hat{\mathbf{x}}\times\mathbf{F}=[i\partial_t\mathbf{L}-i\mathbf{x}\nabla^2+i\boldsymbol{\nabla}(\partial_r r)]\psi+i[-(\boldsymbol{\nabla}r-\partial_r\mathbf{x})\partial_t-\mathbf{L}(\partial_r r)]\psi,$$
$$\mathbf{F}+i\hat{\mathbf{x}}\times\mathbf{F}=\left[\boldsymbol{\nabla}+\hat{\mathbf{x}}\partial_t-\frac{1}{r}\mathbf{L}\right]\alpha, \tag{6a}$$

where

$$\alpha=i(\partial_r r\psi-\partial_t r\psi). \tag{7a}$$

To derive (6a) we have used (2). Similarly

$$\mathbf{F}-i\hat{\mathbf{x}}\times\mathbf{F}=\left[\boldsymbol{\nabla}-\hat{\mathbf{x}}\partial_t+\frac{1}{r}\mathbf{L}\right]\beta \tag{6b}$$

with

$$\beta=i(\partial_r r\psi-\partial_t r\psi). \tag{7b}$$

Note that given $(\mathbf{F}+i\hat{\mathbf{x}}\times\mathbf{F})$ there is no straightforward algebraic manipulation to derive $\mathbf{F}$ due to the fact that the matrix $(I+i\hat{\mathbf{x}}\times)$ is singular. We add (6a), (6b) obtaining

$$2\mathbf{F}=\left[\boldsymbol{\nabla}+\hat{\mathbf{x}}\partial_t-\frac{1}{r}\mathbf{L}\right]\alpha+\left[\boldsymbol{\nabla}-\hat{\mathbf{x}}\partial_t+\frac{1}{r}\mathbf{L}\right]\beta, \tag{8}$$

which is the basic formula expressing $\mathbf{F}$ in terms of $\{\alpha,\beta\}$. Dotting (6a), (6b) with $\hat{\mathbf{x}}$ yields the constraint

$$(\partial_r+\partial_t)\alpha=F_r=(\partial_r-\partial_t)\beta, \tag{9}$$

where $F_r\equiv\hat{\mathbf{x}}\cdot\mathbf{F}$. The operators $(\partial_r+\partial_t),(\partial_r-\partial_t)$ are the radial differential operators on the future, past lightcones, respectively. Given the radial field $F_r(t,\mathbf{x})$, then (9) enables us to calculate α,β as follows. To carry out the integration on the future (past) lightcone we introduce the advanced (retarded) times S and T defined by

$$S=t-r,\quad T=t+r. \tag{10}$$

The hypersurfaces $S=S_0,S_1\ldots$ are future lightcones centered at the origin, while the hypersurfaces $T=T_0,T_1\ldots$ are past lightcones. Then $F_r(S)$ or $F_r(T)$ are obtained by substituting $t=S+r$ or $t=T-r$ into the expression for $F_r(t)$. A solution of (9) is then

$$\alpha(S)=\int_0^r dr\ F_r(S),\quad \beta(T)=\int_0^r dr\ F_r(T). \tag{11}$$

Maxwell's equations can alternatively be formulated from the start using advanced or retarded time,[10] then α or β is found from F_r by a straightforward radial integration.

We now find the evolution equations for α,β, noting that $\alpha=i(\partial_r r-\partial_t r)\psi$ does not satisfy the wave equation like ψ, because the operator $(\partial_r r-\partial_t r)$ does not commute with the d'Alembertian operator $\Box\equiv(\partial_t^2-\nabla^2)$. The d'Alembertian may be expressed as follows:

$$(\partial_t^2-\nabla^2)\psi=\left[-\frac{1}{r}(\partial_r+\partial_t)(\partial_r-\partial_t)r+\frac{1}{r^2}L^2\right]\psi=0. \tag{12}$$

Now multiply (11) by $(i/r^2)(\partial_r-\partial_t)r^3$ obtaining

$$\left[-\frac{1}{r^2}(\partial_r-\partial_t)r^2(\partial_r+\partial_t)+\frac{1}{r^2}L^2\right]i(\partial_r-\partial_t)r\psi=\left[\partial_t^2-\nabla^2-\frac{2}{r}\partial_t\right]\alpha=0 \tag{13a}$$

so that the evolution operator for α is a modified d'Alembertian, having the extra term $-(2/r)\partial_t$. Similarly

$$\left[\partial_t^2-\nabla^2+\frac{2}{r}\partial_t\right]\beta=0. \tag{13b}$$

We see from (8) that adding any function $f(t-r)$ to α, or adding any function $g(t+r)$ to β leaves $\mathbf{F}$ unchanged. Also the evolution operators (13) for α,β, annihilate $f(t-r),g(t+r)$, respectively. So the gauge transformations for α,β are

$$\begin{array}{ll}\alpha\to\alpha', & \alpha'=\alpha+f(t-r),\\ \beta\to\beta' & \beta'=\alpha+g(t+r).\end{array} \tag{14}$$

II. THE POTENTIALS $\{\alpha,\beta\}$ CORRESPONDING TO RADIATION FIELDS

We first investigate some symmetries between α,β. Consider the parity transformation $\mathscr{P}:\mathbf{x}\to-\mathbf{x}$ and the time reversal transformation $\mathscr{T}:t\to-t$. Under $\mathscr{P},\mathscr{T}$ the fields transform as follows:[11]

$$\begin{array}{lll}\mathscr{P}\mathbf{E}(t,\mathbf{x})=-\mathbf{E}(t,-\mathbf{x}), & \mathscr{P}\mathbf{B}(t,\mathbf{x})=+\mathbf{B}(t,-\mathbf{x}), & \mathscr{P}\mathbf{F}(t,\mathbf{x})=-\mathbf{F}^*(t,-\mathbf{x}),\\ \mathscr{T}\mathbf{E}(t,\mathbf{x})=+\mathbf{E}(-t,\mathbf{x}), & \mathscr{T}\mathbf{B}(t,\mathbf{x})=-\mathbf{B}(-t,\mathbf{x}), & \mathscr{T}\mathbf{F}(t,\mathbf{x})=+\mathbf{F}^*(-t,\mathbf{x}),\end{array}$$

and

$$\mathscr{P}\mathscr{T}\mathbf{F}(t,\mathbf{x})=-\mathbf{F}(-t,-\mathbf{x}).$$

For brevity we will write a bar over any variable signifying its $\mathscr{P}\mathscr{T}$ transform, e.g., $\overline{\mathbf{F}}=\mathscr{P}\mathscr{T}\mathbf{F}$, $\overline{\alpha}=\mathscr{P}\mathscr{T}\alpha$, etc. Both α,β are scalars under $\mathscr{P}\mathscr{T}$, so that $\overline{\alpha}(t,\mathbf{x})=\alpha(-t,-\mathbf{x})$. Maxwell's equations are invariant under the $\mathscr{P}\mathscr{T}$ transformation, so that if $\mathbf{F}$ satisfies Maxwell's equations then so does $\mathbf{F}'=\overline{\mathbf{F}}$. In some cases of interest the field is even or odd under $\mathscr{P}\mathscr{T}$, by which we mean $\overline{\mathbf{F}}_{ev}=\mathbf{F}_{ev}$ and $\overline{\mathbf{F}}_{odd}=-\mathbf{F}_{odd}$ (from now on we will use the terms even and odd meaning even or odd under $\mathscr{P}\mathscr{T}$). Recall the fields $(\mathbf{F}+i\hat{\mathbf{x}}\times\mathbf{F}),(\mathbf{F}-i\hat{\mathbf{x}}\times\mathbf{F})$ which are derived from α,β, respectively. Then if the field is even/odd,

$$(\underset{odd}{\mathbf{F}^{ev}}-i\hat{\mathbf{x}}\times\underset{odd}{\mathbf{F}^{ev}})=\pm\mathscr{P}\mathscr{T}(\underset{odd}{\mathbf{F}^{ev}}+i\hat{\mathbf{x}}\times\underset{odd}{\mathbf{F}^{ev}}). \tag{15}$$

In either of these cases the field is effectively given by one potential, α say, because after calculating $(\mathbf{F}+i\hat{\mathbf{x}}\times\mathbf{F})$ from α, one can write down $(\mathbf{F}-i\hat{\mathbf{x}}\times\mathbf{F})$ using (15). Applying the $\mathscr{PT}$ transformation to equations (6):

$$\overline{\mathbf{F}}-i\hat{\mathbf{x}}\times\overline{\mathbf{F}}=-\left[\boldsymbol{\nabla}-\hat{\mathbf{x}}\partial_t+\frac{1}{r}\mathbf{L}\right]\overline{\alpha},\quad \overline{\mathbf{F}}+i\hat{\mathbf{x}}\times\overline{\mathbf{F}}=-\left[\boldsymbol{\nabla}+\hat{\mathbf{x}}\partial_t-\frac{1}{r}\mathbf{L}\right]\overline{\beta},$$

so that

$$\mathbf{F}\to\overline{\mathbf{F}}\quad\text{is equivalent to}\quad\{\alpha,\beta\}\to\{-\overline{\beta},-\overline{\alpha}\}. \tag{16}$$

From (16) we see that

$$\{\mathbf{F}_{ev}:\quad\beta=-\overline{\alpha}\},\quad\{\mathbf{F}_{odd}:\quad\beta=+\overline{\alpha}\}. \tag{17}$$

We now find the potentials $\{\alpha,\beta\}$ corresponding to the radiation fields. Equations (11) enable us to calculate the potentials for a known field—which approach we follow in this section. Alternatively we can look for solutions of the evolution equations for the potentials (13), satisfying the constraint (9)—the approach we take in Appendix A. It turns out that these evolution equations (13) are separable in either spherical or parabolic coordinates—the spherical solutions yield the potentials corresponding to the multipole fields (which are singular at the origin), while the parabolic solutions are potentials for non-singular fields, including the plane wave fields.

Consider the plane wave field $\mathbf{F}$ propagating in the x_3 direction, the left circularly polarized (positive helicity) field $\mathbf{F}_L$ is

$$\mathbf{F}_L=\{1,i,0\}e^{ikx_3-ikt},\quad F_{rL}=(\hat{x}_1+i\hat{x}_2)e^{ikx_3-ikt}, \tag{18}$$

and its $\mathscr{PT}$ transform the right circularly polarized (negative helicity) field $\mathbf{F}_R$ is

$$\mathbf{F}_R=\overline{\mathbf{F}}_L=-\{1,i,0\}e^{-(ikx_3-ikt)},\quad F_{rR}=-(\hat{x}_1+i\hat{x}_2)e^{-(ikx_3-ikt)}.$$

Then recalling (10) we integrate $F_{rL}(S)=(\hat{x}_1+i\hat{x}_2)e^{-ikS}e^{-ikr(1-\hat{x}_3)}$ to find α, and follow the equivalent procedure for β, obtaining

$$\begin{aligned}\alpha_L&=\left(\frac{\hat{x}_1+i\hat{x}_2}{1-\hat{x}_3}\right)[e^{ikx_3}-e^{ikr}]\,\frac{e^{-ikt}}{ik},\\ \beta_L&=-\left(\frac{\hat{x}_1+i\hat{x}_2}{1+\hat{x}_3}\right)[e^{ikx_3}-e^{-ikr}]\,\frac{e^{-ikt}}{ik},\end{aligned} \tag{19}$$

which potentials are non-singular. The second term in the square brackets does not contribute to the field but its absence would make the potentials singular. Direct calculation verifies that

$$\left[\boldsymbol{\nabla}+\hat{\mathbf{x}}\partial_t-\frac{1}{r}\mathbf{L}\right]\alpha_L=\{1+\hat{x}_3,i+i\hat{x}_3,-\hat{x}_1-i\hat{x}_2\}e^{ikx_3-ikt}$$

which is $\mathbf{F}_L+i\hat{\mathbf{x}}\times\mathbf{F}_L$, noting that the operator $[\boldsymbol{\nabla}+\hat{\mathbf{x}}\partial_t-(1/r)\mathbf{L}]$ commutes with the $((x_1+ix_2)/(r-x_3))$ factor in α_L, and annihilates the term $e^{ik(r-t)}$. Similarly it can be verified that $[\boldsymbol{\nabla}-\hat{\mathbf{x}}\partial_t+(1/r)\mathbf{L}]\beta_L=\mathbf{F}_L-i\hat{\mathbf{x}}\times\mathbf{F}_L$.

As $\mathbf{F}_R=\overline{\mathbf{F}_L}$, then recalling (16)

$$\alpha_R=-\overline{\beta_L}=-\left(\frac{\hat{x}_1+i\hat{x}_2}{1-\hat{x}_3}\right)[e^{-ikx_3}-e^{-ikr}]\,\frac{e^{ikt}}{ik}, \tag{20}$$

$$\beta_R = -\overline{\alpha_L} = \left(\frac{\hat{x}_1 + i\hat{x}_2}{1+\hat{x}_3}\right)[e^{-ikx_3} - e^{ikr}]\,\frac{e^{ikt}}{ik}.$$

The potentials for any plane wave propagating in the x_3 direction are a linear superposition of $\{\alpha_L,\beta_L\},\{\alpha_R,\beta_R\}$. Both $\{\alpha_L,\beta_L\},\{\alpha_R,\beta_R\}$ are eigenstates of L_3, the angular momentum operator in the direction of propagation, with eigenvalue $+1$.

We obtain the potential $\alpha_L(\mathbf{k})$ for a left circularly polarized wave propagating in the $\hat{\mathbf{k}} \equiv \mathbf{k}/|\mathbf{k}|$ direction with wavelength $2\pi/|\mathbf{k}|$, by first defining the null complex vector $\mathbf{h}$ satisfying

$$\mathbf{h}\times\hat{\mathbf{k}} = i\mathbf{h}, \quad \mathbf{h}^*\cdot\mathbf{h} = 2, \tag{21}$$

which so defined is unique up to a phase factor. Then

$$\{\alpha_L(\mathbf{k}),\beta_L(\mathbf{k})\} = \left\{ -\left(\frac{\mathbf{h}\cdot\mathbf{x}}{r-\hat{\mathbf{k}}\cdot\mathbf{x}}\right)[e^{i\mathbf{k}\cdot\mathbf{x}} - e^{i|\mathbf{k}|r}], \left(\frac{\mathbf{h}\cdot\mathbf{x}}{r+\hat{\mathbf{k}}\cdot\mathbf{x}}\right)[e^{i\mathbf{k}\cdot\mathbf{x}} - e^{-i|\mathbf{k}|r}] \right\} \frac{e^{-i|\mathbf{k}|t}}{ik}, \tag{22}$$

and $\{\alpha_R(\mathbf{k}),\beta_R(\mathbf{k})\} = \{-\beta_L(\mathbf{k}), -\alpha_L(\mathbf{k})\}$. We check that $\alpha_L(\mathbf{k}),\beta_L(\mathbf{k})$ are eigenstates of $(\hat{\mathbf{k}}\cdot\mathbf{L})$ the angular momentum operator in the direction of propagation, with eigenvalue $+1$

$$\hat{\mathbf{k}}\cdot\mathbf{L}(\mathbf{h}\cdot\mathbf{x}) = \hat{\mathbf{k}}\cdot(-i\mathbf{x}\times\mathbf{h}) = -i\mathbf{x}\cdot(\mathbf{h}\times\hat{\mathbf{k}}) = -i\mathbf{x}\cdot(i\mathbf{h}) = \mathbf{h}\cdot\mathbf{x}. \tag{23}$$

In the next section we investigate the orthonormality of the basis potentials $\{\alpha(\mathbf{k}),\beta(\mathbf{k})\}$ and $\{\alpha(\mathbf{k}'),\beta(\mathbf{k}')\}$.

We next briefly consider the multipole radiation fields and their corresponding potentials, noting some symmetry relations under the $\mathcal{PT}$ transformation. The Debye potential ψ in this case is a spherical solution of the wave equation, then the potentials $\{\alpha,\beta\}$ follow from (7). Consider

$$\psi_{lm} = j_l(kr)Y_{lm}(\theta,\phi)\cos(kt), \tag{24}$$

where j_l is the spherical Bessel function of order l, and Y_{lm} are the spherical harmonics. This ψ_{lm} when substituted into (2) yields $\mathbf{F}_{lm}$, the magnetic multipole field of order (l,m). (Multiplying the potential by i yields the corresponding electric multipole field $i\mathbf{F}_{lm}$.) Then from (7) the potentials $\{\alpha_{lm},\beta_{lm}\}$ for the magnetic multipole field of order (l,m) are

$$\alpha_{lm} = i(\partial_r - \partial_t)[rj_l(kr)Y_{lm}(\theta,\phi)\cos(kt)],$$

$$\beta_{lm} = i(\partial_r + \partial_t)[rj_l(kr)Y_{lm}(\theta,\phi)\cos(kt)].$$

We see that

$$\beta_{lm} = (-1)^l\overline{\alpha_{lm}}$$

following the parity of Y_{lm}. This means, recalling (17), that $\mathbf{F}_{lm}$ is odd or even, depending on whether l is an even or odd number. [If we had considered the potential ψ of (21) with a $(\sin(kt))$ instead of a $(\cos(kt))$ factor, then $\beta'_{lm} = (-1)^{l+1}\overline{\alpha'_{lm}}$.] Then, as discussed previously, $\mathbf{F}_{lm}$ can be calculated from either one of the potentials α,β.

III. THE CONSERVED DENSITY ρ AND THE ENERGY E

A. The radiation density ρ

The electromagnetic field is the classical ''first-quantized'' version of the massless spin-1 photon field, and as such should have a conserved density corresponding to the well-known densities for the Klein-Gordon (spin-zero) or Dirac (spin-$\frac{1}{2}$) fields. The only text on classical (non-quantized) electromagnetism which discusses a radiation density, or an inner product, for the electromagnetic field that I have come across is the book by Good and Nelson,[12] otherwise one has

to turn to texts on QED such as that by Schweber.[13] For an excellent recent review on this subject, see Ref. 14. This inner product for the electromagnetic field involves the non-local (integral) operator $(\nabla^2)^{-1/2}$.

The evolution equations (7) for α,β can be expressed in the form

$$(\boldsymbol{\nabla}-\hat{\mathbf{x}}\partial_t)\cdot(\boldsymbol{\nabla}+\hat{\mathbf{x}}\partial_t)\alpha=0, \quad (\boldsymbol{\nabla}+\hat{\mathbf{x}}\partial_t)\cdot(\boldsymbol{\nabla}-\hat{\mathbf{x}}\partial_t)\beta=0. \tag{25}$$

It follows that

$$(\boldsymbol{\nabla}+\hat{\mathbf{x}}\partial_t)\cdot[\alpha(\boldsymbol{\nabla}-\hat{\mathbf{x}}\partial_t)\beta^*-\alpha^*(\boldsymbol{\nabla}-\hat{\mathbf{x}}\partial_t)\beta]-(\boldsymbol{\nabla}-\hat{\mathbf{x}}\partial_t)\cdot[\beta^*(\boldsymbol{\nabla}+\hat{\mathbf{x}}\partial_t)\alpha-\beta(\boldsymbol{\nabla}+\hat{\mathbf{x}}\partial_t)\alpha^*]=0. \tag{26}$$

Collecting terms and multiplying by $(-i)$ we can write (26) in the form of a continuity equation $\partial_t\rho+\boldsymbol{\nabla}\cdot\mathbf{J}=0$, where

$$\rho=-\frac{i}{4}[\alpha(\partial_r-\partial_t)\beta^*-\alpha^*(\partial_r-\partial_t)\beta+\beta^*(\partial_r+\partial_t)\alpha-\beta(\partial_r+\partial_t)\alpha^*], \tag{27}$$

$$\rho=-\frac{i}{4}(\alpha-\beta)F_r^*+\text{c.c.}=-\frac{i}{4}[(\alpha-\beta)(\partial_r+\partial_t)\alpha^*]+\text{c.c.}$$

$$\mathbf{J}=-\frac{i}{4}[\alpha(\boldsymbol{\nabla}-\hat{\mathbf{x}}\partial_t)\beta^*-\alpha^*(\boldsymbol{\nabla}-\hat{\mathbf{x}}\partial_t)\beta-\beta^*(\boldsymbol{\nabla}+\hat{\mathbf{x}}\partial_t)\alpha+\beta(\boldsymbol{\nabla}+\hat{\mathbf{x}}\partial_t)\alpha^*], \tag{28}$$

where we have used (9), and c.c. stands for the complex conjugate terms. Let us substitute the $\{\alpha_L,\beta_L\}$ of (19) into (27):

$$\rho_L=-\frac{1}{4k}\left(-\left(\frac{\hat{x}_1+i\hat{x}_2}{1-\hat{x}_3}\right)[e^{ikx_3}-e^{ikr}]-\left(\frac{\hat{x}_1+i\hat{x}_2}{1+\hat{x}_3}\right)[e^{ikx_3}-e^{-ikr}]\right)((\hat{x}_1-i\hat{x}_2)e^{-ikx_3})+\text{c.c.}$$

$$=\frac{1}{2k}((1+\hat{x}_3)[1-\cos(kr-kx_3)]+(1-\hat{x}_3)[1-\cos(kr+kx_3)])\geqslant 0.$$

Inserting $\{\alpha_R,\beta_R\}=-\{\overline{\beta_R},\overline{\alpha_R}\}$ into (27), we obtain $\rho_R=-\rho_L$. Hence ρ_L is non-negative and ρ_R is non-positive.

The density ρ has close similarity with the Klein–Gordon density for a spin-zero particle: $\rho_{KG}=-(i/2)(\phi^*\partial_t\phi-\phi\partial_t\phi^*)$. In this case solutions ϕ with time dependence $e^{-i\omega t}$ with ω positive are regarded as particle solutions, those with time dependence $e^{+i\omega t}$ are regarded as anti-particle solutions. Analagously we can regard the right circularly polarized (negative helicity) field as the ''anti-photons'' of the left circularly polarized (positive helicity) photon field. There appears to be no comparable radiation density in the literature, although of course one can project out the different polarizations when the field is expressed as a Fourier integral.[15,16]

We now investigate the orthogonality of the potentials for two different fields $\mathbf{F}_1$ and $\mathbf{F}_2$. It will be convenient to represent the potentials for the field $\mathbf{F}_1$ by the 2×1 matrix $U_1\equiv[{}^{\alpha_1}_{\beta_1}]$, then we construct the following indefinite scalar product space

$$\langle U_1|U_2\rangle\equiv\int d^3x\ \rho_{12}, \tag{29}$$

where ρ_{12} is the conserved density

$$\rho_{12}=-\frac{i}{4}[U_1^T(I\partial_t+\sigma^3\partial_r)U_2^*-U_2^{T*}(I\partial_t+\sigma^3\partial_r)U_1], \tag{30}$$

$$\rho_{12}=-\frac{i}{4}[(\alpha_1-\beta_1)F_{r2}^*-(\alpha_2^*-\beta_2^*)F_{r1}].$$

Here $U^T=[\alpha\beta]$ is the transpose of U, and σ^3 is the Pauli matrix $\left[\begin{smallmatrix}1 & 0\\ 0 & -1\end{smallmatrix}\right]$. Note that when $U_1=U_2=U$, then $\rho_{12}=\rho$. In Appendix B we show that

$$\begin{aligned}\langle U_L(\mathbf{k})|U_L(\mathbf{k}')\rangle&=(2\pi)^3k\,\delta(\mathbf{k}-\mathbf{k}'),\\ \langle U_R(\mathbf{k})|U_R(\mathbf{k}')\rangle&=-(2\pi)^3k\,\delta(\mathbf{k}-\mathbf{k}'),\\ \langle U_L(\mathbf{k})|U_R(\mathbf{k}')\rangle&=0.\end{aligned}\tag{31}$$

The relations (31) enable one to project out the positive/negative helicity states of momentum $\mathbf{k}$, and show that ρ integrated over all space is the amount of left minus right circularly polarized radiation.

B. The energy density *E*

As a consequence of Maxwell's equations (5)

$$\partial_t\left(\frac{1}{2}\mathbf{F}\cdot\mathbf{F}^*\right)+\boldsymbol{\nabla}\cdot\left(\frac{i}{2}\,\mathbf{F}\times\mathbf{F}^*\right)=0,$$

where $E=\frac{1}{2}\mathbf{F}\cdot\mathbf{F}^*\equiv\frac{1}{2}(\mathbf{E}^2+\mathbf{B}^2)$ is the usual energy density, and $(i/2)\mathbf{F}\times\mathbf{F}^*\equiv\mathbf{E}\times\mathbf{B}$ is the momentum density. To simplify $\mathbf{F}\cdot\mathbf{F}^*$ in terms of α,β, we note the following: that from (8) we can express $\mathbf{F}$ as[17]

$$\mathbf{F}=\boldsymbol{\nabla}_\uparrow\alpha+\boldsymbol{\nabla}_\downarrow\beta+\hat{\mathbf{x}}F_r\tag{32}$$

with F_r expressed in terms of α,β by (9), and the operators $\boldsymbol{\nabla}_\uparrow,\boldsymbol{\nabla}_\downarrow$ are defined as

$$\boldsymbol{\nabla}_\uparrow\equiv\tfrac{1}{2}(\boldsymbol{\nabla}-\hat{\mathbf{x}}\partial_r+i\hat{\mathbf{x}}\times\boldsymbol{\nabla}),\quad \boldsymbol{\nabla}_\downarrow=(\boldsymbol{\nabla}_\uparrow)^*\equiv\tfrac{1}{2}(\boldsymbol{\nabla}-\hat{\mathbf{x}}\partial_r-i\hat{\mathbf{x}}\times\boldsymbol{\nabla}).\tag{33}$$

These operators have the property that for any scalars χ,ζ

$$\begin{aligned}\boldsymbol{\nabla}_\uparrow\chi\cdot\boldsymbol{\nabla}_\uparrow\zeta=\boldsymbol{\nabla}_\downarrow\chi\cdot\boldsymbol{\nabla}_\downarrow\zeta=\hat{\mathbf{x}}\cdot\boldsymbol{\nabla}_\uparrow\chi=\hat{\mathbf{x}}\cdot\boldsymbol{\nabla}_\downarrow\chi=0,\\ \boldsymbol{\nabla}_\uparrow\chi\cdot\boldsymbol{\nabla}_\downarrow\zeta=\tfrac{1}{2}[(\hat{\mathbf{x}}\times\boldsymbol{\nabla}\chi)\cdot(\hat{\mathbf{x}}\times\boldsymbol{\nabla}\zeta)+i\hat{\mathbf{x}}\cdot(\boldsymbol{\nabla}\chi\times\boldsymbol{\nabla}\zeta)].\end{aligned}\tag{34}$$

Then substituting (32) into $(\mathbf{F}\cdot\mathbf{F}^*)$, and with the aid of (34), we find

$$\begin{aligned}2E=\mathbf{F}\cdot\mathbf{F}^*=[\boldsymbol{\nabla}_\uparrow\alpha+\boldsymbol{\nabla}_\downarrow\beta+\hat{\mathbf{x}}F_r]\cdot[\boldsymbol{\nabla}_\downarrow\alpha^*+\boldsymbol{\nabla}_\uparrow\beta^*+\hat{\mathbf{x}}F_r^*],\\ 2E=|\boldsymbol{\nabla}_\uparrow\alpha|^2+|\boldsymbol{\nabla}_\downarrow\beta|^2+|F_r|^2\end{aligned}\tag{35}$$

with F_r given by (9). We will further expand (35) as we shall see that E contains a divergence term, which can be removed such that the resulting energy E' is still conserved. Again using (34),

$$4E=|\hat{\mathbf{x}}\times\boldsymbol{\nabla}\alpha|^2+|\hat{\mathbf{x}}\times\boldsymbol{\nabla}\beta|^2+2|F_r|^2+i\hat{\mathbf{x}}\cdot[(\boldsymbol{\nabla}\alpha\times\boldsymbol{\nabla}\alpha^*)-(\boldsymbol{\nabla}\beta\times\boldsymbol{\nabla}\beta^*)],\tag{36}$$

and the last terms of (36) can be expressed as $i\boldsymbol{\nabla}\cdot[-\alpha(\hat{\mathbf{x}}\times\boldsymbol{\nabla}\alpha^*)+\beta(\hat{\mathbf{x}}\times\boldsymbol{\nabla}\beta^*)]$, so that the modified energy density E'

$$4E'=|\hat{\mathbf{x}}\times\boldsymbol{\nabla}\alpha|^2+|\hat{\mathbf{x}}\times\boldsymbol{\nabla}\beta|^2+2|F_r|^2\tag{37}$$

is also a conserved non-negative density, so is also a plausible candidate for the energy density.

IV. THE POTENTIALS $\{\alpha,\beta\}$ CORRESPONDING TO THE FIELD OF A CHARGED PARTICLE

First consider the static case, then the constraint $(\partial_r+\partial_t)\alpha=(\partial_r-\partial_t)\beta$ implies $\beta=\alpha$, then from (8) we obtain

$$\mathbf{F}_{\rm stc}=\boldsymbol{\nabla}\alpha_{\rm stc}$$

so that

$$\mathrm{Re}[\alpha]=-\Phi,\quad \mathrm{Im}[\alpha]=\Phi_m,$$

where Φ is the usual scalar potential, and Φ_m is the magnetic scalar potential. The potentials Φ,Φ_m for the electrostatic, magnetostatic fields are well known. The energy E' for the static field is $E'=\frac{1}{2}|\boldsymbol{\nabla}\alpha|^2$.

Magnetic monopole fields are also accomodated: the potential for a magnetic monopole at position $\mathbf{a}$ is just $\alpha=\beta=iq_m/|\mathbf{x}-\mathbf{a}|$. Note that if we use (11) to derive α from the radial field

$$F_r=q(r-\hat{\mathbf{x}}\cdot\mathbf{a})/|\mathbf{x}-\mathbf{a}|^3$$

of a charge at position $\mathbf{a}$, we obtain $\alpha=\int_0^r dr F_r=-(q/|\mathbf{x}-\mathbf{a}|)+(q/|\mathbf{a}|)$. For non-radiation fields, we can lose the constant of integration by instead obtaining α from F_r, so that (9) is satisfied, as follows:

$$\alpha(S)=\int_\infty^r dr\ F_r(S). \tag{38}$$

We will use (38) to determine the potentials $\{\alpha,\beta\}$ for a uniformly moving charge. The field of a charge passing through the origin in the x_1 direction is[18]

$$\mathbf{F}=\{x_1-vt,x_2-ivx_3,x_3+ivx_2\}\ \frac{q\gamma}{r'^{3/2}},\quad F_r=\frac{q\gamma(r-v\hat{x}_1t)}{r'^{3/2}}, \tag{39}$$

where $r'=[\gamma^2(x_1-vt)^2+x_2^2+x_3^2]^{1/2}$. Substituting $t=S+r$ into the expression for F_r,

$$F_r(S)=\frac{q\gamma(r-v\hat{x}_1S-v\hat{x}_1r)}{[\gamma^2(\hat{x}_1r-vS-vr)^2+(\hat{x}_2^2+\hat{x}_3^2)r^2]^{3/2}} \tag{40}$$

and integrating over r we obtain

$$\alpha=\left|{}^{r}_{\infty}-\frac{q\gamma[r(1-\hat{x}_1v)+S]}{S[\gamma^2(\hat{x}_1r-vS-vr)^2+(\hat{x}_2^2+\hat{x}_3^2)r^2]^{1/2}}\right|,$$
$$\alpha=-q\left(\frac{t'-r'}{t-r}\right)\frac{1}{r'}, \tag{41}$$

where $t'=\gamma(t-vx_1)$. This potential is non-singular except at the charge position, because when $t=r$, $r'=\gamma(r-vx_1)$, and $((t'-r')/(t-r))=\gamma$. The field $\mathbf{F}$ of (39) is an even field (which is only the case because the particle is passing through the origin), and so from (17)

$$\beta=-\bar{\alpha}=-q\left(\frac{t'+r'}{t+r}\right)\frac{1}{r'}.$$

V. OUTLOOK

We have calculated the potentials $\{\alpha,\beta\}$ corresponding to various fields: The simple relation (9) between the potentials and the radial field F_r makes the calculation of the potential from a given field quite straightforward, or one can solve the equations for the potentials from which one then calculates the field, as in Appendix A. Although $\{\alpha,\beta\}$ are scalars under rotations, they have complicated transformation properties under the Lorentz transformations—we will discuss these transformation properties elsewhere. (For the Lorentz transformation of the Debye potential ψ, also complicated, see the paper by Monroe.[19]) The stationary solutions for the potentials with time

dependence $e^{-ikt}(e^{+ikt})$ correspond to the left (right) circularly polarized waves: the orthogonality properties (31) suggest an alternative approach to second quantizing the electromagnetic field, which we hope to address in the future.

Under the duality transformation $(\mathbf{E}\rightarrow\mathbf{B},\mathbf{B}\rightarrow-\mathbf{E})$, or $\mathbf{F}\rightarrow i\mathbf{F}$, the transformation of the potentials is just $\{\alpha,\beta\}\rightarrow i\{\alpha,\beta\}$. The absence of any duality transformation for the usual potentials $A^{\mu}\equiv(\Phi,\mathbf{A})$ has been commented on recently by Witten.[20] On the other hand the interaction of a charged particle with the field is naturally described via the potentials A^{μ}, by replacing the free momentum p^{μ} with the gauge invariant $(p^{\mu}-eA^{\mu})$, whereas the role of the $\{\alpha,\beta\}$ potentials in gauge theory is not clear.

APPENDIX A: SOLUTIONS OF (13) IN PARABOLIC COORDINATES

We solve the equations for the potentials (13). The spherical solutions yield the multipole fields and here we discuss a few of the parabolic solutions. Defining λ,μ,ϕ such that λ,μ have the dimension of length[21,22]

$$x_1+ix_2=2\sqrt{\lambda\mu}e^{i\phi},\quad x_3=\lambda-\mu,\quad r=\lambda+\mu,$$

then[21,22]

$$\boldsymbol{\nabla}^2\equiv\frac{1}{\lambda+\mu}(\partial_\lambda\lambda\partial_\lambda+\partial_\mu\mu\partial_\mu)+\frac{1}{4\lambda\mu}\partial_\phi^2,$$

$$\boldsymbol{\nabla}^2-\partial_t^2+\frac{2}{r}\partial_t\equiv\frac{1}{\lambda+\mu}(\partial_\lambda\lambda\partial_\lambda+\partial_\mu\mu\partial_\mu+2\partial_t)+\frac{1}{4\lambda\mu}\partial_\phi^2-\partial_t^2$$

and with $\alpha=f(\lambda)g(\mu)e^{im\phi}e^{-ikt}$ then

$$\left[(\partial_\lambda\lambda\partial_\lambda+\partial_\mu\mu\partial_\mu-2ik)-\frac{m^2}{4\lambda}-\frac{m^2}{4\mu}+k^2\lambda+k^2\mu\right]f(\lambda)g(\mu)=0.$$

Inserting a separation constant $2ikc$, then

$$\left[\partial_\lambda\lambda\partial_\lambda-ik(1+2c)-\frac{m^2}{4\lambda}+k^2\lambda\right]f(\lambda)=0, \tag{A1}$$

$$\left[\partial_\mu\mu\partial_\mu-ik(1-2c)-\frac{m^2}{4\mu}+k^2\mu\right]g(\mu)=0. \tag{A2}$$

The solution of (A1) is $f(\lambda)=\lambda^{m/2}e^{-ik\lambda}{}_1F_1(1+m/2+c,m+1,2ik\lambda)$, where ${}_1F_1$ is the confluent hypergeometric function. So the solution for α is

$$\alpha=(\lambda\mu)^{m/2}e^{im\phi}e^{-ik(\lambda+\mu)}\ {}_1F_1(1+m/2+c,m+1,2ik\lambda)\,{}_1F_1(1+m/2-c,m+1,2ik\mu)e^{-ikt}. \tag{A3}$$

The confluent hypergeometric function reduces to a simpler expression for integer or half-integer values of c.

1. The case $m=0$, $c=0$

As ${}_1F_1(1,1,i\zeta)\equiv e^{i\zeta}$ we have

$$\alpha=e^{-ikt}e^{-ik(\lambda+\mu)}e^{2ik\lambda}e^{2ik\mu}=e^{-ikt}e^{ik(\lambda+\mu)}\equiv e^{ikr-ikt}$$

which potential substituted into (6a) yields a zero field.

2. The case $m=1$, $c=1/2$

Inserting these values of m,c into (A1), and using the identities ${}_1F_1(2,2,2i\zeta)\equiv e^{2i\zeta}$, ${}_1F_1(1,2,2i\zeta)\equiv(\sin\zeta/\zeta)e^{i\zeta}$, then

$$\alpha=\sqrt{\lambda\mu}e^{i\phi}e^{-ik(\lambda+\mu)}\ {}_1F_1(2,2,2ik\lambda)_1F_1(1,2,2ik\mu)e^{-ikt},$$

$$\alpha=\sqrt{\lambda\mu}e^{i\phi}e^{-ik(\lambda+\mu)}e^{2ik\lambda}\ \frac{\sin(k\mu)}{k\mu}e^{ik\mu}e^{-ikt},$$

$$\alpha=\sqrt{\lambda\mu}e^{i\phi}e^{ik\lambda}\ \frac{\sin(k\mu)}{k\mu}\ e^{-ikt},$$

which is the α_L of (19).

3. The case $m=1$, $c=0$

Substituting these values for m,c, into (A3) we have

$$\alpha_Z=\sqrt{\lambda\mu}e^{im\phi}e^{-ik(\lambda+\mu)}\ {}_1F_1(3/2,2,2ik\lambda)_1F_1(3/2,2,2ik\mu)e^{-ikt}.$$

As ${}_1F_1(3/2,2,2i\zeta)\equiv[J_0(\zeta)+iJ_1(\zeta)]e^{i\zeta}$, where J_0,J_1 are the Bessel functions of order zero and one, we have

$$\alpha_Z=\sqrt{\lambda\mu}e^{i\phi}[(J_0+iJ_1)(k\lambda)][(J_0+iJ_1)(k\mu)]e^{-ikt}, \tag{A4}$$

where we have written $(J_0+iJ_1)(k\lambda)$ as shorthand for $J_0(k\lambda)+iJ_1(k\lambda)$. For large λ, $\sqrt{\lambda}(J_0+iJ_1)(k\lambda)\simeq\sqrt{2/\pi k}e^{ik\lambda-\pi/4}$, so that α_Z is everywhere bounded. The potential β_Z such that the constraint (9) is satisfied is

$$\beta_Z=\sqrt{\lambda\mu}e^{i\phi}[(J_0-iJ_1)(k\lambda)][(J_0-iJ_1)(k\mu)]e^{-ikt}. \tag{A5}$$

We can determine the corresponding Debye potential ψ_Z, such that $i(\partial_r r\psi_Z-\partial_t r\psi_Z)=\alpha_Z$

$$\psi_Z=\frac{1}{ik}\left(\frac{\sqrt{\lambda\mu}}{\lambda+\mu}\right)e^{i\phi}[J_0(k\lambda)J_1(k\mu)+J_1(k\lambda)J_0(k\mu)]. \tag{A6}$$

The field $\mathbf{F}_Z$ may be calculated by substituting (A4), (A5) into (8), or (A6) into (3). After some labor one obtains the components of $\mathbf{F}_Z$

$$2\begin{bmatrix}F_1\\F_2\\F_3\end{bmatrix}_Z=\frac{e^{-ikt}}{(\lambda+\mu)}\left[\begin{pmatrix}\lambda[(J_0+iJ_1)(k\lambda)J_0(k\mu)]+\mu[J_0(k\lambda)(J_0-iJ_1)(k\mu)]\\ i\lambda[(J_0+iJ_1)(k\lambda)J_0(k\mu)]+i\mu[J_0(k\lambda)(J_0-iJ_1)(k\mu)]\\ -2i\sqrt{\lambda\mu}e^{i\phi}[J_0(k\lambda)J_1(k\mu)+J_1(k\lambda)J_0(k\mu)]\end{pmatrix}\right.$$
$$\left.+e^{2i\phi}\begin{pmatrix}-i\mu[J_1(k\lambda)(J_0+iJ_1)(k\mu)]+i\lambda[(J_0-iJ_1)(k\lambda)J_1(k\mu)]\\ -\mu[J_1(k\lambda)(J_0+iJ_1)(k\mu)]+\lambda[(J_0-iJ_1)(k\lambda)]J_1(k\mu)\\ 0\end{pmatrix}\right]. \tag{A7}$$

It is interesting to see the behavior of this field $\mathbf{F}_Z$ along the x_3 axis. For the positive x_3 axis $\mu=0$ and $\lambda=x_3$, and the field is just

$$2(\mathbf{F}_Z)_{\mu=0}=e^{-ikt}\begin{pmatrix}(J_0+iJ_1)(kx_3)\\ i(J_0+iJ_1)(kx_3)\\ 0\end{pmatrix}\xrightarrow{kx_3\gg1}e^{-i\pi/4}\sqrt{\frac{2}{\pi|x_3|}}\begin{pmatrix}1\\ i\\ 0\end{pmatrix}e^{ikx_3-ikt}. \tag{A8}$$

For the negative x_3 axis $\lambda=0$ and $\mu=-x_3$, and we obtain the same expression (A8) for the field along the negative x_3 axis. Along the x_3 axis the field $\mathbf{F}_Z$ appears as a right-circularly polarized plane wave propagating in the $+x_3$ direction, with amplitude decaying by $|x_3|^{-1/2}$ from the origin. Away from the x_3 axis the field decays more rapidly: the x_1,x_2 plane through the origin is parametrized by $\lambda=\mu=\sqrt{x_1^2+x_2^2}/2$, then substituting $\lambda=\mu=\rho$ into (A7) one finds that the field decays by ρ^{-1} from the origin. Thus the field $\mathbf{F}_Z$ is highly directional along the axis of propagation.

When $m=1$, $c>1/2$, the resulting field becomes infinite at spatial infinity.

APPENDIX B: ORTHONORMALITY OF THE BASIS FUNCTIONS $\boldsymbol{U}(\mathbf{k})$

First we will consider the orthogonality of two left-circularly polarized waves, $U_L(\mathbf{k})$, $U_L(\mathbf{k}')$. Due to the fact that the $U_L(\mathbf{k}), U_L(\mathbf{k}')$ are eigenstates of the angular momentum in the direction of propagation $\mathbf{k}$ or $\mathbf{k}'$, and the $\mathbf{L}$ operator is Hermitian, then

$$\langle U_L(\mathbf{k})|U_L(\mathbf{k}')\rangle = 0 \quad \text{when } \hat{\mathbf{k}} \neq \hat{\mathbf{k}}'.$$

So we need only consider the case when the waves are propagating in the same direction but with different frequencies, i.e., when $\mathbf{k}=\{0,0,k\}$ and $\mathbf{k}'=\{0,0,k'\}$. Then recalling the U_L of (19) we have the inner product

$$\begin{aligned}
&\langle U_L(\mathbf{k})|U_L(\mathbf{k}')\rangle \\
&= -\frac{1}{4}\int d^3x\left[\left(-\left(\frac{\hat{x}_1+i\hat{x}_2}{1-\hat{x}_3}\right)[e^{ikx_3}-e^{ikr}]-\left(\frac{\hat{x}_1+i\hat{x}_2}{1+\hat{x}_3}\right)[e^{ikx_3}-e^{-ikr}]\right)(k'(\hat{x}_1-i\hat{x}_2)e^{-ikx_3})\right. \\
&\quad \left.+\left(-\left(\frac{\hat{x}_1-i\hat{x}_2}{1-\hat{x}_3}\right)[e^{-ik'x_3}-e^{-ik'r}]-\left(\frac{\hat{x}_1-i\hat{x}_2}{1-\hat{x}_3}\right)[e^{-ik'x_3}-e^{ik'r}]\right)(k(\hat{x}_1+i\hat{x}_2)e^{ikx_3})\right. \\
&= \frac{1}{4}\int d^3x[k'((1+\hat{x}_3)[e^{i(k-k')x_3}-e^{i(kr-k'x_3)}]+(1-\hat{x}_3)[e^{i(k-k')x_3}-e^{-ikr-ik'x_3}]) \\
&\quad +k((1+\hat{x}_3)[e^{i(k-k')x_3}-e^{-i(k'r-kx_3)}]+(1-\hat{x}_3)[e^{i(k-k')x_3}-e^{i(k'r+ikx_3)}])] \\
&= \frac{1}{4}\int d^3x[2(k+k')e^{i(k-k')x_3}-(1+\hat{x}_3)[k'e^{i(kr-k'x_3)}+ke^{-i(k'r-kx_3)}] \\
&\quad -(1-\hat{x}_3)[k'e^{-ikr-ik'x_3}+ke^{i(k'r+ikx_3)}]].
\end{aligned}$$

The first term yields the delta function $(2\pi)^3 k\,\delta(\mathbf{k}-\mathbf{k}')$. We go over to spherical coordinates to evaluate the remaining terms, putting $\hat{x}_3=\cos\theta=\nu$, the rest of the integral is

$$\begin{aligned}
&-\frac{2\pi}{4}\int_0^\infty r^2dr\int_{-1}^1 d\nu((1+\nu)[k'e^{ir(k-k'\nu)}+ke^{-ir(k'-k\nu)}]+(1-\nu)[k'e^{-ir(k+k'\nu)}+ke^{ir(k'+k\nu)}]) \\
&= -\frac{4\pi}{4}\int_0^\infty r^2dr\int_{-1}^1 d\nu((1+\nu)[k'\cos(r(k-k'\nu))+k\cos(r(k'-k\nu))]) \\
&= -\frac{4\pi}{4}\int_0^\infty r^2dr(\partial_k-\partial_{k'})\int_{-1}^1 d\nu\left(\frac{1}{r}[k'\sin(r(k-k'\nu))-k\sin(r(k'-k\nu))]\right) \\
&= -\frac{4\pi}{4}\int_0^\infty r^2dr(\partial_k-\partial_{k'})\left|\int_{-1}^1 \frac{1}{r^2}[\cos(r(k-k'\nu))-\cos(r(k'-k\nu))]\right| = 0,
\end{aligned}$$

so that finally

$$\langle U_L(\mathbf{k})|U_L(\mathbf{k}')\rangle = (2\pi)^3 k\,\delta(\mathbf{k}-\mathbf{k}')$$

with $k\equiv|\mathbf{k}|$. The other identities of (31) follow similarly.

(Received 20 October 1997; accepted for publication 28 January 1998)

The usual formulation of time-dependent mechanics implies a given splitting $Y=\mathbf{R}\times M$ of an event space Y. This splitting, however, is broken by any time-dependent transformation, including transformations between inertial frames. The goal is the frame-covariant formulation of time-dependent mechanics on a bundle $Y\to\mathbf{R}$, whose fibration $Y\to M$ is not fixed. Its phase space is the vertical cotangent bundle V^*Y, provided with the canonical 3-form and the corresponding canonical Poisson structure. An event space of relativistic mechanics is a manifold Z whose fibration $Z\to\mathbf{R}$ is not fixed. © *1998 American Institute of Physics.*

I. INTRODUCTION

The symplectic technique is well known to provide an adequate mathematical formulation of autonomous mechanics, when Hamiltonians are independent of time.[1–4] Its canonical example is a mechanical system whose phase space is the cotangent bundle T^*M of an event manifold M. This phase space is provided with the canonical symplectic form

$$\Omega=dp_i\wedge dy^i,$$

written with respect to the holonomic coordinates $(y^i,\ p_i=\dot q_i)$ on T^*M. A Hamiltonian $\mathscr{H}$ is defined as a real function on T^*M. The motion trajectories are integral curves of the Hamiltonian vector field $\vartheta=\vartheta_i\partial^i+\vartheta^i\partial_i$ on T^*M, which obeys the Hamilton equations

$$\begin{gathered}\vartheta\rfloor\Omega=d\mathscr{H},\\ \vartheta^i=\partial^i\mathscr{H},\quad \vartheta_i=-\partial_i\mathscr{H}.\end{gathered}\tag{1}$$

The usual formulation of time-dependent mechanics implies a splitting $Y=\mathbf{R}\times M$ of the event manifold Y and the corresponding splitting $\mathbf{R}\times T^*M$ of the phase space.[5–10] The phase space is provided with the pull-back $\mathrm{pr}_2^*\Omega$ of the symplectic form on T^*M. By a time-dependent Hamiltonian is meant a real function on $\mathbf{R}\times T^*M$, while motion trajectories are integral curves of the time-dependent Hamiltonian vector field,

$$\vartheta:\mathbf{R}\times T^*M\to TT^*M,$$

which obeys the Hamilton equations (1). The problem is that the above-mentioned splittings are broken by any time-dependent transformation, including the inertial frame transformations. Therefore, the form $\mathrm{pr}_2^*\Omega$ on the phase space of time-dependent mechanics fails to be canonical.[11]

We will formulate first-order time-dependent mechanics as a particular field theory, when an event space is a fibered manifold $Y\to\mathbf{R}$, coordinated by (t,y^i).[5,12–14] Unless otherwise stated, the base $\mathbf{R}$ is parametrized by the coordinates t with transition functions $t'=t+\text{const}$. Relative to these coordinates, $\mathbf{R}$ is equipped with the standard vector field ∂_t and the standard 1-form dt, which is also the volume element on $\mathbf{R}$. This is not the case for relativistic mechanics.

The configuration space of time-dependent mechanics is the first-order jet manifold J^1Y of sections of $Y\to\mathbf{R}$, which is provided with the adapted coordinates (t,y^i,y^i_t). There is the canonical monomorphism,

$$\lambda:J^1Y\hookrightarrow TY,\quad \lambda=\partial_t+y^i_t\partial_i,$$

 © 1998 American Institute of Physics

over Y. It is easy to see that $\pi^1_0: J^1Y \to Y$ is an affine bundle modeled over the vertical tangent bundle $VY \to Y$. For the sake of simplicity, we will identify J^1Y with the corresponding subbundle of TY. In particular, every connection on a bundle $Y \to \mathbf{R}$ can be identified with the horizontal lift,

$$\Gamma: Y \to J^1Y \subset TY, \quad \Gamma = \partial_t + \Gamma^i \partial_i, \tag{2}$$

of the standard vector field ∂_t by this connection. We will call (2) a connection in order to refer to the standard properties of connections without an additional explanation.

The one-dimensional reduction of the polysymplectic Hamiltonian formalism[13–16] provides the adequate mathematical formulation of time-dependent Hamiltonian mechanics on the Legendre bundle $\pi_\Pi: \Pi = V^*Y \to Y$. The phase space V^*Y is endowed with the canonical 3-form,

$$\mathbf{\Omega} = dp_i \wedge dy^i \wedge dt, \tag{3}$$

written with respect to the holonomic coordinates $(t, y^i, p_i = \dot{y}_i)$ on V^*Y.

The following peculiarities of time-dependent Hamiltonian mechanics should be emphasized.

(i) The form $\mathbf{\Omega}$ (3) defines the canonical degenerate Poisson structure on the phase space V^*Y.

(ii) A Hamiltonian is not a function on a phase space. As a consequence, the evolution equation is not reduced to a Poisson bracket, and integrals of motion cannot be defined as functions in involution with a Hamiltonian.

(iii) Hamiltonian and Lagrangian formulations of time-dependent mechanics are equivalent in the case of hyperregular Lagrangians. A degenerate Lagrangian requires a set of associated Hamiltonians and Hamilton equations in order to exhaust all solutions of the Lagrange ones.

(iv) A complete connection Γ on the event space $Y \to \mathbf{R}$ defines a reference frame so that one can think of the difference $y^i_t - \Gamma^i(y)$ as being the velocity relative to the reference frame Γ. There is one-to-one correspondence between the complete connections Γ and the trivializations of $Y \to \mathbf{R}$.

For the sake of simplicity, $Y \to \mathbf{R}$ is assumed to be a bundle with a typical fiber M. It is trivial. Different trivializations,

$$Y \cong \mathbf{R} \times M, \tag{4}$$

differ from each other in fibrations $Y \to M$, while the fibration $\pi: Y \to \mathbf{R}$ is once for all. Given a trivialization (4), there are the corresponding splittings of the configuration and phase spaces,

$$J^1Y \cong \mathbf{R} \times TM, \quad V^*Y \cong \mathbf{R} \times T^*M.$$

If a fibration $Z \to \mathbf{R}$ of an event space Z is not fixed, we obtain the general formulation of relativistic mechanics, including Special Relativity on the Minkowski space $Z = \mathbf{R}^4$. Its configuration space is the first-order jet manifold $J^1_1 Z$ of one-dimensional submanifolds of Z. The bundle $J^1_1 Z \to Z$ is projective, and one can think on its fibers as being spaces of nonrelativistic velocities. Relativistic velocities are represented by elements of the tangent bundle TZ, while the cotangent bundle T^*Z plays the role of the phase space of relativistic mechanics.

All manifolds throughout are assumed to be paracompact and connected.

II. CANONICAL POISSON STRUCTURE

The Legendre bundle V^*Y of time-dependent mechanics is provided with the canonical Poisson structure as follows. Let us consider the cotangent bundle T^*Y with the holonomic coordinates (t, y^i, p, p_i), which is the homogeneous Legendre bundle of time-dependent mechanics. It admits the canonical Liouville form

$$\Xi = p\,dt + p_i dy^i, \tag{5}$$

and the canonical symplectic form

$$d\Xi = dp \wedge dt + dp_i \wedge dy^i.$$

The corresponding Poisson bracket on the space $C^\infty(T^*Y)$ of functions on T^*Y reads as

$$\{f,g\}=\partial^p f\partial_t g-\partial^p g\partial_t f+\partial^i f\partial_i g-\partial^i g\partial_i f. \tag{6}$$

Let us consider the subspace of $C^\infty(T^*Y)$ that comprises the pull-backs of functions on V^*Y by the projection $T^*Y\to V^*Y$. This subspace is closed under the Poisson bracket (6). Then there exists the canonical Poisson structure,

$$\{f,g\}_V=\partial^i f\partial_i g-\partial^i g\partial_i f, \tag{7}$$

on V^*Y induced by (6).[3] The corresponding Poisson bivector,

$$w(df,dg)=\{f,g\}_V,$$

on V^*Y is vertical with respect to the fibration $V^*Y\to\mathbf{R}$, and reads as

$$w^{ij}=0,\quad w_{ij}=0,\quad w^i_j=1.$$

A glance at this expression shows that the holonomic coordinates on V^*Y are canonical for the Poisson structure (7), which is regular and degenerate.

Given the Poisson bracket (7), the Hamiltonian vector field ϑ_f of a function f on V^*Y, defined by the relation $\{f,g\}_V=\vartheta_f\rfloor dg$, $\forall g\in C^\infty(V^*Y)$, is the vertical vector field

$$\vartheta_f=\partial^i f\partial_i-\partial_i f\partial^i, \tag{8}$$

on $V^*Y\to\mathbf{R}$. Hence, the characteristic distribution of the Poisson structure (7), generated by Hamiltonian vector fields, is precisely the vertical tangent bundle VV^*Y of $V^*Y\to\mathbf{R}$.

By virtue of the well-known theorem,[4] the Poisson structure (7) defines the symplectic foliation on V^*Y that coincides with the fibration $V^*Y\to\mathbf{R}$. The symplectic forms on the fibers of $V^*Y\to\mathbf{R}$ are the pull-backs,

$$\Omega_t=dp_i\wedge dy^i,$$

of the canonical symplectic form on the typical fiber T^*M of $V^*Y\to\mathbf{R}$ with respect to trivialization morphisms.[11]

The Poisson structure (7) can be introduced in a different way. The Legendre bundle V^*Y admits the canonical closed 3-form (3), which is the particular case of the polysymplectic form.[14–16] Then every function f on V^*Y defines the corresponding Hamiltonian vector field ϑ_f (8) by the relation

$$\vartheta_f\rfloor\mathbf{\Omega}=-df\wedge dt,$$

while the Poisson bracket (7) is recovered by the condition

$$\{f,g\}_V dt=\vartheta_g\rfloor\vartheta_f\rfloor\mathbf{\Omega}.$$

III. HAMILTONIAN FORMS

In comparison with autonomous mechanics, Hamiltonian time-dependent mechanics is formulated in the terms of Hamiltonian connections and Hamiltonian forms.

We will say that a connection,

$$\gamma=\partial_t+\gamma^i\partial_i+\gamma_i\partial^i, \tag{9}$$

on the phase space $V^*Y\to\mathbf{R}$ is locally Hamiltonian if the exterior form $\gamma\rfloor\mathbf{\Omega}$ is closed, i.e.,

$$\mathbf{L}_\gamma\mathbf{\Omega}=d(\gamma\rfloor\mathbf{\Omega})=0, \tag{10}$$

where $\mathbf{L}$ denotes the Lie derivative.

For instance, every connection Γ on the event space $Y\to\mathbf{R}$ gives rise to the locally Hamiltonian connection,

$$\widetilde{\Gamma}=\partial_t+\Gamma^i\partial_i-p_i\partial_j\Gamma^i\partial^j,$$

on the phase space, such that

$$\widetilde{\Gamma}\rfloor\mathbf{\Omega}=dH_\Gamma,\quad H_\Gamma=p_i dy^i-p_i\Gamma^i dt. \tag{11}$$

Locally Hamiltonian connections constitute an affine space modeled over the linear space of vertical vector fields ϑ on $V^*Y\to\mathbf{R}$ that obey the same condition (10), and are locally Hamiltonian vector fields as follows.

Lemma 1: Every closed form $\gamma\rfloor\mathbf{\Omega}$ on $V^*Y\to\mathbf{R}$ is exact.

Proof: Let us consider the decomposition

$$\gamma=\widetilde{\Gamma}+\vartheta, \tag{12}$$

where Γ is a connection on $Y\to\mathbf{R}$, while ϑ satisfies the relation $d(\partial\rfloor\mathbf{\Omega})=0$. It is easily seen that $\vartheta\rfloor\mathbf{\Omega}=\sigma\wedge dt$, where σ is a 1-form. Using properties of the De Rham cohomology groups of a manifold product, one can show that every closed 2-form $\sigma\wedge dt$ on V^*Y is exact, and so is $\gamma\rfloor\mathbf{\Omega}$. Moreover, in accordance with the relative Poincaré lemma, we can write locally $\vartheta\rfloor\mathbf{\Omega}=df\wedge dt$.

Definition 2: A 1-form H on the Legendre bundle V^*Y is called locally Hamiltonian if

$$\gamma\rfloor\mathbf{\Omega}=dH,$$

for a connection γ on $V^*Y\to\mathbf{R}$.

By virtue of Proposition 1, there is one-to-one correspondence between the locally Hamiltonian connections and the locally Hamiltonian forms considered throughout modulo closed forms.

Definition 3: By a Hamiltonian form H on the phase space V^*Y is meant the pull-back,

$$H=h^*\Xi=p_i dy^i-\mathscr{H}dt, \tag{13}$$

of the Liouville form Ξ (5) on T^*Y by a section h of the bundle

$$\zeta: T^*Y\to V^*Y. \tag{14}$$

Given a trivialization (4) of $Y\to\mathbf{R}$ the Hamiltonian form (13) looks like the well-known Poincaré–Cartan integral.[2] However, the Hamiltonian $\mathscr{H}$ in the expression (13) is not a function as follows. Any connection Γ on $Y\to\mathbf{R}$ defines the Hamiltonian form H_Γ (11) on V^*Y, and every Hamiltonian form on V^*Y admits the splitting

$$H=p_i dy^i-(p_i\Gamma^i+\widetilde{\mathscr{H}}_\Gamma)dt, \tag{15}$$

where Γ is a connection on $Y\to\mathbf{R}$ and $\widetilde{\mathscr{H}}_\Gamma$ is a real function on V^*Y, called the Hamiltonian function.

Proposition 4: Locally Hamiltonian forms are Hamiltonian forms locally.

Proof: Given locally Hamiltonian forms H_γ and $H_{\gamma'}$, their difference,

$$\sigma=H_\gamma-H_{\gamma'},\quad d\sigma=(\gamma-\gamma')\rfloor\mathbf{\Omega},$$

is a 1-form on V^*Y such that the 2-form $\sigma\wedge dt$ is closed and, consequently, exact. In accordance with the relative Poincaré lemma, this condition implies that $\sigma=f dt+dg$, where f and g are local functions on V^*Y. Then it follows from the splitting (12) that, in a neighborhood of every point $p\in V^*Y$, a locally Hamiltonian form H_γ coincides with the pull-back of the Liouville form Ξ on T^*Y by the local section

$$(t,y^i,p_i)\mapsto(t,y^i,p_i,p=-p_i\Gamma^i+f\ )$$

of $T^*Y\to V^*Y$, where f is a local function on V^*Y.

Proposition 5: Conversely, let H be a Hamiltonian form H on the Legendre bundle V^*Y. There exists a unique connection γ_H on $V^*Y\to\mathbf{R}$, called the Hamiltonian connection, such that $\gamma_H\rfloor\mathbf{\Omega}=dH$.

Proof: Let us introduce the Hamilton operator,

$$\mathscr{E}_H=dH-\lambda\rfloor\mathbf{\Omega}=[(y^i_t-\partial^i\cdot\mathscr{H})dp_i-(p_{ti}+\partial_i\cdot\mathscr{H})dy^i]\wedge dt,$$

on the phase space V^*Y. It is readily observed that this operator is an image of the global section,

$$\gamma_H=\partial_t+\partial^i\cdot\mathscr{H}\partial_i-\partial_i\cdot\mathscr{H}\partial^i, \tag{16}$$

of the jet bundle $J^1V^*Y\to V^*Y$. This is the unique solution of the first-order differential Hamilton equations,

$$y^i_t=\partial^i\cdot\mathscr{H},\quad p_{ti}=-\partial_i\cdot\mathscr{H}, \tag{17}$$

on V^*Y, and is a Hamiltonian connection for the Hamiltonian form H.

The integral curves of the Hamiltonian connection (16) are classical solutions of the Hamilton equations (17). Conversely, since $r(\mathbf{R})\subset V^*Y$ is closed, every classical solution $r:\mathbf{R}\to V^*Y$ of the Hamilton equations (17) can be extended to a unique Hamiltonian connection for H.

Hamiltonian connections γ_H (16) form an affine space modeled over the linear space of Hamiltonian vector fields (8).

Remark: The Hamilton equations (17) can be introduced without appealing to the Hamilton operator. They are equivalent to the relation

$$r^*(u\rfloor dH)=0,$$

which is assumed to hold for any vertical vector field u on $V^*Y\to\mathbf{R}$.

With a Hamiltonian form H (15) and the corresponding Hamiltonian connection γ_H (16), we have the Hamilton evolution equation,

$$d_{Ht}f=\gamma_H\rfloor df=(\partial_t+\partial^i\cdot\mathscr{H}\partial_i-\partial_i\cdot\mathscr{H}\partial^i)f, \tag{18}$$

on functions on the Legendre bundle V^*Y. Substituting a classical solution of the Hamilton equations (17) in (18), we obtain the time evolution of the function f. Given the splitting (15) of a Hamiltonian form H, the Hamilton evolution equation (18) is brought into the form

$$d_{Ht}f=\partial_t f+(\Gamma^i\partial_i-\partial_i\Gamma^j p_j\partial^i)f+\{\widetilde{\mathscr{H}}_\Gamma,f\}_V. \tag{19}$$

A glance at this expression shows that the Hamilton evolution equation in time-dependent mechanics does not reduce to the Poisson bracket. This fact may be relevant to the quantization problem. Under quantization, the Poisson bracket on the right-hand side of the equation (19) becomes the operator one, while the second term remains classical and depends on the choice of a reference frame.

IV. CANONICAL TRANSFORMATIONS

Canonical transformations in time-dependent mechanics are not compatible with the fibration $V^*Y\to Y$, in general.

Definition 6: By a canonical automorphism is meant an automorphism ρ over $\mathbf{R}$ of the bundle $V^*Y\to\mathbf{R}$ that preserves the canonical Poisson structure (7) on V^*Y, i.e.,

$$\{f\circ\rho,g\circ\rho\}_V=\{f,g\}_V\circ\rho,$$

and, equivalently, the canonical form $\mathbf{\Omega}$ (3) on V^*Y, i.e., $\mathbf{\Omega}=\rho^*\mathbf{\Omega}$.

The bundle coordinates on $V^*Y\to\mathbf{R}$ are called canonical if they are canonical for the Poisson structure (7). Canonical coordinate transformations satisfy the relations

$$\frac{\partial p'_i}{\partial p_j}\frac{\partial y'^i}{\partial p_k}-\frac{\partial p'_i}{\partial p_k}\frac{\partial y'^i}{\partial p_j}=0, \quad \frac{\partial p'_i}{\partial y^j}\frac{\partial y'^i}{\partial y^k}-\frac{\partial p'_i}{\partial y^k}\frac{\partial y'^i}{\partial y^j}=0, \quad \frac{\partial p'_i}{\partial p_k}\frac{\partial y'^i}{\partial y^j}-\frac{\partial p'_i}{\partial y^j}\frac{\partial y'^i}{\partial p_k}=\delta^k_j.$$

By definition, the holonomic coordinates on V^*Y are the canonical ones. Accordingly, holonomic automorphisms,

$$(y^i,p_i)\mapsto\left(y'^i,p'_i=\frac{\partial y^j}{\partial y'^i}\,p_j\right)$$

of the phase space $V^*Y\to Y$ induced by the vertical automorphisms of $Y\to\mathbf{R}$ are also canonical.

Proposition 7: Canonical automorphisms send locally Hamiltonian connections onto the locally Hamiltonian ones (and, consequently, locally Hamiltonian forms onto each other).

Proof: If γ is a locally Hamiltonian connection for H, we have

$$T\rho(\gamma)\rfloor\mathbf{\Omega}=(\rho^{-1})^*(\gamma\rfloor\mathbf{\Omega})=d((\rho^{-1})^*H).$$

It should be emphasized that, in general, canonical automorphisms do not send Hamiltonian forms onto Hamiltonian forms, but only locally.

Proposition 8: Let γ be a complete locally Hamiltonian connection on $V^*Y\to\mathbf{R}$, i.e., the vector field (9) is complete. There exist canonical coordinate transformations that bring all components of γ to zero, i.e., $\gamma=\partial_t$.

Proof: A glance at the relation (10) shows that each locally Hamiltonian connection γ is the generator of a local one-parameter group G_γ of canonical automorphisms of the phase space $V^*Y\to\mathbf{R}$. Let V^*_0Y be the fiber of $V^*Y\to\mathbf{R}$ at $0\in\mathbf{R}$. Then canonical coordinates of V^*_0Y dragged along integral curves of the complete vector field γ satisfy the statement of the proposition.

In particular, let H be a Hamiltonian form (15) such that the corresponding Hamiltonian connection γ_H (16) is complete. By virtue of Proposition 8, there exist canonical coordinate transformations that bring the Hamiltonian $\mathscr{H}$ into zero. Then the corresponding Hamilton equations reduce to the equilibrium ones. Accordingly, any Hamiltonian for H can be locally brought into the form where $\mathscr{H}=0$ by local canonical coordinate transformations.

Every canonical transformation admits a local generating function as follows. Let H be a Hamiltonian form (13) on V^*Y. Given a canonical automorphism ρ, we have

$$d(\rho^*H-H)=0,$$

$$\rho^*H-H=dS,$$

where S is a local function on V^*Y. We can write locally

$$\rho^*H=\rho_i d\rho^i-\mathscr{H}\circ\rho dt.$$

Then the corresponding coordinate relations read as

$$\partial_i S=\rho_j\partial_i\rho^j-p_i, \quad \partial^i S=\rho_j\partial^i\rho^j, \quad \mathscr{H}'-\mathscr{H}=\rho_i\partial_t\rho^i-\partial_t S.$$

Taken on the graph,

$$\Delta_\rho=\{(p,\rho(p))\in V^*Y\times V^*Y\},$$

of the canonical automorphism, the function S plays the role of a local generating function. For instance, if the graph Δ_ρ is coordinated by (t,y^i,y'^i), we obtain the familiar expression $\mathscr{H}'-\mathscr{H}=\partial_t S(t,y^i,y'^i)$.

V. REFERENCE FRAMES

Every connection Γ on the bundle $\pi:Y\to\mathbf{R}$ defines a horizontal foliation on $Y\to\mathbf{R}$ whose leaves are the integral curves of the nowhere vanishing vector field (2). Conversely, let Y admit a horizontal foliation such that, for each point $y\in Y$, the leaf of this foliation through y is locally determined by a section s_y of $V^*Y\to\mathbf{R}$ through y. Then, the map

$$\Gamma: Y \to J^1Y, \quad \Gamma(y) = j^1_t s_y, \quad \pi(y) = t,$$

is well defined. This is a connection on $Y \to \mathbf{R}$.

Given a horizontal foliation on Y, there exists the associated atlas of constant local trivializations of Y such that every leaf of this foliation is locally generated by the equations $y^i = \text{const}$, and the transition functions $y^i \to y'^i(y^j)$ are independent of the coordinate t.[16,17] Two such atlases are said to be equivalent if their union is also an atlas of constant local trivializations. They are associated with the same horizontal foliation. Thus, we have proved the following assertion.

Proposition 9: There is one-to-one correspondence between the connections Γ on $Y \to \mathbf{R}$ and the equivalence classes of atlases of constant local trivializations of Y such that $\Gamma^i = 0$ relative to the associated coordinates, called adapted to Γ.

Proposition 10: Every trivialization of $Y \to \mathbf{R}$ yields a complete connection on this bundle. Conversely, every complete connection on $Y \to \mathbf{R}$ defines a trivialization $Y \cong \mathbf{R} \times M$ such that the associated coordinates are adapted to Γ.

Proof: Every trivialization of $Y \to \mathbf{R}$ defines the horizontal lift $\Gamma = \partial_t$ onto Y of the standard field ∂_t on $\mathbf{R}$, which is obviously a complete connection on $Y \to \mathbf{R}$. Conversely, let Γ be a complete connection on $Y \to \mathbf{R}$. This is the generator of the one-parameter group G_Γ that acts freely on Y. The orbits of this action are, of course, the integral curves of Γ. Hence, we obtain a projection,

$$\pi_\Gamma : Y \to Y/G_\Gamma = M.$$

This projection together with $\pi: Y \to \mathbf{R}$ defines a trivialization of Y.

One can say that a complete connection Γ on an event space $Y \to \mathbf{R}$ describes a reference frame in time-dependent mechanics. Given a reference frame Γ, we have the corresponding covariant differential,

$$D_\Gamma: \ J^1Y \to VY, \quad (t, y^i, y^i_t) \mapsto (t, y^i, \dot{y}^i = y^i_t - \Gamma^i).$$

Let s be a (local) section of $Y \to \mathbf{R}$. One can think of $D_\Gamma \circ J^1 s$ as being the relative velocity of the motion s with respect to the reference frame Γ. Indeed, $D_\Gamma \circ J^1 s$ vanishes identically iff s is an integral curve of Γ.

Let us consider the Hamilton evolution equation (19). For any connection Γ in the splitting (19), there exist holonomic canonical transformations of V^*Y to the coordinates adapted to Γ that bring (19) into the familiar Poisson bracket form,

$$d_{Ht} f = \partial_t f + \{\widetilde{\mathscr{H}}, f\}_V.$$

VI. LAGRANGIAN POISSON STRUCTURE

In contrast with the Legendre bundle V^*Y, the configuration space J^1Y of time-dependent mechanics does not possess any canonical Poisson structure, in general. A Poisson structure on J^1Y depends on the choice of a Lagrangian,

$$L = \mathscr{L} dt, \quad \mathscr{L}: \ J^1Y \to \mathbf{R}. \tag{20}$$

We will use the notation $\pi_i = \partial^t_i \mathscr{L}$, $\pi_{ij} = \partial^t_i \partial^t_j \mathscr{L}$.

Every Lagrangian L (20) defines the Legendre map,

$$\hat{L}: J^1Y \to V^*Y, \quad p_i \circ \hat{L} = \pi_i. \tag{21}$$

The pull-back on J^1Y of the canonical 3-form $\mathbf{\Omega}$ (3) by the Legendre map $\hat{L}$ (21) reads as

$$\mathbf{\Omega}_L = \hat{L}^* \mathbf{\Omega} = d\pi_i \wedge dy^i \wedge dt.$$

By means of $\mathbf{\Omega}_L$, every vertical vector field $\vartheta = \vartheta^i \partial_i + \dot{\vartheta}^i \partial^t_i$ on $J^1Y \to \mathbf{R}$ yields the 2-form

$$\vartheta \rfloor \mathbf{\Omega}_L = \{[\dot{\vartheta}^j \pi_{ji} + \vartheta^j (\partial_j \pi_i - \partial_i \pi_j)] dy^i - \vartheta^i \pi_{ji} dy^j_t\} \wedge dt.$$

This is one-to-one correspondence, if the Lagrangian L is regular. Indeed, given any 2-form $\phi=(\phi_i dy^i+\dot\phi_i dy^i_t)\wedge dt$ on J^1Y, the algebraic equations,

$$\dot\vartheta^j\pi_{ji}+\vartheta^j(\partial_j\pi_i-\partial_i\pi_j)=\phi_i, \quad -\vartheta^i\pi_{ji}=\dot\phi_j,$$

have a unique solution,

$$\vartheta^i=-(\pi^{-1})^{ij}\dot\phi_j, \quad \dot\vartheta^j=(\pi^{-1})^{ji}[\phi_i+(\pi^{-1})^{kn}\dot\phi_n(\partial_k\pi_i-\partial_i\pi_k)].$$

In particular, every function f on J^1Y determines a vertical vector field,

$$\vartheta_f=(\pi^{-1})^{ij}\partial^t_j f\partial_i-(\pi^{-1})^{ji}[\partial_i f+(\pi^{-1})^{kn}\partial^t_n f(\partial_k\pi_i-\partial_i\pi_k)]\partial^t_j, \tag{22}$$

on $J^1Y\to\mathbf{R}$ in accordance with the relation

$$\vartheta_f\rfloor\mathbf{\Omega}_L=-df\wedge dt.$$

Then the Poisson bracket,

$$\{f,g\}_L dt=\vartheta_g\rfloor\vartheta_f\rfloor\mathbf{\Omega}_L, \quad f,g\in C^\infty(J^1Y), \tag{23}$$

can be defined on functions on J^1Y, and reads as

$$\{f,g\}_L=(\pi^{-1})^{ij}(\partial^t_i f\partial_j g-\partial^t_i g\partial_j f)+(\partial_n\pi_k-\partial_k\pi_n)(\pi^{-1})^{ki}(\pi^{-1})^{nj}\partial^t_i f\partial^t_j g.$$

The vertical vector field ϑ_f (22) is the Hamiltonian vector field of the function f with respect to the Poisson structure (23).

In particular, if the Lagrangian L is hyperregular, that is, the Legendre map $\hat L$ is a diffeomorphism, the Poisson structure (23) is obviously isomorphic to the Poisson structure (7) on the phase space V^*Y.

The Poisson structure (23) defines the corresponding symplectic foliation on J^1Y that coincides with the fibration $J^1Y\to\mathbf{R}$. The symplectic form on the leaf J^1_tY of this foliation is $\Omega_t=d\pi_i\wedge dy^i$.[18]

We will see below that the Lagrangian counterpart of Hamiltonian forms is the Poincaré–Cartan form,

$$H_L=\pi_i dy^i-(\pi_i y^i_t-\mathscr{L})dt.$$

This is the unique Lepagian equivalent of a Lagrangian L that participates in the first variational formula. The Poincaré–Cartan form defines the morphism

$$\hat H_L: J^1Y\to T^*Y, \quad p\circ\hat H_L=\mathscr{L}-\pi_i y^i_t, \quad p_i\circ\hat H_L=\pi_i. \tag{24}$$

There is the relation $\hat L=\zeta\circ\hat H_L$, where ζ is the canonical projection (14).

Let

$$u=u^t\partial_t+u^i\partial_i, \quad u^t=0,1, \tag{25}$$

be a vector field on $Y\to\mathbf{R}$. The first variational formula provides the canonical decomposition of the Lie derivative,

$$\mathbf{L}_{J^1u}L=(J^1u\rfloor d\mathscr{L})dt=(u^t\partial_t+u^i\partial_i+d_t u^i\partial^t_i)\mathscr{L}dt, \qquad d_t=\partial_t+y^i_t\partial_i+\cdots, \tag{26}$$

in accordance with the variational task.[16,19] We have

$$J^1u\rfloor d\mathscr{L}=(u^i-u^t y^i_t)\mathscr{E}_i+d_t(u\rfloor H_L), \tag{27}$$

where

$$\mathscr{E}_L=(\partial_i-d_t\partial_i^t)\mathscr{L}dy^i\wedge dt \tag{28}$$

is the Euler–Lagrange operator for L. The kernel $\mathrm{Ker}\,\mathscr{E}_L\subset J^2Y$ of this operator defines the second–order Lagrange equations on Y,

$$(\partial_i-d_t\partial_i^t)\mathscr{L}=0. \tag{29}$$

Definition 11: A connection,

$$\xi=\partial_t+\xi^i\frac{\partial}{\partial^i}+\xi_t^i\frac{\partial}{\partial\hat{y}_t^i},$$

on the configuration space $J^1Y\to\mathbf{R}$ is said to be a Lagrangian connection for the Lagrangian L if it obeys the condition

$$\xi\rfloor\Omega_L=dH_L, \tag{30}$$

which takes the coordinate form

$$(\xi^i-y_t^i)\pi_{ij}=0,$$

$$\partial_i\mathscr{L}-\partial_t\pi_i-\xi^j\partial_j\pi_i-\xi_t^j\pi_{ij}+(\xi^j-y_t^j)\partial_i\pi_j=0,$$

relative to the adapted coordinates $(t,y^i,y_t^i,\hat{y}_t^i,y_{tt})$ on J^1J^1Y.

In order to clarify the meaning of (30), let us consider the Lagrangian,

$$\overline{L}=L+(\hat{y}_t^i-y_t^i)\pi_i dt,$$

on the repeated jet manifold J^1J^1Y. The corresponding Euler–Lagrange operator, called the Euler–Lagrange–Cartan one, reads as

$$\begin{aligned}\mathscr{E}_{\overline{L}}&=[(\partial_iL-\hat{d}_t\pi_i+\partial_i\pi_j(\hat{y}_t^j-y_t^j))dy^i+\partial_i^t\pi_j(\hat{y}_t^j-y_t^j)dy_t^i]\wedge dt,\\ \hat{d}_t&=\partial_t+\hat{y}_t^i\partial_i+y_{tt}^i\partial_i^t.\end{aligned} \tag{31}$$

Then the condition (30) is equivalent to the one $\mathrm{Im}\,\xi\subset\mathrm{Ker}\,\mathscr{E}_{\overline{L}}$, and leads to the first-order differential equations on the jet manifold J^1Y, called the Cartan equations,

$$\partial_i^t\pi_j(\hat{y}_t^j-y_t^j)=0,\quad \partial_iL-\hat{d}_t\pi_i+(\hat{y}_t^j-y_t^j)\partial_i\pi_j=0. \tag{32}$$

Integral curves of Lagrangian connections ξ for L provide classical solutions $\overline{s}:\mathbf{R}\to J^1Y$ of these equations.

The restriction of $\mathscr{E}_{\overline{L}}$ to the holonomic jet manifold J^2Y defines the first-order Euler–Lagrange operator whose kernel is the system of the first-order Lagrange equations,

$$\hat{y}_\lambda^i-y_\lambda^i=0,\quad (\partial_i-d_\lambda\partial_i^\lambda)\mathscr{L}=0. \tag{33}$$

These are equivalent to the second-order Lagrange equations (29), and represent their familiar first-order reduction.

It is easily seen that the first-order Lagrange equations (33) [and consequently the second-order ones (29)] are equivalent to the Cartan equations (32) on the integrable sections $\overline{s}=J^1s$ of $J^1Y\to\mathbf{R}$. They are completely equivalent to the Cartan equations in the case of regular Lagrangians.

VII. DEGENERATE SYSTEMS

Let us consider the relations between the solutions of Hamilton and Lagrange equations. Every Hamiltonian form H on the phase space V^*Y defines the Hamiltonian map

$$\hat{H}: V^*Y \to J^1Y, \quad y^i_t \circ \hat{H} = \partial^i \mathscr{H}.$$

Its jet prolongation reads as

$$J^1\hat{H}: J^1V^*Y \to J^1J^1Y, \quad (y^i_t, \hat{y}^i_t, y^i_{tt}) \circ J^1\hat{H} = (\partial^i \mathscr{H}, y^i_t, d_t\partial^i \mathscr{H}).$$

Following the general polysymplectic scheme, we say that a Hamiltonian form H on V^*Y is associated with a Lagrangian L if H obeys the conditions[14–16]

$$\hat{L} \circ \hat{H} \circ \hat{L} = \hat{L}, \tag{34a}$$

$$p_i \partial^i \mathscr{H} - \mathscr{H} = \mathscr{L} \circ \hat{H}. \tag{34b}$$

It follows from the condition (34a) that $\hat{L} \circ \hat{H}$ is the projection operator to $Q = \hat{L}(J^1Y) \subset V^*Y$, called the Lagrangian constraint space, and $\hat{H} \circ \hat{L}$ is the projection operator to $\hat{H}(Q) \subset J^1Y$. Given a Hamiltonian form H associated with L, the Lagrangian constraint space is defined by the coordinate relation,

$$p_i = \partial^t_i \mathscr{L}(t, y^j, \partial^j \mathscr{H}).$$

If a Lagrangian L is hyperregular, there exists a unique Hamiltonian form associated with L.

Let a Lagrangian L be semiregular, i.e., the preimage $\hat{L}^{-1}(p)$ of any point $p \in Q$ is a connected submanifold of J^1Y. The following assertions issue from the corresponding theorems of a polysymplectic formalism.[14,16,20]

Proposition 12: All Hamiltonian forms H associated with a semiregular Lagrangian L coincide on the Lagrangian constraint space Q, and the Poincaré–Cartan form H_L is the pull-back of any such a Hamiltonian form H by the Legendre map $\hat{L}$, i.e.,

$$\pi_i y^i_t - \mathscr{L} = \mathscr{H}(t, y^i, \pi_i). \tag{35}$$

Proposition 13: Let a section r of the bundle $V^*Y \to \mathbf{R}$ be a solution of the Hamilton equations (17) for a Hamiltonian form H associated with a semiregular Lagrangian density L. If r lives in the Lagrangian constraint space Q, the section $s = \pi_\Pi \circ r$ of the bundle $Y \to \mathbf{R}$ satisfies the Lagrange equations (29), while its jet prolongation $\overline{s} = \hat{H} \circ r = J^1 s$ obeys the Cartan equations (32). Conversely, let a section $\overline{s}$ of $J^1Y \to \mathbf{R}$ be a solution of the Cartan equations (32) for a semiregular Lagrangian L. Let H be a Hamiltonian form associated with L so that the corresponding Hamiltonian map satisfies the condition

$$\hat{H} \circ \hat{L} \circ \overline{s} = J^1(\pi^1_0 \circ \overline{s}). \tag{36}$$

Then the section $r = \hat{L} \circ \overline{s}$ of $V^*Y \to \mathbf{R}$ is a solution of the Hamilton equations for H.

Proof: One can show that, in the case of a semiregular Lagrangian L, the Euler–Lagrange–Cartan operator (31) is the pull-back,

$$\mathscr{E}_{\overline{L}} = (J^1\hat{L})^* \mathscr{E}_H, \tag{37}$$

of the Hamilton operator for a Hamiltonian form H associated with L. In accordance with the relation (37), if γ_H is a Hamiltonian connection for H, the composition,

$$J^1\hat{H} \circ \gamma_H : V^*Y \to J^2Y, \quad (y^i_t, \hat{y}^i_t, y^i_{tt}) \circ J^1\hat{H} \circ \gamma_H = (\partial^i \mathscr{H}, \partial^i \mathscr{H}, d_{Ht}\partial^i \mathscr{H}),$$

takes its values into the kernel of the Euler–Lagrange operator $\mathscr{E}_L$. Then the morphism $J^1\hat{H}\circ\gamma_H\circ\hat{L}$ restricted to $\hat{H}(Q)$ is a local Lagrangian connection on $\hat{H}(Q)\subset J^1Y$. Conversely, the first of the Hamilton equations (17) is satisfied due to the condition (36), while the second one reduces to the second of the Cartan equations (32) because of the relation (35).

Since, by Proposition 13, solutions of the Lagrange equations for a degenerate Lagrangian may correspond to solutions of different Hamilton equations, we can conclude that, roughly speaking, the Hamilton equations involve some additional conditions in comparison with the Lagrange ones. Therefore, let us separate a part of the Hamilton equations which are defined on the Lagrangian constraint space Q in the case of almost regular Lagrangians.

Definition 14: A semiregular Lagrangian L is said to be almost regular if (i) the Lagrangian constraint space $Q\to Y$ is a closed imbedded subbundle $i_Q:Q\hookrightarrow V^*Y$ of the Legendre bundle $V^*Y\to Y$; and (ii) the Legendre map $\hat{L}:J^1Y\to Q$ is a bundle.

Let $H_Q=i_Q^*H$ be the restriction of a Hamiltonian form H associated with L to the constraint space Q. By virtue of Proposition 12, this restriction, called the constrained Hamiltonian form, is uniquely defined, and $H_L=\hat{L}^*H_Q$. For sections r of the bundle $Q\to\mathbf{R}$, we can write the constrained Hamilton equations,

$$r^*(u_Q\rfloor dH_Q)=0, \tag{38}$$

where u_Q is an arbitrary vertical vector field on $Q\to\mathbf{R}$.[14,16,21] In brief, we can identify a vertical vector field u_Q on $Q\to\mathbf{R}$ with its image $Ti_Q(u_Q)$ and can bring the constrained Hamilton equations (38) into the form

$$r^*(u_Q\rfloor dH)=0, \tag{39}$$

where r is a section of $Q\to\mathbf{R}$ and u_Q is an arbitrary vertical vector field on $Q\to\mathbf{R}$. These equations fail to be equivalent to the Hamilton equations restricted to the constraint space Q.

The following two assertions together with Proposition 13 give the relations between Cartan, Hamilton, and constrained Hamilton equations when a Lagrangian is almost regular.[16]

Proposition 15: For any Hamiltonian form H associated with an almost regular Lagrangian L, every solution r of the Hamilton equations that lives in the Lagrangian constraint space is a solution of the constrained Hamilton equations (39).

Proposition 16: A section $\overline{s}$ of $J^1Y\to\mathbf{R}$ is a solution of the Cartan equations (32) iff $\hat{L}\circ\overline{s}$ is a solution of the constrained Hamilton equations (39).

In the spirit of a well-known Dirac–Bergmann algorithm for analyzing constrained systems in symplectic mechanics, the Lagrangian constraint space Q plays the role of the primary constraint one. However, we cannot extend this algorithm to time-dependent mechanics because the Poisson bracket of a Hamiltonian and constraint functions fails to be defined.

At the same time, one can hope to find a complete family of Hamiltonian forms associated with a degenerate Lagrangian L so that, for each solution of the Lagrange equations, there exists the corresponding solution of the Hamilton ones for some Hamiltonian form from this family. By Proposition 13, if L is semiregular, such a complete family of associated Hamiltonian forms exists iff, for every solution s of the Lagrange equations, there is a Hamiltonian form H from this family such that

$$\hat{H}\circ\hat{L}\circ J^1s=J^1s.$$

In particular, a complete family of Hamiltonian forms associated with an almost regular quadratic Lagrangian always exists.[14–16]

Note that, since Hamiltonians in time-dependent mechanics are not functions on a phase space, we cannot apply to them the well-known analysis of the normal forms[22] (e.g., quadratic Hamiltonians[2]) in symplectic mechanics.

VIII. CONSERVATION LAWS

In autonomous mechanics, an integral of motion, by definition, is a function on the phase space whose Poisson bracket with a Hamiltonian is equal to zero. This notion cannot be extended to time-dependent mechanics because the Hamiltonian evolution equation (19) is not reduced to the Poisson bracket.

Let us start from conservation laws in Lagrangian mechanics. To obtain differential conservation laws, we use the first variational formula (27).[16,19] On shell, this leads to the weak identity

$$J^1u \rfloor d\mathscr{L} \approx -d_t\mathscr{T}, \tag{40}$$

where

$$\mathscr{T} = \pi_i(u^t y^i_t - u^i) - u^t\mathscr{L} \tag{41}$$

is the current along the vector field u (25). If the Lie derivative $\mathbf{L}_{J^1u}L$ (26) vanishes, we have the conservation law

$$0 \approx -d_t[\pi_i(u^t y^i_t - u^i) - u^t\mathscr{L}].$$

This is brought into the differential conservation law,

$$0 \approx -\frac{d}{dt}(\pi_i \circ s(u^t \partial_t s^i - u^i \circ s) - u^t\mathscr{L} \circ s),$$

on solutions s of the Lagrange equations. A glance at this expression shows that, in time-dependent mechanics, the conserved current (41) plays the role of an integral of motion.

Every symmetry current (41) along a vector field u (25) on Y can be represented as a superposition of the Nöther current along a vertical vector field ϑ and of the energy current along some connection Γ (2) on $Y \to \mathbf{R}$, where $u = \vartheta + \Gamma$.[19,23]

If ϑ is a vertical vector field, the weak identity (40) reads as

$$(\vartheta^i \partial_i + d_t\vartheta^i \partial^t_i)\mathscr{L} \approx d_t(\pi_i \vartheta^i).$$

If the Lie derivative of L along ϑ equals zero, we have the integral of motion $\mathscr{T} = \pi_i \vartheta^i$.

In the case of a connection Γ (2), the weak identity (40) takes the form

$$(\partial_t + \Gamma^i \partial_i + d_t\Gamma^i \partial^t_i)\mathscr{L} \approx -d_t(\pi_i(y^i_t - \Gamma^i) - \mathscr{L}), \tag{42}$$

where one can think of

$$\mathscr{T}_\Gamma = \pi_i(y^i_t - \Gamma^i) - \mathscr{L} \tag{43}$$

as being the energy function with respect to the reference frame Γ. In particular, the energy conservation law (42) written relative to the coordinates adapted to Γ takes the familiar form

$$\partial_t\mathscr{L} = -d_t(\pi_i y^i_t - \mathscr{L}). \tag{44}$$

To discover conservation laws within the framework of Hamiltonian formalism, we will do the following trick. Given a Hamiltonian form H (13) on V^*Y, let us consider the Lagrangian,

$$L_H = (p_i y^i_t - \mathscr{H})dt, \tag{45}$$

on the jet manifold J^1V^*Y. It is readily observed that the Poincaré–Cartan form of the Lagrangian L_H coincides with the Hamiltonian form H, and the Euler–Lagrange operator for L_H is precisely the Hamilton operator for H. As a consequence, the Lagrange equations for L_H are equivalent to the Hamilton equations for H. Therefore, let us apply the first variational formula (27) to the Lagrangian (45).[19]

Given a vector field (25) on the event bundle Y, its canonical lift onto V^*Y reads as

$$\widetilde{u}=u^t\partial_t+u^i\partial_i-\partial_i u^j p_j\partial^i, \quad u^t=0,1.$$

Substituting this vector field into the weak identity (40), we obtain

$$-u^i\partial_i\mathscr{H}-u^t\partial_t\mathscr{H}+p_i d_t u^i\approx -d_t(-p_i u^i+u^t\mathscr{H}), \tag{46}$$

for the current

$$\widetilde{\mathscr{T}}=-p_i u^i+u^t\mathscr{H}. \tag{47}$$

In the case of $u=\Gamma$, the weak identity (46) takes the form

$$-\partial_t\mathscr{H}-\Gamma^i\partial_i\mathscr{H}+p_i d_t\Gamma^i\approx -d_t\widetilde{\mathscr{H}}_\Gamma,$$

where $\widetilde{\mathscr{H}}_\Gamma=\mathscr{H}-p_i\Gamma^i$ is the Hamiltonian function in the splitting (15).

The following assertion shows that the Hamiltonian function $\widetilde{\mathscr{H}}_\Gamma$ is the Hamiltonian counterpart of the Lagrangian energy function $\mathscr{T}_\Gamma$ (43) in the case of semiregular Lagrangians.[16]

Proposition 17: Let a Hamiltonian form H on the Legendre bundle V^*Y be associated with a semiregular Lagrangian $\mathscr{L}$ on J^1Y. Let r be a solution of the Hamilton equations (17) for H that lives in the Lagrangian constraint space Q and s the corresponding solution of the Lagrange equations for L. Then, we have

$$\widetilde{\mathscr{T}}(r)=\mathscr{T}(\hat{H}\circ r), \quad \widetilde{\mathscr{T}}(\hat{L}\circ J^1 s)=\mathscr{T}(s),$$

where $\mathscr{T}$ is the current (41) on J^1Y and $\widetilde{\mathscr{T}}$ is the current (47) on V^*Y.

Therefore, we can treat $\widetilde{\mathscr{H}}_\Gamma$ as the energy function with respect to the reference frame Γ. In particular, if $\Gamma^i=0$, we obtain the well-known energy conservation law

$$\partial_t\mathscr{H}\approx d_t\mathscr{H},$$

which is the Hamiltonian variant of the Lagrangian conservation law (44).

IX. RELATIVISTIC MECHANICS

Let us consider a mechanic system whose event space Z has no fibration $Z\to\mathbf{R}$ or admits different such fibrations. We come to relativistic mechanics where a configuration space is the jet manifold of one-dimensional submanifolds of Y that generalizes the notion of jets of sections of a bundle.[16,24,25]

Let Z be a manifold of dimension $m+n$. The first-order jet manifold $J^1_n Z$ of n-dimensional submanifolds of Z comprises the equivalence classes $[S]^1_z$ of n-dimensional imbedded submanifolds of Z that pass through $z\in Z$ and that are tangent to each other at z. It is provided with a manifold structure as follows.

Let $Y\to X$ be an $(m+n)$-dimensional bundle over an n-dimensional base X and Φ an imbedding of Y into Z. Then there is the natural injection,

$$J^1\Phi:\ J^1Y\to J^1_n Z,$$

$$j^1_x s\mapsto[S]^1_{\Phi(s(x))}, \quad S=\mathrm{Im}(\Phi\circ s),$$

where s are sections of $Y\to X$. This injection defines a chart on $J^1_n Z$. Such charts cover the set $J^1_n Z$, and transition functions between these charts are differentiable. They provide $J^1_n Z$ with the structure of a finite-dimensional manifold.

Hereafter, we will use the following coordinate atlases on the jet manifold $J^1_n Z$ of submanifolds of Z. Let Z be endowed with a manifold atlas with coordinate charts,

$$(z^A), \quad A=1,\ldots,n+m. \tag{48}$$

Though $J^0_n Z$, by definition, is diffeomorphic to Z, let us provide $J^0_n Z$ with the atlas obtained by replacing every chart (z^A) on a domain $U \subset Z$ with the charts on the same domain U that correspond to the different partitions of the collection (z^A) in collections of n and m coordinates. We denote these coordinates by

$$(x^\lambda, y^i), \quad \lambda = 1,...,n, \quad i = 1,...,m. \tag{49}$$

The transition functions between the coordinate charts (49) of $J^0_n Z$ associated with the coordinate chart (48) of Z are reduced simply to exchange between coordinates x^λ and y_i. Transition functions between arbitrary coordinate charts of the manifold $J^0_n Z$ take the form

$$\widetilde{x}^\lambda = \widetilde{g}^\lambda(x^\mu, y^j), \quad \widetilde{y}^i = \widetilde{f}^i(x^\mu, y^j). \tag{50}$$

Given the coordinate atlas (49) of the manifold $J^0_n Z$, the jet manifold $J^1_n Z$ of Z is endowed with the adapted coordinates $(x^\lambda, y^i, y^i_\lambda)$. Using the formal total derivatives $d_\lambda = \partial_\lambda + y^i_\lambda \partial^i$, one can write the transformation rules for these coordinates in the following form. Given the coordinate transformations (50), it is easy to find that

$$d_{\widetilde{x}^\lambda} = [d_{\widetilde{x}^\lambda} g^\alpha(\widetilde{x}^\lambda, \widetilde{y}^i)] d_{x^\alpha}. \tag{51}$$

Then we have

$$\widetilde{y}^i_\lambda = \left[\left(\frac{\partial}{\partial \widetilde{x}^\lambda} + \widetilde{y}^p_\lambda \frac{\partial}{\partial \widetilde{y}^p}\right) g^\alpha(\widetilde{x}^\lambda, \widetilde{y}^i)\right]\left(\frac{\partial}{\partial x^\alpha} + y^j_\alpha \frac{\partial}{\partial y^j}\right)\widetilde{f}^i(x^\mu, y^j). \tag{52}$$

Remark: Given a manifold Z, there is one-to-one correspondence between the jets $[S]^1_z$ at a point $z \in Z$ and the n-dimensional vector subspaces of the tangent space $T_z Z$:

$$[S]^1_z \mapsto \dot{x}^\lambda(\partial_\lambda + y^i_\lambda([S]^1_z)\partial_i).$$

The bundle $J^1_n Z \to Z$ possesses the structure group $\mathrm{GL}(n,m;\mathbf{R})$ of linear transformations of the vector space $\mathbf{R}^{m+n}$ that preserve the subspace $\mathbf{R}^n$. Its typical fiber is the Grassmann manifold $\mathrm{GL}(n+m;\mathbf{R})/\mathrm{GL}(n,m;\mathbf{R})$ of n-dimensional vector subspaces of the vector space $\mathbf{R}^{m+n}$. In particular, if $n=1$, the fiber coordinates y^i_0 of $J^1_1 Z \to Z$ with the transition functions (52) are exactly the standard coordinates of the projective space $\mathbf{RP}^m$.

When $n=1$, the formalism of jets of submanifolds provides the adequate mathematical description of relativistic mechanics as follows.

Let Z be a $(m+1)$-dimensional manifold equipped with an atlas of coordinates (z^0, z^i), $i = 1,...,m$, (49) with the transition functions (50), which take the form

$$z^0 \to \widetilde{z}^0(z^0, z^j), \quad z^i \to \widetilde{z}^i(z^0, z^j). \tag{53}$$

The coordinates z^0 in different charts of Z play the role of the temporal ones.

Let $J^1_1 Z$ be the jet manifold of one-dimensional submanifolds of Z. This is provided with the adapted coordinates (z^0, z^i, z^i_0). Then one can think of z^i_0 as being the coordinates of nonrelativistic velocities. Their transition functions are obtained as follows.

Given the coordinate transformations (53), the total derivative (51) reads as

$$d_{\widetilde{z}^0} = d_{\widetilde{z}^0}(z^0) d_{z^0} = \left(\frac{\partial z^0}{\partial \widetilde{z}^0} + \widetilde{z}^k_0 \frac{\partial z^0}{\partial \widetilde{z}^k}\right) d_{z^0}.$$

In accordance with the relation (52), we have

$$\widetilde{z}^i_0 = d_{\widetilde{z}^0}(z^0) d_{z^0}(\widetilde{z}^i) = \left(\frac{\partial z^0}{\partial \widetilde{z}^0} + \widetilde{z}^k_0 \frac{\partial z^0}{\partial \widetilde{z}^k}\right)\left(\frac{\partial \widetilde{z}^i}{\partial z^0} + z^j_0 \frac{\partial \widetilde{z}^i}{\partial z^j}\right).$$

The solution of this equation is

$$\widetilde{z}^i_0=\left(\frac{\partial\widetilde{z}^i}{\partial z^0}+z^j_0\,\frac{2\partial\widetilde{z}^i}{\partial z^j}\right)\Big/\left(\frac{\partial\widetilde{z}^0}{\partial z^0}+z^k_0\,\frac{\partial\widetilde{z}^0}{\partial z^k}\right).$$

This is the transformation law of nonrelativistic velocities, which illustrates that the jet bundle $J^1_1Z\to Z$ is not affine, but projective.

To obtain the relation between nonrelativistic and relativistic velocities, let us consider the tangent bundle TZ equipped with the induced coordinates $(z^0,z^i,\dot z^0,\dot z^i)$. There is the morphism

$$\rho:\ TZ\to J^1_1Z,\quad z^i_0\circ\rho=\dot z^i/\dot z^0. \tag{54}$$

It is readily observed that the coordinate transformation laws of z^i_0 and $\dot z^i/\dot z^0$ are the same. Thus, one can think of the coordinates $(z^0,\dot z^i)$ as being relativistic velocities.

The morphism (54) is a surjection. Let us assume that the tangent bundle is equipped with a pseudo-Riemannian metric g and $Q_z\subset T_zZ$ is the hyperboloid given by the relation

$$g_{\mu\nu}(z)\dot z^\mu\dot z^\nu=1,\quad \mu,\nu=0,1,...,m. \tag{55}$$

The union of these hyperboloids over Z,

$$Q=\bigcup_{z\in Z}Q_z=Q^+\cup Q^-$$

is the union of two connected imbedded subbundles of TZ. Then the restriction of the morphism (54) to each of these subbundles is an injection of Q into J^1_1Z.

Let us consider the image of this injection in the fiber of J^1_1Z over a point $z\in Z$. There are coordinates (z^0,z^i) in a neighborhood around z such that the pseudo-Riemannian metric $g(z)$ at z comes to the Minkowski one,

$$g(z)=\eta=\mathrm{diag}(1,-1,...,-1).$$

In this coordinates the hyperboloid $Q_z\subset T_zZ$ is given by the relation

$$(\dot z^0)^2-\sum_i\,(\dot z^i)^2=1.$$

This is the union of the subsets Q^+_z where $z^0>0$ and Q^-_z where $z^0<0$. The image $\rho(Q^+_z)$ is given by the coordinate relation

$$\sum_i\,(z^i_0)<1.$$

From the physical viewpoint, this relation means that nonrelativistic velocities are bounded in accordance with Special Relativity.

In general, Lagrangian formalism fails to be appropriate to relativistic mechanics because a Lagrangian $L=\mathscr{L}dz^0$ can be defined only locally. Its Hamiltonian formulation is more promising.

The phase space of relativistic mechanics is the cotangent bundle T^*Z provided with the holonomic coordinates $(z^0,\ z^i,\ p_0=\dot z_0,\ p_i=\dot z_i)$. This admits the canonical symplectic form

$$\Omega=dp_\mu\wedge dz^\mu,\quad \mu=0,1,2,3.$$

Hamiltonian relativistic mechanics is formulated as an autonomous Hamiltonian mechanics on the symplectic manifold T^*Z. Every Hamiltonian $\mathscr{H}$ on the phase space T^*Z defines the Hamiltonian map,

$$\hat{\mathscr{H}}:\ T^*Z\to TZ,\quad \dot z^\mu\circ\hat{\mathscr{H}}=\partial^\mu\mathscr{H}.$$

Since relativistic velocities live in the hyperboloid (55), we have the similar constraint,

$$g_{\mu\nu}\frac{\partial\mathscr{H}}{\partial p_\mu}\frac{\partial\mathscr{H}}{\partial p_\nu}=1, \tag{56}$$

on the phase space T^*Z. Thus, relativistic mechanics is described as a Dirac constraint system on the primary constraint space Q (56). Its solutions are integral curves of the Hamiltonian vector field ϑ on $Q\subset T^*Z$ that obeys the Hamilton equation

$$\vartheta\rfloor i_Q^*\Omega=-i_Q^*d\mathscr{H}. \tag{57}$$

It should be emphasized that, as follows from the relation (24), the coordinate $-p$, but not a Hamiltonian $\mathscr{H}$ plays the role of a relativistic energy function. For example, let us write (i) the Hamiltonian,

$$\mathscr{H}=-\frac{1}{2m}\,\eta^{\mu\nu}p_\mu p_\nu,$$

of a free relativistic mass m in Special Relativity on the Minkowski space $\mathbf{R}^4$; (ii) the Hamiltonian,

$$\mathscr{H}=-\frac{1}{2m}\,\eta^{\mu\nu}(p_\mu-eA_\mu)(p_\nu-eA_\nu),$$

of a relativistic electric charge e in the presence of an electromagnetic field A_μ; and (iii) the Hamiltonian,

$$\mathscr{H}=-\frac{1}{2m}\,\gamma^{\mu\nu}p_\mu p_\nu,$$

of a point mass m in the presence of a metric gravitational field g. Substituting these Hamiltonians into the equations (56) and (57), we obtain the well-known solutions of relativistic mechanics.

New structures in the theory of the laser model. II. Microscopic dynamics and a nonequilibrium entropy principle

Fabio Bagarello[a] and Geoffrey L. Sewell[b]
Department of Physics, Queen Mary and Westfield College, Mile End Road, London E1 4NS, England

(Received 22 December 1997; accepted for publication 7 January 1998)

In a recent article, Alli and Sewell [J. Math. Phys. **36**, 5598 (1995)] formulated a new version of the Dicke–Hepp–Lieb laser model in terms of quantum dynamical semigroups, and thereby extended the macroscopic picture of the model. In the present article, we complement that picture with a corresponding microscopic one, which carries the following new results. (a) The local microscopic dynamics of the model is piloted by the classical, macroscopic field, generated by the collective action of its components; (b) the global state of the system carries no correlations between its constituent atoms after transient effects have died out; and (c) in the latter situation, the state of the system at any time t maximizes its entropy density, subject to the constraints imposed by the instantaneous values of its macroscopic variables. © *1998 American Institute of Physics.* [S0022-2488(98)01805-2]

I. INTRODUCTION

The classic work by Hepp and Lieb[1] (HL) on the theory of the Dicke laser model[2] represents a landmark in the constructive quantum theory of phase transitions, far from equilibrium, in open quantum systems. Most notably, it demonstrated how the model undergoes a transition from normal to coherent radiation when the optical pumping strength reaches a critical value. This substantiated ideas that had been proposed by Graham and Haken[3] at a more heuristic level.

In a recent article, which we shall refer to as (I), Alli and Sewell[4] constructed a new version[5] of the Dicke model in which the dynamics of the matter and radiation is governed by a quantum dynamical semigroup, which incorporates the dissipative action of an array of pumps and sinks: by contrast, the HL model represented a conservative system, comprising the matter, radiation, and these reservoirs. The principle new results of (I) were (a) a generalization of the HL form of the dynamics of the matter–radiation composite, (b) a demonstration that the model exhibits optically chaotic phases, in addition to the normal and coherent ones, and (c) a generalization of the theory of quantum dynamical semigroups[6] to ones with unbounded generators.

The theories of both HL and (I) were centered on the macroscopic equations of motion, derived from the underlying quantum dynamics of their respective models in a limit where their sizes become infinite. In fact, they did not provide any treatment of the microdynamics in this limit. The object of the present article is to complement the macroscopic picture of (I) with a corresponding microscopic one.

In seeking a microscopic-cum-macroscopic picture of the dynamics of the model, we note that this has already been achieved for certain *conservative* systems with long range forces. For such systems, Morchio and Strocchi[7] have shown that the evolutes, b_t, of the local microscopic observables, b, depend not only on b and the time t, but also on certain macroscopic observables, i.e., ''observables at infinity'': this represents a picture completely different from that of the Haag–Kastler scheme,[8] in which the dynamics of the micro-observables is autonomous. Furthermore, the explicit structure of the equations of motion for the microscopic and macroscopic

 © 1998 American Institute of Physics

observables, b_t and B_t, has been obtained by Bagarello and Morchio[9] (BM) for a class of conservative, mean field theoretic models in the following form:

$$\frac{db_t}{dt}=f(b_t,B_t); \quad \frac{dB_t}{dt}=F(B_t). \tag{1.1}$$

Thus, the microscopic dynamics is piloted by the macroscopic observables, which, for their part, evolve according to a self-contained law.

The question now arises as to whether a similar state of affairs prevails in the case of open dissipative systems, such as the laser model, and the first thing to say about that is that the methods of BM, which led to Eq. (1.1), are not applicable there. The reason is simply that those methods depended heavily on the fact that, in a conservative system, the dynamics is automorphic and so preserves the algebraic structure of the observables. In an open dissipative system, on the other hand, the dynamics is governed by a semigroup[4] of transformations of the observables that does not preserve that structure, i.e., in general, $(ab)_t \neq a_t b_t$.

Thus, any attempt to derive equations of the form (1.1) for the laser model must be based on methods that are applicable to dissipative systems. Here, the essential problem is to pass to a limit where the size of the system becomes infinite, since the dynamics of the finite version of the model has already been formulated in (I). In fact, we surmount this problem by means of a compactness argument that lends itself to the application of the Arzela–Ascoli theorem. As a result, we do indeed obtain a microscopic-cum-macroscopic dynamics of the form (1.1), though now, of course, the functions f and F incorporate the dissipative action of the pumps and sinks on the system.

The principal new results that we obtain in this way are of a very simple character, and may be summarized as follows.

(1) The microscopic observables of *this particular model* are those of the matter only, since the radiation field reduces to a classical macroscopic one.
(2) The dynamics of the local microscopic observables is piloted by that classical radiation field.
(3) The microdynamics contains certain transients, whose lifetimes are of the order of that of an atomic excited state. This dynamics simplifies considerably after these transients have died out, and leads to the decorrelation of the observables of different atoms. Furthermore, the resultant global microstate of the system is stationary and space-translationally invariant in the normal phase, and periodic with respect to both space and time in the coherent one. Evidently, it is very complicated in the chaotic phase.
(4) Following the decay of the transients, the instantaneous state of the model is determined by a nonequilibrium variational principle. Specifically, this state maximizes the global entropy density, subject to the constraints imposed by the prevailing values of the macroscopic observables. As far as we know, this is the first example for which a principle of this kind has been proved for the nonequilibrium regime.

We shall present our arguments as follows. In Secs. II and III, we shall provide a brief summary of (I), re-expressed in a form suitable for our present purposes. Specifically, Sec. II will be devoted to a formulation of the model and Sec. III to a resume of its macroscopic properties. In Sec. IV, we shall derive the above results (1) and (2) by passing to the infinite size limit of the quantum dynamics of the finite version of the model. We shall then derive the results (3) and (4) in Secs. V and VI, respectively. We shall conclude, in Sec. VII, with a brief discussion of our main results and their possible ramifications.

II. THE MODEL

Our model, as formulated in (I), is a dissipative quantum system, $\Sigma^{(N)}$, consisting of a chain of $2N+1$ identical two-level atoms interacting with an n-mode radiation field. We label it by N only, since we shall be concerned with its properties in a limit where N tends to infinity, while n remains fixed and finite. We formulate $\Sigma^{(N)}$ as a quantum dynamical system $(\mathscr{B}^{(N)},T^{(N)},\mathscr{S}^{(N)})$, where $\mathscr{B}^{(N)}$ is a $\star$-algebra of observables, $T^{(N)}$ is a one-parameter semigroup of completely positive (CP) transformations of $\mathscr{B}^{(N)}$, and $\mathscr{S}^{(N)}$ is a family of normal states on $\mathscr{B}^{(N)}$ that is

stable under the dual of $T^{(N)}$. Most importantly, $T^{(N)}$ incorporates the dissipative action of pumps and sinks, which do not appear explicitly in the model, on the matter–radiation system. We build the model from its constituent parts as follows.

A. The single atom

This is assumed to be a two-state atom or spin, $\Sigma_{\rm at}$. Its algebra of observables, $\mathscr{A}_{\rm at}$, is that of the two-by-two matrices, and is thus the linear span of Pauli matrices $(\sigma_x,\sigma_y,\sigma_z)$ and the identity, I. Its algebraic structure is provided by the relations

$$\sigma_x^2=\sigma_y^2=\sigma_z^2=I; \quad \sigma_x\sigma_y=i\sigma_z, \quad \text{etc.} \tag{2.1}$$

We define the spin raising and lowering operators

$$\sigma_\pm=\tfrac{1}{2}(\sigma_x\pm i\sigma_y). \tag{2.2}$$

We assume that the atom is coupled to a pump and a sink, and that accordingly [cf. (I)] its dynamics is given by a one-parameter semigroup $\{T_{\rm at}(t)|t\in\mathbf{R}_+\}$ of completely positive, identity-preserving contractions of $\mathscr{A}_{\rm at}$, whose generator, $L_{\rm at}$, is of the following form:

$$L_{\rm at}\sigma_\pm=-(\gamma_1\mp i\epsilon)\sigma_\pm; \quad L_{\rm at}\sigma_z=-\gamma_2(\sigma_z-\eta I), \tag{2.3}$$

where $\epsilon\,(>0)$ is the energy difference between the ground and excited states of an atom, and the γ's and η are constants whose values are determined by the atomic coupling to the energy source and sink, and are subject to the restrictions that

$$0<\gamma_2\leqslant 2\gamma_1; \quad -1\leqslant\eta\leqslant 1. \tag{2.4}$$

In particular, η is positive or negative according to whether the coupling of the atom to the pump or the sink is the stronger. In the former case, these couplings drive the atom to a terminal mixed state with *inverted population*, i.e., with higher occupation probability for the excited state than for the ground state.

B. The matter

This consists of $2N+1$ noninteracting copies of $\Sigma_{\rm at}$, located at the sites $r=-N,\ldots,N$ of the one-dimensional lattice $\mathbf{Z}$. Thus, at each site, r, there is a copy, Σ_r, of $\Sigma_{\rm at}$, whose algebra of observables, $\mathscr{A}_r$, and dynamical semigroup, T_r, are isomorphic with $\mathscr{A}_{\rm at}$ and $T_{\rm at}$, respectively. We denote by $\sigma_{r,u}$ the copy of σ_u at r, for $u=x,y,z,\pm$.

We define the algebra of observables, $\mathscr{A}^{(N)}$, and the dynamical semigroup, $T^{(N)}_{\rm mat}$, of the matter to be $\otimes_{r=-N}^{N}\mathscr{A}_r$ and $\otimes_{r=-N}^{N}T_r$, respectively. Thus, $\mathscr{A}^{(N)}$ is the algebra of linear transformations of $\mathbf{C}^{4N+2}$. We identify elements A_r of $\mathscr{A}_r$ with those of $\mathscr{A}^{(N)}$ given by their tensor products with the identity operators attached to the remaining sites. Under this identification, the commutant, $\mathscr{A}_r'$, of $\mathscr{A}_r$ is the tensor product $\otimes_{s\neq r}\mathscr{A}_s$.

It follows from these specifications that the generator, $L^{(N)}_{\rm mat}$, of $T^{(N)}_{\rm mat}$ is given by the formula

$$L^{(N)}_{\rm mat}=\sum_{r=-N}^{N}L_r, \tag{2.5}$$

where

$$\begin{aligned} &L_r\sigma_{r,\pm}=-(\gamma_1\mp i\epsilon)\sigma_{r,\pm}; \quad L_r\sigma_{r,z}=-\gamma_2(\sigma_{r,z}-\eta I),\\ &L_r(A_rA_r')=(L_rA_r)A_r' \quad \forall A_r\in\mathscr{A}_r, \quad A_r'\in\mathscr{A}_r'. \end{aligned} \tag{2.6}$$

C. The radiation

We assume that the radiation field consists of n ($<\infty$) modes, represented by creation and destruction operators $\{a_l^\star, a_l | l=0,...,n-1\}$ in a Fock–Hilbert space $\mathscr{H}_{\rm rad}$, as defined by the standard specifications that (a) these operators satisfy the CCR,

$$[a_l,\ a_m^\star]=\delta_{lm}I; \quad [a_l,\ a_m]=0, \tag{2.7}$$

and (b) $\mathscr{H}_{\rm rad}$ contains a (vacuum) vector Φ, that is annihilated by each of the a's and is cyclic wrt the algebra of polynomials in the $a^\star$'s.

We define the Weyl map $z=(z_0,\ldots,z_{n-1})\to W(z)$, of C^n into $\mathscr{L}(\mathscr{H}_{\rm rad})$ by the formula

$$W(z)\equiv W(z_0,\ldots,z_{n-1})=\exp[i(z.a+(z.a)^*)], \quad \text{with } z.a=\sum_0^{n-1} z_l a_l. \tag{2.8}$$

We then define $\mathscr{R}$ to be the $\star$-algebra of polynomials in the a's, $a^\star$'s, and the Weyl operators $W(z)$, with z running through $\mathbf{C}^n$. Thus, in view of the CCR (2.7), this algebra is the linear span of terms of the form $W(z)a_{l_1}^\sharp \ldots a_{l_m}^\sharp$, where $a^\sharp$ denotes a or $a^\star$. Equivalently, it is the linear span of the derivatives, of all orders, of the operators $W(t_0z_0,\ldots,t_{n-1}z_{n-1})$ wrt the real variables $(t_0,\ldots,t_{n-1})$.

We assume that the radiation dynamics is given by the canonical extension to $\mathscr{R}$ of Vanheuverszwijn semigroup,[10] $T_{\rm rad}$, of quasi-free CP transformations of the Weyl algebra of linear combinations of $\{W(z)|z\in\mathbf{C}^n\}$. The formal generator of this semigroup is

$$L_{\rm rad}=\sum_{l=0}^{n-1} (i\omega_l[a_l^\star a_l,.]+2\kappa_l a_l^\star(.)a_l-\kappa_l\{a_l^\star a_l,.\}), \tag{2.9}$$

where $\{.,.\}$ denotes anticommutator, and the frequencies, ω_l, and the damping constants, κ_l, are positive.

D. The composite system

This is the coupled system, $\Sigma^{(N)}$, comprising the matter and radiation. We assume that its algebra of observables, $\mathscr{B}^{(N)}$, is the tensor product $\mathscr{A}^{(N)}\otimes\mathscr{R}$. Thus, $\mathscr{B}^{(N)}$, like $\mathscr{R}$, is an algebra of both bounded and unbounded operators in the Hilbert space $\mathscr{H}^{(N)}:=\mathbf{C}^{4N+2}\otimes\mathscr{H}_{\rm rad}$. We shall identify elements A and R, of $\mathscr{A}^{(N)}$ and $\mathscr{R}$, with $A\otimes I_{\rm rad}$ and $I_{\rm mat}\otimes R$, respectively.

We assume that the matter–radiation coupling is dipolar and is given by the interaction Hamiltonian

$$H_{\rm int}^{(N)}=i(2N+1)^{-1/2}\sum_{r=-N}^{N}\sum_{l=0}^{n-1}\lambda_l(\sigma_{r,-}a_l^\star\exp(-2\pi ilr/n)-\text{h.c.}), \tag{2.10}$$

where the λ's are real-valued, N-independent coupling constants. Correspondingly, we define the radiation field, $\phi^{(N)}$, of the model by the stipulation that its value at the site r is the coefficient of $\sigma_{r,+}$ in this formula. Thus,

$$\phi_r^{(N)}=-i(2N+1)^{-1/2}\sum_{l=0}^{n-1}\lambda_l a_l\exp(2\pi ilr/n). \tag{2.11}$$

We now need to define the state space, $\mathscr{S}^{(N)}$, and the dynamical semigroup, $T^{(N)}$, in a way that takes account of the unboundedness both of $H_{\rm int}^{(N)}$ and of some of the elements of $\mathscr{B}^{(N)}$. To this end, we start by defining $\mathscr{D}_0^{(N)}$ to be the space of density matrices in $\mathscr{H}^{(N)}$, with the trace norm topology, and $\mathscr{D}_1^{(N)}$ to be the subset of its elements, $\rho^{(N)}$, for which $\mathrm{Tr}(B^\star\rho^{(N)}B)$ is finite for all B in $\mathscr{B}^{(N)}$. We define $\mathscr{S}_1^{(N)}$ to be the set of positive, normalized, linear functionals, $\psi^{(N)}$, on $\mathscr{B}^{(N)}$, that are in the one-to-one correspondence with the $\mathscr{D}_1^{(N)}$-class density matrices, given by the standard formula $\psi^{(N)}(B)=\mathrm{Tr}(\rho^{(N)}B)$. We then adopt the formulation of $T^{(N)}$ and $\mathscr{S}^{(N)}$

provided by (I), in which $T^{(N)}$ is constructed as the modification of $T^{(N)}_{\rm mat}\otimes T_{\rm rad}$ due to the interaction $H^{(N)}_{\rm int}$, and $\mathscr{S}^{(N)}$ is a ''large'' subset of $\mathscr{S}^{(N)}_1$ that is stable wrt this dynamical semigroup. Specifically, the construction yields the following results.[4]

(1) The density matrices corresponding to $\mathscr{S}^{(N)}$ form a dense subset of $\mathscr{D}^{(N)}_0$ in the topology corresponding to the trace norm.

(2) $\mathscr{S}^{(N)}$ is stable under the transformations $\psi^{(N)}\to\psi^{(N)}\circ T^{(N)}(t):=\psi^{(N)}_t$.

(3)

$$\frac{d}{dt}\,\psi^{(N)}_t(B)=\psi^{(N)}_t(L^{(N)}B)\quad \forall B\in\mathscr{B}^{(N)},\quad t\in\mathbf{R}_+, \tag{2.12}$$

where

$$L^{(N)}=L^{(N)}_{\rm mat}+L_{\rm rad}+i[H^{(N)}_{\rm int},\ .]. \tag{2.13}$$

This completes our specification of $\Sigma^{(N)}=(\mathscr{B}^{(N)},T^{(N)},\mathscr{S}^{(N)})$.

E. The sequence of systems $\{\Sigma^{(N)}\}$

Since we shall be concerned with the properties of the above model in a limit where N tends to infinity and n remains fixed, we need to consider the sequence of systems $\{\Sigma^{(N)}|N\in\mathbf{N}\}$. Specifically, we shall investigate the evolution of these systems from initial states, $\psi^{(N)}$, for which the mean photon number is not superextensive, i.e., its ratio to N is bounded. Thus, we assume that, for some finite constant C,

$$\psi^{(N)}(a^\star_l a_l)<CN,\quad \forall N\in\mathbf{N},\quad l\in[0,n-1]. \tag{2.14}$$

This exclusion of super-extensivity was shown in (I) to persist, in a uniform way, at later times, in that

$$\psi^{(N)}_t(a^\star_l a_l)<DN,\quad \forall N\in\mathbf{N},\quad t\in\mathbf{R}_+,\quad l\in[0,n-1], \tag{2.15}$$

where D is a finite constant.

III. MACROSCOPIC DYNAMICS AND PHASE STRUCTURE

We formulate the macroscopic description of the model, as in (I), in terms of the global intensive observables

$$s^{(N)}_l=(2N+1)^{-1}\sum_{r=-N}^{N}\sigma_{r,-}\,\exp(-2\pi ilr/n);\quad l=0,...,n-1, \tag{3.1}$$

and

$$p^{(N)}_l=(2N+1)^{-1}\sum_{r=-N}^{N}\sigma_{r,z}\,\exp(-2\pi ilr/n);\quad l=0,...,n-1, \tag{3.2}$$

together with the operators

$$\alpha^{(N)}_l=(2N+1)^{-1/2}a_l;\quad l=0,...,n-1, \tag{3.3}$$

corresponding to a scaling of the number operators $a^\star_l a_l$ in units of $2N+1$. We note that the set of $p^{(N)}$'s is the same as that of their adjoints, since

$$p^{(N)\star}_0=p^{(N)}_0\quad\text{and}\quad p^{(N)\star}_l=p^{(N)}_{n-l}\quad\text{for } l=1,...,n-1. \tag{3.4}$$

The set $M^{(N)} := \{s_l^{(N)}, s_l^{(N)\star}, p_l^{(N)}, \alpha_l^{(N)}, \alpha_l^{(N)\star}\}$ of macroscopic variables is a Lie algebra wrt commutation, and, by Eqs. (2.10), (2.11), and (3.3), the radiation field and the interaction Hamiltonian are the algebraic functions of them given by

$$\phi_r^{(N)} = -i \sum_{l=0}^{n-1} \lambda_l \alpha_l^{(N)} \exp(2\pi i r l/n) \tag{3.5}$$

and

$$H_{\text{int}}^{(N)} = i(2N+1) \sum_{l=0}^{n-1} \lambda_l (s_l^{(N)} \alpha_l^{(N)\star} - \text{h.c.}). \tag{3.6}$$

In (I), the dynamics of $M^{(N)}$ was extracted from the microscopic equation of motion (2.12), in a limit where $N \to \infty$ and n remains fixed and finite, subject to the assumptions of Sec. II. As one might anticipate from the fact that the commutators of the elements of $M^{(N)}$ tend normwise to zero in this limit, this macrodynamics is classical.

To describe this dynamics, we simplify our notation by defining $x^{(N)} \equiv (x_1^{(N)}, \ldots, x_{5n}^{(N)})$ to be the $5n$ self-adjoint operators, which, by Eqs. (3.1)–(3.4), comprise the Hermitian and anti-Hermitian parts of the elements of $M^{(N)}$. Correspondingly, in anticipation of a classical limit for the dynamics of these observables, as $N \to \infty$, we introduce a phase space, $X = \mathbf{R}^{5n}$, and, for each point $x = (x_1, \ldots, x_{5n}) \in X$, we define $\{\alpha_l, s_l, p_l | l = 0, \ldots, n-1\}$ to be the complex numbers related to x in precisely the same way that the elements of $M^{(N)}$ are to $x^{(N)}$. We define $\mathscr{C}_0(X)$ to be the space of bounded continuous functions on X that tend to zero at infinity.

We formulate the macroscopic dynamics of $\Sigma^{(N)}$ in terms of the time-dependent quantum characteristic function $\mu_t^{(N)}$ on X, defined by the formula

$$\mu_t^{(N)}(y) = \psi_t^{(N)}(\exp(iy.x^{(N)})) \quad \forall y \in X, \quad t \in \mathbf{R}_+ . \tag{3.7}$$

Further [cf. (I)], we relate the limiting form of this function, as $N \to \infty$, to the following classical dynamical system.

Definition 3.1: We define $\mathscr{K}$ to be the flow in X, whose equation of motion,

$$\frac{dx_t}{dt} = F(x_t), \tag{3.8}$$

is of the explicit form

$$\frac{d\alpha_{l,t}}{dt} = -(i\omega_l + \kappa_l)\alpha_{l,t} + \lambda_l s_{l,t} \tag{3.9a}$$

$$\frac{ds_{l,t}}{dt} = -(i\epsilon + \gamma_1)s_{l,t} + \sum_{m=0}^{n-1} \lambda_m p_{[l-m],t} \alpha_{m,t} \tag{3.9b}$$

and

$$\frac{dp_{l,t}}{dt} = -\gamma_2(p_{l,t} - \eta\delta_{l,0}) - 2\sum_{m=0}^{n-1} \lambda_m (\overline{\alpha}_{m,t} s_{[l+m],t} + \alpha_{m,t} \overline{s}_{[m-l],t}), \tag{3.9c}$$

where $[l \pm m] = l \pm m (\text{mod } n)$.

The following Propositions were proved in (I).

Proposition 3.2: The equation of motion (3.8) [i.e., (3.9)] has a unique global solution, corresponding to a one-parameter semigroup of transformations $x \to \tau_t x (\equiv x_t)$ of X that maps the compacts into compacts.

Proposition 3.3: (i) Under the above assumptions, $\mu_t^{(N)}$ tends pointwise, as $N \to \infty$, to the characteristic function, μ_t, of a probability measure, m_t, on X, i.e.,

$$\lim_{N\to\infty} \mu_t^{(N)}(y) = \mu_t(y) = \int_X \exp\, i(x.y)\, dm_t(x), \tag{3.10}$$

convergence being uniform on the X-compacts.

(ii) The evolution of m_t is induced by the dynamical semigroup, τ, of $\mathscr{K}$, according to the formula

$$\int_X dm_t f = \int_X dm_0 f\circ\tau(t) \quad \forall f\in\mathscr{C}_0(X), \quad t\in\mathbf{R}_+ . \tag{3.11}$$

(iii) In the particular case of a pure phase, where m_0 is a Dirac measure, δ_x, with support at some point x, then $m_t=\delta_{x_t}$.

Comment: This last proposition signifies that, in the limit $N\to\infty$, the macroscopic variables $(\alpha^{(N)},s^{(N)},p^{(N)})$ reduce to classical ones (α,s,p). Correspondingly, the radiative field, $\phi^{(N)}$, as given by Eq. (3.5), reduces to a classical one, ϕ, whose value at the site τ and time t is

$$\phi_{r,t} = -i\sum_{l=0}^{n-1} \lambda_l \alpha_{t,l} \exp(2\pi i r l/n). \tag{3.12}$$

A. Phase structure

By Definition 3.1 and Propositions 3.2 and 3.3(iii), the properties of the pure phase are governed by the classical dynamical system $\mathscr{K}$. A study of this system yields the following results [cf. (I)].

(1) For η less than a certain specified critical value, $\eta_1(>0)$, the system has a unique stable stationary state corresponding to the fixed point, $x_0(\in X)$, given by

$$\alpha_l = 0; \quad s_l = 0; \quad p_l = \eta\delta_{l0} \quad \forall l\in[0, n-1]. \tag{3.13}$$

(2) As η increases through a certain positive value, η_1, the fixed point x_0 becomes unstable, and, by Hopf bifurcation, gives way to a periodic orbit of the form

$$\alpha_{l,t} = \alpha_l^{(0)} \exp(-i(\nu t+\theta^{(0)}))\delta_{lk}; \quad s_{l,t} = s_l^{(0)} \exp((-i\nu t+\theta^{(0)}))\delta_{lk}; \quad p_{l,t} = \eta_1\delta_{l0}, \tag{3.14}$$

where the selection of the kth mode and the values of the constants $\alpha^{(0)}$, $s^{(0)}$, and ν are determined by the parameters of the model, while the phase angle $\theta^{(0)}$ is indeterminate. Thus, in optical terms, there is a transition from normal to coherent radiation as η passes through η_1. This entails a breakdown of the gauge symmetry, represented by the transformations in which the $\sigma_{r,-}$, a_l, and correspondingly s_l, α_l, are all rephased by the same factor $\exp(i\theta)$.

(3) The model generically undergoes a further transition from coherent to chaotic radiation, as η passes through a second critical value, $\eta_2(>\eta_1)$. Specifically, the following two scenarios, both of which involve gauge symmetry breakdown, are feasible.

(a) There can be a bifurcation, at $\eta=\eta_2$, from a periodic orbit to a strange attractor, as specified in the Ruelle–Takens scheme.[11] This scenario is actually realized in the single mode case.[4]

(b) For large n, there could be a succession of bifurcations, corresponding to the activation of different modes, leading to a chaotic phase along the lines of Landau's theory of hydrodynamical turbulence.[12]

IV. THE MICROSCOPIC DYNAMICS IN PURE PHASES

Our objective now is to obtain the microscopic dynamics of the model, in the limit $N\to\infty$. We take the local microscopic observables to be those of the matter only, since, as noted in the Comment following Proposition 3.3, the radiation field reduces to a classical macroscopic one in this limit, and therefore this field carries no local microscopic observables within the terms of this model.[13]

We formulate the $C^\star$-algebra of the observables of the matter, in the limit $N\to\infty$, as the standard quasi-local one for the infinite chain of atoms of the given species, occupying the sites of the lattice $\mathbf{Z}$. Thus, in order to construct this algebra, we define L to be the family of all finite point subsets of $\mathbf{Z}$, and we assign to each $\Lambda\in L$ the $C^\star$-algebra $\mathscr{A}_\Lambda := \otimes_{r\in\Lambda}\mathscr{A}_r$, with $\mathscr{A}_r$ as defined in Sec. II. For $\Lambda\subset\Lambda'$, we identify elements A of $\mathscr{A}_\Lambda$ with $A\otimes I_{\Lambda'\setminus\Lambda}(\in\mathscr{A}_{\Lambda'})$, thereby rendering $\mathscr{A}_\Lambda$ isotonic wrt Λ. We then define $\mathscr{A}$ to be the completion of the local algebra $\mathscr{A}_L := \cup_{\Lambda\in L}\mathscr{A}_\Lambda$ wrt the norm it inherits from the $\mathscr{A}_\Lambda$'s. Thus, the algebras $\mathscr{A}^{(N)}$ of the material observables of the systems $\Sigma^{(N)}$ are just the local subalgebras $\mathscr{A}_{[-N,N]}$ of $\mathscr{A}$.

We denote by $\mathscr{S}(\mathscr{A})$ the set of all states on $\mathscr{A}$, and we represent the space translation group $\mathbf{Z}$ by the automorphisms V of this algebra, defined by the formula

$$V(m)\sigma_{r,u}=\sigma_{r+m,u}, \quad \forall r,m\in\mathbf{Z}, \quad u=\pm,z. \tag{4.1}$$

We note that it follows from our specifications of the local structure of $\mathscr{A}$ that the semigroup $T^{(N)}_{\mathrm{mat}}$, defined in Sec. II, is just the restriction to $\mathscr{A}^{(N)}$ of the global one-parameter semigroup $T_{\mathrm{mat}} := \otimes T_r$ of CP transformations of $\mathscr{A}$. The generator of T_{mat} is therefore

$$L_{\mathrm{mat}}=\sum_{r\in\mathbf{Z}} L_r, \tag{4.2}$$

where L_r is given by Eq. (2.6). The effects of the matter–field coupling on the properties of $\Sigma^{(N)}$, in the limit $N\to\infty$, will be treated presently.

Our aim now will be to obtain the microdynamics of the matter induced by that of the systems $\Sigma^{(N)}$ in the limit $N\to\infty$, subject to the following conditions, characteristic of pure phases, on their initial states.

(P1) The restrictions of the initial states, $\psi^{(N)}$, of the systems $\Sigma^{(N)}$, to the algebras $\mathscr{A}^{(N)}\equiv\mathscr{A}_{[-N,N]}$ are the same as those of a certain primary element, ω, of $\mathscr{S}(\mathscr{A})$, i.e.,

$$\omega_{|\mathscr{A}^{(N)}}=\psi^{(N)}_{|\mathscr{A}^{(N)}}, \quad \forall N\in\mathbf{N}.$$

(P2) $\omega(s_l^{(N)})$ and $\omega(p_l^{(N)})$ converge to values s_l and p_l, respectively, for each $l\in[0,n-1]$, as $N\to\infty$: Since ω is primary, the dispersions of $s_l^{(N)}$ and $p_l^{(N)}$ vanish in this limit.

(P3) The mean and dispersion of $\alpha_l^{(N)}$, for the state $\psi^{(N)}$, converge to values α_l and zero, respectively, for each $l\in[0,n-1]$, as $N\to\infty$.

The following lemma serves to confirm that the assumptions (P1)–(P3), together with Eq. (3.7), imply that the conditions of Proposition 3.3(iii) prevail.

Lemma 4.1: Under the above assumptions, the macroscopic probability measure, m_t, is simply δ_{x_t}, where $x_t=\tau(t)x$ and x is the initial phase point corresponding to (α,s,p) of conditions (P2) and (P3).

Proof: By Eq. (3.7) and the Schwartz inequality,

$$\begin{aligned}|\mu_0^{(N)}(y)-\exp(iy.x)| &\equiv |\psi^{(N)}(\exp(iy.(x^{(N)}-x))-I)|\\ &\leqslant 2\left[\psi^{(N)}\left(\sin^2\left(\frac{y.(x^{(N)}-x)}{2}\right)\right)\right]^{1/2}\\ &\leqslant[\psi^{(N)}(y.(x^{(N)}-x))^2]^{1/2},\end{aligned}$$

and, in view of (P2) and (P3), this tends to zero as $N\to\infty$. Hence, by Proposition 3.3(i), $\mu_0(y)=\exp(iy.x)$, i.e., $m_0=\delta_z$; and, consequently, by Proposition 3.3(iii), $m_t=\delta_{x_t}$, as required.

The following proposition signifies that, in the limit $N\to\infty$, the microscopic dynamics is precisely that of the matter, under the action of the classical macroscopic radiation field, ϕ.

Proposition 4.2: (i) Assuming the conditions (P1)–(P3), the microscopic dynamics of the model corresponds, in the limit $N\to\infty$, to a two-parameter family,

$$\{\mathscr{T}(s,t|\phi)|0\leqslant s\leqslant t;\mathscr{T}(s,u|\phi).\mathscr{T}_\mu(u,t|\phi)=\mathscr{T}(s,t|\phi)\},$$

of CP contractions of $\mathscr{A}$, in that

$$\lim_{N\to\infty} \psi^{(N)}(T^{(N)}(t)A) = \omega(\mathscr{T}(0,t|\phi)A) \quad \forall A \in \mathscr{A}_L, \quad t \in \mathbf{R}_+ . \tag{4.3}$$

Furthermore, the generator of $\mathscr{T}$ is

$$\mathscr{L}(t|\phi) := \frac{\partial}{\partial t}\mathscr{T}(s,t|\phi)_{|s=t} = L_{\mathrm{mat}} + \sum_{r\in\mathbf{Z}} [\phi_{r,t}\sigma_{r,+} - \mathrm{h.c.},.]. \tag{4.4}$$

Thus,

$$\mathscr{T}(s,t|\phi) = \mathbf{T}_a \exp\left(\int_s^t du\ \mathscr{L}(u|\phi)\right), \tag{4.5}$$

where $\mathbf{T}_a$ is the antichronological operator. We define

$$\omega_t := \omega \circ T(0,t). \tag{4.6}$$

(ii) $\mathscr{T}$ factorizes into a product of single site contributions according to the formula

$$\mathscr{T}(s,t|\phi) = \bigotimes_{r\in\mathbf{Z}} \mathscr{T}_r(s,t|\phi_r), \tag{4.7}$$

where

$$\mathscr{T}_r(s,t|\phi_r) = \mathbf{T}_a \exp\left(\int_s^t du\ \mathscr{L}_r(u|\phi)\right) \tag{4.8}$$

and

$$\mathscr{L}_r(t|\phi) = L_r + [\phi_{r,t}\sigma_{r,+} - \mathrm{h.c.},.]. \tag{4.9}$$

Comment: This result is similar to that obtained by Bagarello and Morchio[9] for a class of conservative systems, in that the microscopic evolution is governed by a classical field, formed by the time-dependent macroscopic observables.

The proof of the proposition requires the following lemmas.

Lemma 4.3: Defining

$$\tilde{\alpha}^{(N)}_{l,t} := \alpha^{(N)}_l - \alpha_{l,t}, \tag{4.10}$$

$$\lim_{N\to\infty} \psi^{(N)}_t(\tilde{\alpha}^{(N)\star}_{l,t}\tilde{\alpha}^{(N)}_{l,t}) = \lim_{N\to\infty} \psi^{(N)}_t(\tilde{\alpha}^{(N)}_{l,t}\tilde{\alpha}^{(N)\star}_{l,t}) = 0, \tag{4.11}$$

the convergence being uniform on the t-compacts.

Lemma 4.4: Defining

$$\tilde{s}^{(N)}_{l,t} := s^{(N)}_l - s_{l,t}, \tag{4.12}$$

$$\lim_{N\to\infty} \psi^{(N)}_t(\tilde{s}^{(N)}_{l,t}\tilde{s}^{(N)\star}_{l,t}) = 0, \tag{4.13}$$

the convergence being uniform on the t-compacts.

Proof of Proposition 4.2, assuming Lemma 4.3: (i) By Eqs. (2.5), (2.6), (2.9), (2.10), (2.12), and (2.13),

$$\psi_t^{(N)}(A)-\psi_0^{(N)}(A)=\int_0^t ds\ \psi_s^{(N)}(L_{\mathrm{mat}}A)+\int_0^t ds\sum_{l=0}^{n-1}\psi_s^{(N)}(\alpha_l^{(N)}\delta_l^+A+\alpha_l^{(N)\star}\delta_l^-A)\quad \forall A\in\mathscr{A}_L,$$

$$t\in\mathbf{R}_+, \tag{4.14}$$

where

$$\delta_l^{\pm}=\pm\lambda_l\sum_{r\in\mathbf{Z}}\exp(\pm 2\pi irl/n)[\sigma_{r,\pm},.]. \tag{4.15}$$

We note now that $\mathscr{A}_L$ is stable under $\delta_l^{\pm}$, and that, by Eqs. (2.14), (2.15), and (3.3), $\psi_t^{(N)}(\alpha_l^{(N)\star}\alpha_l^{(N)})$ is bounded, uniformly wrt N and t. It therefore follows from the Schwartz inequality that, for each $A\in\mathscr{A}_L$, the norm of the rhs of Eq. (4.14) is likewise uniformly bounded. Hence, by the Arzela–Ascoli theorem, $\psi_t^{(N)}(A)$ converges to a limit, uniformly over the t-compacts, as $N\to\infty$ over some subsequence of N. Therefore, as $\mathscr{A}$ is norm separable, it follows from the standard diagonalization procedure that there is a state ω_t' on $\mathscr{A}$, such that, over some subsequence of the integers,

$$\lim_{N\to\infty}\psi_t^{(N)}(A)=\omega_t'(A)\quad \forall\in\mathscr{A}_L, t\in\mathbf{R}_+. \tag{4.16}$$

Further, by Eqs. (2.7), (4.2), (4.4), (4.8), and (4.10), we may re-express Eq. (4.14) in the form

$$\psi_t^{(N)}(A)-\psi_0^{(N)}(A)=\int_0^t ds\ \psi_s^{(N)}(\mathscr{L}(s|\phi)A)+\int_0^t ds\sum_{l=0}^{n-1}\psi_s^{(N)}(\tilde{\alpha}_{l,s}^{(N)}\delta_l^+A+\tilde{\alpha}_{l,s}^{(N)\star}\delta_l^-A). \tag{4.17}$$

By Schwartz's inequality and Lemma 4.3, the last integral in this equation tends to zero, uniformly on the compacts, as $N\to\infty$. Hence, by Eq. (4.16), we see that Eq. (4.17) reduces to the following form in this limit:

$$\omega_t'(A)-\omega_0'(A)=\int_0^t ds\ \omega_s'(\mathscr{L}(s|\phi)A),$$

and hence

$$\frac{d}{dt}\omega_t'(A)=\omega_t'(\mathscr{L}(t|\phi)A). \tag{4.18}$$

Consequently, since Eq. (4.5) implies that

$$\frac{\partial}{\partial s}\mathscr{T}(s,t|\phi)=-\mathscr{L}(s|\phi).\mathscr{T}(s,t|\phi),$$

it follows from Eq. (4.18) that

$$\frac{\partial}{\partial s}\omega_s'(\mathscr{T}(s,t|\phi)A)=0\quad \forall 0\leqslant s\leqslant t,\quad A\in\mathscr{A}_L.$$

Hence, $\omega_s'(\mathscr{T}(s,t|\phi)A)$ is independent of s, and consequently, by assumption (P1) and Eq. (4.16),

$$\omega_t'(A)=\omega_0'(\mathscr{T}(0,t|\phi)A)\equiv\omega(\mathscr{T}(0,t|\phi)A),$$

i.e., by Eq. (4.6),

$$\omega_t'=\omega_t=\omega\circ\mathscr{T}(0,t|\phi). \tag{4.19}$$

Equations (4.3) and (4.4) now follow, at least for convergence over a subsequence of integers,

from Eqs. (4.16), (4.18), and (4.19). The removal of the restriction to a subsequence is achieved by noting that, in view of the uniqueness of the evolution $\omega \to \omega_t$, specified by Eq. (4.6), the compactness argument underlying the derivation of Eq. (4.19) may be reemployed to show that all subsequential limits of $\{\psi^{(N)}(T^{(N)}(t)A) | N \in \mathbf{N}\}$ are equal to $\omega_t(A)$.

(ii) The factorization property is an immediate consequence of the fact that, by Eqs. (4.4) and (4.9),

$$\mathscr{L}(t|\phi) = \sum_{r \in \mathbf{Z}} \mathscr{L}_r(t|\phi_r).$$

Proof of Lemma 4.3, assuming Lemma 4.4: Since, by Eqs. (2.7), (3.3), and (4.10), $[\overline{\alpha}_{l,t}^{(N)}, \overline{\alpha}_{l,t}^{(N)\star}] = N^{-1}$, it suffices to establish that the lhs of Eq. (4.11) tends to zero, uniformly on the t-compacts, as $N \to \infty$.

To this end, we define

$$J_{l,t}^{(N)} := \psi_t^{(N)}(\widetilde{\alpha}_{l,t}^{(N)\star} \widetilde{\alpha}_{l,t}^{(N)}), \tag{4.20}$$

and then infer from this equation and Eqs. (2.12) and (4.10) that

$$\frac{dJ_{l,t}^{(N)}}{dt} = \psi_t^{(N)}\left(\left(L^{(N)} + \frac{\partial}{\partial t}\right)\widetilde{a}_{l,t}^{(N)\star} \widetilde{\alpha}_{l,t}^{(N)}\right).$$

It follows from this equation, together with Eqs. (2.13), (3.1)–(3.3), (4.10), (4.12), and (4.20) that

$$\frac{dJ_{l,t}^{(N)}}{dt} = -2\kappa_l J_{l,t}^{(N)} + 2\lambda_l \,\mathrm{Re}\,(\psi_t^{(N)}(\overline{\alpha}_{l,t}^{(N)\star} \widetilde{s}_{l,t}^{(N)})), \tag{4.21}$$

and, consequently,

$$J_{l,t}^{(N)} = J_{l,0}^{(N)} \exp(-2\kappa_l t) + 2\lambda_l \,\mathrm{Re} \int_0^t dt' \exp(-2\kappa_l(t-t'))\psi_{t'}^{(N)}(\widetilde{\alpha}_{l,t'}^{(N)\star} \widetilde{s}_{l,t'}^{(N)}). \tag{4.22}$$

Therefore, defining

$$K_{l,t}^{(N)} := \psi_t^{(N)}(\widetilde{s}_{l,t}^{(N)} \widetilde{s}_{l,t}^{(N)\star}), \tag{4.23}$$

it follows from the Schwartz inequality and Eq. (4.22) that

$$J_{l,t}^{(N)} \leqslant J_{l,0}^{(N)} \exp(-2\kappa_l t) + \int_0^t dt' |\lambda_l| \exp(-2\kappa_l(t-t'))[K_{l,t'}^{(N)} J_{l,t'}^{(N)}]^{1/2}. \tag{4.24}$$

For any fixed $T(>0)$, we now define

$$C_{l,T}^{(N)} := \sup_{t \in [0,T]} J_{l,t}^{(N)} \tag{4.25}$$

and

$$D_{l,T}^{(N)} := \sup_{t \in [0,T]} K_{l,t}^{(N)}, \tag{4.26}$$

noting that these are both finite, in view of Eq. (2.15) and the uniform boundedness of $s^{(N)}$. Hence, by Eqs. (4.24)–(4.26),

$$J_{l,t}^{(N)} \leqslant J_{l,0}^{(N)} \exp(-2\kappa_l t) + 2|\lambda_l| \int_0^t dt' \exp(-2\kappa_l(t-t'))[C_{l,T}^{(N)} D_{l,T}^{(N)}]^{1/2} \quad \forall t \in [0, T]. \tag{4.27}$$

From this formula it follows easily that

$$J_{l,t}^{(N)} \leqslant J_{l,0}^{(N)} + \frac{|\lambda_l|}{\kappa_l} [C_{l,T}^{(N)} D_{l,T}^{(N)}]^{1/2},$$

and hence that

$$C_{l,T}^{(N)} \leqslant J_{l,0}^{(N)} + \frac{|\lambda_l|}{\kappa_l} [C_{l,T}^{(N)} D_{l,T}^{(N)}]^{1/2}, \tag{4.28}$$

which in turn implies that

$$C_{l,T}^{(N)} \leqslant \frac{1}{4} \left[\frac{|\lambda_1|}{\kappa_l} (D_{l,T}^{(N)})^{1/2} + \left(\frac{\lambda_l^2}{\kappa_l^2} D_{l,T}^{(N)} + 4 J_{l,0}^{(N)} \right)^{1/2} \right]^2. \tag{4.29}$$

Further, by definition (4.20) and assumption (P3), $J_{l,0}^{(N)}$ converges to zero as $N \to \infty$; and, by Lemma 4.4, the same is true of $D_{l,T}^{(N)}$. Hence, by Eq. (4.29), $C_{l,T}^{(N)}$ tends to zero as $N \to \infty$. By Eqs. (4.20) and (4.25), this is just the required result.

Proof of Lemma 4.4: Let $q_l^{(N)}$ denote the Hermitian or anti-Hermitian part of $s_l^{(N)}$; and, correspondingly, let $q_{l,t}$ denote the real or imaginary part of $s_{l,t}$. Then, defining

$$c_{l,t}^{(N)}(v) := \psi_t^{(N)}(\exp(iv q_l^{(N)})) \quad \forall v \in \mathbf{R}, \tag{4.30}$$

we see from Eq. (3.7) that $c_{l,t}^{(N)}$ is just the restriction of the characteristic function $\mu_t^{(N)}$ to one matter mode. Thus, by Proposition 3.3(iii) and Lemma 4.1,

$$\lim_{N \to \infty} c_{l,t}^{(N)}(v) = \exp(iv q_{t,l}), \quad \forall v \in \mathbf{R}, t \in \mathbf{R}_+, \tag{4.31}$$

convergence being uniform on the compacts. On integrating this equation against the Fourier transform, $\hat{f}(v)$, of any element, f, of the Schwartz space $\mathscr{D}(\mathbf{R})$, we see that

$$\lim_{N \to \infty} \psi_t^{(N)}(f(q_l^{(N)})) = f(q_{l,t}) \quad \forall f \in \mathscr{D}(\mathbf{R}), t \in \mathbf{R}_+, \tag{4.32}$$

convergence being uniform on the t-compacts for given f. We shall now use this formula to prove the required result, in the form of the equation

$$\lim_{N \to \infty} \psi_t^{(N)}((q_l^{(N)})^m) = (q_{l,t})^m \quad \text{for } m = 1,2, \tag{4.33}$$

convergence being uniform on the compacts.

To establish this formula, we first note that, by Eqs. (2.2) and (3.1), together with our definition of $q_l^{(N)}$, the norm of this operator is $\frac{1}{2}$. Thus, if f is any $\mathscr{D}(\mathbf{R})$-class function with support disjoint from $[-\frac{1}{2}, \frac{1}{2}]$, then $f(q_l^{(N)}) = 0$, and hence, by Eq. (4.32), $f(q_{l,t}) = 0$. This implies that $q_{l,t}$ must lie in the interval $[-\frac{1}{2}, \frac{1}{2}]$. We now reemploy Eq. (4.32), choosing f to be of the form $f(q) = q^m h(q)$, where $m = 1$ or 2, and h is an element of $\mathscr{D}(\mathbf{R})$, whose value is unity over the interval $[-\frac{1}{2}, \frac{1}{2}]$. This choice yields precisely the required result (4.33).

V. ASYMPTOTIC FORM OF THE DYNAMICS AND STATES OF PURE PHASES

We shall now show that the microscopic dynamics of the model simplifies greatly when transient effects, which decay in times of the order of the lifetime of the excited states of its atoms, are discarded.

We start by noting that, by Proposition 4.2, the microscopic dynamics of the model is completely determined by the action of the CP contractions, $\mathscr{T}_r$, on the single site algebras $\mathscr{A}_r$. Thus, defining

$$\sigma_{r,u}(t) := \mathscr{T}_r(0,t)\sigma_{r,u} \quad \text{for } u = +, -, x, y, z, \tag{5.1}$$

we see from Eqs. (2.1), (4.5), and (4.7)–(4.9) that

$$\frac{d\sigma_{r,-}(t)}{dt}+(i\epsilon+\gamma_1)\sigma_{r,-}(t)-i\phi_{r,t}\sigma_{r,z}(t)=0 \tag{5.2}$$

and

$$\frac{d\sigma_{r,z}(t)}{dt}+\gamma_2\sigma_{r,z}(t)-2i(\overline{\phi}_{r,t}\sigma_{r,-}(t)-\text{h.c.})=\gamma_2\eta I. \tag{5.3}$$

Thus, the spin vector $\sigma_r(t)=(\sigma_{r,x}(t),\sigma_{r,y}(t),\sigma_{r,z}(t))$ evolves according to a linear inhomogeneous equation

$$\frac{d\sigma_r(t)}{dt}=b_r(t)\sigma_r(t)+cI, \tag{5.4}$$

where $b_r(t)$ is a linear transformation of $\mathbf{C}^3$, whose explicit form is obtained from the equivalence of Eq. (5.4) to the pair of equations (5.2) and (5.3), and

$$c=(0,0,\gamma_2\eta). \tag{5.5}$$

The solution of Eq. (5.4) may be expressed in the form

$$\sigma_r(t)=g_r(t,0)\sigma_r(0)+\int_0^t dt'\ g_r(t,t')cI, \tag{5.6}$$

where g_r is the Green function for b_r, determined by the formula

$$\frac{\partial}{\partial t}\,g_r(t,t')=b_r(t)g_r(t,t') \quad \forall t\geqslant t'\geqslant 0;\ \ g_r(t,t)=I_3, \tag{5.7}$$

and I_3 is the identity operator in $\mathbf{C}^3$.

Lemma 5.1: For fixed t', $g(t,t')$ decays to zero, with increasing t, at least as fast as $\exp(-\gamma t)$, *where* $\gamma=\min(\gamma_1,\gamma_2)$.

Proof: Let ξ_r be an arbitrary element of $\mathbf{R}^3$, and, for fixed $t'(\in\mathbf{R}_+)$ and any $t>t'$, let $\xi_r(t)=(\xi_{r,x}(t),\xi_{r,y}(t),\xi_{r,z}(t)):=g_r(t,t')\xi_r$. Then, by Eq. (5.7), $\xi_r(t)$ satisfies the homogeneous linear equation obtained by replacing σ_r by ξ_r in Eq. (5.4) and discarding the term cI on the rhs. Hence, defining $\xi_{r,\pm}=1/2(\xi_{r,x}\pm i\xi_{r,y})$, it follows from the equivalence between Eq. (5.4) and the pair of equations (5.2) and (5.3) that the equation of motion for $\xi_r(t)$ is also given by replacing σ by ξ in the latter equations and discarding the rhs of (5.3). Thus,

$$\frac{d}{dt}\,\xi_{r,-}(t)+(\gamma_1-i\epsilon)\xi_{r,-}(t)-i\phi_{r,t}\xi_{r,z}(t)=0$$

and

$$\frac{d}{dt}\,\xi_{r,z}(t)+\gamma_2\xi_{r,z}(t)-2i(\overline{\phi}_{r,t}\xi_{r,-}(t)-\text{c.c.})=0.$$

Hence,

$$\begin{aligned}\frac{d}{dt}\,|\xi_r(t)|^2&\equiv\frac{d}{dt}\,(4|\xi_{r,-}(t)|^2+\xi_{r,z}(t)^2)\\&=-8\gamma_1|\xi_{r,-}(t)|^2-2\gamma_2\xi_{r,z}(t)^2\\&=-2[\gamma_1\xi_{r,x}(t)^2+\gamma_1\xi_{r,y}(t)^2+\gamma_2\xi_{r,z}(t)^2]\leqslant-2\min(\gamma_1,\gamma_2)|\xi_r(t)|^2.\end{aligned}$$

Consequently, defining $\gamma:=\min(\gamma_1,\gamma_2)$,

$$\frac{d}{dt}\left(|\xi_r(t)|^2 \exp(2\gamma t)\right) \leqslant 0,$$

which implies that $|\xi_r(t)|$, and hence $g_r(t,t')$, decay to zero at least as fast as $\exp(-\gamma t)$, with increasing t.

Comment: This lemma signifies that the first term on the rhs of Eq. (5.6) is merely a transient, which decays in a time, γ^{-1}, of the order of the lifetime of an atomic excited state. Consequently, by (5.5), the asymptotic form for $\sigma_r(t)$, obtained by discarding the transients, is

$$\sigma_r(t) = \theta_r(t) I, \tag{5.8}$$

where

$$\theta_r(t) = \int_0^t dt'\ g_r(t,t')(0,0,\gamma_2 \eta). \tag{5.9}$$

Hence, since the state ω_t is given by its action on the finite monomials in the components of the σ_r's, the following Proposition is a simple consequence of these last two equations, together with Proposition 4.1.

Proposition 5.2: The asymptotic form of the time-dependent state ω_t carries no correlations between the observables at the different sites and is therefore of the form

$$\omega_t = \bigotimes_{r \in \mathbf{Z}} \omega_{r,t}, \tag{5.10}$$

where the atomic state $\omega_{r,t}$ is given by

$$\omega_{r,t}(\sigma_r) = \theta_r(t). \tag{5.11}$$

Comment: It follows immediately from this Proposition that the asymptotic state of the model is completely determined by the form of θ_r. We shall denote the components of θ_r analogously with those of σ_r: thus $\theta_r = (\theta_{r,x}, \theta_{r,y}, \theta_{r,z})$ and $\theta_{r,\pm} = \frac{1}{2}(\theta_{r,x} \pm i\theta_{r,y})$. The following Proposition provides an explicit formula for θ_r in terms of the asymptotic forms of the macroscopic variables s and p.

Proposition 5.3: The function θ_r is given by the equations

$$\theta_{r,-}(t) = \sum_{l=0}^{n-1} s_{l,t} \exp(2\pi i r l/n) \tag{5.12}$$

and

$$\theta_{r,z}(t) = \sum_{l=0}^{n-1} p_{l,t} \exp(2\pi i r l/n). \tag{5.13}$$

Proof: By Eqs. (5.2), (5.3), (5.7), and (5.9), the equations of motion for θ_r are formally the same as those for σ_r, i.e.,

$$\frac{d\theta_{r,-}(t)}{dt} + (i\epsilon + \gamma_1)\theta_{r,-}(t) - i\phi_{r,t}\theta_{r,z}(t) = 0 \tag{5.14}$$

and

$$\frac{d\theta_{r,z}(t)}{dt} + \gamma_2 \theta_{r,z}(t) - 2i(\bar{\phi}_{r,t}\theta_{r,-}(t) - \text{c.c.}) = \gamma_2 \eta. \tag{5.15}$$

Further, defining

$$\hat{s}_r(t)=\sum_{l=0}^{n-1} s_{l,t}\exp(2\pi irl/n) \tag{5.16}$$

and

$$\hat{p}_r(t)=\sum_{l=0}^{n-1} p_{l,t}\exp(2\pi irl/n), \tag{5.17}$$

we see, by elementary Fourier analysis, that Eqs. (3.9b) and (3.9c) are equivalent to

$$\frac{d\hat{s}_r(t)}{dt}+(i\epsilon+\gamma_1)\hat{s}_r(t)-i\phi_{r,t}\hat{p}_r(t)=0 \tag{5.18}$$

and

$$\frac{d\hat{p}_r(t)}{dt}+\gamma_2\hat{p}_r(t)-2i(\overline{\phi}_{r,t}\hat{s}_r(t)-\text{c.c.})=\gamma_2\eta, \tag{5.19}$$

respectively. Hence, the equations of motion (5.14) and (5.15) for $\theta_{r,-}$ and $\theta_{r,z}$ are equivalent to those given by (5.18) and (5.19) for $\hat{s}_r$ and $\hat{p}_r$. Consequently, in the asymptotic regime, where the initial conditions are irrelevant, $\theta_{r,-}=\hat{s}_r$ and $\theta_{r,z}=\hat{p}_r$. By Eqs. (5.16) and (5.17), this is the required result.

The following Corollary is an immediate consequence of Propositions 5.2 and 5.3.

Corollary 5.4: The asymptotic state ω_t is spatially periodic, with periodicity n, i.e.,

$$\omega_t=\omega_t\circ V(n), \tag{5.20}$$

where V is the group of spatial translational automorphisms of $\mathscr{A}$ defined by Eq. (4.1).

A. Explicit asymptotic form of ω_t

Equations (5.10)–(5.13) serve to express the time-dependent microstate ω_t in terms of the macroscopic variables. We shall now present its explicit form for both the normal and coherent phases. We have no means of doing the same thing for the chaotic phase, since we have no explicit solution for the macroscopic dynamics there.

1. The normal phase

Here, by Eqs. (3.13) and (5.10)–(5.13), ω_t takes the stationary asymptotic value ω_∞, defined by the equations

$$\omega_\infty=\bigotimes_{r\in\mathbf{Z}}\omega_{\infty,r} \tag{5.21a}$$

and

$$\omega_{\infty,r}(\sigma_{r,\pm})=0,\quad \omega_{\infty,r}(\sigma_{r,z})=\eta. \tag{5.21b}$$

2. The coherent phase

In this phase, it follows from Eqs. (3.14) and (5.10)–(5.13) that the asymptotic form, ω_t^{coh}, of ω_t is given by the formula

$$\omega_t^{\text{coh}}=\bigotimes_{r\in Z}\omega_{r,t}^{\text{coh}}, \tag{5.22a}$$

where

$$\omega_{r,t}^{\text{coh}}(\sigma_{r,-})=s_l^{(0)}\exp\left(i\left(\frac{2\pi ikr}{n}-\nu t-\theta_0\right)\right),\quad \omega_{r,t}^{\text{coh}}(\sigma_{r,z})=\eta. \tag{5.22b}$$

Comment: By contrast with the thermal equilibrium states of pure phases, the stable states ω_t^{coh} are time dependent. The same is true for the pure chaotic phases, since the macroscopic variables s_t and p_t are time dependent there, too.[14]

VI. A NONEQUILIBRIUM MAXIMUM ENTROPY PRINCIPLE

We shall now establish that, as a further consequence of the results of Sec. V, ω_t maximizes the global entropy density of the matter, as defined on the states with spatial periodicity n, subject to the condition that the limiting value, as $N\to\infty$, of the expectation values of the macroscopic variables $s^{(N)},p^{(N)}$ are s_t,p_t, respectively.

For this purpose, we start by defining $\mathscr{S}_n$ to be the set of spatially periodic states, ψ, on $\mathscr{A}$, with period n, and $\mathscr{S}_{n,x_t}$ to be the subset of these states for which

$$\lim_{N\to\infty}\ \psi(s_l^{(N)})=s_{l,t}\quad\text{and}\quad\lim_{N\to\infty}\ \psi(p_l^{(N)})=p_{l,t}\quad\forall\, l\in[0,n],t\in\mathbf{R}_+ .$$

Equivalently, by Eqs. (3.1) and (3.2), $\mathscr{S}_{n,x_t}$ consists of the states, ψ, of spatial periodicity n, which satisfy the conditions

$$n^{-1}\sum_{r=0}^{n-1}\ \psi(\sigma_{r,-})\exp(-2\pi ilr/n)=s_{l,t} \tag{6.1}$$

and

$$n^{-1}\sum_{r=0}^{n-1}\ \psi(\sigma_{r,z})\exp(-2\pi ilr/n)=p_{l,t}, \tag{6.2}$$

for $l=0,...,n-1$ and $t\in\mathbf{R}_+$.

We formulate the global entropy density functional, s, on $\mathscr{S}_n$ in the following standard way.[15] For $\psi\in\mathscr{S}_n$ and $\Lambda\in L$, we define ρ_Λ^ψ to be the density matrix in $\mathscr{H}(\Lambda)$ representing the restriction of ψ to $\mathscr{A}(\Lambda)$, and $S_\Lambda(\psi)$ to be the corresponding local entropy, i.e.,

$$S_\Lambda(\psi)=-k\ \mathrm{Tr}(\rho_\Lambda^\psi\ \ln\ \rho_\Lambda^\psi), \tag{6.3}$$

k being Boltzmann's constant. We define the global entropy density functional, s, on $\mathscr{S}_n$ by the formula

$$s(\psi)=\lim_{\Lambda\uparrow\mathbf{z}}\frac{S_\Lambda(\psi)}{|\Lambda|}, \tag{6.4}$$

the convergence being guaranteed by the subadditivity of entropy[16] and the periodicity of ψ.

Proposition 6.1: The asymptotic time-dependent state ω_t maximizes the functional s, as restricted to $\mathscr{S}_{n,x_t}$.

Proof: We first note that, by Corollary 5.4, $\omega_t\in\mathscr{S}_n$, and that, by Eqs. (5.10)–(5.13), it satisfies the conditions (6.1) and (6.2). Hence, $\omega_t\in\mathscr{S}_{n,x_t}$.

Next, we observe that, if ψ is an arbitrary element of S_{n,x_t}, then it follows by elementary Fourier analysis from Eqs. (5.12), (5.13), (6.1), and (6.2) that $\psi(\sigma_r)=\theta_r(t)$, for $r\in[0,n-1]$, and, consequently, by the periodicity of ψ, for all $r\in\mathbf{Z}$. Therefore, by Eq. (5.11), the restrictions of ψ and ω_t to each single site algebra $\mathscr{A}_r$ are identical. In other words, *all the elements of $\mathscr{S}_{n,x_t}$ coincide on each of the single site algebras.*

Further, by the subadditivity of entropy,

$$S_\Lambda(\psi)\leqslant\sum_{r\in\Lambda}\ S_{\{r\}}(\psi),\quad\forall\,\psi\in\mathscr{S}_{n,x_t},$$

while, by Eqs. (5.10) and (6.3),

$$S_\Lambda(\omega_t)=\sum_{r\in\Lambda} S_{\{r\}}(\omega_t).$$

Consequently, as ψ and ω_t coincide on the single site algebras,

$$S_\Lambda(\psi)\leqslant S_\Lambda(\omega_t),$$

and therefore, by Eq. (6.4),

$$s(\psi)\leqslant s(\omega_t) \quad \forall \psi\in\mathscr{S}_{n,x_t},$$

which proves the Proposition.

VII. CONCLUDING REMARKS

We have provided a microscopic picture of the multi-mode laser model that is complementary to the macroscopic one of (I). Our principal new results are the following.

(1) The microscopic dynamics is governed by the classical, macroscopic field, ϕ, which in turn is generated by the collective action of the atoms on the radiation (Proposition 4.1).
(2) This microdynamics serves to drive the system into states in which the observables of different atoms are uncorrelated (Proposition 5.2). These states have particularly simple forms in both the normal and coherent phases, being stationary and space-translationally invariant in the former and periodic wrt both space and time, in the latter.
(3) In each phase, the eventual time-dependent microstate of the system maximizes the specific entropy of the model, subject to the constraints imposed by the instantaneous values of the macroscopic variables. To the best of our knowledge, this is the first example where such a variational principle has been established in a regime far from thermal equilibrium.[17,18]

These results concern (1) an interplay between microphysics and macrophysics, (2) the decorrelation of certain micro-observables in the course of time, and (3) a maximum entropy principle, corresponding to a conditional thermodynamic stability far from thermal equilibrium. Although the model treated here is but a caricature of a laser, one might envisage that counterparts of these results might have at least some measure of validity in the physics of real dissipative systems. For example, one might expect a local version of the maximum entropy principle (3) to prevail in hydrodynamics, in such a way as to impose local equilibrium conditions on the states of fluids.

[13] In the present model, this is due to the fact that the radiation field is truncated to n modes. Note that here, as in the

nontruncated model of the radiation, the Fourier coefficients of $\phi^{(N)}$ are N-independent multiples of the $\alpha^{(N)}$'s, rather than the a's; consequently, the latter do not appear in the local field algebra when one passes to the limit $N\to\infty$.

[14] If s_t and p_t were constant, then it would follow from Eq. (3.9a) that α_t, and hence x_t, would tend to a constant as t tended to infinity, and consequently that the macroscopic dynamics would not be chaotic.

(Received 26 January 1996; accepted for publication 22 January 1998)

The notion of q-Brownian motion introduced by Majid is extended to braided spaces corresponding to a generic R-matrix, and combined with the theory of quantum probability. This leads to a definition of diffusions on these spaces. The corresponding heat equations (difference-differential equations) are solved in terms of Appell polynomials (i.e., shifted moment systems). Some examples of interest for applications are given. © *1998 American Institute of Physics.* [S0022-2488(98)00805-6]

I. INTRODUCTION

The applications of diffusions in physics go far beyond the description of the physical phenomenon they are named after. Functional integrals can be used to solve partial differential equations, cf. the celebrated Feynman–Kac formula. Wiener integrals are very close to Feynman path integrals. Another interesting application of diffusions is the stochastic mechanics of Nelson.[1]

We will present an approach to diffusions on braided spaces here. Diffusions on manifolds are characterized by two properties, the first being their Markov property, i.e., that at every instant t they start again, and their evolution does not depend on their history, but only on their distribution at time t. This gives rise to a semi-group and this property will also play a central role for the study of diffusions on braided spaces. The other property, i.e., that they have continuous sample paths, does not have a direct counterpart on braided spaces. We replace it by the condition that diffusions can be obtained as the limit of a (simple) random walk.

The motivations for our approach come from two directions. First, there is Majid's random walk approach to Brownian motion on the braided line and on anyspaces.[2,3] We extend his definition to (pseudo-) diffusions on multi-dimensional braided spaces and, using coalgebraic limit theorems due to Schürmann,[4] give their explicit form. This allows one to consider semigroups of functionals and Markovian transition operators, as well as the associated heat equations, and to introduce Appell systems as their polynomial solutions. Heat kernels, i.e., the densities of the functionals, are also considered.

The second ingredient, Schürmann's theory of quantum Lévy processes, comes into play to assure the existence of the associated processes, e.g., as operators on a Hilbert space. We propose a definition of *-structures for braided Hopf algebras (differing from that due to Majid), and give several examples that satisfy our axioms. Then we generalize Schürmann's definitions and a result assuring the positivity of the convolution of positive functionals under certain conditions to braided groups.

To distinguish the two levels of the constructions, we call the functionals and semigroups obtained via Majid's construction pseudo-diffusions, and reserve the name diffusion for the case where the processes can be realized as operators and are Lévy processes (i.e., independent increment processes) in the sense of Schürmann.

This paper starts with a brief summary of the definition of braided spaces and their main

 © 1998 American Institute of Physics

properties in Sec. II. We also introduce some basic notions of quantum probability such as independence and Lévy processes, including a few generalizations that are necessary to apply the existing theory to braided spaces.

The next section (Sec. III) shows how (pseudo-) diffusion processes can be constructed on generic braided spaces associated to a pair of matrices (R,R'). The approach is based on the idea that diffusions can be approximated by random walks on lattices. This replaces the classical condition of the continuity of sample paths. We obtain the explicit form of the limiting process as the chosen time interval and the lattice parameters tend to zero.

Section IV investigates the relation between the diffusion processes and associated evolution equations. These equations are of the form $(\partial_t - L)u = 0$, where L is an operator consisting of linear and quadratic terms in the braided-partials ∂^i. Appell systems (introduced as shifted moment polynomials) are shown to be solutions of the evolution equation. We investigate their properties.

In Sec. V we discuss briefly how density functions can be introduced.

We close with a few final remarks in Sec. VI.

II. PRELIMINARIES

A. Braided spaces

Let us recall the notion of a braided group. This is $(B,m,1,\underline{\Delta},\epsilon,\underline{S},\Psi)$ where $(B,m,1)$ is a unital associative algebra, $(B,\underline{\Delta},\epsilon)$ is a coalgebra, Ψ is a braiding (satisfies the braid relations), and $\underline{S}$ is an antipode (i.e., $m\circ(\mathrm{id}\otimes\underline{S})\circ\underline{\Delta} = m\circ(\underline{S}\otimes\mathrm{id})\circ\underline{\Delta} = 1\circ\epsilon$). The difference that distinguishes braided groups from quantum groups (Hopf algebras) is that now $\underline{\Delta}$ is braided-multiplicative, i.e.,

$$\underline{\Delta}\circ m = m_\Psi^{\otimes}\circ\underline{\Delta},$$

where $m_\Psi^{\otimes}$ is defined by $m_\Psi^{\otimes}((a\otimes c)(b\otimes d)) = a\Psi(c\otimes b)d$. For a more detailed and elegant introduction, see e.g., Refs. 5 and 6.

Braided spaces are braided groups with a particular form of the product and coproduct (see below). They are a generalization of superspaces; there are braided lines, braided planes, braided matrices, etc., all in analogy with superlines, superplanes, etc. Braided spaces are the elementary building blocks of the ''braided world'' or braided linear algebra.

For a pair of invertible matrices (R,R') that satisfy

(i) $R_{12}R_{13}R_{23} = R_{23}R_{13}R_{12}$ (i.e., the Quantum–Yang–Baxter equation),
(ii) $R_{12}R_{13}R'_{23} = R'_{23}R_{13}R_{12}$, $R_{23}R_{13}R'_{12} = R'_{12}R_{13}R_{23}$,
(iii) $(PR+1)(PR'-1) = 0$,
(iv) $R_{21}R'_{12} = R'_{21}R_{12}$,

where P is the permutation matrix $(\mathbf{x}_2\otimes\mathbf{x}_1 P = \mathbf{x}_1\otimes\mathbf{x}_2)$, and $R_{12} = R\otimes\mathrm{id}$, $R_{23} = \mathrm{id}\otimes R$, etc., there exist two braided Hopf algebras $V(R,R')$ and $V^{\check{}}(R,R')$ with generators $v_1,\ldots,v_n$ and $x_1,\ldots,x_n$ and relations
(i) for $V(R,R')$,

$$\underline{\Delta}v^i = v^i\otimes 1 + 1\otimes v^i, \quad \Psi(v^i\otimes v^j) = R^{i\ j}_{k\ l}v^l\otimes v^k,$$

$$v^i v^j = R'^{i\ j}_{k\ l}v^l v^k, \quad \underline{S}(v^i) = -v_i, \quad \epsilon(v^i) = 0;$$

(ii) and for $V^{\check{}}(R,R')$:

$$\underline{\Delta}x_i = x_i\otimes 1 + 1\otimes x_i,$$

$$\Psi(x_i\otimes x_j) = x_l\otimes x_k R^{k\ l}_{i\ j},$$

$$x_i x_j = x_l x_k R'^{k\ l}_{i\ j}, \quad \underline{S}(x_i) = -x_i, \quad \epsilon(x_i) = 0$$

(see Ref. 7, Theorem 1). Here the first two indices (i,k) correspond to the first factor in the tensor product, and the last two (j,l) to the second factor. We use the summation convention, i.e., indices that appear twice (once as subscript and once as superscript) are summed over. In a shorter notation this becomes

(i) for $V(R,R')$: $\underline{\Delta}\mathbf{v}=\mathbf{v}\otimes 1+1\otimes\mathbf{v}$, $\Psi(\mathbf{v}_1\otimes\mathbf{v}_2)=R_{12}\mathbf{v}_2\otimes\mathbf{v}_1$, $R'_{12}\mathbf{v}_2\mathbf{v}_1=\mathbf{v}_1\mathbf{v}_2$, $\underline{S}(\mathbf{v})=-\mathbf{v}$, $\epsilon(\mathbf{v})=0$,

(ii) for $V^{\check{}}(R,R')$: $\underline{\Delta}\mathbf{x}=\mathbf{x}\otimes 1+1\otimes\mathbf{x}$, $\Psi(\mathbf{x}_1\otimes\mathbf{x}_2)=\mathbf{x}_2\otimes\mathbf{x}_1R_{12}$, $\mathbf{x}_2\mathbf{x}_1R'_{12}=\mathbf{x}_1\mathbf{x}_2$, $\underline{S}(\mathbf{x})=-\mathbf{x}$, $\epsilon(\mathbf{x})=0$.

The braided Hopf algebras $V(R,R')$ and $V^{\check{}}(R,R')$ are called the braided vector space and the braided covector space associated to (R,R'). For a detailed development of their properties see also Refs. 5, 6, and 8. We will summarize here only some facts that are used in this presentation.

Let $\mathcal{S}\{1,...,n\}$ be the set of all finite sequences composed of the elements 1,...,n, i.e., $\mathcal{S}\{1,...,n\}=\{\emptyset;1,...,n;11,12,...,nn;111,...\}$. Set $\mathbf{v}^a=v^{a_k}\cdots v^{a_1}$ if $a=(a_1\cdots a_k)\in\mathcal{S}\{1,...,n\}\backslash\{\emptyset\}$, and $\mathbf{v}^{\emptyset}=1$, and analagously, but in reversed order, for $\mathbf{x}_a=x_{a_1}\cdots x_{a_k}$. Then $\{\mathbf{v}^a;a\in\mathcal{S}\{1,...,n\}\}$, $\{\mathbf{x}_a;a\in\mathcal{S}\{1,...,n\}\}$ span $V(R,R')$ and $V^{\check{}}(R,R')$, respectively. Notice that in general these sets do not form a basis. But a basis can easily be extracted from them, if one orders them, and eliminates all elements that are linearly dependent on those that precede them.

The algebras $V(R,R')$ and $V^{\check{}}(R,R')$ are $\mathbb{N}$-graded with

$$V(R,R')^{(r)}=\text{span}\ \{\mathbf{v}^a;a\in S^r\{1,...,n\}\},$$

$$V^{\check{}}(R,R')^{(r)}=\text{span}\ \{x_a;a\in S^r\{1,...,n\}\},$$

where $\mathcal{S}^r\{1,...,n\}\subseteq\mathcal{S}\{1,...,n\}$ contains only the sequences of length r. This allows us to define a scaling $s(\lambda):V^{\check{}}(R,R')\to V^{\check{}}(R,R')$ by $s(\lambda)a=\lambda^{\deg(a)}a$ for homogeneous elements $a\in V^{\check{}}(R,R')$ or $V(R,R')$.

Here $V(R,R')$ and $V^{\check{}}(R,R')$ are mutually dual with the definition

$$\langle\mathbf{v}^a,\mathbf{x}_a\rangle=\delta_{|a|,|b|}[|a|,R]!^a_b,$$

where $|a|,|b|$ is the length of $a,b\in\mathcal{S}\{1,...,n\}$ and

$$[m;R]=1+(PR)_{12}+(PR)_{12}(PR)_{23}+\cdots+(PR)_{12}\cdots(PR)_{m-1,m}, \tag{1}$$

$$[m;R]!=[2;R]_{m-1,m}[3;R]_{m-2,m-1,m}\cdots[m;R]_{1,...,m} \tag{2}$$

(cf. Ref. 6, Section 5). This defines also an action of $V(R,R')$ on $V^{\check{}}(R,R')$ (and *vice versa*) by

$$\rho(v^i)=\partial^i=(\langle v^i,\cdot\rangle\otimes\text{id})\circ\underline{\Delta},$$

$$\rho(x_i)=\hat{\partial}_i=(\langle\cdot,x_i\rangle\otimes\text{id})\circ\underline{\Delta}.$$

Braided exponentials $\exp(\mathbf{x}|\mathbf{v})$ are defined as solutions of

$$\partial^i\ \exp(\mathbf{x}|\mathbf{v})=\exp(\mathbf{x}|\mathbf{v})v^i,\quad(\epsilon\otimes\text{id})\exp(\mathbf{x}|\mathbf{v})=1,$$

$$\exp(\mathbf{x}|\mathbf{v})\hat{\partial}_i=x_i\ \exp(\mathbf{x}|\mathbf{v}),\quad(\text{id}\otimes\epsilon)\exp(\mathbf{x}|\mathbf{v})=1.$$

If the braided integers $[m;R]$ are all invertible, the $\exp(\mathbf{x}|\mathbf{v})$ is given by

$$\exp(\mathbf{x}|\mathbf{v})=\sum\ \mathbf{x}_a([m;R]!^{-1})^a_b\mathbf{v}^b.$$

We will assume that this is the case in what follows, or rather that there exists a braided-exponential $\exp(\mathbf{x}|\mathbf{v})=\Sigma\mathbf{x}_aF(m;R)^a_b\mathbf{v}^b$ (see Ref. 6, Section 5.4).

B. Quantum probability and quantum Lévy processes

A quantum probability space is defined as a pair $(\mathscr{A},\Phi)$ consisting of a *-algebra $\mathscr{A}$ and a state (i.e., a normed positive linear functional) Φ on $\mathscr{A}$, and a quantum random variable j over a quantum probability space $(\mathscr{A},\Phi)$ on a *-algebra $\mathscr{B}$ is a *-algebra homomorphism $j:\mathscr{B}\to\mathscr{A}$. In particular, every element a of $\mathscr{A}$ defines a random variable on the free algebra $\mathbb{C}\langle z,z^*\rangle$ with two generators z,z^* (with the obvious *-structure); simply set $j(z)=a$, $j(z^*)=a^*$, and extend as a*-algebra homomorphism. If a is self-adjoint, then we can take $\mathscr{B}=\mathbb{C}[z]$, with the *-structure defined by $z^*=z$, i.e., the algebra of complex-valued polynomials on the real line.

A central notion to this work is that of independence. Independence in quantum probability is closely related to the notion of products of (*-)algebra, as, e.g., the tensor product or the free product. The kind of independence we use here is related to tensor product of algebras in braided categories. It generalizes the tensorial independence introduced by Schürmann for braidings that arise from an action α and a coaction γ of some group algebra $\mathbb{CL}$ as $\Psi=(\alpha\otimes\mathrm{id})\circ(\mathrm{id}\otimes\tau)\circ(\gamma\otimes\mathrm{id})$ or $\Psi=(\mathrm{id}\otimes\alpha)\circ(\tau\otimes\mathrm{id})\circ(\mathrm{id}\otimes\gamma)$. For a more general definition of independence see Ref. 9; for a general analysis of the notion of independence we refer to Refs. 10 and 11.

Definition 1: The quantum random variables $j_1,j_2,\ldots,j_n:\mathscr{B}\to\mathscr{A}$ are called Ψ-independent (wrt the state Φ), if

(i)

$$\Phi(j_{\sigma(1)}(b_1)\cdots j_{\sigma(n)}(b_n))=\Phi(j_{\sigma(1)}(b_l))\cdots\Phi(j_{\sigma(n)}(b_n))$$

for all permutations $\sigma\in\mathscr{S}(n)$ and all $b_1,\ldots,b_n\in\mathscr{B}$, and

(ii)

$$m_{\mathscr{A}}\circ(j_k\otimes j_l)=m_{\mathscr{A}}\circ(j_l\otimes j_l)=m_{\mathscr{A}}\otimes(j_l\otimes j_k)\circ\Psi$$

for all $1\leqslant k<l\leqslant n$.

Remark: If $\mathscr{A}$ is commutative, then (i) is equivalent to the condition used in classical probability theory:

(i′)

$$\Phi(j_1(b_l)\cdots j_n(b_n))=\Phi(j_l(b_1))\cdots\Phi(j_n(b_n))$$

for all $b_1,\ldots,b_n\in\mathscr{B}$.

We will call $j_1,\ldots,j_n$ pseudo-(Ψ-)independent, if they satisfy only (i′) and (ii). For many of the algebraic aspects this behaves like ''true'' independence.

Let us investigate when two quantum random variables on a braided space $V^{\vee}$ are (pseudo-) independent. Condition (ii) implies that $j_1(x_i)$ and $j_2(x_j)$ satisfy the braid relations. Therefore we can assume $\mathscr{A}=V^{\vee}\underline{\otimes}V^{\vee}$, and $j_1(u)=u\otimes 1$, $j_2(u)=1\otimes u$ [take $\hat{\Phi}=\Phi\circ(j_1\otimes j_2)$]. Condition (i′), i.e., pseudo-independence, is now equivalent to the fact that $\hat{\Phi}$ can be factorized into $\hat{\Phi}=\phi^{(2)}\otimes\phi^{(1)}$, were $\phi^{(i)}=\Phi\circ j_i$, $i=1,2$. Thus the joint distribution of j_1 and j_2 is uniquely determined by the marginal distributions.

Condition (i) is stronger; for independence in the sense of the preceding definition we need a kind of invariance or commutativity condition in addition to the factorization, namely $\phi^{(1)}\otimes\phi^{(2)}(u\otimes v)=\phi^{(2)}\otimes\phi^{(1)}(\Phi(v\otimes u))$, or $\phi^{(1)}\otimes\phi^{(2)}=\Psi(\phi^{(2)}\otimes\phi^{(1)})$, i.e., $\underline{\varepsilon}\otimes\phi^{(2)}$ and $\phi^{(1)}\otimes\underline{\varepsilon}$ have to commute.

We will study here time and space homogeneous Markov processes, i.e., Lévy processes.

Definition 2: A quantum Lévy process on a (braided)-Hopf algebra $\mathscr{B}$ is a quantum stochastic process $\{j_t:\mathscr{B}\to(\mathscr{A},\Phi)\,|\,t\in\mathbb{R}_+\}$, such that*

(i) $\{j_t|t\in\mathbb{R}_+\}$ *has independent increments, i.e., $j_{s_1t_1},\ldots,j_{s_nt_n}$ are (Ψ-)independent for all $0\leqslant s_1\leqslant t_1\leqslant\cdots\leqslant s_n\leqslant t_n$, where the increments are defined by $j_{st}=(j_s\circ S)\star j_t=m_{\mathscr{A}}\circ((j_s\circ S)\otimes j_t)\circ\Delta$,*

(ii) *the distribution $\Phi\circ j_{st}$ of an increment j_{st} depends only on $t-s$ (stationarity),*

(iii) *j_{st} converges to j_{ss} in distribution for $t\searrow s$ (weak continuity).*

We shall speak of pseudo-Lévy processes, if the increments are only pseudo-independent. In this case we will not insist on the positivity of the state either. We study pseudo-Lévy processes (and pseudo-diffusions, see below) only to illustrate the algebraic part of the theory.

It follows from the general theory (cf. Ref. 4) that a Lévy process is uniquely determined by its marginal distributions $\varphi_t=\Phi\circ j_t$, that the marginal distribution form a convolution semigroup, i.e., $\varphi_0=\underline{\varepsilon}$, $\varphi_s\star\varphi_t=(\varphi_s\otimes\varphi_t)\circ\Delta=\varphi_{s+t}$, and that there exists a unique functional L, called generator, such that $\varphi_t=\exp(tL)$. *Vice versa*, the semigroup, and thus the process, is also uniquely determined by its generator. All this is also true for pseudo-Lévy processes.

Let us now look at the differences. The independence of the increments implies $\Psi(e^{tL}\otimes e^{sL})=e^{sL}\otimes e^{tL}$, and thus $\Psi(L\otimes L)=L\otimes L$, i.e., $L\otimes\underline{\varepsilon}$ and $\underline{\varepsilon}\otimes L$ commute (in the convolution algebra of functionals on $V\check{}\underline{\otimes}V\check{}$). Also, since the semigroup is positive, L is conditionally positive (i.e., positive on the kernel of $\underline{\varepsilon}$), to see this just differentiate wrt t, and Hermitian. In the sequel, when we speak of Lévy processes, we will always assume that our states ϕ (on $\mathscr{A}$) are Ψ-invariant in the sense that $\Psi(\phi\otimes u)=u\otimes\phi$ for all functionals $u:\mathscr{B}\to\mathbb{C}$, i.e., that we can pull it across braidings.

If L is a Hermitian, conditionally positive, and Ψ-invariant functional, then all the convolution powers of L are positive (see Lemma 4), and the semigroup associated to L is positive. Thus there exists a Lévy process with $\varphi_t=\exp(tL)$ as marginal distributions.

We summarize this in the following proposition.

Proposition 3: Let $\mathscr{A}$ be a (braided) (-)Hopf algebra (cf. Sec. II C).*

(i) *There is a one-to-one correspondence between pseudo-Lévy processes $\{j_t|t\in\mathbb{R}_+\}$, normed convolution semi-groups $\{\varphi_t|t\in\mathbb{R}_+\}$, $\varphi_t=\exp(tL)=\Phi\circ j_t$, and functionals $L=d/dt\ \varphi_t|_{t=0}$ with $L(1)=0$ on $\mathscr{A}$.*

(ii) *There is also a one-to-one correspondence between Lévy processes, normed positive convolution semigroups of Ψ-invariant states, and Ψ-invariant, Hermitian, conditionally positive functionals.*

C. A remark on braided*-Hopf algebras

Majid has studied *-structures on braided Hopf algebras in a series of articles.[12–14] An essential result of his work is a new set of axioms for the braided case. However, we found it necessary to use different axioms here; in particular, it is important for our purposes that the coproduct is a *-algebra homomorphism.

We fix the *-structure in the tensor product $\mathscr{A}\underline{\otimes}\mathscr{A}$ by the condition that the canonical inclusions $\mathscr{A}\xrightarrow{i_1}\mathscr{A}\underline{\otimes}\mathscr{A}\xrightarrow{i_2}\mathscr{A}$ are *-algebra homomorphism, i.e., $(1\otimes a)^*=1\otimes a^*$ and $(a\otimes 1)^*=a^*\otimes 1$ for all $a\in\mathscr{A}$. This implies $(a\otimes b)^*=\psi(b^*\otimes a^*)$ for all $a,b\in\mathscr{A}$. Then we say that $\mathscr{A}$ is a (braided) *-Hopf algebra if $(\mathscr{A},*)$ is a *-algebra, and $\underline{\Delta}$ and $\underline{\varepsilon}$ are *-algebra homomorphism (with the *-structure of $\mathscr{A}\underline{\otimes}\mathscr{A}$ defined as above!).

For examples of braided *-Hopf algebras satisfying these conditions, see Sec. III B.

Let us outline the main step and ideas of their construction. We start with a braided-covector space $V\check{}(R,R')$ with R,R' of real type I, i.e., $\overline{R^{i\ k}_{j\ l}}=R^{l\ j}_{k\ i}$. Majid has defined a map $*$ for this case that goes from $V\check{}(R,R')$ to $V(R,R')$, and *vice versa* (cf. Ref. 13, Lemma 2.1). The free product $V(R,R')*V\check{}(R,R')$ thus becomes a *-algebra with this map, and the coproducts of $V(R,R')$ and $V\check{}(R,R')$ define a *-algebra homomorphism $\underline{\Delta}_0:V(R,R')*V\check{}(R,R')\to(V(R,R')\otimes(R,R'))*(V\check{}(R,R')\underline{\otimes}V\check{}(R,R'))$. Now it turns out that $(V(R,R')*V\check{}(R,R'))\otimes(V(R,R')*V\check{}(R,R'))$ can be obtained as a quotient of $(V(R,R')\underline{\otimes}V(R,R'))*(V\check{}(R,R')\otimes V\check{}(R,R'))$ in such a way that the canonical projection is a *-algebra homomorphism, and that $V(R,R')*V\check{}(R,R')$ is a braided *-Hopf algebra in the sense of our definition with $\underline{\Delta}=\pi\circ\underline{\Delta}_0$. Set $x_{1i}=x_i\otimes 1$, $v^i_1=v^i\otimes 1$, $x_{2i}=1\otimes x_i$, and $v^i_2=1\otimes v^i$. Then the relations defining the braided *-Hopf algebra structure of $V(R,R')*V\check{}(R,R')$ are

$$x_ix_j=x_lx_kR'^{k\ \ l}_{i\ \ j},\quad v^jv^i=R'^{j\ \ i}_{l\ \ k}v^kv^l,$$

$$x_i^*=v^i,\quad (v^i)^*=x_i,$$

$$\underline{\Delta}(x_i)=x_{1i}+x_{2i}, \quad \underline{\Delta}(v^i)=v_1{}^i+v_2{}^i,$$

$$\underline{S}(x_i)=-x_i, \quad \underline{S}(v^i)=-v^i, \quad \underline{\varepsilon}(x_i)=\underline{\varepsilon}(v^i)=0$$

$$x_{\alpha,i}x_{\alpha,j}=x_{\alpha,l}x_{\alpha,k}R'^{k}{}_{i}{}^{l}{}_{j}, \quad v_\alpha{}^j v_\alpha{}^i=R'^{j}{}_{l}{}^{i}{}_{k}v_\alpha{}^k v_\alpha{}^l, \quad \alpha=1,2,$$

$$(x_{\alpha,i})^*=v_\alpha{}^i, \quad (v_\alpha{}^i)^*=x_{\alpha,i}, \quad \alpha=1,2,$$

$$x_{2i}x_{1j}=R^{k}{}_{i}{}^{l}{}_{j}x_{1l}x_{2k}, \quad v_2{}^i x_{1j}=(R^{-1})^{i}{}_{k}{}^{l}{}_{j}x_{1l}v^{k}{}_{2},$$

$$v_1{}^j x_{2i}=(R^{-1})^{j}{}_{l}{}^{k}{}_{i}x_{2k}v_1{}^l, \quad v_1{}^j v_2{}^i=R^{j}{}_{l}{}^{i}{}_{k}v_2{}^k v_i{}^l.$$

We observe that, with the definitions $x_i^*=v_i$, $x_{\alpha,i}^*=v^i{}_\alpha$, the '$v$-$v$' relations follow from the corresponding 'x-x' relations, and the second line of the braid relations from the first (where we use that R, R' are real type I).

Note also that $x_{1i}v_1{}^i, v_1{}^i x_{1i}$ (or $x_{2i}v_2{}^i, v_2{}^i x_{2i}$, resp.), $i=1,...,n$, (no summation!) commute with all $x_{2j}, x_2{}^j$ ($x_{1j}, x_1{}^j$, resp.). Thus the functionals that are nonzero only on these elements are Ψ-invariant.

We prove the following.

*Lemma 4: Let $\mathscr{A}$ be a braided *-bialgebra (in the sense of the preceding definition, i.e., the *-structure in the braided product algebra $\mathscr{A}\underline{\otimes}\mathscr{A}$ is given by $\Psi\circ(*\otimes *)\circ\tau$, and $\underline{\Delta}$ is a *-algebra homomorphism), and let ϕ be a Ψ-invariant positive functional on $\mathscr{A}$, and θ be a positive functional on $\mathscr{A}$. Then $\phi\star\theta=(\phi\otimes\theta)\circ\underline{\Delta}$ is also positive.*

Proof: Let $a\in\mathscr{A}$, and $\underline{\Delta}(a)=\Sigma_i a_i^{(1)}\otimes a_i^{(2)}$ (Sweedler's notation). Then $\underline{\Delta}(a^*)=\Sigma_j\Psi((a_j^{(2)})^*\otimes(a_j^{(1)})^*)$ and therefore $(\phi\otimes\theta)\circ\underline{\Delta}(a^*a)=(\phi\otimes\theta)\circ(m\otimes m)\circ(\mathrm{id}\otimes\Psi\otimes\mathrm{id})\circ(\Psi\otimes id\otimes id)(\Sigma_{i,j}(a_j^{(2)})^*\otimes(a_j^{(1)})^*\otimes a_i^{(1)}\otimes a_i^{(2)}) = \theta\circ(\phi\otimes m)\circ(\Psi\circ\mathrm{id})\circ(\mathrm{id}\otimes m\otimes\mathrm{id})(\Sigma_{i,j}(a_j^{(2)})^*\otimes(a_j^{(1)})^*\otimes a_i^{(1)}\otimes a_i^{(2)})=\Sigma_{i,j}\Theta((a_j^{(2)})^*a_i^{(2)})\phi((a_j^{(1)})^*a_i^{(1)})$ is positive, since it is the Schur product of two positive definite matrices. ■

III. A CONSTRUCTION OF (PSEUDO-) DIFFUSIONS ON BRAIDED SPACES

Following Majid we first define a quantum random walk. Consider a classical random walk on the lattice. We assume that the process can only jump from a lattice site x to a finite number of other sites $x+d_i$, $i=1,...,k$. If at time t the particle is located at x, then it will be at $x+d_i$ at time $t+\Delta t$ with a probability p_i, $0\leqslant p_i\leqslant_1$, and naturally the probabilities add to one,

$$\sum_{i=1}^{k} p_i=1.$$

In classical probability theory there corresponds an evolution operator to this which maps a function (i.e., an observable) at time t to the corresponding function one time step later

$$f_t(x)\mapsto f_{t+\Delta t}(x)=\sum_{i=1}^{k} p_i f_t(x+d_i).$$

Let $\phi^{(d_i)}$ be the functional corresponding to evaluation of a function at d_i, i.e., $\phi^{(d_i)}$: $f(x)\mapsto f(d_i)$. Then the above equation can be written as

$$f_t(x)\mapsto f_{t+\Delta t}(x)=(\phi\otimes\mathrm{id})\circ\Delta f_t(x),$$

where $\phi=\Sigma p_i\phi^{(d_i)}$ and Δ stands for the usual cocommutative coproduct on $\mathbb{R}[x_1,\ldots,x_n]$. This can be done in the same manner on braided spaces and quantum groups, if one chooses an appropriate functional ϕ. The problem here (in dimension >1) is that one cannot define the $\phi^{(d_i)}$ simply as replacing the variables x_i by the components of the vectors $d_j=(d_{j1},\ldots,d_{jn})$ due to the noncommutativity. One possibility is to bring the variables into some fixed order (i.e., fix a basis of monomials) and replace them then by the d_{ji}. We shall see later that in the limit only the choice on the quadratic and linear terms matters.

A functional $\phi^{(d)}$ that corresponds to evaluation at $d=(d_1,\ldots,d_n)$ should satisfy
F1: $\phi^{(d)}(1)=1$, or equivalently $\phi^{(d)}|_{V^\vee(R,R')^{(0)}}=\epsilon$;
F2: evaluation on the generators gives the components of d, i.e.,

$$\phi^{(d)}(x_i)=d_i,$$

for $i=1,\ldots,n$;
F3: it has the correct behavior with respect to a rescaling of d, more precisely,

$$\phi^{(\lambda d)}(a)=\phi^{(d)}(s(\lambda)a)=\lambda^{\deg(a)}\phi^{(d)}(a)$$

for homogeneous $a\in V^\vee(R,R')$.
However, these conditions do not determine $\phi^{(d)}$ uniquely.
A possible choice for $\phi^{(d)}$ with $d=(d_1,\ldots,d_n)$ is to use the braided-exponential

$$\phi^{(d)}=\exp(d|\mathbf{v})=\sum_{a\in\mathcal{T}\{1,\ldots,n\}} d_a([m;R]!^{-1})^a_b\mathbf{v}^b. \tag{3}$$

This definition makes sense for all cases where the braided-integers $[m;R]$ are invertible, and can also be used if this is not the case, if an appropriate braided-exponential is chosen. For the commutative case we have $\phi^{(d)}f(\mathbf{x})=f(d)$ by Taylor's theorem, and similarly for the braided line $\mathbb{R}_q$ by a q-Taylor theorem. On anyspace this agrees with definition of the Dirac δ-function (see Ref. 3).

Another possibility is to use (positive) Dirac functionals, defined as functionals φ for which there exists a (*-)algebra $\mathcal{A}$, a state Φ on $\mathcal{A}$, and a (*-)algebra homomorphism $j:V^\vee(R,R')\to\mathcal{A}$ such that $\varphi=\Phi\circ j$ and the pair (j,j) is independent. Typically these Dirac functionals replace one generator by a real or complex number, and all other generators by zero, and lead to the same class of diffusions as the functional presented above.

Assume now that we have defined the functionals $\phi^{(d_i)}$, and chosen values for the transition probabilities p_i, i.e., fixed ϕ. Then this defines an evolution for functions, i.e., observables on our space by

$$f_t\mapsto f_{t+\Delta t}=(\phi\otimes\mathrm{id})\circ\underline{\triangle}f_t$$

as before. As explained in Ref. 2 there is a one-to-one correspondence between functionals ϕ and transition operators T; to pass from one to the other take

$$\phi\mapsto T_\phi=(\phi\otimes\mathrm{id})\circ\underline{\triangle},$$

$$T\mapsto\phi_T=\epsilon\circ T.$$

The transition operators form a (discrete) semi-group with respect to composition, and the functionals with respect to convolution. The passage from one to the other is in fact a homomorphism, i.e., $T_\phi\circ T_\psi=T_{\phi\psi}$ and $\phi_T\phi_S=\phi_{TS}$.

We study the limit that arises if the lattice parameters d_i and the time step Δt go to zero. The discrete semi-groups (indexed by $\mathbb{N}$) will then converge to continuous ones (indexed by $\mathbb{R}_+$).

Theorem 5: *Let $d_1,\ldots,d_k$ and $p_1^0,\ldots,p_k^0$ be chosen such that $\Sigma_{i=1}^k p_i^0=1$ and $\phi=\Sigma_{i=1}^k p_i^0\phi^{(d_i)}$ vanishes on $V^\vee(R,R')^{(1)}$, i.e., $\Sigma_{i=1}^k p_i^0 d_{ij}=0$ for all $j=1,\ldots,n$.*

Choose furthermore $p_1^1,\ldots,p_k^1$ such that $p_1(\mu)=p_1^0+\mu p_1^1,\ldots,p_k(\mu)=p_k^0+\mu p_k^1$ satisfy $0\leqslant p_i\leqslant 1$ and $\Sigma_{i=1}^k p_i=1$ for sufficiently small μ (this implies in particular $\Sigma_{i=1}^k p_i^1=0$).

Then for $\phi_N=\Sigma_{i=1}^k p_i(1/\sqrt{N})\phi^{(d_i/\sqrt{N})}$ we have

$$\lim_{N\to\infty}(\phi_N)^N=\exp\left(\sum_{k,l=1}^n a_{kl}v^kv^l+\sum_{j=1}^n b_iv^i\right),$$

where $a_{kl}=\Sigma_{i=1}^k p_i^0\Sigma_{r,s=1}^n d_{ir}d_{is}([2;R]^{-1})^{rs}_{kl}$ and $b_j=\Sigma_{i=1}^k p_i^1 d_{ij}$.

Proof: We apply Ref. 4, Theorem 6.1.1. Let $k_N=N$ and $\varphi_{Nk}=\phi_N$ for $k=1,\ldots,N$. We have to check the conditions of the theorem.

(i) $\varphi_{N1},\ldots,\varphi_{NN}$ commute since they are identical.
(ii) Let $c=\Sigma_{a\in\mathscr{S}\{1,\ldots,n\}}c^a\mathbf{x}_a$ with some coefficients $c^a\in\mathbb{C}$. Then

$$\max_{l\leqslant k\leqslant N}|(\varphi_{Nk}-\epsilon)(c)|=\phi_N(c)-c^{\varnothing}=O(1/\sqrt{N})$$

goes to zero as $N\to\infty$.
(iii)

$$\sum_{k=1}^{N}(\varphi_{Nk}-\epsilon)(c)=N(\phi_N(c)-c^{\varnothing})=\sum_{i=1}^{k}p_i^1\sum_{j=1}^{n}d_{ij}c^{\{j\}}+\sum_{i=1}^{k}p_i^0\sum_{r,s=1}^{n}d_{ir}d_{is}c^{rs}+O(1/\sqrt{N})$$

is bounded and tends to $(\Sigma_{k,l=1}^{n}a_{kl}v^kv^l+\Sigma_{j=1}^{n}b_iv^i)(c)$.
Thus $\lim_{N\to\infty}(\Pi_{k=1}^{N}\varphi_{Nk})(c)=\exp(\Sigma_{k,l=1}^{n}a_{kl}v^kv^l+\Sigma_{j=1}^{n}b_iv^i)(c)$.

We will consider functionals that can be obtained in this way as diffusions on braided spaces and call $L=\Sigma_{k,l=1}^{n}a_{kl}v_kv_l+\Sigma_{j=1}^{n}b_iv^i$ their generator.

Definition 6: We will call a semi-group of functionals $\exp(tL)$ *on* $V^{\check{}}(R,R')$ *a (homogeneous) pseudo-diffusion, if there exist parameters* $d_i=(d_{i1},\ldots,d_{in})$, p_i^0,p_i^1 $(i=1,\ldots,k)$ *such that the conditions of Theorem 5 are satisfied, and such that* $L=\Sigma_{k,l=1}^{n}a_{kl}v^kv^l+\Sigma_{j=1}^{n}b_iv^i$ *with* $a_{kl}=\Sigma_{i=1}^{k}p_i^0\Sigma_{r,s=1}^{n}d_{ir}d_{is}([2;R]^{-1})_{kl}^{rs}$ *and* $b_j=\Sigma_{i=1}^{k}p_i^1d_{ij}$.

If the process associated to $\exp(tL)$ *is also a Lévy process, then we will call it a diffusion.*
Remarks:

(1) We have formulated the limit theorem in terms of the functionals; analogous theorems for the associated transition operators hold also.
(2) In the statements of Theorem 5 we assumed that the braided-integers are invertible. The theorem remains valid if this is not the case; as long as a braided-exponential $\exp(\mathbf{x}|\mathbf{v})=\Sigma\mathbf{x}_aF(m;R)_b^a\mathbf{v}^b$ exists, the inverted braided-exponentials just have to be replaced by the $F(m;R)$.

A. Examples of (pseudo-) diffusions

1. Dimension n=1: The braided line $\mathbb{R}_q$

Here $R=(q)$ and $R'=(1)$. This leads to the braiding $\Psi(x^m\otimes x^p)=q^{mp}x^p\otimes x^m$ (i.e., $x'x=qxx'$, where $x=x\otimes 1$, $x'=1\otimes x$). The diffusions on the braided line have the form

$$\phi_t=\exp\left[t\left(\frac{a^2}{1+q}v^2+bv\right)\right].$$

Using the expansion $e^{-tu^2/2+xu}=\Sigma_{p=0}^{\infty}(u^p/p!)H_p(x,t)$ with the Hermite polynomials $H_p(x,t)=\Sigma_{k=0}^{[p/2]}\binom{p}{2k}[(2k)!/2^kk!]x^{p-2k}(-t)^k$ we find for the moments

$$\phi_t\left(\frac{x^p}{[p;q]!}\right)=\frac{H_p(bt,-2a^2t/(1+q))}{p!}.$$

2. Dimension n=2: The quantum plane $\mathbb{C}_q^{2|0}$

Here

$$R=\begin{pmatrix}q^2&0&0&0\\0&q&q^2-1&0\\0&0&q&0\\0&0&0&q^2\end{pmatrix},\quad R'=q^{-2}R.$$

This is the standard two-dimensional quantum plane. It has two generators x,y with relations $yx=qxy$ and braid statistics $x'x=q^2xx'$, $x'y=qyx'$, $y'y=q^2yy'$, and $y'x=qxy'+(q^2-1)yx'$. For the second braided-integer we obtain

$$[2;R]=\begin{pmatrix} 1+q^2 & 0 & 0 & 0 \\ 0 & 1 & q & 0 \\ 0 & q & q^2 & 0 \\ 0 & 0 & 0 & 1+q^2 \end{pmatrix},$$

i.e. it is not invertible. There exists nonetheless a braided-exponential (Ref. 6, Example 5.4)

$$\exp(\mathbf{x}|\mathbf{v})=\sum_{a\in\mathscr{S}\{1,\ldots,n\}}\frac{\mathbf{x}_a\mathbf{v}^a}{[|a|;q^2]!}=\sum_{p=0}^{\infty}\frac{(\mathbf{x}\cdot\mathbf{v})^p}{[p;q^{-2}]!},$$

where $[m;q^2]=(1-q^{2m})/(1-q^2)$ and $[m;q^2]!=\Pi_{\mu=1}^{m}[\mu;q^2]$. For the generator we obtain

$$L=\frac{1}{1+q^2}\sum a_{ij}\partial_i\partial_j+\sum b_i\partial_i.$$

3. The free braided-space

Here $R'=P$ and there are no relations in the algebras $V(R,R')$ and $V^{\check{}}(R,R')$ since the ideal generated by $R'_{12}\mathbf{v}_2\mathbf{v}_1=\mathbf{v}_1\mathbf{v}_2$ (respectively $\mathbf{x}_1\mathbf{x}_2R'_{12}=\mathbf{x}_2\mathbf{x}_1$) is equal to $\{0\}$, i.e., we have the free algebra with n generators. $\{\mathbf{v}^a;a\in\mathscr{S}\{1,\ldots,n\}\}$ (respectively $\{\mathbf{x}_a;a\in\mathscr{S}\{1,\ldots,n\}\}$) is thus a basis of $V(R,R')$ [respectively $V^{\check{}}(R,R')$].

We will assume that R is also equal to P, i.e., that the braiding is given by $\Psi(v^i\otimes v^j)=(v^i\otimes v^j)$ [respectively $\Psi(x_i\otimes x_j)=(x_i\otimes x_j)$]. In this case the braided-integers $[m;P]_b^a=m\,\delta_{ab}$, $m=|a|=|b|$, are invertible and thus

$$\exp(\mathbf{x}|\mathbf{v})=\sum_{k=0}^{\infty}\frac{1}{k!}\sum_{a\in\mathscr{S}^k\{1,\ldots,n\}}\mathbf{x}_a\mathbf{v}^a.$$

The dual action is

$$\rho(v^i)\mathbf{x}_a=\begin{cases}|a|\mathbf{x}_{a_2\ldots a_{|a|}} & \text{if } a_1=i,\\ 0 \quad \text{else,}\end{cases}$$

on the basis elements. Generators of diffusions have again the form

$$L=\sum_{k,l=1}^{n}a_{kl}\partial_k\partial_l+\sum_{j=1}^{n}b_j\partial_j \tag{4}$$

with symmetric a_{kl}.

B. Examples of true diffusions

1. A free two-dimensional braided plane: $V^{\check{}}=\mathbb{R}_q*\check{\mathbb{R}}_q$

The algebra underlying this example can be considered as the free product of the braided line with its dual. As an algebra it is the free unital algebra $\mathbb{C}\langle x,p\rangle$ with two generators. Let x be the generator of the braided-covector space $\mathbb{R}_q$, and p that of the braided-vector space dual to it (i.e., another copy of $\mathbb{R}_q$). Let $q\in\mathbb{R}\backslash\{0\}$, so that $R=(q)$ is of real type I in the sense of Ref. 13. Following Majid's definitions we have the braid relations

$$x'x=qxx,\quad x'p=q^{-1}px',\quad p'x=q^{-1}xp',\quad p'p=qpp',$$

and

$$*_{\mathbb{R}_q\underline{\otimes}\check{\mathbb{R}}_q}:\mathbb{R}_q\underline{\otimes}\check{\mathbb{R}}_q\to\mathbb{R}_q\underline{\otimes}\check{\mathbb{R}}_q,\quad x^*=p,$$

$$*_{\mathbb{R}_q\underline{\otimes}\check{\mathbb{R}}_q\underline{\otimes}\mathbb{R}_q\underline{\otimes}\check{\mathbb{R}}_q}:\mathbb{R}_q\underline{\otimes}\check{\mathbb{R}}_q\underline{\otimes}\check{\mathbb{R}}_q\to\mathbb{R}_q\underline{\otimes}\check{\mathbb{R}}_q\underline{\otimes}\check{\mathbb{R}}_q,\quad x^*=p',\ (x')^*=p,$$

turn $\mathbb{R}_q\underline{\otimes}\check{\mathbb{R}}_q$ and $\mathbb{R}_q\underline{\otimes}\check{\mathbb{R}}_q\underline{\otimes}\mathbb{R}_q\underline{\otimes}\check{\mathbb{R}}_q$ into *-algebras such that $\underline{\triangle}\ \mathbb{R}_q\underline{\otimes}\check{\mathbb{R}}_q\to\mathbb{R}_q\underline{\otimes}\check{\mathbb{R}}_q\underline{\otimes}\mathbb{R}_q\underline{\otimes}\check{\mathbb{R}}_q$ satisfies $\underline{\triangle}\circ *_{\mathbb{R}_q\underline{\otimes}\check{\mathbb{R}}_q}=*_{\mathbb{R}_q\underline{\otimes}\check{\mathbb{R}}_q\underline{\otimes}\mathbb{R}_q\underline{\otimes}\check{\mathbb{R}}_q}\circ\tau\circ\underline{\triangle}$. Even though this *-structure does not suit our purposes, at least not in this form, it does tell how we can guess a ''better'' one.

The coproduct on $\mathbb{R}_q$ and its dual extends to a map $\underline{\triangle}_0$: $\mathbb{R}_q*\check{\mathbb{R}}_q\to(\mathbb{R}_q\underline{\otimes}\mathbb{R}_q)*(\check{\mathbb{R}}_q\underline{\otimes}\check{\mathbb{R}}_q)=\mathbb{C}\langle p,p',x,x'\rangle/\mathscr{T}_0$, where $\mathscr{T}_0$ is the ideal generated by $x'x-qxx'$ and $p'p-qpp'$, and satisfies $\underline{\triangle}\circ *_{\mathbb{R}_q*\check{\mathbb{R}}_q}=*_{(\mathbb{R}_q\underline{\otimes}\mathbb{R}_q)*(\check{\mathbb{R}}_q\underline{\otimes}\check{\mathbb{R}}_q)}\circ\underline{\triangle}$, if we define the *-structures in those algebras by

$$*_{\mathbb{R}_q*\check{\mathbb{R}}_q}:\quad \mathbb{R}_q*\check{\mathbb{R}}_q\to\mathbb{R}_q*\check{\mathbb{R}}_q,\quad x^*=p,$$

$$*_{(\mathbb{R}_q\underline{\otimes}\mathbb{R}_q)*(\check{\mathbb{R}}_q\underline{\otimes}\check{\mathbb{R}}_q)}:\quad (\mathbb{R}_q\underline{\otimes}\mathbb{R}_q)*(\check{\mathbb{R}}_q\underline{\otimes}\check{\mathbb{R}}_q)\to(\mathbb{R}_q\underline{\otimes}\mathbb{R}_q)*(\check{\mathbb{R}}_q\underline{\otimes}\check{\mathbb{R}}_q),\quad x^*=p',\ (x')^*=p.$$

We now note that we obtain $(\mathbb{R}_q*\check{\mathbb{R}}_q)\underline{\otimes}(\mathbb{R}_q*\check{\mathbb{R}}_q)$ if we quotient by the relations $qxp=px$ and $qp'x'=x'p'$, i.e., $(\mathbb{R}_q*\check{\mathbb{R}}_q)\underline{\otimes}(\mathbb{R}_q*\check{\mathbb{R}}_q)=(\mathbb{R}_q\underline{\otimes}\mathbb{R}_q)*(\check{\mathbb{R}}_q\underline{\otimes}\check{\mathbb{R}}_q)/\{qxp=pxp,qp'x'=x'p'\}=\mathbb{C}\langle p',x,p,x'\rangle/\mathscr{I}$, where $\mathscr{I}$ is the ideal generated by $x'x-qxx'$, $qxp-px$, $qp'x'-x'p'$, and $p'p-qpp'$. The canonical projection π: $(\mathbb{R}_q)\underline{\otimes}(\mathbb{R}_q)*(\check{\mathbb{R}}_q\underline{\otimes}\check{\mathbb{R}}_q)\to(\mathbb{R}_q*\check{\mathbb{R}}_q)\underline{\otimes}(\mathbb{R}_q*\check{\mathbb{R}}_q)$ is a *-algebra homomorphism, and $\underline{\triangle}=\pi\circ\underline{\triangle}_0$ turns $V^{\check{}}=\mathbb{R}_q*\check{\mathbb{R}}_q$ into a braided *-Hopf algebra in the sense we need. In particular, the coproduct is a *-algebra homomorphism. Note that we now have $p_1=p'$ and $x_1=x$ in the first factor of the tensor product, and $p_2=p$ and $x_2=x'$ in the second, i.e., the braid relations take the form

$$x_2x_1=qx_1x_2,\quad p_2x_1=q^{-1}x_1p_2,$$

$$x_2p_1=qp_1x_2,\quad p_2p_1=q^{-1}p_1p_2,$$

and the *-structure becomes $x_i'=p_i$, $i=1,2$.

The braiding of the real line, and thus also that of $V^{\check{}}$, are induced by an action and coaction of the group algebra $\mathbb{CZ}$. $V^{\check{}}$ is the (free) braided plane associated to the matrices

$$R'=\begin{pmatrix}1&0&0&0\\0&0&1&0\\0&1&0&0\\0&0&0&1\end{pmatrix},\quad R=\begin{pmatrix}q&0&0&0\\0&q^{-1}&0&0\\0&0&q&0\\0&0&0&q^{-1}\end{pmatrix}.$$

The possible generators of pseudo-diffusions are of the same form as in Eq. (4), but now we are interested in generators of ''true'' diffusions, i.e., Ψ-invariant, Hermitian, conditionally positive generators. Choose the set of all words $\{1=\varnothing,x,p,xx,xp,px,pp,\ldots\}$ as basis of $V^{\check{}}$. Then ϕ_{xp} and ϕ_{px} with

$$\phi_{xp}(u)=\begin{cases}1 & \text{if } u=xp,\\ 0 & \text{else}\end{cases}\qquad \phi_{px}(u)=\begin{cases}1 & \text{if } u=px,\\ 0 & \text{else,}\end{cases}$$

on basis elements u are such generators. The processes associated to these generators have been studied by Schürmann.[4] We find the processes that have the Azéma martingales as a classical version.

Let us now consider an example whose braiding does not come from a group, but from a noncommutative and non-cocommutative bialgebra.

2. Diffusions on the four-dimensional braided-covector space $V^{\check{}}=\mathbb{C}_q^{2|0}*\check{\mathbb{C}}_q^{2|0}$

Again let q be in $\mathbb{R}\{0\}$, and set $V^{\check{}}=\mathbb{C}_q^{2|0}*\check{\mathbb{C}}_q^{2|0}=\mathbb{C}\langle v,w,x,y\rangle/\{yx-qxy,vw-qwv\}$. A similar construction as in the preceding example leads to a four-dimensional braided-covector space, where the braid relations between x_1,y_1 and x_2,y_2 are described by the R-matrix of the braided plane,

$$R=\begin{pmatrix} q^2 & 0 & 0 & 0 \\ 0 & q & q^2-1 & 0 \\ 0 & 0 & q & 0 \\ 0 & 0 & 0 & q^2 \end{pmatrix},$$

those between x_1, y_1 and v_2, w_2 by its inverse,

$$R^{-1}=\begin{pmatrix} q^{-2} & 0 & 0 & 0 \\ 0 & q^{-1} & q^{-2}-1 & 0 \\ 0 & 0 & q_{-1} & 0 \\ 0 & 0 & 0 & q_{-2} \end{pmatrix},$$

those between v_1, w_2 and x_2, y_2 again by R, and, finally, those between v_2, w_2 again by R^{-1}. The $*$-structure is defined by $x^*=v$ and $y^*=w$ (compare also Ref. 13).

Here $\{x^n y^m | n,m \in \mathbb{N}\}$ and $\{w^m v^n | n,m \in \mathbb{N}\}$ are bases of the two components of the free product defining $V^{\vee}$, and therefore we can take the finite, alternating sequences of elements of these bases as a basis of $V^{\vee}$:

$$\{1=\varnothing, x^{n_1}y^{m_1}, w^{m_1}v^{n_1}, x^{n_1}y^{m_1}w^{m_2}v^{n_2}, w^{m_1}v^{n_1}x^{n_2}y^{m_2}, \ldots | n_1, n_2, \ldots, m_1, m_2, \ldots \in \mathbb{N}\}.$$

The functionals defined on this basis by

$$\phi_{xv}(u)=\begin{cases} 1 & \text{if } u=xv, \\ 0 & \text{else,} \end{cases} \qquad \phi_{vx}(u)=\begin{cases} 1 & \text{if } u=vx, \\ 0 & \text{else,} \end{cases}$$

$$\phi_{yw}(u)=\begin{cases} 1 & \text{if } u=yw, \\ 0 & \text{else,} \end{cases} \qquad \phi_{wy}(u)=\begin{cases} 1 & \text{if } u=wy, \\ 0 & \text{else,} \end{cases}$$

as well as linear combinations thereof with positive coefficients, are generators of diffusions.

IV. APPELL SYSTEMS

Appell systems $\{h_k; k \in \mathbb{N}\}$ can be defined by the conditions
A1: h_k is a polynomial of degree k,
A2: $Dh_k = kh_{k-1}$,

where $D=d/dx$. Examples are furnished by shifted moment sequences of the form

$$h_k(x)=\int_{\mathbb{R}} (x+y)^k p(dx),$$

where p is any probability measure on $\mathbb{R}$ with all moments finite. For example, in the Gaussian case this gives the Hermite polynomials $H_n(x)=(1/\sqrt{2\pi})\int_{\mathbb{R}}(x+iy)^n e^{-y^2/2}\,dy$. Recently analogous classes of ''moment polynomials'' on Lie groups[15] and quantum groups[16] have been introduced. They cease to be polynomials in general.

The definition on quantum groups is easily adapted to braided groups.

Definition 7: We define the Appell polynomials on the braided covector space $V^{\vee}(R,R')$ with respect to the functional ϕ by

$$h_a=(\phi\otimes \mathrm{id})\circ \underline{\Delta}\mathbf{x}_a,$$

i.e., $h_a=T_\phi(\mathbf{x}_a)$, *for* $a \in \mathscr{S}\{1,\ldots,n\}$.

We are particularly interested in the Appell systems with respect to diffusions.

Proposition 8: Let ϕ_t be a diffusion on $V^{\vee}(R,R')$ with generator L and $\{h_a(t); a \in \mathscr{S}\{1,\ldots,n\}\}$ the associated Appell system. Then we have the following:

(1) $h_a(t)=\mathbf{x}_a+p_a(t)$, *where* $p_a(t) \in \otimes_{\alpha=0}^{|a|-1} V^{\vee}(R,R')^{(\alpha)}$,

(2) $D^i h_a = \Sigma_{b \in \mathcal{S}^{|a|-1}\{1,\ldots,n\}} [|a|;R]_a^{i,b} h_b$, *where* $D^i = \exp(tL)\partial^i \exp(-tL)$ *and* $i.b$ *is the concatenation of* i *with* b, *i.e.*, $i.b = ib_1 \cdots b_{|a|-1}$,
(3) *the* $h_a(t)$ *satisfy the evolution equation* $\partial_t u = Lu$.

Proof: Note that (1) and (2) are the analogues of A1 and A2.
(1) The braided-binomial theorem [Ref. 6, Equation (91)] tells us that

$$\underline{\Delta}\mathbf{x}_a = \sum_{i=0}^{|a|} \sum_{b \in S^i\{1,\ldots,n\}, c \in S^{|a|-i}\{1,\ldots,n\}} \begin{bmatrix} |a| \\ i \end{bmatrix}_a^{b.c} \mathbf{x}_b \otimes \mathbf{x}_c .$$

where the braided-binomial coefficients are defined by

$$\begin{bmatrix} m \\ r \end{bmatrix} = (PR)_{r,r+1} \cdots (PR)_{m-1,m} \begin{bmatrix} m-1 \\ r-1 \end{bmatrix} + \begin{bmatrix} m-1 \\ r \end{bmatrix},$$

$$\begin{bmatrix} m \\ 0 \end{bmatrix} = 1,$$

$$\begin{bmatrix} m \\ r \end{bmatrix} = 0 \quad \text{for } r > m.$$

The statement follows now since $\phi(t)|_{V^\vee(R,R')^{(0)}} = \epsilon$, i.e., $h_a(t) = \mathbf{x}_a + p_a(t)$ with

$$p_a(t) = \sum_{i=0}^{|a|-1} \sum_{b \in S^{|a|-i}\{1,\ldots,n\}, c \in S^{|i}\{1,\ldots,n\}} \begin{bmatrix} |a| \\ i \end{bmatrix}_a^{b.c} \phi_t(\mathbf{X}_b)\mathbf{x}_c .$$

Note that this formula can also be used to calculate the Appell systems, if the moments of the process are known.
(2)

$$\begin{aligned} D^i h_a &= \exp(tL)\partial^i \exp(-tL)\exp(tL)x_a \\ &= \exp(tL)\partial^i x_a \\ &= \exp(tL) \sum_{b \in \mathcal{S}^{|a|-1}\{1,\ldots,n\}} [|a|;R]_a^{i,b}\mathbf{x}_b = \sum_{\tilde{b} \in \mathcal{S}^{|a|-1}\{1,\ldots,n\}} [|a|;R]_a^{i,b} h_b \end{aligned}$$

with Ref. 6, Equation (77).
(3)

$$\partial_t h_a(t) = \partial_t \exp(tL)\mathbf{x}_a = L \exp(tL)\mathbf{x}_a = L h_a(t).$$

■

Property 2 shows that the D^i act as lowering operators. We also define raising operators.
Proposition 9: Let $X_i = \exp(tL)x_i \exp(-tL)$. *Then*

$$X_i h_a(t) = h_{i,a}(t).$$

A. Example 1: The braided line $\mathbb{R}_q$

The Appell polynomials associated to the functional $\phi_t = \exp(tL)$ where $L = [a^2/(1+q)]v^2 + bv$ are

$$h_k(x;t) = (\phi_t \otimes \mathrm{id}) \circ \underline{\Delta} x^k = \sum_{\nu=0}^{k} \begin{bmatrix} k \\ \nu ; q \end{bmatrix} \phi_t(x^\nu) x^{k-\nu} = \sum_{\nu=0}^{K} \frac{[k;q]! H_\nu(bt, -(2a^{2t})/(1+q))}{[k-\nu;q]!\,\nu!} x^{k-\nu}$$

These polynomials are solutions of

$$\partial_t u = \frac{a^2}{1+q} \delta^2 u + b\,\delta u$$

with $u(x,t=0)=x^k$ {where δ is the q-difference operator $(\delta f)(x)=[f(qx)-f(x)]/x(q-1)$}.

For $b=0$, $a=\sqrt{(1+q)/2}$, the Appell polynomials simplify to

$$h_k(x;t)=\sum_{\nu=0}^{[k/2]}\frac{[k;q]!t^\nu x^{k-2\nu}}{[k-2\nu;q]!2^\nu\nu!}.$$

These polynomials are a q-analogue of the Hermite polynomials (see also Ref. 16).

B. Example 2: The quantum plane $\mathbb{C}_q^{2|0}$

We choose $\phi_t=\exp tL$ with $L=[1/(1+q^2)](\partial_1^2+\partial_2^2)$. We obtain

$$\phi=\sum_{r=0}^{\infty}\frac{t^r}{(1+q^2)^r r!}\sum_{\nu=0}^{r}\begin{bmatrix}r\\ \nu;q^{-4}\end{bmatrix}\partial_2^{2\nu}\partial_1^{2(r-\nu)}$$

since $\partial_2\partial_1=q^{-1}\partial_1\partial_2$. This leads to the following formula for the Appell polynomials:

$$h_{rm}(x,y;t)=\exp(tL)x^r y^m$$
$$=\sum_{\nu=0}^{[r/2]}\sum_{\mu=0}^{[m/2]}\frac{\begin{bmatrix}\mu+\nu\\ \nu;q^{-4}\end{bmatrix}[m;q^2]![r;q^2]!q^{2\mu(r-2\nu)}t^{\mu+\nu}}{[m-2\mu-1;q^2]![r-2\nu-1;q^2]!(1+q^2)^{\mu+\nu}(\mu+\nu)!}x^{r-2\nu}y^{m-2\mu},$$

where $\begin{bmatrix}r\\ \nu;q^{-4}\end{bmatrix}$ are the braided-binomial coefficients with respect to $R=(q^{-4})\in M(1)\otimes M(1)$. These polynomials solve the evolution equation

$$\partial_t u=\frac{1}{1+q^2}(\partial_1^2+\partial_2^2)u,$$

where ∂_1, ∂_2 can be defined by

$$\partial_1 f(x,y)=\frac{f(q^2x,y)-f(x,y)}{x(q^2-1)},\quad \partial_2 f(x,y)=\frac{f(qx,q^2y)-f(qx,y)}{y(q^2-1)}.$$

C. Example 3: The free braided-space

We consider again the free braided-space associated to $R=R'=P$. It is straightforward to calculate the action of the generator of a diffusion on a basis element:

$$L\mathbf{x}_k=r(r-1)a_{k_1k_2}\mathbf{x}_{k_3\cdots k_r}+rb_{k_1}\mathbf{x}_{k_2\cdots k_r},$$

for $L=\Sigma_{k,l=1}^n a_{kl}\partial_k\partial_l+\Sigma_{j=1}^n b_j\partial_j$ and $k=(k_1,\ldots,k_r)\in\mathcal{S}\{1,...,n\}$. Thus we obtain for the Appell polynomials

$$\begin{aligned}h_k=\exp(tL)\mathbf{x}_k=\mathbf{x}_k+t\big((r-1)a_{k_1k_2}\mathbf{x}_{k_3\cdots k_r}+rb_{k_1}\mathbf{x}_{k_2\cdots k_r}\big)\\ +\frac{t^2}{2}\big(r(r-1)(r-2)(r-3)a_{k_1k_2}a_{k_3k_4}\mathbf{x}_{k_5\cdots k_r}\\ +r(r-1)(r-2)(b_{k_1}a_{k_2k_3}+a_{k_1k_2}b_{k_3})\mathbf{x}_{k_4\cdots k_r}\\ +r(r-1)b_{k_1}b_{k_2}\mathbf{x}_{k_3\cdots k_r}\big)+\cdots,\end{aligned}$$

If the drift term vanishes, i.e., $b_j=0$ for $j=1,...,n$, then

$$h_k=\sum_{\rho=0}^{[r/2]}\frac{t^\rho}{\rho!}r(r-1)\cdots(r-2\rho+1)a_{k_1k_2}\cdots a_{k_{2\rho-1}k_{2\rho}}\mathbf{x}_{k_{2\rho+1}\cdots k_r}.$$

V. DENSITIES

There are two ways in which densities can be associated to the diffusions constructed here.

This first uses the (right or left) invariant integrals that are defined on Hopf algebras. Fix such a functional $\int: V^{\check{}}(R,R') \to \mathbb{C}$. One can look for an element $\rho_t \in V^{\check{}}(R,R')$ such that

$$\phi_t(a) = \int (\rho_t a) \quad \left(\text{or} \quad \phi_t(a) = \int (a \rho_t) \right)$$

is satisfied for all $a \in V^{\check{}}(R,R')$ [where $\phi_t(a) = \langle \phi_t, a \rangle$ denotes the evaluation map between $V^{\check{}}(R,R')$ and $V(R,R')$]. This defines a (noncommutative) left (or right) density. For anyspace, this leads to the results exhibited in Ref. 3. To calculate it the Fourier transform (wrt to the integral considered) can be used. For a braided-Hopf algebra B with dual B^*, exponential exp and invariant integral $\int: B \to \mathbb{C}$, the Fourier transform $\mathscr{F}: B \to B^*$ is defined by $\mathscr{F} = (\int \otimes \mathrm{id}) \circ (m \otimes \mathrm{id}) \circ (\mathrm{id} \otimes \exp)$ (see Ref. 17). Now let $\int$ be a left-invariant integral on $V^{\check{}}(R,R')$ and $\int^*$ a right-invariant integral on $V(R,R')$. Then, since $(\mathrm{id} \otimes \langle \cdot, \cdot \rangle) \circ (\exp \otimes \mathrm{id}) = \mathrm{id}$,

$$\int (\rho a) = \langle \mathscr{F}(\rho), a \rangle$$

for all $a \in V^{\check{}}(R,R')$ and $\rho \in V(R,R')$. Thus we need to invert the Fourier transform $\mathscr{F}$ to find the density corresponding to the functional ϕ_t. By Ref. 17, Proposition 6.4, $\mathscr{F}^* \circ \mathscr{F} = \mathrm{vol}\, \underline{S}$, where vol is a constant and $\mathscr{F}^*$ the Fourier transform wrt $\int^*$, i.e., $\mathscr{F}^* = (\mathrm{id} \otimes \int^* \circ m) \circ (\Psi \otimes \mathrm{id}) \circ (\mathrm{id} \circ \exp)$. Thus

$$\rho_t = \frac{1}{\mathrm{vol}}\, \underline{S}^{-1} \circ \mathscr{F}^*(\phi_t).$$

Take, e.g., the braided-line and $\phi_t = \exp(tv^2/2)$. We shall use the Jackson integral $\int_{-\gamma \cdot \infty}^{+\gamma \cdot \infty} f(x)\, d_q x$ where γ is a parameter. For $f(x) = \Sigma f_n x^n$ we set $f(\gamma) = \Sigma f_n \gamma^n$ and

$$\int_{-\gamma \cdot \infty}^{+\gamma \cdot \infty} f(x) d_q x = (1-q) \sum_{k=-\infty}^{\infty} (f(q^k \gamma) + f(-q^k \gamma)) q^k \gamma$$

if the right-hand side converges. We will express the density in terms of the discrete q-Hermite II polynomials

$$\widetilde{h}_n(x;q) = (1-q)^n [n;q]! \sum_{k=0}^{[n/2]} \frac{(-1)^k q^{-2nk} q^{k(2k+1)} x^{n-2k}}{(1-q^2)^k [k;q^2]! (1-q)^{n-2k} [n-2k;q]!}.$$

With the orthogonality relations for the discrete q-Hermite II polynomials [Ref. 18, Equation (8.14)] and

$$\phi_t(\widetilde{h}_n(x;q)) = \begin{cases} 0 & \text{if } n \text{ is odd}, \\ (1-q)^n [n;q]! \displaystyle\sum_{k=0}^{[n/2]} \frac{(-1)^k q^{-2nk} q^{k(2k+1)} t^{n/2-k}}{(1-q^2)^k [k;q^2]! (1-q)^{n-2k} 2^{n/2-k}} & \text{if } n \text{ is even}, \end{cases}$$

we obtain

$$\rho_t = \frac{1}{c_q(\gamma)} \sum_{m=0}^{\infty} q^{4m^2} \sum_{k=0}^{m} \frac{(-1)^k q^{-4mk} q^{k(2k+1)} t^{m-k}}{(1-q^2)^k [k;q^2]!\, 2^{m-k}}\, \widetilde{h}_{2m}(x;q)\, e_{q^2}(-(1-q^2)x^2), \tag{5}$$

where $e_{q^2}(z) = \Sigma_{n=0}^{\infty} z^n / [n;q^2]!$, and $c_q(\gamma)$ is a constant depending only on q and γ [for its value see Ref. 18, Equation (8.15)].

The other way, commonly used in quantum probability (see, e.g., Ref. 19), leads to a density on the usual real line. Consider, for example, a diffusion $\phi_t = \exp(tv^2/2)$ on the braided line, and the generator x. Then $\phi_t(e^{itx})$ can be interpreted as the Fourier transform of the density of x in the

state ϕ_t. Let $0<q<1$ and $Y=(1-q)\Sigma_{i=0}^{\infty}X_i$, where the X_i are independent, and exponentially distributed with respective means q^i (see Ref. 20). Then $E(e^{iuY})=\Pi_{i=0}^{\infty}(1-iu(1-q)q^i)^{-1}$ $=\Sigma_{n=0}^{\infty}(iu)^n/[n;q]!=e_q^{iu}$. Thus $\phi_t(E(e^{iuYx}))=\phi_t(e_q^i ux)=e^{-tu^2/2}$, and it follows that Yx has a Gauss distribution. This determines the distribution of x uniquely (see Ref. 20, Theorem 3).

VI. CONCLUSION

The notion of q-Brownian motion introduced by Majid is extended in this paper to braided spaces. The resulting processes differ from the ones obtained in Refs. 21 and 22 by more algebraic considerations. To obtain these (for fixed parameter $t=1$, say), we can consider the semidirect cross product of the braided line with its dual. This algebra has basis $\{v^n\otimes x^m;n,m\in\mathbb{N}\}$ and the defining relations are $vx-qxv=1$ (where $v=v\otimes 1$, $x=1\otimes x$). Take the functional ϕ defined by $\phi(\Sigma a_{nm}v^n\otimes x^m)=a_{00}$. Then the distribution of $x+v$ in the state ϕ is equal to that of Ref. 21 for $t=1$ (for a study of its density see Ref. 23). This density is concentrated on the bounded interval $[-1/\sqrt{1-q},2/\sqrt{1-q}]$ (for $-1<q<1$). The q-deformed Brownian motion of Ref. 22 can be obtained similarly. Obviously, there is still some more nontrivial construction required to pass from the random variable presented here to the full process.

Brownian motion of quantum harmonic oscillators: Existence of a subdynamics

Göran Lindblad[a)]
Theoretical Physics, Royal Institute of Technology, SE-100 44 Stockholm, Sweden

(Received 13 May 1997; accepted for publication 22 January 1998)

The effects of system-environment correlations on the dynamics of an open quantum system are investigated for the standard model of a set of quantum harmonic oscillators interacting with a heat bath of oscillators. By definition, a subdynamics is described by transformations of the open system observables. It is shown that such a construction can reproduce the observable properties of the exact dynamics only when the states of system and environment are uncorrelated, while for classical systems there is always a subdynamics. A quantum subdynamics cannot have the properties we associate with thermal fluctuations; the KMS relation at a finite temperature for the open system implies that the system must be closed. The conditions for having a subdynamics as a good approximation to the exact closed dynamics are investigated, and so are the similar but stronger conditions for a Markovian dynamics. It is also shown that a subdynamics defines the response of the open system to some types of time dependent external forces. © *1998 American Institute of Physics.* [S0022-2488(98)00705-1]

I. INTRODUCTION

In the description of irreversible quantum processes a fundamental concept is that of an *open quantum system*. We can directly observe a quantum system which evolves in contact with reservoirs and responds to driving forces. The observed system is small (sometimes of atomic or molecular size) or at least finite, and the reservoirs are often assumed infinite. The mathematical problem encountered is how the evolution of the observed subsystem can be given a reduced description, here called a *subdynamics*, where the degrees of freedom of the environment have been traced out. It is assumed that the closed composite system including the environment has a reversible, conservative dynamics, while the evolution of the small system will generally have irreversible and random properties.

Many different answers have been given to the question of what mathematical structure a subdynamics should have; here we will use a general one allowing for memory effects.[1–3] It means in essence that all probability distributions accessible by observations on the small system can be expressed as expectations on the initial partial state of this subsystem. The mathematical structure which results when a subdynamics exists was called a *quantum stochastic process* in Refs. 1 and 2, but there no emphasis was given to the environment and the system-environment correlations. In Ref. 3 the focus was precisely on the latter point, and it was shown that such a subdynamics will exist only when the state of the observed system and its environment is uncorrelated (it factorizes into a product), while it always exists for open systems based on commutative algebras of observables. This result is closely related to general theorems restricting the existence of conditional expectations in non-commutative operator algebras.[4–6] An uncorrelated initial state is also an almost universal ingredient in the derivation of master equations, but here we must demand this to hold for all times.

The goal of this paper is to display the conditions for the existence of a subdynamics and its properties for a class of models where they have a particularly simple form. The CCR algebra and the states and maps on this algebra which preserve the quadratic structure associated with multidimensional harmonic oscillators form a simple laboratory for studying the dynamics of open systems. This class of models is often given the name *quantum Brownian motion*. A very large

number of papers have been written on this subject, using many different methods, but it is not intended to give an overview here (reviews can be found in Refs. 7–10). A rather abstract, algebraic approach will be followed here, similar to the methods used in Refs. 1 and 11. However, we have dispensed with mathematical refinements which are not essential in this context. The properties we are interested in turn out to have quite simple and explicit representations as matrix relations.

The layout of the paper is as follows. We first review some well known but essential details of the formalism, introducing the Weyl form of the CCR and quasifree states (Sec. II), and quasifree maps and dynamics (Sec. III). The observable multi-time correlation functions for an open subsystem are defined and the concept of subdynamics formulated (Sec. IV). For these models the full set of correlation functions is always completely specified by a matrix-valued covariance function, in complete analogy with stationary Gaussian stochastic processes.

There is a subdynamics when this covariance function results from a dynamical transformation of the canonical operators for the subsystem. It is shown that the condition for having a subdynamics as an exact property is a factorization of the state of open system and reservoir. A classical (commutative) limit can be introduced and it is straightforward to see why there are no restrictions on the existence of a subdynamics in this case (Sec. V). It is proved that the KMS property characteristic of the quantum correlation functions in thermal equilibrium at a finite temperature, when imposed on the covariance function, is incompatible with having a non-trivial subdynamics (Sec. VI). In Sec. VII we consider the case where the initial state is not stationary. If the state of the system factorizes for all times there is still a non-stationary subdynamics which suffices to recreate the covariance function, but if it factorizes only for the initial time this no longer holds true. The structure of Markov processes and the conditions for the Markov property to hold are given in Sec. VIII.

The observable multi-time correlations not only give the statistics of observations of the system, they also define the response of the system to certain kinds of time dependent external forces acting on the small subsystem. The forces are of a harmonic type which preserves the quasifree property. In some cases the response of the system can be given an explicit form in terms of the maps which define the subdynamics (Sec. IX).

In Sec. X we find conditions which will allow a subdynamics as a good approximation to the exact evolution also for correlated system-reservoir states. These include that the back reaction of the system on the reservoir spreads effectively over a large number of degrees of freedom. A subdynamics as defined here contains a large amount of information, resulting in the strong restrictions already mentioned. If we restrict ourselves to describing the evolution of a non-stationary initial state of the open system, there are solutions also in cases where a subdynamics cannot be defined (Sec. XI). In general the dynamical maps will then fail to be positive due to the system-reservoir correlations. There is a considerable literature on the consequences of such quantum correlations. In the discussion (Sec. XII) a number of references are given to earlier work on this and similar problems.

II. QUASIFREE STATES ON THE CCR ALGEBRA

Let $\mathscr{H}$ be a separable real Hilbert space. For most of this paper we will do the algebraic manipulations as if it has a finite dimension $2N$, and thus avoid a discussion of a number of mathematical subtleties.

It is convenient to consider also operators in the complexified Hilbert space. The star (*) is used for the complex conjugation in the given real basis and real operators satisfy $A^*=A$. Let $\sigma(x,y)$ be a bounded real symplectic (antisymmetric, bilinear) form on this space. We can write it as a matrix element of a real antisymmetric operator S: $\sigma(x,y)=(x|S|y)$. The CCR algebra $\mathscr{A}(\mathscr{H})=\mathscr{A}$ is the closure in a suitable C^* norm of the $*$-algebra generated by unitary elements $\{W(x)=W(-x)^\dagger; x\in\mathscr{H}\}$ which satisfy the Weyl relation[12]

$$W(x)W(y)=\exp[-i\sigma(x,y)]W(x+y). \tag{2.1}$$

In fact, $\mathscr{A}$ is generated as a complex linear space by the operators $W(x)$. If the projector P

$\in B(\mathscr{H})$ is real, then so is $P^{\perp}:=\mathbb{1}-P$, furthermore the real Hilbert subspaces $P.\mathscr{H}$ and $P^{\perp}.\mathscr{H}$ generate CCR subalgebras. If in addition $[P,S]=0$, the symplectic form decomposes, the subalgebras commute, and there is a tensor product decomposition

$$\mathscr{A}(\mathscr{H})=\mathscr{A}(P.\mathscr{H})\otimes\mathscr{A}(P^{\perp}.\mathscr{H}).$$

We call the state ρ on $\mathscr{A}$ *quasifree* or *Gaussian* if it is defined by a bounded quadratic form g with $g(0)=0$ through

$$\rho[W(x)]=\exp[g(x)]. \tag{2.2}$$

There is no essential restriction in assuming g to be homogenous (without linear terms) and hence real. It is then defined by a symmetric, real operator G

$$g(x)=-\tfrac{1}{2}(x|G|x).$$

The positivity of the linear functional ρ is equivalent to the *positive definiteness* of the form

$$R(x,y)=\exp[g(y-x)+i\sigma(x,y)],$$

which means that for all sequences $\{x_j\in\mathscr{H},\lambda_j\in\mathbb{C}\}$ it holds that

$$\sum_{j,k}\lambda_j^{*}\lambda_k R(x_j,x_k)\geqslant 0. \tag{2.3}$$

A general argument[13] shows that this again is equivalent to the *conditional positive definiteness* of the form

$$L(x,y):=g(y-x)+i\sigma(x,y),$$

which means that for all sequences $\{x_j\in\mathscr{H},\lambda_j\in\mathbb{C};\Sigma_j\lambda_j=0\}$ it holds that

$$\sum_{j,k}\lambda_j^{*}\lambda_k L(x_j,x_k)\geqslant 0.$$

But this is again equivalent to the positive definiteness of the Hermitian form

$$(x|K|y):=L(x,y)+L(0,0)-L(x,0)-L(0,y)=g(y-x)-g(x)-g(y)+i\sigma(x,y).$$

Because $g(y-x)-g(x)-g(y)=(x|G|y)$ we can write this as

$$K=G+iS\geqslant 0. \tag{2.4}$$

The $2N$ canonical self-adjoint (unbounded) operators X_k are formally related to the Weyl ones through $W(x)=\exp(i\Sigma_k x_k X_k)$. The Weyl relation (2.1) corresponds to the CCR

$$[X_k,X_l]=2i\mathbb{1}\cdot S_{kl}.$$

The covariance matrix for the canonical operators is K: in the general case

$$\rho(X_kX_l)=K_{kl}+\rho(X_k)\rho(X_l),$$

but here we have assumed that the states satisfy $\rho(X_k)=0$ for all k. The higher order correlations are then given by the second order one in the well known way; for example,

$$\rho(X_kX_lX_mX_n)=K_{kl}K_{mn}+K_{km}K_{ln}+K_{kn}K_{lm}. \tag{2.5}$$

III. QUASIFREE MAPS ON THE CCR ALGEBRA

A set of *completely positive* (CP) maps is now introduced. They correspond to convolutions with Gaussian measures in the commutative case, and we again call them quasifree or Gaussian.[2,14–16] For general information on CP maps see also Ref. 17. The most general quasifree CP map is defined through

$$T[W(x)]=W(Ax)\exp[f(x)] \tag{3.1}$$

by a real operator $A\in B(\mathscr{H})$ and a quadratic form f such that $f(y-x)+i\sigma(x,y)-i\sigma(Ax,Ay)$ is conditionally positive definite. If $T[\mathbb{1}]=\mathbb{1}$, then $f(0)=0$ (this corresponds to conservation of probability). Again we can restrict our attention to homogenous, real f and write

$$f(y-x)-f(x)-f(y)=(x|F|y),\quad f(x)=-\tfrac{1}{2}(x|F|x),$$

where the symmetric, real operator F must satisfy

$$D:=F+iS-iA^{\dagger}SA\geqslant 0. \tag{3.2}$$

Thus the map (3.1) is uniquely defined by the pair $\{A,F\}$. It leaves the state ρ invariant if for all $y\in\mathscr{H}$

$$\rho\{T[W(y)]\}=\rho[W(y)], \tag{3.3}$$

which holds precisely when $F=G-A^{\dagger}GA$. We can rewrite this condition and (3.2) as

$$D=K-A^{\dagger}KA\geqslant 0. \tag{3.4}$$

If the state is not stationary, then the change in the state is given by $G\mapsto A^{\dagger}GA+F$, or, equivalently, by $K\mapsto A^{\dagger}KA+D$.

The transformation properties of the first and second powers of the canonical operators corresponding to (3.1) are

$$\begin{aligned} T[X_k]&=(XA)_k:=\sum_j X_jA_{jk},\\ T[X_kX_l]&=(XA)_k(XA)_l+\mathbb{1}\cdot D_{kl}. \end{aligned} \tag{3.5}$$

The transformation of the higher powers are defined by similar formulas involving the pairs of matrices $\{A,F\}$ or $\{A,D\}$. This is an obvious analog to well known properties of the commutative multidimensional Gaussian transformations. The lowest order correlation functions associated with the map is, for the Weyl operators

$$\rho\{W(-x)T[W(y)]\}=\exp[i\sigma(x,Ay)+f(x)+g(x-Ay)],$$

and for the canonical ones we obtain the covariance matrix

$$\rho[X_kT(X_l)]=(KA)_{kl}. \tag{3.6}$$

A particularly important class of maps are of the form (3.1) with $A=P$ a real projector satisfying $[P,S]=0$. If $PFP=0$, then (3.1) is the identity map on $\mathscr{A}(P.\mathscr{H})$ and maps $\mathscr{A}(\mathscr{H})$ onto this subalgebra. From the CP condition (3.2) we then find that $PFP^{\perp}=0$, and consequently find the characteristic property of a *conditional expectation*:[3–5]

$$E[W(x)W(y)W(z)]=W(x)E[W(y)]W(z),\quad \forall x,z\in P.\mathscr{H},y\in\mathscr{H}.$$

The invariance (3.3) of ρ under E means that $F=G-PGP$, and $PFP^{\perp}=0$ is then equivalent to $[P,G]=0$. This relation means that the invariant state for the composite system is a product of the partial states on the two algebras $\mathscr{A}(P.\mathscr{H}),.\mathscr{A}(P^{\perp}.\mathscr{H})$. Recalling that $[P,S]=0$ we find that there is a conditional expectation onto $\mathscr{A}(P.\mathscr{H})$ leaving ρ invariant only if

$$[P,K]=0, \tag{3.7}$$

and, conversely, if this equation holds, then

$$E[W(x)]=W(Px)\exp[g(P^{\perp}x)] \tag{3.8}$$

defines the desired conditional expectation (note that it does not depend on PGP).

The set of quasifree CP maps also includes a subset representing reversible (conservative) dynamics. In this case $f=0$ in (3.1) and A is now an invertible map V which is symplectic in the sense that the form S is left invariant

$$V^{\dagger}SV=S \tag{3.9}$$

(i.e., the CCR are invariant). Furthermore, the initial state defined by g is stationary if $V^{\dagger}GV=G$. The stationarity condition and (3.9) can be summed up in

$$V^{\dagger}KV=K. \tag{3.10}$$

We will use either a discrete or a continuous time parameter, with a group $V(t)$ of dynamical maps in the reversible case: $V(s)V(t)=V(s+t)$. For a continuous time parameter t we have to demand some continuity of $V(t)$.

In Sec. XI it will be necessary to consider maps which can fail to be CP or even positive. This means that (3.2) and (3.4) are no longer satisfied, but we can retain the rest.

IV. CORRELATION FUNCTIONS AND SUBDYNAMICS

Consider the algebra $\mathcal{A}(\mathcal{H})$ defined above to represent a closed system (observed system $\mathcal{S}$ and reservoir $\mathcal{R}$) with a given reversible quasifree dynamics defined by $V(t)$. The open subsystem $\mathcal{S}$ is defined by a finite-dimensional (say of dimension $2M \ll 2N$) real projection P commuting with S. The corresponding algebra of observables is $\mathcal{A}_{\mathcal{S}}=\mathcal{A}(P\mathcal{H})$. Assume that the operators S,G which define the CCR and the reference state ρ through (2.2) on $\mathcal{S}+\mathcal{R}$ are given.

We now want to define a notion of subdynamics for $\mathcal{S}$. In the general scheme outlined in Ref. 3 the construction of a subdynamics is based on finding a conditional expectation from the algebra of $\mathcal{S}+\mathcal{R}$ onto that of the subsystem $\mathcal{S}$, such that the state ρ is left invariant. Here we can start from the more explicit form for the correlation functions available in the CCR case and formulate the condition that the correlation functions can be written in terms of operators in the subspace $P\mathcal{H}$ only.

If we are restricted to observing $\mathcal{S}$, then the physics is given by the correlation functions of the following general structure:

$$R_n(\mathbf{x}|\mathbf{y})=\rho[W(-V_1x_1)W(-V_2x_2)\cdots W(-V_nx_n)W(V_ny_n)\cdots W(V_1y_1)], \tag{4.1}$$

where ρ is the state of $\mathcal{S}+\mathcal{R}$ at time t_0, $x_k,y_k \in P\mathcal{H}, V_k=V(t_k-t_0), t_0 \leqslant t_1 \leqslant \ldots \leqslant t_n$.[2,18] If ρ is stationary, the expression is invariant under time translation $t_k \mapsto t_k+s$. The correlation function is Gaussian, i.e., an exponent of a quadratic form in the variables (x_k,y_k):

$$R_n(\mathbf{x}|\mathbf{y})=\exp[g(\eta_n-\xi_n)+ih(\xi_n,\eta_n)],$$

$$h(\xi_n,\eta_n)=\sigma(\xi_n,\eta_n)+\sum_{k=2}^{n}[\sigma(\xi_k,\xi_{k-1})-\sigma(\eta_k,\eta_{k-1})], \tag{4.2}$$

$$\xi_m=\sum_{k=1}^{m}V_kx_k, \quad \eta_m=\sum_{k=1}^{m}V_ky_k.$$

An examination shows that the expression (4.2) is completely defined by the matrix-valued covariance kernel

$$K_P(s,t)=PV(s)^{\dagger}KV(t)P=K_P(t,s)^{\dagger} \tag{4.3}$$

(we will leave out the index P when this can be done without confusion). Recall that $V(t)$ is a real operator. This means that (4.3) determines the real and imaginary parts obtained by replacing K by G and S, respectively. The most important property of the correlation functions R_n is the condition (2.3), where we now let $x_j \in \oplus^n P\mathscr{H}$. By the line of argument leading to (2.4) this condition is equivalent to the positive definiteness of the covariance kernel: for all $\lambda_j \in \mathbb{C}, t_j \in \mathbb{R}, x_j \in P\mathscr{H}$,

$$\sum_{j,k} \lambda_j^* \lambda_k (x_j | K(t_j, t_k) | x_k) \geqslant 0. \tag{4.4}$$

If G defines a stationary state, which means that (3.10) is fulfilled by $V(t)$ for all t, then the covariance kernel simplifies to a covariance function of a single variable: for $s \leqslant t$

$$K(s,t) = K(t-s) = PKV(t-s)P. \tag{4.5}$$

We will mainly consider this stationary case.

We can now introduce the concept of a *stationary subdynamics* on the subsystem $\mathscr{S}$ as follows. Given is an operator $K_P = G_P + iS_P$ which defines the CCR (through S_P) and the stationary state (through G_P) on the Hilbert space $P\mathscr{H}$. We also need a real operator-valued function $A(t)$ in $P\mathscr{H}$ which satisfies $A(0) = P$. By the assumption of stationarity we must have (3.3), so if we put

$$F(t) = G_P - A(t)^\dagger G_P A(t), \tag{4.6}$$

then $\{A(t), F(t)\}$ define the evolution of the Weyl operators for $x \in P\mathscr{H}$ through (3.1) and the evolution of powers of the canonical operators X_k belonging to the same subspace through (3.5). From (3.6) the covariance function can be identified as

$$K_P(t) = K_P(-t)^\dagger = K_P A(t), \quad t \geqslant 0, \quad = A(-t)^\dagger K_P, \quad t \leqslant 0. \tag{4.7}$$

Provided that (4.4) is fulfilled we obtain a full set of positive definite correlation functions by replacing (4.3) by (4.7) in (4.2).

We now want to impose that the reduced dynamics is an exact consequence of the full dynamics of the system $\mathscr{S} + \mathscr{R}$. First the CCR and the state ρ on $\mathscr{S}$ are those obtained from $\mathscr{S} + \mathscr{R}$ by restriction to $\mathscr{S}$, hence $K_P = PKP$. Then we demand the identity of the correlation functions (4.1), which just means the equality of the covariance matrix functions (4.5) and (4.7) for arguments in $P\mathscr{H}$:

$$PK[A(t) - V(t)]P = 0, \quad \forall t \geqslant 0$$

(for $t \leqslant 0$ we get the conjugate relation). The imaginary part of this relation, using $[P,S] = 0$, says that

$$S[A(t) - PV(t)P] = 0. \tag{4.8}$$

If we take S to be nondegenerate (in the standard form of the CCR we have $S^\dagger S \propto \mathbb{1}$), we obtain, as the only solution

$$A(t) = PV(t)P, \quad \forall t \geqslant 0. \tag{4.9}$$

The relation (4.8) is then equivalent to

$$PGP^\perp V(t)P = 0, \quad \forall t \geqslant 0. \tag{4.10}$$

It is clear that if $[P,G] = 0$, then (4.10) is satisfied. Are there other solutions? From the form (4.1) of the correlation functions it is rather obvious that we can restrict our attention to the space $\mathscr{H}_+ \subseteq \mathscr{H}$ which is defined as the smallest Hilbert subspace satisfying the conditions

$$P\mathscr{H} \subseteq \mathscr{H}_+, \quad V(t)\mathscr{H}_+ \subseteq \mathscr{H}_+, \quad \forall t \geqslant 0.$$

It is the minimal subspace of $\mathscr{H}$ which contains $P\mathscr{H}$ and is invariant under forward time translations, and thus represents the relevant part of the total closed system. There is no real restriction in taking $\mathscr{H}_+$ to be the whole of $\mathscr{H}$, which means that in a well-defined sense the system is chosen to be minimal or irreducible. We note that if there is no shift in the dynamics $V(t)$, then $\mathscr{H}_+$ is invariant also under backward time translations, while if $V(t)$ contains a shift this need not be the case (and $\dim\mathscr{H}=\infty$, of course).[18,19] For Markov processes there must be a shift.[18]

With the minimal choice of Hilbert space it follows from (4.10) that there is an exact subdynamics only if it holds that

$$PKP^{\perp}=0, \tag{4.11}$$

which is equivalent to (3.7). But (3.7) says that there is a conditional expectation E defined by (3.8). The correlation functions for the subdynamics are then completely defined by the partial state $\rho_{\mathscr{S}}$ ($=\rho$ restricted to $\mathscr{A}(P\mathscr{H})$):

$$R_{\mathscr{S},n}(\mathbf{x}|\mathbf{y})=\rho_{\mathscr{S}}\{E[W(-V_1x_1)W(-V_2x_2)\cdots W(V_2y_2)W(V_1y_1)]\}. \tag{4.12}$$

An expansion of the exponent in the resulting expression using (3.7) shows that it is indeed identical to (4.2). In particular, the covariance function can be expressed as an expectation in the state of $\mathscr{S}$:

$$K_P(t)_{jk}=\rho_{\mathscr{S}}(X_jE[XV(t)]_k).$$

This property provides an alternative, and equivalent, definition of a subdynamics: all correlation functions are expectations in the partial initial state of $\mathscr{S}$. The matrix-valued function on $P\mathscr{H}$ defined in (3.4) is positive,

$$D(t)=PV(t)^{\dagger}P^{\perp}KP^{\perp}V(t)P=PKP-A(t)^{\dagger}KA(t)\geqslant 0,$$

which means that the pair of functions $\{A(t),F(t)=\Re D(t)\}$ define a family of CP maps $\{T(t);t\geqslant 0\}$ through (3.1). We find that

$$K_P(t)_{jk}=\rho_{\mathscr{S}}(X_jT(t)[X_k]),$$

and the stationarity of the dynamics means that $\rho_{\mathscr{S}}(T(t)[X])=\rho_{\mathscr{S}}(X)$. Note that if we want to construct $K_P(t)$ starting from $\rho_{\mathscr{S}}$ and $\{T(t)\}$, then the CP property for each t is not sufficient for (4.4) to hold, except when $\{T(t)\}$ forms a semigroup (Sec. VIII).

To sum up: the subdynamics is defined by $\{K,A(t)\}$, and from this we get a positive $D(t)$, the real part of which is $F(t)$. The pair $\{A(t),F(t)\}$ defines $\{T(t)\}$ while $\{A(t),D(t)\}$ gives a simple expression for the subdynamics as transformations of the canonical operators through (3.5).

We have already noted that $K(t)$ defines the full set of correlation functions (4.1). It is also true that this set allows us to reconstruct the state and dynamics of the system $\mathscr{S}+\mathscr{R}$, though not always uniquely[18]. Note that there is a good deal of formal similarity between the formalism used here and standard projection methods,[20] but here the projections all act in a Hilbert space.

V. THE CLASSICAL LIMIT

It is a rather elementary fact that a subdynamics always exists for dynamical systems based on commutative algebras of observables.[3] The necessary conditional expectations are directly related to the marginal distribution for the random variables describing the open system $\mathscr{S}$. For the models based on the CCR we can consider a *classical limit* simply and formally by setting $S=0$. How does the condition for having a subdynamics change?

Without a non-degenerate S there is no longer the earlier conclusion to be drawn from (4.8). For $S=0$ we obtain only

$$PG[V(t)-A(t)]P=0.$$

There is a nontrivial solution, assuming PGP to be non-degenerate for simplicity. We introduce an idempotent operator Q which satisfies $QP=P$, $PQ=Q$, but which is not self-adjoint:

$$Q=(PGP)^{-1}PG.$$

We choose

$$A(t)=QV(t)P.$$

If we replace P in (3.8) by Q and $P^{\perp}GP^{\perp}$ by $F=G-Q^{\dagger}GQ$, then (3.8) still defines a conditional expectation associated with the marginal distribution for the variables in $P\mathscr{H}$. The only thing we have to check is that $PFP=0$ and that

$$F=G-GP(PGP)^{-1}PG\geqslant 0,$$

which is a known Schwarz type inequality.[21] We note that the same method works also in the non-stationary case (see Sec. VII below).

VI. KMS CONDITION AND SUBDYNAMICS

It is well known that the KMS condition (describing the regression properties of fluctuations in thermal equilibrium) for a finite temperature is incompatible with the existence of a Markovian, exponential relaxation of the open subsystem.[22–27] Here it will be shown that in the present setup it does not help to use non-Markovian subdynamics: it is not possible to choose a dissipative quasifree subdynamics in such a way that the covariance function for the open system satisfies the KMS condition for a finite temperature. If the KMS condition holds, the dynamics is either of the conservative type of closed systems or the temperature is infinite. This is a CCR version of a more general theorem proved in Ref. 3. It is included for completeness and because of its simplicity. In this section the time parameter is continuous.

Let ρ be a quasifree state (for $\mathscr{S}$) which is stationary under the family of quasifree maps $T(t)$ defined by $A(t)$ and (4.6). We have to assume the continuity of $A(t)$, such that $\lim_{t\to 0}A(t)=\mathbb{1}$. Consider the following correlation function for $t>0$

$$R(x,y;t)=\rho\{W(-x)T(t)[W(y)]\}=\rho[W(-x)W(A(t)y)]\exp[-\tfrac{1}{2}(y|F(t)|y)]$$

$$=\exp[-\tfrac{1}{2}(x|G|x)-\tfrac{1}{2}(y|G|y)+(x|K(t)|y)],$$

where $x,y\in P\mathscr{H}$ and we have dropped the P in (4.7). It is continued to negative values of t through $R(x,y;-t)=R(y,x;t)^*$, which is equivalent to $K(t)^{\dagger}=K(-t)$, cf. (4.3). The KMS condition with parameter $\beta=\hbar/k\Theta$ reads:[28] the correlation function has an analytic continuation in the time parameter into the strip $0\leqslant\Im z\leqslant\beta$ such that for all real t the identity $R(x,y;t)=R(y,x;-t+i\beta)$ holds. Translated to the covariance function it reads

$$K(t)^*=K(t+i\beta). \tag{6.1}$$

There is also the condition that $A(t)$ must be real: for $t\geqslant 0$

$$K(t)^*=K^*K^{-1}K(t). \tag{6.2}$$

The condition (4.4) applied to $K(t)$ and Bochner's theorem implies that there is a positive-operator-valued measure $E(\cdot)$ such that

$$K(t)=\sqrt{K}\left[\int_{-\infty}^{\infty}dE(\omega)\exp(-i\omega t)\right]\sqrt{K},$$

$$\int_{-\infty}^{\infty}dE(\omega)=\mathbb{1}.$$

If (6.1) and (6.2) are translated to this measure, we find that

$$dE(-\omega)^*=\exp(\beta\omega)M^{\dagger}dE(\omega)M=M^{-1}dE(\omega)M,$$

where we have used the notation $M=K^{1/2}(K^*)^{-1/2}$ and assumed K to be nondegenerate. Simplification gives

$$MM^\dagger dE(\omega)=\exp(-\beta\omega)dE(\omega).$$

But $MM^\dagger$ is a self-adjoint operator, and its eigenspaces must be orthogonal. Using the normalization of $E(\cdot)$ we can then show that it must actually be a projection-valued measure, and

$$W(t)=\int_{-\infty}^{\infty} dE(\omega)\exp(-i\omega t)=\exp(-iHt)=K^{1/2}A(t)K^{-1/2}$$

is a group of unitary operators. Thus $\{A(t)\}$ is also a group of invertible maps satisfying (3.10), and they give a closed, conservative, evolution of $\mathscr{S}$. Note that in the classical $\hbar=0$ or ∞-temperature limit it holds that $\beta=0$, which means that $K(t)=K(t)^*$ and (6.1) and (6.2) coincide.

We note that the KMS condition is intimately related to the passivity of the thermal reservoir and hence to the validity of the second law of thermodynamics.[28] Thus losing this property is serious even though the effect may be small.

VII. THE NON-STATIONARY CASE

We now go back to (4.3) where we no longer assume stationarity; instead the state is time dependent: $G(t):=V(t)^\dagger GV(t)\neq G(0)$. In order to have a subdynamics defined for all t we need that

$$[P,G(t)]=0, \quad \forall t\geqslant 0. \tag{7.1}$$

There is then a time dependent conditional expectation which is defined by (3.8) if we replace $P^\perp GP^\perp$ by $P^\perp G(t)P^\perp$. In order to reconstruct all the correlation functions we need the function $G_P(t)=PG(t)P$ in addition to $A(t)$, and instead of (4.5) and (4.7) there is, for $s<t$,

$$K_P(s,t)=PV(s)^\dagger KV(s)PV(t-s)P=[G(s)_P+iS_P]A(t-s)=K_P(s)A(t-s).$$

There is a two-parameter family of quasifree maps $T(s,t)$ defined by $A(t-s)$ and

$$F(s,t)=G_P(t)-A(t-s)^\dagger G_P(s)A(t-s) \quad (s<t),$$

and they are all CP as we find that

$$D(s,t):=K_P(t)-A(t-s)^\dagger K_P(s)A(t-s)=PV(t-s)^\dagger P^\perp K(s)P^\perp V(t-s)P\geqslant 0.$$

The relation (3.3) is still satisfied if ρ in the RHS is replaced by the time dependent state $\rho(t)$ defined by $G(t)$ for the pertinent value of t. The relation (3.5) still holds if we replace $\{T,D\}$ by the corresponding time dependent quantities defined above.

Now consider the case where the initial state of $\mathscr{S}+\mathscr{R}$ is a product state: (7.1) holds for $t=0$ but not for $t>0$. Now we must allow the initial instant to be singled out, and there will in general only be maps from $t=0$ to arbitrary $t>0$. However, we will see that the covariance function is no longer defined by a family of dynamical maps (CP or otherwise).

At the initial time there is still a conditional expectation of the type (3.8). If $V(t)$ again represents the reversible dynamics of the closed system, we can calculate the evolution of canonical operators in $\mathscr{S}$:

$$E[X\cdot V(t)]=X\cdot A(t), \quad A(t)=PV(t)P.$$

The covariance function for $\mathscr{S}+\mathscr{R}$ is

$$K(s,t)=V(s)^\dagger KV(t)=K(t,s)^\dagger,$$

given that $V(t)$ is real. The conservation of the CCR means that the imaginary part is (for $s<t$)

$$S(s,t)=V(s)^\dagger SV(t)=-S(t,s)^\dagger=SV(t-s).$$

From this follows that $S(t,t)=S$ and that the projected part is

$$PS(s,t)P=S_P(s,t)=S_PA(t-s)\quad(s\leqslant t),\quad =A(s-t)^\dagger S_P\quad(t\leqslant s),$$

where $A(t)=PV(t)P$ as before. We reduce the covariance to the subspace by projection by P, as before, and obtain

$$\begin{aligned}PK(s,t)P=K_P(s,t)=A(s)^\dagger K_PA(t)+D(s,t),\\ D(s,t)=PV(s)^\dagger P^\perp KP^\perp V(t)P,\end{aligned}\tag{7.2}$$

where $\{K_P,D\}$ are positive definite kernels. In particular, for the imaginary part we find for $s\leqslant t$

$$PSA(t-s)=A(s)^\dagger SA(t)+\Im[D(s,t)].$$

If we assume $A(t)$ given, the CCR imply the following condition on the kernel D:

$$\Im[D(s,t)]=PSA(t-s)-A(s)^\dagger SA(t),\quad s\leqslant t.\tag{7.3}$$

From the continuity of the dynamics we get the condition

$$D(0,t)=0,\quad \forall t\geqslant 0.\tag{7.4}$$

Given a real function $A(t),t\geqslant 0$ with $A(0)=\mathbb{1}$ and a positive definite kernel $D(s,t)$ which satisfy the conditions (7.3) and (7.4) above, then (7.2) defines a non-stationary covariance kernel $K_P(s,t)$ for $s,t>0$ with a preferred initial instant $t=0$ where the state of the system factorizes. Furthermore, $\{A(t),D(t,t)\}$ defines a one-parameter family $T(t)$ of CP maps through (3.1), but this information is no longer sufficient to recreate the two-parameter function $K_P(s,t)$.

VIII. MARKOV PROCESSES

For quantum dynamics it is necessary to define what we mean by a Markov process. This subject has been treated extensively and we will use a standard definition.[1,2,23] It starts from a quantum dynamical semigroup of CP maps.[11,29–31] In general the semigroup property alone is not sufficient. The multitime correlation functions are not necessarily of the form (8.5) below. For the quasifree case we are treating here, however, we have seen already that the covariance function defines the whole process, including the higher order correlation functions. It will be evident from the following that the semigroup defines the covariance function.

Assume that on the Hilbert space $P\mathscr{H}$ we are given an operator $K_P\geqslant 0$ which defines G_P,S_P and a family of operators $A(t)$ which form a semigroup

$$A(s+t)=A(s)A(t),\quad s,t=0,1,2,\ldots,\tag{8.1}$$

where we use a discrete time parameter for the moment. The pair $\{A(t),F(t)\}$ and (4.6) define a semigroup of maps $T(s)T(t)=T(s+t)$ provided that

$$F(s+t)=F(t)+A(t)^\dagger F(s)A(t),\quad s,t>0.$$

This relation is fulfilled with the choice (3.1), and the maps are all CP if (3.4) holds:

$$K_P-A(t)^\dagger K_PA(t)\geqslant 0,\quad \forall t>0.\tag{8.2}$$

If this relation holds for $t=1$, it holds for all $t=n>0$. Furthermore the state defined by G_P is invariant.

If we are given the dynamics $V(t)$ for the system $\mathscr{S}+\mathscr{R}$, an operator $K\geqslant 0$ satisfying (4.11), and the expectation E given by (3.8), then we can introduce the characteristic Markov property for the subdynamics on $\mathscr{S}$ in the following way:[3]

$$T(t)\{E[W(x)]\}=E\{W[V(t)x]\},\quad \forall x\in\mathscr{H}. \tag{8.3}$$

If this holds for $t=1$, then it holds for $t=2,3,\ldots$, and the family $T(t)$ of maps acting on $\mathscr{A}(P\mathscr{H})$ then form a semigroup. Hence (8.1) holds, and from (8.3) it also follows that $A(t)P=PV(t)$, $\forall t\geqslant 0$. This relation implies not only (4.9) but in addition

$$PV(t)P^{\perp}=0,\quad \forall t\geqslant 0. \tag{8.4}$$

Using the invariance condition (3.10), (3.7) and (8.4) we obtain

$$V(t)^{\dagger}P^{\perp}KP^{\perp}V(t)=K-A(t)^{\dagger}KA(t)\geqslant 0.$$

Then the pair $K_P=PKP$ and $A(t)$ satisfy (8.2) and the CP property is fulfilled. The correlation function (4.12) now takes a simple form obtained just by iterating the dynamical map and the Weyl operators. Setting $t_0=t_1$ in (4.1) or (4.12) we find that

$$R_n(\mathbf{x}|\mathbf{y})=\rho_{\mathscr{A}}\{W(-x_1)T[W(-x_2)T[\ldots T[W(-x_n)W(y_n)]\ldots]]W(y_2)]W(y_1)\}. \tag{8.5}$$

We already remarked that for a dissipative Markov process the underlying closed system dynamics must contain a shift.[18] This applies to the family $V(t)$ in the present situation. If we restrict all considerations to the minimal subspace $\mathscr{H}_+\subseteq\mathscr{H}$ defined in Sec. IV we can retain the condition (4.11) for the existence of a subdynamics and the conditional expectation E.

After some manipulations the semigroup property of the maps $A(t)$ is obtained in the following form:

$$A(t)=PV(t)P=A(1)^t,\quad t=1,2,\ldots. \tag{8.6}$$

If this relation holds for all t, as indicated, then (8.4) is fulfilled. If (8.4) does not hold, simple calculations show that (8.6) holds for a finite number of values $t=1,2,\ldots,n$ if and only if the same finite order of correlation functions has the Markov form (8.5).

For completeness the properties of the CP semigroups in the continuous time case will be spelled out.[32] In the stationary case the semigroup property for $A(t), t\geqslant 0$, means that $A(t)=\exp(tL)$, where the matrix L lives in the subspace $P\mathscr{H}$, of course. From (3.4) the CP property reads

$$L^{\dagger}K_P+K_PL\leqslant 0,$$

which implies (8.2), and we get the CP property for the maps $T(t)$ defined by by $A(t)$ and (4.6), and the state on $\mathscr{S}$ defined by G_P is stationary. This is generalized to the case where L depends on time:

$$\frac{dA(0,t)}{dt}=A(0,t)L(t), \tag{8.7}$$

leading to a time-ordered exponential, of course, corresponding to the semigroup rule $T(0,s)T(s,t)=T(0,t)$, $0<s<t$. This implies for $F(0,t)$

$$F(0,t+dt)=F(t,t+dt)+A(t,t+dt)^{\dagger}F(0,t)A(t,t+dt),\quad 0<t<t+dt.$$

With the notation $M(t)=\lim_{\delta t\to 0}F(t,t+\delta t)/\delta t$ the differential equation becomes

$$\frac{dF(0,t)}{dt}=M(t)+L(t)^{\dagger}F(0,t)+F(0,t)L(t).$$

The CP property is assured by choosing $\{M(t),L(t)\}$ satisfying the differential form of (3.2):

$$M(t)-i[L(t)^{\dagger}S+SL(t)]\geqslant 0,\quad \forall t>0.$$

For dealing with Markov processes in continuous time with greater mathematical rigor one can use the formalism of quantum stochastic calculus.[33,34]

IX. RESPONSE TO TIME DEPENDENT FORCES

In this section we let the time parameter t be continuous, and consider the response of the system $\mathscr{S}+\mathscr{R}$ to external forces acting on the subsystem $\mathscr{S}$. It is well known that the equations of motion for the Hamiltonian (reversible) dynamics of a QHO can be solved explicitly for certain types of time dependent parameters and this applies to $\mathscr{S}+\mathscr{R}$.[35] It is also clear that the expression (4.1) for the full set of correlation functions of all orders [and hence the covariance function (4.3)] does in principle determine the response of the system to a large class of time dependent external perturbations acting on $\mathscr{S}$. The necessary condition is that this action can be expressed as a limit of combinations of the operations

$$X \mapsto W(-x)XW(y), \quad x,y \in P\mathscr{H}. \tag{9.1}$$

As the Weyl operators are dense in the CCR algebra this allows a large set of operations. There is an interesting subclass of harmonic forces which generate quasifree maps and conserve the quasifree form of the correlation functions.

We start with the simplest case of a force corresponding to a perturbation Hamiltonian linear in the canonical operators. In this particular case we can give an answer which is not dependent on the existence of a subdynamics. The external (generalized) force $f(t) \in P\mathscr{H}$, $t \in \mathbb{R}_+$, is understood to mean, in the absence of the intrinsic dynamics, a scalar translation of the canonical operators (a gauge transformation)

$$\frac{d}{dt}X(t) = \mathbb{1} \cdot \xi(t),$$

which is generated by a linear Hamiltonian $\Sigma_k f(t)_k X_k = f(t)X$. From the CCR we find $\xi(t) = i[f(t)X, X(t)] = -2f(t)S$. We can implement $f(t)$ as a driving force on the system defined by the correlation function (4.1) by introducing the following choices of arguments in (4.2):

$$y_k = x_k = -f(t_k)(t_{k+1} - t_k) \in P\mathscr{H}, \quad k = 1, \ldots, n-1,$$

$$y_n = x, \quad x_n = 0.$$

The exponent in (4.2) is found to be $g(x) - i(a|x)$ where the translation vector a is given by

$$a = \sum_{k=0}^{n-1} (t_{k+1} - t_k)\ \xi(t_k) A(t_n - t_k).$$

The obvious transition to a continuous time parameter gives us

$$a(t) = \int_0^t ds\, \xi(s) A(t-s) = -2 \int_0^t ds\ f(s) S A(t-s).$$

Here $A(t)$ is defined by (4.9) independently of the validity of (4.11). Using (9.1) (with $x = y$) to translate the initial state it is shown, even more directly, that $A(t)$ also is the after-effect function which describes the relaxation of an initial deviation from the equilibrium value for the expectation of the canonical operators of $\mathscr{S}$.

Now turn to the case of a time dependent quadratic Hamiltonian perturbation in the subspace $P\mathscr{H}$. This is an interesting situation which includes squeezing of oscillators with a dissipative evolution. The response of $\mathscr{S}+\mathscr{R}$ should still be defined by (4.3), but in order to obtain a more explicit formula involving the function $A(t)$ we have to assume a subdynamics.

The Hamiltonian driving means that there is a real matrix function $L(t) \in B(P\mathscr{H})$ satisfying

$$L(t)^\dagger S_P + S_P L(t) = 0, \tag{9.2}$$

which generates a family of symplectic maps through (8.7), i.e., satisfying (3.9), but which does not leave G invariant, in general. If the unperturbed evolution of the whole system is given by $V(t)$, then the response to this external driving force acting on the small subsystem is then given by standard time dependent methods as the solution of

$$U(0,t)=V(t)+\int_0^t ds\ U(0,s)L(s)V(t-s). \tag{9.3}$$

Inserting this dynamic in (4.1), instead of $V(t)$ and with appropriate values for the time parameters, we obtain all multitime correlations for the perturbed dynamics. However, stationarity will no longer hold, in general. We get a corresponding equation for the evolution of any operator in the Hilbert space

$$X_d(t)=X(t)+\int_0^t ds\ V(t-s)^\dagger[L(s)X_d(s)+X_d(s)L(s)]V(t-s), \tag{9.4}$$

using the notation $X_d(u)=U(0,u)^\dagger XU(0,u), X(u)=V(u)^\dagger XV(u)$.

We are interested in the favorable cases where the effect of the driving can be derived directly from the functions $\{A(t),F(t)\}$ describing the unperturbed stationary subdynamics. Using $P^\perp L(s)=L(s)P^\perp=0$ we find from (9.3) the corresponding equation for the family of operators $A_d(0,t)=PU(0,t)P$:

$$A_d(0,t)=A(t)+\int_0^t ds\ A_d(0,s)L(s)A(t-s),$$

with initial condition $A_d(0,0)=P$, so the solution is completely defined by $\{A(t),L(t)\}$.

We need also the evolution of the state of the system. If we put $X=K$ in (9.4) and assume (4.11) and (3.10) for all $V=V(t)$, then it follows that

$$PK_d(t)P=K_P+\int_0^t ds\ PV(t-s)^\dagger[L(s)K_d(s)+K_d(s)L(s)]V(t-s)P.$$

Now, if we assume that $[P,K_d(t)]=0,\forall t>0$, i.e., that the state of the system still factorizes for all times, then we find that

$$PK_d(t)P=K_P+\int_0^t ds\ A(t-s)^\dagger[L(s)PK_d(s)P+PK_d(s)PL(s)]A(t-s)P,$$

and the solution is again defined by $\{K_P,A(t),L(t)\}$. However, the factorization will not hold in general. In fact,

$$PK_d(t)P^\perp=\int_0^t ds\ PV(t-s)^\dagger[L(s)K_d(s)+K_d(s)L(s)]V(t-s)P^\perp,$$

and there seems to be no reason why this should have only the trivial solution in the general case. It is not a homogenous system as matrix elements in $PK_d(t)P$ enter.

In the Markov case (8.4) holds, which means that the equation above reduces to

$$PK_d(t)P^\perp=\int_0^t ds\ A(t-s)^\dagger L(s)PK_d(s)P^\perp V(t-s)P^\perp,$$

which is a homogenous equation, initial value $PK_d(0)P^\perp=0$, which will have only the zero solution under some regularity assumptions (allowing a series expansion in the time parameter, for instance). We also find from (9.3) that

$$PU(s,t)P^\perp=PV(t-s)P^\perp+\int_s^t du\ PU(s,u)PL(u)PV(t-u)P^\perp,$$

which in general has a nonzero solution. However, if (8.4) holds for $V(t)$, then it clearly holds for $U(0,t)$ as well, so we have the Markov property for the driven process. Writing $A(t)=\exp(tL_0)$ we find from the simple form of the Markovian correlation functions (8.5) that

$$\frac{d}{dt}A_d(0,t)=A_d(0,t)[L_0+L(t)],$$

$$\frac{d}{dt}F(t)_d=M(t)+[L_0+L(t)]^\dagger F(t)_d+F(t)_d[L_0+L(t)].$$

Together these equations define the driven Markovian subdynamics from which we can recover the full set of correlation functions.

The fact that the full set of quantum correlation functions define the response of the system to external forces acting on $\mathscr{S}$ means that they contain more information on the dynamics of $\mathscr{S}+\mathscr{R}$ than the corresponding data do in commutative probability theory. This is just another of the crucial non-commutative properties. The standard way of finding relations between fluctuations and the response to external forces from the Hamiltonian dynamics of the closed system $\mathscr{S}+\mathscr{R}$ is the linear response theory set down in textbooks on statistical mechanics.[36] In the present formalism, and with forces acting only on $\mathscr{S}$, the same information should be given by the covariance function (4.3). However, if we impose the condition (4.11), then there will result a classical version of the fluctuation-dissipation relation with the proportionality (4.7) between $K(t)$ and $A(t)$. This is also essentially the classical Onsager relation between the regression of fluctuations and the decay of deviations from equilibrium. The quantum version of these relations demand that we retain the exact covariance function $K(t)$ which is not of the form (4.7). This point has been discussed recently in the framework of the Langevin equation approach.[37]

X. APPROXIMATE VALIDITY OF THE SUBDYNAMICS PICTURE

Now consider the case where (3.7) does not hold. Then there will be a difference between the covariance matrix coming from the evolution of $\mathscr{S}+\mathscr{M}$ and the expression (4.7), where A is defined by (4.9), which corresponds to a subdynamics. The difference is

$$PKV(t)P-PKA(t)=PKP^\perp V(t)P. \tag{10.1}$$

As the covariance matrix defines the dynamics, if we can show that the matrix elements of (10.1) are negligible in suitable circumstances, we will also obtain conditions for $\{K_P,A(t)\}$ approximating a subdynamics.

Note that such conditions can be fulfilled for some ranges of t and not for others, so we can discuss this problem for a given t and leave out this parameter. Clearly we have to use the properties of V as well as those of K. The physical idea is that the effects of the back action of $\mathscr{S}$ on $\mathscr{R}$ spreads over a large number of degrees of freedom of $\mathscr{R}$ on a time scale which is shorter than the relaxation time for $\mathscr{S}$.

We want to see how this idea could work in the present scheme, but lacking an explicit model for the heat bath we can do this only in very general terms. Consider arbitrary unit vectors $x,y\in P\mathscr{H}$ and the matrix element $(x|KP^\perp V|y)$. Also introduce the vectors in $\mathscr{H}$: $\phi=K|x)$, $\chi=P^\perp V|y)$. We can then write

$$|(x|KP^\perp V|y)|^2=|(\phi|\chi)|^2=(\phi|\phi)(\chi|\chi)|(\hat{\phi}|\hat{\chi})|^2,$$

where $\{\hat{\phi},\hat{\chi}\}$ are normalized vectors. The simplest case is where the matrix elements of $P^\perp VP$ behave effectively as independent random variables, and all of a similar magnitude. Then $\hat{\chi}$ can be considered randomly chosen in the Hilbert space $P^\perp\mathscr{H}$. This corresponds to an equidistribution over the degrees of freedom of $\mathscr{R}$. We can then make the order of magnitude estimate $|(\hat{\phi}|\hat{\chi})|^2\simeq(\dim P^\perp\mathscr{H})^{-1}$, and for a reservoir with a large number of degrees of freedom we see why the matrix elements of (10.1) can be expected to be negligible. In more general and realistic models of heat baths we may have to replace $P^\perp\mathscr{H}$ by a Hilbert space of degrees of freedom of $\mathscr{R}$ which has an effective dimension increasing with the strength of the $\mathscr{S}-\mathscr{R}$ interaction.

Introduce $B=P^{\perp}VP$, then (10.1) equals PKB. Using the invariance of K we can write

$$K_P=A^{\dagger}KA+B^{\dagger}KB+A^{\dagger}KB+B^{\dagger}KA, \tag{10.2}$$

where the last two terms in the RHS are going to negligible if the preceding argument holds. If the dynamics mixes the degrees of freedom of $\mathscr{S}+\mathscr{R}$ thoroughly, then, by the same kind of reasoning, also the first term will be negligible and only the second term remains (under the assumption $\dim P.\mathscr{H} \ll \dim P^{\perp}.\mathscr{H}$). This situation corresponds to a final equilibrium for the open system, which means that the lowest order correlation approximately factorizes

$$R_2(\mathbf{x}|\mathbf{y}) \approx R_1(x_1|y_1)R_1(x_2|y_2).$$

In order for $\{K_P, A\}$ to reproduce $PKVP$ in a non-trivial way we then find that the first two terms in (10.2) must be of comparable magnitude, while the last two are negligible. If this holds for a useful range for the time parameter we will obtain a subdynamics for $\mathscr{S}$ which approximates the exact covariance function in this range.

We can use similar arguments to discuss the degree of approximation for the Markov property. Again using a discrete time parameter, in order to show that (8.6) holds to some approximation up to a given finite order n, we must show that the matrix elements of the following operator are small:

$$PKV(n)P-PKA(1)^n=PK\left\{P^{\perp}V(n)+\sum_{k=2}^{n}A(1)^{n-k}PV(1)P^{\perp}V(k-1)\right\}P.$$

Each term in the RHS gives matrix elements of a similar structure to those coming from the RHS of (10.1). Thus we can make the previous assumptions for each of the iterates $V(k)$ of the dynamical map to get sufficient conditions.

XI. EVOLUTION OF NON-STATIONARY INITIAL STATES

We have seen the rigorous conditions which have to be fulfilled for a subdynamics to exist and also how much information about the system is contained in this structure. If we renounce the full set of correlation functions and let ourselves be satisfied by a family of dynamical maps giving the evolution of an arbitrary initial state of $\mathscr{S}$, then the restrictions on the existence of solutions will largely disappear.

In the lowest order correlation function

$$\rho[W(-x)W(V(t)y)]=R(x,y;t), \quad x,y\in P.\mathscr{H},$$

we can set $x=0$ to find a restricted function of one argument $y\in P.\mathscr{H}$ which gives the evolution of the state of $\mathscr{S}$:

$$R(0,y;t)=\rho_{\mathscr{S}}(t)[W(y)], \quad t\geqslant 0.$$

If the initial ($t=0$) state ρ of $\mathscr{S}+\mathscr{R}$ factorizes, the family of maps $T(t)$ defined in Sec. VII by $\{A(t),D(t,t)\}$ also gives the evolution of the state

$$\rho_{\mathscr{S}}(t)[W(y)]=\rho_{\mathscr{S}}(0)\{T(t)[W(y)]\}.$$

We can now ask: if the initial state does not factorize, can we still describe the evolution of the initial state exactly by such evolution maps $T(t)$? The answer is yes, there is now no restriction, except that the maps will fail to be CP, or even positive, in general. Let $T(t)$ be defined by $\{A(t),F(t)\}$, which do not necessarily satisfy (3.2), while $\rho_R(t)$ is defined by the quadratic form $G_P(t)$. In order to have the desired evolution of the partial state of $\mathscr{S}$ we should choose F as follows:

$$F(t)=G_P(t)-A(t)^{\dagger}G_P(0)A(t)=PV(t)^{\dagger}P^{\perp}GP^{\perp}V(t)P-PV(t)^{\dagger}P^{\perp}GPA(t) \\ -A(t)^{\dagger}PGP^{\perp}V(t)P. \tag{11.1}$$

This expression is actually independent of $G_P(0)=PGP$, hence $\{A(t),F(t)\}$ defines a family of maps on $G_P(0)$. If we choose $G_P(0)$ arbitrary while $\{PGP^\perp,P^\perp GP,P^\perp GP^\perp\}$ are kept constant, then the initial ''state'' of $\mathscr{S}+\mathscr{R}$ will not necessarily be positive. Consequently the maps will not be positive in general, and they will not reproduce the covariance function unless (4.10) holds. (In the latter case the two last terms in (11.1) vanish, (3.2) holds, and we are back to a factorizing initial state!) Still, there will be a subset of initial values $G_P(0)$ which are mapped into a genuine, positive state of $\mathscr{S}$ at time t.

If the family $A(t)$ forms a semigroup, then there is a semigroup of maps $T(s,t)$ defined by $\{A(t),F(s,t)\}$ where

$$F(s,t)=G_P(t)-A(t-s)^\dagger G_P(s)A(t-s), \quad s<t.$$

Using some limiting procedures (which involves a manipulation of the time scales) one can obtain such a semigroup of maps which are generally not positive, but which still serve as an effective reduced dynamics for $\mathscr{S}$, perhaps relevant only for a restricted set of initial conditions.[25] For this allowed set there may still be convergence to a genuine positive final state of $\mathscr{S}$.

In order to see how this may work, consider a discrete semigroup. We have a map T defined by $\{A,F\}$ which need not satisfy (3.2). Assume that the semigroup has a unique limit state, which means that for any quadratic G

$$\lim_{n\to\infty} A^{n\dagger}GA^n=0.$$

Then it is easy to see that the limit obtained by iterating the transformation $G\mapsto A^\dagger GA+F$ is the following sum (if it converges):

$$G_P(\infty)=\sum_{n=0}^{\infty} A^{n\dagger}FA^n.$$

The limit is a genuine state for $\mathscr{S}$ if and only if $G_P(\infty)+iS_P=K_P(\infty)\geqslant 0$. Given any matrix $G_P(\infty)$ satisfying this condition, we can choose $F=G_P(\infty)-A^\dagger G_P(\infty)A$ to obtain a semigroup of maps such that every initial ''state'' (positive or not) converges to the final state defined by $G_P(\infty)$. The map T is CP if (8.2) holds for $K_P(\infty)$, but this is not true in general.

XII. DISCUSSION

There is an overwhelming number of papers on the dynamics of open quantum systems, even if we restrict ourselves to systems of oscillators. Here we can only mention a few which deal with the problems involved in the existence of system-reservoir correlations and of the intrinsic time scale $\beta=\hbar/k\Theta$.

The first problem we meet in the literature is that of deriving a quantum Markovian master equation for an open system $\mathscr{S}$. The fact that $\beta\neq 0$ when $\Theta<\infty$ is incompatible with a strictly exponential relaxation has been appreciated for a long time.[22–27,38,39] A derivation of master equations from the microscopic dynamics inevitably involves a separation of time scales and some form of averaging method.[40,41] The quantum case differs from the classical one mainly through the fact that the time scale β is independent of the details of the reservoir. The master equation alone is equivalent with having a semigroup of dynamical maps. We have already remarked that the full set of multitime correlation functions (8.5) follows from the semigroup property for the model treated here, but this is not so for general models of open quantum systems.

The second problem is that coming from the system-reservoir correlations. Most papers on the derivation of master equations from the microscopic dynamics accept the factorization of the initial state, at least. However, we have seen in Sec. IV how the correlations forbid an exact subdynamics, and in particular having a family of CP maps defining the covariance function. In Sec. XI we saw that there are non-positive dynamical maps which can describe the evolution of some initial conditions. The role of the correlations in destroying the positivity of the dynamical maps has been the subject of a considerable number of papers, of which we can list just a few.[25,42–45]

One possible way out of the factorization condition is thus to restrict oneself to finding a family of dynamical maps which preserve the positivity of a subset of initial states, though they cannot be extended to positive maps on the whole state space. We then need a prescription of how such states are prepared from a stationary initial state of the composite system, e.g., by the action on the subsystem $\mathscr{S}$ by a well-defined set of operations. This is a solution which has been suggested in several places.[25,43,45] In particular, certain versions of the path integral formalism allow correlated initial states.[8,41] The evolution maps can exist for some correlated states of the system, but they will not define the very strong and rigid structure we have called a subdynamics, and which contain much more information than just these maps. For this reason there is no contradiction in the body of work cited above with the results of earlier papers where the structure of a subdynamics (called a quantum stochastic process there) was imposed more or less as an axiom.[1,2] Neither is there a contradiction of the results on the form of the generators of quantum dynamical semigroups, which were assumed to act on the space of all states of $\mathscr{S}$.[29–31]

The main message of this paper, and of Ref. 3, is that the problems remain even if we drop the Markov property. The correlations in the initial state can not be accounted for just by introducing some memory in the process. In the present scheme based on the CCR, the dynamics of the open system is described completely by the time dependence of the covariance matrix, and this description does not necessarily involve any approximation. However, the non-commutativity of the observables means that this time dependence cannot be exactly reproduced by dissipative dynamical maps acting only on the observables of the open system, except when the state factorizes for all times. (This happens in particular when the reservoir has an infinite temperature, i.e., $\beta=0$.) We can still have a subdynamics as an approximation involving assumptions on the time scale and on the relaxation properties of the reservoir. These assumptions are weaker than those needed to make the dynamics Markovian, but they are of a similar type.

In this paper we have not tried to compare the formalism with the Langevin equation approach. However, it seems fairly clear that using colored noise in a quantum Langevin equation (as one should in order to stay consistent with thermodynamics) will give a covariance function which is not of the type which is reducible to a subdynamics. It was noted that the solutions will not give Markov processes even if the Langevin equation itself has no memory term.[46]

Finally we note that the present model is an exceptional one in that there are methods of finding exact solutions.[25,47,48] This allows a solution for the covariance function, which is sufficient to define the dynamics of the whole system $\mathscr{S}+\mathscr{R}$ even when no subdynamics exists.

Study of hydrodynamical limits in a multicollision scale Boltzmann equation for semiconductors

Philippe Montarnal[a)]
INRIA, M3N project, 78153 Le Chesnay, Cedex, France

(Received 3 November 1997; accepted for publication 1 December 1997)

We derive in this paper a generalized hydrodynamical model for semiconductors from a multicollision scale Boltzmann equation. We apply a Chapman–Enskog method for two time-scale collisional operators. These two time scales are linked respectively with the elastic part of the electron/lattice scattering term and the electron/electron collision term. Our model has a global entropy function and a symmetric formulation. It is a generalization of the classical hydrodynamical model since we add two terms: a ''thermal friction force'' and a ''friction heat flux.'' Moreover, with some changes of parameters we obtain both the energy-transport model and the Euler–Poisson hydrodynamical model. © *1998 American Institute of Physics.* [S0022-2488(98)03404-5]

I. INTRODUCTION

In order to study submicrometer semiconductors, it is necessary to use richer macroscopic models than the drift-diffusion model. In particular, one must take into account the energy of the carriers. The two main fluid models of this type are currently the hydrodynamical model (obtained with the three first moments of the Boltzmann transport equation and some closure conditions[1,2]) and the energy-transport model (obtained with the moments of order zero and two of the Boltzmann transport equation at a diffusion scale[3–5]). Here, we develop a unified vision of these two classes of models.

We derive in this paper a generalized hydrodynamical model for semiconductors from a multicollision scale Boltzmann equation. We apply a Chapman–Enskog method[6–8] for two time-scale collisional operators. These two time scales are linked respectively with the elastic part of the electron/lattice scattering term and the electron/electron collision term. Our model has a global entropy function and a symmetric formulation. It is a generalization of the classical hydrodynamical model since we add two terms: a ''thermal friction force'' and a ''friction heat flux.'' Moreover, with some changes of parameters we obtain both the energy-transport model and the Euler–Poisson hydrodynamical model.

We consider a nondegenerate electron gas with a parabolic band structure. Using the same scaling as in Refs. 5, 9, and 10, we obtain the following perturbed Boltzmann transport equation:

$$\partial_t f + \frac{1}{\varepsilon_1}\, \underline{v}.\nabla_x f + \frac{1}{\varepsilon_1}\, \nabla_x \Phi.\nabla_v f = \frac{1}{\varepsilon_1^2}\left(\frac{1}{\varepsilon_2}\, Q_{e,e}(f,f) + Q_{\text{elas}}(f)\right) + Q_{\text{ine}}(f), \quad \text{(BTE)}$$

where $f = f(\underline{x},\underline{v},t)$ is the electron distribution function depending on the position $\underline{x}$, the velocity $\underline{v}$ and the time t, and Φ is the electric potential which is assumed to be given and smooth.

The specifications of the collision operators are the following: $Q_{e,e}$ describes binary collisions between electrons, Q_{elas} models impurity scattering and the elastic part of phonon scattering, and Q_{ine} accounts for the inelastic part of phonon scattering.

The dimensionless parameter ε_1^2 measures the typical energy gain or loss during a collision with a phonon (inelastic contribution), while ε_2 quantifies the ratio between the magnitude orders of the phonon scattering and the electron/electron collision (see Ref. 9).

We assume in this paper that

a)Electronic mail: philippe.montarnal@inria.fr

 © 1998 American Institute of Physics

$$\varepsilon_1 \ll 1, \quad \varepsilon_2 \ll 1. \tag{1}$$

In this case the elastic part of phonon scattering is considered to be dominant as compared with the inelastic part (ε_1^2, the relative energy gain or loss of electron energy during a phonon collision, is very small) and the electron/electron collision operator is of the dominant order of magnitude. This last hypothesis on ε_2 is not studied in Ref. 9 but is justified in the case of high doping.[11,12]

We introduce the density n, the mean velocity $\underline{u}$, and the energy e of the electrons by

$$\begin{pmatrix} n \\ \varepsilon_1 n\underline{u} \\ ne \end{pmatrix} = \int_{\mathbb{R}^3} \underline{K}(\underline{v}) f \, d\underline{v}, \tag{2}$$

with

$$\underline{K}(\underline{v}) = \begin{pmatrix} 1 \\ \underline{v} \\ \dfrac{|\underline{v}|^2}{2} \end{pmatrix}.$$

Thanks to the scale in the definition of the velocity $\underline{u}$, we later deal with order one quantities in the mass conservation equation [see Eq. (13)].

We also define the electronic temperature T by

$$e = \tfrac{1}{2}\varepsilon_1^2 |\underline{u}|^2 + \tfrac{3}{2} T. \tag{3}$$

In this paper we will derive from the Boltzmann transport equation (BTE) the following macroscopic system of $2+3$ equations [considering assumption (1)]:

$$\partial_t n + \operatorname{div}(n\underline{u}) = 0,$$

$$\partial_t(\varepsilon_1^2 n\underline{u}) + \operatorname{div}(\varepsilon_1^2 n\underline{u} \otimes \underline{u} + nT\underline{\underline{I_d}} + \varepsilon_2 \nu_4(T)\underline{\underline{I_d}}) - n\nabla_x \Phi$$
$$+ \left(\nu_1(T) + \frac{\varepsilon_1}{\tau_{\text{ine}}} + \varepsilon_1^2 \nu_2(T, \underline{u}) + \frac{\varepsilon_2}{n} \nu_3(T) \right) n\underline{u} = 0, \quad \text{(HD)}$$

$$\partial_t\left(\tfrac{1}{2} n(\varepsilon_1^2 |\underline{u}|^2 + 3T) \right) + \operatorname{div}\left(\tfrac{1}{2} n\underline{u}(\varepsilon_1^2 |\underline{u}|^2 + 5T) + \varepsilon_2 \nu_5(T)\underline{u} - \varepsilon_2 \kappa(T) \nabla_x T \right)$$
$$- n\underline{u}\nabla_x \Phi + n \frac{e - \frac{3}{2}T_0}{\tau_e} = 0.$$

This system contains at once the classical hydrodynamical model[1,13] (obtain by cancelling the ''thermal friction force'' and the ''friction heat flux'' defined in Sec. V), the Euler–Poisson model (obtained when $\varepsilon_2 \to 0$), and the energy-transport model[3–5] (obtained when $\varepsilon_1 \to 0$).

Moreover, our model has an entropy function

$$\eta = n \ln\left(\frac{n}{(2\pi T)^{3/2}} \right) - \frac{5}{2} n, \quad \text{(EF)}$$

which is linked with the following entropy conservation equation (which can be obtained from the H theorem)

$$\partial_t\left(n \ln\left(\frac{n}{(2\pi T)^{3/2}} \right) - \frac{5}{2} n \right) + \operatorname{div}\left(n\underline{u} \ln\left(\frac{n}{(2\pi T)^{3/2}} \right) - \frac{5}{2} n\underline{u} - \frac{\varepsilon_2}{T} \nu_5(T)\underline{u} + \varepsilon_2 \frac{\kappa(T)}{T} \nabla_x T \right)$$
$$= -\frac{n}{T}\left(\nu_1(T) + \frac{\varepsilon_1}{\tau_{\text{ine}}} + \varepsilon_1^2 \nu_2(T, \underline{u}) + \frac{\varepsilon_2}{n} \nu_3(T) \right) |\underline{u}|^2 - \frac{n}{T} \frac{e - \frac{3}{2}T_0}{\tau_e} - \varepsilon_2 \frac{\kappa(T)}{T^2} |\nabla_x T|^2 \quad \text{(EL)}.$$

This entropy function is compatible with both the hyperbolic entropy of the classical hydrodynamical model and the parabolic entropy of the energy-transport model. Moreover, the entropy function η is also linked with the existence of a symmetric formulation of the system (HD).

An outline of this paper is as follows. In Sec. II we give the definition and the principal properties of the collision operators. Then, in Sec. III, we derive the macroscopic hydrodynamical system with a Chapman–Enskog method. Section IV is devoted to the study of the entropy function and its links with the symmetric variables. Finally, in Sec. V, we describe the relations of our model with other semiconductor models.

We derive the macroscopic entropy relation from the kinetic entropy in Appendix A. In Appendix B we give the proof of Lemma 10.

II. DEFINITION AND PROPERTIES OF THE COLLISION OPERATORS

In this section, we first describe $Q_{e,e}$, the nonlinear Boltzmann collision operator for binary collisions between electrons. We present the H theorem and we introduce the associated linearized operator. Then, we present the operator Q_{elas} and its properties (H theorem), and the collision term Q_{ine} as an energy relaxation term.

The electron–electron collision operator is given by (see Ref. 14 and the references therein)

$$Q_{e,e}(f,f)=\int_{\mathbb{R}^3}\int_0^{2\pi}\int_0^{\pi/2}B_{e,e}(|\underline{v}-\underline{v}_1|,\theta)(f'f_1'-ff_1)d\theta\, d\varphi\, d\underline{v}_1,$$

with $f=f(\underline{v})$, $f=f_1(\underline{v}_1)$, $f'=f(\underline{v}')$, and $f_1'=f(\underline{v}_1')$. Here $\underline{v}$ and $\underline{v}_1$ are the velocities before the collision, $\underline{v}'$ and $\underline{v}_1'$ the velocities after the collision:

$$\underline{v}'=\underline{v}+(\underline{v}_1-\underline{v}).\underline{\omega}\,\underline{\omega},\qquad \underline{v}_1'=\underline{v}_1-(\underline{v}_1-\underline{v}).\underline{\omega}\,\underline{\omega},$$

with $\underline{\omega}\in\mathscr{S}^2_+=\{\underline{\omega}\in\mathscr{S}^2\text{ s.t.}(\underline{v}_1-\underline{v}).\underline{\omega}\geqslant 0\}$, $\mathscr{S}^2$ is the unit sphere of $\mathbb{R}^3$, and (θ,φ) are the spherical coordinates on $\mathscr{S}^2$.

The collision kernel $B_{e,e}$ satisfies the following conditions:

$$B_{e,e}\geqslant 0,\quad B_{e,e}(g,\theta)=\mathscr{B}_{e,e}(|g|,|g.\theta|). \tag{4}$$

The following H theorem holds (see Refs. 7 and 14).

Theorem 1: *Let $B_{e,e}$ satisfy (4). Then*

(i)

$$\int_{\mathbb{R}^3}Q_{e,e}(f)\ln f\,d\underline{v}\leqslant 0; \tag{5}$$

(ii) $Q_{e,e}(f)=0$ *if and only if for some* $n,T\geqslant 0$, $\underline{u}\in\mathbb{R}^3$,

$$f(\underline{v})=\frac{n}{(2\pi T)^{3/2}}\exp\left(-\frac{|\underline{v}-\underline{u}|^2}{2T}\right); \tag{6}$$

(ii)

$$\int_{\mathbb{R}^3}\underline{K}(\underline{v})Q_{e,e}(f,f)d\underline{v}=\begin{pmatrix}0\\0\\0\end{pmatrix}. \tag{7}$$

The linearized operator of $Q_{e,e}$ around a Maxwellian M is defined by (see Ref. 8)

$$\Gamma_{e,e}(g)=2M^{-1}Q_{e,e}(M,Mg).$$

Next, we introduce the notations

$$\mathscr{D}(\Gamma_{e,e})=\{g\in L^2(M\,d\underline{v})\,\text{s.t.}\,\vartheta_{e,e}g\in L^2(M\,d\underline{v})\},$$

$$\vartheta_{e,e}(\underline{v})=2\int_{\mathbb{R}^3}\int_0^{2\pi}\int_0^{\pi/2}B_{e,e}(|\underline{v}-\underline{v}_1|,\theta)M(\underline{v}_1)\,d\theta\;d\varphi\;d\underline{v}_1.$$

Also, we have the following (see Ref. 15).

Proposition 2:

(i) $\Gamma_{e,e}:\mathscr{D}(\Gamma_{e,e})\subset L^2(M\,d\underline{v})\to L^2(M\,d\underline{v})$ *is negative self-adjoint,*
(ii) $\mathrm{Ker}(\Gamma_{e,e})=\{a+\underline{b}.\underline{v}+c|\underline{v}|^2, a,c\in\mathbb{R},\underline{b}\in\mathbb{R}^3\}$,
(iii) $\forall g\in L^2(M\,d\underline{v}),\Gamma_{e,e}(f)=g$ *has a solution if and only if* $g\in(\mathrm{Ker}(\Gamma_{e,e}))^{\perp}$, i.e.,

$$\int_{\mathbb{R}^3}g\underline{K}(\underline{v})M\;d\underline{v}=0. \tag{8}$$

Moreover, we have unicity of the solution in $(\mathrm{Ker}(\Gamma_{e,e}))^{\perp}$.

We recall that Q_{elas} models impurity scattering and the elastic part of phonon scattering. Its definition is the following (see Ref. 10):

$$Q_{\mathrm{elas}}(f)=\int_{\mathscr{S}^2}B_{\mathrm{elas}}(|\underline{v}|,\alpha)(f(|\underline{v}|\underline{\omega})-f(\underline{v}))\;d\underline{\omega},$$

where α is the angle between $\underline{v}$ and $\underline{\psi}$. B_{elas} is related to the differential cross section and satisfies

$$B_{\mathrm{elas}}\geqslant 0,\;\; B_{\mathrm{elas}}(|\underline{v}|,-\alpha)=B_{\mathrm{elas}}(|\underline{v}|,\alpha). \tag{9}$$

Let us also introduce B^T_{elas} by

$$B^T_{\mathrm{elas}}=\int_{\mathscr{S}^2}B_{\mathrm{elas}}(|\underline{v}|,\alpha)\,d\underline{\omega}.$$

For Q_{elas}, we have the following H theorem:

Theorem 3: *Let* B_{elas} *satisfy (9). Then*

(i)

$$\int_{\mathbb{R}^3}Q_{\mathrm{elas}}(f)\ln f\;d\underline{v}\leqslant 0. \tag{10}$$

(ii) $Q_{\mathrm{elas}}(f)=0$ *if and only if for some* $n,T\geqslant 0$,

$$f(\underline{v})=\frac{n}{(2\pi T)^{3/2}}\exp\left(-\frac{|\underline{v}|^2}{2T}\right). \tag{11}$$

(iii) *If* $g=g(|\underline{v}|^2)$, *then*

$$\int_{\mathbb{R}^3}gQ_{\mathrm{elas}}(f)\,d\underline{v}=\begin{pmatrix}0\\0\end{pmatrix}.$$

Finally, Q_{ine} accounts for the inelastic part of phonon scattering. It expresses the exchange of energy with the high electron phonons. We will only write and use the following property:

$$\int_{\mathbb{R}^3}\underline{K}(\underline{v})Q_{\mathrm{ine}}(f)\,d\underline{v}=\begin{pmatrix}0\\-\dfrac{n\underline{u}}{\tau_{\mathrm{ine}}}\\-n\,\dfrac{e-\frac{3}{2}T_0}{\tau_e}\end{pmatrix}, \tag{12}$$

where τ_e and τ_{ine} are respectively the energy and momentum relaxation times from the inelastic contribution of phonon scattering.

III. DERIVATION OF THE HYDRODYNAMICAL MACROSCOPIC MODEL

The three first moments of the Boltzmann transport equation (BTE) give the following equations:

$$\partial_t n + \operatorname{div}(n\underline{u}) = 0, \tag{13}$$

$$\partial_t(\varepsilon_1^2 n\underline{u}) + \operatorname{div}(\varepsilon_1^2 n\underline{u}\otimes\underline{u} + \underline{\underline{p}}) - n\nabla_x\Phi = \underline{r}, \tag{14}$$

$$\partial_t(ne) + \operatorname{div}(\underline{u}(ne+\underline{\underline{p}}) + \underline{q}) - n\underline{u}\nabla_x\Phi = -n\,\frac{e-\frac{3}{2}T_0}{\tau_e}, \tag{15}$$

with

$$\underline{\underline{p}} = \int_{\mathbb{R}^3}(\underline{v}-\varepsilon_1\underline{u})\otimes(\underline{v}-\varepsilon_1\underline{u}) f\, d\underline{v},$$

$$\underline{r} = \frac{1}{\varepsilon_1}\int_{\mathbb{R}^3}\underline{v}\,Q_{\text{elas}}(f)\,d\underline{v} - \varepsilon_1\,\frac{n\underline{u}}{\tau_{\text{ine}}}, \qquad \underline{q} = \frac{1}{\varepsilon_1}\int_{\mathbb{R}^3}(\underline{v}-\varepsilon_1\underline{u})\,\frac{|\underline{v}-\varepsilon_1\underline{u}|^2}{2} f\, d\underline{v}.$$

In order to close this system, we will compute the asymptotic expansion of f. We will thus be able to express relations between $\underline{\underline{p}}$ (pressure tensor), r (friction force), q (heat flux), and the macroscopic quantities defined by the equation (2).

We denote by M_{ε_1} the Maxwellian with the same moments as f,

$$M_{\varepsilon_1} = \frac{n}{(2\pi T)^{3/2}}\exp\left(-\frac{|\underline{v}-\varepsilon_1\underline{u}|^2}{2T}\right).$$

We can write

$$Q_{e,e}(f,f) = M_{\varepsilon_1}\Gamma_{e,e}(M_{\varepsilon_1}^{-1}(f-M_{\varepsilon_1})) + Q_{e,e}(f-M_{\varepsilon_1}, f-M_{\varepsilon_1}),$$

where $\Gamma_{e,e}$ is the linearized operator of the collision term $Q_{e,e}$ around the Maxwellian M_{ε_1}.

We can rewrite the equation (BTE) in the following form:

$$\begin{aligned} &M_{\varepsilon_1}\Gamma_{e,e}(M_{\varepsilon_1}^{-1}(f-M_{\varepsilon_1})) + Q_{e,e}(f-M_{\varepsilon_1}, f-M_{\varepsilon_1}) \\ &\quad = -\varepsilon_2 Q_{\text{elas}}(f) + \varepsilon_1\varepsilon_2\underline{v}.\nabla_x f + \varepsilon_1\varepsilon_2\nabla_x\Phi.\nabla_v f - \varepsilon_1^2\varepsilon_2 Q_{\text{ine}}(f) + \varepsilon_1^2\varepsilon_2\partial_t f. \end{aligned} \tag{16}$$

We can also expand M_{ε_1} in ε_1:

$$\begin{aligned} M_{\varepsilon_1} = n.\mathcal{M}_0 + \varepsilon_1\,\frac{\underline{v}.\underline{u}}{T}\,n.\mathcal{M}_0 + \varepsilon_1^2\,\frac{1}{2}\left(\frac{(\underline{u}.\underline{v})^2}{T^2} - \frac{|\underline{u}|^2}{T}\right)n.\mathcal{M}_0 \\ + \varepsilon_1^3\,\frac{1}{6}\,\underline{u}.\underline{v}\left(\frac{(\underline{u}.\underline{v})^2}{T^3} - 3\,\frac{|\underline{u}|^2}{T^2}\right)n.\mathcal{M}_0 + O(\varepsilon_1^4), \end{aligned} \tag{17}$$

with

$$.\mathcal{M}_0 = \frac{1}{(2\pi T)^{3/2}}\exp\left(-\frac{|\underline{v}|^2}{2T}\right).$$

It follows

$$f = n\mathscr{M}_0 + \varepsilon_1 \frac{\underline{v}.\underline{u}}{T} n\mathscr{M}_0 + O(\varepsilon_1^2) + O(\varepsilon_1\varepsilon_2), \tag{18}$$

which gives

$$\varepsilon_2 Q_{\text{elas}}(f\ ) = \frac{\varepsilon_1\varepsilon_2}{T} n\underline{u}.Q_{\text{elas}}(\underline{v}.\mathscr{M}_0) + O(\varepsilon_1^2\varepsilon_2) + O(\varepsilon_1\varepsilon_2^2), \tag{19}$$

$$\varepsilon_1\varepsilon_2\underline{v}.\nabla_x f = \varepsilon_1\varepsilon_2\underline{v}.\nabla_x(n.\mathscr{M}_0) + O(\varepsilon_1^2\varepsilon_2), \tag{20}$$

$$\varepsilon_1\varepsilon_2\nabla_x\Phi.\nabla_v f = -\frac{\varepsilon_1\varepsilon_2}{T} n.\mathscr{M}_0\underline{v}.\nabla_x\Phi + O(\varepsilon_1^2\varepsilon_2). \tag{21}$$

We further manipulate the equation (20) in order to obtain an expression depending only on the temperature gradient.

On the one hand, we have

$$\nabla_x(n.\mathscr{M}_0) = \frac{\mathscr{M}_0}{T}\nabla_x(nT) + \frac{n.\mathscr{M}_0}{T}\left(\frac{|\underline{v}|^2}{2T} - \frac{5}{2}\right)\nabla_x T.$$

On the other hand, thanks to the asymptotical expansion (18), we obtain

$$\underline{\underline{p}} = nT\underline{\underline{\mathrm{I}_d}},$$

$$\underline{r} = \frac{n}{T}\left(\int_{\mathbb{R}^3}\underline{v}\otimes Q_{\text{elas}}(\underline{v}.\mathscr{M}_0)d\underline{v}\right)\underline{u} + O(\varepsilon_1) + O(\varepsilon_2),$$

which gives, thanks to Eq. (14),

$$\nabla_x(nT) = \frac{n}{T}\left(\int_{\mathbb{R}^3}\underline{v}\otimes Q_{\text{elas}}(\underline{v}.\mathscr{M}_0)d\underline{v}\right)\underline{u} + n\nabla_x\Phi + O(\varepsilon_1) + O(\varepsilon_2).$$

The operator B_{elas} being symmetric, matrix

$$\int_{\mathbb{R}^3}\underline{v}\otimes Q_{\text{elas}}(\underline{v}.\mathscr{M}_0)d\underline{v},$$

is diagonal and its diagonal term is defined by

$$-\int_{\mathbb{R}^3}\int_{\mathscr{S}^2} B_{\text{elas}}(|\underline{v}|,\alpha)\frac{|\underline{v}|^2}{3}\mathscr{M}_0\, d\underline{\omega}\, d\underline{v} = -\int_{\mathbb{R}^3} B^T_{\text{elas}}(|\underline{v}|)\frac{|\underline{v}|^2}{3}\mathscr{M}_0\, d\underline{v}.$$

We now define $\nu_1(T)$ by

$$\nu_1(T)\underline{\underline{\mathrm{I}_d}} = -\frac{1}{T}\int_{\mathbb{R}^3}\underline{v}\otimes Q_{\text{elas}}(\underline{v}.\mathscr{M}_0)d\underline{v} = \frac{1}{T}\int_{\mathbb{R}^3} B^T_{\text{elas}}(|\underline{v}|)\frac{|\underline{v}|^2}{3}\mathscr{M}_0\, d\underline{v}\ \underline{\underline{\mathrm{I}_d}},$$

hence

$$\nabla_x(nT) = -n\nu_1(T)\underline{u} + n\nabla_x\Phi + O(\varepsilon_1) + O(\varepsilon_2).$$

All this together yields

$$\varepsilon_1\varepsilon_2 \underline{v}.\nabla_x f = \frac{\varepsilon_1\varepsilon_2}{T}\mathscr{M}_0 \underline{v}._x(nT) + \frac{\varepsilon_1\varepsilon_2}{T} n\mathscr{M}_0\left(\frac{|\underline{v}|^2}{2T} - \frac{5}{2}\right)\underline{v}.\nabla_x T + O(\varepsilon_1^2\varepsilon_2)$$

$$= -\frac{\varepsilon_1\varepsilon_2}{T} n\mathscr{M}_0 \nu_1(T)\underline{v}.\underline{u} + \frac{\varepsilon_1\varepsilon_2}{T} n\mathscr{M}_0 \underline{v}.\nabla_x \Phi + \frac{\varepsilon_1\varepsilon_2}{T} n\mathscr{M}_0\left(\frac{|\underline{v}|^2}{2T} - \frac{5}{2}\right)\underline{v}.\nabla_x T$$

$$+ O(\varepsilon_1^2\varepsilon_2) + O(\varepsilon_1\varepsilon_2^2).$$

Therefore we have the following equality:

$$-\varepsilon_2 Q_{\text{elas}}(f) + \varepsilon_1\varepsilon_2 \underline{v}.\nabla_x f + \varepsilon_1\varepsilon_2 \nabla_x \Phi.\nabla_v f - \varepsilon_1^2\varepsilon_2 Q_{\text{ine}}(f) + \varepsilon_1^2\varepsilon_2 \partial_t f$$

$$= -\frac{\varepsilon_1\varepsilon_2}{T} n\underline{u}.(Q_{\text{elas}}(\underline{v}\mathscr{M}_0) + \nu_1(T)\underline{v}\mathscr{M}_0) + \frac{\varepsilon_1\varepsilon_2}{T} n\nabla_x T.\left(\frac{|\underline{v}|^2}{2T} - \frac{5}{2}\right)\underline{v}\mathscr{M}_0$$

$$+ O(\varepsilon_1^4) + O(\varepsilon_1^2\varepsilon_2) + O(\varepsilon_1\varepsilon_2^2),$$

which gives

$$\Gamma_{e,e}(M_{\varepsilon_1}^{-1}(f - M_{\varepsilon_1})) = -M_{\varepsilon_1}^{-1}\frac{\varepsilon_1\varepsilon_2}{T} n\underline{u}.(Q_{\text{elas}}(\underline{v}\mathscr{M}_0) + \nu_1(T)\underline{v}\mathscr{M}_0)$$

$$+ M_{\varepsilon_1}^{-1}\frac{\varepsilon_1\varepsilon_2}{T} n\nabla_x T.\left(\frac{|\underline{v}|^2}{2T} - \frac{5}{2}\right)\underline{v}\mathscr{M}_0 + O(\varepsilon_1^4) + O(\varepsilon_1^2\varepsilon_2) + O(\varepsilon_1\varepsilon_2^2).$$

We now study more precisely the linearized operator $\Gamma_{e,e}$. Moreover, we introduce $\widetilde{\Gamma}_{e,e}$, the linearized operator around $\mathscr{M}_0$:

$$\widetilde{\Gamma}_{e,e}(f) = 2\mathscr{M}_0 Q_{e,e}(\mathscr{M}_0, \mathscr{M}_0 f).$$

The operator $\widetilde{\Gamma}_{e,e}$ possesses the properties listed in Proposition 2. In the following, we use the notation $\langle f, g\rangle_0$ for the scalar product in the space $L^2(\mathscr{M}_0 d\underline{v})$.

We have the following two lemmas.

Lemma 4: There exist two functions $\underline{\Upsilon}_1$ *and* $\underline{\Upsilon}_2$ *such that* $M_{\varepsilon_1}^{-1}\underline{\Upsilon}_i$ *belongs to* $(\text{Ker}\ (\Gamma_{e,e}))^\perp$ *and*

$$\Gamma_{e,e}(M_{\varepsilon_1}^{-1}\underline{\Upsilon}_1) = -nM_{\varepsilon_1}^{-1}(Q_{\text{elas}}(\underline{v}\mathscr{M}_0) + \nu_1(T)\underline{v}\mathscr{M}_0), \tag{22}$$

$$\Gamma_{e,e}(M_{\varepsilon_1}^{-1}\underline{\Upsilon}_2) = -nM_{\varepsilon_1}^{-1}\left(\frac{|\underline{v}|^2}{2T} - \frac{5}{2}\right)\underline{v}\mathscr{M}_0. \tag{23}$$

Lemma 5: For the order one in ε_1, *the functions* $\underline{\Upsilon}_i$ *also satisfy*

$$\widetilde{\Gamma}_{e,e}(\mathscr{M}_0^{-1}\underline{\Upsilon}_1) = (B_{\text{elas}}^T(|\underline{v}|) - \nu_1(T))\underline{v}, \tag{24}$$

$$\widetilde{\Gamma}_{e,e}(\mathscr{M}_0^{-1}\underline{\Upsilon}_2) = -\left(\frac{|\underline{v}|^2}{2T} - \frac{5}{2}\right)\underline{v}. \tag{25}$$

Moreover, they have the following form:

$$\underline{\Upsilon}_1 = a(|\underline{v}|, T)\underline{v} + O(\varepsilon_1), \qquad \underline{\Upsilon}_2 = b(|\underline{v}|, T)\underline{v} + O(\varepsilon_1). \tag{26}$$

Before proving these lemmas, let us recall the four equalities

$$\int_{\mathbb{R}^3}\mathscr{M}_0\, d\underline{v} = 1, \quad \int_{\mathbb{R}^3}\underline{v}\otimes\underline{v}\mathscr{M}_0\, d\underline{v} = T\underline{\underline{\mathrm{I}}}_{\mathrm{d}},$$

$$\int_{\mathbb{R}^3}|\underline{v}|^2\underline{v}\otimes\underline{v}\mathscr{M}_0\, d\underline{v} = 5T^2\underline{\underline{\mathrm{I}}}_{\mathrm{d}}, \quad \int_{\mathbb{R}^3}|\underline{v}|^4\underline{v}\otimes\underline{v}\mathscr{M}_0\, d\underline{v} = 35T^3\underline{\underline{\mathrm{I}}}_{\mathrm{d}}. \tag{27}$$

Proof of Lemma 4: The proof is a direct application of Proposition 2. We have to prove that the right-hand sides of (22) and (23) belong to

$$(\mathrm{Ker}(\Gamma_{e,e}))^{\perp} \cap L^2(M_{\varepsilon_1} d\underline{v}).$$

The rhs of (22) and (23) belong obviously to $L^2(M_{\varepsilon_1} d\underline{v})$. Thus we only need the proof of the following points:

$$\int_{\mathbb{R}^3} (Q_{\mathrm{elas}}(\underline{v}.\mathscr{M}_0) + \nu_1(T)\underline{v}.\mathscr{M}_0)\, d\underline{v} = 0,$$

(i)

$$\int_{\mathbb{R}^3} \left(\frac{|\underline{v}|^2}{2T} - \frac{5}{2}\right) \underline{v}.\mathscr{M}_0\, d\underline{v} = 0,$$

$$\int_{\mathbb{R}^3} \underline{v} \otimes (Q_{\mathrm{elas}}(\underline{v}.\mathscr{M}_0) + \nu_1(T)\underline{v}.\mathscr{M}_0)\, d\underline{v} = 0,$$

(ii)

$$\int_{\mathbb{R}^3} \underline{v} \otimes \left(\frac{|\underline{v}|^2}{2T} - \frac{5}{2}\right) \underline{v}.\mathscr{M}_0\, d\underline{v} = 0,$$

$$\int_{\mathbb{R}^3} |\underline{v}|^2 (Q_{\mathrm{elas}}(\underline{v}.\mathscr{M}_0 + \nu_1(T)\underline{v}.\mathscr{M}_0)\, d\underline{v} = 0,$$

(iii)

$$\int_{\mathbb{R}^3} |\underline{v}|^2 \left(\frac{|\underline{v}|^2}{2T} - \frac{5}{2}\right) \underline{v}.\mathscr{M}_0\, d\underline{v} = 0.$$

The proofs of the points (i) and (iii) are straightforward because the arguments are odd. For the point (ii), thanks to equalities (27) and the definition of ν_1, we have

$$\int_{\mathbb{R}^3} \underline{v} \otimes Q_{\mathrm{elas}}(\underline{v}.\mathscr{M}_0) d\underline{v} + \nu_1(T) \int_{\mathbb{R}^3} \underline{v} \otimes \underline{v}.\mathscr{M}_0\, d\underline{v} = -T\nu_1(T)\underline{\underline{\mathrm{I}_d}} + \nu_1(T) T \underline{\underline{\mathrm{I}_d}} = 0,$$

and

$$\int_{\mathbb{R}^3} \left(\frac{|\underline{v}|^2}{2T} - \frac{5}{2}\right) \underline{v} \otimes \underline{v}.\mathscr{M}_0\, d\underline{v} = \frac{1}{2T} 5T^2 \underline{\underline{\mathrm{I}_d}} - \frac{5}{2} T \underline{\underline{\mathrm{I}_d}} = 0. \qquad \square$$

Proof of Lemma 5. First we have

$$\Gamma_{e,e}(f) = 2M_0^{-1} Q_{e,e}(M_0, M_0 f) = 2n.\mathscr{M}_0^{-1} Q_{e,e}(\mathscr{M}_0, \mathscr{M}_0 f) + O(\varepsilon_1) = n\widetilde{\Gamma}_{e,e}(f) + O(\varepsilon_1).$$

Moreover,

$$Q_{\mathrm{elas}}(\underline{v}.\mathscr{M}_0) = -B^T_{\mathrm{elas}}(|\underline{v}|)\underline{v}.\mathscr{M}_0.$$

By a simple computation we obtain Eqs. (24) and (25). They are well defined because their right-hand sides belong to $(\mathrm{Ker}\ (\widetilde{\Gamma}_{e,e}))^{\perp} \cap L^2(\mathscr{M}_0 d\underline{v})$.

The second part of the lemma is due to symmetry and rotational invariance properties of the linearized operator $\widetilde{\Gamma}_{e,e}$ (see refs. 8 and 16). $\square$

Finally, we have the following asymptotic expansion for f:

$$f = M_{\varepsilon_1} + \frac{\varepsilon_1\varepsilon_2}{T}\,\underline{u}.\underline{\Upsilon}_1 - \frac{\varepsilon_1\varepsilon_2}{T}\,\boldsymbol{\nabla}_x T.\underline{\Upsilon}_2 + O(\varepsilon_1^4) + O(\varepsilon_1^2\varepsilon_2) + O(\varepsilon_1\varepsilon_2^2)$$
$$= n.\mathscr{M}_0 + \varepsilon_1\,\frac{\underline{v}.\underline{u}}{T}\,n.\mathscr{M}_0 + \varepsilon_1^2\,\frac{1}{2}\left(\frac{(\underline{u}.\underline{v})^2}{T^2} - \frac{|\underline{u}|^2}{T}\right)n.\mathscr{M}_0 + \varepsilon_1^3\,\frac{1}{6}\,\underline{u}.\underline{v}\left(\frac{(\underline{u}.\underline{v})^2}{T^3} - 3\,\frac{|\underline{u}|^2}{T^2}\right)n.\mathscr{M}_0$$
$$+ \frac{\varepsilon_1\varepsilon_2}{T}\,\underline{u}.\underline{\Upsilon}_1 - \frac{\varepsilon_1\varepsilon_2}{T}\,\boldsymbol{\nabla}_x T.\underline{\Upsilon}_2 + O(\varepsilon_1^4) + O(\varepsilon_1^2\varepsilon_2) + O(\varepsilon_1\varepsilon_2^2). \tag{28}$$

Thus, we can now compute the approximation of the macroscopic quantities $\underline{\underline{p}}$, $\underline{r}$, and $\underline{q}$:

$$\underline{\underline{p}} = nT\underline{\underline{\mathrm{I}_d}} + O(\varepsilon_1\varepsilon_2) + O(\varepsilon_1^4), \tag{29}$$

$$\underline{r} = -\left(\nu_1(T) + \frac{\varepsilon_1}{\tau_{\mathrm{ine}}} + \varepsilon_1^2\nu_2(T,\underline{u}) + \frac{\varepsilon_2}{n}\,\nu_3(T)\right)n\underline{u} - \varepsilon_2\,\mathrm{div}(\nu_4(T)\underline{\underline{\mathrm{I}_d}}) + O(\varepsilon_1^3) + O(\varepsilon_1\varepsilon_2) + O(\varepsilon_2^2), \tag{30}$$

$$\underline{q} = \varepsilon_2\nu_5(T)\underline{u} - \varepsilon_2\nu_6(T)\boldsymbol{\nabla}_x T + O(\varepsilon_1^3) + O(\varepsilon_1\varepsilon_2) + O(\varepsilon_2^2), \tag{31}$$

with

$$\nu_2(T,\underline{u})\underline{\underline{\mathrm{I}_d}} = -\frac{1}{6T^3}\int_{\mathbb{R}^3}\underline{v}\otimes Q_{\mathrm{elas}}((\underline{u}.\underline{v})^2\underline{v}.\mathscr{M}_0)d\underline{v} + \frac{|\underline{u}|^2}{2T^2}\int_{\mathbb{R}^3}\underline{v}\otimes Q_{\mathrm{elas}}(\underline{v}.\mathscr{M}_0)d\underline{v}$$
$$= \frac{1}{6T^3}\int_{\mathbb{R}^3}B^T_{\mathrm{elas}}(|\underline{v}|)(\underline{u}.\underline{v})^2\,\frac{|\underline{v}|^2}{3}\,\mathscr{M}_0\,d\underline{v}\;\underline{\underline{\mathrm{I}_d}} - \frac{|\underline{u}|^2}{2T}\,\nu_1(T)\underline{\underline{\mathrm{I}_d}}, \tag{32}$$

$$\nu_3(T)\underline{\underline{\mathrm{I}_d}} = -\frac{1}{T}\int_{\mathbb{R}^3}\underline{v}\otimes Q_{\mathrm{elas}}(\underline{\Upsilon}_1)d\underline{v} = \frac{1}{T}\int_{\mathbb{R}^3}B^T_{\mathrm{elas}}(|\underline{v}|)\,\frac{|\underline{v}|^2}{3}\,a(|\underline{v}|,T)d\underline{v}\;\underline{\underline{\mathrm{I}_d}} + O(\varepsilon_1), \tag{33}$$

$$\partial_T\nu_4(T)\underline{\underline{\mathrm{I}_d}} = \frac{1}{T}\int_{\mathbb{R}^3}\underline{v}\otimes Q_{\mathrm{elas}}(\underline{\Upsilon}_2)d\underline{v} = -\frac{1}{T}\int_{\mathbb{R}^3}B^T_{\mathrm{elas}}(|\underline{v}|)\,\frac{|\underline{v}|^2}{3}\,b(|\underline{v}|,T)d\underline{v}\;\underline{\underline{\mathrm{I}_d}} + O(\varepsilon_1), \tag{34}$$

$$\nu_5(T)\underline{\underline{\mathrm{I}_d}} = \frac{1}{T}\int_{\mathbb{R}^3}\frac{|\underline{v}|^2}{2}\,\underline{v}\otimes\underline{\Upsilon}_1\,d\underline{v} = \frac{1}{T}\int_{\mathbb{R}^3}\frac{|\underline{v}|^4}{6}\,a(|\underline{v}|,T)d\underline{v}\;\underline{\underline{\mathrm{I}_d}} + O(\varepsilon_1), \tag{35}$$

$$\nu_6(T)\underline{\underline{\mathrm{I}_d}} = \frac{1}{T}\int_{\mathbb{R}^3}\frac{|\underline{v}|^2}{2}\,\underline{v}\otimes\underline{\Upsilon}_2\,d\underline{v} = \frac{1}{T}\int_{\mathbb{R}^3}\frac{|\underline{v}|^4}{6}\,b(|\underline{v}|,T)d\underline{v}\;\underline{\underline{\mathrm{I}_d}} + O(\varepsilon_1) = \kappa(T)\underline{\underline{\mathrm{I}_d}} + O(\varepsilon_1). \tag{36}$$

Therefore we rewrite the moments system in the following conservative form:

$$\partial_t n + \mathrm{div}(n\underline{u}) = 0, \tag{37}$$

$$\partial_t(\varepsilon_1^2 n\underline{u}) + \mathrm{div}(\varepsilon_1^2 n\underline{u}\otimes\underline{u} + nT\underline{\underline{\mathrm{I}_d}} + \varepsilon_2\nu_4(T)\underline{\underline{\mathrm{I}_d}}) - n\boldsymbol{\nabla}_x\Phi$$
$$+\left(\nu_1(T) + \frac{\varepsilon_1}{\tau_{\mathrm{ine}}} + \varepsilon_1^2\nu_2(T,\underline{u}) + \frac{\varepsilon_2}{n}\,\nu_3(T)\right)n\underline{u}$$
$$= O(\varepsilon_1^3) + O(\varepsilon_1\varepsilon_2) + O(\varepsilon_2^2), \tag{38}$$

$$\partial_t\Big(\tfrac{1}{2}\,n(\varepsilon_1^2|\underline{u}|^2+3T)\Big)+\mathrm{div}\Big(\tfrac{1}{2}\,n\underline{u}(\varepsilon_1^2|\underline{u}|^2+5T)+\varepsilon_2\nu_5(T)\underline{u}-\varepsilon_2\kappa(T)\nabla_x T\Big)$$

$$-n\underline{u}\nabla_x\Phi+n\,\frac{e-\frac{3}{2}T_0}{\tau_e}=O(\varepsilon_1^3)+O(\varepsilon_1\varepsilon_2)+O(\varepsilon_2^2). \tag{39}$$

IV. ENTROPY FUNCTION AND THE SYMMETRIZABLE SYSTEM

In this section we prove that the macroscopic entropy balance law (EL) gives a generalized entropy function of the hyperbolic–parabolic system (HD) in the sense of S. Kawashima and Y. Shizuta.[17] Moreover, using this entropy function, we derive a conservative symmetric form of the system.

Remark: At the kinetic level, the entropy is $H(f)=f\ln f$ (Theorems 1 and 3). We obtain equation (EL) by computing the asymptotic expansion of

$$\partial_t\int_{\mathbb{R}^3}H(f)\,d\underline{v}+\frac{1}{\varepsilon_1}\,\mathrm{div}_x\Big(\int_{\mathbb{R}^3}\underline{v}H(f)\,d\underline{v}\Big)+\frac{1}{\varepsilon_1}\int_{\mathbb{R}^3}\nabla_x\Phi.\nabla_v H(f)\,d\underline{v}$$
$$=\int_{\mathbb{R}^3}(1+\ln f)\Big(\frac{1}{\varepsilon_1^2}\Big(\frac{1}{\varepsilon_2}\,Q_{e,e}(f)+Q_{\mathrm{elas}}(f)\Big)-Q_{\mathrm{ine}}(f)\Big)d\underline{v}. \tag{40}$$

This computation is presented in Appendix A.

The relation between the conservative symmetric formulation and the entropy function was first studied for hyperbolic systems of the form

$$\partial_t\underline{w}+\sum_{j=1}^{n}\partial_j\underline{g}^j(\underline{w})=0, \tag{41}$$

where $\underline{g}^j$, $j=1,...,n$, and $\underline{w}$ denote m-dimensional vectors, with $\underline{g}^j$ smooth functions of $\underline{w}$. It was shown that the existence of an entropy function for (41) is characterized by the property that (41) can be symmetrized by introducing a new dependent variable (see Refs. 18–21).

These results were generalized by S. Kawashima and Y. Shizuta[17] to the case of second-order quasilinear systems of the form

$$\partial_t\underline{w}+\sum_{j=1}^{n}\partial_j\underline{g}^j(\underline{w})=\sum_{i,j=1}^{n}\partial_i(\underline{\underline{G}}^{i,j}(\underline{w})\partial_j\underline{w})+\underline{S}(\underline{w}), \tag{42}$$

where $\underline{\underline{G}}^{ij}(\underline{w}),i,j=1,...,n$, denote $m\times m$ matrices depending smoothly on $\underline{w}$. Both $\underline{g}^j(\underline{w})$ and $\underline{\underline{G}}^{ij}(\underline{w})$ are defined on an open set $\mathcal{O}\subset\mathbb{R}$.

The following definition of an entropy function was given by Kawashima.[17,22]

Definition 6: Let $\eta=\eta(\underline{w})$ be a real-valued smooth function defined on a convex open set $\mathcal{O}_w\subset\mathcal{O}$. Then η is called an entropy function for (42), if the following properties hold:

(i) *The function η is a strictly convex function on $\mathcal{O}_{\underline{w}}$ in the sense that the Hessian matrix is positive definite on $\mathcal{O}_{\underline{w}}$.*

(ii) *There exist real-valued smooth functions $\sigma^j=\sigma^j(\underline{w})$, $j=1,...,n$, such that*

$$\partial_{\underline{w}}\eta\partial_{\underline{w}}g^j=\partial_{\underline{w}}\sigma^j,\quad j=1,...,n,$$

for $\underline{w}\in\mathcal{O}_w$. These functions are called the entropy fluxes.

(iii) *We have the property*

$$(\partial_{\underline{w}}^2\eta)^{-1}\,{}^t\underline{\underline{G}}^{i,j}=\underline{\underline{G}}^{j,i}(\partial_{\underline{w}}^2\eta)^{-1},$$

for $\underline{w}\in\mathcal{O}_{\underline{w}}$.

(iv) *The matrix $\Sigma_{i,j=1}^{n}\underline{\underline{G}}^{i,j}(\underline{w})(\partial_{\underline{w}}^2\eta)^{-1}\boldsymbol{\omega}_i\boldsymbol{\omega}_j$ is symmetric and positive semi-definite for $\underline{w}\in\mathcal{O}_w$ and $\boldsymbol{\omega}\in\mathcal{S}^{n-1}$.*

In order to define the symmetric form of system (42), we introduce a new dependent variable $\underline{\psi}$ instead of $\underline{w}$. It is assumed that there is a diffeomorphism from $\mathcal{O}_{\underline{\psi}}$ onto $\mathcal{O}_{\underline{w}}$. We denote $\underline{\psi} = \underline{\psi}(\underline{w})$. Then (42) assumes the following form:

$$\underline{\underline{A}}^{(0)}(\underline{\psi})\partial_t\underline{\psi} + \sum_{j=1}^{n} \underline{\underline{A}}^{ij}(\underline{\psi})\partial_j\underline{\psi} = \sum_{i,j=1}^{n} \partial_i(\underline{\underline{B}}^{i,j}(\underline{\psi})\partial_j\underline{\psi}) + \underline{\tilde{S}}(\underline{\psi}), \tag{43}$$

with

$$\underline{\underline{A}}^{0}(\underline{\psi}) = \partial_{\underline{\psi}}\underline{w}(\underline{\psi}), \qquad \underline{\underline{A}}^{j}(\underline{\psi}) = \partial_{\underline{\psi}} g^j(\underline{w}(\underline{\psi})) = (\partial_{\underline{w}} f^j)(\underline{w}(\underline{\psi}))\underline{\underline{A}}^{0}(\underline{\psi}),$$

$$\underline{\underline{B}}^{i,j}(\underline{\psi}) = \underline{\underline{G}}^{i,j}(\underline{w}(\underline{\psi}))\underline{\underline{A}}^{0}(\underline{\psi}).$$

The following definition of a symmetric form is due to Ref. 17.

Definition 7: The system (43) is said to be of the symmetric form if the coefficient matrices satisfy the following properties:

(i) *The matrix $\underline{\underline{A}}^{0}(\underline{\psi})$ is symmetric and positive definite for $\underline{\psi} \in \mathcal{O}_{\underline{\psi}}$.*
(ii) *The matrices $\underline{\underline{A}}^{j}(\underline{\psi}), j = 1,...,n$, are symmetric for $\underline{\psi} \in \mathcal{O}_{\underline{\psi}}$.*
(iii) *We have ${}^t(\underline{\underline{B}}^{i,j}(\underline{\psi})) = \underline{\underline{B}}^{j,i}(\underline{\psi}), i,j = 1,...,n$, for $\underline{\psi} \in \mathcal{O}_{\underline{\psi}}$.*
(iv) *The matrix $\Sigma_{i,j=1}^{n} \underline{\underline{B}}^{i,j}(\underline{\psi})\boldsymbol{\omega}_i\boldsymbol{\omega}_j$ is symmetric and positive semi-definite, for $\underline{w} \in \mathcal{O}_{\underline{w}}$ and $\underline{\omega} \in \mathcal{S}^{n-1}$.*

S. Kawashima and Y. Shizuta established the following theorem.

Theorem 8: *For the second-order quasi-linear system (42) the two following properties are equivalent:*

(i) *The system (42) has an entropy function η defined on a convex open set $\mathcal{O}_{\underline{w}} \subset \mathcal{O}$.*
(ii) *The system (42) can be symmetrized, using the symmetrizing variable $\underline{\psi}$, on a convex open set $\mathcal{O}_{\underline{w}} \subset \mathcal{O}$.*

Moreover, the symmetrizing variable $\underline{\psi}$ can be expressed in terms of the gradient of the entropy function η as

$$\underline{\psi} = {}^t(\partial_{\underline{w}}\eta). \tag{44}$$

We now consider the system (HD) and apply the previous results. It can be written in the following form:

$$\partial_t\underline{w} + \sum_{j=1}^{n} \partial_j\underline{g}^j(\underline{w}) = \sum_{j=1}^{n} \partial_j(\underline{\underline{G}}^{i,j}(\underline{w})\partial_j\underline{w}) + \underline{S}(\underline{w}), \tag{45}$$

with

$$\underline{w} = \begin{pmatrix} n \\ \varepsilon_1^2 n u_1 \\ \varepsilon_1^2 n u_2 \\ \varepsilon_1^2 n u_3 \\ \frac{1}{2} n(\varepsilon_1^2 |\underline{u}|^2 + 3T) \end{pmatrix},$$

$$\underline{g}^j = \begin{pmatrix} n u_j \\ \varepsilon_1^2 n u_1 u_j + nT\delta_{1,j} + \varepsilon_2 \nu_4(T)\delta_{1,j} \\ \varepsilon_1^2 n u_2 u_j + nT\delta_{2,j} + \varepsilon_2 \nu_4(T)\delta_{2,j} \\ \varepsilon_1^2 n u_3 u_j + nT\delta_{3,j} + \varepsilon_2 \nu_4(T)\delta_{3,j} \\ \frac{1}{2} n u_j(\varepsilon_1^2 |\underline{u}|^2 + 5T) + \varepsilon_2 \nu_5(T) u_j \end{pmatrix},$$

$$\underline{\underline{G}}^{i,j}=\underline{\underline{G}}\,\delta_{i,j},$$

$$\underline{\underline{G}}=\begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ -\dfrac{\kappa(T)T}{n}+\varepsilon_1^2\dfrac{1}{3}\dfrac{\kappa(T)}{n}|\underline{u}|^2 & -\dfrac{2}{3}\dfrac{\kappa(T)}{n}u_1 & -\dfrac{2}{3}\dfrac{\kappa(T)}{n}u_2 & -\dfrac{2}{3}\dfrac{\kappa(T)}{n}u_3 & \dfrac{2}{3}\dfrac{\kappa(T)}{n} \end{pmatrix},$$

$$\underline{S}=\begin{pmatrix} 0 \\ n\partial_{x_1}\Phi-\left(\nu_1(T)+\dfrac{\varepsilon_1}{\tau_{\text{ine}}}+\varepsilon_1^2\nu_2(T,\underline{4})+\dfrac{\varepsilon_2}{n}\nu_3(T)\right)nu_1 \\ n\partial_{x_2}\Phi-\left(\nu_1(T)+\dfrac{\varepsilon_1}{\tau_{\text{ine}}}+\varepsilon_1^2\nu_2(T,\underline{u})+\dfrac{\varepsilon_2}{n}\nu_3(T)\right)nu_2 \\ n\partial_{x_3}\Phi-\left(\nu_1(T)+\dfrac{\varepsilon_1}{\tau_{\text{ine}}}+\varepsilon_1^2\nu_2(T,\underline{u})+\dfrac{\varepsilon_2}{n}\nu_3(T)\right)nu_3 \end{pmatrix}.$$

Hence we have the following.

Theorem 9: (i) *The hydrodynamical system (45) has an entropy function*

$$\eta=n\,\ln\left(\frac{n}{(2\pi T)^{3/2}}\right)-\frac{5}{2}\,n. \tag{46}$$

(ii) *The associated entropy fluxes are*

$$\sigma^j=nu_j\,\ln\left(\frac{n}{(2\pi T)^{3/2}}\right)-\frac{5}{2}\,nu_j-\frac{\varepsilon_2}{T}\,\nu_5(T)u_j,\quad j=1,\ldots,n. \tag{47}$$

(iii) *The system (45) can be symmetrized using the following symmetrizing variables:*

$$\underline{\psi}=\begin{pmatrix} \ln\left(\dfrac{n}{(2\pi T)^{3/2}}\right)-\varepsilon_1^2\dfrac{|\underline{u}|^2}{2T} \\ \dfrac{u_1}{T} \\ \dfrac{u_2}{T} \\ \dfrac{u_3}{T} \\ -\dfrac{1}{T} \end{pmatrix}. \tag{48}$$

Remark: One can obtain the entropy balance law (EL) by multiplying each term of (HD) by $\underline{\psi}$ and then adding the results.

Before giving the proof of the theorem, we need the following lemma.

Lemma 10: (i) $\nu_5(T)=T\partial_T\nu_4(T)+O(\varepsilon_1)$ and (ii) $\kappa(T)>0$ *for all* $T>0$.

The proof of this lemma is given in Appendix B.

Proof of Theorem 9: We will prove points (i) and (ii). Point (iii) is a simple consequence of Theorem 8.

The strict convexity of η is a classical result of the Euler or Navier–Stokes equations theory.[17,23] Indeed we have exactly the same entropy function.

Let us write $\underline{g}^j$ in two parts:

$$\underline{g}^j=\underline{g}_a^j+\varepsilon_2\underline{g}_b^j=\begin{pmatrix} nu_j \\ \varepsilon_1^2 nu_1u_j+nT\delta_{1,j} \\ \varepsilon_1^2 nu_2u_j+nT\delta_{2,j} \\ \varepsilon_1^2 nu_3u_j+nT\delta_{3,j} \\ \frac{1}{2}nu_j(\varepsilon_1^2|\underline{u}|^2+5T) \end{pmatrix}+\varepsilon_2\begin{pmatrix} 0 \\ \nu_4(T)\delta_{1,j} \\ \nu_4(T)\delta_{2,j} \\ \nu_4(T)\delta_{3,j} \\ \nu_5(T)u_j \end{pmatrix}.$$

For one part, we know that (Euler entropy function)

$$\partial_{\underline{w}}\eta\partial_{\underline{w}}\underline{g}_a^j=\partial_{\underline{w}}\left(nu_j\ \ln\left(\frac{n}{(2\pi T)^{3/2}}\right)-\frac{5}{2}\,nu_j\right).$$

For the other part, we have for all $l=1,\ldots,5$,

$$\begin{aligned}\partial_{w_l}\left(-\frac{1}{T}\,\nu_5(T)u_j\right)&=\nu_5(T)u_j\partial_{w_l}\left(-\frac{1}{T}\right)-\frac{1}{T}\,\partial_{w_l}(\nu_5(T)u_j)\\&=T\partial_T\nu_4(T)u_j\,\frac{1}{T^2}\,\partial_{w_l}T-\frac{1}{T}\,\partial_{w_l}(\nu_5(T)u_j)\\&=\frac{u_j}{T}\,\partial_{w_l}(\nu_4(T))-\frac{1}{T}\,\partial_{w_l}(\nu_5(T)u_j)\\&=\sum_{i=1}^{3}\frac{u_i}{T}\,\partial_{w_l}(\nu_4(T)\delta_{i,j})-\frac{1}{T}\,\partial_{w_l}(\nu_5(T)u_j)\\&=\partial_{\underline{w}}\eta\partial_{w_l}\underline{g}_b^j,\end{aligned}$$

which gives

$$\partial_{\underline{w}}\left(-\frac{1}{T}\,\nu_5(T)u_j\right)=\partial_{\underline{w}}\eta\partial_{\underline{w}}\underline{g}_b^j.$$

This ends the proof of points (i) and (ii) of the entropy definition 6. In our case, in order to obtain points (iii) and (iv), we only need to prove that the matrix

$$\partial_{\underline{w}}^2\eta\underline{\underline{G}}$$

is symmetric and positive semi-definite. With straightforward computations we obtain the symmetry of the matrix and that the positivity condition is only linked to the sign of κ. Finally, thanks to Lemma 10, we know that κ is positive. □

V. LINKS WITH OTHER SEMICONDUCTOR MODELS

In this part, we describe the relations between our model and others semiconductor models.

A. A generalized hydrodynamical model

First of all, the complete model appears like a generalization of the classical hydrodynamical model.[1,2] Indeed, we have two additional terms: a ''thermal friction force'' and a ''friction heat flux.''

More precisely, the friction force $\underline{r}$ is the sum of two contributions [see Eq. (30)]. The first one expresses the momentum relaxation with the relaxation time τ_m given by

$$\tau_m=\frac{n}{n\nu_1(T)+\varepsilon_1 n/\tau_{\text{ine}}+\varepsilon_1^2 n\nu_2(T,\underline{u})+\varepsilon_2\nu_3(T)}.$$

The second contribution is proportional to the gradient of the electron temperature:

$$\mathrm{div}(\varepsilon_2 \nu_4(T) \underline{\underline{\mathrm{I_d}}}) = \varepsilon_2 \frac{\nu_5(T)}{T} \nabla_x T.$$

This last expression is absent from the classical hydrodynamical semiconductor models. Let us call it the ''thermal friction force.''

In the same way, the heat flux $\underline{q}$ [see Eq. (31)] is the sum of a thermal heat flux associated with the heat conductivity coefficient κ and a term proportional to the velocity $\underline{u}$:

$$\varepsilon_2 \nu_5(T) \underline{u}.$$

This term, called the ''friction heat flux,'' is also new in the field of hydrodynamical models for semiconductors.

On the other hand, these two terms appear in the energy transport models.[5,9] They are linked with the Peltier and Soret effects.

Finally, let us remark that if we neglect the ε_2 terms, we obtain a hydrodynamical model without heat flux term. In fact we get a Euler–Poisson system (see Refs. 24 and 25 and the references therein).

B. Reduction to an energy-transport model

If we neglect the ε_1 terms, we obtain an energy-transport model:[3–5]

$$\partial_t n - \mathrm{div}\ \underline{J}_n = 0, \qquad \partial_t \frac{3}{2} nT + \mathrm{div}\ \underline{S} + \underline{J}_n . \nabla_x \Phi = \frac{3}{2} n \frac{T - T_0}{\tau_e}, \tag{49}$$

where the electron current density $\underline{J}_n$ and the thermal energy flow density are defined by

$$\begin{aligned} \underline{J}_n &= \mu(n,T)\left(\nabla_x nT + \frac{\varepsilon_2}{T} \nu_5(T) \nabla_x T - n \nabla_x \Phi \right), \\ \underline{S} &= -\left(\frac{5}{2} T + \frac{\varepsilon_2}{n} \nu_5(T) \right) \underline{J}_n - \varepsilon_2 \kappa(T) \nabla_x T, \end{aligned} \tag{50}$$

and $\mu(n,T)$, the electronic mobility, is defined by

$$\mu(n,T) = \frac{n}{n \nu_1(T) + \varepsilon_2 \nu_3(T)}.$$

Remark: We assume that, for ε_2 small enough, we have

$$\nu_1(T) + \frac{\varepsilon_2}{n} \nu_3(T) > 0 \quad \text{for all} \quad T > 0.$$

We will now study the entropy function and the symmetric form of this model.

First of all, we write the system in a conservative form by introducing a new flux variable $\underline{J}_T$ (we suppose that the electrostatic potential does not depend on time). Then we have

$$\partial_t n - \mathrm{div}\ \underline{J}_n = 0, \qquad \partial_t \left(\frac{3}{2} nT - n\Phi \right) - \mathrm{div}\ \underline{J}_T = \frac{3}{2} n \frac{T - T_0}{\tau_e}, \tag{51}$$

with

$$\underline{J}_T = -\underline{S} - \Phi \underline{J}_n .$$

In order to obtain a symmetric formulation, let us introduce the electron quasi-Fermi level φ_n defined, in the nondegenerate case, by a Boltzmann statistic

$$n=(2\pi T)^{3/2}\exp\left(\frac{\varphi_n+\Phi}{T}\right). \tag{52}$$

Then, the fluxes $\underline{J}_n$ and $\underline{J}_T$ have the following form:

$$\underline{J}_n=d_{1,1}\nabla_x\left(\frac{\varphi_n}{T}\right)+d_{1,2}\nabla_x\left(\frac{-1}{T}\right),\qquad \underline{J}_T=d_{2,1}\nabla_x\left(\frac{\varphi_n}{T}\right)+d_{2,2}\nabla_x\left(\frac{-1}{T}\right), \tag{53}$$

with

$$d_{1,1}=\mu nT,$$

$$d_{1,2}=d_{2,1}=\mu nT\left(\frac{5}{2}\,T+\frac{\varepsilon_2}{n}\,\nu_5(T)-\Phi\right), \tag{54}$$

$$d_{2,2}=\mu nT\left(\frac{5}{2}\,T+\frac{\varepsilon_2}{n}\,\nu_5(T)-\Phi\right)^2+\varepsilon_2 T^2\kappa(T).$$

The matrix $d_{i,j}$ is obviously symmetric positive definite. Hence we have proved the existence of a symmetric form and therefore of an entropy function (by using Kawashima and Shizuta's theorem). Let us remark that it is exactly the same entropy function as in the hydrodynamical case.

To sum up let us say that we obtain, by neglecting the ε_1 terms, an energy-transport model which can be expressed in a conservative form with the following variables:

$$\underline{w}_{\mathrm{ET}}=\begin{pmatrix} n \\ \frac{3}{2}nT-n\Phi \end{pmatrix}.$$

This model has the same entropy function as the hydrodynamical one:

$$\eta=n\,\ln\left(\frac{n}{(2\pi T)^{3/2}}\right)-\frac{5}{2}\,n.$$

With this entropy function, we obtain the following symmetric variables:

$$\underline{\psi}_{\mathrm{ET}}=\partial_{\underline{w}_{\mathrm{ET}}}\eta=\begin{pmatrix} \ln\left(\frac{n}{(2\pi T)^{3/2}}\right)-\frac{\Phi}{T} \\ -\frac{1}{T} \end{pmatrix}.$$

Moreover,we can also obtain a drift-diffusion model[26–28] by neglecting both the ε_1 and the ε_2 terms and putting an infinitely small energy relaxation time. This limit is well established in a paper by Marcati and Natalini.[29,30]

VI. CONCLUSION

In this work, we derive a generalized hydrodynamical model which gives a unified vision of the classical hydrodynamical model and the energy-transport model. We also introduce a unique entropy function for the different levels of modelization. Let us notice that this entropy function is very useful for existence and unicity results. Moreover, we also derive from this entropy function a set of symmetric variables thanks to a theorem by Kawashima and Shizuta.[17] These variables, called the entropy variables, are attractive from a numerical point of view.

The main extension of this work could be to obtain an explicit formulation of the model by computing the integral terms. In this way we would be able to make numerical comparisons with the other existing semiconductor models.

ACKNOWLEDGMENTS

The author wishes to thank B. Perthame of the LAN, UMPC, Paris for fruitful discussions and J. F. Palmier of France-Telecom/CNET for his advice and financial support.

APPENDIX A: DERIVATION OF THE ENTROPY BALANCE LAW FROM THE KINETIC ENTROPY

In this Appendix, we compute the asymptotic expansion of the equation (40) in order to obtain the entropy balance law (EL). This gives another motivation for the entropy function.

From the equation (28), we can write

$$\ln f = \ln M_{\varepsilon_1} + \frac{\varepsilon_1\varepsilon_2}{T}\,\mathscr{M}_0^{-1}\underline{u}.\underline{\Upsilon}_1 - \frac{\varepsilon_1\varepsilon_2}{T}\,\mathscr{M}_0^{-1}\nabla_x T.\underline{\Upsilon}_2 + O(\varepsilon_1^4) + O(\varepsilon_1^2\varepsilon_2) + O(\varepsilon_1\varepsilon_2^2)$$

$$= \underline{\psi}..\underline{\mathscr{K}}(\underline{v}) + \frac{\varepsilon_1\varepsilon_2}{T}\,\mathscr{M}_0^{-1}\underline{u}.\underline{\Upsilon}_1 - \frac{\varepsilon_1\varepsilon_2}{T}\,\mathscr{M}_0^{-1}\nabla_x T.\underline{\Upsilon}_2 + O(\varepsilon_1^4) + O(\varepsilon_1^2\varepsilon_2) + O(\varepsilon_1\varepsilon_2^2),$$

with

$$\underline{\psi} = \begin{pmatrix} \ln\left(\dfrac{n}{(2\pi T)^{3/2}}\right) - \varepsilon_1^2\,\dfrac{|\underline{u}|^2}{2T} \\ \dfrac{u_1}{T} \\ \dfrac{u_2}{T} \\ \dfrac{u_3}{T} \\ -\dfrac{1}{T} \end{pmatrix},$$

$$\underline{\mathscr{K}}(\underline{v}) = \begin{pmatrix} 1 \\ \varepsilon_1\underline{v} \\ \dfrac{|\underline{v}|^2}{2} \end{pmatrix}.$$

Now, we will compute successively each term of (40). First, for the $\partial_t f$ term we obtain

$$\partial_t \int_{\mathbb{R}^3} H(f)\,d\underline{v} = \partial_t \int_{\mathbb{R}^3} \underline{\psi}..\underline{\mathscr{K}}(\underline{v}) M_{\varepsilon_1}\,d\underline{v} + O(\varepsilon_1^4) + O(\varepsilon_1\varepsilon_2)$$

$$= \partial_t\left(n\,\ln\left(\frac{n}{(2\pi T)^{3/2}}\right) - \frac{3}{2}\,n\right) + O(\varepsilon_1^4) + O(\varepsilon_1\varepsilon_2).$$

For the $\underline{v}.\nabla_x f$ term, we have

$$\operatorname{div}\left(\frac{1}{\varepsilon_1}\int_{\mathbb{R}^3}\underline{v}H(f)\,d\underline{v}\right) = \operatorname{div}\left(\frac{1}{\varepsilon_1}\int_{\mathbb{R}^3}\underline{v}\,\underline{\psi}..\underline{\mathscr{K}}(\underline{v}) f\,d\underline{v}\right) + \operatorname{div}\left(\frac{\varepsilon_2}{T}\int_{\mathbb{R}^3}\mathscr{M}_0^{-1}\underline{v}(\underline{u}.\underline{\Upsilon}_1 - \nabla_x T.\underline{\Upsilon}_2) f\,d\underline{v}\right) + O(\varepsilon_1^3) + O(\varepsilon_1\varepsilon_2) + O(\varepsilon_2^2)$$

$$= \operatorname{div}\left(n\underline{u}\,\ln\left(\frac{n}{(2\pi T)^{3/2}}\right) - \frac{3}{2}\,n\underline{u} - \frac{\varepsilon_2}{T}\,\nu_5(T)\underline{u} + \varepsilon_2\,\frac{\kappa(T)}{T}\,\nabla_x T\right) + O(\varepsilon_1^3) + O(\varepsilon_1\varepsilon_2) + O(\varepsilon_2^2).$$

For the $\nabla_x\Phi.\boldsymbol{\nabla}_v f$ term, we have simply

$$\frac{1}{\varepsilon_1}\int_{\mathbb{R}^3}\boldsymbol{\nabla}_x\Phi.\boldsymbol{\nabla}_v H(f\,)d\underline{v}=0.$$

For the $Q_{e,e}(f,f\,)$ term, we compute

$$\frac{1}{\varepsilon_1^2\varepsilon_2}\int_{\mathbb{R}^3}(1+\ln f\,)Q_{e,e}(f,f\,)d\underline{v}$$

$$=\frac{\varepsilon_2}{T^2}\int_{\mathbb{R}^3}\mathscr{M}_0{}^{-1}(\underline{u}.\underline{\Upsilon}_1-\boldsymbol{\nabla}_x T.\underline{\Upsilon}_2).\mathscr{M}_0\widetilde{\Gamma}_{e,e}\mathscr{M}_0^{-1}(\underline{u}.\underline{\Upsilon}_1-\boldsymbol{\nabla}_x.\underline{\Upsilon}_2)d\underline{v}$$
$$+O(\varepsilon_1^3)+O(\varepsilon_1\varepsilon_2)+O(\varepsilon_2^2)$$

$$=\frac{\varepsilon_2}{T^2}\left(\langle\mathscr{M}_0^{-1}\underline{u}.\underline{\Upsilon}_1,\widetilde{\Gamma}_{e,e}(\mathscr{M}_0^{-1}\underline{u}.\underline{\Upsilon}_1)\rangle_0+\langle\mathscr{M}_0^{-1}\boldsymbol{\nabla}_x T.\underline{\Upsilon}_2,\widetilde{\Gamma}_{e,e}(\mathscr{M}_0^{-1}\boldsymbol{\nabla}_x T.\underline{\Upsilon}_2)\rangle_0\right.$$
$$\left.-2\langle\mathscr{M}_0^{-1}\underline{u}.\underline{\Upsilon}_1,\widetilde{\Gamma}_{e,e}(\mathscr{M}_0^{-1}\boldsymbol{\nabla}_x T.\underline{\Upsilon}_2)\rangle_0\right)+O(\varepsilon_1^3)+O(\varepsilon_1\varepsilon_2)+O(\varepsilon_2^2).$$

For the $Q_{\text{elas}}(f\,)$ term we use Lemma 10 and we obtain

$$\frac{1}{\varepsilon_1^2}\int_{\mathbb{R}^3}(1+\ln f\,)Q_{\text{elas}}(f\,)d\underline{v}$$
$$=\frac{1}{\varepsilon_1^2}\int_{\mathbb{R}^3}\left(\underline{\psi}.\underline{\mathscr{K}}(\underline{v})+\frac{\varepsilon_1\varepsilon_2}{T}\mathscr{M}_0^{-1}(\underline{u}.\underline{\Upsilon}_1-\boldsymbol{\nabla}_x T.\underline{\Upsilon}_2)+O(\varepsilon_1^4)+O(\varepsilon_1^2\varepsilon_2)+O(\varepsilon_1\varepsilon_2^2)\right)$$

$Q_{\text{elas}}(f\,)d\underline{v}$

$$=-\frac{n}{T}\left(\nu_1(T)+\varepsilon_1^2\nu_2(T,\underline{u})+\frac{\varepsilon_2}{n}\,\nu_3(T)\right)|\underline{u}|^2$$
$$-\frac{\varepsilon_2}{T}\,\underline{u}.\,\operatorname{div}(\nu_4(T)\underline{\underline{\mathrm{I}_d}})+\frac{\varepsilon_2}{T^2}\int_{\mathbb{R}^3}\mathscr{M}_0^{-1}(\underline{u}.\underline{\Upsilon}_1-\boldsymbol{\nabla}_x T.\underline{\Upsilon}_2)n\underline{u}.Q_{\text{elas}}(\underline{v}.\mathscr{M}_0)d\underline{v}+O(\varepsilon_1^3)$$
$$+O(\varepsilon_1\varepsilon_2)+O(\varepsilon_2^2)$$
$$=-\frac{n}{T}\left(\nu_1(T)+\varepsilon_1^2\nu_2(T,\underline{u})+\frac{\varepsilon_2}{n}\,\nu_3(T)\right)|\underline{u}|^2-\frac{\varepsilon_2}{T^2}\,\nu_5(T)\underline{u}.\boldsymbol{\nabla}_x T$$
$$-\frac{\varepsilon_2}{T^2}\left(\langle\mathscr{M}_0^{-1}\underline{u}.\underline{\Upsilon}_1,\widetilde{\Gamma}_{e,e}(\mathscr{M}_0^{-1}\underline{u}.\underline{\Upsilon}_1)\rangle_0-\langle\mathscr{M}_0^{-1}\underline{u}.\underline{\Upsilon}_1,\widetilde{\Gamma}_{e,e}(\mathscr{M}_0^{-1}\boldsymbol{\nabla}_x T.\underline{\Upsilon}_2)\rangle_0\right)+O(\varepsilon_1^3)$$
$$+O(\varepsilon_1\varepsilon_2)+O(\varepsilon_2^2).$$

Finally, for the $Q_{\text{ine}}(f\,)$ term, we have

$$\int_{\mathbb{R}^3}(1+\ln f\,)Q_{\text{ine}}(f\,)d\underline{v}=\int_{\mathbb{R}^3}\underline{\psi}.\underline{\mathscr{K}}(\underline{v})Q_{\text{ine}}(f\,)d\underline{v}+O(\varepsilon_1^4)+O(\varepsilon_1\varepsilon_2)$$
$$=-\frac{n}{T}\,\frac{e-\frac{3}{2}T_0}{\tau_e}+O(\varepsilon_1^4)+O(\varepsilon_1\varepsilon_2).$$

Moreover, we have the following equalities:

$$\langle \mathscr{M}_0^{-1}\nabla_x T.\underline{\Upsilon}_2, \widetilde{\Gamma}_{e,e}(\mathscr{M}_0^{-1}\nabla_x T.\underline{\Upsilon}_2)\rangle_0 = -\int_{\mathbb{R}^3} \nabla_x T.\underline{\Upsilon}_2 \nabla_x T\cdot\left(\frac{|\underline{v}|^2}{2T}-\frac{5}{2}\right)\underline{v}\ d\underline{v}$$

$$= -{}^t\nabla_x T\left(\frac{1}{T}\int_{\mathbb{R}^3}\frac{|\underline{v}|^2}{2}\Upsilon_2\otimes\underline{v}\,d\underline{v}\right)\nabla_x T = -\kappa(T)|\nabla_x T|^2,$$

$$\langle \mathscr{M}_0^{-1}\underline{u}.\underline{\Upsilon}_1, \widetilde{\Gamma}_{e,e}(\mathscr{M}_0^{-1}\nabla_x T.\underline{\Upsilon}_2)\rangle = -\int_{\mathbb{R}^3}\underline{u}.\underline{\Upsilon}_1\nabla_x T.\left(\frac{|\underline{v}|^2}{2T}-\frac{5}{2}\right)\underline{v}\ d\underline{v}$$

$$= -{}^t\underline{u}\left(\frac{1}{T}\int_{\mathbb{R}^3}\frac{|\underline{v}|^2}{2}\Upsilon_1\otimes\underline{v}\,d\underline{v}\right)\nabla_x T$$

$$= -\nu_5(T)\underline{u}.\nabla_x T.$$

With these two last equalities and Eq. (13) we obtain the balance entropy law (EL).

APPENDIX B: PROOF OF LEMMA 10

By using the fact that $M_{\varepsilon_1}^{-1}\overline{\Upsilon}_i \in (\mathrm{Ker}(\Gamma_{e,e}))^{\perp}$, let us first recall that

$$\int_{\mathbb{R}^3}\underline{v}\otimes\underline{\Upsilon}_i\ d\underline{v}=0.$$

Hence, we have on one hand

$$\partial_T\nu_4(T)\underline{\underline{\mathrm{I}_d}} = \frac{1}{T}\int_{\mathbb{R}^3}\underline{v}\otimes Q_{\mathrm{elas}}(\underline{\Upsilon}_2)d\underline{v}$$

$$= -\frac{1}{T}\int_{\mathbb{R}^3}\mathscr{M}_0(B^T_{\mathrm{elas}}(|\underline{v}|)-\nu_1(T))\underline{v}\otimes\mathscr{M}_0^{-1}\underline{\Upsilon}_2\ d\underline{v}$$

$$= -\frac{1}{T}\int_{\mathbb{R}^3}\mathscr{M}_0\widetilde{\Gamma}_{e,e}(\mathscr{M}_0^{-1}\underline{\Upsilon}_1)\otimes\mathscr{M}_0^{-1}\underline{\Upsilon}_2 t d\underline{v}+O(\varepsilon_1)$$

$$= -\frac{1}{T}\langle\widetilde{\Gamma}_{e,e}(\mathscr{M}_0^{-1}a(|\underline{v}|,T)\underline{v}),\mathscr{M}_0^{-1}b(|\underline{v}|,T)\underline{v}\rangle_0\underline{\underline{\mathrm{I}_d}}+O(\varepsilon_1)$$

$$= -\frac{1}{T}\langle\mathscr{M}_0^{-1}a(|\underline{v}|,T)\underline{v},\widetilde{\Gamma}_{e,e}(\mathscr{M}_0^{-1}b(|\underline{v}|,T)\underline{v})\rangle_0\underline{\underline{\mathrm{I}_d}}+O(\varepsilon_1)$$

$$= -\frac{1}{T}\int_{\mathbb{R}^3}\underline{\Upsilon}_1\otimes\widetilde{\Gamma}_{e,e}(\mathscr{M}_0^{-1}\underline{\Upsilon}_2)d\underline{v}+O(\varepsilon_1)$$

$$= +\frac{1}{T}\int_{\mathbb{R}^3}\underline{\Upsilon}_1\otimes\underline{v}\left(\frac{|\underline{v}|^2}{2T}-\frac{5}{2}\right)d\underline{v}+O(\varepsilon_1)=\frac{1}{T}\nu_5(T)\underline{\underline{\mathrm{I}_d}}+O(\varepsilon_1),$$

and on the other hand

$$\kappa(T)\underline{\underline{\mathrm{I}_d}} = \int_{\mathbb{R}^3}\frac{|v|^2}{2T}\underline{v}\otimes\underline{\Upsilon}_2\ d\underline{v}=\int_{\mathbb{R}^3}\left(\frac{|v|^2}{2T}-\frac{5}{2}\right)\underline{v}\otimes\underline{\Upsilon}_2\ d\underline{v}=-\int_{\mathbb{R}^3}\widetilde{\Gamma}_{e,e}(\mathscr{M}_0^{-1}\underline{\Upsilon}_2)\otimes\underline{\Upsilon}_2\ d\underline{v}+0(\varepsilon_1)=$$

$$-\langle\widetilde{\Gamma}_{e,e}(\mathscr{M}_0^{-1}b(|\underline{v}|,T)\underline{v}),\mathscr{M}_0^{0-1}b(|vt|,T)\underline{v}\rangle_0\underline{\underline{\mathrm{I}_d}}+0(\varepsilon_1)>0+0(\varepsilon_1)$$

because the operator $\widetilde{\Gamma}_{e,e}$ is negative.

Miura transformation between two non-linear equations in 2+1 dimensions

J. M. Cerveró and P. G. Estévez[a)]
Area de Física Teórica, Facultad de Física, Universidad de Salamanca, 37008 Salamanca, Spain

(Received 21 November 1997; accepted for publication 13 February 1998)

A Dispersive Wave equation in $2+1$ dimensions (2LDW) widely discussed by different authors is shown to be nothing but the modified version of the Generalized Dispersive Wave equation (GLDW). Using Singularity Analysis and techniques based upon the Painlevé Property leading to the Double Singular Manifold Expansion we shall find the Miura Transformation which converts the 2LDW equation into the GLDW equation. Through this Miura transformation we shall also present the Lax pair of the 2LDW equation as well as some interesting reductions to several already known integrable systems in $1+1$ dimensions. As the 2LDW equation arises from a Miura transformation we propose that it should be treated conventionally as a Modified Equation. In this case, we propose its designation as **The MGLDW Equation**. © *1998 American Institute of Physics.*

I. INTRODUCTION

Recently the following system of non-linear partial differential equations in $2+1$ dimensions has prompted a great deal of interest and several papers have appeared dealing with this system.[1,2] It could also be considered as a Long Dispersive Wave Equation (2LDW) in the form

$$\begin{aligned} 0&=\lambda q_t+q_{xx}-2qV,\\ 0&=\lambda r_t-r_{xx}+2rV,\\ 0&=(qr)_x-V_y\Rightarrow V=\int_{-\infty}^{y}(qr)_x dy'. \end{aligned} \tag{1.1}$$

(i) For $\lambda=i$ and $r=q^*$, it is identical to the equation proposed by Fokas[3] as the simplest integrable equation in $2+1$ dimensions. In this reference, the author presents the Lax pair of this particular case of (1.1). It is also worth pointing out that when $x=y$ the equation proposed by Fokas reduces to the Non-Linear Schrödinger Equation.[4]

(ii) The real version of (1.1) has been obtained by Chakravarty, Kent, and Newman[5] as a particular reduction of the General Self-Dual Yang Mills equations while the complex version of (1.1) has recently been discussed by Maccari[6] using the so-called Asymptotically Exact Reduction Method with the Kadomtsev–Petviashily equation as a starting point.

(iii) The Painlevé Property[7,8] as well as the Bilinear Hirota equations for the equation under consideration have been studied by Porsezian[2] for the complex version and by Radha and Lakhsmanan[1] for the real case. In this latter reference, a systematic use of the Bilinear Formalism is made in order to obtain soliton-like solutions of dromion type.

The aim of this paper is to show that equation (1.1) is nothing but the modified version of the Generalized Dispersive Wave Equation (GLDW) which has been thoroughly studied by Boiti, León and Pempinelli.[9] In order to show this, we shall be using the singularity analysis of the GLDW that has already been successfully applied to this equation by one of the present authors.[10] Also using techniques based upon Painlevé Analysis, we shall find the Miura transformation

[a)]Electronic mail: pilar@sonia.usal.es

 © 1998 American Institute of Physics

which converts (1.1) into the GLDW. In view of these results, it appears reasonable to refer to equation (1.1) as the Modified Generalized Dispersive Wave Equation (MGDLW). Since the Lax pair of the GLDW equation is known,[11,9] the Miura transformation that we shall present in this paper can easily be used to find the Lax pair for equation (1.1). As a final point, we shall offer several interesting reductions of our equation to some integrable equations in $1+1$ dimensions.

II. THE MIURA TRANSFORMATION BETWEEN THE GDLW AND THE MGDLW

In 1987 Boiti *et al.*[9] proposed a dispersive wave equation in $2+1$ dimensions,

$$0=u_{ty}+(\eta_{xy}+2uu_y)_x, \quad 0=\eta_{ty}+(u_{xy}+2u\eta_y)_x, \tag{2.1}$$

which we shall hereafter call the Generalized Dispersive Long Wave Equation (GDLW) since its reduction when $x=y$ is the dispersive wave equation also called the Kaup System[12] or Classical Boussinesq System.[13] Furthermore, the stationary version of (2.1) corresponds to the Sinh-Gordon equation.[9,14]

(i) **The Painlevé Property:** One of the present authors[10] has studied and discussed the system given by (2.1) from the point of view of a Painlevé Analysis. As is well known[7] the Painlevé Property (PP), for practical purposes, can be summarized in the statement that all solutions of equation (2.1) could be written in the form

$$u=\sum_{j=0}^{\infty} u_j\chi^{j-a}, \quad \eta=\sum_{j=0}^{\infty} \eta_j\chi^{j-b}, \tag{2.2}$$

where $\chi=0$ is an arbitrary function called the Movable Singularities Manifold while u_j and η_j are analytic functions in an arbitrary neighborhood of this manifold. Inserting (2.2) in (2.1) (the dominant terms balance easily) yields

$$a=b=1, \tag{2.3}$$

$$u_o=\pm\chi_x \quad \eta_o=\chi_x, \tag{2.4}$$

where $\pm$ means that two Painlevé expansions are in principle possible. In Ref. 10 a detailed discussion is presented on how to deal with both expansions simultaneously.

(ii) **The Double Singular Manifold Method:** In 1983 Weiss[8] proposed the Singular Manifold Method (SMM) which has been proved to be extremely successful in dealing with a large class of non-linear equations. The method is based on the restriction of the solutions of (2.1) for which expansion (2.2) becomes truncated at the constant level. In this case, one can prove that χ is no longer an arbitrary function since it must verify the truncation condition. Accordingly, henceforth it is called the *Singular Manifold.* As system (2.1) presents two different Painlevé branches, the suggestion made in Ref. 10 is to use **two singular manifolds** ϕ and $\hat{\phi}$ (one for each expansion branch) in such a way that the truncation of (2.2) adopts the form

$$u'=u+\frac{\phi_x}{\phi}-\frac{\hat{\phi}_x}{\hat{\phi}}, \quad \eta'=\eta+\frac{\phi_x}{\phi}+\frac{\hat{\phi}_x}{\hat{\phi}}. \tag{2.5}$$

(iii) **Superposition of solutions:** Expansion (2.5) suggests the following change of dependent variables:

$$u=m-\hat{m}, \quad \eta=m+\hat{m}, \tag{2.6}$$

such that m and $\hat{m}$ satisfy individual equations, each with just one branch of the Painlevé expansion. In order to find which equations m and $\hat{m}$ should satisfy, we add and subtract (2.1), and using (2.6) we finally obtain

$$0=m_{ty}+[m_{xy}+2(m-\hat{m})m_y]_x,$$
$$0=\hat{m}_{ty}+[-\hat{m}_{xy}+2(m-\hat{m})\hat{m}_y]_x. \tag{2.7}$$

Let us now define

$$m_t=n_x, \quad \hat{m}_t=\hat{n}_x. \tag{2.8}$$

After an integration over the variable x in (2.7) we obtain

$$0=n_y+m_{xy}+2(m-\hat{m})m_y, \tag{2.9}$$

$$0=\hat{n}_y-\hat{m}_{xy}+2(m-\hat{m})\hat{m}_y, \tag{2.10}$$

These equations allow us to obtain m and $\hat{m}$ from (2.9) and (2.10). The result is

$$m=\hat{m}+\frac{\hat{m}_{xy}-\hat{n}_y}{2\hat{m}_y}, \tag{2.11}$$

$$\hat{m}=m+\frac{m_{xy}+n_y}{2m_y}. \tag{2.12}$$

By substituting (2.11) in (2.9) and (2.12) in (2.10), one can easily decouple these equations, thus obtaining one that is satisfied by m and another one that is satisfied just by $\hat{m}$. Is trivial to check that both equations are one and the same but written with different variables. In fact (m,n) satisfies

$$0=m_t-n_x,$$
$$0=m_y^2(n_{yt}-m_{xxxy})+m_{xy}(n_y^2-m_{xy}^2)+2m_y(m_{xy}m_{xxy}-n_y n_{xy})-4m_y^3 m_{xx}, \tag{2.13}$$

while $(\hat{m},\hat{n})$ satisfies

$$0=\hat{m}_t-\hat{n}_x,$$
$$0=\hat{m}_y^2(\hat{n}_{yt}-\hat{m}_{xxxy})+\hat{m}_{xy}(\hat{n}_y^2-\hat{m}_{xy}^2)+2\hat{m}_y(\hat{m}_{xy}\hat{m}_{xxy}-\hat{n}_y\hat{n}_{xy})-4\hat{m}_y^3\hat{m}_{xx}, \tag{2.14}$$

which is obviously the same equation. Therefore, m and $\hat{m}$ are both solutions of equation (2.13) but constrained by the transformation (2.11)–(2.12). It is not difficult to recognize the constraint as an **Auto-Bäcklund Transformation** between two solutions of (2.13).

(iv) **The Miura Transformation:** With regard to u and η, these can be expressed through (2.6) as a linear superposition of m and $\hat{m}$. Taking into account (2.6) and (2.11), one can write

$$u=m-\hat{m}=\frac{\hat{m}_{xy}-\hat{n}_y}{2\hat{m}_y}=-\frac{m_{xy}+n_y}{2m_y},$$
$$\eta=m+\hat{m}=2\hat{m}+\frac{\hat{m}_{xy}-\hat{n}_y}{2\hat{m}_y}=2m+\frac{m_{xy}+n_y}{2m_y}. \tag{2.15}$$

In order to express m and $\hat{m}$ as a function of u and η with the help of (2.15), we must previously realize that the first of the equations (2.1) can be integrated in the form

$$\eta_x=-\partial_x^{-1}u_t-u_x^2, \tag{2.16}$$

in such a way that m and $\hat{m}$ can be finally expressed as

$$\begin{aligned} 2m_x &= u_x + \eta_x = u_x - u^2 - \partial_x^{-1} u_t, \\ 2\hat{m}_x &= \eta_x - u_x = -u_x - u^2 - \partial_x^{-1} u_t. \end{aligned} \tag{2.17}$$

Expressions (2.17) are Miura transformations between solutions of the non-linear systems (2.1) and (2.14). In the next Section we shall show that system (2.14) is nothing but the initial system given by (1.1). Obviously, (2.13) must be considered as the **Modified GLDW equation** since it has been transformed through the **Miura transformation** (2.17) from the GLDW equation. Hereafter, we shall refer to (2.13) as the MGLDW equation.

III. THE MODIFIED GDLW EQUATION

We now attempt to show that (1.1) must truly be considered the modified GDLW equation (2.13).

A. Equation (1.1) as the Modified GDLW equation

We first try to write down (1.1) as a equation for just one field. In order to do so, we make the change,

$$V = -m_x, \tag{3.1}$$

in such a way that (1.1) becomes

$$0 = q_t + q_{xx} + 2qm_x, \tag{3.2}$$

$$0 = r_t - r_{xx} - 2rm_x, \tag{3.3}$$

$$0 = qr + m_y, \tag{3.4}$$

where time has been rescaled in the form

$$t \to \lambda t.$$

Taking q out of (3.4) and substituting it in (3.2), we find

$$0 = \frac{m_{yt} + m_{xxy}}{r} - 2m_{xy}\frac{r_x}{r^2} + m_y\left(\frac{2m_x}{r} - \frac{r_t}{r^2} - \frac{r_{xx}}{r^2} - 2\frac{r_x^2}{r^3}\right). \tag{3.5}$$

Using (3.3) in (3.5), we also obtain

$$0 = m_{xxy} + m_{yt} - \left(2m_y\frac{r_x}{r}\right)_x, \tag{3.6}$$

which can easily be integrated by setting $m_t = n_x$, which yields

$$\frac{r_x}{r} = \frac{m_{xy} + n_y}{2m_y}. \tag{3.7}$$

Substituting (3.7) in (3.3), we obtain

$$\frac{r_t}{r} = 2m_x + \frac{m_{xxy} + n_{xy}}{2m_y} - \frac{m_{xy}^2 - n_y^2}{4m_y^2}. \tag{3.8}$$

Next, we calculate the obvious identity $(r_t/r)_x = (r_x/r)_t$ using (3.7) and (3.8), and finally we obtain for m the equation

$$0 = m_t - n_x,$$
$$0 = m_y^2(n_{yt} - m_{xxxy}) + m_{xy}(n_y^2 - m_{xy}^2) + 2m_y(m_{xy}m_{xxy} - n_y n_{xy}) - 4m_y^3 m_{xx}, \tag{3.9}$$

which is precisely equation (2.13). Taking into account (3.1) and (2.17), we also find

$$V = \tfrac{1}{2}(u_x + u^2 + \partial_x^{-1} u_t), \tag{3.10}$$

that establishes the relationship between the V-field of (1.1) and the u-field of (2.1).

Also, one can compare (3.7)–(3.8) and (2.15) yielding

$$\frac{r_x}{r} = -u, \quad \frac{r_t}{r} = \eta_x + u^2. \tag{3.11}$$

B. The Lax pair for MGDLW

The Lax pair of the GLDW equation (2.1) is well known and can easily be written as[10]

$$0 = \varphi_t - \varphi_{xx} + 2u\varphi_x, \quad 0 = \varphi_{xy} - \partial_x^{-1} u_y \varphi_x + \frac{\eta_y - u_y}{2}\varphi. \tag{3.12}$$

Alternatively, one can also write the Lax pair by using the gauge transformation:

$$\varphi = e^{\partial_x^{-1} u}\psi,$$

which leads equation (3.12) to the expression

$$0 = \psi_t - \psi_{xx} + [\partial_x^{-1} u_t - u_x + u^2]\psi, \quad 0 = \psi_{xy} + u\psi_y + \frac{\eta_y + u_y}{2}\psi. \tag{3.13}$$

This is the form of the Lax pair obtained by other authors.[11,9] Using (2.15)–(2.17), expression (3.13) becomes

$$0 = \psi_t - \psi_{xx} - 2m_x\psi,$$
$$0 = \psi_{xy} - \frac{m_{xy} + n_y}{2m_y}\psi_y + m_y\psi, \tag{3.14}$$

which can be considered as the Lax pair for the MGLDW equation (2.13). Taking into account (3.1), (3.4), and (3.8), this latter expression can also be written as

$$0 = \psi_t - \psi_{xx} + 2V\psi, \quad 0 = \psi_{xy} - \frac{r_x}{r}\psi_y - qr\psi, \tag{3.15}$$

which would be the same Lax pair but for form (3.2)–(3.4) of the MGLDW equation. Since (3.1)–(3.4) is invariant under the transformation

$$t \to -t, \quad r \to q,$$

the following pair of equations:

$$0 = \hat{\psi}_t + \hat{\psi}_{xx} - 2V\hat{\psi}, \quad 0 = \hat{\psi}_{xy} - \frac{q_x}{q}\hat{\psi}_y - qr\hat{\psi}, \tag{3.16}$$

would also be a Lax pair for the MGLDW equation.

IV. PARTICULAR CASES

Let us now examine the Miura transformations induced in some interesting reductions of the MGLDW equation.

A. The stationary case: Sinh-Gordon versus AKNS

(i) Let us assume that the fields of the **MGDLW equation** (3.9) do not depend on t. The equation takes the form

$$0=-m_y^2 m_{xxxy}-m_{xy}^3+2m_y m_{xy} m_{xxy}-4m_y^3 m_{xx}, \tag{4.1}$$

which can be integrated with respect to x to give

$$2m_{xxy}m_y+8m_x m_y^2-m_{xy}^2=0. \tag{4.2}$$

Eliminating m_{xxy} between (4.1) and (4.2), we finally obtain

$$m_{xxxy}+8m_x m_{xy}+4m_y m_{xx}=0, \tag{4.3}$$

which is the **AKNS equation in** $1+1$ **dimensions**.[15]

(ii) With the same reduction of time-independent fields, **The GLDW equation** (2.1) can also be written as

$$0=\eta_{xy}+2uu_y, \tag{4.4}$$

$$0=u_{xy}+2u\eta_y. \tag{4.5}$$

Let us now multiply (4.4) by η_y, (4.5) by u_y, and subtract. The result is

$$\frac{d(\eta_y^2-u_y^2)}{dx}=0.$$

Next, we introduce the change of variables,

$$\eta_y=a_0\cosh 2q, \quad u_y=a_0\sinh 2q, \tag{4.6}$$

and so equations (4.4)–(4.5) take the form

$$u=-q_x. \tag{4.7}$$

Alternatively, using (4.6) we finally obtain

$$q_{xy}=a_0\sinh 2q, \tag{4.8}$$

which is **the Sinh-Gordon equation**.[11,14]

(iii) Therefore, the particularization of the Miura transformation (2.17) to the stationary case,

$$2m_x=u_x-u^2=-q_{xx}-q_x^2, \quad 2\hat{m}_x=-u_x-u^2=q_{xx}-q_x^2, \tag{4.9}$$

yields the corresponding Miura transformation between solutions of the AKNS equation (4.3) and the Sinh-Gordon equation (4.8).

B. Non-local Boussinesq equation versus the Kaup system

In the next subsection we shall deal with the reduction which arises from setting $x=y$.

(i) In the present case, the MGLDW equation (3.10) is reduced to

$$0=m_t-n_x,$$
$$0=m_x^2(n_{xt}-m_{xxxx})+m_{xx}(n_x^2-m_{xx}^2)=2m_x(m_{xx}m_{xxx}-n_xn_{xx})-4m_x^3m_{xx}. \tag{4.10}$$

The set of equations (4.10) can be integrated with respect to x. One easily obtains

$$0=m_t-n_x, \quad 0=m_x(n_t-m_{xxx})-(n_x^2-m_{xx}^2)-2m_x^3. \tag{4.11}$$

Alternatively, we can eliminate the field n. Thus, for m we find the following equation:

$$m_{tt}=\left[m_{xxx}+2m_x^2+\frac{n_x^2-m_{xx}^2}{m_x}\right]_x. \tag{4.12}$$

Lambert *et al.*[16,17] have called (4.12) **the non-local Boussinesq equation (NLBq)**.

(ii) We now apply the reduction $x=y$ to the GLDW equation (2.1):

$$0=u_t+\eta_{xx}+2uu_x, \quad 0=\eta_t+u_{xx}+2u\eta_x. \tag{4.13}$$

This system has been known as the classical Boussinesq system[13] or **the Kaup system**.[18,12,19,16]

(iii) The Miura transformation (2.17) establishes a relationship between the solutions of the non-local Boussinesq equation (4.12) and the Kaup system (4.13).

(iv) An important subcase of this reduction is the **non-linear Schrödinger equation**. To see this, we must notice that the reduction $x=y$ applied to the MGLDW in its form given by (3.2)–(3.4) appears as

$$0=q_t+q_{xx}-2q^2r, \quad 0=r_t-r_{xx}+2r^2q, \tag{4.14}$$

which for imaginary time, $t\to it$ and $q=r^*$, is clearly the non-linear Schrödinger equation.[3,20]

V. CONCLUSIONS

(i) First, starting from Painlevé analysis of the Dispersive Long Wave Equation in $2+1$ dimensions (GDLW), we have been able to decompose the solutions of this equation as a **linear superposition** of two solutions of another equation in $2+1$ that has been called a Modified Dispersive Long Wave Equation (MGDLW).

(ii) The expansion of the solutions of the GDLW as a linear superposition of its modified version (MGDLW) is shown to be invertible and gives rise to the Miura transformation between both equations. This Miura transformation has been obtained explicitly.

(iii) In Section III we have shown that the MGLDW equation is nothing but the equation proposed by several authors[3,1,6,2] as one of the simplest possible integrable equation in $2+1$ dimensions.

(iv) Since the Lax pair of the GDLW equation is already known,[9] the Miura transformation allows one to pass from the GDLW equation to the MGDLW equation. In particular, we can easily find the Lax pair of the latter equation.

(v) In Section IV some interesting reductions of the MGDLW equation are presented using the Miura transformation between GDLW and MGDLW. In this way, one can obtain the Miura transformations between AKNS and Sinh-Gordon in $1+1$ and between the non-local Boussinesq equation and the Kaup system, also in $1+1$ dimensions.

(vi) In view of the above results one could conjecture that when two or more expansion branches in the Painlevé expansion appear in a given non-linear partial differential equation, a Miura transformation exists that converts the initial equation into one with just one branch in this expansion.

(vii) Systematic application of the Singular Manifold Method[8] and use of it to find the Darboux transformation for the MGDLW equation pave the way for finding extremely simple algorithms for the construction of solutions that generalize the ones already obtained by other

authors[1] using the bilinear formalism. We shall shortly be presenting these results in a forthcoming publication.

A model for the 2×2 AKNS system is extended for the two-block AKNS system. Zeroes of the determinant of the J-diagonal scattering matrix blocks give the bound states of such a system. The couple coefficients are now matrices. © *1998 American Institute of Physics.* [S0022-2488(98)00905-0]

I. INTRODUCTION

In Ref. 1 Sasa and Satsuma found that a certain type of higher-order nonlinear Schrödinger equation can be solved by the inverse scattering transform method. This kind of equation is associated with the AKNS operator D_x given by

$$D_x = D_x(z,q) = \frac{\partial}{\partial x} - zJ - q$$

for

$$J = i\begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix}$$

and z a complex number called spectral value. Here we consider the $n\times n$ constant matrix

$$J = \begin{pmatrix} p_- \mathbf{1}_{p_+} & 0_{p_+\times p_-} \\ 0_{p_-\times p_+} & -p_+ \mathbf{1}_{p_-} \end{pmatrix},$$

$p_\pm$ being positive integers whose sum is n; $\mathbf{1}_{p_\pm}$ are the $p_\pm\times p_\pm$ identity matrices, respectively, and $0_{p_\pm\times p_\mp}$ are the $p_\pm\times p_\mp$ null matrices, respectively. The $n\times n$ matrix-valued function is defined on the real line $q=\left(\begin{smallmatrix} 0_{p_+} & r_+ \\ r_- & 0_{p_-} \end{smallmatrix}\right)$ whose entries are in the Schwartz class where $0_{p_\pm}$ are the $p_\pm\times p_\pm$ null matrices, respectively, and $r_\pm$ are $(p_\pm\times p_\mp)$ matrix-valued functions. In the sequel, we refer to this system as the two-block AKNS system. For $p_+=1$ and $p_-=2$ the coupled nonlinear Schrödinger equation (cf. Ref. 2) is associated with this operator.

Three years before Ref. 1 appeared, Sattinger and Zurkowsky in Ref. 3 found a method to characterize the zeroes of the diagonal coefficients of the scattering matrix 2×2 case: $p_-=p_+=1$.

The above method cannot be extended to the generic case where the matrix J has different diagonal entries, but in this paper we extend it to study the two-block AKNS system.

II. CONSTRUCTION OF THE WAVE FUNCTIONS

We generalize the construction given in Ref. 3 of the wave functions ϕ for the present case, i.e., those functions ϕ such that $D_x(z,q)\phi=0$. These functions are also called the eigenfunctions [roughly speaking of the operator $J^{-1}(d/dx-q)$ corresponding to the eigenvalue or spectral value z see Ref. 4]. In the sequel, we refer to them as wave functions of D_x or just the wave functions.

a)Electronic mail: ccg@hp9000a1.uam.mx

 © 1998 American Institute of Physics

The $n\times p_+$ matrix e_+ and the $n\times p_-$ matrix e_- are defined by

$$e_+=\begin{pmatrix}\mathbf{1}_{p_+}\\ 0_{p_-}\times p_+\end{pmatrix},\quad e-=\begin{pmatrix}0_{p_+\times p_-}\\ \mathbf{1}_{p_-}\end{pmatrix}.$$

respectively.

The wave functions are obtained by rewriting the differential equation as a Volterra integral equation. For example, write $\phi=\ell e^{-p_+xz}$. Then we obtain differential equation

$$\frac{d\ell}{dx}=zE\ell+q\ell,\quad E=\begin{pmatrix}ni\mathbf{1}_{p_+} & 0_{p_+\times p_-}\\ 0_{p_-}\times p_+ & 0_{p_-}\end{pmatrix},$$

where 0_{p_-} is the null $p_-\times p_-$ square matrix. This may be rewritten as the Volterra integral equation; for instance,

$$\ell=e_-+\int_\infty^x e^{zE(x-y)}(q\ell)(y)\,dy.$$

The convergence of the successive approximations depends upon the potential q. For instance, if $q\in L_1(\mathbb{R})$, these converge uniformly in $\operatorname{Im} z\geqslant 0$; the solution ℓ is analytic in the upper half-plane $\operatorname{Im} z\geqslant 0$, is bounded for real x, and tends to e_- as x tends to $-\infty$.

The smoothness of the potential q gives an asymptotic expansion for ℓ. If $q\in C^r$, then

$$\ell\sim\sum_{j=0}^{r}\ell_j z^{-j},$$

where $\ell_0=e_-$, $E\ell_1=-qe_-$, and $E\ell_{j+1}=d\ell_j/dx-q\ell_j$.

So there exist wave matrix-valued functions $\phi_\pm$ and $\psi_\pm$, analytic in $\pm\operatorname{Im} z>0$ with the asymptotic behavior

$$\phi_\pm\sim e^{\mp ip_\mp xz}e_\mp,\quad x\to-\infty,\quad \psi_\pm\sim e^{\pm ip_\pm xz}e_\pm,\quad x\to\infty, \tag{1}$$

is proven in this manner.

Let Φ and Ψ denote matrices

$$\Phi(x,k)=\|\phi_-(x,k),\phi_+(x,k)\|,\quad \Psi(x,k)=\|\psi_+(x,k),\psi_-(x,k)\|$$

for real spectral value k. In general, the wave functions (with the spectral value k) Φ and Ψ are defined only for real k and satisfy the integral Volterra equations

$$\begin{aligned}\Phi(x,k)&=e^{xkJ}+\int_{-\infty}^{x}e^{(x-y)kJ}q\Phi\,dy,\\ \Psi(x,k)&=e^{xkJ}-\int_{x}^{\infty}e^{(x-y)kJ}q\Psi\,dy.\end{aligned} \tag{2}$$

Remark 1: However, if the potential q has compact support, Φ and Ψ are entire functions of the spectral value k.

III. THE ZEROES OF THE DETERMINANT OF *J*-DIAGONAL BLOCKS OF THE SCATTERING MATRIX

Each of these matrix-valued functions is a fundamental solution set on the real axis, so for each real spectral k there exists a matrix $S(k)$ such that they are related by

$$\Phi(x,k)=\Psi(x,k)s(k),\quad s(k)=\begin{pmatrix}a(k) & b(k)\\ c(k) & d(k)\end{pmatrix}. \tag{3}$$

Here $a(k)$ and $d(k)$ are $p_\pm \times p_\pm$-square matrices, respectively, and $b(k)$ and $c(k)$ are $p_\pm \times p_\pm$ matrices, respectively. From now on we call the former the J-diagnonal blocks.

By a standard argument, it is found that $\det \Phi(x,k)$ and $\det \Psi(x,k)$ are constant as functions of x for each real spectral value k. Evaluating them as $x \to \pm\infty$, respectively, we find that they are identically one. Therefore, $s(k) \in \mathrm{SL}(n,\mathbb{C})$ for each real k.

Remark 2: Solving (2) for $s(k)$ and taking into account Remark 1 we find $s(k)$ is defined for all complex numbers k and is an entire function of k whenever we let q have compact support; in particular, the matrices a and d are entire functions of k.

Substituting the left relation in (3) into the first equation in (2) and assuming that q has compact support, we obtain

$$s(k) = \mathbf{1}_{n\times n} + \int_{-\infty}^{x} e^{-ykJ} q(y,k) \Phi(y,k)\, dy, \quad x > n,$$

for some positive integer n and any fixed x.

If q' is another potential with compact support, we have for the upper J-diagonal block of $s(k) - s'(k)$ that

$$\begin{aligned} d(k) - d'(k) = & \int_{-\infty}^{x} e^{iykp_-} \| r_-(y,k) - r'_-(y,k) 0 \| \phi_+(y,k)\, dy \\ & + \int_{-\infty}^{x} e^{iykp_-} \| r'_-(y,k) 0 \| (\phi_+(y,k) - \phi'_+(y,k))\, dy. \end{aligned} \tag{4}$$

Remark 3: Since the successive approximations for ϕ_- converge uniformly in the lower half-plane $-\operatorname{Im} k \geqslant 0$, it is bounded uniformly in the same half-plane. Hence the first term in (4) is bounded by $C_- |q_1 - q'_1|_{L_1}$, where $C_- = C_-(q,x)$ is a bound for ϕ_- in the lower half-plane. It is not hard to see that $\phi_- - \phi'_-$ is bounded by $C_- = C_-(q,q',x)|q - q'|_{L_1}$ in the lower half-plane. So the second term is bounded by $C_- |q'|_{L_1} |q - q'|_{L_1}$.

As a consequence of this last remark, we have the next result.

Theorem 1: *For any potential q, the matrices a and d can be analytically extended to the lower and upper half-planes, respectively.*

Proof: Because of Remark 2, if the potential has compact support, then d is an entire function. If q does not have compact support, then we approximate it by potentials of compact support. By Remark 3, d is the uniform limit of analytic functions in $-\operatorname{Im} z \geqslant 0$. Therefore it can be extended analytically by Morera's theorem. Similarly, we proceed with a. □

Decoupling (3) by blocks, we get a matrix equation system, namely,

$$\begin{aligned} \phi_+ &= \psi_+ b + \psi_- d, \\ \phi_- &= \psi_+ a + \psi_- c. \end{aligned} \tag{5}$$

For instance, rewriting the first as a system for the unknowns $b_{1j}, \ldots b_{p_+ j}$, and $d_{1j}, \ldots d_{p_- j}$ for fixed $j = 1,\ldots,p_-$, we can see that

$$d_{lj} = |\, \psi_+ \quad \psi_-^1 \cdots \psi_-^{j-1} \quad \phi_+^l \quad \psi_-^{j+1} \cdots \psi_-^{p_-} |, \quad l,j = 1,\ldots,p_- . \tag{6a}$$

Similarly,

$$a_{lj} = |\, \psi_+^1 \cdots \psi_+^{j-1} \quad \phi_-^l \quad \psi_+^{j+l} \cdots \psi_+^{p_+} \quad \psi_- |, \quad l,j = 1,\ldots,p_+ . \tag{6b}$$

Here the superscript denotes the column of the matrix.

Definition 1: Let ψ and ϕ be two matrices with the same number of rows and with p_+, p_- columns, respectively. Its right wedge product by columns is a matrix given by

$$\psi \wedge^c \phi = \| \wedge_{\ell=1}^{p_+} \psi^\ell \wedge \wedge_{\ell=2}^{p_-} \phi^\ell \quad \cdots \quad \wedge_{\ell=1}^{p_+} \psi^\ell \wedge \wedge_{\substack{\ell=1 \\ \ell \neq j}}^{p_-} \phi^\ell \quad \cdots \quad \wedge_{\ell=2}^{p_+} \psi^\ell \wedge \wedge_{\ell=1}^{p_- - 1} \phi^\ell \|.$$

Analogously, the left wedge product $\psi^c\wedge\phi$ is defined.

If ρ is a third matrix with p_- columns, then the wedge product by columns with $\psi\wedge^c\phi$ is the matrix given by

$$(\psi\wedge^c\phi)\wedge^c\rho=(\wedge_{\ell=1}^{p_+}\psi^{\ell}\wedge\phi^1\wedge\quad\cdots\quad\wedge\phi^{j-1}\wedge\rho^l\wedge\phi^{j+1}\wedge\quad\cdots\quad\wedge\phi^{p_+})_{lj}.$$

Similarly, we define $\psi^c\wedge\phi$.

With this notation at hand, we obtain from (5), (6a), and (6b) that

$$d=(\psi_+\wedge^c\psi_-)\wedge^c\phi_+,\quad a=\phi_-{}^c\wedge(\psi_+{}^c\wedge\psi_-). \tag{7}$$

Also $\wedge^c$-multiplying (5) by $\psi_+\wedge^c\phi_+$, we obtain the relation

$$(\psi_+\wedge^c\phi_+)\wedge^c\psi_-d=(\psi_+\wedge^c\phi_+)\wedge^c\psi_+. \tag{8}$$

By a direct calculation, we may check that

$$(\psi_+\wedge^c\phi_+)\wedge^c\psi_+=\det\|\psi_+\quad\phi_+\|\mathbf{1}_{n\times n}. \tag{9}$$

On the other hand, the limits as x tends to infinity of $(\psi_+\wedge^c\psi_-)\wedge^c\phi_+$ and $(\psi_+\wedge^c\phi_+)\wedge^c\psi_-$ have the form $(\psi_+^l\wedge^c e_-)\wedge^c e_+$ and $(\psi_+^l\wedge^c e_+)\wedge^c e_-$, respectively, because of (1). It is a straightforward calculation to check that

$$(\psi_+\wedge^c\phi_+)\wedge^c\psi_-d=((\psi_+^l\wedge^c e_-)\wedge^c e_+)(\psi_+^l\wedge^c e_+)\wedge^c e_-=\det d\,\mathbf{1}_{n\times n}. \tag{10}$$

The determinants $\det\|\psi_+\quad\phi_+\|$ and $\det\|\psi_-\quad\phi_-\|$ do not depend of x, since $\|\psi_+\quad\phi_+\|$ and $\|\psi_-\quad\phi_-\|$ are solutions of $D_x\psi=0$ by construction of $\psi_\pm$ and $\phi_\pm$. Thus we have from (7)–(10), and doing a similar procedure for a, that

$$\det d=\det\|\psi_+\quad\phi_+\|,\quad \det a=\det\|\phi_-\quad\psi_-\|. \tag{11}$$

Therefore, by means of Theorem 1, we can establish the next result.

Theorem 2: *The determinants* $\det d$ *and* $\det a$ *can be analytically extended to the upper and lower half-planes, respectively. In addition, their zeroes are the same as those of* $\det\|\psi_+\quad\phi_+\|$ *and* $\det\|\phi_-\quad\psi_-\|$, *respectively*.

Remark 4: Theorem 2 can be directly proved from relations in (7) and (8). In the case that $p_+=1$ and $n=3$, the identity in (10) follows from a straight calculation, without taking the time as x goes to infinity. In addition, we have

$$a=\det\|\phi_-\quad\psi_-\|,\quad \det d=\|\psi_+\quad\phi_+\|.$$

Remark 5: From the identities in (6) we can estimate the limits of $e^{xzp_-}\phi_-$, $e^{xzp_-}\phi_+$ as $x\to\infty$. For instance, $e^{xzp_\mp}\phi_+\to\|{}^0_d\|$ as $x\to\infty$. Using this limit, one may check that the matrix functions defined on the real line by

$$\|\psi_+\quad\phi_+d^{-1}\|=\hat{m}_+e^{xzJ},\quad \operatorname{Im} z>0,\quad \|\phi_-a^{-1}\quad\psi_-\|=\hat{m}_-e^{xzJ},\quad \operatorname{Im} z<0,$$

satisfy that $\hat{m}_\pm\to\mathbf{1}$ as $x\to\infty$, and the others properties of a reduced wave function (see e.g., Ref. 5). However, we cannot obtain wave functions with the property $m_\pm\to\mathbf{1}$ as $x\to-\infty$ in this way, in contrast to the case $p_-=p_+=1$ (cf. Ref. 2). To construct those wave functions we must use another method, for instance that of X. Zhou (cf. Ref. 5).

IV. THE COUPLE MATRIX COEFFICIENTS

Definition 2: Let ϕ and ψ be two wave functions of D_x. If there exists a constant matrix c such that $\phi=c\psi$ or $c\phi=\psi$, we say that those matrices are matrix multiples. The matrix c is called the corresponding couple-matrix coefficient.

According to Theorem 2, $\det d(k^+)=0$ and $\det a(k^-)=0$ if and only if the eigenfunctions $\phi_\pm(k^\pm)$ and $\psi_\pm(k^\pm)$, corresponding to the eigenvalues $k^\pm$, respectively, are matrix multiples.

Extending the definition used in 2×2 AKNS systems to the present case, we call these wave functions the bound states associated to the potential q. With this notation at hand, as an immediate consequence of Theorem 2, we can state the following.

Corollary 1: The zeroes of det d *and* det a *give the bound states*.

Remark 4: In the case of $p_+=p_-=1$, in each zero $k^{\pm}$ of det d and det a, respectively, we have at the same time the relations

$$\phi_+=\psi_+c_+ \quad \text{and} \quad \phi_-=\psi_-c_-. \tag{12}$$

In addition, $c_\pm$ are scalars. However, this is no longer true in the other cases. For instance, we encountered that in the case $p_+\leqslant p_-$ then

$$\phi_-=\psi_-c_- \quad \text{but} \quad \phi_+c_+=\psi_+, \tag{13}$$

where $c_\pm$ are now matrices.

If we still assume that $p_+\leqslant p_-$, from (12) we obtain that

$$c_-=\frac{1}{|\wedge_{\ell=1}^{p_+}\psi_-^{\ell}|^2}(\langle\wedge_{\ell=1}^{i-1}\psi_-^{\ell}\wedge\phi_-^{j}\wedge_{\ell=i+i}^{p_+}\psi_-^{\ell},\wedge_{\ell=1}^{p_+}\psi^{\ell}\rangle)_{ij},$$

$$c_+=\frac{1}{|\wedge_{\ell=1}^{p_-}\phi_+^{\ell}|^2}(\langle\wedge_{\ell=1}^{i-1}{}_+\phi_+^{\ell}\wedge\psi_+^{j}\wedge_{\ell=i+i}^{p_+}\phi_-^{\ell},\wedge_{\ell=1}^{p_-}\phi_+^{\ell}\rangle)_{ij},$$

where $\langle\cdot,\cdot\rangle$ denotes any inner product on the complex Eculidian space $\mathbb{C}^n$, and $|\cdot|$ denotes the corresponding norm. Since we can obtain formulas similar to that in (6) for the coefficients b and c of the scattering matrix s, we recover in a different way the standard result (see Ref. 5), namely, s and $(a,b,c,b,c_\pm(k_j^\pm))$ smoothly depend of q. Here we suppose the number of zeroes $k_j^\pm$ of a and d, respectively, to be finite.

CONCLUSIONS

We have given a different method to construct wave functions from those given in the literature based on the method used for the 2×2 case by Sattinger and Zarkowsky in Ref. 3. However, other types of wave functions required in scattering theory (see Remark 5) should be constructed by using a method given in standard literature (e.g., as in Ref. 5). This method let us study the bound states in a precise sense for the two-by-two-blocks AKNS systems. The couple coefficients are now matrices. In the case that they are scalar, i.e., the 2×2 case, they need to be different from zero. For the present case, they must be left or right invertible to have, for example, the relations in (12) at the same time. A similar assumption should also be made for the model given by Satsuma and Sasa in the case $p_+=1$ and $p_-=2$ (see Ref. 1).

This is not a surprising fact, since we know that the inverse theory via a Riemman–Hilbert problem is only developed for a kind of potential (see Refs. 2 and 5).

(Received 21 July 1997; accepted for publication 5 January 1998)

We extend the study on the algebraic structure of the su(n) color Calogero–Sutherland (CS) models to the case of gl($n|m$) color CS model and show that the generators of the super-Yangian $Y(\mathrm{gl}(n|m))$ can be obtained from two gl($n|m$) loop algebras. Also, a super W_∞ algebra for the SUSY CS model is constructed. © *1998 American Institute of Physics.* [S0022-2488(98)01804-0]

I. INTRODUCTION

The Calogero–Sutherland (CS) models[1,2] are one-dimensional particle systems in which all particles interact through inverse square pairwise interactions. The systems are integrable in both classical and quantum cases and have many interesting properties (e.g., the particles have fractional statistics[3]).

There are various generalizations to the CS models. One of the examples is the su(n) color generalization in which particles have internal degrees of freedom with n possible values.[4] The su(n) extension of the CS models is also integrable and has a new symmetry—Yangian $Y(\mathrm{su}(n))$.[5,6] For the su(n) CS system, Hikami and Wadati[7–9] have made a distinction between the Calogero-type model and the Sutherland-type model and investigated in detail their integrability and algebraic structure. Hikami and Wadati found that the W_∞ algebra, which is the underlying symmetry of the quantum integrable system with long-range interactions, unifies the Yangian in the Sutherland-type model and the loop algebras in the Calogero-type model and revealed that Yangian is a subalgebra of the deformed W_∞ algebra.

Recently, Yangians associated with the simple Lie superalgebras, which are called super-Yangians, have been studied.[10–13] Based on the super-Yangian $Y(\mathrm{gl}(n|m))$, a supersymmetric extension of the su(n) color CS model is constructed and its integrability has been proved.[12] Now the question to be asked is whether the algebraic structure and some properties for the su(n) CS model discussed by Hikami, Wadati, and others still prevail in this supersymmetric extension. In this paper, we will make a study to the algebraic structure of the SUSY CS model.

The paper is organized as follows. In Sec. II, the definition of the super-Yangian $Y(\mathrm{gl}(n|m))$, the SUSY CS models, the Lax pairs for these models, and some notations are given. We then study in Sec. III the relations between the super-Yangian $Y(\mathrm{gl}(n|m))$ for the SUSY Sutherland-type model and two noncommuting loop algebras of which one is for the SUSY Calogero-type model. Moreover, we also derive a super W_∞ algebra from the Lax operators for the SUSY Calogero-type model. Finally, some discussions and remarks are made in Sec. IV.

II. SUPERSYMMETRIC CALOGERO–SUTHERLAND MODEL AND SUPER-YANGIAN $Y(\mathrm{gl}(n|m))$

We begin with the definition of the su(n) color Calogero-type and Sutherland-type models. Assume that there are N particles in these systems. Their positions are described by x_i $(i=1,\ldots,N)$

 © 1998 American Institute of Physics

and each particle carries a color degree of freedom labeled by index a, $a=1,\ldots,n$. The Hamiltonians for the su(n) color Calogero-type and Sutherland-type models are respectively defined as[4,7]

$$H_c=\frac{1}{2}\sum_i (\partial_i)^2+\frac{\lambda}{2}\sum_{i\neq j}(P_{ij}\partial_i\omega_{ij}+\lambda\omega_{ij}\omega_{ji}), \tag{II.1}$$

$$H_s=\frac{1}{2}\sum_i (x_i\partial_i)^2+\frac{\lambda}{2}\sum_{i\neq j}(P_{ij}+\lambda)\frac{x_ix_j}{(x_i-x_j)(x_j-x_i)}, \tag{II.2}$$

where

$$\omega_{ij}=\frac{1}{x_i-x_j}, \tag{II.3}$$

and P_{ij} is a permutation operator that interchanges the color degrees of freedom of the ith and jth particles. We denote by E_i^{ab}, $a,b=1,\ldots,n$, the matrices which act as $|a\rangle\langle b|$ on the color degrees of freedom of the ith particle and leave the other particles untouched. It is then straightforward to check that

$$P_{ij}=\sum_{a,b=1}^{n} E_i^{ab}E_j^{ba}. \tag{II.4}$$

The matrix unit E_i^{ab} can furnish a vector representation for the Lie algebra su(n).

We extend the su(n) color CS models to the gl($n|m$) case, that is, the particles in the systems now carry the graded color indices. Let V be an $n+m$ dimensional Z_2 graded vector space and $\{v^a, a=1,\ldots,n+m\}$ be a homogeneous basis with grading being defined as follows:

$$p(a)=\begin{cases}0, & a=1,\ldots,n\\ 1, & a=n+1,\ldots,n+m.\end{cases} \tag{II.5}$$

The graded matrix unit E^{ab} is defined as

$$E^{ab}v^c=\delta_{bc}v^a. \tag{II.6}$$

It is clear that we have a vector representation for the Lie superalgebra gl($n|m$) given by

$$[E^{ab},E^{cd}\}=\delta_{bc}E^{ad}-(-1)^{\eta}\delta_{ad}E^{cb}, \tag{II.7}$$

where $\eta=(p(a)+p(b))(p(c)+p(d))$ and the graded bracket is defined by

$$[E^{ab},E^{cd}\}\equiv E^{ab}E^{cd}-(-1)^{\eta}E^{cd}E^{ab}. \tag{II.8}$$

If we consider N copies of the matrix units E_i^{ab} ($i=1,\ldots,N$) that act on the ith space of the tensor product of graded vector spaces $V_1\otimes\cdots\otimes V_N$ with $V_i\cong V$, then we can show that the permutation operator P_{ij} defined as

$$P_{ij}=\sum_{a,b=1}^{n+m}(-1)^{p(b)}E_i^{ab}E_j^{ba} \tag{II.9}$$

exchanges the basis vectors v_i, v_j of i,j spaces and has the following properties:

$$P_{ij}=P_{ji},\quad P_{ij}P_{ij}=1,\quad P_{ij}P_{jk}=P_{ik}P_{ij}. \tag{II.10}$$

As before, we consider the one-dimensional system with N identical particles. x_i ($i=1,\ldots,N$) and index a denote, respectively, the positions and the color degrees of freedom of the particles, but now a is Z_2 graded as defined in Eq. (II.5) and takes values $a=1,\ldots,n+m$. If we replace P_{ij} in Eqs. (II.1) and (II.2) by that defined in Eq. (II.9), then we get two Hamiltonians that govern the

dynamics of the systems with graded internal degrees of freedom. In this sense, we call the models described by H_s and H_c SUSY Sutherland-type and SUSY Calogero-type models, respectively, similar to that discussed in Ref. 7.

The SUSY CS models are integrable. To prove the integrability of the systems, we may either directly construct the integrals of motion or find a Lax pair. In the former, the system is integrable if the integrals of motion commute among themselves and also commute with the Hamiltonian of the system; while in the latter, the model is integrable if two matrices L_{ij} and M_{ij} with operator entries obey

$$[H,L_{ij}]=\sum_k (L_{ik}M_{kj}-M_{ik}L_{kj}). \tag{II.11}$$

In Ref. 12, the integrability of the SUSY Sutherland-type model is guaranteed through the construction of the conserved quantities. Here we prove the integrability of SUSY CS models by giving the Lax pairs. For the SUSY Sutherland-type model, the Lax pair is given by

$$L_{ij}=\delta_{ij}\left(x_i\frac{\partial}{\partial x_i}+\frac{1}{2}\right)+\lambda(1-\delta_{ij})\theta_{ij}P_{ij}, \tag{II.12}$$

$$M_{ij}=-\delta_{ij}\lambda\sum_{k\neq i}\theta_{ik}\theta_{ki}P_{ik}+\lambda(1-\delta_{ij})\theta_{ij}\theta_{ji}P_{ij}; \tag{II.13}$$

where $\theta_{ij}=x_i/(x_i-x_j)$. While for the SUSY Calogero-type model, a possible choice is as follows:

$$L_{ij}=\delta_{ij}\frac{\partial}{\partial x_i}+\lambda(1-\delta_{ij})\omega_{ij}P_{ij}, \tag{II.14}$$

$$M_{ij}=-\delta_{ij}\lambda\sum_{k\neq i}\omega_{ik}\omega_{ki}P_{ik}+\lambda(1-\delta_{ij})\omega_{ij}\omega_{ji}P_{ij}. \tag{II.15}$$

M_{ij} in Eqs. (II.13) and (II.15) satisfies the conditions:

$$\sum_i M_{ij}=\sum_j M_{ij}=0, \tag{II.16}$$

which are the same as that in the su(n) color CS models[14] and are essential for the proof of the integrability of the models.

The SUSY Sutherland-type model possesses the super-Yangian $Y(\mathrm{gl}(n|m))$.[12] Let $\{T_p^{ab}, p\geqslant 0, a,b=1,\ldots,n+m\}$ be the generators of the super-Yangian $Y(\mathrm{gl}(n|m))$, then T_p^{ab} satisfies the following relations:[10–13]

$$[T_s^{ab},T_{p+1}^{cd}\}-[T_{s+1}^{ab},T_p^{cd}\}=\lambda(-1)^{(p(c)p(a)+p(c)p(b)+p(b)p(a))}(T_p^{cb}T_s^{ad}-T_s^{cb}T_p^{ad}) \tag{II.17}$$

for $s,p\geqslant -1$, where $T_{-1}^{ab}\equiv\lambda^{-1}\mathbf{1}\delta_{ab}$. It is easy to check that only T_0^{ab},T_1^{ab} are the basic operators, while all other T_p^{ab} $(p>1)$ are defined recursively from T_0^{ab},T_1^{ab}.[13] Therefore, we need to know the action of operators T_0^{ab},T_1^{ab} on the corresponding configuration space of the system in order to prove that the SUSY Sutherland-type model has symmetry $Y(\mathrm{gl}(n|m))$. The action of the operators T_0^{ab},T_1^{ab} on the configuration space of the system is of the following form:

$$T_0^{ab}=\sum_{i=1}^N E_i^{ab}, \tag{II.18}$$

$$T_1^{ab}=\sum_{i,j=1}^N E_i^{ab}L_{ij}, \tag{II.19}$$

where L_{ij} is given by Eq. (II.12). In addition, we also find that

$$T_p^{ab}=\sum_{i,j} E_i^{ab}(L^p)_{ij}, \quad p\geqslant 0 \tag{II.20}$$

satisfies the relation (II.17). It is straightforward to prove that generators T_0^{ab}, T_1^{ab} are conserved operators for the SUSY Sutherland-type model, that is,

$$[T_0^{ab}, H_s]=[T_1^{ab}, H_s]=0. \tag{II.21}$$

The SUSY Calogero-type model is a rational limit of the SUSY Sutherland-type model.[12] It only has gl$(n|m)$ loop algebra symmetry, which we will discuss in Sec. III.

III. THE ALGEBRAIC STRUCTURE OF THE SUSY CALOGERO–SUTHERLAND MODEL

In this section, we first discuss the defining relations of $Y(\mathrm{gl}(n|m))$ in terms of the action of T_0^{ab}, T_1^{ab} on the configuration space of the SUSY Sutherland-type model, then we study the loop algebra structure of the SUSY Calogero-type model and its relation with $Y(\mathrm{gl}(n|m))$. In the second part of this section, a super W_∞ algebra constructed from the Lax operator for the SUSY Calogero-type model is derived.

From Sec. II, we know that the SUSY Sutherland-type model possesses the super-Yangian $Y(\mathrm{gl}(n|m))$ generated by operators T_0^{ab}, T_1^{ab} in Eqs. (II.18) and (II.19). Using Eq. (II.7), it can be shown that operators T_0^{ab}, T_1^{ab} satisfy the following relations:

$$[T_0^{ab}, T_0^{cd}\}=\delta_{bc}T_0^{ad}-(-1)^{\eta}\delta_{da}T_0^{cb}, \tag{III.1}$$

$$[T_0^{ab}, T_1^{cd}\}=\delta_{bc}T_1^{ad}-(-1)^{\eta}\delta_{da}T_1^{cb}, \tag{III.2}$$

$$[T_1^{ab}, T_1^{cd}\}=\delta_{bc}T_2^{ad}-(-1)^{\eta}\delta_{da}T_2^{cb}-\lambda(-1)^{\beta}(T_0^{ad}T_1^{cb}-T_1^{ad}T_0^{cb}), \tag{III.3}$$

where $\beta=p(b)p(c)+p(c)p(d)+p(b)p(d)$ and T_2^{ab} can be written explicitly as

$$T_2^{ab}=\sum_i E_i^{ab}\left(x_i\partial_i+\frac{1}{2}\right)^2+\lambda\sum_{i\neq j}(E_iE_j)^{ab}(x_i\partial_i\theta_{ij}+\theta_{ij}(x_i\partial_i+x_j\partial_j+1))$$

$$+\lambda^2\sum_{i\neq j,j\neq k}(E_iE_jE_k)^{ab}\theta_{ij}\theta_{jk}. \tag{III.4}$$

Here we apply the conventional notations, $(E_iE_j)^{ab}=\sum_{c=1}^{n+m}(-1)^{p(c)}E_i^{ac}E_j^{cb}$, $(E_iE_jE_k)^{ab}=\sum_{c,d=1}^{n+m}(-1)^{p(c)+p(d)}E_i^{ac}E_j^{cd}E_k^{db}$. We can also obtain the following Serre-like relation for operators T_0^{ab}, T_1^{ab}:

$$[T_0^{ab},[T_1^{cd},T_1^{ef}\}\}-[T_1^{ab},[T_0^{cd},T_1^{ef}\}\}=\lambda(\delta_{bc}O_{ef}^{ad}-\delta_{de}O_{cf}^{ab}+(-1)^{\delta}\delta_{cf}O_{ed}^{ab}+(-1)^{\eta}\delta_{be}O_{af}^{cd}$$
$$-(-1)^{\eta}\delta_{ad}O_{ef}^{cb}-(-1)^{\gamma}\delta_{af}O_{eb}^{cd}), \tag{III.5}$$

with $\delta=(p(c)+p(d))(p(e)+p(f))$, $\gamma=(p(a)+p(b))(p(c)+p(d)+p(e)+p(f))$, and O_{cd}^{ab} being defined as

$$O_{cd}^{ab}=-(-1)^{\beta}(T_0^{ad}T_1^{cb}-T_1^{ad}T_0^{cb}). \tag{III.6}$$

Equations (III.1)–(III.3) and (III.5) are the defining relations for the super-Yangian $Y(\mathrm{gl}(n|m))$.

For the SUSY Calogero-type model (II.1), we introduce two operators:

$$J_0^{ab}=T_0^{ab}, \tag{III.7}$$

$$J_1^{ab}=\sum_{i,j} E_i^{ab}I_{ij}, \tag{III.8}$$

where

$$I_{ij}=\delta_{ij}\frac{\partial}{\partial x_i}+\lambda(1-\delta_{ij})\omega_{ij}P_{ij} \tag{III.9}$$

is a Lax operator given in Eq. (II.14). Here we use another notation I_{ij} for L_{ij}. It is easy to check that J_0^{ab},J_1^{ab} satisfy the following commutation relations:

$$[J_0^{ab},J_1^{cd}\}=\delta_{bc}J_1^{ad}-(-1)^{\eta}\delta_{da}J_1^{cb}, \tag{III.10}$$

$$[J_1^{ab},J_1^{cd}\}=\delta_{bc}J_2^{ad}-(-1)^{\eta}\delta_{da}J_2^{cb}, \tag{III.11}$$

$$[J_0^{ab},[J_1^{cd},J_1^{ef}\}\}-[J_1^{ab},[J_0^{cd},J_1^{ef}\}\}=0, \tag{III.12}$$

where

$$J_2^{ab}=\sum_{i,j}E_i^{ab}(I^2)_{ij}. \tag{III.13}$$

In general, we have

$$J_p^{ab}=\sum_{i,j}E_i^{ab}(I^p)_{ij}\quad(p\geqslant 0), \tag{III.14}$$

$$[J_s^{ab},J_p^{cd}\}=\delta_{bc}J_{s+p}^{ad}-(-1)^{\eta}\delta_{da}J_{s+p}^{cb}. \tag{III.15}$$

Equation (III.12) is the Serre relation for the gl$(n|m)$ loop algebra. We can show that J_p^{ab} are conserved operators for the SUSY Calogero-type model, that is, the SUSY Calogero-type model has the gl$(n|m)$ loop algebra symmetry. Furthermore, there is another representation of the gl$(n|m)$ loop algebra with the generators K_p^{ab} being defined by

$$K_p^{ab}=\sum_{i=1}^{N}E_i^{ab}x_i^p\quad(p\geqslant 0), \tag{III.16}$$

and having the relations

$$[K_s^{ab},K_p^{cd}\}=\delta_{bc}K_{s+p}^{ad}-(-1)^{\eta}\delta_{da}K_{s+p}^{cb}, \tag{III.17}$$

$$[K_0^{ab},[K_1^{cd},K_1^{ef}\}\}-[K_1^{ab},[K_0^{cd},K_1^{ef}\}\}=0. \tag{III.18}$$

The K_0^{ab},K_1^{ab} are the two basic operators with the following forms, respectively:

$$K_0^{ab}=J_0^{ab}, \tag{III.19}$$

$$K_1^{ab}=\sum_{i}E_i^{ab}x_i. \tag{III.20}$$

We consider now the algebras constructed from the elements $\{J_0^{ab},J_1^{ab},K_1^{ab}\}$. Just as in the nongraded case,[7,15] the super-Yangian $Y(\mathrm{gl}(n|m))$ appears by unifying two gl$(n|m)$ loop algebras $\{J_0^{ab},J_1^{ab}\}$ and $\{K_0^{ab},K_1^{ab}\}$, that is to say, T_1^{ab} can be obtained from the commutators between two sets of generators $\{J_0^{ab},J_1^{ab}\}$ and $\{K_0^{ab},K_1^{ab}\}$:

$$[J_1^{ab},K_1^{cd}\}+[K_1^{ab},J_1^{cd}\}-\lambda[J_0^{ab},J_0^{cd}\}+\lambda[J_0^{ab},(J_0J_0)^{cd}\}=2(\delta_{bc}T_1^{ad}-(-1)^{\eta}\delta_{da}T_1^{cb}). \tag{III.21}$$

In this sense, the algebra generated by $\{J_0^{ab},J_1^{ab},K_1^{ab}\}$ is a larger algebra including both super-Yangian $Y(\mathrm{gl}(n|m))$ and two loop algebras. In addition, we have two extra Serre-like relations:

$$
\begin{aligned}
&[J_0^{ab},[J_1^{cd}+T_1^{cd},J_1^{ef}+T_1^{ef}\}\}-[J_1^{ab}+T_1^{ab},[J_0^{cd},J_1^{ef}+T_1^{ef}\}\}\\
&\quad=\lambda(\delta_{bc}M_{ef}^{ad}-\delta_{de}M_{cf}^{ab}+(-1)^{\delta}\delta_{cf}M_{ed}^{ab}\\
&\qquad+(-1)^{\eta}\delta_{be}M_{af}^{cd}-(-1)^{\eta}\delta_{ad}M_{ef}^{cb}-(-1)^{\gamma}\delta_{af}M_{eb}^{cd}),
\end{aligned}
\tag{III.22}
$$

$$
\begin{aligned}
&[J_0^{ab},[K_1^{cd}+T_1^{cd},K_1^{ef}+T_1^{ef}\}\}-[K_1^{ab}+T_1^{ab},[J_0^{cd},K_1^{ef}+T_1^{ef}\}\}\\
&\quad=\lambda(\delta_{bc}N_{ef}^{ad}-\delta_{de}N_{cf}^{ab}+(-1)^{\delta}\delta_{cf}N_{ed}^{ab}\\
&\qquad+(-1)^{\eta}\delta_{be}N_{af}^{cd}-(-1)^{\eta}\delta_{ad}N_{ef}^{cb}-(-1)^{\gamma}\delta_{af}N_{eb}^{cd}),
\end{aligned}
\tag{III.23}
$$

where

$$
\begin{aligned}
M_{cd}^{ab}=(-1)^{\beta}&\left[\sum_{i\neq j}E_i^{ad}E_j^{cb}\left((x_i+1)\frac{\partial}{\partial x_i}-(x_j+1)\frac{\partial}{\partial x_j}\right)+\lambda\sum_{ijk}{}'\ \frac{x_i+1}{x_i-x_j}(E_iE_j)^{ad}E_k^{cb}\right.\\
&\left.-\lambda\sum_{ijk}{}'\ \frac{x_j+1}{x_j-x_k}E_i^{ad}(E_jE_k)^{cb}\right]+\lambda\sum_{i\neq j}\ \frac{x_i+x_j+2}{x_i-x_j}E_i^{ab}E_j^{cd},
\end{aligned}
\tag{III.24}
$$

$$
\begin{aligned}
N_{cd}^{ab}=(-1)^{\beta}&\left[\sum_{i\neq j}E_i^{ad}E_j^{cb}\left(\frac{\partial}{\partial x_i}-\frac{\partial}{\partial x_j}+x_i-x_j\right)+\lambda\sum_{ijk}{}'\ \frac{1}{x_i-x_j}(E_iE_j)^{ad}E_k^{cb}\right.\\
&\left.-\lambda\sum_{ijk}{}'\ \frac{1}{x_j-x_k}E_i^{ad}(E_jE_k)^{cb}\right]+\lambda\sum_{i\neq j}\ \frac{2}{x_i-x_j}E_i^{ab}E_j^{cd}
\end{aligned}
\tag{III.25}
$$

and Σ' means that any two summation indices do not coincide. The Serre-like relations (III.5), (III.22), and (III.23) may be written in a more compact form. To do this, we define the operator $Q_1^{ab}(x,y)$ to be of the following form:

$$
Q_1^{ab}(x,y)\equiv T_1^{ab}+xJ_1^{ab}+yK_1^{ab},
\tag{III.26}
$$

where x and y are two complex numbers. Using the operator $Q_1^{ab}(x,y)$, we get the following relation:

$$
\begin{aligned}
&[J_0^{ab},[Q_1^{cd}(x,y),Q_1^{ef}(x,y)\}\}-[Q_1^{ab}(x,y),[J_0^{cd},Q_1^{ef}(x,y)\}\}\\
&\quad=\lambda(\delta_{bc}P_{ef}^{ad}(x,y)-\delta_{de}P_{cf}^{ab}(x,y)+(-1)^{\delta}\delta_{cf}P_{ed}^{ab}(x,y)\\
&\qquad+(-1)^{\eta}\delta_{be}P_{af}^{cd}(x,y)-(-1)^{\eta}\delta_{ad}P_{ef}^{cb}(x,y)-(-1)^{\gamma}\delta_{af}P_{eb}^{cd}(x,y)),
\end{aligned}
\tag{III.27}
$$

where

$$
\begin{aligned}
P_{cd}^{ab}(x,y)=O_{cd}^{ab}+x\left\{(-1)^{\beta}\left[\sum_{i\neq j}E_i^{ad}E_j^{cb}\left(\frac{\partial}{\partial x_i}-\frac{\partial}{\partial x_j}\right)+\lambda\sum_{ijk}{}'\frac{1}{x_i-x_j}(E_iE_j)^{ad}E_k^{cb}\right.\right.\\
\left.\left.-\lambda\sum_{ijk}{}'\frac{1}{x_j-x_k}E_i^{ad}(E_jE_k)^{cb}\right]+\sum_{i\neq j}\ \frac{2}{x_i-x_j}E_i^{ab}E_j^{cd}\right\}+y(-1)^{\beta}\sum_{i\neq j}E_i^{ad}E_j^{cb}(x_i-x_j).
\end{aligned}
\tag{III.28}
$$

From Eq. (III.27), we see that generators $Q_1^{ab}(x,y)$ also form a representation of the super-Yangian $Y(\mathrm{gl}(n|m))$ for any x and y. Therefore, we can get a family of super-Yangian subalgebras from generators $Q_1^{ab}(x,y)$, all these subalgebras have a common deformation parameter λ.

Using the generators J_p^{ab} and K_p^{ab}, we can also construct another algebra. We introduce two set of operators as

$$
\mathscr{W}_p^{(s)}=\frac{1}{2(p+s)}\left[\sum_i x_i^2,\mathscr{W}_{p+2}^{(s-1)}\right],
\tag{III.29}
$$

$$\mathcal{Q}_p^{(s)ab}=\frac{1}{2(p+s)}\left[\sum_i x_i^2,\mathcal{Q}_{p+2}^{(s-1)ab}\right],\quad s=2,3,\ldots, \tag{III.30}$$

where $\mathcal{W}_p^{(1)}=J_p=\Sigma_{ij}(I^p)_{ij}$, $\mathcal{Q}_p^{(1)ab}=J_p^{ab}$. $\mathcal{W}_p^{(s)}$ and $\mathcal{Q}_p^{(s)ab}$ can be considered to have conformal spin s. We can write $\mathcal{W}_p^{(s)}$ and $\mathcal{Q}_p^{(s)ab}$ explicitly as

$$\mathcal{W}_p^{(s)}=\frac{1}{2^{s-1}(p+s)_{s-1}}[\underbrace{\sum_i x_i^2,[\cdots,[\sum_i x_i^2}_{s-1},J_{p+2s-2}]\cdots]]=\sum_j(-x_j)^{s-1}(\partial_{x_j})^{p+s-1}+\cdots, \tag{III.31}$$

$$\mathcal{Q}_p^{(s)ab}=\frac{1}{2^{s-1}(p+s)_{s-1}}[\underbrace{\sum_i x_i^2,[\cdots,[\sum_i x_i^2}_{s-1},J_{p+2s-2}^{ab}]\cdots]]=\sum_j E_j^{ab}(-x_j)^{s-1}(\partial_{x_j})^{p+s-1}+\cdots, \tag{III.32}$$

where $(p)_s$ denotes

$$(p)_s=p(p+1)\cdots(p+s-1), \tag{III.33}$$

and $(\cdots)$ represents the lower order terms of ∂_{x_j} and is not necessarily zero in the limit $\lambda\to 0$. Similar to the proofs by Hikami and Wadati,[7] we can show that $\mathcal{W}_p^{(s)}$ and $\mathcal{Q}_p^{(s)ab}$ satisfy the following commutation relations:

$$[\mathcal{W}_p^{(s)},\mathcal{W}_q^{(s')}]=((s-1)q-(s'-1)p)\mathcal{W}_{p+q}^{(s+s'-2)}+\cdots, \tag{III.34}$$

$$[\mathcal{W}_p^{(s)},\mathcal{Q}_q^{(s')ab}]=((s-1)q-(s'-1)p)\mathcal{Q}_{p+q}^{(s+s'-2)}+\cdots, \tag{III.35}$$

$$[\mathcal{Q}_p^{(s)ab},\mathcal{Q}_q^{(s')cd}\}=(\delta_{bc}\mathcal{Q}_{p+q}^{(s+s'-1)ad}-(-1)^{\eta}\delta_{ad}\mathcal{Q}_{p+q}^{(s+s'-1)cb})+\cdots, \tag{III.36}$$

where $(\cdots)$ includes lower spin operators. Equation (III.34) shows that the operators $\mathcal{W}_p^{(s)}$ constitute the quantum W_∞ algebra as in the CS models.[7] However, Eqs. (III.35) and (III.36) indicate that algebra generated by operators $\mathcal{W}_p^{(s)}$ and $\mathcal{Q}_p^{(s)ab}$ is a kind of super W_∞ algebra with color.[16]

In the case of $\lambda\to 0$, if we define a operator which is of the following form,

$$\mathcal{Q}_p^{(s)ab}=\sum_{i=1}^{N} E_i^{ab}x_i^{s-1}(\partial_{x_i})^{p+s-1}, \tag{III.37}$$

that is we only consider the first term of $\mathcal{Q}_p^{(s)ab}$ in Eq. (III.32) up to a constant factor, then it is easy to show that $\mathcal{Q}_p^{(s)ab}$ satisfy the commutation relations:

$$[\mathcal{Q}_p^{(s)ab},\mathcal{Q}_q^{(s')cd}\}=\delta_{bc}\cdot\sum_{k=0}^{p+s-1}\frac{(p+s-1)!(s'-1)!}{k!(p+s-k-1)!(s'-k-1)!}\mathcal{Q}_{p+q}^{(s+s'-1-k)ad}-(-1)^{\eta}\delta_{da}$$
$$\cdot\sum_{k=0}^{q+s'-1}\frac{(q+s'-1)!(s-1)!}{k!(q+s'-k-1)!(s-k-1)!}\mathcal{Q}_{p+q}^{(s+s'-1-k)cb}. \tag{III.38}$$

It can be seen that the algebra generated by $\mathcal{Q}_p^{(s)ab}$ in Eq. (III.37) is a kind of super W_∞ algebra without central terms.[16]

IV. REMARKS AND DISCUSSIONS

In this paper, we have discussed the algebraic structure of the SUSY CS models. We know that SUSY CS models have super-Yangian $Y(\mathrm{gl}(n|m))$ symmetry, and we give the realization of $Y(\mathrm{gl}(n|m))$ and its relations with two $\mathrm{gl}(n|m)$ loop algebras. Also, a super W_∞ algebra realized in terms of generators $\mathcal{W}_p^{(s)}$ and $\mathcal{Q}_p^{(s)ab}$ is shown. Compared with the CS models, there also exists a larger symmetry generated by two loop algebras for the SUSY CS models. But, there are three points to be remarked. First, the operator L_{ij} [Eq. (II.14)] is different from the one for the Sutherland-type model in Refs. 7 and 15, so that the right-hand sides of the Serre-like relations

(III.22) and (III.23) are nonzero. Second, in the right-hand side of Eq. (III.27), there is an x,y dependence which is absent in the nongraded CS models.[7,15] Third, the W_∞ algebra is graded with respect to the color indices a,b.

For the su(n) CS models, the problem of energy spectrum and the symmetry of the system confined in a harmonic potential have been studied in Refs. 7, 8, and 17. Because of the above similarity between SUSY CS models and the CS models, these problems for the SUSY CS models shall not be discussed further.

Nonalgebraic integrability of one reversible dynamical system of the Cremona type

K. V. Rerikh[a)]
Bogoliubov Laboratory of Theoretical Physics, JINR, 141980, Dubna, The Moscow Region, Russia

(Received 26 January 1996; accepted for publication 19 December 1997)

A reversible dynamical system (RDS) and a system of nonlinear functional equations, defined by a certain rational quadratic Cremona mapping and arising from the static model of the dispersion approach in the theory of strong interactions [the Chew–Low-type equations with crossing-symmetry matrix $A(l,1)$], are considered. This RDS is split into one- and two-dimensional ones. An explicit Cremona transformation that completely determines the exact solution of the two-dimensional system is found. This solution depends on an odd function satisfying a nonlinear autonomous three-point functional equation. Nonalgebraic integrability of RDS under consideration is proved using the method of Poincaré normal forms and the Siegel theorem on biholomorphic linearization of a mapping at a nonresonant fixed point. © *1998 American Institute of Physics.* [S0022-2488(98)01105-0]

I. INTRODUCTION

Reversible dynamical systems (RDS) are qualitatively very similar to Hamiltonian systems.[1–9] In particular, the existence of the Kolmogorov–Arnold–Moser tori in reversible non-Hamiltonian flows,[1–6] and nonsymplectic mappings,[4–7] has been proved. Reversible dynamical systems are of great importance in physics, which is a consequence of the time-reversible invariance of many physical laws (see surveys of Ref. 9).

One example of RDS is the system of nonlinear functional (difference) equations[10] of the static model of the dispersion approach.[11] This system is defined by a reversible mapping that is the composition of two involutions: the standard Cremona transformation[12] and the crossing-symmetry mapping. Dynamical systems (DS) of this type, distinguished only by the crossing-symmetry matrix A and defined by the quadratic Cremona mappings, have been investigated in Refs. 13–22. Interest in integrating these DS is related to besides the physical one, with a problem of integrating general Cremona mappings which, according to the M. Noether theorem, can be constructed from different quadratic Cremona mappings.[12] Moreover, such DS do not belong to the Quispel 18-parametric family of integrable mappings,[9,23] and were not considered in the survey on integrable maps.[24] The problem of integrating these two-dimensional DS with the second-order matrix A was solved long ago in Refs. 14 and 15, but only recently three-dimensional DS with the third-order matrices $A(1,1)$ and $A^{\text{Chew–Low}}$ have been integrated in Refs. 17 and 18. A general approach to integrating such n-dimensional DS was developed in Ref. 19.

This paper is devoted to the problem of integrating three-dimensional dynamical system with crossing-symmetry matrix $A(l,1)$, describing the scattering of two particles with spins equal l and 1 within the framework of the static model. This dynamical system is represented by the following system of functional equations:

$$S_i(-w)=\sum_{j=1}^{3} A_{ij}S_j(w), \quad i,j\in(1,2,3),$$

$$S_i(w+1)=1/\sum_{j=1}^{3} A_{ij}S_j(w),$$

[a)]Electronic mail: rerikh@thsun1.jinr.dubna.su

 © 1998 American Institute of Physics

where $S_i(w)$ are the S-matrix elements in the states $i(l-1,l,l+1)$ and $A_{i,j}$ are the elements of the crossing-symmetry matrix $A(l,1)$. Solutions to the system should be meromorphic functions of uniformizing variable $w=\pi^{-1}\arcsin\omega$, in which ω is the energy of a light particle scattered by heavy (static) one. (See, for example, Refs. 10 and 11 about derivation of equations of this type from the dispersion relations.)

Investigating integrability of the dynamical system at the value of $l=1$ in Ref. 17, we see that it splits into the one-dimensional and two-dimensional systems; moreover, the last system does not have a rational first integral and is not algebraically integrable but has a holomorphic first integral. It is obvious that at an arbitrary value of l the dynamical system is not algebraically integrable as well. Let us give the definition of the algebraic and nonalgebraic integrability.[25]

Definition 1: Let $f(x)$ be a birational (inverse map is also rational) mapping $C^2\to C^2$, $x\in C^2$, and consider an autonomous dynamical system in C^2 with discrete time

$$x_i(n+1)=f_i(x_1(n),x_2(n)),\quad i=(1,2), \tag{1}$$

and a system of autonomous functional equations for functions $x_i(w)$, $x\in C^2$, $w\in C$, $i=(1,2)$:

$$x_i(w+1)=f_i(x_1(w),x_2(w)),\quad i=(1,2). \tag{2}$$

Let us call the systems (1) and (2) algebraically integrable, if there exists a mapping $C^2\to C$ defined by the ratio $I_\mu(x)=g_\mu(x)/h_\mu(x)$ of two polynomials of degree μ, which is invariant with respect to the change $n\to n+1$ or $w\to w+1$:

$$I_\mu(x(n+1))=I_\mu(x(n)),\quad I_\mu(x(w+1))=I_\mu(x(w)).$$

Then, the equations

$$I_\mu(x(n))=c,\quad c=\text{const},\quad I_\mu(x(w))=\delta(w),\quad \delta(w+1)=\delta(w), \tag{3}$$

defining the level lines of the first integral or invariant of dynamical systems (1) and (2), give the one-parameter family or pencil of algebraic curves of degree μ due to a rationality $I_\mu(x)$. Otherwise, if there exists an invariant mapping $I(x)$, $I\circ f(x)=I(x)$,: $C^2\to C$, being holomorphic in a certain neighbotrhood of a fixed point of the mapping $f(x)$, let us call the systems (1) and (2) nonalgebraically integrable.

II. THE GENERAL FORMULATION OF THE PROBLEM. STRUCTURE OF THE GENERAL SOLUTION

Definition 2: Let X be an arbitrary set. A one-to-one mapping $T:X\to X$ is said to be reversible if there exists another mapping $G:X\to X$ for which $T^{-1}=G\circ T\circ G$ and G is an involution: $G^2=\mathrm{id}$.[6,8,9]

These conditions imply that $T\circ G$ is also an involution and $T=(T\circ G)\circ G$ is the composition of two involutions. Conversely, the composition of any two involutions is reversible with respect to each of them.

Consider the following two involutions of the complex plane $\mathbf{C}$: the linear one,

$$A_1:\mathbf{C}\to\mathbf{C},\quad A_1:w\mapsto -w,$$

and the affine one,

$$I_1:\mathbf{C}\to\mathbf{C},\quad I_1:w\mapsto 1-w.$$

These involutions do not commute. Their compositions $A_1\circ I_1$ and $I_1\circ A_1$ define two reciprocal reversible dynamical systems on $\mathbf{C}$.

On the other hand, consider the following two involutions of the space $\mathbf{C}^3$: the linear one, defined by the crossing symmetry involutive matrix $A\overset{\text{def}}{=}A(l,1)$,

$$z\mapsto Az\,,\quad A=\begin{pmatrix} 1-\dfrac{(2l-1)(l+1)}{(2l+1)l} & -\dfrac{1}{l} & \dfrac{2l+3}{2l+1} \\ -\dfrac{2l-1}{(2l+1)l} & 1-\dfrac{1}{l(l+1)} & \dfrac{2l+3}{(2l+1)(l+1)} \\ \dfrac{2l-1}{2l+1} & \dfrac{1}{l+1} & 1-\dfrac{(2l+3)l}{(2l+1)(l+1)} \end{pmatrix}, \tag{4}$$

with $\det A=-1$, and the nonlinear one

$$I:\mathbf{C}^3\to\mathbf{C}^3,\quad I(z_1,z_2,z_3)=\left(\frac{1}{z_1},\frac{1}{z_2},\frac{1}{z_3}\right)$$

(the latter being the standard Cremona transformation). These involutions do not commute either. Their compositions $A\circ I$ and $I\circ A$ define a two reciprocal reversible dynamical systems on $\mathbf{C}^3$. Let us remark that the parameter $l\in\mathbf{N}$, though one can consider $l\in\mathbf{R}$.

We look for a meromorphic mapping $\mathbf{C}\to\mathbf{C}^3$ which realizes the equivalence of these two reversible dynamical systems. In other words, we seek a meromorphic mapping $S:\mathbf{C}\to\mathbf{C}^3$ satisfying the following system of functional equations (FE):

$$S(-w)=AS(w), \tag{5}$$

$$S(w+1)=I\circ AS(w), \tag{6}$$

where $w\in\mathbf{C}$. This system describes a scattering of two particles with spins equal l and 1 within the framework of the static model.

Taking liberty with speech, we will sometimes call the system of FE (5) and (6) a dynamical system (DS).

One can say that the involutions A and I of $\mathbf{C}^3$ are representations of the involutions A_1 and I_1 of $\mathbf{C}$, respectively. Meromorphic mappings $S:\mathbf{C}\to\mathbf{C}^3$ satisfying FE (5) and (6), realize these representations.

Each meromorphic mapping $S:\mathbf{C}\to\mathbf{C}^3$ defines some curve in $\mathbf{C}^3$. The system of FE (5) and (6) completely determines this curve up to the group of automorphisms. One can easily verify that every transformation of the form

$$S(w)\to S(w+\beta(w))\exp((\alpha(w-1/2)), \tag{7}$$

where

$$\beta(w+1)=\beta(w),\quad \beta(-w)=-\beta(w),$$

$$\alpha(w+1)=-\alpha(w),\quad \alpha(-w)=-\alpha(w),$$

is an automorphism of the solution space for DS (5) and (6) (β defining an inner automorphism of the curve). Obviously, there should also exist an automorphism which depends on another arbitrary function in w with a period equal to 1.

As $A^2=\mathrm{id}$, the matrix A is of a simple structure (i.e., diagonalizable):

$$A=B\Lambda^a B^{-1},\quad \Lambda^a=\mathrm{diag}(\lambda_1^a,\lambda_2^a,\lambda_3^a),\quad \lambda_1^a=-1,\quad \lambda_{2,3}^a=1, \tag{8}$$

$$B_{ij}=\mu_i^{(j)},\quad A\mu^{(j)}=\lambda_j^a\mu^{(j)},\quad i,j=1,2,3, \tag{9}$$

where B is the fundamental matrix for A in the basis of eigenvectors $\mu^{(j)}$ of the matrix A,[26] which are the following:

$$\mu^{(1)}=(-2(l+1),-2,2l),\quad \mu^{(2)}=\frac{(2l+1)(2l-1)}{4}\left(\frac{2l+3}{2l-1},-\frac{2l+3}{2l+1},1\right),\quad \mu^{(3)}=(1,1,1). \tag{10}$$

According to the general approach,[19] introduce the functions $z:\mathbf{C}\to\mathbf{C}^3$, $j:\mathbf{C}^3\to\mathbf{C}^3$, $\pi:\mathbf{C}^3\to\mathbf{C}$,

$$z(w)=B^{-1}S(w), \tag{11}$$

$$j(z)=ABz, \quad \pi(z)=\prod_{i=1}^{3} j_i(z). \tag{12}$$

Define the mapping $\Phi:\mathbf{C}^3\to\mathbf{C}^3$:

$$\Phi: z\mapsto\widetilde{z}=\Phi(z)=\phi(z)/\pi(z), \tag{13}$$

where $\phi:\mathbf{C}^3\to\mathbf{C}^3$ is the mapping

$$\phi(z)=\pi(z)B^{-1}(Ij(z)). \tag{14}$$

The DS (5) and (6) can be rewritten as

$$z(-w)=\Lambda^a z(w), \tag{15}$$

$$z(w+1)=\phi(z(w))/\pi(z(w)). \tag{16}$$

Remark 1: Note that the mapping (13) is a birational Cremona transformation in $\mathbf{C}^3$. Transformations of the form (13) with different denominators $\pi(z)$ [but the same numerator $\phi(z)$] induce the same projective Cremona transformation in $\mathbf{C}P^2$:[12]

$$\widetilde{z}_1:\widetilde{z}_2:\widetilde{z}_3=\phi_1:\phi_2:\phi_3.$$

According to (8)–(12), and taking into account that $A^2=\mathrm{id}$, we have

$$\Lambda^a=B^{-1}AB, \quad S(w)=j(\Lambda^a z(w))\overset{\text{def}}{=}j'(z(w)). \tag{17}$$

A. Partial automorphic forms

Let $m=(m_1,m_2,m_3)\in\mathbf{Z}_+^3$ be a multiindex, $m_i\in\mathbf{Z}_+$, $|m|=m_1+m_2+m_3$, where $\mathbf{Z}_+$ is a set of non-negative integral numbers.

Definition 3: A polynomial $P:\mathbf{C}^3\to\mathbf{C}$ is said to be invariant if $P(\Phi(z))=0$ whenever $P(z)=0$.

Theorem 1:[19] For any invariant irreducible homogeneous polynomial $P(z)$ of degree k there exists a multiindex m with $|m|=k$ such that $P(z)$ satisfies the following system of FE:

$$P(\phi(z))=\varepsilon P(z)j^m(z), \quad j^m=j_1^{m_1}j_2^{m_2}j_3^{m_3}, \quad \varepsilon=\pm 1, \tag{18}$$

$$P(\Lambda^a z)=\nu P(z), \quad \nu=\pm 1. \tag{19}$$

We will denote any solution of these equations by $P_m(z)$ provided that it is an irreducible homogeneous polynomial of degree $|m|$.

As the matrix Λ (4) has the only eigenvalue equal to -1, we can assume that $\nu=+1$ because for $\nu=-1$ any solution P of FE (18) and (19) will be reducible:

$$P(z)=z_1^{2n+1}\hat{P}(z), \quad \deg\hat{P}=|m|-2n-1.$$

Following Ref. 19, we shall call polynomials $P_m(z)$ the partial automorphic forms (PAF) for the DS (5) and (6) of weight $m=(m_1,m_2,m_3)$.

Definition 4: PAF $P_m(z)$ is said to be an automorphic form (AF) of weight q if

$$P_m(\Phi(z))\equiv P_m(z)J^q(z),$$

where J denotes the Jacobian of the mapping Φ (13).

One can easily verify that the Jacobian J of the mapping Φ (13) is equal to $\pi^{-2}(z)$. Indeed,

$$J=-\det\,(B^{-1}\overline{J}B\Lambda^a)=-\det\,(A\overline{J})=\pi^{-2}(z),$$

where $\overline{J}=\mathrm{diag}\,(1/j_1^2(z),\ 1/j_2^2(z),\ 1/j_3^2(z))$.

A mapping Φ has a polynomial AF of weight q if and only if it possesses a PAF of weight $m=\{q,q,q\}$. It has a rational AF of weight q if there exists a rational function of the PAF that satisfies equations (18) and (19) with $m_1=m_2=m_3=q$.

According to Ref. 17, the DS (5) and (6) with the crossing-symmetry matrix $A(1,1)$ $(l=1)$ has an AF of weight one (recall that it has three PAF) and is equivalent to an APM but it is non-algebraically integrable, i.e., it possesses a first nonalgebraic integral. From this it follows that the DS (5) and (6) with matrix (4) is not also algebraic integrable. The one has the PAF $(z_1/z_3=x,\ z_2/z_3=y)$:

$$P_{(1,1,0)}(z)=z_3z_2-z_1^2=z_3^2(y-x^2)$$

—the solution of (18) with $\varepsilon=-1$.

B. Fundamental points and principal lines of a quadratic Cremona mapping

Let $\widetilde{z}=z(w+1)$. Then, according to (17), (16), and (12) we have

$$j'(\widetilde{z})=Ij(z).$$

Consider some special points and lines on the projective plane $\mathbf{C}P^2$ of homogeneous coordinates z known from the theory of quadratic Cremona transformations. Introduce six principal lines (P-lines) J_k, J_k' $(k=1,2,3)$ of the direct mapping Φ specified by (13) and the inverse one Φ^{-1}:

$$J_k=\{z:j_k(z)=0\},\quad J_k'=\{z:j_k'(z)=0\}\quad (k=1,2,3),$$

and six points of pairwise intersections of these lines $\{O_1,O_2,O_3\}$ and $\{O_1',O_2',O_3'\}$:

$$O_i=J_k\cap J_n,\quad O_i'=J_k'\cap J_n'.$$

They are called fundamental points (F-points)[12] of the direct mapping (16) and the inverse one. Here $\{ikn\}$ is a permutation of $\{123\}$.

Under the direct mapping (16) and its inverse

$$z(w)=\frac{\Lambda^a\phi(\Lambda^a\widetilde{z})}{\pi(\Lambda^a\widetilde{z})},$$

the images of the F-points O_i, O_i' and those of the P-lines J_i, J_i' are

$$\Phi:O_i\mapsto J_i',\quad \Phi:J_i\mapsto O_i',\quad \Phi^{-1}:O_i'\mapsto J_i,\quad \Phi^{-1}:J_i'\mapsto O_i.$$

Thus, the F-points and P-lines $\{O_i,J_i\}$ and $\{O_i',J_i'\}$ are the only elements of the mapping (16) where the one-to-one correspondence is violated.

Notice that the mappings Φ and Φ^{-1} realize blowing up and contraction (see the Codaira theorem, Ref. 27, Ch. 1, §4) and also the concept of σ-process of blowing up of singularities in the theory of ordinary differential equations (Ref. 28, §2).

The F- and P-elements have the form

$$J_i=\{z:j_i(z)=\mu_i^{(k)}\lambda_k^{(a)}z_k=0\},\quad J_i'=\{z:j_i'(z)=\mu_i^{(k)}z_k=0\},$$

$$O_1=\left(\frac{2}{2l-1},\frac{4}{(2l-1)^2},1\right),\quad O_2=\left(\frac{2}{4l^2+4l-1},-\frac{4}{4l^2+4l-1},1\right),\tag{20}$$

$$O_3=\left(-\frac{2}{2l+3},\frac{4}{(2l+3)^2},1\right),\quad O_i'=\Lambda^a O_i\,.$$

Remark 2: Similarly to Refs. 17 and 21, the multiindex $m=(m_1,m_2,m_3)$ has the meaning of multiplicities m_i of the algebraic invariant curve $P_m(z)=0$ at the F-points O_i [see (18) and (19)], and, consequently, at the points O_i', according to the symmetry of (19).

C. Structure of the general solution

Let us proceed from homogeneous projective coordinates $z(w)\in\mathbf{C}^3$ to the coordinates

$$(x_1(w),x_2(w),z_3(w)),\quad x_i=\frac{z_i}{z_3}\quad (i=1,2),\quad x(w)=(x_1(w),x_2(w))\in\mathbf{C}^2. \tag{21}$$

Then instead of (15) and (16) we obtain

$$x_i(-w)=\Lambda_{ii}^a x_i(w)\quad (i=1,2),\quad z_3(-w)=z_3(w), \tag{22}$$

$$x_i(w+1)=\frac{\phi_i(xz_3,z_3)}{\phi_3(xz_3,z_3)}\overset{\text{def}}{=}f_i(x)\quad (i=1,2),\quad z_3(w+1)=\Phi_3(xz_3,z_3), \tag{23}$$

where ϕ_i and Φ_3 are defined by (8)–(14) and are (below and in the sequel, we set $x_1\equiv x$, $x_2\equiv y$)

$$\phi_1(x,1)=x+3x^2-\frac{4l^2+4l-11}{4}xy-\frac{(2l+3)(2l-1)}{4}y^2, \tag{24}$$

$$\phi_2(x,1)=-y+2x^2+2xy-\frac{(2l-1)(2l+3)}{4}y^2, \tag{25}$$

$$\phi_3(x,1)=1+4x+\frac{4l^2+4l+5}{4}y-\frac{4l^2+4l-9}{2}x^2-\frac{4l^2+4l-7}{2}xy-\frac{(2l+3)(2l-1)}{4}y^2. \tag{26}$$

The following theorem on the structure of the general solution of the FE (22) and (23) is valid.

Theorem 2: The general solution of FE (22) and (23) has the form

$$x(w)=\frac{2(F(w+\frac{1}{2})+F(w-\frac{1}{2}))}{2(l-1)-(2l-3)(F(w+\frac{1}{2}-F(w-\frac{1}{2}))+4F(w+\frac{1}{2})F(w-\frac{1}{2})},$$
$$y(w)=(2l-1)^{-1}\frac{4(2(l-1)+F(w+\frac{1}{2})-F(w-\frac{1}{2}))}{2(l-1)-(2l-3)(F(w+\frac{1}{2})-F(w-\frac{1}{2}))+4F(w+\frac{1}{2})F(w-\frac{1}{2})}, \tag{27}$$

where the meromorphic function $F(w)$ is a solution of the functional equations $[F''=F(w+2),F'=F(w+1),F=F(w)]$

$$F''=\frac{2(l-1)^2(2l+3)+(l-1)(2l^2+l-5)F-2(4l-1)F'^2+2FF'-(2l-1)FF'^2}{(l-1)(2l^2+l-5)-2F'-4(l-1)F-(2l-1)F'^2}, \tag{28}$$

$$F(-w)=-F(w). \tag{29}$$

Proof: Introduce the quadratic Cremona mapping casting the functions $x(w),y(w)$ to $u_1(w),u_2(w)$:

$$u_1=\frac{y-4/(2l-1)^2}{y-[2/(2l-1)]x},\quad u_2=\frac{y-4/(2l-1)^2}{y+[2/(2l-1)]x}. \tag{30}$$

The inverse mapping is single valued and has the form

$$x=\frac{2}{2l-1}\,\frac{u_1-u_2}{u_1+u_2-2u_1u_2},\quad y=\frac{4}{(2l-1)^2}\,\frac{u_1+u_2}{u_1+u_2-2u_1u_2}. \tag{31}$$

Using (30), (31), and (24)–(26) one can obtain a simpler expression for the system (23):

$$u_1(w+1)=\frac{(4l(2l+1)u_1+4u_2-(2l-1)^2u_1u_2)(4(l-1)/(2l-1)-u_1)}{4l(2l-3)u_1+8(l-1)u_2-(2l-1)^2u_1^2},$$

$$u_2(w+1)=\frac{4(l-1)}{2l-1}-u_1, \tag{32}$$

where on the right-hand side we have set $u_1=u_1(w)$, $u_2=u_2(w)$. According to (22) an (30) we have

$$u_1(w)=u_2(-w). \tag{33}$$

Substituting (33) into the second equation of (32) and assuming

$$u_2(w)=\frac{2(l-1)}{2l-1}-\frac{2}{2l-1}\,F(w-1/2), \tag{34}$$

we obtain (29). Equations (31), (33), and (34) imply (27). Substituting (33) and (34) into the first equation of (32) we obtain Eq. (28) for $F(w)$.

This equation has a particular solution $F(w)=w$ corresponding to particular rational solution for $S(w)$ in Ref. 16.

III. INTEGRATION OF THE EQUATION FOR THE FUNCTION $F(w)$

Let $F(w-1)=u(w)$, $F(w)=v(w)$, and consider the mapping T corresponding to Eq. (28) for $F(w)[\widetilde{U}=(\widetilde{u},\widetilde{v})=(u(w+1),v(w+1)),U=(u,v)]$:

$$T:\widetilde{U}=T(U),\quad \widetilde{u}=v,$$

$$\widetilde{v}=\frac{2(l-1)^2(2l+3)+(l-1)(2l^2+l-5)u-2(4l-1)v^2+2uv-(2l-1)uv^2}{(l-1)(2l^2+l-5)-2v-4(l-1)u-(2l-1)v^2}. \tag{35}$$

The mapping T is reversible since it can be represented in the form $T=R\circ W$, where R and W are involutions:

$$R:U'=R(U),\quad u'=-u,$$

$$v'=\frac{2(l-1)^2(2l+3)-(l-1)(2l^2+l-5)v-2(4l-1)u^2+2uv+(2l-1)vu^2}{(l-1)(2l^2+l-5)+2v+4(l-1)v-(2l-1)u^2}; \tag{36}$$

$$W:U'=W(U),\quad u'=-v,\quad v'=-u.$$

Besides the parabolic fixed point $d_1:u=v=\infty$, the mapping (35) has two symmetrical hyperbolic fixed points

$$d_2:u=v=(l-1)\sqrt{\frac{2l+3}{2l-l}},\quad d_3:u=v=-(l-1)\sqrt{\frac{2l+3}{2l-1}}, \tag{37}$$

$$R(d_2)=d_3,\quad R(d_3)=d_2,\quad W(d_2)=d_3,\quad W(d_3)=d_2. \tag{38}$$

The eigenvalues λ_1,λ_2 of the linear part of the mapping (35) at the fixed point d_2 of (37) and λ_3,λ_4 at d_3 are the roots of fundamental polynomial $P_4(\lambda)$ of algebraic number λ:

$$\lambda_{1,2}=\frac{2\sqrt{(2l+3)(2l-1)}\pm\sqrt{3(2l+3)(2l-1)+1}}{\sqrt{(2l+3)(2l-1)}+1} \quad (+ \text{ for } \lambda_1); \quad \lambda_3=\lambda_1^{-1}, \quad \lambda_4=\lambda_2^{-1}. \tag{39}$$

Notice that the numbers λ_i are called conjugate algebraic numbers (see Ref. 29). The eigenvalues λ_1,λ_2 of the mapping (35) at d_2 for $l\in\mathbf{N}$ belong to Siegel's domain $(0<\lambda_2<1<\lambda_1)$. The same holds for the eigenvalues λ_3,λ_4.

Theorem 3: The set of eigenvalues λ_1,λ_2 at the fixed point d_2 and the set λ_3,λ_4 at the fixed point d_3 (39) are not resonant, i.e.,

$$\lambda_j-\lambda_1^{m_1}\lambda_2^{m_2}\neq 0 \quad \text{for } j=1,2 \quad \text{and } |m|=m_1+m_2\geqslant 2,\ m_i\in\mathbf{Z}_+,$$

$$\lambda_j-\lambda_3^{m_1}\lambda_4^{m_2}\neq 0 \quad \text{for } j=3,4 \quad \text{and } |m|=m_1+m_2\geqslant 2,\ m_i\in\mathbf{Z}_+.$$

Proof: We have to prove that algebraic numbers $\chi_1=1-\lambda_1^{m_1-1}\lambda_2^{m_2}$ and $\chi_2=1-\lambda_1^{m_1}\lambda_2^{m_2-1}$ are not equal to zero for any integers m_1 and m_2, $|m|\geqslant 2$. Consider the number χ_1. As $\lambda_1,\lambda_2\in\mathbf{Q}(\sqrt{N_1},\sqrt{N_2})$, $N_1=(2l+3)(2l-1)$ and $N_2=3(2l+3)(2l-1)+1$, a quadratic extension of the rational number field (Ref. 29, see §17), then χ_1 belongs to $\mathbf{Q}(\sqrt{N_1},\sqrt{N_2})$ and has relative degree $\leqslant 4$. The equality $\chi_1=0$ implies $\chi_1\in\mathbf{Q}(\sqrt{N_1})$. Since $\lambda_{1,2}=R_1\pm R_2\sqrt{N_2}$, where $R_1,R_2\in\mathbf{Q}(\sqrt{N_1})$, then, obviously, $\chi_1\in\mathbf{Q}(\sqrt{N_1})$ if and only if $m_2=m_1-1$. Let $m_2=m_1-1$. Then $\chi_1=1-((N_1+1-2\sqrt{N_1})/(N_1-1))^{m_2}$. It is clear that for $|m|=2m_2+1\geqslant 2$ $(m_2\geqslant 1)$ one has $\chi_1\notin\mathbf{Q}$ and, consequently, $\chi_1\neq 0$. Analogously, one can prove that $\chi_2\neq 0$. It is obvious that also the set λ_3,λ_4 is nonresonant at the fixed point d_3. ◁

The problem of linearization of the mapping (35) will be solved on the basis of the following Siegel theorem.

Definition 5: A set $(\lambda_1,\ldots,\lambda_n)\in\mathbf{C}^n$ is of the multiplicative type (C,ν), if the following inequality,

$$|\lambda_j-\lambda^m|\geqslant C|m|^{-\nu}, \quad (|m|=m_1+\cdots+m_n, \quad \lambda^m=\lambda_1^{m_1}\cdots\lambda_n^{m_n}), \tag{40}$$

is satisfied for all $j\in(1,2,\ldots,n), m_i\in\mathbf{Z}_+, |m|\geqslant 2$ $(C>0,\nu>0)$.

Theorem 4: [C. L. Siegel for $n=1$, E. Zehnder's generalization for $n>1$ (Ref. 30).] If the set $\{\lambda\}$ of eigenvalues of the linear part of a mapping, holomorphic near a fixed point, is of the multiplicative type (C,ν) for some $C>0$, $\nu>0$, then the mapping is biholomorphically equivalent to its linear part in some neighborhood of the fixed point (see Ref. 28, §28).

The following theorem on sets $\{\lambda\}$ of the multiplicative type (C,ν) is valid.[18]

Theorem 5: (See Ref. 18.) A set $(\lambda_1,\ldots,\lambda_n)\in\mathbf{C}^n$ is of the multiplicative type (C,ν), if this set is multiplicatively nonresonant and numbers $\lambda_j\in\mathbf{A}$, where $\mathbf{A}$ is an algebraic number field.

This theorem is a corollary of the Feldman theorem (Ref. 31 see chapter 10, §4.10) about the evaluation of linear forms of the logarithms of algebraic numbers.

Now we can make a general proposition about the solutions of Eqs. (28) and (29) for the function $F(w)$, defining the general solution (27) of the initial FE (23).

Theorem 6: The function $F_\delta(w)$, as a function of a one-parametric family of solutions of the system (28) and (29), is in certain finite neighborhoods of the origin in C^2, a holomorphic, function of variables z_1, z_2 or z_3, z_4:

$$z_i(w)=\delta(w)\exp((w+\beta(w)-\tfrac{1}{2})\ln\lambda_i), \quad 1\leqslant i\leqslant 4, \tag{41}$$

where λ_i are determined by (39) while arbitrary functions $\delta(w)$ and $\beta(w)$ [cf. (7)] have the following properties:

$$\begin{aligned}&\delta(-w)=\delta(w), \quad \delta(w+1)=\delta(w),\\ &\beta(-w)=-\beta(w), \quad \beta(w+1)=\beta(w).\end{aligned} \tag{42}$$

The family $F_\delta(w)$ is defined by the Taylor expansion in z_1, z_2,

$$F(w)=\sum_k f_k z^k, \quad k\in \mathbf{Z}_+^2, \quad f_k=f_{k_1,k_2}, \quad z^k=z_1^{k_1}z_2^{k_2}, \tag{43}$$

with the coefficients f_k determined by the recurrent relation

$$\begin{aligned} f_k=\Bigg\{ \sum_{|m|=1}^{|k|-1} f_{k-m}\Big[&(-((2l-1)f_0+1)\lambda^{2k-m}+((2l-1)f_0-1)\lambda^m-2(l-1)\lambda^{2k-2m} \\ &+(4l-1)\lambda^k)f_m-(2l-1)/2(\lambda^{2k-m}-\lambda^m)\sum_{|l|=1}^{|m|-1} f_{m-1}f_l\Big]\Bigg\} \\ &\times[((2l-1)f_0+l-1)(\lambda^k-\lambda_1)(\lambda^k-\lambda_2)]^{-1}, \end{aligned} \tag{44}$$

where $\lambda^k=\lambda_1^{k_1}\lambda_2^{k_2}$, $f_0=(l-1)\sqrt{(2l+3)/(2l-1)}$, $f_{0,1}$ and $f_{1,0}$ are arbitrary, and the sum is taken over all permissible values. The coefficients $\tilde{f}_k$ of the Taylor expansion of F in z_3, z_4 satisfy the same recurrent relation with λ_1, λ_2 replaced by λ_3, λ_4 and they are

$$\tilde{f}_0=-(l-1)\sqrt{\frac{2l+3}{2l-1}}, \quad \tilde{f}_{0,1}=-\lambda_3 f_{0,1}, \quad \tilde{f}_{1,0}=-\lambda_4 f_{1,0}, \quad \tilde{f}_k=-f_k/\lambda^k.$$

Each local solution of the family $F_\delta(w)$ (the germ), defined by (41)–(44), can be extended up to the global one by using $F_\delta(w)$, $F_\delta(w-1)$, and iterations of Eq. (28), and lies on the invariant manifold Γ_δ

$$\Gamma_\delta: z_1^{\gamma_1}(w+1)z_2^{\gamma_2}(w+1)=z_1^{\gamma_1}(w)z_2^{\gamma_2}(w)=\delta^2(w), \tag{45}$$

where

$$\gamma_1=\frac{-2\ln\lambda_2}{\ln\lambda_1-\ln\lambda_2}, \quad \gamma_2=\frac{2\ln\lambda_1}{\ln\lambda_1-\ln\lambda_2}.$$

Proof: According to Theorems 3 and 5, the set (λ_1,λ_2) from (39) of the eigenvalues of the mapping T of (35) at the hyperbolic fixed point d_2 given by (37) is of the multiplicative type (C,ν). Therefore, Theorem 4 guarantecs the existence of a biholomorphic mapping $U=G(z)$, $U=(u,v)$, $z=(z_1,z_2)$, and $G(0)=d_2$, which transforms a neighborhood of the origin in $\mathbf{C}^2$ to a neighborhood of the point d_2 and reduces the mapping T to the normal form at d_2:

$$G^{-1}TG:(z_1,z_2)\mapsto(\lambda_1 z_1,\lambda_2 z_2).$$

On the other hand, the biholomorphic mapping WG, where W is involution (36), transforms a neighborhood of the origin in $\mathbf{C}^2$ to a neighborhood of the point d_3 of (37) and reduces the mapping T to the normal form at d_3:

$$G^{-1}WTWG:(z_3,z_4)\mapsto(\lambda_3 z_3,\lambda_4 z_4).$$

Indeed, since involution W reverses mapping T, the mappings $G^{-1}TG$ and $G^{-1}WTWG$ are inverse to each other.

Set $(z_3,z_4)=\zeta$ and

$$G(z)=(g_1(z),g_2(z)), \quad WG(\zeta)=(-g_2(\zeta),-g_1(\zeta)).$$

If some functions $z_i(w)$, $1\leqslant i\leqslant 4$, satisfy FE

$$z_i(w+1)=\lambda_i z_i(w), \tag{46}$$

the functions $F(w)=g_2(z(w))$ or $F(w)=-g_1(\zeta(w))$ satisfy FE (28). Morcover, one will have $g_1(z(w))=F(w-1)$ or $-g_2(\zeta(w))=F(w-1)$, respectively.

Now we should determine the relations between $z(w)$ and $\zeta(w)$ which make $F(w)$ satisfy FE (29), i.e., make $F(w)$ odd. Let $F(w)=g_2(z(w))$ be close to $1/\sqrt{2}$. Then, we have $F(-w)=-g_2(\zeta(1-w))$. The equality $F(-w)=-F(w)$ is therefore ensured by

$$\zeta(1-w)=z(w). \tag{47}$$

If

$$z_i(w)=\delta_i(w)\exp((w+\alpha_i)\ln\lambda_i), \quad 1\leqslant i\leqslant 4, \tag{48}$$

then (46) is equivalent to $\delta_i(w+1)=\delta_i(w)$ and (47) is equivalent to $\zeta(w)=\Lambda z(-w)$, where $\Lambda=\mathrm{diag}(\lambda_1,\lambda_2)$, i.e.,

$$\delta_{i+2}(-w)=\lambda_i\delta_i(w)\ \exp\ ((\alpha_i+\alpha_{i+2})\ln\lambda_i), \quad i=1,2.$$

For $\alpha_i=-1/2(1\leqslant i\leqslant 4)$ we have

$$\delta_3(-w)=\delta_1(w), \quad \delta_4(-w)=\delta_2(w). \tag{49}$$

Equations (46) and (48) result in the existence of the invariant manifold Γ_δ [cf. (45)],

$$\Gamma_\delta:\tilde{z}_1^{\gamma_1}\tilde{z}_2^{\gamma_2}=z_1^{\gamma_1}z_2^{\gamma_2}=\delta^2(w), \quad \tilde{z}_3^{\gamma_3}\tilde{z}_4^{\gamma_4}=z_3^{\gamma_3}z_4^{\gamma_4}=\delta^2(w), \tag{50}$$

where $\tilde{z}\equiv z(w+1)$, and exponents γ_1, γ_2 are determined by (45) and are invariant relative to the change $\lambda_1,\lambda_2\to\lambda_3,\lambda_4$. Substituting (48) and (49) into (50) we have

$$\delta_1^{\gamma_1}(w)\,\delta_2^{\gamma_2}(w)=\delta^2(w), \quad \delta_1^{\gamma_1}(-w)\,\delta_2^{\gamma_2}(-w)=\delta^2(w). \tag{51}$$

From (51) we have

$$\left(\frac{\delta_1(w)}{\delta_1(-w)}\right)^{\gamma_1}\left(\frac{\delta_2(w)}{\delta_2(-w)}\right)^{\gamma_2}=1. \tag{52}$$

Since $\delta_i(w+1)=\delta_i(w)$ and supposing

$$\frac{\delta_i(w)}{\delta_i(-w)}=\exp\ (\beta_i(w)\ln\lambda_i), \quad i=1,2, \tag{53}$$

we obtain from (52)

$$\exp\ [(-\beta_1(w)+\beta_2(w))\ \ln\lambda_1\ \ln\lambda_2]=1. \tag{54}$$

From (52)–(54) it follows that

$$\beta_1(w)=\beta_2(w)=2\beta(w), \tag{55}$$

where $\beta(w)$ is odd function with period equal to 1 [cf. (42)]. From (53) and (55) we have

$$\delta_i(w)=\delta(w)\ \exp\ (\beta(w)\ \ln\lambda_i), \quad \delta(-w)=\delta(w),$$

and we obtain (41) and (42).

Finally, let

$$F(w)=g_2(z(w))=\sum_k\ f_k(z(w))^k$$

for $F(w)$ close to $1/\sqrt{2}$ and

$$F(w)=-g_1(\zeta(w))=\sum_k \tilde{f}_k(\zeta(w))^k$$

for $F(w)$ close to $-1/\sqrt{2}$. Substituting these expansions into (28), we derive the desired recurrent relations on f_k and $\tilde{f}_k$. The arbitrariness in the choice of $f_{1,0}$ and $f_{0,1}$ corresponds to the ambiguity in the choice of the normalizing mapping G. ◁

Let us consider Eq. (28) at $l=-3/2$. It has the form

$$F''=\frac{5F+14F'^2+2FF'+4FF'^2}{5-2F'+10F+4F'2} \tag{56}$$

and admits a reduction of the order of (56):

$$\Phi(F'',F')=\Phi(F',F)+1, \quad \Phi(F',F)=\frac{2F'F+(5F'-7F-5)/2}{F'+F}. \tag{57}$$

It follows from (57) that $\Phi(F',F)=w+\beta(w)$ and we have the equation of lower order for the function $F(w)$ [we omit below $\beta(w)$]:

$$F(w+1)=\frac{(w+7/2)F(w)+5/2}{2F(w)-w+5/2}. \tag{58}$$

The general solution of (58) has the form

$$F(w)=w\,\frac{f(w)-1}{f(w)+1}, \quad f(-w)=f(w), \tag{59}$$

where the function $f(w)$ has the form

$$f(w)=\frac{(w^2-1/4)(w^2-9/4)}{w}\left(p\left(\frac{w+1/2}{2}\right)-p\left(\frac{w-1/2}{2}\right)+\gamma\left(\frac{w+1/2}{2}\right)\right),$$

$$p(w)=\tfrac{1}{2}\,(\Psi(w)+\Psi(-w))+\tfrac{1}{2}\,(\Psi(w+1/2)+\Psi(-w+1/2)),$$

where

$$\gamma(-w)=\gamma(w), \quad \gamma(w+1/2)=-\gamma(w).$$

The function $\Psi(z)\overset{\text{def}}{=}d/dz\,\ln\Gamma(z)$ is a solution of functional equation

$$\Psi(z+1)-\Psi(z)=\frac{1}{z}.$$

Schlesinger–Bäcklund transformations for the *N*-component KP

Johan van de Leur[a)]
Faculty of Applied Mathematics, University of Twente,
P.O. Box 217, 7500 AE Enschede, The Netherlands

(Received 22 April 1997; accepted for publication 21 January 1998)

The n-component Kadomtsev–Petviashvili (KP) hierarchy was introduced by Sato as the set of deformation equations, i.e., Lax equations, of $n+1$ $n\times n$-matrix pseudodifferential operators. On such a set of operators we define a Schlesinger–Bäcklund transformation, which produces from a set of solutions of the KP hierarchy a new set of solutions. Applying such transformations recursively we obtain a whole family of solutions, from which we can then derive the KP tau function.

I. INTRODUCTION AND FORMULATION OF THE PROBLEM

The n-component Kadomtsev–Petviashvili (KP) hierarchy was introduced by Sato in Ref. 1 (see also Refs. 2, 3) as the set of deformation equations, also called Lax equations ($i,j=1,2,...,n,\ k=1,2,...$),

$$\frac{\partial L}{\partial t_k^{(i)}}=[(L^kC^{(i)})_+,L],$$
$$\frac{\partial C^{(j)}}{\partial t_k^{(i)}}=[(L^kC^{(i)})_+,C^{(j)}], \tag{1.1}$$

of the $n\times n$-matrix pseudodifferential operators,

$$L\equiv L(x,t,\partial)=I_n\partial+U^{(1)}(x,t)\partial^{-1}+U^{(2)}(x,t)\partial^{-2}+\cdots,$$
$$C^{(j)}\equiv C^{(j)}(x,t,\partial)=E_{jj}+C^{(j1)}(x,t)\partial^{-1}+C^{(j2)}(x,t)\partial^{-2}+\cdots, \tag{1.2}$$

which satisfy the conditions

$$LC^{(j)}=C^{(j)}L,\quad C^{(i)}C^{(j)}=\delta_{ij}C^{(i)},\quad \sum_{i=1}^{n}C^{(i)}=I_n. \tag{1.3}$$

Here $\partial=\partial/\partial x$, $t=\{t_k^{(i)}|1\leqslant i\leqslant n,\ k=1,2,...\}$ and the coefficients $U^{(k)}$ and $C^{(jk)}$ are formal power series over $\mathbb{C}$ in the indeterminates x and t. $(A)_+$ stands for the differential part of a pseudodifferential operator A. The multiplication of pseudodifferential operators is given by

$$A(x,t)\partial^k\circ B(x,t)\partial^{-l}=\sum_{m=0}^{\infty}\binom{k}{m}A(x,t)\,\frac{\partial^m B(x,t)}{\partial x^m}\,\partial^{k-m-l},\quad k\in\mathbb{Z}.$$

The n-component KP hierarchy contains many of the well-known partial differential equations, e.g., the classical Kadomtsev–Petviashvili ($n=1$), Davey–Stewartson ($n=2$), and the n-wave interaction equations ($n\geqslant 3$).

Starting from the level 1 representation theory of the infinite matrix group GL_∞, Kac and the author[4] and, independently, Bergvelt and ten Kroode[5] showed that with every element τ of the

[a)]Electronic mail: vdleur@math.utwente.nl

 © 1998 American Institute of Physics

GL_∞-group orbit of the highest weight vector there exists a whole family of solutions $L(\alpha)$, $C^{(j)}(\alpha)$ of (1.1). These solutions are parametrized by the root lattice $\mathfrak{L}$ of sl_n, i.e., $\alpha \in \mathfrak{L}$.

Inspired by these articles, we want to consider the following problem in this paper. Suppose one has one nontrivial set of solutions L, $C^{(j)}$ $(1 \leqslant j \leqslant n)$, of the KP hierarchy. Is it then possible to find the corresponding tau function? So, does one such solution contain enough information? One can solve this problem using the geometry, i.e., Sato's infinite Grassmannian. However, this is, in general, not so simple. In this paper we want to give an algebraic and recursive approach. So, in order to solve this problem, one first has to find a whole family of such pseudodifferential operators that are all separate solutions of the KP hierarchy. To achieve such a result, we define a Schlesinger–Bäcklund transformation, which produces from a solution of (1.1) a new solution of (1.1). Applying such transformations recursively we obtain a whole family of solutions of (1.1), from which we can then destilate, with some restrictions, the τ function. For this construction, it will be convenient to formulate the KP hierarchy in terms of the Sato equation.

For more information on n-component KP and on some of the ideas used in this paper, we refer the reader to Ref. 4.

II. THE WAVE FUNCTION AND THE SATO EQUATION

The n-component KP hierarchy can be seen as the integrability or compatibility conditions for a linear problem. A formal oscillating function,

$$W(x,t,z) = \sum_{k=0}^{\infty} W^{(k)}(x,t) z^{-k} e^{\Xi(t,z)} e^{xz},$$

with (2.1)

$$\Xi(t,z) = \sum_{j=1}^{n} \left(\sum_{k=1}^{\infty} t_k^{(j)} z^k E_{jj} \right),$$

and $W^{(0)}(x,t) = I_n$, is called a wave function for the set of pseudodifferential operators L and $C^{(j)}$ $(1 \leqslant j \leqslant n)$ of the form (1.2) satisfying (1.3), if it satisfies the following set of linear equations:

$$LW = Wz, \quad C^{(j)}W = WE_{jj}, \quad \frac{\partial W}{\partial t_k^{(j)}} = (L^k C^{(j)})_+ W. \tag{2.2}$$

We rewrite (2.1) as follows:

$$W(x,t,z) = P(x,t,\partial) e^{\Xi(t,\partial)} e^{xz},$$

with

$$P \equiv P(x,t,\partial) = I_n + \sum_{k=1}^{\infty} W^{(k)}(x,t) \partial^{-k}. \tag{2.3}$$

Denote by A_+ (resp., $A_- = A - A_+$) the purely differential (resp., negative) part of a pseudodifferential operator A. Then clearly one has the following.

Proposition 2.1: One can find a wave function of the form (2.1) for the set of pseudodifferential operators L, $C^{(j)}$, $1 \leqslant j \leqslant n$ of the form (1.2), which satisfy (2.3) if and only if we can find an operator P of the form (2.3), which satisfies the following set of equations:

$$LP = P\partial, \quad C^{(j)}P = PE_{jj}, \quad \frac{\partial P}{\partial t_k^{(j)}} = -(L^k C^{(j)})_- P. \tag{2.4}$$

This proposition is intimately related to the Zakharov–Shabat dressing method, viz. from (2.4) we deduce that $L = P\partial P^{-1}$, $C^{(j)} = PE_{jj}P^{-1}$, and hence the last equation of (2.4) can be rewritten as

$$\frac{\partial P}{\partial t_k^{(j)}} = -(P\partial^k E_{jj} P^{-1})_- P. \tag{2.5}$$

This equation is called the Sato equation.

Proposition 2.2: Let L and $C^{(j)}$, $1 \leqslant j \leqslant n$, be of the form (1.2), satisfying (1.3). Then the equations (2.4) have a solution P of the form (2.3) if and only if L and $C^{(j)}$, $1 \leqslant j \leqslant n$, satisfy (1.1). Such a P is unique up to multiplication on the right by a pseudodifferential operator of the form

$$D(\partial) = I_n + \sum_{j=1}^{\infty} A_j \partial^{-j}, \tag{2.6}$$

where the A_j are matrices over $\mathbb{C}$.

Proof: Given L and $C^{(j)}$'s, the equations (2.4) reduce to infinitely many ordinary differential equations of the form

$$\frac{\partial W^{(j)}}{\partial x} E_{ii} = \text{linear combination of } \frac{\partial^l W^{(k)}}{\partial x^l}, \quad \text{with } k+l<j,$$

$$\frac{\partial W^{(j)}}{\partial t_m^{(i)}} = \text{linear combination of } \frac{\partial^l W^{(k)}}{\partial x^l}, \quad \text{with } k+l<j,$$

with coefficient scalar multiples of the coefficients of the $LC^{(i)}$. These equations can be solved recursively. Uniqueness up to multiplication on the right by elements $D(\partial)$ of the form (2.6) is clear. The converse is obvious, $L = P\partial P^{-1}$, $C^{(j)} = PE_{jj}P^{-1}$, and the Lax equation (1.1) follows then immediately from the Sato equation. □

Notice that from the first Lax equations (1.1) and the first Sato equations (2.5), i.e., $k=1$, we deduce that

$$\sum_{i=1}^{n} \frac{\partial L}{\partial t_1^{(i)}} = \frac{\partial L}{\partial x}, \quad \sum_{i=1}^{n} \frac{\partial C^{(j)}}{\partial t_1^{(i)}} = \frac{\partial C^{(j)}}{\partial x}, \quad \sum_{i=1}^{n} \frac{\partial P}{\partial t_1^{(i)}} = \frac{\partial P}{\partial x}. \tag{2.7}$$

Using the Sato equation we calculate explicitly

$$\frac{\partial W_{ij}^{(1)}}{\partial t_1^{(k)}} = W_{ik}^{(1)} W_{kj}^{(1)} - \delta_{jk} W_{ij}^{(2)} + \delta_{ik}\left(\frac{\partial W_{ij}^{(1)}}{\partial x} + W_{ij}^{(2)} - \sum_{l=1}^{n} W_{il}^{(1)} W_{lj}^{(1)} \right). \tag{2.8}$$

III. THE SCHLESINGER–BÄCKLUND TRANSFORMATION

Let P be of the form (2.3) satisfying the Sato equation (2.5) and let $L = P\partial P^{-1}$, $C^{(j)} = PE_{jj}P^{-1}$, $1 \leqslant j \leqslant n$, then the equations (1.1), (1.3), and (2.4) clearly hold. Suppose that the coefficient $W_{ij} := W_{ij}^{(1)} = C_{ij}^{(j1)} \neq 0$. Inspired by Proposition 3.3 of Ref. 4 and the articles of Refs. 5 and 6, we define the following differential operator, which we call a Schlesinger–Bäcklund operator for P or for the set $\{L, C^{(1)}, \ldots, C^{(n)}\}$:

$$Q(i,j;P) = \epsilon_{ij}\left(\left(\partial - \frac{\partial \log W_{ij}}{\partial t_1^{(i)}} \right) E_{ii} - \frac{1}{W_{ij}} E_{ji} - \sum_{k \neq i} W_{ik} E_{ik} \right) + \sum_{k \neq i,j} \epsilon_{ki}\epsilon_{kj}\left(E_{kk} - \frac{W_{kj}}{W_{ij}} E_{ki} \right). \tag{3.1}$$

Here ϵ_{ij} is defined by

$$\epsilon_{ij} = \begin{cases} 1, & \text{if } i \leqslant j. \\ -1, & \text{if } i > j. \end{cases}$$

Lemma 3.1: The Schlesinger–Bäcklund operator $Q(i,j;P)$ is invertible; its inverse is

$$Q(i,j;P)^{-1}=\epsilon_{ij}\Bigg(\Bigg(-\partial-\frac{\partial\log W_{ij}}{\partial t_1^{(j)}}\Bigg)E_{jj}-\frac{1}{W_{ij}}E_{ji}-\sum_{k\neq j}W_{kj}E_{kj}\Bigg)+\sum_{k\neq i,j}\epsilon_{ki}\epsilon_{kj}\Bigg(E_{kk}-\frac{W_{ik}}{W_{ij}}E_{jk}\Bigg). \tag{3.2}$$

Proof: Multiply $Q(i,j;P)$ on the left (or on the right) by the right-hand side of (3.2). A straightforward calculation using the equations (2.8) then shows that this product is the identity matrix. □

Define the constant pseudodifferential operator,

$$R(ij)=\epsilon_{ij}(\partial E_{ii}-\partial^{-1}E_{jj})+\sum_{k\neq i,j}\epsilon_{ki}\epsilon_{kj}E_{kk}. \tag{3.3}$$

We now calculate the coefficients of $\widetilde{P}:=Q(i,j;P)PR(i,j)^{-1}=\Sigma_l\widetilde{W}^{(l)}\partial^{-l}$ explicitly. One obtains $1\leqslant p,\ k\leqslant n,\ k\neq i,j$:

$$\begin{aligned}
\widetilde{W}_{ip}^{(l)}&=\epsilon_{ij}\epsilon_{pi}\epsilon_{pj}\Bigg(W_{ip}^{(l+1+\delta_{pj}-\delta_{pi})}+\frac{\partial W_{ip}^{(l+\delta_{pj}-\delta_{pi})}}{\partial x}\\
&\quad-W_{ip}^{(l+\delta_{pj}-\delta_{pi})}\frac{\partial\log W_{ij}^{(1)}}{\partial t_1^{(i)}}-\sum_{r\neq i}W_{ir}^{(1)}W_{rp}^{(l+\delta_{pj}-\delta_{pi})}\Bigg),\\
\widetilde{W}_{jp}^{(l)}&=-\epsilon_{ij}\epsilon_{pi}\epsilon_{pj}\frac{W_{ip}^{(l+\delta_{pj}-\delta_{pi})}}{W_{ij}^{(1)}},\\
\widetilde{W}_{kp}^{(l)}&=\epsilon_{ki}\epsilon_{kj}\epsilon_{pi}\epsilon_{pj}\Bigg(W_{kp}^{(l+\delta_{pj}-\delta_{pi})}-\frac{W_{kj}^{(1)}W_{ip}^{(l+\delta_{pj}-\delta_{pi})}}{W_{ij}^{(1)}}\Bigg).
\end{aligned} \tag{3.4}$$

From this it is easy to deduce that $\widetilde{P}$ is again of the form (2.3). The proof of the following Lemma is less straightforward.

Lemma 3.2: If P satisfies the Sato equation then so does $\widetilde{P}$, i.e.,

$$\frac{\partial\widetilde{P}}{\partial t_k^{(i)}}=-(\widetilde{P}\partial^kE_{ii}\widetilde{P}^{-1})_-\widetilde{P}.$$

Proof: We calculate

$$\begin{aligned}
\frac{\partial\widetilde{P}}{\partial t_k^{(i)}}\widetilde{P}^{-1}&=\frac{\partial Q(i,j;P)}{\partial t_k^{(i)}}Q(i,j;P)^{-1}+Q(i,j;P)\frac{\partial P}{\partial t_k^{(i)}}P^{-1}Q(ij;P)^{-1}\\
&=\frac{\partial Q(i,j;P)}{\partial t_k^{(i)}}Q(i,j;P)^{-1}-Q(i,j;P)(P\partial^kE_{ii}P^{-1})_-Q(i,j)^{-1}.
\end{aligned}$$

Now clearly the Sato equation holds if the following equation holds:

$$\begin{aligned}
\frac{\partial Q(i,j;P)}{\partial t_k^{(i)}}Q(i,j;P)^{-1}&=-Q(i,j;P)\frac{\partial P}{\partial t_k^{(i)}}P^{-1}Q(ij;P)^{-1}\\
&\quad-(Q(i,j;P)P\partial^kE_{ii}P^{-1}Q(i,j;P)^{-1})_-.
\end{aligned} \tag{3.5}$$

Denote for simplicity of notation,

$$-\frac{\partial P}{\partial t_k^{(i)}}P^{-1}=\sum_{k=1}^{\infty}S^{(k)}\partial^{-k},$$

then

$$S^{(1)}=-\frac{\partial W^{(1)}}{\partial t_k^{(i)}},\quad S^{(2)}=-\frac{\partial W^{(2)}}{\partial t_k^{(i)}}+\frac{\partial W^{(1)}}{\partial t_k^{(i)}}\,W^{(1)}. \tag{3.6}$$

And split up

$$Q=Q(i,j;P)=Q_1\partial^1+Q_0\quad\text{and}\quad Q(i,j;P)^{-1}=T_1\partial^1+T_0,$$

with

$$\begin{aligned}
&Q_1=\epsilon_{ij}E_{ii},\quad T_1=-\epsilon_{ij}E_{jj},\\
&Q_0=\epsilon_{ij}\left(\left(-\frac{\partial\log W_{ij}}{\partial t_1^{(i)}}\right)E_{ii}-\frac{1}{W_{ij}}E_{ji}-\sum_{k\neq i}W_{ik}E_{ik}\right)+\sum_{k\neq i,j}\epsilon_{ki}\epsilon_{kj}\left(E_{kk}-\frac{W_{kj}}{W_{ij}}E_{ki}\right),\\
&T_0=\epsilon_{ij}\left(\left(-\frac{\partial\log W_{ij}}{\partial t_1^{(j)}}\right)E_{jj}-\frac{1}{W_{ij}}E_{ji}-\sum_{k\neq j}W_{kj}E_{kj}\right)+\sum_{k\neq i,j}\epsilon_{ki}\epsilon_{kj}\left(E_{kk}-\frac{W_{ik}}{W_{ij}}E_{jk}\right);
\end{aligned} \tag{3.7}$$

then it is straightforward to check that (3.5) is equivalent to

$$-\frac{\partial Q^{(0)}}{\partial t_k^{(i)}}(T_1\partial^1+T_0)+Q^{(0)}S^{(1)}T^{(1)}+Q^{(1)}S^{(1)}T^{(0)}+Q^{(1)}\left(S^{(1)}\partial+\frac{\partial S^{(1)}}{\partial x}+S^{(2)}\right)T^{(1)}=0. \tag{3.8}$$

Next, substitute (3.6) and (3.7) onto the left-hand side of (3.8) and calculate the coefficients of E_{pq}. It is then straightforward to verify that indeed (3.8) holds. □

From all this we have the following Schlesinger–Bäcklund transformation.

Proposition 3.3: Let P be a pseudodifferential operator of the form (2.3) that satisfies the Sato equation (2.5) and let $\{L,C^{(1)},C^{(2)},\ldots,C^{(n)}\}$ be a set of pseudodifferential operators of the form (1.2) satisfying (1.1) and (1.3). If $W_{ij}^{(1)}=C_{ij}^{(j1)}\neq 0$ for $i\neq j$, then $Q(i,j;P)PR(i,j)^{-1}$ also satisfies (2.3) and (2.5), respectively, the set $\{Q(i,j;P)LQ(i,j;P)^{-1}$, $Q(i,j;P)C^{(1)}Q(i,j;P)^{-1},\ldots,Q(i,j;P)C^{(n)}Q(i,j;P)^{-1}\}$ satisfies (1.1)–(1.3).

IV. A FAMILY OF SOLUTIONS

Let P be a pseudodifferential operator satisfying (2.3) and (2.5). If $W_{ij}^{(1)}\neq 0$ for $i\neq j$, then we can use the Schlesinger–Bäcklund operator $Q(i,j;P)$ to obtain new solutions of (2.3) and (2.5). Doing this recursively, we obtain a whole family of solutions. To describe this family better we introduce the root lattice of sl_n.

Let $\tilde{\mathfrak{L}}$ be a lattice over $\mathbb{Z}$ with basis $\delta_1,\delta_2,\ldots,\delta_n$ and let $(\,|\,)$ be a symmetric bilinear form on $\tilde{\mathfrak{L}}$, defined by $(\delta_i|\delta_j)=\delta_{ij}$. Let $\delta=\delta_1+\delta_2+\cdots\delta_n$, denote by $\mathfrak{L}$ the sublattice of $\tilde{\mathfrak{L}}$ defined by $\mathfrak{L}=\{\gamma\in\tilde{\mathfrak{L}}|(\delta|\gamma)=0\}$. This lattice $\mathfrak{L}$ is the root lattice of sl_n. Using the Schlesinger–Bäcklund transformation, we can define new solutions of (2.5) parametrized by $\mathfrak{L}$. Define $P(0)=P$; suppose we have defined $P(\alpha)=\Sigma_l W^{(l)}\partial^{-l}$ for some $\alpha\in\mathfrak{L}$. If $W_{ij}^{(1)}(\alpha)\neq 0$, we define

$$P(\alpha+\delta_i-\delta_j)=Q(i,j;P(\alpha))P(\alpha)R(i,j)^{-1}. \tag{4.1}$$

However, there is a slight problem, it is not clear that in this way these solutions are well defined e.g., does the following equation hold?:

$$\begin{aligned}
&Q(i,j;Q(k,l;P(0))P(0)R(k,l)^{-1})Q(k,l;P(0))P(0)R(k,l)^{-1}R(i,j)^{-1}\\
&\quad=Q(k,l;Q(i,j;P(0))P(0)R(i,j)^{-1})Q(i,j;P(0))P(0)R(i,j)^{-1}R(k,l)^{-1}.
\end{aligned} \tag{4.2}$$

Clearly,

$$R(k,l)^{-1}R(i,j)^{-1}=R(i,j)^{-1}R(k,l)^{-1},$$

and for $\alpha\in\mathfrak{L}$ it makes sense to define $R(\alpha)$; let $\alpha=\Sigma_{i=1}^n k_i\delta_i\in\mathfrak{L}$; then we define

$$R(\alpha)=R(1,2)^{k_1}R(2,3)^{k_1+k_2}\cdots R(n-1,n)^{k_1+k_2+\cdots k_{n-1}}. \tag{4.3}$$

Notice that this is well defined. Following Ref. 4, we define a bimultiplicative function ϵ: $\mathfrak{L}\times\mathfrak{L}\to\{\pm 1\}$ by letting

$$\epsilon(\delta_i,\delta_j)=\epsilon_{ij}, \tag{4.4}$$

then

$$R(\alpha)=\sum_{i=1}^{n}\epsilon(\delta_i,\alpha)E_{ii}\partial^{(\delta_i|\alpha)}. \tag{4.5}$$

One could try to prove (4.2) by a straightforward calculation. This is tedious but possible. One has to use the equations (2.8), i.e., the first Sato equations to show that (4.2) holds. So one can say that the equations (2.8) are the Bianchi equations for the Schlesinger–Bäcklund transformations. However, such a computation does not exclude the fact that $P(\alpha)$ might be not uniquely defined, that it might depend on the path. However, this is not the case, as the following proposition shows.

Proposition 4.1: Suppose we have two paths:

$$\begin{aligned} &0=\alpha_0\mapsto\alpha_1\mapsto\alpha_2\mapsto\cdots\mapsto\alpha_p=\alpha, \quad \text{with } \alpha_k-\alpha_{k-1}=\delta_{i_k}-\delta_{j_k},\\ &0=\beta_0\mapsto\beta_1\mapsto\beta_2\mapsto\cdots\mapsto\beta_q=\beta, \quad \text{with } \beta_k-\beta_{k-1}=\delta_{l_k}-\delta_{m_k}, \end{aligned} \tag{4.6}$$

such that

$$\begin{aligned} P(\alpha_k)&=Q(i_k,j_k;P(\alpha_{k-1}))P(\alpha_{k-1})R(i_k,j_k)^{-1},\\ P(\beta_k)&=Q(l_k,m_k;P(\beta_{k-1}))P(\beta_{k-1})R(l_k,m_k)^{-1}. \end{aligned} \tag{4.7}$$

Then

$$(P(\alpha)R(\alpha-\beta)P(\beta)^{-1})_-=0, \tag{4.8}$$

and if $\alpha=\beta$, then $P(\alpha)=P(\beta)$.

Proof: Write $Q_k=Q(i_k,j_k;P(\alpha_{k-1}))$ and $\widetilde{Q}_k=Q(l_k,m_k;P(\beta_{k-1}))$ and notice that Q_k, $\widetilde{Q}_k$, Q_k^{-1}, and $\widetilde{Q}_k^{-1}$ are all first-order differential operators. Hence,

$$\begin{aligned} P(\alpha)R(\alpha-\beta)P(\beta)^{-1}&=Q_pQ_{p-1}\cdots Q_1P(0)R(\alpha)^{-1}R(\alpha-\beta)R(\beta)P(0)^{-1}\widetilde{Q}_1^{-1}\widetilde{Q}_2^{-1}\cdots\widetilde{Q}_q^{-1}\\ &=Q_pQ_{p-1}\cdots Q_1\widetilde{Q}_1^{-1}\widetilde{Q}_2^{-1}\cdots\widetilde{Q}_q^{-1} \end{aligned}$$

is a differential operator. Now if $\alpha=\beta$, then since $R(0)=I_n$ and both $P(\alpha)$ and $P(\beta)^{-1}$ are of the form (2.3), we deduce that $P(\alpha)P(\beta)^{-1}=I_n$. □

We conclude from this proposition that there is no ambiguity in the definition of $P(\alpha)$.

Now suppose $P(\alpha)$ and $P(\beta)$ exist and $\alpha-\beta=\delta_i-\delta_j$; then

$$P(\alpha)R(\delta_i-\delta_j)P(\beta)^{-1}=\epsilon_{ij}\partial E_{ii}+\sum_{k\neq i,j}\epsilon_{ki}\epsilon_{kj}E_{kk}+\epsilon_{ij}(W^{(1)}(\alpha)E_{ii}-E_{ii}W^{(1)}(\beta)), \tag{4.9}$$

where $P(\gamma)=I_n+\Sigma_{k>0}W^{(k)}(\gamma)\partial^{-k}$. Now, expressing $P(\alpha)$ in $P(\beta)$ one obtains the following expression:

$$\epsilon_{ij}W^{(m+1)}(\alpha)E_{ii}+\sum_{k\neq i,j}\epsilon_{ki}\epsilon_{kj}W^{(m)}(\alpha)E_{kk}-\epsilon_{ij}W^{(m-1)}(\alpha)E_{jj}$$

$$=\epsilon_{ij}E_{ii}\left(\frac{\partial W^{(m)}(\beta)}{\partial x}+W^{(m+1)}(\beta)-W^{(1)}(\beta)W^{(m)}(\beta)\right)$$

$$+\sum_{k\neq i,j}\epsilon_{ki}\epsilon_{kj}E_{kk}W^{(m)}(\beta)+\epsilon_{ij}W^{(1)}(\alpha)E_{ii}W^{(m)}(\beta). \tag{4.10}$$

Now take $m=1$ and take the (l,j)th coefficient of this expression, which gives

$$\epsilon_{ij}\delta_{li}\left(\frac{\partial W^{(1)}_{ij}(\beta)}{\partial x}+W^{(2)}_{ij}(\beta)-\sum_{k=1}^{n}W^{(1)}_{ik}(\beta)W^{(1)}_{kj}(\beta)\right)+(1-\delta_{il}-\delta_{jl})\epsilon_{li}\epsilon_{lj}W^{(1)}_{lj}(\beta)$$

$$+\epsilon_{ij}W^{(1)}_{li}(\alpha)W^{(1)}_{ij}(\beta)=-\epsilon_{ij}\delta_{lj}. \tag{4.11}$$

Taking $l=j$, we see that $W^{(1)}_{ij}(\beta)$ is invertible, and we can determine $W^{(1)}_{ji}(\alpha)$. If $l\neq i,j$ then one easily determines $W^{(1)}_{li}(\alpha)$. If $l=i$ one can use the equations (2.8) to express $W^{(1)}_{ii}(\alpha)$ in $W^{(1)}(\beta)$. In fact, one obtains that $P(\alpha)R(\delta_i-\delta_j)P(\beta)^{-1}=Q(i,j;P(\beta))$. Using (3.4) we see that since $W^{(1)}_{ij}(\beta)\neq 0$ then also $W^{(1)}_{ji}(\alpha)\neq 0$; hence one can define the inverse Schlesinger–Bäcklund operator $Q(j,i;P(\alpha))$.

Define the support $\mathrm{supp}(P)\subset\mathfrak{L}$ of P. We say that $\alpha\in\mathfrak{L}$ is in $\mathrm{supp}(P)$ if there exists a path of the form (4.6) from 0 to α such that (4.7) holds. Above we proved the following proposition:

Proposition 4.2: Let $\alpha,\beta\in supp(P)$ be such that $\alpha-\beta=\delta_i-\delta_j$; then

$$P(\alpha)=Q(i,j;P(\beta))P(\beta)R(i,j)^{-1}\quad\text{and}\quad P(\beta)=Q(j,i;P(\alpha))P(\alpha)R(j,i)^{-1}.$$

We will now introduce a wave function for every $\alpha\in\mathrm{supp}(P)$. Define

$$W(\alpha)\equiv W(\alpha,x,t,z)=P(\alpha)R(\alpha)e^{\Xi(t,z)}e^{xz}, \tag{4.12}$$

and the corresponding operators

$$L(\alpha)\equiv L(\alpha,x,t,\partial)=P(\alpha)\partial P(\alpha)^{-1},$$

$$C^{(j)}(\alpha)\equiv C^{(j)}(\alpha,x,t,\partial)=P(\alpha)E_{jj}P(\alpha)^{-1}, \tag{4.13}$$

$$N(\beta,\alpha)\equiv N(\beta,\alpha,x,t,\partial)=P(\beta)R(\beta-\alpha)P(\alpha)^{-1}.$$

Notice that by Proposition 4.1 $N(\beta,\alpha)$ is a differential operator. Since $P(\alpha)$ satisfies the Sato equation

$$\frac{\partial P(\alpha)}{\partial t^{(j)}_k}=-(P(\alpha)\partial^k E_{jj}P(\alpha)^{-1})_-P(\alpha), \tag{4.14}$$

the set of wave functions $W(\alpha)$ for $\alpha\in\mathrm{supp}(P)$ satisfy the following equations:

$$L(\alpha)W(\alpha)=W(\alpha)z,\quad C^{(j)}(\alpha)W(\alpha)=W(\alpha)E_{jj},$$

$$N(\beta,\alpha)W(\alpha)=W(\beta),\quad \frac{\partial W(\alpha)}{\partial t^{(i)}_k}=(L(\alpha)^kC^{(i)}(\alpha))_+W(\alpha), \tag{4.15}$$

and the operators $L(\alpha),C^{(j)}(\alpha),N(\beta,\alpha)$ satisfy (1.3) and the Lax equations:

$$\frac{\partial L(\alpha)}{\partial t_k^{(i)}} = [(L(\alpha)^k C^{(i)}(\alpha))_+, L(\alpha)],$$

$$\frac{\partial C^{(j)}(\alpha)}{\partial t_k^{(i)}} = [(L(\alpha)^k C^{(i)}(\alpha))_+, C^{(j)}(\alpha)], \tag{4.16}$$

$$\frac{\partial N(\beta,\alpha)}{\partial t_k^{(i)}} = (L(\beta)^k C^{(i)}(\beta))_+ N(\beta,\alpha) - N(\beta,\alpha)(L(\alpha)^k C^{(i)}(\alpha))_+ .$$

V. THE ADJOINT WAVE FUNCTIONS AND THE BILINEAR IDENTITY

On the algebra of formal $n\times n$-matrix pseudodifferential operators exists a natural linear anti-involution $*$, defined by

$$(A(x,t)\partial^k)^* = (-\partial)^k \circ {}^t A(x,t); \tag{5.1}$$

here ${}^tA$ stands for the transposed of the matrix A. The anti-involution preserves the decomposition $A = A_+ + A_-$, i.e., $(A^*)_+ = (A_+)^*$ and $(A^*)_- = (A_-)^*$. Let $W(\alpha)$ be defined by (4.12), we introduce the corresponding adjoint wave function by

$$W^*(\alpha) \equiv W^*(\alpha,x,t,z) = P(\alpha)^{*-1} R(\alpha)^{*-1} e^{-\Xi(t,z)} e^{-xz}. \tag{5.2}$$

Since $P(\alpha)^{*-1}$ satisfies the adjoint Sato equation:

$$\frac{\partial P(\alpha)^{*-1}}{\partial t_k^{(i)}} = (P(\alpha)^{*-1}(-\partial)^k E_{ii} P(\alpha)^*)_- P(\alpha)^{*-1}, \tag{5.3}$$

we have the following equations for the adjoint wave function:

$$\begin{gathered} L(\alpha)^* W^*(\alpha) = W^*(\alpha) z, \quad C^{(j)}(\alpha)^* W^*(\alpha) = W^*(\alpha) E_{jj}, \\ N(\beta,\alpha)^* W^*(\beta) = W^*(\alpha), \quad \frac{\partial W^*(\alpha)}{\partial t_k^{(i)}} = -(L(\alpha)^{*k} C^{(i)}(\alpha)^*)_+ W^*(\alpha), \end{gathered} \tag{5.4}$$

and the operators $L(\alpha)^*$, $C^{(j)}(\alpha)^*$, and $N(\beta,\alpha)^*$ satisfy (1.3) and the Lax equations:

$$\frac{\partial L(\alpha)^*}{\partial t_k^{(i)}} = -[(L(\alpha)^{*k} C^{(i)}(\alpha)^*)_+, L(\alpha)^*],$$

$$\frac{\partial C^{(j)}(\alpha)^*}{\partial t_k^{(i)}} = -[(L(\alpha)^{*k} C^{(i)}(\alpha)^*)_+, C^{(j)}(\alpha)^*], \tag{5.5}$$

$$\frac{\partial N(\beta,\alpha)^*}{\partial t_k^{(i)}} = -(L(\alpha)^{*k} C^{(i)}(\alpha)^*)_+ N(\beta,\alpha)^* + N(\beta,\alpha)^* (L(\beta)^{*k} C^{(i)}(\beta)^*)_+ .$$

The set of wave functions and their corresponding adjoint wave functions satisfy the following.

Theorem 5.1: *Let $\alpha,\beta \in supp(P)$; then one has the following bilinear identity:*

$$\mathrm{Res}_{z=0} W(\alpha,x,t,z)\, {}^t W^*(\beta,x',t',z) = 0.$$

Proof: Let $P(\alpha,x,t,z)R(\alpha) = \Sigma_i P_i \partial^{-i}$ and $P(\beta,x',t,z)^{-1} R(\beta)^{-1} = \Sigma_j Q_j \partial^{-j}$; then (4.8) is equivalent to

$$0=\left(\sum_i P_i\partial^{-i}\sum_j(-\partial)^{-j}{}^tQ_j\right)_-$$
$$=\left(\sum_{\substack{i,j\\ l\geqslant 0}}(-)^j\binom{-j-j}{l}P_i\frac{\partial^l{}^tQ_j}{\partial x^l}\partial^{-i-j-l}\right)_-.$$

Hence each coefficient of ∂^{-m-1} for $m\geqslant 0$ of this last expression, which is

$$\sum_{\substack{0\leqslant l\\ i+j+l=m+1}}(-)^j\binom{-i-j}{l}P_i\frac{\partial^l{}^tQ_j}{\partial x^l},$$

must be equal to 0. We rewrite this as

$$0=\sum_{\substack{0\leqslant l\leqslant m\\ i+j+l=m+1}}(-)^{j+l}\binom{m}{l}P_i\frac{\partial^l{}^tQ_j}{\partial x^l}$$
$$=\mathrm{Res}_{z=0}\sum_{i,j}\sum_{l=0}^{m}(-)^{j+m-l}\binom{m}{l}P_i\frac{\partial^l{}^tQ_j}{\partial x^l}z^{m-i-j-l}$$
$$=\mathrm{Res}_{z=0}\sum_{i,j}P_iz^{-i}e^{\Xi(t,z)}e^{xz}\frac{\partial^m}{\partial x^m}{}^t(Q_j(-z)^je^{-\Xi(t,z)}e^{-xz}).$$

The Lemma then follows by using the equations (5.4) and Taylor's formula. □

VI. THE TAU FUNCTION

In this section we want to introduce tau functions. For every $\alpha\in\mathrm{supp}(P)$ we introduce a tau function τ_α. We give an algebraic proof for the existence of these tau functions. This proof was inspired by the work of Ueno and Takasaki[7] on the Toda lattice hierarchy.

Before we give the main Theorem, we first introduce some notations. We write

$$P^\vee_{ij}(\alpha,x,t,z)=(P(\alpha,x,t,-z)^{*-1})_{ij},\quad R^\vee(\alpha,z)=R(\alpha,-z)^{*-1},$$

then

$$W^*(\alpha,x,t,z)=P^\vee(\alpha,x,t,z)R^\vee(\alpha,x,z)e^{-\Xi(t,z)}e^{-xz}.$$

Theorem 6.1: *For all $\alpha\in supp(P)$ we find $\tau_{\alpha+\delta_i-\delta_j}$, uniquely determined up to a constant multiple, such that*

$$P_{ij}(\alpha,x,t,z)=\epsilon_{ji}\frac{\tau_{\alpha+\delta_i-\delta_j}\left(t_k^{(p)}+\delta_{k,1}x-\delta_{pj}\frac{z^{-k}}{k}\right)}{\tau_\alpha(t_k^{(p)}+\delta_{k,1}x)},$$
$$P^\vee_{ij}(\alpha,x,t,z)=\epsilon_{ji}\frac{\tau_{\alpha+\delta_j-\delta_i}\left(t_k^{(p)}+\delta_{k,1}x+\delta_{pj}\frac{z^{-k}}{k}\right)}{\tau_\alpha(t_k^{(p)}+\delta_{k,1}x)}.\tag{6.1}$$

The proof of this theorem is based on several identities, which all follow from the bilinear identity for the wave function (Theorem 5.1). Notice that the x dependence is given by formula (2.7) and a similar formula for the adjoint wave function [which follows from (5.3)]. So from now on in the proof of the above Theorem we will concentrate on the t dependence.

Lemma 6.2: Let α *and* $\alpha+\delta_a-\delta_c\in supp(P)$ $(0\leqslant a\neq c\leqslant n)$; *then the following identities hold* $(0\leqslant b\leqslant n)$:

$$\nu P_{ab}(\alpha,x,t_r^{(p)},\nu)P^{\vee}_{bb}\left(\alpha,x,t_r^{(p)}-\delta_{pb}\frac{\nu^{-r}}{r},\nu\right)=\delta_{ab}\nu-(1-\delta_{ab})P^{\vee(1)}_{ba}\left(\alpha,x,t_r^{(p)}-\delta_{pb}\frac{\nu^{-r}}{r}\right), \tag{6.2}$$

$$\nu P^{\vee}_{ab}(\alpha,x,t_r^{(p)},\nu)P_{aa}\left(\alpha,x,t_r^{(p)}+\delta_{pa}\frac{\nu^{-r}}{r},\nu\right)=\delta_{ab}\nu-(1-\delta_{ab})P^{(1)}_{ba}\left(\alpha,x,t_r^{(p)}+\delta_{pa}\frac{\nu^{-r}}{r}\right), \tag{6.3}$$

$$\begin{aligned}&\nu P_{ac}(\alpha,x,t_r^{(p)},\nu)P^{\vee}_{bc}\left(\alpha,x,t_r^{(p)}-\delta_{pc}\frac{\nu^{-r}}{r}-\delta_{pa}\frac{\rho^{-r}}{r},\nu\right)\\&\quad=\delta_{ab}\rho-(1-\delta_{ab}-\delta_{bc})P^{(1)}_{ab}(\alpha,x,t_r^{(p)})\\&\qquad-\rho P_{aa}(\alpha,x,t_r^{(p)},\rho)P^{\vee}_{ba}\left(\alpha,x,t_r^{(p)}-\delta_{pc}\frac{\nu^{-r}}{r}-\delta_{pa}\frac{\rho^{-r}}{r},\rho\right),\end{aligned} \tag{6.4}$$

$$\begin{aligned}&\epsilon_{bc}\nu^{1-\delta_{bc}}P_{bb}(\alpha+\delta_a-\delta_c,x,t_r^{(p)},\nu)P^{\vee}_{cb}\left(\alpha,x,t_r^{(p)}-\delta_{pb}\frac{\nu^{-r}}{r},\nu\right)\\&\quad=-\epsilon_{ca}\epsilon_{ab}P^{(1-\delta_{ab})}_{ba}(\alpha+\delta_a-\delta_c,x,t_r^{(p)})P^{\vee(1)}_{ca}\left(\alpha,x,t_r^{(p)}+\delta_{pb}\frac{\nu^{-r}}{r}\right),\end{aligned} \tag{6.5}$$

$$\begin{aligned}&P_{aa}\left(\alpha,x,t_r^{(p)}+\delta_{pa}\frac{\nu^{-r}}{r},\nu\right)P^{\vee}_{aa}\left(\alpha,x,t_r^{(p)}-\delta_{pa}\frac{\rho^{-r}}{r},\nu\right)\\&\quad=P_{aa}\left(\alpha,x,t_r^{(p)}+\delta_{pa}\frac{\nu^{-r}}{r},\rho\right)P^{\vee}_{aa}\left(\alpha,x,t_r^{(p)}-\delta_{pa}\frac{\rho^{-r}}{r},\rho\right).\end{aligned} \tag{6.6}$$

Proof: We will give the proof of the identity (6.4); the proof of all other identities are analogous. We first introduce the formal delta function $\delta(y-z)=z^{-1}\Sigma_{k\in\mathbb{Z}}(z/y)^k$, for which one has $\Sigma_{k=0}^{\infty}(z/y)^k=z\,\delta(y-z)-\Sigma_{k=1}^{\infty}(y/z)^k$ and $\mathrm{Res}_{z=0}\,f(y,z)\delta(y-z)=f(y,y)$. Using Theorem 5.1, we deduce

$$\begin{aligned}0&=\mathrm{Res}_{z=0}\sum_{l=1}^{n}W_{al}(\alpha,x,t_r^{(p)},z)W^{*}_{bl}\left(\alpha,x,t_r^{(p)}-\delta_{pc}\frac{\nu^{-r}}{r}-\delta_{pa}\frac{\rho^{-r}}{r},z\right)\\&=\mathrm{Res}_{z=0}\left\{P_{ac}(\alpha,x,t_r^{(p)},z)P^{\vee}_{bc}\left(\alpha,x,t_r^{(p)}-\delta_{pc}\frac{\nu^{-r}}{r}-\delta_{pa}\frac{\rho^{-r}}{r},z\right)\sum_{k=0}^{\infty}\left(\frac{z}{\nu}\right)^k\right.\\&\quad\left.+P_{aa}(\alpha,x,t_r^{(p)},z)P^{\vee}_{bc}\left(\alpha,x,t_r^{(p)}-\delta_{pc}\frac{\nu^{-r}}{r}-\delta_{pa}\frac{\rho^{-r}}{r},z\right)\sum_{k=0}^{\infty}\left(\frac{z}{\rho}\right)^k\right\}\\&\quad+(1-\delta_{ab}-\delta_{ac})P^{(1)}_{ab}(\alpha,x,t_r^{(p)})\\&=\mathrm{Res}_{z=0}\left\{P_{ac}(\alpha,x,t_r^{(p)},z)P^{\vee}_{bc}\left(\alpha,x,t_r^{(p)}-\delta_{pc}\frac{\nu^{-r}}{r}-\delta_{pa}\frac{\rho^{-r}}{r},z\right)\right.\\&\quad\left.\times\left(z\,\delta(\nu-z)-\sum_{k=1}^{\infty}\left(\frac{\nu}{z}\right)^k\right)+P_{aa}(\alpha,x,t_r^{(p)},z)P^{\vee}_{bc}\left(\alpha,x,t_r^{(p)}-\delta_{pc}\frac{\nu^{-r}}{r}-\delta_{pa}\frac{\rho^{-r}}{r},z\right)\right.\end{aligned}$$

$$\times\left(z\,\delta(\rho-z)-\sum_{k=1}^{\infty}\left(\frac{\rho}{z}\right)^k\right)\Bigg\}+(1-\delta_{ab}-\delta_{ac})P^{(1)}_{ab}(\alpha,x,t^{(p)}_r)$$

$$=\nu P_{ac}(\alpha,x,t^{(p)}_r,\nu)P^{\vee}_{bc}\left(\alpha,x,t^{(p)}_r-\delta_{pc}\frac{\nu^{-r}}{r}-\delta_{pa}\frac{\rho^{-r}}{r},\nu\right)$$

$$+\rho P_{aa}(\alpha,x,t^{(p)}_r,\rho)P^{\vee}_{bc}\left(\alpha,x,t^{(p)}_r-\delta_{pc}\frac{\nu^{-r}}{r}-\delta_{pa}\frac{\rho^{-r}}{r},\rho\right)-\rho\,\delta_{ab}$$

$$+(1-\delta_{ab}-\delta_{ac})P^{(1)}_{ab}(\alpha,x,t^{(p)}_r).$$

□

We are now able to proof the following proposition.

Proposition 6.3: For $\alpha\in supp(P)$ *one has the following identities* $(1\leqslant i\neq j\leqslant n)$:

$$P_{jj}(\alpha,x,t^{(p)}_r,\lambda)=P_{jj}\left(\alpha,x,t^{(p)}_r-\delta_{pj}\frac{\lambda^{-r}}{r},\lambda\right)^{-1}, \tag{6.7}$$

$$P^{(1)}_{ij}(\alpha,x,t^{(p)}_r)=-P^{(1)}_{ji}(\alpha,x,t^{(p)}_r), \tag{6.8}$$

$$\lambda P_{ij}(\alpha,x,t^{(p)}_r,\lambda)=P^{(1)}_{ij}\left(\alpha,x,t^{(p)}_r-\delta_{pj}\frac{\lambda^{-r}}{r}\right)P_{jj}(\alpha,x,t^{(p)}_r,\lambda), \tag{6.9}$$

$$\lambda P^{\vee}_{ij}(\alpha,x,t^{(p)}_r,\lambda)=P^{\vee(1)}_{ij}\left(\alpha,x,t^{(p)}_r-\delta_{pj}\frac{\lambda^{-r}}{r}\right)P^{\vee}_{jj}(\alpha,x,t^{(p)}_r,\lambda). \tag{6.10}$$

Proof: The identity (6.7) is a consequence of (6.2), where one chooses $a=b=j$. To prove (6.8), we take the constant coefficient of (6.2) for $i=a\neq b=j$. The other identities follow immediately using (6.2), (6.3), and (6.8). □

Consider now the following equations $[\alpha\in\mathrm{supp}(P),\ 1\leqslant i\neq j\leqslant n]$:

$$\log P_{jj}(\alpha,0,t,z)=(e^{-\eta(t^j,z)}-1)\log\tau_a(t),\quad P^{(1)}_{ij}(\alpha,0,t)=\epsilon_{ji}\frac{\tau_{\alpha+\delta_i-\delta_j}(t)}{\tau_\alpha(t)}, \tag{6.11}$$

where

$$\eta(t,z):=\sum_{k=1}^{\infty}\frac{\partial}{\partial t_k}\frac{z^{-k}}{k}. \tag{6.12}$$

Define $p_j(\partial^{(i)})$ for $\partial^{(i)}=(\partial/\partial t^{(i)}_1,\partial/\partial t^{(i)}_2,\ldots)$ as follows:

$$\sum_{j=0}^{\infty}p_j(\partial^{(i)})z^{-j}=e^{-\eta(t^{(i)},z)},$$

and set

$$\log P_{jj}(\alpha,0,t,z)=\sum_{k=1}^{\infty}T^{(k)}_j(\alpha)z^{-k},\quad \log\epsilon_{ji}P^{(1)}_{ij}(\alpha,0,t)=T_{ij}(\alpha). \tag{6.13}$$

Of course (6.13) is not well defined if $P^{(1)}_{ij}(\alpha,0,t,z)=0$; however, this is only the case if $\alpha+\delta_i-\delta_j\notin\mathrm{supp}(P)$. In that case one simply defines $\tau_{\alpha+\delta_i-\delta_j}(t)=0$.

The equations (6.11) are solvable if the following compatibility conditions hold $(1\leqslant i,j,k\leqslant n,l,m=1,2,\ldots)$:

$$p_l(\partial^{(i)})(T^{(m)}_j(\alpha))=p_m(\partial^{(j)})(T^{(l)}_i(\alpha)), \tag{6.14}$$

$$p_l(\partial^{(i)})(T_{kj}(\alpha))=T_i^{(l)}(\alpha+\delta_k-\delta_j)-T_i^{(l)}(\alpha).$$

The ring of differential operators over $\mathbb{C}$ with generators $\partial/\partial t_l^{(i)}$, $1\leqslant i\leqslant n$, $l=1,2,...$, also have the $p_l(\partial^{(i)})$ as generators. In fact, from the first formula of (6.11) one can deduce the more explicit formula:[4]

$$\frac{\partial \log \tau_\alpha(t)}{\partial t_k^{(j)}}=\mathrm{Res}_{z=0}\, z^k\left(\frac{\partial}{\partial z}-\sum_{l>1} z^{-l-1}\frac{\partial}{\partial t_l^{(j)}}\right)\log P_{jj}(\alpha,0,t,z),$$

from which one can determine the tau function $\tau_\alpha(t)$ up to a constant factor. Hence, if the compatibility conditions (6.14) hold, then the $\tau_{\alpha+\delta_i-\delta_j}(t)$ are uniquely defined up to a constant multiple factor. These compatibility conditions follow from the next proposition.

Proposition 6.4: Let α and $\alpha+\delta_k-\delta_j\in supp(P)$, $1\leqslant j\neq k\leqslant n$; then one has the following identities $(1\leqslant i\leqslant n)$:

$$P_{ii}(\alpha,x,t_r^{(p)},\mu)P_{jj}\left(\alpha,x,t_r^{(p)}-\delta_{pi}\frac{\mu^{-r}}{\rho},\lambda\right)=P_{jj}(\alpha,x,t_r^{(p)},\lambda)P_{ii}\left(\alpha,x,t_r^{(p)}-\delta_{pi}\frac{\lambda^{-r}}{r},\mu\right),\tag{6.15}$$

$$\begin{aligned}&\epsilon_{ji}P_{ii}(\alpha+\delta_k-\delta_j,x,t_r^{(p)},\mu)P_{ij}^{(1-\delta_{ij})}(\alpha,x,t_r^{(p)})\\&\quad=\epsilon_{jk}\epsilon_{ki}P_{ii}(\alpha,x,t_r^{(p)},\mu)P_{ik}^{(1-\delta_{ik})}(\alpha+\delta_k-\delta_j,x,t_r^{(p)})P_{kj}^{(1)}\left(\alpha,x,t_r^{(p)}-\delta_{pi}\frac{\mu^{-r}}{r}\right).\end{aligned}\tag{6.16}$$

Proof: The identity (6.15) for $i=j$ follows immediately from (6.6) and (6.7). If $i\neq j$ one uses (6.4) with $a=i$, $b=c=j$, $\nu=\lambda$, $\rho=\mu$ and with $a=j$, $b=c=i$, $\nu=\mu$, $\rho=\lambda$, respectively. One thus obtains

$$\begin{aligned}&\mu^2P_{ii}(\alpha,x,t_r^{(p)},\mu)P_{ii}^{\vee}\left(\alpha,x,t_r^{(p)}-\delta_{pi}\frac{\mu^{-r}}{r}-\delta_{jp}\frac{\lambda^{-r}}{r},\mu\right)\\&\qquad\times P_{ji}(\alpha,x,t_r^{(p)},\mu)P_{ji}^{\vee}\left(\alpha,x,t_r^{(p)}-\delta_{pi}\frac{\mu^{-r}}{r}-\delta_{jp}\frac{\lambda^{-r}}{r},\mu\right)\\&=\lambda^2P_{jj}(\alpha,x,t_r^{(p)},\lambda)P_{ii}^{\vee}\left(\alpha,x,t_r^{(p)}-\delta_{pi}\frac{\mu^{-r}}{r}-\delta_{jp}\frac{\lambda^{-r}}{r},\lambda\right)\\&\qquad\times P_{ij}(\alpha,x,t_r^{(p)},\lambda)P_{ji}^{\vee}\left(\alpha,x,t_r^{(p)}-\delta_{pi}\frac{\mu^{-r}}{r}-\delta_{jp}\frac{\lambda^{-r}}{r},\lambda\right).\end{aligned}$$

Again use (6.4), but now with $a=b=i$, $c=j$, $\nu=\lambda$, $\rho=\mu$ and $a=b=i$, $c=j$, $\nu=\mu$, $\rho=\lambda$, respectively. Then (6.15) follows immediately.

The identity (6.16) follows from (6.5), where one uses (6.7), (6.8), and (6.10). □

Corollary 6.5: Let α and $\alpha+\delta_i-\delta_k\in supp(P)$; then one has $(1\leqslant i\leqslant nl,\ m=1,2,...)$:

$$p_l(\partial^{(i)})(T_j^{(m)}(\alpha))=p_m(\partial^{(j)})(T_i^{(l)}(\alpha))$$

$$T_{kj}(\alpha)=(1-\delta_{ij})T_{ij}(\alpha)-(1-\delta_{ik})T_{ik}(\alpha+\delta_k-\delta_j)$$

$$p_l(\partial^{(i)})(T_{kj}(\alpha))=T_i^{(l)}(\alpha+\delta_k-\delta_j)-T_i^{(l)}(\alpha).$$

Hence, the compatibility conditions hold. Finally, combining Proposition 6.3, the formula (6.11) and the fact that the x dependence of the tau functions follow from the last formula of (2.7), this finishes the proof of Theorem 6.1.

We next extend the definition of the tau function (following Ref. 4). We define $\tau_\alpha=0$ for $\alpha\notin \mathrm{supp}(P)$. Let $\mathbb{C}[\tilde{\mathfrak{L}}]$ be the twisted group algebra of $\tilde{\mathfrak{L}}$, with basis e^γ, $\gamma\in\tilde{\mathfrak{L}}$ and algebra product

$$e^{\alpha}e^{\beta}=\epsilon(\alpha,\beta)e^{\alpha+\beta}. \tag{6.17}$$

Define the operator γ for $\gamma\in\tilde{\mathfrak{L}}$ on $\mathbb{C}[\tilde{\mathfrak{L}}]$ by

$$\gamma(e^{\beta})=(\gamma|\beta)e^{\beta}.$$

Notice that $\mathbb{C}[\mathfrak{L}]$ is a subalgebra of $\mathbb{C}[\tilde{\mathfrak{L}}]$. Using this group algebra we define a generating series of tau functions as follows:

$$\tau\equiv\tau(P,x,t)=\sum_{\gamma\in\mathfrak{L}}\tau_{\gamma}(x,t)e^{\gamma}. \tag{6.18}$$

Then using Theorem 5.1 and Theorem 6.1 we deduce the following important result.

Theorem 6.6: *The following bilinear identity holds for the tau function* $\tau(P,x,t)$:

$$\mathrm{Res}_{z=0}\sum_{j=1}^{n}\{e^{\delta_j z^{\delta_j}}e^{\eta(t^{(j)},z)}\tau(P,x,t)\}\{e^{-\delta_j z^{-\delta_j}}e^{-\eta(s^{(j)},z)}\tau(P,y,s)\}e^{\Sigma_{h=1}^{\infty}(t_k^{(j)}-s_k^{(j)})z^j}e^{(x-y)z}=0.$$

Remark 6.7: Notice that τ_0 *is given by the choice* $P(0,x,t)=P(x,t)$. *If one chooses a* $P(\alpha,x,t)=P(x,t)$ *for a specific* $\alpha\in\mathfrak{L}$, *one also gets a tau function. So we may conclude that the tau function belonging to* P *is uniquely defined up to a constant multiple factor and up to a translation over the root lattice* $\mathfrak{L}$. *Such a translation* $\alpha\mapsto\alpha+\beta$ *is called a Schlesinger transformation.*

Remark 6.8: Notice that with this construction it is only possible to obtain tau functions that have a connected support. It is unclear if there exist tau functions that do not have a connected support. If they exist, our construction would clearly only give a connected component. It was shown in Ref. 4 that in the polynomial case the support is always convex.

VII. THE DAVEY–STEWARTSON AND AKNS HIERARCHIES

In this section we consider the two-component KP hierarchy, which we call the Davey–Stewartson hierarchy, and its reduction the well-known AKNS hierarchy (see, e.g., Ref. 4 for more details).

From now on let $n=2$. Notice that $\alpha\in\mathfrak{L}$ is of the form $\alpha=k\delta_1-k\delta_2$ with $k\in\mathbb{Z}$. So from now on it will be convenient to write $W(k),P(k),Q(i,j,k),\ldots,$ instead of $W(\alpha),P(\alpha),Q(i,j;P(\alpha)),\ldots$. Define

$$\begin{gathered}\overline{W}(k)=P(k)R(k)=(I_2+W^{(1)}(k)\partial^{-1}+\cdots)(E_{11}\partial^k+E_{22}(-\partial)^{-k}),\\ \overline{W}^*(k)=P(k)^{*-1}R(k)^{*-1}.\end{gathered} \tag{7.1}$$

We will also write

$$\overline{W}_{ij}(k)=(\delta_{ij}+W_{ij}^{(1)}(k)\partial^{-1}+\cdots)(\delta_{j1}\partial^k+\delta_{j2}(-\partial)^{-k}),$$

and a similar expression for $\overline{W}^*_{ij}(k)$. Then one has

$$\overline{W}(k+1)=Q(i,j,k)\overline{W}(k),\quad \overline{W}^*(k+1)=Q(i,j,k)^{*-1}\overline{W}^*(k),$$

which gives for $a=1,2$:

$$\overline{W}_{1a}(k+1)=\frac{\partial\overline{W}_{1a}(k)}{\partial x}+\overline{W}_{1a}(k)\left(\partial-\frac{\partial\log W_{12}^{(1)}(k)}{\partial t_1^{(1)}}\right)-W_{12}^{(1)}(k)\overline{W}_{2a}(k), \tag{7.2}$$

$$\overline{W}_{2a}(k+1)=-\frac{\overline{W}_{1a}(k)}{W_{12}^{(1)}(k)}, \tag{7.3}$$

$$\overline{W}^*_{1a}(k+1)=-\frac{\overline{W}^*_{2a}(k)}{W^{(1)}_{12}(k)}, \tag{7.4}$$

$$\overline{W}^*_{2a}(k+1)=\frac{\partial\overline{W}^*_{2a}(k)}{\partial x}+\overline{W}^*_{2a}(k)\left(\partial-\frac{\partial \log W^{(1)}_{12}(k)}{\partial t^{(2)}_1}\right)-W^{(1)}_{12}(k)\overline{W}^*_{1a}(k). \tag{7.5}$$

Now substitute (7.3) and (7.4) in (7.2), respectively (7.5); one thus obtains the following recursion relations:

$$\begin{aligned}
\overline{W}_{1a}(k+1)&=\frac{\partial\overline{W}_{1a}(k)}{\partial x}+\overline{W}_{1a}(k)\left(\partial-\frac{\partial \log W^{(1)}_{12}(k)}{\partial t^{(1)}_1}\right)+\frac{W^{(1)}_{12}(k)}{W^{(1)}_{12}(k-1)}\,\overline{W}_{1a}(k-1),\\
\overline{W}^*_{2a}(k+1)&=\frac{\partial\overline{W}^*_{2a}(k)}{\partial x}+\overline{W}^*_{2a}(k)\left(\partial-\frac{\partial \log W^{(1)}_{12}(k)}{\partial t^{(2)}_1}\right)+\frac{W^{(1)}_{12}(k)}{W^{(1)}_{12}(k-1)}\,\overline{W}^*_{2a}(k-1).
\end{aligned} \tag{7.6}$$

The recursion formulas (7.6), when corresponding to very special tau functions, form recursion relations for string-orthogonal polynomials, as considered by Adler and van Moerbeke in Ref. 8.

Now consider the [1,1]-reduction of the Davey–Stewartson hierarchy (for more details see Ref. 4); this is the famous AKNS hierarchy. This means that $L(k)=\partial$ and $\partial W(k)/\partial x=zW(k)$, so

$$\frac{\partial\overline{W}_{1a}(k)}{\partial x}=\frac{\partial\overline{W}_{2a}(k)}{\partial x}=\frac{\partial\overline{W}^*_{1a}(k)}{\partial x}=\frac{\partial\overline{W}^*_{2a}(k)}{\partial x}=0.$$

Using (2.7) one has $\partial/\partial t^{(1)}_1=-\partial/\partial t^{(2)}_1$; hence the equations (6.7) turn into ($t_1=t^{(1)}_1$):

$$\begin{aligned}
\overline{W}_{1a}(k+1)&=\overline{W}_{1a}(k)\left(\partial-\frac{\partial \log W^{(1)}_{12}(k)}{\partial t_1}\right)+\frac{W^{(1)}_{12}(k)}{W^{(1)}_{12}(k-1)}\,\overline{W}_{1a}(k-1),\\
\overline{W}^*_{2a}(k+1)&=\overline{W}^*_{2a}(k)\left(\partial+\frac{\partial \log W^{(1)}_{12}(k)}{\partial t_1}\right)+\frac{W^{(1)}_{12}(k)}{W^{(1)}_{12}(k-1)}\,\overline{W}^*_{2a}(k-1).
\end{aligned} \tag{7.7}$$

These types of recursion relations also appear in the description of orthogonal polynomials related to the Toda lattice hierarchy, as described in Ref. 9 (see also Ref. 10).

We finally investigate the effect of the Schlesinger–Bäcklund transformation on the Lax formulation of the AKNS hierarchy. Consider again the Davey–Stewartson hierarchy and make the following change of variables:

$$x_i=t^{(1)}_i+t^{(2)}_i,\quad y_i=t^{(1)}_i-t^{(2)}_i.$$

Again consider the reduction, so $L(k)=\partial$ and $C^{(1)}(k)$ and $C^{(2)}(k)$ are independent of the x_i's and of x. Denote by $S(k)=C^{(1)}(k)-C^{(2)}(k)$; then since $S(k)^2=I_2$ and $\partial S(k)/\partial x=0$, the AKNS hierarchy is the following set of Lax equations:

$$\frac{\partial S(k)}{\partial y_i}=[(S(k)\partial^i)_+,S(k)]. \tag{7.8}$$

Let $y=y_1$, $t=-2iy_2$, $q_k=W^{(1)}_{12}(k)$, and $r_k=W^{(1)}_{21}(k)$; then it is straightforward to check that

$$\begin{aligned}
S(k)=&\begin{pmatrix}1&0\\0&-1\end{pmatrix}+\begin{pmatrix}0&-2q_k\\2r_k&0\end{pmatrix}\partial^{-1}+\begin{pmatrix}2q_kr_k&-2\partial q_k/\partial y\\-2\partial r_k/\partial y&-2q_kr_k\end{pmatrix}\partial^{-2}\\
&+\begin{pmatrix}*&-2\partial^2q_k/\partial y^2-4q_k^2r_k\\2\partial^2r_k/\partial y^2+4q_kr_k^2&*\end{pmatrix}\partial^{-3}+\cdots,
\end{aligned}$$

and that the q_k and r_k satisfy the nonlinear Schrödinger system,

$$i\,\frac{\partial q_k}{\partial t}=-\frac{1}{2}\,\frac{\partial^2 q_k}{\partial y^2}-q_k^2 r_k,\quad i\,\frac{\partial r_k}{\partial t}=\frac{1}{2}\,\frac{\partial^2 r_k}{\partial y^2}+q_k r_k^2.$$

Now

$$Q(1,2,k)=\begin{pmatrix}\partial-\partial\,\log\,q_k/\partial y & -q_k\\ -1/q_k & 0\end{pmatrix},$$

so $S(k+1)=Q(1,2,k)S(k)Q(1,2,k)^{-1}$, and this gives the following recursion relation for the q_k's and r_k's:

$$q_{k+1}=-\frac{\partial^2\,\log\,q_k}{\partial y^2}-q_k^2 r_k,\quad r_{k+1}=-\frac{1}{q_k}.$$

These are the one-dimensional Toda lattice equations. Similar equations were also obtained in Refs. 6 and 11.

Lax representation, *r*-matrix method, and separation of variables for the Neumann-type restricted flow

Ruguang Zhou[a)]
Department of Mathematics, Xuzhou Normal University, Xuzhou, 221009, People's Republic of China

(Received 25 November 1996; accepted for publication 9 June 1997)

The *r*-matrix method and the method of separation of variables for restricted flows with Neumann constraints are considered. Restricted Jaulent–Miodek flows are taken as illustrative examples. Lax representations are obtained from the adjoint representation of the corresponding soliton hierarchy; the *r*-matrix formula, based on this Lax representation, is derived; and the separation of variables for the Hamilton–Jacobi equation are performed. © *1998 American Institute of Physics.* [S0022-2488(98)01405-4]

I. INTRODUCTION

A great number of finite-dimensional integrable systems have arisen from the soliton equations by using the nonlinearization technique[1,2] or the restricted flow technique.[3,4] Following Ref. 3 we call these finite-dimensional integrable systems the restricted flows. Among them are the Neumann-type restricted flows which are the constrained integrable Hamiltonian system with the Neumann constraints.[1] They include the well-known Neumann model[1] and the geodesic flow on the ellipsoid.[5]

For the Neumann systems (or constrained dynamical systems) many techniques have been developed. For example, for the Neumann model, after Uhlenkbeck first found its conserved quantities, Moser,[6] Adler, van Moerbeke,[7] and Mumford[8] also obtained these conserved quantities from the geometrical interpretation. This construction enabled them to obtain the angle-action variables linearizing the Hamiltonian flow. In addition, Avan and Talon also considered the Poisson structure and the *r*-matrix formulas for the Lax operator[9,10] and again obtained the conserved quantities. These methods have been used in many other Neumann systems. But the most widely used method to study the Neumann-type restricted flows[1,11,12] is the method used by Moser in Ref. 13.

In this paper our aim is to develop the *r*-matrix method and separation of variables for Neumann-type restricted flows. As we know, the *r*-matrix formula is a powerful tool for studying the finite-dimensional integrable system.[14] From the *r*-matrix formula the involutivity of motion integrals generated from the Lax operator can be easily deduced. And the general approach to constructing separable variables for the finite-dimensional integrable systems, starting from the *r*-matrix formula, has been proposed by Sklaynin.[15–17] Crucial to our method is the use of the Dirac bracket. It is the Dirac bracket that transfers the trouble of the Hamiltonian for the constrained systems to the Poisson bracket (the standard Poisson bracket changes to the Dirac bracket) and thus enables us to more easily seek the involutive motion integrals and perform the separation of variables.

In the next section we first describe the relations between the Dirac bracket and the Neumann systems and give a general frame to treat the constrained systems using the *r*-matrix method in the Dirac bracket.

In Sec. III, we take the restricted Jaulent–Miodek flows with the Neumann constraints as examples to illustrate our method. First, according to the general procedure of the nonlinearization technique of the Lax pair,[1] we obtain two Neumann-type restricted Jaulent–Miodek flows. And then we show that the method to deduce the Lax representation for the restricted Bargmann systems from the corresponding soliton hierarchy proposed in Ref. 18 is still valid for the Neu-

mann system. Therefore the integrals of motion arise naturally. Moreover, we show that the Lax operator admits the representation of an r-matrix formula, both in the standard Poisson bracket and the Dirac bracket. The r-matrix formula under the Dirac bracket ensures the involutivity of the motion integrals in the constrained submanifold. Subsequently, the complete integrabilities are obtained. Finally, we discuss the separations of the Hamilton–Jacobi equation for the Neumann-type restricted Jaulent–Miodek flows using the method suggested in Ref. 19 and Ref. 20. The advantage of this method is that we can consider the separation of variables of the integrable equation hierarchy simultaneously. Finally, we reduce the Neumann-type restricted Jaulent–Miodek flows to linearizing flows. Some concluding remarks are given in Sec. IV.

II. THE *r*-MATRIX METHOD FOR THE CONSTRAINED SYSTEM

Let $\omega=\Sigma_{j=1}^{N} dq_j\wedge dp_j$ be the standard symplectic form on R^{2N} and $\{f,g\}$ the corresponding Poisson bracket between two smooth functions f and g. If $H\in C^{\infty}(R^{2N})$ we denote by V_{H} the corresponding Hamiltonian vector field, for which $dH(\cdot)=\omega(V_{\mathrm{H}}\cdot)$.

Define the submanifold M by two smooth functions F, G, satisfying $\{F,G\}\neq 0$ and dF, dG independent,

$$M=\{(q,p)\in R^{2N}|F(q,p)=G(q,p)=0\}. \tag{1}$$

Then we know that M is a symplectic submanifold with the closed 2-form $\omega|_M$, the ω restricted to TM.

In general, the vector field V_{H} need not be tangential to M, but we can construct such a vector field by replacing H with H_M, the restriction of H to M,

$$H_M=H+\frac{1}{\{F,G\}}\,(-\{H,G\}F+\{H,F\}G), \tag{2}$$

such that V_{H_M} is tangential to the submanifold M (see Ref. 6 and Ref. 21). And thus on M for any two functions $f,g\in C^{\infty}(R^{2N})$, we have

$$\{f_M,g_M\}=\{f,g\}+\frac{1}{\{F,G\}}\,(\{f,F\}\{G,g\}-\{f,G\}\{F,g\}). \tag{3}$$

However the rhs of (3) is just the definition of the Dirac bracket,[22] i.e.,

$$\{f,g\}_{\mathrm{D}}=\{f,g\}+\frac{1}{\{F,G\}}\,(\{f,F\}\{G,g\}-\{f,G\}\{F,g\}). \tag{4}$$

The Dirac bracket is a nonstandard Poisson bracket and satisfies many properties that the standard Poisson bracket satisfies, such as the antisymmetry, the linearity, the Jacobi identity, the Leibntz rule:

$$\{fg,h\}_{\mathrm{D}}=f\{g,h\}_{\mathrm{D}}+g\{f,h\}_{\mathrm{D}}, \tag{5}$$

and the derivative rule:

$$\{f(h),g\}_{\mathrm{D}}=f'\{h,g\}_{\mathrm{D}}. \tag{6}$$

These properties make the theory of the r matrix for the standard Poisson bracket in Ref. 14 hold true under the Dirac bracket. Besides we know that under the Dirac bracket, the Hamiltonian system reads as

$$q_{j,x}=\{q_j,H_M\}\equiv\{q_j,H\}_{\mathrm{D}},\quad p_{j,x}=\{p_j,H_M\}\equiv\{p_j,H\}_{\mathrm{D}},\quad j=1,2,...,N. \tag{7}$$

From the analysis above, we know that the involutivity of the restricted Hamiltonian functions of $f|_M$ and $g|_M$ in the submanifold M is equivalent to $\{f,g\}_{\mathrm{D}}=0$.

Assume we have a completely integrable Hamiltonian system H in R^{2N} with N functionally independent and involutive integrals $I_1,I_2\ldots,I_N$, i.e.,

$$\{H,I_j\}=\{I_i,I_j\}=0, \quad i,j=1,2,...,N. \tag{8}$$

Now we are concerned as to whether the Hamiltonian system restricted H to the submanifold M is still completely integrable. Namely, we want to find $N-1$ independent involutive integrals in M. The most natural idea is to make use of the original integrals $I_1,I_2,\ldots,I_N$. That is to say, we consider whether these restricted integrals are still in involution, i.e.,

$$\{H,I_j\}_{\mathrm{D}}=\{I_i,I_j\}_{\mathrm{D}}=0, \quad i,j=1,2,...,N. \tag{9}$$

From the definition of the Dirac bracket (3), it is easy to see the following.

Proposition 1: If H and F or G are the functions of $I_1,I_2,\ldots,I_N$. *i.e.,* $H=H(I_1,I_2,\ldots,I_N)$, $F=F(I_1,I_2,\ldots,I_N)$, *or* $G=G(I_1,I_2,\ldots,I_N)$, *then (9) holds.*

It is the essential element of the Moser constraint method used in Ref. 6 to derive the integrability of the Neumann model, and so on. However, for the most constrained systems the condition of the proposition above does not hold. We have to consider (9) explicitly.

For the restricted flow with the Neumann constraints, we may find the Lax representation with the aid of the adjoint representation of the corresponding soliton hierarchy, as in Ref. 18. Thus, we can obtain the motion integrals. The problem is whether the restrictions of these integrals to submanifold are in involution in the submanifold. From the general theory of the r matrix, we know if the Lax operator $L(\lambda)$ satisfies the r-matrix relation,[14]

$$\{L_1(\lambda)\overset{\otimes}{,}L_2(\mu)\}=[r_{12}(\lambda,\mu),L_1(\lambda)]+[r_{21}(\lambda,\mu),L_2(\mu)], \tag{10}$$

where the notation is as follows:[23] $L_1(\lambda)=L(\lambda)\otimes I$, $L_2(\mu)=I\otimes L(\mu)$, I is the 2×2 unit matrix; $\{L_1(\lambda)\overset{\otimes}{,}L_2(\mu)\}_{ij,kl}=\{L_1(\lambda)_{ik},L_2(\mu)_{jl}\}$; [ ] is the commutator of the matrix.

Then

$$\{L_1^2(\lambda)\overset{\otimes}{,}L_2^2(\mu)\}=[\overline{r}_{12}(\lambda,\mu),L_1(\lambda)]+[\overline{r}_{21}(\lambda,\mu),L_2(\mu)], \tag{11}$$

where

$$\overline{r}_{ij}(\lambda,\mu)=\sum_{k=0}^{1}\sum_{l=0}^{1}L_1^{1-k}(\lambda)L_2^{1-l}(\mu)r_{ij}(\lambda,\mu)L_1^k(\lambda)L_2^l(\mu). \tag{12}$$

Thus

$$\{\mathrm{Tr}\,L^2(\lambda),\mathrm{Tr}\,L^2(\mu)\}=\tfrac{1}{4}\,\mathrm{Tr}\{L_1^2(\lambda),L_2^2(\mu)\}=0, \tag{13}$$

which ensures the involution property of the integrals of motion obtained from expanding $L^2(\lambda)$ in powers of λ.

This result for the general Poisson bracket is still true for the Dirac bracket. These imply that to derive the involutivity we only need to show the r-matrix relation is true.

III. THE NEUMANN-TYPE RESTRICTED JAULENT–MIODEK FLOWS

A. The nonlinearizations of Lax systems of Jaulent–Miodek equation

The well-known Jaulent–Miodek eigenvalue problem[24] is

$$\psi_x=U(u,\lambda)\psi\equiv\begin{pmatrix}0 & 1\\ -\lambda^2+q\lambda+r & 0\end{pmatrix}\psi, \quad \psi=\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}, \quad u=\begin{pmatrix}q\\ r\end{pmatrix}, \tag{14}$$

where λ is a spectral parameter; q and r are the potentials.

To deduce the Jaulent–Miodek hierarchy, following Tu,[25] we first solve the adjoint representation of (14),

$$V_x=[U,V]\equiv UV-VU, \tag{15}$$

where V has a Laurent series expansion,

$$V(u,\lambda)=\sum_{j=1}^{\infty}\begin{pmatrix} a_m(u) & b_m(u) \\ c_m(u) & -a_m(u)\end{pmatrix}\lambda^{-m}, \tag{16}$$

which leads to the following recursion relation:

$$KG_m=JG_m, \quad a_m=-\tfrac{1}{2}b_{mx}, \quad c_m=a_{mx}-b_{m+2}+qb_{m+1}+rb_m, \tag{17}$$

$$K=\begin{pmatrix} \partial & 0 \\ 0 & -\frac{3}{4}\partial^3+r\partial+\frac{1}{2}r_x\end{pmatrix}, \quad J=\begin{pmatrix} 0 & \partial \\ \partial & -q\partial-\frac{1}{2}q_x\end{pmatrix}, \quad G_m=\begin{pmatrix} b_{m+1} \\ b_m\end{pmatrix}, \tag{18}$$

with the initial condition

$$a_0=a_1=a_2=b_0=b_1=0, \quad b_2=-1, \quad b_3=-\tfrac{1}{2}q, \quad c_0=1, \quad c_1=-\tfrac{1}{2}q. \tag{19}$$

Following Ref. 25, we know that the corresponding auxiliary spectral problem (14) is as follows:

$$\psi_{t_n}=V^{(n)}(u,\lambda)\psi, \tag{20}$$

with

$$V^{(n)}=\sum_{m=0}^{n}\begin{pmatrix} a_m & b_m \\ c_m & -a_m\end{pmatrix}\lambda^{n-m}+\begin{pmatrix} 0 & 0 \\ \lambda b_{n+1}+b_{n+2}-qb_{n+1} & 0\end{pmatrix}. \tag{21}$$

The compatible condition of (14) and (20) is

$$U_{t_n}-V_x^{(n)}+[U,V^{(n)}]=0, \tag{22}$$

which leads to the Jaulent–Miodek equation hierarchy,

$$u_{t_n}=2JG_{n+1}. \tag{23}$$

Especially, as $n=3$, the Jaulent–Miodek equation is obtained.

As usual,[2,18] we take N distinct numbers $\lambda_1,\lambda_2,\ldots,\lambda_N$ and consider the following system of equations:

$$\begin{pmatrix} \psi_{1j} \\ \psi_{2j}\end{pmatrix}_x=U(u,\lambda_j)\begin{pmatrix} \psi_{1j} \\ \psi_{2j}\end{pmatrix}\equiv\begin{pmatrix} 0 & 1 \\ -\lambda_j^2+q\lambda_j+r & 0\end{pmatrix}\begin{pmatrix} \psi_{1j} \\ \psi_{2j}\end{pmatrix}, \quad j=1,2,\ldots,N. \tag{24}$$

Under the zero boundary condition at infinity or a periodic boundary, through a direct calculation, we can get (up to a constant factor)

$$\frac{\delta\lambda_j}{\delta u}=-\begin{pmatrix} \lambda_j\psi_{1j}^2 \\ \psi_{1j}^2\end{pmatrix}, \quad j=1,\ldots,N. \tag{25}$$

As in Ref. 1, we can consider the constraints

$$G_k=\sum_{j=1}^{N}\frac{\delta\lambda_j}{\delta u}, \quad k=2,3,\ldots. \tag{26}$$

In this paper we focus on the Neumann constraint,[1]

$$G_2\equiv\begin{pmatrix} b_3 \\ b_2\end{pmatrix}=\sum_{j=1}^{N}\frac{\delta\lambda_j}{\delta u}\equiv-\begin{pmatrix} \langle\Lambda\Psi_1,\Psi_1\rangle \\ \langle\Psi_1,\Psi_1\rangle\end{pmatrix}, \tag{27}$$

i.e.,

$$\langle \Psi_1, \Psi_1 \rangle = 1, \quad q = 2\langle \Lambda \Psi_1, \Psi_1 \rangle. \tag{28}$$

Here and hereafter, we accept the following notation: $\Psi_j = (\psi_{j1}, \ldots, \psi_{jN})^T$, $\Lambda = \mathrm{diag}(\lambda_1, \ldots, \lambda_N)$; by $\langle .,. \rangle$ denote the standard inner product in space R^N.

Differentiating twice on the equation $\langle \Psi_1, \Psi_1 \rangle = 1$ yields

$$r = -\langle \Psi_2, \Psi_2 \rangle + \langle \Lambda^2 \Psi_1, \Psi_1 \rangle - 2\langle \Lambda \Psi_1, \Psi_1 \rangle^2. \tag{29}$$

Under the constraint (28) and (29), (14) is nonlinearized into the following system:

$$\Psi_{1,x} = \Psi_2,$$

$$\Psi_{2,x} = -\Lambda^2 \Psi_1 + 2\langle \Lambda \Psi_1, \Psi_1 \rangle \Lambda \Psi_1 + (\langle \Lambda^2 \Psi_1, \Psi_1 \rangle + \langle \Psi_2, \Psi_2 \rangle - 2\langle \Lambda \Psi_1, \Psi_1 \rangle^2) \Psi_1,$$

$$\langle \Psi_1, \Psi_1 \rangle = 1, \langle \Psi_1, \Psi_2 \rangle = 0. \tag{30}$$

Making use of the relation

$$K \frac{\delta \lambda_j}{\delta u} = \lambda_j J \frac{\delta \lambda_j}{\delta u},$$

we have

$$\tilde{b}_i = -\langle \Lambda^{i-2} \Psi_1, \Psi_1 \rangle, \quad \tilde{a}_i = \langle \Lambda^{i-2} \Psi_1, \Psi_2 \rangle, \quad \tilde{c}_i = \langle \Lambda^{i-2} \Psi_2, \Psi_2 \rangle, \quad i = 2,3,\ldots. \tag{31}$$

Here and hereafter, an overtilde indicates the corresponding nonlinearized quantity. We have

$$\lambda \tilde{V} = \begin{pmatrix} \sum_{k=1}^{N} \frac{\psi_{1k}\psi_{2k}}{\lambda - \lambda_k} & -\sum_{k=1}^{N} \frac{\psi_{1k}^2}{\lambda - \lambda_k} \\ \lambda - \langle \Lambda \Psi_1, \Psi_1 \rangle + \sum_{k=1}^{N} \frac{\psi_{2k}^2}{\lambda - \lambda_k} & -\sum_{k=1}^{N} \frac{\psi_{1k}\psi_{2k}}{\lambda - \lambda_k} \end{pmatrix}. \tag{32}$$

Under the condition (28) and (29), the following equation still holds:

$$\tilde{V}_x = [\tilde{U}, \tilde{V}]. \tag{33}$$

Conversely, a direct calculation can verify that (33) is just the Lax representation of equation (30). For simplicity of notation, we set $L(\lambda) = \lambda \tilde{V}$, and $M_i = \tilde{V}^{(i)}$. Therefore we have the following theorem.

Theorem 1: *The equation (30) has the Lax representation*

$$L_x = [M_0, L], \tag{34}$$

with

$$L(\lambda) = \begin{pmatrix} A(\lambda) & B(\lambda) \\ C(\lambda) & -A(\lambda) \end{pmatrix}, \quad M_0(\lambda) = \begin{pmatrix} 0 & 1 \\ D(\lambda) & 0 \end{pmatrix}, \tag{35}$$

where

$$A(\lambda) = \sum_{k=1}^{N} \frac{\psi_{1k}\psi_{2k}}{\lambda - \lambda_k}, \quad B(\lambda) = -\sum_{k=1}^{N} \frac{\psi_{1k}^2}{\lambda - \lambda_k}, \quad C(\lambda) = \lambda - \langle \Lambda \Psi_1, \Psi_1 \rangle + \sum_{k=1}^{N} \frac{\psi_{2k}^2}{\lambda - \lambda_k} \tag{36}$$

and

$$D(\lambda) = -\lambda^2 + 2\langle \Lambda \Psi_1, \Psi_1 \rangle \lambda + \langle \Lambda^2 \Psi_1, \Psi_1 \rangle - \langle \Psi_2, \Psi_2 \rangle - 2\langle \Lambda \Psi_1, \Psi_1 \rangle^2. \tag{37}$$

In the same way, we can discuss the nonlinearization of the auxiliary spectral problem,

$$\begin{pmatrix} \psi_{1j} \\ \psi_{2j} \end{pmatrix} = V^{(n)}(\lambda_j, u) \begin{pmatrix} \psi_{1j} \\ \psi_{2j} \end{pmatrix}, \quad j = 1,...,N, \tag{38}$$

under the constraints (28), (29), and (30). And we can obtain a hierarchy of finite-dimensional systems with the Neumann constraints $\langle \Psi_1, \Psi_1 \rangle = 1$ and $\langle \Psi_1, \Psi_2 \rangle = 0$. We call the restricted t_n flow. Just like in the case of the Bargmann constraint, the identity

$$V_{t_n} = [V^{(n)}, V] \tag{39}$$

is nonlinearization of the Lax representation of the restricted t_n-flow. In particular, for $n = 3$ we obtain the following system:

$$\begin{aligned} \Psi_{1,t_3} &= \langle \Lambda\Psi_1, \Psi_2 \rangle \Lambda\Psi_1 - \langle \Lambda\Psi_1, \Psi_1 \rangle \Psi_2, \\ \Psi_{2,t_3} &= E\Psi_1 - \langle \Lambda\Psi_1, \Psi_2 \rangle \Psi_2, \\ \langle \Psi_1, \Psi_1 \rangle &= 1, \langle \Psi_1, \Psi_2 \rangle = 0, \end{aligned} \tag{40}$$

with

$$\begin{aligned} E = \Lambda^3 &- \langle \Lambda\Psi_1, \Psi_1 \rangle \Lambda^2 + \Lambda(\langle \Psi_2, \Psi_2 \rangle - \langle \Lambda^2\Psi_1, \Psi_1 \rangle) - \langle \Lambda\Psi_2, \Psi_2 \rangle - \langle \Lambda^3\Psi_1, \Psi_1 \rangle \\ &+ 2\langle \Lambda\Psi_1, \Psi_1 \rangle \langle \Lambda^2, \Psi_1 \rangle, \end{aligned}$$

and the equation (40) has the Lax representation.

Theorem 2: *The equation (40) possess the following Lax representation:*

$$L_{t_3} = [M_1, L], \tag{41}$$

$$M_1(\lambda) = \begin{pmatrix} -\langle \Lambda\Psi_1, \Psi_2 \rangle & -\lambda - \frac{1}{2}\langle \Lambda\Psi_1, \Psi_1 \rangle \\ T(\lambda) & \langle \Lambda\Psi_1, \Psi_2 \rangle \end{pmatrix}, \tag{42}$$

where

$$\begin{aligned} T(\lambda) = \lambda^3 &- \langle \Lambda\Psi_1, \Psi_1 \rangle \lambda^2 + \lambda(\langle \Psi_2, \Psi_2 \rangle - \langle \Lambda^2\Psi_1, \Psi_1 \rangle) - \langle \Lambda\Psi_2, \Psi_2 \rangle \\ &- \langle \Lambda^3\Psi_1, \Psi_+ \rangle 2\langle \Lambda\Psi_1, \Psi_1 \rangle \langle \Lambda^2\Psi_1, \Psi_1 \rangle. \end{aligned}$$

B. *r* matrix and integrability

Now we turn to discuss the r-matrix relation for $L(\lambda)$. In the standard Poisson bracket of the symplectic space $(R^{2N}, d\Psi_2 \wedge d\Psi_1)$, it is not difficult to find that

$$\{A(\lambda), A(\mu)\} = \{B(\lambda), B(\mu)\} = 0, \tag{43}$$

$$\{C(\lambda), C(\mu)\} = 4(\lambda + \mu - 2\langle \Lambda\Psi_1, \Psi_1 \rangle)(A(\lambda) - A(\mu)), \tag{44}$$

$$\{A(\lambda), B(\mu)\} = \frac{2}{\mu - \lambda}(B(\mu) - B(\lambda)), \tag{45}$$

$$\{B(\lambda), C(\mu)\} = \frac{4}{\mu - \lambda}(A(\mu) - A(\lambda)), \tag{46}$$

$$\{A(\lambda), C(\mu)\} = \frac{2}{\mu - \lambda}(C(\lambda) - C(\mu)) + 2B(\lambda)(2\langle \Lambda\Psi_1, \Psi_1 \rangle - \lambda - \mu), \tag{47}$$

where λ,μ are two arbitrary parameters.

Thus we obtain the following.

Proposition 2: The L-operator $L(\lambda)$ satisfies

$$\{L_1(\lambda)\overset{\otimes}{,} L_2(\mu)\}=[r_{12}(\lambda,\mu),L_1(\lambda)]-[r_{21}(\lambda,\mu),L_2(\mu)], \tag{48}$$

with

$$r_{12}(\lambda,\mu)=\frac{2}{\mu-\lambda}P+2(-2\langle\Psi_1,\Psi_1\rangle+\lambda+\mu)\sigma_-\otimes\sigma_- \tag{49}$$

and

$$r_{21}(\lambda,\mu)=-\frac{2}{\mu-\lambda}P+2(-2\langle\Psi_1,\Psi_1\rangle+\lambda+\mu)\sigma_-\otimes\sigma_-, \tag{50}$$

where $P=1/2(I+\Sigma_{j=1}^{3}\sigma_j\otimes\sigma_j)$ is the permutation matrix, and σ_j is the Pauli matrix.

Then according to the theory of the r matrix,[14] we have

$$\{\mathrm{Tr}\ L^2(\lambda),\mathrm{Tr}\ L^2(\mu)\}=0, \tag{51}$$

which ensures the involution property of the integrals of motion obtained from expanding $L^2(\lambda)$ in powers of λ. Explicitly,

$$\det L(\lambda)=-\tfrac{1}{2}\mathrm{Tr}\ L^2(\lambda)=-A^2(\lambda)-B(\lambda)C(\lambda)=\langle\Psi_1,\Psi_1\rangle+\sum_{j=1}^{N}\frac{I_j}{\lambda-\lambda_j}, \tag{52}$$

where

$$I_k=\lambda_k\psi_{1k}^2-\langle\Lambda\Psi_1,\Psi_1\rangle\psi_{1k}^2++\sum_{\substack{i=1\\ j\neq k}}^{N}\frac{(\psi_{1j}\psi_{2k}-\psi_{1k}\psi_{2j})^2}{\lambda_k-\lambda_j},\quad k=1,2,...,N, \tag{53}$$

we have

$$\{I_j,I_k\}=0. \tag{54}$$

Moreover, it is easy to prove that $I_1,I_2,\ldots,I_N$ are N functionally independent in R^{2N}.

Since we are dealing with the involutivity in the submanifold, defined by $F=\langle\Psi_1,\Psi_1\rangle-1$ and $G=\langle\Psi_1,\Psi_2\rangle$, we have to use the Dirac bracket. Next we first give the Hamiltonian for Eqs. (30) and (40).

From the definition given in (4) as $F=\langle\Psi_1,\Psi_1\rangle-1$ and $G=\langle\Psi_1,\Psi_2\rangle$, we have

$$\{f,g\}_{\mathrm{D}}=\{f,g\}+\tfrac{1}{2}\{f,F\}\{G,g\}-\tfrac{1}{2}\{f,G\}\{F,g\}. \tag{55}$$

A direct calculation yields the following.

$$\{\psi_{1k},\psi_{1l}\}_{\mathrm{D}}=0,\quad \{\psi_{1k},\psi_{2l}\}_{\mathrm{D}}=\delta_{kl}-\psi_{1k}\psi_{1l},\quad \{\psi_{2k},\psi_{2l}\}_{\mathrm{D}}=-\psi_{1k}\psi_{2l}+\psi_{2k}\psi_{1l}. \tag{56}$$

Proposition 3: The constrained systems (30) and (40) can be written as the following Hamiltonian forms, respectively:

$$\Psi_{1,x}=\{\Psi_1,H_1\}_{\mathrm{D}},\quad \Psi_{2,x}=\{\Psi_2,H_1\}_{\mathrm{D}}. \tag{57}$$

and

$$\Psi_{1,t_3}=\{\Psi_1,H_2\}_{\mathrm{D}},\quad \Psi_{2,t_3}=\{\Psi_2,H_2\}_{\mathrm{D}}, \tag{58}$$

where

$$H_1=\tfrac{1}{2}(\langle\Lambda^2\Psi_1,\Psi_1\rangle-\langle\Lambda\Psi_1,\Psi_1\rangle^2+\langle\Psi_2,\Psi_2\rangle) \tag{59}$$

and

$$H_2=\langle\Lambda^3\Psi_1,\Psi_1\rangle-\langle\Lambda\Psi_1,\Psi_1\rangle\langle\Lambda^2\Psi_1,\Psi_1\rangle+\langle\Lambda\Psi_1,\Psi_1\rangle\langle\Psi_2,\Psi_2\rangle+\langle\Lambda\Psi_2,\Psi_2\rangle. \tag{60}$$

After a lengthy but direct calculation, we get

$$\{A(\lambda),A(\mu)\}_D=\{B(\lambda),B(\mu)\}_D=0,$$

$$\{C(\lambda),C(\mu)\}_D=4(C(\lambda)A(\mu)-A(\lambda)C(\mu))+4(\lambda+\mu-2\langle\Lambda\Psi_1,\Psi_1\rangle)(A(\lambda)-A(\mu)),$$

$$\{A(\lambda),B(\mu)\}_D=\frac{2}{\mu-\lambda}\,(B(\mu)-B(\lambda))-2B(\lambda)B(\mu),$$

$$\{B(\lambda),C(\mu)\}_D=\frac{4}{\mu-\lambda}\,(A(\mu)-A(\lambda))-4B(\lambda)A(\mu),$$

$$\{A(\lambda),C(\mu)\}_D=\frac{2}{\mu-\lambda}\,(C(\lambda)-C(\mu))+2B(\lambda)(2\langle\Lambda\Psi_1,\Psi_1\rangle-\lambda-\mu)+2B(\lambda)C(\mu).$$

From these relations Proposition 4 follows.

Proposition 4: The Lax operator $L(\lambda)$ admits the following r-matrix representation:

$$\{L_1(\lambda)\overset{\otimes}{,}L_2(\mu)\}_D=[a_{12}(\lambda,\mu),L_1(\lambda)]-[a_{21}(\lambda,\mu),L_2(\mu)], \tag{61}$$

with

$$a_{12}(\lambda,\mu)=-\frac{2}{\mu-\lambda}\,P+2(\lambda+\mu-2\langle\Lambda\Psi_1,\Psi_1\rangle)\sigma_-\otimes\sigma_-+Q_{12}, \tag{62}$$

$$a_{21}(\lambda,\mu)=\frac{2}{\mu-\lambda}\,P+2(\lambda-\mu-2\langle\Lambda\Psi_1,\Psi_1\rangle)\sigma_-\otimes\sigma_-+Q_{21}, \tag{63}$$

and

$$Q_{12}=\begin{pmatrix}1&0\\0&0\end{pmatrix}\otimes\begin{pmatrix}B(\mu)&0\\-2A(\mu)&-B(\mu)\end{pmatrix}+\begin{pmatrix}0&0\\1&0\end{pmatrix}\otimes\begin{pmatrix}0&B(\mu)\\-C(\mu)&0\end{pmatrix}, \tag{64}$$

$$Q_{21}=\begin{pmatrix}B(\lambda)&0\\-2A(\lambda)&-B(\lambda)\end{pmatrix}\otimes\begin{pmatrix}1&0\\0&0\end{pmatrix}+\begin{pmatrix}0&B(\lambda)\\-C(\lambda)&0\end{pmatrix}\otimes\begin{pmatrix}0&0\\1&0\end{pmatrix}. \tag{65}$$

Just like in the case of the standard Poisson bracket, from (61), we obtain

$$\{\mathrm{tr}\,L^2(\lambda),\mathrm{tr}\,L^2(\mu)\}_D=0. \tag{66}$$

That is to say, the restriction of $I_1,I_2,\ldots,I_N$ to M are still in involution. Since $\Sigma_{j=1}^N I_j=0$, we know $I_1,\ldots,I_N$ are not independent in M. It is not difficult to find that there are $N-1$ functions that are functionally independent among $I_1,I_2,\ldots,I_N$ in R^{2N}.

Moreover we notice that $H_1=1/2\Sigma_{j=1}^N\lambda_j I_j$, $H_2=1/2\Sigma_{j=1}^N\lambda_j^2 I_j$.

Hence we have

$$\{H_1,I_j\}_D=\{H_2,I_j\}_D=\{I_i,I_j\}_D=0,\quad i,j=1,2,...,N. \tag{67}$$

Proposition 5 follows.

Proposition 5: Both the Hamiltonian systems (30) and (40) are completely integrable systems in the Liouville's sense. Besides, the x flow and t_3 flow are commutative in the symplectic submanifold M.

C. Separation of variables

Let us introduce new variables in the $2N-2$-dimensional symplectic submanifold M. First let $u_1,\ldots,u_{N-1}$ be the $N-1$ zero points of $B(\lambda)$, i.e.,

$$\sum_{j=1}^{N} \frac{\psi_{1j}^2}{\lambda-\lambda_j} = \frac{\Pi_{k=1}^{N-1}(\lambda-u_k)}{\Pi_{k=1}^{N}(\lambda-\lambda_j)}. \tag{68}$$

It is easy to see that the choices of the λ_j's ensure $B(\lambda)$ exactly have $N-1$ simple roots.

Another $N-1$ new variables: $v_1,v_2,\ldots,v_{N-1}$, are defined by

$$v_k=\tfrac{1}{2}A(u_k), \quad k=1,2,...,N-1. \tag{69}$$

For these new variables, we have the following.

Proposition 6: New variables $\{u_k,v_k\}_{k=1}^{N-1}$ are canonically conjugated in the submanifold M, i.e.,

$$\{u_j,u_k\}_{\mathrm{D}}=\{v_j,v_k\}_{\mathrm{D}}=0, \quad \{u_j,v_k\}_{\mathrm{D}}=\delta_{jk}. \tag{70}$$

Proof: First, since the u_k's only are determined by $B(\lambda)$ and $B(\lambda)$ only depends on the variables ψ_{1j}'s, the relation $\{u_i,u_j\}_{\mathrm{D}}=0$ follows.

Second,

$$\{B(\lambda),v_k\}_{\mathrm{D}}=\{B(\lambda),\tfrac{1}{2}A(u_k)\}_{\mathrm{D}}=\tfrac{1}{2}\{B(\lambda),A(\mu)\}_{\mathrm{D},\mu=u_k}+\tfrac{1}{2}A'(u_k)\{B(\lambda),u_k\}_{\mathrm{D}}$$
$$=-\frac{1}{\mu-\lambda}\,(B(\mu)-B(\lambda))\big|_{\mu=u_k}+B(\lambda)B(\mu)\big|_{\mu=u_k}=\frac{B(\lambda)}{u_k-\lambda}.$$

However,

$$0=\{B(u_j),v_k\}_{\mathrm{D}}=\{B(\lambda),v_k\}_{\mathrm{D},\lambda=u_j}+B'(u_j)\{u_j,v_k\}_{\mathrm{D}}; \tag{71}$$

thus

$$\{u_j,v_k\}_{\mathrm{D}}=-\frac{1}{B'(u_j)}\,\{B(\lambda),v_k\}_{\mathrm{D},\lambda=u_j}. \tag{72}$$

Therefore we have

$$\{u_j,v_k\}_{\mathrm{D}}=-\frac{1}{B'(u_k)}\,\frac{B(\lambda)}{u_k-\lambda}\bigg|_{\lambda=u_j}=\delta_{jk}. \tag{73}$$

Finally, we have

$$4\{v_k,v_j\}_{\mathrm{D}}=\{A(u_k),A(u_j)\}_{\mathrm{D}}=\{A(\lambda),A(\mu)\}_{\mathrm{D},\lambda=u_k,\mu=u_j}+A'(u_j)\{v_k,u_j\}_{\mathrm{D}}+A'(u_k)\{u_k,v_j\}_{\mathrm{D}}$$
$$-A'(u_k)A'(u_j)\{u_k,u_j\}_{\mathrm{D}}=0. \tag{74}$$

This completes the proof of the proposition.

Write

$$\det L(\lambda)=\frac{P(\lambda)}{K(\lambda)}, \tag{75}$$

where

$$K(\lambda)=\prod_{k=1}^{N}(\lambda-\lambda_k)=\sum_{j=1}^{N}(-1)^j\alpha_j\lambda^{N-j} \tag{76}$$

and

$$P(\lambda)=\lambda^N+P_{N-1}\lambda^{N-1}+\cdots+P_0 \tag{77}$$

is a polynomial of order N in terms of λ.

Here (75) yields

$$P_{N-1}=-\alpha_1,\quad P_{N-2}=\alpha_2+2H_1,\quad P_{N-3}=-\alpha_3-2\alpha_1H_1+2H_2. \tag{78}$$

In general, P_k consists of the I_j's and the constants λ_j's; thus, P_k and P_j are in involution with each other. For our Hamiltonian function H_1 and H_2, we have

$$H_1=\tfrac{1}{2}(P_{N-2}-\alpha_2),\quad H_2=\tfrac{1}{2}\,(P_{N-3}+\alpha_3+\alpha_1P_{N-2}-\alpha_2\alpha_2). \tag{79}$$

Following Refs. 19 and 20, we consider the separation of variables of the Hamiltonian $P(\lambda)$ instead; directly consider the explicit H_1 and H_2, respectively.

From (75), we know that

$$P(u_k)=-4v_k^2K(u_k),\quad k=1,...,N-1. \tag{80}$$

Using the Lagrange interpolation, $P(\lambda)$ can be expressed as

$$P(\lambda)=Q(\lambda)\left(\lambda-\alpha_1+\sum_{k=1}^{N-1}u_k\right)-4\sum_{k=1}^{N-1}\frac{Q(\lambda)K(u_k)}{(\lambda-u_k)Q'(u_k)}\,v_k^2, \tag{81}$$

where

$$Q(\lambda)=\prod_{k=1}^{N-1}(\lambda-u_k). \tag{82}$$

By $\partial S/\partial u_k$, replace v_k and interpret the coefficient of $P(\lambda)$: $P_0,\ldots,P_1,\ldots,P_{N-2}$ as the integration constants. The Hamilton–Jacobi equation follows:

$$Q(\lambda)\left(\lambda-\alpha_1+\sum_{k=1}^{N-1}u_k\right)-4\sum_{k=1}^{N-1}\frac{Q(\lambda)K(u_k)}{(\lambda-u_k)Q'(u_k)}\left(\frac{\partial S}{\partial u_k}\right)^2=P(\lambda). \tag{83}$$

We wish to look for the action function S with the form $S(u_1,\ldots,u_{N-1})=\Sigma_{k=1}^{N-1}s_k(u_k)$.

Inserting into Eq. (83), dividing two sides by $Q(\lambda)$, and taking residue at $\lambda=u_k$, we get

$$4\left(\frac{\partial s_k}{\partial u_k}\right)^2=-\frac{P(u_k)}{K(u_k)},\quad k=0,...,N-2. \tag{84}$$

Finally, we have

$$S=\frac{1}{2}\sum_{k=1}^{N-1}\int_0^{u_k}\sqrt{-\frac{P(\lambda)}{K(\lambda)}}\,d\lambda. \tag{85}$$

Therefore the linearizing coordinates are

$$Q_j=\frac{\partial S}{\partial P_j}=\frac{1}{4}\sum_{k=1}^{N-1}\int_0^{u_k}\frac{\lambda^k}{\sqrt{-K(\lambda)P(\lambda)}}\,d\lambda,\quad j=0,...,N-2. \tag{86}$$

Thus, in the symplectic submanifold $(M,\Sigma_{j=0}^{N-2}dQ_j\wedge dP_j)$, the flows generating from the Hamiltonians H_1 and H_2 are, respectively,

$$Q_j=Q_j^0+\tfrac{1}{2}\,\delta_{j,N-2}x, \tag{87}$$

and

$$Q_j = Q_j^0 + \tfrac{1}{2}(\delta_{j,N-3} + \alpha_1 \delta_{j,N-2}) t_3, \quad j = 0,...,N-2, \tag{88}$$

where Q_0^0, $Q_1^0,\ldots,Q_{N-2}^0$ are $N-1$ constants.

These involve Abelian integrals of the first kind and essentially define the Abel map to the Jacobi variety. Using the reciprocity theorem relating Abelian integrals of the first kind, the equations (87) and (88) may be solved in terms of the Riemann theta function.

IV. CONCLUDING REMARKS

We have shown how to use the r-matrix approach to the Neumann system and how to separate the variables for the Neumann system. From the procedure we can see that since the use of the Dirac bracket the r matrix must be a dynamical r matrix. This will provide us with a large number of examples of the dynamical. In addition, we notice that the constraint between the potentials of the soliton hierarchy and the eigenfunctions may give the finite-gap solutions of the soliton hierarchy.[1,5] Since the system of the equation with respect to the eigenfunctions can be solved, we can search for the finite-gap solution for the soliton equation. This will be discussed in the future. Besides, as we know that the r-matrix formula and separation of variables have a direct link between the classical integrable problem and the quantum integrable problem. We hope our results obtained here will be helpful to the quantizations of the Neumann systems.

Curvature-free asymmetric metric connections and Lanczos potentials in Kerr–Schild spacetimes

F. Andersson[a] and S. Brian Edgar[b]
Department of Mathematics, Linköping University, Linköping, S581 83 Sweden

(Received 14 October 1997; accepted for publication 2 February 1998)

The set of spinor equations linking the curvature spinors of a Riemann–Cartan space with the curvature spinors of the corresponding Riemann space is derived, and these are used to establish a simple relationship between Ψ-flat connections of the Riemann–Cartan space and Lanczos potentials of the Riemann space. This not only yields, very easily, a recent result of Bergqvist for the Kerr metric, but also enables Bergqvist's result to be generalized; specifically we show that a curvature-free connection, associated with a class of Kerr–Schild metrics, can be identified as a Lanczos potential for the Weyl conformal curvature spinor of these spaces. © *1998 American Institute of Physics.* [S0022-2488(98)01205-5]

I. RIEMANN–CARTAN SPINOR EQUATIONS

When a symmetric metric connection ∇_a of a Riemannian space (with curvature tensor R_{abcd}) is generalized by the addition of a tensor $\Gamma_{abc}(=\Gamma_{[ab]c})$ to give a new asymmetric connection $\hat{\nabla}_a$ by

$$\hat{\nabla}_a\xi_b=\nabla_a\xi_b-2\Gamma_b{}^c{}_a\xi_c\,, \tag{1}$$

this new Riemann–Cartan space is still metric compatible and has curvature tensor $\hat{R}_{abcd}$ given by

$$\hat{R}_{abcd}=R_{abcd}+4\nabla_{[a}\Gamma_{|cd|b]}+8\Gamma_{ed[a}\Gamma_{|c|}{}^e{}_{b]}\,. \tag{2}$$

(The standard notation of Ref. 1 is used.) The spinor version of Γ_{abc} is given by

$$\Gamma_{abc}=\Gamma_{ABCC'}\epsilon_{A'B'}+\overline{\Gamma}_{A'B'C'C}\epsilon_{AB}\,, \tag{3}$$

where $\Gamma_{ABCC'}=\Gamma_{(AB)CC'}$, so that (1) becomes[1]

$$\hat{\nabla}_{AA'}\xi_B=\nabla_{AA'}\xi_B-2\Gamma^E{}_{BAA'}\xi_E\,. \tag{4}$$

The spinor version of $\hat{R}_{abcd}$ is given by[1]

$$\begin{aligned}\hat{R}_{abcd}=\epsilon_{A'B'}\epsilon_{C'D'}[&\hat{\Psi}_{ABCD}+2(\epsilon_{B(C}\hat{\Sigma}_{D)A}+\epsilon_{A(C}\hat{\Sigma}_{D)B})+\hat{\Lambda}(\epsilon_{AD}\epsilon_{BC}+\epsilon_{AC}\epsilon_{BD})]\\&+\hat{\Phi}_{ABC'D'}\epsilon_{A'B'}\epsilon_{CD}+\text{c.c.}\end{aligned} \tag{5}$$

After the substitution of (3) and the usual spinor decomposition for R_{abcd} into the right hand side of (2), the resulting spinor expression can be equated to the right hand side of (5). Then, this spinor version of (2) can be written out as a number of equations,[2]

$$\begin{aligned}\hat{\Psi}_{ABCD}&=\Psi_{ABCD}-2\nabla_{(A}{}^{E'}\Gamma_{BCD)E'}-4\Gamma_{E(AB}{}^{E'}\Gamma^E{}_{CD)E'},\\3\hat{\Lambda}&=3\Lambda-\nabla_A{}^{E'}\Gamma^{AB}{}_{BE'}-\Gamma_{EABF'}\Gamma^{BEAF'}+\Gamma^B{}_{EBF'}\Gamma^{EA}{}_A{}^{F'},\end{aligned}$$

$$4\hat{\Sigma}_{AD}=\nabla^{BE'}\Gamma_{B(AD)E'}-\nabla_{(A}{}^{E'}\Gamma^{B}{}_{D)BE'}-2\Gamma_{E(D|B|}{}^{F'}\Gamma^{BE}{}_{A)F'}-2\Gamma_{E(AD)}{}^{F'}\Gamma^{BE}{}_{BF'},$$
$$\hat{\Phi}_{ABC'D'}=\Phi_{ABC'D'}+2\nabla_{(B|E'}\overline{\Gamma}_{C'D'|}{}^{E'}{}_{A)}+4\overline{\Gamma}_{E'D'F'(A}\overline{\Gamma}_{|C'|}{}^{E'F'}{}_{B)}. \tag{6}$$

To our knowledge, the precise set of equations (6) has not appeared before in the literature, although an NP spin-coefficient version of related equations has been given.[3,4]

II. LANCZOS POTENTIALS AND FLAT CONNECTIONS

Illge[5] has shown that the Weyl curvature spinor Ψ_{ABCD} of a Riemann space can always be given locally in terms of a symmetric potential $L_{ABCA'}(=L_{(ABC)A'})$ as

$$\Psi_{ABCD}=2\nabla_{(A}{}^{A'}L_{BCD)A'}. \tag{7}$$

(It should be noted that Lanczos[6] originally proposed a potential for the Weyl tensor C_{abcd}; this 3-tensor H_{abc} had the properties $H_{abc}=H_{[ab]c}$ and $H_{[abc]}=0$, with an associated algebraic gauge $H_{ab}{}^{a}=\chi_b$. It is easy to see that the gauge choice $\chi_b=0$ reduces the 3-tensor H_{abc} to be equivalent to the symmetric spinor $L_{ABCA'}$. A formal local existence proof for this tensor version has been given by Bampi and Caviglia.[7] See Ref. 8 for a recent review on the Lanczos spinor/tensor.)

We therefore have the following result, directly from the first of equations (6).

Lemma: For an asymmetric metric connection $\hat{\nabla}_{AA'}$ defined as in (4), any two of the following properties implies the third:

(i) $\hat{\Psi}_{ABCD}=0$, *i.e., the Riemann–Cartan space is Ψ-flat.*
(ii) $\Gamma_{E(AB}{}^{A'}\Gamma^{E}{}_{CD)A'}=0$.
(iii) $L_{ABCA'}=\Gamma_{(ABC)A'}$ *is a Lanczos potential for the Weyl spinor Ψ_{ABCD} of the original Riemann space, i.e., (7) is satisfied.*

III. FLAT CONNECTIONS WHICH YIELD LANCZOS POTENTIALS

A few years ago Bergqvist and Ludvigsen[9] constructed, for the Kerr spacetime, a metric-compatible asymmetric connection with vanishing curvature, which they have proposed has significant physical relevance. Shortly afterwards, Harnett[10] showed a similar construction can be carried out for the whole Kerr–Schild class of metrics,[11]

$$g_{ab}=g_{o^{ab}}+fl_al_b, \tag{8}$$

where $g_{o^{ab}}$ is the Minkowski metric, f is a scalar function of the coordinates and l_a is a null vector with respect to both metrics. An associated metric-compatible asymmetric connection, which has vanishing curvature, is constructed from the symmetric connection via (4) by choosing

$$\Gamma_{ABCC'}=\nabla_{(A}{}^{A'}(f\,o_{B)}o_Co_{A'}o_{C'}), \tag{9}$$

where $l_a=o_Ao_{A'}$.

Recently, Bergqvist[12] has shown that the flat connection found in Ref. 9 can be used to determine a Lanczos potential for the Weyl spinor of the Kerr metric.

We will now generalize Bergqvist's result and show—for a large class of the Kerr–Schild spaces—that the flat connection found in Ref. 10 can be used to determine a Lanczos potential for the Weyl spinor of these Kerr–Schild metrics.

Theorem: *For those Kerr–Schild metrics given by (8), where l_a is tangent to a shear-free null geodesic congruence, the Weyl spinor has a Lanczos potential given by*

$$L_{ABCA'}=\nabla_{(A}{}^{C'}(f\,o_Bo_{C)}o_{A'}o_{C'}).$$

Proof: As noted above, from Ref. 10 the connection given by substituting (9) in (4) is curvature-free, and so, in particular, condition (i) holds in the Lemma above. Hence $\Gamma_{(ABC)A'}$ is a Lanczos potential if and only if condition (ii) holds.

Noting that

$$o^{A'}\Gamma_{ABCA'} = o^{A'}\nabla_{(A}{}^{A'}(f\, o_{B)}o_C o_{A'}o_{C'}) = f\, o_C o_{(B}o^{B'}o^{A'}\nabla_{A)B'}o_{A'} = 0,$$

where the fact that o^A represents a shear-free null geodesic congruence is used in the last step, we can write

$$\Gamma_{ABCA'} = M_{ABC}o_{A'}$$

for some M_{ABC}. Hence condition (ii) follows.

This proof, for the whole Kerr–Schild subclass, is much more concise than Bergqvist's proof[12] for the special case of Kerr spacetime. This result will enable the physical applications of the Lanczos spinor, which Bergqvist has been developing for Kerr space, to be applicable to this larger class of Kerr–Schild spaces.

In conclusion, we point out that there are a number of algorithms in the literature for constructing Lanczos potentials for various spacetimes;[13–17] the Lemma in Section II gives us a means of checking whether such Lanczos potentials enable us to construct a $\Psi-$flat connection, while the equations in Section I enable us to test which other parts of the curvature tensor also vanish. It is straightforward to show that the Lanczos potentials defined in Refs. 14 and 15 do not permit a $\Psi-$flat connection by the construction in this paper; on the other hand, the Lanczos potential defined in Ref. 17 is easily confirmed to permit such a Ψ-flat connection, and indeed some other parts of the connection are also flat. We shall look at these Lanczos potentials in more detail elsewhere.

"Clock rate synchronizable" reference frames in curved space–times

Sijie Gao
Department of Physics, Beijing Normal University, Beijing, People's Republic of China

Zhiquan Kuang[a] and Canbin Liang[b]
Center of Theoretical Physics, China Center of Advanced Science and Technology (World Lab), Beijing, People's Republic of China

(Received 12 September 1997; accepted for publication 6 January 1998)

It is well known that all reference frames that are clock synchronizable are hypersurface orthogonal. A weaker requirement for clock synchronization was first suggested by Zhao [Z. Zhao, Sci. China **34**(7), 835 (1991)] using coordinate language. Reference frames satisfying this requirement are hence referred to as class Z in the present paper. We give a geometrical definition of class Z reference frames and investigate their physical meaning as well as geometrical properties in detail. Finally, another kind of reference frame referred to as class $\tilde{\mathrm{z}}$ is introduced and its possible relation to another of Zhao's claims is pointed out. © *1998 American Institute of Physics.* [S0022-2488(98)02604-8]

I. INTRODUCTION

It is well accepted in general relativity that an observer in a space–time (M,g_{ab}) is a future pointing timelike curve (his world line) in M with $g_{ab}(\partial/\partial\tau)^a(\partial/\partial\tau)^b=-1$, where τ is the proper time of the observer, and a reference frame $\mathscr{R}$ in (M,g_{ab}) is a vector field, each of whose integral curves is an observer.[1] (In this paper we use the "abstract index notation,"[2] where a letter with Latin letter indices represents a tensor itself while the same letter with Greek letter indices represent the components of that tensor with respect to some basis.) Since each observer has his own clock, there exists the issue of synchronization among clocks of different observers in $\mathscr{R}$. In the literature there is a series of definitions of synchronizability of reference frames:[1] $\mathscr{R}$ is called (a) *proper time synchronizable* iff $\exists$ smooth function t on M such that $\nu_a=-(dt)_a$, where ν^a is the four-velocity of observers in $\mathscr{R}$; (b) *locally proper time synchronizable* iff $(d\nu)_{ab}=0$; (c) *synchronizable* iff $\exists$ smooth functions t and $h(>0)$ on M such that $\nu_a=-h(dt)_a$; (d) *locally synchronizable* iff $\nu_a\wedge(d\nu)_{bc}=0$. The last condition, being the weakest one of the four, is equivalent to requiring that $\mathscr{R}$ be hypersurface orthogonal. Physically, orthogonal hypersurfaces (short for hypersurface orthogonal to all world lines in $\mathscr{R}$) are interpreted as simultaneity surfaces, and hence all (standard or coordinate) clocks in $\mathscr{R}$ are required be adjusted (synchronized) so that they give the same reading on each such surface. To this end one needs only to choose an arbitrary observer (denoted γ_P) in $\mathscr{R}$ to take the lead and command all other observers in $\mathscr{R}$ to adjust their clock settings. In the case where $\mathscr{R}$ is not hypersurface orthogonal, one can choose any "one-dimensional family" of observers in $\mathscr{R}$ (their world lines comprise a two-dimensional submanifold of M) and require that all clocks in this family be adjusted so that they give the same reading on each "simultaneity curve" (a curve orthogonal to all world lines in this family). The problem, however, is that orthogonal lines might not be closed curves, and, as a result, after observers γ_Q and $\gamma_{Q'}$ in $\mathscr{R}$ adjust their clocks to agree with γ_P, they will find that they do not agree with each other, i.e., if η is a simultaneity curve connecting γ_Q to $\gamma_{Q'}$, the readings of γ_Q and $\gamma_{Q'}$ on $\gamma_Q\cap\eta$ and $\gamma_{Q'}\cap\eta$ will be different. An interesting point suggested by Ref. 3 is that there does exist a class of reference frames satisfying the following requirement: if γ_Q and $\gamma_{Q'}$ are two clocks in $\mathscr{R}$ and η_1 and η_2 are any simultaneity curves connecting γ_Q to $\gamma_{Q'}$ and if $q_1=\gamma_Q\cap\eta_{1'}$, $q_2=\gamma_Q\cap\eta_2$, $q_1'=\gamma_{Q'}\cap\eta_1$, and $q_2'=\gamma_{Q'}\cap\eta_2$ (Fig. 1), then $\Delta t\equiv t(q_2)-t(q_1)$ equals $\Delta t'$

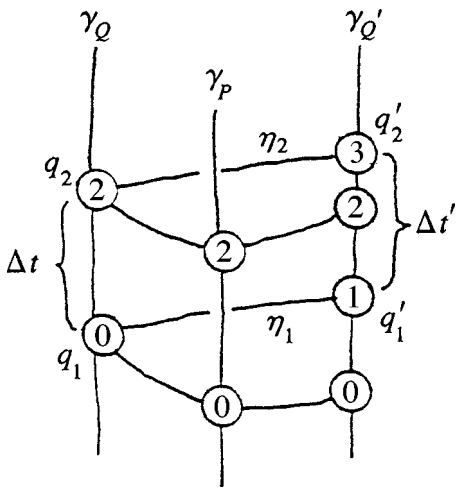

FIG. 1. Here $\Delta t' = \Delta t$ implies that all clocks in reference frame $\mathscr{R}$ have the same *rate* despite the fact that their initial settings *cannot* be adjusted to give the same readings on all simultaneity curves.

$\equiv t(q_2') - t(q_1')$, where t is the time coordinate of the comoving coordinate system. This can be interpreted physically as that all coordinate clocks in $\mathscr{R}$ have the same *rate* despite the fact that their initial settings *cannot* be adjusted to give the same readings on all simultaneity curves. This property of reference frames is referred to as ''transitivity of clock rate synchronizability'' in Ref. 3. Reference frames satisfying any one of the previous conditions (a)–(d) all admit this property since they are all hypersurface orthogonal, but the converse is not true. To avoid awkward wording, the jargon ''clock rate synchronizable reference frames'' is replaced by ''reference frames of class Z'' in this paper.

II. REFERENCE FRAMES OF CLASS Z

Throughout the paper we use (M, g_{ab}), $\mathscr{R}$, γ, and ν^a to represent respectively a space–time, a reference frame with domain $M_{\mathscr{R}} \subseteq M$, an observer in this frame, and the four velocity of the observer. Let $\hat{M}_{\mathscr{R}}$ be the set consisting of all world lines γ in $\mathscr{R}$ as elements. For the purpose of this paper it is enough to confine ourselves to reference frames in each of which $\hat{M}_{\mathscr{R}}$ is a three-dimensional manifold and there is a natural projection map $\pi: M_{\mathscr{R}} \to \hat{M}_{\mathscr{R}}$. A smooth curve $\hat{\eta} \subset \hat{M}_{\mathscr{R}}$ can be interpreted as a one-dimensional family of observers. A simultaneity curve $\eta \subset M_{\mathscr{R}}$ is called a *horizontal lift* of $\hat{\eta}$ if $\pi[\eta] = \hat{\eta}$. A reference frame $\mathscr{R}$ is said to belong to class Z if there exists a smooth function t on $M_{\mathscr{R}}$ satisfying (a) $t \circ \gamma$ is a monotone increasing function of the proper time τ for any observer γ in $\mathscr{R}$ and (b) if η and η' are simultaneity curves with $\pi[\eta] = \pi[\eta']$, γ_P and γ_Q are world lines in $\mathscr{R}$ intersecting η and η' at p, p', q, and q' (Fig. 2), then

$$\Delta t_{p'p} = \Delta t_{q'q}, \tag{1}$$

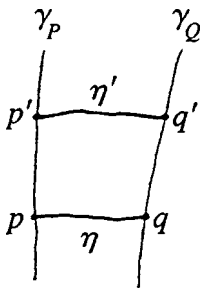

FIG. 2. Any pair of world lines γ_P and γ_Q in a class Z reference frame satisfies $\Delta t_{p'p} = \Delta t_{q'q}$ if η and η' are simultaneity curves with $\pi[\eta] = \pi[\eta']$.

where $\Delta t_{p'p} \equiv t(p') - t(p)$ and $\Delta t_{q'q} \equiv t(q') - t(q)$. Here $\mathscr{R}$ is said to belong to class Z locally iff $\forall\ p \in M_{\mathscr{R}}$ $\exists$ a neighborhood O_p of p such that $\exists$ a smooth function on O_p satisfying conditions (a) and (b). We now investigate the geometrical properties of class Z reference frames.

A smooth vector field w^a on γ is called a *neighbor* of γ in $\mathscr{R}$ iff $g_{ab} w^a \nu^b = 0$ and

$$\mathscr{L}_\nu w^a = \alpha \nu^a \tag{2}$$

with α a smooth function on γ. Note that this definition is equivalent to that given in Ref. 1.

Proposition 1: $\mathscr{R}$ belongs to class Z iff there exists a smooth function $f \neq 0$ on $M_{\mathscr{R}}$ such that

$$\mathscr{L}_\xi w^a = 0 \tag{3}$$

for any neighbor w^a, where $\xi^a \equiv f \nu^a$.

Proof: Suppose there exists f such that Eq. (3) holds. Then there exists a smooth function t on $M_{\mathscr{R}}$ such that $\xi^a = (\partial/\partial t)^a$. Let $\hat{\eta}$ be a nonclosed smooth curve in $\hat{M}_{\mathscr{R}}$. Then $\mathscr{S} \equiv \pi^{-1}[\hat{\eta}]$ is a two-dimensional submanifold in M. The commutivity of ξ^a and w^a [Eq. (3)] ensures the existence of coordinates t' and x' on $\mathscr{S}$ such that

$$(\partial/\partial t')^a = \xi^a = (\partial/\partial t)^a \quad \text{and} \quad (\partial/\partial x')^a = w^a. \tag{4}$$

The orthogonality of w^a to ν^a implies that each integral curve of w^a is a simultaneity curve, and Eq. (4) guarantees $\Delta t_{p'p} = \Delta t_{q'q}$ between any two simultaneity curves η and η' (Fig. 2), and hence $\mathscr{R}$ belongs to class Z by definition. Conversely, suppose $\mathscr{R}$ belongs to class Z. Then there exists a function t on $M_{\mathscr{R}}$ such that $\Delta t_{p'p} = \Delta t_{q'q} \equiv \Delta t$. Using t as a new parameter of each world line γ in $\mathscr{R}$, then the tangent vector field $\xi^a = (\partial/\partial t)^a$ defines, for any Δt, a diffeomorphism $\phi_{\Delta t}$ with $\phi_{\Delta t}[\eta] = \eta'$ (Fig. 2). Therefore $\phi_{\Delta t *} w^a|_p = w^a|_{p'}$ for any neighbor w^a, and hence $\mathscr{L}_\xi w^a = 0$. □

Proposition 2: $\mathscr{R}$ belongs to class Z iff there exists a smooth function f on $M_{\mathscr{R}}$ such that

$$H^a \nabla_a \ln f = H^a A_a, \quad \forall p \in M_{\mathscr{R}}, \tag{5}$$

where A^a is the four-acceleration of the observers in $\mathscr{R}$, and H^a satisfies $g_{ab} H^a \nu^b = 0$.

Proof: Suppose $\mathscr{R}$ belongs to class Z. Then Proposition 1 ensures the existence of a smooth function f such that

$$0 = \mathscr{L}_{f\nu} w^a = f(\nu^b \nabla_b w^a - w^b \nabla_b \nu^a - \nu^a w^b \nabla_b \ln f). \tag{6}$$

Contracting both sides with ν_a, making use of $\nu_a w^a = 0$ and $\nu^a \nu_a = -1$, one obtains $w^a A_a = w^b \nabla_b \ln f$. For any vector H^a orthogonal to γ there is a neighbor w^a such that $H^a = \lambda w^a$, $\lambda \in \mathbb{R}$, therefore Eq. (5) follows. Conversely, if there is a smooth function f satisfying Eq. (5), then $\mathscr{L}_{f\nu} w^a = 0$ for any neighbor w^a since it follows from Eqs. (6), (5), and (2) that

$$\nu_a \mathscr{L}_{f\nu} w^a = -w^a A_a + w^b \nabla_b \ln f = 0$$

and

$$H_a \mathscr{L}_{f\nu} w^a = f H_a \mathscr{L}_\nu w^a = f H_a \alpha \nu^a = 0 \quad \forall H^a \text{ orthogonal to } \gamma. \qquad \square$$

Proposition 3: $\mathscr{R}$ belongs to class Z locally iff $\forall p \in M_{\mathscr{R}}$ there exists a comoving coordinate system (t, x^i) $(i = 1,2,3)$ with a coordinate patch containing p such that

$$\frac{\partial}{\partial t}\left(\frac{g_{0i}}{g_{00}}\right) = 0, \tag{7}$$

where $g_{\mu\nu}$ are components of g_{ab} with respect to this coordinate system.

Note: Equation (7) is used in Ref. 3 to define ''transitivity of clock rate synchronizability.''

Proof: Suppose there exist comoving coordinates (t, x^i) satisfying Eq. (7). Let

$$e^a_{(i)}=\left(\frac{\partial}{\partial x^i}\right)^a-\frac{g_{0i}}{g_{00}}\left(\frac{\partial}{\partial t}\right)^a,\quad i=1,2,3. \tag{8}$$

Then it is easily checked that $e^a_{(i)}$ is a neighbor, and any neighbor w^a can be written as $w^a=w^{(i)}e^a_{(i)}$ with $w^{(i)}$ satisfying $\partial w^{(i)}/\partial t=0$, therefore

$$\mathscr{L}_{\partial/\partial t}w^a=\mathscr{L}_{\partial/\partial t}w^{(i)}e^a_{(i)}=-w^{(i)}\left(\frac{\partial}{\partial t}\right)^a\frac{\partial}{\partial t}\left(\frac{g_{0i}}{g_{00}}\right)=0,$$

where Eqs. (2)–(7) are used in the last step. Consequently $\mathscr{R}$ belongs to class Z locally. Conversely, if $\mathscr{R}$ belongs to class Z locally, then $\forall p\in M_{\mathscr{R}}$ there is a comoving coordinate system (t,x^i) satisfying $\mathscr{L}_{\partial/\partial t}w^a=0$ $\forall$ neighbors w^a confined in the coordinate patch, hence

$$0=\mathscr{L}_{\partial/\partial t}e^a_{(i)}=-\left(\frac{\partial}{\partial t}\right)^a\frac{\partial}{\partial t}\left(\frac{g_{0i}}{g_{00}}\right),$$

implying Eq. (7). □

Note that the time coordinate t in the comoving coordinate systems involved in Proposition 3 can be chosen to agree with the function involved in the definition of class Z.

It follows from Propositions 2 and 3 that (a) all reference frames with $(dA)_{ab}=0$ belong to class Z at least locally; (b) all hypersurface orthogonal reference frames belong to class Z at least locally; (c) all conformally stationary reference frames belong to class Z; and (d) $\mathscr{R}$ belongs to class Z iff there exists a conformal transformation that turns the world lines of observers in $\mathscr{R}$ to geodesics.

III. REFERENCE FRAMES OF CLASS $\tilde{Z}$ AND ZHAO'S CONCLUSION

A reference frame $\mathscr{R}$ is said to belong to class $\widetilde{\mathrm{Z}}$ iff the four-acceleration A^a of observers in $\mathscr{R}$ satisfies $\oint_\eta A_a=0$, where η is any closed, continuous, piecewise differentiable simultaneity curve.

We introduce class $\widetilde{\mathrm{Z}}$ here because this class is closely related to class Z. In fact, we have shown (although not presented in this paper) that they are equivalent locally in most cases. In addition, Zhao claimed in Ref. 3 the equivalence of transitivity of clock rate synchronizability and transitivity of thermal equilibrium. Although we have found some clues implying that class $\widetilde{\mathrm{Z}}$ reference frames may be interpreted as thermal equilibrium transitive reference frames, our investigation on this issue is far from mature.

ACKNOWLEDGMENTS

We would like to thank the referee for his valuable suggestion of writing this revised version of our paper. The first author would like to thank Professor Zhao Zheng for calling his attention to Ref. 3 and his encouragement during the investigation of this work. This work has been supported by the Natural Science Foundation of China.

Multidimensional classical and quantum cosmology with intersecting *p*-branes

V. D. Ivashchuk and V. N. Melnikov[a)]
Center for Gravitation and Fundamental Metrology, VNIIMS, 3-1 M. Ulyanovoy Str., Moscow, 117313, Russia

(Received 9 September 1997; accepted for publication 6 October 1997)

A multidimensional cosmological model describing the evolution of $(n+1)$ Einstein spaces in the theory with several scalar fields and forms is considered. When a (electro-magnetic composite) p-brane ansatz is adopted the field equations are reduced to the equations for the Toda-like system. The Wheeler–De Witt equation is obtained. In the case when n ''internal'' spaces are Ricci-flat, one space M_0 has a non-zero curvature, and all p-branes do not ''live'' in M_0; the classical and quantum solutions are obtained if certain orthogonality relations on parameters are imposed. Spherically symmetric solutions with intersecting non-extremal p-branes are singled out. A non-orthogonal generalization of intersection rules corresponding to (open, closed) Toda lattices is obtained. A chain of bosonic $D \geqslant 11$ models (that may be related to hypothetical higher dimensional supergravities and F-theories) is suggested. © *1998 American Institute of Physics.* [S0022-2488(98)02504-3]

I. INTRODUCTION

In this paper we continue our investigations of p-brane solutions (see, for example, Refs. 1–3 and references therein) based on the sigma-model approach.[4–6] (For pure gravitational sector see Refs. 7 and 8.)

Here we consider a cosmological case, when all functions depend upon one variable (time). The model under consideration contains several scalar fields and antisymmetric forms and is governed by action (2.1).

The considered cosmological model contains some stringy cosmological models (see, for example, Ref. 9). It may be obtained (at the classical level) from the multidimensional cosmological model with perfect fluid[10–14] as an interesting special case.

The paper is organized as follows. In Sec. II the model with composite electro-magnetic p-branes is described. In Sec. III the σ-model representation (under certain constraints on p-branes) is considered and certain scalar invariants are calculated. In Sec. IV the Wheeler–De Witt equation is obtained. Section V is devoted to exact solutions (classical and quantum) for the orthogonal case, when one factor space is curved. In Subsec. V C spherically symmetric configurations with non-extremal p-branes are singled out. In Sec. VI the intersection rules are generalized to the non-orthogonal case and a chain of bosonic B_D-models ($D \geqslant 11$) containing a ''truncated'' $D=11$ supergravity model[15] and a $D=12$ model from Ref. 16 is suggested. (It may be supposed that these models or their analogues may be connected with higher dimensional generalization of M- and F-theories.[17–20])

II. THE MODEL

Here as in Ref. 5 we consider the model governed by the action

$$S=\frac{1}{2\kappa^2}\int_M d^D z\sqrt{|g|}\{R[g]-2\Lambda-h_{\alpha\beta}g^{MN}\partial_M\varphi^\alpha\partial_N\varphi^\beta \tag{2.1}$$

a)Electronic mail: melnikov@rgs.phys.msu.su

 © 1998 American Institute of Physics

$$-\sum_{a\in\Delta}\frac{\theta_a}{n_a!}\exp[2\lambda_a(\varphi)](F^a)^2_g\}+S_{GH},$$

where $g=g_{MN}dz^M\otimes dz^N$ is the metric $(M,N=1,\ldots,D)$, $\varphi=(\varphi^\alpha)\in\mathbb{R}^l$ is a vector from dilatonic scalar fields, $(h_{\alpha\beta})$ is a symmetric non-degenerate $l\times l$ matrix $(l\in\mathbb{N})$, $\theta_a=\pm 1$,

$$F^a=dA^a=\frac{1}{n_a!}F^a_{M_1\ldots M_{n_a}}dz^{M_1}\wedge\ldots\wedge dz^{M_{n_a}} \tag{2.2}$$

is an n_a-form $(n_a\geqslant 1)$ on a D-dimensional manifold M, Λ is a cosmological constant and λ_a is a 1-form on $\mathbb{R}^l$: $\lambda_a(\varphi)=\lambda_{a\alpha}\varphi^\alpha$, $a\in\Delta$, $\alpha=1,\ldots,l$. In (2.1) we denote $|g|=|\det(g_{MN})|$,

$$(F^a)^2_g=F^a_{M_1\ldots M_{n_a}}F^a_{N_1\ldots N_{n_a}}g^{M_1N_1}\ldots g^{M_{n_a}N_{n_a}}, \tag{2.3}$$

$a\in\Delta$, where Δ is some finite set, and $S_{\rm GH}$ is the standard Gibbons-Hawking boundary term.[21] In the models with one time all $\theta_a=1$ when the signature of the metric is $(-1,+1,\ldots,+1)$.

The equations of motion corresponding to (2.1) have the following form:

$$R_{MN}-\frac{1}{2}g_{MN}R=T_{MN}-\Lambda g_{MN}, \tag{2.4}$$

$$\Delta[g]\varphi^\alpha-\sum_{a\in\Delta}\theta_a\frac{\lambda^\alpha_a}{n_a!}e^{2\lambda_a(\varphi)}(F^a)^2_g=0, \tag{2.5}$$

$$\nabla_{M_1}[g](e^{2\lambda_a(\varphi)}F^{a,M_1\ldots M_{n_a}})=0, \tag{2.6}$$

$a\in\Delta$; $\alpha=1,\ldots,l$. In (2.5) $\lambda^\alpha_a=h^{\alpha\beta}\lambda_{a\beta}$, where $(h^{\alpha\beta})$ is matrix inverse to $(h_{\alpha\beta})$. In (2.4)

$$T_{MN}=T_{MN}[\varphi,g]+\sum_{a\in\Delta}\theta_a e^{2\lambda_a(\varphi)}T_{MN}[F^a,g], \tag{2.7}$$

where

$$T_{MN}[\varphi,g]=h_{\alpha\beta}\left(\partial_M\varphi^\alpha\partial_N\varphi^\beta-\frac{1}{2}g_{MN}\partial_P\varphi^\alpha\partial^P\varphi^\beta\right), \tag{2.8}$$

$$T_{MN}[F^a,g]=\frac{1}{n_a!}\left[-\frac{1}{2}g_{MN}(F^a)^2_g+n_aF^a_{MM_2\ldots M_{n_a}}F^{a,M_2\ldots M_{n_a}}_N\right]. \tag{2.9}$$

In (2.5) and (2.6) $\Delta[g]$ and $\nabla[g]$ are Laplace–Beltrami and covariant derivative operators, respectively, corresponding to g.

Let us consider the manifold

$$M=\mathbb{R}\times M_0\times\ldots\times M_n \tag{2.10}$$

with the metric

$$g=we^{2\gamma(u)}du\otimes du+\sum_{i=0}^{n}e^{2\phi^i(u)}g^i, \tag{2.11}$$

where $w=\pm 1$, u is a distinguished coordinate which, by convention, will be called ''time''; $g^i=g^i_{m_in_i}(y_i)dy_i^{m_i}\otimes dy_i^{n_i}$ is a metric on M_i satisfying the equation

$$R_{m_in_i}[g^i]=\xi_i g^i_{m_in_i}, \tag{2.12}$$

$m_i, n_i = 1, \ldots, d_i$; $d_i = \dim M_i$, $\xi_i = \text{const}$, $i = 0, \ldots, n$; $n \in \mathbf{N}$. Thus, (M_i, g^i) are Einstein spaces. The functions γ, ϕ^i: $(u_-, u_+) \to \mathbf{R}$ are smooth.

Each manifold M_i is assumed to be oriented and connected, $i = 0, \ldots, n$. Then the volume d_i-form

$$\tau_i = \sqrt{|g^i(y_i)|}\, dy_i^1 \wedge \ldots \wedge dy_i^{d_i}, \tag{2.13}$$

and the signature parameter

$$\varepsilon(i) = \text{ sign } \det(g^i_{m_i n_i}) = \pm 1, \tag{2.14}$$

are correctly defined for all $i = 0, \ldots, n$.

Let

$$\Omega_0 = \{\varnothing, \{0\}, \{1\}, \ldots, \{n\}, \{0,1\}, \ldots, \{0,1, \ldots, n\}\} \tag{2.15}$$

be a set of all subsets of

$$I_0 \equiv \{0, \ldots, n\}. \tag{2.16}$$

For any $I = \{i_1, \ldots, i_k\} \in \Omega_0$, $i_1 < \ldots < i_k$, we define a form

$$\tau(I) \equiv \tau_{i_1} \wedge \ldots \wedge \tau_{i_k} \tag{2.17}$$

of rank

$$d(I) \equiv \sum_{i \in I} d_i = d_{i_1} + \ldots + d_{i_k}, \tag{2.18}$$

and a corresponding p-brane submanifold

$$M_I \equiv M_{i_1} \times \ldots \times M_{i_k}, \tag{2.19}$$

where $p = d(I) - 1$ ($\dim M_I = d(I)$). We also define an ε-symbol

$$\varepsilon(I) \equiv \varepsilon(i_1) \ldots \varepsilon(i_k). \tag{2.20}$$

For $I = \varnothing$ we put $\tau(\varnothing) = \varepsilon(\varnothing) = 1$, $d(\varnothing) = 0$.

For fields of forms we adopt the following ''composite electro-magnetic'' ansatz

$$F^a = \sum_{I \in \Omega_{a,e}} F^{(a,e,I)} + \sum_{J \in \Omega_{a,m}} F^{(a,m,J)}, \tag{2.21}$$

where

$$F^{(a,e,I)} = d\Phi^{(a,e,I)} \wedge \tau(I), \tag{2.22}$$

$$F^{(a,m,J)} = \mathrm{e}^{-2\lambda_a(\varphi)} * (d\Phi^{(a,m,J)} \wedge \tau(J)), \tag{2.23}$$

$a \in \Delta$, $I \in \Omega_{a,e}$, $J \in \Omega_{a,m}$ and

$$\Omega_{a,e}, \Omega_{a,m} \subset \Omega_0. \tag{2.24}$$

(For empty $\Omega_{a,v} = \varnothing$, $v = e, m$, we put $\Sigma_\varnothing = 0$ in (2.21).) In (2.23) $* = *[g]$ is the Hodge operator on (M, g).

For the potentials in (2.22) and (2.23) we put

$$\Phi^s = \Phi^s(u), \tag{2.25}$$

$s \in S$, where

$$S = S_e \sqcup S_m, \quad S_v \equiv \sqcup_{a \in \Delta} \{a\} \times \{v\} \times \Omega_{a,v}, \tag{2.26}$$

$v = e, m$.

For dilatonic scalar fields we put

$$\varphi^\alpha = \varphi^\alpha(u), \tag{2.27}$$

$\alpha = 1, \ldots, l$.

From (2.22) and (2.23) we obtain the relations between dimensions of p-brane world-sheets and ranks of forms

$$d(I) = n_a - 1, \quad I \in \Omega_{a,e}, \tag{2.28}$$

$$d(J) = D - n_a - 1, \quad J \in \Omega_{a,m}, \tag{2.29}$$

in the electric and magnetic cases, respectively.

III. σ-MODEL REPRESENTATION

Restrictions on $\Omega_{a,v}$. Let

$$w_1 \equiv \{i | i \in \{1, \ldots, n\}, d_i = 1\}. \tag{3.1}$$

The set w_1 describes all 1-dimensional manifolds among M_i ($i \geqslant 0$). We impose the following restrictions on the sets $\Omega_{a,v}$ (2.24):

$$W_{ij}(\Omega_{a,v}) = \varnothing, \tag{3.2}$$

$a \in \Delta$; $v = e, m$; $i, j \in w_1$, $i < j$ and

$$W_j^{(1)}(\Omega_{a,m}, \Omega_{a,e}) = \varnothing, \tag{3.3}$$

$a \in \Delta$; $j \in w_1$. Here

$$W_{ij}(\Omega_*) \equiv \{(I,J) | I, J \in \Omega_*, I = \{i\} \sqcup (I \cap J), J = \{j\} \sqcup (I \cap J)\}, \tag{3.4}$$

$i, j \in w_1$, $i \neq j$, $\Omega_* \subset \Omega_0$ and

$$W_j^{(1)}(\Omega_{a,m}, \Omega_{a,e}) \equiv \{(I,J) \in \Omega_{a,m} \times \Omega_{a,e} | \overline{I} = \{j\} \sqcup J\}, \tag{3.5}$$

$j \in w_1$. In (3.5)

$$\overline{I} \equiv I_0 \backslash I \tag{3.6}$$

is a ''dual'' set. (The restrictions (3.2) and (3.3) are trivially satisfied when $n_1 \leqslant 1$ and $n_1 = 0$, respectively, where $n_1 = |w_1|$ is the number of 1-dimensional manifolds among M_i.)

It follows from Ref. 5 (see Proposition 2 in Ref. 5) that the equations of motion (2.4)–(2.6) and the Bianchi identities

$$dF^s = 0, \quad s \in S, \tag{3.7}$$

for the field configuration (2.11), (2.21)–(2.25), and (2.27) with the restrictions (3.2) and (3.3) imposed are equivalent to equations of motion for the σ-model with the action

$$S_\sigma = \frac{\mu}{2} \int du \mathscr{N} \left\{ G_{ij} \dot{\phi}^i \dot{\phi}^j + h_{\alpha\beta} \dot{\varphi}^\alpha \dot{\varphi}^\beta + \sum_{s \in S} \varepsilon_s \exp[-2U^s(\phi, \varphi)] (\dot{\Phi}^s)^2 - 2\mathscr{N}^{-2} V(\phi) \right\}, \tag{3.8}$$

where $\dot{x} \equiv dx/du$,

$$V = V(\phi) = -w\Lambda\, \mathrm{e}^{2\gamma_0(\phi)} + \frac{w}{2}\sum_{i=0}^{n} \xi_i d_i\, \mathrm{e}^{-2\phi^i + 2\gamma_0(\phi)} \tag{3.9}$$

is the potential with

$$\gamma_0(\phi) \equiv \sum_{i=0}^{n} d_i \phi^i, \tag{3.10}$$

$$\mathcal{N} = \exp(\gamma_0 - \gamma) > 0 \tag{3.11}$$

is the lapse function,

$$U^s = U^s(\phi, \varphi) = -\chi_s \lambda_{a_s}(\varphi) + \sum_{i \in I_s} d_i \phi^i, \tag{3.12}$$

$$\varepsilon_s = (-\varepsilon[g])^{(1-\chi_s)/2} \varepsilon(I_s)\, \theta_{a_s} \tag{3.13}$$

for $s = (a_s, v_s, I_s) \in S$, $\varepsilon[g] = \mathrm{sign}\ \det(g_{MN})$,

$$\chi_s = +1, \quad v_s = e, \tag{3.14}$$

$$\chi_s = -1, \quad v_s = m, \tag{3.15}$$

and

$$G_{ij} = d_i \delta_{ij} - d_i d_j \tag{3.16}$$

are components of the ''pure cosmological'' minisupermetric, $i, j = 0, \ldots, n$.[22]

In the electric case ($F^{(a,m,I)} = 0$) for finite internal space volumes V_i the action (3.8) coincides with the action (2.1) if $\mu = -w/\kappa_0^2$, $\kappa^2 = \kappa_0^2 V_0 \ldots V_n$.

Action (3.8) may be also written in the form

$$S_\sigma = \frac{\mu}{2} \int du \mathcal{N} \{ \mathcal{G}_{\hat{A}\hat{B}}(X) \dot{X}^{\hat{A}} \dot{X}^{\hat{B}} - 2\mathcal{N}^{-2} V(X) \}, \tag{3.17}$$

where $X = (X^{\hat{A}}) = (\phi^i, \varphi^\alpha, \Phi^s) \in \mathbf{R}^N$, and minisupermetric

$$\mathcal{G} = \mathcal{G}_{\hat{A}\hat{B}}(X) dX^{\hat{A}} \otimes dX^{\hat{B}} \tag{3.18}$$

on minisuperspace

$$\mathcal{M} = \mathbf{R}^N, \quad N = n + 1 + l + |S| \tag{3.19}$$

($|S|$ is the number of elements in S) is defined by the relation

$$(\mathcal{G}_{\hat{A}\hat{B}}(X)) = \begin{pmatrix} G_{ij} & 0 & 0 \\ 0 & h_{\alpha\beta} & 0 \\ 0 & 0 & \varepsilon_s\, \mathrm{e}^{-2U^s(X)} \delta_{ss'} \end{pmatrix}. \tag{3.20}$$

A. Scalar products

The minisuperspace metric (3.18) may be also written in the form

$$\mathcal{G} = \overline{G} + \sum_{s \in S} \varepsilon_s\, \mathrm{e}^{-2U^s(x)} d\Phi^s \otimes d\Phi^s, \tag{3.21}$$

where $x=(x^A)=(\phi^i,\varphi^\alpha)$,

$$\overline{G}=\overline{G}_{AB}dx^A\otimes dx^B=G_{ij}d\phi^i\otimes d\phi^j+h_{\alpha\beta}d\varphi^\alpha\otimes d\varphi^\beta, \tag{3.22}$$

$$(\overline{G}_{AB})=\begin{pmatrix} G_{ij} & 0 \\ 0 & h_{\alpha\beta}\end{pmatrix}, \tag{3.23}$$

$U^s(x)=U^s_A x^A$ is defined in (3.12) and

$$(U^s_A)=(d_i\delta_{iI_s},-\chi_s\lambda_{a_s\alpha}). \tag{3.24}$$

Here

$$\delta_{iI}\equiv\sum_{j\in I}\delta_{ij}=\begin{matrix}1, & i\in I,\\ 0, & i\notin I,\end{matrix} \tag{3.25}$$

is an indicator of i belonging to I. The potential (3.9) reads

$$V=(-w\Lambda)\,\mathrm{e}^{2U^\Lambda(x)}+\sum_{j=0}^{n}\frac{w}{2}\xi_j d_j\,\mathrm{e}^{2U^j(x)}, \tag{3.26}$$

where

$$U^j(x)=U^j_A x^A=-\phi^j+\gamma_0(\phi), \tag{3.27}$$

$$U^\Lambda(x)=U^\Lambda_A x^A=\gamma_0(\phi), \tag{3.28}$$

$$(U^j_A)=(-\delta^j_i+d_i,0), \tag{3.29}$$

$$(U^\Lambda_A)=(d_i,0). \tag{3.30}$$

The integrability of the Lagrange system (3.17) crucially depends upon the scalar products of co-vectors U^Λ, U^j, U^s corresponding to $\overline{G}$:

$$(U,U')=\overline{G}^{AB}U_AU'_B, \tag{3.31}$$

where

$$(\overline{G}^{AB})=\begin{pmatrix} G^{ij} & 0 \\ 0 & h^{\alpha\beta}\end{pmatrix} \tag{3.32}$$

is matrix inverse to (3.23). Here (as in Ref. 22)

$$G^{ij}=\frac{\delta^{ij}}{d_i}+\frac{1}{2-D}, \tag{3.33}$$

$i,j=0,\ldots,n$. These products have the following form:

$$(U^i,U^j)=\frac{\delta_{ij}}{d_j}-1, \tag{3.34}$$

$$(U^i,U^\Lambda)=-1, \tag{3.35}$$

$$(U^\Lambda,U^\Lambda)=-\frac{D-1}{D-2}, \tag{3.36}$$

$$(U^s,U^{s'})=q(I_s,I_{s'})+\chi_s\chi_{s'}\lambda_{a_s}\cdot\lambda_{a_{s'}}, \tag{3.37}$$

$$(U^s,U^i)=-\delta_{iI_s}, \tag{3.38}$$

$$(U^s,U^\Lambda)=\frac{d(I_s)}{2-D}, \tag{3.39}$$

where $s=(a_s,v_s,I_s)$, $s'=(a_{s'},v_{s'},I_{s'})\in S$,

$$q(I,J)\equiv d(I\cap J)+\frac{d(I)d(J)}{2-D}, \tag{3.40}$$

$$\lambda_a\cdot\lambda_b\equiv\lambda_{a\alpha}\lambda_{b\beta}h^{\alpha\beta}. \tag{3.41}$$

Relations (3.34)–(3.36) were found in Ref. 14 and (3.37) in Ref. 5.

IV. WHEELER–DE WITT EQUATION

Here we fix the gauge as follows:

$$\gamma_0-\gamma=f(X),\quad \mathcal{N}=e^f, \tag{4.1}$$

where $f:\mathcal{M}\to\mathbf{R}$ is a smooth function. Then we obtain the Lagrange system with the Lagrangian

$$L_f=\frac{\mu}{2}\,\mathrm{e}^f\mathcal{G}_{\hat{A}\hat{B}}(X)\dot{X}^{\hat{A}}\dot{X}^{\hat{B}}-\mu\,\mathrm{e}^{-f}V \tag{4.2}$$

and the energy constraint

$$E_f=\frac{\mu}{2}\,\mathrm{e}^f\mathcal{G}_{\hat{A}\hat{B}}(X)\dot{X}^{\hat{A}}\dot{X}^{\hat{B}}+\mu\,\mathrm{e}^{-f}V=0. \tag{4.3}$$

Using the standard prescriptions of (covariant and conformally covariant) quantization (see, for example, Refs. 22–24) we are led to the Wheeler–De Witt (WDW) equation

$$\hat{H}^f\Psi^f\equiv\left(-\frac{1}{2\mu}\Delta[e^f\mathcal{G}]+\frac{a}{\mu}R[e^f\mathcal{G}]+e^{-f}\mu V\right)\Psi^f=0, \tag{4.4}$$

where

$$a=a_N=\frac{N-2}{8(N-1)}. \tag{4.5}$$

Here $\Psi^f=\Psi^f(X)$ is the so-called ''wave function of the universe'' corresponding to the f-gauge (4.1), and satisfying the relation

$$\Psi^f=e^{bf}\Psi^{f=0},\quad b=(2-N)/2, \tag{4.6}$$

($\Delta[\mathcal{G}_1]$ and $R[\mathcal{G}_1]$ denote the Laplace–Beltrami operator and the scalar curvature corresponding to $\mathcal{G}_1$).

For the scalar curvature of minisupermetric (3.21) we get [see (2.29) in Ref. 5)]

$$R[\mathcal{G}]=-\sum_{s\in S}(U^s,U^s)-\sum_{s,s'\in S}(U^s,U^{s'}). \tag{4.7}$$

For the Laplace operator we obtain

$$\Delta[\mathcal{G}] = \mathrm{e}^{U(x)} \frac{\partial}{\partial x^A}\left(\overline{G}^{AB} \mathrm{e}^{-U(x)} \frac{\partial}{\partial x^B}\right) + \sum_{s\in S} \varepsilon_s \mathrm{e}^{2U^s(x)} \left(\frac{\partial}{\partial \Phi^s}\right)^2, \tag{4.8}$$

where $U(x)=\Sigma_{s\in S}U^s(x)$.

Harmonic-time gauge. The WDW Eq. (4.4) for $f=0$,

$$\hat{H}\Psi \equiv \left(-\frac{1}{2\mu}\Delta[\mathcal{G}] + \frac{a}{\mu} R[\mathcal{G}] + \mu V\right)\Psi = 0, \tag{4.9}$$

may be rewritten, using relations (4.7), (4.8) and

$$U^{si} = G^{ij}U^s_j = \delta_{iI_s} - \frac{d(I_s)}{D-2}, \quad U^{s\alpha} = -\chi_s \lambda^{\alpha}_{a_s}, \tag{4.10}$$

as follows:

$$\begin{aligned} 2\mu \hat{H}\Psi = \Bigg\{ & -G^{ij}\frac{\partial}{\partial \phi^i}\frac{\partial}{\partial \phi^j} - h^{\alpha\beta}\frac{\partial}{\partial \varphi^\alpha}\frac{\partial}{\partial \varphi^\beta} - \sum_{s\in S}\varepsilon_s \mathrm{e}^{2U^s(\phi,\varphi)}\left(\frac{\partial}{\partial \Phi^s}\right)^2 \\ & + \sum_{s\in S}\left[\sum_{i\in I_s}\frac{\partial}{\partial \phi^i} - \frac{d(I_s)}{D-2}\sum_{j=0}^{n}\frac{\partial}{\partial \phi^j} - \chi_s \lambda^{\alpha}_{a_s}\frac{\partial}{\partial \varphi^\alpha}\right] + 2aR[\mathcal{G}] + 2\mu^2 V\Bigg\}\Psi = 0. \end{aligned} \tag{4.11}$$

Here $\hat{H}\equiv \hat{H}^{f=0}$ and $\Psi \equiv \Psi^{f=0}$.

V. EXACT SOLUTIONS WITH ONE CURVED FACTOR SPACE AND ORTHOGONAL U^s

Here we put the following restrictions on the parameters of the model:

$$\textbf{(i)} \quad \Lambda = 0, \tag{5.1}$$

i.e., the cosmological constant is zero;

$$\textbf{(ii)} \quad \xi_0 \neq 0, \quad \xi_1 = \ldots = \xi_n = 0, \tag{5.2}$$

i.e., one space is curved and others are Ricci-flat;

$$\textbf{(iii)} \quad 0 \notin I_s, \quad \forall s = (a_s, v_s, I_s) \in S, \tag{5.3}$$

i.e., all ''brane'' submanifolds M_{I_s} [see (2.19)] do not contain M_0.

We also put the following orthogonality restriction on the vectors U^s:

$$\textbf{(iv)} \quad (U^s, U^{s'}) = d(I_s \cap I_{s'}) + \frac{d(I_s)d(I_{s'})}{2-D} + \chi_s \chi_{s'} \lambda_{a_s \alpha}\lambda_{a_{s'}\beta}h^{\alpha\beta} = 0, \tag{5.4}$$

for $s\neq s'$, $s=(a_s, v_s, I_s)$, $s'=(a_{s'}, v_{s'}, I_{s'})\in S$ and

$$\textbf{(v)} \quad (U^s, U^s) \neq 0 \tag{5.5}$$

for all $s\in S$.

From **(i)** and **(ii)** we get for the potential (3.26)

$$V = \frac{1}{2} w \xi_0 d_0 \mathrm{e}^{2U^0(x)}, \tag{5.6}$$

where

$$(U^0,U^0)=\frac{1}{d_0}-1<0 \tag{5.7}$$

[see (3.34)].

From **(iii)** and (3.38) we get

$$(U^0,U^s)=0 \tag{5.8}$$

for all $s\in S$. Thus, all co-vectors U^0, U^s ($s\in S$) belonging to dual space $(\mathbf{R}^{n+1+l})^*\simeq\mathbf{R}^{n+1+l}$ are orthogonal with respect to the scalar product (3.31).

Let

$$\eta_s\equiv \operatorname{sign}(U^s,U^s), \tag{5.9}$$

and $|S|_\pm$ is the number of U^s with $\eta_s=\pm 1$; $|S|_+ + |S|_- = |S|$. Let the matrix $(h_{\alpha\beta})$ have the signature $(-1,\ldots,-1_{l_-},+1,\ldots,+1_{l_+})$ ($l_- + l_+ = l$). The matrix (G_{ij}) has a pseudo-Euclidean signature $(-1,+1,\ldots,+1_n)$.[22] Then from (5.7)–(5.8) we obtain $|S|_-\leqslant l_-$, $|S|_+\leqslant n+l_+$ and hence

$$|S|\leqslant n+l. \tag{5.10}$$

Thus we obtain the restriction on the number of orthogonal p-brane configurations.

A. Quantum solutions

The truncated minisuperspace metric (3.23) may be diagonalized by the linear transformation

$$z^A=S^A{}_B x^B, \quad (z^A)=(z^0,z^a,z^s) \tag{5.11}$$

as follows:

$$\overline{G}=\overline{G}_{AB}dx^A\otimes dx^B=-dz^0\otimes dz^0+\sum_{s\in S}\eta_s dz^s\otimes dz^s+dz^a\otimes dz^b\,\eta_{ab}\,, \tag{5.12}$$

where $a,b=1,\ldots,n+l-|S|$; $\eta_{ab}=\eta_{aa}\delta_{ab}$; $\eta_{aa}=\pm 1$, and

$$q_0 z^0=U^0(x), \tag{5.13}$$

$$q_s z^s=U^s(x), \tag{5.14}$$

with

$$q_0\equiv\sqrt{|(U^0,U^0)|}=\sqrt{1-\frac{1}{d_0}}>0, \tag{5.15}$$

$$q_s=\nu_s^{-1}\equiv\sqrt{|(U^s,U^s)|}=\sqrt{\left|d(I_s)\left(1+\frac{d(I_s)}{2-D}\right)+\lambda_{a_s}^2\right|}>0, \tag{5.16}$$

$s=(a_s,v_s,I_s)\in S$.

From (4.8), (5.11), (5.12) and (5.14) we get

$$\Delta[\mathcal{G}]=-\left(\frac{\partial}{\partial z^0}\right)^2+\eta^{ab}\frac{\partial}{\partial z^a}\frac{\partial}{\partial z^b}+\sum_{s\in S}\eta_s\,\mathrm{e}^{q_s z^s}\frac{\partial}{\partial z^s}\left(\mathrm{e}^{-q_s z^s}\frac{\partial}{\partial z^s}\right)$$

$$+\sum_{s\in S}\varepsilon_s\,\mathrm{e}^{2q_s z^s}\left(\frac{\partial}{\partial\Phi^s}\right)^2. \tag{5.17}$$

The relation (4.7) in the orthogonal case reads as

$$R[\mathcal{G}] = -2\sum_{s\in S}\,(U^s,U^s) = -2\sum_{s\in S}\,\eta_s q_s^2\,. \tag{5.18}$$

We are seeking the solution to WDW Eq. (4.9) by the method of the separation of variables, i.e., we put

$$\Psi_*(z) = \Psi_0(z^0)\left(\prod_{s\in S}\,\Psi_s(z^s)\right)\,\mathrm{e}^{\mathrm{i}P_s\Phi^s}\,\mathrm{e}^{\mathrm{i}p_a z^a}. \tag{5.19}$$

It follows from (5.17) that $\Psi_*(z)$ satisfies WDW Eq. (4.9) if

$$2\hat{H}_0\Psi_0 \equiv \left\{\left(\frac{\partial}{\partial z^0}\right)^2 + \mu^2 w\xi_0 d_0\,\mathrm{e}^{2q_0 z^0}\right\}\Psi_0 = 2\mathcal{E}_0\Psi_0\,, \tag{5.20}$$

$$2\hat{H}_s\Psi_s \equiv \left\{-\eta_s\,\mathrm{e}^{q_s z^s}\frac{\partial}{\partial z^s}\left(\,\mathrm{e}^{-q_s z^s}\frac{\partial}{\partial z^s}\right) + \varepsilon_s P_s^2\,\mathrm{e}^{2q_s z^s}\right\}\Psi_s = 2\mathcal{E}_s\Psi_s\,, \tag{5.21}$$

$s\in S$, and

$$2\mathcal{E}_0 + \eta^{ab}p_a p_b + 2\sum_{s\in S}\,\mathcal{E}_s + 2aR[\mathcal{G}] = 0, \tag{5.22}$$

with a and $R[\mathcal{G}]$ from (4.5) and (5.18), respectively.

Using the relations from Appendix A we obtain linearly independent solutions to (5.20) and (5.21), respectively,

$$\Psi_0(z^0) = B^0_{\omega_0(\mathcal{E}_0)}\left(\sqrt{-w\mu^2\xi_0 d_0}\,\frac{\mathrm{e}^{q_0 z^0}}{q_0}\right), \tag{5.23}$$

$$\Psi_s(z^s) = \,\mathrm{e}^{q_s z^s/2}B^s_{\omega_s(\mathcal{E}_s)}\left(\sqrt{\eta_s\varepsilon_s P_s^2}\,\frac{\mathrm{e}^{q_s z^s}}{q_s}\right), \tag{5.24}$$

where

$$\omega_0(\mathcal{E}_0) = \sqrt{2\mathcal{E}_0}/q_0\,, \quad \omega_s(\mathcal{E}_s) = \sqrt{\frac{1}{4} - 2\,\eta_s\mathcal{E}_s\nu_s^2}, \tag{5.25}$$

$s\in S$ and $B^0_\omega, B^s_\omega = I_\omega, K_\omega$ are the modified Bessel function.

The general solution of the WDW Eq. (4.9) is a superposition of the ''separated'' solutions (5.19):

$$\Psi(z) = \sum_B\,\int dp\,dP\,d\mathcal{E}\,C(p,P,\mathcal{E},B)\Psi_*(z|p,P,\mathcal{E},B), \tag{5.26}$$

where $p=(p_a)$, $P=(P_s)$, $\mathcal{E}=(\mathcal{E}_s)$, $B=(B^0,B^s)$, $B^0,B^s = I,K$; and $\Psi_* = \Psi_*(z|p,P,\mathcal{E},B)$ is given by relation (5.19) and (5.23)–(5.25) with $\mathcal{E}_0$ from (5.22). Here $C(p,P,\mathcal{E},B)$ are smooth enough functions. In the non-composite electric case these solutions were considered recently in Ref. 25.

B. Classical solutions

1. Toda-like representation

Here we will integrate the Lagrange equations corresponding to the Lagrangian (4.2) with the energy constraint (4.3) and hence we will find classical exact solutions when the restrictions (5.1)–(5.5) are imposed. We put $f=0$, i.e., the harmonic time gauge is considered.

The problem of integrability may be simplified if we integrate the Maxwell equations (for $s \in S_e$) and Bianchi identities (for $s \in S_m$):

$$\frac{d}{du}[\exp(-2U^s)\dot{\Phi}^s]=0 \Leftrightarrow \dot{\Phi}^s=Q_s \exp(2U^s), \tag{5.27}$$

where Q_s are constants, $s=(a_s,v_s,I_s)\in S$.

Let

$$Q_s \neq 0, \quad s \in S_*; \tag{5.28}$$

$$Q_s=0, \quad s \in S \backslash S_*,$$

where $S_* \subset S$ is a non-empty subset of S.

For fixed $Q=(Q_s, s\in S_*)$ the Lagrange equations for the Lagrangian (4.2) with $f=0$ corresponding to $(x^A)=(\phi^i,\varphi^\alpha)$, when equations (5.27) are substituted, are equivalent to the Lagrange equations for the Lagrangian

$$L_Q=\frac{1}{2}\overline{G}_{AB}\dot{x}^A\dot{x}^B-V_Q, \tag{5.29}$$

where

$$V_Q=V+\frac{1}{2}\sum_{s\in S_*}\varepsilon_s Q_s^2 \exp[2U^s(x)], \tag{5.30}$$

and $(\overline{G}_{AB})$ and V are defined in (3.23) and (3.9), respectively. The zero-energy constraint (4.3) reads

$$E_Q=\frac{1}{2}\overline{G}_{AB}\dot{x}^A\dot{x}^B+V_Q=0. \tag{5.31}$$

2. Exact solutions for one curved space and orthogonal U^s

When the conditions **(i)**–**(v)** are satisfied exact solutions for Lagrangian (5.29) with the potential (5.30), and V from (5.6) could be readily obtained using the relations from Appendix B.

The solutions read

$$x^A(u)=-\frac{U^{0A}}{(U^0,U^0)}\ln|f_0(u-u_0)|-\sum_{s\in S_*}\frac{U^{sA}}{(U^s,U^s)}\ln|f_s(u-u_s)|+c^A u+\overline{c^A}, \tag{5.32}$$

where u_0 and u_s are constants and $s\in S_*$. Functions f_0 and f_s in (5.32) are the following:

$$f_0(\tau)=\left|\frac{\xi_0(d_0-1)}{C_0}\right|^{1/2}\mathrm{sh}(\sqrt{C_0}\tau), \quad C_0>0, \quad \xi_0 w>0; \tag{5.33}$$

$$=\left|\frac{\xi_0(d_0-1)}{C_0}\right|^{1/2}\sin(\sqrt{|C_0|}\tau), \quad C_0<0, \quad \xi_0 w>0; \tag{5.34}$$

$$=\left|\frac{\xi_0(d_0-1)}{C_0}\right|^{1/2}\mathrm{ch}(\sqrt{C_0}\tau), \quad C_0>0, \quad \xi_0 w<0; \tag{5.35}$$

$$=|\xi_0(d_0-1)|^{1/2}\tau, \quad C_0=0, \quad \xi_0 w>0, \tag{5.36}$$

and

$$f_s(\tau)=\frac{|Q_s|}{\nu_s|C_s|^{1/2}}\,\mathrm{sh}(\sqrt{C_s}\tau),\quad C_s>0,\quad \eta_s\varepsilon_s<0; \tag{5.37}$$

$$=\frac{|Q_s|}{\nu_s|C_s|^{1/2}}\,\sin(\sqrt{|C_s|}\tau),\quad C_s<0,\quad \eta_s\varepsilon_s<0; \tag{5.38}$$

$$=\frac{|Q_s|}{\nu_s|C_s|^{1/2}}\,\mathrm{ch}(\sqrt{C_s}\tau),\quad C_s>0,\quad \eta_s\varepsilon_s>0; \tag{5.39}$$

$$=\frac{|Q^s|}{\nu_s}\tau,\quad C_s=0,\quad \eta_s\varepsilon_s<0, \tag{5.40}$$

where C_0 and C_s are constants. Here we used the relations (5.7)–(5.9). The contravariant components $U^{0A}=\overline{G}^{AB}U^0_B$ are

$$U^{0i}=-\frac{\delta^i_0}{d_0},\quad U^{0\alpha}=0. \tag{5.41}$$

Corresponding relations for U^{sA}, $s\in S$, were presented in (4.10).

Using (5.32), (5.7), (5.16), (4.10) and (5.41) we obtain

$$\phi^i=\frac{\delta^i_0}{1-d_0}\,\ln|f_0|+\sum_{s\in S_*}\alpha^i_s\,\ln|f_s|+c^iu+\overline{c^i}, \tag{5.42}$$

where

$$\alpha^i_s=-\eta_s\nu_s^2\left(\delta_{iI_s}-\frac{d(I_s)}{D-2}\right), \tag{5.43}$$

$s\in S$, and

$$\varphi^\alpha=\sum_{s\in S_*}\eta_s\nu_s^2\chi_s\lambda^\alpha_{a_s}\,\ln|f_s|+c^\alpha u+\overline{c^\alpha}, \tag{5.44}$$

$\alpha=1,\ldots,l$.

Vectors $c=(c^A)$ and $\overline{c}=(\overline{c^A})$ satisfy the linear constraint relations (see Appendix B)

$$U^0(c)=U^0_Ac^A=-c^0+\sum_{j=0}^n d_jc^j=0, \tag{5.45}$$

$$U^0(\overline{c})=U^0_A\overline{c^A}=-\overline{c^0}+\sum_{j=0}^n d_j\overline{c^j}=0, \tag{5.46}$$

$$U^s(c)=U^s_Ac^A=\sum_{i\in I_s}d_ic^i-\chi_s\lambda_{a_s\alpha}c^\alpha=0, \tag{5.47}$$

$$U^s(\overline{c})=U^s_A\overline{c^A}=\sum_{i\in I_s}d_i\overline{c^i}-\chi_s\lambda_{a_s\alpha}\overline{c^\alpha}=0, \tag{5.48}$$

$s\in S$. The harmonic gauge function (3.10) reads

$$\gamma_0(\phi)=\frac{d_0}{1-d_0}\,\ln|f_0|+\sum_{s\in S_*}\frac{d(I_s)}{D-2}\,\eta_s\nu_s^2\,\ln|f_s|+c^0u+\overline{c^0}. \tag{5.49}$$

The zero-energy constraint reads (see Appendix B)

$$E = E_0 + \sum_{s \in S_*} E_s + \frac{1}{2} \overline{G}_{AB} c^A c^B = 0, \tag{5.50}$$

where $C_0 = 2E_0(U^0, U^0)$, and $C_s = 2E_s(U^s, U^s)$. Using the relations (5.15), (5.16), and (5.45) we rewrite (5.50) as

$$C_0 \frac{d_0}{d_0 - 1} = \sum_{s \in S_*} C_s \nu_s^2 \eta_s + h_{\alpha\beta} c^\alpha c^\beta + \sum_{i=1}^{n} d_i (c^i)^2 + \frac{1}{d_0 - 1} \left(\sum_{i=1}^{n} d_i c^i \right)^2. \tag{5.51}$$

From the relation

$$\exp 2U^s = f_s^{-2}, \tag{5.52}$$

following from (5.32), (5.4), (5.8), (5.47), and (5.48) we get for electric-type forms (2.22)

$$F^s = Q_s f_s^{-2} du \wedge \tau(I_s), \tag{5.53}$$

$s \in S_e$, and for magnetic-type forms (2.23)

$$F^s = \mathrm{e}^{-2\lambda_a(\varphi)} * [Q_s f_s^{-2} du \wedge \tau(I_s)] = \overline{Q}_s \tau(\overline{I}_s), \tag{5.54}$$

$s \in S_m$, where $\overline{Q}_s = Q_s \varepsilon(I_s) \mu(I_s) w$ and $\mu(I) = \pm 1$ is defined by the relation $\mu(I) du \wedge \tau(I_0) = \tau(\overline{I}) \wedge du \wedge \tau(I)$. The relation (5.54) may be readily obtained using the formula (5.28) from Ref. 5 (for $\gamma = \gamma_0$).

Relations for the metric follows from (5.42), (5.43) and (5.49):

$$g = \left(\prod_{s \in S_*} [f_s^2(u - u_s)]^{\eta_s d(I_s) \nu_s^2/(D-2)} \right) \left\{ [f_0^2(u - u_0)]^{d_0/(1-d_0)} \mathrm{e}^{2c^0 u + 2\overline{c^0}} \right.$$

$$\left. \times [w du \otimes du + f_0^2(u - u_0) g^0] + \sum_{i \neq 0} \left(\prod_{\substack{s \in S_* \\ I_s \ni i}} [f_s^2(u - u_s)]^{-\eta_s \nu_s^2} \right) \mathrm{e}^{2c^i u + 2\overline{c^i}} g^i \right\}. \tag{5.55}$$

Thus we obtained exact solutions for multidimensional cosmology, describing the evolution of $(n+1)$ spaces $(M_0, g_0), \ldots, (M_n, g_n)$, where (M_0, g_0) is an Einstein space of non-zero curvature, and (M_i, g^i) are ''internal'' Ricci-flat spaces, $i = 1, \ldots, n$; in the presence of several scalar fields and forms. The solution is presented by relations (5.44) and (5.53)–(5.55) with the functions f_0, f_s defined in (5.33)–(5.40) and the relations on the parameters of solutions c^A, $\overline{c^A}$ $(A = i, \alpha)$, C_0, C_s $(s \in S_*)$, and ν_s, imposed in (5.45)–(5.48), (5.51), and (5.16), respectively.

This solution describes a set of charged (by forms) overlapping p-branes ($p_s = d(I_s) - 1$, $s \in S_*$) ''living'' on submanifolds M_{I_s} (2.19), where the sets I_s do not contain 0, i.e., all p-branes live in ''internal'' Ricci-flat spaces.

The solution is valid if the dimensions of the p-branes and the dilatonic coupling vector satisfy the relations (5.4). In the non-composite case these solutions were considered recently in Refs. 25,26 (electric case), and 27 (electro-magnetic case). For $n = 1$, see also Refs. 9 and 28.

C. Spherically symmetric solutions

To illustrate the general solution from Subsec. V B let us consider also the spherically symmetric case

$$w = 1, \quad M_0 = S^{d_0}, \quad g^0 = d\Omega_{d_0}^2, \tag{5.56}$$

where $d\Omega^2_{d_0}$ is canonical metric on unit sphere S^{d_0}. We also assume that $M_1=\mathbf{R}$, $g^1=-dt\otimes dt$ and

$$1\in I_s, \quad \forall s\in S_*, \tag{5.57}$$

i.e., all p-branes have common time direction t. Let

$$\eta_s\varepsilon_s=-1, \tag{5.58}$$

$s\in S_*$. For integration constants we put $\overline{c^A}=0$,

$$c^A=\overline{\mu}\sum_{r\in\overline{S}}\frac{U^{rA}}{(U^r,U^r)}-\overline{\mu}\delta^A_1, \tag{5.59}$$

$$C_0=C_s=\overline{\mu^2}, \tag{5.60}$$

where $\overline{\mu}>0$ and $\overline{S}=\{0\}\cup S$. Here $A=(i_A,\alpha_A)$ and $A=1$ means $i_A=1$. It may be verified that the restrictions (5.45)–(5.48) and (5.51) are satisfied identically.

We also introduce a new radial variable $R=R(u)$ by relations

$$\exp(-2\overline{\mu}u)=1-\frac{2\mu}{R^{\overline{d}}}, \quad \mu=\overline{\mu^{\overline{d}}}>0, \quad \overline{d}=d_0-1, \tag{5.61}$$

and put $u_0=0$, $u_s<0$,

$$\frac{|Q_s|}{\overline{\mu}\nu_s}\sinh\beta_s=1, \quad \beta_s\equiv\overline{\mu}|u_s|, \quad s\in S_*. \tag{5.62}$$

Then, solutions for the metric and scalar fields (see (5.44) and (5.55)) are the following

$$g=\left(\prod_{s\in S_*}H_s^{2\eta_s d(I_s)\nu_s^2/(D-2)}\right)\left\{\frac{dR\otimes dR}{1-2\mu/R^{\overline{d}}}+R^2d\Omega^2_{d_0}\right.$$
$$\left.-\left(\prod_{s\in S_*}H_s^{-2\eta_s\nu_s^2}\right)\left(1-\frac{2\mu}{R^d}\right)dt\otimes dt+\sum_{i=2}^{n}\left(\prod_{\substack{s\in S_*\\ I_s\ni i}}H_s^{-2\eta_s\nu_s^2}\right)g^i\right\}, \tag{5.63}$$

$$\varphi^\alpha=\sum_{s\in S_*}\eta_s\nu_s^2\chi_s\lambda^\alpha_{a_s}\ln H_s, \tag{5.64}$$

where

$$H_s=1+\frac{\mathscr{P}_s}{R^d}, \quad \mathscr{P}_s\equiv\frac{|Q_s|\overline{d}}{\nu_s}e^{-\beta_s}, \tag{5.65}$$

$s\in S_*$.

The fields of forms are given by (2.22) and (2.23) with

$$\Phi^s=\frac{\nu_s}{H_s'}, \tag{5.66}$$

$$H_s'=\left(1-\frac{\mathscr{P}_s'}{H_sR^d}\right)^{-1}=1+\frac{\mathscr{P}_s'}{R^d+\mathscr{P}_s-\mathscr{P}_s'}, \tag{5.67}$$

$$\mathscr{P}'_s \equiv -\frac{Q_s \overline{d}}{\nu_s}, \tag{5.68}$$

$s \in S_*$. It follows from (5.62), (5.65) and (5.68) that

$$|\mathscr{P}'_s| = \frac{\mu}{\sinh \beta_s} = \mathscr{P}_s e^{\beta_s} = \sqrt{\mathscr{P}_s(\mathscr{P}_s + 2\mu)}, \tag{5.69}$$

$s \in S_*$.

The solutions obtained describe non-extremal charged intersecting p-branes and agree with those from Refs. 29,30,31 ($d_1 = \ldots = d_n = 1$, $\eta_s = +1$) and Ref. 27 ($\eta_s = +1$, non-composite case).

We note that Hawking temperature corresponding to the solution is (see also Refs. 27 and 31)

$$T_H = \frac{\overline{d}}{4\pi (2\mu)^{1/\overline{d}}} \prod_{s \in S_*} \left(\frac{2\mu}{2\mu + \mathscr{P}_s} \right)^{\eta_s \nu_s^2}. \tag{5.70}$$

Recall that $\eta_s \nu_s^2 = (U^s, U^s)^{-1}$.

D. WDW equation with fixed charges

We may consider also another scheme based on zero-energy constraint relation (5.31). The corresponding WDW equation in the harmonic gauge reads

$$\hat{H}_Q \Psi \equiv \left(-\frac{1}{2\mu} \overline{G}^{AB} \frac{\partial}{\partial x^A} \frac{\partial}{\partial x^B} + \mu V_Q \right) \Psi = 0, \tag{5.71}$$

where potential V_Q is defined in (5.30). This equation describes quantum cosmology with classical fields of forms and quantum scale factors and dilatonic fields. Such an approach is equivalent to the scheme of quantization of multidimensional perfect fluid considered in Ref. 10.

Equation (5.71) is readily solved in the orthogonal case (5.4). The basis of solutions is given by the following replacements in (5.19), (5.22), (5.24) and (5.25), respectively:

$$P_s \mapsto Q_s, \tag{5.72}$$

$$2aR[\mathscr{S}] \mapsto 0, \tag{5.73}$$

$$\Psi_s(z^s) \mapsto B^s_{\omega_s}\left(\sqrt{\eta_s \varepsilon_s Q_s^2} \frac{e^{q_s z^s}}{q_s} \right), \tag{5.74}$$

$$\omega_s \mapsto \sqrt{-2\eta_s \mathscr{E}_s \nu_s^2}. \tag{5.75}$$

We note that recently such a solution for the special case with one internal space ($n = 1$) and non-composite p-branes was considered in Ref. 32.

VI. INTERSECTION RULES FOR INTEGRABLE CONFIGURATIONS WITH ORTHOGONAL AND NON-ORTHOGONAL U^s

In this section we analyze in detail the orthogonality relation (5.4). According to (2.28), (2.29), (5.3) and (5.4) there exist some obstacles for the existence of binary configurations, i.e., solutions with two p-branes. For these reasons some restrictions on the model (2.1) (e.g., on dimension D, ranks of forms n_a and scalar products for dilatonic couplings $\lambda_a \cdot \lambda_b$) and the manifold (2.10) (e.g., on dimensions $d_0, d_1, \ldots d_n$) should be imposed. For example, there are no binary configurations when: (i) all $\lambda_a \cdot \lambda_b$ are irrational; (ii) d_0 is big enough, i.e., the dimension of ''internal'' space (where all p-branes live) $D - d_0 - 1$ is too small; (iii) dimensions of factor spaces d_i ($i \geqslant 1$) do not fit the ranks of forms n_a [see (2.28) and (2.29)].

In Subsec. VI A we propose a sufficiency condition for the existence of ''full'' spectrum of p-brane pairs (see Propositions 1 and 2). This condition is formulated in terms of the so-called fundamental matrix of the model.

In Subsec. VI B we suggest a chain of $D \geqslant 11$ models (''beautiful'' models). These models satisfy conditions of Proposition 1 for $d_0=2$. They may be considered as a nice polygon for investigation of solutions with intersecting p-branes and possible generalization to higher dimensional supergravitational and super-p-brane models (F_D- or M_D-theories).

In Subsec. VI C we consider the generalization of the orthogonality relation leading to some other integrable Euclidean Toda-like Lagrangians and find corresponding intersection rules. This result may be considered as a ''bridge'' between Toda lattices (open, closed, etc.) and intersecting p-branes. It opens a new area for use of Lie algebras (e.g., affine Lie algebras, etc.) in the (classical and quantum) models with p-branes.

A. Orthogonal U^s

In Sec. V we obtained exact cosmological solutions for the model (2.1) with $\Lambda=0$ defined on the manifold (2.10). In (2.10) M_0 is an Einstein space of non-zero curvature and hence $d_0 = \dim M_0 > 1$. All p-branes ''live'' in internal space

$$\overline{M}=M_1\times \ldots \times M_n \tag{6.1}$$

((M_i,g^i) are Ricci-flat). Here we treat the existence of the solutions with two p-branes. Let us consider such a solution with a set of indices $S_*=\{s_1,s_2\}$, $s_1\neq s_2$, where $s_1=(a_{s_1},v_{s_1},I_{s_1})$, $s_2=(a_{s_2},v_{s_2},I_{s_2})$; $a_{s_1},a_{s_2}\in\Delta$; $v_{s_1},v_{s_2}\in\{e,m\}$; $I_{s_1},I_{s_2}\subset\{1,\ldots,n\}$.

The orthogonality relation (5.4) defines the intersection rules

$$d(I_{s_1}\cap I_{s_2})=\Delta(s_1,s_2), \tag{6.2}$$

where

$$\Delta(s_1,s_2)\equiv \frac{d(I_{s_1})d(I_{s_2})}{D-2}-\chi_{s_1}\chi_{s_2}\lambda_{a_{s_1}}\cdot\lambda_{a_{s_2}}, \tag{6.3}$$

$s_1\neq s_2$. It follows from (6.2) that in orthogonal case

$$\Delta(s_1,s_2)\in \mathbf{Z}_+\equiv\{0,1,2,\ldots\}. \tag{6.4}$$

The intersection symbol (6.3) is symmetric: $\Delta(s_1,s_2)=\Delta(s_2,s_1)$. In the orthogonal case it satisfies the obvious restrictions

$$\Delta(s_1,s_2)\leqslant \min(d(I_{s_1}),d(I_{s_2})), \tag{6.5}$$

$$d(I_{s_1}\cup I_{s_2})=d(I_{s_1})+d(I_{s_2})-\Delta(s_1,s_2)\leqslant D-d_0-1=\dim\ \overline{M}. \tag{6.6}$$

The latter follows from the inclusion $M_{I_{s_1}\cup I_{s_2}}\subset\overline{M}$.

We recall that dimensions $d(I_s)$ obey the relations (2.28) and (2.29) that may be written as follows:

$$d(I_s)=\overline{D}\overline{\chi_s}+\overline{n}_{a_s}\chi_s, \tag{6.7}$$

where $\overline{D}=D-2$, $\overline{n_a}=n_a-1$ and $\overline{\chi_s}=\frac{1}{2}(1-\chi_s)=0,1$ $(\chi_s=1,-1)$ for $v_s=e,m$, respectively.

Let

$$N(a,b)\equiv \frac{(n_a-1)(n_b-1)}{D-2}-\lambda_a\cdot\lambda_b, \tag{6.8}$$

$a,b \in \Delta$. We call $[N(a,b)]$ fundamental matrix of the model (2.1).

From (6.3) and (6.7) we obtain

$$\Delta(s_1,s_2)=\overline{D\chi_{s_1}}\overline{\chi}_{s_2}+\overline{n}_{a_{s_1}}\chi_{s_1}\overline{\chi}_{s_2}+\overline{n}_{a_{s_2}}\chi_{s_2}\overline{\chi}_{s_1}+N(a_{s_1},a_{s_2})\chi_{s_1}\chi_{s_2}, \tag{6.9}$$

or, more explicitly,

$$\Delta(s_1,s_2)=N(a_{s_1},a_{s_2}), \quad v_{s_1}=v_{s_2}=e; \tag{6.10}$$

$$=\overline{n}_{a_{s_1}}-N(a_{s_1},a_{s_2}), \quad v_{s_1}=e, \quad v_{s_2}=m; \tag{6.11}$$

$$=\overline{D}-\overline{n}_{a_{s_1}}-\overline{n}_{a_{s_2}}+N(a_{s_1},a_{s_2}), \quad v_{s_1}=v_{s_2}=m. \tag{6.12}$$

Thus $N(a,b)$ is the dimension of intersection for two electric p-branes charged by forms F^a and F^b, respectively. The fundamental matrix defines the intersection rules in the electro-magnetic case, too.

Remark 1: The matrix (6.8) is unchanged if $\overline{n}_a \mapsto k\overline{n}_a$, $\overline{D}\mapsto k^2\overline{D}$, $k\in\mathbf{N}$. For example, we may consider the chain of models with $D=9k^2+2$, $n=\text{rank } F=3k+1$ originating from the truncated bosonic part of $D=11$ supergravity.

Proposition 1: Let matrix (6.8) satisfy the following restrictions:

$$(\mathbf{A}) \quad N(a_1,a_2)\in\mathbf{Z}_+; \quad N(a_1,a_2)\geqslant d_0-1,$$

$$(\mathbf{B}) \quad N(a_1,a_2)\leqslant \min(n_{a_1},n_{a_2})-d_0,$$

$$(\mathbf{C}) \quad N(a_1,a_2)\geqslant n_{a_1}+n_{a_2}-D+d_0-1,$$

for any $a,b\in\Delta$ ($d_0>1$). Then $\Delta(s_1,s_2)$ from (6.9) satisfies consistency relations (6.4)–(6.6) for any $s_1\neq s_2$ [with $d(I_s)$ from (6.7)].

Proof: Let us consider three cases: (ee) $v_{s_1}=v_{s_2}=e$; (em) $v_{s_1}=e$, $v_{s_2}=m$; (mm) $v_{s_1}=v_{s_2}=m$. Relation (6.4) follows from restrictions (**A**), (**B**) and (**C**) for (ee), (em) and (mm) cases, respectively. Analogously (6.5) follows from (**B**), (**C**) and (**B**) and (6.6) follows from (**C**), (**B**) and (**A**) for (ee), (em) and (mm) cases, respectively. The proposition is proved.

From relation (**B**) and $d_0>1$ we get

$$K(a)\equiv n_a-1-N(a,a)>0 \tag{6.13}$$

and hence

$$(U^s,U^s)=K(a_s)>0. \tag{6.14}$$

Thus, inequalities (5.5) are satisfied.

Definition 1: The model (2.1) with $\Lambda=0$ defined on the manifold (2.10) is called binary complete if for any $a_1,a_2\in\Delta$, $v_1,v_2\in\{e,m\}$ there exists cosmological solution from V B.2 with two intersecting p-branes defined by indices $s_1=(a_1,v_1,I_1)\neq s_2=(a_2,v_2,I_2)$.

For the binary complete model we have the maximal number $|\Delta|(2|\Delta|+1)$ of different types of binary configurations (formed by $|\Delta|$ electric and $|\Delta|$ magnetic p-branes).

Definition 2: The matrix (6.8) satisfying the restrictions (**A**), (**B**) and (**C**) of Proposition 1 is called d_0-proper.

From Proposition 1 and (6.14) we obtain the following.

Proposition 2: The model (2.1) with $\Lambda=0$ defined on the manifold (2.10) with $M_1=\ldots M_n=\mathbf{R}$ ($n=D-1-d_0$, $d_0>1$) is binary complete if fundamental matrix (6.8) of this model is d_0-proper.

In the next subsection we apply these propositions for $D=11$ supergravity and the chain of $D>11$ models.

B. Example: chain of B_D-models

Let us consider the action in dimension D

$$S_D=\int_M d^Dz\sqrt{|g|}\left\{R[g]+g^{MN}\partial_M\vec{\varphi}\partial_N\vec{\varphi}-\sum_{a=4}^{D-7}\frac{1}{a!}\exp[2\vec{\lambda}_a\vec{\varphi}](F^a)^2\right\},\tag{6.15}$$

where $\vec{\varphi}=(\varphi^1,\ldots,\varphi^l)\in\mathbf{R}^l$, $\vec{\lambda}_a=(\lambda_{a1},\ldots,\lambda_{al})\in\mathbf{R}^l$, $l=D-11$, rank $F^a=a$, and $a=4,\ldots,D-7$. Here vectors $\vec{\lambda}_a$ satisfy the relations

$$\vec{\lambda}_a\vec{\lambda}_b=N(a,b)-\frac{(a-1)(b-1)}{D-2},\tag{6.16}$$

$$N(a,b)=\min(a,b)-3,\tag{6.17}$$

$a,b=4,\ldots,D-7$.

The vectors $\vec{\lambda}_a$ are linearly dependent:

$$\vec{\lambda}_{D-7}=-2\vec{\lambda}_4.\tag{6.18}$$

For $D>11$ vectors $\vec{\lambda}_4,\ldots,\vec{\lambda}_{D-8}$ are linearly independent.

The model (6.15) contains l scalar fields with negative kinetic term (i.e., $h_{\alpha\beta}=-\delta_{\alpha\beta}$ in (2.1)) coupled with $l+1$ forms. For $D=11$ ($l=0$) the model (6.15) coincides with the truncated bosonic sector of $D=11$ supergravity (''truncated'' means without Chern–Simons term). For $D=12$ ($l=1$) (6.15) coincides with the truncated $D=12$ model from Ref. 16 (see also Ref. 5). We call the model (6.15) the B_D-model.

The matrix (6.17) is a fundamental matrix [see (6.8)] of the model (since $\lambda_a\cdot\lambda_b=-\vec{\lambda}_a\vec{\lambda}_b$, $n_a=a$).

The dimensions of p-brane worldsheets are [see (6.7)]

$$d(I)=\begin{cases}3,\ldots,D-8, & I\in\Omega_{a,e},\\ D-5,\ldots,6, & I\in\Omega a,m.\end{cases}\tag{6.19}$$

(6.20)

We have $(l+1)$ electric and $(l+1)$ magnetic p-branes $p=d(I)-1$. The intersection rules are given by (6.9). For $D=12$ see also Ref. 5.

Fundamental matrix (6.17) is d_0-proper, iff $d_0=2$ and hence the B_D-model is binary complete if the manifold decomposition (2.10) with $M_1=\ldots M_n=\mathbf{R}$, $n=D-3$, $d_0=2$ is chosen. So, for spherically symmetric solutions the binary-completeness takes place only in ''non-Tangerlini'' case $M_0=S^2$.

We note that in the B_D-models $(U^s,U^s)=2>0$, since

$$K(a)=2\tag{6.21}$$

[see (6.14)] for all $a=4,\ldots,D-7$.

Remark 2: Here two problems arise. The first one is the existence of the chain of extensions

$$B_D\leftarrow\hat{B}_D\leftarrow SG_D\leftarrow M_D=F_D,\tag{6.22}$$

where $M_D=F_D$ is M- or F-theory in dimension D, SG_D is supergravitational (field) theory coinciding with low-energy limit of F_D and $\hat{B}_D$ is the bosonic sector of SG_D. $\hat{B}_D$-action is the sum of the B_D-action and the Chern–Simons terms. The second problem is the existence of relations between B_D-models via dimensional reduction

$$B_{11}\leftarrow B_{12}\leftarrow B_{13}\leftarrow B_{14}\leftarrow\ldots.\tag{6.23}$$

For $B_{11} \leftarrow B_{12}$ see Ref. 16.

We note that B_D-models have also rather interesting classes of Toda lattice solutions. The intersection rules for these ''Toda p-branes'' may be obtained using general relations described in the next subsection. (To our knowledge p-brane solutions governed by open Toda lattices with a_n Lie algebras were studied first in Refs. 9 and 28.)

C. Generalizations to Toda lattices

Let us consider the Lagrange system (5.29) and (5.30), where V (curvature part of potential) is defined in (5.6). Here we put

$$(U^s, U^s) > 0, \quad s \in S_*. \tag{6.24}$$

The Lagrangian (5.29) may be ''block-diagonalized'' in z-variables (5.11) satisfying (5.12), (5.13), $\eta_s = +1$ and

$$B^s_{s'} z^{s'} = U^s(x), \tag{6.25}$$

$s \in S_*$, instead (5.14). Vectors $\vec{B}^s = (B^s_{s'})$ obey the relations

$$\vec{B}^{s_1} \vec{B}^{s_2} = (U^{s_1}, U^{s_2}), \tag{6.26}$$

$s_1, s_2 \in S_*$. In z-variables the Lagrangian (5.29) reads

$$L_Q = L_0 + L_{T,Q} + L_f, \tag{6.27}$$

where

$$L_0 = -\frac{1}{2}(\dot{z}^0)^2 - \frac{1}{2} w \xi_0 d_0 \, \mathrm{e}^{2q_0 z^0}, \tag{6.28}$$

$$L_{T,Q} = \frac{1}{2} \sum_{s \in S_*} (\dot{z}^s)^2 - \frac{1}{2} \sum_{s \in S_*} \varepsilon_s Q_s^2 \exp(2 \vec{B}^s \vec{z}), \tag{6.29}$$

$$L_f = \frac{1}{2} \eta_{ab} \dot{z}^a \dot{z}^b, \tag{6.30}$$

$\vec{z} = (z^s)$; $\varepsilon_s Q_s \neq 0$, $s \in S_*$.

Thus, the problem of integrability of the Lagrange system (6.27) is reduced to the problem of integrability of the Euclidean Toda-like system with the Lagrangian (6.29).

Let vectors $\vec{B}^s$ (or, equivalently, U^s), $s \in S_*$, be linearly independent. According to Adler–van Moerbeke criterion[33] the equations of motion corresponding to (6.29) are integrable in quadratures if and only if

$$\frac{2 \vec{B}^{s_1} \vec{B}^{s_2}}{\vec{B}^{s_2} \vec{B}^{s_2}} = \frac{2(U^{s_1}, U^{s_2})}{(U^{s_2}, U^{s_2})} = C_{s_1 s_2}, \tag{6.31}$$

where $C = (C_{s_1 s_2})$ is the Cartan matrix for some semisimple Lie algebra $\mathbf{g}$. When $\mathbf{g}$ is simple $L_{T,Q}$ describes a Toda lattice corresponding to $\mathbf{g}$[34–36]. From (5.4), (6.14), (6.3) and (6.31) we obtain the intersection rules

$$d(I_{s_1} \cap I_{s_2}) = \Delta(s_1, s_2) + \frac{1}{2} K(a_{s_2}) C_{s_1 s_2}, \tag{6.32}$$

$s_1 \neq s_2$, where $\Delta(s_1, s_2)$ is defined in (6.3) and $K(a)$ in (6.13).

When $\mathrm{rank}(\vec{B}^s, s \in S_*) = |S_*| - 1$ (i.e., only one vector linearly depends upon others) the Adler–van Moerbeke criterion has the form (6.31) with the Cartan matrix corresponding to some affine Lie algebra.[33] In this case a closed Toda lattice arises.

Thus, when relations (6.13) and (6.32) are satisfied, the cosmological model is integrable since it is reduced effectively to (open or closed) a Toda lattice.

Uninorm models. Let $K(a) = K$, $a \in \Delta$, and $|S| \geqslant 2$. Then from (6.32) we get that the Cartan matrix is symmetric. Hence $\mathbf{g}$ is of A-D-E type (or simply laced), i.e., it belongs to one of a_n, d_n, e_n series. In this case $C_{s_1 s_2} = 0, -1$, for $s_1 \neq s_2$ and -1 takes place for some $s_1 \neq s_2$. Let $\Delta(s_1, s_2) \in \mathbf{Z}$. Then, it follows from (6.32) that K should be even.

Example 1: In $D = 11$ supergravity $K(a) = 2$. For $S = \{s_1, s_2\}$ and $\mathbf{g} = a_2 = \mathrm{sl}(3)$ we get the intersection rule

$$d(I_{s_1} \cap I_{s_2}) = \Delta(s_1, s_2) - 1 = 0, 1, 3 \tag{6.33}$$

for $\{d(I_{s_1}), d(I_{s_2})\} = \{3,3\}, \{3,6\}, \{6,6\}$, respectively. We see that two membranes are intersecting in a point.

Example 2: Let us consider truncated $D = 11$ supergravity and put $|S| = n = 3$, $d_1 = d_2 = d_3 = 3$, $d_0 = 1$. Let $\Omega_e = \{1,2,3\}$, i.e., we consider three non-intersecting electric 2-branes (Euclidean for $w = -1$) attached to M_1, M_2, M_3, respectively. In this case $C_{s_1 s_2} = -1$ for $s_1 \neq s_2$ (the Dynkin diagram is a triangle) and the Lagrangian $L_{T,Q}$ from (6.29) is closed Toda-lattice Lagrangian corresponding to affine Lie algebra $a_2^{(1)}$. (In this case the curvature term in Lagrangian L_0 from (6.28) is absent and (5.13) should be modified.) The corresponding solutions are expressed in terms of θ-functions.[37]

Example 3: Let $K(a) = 2$ and $n_a = 1$ for all $a \in \Delta$. From (6.3) and (6.32) we get

$$\chi_{s_1} \chi_{s_2} \lambda_{a_{s_1}} \cdot \lambda_{a_{s_2}} = C_{s_1 s_2}. \tag{6.34}$$

This relation implies the appearance of E_N (open) Toda lattices in maximal supergravities in D dimensions coming from $D = 11$ supergravity.[32]

We see that the appearance of A-D-E algebras seems to be rather typical for supergravitational models (with $K(a) = 2$).

VII. CONCLUSIONS

In this paper we obtained exact solutions to Einstein and Wheeler–De Witt equations for the multidimensional cosmological model describing the evolution of n Ricci-flat spaces and one Einstein space M_0 of non-zero curvature in the presence of composite electro-magnetic p-branes. The solutions were obtained in orthogonal case (5.4), when p-branes do not ''live'' in M_0. As an illustration we singled out the spherically-symmetric solutions with intersecting non-extremal p-branes.

In the classical case we reduced the model to the Euclidean Toda-like system. Applying the Adler–van Moerbeke criterion we obtained (Toda) intersection rules (6.32) that imply the reduction of the cosmological model to (open or closed) Toda lattice. For uniform models [$K(a) = K$, $a \in \Delta$] simply laced (A-D-E) Lie algebras appear. We gave some examples of reduction to Toda lattice (e.g., closed one). Concrete exact solutions will be considered in a separate publication.

Also we developed (general) formalism of (orthogonal) intersections using the notions of fundamental matrix and binary completeness of the model and gave examples of binary complete models for $d_0 = \dim M_0 = 2$ (B_D-models). We may suppose that investigations of intersecting (e.g., Toda) p-branes may be a powerful tool in constructing new higher dimensional models (that may have supersymmetric or non-local extensions).

APPENDIX A: SOLUTIONS WITH BESSEL FUNCTIONS

Let us consider two differential operators

$$2\hat{H}_0 = -\frac{\partial^2}{\partial z^2} + 2A\mathrm{e}^{2qz}, \tag{A1}$$

$$2\hat{H}_1 = -\ \mathrm{e}^{qz}\frac{\partial}{\partial z}\left(\ \mathrm{e}^{-qz}\frac{\partial}{\partial z}\right) + 2A\ \mathrm{e}^{2qz}. \tag{A2}$$

Equation

$$H_k\Psi_k = \mathscr{E}\Psi_k \tag{A3}$$

has the following linearly independent solutions for $q \neq 0$:

$$\Psi_k(z) = \mathrm{e}^{kqz/2}B_{\omega_k(\mathscr{E})}\left(\sqrt{2A}\frac{\mathrm{e}^{qz}}{q}\right), \tag{A4}$$

$$\omega_k(\mathscr{E}) = \sqrt{\frac{k}{4} - \frac{2\mathscr{E}}{q^2}}, \tag{A5}$$

where $k = 0,1$ and $B_\omega = I_\omega, K_\omega$ are modified Bessel function.

APPENDIX B: CLASSICAL SOLUTIONS WITH ORTHOGONAL VECTORS

Let

$$L = \frac{1}{2}\langle \dot{x}, \dot{x}\rangle - \sum_{s=1}^{m} A_s\ \exp[2\langle b_s, x\rangle] \tag{B1}$$

be a Lagrangian, defined on $V \times V$, where V is n-dimensional vector space, over $\mathbf{R}$, $A_s \neq 0$, $s = 1,\ldots,m$; $m \leqslant n$, and $\langle \cdot,\cdot \rangle$ is non-degenerate real-valued quadratic form on V. Let

$$\langle b_s, b_s\rangle \neq 0, \tag{B2}$$

$$\langle b_s, b_l\rangle = 0, \quad s \neq l, \tag{B3}$$

$s, l = 1,\ldots,m$. Denote

$$\eta_s = \ \mathrm{sign}\langle b_s, b_s\rangle. \tag{B4}$$

Then, the Euler–Lagrange equations for the Lagrangian (B1) have the following solutions:[14]

$$x(t) = -\sum_{s=1}^{m}\frac{b_s}{\langle b_s, b_s\rangle}\ \ln|f_s(t - t_{0s})| + t\alpha + \beta, \tag{B5}$$

where $\alpha, \beta \in V$,

$$\langle \alpha, b_s\rangle = \langle \beta, b_s\rangle = 0, \tag{B6}$$

and

$$f_s(\tau)=\left|\frac{A_s}{E_s}\right|^{1/2}\mathrm{sh}(\sqrt{C_s}\tau),\quad C_s>0,\quad A_s\eta_s<0, \tag{B7}$$

$$=\left|\frac{A_s}{E_s}\right|^{1/2}\sin(\sqrt{|C_s|}\tau),\quad C_s<0,\quad A_s\eta_s<0, \tag{B8}$$

$$=\left|\frac{A_s}{E_s}\right|^{1/2}\mathrm{ch}(\sqrt{C_s}\tau),\quad C_s>0,\quad A_s\eta_s>0, \tag{B9}$$

$$=|2A_s\langle b_s,b_s\rangle|^{1/2}\tau,\quad C_s=0,\quad A_s\eta_s<0, \tag{B10}$$

$C_s=2E_s\langle b_s,b_s\rangle$, and E_s, t_{0s} are constants.

For the energy corresponding to the solution (B5) we have

$$E=\sum_{s=1}^{m}E_s+\frac{1}{2}\langle\alpha,\alpha\rangle. \tag{B11}$$

For dual vectors $u^s\in V^*$ defined as $u^s(x)=\langle b_s,x\rangle$, $\forall x\in V$, we have $\langle u^s,u^l\rangle_*=\langle b_s,b_l\rangle$, where $\langle\cdot,\cdot\rangle_*$ is dual form on V^*. The orthogonality conditions (B6) read

$$u^s(\alpha)=u^s(\beta)=0, \tag{B12}$$

$s=1,\ldots,m$.

(Received 10 July 1997; accepted for publication 4 December 1997)

The Green functions of the partial differential operators of even order acting on smooth sections of a vector bundle over a Riemannian manifold are investigated via the heat kernel methods. We study the resolvent of a special class of higher-order operators formed by the products of second-order operators of Laplace type defined with the help of a unique Riemannian metric but with different bundle connections and potential terms. The asymptotic expansion of the Green functions near the diagonal is studied in detail in any dimension. As a by-product a simple criterion for the validity of the Huygens principle is obtained. It is shown that all the singularities as well as the non-analytic regular parts of the Green functions of such high-order operators are expressed in terms of the usual heat kernel coefficients a_k for a special Laplace type second-order operator. © *1998 American Institute of Physics.* [S0022-2488(98)02905-3]

I. INTRODUCTION

The Green functions of partial differential operators are of great importance in mathematical physics and quantum theory.[1–4] In particular, the singularities of the Green functions on the diagonal play a crucial role in the renormalization procedure of quantum field theory.[5]

In this paper we study a special class of differential operators of higher orders that appear, in particular, in higher-derivative field theories (for example, in higher-derivative quantum gravity[6]). Namely, we consider differential operators of higher *even* orders, $2N$, of the form

$$H=(F_N+m^2)\cdots(F_2+m^2)(F_1+m^2), \tag{1}$$

where F_i, $(i=1,\ldots,N)$ are Laplace type operators, i.e. second-order operators with the scalar leading symbol determined by the metric of the manifold

$$\sigma_L(F_i)=|\xi|^2, \tag{2}$$

where $|\xi|^2\equiv g^{\mu\nu}(x)\xi_\mu\xi_\nu$, and m is some constant. In the next section we give precise definition of Laplace type operators and describe their properties. Obviously, the operator H also has a scalar leading symbol

$$\sigma_L(H)=|\xi|^{2N}, \tag{3}$$

and is a particular case of the so called minimal higher-derivative operators.

We would like to stress from the beginning that the operators F_i, even if of the same Laplace type, are *different* and, in general, *do not commute*. They only have the same leading, second-derivatives, part, but differ in the first and zero order parts.

The Green function, or the resolvent kernel, $G_{H-\lambda}(x,x')$ of the operator H is the kernel of the Green, or resolvent, operator $G_{H-\lambda}=(H-\lambda)^{-1}$ and is defined by requring it to satisfy the differential equation

$$(H-\lambda)G_{H-\lambda}(x,x')=\delta(x,x'), \tag{4}$$

with H acting on the first argument of the Green function and $\delta(x,x')$ being the covariant delta-distribution.

In the present paper we will consider mainly the case of compact complete manifolds without boundary and assume the metric of the manifold to be positive definite. Then the Laplace type operators F_i as well as the operator H are *elliptic* and eq. (4) defines a unique Green function. We will also assume for simplicity the constant m to be sufficiently large so that all operators $(F_i + m^2)$ and also H are *positive*.

However, we would like to make some remarks concerning this subject:

(i) First, for manifolds with boundary (in elliptic case) one has to impose additionally some suitable boundary conditions to make the solution of eq. (4) unique. However, the singularities of the Green function near the diagonal and the asymptotic expansions of it as $m \to \infty$ do not depend on the boundary conditions.

(ii) Second, when the metric of the manifold has Minkowski type signature, sign $g=(-,+,\ldots,+)$, the Laplace type operators F_i are *hyperbolic*. In this case the Green function can be fixed by the Wick rotation, i.e. the analytic continuation from the Euclidean case, which is equivalent to adding an infinitesimal negative imaginary part to the constant m^2, $m^2 \to m^2 - i\varepsilon$. In other words, we consider the *Feynman propagators*. The formulas for the hyperbolic case can be obtained just by analytic continuation.

II. LAPLACE TYPE OPERATORS

Let (M,g) be a smooth Riemannian manifold of dimension d with a metric g. To simplify the exposition we assume the manifold M to be complete and compact, i.e., without boundary, $\partial M = \varnothing$, and the metric g to be positive definite.

Let $V(M)$ be a smooth vector bundle over the manifold M, End (V) be the bundle of all smooth endomorphisms of the vector bundle V, and $C^\infty(M,V)$ and $C^\infty(M,\mathrm{End}\,(V))$ be the spaces of all smooth sections of the vector bundles V and End (V). We assume, as usual, the vector bundle V to be Hermitian, i.e., there is a Hermitian pointwise fibre scalar product. Then the dual vector bundle V^* is naturally identified with V and a natural L^2 inner product is defined using the invariant Riemannian volume element $d\mathrm{vol}\,(x)$ on the manifold M. The completion of $C^\infty(M,V)$ in this norm defines the Hilbert space of square integrable sections of the vector bundle $L^2(M,V)$.

Let, further, ∇ be a connection, or covariant derivative, on the vector bundle V which is compatible with the Hermitian metric on the vector bundle V. Denoting by T^*M the cotangent bundle we define the tensor product connection on the tensor product bundle $T^*M \otimes V$ by means of the Levi-Civita connection. Similarly, we extend the connection ∇ with the help of the Levi-Civita connection to $C^\infty(M,V)$-valued tensors of all orders and denote it just by ∇. Usually there is no ambiguity and the precise meaning of the covariant derivative is always clear from the nature of the object it is acting on.

Let, further, tr_g denote the contraction of sections of the bundle $T^*M \otimes T^*M \otimes V$ with the metric on the cotangent bundle, and $Q \in C^\infty(M,\mathrm{End}(V))$ be a smooth Hermitian section of the endomorphism bundle. Then we define the generalized Laplacian

$$\Box = \mathrm{tr}_g \nabla\nabla \tag{5}$$

and a *Laplace type* differential operator F: $C^\infty(M,V) \to C^\infty(M,V)$ by

$$F = -\Box + Q. \tag{6}$$

Let x^μ, $(\mu = 1,2,\ldots,d)$, be a system of local coordinates and ∂_μ and dx^μ be the local coordinate frames for the tangent and the cotangent bundles. We adopt the notation that the Greek indices label the tensor components with respect to local coordinate frame and range from 1 through d. Besides, a summation is always carried out over repeated indices. Let $g_{\mu\nu} = (\partial_\mu, \partial_\nu)$ be the metric on the tangent bundle, $g^{\mu\nu} = (dx^\mu, dx^\nu)$ be the metric on the cotangent bundle, $g = \det g_{\mu\nu}$, and $\mathscr{A}_\mu$ be the connection 1-form on the vector bundle V. Then the generalized Laplacian reads

$$\Box = g^{\mu\nu}\nabla_\mu\nabla_\nu = g^{-1/2}(\partial_\mu + \mathscr{A}_\mu) g^{1/2} g^{\mu\nu} (\partial_\nu + \mathscr{A}_\nu). \tag{7}$$

It is worth noting that every second-order differential operator with a scalar leading symbol given by the metric tensor is of Laplace type and can be put in the form (6) by choosing the appropriate connection 1-form $\mathscr{A}$ and the endomorphism Q.

The operator F has a positive leading symbol and is elliptic. It is symmetric with respect to the natural L^2 inner product. Moreover, the operator F is essentially self-adjoint, i.e., there is a unique self-adjoint extension $\overline{F}$ of the operator F. However, we will not be very careful about distinguishing between the operator F and its closure $\overline{F}$, and will simply say that the operator F is elliptic and self-adjoint.

A. Heat kernel of a Laplace type operator

Hence, the operator $U_F(t)=\exp(-tF)$ for $t>0$ is well defined as a *bounded* operator on the Hilbert space $L^2(M,V)$ of square integrable sections of the vector bundle V. This operator forms a one-parameter semi-group. The kernel $U_F(t|x,x')$ of this operator satisfies the heat equation and is called the heat kernel. For $t>0$ the heat kernel is a smooth section of the external tensor product of the vector bundles V and V^* over the tensor product manifold $M\times M$.

In the following we are going to study the Green function and the heat kernel only locally (like in Ref. 7), i.e. in the neighborhood of the diagonal of $M\times M$. We will keep a point x' of the manifold fixed and consider a small geodesic ball, i.e. a small neighborhood of the point x': $B_{x'}=\{x\in M|r(x,x')<\varepsilon\}$, $r(x,x')$ being the geodesic distance between the points x and x'. We will take the radius of the ball sufficiently small, so that each point x of the ball of this neighborhood can be connected by a unique geodesic with the point x'. This can always be done if the size of the ball is smaller than the injectivity radius of the manifold at x', $\varepsilon<r_{\text{inj}}(x')$.

Let $\sigma(x,x')$ be the geodetic interval, also called world function, defined as one half the square of the length of the geodesic connecting the points x and x'

$$\sigma(x,x')=\tfrac{1}{2}r^2(x,x'). \tag{8}$$

The first derivatives of this function with respect to x and x' define the tangent vector fields to the geodesic at the end points x and x' and the determinant of the mixed second derivatives defines a so called Van Vleck-Morette determinant[2,8,9]

$$\Delta(x,x')=g^{-1/2}(x)\det\left(-\nabla_\mu\nabla'_{\nu'}\sigma(x,x')\right)g^{-1/2}(x'). \tag{9}$$

Let, finally, $\mathscr{P}(x,x')$ denote the parallel transport operator along the geodesic from the point x' to the point x. It is a section of the external tensor product of the vector bundle V and V^* over $M\times M$, or, in other words, it is an endomorphism from the fiber of V over x' to the fiber of V over x. Near the diagonal of $M\times M$ all these two-point functions are smooth single-valued functions of the coordinates of the points x and x'. To simplify the consideration, one can assume that these functions are *analytic* in the ball $B_{x'}$.

The heat kernel of a Laplace type operator is well described by factorizing out the semi-classical factor[2,6,7]

$$U_F(t|x,x')=(4\pi t)^{-d/2}\Delta^{1/2}(x,x')\exp\left(-\frac{1}{2t}\sigma(x,x')\right)\Omega_F(t|x,x'). \tag{10}$$

The function $\Omega_F(t|x,x')$ is called the *transfer function* of the operator F. Obviously,

$$U_{F+m^2}(t)=e^{-tm^2}U_F(t),\quad \Omega_{F+m^2}(t)=e^{-tm^2}\Omega_F(t). \tag{11}$$

It can be proved[7] that for a positive operator $F+m^2$ the transfer function $\Omega_{F+m^2}(t)$ can be presented in form of an inverse Mellin transform (we slightly change notation here in comparison to Ref. 7)

$$\Omega_{F+m^2}(t)=\frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty}dq\ t^q\Gamma(-q)b_{F+m^2}(q), \tag{12}$$

where c is a negative constant. The function $b_{F+m^2}(q)$ is an *entire* function of q, so that the integrand has simple poles at the positive integer points $q=k$ $(k=0,1,\dots)$. The function $b_{F+m^2}(q|x,x')$ satisfies a functional-differential equation[7]

$$\left(1+\frac{1}{q}D\right)b_{F+m^2}(q)=L\ b_{F+m^2}(q-1), \tag{13}$$

where

$$L=\Delta^{-1/2}F\Delta^{1/2}+m^2=-\Delta^{-1/2}\Box\Delta^{1/2}+Q+m^2, \tag{14}$$

$$D=\sigma^\mu\nabla_\mu, \quad \sigma_\mu=\nabla_\mu\sigma, \tag{15}$$

and the initial condition

$$b_{F+m^2}(0|x,x')=\mathscr{P}(x,x'). \tag{16}$$

This equation (together with the condition of analyticity and some asymptotic condition at $q\to\text{const}\pm i\infty$) enables one to compute $b_{F+m^2}(q)$ if one fixes its initial value at some arbitrary point $q=q_0$. (For more details, see Ref. 7.) The initial condition at the origin produces the values of $b_{F+m^2}(k)$ at positive integer points, the initial condition at the point $q=1/2$ would give the values of $b_{F+m^2}(q)$ at all half-integer positive points $b_{F+m^2}(k+1/2)$, etc. Differentiating eq. (13) with respect to q one obtains another recursion

$$\left(1+\frac{1}{q}D\right)b'_{F+m^2}(q)=L\ b'_{F+m^2}(q-1)+\frac{1}{q^2}Db_{F+m^2}(q), \tag{17}$$

where

$$b'_{F+m^2}(q)=\frac{\partial}{\partial q}b_{F+m^2}(q), \tag{18}$$

which enables one to compute the derivatives of the function $b_{F+m^2}(q)$ at positive integer points if one fixes its value $b'_{F+m^2}(0)$.

Moving the contour of integration to the right and taking into account that the residues of the gamma-function $\Gamma(-q)$ at the points $q=k$ equal $(-1)^k/k!$ one obtains[7]

$$\Omega_{F+m^2}(t)=\sum_{k=0}^{n-1}\frac{(-t)^k}{k!}a_k(F+m^2)+\frac{1}{2\pi i}\int_{c_n-i\infty}^{c_n+i\infty}dq\ t^q\Gamma(-q)b_{F+m^2}(q), \tag{19}$$

where

$$a_k(F+m^2)\equiv b_{F+m^2}(k)=\left(-\frac{\partial}{\partial t}\right)^k\Omega_{F+m^2}(t)|_{t=0}, \tag{20}$$

n is an arbitrary positive integer, $n\geqslant 1$, and c_n ranges in the interval $n-1<c_n<n$. The coefficients $a_k(F+m^2)$ are the famous Hadamard-Minakshisundaram-De Witt-Seeley (HMDS)-coefficients[1,10,2,11] to the operator $F+m^2$. They can be computed in form of covariant Taylor series from the recursion relations that are obtained from eq. (13) (by putting $q\to k$) with the initial condition $a_0(F+m^2)=\mathscr{P}$. The diagonal values of the HMDS-coefficients are known in general case up to a_4.[12,6,13,7,14] In some particular cases, e.g., in flat space, there are results for higher-order coefficients. For a review of the methods for calculation of HMDS-coefficients and further references see Refs. 15 and 16.

Taking into account eq. (11) we find from (20)

$$a_k(F+m^2)=\sum_{n=0}^{k}\binom{k}{n}m^{2(k-n)}a_n(F). \tag{21}$$

Moreover, one can obtain an asymptotic expansion of the function $b_{F+m^2}(q)$ as $m\to\infty$[7]

$$b_{F+m^2}(q)\sim\sum_{n\geqslant 0}\frac{\Gamma(q+1)}{n!\Gamma(q-n+1)}\,m^{2(q-n)}a_n(F). \tag{22}$$

From (19) there follows an asymptotic expansion of the transfer function as $t\to 0$ (called Schwinger-De Witt expansion in the physical literature)[2–4,6,7]

$$\Omega_{F+m^2}(t)\sim\sum_{k\geqslant 0}\frac{(-t)^k}{k!}a_k(F+m^2)=e^{-tm^2}\sum_{k\geqslant 0}\frac{(-t)^k}{k!}a_k(F). \tag{23}$$

Using this equation one obtains from (10) the well known formula for the asymptotic expansion of the functional trace of the heat kernel

$$\mathrm{Tr}_{L^2}\exp(-tF)\sim(4\pi)^{-d/2}t^{-d/2}\sum_{k\geqslant 0}\frac{(-t)^k}{k!}A_k(F), \tag{24}$$

where

$$A_k(F)=\mathrm{Tr}_{L^2}a_k(F)=\int_M d\mathrm{vol}\,(x)\ \mathrm{tr}_V a_k(F|x,x), \tag{25}$$

with tr_V being the fiber trace.

B. Green function of a Laplace type operator

The Laplace type operator F is a self-adjoint elliptic operator with a real spectrum bounded from below. Thus for sufficiently large m the operator $(F+m^2)$ is positive and its Green operator, or the resolvent operator, $G_{F+m^2}=(F+m^2)^{-1}$ is a bounded operator. It can be defined by

$$G_{F+m^2}=\int_0^\infty dt\ e^{-tm^2}\exp(-tF). \tag{26}$$

The Green function of the operator $(F+m^2)$ is obtained by the kernel form of this equation

$$G_{F+m^2}=(4\pi)^{-d/2}\Delta^{1/2}\int_0^\infty dt\ t^{-d/2}\exp\left(-tm^2-\frac{\sigma}{2t}\right)\Omega_F(t). \tag{27}$$

This integral converges at infinity for sufficiently large m. It also converges at $t=0$ outside the diagonal, i.e. for $\sigma\neq 0$. By using the ansatz (10) and (12) for the heat kernel one obtains a corresponding ansatz for the Green function

$$G_{F+m^2}=(4\pi)^{-d/2}\Delta^{1/2}\frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty}dq\,\left(\frac{\sigma}{2}\right)^{q+1-d/2}\Gamma(-q)\Gamma(-q-1+d/2)b_{F+m^2}(q), \tag{28}$$

where $c<-1/2$.

This ansatz is especially useful for studying the singularities of the Green function, or more general, for constructing the Green function as a power series in σ. The integrand in (28) is again a meromorphic function. However, contrary to (12), we have now a more complicated structure of the poles. There are always poles at the points $q=k$ and $q=k-1+d/2$, $(k=0,1,2,\dots)$. Here one has to distinguish between odd and even dimensions. In odd dimensions, the poles are at the points $q=k$ and $q=k+[d/2]-1/2$ and are *simple*, whereas in even dimension there are simple poles at $q=0,1,2,\dots,d/2-2$ and *double* poles at the points $q=k+d/2-1$.

Moving the contour of integration in (28) to the right one can obtain an expansion of the Green function in powers of σ (Hadamard series). Generally, we obtain

$$G_{F+m^2}=G^{\mathrm{sing}}_{F+m^2}+G^{\text{non-anal}}_{F+m^2}+G^{\mathrm{reg}}_{F+m^2}. \tag{29}$$

Here $G^{\rm sing}_{F+m^2}$ is the singular part which is polynomial in the inverse powers of $\sqrt{\sigma}$

$$G^{\rm sing}_{F+m^2}=(4\pi)^{-d/2}\Delta^{1/2}\sum_{k=0}^{[(d+1)/2]-2}\frac{(-1)^k}{k!}\Gamma(d/2-k-1)\left(\frac{2}{\sigma}\right)^{d/2-k-1}a_k(F+m^2), \tag{30}$$

For the rest we get in *odd* dimensions

$$\begin{aligned}G^{\rm non\text{-}anal}_{F+m^2}+G^{\rm reg}_{F+m^2}=&(-1)^{(d-1)/2}(4\pi)^{-d/2}\Delta^{1/2}\sum_{k=0}^{n-(d+1)/2}\frac{\pi}{\Gamma(k+(d+1)/2)\Gamma(k+3/2)}\\&\times\left(\frac{\sigma}{2}\right)^{k+1/2}a_{k+(d-1)/2}(F+m^2)\\&+(-1)^{(d+1)/2}(4\pi)^{-d/2}\Delta^{1/2}\sum_{k=0}^{n-(d+1)/2}\frac{\pi}{k!\Gamma(k+d/2)}\left(\frac{\sigma}{2}\right)^{k}b_{F+m^2}(k-1+d/2)\\&+(4\pi)^{-d/2}\Delta^{1/2}\frac{1}{2\pi i}\int_{c_n-i\infty}^{c_n+i\infty}dq\left(\frac{\sigma}{2}\right)^{q+1-d/2}\Gamma(-q)\Gamma(-q-1+d/2)b_{F+m^2}(q),\end{aligned} \tag{31}$$

where $n-1<c_n<n-1/2$ and $n>(d-1)/2$. Thus, by putting $n\to\infty$ we recover herefrom the Hadamard power series in σ for *odd* $d=1,3,5,\ldots$

$$\begin{aligned}G^{\rm non\text{-}anal}_{F+m^2}\sim&(-1)^{(d-1)/2}(4\pi)^{-d/2}\Delta^{1/2}\sum_{k=0}^{\infty}\frac{\pi}{\Gamma(k+(d+1)/2)\Gamma(k+3/2)}\left(\frac{\sigma}{2}\right)^{k+1/2}\\&\times a_{k+(d-1)/2}(F+m^2)\ ,\end{aligned} \tag{32}$$

$$G^{\rm reg}_{F+m^2}\sim(-1)^{(d+1)/2}(4\pi)^{-d/2}\Delta^{1/2}\sum_{k=0}^{\infty}\frac{\pi}{k!\Gamma(k+d/2)}\left(\frac{\sigma}{2}\right)^{k}b_{F+m^2}(k-1+d/2). \tag{33}$$

In *even* dimensions, the point is more subtle due to the presence of double poles. Moving the contour in (28) to the right and calculating the contribution of the residues at the simple and double poles we obtain

$$\begin{aligned}&G^{\rm non\text{-}anal}_{F+m^2}+G^{\rm reg}_{F+m^2}\\&\quad=(-1)^{d/2-1}(4\pi)^{-d/2}\Delta^{1/2}\log\left(\frac{\mu^2\sigma}{2}\right)\sum_{k=0}^{n-1}\frac{1}{k!\Gamma(k+d/2)}\left(\frac{\sigma}{2}\right)^{k}a_{k-1+d/2}(F+m^2)\\&\quad+(-1)^{d/2-1}(4\pi)^{-d/2}\Delta^{1/2}\sum_{k=0}^{n-1}\frac{1}{k!\Gamma(k+d/2)}\left(\frac{\sigma}{2}\right)^{k}\Big\{b'_{F+m^2}(k-1+d/2)\\&\quad-[\log\mu^2+\Psi(k+1)+\Psi(k+d/2)]a_{k-1+d/2}(F+m^2)\Big\}\\&\quad+(4\pi)^{-d/2}\Delta^{1/2}\frac{1}{2\pi i}\int_{c_n-i\infty}^{c_n+i\infty}dq\left(\frac{\sigma}{2}\right)^{q+1-d/2}\Gamma(-q)\Gamma(-q-1+d/2)b_{F+m^2}(q),\end{aligned} \tag{34}$$

where μ is an arbitrary mass parameter introduced to preserve dimensions, $n-1<c_n<n$ and $\Psi(z)=(d/dz)\log\Gamma(z)$. If we let $n\to\infty$ we obtain the Hadamard expansion of the Green function for *even* $d=2,4,\ldots$

$$G^{\text{non-anal}}_{F+m^2}\sim(-1)^{d/2-1}(4\pi)^{-d/2}\Delta^{1/2}\log\left(\frac{\mu^2\sigma}{2}\right)\sum_{k=0}^{\infty}\frac{1}{k!\Gamma(k+d/2)}\left(\frac{\sigma}{2}\right)^k a_{k-1+d/2}(F+m^2)\ , \tag{35}$$

$$G^{\text{reg}}_{F+m^2}\sim(-1)^{d/2-1}(4\pi)^{-d/2}\Delta^{1/2}\sum_{k=0}^{\infty}\frac{1}{k!\Gamma(k+d/2)}\left(\frac{\sigma}{2}\right)^k \times\left\{b'_{F+m^2}(k-1+d/2)-[\log\mu^2+\Psi(k+1)+\Psi(k+d/2)]a_{k-1+(d/2)}(F+m^2)\right\}. \tag{36}$$

Note that the singular part (which is a polynomial in inverse powers of $\sqrt{\sigma}$) and the *non-analytical* parts (proportional to $\sqrt{\sigma}$ and $\log\sigma$) are expressed *uniquely only in terms of the local HMDS-coefficients* $a_k(F+m^2)$, whereas the regular analytical part contains the values of the function $b_{F+m^2}(q)$ at half-integer positive points and the derivatives of the function $b_{F+m^2}(q)$ at integer positive points, which are *not* expressible in terms of the local information. These objects are global and cannot be expressed further in terms of the local HMDS-coefficients. However, they can be computed from eqs. (13) and (17) almost by the same algorithm as the HMDS-coefficients in terms of the value of the function $b(q)$ at some fixed q_0 (see Refs. 7).

The regular part of the Green function has a well defined diagonal value and the functional trace. It reads in odd dimensions ($d=1,3,5,\dots$):

$$\begin{aligned}\mathrm{Tr}_{L^2}\,G^{\text{reg}}_{F+m^2}&=(-1)^{(d+1)/2}(4\pi)^{-d/2}\frac{\pi}{\Gamma(d/2)}B_{F+m^2}(d/2-1)\\&\overset{m\to\infty}{\sim}(-1)^{(d+1)/2}(4\pi)^{-d/2}\pi\sum_{k\geqslant 0}\frac{m^{d-2-2k}}{k!\Gamma(d/2-k)}A_k(F)\end{aligned} \tag{37}$$

and in even dimensions ($d=2,4,6,\dots$)

$$\begin{aligned}\mathrm{Tr}_{L^2}\,G^{\text{reg}}_{F+m^2}&=(-1)^{d/2-1}\frac{(4\pi)^{-d/2}}{\Gamma(d/2)}\{B'_{F+m^2}(d/2-1)-[\log\,\mu^2+\Psi(d/2)-\mathbb{C}]A_{d/2-1}(F+m^2)\}\\&\overset{m\to\infty}{\sim}(-1)^{d/2-1}(4\pi)^{-d/2}\Bigg\{\sum_{k=0}^{d/2-1}\frac{m^{d-2-2k}}{k!\Gamma(d/2-k)}[\mathbb{C}-\Psi(d/2-k)\\&\quad+\log\,(m^2/\mu^2)]A_k(F)+\sum_{k\geqslant d/2}\frac{(-1)^{k-d/2}}{k!}m^{d-2-2k}\Gamma(k+1-d/2)A_k(F)\Bigg\},\end{aligned} \tag{38}$$

where

$$B_{F+m^2}(q)=\mathrm{Tr}_{L^2}b_{F+m^2}(q)=\int_M d\mathrm{vol}\,(x)\mathrm{tr}_V\,b_{F+m^2}(x,x), \tag{39}$$

and $\mathbb{C}=-\Psi(1)=0.577\dots$ is the Euler's constant.

Thus, we see that

(i) all the singularities of the Green function and the non-analytical parts thereof (proportional to $\sqrt{\sigma}$ in odd dimensions and to $\log\sigma$ in even dimensions) are determined by the HMDS-coefficients $a_k(F)$;

(ii) there are no power singularities, i.e., $G^{\text{sing}}_{F+m^2}=0$, in lower dimensions $d=1,2$;

(iii) there is no logarithmic singularity (more generally, no logarithmic part at all) in odd dimensions;

(iv) the regular part depends on the values of the function $b_{F+m^2}(q)$ at half-integer points and its derivative at integer points and is a global object that cannot be reduced to purely local information like the HMDS-coefficients.

The logarithmic part of the Green function is very important. On the one hand it determines, as usual, the renormalization properties of the regular part of the Green function, i.e. the derivative $\mu(\partial/\partial\mu)G^{\rm reg}_{F+m^2}$. In particular,

$$\mu\frac{\partial}{\partial\mu}{\rm Tr}_{L^2}G^{\rm reg}_{F+m^2}=\begin{cases}0 & \text{for odd } d\\ \dfrac{(4\pi)^{-d/2}}{\Gamma(d/2)}A_{d/2-1}(F+m^2) & \text{for even } d.\end{cases}\tag{40}$$

On the other hand, it is of crucial importance in studying the Huygens principle. Namely, the absence of the logarithmic part of the Green function is a necessary and sufficient condition for the validity of the Huygens principle for hyperbolic operators.[17–19] The HMDS-coefficients and, therefore, the logarithmic part of the Green function are defined for the hyperbolic operators just by analytic continuation from the elliptic case. Thus, the condition of the validity of Huygens principle reads

$$\sum_{k=0}^{\infty}\frac{\Gamma(d/2)}{k!\Gamma(k+d/2)}\left(\frac{\sigma}{2}\right)^k a_{k-1+d/2}(F+m^2)=0,\tag{41}$$

or, by using (21),

$$\sum_{k=0}^{\infty}\sum_{n=0}^{k-1+d/2}\frac{\Gamma(d/2)}{k!n!\Gamma(k-n+d/2)}\left(\frac{\sigma}{2}\right)^k m^{2(k-n)}a_n(F)=0.\tag{42}$$

By expanding this equation in covariant Taylor series using the methods of Ref. 7 one can obtain an infinite set of local conditions for validity of the Huygens principle.

$$\sum_{k=0}^{[n/2]}\frac{n!\Gamma(d/2)}{4^k k!(n-2k)!\Gamma(k+d/2)}(\vee^k g)\vee\langle n-2k|a_{k-1+d/2}(F+m^2)\rangle=0,\tag{43}$$

where $\vee$ is the exterior symmetric tensor product, g is the metric tensor on the tangent bundle, and $\langle n|a_k\rangle$ denotes the diagonal value of the symmetrized covariant derivative of nth order.[7] More explicitly,

$$[a_{d/2-1}(F+m^2)]=0,\tag{44}$$

$$[\nabla_\mu a_{d/2-1}(F+m^2)]=0,\tag{45}$$

$$[\nabla_{(\mu}\nabla_{\nu)}a_{d/2-1}(F+m^2)]+\frac{1}{2d}g_{\mu\nu}[a_{d/2}(F+m^2)]=0,\tag{46}$$

$$\dots,$$

where the square brackets denote the diagonal value of two-point quantities: $[f(x,x')]=f(x,x)$.

III. HIGHER ORDER OPERATORS

Let us now describe in detail the class of higher order operators we are going to study. We consider again a Riemannian manifold (M,g) and a vector bundle $V(M)$ with a connection ∇. Let $\mathscr{A}_{(i)}$, $(i=1,\dots,N)$ be a set of different smooth sections of the vector bundle $T^*M\otimes{\rm End}(V)$. They define a set of *different* connections

$$\nabla_{(i)}=\nabla+\mathscr{A}_{(i)}\tag{47}$$

on the vector bundle $V(M)$, and therefore, a set of different generalized Laplacians

$$\begin{aligned}\Box_i&={\rm tr}_g\nabla_{(i)}\nabla_{(i)}=g^{\mu\nu}(\nabla_\mu+\mathscr{A}_{(i)\,\mu})(\nabla_\nu+\mathscr{A}_{(i)\,\nu})\\&=\Box+g^{\mu\nu}(\mathscr{A}_{(i)\mu}\nabla_\nu+\nabla_\nu\mathscr{A}_{(i)\mu})+g^{\mu\nu}\mathscr{A}_{(i)\mu}\mathscr{A}_{(i)\nu}.\end{aligned}\tag{48}$$

Let, further, Q_i be a set of different smooth sections of the vector bundle $\mathrm{End}(V)$. Then, we define a set of *different* Laplace type operators

$$F_i = -\Box_i + Q_i \tag{49}$$

and a higher order operator of a special form

$$H = (F_N + m^2)\cdots(F_2 + m^2)(F_1 + m^2). \tag{50}$$

A. Algebraical reduction to Laplace type operators

We are going to study the Green function $G_{H-\lambda}(x,x')$ of the higher order operator $H-\lambda$, where λ is an arbitrary sufficiently large negative constant. To do this, we show, first, that the Green operator $G_{H-\lambda}=(H-\lambda)^{-1}$ can be reduced to the Green operator of an auxiliary Laplace type operator. This will mean that the Green function of the higher order differential operator will be reduced to the Green function of a *second-order* differential operator of Laplace type, which is described in previous section.

Theorem 1: *Let F_i, $(i=1,\ldots,N)$, be some positive elliptic operators and H be an operator defined by*

$$H = (F_N + m^2)\cdots(F_2 + m^2)(F_1 + m^2), \tag{51}$$

where m is a sufficiently large constant. Let I_{N-1} be the unit $(N-1)\times(N-1)$ matrix and O_{N-1} be the square $(N-1)\times(N-1)$ null matrix. Let P and Π be square $N\times N$ matrices defined by the following block form

$$P = \begin{pmatrix} 0 & I_{N-1} \\ \lambda & 0 \end{pmatrix}, \quad \Pi = \frac{\partial}{\partial\lambda} P = \begin{pmatrix} 0 & O_{N-1} \\ 1 & 0 \end{pmatrix}, \tag{52}$$

where λ is a constant, and let $\widetilde{F} = F_1 \oplus \cdots \oplus F_N$ be a $N\times N$ diagonal matrix formed by the operators F_i

$$\widetilde{F} = \begin{pmatrix} F_1 & \ldots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \ldots & F_N \end{pmatrix}. \tag{53}$$

Let $\mathscr{F}$ be an operator defined by

$$\mathscr{F} = \widetilde{F} - P. \tag{54}$$

Let $G_{H-\lambda}$ and $G_{\mathscr{F}+m^2}$ be the Green operators of the operators $(H-\lambda)$ and $(\mathscr{F}+m^2)$ satisfying the equations

$$(H-\lambda)G_{H-\lambda} = 1 \tag{55}$$

and

$$(\mathscr{F}+m^2)G_{\mathscr{F}+m^2} = 1. \tag{56}$$

Then there holds

$$G_{H-\lambda} = \mathrm{tr}\ \Pi\ G_{\mathscr{F}+m^2}, \tag{57}$$

$$\frac{\partial}{\partial m^2} G_{H-\lambda} = -\frac{\partial}{\partial\lambda}\mathrm{tr}\ G_{\mathscr{F}+m^2}, \tag{58}$$

Proof: Let us introduce some auxiliary operators

$$Z_1 = G_{H-\lambda}$$

$$Z_2 = (F_1 + m^2) Z_1$$

$$\vdots$$

$$Z_N = (F_{N-1} + m^2) Z_{N-1}. \tag{59}$$

Then eq. (55) can be rewritten as

$$(F_N + m^2) Z_N - \lambda G_{H-\lambda} = 1. \tag{60}$$

Let us collect the operators Z_i in a column-vector

$$Z = \begin{pmatrix} Z_1 \\ \vdots \\ Z_N \end{pmatrix}. \tag{61}$$

The Green operator $G_{H-\lambda}$ is the first component of the vector Z and can be obtained by multiplying with the row-vector $\Pi_1^\dagger = (1,0,\ldots,0)$

$$G_{H-\lambda} = \Pi_1^\dagger Z. \tag{62}$$

Further, let us define another column-vector

$$\Pi_N = \begin{pmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{pmatrix}, \tag{63}$$

so that

$$\Pi = \Pi_N \otimes \Pi_1^\dagger. \tag{64}$$

It is not difficlut to show that eqs. (59) can be rewritten in a matrix form

$$(\mathscr{F} + m^2) Z = \Pi_N. \tag{65}$$

Using the Green operator $G_{\mathscr{F}+m^2}$ of the operator $(\mathscr{F} + m^2)$ we obtain

$$Z = G_{\mathscr{F}+m^2} \Pi_N. \tag{66}$$

Finally, from (62) by taking into account (64) we get the Green operator $G_{H-\lambda}$

$$G_{H-\lambda} = \Pi_1^\dagger \; G_{\mathscr{F}+m^2} \Pi_N = \mathrm{tr}\; \Pi \; G_{\mathscr{F}+m^2}, \tag{67}$$

which proves eq. (57). To prove eq. (58) we note that

$$\frac{\partial}{\partial \lambda} \mathrm{tr}\; G_{\mathscr{F}+m^2} = -\,\mathrm{tr}\; G_{\mathscr{F}+m^2} \frac{\partial \mathscr{F}}{\partial \lambda} G_{\mathscr{F}+m^2}$$

$$= -\,\mathrm{tr}\; \Pi \; G^2_{\mathscr{F}+m^2}. \tag{68}$$

Further, from the definition of the Green operator we have, obviously,

$$\frac{\partial}{\partial m^2} \mathrm{tr}\; \Pi \; G_{\mathscr{F}+m^2} = -\,\mathrm{tr}\; \Pi \; G^2_{\mathscr{F}+m^2}. \tag{69}$$

Comparing (68) and (69) and using eq. (67) we convince ourselves that eq. (58) is correct too.

Let us make some remarks. First, ''tr'' denotes here the usual matrix trace and has nothing to do with the trace over the bundle indices which are left intact. Second, the operator $\widetilde{F}$ has, obviously, the form

$$\widetilde{F}=-\widetilde{\Box}+\widetilde{Q}, \tag{70}$$

where $\widetilde{\Box}=\Box_1\oplus\cdots\oplus\Box_N$ and $\widetilde{Q}=Q_1\oplus\cdots\oplus Q_N$ have the same diagonal structure. Obviously

$$\widetilde{\Box}=\mathrm{tr}_g\widetilde{\nabla}\widetilde{\nabla} \tag{71}$$

where $\widetilde{\nabla}=\nabla_1\oplus\cdots\oplus\nabla_N$ is a new connection which also has the same diagonal structure. Therefore, the operator $\mathscr{F}$ reads

$$\mathscr{F}=-\widetilde{\Box}+\widetilde{Q}-P. \tag{72}$$

Remember that the matrix P is constant. Thus, both the operator $\widetilde{F}$ and $\mathscr{F}$ are *second-order* elliptic Laplace type differential operators. However, the operator $\mathscr{F}$ is *not self-adjoint* because the matrix P is not symmetric. In spite of this, the operator $(\mathscr{F}+m^2)$ for sufficiently large m is non-degenerate, i.e., there exists a well defined Green operator $G_{\mathscr{F}+m^2}$, which justifies made assumptions.

1. Properties of the matrix P

The matrix P plays the role of the matrix term and is of great importance in further considerations. That is why, we state below some important properties of it.

First of all, we note that the matrix Π is nilpotent

$$\Pi^2=0 \tag{73}$$

and, of course, degenerate. The matrix P is not degenerate. The matrix P as well as its powers belong to the class of two-diagonal matrices. We compute first the powers of this matrix.

$$P=\begin{pmatrix}0 & I_{N-1}\\ \lambda & 0\end{pmatrix},\quad P^2=\begin{pmatrix}0 & I_{N-2}\\ \lambda I_2 & 0\end{pmatrix},\cdots,\quad P^{N-1}=\begin{pmatrix}0 & 1\\ \lambda I_{N-1} & 0\end{pmatrix}, \tag{74}$$

$$P^N=\lambda I_N. \tag{75}$$

It is also not difficult to show that

$$\det(z-P)=z^N-\lambda. \tag{76}$$

Therefore, the eigenvalues p_j of the matrix P are just the Nth roots of λ

$$p_j=(-\lambda)^{1/N}e^{i\,\pi(2j-1)/N},\quad j=1,\ldots,N, \tag{77}$$

where $|\arg(-\lambda)|<\pi$. The roots p_j lie on the circle $|z|=|\lambda|^{1/N}$.

The higher powers of the matrix P are expressed in terms of the lower order powers (74) and (75)

$$P^{iN+j}=\lambda^i P^j, \tag{78}$$

where $j=0,1,2,\ldots,N-1$ and $i=0,1,2,\ldots$. Using these formulas we find that for any function $f(z)$ that is analytic at the points $p_j(\lambda)$ there holds

$$f(P)=\frac{1}{2\pi i}\int_{C_P} dz\ f(z)\ (z-P)^{-1}$$

$$=\sum_{j=0}^{N-1}\beta_{N-1-j}(\lambda;f)P^j, \tag{79}$$

where

$$\beta_n(\lambda;f)=\frac{1}{2\pi i}\int_{C_P} dz\ \frac{z^n}{z^N-\lambda}f(z) \tag{80}$$

and the contour C_P goes counter-clockwise around the points p_j in such a way that it does not contain the singularities of the function $f(z)$ — inside the contour C_P there must be no other singularities except for the points p_j. Evidently, the coefficients $\beta_n(\lambda;f)$ possess the following ''periodicity'' property

$$\beta_{n+kN}(\lambda;f)=\lambda^k\beta_n(\lambda;f),\quad k=0,1,2,\ldots, \tag{81}$$

so that there are essentially only N independent coefficients $\beta_0,\beta_1,\ldots,\beta_{N-1}$.

Equations (79) and (85) determine any function of the matrix P. In particular, using the traces of the powers of the matrix P

$$\text{tr}\ P^n=\begin{cases} N\lambda^i & \text{for}\quad n=iN,\ i=0,1,2,\ldots, \\ 0 & \text{otherwise}\end{cases} \tag{82}$$

we can compute the trace of any function of P

$$\text{tr}\ f(P)=N\beta_{N-1}(\lambda;f). \tag{83}$$

More generally,

$$\text{tr}\ P^n\ f(P)=N\beta_{N-1+n}(\lambda;f). \tag{84}$$

From here we obtain the coefficients $\beta_n(\lambda;f)$

$$\beta_n(\lambda;f)=\frac{1}{N\lambda}\sum_{j=1}^{N} p_j^{n+1}f(p_j)$$

$$=-\frac{1}{N}(-\lambda)^{(n-N+1)/N}\sum_{j=1}^{N} e^{i\,\pi(2j-1)(n+1)/N}f(p_j). \tag{85}$$

From (82), it follows, in particular,

$$\sum_{j=1}^{N} p_j^n=0\quad \text{for}\quad n\neq 0,\pm N,\pm 2N,\ldots. \tag{86}$$

Moreover, using the definition (52) we calculate the traces of the product of the powers of the matrix P with the matrix Π

$$\text{tr}\ \Pi\ P^n=\frac{1}{(n+1)}\frac{\partial}{\partial\lambda}\text{tr}\ P^{n+1}=\begin{cases}\lambda^i & \text{for}\quad n=iN+N-1,\ i=0,1,2,\ldots, \\ 0 & \text{otherwise}.\end{cases} \tag{87}$$

By using the equation

$$\frac{\partial}{\partial\lambda}\text{tr}\ f(P)=\text{tr}\ \frac{\partial P}{\partial\lambda}\,f'(P) \tag{88}$$

where $f'(z)=(\partial/\partial z)f(z)$, and eq. (52) or using directly eq. (87) we calculate the trace of the product of the function $f(P)$ with the matrix Π

$$\text{tr}\ \Pi\ f(P)=\beta_0(\lambda;f)=-\frac{1}{N}(-\lambda)^{-(N-1)/N}\sum_{j=1}^{N} e^{i\,\pi(2j-1)/N}f(p_j). \tag{89}$$

More generally, one can obtain also

$$\text{tr}\ \Pi(z-P)^{-1}=-\frac{\partial}{\partial\lambda}\log\,\det\,(z-P)=\frac{1}{z^N-\lambda} \tag{90}$$

as well as

$$\text{tr}\ \Pi\ e^{tP}=\frac{1}{2\pi i}\int_{C_P} dz\,\frac{e^{tz}}{z^N-\lambda}=-\frac{1}{N}(-\lambda)^{-(N-1)/N}\sum_{j=1}^{N} e^{i\,\pi(2j-1)/N}e^{tp_j}. \tag{91}$$

In the next section we will also need the following lemma, which is actually a generalization of eq. (82).

Lemma 1: Let P and Π be the $N\times N$ matrices defined by (52) and $B_1,\dots,B_{N-2}$ be arbitrary diagonal matrices. Then for any $k\leqslant N-2$ and arbitrary non-negative integers $n_1,\dots,n_k$ satisfying the condition $n_1+\cdots+n_k\leqslant N-2$ there holds

$$\text{tr}\ \Pi\ B_1P^{n_1}B_2P^{n_2}\cdots B_kP^{n_k}=0. \tag{92}$$

2. Properties of the symbol $\sigma(\mathscr{F})$

Let us consider now the symbol $\sigma(\mathscr{F})$ of the operator $\mathscr{F}$. It has the form

$$\sigma(\mathscr{F})=\sigma(\widetilde{F})-P, \tag{93}$$

where $\sigma(\widetilde{F})$ is a diagonal matrix.

That is why we consider the following matrix:

$$M\equiv\widetilde{\mu}-P, \tag{94}$$

where $\widetilde{\mu}=\mu_1\oplus\cdots\oplus\mu_N$ is a diagonal matrix with some constants μ_j on the diagonal. Note that the matrices $\widetilde{\mu}$ and P do not commute with each other $[\widetilde{\mu},P]\neq 0$.

We are interested in the eigenvalues q_j of the matrix M. It is not difficult to calculate

$$\text{tr}\,M^n=\text{tr}\,(\widetilde{\mu})^n=\sum_{j=1}^{N}\mu_j^n \qquad (n=1,2,\dots,N-1), \tag{95}$$

$$\text{tr}\,M^N=\sum_{j=1}^{N}\mu_j^N+(-1)^N N\lambda, \tag{96}$$

$$\det\,(z-M)=\prod_{j=1}^{N}(z-\mu_j)-(-1)^N\lambda. \tag{97}$$

Thus the eigenvalues q_j of the matrix M are determined either from one algebraical equation of Nth order

$$(\mu_1-z)\cdots(\mu_N-z)-\lambda=0 \tag{98}$$

or from the system of N equations

$$q_1+\cdots+q_N=\sum_{j=1}^{N}\mu_j, \tag{99}$$

$$\cdots$$

$$q_1^{N-1}+\cdots+q_N^{N-1}=\sum_{j=1}^{N}\mu_j^{N-1}, \tag{100}$$

$$q_1^{N}+\cdots+q_N^{N}=\sum_{j=1}^{N}\mu_j^{N}+(-1)^N N\lambda. \tag{101}$$

This enables one to calculate the traces

$$\mathrm{tr}\ f(M)=\sum_{j=1}^{N} f(q_j). \tag{102}$$

One can also get analogous to (80) integral representation

$$\mathrm{tr}\ f(M)=\frac{1}{2\pi i}\int_{C_M} dz\ f(z)\frac{A(z,\mu,\lambda)}{(z-\mu_1)\cdots(z-\mu_N)-(-1)^N\lambda}, \tag{103}$$

where C_M is a counter-clockwise contour around the spectrum of the matrix M and

$$A(z,\mu,\lambda)=\sum_{j=1}^{N}\prod_{k=1;\ k\neq j}^{N}(z-q_k) \tag{104}$$

is a polynomial of order $(N-1)$.

Further, by using the equation

$$\frac{\partial}{\partial\lambda}\mathrm{tr}\ f(M)=\mathrm{tr}\ \frac{\partial M}{\partial\lambda}f'(M), \tag{105}$$

where $f'(z)=(\partial/\partial z)f(z)$, and the obvious equation

$$\frac{\partial}{\partial\lambda}M=-\Pi, \tag{106}$$

which follows from the definition of the matrix M and eq. (52), we calculate the trace of the product of the function $f'(M)$ with the matrix Π

$$\mathrm{tr}\ \Pi\ f'(M)=-\frac{\partial}{\partial\lambda}\mathrm{tr}\ f(M). \tag{107}$$

Using eqs. (95) and (96) we get, in particular

$$\mathrm{tr}\ \Pi\ M^n=-\frac{1}{n+1}\frac{\partial}{\partial\lambda}\mathrm{tr}\ M^{n+1}=0 \quad \text{for} \quad n=0,1,\ldots,N-2, \tag{108}$$

$$\mathrm{tr}\ \Pi\ M^{N-1}=-\frac{1}{N}\frac{\partial}{\partial\lambda}\mathrm{tr}\ M^N=(-1)^{N-1}. \tag{109}$$

Note that (108) is a particular case of eq. (92). Further, from (99)–(101) one obtains

$$\sum_{j=1}^{N}\frac{\partial q_j}{\partial\lambda}q_j^n=0 \quad \text{for}\ n=0,1,2,\ldots,N-2, \tag{110}$$

$$\sum_{j=1}^{N} \frac{\partial q_j}{\partial \lambda} q_j^{N-1} = (-1)^N. \tag{111}$$

Further, we also get

$$\mathrm{tr}\ \Pi\ (z-M)^{-1} = \frac{\partial}{\partial \lambda} \log \det (z-M) = \frac{(-1)^{N-1}}{(z-\mu_1)\cdots(z-\mu_N)-(-1)^N\lambda}, \tag{112}$$

$$\mathrm{tr}\ \Pi\ M^{-k} = \frac{(-1)^N}{(k-1)!}\left(\frac{\partial}{\partial z}\right)^{k-1} \frac{1}{(z-\mu_1)\cdots(z-\mu_N)-(-1)^N\lambda}\bigg|_{z=0}, \tag{113}$$

$$\mathrm{tr}\ \Pi\ M^{k} = -\frac{1}{\Gamma(k-N+2)}\left(\frac{\partial}{\partial y}\right)^{k-N+1} \frac{1}{(y\mu_1-1)\cdots(y\mu_N-1)-y^N\lambda}\bigg|_{y=0}. \tag{114}$$

Note that for $k \leqslant N-2$ the last equation gives zero in accordance with (109).

This leads to a very simple and convenient representation

$$\mathrm{tr}\ \Pi\ f(M) = (-1)^{N-1} \frac{1}{2\pi i} \int_{C_M} dz\ \frac{f(z)}{(z-\mu_1)\cdots(z-\mu_N)-(-1)^N\lambda}. \tag{115}$$

We will also need, in particular, the following formula

$$\begin{aligned} \mathrm{tr}\ \Pi\ e^{-tM} &= (-1)^{N-1} \frac{1}{2\pi i} \int_{C_M} dz\ \frac{e^{-tz}}{(z-\mu_1)\cdots(z-\mu_N)-(-1)^N\lambda} \\ &= \frac{1}{t}\frac{\partial}{\partial \lambda} \mathrm{tr}\ e^{-tM} = -\sum_{j=1}^{N} \frac{\partial q_j}{\partial \lambda} e^{-tq_j}. \end{aligned} \tag{116}$$

From (108) it follows that this function is of order $O(t^{N-1})$ as $t \to 0$. Using eq. (98) we obtain

$$\frac{\partial q_j}{\partial \lambda} = -\left\{ \sum_{k=1}^{N} \prod_{i=1;\ i\neq k}^{N} (\mu_i - q_j) \right\}^{-1}. \tag{117}$$

In particular, for case $\lambda = 0$ we have

$$q_j|_{\lambda=0} = \mu_j, \tag{118}$$

hence,

$$\frac{\partial q_j}{\partial \lambda}\bigg|_{\lambda=0} = -\prod_{k=1;\ k\neq j}^{N} \frac{1}{(\mu_k - \mu_j)} \tag{119}$$

and

$$\mathrm{tr}\ \Pi\ e^{-tM}|_{\lambda=0} = \sum_{j=1}^{N} e^{-t\mu_j} \prod_{k=1;\ k\neq j}^{N} \frac{1}{(\mu_k - \mu_j)}. \tag{120}$$

These formulas will be useful when studying the heat kernel for the operator $\mathscr{F}$.

B. Green function of the operator $H-\lambda$

This shows that the problem is reduced to a Laplace type operator $\mathscr{F}$ with an additional matrix structure. Using the usual heat kernel representation for the Green function $\mathscr{G}$ of the Laplace type operator $\mathscr{F}$ we have from eq. (57)

Corollary 1:

$$G_{H-\lambda}=\int_0^\infty dt\ e^{-tm^2}\mathrm{tr}\ \Pi\ \exp(-t\mathscr{F}), \tag{121}$$

or in the kernel form

$$G_{H-\lambda}=(4\pi)^{-d/2}\Delta^{1/2}\int_0^\infty dt\ t^{-d/2}\exp\left(-tm^2-\frac{\sigma}{2t}\right)\omega_{\mathscr{F}}(t), \tag{122}$$

where

$$\omega_{\mathscr{F}}(t)=\mathrm{tr}\ \Pi\ \Omega_{\mathscr{F}}(t), \tag{123}$$

$\Omega_{\mathscr{F}}(t)=\Omega_{\mathscr{F}}(t|x,x')$ *is the transfer function of the operator* $\mathscr{F}$ *(54).*

Thus we see that there is analogous heat kernel representation for the Green function of higher-order operator $H-\lambda$ with a new ''transfer function'' $\omega_{\mathscr{F}}(t)$.

1. Power of a Laplace type operator

The simplest case is, of course, the case of equal potential terms Q_j and the connections $\nabla^{(i)}$, i.e.,

$$Q_i=Q,\quad \nabla^{(i)}=\nabla. \tag{124}$$

In this case all operators F_j are equal to each other

$$F_j=F=-\Box+Q, \tag{125}$$

and the operator H is the Nth power of the Laplace type operator $F+m^2$

$$H=(F+m^2)^N. \tag{126}$$

Further, in this simple case we have

$$\mathscr{F}=F-P \tag{127}$$

and the operator F commutes with the matrix P

$$[F,P]=0. \tag{128}$$

Therefore,

$$\exp(-t\mathscr{F})=\exp(tP)\exp(-tF). \tag{129}$$

and, using eqs. (57) and (26) we get

$$\omega_{\mathscr{F}}(t)=f(t)\Omega_F(t),\quad f(t)=\mathrm{tr}\ \Pi\exp(tP), \tag{130}$$

which is determined by (91) and (85)

$$f(t)=\frac{1}{2\pi i}\int_{C_P}dz\frac{e^{tz}}{z^N-\lambda}=-\frac{1}{N}(-\lambda)^{-(N-1)/N}\sum_{j=1}^{N}e^{i\ \pi(2j-1)/N}e^{tp_j(\lambda)}. \tag{131}$$

On the other hand, expanding the integrand in powers of λ and using the formula (163) we obtain $\omega_{\mathscr{F}}(t)$ in form of a power series

$$f(t)=t^{N-1}\sum_{k\geq 0}\frac{\lambda^k t^{Nk}}{(Nk+N-1)!}. \tag{132}$$

Thus, the function $\omega_{\mathscr{F}}(t)$ is of order $O(t^{N-1})$ as $t\to 0$.

In case $\lambda=0$ we obtain herefrom the usual heat kernel representation for the inverse power of the operator $(F+m^2)$

$$G_H=(F+m^2)^{-N}=\frac{1}{(N-1)!}\int_0^\infty dt\ t^{N-1}e^{-tm^2}\exp(-tF). \tag{133}$$

2. Constant perturbations of the potential terms

Let us consider now the case when the Laplace type operators F_j differ from each other only by a constant part of the potential terms, i.e., the connection $\nabla^{(j)}$ is the same, but the endomorphisms Q_j are different

$$Q_j=Q+\mu_j, \tag{134}$$

so that

$$F_j=F+\mu_j, \tag{135}$$

where

$$F=-\Box+Q. \tag{136}$$

The operator H has the form

$$H=(F+m^2+\mu_N)\cdots(F+m^2+\mu_2)(F+m^2+\mu_1). \tag{137}$$

The operators F_i, even if different, commute. The corresponding operator $\mathscr{F}$ has the form

$$\mathscr{F}=F+M, \tag{138}$$

where $M=\widetilde{\mu}-P$ and $\widetilde{\mu}=\mu_1\oplus\cdots\oplus\mu_N$ is a diagonal matrix with the constants μ_j on the diagonal. The matrix M commutes with the operator F

$$[F,M]=0. \tag{139}$$

Therefore,

$$\omega_{\mathscr{F}}(t)=h(t)\Omega_F(t),\quad h(t)=\mathrm{tr}\ \Pi\exp(-tM). \tag{140}$$

Using the eigenvalues of the matrix M, which are determined by eq. (98), we obtained this function in the form

$$h(t)=(-1)^{N-1}\frac{1}{2\pi i}\int_{C_M}dz\ \frac{e^{-tz}}{(z-\mu_1)\cdots(z-\mu_N)-(-1)^N\lambda}=-\sum_{j=1}^N\frac{\partial q_j}{\partial\lambda}e^{-tq_j}. \tag{141}$$

As it has been shown in section III A, this function is of order $O(t^{N-1})$ as $t\to0$. For $\lambda=0$ we obtained

$$h(t)|_{\lambda=0}=\sum_{j=1}^N\left[\prod_{k=1;\ k\neq j}^N\frac{1}{(\mu_k-\mu_j)}\right]e^{-t\mu_j}. \tag{142}$$

3. General case

As we have seen, in particular cases studied before the function $\omega_{\mathscr{F}}(t)$ defined by (123) is of order $O(t^{N-1})$ as $t\to0$. It is almost clear that this is also valid in general, since the main contribution to the asymptotics give the constant background fields. This can be formulated in the form of a lemma.

Lemma 2: Let $\mathscr{F}$ be the Laplace type operator defined by (54) and Π be the matrix defined by (52). Then for its HMDS-coefficients $a_k(\mathscr{F})$ there holds

$$\mathrm{tr}\ \Pi\ a_k(\mathscr{F})=0 \quad \text{for}\ \ k=0,1,\dots,N-2. \tag{143}$$

In other words, for the asymptotic expansion as $t\to 0$ of its transfer function $\omega_{\mathscr{F}}(t)$ there holds

$$\omega_{\mathscr{F}}(t)\big|_{t\to 0}\sim \frac{(-t)^{N-1}}{(N-1)!}\sum_{k\geqslant 0}\frac{(-t)^k}{k!}c_k(\mathscr{F}), \tag{144}$$

where

$$c_k(\mathscr{F})=\frac{(N-1)!k!}{(N+k-1)!}\mathrm{tr}\ \Pi\ a_{k+N-1}(\mathscr{F}). \tag{145}$$

Proof: The coefficients a_k can be calculated in form of a covariant Taylor series near the diagonal (for details and notation see Ref. 7)

$$a_k=\sum_{n\geqslant 0}|n\rangle\langle n|a_k\rangle, \tag{146}$$

where $|n\rangle$ is the covariant Taylor basis and $\langle n|a_k\rangle$ are the diagonal values of the symmetrized covariant derivatives. $\langle n|a_k\rangle$ have the following general form[7]

$$\langle n|a_k\rangle=\sum_{n_1,\dots,n_{k-1}\geqslant 0}c(n_1,\dots,n_{k-1})\langle n|M|n_{k-1}\rangle\langle n_{k-1}|M|n_{k-2}\rangle\cdots\langle n_1|M|0\rangle, \tag{147}$$

where $c(n_1,\dots,n_{k-1})$ are some constants and $\langle m|M|n\rangle$ are some End (V)-valued tensors that vanish for $n>m+2$ and for $n=m+1$. Important for us is that, since the matrix P is constant, it appears only in $\langle n|M|n\rangle$

$$\langle n|M|n\rangle=P+B, \tag{148}$$

where B is a diagonal matrix. *All* others tensors $\langle n|M|m\rangle$ do not depend on the matrix P and are diagonal—they are actually polynomials in the curvatures and their covariant derivatives.[7] So, all the terms in the sum (147) have the form

$$B_1P^{n_1}\dots B_jP^{n_j},\quad j=1,2,\dots,k, \tag{149}$$

where B_i are some diagonal matrices and the total power of the matrix P is restricted by $n_1+\cdots+n_j\leqslant k$. Therefore, from (92) we find that $\mathrm{tr}\,\Pi\langle n|a_k\rangle=\mathrm{tr}\ \Pi\ a_k=0$ for $k\leqslant N-2$, which proves the lemma.

Actually, using (148) and (87) one can prove more, namely,

$$c_0(\mathscr{F})=\mathrm{tr}\ \Pi\ a_{N-1}(\mathscr{F})=\mathrm{tr}\,\Pi\ P^{N-1}=1. \tag{150}$$

4. Hadamard expansion of the Green function of the operator $H-\lambda$

The behavior of the Green function of Laplace type operators near the diagonal is studied in the previous section. So, by using the equations of section II we obtain from (57) the Hadamard series for the Green function of the higher order operator $H-\lambda$

$$G_{H-\lambda}=G^{\mathrm{sing}}_{H-\lambda}+G^{\text{non-anal}}_{H-\lambda}+G^{\mathrm{reg}}_{H-\lambda}, \tag{151}$$

where the singular part reads

$$G^{\mathrm{sing}}_{H-\lambda}=(4\pi)^{-d/2}\frac{\Delta^{1/2}}{(N-1)!}\sum_{k=0}^{[(d+1)/2]-N-1}(-1)^{N+k}\frac{\Gamma\left(\frac{d}{2}-k-N\right)}{k!}\left(\frac{2}{\sigma}\right)^{d/2-k-N}c_k(\mathscr{F}+m^2). \tag{152}$$

Further, we get in odd dimensions:

$$G^{\text{non-anal}}_{H-\lambda}\sim(-1)^{(d-1)/2}(4\pi)^{-d/2}\frac{\Delta^{1/2}}{(N-1)!}\sum_{k=0}^{\infty}\frac{\pi(\sigma/2)^{k+1/2}c_{k-N+(d+1)/2}(\mathscr{F}+m^2)}{\Gamma\left(k-N+1+\frac{d+1}{2}\right)\Gamma\left(k+\frac{3}{2}\right)} \tag{153}$$

$$G^{\text{reg}}_{H-\lambda}\sim(-1)^{(d+1)/2}(4\pi)^{-d/2}\frac{\Delta^{1/2}}{(N-1)!}\sum_{k=0}^{\infty}\frac{\pi(\sigma/2)^{k}}{k!\Gamma(k-N+1+d/2)}\varphi_{\mathscr{F}+m^2}(k-N+d/2), \tag{154}$$

and in even dimensions:

$$G^{\text{non-anal}}_{H-\lambda}\sim(-1)^{d/2-1}(4\pi)^{-d/2}\frac{\Delta^{1/2}}{(N-1)!}\log\left(\frac{\mu^2\sigma}{2}\right)\sum_{k=0}^{\infty}\frac{(\sigma/2)^{k}c_{k-N+d/2}(\mathscr{F}+m^2)}{k!\Gamma(k-N+1+(d/2))}, \tag{155}$$

$$G^{\text{reg}}_{H-\lambda}\sim(-1)^{d/2-1}(4\pi)^{-d/2}\frac{\Delta^{1/2}}{(N-1)!}\sum_{k=0}^{\infty}\frac{1}{k!\Gamma(k-N+1+d/2)}\left(\frac{\sigma}{2}\right)^{k}$$
$$\times\{\varphi'_{\mathscr{F}+m^2}(k-N+d/2)-[\log\mu^2+\Psi(k+1)+\Psi(k+d/2)]c_{k-N+(d/2)}(\mathscr{F}+m^2)\}, \tag{156}$$

where

$$\varphi_{\mathscr{F}+m^2}(q)\equiv\frac{(N-1)!\Gamma(q+1)}{\Gamma(q+N)}\text{tr}\ \Pi\ b_{\mathscr{F}+m^2}(q+N-1). \tag{157}$$

Thus, we find that

(i) the structure of the diagonal singularities of the Green function $G_{H-\lambda}$ is determined by the coefficients $c_k(\mathscr{F}+m^2)$;
(ii) in odd dimensions there is no logarithmic singularity;
(iii) for $N>d/2$ there are *no* singularities at all and the Green function is regular on the diagonal, i.e. there exists finite coincidence limit $G^{\text{diag}}_{H-\lambda}\equiv G_{H-\lambda}(x,x)=G^{\text{reg}}_{H-\lambda}(x,x)$;
(iv) for $N=[(d+1)/2]$ there are no singularities for odd dimension $d=2N-1$ and there is only logarithmic singularity in even dimension $d=2N$.
(v) The condition for the validity of the Huygens principle for the operator $H-\lambda$ in even dimensions reads

$$\sum_{k=0}^{\infty}\frac{1}{k!\Gamma(k-N+1+d/2)}\left(\frac{\sigma}{2}\right)^{k}c_{k-N+d/2}(\mathscr{F}+m^2)=0. \tag{158}$$

Similarly to (43) this also produces an infinite set of local conditions.

C. Heat kernel of the operator *H*

The heat semigroup for the operator H can be obtained by using the standard formula

$$\exp(-tH)=-\frac{1}{2\pi i}\int_{C_H}d\lambda e^{-t\lambda}G_{H-\lambda}$$
$$=\frac{t^{-k}}{2\pi i}\int_{c-i\infty}^{c+i\infty}d\lambda e^{-t\lambda}\left(\frac{\partial}{\partial\lambda}\right)^{k}G_{H-\lambda}, \tag{159}$$

where the contour of integration C_H goes counter-clockwise around the spectrum of the operator H, k is some sufficiently large integer and c is a negative constant. Since the operator H is a positive self-adjoint operator its spectrum lies on the positive real half-axis, i.e., the contour C_H should go from $i\varepsilon+\infty$ to $-i\varepsilon+\infty$ enclosing the origin. Using the Theorem 1 one can express the heat semigroup for the higher order operator H in terms of the heat semigroup of the Laplace type operator $\mathscr{F}$. We have first

$$\exp(-tH)=\frac{t^{-k}}{2\pi i}\int_{c-i\infty}^{c+i\infty}d\lambda\ e^{-t\lambda}\left(\frac{\partial}{\partial\lambda}\right)^k \mathrm{tr}\ \Pi\ G_{\mathscr{F}+m^2}, \tag{160}$$

Now, using the heat kernel representation of the Green operator $G_{\mathscr{F}+m^2}$ we obtain

Corollary 2: The heat semigroup for the operator H is determined by the heat semigroup for the operator $\mathscr{F}$

$$\exp(-tH)=\frac{t^{-k}}{2\pi i}\int_{c-i\infty}^{c+i\infty}d\lambda\ e^{-t\lambda}\int_0^\infty ds\ e^{-sm^2}\left(\frac{\partial}{\partial\lambda}\right)^k \mathrm{tr}\ \ \Pi\ \exp(-s\mathscr{F}) \tag{161}$$

and, consequently, the heat kernel for the operator H is given by

$$U_H(t)=(4\pi)^{-d/2}\Delta^{1/2}\frac{t^{-k}}{2\pi i}\int_{c-i\infty}^{c+i\infty}d\lambda\ e^{-t\lambda}\int_0^\infty ds\ s^{-d/2}\exp\left(-sm^2-\frac{\sigma}{2s}\right)\left(\frac{\partial}{\partial\lambda}\right)^k \omega_{\mathscr{F}}(s). \tag{162}$$

We studied the expansion of the Green function of a Laplace type operator in the previous section in detail. The important fact is, that the HMDS-coefficients $a_k(\mathscr{F}+m^2)$ for the Laplace type operator $(\mathscr{F}+m^2)$ are polynomial in λ, they are, of course, also polynomial in m^2. This means that the singular part of the Green function (including the logarithmic singularity), which are expressed in terms of $a_k(\mathscr{F}+m^2)$, are also polynomial in λ. On the other hand, it is well known that

$$-\frac{1}{2\pi i}\int_{C_H}d\lambda\ e^{-\lambda}(-\lambda)^z=\frac{1}{\Gamma(-z)}. \tag{163}$$

For integer $z=k=0,1,2,\ldots$ we have, therefore,

$$-\frac{1}{2\pi i}\int_{C_H}d\lambda\ e^{-\lambda}(-\lambda)^k=0. \tag{164}$$

Thus, the singular part, which is polynomial in λ, does not contribute to the integral (160). Therefore, one can substitute in this equation instead of the whole Green function only the regular part of it G^{reg}, go to the diagonal and take the trace

$$\mathrm{Tr}_{L^2}\exp(-tH)=\frac{t^{-k}}{2\pi i}\int_{c-i\infty}^{c+i\infty}d\lambda\ e^{-t\lambda}\left(\frac{\partial}{\partial\lambda}\right)^k \mathrm{Tr}_{L^2}\mathrm{tr}\ \Pi\ G^{\mathrm{reg}}_{\mathscr{F}+m^2}, \tag{165}$$

Finally, using eqs. (37) and (38) or (154) and (156) we have: in odd dimensions

$$\mathrm{Tr}_{L^2}\exp(-tH)=\frac{(-1)^{(d+1)/2}(4\pi)^{-d/2}\pi}{(N-1)!\Gamma(d/2)-N+1)}\ \ \frac{t^{-k}}{2\pi i}\int_{c-i\infty}^{c+i\infty}d\lambda\ e^{-t\lambda}\left(\frac{\partial}{\partial\lambda}\right)^k \Phi_{\mathscr{F}+m^2}(d/2-N), \tag{166}$$

and in even dimensions

$$\mathrm{Tr}_{L^2}\exp(-tH)=\frac{(-1)^{d/2-1}(4\pi)^{-d/2}}{(N-1)!\Gamma(d/2-N+1)}\ \ \frac{t^{-k}}{2\pi i}\int_{c-i\infty}^{c+i\infty}d\lambda\ e^{-t\lambda}\left(\frac{\partial}{\partial\lambda}\right)^k \Phi'_{\mathscr{F}+m^2}(d/2-N), \tag{167}$$

where $\Phi_{\mathscr{F}+m^2}(q)=\mathrm{Tr}_{L^2}\varphi_{\mathscr{F}+m^2}(q)$ and $\Phi'_{\mathscr{F}+m^2}(q)=(d/dq)\Phi_{\mathscr{F}+m^2}(q)$.

These formulas may be used, for example, to compute the asymptotic expansion of the functional trace of the heat kernel for the higher order operator H, which is known to have the following general form:[3]

$$\mathrm{Tr}_{L^2}\exp(-tH)\sim(4\pi)^{-d/2}\frac{\Gamma[d/(2N)]}{N\Gamma(d/2)}\,t^{-d/(2N)}\sum_{k\geqslant 0}t^{k/N}E_k(H). \tag{168}$$

We normalize the coefficients $E_k(H)$ so that $E_0(H)=\mathrm{Tr}_{L^2}1$. For $N=1$ the coefficients E_k are determined by the HMDS-coefficients $E_k=[(-1)^k/k!]A_k$. However, one should note that to compute the coefficients $E_k(H)$ one needs to know the asymptotics of the function $\omega_{\mathscr{F}}(t)$ [or the functions $\Phi_{\mathscr{F}+m^2}(d/2-N)$ and $\Phi'_{\mathscr{F}+m^2}(d/2-N)$] as $\lambda\to-\infty$, which is unknown, in general, in terms of the known asymptotic expansion as $t\to 0$, i.e. in terms of the HMDS-coefficients for a Laplace type operator. The known asymptotics of these functions as $s\to 0$ and $m\to\infty$ do not contribute at all in eqs. (162), (166), and (167).

(Received 8 December 1997; accepted for publication 14 January 1998)

We give a complete description of the quasifinite highest weight modules over the central extension of the Lie algebra of $M\times M$-matrix differential operators on the circle and obtain them in terms of representation theory of the Lie algebra $\hat{\mathfrak{gl}}(\infty,R_m)$ of infinite matrices with only finitely many nonzero diagonals over the algebra $R_m=\mathbb{C}[t]/(t^{m+1})$. We also classify the unitary ones, and construct them in terms of charged free fermions. This construction provides a large (and conjecturally complete) family of irreducible modules over the associated vertex algebra $W^M_{1+\infty,c}$, where c is a positive integer. © *1998 American Institute of Physics.* [S0022-2488(98)03005-9]

I. INTRODUCTION

The study of representation theory of the Lie algebra $\hat{\mathscr{D}}$ (the universal central extension of the Lie algebra of differential operators on the circle, also denoted by $W_{1+\infty}$), was initiated in Ref. 1. In that paper, Kac and Radul classified the irreducible quasifinite highest weight representations of $\hat{\mathscr{D}}$, realized them in terms of irreducible highest weight representations of the Lie algebra of infinite matrices, and described the unitary ones. This study was continued in Refs. 2 and 3 in the framework of vertex algebra theory.

It was mentioned at the end of Ref. 1 that similar results can be obtained in the matrix case, and this is the main goal of the present paper.

The paper is organized as follows. In Secs. II and III we study the structure of the central extension $\widehat{\mathscr{D}^M}$ of the Lie algebra of $M\times M$-matrix differential operators on the circle, its parabolic subalgebras, and the relation with $\hat{\mathfrak{gl}}(\infty,R_m)$. In Secs. IV and V we classify and construct irreducible quasifinite highest weight modules over $\widehat{\mathscr{D}^M}$ and classify the unitary ones.

In Sec. VI, we consider the simple vertex algebra $W^M_{1+\infty,c}$ constructed on the irreducible vacuum module of $\widehat{\mathscr{D}^M}$, and we construct a large family of representations of this vertex algebra using twisted modules over MN free charged fermions, proving thereby that all primitive $\widehat{\mathscr{D}^M}$-modules are vertex algebra modules for $c\in\mathbb{Z}_+$. We conjecture that these are all irreducible modules over the vertex algebra $W^M_{1+\infty,c}$ if c is a positive integer.

II. LIE ALGEBRAS $\widehat{\mathscr{D}^M}$ AND $\widehat{\mathscr{D}^{M\mathscr{O}}}$

Let M be a positive integer. Denote by $\mathscr{D}^M_{\mathrm{as}}$ the associative algebra of all regular matrix differential operators on $\mathbb{C}^\times$, i.e., the operators on $\mathbb{C}^M[z,z^{-1}]$ of the form

[a)]Current address: Department of Mathematics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139.

$$E=e_k(z)\partial_z^k+e_{k-1}(z)\partial_z^{k-1}+\cdots+e_0(z), \quad \text{where } e_i(z)\in \mathrm{Mat}_M\mathbb{C}[z,z^{-1}],$$

and denote by $\mathscr{D}^M$ the corresponding Lie algebra. Here and further we denote by $\mathrm{Mat}_M R$ the associative algebra of all $M\times M$ matrices over an algebra R. It is more convenient to write the differential operators as linear combinations of elements of the form $z^k f(D)A$, where f is a polynomial, $D=z\partial_z$, $k\in\mathbb{Z}$, and $A\in\mathrm{Mat}_M\mathbb{C}$. The product in $\mathscr{D}^M_{\mathrm{as}}$ is then given by

$$(z^r f(D)A)(z^s g(D)B)=z^{r+s}f(D+s)g(D)AB. \tag{2.1}$$

Fix a *trace functional* on $\mathrm{Mat}_M\mathbb{C}[w]$, which is a linear map $T:\mathrm{Mat}_M\mathbb{C}[w]\to\mathbb{C}$, such that $T(ab)=T(ba)$. Then we have the following 2-cocycle on $\mathscr{D}^M$, where $f(w)$, $g(w)\in\mathrm{Mat}_M\mathbb{C}[w]$ (see Ref. 1):

$$\Psi_T(z^r f(D),z^s g(D))=\begin{cases} T\left(\sum\limits_{-r\leqslant m\leqslant -1} f(w+m)g(w+m+r)\right), & \text{if } r=-s\geqslant 0,\\ 0, \quad \text{if } r+s\neq 0. \end{cases} \tag{2.2}$$

In particular, if $T:\mathrm{Mat}_M\mathbb{C}[w]\to\mathbb{C}$ is the usual trace tr composed with the evaluation map at $w=0$, we obtain the following 2-cocycle on the Lie algebra $\mathscr{D}^M$, where $r,s\in\mathbb{Z}$, $f,g\in\mathbb{C}[w]$, $A,B\in\mathrm{Mat}_M\mathbb{C}$:

$$\Psi(z^r f(D)A,z^s g(D)B)=\begin{cases} \mathrm{tr}(AB)\sum\limits_{-r\leqslant m\leqslant -1} f(m)g(m+r), & \text{if } r=-s\geqslant 0,\\ 0, \quad \text{if } r+s\neq 0. \end{cases} \tag{2.3}$$

Later we shall need another formula for this cocycle (see Ref. 4):

$$\Psi(f(z)\partial_z^m A,g(z)\partial_z^n B)=\frac{(\mathrm{tr}\,AB)m!n!}{(m+n+1)!}\,\mathrm{Res}_{z=0}\, f^{(n+1)}(z)g^{(m)}(z)dz. \tag{2.4}$$

Let

$$\widehat{\mathscr{D}^M}=\mathscr{D}^M+\mathbb{C}C$$

denote the central extension of $\mathscr{D}^M$ corresponding to the cocycle (2.3), i.e., the bracket in the subspace $\mathscr{D}^M$ is given by

$$[E_1E_2]=E_1E_2-E_2E_1+\Psi(E_1,E_2)C, \tag{2.5}$$

and C is a nonzero central element.

The elements $z^kD^me_{ij}$ ($k\in\mathbb{Z}$, $m\in\mathbb{Z}_+$, $i,j=1,...,M$) form a basis of $\mathscr{D}^M$. Here and further e_{ij} is the standard basis of $\mathrm{Mat}_M\mathbb{C}$. Define the *weight* wt on $\mathscr{D}^M$ by

$$\mathrm{wt}\, z^k f(D)e_{ij}=kM+i-j, \quad \mathrm{wt}\, C=0. \tag{2.6}$$

This gives us the *principal* $\mathbb{Z}$-gradation of $\widehat{\mathscr{D}^M}$:

$$\widehat{\mathscr{D}^M}=\bigoplus_{j\in\mathbb{Z}}\widehat{\mathscr{D}^M}_j.$$

Let $\mathscr{O}$ be the algebra of all holomorphic functions on $\mathbb{C}$ with the topology of uniform convengence on compact sets. We consider the vector space $\mathscr{D}^{M\mathscr{O}}_{\mathrm{as}}$ spanned by the matrix differential operators (of infinite order) of the form $z^k f(D)A$, where $f\in\mathscr{O}$. The product in $\mathscr{D}^M_{\mathrm{as}}$ extends to $\mathscr{D}^{M\mathscr{O}}_{\mathrm{as}}$ by formula (2.1). The principal gradation extends as well by (2.6). Denote by $\mathscr{D}^{M\mathscr{O}}$ the

corresponding Lie algebra. Then the cocycle Ψ extends to a 2-cocycle on $\mathscr{D}^{M\mathscr{O}}$ by formula (2.3). Let $\widehat{\mathscr{D}^{M\mathscr{O}}}=\mathscr{D}^{M\mathscr{O}}+\mathbb{C}C$ be the corresponding central extension with the principal gradation as above.

Observe that for elements $z^re^{\lambda D}A$ ($r\in\mathbb{Z}$, $\lambda\in\mathbb{C}$, $A\in \mathrm{Mat}_M\mathbb{C}$) the commutator in $\widehat{\mathscr{D}^{M\mathscr{O}}}$ is given by a very simple formula (cf. Ref. 1):

$$[z^re^{\lambda D}A,z^se^{\mu D}B]=z^{r+s}e^{(\lambda+\mu)D}(e^{\lambda s}AB-e^{\mu r}BA)+\delta_{r,-s}(\mathrm{tr}\,AB)\,\frac{e^{-\lambda r}-e^{\mu s}}{1-e^{\lambda+\mu}}\,C.$$

Remark 2.1: Consider the following traces on $\mathrm{Mat}_M\mathscr{O}$:

$$\mathrm{tr}_{a,b}\,f(w)=\mathrm{tr}(f(a)-f(b)),\quad \text{where}\quad f\in\mathrm{Mat}_M\mathscr{O},\quad \text{and}\quad a,b\in\mathbb{C},$$

$$\mathrm{tr}_s^{[m]}\,f(w)=\frac{d^m}{dw^m}\bigg|_{w=s}\mathrm{tr}(f(w)),\quad \text{where}\quad s\in\mathbb{C},\quad m\in\mathbb{Z}_+,$$

and denote the corresponding cocycles by $\Psi_{a,b}:=\Psi_{\mathrm{tr}_{a,b}}$ and $\Psi_s^{(m)}:=\Psi_{\mathrm{tr}_s^{[m]}}$; see (2.2). On $\mathscr{D}^{M\mathscr{O}}$ these cocycles are nontrivial. However, when we restrict to $\mathscr{D}^M$ they become trivial [see Ref. 1, 1.3(d)]. We have the following explicit formulas for these trivial cocycles on $\mathscr{D}^M$:

$$\Psi_{a,b}(z^rf(D)A,z^sg(D)B)=\delta_{r,-s}\Lambda_{a,b}([z^rf(D)A,z^sg(D)B]),\tag{2.7}$$

$$\Psi_s^{(m)}(z^rf(D)A,z^sg(D)B)=\delta_{r,-s}\Lambda_s^{[m]}([z^rf(D)A,z^sg(D)B]),\tag{2.8}$$

where $\Lambda_{a,b}$ and $\Lambda_s^{[m]}$ are the linear functions on $\mathrm{Mat}_M\mathbb{C}[w]$ defined by the following generating series in x:

$$\Lambda_{a,b}(e^{xw}A)=-\frac{e^{ax}-e^{bx}}{e^x-1}\,\mathrm{tr}\,A,\quad \Lambda_s^{[m]}(e^{xw}A)=-\frac{x^me^{sx}}{e^x-1}\,\mathrm{tr}\,A.\tag{2.9}$$

Define a *parabolic* subalgebra $\mathfrak{p}$ of $\widehat{\mathscr{D}^M}$ as a subalgebra of the following form:

$$\mathfrak{p}=\bigoplus_{j\in\mathbb{Z}}\mathfrak{p}_j,\quad \text{where}\quad \mathfrak{p}_j=\widehat{\mathscr{D}^M}_j,\quad \text{for}\quad j\geqslant 0,\quad \text{and}\quad \mathfrak{p}_j\subset\widehat{\mathrm{D}^M}_j,\quad \text{for}\quad j<0.$$

Observe that

$$\widehat{\mathscr{D}^M}_j=\bigoplus_{k,l,m:kM+l-m=j}z^k\mathbb{C}[D]e_{lm};$$

hence, for each $j\in\mathbb{N}$ we have

$$\mathfrak{p}_{-j}=\bigoplus_{k,l,m:kM+l-m=-j}z^kI_{-j}^le_{lm},\tag{2.10}$$

where I_{-j}^l is a subspace of $\mathbb{C}[w]$. Since

$$[f(D)e_{ll},p(D)e_{lm}]=f(D)p(D)e_{lm},\quad l\neq m,$$

and

$$[f(D)I_M,z^kp(D)e_{lm}]=z^k(f(D+k)-f(D))p(D)e_{lm},$$

we see that I_{-j}^l is an ideal of $\mathbb{C}[w]$.

Remark 2.2: There exist parabolic subalgebras $\mathfrak{p}$ of $\widehat{\mathscr{D}^M}$ for $M>1$, such that $\mathfrak{p}_j\neq 0$ for some $j<0$, but $\mathfrak{p}_j=0$ for $j\ll 0$ (cf. Ref. 1, Sec. 2.4). For example,

$$\mathfrak{p}=\bigoplus_{j\geqslant 0}(\widehat{\mathscr{D}^M})_j\oplus\mathbb{C}[w]e_{12}.$$

Given a parabolic subalgebra $\mathfrak{p}$, denote by $b_j^l(w)$ a generator of the ideal $I_{-j}^l\subset\mathbb{C}[w]$. We will assume that $b_j^l(w)$ is a monic polynomial if I_{-j}^l is nonzero, otherwise $b_j^l(w)=0$. Thus, we have associated to a parabolic subalgebra $\mathfrak{p}$ a collection $\{b_j^l(w)\}_{j\in\mathbb{N},1\leqslant l\leqslant M}$, consisting of monic polynomials or zero, called *characteristic* polynomials of $\mathfrak{p}$.

Lemma 2.1: Let $\{b_j^l\}$ *be the set of characteristic polynomials of a parabolic subalgebra* $\mathfrak{p}$ *of the Lie algebra* $\widehat{\mathscr{D}^M}$. *Then*

(1) *If* $b_j^{i+1}(w)\neq 0$, *then it divides* $b_{j+1}^i(w)$ *for all* $j\in\mathbb{N}$ *and* $i=1,...,M$ (*we let* $b_j^{M+1}=b_j^1$).
(2) *If* $b_j^i(w)\neq 0$, *then it divides* $b_{j+1}^i(w)$, *except in the special case*: $-j=kM+i$, *when it divides* $b_{j+1}^i(w+1)$.
(3) *If* $b_{(k+l)M+n-i}^i(w)\neq 0$, *then it divides* $b_{kM+p-i}^i(w-l)b_{lM+n-p}^p(w)$ *for all* $k,l\in\mathbb{N}$, $1\leqslant i$, $p\leqslant M$.

Proof: Using $[\mathfrak{p}_1,\mathfrak{p}_{-j-1}]\subseteq\mathfrak{p}_{-j}$ and the commutator

$$[e_{i+1,i},z^{-k}b_{j+1}^i(D)e_{il}]=z^{-k}b_{j+1}^i(D)e_{i+1,l}-z^{-k}\delta_{i+1,l}b_{j+1}^i(D)e_{ii},$$

we see that $b_{j+1}^i(D)\in I_{-j}^{i+1}$ for $1\leqslant i\leqslant M-1$. Since

$$[ze_{1,M},z^{-k}b_{j+1}^i(D)e_{im}]=z^{-k+1}b_{j+1}^i(D)\,\delta_{i,M}e_{1,m}-z^{-k+1}b_{j+1}^i(D+1)\,\delta_{1,m}e_{i,M},$$

we obtain that $b_j^1(w)$ divides $b_{j+1}^M(w)$, proving (1). The proof of (2) follows from the above commutator and

$$[e_{l,l-1},z^{-k}b_{j+1}^i(D)e_{il}]=z^{-k}b_{j+1}^i(D)\,\delta_{l-1,i}e_{l,l}-z^{-k}b_{j+1}^i(D)e_{i,l-1}.$$

Finally, the proof of (3) is similar by computing the commutator

$$[z^{-k}b_{kM+m-i}^ie_{i,m},z^{-l}b_{lM+n-p}^p(D)e_{p,n}].$$ □

A parabolic subalgebra is called *nondegenerate* if all $\mathfrak{p}_j$, $j\in\mathbb{Z}$, are nonzero. It is immediate to deduce from Lemma 2.1 the following corollary.

Corollary 2.1: Let $\mathfrak{p}$ *be a parabolic subalgebra of* $\widehat{\mathscr{D}^M}$. *Then* $\mathfrak{p}$ *is nondegenerate if and only if all polynomials* $b_1^1(w),\ldots,b_1^M(w)$ *are nonzero.*

Given M monic polynomials $\mathbf{b}=(b^1(w),\ldots,b^M(w))$, we define (cf. Lemma 2.1)

$$\begin{aligned}(b^{\min})_{kM+m-i}^i(w)=&\,b^i(w-k)b^{i+1}(w-k)\cdots b^{M-1}(w-k)b^M(w-k+1)\\&\times b^1(w-k+1)\cdots b^{M-1}(w-k+1)b^M(w-k+2)b^1(w-k+2)\cdots b^M(w-1)\\&\times b^1(w-1)\cdots b^{M-1}(w-1)b^M(w)b^1(w)\cdots b^{m-1}(w).\end{aligned}$$

It is clear that there exists (a unique nondegenerate) parabolic subalgebra that we denote by $\mathfrak{p}_{\min}(\mathbf{b})$, for which the characteristic polynomials are $\{(b^{\min})_j^i\}$. We also have

$$\dim(\widehat{\mathscr{D}^M}_k/\mathfrak{p}_{\min}(\mathbf{b})_k)<\infty,\quad k\in\mathbb{Z}.\tag{2.11}$$

Remark 2.3: Any parabolic subalgebra $\mathfrak{p}$ such that $b_1^i=b^i$, satisfies $\mathfrak{p}_{\min}(\mathbf{b})\subseteq\mathfrak{p}$. This follows from Lemma 2.1.

Given M polynomials $\mathbf{b}=(b^1(w),\ldots,b^M(w))$, consider the following subspace of $\widehat{\mathscr{D}^M}_0$:

$$\begin{aligned}(\widehat{\mathscr{D}^M}_0)^{\mathbf{b}}=&\{b^i(D)g(D)e_{i+1,i+1}-b^i(D)g(D)e_{ii}|1\leqslant i\leqslant M-1,g(w)\in\mathbb{C}[w]\}\oplus\{b^M(D)g(D)e_{1,1}\\&-b^M(D+1)g(D+1)e_{MM}+b^M(0)g(0)C|g(w)\in\mathbb{C}[w]\}.\end{aligned}$$

We shall need the following proposition to study modules over $\widehat{\mathscr{D}^M}$ induced from its parabolic subalgebras.

Proposition 2.1: Let $\mathfrak{p}$ *be a parabolic subalgebra of* $\widehat{\mathscr{D}^M}$ *and let* $\mathbf{b}=(b^1(w),\dots,b^M(w))$ *be its first* M *characteristic polynomials. Then*

$$[\mathfrak{p},\mathfrak{p}]=(\underset{k\neq 0}{\oplus}\mathfrak{p}_k)\bigoplus(\widehat{\mathscr{D}^M}_0)^{\mathbf{b}}.$$

Proof: First, clearly $[\mathfrak{p}_0,\mathfrak{p}_k]=\mathfrak{p}_k$ for $k\neq 0$. Next, since $[\mathfrak{p}_1,\mathfrak{p}_k]=\mathfrak{p}_{k+1}$ for $k\geqslant 1$, we have

$$\begin{aligned}[\mathfrak{p}_{1+k},\mathfrak{p}_{-(1+k)}]&\subseteq[[\mathfrak{p}_1,\mathfrak{p}_k],\mathfrak{p}_{-(1+k)}]\\&\subseteq[[\mathfrak{p}_k,\mathfrak{p}_{-(k+1)}],\mathfrak{p}_1]+[[\mathfrak{p}_{-(k+1)},\mathfrak{p}_1],\mathfrak{p}_k]\\&\subseteq[\mathfrak{p}_{-1},\mathfrak{p}_1]+[\mathfrak{p}_{-k},\mathfrak{p}_k].\end{aligned}$$

Hence, by induction, $[\mathfrak{p},\mathfrak{p}]_0=[\mathfrak{p}_{-1},\mathfrak{p}_1]$. Now, using that

$$[g(D)e_{i+1,i},b^i(D)e_{i,i+1}]=b^i(D)g(D)e_{i+1,i+1}-b^i(D)g(D)e_{ii}$$

and

$$[zg(D+1)e_{1,M},z^{-1}b^M(D)e_{M,1}]=b^M(D)g(D)e_{1,1}-b^M(D+1)g(D+1)e_{MM}+b^M(0)g(0)C,$$

we see that $[\mathfrak{p}_{-1},\mathfrak{p}_1]=(\widehat{\mathscr{D}^M}_0)^{\mathbf{b}}$; hence the proposition follows. □

III. CONNECTION BETWEEN $\widehat{\mathscr{D}^M}$ AND $\widehat{\mathfrak{gl}}(\infty)[m]$

We will discuss the relation between $\widehat{\mathscr{D}^M}$ and the Lie algebra of infinite matrices with finitely many nonzero diagonals over the algebra of truncated polynomials.

Let R be an associative algebra over $\mathbb{C}$ and denote by R^∞ a free R-module with a fixed basis $\{v_j\}_{j\in\mathbb{Z}}$ and define the operators E_{ij} on R^∞ by $E_{ij}v_k=\delta_{jk}v_i$.

Let $\widetilde{M}(\infty,R)$ be the associative subalgebra of $\operatorname{End}R^\infty$ consisting of all operators $\Sigma_{i,j\in\mathbb{Z}}a_{ij}E_{ij}$, where $(a_{ij})_{i,j\in\mathbb{Z}}$ has a finite number of nonzero diagonals. Recall that $\widetilde{M}(\infty,R)$ is a $\mathbb{Z}$-graded algebra with the *principal* gradation defined by $\deg E_{ij}=j-i$.

Let $\varphi:R^M[z,z^{-1}]\to R[z,z^{-1}]$ be the isomorphism defined by

$$e_iz^j\longrightarrow z^{jM+i-1}.$$

Fix $s\in\mathbb{C}$ and a nilpotent element $t\in R$. Consider $R[z,z^{-1}]z^s$ as a free R-module with basis $v_j=z^{-j+s}$, $j\in\mathbb{Z}$. Using the isomorphism φ we associate to an element $z^kf(D)e_{ij}\in\mathscr{D}^M_{\text{as}}$ the operator $z^kf(D+t)e_{ij}$ on $R[z,z^{-1}]z^s$. More precisely, $(z^kf(D)e_{ij})(v_{lM-m+1})=(z^kf(D+t)e_{ij})(e_mz^{-l+s})=\delta_{jm}f(-l+s+t)e_iz^{k-l+s}=\delta_{jm}f(-l+s+t)v_{(l-k)M-i+1}$.

Thus, we obtain an embedding $\varphi_{s,t}:\mathscr{D}^M_{\text{as}}\to\widetilde{M}(\infty,R)$ of associative algebras over $\mathbb{C}$, which is compatible with the principal gradation. Explicitly,

$$\varphi_{s,t}(z^kf(D)e_{ij})=\sum_{l\in\mathbb{Z}}f(-l+s+t)E_{lM-kM-i+1,lM-j+1},\tag{3.1}$$

and $\varphi_{s,t}$ extends to a homomorphism $\varphi_{s,t}:\mathscr{D}^{M\mathscr{O}}_{\text{as}}\to\widetilde{M}(\infty,R)$.

Consider the truncated polynomial algebra $R_m=\mathbb{C}[t]/(t^{m+1})$, where $m\in\mathbb{Z}_+$, and let $\widetilde{M}(\infty)[m]=\widetilde{M}(\infty,R_m)$. The homomorphism $\varphi_{s,t}:\mathscr{D}^{M\mathscr{O}}_{\text{as}}\to\widetilde{M}(\infty)[m]$ given by (3.1) will be denoted by $\varphi_s^{[m]}$. It follows from Taylor's formula that

$$\varphi_s^{[m]}(z^kf(D)e_{ij})=\sum_{r=0}^m\sum_{l\in\mathbb{Z}}\frac{f^{(r)}(-l+s)}{r!}t^rE_{lM-kM-i+1,lM-j+1}.\tag{3.2}$$

Let

$$I_s^{[m]}=\{f\in\mathscr{O}\,|\,f^{(i)}(j+s)=0,\quad \text{for all } j\in\mathbb{Z},\ i=0,1,...,m\}$$

and

$$J_s^{[m]}=\bigoplus_{i,j=1}^{M}\ \bigoplus_{k\in\mathbb{Z}} z^k I_s^{[m]}e_{ij}\in\mathscr{D}_{\text{as}}^{M\mathscr{O}}.$$

We obviously have

$$\text{Ker }\varphi_s^{[m]}=J_s^{[m]}. \tag{3.3}$$

Now, let us fix $\mathbf{s}=(s_1,\ldots,s_n)\in\mathbb{C}^n$, such that

$$s_i-s_j\notin\mathbb{Z},\quad \text{for } i\neq j, \tag{3.4}$$

and fix $\mathbf{m}=(m_1,\ldots,m_n)\in\mathbb{Z}_+^n$.

Let $\widetilde{M}(\infty)[\mathbf{m}]=\oplus_{i=1}^n\widetilde{M}(\infty)[m_i]$. Consider the homomorphism

$$\varphi_{\mathbf{s}}^{[\mathbf{m}]}=\bigoplus_{i=1}^{n}\varphi_{s_i}^{[m_i]}:\mathscr{D}_{\text{as}}^{M\mathscr{O}}\to\widetilde{M}(\infty)[\mathbf{m}].$$

Proposition 3.1: We have an exact sequence of $\mathbb{Z}$*-graded associative algebras*:

$$0\to J_{\mathbf{s}}^{[\mathbf{m}]}\to\mathscr{D}_{\text{as}}^{M\mathscr{O}}\xrightarrow{\varphi_{\mathbf{s}}^{[\mathbf{m}]}}\widetilde{M}(\infty)[\mathbf{m}]\to 0,$$

where $J_{\mathbf{s}}^{[\mathbf{m}]}=\cap_{i=1}^n J_{s_i}^{[m_i]}$.

Proof: The first part is clear from (3.3). The surjectivity of $\varphi_{\mathbf{s}}^{[\mathbf{m}]}$ follows from the following well-known fact: for every discrete sequence of points in $\mathbb{C}$ and a nonnegative integer m, there exists $f(w)\in\mathscr{O}$ having prescribed values of its first m derivatives at these points. We have used (3.4) here. □

Now, denote by $\widetilde{\mathrm{gl}}(\infty,R_m)$ the Lie algebra corresponding to the associative algebra $\widetilde{M}(\infty)[m]$. Let $\widehat{\mathrm{gl}}(\infty,R_m)=\widetilde{\mathrm{gl}}(\infty,R_m)+R_m$ be the central extension with this 2-cocycle,

$$\Phi(A,B)=\mathrm{tr}([J,A]B), \tag{3.5}$$

where $J=\Sigma_{i\leqslant 0}E_{ii}$. The principal $\mathbb{Z}$-gradation of this Lie algebra extends from $\widetilde{\mathrm{gl}}(\infty,R_m)$ by letting wt $R_m=0$.

The associative algebra homomorphism $\varphi_s^{[m]}$ defines a Lie algebra homomorphism, which we denote by the same letter.

The restriction of the cocycle Φ to $\varphi_s^{[m]}(\mathscr{D}^{M\mathscr{O}})$ gives us the following R_m-valued 2-cocycle on $\mathscr{D}^{M\mathscr{O}}$:

$$\Psi_s^{[m]}:=\Psi+\Psi_{s,0}+\sum_{j=1}^{m}\Psi_s^{(j)}\frac{t^j}{j!},$$

where the cocycle Ψ is given by (2.3) and the cocycles $\Psi_{s,0}$ and $\Psi_s^{(m)}$ are defined in Remark 2.1. Thus, formulas (2.7)–(2.9) imply the following result.

Proposition 3.2: The $\mathbb{C}$*-linear map* $\hat{\varphi}_s^{[m]}:\widehat{\mathscr{D}^M}\to\widehat{\mathrm{gl}}(\infty,R_m)$*, defined by*

$$\hat{\varphi}_s^{[m]}|_{\widehat{\mathscr{D}^M}_j}=\varphi_s^{[m]}|_{\mathscr{D}^M{}_j},\quad \text{if } j\neq 0,$$

$$\hat{\varphi}_s^{[m]}(e^{xD}e_{ii}) = \varphi_s^{[m]}(e^{xD}e_{ii}) - \frac{e^{sx}-1}{e^x-1} - \sum_{j=1}^{m} \frac{x^j e^{sx}}{e^x-1}\, t^j/j!, \tag{3.6}$$

$$\hat{\varphi}_s^{[m]}(C) = 1 \in R_m,$$

is a homomorphism of Lie algebras over $\mathbb{C}$. □

IV. QUASIFINITE HIGHEST WEIGHT MODULES OVER $\widehat{\mathscr{D}^M}$

Recall that, given $\lambda \in (\widehat{\mathscr{D}^M}_0)^*$, the *Verma module* over $\widehat{\mathscr{D}^M}$ is defined as follows:

$$M(\lambda) = M(\widehat{\mathscr{D}^M}, \lambda) := \mathscr{U}(\widehat{\mathscr{D}^M}) \oplus_{\mathscr{U}(\oplus_{j\in\mathbb{Z}_+} \widehat{\mathscr{D}^M}_j)} \mathbb{C}_\lambda,$$

where $\mathbb{C}_\lambda$ is the one-dimensional $\oplus_{j\in\mathbb{Z}_+} \widehat{\mathscr{D}^M}_j$-module given by $h \mapsto \lambda(h)$ if $h \in \widehat{\mathscr{D}^M}_0$, $\widehat{\mathscr{D}^M}_j \mapsto 0$ for $j>0$, and the action of $\widehat{\mathscr{D}^M}$ is induced by the left multiplication in $\mathscr{U}(\widehat{\mathscr{D}^M})$. The vector $v_\lambda := 1 \otimes 1$ is called the *highest weight vector*.

Let $L(\lambda) = L(\widehat{\mathscr{D}^M}, \lambda)$ denote the unique irreducible quotient of $M(\widehat{\mathscr{D}^M}, \lambda)$. Modules $M(\lambda)$ and their quotients [including $L(\lambda)$] are called *highest weight modules* (with highest weight λ). Note that the principal gradation on $\widehat{\mathscr{D}^M}$ induces the principal gradation on any highest weight module V:

$$V = \bigoplus_{j\in\mathbb{Z}+} V_{-j}, \quad \text{where} \quad V_0 = \mathbb{C}v_\lambda. \tag{4.1}$$

Consider a parabolic subalgebra $\mathfrak{p}$ and let $\mathbf{b}$ be its first M characteristic polynomials. Let $\lambda \in (\widehat{\mathscr{D}^M}_0)^*$ be such that $\lambda|_{(\widehat{\mathscr{D}^M}_0)^{\mathfrak{b}}} = 0$. Then the $\oplus_{j\in\mathbb{Z}_+} \widehat{\mathscr{D}^M}_j$-module $\mathbb{C}_\lambda$ extends to $\mathfrak{p}$ by letting $[\mathfrak{p},\mathfrak{p}] \mapsto 0$ (see Proposition 2.1). Denote by $M(\lambda;\mathbf{b})$ the *generalized Verma module*, i.e., the $\widehat{\mathscr{D}^M}$-module,

$$M(\widehat{\mathscr{D}^M}, \mathfrak{p}, \lambda) = \mathscr{U}(\widehat{\mathscr{D}^M}) \bigoplus_{\mathscr{U}(\mathfrak{p})} \mathbb{C}_\lambda.$$

Recall that a nonzero vector v in a highest weight module over $\widehat{\mathscr{D}^M}$ is called *singular* if $(\widehat{\mathscr{D}^M})_j v = 0$, for all $j>0$.

Definition 4.1: A Verma module $M(\lambda)$ over $\widehat{\mathscr{D}^M}$ is called *highly degenerate* if there exists a singular vector $v \in M(\lambda)_{-1}$ of the following form: $v = Av_\lambda$, where $A \in (\widehat{\mathscr{D}^M})_{-1}$ and $\det A \neq 0$.

Proposition 4.1: $M(\lambda)$ is highly degenerate if and only if $\lambda((\widehat{\mathscr{D}^M}_0)^{\mathbf{b}}) = 0$ for some $\mathbf{b} = (b^1(w),\ldots,b^M(w))$ where all $b^i(w)$ are monic polynomials.

Proof: Suppose that $v = Av_\lambda$, with $A \in (\widehat{\mathscr{D}^M})_{-1}$ and $\det A \neq 0$. Then

$$A = \begin{pmatrix} 0 & b^1(D) & 0 & \ldots & 0 \\ 0 & 0 & b^2(D) & \ldots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \ldots & b^{M-1}(D) \\ z^{-1}b^M(D) & 0 & 0 & \ldots & 0 \end{pmatrix};$$

hence $b^i(D) \neq 0$ for all i. Observe that v is a singular vector if and only if $(\widehat{\mathscr{D}^M})_1 v = 0$. Given $B \in (\widehat{\mathscr{D}^M})_1$, we have $Bv = BAv_\lambda = [B,A]v_\lambda + ABv_\lambda = \lambda([B,A])v_\lambda$; hence the proposition follows. □

An irreducible highest weight $\widehat{\mathscr{D}^M}$-module V is called *quasifinite* if $\dim V_{-j}<\infty$ for all $j \in \mathbb{Z}_+$. The following key proposition follows from Propositions 2.1 and 4.1, and formula (2.11).

Proposition 4.2: The following conditions on $\lambda \in (\widehat{\mathscr{D}^M}_0)^*$ *are equivalent*:
(1) $M(\lambda)$ is *highly degenerate*;
(2) $L(\lambda)$ *is quasifinite*;
(3) $L(\lambda)$ *is the irreducible quotient of a generalized Verma module* $M(\lambda;\mathbf{b})$ *for some monic polynomials* $\mathbf{b}=(b^1(w),\ldots,b^M(w))$.

Let $L(\lambda)$ be a quasifinite highest weight module over $\widehat{\mathscr{D}^M}$. By Proposition 4.2 there exist some monic polynomials $b^1(w),\ldots,b^M(w)$, such that

$$(b^i(D)e_{i,i+1})v_\lambda=0 \quad (i=1,\ldots,M-1), \quad (z^{-1}b^M(D)e_{M,1})v_\lambda=0.$$

We shall call such monic polynomials of minimal degree the *characteristic* polynomials of $L(\lambda)$. Note that $L(\lambda)$ is the irreducible quotient of $M(\lambda;\mathbf{b})$, where $\mathbf{b}=(b^1(w),\ldots,b^M(w))$ are the characteristic polynomials of $L(\lambda)$.

A functional $\lambda \in (\widehat{\mathscr{D}^M}_0)^*$ is described by its *labels* $\Delta_{i,m}=-\lambda(D^m e_{ii})$ and the *central charge* $c=\lambda(C)$. We shall consider the generating series

$$\Delta_i(x)=\sum_{m=0}^{\infty} \frac{x^m}{m!}\Delta_{i,m}.$$

Recall that a *quasipolynomial* is a linear combination of functions of the form $p(x)e^{\alpha x}$, where $p(x)$ is a polynomial and $\alpha \in \mathbb{C}$.

Theorem 4.1: *A* $\widehat{\mathscr{D}^M}$*-module* $L(\lambda)$ *is quasifinite if and only if*

$$\Delta_M(x)=\frac{\varphi_M(x)}{e^x-1},$$

$$\Delta_i(x)=\frac{\varphi_i(x)(e^x-1)+\varphi_M(x)}{e^x-1}, \quad \text{for} \quad i=1,\ldots,M-1,$$

where $\varphi_i(x)$ *are all quasipolynomials and* $\varphi_M(0)=0$.

Proof: From Propositions 4.1, 4.2, and 2.1, we have that $L(\lambda)$ is quasifinite if and only if there exist polynomials

$$b^i(w)=w^{m_i}+f_{i,m_i-1}w^{m_i-1}+\cdots+f_{i,0}, \quad \text{for} \quad i=1,\ldots,M,$$

such that for all $s=0,1,\ldots$, we have

$$\lambda(b^i(D)D^s e_{i+1,i+1}-b^i(D)D^s e_{ii})=0, \quad i=1,\ldots,M-1,$$

$$\lambda(b^M(D)D^s e_{1,1}-b^M(D+1)(D+1)^s e_{MM}+\delta_{s,0}b^M(0)C)=0.$$

These conditions can be rewritten as follows:

$$\sum_{n=0}^{m_i} f_{i,n}F_{i,n+s}=0, \quad \text{for all} \quad s=0,1,\ldots, \tag{4.2}$$

where

$$F_{i,n}=\Delta_{i,n}-\Delta_{i+1,n}, \quad \text{for} \quad i=1,\ldots,M-1,$$

$$F_{M,n}=\delta_{n,0}c-\Delta_{1,n}+\sum_{j=0}^{n}\Delta_{M,j}.$$

Introducing the generating series,

$$F_i(x)=\sum_{n=0}^{\infty}\frac{x^n}{n!}F_{i,n},$$

we may rewrite (4.2) in the form

$$\left(\sum_{j=0}^{m_i} f_{i,j}\left(\frac{d}{dx}\right)^j\right)F_i(x)=0.$$

Thus, $L(\lambda)$ is quasifinite if and only if $F_i(x)$ are quasipolynomials. But

$$\begin{aligned} &F_i(x)=\Delta_i(x)-\Delta_{i+1}(x), \quad \text{for} \quad i=1,...,M-1,\\ &F_M(x)=c-\Delta_1(x)+e^x\Delta_M(x); \end{aligned} \tag{4.3}$$

hence the theorem follows. □

Definition 4.2: Each of the quasipolynomials $F_i(x)$ $(i=1,...,M)$ in (4.3) can be (uniquely) written in the form

$$F_i(x)=\sum_{r\in\mathbb{C}} p_{i,r}(x)e^{rx}, \quad p_{i,r}(x)\neq 0. \tag{4.4}$$

The numbers r appearing in (4.4) are called *exponents* of the $\widehat{\mathscr{D}^M}$-module $L(\lambda)$.

Corollary 4.1: Let $L(\Lambda)$ be a quasifinite irreducible highest weight module over $\widehat{\mathscr{D}^M}$, and let $\mathbf{b}=(b^1(w),\ldots,b^M(w))$ be its first M characteristic polynomials. By Theorem 4.1, $F_i=\Delta_i(x)-\Delta_{i+1}(x)$, $i=1,...,M-1$, and $F_M=c+e^x\Delta_M(x)-\Delta_1(x)$ are quasipolynomials. Let $(F_i)^{(m_i)}+f_{i,m_i-1}(F_i)^{(m_i-1)}+\cdots+f_{i,0}F_i=0$ be the minimal-order homogeneous linear differential equations with constant coefficients satisfied by $F_i(x)$. Then $b^i(w)=w^{m_i}+f_{i,m_i-1}w^{m_i-1}+\cdots+f_{i,0}$. Moreover, the exponents appearing in (4.4) are all the roots of the polynomials $b^i(w)$.

We shall need the following proposition.

Proposition 4.3: Let V be a quasifinite $\widehat{\mathscr{D}^M}$-module. Then the action of $\widehat{\mathscr{D}^M}$ on V naturally extends to the action of $\widehat{\mathscr{D}^M\mathscr{O}}_k$ on V for any $k\neq 0$.

Proof: Replace $B=\operatorname{ad} D^2-k^2$ by $B=\frac{1}{2}\operatorname{ad}(D^2e_{i,i}-(D-k)^2e_{j,j})$ in the proof of Proposition 4.3 in Ref. 1. The rest of the proof remains the same. □

We return now to the $\mathbb{Z}$-graded complex Lie algebra $\mathfrak{g}^{[m]}:=\widehat{\mathrm{gl}}(\infty,R_m)=\widetilde{\mathrm{gl}}(\infty,R_m)+R_m$ considered in Sec. III. Recall that it is a central extension of the Lie algebra $\widetilde{\mathrm{gl}}(\infty,R_m)$ over $\mathbb{C}$ by the $m+1$-dimensional space R_m.

An element $\lambda\in(\mathfrak{g}_0^{[m]})^*$ is characterized by its *labels*,

$$\lambda_k^{(j)}=\lambda(t^jE_{kk}), \quad k\in\mathbb{Z}, \quad j=0,...,m,$$

and *central charges*,

$$c_j=\lambda(t^j), \quad j=0,1,...,m.$$

Let

$$h_k^{(j)}=\lambda_k^{(j)}-\lambda_{k+1}^{(j)}+\delta_{k,0}c_j, \quad k\in\mathbb{Z}, \quad j=0,...,m. \tag{4.5}$$

As usual, we have the irreducible highest weight $\mathfrak{g}^{[m]}$-module $L(\mathfrak{g}^{[m]},\lambda)$ associated to λ. The proof of the following proposition is standard.

Proposition 4.4: The $\mathfrak{g}^{[m]}$-module $L(\mathfrak{g}^{[m]},\lambda)$ is quasifinite if and only if for each $j=0,1,...,m$ all but finitely many of the $h_k^{(j)}$ are zero.

Given $\mathbf{m}=(m_1,\dots,m_n)\in\mathbb{Z}_+^n$, we let $\mathfrak{g}^{[\mathbf{m}]}=\oplus_{i=1}^n \mathfrak{g}^{[m_i]}$. By Proposition 3.1, we have a surjective homomorphism of Lie algebras over $\mathbb{C}$ for $\mathbf{s}$ satisfying (3.4):

$$\hat{\varphi}_{\mathbf{s}}^{[\mathbf{m}]}=\bigoplus_{i=1}^{n}\hat{\varphi}_{s_i}^{[m_i]}:\widehat{\mathscr{D}^{M\mathscr{O}}}\to\mathfrak{g}^{[\mathbf{m}]}. \tag{4.6}$$

Take $\lambda(i)\in(\mathfrak{g}_0^{[m_i]})^*$ such that $L(\mathfrak{g}^{[m_i]},\lambda(i))$ is a quasifinite irreducible $\mathfrak{g}^{[m_i]}$-module. Then

$$L(\mathfrak{g}^{[\mathbf{m}]},\boldsymbol{\lambda})=\bigotimes_{i=1}^{n}L(\mathfrak{g}^{[m_i]},\lambda(i))$$

is an irreducible $\mathfrak{g}^{[\mathbf{m}]}$-module. Now, via the homomorphism (4.6), we consider $L(\mathfrak{g}^{[\mathbf{m}]},\boldsymbol{\lambda})$ as a $\widehat{\mathscr{D}^M}$-module, and we denote it by $L_{\mathbf{s}}^{[\mathbf{m}]}(\boldsymbol{\lambda})$.

We have the following important theorem.

Theorem 4.2: *Let* $\mathbf{s}=(s_1,\dots,s_n)$ *satisfy (3.4). Consider the embedding* $\hat{\varphi}_{\mathbf{s}}^{[\mathbf{m}]}:\widehat{\mathscr{D}^M}\to\mathfrak{g}^{[\mathbf{m}]}$ *and let V be a quasifinite* $\mathfrak{g}^{[\mathbf{m}]}$*-module. Then any* $\widehat{\mathscr{D}^M}$*-submodule of V is a* $\mathfrak{g}^{[\mathbf{m}]}$*-submodule as well. In particular, the* $\widehat{\mathscr{D}^M}$*-modules* $L_{\mathbf{s}}^{[\mathbf{m}]}(\boldsymbol{\lambda})$ *are irreducible.*

Proof: The same proof as of Theorem 4.5 in Ref. 1. □

By Proposition 4.4 and Theorem 4.2, we have that the $\widehat{\mathscr{D}^M}$-modules $L_{\mathbf{s}}^{[\mathbf{m}]}(\boldsymbol{\lambda})$ are irreducible quasifinite highest weight modules. Using formulas (3.2) and (3.6), it is easy to calculate the generating series $\Delta_{\mathbf{m},\mathbf{s},\boldsymbol{\lambda},i}(x)=\Sigma_{n\geqslant 0}\Delta_{i,n}(x^n/n!)$ of the highest weight and the central charge c of the $\widehat{\mathscr{D}^M}$-module $L_{\mathbf{s}}^{[\mathbf{m}]}(\boldsymbol{\lambda})$. We have

$$\Delta_{m,s,\lambda,i}(x)=-\sum_{p=0}^{m}\sum_{l\in\mathbb{Z}}\frac{\lambda_{lM-i+1}^{(p)}}{p!}x^p e^{(s-l)x}+\frac{e^{sx}-1}{e^x-1}c_0+\sum_{p=1}^{m}\frac{x^p e^{sx}}{e^x-1}\frac{c_p}{p!}, \tag{4.7}$$

$$c=c_0, \tag{4.8}$$

and

$$\Delta_{\mathbf{m},\mathbf{s},\boldsymbol{\lambda},i}(x)=\sum_j \Delta_{m_j,s_j,\lambda(j),i}(x),\quad c=\sum_j c_0(j). \tag{4.9}$$

Introduce the polynomials [see (4.5)]

$$g_k(x)=\sum_{j=0}^{m}h_k^{(j)}x^j/j!\quad(k\in\mathbb{Z}). \tag{4.10}$$

Then (4.7) can be rewritten as follows:

$$\Delta_{m,s,\lambda,i}(x)=\frac{\Sigma_{l\in\mathbb{Z}}e^{(s-l)x}(g_{lM-i+1}(x)+g_{lM-i+2}(x)+\cdots+g_{lM+M-i}(x))-c_0}{e^x-1}. \tag{4.11}$$

Furthermore, notice that

$$\Delta_{m,s,\lambda,i}(x)-\Delta_{m,s,\lambda,i+1}(x)=\sum_{l\in\mathbb{Z}}e^{(s-l)x}g_{lM-i}(x),\quad\text{for}\quad i=1,\dots,M-1. \tag{4.12}$$

Note that these formulas imply that any irreducible quasifinite highest weight module $L(\widehat{\mathscr{D}^M},\lambda)$ can be obtained as above in an essentially unique way. More precisely, we have the following result.

Theorem 4.3: *Let* $L=L(\widehat{\mathscr{D}^M},\lambda)$ *be an irreducible quasifinite highest weight module with central charge* c *and generating series* $\Delta_i(x)$*, such that*

$$\Delta_i(x)-\Delta_{i+1}(x)=F_i(x) \quad (i=1,...,M-1), \quad \Delta_M(x)=\frac{\Sigma_{i=1}^M F_i(x)-c}{e^x-1},$$

where $F_i(x)$ *are quasipolynomials and* $\Sigma_{i=1}^M F_i(0)=c$ *(see the proof of Theorem 4.1). We write* $F_i(x)=\Sigma_{r\in\mathbb{C}} p_{i,r}(x)e^{rx}$*, where* $p_{i,r}(x)$ *are nonzero polynomials. We decompose the set of exponents* $\{r\}$ *in a disjoint union of congruence classes mod* $\mathbb{Z}$*. Let* $S=\{s,s-k_1,s-k_2,\ldots\}$ *be such a congruence class, let* $m=\max_{r\in S}\deg p_{i,r}$ *and let* $h^{(j)}_{k_rM-i}=(d/dx)^j p_{i,s-k_r}(0)$*, for* $i=1,2,...,M$*. We associate to* S *the* $\mathfrak{g}^{[m]}$*-module* $L^{[m]}(\lambda_S)$ *with central charges,*

$$c_j=\sum_{k_rM-i} h^{(j)}_{k_rM-i},$$

and labels,

$$\lambda^{(j)}_l=\sum_{(k_r+\delta_{i,M})M-i\geq l}(h^{(j)}_{k_rM-i}-c_j\delta_{(k_r+\delta_{i,M})M-i,0}).$$

Then the $\widehat{\mathscr{D}^M}$*-module* L *is isomorphic to the tensor product of all the modules* $L_s^{[m]}(\lambda_S)$*.*

Proof: The tensor product L' of all the modules $L_s^{[m]}(\lambda_S)$ is irreducible due to Theorem 4.2. It remains to show that L' has the same highest weight as L does. This is done by exploiting the observation that $-\Delta_i(x)$ is the value of the highest weight of L' on $e^{xD}e_{ii}$, and using the formulas (4.7)–(4.12). □

V. UNITARY QUASIFINITE HIGHEST WEIGHT MODULES OVER $\widehat{\mathscr{D}^M}$

In this section we shall classify all *unitary* (irreducible) quasifinite highest weight modules over $\widehat{\mathscr{D}^M}$ with respect to the anti-involution ω on $\mathscr{D}^M_{\text{as}}$, defined by

$$\omega(z^k f(D)e_{ij})=z^{-k}\overline{f}(D-k)e_{ji},$$

where for $f(D)=\Sigma_i f_i D^i$ we let $\overline{f}(D)=\Sigma_i \overline{f_i}D^i (f_i\in\mathbb{C})$. The anti-involution ω extends to the whole algebra $\mathscr{D}^{M\mathscr{O}}_{\text{as}}$.

Observe that

$$\Psi(\omega(A),\omega(B))=\omega(\Psi(B,A)), \quad A,B\in\mathscr{D}^{M\mathscr{O}}_{\text{as}}.$$

Therefore, the anti-involution ω of the Lie algebras $\mathscr{D}^M$ and $\mathscr{D}^{M\mathscr{O}}$, lifts to an anti-involution of their central extensions, $\widehat{\mathscr{D}^M}$ and $\widehat{\mathscr{D}^{M\mathscr{O}}}$, such that $\omega(C)=C$, which we again denote by ω.

Remark 5.1: (a) Under the homomorphism $\varphi_s=\varphi_{s,0}:\mathscr{D}^{M\mathscr{O}}_{\text{as}}\to\widetilde{M}(\infty,\mathbb{C})$ we have

$$(\varphi_s(z^k f(D)e_{ij}))^*=\varphi_{\bar{s}}(\omega(z^k f(D)e_{ij})).$$

Here A^* stands for the complex conjugate transpose of the matrix $A\in\widetilde{M}(\infty,\mathbb{C})$.

(b) (see, e.g., Ref. 5). For the anti-involution ω of $\widehat{\mathrm{gl}}(\infty,\mathbb{C})$ defined by $\omega(A)={}^t\overline{A}$, $\omega(1)=1$, a highest weight $\widehat{\mathrm{gl}}(\infty,\mathbb{C})$-module with highest weight λ and central charge c is unitary if and only if the numbers $h_i^{(0)}$ are non-negative integers and $c=\Sigma_i h_i^{(0)}$.

We shall need the following lemma.

Lemma 5.1: Let V *be a unitary quasifinite highest weight module over* $\widehat{\mathscr{D}^M}$ *and let* $\mathbf{b}=(b^1(w),\ldots,b^M(w))$ *be its first* M *characteristic polynomials. Then each* $b^i(w)$ *has only simple real roots.*

Proof: The proof is the same as that of Lemma 5.2 in Ref. 1 with the following changes. Let $S_i=De_{ii}$ for $i=1,2,...,M-1$, $S_M=-\frac{1}{2}(D^2+\Delta_{1,2}-1)e_{MM}$ and $v_i=e_{i,i+1}v_\lambda$, $i=1,2,...,M-1$,

$v_M = z^{-1} e_{M,1} v_\lambda$. Then replace $(s, z^{-1} v_\lambda, b(w))$ in the proof of the Lemma 5.2 in Ref. 1 by $(S_i, v_i, b^i(w))$. □

Now we can formulate the main result of this section.

Theorem 5.1: *(a) A nontrivial quasifinite irreducible highest weight module* $L(\widehat{\mathscr{D}^M}, \lambda)$ *is unitary if and only if the central charge* c *is a positive integer and there exist* $r_1, \ldots, r_c \in \mathbb{R}$ *and a partition* $\{1,...,c\} = I_0 \cup \cdots \cup I_{M-1}$, *such that*

$$\Delta_i(x) = \sum_{j \in I_0 \cup \cdots \cup I_{i-1}} \frac{e^{r_j x} - 1}{e^x - 1} + \sum_{j \in I_i \cup \cdots \cup I_{M-1}} \frac{e^{(r_j+1)x} - 1}{e^x - 1}. \tag{5.1}$$

(b) Any unitary quasifinite $\widehat{\mathscr{D}^M}$*-module* V *is obtained by taking tensor product of* n *unitary irreducible quasifinite highest weight modules over* $\widehat{\mathrm{gl}}(\infty, \mathbb{C})$ *and restricting to* $\widehat{\mathscr{D}^M}$ *via an embedding* $\hat{\varphi}_{\mathbf{s}}^{[0]}$, *where* $\mathbf{s} = (s_1, \ldots, s_n)$ *is a real vector and* $s_i - s_j \notin \mathbb{Z}$ *if* $i \neq j$.

Proof: By Theorem 4.3, being a quasifinite irreducible highest weight $\widehat{\mathscr{D}^M}$-module, V is isomorphic to one of the modules $L_{\mathbf{s}}^{[\mathbf{m}]}(\boldsymbol{\lambda})$. It follows from Lemma 5.1 and Corollary 4.1 that $\mathbf{m} = 0$. Now the claim (b) follows from Remark 5.1. The claim (a) follows from (b) and (4.11)–(4.12). □

Corollary 5.1: Suppose that only finitely many labels $\Delta_{i,n}$ *of* λ *are nonzero. Then the* $\widehat{\mathscr{D}^M}$*-module* $L(\lambda)$ *is unitary if and only if*

$$\Delta_{i,0} \in \mathbb{Z}_+ \quad (i = 1,...,M), \quad 0 \leqslant \Delta_{M,0} \leqslant \Delta_{M-1,0} \leqslant \cdots \leqslant \Delta_{1,0} \leqslant c \in \mathbb{Z}_+$$

and

$$\Delta_{i,n} = 0, \quad \text{for} \quad n > 0, \quad i = 1,...,M.$$

Proof: By the hypothesis, $\Delta_i(x)$ are polynomials for $i = 1,...,M$. Using Theorem 5.1, it follows that $\Delta_i(x) - \Delta_{i+1}(x) = \Sigma_{j \in I_i} e^{r_j x}$ $(i = 1,...,M-1)$ and $\Delta_M(x) = \Sigma_{j=1}^{c} (e^{r_j x} - 1)/(e^x - 1)$ are constant. Therefore $\Delta_{i,n} = 0$ for $n > 0$, $i = 1,...,M$. Moreover, we have that $r_j = 0$ for all $j \in I_i$ $(i = 1,...,M-1)$, $\Delta_{i,0} - \Delta_{i+1,0} = \#I_i$ and $\Delta_{M,0} = \#\{r_j | r_j = 1 \text{ and } j \in I_0\} \leqslant \#I_0$. Observe that $c = \Sigma \#I_i \geqslant \Delta_{1,0} \geqslant \Delta_{2,0} \geqslant \cdots \geqslant \Delta_{M,0} \geqslant 0$. The converse is immediate from Theorem 5.1. □

Now we consider the ''analytic continuation'' of quasifinite irreducible unitary modules of $\widehat{\mathscr{D}^M}$.

Definition 5.1: A $\widehat{\mathscr{D}^M}$-module $L(\widehat{\mathscr{D}^M}, \lambda)$ is called *primitive* if $\Delta_i(x)$ are of the form (5.1) with $r_j \in \mathbb{C}$. (Recall that the numbers r_j are the exponents of this module.) Note that primitive $\widehat{\mathscr{D}^M}$-modules are parametrized by the set of exponents $E = \{r_1, \ldots, r_c\}$ (with multiplicities) and a partition p of this set in M disjoint parts. We therefore will denote this $\widehat{\mathscr{D}^M}$ module by $L(\widehat{\mathscr{D}^M}, E, p)$.

Denote $\widetilde{\mathrm{gl}} = \widetilde{\mathrm{gl}}(\infty, \mathbb{C})$ and $\widehat{\mathrm{gl}} = \widehat{\mathrm{gl}}(\infty, \mathbb{C})$ (see Sec. III). Given $\lambda \in \widetilde{\mathrm{gl}}_0^*$ and $c \in \mathbb{C}$, we have a unique irreducible $\widehat{\mathrm{gl}}$-module $L(\lambda, c) = L(\widehat{\mathrm{gl}}, \lambda, c)$ with $C = cI$, which admits a nonzero vector v_λ, such that

$$E_{ij} v_\lambda = 0, \quad \text{for } i < j,$$

$$E_{ii} v_\lambda = \lambda(E_{ii}) v_\lambda, \quad \text{for } i \in \mathbb{Z}.$$

Define $\Lambda_j \in \widetilde{\mathrm{gl}}_0^*$, $j \in \mathbb{Z}$, as follows:

$$\Lambda_j(E_{ii}) = \begin{cases} 1, & \text{for } 0 < i \leqslant j, \\ -1, & \text{for } j < i \leqslant 0, \\ 0, & \text{otherwise.} \end{cases}$$

Let $H_N = \{(\nu_1, \ldots, \nu_N) \in \mathbb{Z}^N | \nu_1 \geqslant \cdots \geqslant \nu_N\}$, and consider for each $\nu \in H_N$,

$$\Lambda_\nu=\Lambda_{\nu_1}+\cdots+\Lambda_{\nu_N}. \tag{5.2}$$

Due to Remark 5.1(b), a $\widehat{\mathrm{gl}}$-module $L(\widehat{\mathrm{gl}},\lambda,c)$ is a nontrivial unitary module if and only if c is a positive integer and $\lambda=\Lambda_\nu$ for some $\nu\in H_c$.

Let

$$A=-\left(MDI_M+\sum_{i=1}^{M}(i-1)e_{ii}\right)\in\widehat{\mathscr{D}^M}. \tag{5.3}$$

Fix a positive integer N and $\nu\in H_N$. Observe that all the eigenspaces of $\widehat{\varphi_s}(A)$ in $L(\widehat{\mathrm{gl}},\Lambda_\nu,N)$ are finite dimensional, and recall that one has the following ''specialized'' character formula for these modules (cf. Ref. 2):

$$\mathrm{tr}_{L(\widehat{\mathrm{gl}},\Lambda_\nu,N)}\,q^{\widehat{\varphi_s}(A)}=q^{a(\Lambda_\nu)}\prod_{1\leqslant i<j\leqslant N}(1-q^{\nu_i-\nu_j+j-i})/\phi(q)^N, \tag{5.4}$$

where $a(\Lambda_\nu)=\Sigma_k\nu_k((\nu_k+1)/2-Ms)$, and $\phi(q)=\Pi_{j=1}^{\infty}(1-q^j)$ is the Euler product.

The following result is a special case of Theorem 4.2 and formulas (4.11)–(4.12).

Proposition 5.1: Let $\nu\in H_N$, and consider the sets $I_i=\{j\,|\,\nu_j=l_jM-i\}$, $i=0,...,M-1$. Then, when restricted to $\hat{\varphi}_s(\widehat{\mathscr{D}^M})$ the module $L(\Lambda_\nu,N)$ becomes an irreducible quasifinite $\widehat{\mathscr{D}^M}$-module with central charge N and

$$\Delta_i(x)=\sum_{j\in I_0\cup\cdots\cup I_{i-1}}\frac{e^{(s-l_j)x}-1}{e^x-1}+\sum_{j\in I_i\cup\cdots\cup I_{M-1}}\frac{e^{(s-l_j+1)x}-1}{e^x-1}.$$

In other words, it is the primitive $\widehat{\mathscr{D}^M}$-module with exponents $\{s-l_1,\ldots,s-l_N\}$ and partition $\{I_i\}_{i=0}^{M-1}$.

A primitive $\widehat{\mathscr{D}^M}$-module with positive integral central charge N is called *integral* if all exponents $r_1,\ldots,r_N$ are integral.

Recall that primitive $\widehat{\mathscr{D}^M}$-modules are completely determined by the set E of exponents and a partition p of this set in M disjoint parts.

Remark 5.2: There is a correspondence between H_N and the set of integral primitive $\widehat{\mathscr{D}^M}$-modules. More precisely, given $\nu\in H_N$ consider the partition p_ν defined by the sets of congruence classes $\{\nu_j\,|\,\nu_j=l_jM-i\}$, $i=0,...,M-1$, and take $E_\nu=\{-l_1,\ldots,-l_N\}$.

Conversely, given a set of exponents E and a partition p of this set in M disjoint parts $E=\cup_{i=0}^{M-1}I_i$, we can construct $\nu\in H_N$: take the N integers $\{-r_jM-i\,|\,r_j\in I_i\}$ and then order them in decreasing order.

Thus we have the following proposition for primitive $\widehat{\mathscr{D}^M}$-modules.

Proposition 5.2. *Let V be a primitive $\widehat{\mathscr{D}^M}$-module with exponents $\{r_i\}$. Decompose the set $\{r_i\}$ into a disjoint union of congruence classes $\mathrm{mod}\,\mathbb{Z}$, i.e.,*

$$\{r_i\}=S_1\cup\cdots\cup S_m,$$

where $S_i=\{s_i-n_1^{(i)},\ldots,s_i-n_{N_i}^{(i)}\}$, $n_j^{(i)}\in\mathbb{Z}$ and $s_i-s_j\notin\mathbb{Z}$. Let $\mathbf{s}=(s_1,\ldots,s_m)$ and $\Lambda^{(i)}(V)=\Lambda_{n_1^{(i)}}+\ldots+\Lambda_{n_{N_i}^{(i)}}$. Then the $\widehat{\mathscr{D}^M}$-module V is isomorphic to the $\widehat{\mathrm{gl}}^m$-module,

$$\bigotimes_{i=1}^{m}L(\widehat{\mathrm{gl}},\Lambda^{(i)}(V),N_i),$$

by restricting to $\hat{\varphi}_{\mathbf{s}}(\widehat{\mathscr{D}^M})$. In particular, the specialized character $\mathrm{tr}_V\,q^A$ is equal to the product of the corresponding characters of the irreducible $\widehat{\mathrm{gl}}$-modules [given by formula (5.4)]. □

VI. VERTEX ALGEBRA STRUCTURE ON THE VACUUM MODULE OF $\widehat{\mathscr{D}^M}$ AND VERTEX ALGEBRA MODULES

In this section we will construct the structure of a vertex algebra on the vacuum module M_c and hence on the irreducible quotient module L_c over $\widehat{\mathscr{D}^M}$. The original definition of a vertex algebra was given by Ref. 6. We will, however, use a different approach, inspired by Ref. 7 and developed in Refs. 2 and 8.

The following theorem allows one to construct vertex algebras.

Theorem 6.1: (Existence Theorem, Refs. 2, and 8) *Let V be a vector space, let $|0\rangle$ be a vector of V and T an endomorphism of V. Let $\{a^\alpha(x)\}_{\alpha\in I}$ be a collection of fields: $a^\alpha(x)=\Sigma_m a^\alpha_{(m)}x^{-m-1}$, where $a^\alpha_{(m)}\in End\ V$, such that the following properties hold.*

(1) *$a^\alpha(x)$ and $a^\beta(x)$ are mutually local, $(\alpha,\beta\in I):(x-y)^N[a^\alpha(x),a^\beta(y)]=0$, for $N\gg 0$.*

(2) *$a^\alpha(x)|0\rangle|_{x=0}=a^\alpha$ $(\alpha\in I)$, where the a^α are linearly independent.*

(3) *The space V is spanned by the vectors*

$$a^{\alpha_s}_{(-j_s-1)}\cdots a^{\alpha_1}_{(-j_1-1)}|0\rangle,\quad j_1,\ldots,j_s\in\mathbb{Z}_+.$$

(4) $[T,a^\alpha(x)]=\partial_x a^\alpha(x)$ $(\alpha\in I)$, $\quad T|0\rangle=0$.

Then the formula

$$Y(a^{\alpha_s}_{(-j_s-1)}\cdots a^{\alpha_1}_{(-j_1-1)}|0\rangle,x)=(j_1!\cdots j_s!)^{-1}:\partial_x^{j_s}a^{\alpha_s}(x)\cdots\partial_x^{j_2}a^{\alpha_2}(x)\partial_x^{j_1}a^{\alpha_1}(x):$$

(where the normal ordering of more than two fields is from right to left as usual), defines a unique structure of a vertex algebra on V such that $|0\rangle$ is the vacuum vector, T is the infinitesimal translation operator, and $Y(a^\alpha,x)=a^\alpha(x)$, $\alpha\in I$. □

In this case, we shall say that the vertex algebra is *generated* by the fields $a^\alpha(x)$, $\alpha\in I$.

Let

$$J^n_{(k)}=-z^k(\partial_z)^n\quad(k\in\mathbb{Z},n\in\mathbb{Z}_+).$$

These elements form a basis of $\mathscr{D}$. The elements

$$J^n_{(k)}e_{ij}\quad(k\in\mathbb{Z},n\in\mathbb{Z}_+,1\leqslant i,j\leqslant M)$$

form a basis of $\mathscr{D}^M$. Denote by $\mathscr{P}$ the subalgebra of $\mathscr{D}^M$, which consists of ($\mathrm{Mat}_M\mathbb{C}$ valued) operators that can be extended to regular differential operators on $\mathbb{C}$. We have

$$\mathscr{P}=\text{linear span of }\{J^n_{(k)}e_{ij}|k\geqslant 0,1\leqslant i,j\leqslant M\}.$$

The cocycle of our central extension [see (2.4)] restricts to a zero cocycle on $\mathscr{P}$. It follows that $\mathscr{P}$ is a subalgebra of $\widehat{\mathscr{D}^M}$. Let $\hat{\mathscr{P}}=\mathscr{P}\oplus\mathbb{C}C$; note that $[\hat{\mathscr{P}},\hat{\mathscr{P}}]=\mathscr{P}$.

Now, fix $c\in\mathbb{C}$, and denote by M_c the $\widehat{\mathscr{D}^M}$-module $M(\widehat{\mathscr{D}^M},\hat{\mathscr{P}},c)$ defined in Sec. IV, i.e., the $\widehat{\mathscr{D}^M}$-module induced from the one-dimensional module of the subalgebra $\hat{\mathscr{P}}$ defined by $\mathscr{P}\mapsto 0$, $C\mapsto c$. The module M_c is called the *vacuum $\widehat{\mathscr{D}^M}$-module* with central charge c. Denote by L_c the (unique) irreducible quotient of M_c, called the *irreducible vacuum $\widehat{\mathscr{D}^M}$-module*.

Recall that $(J^n_{(k)}e_{ij})|0\rangle=0$ for $n\in\mathbb{Z}_+$, $k\geqslant 0$ and $1\leqslant i,j\leqslant M$, where $|0\rangle$ is the highest weight vector of M_c. Note that the vectors of the form

$$(J^{n_r}_{(-k_r-1)}e_{i_r,j_r})\cdots(J^{n_1}_{(-k_1-1)}e_{i_1,j_1})|0\rangle,$$

where $(n_l,k_l)\in\mathbb{Z}_+^2$ and $1\leqslant i_l,j_l\leqslant M$, span M_c. It follows that the fields

$$J^n_{ij}(x)=\sum_{k\in\mathbb{Z}}J^n_{(k)}e_{ij}x^{-k-1}$$

satisfy conditions (2) and (3) of Theorem 6.1. Condition (1) follows from the operator product expansion [see Ref. 2, (3.9)]:

$$J_{ij}^m(x)J_{kl}^n(y)\sim\delta_{jk}\Bigg\{\sum_{a=1}^{m+n}([n]_aJ_{il}^{m+n-a}(y)-(-1)^a[m]_aJ_{il}^{m+n-a}(x))/(x-y)^{a+1}$$

$$+(-1)^m\delta_{il}m!n!c/(x-y)^{m+n+2}\Bigg\}.$$

It is easy to check condition (4) with $T=-\partial_z I$. Hence, the vacuum $\widehat{\mathscr{D}^M}$-module M_c is a vertex algebra. It follows that any quotient of the $\widehat{\mathscr{D}^M}$-module M_c is a vertex algebra. In particular, the irreducible vacuum module L_c is a vertex algebra, which is denoted by $W_{1+\infty,c}^M$.

A vertex algebra is called *conformal* of rank $c\in\mathbb{C}$ if there exists a vector $\nu\in V$ (called the Virasoro element), such that the corresponding vertex operator $Y(\nu,x)=\Sigma_{n\in\mathbb{Z}}L_nx^{-n-2}$ satisfies the following properties:
(1) $\{L_n\}_{n\in\mathbb{Z}}$ generates a Virasoro algebra with central charge c;
(2) $L_{-1}=T$, and L_0 is diagonalizable in V.

Let $\boldsymbol{\beta}=(\beta_1,\ldots,\beta_M)\in\mathbb{C}^M$ and $\nu(\boldsymbol{\beta})=(J_{(-1)}^1I-\Sigma_{i=1}^M\beta_iJ_{(-2)}^0e_{ii})|0\rangle$. Then it is easy to check that $Y(\nu(\boldsymbol{\beta}),x)=\Sigma_{k\in\mathbb{Z}}L_k(\boldsymbol{\beta})x^{-k-2}$, where

$$L_k(\boldsymbol{\beta})=J_{(k+1)}^1I+\sum_{i=1}^M\beta_i(k+1)J_{(k)}^0e_{ii}.$$

generate a Virasoro algebra $\mathrm{Vir}(\boldsymbol{\beta})$ with central charge

$$c_{\boldsymbol{\beta}}=-\sum_i(12\beta_i^2-12\beta_i+2)c.$$

It is easy to check that condition (2) holds for any element $\nu(\boldsymbol{\beta})$. Thus, we have established the following result.

Theorem 6.2: *For any c and $\boldsymbol{\beta}$, the quadrupole $(M_c,|0\rangle,\nu(\boldsymbol{\beta}),Y(\cdot,x))$ is a conformal vertex algebra of rank $c_{\boldsymbol{\beta}}$ generated by the fields $J_{ij}^n(x)$ $(n=0,1,2,\ldots,1\leqslant i,j\leqslant M)$. The same holds for L_c.* □

Remark 6.1: (a) Define

$$L_k^-(\boldsymbol{\beta})=J_{(k+1)}^1I+\sum_{i=1}^M(k+\beta_i(-k+1))J_{(k)}^0e_{ii}.$$

These elements generate a new family of Virasoro subalgebras $\mathrm{Vir}^-(\boldsymbol{\beta})$ with the same central charge $c_{\boldsymbol{\beta}}$, and the two families $\mathrm{Vir}^-(\boldsymbol{\beta})$ and $\mathrm{Vir}(\boldsymbol{\beta})$ intersect at $\beta_i=\underline{\frac{1}{2}}$. In this case $c_{\mathbf{1}/2}=Mc$.

(b) Observe that $\omega(L_k(\boldsymbol{\beta}))=L_{-k}^-(\boldsymbol{\beta}')$, where $\boldsymbol{\beta}'$ has coordinates β_i. Therefore, $\mathrm{Vir}(\boldsymbol{\beta})$ is ω-stable iff $\beta_i=\frac{1}{2}$ for all i.

(c) The operator A in (5.3) is equal to $ML_0(\boldsymbol{\beta})$ with $\beta_i=(i-1)/M$.

Consider the *Clifford algebra* C_{NM} over $\mathbb{C}$, on generators $\psi_{m[k]}^i$, $\psi_{m[k]}^{*i}$ $(k\in\mathbb{Z},\ i=1,\ldots,N,$ and $m=1,\ldots,M)$, with defining relations

$$[\psi_{m[k]}^{*i},\psi_{n[l]}^j]_+\equiv\psi_{m[k]}^{*i}\psi_{n[l]}^j+\psi_{n[l]}^j\psi_{m[k]}^{*i}=\delta_{ij}\delta_{mn}\delta_{k,-l},$$

and all other anticommutators equal to zero.

There exists a unique irreducible representation of the algebra C_{NM} in a vector space $\mathscr{F}=\mathscr{F}^{NM}$, called the *spin representation*, which admits a nonzero vacuum vector $|0\rangle$, satisfying

$$\psi_{m[k]}^i|0\rangle=0,\quad\text{for}\quad k\geqslant0,\quad\psi_{m[k]}^{*i}|0\rangle=0,\quad\text{for}\quad k>0.$$

In other words, we have NM pairs of free charged fermionic fields:

$$\psi_m^i(x)=\sum_{k\in\mathbb{Z}}\psi_{m[k]}^i x^{-k-1},\quad \psi_m^{*i}(x)=\sum_{k\in\mathbb{Z}}\psi_{m[k]}^{*i}x^{-k},\tag{6.1}$$

i.e., local odds fields with OPE:

$$\psi_m^{*i}(x)\psi_n^j(y)\sim\frac{\delta_{mn}\delta_{ij}}{x-y},\quad \text{and all other OPE}\sim 0.$$

Using the Existence Theorem, the space $\mathscr{F}^{NM}$ of the spin representation has a structure of a vertex algebra with vacuum vector $|0\rangle$ and generated by the fields given in (6.1).

Now, set

$$e_{mn}^{ij}(x)=:\psi_m^i(x)\psi_n^{*j}(x):\equiv\sum_{k\in\mathbb{Z}}e_{mn(k)}^{ij}x^{-k-1}\quad(1\leqslant i,j\leqslant N;1\leqslant m,n\leqslant M)$$

and

$$E^{ij}(x,y)=\sum_{p=1}^{N}:\psi_i^p(x)\psi_j^{*p}(y):\equiv\sum_{k,l\in\mathbb{Z}}E_{kl}^{ij}x^{k-1}y^{-l}\quad(1\leqslant i,j\leqslant M).$$

Then, using Wick's formula, we obtain that the operators $e_{mn(k)}^{ij}$ define a representation in $\mathscr{F}$ of the affine Lie algebra $\widehat{\mathrm{gl}}_{NM}$ of level 1:

$$[e_{mn(p)}^{ij},e_{kl(q)}^{st}]=\delta_{js}\delta_{nk}e_{ml(p+q)}^{it}-\delta_{it}\delta_{ml}e_{kn(p+q)}^{sj}+p\,\delta_{p,-q}\delta_{js}\delta_{nk}\delta_{it}\delta_{ml}.\tag{6.2}$$

Letting charge $\psi_i^p=1$, charge $\psi_i^{*p}=-1$, charge $|0\rangle=0$ defines the *charge decomposition* of $\mathscr{F}$:

$$\mathscr{F}^{NM}=\bigoplus_{m\in\mathbb{Z}}\mathscr{F}_{(m)}^{NM}.$$

Clearly each $\mathscr{F}_{(m)}^{NM}$ is a submodule of the $\widehat{\mathrm{gl}}_{NM}$-module $\mathscr{F}$.

Proposition 6.1: Each $\widehat{\mathrm{gl}}_{NM}$-module $\mathscr{F}_{(m)}^{NM}$ is irreducible.

Proof: This follows from the boson–fermion correspondence (see, e.g., Ref. 8). □

Denote by $V^1(\mathrm{gl}_N)$ the vertex algebra constructed on the irreducible vacuum module of level 1 over the affine Lie algebra $\widehat{\mathrm{gl}}_N$ (see, e.g., Ref. 8). Proposition 6.1 implies the following.

Corollary 6.1: The subspace $\mathscr{F}_{(0)}^{NM}$ is a subalgebra of the vertex algebra $\mathscr{F}^{NM}$ isomorphic to the vertex algebra $V^1(\mathrm{gl}_{NM})$.

It follows from (6.2) that the diagonal embedding Δ of gl_N into gl_{NM} defined by

$$\Delta(e_{ij}):=\sum_{m=1}^{M}e_{mm(0)}^{ij},$$

defines a representation of the general linear Lie algebra gl_N in $\mathscr{F}^{NM}$.

Moreover, the operators E_{kl}^{ij} $(k,l\in\mathbb{Z};\ 1\leqslant i,j\leqslant M)$ form a representation in $\mathscr{F}^{NM}$ of a central extension of the Lie algebra $\mathrm{gl}_M\otimes\mathrm{gl}_\infty$, denoted by $\widehat{\mathrm{gl}_M\otimes\mathrm{gl}_\infty}$, with central charge N:

$$[E_{kl}^{ij},E_{mn}^{st}]=\delta_{js}\delta_{lm}E_{kn}^{it}-\delta_{it}\delta_{kn}E_{ml}^{sj}+N\Phi_1(E_{kl}^{ij},E_{mn}^{st}),\tag{6.3}$$

where the 2-cocycle Φ_1 is defined by

$$\Phi_1(E^{ij}\otimes A,E^{st}\otimes B)=\delta_{it}\delta_{js}\Phi(A,B),$$

and Φ is given by (3.5). Observe that the map $\mathrm{gl}_M\otimes\mathrm{gl}_\infty\to\mathrm{gl}_\infty$, defined by

$$E^{ij}\otimes E_{kl}\mapsto E^{(k-1)M+i,(l-1)M+j},\tag{6.4}$$

is an isomorphism of associative algebras, and this map induces an isomorphism of Lie algebras: $\widehat{\mathrm{gl}_M \otimes \mathrm{gl}_\infty} \simeq \widehat{\mathrm{gl}}_\infty$.

The two actions defined above commute:

$$[e_{ij}, E^{st}_{kl}] = 0, \quad \text{for} \quad \text{all} \quad k,l \in \mathbb{Z}; \quad 1 \leqslant i,j \leqslant N; \quad 1 \leqslant s,t \leqslant M,$$

since

$$[e^{ij}_{mn(0)}, E^{st}_{kl}] = \sum_{q \in \mathbb{Z}} \sum_{p=1}^{N} [:\psi^i_{m[-q]} \psi^{*j}_{n[q]}:, :\psi^p_{s[-k]} \psi^{*p}_{t[l]}:] = \delta_{ns} \psi^i_{m[-k]} \psi^{*j}_{t[l]} - \delta_{mt} \psi^i_{s[-k]} \psi^{*j}_{n[l]}.$$

It is easy to see the following commutation relations:

$$[e_{ij}, \psi^s_{t[l]}] = \delta_{js} \psi^i_{t[l]}, \quad [e_{ij}, \psi^{*s}_{t[l]}] = -\delta_{is} \psi^j_{t[l]}, \tag{6.5}$$

and

$$[E^{ij}_{kl}, \psi^s_{t[-m]}] = \delta_{ml} \delta_{jt} \psi^s_{i[-k]}, \quad [E^{ij}_{kl}, \psi^{*s}_{t[m]}] = -\delta_{it} \delta_{km} \psi^{*s}_{j[l]}. \tag{6.6}$$

Let us define the following subspaces of the algebra C_{NM}:

$$U_{t,m} = \sum_{i=1}^{N} \mathbb{C} \psi^i_{t[-m]}, \quad U^*_{t,m} = \sum_{i=1}^{N} \mathbb{C} \psi^{*i}_{t[m]},$$

$$U = \sum_{m \in \mathbb{Z}} \sum_{t=1}^{M} U_{t,m}, \quad U^* = \sum_{m \in \mathbb{Z}} \sum_{t=1}^{M} U^*_{t,m},$$

$$U_+ = \sum_{m>0} \sum_{t=1}^{M} U_{t,m}, \quad U^*_- = \sum_{m \leqslant 0} \sum_{t=1}^{M} U^*_{t,m}.$$

Using (6.5), we have the following observations.

Remark 6.2: (a) The subspaces $U_{t,m}$ (resp., $U^*_{t,m}$) are gl_N-submodules of C_{NM} isomorphic to the standard gl_N-module $\mathbb{C}^N$ (resp., its dual).

(b) C_{NM} is isomorphic to $\wedge(U^* + U)$ as a gl_N-module.

(c) As a gl_N-module, $\mathscr{F}$ is isomorphic to $\wedge(U^*_- + U_+)$.

Proposition 6.2: (a) The centralizer $(C_{NM})^{\mathrm{gl}_N}$ *is the associative subalgebra generated by the elements*

$$E^{ij}_{kl} = \sum_{p=1}^{N} :\psi^{\ p}_{i[-k]} \psi^{*p}_{j[l]}:,$$

where $k,l \in \mathbb{Z}$ *and* $1 \leqslant i,j \leqslant M$.

(b) *Let* $\mathscr{F} = \Sigma_E \mathscr{F}_E$ *be the decomposition of* $\mathscr{F}$ *in a direct sum of isotypic components with respect to* gl_N. *Then each* $\mathscr{F}_E$ *is irreducible with respect to the Lie algebra* $\mathrm{gl}_N \oplus \mathrm{gl}_\infty$ *[cf. (6.4)].*

Proof: The proof of (a) is the same as that of Proposition 2.1 in Ref. 3. Part (b) follows from (a), Remark 6.2, and the modification of the theory of dual pairs of Howe given in Ref. 3, Theorem 1.1. We are also using the isomorphism (6.4). □

Consider

$$\mathrm{gl}_M \otimes \mathrm{gl}_- = \sum_{k,l \leqslant 0} \sum_{i,j=1}^{M} \mathbb{C} E^{ij}_{kl} \subset C^-_{NM},$$

$$\mathrm{gl}_M \otimes \mathrm{gl}_+ = \sum_{k,l > 0} \sum_{i,j=1}^{M} \mathbb{C} E^{ij}_{kl} \subset C^+_{NM}.$$

Under the isomorphism (6.4), these subalgebras correspond to the subalgebras gl_- and gl_+ of gl_∞ defined in Ref. 3, that is, $\mathrm{gl}_- = \Sigma_{k,l\leqslant 0}\ \mathbb{C}E_{kl}$, and $\mathrm{gl}_+ = \Sigma_{k,l>0}\ \mathbb{C}E_{kl}$. From now on we will identify these subalgebras by isomorphism (6.4).

Recall that the standard gl_+ (resp., gl_-)-module is $\mathbb{C}^{+\infty} = \oplus_{j>0}\mathbb{C}v_j$ (resp., $\mathbb{C}^{-\infty} = \oplus_{j\leqslant 0}\mathbb{C}v_j$), with the usual action $E_{ij}v_k = \delta_{jk}v_i$.

Let $\mathfrak{g} = \mathrm{gl}_N \oplus \mathrm{gl}_- \oplus \mathrm{gl}_+$ be a direct sum of Lie algebras. Using (6.5) and (6.6), we obtain the following.

Proposition 6.3: (a) Both $U_\pm^*$ and U_+ are $\mathfrak{g}$-modules. The $\mathfrak{g}$-module U_+ (resp., U_-^*) is isomorphic to the $\mathrm{gl}_N \oplus \mathrm{gl}_+$-(resp., $\mathrm{gl}_N \oplus \mathrm{gl}_-$)-module $\mathbb{C}^N \otimes \mathbb{C}^{+\infty}$ (resp., $\mathbb{C}^N \otimes \mathbb{C}^{-\infty}$) with the trivial action of gl_- (resp., gl_+).

(b) As a $\mathfrak{g}$-module, $\mathscr{F}^{NM}$ is isomorphic to $\wedge(U_-^*) \otimes \wedge(U_+)$.

Thus, we can use the results of Ref. 3 in order to obtain the decomposition of $\mathscr{F}^{NM}$ as a $\mathrm{gl}_N \oplus \widehat{\mathrm{gl}}_\infty$-module.

Theorem 6.3: (cf. Refs. 2 and 3) *The decomposition of the spin representation $\mathscr{F}^{NM}$ as $\mathrm{gl}_N \oplus \mathrm{gl}_\infty$-module is as follows*:

$$\mathscr{F}^{NM} = \bigoplus_{\nu \in H_N} L_N(\nu) \otimes L(\Lambda_\nu, N), \tag{6.7}$$

where $L_N(\nu)$ is the finite-dimensional irreducible representation of gl_N with highest weight ν [i.e., $\nu(e_{ii}) = \nu_i$], and Λ_ν is given by (5.2).

Corollary 6.2. $(\mathscr{F}^{NM})^{\Delta(\mathrm{gl}_N)} \simeq L(0,N)$ *as $\widehat{\mathrm{gl}}_\infty$-modules. Hence, the vertex algebras $(\mathscr{F}^{NM})^{\Delta(\mathrm{gl}_N)}$, $W^M_{1+\infty,N}$, and $V^1(\mathrm{gl}_{NM})^{\Delta(\mathrm{gl}_N)}$ are isomorphic.*

Recall that the labels of the highest weight $\Lambda = (\Lambda_j)_{j\in\mathbb{Z}}$ of the $\widehat{\mathrm{gl}}_\infty$-module $L(\Lambda, c)$ are the numbers $h_i = \Lambda_i - \Lambda_{i+1} + \delta_{i,0}c$, $i \in \mathbb{Z}$; cf. (4.5). It is clear that a sequence $\{h_i\}_{i\in\mathbb{Z}}$ is a sequence of labels of a highest weight Λ that occurs in the decomposition (6.7), iff

$$h_i \in \mathbb{Z}_+, \quad \text{for all} \quad i \in \mathbb{Z}, \quad \text{and} \quad \sum_i h_i = N. \tag{6.8}$$

Remark 6.3: The embedding φ_s of $\mathscr{D}^M$ into $\mathrm{gl}(\infty,\mathbb{C})$ given in (3.1) corresponds to the embedding,

$$\mathscr{D}^M = \mathrm{gl}_M \otimes \mathscr{D} \hookrightarrow \mathrm{gl}_M \otimes \mathrm{gl}_\infty \xrightarrow{\sim} \mathrm{gl}_\infty.$$

Using Theorem 6.3 and Proposition 5.1, we obtain the following.

Theorem 6.4: *With respect to the commuting pair $(\mathrm{gl}_N, \widehat{\mathscr{D}^M})$, the module $\mathscr{F}^{NM}$ decomposes as follows:*

$$\mathscr{F}^{NM} = \bigoplus_{\nu \in H_N} L_N(\nu) \otimes L(\widehat{\mathscr{D}^M}, E_\nu, p_\nu),$$

where E_ν and p_ν are given in Remark 5.2.

Let $s \in \mathbb{C}$ and denote by Γ_s the additive subgroup of $\mathbb{C}$ generated by 1 and s. Consider a Γ_s-twisting of $\mathscr{F}$ by letting the twist of

$$\psi^{i_1}_{m_1[k_1]} \cdots \psi^{i_u}_{m_u[k_u]} \psi^{*j_1}_{n_1[l_1]} \cdots \psi^{*j_t}_{n_t[l_t]} |0\rangle, \quad \text{equal} \quad s(u-t) + \mathbb{Z}.$$

Now, we define a Γ_s-twisted $\mathscr{F}$-module $\mathscr{F}_s$ as follows (cf. Ref. 3). As a vector space we consider $\mathscr{F}_s = \mathscr{F}$, and let

$$Y^{\mathscr{F}_s}(\psi^p_{i[-1]}|0\rangle, x) := x^{-s}\psi^p_i(x), \quad Y^{\mathscr{F}_s}(\psi^{*p}_{j[0]}|0\rangle, x) := x^s \psi^{*p}_j(x),$$

with $1 \leqslant i,j \leqslant M$. In the same way as in Ref. 3, this can be extended inductively to a Γ_s-twisted module structure on $\mathscr{F}_s$.

Let $W^M_{1+\infty,N}$ be the vertex subalgebra of the vertex algebra $\mathscr{F}$ generated by the fields

$$J^l_{ij}(x)=\sum_{p=1}^{N} :\psi_i^p(x)\partial_x^l\psi_j^{*p}(x):, \quad 1\leqslant i,j\leqslant M, \quad l\in\mathbb{Z}_+;$$

in other words, $W^M_{1+\infty,N}$ is the subspace of $\mathscr{F}$ given by the polynomials of the modes of $J^l_{ij}(x)$ applied to $|0\rangle$.

From Corollary 6.2, we obtain the isomorphism of vertex algebras:

$$W^M_{1+\infty,N}=(\mathscr{F}^{NM})^{\Delta(\mathrm{gl}_N)}.$$

Finally, using Theorem 6.3 and Proposition 5.1, we obtain the following result.

Theorem 6.5: *The twisted $\mathscr{F}$-module $\mathscr{F}_s$, viewed as a (nontwisted) module over the vertex algebra $W^M_{1+\infty,N}$, decomposes in a direct sum (with multiplicities) of all primitive modules for which the set of exponents lies in $s+\mathbb{Z}$. In particular, all these primitive $\widehat{\mathscr{D}^M}$-modules are modules over the vertex algebra $W^M_{1+\infty,N}$.*

Corollary 6.3: Any primitive $\widehat{\mathscr{D}^M}$-module extends to a (irreducible) module over the vertex algebra $W^M_{1+\infty,N}$.

*Conjecture 6.1: Let N be a positive integer. Then all irreducible modules over the vertex algebra $W^M_{1+\infty,N}$ are primitive $\widehat{\mathscr{D}^M}$-*modules.

For $M=1$ this has been proved in Ref. 2 using the representation theory of $W(\mathrm{gl}_N)=V^1(\mathrm{gl}_N)^{\mathrm{gl}_N}$. In order to prove Conjecture 6.1 for $M>1$, one needs to develop a representation theory of the vertex algebra $V^1(\mathrm{gl}_{NM})^{\Delta(\mathrm{gl}_N)}$.

Algebraic tools are applied to find integrability properties of ODEs. Bilinear nonassociative algebras are associated to a large class of polynomial and nonpolynomial systems of differential equations, since all equations in this class are related to a canonical quadratic differential system: the Lotka–Volterra system. These algebras are classified up to dimension 3 and examples for dimension 4 and 5 are given. Their subalgebras are associated to nonlinear invariant manifolds in the phase space. These manifolds are calculated explicitly. More general algebraic invariant surfaces are also obtained by combining a theorem of Walcher and the Lotka–Volterra canonical form. Applications are given for Lorenz model, Lotka, May–Leonard, and Rikitake systems. © *1998 American Institute of Physics.* [S0022-2488(98)01905-7]

I. INTRODUCTION

Given a dynamical system it is relevant to determine if the system is integrable. This can be achieved by obtaining constants of motion. If the system is not integrable, the existence of a constant of motion gives substantial information about its solutions. If the system depends on parameters, it is useful to obtain the parameter values for which such constants of motion exist. Even though this is a difficult problem some methods offer a partial answer. We can cite the Painlevé analysis,[1–4] the Lie symmetry method,[5–8] and the compatibility analysis.[9]

In this paper we present a new approach based on an algebraic theory of differential equations initiated by L. Markus[10] and allow for a systematic study of quasi-polynomial dynamical systems. The fundamental contribution of Markus has been the discovery of a link between systems of differential equations with homogeneous quadratic polynomial vector fields and nonassociative commutative algebras.[11] To such a differential system $\dot{x}=p(x)$ defined on an *n-dimensional* vector space V one can associate an algebra with a bilinear multiplication operation as defined below.

Markus showed that two quadratic differential systems are linearly equivalent if and only if their respective associated algebras are isomorphic. He also established a direct connection between geometrical objects such as invariant hyperplanes in V and subalgebras belonging to the above described algebras. Thus, certain properties of the flows generated by differential equations can be studied by investigating the structure of the associated algebras.[12–14]

These concepts have been generalized to polynomial differential systems with degrees higher than 2.[12–14] To a differential system with homogeneous polynomial vector field of degree $m>1$ may be associated a nonassociative commutative m-ary algebra. Their subalgebras are also related to invariant hyperplanes in the phase space of the differential system.

Nonhomogeneous polynomial differential systems[13,14] may also be related to such nonassociative algebras by a straightforward embedding. However, these more general nonassociative algebras are less popular than the bilinear algebras since calculations may become very complex when $m>2$.

In this article we present a different generalization of the ideas of Markus. We show that bilinear algebras may be associated to any polynomial (even of degree larger than 2 and nonhomogeneous) differential systems. This property is even deeper since it applies also to a larger class of differential systems including ''monomials'' with noninteger exponents in their vector fields, the so-called quasi-polynomial systems for which the previous algebras do not exist. This association may be established thanks to the fact that any differential system in the quasi-polynomial class of equations may be related to a universal quadratic canonical form, the Lotka–Volterra system.[15–19] This canonical form is also combined with a theorem due to Walcher relating ideals of polynomials and invariant surfaces. These concepts lead to a constructive theory of very general invariant surfaces and invariants for the quasi-polynomial class of ordinary differential equations (ODEs).

The article is divided into four sections plus four appendices. In Sec. II we present the association of bilinear Lotka–Volterra algebras to general quasi-polynomial differential systems. In Sec. III, the general properties of the Lotka-Volterra nonassociative algebras are studied. A general algorithm is constructed for analyzing the subalgebras. It is illustrated by classifying the 2.3-dimensional Lotka–Volterra algebras. The method presented in Sec. III is applied on two examples: May–Leonard and Lorenz. In Sec. IV the conditions for the existence of algebraic invariant surfaces are obtained and applied on four systems: (α,β,δ) Lotka–Volterra, May–Leonard, Lorenz, and Rikitake. New integrability cases are found. The results of this method are given in the four tables of Appendix D.

II. DIFFERENTIAL EQUATIONS AND NONASSOCIATIVE ALGEBRAS

Let us define the class of quasi-polynomial differential equations as follows:

$$\dot{x}_i = x_i \sum_{j=1}^{m} A_{ij} \prod_{k=1}^{n} x_k^{B_{jk}}, \quad i = 1,...,n, \tag{1}$$

which is defined on R^n or C^n and where the dot means time derivative.

In Eq. (1), A and B are real or complex, constant and rectangular matrices. Moreover, the number m is related to the number of monomials appearing in the vector field of Eq. (1). Thus, m is generally different from n. The use of the term ''quasi-monomial'' for $\Pi_{k=1}^{n}(x_k)^{B_{jk}}$ is, of course, more accurate since the exponents B_{jk} may be real or complex. This explains the denomination of quasi-polynomial differential equation. These equations are ubiquitous in physics, chemical physics, and biomathematics.

The class (1) includes all polynomial differential equations. Indeed, the factor x_i in front of the right side in Eq. (1) may disappear by cancellation with some factors included in $\Pi_{k=1}^{n}(x_k)^{B_{jk}}$. The factor x_i is extracted in Eq. (1) in order to yield certain useful properties for the matrices A and B. Moreover, linear terms may be hidden in the expression (1) depending on the values of certain entries of the B matrix. In order to give a more systematic idea of the domain of applications of the equations of type (1), let us remark that many equations with right-hand sides more general than quasi-polynomials [like $\sin(x)$, $\exp(x)$,...] may be brought to form (1) by an appropriate embedding.[20–22]

A first step in establishing a connection between Eq. (1) and bilinear nonassociative commutative algebra (NACA) is based on the following lemma:

Lemma 1: Any differential system of class (1) is associated to a homogeneous Lotka–Volterra system.

Proof: One way to exhibit this property is to consider the time evolution of all the quasi-monomials in Eq. (1). Thus, let us define new variables $U_j = \Pi_{k=1}^{n}(x_k)^{B_{jk}}$, $j = 1,...,m$. The differential equations obeyed by these variables can easily be derived from Eq. (1) and read

$$\dot{U}_i = U_i \sum_{l=1}^{m} M_{jl} U_l, \quad j = 1,...,m, \tag{2}$$

where $M = BA$ (matrix product). The same result has been shown earlier by using quasi-monomials transformations and an appropriate embedding.[15,16]

Thus, Eq. (1) can be recast in the following system:

$$\dot{x}_i = x_i \sum_{j=1}^{n} A_{ij} U_j, \quad \dot{U}_j = U_j \sum_{l=1}^{m} M_{jl} U_l, \quad i = 1,...,n, \quad j = 1,...,m. \tag{3}$$

Since the first equation in this system is linear in x, the essential properties of the solutions of Eq. (1) are already embedded in Eq. (2) which is closed in U.

We want to stress here that Eq. (2) is a homogeneous quadratic equation but not the most general one which would be given by

$$\dot{V}_i = \sum_{j,k=1}^{m} C_{ijk} V_j V_k, \quad i = 1,...,m. \tag{4}$$

In fact, Eq. (2), the so-called homogeneous Lotka–Volterra equation,[23–25] is a particular case of (4) which amounts to choosing the tensor C as follows:

$$C_{ijk} = \tfrac{1}{2}(\delta_{ik} M_{kj} + \delta_{ij} M_{jk}). \tag{5}$$

We are now ready for the second step, i.e., the connection of (1) with a nonassociative commutative algebra (NACA).[26,27] This is made along the definition given by Markus in 1960[10] for homogeneous quadratic differential equations:

Definition 1: To a homogeneous quadratic differential system of type (4), where C_{ijk} is symmetric in j,k, one can associate an algebra based on the vector space R^n or C^n and whose multiplication is defined for a basis $e_1,\ldots,e_m$ as follows:

$$e_i \cdot e_j = \sum_{k=1}^{m} C_{kij} e_k. \tag{6}$$

We may thus apply this definition to Eq. (2) which is homogeneous and quadratic. This leads to the following theorem.

Theorem 1: *Differential equations with quasi-polynomial vector fields (1) are associated to bilinear NACAs, whose structure tensor is given by (5), where $M = BA$.*

We would like to stress at this level that in previous works differential systems with homogeneous polynomial vector fields of degree k were only associated to a k-ary NACA.[12–14] Furthermore, such algebras are not defined whenever noninteger exponents appear in the vector field.

In contrast, we have shown here the following: *any quasi-polynomial differential system is associated to a bilinear NACA.*

To end this section, let us remark that the bilinear NACAs we found have a universal structure based on an object which is a matrix: the Lotka–Volterra interaction matrix M. All differential systems of type (1) with matrices A and B such that the product BA is equal to the same matrix M have the same bilinear algebra. They belong to the same equivalence class.

III. STRUCTURE OF LOTKA–VOLTERRA ALGEBRAS

A. Definitions and theorems

The qualitative behavior of the solutions to the systems belonging to the class (1) will now be analyzed through their associated Lotka–Volterra algebras. Indeed, Markus[10] proved two basic theorems for quadratic differential systems. They are the following:

Theorem 2: *Two quadratic differential systems are equivalent under a nonsingular linear transformations iff their related NACAs are isomorphic.*

Theorem 3: *A quadratic m-dimensional differential system has an invariant r-plane* ($1 \leqslant r \leqslant m$) *through the origin iff the related NACA has an r-dimensional subalgebra.*

These results may be directly applied to the Lotka–Volterra equation associated to a given quasi-polynomial system. We consequently may find invariant r-planes for this Lotka–Volterra

equation. Now, how are these r-planes related to the geometry of the phase portrait of the original equation (1)? To clarify this, let us first write the equation of an r-plane passing through the origin in the m-dimensional phase space of the Lotka–Volterra system (2):

$$\sum_{j=1}^{m} l_{ij} U_j = 0, \quad i = 1,...,m-r.$$

It is an invariant r-plane if the coefficients l_{ij} satisfy the existence conditions of a r-dimensional subalgebra of the Lotka–Volterra NACA. Next, we know that the U_i are quasi-monomials in the variable x_i of the equation (1):

$$U_i = \prod_{k=1}^{n} x_k^{B_{ik}}, \quad i = 1,...,m.$$

We have thus shown the following result: *the invariant surface for the original system (1) associated to the existence of an r-dimensional subalgebra of the Lotka–Volterra NACA is an r-dimensional manifold:*

$$\sum_{j=1}^{m} l_{ij} \prod_{k=1}^{n} x_k^{B_{jk}} = 0, \quad i = 1,...,m-r. \tag{7}$$

The geometric properties of the phase portrait for (1) can thus be classified along the structures of the Lotka–Volterra NACAs. We propose now to carry on this algebraic classification. First of all we must introduce some useful definitions:

Definition 2: Let us define a basis of the Lotka–Volterra algebra—LV-NACA—as the set of linearly independent vectors $e_1,\ldots,e_m$ *for which the multiplication is defined by Eq. (6) and tensor (5). We shall call axial algebras the one-dimensional subalgebras generated by each of the* e_i. $\langle e_i \rangle$.

Definition 3: The algebras $\langle e_{i_1},\ldots,e_{i_p} \rangle$ *will be called faces or facial algebras. Here the indices* $i_1,\ldots,i_p$ *are all different and take the values* $1,...,m$.

Definition 4: We define $v_{(i_1,\ldots,i_p)}$ *as the generator of a one-dimensional subalgebra which belongs to the face* $\langle e_{i_1},\ldots,e_{i_p} \rangle$ *and does not belong to any subface belonging to the face* $\langle e_{i_1},\ldots,e_{i_p} \rangle$.

Since $v_{(i_1,\ldots,i_p)}$ generates a one-dimensional algebra, it must satisfy

$$v_{(i_1,\ldots,i_p)} \cdot u_{(i_1,\ldots,i_p)} = \lambda v_{(i_1,\ldots,i_p)}, \tag{8}$$

where $\lambda \in C$. When $\lambda = 0$, $v_{(i_1,\ldots,i_p)}$ is called a *nilpotent* element; if $\lambda = 1$, $v_{(i_1,\ldots,i_p)}$ is an *idempotent* element.

Definition 5: The $p \times p$ *submatrix of M obtained by erasing the lines and columns of indices not in* $\{i_1,\ldots,i_p\}$ *will be denoted* $M^{(i_1,\ldots,i_p)}$.

Definition 6: The matrix obtained by replacing the column i of a matrix N by a column where all entries are 1 is denoted $N^{(i)}$.

Another useful property concerns the multiplication rule. Let us compute the product of two elements of the algebra

$$w_1 \cdot w_2 = \left(\sum_{i=1}^{m} w_{1i} e_i \right) \cdot \left(\sum_{j=1}^{m} w_{2j} e_j \right).$$

Hence

$$w_1 \cdot w_2 = \sum_{i,j=1}^{m} w_{1i} w_{2j} e_i \cdot e_j$$

and finally

$$w_1 \cdot w_2 = \sum_{k=1}^{m} [w_{1k}(Mw_2)_k + w_{2k}(Mw_1)_k]e_k, \tag{9}$$

where Mw_i means the action of matrix M on vector w_i. We now state two fundamental theorems:

Theorem 4: *Let us consider* $N = M^{(i_1,\ldots,i_p)}$. *Two cases are possible: (a) If* $\det(N) \neq 0$ *and* $\det(N^{(i)}) \neq 0$, *then a one-dimensional subalgebra generated by* $v_{(i_1,\ldots,i_p)}$ *exists. (b) If* $\det(N) = 0$, *then the kernel of N generates a nilpotent subalgebra (called in the following nul-algebra).*

Proof: Let us expand $v_{(i_1,\ldots,i_p)}$ in the basis $e_{i_1},\ldots,e_{i_p}$:

$$v_{(i_1,\ldots,i_p)} = \sum_{k=1}^{p} \gamma_k e_{i_k}, \tag{10}$$

where by definition $\gamma_1,\ldots,\gamma_p$ are all different of zero. We now insert Eq. (10) into Eq. (8), yielding

$$\sum_{k,l=1}^{p} \gamma_l \gamma_k (e_{i_k} \cdot e_{i_l}) = \lambda \sum_{r=1}^{p} \gamma_r e_{i_r}. \tag{11}$$

We use formula (9) for the left-hand side of (11) and obtain

$$(M^{(i_1,\ldots,i_p)}\gamma)_i = \frac{\lambda}{2}, \quad i = 1,\ldots,p, \tag{12}$$

where γ is the vector $(\gamma_1,\ldots,\gamma_p)$. From (12) it is clear that if $\det(M^{(i_1,\ldots,i_p)}) \neq 0$, then necessarily $\lambda \neq 0$ and the vector γ is uniquely determined. The solution of (12) is given by

$$\gamma_i = \frac{\det(N^{(i)})}{\det(N)} \frac{\lambda}{2}. \tag{13}$$

Otherwise, if $\det(M^{(i_1,\ldots,i_p)}) = 0$, the kernel of $M^{(i_1,\ldots,i_p)}$ generates a nilpotent algebra. Some comments on these results are here necessary:

(1) The property of idempotence or nilpotence depends entirely on the rank of the corresponding submatrix $M^{(i_1,\ldots,i_p)}$.
(2) When $M^{(i_1,\ldots,i_p)}$ is not of maximal rank, then its kernel is itself a nul-algebra.
(3) In some exceptional but evident cases the condition $\det(M^{(i_1,\ldots,i_p)}) = 0$ may not necessarily imply $\lambda = 0$.

This result exhausts all the possible structures of the one-dimensional subalgebras of a LV-NACA. The second fundamental theorem is the following:

Theorem 5: *A p-dimensional subalgebra of the LV-NACA is always generated by a set of one-dimensional subalgebras.*

Proof: The proposition is clearly true for Lotka–Volterra algebras of dimension 1. Let us suppose the theorem to be true for a Lotka–Volterra with dimension $m-1$. Now, let us consider a p-dimensional subalgebra $B_{(p)}$ which belongs to an m-dimensional LV-NACA. It is easy to see that the intersection between $B_{(p)}$ and any face in this LV-NACA is a $(p-1)$-dimensional subalgebra belonging to the face. However, any face is a LV-NACA of dimension $m-1$, hence this intersection is generated by $(p-1)$ one-dimensional subalgebras. This shows that there exists a set of one-dimensional subalgebras which generates $B_{(p)}$.

Those two theorems provide an algorithm for constructing the existence conditions of any $(m-r)$-dimensional subalgebra of a LV-NACA of dimension m.

Indeed, let us consider an $(m-r)$-dimensional subalgebra $B_{(m-r)}$ and the facial algebra $\langle e_1,\ldots e_{m-1}\rangle$. Then

$$B_{(m-r)} \cap \langle e_1,\ldots,e_{m-1}\rangle = A_{(m-r-1)},$$

which is an $(m-r-1)$-dimensional subalgebra of the face.

By construction, there always exist $r+1$ axial vectors which are transversal to $A_{(m-r-1)}$. These vectors constitute a subface $\langle e_{i_1},\ldots,e_{i_r},e_m\rangle$ with $i_1,\ldots,i_r\in\{1,...,m-1\}$. Now, the intersection

$$B_{(m-r)}\cap\langle e_{i_1},\ldots,e_{i_r},e_m\rangle$$

is a one-dimensional subalgebra generated by a vector $v_{(j_1,\ldots,j_p)}$ (with $p\leqslant r+1$ and $j_1,\ldots,j_p\in\{i_1,\ldots,i_r,m\}$). Thus

$$B_{(m-r)}=\langle A_{(m-r-1)},v_{(j_1,\ldots,j_p)}\rangle.$$

If $A_{(m-r-1)}$ is known, this yields $B_{(m-r)}$.

We now illustrate this algorithm on 2-dimensional and 3-dimensional algebras.

B. Two-dimensional LV-NACAs

Let us construct the conditions for the existence of one-*dimensional* nonaxial algebras for a two-dimensional LV-NACA. By definition, the generator satisfies

$$v_{(1,2)}\cdot v_{(1,2)}=\lambda v_{(1,2)}.$$

Here $v_{(1,2)}=w_1e_1+w_2e_2$.

Using formula (9) we obtain

$$w_1(Mw)_1=\frac{\lambda}{2}w_1,\quad w_2(Mw)_2=\frac{\lambda}{2}w_2, \tag{14}$$

where M is a 2×2 matrix and w_1 and w_2 are nonvanishing (if this would not be the case, the one-dimensional subalgebra would be axial). Now, there are two possibilities:

(1) $\det(M)\neq0$: In this case the solution of (14) is the generator of a one-dimensional subalgebra:

$$v_{(1,2)}=(M_{12}-M_{22})e_1+(M_{21}-M_{11})e_2, \tag{15}$$

where $(M_{12}-M_{22})(M_{21}-M_{11})\neq0$.

(2) $\det(M)=0$: Here again, there are two possibilities:

(a) $(M_{12}-M_{22})(M_{21}-M_{11})\neq0$. Here, formula (8) is still true but $v_{(1,2)}\cdot v_{(1,2)}=0$.

(b) $M_{12}=M_{22}$ and $M_{21}=M_{11}$. Then w_1 and w_2 are arbitrary and $v_{(1,2)}=w_1e_1+w_2e_2$ is any vector. There is an infinite family of one-dimensional subalgebras.

C. Three-dimensional LV-NACAs

We first analyze the one-dimensional subalgebras. The possible generators are, in this case, e_1, e_2, e_3, $v_{(1,2)}$, $v_{(1,3)}$, $v_{(2,3)}$, and $v_{(1,2,3)}$. The algebras generated respectively by e_1,e_2,e_3 are obvious. As to the generators $v_{(1,2)},v_{(1,3)},v_{(2,3)}$, the analysis is the same as for the two-dimensional LV-NACA with the matrix M successively replaced by $M^{(1,2)}$, $M^{(2,3)}$, and $M^{(1,3)}$. Finally, concerning the one-dimensional algebras generated by $v_{(1,2,3)}=w_1e_1+w_2e_2+w_3e_3$ (with $w_1,w_2,w_3\neq0$), we have

$$Mv_{(1,2,3)}=\frac{\lambda}{2}. \tag{16}$$

Hence, there are again two cases:

(a) $\det(M)\neq0$: thus, $v_{(1,2,3)}=M^{-1}\frac{\lambda}{2}$. This yields a one-dimensional non-nul-algebra.

(b) $\det(M)=0$: in this case $\lambda=0$. If rank $(M)=2$, there exists a one-dimensional nul-algebra, and if rank $(M)=1$, there exists a two-dimensional nul-algebra. This closes the analysis of the one-dimensional subalgebras.

Next, we study the two-dimensional subalgebras of a three-dimensional LV-NACA. Clearly, we may limit the existence analysis to the nonfacial two-dimensional subalgebras. We now apply the second fundamental theorem to this case: let B_2 be a two-dimensional subalgebra. Then, the intersection $B_2 \cap \langle e_1, e_2 \rangle = A_1$ may be generated by three possible generators: e_1, e_2, and $v_{(1,2)}$. For each of these generators we may proceed as follows: we consider the two-dimensional facial subalgebra $\langle e_i, e_3 \rangle$ $(i=1,2)$ which excludes A_1. The last step in building the two-dimensional subalgebras amounts to taking $B_2 \cap \langle e_i, e_3 \rangle$, which yields as possible generators e_3 or $v_{(i,3)}$. Thus, the admitted two-dimensional subalgebras are $B_2 = \langle A_1, e_3 \rangle$ or $B_2 = \langle A_1, v_{(i,3)} \rangle$, $i=1,2$.

Let us now explicitly list these B_2 subalgebras (excluding from it the facial subalgebras) and their respective existence conditions:

$$
\begin{aligned}
&B_2 = \langle e_1, v_{(2,3)} \rangle, \quad M_{21} = M_{31}, \\
&B_2 = \langle e_2, v_{(1,3)} \rangle, \quad M_{12} = M_{32}, \\
&B_2 = \langle v_{(1,2)}, e_3 \rangle, \quad M_{13} = M_{23}, \\
&B_2 = \langle v_{(1,2)}, v_{(2,3)} \rangle, \\
&(M_{12} - M_{22})(M_{23} - M_{33})(M_{31} - M_{11}) + (M_{13} - M_{33})(M_{21} - M_{11})(M_{32} - M_{22}) = 0.
\end{aligned}
\tag{17}
$$

The above considerations yield the existence conditions for all the possible subalgebras of a three-dimensional LV-NACA. It should be stressed that these conditions are all expressed in terms of the matrix $M = BA$ of the quasi-polynomial system (1). We end this chapter with two applications.

D. Applications

We apply the above method to the May–Leonard and Lorenz systems. For both examples the Lotka–Volterra matrix $M = BA$ is easily computed. For the May–Leonard system the M matrix is 4×4, whereas for the Lorenz system M is 5×5. The algebraic structures of both systems are to be obtained as follows.

1. May–Leonard system

The May–Leonard system[28] is given by

$$
\begin{aligned}
\dot{x}_1 &= l_1 x_1 - x_1(x_1 + \alpha x_2 + \beta x_3), \\
\dot{x}_2 &= l_2 x_2 - x_2(\beta x_1 + x_2 + \alpha x_3), \\
\dot{x}_3 &= l_3 x_3 - x_3(\alpha x_1 + \beta x_2 + x_3).
\end{aligned}
\tag{18}
$$

It can be cast in the Lotka–Volterra form using the monomials $U_1 = 1$, $U_2 = x_1$, $U_3 = x_2$, and $U_4 = x_3$. The corresponding M matrix as defined in Eq. (2) is given by

$$
M = \begin{bmatrix} 0 & 0 & 0 & 0 \\ l_1 & -1 & -\alpha & -\beta \\ l_2 & -\beta & -1 & -\alpha \\ l_3 & -\alpha & -\beta & -1 \end{bmatrix}. \tag{19}
$$

The generators of one-dimensional sub-algebras are obtained solving equation (12) and using Theorem 3. The results are summarized in Table I (Appendix A) for the case (1) and (2) (a) in Sec. III B corresponding to face $U_1 = 0$. The degenerate case $(\alpha = \beta = 1)$, which corresponds to case (2)(b) in Sec. III B for the face $U_1 = 0$, has a different structure as shown in Table II (Appendix A).

Two- and three-dimensional subalgebras existence conditions are given in Tables IV and VI (Appendix B) for the general and degenerate cases, respectively. For the degenerate case the two- and three-dimensional subalgebras are given in Table V (Appendix B). We obtained one- and

two-dimensional invariant manifolds for the May–Leonard system for the parameters values given in the tables of Appendix B. This is, to our knowledge, a result not found in the literature.

For the three-dimensional subalgebras the existence conditions reported in tables of Appendix B correspond to similar result by Cairo and Feix[29] who obtained algebraic equations for the components of M. In contrast to the method of Cairo and Feix our approach yields all the solutions of these equations.

2. Lorenz system

The Lorenz system[30,31] reads

$$\begin{aligned} \dot{x}_1 &= \sigma(x_2 - x_1), \\ \dot{x}_2 &= \rho x_1 - x_2 - x_1 x_3, \\ \dot{x}_3 &= -\beta x_3 + x_1 x_2. \end{aligned} \tag{20}$$

The Lotka–Volterra form is obtained using the quasi-monomials $U_1=1$, $U_2=x_1^{-1}x_2$, $U_3=x_1x_2^{-1}$, $U_4=x_1x_2^{-1}x_3$, and $U_5=x_1x_2x_3^{-1}$. Its form is given by Eq. (2) with the following matrix:

$$M=\begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ \sigma-1 & -\sigma & \rho & -1 & 0 \\ 1-\sigma & \sigma & -\rho & 1 & 0 \\ 1-\sigma-\beta & \sigma & -\rho & 1 & 1 \\ \beta-1-\sigma & \sigma & \rho & -1 & -1 \end{bmatrix}. \tag{21}$$

In our analysis the parameters σ, ρ, and β are considered as nonvanishing.

The generator of one-dimensional subalgebras are given in Table III (Appendix A). The higher dimensional subalgebras are given in Tables VII (Appendix C). The subalgebras existence conditions are given in Table VIII (Appendix C).

IV. ALGEBRAIC INVARIANT SURFACES

As seen above, the LV-NACA's subalgebras yield invariant manifolds whose equations may only contain quasi-monomials already appearing in the vector field of Eq. (1). In this section, we briefly present a further extension of the algebraic method in order to study a larger class of invariant manifolds including more general quasi-monomials.

We define the flow of the Lotka–Volterra system (2) by the function $U(U_0,t)$ which satisfies (2) and such that $U(U_0,0)=U_0$. In fact, $U(U_0,t)$ is the solution curve to the system (2) with initial conditions U_0. We say that a surface $S\subset R^m$ is an invariant surface of the Lotka–Volterra system (2) if, for any $U_0\in S$, $U(U_0,t)\in S$ for all t.

Now, we denote the ring of all polynomial functions by $\mathrm{Pol}\,[U]$. We consider a surface $S\subset\mathbb{R}^m$, an ideal $I\subset\mathrm{Pol}\,[U]$, and define two special sets: (a) the ideal $J(S)=\{f\in\mathrm{Pol}\,[U]/f(S)=0\}$ and (b) the surface $S(I)=\{U\in\mathbb{R}^m/\forall f\in I, f(U)=0\}$.

According to the above definitions and using results due to Walcher[14] we can state the following theorem.

Theorem 6: *For any autonomous polynomial dynamical system we have the following properties:*

(a) *If* $(d/dt)(I)\subset I$, *then* $S(I)$ *is an invariant surface.*
(b) *If* $S\subset\mathbb{R}^m$ *is an invariant surface, then* $(d/dt)(J(S))\subset J(S)$.

Here, we remember that

$$\frac{d}{dt}=\sum_{i=1}^{m}\left(U_i\sum_{j=1}^{m}M_{ij}U_j\right)\frac{\partial}{\partial U_i}$$

is a differential operator and $\dot{f}=(d/dt)(f)$ is the derivative of f along the flow of the Lotka–Volterra system (2).

We know that any ideal $I\subset \mathrm{Pol}[U]$ is finitely generated. Hence, if $I=\langle P_1,\ldots P_q\rangle$, then the surface $S(I)$ is defined by the system of q polynomials equations

$$P_i(U_1,\ldots,U_m)=0, \quad i=1,...,q. \tag{22}$$

Here $S(I)$ is a surface of dimension $m-q$. In fact, the polynomials invariant surfaces S given by Eqs. (22) generalize the invariant hyperplanes presented in Sec. IV. Indeed, the invariant hyperplanes correspond to the case where the P_i are linear.

If there exists a polynomial $P(U)$ satisfying the equation $P=\lambda P$, with $\lambda\in \mathrm{Pol}[U]$, then, by Theorem 6, we conclude that the surface, given by $P(U)=0$, is an $(m-1)$-dimensional invariant surface for the system (2). In this case $P(U)$ is called a semi-invariant or a Darboux polynomial[32,33] and we denote the set of all semi-invariants of a given Lotka–Volterra system by $SI[U]$. Moreover, it can be shown that λ (see Ref. 14) is necessarily a linear function.

Let us show now the link between semi-invariants and a particular class of invariants for the system (2). Consider a class of invariants of the form

$$K=\prod_{i=1}^{m} U_i^{\alpha_i} P(U_1,\ldots,U_m), \tag{23}$$

where the α_i are real numbers and $P(U)$ is a polynomial function. Cairo, Feix, and Hua[29,33] have studied invariants of this form. The equation for an invariant is

$$\dot{K}=\sum_{j=1}^{m} \frac{\partial K}{\partial U_j}\,\dot{U}_j=0. \tag{24}$$

Then, by inserting (2) and (23) in (24) we obtain

$$\prod_{i=1}^{m} U_i^{\alpha_i}(\dot{P}-\lambda P)=0, \tag{25}$$

where $\lambda=-\Sigma_{j=1}^{m}(\alpha M)_j U_j$ and $(\alpha M)_j=\Sigma_{k=1}^{m}\alpha_k M_{kj}$. The condition (25) is equivalent to

$$\dot{P}=\lambda P. \tag{26}$$

Thus, P is a semi-invariant.

Let us define the set $L[U]$ of all linear functions on U, and the set $SI[U]$ of all semi-invariants of the system (3). We also define the function $\Lambda: SI[U]\to L[U]$ associating to any $P\in SI[U]$ its corresponding eigenvalue given in Eq. (26), and the mapping $\hat{M}: R^m\to L[U]$ which associates the vector $\alpha\in R^m$ to the linear function $\Sigma_{i=1}^{m}(\alpha M)_i U_i$. With these definitions, we conclude that a function of the type (23) is an invariant for the system (2) if two conditions are satisfied:

(a) There is a semi-invariant for the system.
(b) Image $(\hat{M})\cap$ Image $(\Lambda)\neq\varnothing$.

To end this section, we observe that the invariant surface given by (22) and the invariant of the form (23) in the Lotka–Volterra variables correspond respectively to the following invariant surface and invariant in the original variable x of system (1):

$$P_i\left(\prod_{k=1}^{n} x^{B_{1k}},\ldots,\prod_{k=1}^{n} x^{B_{mk}}\right)=0, \quad i=1,...,q,$$

and

$$K=\prod_{k=1}^{n} x_i^{(\alpha B)_i} P\left(\prod_{k=1}^{n} x^{B_{1k}},\ldots,\prod_{k=1}^{n} x^{B_{mk}}\right).$$

Such invariants are clearly more general than those furnished by the NACA approach.

A. Applications

In this section we apply our method to the well studied (α,β,δ) Lotka–Volterra. May–Leonard, Lorenz, and Rikitake systems. To obtain the solutions for Eq. (25) we used a computer algebra in MAPLE written by the authors.[34] All computations for the semi-invariants are performed to polynomials of degree up to 5. The results are shown in Appendix D. We observe that since any quasi-monomial is a semi-invariant, they are not reported in the tables.

1. (α,β,δ) Lotka–Volterra system

The (α,β,δ) Lotka–Volterra system with vanishing eigenvalues[35] is given by

$$\begin{aligned}\dot{x}_1&=x_1(\delta x_2+x_3),\\ \dot{x}_2&=x_2(x_1+\alpha x_3),\\ \dot{x}_3&=x_3(\beta x_1+x_2).\end{aligned}\tag{27}$$

The monomials are trivially obtained: $U_1=x_1$, $U_2=x_2$, and $U_3=x_3$. The matrix M is given by

$$M=\begin{bmatrix}0 & \delta & 1\\ 1 & 0 & \alpha\\ \beta & 1 & 0\end{bmatrix}.\tag{28}$$

The semi-invariants and the corresponding quasi-polynomials invariants (QP-invariants) obtained for this system are given in Table IX (Appendix D). We obtained more cases than in a similar study performed by Labrunie and Conte,[32] who looked for rational invariants obtained from semi-invariants with the same eigenvalue.

Our analysis yields some interesting results: cases 4 and 10–20 are new integrable cases not found in the literature to the authors' knowledge (an exhaustive study of all known cases can be found in Ref. 35). Cases 3, 5, 8, and 9 are particular cases for more general classes of integrable Lotka–Volterra systems for which only one invariant was known[35] and the invariant obtained in this work is a new one not yet obtained. Case 2 is a known integrable class with a new invariant obtained here. Cases 6 and 7 are particular cases of integrable classes for which our approach does not yield any invariant. Nonetheless we obtained an invariant surface that, together with the known invariant, determines the orbit of the system. All know quasi-polynomial invariants for this system plus some new cases were obtained.

2. May–Leonard system

This system, the corresponding monomials, and the matrix M are given in Sec. III D by Eqs. (18) and (19). The semi-invariants and the corresponding QP-invariants are given in Table IX (Appendix D). The linear semi-invariants correspond to cases already obtained by the three-dimensional subalgebras in Table I (Appendix B).

3. Lorenz system

This system is described in Sec. III D by Eqs. (20) and (21). The results obtained are given in Table XI (Appendix C). Most known integrable cases[31] are obtained here while Labrunie and Conte[32] obtained only the cases ($\beta=2\sigma$) and ($\beta=1$, $\rho=0$).

4. Rikitake system

The Rikitake system[36] is given by

$$\dot{x}_1=-\mu x_1+x_2(x_3+\beta),$$

$$\dot{x}_2=-\mu x_2+x_1(x_3-\beta), \tag{29}$$

$$\dot{x}_3=\alpha-x_1x_2.$$

The monomials are $U_1=1$, $U_2=x_1^{-1}x_2x_3$, $U_3=x_1^{-1}x_2$, $U_4=x_1x_2^{-1}x_3$, $U_5=x_1x_2^{-1}$, $U_6=x_3^{-1}$, and $U_7=x_1x_2x_3^{-1}$. The matrix M is given by

$$M=\begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & -\beta & 1 & -\beta & 1 & -1 \\ 0 & -1 & -\beta & 1 & -\beta & 0 & 0 \\ 0 & 1 & \beta & -1 & \beta & 1 & -1 \\ 0 & 1 & \beta & -1 & \beta & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 & 1 \\ -2\mu & 1 & \beta & 1 & -\beta & -1 & 1 \end{bmatrix}. \tag{30}$$

Our results are shown in Table XII (Appendix D) and coincide with those obtained by Labrunie and Conte.[32]

V. CONCLUSION

We have shown how some algebraic concepts such as nonassociative algebras and polynomial ideals associated to systems of ODEs generate a systematic theory for finding invariant surfaces and invariants for the quasi-polynomial ODEs systems. These results are both exhaustive and constructive in a given functional class. Our next step will be, using the same tools, the generalization of these results to more general functional classes of invariants and the exploration of nonintegrability conditions.

ACKNOWLEDGMENTS

We are all indebted to Mr. L. Ferier for useful discussions during the preparation of this manuscript. Davey–Stewartson type equations of the second and third order: Derivation and classification

Alejandra Folguera
Department of Theoretical and Applied Mechanics, University of Illinois, Urbana, Illinois 61801

(Received 17 November 1997; accepted for publication 17 December 1997)

The inverse spectral method provides an algorithm for generating and solving integrable equations. Here we apply this method to study a family of nonlinear partial differential equation (PDEs) which are two spatial dimensional generalizations of the nonlinear Schrödinger (NLS), the Korteweg–de Vries (KdV) and the modified Korteweg–de Vries (m-KdV) equations. We find simple transformations which reduce this family to a few canonical systems which include the Davey–Stewartson, the Nizkhik–Veselov–Novikov (NVN), and the modified NVN (mod-NVN) equations, and the equations recently derived by Fokas. We also construct Miura maps between the modified NVN and the NVN equations which are valid without any restrictions in the space of solutions. Finally, we present the bi-Hamiltonian formulation of some of the systems presented here. © *1998 American Institute of Physics.* [S0022-2488(98)02005-2]

I. INTRODUCTION

There exists the misconception that there are fewer nonlinear integrable equations in $2+1$ (two space, one time) dimensions than in $1+1$ (one space, one time). It was noticed in Ref. 1 that the $2+1$ generalization of $1+1$ systems corresponding to the NLS equation yields a family of $2+1$ systems that can be parametrized by two real numbers. As it turns out, this family reduces to a few canonical systems. In this paper we study the general structure of the $2+1$ equations generated by the procedure proposed in Ref. 1. The main contributions of this work are:

(a) we derive the two-parameter family of $2+1$ equations of second and third order whose one-dimensional reduction is the nonlinear Schrödinger equation, the KdV, and the modified KdV equations;
(b) we give the transformations that reduce this family to a few canonical systems;
(c) we give the complete list of all canonical systems;
(d) for the third-order systems, we construct Miura maps; and
(e) we derive the bi-Hamiltonian formulation for the above systems.

The equations considered here support *dromion* solutions. That is, there is a family of traveling wave solutions that is localized in space whose path is determined by the so-called boundary functions [the terms containing U and V's in Eqs. (6) and (11)]. The problem of finding such solutions is considered in Ref. 2 and in a companion paper.[3]

Consider the prototypical example of an integrable equation in $1+1$, the nonlinear Schrödinger equation,

$$iq_t+q_{xx}\pm\tfrac{1}{2}q|q|^2=0, \tag{1}$$

and its natural integrable generalization to $2+1$ dimensions, the Davey–Stewartson (DS) equation,

$$iq_t=q_{\eta\eta}+q_{\xi\xi}+\frac{q}{2}\left[\partial_\xi^{-1}(|q|^2)_\eta+\partial_\eta^{-1}(|q|^2)_\xi\right]. \tag{2}$$

The DS equation was introduced in Ref. 4 and by Ref. 5 in the context of water waves.

 © 1998 American Institute of Physics

For our purposes, a system of nonlinear partial differential equations (PDEs) is said to be integrable if it admits a Lax pair formulation. The Lax pair is completely determined by the Lax equation and the degree of the dispersion relation. In the case of the NLS equation, the Lax equation is

$$L\Psi=\left[\begin{pmatrix}\partial_x+ik & 0\\ 0 & \partial_x-ik\end{pmatrix}+Q\right]\Psi=0,\quad \text{where } Q=\begin{pmatrix}0 & q\\ r & 0\end{pmatrix}, \tag{3}$$

and $r=\pm q$. We postulate a solution of the form $\Psi=\mu\ \exp(ikJ+\Omega(k)t)$, where $J=\mathrm{diag}\{1,-1\}$, $\mu=I+\mathcal{O}(1/k)$, and Ω is called the *dispersion function*. For a dispersion of order two, i.e., $\Omega(k)=k^2$, we denote the second equation in the Lax pair by

$$L_2\Psi=0.$$

For order three, i.e., $\Omega(k)=k^3$, we denote the second equation in the Lax pair by

$$L_3\Psi=0.$$

The compatibility of L and L_2 yields the system of two nonlinear equations for q and r:

$$iq_t+q_{xx}+\tfrac{1}{2}q(qr)=0,\quad ir_t+r_{xx}+\tfrac{1}{2}r(rq)=0.$$

These equations reduce to (1) in the case $q=\pm\overline{r}$. The compatibility of L and L_3 yields the third-order system

$$q_t+q_{xxx}+6qrq_x=0,\quad r_t+r_{xxx}+6qrr_x=0.$$

This system has two possible reductions. If $r=q$, then the system reduces to the modified KdV equation,

$$q_t+q_{xxx}+6q^2q_x=0.$$

If $r=-1$, then the system reduces to the KdV equation,

$$q_t+q_{xxx}-6qq_x=0.$$

The following chart summarizes the list of $1+1$ nonlinear equations stemming from the Lax equation (3), together with $\Omega(k)=k^2$ and $\Omega(k)=k^3$.

2nd Order Equations	3rd Order Equations
Nonlinear Schrödinger	KdV modified KdV

The above scheme generalizes to $2+1$ equations by replacing the ik appearing in (3) by ∂_y. A problem will be said to be of the DS type if it can be obtained as the compatibility condition of a pair of matrix differential operators, one of which is

$$L=\begin{pmatrix}\partial_x+\sigma\partial_y & 0\\ 0 & \partial_x-\sigma\partial_y\end{pmatrix}+\begin{pmatrix}0 & q\\ r & 0\end{pmatrix},\quad \sigma^2=\pm1. \tag{4}$$

As before, the operator which involves the variable t is completely determined once the order of the dispersion function Ω is chosen. In $2+1$, the dispersion relation $\Omega(k)=k^n$ can be generalized by introducing two real parameters α and β as follows:

$$\Omega(k)=k^n\begin{pmatrix}\alpha+\beta & 0\\ 0 & \alpha-\beta\end{pmatrix}. \tag{5}$$

We call DS-type systems of order two and three those equations corresponding to $n=2$ and 3, respectively. Thus the DS-type systems are parametrized by two real parameters α and β. It turns out that simple transformations reduce them to a few canonical systems. We summarize the comprehensive list of all such systems here and refer the reader to Sec. II for the actual equations.

The canonical second-order systems of order three: [i.e., equations corresponding to (4) and (5) with $n=2$]

	$\sigma=1$	$\sigma=i$
$\alpha=0,\ \beta=1$	DST stystem I	DST system II
$\alpha=1,\ \beta=0$	DST system III	DST system II
$\alpha=\beta=1/2$	2nd order F T system I	2nd order F T system II

where DST is DS type and FT is Fokas' type. We note that for $\sigma=i$ the equations for $(\alpha,\beta)=(1,0)$ and $(\alpha,\beta)=(0,1)$ are equivalent.

These systems reduce to a single equation when certain relations are imposed on q and r. In the case of the second-order system, the reduction $r=\epsilon\overline{q}$ ($\epsilon=\pm 1$ and $\overline{q}$ denotes the complex conjugate of q) yields

	$\sigma=1$	$\sigma=i$
$\alpha=0,\ \beta=1$	DS I	DS II
$\alpha=1,\ \beta=0$	DS III	DS II
$\alpha=\beta=1/2$	2nd order Fokas I	2nd order Fokas II

The canonical systems of order three: [i.e., equations corresponding to (4) and (5) with $n=3$]

	$\sigma=1$	$\sigma=i$
$\alpha=1,\ \beta=0$	NVN system I	NVN system II
$\alpha=\beta=1/2$	3rd order F T system I	3rd order F T system II

In the case of third-order systems, there are two different reductions that reduce the systems to a single equation, yielding generalizations to $2+1$ dimensions of the KdV and m-KdV equations. These are

	$q=-r,\ (\sigma=1/\sigma=i)$	$r=-1(\sigma=1/\sigma=i)$
$\alpha=1,\ \beta=0$	modified NVN (I/II)	NVN (I/II)
$\alpha=\beta=1/2$	3rd order Fokas (I/II)-1	3rd order Fokas (I/II)-2

Several of these systems have appeared in the literature previously. The DS I and DS II equations represent the amplitude of water waves in a shallow medium, and were derived in Ref. 5. The DS III equation can be found in Refs. 6–8. The second-order equation that we are calling Fokas' can be found in Ref. 1. The third-order systems are first found in the literature in Ref. 9, where the system with $\sigma=1$ was studied; the case $\sigma=i$ was treated in Ref. 10; Ref. 6 has a brief comment on the third-order case; and for a more organized treatment see Ref. 11. None of these references consider the more general situation arising from introducing the two real parameters α and β in the third-order system.

This paper is organized as follows. In the next section we give the complete list of DS-type systems of the second and third order. In Sec. III we derive the relevant systems and their reductions. The method for solving the equations corresponding to $\sigma=i$ is sketched in the proof of Propositions 5 and 6. Section IV contains the transformations. These include transformations used

to classify the systems in terms of canonical systems, as well as the Miura map between mod-NVN and NVN. In the last section we give a brief description of the bi-Hamiltonian operators for this hierarchy of equations.

II. LIST OF DS-TYPE EQUATIONS OF THE SECOND AND THIRD ORDER

In this section we give a comprehensive list of all the DS-type equations of the second and third order. We give the general systems (that is with the parameters α and β in them) as well as the canonical ones. For each of them we also consider their reductions to one equation.

(1) General DS type systems and their reductions.

The general second-order DST system I ($\sigma=1$)*:*

$$iq_t=(\beta-\alpha)q_{\xi\xi}+(\beta+\alpha)q_{\eta\eta}-\frac{q}{2}\left((\beta-\alpha)\partial_\eta^{-1}(qr)_\xi+(\beta+\alpha)\partial_\xi^{-1}(qr)_\eta\right)$$
$$+q\left((\beta-\alpha)U(\xi,t)+(\beta+\alpha)V(\eta,t)\right), \tag{6}$$

$$ir_t=(\beta-\alpha)r_{\xi\xi}+(\beta+\alpha)r_{\eta\eta}-\frac{r}{2}\left((\beta-\alpha)\partial_\eta^{-1}(qr)_\xi+(\beta+\alpha)\partial_\xi^{-1}(qr)_\eta\right)$$
$$+r\left((\beta-\alpha)U(\xi,t)+(\beta+\alpha)V(\eta,t)\right), \tag{7}$$

where $\eta=x-y$, $\xi=x+y$, and $U(\xi,t)$ and $V(\eta,t)$ are arbitrary functions.

General DS equation I: System (6) is reduced to a single equation by the choice $r=\epsilon\bar{q}$ where $\epsilon=\pm1$ and the bar denotes complex conjugation:

$$iq_t=(\beta-\alpha)q_{\xi\xi}+(\beta+\alpha)q_{\eta\eta}-\epsilon\frac{q}{2}\left((\beta-\alpha)\partial_\eta^{-1}(|q|^2)_\xi+(\beta+\alpha)\partial_\xi^{-1}(|q|^2)_\eta\right)$$
$$+\epsilon q\left((\beta-\alpha)U(\xi,t)+(\beta+\alpha)V(\eta,t)\right). \tag{8}$$

The general second-order DST system II ($\sigma=i$)*:*

$$iq_t=(\beta-\alpha)q_{zz}+(\beta+\alpha)q_{\bar{z}\bar{z}}-\frac{q}{2}\left((\beta-\alpha)\partial_{\bar{z}}^{-1}(qr)_z+(\beta+\alpha)\partial_z^{-1}(qr)_{\bar{z}}\right),$$
$$ir_t=(\beta-\alpha)r_{zz}+(\beta+\alpha)r_{\bar{z}\bar{z}}-\frac{r}{2}\left((\beta-\alpha)\partial_{\bar{z}}^{-1}(qr)_z+(\beta+\alpha)\partial_z^{-1}(qr)_{\bar{z}}\right), \tag{9}$$

where $z=x+iy$ and $z=x-iy$.

General DS equation II: As before, this system reduces to the single equation

$$iq_t=(\beta-\alpha)q_{zz}+(\beta+\alpha)q_{\bar{z}\bar{z}}-\epsilon\frac{q}{2}\left((\beta-\alpha)\partial_{\bar{z}}^{-1}(|q|^2)_z+(\beta+\alpha)\partial_z^{-1}(|q|^2)_{\bar{z}}\right). \tag{10}$$

The general third-order DST system I ($\sigma=1$)*:*

$$q_t=(\beta-\alpha)q_{\xi\xi\xi}+(\alpha+\beta)q_{\eta\eta\eta}-\tfrac{3}{4}(\beta-\alpha)q\partial_\eta^{-1}(rq_\xi)_\xi-\tfrac{3}{4}(\alpha+\beta)q\partial_\xi^{-1}(rq_\eta)_\eta$$
$$-\tfrac{3}{4}(\beta-\alpha)q_\xi\partial_\eta^{-1}(qr)_\xi-\tfrac{3}{4}(\alpha+\beta)q_\eta\partial_\xi^{-1}(qr)_\eta+(\beta-\alpha)q_\xi U_0(\xi,t)$$
$$+(\beta+\alpha)q_\eta V_0(\eta,t)+q\left((\beta-\alpha)U_1(\xi,t)+(\beta+\alpha)V_1(\eta,t)\right), \tag{11}$$

$$
\begin{aligned}
r_t=&(\beta-\alpha)r_{\xi\xi\xi}+(\alpha+\beta)r_{\eta\eta\eta}-\tfrac{3}{4}(\beta-\alpha)r\partial_\eta^{-1}(qr_\xi)_\xi-\tfrac{3}{4}(\alpha+\beta)r\partial_\xi^{-1}(qr_\eta)_\eta\\
&-\tfrac{3}{4}(\beta-\alpha)r_\xi\partial_\eta^{-1}(rq)_\xi-\tfrac{3}{4}(\alpha+\beta)r_\eta\partial_\xi^{-1}(rq)_\eta\\
&+(\beta-\alpha)r_\xi U_0(\xi,t)+(\beta+\alpha)r_\eta V_0(\eta,t)+r((\beta-\alpha)(U_0'-U_1)(\xi,t)\\
&+(\beta+\alpha)(V_0'-V_1)(\eta,t)).
\end{aligned}
$$

There are two reductions of this system.
(i) *General NVN equation I* $(r=-1)$*:*

$$
\begin{aligned}
q_t=&(\beta-\alpha)q_{\xi\xi\xi}+(\beta+\alpha)q_{\eta\eta\eta}+\tfrac{3}{4}(\alpha+\beta)(q\partial_\xi^{-1}q_\eta)_\eta+\tfrac{3}{4}(\beta-\alpha)(q\partial_\eta^{-1}q_\xi)_\xi\\
&+q((\beta-\alpha)U_0'(\xi,t)+(\beta+\alpha)V_0'(\eta,t))+(\alpha-\beta)U_0(\xi,t)q_\xi+(\beta+\alpha)V_0(\eta,t)q_\eta. \qquad (12)
\end{aligned}
$$

(ii) *General modified NVN equation I* $(r=-q)$:

$$
\begin{aligned}
q_t=&(\beta-\alpha)q_{\xi\xi\xi}+(\alpha+\beta)q_{\eta\eta\eta}+\tfrac{3}{8}(\beta-\alpha)q\partial_\eta^{-1}(q^2)_{\xi\xi}+\tfrac{3}{8}(\alpha+\beta)q\partial_\xi^{-1}(q^2)_{\eta\eta}\\
&+\tfrac{3}{4}(\beta-\alpha)q_\xi\partial_\eta^{-1}(q^2)_\xi+\tfrac{3}{4}(\alpha+\beta)q_\eta\partial_\xi^{-1}(q^2)_\eta+\frac{q}{2}((\beta-\alpha)U_0'(\xi,t)\\
&+(\beta+\alpha)V_0'(\eta,t))+(\beta-\alpha)U_0(\xi,t)q_\xi+(\beta+\alpha)V_0(\eta,t)q_\eta. \qquad (13)
\end{aligned}
$$

(iii) *General third-order DST system II* $(\sigma=i)$*:*

$$
\begin{aligned}
q_t=&(\beta-\alpha)q_{zzz}+(\alpha+\beta)q_{\bar z\bar z\bar z}-\tfrac{3}{4}(\alpha+\beta)q\partial_z^{-1}(rq_{\bar z})_{\bar z}-\tfrac{3}{4}(\beta-\alpha)q\partial_{\bar z}^{-1}(rq_z)_z\\
&-\tfrac{3}{4}(\alpha+\beta)q_{\bar z}\partial_z^{-1}(qr)_{\bar z}-\tfrac{3}{4}(\beta-\alpha)q_z\partial_{\bar z}^{-1}(qr)_z,\\
r_t=&(\beta-\alpha)r_{zzz}+(\alpha+\beta)r_{\bar z\bar z\bar z}-\tfrac{3}{4}(\alpha+\beta)r\partial_z^{-1}(qr_{\bar z})_{\bar z}-\tfrac{3}{4}(\beta-\alpha)r\partial_{\bar z}^{-1}(qr_z)_z\\
&-\tfrac{3}{4}(\alpha+\beta)r_{\bar z}\partial_z^{-1}(rq)_{\bar z}-\tfrac{3}{4}(\beta-\alpha)r_z\partial_{\bar z}^{-1}(rq)_z.
\end{aligned} \qquad (14)
$$

There exist two reductions of this system.
(i) *General NVN equation II* $(r=-1)$*:*

$$
q_t=(\beta-\alpha)q_{zzz}+(\beta+\alpha)q_{\bar z\bar z\bar z}+\tfrac{3}{4}(\alpha+\beta)(q\partial_z^{-1}q_{\bar z})_{\bar z}+\tfrac{3}{4}(\beta-\alpha)(q\partial_{\bar z}^{-1}q_z)_z. \qquad (15)
$$

(ii) *General modified NVN-II* $(r=-q)$*:*

$$
\begin{aligned}
q_t=&(\beta-\alpha)q_{zzz}+(\alpha+\beta)q_{\bar z\bar z\bar z}+\tfrac{3}{4}(\alpha+\beta)q\partial_z^{-1}(qq_{\bar z})+\tfrac{3}{4}(\beta-\alpha)q\partial_{\bar z}^{-1}(qq_z)_z\\
&+\tfrac{3}{4}(\alpha+\beta)q_{\bar z}\partial_z^{-1}(q^2)_{\bar z}+\tfrac{3}{4}(\beta-\alpha)q_z\partial_{\bar z}^{-1}(q^2)_z. \qquad (16)
\end{aligned}
$$

(2) Canonical DS type systems and their reductions.

A. Canonical second-order systems and their reductions

DST I system $(\alpha=0,\ \beta=1)$*:*

$$
\begin{aligned}
&iq_t+q_{\xi\xi}+q_{\eta\eta}-\frac{q}{2}(\partial_\eta^{-1}(qr)_\xi+\partial_\xi^{-1}(qr)_\eta)+q(U(\xi,t)+V(\eta,t)),\\
&ir_t+r_{\xi\xi}+r_{\eta\eta}-\frac{r}{2}(\partial_\eta^{-1}(qr)_\xi+\partial_\xi^{-1}(qr)_\eta)+r(U(\xi,t)+V(\eta,t)),
\end{aligned} \qquad (17)
$$

and its reduction, *DS I*,

$$iq_t = q_{\xi\xi} + q_{\eta\eta} - \epsilon \frac{q}{2} (\partial_\eta^{-1}(|q|^2)_\xi + \partial_\xi^{-1}(|q|^2)_\eta) + q(U(\xi,t) + V(\eta,t)). \tag{18}$$

DST III system ($\alpha = 1$, $\beta = 0$)*:*

$$\begin{aligned} iq_t &= q_{\xi\xi} - q_{\eta\eta} - \frac{q}{2} (\partial_\eta^{-1}(qr)_\xi - \partial_\xi^{-1}(qr)_\eta) + q(U(\xi,t) - V(\eta,t)), \\ ir_t &= r_{\xi\xi} - r_{\eta\eta} - \frac{r}{2} (\partial_\eta^{-1}(qr)_\xi - \partial_\xi^{-1}(qr)_\eta) + r(U(\xi,t) - V(\eta,t)), \end{aligned} \tag{19}$$

and its reduction, *DS III*,

$$iq_t = q_{\xi\xi} - q_{\eta\eta} - \epsilon \frac{q}{2} (\partial_\eta^{-1}(|q|^2)_\xi - \partial_\xi^{-1}(|q|^2)_\eta) + q(U(\xi,t) + V(\eta,t)). \tag{20}$$

Second-order Fokas type I system ($\alpha = \beta = \frac{1}{2}$)*:*

$$iq_t = q_{\xi\xi} - \frac{q}{2} \partial_\eta^{-1}(qr)_\xi + qU(\xi,t), \quad ir_t = r_{\xi\xi} - \frac{r}{2} \partial_\eta^{-1}(qr)_\xi + rU(\xi,t), \tag{21}$$

and its reduction *second-order Fokas I equation*,

$$iq_t = q_{\xi\xi} - \frac{q}{2} \partial_\eta^{-1}(|q|^2)_\xi + \epsilon q U(\xi,t). \tag{22}$$

DST II system:

$$\begin{aligned} iq_t &= q_{zz} + q_{\bar{z}\bar{z}} - \frac{q}{2} (\partial_z^{-1}(qr)_z + \partial_{\bar{z}}^{-1}(qr)_{\bar{z}}), \\ ir_t &= r_{zz} + r_{\bar{z}\bar{z}} - \frac{r}{2} (\partial_z^{-1}(qr)_z + \partial_{\bar{z}}^{-1}(qr)_{\bar{z}}), \end{aligned} \tag{23}$$

and its reduction, *DS II*,

$$iq_t = q_{zz} + q_{\bar{z}\bar{z}} - \epsilon \frac{q}{2} (\partial_z^{-1}(|q|^2)_z + \partial_{\bar{z}}^{-1}(|q|^2)_{\bar{z}}). \tag{24}$$

Fokas type system II:

$$iq_t = q_{zz} + \frac{q}{2} \partial_z^{-1}(qr)_z, \quad ir_t = r_{zz} + \frac{r}{2} \partial_z^{-1}(qr)_z, \tag{25}$$

and its reduction, *Fokas' simplest II*,

$$iq_t = q_{zz} + \epsilon \frac{q}{2} \partial_z^{-1}(|q|^2)_z. \tag{26}$$

B. Canonical third-order systems and their reductions

Third-order DST system I:

$$\begin{aligned} q_t = {} & q_{\xi\xi\xi} + q_{\eta\eta\eta} - \tfrac{3}{4} q \partial_\eta^{-1}(rq_\xi)_\xi - \tfrac{3}{4} q \partial_\xi^{-1}(rq_\eta)_\eta - \tfrac{3}{4} q_\xi \partial_\eta^{-1}(qr)_\xi \\ & - \tfrac{3}{4} q_\eta \partial_\xi^{-1}(qr)_\eta + q_\xi U_0(\xi,t) + q_\eta V_0(\eta,t) + q(U_1(\xi,t) + V_1(\eta,t)), \end{aligned} \tag{27}$$

$$r_t = r_{\xi\xi\xi} + r_{\eta\eta\eta} - \tfrac{3}{4} r \partial_\eta^{-1}(q r_\xi)_\xi - \tfrac{3}{4} r \partial_\xi^{-1}(q r_\eta)_\eta - \tfrac{3}{4} r_\xi \partial_\eta^{-1}(rq)_\xi - \tfrac{3}{4} r_\eta \partial_\xi^{-1}(rq)_\eta + r_\xi U_0(\xi,t) + r_\eta V_0(\eta,t) + r(U_2(\xi,t) + V_2(\eta,t)).$$

There exist two reductions for this system: *NVN-I equation* $(r=-1)$,

$$q_t = q_{\xi\xi\xi} + q_{\eta\eta\eta} + \tfrac{3}{4}(q\partial_\xi^{-1} q_\eta)_\eta + \tfrac{3}{4}(q\partial_\eta^{-1} q_\xi)_\xi + q \times (U_0'(\xi,t) + V_0'(\eta,t)) + U_0(\xi,t) q_\xi + V_0(\eta,t) q_\eta, \tag{28}$$

and *modified NVN-I equation* $(r=-q)$,

$$q_t = q_{\xi\xi\xi} + q_{\eta\eta\eta} + \frac{3}{8} q \partial_\eta^{-1}(q^2)_{\xi\xi} + \frac{3}{8} q \partial_\xi^{-1}(q^2)_{\eta\eta} + \frac{3}{4} q_\xi \partial_\eta^{-1}(q^2)_\xi + \frac{3}{4} q_\eta \partial_\xi^{-1}(q^2)_\eta + \frac{q}{2}(U_0'(\xi,t) + V_0'(\eta,t)) + U_0(\xi,t) q_\xi + V_0(\eta,t) q_\eta. \tag{29}$$

Third Order Fokas system I:

$$\begin{aligned} q_t &= q_{\xi\xi\xi} - \tfrac{3}{4} q \partial_\eta^{-1}(r q_\xi)_\xi - \tfrac{3}{4} q_\xi \partial_\eta^{-1}(qr)_\xi + q_\xi U_0(\xi,t) + + q U_1(\xi,t), \\ r_t &= r_{\xi\xi\xi} - \tfrac{3}{4} r \partial_\eta^{-1}(q r_\xi)_\xi - \tfrac{3}{4} r_\xi \partial_\eta^{-1}(rq)_\xi + r_\xi U_0(\xi,t) + r U_2(\xi,t), \end{aligned} \tag{30}$$

and its reductions, *third-order Fokas equation I-1* $(r=-1)$,

$$q_t = q_{\xi\xi\xi} + \tfrac{3}{4} q \partial_\eta^{-1} q_{\xi\xi} + \tfrac{3}{4} q_\xi \partial_\eta^{-1} q_\xi + q_\xi U_0(\xi,t) + q U_1(\xi,t), \tag{31}$$

and *third-order Fokas equation I-2* $(r=-q)$,

$$q_t = q_{\xi\xi\xi} + \tfrac{3}{4} q \partial_\eta^{-1}(q q_\xi)_\xi + \tfrac{3}{4} q_\xi \partial_\eta^{-1}(q^2)_\xi + q_\xi U_0(\xi,t) + q U_1(\xi,t). \tag{32}$$

Third-order DST system II:

$$\begin{aligned} q_t &= q_{zzz} + q_{\overline{zzz}} - \tfrac{3}{4} q \partial_z^{-1}(r q_{\bar z})_{\bar z} - \tfrac{3}{4} q \partial_{\bar z}^{-1}(r q_z)_z - \tfrac{3}{4} q_{\bar z} \partial_z^{-1}(qr)_{\bar z} - \tfrac{3}{4} q_z \partial_{\bar z}^{-1}(qr)_z, \\ r_t &= r_{zzz} + r_{\overline{zzz}} - \tfrac{3}{4} r \partial_z^{-1}(q r_{\bar z})_{\bar z} - \tfrac{3}{4} r \partial_{\bar z}^{-1}(q r_z)_z - \tfrac{3}{4} r_{\bar z} \partial_z^{-1}(rq)_{\bar z} - \tfrac{3}{4} r_z \partial_{\bar z}^{-1}(rq)_z, \end{aligned} \tag{33}$$

and its reductions, *NVN-II* $(r=-1)$,

$$q_t = q_{zzz} + q_{\overline{zzz}} + \tfrac{3}{4}(q\partial_z^{-1} q_{\bar z})_{\bar z} + \tfrac{3}{4}(q\partial_{\bar z}^{-1} q_z)_z, \tag{34}$$

and *modified NVN-II* $(r=-q)$,

$$q_t = q_{zzz} + q_{\overline{zzz}} + \tfrac{3}{4} q \partial_z^{-1}(q q_{\bar z})_{\bar z} + \tfrac{3}{4} q \partial_{\bar z}^{-1}(q q_z)_z + \tfrac{3}{4} q_{\bar z} \partial_z^{-1}(q^2)_{\bar z} + \tfrac{3}{4} q_z \partial_{\bar z}^{-1}(q^2). \tag{35}$$

Third-order Fokas' system II:

$$\begin{aligned} q_t &= q_{zzz} + \tfrac{3}{4} q \partial_{\bar z}^{-1}(r q_z)_z - \tfrac{3}{4} q_z \partial_{\bar z}^{-1}(qr)_z, \\ r_t &= r_{zzz} + \tfrac{3}{4} r \partial_{\bar z}^{-1}(q r_z)_z - \tfrac{3}{4} r_z \partial_{\bar z}^{-1}(rq)_z, \end{aligned} \tag{36}$$

and its reductions, *third-order reduced Fokas II-1* $(r=-1)$,

$$q_t = q_{zzz} - \tfrac{3}{4}(q \partial_{\bar z}^{-1} q_z)_z + \tfrac{3}{4} q_z \partial_{\bar z}^{-1}(q)_z, \tag{37}$$

and *third-order reduced Fokas II-2* $(r=-q)$,

$$q_t = q_{zzz} - \tfrac{3}{4} q \partial_{\bar z}^{-1}(q q_z)_z + \tfrac{3}{4} q_z \partial_{\bar z}^{-1}(q^2)_z. \tag{38}$$

III. DERIVATION OF SYSTEMS OF INTEGRABLE EQUATIONS OF THE DS TYPE

We present the derivation of the systems of integrable equations named *general* in Sec. II, that is, where the parameters (α,β) have not yet been eliminated. The reduction of these systems to their canonical versions is discussed in the next section. This section is organized as follows. We first derive the DS-type systems with (4) as their Lax equation where σ has been set equal to 1. We refer to these systems as *systems of type I*. They admit $\xi=x+y$ and $\eta=x-y$ as characteristic variables. We see that these systems arise in connection with a nonlocal matrix Riemann–Hilbert problem on the complex plane. We do this in two steps. In Sec. III A, we derive the systems for zero boundary functions in two propositions. In Proposition 1, we derive the second-order system and Proposition 2 contains the derivation of the third-order system. The equations resulting from this method do not contain the boundary functions, that is, the additional terms in only one of the variables η and ξ that appear in the equations in the list of the Introduction. In Sec. III B, we modify the t-part of the Lax pair to include nonzero boundary functions. This is done in two propositions. Proposition 3 contains the derivation of the second-order system, while Proposition 4 contains the derivation of the third-order system. This is the formulation which yields the equations as listed in Sec. II. Subsection III C, contains the derivation of the second and third-order systems arising from a slight modification of the Lax equation resulting in characteristic variables being complex numbers $z=x+iy$ and $\bar{z}=x-iy$. This is done in two propositions (Propositions 5 and 6). Again, these two systems have a common solution technique, based on a nonlocal DBAR problem. We shall call this systems *systems of type II*.

In what follows, α and β are real numbers, $J=\mathrm{diag}\{1,-1\}$ is a 2×2 matrix, and q and r are complex-valued functions of x, y, and t. In order to match the equations in this work with the ones appearing in the literature the parameter λ should be replaced by ik. This change accounts for the missing i multiplying the derivatives with respect to t in the second-order equations. The change $t\to it$ restores the equations to the usual form.

A. Derivations of type I systems for zero boundary functions

Proposition 1: The Lax pair formed by L and L_2, where L is as in (4),

$$L_2=\partial_t-(\alpha+\beta J)\partial_y^2-\beta P\partial_y+Q,$$

and Q is defined by (42), gives rise to the system of equations

$$q_t=(\beta-\alpha)q_{\xi\xi}+(\beta+\alpha)q_{\eta\eta}-\frac{q}{2}\left((\beta-\alpha)\partial_\eta^{-1}(qr)_\xi+(\beta+\alpha)\partial_\xi^{-1}(qr)_\eta\right),$$

$$r_t=(\beta-\alpha)r_{\xi\xi}+(\beta+\alpha)r_{\eta\eta}-\frac{r}{2}\left((\beta-\alpha)\partial_\eta^{-1}(qr)_\xi+(\beta+\alpha)\partial_\xi^{-1}(qr)_\eta\right).$$

Proposition 2: The Lax pair formed by L and L_3, where

$$L_3=\partial_t+(\alpha+\beta J)\partial_y^3+\beta P\partial_y^2+C\partial_y+Q,$$

and C and Q are defined by (44) and (45), respectively, gives rise to the system of equations

$$\begin{aligned}q_t=&(\beta-\alpha)q_{\xi\xi\xi}+(\alpha+\beta)q_{\eta\eta\eta}-\tfrac{3}{4}(\beta-\alpha)q\partial_\eta^{-1}(rq_\xi)_\xi-\tfrac{3}{4}(\alpha+\beta)q\partial_\xi^{-1}(rq_\eta)_\eta\\&-\tfrac{3}{4}(\beta-\alpha)q_\xi\partial_\eta^{-1}(qr)_\xi-\tfrac{3}{4}(\alpha+\beta)q_\eta\partial_\xi^{-1}(qr)_\eta,\\ r_t=&(\beta-\alpha)r_{\xi\xi\xi}+(\alpha+\beta)r_{\eta\eta\eta}-\tfrac{3}{4}(\beta-\alpha)r\partial_\eta^{-1}(qr_\xi)_\xi-\tfrac{3}{4}(\alpha+\beta)r\partial_\xi^{-1}(qr_\eta)_\eta\\&-\tfrac{3}{4}(\beta-\alpha)r_\xi\partial_\eta^{-1}(rq)_\xi-\tfrac{3}{4}(\alpha+\beta)r_\eta\partial_\xi^{-1}(rq)_\eta.\end{aligned}$$

Proof of Proposition 1:

We will show that the second-order system possesses a Lax pair; the system arises as the compatibility condition for a pair of overdetermined linear differential operators with matrix

coefficients. In what follows, let Ψ be a matrix function with variables λ, x, y, and t and let $\mathscr{L}_1$ and $\mathscr{L}_2$ be differential operators with matrix coefficients so that $\mathscr{L}_1\Psi=0$ and $\mathscr{L}_2\Psi=0$. We shall write

$$\Psi=\mu(x,y,t,\lambda)\exp\{\lambda(Jx-y)+\lambda^2(\alpha+\beta J)t\},$$

where μ is a matrix function. It is convenient to introduce the operators

$$D_x\mu=\mu_x+\lambda\mu J,\quad D_y\mu=\mu_y-\lambda\mu,$$

$$D_t\mu=\mu_t+\lambda^2\mu(\alpha+\beta J).$$

Thus $\mathscr{L}\Psi=(\Sigma_{i=1}^N A_i\partial_x^i+\Sigma_{i=1}^N B_i\partial_y^i+\partial_t)\Psi=0$ if and only if $L\mu=(\Sigma_{i=1}^N A_iD_x^i+\Sigma_{i=1}^N B_iD_y^i+D_t)\mu=0$.

We begin by considering a nonlocal Riemann–Hilbert problem,

$$\mu^+(k,x,y,t)=\int_R dl\ \mu^-(l,x,y,t)F(l,k,x,y,t),\quad k\in R$$
$$\mu\sim 1+\frac{\mu_1(x,y,t)}{\lambda}+\frac{\mu_2(x,y,t)}{\lambda^2}+O\left(\frac{1}{\lambda^3}\right),\quad \lambda\to\infty. \tag{39}$$

In this equation μ^+, μ^-, and F are matrix-valued functions and the super indices $+$ and $-$ denote holomorphicity in the upper and lower complex planes, respectively. We assume that (39) has unique solution μ^+,μ^- for a given function F. Denote by P_F the rhs of Eq. (39), that is,

$$P_F\mu\equiv\int_R dl\ \mu(l,x,y,t)F(l,k,x,y,t),$$

and choose F so that P_F and the operators D_x, D_y, and D_t commute. The conditions on F that arise from this are

$$F_x=(lJF-kFJ),\quad F_y=(l-k)F,$$

$$F_t=l^2F(\alpha+\beta J)-k^2(\alpha+\beta J)F.$$

Next, look for linear combinations of $D_x\mu$, $D_y\mu$, and $D_t\mu$ that vanish for $\lambda\to\infty$. This guarantees that these combinations must be identically zero since we are assuming that the homogeneous Riemann–Hilbert problem has unique zero solution. The simplest such linear combination L_1 is of the form $L_1=D_x+JD_y+P$. The $\mathscr{O}(\lambda)$ term cancels and the $\mathscr{O}(1)$ also cancels by choosing $P=[J,\mu_1]=\left(\begin{smallmatrix}0 & q\\ r & 0\end{smallmatrix}\right)$. This is the time-independent part of the Lax pair.

Using (39) and grouping powers of λ we find

$$\mathscr{O}(\lambda^{-i}):\mu_{ix}+J\mu_{iy}+[\mu_{i+1},J]+P\mu_i=0. \tag{40}$$

These are recursive equations for the coefficients $\mu_i=\left(\begin{smallmatrix}a_i & b_i\\ c_i & d_i\end{smallmatrix}\right)$ of the function μ. These coefficients are determined only up to the addition of arbitrary functions of ξ or η and t. That is,

$$\begin{aligned}0=L_1\mu&=\mu_x+\lambda\mu J+J\mu_y-\lambda J\mu+P\mu\\&=(\mu_x+J\mu_y)+\lambda[\mu_1,J]+P\mu\\&=2\sum_{k=0}^{\infty}\left\{\begin{pmatrix}a_{k\xi} & b_{k\xi}\\ c_{k\eta} & d_{k\eta}\end{pmatrix}+\begin{pmatrix}0 & b_{k+1}\\ c_{k+1} & 0\end{pmatrix}+\frac{1}{2}\begin{pmatrix}qc_k & qd_k\\ ra_k & rb_k\end{pmatrix}\right\}\lambda^{-k}.\end{aligned}$$

So for $k=0$ one obtains $b_1=q/2$ and $c_1=-r/2$ from the off diagonal entries. From the diagonal entries one has that $a_1=\frac{1}{4}\partial_\xi^{-1}(qr)+v_0(\eta,t)$ and $d_1=-\frac{1}{4}\partial_\eta^{-1}(qr)+u_0(\xi,t)$, where u_0 and v_0 are arbitrary functions of ξ or η and t. We will assume here that the functions u_0 and v_0 are zero. To find the time-dependent part of the Lax pair we set

$$\begin{aligned} L_2\mu &= D_t\mu + AD_y^2\mu + BD_y\mu + Q\mu \\ &= \mu_t + \lambda^2\mu(\alpha+\beta J) + A(\mu_{yy} - 2\lambda\mu_y + \lambda^2\mu) + B(\mu_y - \lambda\mu) + Q\mu = 0. \end{aligned} \tag{41}$$

Collecting the powers of the parameter λ we obtain the following equations for the coefficients A, B, and Q:

$$\mathcal{O}(\lambda^2):(\alpha+\beta J)+A=0,$$

$$\mathcal{O}(\lambda):\mu_1(\alpha+\beta J)-(\alpha+\beta J)\mu_1-B=\beta[\mu_1,\ J]-B=0,$$

$$\mathcal{O}(1):\mu_2(\alpha+\beta J)-2A\mu_{1y}-(\alpha+\beta J)\mu_2-B\mu_1+Q=0.$$

Solving these equations one obtains $A=-(\alpha+\beta J)$, $B=\beta[\mu_1,\ J]=-\beta P$ and $Q=\left(\begin{smallmatrix} Q^{11} & Q^{12} \\ Q^{21} & Q^{22}\end{smallmatrix}\right)$ with

$$\begin{aligned} Q^{11} &= -\tfrac{1}{2}\alpha qr + \tfrac{1}{2}(\beta+\alpha)\partial_\xi^{-1}(qr)_\eta, \quad Q^{12} = -\alpha q_\xi + (\beta+\alpha)q_\eta, \\ Q^{22} &= -\tfrac{1}{2}\alpha qr - \tfrac{1}{2}(\beta-\alpha)\partial_\eta^{-1}(qr)_\xi, \quad Q^{21} = -\alpha r_\eta - (\beta-\alpha)r_\xi. \end{aligned} \tag{42}$$

The $\mathcal{O}(\lambda^{-1})$ order of (41) produces the equation

$$\begin{aligned} 0 &= \mu_{1t} + \mu_3(\alpha+\beta J) + A\mu_{1yy} - 2A\mu_{2y} + A\mu_3 + B\mu_{1y} - B\mu_2 + Q\mu_1 \\ &= \mu_{1t} + \beta[\mu_3, J] + 2(\alpha+\beta J)\mu_{2y} - (\alpha+\beta J)\mu_{1yy} \\ &\quad + 2(\alpha+\beta J)\mu_{2y} - \beta P\mu_{1y} + \beta P\mu_2 + Q\mu_1. \end{aligned} \tag{43}$$

From the off diagonal entries in the equation above and using the specific formulas for Q and the recursion relations (40), we obtain the desired equations for q and r.

Remark 1: The same equations can be obtained as a compatibility condition, that is, from the statement that $\partial_x\partial_t\Psi=\partial_t\partial_x\Psi$. □

Proof of Proposition 2:

Let Ψ be of the form

$$\Psi=\mu\ \exp\{\lambda(Jx-y)+\lambda^3(\alpha+\beta J)t\}.$$

The difference between this and the previous Ψ is the cube power of λ that accompanies the variable t in the exponential. Now we search for operators $\mathcal{L}_1$ and $\mathcal{L}_3$ such that $\mathcal{L}_1\Psi=0$ and $\mathcal{L}_3\Psi=0$.

Remark 2: The operator $\mathcal{L}_1$ obtained above together with the recursion relations (40) satisfies $\mathcal{L}_1\Psi=0$.

Set $L_3\mu=0$ for a general operator $L_3=D_t+AD_y^3+BD_y^2+CD_y+Q$:

$$\begin{aligned} L_3\mu &= \mu_t + \lambda^3\mu(\alpha+\beta J) + A(\mu_{yyy} - 3\lambda\mu_{yy} + 3\lambda^2\mu_y - \lambda^3\mu) \\ &\quad + B(\mu_{yy} - 2\lambda\mu_y + \lambda^2\mu) + C(\mu_y - \lambda\mu) + Q\mu. \end{aligned}$$

Collecting powers of λ one obtains the following equations:

$$\mathcal{O}(\lambda^3):(\alpha+\beta J)-A=0, \quad \mathcal{O}(\lambda^2):\beta[\mu_1,\ J]+B=0,$$

$$\mathcal{O}(\lambda^1):\beta[\mu_2,\ J]+B\mu_1+3A\mu_{1y}-C=0,$$

$$\mathcal{O}(1):\beta[\mu_3,\ J]+3(\alpha+\beta J)\mu_{2y}-3(\alpha+\beta J)\mu_{1yy}-\beta P\mu_2-2\beta P\mu_{1y}-C\mu_1+Q=0.$$

Solving these equations we obtain $A=(\alpha+\beta J)$, $B=\beta P$, $C=\begin{pmatrix} C^{11} & C^{12} \\ C^{21} & C^{22} \end{pmatrix}$ and $Q=\begin{pmatrix} Q^{11} & Q^{12} \\ Q^{21} & Q^{22} \end{pmatrix}$ with

$$\begin{aligned} C^{11}&=(\tfrac{3}{4}\alpha+\tfrac{1}{4}\beta)qr-\tfrac{3}{4}(\alpha+\beta)\partial_\xi^{-1}(qr)_\eta,\\ C^{12}&=(\tfrac{3}{4}\alpha+\tfrac{1}{2}\beta)q_\xi-\tfrac{3}{2}(\alpha+\beta)q_\eta,\\ C^{21}&=(\tfrac{3}{2}\alpha-\tfrac{1}{2}\beta)r_\eta-\tfrac{3}{2}(\alpha-\beta)r_\xi,\\ C^{22}&=(\tfrac{3}{4}\alpha-\tfrac{1}{4}\beta)qr-\tfrac{3}{4}(\alpha-\beta)\partial_\eta^{-1}(qr)_\xi, \end{aligned} \tag{44}$$

and

$$Q=-3(\alpha+\beta J)\mu_{2y}+3(\alpha+\beta J)\mu_{1yy}+\beta P\mu_2+2\beta P\mu_{1y}+C\mu_1+\beta[J,\ \mu_3]. \tag{45}$$

Compatibility of the operators L_1 and L_3 produce the following equations for q and r:

$$\begin{aligned} q_t&=2Q^{12}_\xi+q(Q^{22}-Q^{11})-C^{11}q_y-(\alpha+\beta)q_{yyy},\\ r_t&=2Q^{21}_\eta+r(Q^{11}-Q^{22})-C^{22}r_y-(\alpha-\beta)r_{yyy}. \end{aligned} \tag{46}$$

When the expressions for Q and C are substituted in we obtain the equations in Propositions 2 and 6. □

B. Modified *t*-part of the Lax pair for type I systems

Proposition 3: The system (6),

$$\begin{aligned} iq_t=&(\beta-\alpha)q_{\xi\xi}+(\beta+\alpha)q_{\eta\eta}-\frac{q}{2}\left((\beta-\alpha)\partial_\eta^{-1}(qr)_\xi+(\beta+\alpha)\partial_\xi^{-1}(qr)_\eta\right)\\ &+q\left((\beta-\alpha)U(\xi,t)+(\beta+\alpha)V(\eta,t)\right),\\ ir_t=&(\beta-\alpha)r_{\xi\xi}+(\beta+\alpha)r_{\eta\eta}-\frac{r}{2}\left((\beta-\alpha)\partial_\eta^{-1}(qr)_\xi+(\beta+\alpha)\partial_\xi^{-1}(qr)_\eta\right)\\ &+r\left((\beta-\alpha)U(\xi,t)+(\beta+\alpha)V(\eta,t)\right), \end{aligned}$$

can be obtained from the following Lax pair:

$$\begin{aligned} &L\Psi=0,\\ &\Psi_t=(\alpha+\beta J)\Psi_{yy}+\beta P\Psi_y+Q\Psi+\int_R dl\ \Psi(l)\mathbf{f}(k,l), \end{aligned} \tag{47}$$

where L is as in (4), Q is defined by (49) below, and $\mathbf{f}=\mathrm{diag}\{f_1,f_2\}$:

$$\begin{aligned} f_1(k,l)&=(\beta+\alpha)\left[k^2\delta(k-l)+\frac{1}{2\pi}\int_R d\eta\ V(\eta)\exp\left(-i(k-l)\eta\right)\right],\\ f_2(k,l)&=(\beta-\alpha)\left[k^2\delta(k-l)+\frac{1}{2\pi}\int_R d\xi\ U(\xi)\exp\left(-i(k-l)\xi\right)\right]. \end{aligned}$$

If U and V are real valued functions, this system admits the reduction $r=\epsilon\bar{q}$:

$$\begin{aligned} q_t=&(\beta-\alpha)q_{\xi\xi}+(\beta+\alpha)q_{\eta\eta}-\epsilon\frac{q}{2}\left((\beta-\alpha)\partial_\eta^{-1}(|q|^2)_\xi+(\beta+\alpha)\partial_\xi^{-1}(|q|^2)_\eta\right)\\ &+\epsilon q\left((\beta-\alpha)U(\xi,t)+(\beta+\alpha)V(\eta,t)\right). \end{aligned}$$

Proof: Recall that the t-part of the Lax pair for the system (6) is given by

$$\Psi_t=(\alpha+\beta J)\Psi_{yy}+\beta P\Psi_y+Q\Psi \tag{48}$$

with $Q=\left(\begin{smallmatrix}Q^{11} & Q^{12}\\ Q^{21} & Q^{22}\end{smallmatrix}\right)$ as in (42) and where $\Psi=(\Psi_1,\Psi_2)^T$. In the case that the boundary functions are not zero, the coefficients in Q can be expanded as follows:

$$\begin{aligned}
Q^{11}&=-\tfrac{1}{2}\alpha qr+\tfrac{1}{2}(\beta+\alpha)\partial_\xi^{-1}(qr)_\eta+(\beta+\alpha)v_0'(\eta),\\
Q^{12}&=-\alpha q_\xi+(\beta+\alpha)q_n,\\
Q^{22}&=-\tfrac{1}{2}\alpha qr-\tfrac{1}{2}(\beta-\alpha)\partial_\eta^{-1}(qr)_\xi-(\beta-\alpha)u_0'(\xi),\\
Q^{21}&=-\alpha r_\eta-(\beta-\alpha)r_\xi.
\end{aligned} \tag{49}$$

In this case, the equation (48) for Ψ must be modified. We start by defining

$$\Psi_1=\mu_{12}^- e^{-ik\xi},\quad \Psi_2=\mu_{22}^- e^{-ik\xi},$$

so from (4)

$$\Psi_1=\frac{1}{2}\int_\xi^\infty d\xi'\ q\Psi_2,\quad \Psi_2=e^{-ik\xi}-\frac{1}{2}\int_{-\infty}^\eta d\eta'\ r\Psi_1.$$

Now add an extra term of the form $\int_R dl\ f(k,l)\Psi(l)$ to the t-part of the Lax pair (48),

$$\Psi_t=(\alpha+\beta J)\Psi_{yy}+\beta P\Psi_y+Q\Psi+\int_R dl\ f(k,l)\Psi(l),$$

and compute the limits of the equation above as $\eta\to-\infty$. Taking into account that $\Psi_1\to 0$, $\Psi_2\sim e^{-ik\xi}$, and $q,r\sim 0$, we obtain

$$0=-(\beta-\alpha)(-ik)^2e^{-ik\xi}-(\beta-\alpha)U(\xi)e^{-ik\xi}+\int dl\ f(k,l)e^{-il\xi}.$$

So

$$\begin{aligned}
\int_R d\xi\int_R dl'\ f(k,l')\exp(-i(l'-l)\xi)&=(\beta-\alpha)k^2\int_R d\xi\ \exp(-i(k-l)\xi)\\
&\quad+(\beta-\alpha)\int_R d\xi\ U(\xi)\exp(-i(k-l)\xi),
\end{aligned}$$

or

$$f(k,l)=(\beta-\alpha)k^2\delta(k-l)+(\beta-\alpha)\frac{1}{2\pi}\int_R d\xi\ U(\xi)\exp(-i(k-l)\xi).$$

□

Proposition 4: The system (11) can be obtained from the following Lax pair:

$$L\Psi=0,$$

$$-\Psi_t=(\alpha+J\beta)\Psi_{yyy}+\beta P\Psi_{yy}+C\Psi_y+Q\Psi+\mathbf{v},$$

where C and Q are defined by (53) and (54) and $\mathbf{v}=\operatorname{diag}\{v,u\}$:

$$v=-(\beta+\alpha)\left((ik)^3\Psi+\int_R\gamma_1(k-l)\Psi(l)\,dl+(ik)\int\gamma_2(k-l)\Psi(l)\,dl\right),$$

$$u=(\beta-\alpha)\left((ik)^3\Psi+\int_R\delta_1(k-l)\Psi(l)\,dl+(ik)\int\delta_2(k-l)\Psi(l)\,dl\right),$$

where

$$\gamma_1(n)=\frac{1}{2\pi}\int_R V_2(\eta)e^{-in\eta}\,d\eta,\quad \delta_1(s)=\frac{1}{2\pi}\int_R U_2(\xi)e^{-is\xi}\,d\xi,$$

$$\gamma_2(n)=\frac{1}{2\pi}\int_R V_0(\eta)e^{-in\eta}\,d\eta,\quad \delta_2(s)=\frac{1}{2\pi}\int_R U_0(\xi)e^{-is\xi}\,d\xi.$$

The functions U_0,U_1,U_2 *and* V_0,V_1,V_2 *are related by the equations*

$$\begin{aligned}U_1(\xi,t)&=-U_2(\xi,t)+U_0'(\xi,t),\\ V_1(\eta,t)&=-V_2(\eta,t)+V_0'(\eta,t).\end{aligned}\tag{50}$$

This system admits the following reductions:

(1) $r=-1$. *Setting* $r=-1$ *in the above system, imposing the condition* $U_2=V_2=0$ [*so that* $U_0'(\xi,t)=U_1(\xi,t)$ *and* $V_0'(\eta,t)=V_1(\eta,t)$ *by virtue of (50)*], *and writing* $q=u$, *the system reduces to the single equation*

$$\begin{aligned}u_t=&(\beta-\alpha)u_{\xi\xi\xi}+(\beta+\alpha)u_{\eta\eta\eta}+\tfrac{3}{4}(\alpha+\beta)(u\partial_\xi^{-1}u_\eta)_\eta+\tfrac{3}{4}(\beta-\alpha)(u\partial_\eta^{-1}u_\xi)_\xi\\&+u((\beta-\alpha)U_1(\xi,t)+(\beta+\alpha)V_1(\eta,t))+(\alpha-\beta)U_0(\xi,t)u_\xi+(\beta+\alpha)V_0(\eta,t)u_\eta.\end{aligned}\tag{51}$$

(2) $r=-q$. *Setting* $-r=q=v$ *and imposing the condition* $U_1=U_2$ *and* $V_1=V_2$, *the system reduces to the single equation*

$$\begin{aligned}v_t=&(\beta-\alpha)v_{\xi\xi\xi}+(\alpha+\beta)v_{\eta\eta\eta}+\tfrac{3}{8}(\beta-\alpha)v\partial_\eta^{-1}(v^2)_{\xi\xi}+\tfrac{3}{8}(\alpha+\beta)v\partial_\xi^{-1}(v^2)_{\eta\eta}\\&+\tfrac{3}{4}(\beta-\alpha)v_\xi\partial_\eta^{-1}(v^2)_\xi+\tfrac{3}{4}(\alpha+\beta)v_\eta\partial_\xi^{-1}(v^2)_\eta+v((\beta-\alpha)U_1(\xi,t)\\&+(\beta+\alpha)V_1(\eta,t))+(\beta-\alpha)U_0(\xi,t)v_\xi+(\beta+\alpha)V_0(\eta,t)v_\eta.\end{aligned}\tag{52}$$

Proof: When the additional terms coming from the integration of the recursion relations (40) are considered, the following terms must be added to the coefficients C and Q in (44) and (45), respectively:

$$C_{11}=\text{old } C_{11}-\tfrac{3}{4}(\beta-\alpha)v_0'(\eta,t),\quad C_{22}=\text{old } C_{22}-\tfrac{3}{4}(\beta+\alpha)u_0'(\xi,t),\tag{53}$$

$$\begin{aligned}Q_{12}&=\text{old } Q_{12}+\tfrac{3}{8}q[(\beta-\alpha)u_0'(\xi,t)-(\beta+\alpha)v_0'(\eta,t)],\\ Q_{21}&=\text{old } Q_{21}+\tfrac{3}{8}r[(\beta-\alpha)u_0'(\xi,t)-(\beta+\alpha)v_0'(\eta,t)],\\ Q_{11}&=\text{old } Q_{11}+3(\beta+\alpha)[-v_1'(\eta)+\tfrac{1}{4}v_0''(\eta)-\tfrac{1}{8}(v_0^2(\eta))'],\\ Q_{22}&=\text{old } Q_{22}+3(\beta-\alpha)[-u_1'(\xi)+\tfrac{1}{4}u_0''(\xi)-\tfrac{1}{8}(u_0^2(\xi))'].\end{aligned}\tag{54}$$

In turn, these add new terms to Eqs. (46):

$$q_t = \text{old terms} - \tfrac{3}{4}(\beta+\alpha) q_\eta v_0'(\eta) + (\beta+\alpha) q(-\tfrac{3}{4} v_0''(\eta) + 3v_1'(\eta) + \tfrac{3}{8}(v_0^2(\eta))')$$
$$- \tfrac{3}{4}(\beta-\alpha) q_\xi u_0'(\xi) + (\beta-\alpha) q(-3u_1'(\xi) - \tfrac{3}{8}(u_0(\xi)^2)'),$$

$$r_t = \text{old terms} - \tfrac{3}{4}(\beta-\alpha) r_\xi u_0'(\xi) + (\beta-\alpha) r(-\tfrac{3}{4} u_0''(\xi) + 3u_1'(\tau) + \tfrac{3}{8}(u_0(\xi)^2)')$$
$$- \tfrac{3}{4}(\alpha+\beta) r_\eta v_0'(\eta) + (\beta+\alpha) r(-3v_1'(\eta) - \tfrac{3}{8}(v_0^2(\eta))').$$

We define

$$U_0 = -\tfrac{3}{4} u_0', \quad V_0 = -\tfrac{3}{4} v_0',$$

$$U_1 = (-3u_1' - \tfrac{3}{8}(u_2^2)'), \quad V_1 = (-\tfrac{3}{4} v_0'' + 3v_1' + \tfrac{3}{8}(v_0^2)'),$$

$$U_2 = (-\tfrac{3}{4} u_0'' + 3u_1' + \tfrac{3}{8}(u_0^2)'), \quad V_2 = (-3v_1' - \tfrac{3}{8}(v_0^2)').$$

The original equation for Ψ_t for the third-order system is

$$\Psi_t + (\alpha+\beta J)\Psi_{yyy} + \beta P \Psi_{yy} + C\Psi_y + Q\Psi = 0. \tag{55}$$

We define

$$\Psi_1 = \mu_{11}^+ e^{ik\eta}, \quad \Psi_2 = \mu_{21}^+ e^{ik\eta}.$$

Then, from (4),

$$\Psi_1 = e^{ik\eta} - \frac{1}{2} \int_{-\infty}^{\xi} d\xi' \; q\Psi_2, \quad \Psi_2 = \frac{1}{2} \int_{\eta}^{\infty} d\eta' \; r\Psi_1.$$

In order to find the t-part of the Lax pair in the case that the functions U_0, U_1, U_2 and V_0, V_1 and V_2 are not zero, we add an extra term of the form $\int_R dl \; f(k,l)\Psi(l)$ to the t-part of the Lax pair (55):

$$-\Psi_t = (\alpha+\beta J)\Psi_{yyy} + \beta P \Psi_{yy} + C\Psi_y + Q\Psi + \int_R dl \; f(k,l)\Psi(l). \tag{56}$$

Writing (56) in components,

$$-\Psi_{1t} = (\alpha+\beta)\Psi_{1yyy} + q\Psi_{2yy} + C^{11}\Psi_{1y} + C^{12}\Psi_{2y} + Q^{11}\Psi_1 + Q^{12}\Psi_2 + \int f(k,l)\Psi_1(l) \; dl. \tag{57}$$

$$-\Psi_{2t} = (\alpha-\beta)\Psi_{2yyy} + r\Psi_{1yy} + C^{21}\Psi_{1y} + C^{22}\Psi_{2y} + Q^{21}\Psi_1 + Q^{22}\Psi_2 + \int f(k,l)\Psi_2(l) \; dl.$$

When $\xi \to -\infty$ we have $\binom{\Psi_1}{\Psi_2} \sim \binom{e^{ik\eta}}{0}$. Taking the limit $\xi \to -\infty$ in (57) we find

$$\lim_{\xi \to -\infty} (Q^{21} e^{-ik\eta}) = 0$$

and

$$0 = (\beta+\alpha)(ik)^3 e^{ik\eta} - \frac{3}{4}(\beta+\alpha) v_0' \eta (ik) e^{ik\eta} + \lim_{\eta \to -\infty} Q^{11} e^{ik\eta} + \int_R f(k,l) e^{ik\eta} \, dl. \tag{58}$$

From the expression for Q^{11} we obtain

$$\lim_{\eta \to \infty} Q^{11} = (\beta+\alpha)(-3v_1'(\eta) + \tfrac{3}{4} v_0''(\eta) + \tfrac{3}{8}(v_0(\eta)^2)').$$

Assumption 1: In order to justify the limits above we only need to assume that the functions U_n and V_n are bounded, and not that they go to zero necessarily, since q decays as η and ξ go to either infinity.

From (58),

$$\int dl'\ f(k,l)e^{-il'\eta} = -(\beta+\alpha)((ik)^3 e^{ik\eta} + V_0(\eta)e^{ik\eta} + e^{ik\eta}V_2(\eta)),$$

where we have used the definitions of V_0 and V_2 given in the proof of Proposition 2. Multiplying both sides by $e^{il\eta}$ and integrating the variable η,

$$f(k,l) = -(\beta+\alpha)\left((ik)^3\delta(k-l) + \frac{ik}{2\pi}\int_R V_0(\eta)e^{-i(k-l)\eta}\,d\eta + \frac{1}{2\pi}\int_R V_2(\eta)e^{-i(k-l)\eta}\,d\eta \right).$$

Thus, the correct Lax pair is obtained by adding the vector

$$\mathrm{v} = -(\beta+\alpha)\left((\mathrm{ik})^3\Psi + \int_{\mathrm{R}} \gamma_1(\mathrm{k}-\mathrm{l})\Psi(\mathrm{l})\,\mathrm{dl} + (\mathrm{ik})\int \gamma_2(\mathrm{k}-\mathrm{l})\Psi(\mathrm{l})\,\mathrm{dl} \right),$$

where

$$\gamma_1(n) = \frac{1}{2\pi}\int_R V_2(\eta)e^{-in\eta}\,d\eta, \qquad \gamma_2(n) = \frac{1}{2\pi}\int_R V_0(\eta)e^{-in\eta}\,d\eta. \qquad \square$$

C. Derivation of type II systems

In what follows, we assume that $\sigma = i$ in (4), thus ∂_η becomes ∂_z and ∂_ξ becomes $\partial_{\bar z}$.

Proposition 5: The Lax pair formed by L and L_2, where L is as in (4),

$$L_2 = \partial_t + (\alpha+\beta J)\partial_y^2 + i\beta P\partial_y + Q,$$

and Q is defined by (42), gives rise to the system of equations

$$q_t = (\beta-\alpha)q_{zz} + (\beta+\alpha)q_{\bar z\bar z} - \frac{q}{2}\left((\beta-\alpha)\partial_{\bar z}^{-1}(qr)_z + (\beta+\alpha)\partial_z^{-1}(qr)_{\bar z}\right),$$

$$r_t = (\beta-\alpha)r_{zz} + (\beta+\alpha)r_{\bar z\bar z} - \frac{r}{2}\left((\beta-\alpha)\partial_{\bar z}^{-1}(qr)_z + (\beta+\alpha)\partial_z^{-1}(qr)_{\bar z}\right).$$

This system admits the reduction $r = \epsilon\bar q$ and in this case it reduces to

$$q_t = (\beta-\alpha)q_{zz} + (\beta+\alpha)q_{\bar z\bar z} - \epsilon\frac{q}{2}\left((\beta-\alpha)\partial_{\bar z}^{-1}(|q|^2)_z + (\beta+\alpha)\partial_z^{-1}(|q|^2)_{\bar z}\right).$$

Proposition 6: The Lax pair formed by L and L_3, where

$$L_3 = \partial_t + i(\alpha+\beta J)\partial_y^3 - \beta P\partial_y^2 - iC\partial_y + Q,$$

and C and Q are defined by (44) and (45), respectively, gives rise to the system of equations

$$\begin{aligned} q_t &= (\beta-\alpha)q_{zzz} + (\alpha+\beta)q_{\bar z\bar z\bar z} - \tfrac{3}{4}(\alpha+\beta)q\partial_z^{-1}(rq_{\bar z})_{\bar z} - \tfrac{3}{4}(\beta-\alpha)q\partial_{\bar z}^{-1}(rq_z)_z \\ &\quad - \tfrac{3}{4}(\alpha+\beta)q_{\bar z}\partial_z^{-1}(qr)_{\bar z} - \tfrac{3}{4}(\beta-\alpha)q_z\partial_{\bar z}^{-1}(qr)_z, \\ r_t &= (\beta-\alpha)r_{zzz} + (\alpha+\beta)r_{\bar z\bar z\bar z} - \tfrac{3}{4}(\alpha+\beta)r\partial_z^{-1}(qr_{\bar z})_{\bar z} - \tfrac{3}{4}(\beta-\alpha)r\partial_{\bar z}^{-1}(qr_z)_z \\ &\quad - \tfrac{3}{4}(\alpha+\beta)r_{\bar z}\partial_z^{-1}(rq)_{\bar z} - \tfrac{3}{4}(\beta-\alpha)r_z\partial_{\bar z}^{-1}(rq)_z. \end{aligned} \tag{59}$$

This system admits the following reductions:

(1) $r=-1$. Setting $r=-1$, the system reduces to the single equation

$$u_t=(\beta-\alpha)u_{zzz}+(\beta+\alpha)u_{\bar{z}\bar{z}\bar{z}}+\tfrac{3}{4}(\alpha+\beta)(u\partial_z^{-1}u_{\bar{z}})_{\bar{z}}+\tfrac{3}{4}(\beta-\alpha)(u\partial_{\bar{z}}^{-1}u_z)_z, \tag{60}$$

where $q=u$.

(2) $r=-q=-v$. Setting $r=-q=-v$, the system reduces to the single equation

$$\begin{aligned} v_t=&(\beta-\alpha)v_{zzz}+(\alpha+\beta)v_{\bar{z}\bar{z}\bar{z}}+\tfrac{3}{4}(\alpha+\beta)v\partial_z^{-1}(vv_{\bar{z}})_{\bar{z}}+\tfrac{3}{4}(\beta-\alpha)v\partial_{\bar{z}}^{-1}(vv_z)_z\\ &+\tfrac{3}{4}(\alpha+\beta)v_{\bar{z}}\partial_z^{-1}(v^2)_{\bar{z}}+\tfrac{3}{4}(\beta-\alpha)v_z\partial_{\bar{z}}^{-1}(v^2)_z. \end{aligned} \tag{61}$$

Proof of Propositions 5 and 6: The starting point in this case is the DBAR problem,

$$\begin{aligned} &\partial_\lambda^{-}\mu(k,x,y,t)=\int dl\ \mu(l,x,y,t)R_0(l,k,x,y,t),\\ &\mu(k,x,y,t)\sim 1+\frac{\mu_1(x,y,t)}{\lambda}+\frac{\mu_2(x,y,t)}{\lambda^2}+O\left(\frac{1}{\lambda^3}\right),\quad \lambda\to\infty. \end{aligned} \tag{62}$$

The functions μ and R_0 are matrix-valued functions. We introduce the operators

$$\begin{aligned} &D_x\mu=\mu_x+\lambda\mu J,\quad D_y\mu=\mu_y-i\lambda\mu,\\ &D_t\mu=\mu_t+\lambda^2\mu(\alpha+\beta J). \end{aligned} \tag{63}$$

Again we assume that the $\bar{\partial}$ problem (62) has a unique solution. Let P_R be given by the rhs of (62), that is

$$P_R\mu(k,x,y,t)\equiv\int dl\ \mu(l,x,y,t)R(l,k,x,y,t),$$

and choose R so that P_R commutes with the operators (63). This produces the following equations for the function R:

$$\begin{aligned} &R_x=-kJR+lRJ,\quad R_y=i(k-l)R,\\ &R_t=-l^2R(\alpha+\beta J)+k^2(\alpha+\beta J)R. \end{aligned}$$

These equations are satisfied if, for example,

$$R(k,l,x,y,t)=\exp\{-k(xJ-iy)+k^2(\alpha+\beta J)t\}R_0(k,l)\exp\{k(xJ-iy)-k^2(\alpha+\beta J)t\}.$$

Now we look for linear combinations of the operators D_x, D_y, and D_t that vanish for $k\to\infty$. By the assumption of uniqueness of solution for the DBAR problem, these linear combinations must be identically zero. □

IV. RELATIONS BETWEEN THE VARIOUS EQUATIONS

A. Simple transformations

In this section we analyze the relation between the various systems derived in the previous chapter. We show that there are three different cases of the system (6) in Proposition 1 corresponding to the values $(\alpha,\beta)=(0,1)$, $(\alpha,\beta)=(1,0)$, and $(\alpha,\beta)=(\frac{1}{2},\ \frac{1}{2})$; and only two cases of the systems considered in Propositions 5, 2, and 6. These correspond to $(\alpha,\beta)=(0,1)$ and $(\alpha,\beta)=(\frac{1}{2},\ \frac{1}{2})$.

Proposition 7: If q and r satisfy (6) with α and β such that $\alpha+\beta>0$ and $\beta-\alpha>0$, then the transformed $\tilde{q}$ and $\tilde{r}$ given by

$$\tilde{q}(\eta,\xi,t)=\frac{1}{a}\,q\left(\frac{\eta}{a},\frac{\xi}{b},t\right),\quad \tilde{r}(\eta,\xi,t)=\frac{1}{b}\,r\left(\frac{\eta}{a},\frac{\xi}{b},t\right),\tag{64}$$

where $a^2=\alpha+\beta$ *and* $b^2=\beta-\alpha$, *satisfy the system (6) with* $\alpha=0$, $\beta=1$, $\tilde{U}(\eta)=U(\eta/a)$, *and* $\tilde{V}(\xi)=V(\xi/b)$.

If q *and* r *satisfy (6) with* $\alpha+\beta>0$ *and* $\beta-\alpha<0$, *then* $\tilde{q}$ *and* $\tilde{r}$ *defined by (64), where* $a^2=\beta+\alpha$ *and* $b^2=\alpha-\beta$, *satisfy (6) with* $\alpha=1$ *and* $\beta=0$.

If q *and* r *satisfy (11) with* $\beta+\alpha\neq 0$ *and* $\beta-\alpha\neq 0$, *then* $\tilde{q}$ *and* $\tilde{r}$ *defined by (64), where* $a^3=\beta+\alpha$ *and* $b^3=\alpha-\beta$, *satisfy (11) with* $\alpha=0$ *and* $\beta=1$.

Proof: The proof is a straightforward computation that makes use of the fact that

$$\tilde{f}_{\eta}(\eta,\xi,t)=\frac{1}{a}\,f\left(\frac{\eta}{a},\frac{\xi}{b},t\right),\quad \tilde{f}_{\xi}(\eta,\xi,t)=\frac{1}{b}\,f\left(\frac{\eta}{a},\frac{\xi}{b},t\right),$$

and that

$$\partial_{\eta}^{-1}\tilde{f}(\eta,\xi)=\int_{-\infty}^{\eta}\tilde{f}(s,\xi)\,ds=\int_{-\infty}^{\eta}f\left(\frac{s}{a},\frac{\xi}{b}\right)\,ds=a\int_{-\infty}^{\eta/a}f\left(s,\frac{\xi}{b}\right)\,ds=a\,\partial_{\eta}^{-1}f\left(\frac{\eta}{a},\frac{\xi}{b}\right).$$

From this computation we see that if we assume that $\alpha+\beta>0$ and $\beta-\alpha>0$ and we take $a^2=\beta+\alpha$ and $b^2=\beta-\alpha$, then we can transform (6) to the same equation but with $\beta+\alpha=1$ and $\beta-\alpha=1$. This transformation will preserve the reality of the variables ξ and η.

Performing the transformation (64) to a solution of the system in (11) with $a^3=\beta+\alpha$ and $b^3=\beta-\alpha$ we produce a solution to (11) with $(\alpha,\beta)=(0,1)$. In this case no restriction is necessary in the signs of $\alpha+\beta$ and $\beta-\alpha$, provided that neither of those quantities is zero, since we can always find a real cube root for the equations $a^3-(\beta+\alpha)=0$ and $b^3-(\beta-\alpha)=0$. □

Proposition 8: Let q *and* r *satisfy (9). Define*

$$\tilde{q}(z,\bar{z},t)=\frac{1}{a}\,q\left(\frac{z}{a},\frac{\bar{z}}{b},t\right),\quad \tilde{r}(z,\bar{z},t)=\frac{1}{b}\,r\left(\frac{z}{a},\frac{\bar{z}}{b},t\right).$$

where $a^2=\beta+\alpha$ *and* $b^2=\beta-\alpha$. *Then* $\tilde{q}$ *and* $\tilde{r}$ *satisfy the system (9) with* $\alpha=0$ *and* $\beta=1$. *Let* q *and* r *be solutions to (59). Then* $\tilde{q}$ *and* $\tilde{r}$ *given by (64), where* $a^3=\beta+\alpha$ *and* $b^3=\beta-\alpha$, *solve (59) with* $\alpha=0$ *and* $\beta=1$.

Proof: The proof is similar to that of the previous proposition. We show in detail the action of the change of variables on the operators ∂_z^{-1} and $\partial_{\bar{z}}^{-1}$. For any function $f(x,y)=f(z)=f(z,\bar{z})$, we have

$$(\partial_z^{-1}f\,)(z)=\frac{1}{\pi}\int dx\,dy\,\frac{f(\zeta,\bar{\zeta})}{z-\zeta},$$

where $z=x+iy$ and $\bar{z}=x-iy$. Setting $f(z,\bar{z})=\hat{f}(az,b\bar{z})$, the above transforms to

$$\begin{aligned}(\partial_z^{-1}f\,)(z)&=\frac{1}{\pi}\int dx\,dy\,\frac{\tilde{f}(a\zeta,b\bar{\zeta})}{z-\zeta}\\&=\frac{1}{\pi}\int dx'\,dy'\,\frac{\partial(x,y)}{\partial(x',y')}\,\frac{\tilde{f}(x',y')}{z-\eta/a}=\frac{1}{b\pi}\int dx'\,dy'\,\frac{\tilde{f}(x',y')}{az-\eta}=\frac{1}{b}\,(\partial_z^{-1}\tilde{f}\,)(az),\end{aligned}$$

where we have used the change of variables $x'+iy'=a\zeta$ and $x'-iy'=b\bar{\zeta}$ inside the integral, so that the Jacobian $\partial(x,y)/\partial(x',y')$ has the value $(ab)^{-1}$. Similarly,

$$(\partial_{\bar z}^{-1} f\,)(\bar z) = \frac{1}{a}\,\partial_{\bar z}^{-1}\tilde f(b\bar z). \qquad \square$$

Remark 3: An interesting feature of this transformation is that in order to consider the reductions of the systems, the substitution $r=\epsilon\bar q$ in the case of the second-order systems or $r=-q$ in the case of the third-order systems must be done after the change of variables.

B. The Miura map between NVN and modified NVN

Proposition 9: If v is a solution of (61) and u is defined by

$$u = v\,\partial_{\bar z}^{-1} v_z - v_z, \tag{65}$$

then u is a solution of (60).

Remark 4: The same transformation holds in the case of the systems (11) with z substituted for ξ and $\bar z$ substituted for η.

Proof: This proof is a generalization to two dimensions of the following one-dimensional argument to derive the Miura map for the KdV equation. Let $v=\Psi_1/\Psi_2$ with Ψ_1 and Ψ_2 such that

$$\left[\begin{pmatrix}\partial_z & 0\\ 0 & \partial_{\bar z}\end{pmatrix}+\begin{pmatrix}0 & u\\ 1 & 0\end{pmatrix}\right]\begin{pmatrix}\Psi_1\\ \Psi_2\end{pmatrix}=\begin{pmatrix}0\\ 0\end{pmatrix}. \tag{66}$$

Define (Φ_1,Φ_2) solutions to

$$\left[\begin{pmatrix}\partial_z & 0\\ 0 & \partial_{\bar z}\end{pmatrix}+\begin{pmatrix}0 & v\\ -v & 0\end{pmatrix}\right]\begin{pmatrix}\Phi_1\\ \Phi_2\end{pmatrix}=\begin{pmatrix}0\\ 0\end{pmatrix}. \tag{67}$$

This can be written as

$$\Psi_2\Phi_{1z}+\Psi_1\Phi_2=0, \tag{68a}$$

$$\Psi_2\Phi_{2\bar z}-\Psi_1\Phi_1=0. \tag{68b}$$

Differentiating (68a) with respect to $\bar z$ and (68b) with respect to z we obtain

$$\Psi_{2\bar z}\Phi_{1z}+\Psi_2\Phi_{1z\bar z}+\Psi_{1\bar z}\Phi_2+\Psi_1\Phi_{2\bar z}=0,$$

$$\Psi_{2z}\Phi_{2\bar z}+\Psi_2\Phi_{2z\bar z}-\Psi_{1z}\Phi_1-\Psi_1\Phi_{1z}=0. \tag{69}$$

From (67)

$$\Phi_{1z\bar z}=(-v\Phi_2)_{\bar z}=-v_{\bar z}\Phi_2-v\Phi_{2\bar z}=-v_{\bar z}\Phi_2-v^2\Phi_1,$$

$$\Phi_{2z\bar z}=(v\Phi_1)_z=v_z\Phi_1+v\Phi_{1z}=v_z\Phi_1-v^2\Phi_2.$$

Using this and (67) to substitute all Φ_{1z} and $\Phi_{2\bar z}$, (69) can be written as

$$-v\Psi_{2\bar z}\Phi_2-v_{\bar z}\Psi_2\Phi_2-v^2\Phi_2\Phi_1+\Psi_{1\bar z}\Phi_2+v\Psi_1\Phi_1=0,$$

$$v\Psi_{2z}\Phi_1+v_z\Psi_2\Phi_1-v^2\Psi_2\Phi_2-\Psi_{1z}\Phi_1+v\Psi_1\Phi_2=0,$$

or

$$\begin{aligned}(-v^2\Psi_2+v\Psi_1)\Phi_1-(v\Psi_{2\bar z}+v_{\bar z}\Psi_2-\Psi_{1\bar z})\Phi_2=0,\\ (v\Psi_{2z}+v_z\Psi_2-\Psi_{1z})\Phi_1+(-v^2\Psi_2+v\Psi_1)\Phi_2=0.\end{aligned} \tag{70}$$

However,

$$v^2\Psi_2 - v\Psi_1 = \left(\frac{\Psi_1}{\Psi_2}\right)^2 \Psi_2 - \frac{\Psi_1}{\Psi_2}\Psi_1 = \frac{\Psi_1^2}{\Psi_2} - \frac{\Psi_1^2}{\Psi_2} = 0$$

and $\Psi_1 = v\Psi_2$, so $\Psi_{1\bar{z}} = v_{\bar{z}}\Psi_2 + v\Psi_{2\bar{z}}$. Therefore (70) is always satisfied.

The reasoning above shows that taking $v = \Psi_1/\Psi_2$ where (Ψ_1, Ψ_2) solves the system (66) with u a solution to (60) imposes no condition on Ψ_1 and Ψ_2, that is that this is a compatible procedure; here (Φ_1, Φ_2) solve (67) with $v = \Psi_1/\Psi_2$. Now we derive the relation between u and v. From (66) we find that $u = -\Psi_{1z}/\Psi_2$. Then,

$$v_z = \left(\frac{\Psi_1}{\Psi_2}\right)_z = \frac{\Psi_{1z}}{\Psi_2} - \frac{\Psi_1}{\Psi_2}\frac{\Psi_{2z}}{\Psi_2} = -u - v\frac{\Psi_{2z}}{\Psi_2} \tag{71}$$

or

$$\frac{\Psi_{2z}}{\Psi_2} = -\frac{u + v_z}{v}. \tag{72}$$

Differentiating (72) with respect to $\bar{z}$,

$$\frac{\Psi_{2z\bar{z}}}{\Psi_2} - \frac{\Psi_{2z}}{\Psi_2}\frac{\Psi_{2\bar{z}}}{\Psi_2} = -\left(\frac{u + v_z}{v}\right)_{\bar{z}}. \tag{73}$$

Substituting $\Psi_{2\bar{z}z} = -\Psi_1$ from (66) on the left hand side and using (71)

$$\text{lhs} = -\frac{\Psi_{1z}}{\Psi_2} + \frac{\Psi_{2z}}{\Psi_2}\frac{\Psi_1}{\Psi_2} = -v_z.$$

Therefore (73) can be written as

$$u = v\partial_{\bar{z}}^{-1}v_z - v_z.$$

□

V. BI-HAMILTONIAN STRUCTURE

We omit in this section the preliminary material and refer the reader to the paper by Fokas and Gel'fand.[12] We give the results on the bi-Hamiltonian nature of the DS-type equation that are not of the degenerate ($\alpha = \beta$) kind.

The Hamiltonian approach to integrability of nonlinear evolution equations in $1+1$, in one spatial and one temporal dimension, has its origin in the works of Zakharov and Fadeev[13,14] and Gardner[15] who interpreted the KdV equation

$$u_t = u_{xxx} + 6uu_x$$

as a completely integrable Hamiltonian system in an infinite-dimensional phase space. It was shown in Ref. 13 that the inverse spectral method yields action-angle variables for this equation. Hierarchies of infinitely many commuting vector fields and constants of motion in involution for the KdV equation were constructed by Lax[16,17] and by Gel'fand and Dikii[18–20] using the equation for the resolvent of the Schrödinger operator (which is related to the equation for the squared eigenfunctions). The approach of Lax is based on what became later known as the Lenard scheme (see below), while Gel'fand and Dikii obtained the constants of motion explicitly in terms of fractional powers of the Schrödinger operator, using what is known as the resolvent scheme.

In this work we use the fact that the squared eigenfunction operator can be factorized in terms of two compatible Hamiltonian operators to compute the pair of Hamiltonian operators associated to systems of the DS type.

We consider the ring $\mathscr{R}$ consisting of smooth functions of the basic dynamical variables $u(x,y,t)$, of its x and y derivatives, and of primitives (integrals) with respect to ∂_x of smooth functions of u and of $\partial^{\alpha+\beta}/\partial_x^\alpha \partial_y^\beta$. We assume that the operator ∂_x^{-1} is skew-symmetric, for example, if the dynamical variables decay fast enough at infinity, $\partial_x^{-1}=\frac{1}{2}(\int_{-\infty}^{x}-\int_{x}^{\infty})$. The inclusion of ∂^{-1} in the construction of this ring is a necessary consequence of the fact that the bi-Hamiltonian equations in $2+1$ are nonlocal equations. With the ring $\mathscr{R}$ we consider the ring $\mathscr{R}\{\partial_y\}$ of formal pseudodifferential operators in ∂_y with coefficients in $\mathscr{R}$. The multiplication law is uniquely defined by $\partial_y \cdot a = a\partial_y + (\partial_y a)$, $\partial_y^{-1}\cdot a = a\partial_y^{-1} - (\partial_y a)\partial_y^{-2} + (\partial_y^2 a)\partial_y^{-3} - \cdots$, $a \in \mathscr{R}$. Under this multiplication, $\mathscr{R}\{\partial_y\}$ becomes an associative ring.

Vector fields, denoted by v, are elements of $\mathscr{R}\{\partial_y\}$ which are equipped with the commutator

$$L_{v_1} v_2 = v_2' v_1 - v_1' v_2, \quad v_1, v_2 \in \mathscr{R}\{\partial_y\}.$$

We refer the reader to Ref. 12 for the construction of the complex Ω^k of differential forms and proceed to review the *square eigenfunction* method of deriving the Hamiltonian operator for $1+1$ and $2+1$ systems.

The equation $Lv=0$ can be written in the form $\Psi = W\Psi$, where W is an operator in ∂_y. We can define the adjoint of this equation and obtain

$$\Phi = [W, \Phi], \Phi = \Psi\hat{\Psi}. \tag{74}$$

Hamiltonian operators can be used to derive integrable Hamiltonian equations via the *Lenard scheme*.

Proposition 10: The Lenard scheme.[12] *Let Θ and Λ be two compatible Hamiltonian operators $\Omega^1 \to V$ and let v_1 be a vector field in V such that*

$$v_1 = \Theta\xi_0 = \Lambda\xi_1, \quad \xi_0, \xi_1 \in \Omega^1, \quad d\xi_0, d\xi_1 = 0.$$

Consider the hierarchy

$$v_i = \Theta\xi_{i-1} = \Lambda\xi_i, \quad i = 1,2,...,$$

and assume that if some $\xi \in \Omega^1$ is closed on the image of Λ, then $d\xi = 0$. Then,
(i) all ξ_i are closed, i.e., $d\xi_i = 0$;
(ii) all v_i commute in V; and
(iii) all ξ_i commute.

Thus, if $\xi_i = d\uparrow f_i\downarrow$, then

$$\{f_i, f_j\}_\Theta = \{f_i, f_j\}_\Lambda = 0,$$

and $u_t = v_i$, $i=1,2,...$, is a completely integrable Hamiltonian system.

A. Bi-Hamiltonian structures for equations of the DS type

Consider the wave function Ψ and the Lax equation

$$\Psi_x = W\Psi, \quad \text{with} \quad W = -J\partial_y - P - ikJ,$$

and its *adjoint* modified version

$$\hat{\Psi}_x = -\hat{\Psi}AWA^{-1} \quad \text{with} \quad A = \begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}.$$

Then the squared eigenfunction $\Phi \equiv \Psi\hat{\Psi}$ satisfies the equation

$$\Phi = W\Phi - \Phi AWA^{-1}.$$

Therefore, the operator

$$\partial_x + \cdot AWA^{-1} - W = \partial_x + \cdot (-J\partial_y - APA^{-1} - ikJ) + (J\partial_y + P + ikJ)\cdot$$
$$= \mathscr{R} = \partial_x \cdot + [J\partial_y, \cdot] + \{P\cdot - \cdot (APA^{-1})\} + ik[J, \cdot]$$

is Hamiltonian. This suggests the following two compatible Hamiltonian operators:

$$\Theta \cdot = \partial_x \cdot + [J\partial_y, \cdot] + \{P\cdot - \cdot (APA^{-1})\}, \quad \Lambda \cdot = [iJ, \cdot]. \tag{75}$$

Applying (75) to a vector $v = \begin{pmatrix} v^{(11)} & v^{(12)} \\ v^{(21)} & v^{(22)} \end{pmatrix}$ one obtains

$$\Theta v = \begin{pmatrix} 2v_\xi^{(11)} + qv^{(21)} - \dfrac{a}{b} v^{(12)} r & 2v_\xi^{(12)} + 2v^{(12)}v^{(22)}\partial_y + qv^{(22)} - \dfrac{a}{b} v^{(11)} q \\ rv^{(11)} - \dfrac{a}{b} v^{(22)} r + 2v_\eta^{(21)} - 2v^{(21)}v^{(22)}\partial_y & 2v_\eta^{(22)} + rv^{(12)} - \dfrac{a}{b} v^{(21)} q \end{pmatrix},$$

$$\Lambda v = \begin{pmatrix} 0 & 2iv^{(12)} \\ -2iv^{(21)} & 0 \end{pmatrix}.$$

Proposition 11: The second- and third-order systems possess a bi-Hamiltonian structure with the operators (75).

Proof: We apply Proposition 10 and note that the combination $i\Theta v_2 - 2\Theta v_1' - i\Theta v_0''$ is a function (as opposed to a pseudodifferential operator). This combination yields the right-hand side of the second-order system (6) with boundary functions equal to zero and $a^2 = \beta + \alpha$ and $b^2 = \beta - \alpha$. □

Remark 5: If a or b is zero (that is if $\alpha = \pm\beta$), then the above construction breaks down. The problem of computing the bi-Hamiltonian structure for the Fokas-type systems is, to the best of our knowledge, not solved.

The representations of the Heisenberg algebra in Krein spaces, more generally in weakly complete inner product spaces, are classified under general regularity and irreducibility conditions. Besides the Fock representation, two other types appear; one with negative, the other with a two-sided discrete spectrum of the number operator. © *1998 American Institute of Physics.* [S0022-2488(98)00405-8]

I. INTRODUCTION

The main motivation of this paper is the classification of the representations of the canonical commutation relations in Krein spaces; this problem arises for the mathematical foundations of the quantization in indefinite metric spaces proposed by Dirac and Heisenberg[1,2] and crucially enters in the local formulation of gauge QFTs,[3,4] where locality and covariance of the gauge fields are incompatible with positivity of the inner product. In this paper we start by looking at the case of finite degrees of freedom and classify the irreducible representations of the Heisenberg algebra in Krein spaces, actually in all weakly complete indefinite inner product spaces.

The Heisenberg algebra is the algebraic structure at the basis of Quantum Mechanics (QM), and it is of great interest, not only from a physical point of view, but also as a basic mathematical structure. It is the Lie algebra generated by the so-called canonical variables, q_i, p_i, $i=1,\dots n$, satisfying the following commutation relations (CCR in unbounded form):[5–7]

$$[p_i,q_j]=-i\delta_{i,j},\quad [q_i,q_j]=0=[p_i,p_j]. \tag{1.1}$$

The foundations of QM rely on the analysis of the representations of such an algebra and great clarification of the mathematical structures of QM has been obtained by this analysis.[8–10]

From a technical point of view, nontrivial problems arise because the commutation relations (1.1) imply that q_i and p_i cannot be represented by bounded operators (in fact, the corresponding group is not compact); as a consequence, domain questions become important, the concept of irreducibility is delicate (see below), etc. For these reasons, one usually considers the algebra $\mathscr{A}$ generated by the Weyl exponentials $\exp i\alpha q$, $\exp i\beta p$, $\alpha,\beta\in\mathbb{R}^n$ (briefly, the Weyl algebra). This amounts to consider, instead of the Lie algebra (1.1), the associated group (the Heisenberg group), and to analyze its representations. A systematic classification of such representations in a Hilbert space, under general regularity conditions, is available.[9,10] It should, however, be remarked that the choice of the Weyl algebra, generated by rather special functions of the canonical variables q_i,p_i, gives rise to problems, e.g., for the algebraic setting of the dynamics, since, in general, the time evolution does not leave the Weyl algebra stable.[11] Actually, most of the standard treatments of QM models deal with the canonical variables directly, and therefore it is of some interest to consider the problem of analyzing the representations of the Heisenberg algebra directly.

This strategy is actually the most convenient one if one wants to consider the case of the representations of the CCRs in indefinite metric spaces, in particular in Krein spaces, since in this

 © 1998 American Institute of Physics

case q_i and p_i are not self-adjoint operators, the construction of the Weyl exponentials is, in general, problematic and requires domain and regularity assumptions, and the advantage is not significant since the Weyl exponentials need not be bounded operators.

A notable case of an analysis of the Hilbert space representations of the CCRs based on the Heisenberg algebra is the theorem by Rellich and Dixmier,[12–14] which overcomes the difficulties mentioned above, by assuming that $N=1/2(p^2+q^2-1)$ is essentially self-adjoint on a dense domain invariant under the closure of p and q. The result of this paper is a generalization of the theorem by Rellich and Dixmier, which covers the case of representations of the Heisenberg algebra in Krein spaces, together with a discussion of irreducibility.

Crucial technical points of our approach are the following: (i) a proper position of the irreducibility problem in a situation in which the algebra consists of unbounded operators; and (ii) regularity assumptions in the same spirit of Rellich and Dixmier. The result is that the spectrum of $N=1/2(p^2+q^2-1)$ is discrete (but not semibounded, in general), and in terms of it one has a classification of the irreducible representations of the Heisenberg algebra in Krein spaces (more generally, in weakly complete nondegenerate inner product spaces). Up to isometries between indefinite spaces, such representations are completely described by the action of the algebra on the (weakly) dense domain generated by the eigenvector of N.

II. GENERAL SETTING

*Definition 1: The Heisenberg algebra $\mathscr{H}$ for n degrees of freedom is the complex * algebra generated by p_i, q_i, $i=1,\ldots n$, with the relations (1.1) and $p_i^*=p_i$, $q_i^*=q_i$.*

In the following, we will use the standard notation

$$a_i^*\equiv 1/\sqrt{2}(q_i-ip_i),\quad a\equiv 1/\sqrt{2}(q_i+ip_i),\quad N=\sum_i a_i^* a_i .$$

The Heisenberg relations become

$$[a_i,a_j^*]=\delta_{i,j},\quad [a_i,a_j]=[a_i^*,a_j^*]=0.$$

For simplicity, in the following we restrict our attention to the Heisenberg algebra for one degree of freedom, the extension to a finite number of degrees of freedom being straightforward.

A Krein space $\mathscr{K}$[15,16] is a vector space with indefinite inner product $\langle\cdot,\cdot\rangle$ and a linear operator J, such that

(i) $J^2=1$,
(ii) $(x,x)\equiv\langle x,Jx\rangle\geqslant 0,\quad \forall x\in\mathscr{K}$,
(iii) $\mathscr{K}$ is complete in the norm $\|x\|=(x,x)^{1/2}$.

We recall that in a Krein space the weak Krein topology, defined by the inner product $\langle\cdot,\cdot\rangle$, coincides with the weak Hilbert topology, defined by the Hilbert scalar product $(\cdot,\cdot)$. In the following, we will only consider separable Krein spaces.

For any densely defined operator A on $\mathscr{K}$, the adjoint $A^\dagger$ is defined, as in the Hilbert space case, by

$$\langle A^\dagger x,y\rangle=\langle x,Ay\rangle,\quad \forall y\in\mathscr{D}_A .$$

An operator A is closable (in the strong Hilbert topology) iff its adjoint $A^\dagger$ is densely defined, and then its closure $\bar{A}$ coincides with $(A^\dagger)^\dagger$. An operator A is said to be weakly closable if $x_n\to 0$ weakly and Ax_n weakly convergent implies $Ax_n\to 0$ weakly. Since weak and strong closures of operators coincide in Hilbert spaces, they also coincide in Krein spaces.

Given Krein spaces $\mathscr{K}_1,\mathscr{K}_2$, a linear operator U, defined on a dense domain $\mathscr{D}_1\subset\mathscr{K}_1$ with range in $\mathscr{K}_2$ is called an *isometry* if $\forall x,y\in\mathscr{D}_1$,

$$\langle Ux,Uy\rangle_{\mathscr{K}_2}=\langle x,y\rangle_{\mathscr{K}_1}.$$

From the nondegeneracy of the inner product and the density of $\mathscr{D}_1$, it follows that U has an inverse, defined on its range.

Definition 2: A representation of a $*$ algebra $\mathscr{A}$ in a Krein space $\mathscr{K}$ is a $*$ morphism ρ of $\mathscr{A}$ into the algebra of operators acting on a dense invariant common domain $\mathscr{D}\subset\mathscr{K}$, namely

$$\rho(\mathscr{A})\mathscr{D}\subset\mathscr{D},$$

and, $\forall x,y\in\mathscr{D}$, $A\in\mathscr{A}$,

$$\langle x,\rho(A)y\rangle=\langle\rho(A^*)x,y\rangle. \tag{2.1}$$

Equation (2.1) implies that all the operators $\rho(A)$, $A\in\mathscr{A}$, have a densely defined adjoint $\rho(A)^\dagger$, with respect to the indefinite inner product, and $\rho(A^*)\subset\rho(A)^\dagger$; all the operators $\rho(A)$ are therefore closable. For a discussion of representations of unbounded operator algebras, see Refs. 17 and 18.

In general, the common domain of the closures $\overline{\rho(A)}$, $A\in\mathscr{A}$, may not be invariant under the operators $\overline{\rho(A)}$, and therefore it may not define a representation of $\mathscr{A}$. However, any dense subspace $\mathscr{D}'$, invariant under all the closures $\overline{\rho(A)}$, $A\in\mathscr{A}$, provides a representation of the algebra in the sense of Definition 1. In fact, Eq. (2.1) implies $\overline{\rho(A)}\subset\rho(A^*)^\dagger$, and the invariance of $\mathscr{D}'$ implies $\forall x\in\mathscr{D}'$, $\overline{\rho(B)}x\in\mathscr{D}_{\overline{\rho(A)}}\subset\mathscr{D}_{\rho(A^*)^\dagger}$, so that $\forall y\in\mathscr{D}$, $x_n\in\mathscr{D}$, with $x_n\to x$ and $\rho(AB)x_n$ convergent,

$$\begin{aligned}\langle y,\overline{\rho(AB)}x\rangle&=\lim_n\langle y,\rho(AB)x_n\rangle=\lim_n\langle\rho(B^*)\rho(A^*)y,x_n\rangle\\&=\langle\rho(B^*)\rho(A^*)y,x\rangle\\&=\langle\rho(A^*)y,\overline{\rho(B)}x\rangle=\langle y,\overline{\rho(A)}\ \overline{\rho(B)}x\rangle.\end{aligned} \tag{2.2}$$

Thus, any representation, in the sense of Definition 2, is naturally associated with all the representations defined by dense domains invariant under the closures $\overline{\rho(A)}$, $A\in\mathscr{A}$. Since such representations are uniquely determined by ρ, it is convenient to introduce a notion of equivalence that identifies representations determined one from the other in the above sense.

Definition 3: Given two representations ρ_1, ρ_2 of a $*$ algebra $\mathscr{A}$ in Krein spaces $\mathscr{K}_1,\mathscr{K}_2$, with domains $\mathscr{D}_1,\mathscr{D}_2$, respectively, ρ_1 is said to be in the closure of ρ_2, briefly $\rho_1\subset\overline{\rho_2}$, if there exists an isometry $U:\mathscr{D}_1\to\mathscr{K}_2$, such that

$$U\rho_1(A)U^{-1}\subset\overline{\rho_2(A)},\quad\forall A\in\mathscr{A}.$$

The two representations are said to be equivalent if $\rho_1\subset\overline{\rho_2}$ and $\rho_2\subset\overline{\rho_1}$.
Clearly, $\rho_1\subset\overline{\rho_2}$ implies that $U\mathscr{D}_1$ is an invariant domain for the closures $\overline{\rho_2(A)}$.

We stress that for the analysis of the representations it is essential to consider the closures of the operators, since otherwise the restrictions of the same representation to different domains would appear as different, in general inequivalent, representations. Such phenomena occur in general when representations of unbounded algebras are considered,[17,18] but their control is more difficult in Krein spaces, due to the failure of some of the corresponding Hilbert space constructions.

According to the discussion given above, we will consider representations of the Heisenberg algebra that satisfy an additional *regularity condition*.

Definition 4: A representation ρ of the Heisenberg algebra $\mathscr{H}$ on a domain $\mathscr{D}$ will be called regular iff it satisfies the following condition:

(A) *(Regularity condition). The operator $\rho(N)=\frac{1}{2}\rho(q^2+p^2-1)$ is the weak derivative, on $\mathscr{D}$, of a one-parameter group $U(s)$, $s\in\mathbb{R}$:*

$$\frac{d}{ds}\langle y,U(s)x\rangle|_{s=0}=i\langle y,\rho(N)x\rangle,\quad\forall y\in\mathscr{K},\quad x\in\mathscr{D}, \tag{2.3}$$

with

$$U(s)\mathscr{D}\subset\mathscr{D}, \tag{2.4}$$

$$U(s)U(t)=U(s+t), \quad \text{on } \mathscr{D}. \tag{2.5}$$

Condition (A) implies

$$\langle U(s)x,U(s)y\rangle=\langle x,y\rangle, \quad \forall x,y\in D, \tag{2.6}$$

and therefore $U(-s)\subset U(s)^{\dagger}$, so that $U(s)$, $s\in\mathbb{R}$, are closable operators. Moreover, weakly on $\mathscr{D}$,

$$\frac{d}{ds}\,(U(s)\rho(a)U(-s))=iU(s)\rho([a^*a,a])U(-s)=-iU(s)\rho(a)U(-s),$$

so that

$$U(s)\rho(a)U(-s)=e^{is}\rho(a), \quad U(s)\rho(a^*)U(-s)=e^{is}\rho(a^*), \quad \text{on } \mathscr{D}. \tag{2.7}$$

Therefore, $U(s)$ implements the one-parameter group of ''gauge'' automorphisms of $\mathscr{H}$,

$$\gamma^s(a)=e^{-is}a, \quad \gamma^s(a^*)=e^{is}a^*. \tag{2.8}$$

Condition (A), Eq. (2.3), also implies that $U(s)$ is weakly continuous at the origin, and then, by the group law, for all $s\in\mathbb{R}$. Equations (2.3)–(2.5) immediately imply that

$$\frac{d}{ds}\,U(s)=i\rho(N)U(s), \quad \forall s\in\mathbb{R}, \tag{2.9}$$

as a weak derivative, on $\mathscr{D}$.

By Definition 2, a regular representation ρ defines an *extended algebra* $\mathscr{H}_{\text{ext}}$, as the concrete $*$ algebra generated by $\rho(\mathscr{H})$ and the group $U(s)$, $s\in\mathbb{R}$, satisfying $U(s)^*=U(-s)$ and the relations (2.7). In the following, when discussing a fixed representation ρ, we will denote, for simplicity, $\rho(A)$ by A. We will denote by $\mathscr{D}_c$ the common domain of the closure of the operators of $\mathscr{H}_{\text{ext}}$; we will omit the bar that denotes the closure, when no ambiguity may arise.

The regularity condition plays the rôle of the Rellich–Dixmier condition (essential self-adjointness of N on $\mathscr{D}$), and, in fact, in the ordinary Hilbert space case, the stability of $\mathscr{D}$ under $U(s)$ implies the essential self-adjointness of its generator N on $\mathscr{D}$. A stronger form of the Rellich–Dixmier condition is justified here because, without positivity of the inner product, the $U(s)$ need not to be continuous everywhere defined operators.

The next issue is a proper notion of irreducibility. As it is well known, the concept of irreducibility is delicate in the case of algebras of unbounded operators. Algebraic reducibility is a very weak property for algebras of *unbounded* operators, but also the existence of a proper closed subspace $\mathscr{K}_1\subset\mathscr{K}$ containing a common linear domain $\mathscr{D}_1$ invariant under $\mathscr{H}$ *(topological reducibility)*[19] is too weak, in particular for the Heisenberg algebra; in fact, in the ordinary Schrödinger representation in $L^2(\mathbb{R})$, which is irreducible for the Weyl algebra, the Heisenberg algebra, defined on the dense domain of C^∞ functions $f(x)$ of a fast decrease, with all derivatives vanishing at $x=0$, is topologically *reducible*, since the subdomain of the function with positive support is invariant and not dense (see the Appendix for more details).

A more relevant notion, which uses the regularity properties of the representation, is that of topological irreducibility *for the extended algebra* $\mathscr{H}_{ext}$:

Definition 5: A regular representation of $\mathscr{H}$ *is called domain irreducible if there is no nontrivial domain* $\mathscr{D}_1\subset\mathscr{D}_c$ *(the common dense domain of the weak closures of the elements of* $\mathscr{H}_{ext}$*), such that*

(i) $\mathscr{D}_1$ *is invariant under* $\mathscr{H}_{ext}$*; and*

(ii) $\mathscr{D}_1$ *is not dense in* $\mathscr{K}$.

The above definition recognizes the crucial role played by the ''integrated'' elements $U(s)$, very close to the role of the one-parameter group generated by the Nelson elliptic operator Δ in the classification of the Hilbert space representations of unbounded Lie algebras.[19,20]

It is immediate to see that domain irreducibility in the above sense is equivalent to cyclicity of all vectors x belonging to subspaces of $\mathscr{D}_c$ invariant under $\mathscr{H}_{\text{ext}}$, i.e., $\mathscr{H}_{\text{ext}}x$ is dense in $\mathscr{K}$. In fact, if x belongs to an invariant domain, by applying elements of $\mathscr{H}_{\text{ext}}$ to x, one gets an invariant subspace of $\mathscr{D}_c$, which must be dense, by Definition 5 (the converse is obvious).

An alternative definition of irreducibility is the one related to the triviality of the commutant, and it is often used in the analysis of unbounded operator algebras.[19] Given the representation of $\mathscr{H}$ on the domain $\mathscr{D}$, one could formulate commutant irreducibility by asking that any (weakly closable) operator $\mathscr{B}$ that leaves $\mathscr{D}$ invariant and commutes on $\mathscr{D}$ with $\mathscr{H}$ and $U(s)$, is a multiple of the identity.

The relation between this notion and Definition 5 does not appear as trivial as in the bounded positive case, because a spectral theory of unbounded operators in Krein spaces is not available. Moreover, reduction may take place only after the operators have been extended by closure, and, in fact a more relevant notion of commutant irreducibility must be given in terms of the extended domain $\mathscr{D}_c$.

Definition 6: A regular representation of $\mathscr{H}$ is said to be commutant irreducible if whenever a (densely defined) weakly closable operator B has the properties

(i) *B leaves invariant a nontrivial domain $\mathscr{D}_1 \subset \mathscr{D}_c$, invariant under $\mathscr{H}_{\text{ext}}$; and*

(ii) *B commutes with $\mathscr{H}_{\text{ext}}$ on $\mathscr{D}_1$,*

then B is a multiple of the identity.

It is easy to see that commutant irreducibility in the sense of Definition 6 implies domain irreducibility (Definition 5).

In Sect. III, we analyze irreducible representations in the sense of Definition 6. In Sect. IV, the same classification will be obtained (Theorem 13), assuming only domain irreducibility (Definition 5), but using additional regularity assumptions on $U(s)$.

III. REGULAR COMMUTANT IRREDUCIBLE REPRESENTATIONS OF THE HEISENBERG ALGEBRA IN KREIN SPACES

The general setting discussed in the previous section allows for the following characterization of the regular (Definition 4) irreducible (Definition 6) representations of the Heisenberg algebra. The proof essentially relies on the fact that commutant irreducibility implies the compactness of the group $U(s)$.

Theorem 7: *All regular, commutant irreducible representations of the Heisenberg algebra $\mathscr{H}$ in a Krein space $\mathscr{K}$ fall in the equivalence classes (Definition 3) of the following representations.*

(1) π_+: *The operators $U(s)$, $s \in \mathbb{R}$ have a common complete set of eigenvectors ψ_n, $n \in \mathbb{N}$, with*

$$U(s)\psi_n = e^{ins}\psi_n, \quad \langle \psi_l, \psi_m \rangle = \eta_0 \delta_{l,m}, \quad \eta_0 = \pm 1, \quad J = \eta_0 \mathbb{1}. \tag{3.1}$$

The representation is also characterized by the existence of a vector $\psi_0 \in \mathscr{D}_c$ (Fock vector), satisfying

$$a\psi_0 = 0. \tag{3.2}$$

(2) π_-: *The operators $U(s)$ have a common complete set of eigenvectors ψ_n, $n = -1, -2, \ldots$, satisfying Eq. (3.1), with*

$$\langle \psi_l, \psi_m \rangle = \eta_1 (-1)^m \delta_{l,m}, \quad \eta_1 = \pm 1, \quad J = \eta_1 (-1)^N.$$

The representation is also characterized by the existence of a vector $\psi_{-1} \in \mathscr{D}_c$ (anti-Fock vector), satisfying

$$a^* \psi_{-1} = 0. \tag{3.3}$$

(3) π_θ, $\theta \in (0,1)$: *The operators $U(s)$ have a common complete set of eigenvectors ψ_n, $n \in \mathbb{Z}$, with*

$$U(s)\psi_n = e^{i(\theta+n)s}\psi_n, \tag{3.4}$$

$$\langle \psi_l, \psi_m \rangle = \eta_\theta \delta_{l,m}, \quad m \geqslant 0, \quad \langle \psi_l, \psi_m \rangle = \eta_\theta \delta_{l,m}(-1)^{m+1}, \quad m < 0,$$

$$J\psi_m = \eta_\theta \psi_m, \quad m \geqslant 0, \quad J\psi_m = \eta_\theta(-1)^{m+1}\psi_m, \quad m < 0, \quad \eta_\theta = \pm 1 \tag{3.5}$$

(''Dirac sea states'').

In all the cases, the domain $\mathscr{D}$ can be taken as the linear span of the vectors ψ_n; the (closure of the) operators $U(s)$, $s \in \mathbb{R}$, commute with the metric operator J and are therefore unitary, with a simple point spectrum given by Eqs. (3.1), (3.4).

The proof follows from a few lemmas.

Lemma 8: The closures of $U(s)$, $s \in \mathbb{R}$, have common eigenvectors ψ_n, $n \in \mathbb{Z}$,

$$U(s)\psi_n = e^{i(n+\theta)s}\psi_n, \tag{3.6}$$

with θ fixed in [0,1); the linear span of such vectors is dense in $\mathscr{H}$.

Proof: By Eq. (2.4), the operator $U(2\pi)$ leaves $\mathscr{D}$ invariant, and by Eq. (2.8) it commutes with $\mathscr{H}$ and obviously with $U(s)$, $\forall s \in \mathbb{R}$. Therefore, by the commutant irreducibility of the representation, $U(2\pi)$ is a multiple of the identity, and actually a phase, by Eq. (2.6):

$$U(2\pi) = e^{2\pi i\theta}, \quad \theta \in [0,1). \tag{3.7}$$

Thus, the one-parameter group,

$$V(s) \equiv U(s)e^{-is\theta}, \quad s \in \mathbb{R}, \tag{3.8}$$

is a $U(1)$ group:

$$V(2\pi) = 1, \tag{3.9}$$

and $\forall \psi \in \mathscr{D}$, the vector-valued function $V(s)\psi$ is periodic and weakly continuous, by condition *A*. Hence, the Riemann sums,

$$\psi_n^{(\epsilon)} \equiv \frac{\epsilon}{2\pi} \sum_{s_k = k\epsilon, 0 \leqslant k < 2\pi/\epsilon} e^{-ins_k} V(s_k)\psi, \tag{3.10}$$

converge weakly, as $\epsilon \to 0$, to the (weak) integral,

$$\psi_n \equiv \frac{1}{2\pi} \int_0^{2\pi} e^{-ins} V(s)\psi ds, \tag{3.11}$$

which defines a vector in $\mathscr{H}$, by weak completeness. Moreover, $\forall t \in \mathbb{R}$, $V(t)\psi_n^{(\epsilon)}$ also converges weakly as $\epsilon \to 0$:

$$V(t)\psi_n^{(\epsilon)} = \frac{\epsilon}{2\pi} \sum_{s_k = k\epsilon, 0 \leqslant k < 2\pi/\epsilon} e^{-ins_k} V(t+s_k)\psi = \frac{\epsilon}{2\pi} \sum_{s_k} e^{-ins_k} e^{int} V(s_k)\psi \to e^{int}\psi_n, \tag{3.12}$$

where the periodicity of $V(s)$ has been used. Thus, all the vectors ψ_n are in the domain of the closures of $V(t)$, and

$$V(s)\psi_n = e^{ins}\psi_n. \tag{3.13}$$

Furthermore, the vector-valued weakly continuous periodic functions $V(s)\psi$ can be expressed (pointwise in s) by their (weakly convergent) Fourier series,

$$V(s)\psi=\sum_{n\in\mathbb{Z}} e^{ins}\psi_n . \tag{3.14}$$

For $s=0$, Eq. (3.14) expresses all $\psi\in\mathscr{D}$ as weak limits of linear combinations of the vectors ψ_n, so that their linear span is dense in $\mathscr{K}$.

Lemma 9: The vectors ψ_n constructed in Lemma 8 are eigenvectors of the closure of a^*a:

$$a^*a\psi_n=(n+\theta)\psi_n . \tag{3.15}$$

Proof: With the notations of the proof of Lemma 8, by condition (A), in the sense of weak derivatives:

$$\begin{aligned}(a^*a-\theta)\psi_n^{(\epsilon)}&=\frac{-i}{2\pi}\,\epsilon\sum_{s_k} e^{-ins_k}\frac{d}{dt}\,V(t)V(s_k)\psi\Big|_{t=0}\\&=\frac{-i}{2\pi}\,\epsilon\sum_{s_k} e^{-ins_k}V(s_k)\,\frac{d}{dt}\,V(t)\psi\Big|_{t=0}\\&\to\frac{-i}{2\pi}\int_0^{2\pi}ds e^{-ins}\frac{d}{ds}\,V(s)\psi=n\,\frac{1}{2}\int_0^{2\pi}ds e^{-ins}V(s)\psi,\end{aligned}$$

where an integration by parts has been performed in the last step.

Lemma 10: The linear span $\mathscr{D}_1$ of all the vectors ψ_n constructed in Lemma 8, as ψ varies on $\mathscr{D}$, is contained in $\mathscr{D}_c$ (the common domain of the weak closures of the elements of $\mathscr{K}_{\rm ext}$), and it is left invariant by $\mathscr{K}_{\rm ext}$. The Heisenberg relations hold on $\mathscr{D}_1$, and each vector in $\mathscr{D}_1$ is cyclic for $\mathscr{K}_{\rm ext}$. $\mathscr{D}_1$ provides a regular representation ρ_1 of $\mathscr{K}$, equivalent (Definition 3) to the representation ρ on $\mathscr{D}$. For any $\psi\in\mathscr{D}$ there is an integer $\bar{n}$ such that the vectors $(a^*)^k\psi_{\bar{n}}$, $a^l\psi_{\bar{n}}$ generate a dense subspace of $\mathscr{D}_1$.

Proof: By Eq. (3.10),

$$a\psi_n^{(\epsilon)}=\frac{\epsilon}{2\pi}\sum_{s_k} e^{-ins_k}aV(k\epsilon)\psi=\frac{\epsilon}{2\pi}\sum_{s_k} e^{-ins_k}e^{is_k}V(s_k)a\psi=(a\psi)_{n-1}^{(\epsilon)}, \tag{3.16}$$

and similarly,

$$a^*\psi_n^{(\epsilon)}=(a^*\psi)_{n+1}^{(\epsilon)} . \tag{3.17}$$

Since the rhs of Eqs. (3.16) and (3.17) converge by Lemma 8, the vectors ψ_n belong to the domain of the weak closure of a and a^*, and

$$\bar{a}\psi_n=(a\psi)_{n-1}, \quad \bar{a^*}\psi_n=(a^*\psi)_{n+1} . \tag{3.18}$$

The same treatment applies to all the products of a and a^*, so that $\mathscr{D}_1\subset\mathscr{D}_c$ and $\mathscr{K}_{\rm ext}\mathscr{D}_1\subset\mathscr{D}_1$. By irreducibility, $\mathscr{K}_{\rm ext}\chi$ is dense in $\mathscr{K}$, $\forall\chi\in\mathscr{D}_1$. The Heisenberg commutation relations hold on $\mathscr{D}_1$, as a consequence of their validity on $\mathscr{D}$, by Eq. (3.18):

$$(aa^*-a^*a)\psi_n=a(a^*\psi)_{n+1}-a^*(a\psi)_{n-1}=((aa^*-a^*a)\psi)_n=\psi_n . \tag{3.19}$$

Thus, $\mathscr{D}_1$ defines a representation ρ_1 contained in the closure of ρ; moreover, Eqs. (3.18) and (3.14) imply that $\mathscr{D}$ is contained in the domain of the closures of $\rho_1(A)$, for all $A\in\mathscr{A}$, so that $\rho\subset\bar{\rho_1}$, and the two representations are equivalent.

From Eqs. (3.19) and (3.15) one easily gets

$$aa^*\psi_n=(n+1+\theta)\psi_n \tag{3.20}$$

(an equation that could have been derived directly as in Lemma 9). For each ψ in $\mathscr{D}$, by Eq. (3.14), there is at least one $\psi_{\bar{n}}$ that does not vanish, and is then cyclic. Given any product of operators a,a^* applied to $\psi_{\bar{n}}$, by using Eqs. (3.18), (3.15), and (3.20), one can write it as a constant times

$(a^*)^k\psi_{\overline{n}}$, if the number of a^* operators exceeds, by k, that of the a's, or, otherwise, as $a^k\psi_{\overline{n}}$. The cyclicity of $\psi_{\overline{n}}$ implies therefore the density in $\mathscr{K}$ of the linear span of the vectors $\{(a^*)^k\psi_{\overline{n}}, a^l\psi_{\overline{n}}, k,l\in\mathbb{N}\}$.

Proof of Theorem 7: By Lemma 10, the analysis of regular irreducible representations of $\mathscr{H}$ can be done on the domain $\mathscr{D}_1$. Given a vector $\psi_{\overline{n}}\in\mathscr{D}_1$, we consider first the case in which at least one of the sequences $a^k\psi_{\overline{n}}$ terminates. If, for some $k>0$,

$$a^k\psi_{\overline{n}}=0, \quad a^{k-1}\psi_{\overline{n}}\neq 0, \tag{3.21}$$

then, by Eqs. (3.15) and (3.18) one has

$$0=a^*a\,a^{k-1}\psi_{\overline{n}}=a^*a(a^{k-1}\psi)_{\overline{n}-k+1}=(\overline{n}-k+1+\theta)a^{k-1}\psi_{\overline{n}},$$

i.e.,

$$\overline{n}-k+1+\theta=0, \tag{3.22}$$

which implies $\theta=0$, since $\theta\in[0,1)$. Similarly,

$$(a^*)^l\psi_{\overline{n}}=0, \quad (a^*)^{l-1}\psi_{\overline{n}}\neq 0 \tag{3.23}$$

implies, by Eqs. (3.18) and (3.20),

$$\overline{n}+l+\theta=0, \tag{3.24}$$

and therefore again $\theta=0$, Eqs. (3.22) and (3.24) are incompatible, and therefore only one sequence can terminate.

Case 1: Equation (3.21) holds. Then, putting

$$\psi_0\equiv a^{k-1}\psi_{\overline{n}}=(a^{k-1}\psi)_0, \tag{3.25}$$

one has

$$a\,\psi_0=0, \tag{3.26}$$

and $\mathscr{D}_1$ is generated by the vectors $(a^*)^l\psi_0, l\geqslant 0$. (*Fock representation*). By using Eqs. (3.18), (3.20), and (3.25) one gets

$$\langle(a^*)^l\psi_0,(a^*)^m\psi_0\rangle=m!\,\delta_{lm}\langle\psi_0,\psi_0\rangle. \tag{3.27}$$

Since the linear span of the vectors $(a^*)^m\psi_0$ is dense in $\mathscr{K}$ (Lemma 10), the nondegeneracy of the inner product implies $\langle\psi_0,\psi_0\rangle\neq 0$, and Eq. (3.27) fully determines the inner product in $\mathscr{K}$, which turns out to be definite. Without loss of generality we can normalize $\langle\psi_0,\psi_0\rangle\equiv\eta_0=\pm 1$, and the Krein metric operator is then

$$J=\eta_0\mathbb{1}.$$

Apart from the sign of the inner product, the representation is the usual Fock representation in a Hilbert space.

Case 2. Equation (3.23) holds. Then, putting

$$\psi_{-1}\equiv(a^*)^{l-1}\psi_{\overline{n}}=((a^*)^{l-1}\psi)_{-1}, \tag{3.28}$$

one has

$$a^*\psi_{-1}=0, \tag{3.29}$$

and $\mathscr{D}_1$ is generated by the vectors $a^l\psi_0, l>0$ (''*anti-Fock representation*''). By using Eqs. (3.15), (3.18), and (3.28), one gets

$$\langle a^l\psi_{-1},a^m\psi_{-1}\rangle=\delta_{l,m}m!(-1)^m\langle\psi_{-1},\psi_{-1}\rangle. \tag{3.30}$$

The nondegeneracy of the inner product implies $\langle \psi_{-1}, \psi_{-1} \rangle \neq 0$, and the inner product in $\mathscr{K}$ is fully determined by Eq. (3.30), and it is not definite.

The metric operator that defines the Hilbert space structure of $\mathscr{K}$ is not uniquely determined by Eq. (3.30). There is, however, a distinguished Krein structure associated to Eq. (3.30), defined by the metric operator

$$J = \eta_1 (-1)^N, \tag{3.31}$$

where $\eta_1 \equiv \langle \psi_{-1}, \psi_{-1} \rangle = \pm 1$.

In general, the representation defined (on $\mathscr{D}_1$) by Eq. (3.30) may live in a Krein space obtained by closing $\mathscr{D}$ with a (weak) topology different from that defined by the above metric operator. However, all such Krein spaces contain dense domains $\mathscr{D}_1$, on which the corresponding representations are related by indefinite space isometries. Thus, any representation of type 2 is equivalent to the representation defined by Eq. (3.30) on the Krein space given by the metric (3.31).

Case 3. None of the sequences $a^k \psi_{\overline{n}}, (a^*)^l \psi_{\overline{n}}$ terminates. Then one of the sequences contains a vector ψ_θ with

$$a^* a \psi_\theta = \theta \psi_\theta, \tag{3.32}$$

and $\mathscr{D}_1$ is generated by the vectors $a^l \psi_\theta, (a^*)^k \psi_\theta, l, k \in \mathbb{N}$ (''Dirac sea states''). Different eigenvalues of $U(s)$ define orthogonal eigenspaces (with the indefinite inner product), and, using the commutation relations of Lemma 10, one has

$$\langle (a^*)^l \psi_\theta, (a^*)^m \psi_\theta \rangle = \delta_{l,m} (\theta+1)(\theta+2) \cdots (\theta+m) \langle \psi_\theta, \psi_\theta \rangle, \tag{3.33}$$

$$\begin{aligned} \langle a^l \psi_\theta, a^m \psi_\theta \rangle &= \delta_{l,m} \theta(\theta-1) \cdots (\theta-m+1) \langle \psi_\theta, \psi_\theta \rangle \\ &= \delta_{l,m} (-1)^{m-1} \theta(1-\theta) \cdots (m-1-\theta) \langle \psi_\theta, \psi_\theta \rangle. \end{aligned} \tag{3.34}$$

Again $\langle \psi_\theta, \psi_\theta \rangle \neq 0$ follows from nondegeneracy of the inner product, which is fully determined by Eqs. (3.33) and (3.34), and is not definite. Again, the metric operator is not uniquely determined, and a distinguished Krein structure is defined by

$$J(a^*)^m \psi_\theta = \eta_\theta (a^*)^m \psi_\theta, \quad J a^l \psi_\theta = \eta_\theta (-1)^{l-1} a^l \psi_\theta, \tag{3.35}$$

with $\eta_\theta \equiv \langle \psi_\theta, \psi_\theta \rangle = \pm 1$. The same arguments as in case 2 then apply to the equivalence of representations in different Krein spaces.

In order to control all the common eigenvectors of $U(s)$, $s \in \mathbb{R}$, assume that a vector χ, in the domain of the closure of all the operators $U(s)$, satisfies

$$U(s)\chi = \lambda(s)(\chi).$$

By weak continuity, and Eq. (2.5),

$$\lambda(s) = e^{i\mu s}.$$

From Eq. (2.6) (extended to the closure of the operators), it follows that χ is orthogonal to all the eigenvectors of $U(s)$ with different eigenvalues, and therefore, by the density of the domains $\mathscr{D}_1$ constructed above, $\exp i\mu s$ is, in the three different cases, one of the eigenvalues classified above,

$$e^{i\mu s} = e^{i(n+\theta)s}.$$

For each $\psi \in \mathscr{D}$ the set of eigenvectors constructed in Lemma 10 generates a dense subspace; since, by the argument given above, χ is orthogonal to all such eigenvectors, except for the eigenvalue $\exp i(\overline{n}+\theta)s$, it follows that χ is a multiple of the corresponding eigenvector, which is therefore unique. It also follows that all the subspaces of $\mathscr{D}_1$ introduced in Lemma 10 actually coincide with $\mathscr{D}_1$.

In order to complete the classification, it is necessary to show that indeed all the representations constructed in cases 1–3 fulfill the regularity and irreducibility conditions. The regularity is obvious, and the proof of irreducibility follows from the absence of multiplicities for the common eigenvalues of $U(s)$, $s\in\mathbb{R}$.

In fact, if a closable operator B leaves a domain $\mathscr{D}'\subset\mathscr{D}_c$ invariant, with $\mathscr{H}_{\text{ext}}\mathscr{D}'\subset\mathscr{D}'$, then for any $\psi\in\mathscr{D}'$ one can construct vectors $\psi_n^{(\epsilon)}$ as in Lemma 8, Eq. (3.10), which converge weakly to vectors ψ_n, Eq. (3.12), still belonging to an invariant domain contained in $\mathscr{D}_c$; if B commutes with $\mathscr{H}_{\text{ext}}$, then

$$B\psi_n^{(\epsilon)}\to(B\psi)_n, \quad \text{weakly.} \tag{3.36}$$

We can fix n so that ψ_n is nonvanishing; since B is (weakly) closable, ψ_n belongs to the domain of its weak closure $\bar{B}$, and

$$\bar{B}\psi_n=(B\psi)_n. \tag{3.37}$$

Both ψ_n and $(B\psi)_n$ are eigenvectors of $U(s)$, $\forall s\in\mathbb{R}$, as in Lemma 8, Eq. (3.6). Since there are no multiplicities, Eq. (3.37) implies

$$B\psi_n=\lambda\psi_n. \tag{3.38}$$

Since B commutes with $\mathscr{H}$, Eq. (3.38) also holds, with the same λ, for the vectors $\{a^k\psi_n^-,(a^*)^l\psi_n^-\}$, generating a dense domain. B is closable, and therefore $B=\lambda 1$.

IV. TEMPERED DOMAIN-IRREDUCIBLE REPRESENTATIONS OF THE HEISENBERG ALGEBRA IN KREIN SPACES

The classification of the *a priori* more general set of domain irreducible representations of the Heisenberg algebra in Krein spaces is more difficult, since, in general, domain irreducibility does not seem to imply compactness of the group $U(s)$. This property, however, follows if the behavior of $U(s)$ at infinity is not too singular. We therefore introduce the following notion.

Definition 11: A representation of the Heisenberg algebra $\mathscr{H}$ on a domain $\mathscr{D}$ will be called tempered if

(i) *It is regular (Definition 4);*

(ii) *$U(s)$ is weakly polynomially bounded, i.e., if $\forall x\in\mathscr{D}$, there exists a polynomial $P_x(n)$ such that $\forall y\in\mathscr{K}$ there exists a constant C_y, such that*

$$|\langle y,U(2\pi n)x\rangle|\leqslant C_yP_x(n), \quad \forall n\in\mathbb{Z}. \tag{4.1}$$

We then have the following.

Proposition 12: For tempered domain irreducible representations of the Heisenberg algebra in Krein spaces, the operator $U(2\pi n)$ is a multiple of the identity,

$$U(2\pi n)=e^{2\pi i\theta}\mathbb{1}. \tag{4.2}$$

From the proof of Theorem 7 we have the following.

Theorem 13: *The tempered domain irreducible representations of the Heisenberg algebra in Krein spaces are classified as in Theorem 7.*

Proof of Proposition 12: By Eq. (2.7), $U(2\pi n)$ commutes with the algebra $\mathscr{H}$ on $\mathscr{D}$, but Eq. (4.2) does not immediately follow, as in the standard case (bounded operators in Hilbert spaces), where a crucial role is played by the spectral theorem. A substitute for the spectral theory of the group $U(2\pi n)$ is necessary, and can be based on temperedness. The Fourier transform of $U(2\pi n)$,

$$T(t)=\sum_{n=-\infty}^{\infty}U(2\pi n)e^{int},$$

is, in fact, well defined as an operator-valued distribution on $\mathscr{D}$: denote

$$T_N(t) \equiv \sum_{n=-N}^{N} U(2\pi n) e^{int},$$

and, for all $f(t)$ infinitely differentiable on the circle, $t \in [0,2\pi)$,

$$T_N(f) \equiv \int_0^{2\pi} T_N(t) f(t) dt = \sum_{n=-N}^{N} c_f^{(n)} U(2\pi n), \tag{4.3}$$

with $c_f^{(n)}$ the Fourier coefficients of f. Since such coefficients decrease faster than any polynomial, the temperedness condition immediately implies that $T_N(f)$ converges weakly on $\mathscr{D}$, as $N \to \infty$. By the weak completeness of $\mathscr{K}$, the limit defines an operator that maps $\mathscr{D}$ in $\mathscr{K}$. Furthermore, since all the elements $A \in \mathscr{H}$ are closable,

$$AT_N(f)x = T_N(f)Ax \to T(f)Ax, \quad \forall x \in \mathscr{D},$$

implies

$$AT_N(f)x \to AT(f)x, \tag{4.4}$$

and therefore

$$[A, T(f)] = 0, \quad \text{on } \mathscr{D}. \tag{4.5}$$

The operator-valued distribution $T(f)$ satisfies on $\mathscr{D}$,

$$T(1) = \sum_{n=-\infty}^{\infty} U(2\pi n) \int_0^{2\pi} e^{int} dt = U(0) = 1.$$

If $f_1(t)$ and $f_2(t)$ have disjoint support, $f_1(t) f_2(t) = 0$, then

$$T(f_1) T(f_2) = 0. \tag{4.6}$$

In fact, on $\mathscr{D}$,

$$T(f_1) T(f_2) = \sum_{n,m} U(2\pi n) U(2\pi m) c_{f_1}^{(n)} c_{f_2}^{(m)} = \sum_{k,m} U(2\pi k) c_{f_1}^{(k-m)} c_{f_2}^{(m)} \equiv \sum_{k} U(2\pi k) c^{(k)},$$

with

$$\begin{aligned} c^{(k)} &= \sum_m c_{f_1}^{(k-m)} c_{f_2}^{(m)} \\ &= \sum_m \int_0^{2\pi} e^{ikt} e^{-imt} f_1(t) dt \int_0^{2\pi} e^{imt'} f_2(t') dt' \\ &= \sum_m \int_0^{2\pi} e^{ikt} e^{-im(t-t')} f_1(t) f_2(t') dt dt' = \int_0^{2\pi} e^{ikt} f_1(t) f_2(t) dt = 0. \end{aligned}$$

In order to prove that $U(2\pi n)$ is a multiple of the identity, we have to consider two possibilities.

(i) The support of T consists of only one point, denoted by t_0. Let us fix $x \in \mathscr{D}$; the bound (4.1) and the support property of T imply $\forall y \in \mathscr{D}$,

$$\langle y, U(2\pi n) e^{-int_0} x \rangle = \sum_{k=0}^{N} a_k(y) n^k. \tag{4.7}$$

Then, by putting

$$x_k \equiv \sum_{m=0}^{N} A_{kn} U(2\pi n) e^{-int_0} x, \quad k=0,1,...N, \tag{4.8}$$

with A_{kn} the inverse matrix of $B_{nj} \equiv n^j$,

$$\sum_{n=0}^{N} A_{kn} n^j = \delta_{kj},$$

one has

$$a_k(y) = \langle y, x_k \rangle,$$

and therefore

$$U(2\pi n)x = \sum_{j=0}^{N} n^j e^{int_0} x_j. \tag{4.9}$$

The lowest integer N for which Eq. (4.7) holds will be called the degree of x. The subspace $\mathscr{D}_M \subset \mathscr{D}$ of vectors of degree less or equal to some M is invariant under $\mathscr{H}_{\text{ext}}$, and nonempty for sufficiently large M; we have therefore constructed operators O_j, $j=0,\ldots M$, defined on $\mathscr{D}_M$ by $O_j x = x_j$; by Eq. (4.8), the operators O_j are given by finite linear combinations of operators $U(2\pi n)$, so that they are closeable and leave $\mathscr{D}_M$ invariant. The operator O_M does not vanish, if M is chosen small enough, and, if $M>0$, it satisfies, by the group law for $U(s)$,

$$O_M^2 = 0. \tag{4.10}$$

$O_M \mathscr{D}_M$ is invariant under $\mathscr{H}_{\text{ext}}$ and is therefore dense, by domain irreducibility; this is incompatible with Eq. (4.10); all vectors in $\mathscr{D}$ are therefore of degree 0, i.e.,

$$U(2\pi n)x = e^{int_0} x, \quad \forall x \in \mathscr{D}. \tag{4.11}$$

(ii) The support contains at least two points. There are then two functions, f_1, f_2, with $T(f_i) \neq 0$, $i=1,2$, and $f_1 f_2 = 0$. Then, $T(f_1)\mathscr{D}$, by Eq. (4.4) a subspace of $\mathscr{D}_c$, must be dense, since it is invariant under $\mathscr{H}$, and the representation is domain irreducible. But then $T(f_2)T(f_1) = 0$ is incompatible with $T(f_2) \neq 0$, since all $T(f)$ are closable.

The same analysis as in Theorems 7 and 13 can be done under the weaker assumption that $\mathscr{D}$ is a dense subspace of a sequentially weakly complete nondegenerate inner product space $\mathscr{V}$, rather than a Krein space. The assumption is indeed weaker, since there exist weakly complete inner product spaces that are not Krein spaces. In fact, all the assumptions of Theorems 7 and 13 make sense in sequentially weakly complete spaces, and we have the following.

Proposition 14: The regular, commutant irreducible or tempered domain irreducible, representations of the Heisenberg algebra in sequentially weakly complete spaces are classified as in Theorem 7, up to isometries defined on dense subspaces.

Proof: The proofs of Theorems 7 and 13 only use the representation of $\mathscr{H}$ on a weakly dense domain $\mathscr{D}$, the regularity condition (A) (and temperedness) on $\mathscr{D}$, and construct the common eigenvectors of $U(s)$ by taking weak limits and extending weakly closable operators.

APPENDIX: REGULARITY, DOMAIN AND COMMUTANT IRREDUCIBILITY, WEAK COMPLETENESS

The notion of irreducibility discussed in Sec. II crucially relies on the regularity of the representation and on making reference to the extended algebra $\mathscr{H}_{\text{ext}}$. In fact, even for the standard regular irreducible representations of the Weyl algebra in a Hibert space, neither domain

nor commutant irreducibility hold, in general, for the Heisenberg algebra, on an invariant domain $\mathscr{D}$, either because on $\mathscr{D}$ regularity fails, or because the subdomain $\mathscr{D}_1$ (see Definitions 5 and 6) is not stable under $\mathscr{H}_{\text{ext}}$.

For example, if for $\mathscr{D}$ one takes the dense domain $\mathscr{D}_0$ of C^∞ functions $f(x)$ of fast decrease, vanishing together with all their derivatives at $x=0$, $\mathscr{D}_0$ is clearly invariant under the Heisenberg algebra, but the representation of the Heisenberg algebra on $\mathscr{D}_0$ does *not* satisfy the regularity condition, since the operators $U(s)$ exist but do not leave $\mathscr{D}_0$ invariant. The subdomains $\mathscr{D}_0^+$ and $\mathscr{D}_0^-$, consisting of a function with positive, respectively negative, support are invariant, and their closure are proper orthogonal subspaces of $L^2(\mathbb{R})$. The representation is therefore *domain reducible*. It is also *commutant reducible*, since the projector on $L^2(0,\infty)$ commutes with the Heisenberg algebra on $\mathscr{D}_0$ (not only in the weak sense, since the domain is left invariant by the projector).

If the representation of $\mathscr{H}$ is defined, on a domain $\mathscr{D}\supset\mathscr{D}_0$, invariant under $\mathscr{H}$ and $U(s)$, $s\in\mathbb{R}$, then the regularity condition is satisfied. However, domain irreducibility does *not* hold for the *Heisenberg algebra* on $\mathscr{D}$, since the previously considered domains are obviously still invariant under $\mathscr{H}$. Domain irreducibility *holds for the extended algebra* $\mathscr{H}_{\text{ext}}$; in fact, invariance of a domain $\mathscr{D}'$ under $U(s)$ implies, using the construction given in the proof of Theorem 7, that one, and therefore every, eigenvector of the operators $U(s)$ belongs to the closure of $\mathscr{D}'$, and $\mathscr{D}'$ is therefore dense.

Identical conclusions hold for commutant reducibility, since one may still consider the same projectors as above, as operators defined on $\mathscr{D}_0$, commuting there with $\mathscr{H}$. On the other hand, commutativity with $\mathscr{H}_{\text{ext}}$ on an invariant domain (Definition 6) implies triviality, as in the proof of Theorem 7.

The operator N is *not* essentially self-adjoint on $\mathscr{D}_0$, and the extended algebra [with the validity of relations (2.7)] can be constructed only on the basis of *one* choice for its self-adjoint extension (namely by taking functions continuous, together with their derivative, at $x=0$). All other choices lead to different extensions of $\mathscr{H}$, with algebraic relations different from (2.7), and, in general, to different spectra of N.

A weakly complete inner product space that is not a Krein space is easily constructed as follows: we start with the space V_0 of *finite* sequences a_n, $n\in\mathbb{Z}$, with the inner product

$$\langle a_n, b_m\rangle \equiv \sum_n \bar{a}_{-n} b_n .$$

On the space V_0 it is easy to define positive scalar products that majorize the indefinite inner product (see Ref. 15), and therefore V_0 can be completed to a Krein space (inequivalent scalar products defining different Krein completions).

However, not all weakly complete inner product spaces that contain V_0 as a dense subspace are Krein spaces. Consider, in fact, the space $V\supset V_0$ consisting of *all* sequences that terminate on the right, $a_n=0$, for n large enough. The space V is weakly complete, because (i) weak convergence implies convergence of each term of the sequences, (ii) by completeness of the l^2 spaces, the limit sequences x_n belong to all the spaces l^2 with *any* weight function $p_n>0$ on $n\in\mathbb{N}$,

$$\sum_{n=0}^{\infty} |x_n|^2 p_n < \infty,$$

and therefore x_n vanishes for n large enough.

Moreover, V is not a Krein space, since in any Krein space containing V_0 there are always sequences that are infinite on the right, and have weakly convergent truncations; one such sequence is immediately constructed, e.g., as $1/(c_k k^2)$, $k>0$, with c_k the Hilbert norm of the sequence $a_n\equiv\delta_{n,k}$, in the given Krein space. The argument also shows that V is not a Banach space, i.e., it cannot be obtained from V_0 by a norm completion.

Quantum group structure on the quantum plane

E. H. Tahri[a)]
Université Mohammed V, Faculté des Sciences, Laboratoire de Physique Théorique, Av. Ibn Battota B.P. 1014, Rabat, Morocco

(Received 6 October 1997; accepted for publication 22 January 1998)

We show that the quantum plane introduced by Manin is a quantum group according to the Faddeev–Reshetikhin–Takhtajan approach. We give its matrix representation, R-matrix, and its Hopf structure. Some quantum properties of the quantum matrix whose elements generate the quantum plane are also discussed. © *1998 American Institute of Physics.* [S0022-2488(98)00205-9]

I. INTRODUCTION

In recent years, there has been much interest in the concept of quantum groups.[1–4] This is due to its close connection to the Yang–Baxter equation, which is central in various physically interesting models and theories, such as the Knizhnik–Zamolodchikov equation, two-dimensional conformal field theory, integrable models, and so on.[5–8] Quantum groups are noncommutative Hopf algebras. The noncommutativity is controlled by the so-called R-matrices that are solutions of the Yang–Baxter equation and whose entries are complex numbers called deformation parameters. Ordinary Lie groups (commutative Hopf algebra) are recovered when the latter parameters go to particular values. So, quantum groups are deformations (and in some sense generalizations) of usual groups.

Manin has discribed quantum general linear group as a natural symmetry of noncommutative algebraic variety defined by quadratic equations (see Refs. 9 and 10). This new object is called ''quantum plane'' or ''quantum space'' or also ''Manin plane.'' It is defined as the deformation of coordinate functions and is mathematically viewed as comodule over the corresponding quantum group. Since its inception, the quantum plane has been attracting a growing amount of attention; it has been envisioned by many as a paradigm for the general program of quantum deformed physics. Indeed, many efforts have been made to set adequate mathematical tools and then attempts to build some quantum deformed models (see, for example, Refs. 11–18, and references therein).

In our knowledge the quantum plane has never been considered a quantum group. In this work we give its matrix representation, which leads to the structure of the quantum group. In this new approach the quantum plane appears as a quantum subgroup of a larger quantum group, with special conditions on deformation parameters.

The paper is organized as follows. In Sec. II, we concern ourself with the two-dimensional case, because of its simplicity and importance in the literature. In the first part we recall the Manin approach and at the same time we set the basic tools for the proof of our main results, which are in the second part. We also discuss some important quantum properties of quantum matrices considered to be the group elements of the quantum plane. In Sec. III, we generalize the above results to a high dimension. Finally, we give some concluding remarks in Sec. IV.

II. TWO-DIMENSIONAL QUANTUM PLANE

A. Review of Manin approach

The simplest quantum group is a deformation $GL_q(2)$ of the classical group $GL(2)$ of 2×2 invertibles matrices. The more general deformed version depends on two parameters, p and q, denoted by $GL_{p,q}(2)$, is well studied in Refs. 19 and 20. It consists of co-commutative Hopf algebra generated by noncommuting elements of the matrix:

[a)]Current mailing address: Université Med I, Faculté des Sciences, Lab. de Physique Théorique et de Particules, B.P. 524, 60000, Oujda, Morocco.

 © 1998 American Institute of Physics

$$M=\begin{pmatrix} a & b \\ c & d \end{pmatrix}. \tag{2.1}$$

The noncommutativity is expressed in terms of the R matrix as

$$RM_1M_2=M_2M_1R, \quad \text{i.e.,} \quad R^{ij}{}_{kl}M^k{}_mM^l{}_n=M^j{}_lM^i{}_kR^{kl}{}_{mn}, \tag{2.2}$$

called the RTT equation, where the matrix R is given by

$$R=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & q^{-1} & 0 & 0 \\ 0 & 1-(qp)^{-1} & p^{-1} & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \tag{2.3}$$

which is the solution of the Yang–Baxter equation:

$$R_{12}R_{13}R_{23}=R_{23}R_{13}R_{12}, \quad \text{i.e.,} \quad R^{ij}{}_{kl}R^{km}{}_{rs}R^{ls}{}_{uv}=R^{jm}{}_{kl}R^{il}{}_{sv}R^{sk}{}_{ru} \tag{2.4}$$

(p and q are arbitrary complex numbers). Explicitly, the commutation relations between the generators a, b, c, and d are given by

$$\begin{gathered} ab=pba, \quad cd=pdc, \\ ac=qca, \quad bd=qdb, \\ pbc=qcb, \quad ad-da=(p-q^{-1})bc. \end{gathered} \tag{2.5}$$

Further, one has to introduce the quantum determinant defined by[19,21]

$$D=ad-pbc=da-q^{-1}bc, \tag{2.6}$$

which satisfies, using (2.5), the following relations:

$$\begin{gathered} Da=aD, \quad Dd=dD, \\ qDb=pbD, \quad pDc=qcD. \end{gathered} \tag{2.7}$$

Then one extends the algebra $GL_{p,q}(2)$ by an element D^{-1}, such that

$$DD^{-1}=D^{-1}D=1, \tag{2.8}$$

from which follows:

$$\begin{gathered} D^{-1}a=aD^{-1}, \quad D^{-1}d=dD^{-1}, \\ pD^{-1}b=qbD^{-1}, \quad qD^{-1}c=pcD^{-1}. \end{gathered} \tag{2.9}$$

This permits the introduction of the left M_L^{-1} and right M_R^{-1} quantum inverse matrices of M as

$$M^{-1}=M_L^{-1}=D^{-1}\begin{pmatrix} d & -q^{-1}b \\ -qc & a \end{pmatrix}=\begin{pmatrix} d & -p^{-1}b \\ -pc & a \end{pmatrix}D^{-1}=M_R^{-1}. \tag{2.10}$$

So, the Hopf structure is given by the following: *(i) the coproduct:*

$$\Delta(M)=M\dot{\otimes}M \quad \text{i.e.,} \quad \Delta\left(\begin{pmatrix} a & b \\ c & d \end{pmatrix}\right)=\begin{pmatrix} a\otimes a+b\otimes c & a\otimes b+b\otimes d \\ c\otimes a+d\otimes c & c\otimes b+d\otimes d \end{pmatrix}, \tag{2.11a}$$

$$\Delta(D^{-1})=D^{-1}\otimes D^{-1}; \tag{2.11b}$$

(ii) the counit:

$$\epsilon(M)=1, \quad \text{i.e.} \quad \epsilon\left(\begin{pmatrix} a & b \\ c & d \end{pmatrix}\right)=\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \tag{2.12a}$$

$$\epsilon(D^{-1})=1; \tag{2.12b}$$

and *(iii) the antipode:*

$$S(M)=M^{-1}, \quad \text{i.e.,} \quad S\left(\begin{pmatrix} a & b \\ c & d \end{pmatrix}\right)=\begin{pmatrix} dD^{-1} & -p^{-1}bD^{-1} \\ -pcD^{-1} & aD^{-1} \end{pmatrix}, \tag{2.13a}$$

$$S(D^{-1})=D. \tag{2.13b}$$

Now let us recall some quantum properties[10] of the quantum matrix M considered as a group element (or a point[10]) of $GL_{p,q}(2)$. First, if one takes another copy M' of the same type as M, that is, M' is also a group element of $GL_{p,q}(2)$ such that its elements mutually commute with those of M, then MM' is an element of $GL_{p,q}(2)$. Second, M^{-1} is a group element of $GL_{p^{-1},q^{-1}}(2)$. Next the nth power $M^n (n \in \mathbb{Z}_+)$ is a group element of $GL_{p^n,q^n}(2)$.

Manin[9,10] has defined in correspondence with the quantum group, a quantum plane and its dual. This consists of free algebras noted $K_q^{2|0}$ and $K_p^{0|2}$ generated by the pairs of coordinates (x,y) and (ξ,η), respectively, such that for $K_q^{2|0}$ we have

$$xy=qyx, \tag{2.14}$$

which is the explicit from the following relation:

$$x^i x^j = R^{ji}{}_{kl} x^k x^l, \tag{2.15}$$

where $x^1=x$, $x^2=y$ and R is the R matrix (2.3).

For $K_p^{0|2}$, we have

$$\xi\eta=-\frac{1}{p}\,\xi\eta, \quad \xi^2=\eta^2=0, \tag{2.16}$$

which also can be expressed in terms of the R matrix (2.3) as

$$\xi^i \xi^j = -pq R^{ji}_{kl} \xi^k \xi^l, \tag{2.17}$$

where $\xi^1=\xi$, $\xi^2=\eta$. In this point of view, the quantum group $GL_{p,q}(2)$ appears as endomorphisms of the quantum planes $K_q^{2|0}$ and $K_p^{0|2}$ under which the quadratic relations (2.14) and (2.16) remain invariant. So, Manin proved the equivalence between the defining quantum group commutation relations (2.5) and the quadratic relations (2.14) and (2.16). This is known in the literature as the Manin approach to the quantum group.

The quantum planes $K_q^{2|0}$ and $K_p^{0|2}$ are viewed mathematically as comodules over $GL_{p,q}(2)$ via the (left) coactions

$$\delta: K_q^{2|0} \mapsto GL_{p,q}(2) \otimes K_q^{2|0}, \quad \delta^*: K_p^{0|2} \mapsto GL_{p,q}(2) \otimes K_p^{0|2},$$

such that

$$\delta(X)=M \otimes X, \quad \text{i.e.,} \quad \begin{cases} \delta(x)=a \otimes x + b \otimes y, \\ \delta(y)=c \otimes x + d \otimes y \end{cases}, \tag{2.18a}$$

$$\delta^*(\Theta)=M \otimes \Theta, \quad \text{i.e.,} \quad \begin{cases} \delta^*(\xi)=a \otimes \xi + b \otimes \eta, \\ \delta^*(\eta)=c \otimes \xi + d \otimes \eta \end{cases}, \tag{2.18b}$$

where X and Θ are column vectors of components x, y and ξ, η, respectively.

B. Quantum plane as quantum group

Before giving the quantum group structure on $K_q^{2|0}$, let us look at the particular case of $GL_{p,q}(2)$ when $p=q^{-1}$. In this case the R matrix (2.3) reduces to

$$R=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & q^{-1} & 0 & 0 \\ 0 & 0 & q & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \tag{2.19}$$

and the commutation relations (2.5) become

$$\begin{gathered} ab=q^{-1}ba, \quad cd=q^{-1}dc, \\ ac=qca, \quad bd=qdb, \\ bc=q^2cb, \quad ad=da. \end{gathered} \tag{2.20}$$

Now, let us observe that if we take $a=d=y$, $b=x$ and $c=0$, then the commutation relations (2.20) reduce to the quadratic relation (2.14) defining the quantum plane $K_q^{2|0}$. It is the fondamental observation that proves the following main result.

Theorem 1: The quantum plane $K_q^{2|0}$ generated by the coordinates x and y satisfying the quadratic relation $xy=qyx$ is a quantum group generated by the elements of the matrix of the type

$$A=\begin{pmatrix} y & x \\ 0 & y \end{pmatrix}, \tag{2.21}$$

modulo the RTT equation:

$$RA_1A_2=A_2A_1R, \quad \text{i.e.,} \quad R^{ij}{}_{kl}A^k{}_mA^l{}_n=A^j{}_lA^i{}_kR^{kl}{}_{mn}, \tag{2.22}$$

where R is solution of the Yang–Baxter equation given by (2.19).

The costructure is given by the following:

(i) the coproduct:

$$\Delta(A)=A\dot{\otimes}A, \quad \text{i.e.,} \quad \begin{cases} \Delta(x)=y\otimes x+x\otimes y, \\ \Delta(y)=y\otimes y; \end{cases} \tag{2.23}$$

(ii) the counit:

$$\epsilon(A)=1, \quad \text{i.e.,} \quad \begin{cases} \epsilon(x)=0, \\ \epsilon(y)=1. \end{cases} \tag{2.24}$$

Moreover, the bialgebra $K_q^{2|0}$ extended by y^{-1}, such that

$$yy^{-1}=y^{-1}y=1 \tag{2.25}$$

is a Hopf algebra with an antipode structure given by

(iii) the antipode:

$$S(A)=A^{-1}, \quad \text{i.e.,} \quad \begin{cases} S(x)=-y^{-1}xy^{-1}, \\ S(y)=y^{-1}. \end{cases} \tag{2.26}$$

The costructure is immediately obtained from the one on $GL_{p,q}(2)$ (2.11a) (2.12a) when $p=q^{-1}$ and M in (2.1) is replaced by A in (2.21). The quantum inverse of A is given by

$$A^{-1}=D^{-1}\begin{pmatrix} y & -q^{-1}x \\ 0 & y \end{pmatrix}=\begin{pmatrix} y & -qx \\ 0 & y \end{pmatrix}D^{-1}, \tag{2.27}$$

where the quantum determinant is now

$$D=y^2, \tag{2.28}$$

from which it follows that $D^{-1}=y^{-2}$, which is an element of the quantum plane extended by y^{-1}. Further, from the quadratic relation (2.14) and (2.25) it follows that

$$y^{-1}x=qxy^{-1}. \tag{2.29}$$

So we get the explicit form of the quantum inverse in (2.27) of A as

$$A^{-1}=\begin{pmatrix} y^{-1} & -y^{-1}xy^{-1} \\ 0 & y^{-1} \end{pmatrix}, \tag{2.30}$$

which gives the relations (2.26). Finally, from (2.25), (2.23), (2.24), and (2.26) it follows that

$$\Delta(y^{-1})=y^{-1}\otimes y^{-1}, \quad \epsilon(y^{-1})=1, \quad S(y^{-1})=y. \tag{2.31}$$

Now all quantum properties of the quantum matrix M in (2.1), considered as a group element of $GL_{p,q}(2)$ when $p=q^{-1}$, hold in the case of a quantum matrix of type A considered as a group element of $K_q^{2|0}$. So, we have the following.

Proposition 1: (a) If A and A' are two copies of group elements of $K_q^{2|0}$ such that their elements mutually commute, then their product is commutative ($AA'=A'A$) and a group element of $K_q^{2|0}$.

(b) The nth power of A is given by

$$A^n=\begin{pmatrix} y^n & [n]_q y^{n-1}x \\ 0 & y^n \end{pmatrix}, \tag{2.32}$$

where $[n]_q=(1-q^n)/(1-q)$, and it is a group element of $K_{q^n}^{2|0}$.

(c) The quantum inverse of A is a group element of $K_{q^{-1}}^{2|0}$.

Proof: (a) The commutativity of product is easily seen. Indeed, we have

$$A''=AA'=\begin{pmatrix} yy' & yx'+xy' \\ 0 & yy' \end{pmatrix}=\begin{pmatrix} y'y & y'x+x'y \\ 0 & y'y \end{pmatrix}=A'A, \tag{2.33}$$

and $\det_q(A'')=\det_q(A)\det_q(A')=y^2y'^2$.

The statements (b) and (c) can be proved by a direct calculus using the quadratic relations (2.14) and (2.29).

Remarks: (1) The power n of A in (b) can also be a negative integer and when it is equal to -1 the expression (2.32) coincides exactly with that of the quantum inverse of A given by (2.30) (since $[-1]_q=-q^{-1}$).

(2) A quantum matrix of type A in (2.21) is actually a particular copy of a general group element M in (2.1) of quantum group $GL_{q^{-1},q}(2)$, so the quantum plane $K_q^{2|0}$ may be viewed as a quantum subgroup of $GL_{q^{-1},q}(2)$.

In a more rigorous mathematical language, the quantum group $GL_{q^{-1},q}(2)$ is bicovariant bicomodule over $K_q^{2|0}$, as can be easily checked in the following statement.

Proposition 2: There exists algebra morphisms:

$$\Delta_L: GL_{q^{-1},q}(2)\mapsto K_q^{2|0}\otimes GL_{q^{-1},q}(2), \quad \Delta_R: GL_{q^{-1},q}(2)\mapsto GL_{q^{-1},q}(2)\otimes K_q^{2|0},$$

such that

$$\Delta_L(M)=A\otimes M, \quad \text{i.e.,} \quad \Delta_L(M_j^i)=A_k^i\otimes M_j^k, \tag{2.34}$$

$$\Delta_R(M)=M\otimes A, \quad \text{i.e.,} \quad \Delta_R(M_j^i)=M_k^i\otimes A_j^k, \tag{2.35}$$

satisfying the properties of left and right coactions:

$$(\Delta\otimes \mathrm{id})\Delta_L=(\mathrm{id}\otimes\Delta_L)\Delta_L,$$
$$(\mathrm{id}\otimes\epsilon)\Delta_L(M)=M, \tag{2.36}$$

and

$$(\mathrm{id}\otimes\Delta)\Delta_R=(\Delta_R\otimes\mathrm{id})\Delta_R,$$
$$(\mathrm{id}\otimes\epsilon)\Delta_R(M)=M, \tag{2.37}$$

respectively, and the condition of bicovariance:

$$(\mathrm{id}\otimes\Delta_R)\Delta_L=(\Delta_L\otimes\mathrm{id})\Delta_R. \tag{2.38}$$

Now let us return to the expression (2.32) of A^n and suppose that the deformation parameter is root of unity, we remark the following.

Remark: If there exists $m\in\mathbb{Z}_+$ such that $q^m=1$, then A^m becomes

$$A^m=\begin{pmatrix} y^m & 0 \\ 0 & y^m \end{pmatrix}. \tag{2.39}$$

Furthermore, (a) if $y^m=0$, then $A^m=0$; (b) if $y^m=1$, then $A^m=1$.

In case (a) we obtain a nilpotent quantum matrix. The quantum plane generated by such coordinates is closely related to the so-called fractional superspace that unifies the boson with a particle of fractional spin. In this case there is no antipode on $K_q^{2|0}$. In case (b) we have a cyclic quantum plane, in the sense that $K_{q^{n+1}}^{2|0}\equiv K_q^{2|0}$. Finally, let us remark that there is no additional condition on the coordinate x as that on y in contrast to the classical plane where we must introduce at the same time the inverses of x and y to get the structure of the group. We interpret this as a broken symmetry between the two directions.

III. HIGH-DIMENSIONAL CASE

The multiparametric deformation of $GL(n)$ generalizing that of $GL(2)$ of Sec. I is well studied in Refs. 22–24. It is generated by the elements $M^i{}_j(i,j=1,...,n)$ of the $n\times n$ matrix M, such that (for $i<j$ and $k<l$)

$$M^i{}_kM^i{}_l=p_{kl}M^i{}_lM^i{}_k,$$
$$M^i{}_kM^j{}_k=q_{ij}M^j{}_kM^i{}_k,$$
$$M^i{}_lM^j{}_k=\frac{q_{ij}}{p_{kl}}\,M^j{}_kM^i{}_l, \tag{3.1}$$
$$M^i{}_kM^j{}_l=\frac{p_{kl}}{p_{ij}}\,M^j{}_lM^i{}_k+(p_{kl}-q_{kl}^{-1})M^i{}_lM^j{}_k,$$

with $p_{ij}q_{ij}=r$, where r is a complex number. These commutation relations are the explicit form of the RTT equation as in (2.2) with the R matrix is now given by[22]

$$R^{ij}{}_{kl}=\delta^i{}_k\delta^j{}_l\left(\delta^{ij}+\Theta^{ji}\,\frac{1}{q_{ij}}+\Theta^{ij}\,\frac{q_{ji}}{r}\right)+\delta^i{}_l\delta^j{}_k\Theta^{ij}\left(1-\frac{1}{r}\right), \tag{3.2}$$

where $\Theta^{ij}=1$ if $i>j$ and 0 elsewhere. This quantum group is noted $GL_{q_{ij},r}(n)$. The corresponding quantum plane $K_{q_{ij}}^{n|0}$ is generated by the set of coordinates $(x^i)_{1\leqslant i\leqslant n}$ satisfying the following quadratic relations:

$$x^ix^j=q_{ij}x^jx^i, \tag{3.3}$$

such that

$$q_{ii}=1, \quad q_{ij}q_{ji}=1, \tag{3.4}$$

for $i,j=1,...,n$. The quadratic relations (3.3) may be expressed in terms of the R matrix (3.2) as in (2.15).

Now let us look at the following special case. Let us take $r=1$ and the only matrix elements different from zero are $M^i{}_i$ and $M^i{}_n$ for all $i=1,...,n$, i.e.,

$$M=\begin{pmatrix} M^1{}_1 & 0 & \dots & 0 & M^1{}_n \\ 0 & M^2{}_2 & \ddots & \vdots & M^2{}_n \\ \vdots & \ddots & \ddots & 0 & \vdots \\ 0 & \dots & 0 & M^{n-1}{}_{n-1} & M^{n-1}{}_n \\ 0 & \dots & 0 & 0 & M^n{}_n \end{pmatrix}. \tag{3.5}$$

Then the commutation relations (3.1) reduce to $(i<j\leqslant n)$

$$M^i{}_iM^i{}_n=q_{ni}M^i{}_nM^i{}_i, \tag{3.6a}$$

$$M^i{}_nM^j{}_n=q_{ij}M^j{}_nM^i{}_n, \tag{3.6b}$$

$$M^i{}_nM^j{}_j=q_{ij}q_{jn}M^j{}_jM^i{}_n, \tag{3.6c}$$

$$M^i{}_iM^j{}_n=q_{ni}q_{ij}M^j{}_nM^i{}_i, \tag{3.6d}$$

$$M^i{}_iM^j{}_j=M^j{}_jM^i{}_i. \tag{3.6e}$$

Furthermore, if we put $M^i{}_i=x^n$ and $M^i{}_n=x^i$ for $i=1,...,n$, with the following additional conditions on the deformation parameters:

$$q_{ij}q_{jn}q_{ni}=1, \tag{3.7}$$

then we prove the following.

Theorem 2: The n-dimensional quantum plane $K^{n|0}_{q_{ij}}$ generated by the set of coordinates $\{x^i,i=1,...,n\}$ satisfying the following quadratic relations:

$$x^ix^j=q_{ij}x^jx^i, \tag{3.8}$$

such that $q_{ii}=1$, $q_{ij}q_{ji}=1$, and $q_{ij}q_{jn}q_{ni}=1$ for $i,j=1,...,n$, is a quantum group generated by the elements of the matrix of type

$$A=\begin{pmatrix} x^n & 0 & \dots & 0 & x^1 \\ 0 & x^n & \ddots & \vdots & x^2 \\ \vdots & \ddots & \ddots & 0 & \vdots \\ 0 & \dots & 0 & x^n & x^{n-1} \\ 0 & \dots & 0 & 0 & x^n \end{pmatrix}, \tag{3.9}$$

and the quadratic relations (3.8) are just the explicit form of the RTT equation, where R is given by

$$R^{ij}{}_{kl}=\delta^i{}_k\delta^j{}_l\left(\delta^{ij}+\Theta^{ji}\frac{1}{q_{ij}}+\Theta^{ij}q_{ji}\right). \tag{3.10}$$

The costructure is given by the following:
(i) the coproduct:

$$\Delta(A)=A\dot{\otimes}A, \quad \text{i.e.,} \quad \begin{cases} \Delta(x^i)=x^n\otimes x^i+x^i\otimes x^n, & 1\leqslant i\leqslant n-1, \\ \Delta(x^n)=x^n\otimes x^n. \end{cases} \tag{3.11}$$

(ii) the counit:

$$\epsilon(A)=1, \quad \text{i.e.,} \quad \begin{cases} \epsilon(x^i)=0, & 1\leqslant i\leqslant n-1, \\ \epsilon(x^n)=1. \end{cases} \tag{3.12}$$

Moreover, the bialgebra $K_{q_{ij}}^{n|0}$ extended by $(x^n)^{-1}$, such that

$$(x^n)^{-1}x^n=x^n(x^n)^{-1}=1, \tag{3.13}$$

is a Hopf algebra with an antipode structure given by
(iii) the antipode:

$$S(A)=A^{-1} \quad \text{i.e.,} \quad \begin{cases} S(x^i)=-(x^n)^{-1}x^i(x^n)^{-1}, & 1\leqslant i\leqslant n-1, \\ S(x^n)=(x^n)^{-1}. \end{cases} \tag{3.14}$$

Let us prove the explicit form (3.14) of the quantum inverse of A. The quantum determinant of A is given by

$$D=\det_q(A)=(x^n)^n, \tag{3.15}$$

[the second n in $(x^n)^n$ designs the nth power of coordinate x^n] from which it follows that $D^{-1}=(x^n)^{-n}$, which is an element of $K_{q_{ij}}^{n|0}$ extended by $(x^n)^{-1}$. From (3.8) and (3.15) we have

$$Dx^i=(q_{in})^{-n}x^iD, \tag{3.16}$$

from which follows

$$D^{-1}x^i=(q_{in})^nx^iD^{-1}, \tag{3.17}$$

where $i=1,...,n$. Furthermore, the quantum inverse of A is given by

$$\begin{aligned} A^{-1}=D^{-1}&\begin{pmatrix} (x^n)^{n-1} & 0 & \dots & 0 & -q_{1n}^{-1}(x^n)^{n-2}x^1 \\ 0 & (x^n)^{n-1} & \ddots & \vdots & -q_{2n}^{-1}(x^n)^{n-2}x^2 \\ \vdots & \ddots & \ddots & 0 & \vdots \\ 0 & \dots & 0 & (x^n)^{n-1} & -q_{n-1,n}^{-1}(x^n)^{n-2}x^{n-1} \\ 0 & \dots & 0 & 0 & (x^n)^{n-1} \end{pmatrix} \\ =&\begin{pmatrix} (x^n)^{n-1} & 0 & \dots & 0 & -q_{1n}x^1(x^n)^{n-2} \\ 0 & (x^n)^{n-1} & \ddots & \vdots & -q_{2n}x^2(x^n)^{n-2} \\ \vdots & \ddots & \ddots & 0 & \vdots \\ 0 & \dots & 0 & (x^n)^{n-1} & -q_{n-1,n}x^{n-1}(x^n)^{n-2} \\ 0 & \dots & 0 & 0 & (x^n)^{n-1} \end{pmatrix} D^{-1}, \end{aligned} \tag{3.18}$$

which is consistent with (3.17). Then, from (3.8) and (3.13), it follows that

$$A^{-1}=\begin{pmatrix} (x^n)^{-1} & 0 & \dots & 0 & -(x^n)^{-1}x^1(x^n)^{-1} \\ 0 & (x^n)^{-1} & \ddots & \vdots & -(x^n)^{-1}x^2(x^n)^{-1} \\ \vdots & \ddots & \ddots & 0 & \vdots \\ 0 & \dots & 0 & (x^n)^{-1} & -(x^n)^{-1}x^{n-1}(x^n)^{-1} \\ 0 & \dots & 0 & 0 & (x^n)^{-1} \end{pmatrix}, \tag{3.19}$$

which proves the explicit forms given in (3.14).

Finally, using (3.13), (3.11), (3.12), and (3.14), we obtain the actions of Δ, ϵ, and S on the inverse of x^n as

$$\Delta((x^n)^{-1})=(x^n)^{-1}\otimes(x^n)^{-1},\quad \epsilon((x^n)^{-1})=1,\quad S((x^n)^{-1})=x^n. \tag{3.20}$$

Remark: As in the two-dimensional case, the quantum plane $K_{q_{ij}}^{n|0}$ appears as a quantum subgroup of $GL_{q_{ij},1}(n)$ when the additional conditions (3.7) on the parameters are satisfied. The coactions defined in Proposition 2 generalize to the n dimension [as in (2.34) and (2.35), $i,j=1,...,n$], which provides the structure of the bicovariant bicomodule on $GL_{q_{ij},1}(n)$ over $K_{q_{ij}}^{n|0}$.

Now let us look at the quantum properties of quantum matrix A and generalize the two-dimensional case.

Proposition 3: (a) If A and A' are two copies of group elements of $K_{q_{ij}}^{n|0}$ such that their elements pairwise commute, then their product is commutative ($AA'=A'A$) and a group element of $K_{q_{ij}}^{n|0}$.

(b) The mth power of A is a group element of $K_{q_{ij}^m}^{n|0}$ given by

$$A^m=\begin{pmatrix} (x^n)^m & 0 & \dots & 0 & [m]_{q_1}(x^n)^{m-1}x^1 \\ 0 & (x^n)^m & \ddots & \vdots & [m]_{q_2}(x^n)^{m-1}x^2 \\ \vdots & \ddots & \ddots & 0 & \vdots \\ 0 & \dots & 0 & (x^n)^m & [m]_{q_{n-1}}(x^n)^{m-1}x^{n-1} \\ 0 & \dots & 0 & 0 & (x^n)^m \end{pmatrix}, \tag{3.21}$$

where $[m]_{q_i}=[1-(q_{in})^m]/(1-q_{in})$.

(c) The quantum inverse of A is a group element of $K_{q_{ij}^{-1}}^{n|0}$.

Proof: (a) The only nonvanishing elements of AA' are the diagonal and nth column elements, which are, at the ith row, $x^nx^{n'}$ and $x^nx^{i'}+x^ix^{n'}$, respectively, the corresponding elements of $A'A$ are $x^{n'}x^n$ and $x^{n'}x^i+x^{i'}x^n$, which proves the statement.

(b) The form of A^m can be deduced from a straightforward inductive way. To show that it is a group element of $K_{q_{ij}^m}^{n|0}$, let us set $x^{i'}=[m]_{q_i}(x^n)^{m-1}x^i$, then

$$\begin{aligned} x^{i'}x^{j'}&=[m]_{q_i}(x^n)^{m-1}x^i[m]_{q_j}(x^n)^{m-1}x^j=(q_{in})^{m-1}[m]_{q_i}[m]_{q_j}(x^n)^{m-1}(x^n)^{m-1}x^ix^j \\ &=q_{ij}(q_{in})^{m-1}(q_{jn})^{-(m-1)}[m]_{q_i}[m]_{q_j}(x^n)^{m-1}x^j(x^n)^{m-1}x^i=q_{ij}q_{jn}q_{ni}(q_{in})^m(q_{jn})^{-m}x^{j'}x^{i'} \\ &=(q_{ij})^mx^{j'}x^{i'}. \end{aligned} \tag{3.22}$$

In the last equality we used the conditions (3.7) on the deformation parameters.

Remark: (1) The power of A may be negative and when $m=-1$ the expression (3.21) coincides with that of the quantum inverse of A in (3.19).

(2) We check immediately from the expression (3.21) of A^m that if there exists integers m_{in} such that $(q_{in})^{m_{in}}=1$, then we have

$$A^N=\begin{pmatrix} (x^n)^N & 0 & \dots & 0 & 0 \\ 0 & (x^n)^N & \ddots & \vdots & 0 \\ \vdots & \ddots & \ddots & 0 & \vdots \\ 0 & \dots & 0 & (x^n)^N & 0 \\ 0 & \dots & 0 & 0 & (x^n)^N \end{pmatrix}, \tag{3.23}$$

where $N=\mathrm{lcm}(m_{in})_{1\leqslant i\leqslant n-1}$ (here the abbreviation lcm denotes the least common multiple). Furthermore, (a) if $(x^n)^N=0$ then $A^N=0$; (b) if $(x^n)^N=1$ then $A^N=1$.

Note that if q_{in} are roots of unity, then all q_{ij} are also roots of unity because of (3.7), namely, there exist integers $m_{ij}=\mathrm{lcm}(m_{in},m_{jn})$ such that $(q_{ij})^{m_{ij}}=1$. In case (a) there is no antipode on $K_{q_{ij}}^{n|0}$; it is only a bialgebra. This constitutes the so-called fractional superspace.

IV. CONCLUDING REMARKS

The concept of q deformation of Lie groups and spaces is well physically consistent when it is performed in the context of Hopf algebras. This is the motivation of this paper. So, we have shown that the well-known Manin plane, which is viewed mathematically as a comodule over its corresponding quantum group, may be incorporated into the Faddeev–Reshetikhin–Takhtajan approach to the quantum group.[3] We have given its matrix representation, the R-matrix, and its Hopf structure.

We expect that this new approach to the quantum plane will be a starting point to construct more consistent deformed physical models. Of course, this requires more mathematical tools; the bicovariant differential calculus à la Woronowicz[25] and the extension to the quantum superplane are in preparation.[26]

ACKNOWLEDGMENTS

I would like to thank M. Baghdadi for his permanent encouragement, A. El Hassouni for introducing me to this interesting topic, and E. M. Souidi for many valuable comments on a preliminary version of this manuscript. I am also grateful to the referee for the useful remarks.

(Received 2 July 1997; accepted for publication 24 February 1998)

The Friedrichs model has often been used in order to obtain explicit formulas for eigenvectors associated to complex eigenvalues corresponding to lifetimes. Such eigenvectors are called Gamow vectors and they acquire meaning in extensions of the conventional Hilbert space of quantum theory to the so-called rigged Hilbert space. In this paper, Gamow vectors are constructed for a solvable model of an unstable relativistic field. As a result, we obtain a time asymmetric relativistic extension of the Fock space. This extension leads to two distinct Poincaré semigroups. The time reversal transformation maps one semigroup to the other. As a result, the usual PCT invariance should be extended. We show that irreversibility as expressed by dynamical semigroups is compatible with the requirements of relativity. © *1998 American Institute of Physics.* [S0022-2488(98)01206-7]

I. INTRODUCTION

As is well known, in order to describe the unstable quantum states, Gamow conjectured[1] the existence of eigenvectors of the Hamiltonian with complex eigenvalues. These eigenvalues were precisely the points at which the singularities of the S-matrix appear. However, this is impossible within the conventional formulation of quantum theory in Hilbert space[2,3] because the Hamiltonian, being a self-adjoint operator, can only have real eigenvalues. As a result, formal constructions of Gamow vectors appeared in the literature.[4–7] These Gamow vectors describe the scattering resonances.[8–10] In the case of simple poles,[10–12] the real part of the resonance corresponds to the resonance energy while the imaginary part corresponds to the half-width of the cross section, which is twice the mean life of the corresponding unstable state.

In the case of simple scattering resonances, Bohm and Gadella[11] constructed systematically the corresponding Gamow vectors and they provided a clear mathematical meaning to these vectors in terms of a suitable extension of quantum theory on the basis of Gel'fand triplets,[13] also called rigged Hilbert spaces, constructed with Hardy functions.[14] The extended Schrödinger evolution is ''intrinsically'' irreversible because it splits into two distinct semigroups.[11] This result is, moreover, a step towards a rigorous solution of the problem of irreversibility.[15] In fact, Bohm conjectured[16] that extensions to Gel'fand triplets may give meaning to the Brussels–Austin formalism of irreversibility developed under the direction of I. Prigogine.[15,17,18] This conjecture was verified[19] for the Friedrichs model, which has been extensively studied[17–19] as it leads to a time-symmetry breaking. The Bohm–Gadella Gamow vectors follow in fact from the intrinsic proper-

 © 1998 American Institute of Physics

ties of the extended evolution operators as they reduce in special cases[20,21] to the generalized eigenprojections constructed from subdynamics developed by the Brussels–Austin group.[20,22]

This method is, however, much more general. For both classical and quantum unstable systems independent of scattering, there exist intrinsically irreversible extensions of dynamics to suitable Gel'fand triplets which include the resonances as generalized eigenvalues.[20,21]

The purpose of this paper is to discuss relativistic resonances and the corresponding Gamow vectors. In this case, the transformation properties of the Gamow vectors with respect to Lorentz boosts pose nontrivial questions due to the appearance of complex eigenvalues. *The model we study in this paper is a relativistic Friedrich's model* which involves a quadratic coupling of a local scalar field with a bilocal scalar field. This model is presented in Sec. II and its solution given in Sec. III. The redefined vacuum is constructed in Sec. IV and the relativistic Gamow vectors are presented in Sec. V. Their meaning is given in terms of a rigged Fock space of Hardy functions following the similar construction in the nonrelativistic case.[11,19] Finally, we address the question of the action of the Poincaré semigroups on the Gamow state. Some calculations have been reported in the Appendices.

In the case of the Friedrich's model the time symmetry breaking is due to the resolution of the unstable eigenstate to the continuum.[17–19] Evolution is just a shift in the continuum. In order to describe the approach of the system to equilibrium such as the canonical distribution, we have to go to a statistical description that includes density operators in appropriate extensions of the conventional Hilbert space formulation. This formulation has been discussed in Refs. 22 and 23 for systems of nonrelativistic particles.

The main conclusion of this paper is that the construction of dynamical semigroups breaking the time symmetry is compatible with relativistic field theory. This result provides the first example, known to us, of an extension of the PCT theorem, because time reversal leads from one semigroup (for example, the one pointing towards the future) to the other (pointing towards the past).

II. THE MODEL

We shall consider an exactly solvable model for relativistic unstable quantum fields. This model involves a quadratic interaction between a local scalar field φ and a bilocal scalar field ψ. The interaction makes the local scalar field φ unstable. The model is an extension of the well-known Friedrich's model[4,7,17–19] where a single eigenstate interacts with the continuum and becomes unstable.

The local scalar field $\varphi(x)$ with mass M may be written in terms of creation and annihilation operators as follows:

$$\varphi(\mathbf{x},t)=\int d\tilde{\mathbf{k}}[a^{\dagger}(\mathbf{k})e^{ik\cdot x}+a(\mathbf{k})e^{-ik\cdot x}]. \tag{1}$$

By boldface letters we denote three-dimensional vectors. Four-dimensional vectors in Minkowski space are denoted by Roman style letters. The products of two vectors in Minkowski space are characterized by a dot. In Minkowski space we use the metric $+---$. For example, $k\cdot x=k_0x_0-\mathbf{kx}$. The Lorentz invariant measure in (1) is

$$d\tilde{\mathbf{k}}=\frac{d^3\mathbf{k}}{(2\pi)^3 2\omega(\mathbf{k})}, \quad \omega(\mathbf{k})=(\mathbf{k}+M^2)^{1/2}. \tag{2}$$

The creation and annihilation operators in (1) satisfy the usual commutation relations:

$$[a(\mathbf{k}),\ a^{\dagger}(\mathbf{k}')]=(2\pi)^3 2\omega(\mathbf{k})\,\delta(\mathbf{k}-\mathbf{k}'). \tag{3}$$

The Hamiltonian of the field $\varphi(x)$ is given by

$$\mathrm{H}_M=\int d\tilde{\mathbf{k}}\ \omega(\mathbf{k})a^{\dagger}(\mathbf{k})a(\mathbf{k}) \tag{4}$$

We shall consider, in addition, a bilocal scalar field, $\psi(x_\mu,q)$, with continuous mass spectrum. Bilocal fields were introduced first long ago by Yukawa[24] and Markov[25] in their discussion of extended elementary particles. It is used here in a different context. The field depends also on an additional real variable q representing an internal degree of freedom. For simplicity we shall assume that $\psi(x_\mu,q)$ is an even function of q. This means that

$$\psi(x_\mu,-q)=\psi(x_\mu,q). \tag{5}$$

The eigenvalues of the mass operator are defined by the internal variable. The simplest form of the mass operator $\mathbf{M}$ is given by

$$\mathbf{M}^2=4m^2-\frac{\partial^2}{\partial q^2}. \tag{6}$$

The field $\psi(x_\mu,q)$ satisfies then the following generalized Klein–Gordon equation:

$$(\Box-\mathbf{M}^2)\psi(x_\mu,q)=0, \tag{7}$$

where $\Box$ is the usual d'Alembert operator. The solution of Eq. (6) can be written in the following form:

$$\psi(x_\mu,q)=\int d^4k_\mu\int_{-\infty}^{\infty}d\kappa\,\frac{\cos\,q\kappa}{(2\pi)^4}\,e^{-ik_\mu x^\mu}\delta(k^2-4m^2-\kappa^2)B(k_\mu,\kappa), \tag{8}$$

where we took into account (5). The amplitude $B(k_\mu,\kappa)$ is also an even function of κ. Integrating the rhs of (7) over k_0 gives

$$\psi(x_\mu,q)=\int_{-\infty}^{\infty}d\kappa\,\frac{d^3\mathbf{k}\,\cos\,\kappa q}{(2\pi)^4 2E(\mathbf{k},\kappa)}\,(B^*(\mathbf{k},\kappa)e^{ik\cdot x}+B(\mathbf{k},\kappa)e^{-ik\cdot x}), \tag{9}$$

where $k_\mu=(E,\mathbf{k})$ and

$$E(\mathbf{k},\kappa)=[4m^2+\kappa^2+\mathbf{k}^2]^{1/2}. \tag{10}$$

We can change the variables in (8) so that E is the new independent variable instead of κ:

$$\kappa=(E^2-\mathbf{k}^2-4m^2)^{1/2},\quad \frac{d\kappa}{E}=\frac{dE}{\kappa}. \tag{11}$$

Then,

$$\psi(x_\mu,q)=\int_0^{\infty}\frac{dE\;d^3\mathbf{k}\,\cos\,\kappa(k_\mu)q}{(3\pi)^4\kappa(k_\mu)}\,(B^*(\mathbf{k},E)e^{ik\cdot x}+B(\mathbf{k},E)e^{-ik\cdot x}). \tag{12}$$

Following the routine of second quantization of a scalar field, we may introduce the Hamiltonian operator:

$$\mathrm{H}_0=\int d^3\mathbf{x}\;dq\;\frac{1}{2}\left[\dot{\psi}^2+(\boldsymbol{\nabla}\psi)^2+4m^2\psi^2+\left(\frac{\partial\psi}{\partial q}\right)^2\right]. \tag{13}$$

The canonical commutation relations are

$$[\psi(x,q),\;\pi(x',q')]=i\delta^4(x-x')\,\frac{\delta(q+q')+\delta(q-q)}{2}. \tag{14}$$

The canonical commutation relations follow from Dirac's quantization: The classical nonlocal field satisfies the Poisson bracket relation,

$$\{\psi(x,q),\pi(x',q')\}=-\delta^4(x-x')\,\frac{\delta(q+q')+\delta(q-q)}{2}, \tag{15}$$

which results from the canonical formalism.

The classical formula (11) gives the expression of the quantum field $\psi(x,q)$ in terms of the creation and annihilation operators $B^\dagger$ and B,

$$\psi(x_\mu,q)=\int_0^\infty \frac{dE\ d^3\mathbf{k}\ \cos\ \kappa(k_\mu)q}{(2\pi)^4\kappa(k_\mu)}\,[B^\dagger(\mathbf{k},E)e^{ik\cdot x}+B(\mathbf{k},E)e^{-ik\cdot x}], \tag{16}$$

with the following commutation relations:

$$[B(\mathbf{k},E),\ B^\dagger(\mathbf{k}',E')]=(2\pi)^4\kappa(k_\mu)\delta^4(k_\mu-k'_\mu). \tag{17}$$

We now introduce a quadratic interaction Hamiltonian as

$$\mathrm{H_{int}}=-\lambda\int d^3\mathbf{x}\int_{-\infty}^{\infty}dq\ \psi(x,q)f(q)\varphi(x), \tag{18}$$

where the even function $f(q)$ is Lorentz scalar and has the Fourier transform

$$f(q)=\int dy\ \alpha(y)\cos yq. \tag{19}$$

Clearly, $f(q)$ plays the role of a form factor and, to avoid the divergencies, we choose it to have good asymptotic behavior.

The representation of the ten generators of the Poincaré group in terms of creation and annihilation operators may be obtained as usual (see, e.g., Ref. 26). The Hamiltonian is

$$\begin{aligned}P_0=&\int\frac{d^3\mathbf{k}\ dE}{(2\pi)^4\kappa(\mathbf{k},E)}\,EB^\dagger(\mathbf{k},E)B(\mathbf{k},E)+\int\frac{d^3\mathbf{k}}{(2\pi)^3 2\omega(\mathbf{k})}\,\omega(\mathbf{k})a^\dagger(\mathbf{k})a(\mathbf{k})\\&+\int\frac{d^3\mathbf{k}\ dE}{(2\pi)^3 2\omega}\,\frac{\lambda\alpha(\kappa(\mathbf{k},E))}{\kappa(\mathbf{k},E)}\,(a(\mathbf{k})+a^\dagger(-\mathbf{k}))(B^\dagger(\mathbf{k},E)+B(-\mathbf{k},E)).\end{aligned} \tag{20}$$

The generator of three-dimensional translations is

$$\mathbf{P}=\int\frac{d^3\mathbf{k}\ dE}{(2\pi)^4\kappa(\mathbf{k},E)}\,\mathbf{k}B^\dagger(\mathbf{k},E)B(\mathbf{k},E)+\int\frac{d^3\mathbf{k}\ \mathbf{k}}{(2\pi)^3 2\omega(\mathbf{k})}\,a(\mathbf{k}), \tag{21}$$

The generators of three-dimensional rotations are

$$\begin{aligned}J_{ij}=&-i\int\frac{d^3\mathbf{k}}{(2\pi)^4\kappa(\mathbf{k},E)}\,B^\dagger(\mathbf{k},E)\left(k_j\frac{\partial}{\partial k_j}-k_j\frac{\partial}{\partial k_i}\right)B(\mathbf{k},E)\\&-i\int\frac{d^3\mathbf{k}}{(2\pi)^3 2\omega(\mathbf{k})}\,a^\dagger(\mathbf{k})\left(k_i\frac{\partial}{\partial k_j}-k_j\frac{\partial}{\partial k_i}\right)a(\mathbf{k}).\end{aligned} \tag{22}$$

The perturbation does not influence the spatial translation and rotations. However, the Lorentz-boost generators acquire an additional term due to the interaction:

$$\begin{aligned}J_{oi}=&\,i\int\frac{d^3\mathbf{k}\ dE}{(2\pi)^4\kappa(\mathbf{k},E)}\,B^\dagger(\mathbf{k},E)\left(E\frac{\partial}{\partial k_i}+k_i\frac{\partial}{\partial E}\right)B(\mathbf{k},E)+i\int\frac{d^3\mathbf{k}}{(2\pi)^3 2\omega(\mathbf{k})}\,a^\dagger\left(\omega(\mathbf{k})\frac{\partial}{\partial k_i}\right)a(\mathbf{k})\\&+\frac{i}{2}\int\frac{d^3\mathbf{k}\ dE}{(2\pi)^3}\,\frac{\lambda\alpha(\kappa(\mathbf{k},E))}{\kappa(\mathbf{k},E)}\left(E\frac{\partial}{\partial k_i}+k_i\frac{\partial}{\partial E}\right)\frac{B(\mathbf{k},E)+B^\dagger(-\mathbf{k},E)}{E}\,\frac{a(-\mathbf{k})+a^\dagger(\mathbf{k})}{\omega(\mathbf{k})}.\end{aligned} \tag{23}$$

The analogy between the Hamiltonian (20) and the interacting Hamiltonian in the usual Friedrich's model is obvious. We consider here an ''infinite collection'' of Friedrich's models, each corresponding to a value of the momentum **k**. This model is relativistic and contains both ''virtual'' and ''real'' interactions.

III. THE EIGENVALUE PROBLEM

The solution of the eigenvalue problem in our case is a straightforward generalization of the usual Friedrich's solution. The eigenvalue problem can be written as

$$[P_\mu,\ b^\dagger(E,\mathbf{k})]=k_\mu b^\dagger(E,\mathbf{k}), \tag{24}$$

where $k_\mu=(E,\mathbf{k})$ and P_μ is given by (19) and (20). Let $b^\dagger(E,\mathbf{k})$ be a linear combination of $B^\dagger(E,\mathbf{k}),B(E,\mathbf{k});a^\dagger(\mathbf{k}),a(\mathbf{k})$:

$$b^\dagger(E,\mathbf{k})=\int dE'\ (T(E,E',\mathbf{k})B^\dagger(E',\mathbf{k})+R(E,E',\mathbf{k})B(E',-\mathbf{k})) + t(E,\mathbf{k})a^\dagger(\mathbf{k})+r(E,\mathbf{k})a(-\mathbf{k}), \tag{25}$$

which due to the simple form of **P**-operator (24) satisfies

$$[\mathbf{P},\ b^\dagger(E,\mathbf{k})]=\mathbf{k}b^\dagger(E,\mathbf{k}). \tag{26}$$

Note that covariance with respect to three-dimensional rotations implies that coefficients in (24) depend only on $\mathbf{k}^2$. Equation (23) for $\mu=0$ gives

$$(E'-E)T(E,E',\mathbf{k})+\lambda\ \frac{\alpha(\kappa(E',\mathbf{k}))}{\kappa(E',\mathbf{k})}\ (t(E,\mathbf{k})-r(E,\mathbf{k}))=0, \tag{27a}$$

$$-(E'+E)R(E,E',\mathbf{k})+\lambda\ \frac{\alpha(\kappa(E',\mathbf{k}))}{\kappa(E',\mathbf{k})}\ (t(E,\mathbf{k})-r(E,\mathbf{k}))=0, \tag{27b}$$

$$(\omega-E)t(E,\mathbf{k})+\frac{\pi}{\omega}\int dE'\ \lambda\alpha(\kappa(E',\mathbf{k}))(T(E,E',\mathbf{k})-R(E,E',\mathbf{k}))=0, \tag{27c}$$

$$-(\omega+E)r(E,\mathbf{k})+\frac{\pi}{\omega}\int dE'\ \lambda\alpha(\kappa(E',\mathbf{k}))(T(E,E',\mathbf{k})-R(E,E',\mathbf{k}))=0. \tag{27d}$$

First, we express R and r in terms of T and t:

$$R(E,E',\mathbf{k})=-\frac{E'-E}{E'+E}\ T(E,E',\mathbf{k}),\quad r(E,\mathbf{k})=-\frac{\omega(\mathbf{k})-E}{\omega(\mathbf{k})+E}\ t(E,\mathbf{k}). \tag{28}$$

The equations for $T(E,E',\mathbf{k})$ and $t(E,\mathbf{k})$ become

$$(\omega-E)t(E,\mathbf{k})+\frac{\lambda\pi}{\omega(\mathbf{k})}\int dE'\,\alpha(\kappa(E',\mathbf{k}))\,\frac{2E'}{E'+E}\ T(E,E',\mathbf{k})=0, \tag{29a}$$

$$(E'-E)T(E,E',\mathbf{k})+\lambda\ \frac{\alpha(\kappa(E,\mathbf{k}))}{\kappa(E,\mathbf{k})}\ \frac{2\omega(\mathbf{k})}{\omega(\mathbf{k})+E}\ t(E,\mathbf{k})=0. \tag{29b}$$

Equation (29b) gives

$$T(E,E',\mathbf{k})=C\,\delta(E'-E)-\frac{1}{E'-E}\ \frac{\lambda\alpha(\kappa(E',\mathbf{k}))}{\kappa(E',\mathbf{k})}\ \frac{2\omega(\mathbf{k})}{\omega(\mathbf{k})+E}\ t(E,\mathbf{k}). \tag{30}$$

Substituting (29) into (28) we obtain

$$\left[\omega^2-E^2-\int \frac{dE'}{E'^2-E^2}\,2E'\rho(E',\mathbf{k})\right]t(E,\mathbf{k})=-C\,\frac{\lambda\pi}{\omega(\mathbf{k})}\,\alpha(\kappa(E,\mathbf{k})), \tag{31}$$

where we have introduced the function $\rho(E,\mathbf{k})$:

$$\rho(E,\mathbf{k})=2\pi\,\frac{\lambda^2\alpha^2(\kappa(E,\mathbf{k}))}{\kappa(E,\mathbf{k})}. \tag{32}$$

Note that $\rho(E,\mathbf{k})$ depends only of $(E^2-\mathbf{k}^2)$ due to (10). The function in square brackets on the lhs of (30) is the relativistic generalization of the inverse one-particle resolvent. Equation (30) can be written as

$$\frac{1}{G(E,\mathbf{k})}\,t(E,\mathbf{k})=-C\,\frac{\lambda\pi}{\omega(\mathbf{k})}\,\alpha(\kappa(E,\mathbf{k})) \tag{33}$$

where

$$G(E,\mathbf{k})=\frac{1}{\omega^2-E^2-\Pi(E,\mathbf{k})}, \tag{34}$$

$$\Pi(E,\mathbf{k})=\int_{E_0}^{\infty}dE'\;2E'\;\frac{\rho(E',\mathbf{k})}{E'^2-E^2} \tag{35}$$

and $E_0=(4m^2+\mathbf{k}^2)^{1/2}$.

It is clear that the properties of $\Pi(E,\mathbf{k})$ and $G(E,\mathbf{k})$ depend upon the function $\rho(E,\mathbf{k})$ which is defined by the form factor $f(q)$. Equations (33) and (34) are also valid for complex values of E^2. We shall specify their meaning for real E^2 later. First of all, we shall suppose that the integral on the rhs of (34) exists and, moreover,

$$\Pi(E,\mathbf{k})\to 0 \quad \text{as} \quad E\to\infty. \tag{36}$$

From (34) we see that $\Pi(E,\mathbf{k})$ is an analytic function of E^2 with a cut on the physical sheet from $E^2=E_0^2$ to infinity. The jump of $\Pi(E,\mathbf{k})$ at the cut is given by

$$\Delta\Pi(E,\mathbf{k})=\Pi(E+i0,\mathbf{k})-\Pi(E-i0,\mathbf{k})=2\pi i\rho(E,\mathbf{k}). \tag{37}$$

We assume that $\rho(E,\mathbf{k})$ vanishes at the threshold

$$\rho(E_0(\mathbf{k}),\mathbf{k})=0. \tag{38}$$

The function $G(E,\mathbf{k})$ also has the same analytic properties, and its discontinuity has the form

$$\begin{aligned}\Delta G(E,\mathbf{k})&=G(E+i0,\mathbf{k})-G(E-i0,\mathbf{k})\\&=2\pi i\rho(E,\mathbf{k})G(E+i0,\mathbf{k})G(E-i0,\mathbf{k})=2\pi i\rho(E,\mathbf{k})|G(E,\mathbf{k})|^2.\end{aligned} \tag{39}$$

Therefore $G(E,\mathbf{k})$ satisfies the dispersion relation

$$G(E,\mathbf{k})=\int dE'^2\,\frac{1}{E'^2-E^2}\,\rho(E',\mathbf{k})[G(E',\mathbf{k})]^2, \tag{40}$$

This dispersion relation is actually the Källen–Lehmann representation for the propagator. Under the assumption (35), it is evident that

$$G(E,\mathbf{k})\to-\frac{1}{E^2} \tag{41}$$

as $E\to\infty$. From (40) and (39) we conclude therefore that

$$\int_{E_0^2}^{\infty} dE'^2\ \rho(E',\mathbf{k})|G(E',\mathbf{k})|^2=1. \tag{42}$$

From (35) we have

$$G(E,\mathbf{k})\to \frac{1}{\omega^2(\mathbf{k})-E^2}+o\left(\frac{1}{E^4}\right), \tag{43}$$

as $|\omega^2(\mathbf{k})-E^2|\to\infty$

Now, let us calculate the difference $G(E,\mathbf{k})-(\omega^2-E^2)^{-1}$:

$$G(E,\mathbf{k})-\frac{1}{\omega^2-E^2}=\int dE'^2\left(\frac{1}{E'^2-E^2}-\frac{1}{\omega^2-E^2}\right)\rho(E',\mathbf{k})|G(E',\mathbf{k})|^2, \tag{44}$$

where we have used (43). Furthermore,

$$\begin{aligned} G(E,\mathbf{k})-\frac{1}{\omega^2-E^2}&=\frac{1}{\omega^2-E^2}\int dE'^2\,\frac{\omega^2-E'^2}{E'^2-E^2}\,\rho(E',\mathbf{k})|G(E',\mathbf{k})|^2 \\ &\to\frac{1}{E^4}\int dE'^2(\omega^2-E'^2)\rho(E',\mathbf{k})|G(E',\mathbf{k})|^2+o\left(\frac{1}{E^4}\right)\quad \text{as } E\to\infty. \end{aligned} \tag{45}$$

This result is compatible with (42) only if

$$\int_{E_0^2}^{\infty} dE'^2\ (\omega^2(\mathbf{k})-E'^2)\rho(E',\mathbf{k})|G(E',\mathbf{k})|^2=0. \tag{46}$$

The sum rules (41) and (45) will be used in the sequel.

The unstable case which we are going to consider here corresponds to the extended Green's functions $G_+(E,\mathbf{k})$ and $G_-(E,\mathbf{k})$ from the upper to the lower half-plane and from the lower to the upper half-plane, respectively.

In the unstable case, $G_+(E,\mathbf{k})$ has a pole at $E^2=\mathbf{k}^2+\mu_c^2$ and $G_-(E,\mathbf{k})$ has a pole at the conjugate point $E^2=\mathbf{k}^2+\mu_c^{*2}$, where

$$\mu_c^2=\mu^2-i\mu\Gamma \tag{47}$$

and μ and Γ are real positive numbers defined by the form factor $f(q)$.

The equation for the complex pole μ_c^2 is

$$\omega^2(\mathbf{k})-E^2-\int dE'^2\,\frac{\rho(E',\mathbf{k})}{E'^2-E^2}=0$$

or

$$M^2-(E^2-\mathbf{k}^2)-\mathscr{P}\int dE'^2\,\frac{\rho(E',\mathbf{k})}{E'^2-E^2}-i\pi\rho(E,\mathbf{k})=0, \tag{48}$$

where $\mathscr{P}$ stands for the Cauchy principal value. For small values of the coupling constant λ we can omit the integral term

$$\mu_c^2=M^2-i\pi\rho(E,\mathbf{k})|_{E^2-\mathbf{k}^2=M^2}=M^2-2i\pi^2\lambda^2\,\frac{[\alpha(\sqrt{M^2-4m^2})]^2}{\sqrt{M^2-4m^2}}. \tag{49}$$

The pole appears only for $M\geqslant 2m$.

With Green's function, $G(E,\mathbf{k})$, we can proceed further and find the general solution of (27):

$$t(E,\mathbf{k}) = -C\lambda\pi\alpha(\kappa(E,\mathbf{k}))G(E,\mathbf{k})\,\frac{E+\omega(\mathbf{k})}{\omega(\mathbf{k})},$$

$$T(E,E',\mathbf{k}) = C\left[\delta(E-E') + 2\pi\lambda\alpha(\kappa(E,\mathbf{k}))G(E,\mathbf{k})\,\frac{\lambda\alpha(\kappa(E',\mathbf{k}))}{\kappa(E',\mathbf{k})}\,\frac{1}{E'-E}\right], \tag{50}$$

$$R(E,E',\mathbf{k}) = -C2\pi\lambda\alpha(\kappa(E,\mathbf{k}))G(E,\mathbf{k})\,\frac{\lambda\alpha(\kappa(E',\mathbf{k}))}{\kappa(E',\mathbf{k})}\,\frac{1}{E'+E},$$

$$r(E,\mathbf{k}) = -C\,\frac{E-\omega(\mathbf{k})}{\omega(\mathbf{k})}\,\lambda\pi\alpha(\kappa(E,\mathbf{k}))G(E,\mathbf{k}).$$

The formal solution of eigenvalue problem (23) is, for positive energies,

$$b^{\dagger}(E,\mathbf{k}) = C\Bigg\{B^{\dagger}(E,\mathbf{k}) + 2\pi\lambda\alpha(\kappa(E,\mathbf{k}))G(E,\mathbf{k})\Bigg[\int dE'\,\frac{\lambda\alpha(\kappa(E',\mathbf{k}))}{\kappa(E',\mathbf{k})}\,(E',\mathbf{k}) \times\left(\frac{B^{\dagger}(E,\mathbf{k})}{E'-E} - \frac{B(E,-\mathbf{k})}{E'+E}\right) - \frac{(E+\omega(\mathbf{k}))a^{\dagger}(\mathbf{k}) + (E-\omega(\mathbf{k}))a(-\mathbf{k})}{2\omega(\mathbf{k})}\Bigg]\Bigg\}. \tag{51}$$

The negative energy solution of (23) which corresponds to the annihilation operator $b(E,\mathbf{k})$ is

$$b(E,\mathbf{k}) = C\Bigg\{B(E,\mathbf{k}) + 2\pi\lambda\alpha(\kappa(E,\mathbf{k}))G(e,\mathbf{k})\Bigg[\int dE'\,\frac{\lambda\alpha(\kappa(E,\mathbf{k}))}{\kappa(E,\mathbf{k})}\left(\frac{B(E,\mathbf{k})}{E'-E} - \frac{B^{+}(E,-\mathbf{k})}{E'+E}\right) - \frac{(E+\omega(\mathbf{k}))a(\mathbf{k}) + (E-\omega(\mathbf{k}))a^{+}(-\mathbf{k})}{2\omega(\mathbf{k})}\Bigg]\Bigg\}. \tag{52}$$

We call this solution formal because up to now we did not specify the singular integrals in (50) and in the definition of Green's function for real energy. We have different solutions of (23). These correspond to the incoming and outgoing boundary conditions. The incoming operators are

$$b^{\dagger}_{\mathrm{in}}(E,\mathbf{k}) = B^{\dagger}(E,\mathbf{k}) + 2\pi\lambda\alpha(\kappa(E,\mathbf{k}))G(E+i0,\mathbf{k})\Bigg[\int dE'\,\frac{\lambda\alpha(\kappa(E',\mathbf{k}))}{\kappa(E',\mathbf{k})}\left(\frac{B^{\dagger}(E,\mathbf{k})}{E'-E-i0} - \frac{B(E',-\mathbf{k})}{E'+E}\right) - \frac{(E+\omega(\mathbf{k}))a^{\dagger}(\mathbf{k}) + (E-\omega(\mathbf{k}))a(-\mathbf{k})}{2\omega(\mathbf{k})}\Bigg],$$

$$b_{\mathrm{in}}(E,\mathbf{k}) = B(E,\mathbf{k}) + 2\pi\lambda\alpha(\kappa(E,\mathbf{k}))G(E-i0,\mathbf{k})\Bigg[\int dE'\,\frac{\lambda\alpha(\kappa(E',\mathbf{k}))}{\kappa(E',\mathbf{k})}\left(\frac{B(E',\mathbf{k})}{E'-E+i0} - \frac{B^{\dagger}(E',-\mathbf{k})}{E'+E}\right) - \frac{(E+\omega(\mathbf{k}))a(\mathbf{k}) + (E-\omega(\mathbf{k}))a^{\dagger}(-\mathbf{k})}{2\omega(\mathbf{k})}\Bigg], \tag{53}$$

$$E \geqslant E_0(\mathbf{k}) = (4m^2 + \mathbf{k}^2)^{1/2},$$

where we have set the normalization constant $c=1$. The outgoing set of operators corresponds to change $+i0 \to -i0$ in (52).

We end this section with a remark concerning the solution of (23) in the stable case. The latter corresponds to Green's function $G(E,\mathbf{k})$ with simple pole on real axis E which lies below threshold $E=E_0$ in the point $E=\omega(\mathbf{k})$. In this case there appears an additional solution of Eqs. (28) which corresponds to perturbed operators $\tilde{a}(\mathbf{k})$ and $\tilde{a}^{\dagger}(\mathbf{k})$. Together with the operators $b(E,\mathbf{k})$ and $b^{\dagger}(E,\mathbf{k})$, these operators form a complete set which is connected with the initial operators $a(k), a^{\dagger}(\mathbf{k}); B(E,\mathbf{k}), B^{\dagger}(E,\mathbf{k})$ through the Bogolubov transformation. In the unstable case the operators $\tilde{a}(\mathbf{k})$ and $a^{\dagger}(\mathbf{k})$ do not appear although the Bogolubov transformation exists.

IV. THE VACUUM STATE

For the commutation relations of the incoming and outgoing operators $b^{\text{in}}_{\text{out}}(E,\mathbf{k})$ and $b^{\dagger}_{\substack{\text{in}\\\text{out}}}(E,\mathbf{k})$, we have to use the explicit form of $b(E,\mathbf{k})$ and the fundamental commutation relations of the initial operators (3) and (16) together with the properties of Green's function $G(E,\mathbf{k})$ (see Appendix A):

$$[b_{\text{in}}(E,\mathbf{k}),\ b^{\dagger}_{\text{in}}(E',\mathbf{k}')]=[b_{\text{out}}(E,\mathbf{k}),\ b^{\dagger}_{\text{out}}(E',\mathbf{k})]=(2\pi)^4\kappa(E,\mathbf{k})\,\delta(E-E')\,\delta^3(\mathbf{k}-\mathbf{k}'),$$

$$[b_{\text{out}}(E,\mathbf{k}),\ b^{\dagger}_{\text{in}}(E',\mathbf{k}')]=(2\pi)^4\kappa(E,\mathbf{k})\,\delta(E-E')\,\delta^3(\mathbf{k}-\mathbf{k}')\,\frac{G(E+i0,\mathbf{k})}{G(E-i0,\mathbf{k})}, \tag{54}$$

$$[b_{\text{in}}(E,\mathbf{k}),\ b^{\dagger}_{\text{out}}(E',\mathbf{k})]=(2\pi)^4\kappa(E,\mathbf{k})\,\delta(E-E')\,\delta^3(\mathbf{k}-\mathbf{k}')\,\frac{G(E-i0,\mathbf{k})}{G(E+i0,\mathbf{k})};$$

all other commutators vanish.

In terms of creation and annihilation operators, the energy momentum vector is diagonal, as follows from (25) and from the fact that b and $b^{\dagger}$ solve the eigenvalue problem. A direct calculation gives

$$P_{\mu}=\int\ \frac{d^3\mathbf{k}\,dE}{(2\pi)^4\kappa(E,\mathbf{k})}\,k_{\mu}b^{\dagger}_{\substack{\text{in}\\\text{out}}}(E,\mathbf{k})b^{\text{in}}_{\text{out}}(E,\mathbf{k}), \tag{55}$$

where $k_{\mu}=(E,\mathbf{k})$ and the lhs of (54) is given by Eqs. (19) and (20) up to a constant in P_0, which arises due to operator ordering. A further important property of the new operators is the way they change under Lorentz transformations. Three-dimensional rotations present no difficulties and therefore we present only the commutation rules of the b-operators with the Lorentz boosts:

$$[J_{oi},\ b^{\dagger}_{\substack{\text{in}\\\text{out}}}(E,\mathbf{k})]=i\left(E\,\frac{\partial}{\partial k_i}+k_i\,\frac{\partial}{\partial E}\right)b^{\dagger}_{\substack{\text{in}\\\text{out}}}(E,\mathbf{k}). \tag{56}$$

The commutation relation (53) provides a simple way for the construction of the space of states which is the subspace of the whole Fock space formed by the operators $B^{\dagger}(E,\mathbf{k})$ and $a^{\dagger}(\mathbf{k})$ and the initial vacuum state $|0\rangle$ which was defined by

$$B(E,\mathbf{k})|0\rangle=0,\quad a(\mathbf{k})|0\rangle=0. \tag{57}$$

The explicit form of $b(E,k)$ shows us that

$$b(E,\mathbf{k})|0\rangle\neq 0, \tag{58}$$

i.e., there arises a new vacuum state which will be a superposition of states with an arbitrary number of particles of B and a types. The new vacuum Ω has the following form:

$$\Omega=e^{V}|0\rangle, \tag{59}$$

where V is a functional of creation operators $B^{\dagger}(E,\mathbf{k})$ and $a^{\dagger}(\mathbf{k})$.

It should be noted that the operator e^{V} is a part of the general unitary Bogolubov transformation which, besides dressing the vacuum state, transforms also the operators $B(E,\mathbf{k})$ and $a(\mathbf{k})$ into $b(E,\mathbf{k})$. In order to simplify the calculations, we have subdivided the problem into two parts, (1) the construction of the creation and annihilation operators and (2) the introduction of the new vacuum state. Moreover, from the standard theory of Bogolyubov transformations, it follows that the functional V, which gives the solution of the equation

$$b_{\text{in}}(E,\mathbf{k})\Omega=0, \tag{60}$$

is at most a quadratic functional of $B^{\dagger}(E,\mathbf{k})$ and $a^{\dagger}(\mathbf{k})$:

$$V(B^\dagger,a^\dagger)=\int d^3\mathbf{k}\Bigg\{\frac{1}{2}\int dE\ dE'\ f(E,E',\mathbf{k})B^\dagger(E,\mathbf{k})B^\dagger(E,-\mathbf{k}) + \int dE\ B^\dagger(E,\mathbf{k})a^\dagger(-\mathbf{k})f(E,\mathbf{k})+\frac{1}{2}f(\mathbf{k})a^\dagger(\mathbf{k})a^\dagger(-\mathbf{k})\Bigg\}. \tag{61}$$

In Appendix B, we shall see how to obtain the functions $f(E,E',\mathbf{k})$, $f(E,\mathbf{k})$, and $f(\mathbf{k})$. The most important part of the solution is the problem of factorization of Green's function $G(E,\mathbf{k})$ which we introduced in Sec. II. The factorization problem is to find a function $\gamma(E,\mathbf{k})$, analytic in the right half-plane, such that

$$\gamma(E,\mathbf{k})\gamma(-E,\mathbf{k})=G(E,\mathbf{k}) \tag{62}$$

on the whole complex E plane. The additional conditions which guarantee the uniqueness of $\gamma(E,\mathbf{k})$ are discussed in Appendix C. The most important properties of the function $\gamma(E,\mathbf{k})$ are given by the equations

$$\frac{1}{\gamma(E,\mathbf{k})}+E+\omega(\mathbf{k})+2\xi(\mathbf{k})+\int_{E_0}^{\infty}dE'\ \frac{\rho(E',\mathbf{k})\gamma(E',\mathbf{k})}{E'+E}=0, \tag{63}$$

$$\int_{E_0}^{\infty}dE'\ \rho(E',\mathbf{k})\gamma(E',\mathbf{k})=2\xi(\mathbf{k})(\omega(\mathbf{k})+\xi(\mathbf{k})), \tag{64}$$

$$\left(E\frac{\partial}{\partial k_i}+k_i\frac{\partial}{\partial E}\right)\gamma(E,\mathbf{k})+\gamma(E,\mathbf{k})\frac{\partial}{\partial k_i}(\omega(\mathbf{k})+2\xi(\mathbf{k}))=0, \tag{65}$$

where $\rho(E,\mathbf{k})$ has been defined in (22) and $\omega=(\mathbf{k}^2+M^2)^{1/2}$. The new variable $\xi(\mathbf{k})$ describes the shift of the second term of the asymptotic expansion of $\gamma(E,\mathbf{k})$ for $E\to\infty$ due to the interaction. The detailed definition of $\xi(\mathbf{k})$ as well as the derivation of the properties of $\gamma(E,\mathbf{k})$ are discussed in Appendix C.

In terms of the solution of the factorization problem, $\gamma(E,\mathbf{k})$, the functions which define the functional V have the form

$$\begin{aligned} f(E,E',\mathbf{k})&=\frac{1}{(2\pi)^3 2(\omega(\mathbf{k})+\xi(\mathbf{k}))}\,q(E,\mathbf{k})q(E',\mathbf{k})\left(1+\frac{2(\omega(\mathbf{k})+\xi(\mathbf{k}))}{E'+E}\right),\\ f(E,\mathbf{k})&=\frac{1}{(2\pi)^3 2(\omega(\mathbf{k})+\xi(\mathbf{k}))}\,q(E,\mathbf{k}),\\ f(\mathbf{k})&=\frac{1}{(2\pi)^3 2(\omega(\mathbf{k})+\xi(\mathbf{k}))}\left(-\frac{\xi(\mathbf{k})}{\omega(\mathbf{k})}\right),\\ q(E,\mathbf{k})&=\frac{\lambda\alpha(\kappa(E,\mathbf{k}))}{\kappa(E,\mathbf{k})}\,\gamma(E,\mathbf{k}). \end{aligned} \tag{66}$$

Substituting (65) into the definition of V we finally arrive at

$$V(B^\dagger,a^\dagger)=\int\frac{d^3\mathbf{k}}{(2\pi)^3 2(\omega(\mathbf{k})+\xi(\mathbf{k}))}\cdot\Bigg\{\frac{1}{2}\int_{E_0}^{\infty}dE\ dE'\ q(E,\mathbf{k})q(E',\mathbf{k}) \times\left(1+\frac{2(\omega(\mathbf{k})+\xi(\mathbf{k}))}{E+E'}\right)B^\dagger(E,\mathbf{k})B^\dagger(E,-\mathbf{k}) + \int_{E_0}^{\infty}dE\ q(E,\mathbf{k})B^\dagger(E,\mathbf{k})a^\dagger(-\mathbf{k})-\frac{\xi(\mathbf{k})}{2\omega(\mathbf{k})}\,a^\dagger(\mathbf{k})a^\dagger(-\mathbf{k})\Bigg\}. \tag{67}$$

This operator V defines the new Lorentz invariant vacuum state. Note that Ω is a new vacuum for the incoming–outgoing operators $b(E,\mathbf{k})$. The creation operators $b^\dagger(E,\mathbf{k})$ act on Ω and define a new Fock space. In particular the one-particle state is

$$b^\dagger_{\rm in}(E,\mathbf{k})\Omega=\left\{B^\dagger(E,\mathbf{k})+\frac{2\pi\lambda\,\alpha(\kappa(E,\mathbf{k}))}{2(\omega(\mathbf{k})+\xi(\mathbf{k}))}\;\gamma(-E-i0,\mathbf{k})\right.$$
$$\left.\times\left[\int dE'\;q(E',\mathbf{k})\left(1+\frac{2(\omega(\mathbf{k})+\xi(\mathbf{k}))}{E'-E-i0}\right)B^\dagger(E,\mathbf{k})+a^\dagger(\mathbf{k})\right]\right\}\Omega, \tag{68}$$

where we have used explicit form of $B^\dagger(E,\mathbf{k})$ and Ω to eliminate the annihilation operators $B(E,\mathbf{k})$ and $a(\mathbf{k})$.

Comparing Eq. (67) with its nonrelativistic analog,[18] we see that the role of the partial resolvent is now played by $\gamma(-(E+i0),\mathbf{k})$. In particular, Green's function has the following behavior on the vicinity of its pole on the lower half-plane with respect to the Lorentz invariant variable $z=E^2-\mathbf{k}^2$:

$$G_+(E,\mathbf{k})=\gamma_+(E)\,\gamma_+(-E)=\frac{c^2}{-E^2+(\mu_c^2+\mathbf{k}^2)}+\text{regular terms.} \tag{69}$$

At this point $z=\mu_c^2$ the solution of the factorization problem with required asymptotic properties has the form

$$\gamma_+(E)=-\frac{c}{E+(\mu_c^2+\mathbf{k}^2)^{1/2}}+\text{regular terms},$$
$$\gamma_+(-E)=+\frac{c}{E-(\mu_c^2+\mathbf{k}^2)^{1/2}}+\text{regular terms}. \tag{70}$$

V. THE GAMOW VECTORS

Now we are ready to discuss the main point of the present paper: the eigenvectors corresponding to the unstable relativistic field. Consider, for example, the state (67). Due to the presence of $\gamma(-E-i0,\mathbf{k})$, the state

$$\Phi_{\rm in}(E,\mathbf{k})=b^\dagger_{\rm in}(E,\mathbf{k})\Omega \tag{71}$$

has a pole in the second sheet of complex E-plane where we make the analytic extension from above to below. This statement, as well as all other states in the present section, acquire mathematical meaning in the framework of rigged Hilbert spaces[11,13] and rigged Fock spaces.[27] On the energy plane, the resonance pole z_R, which corresponds to the pole μ_c^2 on the plane of the Lorentz invariant variable $E^2-\mathbf{k}^2$, is

$$z_R=(\mathbf{k}+\mu^2-i\mu\Gamma)^{1/2}=A(\mathbf{k})-iB(\mathbf{k}), \tag{72}$$

where

$$A(\mathbf{k})=\left\{\frac{[(\mathbf{k}^2+\mu^2)^2+\mu^2\Gamma^2]^{1/2}+(\mathbf{k}^2+\mu^2)}{2}\right\}^{1/2},$$
$$B(\mathbf{k})=\left\{\frac{[(\mathbf{k}^2+\mu^2)^2+\mu^2\Gamma^2]^{1/2}-(\mathbf{k}^2+\mu^2)}{2}\right\}^{1/2}.$$

Note that, because the imaginary part of z_R defines the decay law, the life time is also $\mathbf{k}$ dependent. Usually, it is supposed that

$$\Gamma(\mathbf{k}) = \Gamma \frac{m}{\omega(\mathbf{k})},$$

which follows from the Lorentz transformation of time scale. From (71) follows that this rather naive answer is valid only for $\Gamma \to 0$.

The state $\Phi_{\text{in}}(E,\mathbf{k})$ can be written in a neighborhood of z_R as

$$\Phi_{\text{in}}(E,\mathbf{k}) = \frac{1}{E - z_R} \varphi^G_{\text{in}}(\mathbf{k}) + \text{regular part.} \tag{73}$$

Here, $\varphi^G_{\text{in}}(\mathbf{k})$ is the Gamow vector associated with the resonance pole z_R.

The Gamow vectors are linear functionals over a suitable space of ''test functions.'' As was done in Ref. 27, this space can be written in the following form:

$$\mathbf{Y}_- = C \oplus \Phi \oplus (\Phi \otimes \Phi) \oplus (\Phi \otimes \Phi \otimes \Phi) \oplus \cdots . \tag{74}$$

Following our previous work[11,21] we may choose as a representation space for the one-particle test function space Φ the following:

$$\Psi = (\mathscr{H}^2_- \cap S) \otimes S(R^3), \tag{75}$$

where the following hold.

(i) $\mathscr{H}^2_-$ is the space of Hardy functions on the lower half-plane.[14]
(ii) S is the space of all real-valued complex functions that are differentiable at all orders such that they as well as their derivatives vanish at the infinity faster than the inverse of any polynomial (the one-dimensional Schwartz space).
(iii) $S(R^3)$ represents the space of all complex functions on the three-dimensional real space R^3 having the same properties as S in (ii).
(iv) The tensor product that we are using in (74) and throughout this paper is the standard π-tensor product of topological vector spaces.[28]

A typical function of $(\mathscr{H}^2_- \cap S) \otimes S(R^3)$ is of the form $\varphi(E,\mathbf{k})$. For a fixed value of the momentum $\mathbf{k}$, this is a function of the energy and belongs to $\mathscr{H}^2_- \cap S$. For a fixed value of the energy E, $\varphi(E,\mathbf{k}) \in S(R^3)$.

Then, if $\varphi(E,\mathbf{k})$ is in the space $(\mathscr{H}^2_- \cap S) \otimes S(R^3)$, we can write explicitly the vectors in Φ (written in bra form) as

$$\langle \varphi | = \int \frac{d^3\mathbf{k}\, dE}{(2\pi)^4 \kappa(E,\mathbf{k})} \langle \Omega | b_{\text{out}}(E,\mathbf{k}) \varphi(E,\mathbf{k}). \tag{76}$$

The above integral goes from E_0 to ∞, which in particular means that the energy is always positive. It is also important to remark that a Hardy function on the lower half-plane, $\varphi_-(E)$, is completely defined by its given boundary values on the semiaxis $[E_0,\infty)$ (and the same occurs for a Hardy function on the upper half-plane). The reason is very simple: take $f(E) = \varphi_-(E + E_0)$, which is also a function in $\mathscr{H}^2_-$. After the van Winter theorem, $f(E)$ is determined by its boundary values on the positive semiaxis and those coincide with the values of $\varphi_-(E)$ on $[E_0,\infty)$.

Thus, there is a bijective (one-to-one and onto) correspondence between Ψ and Φ, so that we can transport the topology from Ψ to Φ. As mentioned earlier, $\Phi \otimes \Phi$ has the π-tensor product topology.

The space $\mathbf{Y}_-$ can be endowed with a stronger topology than the Fock space topology. The action of a functional, F, on $\mathbf{y} \in \mathbf{Y}_-$ is represented here as $\langle \mathbf{y} | F \rangle$.

In order to construct the topology on $\mathbf{Y}_-$, we note that the space Φ_n, which is defined as n times the π-tensor product of Φ by itself, is algebraically isomorphic and topologically homeomorphic to a proper subspace of Φ_{n+1}. Thus, we can write $\Phi_n \subset \Phi_{n+1}$. In this sense, we can say that the original topology of Φ_n coincides with the topology it has as a subspace of Φ_{n+1}. Therefore, from this point of view, it makes sense to write

$$\mathbf{Y}_- = \bigcup_{n=0}^{\infty} \Phi_n, \quad \Phi_0 = C,$$

and to endow $\mathbf{Y}_-$ with the strict inductive limit topology induced by the Φ_n. Then, $\mathbf{Y}_-$ has the following properties:

(i) The spaces Φ_n are nuclear because they are π-products of nuclear spaces. Since the strict inductive limit of nuclear spaces is nuclear, we conclude that $\mathbf{Y}_-$ is nuclear.

(ii) Since Φ is a Fréchet (metrizable) space, all Φ_n, $n=0,1,2,...$, are Fréchet. Therefore, $\mathbf{Y}_-$ is a LF space.[28]

(iii) By the dual space, $\mathbf{Y}_-^\times$, we mean the strong dual of $\mathbf{Y}_-$. Since Φ is a Fréchet space, $(\Phi \otimes \Phi \otimes \cdots \otimes \Phi)^\times = \Phi^\times \otimes \Phi^\times \otimes \cdots \otimes \Phi^\times$. This is a proper subspace of $\mathbf{Y}_-^\times$, so that

$$C \oplus \Phi^\times \oplus (\Phi^\times \otimes \Phi^\times) \oplus \cdots \subset \mathbf{Y}^\times.$$

The Gamow vector $\varphi_{\text{in}}^G(\mathbf{k})$ is a continuous functional on $\mathbf{Y}_-$. When applied to a space of the form C or $\Phi \otimes \cdots \otimes \Phi$ it gives zero, provided that the tensor product involves two or more copies of Φ. On Φ itself $\varphi_{\text{in}}^G(\mathbf{k})$ is nonzero.

Taking into account the commutation relations (53), we can compute the bracket $\langle \varphi | \Phi_{\text{in}}(E,\mathbf{k}) \rangle$:

$$\begin{aligned}
\langle \varphi | \Phi_{\text{in}}(E,\mathbf{k}) \rangle &= \int \frac{dE'\ d^3\mathbf{k}'}{(2\pi)^4 \kappa(E',\mathbf{k}')} \langle \Omega | b_{\text{out}}(E',\mathbf{k}') \varphi(E',\mathbf{k}') b_{\text{in}}^\dagger(E,\mathbf{k}) | \Omega \rangle \\
&= \int dE' t d^3\mathbf{k}'\ \varphi(E'\mathbf{k}') \delta(E-E') \delta(\mathbf{k}-\mathbf{k}') \frac{G(E+i0,\mathbf{k})}{G(E-i0,\mathbf{k})} \langle \Omega | \Omega \rangle \\
&= \varphi(E,\mathbf{k}) \frac{G(E+i0,\mathbf{k})}{G(E-i0,\mathbf{k})} = \varphi(E,\mathbf{k}) \frac{\gamma(E)\gamma(-(E+i0))}{\gamma(E)\gamma(-(E-i0))} = \varphi(E,\mathbf{k}) \frac{\gamma_+(-E)}{\gamma_-(-E)},
\end{aligned} \tag{77}$$

which is well defined because $\Phi_{\text{in}}(E,\mathbf{k})$ is a continuous functional on $\mathbf{Y}_-$. This equation shows that $\langle \varphi | \Phi_{\text{in}}(E,\mathbf{k}) \rangle$ admits a meromorphic extension to the lower half-plane having a pole at z_R.

So far, we have made our calculations for real values of E. If we want to to find the pole of the analytic continuation of (74) from above to below, we must remember that the continuation $\gamma(-(E+i0)) = \gamma_+(-E)$ has a pole at z_R with residue c and that the continuation of $\gamma(-(E+i0)) = \gamma_+(-E)$ has neither a singularity nor a zero at that point. Therefore, on a neighborhood of z_R,

$$\frac{\gamma_+(-E)}{\gamma_-(-E)} \quad \text{behaves as} \quad \frac{c}{E-z_R} \frac{1}{\gamma_-(-E)},$$

and we obtain finally

$$\langle \varphi | \varphi_{\text{in}}^G(\mathbf{k}) \rangle = \varphi(E,\mathbf{k}) \left. \frac{c}{\gamma_-(-E)} \right|_{E=z_R}. \tag{78}$$

Since

$$P_0 b_{\text{out}}^\dagger(E,\mathbf{k})\Omega = E b_{\text{out}}^\dagger(E,\mathbf{k})\Omega, \tag{79}$$

we immediately conclude that the test function space $\mathbf{Y}_-$ is stable under P_0, i.e., $P_0 \mathbf{Y}_- \subset \mathbf{Y}_-$. In addition, one can show that P_0 is continuous on $\mathbf{Y}_-$. Therefore, P_0 can be extended continuously to the dual of $\mathbf{Y}_-$ (the space of continuous functionals on $\mathbf{Y}_-$). Then, the action of P_0 on the Gamow state $\varphi_{\text{in}}^G(\mathbf{k})$ gives the expected formula:

$$P_0 \varphi_{\text{in}}^G(\mathbf{k}) = z_R \varphi_{\text{in}}^G(\mathbf{k}). \tag{80}$$

As in nonrelativistic quantum mechanics, we can extend the evolution operator e^{-itP_0} to the dual space of $\mathbf{Y}_-$, $\mathbf{Y}_-^\times$ for certain values of time only. Formula (79) and the properties of Hardy functions establish that $\mathbf{Y}_-$ is stable under e^{itP_0} if and only if $t\geqslant 0$. The proof of this statement is identical in the nonrelativistic case and is given in Ref. 11. Therefore, e^{-itP_0} can act on $\varphi_{\text{in}}^G(\mathbf{k})$ if and only if $t\geqslant 0$ and gives

$$e^{-itP_0}\varphi_{\text{in}}^G(\mathbf{k})=e^{-itz_R}\varphi_{\text{in}}^G(\mathbf{k}); \quad t\geqslant 0, \tag{81}$$

which shows the exponential decay of the Gamow vector $\varphi_{\text{in}}^G(\mathbf{k})$.

The same procedure can be done for the outgoing Gamow vectors $\varphi_{\text{out}}^G(\mathbf{k})$. In this case, we have to replace the space of Hardy functions on the lower half-plane by the space $\mathscr{H}_+^2$ of Hardy functions on the upper half-plane and b_{in} by b_{out}. Also, the following properties hold:

$$P_0\varphi_{\text{out}}^G(\mathbf{k})=z_R^*\varphi_{\text{out}}^G(\mathbf{k}), \quad e^{-itP_0}\varphi_{\text{out}}^G(\mathbf{k})=e^{-itz_R^*}\varphi_{\text{out}}^G(\mathbf{k}) \quad \text{for } t\leqslant 0 \text{ only.} \tag{82}$$

In this case, $\mathbf{Y}_+$ is the space of test functions and $\mathbf{Y}_+^\times$ its dual.

As in the nonrelativistic case, the group e^{-itP_0}, when extended to the duals, splits into two distict semigroups, one for $\mathbf{Y}_-^\times$ and the other one for $\mathbf{Y}_+$. This demonstrates the intrinsic irreversibility of the relativistic Friedrich's model. The implications for the Poincaré group will be discussed in the next section.

Going back to the definition of creation and annihilation operators $b_{\text{in(out)}}^\dagger(E,\mathbf{k})$ and $b_{\text{in(out)}}(E,\mathbf{k})$ we can also define operators which ''create'' and ''annihilate'' Gamow states. Indeed, let us consider

$$\psi^\dagger(E,\mathbf{k})=\int dE'\,\frac{\lambda\alpha(E',\mathbf{k})}{\kappa(E',\mathbf{k})}\left(\frac{B^\dagger(E',\mathbf{k})}{E'-E}-\frac{B(E',-\mathbf{k}')}{E'+E}\right)-\frac{(E+\omega(\mathbf{k}))a^\dagger(\mathbf{k})+(E-\omega(\mathbf{k}))a(-\mathbf{k})}{2\omega(\mathbf{k})} \tag{83}$$

and

$$\psi(E,\mathbf{k})=\int dE'\,\frac{\lambda\alpha(E',\mathbf{k})}{\kappa(E',\mathbf{k})}\left(\frac{B(E',\mathbf{k})}{E'-E}-\frac{B^\dagger(E',-\mathbf{k})}{E'+E}\right)-\frac{(E+\omega(E',\mathbf{k}))a(\mathbf{k})+(E-\omega(E',\mathbf{k}))a^\dagger(\mathbf{k})}{2\omega(E',\mathbf{k})}. \tag{84}$$

The analytic continuation described above for the state $\psi^+(E,\mathbf{k})\Omega$ produces the states $\varphi_G^{\text{in}}(\mathbf{k})$ or $\varphi_G^{\text{out}}(\mathbf{k})$, and we can consider $\psi^+(\mathbf{k},z_R)$ and $\psi^+(\mathbf{k},z_R^*)$ as the operators which create Gamow ket states. In the same sense $\psi(\mathbf{k},z_R)$ and $\psi(\mathbf{k},z_R^*)$ create Gamow bra states. The nonvanishing commutation relations for these operators are

$$\begin{aligned}&[\psi(\mathbf{k},z_R), \quad \psi^+(\mathbf{k}',z_R)]=(2\pi)^3\delta(\mathbf{k}-\mathbf{k}')2z_RZ,\\ &[\psi(\mathbf{k},z_R^*),\ \psi^+(\mathbf{k}',z_R^*)]=(2\pi)^3\delta(\mathbf{k}-\mathbf{k}')2z_R^*Z^*,\end{aligned} \tag{85}$$

where

$$Z=\frac{d}{dE^2}\,G^{-1}(E,\mathbf{k})|_{E^2-\mathbf{k}^2=\mu_c^2}.$$

These commutation relation may be a starting point for the introduction of a Gamow field, which we intend to consider elsewhere.

VI. THE POINCARÉ SEMIGROUPS

Now let us see how the Gamow vectors transform under Lorentz boosts. Commutation relations (53) together with the Lorentz invariance of vacuum state give us the action of the boost generators on the state (70):

$$J_{oi}\Phi_{\text{in}}(E,\mathbf{k})=i\left(k_i\frac{\partial}{\partial E}+E\frac{\partial}{\partial k_i}\right)\Phi_{\text{in}}(E,\mathbf{k}). \tag{86}$$

The Lorentz transformation generated by J_{0i} is

$$U(\alpha)\Phi_{\text{in}}(\mathbf{k},E)=\exp\{i\alpha_i J_{oi}\}\Phi_{\text{in}}(\mathbf{k},E)=\Phi_{\text{in}}(\mathbf{k}'_\alpha,E'_\alpha), \tag{87}$$

where

$$\begin{aligned}E'_\alpha&=E\cosh\alpha-(\mathbf{nk})\sinh\alpha,\\ \mathbf{k}'_\alpha&=\mathbf{k}-\mathbf{n}(\mathbf{kn})+\mathbf{n}((\mathbf{kn})\cosh\alpha-E\sin\alpha),\\ \alpha_i&=\alpha n_i,\quad \mathbf{n}^2=1.\end{aligned} \tag{88}$$

The rhs of (86) has a pole at the point z'_R which, of course, coincides with z_R on the E plane because the complex mass does not change. Comparing the pole terms in both sides of (86) we come to conclusion that

$$U(\alpha)\varphi^G_{\text{in}}(\mathbf{k})=\varphi^G_{\text{in}}(\mathbf{k}'_\alpha) \tag{89}$$

with

$$\mathbf{k}'_\alpha=\mathbf{k}-\mathbf{n}(\mathbf{kn})+\mathbf{n}((\mathbf{kn})\cosh\alpha-z_R\sinh\alpha).$$

This equation is meaningless because the transformed space components of the momentum become complex. The difficulty can be resolved by using again the rigged Fock spaces. The action of the Lorentz boost $U(\alpha)$ on the Gamow vectors $\varphi^G_{\text{in}}(\mathbf{k})$ is given by

$$\langle f|U(\alpha)\varphi^G_{\text{in}}(\mathbf{k})\rangle\equiv\langle U^\dagger(\alpha)f|\varphi(E,\mathbf{k})\rangle|_{E=z_R} \tag{90}$$

for any test function $f\in\mathbf{Y}_-$.

The action of the general element of the translation subgroup parametrized by the four-vector a_μ on the Gamov ket $\varphi^G_{\text{in}}(\mathbf{k})$ is defined by

$$\langle f|T(a)\varphi^G_{\text{in}}(\mathbf{k})\rangle\equiv\langle T(a)^\dagger f|\varphi^G_{\text{in}}(\mathbf{k})\rangle \tag{91}$$

with

$$T(a)=\exp(-iP_\mu a^\mu).$$

Now let us combine the translation $T(a)$ with a Lorentz transformation:

$$\begin{aligned}\langle f|T(a)U(\alpha)\varphi^G_{\text{in}}(\mathbf{k})\rangle&\equiv\langle U^+(\alpha)T^+(a)f,\varphi^G_{\text{in}}(\mathbf{k})\rangle\\ &=\langle U^+(\alpha)T^+(a)U^{+-1}(\alpha)U^+(\alpha)f|\varphi^G_{\text{in}}(\mathbf{k})\rangle\\ &=\langle T^+(a'(-\alpha))U^+(\alpha)f|\varphi^G_{\text{in}}(\mathbf{k})\rangle\\ &=e^{i(a'_0(-\alpha)z_R-\overline{a}(-\alpha)\mathbf{k})}\langle U^+(\alpha)f|\varphi^G_{\text{in}}(\mathbf{k})\rangle.\end{aligned} \tag{92}$$

In Eq. (91) we have used the fact that $\varphi^G_{\text{in}}(\mathbf{k})$ is the generalized eigenvector of P_μ with eigenvalue $(z_R,\mathbf{k})$. The $a'_\mu(\alpha)$ in (91) is given by

$$\begin{aligned}a'_0(-\alpha)&=a_0\cosh\alpha+\mathbf{na}\sinh\alpha,\\ \mathbf{a}'(-\alpha)&=\mathbf{a}-\mathbf{n}(\mathbf{an})+\mathbf{n}(\mathbf{an}\cosh\alpha+a_0\sinh\alpha).\end{aligned} \tag{93}$$

The space of test functions will remain invariant only if

$$a_0'(-\alpha) \geqslant 0. \tag{94}$$

This inequality gives us the admissible translations. Indeed, if the vector a_μ is timelike with non-negative zero component, then it has this property in each reference frame. So, in the relativistic case, the admissible translations of $\varphi^G_{\text{in}}(\mathbf{k})$ belong to the future cone V_+. Alternatively permitted translations of $\varphi^G_{\text{out}}(\mathbf{k})$ belong to the past cone V_-. Note that in the nonrelativistic case all translations are separated into future and past-oriented translations.

In the relativistic case there exist translations onto spacelike vectors, which have no analog in the nonrelativistic case and which are admissible for neither $\varphi^G_{\text{in}}(\mathbf{k})$ nor $\varphi^G_{\text{out}}(\mathbf{k})$.

The semidirect products of the Lorentz group with the two translation semigroups define the two Poicaré semigroups $P_\pm$ which describe the spacetime transformations of the two Gamow vectors.

VII. CONCLUDING REMARKS

In this paper, we have presented an extension of the conventional Fock space to a rigged Fock space. The extended evolution is no longer the unitary time symmetric group, but instead splits into two distinct semigroups, one in the forward and the other in the backward time direction. The time reversal transformation maps one semigroup onto the other. As a result, the PCT transformation acquires a new meaning and has to be extended.

The form of the Lorentz transformation of the four momentum of unstable particles has been discussed by many authors. For example, Kawai and Goto,[29] Comi *et al.*,[30] and Beltrametti and Luzzatto[31] discussed nonunitary irreducible representations of the Poincaré group. Raczka[32] discussed nonunitary indecomposable representations and Ben Yaacov[33] considered the Lorentz transformation in Liouville space in the context of relativistic subdynamics.

In the nonrelativistic case, the construction of Gamow vectors and the study of their time evolution has been formulated in terms of rigged Hilbert spaces of Hardy functions.[11] In this paper, we have shown that the rigged Hilbert spaces of Hardy functions also give meaning to the relativistic Gamow vectors. We have to replace the usual rigged Hilbert space by the rigged Fock space[27] $\mathbf{Y} \subset \mathscr{F} \subset \mathbf{Y}^\times$, where $\mathscr{F}$ is the Fock space based on the Hilbert space $\mathscr{H} = L^2[0,\infty) \otimes L^2(R^3)$.

In a recent paper,[34] Pelc and Horwitz considered a different type of rigged Fock space. Although inspired by similar principles, there are some differences between their and our constructions. First of all, they introduce statistics, so that N-particle test spaces include symmetric or antisymmetric vectors only. Second, for the basis representation space, our Ψ, they use $\mathscr{D}(\Omega)$, the space of C^∞ functions with compact support on Ω, endowed with an inductive limit topology. While our Ψ is a Frechét space, their $\mathscr{D}(\Omega)$ is not. Also, the configuration space $\dot{\Omega}$ is quite different from ours. In Ref. 34, Ω is written as a product of three components: the spectra of the generators for space–time translations and rotations of the Poincaré group, the points on a mass shell, and an index to specify individual mass shells.

The purpose of the paper by Pelc and Horwitz is also different from ours, because they introduce a mathematical formalism in order to (i) extend the Dirac formulation to the relativistic case, (ii) discuss some representations of the Poincaré group on a rigged Fock space, and (iii) serve as a basis to extend a mathematical theorem in a separate article.[35] Although all this is made compatible from the very beginning with the S-matrix formalism of scattering, no resonance phenomena are addressed in their paper.

The representation theory of noncompact groups in rigged Hilbert space has been discussed by some authors, for example, Maurin,[36] Antoine,[37] and Lindblad and Nagel.[38] The importance of the representations of noncompact groups in rigged Hilbert space for the introduction of irreversibility has been discussed also in previous works.[19,20,21]

In the past it has often been questioned whether irreversibility is compatible with relativity.[39] If a thermodynamic time asymmetry evolution exists for some observer, it should be present for all inertial observers who should observe the same arrow of time. Therefore, special relativity cannot destroy the universality of the second law of thermodynamics. Our paper provides a simple example where the compatibility of irreversibility and relativity is made explicit.

ACKNOWLEDGMENTS

The need for the extension of Gamow vectors to relativistic systems was suggested to us by Professor A. Bohm. We also thank Dr. G. Ordóñez for interesting comments. We received financial support from the International Solvay Institutes, the Belgian Interuniversity Attraction Poles, the European Commission ESPRIT project CTIAC 21042/DG III and the Grant NPSS No. 0992/DG XII, the NATO CRG940077, the Spanish DGICYT PB 95-0719, and the Junta de Castilla y León CP 001/96.

APPENDIX A: COMMUTATION RELATIONS OF THE CREATION AND ANNHILATION OPERATORS b_{in}, b_{out}, $b_{\text{in}}^\dagger$, AND $b_{\text{out}}^\dagger$

In order to obtain the commutation relation (53) for different types of new creation and annihilation operators we shall make use of the commutation relations (3) and (16). Consider, for example, the first commutator in (53). Using the explicit expression (52) for $b_{\text{in}}(E,\mathbf{k})$ and $b_{\text{in}}^\dagger(E,\mathbf{k})$, we obtain

$$\begin{aligned}[b_{\text{in}}(E,\mathbf{k}),\, b_{\text{in}}^\dagger(E',\mathbf{k}')] &= (2\pi)^4\kappa(E,\mathbf{k})\delta^4(k_\mu - k'_\mu) + (2\pi\lambda)^2\alpha(\kappa(E,\mathbf{k}))\alpha(\kappa(E',\mathbf{k}')) \\ &\times G(E-i0,\mathbf{k})G(E'+i0,\mathbf{k}')(2\pi)^3\delta(\mathbf{k}-\mathbf{k}') \\ &\times\Bigg[\int dE''\ \rho(E'',\mathbf{k})\left(\frac{1}{E''-E+i0}\,\frac{1}{E''-E'-i0} - \frac{1}{E''+E}\,\frac{1}{E''+E'}\right) \\ &+ \frac{1}{E-E'-i0}\left(\frac{1}{G(E-i0,\mathbf{k})} - \frac{1}{G(E'+i0,\mathbf{k})}\right) + (E+E')\Bigg]. \end{aligned} \tag{A1}$$

The expression within the square brackets may be written as follows:

$$\begin{aligned}&\int dE''\ \rho(E'',\mathbf{k})\,\frac{2E''}{E-E'}\left(\frac{1}{E''^2-E^2+i0} - \frac{1}{E''^2-E'^2-i0}\right) + \frac{1}{E-E'}\left(\frac{1}{G(E-i0,\mathbf{k})}\right. \\ &\left. - \frac{1}{G(E'+i0,\mathbf{k})}\right) + \frac{1}{E-E'}\,(E^2-E'^2) \\ &= \frac{1}{E-E'}\left\{\left(\frac{1}{G(E-i0,\mathbf{k})} - \frac{1}{G(E'+i0,\mathbf{k})}\right)\right. \\ &\left. - \left(\int dE''^2\,\frac{\rho(E'',\mathbf{k})}{E''^2-E^2+i0} - \int dE''^2\,\frac{\rho(E'',\mathbf{k})}{E''^2-E^2-i0}\right) + E^2-E'^2\right\}. \end{aligned} \tag{A2}$$

Now, using the definition of Green's function given in (33) and (34), we can show that (A2) vanishes and, therefore, one obtains that

$$[b_{\text{in}}(E,\mathbf{k}),\, b_{\text{in}}^\dagger(E,\mathbf{k})] = (2\pi)^4\kappa(E,\mathbf{k})\delta^4(k_\mu - k'_\mu). \tag{A3}$$

The rest of the commutation relations (53) are obtained in a similar way.

APPENDIX B: THE NEW VACUUM STATE

The new vacuum state Ω is defined as the solution to the equation

$$b_{\text{in}}(E,\mathbf{k})\Omega = 0. \tag{B1}$$

The same equation holds true also for $b_{\text{out}}(E,\mathbf{k})$, and this may be checked explicitly. However, in order to fix ideas, we shall consider (B1).

We will be looking for Ω in the following form:

$$\Omega = e^V|0\rangle, \tag{B2}$$

where $|0\rangle$ is the vacuum state in the initial Fock space and V is a quadratic function of creation operators $B^\dagger(E,\mathbf{k})$ and $a^\dagger(\mathbf{k})$:

$$V=\int d^3\mathbf{k}\left\{\frac{1}{2}\int dE\ dE'\ f(E,E',\mathbf{k})B^\dagger(E,\mathbf{k})B^\dagger(E',-\mathbf{k})\right.$$
$$\left.+\int dE\ f(E,k)B^\dagger(E,\mathbf{k})a^\dagger(-\mathbf{k})+\frac{1}{2}f(\mathbf{k})a^\dagger(\mathbf{k})a^\dagger(-\mathbf{k})\right\}. \tag{B3}$$

While parametrizing V in (B3) we already took into account the invariance of Ω with respect to three-dimensional translations and rotations, generated by (17) and (18). The function $f(E,E',\mathbf{k})$ is symmetric with respect to E and E'

The equations (B1) and (B2) give us

$$b_{\text{in}}(E,\mathbf{k})e^V|0\rangle=e^V([b_{\text{in}}(E,\mathbf{k}),\ V]+b_{\text{in}}(E,\mathbf{k}))|0\rangle=0, \tag{B4}$$

because

$$[V,[b_{\text{in}}(E,\mathbf{k}),\ V]]=0. \tag{B5}$$

In order to show (B4) and (B5), let us expand e^V into formal series:

$$e^V=\sum_{n=0}^{\infty}\frac{1}{n!}V^n. \tag{B6}$$

Then, we apply the annihilation operator $b_{\text{in}}(E,\mathbf{k})$ to (B6) on the left and assume that it commutes with the infinite sum on the right-hand side of (B6). Then, each term of the formal series has a product of the following form:

$$b_{\text{in}}V^n=Vb_{\text{in}}V^{n-1}+[b_{\text{in}},\ V]V^{n-1}. \tag{B7}$$

The commutator $[b_{\text{in}},\ V]$ contains only the *creation operators* $B^\dagger(E,\mathbf{k})$ and $a^\dagger(\mathbf{k})$ because of the structure of b_{in} and V. Therefore, this commutator commutes with V, which is a functional of creation operators only:

$$[[b_{\text{in}},\ V],V]=0. \tag{B8}$$

This is the equation (B5). After (B7), we can rewrite (B6) in the following form:

$$b_{\text{in}}V^n=Vb_{\text{in}}V^{n-1}+V^{n-1}[b_{\text{in}},\ V]. \tag{B9}$$

If we use (B9) in the first term of the right-hand side of (B9), we obtain the following equation:

$$b_{\text{in}}V^n=V^2b_{\text{in}}V^{n-2}+2V^{n-1}[b_{\text{in}},\ V]. \tag{B10}$$

After n steps, we arrive at

$$b_{\text{in}}V^n=V^nb_{\text{in}}+nV^n[b_{\text{in}},\ V]. \tag{B11}$$

If we use (B11) in (B6), we obtain

$$b_{\text{in}}e^V=\sum_{n=0}^{\infty}\frac{1}{n!}b_{\text{in}}V^n=\sum_{n=0}^{\infty}\frac{1}{n!}(V^nb_{\text{in}}+nV^{n-1}[b_{\text{in}},\ V])=e^V(b_{\text{in}}+[b_{\text{in}},\ V]). \tag{B12}$$

Equation (B12) implies (B4) and (B5).

Equation (B4) together with the explicit form of $b_{\text{in}}(E,\mathbf{k})$ [see Eq. (93)] gives us the following equations for functions $f(E,E',\mathbf{k})$, $f(E,\mathbf{k})$, and $f(\mathbf{k})$:

$$f(E,E',\mathbf{k})+G(E^2-\mathbf{k}^2-i0)2\pi\lambda^2\,\frac{\alpha(\kappa(E,\mathbf{k}))}{\kappa(E,\mathbf{k})}\int_{E_0}^{\infty}dE''\,\frac{\alpha(\kappa(E',\mathbf{k}))}{E''-E+i0}\,f(E'',E',\mathbf{k})$$
$$=\frac{G(E^2-\mathbf{k}^2-i0)}{(2\pi)^3}\,\lambda\,\frac{\alpha(\kappa(E,\mathbf{k}))}{\kappa(E,\mathbf{k})}\left[\lambda\,\frac{\alpha(\kappa(E,\mathbf{k}))}{\kappa(E,\mathbf{k})}\,\frac{1}{E'+E}+(E+\omega(\mathbf{k}))(2\pi)^3 f(E',\mathbf{k})\right], \tag{B13}$$

$$f(E,\mathbf{k})+G(E^2-\mathbf{k}^2-i0)2\pi\lambda^2\,\frac{\kappa(\alpha(E,\mathbf{k}))}{\kappa(E,\mathbf{k})}\int_{E_0}^{\infty}dE'\,\frac{\alpha(\kappa(E',\mathbf{k}))}{E'-E+i0}\,f(E',\mathbf{k})$$
$$=\frac{G(E^2-\mathbf{k}^2-i0)}{(2\pi)^3}\,\lambda\,\frac{\alpha(\kappa(E',\mathbf{k}))}{\kappa(E',\mathbf{k})}\left[\frac{E+\omega(\mathbf{k})}{2\omega(\mathbf{k})}\,(1+(2\pi)^3 2\omega(\mathbf{k})f(\mathbf{k}))-1\right]. \tag{B14}$$

In order to simplify these equations, let us introduce instead of the f's new functions ϕ as follows:

$$f(E,E',\mathbf{k})=\frac{q(E,\mathbf{k})q(E',\mathbf{k})}{2(2\pi)^3}\,\phi(E,E',\mathbf{k}), \tag{B15}$$

$$f(E,\mathbf{k})=\frac{q(E,\mathbf{k})}{2(2\pi)^3}\,\phi(E,\mathbf{k}), \tag{B16}$$

$$f(\mathbf{k})=\frac{1}{2(2\pi)^3}\,\phi(\mathbf{k}), \tag{B17}$$

where

$$q(E,\mathbf{k})=\lambda\,\frac{\alpha(\kappa(E,\mathbf{k}))}{\kappa(E,\mathbf{k})}\,\gamma(E,\mathbf{k}), \tag{B18}$$

and $\gamma(E,\mathbf{k})$ is the solution of the factorization problem (see Appendix C).

Substituting (B15)–(B17) into (B13) and (B14) and taking into account the properties of $\gamma(E,\mathbf{k})$, we obtain a system of singular integral equations for ϕ:

$$\phi(E,E',\mathbf{k})+\gamma(-E+i0,\mathbf{k})\left[\int_{E_0}^{\infty}dE''\,\frac{\rho(E'',\mathbf{k})\gamma(E'',\mathbf{k})}{E''-E+i0}\,\phi(E'',E',\mathbf{k})-\frac{2}{E+E'}\,\frac{1}{\gamma(E',\mathbf{k})}\right.$$
$$\left.-(E+\omega)\phi(E',\mathbf{k})\right]=0, \tag{B19}$$

$$\phi(E,\mathbf{k})+\gamma(-E+i0,\mathbf{k})\left[\int_{E_0}^{\infty}dE'\,\frac{\rho(E',\mathbf{k})\gamma(E',\mathbf{k})}{E'-E+i0}\,\phi(E',\mathbf{k})-\frac{E-\omega(\mathbf{k})}{\omega(\mathbf{k})}-(E+\omega(\mathbf{k}))\phi(\mathbf{k})\right]=0, \tag{B20}$$

where $\rho(E,\mathbf{k})$ was introduced in (31).

In contradiction with (B13) and (B14), the equations (B20) and (B13) may be considered not only for real values of energy but also on the complex E plane. From (B20) we see that the function $\phi(E,\mathbf{k})$ is analytic in the left half-plane. Let us denote the jump of $\phi(E,k)$ on the cut (E_0,∞) in the right semiplane via $\Delta\phi(E,k)$:

$$\Delta\phi(E,\mathbf{k})=\phi(E+i0,\mathbf{k})-\phi(E-i0,\mathbf{k}). \tag{B21}$$

Further, let us rewrite (B20) for complex E in the following form:

$$\frac{\phi(E,\mathbf{k})}{\gamma(E,\mathbf{k})}=-\int_{E_0}^{\infty}dE'\,\frac{\rho(E',\mathbf{k})\gamma(E',\mathbf{k})}{E'-E}\,\phi(E',\mathbf{k})+\frac{E-\omega(\mathbf{k})}{\omega(\mathbf{k})}+(E+\omega(\mathbf{k}))\phi(\mathbf{k}). \tag{B22}$$

The calculation of the jump on the cut in both sides of (B22) gives the equation,

$$-\Delta\phi(E,\mathbf{k})\left[\frac{1}{\gamma(-E-i0,\mathbf{k})}+2\pi i\gamma(E,\mathbf{k})\rho(E,\mathbf{k})\right]-2\pi i\rho(E,\mathbf{k})\gamma(E,\mathbf{k})\phi(E,\mathbf{k})$$
$$=-2\pi i\rho(E,\mathbf{k})\gamma(E,\mathbf{k})\phi(E,\mathbf{k}). \tag{B23}$$

From (B23) we see that

$$\Delta\phi(E,\mathbf{k})=0, \tag{B24}$$

i.e., the function $\phi(E,\mathbf{k})$ has discontinuity neither in the left, nor in the right E half-plane, so $\phi(E,\mathbf{k})$ is a meromorphic function of E. We shall now show that $\phi(E,\mathbf{k})$ may have poles at the infinity only. Let us rewrite Eq. (B20):

$$\phi(E,\mathbf{k})=-\gamma(-E,\mathbf{k})\left[\int_{E_0}^{\infty}dE'\,\frac{\rho(E',\mathbf{k})\gamma(E',\mathbf{k})}{E'-E}\,\phi(E',\mathbf{k})-\frac{E+\omega(\mathbf{k})}{\omega(\mathbf{k})}-(E+\omega(\mathbf{k}))\phi(\mathbf{k})\right]. \tag{B25}$$

The singularities of $\phi(E,\mathbf{k})$ may come either from $\gamma(E,\mathbf{k})$, or from the integral. Both factors have the branching points at $E=E_0$ and different singularities on the different sheets, but because $\phi(E,\mathbf{k})$ has no branching point, it is sufficient to consider it only on the first sheet, where both $\gamma(E,\mathbf{k})$ and the integral in (B25) may have poles in the infinity only. Therefore, the function $\phi(E,\mathbf{k})$ may have poles only at the infinity, i.e., $\phi(E,\mathbf{k})$ should be a polynomial of E. Now let us make use of the asymptotic expansion of the rhs of (B25):

$$\phi(E,\mathbf{k})=-\left(\frac{1}{E}+\frac{\omega(\mathbf{k})+2\xi(\mathbf{k})}{E^2}+O\left(\frac{1}{E^3}\right)\right)\left[-E\left(\frac{1}{\omega(\mathbf{k})}+\phi(\mathbf{k})\right)+(1-\omega(\mathbf{k})\phi(\mathbf{k}))+O\left(\frac{1}{E}\right)\right]$$
$$=\left(\frac{1}{\omega(\mathbf{k})}+\phi(\mathbf{k})\right)+\frac{1}{E}\left[(\omega(\mathbf{k})+2\xi(\mathbf{k}))\left(\frac{1}{\omega(\mathbf{k})}+\phi(\mathbf{k})\right)-(1-\omega\phi(\mathbf{k}))\right]+O\left(\frac{1}{E^2}\right), \tag{B26}$$

where we have used (C4). It is obvious that our conclusion that $\phi(E,k)$ should be a polynomial of E is compatible with (B19) iff only the first term does not vanish, i.e.,

$$\phi(E,\mathbf{k})=\frac{1}{\omega(\mathbf{k})}+\phi(\mathbf{k}),$$

$$(\omega(\mathbf{k})+2\xi(\mathbf{k}))\left(\frac{1}{\omega(\mathbf{k})}+\phi(\mathbf{k})\right)-(1-\omega(\mathbf{k})\phi(\mathbf{k}))=0, \tag{B27}$$

and all other terms also vanish. From (B27) we obtain

$$\phi(\mathbf{k})=-\frac{\xi(\mathbf{k})}{\omega(\mathbf{k})(\omega(\mathbf{k})+\xi(\mathbf{k}))},$$

$$\phi(E,\mathbf{k})=\frac{1}{\omega(\mathbf{k})+\xi(\mathbf{k})}. \tag{B28}$$

The substitution of (B28) into (B25) cancels all terms of the asymptotic expansion (B26); therefore (B28) is the solution of (B20).

Now, using (B21) we can rewrite Eq. (B19):

$$\phi(E,E',\mathbf{k})+\gamma(-E+i0,\mathbf{k})\left[\int_{E_0}^{\infty}dE''\,\frac{\rho(E'',\mathbf{k})\,\gamma(E'',\mathbf{k})}{E''-E+i0}\,\phi(E'',E',\mathbf{k})\right.$$
$$\left.-\frac{2}{E+E'}\,\frac{1}{\gamma(E',\mathbf{k})}-\frac{E+\omega(\mathbf{k})}{\xi(\mathbf{k})+\omega(\mathbf{k})}\right]=0. \tag{B29}$$

The same arguments as above may be used to prove the absence of discontinuities of $\phi(E,E',\mathbf{k})$ in the E plane. As $\phi(E,E',\mathbf{k})$ is symmetric with respect to E and E', the same it true for E'. Therefore, we conclude the only singularities of $\phi(E,E',k)$ are the poles at $E=-E_0$ and at infinity. Thus, $\phi(E,E',\mathbf{k})$ has the form

$$\phi(E,E',\mathbf{k})=\frac{C(\mathbf{k})}{E+E'}+P(E,E',\mathbf{k}), \tag{B30}$$

where $P(E,E',\mathbf{k})$ is a polynomial of E and E'. The asymptotic expansion of both sides of (B30) gives

$$C(\mathbf{k})=2,\quad P(E,E',\mathbf{k})=\frac{1}{\omega(\mathbf{k})+\xi(\mathbf{k})}, \tag{B31}$$

so

$$\phi(E,E',\mathbf{k})=\frac{1}{\omega(\mathbf{k})+\xi(\mathbf{k})}+\frac{2}{E+E'}. \tag{B32}$$

We may verify that (B32) is the solution of (B29), if we substitute (B32) into (B29) using the integral representation for $\gamma(E,\mathbf{k})$ given in Appendix C [see formula (C9)].

Formula (B32) completes the solution of (B19) and (B20) and gives the expression for functions the $f(E,E',\mathbf{k})$, $f(E,\mathbf{k})$, and $f(\mathbf{k})$ via (B15)–(B17).

APPENDIX C: FACTORIZATION OF GREEN'S FUNCTION

The problem of factorization of Green's functions or the S matrix often arises in different parts of theoretical and mathematical physics. The solutions of the problem may be very different in each case depending on the physical context. In our case the factorization problem is formulated as follows: given Green's function $G(E,\mathbf{k})$ with analytic properties discussed in Sec. III, i.e., on the first sheet the only singularities are the branching points at $E=\pm E_0$ and the asymptotic behavior is given by (40), find a function $\gamma(E,\mathbf{k})$ analytic in the right half-plane such that

$$\gamma(E,\mathbf{k})\,\gamma(-E,\mathbf{k})=G(E,\mathbf{k}) \tag{C1}$$

is valid. Obviously, this condition does not fix the $\gamma(E,\mathbf{k})$, and in order to remove all ambiguities we must require that $\gamma(E,\mathbf{k})$ has neither poles nor essential singularities on the first sheet of E plane and that the only singularity in the whole complex plane is the cut between $E=-E_0$ and infinity in the left half-plane Re $E<0$. Further, because neither $G(E,\mathbf{k})$ nor $G(E,\mathbf{k})^{-1}$ has poles in the finite domain on the first sheet, one could easily prove that $\gamma^{-1}(E,\mathbf{k})$ also has no poles, so $\gamma(E,\mathbf{k})$ has neither poles nor zeros in the finite domain of the first sheet of E plane.

In the absence of interaction ($\lambda=0$), the function $G(E,\mathbf{k})$ becomes Green's function of a Klein–Gordon field:

$$G(E,\mathbf{k})=(\omega^2(\mathbf{k})-E^2)^{-1}. \tag{C2}$$

In this case, the solution of the factorization problem is

$$\gamma(E,\mathbf{k})=-(\omega(\mathbf{k})+E)^{-1}, \tag{C3}$$

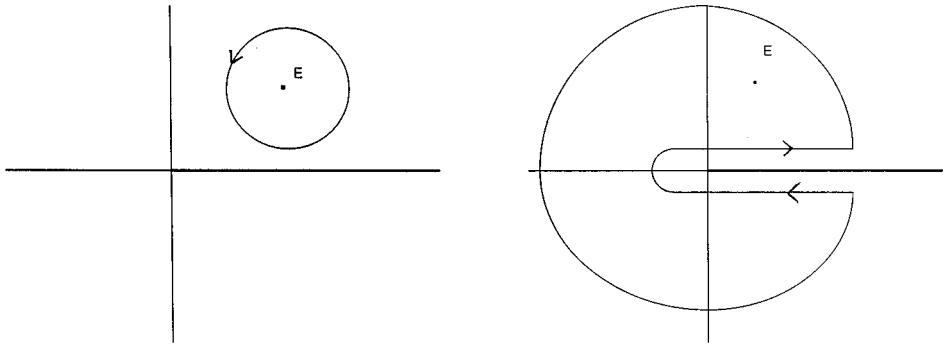

FIG. 1. The contour of integration in Eqs. (C6) and (C7).

where we fixed the sign on the r.h.s. The interaction does not change the asymptotic behavior of Green's function and therefore we can impose the asymptotic condition on $\gamma(E,\mathbf{k})$ in the following form:

$$\gamma^{-1}(E,\mathbf{k}) = -E - (\omega(\mathbf{k}) + 2\xi(\mathbf{k})) + O(1/E), \quad E \to \infty. \tag{C4}$$

The energy shift in the second term $\xi(\mathbf{k})$ appears due to interaction.

Now we can consider the Cauchy integral for function $r(E,\mathbf{k})$, which is defined by

$$r(E,\mathbf{k}) = \gamma^{-1}(-E,\mathbf{k}) - E + \omega(\mathbf{k}) + 2\xi(\mathbf{k}). \tag{C5}$$

This function vanishes at infinity, may have poles in only at infinity, and has a cut in the right half-plane on E from $E = E_0$ to infinity. Thus, in the domain of analyticity of $r(E,\mathbf{k})$, the Cauchy formula holds:

$$r(E,\mathbf{k}) = \frac{1}{2\pi i} \int_C dE' \, \frac{r(E',\mathbf{k})}{E' - E}, \tag{C6}$$

where the contour C lays on the first sheet around point E. Deforming the contour C to the infinite circle excluding the cut on the real axes (Fig. 1), we get

$$r(E,\mathbf{k}) = \frac{1}{2\pi i} \int_{E_0}^{\infty} dE' \, \frac{1}{E' - E} \, (r(E' + i0,\mathbf{k}) - r(E' - i0,\mathbf{k})), \tag{C7}$$

where the integral along infinite circle disappeared due to the asymptotic behavior of $r(E,\mathbf{k})$. The discontinuity of the integrand in (C7) is easily calculated:

$$\begin{aligned} r(E + i0,\mathbf{k}) - r(E - i0,\mathbf{k}) &= \gamma^{-1}(-E - i0,\mathbf{k}) - \gamma^{-1}(-E + i0,\mathbf{k}) \\ &= \gamma(E,\mathbf{k})(G^{-1}(E + i0,\mathbf{k}) - G^{-1}(E - i0,\mathbf{k})) = -2\pi i \gamma(E,\mathbf{k})\rho(E,\mathbf{k}), \end{aligned} \tag{C8}$$

where in the second step we used the fact that $\gamma(E,\mathbf{k})$ has no discontinuity in the right half-plane and in the last step we used Eq. (38).

Taking into account Eq. (C8) we finally obtain the equation

$$\gamma^{-1}(-E,\mathbf{k}) = E - (\omega(\mathbf{k}) + 2\xi(\mathbf{k})) - \int_{E_0}^{\infty} dE' \, \frac{\rho(E',\mathbf{k})\,\gamma(E',\mathbf{k})}{E' - E}, \tag{C9}$$

which is valid for complex E on the first sheet. This equation obviously is the same as Eq. (62).

From (B9) we can obtain the third term of asymptotic expansion of $\gamma^{-1}(E,\mathbf{k})$:

$$\gamma^{-1}(-E,\mathbf{k})=E-(\omega(\mathbf{k})+2\xi(\mathbf{k}))+\frac{1}{E}\int_{E_0}^{\infty}dE'\ \rho(E',\mathbf{k})\gamma(E',\mathbf{k})+o(1/E). \tag{C10}$$

Using (A1) and (38) we obtain the relation (63):

$$\int_{E_0}^{\infty}dE\ \rho(E,\mathbf{k})\gamma(E,\mathbf{k})=2\xi(\mathbf{k})(\omega(\mathbf{k})+\xi(\mathbf{k})). \tag{C11}$$

Now if we will consider instead of the function $r(E,\mathbf{k})$ the $\gamma(-E,\mathbf{k})$ itself, we will obtain the relation

$$\gamma(-E,\mathbf{k})=\int_{E_0}^{\infty}dE'\ \frac{\rho(E',\mathbf{k})|G(E',\mathbf{k})|^2}{\gamma(E',\mathbf{k})}\frac{1}{E'-E}, \tag{C12}$$

which is also valid for complex E on the first sheet. Here, for the calculation of the discontinuity, we used Eq. (39). Combining both (C9) and (C12), which are nonlinear integral equations, we can obtain a linear integral equation of Fredholm type for $\gamma(E,\mathbf{k})$:

$$\gamma(E,\mathbf{k})-\int_{E_0}^{\infty}dE'\ \rho(E',\mathbf{k})\gamma(E',\mathbf{k})v(E,E')=U(E), \tag{C13}$$

where

$$v(E,E')=\frac{R(E,\mathbf{k})-R(E'\mathbf{k})}{E-E'}, \tag{C14}$$

$$U(E)=1+(-E+\omega(\mathbf{k})+2\xi(\mathbf{k}))R(E,\mathbf{k}), \tag{C15}$$

$$R(E,\mathbf{k})=\int_{E_0}^{\infty}dE'\ \frac{\rho(E',\mathbf{k})|G(E',\mathbf{k})|^2}{E+E'}. \tag{C16}$$

The solution of (C13) is the standard Fredholm solution which can be obtained from the expression of the form factor $\rho(E,\mathbf{k})$.

The factorization problem described here is similar although not the same as the factorization problem considered by Krein.[40] The latter is formulated as follows:

Given a function $F(t)$ defined on the real axis R, find two functions of the complex variable z, $f_+(z)$ and $f_-(z)$, analytic on the upper and lower half-plane, respectively, such that

$$f_+(t)f_-(t)|_{t\in R}=F(t) \tag{C17}$$

satisfying the following normalization condition:

$$f_{\pm}(\infty)=1. \tag{C18}$$

This problem is obviously related to the Riemann–Hilbert problem for $f_+(z)$ and $f_-^{-1}(z)$.[41,42]

In our case, we need to construct a solution of (C1) such that $f_+(z)$ [in our notation $\gamma(E)$] coincides with $f_-(-z)$. In addition, our function $F(t)[=G(E)]$ is known for complex E and admits the representation (C1) in the whole complex plane. A *direct* relation between the problem described in (C1) and the Riemann–Hilbert factorization problem is unknown to us. Also, we did not find in the literature any discussion concerning this point.

Quantum martingale measures and stochastic partial differential equations in Fock space

David Applebaum
Department of Mathematics, Statistics and Operational Research,

(Received 21 April 1997; accepted for publication 13 January 1998)

A concept of quantum martingale measure is introduced and examples are constructed as quantum stochastic spectral integrals in Fock space. These are then utilized as space–time noise to drive a parabolic stochastic partial differential equation (spde). We establish the existence and uniqueness of the solutions as families of densely defined closable operators in Fock space that are jointly continuous in time and space variables and satisfy a Markov property. © *1998 American Institute of Physics.* [S0022-2488(98)00206-0]

I. INTRODUCTION

A stochastic partial differential equation (spde) is effectively a partial differential equation that is perturbed by a space–time random field. These arise in a number of different contexts including branching processes, neurophysiology, and constructive quantum field theory, and there is an enormous literature on the subject. Our aim in this paper is to give the first example of an spde, which is perturbed by a quantum noise.

We begin by briefly describing the classical setup that we intend to quantize. We will in this paper be solely concerned with quantum analogs of parabolic spdes of the form

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + f(t,x,u) + g(t,x,u)\dot{W}(t,x), \tag{1.1}$$

with, e.g., reflecting boundary conditions on $\mathbb{R}^+ \times [0,a]$ and suitable Lipshitz conditions on the functions f and g. Here W is a martingale measure, i.e., a martingale with respect to time and a measure with respect to space. The solution of (1.1) when it exists will be a random field. The main technique for studying (1.1) is to first write it in a weak form and then treat an equivalent ''auxiliary equation'' wherein the spatial derivatives are absorbed into the Green's function for the homogeneous version of (1.1). For more information on the existence and uniqueness, see the papers in Refs. 1 and 2, which will be our standard references for the subject.

For more recent progress (especially in hyperbolic spdes)—see the recent review,[3] and for applications to quantum fields see Ref. 4 and references therein.

Most authors have studied (1.1), with W being a Gaussian space–time white noise (i.e., a Brownian sheet). Recently there has been some interest in using different types of noise—so W has been a Poisson white noise in Ref. 5 and a Lévy white noise in Ref. 6. A related equation (in three space dimensions) driven by α-stable Lévy noise has been considered in Ref. 7. Here we will take W to be a quantum noise in a suitable Fock space so that the solution of (1.1) when it exists will be a family of linear operators indexed by space and time. One reason for doing this is to provide an example of a new type of irreversible quantum dynamics constructed by means of the powerful tools of quantum stochastic calculus. Another motivation comes from the modeling of electric currents in neurons.

In fact, we shall only be concerned in this paper with the case where $-f(t,x,u) = g(t,x,u) = u$ in (1.1). This equation is usually called the cable equation, and it was proposed in Refs. 8 and 1 as a model for the evolution in space and time of the electric potential on a neuron when the latter is treated as a long thin cylinder of length a. It is argued that this potential evolves through a combination of diffusion and random fluctuations, the latter of which should be modeled by a Poisson noise or (in the limit of infinitely many small jumps) a Gaussian noise (for a lengthy

 © 1998 American Institute of Physics

discussion of this in the context of an infinite-dimensional stochastic model see the introduction to Ref. 9). The reasoning behind the introduction of a quantum noise in this equation is the recent proposal of Penrose that the propagation of nerve signals might be influenced by quantum coherence effects within the microtubules in the cytoskeletons of the neurons (see Chap. 7 of Ref. 10). The quantum version of (1.1) would then describe the microtubular potential as an observable that evolves in space and time through diffusion and quantum effects, as described by the noise terms. Although this proposed application is highly speculative, it is sufficiently intriguing to merit further investigation.

The organization of this paper is as follows. In Sec. II, we introduce the basic framework for quantum space–time noise—namely, the quantum martingale measure. As its name suggests, this is an obvious analog of the classical concept described above, but the martingale concept is now quantum probabilistic (see Ref. 11 and references therein) and the measure is Hilbert space valued. Our main examples of these objects are quantum stochastic spectral integrals with respect to creation, conservation, and annihilation processes in Fock space.

These involve both a quantum stochastic integral in the sense of Ref. 12 (time) and an integration with respect to a projection-valued measure (space) and were first introduced to realize stochastic flows driven by Lévy processes in Fock space (see Refs. 13 and 14). We review those aspects of this theory that we will need in Sec. III.

With quantum stochastic spectral integrals playing the role of the noise W, we are now able to formulate the spde (1.1) in Fock space.

In Secs. IV and V we follow the line of reasoning of Ref. 1 in first proving that the existence and uniqueness problem for the weak form of (1.1) is equivalent to that for the conceptually simpler auxiliary equation constructed with the aid of the Green's function and then establishing the existence and uniqueness for the solution of the auxiliary equation. We then show that the solution $[u(t,x),\ t\in\mathbb{R}^+,\ 0\leqslant x\leqslant a]$ consists of densely defined closable linear operators that are jointly continuous when evaluated on exponential vectors and give rise to adapted processes for each $0\leqslant x\leqslant a$. We also present an appropriate form of the Markov property and show that this is satisfied by the solution.

If the equation (1.1) is to be taken seriously as a model for a quantum potential, the solution should be essentially self-adjoint. It is easy to show (with appropriate restrictions on the noise) that the solution is symmetric, but we will postpone further consideration of this question to a later paper. It is worth pointing out at this stage that even in the relatively simpler case of the Hudson–Parthasarthy theory there are few results known to the author about self-adjointness of quantum stochastic integrals or of solutions to quantum stochastic differential equations, and he hopes that this paper will succeed in stimulating work on this and related problems. Some interesting recent work in this direction appears in Ref. 15.

Finally, we emphasize that we will only deal with quantum spdes involving one spatial dimension in this paper. By analogy with the classical case, we expect that we will not, in general, be able to find operator-valued solutions for higher-dimensional equations but that generalized (distribution-valued) solutions will exist.

II. QUANTUM MARTINGALE MEASURES

Let S be a measurable space equipped with a σ-algebra of subsets $\mathcal{F}$ and let $\mathcal{H}$ be a complex separable Hilbert space. By an *$\mathcal{H}$-valued measure* on $(S,\mathcal{F})$ we will mean a map $Q\colon \mathcal{F}\to\mathcal{H}$, which is such that, for any sequence $(E_n,\ n\in\mathbb{N})$ of mutually disjoint subsets in $\mathcal{F}$, we have

$$\text{(i)}\quad \sum_{n=1}^{\infty} Q(E_n)\in\mathcal{H}$$

and

$$\text{(ii)}\quad Q\Big(\bigcup_{n\in\mathbb{N}} E_n\Big)=\sum_{n=1}^{\infty} Q(E_n).$$

Any projection-valued measure acting on a fixed vector gives rise to an $\mathscr{H}$-valued measure in the above sense.

Now, let $\{\mathscr{H}_t,\ t\in\mathbb{R}^+\}$ be a family of closed linear subspaces of $\mathscr{H}$ for which

$$\text{(i)}\quad \mathscr{H}_s\subseteq\mathscr{H}_t,\quad \text{whenever } 0\leqslant s\leqslant t<\infty;$$

$$\text{(ii)}\quad \mathscr{H}=\{\bigcup_{t\geqslant 0}\mathscr{H}_t\}^-.$$

We call $\{\mathscr{H}_t,\ t\in\mathbb{R}^+\}$ a *filtration* of $\mathscr{H}$ and denote as Π_t the orthogonal projection from $\mathscr{H}$ into $\mathscr{H}_t$, for each $t\in\mathbb{R}^+$.

A family of linear operators $[X(t),\ t\in\mathbb{R}^+]$ in $\mathscr{H}$ is said to be *adapted* to the filtration $\{\mathscr{H}_t,\ t\in\mathbb{R}^+\}$, if for each $t\in\mathbb{R}^+$,

(i) Π_t leaves Dom $X(t)$ invariant;

(ii) $X(t)\Pi_t\psi=\Pi_t X(t)\psi$, for all $\psi\in\text{Dom}(X(t))$.

Let ϕ be a fixed unit vector in $\mathscr{H}$ such that $\Pi_t\phi=\phi$ for each $t\in\mathbb{R}^+$.

Now take $(S,\mathscr{F})$ to be as above, let $\mathscr{U}$ be a dense linear subspace of $\mathscr{H}$ that contains ϕ and for which $\Pi_t\mathscr{U}\subseteq\mathscr{U}$ for all $t\in\mathbb{R}^+$ and let $M=(M(t,E),t\in\mathbb{R}^+,E\in\mathscr{F})$ be a family of densely defined linear operators in $\mathscr{H}$.

We say that M is a *quantum martingale measure* relative to the filtration $\{\mathscr{H}_t,\ t\in\mathbb{R}^+\}$ and the subspace $\mathscr{U}$ if (i) $\mathscr{U}\subseteq\text{Dom}(M(t,E))$ for each $t\in\mathbb{R}^+$, $E\in\mathscr{F}$; (ii) for each $E\in\mathscr{F}$, $M(\cdot,E)$ is adapted to the filtration $\{\mathscr{H}_t,\ t\in\mathbb{R}^+\}$; (iii) for each $E\in\mathscr{F}$, $M(\cdot,E)$ is a martingale, i.e., for each $s\leqslant t$,

$$\Pi_s M(t,E)\Pi_s\psi=M(s,E)\psi,\quad \text{for all}\quad \psi\in\mathscr{U};$$

(iv) for each $t\in\mathbb{R}^+$, $\psi\in\mathscr{U}$, $M(t,\cdot)\psi$ is an $\mathscr{H}$-valued measure.

Example 1 (classical martingale measures): The concept of an L^2-martingale measure that is used in probability theory is essentially a special case of the above, wherein we take $\mathscr{H}=L^2(\Omega,\mathscr{F},P)$ for some probability space equipped with a filtration $(\mathscr{F}_t,\ t\in\mathbb{R}^+)$, each $\mathscr{H}_t$ to be $L^2(\Omega,\mathscr{F}_t,P)$, ϕ to be the constant function 1, $\mathscr{U}=\{f\phi,f\in L^\infty(\Omega,\mathscr{F},P)\}$ and Π_t to be the usual conditional expectation (see, e.g., Refs. 16 and 1).

Example 2 (W-martingale measures):* Let $\mathscr{A}$ be a von Neumann algebra acting in $\mathscr{H}$ and ϕ be a cyclic and separating vector for $\mathscr{A}$. Suppose that $(\mathscr{A}_t,\ t\in\mathbb{R}^+)$ is a filtration of $\mathscr{A}$ and that there exists a family of ω-compatible conditional expectations $(E_t,\ t\in\mathbb{R}^+)$, where each $E_t:\mathscr{A}\to\mathscr{A}_t$ and ω is the vector state determined by ϕ. In this case we may take $\mathscr{H}_t$ to be the completion of $\mathscr{A}_t\phi$, $\mathscr{U}=\mathscr{A}\phi$ and define each Π_t by $\Pi_t(x\phi)=E_t(x)\phi$ for $t\in\mathbb{R}^+$, $x\in\mathscr{A}$. Now, if $M(t,E)$ is a family of operators in $\mathscr{A}$ such that $M(\cdot,E)$ is an $\mathscr{A}$-valued martingale (see, e.g., Ref. 17) for each $E\in\mathscr{F}$, then for each $x\in\mathscr{A}$, $M(t,E)x\phi$ will be a quantum martingale measure whenever $M(t,\cdot)x\phi$ is an $\mathscr{H}$-valued measure.

Many of the concepts of classical martingale measures such as orthogonality and nuclear covariance can be extended to the present context, but we will not need to develop this here. We will require just one further definition.

A quantum martingale measure will be said to be *dominated* by a family of σ-finite measures $\{\mu_\psi,\ \psi\in\mathscr{U}\}$ on $(S,\mathscr{F})$ if there exists a measurable function h on $\mathbb{R}^+$ such that

$$\|M_t(A)\psi\|^2\leqslant h(t)\mu_\psi(A),\tag{2.1}$$

for all $t\in\mathbb{R}^+$, $A\in\mathscr{F}$, $\psi\in\mathscr{U}$.

We will now give some examples of martingale measures in quantum stochastic calculus. To this end, we will, from now on, take $\mathscr{H}$ to be the symmetric Fock space $\Gamma(L^2(\mathbb{R}^+,K))$, where K is a complex separable Hilbert space, which we will identify, when convenient with $\Gamma(L^2(\mathbb{R}^+)\otimes K)$. Fix a dense linear manifold $\mathscr{D}$ in K and let $\mathscr{M}$ denote the dense linear manifold in $L^2(\mathbb{R}^+,K)$ of locally bounded functions, taking values in $\mathscr{D}$. We denote by $\mathscr{E}$ the linear span of the exponential vectors $\{e(f),\ f\in\mathscr{M}\}$ that is dense in $\mathscr{H}$. We will find it convenient to denote the vacuum vector $e(0)$ as e_0. Given $f\in L^2(\mathbb{R}^+,K)$, the map that sends $e(f)$ to $e(f\chi_{[0,t)})$

$\otimes e(f\chi_{[t,\infty)})$ extends to a canonical isomorphism between $\mathscr{H}$ and $\Gamma(L^2([0,t),K))\otimes\Gamma(L^2([t,\infty),K))$ which we use to identify these two spaces. We denote as e_{0t} and e_0^t the vacuum vectors in $\Gamma(L^2([0,t),K))$ and $\Gamma(L^2([t,\infty),K))$, respectively.

Now for each $f\in L^2(\mathbb{R}^+,K)$ let $a(f)$ and $a^\dagger(f)$ denote the annihilation and creation operators (respectively) in $\mathscr{H}$ and for T a bounded self-adjoint operator in $L^2(\mathbb{R}^+,K)$, let $\lambda(T)$ be the conservation operator in $\mathscr{H}$. We note that $a(f)$ and $a^\dagger(f)$ are densely defined and mutually adjoint on $\mathscr{E}$ and that $\lambda(T)$ is essentially self-adjoint therein. Finally, if T is a contraction on $L^2(\mathbb{R}^+,K)$, then $\Gamma(T)$ denotes its second quantization in $\mathscr{H}$, which is also a contraction. In particular, the functorial properties of Γ ensure that it maps projections in $L^2(\mathbb{R}^+,K)$ to projections in $\mathscr{H}$. Precise definitions and further developments of the concepts described above can be found in Ref. 11, pp. 123–52.

We now give some examples of quantum martingale measures in the following context:

$$\mathscr{H}_t=\Gamma(L^2([0,t),K))\otimes\mathbb{C}e_0^t,$$

$$\Pi_t=\Gamma(\chi_{[0,t)}),\quad \mathscr{U}=\mathscr{E},\quad \phi=e_0.$$

In the sequel, we will also find it useful to denote $\mathscr{M}_t=\mathscr{M}\cap L^2([0,t),K)$.

Now, with $(S,\mathscr{F})$ arbitrary, let P be a projection-valued measure defined on $\mathscr{F}$ and taking values in K. For each $t\in\mathbb{R}^+$, $E\in\mathscr{F}$, define

$$\begin{aligned}A(t,E)&=a(\chi_{[0,t)}\otimes P(E)u),\\ \Lambda(t,E)&=\lambda(\chi_{[0,t)}\otimes P(E)),\\ A^\dagger(t,E)&=a^\dagger(\chi_{[0,t)}\otimes P(E)u),\end{aligned}\tag{2.2}$$

where u is a fixed unit vector in $\mathscr{D}$.

Let $c_j\in\mathbb{C}$ for $j=1,2,3$ and define

$$M(t,E)=c_1A(t,E)+c_2\Lambda(t,E)+c_3A^\dagger(t,E).\tag{2.3}$$

Proposition 2.1: M is a quantum martingale measure.

Proof: Adaptedness and the martingale property is a straightforward exercise in Fock space manipulation. We will obtain countable additivity from a more general result, which we will prove in the next section. □

We now write $\psi=f\otimes k$, where f is a locally bounded function on $\mathbb{R}^+$ and $k\in\mathscr{D}$. A straightforward but tedious computation with the extended CCRs shows that M is dominated by the measure μ_ψ with $h(t)=t(1+\sup_{0\leqslant s\leqslant t}|f(s)|^2)$, where

$$\mu_\psi(E)=(|c_1|^2+|c_2|^2+|c_3|^2)(1+\|\psi\|^2)(\|P(E)k\|^2+\|P(E)u\|^2).$$

Examples 1 (Gaussian white noise): Let $c_2=0$ and $c_3=\overline{c_1}$ in (2.1) with $|c_1|=1$; then it is well known that each $M(t,E)$ is Gaussian distributed in the vacuum state, i.e., the characteristic function (where $x\in\mathbb{R}$) is

$$\langle e_0,\exp(ixM(t,E))e_0\rangle=\exp\{-\tfrac{1}{2}tx^2\|P(E)u\|^2\}.$$

If we take S to be $[0,a]$ equipped with its Borel σ algebra $\mathscr{B}([0,a])$, $K=L^2([0,a])$, each $P(E)=\chi_E$ and $u=a^{-1/2}$ for $a>0$ then the process $M_{t,u}=M(t,[0,u))$ is a Brownian sheet on $\mathbb{R}^+\times[0,a]$.

Example 2 (Poisson random measures): Let $c_j=1$ $(j=1,2,3)$; then $M(t,E)$ is a realization in $\mathscr{H}$ of a compensated Poisson random measure on $\mathbb{R}^+\times\mathscr{F}$ with intensity measure ν given by $\nu(E)=\|P(E)u\|^2$.

In particular, if we define $Y(t,E)=M(t,E)+t\nu(E)$, then for all $x\in\mathbb{R}$,

$$\langle e(0),\exp(ixY(t,E))e(0)\rangle=\exp\{t\nu(E)(e^{ix}-1)\}.$$

If we take S to be of the form $[0,a]\times\mathscr{S}$, $\mathscr{T}=\mathscr{B}([0,a])\times\mathscr{G}$, $K=L^2([0,a],\mathfrak{h})$ where $\mathfrak{h}$ is a complex separable Hilbert space and $P(E\times F)=\chi_E\otimes Q(F)$, where Q is a projection-valued measure on $\mathscr{G}$ taking values in $\mathfrak{h}$; then for $0\leqslant u\leqslant a$, $F\in\mathscr{G}$ if we define

$$Y_{t,u}(F)=Y(t,[0,u)xF),$$

then we have a space–time Poisson random measure on $\mathbb{R}^+\times[0,a]\times\mathscr{T}$ for which M is the compensating martingale measure (Ref. 6).

III. QUANTUM SPECTRAL STOCHASTIC INTEGRALS (Refs. 13,14,18,19)

In this section, we will assume familiarity with the theory of quantum stochastic integration developed in Ref. 12 (see also Ref. 11), and we begin by briefly reviewing how this theory was extended in Ref. 13 to include an additional integration with respect to a projection-valued measure. The aim is to make sense of integrals of the form

$$\int_a^b\int_0^t (F_1(s,x)A^\dagger(ds,dx)+F_2(s,x)\Lambda(ds,dx)+F_3(s,x)A(ds,dx)), \tag{3.1}$$

as linear operators on the domain $\mathscr{E}$, where $A^\dagger$, Λ, and A are the processes (2.2) and F_j $(j=1,2,3)$ are *admissible families* in that they satisfy the following.

A(i) For each $x\in[a,b]$, $(F_j(t,x),t\in\mathbb{R}^+)$ is adapted and stochastically integrable in the sense of Ref. 11 (p. 189).

A(ii) For each $t\in\mathbb{R}^+$, $\psi\in\mathscr{M}$, and given $\epsilon>0$, there exists $\delta>0$, such that whenever $a<x,y<b$ with $|x-y|<\delta$, then

$$\sup_{0\leqslant s\leqslant t}\|(F_j(s,x)-F_j(s,y))e(\psi)\|<\epsilon.$$

Note: (i) Condition (ii) is considerably weakened in Ref. 19.

(ii) In the next section, we will encounter a situation where A(i) and A(ii) do not hold on the whole of $\mathbb{R}^+$.

In the sequel, we will find it useful to introduce the notation

$$\alpha(t,\psi;F_1,F_2,F_3)=\max_{1\leqslant j\leqslant 3}\sup_{a\leqslant x\leqslant b}\sup_{0\leqslant s\leqslant t}\{\|F_j(s,x)e(\psi)\|^2\},$$

and note that the admissibility conditions ensure that this expression is finite.

The procedure of Ref. 13 is to define a sequence $\mathscr{P}_n=\{a=x_0^n<x_1^n<\cdots<x_{m(n)+1}^n=b\}$ of partitions of $[a,b]$, such that $\lim_{n\to\infty}|\mathscr{P}_n|=0$ and define the operators (3.1), which we denote as $(M(t),t\in\mathbb{R}^+)$ on $\mathscr{E}$ by $M(t)e(\psi)=\lim_{n\to\infty}M_n(t)e(\psi)$ for each $t\in\mathbb{R}^+$, where

$$M_n(t)=\sum_{r=0}^{m(n)}\int_0^t (F_1(s,y_r^n)A^\dagger(ds,(x_r^n,x_{r+1}^n))+F_2(s,y_r^n)\Lambda(ds,(x_r^n,x_{r+1}^n))$$
$$+F_3(s,y_r^n)A(ds,(x_r^n,x_{r+1}^n))),$$

and each $x_r^n<y_r^n<x_{r+1}^n$.

$(M(t),t\in\mathbb{R}^+)$ is itself an adapted process and each of the maps $t\to M(t)e(\psi)$ is continuous from $\mathbb{R}^+$ to $\mathscr{H}$.

The extension of these results to the case $a\to-\infty$, $b\to\infty$ can be found in the papers quoted at the section head, but we will not require this herein.

In the sequel, we will need the following two results from Ref. 13, Theorem (3.4)—[note that here and in the sequel, $(\cdot,\cdot)$ denotes the inner product in K and $\langle\cdot,\cdot\rangle$ is that in $\mathscr{H}$].

For any ψ_1, ψ_2, $\psi\in\mathscr{M}$, $t\in\mathbb{R}^+$,

$$\langle e(\psi_1), M(t)e(\psi_2)\rangle$$
$$= \int_0^t \int_a^b \langle e(\Psi_1), [(\psi_1(s), P(dx)u)F_1(s,x) + (\psi_1(s), P(dx)\psi_2(s))F_2(s,x)$$
$$+ (P(dx)u, \psi_2(s))F_3(s,x)]e(\psi_2)\rangle ds; \tag{3.2}$$

$$\text{(ii)} \quad \|M(t)e(\psi)\|^2 \leqslant \int_0^t \int_a^b e^{t-s}\left(\sum_{j=1}^3 \|F_j(s,x)e(\psi)\|^2\right)\rho_{s,\psi}(dx)ds, \tag{3.3}$$

where, for each $0 \leqslant s \leqslant t$, $G \in \mathscr{B}([a,b])$,

$$\rho_{s,\psi}(G) = K(\psi,t)(\|P(G)u\|^2 + \|P(G)f(s)\|^2), \tag{3.4}$$

with each $K(\psi,\cdot)$ being locally bounded.

Now let $E \in \mathscr{B}([a,b])$ and let P_E denote the projection-valued measure defined on $\mathscr{B}(E)$ by

$$P_E(A) = P(E \cap A).$$

Note: Of course, $P_E(E) \neq I$, but this causes us no difficulty. Now replace P by P_E in (2.2) and (3.1). We denote the corresponding noise processes as A_E, Λ_E, and $A_E^\dagger$, and the corresponding quantum stochastic spectral integrals as

$$M(t,E) = \int_E \int_0^t (F_1(s,x)A^\dagger(ds,dx) + F_2(s,x)\Lambda(ds,dx) + F_3(s,x)A(ds,dx))$$
$$= \int_a^b \int_0^t (F_1(s,x)A_E^\dagger(ds,dx) + F_2(s,x)\Lambda_E(ds,dx) + F_3(s,x)A_E(ds,dx)). \tag{3.5}$$

From now on we will take S to be $[a,b]$ and $\mathscr{T}$ to be $\mathscr{B}([a,b])$.

Theorem 3.1: M is a quantum martingale measure.

Proof: The martingale property is a standard exercise in quantum stochastic calculus that we outline for completeness. Let $s<t$ and let $\psi_{1,s}$, $\psi_{2,s} \in \mathscr{M}_s$; then, by adaptedness,

$$\langle e(\psi_{1,s}) \otimes e_0^s, M(t,E)e(\psi_{2,s}) \otimes e_0^s\rangle$$
$$= \langle e(\psi_{1,s}), M(s,E)e(\psi_{2,s})\rangle\rangle + \langle e(\psi_{1,s}), e(\psi_{2,s})\rangle\langle e_0^s, (M(t,E) - M(s,E))e_0^s\rangle$$
$$= \langle e(\psi_{1,s}), M(s,E)e(\psi_{2,s})\rangle \text{ by (3.2).}$$

Hence, for arbitrary ψ_1, $\psi_2 \in \mathscr{M}$, we have

$$\langle e(\psi_1), \Pi_s M(t,E)\Pi_s e(\psi_2)\rangle = \langle e(\psi_1), M(s,E)e(\psi_2)\rangle,$$

and the result follows from the totality in $\mathscr{H}$ of the exponential vectors.

To show that M is a martingale measure, we again write $\psi = f \otimes k$ as in Sec. II and let $(E_n, n \in \mathbb{N})$ be a disjoint partition of $[a,b]$.

Our first step is to show that $\Sigma_{n=1}^\infty M(t,E_n)$ exists on $\mathscr{E}$.

By (3.5), (3.2), and the finite additivity of $A^\dagger$, Λ, and A, it is not difficult to verify that

$$M_n(t) = \sum_{j=1}^n M(t,E_j) = M\left(t, \bigcup_{j=1}^n E_j\right), \quad \text{on } \mathscr{E}.$$

Now, by (3.3), we have

$$\|(M_n(t)-M_m(t))e(\psi)\|^2 \leqslant e^t \alpha(t,\psi;F_1,F_2,F_3) \sup_{o\leqslant s\leqslant t}[K(\psi,s)(1+|f(s)|^2)]$$

$$\times \sum_{j=m+1}^{n} (\|P(E_j)u\|^2+\|P(E_j)k\|^2)\to 0, \quad \text{as } n,m\to\infty.$$

So the sequence $(M_n(t)e(\psi), n\in\mathbb{N})$ is uniformly Cauchy and hence uniformly convergent on each $[0,t)$.

To verify countable additivity, it follows from (3.2) that

$$\left\langle e(\psi_1)\left(\sum_{n=1}^{\infty} M(t,E_n)-M(t,\bigcup_{n=1}^{\infty} E_n)\right)e(\psi_2)\right\rangle = 0,$$

and the result follows. □

Note: (i) The countable additivity result in Proposition 2.1 is obtained by taking each $F_j(x,t)=c_j$ in the above.

(ii) From (3.3), it is easily seen that on taking $\psi=f\otimes k$, M is dominated with $h(t)=e^t t(1+\sup_{0\leqslant s\leqslant t}|f(s)|^2)K(\psi,t)\alpha(t,\psi;F_1,F_2,F_3)$ and

$$\mu_\psi(E)=3(\|P(E)u\|^2+\|P(E)k\|^2).$$

The following notation will be useful in the sequel. Let $(V(t,x),\ t\in\mathbb{R}^+,\ x\in[a,b])$ be a family of densely defined linear operators in $\mathscr{H}$, such that (i) each Dom $V(t,x)\subseteq$Ran $F_j(t,x)$ $(j=1,2,3)$; (ii) the families $(V(t,x)F_j(t,x),\ t\in\mathbb{R}^+,\ x\in[a,b])$ satisfy the admissibility conditions.

We can then make the definition

$$\int_a^b\int_0^t V(s,x)M(ds,dx)=\int_a^b\int_0^t (V(s,x)F_1(s,x)A^\dagger(ds,dx)+V(s,x)F_2(s,x)\Lambda(ds,dx)$$
$$+V(s,x)F_3(s,x)A(ds,dx)). \tag{3.6}$$

We need a final technical result. Suppose that V satisfies all the conditions quoted above for $0\leqslant s<t$ but is undefined at $s=t$. We may still want to make sense of (3.6). We proceed as follows. Define for all $t\in\mathbb{R}^+$ the sequence of linear operators $(I_n(t),n\in\mathbb{N})$ on the domain $\mathscr{E}$ by

$$I_n(t)=\int_a^b\int_0^{t-1/n} V(s,x)M(ds,dx).$$

Lemma 3.2: $(I_n(t)e(\psi),n\in\mathbb{N})$ converges in $\mathscr{H}$ for each $t\in\mathbb{R}^+$.

Proof: The fact that the sequence is Cauchy is a consequence of the estimate (3.3) and the result follows immediately. □

We may now define, for each $\psi\in\mathscr{M}$,

$$\int_a^b\int_0^t V(s,x)M(ds,dx)e(\psi)=\lim_{n\to\infty} I_n(t)e(\psi). \tag{3.7}$$

IV. QUANTUM STOCHASTIC PARTIAL DIFFERENTIAL EQUATIONS

In the sequel we will, for $a>0$, take $S=[0,a]$ and $\mathscr{T}=\mathscr{B}([0,a])$. We will also take $K=L^2([0,a])$, $\mathscr{D}$ to be the locally bounded functions on $[0,a]$, and for each $E\in\mathscr{T}$, $P(E)=\chi_E$. We will also fix M to be the martingale measure defined by (3.5), which we call a *Fock space–time noise* on $\mathbb{R}^+\times[0,a]$ controlled by F_1, F_2, and F_3. We will also take each F_j to be such that each $F_j(t,x)$ leaves the domain $\mathscr{E}$ invariant.

From now on we will always take $\psi=f\otimes k$, and from (3.3) we obtain, for each $E\in\mathscr{T}$, $t\in\mathbb{R}^+$,

$$\rho_{t,\psi}(E)\leqslant\tau_{t,\psi}(E),$$

where

$$\tau_{s,\psi}(E)=K(\psi,t)(1+\sup_{0\leqslant s\leqslant t}|f(s)|^2)\left(\int_E(|u(x)|^2+|k(x)|^2)\right)dx. \tag{4.1}$$

In the future, we will find it more useful to employ the estimate (3.3) with the measure τ replacing ρ. We will denote the Radon–Nikodym derivatives $d\tau_{t,\psi}/dx$ as $g_{t,\psi}$ and note that our assumptions imply that $g_{t,\psi}$ is locally bounded.

Our goal in this and subsequent sections is to study the *quantum cable equation*, given formally as

$$\frac{\partial U}{\partial t}=\frac{\partial^2 U}{\partial x^2}-U+U\dot{M}, \tag{4.2}$$

whose solution $U=(U(t,x),t\in\mathbb{R}^+,x\in[0,a])$ will be a family of linear operators in $\mathscr{H}$ with each $\mathrm{Dom}(U(t,x))\supseteq\mathscr{E}$. We impose the following reflecting boundary conditions where $u_0\in L^2([0,a])$:

$$\begin{gathered}\frac{\partial U}{\partial t}(t,0)=\frac{\partial U}{\partial t}(t,a)=0,\quad \text{for all } t\in\mathbb{R}^+,\\ U(0,x)=u_0(x),\quad \text{for all } x\in[0,a].\end{gathered} \tag{4.3}$$

To make rigorous sense of (4.2), we write it in weak form. To be precise, we say that U is a solution of (4.2) subject to (4.3) if and only if, for each $\phi\in C^\infty([0,a])$ with $\phi'(0)=\phi'(a)=0$, $\psi\in\mathscr{M}$, $t\in\mathbb{R}^+$, we have

$$\begin{aligned}\int_0^a(U(t,x)-u_0(x))\phi(x)e(\psi)dx&=\int_0^t\int_0^a U(s,x)(\phi''(x)-\phi(x))e(\psi)dxds\\&\quad+\int_0^a\int_0^t U(s,x)\phi(x)M(ds,dx)e(\psi),\end{aligned} \tag{4.4}$$

where the first two integrals in (4.4) are Bochner integrals and the last is a quantum spectral stochastic integral of the form (3.6).

Let G: $(0,\infty)\times[0,a]^2\to\mathbb{R}^+$ be the Green's function for the homogeneous equation associated to (4.2) and (4.3). An explicit form for G can be found in Ref. 1, p. 312. We will quote the following properties that we will need below.

(G1) G is continuous in all three variables (but not at $t=0$, where it is undefined),

(G2) $\int_0^a G_s(x,y)G_t(y,z)=G_{s+t}(x,z)$, for all $x,z\in[0,a]$,

(G3) $G_t(x,y)=G_t(y,x)$, for each $t\in\mathbb{R}^+,x,y\in[0,a]$,

(G4) for each $0<r<3$, $\int_0^a G_t^r(x,y)dy\leqslant Ce^{-\mathrm{tr}}t^{(1-r)/2}$,

which is integrable on $(0,\infty)$.

We note that if ϕ is as in (4.4), then $G_t(\phi,y)$ also solves the homogeneous equation, where

$$G_t(\phi,y)=\int_0^a G_t(x,y)\phi(x)dx, \tag{4.5}$$

for $t\in\mathbb{R}^+$, $0\leqslant y\leqslant a$.

Now consider the following integrodifferential equation in $\mathscr{H}$ for $0\leqslant x\leqslant a$, $t\in\mathbb{R}^+$,

$$V(t,x)=\int_0^a u_0(y)G_t(x,y)dx+\int_0^a\int_0^t V(s,y)G_{t-s}(x,y)M(ds,dy), \tag{4.6}$$

whose solution (if it exists) will be a family $V=(V(t,x),t\in\mathbb{R}^+,0\leqslant x\leqslant a)$ of linear operators on $\mathscr{H}$ with each $\mathrm{Dom}(V(t,x))\supseteq\mathscr{E}$. We call (4.6) the *auxiliary equation* to (4.4) and we will discuss the existence and uniqueness of solutions in the next section. We close this one by establishing the following key result.

Theorem 4.1: There is a one-to-one correspondence between solutions U to (4.4) and solutions V to (4.6), for which for all $T>0$, $\psi\in\mathscr{M}$, $\sup\{\|V(t,x)e(\psi)\|,\|U(t,x)e(\psi)\|,0\leqslant x\leqslant a,0<t\leqslant T\}<\infty$.

Proof: This is essentially along the same lines as Ref. 1.

First, suppose that U is a solution to (4.3). We extend (4.4) to appropriate functions φ of both x and t as in Ref. 1, p. 313 and then argue as on p. 314 therein. So, for each $0\leqslant y\leqslant a$, $t\in\mathbb{R}^+$, define $\varphi^n_{y,t}(s,x)=G_{t-s}(\phi^n_y,x)$ by (4.5), where $\lim_{n\to\infty}\phi^n_y(x)=\delta(x-y)$ in the sense of distributions.

Now, the extended version of (4.4) becomes, for each $\psi\in\mathscr{M}$, $n\in\mathbb{N}$,

$$\int_0^a U(t,x)\phi^n_y(x)e(\psi)dx=\int_0^a u_0(x)G_t(\phi^n_y,x)e(\psi)dx + \int_0^a\int_0^t U(s,x)G_{t-s}(\phi^n_y,x)M(dx,ds)e(\psi),$$

and if ψ_1, $\psi_2\in\mathscr{M}$ it is not difficult to establish that (in the sense of distributions), and for all $t\in\mathbb{R}^+$, $0\leqslant y\leqslant a$,

$$\lim_{n\to\infty}\left\langle e(\psi_1),\int_0^a U(t,x)\phi^n_y(x)dxe(\psi_2)\right\rangle=\langle e(\psi_1),U(t,y)e(\psi_2)\rangle,$$

and, using (3.2) and (G3),

$$\lim_{n\to\infty}\left\langle e(\psi_1),\int_0^a\int_0^t U(s,x)G_{t-s}(\phi^n_y,x)M(dx,ds)e(\psi_2)\right\rangle =\left\langle e(\psi_1),\int_0^a\int_0^t U(s,y)G_{t-s}(x,y)M(dx,ds)e(\psi_2)\right\rangle,$$

from which the required result follows.

Now, suppose that V is a solution of (4.6). We simply imitate the argument of Ref. 1, p. 317, utilizing (3.2) and Fubini's theorem, where it is required, to show that

$$\left\langle e(\psi_1),\left\{\int_0^a(U(t,x)-u_0(x))\phi(x)dx-\int_0^t\int_0^a U(s,x)(\phi''(x)-\phi(x))dxds - \int_0^a\int_0^t U(s,x)\phi(x)M(ds,dx)\right\}e(\psi_2)\right\rangle=0.$$

V. EXISTENCE, UNIQUENESS, AND PROPERTIES OF SOLUTIONS

In this section, we will make a further simplification on the noise, namely, we will require that each F_j is a jointly continuous complex-valued function on $\mathbb{R}^+\times[0,a]$.

We also introduce the notation

$$\beta(t,\psi,F_1,F_2,F_3)=3e^t\sup_{U\leqslant x\leqslant a}g_{t,\psi}(x)\alpha(t,\psi;F_1,F_2,F_3),$$

for $\psi=f\otimes k$, $t\in\mathbb{R}^+$.

Following Ref. 1, we seek a solution to (4.6) by using Picard iteration, and we have the following.

Theorem 5.1: There exists a sequence $(V_n(t,x),\ 0\leqslant x\leqslant a,\ t>0,\ n\in\mathbb{N}\cup\{0\})$ of linear operators in $\mathscr{H}$ for which

$$V_0(t,x)=\int_0^a u_0(y)G_t(x,y)dy,$$

$$V_n(t,x)=V_0(t,x)+\int_0^a\int_0^t V_{n-1}(s,y)G_{t-s}(x,y)M(ds,dy),$$

which is such that (a) each V_n satisfies the admissibility conditions A(i) and A(ii); (b) each map $s\to V_n(s,x)e(\psi)$ is continuous on $(0,t)$ for $0\leqslant x\leqslant a,\ \psi\in\mathscr{M}$.

Proof: We proceed by induction on n. Clearly V_0 is well defined and by (G1) we deduce that it is continuous on $(0,t)$ and that it satisfies the admissibility condition (ii) on $(0,t)$. Now, suppose that V_{n-1} is well defined, continuous on $(0,t)$, and satisfies the admissibility conditions.

Define for $0<s<t-1/m,\ 0\leqslant x,y\leqslant a,\ 1\leqslant j\leqslant 3$,

$$T^j_{n-1}(x,y,s)=V_{n-1}(s,y)G_{t-s}(x,y)F_j(s,y);$$

then the map $s\to T^j(x,y,s)e(\psi)$ is clearly adapted and is continuous on $(0,t-1/m)$, hence, by proposition 25.7 of Ref. 11 (p. 190), it follows that the admissibility condition (i) is satisfied.

The second admissibility condition (ii) is verified by a straightforward $\varepsilon/2$ argument. Hence, each $V_n(s,x)e(\psi)$ is well defined on each $(0,t-1/m)\times(0,a)$, is clearly continuous in s, and is easily seen via (3.3) to satisfy the admissibility conditions. Each V_n can now be extended to $(0,t]$ by the procedure of (3.7). □

Theorem 5.2: There exists a unique solution to the auxiliary equation (4.6)

Proof (existence)*:* For $n\in\mathbb{N},\ \psi=f\otimes k,\ t\in\mathbb{R}^+$ define

$$S_n(t)=\sup_{0\leqslant x\leqslant a}\|(V_n(t,x)-V_{n-1}(t,x))e(\psi)\|.$$

It is easily deduced from A(ii) that each $S_n(t)<\infty$.

Now, by (3.3) we have

$$S_n(t)^2\leqslant\sup_{0\leqslant x\leqslant a}\int_0^t\int_0^a e^{t-s}\left(\sum_{j=1}^3\|(V_{n-1}(s,y)-V_{n-2}(s,y))G_{t-s}(x,y)F_j(s,y)e(\psi)\|^2\right)\tau_{s,\psi}(dy)ds$$

$$\leqslant\beta(t,\psi,F_1,F_2,F_3)\sup_{0\leqslant x\leqslant a}\int_0^t\int_0^a G_{t-s}(x,y)^2\|(V_{n-1}(s,y)-V_{n-2}(s,y))e(\psi)\|^2dyds.$$

We can now follow the procedure of Ref. 1, pp. 315–316 and use Hölder's inequality to obtain, for a given $p\geqslant 2$, that there exists $c>-1$, $K>0$, such that

$$S_n(t)^p\leqslant K\beta(t,\psi,F_1,F_2,F_3)^{p/2}\int_0^t S_{n-1}(s)^p(t-s)^c ds;$$

thus, by Lemma 3.3 of Ref. 1, for each $T\geqslant 0$, there exists $K_1>0$ and $q\in\mathbb{N}$, such that for all $n,m\in\mathbb{N}$ and $0\leqslant t\leqslant T$,

$$S_{n+mq}(t)^p\leqslant K_1^m\int_0^t S_n(s)^p\,\frac{(t-s)}{(m-1)!}\,ds.$$

Since each S_n is continuous on $[0,t]$, we easily deduce that

$$\sum_{n=0}^{\infty} S_n(t) = \sum_{k=0}^{q-1} \sum_{m=0}^{\infty} S_{k+mq}(t) \quad \text{converges uniformly on } [0,T].$$

Hence, $(V_n(t,x)e(\psi),\ n\in\mathbb{N})$ is uniformly Cauchy and hence uniformly convergent on $[0,a]\times[0,T]$. We define

$$V(t,x)e(\psi) = \lim_{n\to\infty} V_n(t,x)e(\psi).$$

It is easily verified that each $V(t,x)$ is a densely defined linear operator in $\mathscr{H}$ with each Dom $V(t,x)\supseteq\mathscr{E}$.

To see that V satisfies the equation (4.6), we have by (3.3) that

$$\left\| \int_0^a \int_0^t (V(s,y)-V_{n-1}(s,y))G_{t-s}(x,y)M(ds,dy) \right\|^2$$

$$\leqslant \beta(t,\psi,F_1,F_2,F_3) \sup_{0\leqslant s\leqslant t} \sup_{0\leqslant y\leqslant a} \|(V(s,y)-V_{n-1}(s,y))e(\psi)\|^2 \int_0^t \int_0^a G_{t-s}(x,y)^2 dyds,$$

and the right hand tends to zero as $n\to\infty$ by (G4) and the uniformity of the convergence.

(Uniqueness). This is established by an obvious extension of the argument of Ref. 1, pp. 314–315.

We now investigate some of the properties of the solution. It is clear from the construction that V is adapted to the filtration $(\mathscr{H}_t,\ t\in\mathbb{R}^+)$. By Theorem 5.1 and the uniformity of the convergence on compacts, it is easily deduced that the maps $s\to V(s,y)e(\psi)$ and $y\to V(s,y)e(\psi)$ are continuous on each $(0,t)$ and $(0,a)$, respectively, where $\psi\in\mathscr{M}$ is fixed, from which it follows that the map $(s,y)\to V(s,y)e(\psi)$ is jointly continuous on each $[0,t)\times(0,a]$.

By Theorem 4.1, we immediately deduce that V is the unique solution to the quantum cable equation (4.4).

Now, we formulate and prove the Markov property of the solution. Suppose that $X=(X(t,y),t\in\mathbb{R}^+,0\leqslant y\leqslant a)$ is a family of linear operators in $\mathscr{H}$ with each $\mathrm{Dom}(X(t,y))\supseteq\mathscr{E}$ and such that each $X(\cdot,y)$ is an adapted process. For each $t\in\mathbb{R}^+$, define the Hilbert space $\mathscr{H}_{\{t\}}$ to be the closed linear span of $\{X(t,y),\ 0\leqslant y\leqslant a\}$. We say that X satisfies the *Markov property* if for each $\psi\in\mathscr{M},\ 0\leqslant y\leqslant a,\ s>0$,

$$\Pi_t X(t+s,y)\Pi_t e(\psi)\in\mathscr{H}_{\{t\}}.$$

Remark: This clearly gives the classical Markov property in the case where M is a Brownian sheet and $\mathscr{H}$ is realized as Wiener space. It is interesting to compare this concept of Markovianity with the more algebraic notion of Ref. 20 (see also Ref. 21).

Theorem 5.3: V satisfies the Markov property.

Proof: For each ψ_1,ψ_2 we find by (3.2), (G2), and Fubini's theorem that

$$\begin{aligned}\langle e(\psi_1),V(s+t,x)e(\psi_2)\rangle &= \langle e(\psi_1),V_0(s+t,x)e(\psi_2)\rangle \\ &\quad + \left\langle e(\psi_1), \int_0^a \int_0^{t+s} V(u,y)G_{t+s-u}(x,y)M(du,dy)e(\psi_2)\right\rangle \\ &= \int_0^a G_s(x,z)\Bigg\{\langle e(\psi_1),V_0(s,z)e(\psi_2)\rangle \\ &\quad + \left\langle e(\psi_1), \int_0^a \int_0^t V(u,y)G_{t-u}(z,y)M(du,dy)e(\psi_2)\right\rangle\Bigg\}dz \\ &\quad + \left\langle e(\psi_1), \int_0^a \int_t^{t+s} V(u,y)G_{t+s-u}(x,y)M(du,dy)e(\psi_2)\right\rangle.\end{aligned}$$

So we find that

$$V(s+t,x)=\int_0^a G_s(x,z)V(t,z)dz+\int_0^a\int_t^{t+s}V(u,y)G_{t+s-u}(x,y)M(du,dy).$$

Hence, by adaptedness and (3.2), we have, for each $\psi\in\mathscr{M}$ and writing $\psi_t=\psi\chi_{[0,t)}$,

$$\Pi_t V(s+t,x)\Pi_t e(\psi)=\Pi_t\int_0^a G_s(x,z)V(t,z)dz\Pi_t e(\psi)=\int_0^a G_s(x,z)V(t,z)e(\psi_t)dz.$$

Now, since each $G_s(x,z)V(t,z)e(\psi_t)\in\mathscr{H}_{\{t\}}$, it follows that the Bochner integral $\int_0^a G_s(x,z)V(t,z)e(\psi_t)dz\in\mathscr{H}_{\{t\}}$ and the required result follows. □

Now, let V be as above and W be the unique solution of another quantum cable equation (4.4) that is related to U as follows—the initial condition $w(y)=\overline{u(y)}$ and the admissible families G_1, G_2, and G_3 are given as $G_1(t,y)=\overline{F_3(t,y)}$, $G_3(t,y)=F_1(t,y)$ and $G_2(t,y)=F_2(t,y)$ for all $t\in\mathbb{R}^+$. $0\leqslant y\leqslant a$. A standard exercise in quantum stochastic calculus shows that for all $\psi_1,\psi_2\in\mathscr{M}$,

$$\langle e(\psi_1),V(t,y)e(\psi_2)\rangle=\langle W(t,y)e(\psi_1),e(\psi_2)\rangle,$$

from which we deduce that each $V(t,y)$ is closable. If we take each $u(y)=\overline{u(y)}$, $F_3(t,y)=\overline{F_1(t,y)}$ and $F_2(t,y)=\overline{F_2(t,y)}$ we can further deduce that each $V(t,y)$ is symmetric. In a future paper we will investigate the conditions under which the $V(t,y)$'s are essentially self-adjoint.

(Received 2 December 1997; accepted for publication 21 January 1998)

The interaction energy between vortices of the generalized Abelian Higgs vortices is studied numerically. These are the solitons of the p-th member of the hierarchy of Maxwell–Higgs systems, the $p=1$ member of which is the usual Abelian Higgs model. It is found that for all p, these vortices have both attractive and repulsive phases, the strengths of these interactions decreasing successively for increasing p. A detailed comparison of the $p=1,2$ and $p=3$ cases is made quantitatively, and an extended model, composed of the $p=1$ and $p=2$ members, is studied in some detail and shown to exhibit attractive and repulsive phases. © *1998 American Institute of Physics.* [S0022-2488(98)02106-9]

I. INTRODUCTION

The hierarchy of generalized Abelian Higgs models[1] arise by subjecting the p-th member of the Yang–Mills hierarchy,[2] with gauge group (chiral) $SO_{\pm}(4p)$ and on the direct product space $\mathbb{R}_2 \times S^{4p-2}$, to dimensional descent. (Indeed by performing the descent on $\mathbb{R}_d \times S^{4p-d}$, one obtains the hierarchies of non-Abelian Higgs models[3] on $\mathbb{R}_d$.) These yield the hierarchy of $U(1)$ gauged Higgs models on $\mathbb{R}_2$ which differ from the usual Abelian Higgs model[4] in that they are Skyrme-like gauge field systems.[5] In the present paper we restrict ourselves to the case where the $U(1)$ gauge dynamics is given by a Maxwell-like term. A corresponding generalization of the usual Chern–Simons–Higgs model employing instead Chern–Simons dynamics was also given in Ref. 6 which is not considered here. Accordingly we will refer to these models as Maxwell–Higgs (MH) models in the following. As far as numerical computations are concerned, we restrict ourselves to the $p=2$ and $p=3$ members of the hierarchy.

In Ref. 1, the self-dual solutions of the p-th member of the MH hierarchy were found by integrating the corresponding Bogomol'nyi equations numerically. Subsequently an analytic proof for the existence of self-dual solutions to the $p=2$ MH model, as well as the corresponding generalized Chern–Simons–Higgs model,[6] was given in Ref. 7. In all aspects except their Skyrme-like features, the $p \geqslant 2$ MH models are similar to the $p=1$ MH model, namely the usual Abelian Higgs model.[4] One such example is illustrated by the study[8] of the zero modes of the rotationally symmetric vortices of the $p=2$ MH system and their scattering, in which the head on collision of n vortices exhibits the π/n symmetry present in the $p=1$ model.

In the background of the above described status of the $p \geqslant 2$ MH models, it is natural to ask yet another question pertinent to soliton systems supporting self-dual solutions, namely, whether there exist attractive and repulsive phases like in the $p=1$ case, discovered long ago by Jacobs and Rebbi.[9] The physical relevance of this question is evident in all areas of vortex dynamics, and it is the aim of the present work to study this problem quantitatively using similar numerical methods as in Ref. 9. We shall consider the cases $p=1,2$ in detail and their interaction properties will be compared. In addition, the simplest example of an extended model composed of both $p=1$ and $p=2$ subsystems will be considered.

In Section II we introduce the p-th member of the hierarchy and discuss the topological lower bound on the energy. In Section III we write down the spherically symmetric one-dimensional

 © 1998 American Institute of Physics

subsystems and give the asymptotic solutions and proceed with the numerical integration. Explicit integrations are carried out for the $p=1,2,3$ MH models, the first of which is a repetition of the work of Ref. 9. Section IV is concerned with the extended model whose Hamiltonian is the sum of the Hamiltonians of several MH models of distinct p, and in Section V we end up with a summary of our results.

II. THE MODELS

The (static) energy density functional for the arbitrary-p MH model is given by

$$\mathcal{H}^{(p)}=(\eta^2-|\varphi|^2)^{2(p-2)}(\lambda_2[(\eta^2-|\varphi|^2)F_{ij}+i(p-1)D_{[i}\varphi^*D_{j]}\varphi]^2 +4p(2p-1)\lambda_1(\eta^2-|\varphi|^2)^2|D_i\varphi|^2+2(2p-1)^2\lambda_0(\eta^2-|\varphi|^2)^4), \tag{1}$$

in 2 Euclidean dimensions. For $p=1$, (1) reduces to the usual Abelian Higgs model. $\varphi=\phi_1+i\phi_2$ is the complex Higgs field, $D_\mu\phi=\partial_i\varphi+iA_i\varphi$, $i=1,2$, is the covariant derivative, and the gauge fields F_{ij} are defined in terms of the real gauge potentials A_i as $F_{ij}=\partial_{[i}A_{j]}$. The square brackets mean antisymmetrization in the indices. Note that the constant η has the same dimensions as the Higgs field φ.

Before proceeding to the main subject of this paper, namely the study of the interaction energies of the vortices of the system (1), we comment on an interesting general feature of the $p\geqslant 2$ MH models. Setting the connection and curvature fields A_μ and $F_{\mu\nu}$ equal to zero in the usual Abelian Higgs model, or the $p=1$ MH model, the resulting mutilated system on $\mathbb{R}_2$ does not support soliton solutions because the Derrick scaling requirements are not then satisfied. This is in contrast to the corresponding situation for all the other $p\geqslant 2$ members of the MH hierarchy, where the Derrick requirement is no longer violated and solitons exist. This was discussed in detail in the Appendix of Ref. 10 and such solitons were studied in detail numerically in Ref. 11. What relation the solitons of the ungauged systems[10,11] have to the vortices of the MH models[1] will be addressed quantitatively in our discussion of the vortices of the $p=2$ MH model.

The densities (1) differ from those derived by dimensional reduction and employed in Refs. 1, 7, 8 in respect of the appearance of the dimensionless parameters λ_0, λ_1, and λ_2. When $\lambda_0=\lambda_1=\lambda_2=1$, the topological inequalities bounding the density (1) from below can be saturated and the resulting Bogomol'nyi equations can then be solved to yield the self-dual solutions presented and employed in Refs. 1, 7, 8. We will not repeat these arguments here as they are given in detail in Ref. 1, save to say that when any one of the three dimensionless coupling constants $\lambda_a\neq 1$, $a=0,1,2$, it is impossible to saturate this bound and hence the finite energy topologically stable soliton solutions we seek satisfy only the second order Euler–Lagrange equations rather than the first order Bogomol'nyi equations as in Refs. 1, 7, 8.

Concerning the appearance of the dimensionless coupling constants λ_a in (1), we note that some of these can be eliminated. If we divide the energy,

$$E^{(p)}(\lambda_0,\lambda_1,\lambda_2)=\int d^2x\mathcal{H}^{(p)}(\lambda_0,\lambda_1,\lambda_2), \tag{2}$$

by, say, λ_1, and suitably rescale the coordinate x_i, we find the relation

$$E^{(p)}(\lambda_0,\lambda_1\lambda_2)=\lambda_1E^{(p)}\left(\frac{\lambda_0\lambda_2}{\lambda_1^2},1,1\right). \tag{3}$$

Accordingly, we shall set $\lambda_1=\lambda_2=1$ in (1) and will retain only λ_0 without loss of generality. When in Section IV we consider the extended model, we shall return to this scaling argument.

The topological stability of the solutions is guaranteed by the lower bound on the energy E, given by the topological charge which can be calculated as a surface integral and is equal to the winding number coinciding with the vorticity n. With the appropriate normalizations, this reads as

$$E\geqslant n. \tag{4}$$

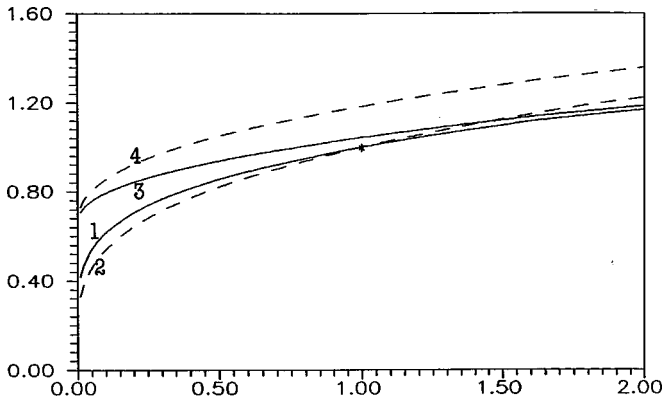

FIG. 1. The energy *per unit charge* of the solution is plotted as a function of λ_0 for the $p=2$ gauged and ungauged models. The curve 1 (resp., 3) refers to the energy of the $n=1$ vortex in the gauged (resp., ungauged) model. The curves 2 and 4 refer to the same data for the $n=2$ vortex. The star represents the self-dual point.

The detailed topological charge densities for $p=1$, 2, and 3 are given explicitly in Ref. 1 by equations (1.4), (2.7a), and (2.7b), respectively, which we do not repeat here. When $\lambda_0=1$ the inequality (4) is saturated.[4,1] It is clear that when $\lambda_0 \geqslant 1$, the topological inequality (4) remains valid. When $0 \leqslant \lambda_0 \leqslant 1$, it can be shown using the argument in Ref. 9 given for the $p=1$ case, that this inequality is altered to read as

$$E \geqslant \lambda_0 n. \tag{5}$$

In Ref. 9 the quantity $\mathcal{E}(n,\lambda_0)=E/n$ was plotted as a function of λ_0 for the solutions to the $p=1$ MH system (1). We shall refer to such graphs as Jacobs–Rebbi plots. At $\lambda_0=1$ all these curves coincide at $\mathcal{E}(n,\lambda_0)=1$ since this point corresponds to all the self-dual solutions for which $E=n$. The stress tensors of all these solutions vanish and the corresponding solitons are therefore noninteracting. It was found[9] that for $\lambda_0>1$ the $n=1$ curve lay below the $n=2$ curve implying repulsion, while for $\lambda_0<1$ the $n=2$ curve lay below the $n=1$ curve implying attraction. We have reproduced this result by repeating the work of Ref. 9 and do not present the graphs of the Jacobs–Rebbi plot here because they are qualitatively the same as those to be given below for the $p=2$ MH model, in Figure 1. We expect to find that this situation holds qualitatively for MH models of arbitrary p, and we have verified it quantitatively for the $p=2$ and $p=3$ cases.

III. RADIAL SYMMETRY

A. The equations

To convert the Euler–Lagrange equations of the system (1) to ordinary differential equations which can readily be integrated numerically, we proceed to subject the system (1) to the radially symmetric Ansatz,

$$\varphi = \eta g(r) e^{-in\theta}, \tag{6}$$

$$A_i = \frac{a(r)-n}{r^2}\varepsilon_{ij}x_j. \tag{7}$$

The resulting reduced one-dimensional energy density functional $H[a(r),g(r)]$ defined by

$$\int H^{(p)}[a(r),g(r)]dr = \frac{1}{2\pi}\int \mathcal{H}^{(p)}d^2x, \tag{8}$$

is then

$$H^{(p)}=\frac{\lambda_2}{r}([(1-g^2)^{p-1}a]')^2+2p(2p-1)\lambda_1\eta^2(1-g^2)^{2(p-1)}$$
$$\times\left[rg'^2+\frac{a^2g^2}{r}\right]+(2p-1)^2\lambda_0\eta^4r(1-g^2)^{2p}, \tag{9}$$

where we have used the notation $g'=dg/dr$; from now on we set $\lambda_1=\lambda_2=1$ in this section.

As a check it is interesting to verify that adding the inequality

$$r(1-g^2)^{2(p-2)}\left(\frac{1}{r}[(1-g^2)a'-2(p-1)agg']+(2p-1)\eta^2(1-g^2)^2\right)^2\geqslant 0, \tag{10}$$

to $2p$ times the inequality

$$\eta^2r(1-g^2)^{2(p-1)}\left(g'-\frac{ag}{r}\right)^2\geqslant 0, \tag{11}$$

yields the functional $H^{(p)}[a,g]$ in (9), plus the total derivative term

$$\sigma_p \overset{def.}{=} 2(2p-1)\eta^2\frac{d}{dr}[(1-g^2)^{2p-1}a], \tag{12}$$

which with a suitable normalization is the topological charge density. The integral of (12) then equals $2(2p-1)\eta^2$ times the vortex number $|n|$ provided that the solution has the following asymptotic values:

$$\lim_{r\to 0}g(r)=0, \quad \lim_{r\to\infty}g(r)=1, \tag{13}$$

$$\lim_{r\to 0}a(r)=n, \quad \lim_{r\to\infty}a(r)=0. \tag{14}$$

We note moreover that the conditions (13)–(14) are consistent with the finiteness of the energy, by inspection of (9).

Anticipating the subsequent numerical integrations, we introduce the function

$$b(r)=(1-g(r)^2)^{p-1}a(r), \tag{15}$$

which is more convenient to employ in the numerical integrations than the function $a(r)$. The Euler–Lagrange equations arising from the variation of $H^{(2)}$ with respect to the arbitrary variations of the function $a(r)$ and of $b(r)$ are identical, so the transformation given by (15) is legitimate. In terms of the dimensionless radial variable $\rho=\eta r$, the Euler–Lagrange equations of (9) with respect to the variations with $g(\rho)$ and $b(\rho)$ are, respectively,

$$[\rho(1-g^2)^{2(p-1)}g_\rho]_\rho+2(p-1)\rho(1-g^2)^{2p-3}g_\rho^2g+(2p-1)\lambda_0\rho(1-g^2)^3g-\frac{1}{\rho}b^2g=0, \tag{16}$$

$$\rho\left[\frac{b_\rho}{\rho}\right]_\rho-2p(2p-1)g^2b=0, \tag{17}$$

where we have used the notation $g_\rho=dg/d\rho$.

The asymptotic solutions in the $r\gg 1$ region can easily be found by linearizing (16) and (17) with the results

$$g(\rho)=1-[K_0(\sqrt{2p(2p-1)\lambda_0}\rho)]^{1/p}, \tag{18}$$

$$b(\rho)=\rho K_1(\sqrt{2p(2p-1)}\rho), \tag{19}$$

in terms of the Bessel functions K_0 and K_1, consistent with the decays of the selfdual solutions in Ref. 1, namely exponential decays. In the $r \ll 1$ region it can be verified that the asymptotic solutions are

$$g(\rho) = A\rho^n + o(\rho^{n+2}), \tag{20}$$

$$a(\rho) = n - B\rho^2 + o(\rho^4), \tag{21}$$

which are consistent with the requirements of analyticity of the fields (6) and (7) at the origin. The constants A and B are determined by the numerical inegration. Note here that except for the $\lambda_0 = \lambda_1 = \lambda_2 = 1$ case when the equations (16)–(17) are solved by the Bogomol'nyi equations arising from the saturation of the inequalities (10)–(11), A and B are independent, while in the self-dual case they are related as given in equations (3.6a)–(3.6b) of Ref. 1.

B. Numerical results

We have integrated numerically the equations of motion (16) and (17) for $p = 1,2,3$ and for vorticities $n = 1,2,3$. The most relevant quantity, for our purpose, is the energy $E(n,\lambda_0)$ per unit charge,

$$\mathcal{E}(n,\lambda_0) = \frac{E(n,\lambda_0)}{n},$$

which we have computed as a function of λ_0 for each type of solution.

The case $p = 1$ was treated in detail by Jacobs and Rebbi;[9] we therefore refrain from presenting it in detail here but in due course we will compare the results obtained for $p > 1$ with their results.

Let us first discuss our results for the $p = 2$ model. The solutions of vorticity $n = 1$ and $n = 2$ exhibit the same property as for the case $p = 1$, namely a repulsion of the two-soliton for $\lambda_0 > 1$ and an attraction for $\lambda_0 < 1$. This behavior is illustrated on Fig. 1 by the curves labelled 1 ($n = 1$) and 2 ($n = 2$). We shall refer to such plots as Jacobs–Rebbi plots in the rest of this paper.

Plots of the profiles of the functions $g(\rho)$ and $b(\rho)$ [or $a(\rho)$] are not presented since they are qualitatively the same as the corresponding curves for the self-dual solutions, exhibited, for example, in Ref. 1.

One of the remarkable features of the $p > 1$ models is that soliton solutions exist also in their ungauged version[10,11] (for $p = 1$ the ungauged model does not support a soliton because Derrick's scaling argument is violated). In Fig. 1 we have superposed the energy of the solitons of the ungauged $p = 2$ model; the curves labelled 3 (resp., 4) representing the energy of the soliton of vorticity 1 (resp., 2). It is seen on the figure that curves 1 and 2 are, respectively, lower than curves 3 and 4. Completing the analysis of Ref. 11 this result provides a nice check of our numerics because it is expected on general grounds, namely that introducing a new set of fields to a system results in a new landscape of energy contours, where the new minima arising because of the new coordinates can only be lower than the old ones.

On the same figure, we also observe that the curves 1,3 (and independently 2,4) approach each other while the parameter λ_0 increases; moreover, the profiles of the function $g(r)$ for a gauged and an ungauged soliton hardly differ in this region. This incited us to analyze the Maxwell field of the gauged solitons. In addition to this, the way in which the Maxwell term enters the $p \geqslant 2$ systems leads to a different dependence of the electromagnetic field energy,

$$E_{e.m.} = \int d^3x F_{ij}^2 \sim \int \frac{a'^2}{r} dr,$$

on the Higgs self-interaction coupling constant λ_0, from that for the $p = 1$ system. The graphs of $E_{e.m.}$ given in Figure 2 show that this quantity increases with λ_0 for the $p = 1$ system and decreases for the $p = 2$ system, which is typical for all $p \geqslant 2$ systems.

The attraction-repulsion phenomenon discovered by Jacobs and Rebbi in the $p = 1$ model is also present in the $p = 3$ model and the energy plot of the $n = 1$ and $n = 2$ solution display the same

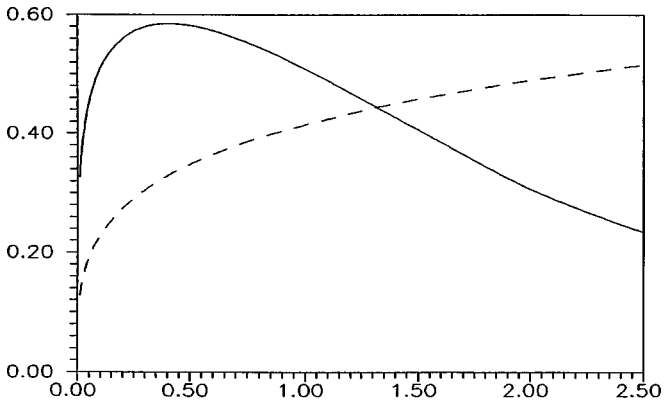

FIG. 2. The energy of the Maxwell field of the $n=1$ vortex as a function of λ_0. The solid (resp., dashed) curve refers to the vortex of the $p=2$ (resp., $p=1$) model.

pattern as in Fig. 1. Because the differences between the magnitudes of the interaction energies for the $p=1,2,3$ models, are not sufficiently large, we have calculated the quantities

$$\Delta E(p,\lambda_0)=\mathcal{E}^{(p)}(2,\lambda_0)-\mathcal{E}^{(p)}(1,\lambda_0), \tag{22}$$

as functions of λ_0. Thus for $\Delta E(p,\lambda_0)>0$ there is repulsion and for $\Delta E(p,\lambda_0)<0$ there is attraction, and the magnitudes of these quantities represent the strengths of the interactions. To illustrate the fact that these interaction energies decrease in magnitude progressively for the higher p MH models, we have listed the values of the three interaction energies $\Delta E(1,\lambda_0)$, $\Delta E(2,\lambda_0)$, and $\Delta E(3,\lambda_0)$ for a small range of λ_0 in Table I.

It is our guess that the attraction-repulsion phenomenon persists for higher p models. Table I manifestly suggests that interaction energies of the higher p MH vortices are of progressively smaller magnitudes. This question arises naturally in the background of our knowledge, from the work of Ref. 1, that the solutions of the higher p models are progressively more tightly localized, i.e., they decay faster at large distances. More generally, this may be of physical interest in quantitative questions arising in the physics of vortices.

IV. EXTENDED MODELS

With the hierarchy of models (1) we can manufacture a family of extended models by considering the linear combination

$$\mathcal{H}=\sum_{p=1}^{N}\eta^{-4(p-1)}\hat{\mathcal{H}}^{(p)}(\lambda^{(p)}), \tag{23}$$

with

$$\lambda^{(p)}\equiv(\lambda_0^{(p)},\lambda_1^{(p)},\lambda_2^{(p)}).$$

TABLE I. Comparison of the quantity (22) for some values of λ_0 and for $p=1,2,3$.

λ_0	$\Delta E(1,\lambda_0)$	$\Delta E(2,\lambda_0)$	$\Delta E(3,\lambda_0)$
0.8000	−0.0134	−0.0126	−0.0123
0.9000	−0.0065	−0.0061	−0.0059
1.0000	0.0000	0.0000	0.0000
1.1000	0.0062	0.0059	0.0057
1.2000	0.0122	0.0115	0.0112

The densitites $\hat{\mathcal{H}}^{(p)}$ are normalized versions of the members (1) of the MH hierarchy:

$$\hat{\mathcal{H}}^{(p)}(\lambda^{(p)})=\frac{1}{2(2p-1)N}\mathcal{H}^{(p)}(\lambda^{(p)}). \tag{24}$$

The normalization, which follows from (12), is made such that the energy of the winding number n vortex should be normalized to n, i.e., if the solution did saturate the topological lower bound, then the energy would equal the topological charge.

The reason for considering systems like (23) is that it may be desirable to have a propagating photon in the theory and hence it would be necessary to include the $p=1$ MH model, which is the only MH system featuring the usual Maxwell term F_{ij}^2 without field dependent coefficients. This may be a particularly relevant requirement in applications to Cosmic Strings.[12]

The mixing parameters giving the relative strengths of each of the component subsystems are absorbed in the coupling constants. Applying the scaling argument leading to the relation (3) to the energy integral pertaining to (23), we can set, as before, $\lambda_1^{(1)}=\lambda_2^{(1)}=1$. This leads to the natural normalization of the kinetic terms and leaves a number of $3N-2$ independent dimensionless coupling constants.

There is one important respect in which the systems (23) differ from the hierarchy of MH systems (1). This is, the absence of solutions which saturate the corresponding topological lower bounds. We illustrate this explicitly in the special case $N=2$ [i.e., the simplest of systems (23)] that we conveniently parametrize as follows:

$$\mathcal{H}=\tfrac{1}{4}\mathcal{H}^{(1)}(\lambda_0,1,1)+\tfrac{1}{12}\eta^{-4}\mathcal{H}^{(2)}(\mu_0,\mu_1,\mu_2). \tag{25}$$

In principle the lower bound on the energy density functional can be saturated when $\lambda_0=1$ and $\mu_0=\mu_1=\mu_2=1$. This absolute minimum will be acheived if all four topological inequalities (10)–(11), namely both for $p=1$ and for $p=2$ are simultaneously saturated. As a result of this we have the following three Bogomol'nyi equations to satisfy:

$$\frac{dg}{dr}=\frac{ag}{r}, \tag{26}$$

$$\frac{da}{dr}=-\eta^2 r(1-g^2), \tag{27}$$

$$(1-g^2)\frac{da}{dr}=-3\eta^2 r(1-g^2)^2+\frac{2}{r}a^2g^2, \tag{28}$$

which can readily be verified to yield the *unacceptable* solution $g^2=\eta^2r^2$, and hence for our purposes (26)–(28) are to be considered overdetermined.

As a consequence of the Bogomol'nyi equations (26)–(28) not being satisfied by the solution to the second-order Euler–Lagrange equations, the stress tensor for this field configuration is *nonzero*, and hence the static soliton solutions do not describe noninteracting vortices. The solutions in question are of course topologically stable by virtue of the pair of topological inequalities (10) and (11) for $p=1$ and $p=2$, respectively. [For the more general systems (23), N pairs of inequalities (10)–(11) are employed for this purpose.] The lower bound on the energy of the system (25) is 1 for all n because of the normalizations, when all the coupling constants $\lambda_0,\mu_0,\mu_1,\mu_2$ *are greater than 1*. When any of these coupling constants *are smaller than 1*, then it follows from an extension of the argument that led to the lower bound (5), that we have

$$E\geqslant \min\{\lambda_0,\mu_0,\mu_1,\mu_2\}. \tag{29}$$

Given this situation, it is interesting to find out by how much the solution differs from the field configuration that saturates the topological lower bound. We refer to this as the putative self-dual field configuration. The most important question is: does the system (25), and hence also all

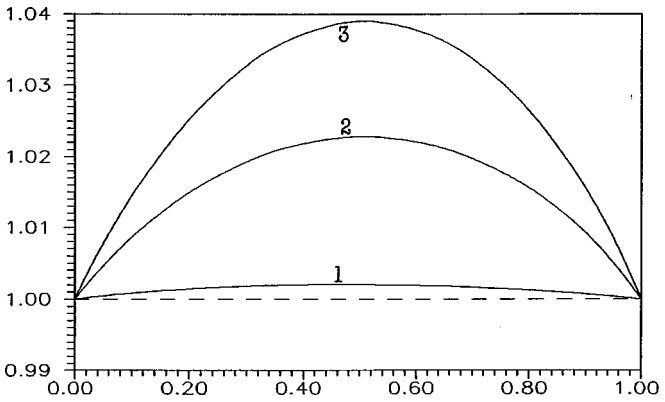

FIG. 3. The energy *per unit charge* of the vortex of the extended model (30) as a function of the mixing parameter θ. The labels 1,2,3 refer to the vorticity.

systems (23), support vortices of both attractive and repulsive phases like the individual members (1) of the MH hierarchy? Both these questions can be answered by performing the relevant numerical experiments on (25).

We have first considered the system

$$\mathcal{H}=\frac{1-\theta}{2}\mathcal{H}^{(1)}(1,1,1)+\frac{\theta}{6}\eta^{-4}\mathcal{H}^{(2)}(1,1,1), \tag{30}$$

where the $p=1$ and $p=2$ self-dual models are superposed by means of a mixing parameter θ. (By self-dual models we mean models whose lower bound on the energy can be saturated by the Bogomol'nyi equations, *and,* the latter support finite energy solutions.) As a check of our equations, we found that the energies *per unit charge* corresponding to the self-dual solutions (i.e., for $\theta=0$ and $\theta=1$) are indeed equal to 1.0. In between, the energy becomes slightly higher than $E=1$ and the numerical result indicates that the deviation culminates at $\theta=\frac{1}{2}$. At this value, the energy of solutions with vorticities $n=1$, $n=2$, and $n=3$ are, respectively, 1.0020, 1.0228, and 1.0390. These values differ very little from the putative self-dual case ($E=1.0$) and their departure from the latter grows with the vorticity n, nonetheless staying within 4 *percent* up to $n=3$.

The energy curves correponding to the $n=1,2,3$ solitons as a function of θ are depicted in Figure 3; it clearly shows that the self-duality property is maximally violated for the model (30) for $\theta=\frac{1}{2}$, or, equivalently, the model (25) for $\lambda_0=\mu_0=\mu_1=\mu_2=1$. Remarkably the three curves are almost symmetric under the reflection $\theta\rightarrow(\theta-1)$; we do not have any analytical explanation for this observation.

In order to offer some answers to the questions posed above, we solved numerically the equations associated with (25) for numerous values of the coupling constants. In fact we studied the equations for all but one of the coupling constants set equal to 1 and varying the remaining one. This way, the set of models addressed was ''relatively close'' to the model (30) with $\theta=\frac{1}{2}$ (i.e., where self-duality is maximally violated).

The evaluation of the energy of $n=1$ and $n=2$ vorticity solutions as a function of λ_0 (with $\mu_0=\mu_1=\mu_2=1$) is summarized by the two solid curves in Fig. 4. The energy *per unit charge* of the $n=2$ solution lies always above the energy of the $n=1$ solution. We conclude that two *unit* vortices at large distances apart will tend to increase their mutual distances to minimize the energy, i.e., repel.

Exactly the same scenario occurs when we vary the coupling constant μ_2 (with $\lambda_0=\mu_0=\mu_1=1$), as depicted by the two dashed lines of Fig. 4. The situation becomes, however, physically more interesting when the parameters μ_0 and/or μ_1 are varied, as discussed now.

Varying the parameter μ_0 (with $\lambda_0=\mu_1=\mu_2=1$), we observe that the $n=1$ and $n=2$ vortices energy are in an attractive phase for $\mu_0<\mu_0^{cr}\approx 0.64$ and in a repulsive phase for $\mu_0>\mu_0^{cr}$. This is clearly indicated in Fig. 5 by the two solid curves. Considering finally the variation of the parameter μ_1, we observe from the dashed curves in Fig. 5 the occurrence of a repulsion phase for

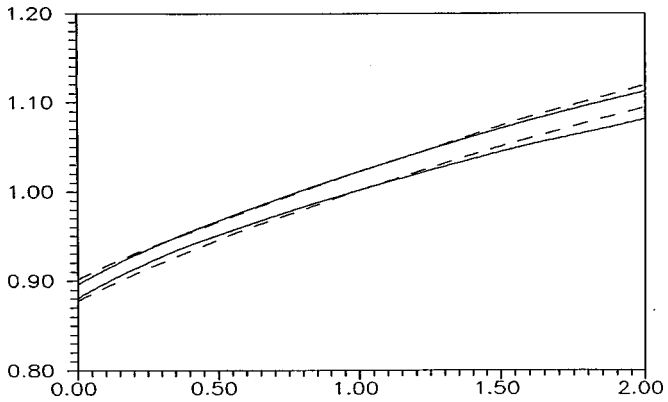

FIG. 4. The energy *per unit charge* of solutions of the extended model (25). The two solid (resp., dashed) lines represent the energy as a function of λ_0 (resp., μ_2); all other coupling constants are set to 1. In the two cases, the upper (resp., lower) line refers to the $n=2$ (resp., $n=1$) vortex.

$\mu_1<\mu_1^{cr}\approx 1.45$ and of an attraction phase for $\mu_1>\mu_1^{cr}$. We note from Fig. 5 that, contrary to the case of μ_0 varying, the two-vortex system is in an attractive phase for $\mu_1>\mu_1^{cr}$ ($\mu_1\approx 1.45$) and in a repulsive phase if $\mu_1<\mu_1^{cr}$.

The occurrence of Jacobs–Rebbi plots or, equivalently, of attraction-repulsion phase transitions in some specific regions of the space of the coupling constants deserves to be studied in more detail. To this end, we remark on two important features of self-dual models.

(i) The energies *per unit charge* of the n-vortex solutions are all equal to 1, irrespectively of the interger n.

(ii) All components of the stress energy tensor T_{ij} vanish, implying noninteracting solitons.

The extended models considered in this Section *do not* support self-dual solutions, thus neither (i) nor (ii) above are satisfied. Nevertheless, in some regions of the space of coupling parameters these criteria are minimally violated. We refer to these regions of the parameter space as ''almost-self-dual regions.''

For our quantitative considerations, it will be convenient to restrict just to the (2,2) component of T_{ij}, whose restriction to the one-dimensional spherically symmetric subsystem is given by

$$T_{22}=\frac{1}{8}\left(\left[\frac{a_\rho^2}{\rho}-\rho(1-g^2)^2\right]+2\left[\rho g_\rho^2-\frac{a^2g^2}{\rho}\right]\right)$$
$$+\frac{1}{24}\left(\left[\frac{[(1-g^2)a]_\rho^2}{\rho}-9\mu_0\rho(1-g^2)^4\right]+12\mu_1(1-g^2)^2\left[\rho g_\rho^2-\frac{a^2g^2}{\rho}\right]\right). \tag{31}$$

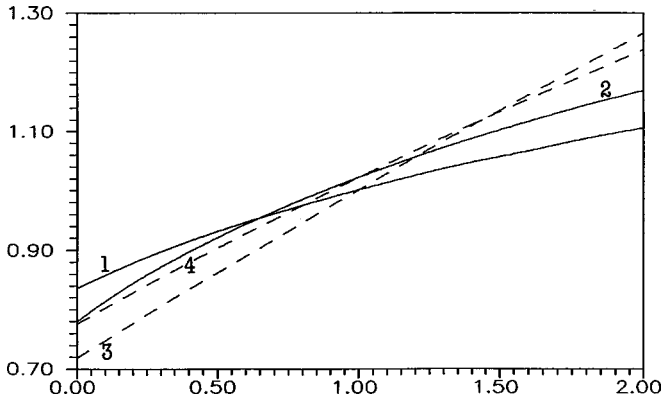

FIG. 5. The energy *per unit charge* of solutions of the extended model (25). The two solid (resp., dashed) lines represent the energy as a function of μ_0 (resp., μ_1); all other coupling constants are set to 1. Curves 1 and 3 (resp., 2 and 4) refer to energy of the $n=1$ (resp., $n=2$) vortex.

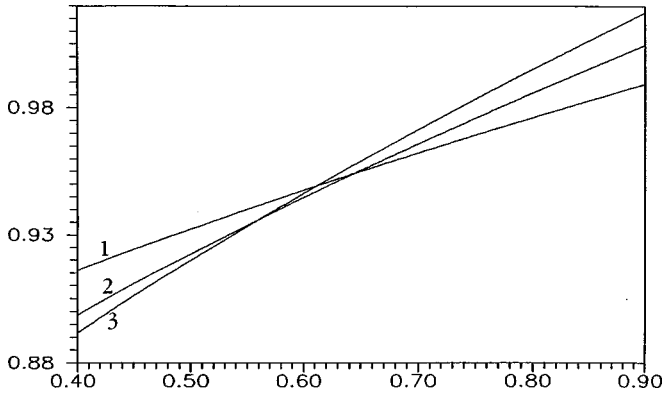

FIG. 6. The details of the energy *per unit charge* for the solutions of vorticity $n=1,2,3$ for the model (25) as a function of μ_0 (other coupling constants are set equal to 1).

In order to characterize more quantitatively the ''almost self-dual region'' of the space of coupling constants obtained above, we calculated *also* the $n=3$ vortex solutions in this region. We evaluated, for the solutions with vorticities $n=1,2,3$, the quantity

$$F=\int (T_{22})^2 dr. \tag{32}$$

We now discuss the results obtained for when we vary the coupling constant μ_0, with all others set equal to 1 as before. The curves of the energies *per unit charge* of the $n=1,2,3$ vorticities are given in Fig. 6. The three curves intersect at the following points:

$$n=1 \text{ intersects } n=2 \quad \text{at } \mu_0=\mu_0^{cr}\approx 0.64, \quad E\approx 0.954,$$

$$n=1 \text{ intersects } n=3 \quad \text{at } \mu_0=\mu_0^{cr}\approx 0.61, \quad E\approx 0.948,$$

$$n=2 \text{ intersects } n=3 \quad \text{at } \mu_0=\mu_0^{cr}\approx 0.56, \quad E\approx 0.941.$$

The values of μ_0 where the intersections occur are indeed very close to each other. Next, the three, $n=1,2,3$, curves of the positive definite quantitity (32) versus μ_0 are depicted in Fig. 7. We see that this quantity F attains very sharp minima at

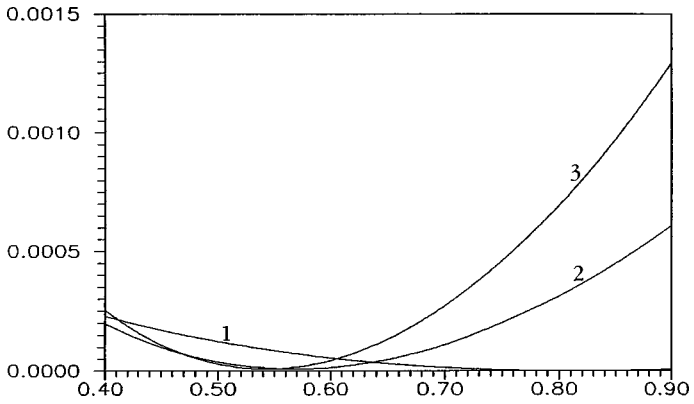

FIG. 7. The quantity (32) for the solutions of vorticity $n=1,2,3$ for the model (25) as a function of μ_0 (other coupling constants are set to 1).

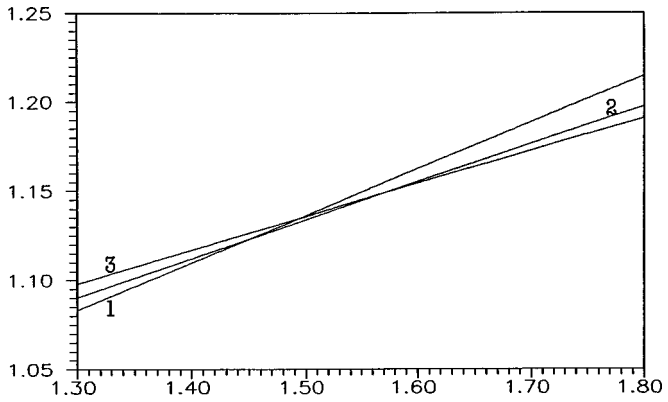

FIG. 8. The details of the energy *per unit charge* for the solutions of vorticity $n=1,2,3$ for the model (25) as a function of μ_1 (other coupling constants are set equal to 1).

$$\mu_0=\mu_0^{min}\approx 0.81, \quad F\approx 0.2\times 10^{-6}, \quad E\approx 0.977, \quad \text{for } n=1,$$

$$\mu_0=\mu_0^{min}\approx 0.57, \quad F\approx 0.8\times 10^{-4}, \quad E\approx 0.938, \quad \text{for } n=2,$$

$$\mu_0=\mu_0^{min}\approx 0.54, \quad F\approx 0.7\times 10^{-4}, \quad E\approx 0.931, \quad \text{for } n=3.$$

A similar analysis was carried out when we varied the coupling constant μ_1, leading to very similar results. The energy is depicted in Fig. 8, and the counterpart of the corresponding data above is

$$n=1 \text{ intersects } n=2 \text{ at } \mu_1=\mu_1^{cr}\approx 1.45, \quad E\approx 1.125,$$

$$n=1 \text{ intersects } n=3 \text{ at } \mu_1=\mu_1^{cr}\approx 1.50, \quad E\approx 1.136,$$

$$n=2 \text{ intersects } n=3 \text{ at } \mu_1=\mu_1^{cr}\approx 1.57, \quad E\approx 1.150.$$

Similarly we calculated the quantity (32) and found its minima. Since these curves are similar to those in Fig. 7, we do not present them but suffice to give the data as in the previous case,

$$\mu_1=\mu_1^{min}\approx 1.20, \quad F\approx 0.9\times 10^{-6}, \quad E\approx 1.056 \quad \text{for } n=1,$$

$$\mu_1=\mu_1^{min}\approx 1.55, \quad F\approx 0.4\times 10^{-5}, \quad E\approx 1.145 \quad \text{for } n=2,$$

$$\mu_1=\mu_1^{min}\approx 1.57, \quad F\approx 0.3\times 10^{-5}, \quad E\approx 1.150 \quad \text{for } n=3.$$

The above data implies the following.

(i) The energies *per unit charge* of the n-vortex solutions for the models characterized by the critical values of the parameters μ_0^{cr} and μ_1^{cr}, or the models at the crossing points of the Jacobs–Rebbi plots, are all close to the topological lower bound 1.0. This departure increases with the vorticity n.

(ii) The quantity F, (32), which is a measure of the departure of the vortices from the strictly noninteracting self-dual case, has minimum values which are very close to *zero* for some values of the coupling contants μ_0 and μ_1. In these regions of the parameters, the systems admit solutions describing ''almost noninteracting'' vortices. This departure also increases with increasing n.

The conclusion is then that for certain values of the coupling constants, the extended models while not admitting strictly noninteracting self-dual solutions, nevertheless support ''almost self-dual'' vortices. This is because for these values of the coupling constants the vortices are almost noninteracting. The energies of these ''almost self-dual'' vortices, while not exactly coincident with, are close to, the energies of the vortices of the systems characterized by the critical values of

the parameters μ_0^{cr} and μ_1^{cr}. It should be pointed out in addition that the critical values of the coupling constants μ^{cr} are fairly close to those values of the coupling constants μ^{min}, for which the quantity F pertaining to $n=2$ and $n=3$ vortices is minimal.

V. SUMMARY

We have calculated the interaction energy of the vortices of the generalized Abelian Higgs models, referred to as the hierarchy of MH models the first member of which is the usual Abelian Higgs model. We find that the vortices of all members of this hierarchy exhibit both an attractive and a repulsive phase, as was shown for the usual case by Jacobs and Rebbi.[9] We have shown, moreover, that the strengths of these interactions become progressively smaller in the case of higher members of the hierarchy. Our numerical demonstration is restricted to the comparative study of the first three members of the hierarchy, which we present as a demonstration by induction of this property for all members of the hierarchy. It is hoped that this quantitative feature of the generalized MH vortices may be of some interest in various areas of vortex physics.

We have also presented a hybrid model consisting of the sum of several members of the hierarchy of MH models, *always including the first member*. The inclusion of the usual Abelian Higgs model endows the photon in this model with the usual propagation properties. This is the physical motivation for introducing these extended models. The solitons of these extended models have nonzero stress tensor because they are not self-dual. It is found that the energies of such solitons are within *a few percent* of the topological lower bound, or the energy of the putative self-dual soliton, this departure growing with the vorticity of the soliton. Most importantly, we have demonstrated that the vortices of these extended models exhibit both attractive and repulsive phases like the individual members of the MH hierarchy, in spite of there being no self-dual solutions to these systems for any values of the parameters in the theory. This has been done for two-vortex and three-vortex systems.

An important and interesting feature of these extended models is that for certain values of the coupling constants the solutions are very close indeed to self-dual field configurations describing noninteracting systems, and that these points in parameter space are close but not coincident with the critical values of the parameters which demarcate the attractive and repulsive phases. In this sense, these field configurations are *almost* self-dual and describe *almost* noninteracting systems of vortices. This analysis been performed for systems of up to three vortices, but it can be extended to an arbitrary number.

A relativistic supersymmetry and some algebraic consequences

Ion I. Cotăescu

(Received 15 August 1997; accepted for publication 23 February 1998)

We analyze the supersymmetry and the shape invariance of the potentials which appear in the Klein–Gordon equations of the $(1+1)$ relativistic Pöschl–Teller oscillators we have recently proposed. We point out how the main operators depend on the value of the unique parameter involved in the shape invariance of the supersymmetric partner potentials, and we propose a unitary transformation that changes its value. © *1998 American Institute of Physics.*

I. INTRODUCTION

The problem of relativistic generalization of the isotropic harmonic oscillator has been discussed by many authors.[1] In the context of general relativity, this has been defined as a free (test) particle on an anti-de-Sitter static background.[2,3] Recently, we have generalized the $(3+1)$ anti-de-Sitter metric of the bag model of Ref. 2 to a family of metrics depending on a real parameter.[4] These generate analytically solvable quantum models which have as nonrelativistic limit just the nonrelativistic harmonic oscillator (NRHO). All these models have interesting energy spectra[5] which could allow one to identify new specific relativistic effects. However, to this end, we have to solve many sensitive problems starting with that of the correct definition of observables up to those concerning the properties of the whole operator algebra. A guide in this direction could be the study of another family of simpler models, obtained as the restriction to $(1+1)$ dimensions of the mentioned ones.[6]

These have the advantage of the special natural frames in which the metrics are conformally flat and, consequently, the relativistic scalar product coincides with the usual one.[7] In these frames the models with countable energy spectra of our family of $(1+1)$ models appear as the relativistic correspondents of the well-known nonrelativistic Pöschl–Teller systems.[8,9] They will be referred as relativistic Pöschl–Teller models (RPTMs). In Ref. 7 we have studied the algebraic properties of their main operators including those of the supersymmetry[10] but without pointing out the mechanisms of supersymmetry and shape invariance of the RPTM. For this reason we consider this problem in the present article. Moreover, we analyze the relation between the algebras of the RPTM with supersymmetric partner (superpartner) potentials with the hope of obtaining a complete image about the algebraic properties of this class of models.

We start in Sec. II with a short review of our previous results concerning the RPTM for which we choose a special parametrization with a unique variable parameter which should determine the mass of the test particle while the background remains unchanged. In Sec. III, we show that the mechanisms of supersymmetry work like in the nonrelativistic case, involving only the mentioned parameter in the shape invariance of the superpartner relativistic potentials. This leads to the conclusion that these correspond to a pair of RPTMs with particles of different masses but the same background. The problem of the structure and the properties of the operators we need in our theory is treated in Sec. IV, where we identify the main operators which depend on the variable parameter, while in Sec. V we introduce transformations able to change its value.

Here we shall use the traditional wave function formalism of the coordinate representations since, in our program, the standard Dirac notation is reserved for the Fock space of the quantum field theory. However, in order to make precise the definitions of several operators introduced here, we give in the Appendix their spectral representation in Dirac notation.

We shall work in natural units with $\hbar = c = 1$.

II. THE PARAMETRIZATION OF THE MODELS

Let us start with a short review of the main results concerning the RPTM. We have shown[7] that there are holonomic frames, (t,x), in which the metrics of our family of models[6] are given by the line elements

$$ds^2=\left(1+\frac{1}{\epsilon^2}\tan^2\hat{\omega}x\right)(dt^2-dx^2), \tag{1}$$

where we have denoted $\hat{\omega}=\epsilon\omega$ understanding that ω is the frequency of the harmonic oscillator obtained as the nonrelativistic limit of these models. Here ϵ is a new parameter that determines the domain of the quantum free motion, $D=(-\pi/2\hat{\omega},\pi/2\hat{\omega})$, for a fixed ω. This has been introduced so that the exact $(1+1)$ anti-de Sitter metric should have $\epsilon=1$. We must specify that in the frame (t,x) the scalar product of the functions defined on D is just the usual one.[7] This means that here the definition of the Hermitian conjugation is also the usual one (e.g., $\partial_x^+=-\partial_x$).

The Klein–Gordon equation of a test particle of the mass m and energy E has the form

$$\left(-\frac{d^2}{dx^2}+\frac{m^2}{\epsilon^2}\tan^2\hat{\omega}x\right)U(x)=(E^2-m^2)U(x). \tag{2}$$

It has a countable discrete energy spectrum, the corresponding square-integrable energy eigenfunctions of which are

$$U_{n_s,s}(x)=N_{n_s,s}\cos^k\hat{\omega}x\,\sin^s\hat{\omega}xF(-n_s,k+s+n_s,s+\tfrac{1}{2},\sin^2\hat{\omega}x), \tag{3}$$

where $N_{n_s,s}$ is the normalization factor[7] and

$$k=\frac{1}{2}\left[1+\sqrt{1+4\frac{m^2}{\epsilon^2\hat{\omega}^2}}\right]>1 \tag{4}$$

is the positive solution of the equation

$$k(k-1)=\frac{m^2}{\epsilon^2\hat{\omega}^2}. \tag{5}$$

The quantum numbers, $n_s=0,1,2,...$ and $s=0,1$, can be embedded into the main quantum number $n=2n_s+s$. This will take even values if $s=0$ and odd values for $s=1$. Hence, the functions $U_{n_s,s}(x)$ are completely determined by n only. They are real polynomials of the degree n in $\sin\hat{\omega}x$, with the factor $\cos^k\hat{\omega}x$, which vanishes at $x=\pm\pi/2\hat{\omega}$. The energy levels also depend on the main quantum number. These can be obtained from the quantization condition

$$E_n^2-m^2\left(1-\frac{1}{\epsilon^2}\right)=\hat{\omega}^2(n+k)^2,\quad n=0,1,2... . \tag{6}$$

We specify that, for the pure anti-de-Sitter oscillator, the resulting energy spectrum is equidistant[3] since $\epsilon=1$.

All these models depend only on three parameters, the mass m, and the parameters which determine the metric, i.e., the frequency ω and the new parameter ϵ. In the following we shall consider that the background remains unchanged (which means that the last two parameters are fixed) and we shall study the free motion of test particles with different masses on this background. In these conditions it is convenient to use the parameter k instead of m. This will be the unique arbitrary parameter giving the properties of a RPTM which will be denoted from now by (k). The mass of its test particle results from (5),

$$m(k)^2=k(k-1)\epsilon^2\hat{\omega}^2, \tag{7}$$

while the energy spectrum, defined by the quantization condition (6), has the energy levels

$$E_n(k)^2=\hat{\omega}^2[(n+k)^2+(\epsilon^2-1)k(k-1)]. \tag{8}$$

Moreover, the second term on the left-hand side of Eq. (2), which is the relativistic potential,[7] can be put in the form

$$V_{PT}(k,x)=k(k-1)\hat{\omega}^2\ \tan^2\ \hat{\omega}x. \tag{9}$$

Based on the previous observation that the eigenfunctions (3) are defined by the main quantum number only, we can denote $U_{n_s,s}\equiv U_{k,n}$. For each $k>1$ the orthonormal and complete set $U_{k,n}, n=0,1,2,...$, represents a basis of the Hilbert state space, $L^2(D)$, of the square integrable functions defined on D. This is the energy basis of the model (k). It is important to specify that all the models (with $k>1$) have the same Hilbert space since the domain D depends only on ω and ϵ, which remain fixed.

III. SUPERSYMMETRY AND SHAPE INVARIANCE

We can construct the supersymmetric quantum mechanics of our RPTM by using adjusted Klein–Gordon operators instead of the Hamiltonians of the nonrelativistic theory. These must admit as eigenvalues the differences

$$d_{k,n}=E_n(k)^2-E_0(k)^2=\hat{\omega}^2n(n+2k), \tag{10}$$

which satisfy $d_{k,0}=0$. Thus, we obtain the new operator $\mathbf{\Delta}[V]$ defined by

$$\{\mathbf{\Delta}[V]U\}(x)=\left(-\frac{d^2}{dx^2}+V(x)\right)U(x), \tag{11}$$

which allows us to rewrite the Klein–Gordon equation in the form

$$\mathbf{\Delta}[V_-(k)]U_{k,n}=d_{k,n}U_{k,n} \tag{12}$$

where we have denoted

$$V_-(k,x)=V_{PT}(k,x)+m(k)^2-E_0(k)^2=\hat{\omega}^2[k(k-1)\ \tan^2\ \hat{\omega}x-k]. \tag{13}$$

Furthermore, from the (normalized[11]) ground-state eigenfunction,

$$U_{k,0}(x)=\left(\frac{\hat{\omega}^2}{\pi}\right)^{1/4}\left[\frac{\Gamma(k+1)}{\Gamma(k+\frac{1}{2})}\right]^{1/2}\ \cos^k\ \hat{\omega}x, \tag{14}$$

we obtain the superpotential,

$$W(k,x)=-\frac{1}{U_{k,0}(x)}\frac{dU_{k,0}(x)}{dx}=\hat{\omega}k\ \tan\ \hat{\omega}x, \tag{15}$$

and the superpartner of V_-,

$$V_+(k,x)=-V_-(k,x)+2W(k,x)^2=\hat{\omega}^2[k(k+1)\ \tan^2\ \hat{\omega}x+k]. \tag{16}$$

According to the standard procedure,[10] we define the pair of adjoint operators, $\mathbf{A}_k$ and $\mathbf{A}_k^+$, having the action

$$(\mathbf{A}_kU)(x)=\left(\frac{d}{dx}+W(k,x)\right)U(x), \tag{17}$$

$$(\mathbf{A}_k^+U)(x)=\left(-\frac{d}{dx}+W(k,x)\right)U(x), \tag{18}$$

and the commutation rule

$$[\mathbf{A}_k,\ \mathbf{A}_k^+]=2k\hat{\omega}^2\mathbf{1}+\frac{1}{2k}\,(\mathbf{A}_k+\mathbf{A}_k^+)^2, \tag{19}$$

where $\mathbf{1}$ is the unit operator. Then, the operators $\mathbf{\Delta}$ of the models with superpartner potentials can be written as

$$\mathbf{\Delta}[V_-(k)]=\mathbf{A}_k^+\mathbf{A}_k,\quad \mathbf{\Delta}[V_+(k)]=\mathbf{A}_k\mathbf{A}_k^+. \tag{20}$$

Other algebraic properties of the operator $\mathbf{A}_k$ can be derived starting with the observation that it is proportional with the operator $\tilde{\mathbf{a}}_k$ we have studied in Ref. 7 (i.e., $\mathbf{A}_k=\hat{\omega}\sqrt{2k}\tilde{\mathbf{a}}_k$).

Let us observe now that the potentials $V_-(k)$ and $V_+(k)$ are shape invariant since

$$V_+(k,x)=V_-(k+1,x)+(2k+1)\hat{\omega}^2. \tag{21}$$

Consequently, we can verify that

$$\mathbf{\Delta}[V_+(k)]U_{k+1,n-1}=d_{k,n}U_{k+1,n-1},\quad n=1,2,..., \tag{22}$$

which means that the spectrum of $\mathbf{\Delta}[V_+(k)]$ coincides with that of $\mathbf{\Delta}[V_-(k)]$, apart from the lowest eigenvalue of the last one, $d_{k,0}=0$. Furthermore, from (22) combined with (12) it results that the normalized energy eigenfunctions satisfy

$$\mathbf{A}_kU_{k,n}=\sqrt{d_{k,n}}U_{k+1,n-1},\quad \mathbf{A}_k^+U_{k+1,n-1}=\sqrt{d_{k,n}}U_{k,n}, \tag{23}$$

for $n>0$, while for $n=0$ we have $\mathbf{A}_kU_{k,0}=0$, according to (15) and (17). Hence, we have obtained the desired relation between the energy basis of the models (k) and $(k+1)$ with the superpartner potentials $V_-(k)$ and $V_+(k)$, respectively. In general, any normalized energy eigenfunction of the model (k) can be written as

$$U_{k,n}=\frac{1}{\hat{\omega}^n\sqrt{n!}}\left[\frac{\Gamma(n+2k)}{\Gamma(2n+2k)}\right]^{1/2}\mathbf{A}_k^+\mathbf{A}_{k+1}^+\cdots\mathbf{A}_{k+n-1}^+U_{k+n,0}, \tag{24}$$

where $U_{k+n,0}$ is the normalized ground-state eigenfunction of the model $(k+n)$, given by (14).

A special case is that of $\epsilon=0$ when the energy eigenfunction, $U_n^{(0)}$, of the relativistic model coincides with those of the NRHO.[7] This is because, in the limit of $\epsilon\to 0$, when $\hat{\omega}\to 0$, $k\to\infty$, but $\epsilon^2k\to m/\omega$, we have

$$\lim_{\epsilon\to 0}V_{PT}(k,x)=\lim_{\epsilon\to 0}V_-(k,x)=\lim_{\epsilon\to 0}V_+(k,x)=m^2\omega^2x^2 \tag{25}$$

and

$$\lim_{\epsilon\to 0}\mathbf{A}_k=\sqrt{2m\omega}\mathbf{a}, \tag{26}$$

where $\mathbf{a}$ is the usual lowering differential operator of the NRHO. Moreover, since $\Gamma(z+a)/\Gamma(z+b)\sim z^{(a-b)}$ for very large z,[11] we can verify that for $\epsilon=0$ Eq. (24) takes the usual form, $U_n^{(0)}=(\mathbf{a}^+)^nU_0^{(0)}/\sqrt{n!}$.

IV. THE OPERATOR ALGEBRA

The operator algebra of our RPTM contains operators independent on k as well as specific operators which depend on this parameter. In order to analyze this dependence it would be useful to introduce an operator with the eigenvalues k, but, in our opinion, this cannot be done. The argument is that the wave functions $U_{k,n}$ and $U_{k',n}$ generally are not orthogonal for $k'\neq k$ and, consequently, they could not represent eigenvectors of a self-adjoint operator. In these conditions

we are forced to consider that the specific operators of these models[7] are functions of k. In the following we restrict ourselves to the precise structure of the most important of them, without entering into other details.

The differential operators of the coordinate representation generally do not depend on k if they are not explicitly defined as functions of k. For example, the coordinate and momentum operators, $\mathbf{X}\sim x$ and $\mathbf{P}\sim i\partial_x$, are the same for all the models (k). In other respects, the main differential operators of the supersymmetry, $\mathbf{A}_k$ and $\mathbf{A}_k^+$, depend on k according to (15) and (17) from which it results that

$$\mathbf{A}_k=-i(\cos\ \hat{\omega}\mathbf{X})^k\mathbf{P}(\cos\ \hat{\omega}\mathbf{X})^{-k}. \tag{27}$$

However, the nondifferential operators can be defined only by giving their action in the energy basis of a model (k) and, therefore, all of them depend on k. In general, they are analytic functions of the operators $\mathbf{a}_k$ and $\mathbf{a}_k^+$ (with $[\mathbf{a}_k,\ \mathbf{a}_k^+]=\mathbf{1}$) of a unitary representation of the standard oscillator (Heisenberg–Weyl) algebra defined directly in the energy basis by

$$\mathbf{a}_kU_{k,n}=\sqrt{n}U_{k,n-1},\quad \mathbf{a}_k^+U_{k,n}=\sqrt{n+1}U_{k,n+1}, \tag{28}$$

or by (A3), so that $\mathbf{N}_k=\mathbf{a}_k^+\mathbf{a}_k$ should be the operator of number of quanta of the model (k). As mentioned, for $\epsilon=0$ the energy basis coincides with that of the NRHO and, consequently,

$$\lim_{\epsilon\to 0}\ \mathbf{a}_k=\mathbf{a}. \tag{29}$$

The above introduced operators allow one to put the wave equations of the RPTM with superpartner potentials, (12) and (22), in the operator form

$$\mathbf{A}_k^+\mathbf{A}_k=\hat{\omega}^2\mathbf{N}_k(\mathbf{N}_k+2k\mathbf{1}), \tag{30}$$

$$\mathbf{A}_k\mathbf{A}_k^+=\hat{\omega}^2(\mathbf{N}_{k+1}+\mathbf{1})[\mathbf{N}_{k+1}+(2k+1)\mathbf{1}], \tag{31}$$

which is in accordance with (10).

Each model (k) has its own pair of shift (i.e., lowering or raising) operators of the energy basis,[9]

$$\mathbf{A}_{k,(-)}=\frac{1}{\hat{\omega}\sqrt{2k}}[(\cos\ \hat{\omega}\mathbf{X})\mathbf{A}_k+\hat{\omega}(\sin\ \hat{\omega}\mathbf{X})\mathbf{N}_k], \tag{32}$$

$$\mathbf{A}_{k,(+)}=\frac{1}{\hat{\omega}\sqrt{2k}}[(\cos\ \hat{\omega}\mathbf{X})\mathbf{A}_k^++\hat{\omega}(\sin\ \hat{\omega}\mathbf{X})\mathbf{N}_k], \tag{33}$$

which decrease or increase the main quantum number with one unit, keeping the value of k unchanged. We have shown[7] that the operators $\sqrt{2k}\mathbf{A}_{k,(-)}$, $\sqrt{2k}\mathbf{A}_{k,(+)}$, and $\mathbf{N}_k+k\mathbf{1}$ are the generators of a nonunitary representation of the so(1,2) algebra which is equivalent with the unitary discrete representation of the minimal weight k generated by

$$\begin{aligned}\mathbf{K}_{k,(+)}&=\mathbf{a}_k^+(\mathbf{N}_k+2k\mathbf{1})^{1/2},\\ \mathbf{K}_{k,(-)}&=(\mathbf{N}_k+2k\mathbf{1})^{1/2}\mathbf{a}_k,\\ \mathbf{K}_{k,3}&=\mathbf{N}_k+k\mathbf{1}.\end{aligned} \tag{34}$$

Notice that, when $\epsilon\to 0$, this algebra degenerates in the standard one of the NRHO[7] (i.e., $\mathbf{K}_{k,(+)}/\sqrt{2k}\to\mathbf{a}^+$, $\mathbf{K}_{k,(-)}/\sqrt{2k}\to\mathbf{a}$, and $\mathbf{K}_{k,3}/k\to\mathbf{1}$).

V. *k*-TRANSITIONS

In the supersymmetric quantum mechanics we have to work simultaneously with two or more different RPTMs, each one having its own specific algebra. For this reason, it is useful to introduce new operators which help us to transform the algebra of a given model into that of another one, performing the change of the value of the parameter k. These transformations will be called k-transitions.

They can be correctly defined since the energy basis of different RPTMs are different orthonormal basis of the *same* Hilbert space. This means that there are unitary operators, $\mathbf{U}(k',k)$, which transform between themselves the basis of two different models, (k) and (k'), as

$$U_{k',n}=\mathbf{U}(k',k)U_{k,n}, \quad n=0,1,2,\ldots . \tag{35}$$

Obviously, these operators may have properties similar to those of the time evolution operators, i.e.,

$$\mathbf{U}(k'',k')\mathbf{U}(k',k)=\mathbf{U}(k'',k), \quad \mathbf{U}(k,k)=\mathbf{1}, \tag{36}$$

$$\mathbf{U}(k',k)^{+}=\mathbf{U}(k',k)^{-1}=\mathbf{U}(k,k'). \tag{37}$$

In the limit of $\epsilon\to 0$ (when $k\to\infty$) we have

$$\lim_{\epsilon\to 0}\mathbf{U}(k,k')=\mathbf{1}. \tag{38}$$

Let us observe that the k-transition is, in fact, the unitary transformation between the equivalent representations (28) of the Heisenberg–Weyl algebra of the models (k) and (k'). This has the usual form

$$\mathbf{a}_{k'}=\mathbf{U}(k',k)\mathbf{a}_k\mathbf{U}(k,k'). \tag{39}$$

On the other hand, for the unitary representations (34) of the so(1,2) algebra, which are not equivalent, we have a more complicated transformation rule, namely

$$\begin{aligned}\mathbf{K}_{k',(+)}&=(\mathbf{K}_{k',(-)})^{+}=\mathbf{U}(k',k)\mathbf{K}_{k,(+)}\left(\frac{\mathbf{N}_k+2k'\mathbf{1}}{\mathbf{N}_k+2k\mathbf{1}}\right)^{1/2}\mathbf{U}(k,k')\\ \mathbf{K}_{k',3}&=\mathbf{U}(k',k)\mathbf{K}_{k,3}\mathbf{U}(k,k')+(k'-k)\mathbf{1}.\end{aligned} \tag{40}$$

However, the major advantage of introducing the unitary operators of the k-transitions is to point out that the differential operator $\mathbf{A}_k$ can be put in the form

$$\mathbf{A}_k=\hat{\omega}\mathbf{U}(k+1,k)\mathbf{a}_k(\mathbf{N}_k+2k\mathbf{1})^{1/2}, \tag{41}$$

and transforms like

$$\mathbf{A}_{k'}=\mathbf{U}(k'+1,k+1)\mathbf{A}_k\left(\frac{\mathbf{N}_k+2k'\mathbf{1}}{\mathbf{N}_k+2k\mathbf{1}}\right)^{1/2}\mathbf{U}(k,k'). \tag{42}$$

Its spectral representation as well as that of $\mathbf{U}$ are given in the Appendix.

VI. COMMENTS

As a conclusion, we can say that our example of relativistic supersymmetric quantum mechanics of a massive scalar particle follows the same general rules as in the nonrelativistic case. The major difference is that the Hamiltonian of the nonrelativistic theory is replaced here by the operator $\mathbf{\Delta}$, which is linearly dependent on the squared energy operator.[7] For this reason, the role of the energies of the nonrelativistic theory of supersymmetry is played now by the differences (10). Moreover, the homogeneous structure of the Klein–Gordon equation induces some kind of regularities which lead to a very simple parametrization of the theory in such a manner that for any

pair of models with superpartner potentials we have $\Delta k=1$. Thus k simulates the behavior of a quantum number even though it cannot be the eigenvalue of a self-adjoint operator.

On the other hand, we have seen that in this parametrization we can easily identify the operators which explicitly depend on k and introduce the unitary operators of k-transitions. Thus we have obtained a large and complicated algebra which seems to have new and interesting properties. Of course, there are many fundamental problems or simple technical details to be solved before drawing definitive conclusions. However, in our opinion, no major difficulties could arise therein since, fortunately, we know the spectral representations of all the above-defined operators in the energy basis where we have the form of the normalized energy eigenfunctions. This means that we can calculate all the (usual or generalized) matrix elements of these operators, either in one of the energy bases or in the coordinate representation, thus having the possibility to find their main algebraic properties.

APPENDIX: SPECTRAL REPRESENTATIONS

In the standard Dirac notation, where $U_{k,n}(x)=\langle x|k,n\rangle$, the energy basis of the model (k) is $\{|k,n\rangle|n=0,1,2,...\}$. It is orthonormal,

$$\langle k,n|k,n'\rangle=\delta_{n,n'}, \tag{A1}$$

and complete,

$$\mathbf{1}=\sum_{n=0}^{\infty}|k,n\rangle\langle k,n|. \tag{A2}$$

According to our previous definitions, we can write the following spectral representations,

$$\mathbf{a}_k=\sum_{n=1}^{\infty}|k,n-1\rangle\sqrt{n}\langle k,n|, \tag{A3}$$

$$\mathbf{A}_k=\sum_{n=1}^{\infty}|k+1,n-1\rangle\sqrt{d_{k,n}}\langle k,n|, \tag{A4}$$

$$\mathbf{U}(k',k)=\sum_{n=0}^{\infty}|k',n\rangle\langle k,n|, \tag{A5}$$

from which we can calculate the matrix elements in one of the energy bases or the generalized matrix elements (i.e., the kernels) in the coordinate representation. For example, herein we have

$$\langle x|\mathbf{U}(k',k)|y\rangle=\sum_{n=0}^{\infty}U^{*}_{k',n}(x)U_{k,n}(y). \tag{A6}$$

(Received 29 October 1997; accepted for publication 7 January 1998)

The information entropies of the two-dimensional harmonic oscillator, $V(x,y)=1/2\lambda(x^2+y^2)$, and the one-dimensional hydrogen atom, $V(x)=-1/|x|$, can be expressed by means of some entropy integrals of Laguerre polynomials whose values have not yet been analytically determined. Here, we first study the asymptotical behavior of these integrals in detail by extensive use of strong asymptotics of Laguerre polynomials. Then, this result (which is also important by itself in a context of both approximation theory and potential theory) is employed to analyze the information entropies of the aforementioned quantum-mechanical potentials for the very excited states in both position and momentum spaces. It is observed, in particular, that the sum of position and momentum entropies has a logarithmic growth with respect to the main quantum number which characterizes the corresponding physical state. Finally, the rate of convergence of the entropies is numerically examined. © *1998 American Institute of Physics.* [S0022-2488(98)00806-8]

I. INTRODUCTION

The two-dimensional $(2D)$ harmonic oscillator $V(\vec{r})=1/2\lambda r^2$, $\vec{r}=(x,y)$, and the one-dimensional $(1D)$ hydrogen atom $V(x)=-1/|x|$, are two quantum-mechanical potentials currently used to model and explain in a simple way various natural phenomena of optical and condensed-matter character.[1–3] Both systems received a great deal of physico-mathematical attention[4–6] because they are prototypes of numerous physical situations.

However, only recently[6] the rigorous study of the entropies of these two systems has been initiated from a technical point of view, i.e., in the sense of information theory.[7–9] The starting point is Born's probability density, which for a single-particle system is $\rho(\vec{r})=|\Psi(\vec{r})|^2$ in the position space and $\gamma(\vec{p})=|\tilde{\Psi}(\vec{p})|^2$ in the momentum space. The symbols $\Psi(\vec{r})$ and its Fourier transform $\tilde{\Psi}(\vec{p})$ denote the position and momentum eigenfunctions of the corresponding potential.

It is well known that the normalized-to-unity position and momentum densities are, respectively,

$$\rho(\vec{r})=\frac{1}{\pi}\,\lambda^{|m|+1}r^{2|m|}e^{-\lambda r^2}[\hat{L}_n^{|m|}(\lambda r^2)]^2, \tag{1a}$$

$$\gamma(\vec{p})=\frac{1}{\lambda^2}\,\rho\left(\frac{\vec{p}}{\lambda}\right); \quad n=0,1,2,..., \tag{1b}$$

for the $2D$-harmonic oscillator[6,10] in the spherical coordinates (r,ϕ) and

$$\rho(x)=\frac{2}{n^4}\,e^{-(2/n)|x|}x^2\left[\hat{L}^1_{n-1}\left(\frac{2}{n}\,|x|\right)\right]^2, \tag{2a}$$

$$\gamma(p)=\frac{2n}{\pi}\,\frac{1}{(1+n^2p^2)^2};\quad n=1,2,..., \tag{2b}$$

for the $1D$ hydrogen atom, where $\hat{L}^\alpha_n(x)$ denotes an orthonormal Laguerre polynomial. Note that the physical densities are characterized by the integer quantum numbers $n=1,2,...,\infty$ and, in the oscillator case, $|m|$ correspondingly to its number of degrees of freedom. The corresponding bound-state energies $\mathscr{E}_n$ of both systems are

$$\mathscr{E}_n=\begin{cases}\lambda(2n+|m|+1), & \text{for the } 2D \text{ oscillator,}\\ -\dfrac{1}{n^2}, & \text{for the } 1D \text{ hydrogen atom.}\end{cases}$$

The lowest (unphysical) state of the hydrogen system with a density $\rho(x)=\delta(x)$ will not be considered here.

The Boltzmann–Shannon information entropy, which measures the spread or extent of the probability density and is closely related to the concept of entropy and disorder in thermodynamics, is defined as[7,11]

$$S_\rho=-\int \rho(\vec{r})\ln\,\rho(\vec{r})d\vec{r} \tag{3}$$

in the position space, and, corresponding,

$$S_\gamma=-\int \gamma(\vec{p})\ln\,\gamma(\vec{p})d\vec{p} \tag{4}$$

in the momentum space. For a D-dimensional single-particle system, these quantities are mutually related by means of the Bialynicki-Birula and Mycielski[12] inequality,

$$S_\rho+S_\gamma\geqslant D\,\ln(e\pi), \tag{5}$$

which is a stronger version of the Heisenberg uncertainty relation.

It has been recently shown[6] that the position and momentum entropies of the two aforementioned quantum-mechanical systems can be expressed by means of the entropy-like functionals of the following general type;

$$S_n(\alpha,\beta):=\int_0^\infty x^\beta\omega_\alpha(x)[\hat{L}^\alpha_n(x)]^2\,\ln[\hat{L}^\alpha_n(x)]^2dx,\quad \beta\geqslant 0, \tag{6}$$

with $\omega_\alpha(x)=x^\alpha e^{-x}$. Notice that this reduces to

$$E_n(\alpha):=-S_n(\alpha,0)=-\int_0^\infty \omega_\alpha(x)[\hat{L}^\alpha_n(x)]^2\,\ln[\hat{L}^\alpha_n(x)]^2dx, \tag{7}$$

for $\beta=0$, and to

$$F_n(\alpha):=-S_n(\alpha,1)=-\int_0^\infty x\omega_\alpha(x)[\hat{L}^\alpha_n(x)]^2\,\ln[\hat{L}^\alpha_n(x)]^2dx, \tag{8}$$

for $\beta=1$. The quantity $E_n(\alpha)$ is referred to as ''entropy for the orthonormal Laguerre polynomial $\hat{L}^\alpha_n(x)$'' or simply as ''entropy of Laguerre polynomials'';[7,13] it plays a very important role in the determination of the information entropies of exactly and quasi-exactly solvable potentials.

The exact evaluation of these entropy-like functionals is a very difficult problem, not yet solved. Here we will attack this problem by means of the determination of the asymptotical behavior (i.e., at large n) of the general functional $S_n(\alpha,\beta)$ by extensive use of the strong asymptotics of Laguerre polynomials, as discussed in detail in Section II. Then, in Section III, the asymptotics of the Laguerre entropy $E_n(|m|)$ is used to evaluate the information entropies of the $2D$-harmonic oscillator in both position and momentum spaces for very excited states. Third, in Section IV, the asymptotical value of the entropic integral $F_n(\alpha)$, evaluated at $\alpha=1$, allows us to find the position entropy of the $1D$ hydrogen atom. The rate of convergence of the information entropies of the aforementioned systems is also numerically discussed. Finally, some concluding remarks and the pertinent bibliography are given.

II. ASYMPTOTICS OF ENTROPY-LIKE FUNCTIONALS OF LAGUERRE POLYNOMIALS

Here the asymptotical behavior (i.e., at large n) of the quantity $S_n(\alpha,\beta)$, given by Eq. (6) is analyzed in detail. It is found that

$$\begin{aligned} S_n(\alpha,\beta) &:= \int_0^\infty x^\beta \omega_\alpha(x)[\hat{L}_n^\alpha(x)]^2 \ln[\hat{L}_n^\alpha(x)]^2 dx \\ &= \frac{2^{2\beta+2}\Gamma(\beta+3/2)}{\sqrt{\pi}\Gamma(\beta+2)} n^{\beta+1} - \frac{2^{2\beta}(\alpha+1)\Gamma(\beta+1/2)}{\sqrt{\pi}\Gamma(\beta+1)} n^\beta \ln n \\ &\quad + \frac{2^{2\beta-1}\Gamma(\beta+1/2)}{\sqrt{\pi}\Gamma(\beta+1)} [2(\alpha+1)\psi(\beta+1) - (2\alpha+1)\psi(\beta+1/2) - 2\ln \pi \\ &\quad - 4(\alpha-1)\ln 2 + \gamma_E + 4 + 2(\alpha+2\beta) + 4\alpha\beta] n^\beta + o(n^\beta), \end{aligned} \tag{9}$$

which holds for any real $\alpha > -1$. For the particular cases $\beta=0$ and $\beta=1$, this expression leads straightforwardly to

$$E_n(\alpha) = -2n + (\alpha+1)\ln n - \alpha - 2 + \ln(2\pi) + o(1), \tag{10}$$

$$F_n(\alpha) = -6n^2 + 2(\alpha+1)n \ln n + 2(\ln 2\pi - 2\alpha - 4)n + o(n). \tag{11}$$

To find the main asymptotic formula (9) we use a general method which consists of the three following steps. First, to express $S_n(\alpha,\beta)$ in terms of the quantities of L_p-norm character,

$$N_n(\beta,p) = \int_0^\infty x^\beta |\omega_\alpha^{1/2} \hat{L}_n^\alpha(x)|^{2p} dx. \tag{12}$$

Second, to find the asymptotical value (i.e., at large n) to be denoted by $N_n(\beta,p)$, of this quantity. The latter will be done (i) by substitution of the strong asymptotics of Laguerre polynomials for some integrals of trigonometric functions in the finite interval of Plancherel–Rotach uniform convergence, and (ii) by calculation of the asymptotics of these integrals via the generalized Bernstein–Fejer lemma of Aptekarev *et al.* (Ref. 14, Lemma 2.1). Third, to evaluate the asymptotical value $S(\alpha,\beta)$ of $S_n(\alpha,\beta)$ from the quantity $N(\beta,p)$.

To start with, let us consider the first derivative of $N_n(\beta,p)$ with respect to p. Its value $N_n'(\beta,p)$ at $p=1$ is given by

$$N_n'(\beta,1) \equiv \frac{d}{dp} N_n(\beta,p)\bigg|_{p=1} = \int_0^\infty x^\beta \omega_\alpha(x) q_n^2(x) \ln[\omega_\alpha(x) q_n^2(x)] dx, \tag{13}$$

where the notation $q_n(x) \equiv \hat{L}_n^\alpha(x)$ will be used hereinafter. By keeping in mind the definition (6) of $S_n(\alpha,\beta)$ one has that

$$S_n(\alpha,\beta) = \frac{d}{dp} N_n(\beta,p)\bigg|_{p=1} + \mathscr{T}_1(\beta) - \alpha \mathscr{T}_2(\beta), \tag{14}$$

where the integrals $\mathscr{T}_1$ and $\mathscr{T}_2$ are given by

$$\mathscr{T}_1(\beta)=\int_0^\infty x^{\beta+1}\omega_\alpha(x)q_n^2(x)dx, \tag{15}$$

$$\mathscr{T}_2(\beta)=\int_0^\infty x^{\beta}\ln x\,\omega_\alpha(x)q_n^2(x)dx. \tag{16}$$

Moreover, the definition of $N_n(\beta,p)$ given by Eq. (12) allows us to write

$$\mathscr{T}_1(\beta)=N_n(\beta+1,1), \tag{17}$$

$$\mathscr{T}_2(\beta)=\frac{d}{d\beta}\mathscr{T}_1(\beta-1)=\frac{d}{d\beta}N_n(\beta,1). \tag{18}$$

Then

$$S_n(\alpha,\beta)=\frac{d}{dp}N_n(\beta,p)\bigg|_{p=1}+N_n(\beta+1,1)-\alpha\frac{d}{d\beta}N_n(\beta,1), \tag{19}$$

so that the study of the asymptotics of the entropy-like functional $S_n(\alpha,\beta)$ transforms into the analysis of the asymptotic behavior of the L_p-norm quantities $N_n(\beta,p)$. To do that we will follow the general procedure of Aptekarev *et al.*,[14] where the asymptotics of L_p-norms of orthogonal polynomials on unbounded sets is analyzed in detail. This procedure allows us to show firstly that the main contribution to $N_n(\beta,p)$ is coming from the interval where the Planchere–Rotach formula approximates polynomials uniformly so that

$$N_n(\beta,p)=\int_\epsilon^{x_n(1-\epsilon)}x^\beta|\omega_\alpha^{1/2}(x)q_n(x)|^{2p}dx[1+o(1)], \tag{20}$$

p being in some interval which includes $p=1$; and, second, we use the asymptotic behavior of the Laguerre polynomials supplied by the Plancherel–Rotach formula (Ref. 15, Theorem 8.22.9) which for

$$x_n=4n+2\alpha+2,\quad N=n+\frac{\alpha+1}{2}, \tag{21}$$

and the ϕ-definition $x=x_n\cos^2\phi$ gives that

$$\omega_\alpha^{1/2}(x)q_n(x)=\left[\frac{2}{\pi\sqrt{x(x_n-x)}}\right]^{1/2}\cos\left[N(\sin 2\phi-2\phi)+\frac{\pi}{4}\right]+o(1), \tag{22}$$

uniformly for $\epsilon\leqslant\phi\leqslant\pi/2-\epsilon/\sqrt{n}$. Then, the integral on the right-hand side of Eq. (20) gets reduced so that one obtains

$$N_n(\beta,p)=\int_\epsilon^{x_n(1-\epsilon)}x^\beta\left|\sqrt{2}\cos\left[N(\sin 2\phi-2\phi)+\frac{\pi}{4}\right]\right|^{2p}\frac{dx}{[\pi\sqrt{x(x_n-x)}]^p}[1+o(1)], \tag{23}$$

in a similar way as described in Ref. 14.

Moreover, taking into account that we may put $\epsilon=0$ in Eq. (23) and with the notation $\zeta(\phi)=\sin 2\phi-2\phi$, one has

$$N_n(\beta,p)=x_n^{\beta+1-p}2\left(\frac{2}{\pi}\right)^p\int_0^{\pi/2}(\cos\phi)^{2\beta}\left|\cos\left[N\zeta(\phi)+\frac{\pi}{4}\right]\right|^{2p}|\cos\phi\sin\phi|^{1-p}d\phi[1+o(1)], \tag{24}$$

where the change of variable $x \to \phi$: $x = x_n \cos^2 \phi$ was carried out. Therefore,

$$\lim_{n\to\infty} \frac{N_n(\beta,p)}{x_n^{\beta+1-p}} = \lim_{n\to\infty} \left(\frac{2}{\pi}\right)^p \int_0^{\pi/2} 2(\cos\ \phi)^{2\beta} |\cos\ \phi\ \sin\ \phi|^{1-p} \left|\cos\left[N\zeta(\phi) + \frac{\pi}{4}\right]\right|^{2p} d\phi,$$

where the right-hand side goes to a constant to be calculated. To go ahead, it is convenient to do another change of variable,

$$\phi \to \theta: \phi = \zeta^{-1}(\zeta(\phi)) \equiv \zeta^{-1}(\theta) = \zeta_1(\theta).$$

Then,

$$\lim_{n\to\infty} \frac{N_n(\beta,p)}{x_n^{\beta+1-p}} = \lim_{n\to\infty} \left(\frac{4}{\pi}\right)^p \int_0^{\pi} [\cos\ \zeta_1(\theta)]^{2\beta} |\sin 2\zeta_1(\theta)|^{1-p} \left|\cos\left(N\theta + \frac{\pi}{4}\right)\right|^{2p} \zeta_1'(\theta) d\theta.$$

Now, the use of Lemma 2.1 of Aptekarev *et al.*[15] leads directly to the searched constant,

$$\lim_{n\to\infty} \frac{N_n(\beta,p)}{x_n^{\beta+1-p}} = \left(\frac{4}{\pi}\right)^p \frac{1}{\pi} \int_0^{\pi} [\cos\ \zeta_1(\theta)]^{2\beta} |\sin 2\zeta_1(\theta)|^{1-p} \zeta_1'(\theta) d\theta \cdot \int_0^{\pi} |\cos\ \theta|^{2p} d\theta + o(1).$$

Recovering back the variable ϕ in the first integral on the right-hand side, one can obtain its exact value as

$$\int_0^{\pi/2} [\cos\ \phi]^{2\beta} |\sin 2\phi|^{1-p} d\phi = \frac{\Gamma(\beta+1-p/2)\Gamma(1-p/2)}{2^p \Gamma(\beta+2-p)}.$$

And the second integral is

$$\int_0^{\pi} |\cos\ \theta|^{2p} d\theta = \frac{\sqrt{\pi}\Gamma(p+1/2)}{\Gamma(p+1)}.$$

Finally we have that

$$\lim_{n\to\infty} \frac{N_n(\beta,p)}{x_n^{\beta+1-p}} = \left(\frac{2}{\pi}\right)^p \frac{\Gamma(\beta+1-p/2)\Gamma(1-p/2)}{\sqrt{\pi}\Gamma(\beta+2-p)} \frac{\Gamma(p+1/2)}{\Gamma(p+1)} \equiv \overline{N}(\beta,p), \tag{25}$$

which is valid uniformly for p in some interval which contains $p=1$, according to the aforementioned indications from Ref. 15.

This limiting expression, which gives the asymptotics of the quantities of L_p-norm type $N_n(\beta,p)$ defined by Eq. (12), allows us to find the asymptotic values of the three components $(d/dp)N_n(\beta,p)|_{p=1}$, $N_n(\beta+1,1)$ and $(d/d\beta)N_n(\beta,1)$ of the searched entropy-like functional $S_n(\alpha,\beta)$. Indeed, because of the uniform convergence[14] one has

$$\left.\frac{d}{dp}\left[\frac{N_n(\beta,p)}{x_n^{\beta+1-p}}\right]\right|_{p=1} \to \left.\frac{d}{dp}\,\overline{N}(\beta,p)\right|_{p=1}$$

$$= \frac{\Gamma(\beta+1/2)}{2\pi^{1/2}\Gamma(\beta+1)} [2 + \gamma_E - 2\ln\ \pi - \psi(\beta+1/2) + 2\psi(\beta+1)] \tag{26}$$

(where $\gamma_E = 0.577215664...$ is the Euler constant) so that

$$\left.\frac{d}{dp} N_n(\beta,p)\right|_{p=1} = x_n^{\beta} \left.\frac{d}{dp}\,\overline{N}(\beta,p)\right|_{p=1} - N_n(\beta,1)\ln\ x_n + o(x_n^{\beta}). \tag{27}$$

On the other hand, taking into account the uniformity in β of the asymptotical formula (25) for $\bar{N}(\beta,p)$ we can derive straightforwardly the first terms of the remaining components $N_n(\beta+1,1)$ and $(d/d\beta)N_n(\beta,1)$ of $S_n(\alpha,\beta)$. Namely,

$$N_n(\beta+1,1)=\frac{\Gamma(\beta+3/2)}{\sqrt{\pi}\Gamma(\beta+2)}\,x_n^{\beta+1}+o(x_n^{\beta+1}), \tag{28}$$

$$\frac{d}{d\beta}N_n(\beta,1)=\frac{\Gamma(\beta+1/2)}{\sqrt{\pi}\Gamma(\beta+1)}\{x_n^{\beta}\ln x_n+(\psi(\beta+1/2)-\psi(\beta+1))x_n^{\beta}\}+o(x_n^{\beta}\ln x_n). \tag{29}$$

Taking into account the definition of x_n given by Eq. (21), the expressions (27)–(29) become as

$$\left.\frac{d}{dp}N_n(\beta,p)\right|_{p=1}=-\frac{2^{2\beta}\Gamma(\beta+1/2)}{\pi^{1/2}\Gamma(\beta+1)}\,n^{\beta}\ln n+\frac{2^{2\beta-1}\Gamma(\beta+1/2)}{\pi^{1/2}\Gamma(\beta+1)}$$
$$\times[2+\gamma_E-2\ln\pi-4\ln 2-\psi(\beta+1/2)+2\psi(\beta+1)]n^{\beta}+o(n^{\beta}), \tag{30}$$

$$N_n(\beta+1,1)=\frac{2^{\beta+2}}{\sqrt{\pi}}\frac{\Gamma(\beta+3/2)}{\Gamma(\beta+2)}\,n^{\beta+1}+o(n^{\beta+1}), \tag{31}$$

and

$$\frac{d}{d\beta}N_n(\beta,1)=\frac{2^{\beta+2}}{\sqrt{\pi}}\frac{\Gamma(\beta+1/2)}{\Gamma(\beta+1)}\{n^{\beta}\ln n+(\psi(\beta+1/2)-\psi(\beta+1))n^{\beta}\}+o(n^{\beta}\ln n). \tag{32}$$

To sum appropriately these three quantities it is convenient to have more accurate expressions for $N_n(\beta+1,1)$ and $(d/d\beta)N_n(\beta,1)$ than Eqs. (31) and (32), respectively. To this end we will use the following formula, first given by Schrödinger[16] and later rediscovered by other authors,[17,18] for the orthonormal Laguerre polynomials $q_n(x)=\hat{L}_n^{\alpha}(x)$:

$$\int_0^{\infty}x^s e^{-x}[q_n(x)]^2dx=\frac{n!}{\Gamma(n+\alpha+1)}\sum_{r=0}^{n}\binom{s-\alpha}{n-r}^2\frac{\Gamma(s+r+1)}{r!},$$

valid for any real $s>-1$. By means of this formula one can exactly evaluate the integral $\mathscr{T}_1(\beta)$ and $\mathscr{T}_2(\beta)$ given by Eqs. (15) and (16) as

$$\mathscr{T}_1(\beta)=\frac{n!}{\Gamma(n+\alpha+1)}\sum_{r=0}^{n}\binom{\beta+1}{n-r}^2\frac{\Gamma(\beta+\alpha+r+2)}{r!}, \tag{33a}$$

$$\mathscr{T}_2(\beta)=\frac{n!}{\Gamma(n+\alpha+1)}\sum_{r=0}^{n}\binom{\beta}{n-r}^2\frac{\Gamma(\beta+\alpha+r++1)}{r!}$$
$$\cdot[2\psi(\beta+1)+\psi(\beta+\alpha+r+1)-2\psi(\beta+r+1-n)]. \tag{33b}$$

On the other hand, it follows straightforwardly that

$$N_n(\beta+1,1)=\frac{2^{2\beta+2}\Gamma(\beta+3/2)}{\sqrt{\pi}\Gamma(\beta+2)}\left[n^{\beta+1}+\frac{1}{2}(\beta+1)(\alpha+1)n^{\beta}\right]+o(n^{\beta}) \tag{34}$$

and

$$\frac{d}{d\beta}N_n(\beta,1)=\frac{2^{2\beta}\Gamma(\beta+1/2)}{\sqrt{\pi}\Gamma(\beta+1)}\{n^{\beta}\ln n+[2\ln 2+\psi(\beta+1/2)-\psi(\beta+1)]n^{\beta}\}+o(n^{\beta}). \tag{35}$$

Finally, by summing up the expressions (30), (34) and (35) in the sense indicated by Eq. (19) one obtains the searched asymptotical formula (9) for the entropy-like functional $S_n(\alpha,\beta)$.

III. ENTROPIES FOR RYDBERG STATES OF THE TWO-DIMENSIONAL HARMONIC OSCILLATOR

Here we study analytically and numerically the information entropies of the two-dimensional harmonic oscillator $V(x,y)=1/2\lambda(x^2+y^2)$ in both position and momentum spaces for any excited state with an emphasis in the Rydberg region which corresponds to a large principal quantum number n.

Recently it has been shown[6,19] that the position and momentum entropies of the system are

$$S_\rho=-\ln\lambda+\ln(e\pi), \tag{36a}$$

$$S_\gamma=\ln\lambda+\ln(e\pi), \tag{36b}$$

for the ground state $(n=0,\ m=0)$ and

$$S_\rho=-\ln\lambda-\ln\left(\frac{n!}{(n+|m|)!\,\pi}\right)+2n+|m|+1-\frac{n!}{(n+|m|)!}\,(|m|I_1+I_2), \tag{37a}$$

$$S_\gamma=\ln\lambda-\ln\left(\frac{n!}{(n+|m|)!\,\pi}\right)+2n+|m|+1-\frac{n!}{(n+|m|)!}\,(|m|I_1+I_2), \tag{37b}$$

for an arbitrary excited state characterized by the quantum numbers $(n,|m|)$. The symbols I_1 and I_2 denote the integrals

$$I_1=\int_0^\infty \ln t\,\omega_{|m|}(t)[L_n^{|m|}(t)]^2dt=\frac{|m|}{n!}\,(n+|m|)!\,\psi(n+|m|+1), \tag{38a}$$

$$I_2=\int_0^\infty \omega_{|m|}(t)[L_n^{|m|}(t)]^2\,\ln[L_n^{|m|}(t)]^2dt=h_n(|m|)^2[\ln h_n(|m|)^2-E_n(|m|)], \tag{38b}$$

where $h_n(\alpha)=[\Gamma(n+\alpha+1)/n!]^{1/2}$ is the Laguerre norm, so that the orthonormal polynomials $\hat{L}_n^\alpha(x)=[h_n(\alpha)]^{-1}L_n^\alpha(x)$. Notice that the value of I_1 immediately follows from Eqs. (16) and (33b).

The substitution of the integral values (38a) and (38b) into Eqs. (37a) and (37b) leads us to the following exact expressions for the position and momentum entropies:

$$S_\rho=2n+|m|+1+\ln\frac{\pi}{\lambda}-|m|\psi(n+|m|+1)+E_n(|m|), \tag{39a}$$

$$S_\gamma=2n+|m|+1+\ln(\pi\lambda)-|m|\psi(n+|m|+1)+E_n(|m|), \tag{39b}$$

respectively, where $E_n(|m|)$ is the entropy of the Laguerre polynomial $\hat{L}_n^{|m|}(x)$.

One observes that the states $(n,\pm m)$ have the same entropies. Moreover, these expressions allow us to obtain easily the exact values of a few of the lowest excited states $(n,|m|)$ because the associated Laguerre entropic integral (7) can be analytically solved in such cases. So, for example, the first excited state $(n=0,\ |\mathrm{m}|=1)$ has the entropies

$$S_\rho=\ln\frac{e\pi}{\lambda}+\gamma_E,$$

$$S_\gamma=\ln(e\pi\lambda)+\gamma_E,$$

where γ_E is Euler's constant.

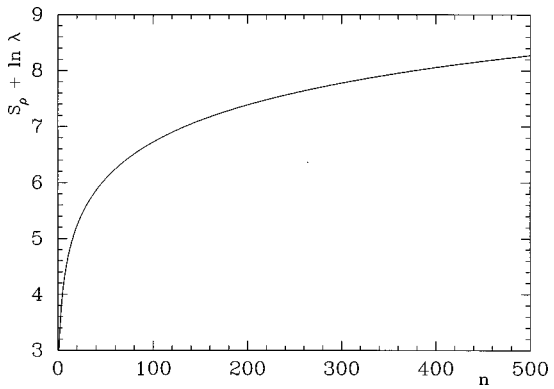

FIG. 1. Shifted position information entropy, $S_\rho + \ln \lambda$, of the two-dimensional harmonic oscillator $V(x,y) = 1/2\lambda(x^2 + y^2)$ for the excited states $(n, m=0)$ with $n = 0-500$.

However, the calculation of the entropic integral associated to an arbitrary state is a quite involved problem, still open.[6,13,14,19–21] Up to now, this integral has been analytically evaluated with high accuracy only in the asymptotic case (i.e., for large values of the degree of the involved polynomial) which physically corresponds to the Rydberg region of very excited states of the system. The asymptotical behavior of the entropy of the Laguerre polynomial was thoroughly discussed in Section II. The use of Eq. (10) together with Eqs. (39a) and (39b) leads us to the following behavior of the position and momentum entropies for very excited states of the two-dimensional harmonic oscillator:

$$S_\rho = \ln n - \ln \lambda + \ln(2\pi^2) - 1 + o(1), \tag{40a}$$

$$S_\gamma = \ln n + \ln \lambda + \ln(2\pi^2) - 1 + o(1), \tag{40b}$$

respectively. Notice that both Rydberg entropies do not depend on the quantum number m. More important it is the identification of a logarithmic dependence of both entropies on the principal quantum number n. Then, the entropy sum $S_\rho + S_\gamma$ has a logarithmic growth with n. In addition, this sum does not depend on the potential strength λ.

To know the accuracy of the position and momentum entropies for Rydberg states, as given by Eqs. (40a) and (40b) respectively, we have numerically analyzed the rate of convergence of the exact entropies [as given by Eqs. (39a) and (39b)] to these values for the excited states $(n, |m|=0)$ with $n = 0-500$. The results in position space are shown in Figures 1 and 2, where the quantity $S_\rho + \ln \lambda$ [as calculated numerically from Eq. (39a)] and the difference between this quantity and its asymptotical value (40a) are given, respectively. Similar results can be obtained for the momentum entropy case.

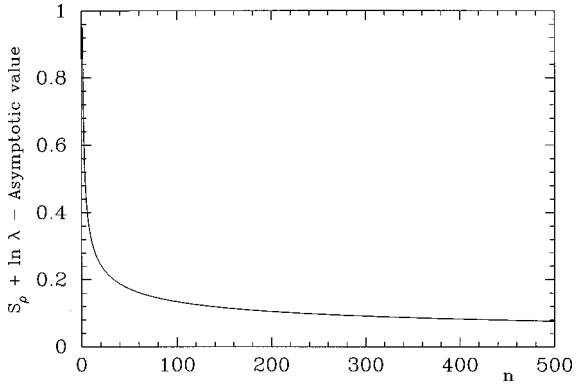

FIG. 2. The difference between the shifted position information entropy, $S_\rho + \ln \lambda$, and its asymptotical value for the excited states $(n, m=0)$, $n = 0-500$, of the two-dimensional harmonic oscillator $V(x,y) = 1/2\lambda(x^2 + y^2)$.

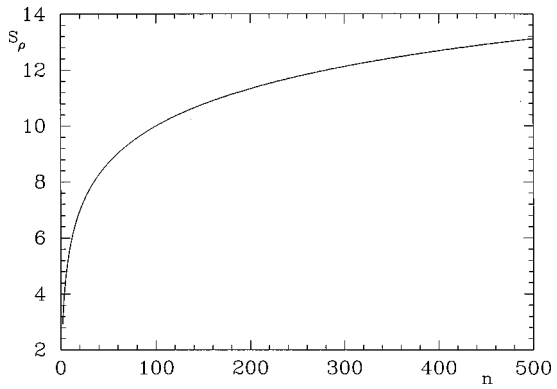

FIG. 3. Position information entropy S_ρ of the one-dimensional hydrogen atom, $V(x)=-1/|x|$, for the excited states characterized by the quantum number $n=0-500$.

IV. ENTROPIES FOR RYDBERG STATES OF THE ONE-DIMENSIONAL HYDROGEN ATOM

Here we study analytically and numerically the information entropies of the $1D$ hydrogen atom in both position and momentum spaces for an arbitrary state. They are[6]

$$S_\rho = \ln(2n^3) + 3n - \frac{1}{n^2}\left[J_2' + \frac{1}{2}J_3\right], \tag{41a}$$

$$S_\gamma = -\ln n + \ln(8\pi) - 2, \tag{41b}$$

respectively. The symbols J_2' and J_3 denote the integrals

$$J_2' = \int_0^\infty x \ln x \omega_1(x)[L_{n-1}^1(x)]^2 dx = n\int_0^\infty x \ln x \omega_1(x)[\hat{L}_{n-1}^1(x)]^2 dx = 2n^2 - n + 2n^2\psi(n+1), \tag{42a}$$

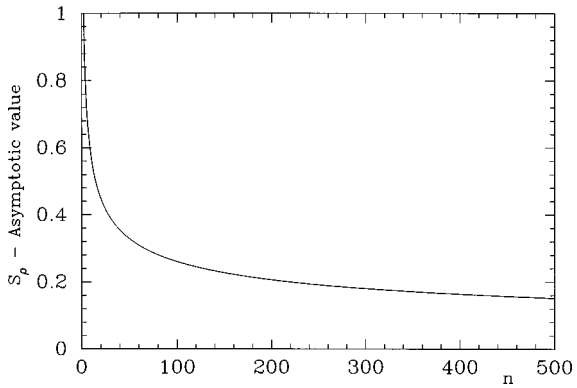

FIG. 4. The difference between the position entropy of the one-dimensional hydrogen atom and its asymptotical value given by Eq. (44) for the excited states with $n=0-500$.

$$J_3=\int_0^\infty x\omega_1(x)[L_{n-1}^1(x)]^2\ \ln[L_{n-1}^1(x)]^2dx=[h_{n-1}(1)]^2$$
$$\times\left\{\ln[h_{n-1}(1)]^2\int_0^\infty x\omega_1(x)[\hat{L}_{n-1}^1(x)]^2dx+S_{n-1}(1,1)\right\}$$
$$=n\{2n\ \ln\ n-F_{n-1}(1)\}. \tag{42b}$$

Notice that the value (42a) for the integral J_2' immediately follows from the general expressions (16) and (33b), and that to find the value (42b) of J_3 we have used Eqs. (15) and (33a) as well as Eqs. (6) and (8).

Putting the values (42a) and (42b) into Eq. (41a) one finds that

$$S_\rho=3n+\ln(2n^2)+\frac{1}{n}-2-2\psi(n+1)+\frac{1}{2n}\,F_{n-1}(1). \tag{43}$$

This expression gives the exact position entropy for a quantum-mechanical state of the $1D$ hydrogen atom characterized by the quantum number n. However, the analytical evaluation of the involved integral $F_{n-1}(1)$ is not generally possible. Only in the asymptotic case (i.e., for large n) this integral can be calculated by means of the expression (11) found in Section II. This observation allows us to find the value

$$S_\rho=2\ln\ n+2\ln 2+\ln\ \pi-2+o(1), \tag{44}$$

for the position entropy of the $1D$ hydrogen atom at a very excited (Rydberg) state. One notices again the logarithmic dependence for this entropy on the quantum number n characterizing the state under consideration. Then, the entropy sum $S_\rho+S_\gamma$ has again a logarithmic growth with n.

To know the accuracy of the Rydberg position entropy (44), we have numerically analyzed the rate of convergence of the exact entropy (43) to this value for the excited states with $n=0-500$. The results are shown in Figures 3 and 4, where the quantity S_ρ [as numerically calculated from Eq. (43)] and the difference between this quantity and its asymptotical value (44) are given, respectively.

Finally, as a concluding remark, we want to emphasize the logarithmically increasing behavior with the principal quantum number n of both the position entropy S_ρ as well as the entropy sum $S_\rho+S_\gamma$ for the two quantum-mechanical systems considered in this work. This behavior is the same in spite of the different increasing behaviors with n of the energies $\mathscr{E}_n$ of the quantum-mechanical states associated to these two systems with different power type potentials. Most probably, this logarithmic behavior of the Boltzmann–Shannon entropies is shared by a much larger set of physical systems, particularly those which are characterized by a potential of r^α type, $\alpha\in\mathbb{R}$, with bound states.

The modified Newton–Sabatier method for the coupled channel inverse scattering problem with charged particles at fixed energy

Matthias Eberspächer and Werner Scheid
Institut für Theoretische Physik der Justus-Liebig-Universität, Giessen, Germany

(Received 2 February 1998; accepted for publication 24 February 1998)

The modified Newton–Sabatier method was recently developed for inelastic inverse problems for the scattering of neutral particles. In this paper, the method is extended to the solution of the inelastic inverse scattering problem with charged particles. The bases are radial Schrödinger equations coupled by a local potential matrix known from a certain distance on. The inversion procedure starts with the S-matrix fixing the asymptotic wave functions of the charged scattering system. This S-matrix can be transformed to another one for asymptotic constant potentials instead of Coulomb potentials. The new S-matrix belongs to the same inner potential matrix as the original one and is solved by the modified Newton–Sabatier method similar to the case of neutral particles. An application with a given S-matrix, belonging to a coupled square-well potential matrix with an outer Coulomb potential yields good agreement between the inverted potential matrix and the original one. © *1998 American Institute of Physics.* [S0022-2488(98)01106-2]

I. INTRODUCTION

The inverse scattering problem (ISP) in quantum mechanics serves to determine potentials from measured cross sections. In the first step, the so-called phase-shift analysis, a set of phase shifts or S-matrix elements is calculated from the differential cross section.[1] Then these phase shifts are used in the inversion procedure to give a local optical potential.[2,3] A first solution for the ISP in quantum mechanics for a spherical potential modeling the elastic scattering of spinless particles at fixed energy was developed by Newton.[4] The method uses the integral representation of the radial Schrödinger equation (Gel'fand–Levitan equation) and requires the asymptotic wave functions for $r\rightarrow\infty$ as input data. Sabatier *et al.* extended the Newton(–Sabatier) method and studied the nonuniqueness of the ISP.[3] They were the first who tested the procedure in numerical calculations.[5] Münchow and Scheid[6] modified the Newton–Sabatier method under the assumption that the spherical potential $V(r)$ is known from a certain radial distance r_0 up to infinity. Thus, the potential is only unknown in the finite interval $[0,r_0]$, where it can be uniquely determined from a finite set of phase shifts. The modified method was worked out for the elastic scattering of neutral[6] and charged particles.[7] The modification made the method applicable to experimental data of heavy ion collisions.[8] Recent developments include a spin-orbit inversion scheme,[9] inversion of polarization-corrected phase shifts[10] and an extension to coupled channels for neutral particles.[11]

Other methods for the solution of the inverse scattering problem at fixed energy are, for example, the Bargmann method of Lipperheide and Fiedeldey,[12] the Wentzel–Kramers–Brillouin method of Kujawski and others,[13] the iterative-perturbative method of Mackintosh and others,[14] and the generalized Darboux transformations of Schnizer and Leeb.[15] The coupled channel inverse scattering problem at fixed angular momentum is discussed by Chadan and Sabatier[3] and Zakhariev and Suzko.[16] Numerical solutions of this problem were given by Kohlhoff *et al.*[17] and Sofianos *et al.*[18] Reviews on the ISP are given in the textbooks.[2,3,16,19,20] The most recent reviews of this field can be found in the Proceedings of the International Conference on ''Inverse and Algebraic Quantum Scattering Theory.''[21]

Recently the modified Newton–Sabatier method was extended to a coupled channel problem for the scattering of neutral particles at a fixed energy.[11] In this paper we generalize this method to the case that the potentials are of Coulomb type for radii larger than some radius r_0. In Section II we derive the coupled channel Schrödinger equations under the assumption that the coupling

 © 1998 American Institute of Physics

matrix does not depend on the angular momentum of relative motion. This special type of potential matrix can only induce monopole transitions. The Coulomb potentials for $r \geqslant r_0$ and the connection of the wave functions with the S-matrix are discussed in Section III. The general method to solve the ISP for coupled channels is described in Section IV. In order to simplify the solution of the ISP we transform the S-matrix belonging to asymptotic Coulomb potentials to an S-matrix belonging to asymptotic constant potentials and solve the ISP with this new S-matrix. The constant potentials have similar solutions to the asymptotic potentials of neutral particles. As explained in Section V both S-matrices yield the same potential matrix in the interior region. The procedure is tested in Section VI by applying it to the case of an S-matrix belonging to a potential matrix which consists of two coupled square wells with outer Coulomb potentials. A summary and comments are given in Section VII. In the Appendix we analytically calculate the S-matrix for a coupled square well model with Coulomb potentials in the outer region.

II. THE COUPLED CHANNEL SCHRÖDINGER EQUATIONS

We consider a scattering system with intrinsic dynamics, e.g., a scattering system consisting of two nuclei. The relative motion between the scattering partners and the intrinsic motion are described by the relative coordinate $\mathbf{r}$ and by a set of coordinates ξ, respectively. The Hamiltonian is assumed to be of the form

$$H = T(\mathbf{r}) + h(\xi) + W(r,\xi), \tag{1}$$

where $T = \mathbf{p}^2/2\mu$ denotes the kinetic energy operator, $h(\xi)$ the Hamiltonian of the intrinsic dynamics and $W(r,\xi)$ the coupling between relative and intrinsic motion. W is a local interaction operator depending on the intrinsic coordinates ξ and on the relative distance r of the colliding partners only. Equation (1) represents a special choice of the Hamiltonian which does not couple the orbital relative motion and the intrinsic motion. The operator of relative angular momentum commutes with H and, therefore, the wave function of the Schrödinger equation $H\Psi = E\Psi$ can be expanded as

$$\Psi_{\ell m,n} = \sum_{\alpha=1}^{N} R^{\ell}_{\alpha n}(r)\chi_\alpha(\xi)Y_{\ell m}(\theta,\phi). \tag{2}$$

$Y_{\ell m}$ describes the orbital motion, $\chi_\alpha(\xi)$ are the eigenfunctions of the intrinsic Hamiltonian

$$h(\xi)\chi_\alpha(\xi) = \varepsilon_\alpha \chi_\alpha(\xi). \tag{3}$$

with $\alpha = 1,\ldots,N$. We assume that N eigenstates exist which are characterized by the quantum number α. The eigenenergies ε_α are the internal excitation energies and are ordered with increasing energy $\varepsilon_1 = 0 \leqslant \varepsilon_2 \leqslant \ldots \leqslant \varepsilon_N$. The radial wave functions $R^{\ell}_{\alpha n}$ depend on the angular momentum quantum number ℓ, on the quatum number α of the intrinsic state, and on the number n of the degenerate solution to the same given channel energy $E_\alpha = E - \varepsilon_\alpha$. N also denotes the number of coupled channels.

With this special form of the Hamiltonian (1) and the wave function (2) only monopole transitions may be described. As an application one might consider transfer reactions, where all scattering partners are in the ground state. A possible system is the $^{16}\mathrm{O}(\alpha,{}^{8}\mathrm{Be}_{gs})^{12}\mathrm{C}$ reaction with the channels $\alpha + {}^{16}\mathrm{O}$ and ${}^{8}\mathrm{Be}_{gs} + {}^{12}\mathrm{C}$. In this case one has to regard different reduced masses in the channels.

Inserting the wave function (2) in the Schrödinger equation $(H-E)\Psi_{\ell m,n} = 0$, we get the following equation:

$$\sum_{\alpha=1}^{N} \chi_\alpha(\xi)\left(-\frac{\hbar^2}{2\mu}\frac{1}{r}\frac{d^2}{dr^2}r + \frac{\ell(\ell+1)\hbar^2}{2\mu r^2} + \varepsilon_\alpha - E + W(r,\xi)\right) R^{\ell}_{\alpha n}(r) = 0. \tag{4}$$

Under the simplifying assumption that the intrinsic wave functions form a complete set of functions, we obtain a set of N coupled equations for the radial wave functions by projecting with the intrinsic channel states $(\alpha = 1,\ldots,N)$:

$$\left[-\frac{\hbar^2}{2\mu}\frac{1}{r}\frac{d^2}{dr^2}r+\frac{\hbar^2}{2\mu}\frac{\ell(\ell+1)}{r^2}+\varepsilon_\alpha-E\right]R^{\ell}_{\alpha n}(r)+\sum_{\beta=1}^{N}V_{\alpha\beta}(r)R^{\ell}_{\beta n}(r)=0, \tag{5}$$

where $V_{\alpha\beta}(r)=<\chi_\alpha|W|\chi_\beta>$ is the effective potential matrix. Introducing the dimensionless quantities

$$\rho=kr=\sqrt{\frac{2\mu E}{\hbar^2}}r, \quad \varphi^{\ell}_{\alpha n}(\rho)=\rho R^{\ell}_{\alpha n}(r), \quad U_{\alpha\beta}(\rho)=\frac{V_{\alpha\beta}(r)}{E}, \tag{6}$$

we rewrite Eq. (5) in the form

$$\sum_{\beta=1}^{N}D^{U}_{\alpha\beta}(\rho)\varphi^{\ell}_{\beta n}(\rho)=\ell(\ell+1)\varphi^{\ell}_{\alpha n}(\rho), \tag{7}$$

with the differential operator

$$D^{U}_{\alpha\beta}(\rho)=\rho^2\left\{\left[\frac{d^2}{d\rho^2}+\frac{E_\alpha}{E}\right]\delta_{\alpha\beta}-U_{\alpha\beta}(\rho)\right\}. \tag{8}$$

III. ASYMPTOTIC COULOMB POTENTIALS

In this paper we consider the scattering of charged particles, e.g., nuclei. Therefore, we assume the charges of the projectile and target to be $Z_p e$ and $Z_t e$, respectively. Then, the potential matrix $U_{\alpha\beta}$ is diagonal and Coulombian from some radius ρ_0 up to infinity:

$$U_{\alpha\beta}(\rho>\rho_0)=\delta_{\alpha\beta}\frac{Z_p Z_t e^2 k}{\rho E}. \tag{9}$$

For this potential matrix, the asymptotic solutions can be written as

$$\varphi^{\ell}_{\alpha n}(\rho>\rho_0)=\sqrt{k_\alpha}\rho(\delta_{\alpha n}H^{-}_{\ell}(k_\alpha\rho)-S^{\ell}_{\alpha n}H^{+}_{\ell}(k_\alpha\rho)) \tag{10}$$

with

$$H^{\pm}_{\ell}(k_\alpha\rho)=\frac{e^{i\sigma^{\ell}_\alpha}}{k_\alpha\rho}(G_\ell(k_\alpha\rho)\pm iF_\ell(k_\alpha\rho)), \quad k_\alpha=\sqrt{1-\frac{\varepsilon_\alpha}{E}}. \tag{11}$$

Here, G_ℓ and F_ℓ are the irregular and regular Coulomb functions, respectively. The quantities σ^{ℓ}_α are the Coulomb phases:

$$\sigma^{\ell}_\alpha=\arg\Gamma(\ell+1+i\eta_\alpha), \quad \eta_\alpha=\frac{Z_p Z_t e^2\mu}{\hbar^2 k k_\alpha}. \tag{12}$$

The S-matrix contains the information about the potential matrix. In the following we use the extended modified Newton–Sabatier method to solve the ISP given by (7) and (10).

IV. THE ISP FOR COUPLED CHANNELS AT FIXED ENERGY

In order to solve the ISP we first introduce a symmetric reference potential matrix $U^0_{\alpha\beta}(\rho)=U^0_{\beta\alpha}(\rho)$. We assume that the regular solutions $\varphi^{0\ell}_{\alpha n}$ of the coupled channel Schrödinger equations are known for the reference potential matrix:

$$\sum_{\beta=1}^{N}D^{U_0}_{\alpha\beta}(\rho)\varphi^{0\ell}_{\beta n}(\rho)=\ell(\ell+1)\varphi^{0\ell}_{\alpha n}(\rho) \tag{13}$$

with

$$D^{U_0}_{\alpha\beta}(\rho)=\rho^2\left\{\left[\frac{d^2}{d\rho^2}+\frac{E_\alpha}{E}\right]\delta_{\alpha\beta}-U^0_{\alpha\beta}(\rho)\right\}. \tag{14}$$

Then it is possible to write the wave function of the coupled channel equations in the form

$$\varphi^{\ell}_{\alpha n}(\rho)=\varphi^{0\ell}_{\alpha n}(\rho)-\sum_{\beta=1}^{N}\int_0^\rho \frac{d\rho'}{\rho'^2}K^{UU_0}_{\alpha\beta}(\rho,\rho')\varphi^{0\ell}_{\beta n}(\rho'), \tag{15}$$

if the potential matrix is given by

$$U_{\alpha\beta}(\rho)=U^0_{\alpha\beta}(\rho)-\frac{2}{\rho}\frac{d}{d\rho}\frac{K^{UU_0}_{\alpha\beta}(\rho,\rho)}{\rho}. \tag{16}$$

The kernel matrix $K^{UU_0}_{\alpha\beta}$ has to fulfill the differential equation

$$\sum_{\beta=1}^{N}D^{U}_{\alpha\beta}(\rho)K^{UU_0}_{\beta\gamma}(\rho,\rho')=\sum_{\beta=1}^{N}D^{U_0}_{\gamma\beta}(\rho')K^{UU_0}_{\alpha\beta}(\rho,\rho'), \tag{17}$$

with the boundary conditions

$$K^{UU_0}_{\alpha\beta}(\rho=0,\rho')=K^{UU_0}_{\alpha\beta}(\rho,\rho'=0)=0. \tag{18}$$

A possible kernel matrix which fulfills Eqs. (17) and (18) can be expanded in terms of the radial functions $\varphi^{\ell}_{\alpha n}$ and $\varphi^{0\ell}_{\alpha n}$ with coefficients $c^{\ell}_{nn'}$:

$$K^{UU_0}_{\alpha\beta}(\rho,\rho')=\sum_{\ell=0}^{\infty}\sum_{n,n'=1}^{N}c^{\ell}_{nn'}\varphi^{\ell}_{\alpha n}(\rho)\varphi^{0\ell}_{\beta n'}(\rho'). \tag{19}$$

Inserting this kernel into Eq. (15) we get the fundamental coupled equations for the solution of the ISP:

$$\varphi^{\ell}_{\alpha n}(\rho)=\varphi^{0\ell}_{\alpha n}(\rho)-\sum_{\ell'=0}^{\infty}\sum_{n'',n'=1}^{N}\varphi^{\ell'}_{\alpha n''}(\rho)c^{\ell'}_{n''n'}L^{\ell'\ell}_{n'n}(\rho), \tag{20}$$

where $L^{\ell\ell'}$ is a matrix determined by the known reference solutions:

$$L^{\ell'\ell}_{n'n}(\rho)=\sum_{\beta=1}^{N}\int_0^\rho\frac{d\rho'}{\rho'^2}\varphi^{0\ell'}_{\beta n'}(\rho')\varphi^{0\ell}_{\beta n}(\rho'). \tag{21}$$

Equation (20) depends on the so called spectral coefficients $c^{\ell}_{nn'}$ which are first unknown. Since the wave functions $\varphi^{\ell}_{\alpha n}(\rho)$ are known for $\rho>\rho_0$ if the S-matrix is given [see Eq. (10)], Eq. (20) can be used to calculate the coefficients $c^{\ell}_{nn'}$ by solving it with the wave functions at values of $\rho>\rho_0$. Then, Eq. (20) can be applied for $\rho<\rho_0$ to obtain the unknown wave functions $\varphi^{\ell}_{\alpha n}(\rho)$ in the inner region, which finally yield the potential matrix $U_{\alpha\beta}(\rho)$ by using Eqs. (16) and (19). This procedure provides us a unique determination of the potential matrix for a given S-matrix inside the family of potential matrices defined by Eq. (16).

V. REDUCTION TO THE CASE OF AN ASYMPTOTIC CONSTANT POTENTIAL

For the case of an asymptotic Coulomb potential (9) one may choose a Coulomb potential as reference potential and Coulomb wave functions as reference wave functions. In order to avoid the difficulties with these functions with respect to the singularity of the Coulomb potential at $\rho=0$

and with respect to the calculation of the matrix elements (21), we first transform the S-matrix to a new S-matrix for a constant asymptotic potential and then solve the ISP with a constant reference potential $U^0_{\alpha\beta}$.

A. Transformation of the *S*-matrix

Let us consider a potential matrix $U^B_{\alpha\beta}(\rho)$ with the properties

$$U_{\alpha\beta}{}^B(\rho)=\begin{cases} U_{\alpha\beta}(\rho) & \rho<\rho_B \\ \delta_{\alpha\beta}\dfrac{Z_pZ_te^2k}{\rho_BE} & \rho\geqslant\rho_B, \end{cases} \tag{22}$$

where ρ_B is a fixed radius situated outside the nuclear interaction region. $U^B_{\alpha\beta}(\rho)$ is schematically shown together with $U_{\alpha\beta}(\rho)$ in Fig. 1. Both potential matrices, $U_{\alpha\beta}(\rho)$ and $U^B_{\alpha\beta}(\rho)$, are identical in the inner region. The S-matrices $S^{\ell}_{\alpha n}$ and $S^{\ell B}_{\alpha n}$ belong to the same potential matrix $U_{\alpha\beta}(\rho)$ for $\rho<\rho_B$, but different matrices for $\rho\geqslant\rho_B$. Solving the ISP we will get the same potential matrix $U_{\alpha\beta}(\rho)$ from $S^{\ell}_{\alpha n}$ and $S^{\ell B}_{\alpha n}$ for $\rho<\rho_B$. However, the solution of the ISP is much easier to handle by starting with $S^{\ell B}_{\alpha n}$ because the reference potential can be chosen as constant, i.e., as independent of ρ. The S-matrix $S^{\ell B}_{\alpha n}$ is obtained by a transformation from $S^{\ell}_{\alpha n}$. The Schrödinger equation with the Coulomb potential is given for $\rho\geqslant\rho_B$ by

$$\left(\frac{1}{\rho}\frac{d^2}{d\rho^2}\rho-\frac{\ell(\ell+1)}{\rho^2}+k_\alpha^2-\frac{Z_pZ_te^2k}{\rho E}\right)T^{\ell}_{\alpha n}(\rho)=0. \tag{23}$$

Its solutions are of the form (10):

$$T^{\ell}_{\alpha n}(\rho\geqslant\rho_B)=\sqrt{k_\alpha}(\delta_{\alpha n}H^-_{\ell}(k_\alpha\rho)-S^{\ell}_{\alpha n}H^+_{\ell}(k_\alpha\rho)), \tag{24}$$

with $H^{\pm}_{\ell}$ already defined by Eq. (11). The Schrödinger equation for $\rho\geqslant\rho_B$ for the potential matrix $U^B_{\alpha\beta}$ is of the form

$$\left(\frac{1}{\rho}\frac{d^2}{d\rho^2}\rho-\frac{\ell(\ell+1)}{\rho^2}+(k^B_\alpha)^2\right)T^{\ell B}_{\alpha n}(\rho)=0, \tag{25}$$

with the abbreviations

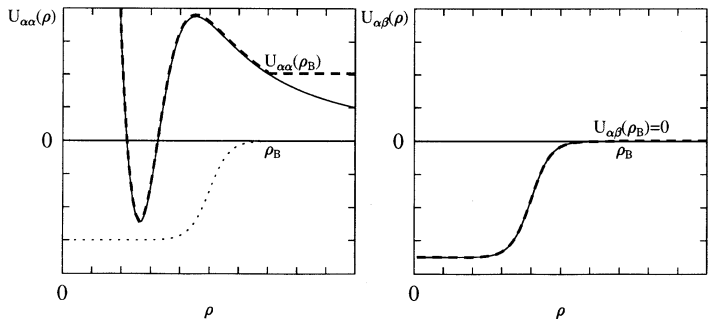

FIG. 1. Schematic picture to the transformation of the S-matrix. The left diagram shows the diagonal elements of $U_{\alpha\alpha}$ (real part: —, imaginary part: $\cdots$) and $U^B_{\alpha\alpha}$ (real part: - - -, imaginary part: $\cdots$). The right diagram gives the off-diagonal elements $U_{\alpha\beta}$ and $U^B_{\alpha\beta}$. ρ_B is the transformation radius.

$$(k_\alpha^B)^2=\frac{E_B-\varepsilon_\alpha}{E},\quad E_B=E-\frac{Z_pZ_te^2k}{\rho_B}. \tag{26}$$

The solutions of Eq. (25) are the modified spherical Hankel functions:

$$T_{\alpha n}^{\ell B}(\rho\geqslant\rho_B)=\sqrt{k_\alpha^B}(\delta_{\alpha n}h_\ell^-(k_\alpha^B\rho)-S_{\alpha n}^{\ell B}h_\ell^+(k_\alpha^B\rho)). \tag{27}$$

The modified Hankel functions are defined in terms of regular and irregular spherical Bessel functions (that is why we use the suffix ''B''):

$$h_\ell^\pm(\rho)=-n_\ell(\rho)\pm ij_\ell(\rho). \tag{28}$$

In order to get the new S-matrix elements $S_{\alpha n}^{\ell B}$, we equate the wave functions composed of the solutions (24) and (27) and their derivatives at $\rho=\rho_B$, e.g.,

$$\sum_{n'=1}^{N}\sqrt{k_\alpha}(\delta_{\alpha n'}H_\ell^-(k_\alpha\rho_B)-S_{\alpha n'}^{\ell}H_\ell^+(k_\alpha\rho_B))D_{n'n}^{\ell}=\sqrt{k_\alpha^B}(\delta_{\alpha n}h_\ell^-(k_\alpha^B\rho_B)-S_{\alpha n}^{\ell B}h_\ell^+(k_\alpha^B\rho_B)). \tag{29}$$

For fixed ℓ this procedure yields two sets of $N\times N$ linear equations for the $N\times N$ unknown coefficients $D_{nn'}^{\ell}$ and the $N\times N$ new S-matrix elements $S_{\alpha n}^{\ell B}$. Similar transformations can also be done for other asymptotic potentials.

B. Solution of ISP with a constant reference potential

With the S-matrix elements $S_{\alpha n}^{\ell B}$ we can solve the ISP with a method which is very similar to the one for neutral particles. For the scattering of neutral particles the potential matrix is zero from a certain radius ρ_0 and the reference potential can be set $U_{\alpha\beta}^0=0$. In our case we choose $U_{\alpha\beta}^0=\delta_{\alpha\beta}(Z_pZ_te^2k/\rho_BE)$ [see Eq.(22)]. The regular solutions of Eq. (13) are then

$$\varphi_{\alpha n}^{0\ell}(\rho)=\rho T_{\alpha n}^{0\ell}(\rho):=\rho j_\ell(k_\alpha^B\rho)\,\delta_{\alpha n}, \tag{30}$$

where the function j_ℓ is the regular spherical Bessel function. The asymptotic solution for the potential matrix $U_{\alpha\beta}^B(\rho)$ was already given in terms of the S-matrix in Eq. (27) and is repeated here:

$$T_{\alpha n}^{\ell B}(\rho\geqslant\rho_B)=\sqrt{k_\alpha^B}(\delta_{\alpha n}h_\ell^-(k_\alpha^B\rho)-S_{\alpha n}^{\ell B}h_\ell^+(k_\alpha^B\rho)), \tag{31}$$

where $h_\ell^\pm$ are modified spherical Hankel functions defined in Eq. (28). The wave functions $\varphi_{\alpha n}^{\ell}(\rho)$ are written as superpositions of all the degenerate solutions with the asymptotic (31) belonging to a single channel α with yet unknown coefficients $A_{nn'}^{\ell}$:

$$\varphi_{\alpha n}^{\ell}(\rho)=\sum_{n'=1}^{N}\rho T_{\alpha n'}^{\ell}(\rho)A_{n'n}^{\ell}. \tag{32}$$

By introducing the wave functions (30) and (32) into Eq. (20), we get the coupled equations

$$\sum_{n'=1}^{N}\left(T_{\alpha n'}^{\ell}(\rho)A_{n'n}^{\ell}+\sum_{\ell'=0}^{\ell_{\max}}T_{\alpha n'}^{\ell'}(\rho)b_{n'n}^{\ell'}L_n^{\ell'\ell}(\rho)\right)=T_{\alpha n}^{0\ell}(\rho) \tag{33}$$

with new matrices

$$L_n^{\ell\ell'}(\rho)=\int_0^{\rho} j_\ell(k_n^B\rho')j_{\ell'}(k_n^B\rho')d\rho', \quad b_{nn'}^{\ell}=\sum_{n''=1}^{N} A_{nn''}^{\ell}c_{n''n'}^{\ell}. \tag{34}$$

In order to get a finite set of equations, we limit the sum over the angular momenta in Eq.(33) to $\ell_{\max}$. The effect of this limitation is discussed in Ref. 22. Equation (33) is twofold used—first, for the calculation of the coefficient matrices $A_{nn'}^{\ell}$ and $b_{nn'}^{\ell}$ at $\rho>\rho_B$ and then for the calculation of the wave functions $T_{\alpha n}^{\ell}(\rho)$ at $\rho<\rho_B$. For the first step, two arbitrary radii $\rho_1,\rho_2>\rho_B$ are chosen to obtain a set of $2\times(\ell_{\max}+1)\times N\times N$ linear equations for the $(\ell_{\max}+1)\times N\times N$ unknown coefficients $A_{nn'}^{\ell}$ and the $(\ell_{\max}+1)\times N\times N$ unknown spectral coefficients $b_{nn'}^{\ell}$. After determining these coefficients the wave functions $T_{\alpha n}^{\ell}(\rho)$ are calculated at discrete points ρ_i in the inner region $0<\rho_i<\rho_B$. Then the kernel matrix (19) needed for the potential matrix is given by

$$K_{\alpha\beta}^{UU_0}(\rho,\rho')=\sum_{\ell=0}^{\ell_{\max}}\sum_{n=1}^{N} b_{\beta n}^{\ell}T_{\alpha n}^{\ell}(\rho)j_\ell(k_\beta^B\rho)\rho^2. \tag{35}$$

The uniqueness of this method of the solution of the ISP was proved and discussed in Ref. 11.

VI. APPLICATIONS

We apply our method to the case of coupled square well potentials with asymptotic Coulomb potentials. For simplicity we restrict ourselves to two channels only. In this case, analytic formulas for the S-matrix for the scattering of neutral particles were derived by Lovas.[23] In the Appendix we extend these calculations to charged particles. This provides us with analytically exact input data for the inversion procedure.

As an example, we assume a potential matrix for two channels with charged particles:

$$\mathbf{V}(r)=\begin{cases}\begin{pmatrix}-6-3i & -4\\ -4 & -5-4i\end{pmatrix}\text{MeV}, & r\leqslant 5 \text{ fm},\\ \dfrac{12e^2}{r}\ \text{MeV}, & r>5 \text{ fm}.\end{cases} \tag{36}$$

The excitation energies are $\varepsilon_1=0$ MeV and $\varepsilon_2=5$ MeV. The charge numbers $Z_p=2$ and $Z_t=6$ and the reduced mass $\mu=2794.50$ MeV/c^2 are chosen to model the scattering system ${}_2^4$He $+{}_6^{12}$C. The scattering energy is $E=200$ MeV. The S-matrix is calculated with the formulas of the Appendix.

Figure 2 shows the obtained potential matrices calculated with three different transformation radii r_B. The diagrams at the top and bottom of Fig. 2 present the diagonal elements V_{11} and V_{22}, respectively. The two diagrams in the middle correspond to the coupling potentials V_{12} and V_{21}. The left side shows the real part, the right side the imaginary part of the potential matrix elements.

The transformation radii are $r_B=5$,6, and 7 fm for the full, dotted and dashed curve, respectively. The radii needed for the calculation of the spectral coefficients in Eq. (33) are $r_1=r_B+0.05$ fm and $r_2=r_B+0.1$ fm. The step width for the discrete points r_i for the calculation of the wave functions in Eq. (33) is $\Delta r=r_{i+1}-r_i=0.05$ fm. All three results reproduce the initial potential matrix (36) with small oscillations, which are caused by a pole at $r=0$ in Eq. (16) and by the discontinuity of the square well potential at $r=5$ fm. The amplitude of the oscillations gets slightly larger, the further out the transformation radius r_B is chosen. The best reproduction is given, when the transformation radius r_B coincides with the radius $r_0=5$ fm.

Let us now consider a way of diminishing the small oscillations which have a wavelength of about $\lambda\approx 0.5$ fm in our example. In order to calculate the potential matrix (16) we take the derivative with respect to ρ by evaluating the kernel matrix $K_{\alpha\beta}^{UU_0}$ at distances r_i separated by a step width Δr and by applying a three-point formula for the derivative. Figure 3 shows the

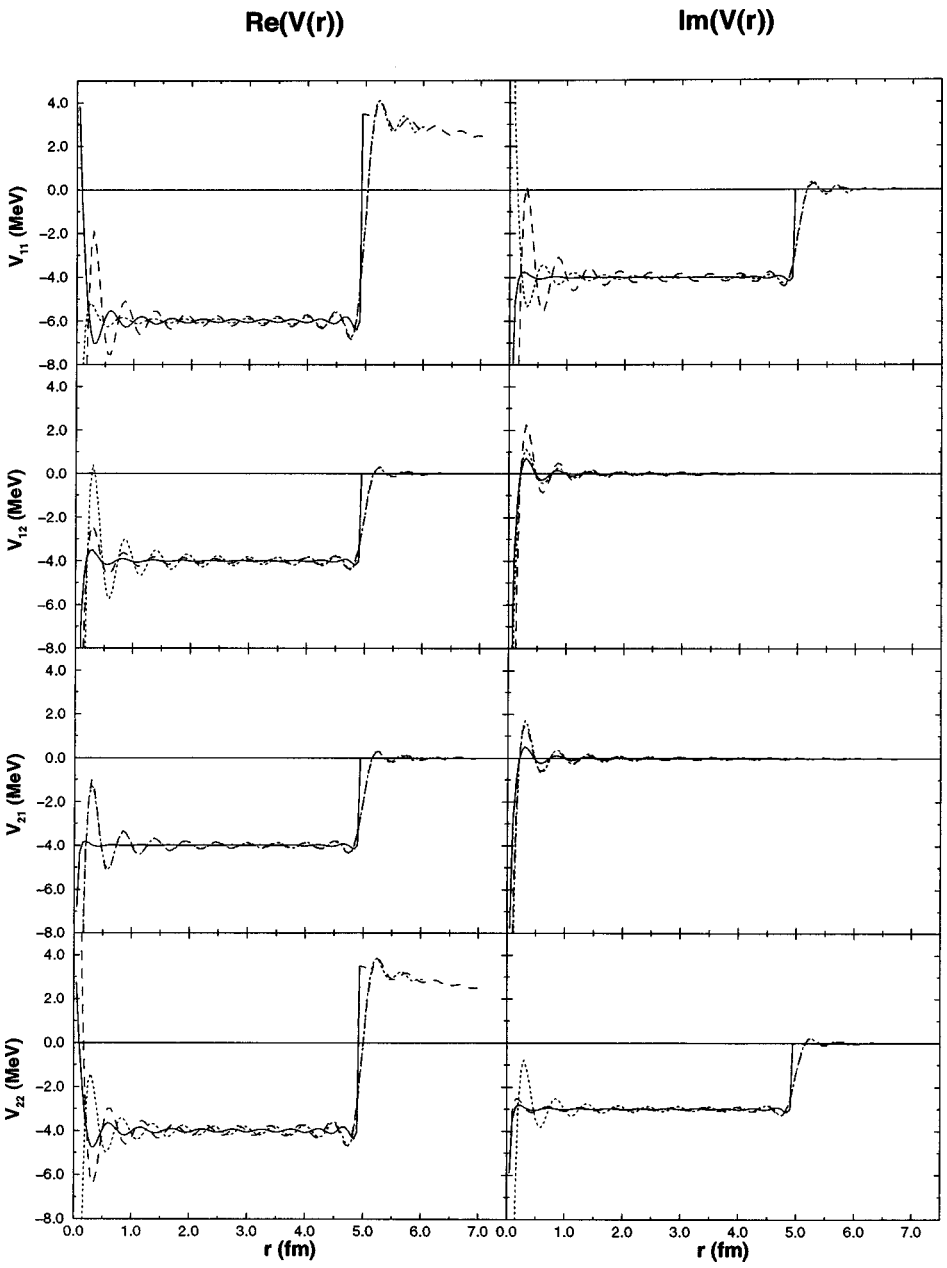

FIG. 2. Inverted potential matrix $V_{\alpha\beta}(r)$ for different transformation radii: $r_B=5$ fm (—) with $\ell_{\max}=24$, 6 fm $(\cdots)$ with $\ell_{\max}=28$, and 7 fm (- - -) with $\ell_{\max}=32$. For further details see text.

potential matrices obtained from the calculations with three different step widths for the discrete points r_i. The original potential matrix is the same as in Eq. (36). The transformation radius is $r_B=6$ fm, the radii for the calculation of the spectral coefficients are $r_1=6.05$ fm and $r_2=6.1$ fm. The step widths used are $\Delta r=0.01,\ 0.05$, and 0.25 fm for the full, dotted and dashed curves, respectively. The inverted potentials are given at 606, 120 and 22 radii for the full, dotted and dashed curve, respectively. The dotted curve is the same as in Fig. 2. As can be seen in Fig. 3, the inverted potential can not be improved by decreasing the step width from 0.05 to 0.01 fm. If we increase the step width to half of the wavelength $\Delta=\lambda/2=0.25$ fm (dashed curve) the oscillations are canceled out. This is a nontrivial process, as the numerical method for the potential matrix (16) takes the kernel (19) at three neighboring points into account. As a result of this improvement, the inverted potential is now only known at 22 radii. If the potential is needed on a finer grid (for example, in order to calculate the S-matrix back numerically), one might apply an interpolation

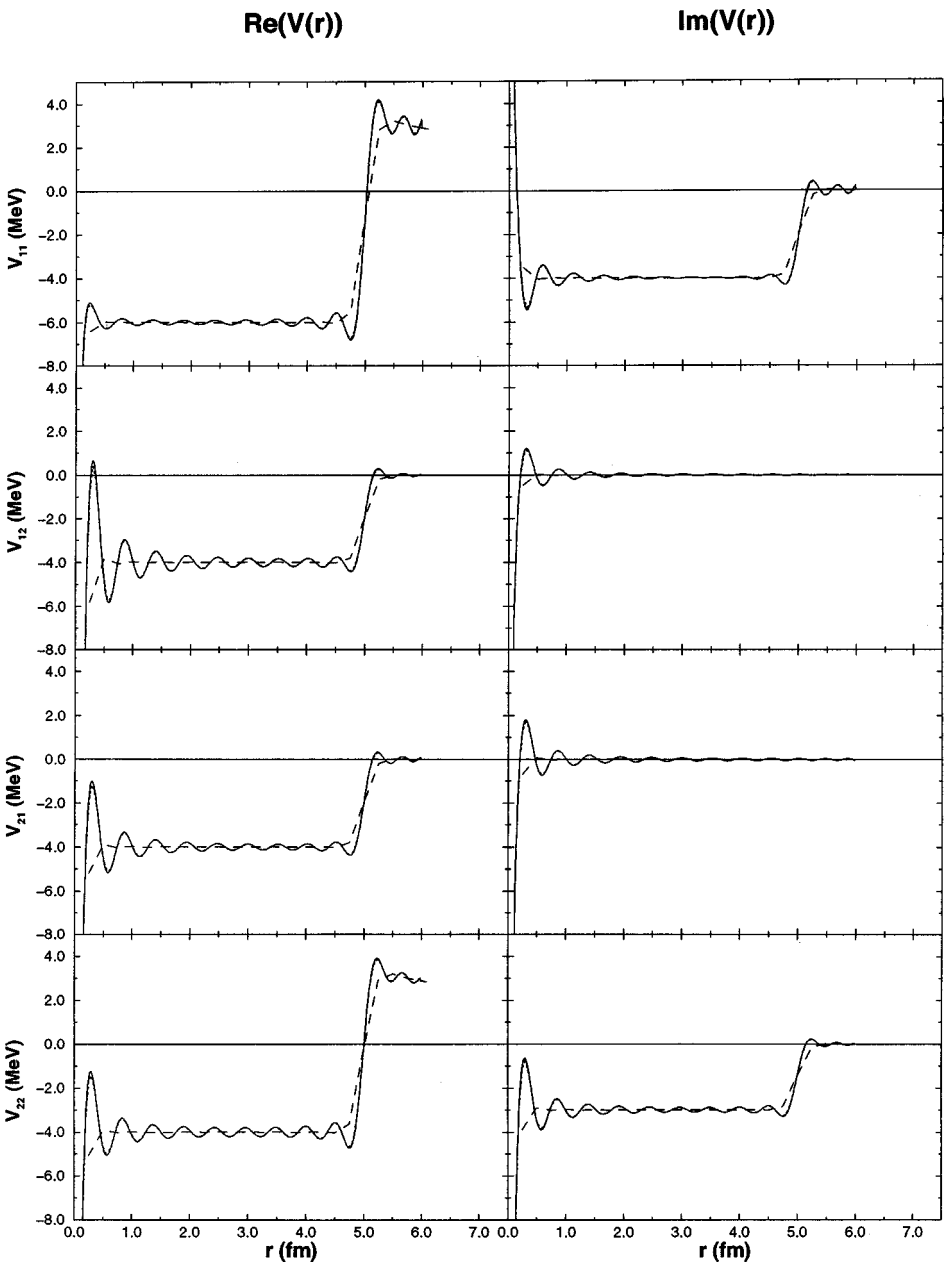

FIG. 3. Inverted potential matrix $V_{\alpha\beta}(r)$ for different step widths: $\Delta r = 0.01$ fm (—), 0.05 fm ($\cdots$), and 0.25 fm (- - -) all with $\ell_{\max} = 28$. For further details see text.

procedure. However, any structure of the potential smaller than the step width is then lost. Thus, the described method is only applicable for smoothly behaving well potentials discussed in this paper. For other potentials different regularization procedures must be considered.

VII. SUMMARY AND CONCLUSIONS

We extended the modified Newton–Sabatier method for coupled channels and neutral particles to the case of charged particles. The method is restricted to cases in which the potential matrix does not depend on the angular momentum of the relative motion. To remove this restriction may be very difficult inside the modified Newton–Sabatier method.

The inversion method for charged particles proposed here is carried out in two steps. First, the S-matrix of the charged particle problem is transformed to an S-matrix belonging to asymptotic

constant potentials. Then, the modified Newton–Sabatier method is applied to this new S-matrix in a similar way as for neutral particles. This procedure shows good agreement with the initial potential matrix for the presented example of two channels coupled by a square well potential matrix. Applications to more realistic potentials are in progress.

Applications to transfer reactions require a channel-dependent reduced mass μ_α and channel-dependent charge numbers Z_p^α and Z_t^α. Both features can be easily included in our present method.

For the inversion procedure in the case of coupled channels the complete S-matrix is needed as input data. This confronts us with the fundamental problem that a complete S-matrix at fixed energy is generally not known from experimental data. Usually in an experiment, the particles are scattered in their ground state. Thus, only one column of the S-matrix can be measured, describing the excitation from this state. Only for two channels and no absorption one might use the unitary condition for the S-matrix and calculate the missing matrix elements.[1]

ACKNOWLEDGMENTS

The authors are thankful to Professor B. Apagyi (Technical University of Budapest) for his advice in several details. APPENDIX: SOLUTION OF A COUPLED SQUARE WELL MODEL WITH CHARGED PARTICLES

We limit ourselves to two channels. The potential matrix is

$$\mathbf{U}(\rho)=\begin{cases}\begin{pmatrix}U_{11} & U_{12}\\ U_{21} & U_{22}\end{pmatrix}, & \rho\leqslant\rho_0\\ \begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}\dfrac{Z_pZ_te^2k}{\rho E}, & \rho>\rho_0\end{cases} \tag{A1}$$

where the matrix elements U_{11}, U_{22} and $U_{12}=U_{21}\equiv U$ are constant. Z_p, Z_t are the charge numbers of the projectile and target, respectively. Then we can rewrite Eq. (5) for the inner region:

$$\left[\frac{d^2}{d\rho^2}+k_\alpha^2-\frac{\ell(\ell+1)}{\rho^2}\right]\varphi_{\alpha n}^{\ell}(\rho)=\sum_{\beta=1}^{2}U_{\alpha\beta}\varphi_{\beta n}^{\ell}(\rho),\rho\leqslant\rho_0 \tag{A2}$$

and for the outer region:

$$\left[\frac{d^2}{d\rho^2}+k_\alpha^2-\frac{\ell(\ell+1)}{\rho^2}-\frac{Z_pZ_te^2k}{\rho E}\right]\varphi_{\alpha n}^{\ell}(\rho)=0,\rho>\rho_0 \tag{A3}$$

with $k_\alpha^2=1-\varepsilon_\alpha/E$. For the solution with number n, let the channel $\alpha=n$ be the one that contains an incoming wave ($\rho>\rho_0$):

$$\varphi_{\alpha n}^{\ell}(\rho)=\sqrt{k_\alpha}\rho(\delta_{\alpha n}H_\ell^-(k_\alpha\rho)-S_{\alpha n}H_\ell^+(k_\alpha\rho)) \tag{A4}$$

with

$$H_\ell^\pm(k_\alpha\rho)=\frac{e^{i\sigma_\alpha^\ell}}{k_\alpha\rho}(G_\ell(k_\alpha\rho)\pm iF_\ell(k_\alpha\rho)), \tag{A5}$$

where G_ℓ and F_ℓ are the irregular and regular Coulomb wave functions and σ_α^ℓ are the Coulomb phases:

$$\sigma_\alpha^\ell=\arg\Gamma(\ell+1+i\eta_\alpha),\quad \eta_\alpha=\frac{Z_pZ_te^2\mu}{\hbar^2kk_\alpha}. \tag{A6}$$

For the solution in the internal region, which is regular at the origin we introduce the ansatz:

$$\varphi^{\swarrow}_{1n}(\rho)=\rho\sum_{n'=1}^{2} j_{\swarrow}(\tilde{k}_{n'}\rho)a_{n'n}, \quad \varphi^{\swarrow}_{2n}(\rho)=\rho\sum_{n'=1}^{2} j_{\swarrow}(\tilde{k}_{n'}\rho)b_{n'n}. \tag{A7}$$

Inserting these expansions into Eq. (A2), we obtain a set of homogeneous linear equations for the coefficients $a_{\alpha n}$, $b_{\alpha n}$:

$$(k_1'^2-\tilde{k}_\alpha^2)a_{\alpha n}-Ub_{\alpha n}=0, \tag{A8}$$

$$Ua_{\alpha n}-(k_2'^2-\tilde{k}_\alpha^2)b_{\alpha n}=0 \tag{A9}$$

with $k_\alpha'^2=k_\alpha^2-U_{\alpha\alpha}$. This system has a nontrivial solution for

$$\left.\begin{matrix}\tilde{k}_1^2\\ \tilde{k}_2^2\end{matrix}\right\}=\frac{k_1'^2+k_2'^2}{2}\pm\sqrt{\frac{(k_1'^2-k_2'^2)^2}{4}+U^2}. \tag{A10}$$

Using Eqs. (A8) and (A9) let us define the ratios

$$\gamma_\alpha\equiv\frac{a_{\alpha n}}{b_{\alpha n}}=\frac{U}{k_1'^2-\tilde{k}_\alpha^2}=\frac{k_2'^2-\tilde{k}_\alpha^2}{U}. \tag{A11}$$

Next we require the continuity of the logarithmic derivatives of the wave functions at $\rho=\rho_0$ in each channel separately. This yields the following ratios of the coefficients:

$$\begin{aligned}&\frac{b_{11}}{b_{21}}=-\frac{W_{22}^+}{W_{21}^+}, \quad \frac{a_{12}}{a_{22}}=-\frac{W_{12}^+}{W_{11}^+}, \quad -\omega_1\equiv\frac{a_{11}}{a_{21}}=-\frac{W_{12}^--S_{11}W_{12}^+}{W_{11}^--S_{11}W_{11}^+},\\ &-\omega_2\equiv\frac{b_{12}}{b_{22}}=-\frac{W_{22}^--S_{22}W_{22}^+}{W_{21}^--S_{22}W_{21}^+}.\end{aligned} \tag{A12}$$

Here, $W_{\alpha\beta}^{\pm}$ is the Wronskian:

$$W_{\alpha\beta}^{\pm}=\tilde{k}_\beta j'_{\swarrow}(\tilde{k}_\beta\rho_0)H_{\swarrow}^{\pm}(k_\alpha\rho_0)-k_\alpha H'^{\pm}_{\swarrow}(k_\alpha\rho_0)j_{\swarrow}(\tilde{k}_\beta\rho_0). \tag{A13}$$

Using Eqs. (A11) and (A12) we obtain

$$S_{11}=\frac{\gamma_2W_{21}^+W_{12}^--\gamma_1W_{22}^+W_{11}^-}{\gamma_2W_{21}^+W_{12}^+-\gamma_1W_{22}^+W_{11}^+}, \quad S_{22}=\frac{\gamma_1W_{11}^+W_{22}^--\gamma_2W_{12}^+W_{21}^-}{\gamma_1W_{11}^+W_{22}^+-\gamma_2W_{12}^+W_{21}^+}. \tag{A14}$$

The coefficients a_{11} and b_{12} can be calculated if we require the continuity of the wave functions at $\rho=\rho_0$:

$$a_{11}=\frac{\sqrt{k_1}(H_{\swarrow}^-(k_1\rho_0)-S_{11}H_{\swarrow}^+(k_1\rho_0))}{(j_{\swarrow}(\tilde{k}_1\rho_0)-j_{\swarrow}(\tilde{k}_2\rho_0)/\omega_1)}, \quad b_{12}=\frac{\sqrt{k_2}(H_{\swarrow}^-(k_2\rho_0)-S_{22}H_{\swarrow}^+(k_2\rho_0))}{(j_{\swarrow}(\tilde{k}_1\rho_0)-j_{\swarrow}(\tilde{k}_2\rho_0)/\omega_2)}. \tag{A15}$$

Repeated applications of Eqs. (A11) and (A12) give $a_{21}, a_{12}, a_{22}, b_{11}, b_{21}$ and b_{22}. Then the off-diagonal elements of the S-matrix can be calculated as:

$$S_{12}=-\frac{a_{12}j_{\swarrow}(\tilde{k}_1\rho_0)+a_{22}j_{\swarrow}(\tilde{k}_2\rho_0)}{\sqrt{k_1}H_{\swarrow}^+(k_1\rho_0)}, \quad S_{21}=-\frac{b_{11}j_{\swarrow}(\tilde{k}_1\rho_0)+b_{21}j_{\swarrow}(\tilde{k}_2\rho_0)}{\sqrt{k_2}H_{\swarrow}^+(k_2\rho_0)}. \tag{A16}$$

All derived formulas are reduced to the form presented by R.G. Lovas [23] if $\eta_\alpha=0$. In this case the Coulomb functions $H_{\swarrow}$ are the modified Hankel functions $h_{\swarrow}^{\pm}$:

$$H_\ell^\pm(\rho) \overset{\eta\to 0}{\to} h_\ell^\pm(\rho) = -n_\ell(\rho) \pm i j_\ell(\rho), \tag{A17}$$

where n_ℓ and j_ℓ are the irregular and regular spherical Bessel functions.

A non-Abelian square root of Abelian vertex operators

K. Frieler and K.-H. Rehren[a)]
II. Institut für Theoretische Physik, Universität Hamburg, Germany

(Received 1 December 1997; accepted for publication 5 February 1998)

The quantum field theoretical formulation of Kadanoff's ''correlations along a line'' in the critical two-dimensional Ising model is given in terms of p-products of Wightman fields. It provides a quadratic factorization, in the sense of operator-valued distributions, of Abelian chiral vertex operators into non-Abelian exchange fields. This basic result implies p-polynomial relations between fields from various conformal models in two dimensions; notably the two-dimensional local fields with chiral $SU(2)$ symmetry at level 2 are shown to share the nontrivial peculiarities of the Ising model order and disorder fields. These examples have interesting implications for the properties of p-products in general. © *1998 American Institute of Physics.* [S0022-2488(98)02706-6]

I. INTRODUCTION AND OUTLINE

Wightman distributions can be pointwise multiplied, unlike general distributions, and the product is again a Wightman distribution. This fact (Ref. 1, Chap. V) is due to the spectral properties, i.e., support properties in momentum space, of Wightman fields. The new Wightman field resulting from this prescription is known as the p-product of the factor fields.

The converse is in general not true: the square root of a Wightman distribution is in general not a Wightman distribution. There is, however, at least one famous nontrivial example, which can be retraced to a factorization property of the anisotropic XY model[2] and was put into quantum field theoretical terms by Schroer and Truong.[3] The exponentials of the potential for the axial current of a free Dirac field in two dimensions can be defined (with an appropriate renormalization, see Sec. II A below) and give rise to local Wightman fields. The sine and the cosine, at a specific value of the coefficient in the exponential, turn out to be the p-squares of the order and disorder fields of the Ising model. This result establishes a deep field theoretical relation between the ''doubled'' Ising model and the free Dirac theory. Analytically it means that the vacuum expectation values of the latter can be computed by taking square roots of v.e.v.'s of the former; the double-valuedness of the square root gives rise to the mutual nonlocality of the order and disorder fields.

The purpose of this paper is the discussion of another instance of nontrivial p-product factorization, related to the (nondoubled) Ising field theory, and some of its consequences pertaining to various other models. The basic statement is formula (3.4) which represents a chiral Abelian vertex operator (cf. Sec. II A) as a p-quadratic expression in terms of chiral non-Abelian exchange fields (Sec. II B); the latter are the well-known chiral constituents of the order and disorder fields of the critical Ising field theory.

The p-product of chiral abelian vertex operators is another abelian vertex operator, with a quadratic addition law for the charges. Conversely, the p-factorization of Abelian vertex operators into Abelian vertex operators of smaller charges is an almost trivial fact (cf. Sec. II A). In contrast, the new feature of our basic result is the non-Abelian nature of the constituents, reflected in their non-Abelian braiding and fusion properties.

The p-product is well-defined also for nonlocal fields, as long as they satisfy the remaining Wightman axioms. We shall refer to such fields as nonlocal Wightman fields. Indeed, our basic result (3.4) is in terms of nonlocal (chiral) fields, while some of its applications pertain to local fields in two dimensions.

[a)]Present address: Institut für Theoretische Physik, Universität Göttingen, Germany.

 © 1998 American Institute of Physics

Viewing Wightman fields as operator-valued distributions, the p-product is the pointwise multiplication as a distribution, and the tensor product as an operator. The p-product, denoted by $\Phi\odot\Psi$, of two Wightman fields Φ and Ψ on Hilbert spaces H_Φ and H_Ψ therefore lives on $H_\Phi \otimes H_\Psi$ (its cyclic subspace may be smaller). Symbolically we write

$$(\Phi\odot\Psi)(f) = \int d^d x f(x)\Phi(x)\otimes\Psi(x). \tag{1.1}$$

The precise statement is that the tensor product of Wightman distributions extends to singular smearing functions of the form $f(x)\delta^d(x-y)$ where f is a smooth test function.

The first input for the basic result (cf. Sec. III) is the old observation in the critical Ising model[4] due to Kadanoff (for the magnetization σ alone) and Kadanoff and Ceva (for mixed correlations involving also the disorder parameter μ) that upon restriction along a line in two-dimensional space, the correlations of σ and μ satisfy certain ''Γ-selection rules'' and simplify considerably. Their analytical form becomes that of the correlations of appropriately assigned electric charges in a one-dimensional Coulomb gas.

Translated to the associated quantum field theory in $1+1$ dimensions, this observation is tantamount to a simple identification between the order and disorder fields along a time-like axis and chiral Abelian vertex operators E_α of charge $\alpha=\pm 1/2$ and scaling dimension $h=1/8$. Explicitly, the Kadanoff–Ceva formulas read as

$$\sigma|_{x=0} \cong E_{+1/2}P_+ + E_{-1/2}P_-, \quad \mu|_{x=0} \cong E_{-1/2}P_+ + E_{+1/2}P_-, \tag{1.2a}$$

$$\Leftrightarrow E_{\pm 1/2} \cong \sigma|_{x=0}P_\pm + \mu|_{x=0}P_\mp, \tag{1.2b}$$

where $P_\pm$ are the projections onto the subspaces of integer and half-integer charge. (For the precise notations see Sec. II A below.)

The general theory says that the restriction of a Wightman field in d dimensions to a time-like hyperplane (such as $x^1=0$) yields another Wightman field in one dimension less.[5] For $d=1+1$, the resulting field is a chiral field; the ''positive'' direction (pertinent to the spectrum condition) is inherited from the forward time-like direction.

In order to prevent confusion, we note that the commutation relations obtained by restricting a $1+1$-dimensional field to the line $x=0$ of course test the time-like commutation relations of that field. There is no conflict between σ and μ being local fields and their representation (1.2a) in terms of nonlocal vertex operators.

The second input is the well-known fact that the (local, but not mutually local) $1+1$-dimensional order and disorder fields σ and μ possess a bilinear factorization into chiral exchange fields a and b along with their adjoints.[6] Exchange fields are also known as non-Abelian vertex operators, referring to the non-Abelian superselection structure of the underlying chiral observables. In the present instance, the chiral observables are generated by the stress-energy tensor T with central charge $c=1/2$, and a and b are the primary fields of scaling dimension $h=1/16$,[7] pertaining to various transitions between the three superselection sectors of T. We shall call a, b, a^+ and b^+ the ''elementary fields'' in the sequel. They are nonlocal Wightman fields. (Still, they are relatively local with respect to the chiral observables; in this sense, all nonlocal fields throughout this article are not as nonlocal as could be. Genuinely nonlocal fields without any organizing local observables might be far more intricate objects.)

We have to distinguish the factorization in two independent light-cone coordinates $u=t+x$, $v=t-x$, as mentioned here, from p-factorization described before. Let Φ and Ψ be two chiral (nonlocal) Wightman fields; then the $\times$-product,

$$(\Phi\times\Psi)(f) = \int dt dx f(t,x)\Phi(t+x)\otimes\Psi(t-x), \tag{1.3}$$

defines a $1+1$-dimensional (*a priori* also nonlocal) Wightman field. The $\times$-product is just the ordinary tensor product of operator-valued distributions (except for the passage to light-cone coordinates), and is therefore the tensor product both as a distribution and as an operator.

The bilinear factorization of the order and disorder fields is given in Eqs. (3.1) below. For the present outline of results, the gross structure,

$$(\sigma \quad \text{and} \quad \mu) \sim (\text{linear}) \times (\text{linear}), \tag{1.4}$$

is sufficient. (Here and in the sequel expressions like ''linear'' or ''quadratic'' mean ''linear or p-quadratic polynomial in the elementary fields.'')

The point is now that the $\times$-product, when restricted along a time-like axis (such as $x=0$), turns into the p-product; symbolically,

$$(\Phi \times \Psi)(t,0) = (\Phi \odot \Psi)(t). \tag{1.5}$$

Thus, restricting a $1+1$-dimensional field which is obtained as a $\times$-product of chiral fields produces the p-product of the chiral fields.

We apply this observation to the decomposition (1.4) and insert it into the Kadanoff-Ceva result (1.2b). This yields a representation of the chiral Abelian vertex operators of charge $\pm 1/2$ (scaling dimension $h=1/8$) as a quadratic p-polynomial in the (nonlocal and non-Abelian) elementary fields of scaling dimension $h=1/16$,

$$E_{\pm 1/2} \sim (\text{quadratic in the elementary fields}). \tag{1.6}$$

The exact formula, Eq. (3.4), is the basic result of the present paper. While it is quite surprising as it stands, it becomes even more interesting by its consequences. Namely, we apply it in several ways by exhibiting various familiar fields of various chiral and two-dimensional models as homogeneous p- and $\times$-product combinations in the elementary fields a and b; we thereby reproduce several well-known observations from a unifying point of view, as well as produce several new results.

(1) In Sec. IV A we give another proof for the massless case of the previously mentioned observation[3] in the ''doubled'' Ising model. It relates the p-squares of the order and disorder fields to the axial potential of the massless Dirac theory. The latter has the form $\varphi_R(t-x)-\varphi_L(t+x)$, so its exponentials are $\times$-product of (oppositely charged) chiral Abelian vertex operators. The identifications given in Ref. 3 are the sine and cosine formulas,

$$\sigma_D \equiv \sigma \odot \sigma \cong \frac{1}{\sqrt{2}i}\,(E_{-1/2} \times E_{1/2} - E_{1/2} \times E_{-1/2}), \tag{1.7a}$$

$$\mu_D \equiv \mu \odot \mu \cong \frac{1}{\sqrt{2}}\,(E_{-1/2} \times E_{1/2} + E_{1/2} \times E_{-1/2}). \tag{1.7b}$$

Since σ and μ are $\times$-bilinear in the elementary fields, their p-squares are $\times$-products of p-quadratic expressions in the elementary fields. The latter arrange in such a way that the basic result turns them into Abelian chiral vertex operators, thus reproducing Eqs. (1.7) (up to a unitary similarity transformation, and only on the joint cyclic Hilbert space of the fields under consideration).

(2) We apply our methods to conformal coset models.[8] In these models, the primary fields with respect to a current algebra are factorized into primary fields with respect to some current subalgebra and primary fields with respect to the corresponding coset algebra (''branching''). This separation of degrees of freedom is another example of p-factorization.

In particular, we consider the $U(2)$ currents of a doublet of complex chiral fermions (the primary fields), and its subalgebra of $SU(2)$ currents at level 1 (Sec. II C). The separation of the $SU(2)$ and $U(1)$ ($=$coset) degrees of freedom of the complex fermion doublet[9] is an instance of

the trivial Abelian p-factorization of Abelian vertex operators as mentioned before. It gives rise to the pseudo-real doublet of $SU(2)$-primary fields represented in terms of chiral Abelian vertex operators with scaling dimension $h=1/4$.

In the next step (Sec. IV B), the latter are p-factorized further into two Abelian vertex operators with scaling dimension $h=1/8$, which in turn are p-quadratic in the elementary fields by the basic result. The resulting p-quartic expression for the level 1 primary fields, when written in the form (linear) $\odot$ (cubic), is precisely the coset model factorization with respect to the coset stress-energy tensor (with central charge $c=1/2$) and the level 2 currents, when the level 2 theory is embedded into the tensor product of two level 1 theories.[8]

The primary chiral exchange fields of scaling dimension $h=3/16$ at level 2 are pseudo-real isospin doublets of non-Abelian exchange fields A_i and B_i along with their adjoints, making transitions between the three sectors of the $SU(2)$ current algebra. The previous discussion yields a p-cubic representation in terms of the elementary fields,

$$A_i \quad \text{and} \quad B_i \sim (\text{cubic in the elementary fields}). \tag{1.8}$$

The exact formulas are Eqs. (4.12) below. This representation explains the observation that the solutions to the Knizhnik–Zamolodchikov equation[10] for isospin 1/2 at level 2 are cubic expressions in the $h=1/16$ conformal blocks of the $c=1/2$ minimal model.[7]

(3) In Sec. IV C we consider the defining matrix field g_{ij} of the Wess–Zumino–Witten (WZW) model (=generalized Thirring model)[11] with $SU(2)_L \times SU(2)_R$ symmetry. It is $\times$-bilinear in the primary chiral exchange field doublet (A_i and B_i and their adjoints) of the level 2 $SU(2)$ current algebra, just as σ and μ factorize into the chiral a and b fields.

According to our previous result (1.8), the chiral exchange field doublets are p-cubic in the elementary fields, and hence g_{ij} are of the form (cubic)$\times$(cubic). It is possible to split off a p-quadratic part in the form of Abelian vertex operators $E_{\pm 1/2}$ in either chiral factor, and the remaining p-factor (linear)$\times$(linear) can be identified with σ and μ for the diagonal and off-diagonal matrix elements. The gross structure is, up to some Klein transformation,

$$\begin{aligned} g_{\text{diag}} &\sim \sigma \odot (E_{\pm 1/2} \times E_{\mp 1/2}), \\ g_{\text{offd}} &\sim \mu \odot (E_{\pm 1/2} \times E_{\pm 1/2}). \end{aligned} \tag{1.9}$$

The trace of g involves σ as well as a field which we already know how to identify with $\sigma \odot \sigma$ by Eq. (1.7a); hence

$$\mathrm{Tr}\, g \cong \sqrt{2}(\sigma \odot \sigma \odot \sigma). \tag{1.10}$$

Next, we restrict g_{ij} to a time-like axis and obtain a p-polynomial of order six in the elementary fields. By Eqs. (1.2a) and (1.9), these polynomials turn into cubic p-products of vertex operators $E_{\pm 1/2}$. The resulting representation (4.19) of $g_{ij|x=0}$ by Abelian chiral vertex operators with scaling dimension 3/8 generalizes Kadanoff's result (1.2a) to the WZW model.

(4) In Sec. IV D we consider p-quadratic expressions in the $1+1$-dimensional matrix field g_{ij}, notably the p-determinant. In terms of the elementary fields, this determinant field is of the form (order six)$\times$(order six). Again arranging p-quadratic polynomials in either chiral factor to yield Abelian vertex operators according to the basic result, and performing some astute similarity transformations, the p-determinant field is finally found to be

$$\mathrm{Det}_{\odot} g \cong \frac{1}{\sqrt{2}i} (E_{-\beta} \times E_{\beta} - E_{\beta} \times E_{-\beta}), \tag{1.11}$$

with charge $\beta = \sqrt{3}/2$ [rather than 1/2 in Eq. (1.7a)]. This generalizes the ''doubling'' result[3] (in the massless case) to the WZW model.

A technical comment might be in order. Throughout the paper, we prove identities between various fields only ''on the cyclic Hilbert space, and up to a unitary similarity transformation which preserves the vacuum vector,'' with the notation $\cong$. This means, of course, no weakening of the statement, since the vacuum expectation values which determine the fields are never af-

fected. A system of fields must of course be subjected to the same transformation. One should, however, keep in mind other fields which are possibly present, and which might or might not be transformed at the same time. Notably, the property of being primary with respect to some chiral stress-energy tensor or current algebra is defined by specific commutation relations with these chiral observables, and will be preserved only if the latter are. This is, e.g., guaranteed if the unitary operator which implements the similarity transformation is a constant on each irreducible representation space of the chiral observables. Otherwise, the latter would have to be transformed along with the primary fields. Even if the state of affairs is not explicitly mentioned in every single instance, it is contextually evident everywhere in the paper by inspection of the specific form of the similarity transformation at hand.

The present work contains the results of the diploma thesis of the first author (KF).[12]

II. PREPARATION OF THE GROUND

A. Abelian vertex operators

Unlike the massless free scalar field in $1+1$ dimensions, its exponentials exist on a positive definite Hilbert space.[1,13–15] Mandelstam[16] has introduced such exponentials depending on only one chiral coordinate when he bosonized the massless Thirring model (at a vanishing coupling constant) in terms of the sine-Gordon model (at $\beta^2=4\pi$). These fields, denoted by $E_\alpha = {:}\exp i\alpha\varphi{:}$ in the sequel, are now known as (Abelian) chiral vertex operators. The ''triple ordering'' [13] refers to the creation and annihilation parts of the auxiliary chiral scalar field and involves a renormalization parameter μ of the dimension of mass which is understood in the limit $\mu \searrow 0$. For rather streamlined treatments see, e.g., Refs. 14 and 17.

The complex free chiral fermion field ψ can be identified with a vertex operator of unit charge $\alpha=1$. Its current $j=:\psi\psi^*:=\partial\varphi$ generates a $U(1)$ symmetry with charge operator $Q=1/(2\pi)\int j(x)dx$. By virtue of

$$QE_\alpha = E_\alpha(Q+\alpha), \tag{2.1}$$

the $U(1)$ symmetry extends to the chiral vertex operators of arbitrary charge α.

Chiral vertex operators of general charge are nonlocal chiral Wightman fields, satisfying anyonic commutation relations,

$$E_\alpha(x)E_\beta(y) = e^{\pm i\pi\alpha\beta}E_\beta(y)E_\alpha(x), \quad \text{if } x\neq y, \tag{2.2}$$

with the sign $\pm=\mathrm{sign}(x-y)$ in the exponent. They are conformally covariant fields with scaling dimension $h=\alpha^2/2$ with respect to the stress-energy tensor $i/(4\pi):\psi\overleftrightarrow{\partial}\psi^*:=1/(4\pi):j^2:$ of the complex fermion (with central charge $c=1$).

The vacuum expectation values of chiral vertex operators satisfy charge conservation and are given by

$$\langle\Omega, E_{\alpha_1}(x_1)\ldots E_{\alpha_n}(x_n)\Omega\rangle = \prod_{i<j}\Delta(x_i-x_j)^{-\alpha_i\alpha_j}, \quad \text{provided } \sum \alpha_i = 0. \tag{2.3}$$

The distributions,

$$\Delta(x-y)^{2h} = \left[\frac{-i}{x-y-i\epsilon}\right]^{2h} = \frac{1}{\Gamma(2h)}\int_0^\infty dk k^{2h-1}e^{-ik(x-y)}, \tag{2.4}$$

contributing to these v.e.v.'s have spectral support on the positive momenta.

Abelian chiral vertex operators with multi-component charges can be defined as exponentials of several independent massless free fields, e.g.,

$$E_{(\alpha,\beta)} = {:}\exp i(\alpha\varphi_1+\beta\varphi_2){:} \cong E_\alpha \odot E_\beta. \tag{2.5}$$

Their vacuum expectation values are given by the same formula (2.3), replacing only products of charges by scalar products of multi-component charges. This replacement results in the factorization of the total v.e.v.'s into the v.e.v.'s for the charge components and therefore justifies the equivalence with the p-product in Eq. (2.5)

On the other hand, it implies an obvious $O(N)$ symmetry for the vertex operators with N-component charges, corresponding to rotations and reflections in charge space. Therefore on its own cyclic Hilbert space, the field (2.5) is also equivalent to $E_{\sqrt{\alpha^2+\beta^2}}$.

B. Exchange fields

Chiral exchange fields arise by a spectral decomposition with respect to global conformal transformations of $1+1$-dimensional fields with conformal symmetry[18] and subsequent chiral factorization. They arise also as point-like limits of bounded intertwining operators in the framework of algebraic quantum field theory,[19,20] or as intertwiners between modules of chiral symmetry algebras such as Virasoro or affine Kac-Moody algebras.[21] They are the fundamental charge-carrying entities which make transitions between the various superselection sectors of a theory of local chiral observables. As such, they are defined on a ''source'' Hilbert space and take values in a ''range'' Hilbert space which are both irreducible sectors of the observables, and are relatively local with respect to the latter.

In specific models where the chiral observables are generated by the stress-energy tensor or by a current algebra, it is convenient to distinguish ''primary'' exchange fields by their specific commutation relations with the observables. These imply certain partial differential equations, reflecting the symmetry of the model, for the vacuum expectation values of primary exchange fields whose solutions are known as ''conformal blocks.'' [7,10] The commutation relations of chiral exchange fields with each other are given by a non-Abelian representation of the braid group. Abelian vertex operators (restricted to a charge sector) are the exchange fields with respect to an Abelian current algebra.

The primary chiral exchange fields of the Ising model were first treated in detail in Ref. 6. In this model, the chiral observables are generated by the stress-energy tensor with central charge $c=1/2$. There are three superselection sectors, which carry representations of the conformal group with primary scaling dimensions 0, 1/16 and 1/2, respectively.

The primary field for the trivial sector 0 is just the unit operator. The primary field for the sector 1/2 is a real free fermion. There are three exchange fields corresponding to this primary field, which are given by the free fermion field in the Neveu-Schwarz representation restricted to the subspaces of even and odd Fermi number, and the free Fermi field in the Ramond representation. The former two are each other's adjoints $\psi_{\mathrm{NS}}:\mathscr{H}_0\to\mathscr{H}_{1/2}$ and $\psi_{\mathrm{NS}}^+:\mathscr{H}_{1/2}\to\mathscr{H}_0$, and the latter is a self-adjoint field $\psi_{\mathrm{R}}:\mathscr{H}_{1/16}\to\mathscr{H}_{1/16}$.

The primary exchange fields for the sector 1/16 are the chiral constituents of the order and disorder parameter of the $1+1$-dimensional Ising model. There are two ''raising'' operators a and b along with their adjoints:

$$\begin{aligned} &a:\mathscr{H}_0\to\mathscr{H}_{1/16} \quad \text{and its adjoint} \quad a^+:\mathscr{H}_{1/16}\to\mathscr{H}_0,\\ &b:\mathscr{H}_{1/16}\to\mathscr{H}_{1/2} \quad \text{and its adjoint} \quad b^+:\mathscr{H}_{1/2}\to\mathscr{H}_{1/16}. \end{aligned} \tag{2.6}$$

The commutation relations of these chiral exchange fields are given by a non-Abelian representation of the braid group of the Hecke type.[6]

We have chosen the normalization such that the two-point function is $\langle\Omega,a^+(x)a(y)\Omega\rangle = \Delta(x-y)^{1/8}$. The only possible four-point functions are given by

$$\begin{aligned} \langle\Omega,a^+(x_1)a(x_2)a^+(x_3)a(x_4)\Omega\rangle &= V^{1/8}\cdot f(x),\\ \langle\Omega,a^+(x_1)b^+(x_2)b(x_3)a(x_4)\Omega\rangle &= V^{1/8}\cdot g(x), \end{aligned} \tag{2.7}$$

where the first factor with

$$V(x_1,x_2,x_3,x_4)=\frac{\Delta(x_1-x_2)\Delta(x_3-x_4)\Delta(x_1-x_4)\Delta(x_2-x_3)}{\Delta(x_1-x_3)\Delta(x_2-x_4)} \tag{2.8}$$

is the four-point function of Abelian vertex operators with alternating charges and the proper scaling dimension 1/16, and the ''conformal block'' functions,

$$f(x)=\sqrt{\tfrac{1}{2}\,(1+\sqrt{1-x})}\quad\text{and}\quad g(x)=\sqrt{\tfrac{1}{2}\,(1-\sqrt{1-x})} \tag{2.9}$$

depend only on the conformally invariant cross ratio $x=\Delta(x_1-x_3)\Delta(x_2-x_4)/\Delta(x_1-x_2)\Delta(x_3-x_4)$.

The higher $2n$-point functions were derived in closed form in Ref. 6.

C. The $SU(2)$ primary fields at level 1 in terms of vertex operators

A doublet of complex free chiral fermions $\psi_\pm$ gives rise to a theory with $U(2)$ symmetry. Its stress-energy tensor with $c=2$ is given by $T=(i/4\pi)(:\psi_+\overleftrightarrow{\partial}\psi_+^*:+:\psi_-\overleftrightarrow{\partial}\psi_-^*:)$, and the currents are

$$j^A=:\psi_i\tau^A_{ij}\psi_j^*:\quad (A=0,1,2,3), \tag{2.10}$$

where $\tau^0=\mathbb{1}$ and τ^a $(a=1,2,3)$ are the Pauli matrices.

The component j^0 generates the Abelian $U(1)$ current algebra with stress-energy tensor $T_U=1/(8\pi):(j^0)^2:(c=1)$, and j^a generate the $SU(2)$ current algebra at level 1 with stress-energy tensor T_S given by the Sugawara formula quadratic in the currents $(c=1)$, such that $T=T_U+T_S$. The $U(1)$ and the $SU(2)$ currents commute with each other, and both transform the fermion doublet in the obvious way.

The $U(1)$ and the $SU(2)$ degrees of freedom of the fermion doublet can be separated as follows in a very explicit manner.[9] The crucial point is the fact that chiral charged fermions can be represented by Abelian vertex operators of unit charge.

The doublet of charged chiral fermions can be represented by a pair of Abelian vertex operators with orthogonal unit charge vectors $\alpha_\pm$. Since the latter constitute a pair of commuting fermions, a Klein transformation is needed to make them anti-commute. Rather than the standard choice [multiplying, e.g., E_{α_+} by the exponential $\exp(i\pi\alpha_- Q)$ of the charge operator of the other component], we prefer a more symmetric one and multiply both components by $\exp[i\pi(\alpha_+-\alpha_-)Q/2]$. Both choices are unitarily equivalent by conjugation with the exponential of some quadratic polynomial of the charge operators.

We choose $\alpha_\pm=1/\sqrt{2}\cdot(1,\pm 1)$ and apply the p-factorization of multi-component vertex operators [Eq. (2.5)]. This gives rise to the simple p-factorization,

$$\psi_\pm=\phi\odot\phi_\pm, \tag{2.11}$$

where

$$\phi=E_\alpha \tag{2.12}$$

is an ordinary Abelian vertex operator of charge $\alpha=1/\sqrt{2}$ carrying the $U(1)$ symmetry, and

$$\phi_\pm=E_{\pm\alpha}e^{i\pi\alpha Q} \tag{2.13}$$

is a pseudo-real doublet carrying the $SU(2)$ symmetry. Pseudo-reality means

$$\phi_i^*=i\epsilon_{ij}\phi_j C=-i\epsilon_{ij}C\phi_j, \tag{2.14}$$

where $\epsilon_{+-}=1$ and $C=e^{2\pi i\alpha Q}=C^{-1}$ is a Casimir operator which equals $+1$ (-1) on all states of integer (half-integer) isospin and thus commutes with the $SU(2)$ symmetry.

In this representation, the factorization of the current algebra becomes manifest: the $U(1)$ current is $j^0=\sqrt{2}\partial\varphi\otimes\mathbb{1}$, and the $SU(2)$ currents are found in the Frenkel–Kac[22] representation $j^3=\mathbb{1}\otimes\sqrt{2}\partial\varphi$ and $j^\pm=\mathbb{1}\otimes E_{\pm\sqrt{2}}$.

Both the $U(1)$ field and the $SU(2)$ doublet are primary fields w.r.t. the respective current algebra, and have scaling dimension $h=1/4$. They both satisfy anyonic commutation relations according to Eq. (2.2), modified for the doublet by the Klein factor $e^{i\pi\alpha Q}$. The two-point functions are $\langle\Omega,\phi^*\phi\Omega\rangle=\Delta^{1/2}$ and $\langle\Omega,\phi_i^*\phi_j\Omega\rangle=\delta_{ij}\Delta^{1/2}$ or equivalently $\langle\Omega,\phi_i\phi_j\Omega\rangle=-i\epsilon_{ij}\Delta^{1/2}$.

The cyclic Hilbert space of the pseudo-real doublet contains all charges which are integer multiples of $\alpha=1/\sqrt{2}$. The primary exchange fields which interpolate the two sectors of the $SU(2)$ current algebra at level 1 (integer and half-integer isospin), are obtained by restricting $\phi_\pm$ to the subspaces of even or odd charge in units of α, or equivalently of integer or half-integer isospin.

D. Goddard–Kent–Olive (GKO) coset construction

Consider two current algebras $\mathscr{A}_i$ for some simple Lie group G at level k_i generated by the currents j_i^a, and with stress-energy tensor T_i given by the affine Sugawara formula. The diagonal currents,

$$J^a=j_1^a\otimes\mathbb{1}+\mathbb{1}\otimes j_2^a, \tag{2.15}$$

generate a current algebra $\mathscr{A}$ at level k_1+k_2 within $\mathscr{A}_1\otimes\mathscr{A}_2$. This current algebra has its own stress-energy tensor T given by the Sugawara formula in terms of J^a which has the same commutation relations with J^a as the total stress-energy tensor $T_1\otimes\mathbb{1}+\mathbb{1}\otimes T_2$. The difference T_{coset} is a stress-energy tensor which commutes with the current algebra $\mathscr{A}$. It belongs (possibly along with other operators) to the coset model $\mathscr{C}$ of fields in $\mathscr{A}_1\otimes\mathscr{A}_2$ commuting with $\mathscr{A}$.

Embedding a primary exchange field at level k_1 by the prescription $\phi\otimes\mathbb{1}$ into the Hilbert space of $\mathscr{A}_1\otimes\mathscr{A}_2$, yields operators which have primary commutation relations with both the diagonal currents J^a and the coset stress-energy tensor. Therefore, according to the same scheme of separation of degrees of freedom as in Sec. II C, there is a factorization of the form

$$\phi\otimes\mathbb{1}\cong\sum\ \varphi_c\odot\varphi, \tag{2.16}$$

where φ_c are primary exchange fields w.r.t. the coset theory and φ are primary exchange fields w.r.t. the current algebra at level k_1+k_2. The quantum numbers of the exchange fields on the right hand side are determined by the branching rules of representations of $\mathscr{A}_1\otimes\mathscr{A}_2$ in restriction to $\mathscr{C}\otimes\mathscr{A}$; in particular, φ carries the G quantum numbers, and the scaling dimensions are additive.

The symbol $\odot$ on the right hand side of the GKO decomposition (2.16) refers to the tensor product of representation spaces of $\mathscr{C}\otimes\mathscr{A}$, while in contrast, on the left hand side $\otimes$ refers to the tensor product $\mathscr{A}_1\otimes\mathscr{A}_2$. The passage is made by a reorganization of the Hilbert space which, in a special case, will become explicit along the way in Sec. IV B.

III. THE BASIC RESULT

Chiral exchange fields can be combined in various ways to yield local $1+1$-dimensional fields. A systematic way to do so was described in Ref. 23 in terms of the algebraic theory of superselection sectors. (Helas, the assignment of σ and μ was interchanged in Ref. 23, and no care was taken to construct local fields which are closed under conjugation; in order to repair that defect, the self-adjoint local fields below differ from the result in Ref. 23 by a nonunitary similarity transformation. One can actually adjust the correct formulas ''by hand'' from the known commutation relations and four-point functions of the elementary a and b fields[6] by imposing the correct commutation relations[3] and four-point functions[6] for σ and μ.)

The upshot is the following. The local field σ interpolates between the ''diagonal'' charge sectors $\mathscr{H}_{ss}\equiv\mathscr{H}_s\otimes\mathscr{H}_s$ where $\mathscr{H}_s$ $(s=0,\frac{1}{16},\frac{1}{2})$ are the three superselection sectors of the chiral observables. It is given by the standard formula $\sigma=a\times a+b\times b+(\text{h.c.})$. The field μ, however carries an ''excess $\mathbb{Z}_2$ charge'' which makes transitions to the ''nondiagonal'' sectors $\mathscr{H}_{0(1/2)}$, $\mathscr{H}_{(1/2)0}$ and another copy of $\mathscr{H}_{(1/16)(1/16)}$. In order to describe both fields simultaneously, σ has of course to be defined also on the nondiagonal sectors. There is some ambiguity on how to define these fields which consists in unitary similarity transformations (which commute with the chiral

observables in order not to spoil the primary commutation relations). These unitaries are given by a complex phase on each of the four simple sectors, and a unitary 2×2 matrix which mixes the two copies of $\mathscr{H}_{(1/16)(1/16)}$.

Our representation of choice is the following:

$$\sigma = u\otimes(a\times a + b^+\times b^+) + v\otimes(a\times b^+ + b^+\times a) + (\text{h.c.}). \tag{3.1a}$$

$$\mu = v\times(a\times a - b^+\times b^+) + iu\otimes(a\times b^+ - b^+\times a) + (\text{h.c.}). \tag{3.1b}$$

We introduced two orthogonal unit vectors u and v in $\mathbb{C}^2$ in order to distinguish the two copies of $\mathscr{H}_{(1/16)(1/16)}$ within $\mathscr{H}_{(1/16)(1/16)}\oplus\mathscr{H}_{(1/16)(1/16)} = \mathbb{C}^2\otimes\mathscr{H}_{(1/16)(1/16)}$; they are multiplied like rectangular matrices. Obviously, σ preserves both $\mathscr{H}_{00}\oplus(u\otimes\mathscr{H}_{(1/16)(1/16)})\oplus\mathscr{H}_{(1/2)(1/2)}$ and $\mathscr{H}_{0(1/2)}\oplus(v\otimes\mathscr{H}_{(1/16)(1/16)})\oplus\mathscr{H}_{(1/2)0}$, while μ alternates between these spaces. Conversely, μ preserves the analogous spaces with u and v interchanged, while σ alternates between them. The following diagram summarizes the situation: σ interpolates according to the horizontal arrows, while μ interpolates according to the diagonal arrows:

$$\begin{array}{ccccc} (00) & \longleftrightarrow & u\otimes(\frac{1}{16}\frac{1}{16}) & \longleftrightarrow & (\frac{1}{2}\frac{1}{2}) \\ & \nwarrow\!\!\searrow & & \nwarrow\!\!\searrow & \\ (0\tfrac{1}{2}) & \longleftrightarrow & v\otimes(\frac{1}{16}\frac{1}{16}) & \longleftrightarrow & (\tfrac{1}{2}0) \end{array} \tag{3.2}$$

Every single term in (3.1) corresponds to an arrow in (3.2).

Our normalization is such that the two-point functions are $\langle\Omega,\sigma\sigma\Omega\rangle = \langle\Omega,\mu\mu\Omega\rangle = (\Delta_L\Delta_R)^{1/8}$ in terms of the left- and right-moving light-cone coordinates. All mixed four-point functions,[6] e.g., $\langle\Omega,\mu\mu\sigma\sigma\Omega\rangle = (V_LV_R)^{1/8}(f_Lf_R - g_Lg_R)$, can be read off Eqs. (2.7) and (3.1).

Each of the fields σ and μ satisfies local commutativity at a space-like distance with itself, but they are not mutually local. Instead, they satisfy the ''dual'' commutation relations,[4]

$$\sigma(x)\mu(y) = \pm\mu(y)\sigma(x), \quad \text{if} \quad (x-y)^2<0, \tag{3.3}$$

with the sign $\pm = \text{sign}\,(x^1-y^1)$.

Let us consider now the Kadanoff-Ceva formulas (1.2). Evaluating the fields σ and μ at $x=0$ means replacing the $\times$-product in (3.1) by the p-product $\odot$. The projections P_+ and P_- project onto the subspaces generated from the vacuum by an even, resp., odd number of applications of the fields σ and μ, i.e., P_+ projects onto $\mathscr{H}_+ = \oplus_{s,t=0,1/2}\,\mathscr{H}_{st}$ while P_- projects onto $\mathscr{H}_- = \mathbb{C}^2\otimes\mathscr{H}_{(1/16)(1/16)}$.

Thus inserting (3.1) into (1.2b) yields the basic result,

$$\begin{aligned} E_{+1/2} = {} & u\otimes(a\odot a + b^+\odot b^+) - iu^+\otimes(a^+\odot b - b\odot a^+) \\ & + v\otimes(a\odot b^+ + b^+\odot a) + v^+\otimes(a^+\odot a^+ - b\odot b), \end{aligned} \tag{3.4}$$

and $E_{-1/2} = E^*_{+1/2}$

Like all formulas below, Eq. (3.4) can easily be checked in all mixed four-point functions of $E_{\pm 1/2}$, using Eqs. (2.3) and (2.7). The important point is, however, its validity on the entire joint cyclic Hilbert space of these fields.

The charge conjugation invariance $E_{+1/2}\leftrightarrow E_{-1/2}$ is manifest in this representation. It is implemented by the involutive unitary operator $\Pi\cdot(P_{00} + iP_{0(1/2)} - iP_{(1/2)0} - P_{(1/2)(1/2)} + M\otimes P_{(1/16)(1/16)})$ involving the discrete ''flip'' operator Π: $\mathscr{H}_{st}\to\mathscr{H}_{ts}$ which interchanges the two tensor factors, and a matrix M in the multiplicity space of $\mathscr{H}_{(1/16)(1/16)}$ which interchanges u and v.

Equation (3.4) shows a $\mathbb{Z}_4$ charge structure as follows. We redisplay the diagram (3.2) with only the arrows pertaining to the combinations $\varepsilon := \sigma P_+ + \mu P_-$ or $E_{+1/2} \equiv \varepsilon|_{x=0}$:

$$\begin{array}{ccccc} (00) & \longrightarrow & u \otimes (\frac{1}{16}\frac{1}{16}) & \longleftarrow & (\frac{1}{2}\frac{1}{2}) \\ & \nwarrow\!\!\searrow & & \swarrow\!\!\nearrow & \\ (0\frac{1}{2}) & \longrightarrow & v \otimes (\frac{1}{16}\frac{1}{16}) & \longleftarrow & (\frac{1}{2}0) \end{array} \tag{3.5}$$

It becomes apparent that the subspaces H_i given by

$$\begin{aligned} H_0 &= \mathscr{H}_{00} \oplus \mathscr{H}_{(1/2)(1/2)}, \quad H_1 = u \otimes \mathscr{H}_{(1/16)(1/16)}, \\ H_2 &= \mathscr{H}_{0(1/2)} \oplus \mathscr{H}_{(1/2)0}, \quad H_3 = v \otimes \mathscr{H}_{(1/16)(1/16)}, \end{aligned} \tag{3.6}$$

are the subspaces of charge $(i \bmod 4)\frac{1}{2}$. The four terms in Eq. (3.4) correspond in turn to $P_{i+1} E_{+1/2} P_i = E_{+1/2} P_i$, $i = 0,1,2,3$.

In terms of these subspaces we have the interpolation diagrams

$$\sigma: \begin{cases} H_0 \leftrightarrow H_1 \\ H_3 \leftrightarrow H_2, \end{cases} \quad \mu: \begin{cases} H_0 & H_1 \\ \updownarrow & \updownarrow, \\ H_3 & H_2 \end{cases} \quad \varepsilon, E_{1/2}: \begin{cases} H_0 & \rightarrow & H_1 \\ \uparrow & & \downarrow. \\ H_3 & \leftarrow & H_2 \end{cases} \tag{3.7}$$

The $\mathbb{Z}_4$ symmetry of the $1+1$-dimensional field ε together with the two $\mathbb{Z}_2$'s $\sigma \to -\sigma$ and $\mu \to -\mu$ generate a total discrete symmetry $\mathbb{Z}_4 \times \mathbb{Z}_2$ (the diagonal of the two $\mathbb{Z}_2$'s coinciding with the $\mathbb{Z}_2$ subgroup of $\mathbb{Z}_4$). Upon restriction to the line, ε turns into the chiral field $E_{1/2}$ and the $\mathbb{Z}_4$ symmetry is enhanced to U(1), corresponding to the Kadanoff–Ceva Γ-charge.

In this picture, the real chiral Ising fermions ψ_L and ψ_R arising in the operator product expansions of $\mu\sigma$ and $\sigma\mu$ carry two units of $\mathbb{Z}_4$ charge.

IV. APPLICATIONS

A. The doubled Ising model

In contrast to the order and disorder fields $\varphi = \sigma, \mu$ with their dual commutation relations (3.3), the ''doubled'' fields $\varphi_D = \varphi \odot \varphi$ satisfy local commutativity also with each other. The asserted identifications (1.7) which we are going to establish are equivalent to

$$\mu_D + i\sigma_D \cong \sqrt{2} \cdot E_{-1/2} \times E_{1/2}, \tag{4.1}$$

where the fields on the right hand side are also local fields made from anyonic chiral constituents.[17]

We compute $E_{-1/2} \times E_{1/2}$ from the basic result (3.4). Its cyclic Hilbert space involves only the conjugate charge sectors $H_{-i} \otimes H_i$. For the vacuum expectation values, we may therefore omit all terms which are defined on $H_j \otimes H_i$, $j \neq -i$. The remaining terms are

$$\begin{aligned} E_{-1/2} \times E_{1/2} \cong\ & Y \otimes (aa - b^+b^+) \times (aa + b^+b^+) + iX \otimes (ab^+ - b^+a) \times (ab^+ + b^+a) \\ & + X^+ \otimes (a^+a^+ + bb) \times (a^+a^+ - bb) - iY^+ \otimes (a^+b + ba^+) \times (a^+b - ba^+), \end{aligned} \tag{4.2}$$

on the cyclic subspace. We omitted the $\odot$ symbols, and put $X = u \otimes v$, $Y = v \otimes u$.

On the other hand, we compute the doubled fields from Eqs. (3.1). Each of the fields σ and μ, according to the scheme (3.7), takes each of the subspaces H_i into a specific H_j. Hence repeated application of the doubled fields connects the vacuum sector $H_0 \otimes H_0$ only with the diagonal sectors $H_i \otimes H_i$, and the latter again exhaust the joint cyclic Hilbert space. Thus we obtain

$$\begin{aligned}\mu_D+i\sigma_D\cong&(V+iU)\otimes(aa\times aa+b^+b^+\times b^+b^++iaa\times b^+b^++ib^+b^+\times aa)\\&-(V-iU)\otimes(ab^+\times ab^++b^+a\times b^+a-iab^+\times b^+a-ib^+a\times ab^+)\\&+(V^++iU^+)\otimes(a^+a^+\times a^+a^++bb\times bb+ia^+a^+\times bb+ibb\times a^+a^+)\\&-(V^+-iU^+)\otimes(a^+b\times a^+b+ba^+\times ba^+-ia^+b\times ba^+-iba^+\times a^+b),\end{aligned}\tag{4.3}$$

on the joint cyclic subspace. We put $U=u\otimes u$, $V=v\otimes v$ and arranged the factors as $(A\times B)\odot(C\times D)\simeq(A\odot C)\times(B\odot D)$. Note that due to the different factor ordering, the individual subspaces $H_j\otimes H_i$ in Eq. (4.2) are different from $H_j\otimes H_i$ in Eq. (4.3).

Equation (4.3) is transformed into $\sqrt{2}$ times Eq. (4.2) by conjugation with a unitary operator which preserves the vacuum vector. The operator which does the job equals (in an obvious notation) $(P_{00\times00}-P_{(1/2)(1/2)\times(1/2)(1/2)}+P_{0(1/2)\times(1/2)0}-P_{(1/2)0\times0(1/2)})+i(P_{00\times(1/2)(1/2)}-P_{(1/2)(1/2)\times00}+P_{0(1/2)\times0(1/2)}-P_{(1/2)0\times(1/2)0})+M\otimes P_{(1/16)(1/16)\times(1/16)(1/16)}$, with a unitary matrix M in the multiplicity space of $\mathscr{K}_{(1/16)(1/16)}\otimes\mathscr{K}_{(1/16)(1/16)}$ taking $V+iU\mapsto\sqrt{2}Y$ and $V-iU\mapsto\sqrt{2}X$. This similarity transformation commutes with the chiral observables of the doubled Ising field theory (two stress-energy tensors with central charge $c=1/2$ on each light-cone), and therefore preserves the structure of the full model.

It might be objected that one obtains apparently different results when one restricts the doubled fields according to Eqs. (1.7) to the line $x=0$, and when one doubles the restricted fields according to Eqs. (1.2a); namely,

$$\begin{aligned}\sigma_D|_{x=0}&=\frac{1}{\sqrt{2}i}\,(E_\alpha-E_{-\alpha}) & (\sigma|_{x=0})_D&=E_\alpha P_++E_{-\alpha}P_-,\\ &\text{vs}\\ \mu_D|_{x=0}&=\frac{1}{\sqrt{2}}\,(E_\alpha+E_{-\alpha}) & (\mu|_{x=0})_D&=E_{-\alpha}P_++E_\alpha P_-,\end{aligned}\tag{4.4}$$

where $P_\pm$ now project on the spaces of even, resp., odd charge in units of $\alpha=1/\sqrt{2}$. In fact, the latter form can be transformed into the former by a chain of similarity transformations exploiting $SU(2)$ invariance. It is implemented by the unitary operator $\mathscr{T}e^{-i\pi(\alpha Q)^2}\mathscr{U}e^{i\pi(\alpha Q)^2}$ where first $e^{i\pi(\alpha Q)^2}$ transforms the Abelian vertex operators into the pseudo-real $SU(2)$ doublet $\phi_\pm$ along with the $SU(2)$-invariant Casimir operator $C=P_+-P_-$ (cf. Sec. II C); next the $SU(2)$ transformation $\mathscr{U}$ takes $\phi_\pm\mapsto\sqrt{(\mp i/2)}(\phi_+\mp\phi_-)$, then $e^{-i\pi(\alpha Q)^2}$ reproduces the vertex operators, and finally $\mathscr{T}=P_++\sqrt{-i}P_-$ (which commutes with the other three operators) removes the charge dependence. We refrain from an explicit demonstration, since a similar transformation will be discussed in detail later (Sec. IV D).

B. The $SU(2)$ primary fields at level 2

We consider the GKO coset $(SU(2)_1\times SU(2)_1)/SU(2)_2$. The coset algebra is the chiral stress-energy tensor with $c=1/2$ whose primary exchange fields were described in Sec. II B.

The level 2 current algebra has also three sectors $\mathscr{K}_I$ distinguished by the isospin $I=0,1/2,1$ of the ground states of the conformal Hamiltonian. The primary exchange fields of isospin $I=1/2$ are four $SU(2)$ doublets which make transitions in analogy to Eqs. (2.6):

$$\begin{aligned}A_i&:\mathscr{K}_0\to\mathscr{K}_{1/2}\quad\text{and}\quad A_i^+:\mathscr{K}_{1/2}\to\mathscr{K}_0,\\ B_i&:\mathscr{K}_{1/2}\to\mathscr{K}_1\quad\text{and}\quad B_i^+:\mathscr{K}_1\to\mathscr{K}_{1/2}.\end{aligned}\tag{4.5}$$

The fields A_i^+ and B_i^+ are not the adjoints of A_i and B_i, since the latter transform in the conjugate representation. We may, however, choose the normalizations such that

$$X_i^*=-\epsilon_{ij}X_j^+,\quad (X_i^+)^*=\epsilon_{ij}X_j\quad(X=A,B,\ \ i,j=\pm).\tag{4.6}$$

Like the elementary fields, the chiral exchange fields of the $SU(2)$ level 2 current algebra satisfy braid group commutation relations given by another non-Abelian Hecke type representation.

The two-point function is $\langle\Omega,A_i^+A_j\Omega\rangle=\epsilon_{ij}\Delta^{3/8}$. The only nonvanishing four-point functions of these exchange fields have the structure $\langle\Omega,A_i^+A_jA_k^+A_l\Omega\rangle=V^{3/8}\cdot F_{ijkl}(x)$ and $\langle\Omega,A_i^+B_j^+B_kA_l\Omega\rangle=V^{3/8}\cdot G_{ijkl}(x)$, with V and x as in Sec. II B. The $SU(2)$ tensors F and G are the two independent ''conformal block'' solutions to the Knizhnik-Zamolodchikov differential equation,

$$\left[(k+2)\partial_x-\frac{C_{12}}{x}+\frac{C_{23}}{1-x}\right]W(x)=0, \tag{4.7}$$

where $k=2$ is the level and $C_{mn}=\Sigma_a(I_m^a+I_n^a)^2$ are the quadratic $SU(2)$ Casimir operators on the product representations due to the m-th and n-th field entry. The solutions

$$\begin{aligned} F_{ijkl}&=\epsilon_{ij}\epsilon_{kl}\cdot f(f^2+g^2)-\epsilon_{ik}\epsilon_{jl}\cdot 2\,fg^2,\\ G_{ijkl}&=-\epsilon_{ij}\epsilon_{kl}\cdot g(f^2+g^2)+\epsilon_{ik}\epsilon_{jl}\cdot 2\,f^2g, \end{aligned} \tag{4.8}$$

involve the same functions $f(x)$ and $g(x)$ as in Eq. (2.9).

Our intention is to give an explanation for the cubic structure of these vacuum expectation values in terms of the v.e.v.'s of the elementary fields. For this purpose, we recall how the level 2 primary exchange fields can be obtained by the GKO coset construction from the level 1 primaries $\phi_\pm\otimes\mathbb{1}$.

According to the general discussion in Sec. II D, the branching rules (in particular, the $SU(2)$ quantum numbers and scaling dimensions) determine the possible terms in the coset factorization of $\phi_\pm\otimes\mathbb{1}$. The result is

$$\phi_i\otimes\mathbb{1}=a\odot A_i-ia^+\odot A_i^++b\odot B_i+ib^+\odot B_i^+\,. \tag{4.9}$$

Here the absolute coefficients 1 in front of the first and third term are chosen by a normalization freedom, and the relative coefficients $\pm i$ in front of the adjoint terms are determined by the pseudo-reality property (2.14) of ϕ_i along with Eq. (4.6). Equation (4.9) can be cross-checked by inserting the four-point functions (2.7) and (4.8) and comparing with the four-point functions of $\phi_\pm$ which are computed with the help of Eqs. (2.13) and (2.3).

Now comes the crucial step. According to Eq. (2.13), $\phi_\pm$ have a representation in terms of vertex operators of charge $\pm\alpha$ with $\alpha^2=\frac{1}{2}$. According to Eq. (2.5) with the choice $\alpha=(\frac{1}{2},\frac{1}{2})$, the latter can be written in the form $E_{\pm1/2}\odot E_{\pm1/2}$, and according to Eq. (3.4), the vertex operators of charge $\pm\frac{1}{2}$ can be written as p-quadratic polynomials in the elementary exchange fields. The operator $e^{i\pi\alpha Q}$ in (2.13) takes values i^p in the sectors of charge $p\alpha$, and the charge quantum numbers p mod 4 in the representation (3.4) have been described in Eqs. (3.5) and (3.6). Since in the cyclic Hilbert space of $E_{\pm1/2}\odot E_{\pm1/2}$ only these ''diagonal'' charges occur, the mixed terms can be omitted from the p-square of (3.4). The result is

$$\begin{aligned} \phi_+\otimes\mathbb{1}\cong&[u\otimes(a\odot a+b^+\odot b^+)]^{\odot2}+i[-iu^+\otimes(a^+\odot b-b\odot a^+)]^{\odot2}\\ &-[v\otimes(a\odot b^++b^+\odot a)]^{\odot2}-i[v^+\otimes(a^+\odot a^+-b\odot b)]^{\odot2}. \end{aligned} \tag{4.10}$$

We reorder this expression by separating the first p-factor (and at the same time make it more lucid by omitting the $\otimes$ and $\odot$ signs):

$$\begin{aligned} \phi_+\otimes\mathbb{1}\cong&\,a\odot[Ua(aa+b^+b^+)-Vb^+(ab^++b^+a)]+a^+\odot[-iU^+b(a^+b-ba^+)\\ &-iV^+a^+(a^+a^+-bb)]+b\odot[iU^+a^+(a^+b-ba^+)+iV^+b(a^+a^+-bb)]\\ &+b^+\odot[Ub^+(aa+b^+b^+)-Va(ab^++b^+a)], \end{aligned} \tag{4.11}$$

where $U=u\otimes u$, $V=v\otimes v$ are just another pair of orthogonal unit vectors pointing to two of the four copies of $\mathscr{H}^{\otimes2}_{(1/16)(1/16)}$ in the representation space of $E_{\pm1/2}\odot E_{\pm1/2}$.

Of course, also the embedded field $1\otimes\phi_\pm$ has an equivalent representation in terms of exchange fields of the coset and level 2 chiral observables. It does, however, not live on the same cyclic Hilbert space $(\mathscr{H}_0\otimes\mathscr{H}_0)\oplus(\mathscr{H}_{1/16}\otimes\mathscr{H}_{1/2})\oplus(\mathscr{H}_{1/2}\otimes\mathscr{H}_1)$ as $\phi_\pm\otimes1$. For example, the field

$\phi_+ \odot \phi_+$ belongs to a triplet of the diagonal $SU(2)$ and has scaling dimension 1/2. These quantum numbers are found in the sectors $\mathscr{H}_0 \otimes \mathscr{H}_1$ and $\mathscr{H}_{1/2} \otimes \mathscr{H}_0$. In fact, the joint cyclic Hilbert space contains apart from the mentioned five sectors also a second copy of $\mathscr{H}_{1/16} \otimes \mathscr{H}_{1/2}$, where the two embedded doublets have similar interpolation properties as σ and μ in (3.2). We refrain from computing these formulas.

By comparing (4.11) with (4.9), we read off the p-cubic representations of the level 2 primary exchange doublet:

$$\begin{aligned} A_+ &= Ua(aa + b^+b^+) - Vb^+(ab^+ + b^+a), \\ A_+^+ &= U^+b(a^+b - ba^+) + V^+a^+(a^+a^+ - bb), \\ B_+ &= iU^+a^+(a^+b - ba^+) + iV^+b(a^+a^+ - bb), \\ B_+^+ &= -iUb^+(aa + b^+b^+) + iVa(ab^+ + b^+a), \end{aligned} \tag{4.12}$$

while the $-$ components are determined by (4.6).

This interpretation of (4.11) means that we choose the embedding in such a way that the coset stress-energy tensor (with $c = 1/2$) acts on the Hilbert spaces belonging to the first p-factor. Then the Sugawara stress-energy tensor of the level 2 current algebra (with $c = 3/2$) acts on the triple tensor products of Hilbert spaces belonging to the remaining three p-factors in the form of three commuting $c = 1/2$ ''stress-energy tensors.'' The latter, of course, do not individually generate the conformal transformations of any level 2 fields, nor are the level 2 currents defined on the individual factor Hilbert spaces; the true stress-energy tensor with $c = 3/2$ is the sum of the three $c = 1/2$ fields.

A nontrivial cross-check of our result (4.12) is that it reproduces the four-point functions (4.8) [using Eq. (2.7)].

Finally, for later use, we display another representation which amounts to viewing the last two p-factors in (4.12) together with the multiplicity vectors as contributions to the Abelian vertex operators from which they originate [cf. Eq. (3.4)]. In this form,

$$\begin{aligned} A_+ &= a \odot E_+ P_0 - b^+ \odot E_+ P_2, \\ A_+^+ &= ib \odot E_+ P_1 + a^+ \odot E_+ P_3, \\ B_+ &= -a^+ \odot E_+ P_1 + ib \odot E_+ P_3, \\ B_+^+ &= -ib^+ \odot E_+ P_0 + ia \odot E_+ P_2, \end{aligned} \tag{4.13}$$

where $E_+ \equiv E_{+1/2}$ and P_i project onto the subspaces (3.6). We observe that each of the three sectors between which the elementary fields in these expressions interpolate arises in two orthogonal copies, distinguished by different Abelian charge projections in the second p-factor. Again, the $-$ components are determined by (4.6).

One might proceed and compute also the primary isospin 1 triplet of real fermions, e.g., from the operator product expansion of the fields (4.12). Inserting the o.p.e.'s for the elementary fields, it is evident that one will obtain the three permutations of $\psi \odot 1 \odot 1$ where ψ is the real Ising chiral fermion, along with some Klein transformations which make the three components anti-commute. Since nothing exciting happens, we do not present the explicit calculations.

C. The 1+1-dimensional Wess–Zumino–Witten (WZW) field at level 2

The $1+1$-dimensional fundamental field of the WZW model is a 2×2 matrix with $SU(2)_L \times SU(2)_R$ symmetry (by left and right matrix multiplication). It is a local field which carries the quantum numbers of the nonlocal primary exchange doublet with respect to both chiral current algebras.

At level 2, it can be represented in the form [23]

$$g_{ij}=(A_i\times A_k+A_i^+\times A_k^++B_i\times B_k+B_i^+\times B_k^+)\,\epsilon_{kj}\,, \tag{4.14}$$

where the ϵ_{kj} is necessary because the right action of $SU(2)$ is in the conjugate representation. This form parallels the representation (3.1a) of the order parameter on its own cyclic subspace [we do not consider the analogue of the disorder parameter, which would enlarge the joint cycle Hilbert space and require a second copy of $\mathscr{H}_{(1/2)(1/2)}$ as in Eqs. (3.1b)]. Due to Eq. (4.2), one has

$$g_{ij}^*=\epsilon_{ik}\epsilon_{jl}g_{kl}\,. \tag{4.15}$$

We insert the expressions (4.13) for the primary exchange fields into the definition (4.14). As before, we first consider the interpolation scheme within the joint cyclic subspace. Every component g_{ij} is a sum of contributions of the form $X_{ij}^{kl}\odot(E\times E)P_{kl}$ where $(E\times E)P_{kl}$ is the $\times$-product of the Abelian vertex operators from Eq. (4.13) on the charge sector $H_k\otimes H_l$ according to Eq. (3.7), the accompanying $\times$-product of the elementary fields from Eq. (4.13) being called X_{ij}^{kl}. As it turns out, on the cyclic Hilbert space every such operator X_{++}^{kl} (resp., X_{+-}^{kl}) can be identified with a contribution to σ (resp. μ) as in Eqs. (3.1), restricted to a Γ-charge sector H_i according to Eq. (3.6). For example, the component g_{+-} involves the combination $X_{00}=a\times a-b^+\times b^+$ which appears in the representation (3.1a) of μ on H_0. For this identification, no multiplicity vectors u, v are needed to keep the two copies H_1 and H_3 of $\mathscr{H}_{(1/16)(1/16)}$ apart, since the accompanying Abelian charge projection operators P_{kl} already have the same effect.

The result of these considerations is the following interpolation diagram in which the horizontal arrows represent the action of the component g_{+-} which involves μ and $E_{+1/2}\times E_{+1/2}$ while the diagonal arrows represent g_{++} which involves σ and $E_{+1/2}\times E_{-1/2}$ [the other two matrix elements interpolate with the reversed arrows according to Eq. (4.15)]:

$$\begin{array}{ccccccccc} 0\odot 00 & \longrightarrow & 3\odot 11 & \longrightarrow & 0\odot 22 & \longrightarrow & 3\odot 33 & \longrightarrow & 0\odot 00 \\ & \searrow\!\!\!\times & & \searrow\!\!\!\times & & \searrow\!\!\!\times & & \searrow\!\!\!\times & \\ 2\odot 02 & \longrightarrow & 1\odot 13 & \longrightarrow & 2\odot 20 & \longrightarrow & 1\odot 31 & \longrightarrow & 2\odot 02 \end{array} \tag{4.16}$$

The vertices $i\odot kl$ of this diagram are labelled by the Γ-charge sectors H_i between which σ and μ interpolate, and the Abelian charge sectors $H_k\otimes H_l$ between which the vertex operators $E_{\pm 1/2}$ interpolate, according to Eqs. (3.7).

The explicit computation of the coefficients yields

$$\begin{aligned} g_{++}&\cong\sigma\odot(E_{+1/2}\times E_{-1/2})(-P_{00}+iP_{11}-iP_{22}-P_{33}+iP_{02}-iP_{13}+P_{20}+P_{31}),\\ g_{+-}&\cong\mu\odot(E_{+1/2}\times E_{+1/2})(P_{00}+P_{11}-P_{22}+P_{33}+iP_{02}+P_{13}-iP_{20}-P_{31}). \end{aligned} \tag{4.17}$$

The charge dependences in Eqs. (4.17) can be removed to a large extent, but not entirely, by a unitary similarity transformation of the form $\mathbb{1}\odot\Sigma_{ij}\omega_{ij}P_{ij}$ with suitable complex phases ω_{ij} on the charge sectors $H_i\otimes H_j$. For later use, we display two convenient simplifications of Eqs. (4.17):

$$g_{++}\cong\sigma\odot(E_{+1/2}\times E_{-1/2}),\quad g_{+-}\cong\mu\odot(E_{+1/2}\times E_{+1/2}e^{-i\pi Q}), \tag{4.18a}$$

or

$$\begin{aligned} g_{++}&\cong\sigma\odot(E_{+1/2}e^{-i\pi Q}\times E_{-1/2}e^{-i\pi Q}),\\ g_{+-}&\cong\mu\odot(E_{+1/2}e^{-i\pi Q}\times E_{+1/2}). \end{aligned} \tag{4.18b}$$

The other matrix elements are given by Eq. (4.15), i.e., $g_{--}=g_{++}^*$ and $g_{-+}=-g_{+-}^*$.

It is amusing to observe how the Klein transformations $e^{-i\pi Q}$ in these expressions ''mimic'' the same dual commutation relations for the Abelian vertex operator fields as for the order and disorder fields [Eq. (3.3)], and hence serve to cancel the corresponding signs such that the

p-products are indeed mutually local. It is also possible to transfer the Klein transformation in Eq. (4.18) from the vertex operators to the order and disorder fields, changing their dual commutation relations into anyonic ones.

In the representation (4.18a), the trace field Tr g looks particularly simple, and with Eq. (1.7a) turns into

$$\mathrm{Tr}\, g \cong \sqrt{2}(\sigma \odot \mu \odot \mu) \cong \sqrt{2}\sigma \odot \sigma \odot \sigma. \tag{4.19}$$

The latter equivalence holds since the cosine $\mu \odot \mu$ differs from the sine $\sigma \odot \sigma$ by a $U(1)$ transformation, cf. Sec. II A.

On the line $x=0$, the fields g_{ij} can be represented as Abelian vertex operators, e.g., inserting (1.2a) into (4.18a),

$$\begin{aligned} g_{++}|_{x=0} &\cong E_\beta(P_0+P_2)+E_\gamma(P_1+P_3), \\ g_{+-}|_{x=0} &\cong E_\delta(P_0-P_2)+iE_\epsilon(P_1-P_3), \end{aligned} \tag{4.20}$$

where $\beta=\frac{1}{2}(1,1,-1)$, $\gamma=\frac{1}{2}(-1,1,-1)$, $\delta=\frac{1}{2}(-1,1,1)$, $\epsilon=\frac{1}{2}(1,1,1)$ (with $\beta+\delta=\gamma+\epsilon$), and P_i project on the subspaces of charge $(\gamma-\delta)Q=(i \bmod 4)\frac{1}{2}$, or equivalently on the subspaces of right-handed WZW isospin component $j^3_R=(i \bmod 4)\frac{1}{2}$. These formulas are another example of ''Abelianization'' of correlations along the line, just like Kadanoff's result for the Ising model. Note, however, the nontrivial angles between the charge vectors.

It is interesting to verify the unitarity of the matrix-valued field g_{ij} in these representations, and to compute the associated chiral $SU(2)$ currents. Of course, one has to consider operator quadratic expressions of the form $g_{ij}g^*_{kj}$ or $g_{ij}\partial g^*_{kj}$ which have to be renormalized. For conformal fields of chiral scaling dimensions (h,h) the proper way of doing so is a point-split regularization and renormalization by $\Delta_L^{-2h}\Delta_R^{-2h}$ in order to single out the leading contribution to the operator product expansion. This indeed reproduces unitarity (using ${}^\circ_\circ\sigma\sigma^\circ_\circ={}^\circ_\circ\mu\mu^\circ_\circ={}^\circ_\circ E_{\pm 1/2}E_{\mp 1/2}{}^\circ_\circ=\mathbb{1}$; actually one finds that rather $g/\sqrt{2}$ is unitary since we have normalized every matrix element such that its two-point function $\langle \Omega, g^*_{ij}g_{ij}\Omega\rangle$ is $(\Delta_L\Delta_R)^{3/8}$), and gives the level 2 currents $J^a_L=i\mathrm{Tr}\tau^a{}^\circ_\circ\partial_+ g g^*{}^\circ_\circ \cong J^a\times\mathbb{1}$ in the form

$$\begin{aligned} J^3 &\cong -\mathbb{1}\odot 2\partial\varphi \cong (\alpha_1+\alpha_2)\partial\varphi, \\ J^+ &\cong (E_{+1}+E_{-1})\odot E_{-1} \cong E_{\alpha_1}+E_{\alpha_2}, \end{aligned} \tag{4.21}$$

where $\alpha_1=(1,-1)$, $\alpha_2=(-1,-1)$, and similar for the right-moving currents $i\mathrm{Tr}\tau^a{}^\circ_\circ\partial_- g^* g^\circ_\circ \cong \mathbb{1}\times J^a$. In order to obtain this result, we have used the relevant leading contributions to the operator product expansions $E_{\pm 1/2}(x)E_{\pm 1/2}(y)\approx\Delta(x-y)^{-1/4}E_{\pm 1}+\cdots$ and $E_{\pm 1/2}E_{\mp 1/2}\approx\Delta^{1/4}(\mathbb{1}\pm(i/2)(x-y)\partial\varphi+\cdots)$, as well as $\sigma\sigma\approx\mu\mu\approx(\Delta_L\Delta_R)^{1/8}\mathbb{1}+\cdots$ and $\mu\sigma\approx i\sigma\mu\approx\sqrt{i}\Delta_L^{-3/8}\Delta_R^{1/8}\psi_L+\cdots$ where the left-moving real chiral Ising fermion ψ_L can in turn be represented in the form $\frac{1}{2}(E_{+1}+E_{-1})\times\mathbb{1}$, up to another Klein transformation which makes ψ_L and ψ_R anti-commute. The form (4.21) complies with Eq. (2.15) with two Frenkel–Kac representations at level 1, if one changes the basis to $\alpha_1=(\sqrt{2},0)$, $\alpha_2=(0,\sqrt{2})$.

D. The determinant field

Every p-quadratic expression in either the diagonal or the off-diagonal matrix elements g_{ij}, Eqs. (4.18), can be expressed in terms of Abelian vertex operators alone, since the doubled non-Abelian factors μ and σ can. This observation generalizes the Schroer–Truong formulas (1.7).

A particularly simple representation of the sine form (1.11) can be obtained for the p-determinant field [which is invariant under $SU(2)_L\times SU(2)_R$],

$$\mathrm{Det}_\odot g := \tfrac{1}{2}\,\epsilon_{ik}\epsilon_{jl}g_{ij}\odot g_{kl} = \tfrac{1}{2}\,(g_{11}\odot g_{22}+g_{22}\odot g_{11}-g_{12}\odot g_{21}-g_{21}\odot g_{12}). \tag{4.22}$$

In order to compute the p-determinant, we take the liberty to use the representations (4.18a) and (4.18b) for the first and second p-factor, respectively. As for the Abelian vertex operators in Eqs. (4.18), we observe that they always combine in (4.22) in the form $E_{\pm 1/2}\odot E_{\mp 1/2}\cong E_{\pm\alpha}$ where $\alpha=1/\sqrt{2}$. Consequently, all charges in the cyclic Hilbert space are integer multiples of α, and the charge operators involved may be replaced by $e^{i\pi Q}\odot\mathbb{1}\cong e^{i\pi\alpha Q}$ and $\mathbb{1}\odot e^{i\pi Q}\cong e^{-i\pi\alpha Q}=e^{i\pi\alpha Q}\cdot C$ where $C=e^{2\pi i\alpha Q}=C^{-1}$ is the Casimir operator introduced previously in Sec. II C.

The crucial point now is that an enhanced symmetry emerges on the vertex operators of charge $\pm\alpha$ which was not present on the vertex operators of charge $\pm 1/2$ in the representation (4.13), i.e., before taking the p-square [and which spoils the original (squared) level 2 affine chiral $SU(2)$ symmetries generated by (4.21)]. Namely, all terms contributing to (4.22) involve $E_{\pm\alpha}e^{i\pi\alpha Q}\times E_{\pm\alpha}e^{i\pi\alpha Q}$, i.e., the components of the pseudo-real $SU(2)$ level 1 doublet $\phi_\pm$ as in Eq. (2.13), possibly along with some Casimir operators. Explicitly, we have

$$\begin{aligned}\mathrm{Det}_\odot g &\cong \tfrac{1}{2}\left[\sigma_D\odot(\phi_+C\times\phi_-C+\phi_-\times\phi_+)-i\mu_D\odot(\phi_+C\times\phi_+C+\phi_-\times\phi_-)\right]\\ &\cong\frac{1}{2\sqrt{2}i}\left[(E_{-1/2}\times E_{+1/2})\odot(\phi_++\phi_-)\times(\phi_++\phi_-)\right.\\ &\quad\left.+(E_{+1/2}\times E_{-1/2})\odot(\phi_+-\phi_-)\times(\phi_+-\phi_-)\right].\end{aligned}\tag{4.23}$$

For the second line, we observed that on the cyclic Hilbert space $C\otimes C$ equals $\mathbb{1}$, and we evaluated σ_D and μ_D according to Eqs. (1.7).

The new level 1 chiral $SU(2)$ symmetries permit us to rotate the components $(\phi_+\pm\phi_-)$ into $\sqrt{2}\phi_\mp$ in the left chiral factor and into $\pm\sqrt{2}\phi_\pm$ in the right chiral factor. This unitary similarity transformation turns the determinant field into

$$\mathrm{Det}_\odot g\cong\frac{1}{\sqrt{2}i}\left[(E_{-1/2}\times E_{+1/2})\odot(\phi_-\times\phi_+)-(E_{+1/2}\times E_{-1/2})\odot(\phi_+\times\phi_-)\right].\tag{4.24}$$

After this transformation, the cyclic Hilbert space is seen to carry opposite charges in the two chiral factors. We may therefore insert $\mathbb{1}=\mathbb{1}\odot(e^{i\pi\alpha Q}\otimes e^{i\pi\alpha Q})$ and re-substitute the vertex operators $E_{\pm\alpha}$ for the doublet $\phi_\pm$. This gives finally the sine formula, to be compared with Eq. (1.7a),

$$\mathrm{Det}_\odot g\cong\frac{1}{\sqrt{2}i}\,(E_{-\beta}\times E_\beta-E_\beta\times E_{-\beta}),\tag{4.25}$$

with $\beta=\frac{1}{2}(1,\sqrt{2})$ or, after an $O(2)$ rotation in charge space, $\beta=\frac{1}{2}\sqrt{3}$. The nontriviality of this formula can be esteemed upon the intricate exercise to test it only at the four-point level.

V. CONCLUSIONS

We have established a sort of ''Quantum Field Lego'' with chiral non-Abelian exchange fields which can be recombined in a large variety of ways to produce several local and nonlocal, chiral and $1+1$-dimensional Wightman fields belonging to different models. It originates in some well-known remarkable properties of the (critical) Ising model,[4,2,3] and entails similar but new results for a WZW (=generalized Thirring) model, and gives rise to relations between various models.

A prominent feature of the basic decomposition (3.4) is that it produces non-Abelian exchange fields, satisfying commutation relations according to a non-Abelian representation of the braid group and possessing a non-Abelian fusion structure, by factorization of Abelian vertex operators with anyonic commutation relations and additive charge structure.

We have seen along the way (Secs. II C and IV C) how the generators of the chiral symmetry can be explicitly computed in our operator representations and are found, of course, in complete agreement with well-known results.

Throughout the paper, we have mentioned only en passant the issue of braid group commutation relations. Let us just add that p-products go along with the tensor products of representa-

tions of the braid group; notably the basic result singles out an Abelian subrepresentation within the square of the Hecke type representations associated with the elementary fields.

Let us consider the question whether one may expect parallel findings in other minimal or coset models. Since Abelian vertex operators are the primary fields for stress-energy tensors with integer central charge c, one may expect representations of Abelian vertex operators as p-products of non-Abelian ones whenever a stress-energy tensor with integer central charge occurs in the product of the chiral observables. In the case of the doubled Ising model, the latter is just the sum of the two stress-energy tensors with $c=\frac{1}{2}$, and in the case of the determinant field, it is the coset stress-energy tensor with $c=1$ for the coupling of two level 2 current algebras into the level 4 current algebra. Admitting sufficiently high p-powers, any model with rational central charge presumably provides another set of non-Abelian roots of Abelian vertex operators. On the other hand, the ''Kadanoff mechanism'' of quadratic Abelianization upon restriction to a time-like axis, which in the present model we consider to be the reason for the possibility of several independent recombinations of the same elementary fields, can only work when the two opposite chiral central charges add up to an integer. This property of course distinguishes the Ising model with $c=\frac{1}{2}$ and the $SU(2)$ model at level 2 with $c=\frac{3}{2}$ studied in this paper from other minimal or WZW models.

An immediate further application, not treated in this paper, is the construction of the primary field ϕ_{21} with dimension $\frac{7}{16}$ of the minimal model with $c=\frac{7}{10}$ which arises in the coset construction as the singlet contribution to the p-product of the $SU(2)$ primary doublets at level 1 [Eq. (2.13)] and at level 2 [Eq. (4.12)], commuting with the level 3 currents.

Although the basic result involves chiral and nonlocal fields, several of our applications pertain to ordinary local Wightman fields in $1+1$-dimensional Minkowski space-time.

We want to draw the attention to a point of general importance which is illustrated by Eq. (4.25). By definition, the determinant field is p-quadratic in the four mutually local fields g_{ij}. On the other hand, the right hand side of Eq. (4.25), by elementary identities using the representation (1.7), equals one half of

$$\sigma_D\odot\sigma_D\odot\sigma_D-\sigma_D\odot\mu_D\odot\mu_D-\mu_D\odot\sigma_D\odot\mu_D-\mu_D\odot\mu_D\odot\sigma_D\,. \tag{5.1}$$

[This formula would not be guessed from Eqs. (4.18) according to which g_{ij} are not p-cubic in σ and μ.] The determinant field is thus at the same time also p-cubic in local fields. Yet, a common sixth-order factorization into mutually local fields cannot be perceived (at least not in terms of our elementary fields). This indicates, with due precaution, that something like a ''prime decomposition'' with respect to the p-product does not exist in general within the class of local Wightman fields. In this context we notice that two-dimensional local and scale-invariant fields such as $E_\alpha\times E_{-\alpha}$ are infinitely factorizable with respect to the p-product. This is certainly impossible in higher dimensions since the scaling dimension is bounded from below by $(d-2)/2$. For the analogous question with respect to the s-product, cf. Ref. 24.

We consider our work as an exercise with noncanonical fields from which several lessons on the general theory of Wightman fields can be drawn. We want to refute the possible impression that the construction of p-products is just an artificial trick to construct new Wightman fields without a proper physical meaning from old ones. On the contrary, all the product fields in this article were previously known and considered in their own model context. The new aspect is the passage between different models enabled by p-products.

(Received 15 July 1997; accepted for publication 17 February 1998)

We analyze constrained quantum systems where the dynamics do not preserve the constraints. This is done, in particular, for the restriction of a quantum particle in $\mathbb{R}^n$ to a curved submanifold, and we propose a method of constraining and dynamics adjustment that produces the right Hamiltonian on the submanifold when tested on known examples. This method will be the germ of a ''Dirac algorithm for quantum constraints.'' We generalize it to the situation where the constraint is a general self-adjoint operator with some additional structures. © *1998 American Institute of Physics.* [S0022-2488(98)00906-2]

I. INTRODUCTION

The problem of enforcing constraints in classical mechanics has had satisfactory solutions for some time now.[1–4] The same is not true in quantum mechanics, contrary to claims of ''quantizations'' of classical constrained systems after constraining. Quantization maps are rarely unique nor well defined.[5–8] Moreover, using noncommutativity, some constraints can be defined in quantum mechanics with zero classical limit. This means that the general problem of quantum constraints needs to be solved in the quantum arena without appealing to classical methods.

There is presently a wide variety of methods for imposing quantum constraints,[1,9–13] but these methods (except Ref. 13) deal with the kinematics only at the quantum level, and their interrelations are unclear. (The method of Ref. 13 does consider the dynamics, producing for the constrained Hamiltonian the projection of the unconstrained one onto the physical subspace. This will not work for the system considered in this paper.) When the given quantum dynamics preserves the constrained subsystem that is fine, one only needs to restrict it to the constrained subsystem to obtain the constrained dynamics. However, when this is not the case, the problem arises of how to appropriately adjust the constraint set and the dynamics into a stable system. (New constraints produced by such a method are generally called secondary constraints). The obvious strategy of fixing the dynamics and extending the constraint set to its orbit under the dynamics, produces the wrong physics in examples. It is our opinion that the question of secondary quantum constraints and dynamics adjustment is a physical problem, and cannot be decided by mathematical arguments alone. In this paper we set out to solve this problem of secondary quantum constraints in the limited class of systems consisting of the restriction of a quantum particle on $\mathbb{R}^n$ to a smooth (possibly curved) submanifold, i.e., the case of holonomic constraints (cf. Ref. 14, p. 75). The motivation for this choice is as follows.

(1) There are several examples of quantum mechanics on surfaces available (e.g., $\mathbf{S}^2$) against which we can test the results of our analysis.

(2) In $\mathbb{R}^n$ there is ample geometry available to guide the intuition, e.g., a metric, hence normal vectors and Lebesgue measure.

(3) Generalizations are easy from this class, in fact, in Sec. VI we propose a generalization of it to the case of a general self-adjoint operator on a Hilbert space with additional structures.

(4) A constraint in this situation is of the form $\varphi(q)=0$, which has an immediate obvious quantization in the Schrodinger representation, whereas a constraint of the form $\varphi(q,p)=0$ need not have a unique quantization.

(5) Physically, these systems in $\mathbb{R}^3$ can be approximated by very thin films or wires and so are close to experimental verification.

(6) The exposition of constraint methods for these systems is more transparent than for more general ones.

(7) Holonomic quantum constraints have been considered in the physics literature.[15,16]

The kinematics of quantum systems of this type has already been done concretely by Landsman[11] and abstractly at the C^* level by Grundling and Hurst,[9] so any new proposed method should be compatible with these. We will not consider BRST methods,[10] as we believe these not to be equivalent at the quantum level to the other methods.[17–19] So, to summarize, we aim to solve for this class of systems the problem of secondary quantum constraints, i.e., given a constrained system where the dynamics do not preserve the constraints, to find a method of adjustment that agrees on known constrained systems with the right physics.

The architecture of the paper is as follows; in Sec. II we summarize the Dirac procedure for constraining a classical particle to a submanifold, both local and global, and we also do two examples. In Sec. III we consider the question of quantum constraints, we first summarize the usual Dirac procedure, then start to analyze the situation of restricting a quantum particle in $\mathbb{R}^n$ to a lower-dimensional submanifold Γ. We obtain the constraining map κ from the Hilbert space $L^2(\mathbb{R}^n)$ of the unconstrained particle to that of the constrained particle $L^2(\Gamma)$, and we discuss generalizations to other types of constrained systems. In Sec. IV we solve the problem of how to obtain from the Hamiltonian of the original particle a constrained Hamiltonian on $L^2(\Gamma)$, and we apply it to two examples; restricting a free particle in $\mathbb{R}^3$ to a sphere and a cylinder, and we obtain in each case the correct Hamiltonian. In Sec. V, we consider how to obtain observables on $L^2(\Gamma)$ from the original observables on $L^2(\mathbb{R}^n)$, i.e., we analyze when we obtain sensible liftings of operators through the map κ, and how to obtain a suitable field algebra for the constrained particle. In Sec. VI we suggest a generalization of the method of the preceding sections to the constraining situation where the constraint is a self-adjoint operator on an abstract Hilbert space, with zero in the continuous part of the spectrum. We find that we need to assume some additional structure to do the work that the geometry of $\mathbb{R}^n$ does in the method of the preceding sections. The reader in a hurry can start with Sec. III.

II. CLASSICAL SECONDARY CONSTRAINTS

We start by recalling the basic Dirac–Bergman method,[1,20,21] which is, of course, a local procedure. However, to keep this brief, we only present it in the context of a particle in $\mathbb{R}^n$ constrained to an $(n-1)$-dimensional submanifold Γ, which is the system at the focus of this paper.

The full phase space is $\mathbb{R}^{2n}$ with generic point $(\mathbf{q},\mathbf{p})$ and the usual Poisson algebra $\mathscr{P}=(C^\infty(\mathbb{R}^{2n}),\{\cdot,\cdot\})$ is the setting for the problem. We specify a smooth $(n-1)$-dimensional submanifold Γ in $\mathbb{R}^n$ as the zero set of a smooth function $\varphi\in C^\infty(\mathbb{R}^n)$, i.e., $\Gamma=\varphi^{-1}(0)$. We also assume $\nabla\varphi\neq 0$ on Γ so we can use the gradient to define a normal on Γ. The Hamiltonian for a particle in a potential V is

$$H_c=\frac{1}{2m}\,\mathbf{p}\cdot\mathbf{p}+V(\mathbf{q}). \tag{2.1}$$

So we have a constrained system with a single primary constraint $\varphi(\mathbf{q},\mathbf{p}):=\varphi(\mathbf{q})$ and primary constraint manifold in phase space $\varphi^{-1}(0)=\Gamma\times\mathbb{R}^n=:\Gamma_p$. The Dirac procedure starts with the new Hamiltonian:

$$H_p:=\frac{1}{2m}\,\mathbf{p}\cdot\mathbf{p}+V(\mathbf{q})+\mu\varphi,$$

where $\mu\in\mathscr{P}$ is a free multiplier, to be determined below. So the new time evolution for $A\in\mathscr{P}$ on Γ_p is

$$\dot{A}\restriction\Gamma_p=\{A,H_p\}\restriction\Gamma_p=(\{A,H_c\}+\mu\cdot\{A,\varphi\})\restriction\Gamma_p.$$

Since time evolution must preserve Γ_p, we require that

$$0=\dot{\varphi}\restriction\Gamma_p=\{\varphi,H_p\}\restriction\Gamma_p=\frac{1}{m}\,\mathbf{p}\cdot(\boldsymbol{\nabla}\varphi)\restriction\Gamma_p.$$

Thus $\chi:=(1/m)\mathbf{p}\cdot(\boldsymbol{\nabla}\varphi)$ is a secondary constraint determining a smaller submanifold $\Gamma_f:=\varphi^{-1}(0)\cap\chi^{-1}(0)$, which again must be preserved by time evolution. In the examples in the rest of this paper we will constrain free motion to a surface, so for this case ($V=0$),

$$\dot{\xi}\restriction\Gamma_f=0=(\{\xi,H_c\}+\mu\cdot\{\xi,\varphi\})\restriction\Gamma_f,\quad\text{where}\quad\xi\ \text{denotes}\ \chi,\varphi,$$

so

$$\begin{aligned}0&=\left(\left\{\frac{1}{m}\,\mathbf{p}\cdot(\boldsymbol{\nabla}\varphi),\frac{1}{2m}\,\mathbf{p}\cdot\mathbf{p}\right\}+\mu\left\{\frac{1}{m}\,\mathbf{p}\cdot(\boldsymbol{\nabla}\varphi),\varphi\right\}\right)\restriction\Gamma_f\\&=\left(\frac{1}{2m^2}\,\mathbf{p}\cdot\{\boldsymbol{\nabla}\varphi,\mathbf{p}\cdot\mathbf{p}\}+\frac{1}{m}\,\mu(\boldsymbol{\nabla}\varphi)\cdot\{\mathbf{p},\varphi\}\right)\restriction\Gamma_f\\&=\left(\frac{1}{m^2}\,\mathbf{p}\cdot(\boldsymbol{\nabla}(\mathbf{p}\cdot\boldsymbol{\nabla}\varphi))-\frac{1}{m}\,\mu(\boldsymbol{\nabla}\varphi)\cdot(\boldsymbol{\nabla}\varphi)\right)\restriction\Gamma_f.\end{aligned}$$

Since $\boldsymbol{\nabla}\varphi\neq 0$ on Γ, we solve on Γ_f,

$$\mu=\frac{\mathbf{p}\cdot(\boldsymbol{\nabla}(\mathbf{p}\cdot\boldsymbol{\nabla}\varphi))}{m\|\boldsymbol{\nabla}\varphi\|^2}=\frac{(\mathbf{p}\cdot\boldsymbol{\nabla})^2\varphi}{m\|\boldsymbol{\nabla}\varphi\|^2},$$

thus

$$H_p=\frac{1}{2m}\,\mathbf{p}\cdot\mathbf{p}+\varphi\cdot\frac{(\mathbf{p}\cdot\boldsymbol{\nabla})^2\varphi}{m\|\nabla\varphi\|^2}.$$

The secondary constraint, looked at on configuration space, restricts momenta by

$$\chi=\left(\frac{1}{m}\,\mathbf{p}\cdot\boldsymbol{\nabla}\varphi\right)\restriction\Gamma=0,\tag{2.2}$$

to guarantee that the motion is tangent to the surface. There are no more constraints. Moreover, since

$$\{\varphi,\chi\}\restriction\Gamma_f=\frac{1}{m}\,\|\boldsymbol{\nabla}\varphi\|^2\restriction\Gamma_f\neq 0,$$

the constraints are second class. The Dirac algorithm continues to construct a Dirac bracket, but we will not need this. For later use we specialize the above to a sphere and a cylinder.

Let Γ be a sphere of radius a in $\mathbb{R}^3$. The phase space is $\mathbb{R}^6$, $\Gamma_p=\mathbf{S}^2\times\mathbb{R}^3$, and we have

$$\varphi(\mathbf{q})=\mathbf{q}\cdot\mathbf{q}-a^2,\quad\text{so}\ \ \chi=\frac{1}{m}\,\mathbf{p}\cdot\boldsymbol{\nabla}\varphi=\frac{2}{m}\,\mathbf{p}\cdot\mathbf{q},$$

and since $\boldsymbol{\nabla}(\mathbf{p}\cdot\boldsymbol{\nabla}\varphi)=2\mathbf{p}$, here we get

$$H_p=\frac{1}{2m}\,\mathbf{p}\cdot\mathbf{p}\left(1+\frac{\mathbf{q}\cdot\mathbf{q}-a^2}{\|\mathbf{q}\|^2}\right).\tag{2.3}$$

An explicit calculation produces

$$H_p \restriction \Gamma_f = \frac{1}{2m}\,\mathbf{p}\cdot\mathbf{p}\Big|_{\substack{|\mathbf{q}|=\alpha \\ \mathbf{q}\cdot\mathbf{p}=0}} = \frac{|\mathbf{L}|^2}{2ma^2}, \tag{2.4}$$

where $\mathbf{L}=\mathbf{q}\times\mathbf{p}|_{r=a}$ is angular momentum on the sphere.

If we take Γ to be a cylinder of radius a around the z axis in $\mathbb{R}^3$, we have

$$\varphi(\mathbf{q})=q_1^2+q_2^2-a^2, \quad \text{so} \quad \chi=\frac{2}{m}\,(p_1q_1+p_2q_2),$$

$$H_p=\frac{1}{2m}\,\mathbf{p}\cdot\mathbf{p}+(q_1^2+q_2^2-a^2)\,\frac{p_1^2+p_2^2}{2m(q_1^2+q^2)}. \tag{2.5}$$

And now,

$$H_p \restriction \Gamma_f = \frac{1}{2m}\,\mathbf{p}\cdot\mathbf{p}\Big|_{\substack{q_1^2+q_2^2=a^2 \\ p_1q_1=-p_2q_2}} = \frac{1}{2m}\left(\frac{L_3^2}{a^2}+p_3^2\right)\restriction \Gamma_f, \tag{2.6}$$

where $L_3 := q_1p_2-q_2p_1$ is the usual angular momentum around the q_3 axis.

Next we recall the global version of the Dirac–Bergman method of constraints as worked out by Gotay, Nester, and Hinds,[2] which is a considerable simplification. Start with a symplectic manifold (M,ω) (finite dimensional here) and a Hamiltonian $H\in C^\infty(M)$. Let $M_1\subset M$ be a given primary constraint submanifold. Now the evolution equation $\iota_X\omega=dH$ may not have solutions for the vector field X tangential to M_1, so let

$$M_2 := \{m\in M_1 \,|\, dH(m)=\iota_X\omega(m), \quad \text{for some} \quad X\in T_mM_1\}.$$

However, the time evolution must now preserve M_2, so iterate

$$M_{k+1} := \{m\in M_k \,|\, dH(m)=\iota_X\omega(m), \quad \text{for some} \quad X\in T_mM_k\}.$$

When this iteration converges sensibly, we obtain a final constraint manifold M_c on which $dH=\iota_X\omega$ has solutions $X\in\Gamma^\infty(M_c)\equiv$smooth vector fields on M_c, which provide the desired time evolutions. Geometrically we can think of M_c as the largest submanifold, which has a vector field X that is tangential at each $m\in M_c$ to a trajectory of the time evolution of the original unconstrained manifold M. The completeness of X is still an open question for the general analysis. (Below we will refer to the above as the GNH algorithm).

We will take this geometric picture as the guiding principle for constraining the dynamics of a quantum system below in Sec. IV.

III. CONSTRAINING THE REPRESENTATION SPACE

For reference, we recall the usual Dirac prescription for first class quantum constraints. Given a field algebra $\mathscr{A}$ of operators preserving a dense domain Δ in a Hilbert space $\mathscr{H}$, as well as a Hamiltonian $H\in\mathscr{A}_{sa}$ and a set of constraints $\{\hat{\varphi}_i\in\mathscr{A}_{sa}\,|\,i\in I\}$ (where I is an abstract index set), one selects the physical subspace by

$$\mathscr{H}_{\text{phys}} := \overline{\{\psi\in\Delta\,|\,\hat{\varphi}_i\psi=0, \quad \forall i\}},$$

and this is assumed to be nonzero (hence zero must be in the discrete spectrum of each $\hat{\varphi}_i$). Decompose $\mathscr{H}=\mathscr{H}_{\text{phys}}\oplus\mathscr{H}_{\text{phys}}^{\perp}$, so for each $A\in\mathscr{A}$ we have a decomposition

$$A=\begin{pmatrix} a & b \\ c & d \end{pmatrix}.$$

Clearly, the only $A\in\mathscr{A}$, which, together with A^* can be restricted to $\mathscr{H}_{\text{phys}}$, are those of the form

$$A=\begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix}.$$

Denote the * algebra of these by $\mathscr{O}$. Those that restrict trivially are of the form

$$A=\begin{pmatrix} 0 & 0 \\ 0 & d \end{pmatrix}$$

and comprise an ideal $\mathscr{D}$ of $\mathscr{O}$. Then the * algebra of physical observables are

$$\mathscr{O}\restriction\mathscr{H}_{\text{phys}}\cong\mathscr{O}/\mathscr{D}=:\mathscr{R}.$$

If $\exp itH$ preserves $\mathscr{H}_{\text{phys}}$, then Ad $\exp(itH)$ lifts to automorphisms on $\mathscr{R}$. Otherwise, we need to alter it (cf. Sec. IV). Let P_{phys} be the projection on $\mathscr{H}_{\text{phys}}$ and define the sesquilinear form

$$(\psi_1,\psi_2)_D:=(P_{\text{phys}}\psi_1,P_{\text{phys}}\psi_2)=(\psi_1,P_{\text{phys}}\psi_2); \tag{3.1}$$

then $\text{Ker}(\cdot,\cdot)_D=\mathscr{H}_{\text{phys}}^{\perp}$, and we write P_{phys} as a factorization $P_{\text{phys}}:\mathscr{H}\to\mathscr{H}/\text{Ker}(\cdot,\cdot)_D\cong\mathscr{H}_{\text{phys}}$ (an obvious identification), and we can think of $\mathscr{O}$ as all $A\in\mathscr{A}$, which together with A^* can lift through the factorization.

Next, we introduce our main object of study. Consider a quantum particle in $\mathbb{R}^n$ in the Schrödinger representation. Its basic data consists of the Hilbert space $\mathscr{H}=L^2(\mathbb{R}^n,\mu)$ (with μ the Lebesgue measure), and on the dense subspace $C_c^\infty(\mathbb{R}^n)$ of smooth functions of compact support, we have the position operator $(\hat{\mathbf{q}}\psi)(\mathbf{x}):=\mathbf{x}\psi(\mathbf{x})$, the momentum operator $(\hat{\mathbf{p}})\psi(\mathbf{x}):=(i\nabla\psi)(\mathbf{x})$, and a Hamiltonian H [which is $(1/2m)\hat{\mathbf{p}}\cdot\hat{\mathbf{p}}$ when the particle is free]. These operators are all essentially self-adjoint and preserve $C_c^\infty(\mathbb{R}^n)$. We wish to constrain this particle to a given smooth $(n-1)$-dimensional submanifold $\Gamma\subset\mathbb{R}^n$. Assume we have a bounded real-valued constraint function $\varphi\in C^\infty(\mathbb{R}^n)$ with $\nabla\varphi$ nonzero and bounded on a neighborhood of Γ, and

$$\Gamma=\{x\in\mathbb{R}^n\,|\,\varphi(\mathbf{x})=0\}=\varphi^{-1}(0).$$

(Notice that the level hypersurfaces of φ form a foliation of this neighborhood.[22]) Quantize φ by the multiplication operator $\varphi(\hat{\mathbf{q}})$, i.e.,

$$(\hat{\varphi}\psi)(\mathbf{x})=\varphi(\mathbf{x})\cdot\psi(\mathbf{x}),\quad\forall\psi\in\mathscr{H},$$

which is self-adjoint since φ is real valued, and bounded because φ is.

Assume we are given a concrete field algebra $\mathscr{F}\subset\mathscr{B}(\mathscr{H})$, which should be a C^* algebra containing all relevant operators in bounded form, e.g., $\hat{\varphi}$, $\exp i\mathbf{a}\cdot\hat{\mathbf{q}}$, $\exp i\mathbf{a}\cdot\hat{\mathbf{p}}$ ($\mathbf{a}\in\mathbb{R}^n$). The choice of field algebra will turn out to be important for producing a meaningful algebra of observables in the constrained system, but we will return to this matter in Sec. V. In summary, we are assuming the following data: (a) the operators $\hat{\mathbf{p}}$, $\hat{\mathbf{q}}$, and H on $C_c^\infty(\mathbb{R}^n)\subset L^2(\mathbb{R}^n)$; (b) a bounded $\varphi\in C^\infty(\mathbb{R}^n)$ with $\Gamma=\varphi^{-1}(0)$ a smooth $(n-1)$-dimensional submanifold, and with $\nabla\varphi$ nonzero and bounded in a neighborhood of Γ; and (c) a unital field algebra $\mathscr{F}$ on $L^2(\mathbb{R}^n)$.

We would like to find a way of imposing the constraint ''$\hat{\varphi}=0$'' on this system. However, since Γ is a null set of μ, we have $\text{Ker}\,\hat{\varphi}=\{0\}$, and so Dirac's method of restriction to the kernel of the constraint fails. The fact that zero is in the continuous spectrum of $\hat{\varphi}$ is physically due to the uncertainty principle; a particle confined to Γ will violate Heisenberg's uncertainty principle in a direction normal to Γ.

At present, there are two methods that can handle the above situation: the T procedure of Ref. 9, as well as Landsman's application of Rieffel induction.[11] The T procedure ''ignores'' the original representation of $\mathscr{F}$, considers $\mathscr{F}$ as an abstract C^* algebra, for which it then finds those representations π for which zero is in the discrete part of the spectrum of $\pi(\hat{\varphi})$, and works out the algebraic structures associated with factoring $\text{Ker}\,\pi(\hat{\varphi})$ out of each of those representations. On the other hand, Landsman's method assumes a locally compact group H with a continuous proper action on $\mathbb{R}^n$ such that Γ is precisely the set of points left invariant. Assuming some initial representation π of H on $L^2(\mathbb{R}^n)$, he makes $C_c(\mathbb{R}^n)$ into an $(\mathscr{A}$–$\mathscr{B})$ bimodule, where $\mathscr{B}$ is the

algebra $C_c(H)$ (with convolution for multiplication) and $\mathscr{A}$ is the part of the commutant of $\pi(H)$ preserving $C_c(\mathbb{R}^n)$. There is then a natural rigging map, and this allows a Rieffel induction from the trivial representation of $\mathscr{B}$ to $\mathscr{A}$.

The T procedure selects the set of all representations in which the Dirac algorithm makes sense, which necessarily excludes the original representation of the current system. This means that one loses the original physical interpretation of the state vectors, and one has the problem of which representation to choose for the constrained system. From the point of view of the physics, one may sometimes be more interested in constructing the constrained operators directly out of the original ones. Landsman's method does this, but requires some additional group structure, and quantizes a fairly small algebra. Both methods do only the kinematics, and if the dynamics do not preserve Γ it is hard to see from these structures what should be done.

We will propose a method for constraining the kinematics of a quantum particle to Γ, which generalizes the usual Dirac prescription and in which the constrained operators are explicitly constructed from the original ones. It will then be fairly easy to see what to do with the dynamics.

In a sense the solution of the kinematics problem is already known. One takes the subspace $C_c(\mathbb{R}^n)\subset L^2(\mathbb{R}^n)$ and restricts it to Γ, thus obtaining a dense subset of the physical Hilbert space $L^2(\Gamma,\gamma)$ (γ denotes the measure induced on Γ by μ). The restriction is the same as factoring out the subspace,

$$N:=\{f\in C_c(\mathbb{R}^n)\,|\, f\restriction\Gamma=0\},$$

from $C_c(\mathbb{R}^n)$. The observables are those operators that ''restrict to Γ,'' i.e., operators A that preserve $C_c(\mathbb{R}^n)$ and N, in which case A lifts through the restriction to define an operator on $C_c(\Gamma)\subset L^2(\Gamma)$. This is the procedure that we intend to refine. Note, however, that the restriction map $\rho: C_c(\mathbb{R}^n)\to C_c(\Gamma)$ is unbounded with respect to the L^2 norms and it is not closable as an operator [let $\psi_k\in L^2(\mathbb{R}^n)$ be a sequence of continuous functions with compact support, all of which have the same restriction to a nonzero $\theta\in L^2(\Gamma)$, and which converge to zero w.r.t. the L^2 norm. Then $\psi_k\to 0$, $\rho(\psi_k)\to\theta\neq 0$, so $\lim \rho(\psi_k)\neq\rho(\lim \psi_k)$]. So we expect some pathologies to arise in operator questions. We would also like to build the inner product of $L^2(\Gamma)$ explicitly out of the inner product of $L^2(\mathbb{R}^n)$. To do this, we adapt a well-known argument from statistical mechanics,[23] and p. 80 of Ref. 24.

Since $\nabla\varphi(\mathbf{x})\neq 0$ on a neighborhood of Γ, locally (i.e., in open bounded sets) the critical points of φ are a finite distance away from Γ. So we have the geometrically obvious lemma:

Lemma 3.2: There is a $t>0$ such that in $\varphi^{-1}[-t,t]$ we have locally a smooth curvilinear orthogonal coordinate system $(\mathbf{y},\varphi)$ where $\mathbf{y}=$ const are curves normal to the level hypersurfaces of φ.

Proof: Consider the vector field $X(\mathbf{x})=\mathbf{n}(\mathbf{x})/|\nabla\varphi(\mathbf{x})|$ on $\varphi^{-1}(-t,t)$, where $\mathbf{n}=\nabla\varphi/|\nabla\varphi|$. Then its integral curves are normal to all level surfaces of φ in $\varphi^{-1}(-t,t)$, and, moreover, for each $s\in(-t,t)$ we have a diffeomorphism $\alpha_s:\varphi^{-1}(0)\to\varphi^{-1}(-t,t)$, such that $\alpha_0=t$ and $(d/ds)\alpha_s(\mathbf{x})=X(\alpha_s(\mathbf{x}))$.[25] Now

$$\frac{d}{ds}\,\varphi(\alpha_s(\mathbf{x}))=X(\varphi)(\alpha_s(\mathbf{x}))=1,$$

because

$$X(\varphi)(\mathbf{x})=\frac{1}{|\nabla\varphi|^2}\left(\sum_{i=1}^{3}\frac{\partial\varphi}{\partial x_i}\frac{\partial}{\partial x_i}\right)\varphi(\mathbf{x})=1.$$

So by the initial condition $\varphi(\alpha_0(\mathbf{x}))=\varphi(\mathbf{x})$ we get $\varphi(\alpha_s(\mathbf{x}))=s+\varphi(\mathbf{x})$, and if $\mathbf{x}\in\Gamma$, the last term is zero. Thus, we have diffeomorphisms $\alpha_s:\varphi^{-1}(0)\to\varphi^{-1}(s)$. Now equip an open neighborhood $U\subset\varphi^{-1}(0)$ with local coordinates $\mathbf{y}$ by a chart, then α_s will equip $\alpha_s(U)\subset\varphi^{-1}(s)$ with the same coordinates. Thus, we have the desired local coordinates $(\mathbf{y},\varphi)$ on the set $V:=\varphi^{-1}(-t,t)\cap\alpha_{(-t,t)}(U)$, providing there are no critical points in V. If there are, we just take a bounded U or a smaller t. (The incompleteness of X on $\varphi^{-1}[-t,t]$ is not an obstacle to the

argument—just attenuate X with appropriate smooth bump functions to make it integrable with speed 1 on φ, where we want it.) ■

For a function $f \in L^1(\mathbb{R}^n)$, we have

$$\int_V f(\mathbf{x})\ d\mu(\mathbf{x}) = \int_V f(\mathbf{y},\varphi) J(\mathbf{y},\varphi)\ d\mathbf{y} d\varphi,$$

where J is the Jacobian and V is as in the preceding proof. Observe that for a fixed $\varphi = s$ that $J(\mathbf{y},s)d\mathbf{y}$ is not yet the surface measure $d\gamma_s$ on $\varphi^{-1}(s)$. For that the orthogonal coordinate φ needs to be expressed in terms of the length of the curves $\mathbf{y} = \text{const}$. Since $d\varphi = |\nabla\varphi| dl$, with dl the length measure on a curve $\mathbf{y} = \text{const}$, we conclude that $d\gamma_s(\mathbf{y}) = [J \cdot |\nabla\varphi|](\mathbf{y},s) d\mathbf{y}$. Now

$$\int_V |\nabla\varphi(\mathbf{x})| f(\mathbf{x}) d\mu(\mathbf{x}) = \int_V f(\mathbf{y},\varphi)[J \cdot |\nabla\varphi|]\ d\mathbf{y} d\varphi = \int_{-t}^{t} \left(\int_U f \cdot J \cdot |\nabla\varphi| d\mathbf{y} \right) d\varphi, \tag{3.3}$$

and this is the expression we wish to exploit. Let $f \in C_c(\mathbb{R}^n)$, and let the thickness of the shell $\varphi^{-1}[-t,t]$ around Γ approach zero; then

$$\lim_{s\to 0} \frac{1}{2s} \int_{V \cap \varphi^{-1}[-s,s]} |\nabla\varphi| \cdot f d\mu = \lim_{s\to 0} \frac{1}{2s} \int_{-s}^{s} \left(\int_U f \cdot J \cdot |\nabla\varphi| d\mathbf{y} \right) d\varphi$$

$$= \int_U (f \cdot J \cdot |\nabla\varphi|)(\mathbf{y},0) d\mathbf{y},$$

where the use of the fundamental theorem of calculus is justified because the function

$$\varphi \to \int_U (f \cdot J \cdot |\nabla\varphi|)(\mathbf{y},\varphi) d\mathbf{y}$$

is continuous due to the uniform continuity of the integrand—a consequence of $f \in C_c(\mathbb{R}^n)$ and $J \cdot |\nabla\varphi| \in C^\infty(V)$. Thus

$$\lim_{s\to 0} \frac{1}{2s} \int_{V \cap \varphi^{-1}[-s,s]} |\nabla\varphi| \cdot f d\mu = \int_U (f \restriction \Gamma) d\gamma.$$

By doing this for all open patches $U \subset \Gamma$ (equipped with charts), we conclude

$$\lim_{s\to 0} \frac{1}{2s} \int_{\varphi^{-1}[-s,s]} |\nabla\varphi| \cdot f d\mu = \int_\Gamma (f \restriction \Gamma) d\gamma, \tag{3.4}$$

for all $f \in C_c(\mathbb{R}^n)$.

In particular, let $\psi_1, \psi_2 \in C_c(\mathbb{R}^n)$; then we have

$$(\psi_1 \restriction \Gamma, \psi_2 \restriction \Gamma)_{L^2(\Gamma)} = \lim_{t\to 0} \frac{1}{2t} \int_{\varphi^{-1}[-t,t]} \overline{\psi_1} \cdot \psi_2 \cdot |\nabla\varphi| d\mu$$

$$= \lim_{t\to 0} \frac{1}{2t} (\psi_1, |\nabla\varphi| \cdot \chi_{\varphi^{-1}[-t,t]} \psi_2) = \lim_{t\to 0} \frac{1}{2t} (\psi_1, \hat{h} P_t \psi_2), \tag{3.5}$$

where we used the notation $(\hat{h}\psi)(\mathbf{x}) := |\nabla\varphi(\mathbf{x})| \psi(\mathbf{x})$ and $P_t := \hat{\chi}_{\varphi^{-1}[-t,t]}$ and (3.5) is the desired relation between the inner products of the initial space $L^2(\mathbb{R}^n)$ and of the physical space $L^2(\Gamma)$. We use the notation χ_S for the characteristic function of S. (Note that P_t is just the spectral projection of $\hat{\varphi}$ on the interval $[-t,t]$, and that $\hat{h}$ is a positive bounded operator on $P_t\mathscr{H}$.) Now the right-hand side of this equation will exist for a much larger class of functions in $L^2(\mathbb{R}^n)$ than $C_c(\mathbb{R}^n)$, though for some of these the restrictions to Γ on the left-hand side may not be defined. However, the limit in (3.5) will definitely fail to exist for some elements of $L^2(\mathbb{R}^n)$. Define

$$(\psi_1,\psi_2)_\Gamma := \lim_{t\to 0}\frac{1}{2t}(\psi_1,\hat{h}P_t\psi_2), \tag{3.6}$$

for all pairs ψ_1,ψ_2 for which the rhs is defined and finite. To obtain a positive sesquilinear form from (3.6), we need to decide on a dense domain on which $(\cdot,\cdot)_\Gamma$ is defined and finite. Clearly, $C_c(\mathbb{R}^n)$ is one such domain, but it is not maximal. In fact, $(\cdot,\cdot)_\Gamma\restriction C_c(\mathbb{R}^n)$ has no closed extensions as a sesquilinear form (cf. Ref. 26, p. 278), so there is no canonical way of getting a maximal domain. The set

$$S := \{\psi\in L^2(\mathbb{R}^n)\,|\,(\psi,\psi)_\Gamma \text{ exists and is finite}\}$$

is not a linear space since $(\psi_1,\psi_2)_\Gamma$ need not exist for $\psi_1,\psi_2\in S$, as one can verify with easy examples. Nevertheless, some domains containing $C_c(\mathbb{R}^n)$ seem quite natural, e.g., the domain C_φ consisting of those $\psi\in L^2(\mathbb{R}^n)$ for which there is some $t>0$ (depending on ψ) such that $P_t\psi\in C_c(\varphi^{-1}[-t,t])$, and clearly the argument that led to Eq. (3.5) is still valid for $\psi_i\in C_\varphi$. Now C_φ is still not maximal and we can, of course, choose a maximal defining subset for $(\cdot,\cdot)_\Gamma$ in S containing C_φ, but this choice is not unique. Equip the factor space $C_\varphi/\mathrm{Ker}(\cdot,\cdot)_\Gamma$ with the inner product $(\cdot,\cdot)_\Gamma$, making it into a pre-Hilbert space that we complete to obtain the Hilbert space $\mathscr{H}_\Gamma$. We identify $\mathscr{H}_\Gamma$ with $L^2(\Gamma)$ in a natural way:

Theorem 3.7: *With the structures above, denote by* $\mathscr{C}:C_\varphi\to C_\varphi/\mathrm{Ker}(\cdot,\cdot)_\Gamma$ *the factor map; then (1)* $(\mathscr{C}\psi_1,\mathscr{C}\psi_2)_\Gamma=(\psi_1\restriction\Gamma,\psi_2\restriction\Gamma)_{L^2(\Gamma)}$ *for all* $\psi_i\in C_c(\mathbb{R}^n)$, *(2) there is a unitary* $U:\mathscr{H}_\Gamma\to L^2(\Gamma,\gamma)$ *such that* $U\mathscr{C}\psi=\psi\restriction\Gamma$ *for all* $\psi\in C_c(\mathbb{R}^n)$, *and* $(U\mathscr{C})(C_c(\mathbb{R}^n))=C_c(\Gamma)$.

Proof: (1) Since $(\psi_1,\psi_2)_\Gamma=(\mathscr{C}\psi_1,\mathscr{C}\psi_2)_\Gamma$, this is already proven above. (2) Let $\psi\in C_c(\mathbb{R}^n)$ and define $U\mathscr{C}\psi := \psi\restriction\Gamma$, which is in $C_c(\Gamma)$, since Γ is a closed subset of $\mathbb{R}^n$. To see that U is well defined on $C_c(\mathbb{R}^n)/\mathrm{Ker}(\cdot,\cdot)_\Gamma$, let $\psi_1,\psi_2\in C_c(\mathbb{R}^n)$ with $(\psi_1-\psi_2)\restriction\Gamma=0$. Then by (3.4) we find $\psi_1-\psi_2\in\mathrm{Ker}(\cdot,\cdot)_\Gamma$, i.e., $\mathscr{C}\psi_1=\mathscr{C}\psi$ so U is well defined. Moreover, from (1) we see that U is unitary on the dense subspace $\mathscr{C}[C_c(\mathbb{R}^n)]$; hence it extends to a unitary on $\mathscr{H}_\Gamma$. Clearly $C_c(\mathbb{R}^n)\restriction\Gamma=C_c(\Gamma)$, so since the image of U contains a dense subspace and U is unitary, we find the map $U:\mathscr{H}_\Gamma\to L^2(\Gamma)$ is onto. ∎

This means the restriction map can be written as $\kappa := U\circ\mathscr{C}:C_\varphi\to L^2(\Gamma)$, but now it implicitly involves a limiting process, which we will exploit below. Note that $C_c(\mathbb{R}^n)\cap\mathrm{Ker}(\cdot,\cdot)_\Gamma=\{\psi\in C_c(\mathbb{R}^n)\,|\,\psi\restriction\Gamma=0\}$ and that κ is unbounded (w.r.t. the Hilbert space norms).

Example: We want to see what the above structure looks like in the restriction of a quantum particle in $\mathbb{R}^3$ to a sphere. So take $\mathscr{H}=L^2(\mathbb{R}^3)$, $\hat{\mathbf{p}}\psi=i\boldsymbol{\nabla}\psi$, $\hat{\mathbf{q}}\psi(\mathbf{x})=\mathbf{x}\psi(\mathbf{x})$ as usual, and for the constraint $\varphi(\mathbf{x})=|\mathbf{x}|^2-a^2$, $a>0$. Now $(\nabla\varphi)(\mathbf{x})=2\mathbf{x}\neq 0$ except if $\mathbf{x}=0$, and so the critical point of φ is distance a away from $\Gamma=\varphi^{-1}(0)$. We have $\varphi^{-1}[-s,t]=\{\mathbf{x}\in\mathbb{R}^3\,|\,|\mathbf{x}|^2\in[a^2-s,a^2+t]\}$, $s,t>0$. So

$$\begin{aligned}(\psi_1,\psi_2)_\Gamma=\lim_{t\to 0}\frac{1}{2t}(\psi_1,\hat{h}P_t\psi_2)&=\frac{1}{2}\frac{d}{dt}\int_{\varphi^{-1}[-t,t]}2|\mathbf{x}|(\overline{\psi_1}\psi_2)(\mathbf{x})d^3x\Big|_{t=0}\\&=\frac{d}{dt}\int_{\sqrt{a^2-t}}^{\sqrt{a^2+t}}r^2dr\int d\Omega\, r(\overline{\psi_1}\psi_2)(\mathbf{x})\Big|_{t=0},\end{aligned}$$

where we used polar coordinates, and Ω denotes the measure on the unit sphere $\mathbf{S}^2$. For functions of the form $\psi_i(\mathbf{x})=f_i(r)\xi_i(\theta,\phi)$, $\xi_i\in L^2(\mathbf{S}^2)$, and f_i continuous on $(a-\epsilon,a+\epsilon)$ we have, by the fundamental theorem of calculus,

$$(\psi_1,\psi_2)_\Gamma=\left(\frac{d}{dt}\int_{\sqrt{a^2-t}}^{\sqrt{a^2+t}}r^3\overline{f_1}f_2(r)dr\Big|_{t=0}\right)\int\overline{\xi_1}\xi_2(\theta,\phi)d\Omega=a^2\overline{f_1}(a)f_2(a)\int\overline{\xi_1}\xi_2\,d\Omega,$$

as expected from (3.5). Moreover, we have that $\psi_i\in\mathrm{Ker}(\cdot,\cdot)_\Gamma$ whenever $f_i(a)=0$.

One may ask how the method above should be generalized to bigger classes of constraints, so toward that a few remarks.

Remarks: (1) If Γ has corners (so φ is not smooth) we can develop an ''approximation'' to it by a sequence of smooth submanifolds $\{\Gamma_k\}$, but need to choose a notion of convergence for $\Gamma_k \to \Gamma$.

(2) If Γ has edges, we can combine the procedure above with enforcing a Dirac constraint. For example, if we want to constrain a particle in $\mathbb{R}^3$ to the upper hemisphere Γ_+ of the sphere Γ of the last example,

$$\Gamma_+ := \{\mathbf{x} \in \mathbb{R}^3 |\ |\mathbf{x}| = a,\ x_1 \geqslant 0\},$$

then first apply the method above to the constraint $\varphi(\mathbf{x}) = |\mathbf{x}|^2 - a^2$ to obtain a dense subspace of $L^2(\Gamma)$, and follow this by applying a Dirac procedure via (3.1) to the constraint $\zeta(\theta, \phi) = \chi_{[0,\pi/2]}(\theta)$ in $L^2(\Gamma)$.

(3) To constrain a particle in $\mathbb{R}^n$ to a smooth $(n-k)$-dimensional submanifold Γ, we need k independent constraints $\varphi_1, \ldots, \varphi_k$ such that $\Gamma = \varphi_1^{-1}(0) \cap \cdots \cap \varphi_k^{-1}(0)$ with critical points well away from Γ. Now it is clear how to adapt the method based on (3.2)—we choose a curvilinear coordinate system $(\mathbf{y}, \varphi_1, \ldots, \varphi_k)$, where φ_i are the coordinates measured along the trajectories of the gradient fields $\boldsymbol{\nabla}\varphi_i$, and $\mathbf{y}$ are the coordinates along the manifolds $\varphi_1^{-1}(c_1) \cap \cdots \cap \varphi_k^{-1}(c_k)$, $\mathbf{c}$ in some ϵ neighborhood of zero in $\mathbb{R}^k$. Then with J the Jacobian, the measure on Γ is $d\gamma = (J \cdot |\boldsymbol{\nabla}\varphi_1| \cdots |\boldsymbol{\nabla}\varphi_k|)(\mathbf{y}, 0, \ldots, 0) d\mathbf{y}$ so (3.3) becomes, for $f \in C_c(\mathbb{R}^n)$,

$$\lim_{s \to 0} [2^k s_1 \cdots s_k]^{-1} \int_{\varphi^{-1}[-\mathbf{s}, \mathbf{s}]} |\boldsymbol{\nabla}\varphi_1| \cdots |\boldsymbol{\nabla}\varphi_k| \cdot f d\mu = \int_\Gamma (f \restriction \Gamma) d\gamma,$$

where $\varphi^{-1}[-\mathbf{s}, \mathbf{s}] := \varphi_1^{-1}[-s_1, s_1] \cap \cdots \cap \varphi_k^{-1}[-s_k, s_k]$. Further adaptations are straightforward.

Alternatively, we can impose the constraints φ_i one by one, but for this we need to generalize the procedure above for $\mathbb{R}^n$ to general Riemannian manifolds.

(4) For φ that are positive, $\Gamma = \varphi^{-1}(0)$ consists only of critical points, though if other critical points are well away from Γ, there is still a neighborhood of Γ foliated by the level hypersurfaces of φ, and it is possible to adapt the method above to this situation.

(5) In the case where $\varphi^{-1}(0) = \Gamma \cup \Delta$ with $\mu(\Gamma) = 0 \neq \mu(\Delta)$, $\Gamma \cap \Delta = \varnothing$, neither the Dirac method [which will only produce $L^2(\Delta)$] nor the method above seem appropriate. So what we want is a method that will give the method above on Γ, and the Dirac procedure on Δ. (We choose not to allow surface terms on Δ.) Assume the critical points of φ are well away from Γ, and that Δ is the closure of an open set. That is, we want a densely defined map $\kappa: L^2(\mathbb{R}^n) \to L^2(\Gamma) \oplus L^2(\Delta)$. Recalling that $L^2(\Delta) = P_{\{0\}} L^2(\mathbb{R}^n)$, this can be done by defining

$$(\psi_1, \psi_2)_R := (\psi_1, P_{\{0\}} \psi_2) + \lim_{t \to 0} \frac{1}{2t} (\psi_1^N, \hat{h} P_t \psi_2^N),$$

for all $\psi_i \in \mathbf{D}_R := \{\psi \in \mathscr{H} | \psi^N \in C_\varphi\}$, where $\psi^N := \chi_N \cdot \psi$ and N is an open neighborhood of Γ such that $N \cap \Delta = \varnothing$. Then proceed as before, taking $\mathbf{D}_R / \mathrm{Ker}(\cdot, \cdot)_R$ with κ the composition of the factor map and the unitary from $\mathbf{D}_R / \mathrm{Ker}(\cdot, \cdot)_R$ to $L^2(\Gamma) \oplus L^2(\Delta)$.

(6) At the cost of complicating the current exposition, we can enlarge the domain C_φ of κ considerably. For instance, by splitting the limit (3.6) into the average of the limits from above and below in t, and letting the domain consist of those $\psi \in L^2(\mathbb{R}^n)$ for which $\varphi \to \psi(\mathbf{y}, \varphi)$ is continuous from above and below at zero (where we used the curvilinear coordinates of Lemma 3.2), we obtain another useful domain for κ. We chose not to do this because the additional analytic details would have obscured the simplicity of our central idea.

(7) The methods proposed here for dynamics reduction can be extended to other holonomic constraints, i.e., if we are given a constraint $\varphi(\mathbf{q}, \mathbf{p})$, which involves only one member of each canonical pair (q_i, p_i), then a partial Fourier transform can convert it to the type $\varphi(\mathbf{q})$ considered here. So there is a unitary transformation of such a system to one of the present type.

IV. CONSTRAINING THE DYNAMICS

In this section we continue the analysis of the problem of constraining a quantum particle in $\mathbb{R}^n$ to a subset and address the problem of how to constrain the dynamics, i.e., how to construct out of the given time evolution on $L^2(\mathbb{R}^n)$ an acceptable time evolution on the physical Hilbert space. We consider four cases.

(1) For an ordinary Dirac constraining we restrict, for example, a quantum particle in $\mathbb{R}^n$ with Hamiltonian H to live on a set T, which is the closure of an open set S [hence $\mu(T)\neq 0$]. Kinematically, one constrains via the projection $P_{\text{phys}}: L^2(\mathbb{R}^n)\to L^2(T)$, as described at the start of Sec. III. If the dynamics preserve T, i.e., each $U_t := \exp itH$ is of the form

$$U_t = \begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}$$

with respect to the decomposition $L^2(\mathbb{R}^n)=L^2(T)\oplus L^2(T)^{\perp}$, then there is no problem; one just restricts U_t to $L^2(T)$ to obtain the constrained dynamics. In practice this is a rare occurrence.

(2) For the case of a Dirac constraining as in (1), where the dynamics does not preserve T, e.g., if the particle is free, $H=\hat{\mathbf{p}}^2/2m$ and T is compact, then $H\restriction L^2(T)$ is not self-adjoint. To equip the constrained particle with a time evolution, we need to choose some self-adjoint extension of the symmetric operator $H\restriction C_c^{\infty}(S)$ [for this to make sense we need to assume that H preserves $C_c^{\infty}(S)$, which will be true if it is a differential operator]. This amounts to the choice of boundary conditions, i.e., deciding how the particle should behave at the walls (e.g., reflection), and this is a physical choice that cannot be determined from mathematical considerations alone.

(3) For the problem of the last section where we constrain a particle in $\mathbb{R}^n$ with Hamiltonian H to a lower-dimensional submanifold Γ, we will need to assume that H is ''smooth enough'' near Γ, i.e., $H(\text{Dom } H\cap C_{\varphi})\subset C_{\varphi}$ and $\kappa(\text{Dom } H\cap C_{\varphi})$ is dense in $L^2(\Gamma)$. In the case where H ''preserves'' Γ, i.e., H preserves Dom $H\cap$Ker κ, H will clearly lift through κ, and we only need to define the constrained Hamiltonian H_{Γ} on $L_2(\Gamma)$ by $H_{\Gamma}\kappa(\psi) := \kappa(H\psi)$ for all $\psi \in \text{Dom } H\cap C_{\varphi}$, and require that it is essentially self-adjoint.

(4) The case of constraining a particle as in (3), but where H does not preserve Γ, will be our object of study for the rest of this section. By analogy with case (2), we expect that some physical choices will need to be made. When H is a Schrödinger operator with smooth potential, physicists already know what to do. One lets the constrained Hamiltonian be $(1/2m)\Delta_{\Gamma}+V\restriction\Gamma$, where Δ_{Γ} is the Laplacian on Γ.

Henceforth, we assume that H on $L^2(\mathbb{R}^n)$ does not preserve Γ in the sense of (3) above. Recalling that $\kappa: C_{\varphi}\to L^2(\Gamma)$ involves a factorization, it is natural to look for linear sections of κ that one can use to construct liftings of operators on C_{φ} to $L^2(\Gamma)$. The image of such a section deserves a name of its own.

Definition: A *transverse space* is a linear space $\mathscr{T}\subset C_{\varphi}$ such that Ker $\kappa\cap\mathscr{T}=\{0\}$ and $\kappa(\mathscr{T})$ is dense in $L^2(\Gamma)$.

Transverse spaces are abundant, and below we will use physical arguments to make a choice of a transverse space but first we show how one can use a transverse space to constrain H. Given a transverse space $\mathscr{T}\subset\text{Dom } H\cap C_{\varphi}$ such that $H.\mathscr{T}\subset C_{\varphi}$, we have the following options.

(i) Define the constrained Hamiltonian $H_{(i)}$ with dense domain $\kappa(\mathscr{T})$ by

$$H_{(i)}\kappa(\psi) := \kappa(H\psi), \quad \forall\,\psi\in\mathscr{T}.$$

This is well defined since, by definition of transverse spaces, κ is injective on $\mathscr{T}$.

(ii) Given that the choice of $\mathscr{T}$ has some physical content (see below), one may object to (i) in that H is not forced to preserve $\mathscr{T}$ in any sense. If we want to include such a restriction, since it is only the behavior near Γ that should be important, we can restrict H to $\mathscr{T}$ ''in the limit,'' i.e., we consider the projection $P^t_{\mathscr{T}}H$ as t goes to zero in the definition of κ, where $P^t_{\mathscr{T}}$ denotes the projection onto $P_t.\mathscr{T}$. So we propose an alternative constrained Hamiltonian $H_{(ii)}$ on $\kappa(\mathscr{T})$ by

$$(H_{(ii)}\kappa(\psi),\ \kappa(\phi))_{L^2(\Gamma)}=\lim_{t\to 0}\frac{1}{2t}\,(P^t_{\mathscr{T}}H\psi,\ \hat{h}P_t\phi),$$

for all $\psi,\ \phi\in\mathscr{T}$.

Below we will test both methods for a suitable choice of transverse space. This choice is the issue we now want to address. Recall that in the classical global method of Gotay, Nester, and Hinds,[2] the idea was to adjust the dynamics so that the motion is always tangential to Γ, thus forcing the particle to remain on Γ. We look for some quantum mechanical version of this.

First we want to give meaning to the concept of motion ''tangential to Γ'' for a quantum particle. While the classical state of a particle is a point in phase space, quantum mechanically a state is here a vector ψ in $L^2(\mathbb{R}^n)$. Classically, a particle with constant mass at position $\mathbf{q}$ moves tangentially to Γ if its momentum $\mathbf{p}=m\dot{\mathbf{q}}$ is tangential to Γ, i.e., $\mathbf{p}\in T_{\mathbf{q}}\Gamma$. Inspired by this, in a quantum mechanical setting, we say a particle in a state $\psi\in C_c^\infty(\mathbb{R}^n)$ moves tangentially to Γ if $(\hat{\mathbf{p}}\psi)(\mathbf{q})\in T_{\mathbf{q}}\Gamma$ for all $\mathbf{q}\in\Gamma$. Now, given the normal vectors $\boldsymbol{\nabla}\varphi$ to Γ, we have $\mathbf{v}\in T_{\mathbf{q}}\Gamma$ iff $\boldsymbol{\nabla}\varphi(\mathbf{q})\cdot\mathbf{v}=0$. So a particle in a state $\psi\in C_c^\infty(\mathbb{R}^n)$ moves tangentially to Γ when $(\boldsymbol{\nabla}\varphi\cdot\hat{\mathbf{p}}\psi)(\mathbf{x})=0$ for all $\mathbf{x}\in\Gamma$, i.e., iff the component of the momentum of ψ normal to Γ is zero. We would like to generalize this notion away from $C_c^\infty(\mathbb{R}^n)$. Since Γ is of μ measure zero, we cannot, in general, specify a property for an L^2 function $\psi\in L^2(\mathbb{R}^n)$ on Γ. Recall that κ is a limiting procedure on the shells $\varphi^{-1}[-t,t]$, in which eventually $t\to 0$. So it may be enough to define tangentiality on the level sets of φ in such a shell, and depend on κ to restrict the property to Γ. Fix a shell $S_{t_0}:=\varphi^{-1}[-t_0,t_0]$ around Γ; then we say a $\psi\in\mathrm{Dom}(\hat{\mathbf{p}}\restriction L^2(S_{t_0}))$ has momentum tangential to the level sets of φ iff $\boldsymbol{\nabla}\varphi\cdot\hat{\mathbf{p}}\psi=0$. Since in terms of the local coordinate system $(\mathbf{y},\varphi)$ of Sec. III this means $\partial\psi/\partial\varphi=0$ on S_{t_0}, we see that $\psi\restriction S_{t_0}$ must be constant in the normal direction (i.e., along the trajectories of the vector field $\boldsymbol{\nabla}\varphi$). So $\psi\restriction S_{t_0}$ is uniquely determined by its restriction to Γ. This defines the notion of ''states with momentum tangential to the level sets of φ in S_{t_0}.''

Conversely, given any $\psi\in L^2(\Gamma)$, we can make out of it a state $\tilde{\psi}\in L^2(\mathbb{R}^n)$ by extending it constantly along the normals in S_{t_0} and set it equal to zero outside S_{t_0}, i.e.,

$$\tilde{\psi}(\mathbf{x})=\psi(\alpha^{-1}_{\varphi(\mathbf{x})}(\mathbf{x})),\qquad \text{for } \mathbf{x}\in S_{t_0} \text{ and zero for } \mathbf{x}\notin S_{t_0}$$

(cf. the proof of Lemma 3.2 for α). Denote the space of these by $\mathscr{H}^T_{t_0}$, and the projection onto $\mathscr{H}^T_{t_0}$ by $P^T_{t_0}$. Then $\mathscr{H}^T_{t_0}$ is thought of as a ''thickening'' of $L^2(\Gamma)$ in $L^2(\mathbb{R}^n)$, and note that $\mathscr{H}^T_{t_0}\cap C_\varphi$ is a transverse space. However, when we deal with differential operators, the discontinuity at the boundary of the shell S_{t_0} is a problem, so we prefer the following smooth version. Let $\zeta_{t_0}\in C^\infty(\mathbb{R})$ be a bump function that is unity on $[-t_0,t_0]$ and zero outside $[-t_0-\epsilon,t_0+\epsilon]$ for a given ϵ. Then define for a $\psi\in L^2(\Gamma)$ the new thickening,

$$\check{\psi}(\mathbf{x})=\zeta_{t_0}(\varphi(\mathbf{x}))\cdot\psi(\alpha^{-1}_{\varphi(\mathbf{x})}(\mathbf{x})).$$

Denote the space spanned by these by $\mathscr{H}^\zeta_{t_0}\subset L^2(\mathbb{R}^n)$, then clearly $P_{t_0}\mathscr{H}^\zeta_{t_0}=\mathscr{H}^T_{t_0}$.

We now want to constrain the Hamiltonian in such a way that it can be thought of as ''projecting the force down to its tangential component,'' where a Hamiltonian tangential to Γ will be one that keeps tangential motion to Γ tangential, i.e., preserves the tangential states on some shell S_{t_0}. Recall that in the GNH algorithm,[2] one restricted the Hamiltonian to all states with motion tangential to Γ. To do the same here, we can now use either of the two proposed methods (i) or (ii) above with the choice of transverse space as

$$\mathscr{T}_{t_0}:=\mathscr{H}^\zeta_{t_0}\cap C_\varphi\cap\mathrm{Dom}\ H.$$

As long as $C_c^\infty(\mathbb{R}^n)\subset\mathrm{Dom}\ H$, we have that $\kappa(\mathscr{T}_{t_0})$ is dense, in which case this is indeed a transverse space. So assuming the latter, and that $H\mathscr{T}_{t_0}\subset C_\varphi$, we define

$$H_{(i)}\cdot\kappa(\psi):=\kappa(H\psi),\quad \forall\,\psi\in\mathscr{T}_{t_0}. \tag{4.1}$$

In fact, when ψ is smooth and H is a differential operator, this becomes $H_{(i)}(\psi\restriction\Gamma)=(H\psi)\restriction\Gamma$, and then the method is nothing but the one used by Helgason, pp. 251–252[27] for the restriction of a differential operator to a submanifold. This is the first reasonable method to consider.

To motivate the use of method (ii), consider how a physicist might object to (4.1). Since H need not preserve $\mathscr{T}_{t_0}$, it is possible that $H\psi$ has momentum that is not tangential to Γ, in which case it seems there is a force acting on the particle, forcing it off Γ. To project this force out of the total force acting on the particle, the restriction procedure above may not be appropriate. Instead, we intend to use the Hilbert space projections to first project out of H the parts that affect the momentum component normal to the level surfaces of φ in the shell $\varphi^{-1}[-t_0,t_0]$; then in the limit of κ when the thickness of the shell goes to zero, we will be left with the appropriate Hamiltonian on $L^2(\Gamma)$ (having maintained tangentiality of momentum to Γ during the limiting process). In the light of this we define $H_{(ii)}$ by

$$(H_{(ii)}\cdot\kappa(\psi_1),\ \kappa(\psi_2))_{L^2(\Gamma)}:=\lim_{t\to 0}\frac{1}{2t}\,(P_t^T H\psi_1,\ \hat{h}P_t\psi_2), \tag{4.2}$$

for all $\psi_1\in\mathscr{T}_{t_0}$ for which this exists for all $\psi_2\in\mathscr{T}_{t_0}$ [so that (4.2) defines a vector $H_{(ii)}\kappa(\psi_1)\in L^2(\Gamma)$]. Since $P_t\overline{\mathscr{T}}_{t_0}\subset\mathscr{H}_t^T$, (4.2) coincides with method (ii). This is the second reasonable method.

One can easily conceive of other methods apart from (i) and (ii) for constraining dynamics, for instance, forcing the particle onto Γ by infinite potential walls.

(iii) Given a system $L^2(\mathbb{R}^n)$, φ, H as before, restrict the particle to a box around Γ, say the shell S_t, but for it to be well defined we need to assume $HC_c^\infty(S_t)\subseteq C_c^\infty(S_t)$ and that we have a self-adjoint extension H_t on $L^2(S_t)$ of the symmetric operator $H\restriction\{\psi\in C_c^\infty(S_t)\,|\,\psi(\varphi^{-1}(\pm t))=0\}$. In the case when H is a differential operator, this means one needs to decide how it behaves at the walls. Henceforth, we assume that H is a differential operator. If we choose ordinary reflection at the walls (quantum billiards), then a $\psi\in\mathrm{Dom}\,H_t$ must satisfy

$$\frac{\partial\psi}{\partial\varphi}=0,\quad \text{when}\quad \varphi=\pm t,$$

but without more detailed knowledge of H we do not know what additional boundary conditions ψ must satisfy to make H_t self-adjoint. So Dom H_t is a subspace of

$$\mathscr{D}_t:=\left\{\psi\in P_tC^\infty(\mathbb{R}^n)\,\middle|\,\psi\in L^2(\mathbb{R}^n),\quad \frac{\partial\psi}{\partial\varphi}=0,\quad \text{when}\quad \varphi(\mathbf{x})=\pm t\right\}\subset C_\varphi.$$

Then, in the limit when t goes to zero, the boxes force the particle (hence H_t) onto Γ. The appropriate way to take this limit, is through κ, i.e.,

$$(H_{(iii)}\cdot\kappa(\psi_1),\ \kappa(\psi_2))_{L^2(\Gamma)}:=\lim_{t\to 0}\frac{1}{2t}\,(H_tP_t\psi_1,\ \hat{h}P_t\psi_2), \tag{4.3}$$

where $\psi_i\restriction S_t\in\mathrm{Dom}\,H_t$ for all $t\in(0,t_0)$ and some fixed t_0. Note that the possible ψ_i's are restricted by the behavior at the boundary. So here for reflection, we get that $(\partial\psi_i/\partial\varphi)(\mathbf{y},t)=0$ for all $t\in[-t_0,0)\cup(0,t_0]$. We recognize that $P_t\psi$ is in our transverse space of earlier on. When the space of $\kappa(\psi)$ for such ψ is dense in $L^2(\Gamma)$, $H_{(iii)}$ is well defined. Other versions of this are possible if we change the behavior at the walls, e.g., introduce a phase with the reflection.

We will not discuss any other methods, but now the surprise is that we have the following equivalences.

Theorem 4.4: (1) *With the assumptions above,* $H_{(i)}=H_{(ii)}=:H_\Gamma$; (2) *moreover, if H is a differential operator, then* $H_{(i)}=H_{(iii)}$ *on Dom* $H_{(iii)}$.

Proof: (1) We first show $H_{(i)}=H_{(ii)}$. Recall that $C_c^\infty(\mathbb{R}^n)\subset\mathrm{Dom}\,H$, and that $\kappa(\mathscr{T}_{t_0}\cap C_c^\infty(\mathbb{R}^n))=C_c^\infty(\Gamma)$; hence it suffices to show that

$$((H_{(i)}-H_{(ii)})\kappa(\psi_1),\ \kappa(\psi_2))_{L^2(\Gamma)}=0,$$

for all $\psi_i \in \mathscr{T}_{t_0} \cap C_c^\infty(\mathbb{R}^n)$. By (4.1) and (4.2), the left-hand side is

$$\lim_{t\to 0} \frac{1}{2t} ((\mathbb{I}-P_t^T)H\psi_1,\ \hat{h}P_t\psi_2) = \lim_{t\to 0} \frac{1}{2t} \int_{S_t} \overline{(\mathbb{I}-P_t^T)H\psi_1}\psi_2 |\nabla\varphi| d\mu.$$

Partition Γ into patches U on which local coordinates exist as in Lemma 3.2; then the right-hand side becomes a finite sum of terms:

$$\lim_{t\to 0} \frac{1}{2t} \int_{-t}^{t} d\varphi \int_U d\mathbf{y} \overline{(\mathbb{I}-P_t^T)H\psi_1}\psi_2 |\nabla\varphi| \qquad (*)$$

(alternatively, take ψ_2 with support in U and let U vary). Now $(\mathbb{I}-P_t^T)H\psi_1 =: \rho_t \perp \mathscr{H}_t^T$, so for all $\phi \in \mathscr{H}_t^T \cap C_c^\infty(S_t)$ we have

$$0 = (\rho_t, \phi) = \int_U d\mathbf{y}\phi(\mathbf{y}) \int_{-t}^{t} d\varphi\ \overline{\rho_t},$$

where we used the fact that on S_t, ϕ is independent of φ, so since this holds for all ϕ [which will span a dense subspace of $L^2(U)$], we have that $\int_{-t}^{t} \rho_t(\mathbf{y},\varphi)d\varphi = 0$, a.e. in $\mathbf{y}$. Now using the continuity of $\psi_2|\nabla\varphi|$, $(*)$ becomes

$$\lim_{t\to 0} \frac{1}{2t} \int_U d\mathbf{y}(\psi_2|\nabla\varphi|)(\mathbf{y},0) \int_{-t}^{t} d\varphi\ \overline{\rho_t} = 0.$$

Since this holds for all U, we find that $H_{(i)} = H_{(ii)}$.

(2) Next we prove that $H_{(i)} = H_{(iii)}$ on $\mathrm{Dom}\, H_{(iii)}$. Clearly $\cap_{t\in[0,t_0]} \mathscr{D}_t \restriction S_{t_0} = \mathscr{H}_{t_0}^T$, so it suffices to show that

$$((H_{(i)} - H_{(ii)})\kappa(\psi_1),\ \kappa(\psi_2))_{L^2(\Gamma)} = 0, \quad \forall \psi_i \in C_c^\infty(S_{t_0}) \cap \Big(\bigcap_{t\in(0,t_0]} \mathrm{Dom}\, H_t\Big),$$

i.e., that

$$\lim_{t\to 0} \frac{1}{2t} ((H - H_tP_t)\psi_1,\ \hat{h}P_t\psi_2) = 0.$$

Now

$$((H - H_tP_t)\psi_1,\ \hat{h}P_t\psi_2) = ((P_tH - H_tP_t)\psi_1,\ \hat{h}P_t\psi_2),$$

and let

$$\mathscr{Q}_t := \{\phi \in C_c^\infty(S_t) \mid \phi(\varphi^{-1}(\pm t)) = 0\},$$

which is dense in $L^2(S_t)$, and $H = H_t$ on $\mathscr{Q}_t$. Now, given an open precompact set $X \subset S_t$, we can write any $\phi \in C_c^\infty(\mathbb{R}^n)$ as $\phi = \phi_X + \tilde{\phi}_X$, where $\phi_X \in \mathscr{Q}_t$ and $\phi \restriction X = \tilde{\phi}_X \restriction X$. Let $\psi \restriction S_t \in \mathrm{Dom}\, H_t \cap C_c^\infty(S_t)$ for all $t \in (0,t_0]$, let $\phi \in \mathscr{Q}_t$ and X be the interior of supp ϕ. Then

$$\begin{aligned}((P_tH - H_tP_t)\psi, \phi) &= ((P_tH - H_tP_t)(\psi_X + \tilde{\psi}_X), \phi) \\ &= ((H - H_t)\psi_X + (P_tH - H_tP_t)\tilde{\psi}_X, \phi) \\ &= ((P_tH - H_tP_t)\tilde{\psi}_X, \phi).\end{aligned} \qquad (\dagger)$$

Since H and H_t are differential operators, they preserve supports; hence $\mathrm{supp}((P_tH - H_tP_t)\tilde{\psi}_X) \subseteq \mathrm{supp}\ \tilde{\psi}_X$, which is disjoint from the support of ϕ, hence, since the inner product in (†) is an integral, we conclude that (†) is zero, i.e., $(P_tH - H_tP_t)\psi \perp \mathscr{Q}_t$; hence $(P_tH - H_tP_t)\psi = 0$. ∎

We remark that any reasonable method of dynamics reduction should produce a constrained Hamiltonian H_Γ on $L^2(\Gamma)$ that is essentially self-adjoint, and the time evolution it generates, $\exp itH_\Gamma$, must preserve the algebra of observables $\mathscr{R}_S$ when we have obtained this (see the next section). We now test the above methods on two examples.

Example 4.5: Recall the previous example of the sphere of radius a, $\Gamma = \mathbf{S}_a^2$ in $\mathbb{R}^3$; $\mathscr{H} = L^2(\mathbb{R}^3) = L^2(\mathbb{R}_+, r^2dr) \otimes L^2(\mathbf{S}_1^2, d\Omega)$ with Hamiltonian $H = \hat{\mathbf{p}}^2/2m = -(1/2m)\Delta$, having domain of essential self-adjointness $C_c^\infty(\mathbb{R}^3)$ and that acts on the decomposable functions $\psi(\mathbf{x}) = f(r) \cdot \xi(\theta, \phi) \in C_c^\infty(\mathbb{R}^3)$ by

$$(-\Delta\psi)(\mathbf{x}) = \left(-\frac{d^2}{dr^2} - \frac{2}{r} \cdot \frac{d}{dr} \right) f(r) \cdot \xi(\theta, \phi) + \frac{1}{r^2} f(r) \cdot B\xi(\theta, \phi),$$

where $B = |\mathbf{L}|^2$ is the Laplace–Beltrami operator on $L^2(\mathbf{S}_1^2)$. Now for $t \in (0, a)$ we have

$$\mathscr{H}_t^T := \{\psi \in \mathscr{H} \mid \psi(\mathbf{x}) = \chi_{[\sqrt{a^2-t}, \sqrt{a^2+t}]}(r) \cdot \xi(\theta, \phi), \quad \xi \in L^2(\Gamma)\}.$$

To obtain the smoothed space, choose a $\zeta_t \in C_c^\infty(\mathbb{R})$, which is one on $[-t, t]$ and zero on $[-t-\epsilon, t+\epsilon]$, and set

$$\mathscr{H}_t^\zeta := \{\psi \in \mathscr{H} \mid \psi(\mathbf{x}) = \zeta_t(r^2 - a^2) \cdot \xi(\theta, \phi), \quad \xi \in L^2(\Gamma)\},$$

and note that if $\psi \restriction \Gamma = \xi \in C^\infty(\Gamma)$, then $\psi \in C^\infty(\mathbb{R}^n) \subset \mathrm{Dom}\ H$. So we choose the transverse space $\mathscr{T}_t = \{\psi \in \mathscr{H}_t^\zeta \mid \psi \restriction \Gamma \in C^\infty(\Gamma)\}$. Now for method (i) for constraining H, let $\psi = (\zeta_t \circ \varphi) \cdot \xi \in \mathscr{T}_t$. Then from the explicit formula for H, we see

$$(H\psi)(\mathbf{x}) = \frac{1}{2mr^2} (B\xi)(\theta, \phi) \cdot \chi_{(\sqrt{a^2-t}, \sqrt{a^2+t})}(r) + \rho(\mathbf{x}),$$

where ρ is a function with support disjoint from $\varphi^{-1}(-t, t)$. So, since $H\psi$ is continuous near Γ, we have $\kappa(H\psi) = (H\psi) \restriction \Gamma$, i.e., $\kappa(H\psi)(\theta, \phi) = (B\xi)(\theta, \phi)/2ma^2$. So

$$H_{(i)}\kappa(\psi) = \kappa(H\psi) = \frac{1}{2ma^2} B\kappa(\psi),$$

for all $\psi \in \mathscr{T}_t$, so, since $\kappa(\mathscr{T}_t) = C^\infty(\Gamma)$ is dense in $L^2(\Gamma)$, $H_{(i)}\xi = (1/2ma^2)B\xi$ for all $\xi \in C^\infty(\Gamma)$ is densely defined, agrees with the classical Hamiltonian $|\mathbf{L}|^2/2ma^2$ obtained in Sec. II [Eq. (2.4)], and is essentially self-adjoint: a good result.

Next, as an exercise in method (ii), we calculate

$$(P_t^T H\psi_1, \hat{h} P_t \psi_2), \quad \psi_i \in \mathscr{T}_{t_0},$$

where $\psi_i = (\zeta_t \circ \varphi) \cdot \xi_i$ as above. Now

$$(P_t^T H\psi_1)(\mathbf{x}) = \left(P_t^T \frac{B}{2mr^2} \right) \xi(\theta, \phi),$$

if $r \in [\sqrt{a^2-t}, \sqrt{a^2+t}] =: I_t$ and zero otherwise. To work out the projection, we only need to consider the radial coordinate. The one-dimensional space N generated by $\chi_{I_t} \in L^2(\mathbb{R}_+, r^2dr)$ corresponds to $\mathscr{H}_t^T$. So we need to decompose the function $\chi_{I_t}(r)/2mr^2$ according to $N \oplus N^\perp$, i.e., $(1/2mr^2)\chi_{I_t}(r) = \lambda_t \cdot \chi_{I_t}(r) + h(r)$, where λ_t is a constant and $h \in N^\perp$, i.e., $\int_{I_t} r^2 h(r) dr = 0$. Now $(\chi_{I_t}, (1/2mr^2)\chi_{I_t}) = (1/2m)\int_{I_t} dr = \lambda_t \int_{I_t} r^2 dr$, i.e.,

$$\lambda_t = \frac{3(\sqrt{a^2+t}-\sqrt{a^2-t})}{2m[(a^2+t)^{3/2}-(a^2-t)^{3/2}]},$$

and so

$$(P_t^T H\psi_1)(\mathbf{x}) = \lambda_t \cdot \chi_{I_t}(r)\cdot (B\xi_1)(\theta,\phi).$$

Thus

$$\begin{aligned}(P_t^T H\psi_1, \hat{h}P_{[-t,t]}\psi_2) &= \int \lambda_t \cdot \chi_{I_t}(r)(B\overline{\xi_1})(\theta,\phi)\cdot 2r\psi_2(\mathbf{x})r^2\, dr\, d\Omega \\ &= 2\lambda_t \int_{\sqrt{a^2-t}}^{\sqrt{a^2+t}} r^3 dr \int (B\overline{\xi_1})\cdot \xi_2 d\Omega \\ &= 2\lambda_t \frac{1}{4a^2}((a^2+t)^2-(a^2-t)^2)\cdot (B\xi_1,\xi_2)_{L^2(\Gamma)} = 2t\lambda_t \cdot (B\xi_1,\xi_2)_{L^2(\Gamma)},\end{aligned}$$

where we used the fact that the measure on Γ is $a^2 d\Omega$ with $d\Omega$ the usual measure on the unit sphere. Now

$$\lim_{t\to 0}\lambda_t = \frac{3}{2m}\lim_{t\to 0}\frac{\sqrt{a^2+t}-\sqrt{a^2-t}}{(a^2+t)^{3/2}-(a^2-t)^{3/2}} = \frac{1}{2ma^2},$$

hence

$$\begin{aligned}\lim_{t\to 0}\frac{1}{2t}(P_t^T H\psi_1, \hat{h}P_{[-t,t]}\psi_2) &= \lim_{t\to 0}\lambda_t (B\xi_1,\xi_2)_{L^2(\Gamma)} \\ &= \left(\frac{B}{2ma^2}\,\xi_1,\xi_2\right)_{L^2(\Gamma)} \\ &= (H_{(ii)}\xi_1,\xi_2), \quad \text{for all } \xi_i \in C^\infty(\Gamma).\end{aligned}$$

Thus, $H_{(ii)} = B/2ma^2 = H_{(i)} = H_\Gamma$ on $C^\infty(\Gamma)$, in agreement with Theorem 4.4.

Without much extra effort, we can also show that Schrödinger operators $H = (1/2m)\hat{\mathbf{p}}^2 + V(\hat{\mathbf{q}})$ for V smooth near Γ, produce, for $\xi \in C^\infty(\Gamma)$,

$$H_{(i)}\xi(\theta,\phi) = H_{(ii)}\xi(\theta,\phi) = \left(\frac{B}{2ma^2}\,\xi\right)(\theta,\phi) + V(a,\theta,\phi)\cdot\xi(\theta,\phi).$$

Example 4.6: We would like to restrict a free quantum particle in $\mathbb{R}^3$ to a cylinder Γ of radius a around the z axis. We do this in exact analogy with the sphere. Let the constraint be $\varphi(\mathbf{x}) = x^2+y^2-a^2$; then $\nabla\varphi(\mathbf{x}) = (2x,2y,0)$; hence the critical points are well away from Γ. So

$$\varphi^{-1}[-s,t] = \{\mathbf{x}\in\mathbb{R}^3 | r^2 \in [a^2-s, a^2+t]\},$$

where we henceforth use cylindrical coordinates (z,r,θ). Then

$$(\psi_1,\psi_2)_\Gamma = \lim_{t\to 0}\frac{1}{2t}(\psi_1,\hat{h}P_t\psi_2) = \frac{1}{2}\frac{d}{dt}\int_{\sqrt{a^2-t}}^{\sqrt{a^2+t}} 2r^2 dr \int_{-\infty}^{\infty} dz \int_0^{2\pi} d\theta\, (\overline{\psi_1}\psi_2)(\mathbf{x})|_{t=0}.$$

Let ψ_i be decomposable, $\psi_i(\mathbf{x}) = f_i(r)\xi_i(z,\theta)$, where $\xi_i \in L^2(\Gamma)$ and f_i is continuous at $r=a$. Then

$$(\psi_1,\psi_2)_\Gamma = \int \overline{\xi_1}\xi_2\, dz d\theta \cdot \frac{d}{dt}\int_{\sqrt{a^2-t}}^{\sqrt{a^2+t}} r^2 \overline{f_1} f_2(r) dr|_{t=0} = a\overline{f_1}(a) f_2(a)\int \overline{\xi_1}\xi_2\, d\theta dz.$$

The free Hamiltonian $H=-\Delta/2m$ in cylindrical coordinates acts by

$$\Delta\psi=\frac{1}{r}\frac{\partial}{\partial r}\left(r\,\frac{\partial\psi}{\partial r}\right)+\frac{1}{r^2}\frac{\partial^2\psi}{\partial\theta^2}+\frac{\partial^2\psi}{\partial z^2}.$$

For $t\in(0,a)$, we have

$$\mathscr{H}_t^T=\{\psi\in\mathscr{H}\mid\ \psi(\mathbf{x})=\chi_{I_t}(r)\cdot\xi(z,\theta),\xi\in L^2(\Gamma)\},$$

where $I_t:=[\sqrt{a^2-t},\sqrt{a^2+t}]$. Then with a bump function $\zeta_t\in C^\infty(\mathbb{R})$, which is unity on $[-t,t]$ and zero outside $[-t-\epsilon,t+\epsilon]$, we have

$$\mathscr{H}_t^\xi:=\{\psi\in\mathscr{H}\mid\ \psi(\mathbf{x})=\zeta_t(r^2-a^2)\cdot\xi(z,\theta),\xi\in L^2(\Gamma)\}.$$

Since the smooth functions of compact support are in the domain of H, we choose

$$\mathscr{T}_t=\{\psi\in\mathscr{H}_t^\xi\mid\ \psi\restriction\Gamma\in C_c^\infty(\Gamma)\}.$$

Now to obtain $H_{(i)}$, let $\psi=(\zeta_t\circ\varphi)\cdot\xi\in\mathscr{T}$, then

$$(H\psi)(\mathbf{x})=\left(\frac{-1}{2m}\right)\chi_{J_t}(r)\left(\frac{1}{r^2}\frac{\partial^2}{\partial\theta^2}+\frac{\partial^2}{\partial z^2}\right)\xi(z,\theta)+\rho(\mathbf{x}),$$

where $J_t:=(\sqrt{a^2-t},\sqrt{a^2+t})$ and ρ has support disjoint from J_t. Now, since $\kappa(H\psi)=(H\psi)\restriction\Gamma$, we get

$$H_{(i)}\xi(z,\theta)=\left(\frac{-1}{2m}\right)\left(\frac{1}{a^2}\frac{\partial^2}{\partial\theta^2}+\frac{\partial^2}{\partial z^2}\right)\xi(z,\theta),$$

for all $\xi\in C_c^\infty(\Gamma)$. Thus, via Theorem 4.4,

$$H_\Gamma=\left(\frac{-1}{2m}\right)\left(\frac{1}{a^2}\frac{\partial^2}{\partial\theta^2}+\frac{\partial^2}{\partial z^2}\right),$$

on $C_c^\infty(\Gamma)$. This is precisely the quantization one would expect of the constrained classical Hamiltonian (2.6).

Remarks: (1) We regard the choice of a transverse space $\mathscr{T}$ as a decision on the direction from which H should be reduced to Γ. Above, we chose the normal direction. In quantum systems with less geometry (e.g., no metric on an underlying manifold), it may be difficult to decide on an appropriate $\mathscr{T}$. This choice has physical content, and seems analogous to the choice of a self-adjoint extension for a Hamiltonian in the Dirac approach sketched early in this section. An alternative way of expressing the choice of the transverse space is to observe that on $L^2(S_{t_0})$ for t_0 small enough, the pair of operators $\hat{\varphi}$ and $P_\varphi:=i\partial/\partial\varphi$ form a canonical pair, i.e., $[P_\varphi,\hat{\varphi}]\psi=i\psi$ for all smooth ψ, with compact support in the interior of S_{t_0}. Then $\mathscr{T}\restriction S_{t_0}=\mathrm{Ker}\ P_\varphi\cap\mathrm{Dom}(H\restriction L^2(S_{t_0}))$. So, in a general quantum system one can look for a given ''local canonical conjugate'' to the constraint to obtain a transverse space as its kernel. In fact, this observation also gives a clue on how to enforce second-class constraints, in the sense that if we are given a canonical pair φ, P_φ to enforce, then we do it as above, by using P_φ to *locally* select a transverse space to $\varphi^{-1}(0)$.

(2) Recall that in Sec. II, the classical secondary constraint we obtained for φ was $(\nabla\varphi)\cdot\mathbf{p}\restriction\Gamma$. The selection of the normal transverse space above can be thought of as the enforcement of the constraint $\nabla\varphi\cdot\hat{\mathbf{p}}\psi=0$ near Γ, which looks very much like what one would expect a ''quantization'' of the classical secondary constraint to be. This leads one to ask whether we can quantize the infinitesimal Dirac procedure that produced this secondary constraint as a whole. Unfortunately, this does not seem to work; we sketch how it goes awry. Given the primary constraint $\hat{\varphi}$ and the Hamiltonian $H=(1/2m)\hat{\mathbf{p}}^2+V(\hat{\mathbf{q}})$, the secondary constraint should be $[H,\hat{\varphi}]$ ''restricted'' to Γ. Now

$$[H,\hat{\varphi}]\psi = -\frac{1}{2m}(\Delta\varphi)\psi - \frac{1}{m}(\nabla\varphi)\cdot(\nabla\psi),$$

for all $\psi \in C_c^\infty(\mathbb{R}^n)$. Restriction to Γ is done by κ. However, while $-(1/m)(\nabla\varphi)\cdot(\nabla\psi)$ is proportional to the desired secondary constraint $\nabla\varphi\cdot\hat{\mathbf{p}}\psi$, the term $-(1/2m)(\Delta\varphi)\psi$ need not vanish on Γ. Moreover, if we use $[H,\hat{\varphi}]$ as a new secondary constraint to select the transverse space instead of $\nabla\varphi\cdot\hat{\mathbf{p}}$, we obtain the wrong result on the sphere. Nevertheless, given the close parallel that the selection of the transverse space has to the classical secondary constraint, we regard the use of a transverse space here as the imposition of a secondary quantum constraint.

(3) We remark that one needs to reduce the dynamics infinitesimally, i.e., through the Hamiltonian, not directly on the time evolution unitaries, $\exp(itH)$.

(4) In general, there is no guarantee that the constraining of a self-adjoint Hamiltonian H to Γ produces an essentially self-adjoint operator on $L^2(\Gamma)$. This is a difficult question that needs further investigation, and its classical equivalent in the GNH algorithm also is unsolved, that is, we do not know whether reducing a given complete Hamiltonian vector field to a submanifold Γ produces a complete vector field on Γ. When Γ has edges, it is very easy to get examples of complete vector fields that will not be complete when constrained to Γ.

(5) The confining potential approach, developed in Refs. 15 and 16, also treats the dynamics of quantum particles on (or near) surfaces. In this, one assumes there is a confining potential depending only on the normal coordinates, and with a deep minimum on Γ. The system is then taken to be in a fixed eigenstate in the normal direction (''normal degrees of freedom are frozen''), and this was applied to some physical examples where such confining potentials actually occur.[15] By contrast, our object is to impose the constraints exactly in order to understand the nature of the mathematical problems involved with the construction of a quantum version of Dirac's theory of constraints. As can be seen from this paper, such a program encounters deep pathologies that do not arise when the potentials only provide approximate confinement. Furthermore, if one has a physical principle that requires the particle to be exactly on Γ, or if one is defining quantum mechanics on a curved manifold, it also seems more appropriate to solve the constraint exactly. In addition to the dynamics, we also do the kinematics.

V. CONSTRAINED OBSERVABLES

In this section we continue the analysis of the problem of the previous sections specifically in regard to the observables. That is, given the unbounded map $\kappa: C_\varphi \to L^2(\Gamma)$ above, we wish to examine how self-adjoint operators and unitaries on $L^2(\mathbb{R}^n)$ lift through κ to produce operators on $L^2(\Gamma)$. Due to the unboundedness and nonclosability of κ there will be some pathology, even for bounded operators on $L^2(\mathbb{R}^n)$.

The choice of field algebra $\mathcal{F} \subseteq \mathcal{B}(\mathcal{H})$ will turn out to be important for obtaining a nontrivial constrained field algebra on $L^2(\Gamma)$. In fact, the CCR algebra $\overline{\Delta(\mathbb{R}^{2n})} = C^*\{\exp(i\hat{\mathbf{q}}\cdot\mathbf{a}), \exp(i\hat{\mathbf{p}}\cdot\mathbf{a}) \,|\, \mathbf{a}\in\mathbb{R}^n\}$ will be too small if Γ is a curved manifold (see later in this section). A more suitable field algebra for curved Γ is $C_b(\mathbb{R}^n) \rtimes \mathrm{Diff}\ \mathbb{R}^n$, which is here concretely the C^* algebra generated in $\mathcal{B}(L^2(\mathbb{R}^n))$ by the multiplication operators $\{T_f \,|\, f \in C_b(\mathbb{R}^n)\}$,

$$(T_f\psi)(\mathbf{x}) := f(\mathbf{x})\psi(\mathbf{x}), \quad \psi \in L^2(\mathbb{R}^n) = \mathcal{H},$$

and the set of unitaries $\{V_\beta \,|\, \beta \in \mathrm{Diff}\ \mathbb{R}^n\}$, where

$$(V_\beta\psi)(\mathbf{x}) := J_\beta(\mathbf{x})^{1/2}\psi(\beta\mathbf{x}), \quad \psi \in L^2(\mathbb{R}^n),$$

with J_β the Jacobian of $\beta \in \mathrm{Diff}\ \mathbb{R}^n$. We will concentrate on these two classes of operators below.

Now an operator $A \in \mathcal{B}(\mathcal{H})$ will lift through κ to a densely defined operator $\Lambda(A)$ on $L^2(\Gamma)$ if the following exists:

(i) there is a space $S \subset C_\varphi$ such that $AS \subseteq C_\varphi$ and $\kappa(S)$ is dense in $L^2(\Gamma)$; (ii) $A\psi \in \mathrm{Ker}(\cdot,\cdot)_\Gamma = \mathrm{Ker}\ \kappa$, for all $\psi \in S \cap \mathrm{Ker}\ \kappa$.

In this case,

$$\Lambda(A)\kappa(\psi) := \kappa(A\psi), \quad \forall \psi \in S, \tag{5.1}$$

or equivalently,

$$(\Lambda(A)\kappa(\phi),\ \kappa(\psi))_\Gamma = \lim_{t\to 0}\frac{1}{2t}\,(A\phi,\ \hat{h}P_t\psi), \quad \forall\,\psi,\phi\in S.$$

Since we are interested in $*$ algebras of operators, we will concentrate on situations where the dense subspace S is invariant under the class of operators under consideration. Define the $*$ algebra:

$$\mathscr{T}_S := \{A\in\mathscr{T} \mid A\psi\in S\ni A^*\psi, \quad \forall\,\psi\in S\}. \tag{5.2}$$

There are three obvious dense subspaces S we can ask to be preserved, C_φ, $C_c(\mathbb{R}^n)$, and the transverse space $\mathscr{T}_t=\mathscr{H}_t^\zeta\cap C_\varphi\cap\text{dom } H$ of the last section (or better still, the space $\mathscr{T}^{(t_0)}$ spanned by all $\mathscr{T}_t$ for $t\in(0,t_0]$ and all possible smoothings ζ), and we will consider all these in due course. A useful way of characterizing $\mathscr{T}^{(t_0)}$ is as

$$\mathscr{T}^{(t_0)}=\left\{\psi\in C_c(\mathbb{R}^n)\,\middle|\,\frac{\partial\psi}{\partial\varphi}(\mathbf{x})=0, \quad \forall\,\mathbf{x}\in S_{t_\psi},\ 0<t_\psi<t_0\right\}\cap\text{Dom } H.$$

The choices $\mathscr{T}_t$ or $\mathscr{T}^{(t_0)}$ can be thought of as enforcing secondary quantum constraints on the observables; cf. Remark 2 of Sec. IV. However, we will see that in the quantum picture there is no compelling reason to do this.

Unless we specify what S is below, we will assume that some choice has been made. The elements of $\mathscr{T}_S$ that will lift via (5.1) are those that preserve $S\cap\text{Ker }\kappa$, and for these we have $\Lambda(A)\Lambda(B)\kappa(\psi)=\kappa(AB\psi)=\Lambda(AB)\kappa(\psi)$ for all $\psi\in S$, i.e., Λ is an algebra homomorphism. However, there are two pathologies associated with Λ; (i) given an $A\in\mathscr{B}(\mathscr{H})$ for which $\Lambda(A)$ exists, then $\Lambda(A)$ need not be bounded; (ii) given an $A\in\mathscr{B}(\mathscr{H})$ for which both $\Lambda(A)$ and $\Lambda(A^*)$ exist, we need not have that $\Lambda(A^*)\subseteq\Lambda(A)^*$.

5.3. Example of (i): Let $\mathscr{H}=L^2(\mathbb{R}^2)$, $\varphi(\mathbf{x})=x_2$ so $\Gamma=\varphi^{-1}(0)$ is the x_1 axis. Choose $S=C_c(\mathbb{R}^n)$. Clearly all V_β preserve $S=C_c(\mathbb{R}^2)$ for all $\beta\in\text{Diff }\mathbb{R}^2$, so since $(V_\beta^*\psi)(\mathbf{x})=J_\beta^{-1/2}(\beta^{-1}\mathbf{x})\cdot\psi(\beta^{-1}\mathbf{x})$ we have $V_\beta\in\mathscr{T}_S$. If $\beta\Gamma\subseteq\Gamma$, we get that V_β preserves $C_c(\mathbb{R}^2\backslash\Gamma)=\text{Ker}(\cdot,\cdot)_\Gamma\cap C_c(\mathbb{R}^2)$, and so $\Lambda(V_\beta)$ exists. Consider now the $\beta\in\text{Diff }\mathbb{R}^2$ given by $\beta(x_1,x_2):=(ax_1,x_2e^{x_1})$, $a>0$, so clearly $\beta\Gamma=\Gamma$ and $J_\beta(\mathbf{x})=ae^{x_1}\neq 0$. [That β is a diffeomorphism is clear since its inverse is $\beta^{-1}(x_1,x_2)=(x_1/a,x_2e^{-x_1/a})$, which is also differentiable]. Now, for $\psi\in C_c(\mathbb{R}^2)$, we have

$$\begin{aligned}(\Lambda(V_\beta)\kappa(\psi),\ \Lambda(V_\beta)\kappa(\psi))_{L^2(\Gamma)} &= (V_\beta\psi,\ V_\beta\psi)_\Gamma = (V_\beta\psi\restriction\Gamma,\ V_\beta\psi\restriction\Gamma)_{L^2(\Gamma)}\\ &= \int|(V_\beta\psi\restriction\Gamma)|^2dx_1 = \int J_\beta(x_1,0)|\psi(ax_1,0)|^2dx_1\\ &= \int e^{x/a}|\psi(x,0)|^2dx =: I_\psi,\end{aligned}$$

and now we can choose a $\psi\in C_c(\mathbb{R}^2)$ with $\|\kappa(\psi)\|=\|\psi\restriction\Gamma\|_{L^2(\Gamma)}=1$, which can make I_ψ arbitrarily large, e.g., $\psi=\chi_{[n,n+1]\times[0,1]}$ and consider I_ψ as $n\to\infty$. Thus $\Lambda(V_\beta)$ is unbounded.

We remark that if we chose a more restrictive space S, e.g., $\mathscr{T}^{(t_0)}$, then the diffeomorphism in the last example will preserve $\mathscr{T}^{(t_0)}$, so this pathology cannot be removed by enforcing ''secondary quantum constraints.''

Example of (ii): Continue the previous example, noting that $\Lambda(V_\beta^*)$ exists because $\beta^{-1}\Gamma=\Gamma$. However, if $\Lambda(V_\beta^*)\subseteq\Lambda(V_\beta)^*$, we have, for all $\psi\in C_c(\mathbb{R}^2)$, that

$$\begin{aligned}(\Lambda(V_\beta)\kappa(\psi),\ \Lambda(V_\beta)\kappa(\psi))_{L^2(\Gamma)} &= (\kappa(\psi),\ \Lambda(V_\beta)^*\kappa(V_\beta\psi))_{L^2(\Gamma)}\\ &= (\kappa(\psi),\ \Lambda(V_\beta^*)\kappa(V_\beta\psi))_{L^2(\Gamma)}\\ &= (\kappa(\psi),\ \kappa(V_\beta^*V_\beta\psi))_{L^2(\Gamma)} = (\kappa(\psi),\kappa(\psi))_{L^2(\Gamma)},\end{aligned}$$

which makes $\Lambda(V_\beta)$ unitary, hence bounded, in contradiction with example (i), so it is false that $\Lambda(V_\beta^*)\subseteq\Lambda(V_\beta)^*$.

Now, it appears reasonable to the authors that in a constraining method, boundedness and the adjoint operation should be preserved, at least on the physical variables. So we want to restrict the set of operators under consideration to those satisfying these two requirements. Observe that an $A\in\mathscr{F}_S$ will lift to a bounded operator $\Lambda(A)$ on $L^2(\Gamma)$ iff

$$(A\psi,A\psi)_\Gamma\leqslant M\cdot(\psi,\psi)_\Gamma \quad \forall\psi\in S, \quad \text{and a fixed } M<\infty.$$

[Clearly, if $\psi\in S\cap\mathrm{Ker}\ \kappa$ then the last inequality implies $(A\psi,A\psi)_\Gamma=0$, i.e., $A\psi\in\mathrm{Ker}\ \kappa$, so $\Lambda(A)$ exists.]

Definition:

$$\mathscr{O}_S:=\{A\in\mathscr{F}_S \mid (A\psi,\ A\psi)_\Gamma\leqslant M_A\cdot(\psi,\psi)_\Gamma\geqslant(A^*\psi,\ A^*\psi)_\Gamma,$$

$$\forall\psi\in S, \quad \text{and some } M_A<\infty, \quad \text{and } \Lambda(A^*)\subseteq\Lambda(A)^*\},$$

$$\mathscr{D}_S:=\{A\in\mathscr{O}_S \mid AS\subseteq\mathrm{Ker}\ \kappa\supseteq A^*S\}.$$

Note that if $A\in\mathscr{O}_S$, then $\Lambda(A)$ is bounded, so we have, in fact, that $\Lambda(A)^*=\overline{\Lambda(A^*)}$, so there are no problems with self-adjointness if A is self-adjoint. These will occur, however, if we consider Λ on unbounded operators.

Lemma 5.4: $\mathscr{O}_S$ and $\mathscr{D}_S$ are *-algebras.

Proof: Both sets are linear spaces. To see that $\mathscr{O}_S$ is closed under taking of adjoints, take the adjoint of $\Lambda(A^*)\subseteq\Lambda(A)^*$ to get $\Lambda(A^{**})=\Lambda(A)\subseteq\overline{\Lambda(A)}=\Lambda(A)^{**}\subseteq\Lambda(A^*)^*$, i.e., A^* is in $\mathscr{O}_S$ if A is. Then clearly $\mathscr{D}_S$ is also closed under taking of adjoints. To see that $\mathscr{O}_S$ is an algebra, let $A,\ B\in\mathscr{O}_S$; then

$$(AB\psi,\ AB\psi)_\Gamma\leqslant M_A\cdot(B\psi,B\psi)_\Gamma\leqslant M_AM_B(\psi,\psi)_\Gamma,$$

for all $\psi\in S$, and similarly for B^*A^*. Moreover,

$$\Lambda(AB)^*=[\Lambda(A)\Lambda(B)]^*\supseteq\Lambda(B)^*\Lambda(A)^*\supseteq\Lambda(B^*)\Lambda(A^*)=\Lambda((AB)^*),$$

and thus $AB\in\mathscr{O}_S$. That $\mathscr{D}_S$ is an algebra is obvious. ■

Now $\mathscr{D}_S=\mathrm{Ker}(\Lambda\restriction\mathscr{O}_S)$ is an * ideal of $\mathscr{O}_S$, and $\mathscr{R}_S:=\mathscr{O}_S/\mathscr{D}_S\cong\Lambda(\mathscr{O}_S)\subset\mathscr{B}(L^2(\Gamma))$. We think of $\mathscr{R}_S$ as the ''physical observables'' obtained from enforcing the constraint on $\mathscr{O}_S$, in analogy to the algebra $\mathscr{R}$ of the T procedure for Dirac constraining. $\mathscr{R}_S$ cannot be zero because the identity operator $\mathbb{I}\in\mathscr{O}_S$ and $\overline{\Lambda(\mathbb{I})}=\mathbb{I}$. We do not expect $\mathscr{R}_S$ to be a C^* algebra, but it can easily generate a C^* algebra since $\mathscr{R}_S\cong\Lambda(\mathscr{O}_S)\subset\mathscr{B}(L^2(\Gamma))$.

Given that the commutant $\hat{\varphi}'$ is the traditional observables, we find here the following.

Theorem 5.5: $\mathscr{F}_S\cap\hat{\varphi}'\cap\hat{h}'\subset\mathscr{O}_S$.

Proof: Let $A\in\mathscr{F}_S\cap\hat{\varphi}'\cap\hat{h}'$, which is an * algebra, so it also contains A^*.

Then

$$(A\psi,\ \hat{h}P_tA\psi)=\|\widehat{h^{1/2}}P_tA\psi\|^2=\|A\widehat{h^{1/2}}P_t\psi\|^2\leqslant\|A\|^2\cdot\|\widehat{h^{1/2}}P_t\psi\|^2=\|A\|^2\cdot(\psi,\ \hat{h}P_t\psi),$$

for all $\psi\in S$. Thus

$$(A\psi,\ A\psi)_\Gamma=\lim_{t\to0}\frac{1}{2t}\,(A\psi,\ \hat{h}P_tA\psi)\leqslant\|A\|^2\lim_{t\to0}\frac{1}{2t}\,(\psi,\ \hat{h}P_t\psi)=\|A\|^2\cdot(\psi,\psi)_\Gamma.$$

The same is true for A^*. Now, for all $\psi,\ \phi\in S$,

$$
\begin{aligned}
(\Lambda(A)\kappa(\psi),\ \kappa(\phi))_{L^2(\Gamma)} &= (\kappa(A\psi),\kappa(\phi))_{L^2(\Gamma)} = (A\psi,\phi)_\Gamma \\
&= \lim_{t\to 0}\frac{1}{2t}\,(A\psi,\ \hat{h}P_t\phi) = \lim_{t\to 0}\frac{1}{2t}\,(\psi,\ A^*\hat{h}P_t\phi) \\
&= \lim_{t\to 0}\frac{1}{2t}\,(\psi,\ \hat{h}P_tA^*\phi) = (\psi,A^*\phi)_\Gamma \\
&= (\kappa(\psi),\ \Lambda(A^*)\kappa(\phi))_{L^2(\Gamma)},
\end{aligned}
$$

so $\Lambda(A^*)\subseteq\Lambda(A)^*$. Thus $A\in\mathscr{O}_S$. ■

Remarks: (1) Note that due to the limit in $(\cdot,\cdot)_\Gamma$, it is only the behavior near Γ, which contributes in the constraining of an operator. In fact, the proof actually shows that an $A\in\mathscr{F}_S$ will be in $\mathscr{O}_S$ if

$$
\lim_{t\to 0}\frac{1}{t}\,\|\widehat{h^{1/2}}P_tA\psi\|^2 = \lim_{t\to 0}\frac{1}{t}\,\|A\widehat{h^{1/2}}P_t\psi\|^2
$$

and

$$
\lim_{t\to 0}\frac{1}{t}\,(\psi,[A^*,\hat{h}P_t]\phi) = 0,
$$

for all $\psi,\ \phi\in S$ and the same for A^*. So, if A commutes with $\hat{\varphi}$ and $\hat{h}$ on a small neighborhood of Γ, it will also be in $\mathscr{O}_S$. The behavior of A away from Γ is irrelevant.

(2) We note by Theorem 5.5 that all multiplication operators by bounded Borel functions that preserve S will be in $\mathscr{O}_S$. In particular, for a reasonable physical system we expect $\hat{\varphi}$ to preserve S, so the constraint $\hat{\varphi}$ is in $\mathscr{O}_S$. In this case $\hat{\varphi}$ is in $\mathscr{D}_S$ by the following argument:

$$
\begin{aligned}
\lim_{t\to 0}\|\widehat{h^{1/2}}P_t\hat{\varphi}\psi\|^2 &= \lim_{t\to 0}\frac{1}{t}\,\|\hat{\varphi}\widehat{h^{1/2}}P_t\psi\|^2 \leqslant \lim_{t\to 0}\frac{1}{t}\,\sup\{|\varphi(\mathbf{x})|^2 \mid \mathbf{x}\in\varphi^{-1}[-t,t]\}\cdot\|\widehat{h^{1/2}}P_t\psi\|^2 \\
&= (\lim_{t\to 0}\sup\{|\varphi(x)|^2 \mid \mathbf{x}\in\varphi^{-1}[-t,t]\})\cdot\lim_{t\to 0}\frac{1}{t}\,\|\widehat{h^{1/2}}P_t\psi\|^2 = 0, \quad \forall\,\psi\in S,
\end{aligned}
$$

using the fact that the limit $\lim_{t\to 0}(1/t)\|\widehat{h^{1/2}}P_t\psi\|^2 = \lim_{t\to 0}(1/t)(\psi,\ \hat{h}P_t\psi)$ exists due to $\psi\in S\subset C_\varphi$, and that the limit of the supremum is zero. Hence $(\hat{\varphi}\psi,\hat{\varphi}\psi)_\Gamma = 0$, i.e., $\hat{\varphi}\psi\in\mathrm{Ker}\ \kappa$ for all $\psi\in S$, so $\Lambda(\hat{\varphi}) = 0$, as expected.

Theorem 5.6: *An $A\in\mathscr{F}_S$ preserves* Ker $\kappa\cap S$ *iff*

$$
\lim_{t\to 0}\frac{1}{t}\,\|P_tA(\mathbb{I}-P_t)\psi\|^2 = 0,
$$

for all $\psi\in\mathrm{Ker}\ \kappa\cap S$.

Proof: We need the following lemma:

Lemma: With assumptions and notation as above, we have

$$
\psi\in\mathrm{Ker}(\cdot,\cdot)_\Gamma, \quad \textit{iff}\ \lim_{t\to 0}\frac{1}{t}\,\|P_t\psi\|^2 = 0.
$$

Proof: $\psi\in\mathrm{Ker}(\cdot,\cdot)_\Gamma$, iff $0 = (\psi,\psi)_\Gamma = \lim_{t\to 0}(1/2t)(\psi,\ \hat{h}P_t\psi)$. Now

$$(\psi,\ \hat{h}P_t\psi)=\int_{\varphi^{-1}[-t,t]}|\nabla\varphi(\mathbf{x})|\cdot|\psi(\mathbf{x})|^2d\mu(\mathbf{x})$$

$$\geqslant \inf\{|\nabla\varphi(\mathbf{x})|\mid \mathbf{x}\in\varphi^{-1}[-t,t]\}\int_{\varphi^{-1}[-t,t]}|\psi(\mathbf{x})|^2d\mu(\mathbf{x}).$$

Since $|\nabla\varphi(\mathbf{x})|$ is assumed to be bounded, continuous, and nonzero on a neighborhood of Γ, we have

$$\lim_{t\to 0}\inf\{|\nabla\varphi(\mathbf{x})|\mid \mathbf{x}\in\varphi^{-1}[-t,t]\}=:M>0.$$

Thus

$$\lim_{t\to 0}\frac{1}{t}(\psi,\ \hat{h}P_t\psi)\geqslant M\ \lim_{t\to 0}\frac{1}{t}\int_{\varphi^{-1}[-t,t]}|\psi(\mathbf{x})|^2d\mu(\mathbf{x})=M\ \lim_{t\to 0}\frac{1}{t}\|P_t\psi\|^2,$$

so $\psi\in\mathrm{Ker}(\cdot,\cdot)_\Gamma$ implies

$$0=\lim_{t\to 0}\frac{1}{t}(\psi,\ \hat{h}P_t\psi)\geqslant M\ \lim_{t\to 0}\frac{1}{t}\|P_t\psi\|^2,$$

and so

$$\lim_{t\to 0}\frac{1}{t}\|P_t\psi\|^2=0.$$

On the other hand, given a $\psi\in\mathscr{H}$ satisfying the last equation, we have

$$(\psi,\ \hat{h}P_t\psi)=\int_{\varphi^{-1}[-t,t]}|\nabla\varphi(\mathbf{x})|\cdot|\psi(\mathbf{x})|^2d\mu(\mathbf{x})$$

$$\leqslant\sup\{|\nabla\varphi(\mathbf{x})|\mid \mathbf{x}\in\varphi^{-1}[-t,t]\}\int_{\varphi^{-1}[-t,t]}|\psi(\mathbf{x})|^2d\mu(\mathbf{x}),$$

and the limit of the supremum (denoted N) exists by the boundedness assumption, and is strictly positive. So

$$\lim_{t\to 0}\frac{1}{t}(\psi,\ \hat{h}P_t\psi)\leqslant N\cdot\lim_{t\to 0}\frac{1}{t}\|P_t\psi\|^2=0,$$

i.e., $\lim_{t\to 0}(1/t)(\psi,\ \hat{h}P_t\psi)=0$, i.e., $\psi\in\mathrm{Ker}(\cdot,\cdot)_\Gamma$. ▼

So by this lemma, $A\in\mathscr{T}_S$ preserves $\mathrm{Ker}\,\kappa\cap S$ iff $\lim_{t\to 0}(1/t)\|P_tA\psi\|^2=0$ for all $\psi\in\mathrm{Ker}\,\kappa\cap S$. Now

$$\lim_{t\to 0}\frac{1}{t}\|P_tAP_t\psi\|^2\leqslant\lim_{t\to 0}\frac{1}{t}\|P_tAP_t\|^2\|P_t\psi\|^2\leqslant\|A\|^2\cdot\lim_{t\to 0}\frac{1}{t}\|P_t\psi\|^2=0,$$

whenever $\psi\in\mathrm{Ker}\,\kappa$. So, by the triangle inequality:

$$\|P_tAP_t\psi\|+\|P_tA(\mathbb{I}-P_t)\psi\|\geqslant\|P_tA\psi\|\geqslant|\|P_tAP_t\psi\|-\|P_tA(\mathbb{I}-P_t)\psi\||,$$

we obtain

$$\lim_{t\to 0}\frac{1}{\sqrt{t}}\|P_tA\psi\|=\lim_{t\to 0}\frac{1}{\sqrt{t}}\|P_tA(\mathbb{I}-P_t)\psi\|,$$

for all $\psi \in \mathrm{Ker}\ \kappa \cap S$. ∎

An immediate consequence is that $\Lambda(A)$ exists for all $A \in \hat{\varphi}' \cap \mathscr{T}_S$ [though $\Lambda(A)$ need not be bounded in general], and, as before, we only need commutativity close to Γ to get this. Also note the similarity with the condition $P_{\mathrm{phys}} A(\mathbb{I} - P_{\mathrm{phys}}) = 0$ for an observable in Dirac constraining. Moreover, the proof of Theorem 5.6 used only the existence of the limit (3.6) for ψ, so it will work for larger domains than C_φ.

In the particular cases where S is either C_φ or $C_c(\mathbb{R}^n)$, we shorten the notation to $\mathscr{A}_\varphi := \mathscr{A}_{C_\varphi}$ and $\mathscr{A}_c := \mathscr{A}_{C_c(\mathbb{R}^n)}$, where $\mathscr{A}$ can be $\mathscr{T}$, $\mathscr{O}$, $\mathscr{D}$, or $\mathscr{R}$. Note that

$$C_c(\mathbb{R}^n) \cap \mathrm{Ker}\ \kappa = \{\psi \in C_c(\mathbb{R}^n) \mid \psi \restriction \Gamma = 0\} = C_c(\mathbb{R}^n \backslash \Gamma),$$

$$\mathscr{D}_c = \{A \in \mathscr{O}_c \mid AC_c(\mathbb{R}^n) \subseteq C_c(\mathbb{R}^n \backslash \Gamma) \supseteq A^* C_c(\mathbb{R}^n)\},$$

and for an $A \in \mathscr{O}_c$ we have $\Lambda(A)\kappa(\psi) = \kappa(A\psi) = (A\psi) \restriction \Gamma$ for all $\psi \in C_c(\mathbb{R}^n)$. Analogous statements hold if we replace $C_c(\mathbb{R}^n)$ by C_φ.

On comparing the method above to that of Landsman,[11] we note that the algebra that Landsman selects to impose the constraint on is the subalgebra of the commutant $\hat{\varphi}'$ that preserves $C_c(\mathbb{R}^n)$, i.e., $\hat{\varphi}' \cap \mathscr{T}_c$. In our case the algebra that we constrain, $\mathscr{O}_c$ can be considerably larger than that, with consequently larger algebra of observables $\mathscr{R}_c$, but, on the other hand, there are also nonzero $A \in \hat{\varphi}' \cap \mathscr{T}_c \backslash \mathscr{O}_c$ (see below).

Next, we wish to examine whether particular classes of operators are in $\mathscr{O}_S$.

(i) Consider the multiplication operator $(T_f\psi)(\mathbf{x}) := f(\mathbf{x}) \cdot \psi(\mathbf{x})$, $\forall \psi \in \mathscr{H}$, where f is bounded and Borel. It is not automatic that $T_f \in \mathscr{T}_S$. In fact, if $S = C_c(\mathbb{R}^n)$, then $T_f C_c(\mathbb{R}^n) \subseteq C_c(\mathbb{R}^n)$ iff f is continuous (in which case $T_f \in \mathscr{O}_c$ by Theorem 5.5). For the choice $S = C_\varphi$, we see that if a Borel function f is discontinuous on Γ, then the restriction to Γ may not be defined, i.e., we may have $T_f \notin \mathscr{T}_\varphi$. (This also shows $\hat{\varphi}' \backslash \mathscr{T}_\varphi \neq \emptyset$ hence that $\hat{\varphi}' \not\subset \mathscr{O}_\varphi \cup \mathscr{O}_c$). On the other hand, if f is continuous and bounded on some shell S_t, we have $T_f \in \mathscr{T}_\varphi$. So $\mathscr{T}_\varphi$ contains a larger class of multiplication operators than $\mathscr{T}_c$, and these are all in $\mathscr{O}_\varphi$. In particular, if $\exp i\hat{\mathbf{q}} \cdot \mathbf{a} \in \mathscr{T}$, then $\exp i\hat{\mathbf{q}} \cdot \mathbf{a} \in \mathscr{O}_c \cap \mathscr{O}_\varphi$. However, a T_f is only in $\mathscr{T}_{\mathscr{T}^{(t)}}$ if $f \in \mathscr{T}^{(t)}$.

(ii) Now consider the unitaries V_β, $\beta \in \mathrm{Diff}\ \mathbb{R}^n$. For the choice $S = C_c(\mathbb{R}^n)$, we have that both V_β and V_β^* preserve $C_c(\mathbb{R}^n)$, hence $V_\beta \in \mathscr{T}_c$ for all $\beta \in \mathrm{Diff}\ \mathbb{R}^n$. This is not, however, true for the choice $S = C_\varphi$. In fact, let β be a fixed translation $\beta\mathbf{x} = \mathbf{x} + \mathbf{a}$ not preserving Γ, and let $\psi \in C_\varphi$ be continuous on a neighborhood of Γ but so discontinuous on $\beta\Gamma$ that the restriction to $\beta\Gamma$ is not defined. Then $V_{\beta^{-1}}\psi \notin C_\varphi$, and so $V_{\beta^{-1}} \notin \mathscr{T}_\varphi$. Thus $\mathscr{T}_\varphi$ contains a smaller set of the unitaries V_β than $\mathscr{T}_c$. Below we will examine when these are in $\mathscr{O}_\varphi$.

(iii) Let $S = C_c(\mathbb{R}^n) \ni \psi$, then

$$\Lambda(V_\beta)\kappa(\psi) = \kappa(V_\beta\psi) = (V_\beta\psi) \restriction \Gamma = (J_\beta^{1/2} \restriction \Gamma) \cdot (\psi \circ \beta) \restriction \Gamma.$$
